is identified as a negative vector; we construct Lax pairs for the negative equations, thus showing that the local and nonlocal constants of the motion for KdV also work for negative equations. Finally, some concluding remarks are presented in Sec. VI.

For simplicity, we work in finite-dimensional notation. All assertions and theorems in Secs. II and III are valid in finite dimensions, and they can be extended to the case of field theory in all the instances dealt with in this paper. We have used a Mathematica code of our invention, to confirm the validity of some of the obtained local and nonlocal action principles, symmetries and constants of the motion for KdV and related equations.

II. PREVIEW AND NOTATION

Consider the autonomous equations of motion

$$\dot{q}^a(t)=V^a[q^b(t)], \quad a\in A. \tag{1}$$

A is a given ordered set called ''label set:'' the elements of it label the degrees of freedom of the theory. From now on, we suppress the dependence of the coordinates $\{q^a\}_{a\in A}$ on time when it is obvious.

Example 1: The KdV Equation for the field $u(x,t)$, $x\in[x_-,x_+]$, $t\in\mathbb{R}$, is

$$u_t=-u_{xxx}-12\,u\,u_x \tag{2}$$

(suffixes denote partial differentiation). The label set is $A=[x_-,x_+]$, and $x\in A$ is a continuous index.

We will use standard boundary conditions for the field: $u, u_x, \cdots\to 0$ as $x\to x_\pm$, and we will set $x_\pm=\pm\infty$, although the methods may be extended for the treatment of other boundary conditions as well (in which case the Weiss action principle[21] and the Witten–Zuckerman two-form[22] come into play).

The evolution equation (1) is naturally defined on a vector space spanned by the derivatives $\{\partial/\partial q^a\}_{a\in A}$ (for the infinite-dimensional case, partial derivatives with respect to the coordinates become functional derivatives). We call $V=V^a(\partial/\partial q^a)$ the flow vector or evolution vector for the system (1), where here, and throughout this paper, Einstein summation convention over repeated indices is assumed (for the infinite-dimensional case, the summation is extended to an integration over continuous indices).

A. Action principles

The equations of motion (1) are related to a variational principle with action

$$S[q^a(t),t]=\int_{t_-}^{t_+}\mathrm{d}t\,(P_a(\dot{q}^a-V^a)+K), \tag{3}$$

where the one-form $P[q^b]$ and the zero-form $K[q^b]$ satisfy the following equation:

$$P_{a,b}V^b+P_bV^b_{,a}=K_{,a},$$

with $K_{,a}\equiv\partial K/\partial q^a$.

We rewrite the above equation in terms of invariant structures:

$$\underset{V}{\mathcal{L}}P=\delta K, \tag{4}$$

where $\mathcal{L}_V$ is the Lie derivative along the vector V, and δ is the exterior differential (see Ref. 23 for a definition of these operators).

Definition 2: We call the pair $(P;K)$ a standard Lagrangian pair for V if $K\neq 0$. In the special case $K=0$ we call P a nonstandard Lagrangian (one-form) for V: the latter case allows for the construction of constants of the motion in a direct way[24] (see Theorem 9).

Remark 3: The above objects should not be confused with the usual "Lagrangian density" $L[q,\dot{q},t]=P_a(\dot{q}^a-V^a)+K$, which is the thing that is integrated in time to give the action: $S=\int L\,\mathrm{d}t$. The one-form P is also understood as a momentum map.[11] When P is a nonstandard Lagrangian, it solves the equation for a "conserved covariant."[5]

The general case of objects which depend explicitly on time is easily worked out,[25] but there is no need to do so in the applications of this paper. Nevertheless, for symmetries and constants of the motion the explicit time dependence will be necessarily taken into account. In the sequel, we give the name "time-(in)dependent" to those objects which do (not) depend explicitly on time.

The Euler–Lagrange equations which come from the action (3) are

$$\Sigma_{ab}(\dot{q}^b-V^b)=0,$$

where $\Sigma\equiv\delta P$ is the symplectic two-form or Lagrange bracket whose components are

$$\Sigma_{ab}=P_{b,a}-P_{a,b}.$$

It is worth mentioning that, in Ref. 22, a symplectic two-form is induced by an action principle in essentially the same way we have derived the above symplectic two-form from the action principle (3).

Notice that these Euler–Lagrange equations do not imply the original equations of motion (1); instead they imply deformed or mixed equations, where the deformation is represented by an additive extra term which is an arbitrary linear combination of vectors belonging to the kernel of the symplectic two-form. In the case of KdV, we will obtain the deformations explicitly. See Ref. 24 for examples in the finite-dimensional case.

The symplectic two-form associated to this action principle is easily shown to satisfy

$$\begin{aligned}\delta\Sigma&=0\ (\text{closure}),\\ \underset{V}{\mathcal{L}}\Sigma&=0,\end{aligned}\tag{5}$$

therefore the inverse process could be done: starting from a symplectic two-form Σ for the flow vector V, we construct the standard Lagrangian one-form, from $\delta P=\Sigma$ and the 0-form K is obtained by integration of Eq. (4). This process suffers from technical difficulties, which increase when the objects are infinite dimensional and nonlocal. Fortunately, for the KdV equation there is a constructive way of finding the action principles (see Theorems 6 and 7).

B. Hamiltonian theories are induced from symplectic structures

The relationship of the symplectic two-form with the Hamiltonian formulation is very simple:[26] consider the formal inverse (i.e., except for a finite kernel that the operators may possess) of the above two-form, the time-independent (2,0) tensor J such that $J\cdot\Sigma=\mathbb{I}$. It is possible to show that Σ is closed if and only if J satisfies the Jacobi identity, which we write in the form

$$\underset{J\cdot U}{\mathcal{L}}\,J=J\cdot\delta U\cdot J,\quad\forall\ \text{one-form}\ U.\tag{6}$$

J is known as a Hamiltonian operator or Poisson bracket. Now, Eq. (5) implies $\mathcal{L}_V J=0$. Therefore, according to the Jacobi identity (6), a Hamiltonian theory for the flow V is induced by the symplectic two-form Σ: the equation $V=J\cdot U$ implies $\delta U=0$, thus $V=J\cdot\delta H$, where H is the Hamiltonian, a time-independent 0-form.

C. Symmetries

Symmetries play a crucial role in the construction of the action principles. A symmetry for the system (1) is known as a vector with components η^a that takes solutions into solutions of Eq. (1), in the sense that given any solution $q^a(t)$ such that $\dot{q}^a(t)=V^a[q^b(t)]$, then $\tilde{q}^a \equiv q^a+\epsilon\,\eta^a[q^b,t]$ is also a solution up to order ϵ^2, i.e., $\dot{\tilde{q}}^a(t)=V^a[\tilde{q}^b(t)]+O(\epsilon^2)$.

It is easily seen[27] that this condition leads to the equation $(\partial/\partial t)\,\eta^a+\eta^a_{,b}\,V^b-V^a_{,b}\,\eta^b=0$ or, in a covariant way $[(\partial/\partial t)+\mathcal{L}_V]\,\eta=0$.

Example 4: The Galilean and the dilatation symmetries for the KdV equation are defined, respectively, by

$$\eta_G[u,t]^x=\tfrac{1}{8}-\tfrac{3}{2}t\,u_x,$$
$$\eta_D[u,t]^x=u+\tfrac{1}{2}x\,u_x-t(\tfrac{3}{2}u_{xxx}+18\,u\,u_x). \tag{7}$$

In Ref. 13, there is an open question concerning the role of the Galilean and dilatation symmetries in the construction of constants of the motion for KdV. An answer to this question is given in this work: these symmetries actually lead to action principles for the KdV equation, which are involved in Noetherian and non-Noetherian constructions[27] of constants of the motion (see Theorems 6, 7, and 9).

D. Constants of the motion

A constant of the motion for the system (1) is a functional (0-form) $C[q^a,t]$ which is conserved in time under the evolutionary system: $(D/Dt)\,C[q^b,t]\big|_{\text{on-shell}}\equiv(\partial/\partial t)\,C+C_{,\,a}\,V^a=0$, where the partial time derivative accounts for the explicit time dependence and D/Dt denotes the convective or total derivative along the variable t.

This equation is best written in a covariant way:[27] $[(\partial/\partial t)+\mathcal{L}_V]C=0$.

We will usually work with time-independent constants of the motion: $(\partial/\partial t)\,C=\mathcal{L}_V C=0$.

E. The Hereditary property: Hierarchies of evolution equations

Many integrable systems are related to a Nijenhuis or hereditary operator, which is a time-independent (1,1) tensor R that solves:[26] $\mathcal{L}_{R\cdot\eta}R=R\cdot\mathcal{L}_\eta R$, $\forall$ vector η.

Out of the kernel of this operator, and of its inverse, hierarchies of integrable evolution equations arise which are symmetries of each other[4] (this will be worked out in detail for the KdV case later on).

According to Ref. 4, given a hereditary operator R and a flow vector field (labeled with a number) V_1 such that $\mathcal{L}_{V_1}R=0$, i.e., R is a recursion operator for V_1, then a hierarchy is defined as a semi-infinite collection of evolution vectors: $\{V_j=R^{j-1}\cdot V_1, j=1,\ldots,\infty\}$, which are symmetries of each other: $\mathcal{L}_{V_i}V_j=0$, $i,j\geqslant 1$, and thus every evolution vector in the hierarchy defines an evolution equation which is integrable. In the KdV hierarchy, the KdV equation is the second member (V_2). The first vector (V_1) represents the translation symmetry, and it is shown to generate the kernel of the inverse hereditary operator, R^{-1}. By convention, we refer to the above as a positive hierarchy.

The hereditary property for the operator R may be used to show formally that R^{-1} is also hereditary.[14] Therefore, we could conjecture that new hierarchies (referred to as negative hierarchies) of evolution vectors may be constructed, which first members generate the kernel of the operator R, and successive members are defined by contraction of the first members with powers of the operator R^{-1}. In the KdV case, there are three negative hierarchies. These new negative equations include the ShG, Liouville, Camassa–Holm, and the Hunter–Zheng equations.

F. Notation: The positive and negative hierarchies in terms of the hereditary operators

The analysis is restricted to the KdV hierarchies, but it is easily generalizable to other systems related to hereditary operators.

We will adopt the following notation for evolution vectors in the hierarchies:

$$u_t = V_n^{(k)}[u],$$

where $k=1$ denotes the positive hierarchy; $k=-1,-2,-3$ for the three negative hierarchies, and $n=1,\ldots,\infty$ denotes the place of a vector within the hierarchy, so that we have $n=1$ for the first vector of each hierarchy, i.e., the relevant generator of the kernel of $R^{-\mathrm{sgn}(k)}$:

$$R^{-1}[u]\cdot V_1^{(1)}[u]=0,$$

$$R[u]\cdot V_1^{(-1)}[u]=R[u]\cdot V_1^{(-2)}[u]=R[u]\cdot V_1^{(-3)}[u]=0. \tag{8}$$

Successive members in the hierarchies are defined by recurrence:

$$V_{n+1}^{(k)}[u]=(R[u])^{\mathrm{sgn}(k)}\cdot V_n^{(k)}[u], \quad n\geqslant 1, \quad k=1,-1,-2,-3.$$

In this way, the positive hierarchy begins with the vector $V_1^{(1)}[u]=-u_x$, continues with the KdV vector $V_2^{(1)}[u]=-u_{xxx}-12\,u\,u_x$, and so on (these vectors were called V_1 and V_2 in the preceding subsection).

For the negative hierarchy, as the operator R^{-1} is harder to work with, there is a recurrent way of writing the negative vectors, in terms of R:

$$V_n^{(k)}[u]=R[u]\cdot V_{n+1}^{(k)}[u], \quad n\geqslant 1, \quad k=-1,-2,-3. \tag{9}$$

The explicit expression for negative vectors relies on the factorized form[14,28] of the hereditary operator, and will be realized in Sec. IV in terms of nonlocal fields which, however, are tractable in the same scheme as the local ones.

III. LADDERS OF ACTION PRINCIPLES AND CONSTANTS OF THE MOTION

Complementary to the well-known bi-Hamiltonian formulation,[4] we may find a bi-symplectic or multisymplectic structure starting from the hereditary property. Assume that we have a Nijenhuis operator R along with one closed two-form $\Sigma^{(1)}$ such that $\Sigma^{(2)}\equiv\Sigma^{(1)}\cdot R$ be a closed two-form: then, the two semi-infinite dimensional sets (symplectic ladders) of two-forms

$$\{\Sigma^{(n)}\equiv\Sigma^{(1)}\cdot R^{n-1}, \quad n=1,\ldots,\infty\} \quad (\text{positive symplectic ladder})$$

and

$$\{\Sigma^{(n)}\equiv\Sigma^{(1)}\cdot R^{n-1}, \quad n=0,-1,\ldots,-\infty\} \quad (\text{negative symplectic ladder}),$$

contain only closed two-forms. The distinction between positive and negative ladders is somewhat arbitrary, for it depends on which hereditary operator, R or R^{-1}, is being used, and which symplectic two-form is taken as $\Sigma^{(1)}$.

The proof of the above statement is very simple. In fact, it is equivalent to the proof for the so-called Poisson pencil or set of compatible implectic operators[4] for multi-Hamiltonian theories, after defining the implectic or Hamiltonian operators as the inverses of the two-forms in the ladder.

The above result is independent of any evolution vector. When we consider the vectors in the hierarchies, however, it is easily checked (as it holds in the examples) that $\mathcal{L}_{V_1}\Sigma^{(1)}=0$. Therefore, using Leibnitz rule, all the two-forms in the ladder are symplectic operators for the first evolution vector in the hierarchy.

Using the identity $\mathcal{L}_{R\cdot\eta}\Sigma-\mathcal{L}_{\eta}(\Sigma\cdot R)=i_{R\cdot\eta}\delta\Sigma-i_{\eta}\delta(\Sigma\cdot R)$, which holds for any vector η, (1,1) tensor R and two-form Σ, where i_{η} stands for interior product (contraction of the vector η with the left component of a p-form), we obtain the important result for any hierarchy:

$$\underset{V_j}{\mathcal{L}}\Sigma^{(n)}=0, \quad j=1,2,\ldots,\infty, \quad n=-\infty,\ldots,\infty, \tag{10}$$

which means that a ladder of action principles may be constructed for every evolution vector in the hierarchy (in particular, for the KdV equation).

This fact is used in Ref. 11 to construct action principles, with the only drawback it needs to integrate the two-forms (Poincaré lemma) in order to get the action principles.

Let us assume for the rest of this section that we have a Nijenhuis operator R along with its inverse R^{-1}, a symplectic ladder $\{\Sigma^{(n)},n=-\infty,\ldots,\infty\}$, and a hierarchy $\{V_j,j=1,\ldots,\infty\}$ with the corresponding properties mentioned above.

The purpose of the following section is to construct, for the second evolution vector in the positive hierarchy (though the analysis is easily extended for other positive and negative evolution vectors), the action principles associated to each of the above symplectic two-forms. These action principles are involved in the explicit construction of constants of the motion for the evolution equation.

A. Construction of action principles and constants of the motion out of symmetries and symplectic operators

Heuristically, if we had a symmetry for a given evolution equation we could obtain in a direct way (by contraction of it with any symplectic two-form) a Lagrangian one-form and therefore an action principle for that equation.

We have done this procedure for any equation in the positive hierarchy, using the Galilean symmetry, obtaining as a result a ladder of action principles which are (explicitly) time-dependent (in fact, linear in time). For simplicity, however, we rewrite the actions as time-independent objects, and the discussion will be restricted to the second vector (which corresponds to the KdV equation), which is from now on referred to as the vector V_2.

The following definition will be a key to the construction of the ladder of action principles for the evolution vector V_2, and it permits a generalization to the negative hierarchies as well as to other systems (e.g., nonlinear Schrödinger equation).

Definition 5: The Galilean vector field η_{gal} is a time-independent vector field, defined by three properties,

$$\begin{aligned}
&\underset{\eta_{\mathrm{gal}}}{\mathcal{L}}R=\mathbb{I},\\
&\underset{\eta_{\mathrm{gal}}}{\mathcal{L}}\Sigma^{(1)}=0,\\
&\underset{\eta_{\mathrm{gal}}}{\mathcal{L}}V_2=\alpha V_1,
\end{aligned} \tag{11}$$

where α is a numeric constant.

As a consequence of the definition, it turns out that η_{gal} is a Mastersymmetry[29] for the hierarchy $\{V_j,\ j=1,\ldots,\infty\}$. Explicitly, we have $\mathcal{L}_{V_{j+1}}\eta_{\mathrm{gal}}=(\alpha+j-1)\,V_j$, for $j=1,\ldots,\infty$.

The aim is to construct time-independent standard Lagrangian pairs $(P;K)$, where $\mathcal{L}_{V_2}P=\delta K$. The action principles will read $S[q^a(t)]=\int_{t_-}^{t_+}\mathrm{d}t\,(P_a(\dot{q}^a-V_2^a)+K)$, and the Euler–Lagrange equations will involve the symplectic two-forms in the ladder, i.e., $\delta P=\Sigma$.

Theorem 6: *The one-forms defined by* $P^{(m)}\equiv i_{\eta_{\mathrm{gal}}}\Sigma^{(m+1)}$, *for* $m=-\infty,\ldots,\infty$ *are "integrals" of the symplectic two-forms in the ladder. That is to say,*

$$\delta P^{(m)} = m\,\Sigma^{(m)}, \quad m = -\infty, \ \ldots, \infty. \tag{12}$$

Proof: If we take the exterior derivatives of the one-forms, using the identity

$$\underset{\eta}{\mathcal{L}} = i_\eta\,\delta + \delta\, i_\eta, \tag{13}$$

which holds (for every vector η) when operating on any p-form, we find

$$\delta P^{(m)} = \underset{\eta_{\mathrm{gal}}}{\mathcal{L}}\,\Sigma^{(m+1)} = \underset{\eta_{\mathrm{gal}}}{\mathcal{L}}\,(\Sigma^{(1)}\cdot R^m) = \Sigma^{(1)}\cdot \underset{\eta_{\mathrm{gal}}}{\mathcal{L}}\,(R^m) = m\,\Sigma^{(1)}\cdot R^{m-1} = m\,\Sigma^{(m)}, \quad m \in \mathbb{Z}$$

after using the definition of Galilean vector and Leibnitz rule. □

In order to complete the action principles, there remains to find the second members of the corresponding standard Lagrangian pairs.

Theorem 7: *For each $m \in \mathbb{Z}$, the pair $(P^{(m)};K^{(m)})$ with $K^{(m)} \equiv \alpha/(m+\alpha)\, i_{V_2} P^{(m)}$, is a standard Lagrangian pair for the evolution equation $\dot{q}^a = V_2^a$,* i.e., *$\mathcal{L}_{V_2} P^{(m)} = \delta K^{(m)}$. For $m \neq 0$, the action principle is*

$$S^{(m)}[q^a(t)] = \int_{t_-}^{t_+} P^{(m)}{}_a \left(\dot{q}^a - \frac{m}{m+\alpha} V_2^a \right) \mathrm{d}t. \tag{14}$$

Moreover, the 0-forms $K^{(m)}$ are constants of the motion for the evolution equation, for $m \in \mathbb{Z}$:

$$\underset{V_2}{\mathcal{L}} K^{(m)} = 0.$$

The above is a Noetherian way to construct constants of the motion, for all the action principles in the ladder for KdV are naturally invariant under the KdV flow V_2 itself [see Eq. (10)].

Remark 8: The case $m = 0$ would lead to a trivial action principle from Eq. (14), for the Euler–Lagrange equations are identically zero: it is shown that this case leads to a time-dependent constant of the motion. This does not mean that the symplectic two-form $\Sigma^{(0)}$ defines a trivial action principle. In fact, its associated action principle may be found by hand (see the end of this section), and it is related to the usual action principle for the ShG equation (see Sec. V B).

Proof: Lagrangian pairs. For $m \in \mathbb{Z}$, take Lie derivatives of the one-forms $P^{(m)}$ along the evolution vector V_2, using Leibnitz rule:

$$\underset{V_2}{\mathcal{L}} P^{(m)} = \underset{V_2}{\mathcal{L}}\, i_{\eta_{\mathrm{gal}}} \Sigma^{(m+1)} = -\alpha\, i_{V_1} \Sigma^{(m+1)} = -\alpha\, i_{V_2} \Sigma^{(m)}. \tag{15}$$

But, using the identity (13) and the result (12) we rewrite the last expression to get

$$m \underset{V_2}{\mathcal{L}} P^{(m)} = -\alpha \left(\underset{V_2}{\mathcal{L}} P^{(m)} - \delta\, i_{V_2} P^{(m)} \right),$$

therefore

$$\underset{V_2}{\mathcal{L}} P^{(m)} = \delta \left(\frac{\alpha}{m+\alpha}\, i_{V_2} P^{(m)} \right) \equiv \delta K^{(m)}. \tag{16}$$

Proof: Constants of the motion. We use the above result (16), to find

$$\frac{m+\alpha}{\alpha} \underset{V_2}{\mathcal{L}} K^{(m)} = i_{V_2} \underset{V_2}{\mathcal{L}} P^{(m)} = i_{V_2} \delta K^{(m)} = \underset{V_2}{\mathcal{L}} K^{(m)},$$

which implies $\mathcal{L}_{V_2}K^{(m)}=0,\ m\neq 0$.

For $m=0$ we find a weaker result: Equation (15) implies $\delta\mathcal{L}_{V_2}K^{(0)}=0$. Therefore $\mathcal{L}_{V_2}K^{(0)}=c$, is a number (usually equal to zero) that may be absorbed to define a time-dependent constant of the motion: $\tilde{K}^{(0)}(t)=K^{(0)}-c\,t$. □

For the KdV equation, when $m\geqslant -1$ we get the usual denumerably infinite set of constants of the motion.[30] Notice that this theorem represents also a constructive method to obtain such constants. On the other hand, when $m\leqslant -2$ the constants are numerical or vanishing boundary terms. Amazingly, this fact allows one to construct an infinite number of nonlocal constants of the motion for KdV, using the nonlocal action principles (see Sec. III C).

Proof: Action principles. The action principles (14) arise directly from Eq. (3), using the definition of $K^{(m)}$. □

From the point of view of Theorem 7, the case $m=0$ also leads to a time-dependent constant of the motion. From Eq. (12), it follows that $P^{(0)}=\delta C^{(0)}$, and thus $\mathcal{L}_{V_2}C^{(0)}=K^{(0)}$. But we know that $\mathcal{L}_{V_2}K^{(0)}=c$ is a number. We obtain the following time-dependent constant of the motion for the evolution vector V_2:

$$C[q^a(t),t]=C^{(0)}-t\,K^{(0)}+\frac{c\,t^2}{2}. \tag{17}$$

Finally, for the case $m=0$, a special (''missing'') action principle is constructed by hand from integration of the two-form $\Sigma^{(0)}$, which leads to the one-form $P^{(M)}$, such that $\delta P^{(M)}=\Sigma^{(0)}$. We will have $\mathcal{L}_{V_2}P^{(M)}=\delta K^{(M)}$, and the action is

$$S^{(0)}[q^a(t)]=\int_{t_-}^{t_+}(P_a^{(M)}(\dot{q}^a-V_2^a)+K^{(M)})\,\mathrm{d}t.$$

B. The Euler–Lagrange equations as deformed evolution equations

The Euler–Lagrange equations that arise from variation of each action $S^{(m)}$, $m\in\mathbb{Z}$ are, apart from nonzero numeric factors,

$$\Sigma_{ab}^{(m)}(\dot{q}^b-V_2^b)=0,\quad m\in\mathbb{Z}.$$

The kernel of the symplectic operators, $\mathrm{Ker}\,\Sigma^{(m)}$, is of importance here. For each action principle we obtain an equivalent, deformed, evolution equation

$$\dot{q}^a=V_2^a+\sum_{j=1}^{N_m}\theta_j\,\eta_{j;m}^a,$$

where $N_m=\dim(\mathrm{Ker}\,\Sigma^{(m)})$, the vectors $\{\eta_{j;m}\}_{j=1}^{N_m}$ generate the kernel of $\Sigma^{(m)}$, and $\theta_j=\theta_j(t)$ are arbitrary 0-forms: it can be said that these Euler–Lagrange equations and the action principles acquire extra symmetries (as compared to the symmetries of the original equations).

As the two-forms here are formed by contraction of powers of the hereditary operators R and R^{-1} with $\Sigma^{(1)}$, it is clear that the kernel of the two-forms are computed essentially from vectors in the kernel of the operators R^m and R^{-m}, for $m>0$: as we have mentioned, these are the positive and negative evolution vectors. In Sec. IV, we will find explicitly the deformed equations for the KdV equation in terms of the positive and negative vectors.

C. Construction of nonlocal constants of the motion from symmetries and nonstandard Lagrangian one-forms

Let us assume, as it will be demonstrated in Sec. IV H for the KdV case (under usual boundary conditions), that the constants of the motion from Theorem 7 are $K^{(m)}=0$ or a numeric constant

for $m\leqslant -2$. This implies that $\mathcal{L}_{V_2}P^{(m)}=0$, i.e., $P^{(m)}$ is a nonstandard Lagrangian one-form for the flow V_2. Assume also that the evolution equation defined by the flow V_2 possesses a symmetry η. Then

Theorem 9: *The* 0*-forms defined by* $Q^{(m)}\equiv i_\eta P^{(m)}$, *for* $m\leqslant -2$, *are constants of the motion for the flow* V_2, *i.e.,* $(\partial_t+\mathcal{L}_{V_2})Q^{(m)}=0$ *for* $m\leqslant -2$.

Proof: The proof follows directly from Leibnitz rule. □

The above is a non-Noetherian way[27] to construct constants of the motion, in the sense that the action principles need not be invariant under the relevant symmetry. In Sec. IV J we construct ''generating functions'' for three infinite-dimensional sets of nonlocal constants of the motion for the KdV equation, setting η as a nonlocal internal symmetry for KdV.

IV. EXAMPLE: THE KDV EQUATION

A. Known objects

We begin by presenting the Nijenhuis operator relevant for the KdV hierarchy: as an operator,[4] $R[u]=\mathrm{D}^2+8\,u+4\,u_x\,\mathrm{D}^{-1}$, where D and D^{-1} are, respectively, the derivative and the antiderivative operators: $\mathrm{D}f(x)\equiv \partial f(x)/\partial x$, $\mathrm{D}^{-1}g(x)\equiv\int_{x_-}^{x_+}\epsilon(x-x')\,g(x')\,\mathrm{d}x'$, with $\epsilon(x-x')=1/2\,\mathrm{sign}(x-x')$.

Next, the positive hierarchy begins with the vector $V_1^{(1)}[u]=-u_x$. The second vector in the positive hierarchy is obtained after application of the Nijenhuis operator on the latter vector: $V_2^{(1)}[u]=R[u]\cdot V_1^{(1)}[u]=-u_{xxx}-12\,u\,u_x\equiv V_2[u]$. We see it represents the KdV equation (2).

Next, we write the first symplectic two-form: as an operator,[4] $\Sigma^{(1)}[u]=\mathrm{D}^{-1}$. The second symplectic operator is constructed just by contracting the latter operator with the Nijenhuis operator: $\Sigma^{(2)}[u]=\Sigma^{(1)}[u]\cdot R[u]=\mathrm{D}+4\,u\,\mathrm{D}^{-1}+4\,\mathrm{D}^{-1}u$. These operators are closed under usual boundary conditions for the vector fields: the ladder, then, contains only closed two-forms. Now, it is easy to show that these operators are symplectic for the flow defined by $V_1^{(1)}$, therefore all operators in the ladder are symplectic for the KdV flow $V_2^{(1)}$, as it is stated in Eq. (10).

Finally, the Galilean vector is just the time-independent part of the Galilean symmetry (7): $\eta_{\mathrm{gal}}[u]=\frac{1}{8}$, and the constant in the last of the defining equations (11) is $\alpha=3/2$.

B. Explicit form of the KdV negative hierarchies: Linear generalization and factorization of the hereditary operator

In order to find explicitly the KdV negative hierarchies, we factorize a generalization of the hereditary operator R, which is obtained by addition of a multiple of the identity tensor $\mathbb{I}$:

$$R(\lambda)[u]\equiv R[u]+4\,\lambda\,\mathbb{I}.$$

This is also a hereditary operator, for fixed λ, which is taken as an arbitrary real number.

The idea behind this generalization, is that the kernel of $R(\lambda)[u]$ contains all the negative hierarchies in its Taylor expansion around $\lambda=0$, so we will write the negative hierarchies in a compact way.

Lemma 10: The vectors $V_1^{(-1)}(\lambda)[u]$, $V_1^{(-2)}(\lambda)[u]$, $V_1^{(-3)}(\lambda)[u]$, *defined by*

$$V_1^{(k)}(\lambda)[u]\equiv\sum_{n=0}^{\infty}(-4\,\lambda)^n\,V_{n+1}^{(k)}[u],\quad k=-1,-2\,-3$$

generate the vectorial kernel of $R(\lambda)[u]$.

Conversely, all vectors in the negative hierarchies may be obtained from the vectorial kernel of $R(\lambda)[u]$:

$$V_{n+1}^{(k)}[u]=\frac{1}{n!}(-4)^{-n}\frac{\partial^n}{\partial\lambda^n}V_1^{(k)}(\lambda)[u]\bigg|_{\lambda=0},\quad k=-1,-2\,-3,\ \ n=0,1,\ldots,\infty. \tag{18}$$

Proof: Consider the action of $R[u]$ on the vector $V_1^{(k)}(\lambda)[u]$. Using Eqs. (8) and (9), we get

$$R[u]\cdot V_1^{(k)}(\lambda)[u]=\sum_{n=0}^{\infty}(-4\lambda)^n R[u]\cdot V_{n+1}^{(k)}[u]=\sum_{n=1}^{\infty}(-4\lambda)^n V_n^{(k)}[u]=-4\lambda V_1^{(k)}(\lambda)[u],$$

therefore $R(\lambda)[u]\cdot V_1^{(k)}(\lambda)[u]=(R(\lambda)[u]+4\lambda)\cdot V_1^{(k)}(\lambda)[u]=0$. □

The factorization process[28] implies the definition of auxiliary fields, which are directly related to nonlocal prepotentials found in the literature[14] and to the associated isospectral linear eigenvalue problem:[31]

$$\psi_{xx}+2u\psi=-\lambda\psi, \tag{19}$$

where $\psi=\psi(x,t;\lambda)$. As usual, we assume $\lambda_t=0$, and $u=u(x,t)$ is independent of λ.

Alternatively, we write the above equation as $L(\lambda)\cdot\psi=0$, where $L(\lambda)=\mathrm{D}^2+2u+\lambda$ or, in a factorized way, $L(\lambda)=(1/\psi)\,\mathrm{D}\,\psi^2\,\mathrm{D}\,(1/\psi)$, is the Lax operator. The elements in the kernel of this operator are solutions of the linear problem (19). Two linearly independent solutions are $\psi(\lambda)\equiv\psi(x,t;\lambda)$ and

$$\overline{\psi}(\lambda)\equiv\psi(\lambda)\mathrm{D}^{-1}(1/\psi(\lambda)^2). \tag{20}$$

The above eigenvalue problem may be understood as an extended coordinate system labeled by $\psi(x,t;\lambda)$, with λ as an additional variable (just like x), and which however must solve an extra equation, $L(\lambda)\cdot\psi(\lambda)=0$, which we call constraint. This constraint lets us write derivatives of the field $\psi(\lambda)$ with respect to λ in terms of the field itself, in a nonlocal way. This will be useful in the next section, when we write the negative ladder of action principles. We obtain, apart from integration constants,

$$\begin{aligned}\frac{\partial^n}{\partial\lambda^n}\psi&=(-1)^n n!\,L(\lambda)^{-n}\psi,\\ \frac{\partial^n}{\partial\lambda^n}\overline{\psi}&=(-1)^n n!\,L(\lambda)^{-n}\overline{\psi},\quad n\geqslant 1,\end{aligned} \tag{21}$$

where $L(\lambda)^{-1}=\psi\,\mathrm{D}^{-1}\,(1/\psi^2)\,\mathrm{D}^{-1}\,\psi$, $\psi=\psi(\lambda)$ and $\overline{\psi}=\overline{\psi}(\lambda)$.

Now, the factorization of $R(\lambda)[u]$ is found to be

$$R(\lambda)[u]=\frac{1}{\psi(\lambda)^2}\,\mathrm{D}\,\psi(\lambda)^2\,\mathrm{D}\,\psi(\lambda)^2\,\mathrm{D}\frac{1}{\psi(\lambda)^2}\,\mathrm{D}^{-1}.$$

It is remarkable that the above operator is *linear* in λ, which is a consequence of the constraint (19).

The kernel of the operator $R(\lambda)[u]$ is easily found to be composed by three nonlocal vectors:

$$\begin{aligned}u_t&=V_1^{(-1)}(\lambda)[u]=(\psi(\lambda)^2)_x,\\ u_t&=V_1^{(-2)}(\lambda)[u]=(\psi(\lambda)\,\overline{\psi}(\lambda))_x,\\ u_t&=V_1^{(-3)}(\lambda)[u]=(\overline{\psi}(\lambda)^2)_x,\end{aligned} \tag{22}$$

where $\psi(\lambda)$, $\overline{\psi}(\lambda)$ [see Eq. (20)] are two linearly independent solutions of the constraint (19). These vectors contain the whole negative hierarchies if λ is left arbitrary, as lemma 10 states. A discrete infinite-dimensional representation of these negative vectors, as nonlocal symmetries of the KdV equation, is known.[14] On the other hand, the continuous representation (22) of these

vectors, more suitable for field theory, allows for considering them also as possible evolution equations, which will be recognized as known integrable equations in Sec. V A.

C. Explicit form and Kernel of the inverse hereditary operator R^{-1}

The inverse hereditary operator, $R^{-1}(\lambda)$, is found easily after inverting every factor. Assuming appropriate boundary conditions on the field ψ, we get

$$R^{-1}(\lambda)[u]=\mathrm{D}\,\psi(\lambda)^2\,\mathrm{D}^{-1}\frac{1}{\psi(\lambda)^2}\mathrm{D}^{-1}\frac{1}{\psi(\lambda)^2}\mathrm{D}^{-1}\,\psi(\lambda)^2.$$

It is easy to show that the kernel of this operator is generated by the vector $V_1^{(1)}=-u_x$.

D. Factorization of positive and negative symplectic and Hamiltonian operators

Using the factorized form of the hereditary operators, we get easily the symplectic operators in factorized form. For the positive ones, we have

$$\Sigma^{(2)}[u]=\mathrm{D}^{-1}\frac{1}{\psi^2}\mathrm{D}\,\psi^2\,\mathrm{D}\,\psi^2\,\mathrm{D}\frac{1}{\psi^2}\mathrm{D}^{-1},$$

$$\Sigma^{(3)}[u]=\mathrm{D}^{-1}\frac{1}{\psi^2}\mathrm{D}\,\psi^2\,\mathrm{D}\,\psi^2\,\mathrm{D}\frac{1}{\psi^2}\mathrm{D}^{-1}\frac{1}{\psi^2}\mathrm{D}\,\psi^2\,\mathrm{D}\,\psi^2\,\mathrm{D}\frac{1}{\psi^2}\mathrm{D}^{-1},$$

and so on, where $\psi=\psi(\lambda=0)$. Notice that the inverses of these operators give new nonlocal Hamiltonian operators for KdV.

For the negative ones, on the other hand, we have

$$\begin{aligned}\Sigma^{(0)}[u]&=\psi^2\,\mathrm{D}^{-1}\frac{1}{\psi^2}\mathrm{D}^{-1}\frac{1}{\psi^2}\mathrm{D}^{-1}\,\psi^2,\\ \Sigma^{(-1)}[u]&=\psi^2\,\mathrm{D}^{-1}\frac{1}{\psi^2}\mathrm{D}^{-1}\frac{1}{\psi^2}\mathrm{D}^{-1}\,\psi^2\,\mathrm{D}\,\psi^2\,\mathrm{D}^{-1}\frac{1}{\psi^2}\mathrm{D}^{-1}\frac{1}{\psi^2}\mathrm{D}^{-1}\,\psi^2,\end{aligned}\tag{23}$$

and so on. By the way, the above expression for $\Sigma^{(0)}[u]$ turns out to solve a puzzle in the recent literature,[10] for it is the inverse of Magri's Hamiltonian operator. As we see, we have got all inverses (in factorized form) of all Hamiltonian operators within the multi-Hamiltonian structure for KdV.

There is another, concise way to write these negative operators, which resembles the way we wrote the negative vectors in terms of the λ-dependent first one. We state the lemma without proof.

Lemma 11: The negative symplectic operators for KdV are written in terms of $\Sigma^{(0)}(\lambda)[u]\equiv\Sigma^{(1)}\cdot R^{-1}(\lambda)[u]$ *in the following way:*

$$\Sigma^{(-n)}[u]=\frac{1}{n!}(-4)^{-n}\frac{\partial^n}{\partial\lambda^n}\Sigma^{(0)}(\lambda)[u]\bigg|_{\lambda=0},\quad n\geqslant 1.$$

A similar formula may be written for the nonlocal Hamiltonian operators.

E. Negative vectors as kernel of positive symplectic operators

The kernel spaces $\mathrm{Ker}\,\Sigma^{(n)}[u]$, for $n=1,\ldots,\infty$, are easily computed in terms of the kernel of positive powers of R, from the fact that $\mathrm{Ker}\,\Sigma^{(1)}[u]$ is null. We get

$$\mathrm{Ker}\,\Sigma^{(n+1)}=\mathrm{span}\{V_m^{(k)}[u],\quad k=-1,-2,-3,\ m=1,\ldots,n\},\quad n\geqslant 0.$$

F. Positive vectors as kernel of negative symplectic operators

Finally we compute the kernel spaces $\mathrm{Ker}\,\Sigma^{(n)}[u]$, for $n=0,-1,\ldots,-\infty$. It is easily seen that the operator $\Sigma^{(0)}[u]$ has a null kernel. This time we have to evaluate the kernel of negative powers of R. We get

$$\mathrm{Ker}\,\Sigma^{(-n)}[u]=\mathrm{span}\{V_m^{(1)}[u],\quad m=1,\ldots,n\},\quad n>0,$$

so that, in particular, the action principle associated to $\Sigma^{(-2)}[u]$ for the KdV equation has the translation vector as well as the KdV vector as generators of its kernel, therefore the action has to be time-reparametrization invariant.[24]

G. Action principles for KdV: Positive Lagrangian ladders

Remark 12: If $P_a\,\delta u^a$ denotes a one-form, where $a\equiv x$ is a continuous index, we will write the component P_a of the one-form as $\mathcal{P}(x,t)$ (which looks more like a density) when dealing with it inside an integral sign.

Following Theorems 6 and 7, we write the action principles from Eq. (14):

$$S^{(m)}[u(x,t)]=\int_{t_-}^{t_+}\int_{x_-}^{x_+}\mathcal{P}^{(m)}[u](x,t)\left(u_t+\frac{m}{m+3/2}(u_{xxx}+12\,u\,u_x)\right)\mathrm{d}x\,\mathrm{d}t,\tag{24}$$

for $m>0$, where

$$\mathcal{P}^{(1)}[u](x,t)=i_{\eta_{\mathrm{gal}}}\Sigma^{(2)}[u]=-(\mathrm{D}+4\,u\,\mathrm{D}^{-1}+4\,\mathrm{D}^{-1}\,u)\,\tfrac{1}{8}=-\,\tfrac{1}{2}(x\,u+\mathrm{D}^{-1}(u)),$$

and successive one-forms are defined by recurrence: $\mathcal{P}^{(m+1)}[u](x,t)=R^{\dagger}[u]\cdot\mathcal{P}^{(m)}[u](x,t)$, where $R^{\dagger}[u]$ is the transpose Nijenhuis operator.

The action principle $S^{(1)}[u(x,t)]$ gives rise to the following Euler–Lagrange equations:

$$\mathrm{D}^{-1}(u_t+u_{xxx}+12\,u\,u_x)=0,$$

which are equivalent to KdV. The associated constant of the motion is

$$H^{(1)}[u]\equiv i_{V_2}P^{(1)}=\frac{1}{2}\int\mathrm{d}x\,(x\,u+\mathrm{D}^{-1}(u))(u_{xxx}+12\,u\,u_x)=\frac{5}{4}\int\mathrm{d}x\,(u_x^2-4\,u^3),$$

which is a member of the known set.

The next action principle is written as Eq. (24), with

$$\mathcal{P}^{(2)}[u](x,t)=R^{\dagger}[u]\cdot\mathcal{P}^{(1)}[u](x,t)=-\,\tfrac{1}{2}(3\,u_x+x\,u_{xx}+6\,x\,u^2+4\,u\,\mathrm{D}^{-1}(u)+6\,\mathrm{D}^{-1}(u^2)).$$

The Euler–Lagrange equations are $2\,(\mathrm{D}+4\,u\,\mathrm{D}^{-1}+4\,\mathrm{D}^{-1}\,u)(u_t+u_{xxx}+12\,u\,u_x)=0$ or, in factorized form, $2\,\mathrm{D}^{-1}\,(1/\psi^2)\,\mathrm{D}\,\psi^2\,\mathrm{D}\,\psi^2\,\mathrm{D}\,(1/\psi^2)\,\mathrm{D}^{-1}\,(u_t+u_{xxx}+12\,u\,u_x)=0$. These equations are not equivalent to the original equations: instead, they are equivalent to the deformed equations

$$u_t=-u_{xxx}-12\,u\,u_x+\theta_1\,(\psi^2)_x+\theta_2\,(\psi\,\overline{\psi})_x+\theta_3\,(\overline{\psi^2})_x,$$

where θ_j are arbitrary 0-forms that multiply the generators of $\mathrm{Ker}\,\Sigma^{(2)}[u]$, and $\psi=\psi(\lambda=0)$.

We could continue this process constructively, obtaining explicitly the constants of the motion and the action principles as well as the Euler–Lagrange equations: the original KdV equation gets deformed with vectors in the negative hierarchies, as it was mentioned before.

H. Action principles for KdV: Negative Lagrangian ladders

Now we turn to the construction of the negative action principles for KdV, whose action functionals are defined by

$$S^{(m)}[u(x,t)]=\int_{t_-}^{t_+}\int_{x_-}^{x_+}\mathcal{P}^{(m)}[u](x,t)\left(u_t+\frac{m}{m+3/2}(u_{xxx}+12\,u\,u_x)\right)\mathrm{d}x\,\mathrm{d}t,$$

for $m<0$. We only need to evaluate $\mathcal{P}^{(-m)}[u](x,t)=(R^{\dagger}[u])^{-m}\cdot\mathcal{P}^{(0)}[u](x,t)$, for $m<0$. This is done easily after stating the following corollary (from lemma 11).

Corollary 13: The negative one-forms are obtained from the first negative one as follows:

$$\mathcal{P}^{(-n-1)}[u](x,t)=\frac{1}{n!}(-4)^{-n}\frac{\partial^n}{\partial\lambda^n}\mathcal{P}^{(-1)}(\lambda)[u](x,t)\Big|_{\lambda=0},\quad n\geqslant 1,$$

where $\mathcal{P}^{(-1)}(\lambda)[u](x,t)=-\frac{1}{8}\psi^2\,\mathrm{D}^{-1}\,1/\psi^2\,\mathrm{D}^{-1}\,1/\psi^2\,\mathrm{D}^{-1}\psi^2$ *or, using Eq.* (21),

$$\mathcal{P}^{(-1)}(\lambda)[u](x,t)=\tfrac{1}{16}(\psi_\lambda\,\overline{\psi}-\psi\,\overline{\psi}_\lambda).$$

The first negative action principle from Eq. (24) is thus

$$S^{(-1)}[u(x,t)]=\int_{t_-}^{t_+}\int_{x_-}^{x_+}\frac{1}{16}(\psi_\lambda\,\overline{\psi}-\psi\,\overline{\psi}_\lambda)\left(u_t+\frac{-1}{-1+3/2}(u_{xxx}+12\,u\,u_x)\right)\mathrm{d}x\,\mathrm{d}t,$$

or, after some manipulations, $S^{(-1)}[u(x,t)]=\int_{t_-}^{t_+}\int_{x_-}^{x_+}(\frac{1}{16}(\psi_\lambda\,\overline{\psi}-\psi\,\overline{\psi}_\lambda)\,u_t-\frac{1}{4}u)\,dx\,dt$, where we have to evaluate the fields ψ, $\overline{\psi}$ at $\lambda=0$. This action principle is highly nonlocal, even in terms of the auxiliary fields [see Eq. (21)]. However, the Euler–Lagrange equations are obtained as usual, varying the action with respect to the field u, and using the appropriate transformation matrices. We obtain $-\Sigma^{(-1)}[u]\cdot(u_t+u_{xxx}+12\,u\,u_x)=0$, or explicitly, using the fact that the kernel of this operator is generated by $V_1^{(1)}$,

$$u_t=-u_{xxx}-12\,u\,u_x+\theta_1\,u_x,$$

where θ_1 is arbitrary.

We stress there is no need to hesitate about the inclusion of auxiliary fields in the negative action principles, for they are not varied independently. Alternatively, we may map the above action into a mixed action principle, in which the fields ψ, u, and a Lagrange multiplier ρ are varied independently,

$$S^{(-1)}[\psi(x,t),u(x,t),\rho(x,t)]=\int_{t_-}^{t_+}\int_{x_-}^{x_+}\left(\frac{1}{16}\frac{\psi_t}{\psi^3}(\mathrm{D}^{-1}\psi^2)+\frac{1}{8}\frac{\psi_{xx}}{\psi}+\rho\left(u+\frac{\psi_{xx}}{2\,\psi}\right)\right)\mathrm{d}x\,\mathrm{d}t.\tag{25}$$

See Ref. 11 for a general discussion.

The next negative action principles are quite simple. Recall that the evolution vector itself V_2 is in the kernel of the symplectic operators $\Sigma^{(m)}$, for $m=-2,\ldots,-\infty$, so that the action principles should be time-reparametrization invariant.[24] From Eq. (14), the only chance is $K^{(m)}\propto i_{V_2}P^{(m)}=0$ or a numeric constant (which would not change the action principle), for $m\leqslant -2$. This is easily shown, from the fact that the interior product $I(\lambda)=i_{V_1^{(1)}}P^{(-1)}(\lambda)[u]=-\frac{1}{16}\int_{x_-}^{x_+}\mathrm{d}x\,(\psi_\lambda\,\overline{\psi}-\psi\,\overline{\psi}_\lambda)\,u_x$, where $\psi=\psi(\lambda)$, is a numeric constant for all λ: $I(\lambda)=-\frac{1}{32}(x_+-x_-)$. We get, then, manifestly time-reparametrization invariant actions:

$$S^{(-n-1)}[u(x,t)]=\frac{1}{16\,(n!)}(-4)^{-n}\int_{t_-}^{t_+}\int_{x_-}^{x_+}\frac{\partial^n}{\partial\lambda^n}(\psi_\lambda\,\overline{\psi}-\psi\,\overline{\psi}_\lambda)|_{\lambda=0}\,u_t\,\mathrm{d}x\,\mathrm{d}t,\quad n\geqslant 1,$$

and we may use Eq. (21) in order to write the λ-derivatives in terms of nonlocal expressions. For example, the second negative action principle is

$$S^{(-2)}[u(x,t)]=-\frac{1}{64}\int_{t_-}^{t_+}\int_{x_-}^{x_+}(\psi_{\lambda\lambda}\,\overline{\psi}-\psi\,\overline{\psi}_{\lambda\lambda})|_{\lambda=0}\,u_t\,\mathrm{d}x\,\mathrm{d}t,$$

where $\psi_{\lambda\lambda}=2\,\psi\,\mathrm{D}^{-1}\,(1/\psi^2)\,\mathrm{D}^{-1}\,\psi^2\,\mathrm{D}^{-1}\,(1/\psi^2)\,\mathrm{D}^{-1}\,\psi^2$ and $\overline{\psi}=\psi\,\mathrm{D}^{-1}(1/\psi^2)$; the Euler–Lagrange equations are equivalent to

$$u_t=\theta_1\,(u_{xxx}+12\,u\,u_x)+\theta_2\,u_x,$$

where, as usual, θ_j are arbitrary functionals. The invariance $t\to\tau(t)$ is evident.

I. The missing action principle for KdV, a time-dependent constant of the motion and the internal vectors

So far we have obtained two ladders of action principles for the KdV equation: the positive (quasilocal) and the negative ladders (highly nonlocal). However, there is a missing action principle: this is the case $m=0$, which is actually twofold: first, the one-form $P^{(0)}[u]\equiv i_{\eta_{\mathrm{gal}}}\Sigma^{(1)}[u]=-x/8$ is closed: $P^{(0)}[u]=\delta C^{(0)}[u]$, where $C^{(0)}[u]=-\int_{x_-}^{x_+}\mathrm{d}x\,x\,u/8$. From Eq. (17), we obtain a known[30] time-dependent constant of the motion for KdV: $C[u,t]=\frac{1}{8}\int_{x_-}^{x_+}(6\,t\,u^2-x\,u)\,\mathrm{d}x$.

Second, the action principle for the symplectic two-form $\Sigma^{(0)}[u]$ [see Eq. (23)] has to be evaluated by hand. After some hard but straightforward calculations, we find that the one-form $\mathcal{P}^{(M)}[u](x,t)\equiv(\psi^2/4)\mathrm{D}^{-1}[(1/\psi^2)\ln\psi]$ is a solution of $\delta P^{(M)}=\Sigma^{(0)}$.

In this case, we map to the ψ-coordinate system for simplicity. We get the action principle

$$S^{(0)}[\psi,u,\rho]=-\frac{1}{8}\int_{x_-}^{x_+}\left(\frac{\psi_x\,\psi_t}{\psi^2}-\frac{\psi_{xx}^2}{\psi^2}+\rho\left(u+\frac{\psi_{xx}}{2\,\psi}\right)\right)\mathrm{d}x\,\mathrm{d}t.$$

The Euler–Lagrange equations we obtain are as follows: for the field ψ,

$$\frac{1}{\psi}\mathrm{D}\frac{1}{\psi}\left(\psi_t+\psi_{xxx}-3\,\frac{\psi_x\psi_{xx}}{\psi}\right)=0,$$

for the field u, $u=-(\psi_{xx}/2\,\psi)\Rightarrow u_t=-u_{xxx}-12\,u\,u_x$, and for the Lagrange multiplier, $\rho=0$.

Notice that the Euler–Lagrange equations for ψ are equivalent to

$$\psi_t=-\psi_{xxx}+3\,\frac{\psi_x\psi_{xx}}{\psi}+\theta_1\,\psi,$$

where θ_1 is arbitrary. This symmetry is one of the three known[14] internal symmetries (i.e., those which do not affect the field u) of the eigenvalue problem (19). In the ψ-coordinate system we write it as $\psi_t=V_0^{(-2)}[\psi]=-\frac{1}{2}\psi$ (the numeric factor is only for simplicity). In the cited reference it is shown that all negative vectors and the internal symmetries span a loop algebra over $\mathrm{SL}(2,\mathbb{R})$.

J. Nonlocal constants of the motion for KdV

As a final result, we will construct explicitly three new sets of constants of the motion for the KdV equation, starting from the nonlocal objects we have obtained. We denote $\psi=\psi(x,t;\lambda=0)$

for simplicity from here on, unless explicitly stated. Consider the action principle (25): the term which multiplies the velocity ψ_t is the mapping of the Lagrangian one-form $P^{(-1)}[u]$ into ψ-coordinates:

$$\mathcal{P}^{(-1)}[\psi](x,t)=\frac{1}{16\,\psi^3}(\mathrm{D}^{-1}\psi^2).$$

On the other hand, from Theorem 7 we have $\mathcal{L}_{V_2}P^{(-1)}=\delta K^{(-1)}$, where $K^{(-1)}=\frac{3}{16}\int_{x_-}^{x_+}dx\,(\psi_x^2/\psi^2)$. Consider now the 0-form

$$H^{(-2)}[\psi]\equiv -16\,i_{V_0^{(-2)}}P^{(-1)}=-\int_{x_-}^{x_+}dx\,\frac{1}{\psi^2}(\mathrm{D}^{-1}\,\psi^2)$$

or, more concisely, $H^{(-2)}[\psi]=\int_{x_-}^{x_+}dx\,\psi\,\overline{\psi}$.

We use Leibnitz rule to show that this is a constant of motion for the KdV equation, which in ψ coordinates reads $V_2[\psi]=-\psi_{xxx}+3(\psi_x\psi_{xx}/\psi)$: as $\mathcal{L}_{V_2}V_0^{(-2)}[\psi]=0$, we find $\mathcal{L}_{V_2}H^{(-2)}[\psi]=\mathcal{L}_{V_0^{(-2)}}K^{(-1)}[\psi]=0$, where the last equality comes from the fact that $K^{(-1)}[\psi]$ is invariant under scaling of ψ.

Thus $H^{(-2)}[\psi]$ is a nonlocal constant of the motion for the KdV flow. But if we recall that the fields ψ, $\overline{\psi}$ are solutions of the linear problem (19), and that u does not change if these fields are replaced by other arbitrary linear combinations, we get indeed three constants of the motion: $H^{(-1)}[\psi]=\int_{x_-}^{x_+}dx\,\psi^2$, $H^{(-2)}[\psi]=\int_{x_-}^{x_+}dx\,\psi\,\overline{\psi}$, $H^{(-3)}[\psi]=\int_{x_-}^{x_+}dx\,\overline{\psi}^2$.

There is a reference that supports this construction: in Ref. 31, in the context of the eigenvalue ''Schrödinger'' problem (19), the author assumes that the total probability (here denoted by $H^{(-1)}[\psi]$) is equal to 1. But it is indeed a constant of motion of its own. Moreover, these are indeed special cases ($\lambda=0$) of more general constants of motion. Along the same lines, we get three families, parametrized by the eigenvalue λ,

$$H^{(-1)}(\lambda)[\psi]=\int_{x_-}^{x_+}dx\,\psi(\lambda)^2,$$

$$H^{(-2)}(\lambda)[\psi]=\int_{x_-}^{x_+}dx\,\psi(\lambda)\,\overline{\psi}(\lambda),$$

$$H^{(-3)}(\lambda)[\psi]=\int_{x_-}^{x_+}dx\,\overline{\psi}(\lambda)^2. \tag{26}$$

These are real new constants (indeed they contain, in their Taylor series around $\lambda=0$, the constants of the motion from Theorem 9). In order to evaluate them explicitly, take, for example, successive derivatives of the first one with respect to λ, evaluate at $\lambda=0$ and use Eq. (21). We get

$$Q^{(-1;n)}[\psi]\equiv\int_{x_-}^{x_+}dx\,\psi L^{-n}\,\psi,\quad n=0,\ldots,\infty,$$

and we see they are increasingly nonlocal constants of the motion.

It is worth to mention that these nonlocal constants, when mapped to the coordinate system in which the KdV equation maps into the Harry–Dym equation (see Ref. 18), reproduce the results obtained independently in a recent work,[20] and add three more constants to the Harry–Dym equation: the mappings of the nonlocal constants of motion (26) for $\lambda=0$ into the Harry–Dym equation $\omega_t=(\omega^{-1/2})_{sss}$ for the field $\omega(s,t)$, are $H^{(-1)}[\omega]=\int_{s_-}^{s_+}ds\,\omega$, $H^{(-2)}[\omega]=\int_{s_-}^{s_+}ds\,s\,\omega$, $H^{(-3)}[\omega]=\int_{s_-}^{s_+}ds\,s^2\,\omega$.

V. RESULTS FOR OTHER KDV POSITIVE AND NEGATIVE EQUATIONS

A. Some positive, negative and internal vectors as known integrable equations

We write the internal vectors after transformation to Schwartzian coordinates, defined by $\zeta_x(x,t;\lambda)=\psi(x,t;\lambda)^{-2}$. The internal vectors in ζ coordinates are $V_0^{(-1)}[\zeta]=1$, $V_0^{(-2)}[\zeta]=\zeta$, $V_0^{(-3)}[\zeta]=\zeta^2$.

The vectors $V_0^{(-3)}$, $(V_0^{(-3)}-V_1^{(-1)})/2$, and $V_2^{(1)}$ give the evolution equations $\zeta_t=\zeta^2$, $\zeta_t=\frac{1}{2}\zeta^2-\frac{1}{8}(\zeta_{x\lambda}/\zeta_x)$, and $\zeta_t=6\lambda\zeta_x+(3\zeta_{xx}^2/2\zeta_x)-\zeta_{xxx}$, where the fields are evaluated at $\lambda=0$. The last of these equations is a special case of the Krichever–Novikov equation,[8] and the first and the second equations, via the transformation $z=\ln(2\zeta_x)$, may be mapped to the Liouville equation $z_{xt}=\exp z$, and the ShG equation $z_{xt}=\sinh z$. For completeness, we just mention that the associated Camassa–Holm equation[32] and the Hunter–Zheng equation[20] are obtainable from the negative vectors $V_1^{(-2)}$ and $V_1^{(-1)}$, respectively, via suitable coordinate transformations, and that the Harry–Dym equation,[18] just like the above case of the Krichever–Novikov equation, is a mapping of the KdV equation.

B. Action principles for the Sinh–Gordon equation

As a representative of the extension of the results on action principles for equations in the negative hierarchies, we work out some examples for the ShG equation. The results in this section are new up to our knowledge, except when it is explicitly stated. We will work in the z-coordinate system, where the ShG equation is $z_t=V_{\mathrm{ShG}}[z]=\mathrm{D}^{-1}\sinh z$.

1. Pure ShG equation: Symplectic matrix $\Sigma^{(0)}$

We look for a standard Lagrangian pair for the ShG equation of the form $(P^{(M)}[z];K^{(M;\mathrm{ShG})}[z])$, where $\mathcal{P}^{(M)}[z]=-\frac{1}{32}z_x$ is the mapping of $\mathcal{P}^{(M)}[u]$ to z coordinates. The symplectic two-form $\Sigma^{(0)}[z]=\frac{1}{16}\mathrm{D}$ has only one vector in the kernel, namely $V_0^{(-2)}[z]=4$. On the other hand, the standard Lagrangian 0-form solves $(\delta/\delta z)K^{(M;\mathrm{ShG})}[z]=\mathcal{L}_{V_{\mathrm{ShG}}}P^{(M)}[z]=-\frac{1}{32}(\sinh z-z\cosh z)$. We get after integration the usual action principle for the ShG equation,[30]

$$S[z(x,t)]=\frac{1}{32}\int_{t_-}^{t_+}\mathrm{d}t\,\mathrm{d}x\,(-z_x z_t-2\cosh z),$$

and the Euler–Lagrange equations are simply $z_t=\mathrm{D}^{-1}\sinh z+\theta_1$, where θ_1 is arbitrary.

2. ShG equation deformed with first positive vector: Symplectic matrix $\Sigma^{(-1)}$

The next negative one-form, $P^{(-1)}$, reads $\mathcal{P}^{(-1)}[z](x,t)=-\frac{1}{32}e^z(\mathrm{D}^{-1}e^{-z})$. The associated symplectic two-form is $\Sigma^{(-1)}[z]=-\frac{1}{32}(e^z\mathrm{D}^{-1}e^{-z}+e^{-z}\mathrm{D}^{-1}e^z)$, which inherits the kernel (generated from $V_1^{(1)}[z]=-z_x$) from that in the u-coordinate system only for special boundary conditions: defining the boundary terms $\overline{f}\equiv f_+ + f_-$ and $f_\pm=f(x_\pm)$, the expression

$$\Sigma^{(-1)}[z]\cdot V_1^{(1)}[z]=\tfrac{1}{64}(e^z\overline{e^{-z}}-e^{-z}\overline{e^z})$$

is zero only for boundary conditions $z_+=z_-+i\pi(2n+1)$, $n\in\mathbb{Z}$.

For other boundary conditions, however, this Lagrange bracket has no kernel, which will show up in the variational principle for the ShG vector by the fact that the Euler–Lagrange equations get deformed by a factor of the vector $V_1^{(1)}[z]$, which is not arbitrary: it depends on the boundary conditions used for the z coordinates.

In the generic case when $\overline{e^z}\neq 0$ (invertible symplectic two-form $\Sigma^{(-1)}$), the action principle is explicitly

$$S[z(x,t)]=\int_{t_-}^{t_+}\mathrm{d}t\left[-\frac{1}{32}\int_{x_-}^{x_+}\mathrm{d}x\, e^{z}(\mathrm{D}^{-1}e^{-z})(z_t-\mathrm{D}^{-1}\sinh z)+K^{(-1;\mathrm{ShG})}[z]\right],$$

and the Euler–Lagrange equations are

$$\tfrac{1}{32}(e^{z}\,\mathrm{D}^{-1}\,e^{-z}+e^{-z}\,\mathrm{D}^{-1}\,e^{z})(z_t-\mathrm{D}^{-1}\sinh z+\theta[A_+,A_-]\,z_x)=0$$

or, equivalently,

$$z_t-\mathrm{D}^{-1}\sinh z+\theta[A_+,A_-]\,z_x=0,$$

where $K^{(-1;\mathrm{ShG})}[z]=\int_{x_-}^{x_+}\mathrm{d}x\, e^{z}(\mathrm{D}^{-1}e^{-z})^2/128+F[A_+,A_-]$, $A_\pm\equiv\int_{x_-}^{x_+}\mathrm{d}x\, e^{\pm z}$, and θ, F solve the equation:

$$\delta F[A_+,A_-]=-\theta[A_+,A_-]\,(\overline{e^{-z}}\,\delta A_+ +\overline{e^{z}}\,\delta A_-)+\tfrac{1}{8}A_-\,(A_--2\,A_+)\,\delta A_+ . \tag{27}$$

There are many solutions of the above equation for a given set of boundary conditions on the limiting values of $z_\pm$, so we discuss, as examples, only two representative, nonintersecting cases of boundary conditions, for which the symplectic two-form $\Sigma^{(-1)}$ is invertible:

(i) $z_+=-z_-+i\pi(2\,n),\ n\in\mathbb{Z};\ \cosh z_+\neq 0.$
A solution of Eq. (27) is $\theta=-A_+\,A_-/4\,\overline{e^{z}}$, $F=A_+\,A_-^2/512$, which is well defined because of the boundary conditions used.

(ii) $z_+=-z_-+i\pi(2\,n+1),\ n\in\mathbb{Z};\ \sinh z_+\neq 0.$
In this case, a solution of Eq. (27) is

$$\theta=-(A_+^2-A_-^2)/8\,\overline{e^{z}},\quad F=-(A_+^2\,A_--\tfrac{1}{3}(A_+^3+A_-^3))/512.$$

The usual constant of the motion for the ShG equation, $H[z]=\int_{x_-}^{x_+}\mathrm{d}x\cosh z$, works in this case also: under the boundary conditions used, we get

$$\dot{H}[z]=\int_{x_-}^{x_+}\mathrm{d}x\,\sinh z\,(\mathrm{D}^{-1}\sinh z-\theta\,z_x)=\theta\,\overline{\cosh z}=0.$$

C. Alternative Lax pairs and constants of the motion for negative equations

In Ref. 16, the authors find alternative Lax pairs for the KdV equation (as well as for every evolution equation in the KdV positive hierarchy) by making no ansatz: they just use the evolution equation and the hereditary operator.

We present a similar construction, this time for the negative vectors. By so doing we are answering an open question in Ref. 20.

As it is shown in Ref. 16, given an evolution equation $u_t=V[u]$, and a recursion operator R for V (i.e., $\mathcal{L}_V R=0$), it follows that

$$\frac{\mathrm{D}}{\mathrm{D}t}R=[V',R], \tag{28}$$

where V' denotes the Frechet derivative, and the square brackets are the commutators. The above equation defines the alternative Lax pair (R,V').

Now, take R as the hereditary operator $R[u]$, and V as the negative vector $V_1^{(-1)}(\lambda)[u]=(\psi(\lambda)^2)_x$, for arbitrary ν,λ. We need to evaluate the Frechet derivative of this vector with respect to the field u. Using the transformation matrix $\delta\psi/\delta u=-2\,\psi\,\mathrm{D}^{-1}\,(1/\psi^2)\mathrm{D}^{-1}\,\psi^2$, where ψ stands for $\psi(\lambda)$ from here on, we get $V_1^{(-1)}(\lambda)'[u]=-4\,\mathrm{D}\,\psi^2\,\mathrm{D}^{-1}\,(1/\psi^2)\mathrm{D}^{-1}\,\psi^2$. On the other hand, the hereditary operator is

$$R[u]=R(\lambda)[u]-4\,\lambda\,\mathbb{I}=\frac{1}{\psi^2}\mathrm{D}\,\psi^2\,\mathrm{D}\,\psi^2\,\mathrm{D}\frac{1}{\psi^2}\mathrm{D}^{-1}-4\,\lambda\,\mathbb{I},$$

and it is also written as $R[u]=\mathrm{D}^2+8\,u+4\,u_x\,\mathrm{D}^{-1}$. Now we apply the Lax pair equation (28), getting after some rearrangements the operator equation $8\,u_t+4\,u_{xt}\,\mathrm{D}^{-1}=8\,(\psi^2)_x+4\,(\psi^2)_{xx}\,\mathrm{D}^{-1}$, which implies $u_t=(\psi(\lambda)^2)_x$. Recall this equation contains all the negative vectors in the corresponding negative hierarchy, so that the Lax pair we have presented indeed works for all vectors in that hierarchy. Similarly, for the other two negative hierarchies we get the Lax pairs (R, B_2) and (R, B_3), with

$$B_2=V_1^{(-2)}(\lambda)'[u]=-4\,\mathrm{D}\,\psi^2\,\mathrm{D}^{-1}\,\overline{\psi}\,\psi^{-1}\,\mathrm{D}\,\overline{\psi}\,\psi^{-1}\,\mathrm{D}^{-1}\,(\overline{\psi})^{-2}\,\mathrm{D}^{-1}\,\psi\,\overline{\psi},$$

$$B_3=V_1^{(-3)}(\lambda)'[u]=-4\,\mathrm{D}\,\overline{\psi^2}\,\mathrm{D}^{-1}\,(\overline{\psi})^{-2}\,\mathrm{D}^{-1}\,\overline{\psi^2}.$$

In this way, we may construct an infinite number of constants of the motion for the negative vectors, from Adler traces of positive, semi-integer powers of the Nijenhuis operator R: these are just the usual (local) constants of the motion for the KdV equation.[16] A natural conjecture is that Adler traces of positive, semi-integer powers of R^{-1} will give our nonlocal constants for KdV defined in Eq. (26). If that is true, we could infer that the nonlocal constants of the motion for KdV should also work for the negative vectors, which can be explicitly checked. We present the results only for the hierarchy $V_1^{(-1)}(\lambda)$, because Lie derivatives of the results along the internal vector $V_0^{(-3)}$ map the objects into similar ones for the other two negative hierarchies.

(i) Conserved currents: defining the boundary term $f\equiv\tilde{f}(x_+)-f(x_-)$, the integral $H^{(-1)}(\nu)[\psi]=\int_{x_-}^{x_+}\mathrm{d}x\,\psi(\nu)^2$ solves

$$\underset{V_1^{(-1)}(\lambda)}{\mathcal{L}}\;H^{(-1)}(\nu)[\psi]=-\overbrace{E(\nu,\lambda)[\psi]},$$

where $E(\nu,\lambda)[\psi]\equiv[\psi(\lambda)\,\psi_x(\nu)-\psi(\nu)\,\psi_x(\lambda)]/(\lambda-\nu)$.

(ii) Constants of the motion: the expression

$$G^{(-1)}(\nu,\lambda)[\psi,t]=\int_{x_-}^{x_+}\mathrm{d}x\,\psi(\nu)^2+t\,\overbrace{\frac{E(\nu,\lambda)[\psi]^2}{1-t\,E(\lambda,\lambda)[\psi]^2}}$$

is a constant of the motion for the flow $V_1^{(-1)}(\lambda)$. These constants and currents are infinite in number and work for every vector in the respective negative hierarchy, because λ and ν are arbitrary. By considering their Taylor expansion around $\lambda=\nu=0$, the explicit expression for the constants and conserved currents for each negative vector is easily worked out using Eqs. (21) and (18).

VI. CONCLUSION

The Lagrangian point of view determines a unifying scheme for the study of integrable equations belonging to hierarchies related to hereditary operators. For all evolution vectors in these hierarchies, nonlocal symmetries, Lax pairs, constants of the motion, conserved currents and an infinite ladder of action principles all come out in a constructive, explicit way from the same structure. Moreover, new equations, which are mixed or deformed versions of known integrable equations, arise as the Euler–Lagrange equations of the action principles obtained. As an example, we apply this scheme to the KdV equation, and the results are directly mappable to other related equations in the positive KdV hierarchies (e.g., Harry–Dym and a special case of Krichever–Novikov equations) as well as in the negative KdV hierarchies (e.g., Sinh–Gordon, Liouville, Camassa–Holm, and Hunter–Zheng equations): in particular, we obtain a new nonlocal action

principle for the Sinh–Gordon equation which leads to a deformed version of this equation, and an infinite number of nonequivalent, nonlocal action principles for KdV, possessing time-reparametrization invariance, are explicitly found. The construction of alternative Lax pairs for negative equations arises naturally, without any ansatz, from this scheme, and it is shown that negative equations essentially share the constants of the motion (local as well as nonlocal) for the KdV equation.

ACKNOWLEDGMENTS

One of the authors (M.B.) wishes to mention that this work was done in part during a research stay at the Relativity Center, The University of Austin, Texas, U.S.A., where M.B. was invited by Professor L. C. Shepley; M.B. is deeply grateful to him, the professors, and students in the Center for their support and the following people whose comments and suggestions were fundamental for his understanding of the topics involved in the present work: P. (Received 29 March 2003; accepted 21 July 2003)

The motion of point charged particles is considered in an even dimensional Minkowski space–time. The potential functions corresponding to the massless scalar and the Maxwell fields are derived algorithmically. It is shown that in all even dimensions particles lose energy due to acceleration. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1613040]

I. INTRODUCTION

Recently Gal'tsov[1] and Kazinski *et al.*[2] have considered the Lorentz–Dirac equation for a radiating point charge in a Minkowski space–time of arbitrary dimension. They showed that the mass renormalization is possible only in three and four dimensions. In their discussion, they have also given the retarded Green's functions of the D'Alembert equation in any dimensions which was in fact constructed rigorously a long time ago.[3] Motivated by these works, we are interested in the radiation problem of accelerated point charges in all even dimensions (for the reason why we did not consider odd dimensions, please see Appendix B). Here we find the Liénard–Wiechert potentials corresponding to the massless scalar and the Maxwell fields in all even dimensions. We then use these potentials to relate the radiation from an accelerated point particle to its motion and the geometry of its trajectory. We derive the energy flux for this radiation and show that accelerating point charged particles lose energy in all even dimensions.

In Sec. II, we develop the kinematics of a curve C in a D-dimensional Minkowski manifold $\mathbf{M_D}$. In Sec. III we find the Liénard–Wiechert potentials of massless free scalar fields in an even dimensional Minkowski space. We calculate the energy radiated due to the acceleration. We show that in all even dimensions such particles lose energy, as can be expected. In Sec. IV, we determine the Liénard–Wiechert potentials for the Maxwell theory. We give a recursion relation between the vector potentials of the theory in two consecutive even dimensions. In Sec. IV, we also show that particles carrying electric charges lose energy in all even dimensions. We construct explicit solutions of the electromagnetic vector field due to the acceleration of charged particles in 4,6,8,10 dimensions. We then find the energy fluxes in 4,6,8 dimensions due to acceleration. In Appendix A, we give the Serret–Frenet equations in an arbitrary Minkowski space–time and also some auxiliary tools used in the calculation of the energy flux integrals. In Appendix B, we give a proof of the recursion relation introduced in Sec. IV.

II. CURVES IN *D*-DIMENSIONAL MINKOWSKI SPACE

In our previous works,[4–6] we developed a curve kinematics to be utilized in finding new solutions and in calculating energy fluxes due to the acceleration in the framework of Einstein's general theory of relativity. Here we use the same approach to solve the scalar and Maxwell field

a)Electronic mail: gurses@fen.bilkent.edu.tr
b)Electronic mail: sarioglu@metu.edu.tr

equations in all even dimensions. For this purpose, we shall now give a summary of the geometry of a regular curve in $\mathbf{M_D}$, Minkowski space–time manifold of dimension D.

Let $z^\mu(\tau)$ describe a smooth curve C in $\mathbf{M_D}$, where τ is the arclength parameter of the curve. From an arbitrary point x^μ outside the curve, there are two null lines intersecting the curve C. These points are called the retarded and the advanced times. Let Φ be the distance (world function) between the points x^μ and $z^\mu(\tau)$, then by definition it is given by

$$\Phi = \tfrac{1}{2}\,\eta_{\mu\nu}\,(x^\mu - z^\mu(\tau))\,(x^\nu - z^\nu(\tau)), \tag{1}$$

where $\eta_{\mu\nu}=\mathrm{diag}(-1,1,\ldots,1)$. Hence Φ vanishes at the retarded, τ_0, and advanced, τ_1, times. In this work we shall focus on the retarded case only. The Green's function for the vector potential chooses this point on the curve C.[7,8] By differentiating Φ with respect to x^μ and letting $\tau=\tau_0$, we get

$$\lambda_\mu \equiv \tau_{,\mu} = \frac{x_\mu - z_\mu(\tau_0)}{R}, \quad R \equiv \dot{z}^\mu(\tau_0)\,(x_\mu - z_\mu(\tau_0)), \tag{2}$$

where R is the retarded distance, λ_μ is a null vector, and a dot over a letter denotes differentiation with respect to τ_0. The derivatives of R and λ_μ, using (2), are given by

$$\lambda_{\mu,\nu} = \frac{1}{R}[\,\eta_{\mu\nu} - \dot{z}_\mu\lambda_\nu - \dot{z}_\nu\lambda_\mu - (A-\epsilon)\,\lambda_\mu\lambda_\nu], \tag{3}$$

$$R_{,\mu} = (A-\epsilon)\,\lambda_\mu + \dot{z}_\mu, \tag{4}$$

where

$$A = \ddot{z}^\mu\,(x_\mu - z_\mu), \quad \dot{z}^\mu\,\dot{z}_\mu = \epsilon = 0, \pm 1. \tag{5}$$

Here $\epsilon = 0, -1$ for null and time-like curves, respectively. Furthermore, we have

$$\lambda_\mu\,\dot{z}^\mu = 1, \quad \lambda^\mu\,R_{,\mu} = 1. \tag{6}$$

Letting $a = A/R$, it is easy to prove that

$$a_{,\mu}\,\lambda^\mu = 0. \tag{7}$$

Similarly, other scalars $(a_1, a_2, \ldots)$, satisfying the same property (7) obeyed by a can be defined

$$a_k \equiv \lambda_\mu \frac{\mathrm{d}^k\,\ddot{z}^\mu}{\mathrm{d}\tau_0^k}, \quad k = 1,2,\ldots,n. \tag{8}$$

Moreover one has

$$a_{k,\alpha}\,\lambda^\alpha = 0, \tag{9}$$

for all k ($k=0$ is also included if we let $a_0 = a$). For a more detailed discussion, please refer to Ref. 4. Here n is a positive integer which depends on the dimension D of the manifold $\mathbf{M_D}$. An analysis using Serret–Frenet frames shows that the scalars (a, a_k) are related to the curvature scalars of the curve C in $\mathbf{M_D}$. The number of such scalars is $D-1$.[9] Hence we let $n = D-1$.

III. MASSLESS SCALAR FIELD

Let ϕ describe a massless scalar field satisfying the free field equation

$$\eta^{\mu\nu}\frac{\partial^2\phi}{\partial x^\mu \partial x^\nu}=0. \tag{10}$$

Let D be a positive even integer, and $\phi^{(D)}$ and $\phi^{(D+2)}$ denote the retarded solutions (Liénard–Wiechert potentials) of the massless scalar field in D and $D+2$ dimensions, respectively. Then

$$\phi^{(D+2)}=\frac{1}{R}\frac{\mathrm{d}}{\mathrm{d}\tau}\phi^{(D)}. \tag{11}$$

In this recursion relation we emphasize that the expressions on the right-hand side are those of D-dimensions. Take the solution $\phi^{(D)}$ in D-dimensions, take its τ derivative and divide this by the R of D-dimensions. The result is the solution $\phi^{(D+2)}$ of $D+2$-dimensions. For the proof of relation (11) see Appendix B. In the following we explicitly give these solutions for $D=4,6,8,10$:

$$\phi^{(4)}=\frac{c}{R}, \tag{12}$$

$$\phi^{(6)}=\frac{1}{R^2}[\dot{c}-pc], \tag{13}$$

$$\phi^{(8)}=\frac{1}{R^3}[\ddot{c}-3p\dot{c}+(-a_1+3p^2)c], \tag{14}$$

$$\phi^{(10)}=\frac{1}{R^4}\left[\frac{\mathrm{d}^3c}{\mathrm{d}\tau^3}-6p\ddot{c}+(15p^2-4a_1)\dot{c}+\left(-a_2+10pa_1-15p^3+\frac{1}{R}\dot{z}_\alpha\frac{\mathrm{d}^3z^\alpha}{\mathrm{d}\tau^3}\right)c\right], \tag{15}$$

where $c=c(\tau)$ is the (time dependent) scalar charge and $p\equiv a-\epsilon/R$.

The flux of massless scalar field energy is then given by (see Refs. 7 and 11 for this definition and also for the integration surface S)

$$\mathrm{d}E=-\int_S \dot{z}_\mu T^{\mu\nu}_\phi \,\mathrm{d}S_\nu, \tag{16}$$

where $T^{\phi}_{\mu\nu}=\partial_\mu\phi\,\partial_\nu\phi-\frac{1}{4}(\eta^{\alpha\beta}\partial_\alpha\phi\,\partial_\beta\phi)\eta_{\mu\nu}$ is the energy momentum tensor of the massless scalar field ϕ. The surface element $\mathrm{d}S_\mu$ on S is given by

$$\mathrm{d}S_\mu=n_\mu R^{D-3}\mathrm{d}\tau\,\mathrm{d}\Omega, \tag{17}$$

where n_ν is orthogonal to the velocity vector field $\dot{z}_\mu$ which is defined through

$$\lambda_\mu=\epsilon\dot{z}_\mu+\epsilon_1\frac{n_\mu}{R},\qquad n^\mu n_\mu=-\epsilon R^2. \tag{18}$$

Here $\epsilon_1=\pm1$. For the remaining part of this work we shall assume $\epsilon=-1$ (C is a time-like curve). One can consider S in the rest frame as a sphere of radius R. Here $\mathrm{d}\Omega$ is the solid angle. Letting $\mathrm{d}E/\mathrm{d}\tau=N_\phi$, we have

$$N^{(D)}_\phi=-\int_{S^{D-2}}\dot{z}_\mu T^{\mu\nu}_\phi n_\nu R^{D-3}\,\mathrm{d}\Omega, \tag{19}$$

where S^{D-2} is the $(D-2)$-dimensional sphere centered at $\tau=\tau_0$ on the curve C. At very large values of R the energy flux is given by

$$N_\phi^{(D)}=-\int_{S^{D-2}} \mathrm{d}\Omega\, R^{D-3}\,(\dot{z}^\alpha\,\partial_\alpha\,\phi)(n^\beta\,\partial_\beta\,\phi).$$

It turns out that the energy flux expression has a fixed sign for all D. The energy flux of the massless scalar field ϕ as $R\to\infty$ is given by

$$N_\phi^{(D)}=-\epsilon_1\int_{S^{D-2}}[\xi^{(D)}]^2\,\mathrm{d}\Omega,$$

where we obtain R independent functions (for each D) $\xi^{(D)}$ from

$$\xi^{(D)}=\lim_{R\to\infty}[R^{D/2}\,\phi^{(D+2)}].$$

As an example let $D=4$. We take $\phi^{(6)}$ from (13), multiply it by R^2 and let $R\to\infty$ (then $p\to a$), and finally we obtain $\xi^{(4)}$. The explicit expressions of $\xi^{(D)}$ are as follows:

$$\xi^{(4)}=\dot{c}-ac, \tag{20}$$

$$\xi^{(6)}=\ddot{c}-3a\dot{c}+(-a_1+3a^2)c, \tag{21}$$

$$\xi^{(8)}=\frac{\mathrm{d}^3c}{\mathrm{d}\tau^3}-6a\ddot{c}+(15a^2-4a_1)\dot{c}+(-a_2+10aa_1-15a^3)c, \tag{22}$$

$$\xi^{(10)}=\frac{\mathrm{d}^4c}{\mathrm{d}\tau^4}-10a\frac{\mathrm{d}^3c}{\mathrm{d}\tau^3}+(45a^2-10a_1)\ddot{c}-(5a_2-60aa_1+105a^3)\dot{c}$$
$$-(a_3-15aa_2-10a_1^2+105a_1a^2-105a^4)\,c. \tag{23}$$

Hence we have (assuming $c=$constant)

$$N_\phi^{(4)}=-\epsilon_1\left(\frac{4\pi}{3}\right)c^2\,\kappa_1^2, \tag{24}$$

$$N_\phi^{(6)}=-\epsilon_1\left(\frac{8\pi^2}{105}\right)c^2[20\kappa_1^4+7\dot{\kappa}_1^2+7\kappa_1^2\kappa_2^2], \tag{25}$$

$$N_\phi^{(8)}=-\epsilon_1\left(\frac{16\pi^3}{10\,395}\right)c^2\{99[(\ddot{\kappa}_1-4\kappa_1^3-\kappa_1\kappa_2^2)^2+(2\dot{\kappa}_1\kappa_2+\kappa_1\dot{\kappa}_2)^2+\kappa_1^2\kappa_2^2\kappa_3^2]$$
$$+\kappa_1^2[900\kappa_1^4+1100\kappa_1^2\kappa_2^2+3597\dot{\kappa}_1^2]\}. \tag{26}$$

IV. ELECTROMAGNETIC FIELD

In the Lorentz gauge $(\partial_\mu A^\mu=0)$, the Maxwell equations reduce to the wave equation for the vector potential A_μ, $\eta^{\mu\nu}\,\partial_\mu\,\partial_\nu A_\alpha=0$. By using the curve C, we can construct divergence free (Lorentz gauge) vector fields A_α satisfying the wave equation outside the curve C in any even dimension D. Similar to the case of the massless scalar field, such vectors obey the following recursion relation

$$A_\mu^{(D+2)}=\frac{1}{R}\frac{\mathrm{d}}{\mathrm{d}\tau}A_\mu^{(D)}. \tag{27}$$

In the recursion relation above $A_\mu^{(D)}$ is the electromagnetic vector potential in even D-dimensions, with $\mu=0,1,\ldots,D-1$. On the right-hand side of the recursion relation all operations are done in D-dimensions, just like the scalar case. However the result is to be considered as the electromagnetic vector potential of $D+2$-dimensions, with $\mu=0,1,\ldots,D+1$ on the left-hand side. As an example we have $A_\mu^{(4)}=\dot{z}_\mu/R$ as the electromagnetic vector potential of four dimensions.[8] Here $\dot{z}_\mu$ is the four velocity, R and τ are, respectively, the retarded distance and time in four dimensions. Using the recursion relation (27) the right-hand side becomes

$$\frac{\ddot{z}_\mu - a\dot{z}_\mu}{R^2} + \epsilon\frac{\dot{z}_\mu}{R^3}.$$

We then regard this expression as the solution $A_\mu^{(6)}$ of the Maxwell field equations in six-dimensions. Indeed it satisfies both the Lorentz condition and the field equations of six-dimensions, as can be verified separately. Starting from $D=4$, we can generate all even dimensional vector potentials satisfying the Maxwell equations. For instance, the vector potentials for $D=4,6,8,10$ are explicitly given by

$$A_\mu^{(4)}=\frac{\dot{z}_\mu}{R}, \tag{28}$$

$$A_\mu^{(6)}=\frac{1}{R^2}[\ddot{z}_\mu - p\dot{z}_\mu], \tag{29}$$

$$A_\mu^{(8)}=\frac{1}{R^3}\left[\frac{\mathrm{d}^3 z_\mu}{\mathrm{d}\tau^3} - 3p\ddot{z}_\mu + (-a_1+3p^2)\dot{z}_\mu\right], \tag{30}$$

$$A_\mu^{(10)}=\frac{1}{R^4}\left[\frac{\mathrm{d}^4 z_\mu}{\mathrm{d}\tau^4} - 6p\frac{\mathrm{d}^3 z_\mu}{\mathrm{d}\tau^3} + (15p^2-4a_1)\ddot{z}_\mu + \left(-a_2+10pa_1-15p^3+\frac{1}{R}\dot{z}_\alpha\frac{\mathrm{d}^3 z^\alpha}{\mathrm{d}\tau^3}\right)\dot{z}_\mu\right]. \tag{31}$$

The flux of electromagnetic energy is then given by[7] (the integration surface S is also given in this reference)

$$\mathrm{d}E = -\int_S \dot{z}_\mu T_e^{\mu\nu}\,\mathrm{d}S_\nu, \tag{32}$$

where $T^e_{\mu\nu}=F_{\mu\alpha}F_\nu{}^\alpha - \frac{1}{4}F^2\eta_{\mu\nu}$ is the Maxwell energy momentum tensor, $F_{\mu\nu}=A_{\nu,\mu}-A_{\mu,\nu}$ is the electromagnetic field tensor and $F^2\equiv F^{\alpha\beta}F_{\alpha\beta}$.

Letting $\mathrm{d}E/\mathrm{d}\tau=N_e$,[10] we have

$$N_e^{(D)} = -\int_{S^{D-2}} \dot{z}_\mu T_e^{\mu\nu} n_\nu R^{D-3}\,\mathrm{d}\Omega. \tag{33}$$

At very large values of R, for all even D, we get

$$N_e^{(D)} = -\epsilon_1\int_{S^{D-2}} \xi_\mu^{(D)}\,\xi_\nu^{(D)}\,\eta^{\mu\nu}\,\mathrm{d}\Omega, \tag{34}$$

where

$$\xi_\mu^{(D)} = \lim_{R\to\infty}[A_\mu^{(D+2)}R^{D/2}], \tag{35}$$

so that $\lambda^\mu\,\xi_\mu^{(D)}=0$ for all D.

Here we have two remarks. The first one is on the gauge dependence of (35). The only gauge freedom left in our solutions is $A_\mu \to A_\mu + \partial_\mu \phi$, where ϕ satisfies the scalar wave equation (10). However we have already found the solutions of the scalar wave equation for all even dimensions. It can be shown that the contribution of such scalar functions to the norm of $\xi_\mu^{(D)}$ is zero in the limit $R \to \infty$. Our second remark is on the sign of $N_e^{(D)}$ in (34). The vectors $\xi_\mu^{(D)}$ in all even dimensions are orthogonal to the null vector λ_μ, hence they must be either (i) space-like vectors, (ii) proportional to λ_μ, or (iii) zero vectors.[11] They are zero only when the curve C is a straight line which leads to no radiation. They cannot be proportional to the null vector λ_μ either, because this again leads to the trivial case of zero radiation. In the first three cases (4, 6, 8 dimensions) it can be easily observed that zero radiation implies that $\xi_\mu^{(D)}$ is a zero vector. Hence $\xi_\mu^{(D)}$ is a space-like vector in all even dimensions. Therefore the sign of the right-hand side of (34) is the same in all dimensions. These vectors are explicitly given as follows:

$$\xi_\mu^{(4)} = \ddot{z}_\mu - a\dot{z}_\mu , \tag{36}$$

$$\xi_\mu^{(6)} = \frac{d^3 z_\mu}{d\tau^3} - 3a\ddot{z}_\mu + (-a_1 + 3a^2)\dot{z}_\mu , \tag{37}$$

$$\xi_\mu^{(8)} = \frac{d^4 z_\mu}{d\tau^4} - 6a\frac{d^3 z_\mu}{d\tau^3} + (15a^2 - 4a_1)\ddot{z}_\mu + (-a_2 + 10aa_1 - 15a^3)\dot{z}_\mu , \tag{38}$$

$$\xi_\mu^{(10)} = \frac{d^5 z_\mu}{d\tau^5} - 10a\frac{d^4 z_\mu}{d\tau^4} + (45a^2 - 10a_1)\frac{d^3 z_\mu}{d\tau^3} + (-5a_2 + 60aa_1 - 105a^3)\ddot{z}_\mu + (-a_3 + 15aa_2 + 10a_1^2 - 105a_1 a^2 + 105a^4)\dot{z}_\mu . \tag{39}$$

These lead to the following energy flux expressions:

$$N_e^{(4)} = -\epsilon_1 \frac{8\pi}{3}\kappa_1^2 , \tag{40}$$

$$N_e^{(6)} = -\epsilon_1 \frac{32\pi^2}{15}\left(\dot{\kappa}_1^2 + \kappa_1^2\kappa_2^2 + \frac{9}{7}\kappa_1^4\right), \tag{41}$$

$$N_e^{(8)} = -\epsilon_1 \frac{32\pi^3}{10395}\left\{297\left[\left(\ddot{\kappa}_1 - \frac{4}{3}\kappa_1^3 - \kappa_1\kappa_2^2\right)^2 + (2\dot{\kappa}_1\kappa_2 + \kappa_1\dot{\kappa}_2)^2 + \kappa_1^2\kappa_2^2\kappa_3^2\right] + 4\kappa_1^2[300\kappa_1^4 + 506\kappa_1^2\kappa_2^2 + 825\dot{\kappa}_1^2]\right\}. \tag{42}$$

To be compatible with the classical results,[7,8] one should take $\epsilon_1 = -1$.

V. CONCLUSION

In this work we have considered radiation of scalar and vector fields due to acceleration of point charged particles. We first examined the geometric properties of their paths in an even dimensional Minkowski space $\mathbf{M_D}$. By using the curve kinematics we developed, we have first found the retarded solutions of the scalar field equations in $\mathbf{M_D}$. These solutions describe the potentials of the accelerated scalar charges and we have examined the energy loss due to such a radiation. We have shown that in all even dimensions such scalar point particles lose energy. We have given explicit examples for $D = 4,6,8,10$. We then found the retarded solutions of the Maxwell field equations that describe the point particles carrying electric charges. Again, using the curve kinematics we developed an algorithm to calculate the vector potential A_μ in

$D+2$-dimensions from the one in D-dimensions. We have given explicit examples for $D=4,6,8$. We have calculated the energy flux in each case, and we have shown that particles lose energy due to acceleration in all even dimensions.

APPENDIX A: SERRET–FRENET FRAMES

In this appendix, we first give the Serret–Frenet frame in D dimensions. Here we shall assume that the curve C described in Sec. II is time-like and has the tangent vector $T^\mu=\dot{z}^\mu$. Starting from this unit tangent vector, by repeated differentiation with respect to the arclength parameter τ_0, one can generate an orthonormal frame $\{T^\mu,N_1^\mu,N_2^\mu,\ldots,N_{D-1}^\mu\}$, the *Serret–Frenet frame*:

$$\dot{T}^\mu=\kappa_1 N_1^\mu, \tag{A1}$$

$$\dot{N}_1^\mu=\kappa_1 T^\mu-\kappa_2 N_2^\mu, \tag{A2}$$

$$\dot{N}_2^\mu=\kappa_2 N_1^\mu-\kappa_3 N_3^\mu, \tag{A3}$$

$$\cdots$$

$$\dot{N}_{D-2}^\mu=\kappa_{D-2} N_{D-3}^\mu-\kappa_{D-1} N_{D-1}^\mu, \tag{A4}$$

$$\dot{N}_{D-1}^\mu=\kappa_{D-1} N_{D-2}^\mu. \tag{A5}$$

Here κ_i $(i=1,2,\ldots,D-1)$ are the curvatures of the curve C at the point $z^\mu(\tau_0)$. The normal vectors N_i $(i=1,2,\ldots,D-1)$ are space-like unit vectors. Hence at the point $z^\mu(\tau_0)$ on the curve we have an orthonormal frame which can be used as a basis of the tangent space (of $\mathbf{M_D}$) at this point. In Sec. II, we have defined some scalars

$$a_k=\frac{\mathrm{d}^k\ddot{z}_\mu}{\mathrm{d}\tau_0^k}\lambda^\mu,$$

where

$$\lambda^\mu=\epsilon T^\mu+\epsilon_1\frac{n^\mu}{R}.$$

Here n^μ is a space-like vector orthogonal to T^μ. It can be expressed as a linear combination of the unit vectors N_i's as

$$n^\mu=\alpha_1 N_1^\mu+\alpha_2 N_2^\mu+\cdots+\alpha_{D-1} N_{D-1}^\mu,$$

where $\alpha_1^2+\alpha_2^2+\cdots+\alpha_{D-1}^2=R^2$. One can choose the spherical angles $\theta,\phi_1,\ldots,\phi_{D-4}\in(0,\pi)$, $\phi_{D-3}\in(0,2\pi)$ such that

$$\alpha_1=R\cos\theta,\quad \alpha_2=R\sin\theta\cos\phi_1,\quad \alpha_3=R\sin\theta\sin\phi_1\cos\phi_2,\ \ldots,$$

$$\alpha_{D-2}=R\sin\theta\sin\phi_1\cdots\sin\phi_{D-4}\cos\phi_{D-3},$$

$$\alpha_{D-1}=R\sin\theta\sin\phi_1\cdots\sin\phi_{D-4}\sin\phi_{D-3}.$$

Hence we can calculate the scalars a_k in terms of the curvatures of the curve C and the angles $(\theta,\phi_1,\ldots,\phi_{D-3})$ at the point $z^\mu(\tau_0)$. We need these expressions in the evaluation of energy flux formulas. As an example we give a and a_1:

$$a=-\epsilon\epsilon_1\kappa_1\cos\theta,\quad a_1=\kappa_1^2-\epsilon\epsilon_1\dot{\kappa}_1\cos\theta+\epsilon\epsilon_1\kappa_1\kappa_2\sin\theta\cos\phi_1. \tag{A6}$$

The rest of the scalars can be determined similarly. It is clear that these scalars, a_k, depend on the curvatures and the spherical angles, for all k.

APPENDIX B: THE PROOF OF THE RECURSION RELATIONS (11) AND (27)

Here we give the proof for the vector potential case. The same type of proof applies also for the scalar case. Using the recursion relation (27) successively we get

$$A_\mu^{(D)}=\left(\frac{1}{R}\frac{\mathrm{d}}{\mathrm{d}\tau}\right)^{(D/2)-2}\frac{\dot{z}_\mu}{R}. \tag{B1}$$

On the other hand, from Refs. 1 and 2, we have

$$A_\mu^{(D)}=\int G(x-z(\tau))\,\dot{z}_\mu\,\mathrm{d}\tau, \tag{B2}$$

where τ is the parameter of the curve C. The integral here is carried on the range of $\tau\in(-\infty,\infty)$. Here $G(x-z(\tau))$ is the retarded Green function given by

$$G(x-z(\tau))=\theta(x^0-z^0)\,\delta^{(D/2)-2}(\Phi). \tag{B3}$$

Here Φ is the world function given by (1), $\theta(x)$ is the Heaviside step function and $\delta^k(x)\equiv(\mathrm{d}^k/\mathrm{d}x^k)\,\delta(x)$. Here we assume that D is an even integer. [When D is an odd integer, the expression for the Green function in (B3) contains the step function instead of the δ-function. Hence the potentials in all odd dimensions remain nonlocal (integral expressions). This makes our curve kinematics ineffective.] The zeros of Φ denote the advanced and retarded proper times on the curve C, but the step function $\theta(x^0)$ chooses the retarded one. Since the integration is over the curve parameter τ in (B2), it is better to transform the derivative of the delta function with respect to Φ to the derivative with respect to τ. As a simple example consider the $D=6$ case

$$\frac{\mathrm{d}}{\mathrm{d}\Phi}\delta(\Phi)=\left[\frac{1}{\mathrm{d}\Phi/\mathrm{d}\tau}\frac{\mathrm{d}}{\mathrm{d}\tau}\delta(\Phi)\right]_{\Phi=0}. \tag{B4}$$

It is easy to show that $\mathrm{d}\Phi/\mathrm{d}\tau=-R$. The delta function $\delta(\Phi)$ can be expressed as follows:

$$\delta(\Phi)=\frac{\delta(\tau-\tau_0)}{R}+\frac{\delta(\tau-\tau_1)}{R}.$$

The second term will vanish identically due to the step function in (B3). Hence

$$A_\mu^{(6)}=\frac{1}{R}\frac{\mathrm{d}}{\mathrm{d}\tau}\frac{\dot{z}_\mu}{R},$$

or simply $A^{(6)}=(1/R)(\mathrm{d}/\mathrm{d}\tau)\,A^{(4)}$. This verifies our relation (27). For the general case, we need higher order derivatives of $\delta(\Phi)$ at $\Phi=0$. We find such terms by using (B4) and taking successive derivatives. In the general case, for all $k=0,1,2,\ldots$ we obtain (when $\Phi=0$)

$$\frac{\mathrm{d}^k}{\mathrm{d}\Phi^k}\delta(\Phi)=\left[\left(\frac{-1}{R}\frac{\mathrm{d}}{\mathrm{d}\tau}\right)^k\delta(\Phi)\right]. \tag{B5}$$

Using this expression in the Green's function (B3) for $k=D/2-2$, inserting it in the integral equation (B2),

$$A_\mu^{(D)}=\int \theta(x^0-z^0)\,\delta^{D/2-2}(\Phi)\,\dot{z}_\mu\,\mathrm{d}\tau \tag{B6}$$

$$=\int \theta(x^0-z^0)\left(\frac{-1}{R}\frac{\mathrm{d}}{\mathrm{d}\tau}\right)^{D/2-2}\delta(\Phi)\,\dot{z}_\mu\,\mathrm{d}\tau, \tag{B7}$$

and integrating by parts, we obtain (B1).

The Green–Kubo formula and power spectrum of reversible Markov processes

Da-Quan Jiang[a] and Fu-Xi Zhang[b]
LMAM, School of Mathematical Sciences, Peking University, Beijing 100871, People's Republic of China

(Received 30 May 2003; accepted 30 June 2003)

As is known, the entropy production rate of a stationary Markov process vanishes if and only if the process is reversible. In this paper, we discuss the reversibility of a stationary Markov process from a functional analysis point of view. It is shown that the process is reversible if and only if it has a symmetric Markov semigroup, equivalently, a self-adjoint infinitesimal generator. Applying this fact, we prove that the Green–Kubo formula holds for reversible Markov processes. By demonstrating that the power spectrum of each reversible Markov process is Lorentz-typed, we show that it is impossible for stochastic resonance to occur in systems with zero entropy production. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1610780]

I. INTRODUCTION

The question whether a steady system is in equilibrium, correspondingly, whether a stationary stochastic process is reversible, has attracted much interest from physicists as well as mathematicians.[14,22,35,24–27,9,19,20,34] In nonequilibrium statistical physics, the concept of entropy production was put forward to describe how far a specific state of a system is from its equilibrium state.[14,22,35] In Refs. 26 and 27, a measure-theoretic definition of entropy production rate is given for stochastic processes, unifying different entropy production formulas in various concrete cases. In fact, the entropy production rate of a stationary Markov process can be defined as the specific relative entropy of the probability distribution of the process on the path space with respect to that of its time-reversal. If the state space of the process is a Polish space and its trajectories are right continuous having left limits, then by Theorem 10.4 in Varadhan,[38] it is obvious that the entropy production rate vanishes if and only if the process is reversible. A stochastic process $\xi=\{\xi_t\}_{t\geqslant 0}$ is called *reversible* if for each $t>0$, $\{\xi_s\}_{0\leqslant s\leqslant t}$ has the same distribution with its time-reversal $\{\xi_{t-s}\}_{0\leqslant s\leqslant t}$. For example, suppose that ξ is a stationary, irreducible and positive recurrent continuous-time Markov chain on its canonical orbit space with finite state space X, transition density matrix $Q=(q_{ij})_{i,j\in X}$, and invariant distribution $\Pi=\{\pi_i\}_{i\in X}$. Let $\mathbf{P}$ and $\mathbf{P}^-$ be the distributions of the Markov chain and its time-reversal, respectively, and denote their restrictions on $\mathcal{F}_0^t=\sigma(\xi_s,0\leqslant s<t)$ by $\mathbf{P}_{[0,t)}$ and $\mathbf{P}^-_{[0,t)}$, respectively, then the *entropy production rate* of ξ is defined as

$$e_p := \lim_{t\to+\infty}\frac{1}{t}H(\mathbf{P}_{[0,t)},\mathbf{P}^-_{[0,t)}),$$

where $H(\mathbf{P}_{[0,t)},\mathbf{P}^-_{[0,t)})$ is the relative entropy of $\mathbf{P}_{[0,t)}$ with respect to $\mathbf{P}^-_{[0,t)}$ and is defined by $E^{\mathbf{P}_{[0,t)}}\log(\mathrm{d}\mathbf{P}_{[0,t)}/\mathrm{d}\mathbf{P}^-_{[0,t)})$ in case that $\mathbf{P}_{[0,t)}$ is absolutely continuous with respect to $\mathbf{P}^-_{[0,t)}$, otherwise, by $+\infty$. One sufficient and necessary condition for $\mathbf{P}_{[0,t)}$ and $\mathbf{P}^-_{[0,t)}$ being mutually absolutely continuous is $q_{ij}>0\Leftrightarrow q_{ji}>0$, $\forall i,j\in X$. The formula for e_p is given in Refs. 25–27, in fact,

[a]Electronic mail: jiangdq@math.pku.edu.cn
[b]Electronic mail: zhangfxi@math.pku.edu.cn

$$e_p=\frac{1}{2}\sum_{i,j\in X}(\pi_i q_{ij}-\pi_j q_{ji})\log\frac{\pi_i q_{ij}}{\pi_j q_{ji}}\geqslant 0. \tag{1}$$

Obviously, e_p vanishes if and only if ξ is in *detailed balance* (i.e., $\pi_i q_{ij}=\pi_j q_{ji},\forall i,j\in X$), equivalently, ξ is reversible. We refer the reader to Refs. 26–29, 31, and 33 for detailed discussion about the entropy production and reversibility of diffusion processes (see also Example III.5 below).

For a stationary Markov process, the adjoint semigroup of its Markov semigroup reflects the evolution of the corresponding time-reversed process. In Sec. II we study its Markov semigroup and the relationship with its adjoint semigroup. The following equivalent conditions for the Markov process being reversible are brought out: (1) the semigroup of the process is the same as its adjoint semigroup; (2) the infinitesimal generator of the process is symmetric; and (3) the infinitesimal generator is self-adjoint.

As is known, in the theory of statistical physics, the fluctuation–dissipation theorem holds for systems close to equilibrium in the linear response regime. The Green–Kubo formula is a version of the fluctuation–dissipation theorem. It tells that the transport coefficients (respectively, the susceptibility, i.e., the Fourier transform of the response function) corresponding to the thermodynamic forces in the system can be expressed as the integral of a time-correlation function (respectively, its Fourier transform) of the thermodynamic currents induced by the forces, where the correlation function is evaluated with respect to the equilibrium state of the system.[3,4,7,10–13,15–18,21,36,37] Thus the formula connects the energy dissipation in an irreversible process to the thermal fluctuation in equilibrium. In the case of diffusion processes, the Green–Kubo formula takes its earliest form, the Einstein relation, which says that the integral of the time-correlation function of velocities is equal to the mean value of the diffusion coefficient.[23,6] By means of matrix calculations, Qian *et al.*[30] deduces the Green–Kubo formula for reversible Markov chains with finite states and continuous time parameter. Ruelle shows in Ref. 34 that the Green–Kubo formula holds for some smooth dynamical systems.

In Sec. III, exploiting the results in Sec. II, we verify that the Green–Kubo formula holds for general reversible Markov processes. Concretely, suppose that $\xi=\{\xi_t\}_{t\geqslant 0}$ is a reversible Markov process with initial invariant distribution μ, and f,g are two arbitrary observables in a certain range. Let V^f and $D^{f,g}$ be, respectively, the drift coefficient and the diffusion coefficient of ξ with respect to f and $\{f,g\}$ (see Sec. III below for the definitions), then

$$\frac{1}{2}\int D^{f,g}(x)\mu(\mathrm{d}x)=\int_0^{+\infty}E[V^f(\xi_t)V^g(\xi_0)]\mathrm{d}t.$$

Though our form of the Green–Kubo formula addresses the functions rather than the paths themselves, it holds for plentiful observables and can be widely applied to jump processes and interacting particle systems.

In Sec. IV, we apply the results in Sec. II to discuss the relationship between reversibility and the occurrence of stochastic resonance. Traditionally, *stochastic resonance* means that the response of a nonlinear system to a periodic signal may be enhanced by an optimal strength of noise, and it is marked by the indispensable biased peaky power spectrum. Now stochastic resonance has been extensively studied, ranging from the conventional one with a periodic driving[2,1,8] to the later extended one without any external periodic force.[5,32] We prove that the power spectrum of each reversible Markov process is Lorentz-typed, which means that the spectrum peak is just centered at the origin. Hence it is impossible for stochastic resonance to occur in systems with zero entropy production. Previously, using matrix calculations, Qian *et al.*[30] obtained such a result for reversible continuous-time Markov chains with finite states.

II. EQUIVALENT CONDITIONS FOR A MARKOV PROCESS BEING REVERSIBLE

Let $\xi=\{\xi_t\}_{t\geqslant 0}$ be a stationary Markov process with Polish state space $(X,\mathcal{B})$ and initial distribution μ. Denote by $L^2(X,\mu)$, or simply by L^2, the Hilbert space of real functions on X which are square-integrable with respect to μ. For any $f,g\in L^2$, let

$$\langle f,g\rangle=\int f(x)g(x)\mu(\mathrm{d}x),\quad \|f\|=\sqrt{\langle f,f\rangle}.$$

Denote the transition semigroup of ξ by $\{T(t):t\geqslant 0\}$, i.e.,

$$T(t)f(x)=E[f(\xi_t)|\xi_0=x]=\int f(y)p(t,x,\mathrm{d}y),$$

where $p(t,x,\mathrm{d}y)$ is the transition function of ξ. Notice that

$$E|E(f(\xi_t)|\xi_0)|^2\leqslant E[E(|f(\xi_t)|^2|\xi_0)]=E|f(\xi_t)|^2=\int |f(x)|^2\mu(\mathrm{d}x),$$

since μ is an invariant measure. This implies that $T(t)$ is contractive on $L^2(X,\mu)$, i.e., $\|T(t)\|\leqslant 1$. Assume that $\{T(t)\}$ is strongly continuous, i.e.,

$$\lim_{t\downarrow 0}\|T(t)f-f\|=0,\quad \forall f\in L^2.$$

Then $\{T(t)\}$ is a strongly continuous contraction semigroup on L^2. Denote its infinitesimal generator by $\mathcal{A}$, i.e.,

$$\mathcal{D}(\mathcal{A})=\{f\in L^2:[T(t)f-f]/t \text{ converges in } L^2 \text{ as } t \text{ decreases to } 0\},$$

$$\mathcal{A}f=\lim_{t\downarrow 0}\frac{T(t)f-f}{t},\quad \forall f\in\mathcal{D}(\mathcal{A}).$$

Remark II.1: The strong continuity of $\{T(t)\}$ is weaker than the condition that $\{T(t)\}$ is normal, i.e., $\lim_{t\downarrow 0}\|T(t)f-f\|_\infty=0$ for any $f\in B(X)$, where $B(X)$ is the set of all essentially bounded measurable functions equipped with the supreme norm $\|f\|_\infty=\inf\{M:|f(x)|\leqslant M,\ \mu\text{-a.s.}\}$. The reason is that $\|\cdot\|_\infty$ is stronger than $\|\cdot\|$ and $B(X)$ is dense in $L^2(X,\mu)$ in $\|\cdot\|$.

Now we consider the adjoint semigroup of $\{T(t)\}$ with respect to μ, which is denoted by $\{T^*(t):t\geqslant 0\}$. By the definition of $T(t)$, for any $f,g\in L^2$,

$$\begin{aligned}\langle f,T(t)g\rangle&=\int f(x)T(t)g(x)\mathrm{d}\mu=E[f(\xi_0)T(t)g(\xi_0)]\\&=E[f(\xi_0)E(g(\xi_t)|\xi_0)]=E[f(\xi_0)g(\xi_t)].\end{aligned}\tag{2}$$

Hence

$$\begin{aligned}\langle T^*(t)f,g\rangle&=\langle f,T(t)g\rangle=E[f(\xi_0)g(\xi_t)]\\&=E[E(f(\xi_0)|\xi_t)g(\xi_t)]=\int E(f(\xi_0)|\xi_t=x)g(x)\mu(\mathrm{d}x),\end{aligned}$$

which yields

$$T^*(t)f(x)=E(f(\xi_0)|\xi_t=x).\tag{3}$$

$T(t)$ is contractive, so is $T^*(t)$. $\{T^*(t):t\geqslant 0\}$ can be restricted on its center of strong continuity to become a strongly continuous and contractive semigroup, whose generator is denoted by $\mathcal{A}^-$.

Remark II.2: There are two reasons to denote the generator of $\{T^*(t)\}$ by $\mathcal{A}^-$ rather than $\mathcal{A}^*$. First, in the theory of functional analysis, $\mathcal{A}^*$ is used to denote the adjoint operator of $\mathcal{A}$, i.e.,

$$\mathcal{D}(\mathcal{A}^*)=\{f\in L^2|\ \exists g\in L^2,\ \text{s.t. } \langle f,\mathcal{A}h\rangle=\langle g,h\rangle,\forall h\in\mathcal{D}(\mathcal{A})\},$$

and $\mathcal{A}^*f:=g$. Notice that $\mathcal{A}^-\subset\mathcal{A}^*$, since for any $f\in\mathcal{D}(\mathcal{A}^-)$ and any $h\in\mathcal{D}(\mathcal{A})$, it holds that

$$\langle\mathcal{A}^-f,h\rangle=\lim_{t\downarrow 0}\left\langle\frac{T^*(t)f-f}{t},h\right\rangle=\lim_{t\downarrow 0}\left\langle f,\frac{T(t)h-h}{t}\right\rangle=\langle f,\mathcal{A}h\rangle.$$

Second, by (3), $\{T^*(t)\}$ is actually the semigroup of the time-reversed process of ξ.

Recall that a stationary Markov process ξ being reversible is equivalent to that (ξ_t,ξ_0) has the same joint distribution as (ξ_0,ξ_t) for any $t\geqslant 0$. Therefore, ξ is reversible if and only if $T(t)=T^*(t)$ for any $t\geqslant 0$, which illumines us to study the reversibility by the semigroup theory. Let

$$L^2_{\mathbf{C}}:=\{f+ig:f,g\in L^2\}$$

be the complex Hilbert space, where $i^2=-1$. Denote by $\tilde{T}(t)$ the natural extension of $T(t)$ to $L^2_{\mathbf{C}}$. Then $\{\tilde{T}(t):t\geqslant 0\}$ is also a strongly continuous and contractive semigroup. Its generator $\tilde{\mathcal{A}}$ acts on the domain $\mathcal{D}(\tilde{\mathcal{A}})=\{f+ig:f,g\in\mathcal{D}(\mathcal{A})\}$ as $\tilde{\mathcal{A}}(f+ig)=\mathcal{A}f+i\mathcal{A}g$.

Theorem II.3: *The following statements are equivalent to each other:*

(1) The Markov process ξ is reversible;
(2) $T(t)=T^*(t)$ for any $t\geqslant 0$;
(3) $\{T^*(t)\}$ is a strongly continuous contraction semigroup on $L^2(X,\mu)$, and its infinitesimal generator $\mathcal{A}^-=\mathcal{A}$;
(4) $\mathcal{A}$ is symmetric, i.e., $\langle\mathcal{A}f,g\rangle=\langle f,\mathcal{A}g\rangle$ for any $f,g\in\mathcal{D}(\mathcal{A})$;
(5) $\tilde{\mathcal{A}}$ is self-adjoint.

Proof: (1)$\Leftrightarrow$(2): ξ is reversible if and only if $E[f(\xi_0)g(\xi_t)]=E[f(\xi_t)g(\xi_0)]$ for any $f,g\in L^2$ and $t\geqslant 0$. By (2), it is equivalent to that $\langle f,T(t)g\rangle=\langle T(t)f,g\rangle$, i.e., $T(t)=T^*(t)$ for any $t\geqslant 0$.

(2)$\Rightarrow$(3) is obvious.

(3)$\Rightarrow$(4): Since $\mathcal{A}=\mathcal{A}^-$, $\mathcal{A}\subset\mathcal{A}^*$ by Remark II.2. Therefore, $\mathcal{A}$ is symmetric.

(4)$\Rightarrow$(2): Let $\{R(\lambda):\lambda>0\}$ be the resolvent operators of the semigroup $\{T(t)\}$. For any $f\in L^2$, $R(\lambda)f\in\mathcal{D}(\mathcal{A})$. Since $\mathcal{A}$ is symmetric,

$$\langle\mathcal{A}R(\lambda)f,R(\lambda)g\rangle=\langle R(\lambda)f,\mathcal{A}R(\lambda)g\rangle,\quad\forall f,g\in L^2,\lambda>0.$$

Since $(\lambda I-\mathcal{A})R(\lambda)=id$, $\langle f,R(\lambda)g\rangle=\langle R(\lambda)f,g\rangle$ for any $\lambda>0$. By the inverse Laplace transform, $\langle f,T(t)g\rangle=\langle T(t)f,g\rangle$ for any $t\geqslant 0$. Hence $T(t)=T^*(t)$ for any $t\geqslant 0$.

(4)$\Leftrightarrow$(5): It is not hard to check that $\mathcal{A}$ is symmetric if $\tilde{\mathcal{A}}$ is self-adjoint. Suppose that $\mathcal{A}$ is symmetric. So is $\tilde{\mathcal{A}}$. Denote, respectively, by $\rho(\tilde{\mathcal{A}})$ and $\sigma(\tilde{\mathcal{A}})$ the resolvent set and the spectrum set of $\tilde{\mathcal{A}}$. Since $\tilde{\mathcal{A}}$ is the generator of the strongly continuous and contractive semigroup $\{\tilde{T}(t)\}$, it is closed, and from the Hille–Yosida theorem follows that $(0,+\infty)\subset\rho(\tilde{\mathcal{A}})$. Notice that the spectrum set of a closed symmetric operator can only be one of the following four cases: (1) the closure of the upper half complex plane; (2) the closure of the lower half complex plane; (3) the whole plane and (4) a subset of the real numbers. It follows that $\sigma(\tilde{\mathcal{A}})\subset(-\infty,0]$. Hence $\tilde{\mathcal{A}}$ is self-adjoint. ■

Remark II.4: The equivalence among (2), (3), and (4) in Theorem II.3 is already known. We present the proof here for the convenience of the reader and for the completeness of the discussion.

III. GREEN–KUBO FORMULA FOR REVERSIBLE MARKOV PROCESSES

In this section we use Theorem II.3 to prove that the Green–Kubo formula holds for reversible Markov processes. As before, let $\xi=\{\xi_t\}_{t\geqslant 0}$ be a stationary Markov process. Then $E[f(\xi_{t+u})|\xi_t=x]=T(u)f(x)$ for any $f\in L^2(X,\mu)$ and $t,u\geqslant 0$.

Proposition III.1: For any $f\in\mathcal{D}(\mathcal{A})$,

$$\lim_{u\downarrow 0}\frac{1}{u}E[f(\xi_{t+u})-f(\xi_t)|\xi_t=x]=\mathcal{A}f(x) \quad in\ L^2(X,\mu). \tag{4}$$

For any $f,g\in\mathcal{D}(\mathcal{A})$ *such that* $fg\in\mathcal{D}(\mathcal{A})$,

$$\lim_{u\downarrow 0}\frac{1}{u}E[(f(\xi_{t+u})-f(\xi_t))(g(\xi_{t+u})-g(\xi_t))|\xi_t=x]$$
$$=\mathcal{A}(fg)(x)-(g\mathcal{A}f)(x)-(f\mathcal{A}g)(x) \quad in\ L^1(X,\mu). \tag{5}$$

Proof: Equation (4) is just the definition of the infinitesimal generator. It is sufficient to prove (5) in the case $t=0$ since ξ is stationary. For any functions f,g,

$$(f(\xi_u)-f(\xi_0))(g(\xi_u)-g(\xi_0))=(fg)(\xi_u)-(fg)(\xi_0)-f(\xi_0)(g(\xi_u)-g(\xi_0))$$
$$-(f(\xi_u)-f(\xi_0))g(\xi_0).$$

We then obtain the result since

$$\frac{1}{u}E[f(\xi_0)(g(\xi_u)-g(\xi_0))|\xi_0=x]=\frac{1}{u}f(x)E[g(\xi_u)-g(\xi_0)|\xi_0=x]\to f(x)\mathcal{A}g(x)$$

as u decreases to 0. ■

Definition III.2: For any $f\in\mathcal{D}(\mathcal{A})$, *the drift coefficient of* ξ *at point* x *with respect to* f *is defined as*

$$V^f(x)=\lim_{u\downarrow 0}\frac{1}{u}E[f(\xi_u)-f(\xi_0)|\xi_0=x].$$

Since ξ is stationary and $V^f(x)=\mathcal{A}f(x)$, we have $E[V^f(\xi_t)]=0,\ \forall t\geqslant 0$.

Definition III.3: For any $f,g\in\mathcal{D}(\mathcal{A})$ *such that* $fg\in\mathcal{D}(\mathcal{A})$, *the diffusion coefficient of* ξ *at point* x *with respect to* $\{f,g\}$ *is defined as*

$$D^{f,g}(x)=\lim_{u\downarrow 0}\frac{1}{u}E[(f(\xi_u)-f(\xi_0))(g(\xi_u)-g(\xi_0))|\xi_0=x].$$

Theorem III.4: [*Green–Kubo Formula*] *Assume that the stationary Markov process* ξ *is reversible. Then, for any* $f,g\in\mathcal{D}(\mathcal{A})$ *such that* $fg\in\mathcal{D}(\mathcal{A})$,

$$\frac{1}{2}\int D^{f,g}(x)\mu(\mathrm{d}x)=\int_0^{+\infty}E[V^f(\xi_t)V^g(\xi_0)]\mathrm{d}t.$$

Proof: By Proposition III.1 and (2),

$$E[V^f(\xi_t)V^g(\xi_0)]=E[\mathcal{A}f(\xi_t)\mathcal{A}g(\xi_0)]=\langle T(t)\mathcal{A}f,\mathcal{A}g\rangle. \tag{6}$$

Since ξ is reversible, by Theorem II.3, $\tilde{\mathcal{A}}$ is self-adjoint. Hence $\tilde{\mathcal{A}}$ has a spectral representation

$$\tilde{\mathcal{A}}=\int_{-\infty}^{0}\lambda\,\mathrm{d}E_\lambda\,.$$

It follows that

$$\tilde{T}(t)=\int_{-\infty}^{0}e^{\lambda t}\mathrm{d}E_\lambda\,,\quad \tilde{T}(t)\tilde{\mathcal{A}}=\int_{-\infty}^{0}e^{\lambda t}\lambda\,\mathrm{d}E_\lambda\,.$$

Since $\tilde{\mathcal{A}}\varphi=\mathcal{A}\varphi$ and $\tilde{T}(t)\psi=T(t)\psi$ for any $\varphi\in\mathcal{D}(\mathcal{A})$ and $\psi\in L^2$,

$$\langle T(t)\mathcal{A}f,\mathcal{A}g\rangle=\left\langle\int_{-\infty}^{0}\lambda e^{\lambda t}\mathrm{d}E_\lambda f,\int_{-\infty}^{0}\lambda\,\mathrm{d}E_\lambda g\right\rangle=\int_{-\infty}^{0}\lambda^2e^{\lambda t}\mathrm{d}\langle E_\lambda f,g\rangle. \tag{7}$$

Denote by $|\mathrm{d}\langle E_\lambda f,g\rangle|$ the total variation measure of the sign measure $\mathrm{d}\langle E_\lambda f,g\rangle$, then by the Fubini theorem and the Cauchy–Schwartz inequality,

$$\begin{aligned}\int_0^{+\infty}\int_{-\infty}^{0}\lambda^2e^{\lambda t}|\mathrm{d}\langle E_\lambda f,g\rangle|\mathrm{d}t&=\int_{-\infty}^{0}\int_0^{+\infty}\lambda^2e^{\lambda t}\mathrm{d}t|\mathrm{d}\langle E_\lambda f,g\rangle|\\&=\int_{-\infty}^{0}(-\lambda)|\mathrm{d}\langle E_\lambda f,g\rangle|\\&\leqslant\left[\int_{-\infty}^{0}(-\lambda)\mathrm{d}\|E_\lambda f\|^2\right]^{1/2}\left[\int_{-\infty}^{0}(-\lambda)\mathrm{d}\|E_\lambda g\|^2\right]^{1/2}\\&=\langle-\mathcal{A}f,f\rangle^{1/2}\langle-\mathcal{A}g,g\rangle^{1/2}<+\infty,\end{aligned}$$

therefore, from (6) and (7) it follows that

$$\begin{aligned}\int_0^{+\infty}E[V^f(\xi_t)V^g(\xi_0)]\mathrm{d}t&=\int_0^{+\infty}\int_{-\infty}^{0}\lambda^2e^{\lambda t}\mathrm{d}\langle E_\lambda f,g\rangle\mathrm{d}t\\&=\int_{-\infty}^{0}\int_0^{+\infty}\lambda^2e^{\lambda t}\mathrm{d}t\,d\langle E_\lambda f,g\rangle\\&=\int_{-\infty}^{0}(-\lambda)\mathrm{d}\langle E_\lambda f,g\rangle\\&=\left\langle\int_{-\infty}^{0}(-\lambda)\mathrm{d}E_\lambda f,\int_{-\infty}^{0}\mathrm{d}E_\lambda g\right\rangle=-\langle\mathcal{A}f,g\rangle.\end{aligned}$$

It remains to prove that $\int D^{f,g}(x)\mu(\mathrm{d}x)=-2\langle\mathcal{A}f,g\rangle$. By Proposition III.1,

$$D^{f,g}(x)=\mathcal{A}(fg)(x)-(g\mathcal{A}f)(x)-(f\mathcal{A}g)(x).$$

Since ξ is stationary, $\int\mathcal{A}(fg)(x)\mu(\mathrm{d}x)=0$. Hence

$$\begin{aligned}\int D^{f,g}(x)\mu(\mathrm{d}x)&=\int[\mathcal{A}(fg)(x)-g\mathcal{A}f(x)-f\mathcal{A}g(x)]\mu(\mathrm{d}x)\\&=-\int g\mathcal{A}f(x)\mu(\mathrm{d}x)-\int f\mathcal{A}g(x)\mu(\mathrm{d}x)=-2\langle\mathcal{A}f,g\rangle,\end{aligned}$$

which completes the proof. ■

Example III.5: Suppose that $\xi=\{\xi_t\}_{t\geqslant 0}$ is a stationary diffusion process on $\mathbf{R}^d$ with infinitesimal generator

$$\mathcal{A}=\frac{1}{2}\nabla\cdot(A(x)\nabla)+b(x)\cdot\nabla=\frac{1}{2}\sum_{i,j=1}^{d}\frac{\partial}{\partial x_i}a_{ij}(x)\frac{\partial}{\partial x_j}+\sum_{i=1}^{d}b_i(x)\frac{\partial}{\partial x_i},$$

where $A(x)=(a_{ij}(x))_{1\leqslant i,j\leqslant d}$, $b(x)=(b_1(x),\ \ldots\ ,b_d(x))^T$, the components $a_{ij}(x)$ and $b_i(x)$ are smooth functions on $\mathbf{R}^d$, and the diffusion coefficient $A(x)$ is locally elliptic. By the construction of ξ in Ref. 29, its invariant initial distribution has a strictly positive smooth density ρ, and its transition semigroup is strongly continuous on $L^2(\mathbf{R}^d,\rho)$. As is shown in Refs. 26–29 and 31, the entropy production rate e_p of ξ can be expressed as

$$e_p=\frac{1}{2}\int_{\mathbf{R}^d}(2A^{-1}b-\nabla\log\rho)^TA(2A^{-1}b-\nabla\log\rho)(x)\rho(x)\mathrm{d}x.$$

Moreover, ξ is reversible if and only if e_p vanishes, equivalently, $2A^{-1}b=\nabla\log\rho$. Suppose $x_i,x_j,x_ix_j\in\mathcal{D}(\mathcal{A})$, $\forall i,j$. For each fixed i,j, let $f(x)=x_i$ and $g(x)=x_j$, then direct computation yields that

$$V_i(x):=V^f(x)=b_i(x)+\frac{1}{2}\sum_{k=1}^{d}\frac{\partial a_{ik}}{\partial x_k}(x),\quad V_j(x):=V^g(x)=b_j(x)+\frac{1}{2}\sum_{k=1}^{d}\frac{\partial a_{jk}}{\partial x_k}(x),$$

and $D^{f,g}(x)=a_{ij}(x)$. In fact, they are just the drift coefficients and diffusion coefficients of ξ. In case that ξ is reversible, by Theorem III.4, one can obtain the following Einstein relation:

$$\int_0^{+\infty}E[V_i(\xi_0)V_j(\xi_t)]\mathrm{d}t=\frac{1}{2}\int_{\mathbf{R}^d}a_{ij}(x)\rho(x)\mathrm{d}x,\forall i,j.$$

IV. POWER SPECTRUM OF REVERSIBLE MARKOV PROCESSES

We keep the assumptions and notations as before. By the strong continuity assumption of the transition semigroup $\{T(t):t\geqslant 0\}$, for each observable function $f\in L^2(X,\mu)$, the autocorrelation function $C^f(t)=E[f(\xi_t)f(\xi_0)]-E[f(\xi_t)]E[f(\xi_0)]$ of the stationary process $\{f(\xi_s)\}_{s\geqslant 0}$ is a continuous function of t. Hence the process $\{f(\xi_s)\}$ is L^2-continuous, i.e.,

$$\lim_{t\to 0}E|f(\xi_{s+t})-f(\xi_s)|^2=0,\quad \forall s\geqslant 0.$$

Suppose

$$\int_0^{+\infty}|C^f(t)|\mathrm{d}t<+\infty, \tag{8}$$

then by the Wiener–Khinchin theorem, the spectral distribution function of $\{f(\xi_t)\}$ has a nonnegative density

$$S^f(\phi)=\frac{1}{\pi}\int_0^{+\infty}C^f(t)\cos(\phi t)\mathrm{d}t,\quad \forall\phi\in\mathbf{R}.$$

Theorem IV.1: *Suppose that the stationary Markov process $\xi=\{\xi_t\}_{t\geqslant 0}$ is reversible, then for each observable function $f\in L^2(X,\mu)$ satisfying the condition (8), the spectral density $S^f(\phi)$ is a decreasing function on $[0,+\infty)$, hence it is Lorentz-typed.*

Proof: Let $\hat{f}=f-\int f(x)\mu(\mathrm{d}x)$, then $C^f(t)=\langle\hat{f},T(t)\hat{f}\rangle$. Since ξ is reversible, by Theorem II.3, $\tilde{\mathcal{A}}$ is self-adjoint. Hence $\tilde{\mathcal{A}}$ has a spectral representation

$$\tilde{\mathcal{A}}=\int_{-\infty}^{0}\lambda\,\mathrm{d}E_\lambda\,.$$

By the dominated convergence theorem, one has

$$\lim_{t\to+\infty}T(t)\hat{f}=\lim_{t\to+\infty}\int_{-\infty}^{0}e^{\lambda t}\mathrm{d}E_\lambda\hat{f}=E_{\{0\}}\hat{f},$$

where the convergence is in L^2 sense. Therefore,

$$\lim_{t\to+\infty}C^f(t)=\langle\hat{f},E_{\{0\}}\hat{f}\rangle=\|E_{\{0\}}\hat{f}\|^2,$$

which together with the condition (8) implies $E_{\{0\}}\hat{f}=0$. Then by the Fubini theorem, it follows that

$$\begin{aligned}S^f(\phi)&=\frac{1}{\pi}\int_0^{+\infty}\langle\hat{f},T(t)\hat{f}\rangle\cos(\phi t)\mathrm{d}t=\frac{1}{\pi}\int_0^{+\infty}\cos(\phi t)\mathrm{d}t\int_{(-\infty,0]}e^{\lambda t}\mathrm{d}\langle E_\lambda\hat{f},\hat{f}\rangle\\&=\frac{1}{\pi}\int_0^{+\infty}\cos(\phi t)\mathrm{d}t\int_{(-\infty,0)}e^{\lambda t}\mathrm{d}\langle E_\lambda\hat{f},\hat{f}\rangle=\frac{1}{\pi}\int_{(-\infty,0)}\mathrm{d}\langle E_\lambda\hat{f},\hat{f}\rangle\int_0^{+\infty}e^{\lambda t}\cos(\phi t)\mathrm{d}t\\&=\frac{1}{\pi}\int_{(-\infty,0)}\frac{|\lambda|}{\lambda^2+\phi^2}\mathrm{d}\langle E_\lambda\hat{f},\hat{f}\rangle,\end{aligned}$$

hence the spectral density $S^f(\phi)$ is a decreasing function on $[0,+\infty)$. ■

The Lorentz-typed power spectrum tells that noise could not induce any periodicity of the system modeled by the reversible Markov process ξ since the spectrum peak is just centered at $\phi=0$. Therefore, it is impossible for stochastic resonance to occur in a reversible system, whose entropy production rate vanishes.

Remark IV.2: As is shown above, if the Markov process ξ is reversible, then $C^f(t)$ decreases to $\|E_{\{0\}}\hat{f}\|^2$. Therefore, the condition that $T(t)f$ converges to $\int f(x)\mu(\mathrm{d}x)$ in $L^2(X,\mu)$ is necessary to define the spectral density $S^f(\phi)$. It can be naturally weakened to

$$\lim_{t\to+\infty}\frac{1}{t}\int_0^t T(s)f\,\mathrm{d}s=\int f(x)\mu(\mathrm{d}x).$$

Here we remark that for the stationary Markov process ξ, whether reversible or not, the distribution $\mathbf{P}$ of ξ on its canonical orbit space $(\Omega,\mathcal{F})$ is ergodic with respect to the family of left-shift operators on Ω if and only if its transition semigroup $\{T(t):t\geqslant 0\}$ is ergodic on $L^2(X,\mu)$ in sense that for each $f\in L^2(X,\mu)$,

$$\lim_{t\to+\infty}\frac{1}{t}\int_0^t T(s)f\,\mathrm{d}s=\int f(x)\mu(\mathrm{d}x),$$

where the convergence is in L^2 sense.

A new algebraic Bethe ansatz scheme is proposed to diagonalize classes of integrable models relevant to the description of Bose–Einstein condensation in dilute alkali gases. This is achieved by introducing the notion of $\mathbb{Z}$-graded representations of the Yang–Baxter algebra. © *2003 American Institute of Physics.*

I. INTRODUCTION

Theoretical studies into the behavior of Bose–Einstein condensates (BECs) continue at a prolific rate, motivated by the experimental successes of producing condensates of atomic alkali gases[1,2] and superpositions of atomic-molecular alkali gases.[3,4] Many of the theoretical results to date have been obtained through use of the Gross–Pitaevskii mean-field theory and generalizations (see, e.g., Refs. 5–9). However, such mean-field theory approaches have limited applicability in regions of the parameter space where quantum fluctuations dominate. In these cases, only an exact treatment of the model will give a reliable description of the physics.

In our recent work we have shown that one model describing Josephson tunneling between two coupled BECs,[10,11] and another that models coherent superpositions of atomic and molecular BECs,[12] can both in fact be solved exactly in the framework of the algebraic Bethe ansatz. Our intention here is to develop a new mathematical approach which allows us to extend this method to establish that very general classes of Hamiltonians for BECs admit exact solutions. These classes of Hamiltonians cannot be solved in the usual form of the algebraic Bethe ansatz.

In this article, three classes of solvable models relevant to Bose–Einstein condensates of dilute alkali gases are determined. This is achieved by formulating a new scheme for the algebraic Bethe ansatz by introducing the notion of $\mathbb{Z}$-graded representations of the Yang–Baxter algebra. The first model we will present is a six-parameter generalization of the canonical Josephson Hamiltonian[7] (which can also be considered as a two site Bose–Hubbard model) describing a tunnel-coupled pair of trapped Bose–Einstein condensates. The Hamiltonian is also applicable to model solid state Josephson junctions and coupled Cooper pair boxes.[13] The second model we present has six free parameters and the third one has ten parameters. They both describe coherent coupling between atomic and diatomic molecular BECs with additional interactions such as S-wave scattering between the atoms, between the molecules, and between atoms and molecules. Such effects were not included in Refs. 9 and 12 but are important for a quantitative description of experiments.[14] Finally, we formulate the Slavnov formula for the scalar products between a Bethe eigenstate and an arbitrary Bethe vector, which facilitates the exact computation of form factors and correlations functions analogous to the results of Ref. 10.

II. BETHE ANSATZ FOR $\mathbb{Z}$-GRADED REPRESENTATIONS OF THE YANG–BAXTER ALGEBRA

The main ingredient in the study of exactly solvable quantum systems through the algebraic Bethe ansatz,[15,16] is the Yang–Baxter equation

[a]Electronic mail: hqz@maths.uq.edu.au
[b]Electronic mail: jrl@maths.uq.edu.au

$$R_{12}(u-v)R_{13}(u)R_{23}(v)=R_{23}(v)R_{13}(u)R_{12}(u-v). \tag{1}$$

Here $R_{jk}(u)$ denotes the matrix in $\mathrm{End}(V\otimes V\otimes V)$ acting nontrivially on the jth and kth spaces and as the identity on the remaining space. The R-matrix solution may be viewed as the structural constants for the Yang–Baxter algebra, denoted $\mathcal{A}$, generated by the monodromy matrix $T(u)$,

$$R_{12}(u-v)T_1(u)T_2(v)=T_2(v)T_1(u)R_{12}(u-v). \tag{2}$$

The simplest case is that for the $sl(2)$ invariant R-matrix, which will be the subject of our study, given by

$$R(u)=\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & b(u) & c(u) & 0 \\ 0 & c(u) & b(u) & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \tag{3}$$

with the rational functions $b(u)=u/(u+\eta)$ and $c(u)=\eta/(u+\eta)$.

Setting

$$T(u)=\begin{pmatrix} A(u) & B(u) \\ C(u) & D(u) \end{pmatrix}, \tag{4}$$

it follows from the defining relations (2) that

$$\begin{aligned} &[A(u),A(v)]=[D(u),D(v)]=0, \\ &[B(u),B(v)]=[C(u),C(v)]=0, \\ &A(u)C(v)=\frac{u-v+\eta}{u-v}C(v)A(u)-\frac{\eta}{u-v}C(u)A(v), \\ &D(u)C(v)=\frac{u-v-\eta}{u-v}C(v)D(u)+\frac{\eta}{u-v}C(u)D(v). \end{aligned} \tag{5}$$

Note that there are many more relations satisfied by the generators of the Yang–Baxter algebra. However, those given above are the only ones needed for the algebraic Bethe ansatz procedure which we investigate in the following. For convenience, we extend $\mathcal{A}$ by a unit element I which we will represent by the identity matrix in any representation.

We also introduce an auxiliary operator Z, called the *grading operator*, which satisfies the relations

$$[Z,X(u)]=p\{X(u)\}.X(u), \tag{6}$$

where $X=A, B, C,$ or D and $p\{A(u)\}=p\{D(u)\}=0, p\{B(u)\}=1$ and $p\{C(u)\}=-1$. We call $p\{X(u)\}\in\mathbb{Z}$ the *gradation* of $X(u)$ and extend the gradation operation to the entire algebra by the requirement

$$p\{\theta.\phi\}=p\{\theta\}+p\{\phi\} \quad \forall\ \theta,\phi\in\mathcal{A}.$$

This definition for the grading operator is consistent with the defining relations of $\mathcal{A}$ governed by (2).

Let us now define a new class of representations of the Yang–Baxter algebra which we call $\mathbb{Z}$-graded representations. We say that a vector space V, equipped with an endomorphism z, is a $\mathbb{Z}$-graded vector space, denoted (V,z), if it admits a decomposition into subspaces

$$V=\bigoplus_{k=-\infty}^{\infty} V_k$$

such that

$$zV_k=k.V_k, \quad k\in\mathbb{Z}.$$

Note that some of the V_k may be trivial subspaces. Formally, the grading operator can be used to define the following projection operators:

$$P_k=\prod_{\substack{j=-\infty\\ j\neq k}}^{\infty}\frac{(z-jI)}{(k-j)} \tag{7}$$

such that

$$P_kP_l=\delta_{kl}P_l, \quad P_kV_j=\delta_{kj}V_k.$$

We say that a $\mathbb{Z}$-graded vector space

$$V'=\bigoplus_{k=-\infty}^{\infty} V'_k$$

is *equivalent* to V if for some $j\in\mathbb{Z}$ there exists a vector space isomorphism between V'_k and V_{j+k} for all k. This terminology is motivated by the fact that for a given (V,z) one can always generate another $\mathbb{Z}$-graded space (V',z') through the mappings $V'_k\to V_{j+k}$, $z'\to z-jI$ for any $j\in\mathbb{Z}$.

For a given $\mathbb{Z}$-graded V we say that π: $\mathcal{A}\to\mathrm{End}\,V$ provides a $\mathbb{Z}$-graded representation of $\mathcal{A}$ if $\pi(Z)=z$ and the relations (2) and (6) are preserved. In such a case we can write

$$\pi(X(u))=\sum_{j=-\infty}^{\infty}X(u,j),$$

where the matrices $X(u,j)$ satisfy

$$X(u,j)V_k=0 \quad \text{for } j\neq k.$$

More specifically, this means that for $|\psi_k\rangle\in V_k$ we have

$$\pi(X(u)Y(v))|\psi_k\rangle=X(u,k+p\{Y(u)\})Y(v,k)|\psi_k\rangle.$$

In view of the equivalence of the above-defined $\mathbb{Z}$-graded vector spaces, there can also exist equivalent representations. We can define a representation π' equivalent to π by specifying some $k\in\mathbb{Z}$ such that

$$\pi'(Z)=\pi(Z-kI)$$

and for

$$\pi'(X(u))=\sum_{j=-\infty}^{\infty}X'(u,j)$$

the matrices $X'(u,j)$ are defined by

$$X'(u,j)=X(u,j+k), \quad \forall\, j\in\mathbb{Z}.$$

For any $\mathbb{Z}$-graded representation it follows from (5) that the following hold:

$$[A(u,j),A(v,j)]=[D(u,j),D(v,j)]=0,$$

$$B(u,j)B(v,j-1)=B(v,j)B(u,j-1),$$

$$C(u,j)C(v,j+1)=C(v,j)C(u,j+1), \tag{8}$$

$$A(u,j)C(v,j+1)=\frac{u-v+\eta}{u-v}C(v,j+1)A(u,j+1)-\frac{\eta}{u-v}C(u,j+1)A(v,j+1),$$

$$D(u,j)C(v,j+1)=\frac{u-v-\eta}{u-v}C(v,j+1)D(u,j+1)+\frac{\eta}{u-v}C(u,j+1)D(v,j+1),$$

From the defining relations (2) the transfer matrix defined by $\tau(u)=A(u)+D(u)$ commutes for different values of the spectral parameter u; viz.

$$[\tau(u),\tau(v)]=0.$$

Moreover, we may express the representation $\pi(\tau(u))$ of the transfer matrix as

$$\pi(\tau(u))=\sum_{j=-\infty}^{\infty}\tau(u,j)$$

such that

$$\tau(u,j)V_k=0 \quad \text{for } j\neq k$$

and

$$[\tau(u,j),\tau(v,k)]=0, \quad \forall\, j,k.$$

Since $p\{\tau(u)\}=0$, the diagonalization of $\pi(\tau(u))$ is thus reduced to the diagonalization of each of the matrices $\tau(u,j)$ on the $\mathbb{Z}$-graded component V_j, where we have

$$[\tau(u,j),\tau(v,j)]=0.$$

We may restrict our attention to the case of $\tau(u,0)$, as each $\tau(u,j)$ is equivalent to some $\tau'(u,0)$ through the use of equivalent representations as introduced earlier.

In order to formulate the algebraic Bethe ansatz solution for this class of representations, we assume the existence of a pseudovacuum vector $|\chi\rangle\in V_k$ such that

$$A(u,k)|\chi\rangle=\alpha(u,k)|\chi\rangle,$$

$$B(u,k)|\chi\rangle=0,$$

$$C(u,k)|\chi\rangle\neq 0,$$

$$D(u,k)|\chi\rangle=\delta(u,k)|\chi\rangle.$$

The above implies that $|\chi\rangle$ is a maximal weight vector with respect to Z. Without loss of generality we can choose $k=M$, again due to the equivalence of representations discussed earlier, and look for Bethe states defined by

$$\Psi(v_1,\ldots,v_M)\equiv\Psi(\{v_i\})=C(v_1,1)C(v_2,2)\cdots C(v_M,M)|\chi\rangle. \tag{9}$$

It is easy to check that this Bethe state is symmetric with respect to the variables v_i, a feature which plays a crucial role in the following. Acting $A(u,0)$ and $D(u,0)$ on the Bethe state we have

$$A(u,0)\Psi(\{v_i\})=\alpha(u,M)\prod_{i=1}^{M}\frac{u-v_i+\eta}{u-v_i}\Psi(\{v_i\})+\sum_{i=1}^{M}\mathcal{M}_i(u,\{v_j\})\Psi(v_1,\ldots,v_{i-1},u,v_{i+1},\ldots,v_M),$$

$$D(u,0)\Psi(v_1,\ldots,v_M)=\delta(u,M)\prod_{i=1}^{M}\frac{u-v_i-\eta}{u-v_i}\Psi(\{v_i\})+\sum_{i=1}^{M}\mathcal{N}_i(u,\{v_j\})\Psi(v_1,\ldots,v_{i-1},u,v_{i+1},\ldots,v_M), \tag{10}$$

with

$$\mathcal{M}_i(u,\{v_j\})=-\frac{\eta}{u-v_i}\alpha(v_i,M)\prod_{j\neq i}^{M}\frac{v_i-v_j+\eta}{v_i-v_j},$$
$$\mathcal{N}_i(u,\{v_j\})=\frac{\eta}{u-v_i}\delta(v_i,M)\prod_{j\neq i}^{M}\frac{v_i-v_j-\eta}{v_i-v_j}. \tag{11}$$

Requiring

$$\mathcal{M}_i(u,\{v_j\})+\mathcal{N}_i(u,\{v_j\})=0$$

forces $\Psi(v_1,\ldots,v_M)$ to be an eigenstate of $\tau(u,0)$ and leads to the Bethe ansatz equations

$$\frac{\alpha(v_i,M)}{\delta(v_i,M)}=\prod_{j\neq i}^{M}\frac{v_i-v_j-\eta}{v_i-v_j+\eta},\quad i=1,\ldots,M. \tag{12}$$

The corresponding eigenvalue of the matrix $\tau(u,0)$ is

$$\Lambda(u,\{v_i\})=\alpha(u,M)\prod_{i=1}^{M}\frac{u-v_i+\eta}{u-v_i}+\delta(u,M)\prod_{i=1}^{M}\frac{u-v_i-\eta}{u-v_i}.$$

III. EXPLICIT $\mathbb{Z}$-GRADED REALIZATIONS

Next we give two nontrivial $\mathbb{Z}$-graded realizations of the algebra $\mathcal{A}$. One is expressible in terms of two Heisenberg algebras with generators a_i, $a_i^\dagger$, $i=1,2$ and reads $X(u,j)=\tilde{X}(u,j)P_j$ with

$$\tilde{A}(u,j)=u^2+\eta uN+\eta^2N_1N_2-\eta(N_1-N_2)\omega(N+jI)-\omega^2(N+jI)+a_2^\dagger a_1,$$
$$\tilde{B}(u,j)=(u+\omega(N+jI)+\eta N_1)a_2+\eta^{-1}a_1,$$
$$\tilde{C}(u,j)=a_1^\dagger(u-\omega(N+jI)+\eta N_2)+\eta^{-1}a_2^\dagger,$$
$$\tilde{D}(u,j)=a_1^\dagger a_2+\eta^{-2}. \tag{13}$$

Above, P_j are the projections defined by (7), $N_i=a_i^\dagger a_i$, $N=N_1+N_2$ and $\omega(x)$ is an arbitrary polynomial function of x. Note that in the case when $\omega(x)$ is constant, the above-noted realization reduces to that discussed in Refs. 10 and 11 and is factorizable into two local representations of the Yang–Baxter algebra expressible in terms of the two Heisenberg algebras. It is important to note that for generic $\omega(x)$ no such factorization exists.

The representation acts on the infinite dimensional Fock space spanned by the vectors

$$|m,n\rangle=(a_1^\dagger)^m(a_2^\dagger)^n|0\rangle, \quad m,n=0,1,2,\ldots,\infty. \tag{14}$$

For this representation, we choose the pseudovacuum $|\chi\rangle$ as the Fock vacuum $|0\rangle$. The representation of the grading operator Z is chosen to be

$$\pi(Z)=M.I-N.$$

We then have

$$\alpha(u,M)=u^2-\omega^2(M), \quad \delta(u,M)=\eta^{-2} \tag{15}$$

and the Bethe ansatz equations become

$$\eta^2(v_i^2-\omega^2(M))=\prod_{j\neq i}^{M}\frac{v_i-v_j-\eta}{v_i-v_j+\eta} \tag{16}$$

for the diagonalization of the matrix $\tau(u,0)$. The eigenstates (9) in this instance are also eigenstates of the total particle number N with eigenvalue M.

Another $\mathbb{Z}$-graded realization of the Yang–Baxter algebra is $X(u,j)=\tilde{X}(u,j)P_j$ with

$$\begin{aligned}
\tilde{A}(u,j)&=-\eta u^2+u(1-\eta^2(K_z+N_c)-\eta\omega(K_z+N_c+jI))+\eta K_z\\
&\quad-\eta^2K_z\omega(K_z+N_c+jI)-\eta^3N_cK_z+\eta^2cK_+,\\
\tilde{B}(u,j)&=\eta(1-\eta u-\eta\omega(K_z+N_c+jI)-\eta^2N_c)K_--\eta c(u-\eta K_z),\\
\tilde{C}(u,j)&=\eta c^\dagger(u+\eta K_z)-\eta K_+,\\
\tilde{D}(u,j)&=u-\eta K_z+\eta^2c^\dagger K_-.
\end{aligned} \tag{17}$$

Here, the operators $c, c^\dagger$ form a Heisenberg algebra, with $N_c=c^\dagger c$, and the operators K_z, K_+, K_- satisfy the relations of the $su(1,1)$ algebra $[K_z,K_\pm]=\pm K_\pm$, $[K_+,K_-]=-2K_z$. As in the previous example, $\omega(x)$ is an arbitrary polynomial function of x and the above realization is factorizable only in the case when $\omega(x)$ is constant.

For this representation, we choose the pseudovacuum $|\chi\rangle$ as the tensor product of the Fock vacuum $|0\rangle$ with a lowest weight state for the algebra $su(1,1)$ of weight κ. The representation of the grading operator may be chosen as

$$\pi(Z)=M.I-K_z-N_c+\kappa.$$

Then,

$$\alpha(u,M)=(1-\eta u-\eta\omega(M))(u+\eta\kappa), \quad \delta(u,M)=u-\eta\kappa \tag{18}$$

and the Bethe ansatz equations are

$$(1-\eta v_i-\eta\omega(M))\left(\frac{v_i+\eta\kappa}{v_i-\eta\kappa}\right)=\prod_{j\neq i}^{M}\frac{v_i-v_j-\eta}{v_i-v_j+\eta}. \tag{19}$$

IV. THREE MODELS OF BOSE–EINSTEIN CONDENSATES

A. Model 1: Two coupled BECs

Consider the following general Hamiltonian describing Josephson tunneling between two coupled Bose–Einstein condensates

$$H=U_{11}N_1^2+U_{12}N_1N_2+U_{22}N_2^2+\mu_1N_1+\mu_2N_2-\frac{\mathcal{E}_J}{2}(a_1^\dagger a_2+a_2^\dagger a_1). \tag{20}$$

The above-mentioned Hamiltonian generalizes the canonical Josephson Hamiltonian studied in Refs. 10 and 11 in that the couplings U_{11},U_{22} for the S-wave scattering terms can be chosen arbitrarily. It also describes a pair of Cooper pair boxes with capacitive coupling.[13] In the limit $U_{22}\to 0$, then $\langle N_2\rangle \gg \langle N_1\rangle$, which can be considered as a single Cooper pair box coupled to a reservoir.

It is an algebraic exercise to show that the Hamiltonian is related with the matrix $\tilde{\tau}(u,0)=\tilde{A}(u,0)+\tilde{D}(u,0)$ through

$$H=-\frac{\mathcal{E}_J}{2}[\tilde{\tau}(0,0)-\eta^{-2}+(\alpha N+\beta)^2-\eta\sigma N-\eta\delta N^2].$$

Here we have chosen $\omega(N)=\alpha N+\beta$ and the coupling constants are identified as

$$\eta^2=\frac{2(U_{11}+U_{22}-U_{12})}{\mathcal{E}_J},$$

$$\alpha=\frac{U_{11}-U_{22}}{\eta\mathcal{E}_J},$$

$$\beta=\frac{\mu_1-\mu_2}{\eta\mathcal{E}_J},$$

$$\sigma=\frac{\mu_1+\mu_2}{\eta\mathcal{E}_J},$$

$$\delta=\frac{U_{11}+U_{22}}{\eta\mathcal{E}_J}.$$

Noting that

$$N=\eta^{-1}\frac{d\tilde{\tau}}{du}(0,0),$$

the above demonstrates that the Hamiltonian (20) is expressible solely in terms of the matrix $\tilde{\tau}(u,0)$ and its derivative.

Since $[H,N]=0$, the Hamiltonian is block diagonal on the Fock basis (14). Thus on a subspace of the Fock space with fixed particle number N, the diagonalization of $\tilde{\tau}(u,0)$ is equivalent to the diagonalization of $\tau(u,0)$ presented earlier in the Bethe ansatz framework. We then deduce that the solution of (20) for the energy spectrum is

$$E=-\frac{\mathcal{E}_J}{2}\left[\eta^{-2}\prod_{i=1}^{N}\frac{v_i+\eta}{v_i}-(\alpha N+\beta)^2\prod_{i=1}^{N}\frac{v_i-\eta}{v_i}-\eta^{-2}+(\alpha N+\beta)^2-\eta\sigma N-\eta\delta N^2\right], \tag{21}$$

where the parameters $\{v_i\}$ are subject to the Bethe ansatz equations

$$\eta^2(v_i^2-(\alpha N+\beta)^2)=\prod_{j\neq i}^{N}\frac{v_i-v_j-\eta}{v_i-v_j+\eta}.$$

B. Model 2: Homo-atomic-molecular BECs

Next we turn our attention to a two-mode model for an atomic-molecular Bose–Einstein condensate with identical atoms. The Hamiltonian takes the form

$$H=U_{aa}N_a^2+U_{ac}N_aN_c+U_{cc}N_c^2+\mu_aN_a+\mu_cN_c+\Omega(a^\dagger a^\dagger c+c^\dagger aa), \tag{22}$$

which acts on a basis of Fock states analogous to (14). For the case of ^{87}Rb, all of these parameters have been estimated from experiment (see Ref. 8). In the experiment described in Ref. 4, the parameter U_{aa} was varied significantly with a magnetic field.

The Hamiltonian commutes with the total atom number $N=N_a+2N_c$. In terms of a realization of the algebra $su(1,1)$ through

$$K_+=\frac{(a^\dagger)^2}{2},\quad K_-=\frac{a^2}{2},\quad K_z=\frac{2N_a+1}{4}, \tag{23}$$

one may establish the relation between the Hamiltonian and the corresponding transfer matrix $\tilde{\tau}(u,0)=\tilde{A}(u,0)+\tilde{D}(u,0)$ arising from the the realization (17) of the Yang-Baxter algebra is

$$H=\sigma+\delta(N/2+1/4)+\gamma(N/2+1/4)^2+2\eta^{-2}\Omega\tilde{\tau}(0,0),$$

with

$$\frac{d\tilde{\tau}}{du}(0,0)=2-\eta(\eta+\alpha)(N/2+1/4)-\eta\beta.$$

Above we have chosen

$$\omega(K_z+N_c)=\alpha(K_z+N_c)+\beta=\alpha(N/2+1/4)+\beta$$

and the following identification has been made for the coupling constants:

$$\eta=\frac{4U_{aa}+U_{cc}-2U_{ac}}{2\Omega},$$

$$\alpha=\frac{U_{cc}-4U_{aa}}{2\Omega},$$

$$\beta=\frac{2\mu_c-4\mu_a+4U_{aa}-U_{ac}}{4\Omega},$$

$$\sigma=\frac{U_{aa}-2\mu_a}{4},$$

$$\delta=\frac{2\mu_c-U_{ac}}{2},$$

$$\gamma=U_{cc}.$$

By the same argument as before, we conclude that the exact solution for the energy spectrum of (22) is determined by

$$E=\sigma+\delta(M+\kappa)+\gamma(M+\kappa)^2 +2\eta^{-1}\kappa\Omega\left[(1-\eta(\alpha(M+\kappa)+\beta))\prod_{i=1}^{M}\frac{v_i-\eta}{v_i}-\prod_{i=1}^{M}\frac{v_i+\eta}{v_i}\right], \tag{24}$$

where the parameters v_i satisfy the Bethe ansatz equations

$$[1-\eta v_i-\eta(\alpha(M+\kappa)+\beta)]\left(\frac{v_i+\eta\kappa}{v_i-\eta\kappa}\right)=\prod_{j\neq i}^{M}\frac{v_i-v_j-\eta}{v_i-v_j+\eta}. \tag{25}$$

For the representation (23) of the $su(1,1)$ algebra there are two lowest weight vectors; viz. the Fock vacuum $|0\rangle$ and the one particle state $a^\dagger|0\rangle$. It follows that the allowed values for κ in (24) and (25) are $\kappa=1/4, 3/4$. This demonstrates that the solution of the model depends on whether the total particle number $N=2M+2\kappa-1/2$ is even or odd, the effects of which on the energy spectrum can be seen through numerical analysis (cf. Ref. 12).

C. Model 3: Hetero-atomic-molecular BECs

The previous construction can be extended to model an atomic-molecular Bose–Einstein condensate with two distinct species of atoms, denoted a and b. For this case the Hamiltonian takes the form

$$H=U_{aa}N_a^2+U_{bb}N_b^2+U_{cc}N_c^2+U_{ab}N_aN_b+U_{ac}N_aN_c +U_{bc}N_bN_c+\mu_aN_a+\mu_bN_b+\mu_cN_c+\Omega(a^\dagger b^\dagger c+c^\dagger ba), \tag{26}$$

which commutes with the total atom number $N=N_a+N_b+2N_c$ and $\mathcal{I}=N_a-N_b$. Here the model acts on the Fock space spanned by the vectors

$$|l,m,n\rangle=(a^\dagger)^l(b^\dagger)^m(c^\dagger)^n|0\rangle.$$

In order to show the solvability of this model, we adopt the realization of the $su(1,1)$ algebra given by

$$K_+=a^\dagger b^\dagger,\quad K_-=ab,\quad K_z=\frac{N_a+N_b+1}{2}, \tag{27}$$

and observe that the operator $\mathcal{I}$ commutes with the $su(1,1)$ algebra in this representation, hence taking a constant value in any irreducible representation. Due to the symmetry upon interchanging the labels a and b, we can assume without loss of generality that the eigenvalues of $\mathcal{I}$ are non-negative. In particular, note then that the lowest weight states for this realization are of the form

$$|m\rangle=(a^\dagger)^m|0\rangle,\quad m=0,1,2,\ldots$$

and $K_z|m\rangle=(m/2+1/2)|m\rangle$. We conclude that the lowest weight labels κ can be taken from the set $\{1/2, 1, 3/2,\ldots\}$ and the eigenvalue of $\mathcal{I}$ on the irreducible representation labeled by κ is $(2\kappa-1.)$

For this case the relation between the Hamiltonian and the corresponding matrix $\tilde{\tau}(u,0)$ is

$$H=\sigma+\delta(N/2+1/2)+\lambda(N/2+1/2)^2+\rho\mathcal{I}+\nu\mathcal{I}^2+\xi\mathcal{I}(N/2+1/2)+\eta^{-2}\Omega\tilde{\tau}(0,0) \tag{28}$$

with

$$\frac{d\tilde{\tau}}{du}(0,0)=2-\eta(\eta+\alpha)(N/2+1/2)-\eta\beta\mathcal{I}-\eta\gamma.$$

Above we have chosen

$$\omega(K_z+N_b)=\alpha(K_z+N_c)+\beta(2\kappa-1)+\gamma=\alpha(N/2+1/2)+\beta\mathcal{I}+\gamma$$

and the coupling constants are related through the relations

$$\eta=\frac{U_{aa}+U_{bb}+U_{cc}+U_{ab}-U_{ac}-U_{bc}}{\Omega},$$

$$\alpha=\frac{U_{cc}-U_{aa}-U_{bb}-U_{ab}}{\Omega},$$

$$\beta=\frac{2U_{bb}-2U_{aa}+U_{ac}-U_{bc}}{2\Omega},$$

$$\gamma=\frac{2U_{aa}+2U_{bb}+2U_{ab}-U_{ac}-U_{bc}+2\mu_c-2\mu_a-2\mu_b}{2\Omega},$$

$$\sigma=\frac{U_{aa}+U_{bb}+U_{ab}-2\mu_a-2\mu_b}{4},$$

$$\delta=\frac{2\mu_c-U_{ac}-U_{bc}}{2},$$

$$\lambda=U_{cc},$$

$$\rho=\frac{U_{bb}-U_{aa}+\mu_a-\mu_b}{2},$$

$$\nu=\frac{U_{aa}+U_{bb}-U_{ab}}{4},$$

$$\xi=\frac{U_{ac}-U_{bc}}{2}.$$

The exact solution in this instance reads

$$E=\sigma+\delta(M+\kappa)+\lambda(M+\kappa)^2+\rho(2\kappa-1)+\nu(2\kappa-1)^2+\xi(2\kappa-1)(M+\kappa)$$
$$+\eta^{-1}\kappa\Omega\left[(1-\eta(\alpha(M+\kappa)+\beta(2\kappa-1)+\gamma))\prod_{i=1}^{M}\frac{v_i-\eta}{v_i}-\prod_{i=1}^{M}\frac{v_i+\eta}{v_i}\right],$$

where the parameters v_i satisfy the Bethe ansatz equations

$$[1-\eta v_i-\eta(\alpha(M+\kappa)+\beta(2\kappa-1)+\gamma)]\left(\frac{v_i+\eta\kappa}{v_i-\eta\kappa}\right)=\prod_{j\neq i}^{M}\frac{v_i-v_j-\eta}{v_i-v_j+\eta} \tag{29}$$

and the total atom number is given by $N=2M+2\kappa-1$.

V. WAVE FUNCTION SCALAR PRODUCTS

Recall that in the usual algebraic Bethe ansatz for the algebra $\mathcal{A}$ there is a formula originally due to Slavnov[17] (see also Refs. 15 and 18) for the wave function scalar products. The Slavnov formula still applies in the $\mathbb{Z}$-graded case and takes the usual form

$$S_M(\{u_j\},\{v_k\})=\Phi(\{u_j\})\Psi(\{v_k\})=\Phi(\{v_k\})\Psi(\{u_j\})=\frac{\det T(\{u_j\},\{v_k\})}{\det V(\{u_j\},\{v_k\})}, \tag{30}$$

with the entries of the $M\times M$ matrices T and V given by

$$T_{ab}=\frac{\partial}{\partial v_a}\Lambda(u_b,\{v_k\}), \quad V_{ab}=\frac{1}{u_b-v_a}, \quad a,b=1,\ldots,M.$$

$\Phi(\{u_i\})$ is the left vector

$$\Phi(u_1,\ldots,u_M)=\langle\chi|B(u_M,M)\cdots B(u_1,1).$$

Above, we have adopted the usual convention to scale the Yang–Baxter algebra such that $\delta(u,M)=1$. Also, $\{v_k\}$ provide a solution of the Bethe ansatz equation (12) and the parameters $\{u_j\}$ can be chosen arbitrarily.

The Yang–Baxter algebra $\mathcal{A}$ admits a conjugation operation $\dagger:\mathcal{A}\to\mathcal{A}$ defined by

$$A(u)^\dagger=A(u), \quad B(u)^\dagger=C(u), \quad C(u)^\dagger=B(u), \quad D(u)^\dagger=D(u)$$

and extended to all of $\mathcal{A}$ through

$$(\theta.\phi)^\dagger=\phi^\dagger.\theta^\dagger, \quad \forall\ \theta,\phi\in\mathcal{A}$$

such that the defining relations (2) are preserved. Consequently the right vector $\Phi(v_1,\ldots,v_M)^\dagger$ is also an eigenvector of the transfer matrix whenever the Bethe ansatz equations for the parameters $\{v_i\}$ are satisfied. However, it is apparent that the $\mathbb{Z}$-graded representations (13) and (17) we have introduced are not unitary, and generally

$$\Phi(\{v_i\})^\dagger\neq\Psi(\{v_i\}).$$

On the other hand, numerical analysis we have undertaken for the above models indicates that for fixed particle numbers, and generic values of the coupling parameters, the energy spectrum is free of degeneracies. This is presumably due to the fact that the only Lie algebra symmetries for these models are $u(1)$ invariances corresponding to conservation of particle numbers, and the nondegenerate spectra are examples of Hund's noncrossing rule.[19,20] Whenever this is the case, we can conclude that

$$\Phi(\{v_i\})^\dagger=K\Psi(\{v_i\})$$

for some constant K and the Slavnov formula can still be invoked for the computation of form factors and correlation functions (cf. the example of Ref. 10 where it was found $K=\pm1$).

VI. CONCLUSION

In conclusion we have introduced a new scheme for the algebraic Bethe ansatz to diagonalize three classes of integrable models relevant to Bose–Einstein condensates of dilute alkali gases. The extension of this construction to other types of models, such as the Jaynes–Cummings model,[21] and generalized Tavis–Cummings model discussed in Ref. 22, is straightforward.

(Received 26 March 2003; accepted 25 June 2003)

Let S be an integrable Pfaffian system. If it is invariant under a transversally free infinitesimal action of a finite dimensional real Lie algebra g, we show that the ''vertical'' variational cohomology of S is equal to the Lie algebra cohomology of g with values in the space of the ''horizontal'' cohomology in a maximum dimension. This result, besides giving an effective algorithm for the computation of the variational cohomology of an invariant Pfaffian system, provides a method for detecting obstructions to the existence of infinitesimal actions leaving a given system invariant. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1607513]

I. INTRODUCTION

We study here a problem that arises naturally in connection with the integration of differential systems invariant under finite or infinitesimal group actions, the theory of such systems, as conceived by Sophus Lie and later brought to its full light by Élie Cartan, being discussed in Ref. 7. Let $\mathcal{D}$ be such a differential system (viewed as a sub-manifold of some Jet or Grassmannian bundle) invariant under the action of a finite dimensional real Lie algebra g of infinitesimal contact transformations and let us further assume that $\mathcal{D}$ is integrable and of finite type (otherwise we are led into the realm of infinite Lie pseudogroups) and that the infinitesimal action of g operates transitively in a direction transverse to each solution (Ref. 7, Sec. 13). Then the integration of $\mathcal{D}$ can be reduced to the integration of a finite family of integrable Pfaffian systems that are invariant under the actions of Abelian or simple algebras, these infinitesimal actions being transversally free (Ref. 7, Sec. 4).

The integration of differential equations, in the sense of devising methods that will eventually lead to explicit solutions or at least that will contribute to simplify and reduce the integration problem (e.g., reduce the order of the equations), was a major theme in the second half of the last century, as witnessed by Lie's own writings (Refs. 8, 9, 11, 13). It is therefore not surprising that Lie's ultimate concern should have been precisely the search of such methods. Using the structure of continuous groups, he could easily say which, among the many integration methods known at that time, were the *best* (the sharpest, in the sense that they involved the least number of operations and the lowest orders for these operations) and would claim, with reason, that his were the best (Refs. 8, 10, 11). Inasmuch, he showed in Ref. 12 that ''*la méthode du dernier multiplicateur de Jacobi*'' was the best on the grounds that the infinite continuous group of all volume preserving transformations is simple.

Élie Cartan abandoned this pursuit, at least as a priority, since, as he claimed, in this endeavor we most often fail rather than succeed. He was the first to point out that we should actually study the *structure* underlying an integration problem and, in understanding this structure, he created integration methods, for invariant differential systems, inconceivable at Lie's time (Refs. 2–5). For such systems, this underlying structure has a very precise meaning and is a direct consequence of the structure of g and of the prescribed invariant infinitesimal action (Refs. 1, 7, Secs. 5–6).

If the differential system $\mathcal{D}$ is invariant under the action of a contact Lie algebra g then its associated Pfaffian system S, obtained by restricting all the contact 1-forms to the underlying manifold $\mathcal{R}$ of $\mathcal{D}$, is integrable and invariant by the restriction of g. Conversely, if S is invariant by the infinitesimal action Φ of a Lie algebra g' then we can extend each vector field $\Phi(v)$, $v \in g'$, to an infinitesimal contact transformation so as to obtain a contact algebra g that leaves $\mathcal{D}$ invariant and such that $\Phi(g') = g|\mathcal{R}$. In general, the actions of g and g' are not transversally free but, as evidenced in Ref. 7, Sec. 5, one can in many cases reach this appropriate setting essentially via restriction and prolongation operations. It therefore becomes relevant, in view of applying the Lie and Cartan theory, to know whether a given integrable Pfaffian system S admits a transversally free invariant infinitesimal action of a given Lie algebra g or, more generally, of some Lie algebra g. Showing the existence of such infinitesimal actions is a rather delicate problem that has to be analyzed in each specific case since there does not seem to exist any general method. On the other hand, showing non-existence can be achieved by displaying some obstructions via cohomological methods and this is actually our main concern in this paper. One last word is due. Whereas the structure of a differential system is a global concept, the integration of such a system can, in a first approach, be viewed as a local problem. Since any integrable Pfaffian system admits locally many automorphisms, in fact, they form an infinite Lie pseudogroup of order one, there exist, in a neighborhood of each point, many transversally free infinitesimal actions leaving the system invariant and the Lie and Cartan theory can always be applied.

The Euler–Lagrange (variational) complex associated to an integrable Pfaffian system S is finite. As is usual, we call *horizontal* that part of the complex preceding the Euler operator E and *vertical* that part subsequent to this operator. The horizontal part is a finite augmentation of E and the vertical part a finite resolution. We show, in Sec. V (Theorem 1), that if S is invariant under a transversally free infinitesimal action of the Lie algebra g then the above finite resolution is equivalent, in positive dimensions, to the Lie algebra complex of g taking values in the horizontal cohomology of maximum dimension. In particular, the resulting cohomology spaces are equal whereupon any discrepancy between the two cohomologies will put in evidence an obstruction to the existence of such an infinitesimal action. The above equivalence also provides an effective method for the computation of the vertical variational cohomology of an invariant Pfaffian system.

Throughout the years, several authors have given distinct though essentially equivalent formulations to the variational complex. We adopt here the approach described in Ref. 6 since it emphasizes the relationship of this complex with the algebra of generalized symmetries. Inasmuch as the usual de Rham complex on a manifold M is the differential complex associated to the algebra of all the vector fields on M, the horizontal part of the variational complex is a de Rham complex associated to the algebra of all trivial symmetries (total derivatives) and the vertical part is a de Rham complex associated to the algebra of all generalized symmetries. Our first task, in this paper, consists in writing down explicitly the complex we shall be dealing with, namely the restriction of the general complex defined in Ref. 6 to an integrable Pfaffian system. This, unfortunately, is a rather long and boring task hence we only state, in Sec. II, a well known lemma that provides all the necessary technical information relevant to the restriction procedure and thereafter construct directly, in Secs. III and IV, the desired complex. It turns out that the trivial symmetries become simply the vector fields annihilated by S and the generalized symmetries become the equivalence classes of the infinitesimal automorphisms of S modulo the trivial symmetries. There is of course nothing new about this restricted complex, just a different make-up. Invariant systems are examined in Sec. V and some examples are discussed in Sec. VI.

For simplicity, we assume that all the data are C^∞ smooth though, in each specific case, C^k

smoothness for some k will suffice. We also assume that all the manifolds are connected and second countable though not necessarily orientable and that all the objects such as functions, vector fields, differential forms, etc. are globally defined on these manifolds unless stated otherwise (e.g., local coordinates, local generators of Pfaffian systems and distributions).

The second named author wishes to thank Piotr Mormul for some very helpful discussions.

II. PFAFFIAN SYSTEMS AND THEIR PROLONGATIONS

Let S be a Pfaffian system, for the time being not necessarily integrable, and $\Sigma = S^{\perp}$ the corresponding distribution, both defined on the manifold M (Ref. 7, Sec. 2). In terms of partial differential equations, it seems preferable to view the distribution Σ (or the Pfaffian system S) as a section of the Grassmannian bundle $\mathbf{G}_1^p M$ of linear contact elements of dimension $p = \operatorname{rank}\Sigma$ or, still better, as the submanifold $\mathcal{R}$ of $\mathbf{G}_1^p M$, an image of this section (Ref. 6, p. 614). Since the dimension p will remain unchanged throughout the present discussion, we abbreviate $\mathbf{G}_k^p M$ by $\mathbf{G}_k$, where k is the order of the contact elements under consideration. Let $\mathcal{R}_1 \subset \mathbf{G}_2$ denote the first prolongation of $\mathcal{R}$.

Lemma 1: The distribution Σ is integrable (involutive) if and only if $\mathcal{R}_1$ projects onto $\mathcal{R}$. A proof of this result can be found in Ref. 7, Sec. 13. This proof tells us, in particular, that a fiber $(\mathcal{R}_1)_X$, $X \in \mathcal{R}$, is either empty or else contains a single element, say Y. The first order linear holonomic contact element $\Sigma_X^{(1)}$ associated to Y is the unique holonomic element tangent to $\mathcal{R}$ at the point X. Since it does not make much sense to define the variational complex for other that *formally integrable* equations (or at least equations that, after prolongation, become formally integrable at large enough orders), we see that in the present situation it becomes natural to assume that Σ is integrable. This does not mean, however, that variational complexes cannot be associated to nonintegrable Pfaffian systems. In this latter context, we ought to specify or determine the dimension $q \leqslant p$ of linear contact elements for which a *sufficient number* of integral contact elements do exist (e.g., Pfaffian systems that are *in involution*, in the sense of Cartan, at dimension q) and consider the variational complex in the realm of the bundles $\mathbf{G}_k^q M$. We shall nevertheless restrict our attention to integrable systems.

When S (or Σ) is integrable, then $\mathcal{R}_1$ is the set of all second order contact elements determined by the p-dimensional integral manifolds of S and the assignement $Y \in \mathcal{R}_1 \mapsto \Sigma_X^{(1)} \subset T_X\mathcal{R}$, $X = \rho_{1,2}(Y)$, is an integrable distribution $\Sigma^{(1)}$, defined on the manifold $\mathcal{R}$, equivalent to Σ via the diffeomorphism $\beta_1 = \rho_{0,1} : \mathcal{R} \to M$. In general, the k-th prolongation $\mathcal{R}_k \subset \mathbf{G}_{k+1}$ is the set of all $(k+1)$-st order contact elements determined by the p-dimensional integral manifolds of S. Furthermore, the assignment $Y \in \mathcal{R}_k \mapsto \Sigma_X^{(k)} \subset T_X\mathcal{R}_{k-1}$, $X = \rho_{k,k+1} Y$, where $\Sigma_X^{(k)}$ is the linear holonomic contact element at order k associated to Y, is an integrable distribution $\Sigma^{(k)}$, defined on the manifold $\mathcal{R}_{k-1}$, equal to the annihilator of the restriction, to $\mathcal{R}_{k-1}$, of the canonical contact structure S_k of $\mathbf{G}_k$ ($[\Sigma^{(k)}]^{\perp} = \iota^* S_k$, $\iota : \mathcal{R}_{k-1} \hookrightarrow \mathbf{G}_k$; cf. Ref. 6, Sec. 2). For any pair of integers $h \leqslant k$, the distributions $\Sigma^{(k)}$ and $\Sigma^{(h)}$ are equivalent via the diffeomorphism $\rho_{h,k} : \mathcal{R}_{k-1} \to \mathcal{R}_{h-1}$ ($\mathcal{R}_0 = \mathcal{R}$, $\Sigma^{(0)} = \Sigma$).

III. THE HORIZONTAL OPERATOR

We now construct directly the so called *horizontal* part of the variational complex associated to an integrable Pfaffian system S, namely that part preceding the Euler operator. We denote by $\mathcal{B}$ the algebra of all the (globally defined) vector fields η tangent to the distribution $\Sigma = S^{\perp}$ ($\eta \in \Gamma(\Sigma)$) and by $\mathcal{F}$ the ring of all the (globally defined) C^{∞} functions on the underlying manifold. The dual space $\mathcal{H} = \mathcal{B}^*$, with respect to the $\mathcal{F}$-module structure, is equal to the set of global sections of the dual bundle $\Sigma^* \simeq T^*M/S$ and, correspondingly, $\wedge \mathcal{H} \simeq \Gamma(\wedge \Sigma^*)$. The differential,

$$d_H : \wedge^s \mathcal{H} \to \wedge^{s+1} \mathcal{H},$$

is defined by the usual formula:

$$d_H\mu(\eta_1,\ldots,\eta_{s+1})=\sum_i(-1)^{i+1}\theta(\eta_i)\,\mu(\eta_1,\ldots,\widehat{\eta_i},\ldots,\eta_{s+1})$$

$$+\sum_{i<j}(-1)^{i+j}\mu([\eta_i,\eta_j],\eta_1,\ldots,\widehat{\eta_i},\ldots,\widehat{\eta_j},\ldots,\eta_{s+1}),\qquad(1)$$

where the η_i are vector fields tangent to Σ, $\theta(\eta_i)$ is the usual Lie derivative and $[\eta_i,\eta_j]$ the usual Lie bracket. Let $(U;x^1,\ldots,x^p,y^1,\ldots,y^q)$ be a foliated chart of Σ for which the integral manifolds, in U, are given by the equations $y^\lambda=c^\lambda$. Then an element of $\wedge\mathcal{H}$ has the local expression

$$\mu=\sum a_{i_1\cdots i_s}dx^{i_1}\wedge\cdots\wedge dx^{i_s},$$

the coefficients $a_{i_1\cdots i_s}$ being C^∞ functions on U, and

$$d_H\mu=\sum(da_{i_1\cdots i_s}|\Sigma)\wedge dx^{i_1}\wedge\cdots\wedge dx^{i_s}=\sum\frac{\partial a_{i_1\cdots i_s}}{\partial x^i}dx^i\wedge dx^{i_1}\wedge\cdots\wedge dx^{i_s},\qquad(2)$$

where $da_{i_1\cdots i_s}|\Sigma$ (resp., dx^i) stands for the restriction of this differential to the integral manifolds of Σ.

We now extend the differential (1) by adding, in the cochains, a term that corresponds in Ref. 6 to the module $\mathcal{C}$ of all the contact 1-forms. Here we consider $\mathcal{C}=\Gamma(S)$ to be the module of all the global sections of S, take the cochain space $\Phi^{r,s}=(\wedge^r\mathcal{C})\otimes(\wedge^s\mathcal{H})$ and consider its elements as horizontal forms with values in $\wedge^r\mathcal{C}$. The extended differential,

$$d_H:(\wedge^r\mathcal{C})\otimes(\wedge^s\mathcal{H})\to(\wedge^r\mathcal{C})\otimes(\wedge^{s+1}\mathcal{H}),$$

is then defined by

$$d_H(\omega\otimes\mu)(\eta_1,\ldots,\eta_{s+1})=\sum_i(-1)^{i+1}\theta(\eta_i)[\mu(\eta_1,\ldots,\widehat{\eta_i},\ldots,\eta_{s+1})\omega]$$

$$+\sum_{i<j}(-1)^{i+j}\mu([\eta_i,\eta_j],\eta_1,\ldots,\widehat{\eta_i},\ldots,\widehat{\eta_j},\ldots,\eta_{s+1})\omega,\qquad(3)$$

where $\eta_i\in\Gamma(\Sigma)$ and $\theta(\eta_i)$ is the Lie derivative. The second term on the right hand side belongs of course to $\wedge^r\mathcal{C}$, the same being true for the first term since S is integrable and consequently $\theta(\eta_i)\,\mathcal{C}\subset\mathcal{C}$. Let

$$(U;x^1,\ldots,x^p,y^1,\ldots,y^q)$$

be a foliated chart for the distribution Σ in which the integral manifolds are given by the slices $y^\lambda=c^\lambda$. Then a typical element of $\Phi^{r,s}$ is locally a sum of terms,

$$\mu=a\,dy^{j_1}\wedge\cdots\wedge dy^{j_r}\otimes dx^{i_1}\wedge\cdots\wedge dx^{i_s}$$

and

$$d_H\mu=\sum_i\frac{\partial a}{\partial x^i}dy^{j_1}\wedge\cdots\wedge dy^{j_r}\otimes dx^i\wedge dx^{i_1}\wedge\cdots\wedge dx^{i_s},\qquad(4)$$

where dx^i stands for the restriction $dx^i|\Sigma$. The last formula as well as the formula (2), though helpful in theoretical considerations, is most often useless in practice since it requires the local integration of Σ. We can nevertheless remedy this situation as follows: We consider any coordinate system $(U;x^i,y^j)$ with the sole requirement that the family $\{dx^i|\Sigma\}$ be free at every point

of U, thus providing a field of coframes for $\Sigma^*|U$. Next, we consider the local basis $\{\eta_i\}$ of Σ defined by $\langle \eta_i, dx^j \rangle = \delta_i^j$. Since Σ is integrable and since each η_i projects onto $\partial/\partial x^i$, it follows that $[\eta_i, \eta_j] = 0$. A typical element of $\Phi^{r,s}$ can now be written locally as a sum of terms,

$$\mu = a\, \omega^{j_1} \wedge \cdots \wedge \omega^{j_r} \otimes dx^{i_1} \wedge \cdots \wedge dx^{i_s},$$

where dx^i stands for $dx^i|\Sigma$ and $\{\omega^\lambda = dy^\lambda - \Sigma_i Y_i^\lambda\, dx^i\}$ is a local basis of S. The formula (3) then reduces to

$$d_H \mu = \sum_i [\theta(\eta_i)(a\, \omega^{j_1} \wedge \cdots \wedge \omega^{j_r})] \otimes dx^i \wedge dx^{i_1} \wedge \cdots \wedge dx^{i_s}, \tag{5}$$

and a similar formula can replace (2), the derivatives $\partial a \ldots / \partial x^i$ being then replaced by $\theta(\eta_i)(a \ldots)$.

Let $\mathcal{I}^r = \mathcal{I}^r(S)$ denote the module of all the (globally defined) invariant forms ω of degree r with respect to the Pfaffian system S, namely those satisfying the following condition (Ref. 7, Sec. 4):

$$\theta(\eta)\omega = 0, \quad \forall\ \eta \in \Gamma(S^\perp).$$

Then, $\mathcal{I}^0 = \mathcal{I}$ is the ring of all the (global) first integrals of S, $\mathcal{I}^r$ is a graded $\mathcal{I}$-sub-algebra of A and the formula (3) shows that the sequence

$$0 \to \mathcal{I}^r \to \Phi^{r,0} \xrightarrow{d_H} \Phi^{r,1} \tag{6}$$

is exact. We next show that the sequence

$$0 \to \mathcal{I} \to \Phi^{0,0} \xrightarrow{d_H} \Phi^{0,1} \xrightarrow{d_H} \cdots \xrightarrow{d_H} \Phi^{0,p} \to 0 \tag{7}$$

is locally exact. In fact, let $(U; x^i, y^\lambda)$ be a foliated chart for Σ. Then the formula (2) defines, for each fixed set of values $y^\lambda = c^\lambda$, the differential of the *de Rham* complex on the corresponding slice, whereupon results the local exactness of (7) since the usual homotopy operators can be written incorporating the parameters y^λ. Let us finally show that

$$\Phi^{r,p-1} \xrightarrow{d_H} \Phi^{r,p} \to 0 \tag{8}$$

is locally exact. A typical element of $\Phi^{r,p}$ is, locally, a sum,

$$\omega = \sum a_{j_1, \ldots, j_r}\, dy^{j_1} \wedge \cdots \wedge dy^{j_r} \otimes dx^1 \wedge \cdots \wedge dx^p,$$

hence, upon integrating for example along x^1, we obtain the element

$$\Omega = \sum A_{j_1, \ldots, j_r}\, dy^{j_1} \wedge \cdots \wedge dy^{j_r} \otimes dx^2 \wedge \cdots \wedge dx^p, \quad \frac{\partial A_{[j]}}{\partial x^1} = a_{[j]},$$

such that $d_H \Omega = \omega$.

IV. THE VERTICAL OPERATOR

Let us next construct the so called *vertical* part of the Euler–Lagrange complex, namely that part subsequent to the Euler operator. We denote by $\mathcal{A}$ the algebra of all the infinitesimal automorphisms of S and by $\mathcal{B}$ the ideal of those vector fields that are tangent to $\Sigma = S^\perp$. The system

S being integrable, any vector field tangent to Σ is an infinitesimal automorphism. Based on the lemma 1, it can be shown that the algebra $\mathcal{S}(\mathcal{R})$ of generalized symmetries of the equation $\mathcal{R}$ associated to S ($\mathcal{S}(D)$ in the notations of Ref. 6, Sec. 9) identifies with $\mathcal{A}/\mathcal{B}$. The following remarks will be used later.

(a) $\mathcal{A}$ is a module over the ring $\mathcal{I}$, $\mathcal{B}$ is a module over $\mathcal{F}$, hence $\mathcal{S}$ is a module over $\mathcal{I}$.

(b) If $\xi\in\mathcal{A}$ is tangent to a leaf of S at a point x_0, then it is also tangent to this leaf at all of its points.

We now define $\Xi^r=\Phi^{r,p}/d_H\Phi^{r,p-1}$ ($p=\dim\Sigma$), denote by $\mathbf{q}_r:\Phi^{r,p}\to\Xi^r$ the quotient map and observe that Ξ^r is an $\mathcal{I}$-module since $d_H\mathcal{I}=0$. An element $\omega\otimes\mu\in(\wedge^r\mathcal{C})\otimes(\wedge^s\mathcal{H})$ can also be considered as an $\mathcal{I}$-multilinear form on $\mathcal{S}(\mathcal{R})$ with values in $\wedge^s\mathcal{H}$ by setting

$$(\omega\otimes\mu)([\xi_1],\ldots,[\xi_r])=\omega(\xi_1,\ldots,\xi_r)\mu,\quad \xi_i\in\mathcal{A},$$

where each $[\xi_i]$ is the class of ξ_i *modulo* $\mathcal{B}$. In fact, when $\eta\in\mathcal{B}$, then $(\omega\otimes\mu)(\ldots,\eta,\ldots)=0$ and consequently $(\omega\otimes\mu)([\xi_1],\ldots,[\xi_r])$ is well defined on $\mathcal{S}(\mathcal{R})$. Furthermore (Ref. 6, Sec. 11), since

$$[d_H(\omega\otimes\mu)](\xi_1,\ldots,\xi_r)=d_H[(\omega\otimes\mu)(\xi_1,\ldots,\xi_r)],$$

the form $d_H(\omega\otimes\mu)$, $\omega\otimes\mu\in(\wedge^r\mathcal{C})\otimes(\wedge^{p-1}\mathcal{H})$, considered as a multilinear form on $\mathcal{S}(\mathcal{R})$, takes values that vanish under the projection $\mathbf{q}_0:\Phi^{0,p}\to\Xi^0$. Hence, to any element $\sigma\in\Xi^r$, we can associate an $\mathcal{I}$-multilinear form $[\sigma]$, defined on $\mathcal{S}(\mathcal{R})$ and taking values in Ξ^0, as follows: We take $\Omega=\Sigma\,\omega_i\otimes\mu_i\in\Phi^{r,p}$ such that $\mathbf{q}_r(\Omega)=\sigma$ and set

$$[\sigma]([\xi_1],\ldots,[\xi_r])=\mathbf{q}_0\,\Omega([\xi_1],\ldots,[\xi_r]).$$

The mapping $\sigma\mapsto[\sigma]$ being injective (Ref. 6, Sec. 11), we are led to consider the formula

$$\begin{aligned}
&d_V(\mathbf{q}_r(\omega\otimes\mu))([\xi_1],\ldots,[\xi_{r+1}])\\
&\quad=\mathbf{q}_0\left\{\sum_i(-1)^{i+1}\theta([\xi_i])[\,\omega([\xi_1],\ldots,\widehat{[\xi_i]},\ldots,[\xi_{r+1}])\mu]\right\}\\
&\qquad+\mathbf{q}_0\left\{\sum_{i<j}(-1)^{i+j}\omega([[\xi_i],[\xi_j]],[\xi_1],\ldots,\widehat{[\xi_i]},\ldots,\widehat{[\xi_j]},\ldots,[\xi_{r+1}])\mu\right\},\qquad(9)
\end{aligned}$$

where $\omega\otimes\mu\in\Phi^{r,p}$ and $\xi_i\in\mathcal{A}$. The second term on the right hand side clearly belongs to Ξ^0. As for the first term, let us write

$$\mu_i=\omega([\xi_1],\ldots,\widehat{[\xi_i]},\ldots,[\xi_{r+1}])\mu\in\Phi^{0,p},$$

and let us assume that some $\xi_j=\eta\in\mathcal{B}$. If $j\neq i$, then $\mu_i=0$ and if $j=i$ then, since $d_H\mu_i=0$,

$$\theta(\eta)\mu_i=i(\eta)d_H\mu_i+d_Hi(\eta)\mu_i=d_Hi(\eta)\mu_i$$

and consequently $\mathbf{q}_0\,\theta(\eta)\mu_i=0$. In any case, (9) provides a well defined multilinear form on $\mathcal{S}(\mathcal{R})$ taking values in Ξ^0 and it can be shown (e.g., in coordinates) that the multilinear form $d_V(\mathbf{q}_r(\omega\otimes\mu))$ is the image of an element $\sigma\in\Xi^{r+1}$.

The Euler–Lagrange (variational) complex associated to the integrable Pfaffian system S is the finite sequence,

$$0\to\mathcal{I}\to\Phi^{0,0}\xrightarrow{d_H}\Phi^{0,1}\xrightarrow{d_H}\cdots\xrightarrow{d_H}\Phi^{0,p-1}\xrightarrow{d_H}\Phi^{0,p}\xrightarrow{E}\Xi^1\xrightarrow{d_V}\cdots\xrightarrow{d_V}\Xi^{q-1}\xrightarrow{d_V}\Xi^q\to0,$$

where E, the *Euler* operator, is the composite,

$$\Phi^{0,p} \xrightarrow{\mathbf{q}_0} \Xi^0 \xrightarrow{d_V} \Xi^1,$$

and $q = \text{rank } S$. This complex is locally exact and reduces, locally, to (7) since Ξ^r vanishes on account of (8).

V. INVARIANT PFAFFIAN SYSTEMS

Let S be an integrable Pfaffian system invariant under the infinitesimal action $\Phi: g \to \chi(M)$ of the finite dimensional real Lie algebra g on the manifold M (Ref. 7, Sec. 3). For every $v \in g$, $\Phi(v) \in \mathcal{A}$, hence the action induces a Lie algebra morphism $\Phi: g \to \mathcal{S}(\mathcal{R})$. If further we assume that the action Φ is transversally free (Ref. 7, Sec. 4), i.e., if

$$(i) \quad \dim g = \dim \Phi(g)_p, \quad \forall\ p \in M,$$

$$(ii) \quad T_p M = \Sigma_p \oplus \Phi(g)_p, \quad \forall\ p \in M,$$

then the above morphism is injective and the following result holds.

Lemma 2: The algebra $\mathcal{S}(\mathcal{R})$ is generated by $\Phi(g)$ over the ring $\mathcal{I}$ of first integrals of S, any $\mathbf{R}$-basis of $\Phi(g)$ is an $\mathcal{I}$-basis of $\mathcal{S}(\mathcal{R})$ and the $\mathcal{I}$-dual $\mathcal{S}(\mathcal{R})^*$ identifies with $\mathcal{I}^1$.

Let us next recall some properties of the invariant forms associated to S. By definition (Ref. 7, Sec. 4), the exterior form ω is an invariant form of S if $\theta(\eta)\,\omega = 0$ for all $\eta \in \Gamma(S^\perp)$. It follows that $\theta(f\,\eta)\,\omega = 0$ for any function f, hence ω is an invariant if and only if $i(\eta)\omega = i(\eta)\,d\omega = 0$, for all $\eta \in \Gamma(S^\perp)$. Consequently, ω is invariant if and only if it can be expressed locally in terms of the first integrals of S and their differentials. When ω is invariant then so are the forms $f\,\omega$, $d\omega$ and $\theta(\xi)\,\omega$, where f is a first integral and ξ an infinitesimal automorphism of S, hence the set of all invariant forms is a differential algebra over the ring $\mathcal{I}$ invariant under the infinitesimal action Φ via the Lie derivative. Let $\{v_i\}$ be a basis of g. The linear forms $\omega^i \in \mathcal{C}$ defined by the conditions $\langle \Phi(v_i), \omega^j \rangle = \delta_i^j$ are a global basis of invariant forms of S, a so-called Cartan basis (Ref. 7, Secs. 6,8), and

$$d\omega^i = \sum_{j<k} c^i_{jk}\, \omega^j \wedge \omega^k,$$

where $\{-c^i_{jk}\}$ is the set of structure constants of g with respect to the above basis. The real subspace $\Omega \subset \Gamma(T^*M)$ generated by forms ω^i only depends on Φ and acts as an $\mathbf{R}$-dual to the space $h = \Phi(g)$. Let us denote by $\mathcal{F}$ be the ring of C^∞ functions on M and by $\wedge\,\Omega$ the exterior algebra of Ω over the field $\mathbf{R}$. Since $\{\omega^i\}$ is a global basis of the Pfaffian system S, it follows that $\mathcal{C} \simeq \Omega \otimes_{\mathbf{R}} \mathcal{F}$ and, more generally, that

$$\Phi^{r,s} = (\wedge^r \mathcal{C}) \otimes_{\mathcal{F}} (\wedge^s \mathcal{H}) \simeq (\wedge^r \Omega) \otimes_{\mathbf{R}} (\wedge^s \mathcal{H}) \simeq (\wedge^r \mathcal{S}(\mathcal{R})^*) \otimes_{\mathcal{I}} (\wedge^s \mathcal{H}). \tag{10}$$

Furthermore, since $d\omega(\xi_1, \xi_2) = -\omega([\,\xi_1, \xi_2\,])$, for any $\omega \in \Omega$ and $\xi_i \in \Phi(g)$, it also follows that the formula (9) reduces, whenever $\omega \in \wedge^r \Omega$ and $\xi_i \in \Phi(g) \subset \mathcal{S}(\mathcal{R})$, to the expression

$$[\, d\omega \otimes \mathbf{q}_0 \mu + (-1)^{\deg \omega}\, \omega \wedge d_V(\mathbf{q}_0 \mu)\,]\,(\xi_1, \ldots, \xi_{r+1}), \tag{11}$$

where $d_V(\mathbf{q}_0 \mu)(\xi)$ is the Lie derivative $\mathbf{q}_0(\theta(\xi)\mu)$. We shall see later that the above formula still holds for any invariant form ω since $d_H \omega = 0$ implies $d_V \omega = d\omega$.

We next consider the elements $\sigma \in \Xi^r$ as i $\mathcal{I}$-multilinear (and skew-symmetric) forms $[\sigma]$ defined on $\mathcal{S}(\mathcal{R})$ and taking values in Ξ^0 (cf. Sec. IV). Each form $[\sigma]$ restricts to an $\mathcal{R}$-multilinear form $\tau = [\sigma]_{\mathbf{R}}$ defined on the real subspace $h \in \mathcal{S}(\mathcal{R})$ and conversely, on account of Lemma 2, each $\mathcal{R}$-multilinear form τ defined on h and taking values in $\sigma \in \Xi^0$ extends, by $\mathcal{I}$-multilinearity, to a form $[\sigma]$ defined on $\mathcal{S}(\mathcal{R})$ and such that $[\sigma]_{\mathbf{R}} = \tau$. Furthermore, since in the realm of real vector spaces the subspace $d_H(\Phi^{0,p-1})$ admits a complement in $\Phi^{0,p}$, the form

τ lifts to a real form $\overline{\tau}$ defined on h and taking values in $\Phi^{0,p}=\wedge^p\mathcal{H}$. Finally, using $\mathcal{F}$-multilinearity on h, $\overline{\tau}$ extends to an $\mathcal{F}$-multilinear form $\tilde{\tau}$ defined on $\chi(M)$ with values in $\wedge^p\mathcal{H}$ by requiring that $i(\eta)\tilde{\tau}=0$, for all $\eta\in\Gamma(\Sigma)$. We thus obtain an element $\tilde{\tau}\in\Phi^{r,p}$ such that $[\tilde{\tau}]_{\mathbf{R}}=\tau$ and consequently the assignment $\sigma\mapsto[\sigma]$ of Sec. IV becomes bijective when S is invariant under a transversally free infinitesimal action. Identifying g with h and thereafter Ω with g^*, the expression (11) or equivalently the formula (9) shows that the cochain complex defining the cohomology of g with values in Ξ^0 and relative to the representation $\rho(v)(\mathbf{q}_0\mu)=\mathbf{q}_0(\theta(\xi)\mu)$, $v\in g$, $\mu\in\Phi^{0,p}$ and $\xi=\Phi(v)$, is equal to

$$\Xi^0\overset{d_V}{\to}\Xi^1\overset{d_V}{\to}\Xi^2\overset{d_V}{\to}\cdots. \tag{12}$$

Since $\mathbf{q}_0$ is surjective, we can rewrite the above complex by

$$\Phi^{0,p}\overset{E}{\to}\Xi^1\overset{d_V}{\to}\Xi^2\overset{d_V}{\to}\cdots, \tag{13}$$

without affecting the cohomology groups in positive dimensions, the latter being the vertical part of the Euler–Lagrange complex associated to S, namely the finite resolution of E.

Theorem 1: *Let S be an integrable Pfaffian system invariant under a transversally free infinitesimal action of the Lie algebra g. Then the finite resolution of the Euler operator E is equal, in positive dimensions, to the cochain complex of the Lie algebra g with values in Ξ^0.*

Since $E=d_V\circ\mathbf{q}_0$, we also infer that the space of cocycles in $\Phi^{0,p}$ (i.e., $\ker E$) is equal to the inverse image, by $\mathbf{q}_0$, of the 0-dimensional cohomology of g, namely the inverse image of the subspace of the g-invariant elements of Ξ^0 ($\rho(v)(\mathbf{q}_0\mu)=0$, $\forall\, v\in g$). Given an integrable Pfaffian system S, we can now confront its variational cohomology with the cohomology of g taking values in Ξ^0 and eventually detect obstructions to the existence of a transversally free infinitesimal action of g leaving S invariant. When $\dim_{\mathbf{R}}\Xi^0<\infty$ (which is very seldom the case), we usually have more information on the cohomology of g. For instance, if g is semi-simple then its cohomology vanishes in dimensions one and two (Whitehead's lemmas) and consequently the same must hold for the variational cohomology.

VI. EXAMPLES

Throughout this section, we replace integrable Pfaffian systems by the corresponding integral foliations. Though all the foliations are naive, the resulting homological calculations are not always so. For the sake of not being too omissive on these calculations, we outline a few in the last example.

A. Example 1: The torus

Let $\mathcal{F}$ be the the foliation on the 2-dimensional torus T whose leaves are the cosets of a 1-dimensional sub-group H. Then $\mathcal{F}$ is invariant under the infinitesimal action generated by any element of the Lie algebra of T ($\equiv\mathbf{R}^2$) this action being transversally free as soon as this element does not belong to the Lie algebra h of H. The variational cohomology at Ξ^1 is equal to $\mathbf{R}$ and, using Green's formula, one shows that the cohomology class of an element $[\omega]\in\Xi^1$ identifies with the real number $\int_T\omega$. When the slope of a generating element of h is rational, the calculations are very simple and both spaces Ξ^0 and Ξ^1 identify with the set of all global first integrals of $\mathcal{F}$. When this slope is irrational, the global first integrals of $\mathcal{F}$ reduce to the constants and it becomes more involved to describe the spaces Ξ^0 and Ξ^1 and to calculate the cohomology. This is an example where the advantage of the Lie algebra cohomology calculations becomes apparent.

B. Example 2: The Möbius strip

Let $\mathcal{F}$ be the foliation on the Möbius strip $\mathcal{M}$ whose leaves are the ''double'' circles, except for the central circle (under the usual identification $(1,y)\equiv(-1,-y)$, $\mathcal{F}$ is the foliation induced by the segments parallel to the x-axis). Both spaces Ξ^0 and Ξ^1 identify again with the set of all global first integrals of $\mathcal{F}$ which in turn identifies with the set of all the even functions defined on the interval $]-1,1[$. The variational cohomology at Ξ^1 vanishes and, whatever the representation $\rho: g=\mathbf{R}\to \mathrm{Der}\ \Xi^0$, the cohomology of g in dimension one is nontrivial (the derivative of an even function usually ceases to be even). This disagreement shows that $\mathcal{F}$ cannot be invariant by any transversally free infinitesimal action, a fact that is geometrically obvious since such an action would provide an orientation to $\mathcal{M}$.

C. Example 3: Foliation with a compact attractor

We consider, on the infinite cylinder $C=\mathbf{R}\times S^1$ with coordinates (t,θ), the foliation $\mathcal{F}$ obtained by integrating the vector field,

$$\eta = t\frac{\partial}{\partial t}+\frac{\partial}{\partial \theta}.$$

The nature of the spaces Ξ^0 and Ξ^1 is rather involved but a straightforward calculation shows that the cohomology at Ξ^1 is null. On the other hand, whatever the representation of the Lie algebra $g=\mathbf{R}$ into $\mathrm{Der}\ \Xi^0$, the Lie algebra cohomology in dimension one cannot vanish. Consequently, the foliation $\mathcal{F}$ does not admit any 1-dimensional transversally free infinitesimal action that leaves it invariant. This fact is also geometrically obvious since the local 1-parameter group (ϕ_u) generated by any such infinitesimal action would be defined, for small u, on a whole neighborhood of the limit circle $\{0\}\times S^1$ and would transform this circle into open compact subsets of the neighboring leaves, this being of course excluded.

An entirely similar situation arises in the double solid torus (two solid tori glued by their boundaries) upon taking the Reeb foliation inside each of the tori. The common boundary torus is the unique compact leaf.

D. Example 4: Spheres and rays

On the space $M=\mathbf{R}^{p+1}-0$, let $\mathcal{F}_1$ be the foliation whose leaves are the spheres centered at the origin and $\mathcal{F}_2$ the foliation whose leaves are the rays issued from the origin. We first consider the *sphere* foliation $\mathcal{F}_1$ and calculate Ξ^0, one possible argument being as follows: Each element $\mu\in\Phi^{0,q}$ identifies canonically with a differentiable 1-parameter family $(\overline{\mu}_\rho)$ of differentiable q-forms defined on the unit sphere S^p and, under this identification, $d_H\mu\in\Phi^{0,q+1}$ also identifies with $(d\overline{\mu}_\rho)$. We next take a differentiable 1-parameter family $(\overline{\mu}_t)$, $t>0$, of p-forms on S^p. Then, upon choosing a fixed volume form Ω on S^p (e.g., the volume form associated to the induced Euclidean metric), we can determine, by integration, a differentiable function $\varphi:\mathbf{R}_+\to\mathbf{R}$ such that $\overline{\mu}_t-\varphi(t)\,\Omega$ is, for each t, a coboundary. Restating the Lemma 4.2 (p. 123) of Ref. 14 in its stronger version (as is proved in the subsequent two pages), we can use it to establish a stronger 1-parameter version of the Lemma 4.2 (p. 126) and prove in the aforementioned context that there exists a differentiable 1-parameter family $(\overline{\eta}_t)$ of $(p-1)$-forms defined on S^p such that $\overline{\mu}_t-\varphi(t)\,\Omega=d\overline{\eta}_t$. Returning to $\Phi^{0,p}$ and taking the form $\tilde{\Omega}=r^*\Omega$, $r:X\mapsto(1/\|X\|)\,X$, defined on M, we conclude that each $\mu\in\Phi^{0,p}$ determines a differentiable function φ such that $\mu-\varphi\,\tilde{\Omega}=d_H\eta$, where $\eta\in\Phi^{0,p-1}$, and consequently that Ξ^0 is equal to the set of all the real-valued differentiable functions defined on $\mathbf{R}_+$ i.e., to the set of all the global first integrals of $\mathcal{F}_1$.

Let us now calculate Ξ^1. Observing that $d\rho$ is a global generator of the Pfaffian system that annihilates $\mathcal{F}_1$, any element $\eta_1\in\Phi^{1,q}$ writes $\eta_1=\eta\wedge d\rho$, with $\eta\in\Phi^{0,q}$, and $d_H\eta_1=(d_H\eta)\wedge d\rho$ since $d_H(d\rho)=0$. Consequently, the element $\mu_1=\mu\wedge d\rho\in\Phi^{1,p}$ is equal to

$d_H\eta_1$, with $\eta_1 \in \Phi^{1,p-1}$, if and only if $\mu = d_H\eta$ hence the present calculation reduces to the previous one and Ξ^1 is again equal to the set of all the global first integrals of $\mathcal{F}_1$.

It now becomes easy to show that the variational cohomology at Ξ^1 is null. The foliation $\mathcal{F}_1$ is of course invariant under many 1-dimensional transversally free infinitesimal actions and the vanishing of the Lie algebra cohomology in dimension one is easily be checked.

We next take the *radial* foliation $\mathcal{F}_2$. Here we can proceed locally, on open sets saturated by rays, and integration along these rays will show that $\Xi^q = 0$, $0 \leqslant q \leqslant p$. The variational as well as the Lie algebra cohomologies vanish, their comparison not revealing the following geometrical facts.

(a) When p is even, there cannot exist a transversally free infinitesimal action leaving the radial foliation $\mathcal{F}_2$ invariant. In fact, since the tangent spaces to $\mathcal{F}_1$ and $\mathcal{F}_2$ are complementary, any such infinitesimal action would project onto the spheres producing an infinitesimal action operating tangentially to the spheres and, in restriction to these spheres, would be free. However, even dimensional spheres do not admit nowhere vanishing vector fields.

(b) When p is odd, such transversally free infinitesimal actions do exist only for $p = 1, 3$. Their nonexistence for $p = 7$ is essentially a consequence of the fact that S^7 is not a Lie group manifold and, for all the other values of p, that the corresponding spheres are not parallelizable.

We can enhance the variational cohomology by adding nontrivial cocycles to the space M. For example, let us take for the manifold M the portion of $\mathbf{R}^{p+1} - 0$ in between the spheres $S^p(1)$ and $S^p(2)$ and identify these two spheres by the radial map. Then $\mathcal{F}_1$ induces a foliation $\overline{\mathcal{F}_1}$ in spheres, $\mathcal{F}_2$ a foliation $\overline{\mathcal{F}_2}$ in circles (in fact, $M \simeq S^p \times S^1$) and one shows, for the foliation $\overline{\mathcal{F}_2}$, that Ξ^0 is equal to the set of all the differentiable functions defined on the sphere $S^p(1)$ or, equivalently, to the set of all the global first integrals of $\overline{\mathcal{F}_2}$. Furthermore, Ξ^r is equal to the product of $\binom{p}{r}$ copies of Ξ^0 and $\Xi^p = \Xi^0$. As for the variational cohomology, we can again apply the 1-parameter version of the Lemmas 4.2 and conclude that it vanishes at Ξ^{r+1} whenever $r+1 < p$ and that it is equal to $\mathbf{R}$ at Ξ^p. Stokes' formula will then show that the cohomology class of an element $[\omega] \in \Xi^p$ identifies with the real number $\int_M \omega$.

Returning to the geometric facts described earlier, we can retrace (a) by looking at the variational cohomology. In fact, since any vector field on an even dimensional sphere has a singularity, whatever the representation ρ of a Lie algebra g into $Der\,\Xi^0 \simeq \chi(S^p)$, the corresponding Lie algebra cohomology cannot vanish in dimension one. As for the property (b), it requires a deeper analysis that seems to be out of reach in the present context. Nevertheless, it can be shown that transversally free Abelian infinitesimal actions leaving $\overline{\mathcal{F}_2}$ invariant cannot exist since the corresponding Lie algebra cohomologies with values in Ξ^0 would vanish in dimension p thus contradicting the variational cohomology.

(Received 9 April 2003; accepted 16 June 2003)

The Dirac operator for a manifold Q, and its chirality operator when Q is even dimensional, have a central role in noncommutative geometry. We systematically develop the theory of this operator when $Q=G/H$, where G and H are compact connected Lie groups and G is simple. An elementary discussion of the differential geometric and bundle theoretic aspects of G/H, including its projective modules and complex, Kähler and Riemannian structures, is presented for this purpose. An attractive feature of our approach is that it transparently shows obstructions to spin- and spin$_c$-structures. When a manifold is spin$_c$ and not spin, U(1) gauge fields have to be introduced in a particular way to define spinors, as shown by Avis, Isham, Cahen, and Gutt. Likewise, for manifolds like SU(3)/SO(3), which are not even spin$_c$, we show that SU(2) and higher rank gauge fields have to be introduced to define spinors. This result has potential consequences for string theories if such manifolds occur as D-branes. The spectra and eigenstates of the Dirac operator on spheres $S^n=\mathrm{SO}(n+1)/\mathrm{SO}(n)$, invariant under $\mathrm{SO}(n+1)$, are explicitly found. Aspects of our work overlap with the earlier research of Cahen *et al.* © *2003 American Institute of Physics.* [DOI: 10.1063/1.1607514]

I. INTRODUCTION

When a group G acts transitively on a manifold Q with stability group H at a point p, we can identify Q with the coset space G/H. Such spaces are important in the description of Goldstone modes created by the spontaneous breakdown of G to H. Models of spacetime such as the Minkowski spacetime $M^{3,1}$ or its compact Euclidean version S^4 are also of this sort. The group G in these cases is the Poincarè group and SO(5), respectively, while H is the Lorentz group and SO(4), respectively. In addition, coset spaces like $\mathbb{C}P^N$ and S^N have begun to proliferate as D-branes in string and boundary conformal field theories.

The Dirac operator for a manifold Q, and its chirality operator when Q is even-dimensional, have a central role in noncommutative geometry. That is a good motivation for their study. In this work we focus on this enterprise when Q is a coset space. In addition, in a subsequent paper, we shall develop fuzzy versions of certain coset spaces and their Dirac and chirality operators, primarily as a device to regularize quantum field theories thereon, and what we do here is also a preparation for it.

We assume throughout that G is a simple compact connected Lie group and H is a compact connected group. Without loss of generality we assume also that G is simply connected. These

a)Electronic mail: bal@physics.syr.edu

restrictions on G and H can be relaxed somewhat, G can be semi–simple for instance, and certain noncompact Lie groups G too seem approachable by our methods.

Not all G/H admit a spin-, or even a spin$_c$-structure.[3] One attractive aspect of our approach is that obstructions to spin- and spin$_c$-structure show up transparently and we can also easily see when and how we can overcome them using suitable generalized spin-structures, spin$_K$. The latter in general involve groups K of any dimension, whereas spin$_c$ ($=$spin$_{U(1)}$ in our notation) uses U(1) of dimension 1. The role of K is roughly that of a gauge group, so insisting on the existence of spinors introduces nontrivial gauge symmetry and internal degrees of freedom. In addition, typically, spin$_K$-theories are chiral, left- and right-chiral spinors transforming differently under K. This suggests that there may be a clever way to use fuzzy spaces to get the chiral fermions of the standard model.

There is a simple global appoach to differential geometry on G/H. We introduce this formalism after setting up the preliminaries in Sec. II. We follow this up in Sec. III, introducing spin- and spin$_K$-structures. Their Dirac and chirality operators are formulated in Sec. IV. We call this version of the Dirac operator ''Kähler–Dirac operator,'' as it is similar to the operator with the same name on a complex manifold. There is another equivalent version using projective modules equally useful for fuzzy physics, which we have decided to call the projective Dirac operator. The ''Dirac'' operator then refers to either of these two versions. Section V takes this up and also establishes its equivalence to the Kähler–Dirac operator. Along the way, the differential geometry of Sec. II is also translated to the language of projective modules. The cut-off versions of these expressions have an important role in fuzzy physics. In Sec. V we also explicitly consider the spheres S^n and $\mathbb{C}P^n$. In particular, for spheres, we compute the curvature and Dirac spectrum for the maximally symmetric metric. In Sec. VI we extend the preceding considerations to gravity on G/H.[4] Finally in Sec. VII we discuss the complex and Kähler structures of coset manifolds.

II. DIFFERENTIAL GEOMETRY ON G/H

A. Preliminaries

G is a simple, simply connected, connected, compact Lie group with Lie algebra $\underline{G}$. $\underline{H}$ is a subalgebra of $\underline{G}$ which by exponentiation generates a compact connected Lie group H.

We think of G concretely as $N\times N$ unitary matrices. The Lie algebra $\underline{H}$ then has a basis $\{T(\alpha)\}$ of Hermitian matrices (we follow physics conventions, more correctly $\{iT(\alpha)\}$ span $\underline{H}$), which are trace orthogonal:

$$\mathrm{Tr}T(\alpha)T(\beta)=c\,\delta_{\alpha\beta},\quad c=\mathrm{const}>0. \tag{2.1}$$

Using trace to define scalar product, $\underline{G}$ can be decomposed as the orthogonal direct sum,

$$\underline{G}=\underline{H}\oplus^{\perp}\underline{G/H}. \tag{2.2}$$

Let $\{S(i)\}$ be a basis for $\underline{G/H}$ with

$$\mathrm{Tr}S(i)S(j)=c\,\delta_{ij}. \tag{2.3}$$

We also of course have

$$\mathrm{Tr}S(i)T(\alpha)=0. \tag{2.4}$$

We denote the elements of the basis $\{T(\alpha),S(i)\}$ collectively as Σ_A, $A\in\{\alpha,i\}$.

Let Ad denote the adjoint representation of G. Then $H\subset G$ leaves $\underline{G/H}$ invariant in this representation:

$$h\,S(i)\,h^{-1}=S(j)(\mathrm{Ad}\ \ h)_{ji},\quad h\in H. \tag{2.5}$$

We refer to this representation of H on G/H as $\mathrm{Ad}_{G/H}$, and the corresponding representation of $\underline{H}$ as $\mathrm{ad}_{G/H}$. $\mathrm{Ad}_{G/H}(h)$ are real matrices as the Hermitian conjugation of (2.5) shows. They are also orthogonal as conjugation leaves the relation (2.3) invariant. Thus, if $|G|$, $|H|$ and $|G/H|=|G|-|H|$ denote the dimensions of G, H and G/H, $\{\mathrm{Ad}_{G/H}(h)\}$ is a subgroup of $SO(|G/H|)$:

$$\{\mathrm{Ad}_{G/H}(h)\}\subseteq SO(|G/H|). \tag{2.6}$$

The above discussion implies the following commutation relations:

$$[T(\alpha),T(\beta)]=ic_{\alpha\beta\gamma}T(\gamma),$$

$$[T(\alpha),S(i)]=ic_{\alpha ij}S(j), \tag{2.7}$$

$$[S(i),S(j)]=ic_{ij\alpha}T(\alpha)+ic_{ijk}S(k). \tag{2.8}$$

The structure constants c_{ABC} are real and totally antisymmetric.

We will call c_{ijk} the torsion of the space G/H. Below we will see that it plays exactly the role of the usual torsion for the canonical covariant derivative on G/H.[5] If $c_{ijk}=0$, the homogeneous space G/H is said to be "symmetric."[6] In that case, $\underline{G}$ admits the involutive automorphism:

$$\sigma \;:\; T(\alpha)\to T(\alpha),\quad S(i)\to -S(i), \tag{2.9}$$

leaving $\underline{H}$ fixed. σ lifts to an involutive automorphism Σ of G leaving H fixed, Σ being defined from

$$\Sigma \;:\; e^{i\theta_\alpha T(\alpha)}\to e^{i\theta_\alpha T(\alpha)},\quad e^{i\theta_i S(i)}\to e^{-i\theta_i S(i)}. \tag{2.10}$$

B. Tensor fields on G/H

Let W be a fixed vector space with an orthonormal basis $\{e_i\}$ which carries the representation $\mathrm{Ad}_{G/H}$ of H, $h\;:e_i\to e_j\,\mathrm{Ad}_{G/H}(h)_{ji}$. The vector space $W^{\otimes n}=W\otimes W\otimes\cdots\otimes W$ (n factors) carries the tensor product representation $\mathrm{Ad}_{G/H}^{\otimes n}=\mathrm{Ad}_{G/H}\otimes\mathrm{Ad}_{G/H}\otimes\cdots\otimes\mathrm{Ad}_{G/H}$ (n factors). Let $\mathbb{C}\equiv W^{\otimes 0}$ also denote the one–dimensional complex vector space carrying the trivial representation $\mathrm{Ad}_{G/H}^{\otimes 0}\colon h\to 1$.

Tensor fields of rank n on G/H can be defined to be equivariant functions on G with values in $W^{\otimes n}$. That means the following: for $n=0$ we have scalar fields $f^{(0)}$, complex (or $W^{\otimes 0}$) valued functions on G invariant under the right–action of H on G (equivariance):

$$f^{(0)}=\text{scalar fields:}\quad f^{(0)}(gh)=f^{(0)}(g),\;\;\forall\;\; h\in H. \tag{2.11}$$

A tensor field $f^{(1)}$ of rank 1 has values in W; we can write it as

$$f^{(1)}=f_i^{(1)}e_i,\quad f_i^{(1)}\;:\quad g\to f_i^{(1)}(g)\in\mathbb{C}. \tag{2.12}$$

Equivariance for $n=1$ means the following transformation property under the right action of H on G:

$$f_i^{(1)}(gh)e_i=f_i^{(1)}(g)\mathrm{Ad}_{G/H}(h)_{ij}e_j. \tag{2.13}$$

Therefore

$$f_i^{(1)}(gh)=f_j^{(1)}(g)\mathrm{Ad}_{G/H}(h)_{ji}. \tag{2.14}$$

Let J label the inequivalent irreducible representations of G by unitary matrices $\{D^J(g)\}$; their matrix elements in a convenient orthonormal basis are $D^J_{mn}(g)$. We have that

$$D^J_{mn}(gh)=D^J_{mn'}(g)D^J_{n'n}(h). \tag{2.15}$$

If the representation $h\to D^J(h)$ contains the identity representation of H, we can choose the basis in the representation space so that the index n in (2.15) transforms trivially when $n\in$ an appropriate index set I_0:

$$D^J_{mi_0}(gh)=D^J_{mi_0}(g),\ \forall\ i_0\in I_0. \tag{2.16}$$

From this, (2.11) and Peter–Weyl theorem it follows that we can expand $f^{(0)}$ in the form

$$f^{(0)}(g)=\sum\ \xi^J_{mi_0}D^J_{mi_0}(g),\quad \xi^J_{mi_0}\in\mathbb{C}. \tag{2.17}$$

$\xi^J_{mi_0}$ is zero if $h\to D^J(h)$ fails to contain the trivial representation of H.

Henceforth we assume for notational simplicity that the identity representation occurs only once in the restriction of the irreducible representations J of G to H, and so drop the index i_0 from $\xi^J_{mi_0}$. Otherwise a degeneracy index has to be included here and elsewhere.

In the same way, if the representation $h\to D^J(h)$ contains $\mathrm{Ad}_{G/H}$, we can choose the basis in the representation space so that the index n in (2.15) transforms by $\mathrm{Ad}_{G/H}$ if i,j belong to an appropriate index set I:

$$D^J_{mi}(gh)=D^J_{mj}(g)[\mathrm{Ad}_{G/H}(h)]_{ji},\quad i,j\in I. \tag{2.18}$$

(For notational simplicity we are assuming that $\mathrm{Ad}_{G/H}$ occurs only once in the representation J, otherwise a degeneracy index has to be added here and elsewhere.) Then we can expand $f^{(1)}_i$ in the form

$$f^{(1)}_i(g)=\sum\ \xi^J_m D^J_{mi}(g),\quad \xi^J_m\in\mathbb{C}. \tag{2.19}$$

ξ^J_m now is zero if $h\to D^J(h)$ fails to contain $\mathrm{Ad}_{G/H}$.

Continuing in this vein we see that tensor fields of rank n in component form look like $f^{(n)}_{i_1\cdots i_n}$ and have the expansion

$$f^{(n)}_{i_1\cdots i_n}(g)=\sum\ \xi^J_m D^J_{m,\{i_1\cdots i_n\}}(g),\quad i_k\in I, \tag{2.20}$$

$$D^J_{m,\{i_1\cdots i_n\}}(gh)=D^J_{m,\{j_1\cdots j_n\}}(g)[\mathrm{Ad}_{G/H}(h)]_{j_1i_1}\cdots[\mathrm{Ad}_{G/H}(h)]_{j_ni_n}. \tag{2.21}$$

We have used a convenient multi-index notation for the second index of D^J. The rest should be clear. Tensor fields of diverse permutation symmetries are readily constructed along similar lines.

C. Covariant derivative

Let $\mathcal{T}^{(n)}$ denote the space of tensor fields of rank n, with a typical member $f^{(n)}=\{f^{(n)}_{i_1\cdots i_n}\}$. $\mathcal{T}^{(0)}$ consists of functions, and it is also an algebra under pointwise multiplication. All $\mathcal{T}^{(n)}$ are $\mathcal{T}^{(0)}$-modules. The covariant derivative ∇ is a map,

$$\nabla\ :\quad \mathcal{T}^{(n)}\to\mathcal{T}^{(n+1)},\quad f^{(n)}\to\nabla f^{(n)}, \tag{2.22}$$

where $\nabla f^{(n)}$ has components $(\nabla f^{(n)})_{ii_1\cdots i_n}$. It has in addition to fulfill the following important derivation property. Note that we can take tensor products of $\mathcal{T}^{(n)}$-s (over $\mathcal{T}^{(0)}$, $\mathcal{T}^{(n)}$ being $\mathcal{T}^{(0)}$ modules):

$$\mathcal{T}^{(n)}\otimes\mathcal{T}^{(m)}=\mathcal{T}^{(n+m)},\quad f^{(n)}\otimes f^{(m)}=f^{(n+m)},\tag{2.23}$$

where

$$f^{(n+m)}_{i_1\cdots i_n j_1\cdots j_m}=f^{(n)}_{i_1\cdots i_n}f^{(m)}_{j_1\cdots j_m}.\tag{2.24}$$

Then we require that

$$\nabla(f^{(n)}\otimes f^{(m)})=\nabla f^{(n)}\otimes f^{(m)}+f^{(n)}\otimes\nabla f^{(m)}.\tag{2.25}$$

There is a natural choice for the covariant derivative in our case. We call it hereafter as X. The action of X on functions is

$$[Xf^{(0)}]_i(g)=\frac{d}{dt}\ f^{(0)}(ge^{itS(i)})\Big|_{t=0}.\tag{2.26}$$

$\nabla f^{(0)}$ transforms correctly in view of (2.5). In the same way the action on $f^{(n)}$ is

$$[Xf^{(n)}]_{ii_1\cdots i_n}(g)=\frac{d}{dt}\ f^{(n)}_{i_1\cdots i_n}(ge^{itS(i)})\Big|_{t=0}.\tag{2.27}$$

The right-hand side defines a vector field X_i. Using X_i the covariant derivative in components is $f^{(n)}_{i_1\cdots i_n}\to X_i f^{(n)}_{i_1\cdots i_n}=$rhs of (2.27).

The torsion of the covariant derivative vanishes only if $[X_i,X_j]f^{(0)}=0$. From the definition and (2.7), we have

$$[X_i,X_j]f^{(0)}=-c_{ijk}X_k f^{(0)}\ .\tag{2.28}$$

So there is torsion if $c_{ijk}\neq 0$. But there is an easy way to construct the torsion–free covariant derivative $\overline{X_i}$. Set

$$\begin{aligned}
&\overline{X_i}f^{(0)}=X_i f^{(0)},\\
&\overline{X_i}f^{(1)}_j=X_i f^{(1)}_j+\tfrac{1}{2}c_{ijk}f^{(1)}_k,\\
&\vdots\\
&\overline{X_i}f^{(n)}_{j_1\cdots j_n}=X_i f^{(n)}_{j_1\cdots j_n}+\tfrac{1}{2}c_{ij_1j_1'}f^{(n)}_{j_1'j_2\cdots j_n}+\tfrac{1}{2}c_{ij_2j_2'}f^{(n)}_{j_1j_2'\cdots j_n}+\cdots+\tfrac{1}{2}c_{ij_nj_n'}f^{(n)}_{j_1\cdots j_n'}.
\end{aligned}\tag{2.29}$$

Then

$$[\overline{X_i},\overline{X_j}]f^{(0)}=[X_i,X_j]f^{(0)}+c_{ijk}X_k f^{(0)}=0,\tag{2.30}$$

just as we want.

Gauge fields will certainly have a central role in further developments. So we briefly indicate what they are here. Let us first consider U(1) gauge fields. The general gauge potential is $A_i=\Sigma\xi^J_M D^J_{Mi}$, $\xi^J_M\in\mathbb{C}$. It is subject to the reality condition $\overline{A_i}=-A_i$. Then if $f^{(n)}$ has charge e, its covariant derivative is $(\overline{X_i}+eA_i)f^{(n)}_{i_1\cdots i_n}$, where A_i acts by pointwise multiplication. This definition is compatible with equivariance. We can substitute X_i for $\overline{X_i}$ at the cost of possible torsion.

The gauge covariant derivative for a general gauge group as usual only involves regarding $eA_i(g)$, that is $e\xi^J_M$, to be Lie algebra valued, its action on $f^{(n)}$ in (2.27) is then dictated by the representation content of the latter.

III. SPIN- AND SPIN$_K$-STRUCTURES

Spinorial fields are essential for physics. We can go about constructing them as follows. The orthogonal group SO($|G/H|$) has a double cover Spin($|G/H|$). Associated with SO($|G/H|$), there is also a Clifford algebra $\mathbb{C}\ell(|G/H|)$ with generators $\gamma_1, \gamma_2, \ldots, \gamma_{|G/H|}$:

$$\gamma_i \gamma_j + \gamma_j \gamma_i = 2\delta_{ij}\mathbb{I}. \tag{3.1}$$

Here $\mathbb{I}$ denotes the unit matrix. (Its dimension should be clear from the context.) $\mathbb{C}\ell(|G/H|)$ has one or two inequivalent IRR's of dimension 2^n if $|G/H| = 2n$ or $|G/H| = 2n+1$. In the latter case, the two IRR's are related by a change of sign of all γ_i's. In either case, they generate a unique faithful representation of Spin($|G/H|$) with generators $\Sigma_{ij} = (1/4i)(\gamma_i\gamma_j - \gamma_j\gamma_i)$ which we call Spin$^{\mathbb{C}\ell}(|G/H|)$.

A recursive scheme for constructing anticommuting sets of Hermitian γ-matrices goes as follows. We start with a set of $2^{n-1}\times 2^{n-1}$ matrices γ_i, $i = 1, \ldots, 2n-1$, satisfying Eq. (3.1), and such that $(-i)^{n-1}\gamma_1 \cdots \gamma_{2n-1} = 1$, e.g., for $n=2$, the three Pauli matrices. Then a set of $2^n \times 2^n$ matrices Γ_λ, $\lambda = 1, \ldots, 2n+1$, satisfying Eq. (3.1), and such that $(-i)^n \Gamma_1 \cdots \Gamma_{2n+1} = \mathbb{I}$ is given by

$$\Gamma_i = \begin{pmatrix} 0 & \gamma_i \\ \gamma_i & 0 \end{pmatrix}, \quad i = 1, \ldots, 2n-1, \quad \Gamma_{2n} = \begin{pmatrix} 0 & -i\mathbb{I} \\ i\mathbb{I} & 0 \end{pmatrix}, \quad \Gamma_{2n+1} = \begin{pmatrix} \mathbb{I} & 0 \\ 0 & -\mathbb{I} \end{pmatrix}. \tag{3.2}$$

The matrices $\gamma_1, \ldots, \gamma_{2n-1}$ span $\mathbb{C}\ell(2n-1)$, and the matrices $\Gamma_1, \ldots, \Gamma_{2n}$ span $\mathbb{C}\ell(2n)$, whereas $\Gamma_1, \ldots, \Gamma_{2n+1}$ span $\mathbb{C}\ell(2n+1)$.

A. Spin manifolds

We say that G/H is a spin manifold if the commutative diagram exists, arrows being homomorphisms (which need not be onto):

$$\begin{array}{ccccc} G & \supset & H & \to & \mathrm{Spin}^{\mathbb{C}\ell}(|G/H|) \\ & & \downarrow & & \downarrow^{\mathbb{Z}_2} \\ & & \mathrm{Ad}_{G/H} & \subset & \mathrm{SO}(|G/H|) \end{array} . \tag{3.3}$$

The vertical homomorphisms are there by construction, so what is to be verified is the existence of the horizontal arrow. If it exists, a general spinor can be constructed as follows. We can reduce Spin$^{\mathbb{C}\ell}(|G/H|)$ restricted to H into a direct sum $\oplus\rho$ of unitary irreducible representations of H. Let $g \to D^J(g)$ be the unitary matrix of g in a representation of G which on restriction to H contains $\oplus\rho$. Then we can restrict its second index a to an index set I so that it transforms by $\oplus\rho$ under $g \to gh$:

$$D^J_{\alpha a}(gh) = D^J_{\alpha b}(g) D^J_{ba}(h), \quad a, b \in I\ . \tag{3.4}$$

By construction we know how the Clifford algebra acts on the index $a \in I$. A general spinor ψ then is a function on G with components

$$\psi_a = \sum \xi^J_M D^J_{Ma}. \tag{3.5}$$

Let us look at examples.

Example 1: $\mathbb{C}P^1 = \mathrm{SO}(3)/\mathrm{SO}(2) = [\mathrm{Spin}(3) = \mathrm{SU}(2)]/[\mathrm{Spin}(2) = \mathrm{U}(1)]$. So $G = \mathrm{SU}(2)$, $H = \mathrm{U}(1) = \{e^{i\sigma_3\theta/2}\}$, σ_A the Pauli matrices. Then $S(i) = \sigma_i$, $i = 1,2$, and

$$e^{i\sigma_3\theta/2}\sigma_i e^{-i\sigma_3\theta/2} = \sigma_j R_{ji}(\theta), \quad R(\theta) = \begin{pmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{pmatrix} \in \mathrm{SO}(2)\ . \tag{3.6}$$

$\mathrm{Spin}^{\mathbb{C}\ell}(|G/H|)$ is just $H=\{e^{i\sigma_3\theta/2}\}$, the homomorphism $\mathrm{Spin}^{\mathbb{C}\ell}(2)\to\mathrm{SO}(2)$ being $e^{i\sigma_3\theta/2}\to R(\theta)$. Thus (3.3) exists and $\mathrm{SU}(2)/\mathrm{U}(1)=S^2\simeq\mathbb{C}P^1$ is spin.

For a thorough treatment of noncommutative geometry and a Dirac operator on S^2, see Ref. 7.

Example 2: Similar arguments show that all the spheres $S^N=\mathrm{SO}(N+1)/\mathrm{SO}(N)=\mathrm{Spin}(N+1)/\mathrm{Spin}(N)$ are spin. G for S^N is $\mathrm{Spin}(N+1)$ while $H=\mathrm{Spin}(N)$. $\mathrm{Ad}_{G/H}$ is $\mathrm{SO}(N)$, the $\mathbb{Z}_2$-quotient of $\mathrm{Spin}(N)$. Since $\mathrm{Spin}^{\mathbb{C}\ell}(|G/H|)$ is isomorphic to $\mathrm{Spin}(N)$, S^N is spin.

Example 3: $\mathbb{C}P^2=\mathrm{SU}(3)/\mathrm{U}(2)$. So $G=\mathrm{SU}(3)$, $H=\mathrm{U}(2)$. A basis for the 3-dimensional SU(3)-Lie algebra consists of the Gell-Mann matrices λ_A. The U(2) Lie algebra has basis λ_1, λ_2, λ_3, λ_8, the hypercharge Y being $(1/\sqrt{3})\lambda_8$. The $S(i)$ are λ_4, λ_5, λ_6, λ_7. Under U(2), they transform as (K^+,K^0) or $(-\overline{K^0},K^-)$ in particle physics notation. That means that $\mathrm{Ad}_{G/H}=\mathrm{U}(2)$. Regarding U(2) as 2×2 unitary matrices U, we can embed U(2) in SO(4) by the map

$$U\to\frac{1}{2}\begin{pmatrix} U+U^* & i(U-U^*) \\ -i(U-U^*) & U+U^* \end{pmatrix}. \tag{3.7}$$

$\mathrm{Spin}^{\mathbb{C}\ell}(4)$ is the $(\frac{1}{2},0)\oplus(0,\frac{1}{2})$ representation of $\mathrm{SU}(2)\otimes\mathrm{SU}(2)$. It is the double cover of SO(4). Now H is U(2) and $\mathrm{Spin}^{\mathbb{C}\ell}(4)$ has no U(2) subgroup. So $\mathbb{C}P^2$ is not spin.[1]

Example 4: $G=\mathrm{SU}(3)$, $H=\mathrm{SO}(3)$. With G as 3×3 unitary matrices, H consists of all real orthogonal matrices and corresponds to the spin 1 representation of SO(3). G/H is of dimension 5. It carries the spin 2 representation of SO(3), isomorphic (but not equivalent!) to the spin 1 representation. There is no homorphism $\mathrm{SO}(3)\to\mathrm{Spin}^{\mathbb{C}\ell}(5)$ compatible with (3.3), so that SU(3)/SO(3) is not spin.[3]

Let us show this result in more detail. We can show it by establishing that the 2π-rotation in SO(3) becomes a noncontractible loop in SO(5) under the embedding in (3.9). Then the inverse image of SO(3) under the homomorphism $\mathrm{Spin}^{\mathbb{C}\ell}(5)\to\mathrm{SO}(5)$ is SU(2), giving us the result.

Now SO(3) acts on real symmetric traceless 3×3 matrices $T=(T_{ij})$ according to $T\to RTR^T$. This is its spin 2 representation. We can eliminate say T_{33} using $\mathrm{Tr}T=0$, thereby representing it as real transformations on $(T_{11},T_{12},T_{13},T_{22},T_{23})$. SO(5) consists of real transformations on this five-dimensional vector, so we now have the needed explicit embedding of SO(3) in SO(5). Let

$$R(\theta)\ :\ \begin{pmatrix} \cos\theta & \sin\theta & 0 \\ -\sin\theta & \cos\theta & 0 \\ 0 & 0 & 1 \end{pmatrix}. \tag{3.8}$$

It generates the 2π-rotation loop in SO(3) as θ increases from 0 to 2π. Consider $T'=R(\theta)TR(\theta)^T$. Then as θ increases from 0 to 2π we have a 2π-rotation in the $T_{13}-T_{23}$ plane. But by the time $\theta=\pi$, T_{ab} $(a,b\leqslant2)$ return to T_{ab} so that the rotations in their planes are by 4π or/and 0 [in fact, $\delta_{ab}(T_{11}+T_{22})$ undergoes no change and $T_{ab}-\frac{1}{2}\delta_{ab}(T_{11}+T_{22})$ undergoes 4π-rotation]. The corresponding loop of matrices in SO(5) is the product of an odd number of 2π-rotations and hence cannot be deformed to a point in SO(5). That concludes the proof.

We will now explain the Dirac operators for Spin- and Spin_K-manifolds after discussing Spin_K-structures.

B. Spin_K-manifolds

K and $\mathcal{H}$ are compact connected Lie groups in what follows. *We say that G/H is a Spin_K-manifold if the commutative diagram exists*:

$$\begin{array}{ccccccc} G & \supset & H & \rightarrow & \mathcal{H} & \supset & \mathrm{Spin}^{C\ell}(|G/H|) \\ & & \downarrow & & \downarrow^{K} & \swarrow \mathbb{Z}_2 & \\ & & \mathrm{Ad}_{G/H} & \subset & \mathrm{SO}(|G/H|) & & \end{array} \tag{3.9}$$

K and $\mathbb{Z}_2$ on the arrows are to show that they are the kernels of those homomorphisms.

$\mathrm{Spin}_{U(1)}$ in our language is what mathematicians call Spin_c.

The intersection $\mathrm{Spin}^{C\ell}(|G/H|)\cap K$ clearly contains $\mathbb{Z}_2$. It cannot be larger, for that would mean that the kernel for the slanting arrow exceeds $\mathbb{Z}_2$.

Thus $\mathcal{H}\supset[\mathrm{Spin}^{C\ell}(|G/H|)\times K]/\mathbb{Z}_2$. Its quotient by K being exactly $\mathrm{SO}(|G/H|)$, we conclude that

$$\mathcal{H}=[\mathrm{Spin}^{C\ell}(|G/H|)\times K]/\mathbb{Z}_2, \tag{3.10}$$

giving the following, also a commutative diagram:

$$\begin{array}{ccccccc} G & \supset & H & \rightarrow & \mathcal{H}=[\mathrm{Spin}^{C\ell}(|G/H|)\times K]/\mathbb{Z}_2 & \supset & \mathrm{Spin}^{C\ell}(|G/H|) \\ & & \downarrow & & \downarrow K & \swarrow \mathbb{Z}_2 & \\ & & \mathrm{Ad}_{G/H} & \subset & \mathrm{SO}(|G/H|) & & \end{array} \quad . \tag{3.11}$$

Let us denote the generators of $\mathbb{Z}_2$ in $\mathrm{Spin}^{C\ell}(|G/H|)$ and K by z_{Spin} and z_K, they square to the respective identities. The inclusion of $\mathrm{Spin}^{C\ell}(|G/H|)$ in (3.3) is to be understood as follows. The elements of $\mathcal{H}$ are the equivalence classes,

$$\langle hs,k\rangle=\langle z_{\mathrm{spin}}s,z_K k\rangle, \quad s\in\mathrm{Spin}^{C\ell}(|G/H|), \quad k\in K. \tag{3.12}$$

Then the top inclusion is via the isomorphism

$$s\rightarrow\langle s,e_K\rangle, \quad e_K=\text{ identity of } K. \tag{3.13}$$

As we think of $\mathcal{H}$ as the concrete matrix group obtained by tensoring $\mathrm{Spin}^{C\ell}(|G/H|)$ with a faithful unitary representation of K where z_K is represented by $-\mathbb{I}$,

$$\mathcal{H}=\mathrm{Spin}^{C\ell}(|G/H|)\otimes K, \tag{3.14}$$

we can write -1 for z_{spin} and z_K. The inclusion of $\mathrm{Spin}^{C\ell}(|G/H|)$ is then just $s\rightarrow s\otimes\mathbb{I}$.

Let us motivate the new requirements in (3.9) and (3.11). For a physicist, a spinor changes sign under "2π rotation." $\mathcal{H}$ is the group acting on Spin_K-spinors. We have required it to contain $\mathrm{Spin}^{C\ell}(|G/H|)$, so we can check this requirement by looking at the action of 2π-rotation $\in\mathrm{Spin}^{C\ell}(|G/H|)\subset\mathcal{H}$. As for asking that $H\rightarrow\mathcal{H}$, we can reduce the representation of $\mathcal{H}$ into a direct sum $\oplus\rho$ of irreducible representations ρ of H just as in the discussion of spin structures. The action of the Clifford algebra on $\oplus\rho$ by construction is known. The wave functions of Spin_K-spinors are then given by linear spans of representations of G induced by $\oplus\rho$; see (3.5). Later we shall see how the Dirac operator can be defined on these wave functions.

Example 5: $G=\mathrm{SU}(3)$, $H=\mathrm{U}(2)$, $G/H=\mathbb{C}P^2$. Here we choose $K=\mathrm{U}(1)$. Elements of U(2) can be written as the equivalence classes,

$$\langle s,u\rangle=\langle -s,-u\rangle, \quad s\in\mathrm{SU}(2), \quad u\in\mathrm{U}(1), \tag{3.15}$$

where we identify SU(2) with 2×2 unitary matrices of unit determinant and u with a phase. $\mathrm{Spin}^{C\ell}(4)$ is $\mathrm{SU}(2)\otimes\mathrm{SU}(2)$ and $\mathcal{H}$ consists of the equivalence classes

$$\langle s_1,s_2,u\rangle=\langle -s_1,-s_2,-u\rangle. \tag{3.16}$$

With elements of SO(4) represented as $\langle s_1,s_2\rangle=\langle -s_1,-s_2\rangle$, the homomorphism $\mathcal{H}\rightarrow\mathrm{SO}(4)$ is $\langle s_1,s_2,u\rangle\rightarrow(s_1,s_2)$. The homomorphism $H\rightarrow\mathcal{H}$ is also simple:

$$[s,u]\to\langle s,s,u\rangle. \tag{3.17}$$

Thus $\mathbb{C}P^2$ is $\mathrm{Spin}_{U(1)}$ or Spin_c.

Example 6: $G=\mathrm{SU}(3)$, $H=\mathrm{SO}(3)$.

We return to the choices $G=\mathrm{SU}(3)$, $H=\mathrm{SO}(3)$. Choosing $K=\mathrm{U}(1)$ is not helpful now, as we lack a suitable homomorphism $H=\mathrm{SO}(3)\to\mathcal{H}=\mathrm{Spin}^{\mathbb{C}\ell}(5)\otimes_{Z_2}\mathrm{U}(1)$. So SU(3)/SO(3) is not even $\mathrm{Spin}_{\mathrm{U}(1)}$, a result originally due to Landweber and Stong.[3] A better choice is $K=\mathrm{SU}(2)$. Then we can find the homomorphism $H\to\mathcal{H}$ as follows. The image of $\mathrm{Ad}_{G/H}$ in SO(5) is an SO(3) subgroup SO(3)′. Its inverse image in $\mathrm{Spin}^{\mathbb{C}\ell}(5)$ is an SU(2) subgroup SU(2)′. Let $\vec{\Sigma}$ and $\vec{T}$ be the angular momentum generators of SU(2)′ and K. If $\vec{L}$ are the angular momentum generators of H, the map at the level of Lie algebras is just $\vec{L}\to\vec{\Sigma}+\vec{T}$. Hence SU(3)/SO(3) is $\mathrm{Spin}_{\mathrm{SU}(2)}$. More such examples can be found.

C. What is $\overline{X}(i)$ now?

We need the extension of the torsion-free connection with components $\overline{X_i}$ to spinors on general spin_K-manifolds. The first step in this direction is the extension of X_i.

A spinor field $\psi=(\psi_a)$ on a Spin_K-manifold has the expansion

$$\psi_a=\sum\ \xi_M^L D_{Ma}^L, \tag{3.18}$$

where a carries the action of the Clifford algebra. The definition of X_i on ψ is immediate from (2.26):

$$(X_i\psi)(g)=\frac{d}{dt}\sum\ \xi_M^L D_{Ma}^L(ge^{itS(i)})|_{t=0}. \tag{3.19}$$

The definition of $\overline{X_i}$ involves the extension of c_{ijk} to spinors so that it can act on the index a. Now, the generators of the $\mathrm{SO}(|G/H|)$-Lie algebra are M_{ij}, where

$$(M_{ij})_{kl}=-i(\delta_{ik}\delta_{jl}-\delta_{il}\delta_{jk}). \tag{3.20}$$

Its image in the spinor representation is $(1/4i)[\gamma_i,\gamma_j]$.

Now

$$c_{ij'k'}(M_{j'k'})_{kj}f_k^{(1)}=-2ic_{ikj}f_k^{(1)}. \tag{3.21}$$

Hence

$$\overline{X_i}f_j^{(1)}=X_if_j^{(1)}+\frac{1}{4i}c_{ij'k'}(M_{j'k'})_{kj}f_k^{(1)}. \tag{3.22}$$

From this follows the definition of $\overline{X_i}$ on spinors:

$$\overline{X_i}\psi_a=X_i\psi_a-\tfrac{1}{16}c_{ijk}([\gamma_j,\gamma_k])_{ba}\psi_b. \tag{3.23}$$

A tensor formed of spinors will then transform correctly.

The introduction of gauge fields follows the earlier discussion.

IV. THE DIRAC AND CHIRALITY OPERATORS

The massless Dirac operator for the torsion free connection $\overline{X_i}$ is just

$$D_W = -i\gamma_i^{\mathcal{R}}\overline{X_i}, \tag{4.1}$$

where the superscript $\mathcal{R}$ indicates that the γ's act on spinors on the right. It is self-adjoint. This expression can be gauged, and $\overline{X_i}$ can be substituted by X_i if we can tolerate torsion.

If $|G/H|$ is even, e.g., if G/H is a [co]adjoint orbit, there is also a chirality operator γ anticommuting with D_W:

$$\gamma = (-i)^{1/2|G/H|}\gamma_1\cdots\gamma_{|G/H|} = \gamma^\dagger, \quad \gamma^2 = \mathbb{I}. \tag{4.2}$$

The subscript "W" is to indicate that it is the form of the Dirac operator used by the Watamuras.[8] For even $|G/H|$ there is also the unitarily equivalent Dirac operator,[9]

$$D = e^{i\gamma^{\mathcal{R}}\pi/4}D_W e^{-i\gamma^{\mathcal{R}}\pi/4} = i\gamma^{\mathcal{R}}D_W, \tag{4.3}$$

which is central to fuzzy physics.

V. PROJECTIVE MODULES AND THEIR DIRAC OPERATOR

A. Projective modules

In the algebraic approach to vector bundles, their sections are substituted by elements of projective modules ("of finite type").[10] A projective module is constructed as follows. Let A be an algebra. It can be the commutative algebra $\mathcal{A}$ of C^∞-functions on a manifold M if our interest is in the algebraic description of its vector bundles. But it can also be a noncommutative algebra, in which case there is no evident correspondence with sections of differential geometric vector bundles. Consider $A^N \equiv A \otimes_C \mathbb{C}^N$ with elements $a = (a_1, \ldots, a_N)$, $a_i \in A$. Let P be an $N \times N$ projector with coefficient in A:

$$P_{ij} \in A, \quad P^\dagger = P = P^2. \tag{5.1}$$

Then $A^N P$ (whose elements are vectors α with components $a_j P_{ji}$) is a projective module. The Serre-Swan theorem (Ref. 10) establishes that sections of any vector bundle can be obtained from some N and P.

It is very helpful for subsequent developments to have a projective module description of vector bundles. We can find the appropriate projectors by a known method described nicely by Landi.[11] It goes as follows.

Consider for example a rank 1 tensor field and any particular D^J matrix occurring in its expansion, with elements $D^J_{\rho i}$. We have

$$(D^J)^\dagger_{i\rho}(g)D^J_{\rho j}(g) = \delta_{ij}. \tag{5.2}$$

Let

$$P^J(g)_{\rho\sigma} = D^J_{\rho i}(g)(D^J)^\dagger_{i\sigma}(g). \tag{5.3}$$

Since $P^J(gh) = P^J(g)$ if $h \in H$, $P^J_{\rho\sigma}$ are functions on G/H. In view of (5.2), they are projectors too. If $P^J(g)$ are $|J| \times |J|$ matrices, a projective module describing rank 1 tensor fields is

$$\mathcal{A}^{|J|}P^J = \langle \alpha^J = (\alpha^J_1, \ldots, \alpha^J_{|J|}), \ \ \alpha^J_i = a^J_k P^J_{ki} \rangle. \tag{5.4}$$

There is no unique correspondence between projective modules and vector bundles. Thus for each J, we can find a projector and its module. But all such modules are equivalent, since there are elements $\alpha^J = a^J P^J$ and $\alpha^K = a^K P^K$ which naturally correspond for different J and K:

$$\alpha^J_\rho = \sum \xi^L_M D^L_{Mi} (D^J)^\dagger_{i\rho}, \quad \alpha^K_\sigma = \sum \xi^L_M D^L_{Mi} (D^K)^\dagger_{i\sigma}. \tag{5.5}$$

B. Differential geometry

There is much to be said on the differential geometry on projective modules, but for reasons of brevity we limit ourselves to indicating how to extend the definitions of $X(i)$ and $\overline{X}(i)$.

Let us first focus on the tensorial case. Let

$$P = (P_{\lambda\rho}), \quad P_{\lambda\rho} = D^J_{\lambda i} (D^J)^\dagger_{i\rho} \tag{5.6}$$

be a projector appropriate for rank 1 tensors. Then what substitutes for the torsion-free X_i acting on α^J is ∇_λ, which is defined by

$$\nabla_\lambda \alpha^J_\rho(g) = \sum \xi^L_M \frac{d}{dt} D^L_{Mi}(g e^{itS(j)}) \Big|_{t=0} (D^J)^\dagger_{i\rho}(g) (D^J)^\dagger_{j\lambda}(g). \tag{5.7}$$

It belongs to the projective module for rank 2 tensors with the natural choice $P \otimes P$ of their projectors. A more compact expression for the covariant derivative can be given in terms of the right-invariant vector fields of G, defined by

$$(\mathcal{L}_A f)(g) = -i \frac{d}{dt} f(e^{-it\Sigma_A} g) \Big|_{t=0}, \tag{5.8}$$

so that

$$\mathcal{L}_A (D^J)^\dagger_{\lambda\mu} = (D^J)^\dagger_{\lambda\rho} (\Sigma_A)^J_{\rho\mu}. \tag{5.9}$$

If functions on G/H are regarded as functions on G invariant by the right action of H on G, $\mathcal{L}_A$ on these correspond to ''orbital'' operators of angular momentum.

The vector fields $\mathcal{L}_A$ are related to the left-invariant vector fields X_A by

$$(X_A f)(g) = \frac{d}{dt} f(g e^{it\Sigma_A}) \Big|_{t=0} = -i (\mathcal{L}_B f)(g) (\mathrm{Ad}\, g)_{BA}. \tag{5.10}$$

From this we may derive the following expression for the covariant derivative:

$$\nabla_\lambda = -i\, \mathrm{Ad}\, g_{Ai} (D^J)^\dagger_{i\lambda} \mathcal{J}_A, \quad \mathcal{J}_A = \text{''total angular momentum''} = \mathcal{L}_A - \Sigma^{\mathcal{R}}_A, \tag{5.11}$$

where $\Sigma^{\mathcal{R}}_A$ are the generators appropriate for representation J acting on the right. In fact, applying (5.10) and then (5.9) to the definition (5.7), we find

$$\nabla_\lambda \alpha^J_\rho = -i \Big(\mathcal{L}_A \sum \xi^L_M D^L_{Mi} \Big) D^{J\dagger}_{i\rho} (\mathrm{Ad}\, g)_{Aj} D^{J\dagger}_{j\lambda} = -i (\mathrm{Ad}\, g)_{Aj} D^{J\dagger}_{j\lambda} ((\mathcal{L}_A - \Sigma^{\mathcal{R}}_A) \alpha^J)_\rho. \tag{5.12}$$

∇_λ maps tensors of rank k to $k+1$. It also has the correct derivation property so that it is a covariant differentiation. Also, (5.7) shows that it corresponds to the operator X_i.

We can define the covariant derivative ∇_ρ on spinors corresponding to X_i in the same way, just changing the index i to a in (3.18), and accordingly changing the choice of J as well.

The canonical torsion c_{ijk} generalizes for tensors to

$$\mathcal{C}_{\lambda\rho\sigma} = (D^J)^\dagger_{i\lambda} (D^J)^\dagger_{j\rho} c_{ijk} D^J_{\sigma k}. \tag{5.13}$$

A torsion-free covariant derivative on tensors when $c_{ijk} \neq 0$ is then defined from

$$\overline{\nabla}_\lambda \alpha^J_\rho = \nabla_\lambda \alpha^J_\rho + \tfrac{1}{2}\mathcal{C}_{\lambda\rho\sigma}\alpha^J_\sigma. \tag{5.14}$$

As for spinors, following (3.23), we define a spinorial torsion which is twice the expression

$$-\frac{i}{4}c_{ijk}\frac{1}{2i}(\gamma_j\gamma_k)_{ba} = -\tfrac{1}{8}c_{ijk}(\gamma_j\gamma_k)_{ba}. \tag{5.15}$$

Let J_s be the representation of choice for the projective module of spinors, and J_T for rank 1 tensors. The transform of (5.15) onto spinorial modules is

$$-\tfrac{1}{8}c_{ijk}[D^{J_s}(\gamma_j\gamma_k)(D^{J_s})^\dagger]_{\sigma'\sigma}(D^{J_T})^\dagger_{i\rho}, \tag{5.16}$$

while the torsion-free covariant derivative $\overline{\nabla}_\rho$ acts on a spinor α^{J_s} represented as an element of a projective module as follows:

$$\overline{\nabla}_\rho \alpha^{J_s}_\sigma = \nabla_\rho \alpha^{J_s}_\sigma - \frac{1}{8}\alpha^{J_s}_{\sigma'}c_{ij'k'}(D^{J_s}(\gamma_{j'}\gamma_{k'})(D^{J_s})^\dagger)_{\sigma'\sigma}(D^{J_T})^\dagger_{i\rho}. \tag{5.17}$$

C. The projective Dirac operator for spheres

The equations (5.5) tell us the invertible transformation of a spinor field of Sec. III C to an element of a projective module. So we can transform the Dirac operator D to one acting on this $\mathcal{A}$-module. The result is not illuminating except in special cases like spheres and $\mathbb{C}P^N$, so we take them up first.

1. Even spheres

For $G/H = S^{2n}$, we can choose $G = \mathrm{Spin}^{\mathbb{C}\ell}(2n+1) = \{g\}$, $H = \mathrm{Spin}^{\mathbb{C}\ell}(2n) = \{h\}$, identifying them with the representations given by γ-matrices, $\mathrm{Spin}^{\mathbb{C}\ell}(2n+1)$ and $\mathrm{Spin}^{\mathbb{C}\ell}(2n)$. We denote the γ-matrices of H by γ_i, $i=1,...,2n$, and by $\gamma = (-i)^n\gamma_1\cdots\gamma_{2n}$ the additional gamma matrix of G, and refer to them collectively as $\Gamma_\lambda = (\gamma_i, \gamma)$, $\lambda = 1,...,2n+1$. The generators of H are $\Sigma_{ij} = (1/4i)[\gamma_i, \gamma_j]$, which together with $\Sigma_{2n+1,i} = (1/2i)\,\gamma\gamma_i$ make up the full set of generators $\Sigma_{\mu\nu}$ of G.

The Γ_λ transform as vectors under conjugation by G. That lets us introduce coordinate functions $x = (x_\lambda)$ for S^{2n}, starting from an "origine" $x^0 = (0,\ldots,0,1)$, as follows:

$$\Gamma_\lambda x_\lambda = g\Gamma_{2n+1}g^{-1}, \quad g \in \mathrm{Spin}(2n+1), \quad x_\lambda x_\lambda = 1. \tag{5.18}$$

We let subscript $A = (\mu\nu)$, $\mu > \nu$ stand for either of the multi-indices (ij), (α of Sec. II), or $(2n+1,i)$, (i of Sec. II). For $A = (2n+1,i)$, X_A gives back $X_{2n+1,i} \equiv X_i$ of Sec. II, which is now torsionless, G/H being symmetric.

Since Γ_{2n+1} commutes with Σ_{ij}, D_W can be written as

$$D_W = -i\gamma^{\mathcal{R}}_i X_i = [\Gamma_{2n+1}, \Sigma_A]^{\mathcal{R}} X_A = [\Gamma_\lambda x_\lambda, \Sigma_A]^{\mathcal{R}} X_A, \text{ at } x = x^0, \tag{5.19}$$

while

$$D = i\Gamma^{\mathcal{R}}_{2n+1}D_W = i\Gamma^{\mathcal{R}}_\lambda x_\lambda D_W, \text{ at } x = x^0. \tag{5.20}$$

We choose J to correspond to the preceding Clifford representation to fix the spinorial projective module. We now show that on this module the above Dirac operators have the beautiful forms

$$\mathcal{D}_W = i[\Gamma^{\mathcal{R}}_\lambda x_\lambda, \Sigma^{\mathcal{R}}_A]\mathcal{J}_A, \quad \mathcal{D} = i\Gamma^{\mathcal{R}}_\lambda x_\lambda \mathcal{D}_W, \tag{5.21}$$

$\mathcal{J}_A$ being again the total "orbital" plus "spin" generators $\mathcal{L}_A$ and $-\Sigma_A^{\mathcal{R}}$ of G. The matrices $\Gamma_\lambda^{\mathcal{R}}$, $\Sigma_A^{\mathcal{R}}$ act on the index a of the spinor,

$$\chi_a = \sum \xi_M^K D_{Mb}^K (D^{\mathbb{C}\ell})_{ba}^\dagger , \tag{5.22}$$

on the right as in $(\Gamma_\lambda^{\mathcal{R}}\chi)_a = \chi_b(\Gamma_\lambda)_{ba}$.

In fact, if we apply (5.21), since by (5.9) $\mathcal{J}_A(D^{\mathbb{C}\ell})^\dagger = 0$, we can see that

$$(\mathcal{D}_W\chi)_a = i\sum (\mathcal{L}_A(\xi_M^K D_{Mb}^K))(D^{\mathbb{C}\ell})_{bc}^\dagger [\Sigma_A, \Gamma_\lambda x_\lambda]_{ca}. \tag{5.23}$$

Inserting

$$\begin{aligned}[\Sigma_A, \Gamma_\lambda x_\lambda] &= (\mathrm{Ad}\, g)_{AB} D^{\mathbb{C}\ell}(g)[\Sigma_B, \Gamma_{2n+1}](D^{\mathbb{C}\ell}(g))^\dagger \\ &= i(\mathrm{Ad}\, g)_{A,(2n+1,i)} D^{\mathbb{C}\ell}(g)\gamma_i (D^{\mathbb{C}\ell}(g))^\dagger ,\end{aligned} \tag{5.24}$$

we get

$$(\mathcal{D}_W\chi)_a = -\sum (\mathcal{L}_A \xi_M^K D_{Mb}^K)(\mathrm{Ad}\, g)_{A,(2n+1,i)} (\gamma_i)_{ba'} (D^{\mathbb{C}\ell}(g))_{a'a}^\dagger . \tag{5.25}$$

But the right-invariant vector fields are related to the left-invariant ones by Eq. (5.10), so

$$(\mathcal{D}_W\chi)_a = -i\left(X_i \sum \xi_M^K D_{Mb}^K \right)(\gamma_i)_{bc} (D^{\mathbb{C}\ell}(g))_{ca}^\dagger . \tag{5.26}$$

Writing $\psi_a = \chi_{a'} D_{a'a}^{\mathbb{C}\ell}$, (5.26) shows that under $\mathcal{D}_W$: $\psi_a \to (D_W\psi)_a$, which is the action (5.19). So $\mathcal{D}_W$ is equivalent to D_W. In a similar manner $\mathcal{D}$ is seen to be equivalent to D.

When acting on functions on S^{2n}, we can use our coordinates to express the right-invariant vector fields in the form

$$\mathcal{L}_{\mu\nu} = -i\left(x_\mu \frac{\partial}{\partial x_\nu} - x_\nu \frac{\partial}{\partial x_\mu} \right), \tag{5.27}$$

and therefore the Dirac operators as

$$\mathcal{D}_W = -x_\mu \Gamma_\nu^{\mathcal{R}} (\mathcal{L}_{\mu\nu} - \Sigma_{\mu\nu}^{\mathcal{R}}), \quad \mathcal{D} = -\Sigma_{\mu\nu}^{\mathcal{R}} \mathcal{L}_{\mu\nu} + n. \tag{5.28}$$

To determine the spectrum and eigenspinors of the Dirac operator we need to be more explicit about the group $\mathrm{Spin}(2n+1)$. It has rank n, and IRR's that can be labeled by the components of the highest weight $(m_1, \ldots, m_n)$, with the m_i's all integers or all half integers, and $m_1 \geqslant m_2 \geqslant \cdots \geqslant m_n \geqslant 0$. The Clifford representation $\mathrm{Spin}^{\mathbb{C}\ell}$ has highest weight $(\frac{1}{2}, \ldots, \frac{1}{2})$, dimension 2^n and quadratic Casimir operator $C_2(\mathbb{C}\ell) \equiv C_2(\mathrm{Spin}^{\mathbb{C}\ell}) = \frac{1}{2}\Sigma_{\mu\nu}\Sigma_{\mu\nu} = \frac{1}{4}n(2n+1)$. We indicate by L an IRR associated with the set I_0 of Sec. II B; it has highest weight $(l,0,...,0)$, where l is an integer, and dimension and quadratic Casimir operator,

$$d(L) = \frac{2l+2n-1}{l+2n-1} \frac{(l+2n-1)!}{l!(2n-1)!}, \quad C_2(L) = l(l+2n-1). \tag{5.29}$$

The final piece of required information is

$$L \otimes \mathbb{C}\ell = (l+\tfrac{1}{2}, \tfrac{1}{2}, \ldots, \tfrac{1}{2}) \oplus (l-\tfrac{1}{2}, \tfrac{1}{2}, \ldots, \tfrac{1}{2}), \tag{5.30}$$

with

$$d\left(j,\frac{1}{2},\ldots,\frac{1}{2}\right)=2^n\frac{(j+2n-\frac{3}{2})!}{(j-\frac{1}{2})!(2n-1)!},\quad C_2\left(j,\frac{1}{2},\ldots,\frac{1}{2}\right)=j(j+2n-1)+\frac{1}{2}(n-1)\left(n-\frac{1}{2}\right). \tag{5.31}$$

With this background it is easy to show that the eigenspinors of $\mathcal{D}$ are of the form

$$\chi_a^{JL}=\sum\ \xi_M^{JL}\langle JM|LN,\mathbb{C}\ell a\rangle D^L_{Ni_0},\ \text{with}\ J=\left(l\pm\frac{1}{2},\frac{1}{2},\ldots,\frac{1}{2}\right), \tag{5.32}$$

where M, N and i_0, and a label vectors in the IRR's J, L and $\mathbb{C}\ell$. In fact,

$$(\mathcal{D}\chi)_a=\sum\ \xi_M^{JL}\langle JM|LN',\mathbb{C}\ell a'\rangle(\Sigma_{\mu\nu})_{a'a}(\Sigma^L_{\mu\nu})_{N'N}D^L_{Ni_0}+n\chi_a, \tag{5.33}$$

where $\Sigma^L_{\mu\nu}$ is the representative of $\mathcal{L}_{\mu\nu}$ in the IRR L. "Completing the square" in this equation, one finds

$$\langle JM|LN',\mathbb{C}\ell a'\rangle(\Sigma_{\mu\nu})_{a'a}(\Sigma^L_{\mu\nu})_{N'N}=(C_2(J)-C_2(L)-C_2(\mathbb{C}\ell))\langle JM|LN,\mathbb{C}\ell a\rangle. \tag{5.34}$$

Using the expressions for the various quadratic Casimir operators, the eigenvalues corresponding to the the eigenspinors (5.32) are found to be

$$\rho=\pm(j+n-\tfrac{1}{2}),\ \text{for}\ j=l\pm\tfrac{1}{2}. \tag{5.35}$$

2. Odd spheres

An odd sphere $S^{2n-1}=\mathrm{SO}(2n)/\mathrm{SO}(2n-1)$ differs from an even sphere S^{2n} in important details. The Clifford algebra $\mathbb{C}\ell(2n-1)$ has two inequivalent 2^{n-1}-dimensional representations, with $(-i)^{n-1}\gamma_1\cdots\gamma_{2n-1}=\mathbb{I}$ and $(-i)^{n-1}\tilde{\gamma}_1\cdots\tilde{\gamma}_{2n-1}=-\mathbb{I}$; we may take $\tilde{\gamma}_i=-\gamma_i$, which makes clear that they give a single IRR's of Spin$(2n-1)$, with generators $(1/4i)[\gamma_i,\gamma_j]$. They do give however two inequivalent IRR's of Spin$(2n)$, with generators $((1/4i)[\gamma_i,\gamma_j],-\frac{1}{2}\gamma_i)$ and $((1/4i)[\gamma_i,\gamma_j],\frac{1}{2}\gamma_i)$, let us label them $\mathbb{C}\ell^+$ and $\mathbb{C}\ell^-$.

For covariance it is better to put these two representations together and work with the 2^n-dimensional Γ_μ, $\mu=1,\ldots,2n$, built from the γ_i's as indicated in (3.2); that particular construction gives

$$\Gamma_{2n+1}=(-i)^n\Gamma_1\cdots\Gamma_{2n}=\begin{pmatrix}\mathbb{I}&0\\0&-\mathbb{I}\end{pmatrix},\quad \tilde{\Gamma}_{2n-1}\equiv(-i)^{n-1}\Gamma_1\cdots\Gamma_{2n-1}=\begin{pmatrix}0&\mathbb{I}\\\mathbb{I}&0\end{pmatrix}. \tag{5.36}$$

For $\mathbb{C}\ell(2n-1)$, Γ_μ splits into the two inequivalent IRR's $\frac{1}{2}(\mathbb{I}\pm\tilde{\Gamma}_{2n-1})\Gamma_j\equiv\Gamma_j^{(1,2)}$, $1\leqslant j\leqslant 2n-1$. The corresponding generators of Spin$^{\mathbb{C}\ell}(2n)$ are

$$\Sigma_{\mu\nu}=\frac{1}{4i}[\Gamma_\mu,\Gamma_\nu]=\left\{\ \Sigma_{ij}=\begin{pmatrix}\frac{1}{4i}[\gamma_i,\gamma_j]&0\\0&\frac{1}{4i}[\gamma_i,\gamma_j]\end{pmatrix};\ \Sigma_{2n,i}=\begin{pmatrix}-\frac{1}{2}\gamma_i&0\\0&\frac{1}{2}\gamma_i\end{pmatrix}\right\}, \tag{5.37}$$

and give, as expected, the direct sum $\mathbb{C}\ell^+\oplus\mathbb{C}\ell^-$; for the group elements of Spin$(2n)$ we have

$$g=\begin{pmatrix}D^{\mathbb{C}\ell^+}&0\\0&D^{\mathbb{C}\ell^-}\end{pmatrix},$$

split by the projectors $\frac{1}{2}(\mathbb{I}\pm\Gamma_{2n+1})$.

Spinors carry the direct sum of these two IRR's on their index, and we can use either of the Dirac operators,

$$D_W^{(1,2)}=\frac{1}{2}(\mathbb{I}\pm\tilde{\Gamma}_{2n-1})^{\mathcal{R}}(-i\,\Gamma_i^{\mathcal{R}})X_i, \tag{5.38}$$

or else we can accept fermion doubling and work with $D_W^{(1)}\oplus D_W^{(2)}$.

There is no chirality in odd dimensions, but Γ_{2n} plays a role in space(time)-reflection, and can be used to give Dirac operators equivalent to $D_W^{(1,2)}$:[9]

$$D^{(1,2)}=e^{i\Gamma_{2n}^{\mathcal{R}}\pi/4}D_W^{(1,2)}e^{-i\Gamma_{2n}^{\mathcal{R}}\pi/4}=\tfrac{1}{2}(\mathbb{I}\mp\Gamma_{2n+1}^{\mathcal{R}})\,\Gamma_{2n}^{\mathcal{R}}\,\Gamma_i^{\mathcal{R}}X_i. \tag{5.39}$$

We can introduce coordinates for S^{2n-1}, starting from $x^0=(0,...,1)$, by

$$\Gamma_\lambda x_\lambda=g\Gamma_\lambda x_\lambda^0 g^{-1}=g\Gamma_{2n}g^{-1}\ ,\ \ x_\lambda x_\lambda=1\ . \tag{5.40}$$

Hence at $x=x^0$,

$$\begin{gathered}D_W^{(1,2)}=p(x^0)_{(1,2)}^R[\Gamma_\lambda x_\lambda^0,\Sigma_A]^{\mathcal{R}}X_A,\ \ D^{(1,2)}=\tfrac{1}{2}(\mathbb{I}\mp\Gamma_{2n+1}^{\mathcal{R}})i\Gamma_\lambda^{\mathcal{R}}x_\lambda^0[\Gamma_\lambda x_\lambda^0,\Sigma_A]^{\mathcal{R}}X_A,\\ p(x^0)_{(1,2)}=\frac{1}{2}(\mathbb{I}\pm\tilde{\Gamma}_{2n-1})=\frac{1}{2}\left(\mathbb{I}\pm\frac{(-i)^{n-1}}{(2n-1)!}\epsilon_{\mu_1\cdots\mu_{2n}}\Gamma_{\mu_1}\cdots\Gamma_{\mu_{2n-1}}x^0_{\mu_{2n}}\right).\end{gathered} \tag{5.41}$$

Their covariant forms follow:

$$\begin{gathered}\mathcal{D}_W^{(1,2)}=p(x)_{(1,2)}^{\mathcal{R}}i\,[\Gamma_\lambda^{\mathcal{R}}x_\lambda,\Sigma_A^{\mathcal{R}}]\mathcal{J}_A,\quad \mathcal{D}^{(1,2)}=-\tfrac{1}{2}(\mathbb{I}\mp\Gamma_{2n+1}^{\mathcal{R}})\Gamma_\rho^{\mathcal{R}}x_\rho[\Gamma_\lambda^{\mathcal{R}}x_\lambda,\Sigma_A^{\mathcal{R}}]\mathcal{J}_A,\\ p(x)_{(1,2)}=\frac{1}{2}\left(\mathbb{I}\pm\frac{(-i)^{n-1}}{(2n-1)!}\epsilon_{\mu_1\,\cdots\,\mu_{2n}}\Gamma_{\mu_1}\cdots\Gamma_{\mu_{2n-1}}x_{\mu_{2n}}\right)=g\,p(x^0)\,g^{-1}.\end{gathered} \tag{5.42}$$

$\mathcal{J}_A$ is defined as before.

Proceeding as we did for even spheres, with $\mathcal{L}_{\mu\nu}$ as in Eq. (5.27) the Dirac operators can be rewritten in the form

$$\mathcal{D}_W^{(1,2)}=-p(x)_{(1,2)}^{\mathcal{R}}x_\mu\Gamma_\nu^{\mathcal{R}}(\mathcal{L}_{\mu\nu}-\Sigma_{\mu\nu}^{\mathcal{R}}),\quad \mathcal{D}^{(1,2)}=\tfrac{1}{2}(\mathbb{I}\mp\Gamma_{2n+1}^{\mathcal{R}})(-\Sigma_{\mu\nu}^{\mathcal{R}}\mathcal{L}_{\mu\nu}+n-\tfrac{1}{2}). \tag{5.43}$$

Given their form, it is easy to find one set of eigenvalues and eigenspinors for the Dirac operators $\mathcal{D}^{(1,2)}$, by the same argument that led us to Eq. (5.32). The IRR's of Spin($2n$) are labeled by highest weights $(m_1,\ldots,m_n)$, $m_1\geqslant m_2\cdots\geqslant|m_n|\geqslant 0$ with the m_i all integers or all half integers. The two 2^{n-1}-D spinor representations $\mathbb{C}\ell^{\pm}$ have $(\frac{1}{2},\ldots,\frac{1}{2},\pm\frac{1}{2})$, with quadratic Casimir $C_2(\mathbb{C}\ell^{\pm})=\frac{1}{2}\Sigma_{\mu\nu}\Sigma_{\mu\nu}=\frac{1}{4}n(2n-1)$. The IRR's associated with the set I_0 of Sec. II B are $L=(l,0,...)$, with dimension $d(L)=(l+n-1)\,(l+2n-3)!/(n-1)\,(2n-3)!\,l!$, and quadratic Casimir $C_2(L)=l(l+2n-2)$. Finally,

$$L\otimes\mathbb{C}\ell^{\pm}=(l+\tfrac{1}{2},\tfrac{1}{2},\ldots,\pm\tfrac{1}{2})\oplus(l-\tfrac{1}{2},\tfrac{1}{2},\ldots,\pm\tfrac{1}{2})\ . \tag{5.44}$$

For these last representations we have $C_2(j,\frac{1}{2},\ldots,\pm\frac{1}{2})=(j-\frac{1}{2})(j+2n-\frac{3}{2})+\frac{1}{4}n(2n-1)$.

With all this information, the analog of (5.33), (5.34) give for the eigenvalues

$$\rho_\pm=\pm(j_\pm+n-1),\ \ \text{with}\ j_\pm=l\pm\tfrac{1}{2}. \tag{5.45}$$

There are eigenstates for each of the two inequivalent representations of the Clifford algebra. They are given by

$$\chi^{JL}_{1,a\pm}=\left(\ 0,\ \sum\ \xi^{JL}_M\left\langle\left(j_\pm,\frac{1}{2},\ldots,-\frac{1}{2}\right),M\middle|L,N';\mathbb{C}\ell^-a\right\rangle D^L_{N'i_0}\right),$$
$$\chi^{JL}_{2,a\pm}=\left(\sum\ \xi^{JL}_M\left\langle\left(j_\pm,\frac{1}{2},\ldots,\frac{1}{2}\right),M\middle|L,N';\mathbb{C}\ell^+a\right\rangle D^L_{N'i_0},0\right). \tag{5.46}$$

However, from Eq. (5.39), we have

$$\Gamma^{\mathcal{R}}_\lambda x_\lambda\,\mathcal{D}^{(1,2)}=-\mathcal{D}^{(2,1)}\,\Gamma^{\mathcal{R}}_\lambda x_\lambda, \tag{5.47}$$

and this implies that there is another set of eigenvectors, with the same eigenvalues, given by

$$\tilde\chi^{JL}_{1,a\pm}=\Gamma_\lambda x_\lambda\,\chi^{J,L}_{2,a\mp}=\left(0,\sum\ \xi^{JL}_M\left\langle\left(j_\mp,\frac{1}{2},\ldots,\frac{1}{2}\right),M|D^J|L,i_0;\mathbb{C}\ell^+\alpha\right\rangle D^{\mathbb{C}\ell^-\dagger}_{\alpha a}\right),$$
$$\tilde\chi^{JL}_{2,a\pm}=\Gamma_\lambda x_\lambda\,\chi^{J,L}_{1,a\mp}=\left(\sum\ \xi^{JL}_M\left\langle\left(j_\mp,\frac{1}{2},\ldots,-\frac{1}{2}\right),M|D^J|L,i_0;\mathbb{C}\ell^-\alpha\right\rangle D^{\mathbb{C}\ell^+\dagger}_{\alpha a},0\right). \tag{5.48}$$

D. The projective Dirac operators on $\mathbb{C}P^N$

For reasons of brevity, we focus on $\mathbb{C}P^2$, a case we have already treated in Ref. 12. $\mathbb{C}P^2$ is SU(3)/U(2). If λ_α are the Gell-Mann matrices, it is the orbit of λ_8 under SU(3):

$$\mathbb{C}P^2:\ \{g\lambda_8 g^{-1}\ ,\ g\in \mathrm{SU}(3)\}\ . \tag{5.49}$$

Writing $g\lambda_8 g^{-1}=\lambda_A\xi_A$ analogously to (5.18), we can regard those $\xi\in\mathbb{R}^8$ given by (5.49), as points of $\mathbb{C}P^2$. The stability group at λ_8, or equally well at $\xi^0=(0,\ldots,0,1)$ is U(2). Its generators are $\lambda_1,\lambda_2,\lambda_3,\lambda_8$.

If we can achieve a covariant–looking form for D and D_W looking like (5.19), (5.20), we can find covariant $\mathcal{D}$ and $\mathcal{D}_W$. Towards this end we introduce the Clifford algebra with eight generators γ_A. They can be transformed by the adjoint representation of SU(3) without disturbing their anticommutators:

$$\gamma'_A=\mathrm{Ad}g_{AB}\gamma_B\to\{\gamma'_A,\gamma'_B\}=2\,\delta_{AB}. \tag{5.50}$$

The generators Σ_A in this representation can actually be written using γ_A:

$$\Sigma_A=\frac{1}{4i}f_{ABC}\gamma_B\gamma_C. \tag{5.51}$$

Consider the action $\gamma_A\to[\Sigma_8,\gamma_A]$ of Σ_8 on γ_A. For this action, the eigenvalues of Σ_8 are $\pm\sqrt{3}/2$ and 0. The 0 eigenvalues are for γ_A with $A=1,2,3,8$; thus

$$[\Sigma_8,[\Sigma_8,\gamma_A]]=0,\ \text{if}\ \ A=1,2,3,8,$$
$$=\tfrac{3}{4}\gamma_A,\quad \text{if}\quad A=4,5,6,7. \tag{5.52}$$

This lets us write the Dirac operator in "covariant" form,

$$D_W=-i\frac{4}{3}[\Sigma\cdot\xi^0,[\Sigma\cdot\xi^0,\gamma_A]]^{\mathcal{R}}X_A,\quad (X_Af)(g)=\frac{d}{dt}f(ge^{it\Sigma_A})|_{t=0}. \tag{5.53}$$

The role of Σ_A and γ_A are reversed here for covariantization as compared to spheres.

For the projective module, for the representation D^J, we have the one given by Σ_A. It is $2^{8/2}=16$-dimensional. The transform $\mathcal{D}_W$ of D_W onto this module is immediate:

$$\mathcal{D}_W=-\tfrac{4}{3}[\Sigma\cdot\xi,[\Sigma\cdot\xi,\gamma_A]]^{\mathcal{R}}\mathcal{J}_A. \tag{5.54}$$

In addition to D_W we can also write the Dirac operators,

$$D'=-i\frac{2}{\sqrt{3}}[\Sigma\cdot\xi^0,\gamma_A]X_A,\quad D=i\Gamma(\xi^0)D_W,\ \ \Gamma(\xi^0)=-\gamma_4\gamma_5\gamma_6\gamma_7. \tag{5.55}$$

D' becomes $\mathcal{D}'=-i\,(2/\sqrt{3})\,[\Sigma\cdot\xi,\gamma_A]J_A$ on the projective module. To find $\mathcal{D}$ we need to find the chirality operator $\Gamma(\xi)$ for all ξ. This is in Ref. 12 and is just

$$\Gamma(\xi)=-\frac{1}{4!}\epsilon_{ABCD}(\xi)\gamma_A\gamma_B\gamma_C\gamma_D,\ \ \epsilon_{ABCD}(\xi)=4(\mathrm{ad}\Sigma\cdot\xi)_{[AB}(\mathrm{ad}\ \ \Sigma\cdot\xi)_{CD]} \tag{5.56}$$

([ ]=antisymmetrization). We cannot have an a in χ_a taking values from 1 to 16: that would give 4 spinors. We must have it taking just 4 values and carrying the representation of just γ_A, $A=4,5,6,7$. The explanation of how this is done takes up some space in Ref. 12.

VI. ON RIEMANNIAN STRUCTURE AND GRAVITY

An inverse metric (η^{ij}) is a symmetric nondegenerate field, which defines a map $\mathcal{T}^{(1)}\otimes\mathcal{T}^{(1)}\to\mathcal{T}^{(0)}$ via $f\otimes f'\to\eta^{ij}f_if'_j$. As the f's transform by $\mathrm{Ad}_{G/H}$ under $g\to gh$, (η^{ij}) transform by the product $\mathrm{Ad}^{-1}_{G/H}\otimes\mathrm{Ad}^{-1}_{G/H}$ of its contragradient representation. Or, the metric (η_{ij}) itself transforms by $\mathrm{Ad}_{G/H}\otimes\mathrm{Ad}_{G/H}$.

A particular metric is $(\hat{\delta}_{ij})$, where $\hat{\delta}_{ij}(g)$ is δ_{ij} (δ=Kronecker δ). The torsion-free covariant derivative compatible with $\hat{\delta}$ is $\overline{X}$:

$$\overline{X}\hat{\delta}=0\,. \tag{6.1}$$

The corresponding curvature tensor of G/H can be calculated in terms of the structure constants of G. From their form we have that for any vector field f_i tangent to G/H,

$$[\overline{X}_i,\overline{X}_j]=R_{ijkl}f_l=(c_{ij\alpha}c_{\alpha kl}+\tfrac{1}{4}(2\,c_{ijk'}c_{k'kl}-c_{ikk'}c_{k'jl}-c_{kjk'}c_{k'il}))f_l\,. \tag{6.2}$$

The scalar curvature is then $R=R_{ijij}=c_{ij\alpha}c_{\alpha ij}+\frac{1}{4}c_{ijk'}c_{k'ij}$. For $S^n=\mathrm{Spin}(n+1)/\mathrm{Spin}(n)$, we found in Sec. V C that in a Clifford representation, $[\Sigma_{n+1,i},\Sigma_{n+1,j}]=i\Sigma_{ij}$. So, with the correspondences $i\leftrightarrow(n+1,i)$, $\alpha\leftrightarrow(i,j)$ we have that $c_{ijk}=0$, and the curvature is $R=n(n-1)$.

A more general H-invariant metric η can be defined as follows. Let us decompose G/H into irreducible subspaces under $\mathrm{Ad}_{G/H}$ and let $\{S^{(\sigma)}_m\}$ be a basis for the unitary irreducible representation σ such that

$$\mathrm{Tr}S^{(\sigma)\dagger}_mS^{(\sigma')}_n=c\,\delta_{\sigma\sigma'}\delta_{mn}. \tag{6.3}$$

(Here σ and σ' can be equivalent representations.) Let $X^{(\sigma)}_m$ be the corresponding (in general, complex) vector field, it is a linear combination of X_i. Then a general H-invariant metric η on vector fields $X^{(\sigma)\dagger}_m$ and $X^{(\sigma')}_n$ is the constant function defined by

$$\eta(X^{(\sigma)\dagger}_m,X^{(\sigma')}_n)(g)=\lambda_\sigma\delta_{\sigma\sigma'}\delta_{mn},\ \ \lambda_\sigma\ \text{ a positive constant,} \tag{6.4}$$

independent of g. Such metrics are essential for certain Kähler structures as we shall see in Sec. VII.

The general covariant differential ∇ can be defined in the usual way:

$$\nabla_i \eta_{jk} = \overline{X}_i \eta_{jk} + \Gamma_{ij}^{j'} \eta_{j'k} + \Gamma_{ik}^{k'} \eta_{jk'}. \tag{6.5}$$

The formula shows that Γ transforms by $\mathrm{Ad}_{G/H} \otimes \mathrm{Ad}_{G/H} \otimes \mathrm{Ad}_{G/H}^{-1}$ under the structure group H. As $\overline{X}$ is torsion-free, so is ∇ if as usual $\Gamma_{ij}^k = \Gamma_{ji}^k$. A standard calculation gives the metric-compatible torsion-free ∇, its Γ being given by

$$\Gamma_{ij}^k = -\tfrac{1}{2}\eta^{kk'}(\overline{X}_i \eta_{jk'} + \overline{X}_j \eta_{ik'} - \overline{X}_{k'} \eta_{ij}). \tag{6.6}$$

These Γ_{ij}^k are not Christoffel symbols, for example, they vanish if $c_{ijk} = 0$. Christoffel symbols are defined with respect to some local coordinates x^a on G/H.

Next, introduce $|G/H|$-beins or soldering forms e_i^a such that

$$\eta_{ij} = \eta(X_i, X_j) = e_i^a e_j^b \eta_{ab}. \tag{6.7}$$

The Christoffel symbols are defined from η_{ab} in the usual way.

The spin connection is defined by

$$\nabla_i e_j^a = \overline{X}_i e_j^a + \Gamma_{ij}^k e_k^a + e_j^b (\omega_i)_{ba} = 0, \tag{6.8}$$

where $(\omega_i)_{ba} = -(\omega_i)_{ab}$ and transforms as a tensor field in i under H. The solution for ω_i is standard:

$$(\omega_i)_{ca} = -E_c^j [\overline{X}_i e_j^a + \Gamma_{ij}^k e_k^a], \quad E_c^j e_j^a = \delta_c^a \quad \text{or} \quad E_c^j = \eta^{jk} e_k^a \eta_{ac}. \tag{6.9}$$

The covariant derivative on spinors ψ is given by

$$(\nabla_i \psi)_a = (\overline{X}_i \psi)_a - \tfrac{1}{4}(\omega_i)_{cd} (\gamma_c \gamma_d \psi)_a. \tag{6.10}$$

The Dirac operator in the presence of a gravity field (η_{ij}) is thus

$$D = \eta^{ij} e_j^a \gamma_a \nabla_j. \tag{6.11}$$

All this stuff is very natural. It remains to transport it to projective modules. In the module picture η_{ij} gets transformed to

$$G_{\lambda\rho} = \eta_{ij} (D^J)_{i\lambda}^\dagger (D^J)_{j\rho}^\dagger, \tag{6.12}$$

while η^{ij} becomes

$$G^{\lambda\rho} = \eta^{ij} D_{\lambda i}^J D_{\rho j}^J. \tag{6.13}$$

The projector for the module is

$$P_\sigma^\lambda = G^{\lambda\rho} G_{\rho\sigma} = D_{\lambda i}^J (D^J)_{i\sigma}^\dagger. \tag{6.14}$$

The projective module analogue of $\overline{X}_i$ is the $\overline{\nabla}_\rho$ defined in Sec. V B. Adding the action of

$$\Gamma_{\lambda\mu}^\nu = \Gamma_{ij}^k (D^J)_{i\lambda}^\dagger (D^J)_{j\nu}^\dagger (D^J)_{k\nu}^\dagger \tag{6.15}$$

to $\overline{\nabla}_\rho$ defines the action of ∇_ρ, the metric-compatible torsion-free covariant derivative on tensors ($\nabla_\rho G_{\mu\nu} = 0$).

The action of ∇_ρ on spinorial modules follows from (6.10). We let $\mathcal{J}_\rho$ be the total angular momentum for the representation J_S chosen for spinors, and

$$\mathcal{C}^{(S)}_{\rho\lambda\sigma}=D^{J_S}_{\lambda b}(c_{ijk}\gamma_j\gamma_k)_{ba}(D^{J_S})^\dagger_{a\sigma}(D^{J_T})^\dagger_{i\rho},$$

$$\Omega_{\rho\lambda\sigma}=D^{J_S}_{\lambda b}((\omega_i)_{jk}\gamma_j\gamma_k)_{ba}(D^{J_S})^\dagger_{a\sigma}(D^{J_T})^\dagger_{i\rho}, \tag{6.16}$$

$$\chi_\sigma=\psi_a(D^{J_S})^\dagger_{a\sigma}.$$

Then, as can easily be shown from (5.17) above,

$$(\nabla_\rho\chi)_\sigma=-i(\mathcal{J}_\rho\chi)_\sigma-\chi_\lambda(\tfrac{1}{8}\mathcal{C}^{(S)}+\tfrac{1}{4}\Omega)_{\rho\lambda\sigma}. \tag{6.17}$$

VII. COMPLEX STRUCTURES AND KÄHLER MANIFOLDS

In favorable circumstances, we can push this program ahead and define more refined ideas like complex and Kähler structures on tensors $\mathcal{T}^{(n)}$ and on their projective modules. We indicate how to treat them briefly.

We consider adjoint orbits only for G/H. Thus let $\underline{k}$ be a fixed element of $\underline{G}$ from the Cartan subalgebra $C(\underline{G})$, and H its stability group:

$$H=\langle h\in G: h\underline{k}h^{-1}=\underline{k}\rangle,\ [\underline{k},T(\alpha)]=0\ \forall\ \alpha,\ [\underline{k},S(i)]\neq 0\ \forall\ i\ . \tag{7.1}$$

The Cartan subalgebra of $\underline{H}$, $C(\underline{H})=C(\underline{G})$, since any element of $\underline{G}$ which commutes with $\underline{k}$ is in $\underline{H}$. The manifold G/H, being an adjoint orbit of the simple Lie group G, has even dimension. These observations have the following implications.

Consider the eigenvalue equation

$$[\underline{k},E_a]=\lambda_a E_a\,. \tag{7.2}$$

Then $\lambda_a\neq 0$. The E_a will be of the form $\Sigma_i\xi_{ai}S(i)$, $\xi_{ai}\in\mathbb{C}$, and span the complexification $(\underline{G/H})_c$ of $(\underline{G/H})$.

By (2.7), $(\underline{G/H})_c$ is invariant under the adjoint action of $\underline{k}$. Also, as $\mathrm{Ad}_{G/H}$ is a real, orthogonal representation, the eigenvalues λ_a are real, while of course the $S(i)$ are Hermitian. So the adjoint of (7.2) shows that $E_a^\dagger$ corresponds to the eigenvalue $-\lambda_a$, and that each positive eigenvalue is paired with a negative one. The eigenvalues λ_a may be degenerate.

We choose E_a, $a=1,\ldots,\frac{1}{2}(|G|-|H|)$, to be solutions of (7.2) with $\lambda_a>0$, $E_{-a}=E_a^\dagger$, and the normalization

$$\mathrm{Tr}\,E_a E_b=\delta_{a+b,0}\,. \tag{7.3}$$

So, if $E_a=\xi_{a\,i}S(i)$ (for both signs of a), $\xi_{-a\,i}=\xi^*_{a\,i}$. We choose $c=1$ in (2.1) and (2.3). Then (2.3) and (7.3) show that the matrix $\{\xi_{a\,i}\}$ is unitary as well.

Let $(\underline{G/H})^\pm_c$ denote the span of the eigenvectors $E_{\pm|a|}$ (where we note that $|a|>0$). The subspaces $(\underline{G/H})^\pm_c$ are of precisely the same dimension and

$$(\underline{G/H})_c=(\underline{G/H})^+_c\oplus(\underline{G/H})^-_c\,. \tag{7.4}$$

The elements $E^+=\Sigma_i\xi^iS(i)\in(\underline{G/H})^+_c$ generate vector fields $X^+=\xi^iX_i$ which we define to be holomorphic. Let $\mathcal{H}^+$ denote the space of holomorphic vector fields. Likewise $(\underline{G/H})^-_c$ gives rise to the space $\mathcal{H}^-$ of antiholomorphic vector fields. This splitting of the space of fields $\mathcal{H}$ as the direct sum $\mathcal{H}^+\oplus\mathcal{H}^-$ gives us the complex structure. The (1,1) tensor J of complex analysis is $\pm i$ on $\mathcal{H}^\pm$: for a vector field $X=\xi^iX_i$, $JX=\xi^j\Sigma_{a>0}i(\xi^*_{aj}\xi_{ai}-\xi_{aj}\xi^*_{ai})X_i$.

This complex structure is Kähler. To show it, let us introduce the Maurer–Cartan forms θ^A, defined by $g^{-1}\,dg=i\Sigma_A\theta^A$, or, setting $c=1$ in (2.1), by

$$\theta^A=-i\,\mathrm{Tr}\,\Sigma_A\,g^{-1}\,dg. \tag{7.5}$$

They are dual to the vector fields $X_A=(X_i, X_\alpha)$, so that, for example, $\theta^i(X_j)=\delta_{ij}$, and fulfill

$$d\theta^A=-\frac{i}{2}\mathrm{Tr}(\Sigma_A[\Sigma_B,\Sigma_C])\,\theta^B\wedge\theta^C=\tfrac{1}{2}c_{BCA}\theta^B\wedge\theta^C. \tag{7.6}$$

Consider the particular Maurer–Cartan form,

$$\Theta=-i\mathrm{Tr}\,\underline{k}\,g^{-1}\,dg=\mathrm{Tr}\,(\underline{k}\,\Sigma_A)\,\theta^A=\mathrm{Tr}(\underline{k}\,T(\alpha))\,\theta^\alpha. \tag{7.7}$$

In the last step we used (2.4). For $d\Theta$ we have

$$d\Theta=-\frac{i}{2}\mathrm{Tr}(k\,[\Sigma_B,\Sigma_C])\,\theta^B\wedge\theta^C. \tag{7.8}$$

But using (7.1) we have $\mathrm{Tr}\underline{k}\,[T(\alpha),T(\beta)]=\mathrm{Tr}[\underline{k},T(\alpha)]T(\beta)=0$ and $\mathrm{Tr}\underline{k}\,[T(\alpha),S(i)]=\mathrm{Tr}[\underline{k},T(\alpha)]\,S(i)=0$. Therefore

$$d\Theta=-\frac{i}{2}\mathrm{Tr}(\underline{k}\,[S(i),S(j)])\theta^i\wedge\theta^j\ . \tag{7.9}$$

Remembering that the matrix $\{\xi_{a\,i}\}$ (with a of both signs) is unitary, we may set

$$S(i)\ \theta^i=E_a\,\xi^*_{a\,i}\,\theta^i\equiv E_a\,\theta^a \tag{7.10}$$

(with an implied sum over a of both signs), and rewrite (7.9) as

$$d\Theta=-\frac{i}{2}(\mathrm{Tr}\underline{k}[E_a,E_b])\,\theta^a\wedge\theta^b=-\frac{i}{2}\lambda_a(\mathrm{Tr}\,E_a\,E_b)\,\theta^a\wedge\theta^b=-i\sum_{a>0}\lambda_a\theta^a\wedge\theta^{-a}, \tag{7.11}$$

where we have used (7.2) and (7.3). The vector fields $X_a=\xi_{ai}X_i$ are dual to θ^a: $\theta^a(X_b)=\delta_{a\,b}$. Consequently, the two-form $\Omega=d\Theta$ can be specified by

$$\Omega(X_a,X_b)=d\Theta(X_a,X_b)=-i\lambda_a\delta_{a+b,0}. \tag{7.12}$$

Since all $\lambda_a\neq 0$, it follows from (7.11) that Ω is a symplectic (i.e., closed and nondegenerate) form on G/H. It has been extensively discussed in Ref. 13, where its physical implications are also explained. It fulfills the Kählerian condition

$$\Omega(JX_a,JX_b)=\Omega(X_a,X_b). \tag{7.13}$$

For vector fields $X=\xi^iX_i$, $Y=\eta^iX_i$, we have $\Omega(X,Y)=\Sigma_{a>0}(i\lambda_a)(\xi_{ai}\xi^*_{aj}-\xi_{aj}\xi^*_{ai})\xi^i\eta^j$.

The Kähler metric η on vector fields (X_a, X_b) is given by

$$\eta(X_a,X_b)=\Omega(JX_a,X_b)=|\lambda_a|\,\delta_{a+b,0}. \tag{7.14}$$

The Levi-Civita connection corresponding to this metric is the torsion-less connection compatible with η. Its coefficients are given by the formula (6.6):

$$\frac{1}{2}c_{abc}+\Gamma^c_{ab}=\frac{1}{2}c_{abc}-\frac{|\lambda_a|-|\lambda_b|}{2|\lambda_c|}c_{abc}\,. \tag{7.15}$$

Note from (7.3) and (2.8) that $c_{abc}=\mathrm{Tr}[E_a,E_b]E_{-c}$. So we have the symmetries

$$c_{abc}=c_{b,-c,-a}=c_{-c,a,-b}. \tag{7.16}$$

Also from $\mathrm{Tr}[\underline{k},[E_a,E_b]E_{-c}]=0$ and (7.2) we have that

$$c_{abc} \text{ and } (7.15) = 0 \text{ if } \lambda_a + \lambda_b - \lambda_c \neq 0. \tag{7.17}$$

Finally, we shall show that the Kähler metric on G/H can be derived from a Kähler potential Φ_ζ. It is a function on G/H and depends on a parameter ζ. It has the property

$$X_a X_{-b} \Phi_\zeta = \eta(X_a, X_{-b}), \tag{7.18}$$

for λ_a and λ_b of the same sign and $|\lambda_a| \leqslant |\lambda_b|$. The ordering is needed because of the torsion term in (2.8). It can be discarded when the torsion is zero, that is for symmetric spaces. Note that Φ_ζ can in general be only locally defined on G/H.

The construction of Φ_ζ involves the member of a specific class of unitary representations $\Sigma_K : g \to \Sigma_K(g)$ of G. Let σ_K be the associated representation of $\underline{G}$. Any such representation contains a normalized highest weight vector $|K\rangle$ with eigenvalue K for $\sigma_K(\underline{k})$, which is annihilated by the orthogonal complement of $\underline{k}$ in $\underline{H}$ and the positive roots E_a:

$$\begin{aligned} &\text{(a)} \quad \sigma_K(\underline{k})|K\rangle = K|K\rangle, \quad K > 0, \\ &\text{(b)} \quad \sigma_K(T(\alpha))|K\rangle = 0, \quad \text{if } \mathrm{Tr} T(\alpha)\underline{k} = 0, \\ &\text{(c)} \quad \sigma_K(E_a)|K\rangle = 0, \quad \text{for } \forall \ a > 0. \end{aligned} \tag{7.19}$$

A representation of G fulfilling (a) and (b) always exists: it is induced from the unitary one-dimensional representation of H given by (a) and (b):

$$\Sigma_K(e^{i\xi_\alpha T(\alpha)})|K\rangle = e^{i(K/\mathrm{Tr}\,\underline{k}^2)\mathrm{Tr}(\underline{k}\,\xi_\alpha T(\alpha))}|K\rangle. \tag{7.20}$$

Here we have used

$$\sigma_K(\xi_\alpha T(\alpha))|K\rangle = \frac{K}{\mathrm{Tr}\,\underline{k}^2}\mathrm{Tr}(\underline{k}\,\xi_\alpha T(\alpha))|K\rangle. \tag{7.21}$$

As for (a), (b) and (c) together, it gives the representation of the group G_c generated by $\underline{H}$ and E_a, $a > 0$, induced from the representation $\sigma_K(\underline{H})$, $\sigma_K(E_a)$, $a > 0$.

Let us fix an orthonormal basis $\{e_1, e_2, \ldots, e_M\}$ in the representation space of dimension M (say) of $\Sigma_K(G)$. Choose a vector $|\zeta\rangle = \Sigma_{i=1}^M \zeta_i e_i$, $\zeta_i \in \mathbb{C}$, $\zeta = (\zeta_1, \zeta_2, \ldots, \zeta_M)$, so that $\langle\zeta|\Sigma_K(g)|K\rangle \neq 0$ when g belongs to some open set $\mathcal{O}$. Such a $|\zeta\rangle$ exists since $\langle\zeta|\Sigma_K(g)|K\rangle = 1$ for $|\zeta\rangle = \Sigma_K(g)|K\rangle$. Further, choose $\mathcal{O}$ so that it is invariant under H-action. That is always possible since for $\langle\zeta|\Sigma_K(g)|K\rangle$ changes only by a phase under this action by (7.20).

Now the function ω_ζ, defined by

$$\omega_\zeta(g) = \langle\zeta|\Sigma_K(g)|K\rangle, \quad g \in \mathcal{O}, \tag{7.22}$$

has the properties

$$\begin{aligned} &(X_a \omega_\zeta)(g) = (X_{-a}\overline{\omega_\zeta})(g) = 0, \quad \text{for } \forall a > 0, \\ &\frac{1}{\omega_\zeta(g)}(X_\alpha \omega)_\zeta(g) = -\frac{1}{\overline{\omega_\zeta}(g)}(X_\alpha \overline{\omega_\zeta})(g) = i\frac{K}{\mathrm{Tr}\,\underline{k}^2}\mathrm{Tr}(\underline{k}\,T(\alpha)). \end{aligned} \tag{7.23}$$

Here the overbar denotes complex conjugation. The first line is a direct consequence of the fact that $|K>$ is the highest weight vector, the second line follows from the relation $\omega_\zeta(gh) = \omega_\zeta(g)\Sigma_K(h)$ valid for any $g \in G$, $h \in H$, with the phase factor $\Sigma_K(h)$ given by (7.20).

If $g \in \mathcal{O}$, the Kähler potential is given by the formula

$$\Phi_\zeta = -\frac{\mathrm{Tr}\,\underline{k}^2}{2K}\log\omega_\zeta(g)\,\overline{\omega}_\zeta(g). \tag{7.24}$$

Φ_ζ is a function on $\mathcal{O}/H\subseteq G/H$, since in the product

$$\omega_\zeta(gh)\overline{\omega}_\zeta(gh)=\Sigma_K(h)\omega_\zeta(g)\overline{\Sigma}_K(h)\overline{\omega}_\zeta(g),$$

the phase factors $\Sigma_K(h)$ and $\overline{\Sigma}_K(h)$ cancel. The Kähler potential is closely related to the one-form Θ introduced in (7.7). Thus the exterior derivative d on G can be written as $d=d_+ + d_- + d_0$, where

$$d_\pm f(g)=(X_{\pm|a|}f)(g)\,\theta^{\pm|a|},\quad d_0 f(g)=(X_\alpha f)(g)\,\theta^\alpha\ . \tag{7.25}$$

Now, using (7.23) one obtains

$$\begin{aligned} i(d_+-d_-)\Phi_\zeta &= i(X_{|a|}\Phi_\zeta)\ \theta^{|a|}-i(X_{-|a|}\Phi_\zeta)\ \theta^{-|a|}\\ &= -i\frac{\mathrm{Tr}\,\underline{k}^2}{2K\overline{\omega}_\zeta}(X_{|a|}\overline{\omega}_\zeta)\ \theta^{|a|}+i\frac{\mathrm{Tr}\,\underline{k}^2}{2K\omega_\zeta}(X_{-|a|}\omega_\zeta)\ \theta^{-|a|}\\ &= i\frac{\mathrm{Tr}\,\underline{k}^2}{2K}d\log\frac{\omega_\zeta}{\overline{\omega}_\zeta}+\mathrm{Tr}(\underline{k}\,T(\alpha))\theta^\alpha = i\frac{\mathrm{Tr}\,\underline{k}^2}{2K}d\log\frac{\omega_\zeta}{\overline{\omega}_\zeta}+\Theta. \end{aligned} \tag{7.26}$$

It follows that

$$d\,i(d_+-d_-)\,\Phi_\zeta = d\,\Theta=\Omega. \tag{7.27}$$

The left hand side of (7.27) can be evaluated using the first line of (7.26) and (7.6). Calculating its values on $iX_a\otimes X_{-b}$ for $0<\lambda_a\leqslant\lambda_b$ and $0<-\lambda_a\leqslant-\lambda_b$, we get (7.18). For this calculation, it is also important that $c_{abc}=0$ if $\lambda_a+\lambda_b\neq\lambda_c$.

In another open set $\mathcal{O}'\subset G$, we may have to work with the Kähler potential Φ_η. Then if $\mathcal{O}\cap\mathcal{O}'\neq\varnothing$, the two potentials on $\mathcal{O}\cap\mathcal{O}'$ are related by

$$\Phi_\eta=\Phi_\zeta-\frac{\mathrm{Tr}\,\underline{k}^2}{2K}\log\frac{\omega_\eta}{\omega_\zeta}+\frac{\mathrm{Tr}\,\underline{k}^2}{2K}\log\frac{\overline{\omega}_\eta}{\overline{\omega}_\zeta}. \tag{7.28}$$

The mapping Φ_ζ to Φ_η is often called a gauge transformation.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 10 OCTOBER 2003

Covariant realization of quantum spaces as star products by Drinfeld twists

Christian Blohmann[a)]
International University Bremen, School of Engineering and Science, Campus Ring 1, 28759 Bremen, Germany

(Received 27 February 2003; accepted 7 May 2003)

Covariance of a quantum space with respect to a quantum enveloping algebra ties the deformation of the multiplication of the space algebra to the deformation of the coproduct of the enveloping algebra. Since the deformation of the coproduct is governed by a Drinfeld twist, the same twist naturally defines a covariant star product on the commutative space. However, this product is in general not associative and does not yield the quantum space. It is shown that there are certain Drinfeld twists which realize the associative product of the quantum plane, quantum Euclidean four-space, and quantum Minkowski space. These twists are unique up to a central two-coboundary. The appropriate formal deformation of real structures of the quantum spaces is also expressed by these twists. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1602553]

I. INTRODUCTION

Noncommutative geometries are described by replacing the commutative algebra of functions on an ordinary space with a noncommutative algebra. The noncommutativity is controlled by a perturbation parameter, if it is a small deviation from ordinary geometry. The algebraic aspects of such a perturbation can be detached from questions of convergence and continuity by considering formal power series. A noncommutative geometry is then described as a formal deformation of a commutative algebra[1] or by a star product.[2] Such a description has attracted a lot of attention lately, due to its application to string theory[3] and to the construction of gauge theories on noncommutative spaces.[4]

The description of physical space–time by an algebra alone would not distinguish Minkowski space from, say, Euclidean four-space, which differs by the symmetry that acts on it. Deforming a space algebra which transforms covariantly under a symmetry Lie group will, in general, break the symmetry. But there are deformations, where the symmetry structure can be deformed together with the space, so that covariance is preserved. Quantum spaces[5–7] are such a class of deformations, carrying a covariant representation of the Drinfeld–Jimbo deformation[8,9] of the enveloping symmetry algebra.

The deformation of an enveloping algebra into a Drinfeld–Jimbo algebra is well understood: As algebra over the ring of formal power series the deformed algebra is isomorphic to the undeformed one. In fact, if the Lie algebra is semisimple, it can be shown by cohomological arguments that the enveloping algebra cannot be deformed at all.[1] It is only the Hopf structure which is truly deformed. The deformed and the undeformed coproduct are nonisomorphic but related by inner automorphisms, called Drinfeld twists.[10] Preserving covariance ties the deformation of the enveloping algebra closely to the deformation of the space algebra. Therefore, one ought to be able to use the knowledge about the deformation of the symmetry in order to deform the space algebra accordingly. Such an approach was suggested in Ref. 11, where a Drinfeld twist was used to realize a quantum space as star product on the undeformed space algebra (for a similar approach see Ref. 12). By construction, such a star product is covariant with respect to the action of the

a)Electronic mail: c.blohmann@iu-bremen.de

Drinfeld–Jimbo algebra. However, the star product is in general not associative. The main question of this article is: Is there a Drinfeld twist which implements the associative product of a given quantum space? We will give a positive answer for three particularly interesting cases: the quantum plane, quantum Euclidean four-space, and quantum Minkowski space.

In Sec. II we review quantum spaces as covariant deformations and relate them to star products defined by Drinfeld twists.[11] We recall the definition and properties of Drinfeld twists in the framework of formal algebraic deformations. Real structures of quantum spaces and of the according quantum algebras are taken into account: Gerstenhaber's rigidity theorem for algebras[1] is extended to $*$-algebras (Proposition 1) and the deformation of space algebras is extended to real structures (Proposition 4). In Sec. III we propose a general approach which reduces the algebraic problem of finding a twist which implements the multiplication of a quantum space to a representation theoretic problem. This works well for cases where the representation theory of the symmetry quantum algebra is well understood: We determine the basis which reduces the quantum plane, quantum Euclidean four-space, and quantum Minkowski space as module into its irreducible highest weight subrepresentations, and calculate the multiplication map with respect to this basis. Comparing the multiplication maps with the representations of the twists leads to the main result: There are Drinfeld twists which realize the quantum plane (Proposition 8), quantum Euclidean four-space (Proposition 9), and quantum Minkowski space (Proposition 10) as covariant star products. These twists are unique up to a central two-coboundary.

Throughout this article we assume that $\mathfrak{g}$ is a semisimple Lie algebra, denoting its enveloping algebra by $\mathcal{U}(\mathfrak{g})$. An element $g \in \mathcal{U}(\mathfrak{g})^{\otimes(n+1)}$ is called $\mathfrak{g}$-invariant if it commutes with the n-fold coproduct $\Delta^{(n)}(g) := g\otimes 1^{\otimes n} + 1\otimes g\otimes 1^{\otimes(n-1)} + \cdots + 1^{\otimes n}\otimes g$ of all $g \in \mathfrak{g}$. The formal perturbation parameter is $\hbar$; the completion of a complex vector space or algebra A with respect to the $\hbar$-adic topology is $A[[\hbar]]$. The topological tensor product $\hat{\otimes}$ of two free $\hbar$-adic vector spaces or algebras is avoided by identifying $A[[\hbar]]\hat{\otimes}A'[[\hbar]] \equiv (A\otimes A')[[\hbar]]$. The $\hbar$-adic Drinfeld–Jimbo deformation[8,9] of $\mathcal{U}(\mathfrak{g})$ is denoted by $\mathcal{U}_\hbar(\mathfrak{g})$. The equality of two elements a, $a' \in A[[\hbar]]$ modulo $\hbar^n$ will be written in Landau notation as $a = a' + \mathcal{O}(\hbar^n)$. Recall that if $a = 1 + \mathcal{O}(\hbar)$, then a is invertible and its square root with $\sqrt{a} = 1 + \mathcal{O}(\hbar)$ is defined and unique in $A[[\hbar]]$ (see, e.g., Ref. 13). The symmetric $\hbar$-adic quantum number is defined by $[n] := (e^{\hbar n} - e^{-\hbar n})(e^{\hbar} - e^{-\hbar})^{-1}$ and for natural n the quantum factorial by $[n]! := [1]\cdot[2]\cdots[n]$.

II. QUANTUM SPACES AND DRINFELD TWISTS

A. Quantum spaces

Let $\mathfrak{g}$ be the Lie algebra of the symmetry group of a space and $\mathcal{X}$ be the function algebra of this space. The elements $g \in \mathfrak{g}$ of the Lie algebra act on $\mathcal{X}$ as derivations, $g\triangleright xy = (g\triangleright x)y + x(g\triangleright y)$ for $x, y \in \mathcal{X}$. A generalized way of writing this is

$$g\triangleright xy = (g_{(1)}\triangleright x)(g_{(2)}\triangleright y) \tag{1}$$

for all $g \in \mathcal{U}(\mathfrak{g})$, where we introduce the coproduct of an enveloping algebra by $g_{(1)}\otimes g_{(2)} \equiv \Delta(g) := g\otimes 1 + 1\otimes g$ on the generators $g \in \mathfrak{g}$ and extend it to a homomorphism $\Delta: \mathcal{U}(\mathfrak{g}) \to \mathcal{U}(\mathfrak{g})\otimes\mathcal{U}(\mathfrak{g})$ on the enveloping algebra.

Using the multiplication map $\mu: \mathcal{X}\otimes\mathcal{X} \to \mathcal{X}$, $\mu(x\otimes y) := xy$ of $\mathcal{X}$ we can write (1) as

$$g\triangleright \mu(x\otimes y) = \mu(\Delta(g)\triangleright[x\otimes y]), \tag{2}$$

the condition for the product μ to be covariant with respect to the action of $\mathcal{U}(\mathfrak{g})$, which is meaningful not only for $\mathcal{U}(\mathfrak{g})$ but for any Hopf algebra. In mathematical terminology, an algebra $\mathcal{X}$ which carries a representation of some Hopf algebra H such that Eq. (1) holds is called an H-module algebra. We will also call it an H-covariant space. The covariant spaces or module algebras of the quantum enveloping algebras $\mathcal{U}_\hbar(\mathfrak{g})$ are called quantum spaces.

As algebra, $\mathcal{U}_\hbar(\mathfrak{g})$ for semisimple $\mathfrak{g}$ is not a true deformation of $\mathcal{U}(\mathfrak{g})$, because $\mathcal{U}_\hbar(\mathfrak{g})$ and $\mathcal{U}(\mathfrak{g})[[\hbar]]$ are isomorphic as algebras (see Sec. II C). This means that every $\hbar$-adic space algebra $\mathcal{X}$

which is a $\mathcal{U}(\mathfrak{g})[[\hbar]]$-module is also a $\mathcal{U}_\hbar(\mathfrak{g})$-module and vice versa. In other words, if we considered only the algebra structure of $\mathcal{U}(\mathfrak{g})$, then there would be no need to replace a commutative space with a noncommutative one when passing from the symmetry algebra to its quantum deformation. It is the Hopf structure which is deformed in an essential way. That is, identifying $\mathcal{U}_\hbar(\mathfrak{g})$ and $\mathcal{U}(\mathfrak{g})[[\hbar]]$ as isomorphic algebras, we can view the quantum deformation as deformation of the Hopf structure of $\mathcal{U}(\mathfrak{g})[[\hbar]]$, $\Delta\to\Delta_\hbar$, $\varepsilon\to\varepsilon_\hbar$, $S\to S_\hbar$. Since the covariance condition (1) ties the algebra structure of a space $\mathcal{X}$ to the coproduct, the multiplication map of the space must be deformed, $\mu\to\mu_\hbar$, along with the deformation of the coproduct, $\Delta\to\Delta_\hbar$, if the covariance is to be preserved. Conversely, deforming the multiplication map of a covariant space, the coproduct of the symmetry algebra must be deformed accordingly,

$$g\triangleright xy=(g_{(1)}\triangleright x)(g_{(2)}\triangleright y)\xrightarrow[\Delta\to\Delta_\hbar]{\mu\to\mu_\hbar} g\triangleright(x\star y)=(g_{(1_\hbar)}\triangleright x)\star(g_{(2_\hbar)}\triangleright y), \tag{3}$$

where $\Delta_\hbar(g)=g_{(1_\hbar)}\otimes g_{(2_\hbar)}$ and $\mu_\hbar(x\otimes y)=x\star y$. While there may be a large class of deformations which are covariant in this sense, we will restrict our attention to quantum spaces.

B. Star products by Drinfeld twists

In the case of quantum spaces, the deformed coproduct belongs to the Drinfeld–Jimbo deformation $\mathcal{U}_\hbar(\mathfrak{g})\cong(\mathcal{U}(\mathfrak{g})[[\hbar]],\Delta_\hbar,\varepsilon_\hbar,S_\hbar)$. Drinfeld has observed (Theorem 1) that $\Delta_\hbar$ is related to the undeformed coproduct Δ by an inner automorphism. That is, there is an invertible element $\mathcal{F}\in(\mathcal{U}(\mathfrak{g})\otimes\mathcal{U}(\mathfrak{g}))[[\hbar]]$ with $\mathcal{F}=1+\mathcal{O}(\hbar)$, called Drinfeld twist, such that

$$\Delta_\hbar(g):=\mathcal{F}\Delta(g)\mathcal{F}^{-1}. \tag{4}$$

Comparing the covariance condition of the deformed multiplication,

$$g\triangleright\mu_\hbar(x\otimes y)=\mu_\hbar(\Delta_\hbar(g)\triangleright[x\otimes y])=\mu_\hbar(\mathcal{F}\Delta(g)\mathcal{F}^{-1}\triangleright[x\otimes y]) \tag{5}$$

with the covariance property (2) of the undeformed product, we see that Eq. (5) is naturally satisfied if we define the deformed product by[11]

$$\mu_\hbar(x\otimes y):=\mu(\mathcal{F}^{-1}\triangleright[x\otimes y])\ \Leftrightarrow\ x\star y:=(\mathcal{F}^{-1}_{[1]}\triangleright x)(\mathcal{F}^{-1}_{[2]}\triangleright y), \tag{6}$$

where we suppress in a Sweedler-like notation the summation of $\Sigma_i\mathcal{F}_{1i}\otimes\mathcal{F}_{2i}\equiv\mathcal{F}_{[1]}\otimes\mathcal{F}_{[2]}$. Since the elements of the Lie algebra $\mathfrak{g}$ act on the undeformed space algebra $\mathcal{X}$ as derivations, $\mathcal{F}^{-1}$ acts as $\hbar$-adic differential operator on $\mathcal{X}\otimes\mathcal{X}$. Hence, writing out the $\hbar$-adic sum of $\mathcal{F}^{-1}=1+\Sigma_k\hbar^k\mathcal{F}_k^{-1}$ we can define the bidifferential operators

$$B_k(x\otimes y):=\mu(\mathcal{F}_k^{-1}\triangleright[x\otimes y])=(\mathcal{F}^{-1}_{k[1]}\triangleright x)(\mathcal{F}^{-1}_{k[2]}\triangleright y), \tag{7}$$

such that the star product (6) can be written in the more familiar form

$$x\star y:=xy+\hbar B_1(x,y)+\hbar^2B_2(x,y)+\cdots. \tag{8}$$

Even though the twist $\mathcal{F}$ yields by Eq. (4) a coassociative coproduct, Eq. (6) will in general not define an associative product. The associativity condition for $\mu_\hbar$ reads

$$\begin{aligned}(x\star y)\star z&=(\mathcal{F}^{-1}_{[1](1)}\mathcal{F}^{-1}_{[1']}\triangleright x)(\mathcal{F}^{-1}_{[1](2)}\mathcal{F}^{-1}_{[2']}\triangleright y)(\mathcal{F}^{-1}_{[2]}\triangleright z)\\&=(\mathcal{F}^{-1}_{[1]}\triangleright x)(\mathcal{F}^{-1}_{[2](1)}\mathcal{F}^{-1}_{[1']}\triangleright y)(\mathcal{F}^{-1}_{[2](2)}\mathcal{F}^{-1}_{[2']}\triangleright z)=x\star(y\star z),\end{aligned} \tag{9}$$

for all $x, y, z\in\mathcal{X}$. Defining the Drinfeld coassociator

$$\Phi:=(\Delta\otimes\mathrm{id})(\mathcal{F}^{-1})(\mathcal{F}^{-1}\otimes 1)(1\otimes\mathcal{F})(\mathrm{id}\otimes\Delta)(\mathcal{F}), \tag{10}$$

the associativity condition (9) can be written as

$$(\Phi_{[1]}\triangleright x)(\Phi_{[2]}\triangleright y)(\Phi_{[3]}\triangleright z)=xyz. \tag{11}$$

The obvious question to ask is: For a given $\mathcal{U}_\hbar(\mathfrak{g})$-covariant quantum space, is there a Drinfeld twist $\mathcal{F}$ which yields by Eq. (6) the associative product of the quantum space? We do not attempt to answer this question in its generality. Instead, we will consider some prototypical and physically important cases: the quantum plane, quantum Euclidean four-space, and quantum Minkowski space.

C. Drinfeld twists of quantum enveloping algebras

For the reader's convenience we gather in this section some well-known results on formal deformations of algebras and Hopf algebras, essentially due to Gerstenhaber[1] and Drinfeld.[10,14]

An $\hbar$-adic algebra A' is called a deformation of an algebra A if $A'/\hbar A'$ and A are isomorphic as algebras. Analogously, an $\hbar$-adic Hopf algebra H' is called a deformation of a Hopf algebra H if $H'/\hbar H'$ and H are isomorphic as Hopf algebras. Recall that $\mathcal{U}(\mathfrak{g})$ is a Hopf algebra with the canonical Lie Hopf structure defined on the generators $g\in\mathfrak{g}$ as coproduct $\Delta(g)=g\otimes 1+1\otimes g$, counit $\varepsilon(g)=0$, and antipode $S(g)=-g$. The Drinfeld–Jimbo algebra $\mathcal{U}_\hbar(\mathfrak{g})$ is a deformation of this Hopf algebra $\mathcal{U}(\mathfrak{g})$. This can be seen by developing the commutation relations and the Hopf structure of $\mathcal{U}_\hbar(\mathfrak{g})$ as formal power series in $\hbar$ and keeping only the zeroth-order terms, which yields the commutation relations and the Lie Hopf structure of $\mathcal{U}(\mathfrak{g})$.

Gerstenhaber has shown[1] that whenever the second Hochschild cohomology of A with coefficients in A is zero, $H^2(A,A)=0$, then all deformations of A are trivial up to isomorphism. That is, any deformation A' of A is isomorphic to the $\hbar$-adic completion of the undeformed algebra, $A'\cong A[[\hbar]]$. Algebras with this property are called rigid. The second Whitehead lemma states that the second Lie algebra cohomology of a semisimple Lie algebra $\mathfrak{g}$ and, hence, the second Hochschild cohomology of its enveloping algebra is zero. Therefore, the enveloping algebra $\mathcal{U}(\mathfrak{g})$ of a semisimple Lie algebra $\mathfrak{g}$ is rigid. In particular, there is an isomorphism of algebras $\alpha:\mathcal{U}_\hbar(\mathfrak{g})\to\mathcal{U}(\mathfrak{g})[[\hbar]]$, by which the Hopf structure Δ', ε', S' of $\mathcal{U}_\hbar(\mathfrak{g})$ can be transfered to $\mathcal{U}(\mathfrak{g})[[\hbar]]$,

$$\Delta_\hbar:=(\alpha\otimes\alpha)\circ\Delta'\circ\alpha^{-1},\quad \varepsilon_\hbar:=\varepsilon'\circ\alpha^{-1},\quad S_\hbar:=\alpha\circ S'\circ\alpha^{-1}, \tag{12}$$

such that α becomes an isomorphism of Hopf algebras from $\mathcal{U}_\hbar(\mathfrak{g})$ to $\mathcal{U}(\mathfrak{g})[[\hbar]]$ with this deformed Hopf structure. Let α' be another such isomorphism and $\Delta'_\hbar$, $\varepsilon'_\hbar$, $S'_\hbar$ be defined as in Eq. (12) with α' instead of α. Then α' is an isomorphism of Hopf algebras from $\mathcal{U}_\hbar(\mathfrak{g})$ to $\mathcal{U}(\mathfrak{g})[[\hbar]]$ with the primed Hopf structure,

$$(\mathcal{U}(\mathfrak{g})[[\hbar]],\Delta_\hbar,\varepsilon_\hbar,S_\hbar)\overset{\alpha}{\leftarrow}\mathcal{U}_\hbar(\mathfrak{g})\overset{\alpha'}{\rightarrow}(\mathcal{U}(\mathfrak{g})[[\hbar]],\Delta'_\hbar,\varepsilon'_\hbar,S'_\hbar), \tag{13}$$

hence, $\alpha'\circ\alpha^{-1}$ is an isomorphism of Hopf algebras. We conclude that, while the Hopf structure Eq. (12) may depend on the isomorphism α, it is unique up to an isomorphism of Hopf algebras.

As a consequence of the first Whitehead lemma, the first Hochschild cohomology of the enveloping algebra $\mathcal{U}(\mathfrak{g})$ of a semisimple Lie algebra is zero. This implies that the two homomorphisms Δ and $\Delta_\hbar$ from $\mathcal{U}(\mathfrak{g})[[\hbar]]$ to $(\mathcal{U}(\mathfrak{g})\otimes\mathcal{U}(\mathfrak{g}))[[\hbar]]$ with $\Delta_\hbar=\Delta+\mathcal{O}(\hbar)$ are related by an inner automorphism, as it was observed by Drinfeld.[10,14]

Theorem 1: *Let $\mathfrak{g}$ be a semisimple Lie algebra, and let $\Delta_\hbar$ be defined as in Eq. (12). Then there is an invertible element $\mathcal{F}\in(\mathcal{U}(\mathfrak{g})\otimes\mathcal{U}(\mathfrak{g}))[[\hbar]]$ such that $\Delta_\hbar(g)=\mathcal{F}\Delta(g)\mathcal{F}^{-1}$, which is called a Drinfeld twist from Δ to $\Delta_\hbar$.*

On the first sight Theorem 1 only relates the coproducts. It turns out that the twist of the coproduct relates counit and antipode, as well.

Corollary 1: Let $\mathcal{F}$ be a Drinfeld twist from Δ to $\Delta_\hbar$ as in Theorem 1.

(i) If $\mathcal{F}'$ is another Drinfeld twist, then $\mathcal{F}^{-1}\mathcal{F}'$ is invertible and $\mathfrak{g}$-invariant. Conversely, let $\mathcal{T}\in(\mathcal{U}(\mathfrak{g})\otimes\mathcal{U}(\mathfrak{g}))[[\hbar]]$ be invertible and $\mathfrak{g}$-invariant. Then $\mathcal{F}\mathcal{T}$ is a Drinfeld twist.

(ii) $\varepsilon_\hbar = \varepsilon$.

(iii) There is a twist $\mathcal{F}$ *such that* $\varepsilon(\mathcal{F}_{[1]})\mathcal{F}_{[2]} = 1 = \mathcal{F}_{[1]}\varepsilon(\mathcal{F}_{[2]})$, *which implies* $\mathcal{F} = 1 + \mathcal{O}(\hbar)$. *Twists with this property are called counital.*

(iv) The two elements of $\mathcal{U}(\mathfrak{g})[[\hbar]]$ *defined as*

$$\sigma_1^{-1} := S(\mathcal{F}_{[1]}^{-1})\mathcal{F}_{[2]}^{-1}, \quad \sigma_2 := \mathcal{F}_{[1]}S(\mathcal{F}_{[2]}) \tag{14}$$

are invertible, $\sigma_1^{-1}\sigma_2 = \sigma_2\sigma_1^{-1}$ *is central in* $\mathcal{U}(\mathfrak{g})[[\hbar]]$, *and* $\sigma_1 S(g)\sigma_1^{-1} = S_\hbar(g) = \sigma_2 S(g)\sigma_2^{-1}$ *for all* $g \in \mathcal{U}(\mathfrak{g})[[\hbar]]$.

(v) The coassociator Φ *defined as in Eq. (10) is* $\mathfrak{g}$*-invariant.*

(vi) The deformed Hopf structure on $\mathcal{U}(\mathfrak{g})[[\hbar]]$ *is isomorphic to the undeformed one if and only if there is a Drinfeld twist of the form* $\mathcal{F} = (u \otimes u)\Delta u^{-1}$ *for some invertible* $u \in \mathcal{U}(\mathfrak{g})[[\hbar]]$.

A proof can be found in the Appendix. The multiplication of a twist with a $\mathfrak{g}$-invariant element as in (i) is sometimes called a gauge transformation of the twist. Counitality (iii) is often part of the definition of twists. Therefore, we will assume from now on that all Drinfeld twists are counital. It can be shown that there are twists for which the elements σ_1 and σ_2 of (iv) are equal.[15] However, this is not the case for all twists. For example, assume that $\sigma_1 = \sigma_2$ for some twist $\mathcal{F}$, and assume that there is a cubic Casimir $c \in \mathcal{U}(\mathfrak{g})$ with $S(c) = -c$. Then $\mathcal{F}' := \mathcal{F}[1 \otimes (1 + \hbar c)]$ is another Drinfeld twist for which $\sigma_1'^{-1}\sigma_2' = \sigma_1^{-1}\sigma_2(1+\hbar c)^{-1}S(1+\hbar c) = (1+\hbar c)^{-1}(1-\hbar c) \neq 1$. Part (vi) of the corollary applies also to the case where Eq. (12) defines for two different isomorphism α and α' two different coproducts $\Delta_\hbar$ and $\Delta'_\hbar$. Here, the automorphism which relates the two coproducts is $\beta := \alpha'\alpha^{-1}$. Note that elements of the form $(u \otimes u)\Delta u^{-1}$ are two-coboundaries in the sense of Ref. 16. Since Δ is cocommutative, two-coboundaries are symmetric. Hence, the twist (4) of Δ by a coboundary yields a cocommutative coproduct. The coproduct of the Drinfeld–Jimbo deformation is not cocommutative, so it cannot be isomorphic to the undeformed, cocommutative coproduct.

D. Real forms of enveloping algebras

Lie groups are usually viewed as real manifolds, even though they may be naturally defined as complex matrix groups. For example, the universal covering of the Lorentz group $\mathrm{SL}(2,\mathbb{C})$ is viewed as real six-parameter Lie group, the generators being the three rotations and the three boosts. When considering the complexification $\tilde{\mathfrak{g}} := \mathbb{C} \otimes_{\mathbb{R}} \mathfrak{g}$ of a real Lie algebra, we have to keep in mind that nonisomorphic real Lie algebras can have the same complexification. For example, su_2 and $\mathrm{sl}_2(\mathbb{R})$ have the same complexification A_1. A practical method to remember the real Lie algebra which a complexification comes from is to observe that for any real Lie algebra $\mathfrak{g}$ there is an antihomomorphism $*$ defined as $g^* := -g$ for all $g \in \mathfrak{g}$, which can be extended to a conjugate linear antihomomorphism on the complexification by $(\alpha \otimes_{\mathbb{R}} g)^* := \overline{\alpha} \otimes_{\mathbb{R}} g^*$ for all $\alpha \in \mathbb{C}$, $g \in \mathfrak{g}$. This defines a $*$-structure on $\tilde{\mathfrak{g}}$, that is, a conjugate linear antihomomorphism, which is an involution, $*^2 = \mathrm{id}$. Given the $*$-structure we can reconstruct the real Lie algebra as being generated by all elements of the form $(g - g^*) \in \tilde{\mathfrak{g}}$.

The identification of real forms of a complex Lie algebra with $*$-structures can be extended to the enveloping Hopf algebra $\mathcal{U}(\mathfrak{g})$. In general, a $*$-structure on a Hopf algebra is a conjugate linear antihomomorphism $*$, which is an involution and a bialgebra homomorphism, $\Delta(g^*) = (\Delta g)^{*\otimes *}$. Algebras and Hopf algebras with such a $*$-structure are called $*$-algebras and Hopf $*$-algebras, respectively. Finally, if H is a Hopf $*$-algebra and $\mathcal{X}$ an H-module algebra with a $*$-structure, such that in addition to Eq. (1) we have

$$(g \triangleright x)^* = (Sg)^* \triangleright x^* \tag{15}$$

for all $g \in H$, $x \in \mathcal{X}$, then $\mathcal{X}$ is called an H-module $*$-algebra, or a real H-covariant space.

Analogously as for algebras, an $\hbar$-adic $*$-algebra A' is called a deformation of a $*$-algebra A if $A'/\hbar A'$ and A are isomorphic as $*$-algebras. A is called rigid as $*$-algebra if for any deformation A' of A the $\hbar$-adic completion $A[[\hbar]]$ and A' are isomorphic as $*$-algebras.

Proposition 1: Let A be a $*$-algebra with zero first and second Hochschild cohomology, $H^1(A,A)=H^2(A,A)=0$. Then A is rigid as $*$-algebra.

Proof: Let $(A',*')$ be a deformation of $(A,*)$ as $*$-algebra. $H^2(A,A)=0$ implies that A is rigid as algebra, so there is an isomorphism of algebras $\beta:A'\to A[[\hbar]]$. Define $*_\beta:=\beta\circ *'\circ\beta^{-1}$. Because $*'$ is a deformation of $*$, we have $*_\beta=*+\mathcal{O}(\hbar)$, and, thus, as $*^2=\mathrm{id}$, $*_\beta\circ *=\mathrm{id}+\mathcal{O}(\hbar)$. $H^1(A,A)=0$ implies that this algebra automorphism is inner, $(g)^{*_\beta\circ *}=ugu^{-1}$ for some invertible $u\in A[[\hbar]]$. Thus, $g^{*_\beta}=(u^*)^{-1}g^*u^*$ for all $g\in A[[\hbar]]$. Since $*_\beta^2=\mathrm{id}$, we have $(g^{*_\beta})^{*_\beta}=g=(u^*)^{-1}ugu^{-1}u^*$, so $u^{-1}u^*=u^*u^{-1}$ is central. Since $*_\beta$ is a deformation of $*$ we can choose u such that $u=1+\mathcal{O}(\hbar)$ and, thus, $u^{-1}u^*=1+\mathcal{O}(\hbar)$, so the square roots of u^* and $u^{-1}u^*$ are defined and invertible. Define an isomorphism of algebras $\alpha:A'\to A[[\hbar]]$ by

$$\alpha(g):=(u^*)^{1/2}\beta(g)(u^*)^{-1/2}. \tag{16}$$

Using that the square root of a central element is central, we get

$$\begin{aligned} g^{*_\alpha}&:=(\alpha\circ *'\circ\alpha^{-1})(g)\\ &=(u^*)^{1/2}(\beta\circ *'\circ\beta^{-1})[(u^*)^{-1/2}g(u^*)^{1/2}](u^*)^{-1/2}\\ &=(u^*)^{1/2}(u^*)^{-1}(u)^{1/2}g^*(u)^{-1/2}u^*(u^*)^{-1/2}\\ &=(u^{-1}u^*)^{-1/2}g^*(u^{-1}u^*)^{1/2}=g^*, \end{aligned} \tag{17}$$

which shows that $\alpha:(A',*')\to(A[[\hbar]],*)$ is an isomorphism of $*$-algebras. □

This proposition applies in particular to the real forms of enveloping algebras of semisimple Lie algebras. In fact, if $*$ is a $*$-structure on $\mathcal{U}(\mathfrak{g})$ and $*'$ is a $*$-structure on $\mathcal{U}_\hbar(\mathfrak{g})$, such that $(\mathcal{U}_\hbar(\mathfrak{g}),*')$ is a deformation of $(\mathcal{U}(\mathfrak{g}),*)$ as Hopf $*$-algebra, we can (and shall) always use an isomorphism of $*$-algebras $\alpha:(\mathcal{U}_\hbar(\mathfrak{g}),*')\to(\mathcal{U}(\mathfrak{g}),*)$ to transfer the Hopf structure by Eqs. (12). In this case there are twists with particularly interesting properties with respect to the $*$-structure: We will call a twist unitary and real, respectively, if

$$\text{unitary:}\quad (*\otimes *)(\mathcal{F})=\mathcal{F}^{-1}, \tag{18a}$$

$$\text{real:}\quad (*\otimes *)(\mathcal{F})=(S\otimes S)(\mathcal{F}_{21}). \tag{18b}$$

A twist which is both, unitary and real, is called orthogonal.

Proposition 2: There is an orthogonal Drinfeld twist from Δ to $\Delta_\hbar$.

Proof: In Theorem 4.1 of Ref. 17 it was shown that there is always a twist with $(S\otimes S)(\mathcal{F})=\mathcal{F}_{21}^{-1}$. By assumption, the $*$-structure is a homomorphism of coalgebras for both, Δ and $\Delta_\hbar$. Thus, $(*\otimes *)(\mathcal{F}^{-1})\equiv(\mathcal{F}^{-1})^*$ is also a twist, so $\mathcal{T}:=\mathcal{F}^{-1}(\mathcal{F}^{-1})^*=1+\mathcal{O}(\hbar)$ is $\mathfrak{g}$-invariant and $\mathcal{F}':=\mathcal{F}\sqrt{\mathcal{T}}$ is another twist. It is easy to check that $\mathcal{F}'$ is unitary and real. □

E. Real structures on star products

The quantum spaces we want to consider here, the quantum plane and quantum Minkowski space, possess a real structure which is covariant with respect to a real form of the symmetry algebra. That is, $(\mathcal{U}(\mathfrak{g}),*)$ is a Hopf $*$-algebra and $(\mathcal{X},\mu,*)$ is a module $*$-algebra, the action of $\mathcal{U}(\mathfrak{g})$ on $\mathcal{X}$ and the $*$-structures satisfying Eq. (15). For a general twist Eq. (6) will not define a multiplication which is compatible with any real structure. Assume that we deform the product $\mu\to\mu_\hbar$ of the real covariant space $(\mathcal{X},\mu,*)$ but not the $*$-structure. Then

$$
\begin{aligned}
(x\star y)^* &= [(\mathcal{F}^{-1}_{[1]}\triangleright x)(\mathcal{F}^{-1}_{[2]}\triangleright y)]^* \\
&= (\mathcal{F}^{-1}_{[2]}\triangleright y)^*(\mathcal{F}^{-1}_{[1]}\triangleright x)^* \\
&= ([S\mathcal{F}^{-1}_{[2]}]^*\triangleright y^*)([S\mathcal{F}^{-1}_{[1]}]^*\triangleright x^*) \\
&= (\mathcal{F}_{[2]}[S\mathcal{F}^{-1}_{[2]}]^*\triangleright y)^*\star(\mathcal{F}_{[1]}[S\mathcal{F}^{-1}_{[1]}]^*\triangleright x)^*,
\end{aligned}
\tag{19}
$$

which shows that the undeformed $*$-structure is an antihomomorphism with respect to the deformed product, if $\mathcal{F}$ is chosen to be real in the sense of Eq. (18b), which was proved to be possible in Proposition 2. However, the undeformed $*$-structure of $\mathcal{X}$ will in general not satisfy the module $*$-algebra property (15). Thus, while Proposition 1 shows that the undeformed and deformed $*$-structures of the symmetry algebra $\mathcal{U}(\mathfrak{g})[[\hbar]]$ can (and shall) be chosen to coincide, this is not possible for the $*$-structures of the deformed and undeformed space algebras. However, there is a unique element σ of the symmetry algebra which mediates the deformation $*\to *_\hbar$ of the real structure of $\mathcal{X}$ by $x^{*_\hbar}:=\sigma^{-1}\triangleright x^*$. This element is characterized by the following.

Proposition 3: There is a unique element $\sigma\in\mathcal{U}(\mathfrak{g})[[\hbar]]$ such that

$$
\sigma=1+\mathcal{O}(\hbar),\quad S_\hbar(g)=\sigma(Sg)\sigma^{-1},\quad \Delta_\hbar(\sigma)=\sigma\otimes\sigma. \tag{20}
$$

Moreover, $\sigma^*=\sigma$.

Proof: Let $\alpha:\mathcal{U}_\hbar(\mathfrak{g})\to\mathcal{U}(\mathfrak{g})[[\hbar]]$ be the isomorphism of algebras which is used to define the deformed Hopf structure by Eqs. (12). Let $\mathcal{R}$ be a universal $\mathcal{R}$-matrix of $\mathcal{U}_\hbar(\mathfrak{g})$ and

$$
\mathcal{R}_\hbar:=(\alpha\otimes\alpha)(\mathcal{R}), \tag{21}
$$

such that $\mathcal{R}_\hbar$ becomes a universal $\mathcal{R}$-matrix with respect to $\Delta_\hbar$. It was shown in Proposition 3.16 of Ref. 10 and Theorem 4.1 of Ref. 17 that there is a Drinfeld twist $\mathcal{F}$ from Δ to $\Delta_\hbar$ such that

$$
\mathcal{R}_\hbar=\mathcal{F}_{21}e^{(\hbar/2)(\Delta(C)-C\otimes 1-1\otimes C)}\mathcal{F}^{-1}\quad\text{and}\quad(S\otimes S)(\mathcal{F})=\mathcal{F}^{-1}_{21}, \tag{22}
$$

with the canonical quadratic Casimir $C:=g_ig_jK^{ij}$, where $\{g_i\}$ is a basis of $\mathfrak{g}$, $K_{ij}:=\mathrm{tr}(\mathrm{ad}g_i\mathrm{ad}g_j)$ is the Killing metric, and K^{ij} its inverse, $K^{ij}K_{jk}=\delta^i_k$.

Let σ_1^{-1} and σ_2 be defined for such a twist as in Eq. (14), and let $\sigma:=\sqrt{\sigma_1\sigma_2}$. Since $\sigma_1^{-1}\sigma_2$ is central, so is its square root. Hence, $S_\hbar(g)=\sigma_1(Sg)\sigma_1^{-1}=\sigma_1\sqrt{\sigma_1^{-1}\sigma_2}(Sg)\sqrt{\sigma_2^{-1}\sigma_1}\sigma_1^{-1}=\sigma(Sg)\sigma^{-1}$.

From the second equation of (22) we deduce $S(\sigma_2)=\sigma_1^{-1}$, so $S(\sigma)=\sigma^{-1}$. From the first equation of (22) we compute $u:=S_\hbar(\mathcal{R}_{\hbar[2]})\mathcal{R}_{\hbar[2]}=\sigma_1S(\sigma_1^{-1})q^{-C}=\sigma_1\sigma_2q^{-C}=\sigma^2q^{-C}$. From the properties of universal $\mathcal{R}$-matrices it follows that $uS_\hbar(u^{-1})=\sigma^4$ is grouplike with respect to $\Delta_\hbar$, $\Delta_\hbar(\sigma_1^4)=\sigma_1^4\otimes\sigma_1^4$. Since σ^4 is grouplike, its fourth root σ is grouplike, as well.

Now let $\sigma'=1+\mathcal{O}(\hbar)$ be another element with $S_\hbar(g)=\sigma'(Sg)\sigma'^{-1}$ which is grouplike with respect to $\Delta_\hbar$. Then $z:=\sigma'\sigma^{-1}$ is central and grouplike, $\Delta_\hbar(z)=z\otimes z=\mathcal{F}^{-1}(z\otimes z)\mathcal{F}=\Delta(z)$, with respect to both coproducts. Since $z=1+\mathcal{O}(\hbar)$ there is an a such that $z=e^{\hbar a}$. Since z is grouplike and central a must be primitive, $\Delta(a)=a\otimes 1+1\otimes a$, and central in every order of $a=\Sigma_i\hbar^ia_i$. Being primitive, the a_i are elements of the Lie algebra, $a_i\in\mathfrak{g}\subset\mathcal{U}(\mathfrak{g})$. Since $\mathfrak{g}$ is semisimple it does not contain nontrivial central elements, so $a_i=0$ for all i, that is, $a=0$. Hence, $z=\sigma'\sigma^{-1}=1$.

Clearly, $\sigma^*=1+\mathcal{O}(\hbar)$. From $S_\hbar=*\circ S_\hbar^{-1}\circ *$ it follows that $S_\hbar(g)=\sigma^*(Sg)(\sigma^*)^{-1}$. Since σ is grouplike with respect to $\Delta_\hbar$, so is σ^*. By uniqueness of an element with properties (20) we conclude that $\sigma^*=\sigma$. □

Now we can show that σ realizes the deformation of the real structure in the promised manner:

Proposition 4: Let $\mathcal{F}$ be a twist from Δ to $\Delta_\hbar$ which is real in the sense of Eq. (18b) and let $(\mathcal{X},\mu,*)$ be an $\hbar$-adic module $*$-algebra of $(\mathcal{U}(\mathfrak{g})[[\hbar]],\Delta,\varepsilon,S,*)$. Define $\mu_\hbar$ as in Eq. (6) and $*_\hbar:\mathcal{X}\to\mathcal{X}$ by

$$x^{*_\hbar} := \sigma^{-1} \triangleright x^* \tag{23}$$

for all $x \in \mathcal{X}$, where σ is the unique element of Proposition 3. Then $(\mathcal{X}, \mu_\hbar, *_\hbar)$ is a module $*$-algebra of $(\mathcal{U}(\mathfrak{g})[[\hbar]], \Delta_\hbar, \varepsilon_\hbar, S_\hbar, *)$.

Proof: By construction, $*_\hbar$ is conjugate linear. We have to show that $*_\hbar$ is an algebra antihomomorphism. Writing $\mu_\hbar(x \otimes y) = x \star y$, we get

$$\begin{aligned}
(x \star y)^{*_\hbar} &= \sigma^{-1} \triangleright [(\mathcal{F}^{-1}_{[1]} \triangleright x)(\mathcal{F}^{-1}_{[2]} \triangleright y)]^* \\
&= \sigma^{-1} \triangleright (\mathcal{F}^{-1}_{[2]} \triangleright y)^* (\mathcal{F}^{-1}_{[1]} \triangleright x)^* \\
&= \sigma^{-1} \triangleright ([S\mathcal{F}^{-1}_{[2]}]^* \triangleright y^*)([S\mathcal{F}^{-1}_{[1]}]^* \triangleright x^*) \\
&= \sigma^{-1} \triangleright (\mathcal{F}^{-1}_{[1]} \triangleright y^*)(\mathcal{F}^{-1}_{[2]} \triangleright x^*) \\
&= (\sigma^{-1}_{(1)} \mathcal{F}^{-1}_{[1]} \triangleright y^*)(\sigma^{-1}_{(2)} \mathcal{F}^{-1}_{[2]} \triangleright x^*) \\
&= (\mathcal{F}^{-1}_{[1]} \sigma^{-1}_{(1_\hbar)} \triangleright y^*)(\mathcal{F}^{-1}_{[2]} \sigma^{-1}_{(2_\hbar)} \triangleright x^*) \\
&= (\mathcal{F}^{-1}_{[1]} \sigma^{-1} \triangleright y^*)(\mathcal{F}^{-1}_{[2]} \sigma^{-1} \triangleright x^*) \\
&= (\sigma^{-1} \triangleright y^*) \star (\sigma^{-1} \triangleright x^*) = (y^{*_\hbar}) \star (x^{*_\hbar}),
\end{aligned} \tag{24}$$

where we have used the module $*$-algebra condition (15), the assumed reality (18b) of $\mathcal{F}$, and that σ is grouplike with respect to $\Delta_\hbar$. Since

$$(x^{*_\hbar})^{*_\hbar} = \sigma^{-1} \triangleright (\sigma^{-1} \triangleright x^*)^* = \sigma^{-1} (S\sigma^{-1})^* \triangleright x = \sigma^{-1} \sigma^* \triangleright x = x, \tag{25}$$

$*_\hbar$ is an involution. Finally, the module $*$-algebra condition (15) holds,

$$\begin{aligned}
(g \triangleright x)^{*_\hbar} &= \sigma^{-1} \triangleright (g \triangleright x)^* \\
&= \sigma^{-1} (Sg)^* \triangleright x^* \\
&= (\sigma^{-1})^* (Sg)^* \triangleright x^* \\
&= (S_\hbar g)^* (\sigma^{-1})^* \triangleright x^* \\
&= (S_\hbar g)^* \triangleright (\sigma^{-1} \triangleright x^*) \\
&= (S_\hbar g)^* \triangleright x^{*_\hbar},
\end{aligned} \tag{26}$$

where we have used the properties of σ from Proposition 3. □

F. Representations

The $\hbar$-adic representations of the algebra $\mathcal{U}(\mathfrak{g})[[\hbar]]$ we are most interested in are those which are the $\hbar$-adic completion of the representations of $\mathcal{U}(\mathfrak{g})$. If $D = (V, \rho)$ is a $\mathcal{U}(\mathfrak{g})$-module with complex vector space V and structure homomorphism $\rho: \mathcal{U}(\mathfrak{g}) \to \mathrm{End}_{\mathbb{C}}(V)$, its $\hbar$-adic completion $\overline{D} = (\overline{V}, \overline{\rho})$ is defined on $\overline{V} = V[[\hbar]]$ with an order by order extension of ρ, $\overline{\rho}(\Sigma_k \hbar^k g_k) := \Sigma_k \hbar^k \rho(g_k) \in \mathrm{End}_{\mathbb{C}}(V)[[\hbar]] = \mathrm{End}_{\mathbb{C}[[\hbar]]}(V[[\hbar]])$. In particular, $\overline{V}$ is free over $\mathbb{C}[[\hbar]]$ and $\overline{\rho}$ is $\mathbb{C}[[\hbar]]$-linear. Note that, even if D is an irreducible representation of $\mathcal{U}(\mathfrak{g})$, this is no longer true for $\overline{D}$. For example, $\hbar \overline{V}$ would be an invariant subspace of $\overline{V}$. $\overline{D}$ is irreducible only in the sense that there is no subspace $U \subset V$ such that $\overline{U} := U[[\hbar]]$ is an invariant subspace of $\overline{V}$.

Let $\{E_k, H_k, F_k | k = 1, \ldots, n\}$ be a Cartan–Weyl basis of the semisimple Lie algebra $\mathfrak{g}$, and $\mathfrak{h}$ be the Cartan subalgebra which is generated by $\{H_k\}$. Clearly, $\mathfrak{h}$ is a Lie subalgebra of the enveloping algebra, $\mathfrak{h} \subset \mathcal{U}(\mathfrak{g})[[\hbar]]$. By construction, the $\hbar$-adic Drinfeld–Jimbo deformation of $\mathcal{U}(\mathfrak{g})$ does contain the Cartan subalgebra as a Lie subalgebra, as well, $\mathfrak{h} \subset \mathcal{U}_\hbar(\mathfrak{g})$. Drinfeld has shown that the isomorphism of $\mathcal{U}(\mathfrak{g})[[\hbar]]$ and $\mathcal{U}_\hbar(\mathfrak{g})$ can be chosen to leave the Cartan subalgebra invariant:

Theorem 2 (Drinfeld,[14] Proposition 4.3): *Let* $\mathfrak{g}$ *be a semisimple Lie algebra and* $\mathfrak{h}\subset\mathfrak{g}$ *a Cartan subalgebra. Then there exists an isomorphism of* $\hbar$*-adic algebras* $\alpha:\mathcal{U}_\hbar(\mathfrak{g})\to\mathcal{U}(\mathfrak{g})[[\hbar]]$ *such that* $\alpha=\mathrm{id}+\mathcal{O}(\hbar)$ *and* $\alpha|_{\mathfrak{h}}=\mathrm{id}_{\mathfrak{h}}$.

This has important consequences for the representation theory. Recall that every finite-dimensional irreducible representation of $\mathcal{U}(\mathfrak{g})$ is a highest weight representation $D^j=(V^j,\rho^j)$, generated by a highest weight vector $v\in V^j$ with $\rho^j(E_k)v=0$ and $\rho^j(H_k)v=j_k v$ for all k, where $j_k\in(1/2)\mathbb{N}_0$, $j:=(j_1,\ldots,j_n)$ being called the highest weight. Furthermore, there is a basis of V^j which consists of simultaneous eigenvectors of H_k, called the weight basis. The same is true for the finite-dimensional representations of the Drinfeld–Jimbo algebra $\mathcal{U}_q(\mathfrak{g})$ for a fixed value of q,[18,19] the weight-j representation $D_q^j=(V^j,\rho_q^j)$ of $\mathcal{U}_q(\mathfrak{g})$ being defined on the same weight basis as D^j. By the substitution $q\mapsto e^\hbar$, D_q^j can be extended to an $\hbar$-adic representation $D_\hbar^j:=(V^j[[\hbar]],\rho_\hbar^j)$. Since $\mathcal{U}_\hbar(\mathfrak{g})$ and $\mathcal{U}(\mathfrak{g})[[\hbar]]$ are isomorphic as algebras, there is a bijection between their representations. Theorem 2 implies that the isomorphism $\alpha:\mathcal{U}_\hbar(\mathfrak{g})\to\mathcal{U}(\mathfrak{g})[[\hbar]]$ can be chosen, such that

$$\rho_\hbar^j=\overline{\rho^j}\circ\alpha. \tag{27}$$

If both $\rho_\hbar^j$ and $\overline{\rho^j}$ are known, this equation can be used to calculate the isomorphism α.

III. CONSTRUCTING COVARIANT STAR PRODUCTS

A. The general approach

As explained in Sec. II B, we are asking if there are Drinfeld twists which implement the product of quantum spaces by Eq. (6). To our knowledge, no Drinfeld twist for the Drinfeld–Jimbo quantum enveloping algebra of a semisimple Lie algebra has ever been computed. This suggests that it will be rather difficult to answer this question on an algebraic level. The representations of Drinfeld twists, however, can be computed as we will demonstrate for $\mathcal{U}_\hbar(\mathrm{su}_2)$ in Proposition 5. Therefore, we propose the following approach, which allows us to tackle the problem on a representation theoretic level:

Consider a $\mathcal{U}_\hbar(\mathfrak{g})$-covariant quantum space algebra $\mathcal{X}_\hbar$ and its undeformed limit, the $\mathcal{U}(\mathfrak{g})$-covariant space algebra $\mathcal{X}$.

(1) Determine the irreducible highest weight representations of all possible Drinfeld twists from Δ to $\Delta_\hbar$.

(2) Determine the basis $\{T_{m,k}^j\}$ of the quantum space $\mathcal{X}_\hbar$ which completely reduces $\mathcal{X}_\hbar$ into irreducible highest weight representations of $\mathcal{U}_\hbar(\mathfrak{g})$,

$$\mathcal{X}_\hbar\cong\bigoplus_{j,k}\mathrm{Span}_{\mathbb{C}[[\hbar]]}\{T_{m,k}^j|m\ \text{ weight of }\ D_\hbar^j\}, \tag{28}$$

such that $g\triangleright T_{m,k}^j=T_{m',k}^j\rho_\hbar^j(g)^{m'}{}_m$ for all $g\in\mathcal{U}_\hbar(\mathfrak{g})$, where m is a weight, j is the highest weight, $\rho_\hbar^j$ is the structure map of the $\hbar$-adic highest weight-j representation $D_\hbar^j$ of $\mathcal{U}_\hbar(\mathfrak{g})$ as explained in Sec. II F, and where k labels the possibly degenerate highest weight-j subrepresentations.

(3) Calculate the multiplication map $\mu_\hbar$ of $\mathcal{X}_\hbar$ with respect to this basis. The undeformed limit $T'^j_{m,k}:=\lim_{\hbar\to 0}T_{m,k}^j$ then yields the basis which completely reduces the undeformed space algebra $\mathcal{X}$. The limit $\mu=\lim_{\hbar\to 0}\mu_\hbar$ is the commutative multiplication map with respect to this basis.

(4) With respect to the basis $\{T'^{j_1}_{m_1,k_1}\otimes T'^{j_2}_{m_2,k_2}\}$ of $(\mathcal{X}\otimes\mathcal{X})[[\hbar]]$ the action of the twist is given by the highest weight representations $(\rho^{j_1}\otimes\rho^{j_2})(\mathcal{F})$. Now we can check if one of the twists realizes the deformed multiplication map by Eq. (6) as linear operator with respect to this basis.

Since this procedure reduces the algebraic problem to a representation theoretic one, it works well for quantum spaces of $\mathcal{U}_\hbar(\mathrm{su}_2)$, $\mathcal{U}_\hbar(\mathrm{so}_4)$, and $\mathcal{U}_\hbar(\mathrm{sl}_2(\mathbb{C}))$ where the representation theory is well understood.

B. The Drinfeld twists of $\mathcal{U}_\hbar(\mathrm{su}_2)$

We now consider the case of $\mathfrak{g}=A_1$, the complex Lie algebra with Cartan–Weyl basis $\{E,H,F\}$ and relations $[H,E]=2E$, $[H,F]=-2F$, $[E,F]=H$. The real form of A_1, which corresponds to the $*$-structure $E^*=F$, $H^*=H$, $F^*=E$, is su_2, the Lie algebra of the group of unitary 2×2-matrices.

Definition 1: The complex $\hbar$-adic algebra generated by E, H, F with commutation relations

$$[H,E]=2E,\quad [H,F]=-2F,\quad [E,F]=\frac{e^{\hbar H}-e^{-\hbar H}}{e^{\hbar}-e^{-\hbar}}, \tag{29}$$

Hopf structure

$$\begin{aligned}
&\Delta'(E)=E\otimes e^{\hbar H}+1\otimes E,\quad S'(E)=-Ee^{-\hbar H},\quad \varepsilon'(E)=0,\\
&\Delta'(F)=F\otimes 1+e^{-\hbar H}\otimes F,\quad S'(F)=-e^{\hbar H}F,\quad \varepsilon'(F)=0,\\
&\Delta'(H)=H\otimes 1+1\otimes H,\quad S'(H)=-H,\quad \varepsilon'(H)=0,
\end{aligned} \tag{30}$$

and involution $E^{*'}=Fe^{\hbar H}$, $F^{*'}=e^{-\hbar H}E$, $H^{*'}=H$ is called $\mathcal{U}_\hbar(\mathrm{su}_2)$, the $\hbar$-deformation of $\mathcal{U}(\mathrm{su}_2)$.[20,21] *It is quasitriangular with universal $\mathcal{R}$-matrix*[22]

$$\mathcal{R}=e^{\hbar(H\otimes H)/2}\sum_{n=0}^{\infty} e^{\hbar n(n-1)/2}\frac{(e^{\hbar}-e^{-\hbar})^n}{[n]!}(E^n\otimes F^n). \tag{31}$$

By construction, the commutation relations and Hopf $*$-structure maps of $\mathcal{U}_\hbar(\mathrm{su}_2)$ coincide in zeroth order of $\hbar$ with those of $\mathcal{U}(\mathrm{su}_2)$. Therefore, $\mathcal{U}_\hbar(\mathrm{su}_2)$ is a deformation of $\mathcal{U}(\mathrm{su}_2)$ as Hopf $*$-algebra. The $\hbar$-adic deformation is obtained from the q-deformation by the substitutions $q=e^{\hbar}$, $K=e^{\hbar H}$, and $K^{-1}=e^{-\hbar H}$. By the same substitution we obtain for each $j\in(1/2)\mathbb{N}_0$ the $\hbar$-adic spin-j $*$-representation

$$\begin{aligned}
&\rho^j_\hbar(E)|j,m\rangle=e^{\hbar(m+1)}\sqrt{[j+m+1][j-m]}\,|j,m+1\rangle,\\
&\rho^j_\hbar(F)|j,m\rangle=e^{-\hbar m}\sqrt{[j+m][j-m+1]}\,|j,m-1\rangle,\\
&\rho^j_\hbar(H)|j,m\rangle=2m|j,m\rangle,
\end{aligned} \tag{32}$$

on the $(2j+1)$-dimensional free $\mathbb{C}[[\hbar]]$-module $V^j[[\hbar]]$ with orthonormal weight basis $\{|j,m\rangle, m=-j,-j+1,...,j\}$, which we denote by $D^j_\hbar:=(V^j[[\hbar]],\rho^j_\hbar)$. Using the coproduct, tensor representations are constructed as

$$D^{j_1}_\hbar\otimes D^{j_2}_\hbar:=(V^{j_1}\otimes V^{j_2},\rho^{j_1\otimes j_2}_\hbar:=(\rho^{j_1}_\hbar\otimes\rho^{j_2}_\hbar)\circ\Delta') \tag{33}$$

and analogously for the undeformed case. The decomposition of such a tensor representation into its irreducible subrepresentations is the Clebsch–Gordan series

$$D^{j_1}_\hbar\otimes D^{j_2}_\hbar\cong D^{|j_1-j_2|}_\hbar\oplus D^{|j_1-j_2|+1}_\hbar\oplus\cdots\oplus D^{j_1+j_2}_\hbar. \tag{34}$$

Let us denote the embedding of the irreducible spin-j component into the tensor representation by $C_q^{j_1j_2j}$ and the projection onto this component by $(C_q^{j_1j_2j})^{-1}$, such that

$$\rho^j_\hbar(g)C_q^{j_1j_2j}=C_q^{j_1j_2j}\rho^{j_1\otimes j_2}_\hbar(g)=C_q^{j_1j_2j}(\rho^{j_1}_\hbar\otimes\rho^{j_2}_\hbar)(\Delta' g) \tag{35}$$

for all $g \in \mathcal{U}_\hbar(\mathrm{su}_2)$. Denoting the basis vectors of $D^{j_1}_\hbar \otimes D^{j_2}_\hbar$ by $|j_1,m_1;j_2,m_2\rangle$ and those of the irreducible spin-j subrepresentation by $|j,m\rangle$, the q–Clebsch–Gordan coefficients are defined as

$$\left(\begin{array}{cc|c} j_1 & j_2 & j \\ m_1 & m_2 & m \end{array}\right)_q := \langle j_1,m_1;j_2,m_2|C_q^{j_1 j_2 j}|j,m\rangle. \tag{36}$$

The q–Clebsch–Gordan coefficients are not unique because the basis vectors $|j,m\rangle$ are only determined up to a phase. We will follow the choice of Ref. 23, where

$$\begin{aligned} \sum_{m_1,m_2} \left(\begin{array}{cc|c} j_1 & j_2 & j \\ m_1 & m_2 & m \end{array}\right)_q \left(\begin{array}{cc|c} j_1 & j_2 & j' \\ m_1 & m_2 & m' \end{array}\right)_q &= \delta_{mm'}\delta_{jj'}, \\ \sum_{j,m} \left(\begin{array}{cc|c} j_1 & j_2 & j \\ m_1 & m_2 & m \end{array}\right)_q \left(\begin{array}{cc|c} j_1 & j_2 & j \\ m_1' & m_2' & m \end{array}\right)_q &= \delta_{m_1 m_1'}\delta_{m_2 m_2'}. \end{aligned} \tag{37}$$

Clearly, the representation theory of $\mathcal{U}_\hbar(\mathrm{su}_2)$ is a deformation of the one of $\mathcal{U}(\mathrm{su}_2)$. In the limit $\hbar \to 0$ or, equivalently, $q \to 1$ of Eq. (36) we get back the undeformed Clebsch–Gordan coefficients. Since $\mathcal{U}_\hbar(\mathrm{su}_2)$ and $\mathcal{U}(\mathrm{su}_2)[[\hbar]]$ are isomorphic as $*$-algebras their representations are isomorphic, as well. Due to Theorem 2 we can choose the isomorphism $\alpha: \mathcal{U}_\hbar(\mathrm{su}_2) \to \mathcal{U}(\mathrm{su}_2)\times[[\hbar]]$ as in Eq. (27) such that

$$\rho^j_\hbar = \rho^j \circ \alpha, \tag{38}$$

where $\rho^j: \mathcal{U}(\mathrm{su}_2)[[\hbar]] \to \mathrm{End}(V^j)[[\hbar]]$ is the $\hbar$-adically extended structure map of the undeformed enveloping algebra. [We omit the bar which denoted the $\hbar$-adic completion in Eq. (27).] If we set $g = \alpha^{-1}(g')$ in Eq. (35), we thus get

$$\rho^j(g')C_q^{j_1 j_2 j} = C_q^{j_1 j_2 j}(\rho^{j_1}\otimes\rho^{j_2})(\Delta_\hbar g') \tag{39}$$

for all $g' \in \mathcal{U}(\mathrm{su}_2)$, where $\Delta_\hbar$ is defined as in Eq. (12).

It is rather obvious that the representations of Drinfeld twists should be given by a contraction of the deformed and undeformed Clebsch–Gordan coefficients, as it was already mentioned in Ref. 24.

Proposition 5: Let $\mathcal{F}$ be a counital Drinfeld twist from $\mathcal{U}(\mathrm{su}_2)$ to $\mathcal{U}_\hbar(\mathrm{su}_2)$. The irreducible representations of $\mathcal{F}$ are of the form

$$(\rho^{j_1}\otimes\rho^{j_2})(\mathcal{F})^{m_1 m_2}{}_{m_1' m_2'} = \sum_{j,m} \eta(j_1,j_2,j) \left(\begin{array}{cc|c} j_1 & j_2 & j \\ m_1 & m_2 & m \end{array}\right)_q \left(\begin{array}{cc|c} j_1 & j_2 & j \\ m_1' & m_2' & m \end{array}\right), \tag{40}$$

where for given values of j_1, j_2, and j the factor $\eta(j_1,j_2,j) \in \mathbb{C}[[\hbar]]$ is a formal power series in $\hbar$ with $\eta(j_1,j_2,j) = 1 + \mathcal{O}(\hbar)$.

Proof: Within a $D^{j_1}\otimes D^{j_2}$ tensor representation we get for all $g \in \mathcal{U}(\mathrm{sl}_2)$

$$\begin{aligned} C_q^{j_1 j_2 j}(\rho^{j_1}\otimes\rho^{j_2})(\mathcal{F})(C^{j_1 j_2 j'})^{-1}\rho^{j'}(g) &= C_q^{j_1 j_2 j}(\rho^{j_1}\otimes\rho^{j_2})(\mathcal{F}\Delta g)(C^{j_1 j_2 j'})^{-1} \\ &= C_q^{j_1 j_2 j}(\rho^{j_1}\otimes\rho^{j_2})((\Delta_\hbar g)\mathcal{F})(C^{j_1 j_2 j'})^{-1} \\ &= \rho^j(g)C_q^{j_1 j_2 j}(\rho^{j_1}\otimes\rho^{j_2})(\mathcal{F})(C^{j_1 j_2 j'})^{-1}, \end{aligned} \tag{41}$$

where we have used Eq. (39) and the analogous relation for the undeformed case. Let us develop $\eta := C_q^{j_1 j_2 j}(\rho^{j_1}\otimes\rho^{j_2})(\mathcal{F})(C^{j_1 j_2 j'})^{-1}$ into an $\hbar$-adic series $\eta = \Sigma_k \hbar^k \eta_k$. Then Eq. (41) implies that

each η_k is a module map from the spin-j' to the spin-j irreducible subrepresentation of the $D^{j_1}\otimes D^{j_2}$ tensor representation. By Schur's lemma each η_k must be zero for $j\neq j'$, while for $j=j'$ the η_k are $\mathbb{C}[[\hbar]]$-scalar multiples of the identity map id_{D^j}. Hence,

$$C_q^{j_1j_2j}(\rho^{j_1}\otimes\rho^{j_2})(\mathcal{F})(C^{j_1j_2j'})^{-1}=\eta(j_1,j_2,j)\,\delta_{jj'}\mathrm{id}_{D^j}$$

$$\Leftrightarrow(\rho^{j_1}\otimes\rho^{j_2})(\mathcal{F})=\sum_j\ \eta(j_1,j_2,j)(C_q^{j_1j_2j})^{-1}C^{j_1j_2j}, \quad (42)$$

where for given j_1, j_2, j, $\eta(j_1,j_2,j)\in\mathbb{C}[[\hbar]]$. Taking matrix elements of the last equation and using the definition (36) of the Clebsch–Gordan coefficients yields Eq. (40). Finally, $\mathcal{F}=1+\mathcal{O}(\hbar)$ implies $\eta(j_1,j_2,j)=1+\mathcal{O}(\hbar)$. □

The Drinfeld twist with the canonically simplest representations would be the one with $\eta(j_1,j_2,j)=1$. Such a twist exists, indeed.

Proposition 6: There is a unique Drinfeld twist $\mathcal{F}_s$, called the standard twist, for which the irreducible representations of Proposition 5 are such that $\eta(j_1,j_2,j)=1$ for all j_1, j_2, j.

Proof: Define a scalar conjugation $u\mapsto\overline{u}$ on $\mathcal{U}(\mathrm{su}_2)$ by extending the identity map on the Cartan–Weyl generators of su_2 to a conjugate linear automorphism of $\mathcal{U}(\mathrm{su}_2)$, e.g., $\overline{\alpha EF}=\overline{\alpha}\overline{E}\overline{F}$ etc. Since both coproducts are real with respect to this conjugation, $\overline{\Delta(g)}=\Delta(\overline{g})$ and $\overline{\Delta_\hbar(g)}=\Delta_\hbar(\overline{g})$, the conjugation of Eq. (4) shows that, if $\mathcal{F}$ is a counital Drinfeld twist, so is $\overline{\mathcal{F}}$ and, hence, $\mathcal{F}':=1/2(\mathcal{F}+\overline{\mathcal{F}})$. In the representation (32) and its undeformed limit the Cartan–Weyl generators are represented by real matrices, thus, $\overline{\rho^j(g)^m{}_{m'}}=\rho^j(g)^m{}_{m'}$. We conclude that if $\eta(j_1,j_2,j)=\eta$ are the factors of the representations of $\mathcal{F}$, $\overline{\eta}$ are those of $\overline{\mathcal{F}}$ and $\eta'=\eta+\overline{\eta}$ those of $\mathcal{F}'$. As in the proof of Proposition 2 the twist $\mathcal{F}'':=\mathcal{F}'(F'^{-1}(F'^*)^{-1})^{1/2}$ is unitary. The factors η'' of the representations of $\mathcal{F}_s$ are real because those of $\mathcal{F}'$ are real, and unitary $\overline{\eta''}=\eta''^{-1}$ because $\mathcal{F}''$ is unitary. Hence, $\eta=\eta(j_1,j_2,j)=1$. Since any two $\mathcal{F}$ with the same representations are equal, $\mathcal{F}''$ is the unique standard twist. □

Proposition 7: The standard twist $\mathcal{F}_s$ is orthogonal.

Proof: It was shown in the proof of Proposition 6 that $\mathcal{F}_s$ is unitary. Moreover,

$$\begin{aligned}(\rho^{j_1}\otimes\rho^{j_2})((S\otimes S)(\mathcal{F}_s))^{m_1m_2}{}_{m_1'm_2'}&=\sum_{j,m}\left(\begin{array}{cc|c}j_1&j_2&j\\-m_1'&-m_2'&m\end{array}\right)_q\left(\begin{array}{cc|c}j_1&j_2&j\\-m_1&-m_2&m\end{array}\right)\\&=\sum_{j,m}\left(\begin{array}{cc|c}j_2&j_1&j\\m_2&m_1&m\end{array}\right)\left(\begin{array}{cc|c}j_2&j_1&j\\m_2'&m_1'&m\end{array}\right)_q\\&=(\rho^{j_1}\otimes\rho^{j_2})(\mathcal{F}_{s21}^{-1})^{m_1m_2}{}_{m_1'm_2'},\end{aligned} \quad (43)$$

where we have used $\rho^j(Sg)^m{}_{m'}=(-1)^{m-m'}\rho^j(g)^{-m'}{}_{-m}$ and that $\left(\begin{smallmatrix}j_1&j_2\\m_1&m_2\end{smallmatrix}\middle|\begin{smallmatrix}j\\m\end{smallmatrix}\right)_q=\left(\begin{smallmatrix}j_2&j_1\\-m_2&-m_1\end{smallmatrix}\middle|\begin{smallmatrix}j\\-m\end{smallmatrix}\right)_q$. We conclude that $(S\otimes S)(\mathcal{F}_s)=\mathcal{F}_{s21}^{-1}=(*\otimes*)(\mathcal{F}_{s21})$. □

C. The quantum plane

The quantum plane[5] is perhaps the simplest nontrivial example of a homogeneous quantum space. In analogy to the undeformed case, the generators x_- and x_+ are defined to carry the fundamental spin-1/2 representation of $\mathcal{U}_\hbar(\mathrm{su}_2)$,

$$g\triangleright x_m:=x_{m'}\rho_\hbar^{1/2}(g)^{m'}{}_m, \quad (44)$$

where the indices run through $\{-,+\}=\{-1/2,+1/2\}$ (summation over repeated upper and lower indices). We also denote the generators by $x\equiv x_-$ and $y\equiv x_+$. Let $\mathbb{C}\langle x_-,x_+\rangle[[\hbar]]$ be the free $\hbar$-adic algebra generated by x_- and x_+. By construction, an algebra which is freely generated by a $\mathcal{U}_\hbar(\mathrm{su}_2)$-module is a $\mathcal{U}_\hbar(\mathrm{su}_2)$-module algebra. The quadratic terms $x_{m_1}x_{m_2}$ thus carry a spin-$(1/2\otimes1/2)$ tensor representation. If we want to divide the free algebra by quadratic relations in

such a way that the quotient algebra is again a $\mathcal{U}_\hbar(\mathrm{su}_2)$-module algebra, we must divide by an ideal which is generated by a submodule of the representation $D^{1/2}_\hbar \otimes D^{1/2}_\hbar \cong D^0_\hbar \oplus D^1_\hbar$ of all quadratic terms. Dividing by $D^1_\hbar$ would yield a deformation of the exterior algebra, whereas dividing by the scalar part $D^0_\hbar$ yields the desired deformation of the commutative algebra of functions on the two-dimensional plane. This amounts to the commutation relations

$$\sum_{m_1,m_2} \left(\begin{matrix} 1/2 & 1/2 \\ m_1 & m_2 \end{matrix} \middle| \begin{matrix} 0 \\ 0 \end{matrix} \right)_q x_{m_1} x_{m_2} = 0 \Leftrightarrow xy = qyx, \tag{45}$$

where $q = e^\hbar$.

Definition 2: The $\hbar$-adic algebra freely generated by $x \equiv x_-$ and $y \equiv x_+$ with commutation relations (45) is called the $\hbar$-adic quantum plane $\mathcal{X}_\hbar(\mathbb{C}^2)$.

We now want to write the product of the quantum plane, $\mu_\hbar(x_1 \otimes x_2) := x_1 x_2$, explicitly as a linear map with respect to a basis. For our purposes, the appropriate choice is the basis which reduces the quantum plane as $\mathcal{U}_\hbar(\mathrm{su}_2)$-module into its irreducible subrepresentations. In order to find such a basis, we recall that, as in the undeformed case, finding the irreducible spin-j subrepresentations is the matter of finding the highest weight-j vectors, that is, the elements of $\mathcal{X}_\hbar(\mathbb{C}^2)$ which transform as $|j,j\rangle$ in Eqs. (32). A simple ansatz shows that, up to scalar multiples, the only element of the quantum plane with this property is x_+^{2j}. Acting on x_+^{2j} with the ladder operator F generates the other basis vectors of the $D^j_\hbar$-subrepresentation. Identifying in Eqs. (32) $|j,m\rangle$ with T^j_m, we have to define

$$T^j_m := q^{(1/2)(j-m)(2m-j+1)} \sqrt{\frac{[j+m]!}{[2j]![j-m]!}} (F^{j-m} \triangleright x_+^{2j}) \tag{46}$$

for $m \in \{-j, -j+1, \ldots, j\}$, such that

$$g \triangleright T^j_m = T^j_{m'} \rho^j_\hbar(g)^{m'}{}_m \tag{47}$$

for all $g \in \mathcal{U}_\hbar(\mathrm{su}_2)$. The basis $\{T^j_m\}$ then reduces the quantum plane into its irreducible subrepresentations, $\mathcal{X}_\hbar(\mathbb{C}^2) = D^0_\hbar \oplus D^{1/2}_\hbar \oplus D^1_\hbar + \cdots$. Calculating Eq. (46) explicitly yields

$$T^j_m = \begin{bmatrix} 2j \\ j+m \end{bmatrix}_{q^{-2}}^{1/2} x_-^{j-m} x_+^{j+m}, \quad \text{where } \begin{bmatrix} n \\ k \end{bmatrix}_{q^{-2}} := q^{k(k-n)} \frac{[n]!}{[n-k]![k]!} \tag{48}$$

is the q-binomial coefficient. By construction, $T^{j_1}_{m_1} T^{j_2}_{m_2}$ carries a spin-$(j_1 \otimes j_2)$ tensor representation which can be reduced using the q–Clebsch–Gordan coefficients. Hence, the elements

$$A^j_m := \sum_{m_1,m_2} \left(\begin{matrix} j_1 & j_2 \\ m_1 & m_2 \end{matrix} \middle| \begin{matrix} j \\ m \end{matrix} \right)_q T^{j_1}_{m_1} T^{j_2}_{m_2} \tag{49}$$

are either zero or the basis of a spin-j subrepresentation of $\mathcal{X}_\hbar(\mathbb{C}^2)$. Since T^j_m generates the only spin-j subrepresentation. A^j_m must be proportional to T^j_m. Moreover, because of its homogeneous commutation relations the algebra $\mathcal{X}_\hbar(\mathbb{C}^2)$ is graded. That is, the degree of the product of two homogeneous elements $T^{j_1}_{m_1}$ and $T^{j_2}_{m_2}$ is the sum of their degrees, $\deg(T^{j_1}_{m_1} T^{j_2}_{m_2}) = \deg(T^{j_1}_{m_1}) + \deg(T^{j_2}_{m_2}) = 2(j_1 + j_2)$. As A^j_m and T^j_m are proportional, they must have the same degree. Thus, A^j_m has to vanish unless $j = j_1 + j_2$. Looking at the highest weight vectors we find $A^{j_1+j_2}_{j_1+j_2} = x_+^{2(j_1+j_2)} = T^{j_1+j_2}_{j_1+j_2}$. Using the orthogonality relation (37) we can move the q–Clebsch–Gordon coefficients to the left-hand side of Eq. (49). As end result, the multiplication map $\mu_\hbar$ of the quantum plane is given with respect to the basis $\{T^j_m\}$ by

$$\mu_\hbar(T^{j_1}_{m_1}\otimes T^{j_1}_{m_1})=\left(\begin{array}{cc|c} j_1 & j_2 & j_1+j_2 \\ m_1 & m_2 & m_1+m_2 \end{array}\right)_q T^{j_1+j_2}_{m_1+m_2}. \tag{50}$$

For the undeformed limit of the basis $T'^{j}_{m}:=\lim_{\hbar\to 0} T^{j}_{m}$ and multiplication map $\mu:=\lim_{\hbar\to 0}\mu_\hbar$ one gets

$$T'^{j}_{m}=\left(\begin{array}{c} 2j \\ j+m \end{array}\right)^{1/2} x_-^{j-m}x_+^{j+m}, \quad \mu(T'^{j_1}_{m_1}\otimes T'^{j_1}_{m_1})=\left(\begin{array}{cc|c} j_1 & j_2 & j_1+j_2 \\ m_1 & m_2 & m_1+m_2 \end{array}\right) T'^{j_1+j_2}_{m_1+m_2}. \tag{51}$$

Comparing Eqs. (50) and (51) with the representations (40) of the Drinfeld twists we obtain the following.

Proposition 8: Let $\mu_\hbar$ be the multiplication map (50) of the $\hbar$-adic quantum plane $\mathcal{X}_\hbar(\mathbb{C}^2)$, $\mu=\lim_{\hbar\to 0}\mu_\hbar$ its undeformed limit, and $\mathcal{F}_s$ the standard twist of Proposition 6. Then $\mu_\hbar$ is the deformation (6) of μ by $\mathcal{F}_s$, $\mu_\hbar(x\otimes y)=\mu(\mathcal{F}_s^{-1}\triangleright[x\otimes y])$.

Finally, let us turn to real structures. Since according to Proposition 3.2 $\mathcal{F}_s$ is real in the sense of Eq. (18b), Proposition 4 applies. Within $\mathcal{U}_\hbar(\mathrm{su}_2)$ we have $S'^2(g)=KgK^{-1}$ with $K=\mathrm{e}^{\hbar H}$ for all $g\in\mathcal{U}_\hbar(\mathrm{su}_2)$. Clearly, K is grouplike, $\Delta'(K)=K\otimes K$. Recall that, in order for the representations of $\mathcal{U}(\mathrm{su}_2)[[\hbar]]$ and $\mathcal{U}_\hbar(\mathrm{su}_2)$ to be related by Eq. (38), we chose the isomorphism $\alpha:\mathcal{U}_\hbar(\mathrm{su}_2)\to\mathcal{U}(\mathrm{su}_2)[[\hbar]]$ according to Theorem 2 such that $\alpha(H)=H$. On the one hand, $S^2_\hbar(g)=(\alpha\circ S'^2\circ\alpha)(g)=KgK^{-1}$. On the other hand, $S^2_\hbar(g)=\sigma^2 g\sigma^{-2}$, for the unique element σ from Proposition 3. Hence, $K\sigma^{-2}=\sigma^{-2}K$ is central, so $S_\hbar(g)=K^{1/2}(Sg)K^{-1/2}$. Since $K^{1/2}=1+\mathcal{O}(\hbar)$ is grouplike the uniqueness of σ implies that $\sigma=K^{1/2}=\mathrm{e}^{\hbar H/2}$. Proposition 4 now tells us that for a given covariant real structure $*$ on the undeformed space algebra $\mathcal{X}\equiv\mathcal{X}(\mathbb{C}^2)=\mathbb{C}[x_-,x_+][[\hbar]]$ of the plane, we have to define the deformed $*$-structure $*_\hbar=*+\mathcal{O}(\hbar)$ by

$$x^{*_\hbar}=\mathrm{e}^{-\hbar H/2}\triangleright x^* \tag{52}$$

such that $(\mathcal{X},\mu_\hbar,*_\hbar)$ becomes a module $*$-algebra of $\mathcal{U}(\mathrm{su}_2)[[\hbar]]$ with respect to the deformed Hopf structure.

D. The quantum Lorentz algebra

We recall the definition of quantum Euclidean algebra in four dimensions and the quantum Lorentz algebra.

Definition 3: The tensor product Hopf $*$-algebra $\mathcal{U}_\hbar(\mathrm{su}_2)\otimes\mathcal{U}_\hbar(\mathrm{su}_2)$ is the $\hbar$-adic quantum enveloping algebra of so_4, $\mathcal{U}_\hbar(\mathrm{so}_4)$. Let $\mathcal{R}$ be the universal $\mathcal{R}$-matrix (31) of $\mathcal{U}_\hbar(\mathrm{su}_2)$. The Hopf algebra obtained by twisting $\mathcal{U}_\hbar(\mathrm{so}_4)$ with $\mathcal{R}_{23}^{-1}=1\otimes\mathcal{R}^{-1}\otimes 1$ together with the $*$-structure

$$(a\otimes b)^*=\mathcal{R}_{21}(b^*\otimes a^*)\mathcal{R}_{21}^{-1} \tag{53}$$

for $a,b\in\mathcal{U}_\hbar(\mathrm{su}_2)$ is the $\hbar$-adic quantum Lorentz algebra $\mathcal{U}_\hbar(\mathrm{sl}_2(\mathbb{C}))$.[25]

The tensor Hopf $*$-structure of $\mathcal{U}_\hbar(\mathrm{so}_4)$ is given by $\varepsilon^{\otimes 2}:=\varepsilon\otimes\varepsilon$, $S^{\otimes 2}:=S\otimes S$, $\Delta^{\otimes 2}:=\tau_{23}\circ(\Delta\otimes\Delta)$, where τ is the flip of the tensor factors, $\tau(a\otimes b)=b\otimes a$, and $*^{\otimes 2}:=*\otimes *$. Looking at Corollary 1 (v) for the twist $\mathcal{F}:=\mathcal{R}_{23}^{-1}$ we find that the coassociator is the unit, $\Phi=1$. Twists with unital coassociator are two-cocycles in the sense of Ref. 16. The cocycle property guarantees that the twisted coproduct is coassociative. For the antipode $S(a\otimes b)=\sigma_1(Sa\otimes Sb)\sigma_1^{-1}$ we have to compute $\sigma_1^{-1}=S(\mathcal{F}^{-1}_{[1]})\mathcal{F}^{-1}_{[2]}=(1\otimes S\mathcal{R}_{[1]})(\mathcal{R}_{[2]\otimes 1})=\mathcal{R}_{21}^{-1}$. Whence, the Hopf structure of $\mathcal{U}_\hbar(\mathrm{sl}_2(\mathbb{C}))$ reads explicitly

$$\Delta(a\otimes b)=\mathcal{R}_{23}^{-1}\Delta^{\otimes 2}(a\otimes b)\mathcal{R}_{23}, \quad S(a\otimes b)=\mathcal{R}_{21}(Sa\otimes Sb)\mathcal{R}_{21}^{-1}, \tag{54}$$

while according to Corollary 1, (ii) the counit stays undeformed.

In the undeformed case so_4 and $\mathrm{sl}_2(\mathbb{C})$ are real forms of the same complex Lie algebra $A_1\otimes A_1$, that is, $\mathcal{U}(\mathrm{so}_4)$ and $\mathcal{U}(\mathrm{sl}_2(\mathbb{C}))$ differ only by their $*$-structure, whereas in the q-deformed

case the Hopf structures differ, as well. The reason for introducing the twist in the Hopf structure of $\mathcal{U}_\hbar(\mathrm{sl}_2(\mathbb{C}))$ is that only then the quantum Lorentz algebra contains a Hopf $*$-subalgebra of rotations, embedded by the coproduct $\Delta:\mathcal{U}_\hbar(\mathrm{su}_2)\hookrightarrow\mathcal{U}_\hbar(\mathrm{sl}_2(\mathbb{C}))$, which is an essential feature for its physical interpretation. The $*$-structure of $\mathcal{U}(\mathrm{sl}_2(\mathbb{C}))$ is not a twist of the product $*$-structure of $\mathcal{U}_\hbar(\mathrm{so}_4)$, but of the flipped $*$-structure $\tau\circ(*\otimes*)$. While Eq. (53) clearly defines an algebra antihomomorphism, the involution property $*^2=\mathrm{id}$ relies on the additional property $\mathcal{R}^{*\otimes *}=\mathcal{R}_{21}$ of the $\mathcal{R}$-matrix of $\mathcal{U}_\hbar(\mathrm{su}_2)$.

The twisting from $\mathcal{U}_\hbar(\mathrm{so}_4)$ to $\mathcal{U}_\hbar(\mathrm{sl}_2(\mathbb{C}))$ can be extended to Drinfeld twists and module algebras.

Corollary 2: Let $\mathcal{F}'$ and $\mathcal{F}''$ be Drinfeld twists from $\mathcal{U}(\mathrm{su}_2)$ to $\mathcal{U}_\hbar(\mathrm{su}_2)$, $\mathcal{R}$ the universal $\mathcal{R}$-matrix of $\mathcal{U}_\hbar(\mathrm{su}_2)$, and $\mathcal{X}$ an $\hbar$-adic $\mathcal{U}_\hbar(\mathrm{su}_2)\otimes\mathcal{U}_\hbar(\mathrm{su}_2)$-module.

(i) $\mathcal{F}'_{13}\mathcal{F}''_{24}$ is a Drinfeld twist of from $\mathcal{U}(\mathrm{so}_4)$ to $\mathcal{U}_\hbar(\mathrm{so}_4)$.

(ii) $\mathcal{R}_{23}^{-1}\mathcal{F}'_{13}\mathcal{F}''_{24}$ is a Drinfeld twist of from $\mathcal{U}(\mathrm{sl}_2(\mathbb{C}))$ to $\mathcal{U}_\hbar(\mathrm{sl}_2(\mathbb{C}))$.

(iii) If $(\mathcal{X},\mu)$ is a module algebra of $\mathcal{U}_\hbar(\mathrm{so}_4)$ with multiplication map μ, then $(\mathcal{X},\tilde{\mu})$ with the twisted multiplication defined as $\tilde{\mu}(x\otimes y):=\mu(\mathcal{R}_{23}\triangleright[x\otimes y])$ is a module algebra of $\mathcal{U}_\hbar(\mathrm{sl}_2(\mathbb{C}))$.

(iv) If $(\mathcal{X},\mu,*)$ is a module $*$-algebra of the Hopf algebra $\mathcal{U}_\hbar(\mathrm{so}_4)$ with flipped $*$-structure $\tau\circ(*\otimes*)$, then $(\mathcal{X},\tilde{\mu},*)$ is a module $*$-algebra of $\mathcal{U}(\mathrm{sl}_2(\mathbb{C}))$.

Proof: (i) $\mathcal{F}'_{13}\mathcal{F}''_{24}=\tau_{23}(\mathcal{F}'\otimes\mathcal{F}'')$ is clearly a tensor product twist of the tensor coproduct $\Delta^{\otimes 2}=\tau_{23}\circ(\Delta\otimes\Delta)$

(ii) Twisting in two steps by $\mathcal{F}'_{13}\mathcal{F}''_{24}$ from $\mathcal{U}(\mathrm{sl}_2(\mathbb{C}))=\mathcal{U}(\mathrm{so}_4)$ to $\mathcal{U}_\hbar(\mathrm{so}_4)$ and then by $\mathcal{R}_{23}^{-1}$ from $\mathcal{U}_\hbar(\mathrm{so}_4)$ to $\mathcal{U}_\hbar(\mathrm{sl}_2(\mathbb{C}))$ is the same as twisting at once by $\mathcal{R}_{23}^{-1}\mathcal{F}'_{13}\mathcal{F}''_{24}$ from $\mathcal{U}(\mathrm{sl}_2(\mathbb{C}))$ to $\mathcal{U}_\hbar(\mathrm{sl}_2(\mathbb{C}))$.

(iii) Note that $\tilde{\mu}$ is the twisted multiplication (6) for $\mathcal{F}=\mathcal{R}_{23}^{-1}$. All we have to check is associativity. The defining properties of a universal $\mathcal{R}$-matrix imply that the Drinfeld coassociator (10) is equal to the unit. Hence, Eq. (11) is trivially satisfied.

(iv) Let us denote the flipped $*$ structure by $*_\tau:=\tau\circ(*\otimes*)$. We verify that $\mathcal{F}=\mathcal{R}_{23}^{-1}$ is real in the sense of Eq. (18b),

$$\begin{aligned}(S^{\otimes 2}\otimes S^{\otimes 2})(\mathcal{F})&=1\otimes(S\otimes S)(\mathcal{R}^{-1})\otimes 1\\&=1\otimes(\mathcal{R}_{21}^{-1})^{*\otimes *}\otimes 1\\&=(\mathcal{R}_{[2]}^{-1}\otimes 1)^{*_\tau}\otimes(1\otimes\mathcal{R}_{[1]}^{-1})^{*_\tau}\\&=(*_\tau\otimes *_\tau)(\mathcal{F}_{21}),\end{aligned}\tag{55}$$

where we have used $(S\otimes S)(\mathcal{R})=\mathcal{R}$ and $\mathcal{R}^{*\otimes *}=\mathcal{R}_{21}$. Equation (19) shows that the $*$-structure of $\mathcal{X}$ is an antihomomorphism with respect to both multiplications, μ and $\tilde{\mu}$. Then we have to check Eq. (15). Denoting by $S_{\mathrm{sl}_2(\mathbb{C})}$ and $*_{\mathrm{sl}_2(\mathbb{C})}$ the antipode and $*$-structure of $\mathcal{U}_\hbar(\mathrm{sl}_2(\mathbb{C}))$, we get

$$\begin{aligned}[S_{\mathrm{sl}_2(\mathbb{C})}(a\otimes b)]^{*_{\mathrm{sl}_2(\mathbb{C})}}&=[\mathcal{R}_{21}(Sa\otimes Sb)\mathcal{R}_{21}^{-1}]^{*_{\mathrm{sl}_2(\mathbb{C})}}\\&=\mathcal{R}_{21}[(\mathcal{R}_{21}^{-1}((Sb)^*\otimes(Sa)^*)\mathcal{R}_{21})]\mathcal{R}_{21}^{-1}\\&=(Sb)^*\otimes(Sa)^*=[S^{\otimes 2}(a\otimes b)]^{*_\tau},\end{aligned}\tag{56}$$

whence $[(a\otimes b)\triangleright x]^*=[S^{\otimes 2}(a\otimes b)]^{*_\tau}\triangleright x^*=[S_{\mathrm{sl}_2(\mathbb{C})}(a\otimes b)]^{*_{\mathrm{sl}_2(\mathbb{C})}}\triangleright x^*$. □

E. Quantum Minkowski space

Quantum Minkowski space $\mathcal{X}_\hbar(\mathbb{R}^{1,3})$ is a noncommutative deformation of the function algebra on real world 1+3-dimensional space–time.[7] By definition, $\mathcal{X}_\hbar(\mathbb{R}^{1,3})$ is the $\mathcal{U}_\hbar(\mathrm{sl}_2(\mathbb{C}))$-module algebra whose generators carry the fundamental representation. It was shown in Corollary 2 that any $\mathcal{U}_\hbar(\mathrm{sl}_2(\mathbb{C}))$-module algebra is the twist of a $\mathcal{U}_\hbar(\mathrm{so}_4)$-module algebra. We will first compute the multiplication map of this $\mathcal{U}_\hbar(\mathrm{so}_4)$-module algebra, quantum Euclidean four-space, and then twist it to obtain the multiplication map of quantum Minkowski space.

Because $\mathcal{U}_\hbar(\mathrm{so}_4)$ is the product Hopf algebra of two $\mathcal{U}_\hbar(\mathrm{su}_2)$, any irreducible representation is the product of two irreducible representations of $\mathcal{U}_\hbar(\mathrm{su}_2)$,

$$D_\hbar^{(j,j')} := (V^j \otimes V^{j'}, \rho_\hbar^j \otimes \rho_\hbar^{j'}). \tag{57}$$

The generators $X_{mm'}$ of the quantum Euclidean four-space are defined to carry the fundamental spin-(1/2,1/2) representation,

$$(g \otimes g') \triangleright X_{mm'} = X_{\tilde{m}\tilde{m}'} \rho_\hbar^{1/2}(g)^{\tilde{m}}{}_m \rho_\hbar^{1/2}(g')^{\tilde{m}'}{}_{m'}, \tag{58}$$

where the indices run through $\{-,+\}=\{-1/2,+1/2\}$. Using Eq. (34), the Clebsch–Gordan decomposition of this representation reads

$$D_\hbar^{(1/2,1/2)} \otimes D_\hbar^{(1/2,1/2)} = D_\hbar^{(0,0)} \oplus D_\hbar^{(1,0)} \oplus D_\hbar^{(0,1)} \oplus D_\hbar^{(1,1)}. \tag{59}$$

The subrepresentation by which we have to divide the free algebra $\mathbb{C}\langle X_{mm'}\rangle[[\hbar]]$ for the right noncommutative limit as $\hbar \to 0$ is $D_\hbar^{(1,0)} \oplus D_\hbar^{(0,1)}$. This corresponds to the quadratic relations

$$\begin{aligned} &\sum_{m_1,m_2,m_1',m_2'} \left(\begin{array}{cc|c} 1/2 & 1/2 & 1 \\ m_1 & m_2 & m \end{array}\right)_q \left(\begin{array}{cc|c} 1/2 & 1/2 & 0 \\ m_1' & m_2' & 0 \end{array}\right)_q X_{m_1 m_1'} X_{m_2 m_2'} = 0, \\ &\sum_{m_1,m_2,m_1',m_2'} \left(\begin{array}{cc|c} 1/2 & 1/2 & 0 \\ m_1 & m_2 & 0 \end{array}\right)_q \left(\begin{array}{cc|c} 1/2 & 1/2 & 1 \\ m_1' & m_2' & m \end{array}\right)_q X_{m_1 m_1'} X_{m_2 m_2'} = 0, \end{aligned} \tag{60}$$

where m runs through $\{-1,0,1\}$. Denoting the generators by $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) := (X_{mm'})$, i.e., $d = X_{++}$ etc., relations (60) read

$$\begin{gathered} ab = qba, \quad ac = qca, \quad bd = qdb, \quad cd = qdc, \\ bc = cb, \quad ad - da = (q - q^{-1})bc, \end{gathered} \tag{61}$$

which are the well-known relations of the algebra of 2×2 quantum matrices.[26] The quantum determinant

$$\det_q := ad - qbc \tag{62}$$

is scalar, $(g \otimes g') \triangleright \det_q = \varepsilon(g \otimes g') \det_q$, and commutes with all generators.

Definition 4: The $\hbar$-adic algebra freely generated by $\{a,b,c,d\}$ with commutation relations (61) is called the $\hbar$-adic quantum Euclidean four-space or the $\hbar$-adic algebra of 2×2 quantum matrices $M_\hbar(2)$.

Quantum Euclidean four-space and $M_q(2)$ are the same algebras, for $\mathrm{SU}_\hbar(2) := M_\hbar(2)/\langle \det_q = 1 \rangle$ is Hopf dual to $\mathcal{U}_\hbar(\mathrm{su}_2)$ in the sense of Ref. 27, which implies that the comodule algebras of $\mathrm{SU}_\hbar(2)$ are the module algebras of $\mathcal{U}_\hbar(\mathrm{su}_2)$. In fact, let Δ be the coproduct of $M_\hbar(2)$, $\Delta(X_{ik}) = \Sigma_j X_{ij} \otimes X_{jk}$, let $T: M_\hbar(2) \to M_\hbar(2)$ be the transposition homomorphism which is defined on the generators by $(X_{ij})^T := X_{ji}$, and let $\pi: M_\hbar(2) \to M_\hbar(2)/\langle \det_q = 1 \rangle$ be the canonical epimorphism, $U^i{}_j := \pi(X_{ij})$ the generators of $\mathrm{SU}_\hbar(2)$, and τ the flip of tensor factors. Then the map $\varphi: M_\hbar(2) \to M_\hbar(2) \otimes \mathrm{SU}_\hbar(2) \otimes \mathrm{SU}_\hbar(2)$ defined as

$$\varphi := [\mathrm{id} \otimes (\pi \circ T) \otimes \pi] \circ \tau_{12} \circ \Delta^{(2)} \Rightarrow \varphi(X_{ij}) = X_{i'j'} \otimes U^{i'}{}_i \otimes U^{j'}{}_j \tag{63}$$

is a homomorphism of algebras because it is a concatenation of homomorphisms, and a corepresentation because $\Delta(U^i{}_k)=U^i{}_j\otimes U^j{}_k$. Hence, $M_\hbar(2)$ together with φ is a comodule algebra of $\mathrm{SO}_\hbar(4):=\mathrm{SU}_\hbar(2)\otimes\mathrm{SU}_\hbar(2)$. The dual of this coaction (63) is the action (58) by which $M_q(2)$ becomes a $\mathcal{U}_\hbar(\mathrm{so}_4)$-module algebra.

A simple ansatz shows that the only homogeneous highest weight vectors of $M_\hbar(2)$ are proportional to $\det_q^k d^l$. In analogy to the quantum plane, we have to define the minimal degree irreducible weight vectors by

$$T^{(j,j)}_{mm'}:=q^{(1/2)[(j-m)(2m-j+1)+(j-m')(2m'-j+1)]}\times\sqrt{\frac{[j+m]![j+m']!}{[2j]!^2[j-m]![j-m']!}}[(F^{j-m}\otimes F^{j-m'})\triangleright d^{2j}], \tag{64}$$

for $j\in 1/2\mathbb{N}_0$, such that they carry a spin-(j,j) representation,

$$(g\otimes g')\triangleright T^{(j,j)}_{mm'}=T'^{(j,j)}_{\tilde m\tilde m'}\rho^j_\hbar(g)^{\tilde m}{}_m\rho^j_\hbar(g')^{\tilde m'}{}_{m'}. \tag{65}$$

The explicit calculation of Eq. (64) leads to

$$T^{(j,j)}_{mm'}=\sum_k q^{k(m'-m-k)}\begin{bmatrix} j-m\\ k\end{bmatrix}_{q^{-2}}\begin{bmatrix} j+m\\ j+m'-k\end{bmatrix}_{q^{-2}}\begin{bmatrix} 2j\\ j+m\end{bmatrix}^{1/2}_{q^{-2}}\begin{bmatrix} 2j\\ j+m'\end{bmatrix}^{-1/2}_{q^{-2}}\times a^{j-m-k}b^kc^{m-m'+k}d^{j+m'-k}, \tag{66}$$

which reduces $M_\hbar(2)$ into irreducible subrepresentations by

$$M_\hbar(2)=\bigoplus_{j\in\mathbb{N}_0/2}\bigoplus_{k\in\mathbb{N}_0}\mathrm{Span}_{\mathbb{C}[[\hbar]]}\{\det_q^k T^{(j,j)}_{mm'}|m,m'=-j,\ldots,j\}. \tag{67}$$

Note that mapping this equation by the canonical epimorphism π onto $\mathrm{SU}_\hbar(2)$ yields the quantum Peter–Weyl decomposition of $\mathrm{SU}_\hbar(2)$ (see Ref. 23, Sec. 4.2.5). As we argued for the quantum plane, the reduction of the product of two irreducible weight vectors with q–Clebsch–Gordan coefficients must again be an irreducible weight vector of the same degree as the product,

$$\sum_{m_1,m_2,m_1',m_2'}\left(\begin{matrix} j_1 & j_2\\ m_1 & m_2\end{matrix}\middle|\begin{matrix} j\\ m\end{matrix}\right)_q\left(\begin{matrix} j_1 & j_2\\ m_1' & m_2'\end{matrix}\middle|\begin{matrix} j'\\ m'\end{matrix}\right)_q T^{(j_1,j_1)}_{m_1m_1'}T^{(j_2,j_2)}_{m_2m_2'}=\delta_{jj'}\beta_{j_1j_2j}\det_q^{j_1+j_2-j}T^{(j,j)}_{mm'}, \tag{68}$$

where the $\beta_{j_1j_2j}\in\mathbb{C}[[\hbar]]$ are $\hbar$-adic scalar coefficients. These coefficients can be easily computed by applying the counit ε of $M_\hbar(2)$, for which we have

$$\varepsilon(T^{(j,j)}_{mm'})=\delta_{mm'},\quad \varepsilon(\det_q)=1, \tag{69}$$

to Eq. (68). This yields $\beta_{j_1j_2j}=1$ for all j_1,j_2,j. Finally, moving the q–Clebsch–Gordan coefficients to the other side of Eq. (68) produces the desired expression for the product $\mu_\hbar$ of $M_\hbar(2)$,

$$\mu_\hbar(T^{(j_1,j_1)}_{m_1m_1'}\otimes T^{(j_2j_z)}_{m_2m_2})=\sum_{m,m',j}\left(\begin{matrix} j_1 & j_2\\ m_1 & m_2\end{matrix}\middle|\begin{matrix} j\\ m\end{matrix}\right)_q\left(\begin{matrix} j_1 & j_2\\ m_1' & m_2'\end{matrix}\middle|\begin{matrix} j\\ m'\end{matrix}\right)_q\det_q^{j_1+j_2-j}T^{(j,j)}_{mm'}. \tag{70}$$

Again, we compare this with the representations (40) and (43) of the Drinfeld twists of $\mathcal{U}_\hbar(\mathrm{su}_2)$ and obtain the following.

Proposition 9: Let $\mu_\hbar$ be the multiplication map (70) of $\hbar$-adic Euclidean four-space $M_\hbar(2)$, $\mu=\lim_{\hbar\to 0}\mu_\hbar$ its undeformed limit, and $\mathcal{F}_s$ the standard twist of Proposition 6. Then $\mu_\hbar$ is the deformation (6) of μ by $\mathcal{F}_{so_4}:=\mathcal{F}_{s13}\mathcal{F}_{s24}$.

Now we can apply Corollary 2 in order to obtain the multiplication map and twist of quantum Minkowski space, twisting once more by $\mathcal{R}_{23}^{-1}$. Of course, the multiplication map of quantum Minkowski space will reproduce the well-known commutation relations of Ref. 7. For the twist we get the following.

Proposition 10: Let $\mu_\hbar$ be the multiplication map of $\hbar$-adic quantum Minkowski space $\mathcal{X}(\mathbb{R}^{1,3})$, $\mu=\lim_{\hbar\to 0}\mu_\hbar$ its undeformed limit, and $\mathcal{F}_s$ the standard twist of Proposition 6. Then $\mu_\hbar$ is the deformation (6) of μ by $\mathcal{F}_{sl_2(\mathbb{C})}:=\mathcal{R}_{23}^{-1}\mathcal{F}_{s13}\mathcal{F}_{s24}$.

Finally, we consider real structures. Since $\mathcal{F}_s$ is real in the sense of Eq. (18b), so is $\mathcal{F}_{so_4}$. Moreover, since $\mathcal{F}_{sl_2(\mathbb{C})}$ is the twist of $\mathcal{F}_{so_4}$ by $\mathcal{R}_{23}^{-1}$, which was shown to be real in the proof of Corollary 2 (iv), $\mathcal{F}_{sl_2(\mathbb{C})}$ is real, as well. Hence, Proposition 4 applies to both, quantum Euclidean four-space and quantum Minkowski space. From a reasoning which is completely analogous to the one that led to Eq. (52) we conclude that the deformation $*_\hbar=*+\mathcal{O}(\hbar)$ of the real structure $*$ of the undeformed Minkowski space–time algebra $\mathcal{X}\equiv\mathcal{X}(\mathbb{R}^{1,3})$ has to be defined by

$$x^{*_\hbar}=(e^{-\hbar H/2}\otimes e^{-\hbar H/2})\triangleright x^* \tag{71}$$

such that $(\mathcal{X},\mu_\hbar,*_\hbar)$ becomes a module $*$-algebra of $\mathcal{U}(sl_2(\mathbb{C}))[[\hbar]]$ with respect to the deformed Hopf structure.

IV. CONCLUSION

It is possible to use Drinfeld twists in order to realize quantum spaces as covariant star products. We have shown this for three important examples, the quantum plane (Proposition 8), quantum Euclidean four-space (Proposition 9), and quantum Minkowski space (Proposition 10). While it was known that the Drinfeld twists control the deformation of enveloping algebras into quantum enveloping algebras, it is now clear that certain twists also control the deformation of spaces into quantum spaces. This is not unexpected, since the covariance condition of the action of a symmetry on a space algebra ties the Hopf structure of the symmetry algebra closely to the multiplicative structure of the space algebra. Our considerations included real structures of quantum enveloping algebras and quantum spaces. In Proposition 4 we have formulated a sufficient condition on the Drinfeld twist, its reality in the sense of Eq. (18b), to be compatible with the real structure of a quantum space, and we have shown that there is a unique element σ of the enveloping algebra which implements the deformation of the real structure.

Star products are often defined by identifying the vector spaces of two space algebras $\mathcal{X}$ and $\mathcal{X}_\hbar$ by an vector space isomorphism, $\varphi:\mathcal{X}\to\mathcal{X}_\hbar$, and transferring the multiplication by $x\star y:=\varphi^{-1}[\varphi(x)\varphi(y)]$. The Moyal–Weyl product is an example of this procedure. The linear isomorphism φ is called an ordering prescription because it defines how an ordered monomial of the commutative algebra $\mathcal{X}$ has to be represented in the noncommutative algebra $\mathcal{X}_\hbar$. For example $\varphi(xy)=\frac{1}{2}[\hat{x}\hat{y}+\hat{y}\hat{x}]$, where $\hat{x}:=\varphi(x)$, $\hat{y}:=\varphi(y)$, for the symmetric ordering. The star product which is obtained by the standard twist of Proposition 8 amounts to the ordering prescription which identifies the basis vectors which completely reduce the space and the quantum space respectively into its irreducible subrepresentations, which is a natural ordering in the context of representation theory. For the quantum plane this is almost the lexicographic (Poincaré–Birkhoff–Witt) ordering,

$$\varphi(x^k y^l)=\begin{bmatrix}k+l\\ k\end{bmatrix}_{q^{-2}}^{1/2}\begin{pmatrix}k+l\\ k\end{pmatrix}^{-1/2}x^k y^l, \tag{72}$$

where we recall that $x\equiv x_-$, $y\equiv x_+$. The basis of the spin-j subrepresentation is unique up to scalar multiples. A rescaling $T^j_m\mapsto\beta(j)T^j_m$ with $\beta(j)=1+\mathcal{O}(\hbar)$ would change the multiplication

map by multiplying the right-hand side of Eq. (50) with $\beta(j)\beta^{-1}(j_1)\beta^{-1}(j_2)$. Identifying the scale factors with the representations $\beta(j)=\rho^j(z)$ of some invertible central element z, the twist which realizes the star product must be redefined by $\mathcal{F}\mapsto\mathcal{F}(z\otimes z)\Delta z^{-1}$. We conclude that the twist of Proposition 8 which realizes the star product of the quantum plane is unique up to a central two-coboundary. The standard twist is the unique twist with the additional property $y^{*n}=y^n$. An analogous statement is true for quantum Euclidean four-space and quantum Minkowski space.

To our knowledge, no Drinfeld twist for the Drinfeld–Jimbo deformation of a semisimple Lie algebra had so far been computed explicitly (see Ref. 15 for the Heisenberg algebra). We have circumvented this problem by reducing the algebraic questions to representation theoretic ones. Although $\mathcal{U}_\hbar(\mathrm{su}_2)$ is the simplest case conceivable, an algebraic order-by-order calculation of the twist runs quickly into overwhelming combinatorial problems.[28] An alternative approach would be the reconstruction of the twist from its representations, which would profit from the computational effort that has gone into the calculation of the q–Clebsch–Gordan coefficients.

APPENDIX: *Proof of Corollary 1*

Let throughout the proof $g\in\mathcal{U}(\mathfrak{g})[[\hbar]]$ be an arbitrary element of the $\hbar$-adic enveloping algebra.

(i) $\mathcal{F}\Delta(g)\mathcal{F}^{-1}=\Delta_\hbar(g)=\mathcal{F}'\Delta(g)\mathcal{F}'^{-1}$ implies that $\mathcal{F}^{-1}\mathcal{F}'$ commutes with $\Delta(g)$ for all g. Conversely, let $\mathcal{T}\Delta(g)\mathcal{T}^{-1}=\Delta(g)$. Then $\mathcal{F}\mathcal{T}\Delta(g)\mathcal{T}^{-1}\mathcal{F}^{-1}=\mathcal{F}\Delta(g)\mathcal{F}^{-1}=\Delta_\hbar(g)$ for all g.

(ii) By the left counit property of $\varepsilon_\hbar$ we get

$$\begin{aligned}\varepsilon(g)&=\varepsilon(\varepsilon_\hbar(g_{(1_\hbar)})g_{(2_\hbar)})\\&=\varepsilon(\varepsilon_\hbar(\mathcal{F}_{[1]})\mathcal{F}_{[2]}\varepsilon_\hbar(g_{(1)})g_{(2)}\varepsilon_\hbar(\mathcal{F}^{-1}_{[1']})\mathcal{F}^{-1}_{[2']})\\&=\varepsilon_\hbar(g_{(1)})\varepsilon(g_{(2)})\varepsilon_\hbar(\mathcal{F}_{[1]})\varepsilon(\mathcal{F}_{[2]})\varepsilon_\hbar(\mathcal{F}^{-1}_{[1']})\varepsilon(\mathcal{F}^{-1}_{[2']})\\&=\varepsilon_\hbar(g_{(1)}\varepsilon(g_{(2)}))=\varepsilon_\hbar(g).\end{aligned}\tag{A1}$$

(iii) Let us define the left and right counit constraints by $l:=\varepsilon(\mathcal{F}_{[1]})\mathcal{F}_{[2]}$ and $r:=\mathcal{F}_{[1]}\varepsilon(\mathcal{F}_{[2]})$. From the left counit property of $\varepsilon_\hbar=\varepsilon$ it follows that $g=\varepsilon(g_{(1_\hbar)})g_{(2_\hbar)}=\varepsilon(\mathcal{F}_{[1]})\mathcal{F}_{[2]}\varepsilon(g_{(1)})g_{(2)}\varepsilon(\mathcal{F}^{-1}_{[1']})\mathcal{F}^{-1}_{[2']}=lgl^{-1}$ and analogously for the right counit property $g=rgr^{-1}$. Hence, $\mathcal{T}:=\varepsilon(l)(r^{-1}\otimes l^{-1})$ is $\mathfrak{g}$-invariant. By (*i*) $\mathcal{F}':=\mathcal{F}\mathcal{T}$ is a twist with $l':=\varepsilon(\mathcal{F}'_{[1]})\mathcal{F}'_{[2]}=\varepsilon(l)\varepsilon(\mathcal{F}_{[1]}r^{-1})\mathcal{F}_{[2]}l^{-1}=\varepsilon(lr^{-1})ll^{-1}=1$, where we have used $\varepsilon(l)=\varepsilon(\mathcal{F}_{[1]}\mathcal{F}_{[2]})=\varepsilon(r)$. Analogously, we find that $r'=1$. Since $\mathcal{F}'$ is invertible, $\mathcal{F}'=\beta 1+\mathcal{O}(\hbar)$ for some complex number $\beta\neq 0$, and $1=l'=\beta+\mathcal{O}(\hbar)$ it follows that $\beta=1$.

(iv) Define $\sigma_1:=S_\hbar(\mathcal{F}_{[1]})\mathcal{F}_{[2]}$. Then

$$\begin{aligned}S_\hbar(g)\sigma_1&=S_\hbar(g_{(1)})\sigma_1 g_{(2)}S(g_{(3)})\\&=S_\hbar(\mathcal{F}_{[1]}g_{(1)(1)})\mathcal{F}_{[2]}g_{(1)(2)}S(g_{(2)})\\&=S_\hbar(g_{(1)(1_\hbar)}\mathcal{F}_{[1]})g_{(1)(2_\hbar)}\mathcal{F}_{[2]}S(g_{(2)})\\&=S_\hbar(\mathcal{F}_{[1]})\varepsilon(g_{(1)})\mathcal{F}_{[2]}S(g_{(2)})=\sigma_1 S(g),\end{aligned}\tag{A2}$$

where we have used the left coinverse property of $S_\hbar$. Analogously, defining $\sigma_2^{-1}:=\mathcal{F}^{-1}_{[1]}S_\hbar(\mathcal{F}^{-1}_{[2]})$ and using the right coinverse property of $S_\hbar$ we get $\sigma_2^{-1}S_\hbar(g)=S(g)\sigma_2^{-1}$. Since $\mathcal{F}$ is invertible, so are σ_1 and σ_2^{-1}. Thus, $S_\hbar$ and S are related by the inner automorphisms $\sigma_1 S(g)\sigma_1^{-1}=S_\hbar(g)=\sigma_2 S(g)\sigma_2^{-1}$. The antipode is surjective, so $\sigma_1^{-1}\sigma_2$ must be central. Moreover, $(\sigma_1^{-1}\sigma_2)(\sigma_1\sigma_2^{-1})=\sigma_1(\sigma_1^{-1}\sigma_2)\sigma_2^{-1}=1$, hence, $\sigma_1^{-1}\sigma_2=\sigma_2\sigma_1^{-1}$. Finally,

$$\sigma_1^{-1}=\sigma_1^{-1}S_\hbar(\mathcal{F}_{[1']}\mathcal{F}^{-1}_{[1]})\mathcal{F}_{[2']}\mathcal{F}^{-1}_{[2]}=\sigma_1^{-1}S_\hbar(\mathcal{F}^{-1}_{[1]})\sigma_1\mathcal{F}^{-1}_{[2]}=S(\mathcal{F}^{-1}_{[1]})\mathcal{F}^{-1}_{[2]},\tag{A3}$$

and, analogously, $\sigma_2=\mathcal{F}_{[1]}S(\mathcal{F}_{[2]})$.

(v) From the coassociativity of $\Delta_\hbar$ we deduce

$$\begin{aligned}[(\Delta_\hbar\otimes\mathrm{id})\circ\Delta_\hbar](g)&=\mathcal{F}_{12}(\Delta\otimes\mathrm{id})(\mathcal{F})(\Delta^{(2)}g)(\Delta\otimes\mathrm{id})(\mathcal{F}^{-1})\mathcal{F}_{12}^{-1}\\&=[(\mathrm{id}\otimes\Delta_\hbar)\circ\Delta_\hbar](g)\\&=\mathcal{F}_{23}(\mathrm{id}\otimes\Delta)(\mathcal{F})(\Delta^{(2)}g)(\mathrm{id}\otimes\Delta)(\mathcal{F}^{-1})\mathcal{F}_{23}^{-1}.\end{aligned}\tag{A4}$$

Hence, the coassociator (10) commutes with all $\Delta^{(2)}g$.

(vi) Since every bialgebra isomorphism is automatically a Hopf algebra isomorphism and since by (ii) the counit stays undeformed, we only have to consider the coproducts. Let Δ and $\Delta_\hbar$ be related by a twist $\mathcal{F}=(u\otimes u)\Delta u^{-1}$. Then $g\mapsto ugu^{-1}$ maps Δ to $\Delta_\hbar$. Conversely, assume that the two Hopf structures are isomorphic, so there is an algebra automorphism β with $\Delta_\hbar=(\beta\otimes\beta)\circ\Delta\circ\beta^{-1}$. Since $\Delta_\hbar=\Delta+\mathcal{O}(\hbar)$ we can choose $\beta=\mathrm{id}+\mathcal{O}(\hbar)$. Since $\mathfrak{g}$ is semisimple we have $H^1(\mathcal{U}(\mathfrak{g}),\mathcal{U}(\mathfrak{g}))=0$, which implies that this automorphism is inner, $\beta(g)=ugu^{-1}$. □

(Received 25 April 2003; accepted 16 June 2003)

We study the supersymmetric extensions of the Harry Dym hierarchy of equations. We obtain the susy-B extension, the doubly susy-B extension as well as the $N=1$ and the $N=2$ supersymmetric extensions for this system. The $N=2$ supersymmetric extension is particularly interesting, since it leads to new classical integrable systems in the bosonic limit. We prove the integrability of these systems through the bi-Hamiltonian formulation of integrable models and through the Lax description. We also discuss the supersymmetric extension of the Hunter–Zheng equation which belongs to the Harry Dym hierarchy of equations. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1606527]

I. INTRODUCTION

Supersymmetric extensions of a number of well-known bosonic integrable models have been studied extensively in the past. The supersymmetric Korteweg–de Vries (sKdV) equation,[1] the supersymmetric nonlinear Schrödinger (sNLS) equation[2] and the supersymmetric two-Boson (sTB) equation[3] represent just a few in this category. A simple supersymmetric covariantization of bosonic integrable models, conventionally known as the B supersymmetrization (susy-B), has also attracted a lot of interest because of the appearance of such models in string theories. We have, for instance, the B extensions of the KdV (sKdV-B) equation,[4] the supersymmetric TB (sTB-B) equation[5] and so on. Supersymmetric extensions of integrable models using a number N of Grassmann variables greater than one[6] and supersymmetric construction of dispersionless integrable models[7] have also been studied extensively in the past few years. The extended supersymmetric models are particularly interesting because, in the bosonic limit, they yield new classical integrable systems.

A classic bosonic integrable equation, the so-called Harry Dym (HD) equation,[8] has attracted much interest recently. The proprieties of this equation are discussed in detail in Ref. 9, and we simply emphasize that this equation shares the properties typical of solitonic equations, namely, it can be solved by the inverse scattering transform, it has a bi-Hamiltonian structure and infinitely many symmetries. In fact, the HD equation is one of the most exotic solitonic equations and the hierarchy to which it belongs, has a very rich structure.[10] In this hierarchy we also have nonlocal integrable equations such as the Hunter–Zheng (HZ) equation,[11] which arises in the study of massive nematic liquid crystals as well as in the study of shallow water waves. The HD equation, on the other hand, is relevant in the study of the Saffman–Taylor problem which describes the motion of a two-dimensional interface between a viscous and a nonviscous fluid.[12]

An earlier attempt to supersymmetrize the HD equation is discussed in Ref. 13. However, this study of $N=1$ supersymmetrization introduces a bosonic as well as an independent fermionic superfield, yielding a pair of coupled equations, and, consequently, is not in the conventional spirit of minimal supersymmetrization. In this paper we intend to study the question of supersymmetri-

zation of the HD hierarchy systematically. The paper is organized as follows. In Sec. II we review some of the essential results for the HD equation and its hierarchy. The simpler susy-B extension (sHD-B) and the doubly B extension (sHD-BB) of the HD hierarchy as well their bi-Hamiltonian formulation and Lax pairs are described in Sec. III. In Sec. IV we derive the $N=1$ supersymmetric extensions of the HD (sHD) equation. We find that, in this case, there exist two nontrivial $N=1$ extensions. In the case of one of them, we have a bi-Hamiltonian description (we have not found a Lax representation yet) while in the second case, we have a Lax description (we have not found a Hamiltonian structure yet that satisfies the Jacobi identity). We also describe the supersymmetric extension for the HZ equation. In Sec. V we describe the $N=2$ supersymmetrization of the HD hierarchy which yields four possibilities and we discuss their properties. We end with a brief conclusion in Sec. VI.

II. THE HARRY DYM HIERARCHY

The Harry Dym equation

$$w_t=(w^{-1/2})_{xxx}, \tag{1}$$

appears in many disguised forms, namely,

$$\begin{aligned} v_t&=\tfrac{1}{4}v^3v_{xxx},\\ u_t&=\tfrac{1}{4}u^{3/2}u_{xxx}-\tfrac{3}{8}u^{1/2}u_xu_{xx}+\tfrac{3}{16}u^{-1/2}u_x^3,\\ r_t&=(r_{xx}^{-1/2})_x, \end{aligned} \tag{2}$$

where $v=-2^{1/3}w^{-1/2}$, $u=v^2$, and $r_{xx}=w$, respectively. In this paper, as in Ref. 10, we will confine ourselves, as much as is possible, to the form of the HD equation as given in (1).

The HD equation is a member of the bi-Hamiltonian hierarchy of equations given by

$$w_t^{(n+1)}=\mathcal{D}_1\frac{\delta H_{n+1}}{\delta w}=\mathcal{D}_2\frac{\delta H_n}{\delta w}, \tag{3}$$

for $n=-2$, where the bi-Hamiltonian structures are

$$\begin{aligned} \mathcal{D}_1&=\partial^3,\\ \mathcal{D}_2&=w\partial+\partial w, \end{aligned} \tag{4}$$

and the Hamiltonians for the HD equation are

$$\begin{aligned} H_{-1}&=\int \mathrm{d}x\,(2w^{1/2}),\\ H_{-2}&=\int \mathrm{d}x(\tfrac{1}{8}w^{-5/2}w_x^2). \end{aligned} \tag{5}$$

We note here that the second structure in (4) corresponds to the centerless Virasoro algebra while

$$\mathcal{D}=\mathcal{D}_2+c\mathcal{D}_1 \tag{6}$$

represents the Virasoro algebra with a central charge c. We note also that the recursion operator following from (4), $R=\mathcal{D}_2\mathcal{D}_1^{-1}$, can be explicitly inverted to yield

$$R^{-1}=\tfrac{1}{2}\partial^3w^{-1/2}\partial^{-1}w^{-1/2}. \tag{7}$$

Also, the conserved charges

$$H_0 = -\int dx\, w,$$

$$H_0^{(1)} = \int dx\, (\partial^{-1} w), \tag{8}$$

$$H_0^{(2)} = \int dx\, (\partial^{-2} w),$$

are Casimirs (or distinguished functionals) of the Hamiltonian operator $\mathcal{D}_1$ (namely, they are annihilated by the Hamiltonian structure $\mathcal{D}_1$). As a consequence of this, it is possible to obtain, in an explicit form, equations from (3) for integers n both positive and negative, i.e., $n \in \mathbb{Z}$. As shown in Ref. 10, for $n>0$, we have three classes of nonlocal equations. However, in this paper we will only study the hierarchy associated with the local Casimir H_0 in (8). In this way, for $n=1$, we obtain from (3), with the conserved charges

$$H_1 = \int dx \frac{1}{2} (\partial^{-1} w)^2,$$

$$H_2 = \int dx \frac{1}{2} (\partial^{-2} w)(\partial^{-1} w)^2, \tag{9}$$

the Hunter–Zheng (HZ) equation

$$w_t = -(\partial^{-2} w) w_x - 2(\partial^{-1} w) w, \tag{10}$$

which is also an important equation that belongs to the Harry Dym hierarchy.

The integrability of the HD equation (1) also follows from its nonstandard Lax representation,

$$L = \frac{1}{w} \partial^2,$$

$$\frac{\partial L}{\partial t} = -2[B, L], \tag{11}$$

where

$$B = (L^{3/2})_{\geqslant 2} = w^{-3/2} \partial^3 - \tfrac{3}{4} w^{-5/2} w_x \partial^2. \tag{12}$$

Conserved charges, for $n = 1,2,3,\ldots$, are obtained from

$$H_{-(n+1)} = \operatorname{Tr} L^{(2n-1)/2}. \tag{13}$$

A Lax representation for the HZ equation (10) is also known and is given by (11) with

$$B = \tfrac{1}{4} (\partial^{-2} w) \partial + \tfrac{1}{4} \partial^{-1} (\partial^{-2} w) \partial^2. \tag{14}$$

However, in this case, the operator B is not directly related to L, and, consequently, the Lax equation is not of much direct use (in the construction of conserved charges, etc.).

III. THE susy-B HARRY DYM (sHD-B, sHD-BB) EQUATIONS

The most natural generalization of an equation to a supersymmetric one is achieved simply by working in a superspace. We note, from the HD equation (1), that by a simple dimensional analysis, we can assign the following canonical dimensions to various quantities:

$$[x]=-1, \quad [t]=3, \quad \text{and} \quad [w]=4. \tag{15}$$

The $N=1$ supersymmetric equations are best described in the superspace parametrized by the coordinates $z=(x,\theta)$, where θ represents the Grassmann coordinate ($\theta^2=0$). In this space, we can define

$$D=\frac{\partial}{\partial\theta}+\theta\frac{\partial}{\partial x}, \tag{16}$$

representing the supercovariant derivative. From (16) it follows that

$$D^2=\partial, \tag{17}$$

which determines the dimension of θ to be

$$[\theta]=-\tfrac{1}{2}. \tag{18}$$

Let us introduce the fermionic superfield

$$W=\psi+\theta w, \tag{19}$$

which has the canonical dimension

$$[W]=[\psi]=\tfrac{7}{2}. \tag{20}$$

A simple supersymmetrization of a bosonic system, conventionally known as the B supersymmetric (susy-B) extension,[4] is obtained by simply replacing the bosonic variable w, in the original equation, by

$$(DW)=w+\theta\psi', \tag{21}$$

where W represents a fermionic superfield. This leads to a manifestly supersymmetric equation and following this for the case of the equation (1), we obtain the susy-B HD (sHD-B) equation

$$W_t=\partial^2 D((DW)^{-1/2}), \tag{22}$$

where W is the fermionic superfield (19).

This system is bi-Hamiltonian with the even Hamiltonian operators

$$\begin{aligned}\mathcal{D}_1&=\partial^2,\\ \mathcal{D}_2&=D(DW)D^{-1}+D^{-1}(DW)D,\end{aligned} \tag{23}$$

and the odd Hamiltonians [which follow from (5) under the substitution $w\to(DW)$]

$$\begin{aligned}H_{-1}&=\int \mathrm{d}z\, 2(DW)^{1/2},\\ H_{-2}&=\int \mathrm{d}z\, \tfrac{1}{8}(DW)^{-5/2}(DW_x)^2.\end{aligned} \tag{24}$$

The Casimirs of $\mathcal{D}_1$ can be easily identified with the ones following from (8).

The sHD-B equation (22) has two possible nonstandard Lax representations. Let

$$L=(DW)^{-1}D^4+cW_x(DW)^{-2}D^3. \tag{25}$$

Then, it can be easily checked that the nonstandard Lax equation

$$\frac{\partial L}{\partial t}=[(L^{3/2})_{\geqslant 3},L], \tag{26}$$

leads to the sHD-B equation (22) for $c=0,-1$. Here the projection $(\ )_{\geqslant 3}$ is defined with respect to the powers of the supercovariant derivative D.

For any given integrable bosonic equation, we can also define a doubly susy-B extension as follows. Just as we defined a superspace in the case of $N=1$ supersymmetry, let us define a superspace parametrized by $z=(x,\theta_1,\theta_2)$, where θ_1,θ_2 define two Grassmann coordinates (anticomuting and nilpotent, namely, $\theta_1\theta_2=-\theta_2\theta_1$, $\theta_1^2=\theta_2^2=0$). In this case, we can define two supercovariant derivatives

$$\begin{aligned} D_1&=\frac{\partial}{\partial\theta_1}+\theta_1\frac{\partial}{\partial x},\\ D_2&=\frac{\partial}{\partial\theta_2}+\theta_2\frac{\partial}{\partial x}, \end{aligned} \tag{27}$$

which satisfy

$$D_1^2=D_2^2=\partial, \quad D_1D_2+D_2D_1=0. \tag{28}$$

Such a superspace naturally defines a system with $N=2$ supersymmetry. Let us consider a bosonic superfield, W, in this space which will have the expansion (we denote it by the same symbol as in the case of $N=1$)

$$W=w_0+\theta_1\chi+\theta_2\psi+\theta_2\theta_1w_1. \tag{29}$$

Then, we can simply replace the bosonic variable in the original equation by (D_1D_2W) which leads to the doubly susy-B extension of a given equation. For the HD equation (1), this leads to

$$W_t=\partial D_1D_2((D_1D_2W)^{-1/2}), \tag{30}$$

which defines the sHD-BB equation. This procedure can, of course, be generalized to any N extended supersymmetry and we do not pursue this any further. We simply point out that Eq. (30) is bi-Hamiltonian, as we would expect. For example, it is Hamiltonian with

$$H=\int \mathrm{d}z\,(D_1D_2W_x)^2(D_1D_2W)^{-5/2} \tag{31}$$

and

$$\begin{aligned} \mathcal{D}=&-\partial W\partial^{-2}D_1D_2-D_1D_2\partial^{-2}W\partial+D_1\partial^{-1}WD_2-D_2W\partial^{-1}D_1\\ &+D_1D_2\partial^{-1}W-WD_1D_2\partial^{-1}+D_1W\partial^{-1}D_2-D_2\partial^{-1}WD_1. \end{aligned} \tag{32}$$

The second Hamiltonian structure can also be easily obtained.

IV. THE SUPERSYMMETRIC $N=1$ HARRY DYM (sHD) AND HUNTER–ZHENG (sHZ) EQUATIONS

As we have seen, the susy-B extension of a system is a very simple supersymmetrization. However, to obtain nontrivial supersymmetrizations, we can follow one of the following two approaches. In this section, we will discuss $N=1$ supersymmetrization of the system and correspondingly, it is appropriate to work in the superspace defined in (16)–(19).

With the superfield (19) as our basic variable, the first approach is to write the most general local equation in superspace which is consistent with all canonical dimensions and which reduces to (1) in the bosonic limit. This involves a free parameter and the equation takes the form

$$\begin{aligned} W_t=\tfrac{1}{8}[&-8(5a-2)W_{xxx}(DW)^{-3/2}+2(65a-6)W_x(DW_{xx})(DW)^{-5/2}\\ &+30(5a+2)W_{xx}(DW_x)(DW)^{-5/2}-15(21a+2)W_x(DW_x)^2(DW)^{-7/2}\\ &+W\{8(5a-6)(DW_{xxx})(DW)^{-5/2}+10(a-6)W_{xxx}W_x(DW)^{-7/2}\\ &+35(6-a)W_{xx}W_x(DW_x)(DW)^{-9/2}+40(6-7a)(DW_{xx})(DW_x)(DW)^{-7/2}\\ &+105(3a-2)(DW_x)^3(DW)^{-9/2}\}], \end{aligned} \tag{33}$$

where a is the arbitrary parameter. In the case of the HD equation, it is possible to supersymmetrize the two Hamiltonian structures in (3), which is easily seen from the fact that the second Hamiltonian structure is the centerless Virasoro algebra. Thus, the supersymmetrized Hamiltonian structures follow to be

$$\begin{aligned} \mathcal{D}_1&=D\partial^2,\\ \mathcal{D}_2&=\tfrac{1}{2}[W\partial+2\partial W+(DW)D]. \end{aligned} \tag{34}$$

Requiring Eq. (33) to be bi-Hamiltonian with respect to (34), namely, requiring

$$W_t=\mathcal{D}_1\frac{\delta H_{-1}}{\delta W}=\mathcal{D}_2\frac{\delta H_{-2}}{\delta W}, \tag{35}$$

determines the parameter to be $a=6$. The Hamiltonians in (35), in this case have the forms ($\mathrm{d}z=\mathrm{d}x\,\mathrm{d}\theta$ with $\int \mathrm{d}\theta=0$ and $\int \mathrm{d}\theta\,\theta=1$),

$$\begin{aligned} H_{-1}&=\int \mathrm{d}z\,2W(DW)^{-1/2},\\ H_{-2}&=\int \mathrm{d}z\,\tfrac{1}{8}[W_x(DW_x)(DW)^{-5/2}-15WW_xW_{xx}(DW)^{-7/2}], \end{aligned} \tag{36}$$

and the $N=1$ sHD equation assumes the simple form

$$W_t=D\partial^2(2(DW)^{-1/2}-3WW_x(DW)^{-5/2}). \tag{37}$$

It is worth noting here that this equation differs from the sHD-B equation (22) in the presence of the second term inside the parentheses on the right-hand side, which vanishes in the bosonic limit. [We would like to point out parenthetically that we do not generate the sHD-B equation in this approach because of our requirement that the equation be bi-Hamiltonian with respect to the structures in (34).]

It is easy to check that the Hamiltonian H_{-1} is a Casimir of $\mathcal{D}_2$ and the conserved charge

$$H_0=-\int \mathrm{d}z\,W \tag{38}$$

is a Casimir of $\mathcal{D}_1$. Furthermore, the Hamiltonian structure $\mathcal{D}_2$ can be written in the form

$$\mathcal{D}_2=\tfrac{1}{2}(DW)^{1/2}D(1+X)(DW)^{1/2}, \tag{39}$$

where

$$X\equiv\frac{3}{2}\left(D\frac{W}{(DW)}D^{-1}+D^{-1}\frac{W}{(DW)}D\right)D, \tag{40}$$

and therefore can be formally inverted. Thus, in this case also the associated recursion operator has a formal inverse.

It can be easily checked that the following charges

$$\begin{aligned} H_1&=\int \mathrm{d}z\,\frac{1}{4}(D^{-1}W)(D^{-2}W),\\ H_2&=\int \mathrm{d}z\,\frac{1}{2}(D^{-1}W)(D^{-2}W)(D^{-3}W), \end{aligned} \tag{41}$$

are conserved and reduce to (9) in the bosonic limit. From

$$W_t=\mathcal{D}_1\frac{\delta H_2}{\delta W}=\mathcal{D}_2\frac{\delta H_1}{\delta W}, \tag{42}$$

we obtain the $N=1$ supersymmetric HZ (sHZ) equation

$$W_t=-\tfrac{3}{2}W(D^{-1}W)-W_x(D^{-3}W)-\tfrac{1}{2}(DW)(D^{-2}W). \tag{43}$$

Both the sHD and the sHZ equations are bi-Hamiltonian systems and the infinite set of commuting conserved charges can be constructed recursively. As a result, they decribe supersymmetric integrable systems.

The second approach to finding a nontrivial $N=1$ supersymmetrization of the HD equation is to start with the Lax operator in (11) and generalize it to superspace. Let us start with the most general Lax operator involving non-negative powers of D,

$$L=a_0^2D^4+\alpha_1D^3+a_1D^2+\alpha_2D+a_2, \tag{44}$$

with the identification

$$a_0=(DW)^{-1/2}, \tag{45}$$

where italic coefficients are bosonic and Greek ones are fermionic. It is easy to verify that, in this case, there are only three projections, $(\,)_{\geqslant 0,1,3}$ (with respect to powers of D), that can lead to a consistent Lax equation. Using this ansatz, we have not yet been able to obtain the sHD equation (22) using fractional powers of the Lax operator (44). The Lax pair for this system, therefore, remains an open question.

On the other hand, when

$$\alpha_1=cW_x(DW)^{-2},\quad a_1=a_2=0=\alpha_2, \tag{46}$$

where c is an arbitrary parameter, the nonstandard Lax equation

$$\frac{\partial L}{\partial t}=[(L^{3/2})_{\geqslant 3},L], \tag{47}$$

yields consistent equations only for $c=0,-1,-\frac{1}{2}$. As we have pointed out in the preceding section, for the values of the parameter, $c=0,-1$, we have the sHD-B equation. The third choice of the parameter, therefore, leads to a new nontrivial $N=1$ supersymmetrization of the HD equation. Namely, with

$$L=(DW)^{-1}D^4-\tfrac{1}{2}W_x(DW)^{-2}D^3, \tag{48}$$

the Lax equation

$$\frac{\partial L}{\partial t}=[(L^{3/2})_{\geqslant 3},L], \tag{49}$$

leads to a second $N=1$ supersymmetrization of the HD equation of the form

$$\begin{aligned} W_t=&\tfrac{1}{16}[8D^5((DW)^{-1/2})-3D(W_{xx}W_x(DW)^{-5/2})\\ &+\tfrac{3}{4}(DW_x)^2W_x(DW)^{-7/2}-\tfrac{3}{4}D^{-1}((DW_x)^3(DW)^{-7/2})]. \end{aligned} \tag{50}$$

This is manifestly a nonlocal susy generalization in the variable W which, however, is a completely local equation in the variable (DW).

Since this system of equations has a Lax description, it is integrable and the conserved charges can be calculated in a standard manner and the first few charges take the following forms:

$$\begin{aligned} H_1=&\int \mathrm{d}z\, W_x(DW_x)(DW)^{-5/2},\\ H_2=&\int \mathrm{d}z\, W_x[16(DW_{xxx})(DW)^{-7/2}-84(DW_{xx})(DW_x)(DW)^{-9/2}\\ &+77(DW_x)^3(DW)^{-11/2}], \end{aligned} \tag{51}$$

and so on. However, we have not yet succeeded in finding a Hamiltonian structure which satisfies Jacobi identity (it is clear that the Hamiltonian structure is nonlocal, since the Hamiltonian is local).

V. THE $N=2$ SUPERSYMMETRIC HARRY DYM HIERARCHY

The most natural way to discuss the $N=2$ supersymmetric extension of the HD equation is in the $N=2$ superspace introduced earlier in (27)–(29). Looking at the bosonic superfield W in (29), we note that it has two bosonic components as well as two fermionic components. In the bosonic limit, when we set the fermions to zero, the $N=2$ equation would reduce to two bosonic equations. Since we have only the single HD equation (1) to start with, the construction of such a system is best carried out in the Lax formalism. This also brings out the interest in such extended supersymmetric systems, namely, they lead to new bosonic integrable systems in the bosonic limit.

As in (44), let us consider the most general $N=2$ Lax operator which contains differential operators in this superspace of the following form (taking a more general Lax involving only differential operators does not lead to equations which reduce to the HD equation):

$$\begin{aligned} L=&W^{-1}\partial^2+(D_1W^{-1})(\kappa_1D_1+\kappa_2D_2)\partial+(D_2W^{-1})(\kappa_3D_1+\kappa_4D_2)\partial\\ &+(\kappa_5(D_1D_2W)W^{-2}+\kappa_6(D_1W)(D_2W)W^{-3})D_1D_2, \end{aligned} \tag{52}$$

where $\kappa_i, i=1,2,\ldots,6$ are arbitrary constant parameters. The $N=2$ supersymmetry corresponds to an internal $O(2)$ invariance that rotates $\theta_1\to\theta_2,\theta_2\to-\theta_1$ and correspondingly $D_1\to D_2, D_2\to -D_1$ (thereby rotating the fermion components of the superfield into each other). This invariance, imposed on the Lax operator, identifies

$$\kappa_4=\kappa_1, \quad \kappa_3=-\kappa_2. \tag{53}$$

Using the computer algebra program REDUCE[14] and the special package SUSY2,[15] we are able to study systematically the hierarchy of equations following from the Lax equation

$$\frac{\partial L}{\partial t}=[(L^{3/2})_{\geqslant 2},L]. \tag{54}$$

Here, the projection [which is the highest consistent projection as is also the case with the bosonic HD equation in (12)] is understood as follows. Let us recall that a general pseudodifferential operator in $N=2$ superspace has the form

$$P=\sum_{n=-\infty}^{n=\infty}(P_0^n+P_1^nD_1+P_2^nD_2+P_3^nD_1D_2)\partial^n. \tag{55}$$

For such a pseudodifferential operator, the projection in (54) is defined as

$$P_{\geqslant 2}=P_3^0D_1D_2+(P_1^1D_1+P_2^1D_2+P_3^1D_1D_2)\partial+\sum_{n\geqslant 2}(P_0^n+P_1^nD_1+P_2^nD_2+P_3^nD_1D_2)\partial^n. \tag{56}$$

The consistency of the equation (54) leads to four possible solutions for the values of the arbitrary parameters

(1) $\kappa_1=\kappa_2=\kappa_5=\kappa_6=0$,
(2) $\kappa_2=0,\ \kappa_1=\kappa_5=-\kappa_6/2=1$,
(3) $\kappa_2=\kappa_5=\kappa_6=0,\ \kappa_1=\frac{1}{2}$,
(4) $\kappa_2=0,\ \kappa_1=\kappa_5=\frac{1}{2},\ \kappa_6=\frac{3}{4}$.

We will now discuss the various cases separately in some detail.

The first and the second cases can be discussed together since they lead to the same dynamical equation. Namely, in this case, the two Lax operators take the forms

$$\begin{aligned} L^{(1)}&=W^{-1}\partial^2,\\ L^{(2)}&=W^{-1}\partial^2+(D_1W^{-1})D_1\partial+(D_2W^{-1})D_2\partial-(D_1D_2W^{-1})D_1D_2\\ &=-D_1D_2W^{-1}D_1D_2. \end{aligned} \tag{57}$$

It can be checked that both these Lax operators lead to the same dynamical equation which is nothing other than the sHD-BB equations we have discussed earlier and, therefore, we do not study this any further.

For the third choice of parameters, the Lax operator can be written in the simple form

$$\begin{aligned} L^{(3)}&=W^{-1}\partial^2+\tfrac{1}{2}((D_1W^{-1})D_1+(D_2W^{-1})D_2)\partial\\ &=\tfrac{1}{2}(D_1W^{-1}D_1+D_2W^{-1}D_2)\partial. \end{aligned} \tag{58}$$

The Lax equation (54), in this case, leads to a nontrivial $N=2$ supersymmetric HD equation of the form

$$\begin{aligned} W_t=\tfrac{1}{64}[&2(W^{-1/2})_{xxx}-12(D_1W_{xx})(D_1W)W^{-5/2}-12(D_2W_{xx})(D_2W)W^{-5/2}\\ &+36(D_1W_x)(D_1W)W_xW^{-7/2}+36(D_2W_x)(D_2W)W_xW^{-7/2}\\ &+6(D_1W)(D_2W)(D_1D_2W_x)W^{-7/2}-9(D_1W)(D_2W)(D_1D_2W)W_xW^{-9/2}]. \end{aligned} \tag{59}$$

In the bosonic sector, where we set all the fermions to zero so that [see (29)]

$$W = w_0 + \theta_2\theta_1 w_1, \tag{60}$$

the equation (59) reduces to

$$\begin{aligned} w_{0,t} &= \tfrac{1}{2}(w_0^{-1/2})_{xxx}, \\ w_{1,t} &= \tfrac{1}{64}[-16w_{1,xxx}w_0^{-3/2} + 96w_{1,xx}w_{0,x}w_0^{-5/2} + 72w_{1,x}w_{0,xx}w_0^{-5/2} - 258w_{1,x}w_{0,x}^2w_0^{-7/2} \\ &\quad - 6w_{1,x}w_1^2w_0^{-7/2} + 9w_1^3w_{0,x}w_0^{-9/2} - 108w_1w_{0,xx}w_{0,x}w_0^{-9/2} + 219w_1w_{0,x}^3w_0^{-9/2}]. \end{aligned} \tag{61}$$

The first of the equations in (61) is, of course, the HD equation (1), but is decoupled from the second component. Consequently, even though this set of equations represents a new integrable system, it is not very interesting. Let us note that we can reduce the $N=2$ supersymmetry of this system to $N=1$ supersymmetry in the following way. Let us define

$$W(x,\theta_1,\theta_2) = U(x,\theta_1) + \theta_2 F(x,\theta_1), \tag{62}$$

and set the fermionic superfield $F(x,\theta_1)=0$. This would, therefore, make the superfield W independent of the Grassmann coordinate θ_2 leaving us with $N=1$ supersymmetry. Under such a reduction, it is straightforward to see that the Lax operator (58) and the equation (59) go over to the ones in (48) and (up to multiplicative factors) the corresponding equation (50) with the identification

$$\theta_1 = \theta, \quad U(x,\theta_1) = (DW(x,\theta)). \tag{63}$$

The conserved charges for this system can be obtained from the Lax operator $L^{(3)}$ in a standard manner, but we do not go into the details of this.

The fourth case is probably the most interesting of all. Here, the Lax operator takes the form

$$\begin{aligned} L^{(4)} &= W^{-1}\partial^2 + \tfrac{1}{2}((D_1W^{-1})D_1 + (D_2W^{-1})D_2)\partial - W^{-1/2}(D_1D_2W^{-1/2})D_1D_2 \\ &= -(W^{-1/2}D_1D_2)^2. \end{aligned} \tag{64}$$

Interestingly enough, this Lax operator possesses two nontrivial square roots, namely,

$$\begin{aligned} L_1^{1/2} &= iW^{-1/2}D_1D_2, \\ L_2^{1/2} &= W^{-1/2}\partial + \tfrac{1}{2}[(D_1W^{-1/2})D_1 + (D_2W^{-1/2})D_2 - (W^{-1/2})_x] + \cdots. \end{aligned} \tag{65}$$

We note here that a similar situation also arises in the study of the $N=2$ sKdV hierarchy[16] (for the case of the parameter $a=4$). In such a case, the general hierarchy of equations can be obtained from the Lax equation

$$\frac{\partial L}{\partial t_n} = [(L_1^{n/2}L_2^{1/2})_{\geqslant 2}, L], \tag{66}$$

where $n=0,1,2,\ldots$. For example, the first two flows of the hierarchy take the following forms:

$$\begin{aligned} W_{t_1} &= \tfrac{1}{8}[-4(D_1D_2W_x)W^{-1} + 6(D_1D_2W)W_xW^2 + 6((D_1W)(D_2W_x) - 6(D_2W)(D_1W_x))W^{-2} \\ &\quad - 15(D_1W)(D_2W)W_xW^{-3}], \end{aligned} \tag{67}$$

$$
\begin{aligned}
W_{t_2} = \tfrac{1}{16}[&8(W^{-1/2})_{xxx} - 6(D_1D_2W)(D_1D_2W_x)W^{-5/2} \\
&+ 9(D_1D_2W)^2W_xW^{-7/2} + 3((D_1W)(D_1W_{xx}) + (D_2W)(D_2W_{xx}))W^{-5/2} \\
&- 9((D_1W)(D_1W_x) + (D_2W)(D_2W_x))W_xW^{-7/2} + 9((D_1W)(D_2W)(D_1D_2W))_xW^{-7/2} \\
&- 36(D_1W)(D_2W)(D_1D_2W)W_xW^{-9/2}] .
\end{aligned}
$$

In the bosonic sector, the second equation in (67) gives

$$
\begin{aligned}
w_{0,t_2} &= \tfrac{1}{16}[8(w_0^{-1/2})_{xxx} - 6w_{1,x}w_1w_0^{-5/2} + 9w_1^2w_{0,x}w_0^{-7/2}], \\
w_{1,t_2} &= \tfrac{1}{32}[-8w_{1,xxx}w_0^{-3/2} + 48(w_{1,x}w_{0,x})_xw_0^{-5/2} - 144w_{1,x}w_{0,x}^2w_0^{-7/2} - 6w_{1,x}w_1^2w_0^{-7/2} \\
&\quad + 9w_1^3w_{0,x}w_0^{-9/2} + 12w_1w_{0,xxx}w_0^{-5/2} - 126w_1w_{0,xx}w_{0,x}w_0^{-7/2} + 177w_{0,x}^3w_1w_0^{-9/2}].
\end{aligned}
\tag{68}
$$

This is a new bosonic system of coupled equations, which reduces on setting $w_1 = 0$ to the HD equation and is integrable.

The conserved charges for this last case of $N=2$ supersymmetrization can be constructed as follows:

$$
\begin{aligned}
H_1 &= \int \mathrm{dz}\ \ \mathrm{sRes}\, L_2^{1/2} = \int \mathrm{dz}\,(D_1W)(D_2W)W^{-5/2}, \\
H_2 &= \int \mathrm{dz}\ \mathrm{sRes}(L_1^{1/2}L_2^{1/2}) \\
&= \int \mathrm{dz}[3(D_1D_2W)^2W^{-3} + 3W_x^2W^{-2} + 2((D_1W)(D_1W_x) \\
&\quad + (D_2W)(D_2W_x))W^{-3} + (D_1W)(D_2W)(D_1D_2W)W^{-4}], \\
H_3 &= \int \mathrm{dz}\ \mathrm{sRes}\, L_2^{3/2} = \int \mathrm{dz}[128(D_1D_2W_x)W_xW^{-7/2} - 40(D_1D_2W)^3W^{-9/2} + \cdots],
\end{aligned}
\tag{69}
$$

where $\mathrm{dz} = \mathrm{d}x\,\mathrm{d}\theta_1\,\mathrm{d}\theta_2$ and "sRes" is defined as the coefficient of the $D_1D_2\partial^{-1}$ term in the pseudodifferential operator. We can also perform the $N=1$ reduction of this system. Requiring that the superfield W has no dependence on θ_2, it is clear from the form of the Lax operator in (64) that it reduces to the one involving the second $N=1$ supersymmetrization (just as $L^{(3)}$ does).

VI. CONCLUSIONS

In this paper, we have studied the question of supersymmetrization of the Harry Dym hierarchy systematically. We have used the simpler B supersymmetrization to derive the sHD-B and sHD-BB systems. The analysis of the nontrivial $N=1$ supersymmetrization leads to two such integrable systems. One has a natural bi-Hamiltonian description for which we have not been able to find the Lax description. On the other hand, the second has a natural Lax description for which we have not yet found a Hamiltonian structure that satisfies the Jacobi identity. Both these systems are integrable. The $N=2$ supersymmetrization from the Lax approach yields four possible Lax operators. Two of these describe the sHD-BB system while the other two give nontrivial $N=2$ supersymmetric extensions. In the bosonic limit, one of them leads to the HD equation decoupled from the second component while the other genuinely gives a coupled two component system of equations that is integrable.

Given an irreducible representation of a group G, we show that all the covariant positive operator valued measures based on G/Z, where Z is a central subgroup, are described by trace class, trace one positive operators. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1598277]

I. INTRODUCTION

Usually, the observables in quantum mechanics are represented by self-adjoint operators that are in one-to-one correspondence with projection valued operator measures. However, in many applications (as, for example, quantum optics, quantum theory of measurement, quantization of classical dynamical systems, and localization observables of relativistic massless particles) this characterization is restrictive and one has to consider a more general description by means of positive operator valued measures (for a review of the applications in physics, see Refs. 3, 6, and 9–11).

In particular, it is of interest both in quantum mechanics and in signal analysis to describe positive operator valued measures that are covariant with respect to a unitary representation of a *symmetry* group G (for a review see Ref. 1 and references therein). In this framework, it is well known[4,13] that, given a square-integrable irreducible representation π of a unimodular group G and a trace class, trace one positive operator T, the family of operators

$$Q(X)=\int_X \pi(g)T\pi(g^{-1})d\mu_G(g)$$

defines a positive operator valued measure (POVM) on G covariant with respect to π (μ_G is a Haar measure on G). In this article, we prove that all the covariant POVMs are of the above form for some T. More precisely, we show this result for non-unimodular groups and for POVMs based on the quotient space G/Z, where Z is a central subgroup.

Let G be a locally compact second countable topological group and Z be a central closed subgroup. We denote by G/Z the quotient group and by $\dot{g}\in G/Z$ the equivalence class of $g\in G$. If $a\in G$ and $\dot{g}\in G/Z$, we let $a[\dot{g}]=\dot{a}\dot{g}$ be the natural action of a on the point $\dot{g}$.

Let $\mathcal{B}(G/Z)$ be the Borel σ-algebra of G/Z. We fix a left Haar measure $\mu_{G/Z}$ on G/Z. Moreover, we denote by Δ the modular function of G and of G/Z.

[c)]Electronic mail: toigo@ge.infn.it

By *representation* we mean a strongly continuous unitary representation of G acting on a complex and separable Hilbert space, with scalar product $\langle \cdot,\cdot \rangle$ linear in the first argument.

Let $(\pi,\mathcal{H})$ be a representation of G. A positive operator valued measure Q defined on G/Z and such that

(1) $Q(G/Z)=I$;

(2) for all $X \in \mathcal{B}(G/Z)$,

$$\pi(g)Q(X)\pi(g^{-1})=Q(g[X]) \quad \forall g \in G$$

is called π-*covariant* POVM on G/Z.

Given a representation $(\sigma,\mathcal{K})$ of Z, we denote by $(\lambda^{\sigma},P^{\sigma},\mathcal{H}^{\sigma})$ the imprimitivity system unitarily induced by σ. We recall that $\mathcal{H}^{\sigma}$ is the Hilbert space of (μ_G-equivalence classes of) functions $f:G\to\mathcal{K}$ such that

(1) f is weakly measurable;

(2) for all $z \in Z$,

$$f(gz)=\sigma(z^{-1})f(g) \quad \forall g \in G;$$

(3)

$$\int_{G/Z} \|f(g)\|^2_{\mathcal{K}} \, \mathrm{d}\mu_{G/Z}(\dot{g}) < +\infty$$

with scalar product

$$\langle f_1,f_2 \rangle_{\mathcal{H}^{\sigma}} = \int_{G/Z} \langle f_1(g),f_2(g) \rangle_{\mathcal{K}} \mathrm{d}\mu_{G/Z}(\dot{g}).$$

The representation λ^{σ} acts on $\mathcal{H}^{\sigma}$ as

$$(\lambda^{\sigma}(a)f)(g) := f(a^{-1}g), \quad g \in G,$$

for all $a \in G$. The projection valued measure P^{σ} is given by

$$(P^{\sigma}(X)f)(g) := \chi_X(\dot{g})f(g), \quad g \in G,$$

for all $X \in \mathcal{B}(G/Z)$, where χ_X is the characteristic function of the set X.

We recall some basic properties of square integrable representations modulo a central subgroup. We refer to Ref. 2 for G unimodular and Z arbitrary and to Ref. 7 for G non-unimodular and $Z=\{e\}$. Combining these proofs, one obtains the following result.

Proposition 1: Let $(\pi,\mathcal{H})$ be an irreducible representation of G and γ be the character of Z such that

$$\pi(z)=\gamma(z)I_{\mathcal{H}} \quad \forall z \in Z.$$

The following facts are equivalent:

(1) there exists a vector $u \in \mathcal{H}$ such that

$$0 < \int_{G/Z} |\langle u,\pi(g)u \rangle_{\mathcal{H}}|^2 \mathrm{d}\mu_{G/Z}(\dot{g}) < +\infty; \tag{1}$$

(2) $(\pi,\mathcal{H})$ is a subrepresentation of $(\lambda^{\gamma},\mathcal{H}^{\gamma})$.

If either of the above conditions is satisfied, there exists a self-adjoint injective positive operator C such that

$$\pi(g)C=\Delta(g)^{-1/2}C\pi(g) \quad \forall g \in G,$$

and an isometry $\Sigma:\mathcal{H}\otimes\mathcal{H}^*\to\mathcal{H}^\gamma$ *such that*

(1) for all $u\in\mathcal{H}$ *and* $v\in\mathrm{dom}\ C$

$$\Sigma(u\otimes v^*)(g)=\langle u,\pi(g)Cv\rangle_{\mathcal{H}},\quad g\in G;$$

(2) for all $g\in G$

$$\Sigma(\pi(g)\otimes I_{\mathcal{H}^*})=\lambda(g)\Sigma;$$

(3) the range of Σ *is the isotypic space of* π *in* $\mathcal{H}^\gamma$.

If Eq. (1) is satisfied, $(\pi,\mathcal{H})$ is called *square-integrable modulo Z*. The square of C is called *formal degree* of π (see Ref. 7). In particular, when G is unimodular, C is a multiple of the identity.

II. CHARACTERIZATION OF *Q*

We fix an irreducible representation $(\pi,\mathcal{H})$ of G and let γ be the character such that $\pi|_Z=\gamma I_{\mathcal{H}}$. The following theorem characterizes all the POVM on G/Z covariant with respect to π in terms of positive trace one operators on $\mathcal{H}$.

Theorem 2: *The irreducible representation* π *admits a covariant POVM based on* G/Z *if and only if* π *is square-integrable modulo* Z.

In this case, let C *be the square root of the formal degree of* π. *There exists a one-to-one correspondence between covariant POVMs* Q *on* G/Z *and positive trace one operators* T *on* $\mathcal{H}$ *given by*

$$\langle Q_T(X)v,u\rangle_{\mathcal{H}}=\int_X\langle TC\pi(g^{-1})v,C\pi(g^{-1})u\rangle_{\mathcal{H}}d\mu_{G/Z}(\dot g)\tag{2}$$

for all $u,v\in\mathrm{dom}\ C$ *and* $X\in\mathcal{B}(G/Z)$.

Proof: Let Q be a π-covariant POVM. According to the generalized imprimitivity theorem[5] there exists a representation $(\sigma,\mathcal{K})$ of Z and an isometry $W:\mathcal{H}\to\mathcal{H}^\sigma$ intertwining π with λ^σ such that

$$Q(X)=W^*P^\sigma(X)W$$

for all $X\in\mathcal{B}(G/Z)$.

Define the following closed invariant subspace of $\mathcal{K}$

$$\mathcal{K}_\gamma=\{v\in\mathcal{K}|\sigma(z)v=\gamma(z)v\}.$$

Let σ_1 and σ_2 be the restrictions of σ to $\mathcal{K}_\gamma$ and $\mathcal{K}_\gamma^\perp$, respectively. The induced imprimitivity system $(\lambda^\sigma,P^\sigma,\mathcal{H}^\sigma)$ decomposes into the orthogonal sum

$$\mathcal{H}^\sigma=\mathcal{H}^{\sigma_1}\oplus\mathcal{H}^{\sigma_2}.$$

If $f\in\mathcal{H}^\sigma$ and $z\in Z$, then

$$(\lambda^\sigma(z)f)(g)=f(z^{-1}g)=f(gz^{-1})=\sigma(z)f(g),\quad g\in G.$$

On the other hand, if $u\in\mathcal{H}$ and $z\in Z$, we have

$$(\lambda^\sigma(z)Wu)(g)=(W\pi(z)u)(g)=\gamma(z)(Wu)(g),\quad g\in G.$$

It follows that $(Wu)(g)\in\mathcal{K}_\gamma$ for μ_G—almost every $g\in G$, that is, $Wu\in\mathcal{H}^{\sigma_1}$. So it is not restrictive to assume that

$$\sigma = \gamma I_{\mathcal{K}}$$

for some Hilbert space $\mathcal{K}$. Clearly, we have

$$\mathcal{H}^{\sigma} = \mathcal{H}^{\gamma} \otimes \mathcal{K}, \quad \lambda^{\sigma} = \lambda^{\gamma} \otimes I_{\mathcal{K}}.$$

In particular, π is a subrepresentation of λ^{γ}, hence it is square-integrable modulo Z.

Due to Proposition 1, the operator $W' = (\Sigma^* \otimes I_{\mathcal{K}})W$ is an isometry from $\mathcal{H}$ to $\mathcal{H} \otimes \mathcal{H}^* \otimes \mathcal{K}$ such that

$$W'\pi(g) = (\pi(g) \otimes I_{\mathcal{H}^* \otimes \mathcal{K}})W' \quad \forall g \in G.$$

Since π is irreducible, given Hilbert spaces $\mathcal{H}_1$ and $\mathcal{H}_2$, a standard result asserts that $\mathcal{C}(\pi \otimes I_{\mathcal{H}_1}, \pi \otimes I_{\mathcal{H}_2}) = I_{\mathcal{H}} \otimes \mathcal{L}(\mathcal{H}_1, \mathcal{H}_2)$. In the present case, this means that

$$W'u = u \otimes B \quad \forall u \in \mathcal{H}$$

for some $B \in \mathcal{H}^* \otimes \mathcal{K}$. Since W' is isometric, B has Hilbert–Schmidt norm 1.

Let $(e_i)_{i \geqslant 1}$ be an orthonormal basis of $\mathcal{H}$ such that $e_i \in \operatorname{dom} C$. Then

$$B = \sum_i e_i^* \otimes k_i,$$

where $k_i \in \mathcal{K}$ and $\Sigma_i \|k_i\|_{\mathcal{K}}^2 = 1$.

If $u \in \operatorname{dom} C$, one has that

$$\begin{aligned}(Wu)(g) &= [(\Sigma \otimes I_{\mathcal{K}})(u \otimes B)](g) \\ &= \sum_i \Sigma(u \otimes e_i^*)(g) \otimes k_i \\ &= \sum_i \langle u, \pi(g) C e_i \rangle_{\mathcal{H}} \otimes k_i \\ &= \sum_i \langle C\pi(g^{-1})u, e_i \rangle_{\mathcal{H}} \otimes k_i \\ &= \sum_i (e_i^* \otimes k_i)(C\pi(g^{-1})u),\end{aligned}$$

where the series converges in $\mathcal{H}^{\sigma}$. On the other hand, for all $g \in G$ the series $\Sigma_i (e_i^* \otimes k_i) \times (C\pi(g^{-1})u)$ converges to $BC\pi(g^{-1})u$, where we identify $\mathcal{H}^* \otimes \mathcal{K}$ with the space of Hilbert–Schmidt operators. By uniqueness of the limit,

$$(Wu)(g) = BC\pi(g^{-1})u, \quad g \in G.$$

If $u, v \in \operatorname{dom} C$, the corresponding covariant POVM is given by

$$\begin{aligned}\langle Q(X)v, u \rangle_{\mathcal{H}} &= \langle P^{\sigma}(X)Wv, Wu \rangle_{\mathcal{H}^{\sigma}} \\ &= \int_{G/Z} \chi_X(\dot{g}) \langle BC\pi(g^{-1})v, BC\pi(g^{-1})u \rangle_{\mathcal{H}} \mathrm{d}\mu_{G/Z}(\dot{g}) \\ &= \int_X \langle TC\pi(g^{-1})v, C\pi(g^{-1})u \rangle_{\mathcal{H}} \mathrm{d}\mu_{G/Z}(\dot{g}),\end{aligned}$$

where

$$T := B^* B$$

is a positive trace class trace one operator on $\mathcal{H}$.

Conversely, assume that π is square integrable and let T be a positive trace class trace one operator on $\mathcal{H}$. Then

$$B := \sqrt{T}$$

is a (positive) operator belonging to $\mathcal{H}^* \otimes \mathcal{H}$ such that $B^* B = T$ and $\|B\|_{\mathcal{H}^* \otimes \mathcal{H}} = 1$. The operator W defined by

$$Wv := (\Sigma \otimes I_{\mathcal{H}})(v \otimes B) \quad \forall v \in \mathcal{H}$$

is an isometry intertwining $(\pi, \mathcal{H})$ with the representation $(\lambda^\sigma, \mathcal{H}^\sigma)$, where

$$\sigma = \gamma I_{\mathcal{H}}.$$

Define Q_T by

$$Q_T(X) = W^* P^\sigma(X) W, \quad X \in \mathcal{B}(G/Z).$$

With the same computation as above, one has that

$$\langle Q_T(X)u, v\rangle_{\mathcal{H}} = \int_X \langle TC\pi(g^{-1})u, C\pi(g^{-1})v\rangle_{\mathcal{H}} \mathrm{d}\mu_{G/Z}(\dot{g})$$

for all $u, v \in \mathrm{dom}\ C$.

Finally, we show that the correspondence $T \mapsto Q_T$ is injective. Let T_1 and T_2 be positive trace one operators on $\mathcal{H}$, with $Q_{T_1} = Q_{T_2}$. Set $T = T_1 - T_2$. Since π is strongly continuous, for all $u, v \in \mathrm{dom}\ C$ the map

$$G/Z \ni \dot{g} \mapsto \langle TC\pi(g^{-1})v, C\pi(g^{-1})u\rangle_{\mathcal{H}} = \Delta(\dot{g})^{-1} \langle T\pi(g^{-1})Cv, \pi(g^{-1})Cu\rangle_{\mathcal{H}} \in \mathbb{C}$$

is continuous. Since

$$\int_X \langle TC\pi(g^{-1})v, C\pi(g^{-1})u\rangle_{\mathcal{H}} \mathrm{d}\mu_{G/Z}(\dot{g}) = \langle [Q_{T_1}(X) - Q_{T_2}(X)]v, u\rangle_{\mathcal{H}} = 0$$

for all $X \in \mathcal{B}(G/Z)$, we have

$$\langle TC\pi(g^{-1})v, C\pi(g^{-1})u\rangle_{\mathcal{H}} = 0 \quad \forall \dot{g} \in G/Z.$$

In particular,

$$\langle TCv, Cu\rangle_{\mathcal{H}} = 0,$$

so that, since C has dense range, $T = 0$. ■

Remark 3: Scutaru shows in Ref. 13 that there exists a one-to-one correspondence between positive trace one operators on $\mathcal{H}$ and covariant POVMs Q based on G/Z with the property

$$\mathrm{tr} Q(K) < +\infty \tag{3}$$

for all compact sets $K \subset G/Z$. Theorem 2 shows that every covariant POVM Q based on G/Z shares property (3).

Remark 4: If G is unimodular, then $C=\lambda I$, with $\lambda>0$, and one can normalize $\mu_{G/Z}$ so that $\lambda=1$. *Hence,*

$$Q_T(X)=\int_X \pi(g)T\pi(g^{-1})\mathrm{d}\mu_{G/Z}(\dot{g}) \quad \forall X\in\mathcal{B}(G/Z),$$

the integral being understood in the weak sense.

Remark 5: If $T=\eta^*\otimes\eta$, with $\eta\in\mathrm{dom}\ C$ and $\|\eta\|_{\mathcal{H}}=1$, we observe that

$$\begin{aligned}\langle Q_T(X)v,u\rangle_{\mathcal{H}}&=\int_X\langle C\pi(g^{-1})v,\eta\rangle_{\mathcal{H}}\langle\eta,C\pi(g^{-1})u\rangle_{\mathcal{H}}d\mu_{G/Z}(\dot{g})\\&=\int_X\langle v,\pi(g)C\eta\rangle_{\mathcal{H}}\langle\pi(g)C\eta,u\rangle_{\mathcal{H}}d\mu_{G/Z}(\dot{g})\\&=\int_X(W_{C\eta}v)(g)\overline{(W_{C\eta}u)(g)}d\mu_{G/Z}(\dot{g})\end{aligned}$$

for all $u,v\in\mathrm{dom}\ C$, where $W_{C\eta}:\mathcal{H}\to\mathcal{H}^\gamma$ is the wavelet operator associated to the vector $C\eta$. In particular,

$$Q_T(X)=W_{C\eta}^*P^\gamma(X)W_{C\eta}.$$

III. TWO EXAMPLES

A. The Heisenberg group

In quantum mechanics, the study of positive operator valued measures covariant with respect to suitable representations of the Heisenberg group is motivated by two problems. They appear as a natural tool in the construction of coherent states associated with the quantum harmonic oscillator (see, for example, Ref. 1). Moreover, they describe the possible localization observables on the phase space of a one dimensional classical particle (for an account, see Ref. 12).

The Heisenberg group H is $\mathbb{R}^3$ with composition law

$$(p,q,t)(p',q',t')=\left(p+p',q+q',t+t'+\frac{pq'-qp'}{2}\right).$$

The center of H is

$$Z=\{(0,0,t)|t\in\mathbb{R}\},$$

and the quotient group G/Z is isomorphic to the Abelian group $\mathbb{R}^2$, with projection

$$q(p,q,t)=(p,q).$$

The Heisenberg group is unimodular with Haar measure

$$\mathrm{d}\mu_{G/Z}(p,q)=\frac{1}{2\pi}\mathrm{d}p\mathrm{d}q.$$

Given an infinite dimensional Hilbert space $\mathcal{H}$ and an orthonormal basis $(e_n)_{n\geqslant 1}$, let a, a^* be the corresponding ladder operators. Define

$$Q = \text{closure of } \frac{1}{\sqrt{2}}(a + a^*),$$

$$P = \text{closure of } \frac{1}{\sqrt{2}i}(a - a^*),$$

It is known[4,8] that the representation

$$\pi(p,q,t) = e^{i(t + pQ + qP)}$$

is square-integrable modulo Z and $C = 1$.

It follows from Theorem 2 that *any* π-covariant POVM Q based on $\mathbb{R}^2$ is of the form

$$Q(X) = \frac{1}{2\pi} \int_X e^{i(pQ+qP)} T e^{-i(pQ+qP)} \mathrm{d}p\, \mathrm{d}q, \quad X \in \mathcal{B}(\mathbb{R}^2),$$

for some positive trace one operator on $\mathcal{H}$. Up to our knowledge, the complete classification of the POVMs on $\mathbb{R}^2$ covariant with respect to the Heisenberg group has been an open problem till now.

B. The $ax+b$ group

The $ax+b$ group is the semidirect product $G = \mathbb{R} \times' \mathbb{R}_+$, where we regard $\mathbb{R}$ as additive group and $\mathbb{R}_+$ as multiplicative group. The composition law is

$$(b,a)(b',a') = (b + ab', aa').$$

The group G is nonunimodular with left Haar measure

$$\mathrm{d}\mu_G(b,a) = a^{-2} \mathrm{d}b\, \mathrm{d}a$$

and modular function

$$\Delta(b,a) = \frac{1}{a}.$$

Let $\mathcal{H} = L^2((0,+\infty), \mathrm{d}x)$ and $(\pi^+, \mathcal{H})$ be the representation of G given by

$$[\pi^+(b,a)f](x) = a^{1/2} e^{2\pi i b x} f(ax), \quad x \in (0,+\infty).$$

It is known[8] that π is square-integrable, and the square root of its formal degree is

$$(Cf)(x) = \Delta(0,x)^{1/2} f(x) = x^{-1/2} f(x), \quad x \in (0,+\infty),$$

acting on its natural domain.

By means of Theorem 2 every POVM based on G and covariant with respect to π^+ is described by a positive trace one operator T according to Eq. (2). Explicitly, let $(e_i)_{i \geqslant 1}$ be an orthonormal basis of eigenvectors of T and $\lambda_i \geqslant 0$ be the corresponding eigenvalues. If $u \in L^2((0,+\infty), \mathrm{d}x)$ is such that $x^{-1/2} u \in L^2((0,+\infty), \mathrm{d}x)$, the π^+-covariant POVM corresponding to T is given by

$$\langle Q_T(X)u,u\rangle_{\mathcal{H}} = \int_X \langle TC\pi^+(g^{-1})u, C\pi^+(g^{-1})u\rangle_{\mathcal{H}} \mathrm{d}\mu_G(g)$$

$$= \int_X \sum_i \lambda_i |\langle C\pi^+(g^{-1})u, e_i\rangle_{\mathcal{H}}|^2 \mathrm{d}\mu_G(g)$$

$$= \sum_i \lambda_i \int_X \left| \int_{\mathbb{R}_+} x^{-1/2} a^{-1/2} e^{-2\pi i b x/a} u\left(\frac{x}{a}\right) \overline{e_i(x)} \mathrm{d}x \right|^2 a^{-2} \mathrm{d}b\,\mathrm{d}a.$$

Renormalization for the Harper equation for quadratic irrationals

J. Dalton and B. D. Mestel[a)]
School of Mathematical Sciences, University of Exeter, Exeter, EX4 4QE, United Kingdom

(Received 29 May 2002; accepted 22 June 2003)

In this paper, we use renormalization methods to study self-similarity in the fluctuations η_i of the Harper equation in the strong-coupling limit for quadratic irrationals of the form $(\sqrt{a^2+4}-a)/2$ for $a\in\mathbb{N}$. Using the decimation method, we obtain a second-order functional recurrence which we prove rigorously has an entire fixed point. This fixed point governs the scaling of the fluctuations η_i in the strong-coupling limit. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1605819]

I. INTRODUCTION

The Harper equation (also known as the almost Mathieu equation),

$$\psi_{i+1}+\psi_{i-1}+2\lambda\cos(2\pi(i\omega+\phi))\psi_i=E\psi_i, \tag{1.1}$$

is an important quantum mechanical model that has been studied extensively in the literature. (For a review we refer the reader to Refs. 10 and 9.) In Eq. (1.1) E is the eigenvalue corresponding to the eigenfunction ψ_i defined on the one-dimensional integer lattice indexed by $i\in\mathbb{Z}$. For $\lambda>1$, Eq. (1.1) has exponentially decaying eigenfunctions ψ_i so that we write $\psi_i=e^{-\gamma|i|}\eta_i$, where $\gamma=\log\lambda$ (the Lyapunov exponent) (see Ref. 1), and η_i is the fluctuation at site i. In terms of η_i, the Harper equation becomes, for $i>0$,

$$\lambda^{-1}\eta_{i+1}+\lambda\eta_{i-1}+2\lambda\cos(2\pi(i\omega+\phi))\eta_i=E\eta_i. \tag{1.2}$$

In this paper we use renormalization methods to study self-similarity in the fluctuations η_i in the strong-coupling limit $\lambda\to\infty$, $E\sim 2\lambda$, for the case of $\omega=(\sqrt{a^2+4}-a)/2$, $a\in\mathbb{N}$, with the phase $\phi=0$. This follows from the work of Ketoja and Satija[3] in which the golden mean case, $\omega=(\sqrt{5}-1)/2)$, is analyzed heuristically. Rigorous results in that case were obtained by Mestel, Osbaldestin, and Winn.[4] General Farey paths were considered by Ketoja and Satija in Ref. 2, although we have not followed this approach here.

Using the so-called *decimation* method of Ketoja and Satija,[2,3] we shall show that the self-similarity in the η_i is determined by a so-called *strong coupling fixed point* of the renormalization operator associated with the recursion

$$t_n(x)=\prod_{i=0}^{a-1} t_{n-1}(-\omega x-i)t_{n-2}(\omega^2 x+a\omega). \tag{1.3}$$

In this paper we shall prove the existence of a fixed point of this recursion and thereby establish the theory on a firm basis. Specifically, we shall prove the following theorem.

Theorem 1: *Let $a\in\mathbb{N}$ and let $\omega=(\sqrt{a^2+4}-a)/2$. Then for each $k\in\mathbb{N}$, there exists a unique, entire function t such that*

a)Corresponding author. Current address: Department of Computing Science and Mathematics, University of Stirling, Stirling FK9 4LA, United Kingdom. Electronic mail: B.D.Mestel@stir.ac.uk

$$t(x)=\left(\prod_{i=0}^{a-1} t(-\omega x-i)\right) t(\omega^2 x+a\omega), \tag{1.4}$$

having a zero of order k at $x=1$ *and satisfying* $t(x)>0$ *on* $(-\omega-(a-1),1)$. *For each k we have* $t(x)=t_*(x)^k$, *where* t_* *is the function corresponding to the case* $k=1$.

The outline of this paper is as follows. In Sec. II we give a brief review of the number-theoretic results, followed by a heuristic derivation of the recurrence (1.3) using the decimation methods of Ketoja and Satija.[2,3] In subsequent sections we give the proof of Theorem 1. The method of proof is an improvement on the techniques employed in Ref. 4.

II. DERIVATION OF THE RENORMALIZATION EQUATIONS

In this section we give a heuristic derivation of the renormalization functional recurrence, based on the decimation method of Ketoja and Satija.

Let us briefly recall some elementary number-theoretic results on which the decimation method is based (see Ref. 8 for further details). Let $a\in\mathbb{N}$ be fixed and let $\omega\in(0,1)$ have continued fraction expansion $[0;a,a,\ldots]$. Then $\omega=(-a+\sqrt{a^2+4})/2$ and satisfies the quadratic equation

$$\omega^2+a\omega=1. \tag{2.1}$$

For these quadratic irrationals the rational convergents p_n/q_n satisfy $p_n=q_{n-1}=G_n$ where $G_{n+1}=aG_n+G_{n-1}$, $G_0=0$, $G_1=1$. An important relation is the following:

$$G_n\omega-G_{n-1}=-(-\omega)^n. \tag{2.2}$$

We now consider (1.2) in the strong-coupling limit $\lambda\to\infty$, at the band edge $E=2\lambda$. Setting $E=2\lambda$, dividing Eq. (1.2) by λ, and letting $\lambda\to\infty$ gives

$$\eta_{i-1}+2(\cos(2\pi(i\omega+\phi))-1)\eta_i=0. \tag{2.3}$$

Following Ketoja and Satija,[3] we define a so-called *decimation* as follows:

$$\eta_{i+G_n}=\hat{t}_n(i)\eta_i. \tag{2.4}$$

Note that this decimation differs from that in Ref. 3, since the coefficient of $\eta_{i+G_{n+1}}$ has been set to zero and we have changed the sign of $\hat{t}_n$. Consequently, (2.4) is only valid in the strong-coupling limit $\lambda\to\infty$.

A general recurrence for t_n may be obtained as follows. Evaluating (2.4) with i set equal to i, $i+G_n$, $i+2G_n,\ldots,i+(a-1)G_n$, gives

$$\eta_{i+G_n}=\hat{t}_n(i)\eta_i$$

$$\eta_{i+2G_n}=\hat{t}_n(i+G_n)\eta_{i+G_n}$$

$$\vdots$$

$$\eta_{i+aG_n}=\hat{t}_n(i+(a-1)G_n)\eta_{i+(a-1)G_n}.$$

Second, evaluating (2.4) at $n-1$ with i set equal to $i+aG_n$ gives

$$\eta_{i+G_{n-1}+aG_n}=\hat{t}_{n-1}(i+aG_n)\eta_{i+aG_n}.$$

Eliminating $\eta_{i+G_n},\ldots,\eta_{i+aG_n}$ between these equations, and using the recurrence for the G_n, we obtain $\eta_{i+G_{n+1}}=\hat{t}_{n+1}(i)\eta_i$, where

$$\hat{t}_{n+1}(i)=\left(\prod_{j=0}^{a-1}\hat{t}_n(i+jG_n)\right)\hat{t}_{n-1}(i+aG_n).$$

We now set the phase $\phi=0$. Evaluating (2.4) at $n=0$ and $n=1$, we obtain $\eta_i=\hat{t}_0(i)\,\eta_i$, $\eta_{i+1}=\hat{t}_1(i)\,\eta_i$, which, on comparing with (2.3) at $i+1$, with $\phi=0$, gives

$$\hat{t}_0(i)=1,\quad \hat{t}_1(i)=\frac{1}{2(1-\cos(2\pi(i+1)\omega))}.$$

Following Ref. 3 we now transform from the discrete variable i to a continuous variable x. We write $x=(-\omega)^{-n}\{i\omega\}$ where $\{\cdot\}$ denotes the fractional part. This transformation must be done carefully since the definition of x depends on the index n of the function. We now write $t_n(x)=\hat{t}_n(i)$, where t_n is a real function of a real variable of period ω^{-n}. Then, we have, for $n>1$,

$$\begin{aligned}
t_{n+1}(x)&=t_{n+1}((-\omega)^{-(n+1)}\{i\omega\})\\
&=\hat{t}_{n+1}(i)\\
&=\left(\prod_{j=0}^{a-1}\hat{t}_n(i+jG_n)\right)\hat{t}_{n-1}(i+aG_n)\\
&=\left(\prod_{j=0}^{a-1}t_n((-\omega)^{-n}\{(i+jG_n)\omega\})\right)t_{n-1}((-\omega)^{-(n-1)}\{(i+aG_n)\omega\})\\
&=\left(\prod_{j=0}^{a-1}t_n((-\omega(-\omega)^{-(n+1)}\{i\omega+j(-(-\omega)^n)\}))\right.\\
&\quad\left.\times t_{n-1}(\omega^2(-\omega)^{-(n+1)}\{(i\omega+a(-(-\omega)^n))\})\right.\\
&=\left(\prod_{j=0}^{a-1}t_n(-\omega x-j)\right)t_{n-1}(\omega^2x+a\omega),
\end{aligned}$$

as required. [In deriving this equation we have implicitly used the periodicity of the function t_n and (2.2).] The initial conditions are now

$$t_0(x)=1,\quad t_1(x)=\frac{1}{2(1-\cos(2\pi(-\omega x+\omega)))},\tag{2.5}$$

since, using $\{i\omega\}=-\omega x$ (for $n=1$) and the periodicity of the cosine function, we have $t_1(x)=t_1((-\omega)^{-1}\{i\omega\})=\hat{t}_1(i)=1/(2(1-\cos(2\pi(i+1)\omega)))=1/(2((1-\cos(2\pi(-\omega x+\omega)))))$. Of particular interest is the singularity/zero structure of these initial conditions. We note that on the interval $[-\omega-(a-1),1]$, the function t_1 has poles of order 2 at the end points $-\omega-(a-1)$ and 1, but no other zeros or singularities. From the recurrence (1.3), we see that $t_2(x)$ has a pole of order 2 at 1, but no other singularities or zeros on the interval $[-\omega-(a-1),1]$. It will then follow that for all $n\geqslant 3$, $t_n(x)$ has a pole of order 2 at 1, but no other zeros or singularities on this interval.

From numerical simulation of the recurrence (1.3), it appears that, starting from the initial conditions (2.5), $t_n(x)$ converges to a solution $t(x)$ of (1.4), with $t(x)$ having a pole of order 2 at 1, and no other singularities or zeros on $[-\omega-(a-1),1]$.

In this paper we prove the existence of this fixed point. It is given by $t(x)=t_*(x)^{-2}$, where t_* is the function given in Theorem 1.

FIG. 1. Diagram to show location of intervals.

III. ITERATED FUNCTION SYSTEM

The analysis of the recurrence (1.3) is based on the iterated function system given by the scaling functions on the right-hand side of (1.3). In this section we define the iterated function system and calculate its fixed point set. The fixed point set is an interval I and the global behavior of the recurrence (1.3) is determined by its behavior close to I.

Define $\phi_{1,i}(x)=-\omega x-i$ for $i=0,...,a-1$ and let $\phi_{2,a}(x)=\omega^2 x+a\omega$. The functions $\{\phi_{1,0},\ldots,\phi_{1,a-1},\phi_{2,a}\}$ are contractions which form an iterated function system (IFS) on $\mathbb{R}$. Let I be the real interval $[-\omega-(a-1),1]$. Then I is the unique compact fixed-point set in $\mathbb{C}$ of the IFS:

Proposition 1: The interval I satisfies $\cup_{i=0}^{a-1}\phi_{1,i}(I)\cup\phi_{2,a}(I)=I$.

Proof: Writing $c=-\omega-(a-1)$, we have $c<0$ and $I=[c,1]$. We calculate $\phi_{1,i}([c,1])=[-\omega-i,-\omega c-i]$, for $i=0,...,a-1$, and $\phi_{2,a}([c,1])=[\omega^2 c+a\omega,1]$. We observe that $\phi_{1,(a-1)}(1)=-\omega-(a-1)=c$, the left-hand end point of I. Moreover, for $k=1,...,a-1$ we have $\phi_{1,k}(c)=\phi_{1,k-1}(1)$, so that the right-hand end point of $\phi_{1,k}(I)$ is the left-hand end point of $\phi_{1,k-1}(I)$. Thus $\cup_{i=0}^{a-1}\phi_{1,i}([c,1])=[c,\phi_{1,0}(c)]=[c,-\omega c]$. Furthermore, we have $\phi_{2,a}(c)=\omega^2(-\omega-(a-1))+a\omega=1-\omega=-\omega c=\phi_{1,0}(c)$, so that $\cup_{i=0}^{a-1}\phi_{1,i}(I)\cup\phi_{2,a}(I)=I$, as required. The locations of the intervals are shown in Fig. 1. □

One further observation which will be useful in what follows is that if V is a nonempty open set in $\mathbb{C}$, containing I, and which is invariant for any one of the affine contractions $\phi_{1,0},\ldots,\phi_{1,a-1}$, $\phi_{2,a}$, then $V=\mathbb{C}$.

IV. THE RENORMALIZATION OPERATORS *R* AND *N*

In terms of the above-mentioned IFS, Eq. (1.4) may be written $t(x)=(\Pi_{i=0}^{a-1}t(\phi_{1,i}(x)))\,t(\phi_{2,a}(x))$. To obtain t_*, we impose the condition $t(x)\sim 1-x$ as $x\to 1$. We also have an associated additive fixed-point equation,

$$T(x)=\left(\sum_{i=0}^{a-1}T(\phi_{1,i}(x))\right)+T(\phi_{2,a}(x)),\quad T(x)\sim\log(1-x)\ \text{ as }\ x\to 1. \tag{4.1}$$

The solution of (1.4) is obtained from a corresponding solution of (4.1), although care must be taken over the logarithmic singularity at $x=1$.

In order to solve (4.1), we introduce the following linear operator R on functions T, given by

$$R(T)(x)=\left(\sum_{i=0}^{a-1}T(\phi_{1,i}(x))\right)+T(\phi_{2,a}(x)). \tag{4.2}$$

A solution of (4.1) corresponds to a fixed point of R, but, unfortunately, the operator R is not a contraction. We may eliminate the unstable direction by introducing the operator N given by $N(T)=R(T)-C(T)$ where $C(T)$ is

$$C(T)=\frac{1}{a}\left(\sum_{i=1}^{a-1}R(T)(\phi_{1,i}(0))+R(T)(\phi_{2,a}(0))\right). \tag{4.3}$$

In Fig. 2 we show of the solution t_* of Eq. (1.4) for the case $a=2$. This figure was obtained as the limit of the iterations of the exponentiated operator $\exp N$ starting from the initial condition $t_0(x)=1-x$.

Our strategy for the proof of Theorem 1 is as follows. We shall describe the functional analytic properties of the operators R and N. In particular, they are compact operators on a suitable space

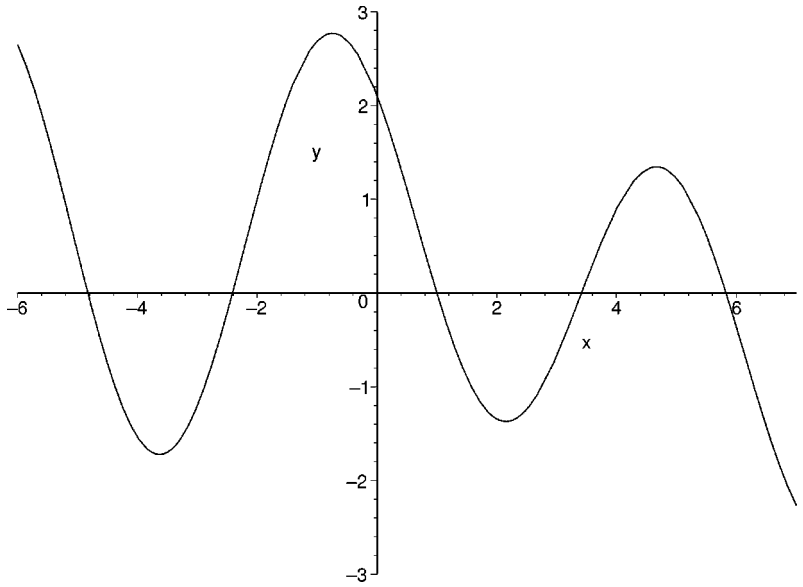

FIG. 2. Graph of the solution t_* of Eq. (1.4) for the case $a=2$.

of analytic functions, and N is spectrally a contraction. Using this fact we prove that there is a fixed point T_* of N with $T_*(x)\sim\log(1-x)$ as $x\to 1$. The operator N has been designed so T_* is also a fixed point of R. We then exponentiate to get an analytic solution of the multiplicative equation (1.4) on a domain in $\mathbb{C}$, which we then extend to the whole complex plane.

A. Function space and properties

In this section we shall define the space of analytic functions in which we shall work. Let r satisfy $\max(1,(a-1)/(1-\omega))<r<1/\omega$. That such an r exists follows from $1/\omega-(a-1)/(1-\omega)=(1-a\omega)/(\omega-\omega^2)>0$, by (2.1). Let $D=D(0,r)=\{z\in\mathbb{C}:|z|<r\}$. We let $\mathcal{F}$ be the space of real analytic functions $f:D\to\mathbb{C}$, $f(z)=\Sigma_{i=0}^{\infty} f_i(z/r)^i$, such that the L^1-norm $\|f\|=\Sigma_{i=0}^{\infty}|f_i|<\infty$. The choice of domain D is motivated by the property

$$\overline{\phi_{1,i}(D)}\subseteq D \quad \text{for } i=0,\ldots,a-1, \quad \overline{\phi_{2,a}(D)}\subseteq D. \tag{4.4}$$

We prove (4.4) as follows. Let $x\in D$ and $0\leqslant i\leqslant a-1$. Then $|\phi_{1,i}(x)|<\omega r+i<\omega r+a-1<\omega r+(1-\omega)r=r$, using $(a-1)/(1-\omega)<r$. Also, $|\phi_{2,a}(x)|<\omega^2 r+a\omega<\omega^2 r+a\omega r=r$, since $r>1$. Thus $\overline{\phi_{1,i}(D)}$, $\overline{\phi_{2,a}(D)}\subseteq D$. From (4.4) we may conclude that the operators R and N are well defined on $\mathcal{F}$.

B. Spectral properties of *R* and *N*

In this section we give a brief account of the spectral properties of the operators N and R and we calculate their spectra explicitly.

Proposition 2: The operators N: $\mathcal{F}\to\mathcal{F}$, R: $\mathcal{F}\to\mathcal{F}$ are compact. The spectrum of R consists of simple eigenvalues $\{\mu_k=a(-\omega)^k+\omega^{2k}:k\geqslant 0\}$, together with 0, while the spectrum of N on $\mathcal{F}$ consists of simple eigenvalues $\{\tilde{\mu}_k=a(-\omega)^k+\omega^{2k}:k\geqslant 1\}$, together with 0, which is also an eigenvalue $\tilde{\mu}_0=0$. The eigenfunctions corresponding to the eigenvalues μ_k and $\tilde{\mu}_k$ are both polynomials of degree k. The spectral radius $r(N)<1$.

Proof: The inclusions (4.4) imply that R and N are analyticity improving and, by standard methods, using the Cauchy estimates to provide uniform bounds on derivatives, one may use Ascoli's theorem to deduce compactness. We obtain the spectrum for N; the corresponding result

for R is proved similarly. We note that all nonzero spectral values of N are eigenvalues since N is compact. Let $\mu \neq 0$ be an eigenvalue of N with eigenfunction $T \in \mathcal{F}$, i.e., $N(T) = \mu T$:

$$\mu T(x) = N(T)(x) = \sum_{i=0}^{a-1} T(-\omega x - i) + T(\omega^2 x + a\omega) - C(T). \tag{4.5}$$

Defining the norm $\|g\|_I = \sup\{|g(x)| : x \in I\}$, and differentiating, we have $\|T^{(j)}\|_I < \infty$ for $j = 0, 1, 2, 3, \ldots$, since I is a compact. Furthermore, we have $|\mu| \|T^{(j)}\|_I = \|N(T)^{(j)}\|_I \leq (a\omega^j + \omega^{2j}) \|T^{(j)}\|_I$. Since $a\omega^j + \omega^{2j} \to 0$ as $j \to \infty$, it follows that $\|T^{(j)}\|_I = 0$ for j sufficiently large, and, since T is analytic, we have $T^{(j)} = 0$. Hence T is a polynomial of degree at most $j-1$. To find the eigenvalues of N, we may therefore assume T is a polynomial, of degree $k \geq 0$, say. Expanding (4.5) and considering the kth-order terms, we have for $k \geq 1$, $\mu = (-\omega)^k a + \omega^{2k}$. For $k = 0$, we have $T(x) = a_0 \neq 0$, and, using (4.3), we find $\mu = 0$. Moreover, it is straightforward to show that for each μ there exists a one-dimensional polynomial eigenspace of N. Finally, we prove that $r(N) < 1$. In fact, for all $a \geq 1$, and for all $k \geq 0$, we have $|\tilde{\mu}_k| \leq a\omega < 1$. The case $k = 0$ is clear, since $\tilde{\mu}_0 = 0$. For $k = 1$, we have $|\tilde{\mu}_1| = a\omega - \omega^2 < a\omega < 1$, as required. For $k \geq 2$, we have $|\tilde{\mu}_k| \leq \omega(\omega^{2k-1} + a\omega^{k-1}) < \omega \leq a\omega$. Hence $|\tilde{\mu}_k| < a\omega < 1$, as before. We deduce that $r(N) < a\omega < 1$.

V. PROOF OF EXISTENCE OF A FIXED POINT OF *R*

We now prove the existence of a fixed point of R. To do this we first of all obtain a fixed point of N and then deduce a fixed point of R. Specifically we prove the following theorem.

Theorem 2: *Let $a \in \mathbb{N}$ and let $\omega = (\sqrt{a^2+4} - a)/2$. Let $r > 0$ satisfy the inequality* $\max(1, (a-1)/(1-\omega)) < r < 1/\omega$. *Then there exists a fixed point T_* of the operator R such that $T_*(x) = \log(1-x) + T_{**}(x)$ where $T_{**} \in \mathcal{F}$.*

From Sec. IV B we know that the spectral radius of N on $\mathcal{F}$ is $r(N) < 1$. We conclude that there exists $\rho \in (r(N), 1)$ and $K > 0$ such that for all $k \geq 1$, $\|N^k(T)\| \leq K\rho^k \|T\|$. Let $T_0(x) = \log(1-x)$, where (here, and in what follows) we take the principal branch of the logarithm. We note that T_0 has a singularity at $1 \in D$, so clearly $T_0 \notin \mathcal{F}$.

We now define a sequence of functions T_n as follows: $T_1 = N(T_0) - T_0$, $T_n = N(T_{n-1})$, $n \geq 2$. We claim that $T_1 \in \mathcal{F}$ so that $T_n \in \mathcal{F}$ for all $n \geq 1$. To prove the claim we observe that

$$\begin{aligned} T_1(x) &= R(T_0)(x) - C(T_0) - T_0(x) \\ &= \sum_{i=1}^{a} \log(i + \omega x) + \log(1 - (\omega^2 x + a\omega)) - C(T_0) - \log(1-x) \\ &= \sum_{i=1}^{a} \log(i + \omega x) + A, \end{aligned}$$

where A is a constant, and we have used (4.2) and $\log(1-(\omega^2 x + a\omega)) - \log(1-x) = \log \omega^2$. It is now clear that the singularities of T_1 are at $x = i/\omega$, for $i = 1, \ldots, a-1$, and, since $r < 1/\omega$, it follows that all the singularities of T_1 lie outside D and so $T_1 \in \mathcal{F}$, and we are done.

We now prove Theorem 2. We have $N^n(T_0) = T_0 + \cdots + T_n$ and it is now immediate that $N^n(T_0)$ converges to a function $T_* = T_0 + T_{**}$ where $T_{**} = \sum_{i=1}^{\infty} T_i \in \mathcal{F}$, since the series $\sum_{i=1}^{\infty} \|T_i\| \leq \sum_{i=1}^{\infty} K\rho^{i-1} \|T_1\| < \infty$. It is clear T_* is a fixed point of N, i.e., $N(T_*) = T_*$, since $N(T_{**}) = T_{**} - T_1$ and $N(T_0) = T_0 + T_1$.

We next show that $R(T_*) = T_*$. Since $N(T_*) = T_*$, we have $R(T_*) = T_* + C(T_*)$. We show that $C(T_*) = 0$. Now $T_*(0) = \sum_{i=0}^{a-1} T_*(\phi_{1,i}(0)) + T_*(\phi_{2,a}(0)) - C(T_*)$, and, hence, $C(T_*) = \sum_{i=1}^{a-1} T_*(\phi_{1,i}(0)) + T_*(\phi_{2,a}(0))$. Recalling (4.3), we now have that

$$C(T_*) = \frac{1}{a}\left(\sum_{i=1}^{a-1} R(T_*)(\phi_{1,i}(0)) + R(T_*)(\phi_{2,a}(0)) \right)$$
$$= \frac{1}{a}\left(\sum_{i=1}^{a-1} T_*(\phi_{1,i}(0)) + T_*(\phi_{2,a}(0)) + aC(T_*) \right)$$
$$= \frac{a+1}{a} C(T_*).$$

We deduce that $C(T_*)=0$, as claimed. This concludes the proof of Theorem 2.

VI. PROOF OF THEOREM 1

We now give the proof of Theorem 1. Let T_* be the fixed point of R given by Theorem 2. Let $t_* = \exp T_*$. Then t_* is analytic on D and we have t_* satisfies Eq. (1.4) there. Moreover, since $T_*(x) \sim \log(1-x)$ as $x \to 1$, we have that t_* has zero of order 1 at $x=1$. This constructs the base solution t_* of Theorem 1. We now extend t_* to the whole of $\mathbb{C}$ by analytic continuation, so that it satisfies (1.4). To do this we use the following lemma:

Lemma 1 (extension lemma): Let t be analytic and satisfy Eq. (1.4) on an open neighborhood U of $[-\omega-(a-1),1]$ *in* $\mathbb{C}$. *Then there exists an analytic extension of t to the whole of* $\mathbb{C}$.

Proof: Consider the set of open, simply connected neighborhoods V of $[-\omega-(a-1),1]$ in $\mathbb{C}$ such that $\phi_{1,i}(V) \subseteq V$, for $i=0,...,a-1$ and $\phi_{2,a}(V) \subseteq V$ and such that there is an analytic extension of t to V. Clearly, since $[-\omega-(a-1),1]$ is the fixed-point set of the iterated function system defined in Sec. III, there exists $V \subseteq U$ satisfying these conditions. Moreover, since the union of two such neighborhoods V is also such a neighborhood, it follows that there is a maximal such neighborhood, V_*, say. Then, by maximality, we have that at least one of $\phi_{1,i}(V_*)=V_*$, for $i=0,...,a-1$ and $\phi_{2,a}(V_*)=V_*$ holds, and, thus, as observed in Sec. III, V_* is the whole of $\mathbb{C}$. □

It is now clear from the lemma that the extension of t_* to $\mathbb{C}$ is possible, since t_* is analytic on $U=D$, which contains $[-\omega-(a-1),1]$. We are therefore able to define for $k \in \mathbb{N}$ the function $t(x) = t_*(x)^k$. Then t is entire, satisfies (1.4), and has a zero of order k at $x=1$.

We next prove that t is unique. Let $k \in \mathbb{N}$. Suppose that t_1 and t_2 are entire functions satisfying Eq. (1.4), with $t_1(x)$, $t_2(x) > 0$ on $[-\omega-(a-1),1)$ and zeros of order k at $x=1$. Let us consider the function $t(x) = t_1(x)/t_2(x)$. Then, on an open neighborhood U of $[-\omega-(a-1),1]$, t is analytic and nonzero and satisfies (1.4). We now extend t to the whole of $\mathbb{C}$ using the extension lemma 1. From the multiplicative property of Eq. (1.4), we have that if $t(x)=0$, for some $x \in \mathbb{C}$, then $t(x')=0$, for some $x' \in U$, a contradiction. Thus t is a nonzero solution of (1.4) on $\mathbb{C}$, and, in particular, on D, with $t(x)>0$ on $[-\omega-(a-1),1]$. We are therefore able to define $\log t$, giving a function T which is a fixed point of R in $\mathcal{F}$, i.e., an eigenfunction with eigenvalue 1. From the spectral analysis of R (Proposition 2), we see that no such eigenfunction exists and thus $T=0$. We conclude that $t=1$ on D and, by extension, on $\mathbb{C}$. It follows that $t_1 = t_2$ on $\mathbb{C}$.

The proof of Theorem 1 is complete.

VII. CONCLUSION

In this paper we have considered the strong coupling fixed point limit of the Harper equation in the case of ω a quadratic irrational of the form $\omega = (\sqrt{a^2+4}-a)/2$, $a \in \mathbb{N}$, and have applied renormalization techniques to study the self-similarity properties of the fluctuations η_i. Although our analysis is only valid in the limit $\lambda \to \infty$, it is believed that it applies for a wider range of λ, and, in particular, large but finite λ.

There are a number of avenues for further research. First, our methods are likely to extend to more general irrational ω with continued fraction $[0;a_1,a_2,\ldots]$. However, it appears that for general ω, the functions t_n will not converge to a fixed point, and, indeed, the fundamental interval I will also vary with n.

Second, the theory for general a presented here can be applied to study problems in which the solutions of the recurrence (1.3) are piecewise constant. Such solutions have application to the study of the correlation function in strange nonchaotic attractors, other quasiperiodcally driven quantum mechanical models, as well as so-called barrier-billiard problems. In particular, the work in Refs. 5 and 6 may be extended from the golden-mean case to general a.

A third direction for future work is the generalization of the so-called Ketoja–Satija orchid, a renormalization strange set for a generalized Harper equation (see Refs. 3 and 7). It is likely that the Ketoja–Satiija orchid and the analysis of its structure can be generalized to irrational numbers other than the golden mean $(\sqrt{5}-1)/2$. Indeed, the goal is to extend the analysis in Ref. 7 to all irrational ω.

ACKNOWLEDGMENTS

The authors would like to thank Andy Osbaldestin for extremely helpful discussions, particularly on the form of the recurrence for $a \geqslant 2$. J.D. wishes to acknowledge the support of the UK Engineering and Physical Sciences Research Council.

Laboratory of Theoretical Physics, P.O. Box 1014, University Mohammed V, Rabat, Morocco

(Received 8 March 2003; accepted 1 May 2003)

We discuss the algebra of $N\times N$ matrices as a reduced quantum plane. A $n=3$-nilpotent deformed differential calculus involving a complex parameter q is constructed. The two cases, q 3rd and Nth root of unity are completely treated. As an application, we establish a gauge field theory for the particular cases $n=2$ and $n=3$. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1598278]

I. INTRODUCTION

In the literature, there exist different points of view[1–6] to generalize the ordinary differential calculus ($d^2=0$); see, for example, Refs. 7–8, to higher orders. An adequate way leading to such generalizations arises from the graded differential algebra.[1–3] In fact in these references it is seen as a graded q-differential algebra which is the sum of k-graded subspaces, where $k \in\{0,1,2,\ldots,m-1\}$. The relevant differential operator is an endomorphism d satisfying $d^m=0$ and the q-Leibniz rule:

$$d(AB)=(dA)B+qAd(B).$$

The most important property of this calculus is that it involves not only first differentials dx^i, $i=1,\ldots,n$, but also the higher-order differentials $d^jx^i, j=1,\ldots,m-1$.

On the other hand, the differential calculus ($d^2=0$) on noncommutative spaces was also studied by different authors; see Refs. 8–13. These differential calculi are covariant with respect to some symmetry quantum group.

In this paper, we construct a covariant differential calculus $d^3=0$ on the algebra $M_3(C)$ of 3×3 matrices considered as a reduced quantum plane. We will show that our differential calculus is covariant under the algebra of transformations with a quantum group structure. The complex deformation parameter q (3rd-root of unity) will play an important role in constructing gauge field theory on $M_3(C)$.

The paper is organized as follows

We start in Sec. II by defining the algebra of $N\times N$ matrices as a reduced quantum plane, where the deformation parameter q is the Nth root of unity. In Sec. III we construct the covariant differential calculus $d^3=0$ on the two-dimensional reduced quantum plane as in Refs. 1–3. The new objects, d^2x and d^2y, appearing in this construction are seen as the analogous of the differential elements dx and dy in the ordinary differential calculus. In Sec. IV, we generalize this result by considering a complex deformation parameter q Nth root of unity.

In Sec. V, we study the application of this new differential calculus ($d^3=0$) to the gauge field theory on $M_3(C)$. We recall in Sec. VI the differential calculus $d^2=0$,[8,11–13] and we apply it to derive a gauge theory on $M_3(C)$.

II. PRELIMINARIES ABOUT THE ALGEBRA $M_3(C)$ OF N×N MATRICES AS A REDUCED QUANTUM PLANE

The associative algebra of $N\times N$ matrices is generated by two elements x and y[14] satisfying the relations

$$xy=qyx \tag{1}$$

and

$$x^N=y^N=1, \tag{2}$$

where 1 is the unit matrix and q $(q\neq 1)$ is a complex parameter Nth root of unity.

In the case $N=3$, an explicit matrix realization of generators x and y[11,15] is given by

$$x=\begin{pmatrix} 1 & 0 & 0 \\ 0 & q^{-1} & 0 \\ 0 & 0 & q^{-2} \end{pmatrix}, \tag{3}$$

$$y=\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix}, \tag{4}$$

and q satisfies the relation

$$1+q+q^2=0. \tag{5}$$

The associative algebra, noted by $C_q\,[x,y]:=C_q$, of formal power series defined over the two-dimensional quantum plane is generated by x and y with a single quadratic relation $xy=qyx$. It is clear that $C_1\,[x,y]$ coincides with the algebra of polynomials over commuting variables x, y. If the generators x, y do not satisfy any additional relations, the algebra C_q is infinite dimensional.

In the case of the algebra $M_3(C)$ of 3×3 matrices over complex numbers, the generators x, y satisfy the above quadratic relation (1) and the cubic ones $x^3=y^3=1$. Thus the algebra $\tilde{C}_q$ of formal power series over $M_3(C)$ is finite dimensional and generated by $\{1, x, y, x^2, y^2, xy, x^2y, xy^2, x^2y^2\}$. In this case, $\tilde{C}_q=C_q^0/I$ where C_q^0 is the unital extension of C_q and I is the bilateral ideal generated by $x^3-1=0$, $y^3-1=0$. That is, in the sense of Refs. 11, 15, the 3×3 matrices over C are seen as a reduced quantum plane.

We note that the functions of x and y are seen as a finite formal power series with a maximum degree 3; this property will be extremely useful in what follows. In fact, the set of these functions is an associative algebra that is used to introduce a gauge field theory on the reduced quantum plane. This idea will be developed in Secs. V and VII.

III. DIFFERENTIAL CALCULUS WITH NILPOTENCY $n=3$ ON REDUCED QUANTUM PLANE, CASE $q^3=1$

Our aim in this section is to construct a covariant $n=3$ nilpotent differential calculus by mixing two approaches. Namely, we adapt to the reduced quantum plane an idea originally proposed by Kerner,[1–3] and we use Couquereaux's technics[11] to ensure covariance. We denote by Ω the differential algebra generated by x, y, dx, dy, d^2x and d^2y, where the "2-forms" d^2x and d^2y are the second differentials of the basic variables x and y.

Let us introduce the differential operator d that satisfies the following conditions: Nilpotency,

$$d^3=0: \tag{6}$$

and Leibniz rule,

$$d(uv)=d(u)v+q^n u d(v), \tag{7}$$

where u is a form of degree n and q is a 3rd root of unity.

By applying the Leibniz rule on the 1-form we obtain

$$d(f(x)\,dx)=(df(x))\,dx+f(x)\,d^2x; \tag{8}$$

$f(x)$ are the 0-forms in the algebra Ω. The set of transformations leaving covariant our differential calculus is $F\subset \mathrm{Fun}(SL_q(2,C))$ and the covariance is described by the left coaction. We start by explaining this coaction.[16]

The left coaction of the group F on the reduced quantum plane is the linear transformation of coordinates given by

$$\begin{pmatrix} x_1 \\ y_1 \end{pmatrix}=\begin{pmatrix} a & b \\ c & d \end{pmatrix}\otimes\begin{pmatrix} x \\ y \end{pmatrix}.$$

We also introduce the line vectors with coordinate functions:

$$(x^1,y^1)=(x,y)\otimes\begin{pmatrix} a & b \\ c & d \end{pmatrix},$$

where the matrix elements a, b, c and d do not commute with each other. We require that x_1, y_1, x^1, y^1 satisfy the same relations as x and y. The two constraints $x_1y_1=qy_1x_1$ and $x^1y^1=qy^1x^1$ lead to the relations

$$ac=qca, \quad bd=qdb,$$

$$ab=qba, \quad cd=qdc,$$

$$bc=cb, \quad ad-da=(q-q^{-1})bc.$$

The algebra generated by a, b, c and d is usually denoted $\mathrm{Fun}(GL_q(2,C))$. The q-determinant $D=da-q^{-1}bc$ is in the center of $\mathrm{Fun}(GL_q(2,C))$. If we set it equal to 1, we define the algebra $\mathrm{Fun}(SL_q(2,C))$. Assuming that the supplementary conditions $(x)^3=1$ and $(y)^3=1$ are also verified by the coordinates x_1, y_1, x^1 and y^1 implies $a^3=1$, $b^3=0$, $c^3=0$, $d^3=1$. These new cubic relations on $\mathrm{Fun}(SL_q(2,C))$ yield a new algebra that we denote F. It is also a Hopf algebra. Indeed, it has a coalgebra structure (coproduct) which is compatible with the algebra one (product), this defines a bialgebra structure. An antipode and a co-unit are also defined. For further details on such structures on F, see, for example, Ref. 11.

The mixture of Kerner's idea and Coquereaux's techniques allows us to construct the left covariant differential algebra $\Omega=\{x,y,dx,dy,d^2x,d^2y\}$; see Appendix A. The commutation relations between the generators of Ω are as follows:

$$x\,dx=q^2\,dx\,x, \tag{9}$$

$$x\,dy=q\,dy\,x+(q^2-1)dx\,y, \tag{10}$$

$$y\,dx=q\,dx\,y, \tag{11}$$

$$y\,dy=q^2\,dy\,y, \tag{12}$$

$$dy\,dx=q^2\,dx\,dy, \tag{13}$$

$$x\,d^2x=q^2d^2x\,x, \tag{14}$$

$$y\,d^2x = q\,d^2x\,y, \tag{15}$$

$$y\,d^2y = q^2 d^2y\,y, \tag{16}$$

$$x\,d^2y = q\,d^2y\,x + (q^2-1)d^2x\,y, \tag{17}$$

$$dx\,d^2y = d^2y\,dx + q(1-q)d^2x\,dy, \tag{18}$$

$$dy\,d^2x = d^2x\,dy, \tag{19}$$

$$dx\,d^2x = q\,d^2x\,dx, \tag{20}$$

$$dy\,d^2y = q\,d^2y\,dy, \tag{21}$$

$$d^2y\,d^2x = q^2 d^2x\,d^2y. \tag{22}$$

As in the standard way, we define the partial derivatives in directions x and y through

$$d = \frac{\partial}{\partial x}dx + \frac{\partial}{\partial y}dy = \partial_x dx + \partial_y dy. \tag{23}$$

Consistency conditions as in Ref. 8 yield

$$\partial_x\,\partial_y = q\partial_y\,\partial_x, \tag{24}$$

$$\partial_x\,x = 1 + q^2 x\,\partial_x + (q^2-1)y\,\partial_y, \tag{25}$$

$$\partial_x\,y = qy\,\partial_x, \tag{26}$$

$$\partial_y\,y = 1 + q^2 y\,\partial_y, \tag{27}$$

$$\partial_y\,y = 1 + q^2 y\,\partial_y, \tag{28}$$

$$(dx)^3 = (dy)^3 = 0. \tag{29}$$

The last equality, Eq. (29), can be related to the nilpotency relation encountered in the description of the fractional statistics. More precisely, we recover the description of physical systems that generalize fermions. In a forthcoming paper,[17] we re-introduce these systems using this new differential calculus by establishing an adequate correspondence between our differential calculus and some deformed Heisenberg algebras, as it is done in Ref. 18 for the particular case ($d^2=0$).

Now, we generalize our differential calculus by considering the case $q^N=1$.

IV. DIFFERENTIAL CALCULUS ON A REDUCED QUANTUM PLANE, CASE $q^N=1$

A two-dimensional reduced quantum plane is an associative algebra generated by x and y with relations (1) and (2). One can always define the differential operator "d" satisfying $d^3=0$ ($d^2\neq 0$) and the Leibniz rule

$$d(uv) = d(u)v + (j)^n u d(v), \tag{30}$$

$u\in\Omega^n$ and $v\in\Omega^m$, where Ω^n and Ω^m are the spaces of n and m forms on the reduced quantum plane, respectively.

In contrast to Eq. (7), one has to distinguish between the deformation parameter q and the j parameter, $j^3=1$ ($j\neq 1$) in Eq. (30).

Following the same method of Sec. III, we get the covariant differential calculus:

$$x\,dx = j^2 dx\,x, \tag{31}$$

$$x\,dy = -\frac{jq}{1+q^2} dy\,x + \frac{j^2q^2-1}{1+q^2} dx\,y, \tag{32}$$

$$y\,dx = \frac{j^2-q^2}{1+q^2} dy\,x - \frac{jq}{1+q^2} dx\,y, \tag{33}$$

$$y\,dy = j^2 dy\,y, \tag{34}$$

$$dx\,dy = q\,dy\,dx, \tag{35}$$

$$x\,d^2x = j^2\,d^2x\,x, \tag{36}$$

$$x\,d^2y = -\frac{jq}{1+q^2} d^2y\,x + \frac{j^2q^2-1}{1+q^2} d^2x\,y, \tag{37}$$

$$y\,d^2x = \frac{j^2-q^2}{1+q^2} d^2y\,x - \frac{jq}{1+q^2} d^2x\,y, \tag{38}$$

$$y\,d^2y = j^2 d^2y\,y, \tag{39}$$

$$dx\,d^2x = j\,d^2x\,dx, \tag{40}$$

$$dx\,d^2y = -\frac{q}{1+q^2} d^2y\,dx + \frac{jq^2-j^2}{1+q^2} d^2x\,dy, \tag{41}$$

$$dy\,d^2x = \frac{j-j^2q^2}{1+q^2} d^2y\,dx - \frac{q}{1+q^2} d^2x\,dy, \tag{42}$$

$$dy\,d^2y = j\,d^2y\,dy, \tag{43}$$

$$d^2x\,d^2y = q\,d^2y\,d^2x. \tag{44}$$

If $q=j$, we recover the differential calculus obtained in Sec. III. As an application of this new differential calculus $d^3=0$ on the reduced quantum plane, we construct in the section below a gauge field theory on $M_3(C)$.

V. COVARIANT DERIVATIVE AND CURVATURE ON $M_3(C)$ AS A REDUCED QUANTUM PLANE WITH $d^3=0$

In this section, we use the $n=3$ differential calculus constructed in Sec. III to establish a gauge theory on the reduced quantum plane.

As in the ordinary case, the covariant differential is defined by

$$D\Phi(x,y) = d\Phi(x,y) + A(x,y)\Phi(x,y), \tag{45}$$

where the field $\Phi(x,y)$ is a function on $M_3(C)$ and the gauge field $A(x,y)$ is a 1-form valued in the associative algebra of functions on the reduced quantum plane $M_3(C)$.

We have assumed that the algebra of functions on $M_3(C)$ is a bimodule over the differential algebra Ω.

As usual, the covariant differential D must satisfy

$$DU^{-1}\Phi(x,y) = U^{-1}D\Phi(x,y), \tag{46}$$

where U is an endomorphism defined on Fun$[M_3(C)]$.

This leads to the following gauge field transformation:

$$A(x,y)\to U^{-1}A(x,y)U+U^{-1}dU. \tag{47}$$

In general, the gauge field $A(x,y)$ can be written as

$$A(x,y)=A_x(x,y)dx+A_y(x,y)dy. \tag{48}$$

The differential calculus $n=3$ allows us to define the curvature R as follows:[2,19]

$$D^3\Phi(x,y)=R\Phi(x,y). \tag{49}$$

Direct computations show that R is a ''three-form'' given by

$$R=d^2A(x,y)+dA^2(x,y)+A(x,y)dA(x,y)+A^3(x,y) \tag{50}$$

$$=d^2A(x,y)+(dA(x,y))A(x,y)+(1+q)A(x,y)dA(x,y)+A^3(x,y) \tag{51}$$

$$=d^2A(x,y)+(dA(x,y))A(x,y)-q^2A(x,y)dA(x,y)+A^3(x,y). \tag{52}$$

One has to express the curvature written above in terms of 3-forms constructed from basic generators dx, dy, d^2x and d^2y of the differential algebra Ω. Since we are dealing with a noncommutative space (reduced quantum plane), this task is not straightforward. In fact, the noncommutativity prevents us from rearranging the different terms in Eq. (52) adequately. To overcome this technical difficulty we require that the components of the gauge field $A_x(x,y)$ and $A_y(x,y)$ are expressed as formal power series of the space coordinates x and y.[20–23] The condition, Eq. (2) in Sec. II ($N=3$), is extremely useful, in the sense that it limits the power series to finite ones rather than infinite:

$$A_x(x,y)=a_{mn}x^my^n; \quad m,n=0,1,2, \tag{53}$$

$$A_y(x,y)=b_{kl}x^ky^l; \quad k,l=0,1,2. \tag{54}$$

Using the formulas (1), (31)–(44), (52)–(54), and after technical computations, the desired expression of the curvature arises as

$$\begin{aligned}R=&qF^q_{xy}d^2x\,dy+F^{q^2}_{yx}d^2y\,dx\times[R_{xxy}+qR_{yxx}+q^2R_{xyx}+(1-q)\{\partial_yA_x(x,y)+q\partial_xA_y(x,y)\\&+\partial_yA_Y(x,y)((1-q)f_2(y)-f_1(x,y))+qf_4(x,y)f_0(x,y)-q^2f_6(x,y)+A_y(x,y)(f_5(x,y)\\&+A_y(x,y)A_y(q^2x,y)((1-q)f_2(y)-f_1(x,y))A_y(x,y)A_x(q^2x,y)f_4(x,y)\\&+qA_x(x,y)A_y(qx,q^2y)f_0(x,y)+q^2A_y(x,y)f_4(x,y)A_y(x,y)\\&+A_y(x,y)f_3(x,y)A_y(q^2x,qy)\}]dx\,dx\,dy+[R_{yyx}+qR_{yxy}+q^2R_{xyy}+(1-q)\\&\times\{-q^2\partial_yA_y(x,y)f_0(x,y)-q^2A_y(x,y)f_7(x,y)-A_y(x,y)A_y(q^2x,qy)f_8(x,y)\}]dy\,dy\,dx,\end{aligned} \tag{55}$$

where

$$\begin{aligned}F^q_{xy}&=\partial_xA_y(x,y)-q\partial_yA_x(x,y)+A_x(x,y)A_y(qx,q^2y)-qA_y(x,y)A_x(q^2x,qy),\\F^{q^2}_{yx}&=\partial_yA_x(x,y)-q^2\partial_xA_y(x,y)+A_y(x,y)A_x(q^2x,qy)-q^2A(x,y)A(qx,q^2y),\end{aligned} \tag{56}$$

and the components R_{ijk}, $f_n(x,y)$ $(i,j,k=x,y;\ n=0,1,\ldots,8)$ are given in Appendix B.

The expression of the curvature components, Eq. (80) Appendix B, and the deformed field strength, Eqs. (56), are formally the same as those obtained by Kerner.[2,19] The functions $f_i(x,y)$ $i=0,\ldots,8$ can be interpreted as a direct consequence of the noncommutativity property of the space.

The $n=3$ covariant differential calculus constructed in Secs. III and IV, respectively, for a q 3rd and Nth-root of unity can be seen as a generalization of the case $n=2$. However, one cannot see $d^2=0$ as a certain limit of the $d^3=0$ case. In the next section, we are reminded of the differential calculus $d^2=0$.

VI. DIFFERENTIAL CALCULUS WITH NILPOTENCY $n=2$ ON A REDUCED QUANTUM PLANE

We recall that the exterior differential "d" on the reduced quantum plane obeys the usual properties,[8,11–13] namely i/linearity, ii/nilpotency,

$$d^2=0. \tag{57}$$

iii/Leibniz rule,

$$d(uv)=d(u)v+(-1)^n u d(v), \tag{58}$$

where

$$u\in\Omega^n, v\in\Omega^m \quad \text{and} \quad d(x)=dx, \quad d(y)=dy, \quad d1=0. \tag{59}$$

The q-deformed differential calculus satisfies

$$x\,dx=q^2\,dx\,x, \tag{60}$$

$$x\,dy=q\,dyx+(q^2-1)dx\,y, \tag{61}$$

$$y\,dx=q\,dx\,y, \tag{62}$$

$$y\,dy=q^2\,dy\,y, \tag{63}$$

$$dy\,dx=-q^2\,dx\,dy, \tag{64}$$

$$(dx)^2=(dy)^2=0. \tag{65}$$

So, the differential algebra Ω is generated by x, y, dx and dy, $\Omega=\{x,y,dx,dy\}$.

Using the standard realization of the differential "d:"

$$d=\frac{\partial}{\partial x}dx+\frac{\partial}{\partial y}dy=\partial_x\,dx+\partial_y\,dy, \tag{66}$$

one can prove that

$$\partial_x x=1+q^2x\partial_x+(q^2-1)y\partial_y, \tag{67}$$

$$\partial_y x=qx\partial_x, \tag{68}$$

$$\partial_x y=qy\partial_x, \tag{69}$$

$$\partial_y y=1+q^2y\partial_y. \tag{70}$$

We apply this covariant differential calculus to study the related gauge field theory on $M_3(C)$.

VII. COVARIANT DERIVATIVE AND CURVATURE ON $M_3(C)$ AS A REDUCED QUANTUM PLANE WITH $d^2=0$

The covariant differential is defined as in Sec. VI:

$$D\Phi(x,y)=d\Phi(x,y)+A(x,y)\Phi(x,y). \tag{71}$$

The expression of the curvature is

$$D^2\Phi(x,y)=(dA(x,y)+A(x,y)A(x,y))\Phi(x,y)=R\Phi(x,y). \tag{72}$$

The differential realization of "d," Eqs. (66)–(70), allows to rewrite the expression of the curvature R:

$$R=(\partial_x A_y(x,y)-q\partial_y A_x(x,y))dx\,dy+A_x(x,y)dx\,A_y(x,y)dy. \tag{73}$$

Using the differential calculus, Eqs. (60)–(70), on the reduced quantum plane and the expressions of $A_x(x,y)$, $A_y(x,y)$, Eqs. (53), (54) as a formal power series, it is easy to establish the curvature expression:

$$\begin{aligned}R=&[\partial_x A_y(x,y)-q\partial_y A_x(x,y)+A_x(x,y)A_y(qx,q^2y)-qAy(x,y)A_x(q^2x,qy)\\&+(1-q)A_y(x,y)\{-qb_{12}-b_{10}y+q^2b_{22}x-q^2b_{11}y^2+qb_{20}xy+b_{21}xy^2\}]dx\,dy;\end{aligned} \tag{74}$$

this permits us to identify the q-deformed antisymetric field strength:

$$\begin{aligned}F^q_{xy}&=\partial_x A_y(x,y)-q\partial_y A_x(x,y)+A_x(x,y)A_y(qx,q^2y)-qAy(x,y)A_x(q^2x,qy)\\&=-q\{\partial_y A_x(x,y)-q^2\partial_x A_y(x,y)+A_x(q^2x,qy)A_y(x,y)\\&\quad-q^2A_x(x,y)A_y(q^2x,qy)\}\\&=-qF^{q^2}_{yx},\end{aligned} \tag{75}$$

The comparison of the two expressions of curvature $d^3=0$, Sec. V and $d^2=0$, will be given in the following section.

VIII. DISCUSSIONS AND CONCLUDING REMARKS

In this paper, we have constructed a differential calculus $n=3$ nilpotent on the reduced quantum plane by mixing Kerner's idea and Coquereaux's techniques. The notion of covariance for this differential calculus is also given and we have shown that there is a quantum group structure behind this covariance. As an application, we have constructed a gauge field theory based on this calculus.

In the case $n=3$, the expression of curvature, Eq. (55), contains additional terms, Eqs. (80), (81) (Appendix B) compared with Eq. (74) ($n=2$). These terms can be interpreted as a generic consequence of the extension of the differential calculus $d^2=0$ to the higher order $d^3=0$.

We can also compare our results with those of Kerner *et al.*[2,19] In fact, Eqs. (56), (80) are formally the same as in Refs. 2, 19; they differ only by the appearance of the deformation parameter q. However, there is no analogy of Eq. (81) in Refs. 2, 19. It is a direct consequence of the noncommutativity of the space considered here.

In a forthcoming paper, we shall treat in a mathematical way the correspondence between this calculus and the Heisenberg algebra. This correspondence is based on the bargman Fock representation and will give a new oscillator algebra. To study the minimization of an uncertainty principle, we will try to find the eigenvectors of the annihilation operator in a way to construct the corresponding Klauder's coherent states.[17]

Zakkari wish to thank the Abdus Salam International Center for Theoretical Physics for financial and scientific support, where a great part of this work has been done. This work was done within the framework of Associateship and Federation Arrangement Schemes of the Abdus Salam ICTP.

APPENDIX A: THE CONSTRUCTION OF A COVARIANT DIFFERENTIAL CALCULUS ON A TWO-DIMENSIONAL QUANTUM PLANE

We start by writing *a priori* $x\,dx$, $x\,dy$, $y\,dx$ and $y\,dy$ in terms of $dx\,x$, $dy\,x$, $dx\,y$ and $dy\,y$, i.e.,

$$x\,dx = a_1\,dx\,x + b_1\,dy\,x + c_1\,dx\,y + d_1\,dy\,y, \tag{A1}$$

$$x\,dy = a_2\,dx\,x + b_2\,dy\,x + c_2\,dx\,y + d_2\,dy\,y, \tag{A2}$$

$$y\,dx = a_3\,dx\,x + b_3\,dy\,x + c_3\,dx\,y + d_3\,dy\,y, \tag{A3}$$

$$y\,dy = a_4\,dx\,x + b_4\,dy\,x + c_4\,dx\,y + d_4\,dy\,y. \tag{A4}$$

Differentiating the commutation relation $xy = qyx$ and replacing $x\,dx$ and $x\,dy$ by their expressions in the formulas above, permits us to fix three unknown coefficients. This leaves us with *nine* independent parameters.

The left coaction of F on a quantum plane is defined by

$$x_1 = a \otimes x + b \otimes y,$$

$$y_1 = c \otimes x + d \otimes y.$$

Hence

$$dx_1 = a \otimes dx + b \otimes dy,$$

$$dy_1 = c \otimes dx + d \otimes dy.$$

We impose that the relations between x_1, y_1 and dx_1, dy_1 be the same as the relations between x, y and dx, dy; these conditions yield to

$$a_2 = a_3 = a_4 = b_1 = b_4 = c_1 = c_4 = d_1 = d_2 = d_3 = 0 \quad \text{and} \quad d_1 = a_4,$$

and the coefficients b_2, b_3, c_2, and c_3 can be expressed in the terms of one unknown coefficient a_1:

$$b_2 = \frac{q(1+a_1)}{1+q^2}, \quad c_2 = \frac{a_1 q^2 - 1}{1+q^2},$$

$$b_3 = \frac{a_1 - q^2}{1+q^2}, \quad c_3 = \frac{q(1+a_1)}{1+q^2}.$$

Differentiating the relations (76)–(79) and noticing that $dx\,dx$, d^2x, $dy\,dy$ and d^2y are independent, we find $a_1 = q^2$. The left covariant differential calculus on a reduced quantum plane is hence constructed, Eqs. (9)–(22).

APPENDIX B: THE CURVATURE COMPONENTS

In this appendix we give the explicit expression of the curvature components appearing in Eq. (55):

$$
\begin{aligned}
R_{xxy} &= \partial_x\partial_x A_y(x,y) + \partial_x A_x(x,y) A_y(q^2x,qy) - q^2 A_x(x,y)\partial_x A_y(qx,q^2y) \\
&\quad + A_x(x,y)A_x(qx,q^2y)A_y(q^2x,qy), \\
R_{yxx} &= \partial_y\partial_x A_x(x,y) + \partial_y A_x(x,y) A_x(x,y) - q^2 A_y(x,y)\partial_x A_x(qx,q^2y) \\
&\quad + A_y(x,y)A_x(q^2x,qy)A_x(x,y), \\
R_{xyx} &= \partial_x\partial_y A_x(x,y) + \partial_x A_y(x,y) A_x(x,y) - q^2 A_x(x,y)\partial_y A(qx,q^2y) \\
&\quad + A_x(x,y)A_y(qx,q^2y)A_x(x,y), \\
R_{yyx} &= \partial_y\partial_y A_x(x,y) + \partial_x A_y(x,y) A(x,y) - q^2 A_x(x,y)\partial_y A_x(qx,q^2y) \\
&\quad + A_y(x,y)A_y(q^2x,qy)A_x(qx,q^2y), \\
R_{yxy} &= \partial_y\partial_x A_y(x,y) + \partial_y A_x(x,y) A_x(x,y) - q^2 A_y(x,y)\partial_x A_y(qx,q^2y) \\
&\quad + A_y(x,y)A_x(q^2x,qy)A_y(x,y), \\
R_{xyy} &= \partial_x\partial_y A_y(x,y) + \partial_x A_y(x,y) A_y(x,y) - q^2 A_x(x,y)\partial_y A_y(qx,q^2y) \\
&\quad + A_x(x,y)A_y(qx,q^2y)A_y(x,y),
\end{aligned}
\tag{B1}
$$

$$
\begin{aligned}
f_0(x,y) &= -b_{11}y^2 - qb_{10}y + q^2b_{22}x + b_{20}xy + qb_{21}xy^2 - b_{21}, \\
f_1(x,y) &= -a_{11}y^2 - a_{10}y + a_{22}x + a_{20}xy + a_{21}xy^2 - a_{12}, \\
f_2(x,y) &= -b_{20}y^2 - q^2b_{21}y - q^2b_{22}y, \\
f_3(x,y) &= -q^2a_{11}y^2 - a_{10}y + q^2a_{22}x + qa_{20}xy + a_{21}xy^2 - qa_{12}, \\
f_4(x,y) &= -q^2b_{11}y^2 - b_{10}y + q^2b_{22}x + qb_{20}xy + b_{21}xy^2 - qb_{12}, \\
f_5(x,y) &= -qb_{21}y^2 - b_{20}y - qb_{22}, \\
f_6(x,y) &= +qa_{12}y^2 + -a_{11}y + qa_{21}xy - qa_{22}xy^2, \\
f_7(x,y) &= +qb_{21}y^2 - b_{11}y + qb_{21}xy^2 - qb_{22}xy^2, \\
f_8(x,y) &= -b_{11}y^2 - b_{10}y + b_{22}x - b_{20}xy + b_{21}xy^2 - b_{12}.
\end{aligned}
\tag{B2}

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 10 OCTOBER 2003

Imaginary Killing spinors in Lorentzian geometry

Felipe Leitner[a)]
University of Edinburgh, School of Mathematics, JCMB–Kings' Buildings, Edinburgh EH9 3JZ, United Kingdom

(Received 16 April 2003; accepted 18 June 2003)

We study the geometric structure of Lorentzian spin manifolds, which admit imaginary Killing spinors. The discussion is based on the cone construction and a normal form classification of skew-adjoint operators in signature $(2,n-2)$. Derived geometries include Brinkmann spaces, Lorentzian Einstein–Sasaki spaces and certain warped product structures. Exceptional cases with decomposable holonomy of the cone are possible. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1606524]

I. INTRODUCTION

A classical object of interest in differential geometry are Killing vector fields. These are by definition infinitesimal isometries, which means that the flow of such a vector field preserves the metric. A spinorial analog are the so-called Killing spinor fields φ, which occur on spin manifolds and are defined as solutions of the field equation $\nabla^S_X\varphi=\lambda X\cdot\varphi$ for all vector fields X and some fixed $\lambda\in\mathbb{C}$, where ∇^S denotes the spinor derivative and the center dot denotes the Clifford multiplication.

In Riemannian geometry, it was proved in Ref. 12 that real Killing spinors realize the lower bound of the eigenvalue estimation for the Dirac equation on compact spaces with positive scalar curvature. In the sequel Riemannian spaces admitting Killing spinors were intensively studied (cf. Refs. 11 and 5) and a complete geometric description of such spaces was established. For the case of imaginary Killing spinors this was done by Baum in Ref. 3 and then for real Killing spinors by Ch. Bär using the cone construction and the holonomy classification of Riemannian spaces with parallel spinors (cf. Ref. 1). Both results characterize Riemannian spaces with Killing spinors by the Einstein condition and the existence of certain differential forms, which can be understood as generalized Killing vectors. Real Killing spinors in Lorentzian geometry were first studied in Ref. 9.

In this paper we will treat the Killing spinor equation to an imaginary Killing number λ on a pseudo-Riemannian space with Lorentzian signature. As a technical tool we will use again the cone construction for the investigation. Contrary to the Riemannian case, a holonomy description of the cone cannot be used, since there is no classification of indecomposable holonomy groups for pseudo-Riemannian manifolds. Moreover, the geodesical completeness of a Lorentzian manifold does not imply that a cone with decomposable holonomy is flat. Instead, our geometrical description is mainly based on a normal form classification of skew-adjoint operators in signature $(2,n-2)$, which is more rich than in the Euclidean case (cf. Ref. 10). The derived Lorentzian geometries are then described by the causal properties of the corresponding Dirac current and the existence of parallel spinors or certain Killing forms. Thereby, we will use the knowledge of structure results for Lorentzian manifolds admitting conformal gradient fields (cf. Ref. 13) and twistor spinors with lightlike Dirac current (cf. Ref. 6). Examples of geometries that occur are the Brinkmann spaces with parallel spinors, the Lorentzian Einstein–Sasaki manifolds and certain warped product structures.

The order of the paper is as follows. In the next section we introduce the basic notations and

a)Electronic mail: f.leitner@maths.ed.ac.uk

definitions appropriate for the study of Killing spinors and state basic curvature conditions for their existence (cf. Proposition 2.1 and 2.2). In Sec. III we recall the cone construction over a Lorentzian base manifold and the correspondence of ''Killing objects'' on the base and parallel objects on its cone (Theorem 3.1). We present the normal form classification of skew-adjoint operators in signature $(2,n-2)$ due to the work of Boubel in Sec. IV. It turns out that there are exactly four generic types of normal forms for skew-adjoint operators coming from a spinor (cf. Corollary 4.7). The cone of a Lorentzian manifold admitting imaginary Killing spinors is furnished with at least one parallel two-form, which corresponds to one of the generic types (Proposition 5.1). According to this type of a parallel two-form on the cone we undertake in three of the four generic cases a discussion of the geometry of Lorentzian manifolds with imaginary Killing spinors. This happens in the last section. The results of the discussion are summerized in Theorem 5.3.

II. BASIC FACTS ON KILLING SPINORS

In this section we recall the definition of Killing spinors on a spin manifold and fix some notations. A basic integrability condition for Killing spinors is stated. For more details we refer to Ref. 5. Moreover, we will come across special Killing forms as they were introduced in Ref. 15.

Let $(M^{n,k},g)$ be a semi-Riemannian spin manifold of dimension $n\geqslant 3$ and signature $(k,n-k)$ (k is the number of timelike vectors in an orthonormal basis at a point). We denote by S the complex spinor bundle and by a center dot the Clifford multiplication on spinors. The Dirac operator $D:\Gamma(S)\to\Gamma(S)$ acting on smooth spinor fields is defined as superposition of spinor derivative ∇^S and Clifford multiplication. A spinor field $\varphi\in\Gamma(S)$ is called *Killing spinor* to the *Killing number* $\lambda\in\mathbb{C}$ if it satisfies the equation

$$\nabla^S_X\varphi=\lambda X\cdot\varphi \quad \text{for all vector fields } X.$$

It follows immediately from this definition that a Killing spinor φ is an eigenspinor of the Dirac operator D to the eigenvalue $-n\lambda$ and φ is obviously a parallel spinor field with respect to the modified spinor derivative $\tilde{\nabla}_\lambda$ defined by

$$\tilde{\nabla}_\lambda:=\nabla^S-\lambda id_{TM}.$$

In particular, this implies that a Killing spinor φ admits no zeros. It holds the following basic integrability condition.

Proposition 2.1 (Ref. 5): Let $\varphi\in\Gamma(S)$ be a Killing spinor to the Killing number $\lambda\in\mathbb{C}$.

(1) It is $\mathcal{W}(\eta)\cdot\varphi=0$ for any two-form η, where $\mathcal{W}$ denotes the Weyl tensor.
(2) $(Ric(X)-4\lambda^2(n-1)X)\cdot\varphi=0$, i.e., the image of the map $Ric-4\lambda^2(n-1)id_{TM}$ is totally lightlike or trivial.
(3) The scalar curvature is constant and given by $\mathrm{scal}=4n(n-1)\lambda^2$. The Killing number λ is real or purely imaginary.

If the Killing number λ is zero ($\mathrm{scal}=0$), φ is a parallel spinor, in case that λ is real and nonzero ($\mathrm{scal}>0$), φ is called real Killing spinor, and in case that λ is purely imaginary ($\mathrm{scal}<0$), φ is called imaginary Killing spinor. We will treat in this paper the Killing spinor equation with imaginary Killing number on a space of Lorentzian signature $(-+\cdots+)$.

So let $(M^{n,1},g)$ be a connected, oriented and time-oriented Lorentzian spin manifold. There exists an indefinite non-degenerate inner product $\langle\cdot,\cdot\rangle$ on the spinor bundle S such that

$$\langle X\cdot\varphi,\psi\rangle=\langle\varphi,X\cdot\psi\rangle,$$

$$X(\langle\varphi,\psi\rangle)=\langle\nabla^S_X\varphi,\psi\rangle+\langle\varphi,\nabla^S_X\psi\rangle$$

for all vector fields X and all spinor fields φ,ψ. Each spinor field $\varphi\in\Gamma(S)$ defines a vector field V_φ on M, the so-called *Dirac current*, by the relation $g(V_\varphi,X):=-\langle X\cdot\varphi,\varphi\rangle$ for all vector fields X. The Dirac current satisfies the following pointwise properties.

Lemma 2.1 (Ref. 14): Let $(M^{n,1},g)$ be a Lorentzian spin manifold and let $\varphi(p)\neq 0$ be a spinor in a point $p\in M^{n,1}$. Then

(1) $V_\varphi(p)\neq 0$ and $V_\varphi(p)$ is causal (i.e., $g_p(V_\varphi,V_\varphi)\leqslant 0$).
(2) If $X\cdot\varphi(p)=\rho\varphi(p)$ for some $0\neq X\in T_pM$ and $\rho\in\mathbb{R}$ then the vector X is parallel to $V_\varphi(p)$.

The lemma makes clear that the Dirac current to a Killing spinor on a Lorentzian manifold is everywhere causal. Moreover, it is now possible to prove a stronger curvature condition for the existence of Killing spinors.

Proposition 2.2: Let $(M^{n,1},g)$ be a Lorentzian spin manifold admitting a Killing spinor φ, whose Dirac current V_φ is timelike. Then (M,g) is an Einstein space.

Proof: Let us assume that $M^{n,1}$ is a non-Einstein space. Then there is an open set U in M, where $H:=\mathrm{Ric}(X)-(\mathrm{scal}/n)X\neq 0$ is lightlike for some vector field X. The Clifford product $H\cdot\varphi$ vanishes and by Lemma 2.1 this implies that H and V_φ are parallel, which is a contradiction to the assumption. □

Especially, for imaginary Killing spinors it holds the following.

Proposition 2.3 (Ref. 5): Let φ be an imaginary Killing spinor on a Lorentzian spin manifold $(M^{n,1},g)$. Then the length $\langle\varphi,\varphi\rangle$ is constant on $M^{n,1}$ and if $\langle\varphi,\varphi\rangle\not\equiv 0$ the space $M^{n,1}$ is Einstein.

Proof: It is $X\langle\varphi,\varphi\rangle=\langle\lambda X\cdot\varphi,\varphi\rangle+\langle\varphi,\lambda X\cdot\varphi\rangle=0$ and with Proposition 2.1 we calculate

$$\frac{1}{4(n-1)}\mathrm{Ric}(X,Y)\langle\varphi,\varphi\rangle=\frac{-1}{4(n-1)}\mathrm{Re}\langle\mathrm{Ric}(X)\cdot\varphi,Y\cdot\varphi\rangle$$
$$=-\mathrm{Re}\langle\lambda^2X\cdot\varphi,Y\cdot\varphi\rangle=\lambda^2g(X,Y)\langle\varphi,\varphi\rangle$$

for all vector fields X and Y, which shows that $\mathrm{Ric}(X)=(\mathrm{scal}/n)X$ in case that $\langle\varphi,\varphi\rangle\neq 0$. □

Propositions 2.2 and 2.3 imply that an imaginary Killing spinor φ on a Lorentzian non-Einstein space $M^{n,1}$ must have vanishing length $\langle\varphi,\varphi\rangle\equiv 0$ and the Dirac current V_φ to φ must be lightlike on an open subset of $M^{n,1}$. We will see later that in this case V_φ is even lightlike everywhere on $M^{n,1}$. Moreover, the Dirac current satisfies

Proposition 2.4: Let φ be an imaginary Killing spinor on a Lorentzian spin manifold $(M^{n,1},g)$. The Dirac current V_φ is a Killing vector field, which in addition satisfies $\nabla_X\,\mathrm{d}V_\varphi^\flat=-4\lambda^2X^\flat\wedge V_\varphi^\flat$.

Proof: It holds

$$g(\nabla_{e_i}V_\varphi,e_j)=-\langle\lambda e_je_i\cdot\varphi,\varphi\rangle-\langle e_j\varphi,\lambda e_i\cdot\varphi\rangle=-g(\nabla_{e_j}V_\varphi,e_i)$$

for all $i,j\in\{1,\ldots,n\}$, where $(e_1,\ldots,e_n)$ is an arbitrary orthonormal basis on $M^{n,1}$. This proves that V_φ is a Killing vector field. Moreover,

$$\mathrm{d}V_\varphi^b=4\lambda\sum_{i<j}\varepsilon_i\varepsilon_j\langle e_ie_j\cdot\varphi,\varphi\rangle e_i^\flat\wedge e_j^\flat,$$

$$\nabla_X\;\mathrm{d}V_\varphi^\flat=4\lambda^2\sum_{i<j}\varepsilon_i\varepsilon_j(\langle e_ie_jX\cdot\varphi,\varphi\rangle-\langle Xe_ie_j\cdot\varphi,\varphi\rangle)e_i^\flat\wedge e_j^\flat=-4\lambda^2X^\flat\wedge V_\varphi^\flat\;.$$

□

In general, a p-form α^p, which solves the equation

$$\nabla_X\,\mathrm{d}\alpha^p=cX^\flat\wedge\alpha^p\quad\text{for all vectors }X$$

and some fixed $c \in \mathbb{R}$, is called a *special Killing p-form* (cf. Ref. 15). Proposition 2.4 states that the dual of the Dirac current to an imaginary Killing spinor is a special Killing one-form. Killing spinors also produce special Killing forms of other degree than 1. For this, we observe that one constructs a p-form α^p_φ to a spinor φ by the rule

$$g(\alpha^p_\varphi, X^p) := -i^{p(p-1)/2}\langle X^p \cdot \varphi, \varphi\rangle \quad \text{for all } p\text{-forms } X^p$$

and, in fact, if p is odd and the Killing number λ of a Killing spinor φ is imaginary (or if p is even and λ is real) then the associated p-form α^p_φ to φ is special Killing.

III. THE CONE $\hat{M}$

In the preceding section we define the Killing spinors and special Killing p-forms on a Lorentzian manifold. In this section we will interpret these as parallel objects on the *cone manifold*. The cone construction was originally applied in order to describe Riemannian geometries admitting real Killing spinors (see Ref. 1) and can be modified here for our requirements. Let $(M^{n,1}, g)$ be a Lorentzian manifold. We consider the cone $\hat{M}$ of signature $(2, n-1)$ on $M^{n,1}$, which is defined as

$$\hat{M} := (M \times \mathbb{R}_+ , \hat{g} := r^2 g - \mathrm{d}r^2) \ .$$

Thereby, let π denote the natural projection of $\hat{M}$ to M. The 1-level $M \times \{1\}$ of the cone $\hat{M}$ is naturally isometric to the base manifold $M^{n,1}$ itself. We denote by $\tilde{X}$ the pullback of an arbitrary base vector field $X \in \Gamma(M)$ to $\hat{M}$ through the projection π. Then we have the following rules for the Levi-Civita connection $\hat{\nabla}$ on the cone:

$$\hat{\nabla}_{\partial_r}\partial_r = 0, \quad \hat{\nabla}_{\partial_r}\tilde{X} = \hat{\nabla}_{\tilde{X}}\partial_r = \frac{1}{r}\tilde{X} \ ,$$

$$\hat{\nabla}_{\tilde{X}}\tilde{Y} = \nabla_X Y - r g(X,Y)\partial_r \, .$$

In case that $M^{n,1}$ is a spin manifold the cone $\hat{M}$ is a spin manifold, too. Then we denote the spinor bundle of the cone with $\hat{S}$. For n even the restriction of $\hat{S}$ to the 1-level $M \times \{1\}$ of the cone is naturally isomorphic to the spinor bundle S on the base manifold $M^{n,1}$ by a map

$$\Phi \ : \ S \ \cong \hat{S}|_{M \times \{1\}}$$

with the property $\Phi(X \cdot \varphi) = X \cdot \Phi(\varphi)$ for all $X \in TM^{n,1}$. Similar, if n is odd, there are isomorphisms $\Phi_\pm : S \cong \hat{S}^\pm|_{M \times \{1\}}$ for the restricted half spinor bundles such that

$$-iX \cdot \Phi_+(\varphi) = \Phi_-(X \cdot \varphi),$$

for all tangent vectors $X \in TM^{n,1}$. With respect to the metric $\hat{g}$ the projection π gives rise to a pullback $\pi^* : \Gamma(\hat{S}|_{M \times \{1\}}) \to \Gamma(\hat{S})$ of spinor fields on the 1-level to the cone. Eventually, we denote by $\mathcal{K}_\lambda(M)$ the space of Killing spinors on $(M^{n,1}, g)$ to the Killing number λ.

Theorem 3.1: *(cf. Refs. 1 and 15) Let $(M^{n,1}, g)$ be a Lorentzian manifold and $\hat{M}$ its cone with signature $(2, n-1)$. The following correspondences exist.*

(1) The special Killing p-forms on $M^{n,1}$ to the positive constant $c = p+1$ are in 1-to-1 *correspondence with the parallel $(p+1)$-forms on the cone $\hat{M}$. The correspondence is given by*

$$\alpha \in \Omega^p(M) \mapsto r^p \, \mathrm{d}r \wedge \alpha - \frac{r^{p+1}}{p+1}\mathrm{d}\alpha \in \Omega^{p+1}(\hat{M}) \ .$$

(2) If $M^{n,1}$ is spin and $\mathrm{scal} = -n(n-1)$ *then there are natural isomorphisms*

$$\begin{aligned} \mathcal{K}_{i/2}(M)\oplus\mathcal{K}_{-i/2}(M) &\cong \mathcal{K}_0(\hat{M}) \\ \varphi &\mapsto \hat{\varphi}:=\pi^*\circ\Phi(\varphi) \end{aligned} \quad \text{for } n \text{ even}$$

$$\begin{aligned} \mathcal{K}_{\pm i/2}(M) &\cong \mathcal{K}_0^{\pm}(\hat{M}) \\ \varphi &\mapsto \hat{\varphi}:=\pi^*\circ\Phi_{\pm}(\varphi) \end{aligned} \quad \text{for } n \text{ odd},$$

where $\mathcal{K}_0^{\pm}(\hat{M})$ is the space of parallel $\pm$-half spinors on the cone.

The Riemannian version of Theorem 3.1 is classical for the application to the case of real Killing spinors. The result for Killing p-forms on Riemannian manifolds was established in Ref. 15. The proof for the correspondence here in case of imaginary Killing spinors φ in Lorentzian geometry is based on the observation that φ is parallel with respect to the modified spinor derivative $\tilde{\nabla}_\lambda$ coming from an affine connection one-form, which takes values in the subset

$$i\mathbb{R}^{1,n-1}\oplus\mathrm{spin}(1,n-1)\cong\mathrm{spin}(2,n-1)$$

of the Clifford algebra $\mathrm{Cliff}^{\mathbb{C}}_{1,n-1}$. We remark for the application of Theorem 3.1 that the metric g on $M^{n,1}$ can be rescaled by a positive constant such that the positive constant c to an arbitrary special Killing p-form equals $p+1$ and the Killing number λ to an arbitrary imaginary Killing spinor satisfies $\lambda^2=-\frac{1}{4}$.

The spinor bundle $S^{n,2}$ on a time-oriented, pseudo-Riemannian spin manifold $(N^{n,2},h)$ of signature $(2,n-2)$ is equipped with an invariant inner product $\langle\cdot,\cdot\rangle_{2,n-2}$ (cf. Ref. 2). Similar to the induced Dirac current of a spinor in Lorentzian geometry, a spinor $\gamma\in\Gamma(S^{n,2})$ induces a two-form α^2_γ on $N^{n,2}$ by the rule

$$h(\alpha^2_\gamma,X^2):=-i\langle X^2\cdot\gamma,\gamma\rangle_{2,n-2} \quad \text{for all two-forms } X^2.$$

In case that $\hat{M}$ is the cone over a Lorentzian spin manifold $M^{n,1}$ the inner product $\langle\cdot,\cdot\rangle_{2,n-1}$ admits the property

$$\langle\varphi,\psi\rangle=-\langle\partial_r\cdot\Phi_-(\varphi),\Phi_+(\psi)\rangle_{2,n-1} \quad \text{for } n \text{ odd},$$

$$\langle\varphi,\psi\rangle=i\langle\partial_r\cdot\Phi(\varphi),\Phi(\psi)\rangle_{2,n-1} \quad \text{for } n \text{ even},$$

on the 1-level of $\hat{M}$, where φ, ψ are spinor fields on $M^{n,1}$. Then the following relation is true.

Lemma 3.2: Let $\varphi\in\Gamma(S)$ be a spinor with Dirac current V_φ on a Lorentzian spin manifold $M^{n,1}$ and let $\hat{\varphi}$ be the corresponding ($\pm$ half) spinor with associated two-form $\alpha^2_{\hat{\varphi}}$ on the cone $\hat{M}$. It holds $V^\flat_\varphi=\partial_r\lrcorner\alpha^2_{\hat{\varphi}}$ on the 1-level $M^{n,1}\subset\hat{M}$.

Proof: With respect to an orthonormal basis $e=(e_0,e_1,\ldots,e_n)$ with $e_0=\partial_r$ in an arbitrary point of the 1-level it holds

$$\begin{aligned} \partial_r\lrcorner\alpha^2_{\hat{\varphi}} &= -i\sum_{i<j}\langle e_ie_j\cdot\hat{\varphi},\hat{\varphi}\rangle_{2,n-1}\cdot\partial_r\lrcorner e_i^*\wedge e_j^* \\ &= -i\sum_{j=1}^{n}\langle\partial_re_j\cdot\hat{\varphi},\hat{\varphi}\rangle_{2,n-1}e_j^* \\ &= -\sum_{j=1}^{n}\langle e_j\varphi,\varphi\rangle e_j^*=V^\flat_\varphi\ . \end{aligned}$$

□

The lemma also shows that $\alpha^2_{\hat{\varphi}}$ is nontrivial for all (half) spinors $\hat{\varphi}\neq 0$ on the cone $\hat{M}$, since the corresponding Dirac current $V^\flat_\varphi$ on $M^{n,1}$ is nontrivial.

IV. NORMAL FORMS FOR SKEW-ADJOINT OPERATORS IN SIGNATURE $(2,n-2)$

In this section we present a complete list of *normal forms* for skew-adjoint endomorphisms acting on the pseudo-Euclidean space $\mathbb{R}^{2,n-2}$ of dimension n and signature $(2,n-2)$. This list was established in Ref. 10. Parallel two-forms on the cone of signature $(2,n-1)$ over a Lorentzian manifold correspond to parallel skew-adjoint operators and are therefore distinguished by the normal forms of the list. This observation will be the crucial point in our description of Lorentzian geometries admitting imaginary Killing spinors in the last section.

Theorem 4.1: (cf. Ref. 10): *Let β be an arbitrary two-form on the pseudo-Euclidean space $\mathbb{R}^{2,n-2}$. Then there exist vector spaces V_i such that $\mathbb{R}^{2,n-2}=\oplus_i V_i$ is an orthogonal direct sum and the skew-adjoint endomorphism b, which corresponds to β, satisfies $b(V_i)\subset V_i$ for all i. Moreover, there is a basis $(e_{i_1},\ldots,e_{i_{r(i)}})$ for every V_i such that the corresponding matrices for the inner product and for b are one pair of blocks as it occurs in the lines of Table I.*

A basis of $\mathbb{R}^{2,n-2}$, in which a skew-adjoint operator takes a normal form, is called an *adapted basis*. There is always an orthogonal decomposition $\mathbb{R}^{2,n-2}=E\oplus P$ to a skew-adjoint operator b such that E is Euclidean and b preserves the decomposition. We call the normal form to b on E an *Euclidean block* and the normal form to b on P a *pseudo-Euclidean block*.

Example 4.2:

(a) Let $\omega_0:=\Sigma_{i=1}^{m} e_{2i-1}^*\wedge e_{2i}^*$ be the standard (pseudo)-Kähler form on $\mathbb{R}^{2,n-2}$, where $(e_1,\ldots,e_{2m})$ is the standard basis. The normal form of the skew-adjoint operator corresponding to a multiple $\omega=\nu\cdot\omega_0$ of the Kähler form with respect to the adapted basis $(e_1,\ldots,e_{2m})$ is built up by one block of the form $B_{II}(\nu)$ (pseudo-Euclidean block) and $(m-1)$ blocks of the form $B(\nu)$ (Euclidean block) (cf. Table I).

(b) A two-form $\omega=l_1^\flat\wedge l_2^\flat$ on $\mathbb{R}^{2,n-2}$, where l_1 and l_2 are lightlike vectors, which span a totally lightlike plane, corresponds as skew-adjoint operator with respect to some adapted basis to a composition of a pseudo-Euclidean block of the form B_{Ia} and an Euclidean 0-block of length $n-4$.

(c) A two-form $\omega=l_1^\flat\wedge t_1^\flat$ on $\mathbb{R}^{2,n-2}$, where l_1 is lightlike, t_1 is timelike and both vectors are orthogonal, corresponds as skew-adjoint operator with respect to some adapted basis to a composition of a block B_{Ib} and a 0-block of length $n-3$.

Let $\hat{\varphi}$ be a spinor on the pseudo-Euclidean space $\mathbb{R}^{2,n-1}$. There corresponds a two-form $\alpha_{\hat{\varphi}}^2$ to $\hat{\varphi}$ on $\mathbb{R}^{2,n-1}$ defined by the rule

$$(\alpha_\varphi^2,x^2):=-i\langle x^2\cdot\varphi,\varphi\rangle_{2,n-2}\quad\text{for all } x^2\in\Lambda^2(\mathbb{R}^{2,n-1^*}),$$

where $(\cdot,\cdot)$ denotes the induced inner product on $\Lambda^2(\mathbb{R}^{2,n-1^*})$ (cf. Sec. III). The following statement is a version of Lemma 3.2 considered in a single point only and the proof for it works the same as before.

Lemma 4.3: Let $\hat{\varphi}$ be a ($\pm$-half) spinor on $\mathbb{R}^{2,n-1}$ and $T\in\mathbb{R}^{2,n-1}$ an arbitrary unit timelike vector. The one-form $\alpha_{T,\hat{\varphi}}:=T\lrcorner\alpha_{\hat{\varphi}}^2$ is dual to the associated vector induced by the spinor φ on the Minkowski space $T^\perp\subset\mathbb{R}^{2,n-1}$, which corresponds naturally to $\hat{\varphi}$.

The lemma imposes a condition on the nature of a two-form induced by a spinor in signature $(2,n-2)$, since the associated vector to a nontrivial spinor on the Minkowski space is not arbitrary, but causal. With some simple calculations we can sort out the normal forms for skew-adjoint operators corresponding to two-forms, which do not satisfy the condition imposed by Lemma 4.3, and therefore cannot be induced by a spinor.

Corollary 4.4: Let ω be a two-form in signature $(2,n-2)$ such that the covector $T\lrcorner\omega$ is causal for every timelike vector $T\in\mathbb{R}^{2,n-2}$.

(1) If there is a timelike T such that $T\lrcorner\omega$ is lightlike then the normal form corresponding to ω is a composition of a pseudo-Euclidean block of the form B_{Ia} or B_{Ib} with an Euclidean 0-block.

TABLE I. These are the building blocks for the normal forms of skew-adjoint operators in signature $(2,n-2)$. The matrices in the first column (denoted by A) indicate an inner product (of index $s\leqslant 2$) with respect to some basis and the matrices in the second column (denoted by B) are skew-adjoint endomorphisms with respect to the inner product in column A and the chosen basis.

Signature (p,q)	$A=$ inner product	$B=$ skew-adjoint operator	
(0,1)	(1)	(0)	
(0,2)	$\begin{pmatrix}1&0\\0&1\end{pmatrix}$	$B(\mu)=\begin{pmatrix}0&-\mu\\\mu&0\end{pmatrix}$	$\mu\neq 0$

(1,2)	$\begin{pmatrix}0&0&-1\\0&1&0\\-1&0&0\end{pmatrix}$	$\begin{pmatrix}0&1&0\\0&0&1\\0&0&0\end{pmatrix}$	
(1,1)	$\begin{pmatrix}0&1\\1&0\end{pmatrix}$	$\begin{pmatrix}\lambda&0\\0&-\lambda\end{pmatrix}$	$\lambda\neq 0$
(2,2)	$\begin{pmatrix}0&0&0&-1\\0&0&1&0\\0&1&0&0\\-1&0&0&0\end{pmatrix}$	$B_{Ia}=\begin{pmatrix}0&0&1&0\\0&0&0&1\\0&0&0&0\\0&0&0&0\end{pmatrix}$	
(2,1)	$\begin{pmatrix}0&0&1\\0&-1&0\\1&0&0\end{pmatrix}$	$B_{Ib}=\begin{pmatrix}0&1&0\\0&0&1\\0&0&0\end{pmatrix}$	
(2,4)	$\begin{pmatrix}0&0&-I_2\\0&I_2&0\\-I_2&0&0\end{pmatrix}$	$\begin{pmatrix}0&I_2&0\\0&0&I_2\\0&0&0\end{pmatrix}$	
(2,0)	$\begin{pmatrix}-1&0\\0&-1\end{pmatrix}$	$B_{II}(\nu)=\begin{pmatrix}0&-\nu\\\nu&0\end{pmatrix}$	$\nu\neq 0$
(2,2)	$\begin{pmatrix}0&0&0&-1\\0&0&1&0\\0&1&0&0\\-1&0&0&0\end{pmatrix}$	$B_{IIa}=\begin{pmatrix}0&-\nu&1&0\\\nu&0&0&1\\0&0&0&-\nu\\0&0&\nu&0\end{pmatrix}$	$\nu\neq 0$
(2,4)	$\begin{pmatrix}0&0&-I_2\\0&I_2&0\\-I_2&0&0\end{pmatrix}$	$\begin{pmatrix}0&-\nu&I_2&0\\\nu&0&0&I_2\\0&\nu&0&-\nu\\0&0&\nu&0\end{pmatrix}$	$\nu\neq 0$
(2,2)	$\begin{pmatrix}0&I_2\\I_2&0\end{pmatrix}$	$\begin{pmatrix}\lambda I_2&0\\0&-\lambda I_2\end{pmatrix}$	$\lambda\neq 0$
(2,2)	$\begin{pmatrix}0&0&0&-1\\0&0&1&0\\0&1&0&0\\-1&0&0&0\end{pmatrix}$	$\begin{pmatrix}\lambda&0&1&0\\0&-\lambda&0&1\\0&0&\lambda&0\\0&0&0&-\lambda\end{pmatrix}$	$\lambda\neq 0$
(2,2)	$\begin{pmatrix}0&0&1&0\\0&0&0&-1\\1&0&0&0\\0&-1&0&0\end{pmatrix}$	$B_{IIb}=\begin{pmatrix}\xi&-\nu&0&0\\\nu&\xi&0&0\\0&0&-\xi&\nu\\0&0&-\nu&-\xi\end{pmatrix}$	$\xi,\nu\neq 0$
(2,3)	$\begin{pmatrix}0&0&0&0&1\\0&0&0&-1&0\\0&0&1&0&0\\0&-1&0&0&0\\1&0&0&0&0\end{pmatrix}$	$\begin{pmatrix}0&1&0&0&0\\0&0&1&0&0\\0&0&0&1&0\\0&0&0&0&1\\0&0&0&0&0\end{pmatrix}$	

(2) If $T \lrcorner \omega$ is timelike for all timelike T then the normal form of ω is a composition of B_{II}, B_{IIa} or B_{IIb} ($\nu^2 \geqslant \xi^2$) with an Euclidean block consisting of blocks of the form $B(\mu)$ and/or a 0-block.

With *stabilizer* of a skew-adjoint operator (respectively, two-form) we mean in the following the subgroup of the (pseudo)-orthogonal group, which leaves the operator (respectively, the two-form) invariant under conjugated action. A simple consideration shows the following fact.

Lemma 4.5: The stabilizer of a normal form, which is built from a pseudo-Euclidean block of the form $B_{IIa}(\nu)$ or $B_{IIb}(\nu,\xi)$ and some Euclidean block of length $n-4$ is included in $\mathrm{U}(1,1) \times \mathrm{SO}(n-4)$ *for all eigenvalues ν and $\xi \neq 0$.*

Definition 4.6: Let $\mathbb{R}^{2,n-2}$ be the pseudo-Euclidean space of signature $(2,n-2)$ and $\omega \in \Lambda^2 \mathbb{R}^{2,n-2*}$ be a nontrivial two-form. We say that ω is of

- *Type (I_a) if $\omega = l_1^\flat \wedge l_2^\flat$ for some vectors l_1 and l_2, which span a totally lightlike plane.*
- *Type (I_b) if $\omega = l_1^\flat \wedge t_1^\flat$ for some lightlike vector l_1 and a l_1-orthogonal timelike vector t_1.*
- *Type (II_a) or Kähler type if ω is a nontrivial multiple of the standard Kähler form.*
- *Type (II_b) if there exists a nontrivial Euclidean subspace E in $\mathbb{R}^{2,n-2}$ such that ω restricted to E vanishes and ω is the (pseudo)-Kähler form on the orthogonal complement of E in $\mathbb{R}^{2,n-2}$.*

Lemma 4.5 makes clear, which stabilizers of the normal forms occurring in Corollary 4.4 are maximal.

Corollary 4.7: A two-form ω on $\mathbb{R}^{2,n-2}$, which is of types (I_a), (I_b), (II_a) or (II_b), is exclusively distinguished by its properties that

(1) the covector $T \lrcorner \omega$ is causal for every timelike vector $T \in \mathbb{R}^{2,n-2}$ and
(2) its stabilizer S_ω in $\mathrm{SO}(2,n-2)$ *is maximal, in the sense that there is no nontrivial two-form satisfying the first property, whose stabilizer properly contains S_ω.*

We observe that the stabilizer of a two-form of type (I_a) and type (I_b) acts indecomposable but reducible on $\mathbb{R}^{2,n-2}$, i.e., there exist nontrivial and invariant subspaces of $\mathbb{R}^{2,n-2}$, but the inner product is degenerate on all of them. The stabilizer of a Kähler-type form is $U(1,m-1)$ and acts irreducible on $\mathbb{R}^{2,2m-2}$. The stabilizer of a form of type (II_b) acts decomposable on $\mathbb{R}^{2,n-2}$.

V. IMAGINARY KILLING SPINORS

With the construction of the cone in Sec. III and the normal form classification for skew-adjoint operators in signature $(2,n-2)$ (coming from a spinor) in the preceding section we are now in the position to discuss a geometric description of Lorentzian manifolds admitting imaginary Killing spinors.

In the following, the metric g on the Lorentzian spin manifold $M^{n,1}$ will be scaled such that the Killing number λ to any Killing spinor satisfies $\lambda^2 = -\frac{1}{4}$. We start with a proposition, which characterizes the cone $\hat{M}$ of a Lorentzian manifold $M^{n,1}$ with imaginary Killing spinor and indicates the different cases that are to be considered for the geometry of the base manifold $M^{n,1}$. We remark that the normal form corresponding to a parallel two-form on the cone is in every point the same.

Proposition 5.1: Let $(M^{n,1},g)$ be a Lorentzian spin manifold admitting an imaginary Killing spinor. Then either there exists a parallel two-form ω of type (II_b) on the cone $\hat{M}$ or there exists at least one parallel (half) spinor $\hat{\varphi}$ on $\hat{M}$ such that the induced parallel two-form $\omega = \alpha^2_{\hat{\varphi}}$ is of types (I_a), (I_b) or (II_a).

Proof: Let ψ be an imaginary Killing spinor on $M^{n,1}$. According to Corollary 4.4 the normal form of the skew-adjoint endomorphism corresponding to $\alpha^2_{\hat{\psi}}$ on the cone is a composition with one block of the form B_{Ia}, B_{Ib}, B_{II}, B_{IIa} or B_{IIb}. In case that the normal form is built with a block of the form B_{Ia} or B_{Ib} the parallel two-form $\omega = \alpha^2_{\hat{\psi}}$ is of types (I_a) or (I_b).

In the other cases there exists a biggest number $s>0$ such that the stabilizer of the normal form to $\alpha^2_{\hat{\psi}}$ is included in $\mathrm{U}(1,s-1)\times\mathrm{SO}(n-2s)$. This group includes the holonomy group of the cone $\hat{M}$. In case that $2s=n$ the cone $\hat{M}$ is a Kähler spin manifold. Moreover, since $V^\flat_\psi=\partial_r\lrcorner\alpha^2_{\hat{\psi}}$ is everywhere timelike (Corollary 4.4), the base $M^{n,1}$ is Einstein and hence the cone is Ricci-flat. This implies that there exists a parallel half-spinor $\hat{\varphi}$, which induces a Kähler form on the cone. If $2s<n$ there exists a parallel two-form ω of type (II_b). □

We discuss now a description of the Lorentzian geometries on the base manifold $M^{n,1}$ with imaginary Killing spinor according to the cases (I_a), (I_b), and (II_a) that occur in Proposition 5.1.

A. Type (I_a)

In this case there exists a parallel (half) spinor $\hat{\varphi}$ on the cone $\hat{M}$, which induces a parallel two-form $\omega\neq 0$ that is locally of the form $l_1^\flat\wedge l_2^\flat$ for some lightlike vector fields l_1 and l_2, which span a totally lightlike plane. The dual $V^\flat_\varphi$ of the Dirac current of the imaginary Killing spinor φ, which corresponds to $\hat{\varphi}$ on $\hat{M}$, is equal to $\partial_r\lrcorner\omega$, which shows that the Dirac current V_φ is everywhere lightlike.

There is a known description of Lorentzian metrics admitting *twistor spinors* with lightlike Dirac current. We call a Lorentzian space admitting a lightlike parallel vector field a *Brinkmann space*. Two spinor fields on (pseudo)-Riemannian spaces are said to be *conformally equivalent* if there exists a conformal diffeomorphism, which identifies both spinor fields. In particular, it holds the following.

Proposition 5.2 (see Ref. 6): Let φ be a spinor field, which satisfies the twistor equation $\nabla^S_X\varphi+(1/n)\,X\cdot D\varphi=0$ for all vector fields X, such that the Dirac current V_φ is a lightlike Killing vector field on $M^{n,1}$. If $Ric(V_\varphi,V_\varphi)=0$ then φ is locally conformally equivalent to a parallel spinor on a Brinkmann space.

This gives rise to the following.

Proposition 5.3: Let φ be an imaginary Killing spinor on $M^{n,1}$ such that $\alpha^2_{\hat{\varphi}}$ on $\hat{M}$ is of type (I_a). Then φ is locally conformally equivalent to a parallel spinor on a Brinkmann space.

Proof: From Proposition 2.1 and Lemma 2.1 we know that $\mathrm{Ric}(V_\varphi)=\rho V_\varphi$ for some real function ρ. Then we can apply Proposition 5.2 to prove the result. □

B. Type (I_b)

There exists a parallel (half-) spinor $\hat{\varphi}$ on the cone $\hat{M}$, which induces a parallel two-form ω of type (I_b). In this situation it holds as follows.

Lemma 5.1: The function $f_\varphi:=\sqrt{-g(V_\varphi,V_\varphi)}$ to the imaginary Killing spinor φ on $M^{n,1}$ satisfies the following:

(1) $Hess(f_\varphi)=f_\varphi\cdot g$, i.e., grad f_φ is a conformal gradient field, and $f^2_\varphi=g(\mathrm{grad}\,f,\mathrm{grad}\,f)$,
(2) $\mathrm{grad}\,f_\varphi\neq 0$ and $f_\varphi\neq 0$ on disjoint subspaces, whose complements are dense in $M^{n,1}$.

Proof: The two-form ω can be written as $r\,\mathrm{d}r\wedge V^\flat_\varphi-(r^2/2)\,\mathrm{d}V^\flat_\varphi$ (Theorem 3.1). The two-dimensional parallel sub-bundle $E_\omega\subset TM^{n,1}$, which corresponds to the indecomposable two-form ω is degenerate and there is a unique parallel lightlike direction in E_ω. In particular, there exists a parallel lightlike vector field l_1 on $\hat{M}$. Moreover, we can find locally a timelike vector t_1 of constant length such that $\omega=l_1^\flat\wedge t_1^\flat$. We choose the parallel lightlike field l_1 with the scaling $\hat{g}(t_1,t_1)=-1$. Since l_1 is parallel, there is a unique function f on $M^{n,1}$ such that $l_1^\flat=f\,\mathrm{d}r-r\,\mathrm{d}f$ and $f^2=g(\mathrm{grad}\,f,\mathrm{grad}\,f)$. The function f is a special Killing 0-form on $M^{n,1}$, i.e., grad f is a conformal gradient field. Since neither dr nor the lift of df to the cone are parallel, it is $f\neq 0$ and $\mathrm{grad}\,f\neq 0$ on a dense subset of $M^{n,1}$.

We calculate the function f with respect to φ. The local field $t_1^\flat$ is given by $t_1^\flat=A\,\mathrm{d}r+ru$, where A is a function and u a one-form on $M^{n,1}$. It follows that $V^\flat_\varphi=fu+A\,\mathrm{d}f$ and

$$g(V_\varphi,V_\varphi)=f^2g(u,u)+A^2g(\mathrm{d}f,\mathrm{d}f)+2\,fA\cdot g(u,\mathrm{d}f).$$

Since $g(u,u)=-1+A^2$ and $g(u,\mathrm{d}f)=-Af$, we can conclude $f^2=-g(V_\varphi,V_\varphi)$, which shows that f_φ has the claimed properties. □

The assertions of Lemma 5.1 imply together with Proposition 2.2 that $M^{n,1}$ is Einstein and $\operatorname{grad} f_\varphi$ is a nonhomothetic conformal gradient field. There is a known description of (pseudo)-Riemannian Einstein metrics admitting such conformal fields. In particular, there is the following.

Proposition 5.4 (cf. Ref. 13): Let $(M^{n,1},g)$ be a Lorentzian Einstein space admitting a non-constant solution f of the equation $\mathrm{Hess}(f)=l\cdot g$ for some function l. Then, in a neighborhood of any point with $v:=g(\mathrm{grad}(f),\mathrm{grad}(f))\neq 0$, the metric g is a warped product $\varepsilon\cdot\mathrm{d}t^2+f'^2(t)k$, where $\varepsilon:=\mathrm{sign}(v)$, k is an Einstein metric and f satisfies

$$f''^2+\frac{\varepsilon\,\mathrm{scal}_g}{n(n-1)}f'^2=\frac{\varepsilon\,\mathrm{scal}_k}{(n-1)(n-2)}.$$

This leads to the following.

Proposition 5.5: Let φ be an imaginary Killing spinor on $M^{n,1}$ such that $\alpha^2_{\hat{\varphi}}$ on $\hat{M}$ is of type (I_b). Then, in a neighborhood of any point with V_φ timelike, the metric g is a warped product of the form $\mathrm{d}t^2+f^2k$, where k is a Lorentzian Einstein metric admitting a Killing spinor to the Killing number

(1) $\lambda_k=0$ *and* $f=\exp t$,
(2) $\lambda_k=\frac{1}{2}$ *and* $f=\sinh t$ or
(3) $\lambda_k=(i/2)$ *and* $f=\cosh t$.

Proof: The function $f_\varphi=\sqrt{-g(V_\varphi,V_\varphi)}$ satisfies the assumptions of Proposition 5.4. Since $f_\varphi^2>0$, the warping function $f=f'_\varphi$ must solve the ordinary differential equation $f'^2-n(n-1)f^2=\mathrm{scal}_k$. There are three different solutions $f=\exp t$, $\cosh t$ and $\sinh t$ according to the values $\mathrm{scal}_k=0,\pm(n-1)(n-2)$. In each case the imaginary Killing spinor φ induces a Killing spinor to the Killing number $\mathrm{scal}_k/(n-1)(n-2)$ on the space with Einstein metric k (cf. Ref. 9). □

C. Type (II_a)

Lemma 5.2: Let $(M^{n,1},g)$ be a Lorentzian Einstein manifold with a Killing vector V such that $g(V,V)=-1$ is constant and $V\lrcorner\mathcal{W}=0$ ($\mathcal{W}$ Weyl tensor). Then the operator J defined by $J(X):=\nabla_X V$ on TM satisfies

(1) $J(V)=0$ *and* $J^2(X)=\mathrm{scal}/[n(n-1)]\,(X+g(V,X)V)$,
(2) $(\nabla_X J)(Y)=\mathrm{scal}/n(n-1)\,(g(V,Y)X-g(X,Y)V)$.

Proof: Because V is Killing with constant length, it follows $\nabla_V V=0$ and $g(\nabla_X V,\nabla_Y V)=\mathcal{R}(V,X,Y,V)$, where $\mathcal{R}$ denotes the Riemannian curvature tensor. It is $\mathcal{R}=\mathcal{W}+g\owedge L$, where

$$L=\frac{1}{n-2}\left(\frac{\mathrm{scal}}{2(n-1)}g-\mathrm{Ric}\right)$$

is the Schouten tensor and $\owedge$ denotes the Kulkarni–Nomizu product (cf. Ref. 7). Then from $V\lrcorner\mathcal{W}=0$ we obtain

$$\begin{aligned}g(J^2(X),Y)&=-g(J(X),J(Y))\\&=-g(V,Y)L(X,V)-g(V,X)L(Y,V)\\&\quad-L(X,Y)+g(X,Y)L(V,V)\ .\end{aligned}$$

The relation for J^2 follows immediately, since for $M^{n,1}$ an Einstein space it holds

$$L=-\frac{\mathrm{scal}}{2(n-1)n}g.$$

Moreover, it is $g(\nabla_{e_k}\nabla_{e_i}V,e_j)=\mathcal{R}(e_i,e_j,e_k,V)$ for all $i,j,k\in\{1,\ldots,n\}$ in $p\in M^{n,1}$ arbitrary, where $(e_1,\ldots,e_n)$ is a local parallel frame in p. Then

$$\begin{aligned}g((\nabla_{e_i}J)(e_k),e_l)&=\mathcal{R}(e_k,e_l,e_i,V)\\&=g(e_k,e_i)L(e_l,V)+g(e_l,V)L(e_k,e_i)\\&\quad-g(e_k,V)L(e_l,e_i)-g(e_l,e_i)L(e_k,V)\ ,\end{aligned}$$

which shows the identity for ∇J in an arbitrary point p of $M^{n,1}$. □

A Lorentzian manifold $(M^{n,1},g,V)$ with V a timelike Killing vector of constant length such that the operator $J=\nabla V$ satisfies the both properties of Lemma 5.2, is called a Lorentzian Sasaki manifold. It is well known that a Sasaki structure (V,J) on $M^{n,1}$ corresponds to a Kähler structure on the cone $\hat{M}$ (cf. Refs. 1 and 4).

Proposition 5.6: A Lorentzian spin manifold $(M^{n,1},g)$ with an imaginary Killing spinor φ, whose Dirac current V_φ is timelike and has constant length, is a Lorentzian Einstein–Sasaki manifold. This is exactly the case when the lift $\hat{\varphi}$ induces a Kähler form on the cone $\hat{M}$.

Proof: We have only to show that $V_\varphi\lrcorner\mathcal{W}=0$ on $M^{n,1}$ and then apply Lemma 5.2. With the identity $\mathcal{W}(\eta)\cdot\varphi=0$ (Proposition 2.1) and the relation $X\cdot\eta=-X\lrcorner\eta+X^\flat\wedge\eta$ in the Clifford algebra, where X denotes a vector and η a two-form, we obtain

$$\mathcal{W}(V_\varphi,X,Y,Z)=\langle\varphi,\mathcal{W}(X,Y,Z)\cdot\varphi\rangle=\langle\varphi,Z^\flat\wedge\mathcal{W}(X,Y)\cdot\varphi\rangle\in\mathbb{R}\ \text{ for all }\ X,Y,Z\in TM.$$

But $\langle\varphi,\rho^3\cdot\varphi\rangle\in i\mathbb{R}$ for all three-forms ρ^3, and therefore $V_\varphi\lrcorner\mathcal{W}=0$. □

We summarize the different cases as follows.

Theorem 5.3: *Let $(M^{n,1},g)$ be a Lorentzian spin manifold with imaginary Killing spinor φ.*

(1) If $M^{n,1}$ is not Einstein then $M^{n,1}$ is locally conformally equivalent to a Brinkmann space with parallel spinor.

(2) If $g(V_\varphi,V_\varphi)$ is constant then

- *(i) $g(V_\varphi,V_\varphi)=0$ and $M^{n,1}$ is locally conformally equivalent to a Brinkmann space with parallel spinor or*
- (ii) *$g(V_\varphi,V_\varphi)<0$ and $M^{n,1}$ is a Lorentzian Einstein–Sasaki manifold.*

(3) If the cone $\hat{M}$ is indecomposable and V_φ does not change the causal type then M is either

- *(i) locally conformally equivalent to a Brinkmann space with parallel spinor,*
- (ii) *locally a warped product of the form $\mathrm{d}t^2+f^2k$, where k is a Lorentzian Einstein metric admitting a Killing spinor and $f=\exp t$, $\cosh t$ or $\sinh t$ or*
- *(iii) a Lorentzian Einstein–Sasaki space (and the cone $\hat{M}$ is irreducible).*

(4) If V_φ changes the causal type then the set $Z_\varphi\subset M^{n,1}$, where V_φ is lightlike, is a hypersurface and $M^{n,1}\backslash Z_\varphi$ admits locally a warped product structure as in (3)(ii).

In case that the metric g does not belong to one of those listed in (3), then either V_φ changes the causal type or there is a parallel two-form of type (II_b) on the cone $\hat{M}$.

Remark 5.4:

(1) In fact, there exist examples of imaginary Killing spinors on non-Einstein spaces, which are generated by an appropriate conformal change of certain non-Einstein Brinkmann spaces with parallel spinors (cf. Ref. 9).

(2) *Partial structure results and examples for Lorentzian metrics with parallel or real Killing spinors are known (cf., e.g., Refs. 8 and 9). The warped product structure in case of type* (I_b) *then provides a construction principle for imaginary Killing spinors on Lorentzian spaces. The complete result in Ref. 13 for the description of Einstein spaces with conformal gradient fields does not apply when the field changes the causal type. A characterization in this case is not known and as consequence, Theorem 5.3 does not describe Lorentzian metrics with imaginary Killing spinors when the Dirac current changes the causal type*.

(3) *There is a construction principle for Lorentzian Einstein–Sasaki spin spaces. They appear as* S^1*-fiber bundles over Riemannian Kähler–Einstein spin spaces of negative scalar curvature (cf. Ref. 4).*

(4) *In case that there exists a parallel two-form of type* (II_b) *the cone* $\hat{M}$ *is decomposable. Different from the Riemannian case, this does not imply that the cone is flat, even if the base* $M^{n,1}$ *is geodesically complete. The geometry of the base* $M^{n,1}$ *with imaginary Killing spinor in this case remains to be investigated and is subject of a forthcoming paper*.

Example 5.5: Let $H^{n,1}:=\{x\in\mathbb{R}^{2,n-1}:\|x\|^2=-1\}\subset\mathbb{R}^{2,n-1}$ be the pseudohyperbolic space of signature $(1,n-1)$ with negative scalar curvature $\mathrm{scal}=-n(n-1)$. The space $H^{n,1}$ is geodesically complete, time-orientable and spin. The cone over $H^{n,1}$ is an open subset of $\mathbb{R}^{2,n-1}$. Each parallel (half) spinor on $\mathbb{R}^{2,n-1}$ restricted to $H^{n,1}$ gives rise to an imaginary Killing spinor. It is not difficult to see that every generic type (I_a), (I_b), (II_a), and (II_b) is realized by a two-form, which comes from a parallel (half) spinor on $\mathbb{R}^{2,n-1}$ and thus belongs to an imaginary Killing spinor on $H^{n,1}$. This means that there are examples of imaginary Killing spinors on $H^{n,1}$, $n\geqslant 3$, for each single case when the Dirac current is everywhere lightlike (I_a), changes the causal type (I_b), timelike with constant length (II_a) or everywhere timelike with nonconstant length.

A matrix model for the β-Jacobi ensemble

Ross A. Lippert[a)]
Applied Biosystems, 45 West Gude Drive, Rockville, Maryland 20850

(Received 12 March 2003; accepted 20 May 2003)

This note presents a random matrix model for general ($\beta>0$) β-Jacobi ensembles. This generalizes the well-known MANOVA models for $\beta=1,2,4$ and eliminates the quantization of β (and other parameters) present in the previously known models. This model is a partial answer to an open problem presented by Dumitriu and Edelman, where they also presented models for the β-Laguerre and β-Hermite ensembles. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1604184]

I. INTRODUCTION

Classical random matrix theory is concerned with various joint distributions of matrix properties (e.g., eigenvalues and singular values) for matrices given by some distribution. The three classical joint distributions of matrix eigenvalues are the Hermite, Laguerre, and Jacobi distributions, which generalize the single variable Gaussian, Poisson, and beta distributions, respectively (see Ref. 7). These distributions capture the statistical properties of *log-potential* gases (see Refs. 6 and 3) where β is analogous to temperature.

Analytic formulas relating to these distributions were derived by Dyson[2] over real, complex, and quaternion matrix elements. The numerical type of the matrix element was nearly irrelevant, appearing only as a single exponent β which was 1 (real), 2 (complex), or 4 (quaternion). While the formulas remain valid for more general β (real $\beta>0$), it was unknown whether random matrix models existed for such distributions.

Recently, Dumitriu and Edelman[1] have demonstrated that two of the classical distributions, the Laguerre and the Hermite, have random matrix models for general β, thereby removing the artificial ''quantization effect'' of the numerical type from Dyson's formulas. The models were given in the form of real bidiagonal and tridiagonal matrices with independent random entries given by certain (β dependent) χ distributions.

The question of the Jacobi model remained. No matrix model has yet been found which generates eigenvalues under the Jacobi distribution for a more general set of β. This note presents a model of the Jacobi for general β employing a *random rank-1 update* recurrence scheme.

In the following section, I briefly present a review of the β-ensemble results of Dumitriu and Edelman, highlighting two important theorems which I am borrowing from their work. Because the model I present is of a fairly different character than the ones Dumitriu and Edelman presented for the other two ensembles, I present a motivational section, showing how the form of this model came about. Finally, the last section gives a proof of the correctness of this model.

A. Background

Let us denote by N_v a real normally distributed, random variable with zero mean and variance v, and by χ_m a chi distributed, random variable with m degrees of freedom. Note $dens(\chi_m=y)\propto y^{m-1}e^{-(1/2)y^2}$, where m and y may be any positive real. Every single occurrence of a χ or N symbol in the formulas below is independent.

Let us define a *Gaussian* matrix over a field ($\mathbb{R}$ or $\mathbb{C}$) or skew field ($\mathbb{H}$) to be a random matrix whose elements are generated by independent, normally distributed Gaussian random processes G_β (N_1 for real, N_1+iN_1 for complex, and $N_1+iN_1+jN_1+kN_1$ for quaternions). A^* denotes the

a)Electronic mail: ripper@eskimo.com

appropriate involution: transpose, Hermitian transpose, or symplectic transpose. Throughout, we will use words like *orthogonal* and *orthonormal* to stand for the appropriate term (e.g., *unitary*) for the appropriate β. Finally, in any equations giving probability densities, we omit the normalizing constants.

Let $\beta=1,2,4$ for $\mathbb{R}$, $\mathbb{C}$, and $\mathbb{H}$, respectively. The m-eigenvalues of a "symmetrized" $m\times m$ Gaussian matrix, $\frac{1}{2}(A+A^*)$, give the β-Hermite ensemble, which has the distribution

$$dens(\lambda_1,\ldots,\lambda_m)=\prod_{i<j}|\lambda_i-\lambda_j|^\beta\prod_{i=1}^m e^{-(1/2)\lambda_i^2}.$$

The m-eigenvalues of a "squared" $n\times m$ Gaussian matrix, A^*A, give the β-Laguerre ensemble, which has the distribution

$$dens(\lambda_1,\ldots,\lambda_m)=\prod_{i<j}|\lambda_i-\lambda_j|^\beta\prod_{i=1}^m \lambda_i^a e^{-(1/2)\lambda_i},$$

where $a=\frac{1}{2}\beta(n-m+1)-1, n\geqslant m$ and $\lambda_i>0$.

Finally, there is the β-Jacobi ensemble (also called MANOVA in Ref. 7), which can be modeled as the eigenvalues of the $m\times m$ matrix

$$(A^*A+B^*B)^{-1}A^*A$$

formed from two Gaussian random matrices, A and B, which are $n_1\times m$ and $n_2\times m$ (resp.). These eigenvalues are always real, bounded between 0 and 1, and are distributed according to

$$dens(\lambda_1,\ldots,\lambda_n)=\prod_{i<j}|\lambda_i-\lambda_j|^\beta\prod_{i=1}^m \lambda_i^a(1-\lambda_i)^b,$$

where $a=\frac{1}{2}\beta(n_1-m+1)-1$, $b=\frac{1}{2}\beta(n_2-m+1)-1$, and $m-1<n_1,n_2$.

These are valid distributions for $\beta>0$ and more general a and b, yet the Gaussian matrix based models above can only be applied when β is 1,2,4 and a,b are in correspondence with the integers. The first models for general β,a,b were found by Edelman and Dumitriu in 2002.[1] They showed that a random tridiagonal matrix,

$$T=\frac{1}{\sqrt{2}}\begin{pmatrix} N_2 & \chi_{(m-1)\beta} & 0 & \cdots & 0 & 0 \\ \chi_{(m-1)\beta} & N_2 & \chi_{(m-2)\beta} & \cdots & 0 & 0 \\ 0 & \chi_{(m-2)\beta} & N_2 & \cdots & 0 & 0 \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ 0 & 0 & 0 & \cdots & \chi_\beta & N_2 \end{pmatrix},$$

has eigenvalues distributed according to the β-Hermite distribution. They also showed that the eigenvalues of LL^* for a random bidiagonal matrix,

$$L=\begin{pmatrix} \chi_{2a+(m-1)\beta} & 0 & 0 & \cdots & 0 & 0 \\ \chi_{(m-1)\beta} & \chi_{2a+(m-2)\beta} & 0 & \cdots & 0 & 0 \\ 0 & \chi_{(m-2)\beta} & \chi_{2a+(m-3)\beta} & \cdots & 0 & 0 \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ 0 & 0 & 0 & \cdots & \chi_\beta & \chi_{2a} \end{pmatrix}, \tag{1}$$

has eigenvalues distributed according to the β-Laguerre distribution.

These results give models for the β-Hermite and β-Laguerre distributions in terms of sparse random matrices, and are thus expected to be computationally more efficient in addition to being more general than the Gaussian matrix models which first motivated them. They have the feature that the corresponding characteristic polynomials can be calculated by a random three term recurrence, generalizing classical three term recurrences satisfied by the Hermite and Laguere polynomials, respectively. From this perspective, the general β-Jacobi ensemble has been constructed (see Ref. 4), but an associated tridiagonal matrix was not found.

B. Motivation and essential result

This section will present and provide the motivation for the matrix model presented for the general β-Jacobi distribution. We will start with the more restricted Gaussian matrix model and reduce it to a model in which the dependence on β,a,b is continuous. This merely gives an alternate model for the β-Jacobi distribution which is guaranteed to be valid for the same set of β,a,b for which the Gaussian matrix model was valid. The proof of its more general validity is in the next section.

We first reformulate the model in a way that avoids the ''squaring'' of the A and B Gaussian matrices. We will assume generic properties of the A and B such as their being full rank. Then

$$(A^*A+B^*B)^{-1}A^*A=(I+(A^*A)^{-1}B^*B)^{-1},$$

allowing us to model the β-Jacobi eigenvalues, λ_i', with the eigenvalues, λ_i, of $(A^*A)^{-1}B^*B$ via the relation $\lambda_i'=1/(1+\lambda_i)$.

Let $A=Q_AR_A^*$ where Q_A is orthogonal and R_A^* $m\times m$ lower triangular, and let $B=Q_BR_B^*$ with Q_B orthogonal and R_B $m\times m$ lower triangular. Then $A^*A=R_AR_A^*$ and $B^*B=R_BR_B^*$, so

$$(A^*A)^{-1}B^*B=(R_AR_A^*)^{-1}R_BR_B^*=(R_A^*)^{-1}R_A^{-1}R_BR_B^*\sim R_A^{-1}R_BR_B^*(R_A^*)^{-1}=(R_A^{-1}R_B)(R_A^{-1}R_B)^*.$$

Thus we see that the eigenvalues of $(A^*A)^{-1}B^*B$ are the squares of the m singular values, σ_i, of $R_A^{-1}R_B$.

We have employed factorizations for A and B into orthogonal and lower triangular matrices. There are a number of ways to carry out such factorizations. The one which we will employ is the QL-decomposition, where one applies a Gramm–Schmidt process starting at the last column and works back to the first. We state without proof an elementary result regarding the distribution of the L factor.

Lemma 1.1 (QL-factorization): Let A be an $n\times m$ Gaussian matrix with $n\geqslant m$. Let $QL=A$ be the QL-factorization. Then L is an $m\times m$ matrix distributed as

$$L=L^{(n,m)}=\begin{pmatrix} \chi_{(n-m+1)\beta} & 0 & 0 & \cdots & 0 \\ G_\beta & \chi_{(n-m+2)\beta} & 0 & \cdots & 0 \\ G_\beta & G_\beta & \chi_{(n-m+3)\beta} & \cdots & 0 \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ G_\beta & G_\beta & G_\beta & \cdots & \chi_{n\beta} \end{pmatrix}.$$

It follows that with $Q_AR_A^*$ the QL-factorization of A, R_A is then distributed as $L^{(n_1,m)*}$. Similarly, R_B is distributed as $L^{(n_2,m)*}$. However, it is to our advantage to specify the latter as the equivalent matrix distribution $R^{(n_2,m)}$ specified by

$$R^{(n,m)} = PL^{(n,m)}P = \begin{pmatrix} \chi_{n\beta} & G_\beta & G_\beta & \cdots & G_\beta \\ 0 & \chi_{(n-1)\beta} & G_\beta & \cdots & G_\beta \\ 0 & 0 & \chi_{(n-2)\beta} & \cdots & G_\beta \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ 0 & 0 & 0 & \cdots & \chi_{(n-m+1)\beta} \end{pmatrix},$$

where P denotes the reverse permutation, $P_{i,n-i+1}=1$, $P_{i,j}=0$ otherwise.

Let $Q_A R_A^*$ be the QL-decomposition of A, with R_A then distributed as $L^{(n_1,m)*}$, and $Q_B P R_B P$ be the QL-decomposition of B, with R_B then distributed as $R^{(n_2,m)}$.

We note the following recurrences for R_A and R_B:

$$R_A = \begin{pmatrix} a & \vec{a} \\ 0 & \tilde{R}_A \end{pmatrix},$$

$$R_B = \begin{pmatrix} b & \vec{b} \\ 0 & \tilde{R}_B \end{pmatrix},$$

where $a=\chi_{\beta(n_1-m+1)}$, $\vec{a}=[G_\beta \cdots G_\beta]$, $\tilde{R}_A = L^*_{n_1,m-1}$, $b=\chi_{\beta n_2}$, $\vec{b}=[G_\beta \cdots G_\beta]$, and $\tilde{R}_B = R^{(n_2-1,m-1)}$ (here, use has been made of the fact that G_β and $\overline{G_\beta}$ have the same distribution). Thus,

$$R_A^{-1}R_B = \begin{pmatrix} b/a & \vec{b}/a - \vec{a}\tilde{R}_A^{-1}\tilde{R}_B \\ 0 & \tilde{R}_A^{-1}\tilde{R}_B \end{pmatrix}. \tag{2}$$

At this point we see the basis for a recursive scheme. The lower right block of Eq. (2) is another instance of the same expression with parameters $\tilde{m}=m-1$, $\tilde{n}_1=n_1$ and $\tilde{n}_2=n_2-1$.

Let $\tilde{U}\tilde{\Sigma}\tilde{V}^* = \tilde{R}_A^{-1}\tilde{R}_B$ be the SVD of the lower right block. Then

$$\begin{pmatrix} 1 & 0 \\ 0 & \tilde{U}^* \end{pmatrix} R_A^{-1}R_B \begin{pmatrix} 1 & 0 \\ 0 & \tilde{V} \end{pmatrix} = \begin{pmatrix} b/a & \frac{1}{a}(\vec{b}\tilde{V} - \vec{a}\tilde{U}\tilde{\Sigma}) \\ 0 & \tilde{\Sigma} \end{pmatrix}.$$

The elements of $\tilde{\Sigma}$ are related to a β-Jacobi distribution with parameters $\tilde{n}_1$ and $\tilde{n}_2$. Since the density of Gaussian vectors, $\vec{a}$, $\vec{b}$, is invariant under orthogonal transformations, $\vec{b}\tilde{V} - \vec{a}\tilde{U}\tilde{\Sigma} = [G_\beta \cdots G_\beta](I+\Sigma^2)^{1/2}$. Thus

$$B = \begin{pmatrix} \frac{1}{\chi_{(n_1-m+1)\beta}} & [\chi_{n_2\beta}(1+\sigma_1^2)^{1/2}G_\beta \cdots (1+\sigma_{m-1}^2)^{1/2}G_\beta] \\ 0 & \mathrm{diag}(\sigma_1, \ldots, \sigma_{m-1}) \end{pmatrix} \tag{3}$$

has singular values which are distributed according to the β-Jacobi distribution with parameters n_1, n_2, if $\sigma_1, \ldots, \sigma_{m-1}$ are distributed as the $m-1$ singular values related to another β-Jacobi distribution with parameters n_1, n_2-1.

To remove the last integral dependence of Eq. (3) on β, we can, by a similarity transformation, remove the phases from the G_β, replacing them with real $|G_\beta| = \chi_\beta$ distributions.

II. DETAILS OF THE DUMITRIU AND EDELMAN RESULTS

The proofs of the Hermite and Laguerre results[1] rest on two lemmas about the relation of tridiagonal matrices to their eigenvalues and eigenvectors, which we will now review.

Given a real diagonal matrix Λ with m-eigenvalues, λ_i, and a real unit vector $\hat{v}$, a symmetric tridiagonal matrix can be generated by the familiar recurrence (see Chap. 9 of Ref. 5):

$$T_{k,k}=(\Lambda\hat{v}^{(k)}-T_{k+1,k}\hat{v}^{(k+1)})^t\hat{v}^{(k)},\quad k=m,\ldots,2,$$

$$T_{k,k-1}\hat{v}^{(k-1)}=\Lambda\hat{v}^{(k)}-T_{k+1,k}\hat{v}^{(k+1)}-T_{k,k}\hat{v}^{(k)},\quad k=m,\ldots,2,$$

with

$$T_{m,m}=\hat{v}^t\Lambda\hat{v},$$

$$\hat{v}^{(m)}=\hat{v},$$

giving the tridiagonal elements, $\delta_k=T_{k,k}$ and $\nu_k=T_{k+1,k}$, and a sequence of orthogonal unit vectors, $\hat{v}^{(k)}$, which form the orthogonal eigenvector matrix, $Q=[\hat{v}^{(m)},\hat{v}^{(m-1)},\ldots,\hat{v}^{(1)}]^t$, such that $T=Q^t\Lambda Q$. This mapping, $T:(\lambda_i,\hat{v})\rightarrow(\delta_i,\nu_i)$, is a bijection when the λ_i are distinct and ordered, and the elements of $\hat{v}$ are non-negative. Two lemmas highlight important properties of this mapping.

The first result gives a useful expression for the Jacobian of the tridiagonalization mapping.

Lemma 2.1: Tridiagonal Jacobian. Given m ordered distinct real values, λ_i, and a unit vector, $\hat{v}$, with non-negative elements, the mapping $T:(\lambda_i,\hat{v})\rightarrow(\delta_i,\nu_i)$ is a diffeomorphism with Jacobian given by

$$J=\frac{\partial(\delta_i,\nu_i)}{\partial(\lambda_i,\hat{v}_i)}=\frac{\Pi_{i=1}^{m-1}\nu_i}{\Pi_{i=1}^{m}\hat{v}_i}.$$

The second result expresses the product of differences of the λ_i in terms of $\hat{v}$ and the tridiagonal coefficients.

Lemma 2.2: Vandermonde Identity. Given n eigenvalues λ_i and a unit vector $\hat{v}$, let (δ_i,ν_i) be the coefficients of the associated tridiagonal matrix, $T(\Lambda,\hat{v})$. Then

$$\prod_{i<j}|\lambda_i-\lambda_j|=\frac{\Pi_{i=1}^{m-1}\nu_i^i}{\Pi_{i=1}^{m}\hat{v}_i}.$$

III. PROOF OF THE β-JACOBI RESULT

The starting point for this proof will be the reformulation of the Jacobi model originally supported on $0<\lambda<1$, to be supported on $0\leqslant\lambda<\infty$ with the change of variable, $\lambda'=1/(1+\lambda)$.

Definition 3.1 (modified Jacobi model): The modified Jacobi model *with parameters β,n_1,n_2 is the distribution on m variables λ_i with density:*

$$dens(\lambda_i;n_1,n_2,m,\beta)=\Delta(\lambda_i)^\beta\prod_i\frac{\lambda_i^{(1/2)\beta(n_2-m+1)-1}}{(1+\lambda_i)^{(1/2)\beta(n_1+n_2)}},$$

where $\Delta(\lambda_i)=\Pi_{i<j}|\lambda_i-\lambda_j|$ and $0\leqslant\lambda<\infty$.

Lemma 3.2: The m values λ_i are distributed according to the modified Jacobi model with parameters β,n_1,n_2, iff $\lambda_i'=1/(1+\lambda_i)$ are distributed according to the density

$$dens(\lambda_1',\ldots,\lambda_m')=\prod_{i<j}|\lambda_i'-\lambda_j'|^\beta\prod_i(\lambda_i')^{(1/2)\beta(n_1-m+1)-1}(1-\lambda_i')^{(1/2)\beta(n_2-m+1)-1}.$$

Proof: Let $X=1/2\beta(n_1-m+1)-1$, and $Y=1/2\beta(n_2-m+1)-1$. By change of variables,

$$dens(\lambda_1',\ldots,\lambda_m')\prod_i d\lambda_i'=\prod_{i<j}|\lambda_i'-\lambda_j'|^\beta\prod_i(\lambda_i')^X(1-\lambda_i')^Y\prod_i d\lambda_i',$$

$$dens(\lambda_1,\ldots,\lambda_m)\prod_i\frac{d\lambda_i}{(1+\lambda_i)^2}=\prod_{i<j}\left|\frac{1}{1+\lambda_i}-\frac{1}{1+\lambda_j}\right|^\beta\prod_i\left(\frac{1}{1+\lambda_i}\right)^X\left(\frac{\lambda_i}{1+\lambda_i}\right)^Y\prod_i d\lambda_i,$$

$$\begin{aligned}dens(\lambda_1,\ldots,\lambda_m)\prod_i d\lambda_i&=\prod_{i<j}\left|\frac{\lambda_i-\lambda_j}{(1+\lambda_i)(1+\lambda_j)}\right|^\beta\prod_i\frac{\lambda_i^Y}{(1+\lambda_i)^{X+Y+2}}\prod_i d\lambda_i\\&=\prod_i\left(\frac{1}{1+\lambda_i}\right)^{X+Y+\beta(m-1)+2}\prod_{i<j}|\lambda_i-\lambda_j|^\beta\prod_i\lambda_i^Y\prod_i d\lambda_i.\end{aligned}$$

□

We now prove a recurrence for the modified Jacobi model.

Theorem 3.3: *Let B be an $m\times m$ random matrix generated as follows:*

$$B=\begin{pmatrix}b/a & \vec{w}/a\\ 0 & \sqrt{\Theta}\end{pmatrix},$$

where $a=\chi_{\beta(n_1-m+1)}$, $b=\chi_{\beta n_2}$, $\vec{w}=(\sqrt{1+\theta_1}\chi_\beta,\ldots,\sqrt{1+\theta_{m-1}}\chi_\beta)$, *and* $\sqrt{\Theta}=\mathrm{diag}(\sqrt{\theta_1},\ldots,\sqrt{\theta_{m-1}})$ *where the $m-1$ values θ_i are distributed according to the modified Jacobi distribution, $dens(\theta_i;n_1,n_2-1,m-1,\beta)$. Then the eigenvalues of B^tB are distributed according to the Jacobi model with parameters (n_1,n_2,m,β).*

Moreover, B^tB is similar to the tridiagonal matrix

$$\begin{pmatrix}\delta & \nu & 0 & \cdots & 0\\ \nu & \delta_{m-1}+\dfrac{\nu^2}{\delta} & \nu_{m-2} & \cdots & 0\\ 0 & \nu_{m-2} & \delta_{m-2} & \cdots & 0\\ \cdots & \cdots & \cdots & \cdots & \cdots\\ 0 & 0 & \cdots & \delta_2 & \nu_1\\ 0 & 0 & \cdots & \nu_1 & \delta_1\end{pmatrix},$$

where

$$\delta=(b/a)^2,\quad \nu=(b/a^2)\|\vec{w}\|,$$

and (δ_i,ν_i), $i=1,\ldots,m-1$, are the tridiagonal matrix entries constructed from the $m-1$ positive eigenvalues, θ_i, and the unit vector $\hat{w}$ according to the recurrence given at the beginning of Sec. II.

Proof: We have that the density of B in terms of a,b,w, and θ_i [from the $(m-1)\times(m-1)$ submatrix Θ] is given by

$$dens(a,b,w,\theta_i)=b^{\beta n_2-1}e^{-b^2}a^{\beta(n_1-m+1)-1}e^{-a^2}\left(\prod_i\frac{w_i^{\beta-1}}{(1+\theta_i)^{(1/2)\beta}}\right)e^{-\Sigma_i[w_i^2/(1+\theta_i)]}D(\theta_i),$$

where $D(\theta_i)=dens(\theta_i;n_1-1,n_2,m-1,\beta)$.

Making a change of variables $x=b/a, z_i=w_i/a$ so that

$$B=\begin{pmatrix} x & z \\ 0 & \sqrt{\Theta} \end{pmatrix},$$

we have

$$dens(x,a,z,\theta_i)=(xa)^{\beta n_2-1}e^{-(xa)^2}a^{\beta(n_1-m+1)-1}e^{-a^2}\left(\prod_i \frac{(az_i)^{\beta-1}}{(1+\theta_i)^{(1/2)\beta}}\right)$$
$$\times e^{-\Sigma_i[(az_i)^2/(1+\theta_i)]}D(\theta_i)a^m,$$

which simplifies to

$$dens(x,a,z,\theta_i)=a^{\beta(n_2+n_1)-1}e^{-a^2(1+x^2+\Sigma_i[z_i^2/(1+\theta_i)])}x^{\beta n_2-1}\left(\prod_i \frac{z_i^{\beta-1}}{(1+\theta_i)^{(1/2)\beta}}\right)D(\theta_i).$$

Since a no longer appears explicitly in B it may be integrated out to give the density of B:

$$dens(x,z,\theta_i)=x^{\beta n_2-1}\left(1+x^2+\sum_i \frac{z_i^2}{1+\theta_i}\right)^{-(1/2)\beta(n_2+n_1)}\left(\prod_i \frac{z_i^{\beta-1}}{(1+\theta_i)^{(1/2)\beta}}\right)D(\theta_i).$$

Given the positivity of x,z_i,θ_i there is a one-to-one mapping from B to B^tB given by

$$B^tB=\begin{pmatrix} x^2 & xz \\ xz^t & \Theta+zz^t \end{pmatrix}=\begin{pmatrix} \delta & v \\ v^t & \Theta+\frac{1}{\delta}vv^t \end{pmatrix},$$

where $\delta=x^2$, $v_i=xz_i$. Making this change of variables, we find that the density for B^tB is given by

$$dens(\delta,v,\theta_i)=\delta^{(1/2)\beta(n_2-m+1)-1}\left(1+\delta+\frac{1}{\delta}\sum_i \frac{v_i^2}{1+\theta_i}\right)^{-(1/2)\beta(n_2+n_1)}$$
$$\times\prod_i v_i^{\beta-1}\prod_i (1+\theta_i)^{-(1/2)\beta}D(\theta_i).$$

We may express the vector v as a product of a unit vector and its magnitude, $v=\nu\hat{v}$, and make the change of variables,

$$dens(\delta,\nu,\hat{v},\theta_i)=\delta^{(1/2)\beta(n_2-m+1)-1}\left(1+\delta+\frac{\nu^2}{\delta}\sum_i \frac{\hat{v}_i^2}{1+\theta_i}\right)^{-(1/2)\beta(n_2+n_1)}$$
$$\times\nu^{\beta(m-1)-1}\prod_i \hat{v}_i^{\beta-1}\prod_i (1+\theta_i)^{-(1/2)\beta}D(\theta_i).$$

Substituting the induction,

$$dens(\delta,\nu,\hat{v},\theta_i)=\delta^{(1/2)\beta(n_2-m+1)-1}\left(1+\delta+\frac{\nu^2}{\delta}\sum_i\frac{\hat{v}_i^2}{1+\theta_i}\right)^{-(1/2)\beta(n_2+n_1)}\nu^{\beta(m-1)-1}$$
$$\times\prod_i\hat{v}_i^{\beta-1}\prod_i(1+\theta_i)^{-(1/2)\beta}\Delta(\theta_i)^\beta\frac{(\Pi_i\theta_i)^{(1/2)\beta(n_2-m+1)-1}}{(\Pi_i(1+\theta_i))^{(1/2)\beta(n_2+n_1-1)}}.$$

Since $\theta_i>0$ and $\hat{v}$ is a unit vector with positive entries, the tridiagonal mapping is one-to-one. Let (δ_i,ν_i) be given by

$$T_2=\begin{pmatrix}\delta_{m-1}&\nu_{m-2}&0&\cdots&0\\ \nu_{m-2}&\delta_{m-2}&\nu_{m-3}&\cdots&0\\ 0&\nu_{m-3}&\delta_{m-3}&\cdots&0\\ \cdots&\cdots&\cdots&\cdots&\cdots\\ 0&0&\cdots&\delta_2&\nu_1\\ 0&0&\cdots&\nu_1&\delta_1\end{pmatrix}=T(\theta_i,\hat{v})$$

with, according to Lemma 2.1, the Jacobian given by

$$J=\frac{\partial(\delta_i,\nu_i)}{\partial(\theta_i,\hat{v}_i)}=\frac{\Pi_{i=1}^{m-2}\nu_i}{\Pi_{i=1}^{m-1}\hat{v}_i}.$$

Let Q_2 be the eigenvector matrix of $T(\theta_i,\hat{v})$ with $\hat{v}$ as the first row. Let

$$Q_1=\begin{pmatrix}1&0\\0&Q_2\end{pmatrix}.$$

Then

$$T_1=Q_1B^tBQ_1^t=\begin{pmatrix}\delta&\nu&0&\cdots&0\\ \nu&\delta_{m-1}+\frac{\nu^2}{\delta}&\nu_{m-2}&\cdots&0\\ 0&\nu_{m-2}&\delta_{m-2}&\cdots&0\\ \cdots&\cdots&\cdots&\cdots&\cdots\\ 0&0&\cdots&\delta_2&\nu_1\\ 0&0&\cdots&\nu_1&\delta_1\end{pmatrix}$$

is a tridiagonalization of B^tB. We change variables from $\theta_i,\hat{v}$ to δ_i,ν_i, setting $\delta_m=\delta$ and $\nu_{m-1}=\nu$, obtaining

$$dens(\delta_i,\nu_i)=\delta_m^{(1/2)\beta(n_2-m+1)-1}\left(1+\delta_m+\frac{\nu_{m-1}^2}{\delta_m}\sum_i\frac{\hat{v}_i^2}{1+\theta_i}\right)^{-(1/2)\beta(n_2+n_1)}\nu_{m-1}^{\beta(m-1)}$$
$$\times\prod_i\hat{v}_i^\beta\Delta(\theta_i)^\beta\frac{\det(T_2)^{(1/2)\beta(n_2-m+1)-1}}{\det(I+T_2)^{(1/2)\beta(n_2+n_1)}}\prod_i\frac{1}{\nu_i},$$

where some expressions have been left in terms of θ_i and $\hat{v}$, though as functions of δ_i,ν_i.

Expanding $\Delta(\theta_i)$ with the Vandermonde identity according to Lemma 2.2,

$$\Delta(\theta_i)=\frac{\Pi_i\nu_i^i}{\Pi_i\hat{v}_i},$$

shows

$$dens(\delta_i,\nu_i)=\delta_m^{(1/2)\beta(n_2-m+1)-1}\left(1+\delta_m+\frac{\nu_{m-1}^2}{\delta_m}\sum_i\frac{\hat{v}_i^2}{1+\theta_i}\right)^{-(1/2)\beta(n_2+n_1)}\nu_{m-1}^{\beta(m-1)-1}$$
$$\times\frac{\det(T_2)^{(1/2)\beta(n_2-m+1)-1}}{\det(I+T_2)^{(1/2\beta(n_2+n_1)}}\prod_{i=1}^{m-2}\nu_i^{\beta i-1},$$

which simplifies to

$$dens(\delta_i,\nu_i)=\delta_m^{(1/2)\beta(n_2-m+1)-1}\left(1+\delta_m+\frac{\nu_{m-1}^2}{\delta_m}\sum_i\frac{\hat{v}_i^2}{1+\theta_i}\right)^{-(1/2)\beta(n_2+n_1)}$$
$$\times\frac{\det(T_2)^{1/2\beta(n_2-m+1)-1}}{\det(I+T_2)^{1/2\beta(n_2+n_1)}}\prod_i\nu_i^{\beta i-1}.$$

We observe that $\det(T_2)=\delta_m\det(T_1)$ and obtain

$$dens(\delta_i,\nu_i)=\left(1+\delta_m+\frac{\nu_{m-1}^2}{\delta_m}\sum_i\frac{\hat{v}_i^2}{1+\theta_i}\right)^{-(1/2)\beta(n_2+n_1)}\frac{\det(T_1)^{(1/2)\beta(n_2-m+1)-1}}{\det(I+T_2)^{(1/2)\beta(n_2+n_1)}}\prod_i\nu_i^{\beta i-1}.$$

Let T_3 be the $(m-3)\times(m-3)$ lower right submatrix of T_2 (and also of T_1). Then

$$\det(I+T_1)=(1+\delta_m)\left(\det(I+T_2)+\frac{\nu_{m-1}^2}{\delta_m}\det(I+T_3)\right)-\nu_{m-1}^2\det(I+T_3)$$
$$=(1+\delta_m)\left(\det(I+T_2)+\frac{\nu_{m-1}^2}{\delta_m(1+\delta_m)}\det(I+T_3)\right)$$
$$=\det(I+T_2)(1+\delta_m)\left(1+\frac{\nu_{m-1}^2}{\delta_m(1+\delta_m)}\frac{\det(I+T_3)}{\det(I+T_2)}\right)$$
$$=\det(I+T_2)\left(1+\delta_m+\frac{\nu_{m-1}^2}{\delta_m}\sum_i\frac{\hat{v}_i^2}{1+\theta_i}\right),$$

where we have observed that

$$\frac{\det(I+T_3)}{\det(I+T_2)}=e_1^t(I+T_2)^{-1}e_1=\sum_i\frac{\hat{v}_i^2}{1+\theta_i}.$$

Thus we have

$$dens(\delta_i,\nu_i)=\frac{\det(T_1)^{(1/2)\beta(n_2-m+1)-1}}{\det(I+T_1)^{(1/2)\beta(n_2+n_1)}}\prod_i\nu_i^{\beta i-1}.$$

At this point, we change variables by $\delta'_{m-1}=\delta_{m-1}+\nu_{m-1}^2/\delta_m$, which has unit Jacobian and express T_1 in the traditional tridiagonal form.

Let $T_1=T(\lambda_i,\hat{q})$ parametrize T_1 by its (non-negative, ordered) eigenvalues λ_i and the (non-negative) unit vector $\hat{q}$. Applying the Vandermonde identity, Lemma 2.2, we have

$$dens(\delta_i,\nu_i)=\frac{\det(T_1)^{(1/2)\beta(n_2-m+1)-1}}{\det(I+T_1)^{(1/2)\beta(n_2+n_1)}}(\Delta(\lambda_i))^\beta\prod_i\hat{q}_i^\beta\prod_i\nu_i^{-1}.$$

Recognizing the Jacobian $\partial(\lambda_i,\hat{q}_i)/\partial(\delta_i,\nu_i)=\Pi_i\hat{q}_i/\Pi_i\nu_i$ we change variables to obtain

$$dens(\lambda_i,\hat{q}_i)=(\Delta(\lambda_i))^{\beta}\frac{\Pi_i\lambda_i^{(1/2)\beta(n_2-m+1)-1}}{\Pi_i(1+\lambda_i)^{(1/2)\beta(n_2+n_1)}}\prod_i \hat{q}_i^{\beta-1},$$

out of which the $\hat{q}_i$ may be integrated to obtain

$$dens(\lambda_i)=(\Delta(\lambda_i))^{\beta}\frac{\Pi_i\lambda_i^{(1/2)\beta(n_2-m+1)-1}}{\Pi_i(1+\lambda_i)^{(1/2)\beta(n_2+n_1)}}.$$

The base case of the induction is trivial. □

IV. DISCUSSION

The style of the model presented here is fairly different from that of the previous models for the Hermite and Laguerre ensembles in that a Jacobi sample in m values is built up from samples on $1,2,\ldots,m-1$ Jacobi values, where at each step a rank-1 update is performed.

It is possible to cast the Hermite and Laguerre models in this form. For example, the L matrix from Eq. (1) can, instead, be written

$$L=L^{(n,m)}=\begin{pmatrix} l & 0 \\ \vec{l} & L^{(n-1,m-1)} \end{pmatrix},$$

where $l=\chi_{n\beta}$ and $\vec{l}=[\chi_\beta,\ldots,\chi_\beta]$. In this case, however, the recursive form is unnecessary, since one can simultaneously bidiagonalize $L^{(n,m)}$ and its $L^{(n-1,m-1)}$ submatrix.

This simultaneous bidiagonalization is possible only because the elements of the $L^{(n-1,m-1)}$ submatrix are not intermingled with the elements of $\vec{l}$ as they are in the Jacobi case. Similar reasoning applies to the Hermite case. This suggests that a wider class of random matrix models is available by using successive rank-1 updates than just sparse forms with independent entries.

ACKNOWLEDGMENTS

The author would like to thank Alan Edelman and Ioanna Dumitriu for posing this problem to him and for laying much of the groundwork in their previous article. The author would also like to thank one of his referees for numerous corrections and suggestions which have greatly increased the clarity of this article.

Using a technique [Mankoč Borštnik *et al.*, J. Math. Phys. **43**, 5782 (2002)] to construct a basis for spinors and ''families'' of spinors in terms of Clifford algebra objects, we define other Clifford algebra objects, which transform the state of one ''family'' of spinors into the state of another ''family'' of spinors, changing nothing but the ''family'' number. The proposed transformation works—as does the technique—for all dimensions and any signature and might open a path to understanding families of quarks and leptons [Mankoč Borštnik, Phys. Lett. B **292**, 25 (1992); J. Math. Phys. **34**, 3731 (1993); Int. J. Theor. Phys. **40**, 315 (2001); Borštnik Bračič and Mankoč Borštnik, hep-ph/0301029]. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1610239]

I. INTRODUCTION

In Ref. 1 we presented the technique to construct a spinor basis as products of nilpotents and projections formed from the objects γ^a for which we only need to know that they obey the Clifford algebra. Nilpotents and projections are odd and even objects of γ^a's, respectively, and are chosen to be eigenstates of a Cartan subalgebra of the Lorentz group in the sense that the left multiplication of nilpotents and projectors by the Cartan subalgebra elements multiplies these objects by a number. The technique can be used to construct a spinor basis for any dimension d and any signature in a simple and transparent way. Equipped with graphic representation of basic states, the technique offers an elegant means of seeing all the quantum numbers of states with respect to the Lorentz group, as well as the transformation properties of states under Clifford algebra objects.

Multiplying products of nilpotents and projectors from the left-hand side by any of the Clifford algebra objects, we get a linear combination of these ''basic'' elements back: our basis spans a left ideal, and has $2^{d/2}$ elements for d even and $2^{(d-1)/2}$ elements for d odd.

But there are 2^d products of nilpotents and projectors, all of them linearly independent. Mapping of ideals to spinor representations (treating all as Hilbert space) led accordingly to $2^{d/2}$ replicas of the usual spinor representation for d even and $d^{(d+1)/2}$ for d odd. We called these replicas ''families'' of representations.

The proposed technique was initiated and developed by one of the authors of this paper (N.M.B.), when proposing an approach[2–4] in which all the internal degrees of freedom of either spinors or vectors can be described in the space of d-anticommuting (Grassmann) coordinates, if the dimension of ordinary space is also d.

In the approach of one of us, however, two kinds of γ^a operators—two kinds of Clifford algebra objects—were defined, both fulfilling the same Clifford algebra relations, while one kind anticommutes with the other kind. When one of the two kinds of γ^a's is used to generate nilpotents and projectors, the products of which define when operating in a vacuum state basic vectors

a)Electronic mail: norma@fiz.uni-lj.si

for the spinor representation of the Lorentz group, it causes another kind of transition among ''families'' of spinors, transforming one state of a ''family'' to a state with the same quantum numbers with respect to the Lorentz group as the starting state but belonging to another ''family.''

We show in this short paper that there are also operators which cause transitions among ''families''[5] within the simple technique presented in Ref. 1. While left multiplication of nilpotents and projectors by Clifford algebra objects generates all the states of one spinor representation (Sec. II), *right multiplication causes transitions among "families"* (Sec. III). (The reader should see also Chevalley's book.[6])

We demonstrate transitions among ''families'' for $d=4$ in Sec. III A.

In this paper, we assume an arbitrary signature of space–time so that our metric tensor η^{ab}, with $a,b \in \{0,1,2,3,5,\ldots\}$ is diagonal with values $\eta^{aa}=\pm 1$, depending on the chosen signature ($+1$ for time-like coordinates and -1 for space-like coordinates).

II. TECHNIQUE TO GENERATE SPINOR REPRESENTATIONS IN TERMS OF CLIFFORD ALGEBRA OBJECTS

We shall briefly repeat the main points of the technique for generating spinor representations from Clifford algebra objects, following Ref. 1. We ask the reader to look for details and proofs in this reference.

We assume the objects γ^a, which fulfill the Clifford algebra

$$\{\gamma^a,\gamma^b\}_+ = I\ 2\eta^{ab} \quad \text{for } a,b \quad \in \{0,1,2,3,5,\ldots,d\}, \tag{1}$$

for any d, even or odd. I is the unit element in the Clifford algebra, while $\{\gamma^a,\gamma^b\}_\pm = \gamma^a\gamma^b \pm \gamma^b\gamma^a$.

We assume the ''Hermiticity'' property for γ^a's,

$$\gamma^{a\dagger} = \eta^{aa}\gamma^a, \tag{2}$$

in order that γ^a are compatible with (1) and formally unitary, i.e., $\gamma^{a\dagger}\gamma^a = I$.

We also define the Clifford algebra objects

$$S^{ab} = \frac{i}{4}[\gamma^a,\gamma^b] := \frac{i}{4}(\gamma^a\gamma^b - \gamma^b\gamma^a) \tag{3}$$

which close the Lie algebra of the Lorentz group $\{S^{ab},S^{cd}\}_- = i(\eta^{ad}S^{bc} + \eta^{bc}S^{ad} - \eta^{ac}S^{bd} - \eta^{bd}S^{ac})$. One finds from Eq. (2) that $(S^{ab})^\dagger = \eta^{aa}\eta^{bb}S^{ab}$ and that $\{S^{ab},S^{ac}\}_+ = \frac{1}{2}\eta^{aa}\eta^{bc}$.

Recognizing from Eq. (3) and the Lorentz algebra relation that two Clifford algebra objects S^{ab},S^{cd} with all indices different commute, we select (out of infinitely many possibilities) the Cartan subalgebra of the algebra of the Lorentz group as follows:

$$\begin{aligned} &S^{0d},S^{12},S^{35},\ldots,S^{d-2\ d-1} \quad \text{if } d=2n, \\ &S^{12},S^{35},\ldots,S^{d-1\ d} \quad \text{if } d=2n+1. \end{aligned} \tag{4}$$

It is useful to define one of the Casimirs of the Lorentz group—the handedness Γ ($\{\Gamma,S^{ab}\}_- = 0$). (For the definition of Γ for any spin in even-dimensional spaces, see Refs. 2–4, 7 and 8.)

$$\begin{aligned} \Gamma &:= (i)^{d/2}\prod_a (\sqrt{\eta^{aa}}\gamma^a) \quad \text{if } d=2n, \\ \Gamma &:= (i)^{(d-1)/2}\prod_a (\sqrt{\eta^{aa}}\gamma^a) \quad \text{if } d=2n+1, \end{aligned} \tag{5}$$

for any integer n. We understand the product of γ^a's in ascending order with respect to index a: $\gamma^0\gamma^1\cdots\gamma^d$. It follows from Eq. (2) for any choice of the signature η^{aa} that $\Gamma^\dagger=\Gamma$, $\Gamma^2=I$.

We also find that for d even, the handedness anticommutes with the Clifford algebra objects γ^a ($\{\gamma^a,\Gamma\}_+=0$), while for d odd it commutes with γ^a ($\{\gamma^a,\Gamma\}_-=0$).

To make the technique simple, we introduce the graphic representation[1] as follows:

$$\begin{aligned}
\overset{ab}{(k)} &:= \frac{1}{2}\left(\gamma^a+\frac{\eta^{aa}}{ik}\gamma^b\right),\\
\overset{ab}{[k]} &:= \frac{1}{2}\left(1+\frac{i}{k}\gamma^a\gamma^b\right),\\
\overset{+}{\bigcirc} &:= \frac{1}{2}(1+\Gamma),\\
\overset{-}{\bullet} &:= \frac{1}{2}(1-\Gamma),
\end{aligned} \tag{6}$$

where $k^2=\eta^{aa}\eta^{bb}$. One can easily check by taking into account the Clifford algebra relation [Eq. (1)] and the definition of S^{ab} [Eq. (3)] that if one multiplies from the left-hand side by S^{ab} the Clifford algebra objects $\overset{ab}{(k)}$ and $\overset{ab}{[k]}$, it follows that

$$\begin{aligned}
S^{ab}\overset{ab}{(k)} &= \frac{1}{2}k\overset{ab}{(k)},\\
S^{ab}\overset{ab}{[k]} &= \frac{1}{2}k\overset{ab}{[k]},
\end{aligned} \tag{7}$$

which means that we get the same objects back multiplied by the constant $\frac{1}{2}k$. This also means that $\overset{ab}{(k)}$ and $\overset{ab}{[k]}$ acting from the left-hand side on anything (on a vacuum state $|\psi_0\rangle$, for example) are eigenvectors of S^{ab}.

We further find

$$\begin{aligned}
\gamma^a\overset{ab}{(k)} &= \eta^{aa}\overset{ab}{[-k]},\\
\gamma^b\overset{ab}{(k)} &= -ik\overset{ab}{[-k]},\\
\gamma^a\overset{ab}{[k]} &= \overset{ab}{(-k)},\\
\gamma^b\overset{ab}{[k]} &= -ik\,\eta^{aa}\overset{ab}{(-k)}.
\end{aligned} \tag{8}$$

It follows that $S^{ac}\overset{ab}{(k)}\overset{cd}{(k)}=-(i/2)\,\eta^{aa}\eta^{cc}\overset{ab}{[-k]}\overset{cd}{[-k]}$, $S^{ac}\overset{ab}{[k]}\overset{cd}{[k]}=(i/2)\overset{ab}{(-k)}\overset{cd}{(-k)}$, $S^{ac}\overset{ab}{(k)}\overset{cd}{[k]}=-(i/2)\,\eta^{aa}\overset{ab}{[-k]}\overset{cd}{(-k)}$, $S^{ac}\overset{ab}{[k]}\overset{cd}{(k)}=(i/2)\,\eta^{cc}\overset{ab}{(-k)}\overset{cd}{[-k]}$. It is useful to deduce the following relations:

$$\overset{ab}{(k)}^{\dagger} = \eta^{aa}\overset{ab}{(-k)}, \quad \overset{ab}{[k]}^{\dagger} = \overset{ab}{[k]}, \tag{9}$$

and

$$\begin{gathered}
\overset{ab}{(k)}\overset{ab}{(k)} = 0, \quad \overset{ab}{(k)}\overset{ab}{(-k)} = \eta^{aa}\overset{ab}{[k]}, \quad \overset{ab}{(-k)}\overset{ab}{(k)} = \eta^{aa}\overset{ab}{[-k]}, \quad \overset{ab}{(-k)}\overset{ab}{(-k)} = 0, \\
\overset{ab}{[k]}\overset{ab}{[k]} = \overset{ab}{[k]}, \quad \overset{ab}{[k]}\overset{ab}{[-k]} = 0, \quad \overset{ab}{[-k]}\overset{ab}{[k]} = 0, \quad \overset{ab}{[-k]}\overset{ab}{[-k]} = \overset{ab}{[-k]}, \\
\overset{ab}{(k)}\overset{ab}{[k]} = 0, \quad \overset{ab}{[k]}\overset{ab}{(k)} = \overset{ab}{(k)}, \quad \overset{ab}{(-k)}\overset{ab}{[k]} = \overset{ab}{(-k)}, \quad \overset{ab}{(-k)}\overset{ab}{[-k]} = 0, \\
\overset{ab}{(k)}\overset{ab}{[-k]} = \overset{ab}{(k)}, \quad \overset{ab}{[k]}\overset{ab}{(-k)} = 0, \quad \overset{ab}{[-k]}\overset{ab}{(k)} = 0, \quad \overset{ab}{[-k]}\overset{ab}{(-k)} = \overset{ab}{(-k)}.
\end{gathered} \tag{10}$$

We recognize in the first equation of the first row and the first equation of the second row the demonstration of the nilpotent and the projector character of the Clifford algebra objects $\overset{ab}{(k)}$ and $\overset{ab}{[k]}$, respectively.

The reader should note that whenever the Clifford algebra objects apply from the left-hand side, they always transform $\overset{ab}{(k)}$ *to* $\overset{ab}{[-k]}$, *never to* $\overset{ab}{[k]}$, *and similarly* $\overset{ab}{[k]}$ *to* $\overset{ab}{(-k)}$, *never to* $\overset{ab}{(k)}$.

According to Ref. 1, we define a vacuum state $|\psi_0\rangle$ so that one finds

$$\begin{gathered}
\langle \overset{ab}{(k)}^{\dagger}\overset{ab}{(k)} \rangle = 1, \\
\langle \overset{ab}{[k]}^{\dagger}\overset{ab}{[k]} \rangle = 1.
\end{gathered} \tag{11}$$

Taking the above-given equations into account it is easy to find a Weyl spinor irreducible representation for d-dimensional space, with d even or odd. (We advise the reader to see Ref. 1.)

For d even, we simply set the starting state as a product of $d/2$, let us say, only nilpotents $\overset{ab}{(k)}$, one for each S^{ab} of the Cartan subalgebra elements [Eq. (4)], applying it on an (unimportant) vacuum state.[1] Then the generators S^{ab}, which do not belong to the Cartan subalgebra, applied to the starting state from the left-hand side, generate all the members of one Weyl spinor,

$$\begin{gathered}
\overset{0d}{(k_{0d})}\overset{12}{(k_{12})}\overset{35}{(k_{35})}\cdots\overset{d-1\ d-2}{(k_{d-1\ d-2})}\psi_0, \\
\overset{0d}{[-k_{0d}]}\overset{12}{[-k_{12}]}\overset{35}{(k_{35})}\cdots\overset{d-1\ d-2}{(k_{d-1\ d-2})}\psi_0, \\
\overset{0d}{[-k_{0d}]}\overset{12}{(k_{12})}\overset{35}{[-k_{35}]}\cdots\overset{d-1\ d-2}{(k_{d-1\ d-2})}\psi_0, \\
\vdots \\
\overset{0d}{[-k_{0d}]}\overset{12}{(k_{12})}\overset{35}{(k_{35})}\cdots\overset{d-1\ d-2}{[-k_{d-1\ d-2}]}\psi_0,
\end{gathered} \tag{12}$$

$$(\overset{od}{k_{0d}})[-\overset{12}{k_{12}}][-\overset{35}{k_{35}}]\cdots(\overset{d-1\ d-2}{k_{d-1\ d-2}})\psi_0,$$

$$\vdots$$

All the states have handedness Γ, since $\{\Gamma,S^{ab}\}_-=0$, which is easily calculated by multiplying from the left-hand side the starting state by Γ of Eq. (5). States belonging to one multiplet with respect to group $SO(q,d-q)$, that is to one irreducible representation of spinors (one Weyl spinor), can have any phase. We chose the simplest one, setting all phases equal to one.

The above graphic representation demonstrated that for d even all the states of one irreducible Weyl representation of a definite handedness follow from the starting state, which is, for example, a product of nilpotents $(\overset{ab}{k})$, by transforming all possible pairs of $(\overset{ab}{k})(\overset{mn}{k})$ into $[-\overset{ab}{k}][-\overset{mn}{k}]$. There are S^{am}, S^{an}, S^{bm}, S^{bn}, which do this. The procedure gives $2^{(d/2-1)}$ states. A Clifford algebra object γ^a applied from the left-hand side transforms a Weyl spinor of one handedness into a Weyl spinor of the opposite handedness. Both Weyl spinors form a Dirac spinor. We call such a set of states a "family."

For d odd a Weyl spinor also has in addition to a product of $(d-1)/2$ nilpotents or projectors either the factor $\overset{+}{\bigcirc}:=\frac{1}{2}(1+\Gamma)$ or the factor $\overset{-}{\bullet}:=\frac{1}{2}(1-\Gamma)$. (See Ref. 1.) As in the case of d even, all the states of one irreducible Weyl representation of a definite handedness follow from a starting state, which is, for example, a product of $\frac{1}{2}(1+\Gamma)$ and $(d-1)/2$ nilpotents $(\overset{ab}{k})$, by transforming all possible pairs of $(\overset{ab}{k})(\overset{mn}{k})$ into $[-\overset{ab}{k}][-\overset{mn}{k}]$. But γ^a's applied from the left-hand side do not change the handedness of the Weyl spinor, since $\{\Gamma,\gamma^a\}_-=0$ for d odd.[1] A Dirac and a Weyl spinor are for d odd identical and a "family" has accordingly $2^{(d-1)/2}$ members of basic states of a definite handedness.

We shall speak about left-handedness when $\Gamma=-1$ and right-handedness when $\Gamma=1$ for either d even or odd.

When the whole Clifford algebra is considered as states in a Hilbert space, then we get "families."

III. "FAMILIES"

When all 2^d states are considered as a Hilbert space, we recognize that for d even there are $2^{d/2}$ "families" and for d odd $2^{(d+1)/2}$ "families" of spinors.

We prove in this section (see also Ref. 5) that there exists an operation which transforms the state of one "family" into the state of another "family," leaving all the properties with respect to the Lorentz group unchanged.

We saw in Sec. II that any Clifford algebra object when multiplying from the left-hand side products of nilpotents and projectors (operating on a vacuum state)—a state of a Dirac spinor—transforms this state into a superposition of states of the same Dirac spinor. We refer to a Dirac spinor as a "family." Since there are 2^d linearly independent states, one finds for d even $2^{d/2}$ "families" and for d odd $2^{(d+1)/2}$ "families" of Dirac spinors. "Families" form left ideals with respect to the multiplication with the Clifford algebra objects.

The question then arises: Which operation transforms the state of one "family" into the state of another "family"?

Statement 1: Right multiplication with the Clifford algebra objects transforms the state of one "family" into the state of another "family."

Proof: The Clifford algebra object $(\overset{ab}{k})$ transforms, when applied from the left-hand side by either γ^a (or by γ^b), into $[-\overset{ab}{k}]$ [Eq. (8)]. One finds this by simply multiplying $(\overset{ab}{k})$ from the

left-hand side by one of these two Clifford algebra objects and taking into account Eq. (1)

$$\gamma^a \overset{ab}{(k)} = \gamma^a \ \frac{1}{2}\left(\gamma^a + \frac{\eta^{aa}}{ik}\gamma^b\right) = \eta^{aa}\frac{1}{2}\left(1 + \frac{i}{-k}\gamma^a\gamma^b\right) = \eta^{aa}\overset{ab}{[-k]}. \tag{13}$$

[And similarly we get $\gamma^b \overset{ab}{(k)} = -ik\overset{ab}{[-k]}$. The product of $\gamma^a\gamma^b$ transforms $\overset{ab}{(k)}$ into itself, multiplying it by $-ik$, since $\overset{ab}{(k)}$ was chosen to be the "eigen vector" of the Cartan subalgebra of the Lorentz algebra in the sense.]

Let us now multiply the same object $\overset{ab}{(k)}$ by γ^a *from the right-hand side*. It follows

$$\overset{ab}{(k)}\gamma^a = \frac{1}{2}\left(\gamma^a + \frac{\eta^{aa}}{ik}\gamma^b\right)\gamma^a = \eta^{aa}\frac{1}{2}\left(1 + \frac{i}{k}\gamma^a\gamma^b\right) = \eta^{aa}\overset{ab}{[k]}. \tag{14}$$

We saw in Eq. (13) that multiplication from the left-hand side by any Clifford algebra object transforms $\overset{ab}{(k)}$ into $\overset{ab}{[-k]}$, never to $\overset{ab}{[k]}$. This means that $\overset{ab}{[k]}$ is going to be a building block of a different "family" than $\overset{ab}{[-k]}$.

Theorem 1: *The two operations—left and right multiplication by* γ^a*—commute.*

Proof: To see this we need to show that the two objects $\overset{ab}{(k)}$ and $\overset{ab}{[k]}$, the second obtained from the first by right multiplication, have all the properties with respect to the Lorentz group (application of the Lorentz algebra objects concerns the left multiplication) equal and that they differ only in the "family" name. Left multiplication by γ^a of the object $\overset{ab}{(k)}$ leads, as we know [Eq. (8)], to $\overset{ab}{[-k]}$, whose $S^{ab}\overset{ab}{[-k]} = -(k/2)\overset{ab}{[-k]}$.

To check the properties of the two Clifford algebra objects $\overset{ab}{(k)}$ and $\overset{ab}{[k]}$ with respect to the Lorentz group, we have to multiply each of the two Clifford algebra objects from the left-hand side by S^{ab}, which is the Cartan subalgebra element. According to Eq. (7) we find $S^{ab}\overset{ab}{(k_{ab})} = (i/2)\frac{1}{2}(\gamma^a\gamma^b\gamma^a + \eta^{aa}/ik\,\gamma^a\gamma^b\gamma^b) = (k/2)\overset{ab}{(k)}$, $S^{ab}\overset{ab}{[k]} = (k/2)\overset{ab}{[k]}$.

Both objects, $\overset{ab}{(k)}$ and $\overset{ab}{[k]}$, have the same eigenvalue for the Cartan subalgebra element S^{ab}, namely $\frac{1}{2}k$. Since right multiplication of the object $\overset{ab}{(k)}$ does not change the properties of the object with respect to the Lorentz group (the properties of which are determined by left multiplication) the two operations—left and right multiplication with γ^a's, both fulfilling the Clifford algebra relation—must commute and the proof is completed.

Since γ^a's are odd Clifford algebra objects, we would like to see the two operations—left and right multiplication with γ^a's—to anticommute rather then commute. With appropriate choice of a phase we can make them commute.

We define[5] *the Clifford algebra objects* $\tilde{\gamma}^a$'s *as operations which operate formally from the left-hand side* (*as* γ^a's *do*) *on objects* $\overset{ab}{(k)}$ *and* $\overset{ab}{[k]}$, *transforming objects to* $\overset{ab}{[k]}$ *and* $\overset{ab}{(k)}$, respectively, *as* γ^a's *would if applied from the right-hand side, up to a phase* i,

$$\tilde{\gamma}^a\overset{ab}{(k)} := -i\overset{ab}{(k)}\gamma^a = -i\,\eta^{aa}\overset{ab}{[k]}, \tag{15}$$

$$\tilde{\gamma}^b(k) := -\overset{ab}{i}(k)\,\gamma^b = -\overset{ab}{k}[k]. \tag{16}$$

One accordingly finds

$$\tilde{\gamma}^a[k] := \overset{ab}{i}[k]\,\gamma^a = \overset{ab}{i}(k), \tag{17}$$

$$\tilde{\gamma}^b[k] := \overset{ab}{i}[k]\,\gamma^b = -k\,\eta^{aa}\overset{ab}{(k)}. \tag{18}$$

We generalize the above definition of $\tilde{\gamma}^a$ to any Clifford algebra object as follows:

$$\tilde{\gamma}^a A = i(-)^{(A)} A\,\gamma^a, \tag{19}$$

with $(-)^{(A)} = -1$, if A is an odd Clifford algebra object and $(-)^{(A)} = 1$, if A is an even Clifford algebra object.

We can prove that $\tilde{\gamma}^a$ obey the same Clifford algebra relation as γ^a,

$$(\tilde{\gamma}^a\tilde{\gamma}^b + \tilde{\gamma}^b\tilde{\gamma}^a)A = -ii((-)^{(A)})^2 A(\gamma^a\gamma^b + \gamma^b\gamma^a) = 2\,\eta^{ab}A \tag{20}$$

and that $\tilde{\gamma}^a$ and γ^a anticommute

$$(\tilde{\gamma}^a\gamma^b + \gamma^b\tilde{\gamma}^a)A = i(-)^{(A)}(-\gamma^b A\,\gamma^a + \gamma^b A\,\gamma^a) = 0. \tag{21}$$

From *Theorem 1* and the above-given calculations, we may write

$$\{\tilde{\gamma}^a, \gamma^b\}_+ = 0, \quad \text{while} \quad \{\tilde{\gamma}^a, \tilde{\gamma}^b\}_+ = 2\,\eta^{ab}. \tag{22}$$

If we define

$$\tilde{S}^{ab} = \frac{i}{4}\ [\tilde{\gamma}^a, \tilde{\gamma}^b] = \frac{1}{4}(\tilde{\gamma}^a\tilde{\gamma}^b - \tilde{\gamma}^b\tilde{\gamma}^a), \tag{23}$$

it follows

$$\tilde{S}^{ab}A = A\,\tfrac{1}{4}(\gamma^b\gamma^a - \gamma^a\gamma^b), \tag{24}$$

manifesting accordingly that $\tilde{S}^{ab}$ fulfill the Lorentz algebra relation as S^{ab} do. Taking into account Eq. (19), we further find

$$\{\tilde{S}^{ab}, S^{ab}\}_- = 0, \quad \{\tilde{S}^{ab}, \gamma^c\}_- = 0, \quad \{S^{ab}, \tilde{\gamma}^c\}_- = 0. \tag{25}$$

One also finds

$$\begin{aligned} &\{\tilde{S}^{ab}, \Gamma\}_- = 0, \quad \{\tilde{\gamma}^a, \Gamma\}_- = 0 \quad \text{for d even,} \\ &\{\tilde{S}^{ab}, \Gamma\}_- = 0, \quad \{\tilde{\gamma}^a, \Gamma\}_+ = 0 \quad \text{for d odd,} \end{aligned} \tag{26}$$

which means that in d even transforming one ''family'' into another with either $\tilde{S}^{ab}$ or $\tilde{\gamma}^a$ leaves handedness Γ unchanged, while the transformation to another ''family'' in d odd with $\tilde{\gamma}^a$ changes the handedness of states, namely the factor $\frac{1}{2}(1 \pm \Gamma)$ changes to $\frac{1}{2}(1 \mp \Gamma)$ in accordance with what we know from before: In spaces with odd d changing the handedness means changing the ''family.''

We advise the reader also to read Refs. 3 and 4 where the two kinds of Clifford algebra objects follow as two different superpositions of a Grassmann coordinate and its conjugate momentum.

We present for $\tilde{S}^{ab}$ some useful relations

$$\tilde{S}^{ab}\overset{ab}{(k)} = \frac{k}{2}\overset{ab}{(k)},$$

$$\tilde{S}^{ab}\overset{ab}{[k]} = -\frac{k}{2}\overset{ab}{[k]},$$

$$\tilde{S}^{ac}\overset{ab\ \ cd}{(k)(k)} = \frac{i}{2}\eta^{aa}\eta^{cc}\overset{ab\ \ cd}{[k][k]},$$

$$\tilde{S}^{ac}\overset{ab\ \ cd}{[k][k]} = -\frac{i}{2}\overset{ab\ \ cd}{(k)(k)}, \tag{27}$$

$$\tilde{S}^{ac}\overset{ab\ \ cd}{(k)[k]} = -\frac{i}{2}\eta^{aa}\overset{ab\ \ cd}{[k](k)},$$

$$\tilde{S}^{ac}\overset{ab\ \ cd}{[k](k)} = \frac{i}{2}\eta^{cc}\overset{ab\ \ cd}{(k)[k]}.$$

According to *Statement 1* we transform the state of one "family" to the state of another "family" by the application of $\tilde{\gamma}^a$ or $\tilde{S}^{ac}$ (formally from the left-hand side) on a state of the first "family" for a chosen a or a,c. To transform all the states of one "family" into states of another "family," we apply $\tilde{\gamma}^a$ or $\tilde{S}^{ac}$ to each state of the starting "family." It is, of course, sufficient to apply $\tilde{\gamma}^a$ or $\tilde{S}^{ac}$ to only one state of a "family" and then use generators of the Lorentz group (S^{ab}), and for d even also γ^a's, to generate all the states of one Dirac spinor.

One must notice that nilpotents $\overset{ab}{(k)}$ and projectors $\overset{ab}{[k]}$ are eigenvectors not only of the Cartan subalgebra S^{ab} but also of $\tilde{S}^{ab}$. Accordingly only $\tilde{S}^{ac}$, which do not carry the Cartan subalgebra indices, cause the transition from one "family" to another "family."

The starting state of Eq. (12) can change, for example, to

$$\overset{0d\quad 12\quad 35\qquad\quad d-1\ d-2}{[k_{0d}][k_{12}](k_{35})\cdots(k_{d-1\ d-2})}, \tag{28}$$

if $\tilde{S}^{01}$ was chosen to transform the Weyl spinor of Eq. (12) to the Weyl spinor of another "family."

In what follows we demonstrate the appearance of "families" for $d=4$ with the Minkowski signature.

"Families" for $d=4$. There are two $(d/2=2)$ operators of the Cartan subalgebra of the Lorentz algebra (which is closed by the operators S^{01}, S^{02}, S^{03}, S^{12}, S^{13}, S^{23}), for which we made a choice, according to Eq. (4) of S^{03} and S^{12}. Following Eq. (5) we find $\Gamma = i\gamma^0\gamma^1\gamma^2\gamma^3$. There are 2^4, that is sixteen basic states, all of them being "eigenstates" of S^{12} and S^{03} in the sense of Eq. (7)

$$\begin{aligned}
&\overset{03}{(\pm i)}\overset{12}{(\pm)} = (\tfrac{1}{2})^2(\gamma^0 \mp \gamma^3)(\gamma^1 \pm i\gamma^2), \quad \overset{03}{(\pm i)}\overset{12}{[\pm]} = (\tfrac{1}{2})^2(\gamma^0 \mp \gamma^3)(1 \pm i\gamma^1\gamma^2),\\
&\overset{03}{[\pm i]}\overset{12}{(\pm)} = (\tfrac{1}{2})^2(1 \pm \gamma^0\gamma^3)(\gamma^1 \pm i\gamma^2), \quad \overset{03}{[\pm i]}\overset{12}{[\pm]} = (\tfrac{1}{2})^2(1 \pm \gamma^0\gamma^3)(1 \pm i\gamma^1\gamma^2),
\end{aligned} \tag{29}$$

TABLE I. Four "families" of the two Weyl spinors of the Lorentz group SO(1,3). Basic vectors are eigenvectors of the two operators of the Cartan subalgebra S^{12} and S^{03}. The eigenvalues of the operator of handedness Γ are also presented. All the basic states are orthonormalized as discussed in Ref. 1. The simplest choice of relative phases is used—all phases are assumed to be equal to $+1$.

a	i	$({}^a\psi_i)_1$	$({}^a\psi_i)_2$	$({}^a\psi_i)_3$	$({}^a\psi_i)_4$	S^{12}	S^{03}	Γ
1	1	$\overset{03}{(+i)}\overset{12}{(+)}$	$\overset{03}{[+i]}\overset{12}{[+]}$	$\overset{03}{[+i]}\overset{12}{(+)}$	$\overset{03}{(+i)}\overset{12}{[+]}$	$\frac{1}{2}$	$\frac{i}{2}$	-1
1	2	$\overset{03}{[-i]}\overset{12}{[-]}$	$\overset{03}{(-i)}\overset{12}{(-)}$	$\overset{03}{(-i)}\overset{12}{[-]}$	$\overset{03}{[-i]}\overset{12}{(-)}$	$-\frac{1}{2}$	$-\frac{i}{2}$	-1
2	1	$\overset{03}{[-i]}\overset{12}{(+)}$	$\overset{03}{(-i)}\overset{12}{[+]}$	$\overset{03}{(-i)}\overset{12}{(+)}$	$\overset{03}{[-i]}\overset{12}{[+]}$	$\frac{1}{2}$	$-\frac{i}{2}$	1
2	2	$\overset{03}{(+i)}\overset{12}{[-]}$	$\overset{03}{[+i]}\overset{12}{(-)}$	$\overset{03}{[+i]}\overset{12}{[-]}$	$\overset{03}{(+i)}\overset{12}{(-)}$	$-\frac{1}{2}$	$\frac{i}{2}$	1

with the "eigenvalues" of the Cartan operator S^{12} equal to $\pm 1/2$ for the $\pm$ sign in the second factor of the graphical presentation and the eigenvalues of the Cartan operator S^{03} equal to $\pm i/2$ for the $\pm i$ sign in the first factor of the graphical representation. All sixteen basic states are orthonormal.[1]

We arrange these sixteen states into four "families" by first choosing the starting state of the first "family" as a product of two nilpotents $\overset{03}{(+i)}\overset{12}{(+)}$. Then we use S^{01}, for example, to find the second state $\overset{03}{[-i]}\overset{12}{[-]}$ of one Weyl spinor. γ^0 generates from the first state of the first Weyl spinor the first state of the second Weyl spinor, namely, $\overset{03}{[-i]}\overset{12}{(+)}$ and S^{01} then the second state of the second spinor $\overset{03}{(+i)}\overset{12}{[-]}$. We set all the phases of the states equal to one.

We transform this first "family" into the second "family" by applying $\tilde{S}^{01}$ (or $\tilde{S}^{02}$, or $\tilde{S}^{31}$, or $\tilde{S}^{32}$) to each of the states of the first "family." By applying $\tilde{\gamma}^a$ to all the states of the first "family" we get the third "family." We also can generate the third "family" from the second by applying $\tilde{\gamma}^1$ (or $\tilde{\gamma}^2$). The fourth "family" can be reached from the first one by the application of $\tilde{\gamma}^1$ (or $\tilde{\gamma}^2$), but it can also be reached from any other with the appropriate choice of operations. For all the "families" the simplest choice of the relative phases, namely, the phase 1, is made.

Each "family" includes two Weyl spinors, one left- and one right-handed. These four "families" are presented in Table I.

We see in Table I that either $\tilde{\gamma}^a$, $a=0,1,2,3$, or $\tilde{S}^{01},\tilde{S}^{02},\tilde{S}^{31},\tilde{S}^{32}$, when applied, change the "family" but do not change either the handedness or the "eigenvalues" of the Cartan subalgebra of the Lorentz algebra.

Any of the four "families" can be used to represent the solution of the Dirac equation for a massive spinor, while massless spinors are either left- or right-handed, so that only half of the space of the massive case is needed to find the solution. The phases chosen for basic states make the matrix representation of γ^a's and S^{ab} equal to the usual ones.

IV. CONCLUSION

In Ref. 1 we constructed the basis for a left ideal out of products of nilpotents and projectors and identified the basis with the spinor space. There are 2^d nilpotents and projectors. Mapping all the ideals to spinor representations, that is treating all as a Hilbert space, leads to "families" of spinors. An irreducible representation of a spinor (a Dirac spinor, which is a Weyl bi-spinor with $2^{d/2}$ members for d even and a Weyl spinor with $2^{(d-1)/2}$ members for d odd) depends on a selection of a "starting" Clifford object. We have for d even $2^{d/2}$ different starting states and for d odd $2^{(d+1)/2}$ different starting states, which can all be made orthogonal with the appropriate

choice of an (unimportant) vacuum state. These are the different bases (that is different spinor spaces, which have all the same properties with respect to the Lorentz group), which we call ''families'' of spinors.

We have shown in this paper that while left multiplication with any Clifford algebra object makes from a ''starting'' state a superposition of basic states of one Dirac spinor, *right multiplication* of a ''starting state'' with any Clifford algebra object makes a superposition of states belonging to different ''families'' but having the same properties with respect to the Lorentz group (defined by left multiplication of Clifford algebra objects) as the starting state. One comes accordingly from one ''family'' to another ''family'' (up to an overall factor) by multiplying the ''starting'' state from the right-hand side by S^{ab}'s for d odd and by S^{ab}'s and γ^a's for d even, if S^{ab} does not belong to the Cartan subalgebra of the Lorentz group.

We have defined in this paper $\tilde{\gamma}^a$'s and $\tilde{S}^{ab}$ with the properties that both transform nilpotents and projectors, when multiplying them from the left-hand side as γ^a's and S^{ab} would if multiplying nilpotents and projectors from the right-hand side. Since neither $\tilde{\gamma}^a$'s nor $\tilde{S}^{ab}$ change properties of nilpotents and projectors (and consequently of a state) with respect to the Lorentz group, and since both—γ^a's and $\tilde{\gamma}^a$'s—are Clifford algebra objects, it follows (with the appropriate choice of phases) that $\{\tilde{\gamma}^a, \gamma^b\}_+ = 0$ and $\{\tilde{\gamma}^a, \tilde{\gamma}^b\}_+ = 2\eta^{ab}$. Consequently, $\tilde{S}^{ab}$ fulfill the same Lorentz algebra relation as S^{ab}. This can be understood since one could construct the spinor basis for a right ideal instead of a left ideal and then use left multiplication to generate ''families.'' (To understand this better, see Refs. 3, 4, 5, and 8.)

We have also demonstrated the application of $\tilde{\gamma}^a$'s and $\tilde{S}^{ab}$ on a basis with the help of the graphic technique introduced in Ref. 1. We demonstrated the procedure for generating ''families'' in the (most familiar) case of $d=1+3$, that is for $d=4$ and one time coordinate, where the number of ''families'' is four.

In conclusion, we must ask ourselves whether the proposed generation of ''families'' can be used to describe the ''families'' of quarks and leptons? This is certainly one of the open problems of the Standard electroweak model. We believe that we have the right way to do this. According to Refs. 4 and 5, one can generate ''families'' of quarks and leptons dynamically if in the covariant derivative $\tilde{S}^{ab}$ appears as charges, accompanied by gauge fields like $\tilde{\omega}_c{}^{ab}$, so that

$$p_o{}^a = p^a - \tfrac{1}{2}\tilde{S}^{ab}\tilde{\omega}_{abc} - \tau^{Ai}A^{Aia}, \tag{30}$$

with τ^{Ai} determining the known charges [U(1),SU(2),SU(3)] and A^{Aia} the corresponding gauge fields. This possibility has been discussed in Ref. 5.

In the presented formalism we worked with the Clifford algebra objects only, using them to express not only the generators of the Lorentz algebra but also the operators transforming one ''family'' into another ''family'' and even the spinor basis for one and several ''families.'' (It is for this reason that we get the ''families'' as explained.) One would accordingly ask oneself if there is possibly any physical reason that the Clifford algebra degrees of freedom are ''more fundamental'' than the spinors.[9]

This is exactly what was taken as the starting point in the works by one of us[2–5] (and which lead to the formalism, presented in this paper) but it is also what is really the case in the Kogut and Susskind lattice fermion formalism.[10] In the latter case the fermion degrees of freedom are interpreted as sitting really on the sites links plaquettes and cubes and hypercubes of a lattice with the double lattice constant. That corresponds to having fields of all the possible antisymmetrized tensor characters, which is just what the Clifford algebra elements have. One therefore has also in the Kogut–Susskind fermions a way of having the Clifford algebra naturally more fundamental than the spinors. Not surprisingly we also get in this case the expected number 4 for families in this lattice model. Also the paper of both of us [8] already introduced ''families'' of spinors with the help of the Clifford algebra objects, but in a slightly different way—the spinor states have two indices.

(Received 23 April 2003; accepted 20 May 2003)

We classify the SU(2)-invariant anti-self-dual metrics with a signature $(+, +, -, -)$. The metrics are specified by a solution of Painlevé VI, V, III or II. Moreover, we show the geometric meaning of the metrics specified by each type of Painlevé function. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1604187]

I. INTRODUCTION

The aim of this article is to classify the anti-self-dual metrics in real dimension four admitting an isometric action of SU(2) with generically three-dimensional orbits. In this article, we study not only the definite metrics, but also the indefinite metrics with a signature $(+, +, -, -)$.

Hitchin[5] shows that the SU(2)-invariant anti-self-dual metric is generically specified by a solution of Painlevé VI with two complex parameters. He used the twistor correspondence[1,13] to associate the anti-self-dual equation and the Painlevé equation. On the twistor space, the lifted action of SU(2) determines a prehomogeneous action of SU(2), and it determines an isomonodromic family of connections on $\mathbb{CP}^1$, and then we obtain the Painlevé equation.

In this framework, Hitchin[5] classified the diagonal anti-self-dual metrics, and Dancer[4] shows that the diagonal scalar-flat Kähler metric is specified by a solution of Painlevé III with a parameter $(0, 4, 4, -4)$, where the *diagonal* metric is the metric in the shape of (1) in Sec. II. Since the anti-self-dual Einstein metrics are diagonal, the classification for diagonal metrics enough serves Hitchin's purpose. However, generically, the SU(2)-invariant metric is in the shape of (4) in Sec. III. In this case, Hitchin shows that the metric is generically specified by a solution of Painlevé VI, but he does not go into detail. We study not only the diagonal metrics but also the nondiagonal metrics. The author[10,11] shows that the SU(2)-invariant anti-self-dual Hermitian metric is specified by a solution of Painlevé III with a parameter $(4\theta, 4(1+\overline{\theta}), 4, -4)$.

The metrics mentioned above are positive definite. In this article we study the indefinite metrics with a signature $(+, +, -, -)$. If the metric is definite, then the anti-self-dual equation reduces to either Painlevé VI or III. On the other hand, we show that, if the metric has a signature $(+, +, -, -)$, then the anti-self-dual equation reduces to not only Painlevé VI or III but also Painlevé V or II. The difference of types of Painlevé is due to the difference of reality on the twistor space.

Painlevé VI is shown to be a deformation equation for a linear problem,

$$\left(\frac{d}{dz}-B_1\right)\begin{pmatrix} y_1 \\ y_2 \end{pmatrix}=0,$$

where B_1 has four simple poles on $\mathbb{CP}^1$.[6] And Painlevé V, IV, III, II are degenerated from Painlevé

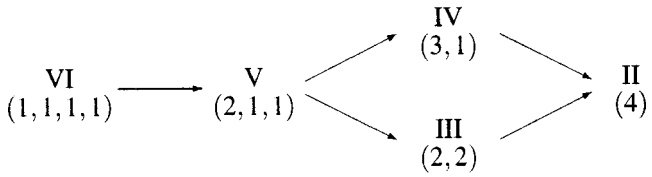
VI:



This is the confluence diagram of poles of B_1, where the Roman numerals represent the types of the Painlevé equation, and the parenthesized numbers represent the orders of poles of B_1. For example, Painlevé V is shown to be a deformation equation for a linear problem with one double and two simple poles.

For the complexified metrics, any type of Painlevé equation from I to VI is derived from the anti-self-dual equation.[8,9] However, it is important to study what types of Painlevé equations are derived from the real anti-self-dual equation.

For the metric with a signature $(+, +, -, -)$, due to the reality of the twistor space, the poles of B_1 make two conjugate pairs. Therefore, the configuration of poles never becomes the type of Painlevé IV.

The multiple pole of B_1 on $\mathbb{CR}$ determines a Hermitian structure, and the multiple pole on $\mathbb{R}$ determines a structure of real twistor surfaces. In each case, we can calculate local exponents at singularities. These local exponents corresponding to the parameter of the Painlevé equation. This is the geometric meaning of the metrics specified by each type of Painlevé function:

(1) Generically, the anti-self-dual metrics are specified by a solution of Painlevé VI with two complex parameters.
(2) If the anti-self-dual metric is specified by a solution of Painlevé III with one complex parameter, then there exists an SU(2)-invariant Hermitian structure.
(3) If the anti-self-dual metric is specified by a solution of Painlevé V with one real and one complex parameter, or Painlevé II with one real parameter, then for any $x \in M$ there exists one real twistor surface passing through x.
(4) If the anti-self-dual metric is specified by a solution of Painlevé III with two real parameters, then for any $x \in M$ there exist two real twistor surfaces passing through x.

II. THE DIAGONAL ANTI-SELF-DUAL EQUATIONS

In this section, we review the anti-self-dual equations on the SU(2)-invariant diagonal metrics. The SU(2)-invariant diagonal metric is represented in the following form:

$$g = w_1 w_2 w_3\, dt^2 + \frac{w_2 w_3}{w_1}\sigma_1^2 + \frac{w_3 w_1}{w_2}\sigma_2^2 + \frac{w_1 w_2}{w_3}\sigma_3^2. \tag{1}$$

w_1, w_2 and w_3 are functions of t, and σ_1, σ_2, σ_3 are left invariant one-forms on each SU(2)-orbit satisfying

$$d\sigma_1 = \sigma_2 \wedge \sigma_3, \quad d\sigma_2 = \sigma_3 \wedge \sigma_1, \quad d\sigma_3 = \sigma_1 \wedge \sigma_2. \tag{2}$$

Tod[14] showed that the (scalar-flat) anti-self-dual equations on the SU(2)-invariant diagonal metric are given by the following system:

$$\begin{aligned}
&\dot{w}_1=-w_2w_3+w_1(\alpha_2+\alpha_3), \quad \dot{w}_2=-w_3w_1+w_2(\alpha_3+\alpha_1),\\
&\dot{w}_3=-w_1w_2+w_3(\alpha_1+\alpha_2), \quad \dot{\alpha}_1=-\alpha_2\,\alpha_3+\alpha_1(\alpha_2+\alpha_3),\\
&\dot{\alpha}_2=-\alpha_3\,\alpha_1+\alpha_2(\alpha_3+\alpha_1), \quad \dot{\alpha}_3=-\alpha_1\,\alpha_2+\alpha_3(\alpha_1+\alpha_2),
\end{aligned} \tag{3}$$

where α_1, α_2, α_3 are auxiliary functions and the dots denote differentiation with respect to t. The anti-self-dual equation (3) has a first integral

$$k=\frac{\alpha_1(w_2^2-w_3^2)+\alpha_2(w_3^2-w_1^2)+\alpha_3(w_1^2-w_2^2)}{8(\alpha_1-\alpha_2)(\alpha_2-\alpha_3)(\alpha_3-\alpha_1)}.$$

Furthermore, if we set

$$x=\frac{\alpha_2-\alpha_1}{\alpha_2-\alpha_3}, \quad q=\frac{w_2(\alpha_1-\alpha_2)(w_2(w_1^2-w_3^2)+2\sqrt{2k}\,w_1w_3(\alpha_1-\alpha_3))}{w_1^2(w_2^2-w_3^2)\alpha_1+w_2^2(w_3^2-w_1^2)\alpha_2+w_3^2(w_1^2-w_2^2)\alpha_3},$$

then the system (3) generically reduces to a family of Painlevé VI with a special parameter

$$(\alpha,\beta,\gamma,\delta)=\left(\frac{(\sqrt{2k}-1)^2}{2},k,-k,\frac{1+2k}{2}\right).$$

We will review the Painlevé equation in the Appendix.

III. THE NONDIAGONAL ANTI-SELF-DUAL EQUATIONS

We can express an SU(2)-invariant metric in the form

$$g=f(\tau)d\tau^2+\sum_{l,m=1}^{3}h_{l\,m}(\tau)\,\sigma_l\sigma_m\,. \tag{4}$$

Using the Killing form, we can diagonalize the metric g on each SU(2)-orbit. Then we can express the metric as follows:

$$g=(abc)^2dt^2+a^2d\hat{\sigma}_1^2+b^2\hat{\sigma}_2^2+c^2\hat{\sigma}_3^2,$$

for some $t=t(\tau)$, $a=a(t)$, $b=b(t)$, $c=c(t)$ and

$$\begin{pmatrix}\hat{\sigma}_1\\ \hat{\sigma}_2\\ \hat{\sigma}_3\end{pmatrix}=R(t)\begin{pmatrix}\sigma_1\\ \sigma_2\\ \sigma_3\end{pmatrix},$$

where $R(t)$ is an SO(3)-valued function.

Since $\dot{R}R^{-1}\in\mathfrak{so}(3)$, we obtain

$$d\begin{pmatrix}\hat{\sigma}_1\\ \hat{\sigma}_2\\ \hat{\sigma}_3\end{pmatrix}=R(t)\begin{pmatrix}\sigma_2\wedge\sigma_3\\ \sigma_3\wedge\sigma_1\\ \sigma_2\wedge\sigma_2\end{pmatrix}+\dot{R}\,dt\wedge\begin{pmatrix}\sigma_1\\ \sigma_2\\ \sigma_3\end{pmatrix}=\begin{pmatrix}\hat{\sigma}_2\wedge\hat{\sigma}_3\\ \hat{\sigma}_3\wedge\hat{\sigma}_1\\ \hat{\sigma}_1\wedge\hat{\sigma}_2\end{pmatrix}+\begin{pmatrix}0 & \xi_3 & -\xi_2\\ -\xi_3 & 0 & \xi_1\\ \xi_2 & -\xi_1 & 0\end{pmatrix}dt\wedge\begin{pmatrix}\hat{\sigma}_1\\ \hat{\sigma}_2\\ \hat{\sigma}_3\end{pmatrix},$$

for some $\xi_1=\xi_1(t)$, $\xi_2=\xi_2(t)$, $\xi_3=\xi_3(t)$.

If $\xi_1=0$, $\xi_2=0$, $\xi_3=0$, then the matrix $(h_{l\,m})$ can be chosen to be diagonal for all τ, and then we say that g is a diagonal metric.

In the following, we mainly study the nondiagonal case.

We set $w_1=bc$, $w_2=ca$, $w_3=ab$ and determine α_1, α_2, α_3 by

$$\begin{aligned}\dot{w}_1&=-w_2w_3+w_1(\alpha_2+\alpha_3),\\ \dot{w}_2&=-w_3w_1+w_2(\alpha_3+\alpha_1),\\ \dot{w}_3&=-w_1w_2+w_3(\alpha_1+\alpha_2).\end{aligned}\tag{5}$$

Then the scalar curvature s is determined by

$$\begin{aligned}w_1w_2w_3\,s=4(&\dot{\alpha}_1+\dot{\alpha}_2+\dot{\alpha}_3-\alpha_2\alpha_3-\alpha_3\alpha_1-\alpha_1\alpha_2)\\&+\frac{(w_2^2-w_3^2)^2}{w_2^2w_3^2}\xi_1^2+\frac{(w_3^2-w_1^2)^2}{w_3^2w_1^2}\xi_2^2+\frac{(w_1^2-w_2^2)^2}{w_1^2w_2^2}\xi_3^2,\end{aligned}$$

and then the anti-self-dual equations are as follows:[10,11]

$$\begin{aligned}\dot{\alpha}_1=&-\alpha_2\alpha_3+\alpha_1(\alpha_2+\alpha_3)+\frac{1}{4}(w_2^2-w_3^2)^2\left(\frac{\xi_1}{w_2w_3}\right)^2+\frac{1}{4}(w_3^2-w_1^2)(3w_1^2+w_3^2)\left(\frac{\xi_2}{w_3w_1}\right)^2\\&+\frac{1}{4}(w_2^2-w_1^2)(3w_1^2+w_2^2)\left(\frac{\xi_3}{w_1w_2}\right)^2-\frac{w_1w_2w_3\,s}{12},\\ \dot{\alpha}_2=&-\alpha_3\alpha_1+\alpha_2(\alpha_3+\alpha_1)+\frac{1}{4}(w_3^2-w_1^2)^2\left(\frac{\xi_2}{w_3w_1}\right)^2+\frac{1}{4}(w_1^2-w_2^2)(3w_2^2+w_1^2)\left(\frac{\xi_3}{w_1w_2}\right)^2\\&+\frac{1}{4}(w_3^2-w_2^2)(3w_2^2+w_3^2)\left(\frac{\xi_1}{w_2w_3}\right)^2-\frac{w_1w_2w_3\,s}{12},\\ \dot{\alpha}_3=&-\alpha_1\alpha_2+\alpha_3(\alpha_1+\alpha_2)+\frac{1}{4}(w_1^2-w_2^2)^2\left(\frac{\xi_3}{w_1w_2}\right)^2+\frac{1}{4}(w_2^2-w_3^2)(3w_3^2+w_2^2)\left(\frac{\xi_1}{w_2w_3}\right)^2\\&+\frac{1}{4}(w_1^2-w_3^2)(3w_3^2+w_1^2)\left(\frac{\xi_2}{w_3w_1}\right)^2-\frac{w_1w_2w_3\,s}{12},\end{aligned}\tag{6}$$

and

$$\begin{aligned}(w_2^2-w_3^2)\frac{d}{dt}\left(\frac{\xi_1}{w_2w_3}\right)&=\frac{\xi_2}{w_3w_1}\frac{\xi_3}{w_1w_2}(-2w_2^2w_3^2+w_3^2w_1^2+w_1^2w_2^2)\\&\quad+\frac{\xi_1}{w_2w_3}(\alpha_2w_2^2-\alpha_3w_3^2+3\alpha_2w_3^2-3\alpha_3w_2^2),\\ (w_3^2-w_1^2)\frac{d}{dt}\left(\frac{\xi_2}{w_3w_1}\right)&=\frac{\xi_3}{w_1w_2}\frac{\xi_1}{w_2w_3}(-2w_3^2w_1^2+w_1^2w_2^2+w_2^2w_3^2)\\&\quad+\frac{\xi_2}{w_3w_1}(\alpha_3w_3^2-\alpha_1w_1^2+3\alpha_3w_1^2-3\alpha_1w_3^2),\end{aligned}\tag{7}$$

$$(w_1^2-w_2^2)\frac{d}{dt}\left(\frac{\xi_3}{w_1w_2}\right)=\frac{\xi_1}{w_2w_3}\frac{\xi_2}{w_3w_1}(-2w_1^2w_2^2+w_2^2w_3^2+w_3^2w_1^2)$$
$$+\frac{\xi_3}{w_1w_2}(\alpha_1w_1^2-\alpha_2w_2^2+3\alpha_1w_2^2-3\alpha_2w_1^2).$$

Remark 1: If $\xi_1=0$, $\xi_2=0$, $\xi_3=0$ and $s=0$, then the system of equations (5), (6) and (7) reduces to a sixth-order system (3) given by Tod.[14] *Furthermore, if $\alpha_1=w_1$, $\alpha_2=w_2$, $\alpha_3=w_3$, then (5)–(7) reduce to a third-order system which determines the Atiyah–Hitchin family,*[1] *and if $\alpha_1=0$, $\alpha_2=0$, $\alpha_3=0$, then the system reduces to a third-order system which determines the BGPP family.*[3]

Remark 2: If $w_2=w_3$, then we can set $\xi_1=0$, $\xi_2=0$ and $\xi_3=0$ by taking another frame. This is also a diagonal case. Therefore we assume $(w_2-w_3)(w_3-w_1)(w_1-w_2)\neq 0$.

IV. THE ISOMONODROMIC DEFORMATIONS

Let (M,g) be an oriented Riemannian four manifold. We define a manifold Z to be the unit sphere bundle in the bundle of anti-self-dual two-forms, and let π: $Z\to M$ denote the projection. Each point z in the fiber over $\pi(z)$ defines a complex structure on the tangent space $T_{\pi(z)}M$, compatible with the metric and its orientation.

Using the Levi-Civita connection, we can split the tangent space T_zZ into horizontal and vertical spaces, and the projection π identifies the horizontal space with $T_{\pi(z)}M$. This space has a complex structure defined by z and the vertical space is the tangent space of the fiber $S^2\cong\mathbb{CP}^1$ which has its natural complex structure.

The almost complex structure on Z is integrable if and only if the metric is anti-self-dual.[2,13] In this situation Z is called the twistor space of (M,g) and the fibers are called the real twistor lines.

The almost complex structure on Z can be determined by the following (1,0)-forms:

$$\Theta_1=z(e^1+\sqrt{-1}e^2)-(e^0+\sqrt{-1}e^3),$$
$$\Theta_2=z(e^0-\sqrt{-1}e^3)+(e^1-\sqrt{-1}e^2),\tag{8}$$
$$\Theta_3=dz+\tfrac{1}{2}z^2(\omega_1^0-\omega_3^2+\sqrt{-1}(\omega_2^0-\omega_1^3))-\sqrt{-1}z(\omega_3^0-\omega_2^1)+\tfrac{1}{2}(\omega_1^0-\omega_3^2-\sqrt{-1}(\omega_2^0-\omega_1^3)),$$

where $\{e^0,e^1,e^2,e^3\}$ is an orthonormal frame, and ω_j^i are the connection forms determined by $de^i+\omega_j^i\wedge e^j=0$ and $\omega_j^i+\omega_i^j=0$. Then the anti-self-dual condition is

$$d\Theta_1\equiv 0,\ \ d\Theta_2\equiv 0,\ \ d\Theta_3\equiv 0\ \ (\mathrm{mod}\ \Theta_1,\Theta_2,\Theta_3).\tag{9}$$

Theorem 3: *If the metric is positive definite, then the Pfaffian is invariant under conjugate action and $z\mapsto -1/\overline{z}$.*[2] *If the metric has a signature $(+,+,-,-)$, then the Pfaffian is invariant under conjugate action and $z\mapsto\overline{z}$.*

Remark 4: Let $TM^{\mathbb{C}}$ be a complexified tangent space of M. We call the set $\mathcal{C}=\{a\in TM^{\mathbb{C}}\mid g(a,a)=0\}$ a null cone. For $a\in TM^{\mathbb{C}}$, we consider

$$\Theta_1\left(a+\lambda\frac{\partial}{\partial z}\right)=0,\ \ \Theta_2\left(a+\lambda\frac{\partial}{\partial z}\right)=0,\ \ \Theta_3\left(a+\lambda\frac{\partial}{\partial z}\right)=0,\tag{10}$$

as algebraic equations of λ, z. Equations (10) have solutions $\lambda\in\mathbb{C}$, $z\in\mathbb{CP}^1$, if and only if $a\in\mathcal{C}$.

If the metric is SU(2) invariant, we obtain

$$\begin{pmatrix}\Theta_1\\ \Theta_2\\ \Theta_3\end{pmatrix}=\begin{pmatrix}0\\0\\1\end{pmatrix}dz+\begin{pmatrix}v_1\\ v_2\\ v_3\end{pmatrix}dt+A\begin{pmatrix}\sigma_1\\ \sigma_2\\ \sigma_3\end{pmatrix}, \tag{11}$$

where $v_1=v_1(z,t)$, $v_2=v_2(z,t)$, $v_3=v_3(z,t)$; $A=(a_{ij}(z,t))_{i,j=1,2,3}$.

If $\det A\equiv 0$, then the metric turns to be diagonal, and the metric is in the BGPP family.[3]

If $\det A\neq 0$, then we obtain

$$\begin{pmatrix}\sigma_1\\ \sigma_2\\ \sigma_3\end{pmatrix}\equiv -A^{-1}\left(\begin{pmatrix}0\\0\\1\end{pmatrix}dz+\begin{pmatrix}v_1\\ v_2\\ v_3\end{pmatrix}dt\right), \quad (\mathrm{mod}\ \Theta_1,\ \Theta_2,\ \Theta_3). \tag{12}$$

If we set

$$\begin{pmatrix}s_1\\ s_2\\ s_3\end{pmatrix}:=-A^{-1}\left(\begin{pmatrix}0\\0\\1\end{pmatrix}dz+\begin{pmatrix}v_1\\ v_2\\ v_3\end{pmatrix}dt\right), \tag{13}$$

then

$$d\begin{pmatrix}s_1\\ s_2\\ s_3\end{pmatrix}\equiv\begin{pmatrix}s_2\wedge s_3\\ s_3\wedge s_1\\ s_1\wedge s_2\end{pmatrix}, \quad (\mathrm{mod}\ \Theta_1,\Theta_2,\Theta_3). \tag{14}$$

Since s_1, s_2, s_3 are one-forms on (z,t)-plane, the congruency equation (14) turns to be a plain equation:

$$d\begin{pmatrix}s_1\\ s_2\\ s_3\end{pmatrix}=\begin{pmatrix}s_2\wedge s_3\\ s_3\wedge s_1\\ s_1\wedge s_2\end{pmatrix}. \tag{15}$$

If the metric is positive definite, then s_1, s_2, s_3 are invariant under conjugate action and $z\mapsto -1/\overline{z}$ by Theorem 3. And if the metric has a signature $(+,+,-,-)$, then s_1, s_2, s_3 are invariant under conjugate action and $z\mapsto\overline{z}$.

If we set

$$\Sigma=\frac{1}{\sqrt{2}}\begin{pmatrix}\sqrt{-1}s_2 & -s_1+\sqrt{-1}s_3\\ s_1+\sqrt{-1}s_3 & -\sqrt{-1}s_2\end{pmatrix} \tag{16}$$

$$=:-B_1\,dz-B_2\,dt, \tag{17}$$

then

$$d\Sigma+\Sigma\wedge\Sigma=0. \tag{18}$$

This is the isomonodromy condition for the the following linear problem,[6]

$$\left(\frac{d}{dz}-B_1\right)\begin{pmatrix}y_1\\ y_2\end{pmatrix}=0. \tag{19}$$

B_2 is determined by B_1 from (18).

Lemma 5: The components of B_1 are rational functions of z,

$$B_1=\frac{F(z)}{G(z)},$$

where $F(z)$ *is degree* 2 *and* $G(z)$ *is degree* 4. *If the metric is positive definite, then* $B_1\mapsto -{}^tB_1$ *under conjugate action and* $z\mapsto -1/\overline{z}$. *And if the metric has a signature* $(+,+,-,-)$, *then* $B_1\mapsto -{}^tB_1$ *under conjugate action and* $z\mapsto\overline{z}$.

For this lemma, generically B_1 has four simple poles. In this case, the deformation equation of (19) is Painlevé VI.

Theorem 6: *The anti-self-dual equations on* SU(2)*-invariant metrics generically reduce to Painlevé VI.*

The idea of Hitchin[5] is that the lifted action of SU(2) on the twistor space Z gives a homomorphism of vector bundles $\alpha: Z\times \mathfrak{su}(2)^{\mathbb{C}}\to TZ$, and the inverse of α gives a flat meromorphic SL(2,$\mathbb{C}$)-connection, which determines isomonodromic deformations. Since one-forms Θ_1, Θ_2, Θ_3 on Z can be considered as infinitesimal variations, we can identify Σ with α^{-1}.

First, we review the positive definite metric. By Lemma 5, the poles of B_1 make antipodal pairs $\zeta_0, -1/\overline{\zeta_0}$, and $\zeta_1, -1/\overline{\zeta_1}$ on $\mathbb{CP}^1$.

Therefore, we obtain two types of configuration of poles of B_1:

(a) B_1 has four simple poles ζ_0, $-1/\overline{\zeta_0}$, ζ_1, $-1/\overline{\zeta_1}$ on $\mathbb{CP}^1$,

$$B_1=\frac{A_0}{z-\zeta_0}+\frac{-{}^t\overline{A_0}}{z+1/\overline{\zeta_0}}+\frac{A_1}{z-\zeta_1}+\frac{-{}^t\overline{A_1}}{z+1/\overline{\zeta_1}}.$$

The deformation equation is Painlevé VI with a parameter,

$$(\alpha,\beta,\gamma,\delta)=(\tfrac{1}{2}(\theta_0-1)^2,\tfrac{1}{2}\overline{\theta_0^2},-\tfrac{1}{2}\theta_1^2,\tfrac{1}{2}(1+\overline{\theta_1^2})),$$

where $\theta_0^2=2\,\mathrm{tr}A_0^2$, $\theta_1^2=2\,\mathrm{tr}A_1^2$.

(b) B_1 has two double poles ζ, $-1/\overline{\zeta}$ on $\mathbb{CP}^1$,

$$B_1=\frac{A_2}{(z-\zeta)^2}+\frac{\sqrt{-1}C}{z-\zeta}+\frac{-\sqrt{-1}C}{z+1/\overline{\zeta}}+\frac{-{}^t\overline{A_2}/\overline{\zeta^2}}{(z+1/\overline{\zeta})^2},$$

where $C=-{}^t\overline{C}$. The deformation equation is Painlevé III with a parameter,

$$(\alpha,\beta,\gamma,\delta)=(4\theta,4(1+\overline{\theta}),4,-4),$$

where $\theta^2=2(\mathrm{tr}(A_2C))^2/\mathrm{tr}A_2^2$.

Theorem 7: *If the metric is positive definite, the anti-self-dual equations reduce to the following Painlevé equations:*

(a) a family of Painlevé VI with two complex parameters,

$$(\alpha,\beta,\gamma,\delta)=(\tfrac{1}{2}(\theta_0-1)^2,\tfrac{1}{2}\overline{\theta_0^2},-\tfrac{1}{2}\theta_1^2,\tfrac{1}{2}(1+\overline{\theta_1^2})),$$

(b) a family of Painlevé III with one complex parameter,

$$(\alpha,\beta,\gamma,\delta)=(4\theta,4(1+\overline{\theta}),4,-4).$$

Remark 8: It is known that the anti-self-dual equations reduce to Painlevé VI with the parameter as above.[9,5] *Dancer*[4] *shows the diagonal scalar-flat Kähler metric is specified by a solution of Painlevé III with a parameter* $(\alpha,\beta,\gamma,\delta)=(0,4,4,-4)$. *Now, Theorem* 7 (b) *is a generalization of Dancer's result.*

From now on, we will classify the anti-self-dual metrics with a signature $(+,+,-,-)$. By Lemma 5 the poles of B_1 make conjugate pairs $\zeta_0,\overline{\zeta_0}$, and $\zeta_1,\overline{\zeta_1}$ in $\mathbb{CP}^1$. Therefore we obtain five types of metrics corresponding to configuration of poles of B_1.

Theorem 9: *If the metric has a signature* $(+,+,-,-)$, *the anti-self-dual equations reduce to the following five Painlevé equations:*

(a) Painlevé VI with two complex parameters

$$(\alpha,\beta,\gamma,\delta)=(\tfrac{1}{2}(\theta_0-1)^2,\tfrac{1}{2}\overline{\theta_0^2},-\tfrac{1}{2}\theta_1^2,\tfrac{1}{2}(1+\overline{\theta_1^2})),$$

(b) Painlevé V with one real and one complex parameters

$$(\alpha,\beta,\gamma,\delta)=(\tfrac{1}{2}(\theta_0+\overline{\theta_0}+\theta_\infty)^2,-\tfrac{1}{2}(\theta_0+\overline{\theta_0}-\theta_\infty)^2,1-\theta_0+\overline{\theta_0},\tfrac{1}{2}),$$

where $\theta_\infty\in\mathbb{R}$.

(c) Painlevé III with one complex parameter

$$(\alpha,\beta,\gamma,\delta)=(4\theta,4(1+\overline{\theta}),4,-4).$$

(d) Painlevé III with with two real parameters

$$(\alpha,\beta,\gamma,\delta)=(4\theta_1,4(1+\theta_2),4,-4).$$

(e) Painlevé II with one real parameter α.

Proof: Since the poles of B_1 make conjugate pairs $\zeta_0,\overline{\zeta_0}$ and $\zeta_1,\overline{\zeta_1}$, we obtain five types of configuration of poles of B_1. In each case, we can calculate local exponents at singularities. These local exponents correspond to the parameter of the Painlevé equation (see Ref. 7).

(a) Generically, B_1 has four simple poles ζ_0, $\overline{\zeta_0}$, ζ_1, $\overline{\zeta_1}$ on $\mathbb{C}\backslash\mathbb{R}$,

$$B_1=\frac{A_0}{z-\zeta_0}+\frac{-{}^t\overline{A_0}}{z-\overline{\zeta_0}}+\frac{A_1}{z-\zeta_1}+\frac{-{}^t\overline{A_1}}{z-\overline{\zeta_1}}.$$

The deformation equation is Painlevé VI with a parameter,

$$(\alpha,\beta,\gamma,\delta)=(\tfrac{1}{2}(\theta_0-1)^2,\tfrac{1}{2}\overline{\theta_0^2},-\tfrac{1}{2}\theta_1^2,\tfrac{1}{2}(1+\overline{\theta_1^2})),$$

where $\theta_0^2=2\,\mathrm{tr}A_0^2$, $\theta_1^2=2\,\mathrm{tr}A_1^2$.

(b) If $\zeta_0=\overline{\zeta_0}(=\eta)$, then B_1 has one double pole η on $\mathbb{R}$, and two simple poles ζ_1, $\overline{\zeta_1}$ on $\mathbb{C}\backslash\mathbb{R}$,

$$B_1=\frac{C}{(z-\eta)^2}+\frac{-A_2+{}^t\overline{A_2}}{z-\eta}+\frac{A_2}{z-\zeta_1}+\frac{-{}^t\overline{A_2}}{z-\overline{\zeta_1}},$$

where $C=-{}^t\overline{C}$. The deformation equation is Painlevé V with a parameter,

$$(\alpha,\beta,\gamma,\delta)=(\tfrac{1}{2}(\theta_0+\overline{\theta_0}+\theta_\infty)^2,-\tfrac{1}{2}(\theta_0+\overline{\theta_0}-\theta_\infty)^2,1-\theta_0+\overline{\theta_0},\tfrac{1}{2}),$$

where $\theta_0^2=2\,\mathrm{tr}A_2^2$, $\theta_\infty^2=2(\mathrm{tr}(A_2-{}^t\overline{A_2})C)^2/\mathrm{tr}C^2$.

(c) If $\zeta_0=\zeta_1(=\zeta)$, then B_1 has two double poles ζ, $\overline{\zeta}$ on $\mathbb{C}\backslash\mathbb{R}$,

$$B_1=\frac{A_3}{(z-\zeta)^2}+\frac{\sqrt{-1}C}{z-\zeta}+\frac{-\sqrt{-1}C}{z-\overline{\zeta}}+\frac{-{}^t\overline{A_3}}{(z-\overline{\zeta})^2},$$

where $C=-{}^t\overline{C}$. The deformation equation is Painlevé III with a parameter,

$$(\alpha,\beta,\gamma,\delta)=(4\theta,4(1+\overline{\theta}),4,-4),$$

where $\theta^2=2(\mathrm{tr}A_3C)^2/\mathrm{tr}A_2^2$.

(d) If $\zeta_0=\overline{\zeta_0}(=\eta_0)$, $\zeta_1=\overline{\zeta_1}(=\eta_1)$, then B_1 has two double poles η_0, η_1 on $\mathbb{R}$,

$$B_1=\frac{C_1}{(z-\eta_0)^2}+\frac{C_2}{z-\eta_0}+\frac{-C_2}{z-\eta_1}+\frac{C_3}{(z-\eta_1)^2},$$

where $C_i=-{}^t\overline{C_i}$ $(i=1,2,3)$. The deformation equation is Painlevé III with a parameter,

$$(\alpha,\beta,\gamma,\delta)=(4\theta_1,4(1+\theta_2),4,-4),$$

where $\theta_1^2=2(\mathrm{tr}C_1C_2)^2/\mathrm{tr}C_1^2$, $\theta_2^2=2(\mathrm{tr}C_2C_3)^2/\mathrm{tr}C_3^2$.

(e) If $\zeta_0=\overline{\zeta_0}=\zeta_1=\overline{\zeta_1}(=\eta)$, then B_1 has one quadruple pole η on $\mathbb{R}$,

$$B_1=\frac{C_1}{(z-\eta)^4}+\frac{C_2}{(z-\eta)^3}+\frac{C_3}{(z-\eta)^2},$$

where $C_i=-{}^t\overline{C_i}$ $(i=1,2,3)$. If $\det C_1\neq 0$, then the deformation equation is Painlevé II with a parameter,

$$\alpha=\tfrac{1}{2}(1+\mathrm{tr}C_2C_3).$$

If $\det C_1=0$, then the deformation equation is Painlevé I, but since $C_1=-{}^t\overline{C_1}$, this never occurs.

Remark 10: The isomonodromic condition (18) determines the null cone $\mathcal{C}$. B_1 and B_2 determine $\mathcal{C}$ as follows. For

$$a_0\frac{\partial}{\partial t}+a_1\sigma_1^*+a_2\sigma_2^*+a_3\sigma_3^*\in TM^{\mathbb{C}},$$

we consider

$$\frac{a_1}{\sqrt{2}}\begin{pmatrix}0&-1\\1&0\end{pmatrix}+\frac{a_2}{\sqrt{2}}\begin{pmatrix}\sqrt{-1}&0\\0&-\sqrt{-1}\end{pmatrix}+\frac{a_3}{\sqrt{2}}\begin{pmatrix}0&\sqrt{-1}\\\sqrt{-1}&0\end{pmatrix}=-\lambda B_1(z)-a_0B_2(z) \quad (20)$$

as an algebraic equation of λ, z, *which is equivalent with (10). Equation (20) has solutions* $\lambda\in\mathbb{C}$, $z\in\mathbb{CP}^1$, *if and only if* $a_0(\partial/\partial t)+a_1\sigma_1^*+a_2\sigma_2^*+a_3\sigma_3^*\in\mathcal{C}$.

V. HERMITIAN STRUCTURE AND NULL SURFACES

In this section, we will study the geometric meaning of the metrics corresponding with each type of Painlevé function.

Lemma 11: Let g be an anti-self-dual metric. If B_1 has a multiple pole on $z=\zeta(t)$, then the Pfaffian $\Theta_1|_{z=\zeta(t)}$, $\Theta_2|_{z=\zeta(t)}$ is integrable. Conversely, if the Pfaffian $\Theta_1|_{z=\zeta(t)}$, $\Theta_2|_{z=\zeta(t)}$ is integrable for some $\zeta(t)$, then B_1 has a multiple pole on $z=\zeta(t)$.

Proof: If $z=\zeta(t)$ is a multiple zero of $G(z)$, then $G|_{z=\zeta(t)}$ and $dG|_{z=\zeta(t)}$ must be vanish. Furthermore, $\Theta_3\equiv 0(\mathrm{mod}\ \Theta_1,\Theta_2,G,dG)$. Therefore, the Pfaffian $\Theta_1|_{z=\zeta(t)},\Theta_2|_{z=\zeta(t)}$ is integrable.

Conversely, if the Pfaffian $\Theta_1|_{z=\zeta(t)}$, $\Theta_2|_{z=\zeta(t)}$ is integrable for some $z=\zeta(t)$, then $\Theta_3|_{z=\zeta(t)}\equiv 0(\mathrm{mod}\ \Theta_1,\Theta_2)$. Therefore the denominator G of B_1 has zero on $z=\zeta(t)$. Furthermore, $\Theta_3|_{z=\zeta(t)}\equiv 0(\mathrm{mod}\ \Theta_1,\Theta_2,G)$ is equivalent to $dG|_{z=\zeta(t)}=0$, therefore $z=\zeta(t)$ is a double pole of B_1.

In Refs. 10 and 11 we show that if a positive definite SU(2) invariant anti-self-dual metric is specified by a solution of Painlevé III with one complex parameter $(4\theta,4(1+\overline{\theta}),4,-4)$, then the Pfaffian $\Theta_1|_{z=\zeta(t)}$, $\Theta_2|_{z=\zeta(t)}$ ($z=\zeta(t)$ is a double pole of B_1) determines an SU(2) invariant Hermitian structure.

In the same way, we obtain the following theorem for the metric with a signature $(+,+,-,-)$.

Theorem 12: *If the anti-self-dual equations reduce to Painlevé III with one complex parameter* $(4\theta,4(1+\overline{\theta}),4,-4)$, *then there exists an* SU(2)*-invariant Hermitian structure. Conversely, if there exists an* SU(2)*-invariant Hermitian structure, then the anti-self-dual equations reduce to Painlevé III with the parameter above.*

Definition 13: If $g(X,X)=0$, *then* $X\in TM$ *is said to be a null direction.*

The Pfaffian $\Theta_1|_{z=\eta(t)},\Theta_2|_{z=\eta(t)}(\eta(t)\in\mathbb{R})$ determines two dimensional null directions on TM.

Definition 14: Let N be a two dimensional subspace of M. If $g(X,X)=0$ *for any* $X\in TN$, *then N is called a real twistor surface.*

From Lemma 11, if $z=\eta(t)\in\mathbb{R}$ is a multiple pole of B_1, then the Pfaffian $\Theta_1|_{z=\eta(t)},\Theta_2|_{z=\eta(t)}$ is integrable, and then for any $x\in M$ there exists an SU(2)-invariant real twistor surface passing through x. Conversely, for any $x\in M$, if there exists an SU(2)-invariant real twistor surface passing through x, then the real twistor surface is represented by Pfaffian $\Theta_1|_{z=\eta(t)},\Theta_2|_{z=\eta(t)}$ for some $\eta(t)\in\mathbb{R}$, and then $z=\eta(t)$ is a multiple pole of B_1

Theorem 15: *If the anti-self-dual equations reduce to Painlevé V with one real and one complex parameter* $(1/2(\theta_0+\overline{\theta_0}+\theta_\infty)^2,-1/2(\theta_0+\overline{\theta_0}-\theta_\infty)^2,1-\theta_0+\overline{\theta_0},1/2)$, *where* $\theta_\infty\in\mathbb{R}$, *or Painlevé II with one real parameter* α, *then for any* $x\in M$ *there exists one* SU(2)*-invariant real twistor surface passing through x. Conversely, for any* $x\in M$ *there exists one* SU(2)*-invariant real twistor surface passing through x, then the anti-self-dual reduces to Painlevé V or II with the parameter above.*

If the anti-self-dual equations reduce to Painlevé III with two real parameters $(4\theta_1,4(1-\theta_2),4,-4)$, *then for any* $x\in M$ *there exist two* SU(2)*-invariant real twistor surfaces passing through x. Conversely, for any* $x\in M$ *there exist two* SU(2)*-invariant real twistor surfaces passing through x, then the anti-self-dual equation reduces to Painlevé III with the parameter above.*

VI. SUMMARY

We classified the SU(2)-invariant anti-self-dual metric with a signature $(+,+,-,-)$ into the five cases (a)–(e) (Theorem 9). The meaning of the types of the Painlevé equations are as follows:

(1) Generically, the anti-self-dual metric is, specified by a solution of Painlevé VI with two complex parameters.
(2) If the anti-self-dual metric is specified by a solution of Painlevé III with one complex parameter, then there exists an SU(2)-invariant Hermitian structure.
(3) If the anti-self-dual metric is specified by a solution of Painlevé V with one real parameter and one complex parameter, or Painlevé II with one real parameter, then for any $x\in M$ there exists one real twistor surface passing through x.
(4) If the anti-self-dual metric is specified by a solution of Painlevé III with two real parameters, then for any $x\in M$ there exist two real twistor surfaces passing through x.

ACKNOWLEDGMENTS

The author would express his gratitude to Professor Yousuke Ohyama, who introduced him to the subject, for enlightening discussions.

APPENDIX: PAINLEVÉ EQUATIONS

We review the Painlevé second order nonlinear differential equations without moving critical points. We list six equations classified by Painlevé and Gambier, where $\alpha,\beta,\gamma,\delta$ are parameters.[12]

(1) Painlevé I:

$$\frac{d^2q}{dx^2}=6q^2+x.$$

(2) Painlevé II:

$$\frac{d^2q}{dx^2}=2q^3+xq+\alpha.$$

(3) Painlevé III:

$$\frac{d^2q}{dx^2}=\frac{1}{q}\left(\frac{dq}{dx}\right)^2-\frac{1}{x}\frac{dq}{dt}+\frac{1}{x}(\alpha q^2+\beta)+\gamma q^3+\frac{\delta}{q}.$$

(4) Painlevé IV:

$$\frac{d^2q}{dx^2}=\frac{1}{2q}\left(\frac{dq}{dx}\right)^2+\frac{3}{2}q^3+4xq^2+2(x^2-\alpha)q+\frac{\beta}{q}.$$

(5) Painlevé V:

$$\frac{d^2q}{dx^2}=\left(\frac{1}{2q}+\frac{1}{q-1}\right)\left(\frac{dq}{dx}\right)^2-\frac{1}{x}\frac{dq}{dx}+\frac{(q-1)^2}{x^2}\left(\alpha q+\frac{\beta}{q}\right)+\frac{\gamma q}{x}+\frac{\delta q(q+1)}{q-1}.$$

(6) Painlevé VI:

$$\begin{aligned}\frac{d^2q}{dx^2}=&\frac{1}{2}\left(\frac{1}{q}+\frac{1}{q-1}+\frac{1}{q-x}\right)\left(\frac{dq}{dx}\right)^2-\left(\frac{1}{x}+\frac{1}{x-1}+\frac{1}{q-x}\right)\frac{dq}{dx}\\&+\frac{q(q-1)(q-x)}{x^2(x-1)^2}\left\{\alpha+\beta\frac{x}{q^2}+\gamma\frac{x-1}{(q-1)^2}+\delta\frac{x(x-1)}{(q-x)^2}\right\}.\end{aligned}$$

(Received 8 April 2003; accepted 22 May 2003)

An invariant characterization of double warped space–times is given in terms of Newman–Penrose formalism and a classification scheme is proposed. A detailed study of the conformal algebra of these space–times is also carried out and some remarks are made on certain classes of exact solutions. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1605496]

I. INTRODUCTION

Given two metric manifolds (M_1,h_1) and (M_2,h_2) and given two smooth real functions $\theta_1:M_1\to\mathbb{R}$, $\theta_2:M_2\to\mathbb{R}$ (*warping functions*), one can build a new metric manifold (M,g) by setting $M=M_1\times M_2$ and

$$g=e^{2\theta_2}\pi_1^*h_1\otimes e^{2\theta_1}\pi_2^*h_2, \tag{1}$$

where π_1,π_2 above are the canonical projections onto M_1 and M_2, respectively, and will be omitted where there is no risk of confusion (thus writing, from now on: $g=e^{2\theta_2}h_1\otimes e^{2\theta_1}h_2$). One such structure will be called *double warped product manifold*, and gives rise to the so-called *warped product manifold* whenever one of the warping functions is constant, see Refs. 1 and 2.

If $\dim M_1+\dim M_2=4$ and g has Lorentz signature [i.e., one of the manifolds (M_i,h_i) is Lorentz and the other Riemann], then (M,g) will be referred to as a *double warped space–time*, and again, if one of the warping functions is constant, one recovers the definition of *warped space–time* (see Refs. 3 and 4).

In what is to follow and unless otherwise stated, we shall assume that we are dealing with "proper" double warped space–times (i.e., neither of the warping functions is constant); further, and without loss of generality (M_1,h_1) will be assumed Lorentzian and (M_2,h_2) Riemannian.

The considerations in this work will be mainly local, thus we shall assume that for each $p\in M$ there exists a neighborhood U of p such that there is a coordinate system x^a, $a=0,\ldots,3$ on U *adapted* to the product structure in the sense that the line element associated with g can be written as

$$\mathrm{d}s^2=e^{2\theta_2(x^D)}h_{1\ \alpha\beta}(x^\gamma)\mathrm{d}x^\alpha\,\mathrm{d}x^\beta+e^{2\theta_1(x^\gamma)}h_{2\ AB}(x^D)\mathrm{d}x^A\,\mathrm{d}x^B; \tag{2}$$

where $x^{\alpha,\beta,\cdots}$ and $x^{A,B,\cdots}$ will designate the coordinates on the submanifolds M_1 and M_2 of M through p, respectively, while n_1 and n_2 denote their respective dimensions; thus, Greek indices will run from 0 to n_1-1 and capital Latin indices from n_1 to 3. Conversely, if a space–time contains an open neighborhood U on which there exists a coordinate system as the one described above, then it will be referred to as *locally double warped space–time*.

The aim of the present paper is to deal with double warped space–times in much the same way as warped space–times were dealt with previously (see Refs. 3 and 4 and references cited

[a]Electronic mail: mpr@mct.uminho.pt

therein); thus their geometrical properties will be deducted and studied starting from those of their lower dimensional factors (M_i, h_i) which are, in general, much easier to deal with.

The paper is structured as follows: in Sec. II an invariant characterization of these space–times is given, including their characterization in terms of the Newman–Penrose formalism, and a classification scheme is put forward. Section III contains some results on the curvature structure of such space–times, whereas Secs. IV and V deal with their conformal algebra. Finally, in Sec. VI, a few remarks are made on double warped exact solutions.

II. INVARIANT CHARACTERIZATION AND CLASSIFICATION

Starting with the form (2) of the line element, let us re-write it as follows:

$$ds^2 = e^{2(\theta_1(x^\gamma)+\theta_2(x^D))}[e^{-2\theta_1(x^\gamma)} h_{1\ \alpha\beta}(x^\gamma)\,dx^\alpha\,dx^\beta + e^{-2\theta_2(x^D)} h_{2\ AB}(x^D)\,dx^A\,dx^B], \tag{3}$$

now, the two terms $e^{-2\theta_1(x^\gamma)} h_{1\ \alpha\beta}(x^\gamma)$ and $e^{-2\theta_2(x^D)} h_{2\ AB}(x^D)$ are metrics on the submanifolds M_1 and M_2, say $\hat{h}_1$ and $\hat{h}_2$. The sum of their associated line elements [that is, the expression within the square brackets in (3)], is the line element, say $d\hat{s}^2$ of a decomposable space–time $(M,\hat{g})$ with $M = M_1 \times M_2$ and $\hat{g} = \hat{h}_1 \otimes \hat{h}_2$ (Again, to be correct one should write $\hat{g} = \pi_1^* \hat{h}_1 \otimes \pi_2^* \hat{h}_2$, π_1, π_2 being the canonical projections onto M_1 and M_2, but since there is no risk of confusion, we omit them for the sake of simplicity), thus we have proven:

Lemma 1: A (locally) double warped space–time is always conformally related to a (locally) decomposable space–time, the conformal factor being separable in the coordinates associated with the two factor submanifolds.

In what follows, we shall refer to the factor submanifolds in the decomposable space–time $(M,\hat{g})$ as $(M_1,\hat{h}_1)$ and $(M_2,\hat{h}_2)$, respectively, assuming that $(M_1,\hat{h}_1)$ is Lorentz and $(M_2,\hat{h}_2)$ Riemann; and we shall write the metric of a double warped space–time as $g = \exp(2\theta)\hat{g}$ in the understanding that $\hat{g}$ is the metric of the underlying decomposable space–time and θ separates as the sum of two functions θ_1 and θ_2 on M_1 and M_2, respectively.

Now, the space–time $(M,\hat{g})$ is locally decomposable if its holonomy group is nondegenerately reducible (and globally decomposable if, on top of this, it is simply connected) (see for instance Ref. 5, and references therein), its holonomy type being then R_2, R_3, R_4, R_6, R_7, R_{10}, or R_{13} (see Ref. 6); one then has the following possibilities for $(M,\hat{g})$.[5]

(1) $(M,\hat{g})$ is $1+3$ decomposable if it admits a global, non-null, nowhere zero covariantly constant vector field $\vec{u}$. One then distinguishes between $1+3$ spacelike (holonomy type R_{13}) or $1+3$ timelike (holonomy types R_3, R_6 or R_{10}) depending on the nature of the three-dimensional submanifold orthogonal to the covariantly constant vector field. In a coordinate system adapted to the covariantly constant vector field, say $\vec{u} = \partial_u$, the line element $d\hat{s}^2$ then takes the following forms, respectively:

$$d\hat{s}^2 = -du^2 + \hat{h}_{AB}(x^D)\,dx^A\,dx^B$$

or

$$d\hat{s}^2 = \hat{h}_{\alpha\beta}(x^\gamma)\,dx^\alpha\,dx^\beta + du^2. \tag{4}$$

If another non-null covariantly constant vector field exists in the space–time, then $(M,\hat{g})$ decomposes further and can be referred to as being $1+1+2$ spacelike (type R_4) or $1+1+2$ timelike (type R_2) in an obvious notation.

(2) $(M,\hat{g})$ is $2+2$ decomposable and then two global, linearly independent recurrent null vector fields exist (holonomy type R_7). This is equivalent to saying that in $(M,\hat{g})$ there exist two linearly independent covariantly constant tensor fields of rank 2, say P and Q such that

$$\hat{g}_{ab} = P_{ab} + Q_{ab}$$

with

$$P_{ab/c}=Q_{ab/c}=0; \tag{5}$$

a stroke denoting covariant derivative in $(M,\hat{g})$; the line element reads in this case

$$d\hat{s}^2=\hat{h}_{1\ \alpha\beta}(x^\gamma)dx^\alpha\,dx^\beta+\hat{h}_{2\ AB}(x^D)dx^A\,dx^B, \tag{6}$$

where $\hat{h}_1$ and $\hat{h}_2$ are two two-dimensional metrics on M_1 and M_2, respectively, such that $\pi_1^*\hat{h}_1=P$ and $\pi_2^*\hat{h}_2=Q$.

Going back to the double warped space–time (M,g) conformally related to $(M,\hat{g})$ via (3), it appears natural to consider the following two classes of double warped space–times.

Class A whenever the underlying space–time $(M,\hat{g})$ is $1+3$ decomposable. If necessary, and following the same notation as in the case of warped space–times, we shall distinguish between classes A_1 ($1+3$ spacelike) and A_2 ($1+3$ timelike). Taking into account (3) and (4), we shall write the canonical form of the line element of these space–times as

$$ds^2=e^{2(\theta_1(u)+\theta_2(x^D))}[-du^2+\hat{h}_{AB}(x^D)dx^A\,dx^B], \tag{7}$$

$$ds^2=e^{2(\theta_1(x^\gamma)+\theta_2(u))}[\hat{h}_{\alpha\beta}(x^\gamma)dx^\alpha\,dx^\beta+du^2], \tag{8}$$

respectively.

Class B whenever the underlying space–time $(M,\hat{g})$ is $2+2$ decomposable. The canonical form of the line element will be in this case

$$ds^2=e^{2(\theta_1(x^\gamma)+\theta_2(x^D))}[\hat{h}_{1\ \alpha\beta}(x^\gamma)dx^\alpha\,dx^\beta+\hat{h}_{2\ AB}(x^D)dx^A\,dx^B]. \tag{9}$$

In what is to follow and whenever no confusion may arise, we shall put $\theta\equiv\theta_1(x^\gamma)+\theta_2(x^D)$ and write accordingly

$$g_{ab}=e^{2\theta}\hat{g}_{ab},$$

and also

$$ds^2=e^{2\theta}d\hat{s}^2. \tag{10}$$

Also, we shall denote the covariant derivatives in (M,g) and $(M,\hat{g})$ by ∇ and $\hat{\nabla}$ or a semicolon (;) and a slash (/), respectively. Further, reference will be often made to conformal Killing vectors and their properties, hence it is in order at this point to recall their definition and basic properties; thus, given an n-dimensional manifold V endowed with a metric g of arbitrary signature, a vector field $\vec{X}$ on V is said to be a *conformal Killing vector* (CKV) iff $\mathcal{L}_{\vec{X}}g=2\phi g$ where ϕ is some function of the coordinates (*conformal factor*) and $\mathcal{L}_{\vec{X}}$ stands for the Lie derivative operator with respect to the vector field $\vec{X}$. The former equation can also be written in an arbitrary coordinate chart as

$$X_{a;b}=\phi g_{ab}+F_{ab} \tag{11}$$

and then, from the Bianchi identities, it follows

$$F_{ab;c}=R_{abcd}X^d-\phi_a g_{bc}+\phi_b g_{ac}, \tag{12}$$

$$\mathcal{L}_{\vec{X}}R_{ab}=-(n-2)\phi_{a;b}-\phi^c{}_{;c}g_{ab}, \tag{13}$$

$$\mathcal{L}_{\vec{X}}R=-2\phi R-2(n-1)\phi^c{}_{;c}, \tag{14}$$

$$\mathcal{L}_{\vec{X}} R_{abcd} = 2\phi R_{abcd} - \phi_{a;c} g_{bd} + \phi_{a;d} g_{bc} - \phi_{b;d} g_{ac} + \phi_{b;c} g_{ad}, \tag{15}$$

where $\phi_a \equiv \phi_{,a}$, a semicolon stands for the covariant derivative with respect to the connection associated with the metric, $F_{ab} = -F_{ba}$ is the so-called *conformal bivector*, and R_{abcd}, R_{ab}, and R stand, respectively, for the components in the chosen chart of the Riemann and Ricci tensors and the Ricci scalar. The special cases $\phi =$ constant and $\phi = 0$ correspond, respectively, to $\vec{X}$ being a *homothetic vector* (HV) and a *Killing vector* (KV), the associated bivector is then said to be the *homothetic bivector*, or *Killing bivector*, respectively. A CKV is said to be *proper* whenever it is nonhomothetic (i.e., $\phi \neq$ const); likewise, we shall use "proper homothetic" to designate a HV which is not a KV (i.e., $\phi =$ const$\neq 0$). A proper CKV is said to be a *special CKV* (SCKV) whenever its associated conformal factor ϕ satisfies $\phi_{a;b} = 0$ in any coordinate chart. Further, it is easy to see that the CKV that (V,g) admits form, under the usual Lie bracket operation, a Lie algebra of vector fields which we shall designate as $\mathcal{C}_r(V,g)$, r being its dimension. Similar statements can be made regarding the SCKV, HV, and KV that (V,g) may admit [Lie algebras $\mathcal{S}_r(V,g)$, $\mathcal{H}_r(M,g)$ and $\mathcal{K}_r(V,g)$ respectively (note from the above considerations it follows that in any given space–time $\mathcal{C}_r \supseteq \mathcal{S}_m \supseteq \mathcal{H}_s \supseteq \mathcal{K}_n$, with $r \geqslant m \geqslant s \geqslant n$)]. We refer the reader to Ref. 7 for further details on CKV and their Lie algebra. Going back now to the problem of characterizing class A and B double warped space–times, we see that this can be carried out by "translating" into (M,g) the properties of the preferred vector fields (non-null covariantly constant or null recurrent) that characterize the underlying decomposable space–times $(M,\hat{g})$. Thus we get:

Theorem 1: *The necessary and sufficient condition for* (M,g) *to be a double warped class A space–time is that it admits a non-null, nowhere vanishing CKV* $\vec{X}$ *which is hypersurface orthogonal and such that the gradient of its associated conformal factor* ψ *is parallel to* $\vec{X}$.

Proof: Let (M,g) be a class A double warped space–time, its line element takes then the form (7) and (8) and it is easy to see that $\vec{X} = \partial_u$ is a CKV which satisfies the required properties, in particular, its associated conformal factor ψ is $\psi = \theta_{,u}$ which on account of the form that θ has (separable in u and the rest of the coordinates) is $\psi = \psi(u)$ and therefore $\psi_{,a} \propto X_a$.

The converse also holds for, assume that (M,g) admits a non-null, nowhere vanishing CKV $\vec{X}$ which is hypersurface orthogonal. Since $\vec{X}$ is nonvanishing and hypersurface orthogonal, a coordinate chart exists, say $\{u,x^k\}$, such that

$$\vec{X} = \partial_u, \quad ds^2 = \epsilon e^{2U(u,x^k)} du^2 + h_{ij}(u,x^k) dx^i\, dx^j,$$

where $\epsilon = \pm 1$ (see for example Ref. 8, p. 168). Further, the conformal equations for $\vec{X}$ above are simply $g_{ab,u} = 2\psi g_{ab}$ (with $\psi = \psi(u,x^k)$) which in turn implies

$$\psi(u,x^k) = U_{,u}(u,x^k), \quad h_{ij}(u,x^k) = e^{2U(u,x^k)} \hat{h}_{ij}(x^k)$$

and the above line element can then be written as

$$ds^2 = e^{2U(u,x^k)} [\epsilon du^2 + \hat{h}_{ij}(x^k) dx^i\, dx^j].$$

Finally, imposing that $\psi_{,a} \propto X_a$ yields $\psi = \psi(u)$ and therefore $U(u,x^k) = \theta_1(u) + \theta_2(x^k)$ and the resulting space–time is then class A double warped. □

The characterization of warped space–times can now be easily recovered as the following corollary shows:

Corollary 2: If the CKV $\vec{X}$ *in theorem 1 is a Killing vector (KV) then the space–time is warped of class* A_2 *in the classification given in Ref. 3. If* $\vec{X}$ *is a proper (non-KV) gradient CKV (i.e., if the associated conformal bivector vanishes* $F_{ab} = X_{a;b} - X_{b;a} = 0$*) the space–time is class* A_1 *warped in that classification.*

It is worthwhile noticing that Theorem 1 also provides an invariant characterization of space–times conformal to $1+3$ locally decomposable space–times:

Corollary 3: The necessary and sufficient condition for (M,g) *to be conformally related to a* $1+3$ *decomposable space–time* $(M,\hat{g})$ *is that it admits a non-null, nowhere vanishing conformal Killing vector (CKV)* $\vec{X}$ *which is hypersurface orthogonal.*

Theorem 1 can be conveniently rephrased in terms of Newman–Penrose (NP) formalism[9] through the two following theorems:

Theorem 4: (M,g) *is a class* A_1 *double warped space–time if and only if there exist a function* $U:M\to\mathbb{R}$ *and a canonical complex null tetrad* $\{k_a,l_a,m_a,\overline{m}_a\}$ $(k^a l_a=-m^a\overline{m}_a=-1)$ *in which:*

$$DU=\epsilon+\overline{\epsilon}, \tag{16}$$

$$\triangle U=-(\gamma+\overline{\gamma}), \tag{17}$$

$$\delta U=\kappa+\overline{\pi}=-(\tau+\overline{\nu}), \tag{18}$$

$$\sigma+\overline{\lambda}=0, \tag{19}$$

$$\alpha+\overline{\beta}=0, \tag{20}$$

$$\epsilon+\overline{\epsilon}+\gamma+\overline{\gamma}=\rho+\overline{\mu}, \tag{21}$$

$$D(\rho+\overline{\mu})=-\Phi, \tag{22}$$

$$\triangle(\rho+\overline{\mu})=\Phi, \tag{23}$$

$$\delta(\rho+\overline{\mu})=\overline{\delta}(\rho+\overline{\mu})=0, \tag{24}$$

where $\Phi=\Phi(u)$ *is a real function of the timelike coordinate* u.

Proof: With the notation of Theorem 1 we have that for a class A_1 double warped space–time a coordinate chart $\{u,x^k\}$ exists such that the line element takes the form (7), $\vec{X}=\partial_u$ is then a timelike hypersurface orthogonal CKV with associated conformal factor $\psi(u)=\theta_{1,u}(u)$, and $\vec{u}=\mathbf{e}^{-U}\partial_u$ is a unit timelike vector field parallel to $\vec{X}$ where we put $U(u,x^k)=\theta_1(u)+\theta_2(x^k)$ for convenience, it is then easy to see that, in the above coordinate chart, one has

$$u_{a;b}=(U_{,c}u^c)g_{ab}-U_{,a}u_b \tag{25}$$

and also

$$\psi_{,a}=\Phi\mathbf{e}^{-U}u_a, \tag{26}$$

where $\Phi=\Phi(u)$ is a real function of the timelike coordinate u [to be precise: $\Phi=-\theta_{1,uu}(u)$].

One can define a canonical null tetrad as follows:

$$k_a=\frac{1}{\sqrt{2}}(u_a+x^1_a),\quad l_a=\frac{1}{\sqrt{2}}(u_a-x^1_a),\quad m_a=\frac{1}{\sqrt{2}}(x^2_a+ix^3_a), \tag{27}$$

where x^1_a, x^2_a, x^3_a are spacelike vectors orthogonal to u_a. Expressions (16)–(24) are then obtained by contracting (25) and (26) with the tetrad (27).

On the other hand, contracting (16)–(24) with the dual of (27) one recovers expressions (25) and (26), which, according to Theorem 1, imply that the space–time is class A_1 double warped. □

Theorem 5: (M,g) *is a class* A_2 *double warped space–time if and only if there exist a function* $U:M\to\mathbb{R}$ *and a canonical complex null tetrad* $\{k_a,l_a,m_a,\overline{m}_a\}$ $(k^a l_a=-m^a\overline{m}_a=-1)$ *in which one of the following sets of equations holds:*

$$DU=\epsilon+\overline{\epsilon}, \tag{28}$$

$$\Delta U=-(\gamma+\overline{\gamma}), \tag{29}$$

$$\delta U=-\kappa+\overline{\pi}=\tau+\overline{\nu}, \tag{30}$$

$$\sigma-\overline{\lambda}=0, \tag{31}$$

$$\alpha+\overline{\beta}=0, \tag{32}$$

$$\epsilon+\overline{\epsilon}-(\gamma+\overline{\gamma})=\rho-\overline{\mu}, \tag{33}$$

$$D(\rho-\overline{\mu})=\Phi, \tag{34}$$

$$\Delta(\rho-\overline{\mu})=\Phi, \tag{35}$$

$$\delta(\rho-\overline{\mu})=\overline{\delta}(\rho-\overline{\mu})=0, \tag{36}$$

$$DU=\sigma+\overline{\rho}, \tag{37}$$

$$\Delta U=-(\overline{\lambda}+\mu), \tag{38}$$

$$\delta U=\overline{\alpha}-\beta, \tag{39}$$

$$\delta U+\overline{\delta}U=\pi+\overline{\pi}=-(\tau+\overline{\tau}), \tag{40}$$

$$\kappa+\overline{\kappa}=0, \tag{41}$$

$$\nu+\overline{\nu}=0, \tag{42}$$

$$\epsilon-\overline{\epsilon}=0, \tag{43}$$

$$\gamma-\overline{\gamma}=0, \tag{44}$$

$$\delta(\pi+\overline{\pi})=\overline{\delta}(\pi+\overline{\pi})=\Phi', \tag{45}$$

$$\Delta(\pi+\overline{\pi})=D(\pi+\overline{\pi})=0, \tag{46}$$

$$DU=-\sigma+\overline{\rho}, \tag{47}$$

$$\Delta U=\overline{\lambda}-\mu, \tag{48}$$

$$\delta U=\overline{\alpha}-\beta, \tag{49}$$

$$\delta U-\overline{\delta}U=-\pi+\overline{\pi}=-\tau+\overline{\tau}, \tag{50}$$

$$\kappa-\overline{\kappa}=0, \tag{51}$$

$$\nu-\overline{\nu}=0, \tag{52}$$

$$\epsilon-\overline{\epsilon}=0, \tag{53}$$

$$\gamma-\overline{\gamma}=0, \tag{54}$$

$$-\delta(\pi-\overline{\pi})=\overline{\delta}(\pi-\overline{\pi})=-\Phi'', \tag{55}$$

$$\Delta(\pi-\overline{\pi})=D(\pi-\overline{\pi})=0, \tag{56}$$

where Φ,Φ' *and* Φ'' *are real functions of the spacelike coordinate* u.

Proof: The proof follows along the same lines as that of Theorem 4. If $\vec{X}=\partial_u$ is the hypersurface orthogonal spacelike CKV and $\vec{u}=\mathbf{e}^{-U}\partial_u$ is the unit spacelike vector field parallel to it whose existence are ensured by theorem 1, then a canonical tetrad can be constructed in one of the following ways:

$$k_a=\frac{1}{\sqrt{2}}(u_a+x^3_a),\quad l_a=\frac{1}{\sqrt{2}}(-u_a+x^3_a),\quad m_a=\frac{1}{\sqrt{2}}(x^2_a+\imath x^1_a), \tag{57}$$

$$k_a=\frac{1}{\sqrt{2}}(x^2_a+x^3_a),\quad l_a=\frac{1}{\sqrt{2}}(-x^2_a+x^3_a),\quad m_a=\frac{1}{\sqrt{2}}(u_a+\imath x^1_a), \tag{58}$$

$$k_a=\frac{1}{\sqrt{2}}(x^2_a+x^3_a),\quad l_a=\frac{1}{\sqrt{2}}(-x^2_a+x^3_a),\quad m_a=\frac{1}{\sqrt{2}}(x^1_a+\imath u_a), \tag{59}$$

where u_a,x^1_a,x^2_a are spacelike vectors and x^3_a is a timelike vector.

Equations (28)–(36) are obtained contracting (25) and (26) with tetrad (57), (37)–(46) arise from contracting (25) and (26) with tetrad (58), while contraction of (25) and (26) with tetrad (59) gives rise to (47)–(56). To recover expressions (25) and (26) one must in turn contract those sets of equations with the corresponding dual tetrad. □

Regarding the characterization of class B double warped space–times, we shall first recall the necessary and sufficient condition for a space–time to be conformally related to a $2+2$ decomposable one, as it was given in theorem 3 of Ref. 3, and next give the condition on the conformal factor that makes it separable in the two sets of coordinates adapted to the two two-dimensional factor submanifolds. We do this in the following theorem:

Theorem 6: *The necessary and sufficient condition for* (M,g) *to be conformally related to a* $2+2$ *decomposable space–time* $(M,\hat{g})$ *with* $g=\exp(2\theta)\hat{g}$ *(*θ *being a real function), is that there exist null vectors* $\vec{l}$ *and* $\vec{k}$ $(l^ak_a=-1)$ *satisfying*

$$l_{a;b}=Ae^{-\theta}l_al_b-\theta_{,a}l_b+(\theta_{,c}l^c)g_{ab},\quad k_{a;b}=-Ae^{-\theta}k_al_b-\theta_{,a}k_b+(\theta_{,c}k^c)g_{ab}; \tag{60}$$

for some function A. *Further,* (M,g) *is class B doublewarped if and only if*

$$H^c_a(h^d_b\theta_{,d})_{;c}+2(h^d_b\theta_{,d})(H^c_a\theta_{,c})=0,$$

where

$$h_{ab}\equiv-2k_{(a}l_{b)},\quad H_{ab}\equiv g_{ab}+h_{ab}. \tag{61}$$

Proof: The reader is referred to Theorem 3 of Ref. 3 for a proof of the first part of the theorem. As for the second part, namely that characterizing double warped space–times within the larger class of space–times which are conformal to $2+2$ decomposable ones, notice that Eq. (61) is nothing but the covariant expression of $\partial_\alpha(\partial_A\theta)=0$, where $\{x^\alpha\}$ and $\{x^A\}$ are coordinate charts on the two 2-dimensional submanifolds M_1 and M_2, respectively (see Sec. I). □

As in the former case, Theorem 6 can be expressed in terms of the NP formalism. To do so, a complex null tetrad $\{k_a,l_a,m_a,\overline{m}_a\}\equiv\{z^m_a\}$ is chosen such that $\vec{k}$ and $\vec{l}$ are the vectors in (60); i.e., $k^al_a=-m^a\overline{m}_a=-1$ all other inner products vanishing.
One then has

Theorem 7: *The necessary and sufficient condition for* (M,g) *to be conformally related to a* $2+2$ *decomposable space–time* $(M,\hat{g})$*, with* $g=e^{2\theta}\hat{g}$*, is that there exist a function* $\theta: M\to\mathbb{R}$ *and a canonical complex null tetrad* $\{k_a,l_a,m_a,\overline{m}_a\}$ *as described above such that*

$$\kappa=\sigma=\lambda=\nu=\alpha+\overline{\beta}=\pi+\overline{\tau}=\rho+(\epsilon+\overline{\epsilon})=0,$$

$$Ae^{-\theta}=\mu+(\gamma+\overline{\gamma}), \tag{62}$$

$$\rho=-D\theta, \quad \mu=\Delta\theta, \quad \tau=-\delta\theta,$$

where A *is the real function appearing in (60). Furthermore,* (M,g) *is class B double warped if and only if*

$$\delta\rho=-2\rho\tau, \quad \delta\mu=-2\mu\tau, \quad \rho\mu=0. \tag{63}$$

Proof: Equation (60) for $\vec{l}$ and $\vec{n}=\vec{k}$ becomes in NP formalism

$$\gamma_{1mn}=b\,\eta_{1m}\eta_{1n}-\theta_{,m}\eta_{1n}+\eta_{mn}D\theta, \tag{64}$$

$$\gamma_{2mn}=-b\,\eta_{2m}\eta_{1n}-\theta_{,m}\eta_{2n}+\eta_{mn}\Delta\theta, \tag{65}$$

where $b\equiv Ae^{-\theta}$, $m,n,\ldots$ are tetrad indices and the notation is the same as in Ref. 9. Contracting (64) and (65) with the tetrad vectors, (62) are easily obtained.

On the other hand, the tetrad version of (61), together with the information contained in (62), yields (63).

Conversely, (62) and (63) contracted with the dual tetrad of $\{k_a,l_a,m_a,\overline{m}_a\}$ give Eqs. (60) and (61). □

The characterization of class A and class B double warped space–times given in Theorems 1 and 6, or alternatively 4, 5, and 7 should prove useful in formulating an algorithm for classifying such metrics. This is so because this characterization is coordinate independent although tetrad dependent. In what follows the tetrads described in Theorems 4, 5, and in Theorem 7 will be designated as *dw tetrads of class A and B, respectively*.

Thus, in order to determine whether a given metric g represents a double warped space–time, one can either use Theorems 1, and 6 (coordinate approach), or else their counterparts 4, 5, and 7 through the following scheme:

(1) Determine the Petrov type of the Weyl tensor associated with the metric g and choose a canonical tetrad $\{k_a,l_a,m_a,\overline{m}_a\}$ such that $g_{ab}=2[-l_{(a}k_{b)}+m_{(a}\overline{m}_{b)}]$.
(2) Determine the NP spin coefficients and their NP derivatives in the chosen tetrad (1).
(3) If the scalars determined in step (2) satisfy the relations of Theorem 4 or 5 (respectively, 7) for some function U (respectively, θ), then the space–time is double warped of class A (respectively, B) and the algorithm stops here, otherwise continue the algorithm.
(4) If possible, find the Lorentz transformation of the invariance group that transforms tetrad (1) into a dw tetrad; i.e., such that the corresponding NP spin coefficients and NP derivatives obey the conditions in Theorem 4 or 5 (respectively, 7). If such a transformation exists, the space–time is double warped of class A (respectively, B), otherwise it is not double warped.

The Lorentz transformations considered in step (4) must belong to the invariance group of the Petrov type of the metric since in step (1) one chooses a canonical tetrad. Thus, for instance, if the given metric is of the Petrov type D or N, then in step (4) one looks for spin and boost transformations or for null rotations respectively.

III. CURVATURE STRUCTURE

The purpose of this section is to study the Riemann tensor of double warped space–times in connection with that of the underlying, conformally related, decomposable space–time, with a special emphasis on the algebraic Petrov and Segre types of the associated Weyl and Ricci tensors, respectively.

First of all, notice that since the metric g of the double warped space–time is conformally related to that of the decomposable space–time $\hat{g}$, their respective Weyl conformal tensors and hence their Petrov types, will be equal. The Petrov types of decomposable space–times can be easily calculated and are in most cases related to the holonomy type of the space–time; thus Ref. 5 one has that if the space–time is $1+3$ spacelike (holonomy type R_{13}) the Petrov type can only be I, D, or O, whence it follows that class A_1 double warped space–times can only be of those Petrov types. In the case of $1+3$ timelike decomposable space–times the Petrov type of the Weyl tensor is unrestricted and the same will hold for A_2 double warped space–times. Finally, the Petrov type of $2+2$ decomposable space–times (holonomy type R_7), and hence that of class B double warped ones, can only be D or O. Further, if it is type D the null vectors $\vec{k}$ and $\vec{l}$ in Theorem 6 are principal null directions of the Weyl tensor $C^a{}_{bcd}$, since the corresponding null vectors in the underlying $2+2$ decomposable space–time (that is: the recurrent null vectors $\hat{l}_a = e^{-\theta} l_a$ and $\hat{k}_a = e^{-\theta} k_a$, see Ref. 3 for details) can be easily seen to be principal null directions of the Weyl tensor in $(M,\hat{g})$; i.e., $\hat{C}^a{}_{bcd}$ (which equals $C^a{}_{bcd}$); see Ref. 10.

Regarding the Segre classification of the Ricci tensor, similar comments to those in the case of warped space–times hold; that is: conformal scaling does change the Ricci tensor and therefore the Segre type of double warped space–times is unrestricted in principle. Further, in the case of class A warped space–times we have that the unit vector field $\vec{u}$ (see proof of Theorem 1) is always an eigenvector of the Ricci tensor[3] (and therefore the Segre type of class A_1 warped space–times is {1,111} or one of its degeneracies), while in the case of double warped space–times this is no longer so for, from the Ricci identity specialized to $\vec{u}$ it follows (see Ref. 11):

$$R^a{}_b u_a = -\tfrac{2}{3}\Theta_{,b} + \tfrac{1}{3}(\dot{\Theta} + \Theta^2) u_b ,$$

now, in order for $\vec{u}$ to be an eigenvector of the Ricci tensor, it should be that $\Theta_{,b} \propto u_b$ and then a trivial calculation using the expressions for $\vec{u}$ and the metric that appear in the proof of Theorem 1 shows that either $\Theta = 0$ and then the conformal factor associated with $\vec{X}$ is $\psi = 0$; i.e., $\vec{X}$ is a KV and the space–time is A_2 warped (see Corollary 2) or else $U(u,x^k) = \theta_1(u)$ the space–time thus being type A_1 warped. Since the converse follows trivially, we have shown

Corollary 8: The necessary and sufficient condition for a class A double warped space–time to be a class A warped space–time is that the CKV $\vec{X}$ in Theorem 1 be a Ricci eigenvector (then it is of class A_1 if it is a proper CKV and of class A_2 if it is a KV).

In the case of type B space–times, all Segre types are possible in principle.

To close this section, we next give the expressions of the Ricci tensors and the Ricci scalar. They can be derived easily from Appendix D in Ref. 12. Notice that, in the notation established in the previous section, $\theta_{\alpha,A} = \theta_{\alpha/A} = 0$,

$$\begin{aligned} R_{\alpha\beta} &= \hat{R}_{\alpha\beta} - 2[\theta_{1\ \alpha/\beta} - \theta_{1\ \alpha}\theta_{1\ \beta}] - S\hat{h}_{1\ \alpha\beta}, \\ R_{\alpha B} &= 2\theta_{1\ \alpha}\theta_{2\ B}, \\ R_{AB} &= \hat{R}_{AB} - 2[\theta_{2\ A/B} - \theta_{2\ A}\theta_{2\ B}] - S\hat{h}_{2\ AB}, \end{aligned} \tag{66}$$

where

$$S \equiv \theta^d{}_{/d} + 2\theta^d\theta_d , \tag{67}$$

that is:

$$S=\frac{1}{\sqrt{-\hat{h}_1}}[\sqrt{-\hat{h}_1}\theta_1^{\mu}]_{,\mu}+2\hat{h}_1^{\mu\nu}\theta_{1\,\mu}\theta_{1\,\nu}+\frac{1}{\sqrt{\hat{h}_2}}[\sqrt{\hat{h}_2}\theta_2^{M}]_{,M}+2\hat{h}_2^{MN}\theta_{2\,M}\theta_{2\,N}, \tag{68}$$

where $\hat{h}_1\equiv\det(\hat{h}_1)_{\mu\nu}$, $\hat{h}_2\equiv\det(\hat{h}_2)_{AB}$, and $\theta_{1\,\alpha}\equiv\theta_{1\,,\alpha}$, etc., and $\hat{R}_{ab}$ stands for the components of the Ricci tensor associated with the decomposable metric $\hat{g}$, which turn out to be $\hat{R}_{\alpha\beta}=\hat{R}_{1\,\alpha\beta}$ and $\hat{R}_{AB}=\hat{R}_{2\,AB}$ that is: the Ricci tensors of the metrics $\hat{h}_1$ and $\hat{h}_2$, respectively. Notice that S is separable as a sum in the coordinates x^{α} and x^{A}. For the Ricci scalar one easily gets

$$\begin{aligned}R=e^{-2(\theta_1+\theta_2)}\{\hat{R}-6[&(-\hat{h}_1)^{-1/2}((-\hat{h}_1)^{1/2}\theta_1^{\mu})_{,\mu}+\hat{h}_1^{\mu\nu}\theta_{1\,\mu}\theta_{1\,\nu}\\&+(\hat{h}_2)^{-1/2}((\hat{h}_2)^{1/2}\theta_2^{M})_{,M}+\hat{h}_2^{MN}\theta_{2\,M}\theta_{2\,N}]\},\end{aligned} \tag{69}$$

where $\hat{R}$ denotes the Ricci scalar of the metric $\hat{g}$, which is simply $\hat{R}_1+\hat{R}_2$, i.e., the sum of the Ricci scalars associated with the metrics $\hat{h}_1$ and $\hat{h}_2$.

IV. THE CONFORMAL LIE ALGEBRA OF CLASS B DOUBLE WARPED SPACE–TIMES

The purpose of this section is to make a few remarks on the Lie algebra of CKV, including Killing vectors (KV) and homothetic vectors (HV), of class B double warped space–times.

A double warped space–time (M,g) admits a CKV $\vec{X}$ iff $\mathcal{L}_{\vec{X}}g=2\psi g$ where ψ is some real function. If $\psi=$constant then $\vec{X}$ is a HV and if $\psi=0$ it is a KV.

Now, since a double warped space–time (M,g) is always conformally related to a decomposable one $(M,\hat{g})$, their respective conformal algebras will be equal; and as it turns out, it is relatively simple to deal with the conformal algebra of the decomposable space–time $(M,\hat{g})$. Conformal algebras in locally decomposable space–times have been studied by Coley and Tupper,[13] Capocci and Hall,[14] and (following a different approach) by Tsamparlis.[15] For the sake of completeness, we next summarize the basic results and refer the reader to the above papers for detailed proofs.

Theorem 9: *Let $(M,\hat{g})$ be a 2+2 decomposable space–time; the following results hold regarding its conformal Lie algebra:*

(1) If $(M,\hat{g})$ is conformally flat (CF) its conformal algebra is 15-dimensional, their generators being those of Minkowski's conformal algebra. In this case the two factor submanifolds must each be of constant curvature, say k_1 and k_2, respectively, with $k_1+k_2=0$.

(2) If it is not CF, the only CKV it may admit are KV or HV.

(3) If $(M,\hat{g})$ is not CF its KV are the KV of the submanifolds $(M_i,\hat{h}_i)$, for $i=1,2$; that is: if $\zeta^a=(\zeta^0,\zeta^1)$ is a KV of $(M_1,\hat{h}_1)$, then $\xi^a=(\zeta^0,\zeta^1,0,0)$ is a KV of $(M,\hat{g})$, etc. Also, $(M,\hat{g})$ will admit a HV if and only if each of $(M_i,\hat{h}_i)$ for $i=1,2$ admit a HV, i.e., if $\kappa^a=(\kappa^0,\kappa^1)$ and $\lambda^a=(\lambda^2,\lambda^3)$ are HV of the 2-spaces (adjusted to the same numerical values of the respective homothetic scalars), then $\eta^a=(\kappa^0,\kappa^1,\lambda^2,\lambda^3)$ is an HV of $(M,\hat{g})$ with the same value for its homothetic scalar.

For the case referred to in the above theorem, the reader is also referred to Ref. 16 where a thorough discussion of conformally decomposable $2+2$ space–times is given, along with a classification in terms of their conformal algebra.

V. THE CONFORMAL LIE ALGEBRA OF CLASS A DOUBLE WARPED SPACE–TIMES

We shall dedicate this section to the study of the conformal algebra of class A double warped space–times, which by our previous remarks, will be the same as that of the underlying $1+3$ decomposable space–time in each case. In so doing, we shall give some interesting results on

particular types of CKV (namely: gradient CKV or GCKV for short) in three-dimensional manifolds which, to the best of our knowledge, are new. Most of the results on proper CKV in $1+3$ decomposable space–times can be found in Ref. 13 and also (although no explicit expressions are given) in Ref. 14, we re-derive them here following a different approach which provides interesting information on the geometry of three-dimensional manifolds, and renders along the way useful and interesting results on particular types of CKV (namely: gradient CKV, GCKV for short) also in three-dimensional manifolds which, to the best of our knowledge, do not exist in the literature.

For this section alone, we shall change our notation slightly so as to avoid unnecessary complications, thus, the line element of the decomposable space–time $(M,\hat{g})$ will be written as

$$\mathrm{d}\hat{s}^2=[\epsilon \mathrm{d}u^2+h_{AB}(x^D)\mathrm{d}x^A\,\mathrm{d}x^B],\quad \epsilon=\pm 1. \tag{70}$$

The three-dimensional submanifold coordinated by x^A, $A=1,2,3$ will be noted as V and its metric (of either signature) as h (instead of $\hat{h}$). We shall represent the covariant derivative with respect to the three-dimensional metric h by a slash ("/"), whereas a semicolon ";" will be used to note that with respect to the four-dimensional metric $\hat{g}$. (The reader is reminded that this notation holds only in the present section: notice that, in the rest of the paper, a semicolon stands for the covariant derivative associated with g, the metric of the double warped space–time, whereas a slash stands for that associated with $\hat{g}$, the metric of the decomposable space–time.) The covariantly constant vector is then $\vec{u}=\partial_u$ (i.e., $u_{a;b}=0$ and therefore it is a non-null gradient KV). Finally note that, in the above coordinate system, the covariant derivatives satisfy

$$X_{ab\cdots\ ;u}=X_{ab\cdots\ ,u},\quad X_{ab\cdots\ ;A}=X_{ab\cdots\ /A}$$

for any tensor $X_{ab\cdots}$, and also that

$$R_{ua}=0,\quad R_{AB}=\overset{(3)}{R}_{AB},$$

where $\overset{(3)}{R}_{AB}$ stands for the Ricci tensor associated to the 3-metric h on V.

In order to investigate its conformal algebra, we first make a few trivial remarks in the paragraphs that follow.

First of all, and making an obvious abuse in the notation, we shall represent points in M by their coordinates in the above chart [that is: $p\in M$ with coordinates $x^a(p)=(u,x^A)$ will be represented simply as (u,x^A)]; next we consider the three-dimensional submanifold (hypersurface) consisting of all the points with the same value of the x^0 coordinate, say $x^0=u$, and note it as $V(u)$; i.e., $V(u)=\{(u,x^A)\ :\ u\ \text{fixed}\}$; the induced metric on $V(u)$ is h and, clearly, any two such submanifolds are diffeomorphic amongst themselves [and diffeomorphic to (V,h)] by the one-parameter group of isometries $\{\tau_t\}$ generated by $\vec{u}$ [that is: $\tau_t:V(u)\to V(u+t)$ where $\tau_t(u,x^A)=(u+t,x^A)$ wherever this makes sense].

Note that $\tau_t^*h=h$; that is, the three-dimensional metric h is invariant under the isometries generated by $\vec{u}$. Further, a vector field $\vec{X}$ in M will be invariant under these isometries ($\tau_{t*}\vec{X}=\vec{X}$) iff $[\vec{u},\vec{X}]=0$. In particular, if $\vec{X}$ is tangent to the submanifolds $V(u)$ it follows that it will be invariant under $\{\tau_t\}$ iff its components with respect to the above coordinate basis do not depend on u, i.e., $\vec{X}=X^A(x^D)\partial_A$.

Finally, we shall use the notation $\mathcal{C}_n(V,h)$ ($\mathcal{S}_n(V,h)$, $\mathcal{H}_n(V,h)$ or $\mathcal{K}_n(V,h)$) to designate the n-dimensional conformal (respectively: special conformal, homothetic or Killing) algebra of (V,h). Such an algebra (and therefore all of its subalgebras) is finite dimensional, its dimension being 10 at most (and (V,h) is then conformally flat). If (V,h) is nonconformally flat, then, a remarkable theorem by Hall and Capocci (see Ref. 17) shows that its dimension can be at most 4. In our subsequent developments we will often have to refer to some basis of $\mathcal{C}_n(V,h)$, which we will generically represent by $\{\vec{\zeta}_k\}$, $k=1,\ldots,n$ with associated conformal factors ψ_k; that is

$$\mathcal{L}_{\vec{\zeta}_k} h = 2\psi_k h. \tag{71}$$

Notice that any such basis is invariant under the isometries generated by $\vec{u}$; that is: $[\vec{u},\vec{\zeta}_k]=0$, $k=1,\ldots,n$, hence $\vec{\zeta}_k=\zeta_k^B(x^D)\partial_B$ and therefore also $\psi_k=\psi_k(x^D)$. (Some of the conformal factors ψ_k may be constant if they correspond to homotheties, or zero in the case of Killing vectors.)

We can now consider the problem of finding the CKV of a $1+3$ reducible space–time $(M,\hat{g})$. Let $\vec{Y}\in\mathcal{C}_r(M,\hat{g})$, one then has

$$Y_{a;b}+Y_{b;a}=2\phi\hat{g}_{ab}.$$

In the chosen coordinate chart, $\vec{Y}=Y^u(u,x^B)\partial_u+Y^A(u,x^B)\partial_A$ and the above equation then reads (on account of our previous remarks):

$$Y_{u,u}=\epsilon_1\phi, \tag{72}$$

$$Y_{u,A}+Y_{A,u}=0, \tag{73}$$

$$Y_{A/B}+Y_{B/A}=2\phi h_{AB}. \tag{74}$$

Now, (74) effectively says that for u fixed the vector field $Y^B(u,x^D)\partial_B$ is a CKV in $V(u)$ [equivalently: if a proper CKV is admitted in $(M,\hat{g})$ then, its projection on the submanifolds $V(u)$ is a CKV there], therefore, given $\{\vec{\zeta}_k\}$ a basis for $\mathcal{C}(V,h)$, it follows that it will also be a basis of $\mathcal{C}(V(u),h)$ (u fixed but otherwise arbitrary) whence, on $V(u)$ we shall necessarily have $Y^B(u,x^D)\partial_B=\lambda^k\vec{\zeta}_k$ with $\lambda^k=$constant and summation over $k=1,\ldots,n$ is to be understood; again this will be so for any $V(u)$ (i.e., u fixed but otherwise arbitrary). Finally, since $[\vec{u},\vec{\zeta}_k]=0$, we will have

$$\vec{Y}=Y^u(u,x^B)\partial_u+\lambda^k(u)\vec{\zeta}_k(x^B), \tag{75}$$

where $\lambda^k(u)$, $k=1,\ldots,n$ are n functions of the coordinate u. Substituting this back into (72)–(74) and putting $\phi\equiv\dot{\Sigma}$, where a dot indicates differentiation with respect to u, yields

$$Y_u=\epsilon_1\Sigma, \quad \phi=\dot{\Sigma}=\lambda_k(u)\psi_k(x^B), \tag{76}$$

$$\epsilon_1\Sigma_{,A}+\dot{\lambda}^k\zeta_{k\ A}=0. \tag{77}$$

Further, $\dot{\lambda}^k(u)\vec{\zeta}_k$ is also a CKV in each $V(u)$ [since for u fixed it is a linear combination of the CKV in the basis of $\mathcal{C}(V,h)$] which, on account of (77), is locally a gradient, i.e., $\dot{\lambda}^k\zeta_{k\ A}=-\epsilon_1\Sigma_{,A}$. The question arises as to how many independent GCKV may (V,h) admit, what are they; namely proper CKV, proper HV, or KV, and what does their existence imply on the 3-metric h.

Before proceeding, the following remarks, which follow trivially from the above equations, are in order:

R0: If no GCKV exist in (V,h), then $\dot{\lambda}^k=0$ [i.e., $\lambda^k(u)=$constant] in the above equations and $\phi=\lambda^k\psi_k(x^B)=$constant (since then $\phi=\lambda^k\psi_k(x^D)\equiv\phi(x^D)$, which yields $Y_u=u\phi(x^D)+B(x^D)$, but then $Y_{u,A}+Y_{A,u}=0$ implies $\phi_{,A}=B_{,A}=0$.), that is: $\vec{Y}$ is homothetic in $(M,\hat{g})$ [and $\lambda^k(u)\vec{\zeta}_k$ is also homothetic in (V,h)]. If (V,h) is such that no HV are admitted, then the only CKV that $(M,\hat{g})$ admits are KV.

R1: Let $\vec{\xi}$ be a KV in (V,h), then $\vec{\xi}$ is also a KV of $(M,\hat{g})$.

R2: Let $\vec{Y}$ be a KV in $(M,\hat{g})$. The following situations may then arise:

(a) (V,h) admits no KV, then $\vec{Y}=a\partial_u$ necessarily.

(b) (V,h) admits KV none of which is locally a gradient. Then, if $\{\vec{\xi}_k\}$ is a basis of $\mathcal{K}(V,h)$, one has

$$\vec{Y}=a\partial_u+b^k\vec{\xi}_k \tag{78}$$

with a,b^k arbitrary constants.

(c) (V,h) admits KV some of which are locally gradients (and therefore, by the Killing equation, covariantly constant vectors). Then one can choose a basis for $\mathcal{K}(V,h)$, say $\{\vec{\xi}_1,\ldots,\vec{\xi}_p,\vec{\xi}_{p+1},\ldots,\vec{\xi}_n\}$ (with $p\leqslant 3$) in a way such that $\vec{\xi}_1,\ldots,\vec{\xi}_p$ are covariantly constant. Then

$$\vec{Y}=A(x^B)\partial_u+a^s u\ \ \vec{\xi}_s+b^k\vec{\xi}_k, \tag{79}$$

where a^s,b^k are arbitrary constants, $(s=1,\ldots,p,\ k=1,\ldots,n)$ and $A(x^B)$ satisfies $A_{,B}=a^s\xi_{s\,B}$. Notice that if one of the gradient KV in (V,h) is non-null, the space–time $(M,\hat{g})$ decomposes still further, becoming a $1+1+2$ decomposable space–time. If (V,h) admits two, then a third one is automatically admitted and the space–time $(M,\hat{g})$ is locally flat. We shall return to this later on in the paper.

R3: Let $\vec{\eta}$ be a proper HV in (V,h) with homothetic constant $k(\neq 0)$, then $\vec{Y}=ku\partial_u+\vec{\eta}$ is also a HV of $(M,\hat{g})$ with homothetic constant k. Further, if $\vec{Y}$ is a proper HV of $(M,\hat{g})$ with homothetic constant $k(\neq 0)$, then it is of the form

$$\vec{Y}=ku\partial_u+\vec{\eta}, \tag{80}$$

$\vec{\eta}$ being a (proper) HV in (V,h) scaled so as to have the same value k for its homothetic constant; the above HV is unique up to the addition of KV such as those given by (78) and/or (79) (if GKV exist).

The various possibilities regarding the existence of GCKV in (V,h) can be summarized as follows:

(1) (V,h) admits no GCKV (either proper or homothetic, including Killing). In that case (77) implies $\dot{\lambda}^k=0$ and the rest of the equations imply then that $\vec{Y}$ is a HV, see Eqs. (78) or (80) above. Thus, in this case $(M,\hat{g})$ admits no proper CKV.

(2) The only GCKV that (V,h) admits are gradient KV (GKV). In this case $(M,\hat{g})$ admits a proper CKV (which turns out to be a SCKV) if and only if the GKV is null and (V,h) admits a proper SCKV (i.e., nonhomothetic) such that the gradient of its conformal factor is parallel to the null GKV. Otherwise the only CKV that $(M,\hat{g})$ admits are HV.

(3) (V,h) admits proper gradient HV (GHV); it may also admit GKV, but no proper GCKV exist in (V,h). In this case, $(M,\hat{g})$ does admit a proper CKV which turns out to be special (i.e., SCKV); that is: its associated conformal factor ϕ satisfies $\phi_{a;b}=0$. This SCKV is unique up to the addition of KV and HV which must then take the forms discussed above.

(4) (V,h) admits proper GCKV (GHV and/or GKV can also be admitted in principle). In this case, the space–time admits proper CKV.

Regarding the maximum number of GCKV that a three-dimensional space may admit, one can easily prove the following results:

Proposition 1: Let (V,h) be a three-dimensional Lorentz or Riemann space admitting two independent proper GCKV, say $\vec{\zeta}$ and $\vec{\chi}$, with associated conformal factors ψ and ϕ, respectively, then:

(1) The Lie bracket $[\vec{\zeta},\vec{\chi}]\equiv\vec{\xi}$ is a KV.

(2) The conformal factors are $\psi=k\zeta$ and $\phi=k\chi$, where k is a constant and ζ and χ are the

functions whose gradients are the GCKV $\vec{\eta}$ *and* $\vec{\chi}$*, respectively.*

(3) (V,h) *is of constant curvature and therefore the Cotton–York tensor vanishes, thus being conformally flat.*

Proof: Suppose $\vec{\eta}$ and $\vec{\chi}$ are linearly independent GCKV satisfying

$$\zeta_{A/B}=\psi h_{AB}, \quad \chi_{A/B}=\phi h_{AB},$$

where $\zeta_A=\zeta_{,A}$, $\chi_A=\chi_{,A}$ and also [see comments following Eq. (111)] $\psi=\psi(\zeta)$ and $\phi=\phi(\chi)$. Now, a direct calculation shows that

$$[\vec{\zeta},\vec{\chi}]=\phi\vec{\zeta}-\psi\vec{\chi}\equiv\vec{\xi}$$

that is, $\vec{\eta}$ and $\vec{\chi}$ are surface-forming.

Compute next

$$\mathcal{L}_{[\vec{\zeta},\vec{\chi}]}h_{AB}=\mathcal{L}_{\vec{\zeta}}(\mathcal{L}_{\vec{\chi}}h_{AB})-\mathcal{L}_{\vec{\chi}}(\mathcal{L}_{\vec{\zeta}}h_{AB})=2(\zeta^D\chi_D)(\tilde{\phi}-\tilde{\psi})h_{AB},$$

where $\tilde{\phi}\equiv \mathrm{d}\phi/\mathrm{d}\chi$ and $\tilde{\psi}\equiv \mathrm{d}\psi/\mathrm{d}\zeta$, and also

$$\mathcal{L}_{\vec{\xi}}h_{AB}=\mathcal{L}_{\phi\vec{\zeta}-\psi\vec{\chi}}h_{AB}=(\tilde{\phi}-\tilde{\psi})(\zeta_A\chi_B+\chi_A\zeta_B)$$

therefore

$$(\tilde{\phi}-\tilde{\psi})(\zeta_A\chi_B+\chi_A\zeta_B)=2(\zeta^D\chi_D)(\tilde{\phi}-\tilde{\psi})h_{AB}.$$

An elementary consideration on the ranks of the tensors at both sides of the equation readily shows that

$$\tilde{\phi}-\tilde{\psi}=0;$$

therefore

$$\psi=k\eta, \quad \phi=k\chi$$

and $\vec{\xi}$ is then a KV given by

$$\vec{\xi}=k(\chi\vec{\zeta}-\zeta\vec{\chi}),$$

which is not a gradient: $\xi_{A/B}=k(\zeta_A\chi_B-\chi_A\zeta_B)$.

Now, since both $\vec{\zeta}$ and $\vec{\chi}$ are GCKV their respective conformal bivectors are zero and (12) applied to them yields

$$R_{ABCD}\zeta^D=k(\zeta_A h_{BC}-\zeta_B h_{AC}),$$

$$R_{ABCD}\chi^D=k(\chi_A h_{BC}-\chi_B h_{AC}),$$

which in turn implies, upon contraction with h^{AC},

$$R_{BD}\zeta^D=-2k\zeta_B, \quad R_{BD}\chi^D=-2k\chi_B.$$

Now, in three dimensions one has

$$R_{ABCD}=R_{AC}h_{BD}-R_{AD}h_{BC}+h_{AC}R_{BD}-h_{AD}R_{BC}+(R/2)(h_{AD}h_{BC}-h_{AC}h_{BD})$$

hence, the above equations imply

$$R_{AC}\zeta_B-\zeta_A R_{BC}+(k+R/2)(\zeta_A h_{BC}-\zeta_B h_{AC}=0,$$

$$R_{AC}\chi_B-\chi_A R_{BC}+(k+R/2)(\chi_A h_{BC}-\chi_B h_{AC}=0,$$

contracting the two equations above with ζ^A and χ^A, respectively, we get, since $\zeta^A\zeta_A, \chi^A\chi_A \neq 0$:

$$R_{AC}=(k+R/2)h_{AC}-(3k+R/2)\zeta_A\zeta_C,$$

$$R_{AC}=(k+R/2)h_{AC}-(3k+R/2)\chi_A\chi_C$$

contracting again both equations with, say ζ^C, equating and rearranging terms we get

$$(3k+R/2)\zeta_A=(3k+R/2)(\zeta_C\chi^C)\chi_A$$

but this contradicts our hypothesis of linear independence unless $3k+R/2=0$, i.e., $R=-6k$ $(=\text{constant})$. Then $R_{AB}=-2kh_{AB}$ and $R_{ABCD}=k(h_{AD}h_{BC}-h_{AC}h_{BD})$; that is: (V,h) is of constant curvature and therefore the associated Cotton–York tensor[11] is zero, i.e., h is conformally flat. □

The converse theorem also holds; namely: if (V,h) is a three-dimensional space or space–time of constant curvature (and therefore conformally flat), it admits two linearly independent GCKV whose associated conformal factors are multiples (with the same multiplicative constant) of the functions whose gradients they are.

Furthermore, with the same notation and hypotheses as in the preceding theorem and following a similar procedure to that outlined in its proof, it is easy to prove the following three results:

Lemma 2: Let $\vec{\zeta}$ be a GCKV and $\vec{\xi}$ a GKV (i.e., $\vec{\xi}$ is covariantly constant). Then $\vec{\zeta}$ is necessarily homothetic, that is, it is a GHV.

Proof: Since $\zeta_{A/B}=\psi h_{AB}$ and $\xi_{A/B}=0$ it follows $[\vec{\zeta},\vec{\xi}]=-\psi\vec{\xi}$. Computing next the Lie derivative of h in two different ways, as in the proof of Theorem 1, and then equating yields

$$2(\xi^D\psi_D)h_{AB}=\tilde{\psi}(\zeta_A\xi_B+\xi_A\zeta_B).$$

Again, considerations on the rank of the tensors that appear on both sides of the equation, imply $\psi_A=0$; that is: $\vec{\zeta}$ is a GHV. □

Lemma 3: Let $\vec{\zeta}$ be a GCKV and $\vec{\eta}$ a GHV. Then $\vec{\zeta}$ is necessarily homothetic and therefore it is the linear combination of $\vec{\eta}$ with some GKV.

Proof: Now $\zeta_{A/B}=\psi h_{AB}$ and $\eta_{A/B}=kh_{AB}$, and their Lie bracket is $[\vec{\zeta},\vec{\xi}]=k\vec{\zeta}-\psi\vec{\eta}$. Computing as above the Lie derivative of h in two different ways and then equating implies

$$2(\eta^D\psi_D)h_{AB}=(\eta_A\psi_B+\psi_A\eta_B),$$

which again implies $\psi_A=0$ and the result follows. □

Lemma 4: Let $\vec{\eta}$ and $\vec{\xi}$ be a proper GHV and a GKV, respectively; (V,h) is then flat.

Proof: In this case we have $R_{ABCD}\eta^D=R_{ABCD}\xi^D=0$, hence $R_{AB}\eta^D=R_{AB}\xi^B=0$, and taking into account the expression of the Riemann tensor in terms of the metric and the Ricci tensor (see the proof of Theorem 1 and recall that $\vec{\eta}$ cannot be null), one gets $R_{AB}=(R/2)(h_{AB}-(\eta^D\eta_D)^{-1}\eta_A\eta_B)$; contracting with ξ^B both sides and equating to zero yields immediately $\eta_D\xi^D=R=0$ (since $\vec{\eta}$ and $\vec{\xi}$ are linearly independent), and this in turn implies $R=R_{AB}=0$ and then $R_{ABCD}=0$. □

The same result holds trivially if two linearly independent GKV exist; since in this case two linearly independent constant vector fields in a manifold of dimension three readily imply (constancy of the metric) that a third one must also exist. Thus, we have proven:

Proposition 2: A three-dimensional space or space–time admitting two linearly independent GHV (proper or Killing) is necessarily flat.

Note that from the above Propositions 1 and 2, it follows that if two (or more) independent GCKV exist in the three-space (V,h), then it is of constant curvature (and therefore conformally flat, being flat in several cases) and then it admits 10 CKV (those of flat three-dimensional space). If this is not the case [i.e., (V,h) is not of constant curvature] then it can admit, at most, one GCKV which will then give rise to a proper CKV in $(M,\hat{g})$. If (V,h) admits no GCKV, then no proper CKV exist in $(M,\hat{g})$, just HV (case 1 above).

In the following sections we shall deal with cases 2, 3, and 4 separately, assuming that the GCKV admitted in each case is unique.

A. (V,h) admits a GKV and no proper GHV or GCKV

From the preceding results it follows that unless (V,h) is conformally flat (in which case its conformal algebra is completely known), the GKV, say $\vec{\xi}$, is the unique GCKV it admits. Taking now a basis of $\mathcal{C}_n(V,h)$ as $\{\vec{\xi},\vec{\eta},\vec{\zeta}_k\}$ where $\vec{\zeta}_k$ and $\vec{\eta}$ denote CKV (including KV) and a HV, respectively [in case one exists in (V,h), if not, just set $\vec{\eta}=0$], we can write, from (74)

$$Y_A=\lambda(u)\xi_A+\mu(u)\eta_A+\lambda^k(u)\zeta_A,$$

which substituted into (73) yields

$$-Y_{u,A}=\dot{\lambda}(u)\xi_A+\dot{\mu}(u)\eta_A+\dot{\lambda}^k(u)\zeta_A.$$

Since by hypothesis, $\vec{\xi}$ is the only GCKV in (V,h) and $\vec{\xi}$, $\vec{\eta}$ (if nonzero) and $\vec{\zeta}_k$ are linearly independent vector fields, it follows that $\dot{\mu}(u)=\dot{\lambda}_k(u)=0$ [otherwise the above equation would imply that, for u fixed, $\dot{\mu}(u)\eta_A+\dot{\lambda}^k(u)\zeta_A$ is a GCKV independent of $\vec{\xi}$]; hence $\mu=a_0$ ($=$constant) [and $a_0=0$ if (V,h) admits no proper HV], and $\lambda^k=a^k$ ($=$constant). Therefore

$$Y_A=\lambda(u)\xi_A+a_0\eta_A+a^k\zeta_A$$

and substituting this back into (74), (72), and (73) one has

$$\phi=\dot{\Sigma}=a_0k+a^k\psi_k(x^D), \tag{81}$$

$$Y_u=\epsilon_1(a_0k+a^k\psi_k(x^D))u+B(x^D),\quad \epsilon_1(a_0k+a^k\psi_k(x^D))_{,A}u+B(x^D)_{,A}+\dot{\lambda}(u)\xi_A=0 \tag{82}$$

hence

$$\dot{\lambda}(u)=au+b,$$

i.e.,

$$\lambda(u)=\frac{a}{2}u^2+bu+c$$

and also

$$a^k\psi_k(x^D)=\epsilon_1(-a\xi+m),\quad B(x^D)=-b\xi+n$$

and substituting this into the expressions for the covariant components of $\vec{Y}$, we would get $Y_u=(\epsilon_1a_0k+m)u-(au+b)\xi+n$ and $Y_A=[(a/2)u^2+bu+c]\xi_A+X_A$ where $X_A\equiv a_0\eta_A+a^k\zeta_{kA}$. Notice that the constants n and c can be set equal to zero without loss of generality, as they amount to adding multiples of $\vec{u}=\partial_u$ and $\vec{\xi}$, respectively. On the other hand, X_A are the covariant components of a CKV whose associated conformal factor is $\epsilon_1(-a\xi+m)+a_0k$ [if no HV exists in (V,h) then the CKV has components $X_A=a^k\zeta_{kA}$ and conformal factor $-\epsilon_1(-a\xi+m)$], that is

$$Y_a dx^a = [(\epsilon_1 k a_0 + m)u - (au + b)\xi]du + \left[\left(\frac{a}{2}u^2 + bu\right)\xi_A + X_A\right]dx^A, \tag{83}$$

where

$$X_A = a_0 \eta_A + a^k \zeta_{k\,A}$$

is such that

$$2X_{(A/B)} = 2[\epsilon_1(-a\xi + m) + a_0 k]h_{AB} \tag{84}$$

and the conformal factor associated to $\vec{Y}$ is

$$\phi = \epsilon_1(-a\xi + m) + a_0 k \tag{85}$$

and satisfies $\phi_{a;b} = 0$, that is: $\vec{Y}$ is a SCKV in $(M,\hat{g})$, whereas $\vec{X}$ is also a SCKV in (V,h).

Notice that some of the constants appearing in the above expressions could have been removed by means appropriate redefinitions of the objects (functions and coordinates) in them. However, as it turns out, it is useful to keep them as they appear because this makes the subsequent analysis much more clear. The following possibilities now arise regarding the nature of $\vec{X}$; namely

Case 1: (V,h) admits no proper SCKV nor proper HV, then $a_0 = 0$ and $X_A = a^k \zeta_{k\,A}$ is a KV, that is $a^k \psi_k = \epsilon_1(-a\xi + m) = 0$; i.e., $a = m = 0$ and the conformal factor ϕ above becomes zero, hence, $\vec{Y}$ is a KV which can be seen to be given by

$$Y_a dx^a = -b\xi\, du + b\xi_A\, dx^A + X_A\, dx^A, \quad \vec{X} \in \mathcal{K}(V,h). \tag{86}$$

Case 2: (V,h) admits no proper SCKV but it admits a proper HV (that is: $a_0 \neq 0$). It then follows that $a^k \zeta_{k\,A}$ must be a KV, hence $a^k \psi_k = \epsilon_1(-a\xi + m) = 0$; and then $a = m = 0$ as before. The conformal factor is then constant $\phi = k a_0$, $\vec{Y}$ then being a HV which can be written as

$$Y_a\, dx^a = a_0[\epsilon_1 k u\, du + \eta_A\, dx^A] - b\xi du + b\xi_A\, dx^A + X_A\, dx^A, \tag{87}$$

where the first term within square brackets is a proper HV and the remaining terms are easily recognizable as a KV [see Eq. (86)].

Case 3: (V,h) admits a proper SCKV, $\vec{X}$ such that $2X_{(A/B)} = 2[\epsilon_1(-a\xi)]h_{AB}$; i.e., $a \neq 0$ and the constants $k a_0, m$ (if nonzero) have been absorbed by suitably redefining the function ξ. We then have

$$X_{A/B} = -\epsilon_1 a \xi h_{AB} + F_{AB},$$

where F_{AB} is the conformal bivector. Computing now the Lie bracket of $\vec{\xi}$ and $\vec{X}$ and making use of the above expression together with the fact that $\xi_{A/B} = 0$ we get

$$[\vec{\xi}, \vec{X}] = \vec{\eta}, \quad \eta_A = -\epsilon_1 a \xi \xi_A + F_{AB}\xi^B \tag{88}$$

computing now $\eta_{A/C}$ and making use of Eq. (12) it follows

$$\eta_{A/C} = -\epsilon_1 a(\xi^D \xi_D) h_{AC} \tag{89}$$

that is: $\vec{\eta}$ is either a GHV (whenever $\vec{\xi}$ is non-null, for in that case it can be scaled so that $\xi^D \xi_D = \epsilon_2$, where $\epsilon_2 = \pm 1$), or else $\vec{\eta}$ is a GKV (including $\vec{\eta} = 0$ as a special case). In the former case ($\vec{\eta}$ is a GHV and therefore $\xi^D \xi_D = \epsilon_2$), Proposition 2 above implies that (V,h) is flat. In the latter case ($\vec{\eta}$ is a GKV and $\xi^D \xi_D = 0$), one has from (88) that $\xi^D \eta_D = 0$ and therefore either

$\eta^D \eta_D \neq 0$, in which case again, proposition 2 implies that (V,h) is flat, or else $\vec{\eta}=k\vec{\xi}$ where k is a constant which may be zero (if it is not zero, it can always be chosen equal to 1 by re-scaling $\vec{X}$ appropriately). This is the only nontrivial case [in the sense that (V,h) is not necessarily flat], and it is easy to see that coordinates v,w,y can be chosen so that the three-dimensional line element takes the form:

$$\mathrm{d}\sigma^2 = -2\mathrm{d}v\ \mathrm{d}w + p_{\pm}(w)M^2(y)[q_{\pm}(w)^{-2}\mathrm{d}w^2 + \mathrm{d}y^2], \tag{90}$$

where

$$\begin{gathered} q_{\pm}(w)=n^2w^2\pm 1, \quad p_{+}(w)\equiv q_{+}(w)\exp[\epsilon_1 kn/a\ \cot^{-1} nw] \\ p_{-}(w)\equiv q_{-}(w)\exp[\epsilon_1 kn/a\ \coth^{-1} nw], \quad n=\text{constant}, \end{gathered} \tag{91}$$

the KV $\vec{\xi}$ and SCKV $\vec{X}$ being, respectively,

$$\vec{\xi}=\partial_v, \quad \vec{X}=kv\partial_v+\frac{1}{n^2}q_{\pm}(w)\partial_w. \tag{92}$$

Alternatively, new coordinates can be chosen, which we still call v,w,y, so that Ref. 11 the line element takes the more familiar form

$$\mathrm{d}\sigma^2 = -2\mathrm{d}v\ \mathrm{d}w - 2H(w,y)\mathrm{d}w^2 + \mathrm{d}y^2 \tag{93}$$

and still $\vec{\xi}=\partial_v$ but the function $H(w,y)$ satisfies then a partial differential equation and $\vec{X}$ then takes a form which depends on H. In this case, the Ricci tensor is

$$R_{AB}=H_{,yy}l_A l_B, \tag{94}$$

where $l_A=\xi_A$.

B. (V,h) admits a proper GHV and no proper GCKV

Since a proper HV is unique up to the addition of KV, we can assume that there is just one GHV (in the sense that, if another exists, then their difference must be a gradient KV—in that respect, if any GKV exists in (V,h) we shall consider that has been added to the GHV, therefore, any remaining proper CKV or KV in $\mathcal{C}(V,h)$ will be nongradient), say $\vec{\eta}$ with homothetic constant $k(\neq 0)$; i.e., $\eta_A \equiv \eta_{,A}$ for some function $\eta(x^B)$.

At this point, it is easy to find an expression for the line element associated with h in coordinates adapted to the GHV $\vec{\eta}$. First of all notice that from $\eta_{A/B}=kh_{AB}$ it readily follows that $\vec{\eta}$ cannot be null; next and provided we are not in the vicinity of a fixed point of the HV, we can always choose a coordinate, say $x^1\equiv v$ adapted to $\vec{\eta}$, i.e., $\vec{\eta}=\partial_v$, now the fact that $\vec{\eta}$ is locally a gradient and a HV with homothetic constant k readily implies (by a similar argument to that used previously) that coordinates $x^i\equiv x^2,x^3$ can be chosen so that the line element associated with h reads

$$\mathrm{d}\sigma^2 = e^{2kv}(\epsilon_2\mathrm{d}v^2+\overline{h}_{ij}(x^k)\mathrm{d}x^i\,\mathrm{d}x^j), \quad \epsilon_2=\pm 1 \tag{95}$$

and then $\eta_A\,\mathrm{d}x^A=\epsilon_2\exp(2kv)\mathrm{d}v$, hence $\eta=(\epsilon_2/2k)\exp(2kv)$. Also, since $\overline{h}_{ij}(x^k)$ is a two-dimensional metric, the coordinates x^i can be chosen so that it takes an explicit conformally flat form, i.e.,

$$\mathrm{d}\sigma^2 = e^{2kv}(\epsilon_2\,\mathrm{d}v^2+\Omega^2(x^k)(\epsilon_3(\mathrm{d}x^2)^2+(\mathrm{d}x^3)^2), \quad \epsilon_2,\epsilon_3=\pm 1, \tag{96}$$

where $\Omega(x^k)$ is some function of its arguments. The line element of $(M,\hat{g})$ then reads

$$d\Sigma^2=\epsilon_1\,\mathrm{d}u^2+e^{2kv}[\,\epsilon_2\,\mathrm{d}v^2+\Omega^2(x^k)(\epsilon_3(\mathrm{d}x^2)^2+(\mathrm{d}x^3)^2)],\tag{97}$$

where

$$\epsilon_\alpha=\pm 1\quad(\alpha=1,2,3),\quad \epsilon_1\epsilon_2\epsilon_3=-1,\quad \epsilon_1+\epsilon_2+\epsilon_3=+1.$$

Alternatively, the following change of coordinates can be carried out:

$$w\equiv k^{-1}\exp(kv),\quad v=k^{-1}\ln kw,\tag{98}$$

which renders $\vec{\eta}$, η and the line element associated with h in the form

$$\vec{\eta}=kw\partial_w,\quad \eta=\frac{k\epsilon_2}{2}w^2,\quad \mathrm{d}\sigma^2=\epsilon_2\,\mathrm{d}w^2+w^2\Omega^2(x^k)(\epsilon_3(\mathrm{d}x^2)^2+(\mathrm{d}x^3)^2)\tag{99}$$

hence

$$\mathrm{d}\hat{s}^2=\epsilon_1\,\mathrm{d}u^2+\epsilon_2\,\mathrm{d}w^2+w^2\Omega^2(x^k)(\epsilon_3(\mathrm{d}x^2)^2+(\mathrm{d}x^3)^2).\tag{100}$$

Now going back to the problem of finding the CKV that $(M,\hat{g})$ admits in this case, let $\{\vec{\eta},\vec{\xi}_k\}$ be a basis for $\mathcal{C}(V,h)$ with $\vec{\eta}$ satisfying

$$\eta_{A/B}=kh_{AB}\tag{101}$$

and $\vec{\xi}_k$ being CKV (including KV) such that no proper CKV (nor any linear combination of them) is a gradient, we then have

$$\zeta_{k\,A/B}+\zeta_{k\,B/A}=2\psi_k h_{AB},$$

where ψ_k is the associated conformal factor.

Equation (74) states that $Y^B(u,x^D)\partial_B$ is a CKV in every $V(u)$ for u fixed, and therefore according to our previous developments, we may write

$$Y^B(u,x^D)\partial_B=\lambda(u)\vec{\eta}+\lambda^k(u)\vec{\xi}_k,\tag{102}$$

which when substituted back again into (72)–(74) yields (recall, the conformal factor ϕ has been renamed as $\dot{\Sigma}$):

$$\dot{\Sigma}(u,x^B)=k\lambda(u)+\lambda^k(u)\psi_k(x^B),\quad Y_u=\epsilon_1[k\mu(u)+\mu^k(u)\psi_k(x^B)+B(x^A)],\tag{103}$$

$$\epsilon_1\mu^k\psi_{k,A}+B_{,A}+\dot{\lambda}\,\eta_A+\dot{\lambda}^k\zeta_{k\ A}=0,\tag{104}$$

where $\mu(u)$ and $\mu^k(u)$ are such that $\dot{\mu}(u)=\lambda(u)$ and $\dot{\mu}^k(u)=\lambda^k(u)$, respectively, and $B(x^A)$ is a function of integration which does not depend on u. Now, (104) above implies that, for u fixed, $\dot{\lambda}^k\zeta_{k\ A}$ must be a GCKV (since η_A is a gradient by assumption), but since, by hypothesis there is none and $\vec{\eta}$, $\vec{\xi}_k$ are independent, it must be $\dot{\lambda}^k=0$, that is $\lambda^k=a^k(=\text{const})$. Plugging this back again into (72) and (73) we get

$$Y_u=\epsilon_1[k\mu(u)+ua^k\psi_k(x^B)+B(x^A)],\quad \epsilon_1 ua^k\psi_{k,A}+B_{,A}+\dot{\lambda}\,\eta_A=0,\tag{105}$$

which, when differentiated with respect to u yields

$$\epsilon_1 a^k\psi_{k,A}+\ddot{\lambda}\,\eta_A=0\tag{106}$$

and two possibilities arise:

case 1: $\ddot{\lambda}=0$, i.e.: $\lambda=au+b$, with a,b constants. Then $a^k\psi_{k,A}=0$, that is: $a^k\psi_k=C$ $(=\text{constant})$.

case 2: $\ddot{\lambda}=a$ (constant), hence $\lambda=a/2u^2+bu+c$ and then $B=-b\eta+m$ and $\epsilon_1 a^k\psi_k=a\eta+C$ where m,C are constants and η is the function such that $\eta_{,A}=\eta_A$.

Case 1: In this case it is straightforward to get from the equations above that $B=-\epsilon a\eta$ and also that $a^k\vec{\zeta}_k$ must satisfy:

$$\mathcal{L}_{a^k\vec{\zeta}_k}h=2Ch$$

that is: $a^k\vec{\zeta}_k$ is a HV, which, on account of the assumed independence of $\vec{\eta}$, $\vec{\zeta}_k$ can be set directly equal to zero. [Alternatively, since homotheties are essentially unique, it would follow $a^k\vec{\zeta}_k=(C/k)\vec{\eta}+\vec{\xi}$, where $\vec{\xi}$ is a KV, which can be absorbed by a suitable redefinition of the constant b in $\lambda=au+b$.] Taking all this into account, redefining nonessential combinations of constants and subtracting any proper KV [i.e., linear combinations of ∂_u and KV in (V,h) such as $\vec{\xi}$ above], we get

$$\vec{Y}=\left[k\left(\frac{a}{2}u^2+pu\right)-\epsilon_1 a\eta\right]\partial_u+(au+p)\vec{\eta},$$

where p is a constant.

It is immediate to check that the above CKV $\vec{Y}$, whose associated conformal factor is $\phi=k(au+p)$, is in fact a SCKV, that is $\phi_{a;b}=0$. Also note that the HV $pu\partial_u+p\vec{\eta}$ can be subtracted from $\vec{Y}$, the resulting vector

$$\vec{Y}'=[k(a/2)u^2-\epsilon_1 a\eta]\partial_u+au\vec{\eta} \tag{107}$$

being, indeed, a SCKV.

Case 2: We now have $\lambda=(a/2)u^2+bu+c$, $B=-b\eta+m$, and also $\epsilon_1 a^k\psi_k=a\eta+C$, where a,b,m and C are constants. This implies that $\vec{X}\equiv a^k\vec{\zeta}_k$ is a CKV in (V,h) whose associated conformal factor is precisely $\epsilon_1(a\eta+C)$. A direct calculation using the forms (96) or (99) readily shows that no such CKV $\vec{X}$ can exist, and therefore this case turns out to be impossible.

C. (V,h) admits a proper GCKV

Let us turn our attention now to the case in which (V,h) admits a proper GCKV. Before analyzing the consequences this has on the conformal algebra of the $1+3$ reducible space–time $(M,\hat{g})$, we shall first explore the situation in a three-space (V,h). To this end, let $\vec{\zeta}$ be a GCKV in (V,h) with associated conformal factor ψ, we then have

$$\zeta_{A/B}=\psi h_{AB},\quad \zeta_A=\zeta_{,A}, \tag{108}$$

where $\zeta=\zeta(x^D)$ is some function. The first equation above readily implies that $\vec{\zeta}$ cannot be null unless it is a KV. Taking a further covariant derivative we have

$$\zeta_{A/BC}=\psi_C h_{AB},\quad \psi_C=\psi_{,C} \tag{109}$$

and the Bianchi identities imply, since $\zeta_{A/B}=\zeta_{B/A}$,

$$R_{ABCD}\zeta^D=\psi_A h_{BC}-\psi_B h_{AC}. \tag{110}$$

Contracting both sides of the above equation with ζ^C yields

$$0=\psi_A\zeta_B-\psi_B\zeta_A \tag{111}$$

and then, unless $\vec{\zeta}$ is a HV (in which case the equation above is satisfied identically) which we are assuming is not, it follows that $\psi=\psi(\zeta)$, hence, from now on we shall write $\psi_A=\tilde{\psi}\zeta_A$, where the tilde stands for the derivative with respect to the function ζ, i.e., $\tilde{\psi}=\mathrm{d}\psi/\mathrm{d}\zeta$. Also, differentiating (111) and using (108) it follows that $\vec{\zeta}$ cannot be a SCKV (unless it is a KV).

Following a procedure similar to the one in Sec. V B, we choose a coordinate v adapted to $\vec{\zeta}$ and two other coordinates x^2,x^3 so that

$$\vec{\zeta}=\partial_v, \quad \zeta_A\,\mathrm{d}x^A=\epsilon_2\exp(2V(v))\mathrm{d}v, \quad \zeta=\epsilon_2\int \mathrm{d}v\,\exp(2V(v)), \tag{112}$$

$$\mathrm{d}\sigma^2=e^{2V(v)}[\,\epsilon_2+\Omega^2(x^k)(\,\epsilon_3(\mathrm{d}x^2)^2+(\mathrm{d}x^3)^2)] \tag{113}$$

the conformal factor then being $\psi=V'(v)$ where the prime indicates derivative with respect to v. Note that

$$\tilde{\psi}=\frac{\mathrm{d}\psi}{\mathrm{d}\zeta}=\frac{\mathrm{d}\psi}{\mathrm{d}v}\left(\frac{\mathrm{d}\zeta}{\mathrm{d}v}\right)^{-1}=\epsilon_2 V''e^{-2V(v)}. \tag{114}$$

Alternatively, a new coordinate w can be defined such that

$$w\equiv\int dv\,\exp(2V(v)) \tag{115}$$

and then

$$\vec{\zeta}=M(w)\partial_w, \quad M(w)=\exp(V(v(w))), \quad \zeta_A\mathrm{d}x^A=\epsilon_2 M(w)\mathrm{d}w, \quad \text{and } \zeta=\epsilon_2\int \mathrm{d}w\,M(w), \tag{116}$$

$$\mathrm{d}\sigma^2=\epsilon_2\mathrm{d}w^2+M^2(w)\Omega^2(x^k)(\,\epsilon_3(\mathrm{d}x^2)^2+(\mathrm{d}x^3)^2) \tag{117}$$

the conformal factor is $\psi=M'(w)$ (the prime now meaning derivative with respect to w) and, as before,

$$\tilde{\psi}=\frac{\mathrm{d}\psi}{\mathrm{d}\zeta}=\frac{\mathrm{d}\psi}{\mathrm{d}w}\left(\frac{\mathrm{d}\zeta}{\mathrm{d}w}\right)^{-1}=\epsilon_2\frac{M''}{M}. \tag{118}$$

The above metric describes the situation in which one proper (non-HV) GCKV exists in (V,h), with h being of arbitrary signature.

Let us now go back to the original problem of finding CKV in the $1+3$ reducible space–time whose three-dimensional factor (V,h) we are assuming to admit a GCKV. We next reproduce, for the sake of convenience, the original equations (72)–(74) with the conformal factor ϕ renamed as $\dot{\Sigma}$:

$$Y_{u,u}=\epsilon_1\dot{\Sigma}, \tag{119}$$

$$Y_{u,A}+Y_{A,u}=0, \tag{120}$$

$$Y_{A/B}+Y_{B/A}=2\dot{\Sigma}\,h_{AB}\,. \tag{121}$$

Again, (121) implies that $Y^B(u,x^D)\partial_B$ is a CKV in every $V(u)$ for u fixed.

Now, assume first that only one proper GCKV is admitted in (V,h), say $\vec{\zeta}$ with conformal factor ψ. From our previous developments it follows that no proper GHV or GKV can exist in (V,h); therefore we may consider a basis of $\mathcal{C}(V,h)$ given by $\{\vec{\zeta},\vec{\chi}_k\}$ where, again, $\vec{\chi}_k$ are nongradient CKV (possibly HV and KV) with conformal factors ϕ_k.

From the remark above it follows that

$$Y^B(u,x^D)\partial_B=\lambda(u)\vec{\zeta}+\lambda^k(u)\vec{\chi}_k$$

which, upon substitution into (121), yields

$$\dot{\Sigma}=\lambda(u)\psi(x^D)+\lambda^k(u)\phi_k(x^D)$$

that can be formally integrated to give

$$\Sigma=\psi(x^D)\int \mathrm{d}u\,\lambda(u)+\phi_k(x^D)\int \mathrm{d}u\,\lambda^k(u)+B(x^D),$$

where the terms resulting from the constants of integration arising from $(\int du\lambda(u))$, etc., have been absorbed into the function of integration $B(x^D)$.

Substituting this into (120) and taking into account that $\psi_{,A}=\tilde{\psi}\zeta_A$ we get

$$\left(\int \mathrm{d}u\,\lambda(u)\right)\tilde{\psi}\zeta_A+\left(\int \mathrm{d}u\,\lambda^k(u)\right)\phi_{k,A}+B_{,A}+\dot{\lambda}(u)\zeta_A+\dot{\lambda}^k(u)\chi_{kA}=0 \tag{122}$$

and this implies that, for u fixed, $\dot{\lambda}^k\chi_{kA}$ must be a GCKV independent of ζ_A. Since this is not possible from our assumptions, it follows that $\dot{\lambda}^k=0$, that is $\lambda^k=a^k(=\text{const})$. Therefore the above-given equation reads now

$$\left[\left(\int \mathrm{d}u\,\lambda(u)\right)\tilde{\psi}+\dot{\lambda}(u)\right]\zeta_A+ua^k\phi_{k,A}+B_{,A}=0 \tag{123}$$

and differentiating with respect to u,

$$[\lambda(u)\tilde{\psi}+\ddot{\lambda}(u)]\zeta_A+a^k\phi_{k,A}=0, \tag{124}$$

which readily implies:

$$\tilde{\psi}=k\quad(\text{constant}),\quad k\lambda(u)+\ddot{\lambda}(u)=a\quad(\text{constant}),\quad a^k\phi_k=-a\zeta+c, \tag{125}$$

where c is a constant. Substituting this information back into (123) and taking into account that from $\tilde{\psi}=k$ and $k\lambda(u)+\ddot{\lambda}(u)=a$ it follows $\tilde{\psi}\int \mathrm{d}u\,\lambda(u)+\dot{\lambda}(u)=a\,u$, one easily gets

$$B_{,A}=0,$$

i.e.,

$$B=b\quad(\text{constant}) \tag{126}$$

and then, using $k\int \mathrm{d}u\,\lambda(u)+\dot{\lambda}(u)=a\,u$, Eq. (119) implies

$$Y_u=\epsilon_1(-\zeta\dot{\lambda}+cu+b).$$

Note that b can be set equal to zero without loss of generality, since it simply amounts to adding a constant multiple of the KV $\vec{u}=\partial_u$, and we shall do that in what follows, thus writing

$$Y_u=\epsilon_1(-\zeta\dot{\lambda}+cu). \tag{127}$$

Also, from the above-mentioned developments we get

$$Y_A=\lambda(u)\zeta_A+X_A, \quad X_A\equiv a^k\chi_{kA}, \tag{128}$$

where $\lambda(u)$ satisfies $\ddot{\lambda}+k\lambda=a$, the conformal factor associated with the GCKV $\vec{\zeta}$ is $\psi=k\zeta$, and $\vec{X}$ is a CKV (nongradient by assumption) whose associated conformal $\phi'\equiv a^k\phi_k$ factor is, from Eq. (125) $\phi'=-a\zeta+c$.

Consider next the CKV $\vec{Z}$ defined by $\vec{Z}\equiv(a/k)\vec{\zeta}+\vec{X}$. From the previous paragraph it follows that

$$\mathcal{L}_{\vec{Z}}h_{AB}=2ch_{AB},$$

that is: $\vec{Z}$ is a HV with homothetic constant c, therefore, put $\vec{X}$ above as $\vec{X}=\vec{Z}-(a/k)\vec{\zeta}$ and then

$$Y_A=\left(\lambda(u)-\frac{a}{k}\right)\zeta_A+Z_A, \tag{129}$$

where $\vec{Z}$ is a HV in (V,h) with homothetic constant c. If (V,h) admits no HV, then $c=\vec{Z}=0$ above; thus we finally have

$$\vec{Y}=(-\zeta\dot{\lambda}+cu)\partial_u+\left(\lambda(u)-\frac{a}{k}\right)\vec{\zeta}+\vec{Z}.$$

Since $cu\partial_u+\vec{Z}$ is a HV with homothetic constant c we can subtract it from the above to get

$$\vec{Y}=(-\zeta\dot{\lambda})\partial_u+\left(\lambda(u)-\frac{a}{k}\right)\vec{\zeta} \tag{130}$$

and $\vec{\zeta}$ is now that given by (112) or (99), the corresponding three-dimensional line elements then being (113) or (117), thus we can finally write for the line element of $(M,\hat{g})$ a $1+3$ reducible space–time admitting a CKV under these hypotheses:

$$d\hat{s}^2=\epsilon_1\,du^2+\epsilon_2\,dw^2+M^2(w)\Omega^2(x^k)(\epsilon_3(dx^2)^2+(dx^3)^2), \tag{131}$$

where

$$\epsilon_\alpha=\pm1 \quad (\alpha=1,2,3) \quad \epsilon_1\epsilon_2\epsilon_3=-1, \quad \epsilon_1+\epsilon_2+\epsilon_3=+1.$$

The CKV is then

$$\vec{Y}=(-\zeta\dot{\lambda})\partial_u+\left(\lambda(u)-\frac{a}{k}\right)M(w)\partial_w, \tag{132}$$

where $\lambda(u)$ and $M(w)$ must satisfy [see (118)]

$$\ddot{\lambda}(u)+k\lambda(u)=a, \quad M''(w)=\epsilon_2kM. \tag{133}$$

These equations can be easily integrated for $\epsilon_2k>0,\epsilon_2k<0$ and $\epsilon_2k=0$ obtaining then explicit expressions for both the line element $d\hat{s}^2$ and proper CKV $\vec{Y}$.

In the next theorem, we make an attempt at summarizing the results thus far obtained.

Theorem 10: *Let $(M,\hat{g})$ a 1+3 decomposable space–time; the following results hold regarding its conformal Lie algebra:*

(1) *If* (V,h) *admits no GCKV then the only CKV that* $(M,\hat{g})$ *admits are HV and KV—their forms are those discussed in remarks* $R0$-$R3$ *at the beginning of this section.*

(2) $(M,\hat{g})$ *can admit a proper CKV* $\vec{Y}$ *if and only if* (V,h) *admits a GCKV, which can be either a GKV* $\vec{\xi}$*, or a GHV* $\vec{\eta}$*, or a (proper) GCKV* $\vec{\zeta}$*.*

(3) *If two or more GCKV are admitted by* (V,h)*, then* (V,h) *is of constant curvature and conformally flat (and it is flat if one of the GCKV admitted is a GHV).*

(4) *If only one GCKV is admitted by* (V,h)*, then:*

(a) *If it is a GKV* $\vec{\xi}$*, then* $(M,\hat{g})$ *admits a proper CKV* $\vec{Y}$ *if and only if* $\vec{\xi}$ *is null and a proper SCKV exists also in* (V,h)*,* $\vec{X}$*, such that* $[\vec{\xi},\vec{X}]=k\vec{\xi}$*; the CKV* $\vec{Y}$ *is also a SCKV and the metric is a special type of generalized pp-wave. Otherwise [i.e., if no proper SCKV* $\vec{X}$ *exists in* (V,h) *or it exists but it does not satisfy* $[\vec{\xi},\vec{X}]=k\vec{\xi}$*], then* $\vec{Y}$ *is a HV, possibly KV.*

(b) *If it is a GHV* $\vec{\eta}$ *then* $(M,\hat{g})$ *admits a proper SCKV* $\vec{Y}$ *(unique up to the addition of HV). The line element and* $\vec{Y}$ *are:*

$$\mathrm{d}\hat{s}^2=\epsilon_1\,\mathrm{d}u^2+\epsilon_2\,\mathrm{d}w^2+w^2\Omega^2(x^i)[\epsilon_3(\mathrm{d}x^2)^2+(\mathrm{d}x^3)^2], \tag{134}$$

$$\epsilon_\alpha=\pm 1\quad(\alpha=1,2,3),\quad \epsilon_1\epsilon_2\epsilon_3=-1,\quad \epsilon_1+\epsilon_2+\epsilon_3=+1$$

$$\vec{Y}=\left(\frac{a}{2}ku^2-\epsilon_1\epsilon_2\frac{a}{2}kw^2\right)\partial_u+au\,\vec{\eta},\quad \vec{\eta}=kw\partial_w\,. \tag{135}$$

(c) *If it is a GCKV* $\vec{\zeta}$ *then* $(M,\hat{g})$ *admits a proper CKV* $\vec{Y}$ *(unique up to the addition of HV). The line element and* $\vec{Y}$ *are:*

$$\mathrm{d}\hat{s}^2=\epsilon_1\,\mathrm{d}u^2+\epsilon_2\,\mathrm{d}w^2+M^2(w)\Omega^2(x^i)[\epsilon_3(\mathrm{d}x^2)^2+(\mathrm{d}x^3)^2], \tag{136}$$

$$\epsilon_\alpha=\pm 1\quad(\alpha=1,2,3),\quad \epsilon_1\epsilon_2\epsilon_3=-1,\quad \epsilon_1+\epsilon_2+\epsilon_3=+1,$$

$$\vec{Y}=-\zeta\dot{\lambda}(u)\,\partial_u+\left(\lambda-\frac{a}{k}\right)\vec{\zeta},\quad \zeta=\epsilon_2\int \mathrm{d}w\,M(w),\quad \vec{\zeta}=M(w)\partial_w \tag{137}$$

and the functions $\lambda(u)$ *and* $M(w)$ *satisfy*

$$\frac{\mathrm{d}^2\lambda}{\mathrm{d}u^2}+k\lambda=a,\quad \frac{\mathrm{d}^2M}{\mathrm{d}w^2}=\epsilon_2 kM. \tag{138}$$

VI. EXAMPLES

In this section we shall briefly discuss instances of double warped space–times. Notice that warped space–times are special cases of double warped ones (i.e., whenever one of the warping functions is constant), and they include relevant classes of space–times such as all the spherically, plane and hyperbolic symmetric space–times, the whole class of Friedmann–Robertson–Walker solutions, the Bertotti–Robertson space–time and many others, see Refs. 3 and 4 for further information.

Fluid space–times. We have not been able to find a proper double warped (i.e., nonwarped) perfect fluid solution due to the complicated form that the field equations take on account of the Ricci tensor (see Sec. III). However, it is indeed possible to find anisotropic fluid solutions satisfying the dominant energy condition (see Ref. 11), as the following two examples show. The energy–momentum tensor is in both cases of the Segre type $\{1,1(11)\}$, and therefore can be written as

$$T_{ab}=\mu u_a u_b+p_1 z_a z_b+p_2[x_a x_b+y_a y_b], \tag{139}$$

where $\{u_a,z_a,x_a,y_a\}$ form an orthogonal tetrad ($-u_a u^a=x^a x_a=y^a y_a=z^a z_a=1$, the rest of the

products being zero), u^a is aligned with the velocity of the fluid, and μ, p_1, p_2 are, respectively, the energy density and two (different) pressures as measured by an observer co-moving with the fluid. The dominant energy condition implies then

$$\mu \geqslant 0, \quad \mu \pm p_1 \geqslant 0, \quad \mu \pm p_2 \geqslant 0. \tag{140}$$

Case 1: Consider the line element given by

$$ds^2 = z(-dt^2 + dx^2) + t(dy^2 + dz^2), \tag{141}$$

where t and z are both non-negative. This space–time can be seen to represent an anisotropic fluid with an energy–momentum tensor given by (139) with

$$u_a = (-z^{1/2}\cosh\Phi, 0, 0, t^{1/2}\sinh\Phi), \qquad z_a = (-z^{1/2}\sinh\Phi, 0, 0, t^{1/2}\cosh\Phi),$$

$$x_a = (0, z^{1/2}, 0, 0), \quad y_a = (0, 0, t^{1/2}, 0),$$

$$\cosh\Phi = \sqrt{\frac{t}{t-z}}, \qquad \sinh\Phi = -\sqrt{\frac{z}{t-z}} \qquad \text{for} \quad t - z > 0$$

$$\cosh\Phi = \sqrt{\frac{z}{z-t}}, \qquad \sinh\Phi = -\sqrt{\frac{t}{z-t}} \qquad \text{for} \quad z - t > 0$$

and also

$$\mu = \frac{|z-t|}{4t^2z^2}, \quad p_1 = \mu, \quad p_2 = \frac{z-t}{4t^2z^2}.$$

This has to be understood as two different open submanifolds; namely, the one defined by $t - z > 0$ and that defined by $z - t > 0$. In both cases the dominant energy condition (140) is satisfied. As a final comment to this example, it can noted that the above metric admits the Killing vectors $\vec{\xi}_1 = \partial_x$, $\vec{\xi}_2 = \partial_y$, and the homothetic vector $\vec{\eta} = t\partial_t + x\partial_x + y\partial_y + z\partial_z$ with homothetic constant $\psi = 3/2$.

Case 2: Consider next the following line element:

$$ds^2 = (m - kz^2)(-dt^2 + dx^2) + (q + kt^2)(dy^2 + dz^2), \tag{142}$$

where m, k, q are constants, $m, q > 0$ and $k \geqslant 0$ in order for the energy conditions and other positivity requirements to be satisfied, and the range of the z coordinate is restricted to $m - kz^2 > 0$. Again, this represents an anisotropic fluid with energy–momentum tensor given by (139) where

$$u_a = (-(m - kz^2)^{1/2}\cosh\Phi, 0, 0, (q + kt^2)^{1/2}\sinh\Phi),$$

$$z_a = (-(m - kz^2)^{1/2}\sinh\Phi, 0, 0, (q + kt^2)^{1/2}\cosh\Phi),$$

$$x_a = (0, (m - kz^2)^{1/2}, 0, 0), \quad y_a = (0, 0, (q + kt^2)^{1/2}, 0),$$

$$\cosh 2\Phi = \frac{qz^2 + mt^2}{|qz^2 - mt^2 + 2kt^2z^2|}.$$

The density μ and the pressures p_1, p_2 are given in this case by

$$\mu = k(m - kz^2)^{-2}(q + kt^2)^{-2}\{k|qz^2 - mt^2 + 2kt^2z^2| + (m - kz^2)(q + kt^2)\},$$

$$p_1 = k(m - kz^2)^{-2}(q + kt^2)^{-2}\{k|qz^2 - mt^2 + 2kt^2z^2| - (m - kz^2)(q + kt^2)\},$$

$$p_2=\frac{(-3\,qm-2\,kt^2m+2\,qkz^2+k^2t^2z^2)k}{(-m+kz^2)^2(q+kt^2)^2}$$

and it can be seen that the dominant energy condition (140) is satisfied.

Vacuum space–times. Notice from the second equation in (66) that any double warped space–time representing a vacuum solution of Einstein's field equations, must in fact be warped (i.e., either $\theta_{1,\alpha}=0$ or $\theta_{2,A}=0$). Examples in this class include Schwarzschild solution and its plane and hyperbolic symmetric equivalents.

The characterization of class A and class B double warped space–times given in Theorems 4, 5, and 7 should prove useful in formulating an algorithm for classifying such metrics. this is so because this characterization is coordinate independent although tetrad dependent. In what follows the tetrads described in Theorems 4, 5, and 7 will be designated as dw tetrads of class A and B, respectively. In order to determine weather g represents a double warped metric we suggest the following classification scheme:

(1) Choose a coordinate system.
(2) Choose a canonical complex null tetrad $\{k_a,l_a,m_a,\overline{m}_a\}$ and write their components in the coordinate system chosen in (1).
(3) Determine the NP spin coefficients and their NP derivatives in tetrad (2).
(4) If the scalars determined in (3) satisfy the relations of Theorems 4 or 5 (Theorem 7) then the metric is a double warped space–time of class A (class B) and the algorithm stops here, otherwise go to step (5).
(5) If possible, find the Lorentz transformations that transform tetrad (2) into a dw tetrad, i.e., such that the corresponding NP spin coefficients and their NP derivatives obey the conditions of Theorems 4 or 5 (Theorem 7). If such transformations exist then the space–time is a double warped space–time of class A (class B), otherwise it is not double warped.

Unfortunately, step (5) of this procedure is not straightforward, since finding the Lorentz transformation which maps tetrad (2) into a dw tetrad can be difficult and such a transformation might not exist in which case the metric is not double warped.

The algorithm described here not only describes a way of determining whether a particular metric is double warped or not but also suggests a method for obtaining such space–times. For example, we suspect that one can obtain type D vacuum warped metrics of class B, for which $\rho=\mu=0$, by following a similar integration procedure to the one performed by Kinnersley.[18] In this paper, Kinnersley chooses coordinates such that $l^\alpha=\delta^\alpha_2$, making $x^2=r$ an affine parameter along l^α. These are the special coordinates given in Ref. 9. The idea would then be to express a dw tetrad in these special coordinates, write the NP equations taking into account (63). In order to determine explicitly the tetrad components in these special coordinates one must integrate the corresponding equations. By following this procedure we hope to obtain such metrics in future work.

Some consequences of Dyson–Lieb's $N^{(7/5)}$ law for the condensation of Bose particles are discussed. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1607515]

During the last week of July 2002, Lieb, Yngvason and one of us (HJB) were together in Vienna. Sometimes at lunch we discussed the implications of the problem stability of matter for quantum field theory. Looking more closely at this problem I observed that Dyson–Lieb's $-N^{(7/5)}$ law for the ground-state of bosons leads to problems in particle physics. In this note we shall discuss some of the problems.

The question of the stability of matter was first discussed by Dyson and Lenard.[1] They concluded that matter is stable as a consequence of the Pauli principle. But their calculation contained an estimate of the ground-state energy with errors some ten powers too large. This problem was taken up again by Lieb and Thirring with an estimate close to reality.[2] (These investigations are based on nonrelativistic quantum mechanics with a classical Coulomb field. We shall not discuss the relativistic approach to this problem, which is not in a satisfactory state. For a review see Lieb and Loss.[3]) In order to show that these results hold only for particles obeying the Pauli principle, Dyson and Lieb and co-workers repeated the same investigation for scalar bosons and found that the ground-state energy behaves like $-N^{(7/5)}$. Dyson[4] obtained the upper bound and Lieb with co-workers[5] showed the existence of a lower bound. This is based on the assumption that there exist different kinds of bosons with different electric charges. Moreover, the case considered is that of nonrelativistic quantum mechanics and a classical Coulomb field. If one assumes that a result similar to the above holds also in relativistic quantum field theory with a quantized Coulomb field, then this would have drastic consequences provided scalar bose particles exist as stable or almost stable objects.

Let us denote the two types of particles by A and B. Since they are charged they must appear in pairs A^+,A^- and B^+,B^-. We now construct two machines, one creating pairs A^+,A^- and the other pairs B^+,B^-. With help of magnetic fields the pairs may be separated and A^+,B^- sent to one and A^-,B^+ to another place. For the creation of the pairs we need the energy

$$E_A+E_B\,.$$

Each of the systems formed by one sort of pairs is attractive. If one adds an additional pair to each of the two lumps of $N-1$ pairs one gains the energy

$$(C_A+C_B)\{N^{(7/5)}-(N-1)^{(7/5)}\}\simeq(C'_a+C'_B)N^{(2/5)}.$$

This means if N is sufficiently large,

$$(C'_A+C'_B)N^{(2/5)}>E_A+E_B\,,$$

a)Electronic mail: borchers@theorie.physik.uni-goettingen.de

holds, i.e., one gains energy. (For C_A and C_B exist only lower and upper bounds, but this does not change the arguments.) This will be called "Dyson–Lieb's perpetuum mobile." Since this is forbidden by the first law of thermodynamics, one has to discuss the possibilities avoiding Dyson–Lieb's perpetuum mobile.

The simplest way would be to postulate that no stable scalar bosons exist. This is in accordance with the experimental experience up to now. But there are theories which include supersymmetries. The GUT and the string theory are only two examples. Depending on the theory, the super-symmetric partner of the electron and the proton will be stable or almost stable particles. This follows from the conservation of charge and nucleon number. Depending on the theory (see, e.g., Ref. 6), the super-symmetric partner will have spin 0 or 1. One knows that the problem of stability of matter in the relativistic situation with a quantized Coulomb field is very delicate. Therefore, it is no danger to guess that also in the spin 1 situation the ground-state energy behaves like $-N^{\alpha}$ with $\alpha>1$. This also leads to Dyson–Lieb's perpetuum mobile and one has to think about possibilities to avoid it.

The first possibility which comes into ones mind is the following. If the pair, say (A^+,B^-), falls into a deep potential cavity, then it might create an electron–positron pair. If this remains at the surface of the lump and combines with particles A^+ and B^-, respectively, then they create neutral particles containing a spin $\frac{1}{2}$ component which do not increase the number N. In this case the perpetuum mobile has stopped. But the surface effect will appear only occasionally. If the lump is large enough, then the particles will form a crystal like an ionic crystal. Although the particles have no extension this could be B1 (NaCl–) or B2 (CsCl structure) in the Strukturbericht designation (see Kleber[7]), which are not close packed. Only at high pressures the system might be forced into a close packed structure, since this gives problems with nearest neighbors of equal charge. This then implies that the electron and positron will be trapped in the conduction band where they can annihilate each other. Therefore, this kind of interaction does not avoid Dyson–Lieb's perpetuum mobile. If one has in mind the super-symmetric partner of the electron and proton, then the formation of an ionic crystal might not be a good picture, but one should think about a system similar to hydrogen. Since condensed hydrogen forms are close packed crystals made out of neutral pairs, the electron–positron pair will destroy such a neutral molecule only occasionally. Therefore, also this is no way out of the perpetuum mobile problem.

The proton is composed of quarks. Therefore, its super-symmetric partner will probably be composed of the super-symmetric partners of the quarks. These will also have entire spin and, therefore, one has to expect that the ground-state energy tends to $-\infty$ with N to infinity.
Our personal conclusion of the discussion is the following:

The first law of thermodynamics forbids the existence of stable super-symmetric partners, i.e. the existence of super-symmetry in the naïve sense.

This argument has some similarity with the conclusion that the second law, together with the existence of the entropy of mixing, implies atomic nature of the matter. However, we think that our conclusion has a more solid base.

Comment on "Time-dependent solution for a star immersed in a background radiation" [H. Liu and Q. Zhang, J. Math. Phys. 43, 4904 (2002)]

K. S. Govinder[a] and M. Govender[b]
School of Mathematical and Statistical Sciences, University of Natal, Durban 4041, South Africa

(Received 4 February 2003; accepted 8 April 2003)

In a recent paper [J. Math. Phys. **43**, 4904 (2002)] Liu and Zhang present a time-dependent solution for a star which is immersed in a background radiation. This solution was obtained by analyzing equations arising from the analysis of a five-dimensional solution that contained their solution. We show that, while their analysis and conclusions are valid, their equations are unnecessarily restrictive when applied to the four-dimensional case. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1610238]

Recently, Liu and Wesson[1] presented a simple class of five-dimensional (5D) solutions. It was further shown that the four-dimensional (4D) part of the 5D metric, together with two restrictions on the metric functions, represents a 4D spherically symmetric solution with heat flux. This form of the solution was further studied by Liu and Zhang[2] in which they showed that the solution could be considered as an exterior of a collapsing star immersed in a homogeneous and isotropic background.

The form of the solution as reported by Liu and Zhang in coordinates $(x^a)=(t,r,\theta,\phi)$ is

$$ds^2=-B(r)dt^2+(1-\lambda t)^2[A(r)dr^2+r^2(d\theta^2+\sin^2\theta\, d\phi^2)], \tag{1}$$

where λ is a constant and the metric functions A and B obey the following equations:

$$\frac{B'}{B}=3\lambda^2 r\frac{A}{B}+\frac{A-1}{r}, \tag{2}$$

$$\frac{A'}{A}=3\lambda^2 r\frac{A}{B}-\frac{A-1}{r}, \tag{3}$$

where primes denote differentiation with respect to r. It was further shown by Liu and Wesson[1] that metric (1) together with the above-given restrictions models a perfect fluid with heat flux in which the energy momentum tensor assumes the following form:

$$T_{ab}=(\rho+p)u_a u_b-pg_{ab}+q_a u_b+u_a q_b, \tag{4}$$

where ρ is the fluid energy density, p is the isotropic pressure, $u_a=(u^0,0,0,0)$ is the fluid four-velocity, and $q_a=(0,q^1,0,0)$ is the radial heat flux vector. The heat flow vector satisfies the condition $q^a u_a=0$ relative to the fluid four-velocity vector. The nontrivial Einstein equations [taking (2) and (3) into account] are given by

[a]Electronic mail: govinder@nu.ac.za
[b]Electronic mail: govenderm43@nu.ac.za

$$\rho = \frac{6\lambda^2}{B(1-\lambda t)^2}, \tag{5}$$

$$p = \frac{2\lambda^2}{B(1-\lambda t)^2}, \tag{6}$$

$$q = \frac{\lambda B'}{A^{1/2}B^{3/2}(1-\lambda t)^2}, \tag{7}$$

where q is a covariant measure of the heat flux ($q^2 = q^a q_a$).

Equations (2) and (3) were obtained by Liu and Wesson[1] from the Ricci tensor for the 5D metric within which (1) was embedded. They assumed that the scalar field was time-like which forced some components of the 4D Ricci tensor to be zero, thus resulting in (2) and (3). An interesting feature of these two equations is that, if $A(r)$ and $B(r)$ satisfy these equations, then the pressure isotropy condition is automatically satisfied and the matter content satisfies the radiation equation of state

$$\rho = 3p. \tag{8}$$

However, if one looks at the metric (1) in isolation, i.e., one does not concern oneself with its origin in the 5D metric, then Eqs. (2) and (3), while simplifying calculations, are unnecessarily restrictive. This is a consequence of the fact that the system consisting of the pressure isotropy equation, viz.

$$\frac{1}{r^2} - \frac{1}{r^2 A} - \frac{A'}{2\,r\,A^2} - \frac{B'}{2\,r\,A\,B} - \frac{A'\,B'}{4\,A^2\,B} - \frac{B'^2}{4\,A\,B^2} + \frac{B''}{2\,A\,B} = 0 \tag{9}$$

and the equation of state

$$\frac{1}{r^2} + \frac{\alpha}{r^2} - \frac{1}{r^2 A} - \frac{\alpha}{r^2 A} + \frac{3\,\lambda^2}{B} + \frac{\alpha\,\lambda^2}{B} + \frac{A'}{r\,A^2} - \frac{\alpha\,B'}{r\,A\,B} = 0 \tag{10}$$

[here we have given the general barotropic equation of state $p = \alpha\rho$—setting $\alpha = 1/3$ regains (8)] is of higher order than the system (2) and (3). Thus a solution of (9) and (10) need not satisfy (2) and (3) while a solution of the latter *must* satisfy the former.

The solutions presented by Liu and Zhang[2] were only approximate. However, exact solutions to (2) and (3) are possible, and indeed have appeared in the literature previously,[3] though in the guise of solutions to (9) and (10). That solution has the form

$$ds^2 = -\beta^2\,Y_o^2\,dt^2 + Y^2(t)\,[2\,Y_o'^2\,dr^2 + Y_o^2\,d\Omega^2] \tag{11}$$

up to the determination of the time-dependence $Y(t)$. In addition to the general solution for $Y(t)$, it was observed in Ref. 3 that a linear form for $Y(t)$ would also suffice.

In order to compare (1) and (11) we need to set

$$\beta^2 = \frac{2\lambda^2(3+\alpha)}{\alpha-1}, \quad Y_o = r, \quad A(r) = 2, \quad B(r) = \beta^2 r^2, \quad Y(t) = (1-\lambda t). \tag{12}$$

Thus the metric

$$ds^2 = -\beta^2 r^2 dt^2 + (1-\lambda t)^2[2dr^2 + r^2\,d\Omega^2] \tag{13}$$

satisfies the pressure isotropy condition as well as the general barotropic equation of state (10). Clearly it will satisfy the radiation equation of state (8) as well.

While our metric (13) does satisfy the general equation of state (10), an attempt to match this metric to the Vaidya solution[4] (which describes the exterior space–time of a radiating star)

$$ds^2 = -\left(1 - \frac{2m(v)}{r}\right)dv^2 - 2\,dv\,dr + r^2(d\theta^2 + \sin^2\theta\, d\phi^2) \tag{14}$$

restricts the value of α to -3 which is unphysical. Thus the solution we present will not satisfy (8) if we match the solution to the Vaidya solution. Indeed, if we match a solution of (2) and (3) to (14), we need to satisfy the condition

$$\lambda = \left.\frac{B'}{2(AB)^{1/2}}\right|_{r=r_\Sigma} \tag{15}$$

at the boundary $r = r_\Sigma$. Thus, given a particular boundary r_Σ, one ought to be able to determine λ. We do not obtain this result in our solution (11) as we have $B \propto \lambda^2$. It would be of interest[5] to find an exact solution to (8) and (9) which can be matched to (14) as the model can be interpreted as a radiating star with an extended atmosphere dissipating energy in the form of radial heat flux.

We observe that the time dependence in the metric (1) is linear. As a result, horizon-free collapse[6] is evident in this model when matching to (14) since m_Σ / r_Σ is independent of time.

We conclude by noting that the solution we present, (13), does not have the same interesting physical properties that the approximate solution of Liu and Zhang[2] does. However, it is an exact solution. It would be useful to examine the full pressure isotropy equation (9) and the general equation of state (10) [or the radiation equation of state (8)] for further exact solutions that may provide similarly interesting physical applications.

(Received 12 July 2003; accepted 24 July 2003)

For the one-dimensional Schrödinger equation, the analysis is provided to recover the potential from the data consisting of the ratio of a reflection coefficient to the transmission coefficient. It is investigated whether such data uniquely constructs a reflection coefficient, the number of bound states, bound-state energies, bound-state norming constants, and a corresponding potential. In all three cases when there is no knowledge of the support of the potential, the support of the potential is confined to a half-line, and the support is confined to a finite interval, various uniqueness and nonuniqueness results are established, the precise criteria are provided for the uniqueness and the nonuniqueness and the degree of nonuniqueness, and the recovery is illustrated with some explicit examples. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1614871]

I. INTRODUCTION

In this paper we investigate the recovery of the potential of the one-dimensional Schrödinger equation from the data consisting of the ratio of a reflection coefficient to the transmission coefficient. We analyze the cases where the potential has no restriction on its support, half-line support, and compact support. We assume no information about the number of bound states, and in fact we try to recover that number as a part of our inverse problem.

Our work is motivated by the work of Rundell and Sacks[1] where it was shown that a bounded, compactly supported potential with a sufficiently small L^2-norm is uniquely determined by the corresponding ratio of a reflection coefficient to the transmission coefficient. In our paper we show exactly when such a determination is possible.

Consider the Schrödinger equation

$$\psi''(k,x)+k^2\,\psi(k,x)=V(x)\,\psi(k,x), \quad x\in\mathbf{R}, \tag{1.1}$$

where the potential V belongs to the Faddeev class, i.e., it is real valued, measurable, and in $L^1_1(\mathbf{R})$. Here, $L^1_n(J)$ denotes the class of measurable functions on an interval J such that $\int_J dx\,(1+|x|^n)\,|V(x)|$ is finite. The prime is used for the derivative with respect to the spatial coordinate x. The scattering solutions to (1.1) behave like e^{ikx} or e^{-ikx} as $x\to\pm\infty$, and they occur for $k\in\mathbf{R}\backslash\{0\}$. A bound state of (1.1) is a solution that belongs to $L^2(\mathbf{R})$ in the x variable, and it is known[2–7] that the bound states can occur only at certain k values on the positive imaginary axis $\mathbf{I}^+$ in $\mathbf{C}^+$. We use $\mathbf{C}^+$ for the upper-half complex plane and $\mathbf{I}^+:=i(0,+\infty)$; later we will let $\overline{\mathbf{C}^+}:=\mathbf{C}^+\cup\mathbf{R}$ and $\mathbf{I}^-:=i(-\infty,0)$. We will use N to denote the number of bound states, which is known to be finite when V is in the Faddeev class, and suppose that the bound states occur at $k=i\kappa_j$ with the ordering $0<\kappa_1<\cdots<\kappa_N$.

Among the scattering solutions to (1.1) are f_l and f_r, the Jost solutions from the left and right, respectively, satisfying the respective boundary conditions

$$e^{-ikx}f_l(k,x)=1+o(1),\quad e^{-ikx}f_l'(k,x)=ik+o(1),\quad x\to+\infty,$$

$$e^{ikx}f_r(k,x)=1+o(1),\quad e^{ikx}f_r'(k,x)=-ik+o(1),\quad x\to-\infty. \tag{1.2}$$

From the spatial asymptotics

$$f_l(k,x)=\frac{e^{ikx}}{T(k)}+\frac{L(k)\,e^{-ikx}}{T(k)}+o(1),\quad x\to-\infty, \tag{1.3}$$

$$f_r(k,x)=\frac{e^{-ikx}}{T(k)}+\frac{R(k)\,e^{ikx}}{T(k)}+o(1),\quad x\to+\infty,$$

we obtain the transmission coefficient T, and the reflection coefficients L and R from the left and right, respectively. It is known[2–7] that

$$T(-k)=T(k)^*,\quad R(-k)=R(k)^*,\quad L(-k)=L(k)^*,\quad k\in\mathbf{R},$$

$$R(k)=-\frac{L(-k)\,T(k)}{T(-k)},\quad |T(k)|^2+|L(k)|^2=1,\quad k\in\mathbf{R}, \tag{1.4}$$

where the asterisk denotes complex conjugation. In general, R and L are defined only for real k values, but T has a meromorphic extension to $\mathbf{C}^+$. Each bound state corresponds to a (simple) pole of T in $\mathbf{C}^+$ and vice versa. Given $|T(k)|$ for $k\in\mathbf{R}$ and the bound-state poles $k=i\kappa_j$, one can construct T as[2–7]

$$T(k)=\left(\prod_{j=1}^{N}\frac{k+i\kappa_j}{k-i\kappa_j}\right)\exp\left(\frac{1}{\pi i}\int_{-\infty}^{\infty}ds\,\frac{\log|T(s)|}{s-k-i0^+}\right),\quad k\in\overline{\mathbf{C}^+}. \tag{1.5}$$

A potential V in the Faddeev class is said to be generic if $T(0)=0$ and exceptional if $T(0)\neq 0$. Generically we have

$$\lim_{k\to 0}\frac{2ik\,L(k)}{T(k)}=(-1)^N|W_0|+o(1),\quad k\to 0\ \text{ in }\mathbf{R}, \tag{1.6}$$

where the Wronskian $W_0:=f_r(0,x)\,f_l'(0,x)-f_r'(0,x)\,f_l(0,x)$ is a nonzero constant. On the other hand, in the exceptional case we have

$$\lim_{k\to 0}\frac{L(k)}{T(k)}=\frac{\gamma_0^2-1}{2\gamma_0}+o(1),\quad k\to 0\ \text{ in }\mathbf{R}, \tag{1.7}$$

where

$$\gamma_0:=\frac{f_l(0,x)}{f_r(0,x)}=(-1)^N\left|\frac{f_l(0,x)}{f_r(0,x)}\right|$$

is a nonzero constant.

A potential in the Faddeev class is uniquely determined from the data $\{L,\{\kappa_j\},\{c_{rj}\}\}$ or $\{L,\{\kappa_j\},\{\gamma_j\}\}$ by using any one of the available methods.[2–7] Here, c_{rj}, for each $j=1,\ldots,N$, represents the bound-state norming constant and γ_j the dependency constant associated with $k=i\kappa_j$, and they are related to the Jost solutions as

$$c_{rj}:=\left[\int_{-\infty}^{\infty}dx\,f_r(i\kappa_j,x)^2\right]^{-1/2},\quad \gamma_j:=\frac{f_l(i\kappa_j,x)}{f_r(i\kappa_j,x)}. \tag{1.8}$$

Given V, we can remove[2–7] all the bound states from the scattering coefficients and construct the resulting potential $V^{[0]}$ corresponding to the transmission coefficient $T^{[0]}$ and the left reflection coefficient $L^{[0]}$, where

$$T(k)=T^{[0]}(k)\prod_{j=1}^{N}\frac{k+i\kappa_j}{k-i\kappa_j},\quad L(k)=(-1)^N L^{[0]}(k)\prod_{j=1}^{N}\frac{k+i\kappa_j}{k-i\kappa_j}. \tag{1.9}$$

The potential $V^{[0]}$ belongs to the Faddeev class whenever V is in that class.

Without loss of any generality, our main problem can be reduced to the recovery of a potential V in the Faddeev class from the data $\mathcal{D}(k):=L(k)/T(k)$ in the following cases:

(i) V has no restrictions on its support.
(ii) The support of V is confined to a half-line.
(iii) The support of V is confined to a finite interval.

Our paper is organized as follows. In Sec. II we study case (i); we see that our data cannot say anything about the value of N in the exceptional case and hence $N\in\{0,1,2,\dots\}$, and for each such N we have a $2N$-parameter family of potentials corresponding to our data. On the other hand, in the generic case from our data we get $N\in\{0,2,4,\dots\}$ or $N\in\{1,3,5,\dots\}$, as indicated in (1.6); for each allowed N we again have a $2N$-parameter family of potentials corresponding to $\mathcal{D}$. Case (ii) is analyzed in Sec. III, and we show that our data puts a further restriction on the maximum allowable value for N and that $N-1$ cannot exceed the number of zeros of $\mathcal{D}$ on $\mathbf{I}^+$. In particular, in the generic case where $\mathcal{D}$ has no zeros on $\mathbf{I}^+$ and the limit in (1.6) is positive, we conclude that $N=0$ and hence there is a unique potential corresponding to $\mathcal{D}$. We also show that our data restricts the (open) intervals in which the κ_j can occur, depending on the sign of $\mathcal{D}$ on $\mathbf{I}^+$. Then, for each allowed N we obtain an N-parameter family of potentials supported on the positive half-line corresponding to our data. We illustrate the nonuniqueness with some explicit examples. Finally, in Sec. IV, we analyze case (iii) and show that our data further puts severe restrictions on the locations of the κ_j. In this case we show that for each allowed N, there can exist only a discrete number of potentials corresponding to the same $\mathcal{D}$. We provide the exact criteria for the uniqueness as well as the nonuniqueness and the degree of nonuniqueness, and we illustrate the theory with some explicit examples.

II. RECOVERY WITH NO RESTRICTION ON THE SUPPORT

We will analyze the construction of V from the data $\mathcal{D}$ by analyzing the construction of $\{L,\{\kappa_j\},\{c_{rj}\}\}$ from $\mathcal{D}$.

Given $\mathcal{D}(k)$ for $k\in\mathbf{R}$, we can construct $T^{[0]}$. This is because, as seen from (1.9) and the second equation in (1.4), we have

$$\frac{1}{|T^{[0]}(k)|^2}=\frac{1}{|T(k)|^2}=1+|\mathcal{D}(k)|^2,\quad k\in\mathbf{R}, \tag{2.1}$$

and hence, (1.5) and (2.1) imply that

$$T^{[0]}(k)=\exp\left(\frac{1}{2\pi i}\int_{-\infty}^{\infty}ds\,\frac{\log(1/[1+|\mathcal{D}(s)|^2])}{s-k-i0^+}\right),\quad k\in\overline{\mathbf{C}^+}. \tag{2.2}$$

Having found $T^{[0]}$, from (1.9) we get

$$L^{[0]}(k)=(-1)^N\mathcal{D}(k)\,T^{[0]}(k),\quad L(k)=\mathcal{D}(k)\,T^{[0]}(k)\left(\prod_{j=1}^{N}\frac{k+i\kappa_j}{k-i\kappa_j}\right). \tag{2.3}$$

Thus, to construct L from $\mathcal{D}$, we must know both the number of bound states and the bound-state energies. In the generic cases, as (1.6) implies, from $\mathcal{D}$ we are only able to determine whether N is even or odd, but in the exceptional case even this is not possible, as implied by (1.7). For $N=0$, as seen from (2.3), $\mathcal{D}$ uniquely determines L and hence also V.

In summary, given the data $\mathcal{D}$, we get, for each value of N, a $2N$-parameter family of corresponding potentials, where $\{\{\kappa_j\},\{c_{rj}\}\}$ represents the parameter set. If $\mathcal{D}(k)$ is bounded at $k=0$ then N can be any non-negative integer; if $\mathcal{D}(k)$ is unbounded at $k=0$, then N is a non-negative integer, which is odd or even depending on the sign of $\lim_{k\to 0}[2ik\,\mathcal{D}(k)]$ as in (1.6).

Example 2.1: Let us demonstrate that we can tell from $\mathcal{D}$ whether N is even or odd in the generic case, but not in the exceptional case. Consider

$$\mathcal{D}(k)=\frac{\alpha}{(k+ic_+)(k+ic_-)},\quad c_\pm:=\sqrt{10\pm\sqrt{\alpha^2+36}},$$

where $\alpha\in[-8,8]$ is a parameter. Note that $\alpha=\pm 8$ corresponds to the generic case and $\alpha\in(-8,8)$ corresponds to the exceptional case. In the generic case from (1.6) we get $2ik\,\mathcal{D}(k)=\alpha/\sqrt{5}+O(k)$ as $k\to 0$, and hence N must be even if $\alpha=8$ and odd if $\alpha=-8$. On the other hand, in the exceptional case, from (1.7) we get $\mathcal{D}(k)=\alpha/\sqrt{64-\alpha^2}+O(k)$ as $k\to 0$, and N can be any non-negative integer. In fact, the corresponding scattering coefficients for $\alpha\in[-8,8]$ are given by

$$L(k)=\frac{(-1)^N\alpha}{(k+2i)(k+4i)}\left(\prod_{j=1}^{N}\frac{k+i\kappa_j}{k-i\kappa_j}\right),\quad T(k)=\frac{(k+ic_+)(k+ic_-)}{(k+2i)(k+4i)}\left(\prod_{j=1}^{N}\frac{k+i\kappa_j}{k-i\kappa_j}\right),$$

where $L(0)=-1$ and $T(0)=0$ are assured in the generic case by the choice $N\in\{0,2,4,\dots\}$ if $\alpha=8$ and $N\in\{1,3,5,\dots\}$ if $\alpha=-8$.

III. RECOVERY WITH SUPPORT ON A HALF-LINE

In this section we analyze the construction of V from $\mathcal{D}$ when we further know that the support of V is confined to a half-line. Equivalently, we analyze the construction of $\{L,\{\kappa_j\},\{c_{rj}\}\}$ from our data.

There is no loss of generality in assuming that the support of V is confined to $\mathbf{R}^+$. This can be seen by the following argument. If the support of the potential is known to be confined to the interval $(a,+\infty)$ for some real constant a, then the value of a can be extracted[8] from $\mathcal{D}$; the shift $V(x)\mapsto V(x-a)$ results in $L(k)/T(k)\mapsto L(k)\,e^{2ika}/T(k)$ and hence there is no loss of generality in assuming that $a\equiv 0$. On the other hand, if the support of the potential is known to be confined to $\mathbf{R}^-$, then, because of the first equation in (1.4), our problem can also be formulated as the recovery of V from R/T, which is equivalent to the recovery of V from $\mathcal{D}$.

When the support of V is confined to $\mathbf{R}^+$, it is already known[9–14] that L uniquely determines V. In fact, the meromorphic extension of $L(k)$ from $\mathbf{R}$ to $\mathbf{C}^+$ uniquely determines $\{\{\kappa_j\},\{c_{rj}\}\}$ as indicated in Theorem 3.3 below. Thus, the number of arbitrary parameters appearing in the reflection coefficient L constructed from our data is the same as the number of parameters appearing in the constructed V.

In Sec. II we have seen that $\mathcal{D}$ in the generic case reveals whether N is even or odd. We will next show that knowledge that the support of V is confined to $\mathbf{R}^+$ leads to an upper bound on N both in the generic and exceptional cases.

Proposition 3.1: Assume $V^{[0]}$ is a potential in the Faddeev class, has support in $\mathbf{R}^+$, and has no bound states. Suppose V is the potential obtained by adding N successive bound states to $V^{[0]}$ at $k=i\kappa_j$ with $0<\kappa_1<\cdots<\kappa_N$, and let $L^{[0]}$ denote the left reflection coefficient for $V^{[0]}$ as in (1.9). If the support of V is confined to $\mathbf{R}^+$, then $(-1)^jL^{[0]}(i\kappa_j)>0$ for $j=1,\dots,N$, or equivalently, $(-1)^{N-j}\mathcal{D}(i\kappa_j)>0$.

Proof: If $V\equiv 0$ for $x<0$, from (1.2) and (1.3) we see that

$$f_r(k,x)=e^{-ikx},\quad f_l(k,x)=\frac{e^{ikx}}{T(k)}+\frac{L(k)\,e^{-ikx}}{T(k)},\quad x\leqslant 0. \tag{3.1}$$

Hence, using $1/T(i\kappa_j)=0$, (3.1), and the second equation in (1.8), we reach the conclusion that $\gamma_j=(L/T)(i\kappa_j)$. Then, with the help of (1.9), we get $L^{[0]}(i\kappa_j)=(-1)^N\gamma_j T^{[0]}(i\kappa_j)$. It is already known that $T^{[0]}(k)>0$ on $\mathbf{I}^+$ and $(-1)^{N-j}\gamma_j>0$. Thus, $(-1)^jL^{[0]}(i\kappa_j)>0$ for $j=1,\ldots,N$. With the help of $\mathcal{D}(k)=(-1)^NL^{[0]}(k)/T^{[0]}(k)$, we equivalently claim that $(-1)^{N-j}\mathcal{D}(i\kappa_j)>0$. ■

For $k\in\mathbf{I}^+$ we know that $L^{[0]}(k)$ is real valued and continuous and $1/T^{[0]}(k)>0$; hence, from Proposition 3.1 we obtain the following result.

Corollary 3.2: Assume V belongs to the Faddeev class, has N bound states, and has support in $\mathbf{R}^+$. *Let* $L^{[0]}$ *denote the left reflection coefficient for* $V^{[0]}$, *which is obtained from V by removing all the bound states, as in (1.9). Then,* $L^{[0]}$ *must have at least* $N-1$ *zeros on* $\mathbf{I}^+$, *equivalently,* $\mathcal{D}$ *must have at least* $N-1$ *zeros on* $\mathbf{I}^+$.

Let us note that the zeros of $L^{[0]}$ on $\mathbf{I}^+$, or equivalently those of $\mathcal{D}$, need not be simple, as indicated in Examples 3.8 and 3.9.

The following theorem gives a characterization of the left reflection coefficient corresponding to a potential in the Faddeev class with support confined to $\mathbf{R}^+$. Let

$$\hat{L}(\alpha):=\frac{1}{2\pi}\int_{-\infty}^{\infty}dk\,L(k)\,e^{ik\alpha},\quad \hat{R}(\alpha)=:-\frac{1}{2\pi}\int_{-\infty}^{\infty}dk\,\frac{L(-k)\,T(k)}{T(-k)}e^{ik\alpha}. \tag{3.2}$$

Theorem 3.3: *The left reflection coefficient L corresponds to a unique potential V in the Faddeev class with support in* $\mathbf{R}^+$ *and with N bound states at* $k=i\kappa_j$ $(j=1,\ldots,N)$ *if and only if the following conditions hold:*

(i) *L is continuous on* $\mathbf{R}$, *and* $L(-k)=L(k)^*$ *for* $k\in\mathbf{R}$.
(ii) $|L(k)|\leqslant 1-Ck^2/(1+k^2)$ *on* $\mathbf{R}$ *for some positive constant C*.
(iii) $L(0)\in[-1,1)$.
(iv) *L has a meromorphic extension to* $\mathbf{C}^+$ *with N simple poles occurring at* $k=i\kappa_j$ *and residues* $\mathrm{Res}L(i\kappa_j)=ic_{rj}^2$ *for some positive constants* c_{rj}. *Of course, if* $N=0$ *then the extension of L to* $\mathbf{C}^+$ *is analytic there.*
(v) $L(k)=o(1/k)$ *as* $k\to\infty$ *in* $\overline{\mathbf{C}^+}$.
(vi) *The function* $k/T(k)$, *where* $T(k)$ *is given in (1.5) with* $|T(s)|=\sqrt{1-|L(s)|^2}$, *is continuous in* $\overline{\mathbf{C}^+}$.
(vii) *The functions* $\hat{L}$ *and* $\hat{R}$ *defined in (3.2) are absolutely continuous,* $\hat{L}'\in L_1^1(-\infty,0)$, *and* $\hat{R}'\in L_1^1(a,+\infty)$ *for any* $a<0$.

Proof: The proof is obtained by modifying the characterization conditions on the scattering data[5,7,15] corresponding to a potential in the Faddeev class in order to take into account the vanishing property of the potential on $\mathbf{R}^-$. It is known[9–14] that (iv) is equivalent to vanishing of V on $\mathbf{R}^-$. The slight modification in (vii) is also related to the vanishing of the potential on $\mathbf{R}^-$. ■

In the following we illustrate the recovery of V, or equivalently of L, by presenting some explicit examples.

Example 3.4: Let our data for a potential with support in $\mathbf{R}^+$ be given by

$$\mathcal{D}(k)=\frac{-\sqrt{3}(k-i)(k-3i)}{(k+i)^2(k+\sqrt{5}i)(k+3i)}.$$

Notice that $\mathcal{D}(k)$ is bounded at $k=0$ and hence this corresponds to an exceptional case. Proceeding as in (2.2), or equivalently by solving the Riemann–Hilbert problem [cf. (2.1)]

$$\frac{1}{T^{[0]}(-k)} = (1+|\mathcal{D}(k)|^2)\, T^{[0]}(k), \quad k \in \mathbf{R},$$

we obtain

$$T^{[0]}(k) = \frac{(k+i)(k+\sqrt{5}i)}{(k+\sqrt{2}i)(k+2i)}.$$

From (2.3) we get

$$L^{[0]}(k) = (-1)^N A(k), \quad A(k) := \frac{-\sqrt{3}\,(k-i)(k-3i)}{(k+i)(k+\sqrt{2}i)(k+2i)(k+3i)}.$$

Notice that $\mathcal{D}$ has two zeros on $\mathbf{I}^+$. Hence, the number of bound states of V cannot exceed 3. Since this is the exceptional case, N is allowed to be any of 0, 1, 2, and 3. Recalling the fact that L uniquely determines V because of the support property of V, with the help of the sign restriction indicated in Proposition 3.1, or equivalently, with the help of Theorem 3.3(iv), we obtain all the following possibilities for L and also for V:

(a) For $N=0$, we have $L(k)=A(k)$, and the potential V is uniquely determined.
(b) For $N=1$, we have $L(k)=A(k)\,(k+i\kappa_1)/(k-i\kappa_1)$, where $\kappa_1 \in (0,1)\cup(3,+\infty)$ is the only arbitrary parameter in V.
(c) For $N=2$, we get $L(k)=A(k)\Pi_{j=1}^{2}(k+i\kappa_j)/(k-i\kappa_j)$, with $\kappa_1 \in (1,3)$ and $\kappa_2 \in (3,+\infty)$ being the only two arbitrary parameters in V.
(d) For $N=3$, we have $L(k)=A(k)\Pi_{j=1}^{3}(k+i\kappa_j)/(k-i\kappa_j)$, where $\kappa_1 \in (0,1)$, $\kappa_2 \in (1,3)$, and $\kappa_2 \in (3,+\infty)$ are the only three arbitrary parameters in V.

Example 3.5: Let $\mathcal{D}(k) = 8/k(k+i\sqrt{20})$. This is the generic case because $\mathcal{D}(k)$ is singular at $k=0$. Using (2.1) we obtain $T^{[0]}(k) = k(k+i\sqrt{20})/(k+2i)(k+4i)$. From (1.6) we see that $\lim_{k\to 0}[2ik\,\mathcal{D}(k)] = 8/\sqrt{5}$, which is positive, and therefore $N \in \{0,2,4,\dots\}$. Then, from the first equation in (2.3) we get $L^{[0]}(k) = 8/(k+2i)(k+4i)$. Since $\mathcal{D}$ has no zeros on $\mathbf{I}^+$, Corollary 3.2 implies that the only possibility is $N=0$. Thus, $L(k)=L^{[0]}(k)$, and our data uniquely determines L and V.

Example 3.6: Let $\mathcal{D}(k) = -8/k(k+i\sqrt{20})$. As in Example 3.5, this is the generic case and $T^{[0]}(k) = k(k+i\sqrt{20})/(k+2i)(k+4i)$. From (1.6) we see that $\lim_{k\to 0}[2ik\,\mathcal{D}(k)] = -8/\sqrt{5}$, which is negative, and hence $N \in \{1,3,5,\dots\}$. Then, from the first equation in (2.3) we get $L^{[0]}(k) = 8/(k+2i)(k+4i)$. Since $\mathcal{D}$ has no zeros on $\mathbf{I}^+$, Corollary 3.2 implies that the only possibility is $N=1$. Thus, we get $L(k) = -L^{[0]}(k)\,(k+i\kappa_1)/(k-i\kappa_1)$, where $\kappa_1 \in (0,+\infty)$ is an arbitrary parameter. Because the constructed L contains one arbitrary parameter, there exists a one-parameter family of potentials corresponding to our data.

Example 3.7: Let $\mathcal{D}(k) = -8(k-3i)(k-4i)/k(k+i\sqrt{20})(k+3i)(k+4i)$. As in Example 3.5, this is the generic case and $T^{[0]}(k) = k(k+i\sqrt{20})/(k+2i)(k+4i)$. From (1.6) we see that $\lim_{k\to 0}[2ik\,\mathcal{D}(k)] = -8/\sqrt{5}$, which is negative, and hence $N \in \{1,3,5,\dots\}$. Then, as in Example 3.5 we get $L^{[0]}(k) = 8(k-3i)(k-4i)/(k+2i)(k+3i)(k+4i)^2$. Since $\mathcal{D}$ has two zeros on $\mathbf{I}^+$, N cannot exceed 3. Thus, we must have $N=1$ or $N=3$. In conjunction with Proposition 3.1 or Theorem 3.3(iv), for $N=1$ we get the one-parameter family $L(k) = -L^{[0]}(k)\,(k+i\kappa_1)/(k-i\kappa_1)$ with $\kappa_1 \in (0,3)\cup(4,+\infty)$ and for $N=3$ we get $L(k) = -L^{[0]}(k)\Pi_{j=1}^{3}(k+i\kappa_j)/(k-i\kappa_j)$ with $\kappa_1 \in (0,3)$, $\kappa_2 \in (3,4)$, and $\kappa_3 \in (4,+\infty)$. Thus, our data corresponds to a one-parameter family of potentials when $N=1$, and it corresponds to a three-parameter family of potentials when $N=3$.

Example 3.8: Let $\mathcal{D}(k) = 8(k-i)^2/k(k+i\sqrt{20})(k+i)^2$. We see that $\mathcal{D}$ has exactly one (double) zero on $\mathbf{I}^+$. As in Example 3.5 we get

$$T^{[0]}(k)=\frac{k(k+i\sqrt{20})}{(k+2i)(k+4i)},\quad L^{[0]}(k)=\frac{8(k-i)^2}{(k+2i)(k+4i)(k+i)^2}. \tag{3.3}$$

Note that $\lim_{k\to 0}[2ik\,\mathcal{D}(k)]=8/\sqrt{5}$, which is positive, and hence (1.6) implies that $N\in\{0,2,4,\dots\}$. On the other hand, Corollary 3.2 implies that $N=0$ or $N=2$; however, a sign analysis of $\mathcal{D}$ on $\mathbf{I}^+$ indicates that $\mathcal{D}(i\beta)<0$ for $\beta\in(0,1)\cup(1,+\infty)$ and $\mathcal{D}(i\beta)=0$ for $\beta=1$. Thus, $N=2$ is incompatible with Proposition 3.1. Hence, $N=0$ is the only possibility, and T and L are uniquely determined by our data as equal to $T^{[0]}$ and $L^{[0]}$, respectively, given in (3.3). Therefore, there exists a unique potential corresponding to our data.

Example 3.9: Let $\mathcal{D}(k)=-8(k-i)^2/k(k+i\sqrt{20})(k+i)^2$. The corresponding $T^{[0]}$ and $L^{[0]}$ are the same as in (3.3). From (1.6) we see that $\lim_{k\to 0}[2ik\,\mathcal{D}(k)]=-8/\sqrt{5}$, which is negative, and hence $N\in\{1,3,5,\dots\}$, as implied by (1.6). A sign analysis of $\mathcal{D}$ on $\mathbf{I}^+$ indicates that $\mathcal{D}(i\beta)>0$ for $\beta\in(0,1)\cup(1,+\infty)$ and $\mathcal{D}(i\beta)=0$ for $\beta=1$. Hence, with the help of Corollary 3.2 we conclude that $N=1$ is the only possibility. We thus obtain

$$T(k)=\frac{k(k+i\sqrt{20})(k+i\kappa_1)}{(k+2i)(k+4i)(k-i\kappa_1)},\quad L(k)=\frac{-8(k-i)^2(k+i\kappa_1)}{(k+2i)(k+4i)(k+i)^2(k-i\kappa_1)},$$

with $\kappa_1\in(0,1)\cup(1,+\infty)$. Therefore, our data corresponds to a one-parameter family of potentials, where κ_1 acts as the parameter.

IV. RECOVERY WITH COMPACT SUPPORT

In this section we analyze the recovery of V, or equivalently of L, from $\mathcal{D}$ when it is further known that the support of V is confined to a finite interval. In constructing $\{L,\{\kappa_j\},\{c_{rj}\}\}$ from $\mathcal{D}$, all the results obtained in Secs. II and III are certainly valid in this section as well. We have the following:

(i) In the generic case, we are able to tell via (1.6) whether the non-negative integer N representing the number of bound states of V is even or odd.
(ii) Using (2.2) and the second equation in (2.3), we are able to construct $T^{[0]}$ and determine L except perhaps for the values of $\kappa_1,\dots,\kappa_N$.
(iii) Let us use Z to denote the number of zeros of $\mathcal{D}$ on $\mathbf{I}^+$. From Corollary 3.2 we conclude that $N\leqslant Z+1$. Moreover, Proposition 3.1 imposes a further restriction on N depending on the sign of $\mathcal{D}$ on $\mathbf{I}^+$.
(iv) The quantity $T^{[0]}$, which is uniquely determined by $\mathcal{D}$, has a meromorphic extension to the entire complex plane due to the fact that the support of V is confined to a finite interval. We will show that the set $\{-i\kappa_j\}$ has to be a subset of the set of zeros of $1/T^{[0]}$ on $\mathbf{I}^-$.

The following result is already known,[2] and hence its proof is omitted. By writing the first equation in (1.9) as

$$\frac{k}{T(k)}\prod_{j=1}^{N}\frac{1}{k-i\kappa_j}=\frac{k}{T^{[0]}(k)}\prod_{j=1}^{N}\frac{1}{k+i\kappa_j},$$

which is valid on the entire complex plane, the reader can compare the zeros of $1/T^{[0]}(k)$ and of $1/T(k)$ on the imaginary axis and verify the result stated in (iv) above as well as those in following proposition.

Proposition 4.1: Assume $V^{[0]}$ is real-valued, is integrable, has support confined to a finite interval, and has no bound states. Suppose V is the potential obtained by adding N successive bound states to $V^{[0]}$ at $k=i\kappa_j$ with $0<\kappa_1<\cdots<\kappa_N$, and let $T^{[0]}$ and T denote the transmission coefficients for $V^{[0]}$ and V, respectively. If the support of V is confined to a finite interval, then $k/T^{[0]}(k)$ and $k/T(k)$ are both entire, $1/T^{[0]}$ has a simple zero at $k=-i\kappa_j$ for $j=1,\dots,N$, and any other zero of $1/T^{[0]}$ on $\mathbf{I}^-$ must also be a zero $1/T$ with the same multiplicity.

In the first example below, we show that not every zero of $1/T^{[0]}$ on $\mathbf{I}^-$ necessarily corresponds to a bound state of V. In the second example we illustrate the recovery of L and V from our data.

Example 4.2: Consider the square-well potential supported on the interval $[0, 1]$ with depth equal to $c\alpha^2$ for some $c, \alpha > 0$. The corresponding transmission coefficient satisfies

$$\frac{1}{T(k)} = e^{ik}\left[\cos\gamma + \frac{k^2+\gamma^2}{2ik\gamma}\sin\gamma\right]$$

with $\gamma := \sqrt{k^2 + c\alpha^2}$. It can be easily checked that $1/T(-i\alpha) = 0$ if we choose $\alpha = \ln 8 = 2.079\,44$ and $c = 8/9$, where the overline on a digit indicates a roundoff. With these values, V has exactly one bound state occurring at $k = i\kappa$ with $\kappa = 1.307\,82$. We have $1/T(i\alpha) \neq 0$ and $1/T(i\kappa) = 1/T^{[0]}(-i\kappa) = 0$. In other words, $k = i\alpha$ does not correspond to a bound state of V even though $1/T^{[0]}(-i\alpha) = 0$.

Example 4.3: Let $\mathcal{D}(k) = -\epsilon e^{ik}\sin\sqrt{k^2+\epsilon}/2ik\sqrt{k^2+\epsilon}$, where ϵ is a non-negative parameter. In fact, one corresponding potential is the square well of depth ϵ with support on the interval $[0, 1]$. For each value of ϵ, let us obtain all the potentials corresponding to $\mathcal{D}(k)$ with support confined to a finite interval. We have $\lim_{k\to 0}[2ik\,\mathcal{D}(k)] = -\sqrt{\epsilon}\sin\sqrt{\epsilon}$, and hence the exceptional case occurs when $\sqrt{\epsilon} = p\pi$ for $p = 0,1,\ldots$ and the generic case occurs when $\sqrt{\epsilon} \neq p\pi$. In the generic case we see that the sign of $\lim_{k\to 0}[2ik\,\mathcal{D}(k)]$ is that of $(-1)^{p+1}$ when $p\pi < \sqrt{\epsilon} < (p+1)\pi$, and hence we can tell from ϵ whether p is even or odd. The sign analysis of $\mathcal{D}$ on $\mathbf{I}^+$ shows that Z mentioned in (iii) in the beginning of this section is equal to $\lfloor\sqrt{\epsilon}/\pi\rfloor$, i.e., the greatest integer less than or equal to $\sqrt{\epsilon}/\pi$; in other words, $\mathcal{D}$ has Z zeros on $\mathbf{I}^+$ occurring at $k = iz_j$ with $z_j = \sqrt{\epsilon - (j-1)^2\pi^2}$ for $j = 1,\ldots,Z$. In this particular example, $\mathcal{D}$ happens to have Z zeros on $\mathbf{I}^-$ as well occurring at $k = -iz_j$ symmetrically located with respect to the origin. With the help of (2.1) and (2.2) we obtain

$$\frac{1}{T^{[0]}(k)} = e^{ik}\left[\cos\sqrt{k^2+\epsilon} + \frac{2k^2+\epsilon}{2ik\sqrt{k^2+\epsilon}}\sin\sqrt{k^2+\epsilon}\right]\prod_{j=1}^{Z+1}\frac{k+i\beta_j}{k-i\beta_j}, \tag{4.1}$$

where the $\{\beta_j\}$ is the ordered set with $0 < \beta_1 < \cdots < \beta_{Z+1}$ consisting of those positive β values satisfying $\tan\sqrt{\epsilon-\beta^2} = (2\beta\sqrt{\epsilon-\beta^2})/(\epsilon - 2\beta^2)$. According to (iii) we must have $N \leq Z+1$. Using all these constraints, we can determine all the possibilities for N, the corresponding bound states, reflection coefficient L, and potential V. For example, we have the following:

(a) When $\epsilon = 5$, the above analysis shows that $Z = 0$ and thus $N \leq 1$, we are in the generic case and N must be odd, the quantity $1/T^{[0]}$ given in (4.1) has one simple zero on $\mathbf{I}^-$ at $k = -i\beta_1$, where $\beta_1 = 1.585\overline{7}$, and another one at $k = -i\beta_2$ with $\beta_2 = 1.543\,\overline{34}$. In the former case, we must have $N = 1$ with the bound state occurring at $k = i\beta_1$, and

$$L(k) = \mathcal{D}(k)\,T^{[0]}(k)\frac{k+i\beta_1}{k-i\beta_1} = \frac{-\epsilon\tan\sqrt{k^2+\epsilon}}{2ik\sqrt{k^2+\epsilon} + (2k^2+\epsilon)\tan\sqrt{k^2+\epsilon}}.$$

(b) When $\epsilon = 10$, we find that $Z = 1$ with $z_1 = 0.036\,110\,\overline{2}$, and thus $N \leq 2$, we are in the generic case and N must be even, the quantity $1/T^{[0]}$ given in (4.1) has two simple zeros on $\mathbf{I}^-$ at $k = -i\beta_j$, where $\beta_1 = 0.324\,42\overline{2}$ and $\beta_2 = 2.547\,5\overline{9}$. Thus, we have either of the two cases where $N = 0$ or $N = 2$. For $N = 0$, we get $L(k) = \mathcal{D}(k)\,T^{[0]}(k)$. On the other hand, for $N = 2$ we get

$$L(k) = \mathcal{D}(k)\,T^{[0]}(k)\frac{(k+i\beta_1)(k+i\beta_2)}{(k-i\beta_1)(k-i\beta_2)}.$$

(c) When $\epsilon=50$, we find that we are in the generic case, N must be odd, $Z=2$ with $z_1=3.243\overline{7}$ and $z_2=6.334\,8\overline{6}$, and thus $N\leqslant 3$; moreover, the quantity $1/T^{[0]}$ given in (4.1) has four simple zeros on $\mathbf{I}^-$ at $k=-i\beta_j$, where $\beta_1=1.871\overline{5}$, $\beta_2=5.198\,3\overline{9}$, $\beta_3=5.426\,4\overline{9}$, and $\beta_4=6.637\overline{6}$. Thus, we have either of the two cases where $N=1$ or $N=3$. For the case $N=1$ there is double nonuniqueness with $L(k)=\mathcal{D}(k)\,T^{[0]}(k)\,(k+i\beta_1)/(k-i\beta_1)$ or $L(k)=\mathcal{D}(k)\,T^{[0]}(k)\,(k+i\beta_4)/(k-i\beta_4)$, which is a consequence of $\mathcal{D}(i\beta_1)>0$, $\mathcal{D}(i\beta_2)<0$, $\mathcal{D}(i\beta_3)<0$, and $\mathcal{D}(i\beta_4)>0$. For $N=3$ we again have double nonuniqueness with the three bound states occurring at $k=i\kappa_j$ with the ordered set $\{\kappa_1,\kappa_2,\kappa_3\}$ being equal to either $\{\beta_1,\beta_2,\beta_4\}$ or $\{\beta_1,\beta_3,\beta_4\}$.

(d) When $\epsilon=100$, we find that we are in the generic case, N must be even, $Z=3$ with $z_1=3.342\,6\overline{9}$, $z_2=7.778\overline{7}$, and $z_3=9.493\,7\overline{9}$, and thus $N\leqslant 4$; moreover, the quantity $1/T^{[0]}$ given in (4.1) has six simple zeros on $\mathbf{I}^-$ at $k=-i\beta_j$, where $\beta_1=1.926\,9\overline{3}$, $\beta_2=5.710\,3\overline{8}$, $\beta_3=6.410\,1\overline{4}$, $\beta_4=8.546\,0\overline{7}$, $\beta_5=9.184\,7\overline{6}$, and $\beta_6=9.652\,6\overline{2}$. Thus, we have either of the three cases where $N=0$, $N=2$, or $N=4$. For $N=0$ our data uniquely determines L and V, with $L(k)=\mathcal{D}(k)\,T^{[0]}(k)$. With $L(k)=\mathcal{D}(k)\,T^{[0]}(k)\Pi_{j=1}^{2}(k+i\kappa_j)/(k-i\kappa_j)$ for $N=2$, we have fivefold nonuniqueness where the two bound states occurring at $k=i\kappa_j$ with the ordered set $\{\kappa_1,\kappa_2\}$ being equal to either of $\{\beta_1,\beta_2\}$, $\{\beta_1,\beta_3\}$, $\{\beta_1,\beta_6\}$, $\{\beta_4,\beta_6\}$, and $\{\beta_5,\beta_6\}$. On the other hand, for $N=4$ we have fourfold nonuniqueness where the four bound states occurring at $k=i\kappa_j$ with the ordered set $\{\kappa_1,\kappa_2,\kappa_3,\kappa_4\}$ being equal to either of $\{\beta_1,\beta_2,\beta_4,\beta_6\}$, $\{\beta_1,\beta_2,\beta_5,\beta_6\}$, $\{\beta_1,\beta_3,\beta_4,\beta_6\}$, $\{\beta_1,\beta_3,\beta_5,\beta_6\}$.

(Received 31 March 2003; accepted 1 July 2003)

The Hopf algebra structure of the fermionic Fock space is unravelled. The tools provided by the Hopf algebra formalism are used to rederive in a more straightforward fashion some known theorems and to open the way to natural generalizations of these results. The algebraic concepts of rank, depth and length of a wave function are given. They allow one to cast a wave function into a canonical form that is simpler and more appropriate to a physical interpretation or a numerical treatment. An original algorithm to re-expand a wave function with the least possible number of spin orbitals is described. © *2003 American Institute of Physics.*

I. INTRODUCTION

The origin of the Hopf algebra formalism can be traced back[1] to a conjecture regarding a topological invariant by Cartan in 1936.[2] Hopf proved that the conjecture was true,[3] essentially by introducing the Hopf algebra formalism as we use it in the present paper. More precisely, he showed that the cohomology of compact Lie groups and of suitable generalizations of them, all have the structure of an exterior algebra, the very structure of the fermionic Fock space.

Later on, the Hopf algebra formalism was extended to cover more general situations and different problems, e.g., the structure of group algebras, see Ref. 4. For example, in some situations, the definition of an Hopf algebra had to include explicitely the definition of an ''antipode map.'' In the case of Lie groups, this map corresponds to the usual inverse map. However, the antipode exists automatically in the case of the exterior algebra, see Ref. 5, and need not be introduced in the definition of the Hopf algebra structure of the fermionic Fock space.

In the late 1970s, Rota and co-workers put forward the idea of using Hopf algebras to deal with combinatorial aspects of Fock spaces (see, for example, Ref. 6). Seemingly, the physicists community did not echo their investigations. However, quantum groups appeared in physics at about the same period in the completely different context of the quantum inverse scattering method. Raychev[7] reviewed the early uses made of quantum groups and quantum algebras in physics. Since then, Connes and Kreimer have introduced Hopf algebra techniques in the theory of renormalization.[8,9]

The exterior algebra and the algebras coming from algebraic topology (precisely, from the cohomology of topological spaces) are ''fermionic'' in nature. In these algebras, the formal permutation of two elements of the algebra has to take into account a sign factor. This sign factor does not appear when defining the Hopf algebra structure on group algebras and quantum groups.[10] So, the Hopf algebras involved in the theory of group algebras and quantum groups are slightly different from the ones we are interested in here.

[b)]Electronic mail: patras@math.unice.fr

The purpose of this paper is to exploit Hopf algebra techniques as a tool for investigating the physical properties of systems of identical fermionic particles.

Our paper is organized as follows.

First, an elementary presentation of the Hopf algebra structure of the Fock space is given. The properties defining an algebra are not all introduced here, as physicists are usually well acquainted with the exterior algebra structure of the fermionic Fock space. We refer the reader to the appendix of Ref. 7 for a more comprehensive presentation intended for nonspecialists of the properties defining an Hopf algebra. In contrast, the co-algebra structure and the Hopf algebra structure of the Fock space are not so familiar and all the properties defining these structures are provided.

Then, we turn attention to the observables, and more particularly to the density operators, defined on the state space. We show how the Hopf algebra formalism simplifies the derivation of several famous results and how it suggests natural generalizations of the latter. Next, we define some new algebraic concepts to analyze and simplify the expansion of a fermionic wave function. We obtain an original algorithm to re-expand a wave function in a more adapted basis set by using the new tools introduced in the preceding section.

We conclude alluding to the wealth of further studies and possible applications which can attract both physicists and mathematicians.

Notation: Let m be a positive integer, we denote by $\mathcal{S}_m$ the symmetric group of order m and for any permutation $\sigma \in \mathcal{S}_m$, $|\sigma|$ the signature of σ, equal to $+1$ if σ is even and to -1 if σ is odd.

For all non-negative integer $n \leqslant m$, we denote by $\mathcal{P}_{m,n}$ the set of n element subsets of $\{1,\ldots,m\}$, *ordered in increasing order*. The set of ordered subsets of $\{1,\ldots,m\}$ is

$$\mathcal{P}_m := \bigcup_{n=0}^{m} \mathcal{P}_{m,n}.$$

For all $I \in \mathcal{P}_{m,p}$, $I=(i_1,\ldots,i_p)$ we denote by $\overline{I} := (\overline{i}_1,\ldots,\overline{i}_{m-p})$ the element of $\mathcal{P}_{m,m-p}$ such that $I \cup \overline{I} = \{1,\ldots,m\}$. For all $I,J \in \mathcal{P}_m, I=(i_1,\ldots,i_p), J=(j_1,\ldots,j_q)$ we denote by $I//J$ the sequence $(i_1,\ldots,i_p,j_1,\ldots,j_q)$. Note that the latter is not necessarily an element of $\mathcal{P}_m$ since it may not be in increasing order and repeated integers may occur. In contrast, set operators such as $I \cup J$ are assumed to give elements of $\mathcal{P}_m$.

We further define the useful quantities $\rho_{I,J}$ by

$$\begin{aligned} \rho_{I,J} &= 0 \quad \text{if } I \cap J \neq \varnothing, \\ \rho_{I,J} &= (-1)^{|\sigma|} \quad \text{if } I \cap J = \varnothing, \end{aligned} \tag{1}$$

where $\sigma \in \mathcal{S}_{p+q}$ is the permutation that reorders $I//J$ into $I \cup J$. We easily note that,

$$\rho_{I,J} = (-1)^{pq} \rho_{J,I}. \tag{2}$$

For all $I,J,K \in \mathcal{P}_m$, denoting by $I \Delta J$ the symmetrical difference of sets I and J, that is the complement of their intersection $I \cap J$ in their union $I \cup J$, the reader can verify that the following relation is satisfied:

$$\rho_{I,K}\rho_{J,K} = \rho_{I\Delta J,K}\rho^2_{I\cap J,K}, \tag{3}$$

from which we deduce by setting $I=J$,

$$\rho_{\varnothing,K} = 1, \tag{4}$$

II. THE HOPF ALGEBRA STRUCTURE OF THE STATE SPACE

Classical and quantum physics can be described in a unified formalism relying on a duality relationship between an algebra of observables and a vector space of states.[11,12] In this section, the

form embodied by quantum states in the formalism of Hopf algebras is presented, together with other mathematical objects of primary importance to express the quantum mechanics of a system of identical fermionic particles.

We have chosen to use a notation close to the notation currently found in the recent mathematical literature because first, we find it convenient and second, we hope to bridge the gap between quantum physics and this field of mathematics where many ideas and results still have to be exploited by physicists. In that sense, this work is a prolongation of the work accomplished by one of us to introduce exterior algebra techniques into quantum chemistry.[13–16] As it will soon become apparent to the reader, the basic tools of the Hopf algebra formalism are very similar to those of the ''second quantization'' formalism, so they suit naturally the treatment of problems formulated in this framework. However, the Hopf algebra formalism also allows us similar formal manipulations, and much more, within the frame of the ''first quantization.''

A. The graded algebra structure of the Fock space

We denote by $\mathcal{H}$ the one-particle Hilbert space which is the tensor product of an orbital Hilbert space $\mathcal{H}_0$ and a spin Hilbert space $\mathcal{H}_s$,

$$\mathcal{H}=\mathcal{H}_0\otimes\mathcal{H}_s. \tag{5}$$

An element ψ of $\mathcal{H}$ is called a spin orbital and is in general a finite sum of tensor products of orbitals $\theta_i\in\mathcal{H}_0$ with spin functions $\tau_i\in\mathcal{H}_s$,

$$\psi=\sum_i \theta_i\otimes\tau_i. \tag{6}$$

The n-fermion Hilbert space induced by $\mathcal{H}$ is the nth exterior power of $\mathcal{H}$, denoted by $\wedge^n\mathcal{H}$. An element Ψ of $\wedge^n\mathcal{H}$ is an n-fermion wave function. It will be more specifically termed a ''single configuration'' (SC) function if it can be cast in the form of a simple exterior product of n spin orbitals $\psi_1,\ldots,\psi_n$,

$$\Psi=\psi_1\wedge\psi_2\wedge\cdots\wedge\psi_n, \tag{7}$$

which corresponds in the second quantization of a fermionic system formalism to the quantum state

$$\Psi=a_1^\dagger\cdots a_n^\dagger|0\rangle, \tag{8}$$

where $a_i^\dagger$ is the creation operator of a fermion in the spin orbital ψ_i.

The fermionic Fock space of the second quantization $\wedge\mathcal{H}$ is the direct sum of all the $\wedge^n\mathcal{H}$,

$$\wedge\mathcal{H}:=\bigoplus_{n\geqslant 0}\wedge^n\mathcal{H}, \tag{9}$$

where $\mathcal{H}$ is identified to $\wedge^1\mathcal{H}$ and the field of complex or real numbers, denoted by $\mathbb{K}$, is identified to $\wedge^0\mathcal{H}$ through the ''unit map,'' $\mathcal{U}$,

$$\mathcal{U}:\mathbb{K}\mapsto\wedge\mathcal{H}$$

$$\lambda\to\mathcal{U}(\lambda)=\lambda\in\wedge^0\mathcal{H}. \tag{10}$$

Provided with Grassmann's exterior product, $\wedge$, which can be seen as a map from the tensor product $\wedge\mathcal{H}\otimes\wedge\mathcal{H}$ to $\wedge\mathcal{H}$,

$$\mathcal{X}:\wedge\mathcal{H}\otimes\wedge\mathcal{H}\mapsto\wedge\mathcal{H}$$

$$\Phi \otimes \Psi \to \mathcal{X}(\Phi \otimes \Psi) = \Phi \wedge \Psi, \tag{11}$$

it acquires the mathematical structure of an ''exterior algebra.'' Note that when one of its factors is a scalar λ, the exterior product reduces to the multiplication by this scalar,

$$\lambda \wedge \Psi = \Psi \wedge \lambda = \lambda \Psi. \tag{12}$$

The fermionic symmetry which traduces the Pauli exclusion principle is built-in in this exterior algebra because of the following antisymmetry relation between exterior products of one-particle functions:

$$\mathcal{X}(\phi \otimes \psi) = \phi \wedge \psi = -\psi \wedge \phi = -\mathcal{X}(\psi \otimes \phi), \tag{13}$$

which entirely determines the behavior of an n-fermion wave function under the symmetric group $\mathcal{S}_n$. That is to say, for an n-fermion single configuration:

$$\psi_1 \wedge \cdots \wedge \psi_n = (-1)^{|\sigma|} \psi_{\sigma(1)} \wedge \cdots \wedge \psi_{\sigma(n)}. \tag{14}$$

The general case is obtained from Eq. (14) by linearity.

Furthermore, the Fock space is what is termed ''a graded algebra.'' That is to say, Eq. (9) and the following relation hold true:

$$\mathcal{X}(\wedge^p \mathcal{H} \otimes \wedge^q \mathcal{H}) \subseteq \wedge^{p+q} \mathcal{H}. \tag{15}$$

The latter relation simply means that the exterior product of a p-fermion wave function with a q-fermion wave function is a $(p+q)$-fermion wave function. In fact, the graded algebra structure of the Fock space is something physicists are familiar with. In contrast, it has an additional coalgebra structure which has never been exploited, as far as we are aware.

B. The coalgebra structure of the Fock space

Inverting the arrows in Eq. (11), we define an ''exterior coproduct'' or simply ''coproduct'' on single configuration functions by

$$\begin{gathered} \mathcal{Y}: \wedge \mathcal{H} \mapsto \wedge \mathcal{H} \otimes \wedge \mathcal{H}, \\ \psi_1 \wedge \cdots \wedge \psi_n \to \mathcal{Y}(\psi_1 \wedge \cdots \wedge \psi_n) = \sum_{I \in \mathcal{P}_n} \rho_{I,\bar{I}} \psi_{i_1} \wedge \cdots \wedge \psi_{i_p} \otimes \psi_{\bar{i}_1} \wedge \cdots \wedge \psi_{\bar{i}_{n-p}}. \end{gathered} \tag{16}$$

The idea behind the coproduct is to split an n-fermion single configuration function into a p and an $(n-p)$-fermion single configuration functions in all possible ways, where p ranges from 0 to n, the exterior product of the two parts so-obtained giving back the initial function, the sign of the reordering permutation being taken care of. The definition extends by linearity to general wave functions.

As an example, let us write down the formula for $\mathcal{Y}$ acting on a 3-fermion configuration,

$$\begin{aligned} \mathcal{Y}(\psi_a \wedge \psi_b \wedge \psi_c) = {} & \psi_a \wedge \psi_b \wedge \psi_c \otimes 1 + \psi_a \wedge \psi_b \otimes \psi_c - \psi_a \wedge \psi_c \otimes \psi_b + \psi_b \wedge \psi_c \otimes \psi_a + \psi_a \otimes \psi_b \wedge \psi_c \\ & - \psi_b \otimes \psi_a \wedge \psi_c + \psi_c \otimes \psi_a \wedge \psi_b + 1 \otimes \psi_a \wedge \psi_b \wedge \psi_c. \end{aligned} \tag{17}$$

The coproduct is coassociative, i.e.,

$$(\mathcal{Y} \otimes \mathrm{Id}) \circ \mathcal{Y} = (\mathrm{Id} \otimes \mathcal{Y}) \circ \mathcal{Y} \tag{18}$$

(where Id is the identity map acting on the Fock space and $\circ$ the composition of mappings), which expresses the fact that when splitting a single configuration into a tensor product of three subconfigurations by iterating the coproduct twice, the component of the tensor product chosen to apply

the second coproduct does not matter. More generally, iterating the coproduct n times splits a single configuration into a tensor product of $n+1$ subconfigurations and the choice of the components on which the coproduct is successively applied is indifferent.

Another important mapping that is needed to obtain a coalgebra structure is the counit map,

$$\mathcal{V}:\wedge\mathcal{H}\mapsto\mathbb{K}$$

$$\Psi\to\mathcal{V}(\Psi)=0 \quad \text{if } \Psi\in\wedge^n\mathcal{H}, \quad n>0, \tag{19}$$

$$\lambda\to\mathcal{V}(\lambda)=\lambda \quad \text{if } \lambda\in\wedge^0\mathcal{H}.$$

The counit is compatible with the coproduct in the sense that

$$\forall\Psi\in\wedge\mathcal{H}, \quad (\mathcal{V}\otimes\mathrm{Id})\circ\mathcal{Y}(\Psi)=(\mathrm{Id}\otimes\mathcal{V})\circ\mathcal{Y}(\Psi)=\Psi. \tag{20}$$

When the Fock space is endowed with the coproduct and the counit it becomes a coalgebra. In the next section, we show that the algebra and the coalgebra structures are compatible. This makes the Fock space a Hopf algebra.

C. The Hopf algebra structure of the Fock space

The compatibility relationship between the exterior product $\mathcal{X}$ and the exterior coproduct $\mathcal{Y}$ which defines the Hopf algebra structure on the Fock space reads,

Proposition 1 (Hopf algebra fundamental relation):

$$\mathcal{Y}\circ\mathcal{X}=(\mathcal{X}\otimes\mathcal{X})\circ(\mathrm{Id}\otimes T\otimes\mathrm{Id})\circ(\mathcal{Y}\otimes\mathcal{Y}), \tag{21}$$

where T is the twisting map

$$\forall\Phi\in\wedge^p\mathcal{H}, \quad \forall\Psi\in\wedge^q\mathcal{H},$$
$$T(\Psi\otimes\Phi)=(-1)^{pq}\Phi\otimes\Psi. \tag{22}$$

The definition of T extends to more general elements of the Fock space by linearity.

The fundamental Hopf algebra relation expresses the fact that the same decomposition of the product of two single configurations into a tensor product of two subconfigurations is obtained by applying the coproduct to the exterior product of the two single configurations, or alternatively [second member of Eq. (21)], by first splitting each single configuration separately $(\mathcal{Y}\otimes\mathcal{Y})$, then grouping the first tensorial components of each decomposition together and the second components together $(\mathrm{Id}\otimes T\otimes\mathrm{Id})$, and finally by taking the exterior product of the first components on the one hand and the exterior product of the second components on the other hand $(\mathcal{X}\otimes\mathcal{X})$.

More explicitly we have

$$\mathcal{Y}(\psi_1\wedge\cdots\wedge\psi_p\wedge\phi_1\wedge\cdots\wedge\phi_q)=\sum_{I\in\mathcal{P}_p,J\in\mathcal{P}_q}\rho_{I,\bar{I}}\rho_{J,\bar{J}}(-1)^{l(p-k)}\psi_{i_1}\wedge\cdots\wedge\psi_{i_k}\wedge\phi_{j_1}\wedge\cdots\wedge\phi_{j_l}$$
$$\otimes\psi_{\bar{i}_1}\wedge\cdots\wedge\psi_{\bar{i}_{p-k}}\wedge\phi_{\bar{j}_1}\wedge\cdots\wedge\phi_{\bar{j}_{q-l}}. \tag{23}$$

The proof of the formula follows almost immediately from the observation that to extract all the $(k+l)$-element subsequences out of a sequence with $(p+q)$ elements $(1,\ldots,p+q)$ amounts to extracting k elements out of the sequence $(1,\ldots,p)$ and l elements out of the sequence $(p+1,\ldots,p+q)$ in all possible ways, where k runs from 0 to p and l from 0 to q.

D. Hermitian structure of the Fock space

A complex (or Hermitian) Hilbert space is, by definition, endowed with an Hermitian product written $\langle\ |\ \rangle$. (If $\mathbb{K}=\mathbb{R}$, the words "complex" must be replaced by "real," "Hermitian product" by "scalar product," "sesquilinear" by "linear" …, in the present and the following sections.)

If $\mathcal{E}$ and $\mathcal{F}$ are two Hermitian spaces, then their tensor product is also Hermitian, with the Hermitian product defined by

$$\forall e,f\in\mathcal{E},\ \ \forall g,h\in\mathcal{F},\ \ \langle e\otimes g|f\otimes h\rangle := \langle e|f\rangle\cdot\langle g|h\rangle. \tag{24}$$

An illustration of this situation is the one-particle Hilbert space of Eq. (5) whose Hermitian product is formed by multiplication of the orbital Hermitian product ($\langle f|g\rangle=\int f^*\cdot g\ \mathrm{d}\vec{r}$ in $\mathbb{L}^2$) and the spin Hermitian product (the standard Hermitian product in dimension $2S+1$).

Similarly, if $\mathcal{H}$ is an Hermitian space, an Hermitian product is induced on $\wedge^n\mathcal{H}$, by

$$\langle\phi_1\wedge\cdots\wedge\phi_n|\psi_1\wedge\cdots\wedge\psi_n\rangle := \det(\langle\phi_i|\psi_j\rangle)_{i,j\in\{1,\ldots,n\}}, \tag{25}$$

which extends by sesquilinearity to all $\wedge\mathcal{H}$.

Then, making use of Eqs. (14), (24), and (25), the Hopf algebra fundamental formula, rewritten as Eq. (23), immediately yields the Laplace formula to expand a determinant.[17]

Proposition 2 (Laplace formula): For any $\phi_1,\ldots,\phi_n,\psi_1,\ldots,\psi_n\in\mathcal{H}$ and for any $p\leqslant n$, $\forall\sigma\in\mathcal{S}_n$ we have

$$\begin{aligned}\langle\phi_1\wedge\cdots\wedge\phi_n|\psi_1\wedge\cdots\wedge\psi_n\rangle = (-1)^{|\sigma|}\langle\mathcal{Y}(\phi_1\wedge\cdots\wedge\phi_n)|(\psi_{\sigma(1)}\wedge\cdots\wedge\psi_{\sigma(p)})\\ \otimes(\psi_{\sigma(p+1)}\wedge\cdots\wedge\psi_{\sigma(n)})\rangle,\end{aligned} \tag{26}$$

which can be rewritten in a more familiar fashion,

$$\begin{aligned}\det(\langle\phi_i|\psi_j\rangle)_{i,j\in\{1,\ldots,n\}} = \sum_{I\in\mathcal{P}_{n,p}}\rho_{I,\bar{I}}\ (-1)^{|\sigma|}\det(\langle\phi_{i_k}|\psi_{\sigma(j)}\rangle)_{k,j\in\{1,\ldots,p\}}\\ \times\det(\langle\phi_{\bar{i}_k}|\psi_{\sigma(p+j)}\rangle)_{k,j\in\{1,\ldots,n-p\}}.\end{aligned} \tag{27}$$

The Laplace formula extended by sesquilinearity with $\sigma=\mathrm{Id}$, writes,

$$\langle\mathcal{X}(\Theta\otimes\Phi)|\Psi\rangle\equiv\langle\Theta\wedge\Phi|\Psi\rangle=\langle\Theta\otimes\Phi|\mathcal{Y}(\Psi)\rangle, \tag{28}$$

which expresses the duality-like relationship between the exterior product and the coproduct.

III. DENSITY OPERATORS ON THE FOCK SPACE

According to the standard axioms of quantum theory, the outcome of a physical experiment is given by the expectation value of an Hermitian operator acting on the state space, called an observable, over the von Neumann's statistical operator,[18] or "density operator," characterizing the physical state of the system. When the observable contains only p-particle operators ($p\leqslant n$ the total number of particle of the system), its expectation value can be obtained from a more compact mathematical object than the density operator, called the "p-particle reduced density operator." In this section, we present the form assumed by these operators in the Hopf algebra formalism and some of their basic properties.

Remark: In fact, it is transitions between quantum states rather than expectation values which should play the central role in quantum axiomatic, because without transitions there is no physical measurement nor observation possible. However, the importance of observables and density operators in quantum physics remains.

A. Creation, annihilation and density operators

The exterior product map, $\mathcal{X}$, defines in a natural manner, for all $\Psi \in \wedge\mathcal{H}$, the map,

$$\vec{\mathcal{X}}_\Psi : \wedge\mathcal{H} \mapsto \wedge\mathcal{H}$$

$$\Phi \to \vec{\mathcal{X}}_\Psi(\Phi) = \mathcal{X}(\Psi \otimes \Phi) = \Psi \wedge \Phi, \tag{29}$$

called the ''left exterior product by Ψ'' map, or in the second quantization terminology, the ''(left) creation operator of Ψ.'' Similarly we can define a right creation operator by

$$\overleftarrow{\mathcal{X}}_\Psi : \wedge\mathcal{H} \mapsto \wedge\mathcal{H}$$

$$\Phi \to \overleftarrow{\mathcal{X}}_\Psi(\Phi) = \mathcal{X}(\Phi \otimes \Psi) = \Phi \wedge \Psi. \tag{30}$$

The Hermitian product allows us to define the conjugate operator $O^\dagger$ of an operator O acting in $\wedge\mathcal{H}$, by

$$\forall \Phi, \Psi \in \wedge\mathcal{H},\ \langle \Phi | O(\Psi) \rangle = \langle O^\dagger(\Phi) | \Psi \rangle. \tag{31}$$

So a left annihilation operator, $\vec{\mathcal{I}}_\Psi := \vec{\mathcal{X}}_\Psi^\dagger$, also called the ''left interior product by Ψ'' and denoted by $\Psi \hookleftarrow$, is associated to the left creation operator,

$$\vec{\mathcal{I}}_\Psi : \wedge\mathcal{H} \mapsto \wedge\mathcal{H}$$

$$\Phi \to \vec{\mathcal{I}}_\Psi(\Phi) = \Psi \hookleftarrow \Phi. \tag{32}$$

Similarly a right annihilation operator, $\overleftarrow{\mathcal{I}}_\Psi := \overleftarrow{\mathcal{X}}_\Psi^\dagger$, also called ''right interior product by Ψ'' and denoted by $\Psi \hookrightarrow$, is associated to the right creation operator,

$$\overleftarrow{\mathcal{I}}_\Psi : \wedge\mathcal{H} \mapsto \wedge\mathcal{H}$$

$$\Phi \to \overleftarrow{\mathcal{I}}_\Psi(\Phi) = \Phi \hookrightarrow \Psi. \tag{33}$$

The conjugation relationships write, for all $\Theta \in \wedge^{q-p}\mathcal{H}$, $\Psi \in \wedge^p\mathcal{H}$, $\Phi \in \wedge^q\mathcal{H}$,

$$\langle \Theta | \Psi \hookleftarrow \Phi \rangle = \langle \Psi \wedge \Theta | \Phi \rangle, \tag{34}$$

$$\langle \Theta | \Phi \hookrightarrow \Psi \rangle = \langle \Theta \wedge \Psi | \Phi \rangle. \tag{35}$$

Note that the left (respectively, right) interior product by Ψ is an antilinear function of Ψ, so it defines a sesquilinear (respectively, antisesquilinear) map on $\wedge\mathcal{H} \times \wedge\mathcal{H}$, the left (respectively, right) interior product, $\hookleftarrow$ (respectively, $\hookrightarrow$). Then from the exterior product property,

$$\Psi \wedge \Theta = (-1)^{p(q-p)}\ \Theta \wedge \Psi \tag{36}$$

we deduce

$$\Psi \hookleftarrow \Phi = (-1)^{p(q-p)} \Phi \hookrightarrow \Psi, \tag{37}$$

which shows that the left and right interior products differ only by a sign factor. In the following the left interior product will often be referred to more simply as the ''interior product.''

Setting, $\Theta = 1$, in Eqs. (34) and (35) shows that for all p, the restriction of the interior products to $\wedge^p\mathcal{H} \times \wedge^p\mathcal{H}$ reduces to the Hermitian product on $\wedge^p\mathcal{H}$.

The expression of the density operator associated to a wave function $\Psi \in \wedge\mathcal{H}$ translates directly from the second quantization formalism. It corresponds, if Ψ is normalized, $\langle\Psi|\Psi\rangle = 1$, to the annihilation of Ψ followed by its creation:

$$\Gamma_\Psi = \vec{\mathcal{X}}_\Psi \circ \vec{\mathcal{I}}_\Psi . \tag{38}$$

If the wave function is that of a fixed number of particles, $\Psi \in \wedge^n\mathcal{H}$, for all $\Phi \in \wedge^p\mathcal{H}$, $\Gamma_\Psi(\Phi) \in \wedge^p\mathcal{H}$, that is to say, Γ_Ψ preserves the number of particles. We will denote by Γ^p_Ψ its restriction to $\wedge^p\mathcal{H}$. For $p<n$, $\Gamma^p_\Psi = 0$.

The density operators of general quantum states, or "mixed states," or "ensemble states," are linear convex combinations of density operators associated to wave functions, that is, associated to "pure states."

In the next sections we show that the reduced density operators related to Γ_Ψ have a particularly elegant expression in the Hopf algebra formalism, and that the coproduct simplifies greatly the investigation of their properties.

B. Reduced density operators

In this section we consider a fermionic system with a fixed number, n, of particles. A general wave function, $\Psi \in \wedge^n\mathcal{H}$ will have the form,

$$\Psi = \sum_l c_l \psi_{l,1} \wedge \cdots \wedge \psi_{l,n} , \tag{39}$$

with $c_l \in \mathbb{K}$ and $\psi_{l,j} \in \mathcal{H}$ for all l,j. For any $K = (k_1,\ldots,k_p) \in \mathcal{P}_n$, we denote by $\Psi_K \otimes \Psi_{\bar{K}}$ the expression,

$$\Psi_K \otimes \Psi_{\bar{K}} := \rho_{K,\bar{K}} \sum_l c_l \psi_{l,k_1} \wedge \cdots \wedge \psi_{l,k_p} \otimes \psi_{l,\bar{k}_1} \wedge \cdots \wedge \psi_{l,\bar{k}_{n-p}}, \tag{40}$$

so that the coproduct writes,

$$\mathcal{Y}(\Psi) = \sum_{K \in \mathcal{P}_n} \Psi_K \otimes \Psi_{\bar{K}}. \tag{41}$$

Another useful self-explanatory notation is

$$\langle \Phi_1 | \Psi_K \rangle \Psi_{\bar{K}} := \rho_{K,\bar{K}} \sum_l c_l \langle \Phi_1 | \psi_{l,k_1} \wedge \cdots \wedge \psi_{l,k_p} \rangle \psi_{l,\bar{k}_1} \wedge \cdots \wedge \psi_{l,\bar{k}_{n-p}}, \tag{42}$$

$$\langle \Phi_1 | \Psi_K \rangle \langle \Phi_2 | \Psi_{\bar{K}} \rangle := \rho_{K,\bar{K}} \sum_l c_l \langle \Phi_1 | \psi_{l,k_1} \wedge \cdots \wedge \psi_{l,k_p} \rangle \langle \Phi_2 | \psi_{l,\bar{k}_1} \wedge \cdots \wedge \psi_{l,\bar{k}_{n-p}} \rangle. \tag{43}$$

The reduced density operator of a normalized n-fermion wave function, D_Ψ acts on a wave function, $\Phi \in \wedge\mathcal{H}$ in the following way:[16]

$$D_\Psi(\Phi) = \Psi \hookrightarrow \Phi \hookleftarrow \Psi. \tag{44}$$

Here, one does not need to put parentheses indicating whether the left or the right interior product has to be performed first, because the solution obtained is indifferent to the order. Like the density operator, Γ_Ψ, the reduced density operator, D_Ψ, preserves the number of particles. Therefore D_Ψ is the direct sum of its restrictions to the $\wedge^p\mathcal{H}$, the so-called "p-order reduced density operators," D^p_Ψ,

$$D_\Psi = \sum_{p \geqslant 0} D^p_\Psi . \tag{45}$$

Note that D_Ψ coincides with Γ_Ψ on $\wedge^n \mathcal{H}$,

$$D^n_\Psi = \Gamma^n_\Psi , \tag{46}$$

and is null for $p > n$.

One of the difficulties in the study of the reduced density operator seems to have been the lack of a suitable algebraic framework for handling computations. We propose, in the next section, a simple closed formula for these operators by using the coproduct. Owing to this formula and the formal rules governing the Fock space as a Hopf algebra, the solutions of many algebraic problems related to reduced density operators become *natural*. Compare, for example, our proof of Sasaki's formula main corollary (Sec. III G below) with the classical one.[19,20] We begin with exhibiting the relationship between the interior products and the coproduct.

C. Generalization of the Greub formula and application to the reduced density operator

Combining the conjugation relation, Eq. (35) with the generalized Laplace formula Eq. (28) we obtain

$$\langle \Theta | \Psi \hookrightarrow \Phi \rangle = \langle \Theta \otimes \Phi | \mathcal{Y}(\Psi) \rangle, \tag{47}$$

valid for all $\Theta, \Psi, \Phi \in \wedge \mathcal{H}$. If now we restrict ourselves to homogeneous elements of the Fock space (i.e., belonging to a given exterior power of $\mathcal{H}$), $\Theta \in \wedge^{n-q}\mathcal{H}$, $\Psi \in \wedge^n \mathcal{H}$, $\Phi \in \wedge^q \mathcal{H}$, we can write further

$$\begin{aligned}
\langle \Theta \otimes \Phi | \mathcal{Y}(\Psi) \rangle &= \left\langle \Theta \otimes \Phi \middle| \sum_{K \in \mathcal{P}_n} \Psi_K \otimes \Psi_{\bar{K}} \right\rangle, \quad \text{by Eq. (41)} \\
&= \left\langle \Theta \otimes \Phi \middle| \sum_{K \in \mathcal{P}_{n,n-q}} \Psi_K \otimes \Psi_{\bar{K}} \right\rangle, \\
&\quad \text{since } \Theta \text{ is a } (n-q)-\text{fermion function} \\
&= \sum_{K \in \mathcal{P}_{n,n-q}} \langle \Theta | \Psi_K \rangle \cdot \langle \Phi | \Psi_{\bar{K}} \rangle, \text{ by Eq. (24) and Eq. (43)} \\
&= \left\langle \Theta \middle| \sum_{K \in \mathcal{P}_{n,n-q}} \langle \Phi | \Psi_{\bar{K}} \rangle \cdot \Psi_K \right\rangle, \text{ by using Eq.(42).}
\end{aligned}$$

Since this holds for all Θ we obtain through Eq. (47) the following closed formula for the right interior product:

$$\Psi \hookrightarrow \Phi = \sum_{K \in \mathcal{P}_{n,n-q}} \langle \Phi | \Psi_{\bar{K}} \rangle \cdot \Psi_K . \tag{48}$$

Similarly, we have for the left interior product,

$$\Phi \hookleftarrow \Psi = \sum_{K \in \mathcal{P}_{n,q}} \langle \Phi | \Psi_K \rangle \cdot \Psi_{\bar{K}}, \tag{49}$$

which is just a generalization by sesquilinearity of the Greub formula for single configurations,[21]

$$(\phi_1 \wedge \cdots \wedge \phi_q) \hookleftarrow (\psi_1 \wedge \cdots \wedge \psi_n) = \sum_{K \in \mathcal{P}_{n,q}} \rho_{K,\bar{K}} \det(\langle \phi_i | \psi_{k_j} \rangle)_{i,j \leqslant q} \, \psi_{\bar{k}_1} \wedge \cdots \wedge \psi_{\bar{k}_{n-q}}. \tag{50}$$

We are now ready to return to the reduced density operator expression. Rewriting Eq. (44) for $\Phi \in \wedge^q \mathcal{H}$, we have

$$
\begin{aligned}
D^q_\Psi(\Phi) &= \Psi \hookrightarrow \Phi \hookleftarrow \Psi \\
&= \Psi \hookrightarrow \left(\sum_{K \in \mathcal{P}_{n,q}} \langle \Phi | \Psi_K \rangle \cdot \Psi_{\bar{K}} \right), \text{ by Eq. (49)} \\
&= \sum_{K \in \mathcal{P}_{n,q}} \langle \Psi_K | \Phi \rangle \cdot (\Psi \hookrightarrow \Psi_{\bar{K}}), \text{ by antilinearity} \\
&= \sum_{K \in \mathcal{P}_{n,q}} \sum_{L \in \mathcal{P}_{n,q}} \langle \Psi_K | \Phi \rangle \cdot \langle \Psi_{\bar{K}} | \Psi_{\bar{L}} \rangle \Psi_L, \text{ by Eq. (48)} \\
&= \sum_{K \in \mathcal{P}_{n,q}} \sum_{L \in \mathcal{P}_{n,q}} \langle \Psi_{\bar{K}} | \Psi_{\bar{L}} \rangle \vec{\mathcal{X}}_{\Psi_L} \circ \vec{\mathcal{I}}_{\Psi_K}(\Phi).
\end{aligned}
$$

In the last equation, the notation of Eq. (42) has been extended to encompass the case where the functions appear as indices of creation or annihilation operators, that is to say, when we have $\Psi_{\bar{K}} \wedge$, or $\Psi_{\bar{K}} \hookleftarrow$ instead of $\Psi_{\bar{K}}$ in Eq. (42). Also, care must be taken that the coefficients of the expansion, Eq. (42), encapsulated in the pair $\Psi_K, \Psi_{\bar{K}}$ are to be replaced by their complex conjugates, because in fact it is the complex conjugate of Eq. (42) that appears above. Since the above equations hold for all Φ we have the following.

Proposition 3: The reduced density operator of order q associated to Ψ written D^q_Ψ or simply D^q when no ambiguity can arise from the notation, is given by

$$
D^q = \sum_{K,L \in \mathcal{P}_{n,q}} \langle \Psi_{\bar{K}} | \Psi_{\bar{L}} \rangle \ \ \vec{\mathcal{X}}_{\Psi_L} \circ \vec{\mathcal{I}}_{\Psi_K}. \tag{51}
$$

Note that the use of the creation and annihilation operators in Eq. (51) allows us to extend the action of D^q to all $\wedge \mathcal{H}$. Remark also that, in contrast with similar expressions obtained previously, the functions $\Psi_L, \Psi_{\bar{L}}, \Psi_K, \Psi_{\bar{K}}$ in this equation are not single configuration element of an induced basis set, but general multiconfigurational functions.

D. Normalization of reduced density operators

To illustrate further how to manipulate the coproduct, we address the problem of the normalization of reduced density operators. First, we establish some technical identities.

Proposition 4: Let $\Psi \in \wedge^n \mathcal{H}$, $\mathcal{Y}_{p,q}$ denotes the component of the coproduct in $\wedge^p \mathcal{H} \otimes \wedge^q \mathcal{H}$ and $\binom{n}{p}$ the binomial coefficient, then we have

$$
\mathcal{X} \circ \mathcal{Y}_{p,n-p}(\Psi) = \binom{n}{p} \Psi, \tag{52}
$$

$$
\mathcal{X} \circ \mathcal{Y}(\Psi) = 2^n \Psi. \tag{53}
$$

Proof: Since the maps $\mathcal{X} \circ \mathcal{Y}_{p,n-p}$ and $\mathcal{X} \circ \mathcal{Y}$ are linear, we may assume in the proof that Ψ is a single configuration wave function, $\Psi = \psi_1 \wedge \cdots \wedge \psi_n$. Recall then that

$$
\mathcal{Y}_{p,n-p}(\Psi) = \sum_{I \in \mathcal{P}_{n,p}} \rho_{I,\bar{I}} \ \psi_{i_1} \wedge \cdots \wedge \psi_{i_p} \otimes \psi_{\bar{i}_1} \wedge \cdots \wedge \psi_{\bar{i}_{n-p}}.
$$

Therefore

$$\mathcal{X}\circ\mathcal{Y}_{p,n-p}(\Psi)=\sum_{I\in\mathcal{P}_{n,p}}\rho_{I,\bar{I}}\psi_{i_1}\wedge\cdots\wedge\psi_{i_p}\wedge\bar{\psi_{i_1}}\wedge\cdots\wedge\bar{\psi_{i_{n-p}}}.$$

Since we have

$$\psi_{i_1}\wedge\cdots\wedge\psi_{i_p}\wedge\bar{\psi_{i_1}}\wedge\cdots\wedge\bar{\psi_{i_{n-p}}}=\rho_{I,\bar{I}}\psi_1\wedge\cdots\wedge\psi_n,$$

$\rho^2_{I,\bar{I}}=1$, and $\Sigma_{I\in\mathcal{P}_{n,p}}1=\binom{n}{p}$, the proof of the first equation in the proposition follows. The second one is a straightforward corollary of the first.

Proposition 5: In the Hopf algebra (and so in the second quantization) formalism, the trace of the pth-order reduced density operator is equal to the the binomial coefficient, $\binom{n}{p}$*, if the wave function is normalized, since,*

$$\mathrm{Tr}(D^p)=\mathrm{Tr}(D^{n-p})=\binom{n}{p}\|\Psi\|^2\ . \tag{54}$$

(This is not true in certain formalisms where different normalization factors are imposed to the reduced density operators see, e.g., Ref. 22.)

Proof: From Eq. (51) we have

$$\mathrm{Tr}(D^p)=\sum_{K,L\in\mathcal{P}_{n,p}}\langle\Psi_{\bar{K}}|\Psi_{\bar{L}}\rangle\vec{\mathcal{I}}_{\Psi_K}(\Psi_L)$$

and, since $\vec{\mathcal{I}}_{\Psi_K}(\Psi_L)=\langle\Psi_K|\Psi_L\rangle$, the trace is the Hermitian product of two coproducts, so that,

$$\mathrm{Tr}(D^p)=\mathrm{Tr}(D^{n-p})=\langle\mathcal{Y}_{p,n-p}(\Psi)|\mathcal{Y}_{p,n-p}(\Psi)\rangle. \tag{55}$$

From the generalized Laplace formula Eq. (28) we have

$$\mathrm{Tr}(D^p)=\langle\Psi|\mathcal{X}\circ\mathcal{Y}_{p,n-p}(\Psi)\rangle,$$

then we conclude with the previous proposition.

E. Convolution and induction

A p-particle operator, O^p, can be defined as an operator from $\wedge\mathcal{H}$ to $\wedge^p\mathcal{H}$ such that, $O^p(\Psi)=0$, if $\Psi\notin\wedge^p\mathcal{H}$. For example, the Coulomb repulsion, $1/\|\vec{r}_1-\vec{r}_2\|$, between two electrons is a two-electron operator. In this definition, the action of the operator O^p on $\wedge^n\mathcal{H}$, $n\neq p$, is trivial. The actual observable induced by O^p on all $\wedge\mathcal{H}$ is given by

$$O:=O^p*\mathrm{Id}:=\mathcal{X}\circ(O^p\otimes\mathrm{Id})\circ\mathcal{Y}. \tag{56}$$

The operation denoted by $*$ is called the ''convolution'' in the Hopf algebra formalism,

$$A*B:=\mathcal{X}\circ(A\otimes B)\circ\mathcal{Y}. \tag{57}$$

The convolution by the identity is thus a convenient way to induce operators on $\wedge\mathcal{H}$. The restriction of the induced observable, O, to $\wedge^n\mathcal{H}$ for $n\leqslant p$ is O^p, and for $n>p$ it is equivalent to the usual operator used in quantum physics, e.g., $\Sigma_{i<j}1/\|\vec{r}_i-\vec{r}_j\|$ in the case of the Coulomb repulsion operator.

According to quantum physics an n-particle quantum state is determined by its density operator Γ^n. As a matter of fact, the expectation value, $\langle O\rangle$, of any observable, O, is given by

$$\langle O\rangle=\mathrm{Tr}[\Gamma^n\circ O]. \tag{58}$$

The reduced density operator is of paramount importance in applications because if O is the induced operator by a p-particle operator O^p, then, $\forall \Psi \in \wedge^n \mathcal{H}$,

$$\begin{aligned}\langle \Psi | O\Psi \rangle &= \langle \Psi | (\mathcal{X} \circ (O^p \otimes \mathrm{Id}) \circ \mathcal{Y}) \Psi \rangle \\ &= \langle \mathcal{Y}(\Psi) | (O^p \otimes \mathrm{Id}) \circ \mathcal{Y}(\Psi) \rangle \\ &= \sum_{K,L \in \mathcal{P}_n} \langle \Psi_K \otimes \Psi_{\bar{K}} | (O^p \otimes \mathrm{Id})(\Psi_L \otimes \Psi_{\bar{L}}) \rangle \\ &= \sum_{K,L \in \mathcal{P}_{n,p}} \langle \Psi_K | O^p(\Psi_L) \rangle \cdot \langle \Psi_{\bar{K}} | \Psi_{\bar{L}} \rangle \\ &= \mathrm{Tr}\left[\left(\sum_{K,L \in \mathcal{P}_{n,p}} \langle \Psi_{\bar{K}} | \Psi_{\bar{L}} \rangle \vec{\mathcal{X}}_{\Psi_L} \circ \vec{\mathcal{I}}_{\Psi_K} \right) \circ O^p \right] \\ &= \mathrm{Tr}[D^p_\Psi \circ O^p]. \end{aligned} \tag{59}$$

Therefore, only the knowledge of D^p_Ψ, an operator acting on $\wedge^p \mathcal{H}$, and not that of Γ^n_Ψ, an operator acting on $\wedge^n \mathcal{H}$, is required to compute the expectation value of the observable induced on $\wedge^n \mathcal{H}$ by a p-particle operator, with $p < n$. In particular, the energy of a Coulombian system can be expressed exactly in terms of D^2_Ψ since the Coulomb potential involves no more than two-particle interactions.

F. A new proof of Carlson and Keller duality property

The Carlson and Keller duality property for reduced density operators[19] is a useful result which has been used, for example, to prove the generalized Koopmans theorem.[23] We now include a simplified proof of the duality property. Recall that, since reduced density operators are Hermitian, they can be diagonalized in an orthonormal basis and their eigenvalues are real and positive.

Proposition 6: The interior products with Ψ *send any* λ*-eigenvector of* D^p*, with* $\lambda \neq 0$*, to an eigenvector of* D^{n-p} *associated to the same eigenvalue, and the "p-external space," i.e., the* 0*-eigenspace of* D^p *(if* 0 *is an eigenvalue), to the null vector space* $\{\vec{0}\}$.

Proof: Let $\Phi \in \wedge^p \mathcal{H}$ be an eigenvector for D^p with eigenvalue λ. Then, by definition

$$\lambda \cdot \Phi = D^p(\Phi) = \Psi \hookrightarrow \Phi \hookleftarrow \Psi.$$

If $\lambda \neq 0$ this shows that $\Phi \hookleftarrow \Psi \neq 0$ and we have

$$D^{n-p}(\Phi \hookleftarrow \Psi) = \Psi \hookrightarrow (\Phi \hookleftarrow \Psi) \hookleftarrow \Psi = (\Psi \hookrightarrow \Phi \hookleftarrow \Psi) \hookleftarrow \Psi = \lambda \cdot \Phi \hookleftarrow \Psi,$$

so that $\Phi \hookleftarrow \Psi \in \wedge^{n-p} \mathcal{H}$ is an eigenvector for D^{n-p} with the same eigenvalue. The same argument shows that $\Psi \hookrightarrow \Phi \in \wedge^{n-p} \mathcal{H}$ is an eigenvector for D^{n-p}, still with the same eigenvalue. If $\lambda = 0$ then

$$\begin{aligned} 0 &= \langle \Phi | \Psi \hookrightarrow (\Phi \hookleftarrow \Psi) \rangle = \langle \Phi \wedge (\Phi \hookleftarrow \Psi) | \Psi \rangle \quad \text{by Eq. (35)}, \\ &= \langle \Phi \hookleftarrow \Psi | \Phi \hookleftarrow \Psi \rangle \quad \text{by Eq. (34)}, \end{aligned}$$

from which we deduce, $\Phi \hookleftarrow \Psi = \Phi \hookrightarrow \Psi = 0$.

Of course, we can change p in $(n-p)$ in the previous proposition. Thus, we see that the interior products are isomorphisms from the nonzero eigenspaces of D^p to the nonzero eigenspaces of D^{n-p}, which is the Carlson and Keller duality property. We will call the space spanned by the nonzero eigenspaces of D^p, the "p-internal space." Its orthogonal complement is the p-external space already defined. The extension of the interior product isomorphisms to the external space does not seem of physical relevance.

G. A simple derivation of Sasaki's formula main corollary

In the development of the N-representability conditions of reduced density matrices (RDM),[22,24] it was soon considered that the properties of partitioning a system of n particles into two subsystems should be one of the keys to the solution of the problem, and Coleman emphasized in particular the rôle that Sasaki's formula[20,25] should play ["this formula should be extremely useful whenever a system is partitioned into two subsystems" (Ref. 24, pp. 677–678)]. In this section we will not expand on the original Sasaki formula and its interest for the study of reduced density matrices that we prefer calling reduced density operators in this work, unless these operators are represented in some finite basis set. We refer the reader to Chapter 3 of the book by Coleman and Yakulov, Ref. 22, where various applications of the Sasaki formula are given, together with historical references on the subject. Instead, we show here that the main corollary of Sasaki's formula, from the point of view of applications, is obtained easily with the help of the coproduct.

This corollary, also due to Sasaki (Ref. 22, Thm. 3.3), is the following.

Theorem 7: *Assuming $n=p+q$, $p\leqslant q$, if f^p (respectively, f^q) is a complex square integrable function of p (respectively, q) variables, then,*

$$\langle f^p f^q | \mathcal{A}_n f^p f^q \rangle = \sum_{j=0}^{p} (-1)^j \binom{p}{j} \binom{q}{j} \mathrm{Tr}[D^j_{f^p} D^j_{f^q}],$$

where $\mathcal{A}_n$ is the antisymmetrization operator acting on functions of n variables.

One expects that, in the exterior algebra formalism, the technical points of the proof related to the symmetric group actions and the related combinatorial operations should disappear. This is indeed the case. In the exterior algebra formalism, the previous result reads as follows.

Theorem 8: *Let $\Psi \in \wedge^p \mathcal{H}$ and $\Phi \in \wedge^q \mathcal{H}$ and assume, for example, that $q\leqslant p$. Then*

$$\langle \Psi \wedge \Phi | \Psi \wedge \Phi \rangle = \sum_{j \leqslant q} (-1)^j \mathrm{Tr}(D^j_\Psi D^j_\Phi). \tag{60}$$

Proof: We have, according to the generalized Laplace formula Eq. (28),

$$\langle \Psi \wedge \Phi | \Psi \wedge \Phi \rangle = \langle \Psi \otimes \Phi | \mathcal{Y}(\Psi \wedge \Phi) \rangle.$$

According to the Hopf algebra fundamental formula Eq. (23), combined with the notation of Eq. (40) we can write [denoting card (K) the cardinal of set K],

$$\mathcal{Y}(\Psi \wedge \Phi) = \sum_{I \in \mathcal{P}_p, J \in \mathcal{P}_q} (-1)^{\mathrm{card}(J)(p-\mathrm{card}(I))} \Psi_I \wedge \Phi_J \otimes \Psi_{\bar{I}} \wedge \Phi_{\bar{J}},$$

and therefore, making use of Eq. (24),

$$\langle \Psi \otimes \Phi | \mathcal{Y}(\Psi \wedge \Phi) \rangle = \sum_{I \in \mathcal{P}_p, J \in \mathcal{P}_q} (-1)^{\mathrm{card}(J)(p-\mathrm{card}(I))} \langle \Psi | \Psi_I \wedge \Phi_J \rangle \langle \Phi | \Psi_{\bar{I}} \wedge \Phi_{\bar{J}} \rangle.$$

Notice that the terms with $\mathrm{card}(J) \neq (p - \mathrm{card}(I))$ vanish because they contain Hermitian products between functions of different particle numbers. Therefore the computed quantity is equal to

$$\sum_{j \leqslant q} \sum_{I \in \mathcal{P}_{p,(p-j)}, J \in \mathcal{P}_{q,j}} (-1)^j \langle \Psi | \Psi_I \wedge \Phi_J \rangle \langle \Phi | \Psi_{\bar{I}} \wedge \Phi_{\bar{J}} \rangle,$$

and, making use again of Eq. (28), it is equal to

$$\sum_{j\leqslant q}\sum_{I\in\mathcal{P}_{p,(p-j)},J\in\mathcal{P}_{q,j}}(-1)^j\langle\mathcal{Y}(\Psi)|\Psi_I\otimes\Phi_J\rangle\langle\mathcal{Y}(\Phi)|\Psi_{\bar{I}}\otimes\Phi_{\bar{J}}\rangle$$

$$=\sum_{j\leqslant q}\sum_{I,K\in\mathcal{P}_{p,(p-j)},J,L\in\mathcal{P}_{q,j}}(-1)^j\langle\Psi_K|\Psi_I\rangle\langle\Psi_{\bar{K}}|\Phi_J\rangle\langle\Phi_L|\Psi_{\bar{I}}\rangle\langle\Phi_{\bar{L}}|\Phi_{\bar{J}}\rangle$$

which can be recast by renaming the indexes $I\mapsto\bar{I},K\mapsto\bar{K}$ (and noting that $\rho_{K,\bar{K}}\rho_{I,\bar{I}}=\rho_{\bar{K},K}\rho_{\bar{I},I}$), in the form

$$=\sum_{j\leqslant q}(-1)^j\sum_{I,K\in\mathcal{P}_{p,j}}\sum_{J,L\in\mathcal{P}_{q,j}}\langle\Psi_{\bar{K}}|\Psi_{\bar{I}}\rangle\vec{\mathcal{I}}_{\Psi_K}(\Phi_J)\circ\langle\Phi_{\bar{L}}|\Phi_{\bar{J}}\rangle\vec{\mathcal{I}}_{\Phi_L}(\Psi_I)$$

where we recognize inside the sum over j the trace of the operator,

$$\sum_{I,K\in\mathcal{P}_{p,j}}\langle\Psi_{\bar{K}}|\Psi_{\bar{I}}\rangle\vec{\mathcal{X}}_{\Psi_I}\circ\vec{\mathcal{I}}_{\Psi_K}\circ\sum_{J,L\in\mathcal{P}_{q,j}}\langle\Phi_{\bar{L}}|\Phi_{\bar{J}}\rangle\vec{\mathcal{X}}_{\Phi_J}\circ\vec{\mathcal{I}}_{\Phi_L},$$

which is according to Eq. (51), the product $D^j_\Psi D^j_\Phi$, hence the result, Eq. (60).

H. Generalization: partitioning a wave function into several blocks

The part played by the coproduct in the derivation of the previous results suggest some natural generalizations, which are developed in the present section. The idea is now to split the n-fermion wave function in more than two blocks. To this end, we introduce a new notation. We denote by $\mathcal{Y}^{[k]}$ the coproduct iterated k times $(k>0)$,

$$\mathcal{Y}^{[k]}:=(\mathrm{Id}\otimes\cdots\otimes\mathrm{Id}\otimes\mathcal{Y})\circ\cdots\circ(\mathrm{Id}\otimes\mathcal{Y})\circ\mathcal{Y}, \tag{61}$$

where in the last iteration factor $(\mathrm{Id}\otimes\cdots\otimes\mathrm{Id}\otimes\mathcal{Y})$, the identity appears $k-1$ times. The action of $\mathcal{Y}^{[k]}$ is to split a wave function into $k+1$ blocks and we recall that, because of the coassociativity property, Eq. (18), the result does not depend upon the position of the coproduct in each factor $\mathrm{Id}\otimes\cdots\otimes\mathrm{Id}\otimes\mathcal{Y}$. From its definition we have the recursion formula

$$\mathcal{Y}^{[k]}=(\mathrm{Id}\otimes\cdots\otimes\mathrm{Id}\otimes\mathcal{Y})\circ\mathcal{Y}^{[k-1]}. \tag{62}$$

We specify further by $\mathcal{Y}^{[k]}_{i_0,\ldots,i_k}$ the component of the iterated coproduct corresponding to the decomposition of a wave function into the tensor product of $(k+1)$ wave functions of $i_0,\ldots,i_k$-particles.

In a dual manner we define recursively the exterior product iterated k times $(k>0)$, $\mathcal{X}^{[k]}$, by

$$\mathcal{X}^{[k]}:=\mathcal{X}\circ(\mathcal{X}^{[k-1]}\otimes\mathrm{Id}), \tag{63}$$

with $\mathcal{X}^{[0]}:=\mathrm{Id}$.

$\mathcal{X}^{[k]}$ acts on $(k+1)$-component tensor products to form their $(k+1)$-component exterior product counterparts,

$$\mathcal{X}^{[k]}(\Psi_0\otimes\cdots\otimes\Psi_k)=\Psi_0\wedge\cdots\wedge\Psi_k. \tag{64}$$

Endowed with these tools we first generalize Eqs. (52) and (53).

Proposition 9: Let $\Psi\in\wedge^n\mathcal{H}$, and $i_0,\ldots,i_k$ such that $i_0+\cdots+i_k=n$, then we have

$$\mathcal{X}^{[k]}\circ\mathcal{Y}^{[k]}_{i_0,\ldots,i_k}(\Psi)=\binom{n}{i_0,\ldots,i_k}\Psi, \tag{65}$$

$$\mathcal{X}^{[k]}\circ\mathcal{Y}^{[k]}(\Psi)=(k+1)^n\Psi. \tag{66}$$

Proof: The generalized binomial coefficient $\binom{n}{i_0,\ldots,i_k}$ is the number of partitions of a set with n elements into an ordered sequence of k subsets with, respectively, $i_0,\ldots,i_k$ elements. That is,

$$\binom{n}{i_0,\ldots,i_k}=\frac{n!}{i_0!\ldots i_k!}.$$

Since $(k+1)^n$ is the number of partitions of a set with n elements into $k+1$ subsets, the second part of the proposition follows from the first identity. We now prove the first identity by induction on k.

The case $k=1$ corresponds precisely to Eq. (52). Assume then the property true up to $k-1$, and let show that it holds for k.

First we remark that $\mathcal{Y}^{[k]}_{i_0,\ldots,i_k}$ can be constructed on $\wedge^n\mathcal{H}$ from the coproduct in the following manner:

$$\mathcal{Y}^{[k]}_{i_0,\ldots,i_k}=(\mathrm{Id}\otimes\cdots\otimes\mathrm{Id}\otimes\mathcal{Y}_{i_{k-1},i_k})\circ\cdots\circ(\mathrm{Id}\otimes\mathcal{Y}_{i_1,n-i_0-i_1})\circ\mathcal{Y}_{i_0,n-i_0}. \tag{67}$$

Remark also that,

$$\mathcal{X}^{[k]}=\mathcal{X}\circ(\mathcal{X}^{[k-2]}\otimes\mathcal{X}). \tag{68}$$

Thus, we have,

$$\begin{aligned}
\mathcal{X}^{[k]}\circ\mathcal{Y}^{[k]}_{i_0,\ldots,i_k}(\Psi)&=\mathcal{X}\circ(\mathcal{X}^{[k-2]}\otimes\mathcal{X})\circ(\mathrm{Id}\otimes\cdots\otimes\mathrm{Id}\otimes\mathcal{Y}_{i_{k-1},i_k})\circ(\mathrm{Id}\otimes\cdots\otimes\mathrm{Id}\otimes\mathcal{Y}_{i_{k-2},i_{k-1}+i_k})\circ\cdots\\
&\quad\circ(\mathrm{Id}\otimes\mathcal{Y}_{i_1,n-i_0-i_1})\circ\mathcal{Y}_{i_0,n-i_0}(\Psi)\\
&=\mathcal{X}\circ(\mathcal{X}^{[k-2]}\otimes(\mathcal{X}\circ\mathcal{Y}_{i_{k-1},i_k}))\\
&\quad\circ(\mathrm{Id}\otimes\cdots\mathrm{Id}\otimes\mathcal{Y}_{i_{k-2},i_{k-1}+i_k})\circ\cdots\circ(\mathrm{Id}\otimes\mathcal{Y}_{i_1,n-i_0-i_1})\circ\mathcal{Y}_{i_0,n-i_0}(\Psi)\\
&=\mathcal{X}\circ\left(\mathcal{X}^{[k-2]}\otimes\binom{i_{k-1}+i_k}{i_k}\mathrm{Id}\right)\circ\mathcal{Y}^{[k-1]}_{i_0,\ldots,i_{k-2},i_{k-1}+i_k}(\Psi),\ \text{by Eq. (52)}\\
&=\binom{i_{k-1}+i_k}{i_k}\mathcal{X}^{[k-1]}\circ\mathcal{Y}^{[k-1]}_{i_0,\ldots,i_{k-2},i_{k-1}+i_k}(\Psi),\ \text{by Eq. (63)}\\
&=\binom{i_{k-1}+i_k}{i_k}\cdot\binom{n}{i_0,\ldots,i_{k-1}+i_k}\Psi,\ \text{by hypothesis,}
\end{aligned}$$

and the proof follows since

$$\binom{n}{i_0,\ldots,i_k}=\binom{n}{i_0,\ldots,i_{k-1}+i_k}\cdot\binom{i_{k-1}+i_k}{i_k}.$$

Next we generalize Eq. (28).

Proposition 10: For any $\Psi\in\wedge^n\mathcal{H}$ and for any $\Phi_0\in\wedge^{i_0}\mathcal{H},\ldots,\Phi_k\in\wedge^{i_k}\mathcal{H}$ with $i_0+\cdots+i_k=n$, we have

$$\langle\Phi_0\wedge\cdots\wedge\Phi_k|\Psi\rangle=\langle\Phi_0\otimes\cdots\otimes\Phi_k|\mathcal{Y}^{[k]}(\Psi)\rangle. \tag{69}$$

Proof: The proof proceeds by induction. The case $k=1$ is precisely Eq. (28). Let us suppose that the property is true up to $k-1$, then we have by Eq. (62),

$$\begin{aligned}
\langle\Phi_0\otimes\cdots\otimes\Phi_k|\mathcal{Y}^{[k]}(\Psi)\rangle&=\langle\Phi_0\otimes\cdots\otimes\Phi_k|(\mathrm{Id}\otimes\cdots\otimes\mathrm{Id}\otimes\mathcal{Y})\circ\mathcal{Y}^{[k-1]}(\Psi)\rangle\\
&=\langle\Phi_0\otimes\cdots\otimes\Phi_{k-2}\otimes(\Phi_{k-1}\wedge\Phi_k)|\mathcal{Y}^{[k-1]}(\Psi)\rangle\\
&=\langle\Phi_0\wedge\cdots\wedge\Phi_{k-2}\wedge(\Phi_{k-1}\wedge\Phi_k)|\Psi\rangle,\ \text{by hypothesis,}
\end{aligned}$$

where we can drop the parentheses thanks to the associativity of the exterior product.

By combining Eqs. (66) and (69) we immediately deduce the following.

Proposition 11: Let $\Psi,\Phi\in\wedge^n\mathcal{H}$. *Then, for any* k,

$$\langle\Psi|\Phi\rangle=\frac{1}{(k+1)^n}\langle\mathcal{Y}^{[k]}(\Psi)|\mathcal{Y}^{[k]}(\Phi)\rangle. \tag{70}$$

Finally, we generalize Eq. (60), by calculating the square norm of $\Phi=\Phi_0\wedge\cdots\wedge\Phi_k$, where $\forall m\in\{0,\ldots,k\},\Phi_m\in\wedge^{i_m}\mathcal{H}$. The latter can be expressed in the form

$$\Phi_m=\Sigma_l c_{m,l}\ \phi_{l,1+\Sigma_{j=0}^{m-1}i_j}\wedge\cdots\wedge\phi_{l,\Sigma_{j=0}^{m}i_j}$$

with

$$\sum_{j=0}^{-1} i_j=0 \quad\text{and}\quad \sum_{j=0}^{k} i_j=n.$$

That is to say, the indices of the spin orbitals of Φ_m run from $i_0+\cdots+i_{m-1}+1$ to $i_0+\cdots+i_{m-1}+i_m$ so that the indices of the spin orbitals of Φ run from 1 to n.

We extend to more than two subsets the notation of Eqs. (40)–(43), to encapsulate the sums on single configuration functions. However, here we leave out of the notation the sign of the reordering permutation. For example, $\forall m\in\{0,\ldots,k\}$, for any partition of

$$\left\{1+\sum_{j=0}^{m-1} i_j,\ldots,\sum_{j=0}^{m} i_j\right\}$$

into $k+1$ subsets, $I_m^0:=\{j_1^0,\ldots,j_{\mathrm{card}(I_m^0)}^0\},\ldots,I_m^k:=\{j_1^k,\ldots,j_{\mathrm{card}(I_m^k)}^k\}$ we note,

$$\begin{aligned}&\langle\Theta_0|\Phi_{I_m^0}\wedge\Psi_0\rangle\cdots\langle\Theta_k|\Phi_{I_m^k}\wedge\Psi_k\rangle\\&\quad:=\sum_l c_{m,l}\langle\Theta_0|\phi_{j_1^0}\wedge\cdots\wedge\phi_{j_{\mathrm{card}(I_m^0)}^0}\wedge\Psi_0\rangle\cdots\langle\Theta_k|\phi_{j_1^k}\wedge\cdots\wedge\phi_{j_{\mathrm{card}(I_m^k)}^k}\wedge\Psi_k\rangle.\end{aligned} \tag{71}$$

By Eq. (69), we have

$$\begin{aligned}\langle\Phi_0\wedge\cdots\wedge\Phi_k|\Phi_0\wedge\cdots\wedge\Phi_k\rangle&=\langle\Phi_0\otimes\cdots\otimes\Phi_k|\mathcal{Y}^{[k]}(\Phi_0\wedge\cdots\wedge\Phi_k)\rangle\\&=\Sigma_{I_m^l}\ \rho_{I_0^0,\ldots,I_k^0,\ldots,I_0^k,\ldots,I_k^k}\langle\Phi_0|\Phi_{I_0^0}\wedge\cdots\wedge\Phi_{I_k^0}\rangle\cdots\langle\Phi_k|\Phi_{I_0^k}\wedge\cdots\wedge\Phi_{I_k^k}\rangle,\end{aligned}$$

where the sum extends over all partitions

$$\bigsqcup_{l\in\{0,\ldots,k\}} I_m^l=\left\{1+\sum_{j=0}^{m-1} i_j,\ldots,\sum_{j=0}^{m} i_j\right\},$$

for $m=0,\ldots,k$, and where $\rho_{I_0^0,\ldots,I_k^0,\ldots,I_0^k,\ldots,I_k^k}$ is the signature of the permutation reordering the sequence obtained by concatenation $(I_0^0//\cdots//I_k^0//\cdots//I_0^k//\cdots//I_k^k)$, in increasing order.

Now because the scalar product is zero between functions of different number of particles, the nonzero terms of the sum must not only satisfy, $\Sigma_{l=0}^k\mathrm{card}(I_m^l)=i_m$, $\forall m\in\{0,\ldots,k\}$, but also, $\Sigma_{m=0}^k\mathrm{card}(I_m^l)=i_l$, $\forall l\in\{0,\ldots,k\}$. We simply note, $\Sigma'_{I_m^l}$, the previous summation on the I_m^l with this additional restriction. We terminate our calculation by using again Eq. (69) and expanding the iterated coproduct, $\mathcal{Y}^{[k]}$, in terms of another set of partitions, J_m^l, we obtain

$$\begin{aligned}\langle \Phi_0 \wedge \cdots \wedge \Phi_k | \Phi_0 \wedge \cdots \wedge \Phi_k \rangle &= \Sigma'_{I_m^l} \Sigma'_{J_m^l} \rho_{I_0^0,\ldots,I_k^0,\ldots,I_0^k,\ldots,I_k^k} \rho_{J_0^0,\ldots,J_k^0,\ldots,J_0^k,\ldots,J_k^k} \langle \Phi_{J_0^0} | \Phi_{I_0^0} \rangle \cdots \langle \Phi_{J_0^k} | \Phi_{I_k^0} \rangle \cdots \\ &\times \langle \Phi_{J_k^0} | \Phi_{I_0^k} \rangle \cdots \langle \Phi_{J_k^k} | \Phi_{I_k^k} \rangle, \end{aligned} \tag{72}$$

where the complex conjugate of the notation defined in Eq. (71) has been used for the sums over the J_m^l, so that the notation encapsulates the summation,

$$\sum_{\substack{l_0,\ldots,l_k \\ l'_0,\ldots,l'_k}} c^*_{0,l_0} \cdots c^*_{k,l_k} c_{0,l'_0} \cdots c_{k,l'_k}.$$

IV. CANONICAL FORMS OF AN *n*-FERMION WAVE FUNCTION

So far we have dealt with general wave functions of the whole Hilbert space. The expansion Eq. (39) of an n-fermion wave function was completely arbitrary, that is to say, we did not impose any orthogonality condition on the spin orbitals, nor did we exclude linear dependencies from occurring in the expansion.

The physics does not depend upon the choice of the spin orbitals used to expand the wave function, however for practical purposes certain choices are more advantageous than others. In the present section, we propose constraints to reduce the arbitrariness of the expansion Eq. (39). These constraints are based on algebraic concepts which, in general, admit a physical interpretation. The resulting expansions have interesting properties for numerical calculations.

A. Miscellaneous definitions

Definition 12 (rank of a wave function): For any $\Phi \in \wedge\mathcal{H}$ the rank of Φ, $r[\Phi]$, is the least element k of $\mathbb{N} \cup \{+\infty\}$, such that,

$$\exists \mathcal{F} \subseteq \mathcal{H},\ \dim \mathcal{F} = k \ \text{ and } \ \Phi \in \wedge\mathcal{F},$$

where $\dim \mathcal{F}$ *is the dimension of the Hilbert subspace $\mathcal{F}$, and where $\wedge\mathcal{F}$ is identified to a subspace of $\wedge\mathcal{H}$ in a natural way.*

For the sake of simplicity and because we have in view numerical applications, from now on we only consider wave functions of finite rank, however most results could be extended to completely general wave functions.

Definition 13 (depth of a wave function): For any $\Phi \in \wedge^n\mathcal{H}$ the depth of Φ, $d[\Phi]$, is the largest integer k, such that, $\exists \Psi_1 \in \wedge^{p_1}\mathcal{H},\ldots,\exists \Psi_k \in \wedge^{p_k}\mathcal{H}$, with $p_1,\ldots,p_k$ non-negative integers, allowing us to express Φ in the form

$$\Phi = \Psi_1 \wedge \cdots \wedge \Psi_k. \tag{73}$$

Definition 14 (length of a wave function): For any $\Phi \in \wedge^n\mathcal{H}$ the length of Φ, $l[\Phi]$, is the least element k of $\mathbb{N} \cup \{+\infty\}$, such that, $\exists \Psi_1 \in \wedge^n\mathcal{H},\ldots,\exists \Psi_k \in \wedge^n\mathcal{H}$, with $\Psi_1,\ldots,\Psi_k$ SC functions, allowing us to express Φ in the form

$$\Phi = \Psi_1 + \cdots + \Psi_k. \tag{74}$$

In the next sections, we exploit the concepts of rank, depth and length of a wave function to cast a wave function into a simpler and less arbitrary form.

B. Internal spin orbital expansion

By Definition 12, the vector subspace, $\mathcal{F}$, of dimension $r[\Psi]$, associated with a wave function Ψ, is the smallest subspace of $\mathcal{H}$ allowing us to express Ψ. It is precisely the 1-internal space,

denoted by $\mathcal{I}^1[\Psi]$, defined in Sec. III F. Its determination allows the expansion of a given wave function, Ψ, with the least possible number of spin orbitals. The importance of the expansion in terms of internal spinorbitals has already been emphasized and taken advantage of in Refs. 26 and 27. Here we present a new algorithm for reexpanding a wave function in terms of a set of internal spin orbitals suggested by Hopf algebra techniques.

1. Determination of the internal space

An alternative definition of the 1-internal space, or simply the ''internal space,'' is the following.

Definition 15: Let $\Psi \in \wedge^n\mathcal{H}$. The internal space of Ψ is the vector space

$$\mathcal{I}^1[\Psi] := \{\phi \in \wedge^1\mathcal{H}, \exists \Phi \in \wedge^{n-1}\mathcal{H}, \Phi \hookleftarrow \Psi = \phi\}. \tag{75}$$

Notice that the substitution of 1 by p in Eq. (75) gives an alternative definition of the p-internal space, $\mathcal{I}^p[\Psi]$. Potential applications of the p-internal spaces have been proposed in Ref. 16.

The definition, Eq. (75), gives rise to a simple method for computing the internal space: Choose a basis $(\Phi_i)_{i\in B}$ of $\wedge^{n-1}\mathcal{H}$ (possibly adapted to the structure of Ψ, so that in general choosing a suitable subset of the basis will be enough) and compute the set $\{\Phi_i \hookleftarrow \Psi\}_i$. The result is a set of generators of the internal space, from which a basis set can be extracted.

Let us give an example. Consider a system of five spin-$\frac{1}{2}$ fermions whose wave function is expanded in 16 single configuration functions, which are themselves constructed out of 12 orthonormal spin orbitals (six of spin α, $\phi_1^\alpha,\ldots,\phi_6^\alpha$, and six of spin β, $\phi_1^\beta,\ldots,\phi_6^\beta$),

$$\begin{aligned}\Psi = \tfrac{1}{4}\{&\phi_1^\alpha\wedge\phi_3^\alpha\wedge\phi_5^\alpha\wedge\phi_1^\beta\wedge\phi_3^\beta+\phi_1^\alpha\wedge\phi_3^\alpha\wedge\phi_6^\alpha\wedge\phi_1^\beta\wedge\phi_4^\beta+\phi_1^\alpha\wedge\phi_4^\alpha\wedge\phi_6^\alpha\wedge\phi_1^\beta\wedge\phi_3^\beta\\
&+\phi_1^\alpha\wedge\phi_4^\alpha\wedge\phi_5^\alpha\wedge\phi_1^\beta\wedge\phi_4^\beta+\phi_1^\alpha\wedge\phi_3^\alpha\wedge\phi_5^\alpha\wedge\phi_2^\beta\wedge\phi_3^\beta+\phi_1^\alpha\wedge\phi_3^\alpha\wedge\phi_6^\alpha\wedge\phi_2^\beta\wedge\phi_4^\beta\\
&+\phi_1^\alpha\wedge\phi_4^\alpha\wedge\phi_6^\alpha\wedge\phi_2^\beta\wedge\phi_3^\beta+\phi_1^\alpha\wedge\phi_4^\alpha\wedge\phi_5^\alpha\wedge\phi_2^\beta\wedge\phi_4^\beta+\phi_2^\alpha\wedge\phi_3^\alpha\wedge\phi_5^\alpha\wedge\phi_1^\beta\wedge\phi_3^\beta\\
&+\phi_2^\alpha\wedge\phi_3^\alpha\wedge\phi_6^\alpha\wedge\phi_1^\beta\wedge\phi_4^\beta+\phi_2^\alpha\wedge\phi_4^\alpha\wedge\phi_6^\alpha\wedge\phi_1^\beta\wedge\phi_3^\beta+\phi_2^\alpha\wedge\phi_4^\alpha\wedge\phi_5^\alpha\wedge\phi_1^\beta\wedge\phi_4^\beta\\
&+\phi_2^\alpha\wedge\phi_3^\alpha\wedge\phi_5^\alpha\wedge\phi_2^\beta\wedge\phi_3^\beta+\phi_2^\alpha\wedge\phi_3^\alpha\wedge\phi_6^\alpha\wedge\phi_2^\beta\wedge\phi_4^\beta+\phi_2^\alpha\wedge\phi_4^\alpha\wedge\phi_6^\alpha\wedge\phi_2^\beta\wedge\phi_3^\beta\\
&+\phi_2^\alpha\wedge\phi_4^\alpha\wedge\phi_5^\alpha\wedge\phi_2^\beta\wedge\phi_4^\beta\}.\end{aligned} \tag{76}$$

Let us compute, for example, the spin orbital ϕ obtained by evaluating $\Phi \hookleftarrow \Psi$, where $\Phi = \phi_4^\alpha\wedge\phi_5^\alpha\wedge\phi_1^\beta\wedge\phi_4^\beta$. By definition of the interior product, this amounts to extracting the remaining fifth spin orbital out of the exterior products containing Φ as a factor, and then combining them linearly by using the expansion coefficients of Ψ. Only two SC in the development of Ψ have to be taken into account, namely, $\phi_1^\alpha\wedge\phi_4^\alpha\wedge\phi_5^\alpha\wedge\phi_1^\beta\wedge\phi_4^\beta$ and $\phi_2^\alpha\wedge\phi_4^\alpha\wedge\phi_5^\alpha\wedge\phi_1^\beta\wedge\phi_4^\beta$. We get therefore, $\phi = \phi_1^\alpha + \phi_2^\alpha$. For each Φ running over a basis set of 4-fermion SC functions, a similar calculation, gives either zero or an internal spin orbital. In fact, since Ψ contains neither ϕ_5^β nor ϕ_6^β, only the subset of the functions Φ which do not contain these spin orbitals, need to be considered. Standard linear algebra techniques permit one to eliminate the linear dependencies in the set of internal spin orbitals so-obtained, and if needed, to orthonormalize the set. In our pedagogical example, the following set of eight spin orbitals is an orthonormal basis of the internal space, $\{\psi_1^\alpha,\psi_1^\beta,\phi_3^\alpha,\phi_3^\beta,\phi_4^\alpha,\phi_4^\beta,\phi_5^\alpha,\phi_6^\alpha\}$, where we have set

$$\psi_1^\alpha := \frac{1}{\sqrt{2}}(\phi_1^\alpha + \phi_2^\alpha), \quad \psi_1^\beta := \frac{1}{\sqrt{2}}(\phi_1^\beta + \phi_2^\beta). \tag{77}$$

A basis of the external space, its orthocomplement, is $\{\psi_2^\alpha,\psi_2^\beta,\phi_5^\beta,\phi_6^\beta\}$, with

$$\psi_2^\alpha := \frac{1}{\sqrt{2}}(\phi_1^\alpha - \phi_2^\alpha), \quad \psi_2^\beta := \frac{1}{\sqrt{2}}(\phi_1^\beta - \phi_2^\beta). \tag{78}$$

2. Re-expansion of the wave function

In practical applications, the bottleneck of numerical codes expressing a wave function in terms of a, possibly symmetry-adapted, basis set of internal spin orbitals, is not the determination of the internal basis set itself, but the re-expansion of the wave function in the new basis.[27] Here, we describe a simple, original algorithm to express explicitly the wave function in the basis of spin orbitals of the internal space.

One of the main advantages of this algorithm is that it does not require the determination of the whole transformation unlike the re-expansion algorithm of Refs. 28 and 29. One or several re-expansion coefficients can be specifically targeted to take advantage of, for example, the knowledge of the population of the internal basis functions and thereby eliminate the less populated functions as in Ref. 27.

The steps followed by the algorithm are

(1) Compute $\mathcal{Y}_{1,n-1}(\Psi)$.
(2) Obtain a (non-necessarily orthogonal) basis $(\phi_1,\ldots,\phi_k)$ of the internal space, $\mathcal{I}^1[\Psi]$, and target an element $\Phi_I = \phi_{i_1}\wedge\ldots\wedge\phi_{i_n}$ of the basis, $(\Phi_J)_{J\in\mathcal{P}_{k,n}}$, it induces in $\wedge^n\mathcal{I}^1[\Psi]$.
(3) Form the linear combination of the components of $\mathcal{Y}_{1,n-1}(\Psi)$, obtained in the first step, corresponding to the term, $\phi_{i_1}\otimes\Psi_{i_1}$, of the decomposition,
$$\mathcal{Y}_{1,n-1}(\Psi) = \sum_{i=1}^{k} \phi_i\otimes\Psi_i .$$
(4) Compute $\mathcal{Y}_{1,n-2}(\Psi_{i_1})$.
(5) Form the linear combination of the components of $\mathcal{Y}_{1,n-2}(\Psi_{i_1})$, obtained in the previous step, corresponding to the term, $\phi_{i_2}\otimes\Psi_{i_1,i_2}$, of the decomposition,
$$\mathcal{Y}_{1,n-2}(\Psi_{i_1}) = \sum_{i=1}^{k} \phi_i\otimes\Psi_{i_1,i} .$$
(6) Proceed iteratively up to the computation of $\mathcal{Y}_{1,0}(\Psi_{i_1,\ldots,i_{n-1}})$.
(7) Form the linear combination of the components of $\mathcal{Y}_{1,0}(\Psi_{i_1,\ldots,i_{n-1}})$, obtained in the previous step, corresponding to the term, $\phi_{i_n}\otimes\Psi_{i_1,\ldots,i_n}$, of the decomposition,
$$\mathcal{Y}_{1,0}(\Psi_{i_1,\ldots,i_{n-1}}) = \sum_{i=1}^{k} \phi_i\otimes\Psi_{i_1,\ldots,i_{n-1},i} .$$

$\Psi_{i_1,\ldots,i_n}$ is the targeted re-expansion coefficient.

This assertion follows from the following three properties:

(i) Eq. (65), which shows that
$$\Psi = \frac{1}{n!}\mathcal{X}^{[n-1]}\circ\mathcal{Y}^{[n-1]}_{1,\ldots,1}(\Psi). \tag{79}$$

(ii) The fact that by construction,
$$\mathcal{Y}^{[n-1]}_{1,\ldots,1}(\Psi) = \sum_{i_1,\ldots,i_n} \Psi_{i_1,\ldots,i_n}\phi_{i_1}\otimes\cdots\otimes\phi_{i_n}. \tag{80}$$

(iii) The property, $\forall\,\sigma\in\mathcal{S}_n$,
$$\Psi_{\sigma(i_1),\ldots,\sigma(i_n)} = (-1)^{|\sigma|}\Psi_{i_1,\ldots,i_n} \tag{81}$$
allowing one to show that, after taking the iterated exterior product in Eq. (79), a factor $n!$ arises from the summation in the right-hand side of Eq. (80).

The latter property is a direct consequence of the co-commutativity of the coproduct, that is, the fact that the coproduct is invariant under the twisting map,

$$T\circ\mathcal{Y}=\mathcal{Y}. \tag{82}$$

As a remark, we note that the algorithm can easily take advantage of the symmetry of the system, if we demand in the second step that the internal basis set be symmetry-adapted.

Let us illustrate the algorithm on the example of the preceding section and compute the coefficient of, say $\psi_1^\alpha\wedge\phi_3^\alpha\wedge\phi_5^\alpha\wedge\psi_1^\beta\wedge\phi_3^\beta$. We obtain successively

$$\mathcal{Y}_{1,4}(\Psi)=\psi_1^\alpha\otimes\frac{1}{2\sqrt{2}}(\phi_3^\alpha\wedge\phi_5^\alpha\wedge\phi_1^\beta\wedge\phi_3^\beta+\phi_3^\alpha\wedge\phi_6^\alpha\wedge\phi_1^\beta\wedge\phi_4^\beta+\phi_4^\alpha\wedge\phi_6^\alpha\wedge\phi_1^\beta\wedge\phi_3^\beta+\phi_4^\alpha\wedge\phi_5^\alpha\wedge\phi_1^\beta\wedge\phi_4^\beta$$
$$+\phi_3^\alpha\wedge\phi_5^\alpha\wedge\phi_2^\beta\wedge\phi_3^\beta+\phi_3^\alpha\wedge\phi_6^\alpha\wedge\phi_2^\beta\wedge\phi_4^\beta+\phi_4^\alpha\wedge\phi_6^\alpha\wedge\phi_2^\beta\wedge\phi_3^\beta+\phi_4^\alpha\wedge\phi_5^\alpha\wedge\phi_2^\beta\wedge\phi_4^\beta)+\cdots.$$

Denoting by $\Psi_{1\alpha}$ the 4-fermion function associated to ψ_1^α above,

$$\mathcal{Y}_{1,3}(\Psi_{1\alpha})=\phi_3^\alpha\otimes\frac{1}{2\sqrt{2}}(\phi_5^\alpha\wedge\phi_1^\beta\wedge\phi_3^\beta+\phi_6^\alpha\wedge\phi_1^\beta\wedge\phi_4^\beta+\phi_5^\alpha\wedge\phi_2^\beta\wedge\phi_3^\beta+\phi_6^\alpha\wedge\phi_2^\beta\wedge\phi_4^\beta)+\cdots.$$

Denoting by $\Psi_{1\alpha,3\alpha}$ the 3-fermion function associated to ϕ_3^α above,

$$\mathcal{Y}_{1,2}(\Psi_{1\alpha,3\alpha})=\phi_5^\alpha\otimes\frac{1}{2\sqrt{2}}(\phi_1^\beta\wedge\phi_3^\beta+\phi_2^\beta\wedge\phi_3^\beta)+\cdots.$$

Denoting by $\Psi_{1\alpha,3\alpha,5\alpha}$ the 2-fermion function associated to ϕ_5^α above,

$$\mathcal{Y}_{1,1}(\Psi_{1\alpha,3\alpha,5\alpha})=\psi_1^\beta\otimes\tfrac{1}{2}\phi_3^\beta.$$

We immediately conclude that the targeted coefficient, denoted $\Psi_{1\alpha,3\alpha,5\alpha,1\beta,3\beta}$, is $\frac{1}{2}$ and that all the other expansion coefficients containing the indexes $(1\alpha,3\alpha,5\alpha)$ are zero. Proceeding in the same manner for the other coefficients, we obtain the expansion of Ψ,

$$\Psi=\tfrac{1}{2}\{\psi_1^\alpha\wedge\phi_3^\alpha\wedge\phi_5^\alpha\wedge\psi_1^\beta\wedge\phi_3^\beta+\psi_1^\alpha\wedge\phi_3^\alpha\wedge\phi_6^\alpha\wedge\psi_1^\beta\wedge\phi_4^\beta+\psi_1^\alpha\wedge\phi_4^\alpha\wedge\phi_6^\alpha\wedge\psi_1^\beta\wedge\phi_3^\beta$$
$$+\psi_1^\alpha\wedge\phi_4^\alpha\wedge\phi_5^\alpha\wedge\psi_1^\beta\wedge\phi_4^\beta\}, \tag{83}$$

which is, as expected, much simpler than the initial expansion, Eq. (76).

C. Factorization of a wave function

The interest of an expansion achieving the depth (Definition 13), is to factorize the fermionic wave function into functions of a lesser number of particles. Note that in our definition we do not require the latter functions to be strongly orthogonal, that is to be such that their 1-internal spaces are mutually orthogonal. Therefore there is a difference between the expansion we are investigating and those based on the group functions of McWeeny.[30]

Factorized wave functions arise naturally in quantum mechanics when certain particles are ''frozen'' in a calculation, for example, the core electrons of an atom or a molecule. However, a general wave function may well admit a hidden factorization.

In the present state of the art, little is known about the general problem of finding the depth of a wave function. However, the particular case of the factorization of a wave function by a SC function is fully understood. The solution follows from Ref. 31 [Lemma B, p.234].

Proposition 16: Any linearly independent set of spin orbitals $\psi_1,\ldots,\psi_k$ belonging to the kernel of the creation operator, $\vec{\mathcal{X}}_\Psi$, factorizes Ψ.

That is to say, $\Psi = \psi_1 \wedge \ldots \wedge \psi_k \wedge \Psi'$, where Ψ' can be computed explicitely as

$$\Psi' = \frac{(\psi_1 \wedge \ldots \wedge \psi_k) \leftarrow \Psi}{\langle \psi_1 \wedge \ldots \psi_k | \psi_1 \wedge \ldots \psi_k \rangle}. \tag{84}$$

In particular, the factorization is optimal (that is, k is maximal), if and only if $k = \dim \mathrm{Ker}(\vec{\mathcal{X}}_\Psi)$.

The physical content of the proposition is clear: a spin orbital is fully occupied in the wave function if and only if creating a fermion in this spin orbital gives 0.

For example, if Ψ is the wave function of Eq. (83), let

$$\psi = x_1^\alpha . \psi_1^\alpha + x_1^\beta . \psi_1^\beta + x_3^\alpha . \phi_3^\alpha + x_3^\beta . \phi_3^\beta + x_4^\alpha . \phi_4^\alpha + x_4^\beta . \phi_4^\beta + x_5^\alpha . \phi_5^\alpha + x_6^\alpha . \phi_6^\alpha$$

be an arbitrary internal spin orbital and write

$$\vec{\mathcal{X}}_\Psi(\psi) = \Psi \wedge \psi = 0.$$

The exterior product can be expanded in terms of the 6-fermion SC basis functions of $\wedge^6 \mathcal{I}^1[\Psi]$ induced by the internal basis set. Then, the linear independency of the 6-fermion SC basis functions gives

$$x_3^\alpha = x_3^\beta = x_4^\alpha = x_4^\beta = x_5^\alpha = x_6^\alpha = 0.$$

We deduce that, Ker $(\vec{\mathcal{X}}_\Psi)$ is spanned by $(\psi_1^\alpha, \psi_1^\beta)$, and, in fact,

$$\Psi = \tfrac{1}{2} \psi_1^\alpha \wedge \psi_1^\beta \wedge (\phi_3^\alpha \wedge \phi_5^\alpha \wedge \phi_3^\beta + \phi_3^\alpha \wedge \phi_6^\alpha \wedge \phi_4^\beta + \phi_4^\alpha \wedge \phi_6^\alpha \wedge \phi_3^\beta + \phi_4^\alpha \wedge \phi_5^\alpha \wedge \phi_4^\beta). \tag{85}$$

Note that the method could have been applied before the extraction of the internal spin orbitals, on the expansion, Eq. (76), where the factorization is less obvious. Note also that, with $k = n$, the number of fermions, the proposition provides a necessary and sufficient condition for a wave function to be condensable into a SC function.

D. Decomposition into a direct sum

The potential usefulness of the concept of length of a wave function is obvious. Obtaining the shortest expansion of a given wave function would concentrate the physical information contained in it and facilitate both its retrieval and its interpretation. However, it is still an unsolved mathematical problem, except in very specific cases.[32,33] The only general result is for the case where the wave function admits a direct sum decomposition. Therefore we will only develop this particular case.

An n-fermion wave function Ψ admits a direct sum decomposition if it can be written as a sum of k SC functions Ω_i,

$$\Psi = \sum_{i=1}^{k} \Omega_i, \tag{86}$$

and if the dimension of its internal space, $\mathcal{I}^1[\Psi]$ is $n.k$,

$$\dim \mathcal{I}^1[\Psi] = n.k, \tag{87}$$

or equivalently, if

$$\Omega_1 \wedge \cdots \wedge \Omega_k \neq 0. \tag{88}$$

Note that the definition in Ref. 31 rewritten in Ref. 16 is not correct, because the condition $\forall i \neq j, \Omega_i \wedge \Omega_j \neq 0$ is not sufficient to have Eq. (87).

It is clear that a wave function satisfying Eqs. (86) and (87) is of length k. However, a function of length k does not have to satisfy Eq. (87).

A general method to first diagnose the existence of a direct sum decomposition and then to derive it, has been proposed in Ref. 31. It relies on the observation, that there exists a direct sum decomposition Eq. (86) if and only if there are exactly k groups of n $(n-1)$-fermion functions of the form $\psi \hookleftarrow \Psi$, $\psi \in \mathcal{H}$, such that (i) Each $(n-1)$-fermion functions can be condensed into a SC function. (ii) In each group the internal spaces of the $(n-1)$-fermion functions are included in the same n-dimensional vector space. (iii) The $n.k$ $(n-1)$-fermion functions are linearly independent.

The application of the method to the part of the 3-fermion wave function inside the parentheses in Eq. (85) has been treated in details in Ref. 16. Here, we only give the final result. The 3-fermion wave function does admit a direct sum decomposition after the following change of basis set:

$$\psi_3^\alpha := \frac{1}{\sqrt{2}}(\phi_3^\alpha + \phi_4^\alpha), \quad \psi_3^\beta := \frac{1}{\sqrt{2}}(\phi_3^\beta + \phi_4^\beta), \tag{89}$$

$$\psi_4^\alpha := \frac{1}{\sqrt{2}}(\phi_3^\alpha - \phi_4^\alpha), \quad \psi_4^\beta := \frac{1}{\sqrt{2}}(\phi_3^\beta - \phi_4^\beta), \tag{90}$$

$$\psi_5^\alpha := \frac{1}{\sqrt{2}}(\phi_5^\alpha + \phi_6^\alpha), \quad \psi_5^\beta := \frac{1}{\sqrt{2}}(\phi_5^\beta + \phi_6^\beta), \tag{91}$$

$$\psi_6^\alpha := \frac{1}{\sqrt{2}}(\phi_5^\alpha - \phi_6^\alpha), \quad \psi_6^\beta := \frac{1}{\sqrt{2}}(\phi_5^\beta - \phi_6^\beta). \tag{92}$$

In this new basis, Eq. (85) can be rewritten as

$$\Psi = \tfrac{1}{2}\psi_1^\alpha \wedge \psi_1^\beta \wedge (\psi_3^\alpha \wedge \psi_5^\alpha \wedge \psi_3^\beta + \psi_4^\alpha \wedge \psi_6^\alpha \wedge \psi_4^\beta). \tag{93}$$

Wave functions admitting a direct sum decomposition arise naturally in physics when several resonant structures are needed to describe a quantum system. For example, the Weinbaum wave function for He_2^+,[34] can be cast in the form of the 3-fermion wave function in parentheses in Eq. (93). More general cases where a direct sum factors the wave function, like in Eq. (93) but possibly more complex, have been given in Ref. 26. There are molecules where three electrons share two centers like the nitroxide π-radicals or the HCO_2 σ-radical. Of course, resonant structures involving more than three fermions are common too.

An important remark is that a direct sum decomposition of a n-fermion wave function is unique if $n>2$. So, Eq. (93) is not only much simpler than the initial expansion, Eq. (76) but it is also less arbitrary. In fact, this expansion can be considered as a canonical form for this wave function since the (normalized) spin orbitals have been uniquely determined up to sign factors, if we do not allow the mixing of α- and β-spin orbitals, or up to a linear transformation of the spin orbitals of the SC function factorizing the wave function in the general case.

V. CONCLUSION

In this paper, we have developed the Hopf algebra formalism for the fermionic Fock space. This formalism is immediately applicable to many fields of physics, ranging from solid state physics, quantum chemistry, and atomic physics, where it allows a formulation of all electronic structure problems, to nuclear physics, where it applies to nucleons.

More precisely, we have introduced new algebraic tools which facilitate the investigation of theoretical and numerical problems in quantum physics. The simple proof of the Carlson and

Keller theorem and the derivation of Sasaki's formula main corollary, that we have obtained, illustrate the advantages of our formalism: The tedious action of the symmetric group is eliminated and many numerical and sign factors are encapsulated in the formalism.

Among the new tools, the co-product defined in Sec. II, and its iterated version defined in Sec. III, arguably stand out. They not only pave the way for a natural generalization of many results based on the partitioning of a wave function into blocks, but they also allow a numerical calculation to be broken into successive steps. This has been exploited in an original, parallelizable, algorithm to re-expand a wave function in the least possible number of spin orbitals.

However, if the re-expansion of a wave function in a set of internal spin orbitals is now a well-understood mathematical issue, the problem of extracting the spin orbitals that achieve the (minimal) length of a wave function remains, except in the particular case where the wave function admits a direct sum decomposition. This is a longstanding problem and probably a hard one.

In contrast, the concept of the depth of a wave function is new and the problem of factorizing a wave function by more general functions than SC functions has not received much attention. Progress on this issue could be very important for physical applications because such a factorization allows a reduction in the dimensionality of many calculations and is the basis for geminal or more generally, group function methods. We hope to report new results on this topics in forthcoming studies.

Scale calculus and the Schrödinger equation

Jacky Cresson[a)]
Equipe de Mathématiques de Besançon, CNRS-UMR 6623, Université de Franche-Comté, 25030 Besançon cedex, France

(Received 7 July 2003; accepted 8 August 2003)

This paper is twofold. In a first part, we extend the classical differential calculus to continuous nondifferentiable functions by developing the notion of scale calculus. The scale calculus is based on a new approach of continuous nondifferentiable functions by constructing a one parameter family of differentiable functions $f(t,\epsilon)$ such that $f(t,\epsilon)\to f(t)$ when ϵ goes to zero. This led to several new notions as representations: fractal functions and ϵ-differentiability. The basic objects of the scale calculus are left and right quantum operators and the scale operator which generalizes the classical derivative. We then discuss some algebraic properties of these operators. We define a natural bialgebra, called quantum bialgebra, associated with them. Finally, we discuss a convenient geometric object associated with our study. In a second part, we define a first quantization procedure of classical mechanics following the scale relativity theory developed by Nottale. We obtain a nonlinear Schrödinger equation via the classical Newton's equation of dynamics using the scale operator. Under special assumptions we recover the classical Schrödinger equation and we discuss the relevance of these assumptions. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1618923]

INTRODUCTION

The origin of the fundamental incompatibility between *quantum mechanics* and Einstein's *general relativity* lies in the microscopic geometric structure of space–time. As pointed out by Greene,[27] Feynman,[25] Cohen-Tannoudji and Spiro (Ref. 14, p. 131) and others, space–time is no more a *differentiable* manifold at the *atomic* scale, contrary to the assumption of general relativity.

From this fact, at least two theories have been constructed:

(i) the *string theory*, which implies a dimensional extension of space–time by allowing a closed dimension at the Planck scale;
(ii) the *scale relativity theory* developed by Nottale,[37] which gives up the Einstein's assumption of the differentiability of space–time by considering what he calls a *fractal space–time*, which can be interpreted as a scale dependant nondifferentiable manifold. He then extends Einstein's relativity principle to scale, and develop the *scale relativity principle*.

In this article, we explore this second alternative.

Nottale[37] has studied what are the consequences of the abandon of the differentiability of space–time. This problem is difficult, in particular because the mathematical foundations of such a theory are not yet constructed. For example, Nottale asserts that there exists an ''infinity of geodesics on a fractal space–time.'' This sentence is difficult to understand because we do not know what is a fractal space–time. (We refer to Ref. 20 for a first definition of a fractal manifold and a discussion of the special scale relativity theory.) Even if we identify this set to a nondifferentiable manifold, we do not know what is the sense of ''geodesic.'' As a consequence, we restrict our attention to a far simpler problem, namely the consequences of the loss of differentiability of a given trajectory. A first approach is to consider that only *space* is a nondifferentiable manifold

[a)]Electronic mail: cresson@math.univ-fcomte.fr

and to take the variable t as an absolute variable. As a consequence, trajectories of quantum particles are nondifferentiable curves parametrized by the time variable t. In this case, we have at least the following two consequences.

(i) By Lebesgues theorem,[46] the *length* of a nondifferentiable curve Γ is *infinite*. What does it means from the physical view point ? That given a parameter $\epsilon>0$, which has the sense of a resolution, the lenght L_ϵ of the curve constructed by connecting small arcs of length ϵ on points of Γ, goes to infinity when ϵ goes to zero. As a consequence, the role of ϵ is now fundamental as L_ϵ loses any sense when ϵ is going to zero, contrary to usual differentiable curves where ϵ is only a parameter of precision and L_ϵ goes to a fixed constant L.

Nottale then introduce *fractal functions*, which are resolution (or scale) dependent functions $f(x,\epsilon)$, which converge to nondifferentiable functions, and a (*renormalization like*) differential equation satisfied by L_ϵ, called a *scale law*, which gives the behavior of $f(x,\epsilon)$ when ϵ goes to zero.

(ii) The derivative along the curve has no sense. Nottale introduces a complex operator, which he calls the *scale derivative*. It takes into account the mean-backward and mean-forward derivative along the curve.

Using these tools, he gives an informal derivation of the *Schrödinger equation* from the classical *Newtonian equation of dynamics*, via a quantization procedure which follows from an extension of Einstein's relativity principle called the *scale relativity principle*.

In this paper, we develop a mathematical framework in which we can explicit the quantization procedure, which we call the *scale quantization procedure*.

The plan of the paper is as follows.

In Part I, we define a natural extension of Leibniz differential calculus which can be used on nondifferentiable functions in order to precise points (i) and (ii). We introduce the *Scale calculus*, which formalizes the concept of ϵ-differentiability. In particular, we define an operator called the *scale difference operator*, which is the rigorous mathematical counterpart of Nottale's scale derivative.

In Part II, we define the scale quantization procedure. We give a precise definition of the quantization map, which allows us to associate to the classical Newtonian equation of dynamics a quantized analog. This analog has the form of a generalized nonlinear Schrödinger equation. We then discuss how to obtain the classical Schrödinger equation.

PART I

I. SCALE CALCULUS

A. Introduction

Nondifferentiable functions, and more generally nondifferentiable manifolds, become more and more important in many part of mathematics and physics, like Brownian motion,[24] and quantum mechanical path by Feynman and Hibbs.[26] Despite many works, our understanding of nondifferentiable functions is nonsatisfactory.

A great deal of effort has been devoted to generalize, as long as possible, the classical differential calculus of Leibniz and Newton. This leads to a different kind of fractional calculus (Riemann, Liouville, Weyl,...). All this fractional calculus is based on a pure analytic generalization of the Cauchy formula. As a consequence, and despite their intrinsic interest, they are difficult to interpret (in particular, from the geometrical view point).

The aim of this paper is to introduce a set of ideas, coming from physics, in order to renew our approach to nondifferentiable functions.

In physic, the nondifferentiability is not studied by itself. On the contrary, this is the effect of nondifferentiability with respect to a differentiable model which is being sought. For example, as explained by Greene (Ref. 27, Chap. 5), in *superstring* theory one is led to a new vision of

space–time because the space–time, at the scale of atoms, cannot be considered differentiable at all, as in the general relativity scheme. Here, one focuses on fluctuations with respect to a differentiable character.

Moreover, one usually does not have access via measurement, to the nondifferentiable object (function, manifold), but to an almost everywhere differentiable model of it. This explains also the previous remark: by measure we obtain a differentiable model, and we must see, when the precision of measure increases, if there is no two strong fluctuations with respect to this model. For a differentiable process, the fluctuations decrease. In the case of a nondifferentiable process, one expects larger and larger fluctuations.

This point of view leads to several new concepts: the representation of continuous nondifferentiable functions, fractals functions and ϵ-differentiability. The idea is to associate to each continuous nondifferentiable function $f(t)$, a one parameter family of differentiable function $f(t,\epsilon)$ such that $f(t,\epsilon)\to f(t)$ when ϵ goes to zero. The next step is to give a useful criterion, which says that $f(t,\epsilon)$ is a "good" model for the function f. An important notion is then the minimal resolution which is, more or less, the precision under which, one cannot use a differentiable model without lacking many features of the underlying function f. We then define quantum derivatives and the scale derivative, which reflects the nondifferentiable character of the underlying function f.

We discuss algebraic properties of quantum derivatives, and the scale derivative. These operators act on the set of continuous real valued functions, denoted by C^0. They are first introduced in Ref. 4 in order to discuss the derivation of Schrödinger's equation from the classical Newton's equation of dynamics using Nottale's scale relativity theory.[37]

In this paper, we construct a natural structure of bialgebra, called quantum bialgebra, using specific properties of quantum derivatives. The quantum algebra can be considered as a small deformation of a classical Hopf algebra. Although we are close to a problem related to quantum groups and quasitriangular Hopf algebras introduced by Drinfeld,[22] we stress that quantum bialgebras are new.

There is no natural bialgebra structure associated with the scale derivative. This follows from the lack of a natural composition rule for scale operators that we define in this paper.

We also discuss the natural geometric object associated with a continuous nondifferentiable function. It turns out that this geometric object is, in the simplest case, the product of a differentiable curve Γ by a two points set $A=\{a,b\}$, so $M\times A$. This is a simple example of a noncommutative space studied by Connes,[15] as a preliminary to his noncommutative model of the standard model.

B. About nondifferentiable functions

The aim of this section is to develop a rigorous mathematical understanding of the idea of fluctuation with respect to a differentiable model for continuous nondifferentiable functions.

1. Representation theory and fractals functions

Here, we introduce two dual notions: the representation of nondifferentiable functions and fractal functions. Representations are well suited to develop a mathematical understanding of a nondifferentiable function based on differentiable functions. Fractal functions take their origin in physical problems.

In the following, we denote by C^0 the set of continuous real valued functions, and by C^1 the set of differentiable real valued functions.

Definition 2.1: Let $f\in C^0$; a representation of f is a one parameter family of operator S_ϵ, defined by

$$S_\epsilon:\begin{array}{ccc} C^0 & \to & C^1 \\ f & \mapsto & S_\epsilon(f)=f_\epsilon, \end{array} \tag{I.1}$$

and such that the differentiable functions $f_\epsilon \in C^1$ converge, in C^0-topology, toward f when ϵ goes to zero.

A basic example is obtained by approximating f by mean functions f_ϵ defined by $f_\epsilon(t) = (1/2\epsilon)\int_{t-\epsilon}^{t+\epsilon} f(s)ds$.

More generally, we can consider a *smoothing function* $\Phi(s;t,\epsilon)$ depending on two parameters, t and ϵ, satisfying the normalization

$$\int_{-\infty}^{\infty} \Phi(s;t,\epsilon)ds = 1. \tag{I.2}$$

For any continuous function, we define a representation by

$$f_\epsilon(t) = \int_{-\infty}^{\infty} \Phi(s;t,\epsilon)f(s)ds. \tag{I.3}$$

In practice, we never have access to f. An idea is to define f via a family of functions which are not functionally dependent of f like in (I.1). We are led to the notion of *fractal functions*, first introduced by Nottale[37] (see also Ref. 18).

Definition 2.2: A fractal function is a parametrized function of the form $f(t,\epsilon)$, depending on $\epsilon > 0$, such that the following occurs.

(i) *For all $\epsilon > 0$, the function $f(t,\epsilon) \in C^1$, except at a finite number of points,*
(ii) *There exists an everywhere nondifferentiable function $f(t)$ such that $f(t,\epsilon)$ converges to $f(t)$ when ϵ goes to zero.*

The main difference between Definitions 2.1 and 2.2 is that for fractal functions, one usually does not know an explicit form of the limit function f, we only require an existence result. Moreover, the set of functions $f(t,\epsilon)$ does not refer to the limit f in its definition, which is closest to the *measurement* process in physical experiment.

2.1.1. Examples of fractal functions: Nottale's functions and iteration of affine systems. The basic example of fractal functions is *Nottale's functions* introduced in Ref. 37:

For all $\epsilon > 0$, and for all $0 < \mu < \epsilon$,

$$x(t,\epsilon) = \int \Phi_{\epsilon,\mu}(t,y)x(y,\mu)dy, \tag{I.4}$$

where $\Phi_{\epsilon,\mu}(x,y)$ is a differentiable function such that

$$\int_{-\infty}^{\infty} \Phi_{\epsilon,\mu}(x,y)dy = 1, \ \ \forall\, x \in \mathbf{R}, \tag{I.5}$$

called a smoothing function.

Definition 2.3: Let $\Phi_{\epsilon,\mu}$ be a smoothing function satisfying (I.5). We denote by $\mathcal{N}(\Phi_{\epsilon,\mu})$, and we call Nottale's set associated with $\Phi_{\epsilon,\mu}$, the set of functions defined by (I.4).

We refer to Ref. 18 for basic properties of this set of functions, in particular for a useful equivalence relation.

An interesting example of fractal functions for which the limit function is not explicit is given by the iteration of *affine systems*.[46]

An affine map in $\mathbb{R}^2$, with a coordinates system (x,y), is a map of the form

$$F\begin{pmatrix} x \\ y \end{pmatrix} = M\begin{pmatrix} x \\ y \end{pmatrix} + T, \tag{I.6}$$

where M is a 2×2 matrix and T is a translation vector.

An *affine system* is given by

(i) a positive integer $N \geqslant 2$;

(ii) $N+1$ points of $\mathbb{R}^2$, $A=A_1,\ldots,A_{N+1}=B$. We denote $A_i=(x_i,y_i)$, $x_1=a$, $x_{N+1}=b$. We assume that

$$a=x_1<x_2<\cdots<x_{N+1}=b;$$

(iii) N affine map $F_1,\ldots,F_N$ such that

$$F_i(AB)=A_iA_{i+1}.$$

We denote by F the map defined by

$$F(E)=\bigcup_{i=1}^{N} F_i(E). \tag{I.7}$$

Let z_0 be the affine function on $[a,b]$ whose graph Γ_0 is the segment AB. The image $\Gamma_1=F(\Gamma)$ is the graph of a continuous function, which is affine. For all n, we define the continuous function z_n whose graph is $\Gamma_n=F(\Gamma_{n-1})$. Following Ref. 46, p. 175, the sequence of functions $(z_n)_{n\in\mathbb{N}}$ converge uniformly to a continuous function z_∞ such that $F(\Gamma_\infty)=\Gamma_\infty$.

2. ϵ-differentiability and minimal resolution

a. Minimal resolution: Formal idea. In our point of view, nondifferentiability is always studied via a one parameter familly of differentiable functions f_ϵ. A basic question is the following.

When ϵ goes to zero, can we find a value ϵ_0 such that for $\epsilon>\epsilon_0$, we can assume that the limit function is differentiable and for $\epsilon>\epsilon_0$, we are sure that the limit function is nondifferentiable?

It is equivalent to ask if the nondifferentiable character of a function can be detected via its approximation.

If we can find a quantity $\epsilon(f)$ of this kind, then we call it *minimal resolution*. It is the best order of approximation under which nondifferentiable effects must be taken into account.

In the following we give two ways in order to defined a minimal resolution, by taking two different effects of nondifferentiability.

b. First approach. A basic properties of differentiable functions is that the quantities,

$$\nabla_+^\epsilon f(t)=\frac{f(t+\epsilon)-f(t)}{\epsilon} \quad \text{and} \quad \nabla_-^\epsilon f(t)=\frac{f(t)-f(t-\epsilon)}{\epsilon}, \tag{I.8}$$

keep sense when ϵ goes to zero and are equal.

As a consequence, the following quantity,

$$a_\epsilon f(t)=\left|\frac{f(t+\epsilon)+f(t-\epsilon)-2f(t)}{\epsilon}\right|, \tag{I.9}$$

converges to zero when ϵ goes to zero.

The underlying idea is that the two representations of a function f, given by the forward and backward mean function, defined as

$$f_\epsilon^+(t)=(1/2\epsilon)\int_t^{t+\epsilon} f(s)ds \qquad \text{and} \qquad f_\epsilon^-(t)=(1/2\epsilon)\int_{t-\epsilon}^{t} f(s)ds, \tag{I.10}$$

respectively, must have derivatives which coincide when ϵ goes to zero.

This remark allows us to introduce the following notion of ϵ-h-differentiability.

Definition 2.4: Let $h>0$ be a given real number. A function $f\in C^0$ is said to be ϵ-h-differentiable at point t, if

$$a_\epsilon f(t) < h. \tag{I.11}$$

We can detect the nondifferentiable character of a function by investigating its ϵ-h-differentiability. Precisely, we define the notion of minimal resolution:

Definition 2.5: Let $h>0$ be a given real number and $f \in C^0$. The h-minimal resolution of f at point t, denoted $\epsilon(f,h)(t)$ is defined as $\inf_\epsilon \{a_\epsilon f(t) < h\}$.

Of course, if for a given h, the h-minimal resolution is nonzero, then f is nondifferentiable.

Remark 2.1: The reverse is wrong, as proved by the following example.

Let $f:\mathbb{R}\to\mathbb{R}$ be a function defined by

$$f: \begin{cases} t\cos(1/t), & \text{if } t \neq 0 \\ 0, & \text{if } t = 0. \end{cases} \tag{I.12}$$

This function is derivable for all $t\neq 0$. Then, we have $\epsilon(f,h)(t)=0$ for all $t\neq 0$. This function is not derivable at $t=0$. However, we have $a_\epsilon(f,h)(0)=0$ for all $\epsilon>0$ by parity. As a consequence, $\epsilon(f,h)=0$, even if f is not derivable on $\mathbb{R}$.

For all $\alpha \in]0,1[$, we denote by C^α the set of continuous real valued functions, defined on $[0,1]$ such that the quantity

$$|f|_\alpha = \sup_{0\leqslant x\neq y\leqslant 1} \frac{|f(x)-f(y)|}{|x-y|^\alpha} \tag{I.13}$$

is finite (Hölderian functions of order α). Then, we have the following lemma.

Lemma 2.1: Let $0<\alpha<1$ and $f \in C^\alpha$. For all $t \in]0,1[$, and all $h>0$, the h-minimal resolution of f at point t satisfies

$$\epsilon(f,h)(t) \leqslant \left(\frac{h}{2|f|_\alpha}\right)^{1/\alpha - 1}. \tag{I.14}$$

Remark 2.2: In this example, the minimal resolution depends on $|f|^\alpha$. As a consequence, for a quantum mechanical path, we expect that the minimal resolution depends on the momentum of the particle. This is indeed the case in Nottale's theory,[37] where the minimal resolution is related to the de Broglie length of the particle.

A global order of h-minimal resolution can be defined.

Definition 2.6: Let $h>0$ be given and $f \in C^0$. The h-minimal resolution of f, denoted $\epsilon(f,h)$, is defined by $\epsilon(f,h)=\sup_{t\in \mathcal{D}f}\epsilon(f,h)(t)$, where $\mathcal{D}f$ is the definition domain of f.

In this definition it is important to take the sup of h-minimal resolution of f at point t. As a consequence, if f is differentiable on a small set of point, the h-minimal resolution is however nonzero.

Remark 2.3: We have $\epsilon(f+c,h)=\epsilon(f,h)$ for all $c\in\mathbb{R}$. But, we have $\epsilon(\lambda f,h)\neq\epsilon(f,h)$ for all $\lambda\neq 1$, contrary to the case of Ref. 4. This inequality is related to the fact that a changing momentum induce a change of regularity for the curve. A physical consequence is that the minimal resolution must depend on the momentum.

The connection to representation theory is done through the backward and forward mean functions, f_ϵ^σ, $\sigma=\pm$, introduced before. Indeed, backward and forward mean functions are differentiable functions. They can be used as a classical representation of a given continuous function f. However, if f admits a nonzero h minimal resolution, this means that these functions are not sufficient to capture the complete local behavior of f as long as $\epsilon<\epsilon(f,h)$. Of course, this notion depends on h. In physical problems, the constant h must correspond to a universal constraint, like the Heisenberg constraint in quantum mechanics.

c. Order of divergence. The previous quantity $a_\epsilon f(t)$ gives a criterion distinguishing differentiable and nondifferentiable functions based on the fact that in some case, the left and right

derivative of a nondifferentiable function (when they exist) are different. Of course, the general case is far more complicated. A complete characterization of differentiability is given by the following.

Let f be a continuous real function. We denote

$$D^{\sigma}f(t)=\lim \sup_{\epsilon\to 0^{\sigma}} \frac{f(t+\epsilon)-f(t)}{\epsilon}, \quad \text{and} \quad D_{\sigma}f(t)=\lim \inf_{\epsilon\to 0^{\sigma}} \frac{f(t+\epsilon)-f(t)}{\epsilon}, \quad \sigma=\pm. \tag{I.15}$$

These quantities are always well defined and belong to $\overline{\mathbb{R}}$. By Refs. 45, 31, p. 319, we know that f is differentiable at point t if and only if

$$D^{+}f(t)=D^{-}f(t)=D_{+}f(t)=D_{-}f(t)\in\mathbb{R}. \tag{I.16}$$

By Ref. 45, we know that the set of continuous functions for which the left and right derivative exists and are distinct is of zero measure. By considering the set of nondifferentiable functions, we then deduce that the left and right derivative does not exist on a set of full measure. More precisely, we have two cases: either $D^{\sigma}f(t)$ and $D_{\sigma}f(t)$ exist but are different, or these quantities diverge with ϵ going to zero, for $\sigma=\pm$.

We denote by $\Delta_{\mu}^{\sigma}f(t)$, $\sigma=\pm$ the quantity

$$\Delta_{\mu}^{\sigma}f(t)=\sigma\frac{f(t+\sigma\mu)-f(t)}{\mu}, \quad \sigma=\pm, \tag{I.17}$$

and for $\epsilon>0$, we denote

$$\overline{d}_{\epsilon}^{\sigma}f(t)=\sup_{\mu\leqslant\epsilon}\Delta_{\mu}^{\sigma}f(t), \underline{d}_{\epsilon}^{\sigma}f(t)=\inf_{\mu\leqslant\epsilon}\Delta_{\mu}^{\sigma}f(t). \tag{I.18}$$

A better object to measure the loss of differentiability is the following quantity:

$$A_{\epsilon}f(t)=\begin{matrix}\inf_{\epsilon>0}\{|\overline{d}_{\epsilon}^{+}f(t)-\underline{d}_{\epsilon}^{+}f(t)|<h, |\overline{d}_{\epsilon}^{-}f(t)-\underline{d}_{\epsilon}^{-}f(t)|<h,\\ (1-1_{D^{+}=D_{+}})(1-1_{D^{-}=D_{-}})|\overline{d}_{\epsilon}^{+}f(t)-\overline{d}_{\epsilon}^{-}f(t)|<h,\end{matrix} \tag{I.19}$$

when ϵ goes to zero.

In the Hölderian case, i.e., $f\in C^{\alpha}$, $0<\alpha<1$, this quantity diverges as $\epsilon^{\alpha-1}$. As a consequence, a possible extension of the notion of minimal resolution can be obtained by the following.

Definition 2.7: Let $h>0$; we call minimal resolution the following quantity:

$$\epsilon(f,h)=\inf_{\epsilon>0}\{A_{\epsilon}f(t)<h\}. \tag{I.20}$$

When the left and right derivatives exist, or diverge, the previous quantity reduces to the minimal resolution defined in Sec. I B 6. However, this quantity can distinguish the case where left and right derivatives are not defined but not infinite.

3. Scale law

For an everywhere nondifferentiable function f, the length L_{ϵ} of the graph of the mean function f_{ϵ} goes to infinity when ϵ goes to 0. Of course, this property cannot be used as a definition of an everywhere nondifferentiable function. We can find curves which are rectifiable with infinite length (see Ref. 6). We want to quantify this divergence. A first idea is to find a differential equation which gives the behavior of L_{ϵ} with respect to ϵ like in (Refs. 6, 18). However, this is difficult because L_{ϵ} is not differentiable with respect to ϵ in general. In this section, we define a less rigid definition of scale law and we discuss its properties.

a. Definition: Let f be an everywhere nondifferentiable continuous function on the interval $I=[0,1]$. For $\epsilon>0$, we denote by f_ϵ the mean function associated with f on I, and $\mathcal{L}_\epsilon$ the length of its graph.

Definition 2.8: We say that f satisfies a scale law if there exist functions $l_\epsilon>0$ and $L_\epsilon>0$ such that

$$l_\epsilon \leqslant \mathcal{L}_\epsilon \leqslant L_\epsilon, \tag{I.21}$$

satisfying

$$\mathcal{L}_\epsilon = O(l_\epsilon), \quad \mathcal{L}_\epsilon = O(L_\epsilon), \tag{I.22}$$

and for which there exists a function $E:\mathbb{R}\to\mathbb{R}$, such that

$$\frac{dl_\epsilon}{d\ln\epsilon} = E(l_\epsilon, \ln\epsilon), \frac{dL_\epsilon}{d\ln\epsilon} = E(L_\epsilon, \ln\epsilon). \tag{I.23}$$

The function E is called a scale law.

Of course, when one knows a scale law of f, we deduce a speed of drift for $\mathcal{L}_\epsilon$.

Basic examples of scale laws are given by the following:

(i) For $a>0$, $E(x,t)=a$,

(ii) For $b>0$, $E(x,t)=bx$.

For (i), we obtain graph with logarithmic drift of order $|a|\ln(1/\epsilon)$. For (ii), we obtain the classical power law drift of order $1/\epsilon^b$.

Using this notion, we are led to two different kind of problems.

(i) Let E be a given function. Find the set of function $\mathcal{E}(E)$ such that for all $f\in\mathcal{E}(E)$, a scale law of f is E.

(ii) Let $\mathcal{E}$ be a given set of functions. Find, if it exists, a scale law for each $f\in\mathcal{E}$.

The first problem is equivalent to estimate a given class of functions by the speed of drift of $\mathcal{L}_\epsilon$. This point is difficult and discussed in Ref. 6.

The second one is more natural and discussed in the following.

b. Scale law of Hölderian functions. We first define an important class of continuous functions.

Definition 2.9: We denote by $H^\alpha(c,C)$ the set of real valued continuous functions f such that for all $\epsilon>0$ sufficiently small, and $|t-t'|<\epsilon$, we have

$$c\epsilon^\alpha \leqslant |f(t)-f(t')| \leqslant C\epsilon^\alpha. \tag{I.24}$$

The set H^α corresponds to continuous functions which are Hölder and inverse Hölder of exponent α.

Example: Let $0<\alpha<1$ and $g(t)$ be the function of period 1 defined on $[0,1]$ by

$$g(t)=\begin{cases} 2t, & \text{if } 0\leqslant t\leqslant 1/2 \\ 2-2t, & \text{if } 1/2\leqslant t\leqslant 1. \end{cases} \tag{I.25}$$

The Knopp or Takagi function, defined by

$$K(t)=\sum_{n=0}^{\infty} 2^{-n\alpha} g(2^n t), \tag{I.26}$$

belongs to H^α (see Ref. 46, Sec. 13.1).

We use notations from Definition 2.8.

Theorem 2.1: *Let $0<\alpha<1$ and $f\in H^\alpha(c,C)$ defined on an open interval $U\subset\mathbb{R}$ such that $I=[0,1]\subset U$. For all $\epsilon>0$, we define*

$$l_\epsilon = \epsilon^{\alpha-1}\sqrt{\epsilon^{2(1-\alpha)}+c^2}, L_\epsilon = \epsilon^{\alpha-1}\sqrt{\epsilon^{2(1-\alpha)}+C^2}. \tag{I.27}$$

A scale law for f is then given by

$$E(y,t) = (\alpha-1)(y-1/y). \tag{I.28}$$

Proof: We have

$$\mathcal{L}_\epsilon = \frac{1}{2\epsilon}\int_0^1 \sqrt{4\epsilon^2+(f(x+\epsilon)-f(x-\epsilon))^2}\,dx. \tag{I.29}$$

As $f \in H^\alpha$, we have

$$4c^2\epsilon^{2\alpha} \leqslant (f(x+\epsilon)-f(x-\epsilon))^2 \leqslant 4C^2\epsilon^{2\alpha}. \tag{I.30}$$

As a consequence, we obtain

$$\epsilon^{\alpha-1}\sqrt{\epsilon^{2(1-\alpha)}+c^2} \leqslant \mathcal{L}_\epsilon \leqslant \epsilon^{\alpha-1}\sqrt{\epsilon^{2(1-\alpha)}+C^2}. \tag{I.31}$$

We deduce

$$l_\epsilon \leqslant \mathcal{L}_\epsilon \leqslant L_\epsilon, \tag{I.32}$$

for ϵ sufficiently small.

By differentiating L_ϵ with respect to ϵ, we obtain

$$\frac{dL_\epsilon}{d\epsilon} = \frac{\alpha-1}{\epsilon}\left[L_\epsilon - \frac{1}{L_\epsilon}\right]. \tag{I.33}$$

Using

$$\frac{dL_\epsilon}{d\ln\epsilon} = \epsilon\frac{dL_\epsilon}{d\epsilon}, \tag{I.34}$$

we obtain the scale function $E(y,t) = (\alpha-1)(y-1/y)$. We verify that l_ϵ satisfies the same differential equations. □

The previous result is best analyzed in term of the new variables,

$$x_\epsilon = 1/l_\epsilon, \quad \mathcal{X}_\epsilon = 1/\mathcal{L}_\epsilon, \quad X_\epsilon = 1/L_\epsilon. \tag{I.35}$$

When ϵ goes to 0, we have x_ϵ, X_ϵ and $\mathcal{X}_\epsilon$ which go to 0. Moreover, the scale law for these new functions is

$$\frac{dx}{dt} = (1-\alpha)(x-x^3). \tag{I.36}$$

Indeed, by making the change of variables $x = 1/y$ in the scale law,

$$\frac{dy}{dt} = (\alpha-1)(y-1/y), \tag{I.37}$$

and using the relation

$$\frac{dx}{dt} = -(1/y^2)\frac{dy}{dt}, \tag{I.38}$$

we obtain the result.

The classical linearization theorem of Poincaré (Refs. 2 and 30) allows us to find, in a neighborhood of $x=0$, an analytic change of variables $z=h(x)$, such that the differential equation (I.36) is transformed into

$$\frac{dz}{dt}=(1-\alpha)z. \tag{I.39}$$

The set of Hölderian functions H^{α} induces, up to analytic changes of variables, the linear scale law (I.39).

Remark 2.4: In Galilean scale relativity, the set of functions which admit a linear scale law allows us to define the Djinn variable (see Ref. 18, Sec. 3.2.5 and Sec. 3.3).

c. Nonuniform Hölderian functions. In this section, we consider nonuniform Höderian functions.

Definition 2.10: Let $\alpha(t):\mathbb{R}\to]0,1[$. *We denote by* $H^{\alpha(.)}$ *the set of continuous Hölderian functions satisfying, for all* $h>0$ *sufficiently small,*

$$ch^{\alpha(t)}<|f(t+h)-f(t)|<Ch^{\alpha(t)}, \tag{I.40}$$

where $c>0$, $C>0$ *are constants.*

For $H^{\alpha(.)}$ functions, we have not been able to derive a scale law. We then introduce a weak notion.

Definition 2.11: We say that f *admits weak-scale laws, if there exists* l_{ϵ} *and* L_{ϵ} *such that*

$$l_{\epsilon}\leqslant\mathcal{L}_{\epsilon}\leqslant L_{\epsilon}, \tag{I.41}$$

satisfying

$$\mathcal{L}_{\epsilon}=O(l_{\epsilon}),\quad \mathcal{L}_{\epsilon}=O(L_{\epsilon}), \tag{I.42}$$

and for which we can find two functions: $E_{-}:\mathbb{R}\times\mathbb{R}\to\mathbb{R}$ *and* $E_{+}:\mathbb{R}\times\mathbb{R}\to\mathbb{R}$ *such that*

$$\frac{dl_{\epsilon}}{d\ln\epsilon}=E_{-}(l_{\epsilon},\ln\epsilon),\ \frac{dL_{\epsilon}}{d\ln\epsilon}=E_{+}(L_{\epsilon},\ln\epsilon). \tag{I.43}$$

For all $\epsilon>0$, we define

$$\alpha_i(\epsilon)=\alpha(i/\epsilon i+1/\epsilon), \tag{I.44}$$

with $i=0,\ldots,[1/\epsilon]$, where $[x]$ denotes the integer part of x.

We define

$$\gamma(\epsilon)=\min_{i=0,\ldots,[1/\epsilon]}\alpha_i(\epsilon),\beta(\epsilon)=\max_{i=0,\ldots,[1/\epsilon]}\alpha_i(\epsilon). \tag{I.45}$$

Theorem 2.2: *Let* $f\in H^{\alpha(.)}$. *For all* $\epsilon>0$ *sufficiently small we assume that the exponents (I.45) are differentiable functions with respect to* ϵ. *Then,* f *admits for weak-scale laws,*

$$E_{-}(x,t)=(1-\alpha-t\gamma')(x-x^3),\ E_{+}(x,t)=(1-\alpha-t\beta')(x-x^3). \tag{I.46}$$

C. Scale calculus

In Ref. 4, we introduce the notion of *quantum derivatives*. In this section, we give a less rigid definition, which allows us to discuss more easily algebraic properties of these operators.

1. Left and right quantum difference operators

Let $h>0$ be given. If f possesses a nonzero h-minimal resolution, then for $\epsilon<\epsilon(f,h)$, one must take into account the nondifferentiable character of f with respect to its forward and backward mean representations. A possible way to do it is to say that the backward and forward derivatives of f at ϵ carry different information on the local behavior of f. The idea of quantum derivatives formalize this idea.

Definition 3.1: Let $h>0$, and f be a continuous, real valued function.

If $\epsilon(f,h)>0$, for all $\epsilon(f,h)>\epsilon>0$, we define left and right quantum difference operators of f at point t, the quantities

$$\nabla_+^\epsilon f(t)=\frac{f(t+\epsilon)-f(t)}{\epsilon},\ \nabla_-^\epsilon f(t)=\frac{f(t)-f(t-\epsilon)}{\epsilon}, \tag{I.47}$$

respectively.

If $\epsilon(f,h)=0$, and f is differentiable then

$$\Delta_+^0 f(t)=\Delta_-^0 f(t)=f'(t). \tag{I.48}$$

Remark 3.1: (1) We can give a more rigid definition of quantum derivatives by fixing the ϵ to be the minimal resolution of the function considered for a given $h>0$.

(2) By remark 2.1, we cannot extend the definition of the left and right quantum operators when $\epsilon(f,h)=0$ in order to cover the set of nondifferentiable function with zero minimal resolution.

2. The scale difference operator

The scale difference operator, first introduced in Ref. 4 following Nottale's work,[37] is intended to summarize the information given by a quantum difference operator, needed to perform the local analysis of a given nondifferentiable function.

Definition 3.2: Let $h>0$, and f be a continuous function such that $\epsilon(f,h)\geqslant\epsilon>0$. The ϵ-scale difference operator of f at point t is a complex operator, denoted by $\Box_\epsilon/\Box t$, defined by

$$\frac{\Box_\epsilon f}{\Box t}(t)=\frac{1}{2}(\nabla_+^\epsilon f(t)+\nabla_-^\epsilon f(t))-i\frac{1}{2}(\nabla_+^\epsilon f(t)-\nabla_-^\epsilon f(t)),\ i^2=-1. \tag{I.49}$$

When $\epsilon=0$, and f is differentiable, we have the following useful property.

Lemma 3.1 (Gluing): Let f be a differentiable function. Then, we have

$$\frac{\Box f}{\Box t}=\frac{df}{dt}. \tag{I.50}$$

Moreover, if we denote by $f_\epsilon(t)$ the mean function $f_\epsilon(t)=(1/2\epsilon)\int_{t-\epsilon}^{t+\epsilon}f(s)ds$, we have that

$$\mathrm{Re}\left(\frac{\Box_\epsilon f}{\Box t}(t)\right)=(f_\epsilon)'(t), \tag{I.51}$$

where Re denotes the real part of a complex number. The imaginary part of $\Box_\epsilon f/\Box t$ is the fluctuation of the forward mean function with respect to the backward mean function.

3. Main result

We denote by H^α the set of real valued functions which are Hölder and inverse Hölder of exponent α, which means that for all ϵ sufficiently small, and $|t'-t|\leqslant\epsilon$, there exists $c>0$ and $C>0$, such that

$$c\epsilon^{\alpha} \leqslant |f(t')-f(t)| \leqslant C\epsilon^{\alpha}. \tag{I.52}$$

An important theorem, from the point of view of the scale relativity, is the following.

Theorem 3.1: *Let $h>0$, $f(x,t)$ be a C^n function, $x(t)$ a continuous function such that $\epsilon(x,h)>0$. Then, for $\epsilon(x,h) \geqslant \epsilon > 0$, ϵ sufficiently small, we have*

$$\frac{\Box_{\epsilon} f(x(t),t)}{\Box t} = \frac{\partial f}{\partial t} + \sum_{j=1}^{n} \frac{1}{j!} \frac{\partial^j f}{\partial x^j}(x(t),t)\epsilon^{j-1} a_{\epsilon,j}(t) + o(\epsilon^{1/n}), \tag{I.53}$$

where

$$a_{\epsilon,j}(t) = \tfrac{1}{2}[((\Delta_+^{\epsilon}x)^j - (-1)^j(\Delta_-^{\epsilon}x)^j) - i((\Delta_+^{\epsilon}x)^j + (-1)^j(\Delta_-^{\epsilon}x)^j)]. \tag{I.54}$$

The proof follows from the following lemma.

Lemma 3.2: Let $f(x,t)$ be a real valued function of class C^{n+1}, $n \geqslant 3$, and let $X(t)$ be a continuous real valued function of class $H^{1/n}$. For ϵ sufficiently small, the right and left derivatives of $f(X(t),t)$ are given by

$$\nabla_{\sigma}^{\epsilon} f(X(t),t) = \frac{\partial f}{\partial t}(X(t),t) + \sigma \sum_{i=1}^{n} \frac{1}{i!} \frac{\partial^i f}{\partial x^i}(X(t),t)\epsilon^{-1}(\sigma\epsilon\nabla_{\sigma}^{\epsilon}X(t))^i + o(\epsilon^{1/n}), \tag{I.55}$$

for $\sigma = \pm$.

For $n=2$, we obtain the so-called Itô formula:

$$\nabla_{\sigma}^{\epsilon} f(X(t),t) = \frac{\partial f}{\partial t}(X(t),t) + \frac{\partial f}{\partial x}(X(t),t)\nabla_{\sigma}^{\epsilon}X(t) + \frac{1}{2}\frac{\partial^2 f}{\partial x^2}(X(t),t)\epsilon(\nabla_{\sigma}^{\epsilon}X(t))^2 + o(\epsilon^{1/2}). \tag{I.56}$$

Proof: This follows from easy computations. First, we remark that, as $X(t) \in H^{1/n}$, we have $|\epsilon\nabla_{\sigma}^{\epsilon}X(t)| = o(\epsilon^{1/n})$. Moreover,

$$f(X(t+\epsilon),t+\epsilon) = f(X(t)+\epsilon\nabla_{+}^{\epsilon}X(t),t+\epsilon). \tag{I.57}$$

By the previous remark, and the fact that f is of order C^{n+1}, we can make a Taylor expansion up to order n with a controlled remainder:

$$f(X(t+\epsilon),t+\epsilon) = f(X(t),t) + \sum_{k=1}^{n} \frac{1}{k!} \sum_{i+j=k} (\epsilon\nabla_{+}^{\epsilon}X(t))^i \epsilon^j \frac{\partial^k f}{\partial^i x\, \partial^j t}(X(t),t) + o((\epsilon\nabla_{+}^{\epsilon}X(t))^{n+1}). \tag{I.58}$$

As a consequence, we have

$$\epsilon\nabla_{+}^{\epsilon} f(X(t),t) = \sum_{k=1}^{n} \frac{1}{k!} \sum_{i+j=k} (\epsilon\nabla_{+}^{\epsilon}X(t))^i \epsilon^j \frac{\partial^k f}{\partial^i x\, \partial^j t}(X(t),t) + o((\epsilon\nabla_{+}^{\epsilon}X(t))^{n+1}). \tag{I.59}$$

By selecting terms of order less or equal to one in ϵ on the rhs of this equation, we obtain

$$\epsilon\nabla_{+}^{\epsilon} f(X(t),t) = \epsilon\left[\frac{\partial f}{\partial t}(X(t),t) + \sum_{i=1}^{n} \frac{1}{i!} \frac{\partial^i f}{\partial x^i}(X(t),t)\epsilon^{-1}(\epsilon\nabla_{+}^{\epsilon}X(t))^i\right] + o(\epsilon^2\nabla_{+}^{\epsilon}X(t)). \tag{I.60}$$

Dividing by ϵ, we obtain the lemma. □

4. The complex case

In Sec. III, we need to apply the scale operator to *complex valued* functions. We extend the definition of $\square_\epsilon/\square t$ in order to cover this case.

In the following, if $z\in\mathbb{C}$, we denote by Re(z) and Im(z), the real and imaginary part of z.

Definition 3.3: Let $h>0$ and $\mathcal{C}(t)$ be a complex valued function. We denote $\mathcal{C}(t)=\mathcal{C}_r(t)+i\mathcal{C}_m(t)$, where $\mathcal{C}_r(t)=\mathrm{Re}\,\mathcal{C}(t)$ and $\mathcal{C}_m(t)=\mathrm{Im}\,\mathcal{C}(t)$. We define $\square_\epsilon\mathcal{C}/\square t$ by

$$\frac{\square_\epsilon\mathcal{C}}{\square t}=\frac{\square_\epsilon\mathcal{C}_r}{\square t}+i\frac{\square_\epsilon\mathcal{C}_m}{\square t}, \tag{I.61}$$

for $0<\epsilon<\min(\epsilon(\mathcal{C}_r,h),\epsilon(\mathcal{C}_m,h))$.

Remark 3.2: The extension of the scale calculus to complex valued functions is not trivial (as it mixes complex terms in a complex operator).

We then have the following.

Lemma 3.3: Let $h>0$ and $C(x,t):\mathbb{R}\times\mathbb{R}\to\mathbb{C}$ be a C^n complex valued function. Let $x(t)$ be a continuous function such that $\epsilon(x,h)>0$. We denote $\mathcal{C}(t)=C(x(t),t)$. Then, for $0<\epsilon\leqslant\epsilon(x,h)$ sufficiently small, we have

$$\frac{\square_\epsilon\mathcal{C}}{\square t}=\frac{\partial C}{\partial t}+\frac{\square_\epsilon x}{\square t}\frac{\partial C}{\partial x}+\sum_{j=2}^{n}\frac{1}{j!}a_{\epsilon,j}(t)\frac{\partial^j C}{\partial x^j}\epsilon^{j-1}+o(\epsilon^{1/n}), \tag{I.62}$$

where

$$a_{\epsilon,j}(t)=\tfrac{1}{2}[(\Delta_+^\epsilon x)^j-(-1)^j(\Delta_-^\epsilon x)^j]-i\,\tfrac{1}{2}[(\Delta_+^\epsilon x)^j+(-1)^j(\Delta_-^\epsilon x)^j],\quad j=2,\ldots,n. \tag{I.63}$$

D. Algebraic properties of quantum difference operators

In the following, we denote by C^0 the set of continuous real valued functions.

Lemma 4.1: For all $\epsilon>0$, and all $f\in C^0$ and $g\in C^0$, we have

(i) $\nabla_\sigma^\epsilon(f+g)=\nabla_\sigma f+\nabla_\sigma g$, $\sigma=\pm$;
(ii) *For all* $\lambda\in\mathbb{R}$, $\nabla(\lambda f)=\lambda\nabla_\sigma f$, $\sigma=\pm$.

The proof is straightforward and left to the reader.

Our main goal is to compare quantum derivatives to classical derivatives. The main property of classical derivatives is the so called *Leibniz rule*, which says that, $(fg)'=f'g+fg'$. In our case, we have a more complicated formula.

Lemma 4.2: For all $\epsilon>0$, and all $f\in C^0$, $g\in C^0$, we have for $\sigma=\pm$,

$$\nabla_\sigma^\epsilon(fg)(x)=\nabla_\sigma^\epsilon f(x)g(x)+f(x)\nabla_\sigma^\epsilon g(x)+\sigma\epsilon\nabla_\sigma^\epsilon f(x)\nabla_\sigma^\epsilon g(x). \tag{I.64}$$

Proof: Easy computations lead to the following formulas:

$$\nabla_+^\epsilon(fg)(x)=\nabla_+^\epsilon f(x)g(x+\epsilon)+f(x)\nabla_+^\epsilon g(x),$$

$$\nabla_-^\epsilon(fg)(x)=\nabla_-^\epsilon f(x)g(x)+f(x-\epsilon)\nabla_-^\epsilon g(x). \tag{I.65}$$

By definition of the quantum derivatives, we have

$$f(x+\epsilon)=f(x)+\epsilon\nabla_+^\epsilon f(x),\quad g(x-\epsilon)=g(x)-\epsilon\nabla_-^\epsilon g(x). \tag{I.66}$$

By replacing $f(x+\epsilon)$ and $g(x-\epsilon)$ in (I.65), we obtain (I.64). □

Of course, one can derived other formulas. However, Eq. (I.64) is the most symmetric one. Here, we give another expression.

For all ϵ, we denote by $\tau_\epsilon:C^0\to C^0$ the classical translation, defined by

$$\tau_\epsilon(f)(x)=f(x+\epsilon),\ \ \forall x. \tag{I.67}$$

We have the following lemma.

Lemma 4.3: For all ϵ, we have $\nabla^\epsilon_-\circ\tau_\epsilon=\nabla^\epsilon_+$ and $\tau_\epsilon\circ\nabla^\epsilon_\sigma=\nabla^\epsilon_\sigma\circ\tau_\epsilon$.

As a consequence, we obtain the following version of Lemma 4.2.

Lemma 4.4: For all $\epsilon>0$, and all $f\in C^0$, $g\in C^0$, we have

$$\begin{aligned}\nabla^\epsilon_+(fg)(x)&=\nabla^\epsilon_+f(x)h_\epsilon(x)+f(x)\nabla^\epsilon_-h_\epsilon(x),\\ \nabla^\epsilon_-(fg)(x)&=\nabla^\epsilon_-f(x)v_\epsilon(x)+f(x)\nabla^\epsilon_+v_\epsilon(x),\end{aligned} \tag{I.68}$$

where $h_\epsilon=\tau_\epsilon\circ g$ and $v_\epsilon=\tau_{-\epsilon}\circ g$.

In the following, we discuss what are the fundamental differences between quantum derivatives and classical derivations.

1. Derivations

We recall that an operator D on an abstract algebra $(A,.)$, is a derivation if for all $(f,g)\in A^2$, it satisfies the Leibniz relation $D(fg)=Df.g+f.Dg$. We refer to Jacobson (Ref. 32, Chap. 1, Sec. 2, pp. 7–8) for more details.

We denote by $\mathrm{Der}(A)$ the set of derivations on A. $\mathrm{Der}(A)$ is a vector space, but not an algebra. However, by posing $[D_1,D_2]=D_1D_2-D_2D_1$, the usual Lie bracket, the set $(\mathrm{Der}(A),[.,.])$ is a Lie algebra.

We denote by $\mathbb{R}\langle\langle\mathrm{Der}(A)\rangle\rangle$ the ring of formal power series on the alphabet $\mathrm{Der}(A)$. We can define a coalgebra structure on $\mathbb{R}\langle\langle\mathrm{Der}(A)\rangle\rangle$. We refer to Bourbaki (Ref. 9, Chap. 3) for more details about coalgebras and bialgebras.

Let $u:\mathbb{R}\langle\langle\mathrm{Der}(A)\rangle\rangle\to\mathbb{R}$ be the homomorphism associating to each series its constant term.

For each $D\in\mathrm{Der}(A)$ we define a linear map $\Delta:\mathrm{Der}(A)\to\mathrm{Der}(A)\otimes\mathrm{Der}(A)$ by $\Delta(D)=D\otimes 1+1\otimes D$. Then, the following diagram commutes:

$$\begin{array}{ccc} A\otimes A & \overset{\Delta(D)}{\to} & A\otimes A,\\ \nu\downarrow & & \downarrow\nu\\ A & \overset{D}{\to} & A,\end{array} \tag{I.69}$$

where ν is the natural morphism defined by

$$\begin{array}{rcl}\nu: & A\otimes A & \to A,\\ & f\otimes g & \mapsto f.g.\end{array} \tag{I.70}$$

We can extend Δ such that for each $\Delta(D_1D_2)=\Delta(D_1)\Delta(D_2)$, D_1, $D_2\in\mathrm{Der}(A)$, and the usual product on $\mathbb{R}\langle\langle\mathrm{Der}(A)\rangle\rangle\otimes\mathbb{R}\langle\langle\mathrm{Der}(A)\rangle\rangle$, $(a\otimes b).(c\otimes d)=(ac\otimes bd)$. For each word, $D_1\cdots D_r$, we define $\Delta(D_1\cdots D_r)=\Delta(D_1)\Delta(D_2\cdots D_r)$. We then extend Δ to $\mathbb{R}\langle\langle\mathrm{Der}(A)\rangle\rangle$ by linearity. With this definition of Δ, for each $S\in\mathbb{R}\langle\langle\mathrm{Der}(A)\rangle\rangle$, the following diagram commutes:

$$\begin{array}{ccc} A\otimes A & \overset{\Delta(S)}{\to} & A\otimes A,\\ \nu\downarrow & & \downarrow\nu\\ A & \overset{S}{\to} & A.\end{array} \tag{I.71}$$

As a consequence, we have the following lemma.

Lemma 4.5: The triple $(\mathbb{R}\langle\langle\mathrm{Der}(A)\rangle\rangle,\Delta,u)$ is a bialgebra.

2. Quantum bialgebra

We follow the previous section on derivations.

Definition 4.1: For all $\epsilon>0$, and $\sigma=\pm$, we denote by ∇_σ^ϵ an operator acting on $C^0\otimes C^0$, where $\otimes$ is the classical tensor product, and defined by

$$\nabla_\sigma^\epsilon:\begin{array}{ccc} C^0\otimes C^0 & \to & C^0\otimes C^0, \\ f\otimes g & \mapsto & \nabla_\sigma^\epsilon f\otimes g+f\otimes\nabla_\sigma^\epsilon g+\sigma\epsilon\nabla_\sigma^\epsilon f\otimes\nabla_\sigma^\epsilon g. \end{array} \tag{I.72}$$

Let $\Omega_\epsilon=\{\nabla_+^\epsilon,\nabla_-^\epsilon\}$ be the alphabet of two letters ∇_+^ϵ and $\nabla_-^\epsilon\}$. We denote by Ω_ϵ^* the set of words $\underline{\omega}=\omega_1\ldots\omega_n$, $\omega_i\in\Omega_\epsilon$ for all $i=1,\ldots,n$, where $\omega_i\omega_j$ denote the natural composition of operators. For example, a possible word is $\nabla_+^\epsilon\nabla_-^\epsilon$.

Remark 4.1: Here we consider the alphabet of quantum operators for a fixed $\epsilon>0$. It is possible that some particular problems of scale relativity require a complete alphabet $\Omega=\{\nabla_\sigma^\epsilon,\sigma=\pm,\epsilon>0\}$.

We denote by $A_\epsilon=\mathbb{R}\langle\langle\Omega_\epsilon\rangle\rangle$ the algebra of formal power series constructed on Ω_ϵ (with its classical algebraic structure).

We can define a linear map from A_ϵ to $A_\epsilon\times_{\mathbb{R}}A_\epsilon$, denoted Δ. First, we define Δ on ∇_σ^ϵ by

$$\begin{array}{c} A_\epsilon\overset{\Delta}{\to}A_\epsilon\otimes A_\epsilon, \\ \nabla_\sigma^\epsilon\mapsto\nabla_\sigma^\epsilon\otimes I+I\otimes\nabla_\sigma^\epsilon+\sigma\epsilon\nabla_\sigma^\epsilon\otimes\nabla_\sigma^\epsilon. \end{array} \tag{I.73}$$

We have the following equality:

$$\nabla_\sigma^\epsilon\circ\nu=\nu\circ\Delta(\nabla_\sigma^\epsilon), \tag{I.74}$$

which is equivalent to the commutativity of the diagram,

$$\begin{array}{ccc} C^0\otimes C^0 & \overset{\Delta(\nabla_{\sigma'}^\epsilon)}{\to} & C^0\otimes C^0, \\ \downarrow\nu & & \downarrow\nu \\ C^0 & \overset{\nabla_\sigma^\epsilon}{\to} & C^0. \end{array} \tag{I.75}$$

We also define $\Delta(I)=I\otimes I$ in order that $I\bigcirc\nu=\nu\bigcirc\Delta(I)$.

We extend Δ to A_ϵ by linearity.

Lemma 4.6: The linear map Δ is an algebra homomorphism.

Proof: The proof is done by induction. Let ∇_σ^ϵ and $\nabla_{\sigma'}^\epsilon$ be two letters of Ω_ϵ. We have

$$\begin{aligned}\nabla_\sigma^\epsilon\nabla_{\sigma'}^\epsilon(fg)=&\nabla_\sigma^\epsilon\nabla_{\sigma'}^\epsilon f.g+f.\nabla_\sigma^\epsilon\nabla_{\sigma'}^\epsilon g+\nabla_\sigma^\epsilon f.\nabla_{\sigma'}^\epsilon g+\nabla_{\sigma'}^\epsilon f.\nabla_\sigma^\epsilon g+\epsilon[\nabla_\sigma^\epsilon\nabla_{\sigma'}^\epsilon f.\nabla_{\sigma'}^\epsilon g+\nabla_{\sigma'}^\epsilon f.\nabla_\sigma^\epsilon\nabla_{\sigma'}^\epsilon g\\&+\nabla_\sigma^\epsilon\nabla_{\sigma'}^\epsilon f.\nabla_\sigma^\epsilon g+\nabla_\sigma^\epsilon f.\nabla_\sigma^\epsilon\nabla_{\sigma'}^\epsilon g]+\epsilon^2\nabla_\sigma^\epsilon\nabla_{\sigma'}^\epsilon f.\nabla_\sigma^\epsilon\nabla_{\sigma'}^\epsilon g.\end{aligned} \tag{I.76}$$

As a consequence, we have

$$\begin{aligned}\Delta(\nabla_\sigma^\epsilon\nabla_{\sigma'}^\epsilon)=&\nabla_\sigma^\epsilon\nabla_{\sigma'}^\epsilon\otimes I+I\otimes\nabla_\sigma^\epsilon\nabla_{\sigma'}^\epsilon+\nabla_\sigma^\epsilon\otimes\nabla_{\sigma'}^\epsilon+\nabla_{\sigma'}^\epsilon\otimes\nabla_\sigma^\epsilon+\epsilon[\nabla_\sigma^\epsilon\nabla_{\sigma'}^\epsilon\otimes\nabla_{\sigma'}^\epsilon+\nabla_{\sigma'}^\epsilon\otimes\nabla_\sigma^\epsilon\nabla_{\sigma'}^\epsilon\\&+\nabla_\sigma^\epsilon\nabla_{\sigma'}^\epsilon\otimes\nabla_\sigma^\epsilon+\nabla_\sigma^\epsilon\otimes\nabla_\sigma^\epsilon\nabla_{\sigma'}^\epsilon]+\epsilon^2\nabla_\sigma^\epsilon\nabla_{\sigma'}^\epsilon\otimes\nabla_\sigma^\epsilon\nabla_{\sigma'}^\epsilon.\end{aligned} \tag{I.77}$$

By definition, the classical product on $A_\epsilon\otimes A_\epsilon$ is defined by the following: for all $a\otimes b$ and $c\otimes d$ in $A_\epsilon\otimes A_\epsilon$, we have

$$(a\otimes b).(c\otimes d)=ac\otimes bd. \tag{I.78}$$

An easy computation proves that

$$\Delta(\nabla_{\sigma}^{\epsilon}\nabla_{\sigma'}^{\epsilon})=\Delta(\nabla_{\sigma}^{\epsilon})\Delta(\nabla_{\sigma'}^{\epsilon}). \tag{I.79}$$

By induction and linearity, we obtain the lemma. □

We define an algebra homomorphism from A_{ϵ} to $\mathbb{R}$, denoted by u, by associating to each formal power series its constant term.

With $u:A_{\epsilon}\to\mathbb{R}$ and $\Delta:A_{\epsilon}\to A_{\epsilon}\otimes A_{\epsilon}$, we define a coalgebra structure on A_{ϵ}.

Lemma 4.7: The triple (A_{ϵ},Δ,u) *is a coalgebra.*

Moreover, as u and Δ are homomorphisms, we obtain the stronger result.

Lemma 4.8: The triple (A_{ϵ},Δ,u) *is a bialgebra.*

We have not found a natural graduation on this bialgebra.

Remark 4.2: (1) It will be interesting to discuss the possible relation to quantum groups introduced by Drinfeld (Refs. 22, 23) and quasi-triangular Hopf algebra. We introduce the natural commutativity involution,

$$\tau:\begin{array}{ccc} A_{\epsilon}\otimes A_{\epsilon} & \to & A_{\epsilon}\otimes A_{\epsilon}, \\ a\otimes b & \mapsto & b\otimes a. \end{array} \tag{I.80}$$

Let $\Delta^{\mathrm{op}}=\tau\circ\Delta$. *The map* τ *is an algebra automorphism of* $A_{\epsilon}\otimes A_{\epsilon}$ *and the following diagram commutes*:

$$\begin{array}{ccc} A_{\epsilon} & \overset{\Delta}{\to} & A_{\epsilon}\otimes A_{\epsilon}, \\ \mathrm{id}_{A_{\epsilon}}\downarrow & & \downarrow\tau \\ A_{\epsilon} & \overset{\Delta^{\mathrm{op}}}{\to} & A_{\epsilon}\otimes A_{\epsilon}. \end{array} \tag{I.81}$$

If (A_{ϵ},Δ,u) *is a quasitriangular algebra, then, following Ref. 43, there exists an invertible element of* $A_{\epsilon}\otimes A_{\epsilon}$ *such that*

$$\Delta^{\mathrm{op}}(a)=R\Delta(a)R^{-1}, \quad \text{for all} \quad a\in A_{\epsilon}. \tag{I.82}$$

In our case, we easily have $\Delta^{\mathrm{op}}=\Delta$ *so that* (A_{ϵ},Δ,u) *so that R is trivial.*

(2) A natural idea is to consider the quantum bialgebra as a "deformation" of the classical Hopf algebra associated with derivations. The word "deformation" must be taken with care, because a notion of deformation for Hopf algebra already exists and it is not clear if this is a good one to consider here.

(3) There is no natural extension of the quantum bialgebra in order to take into account the scale derivative. The basic problem being that the scale derivative is a complex valued operator on real valued functions. Then, we have no natural composition of these operators.

3. A remark on Rieman–Liouville fractional calculus and the local fractional calculus

A basic way to deal with nondifferentiable functions is to use *fractional calculus*. As an example, one can consider the classical (left and right) *Riemann–Liouville derivative*, defined by

$$D_z^{\alpha}f(x)=\frac{\Gamma(\alpha+1)}{2\pi i}\int_0^{z^+} f(t)(t-z)^{-\alpha-1}\,dt, \tag{I.83}$$

for $\alpha\in\mathbb{C}\backslash\{-1,-2,\dots\}$. The Riemann–Liouville derivative is not at all a *derivation* on the algebra of continuous functions. Indeed, one has (see Ref. 40)

$$D_z^{\alpha}(uv)=\sum_{n=0}^{\infty}\left(\begin{array}{c}\alpha\\ n\end{array}\right)D_z^{\alpha-n}uD_z^{n}v. \tag{I.84}$$

Moreover, this operator, which is a direct analytic generalization of the Cauchy formula does not have a clear geometrical interpretation, despite recent advances (see Ref. 3).

In Ref. 5, we have obtain, following a previous work of Kolvankar and Gangal,[29] a derivation, called the (left and right) *local fractional derivative*, by *localizing* the (left and right) Riemann–Liouville derivative.

We have proven that this localization takes a simple form.

Definition 4.2: The right and left local fractional derivative of f at point x_0 of order α is defined by

$$\lim_{x\to x_0^+}\frac{f(x)-f(x_0)}{(x-x_0)^{\alpha}}\quad\text{and}\quad\lim_{x\to x_0^-}\frac{f(x_0)-f(x)}{(x_0-x)^{\alpha}}, \tag{I.85}$$

respectively.

We have introduce the fractional derivative of f at point x_0 by collecting the two quantities $d_+^{\alpha}f(x_0)$ and $d_-^{\alpha}f(x_0)$ in a single quantity, i.e.,

$$d^{\alpha}f(x_0)=\tfrac{1}{2}(d_+^{\alpha}f(x_0)+d_-^{\alpha}f(x_0))+i\,\tfrac{1}{2}(d_+^{\alpha}f(x_0)+d_-^{\alpha}f(x_0)). \tag{I.86}$$

Moreover, we obtain a clear geometrical meaning by connecting the exponent α of differentiation to the local maximal Hölder regularity of the curve.

However, such a derivative has important problems. First, there exists no *integral operator* contrary to the Riemann–Liouville fractional derivative where there exists the Riemann–Liouville integral. Moreover, the set of points on which the local fractional derivative is nonzero is, in most of the cases, trivial, i.e., of zero measure. Precisely, we have the following theorem.

Theorem 4.1: *The fractional differential equations of the form $d^{\alpha}f(x)=a(x)+ib(x)$, $0<\alpha<1$, where $a(x)$ and $b(x)$ are continuous functions such that there exists $x_0\in\mathbb{R}$ such that $|a(x_0)|\neq|b(x_0)|$ have no solutions*.

This theorem solves a conjecture of Ref. 7. It must be pointed out that the condition $|a(x_0)|\neq|b(x_0)|$ is generic.

Proof: We have $d_+^{\alpha}f(x)=c(x)$ and $d_-^{\alpha}f(x)=d(x)$, where $c(x)=a(x)+b(x)$ and $d(x)=a(x)-b(x)$ are continuous functions. By assumption, we have $c(x_0)\neq 0$ and $d(x_0)\neq 0$.

Let us assume that $c(x_0)>0$ [the case where $c(x_0)<0$ is similar]. By continuity, there exits $\epsilon>0$ such that for all x in the open interval $I_{\epsilon}(x_0)=]x_0-\epsilon,x_0+\epsilon[$, we have $d^{\alpha}f(x)>0$. Two cases must be considered: (i) $d_-^{\alpha}f(x_0)>0$ and (ii) $d_-^{\alpha}f(x_0)<0$.

In case (i), we define an open interval $J_{\epsilon}(x_0)$ such that for all $x\in J_{\epsilon}(x_0)$ we have $d^{\alpha}f(x)>0$. As a consequence, the function f is Hölderian of exponent α (see Ref. 4, Theorem 3.9). Moreover, the function f is injective on the interval $x\in K_{\epsilon}(x_0)=J_{\epsilon}(x_0)\cap I_{\epsilon}(x_0)$. Indeed, if there exists $x_1,x_2\in K_{\epsilon}(x_0)$ such that $f(x_1)=f(x_2)$, then by the fractional Rolle's theorem (Ref. 4) there $x\in K_{\epsilon}(x_0)$ such that $d_+^{\alpha}f(x)d_-^{\alpha}f(x)\leqslant 0$, which is impossible by assumption. A continuous function which is injective is strictly monotone (see Ref. 28, Lemma 3.8, p. 207). But a monotone function is almost everywhere differentiable by the Lebesgue theorem (Ref. 31, p. 319), in contradiction with the assumption that $0<\alpha<1$.

In case (ii), we define an open interval $J_{\epsilon}(x_0)$ such that for all $x\in J_{\epsilon}(x_0)$ we have $d^{\alpha}f(x)<0$. Again the function f is a Hölderian function of exponent α. Moreover, by Ref. 4, Theorem 4.9, all points in $K_{\epsilon}(x_0)=J_{\epsilon}(x_0)\cap I_{\epsilon}(x_0)$ are local minima. This is possible if and only if f is a constant function, i.e., a differentiable function in contradiction with the fact that f is Hölderian of exponent $0<\alpha<1$. This concludes the proof of the theorem. □

We can characterize the *spectrum* of f, i.e., the set of values taken by the fractional derivative of a continuous function.

Corollary 4.1: The spectrum of a given α-differentiable function is discontinuous or zero.

Proof: The spectrum cannot be continuous and nonzero by theorem 4.1. As a consequence, the spectrum can be zero or dicontinuous. □

We can be more precise on the nature of this spectrum.

Theorem 4.2: *The set of fractional differential equations* $d^{\alpha}f(x)=a(x)+ib(x)$, *where* $0<\alpha<1$ *and the functions* $c(x)=a(x)+b(x)$, $d(x)=a(x)-b(x)$ *keep a constant sign on a given interval of* $\mathbb{R}$, *has no solutions.*

Proof: This is the same proof as Theorem 4.1. The continuity assumption of Theorem 4.1 being only here to construct an interval where $c(x)$ and $d(x)$ keep a constant sign. □

As a consequence, the spectrum is discontinuous but of very special form, as we cannot find any interval of $\mathbb{R}$ on which we have a constant sign. We define the *Dirichlet function* as follows:

$$\mathcal{D}(x)=\begin{cases}1, & \text{if} \quad x\in\mathbb{Q}\\ -1, & \text{if} \quad x\in\mathbb{R}\backslash\mathbb{Q}.\end{cases} \tag{I.87}$$

Then, the function $a(x)$ and $b(x)$ can be taken such that

$$a(x)=\tfrac{3}{2}\mathcal{D}(x), \quad b(x)=-\tfrac{1}{2}\mathcal{D}(x). \tag{I.88}$$

We can extend all the previous theorems to the case where the order of fractional differentiation is nonconstant, but a function of x.

In Ref. 5, we have derived, in the fractional calulus framework, the Schrödinger equation from Newton's equation of dynamics under the assumption that one-dimensional quantum mechanical trajectories satisfy

$$(d^{\alpha}_{\sigma}f(x))^2=2\overline{h}/2m, \quad \sigma=\pm, \tag{I.89}$$

where $\overline{h}$ is the reduced Planck constant $h/2\pi$ and m is the mass of the particle. Of course, this is impossible by Theorem 4.1, as already proved in Ref. 7. But as the Schrödinger equation is a well established equation of physics, we propose in Ref. 7 to consider a small perturbation of condition (89), like

$$(d^{\alpha}_{\sigma}f(x))^2=2\overline{h}/2m+\epsilon a_{\sigma}(t,f(t)), \quad \sigma=\pm, \tag{I.90}$$

where $0<\epsilon\ll 1$, in order to permit the existence of nontrivial solutions and to obtain a small perturbation of the Schrödinger equation.

However, condition (I.90) lead to a deadlock. Indeed, for ϵ sufficiently small, the quantities $d^{\alpha}_{\sigma}f(x)$ keep a constant sign. As a consequence, by Theorem 4.2 we have no solutions.

All these problems are solved in Part II by using the scale calculus framework.

E. Quantum representation of nondifferentiable functions

We introduce the notion of a quantum geometric representation for a continuous nondifferentiable function. This notion is associated with minimal resolution and the scale derivative. It turns out that a geometric space displaying the basic features of the quantum geometric representation is given by a simplified version of Connes' formulation of the standard model of fundamental interactions within the framework of noncommutative geometry.

1. The quantum representation of a continuous nondifferentiable function

Our previous results allow us to define a natural notion of a scale derivative. The scale derivative, which is a complex valued operator, contains the necessary information in order to perform a local analysis of continuous nondifferentiable functions, and take care of this nondifferentiability.

Let f be a given continuous on a differentiable function. The basic functions associated with f, and from which we can deduce the scale derivative are the forward and backward mean functions defined as $f_\epsilon^+(t)=(1/2\epsilon)\int_t^{t+\epsilon} f(s)ds$ and $f_\epsilon^-(t)=(1/2\epsilon)\int_{t-\epsilon}^t f(s)ds$, respectively.

From a geometrical viewpoint, it means that in order to take into account the nondifferentiable character of f, one must consider the disjoint union $\Gamma_\epsilon^+ \cup \Gamma_\epsilon^-$, where Γ^σ is the graph of f_ϵ^σ, $\sigma = \pm$.

Definition 5.1: Let $h>0$, f be a continuous nondifferentiable function, and $\epsilon(f,h)$ be its minimal resolution. For all $\epsilon>0$, the quantum geometric representation of f, denoted $Q_\epsilon(f)$, is defined by the following:

(i) For all $\epsilon>\epsilon(f,h)$, $Q_\epsilon(f)=\Gamma_\epsilon$;

(ii) for all $0<\epsilon\leqslant\epsilon(f,h)$, $Q_\epsilon(f)=\Gamma_\epsilon^+\cup\Gamma_\epsilon^-$,

where Γ_ϵ, Γ_ϵ^+, Γ_ϵ^-, are the graphs of the mean function f_ϵ, the forward mean function and the backward mean function, respectively.

The nondifferentiability of f induces a change in the geometric structure of the geometric representation of f.

In the following, we consider graphs of real valued functions as a submanifold of $\mathbb{R}^2$. As f_ϵ^+ and f_ϵ^- are differentiable functions, one deals with a disjoint union of differentiable submanifolds Γ_ϵ^+ and Γ_ϵ^-. The basic features of the quantum representation of f, when $0<\epsilon<\epsilon(f,h)$, is that Q_ϵ is composed by two differentiable submanifolds, which are close to each other, their closeness being related to ϵ.

As a consequence, a good understanding of the effects of a nondifferentiable function can be obtained via the following simplified model.

Let M be a one dimensional differentiable submanifold of $\mathbb{R}^2$. Let $A=\{a,b\}$ be a two point space. We consider $Q=M\times A$. Then, Q is the union of two copies of the manifold M: $Q=M_a\cup M_b$.

Remark 5.1: A more accurate model is the following: Let $A_\epsilon=\{a_\epsilon,b_\epsilon\}$ be a two point space, such that for $\epsilon>\epsilon(f,h)$, A_ϵ reduces to a point, i.e., $a_\epsilon=b_\epsilon$. The simplified model is then $Q_\epsilon=M\times A_\epsilon$.

2. Noncommutative geometry

In this paragraph we only sketch a possible connect between our point of view on nondifferentiable functions and noncommutative geometry. The idea is, by the way, to obtain powerful tools to study nondifferentiable functions which will be relevant to physics.

In his book,[15] Connes develops noncommutative geometry. The basic idea is to extend to the noncommutative case the classical result of Gelfand and Naimark relating C^*-algebras and locally compact spaces.

At the end of his book, Connes (Ref. 15, p. 568) discusses a particular example, where his theory already leads to interesting results (this example is viewed as a preliminary step toward a complete noncommutative model for the standard model of quantum particles).

He considers a product of a differentiable manifold (the standard $\mathbb{R}^4$) by a discrete space, $A=\{a,b\}$. Using noncommutative geometry, he can make an analysis on this space. In particular, he defines a ''differential'' operator which contains three terms: the classical derivative on each copy of $\mathbb{R}^4$ and a finite difference.

It will be interesting to discuss the relevance of this construction with respect to our approach to nondifferentiable functions.

PART II

II. SCALE RELATIVITY AND THE SCHRÖDINGER EQUATION

A. Introduction

The Schrödinger equation is one of the basic pieces of quantum mechanics. Many attempts already exist in order to derive it from the expected behaviors of trajectories of quantum particles

or from classical equations of the dynamics. We can cite, for example, the Nelson stochastic approach,[36] the Feynman perturbative approach,[25] and Nottale's approach by the Scale relativity theory.[37]

In the following we discuss the derivation of the Schrödinger equation in the framework of the Scale relativity of Nottale.[37] The main point is that, contrary to the Nelson or Feynman approach, it is based on a *first principle*, namely, the *scale principle of relativity*, which is an extension of the Einstein relativity principle to scales (of time and lengths).

The scale relativity principle introduced by Nottale has a direct consequence on the equations of the dynamics for a given particle. Indeed, they must keep the same form under a scale transform, i.e., going from the classical scale to the atomic scale. Following Feynman and Hibbs, the principal difference between the microscopic and macroscopic scale is that typical paths become nondifferentiable. Then, we must be able to transform the classical differential equations of the dynamics for functions which are not at all differentiable.

This is done using the scale difference operator defined in Part I. The scale relativity principle is then equivalent to changing the classical derivative by the scale difference operator in the Euler–Lagrange equations of the dynamics.

This quantification procedure called the scale quantization can be precisely defined in Sec. II B, by introducing a quantization map, associating with each classical variable and differential operator its quantum counterpart. One of the main problems is then that the scale quantization procedure of the Euler–Lagrange equation is not unique. Indeed, we can first quantify the Lagrangian of the system and then define a quantized Euler–Lagrange equation, or we can quantify directly the classical Euler–Lagrange equation. The main point, proved in the coherence lemma in Sec. II D 2, is that these two procedures coincide.

The scale quantization procedure being precisely defined, we can specialize it to the quantum mechanical case. The principal free parameter in the quantization lies in the order of the regularity of the nondifferentiable curve, i.e., its Hölder exponent. Using the Feynman–Hibbs characterization of quantum paths, as well as the Heisenberg inequalities, we prove in Sec. II C that the Hölder regularity of a quantum path is 1/2. Using this result, we prove in Sec. II D 4 that the quantized analog of the Newtonian equation of dynamics is a generalized nonlinear Schrödinger equation. This is done by introducing a wave-function in Sec. II D 3, which is the direct consequence of the complex nature of the speed, being itself a consequence of the nondifferentiability of the curve. Under special assumptions, which can be interpreted, we recover the classical Schrödinger equation.

B. Scale quantization procedure for classical Lagrangian systems

1. Classical Lagrangian systems and Euler–Lagrange equation

In this article, we only discuss classical Lagrangian systems defined as follows.

Definition 2.1: A Lagrangian $L(x,v,t)$ is called classical if it is of the form kinetic energy +potential, i.e.,

$$L(x,v,t)=K(v)+U(x,t), \tag{II.1}$$

where $K(v)$ is a quadratic form.

The basic example for $K(v)$ is the classical kinetic energy of a particle of mass m given by

$$K(v)=\tfrac{1}{2}mv^2. \tag{II.2}$$

The dynamics associated to a Lagrangian system is determined by the *Euler–Lagrange equations*.

Definition 2.2: Let $L(x,v,t)$ be a classical Lagrangian system. The Euler–Lagrange equation associated with L is the following partial differential equation:

$$\frac{d}{dt}\left(\frac{\partial L}{\partial v}(x(t),v(t),t)\right)=\frac{\partial L}{\partial x}(x(t),v(t),t). \qquad \text{EU}$$

We denote by E the mapping associating to L its Euler–Lagrange equation (EU).

2. The scale quantization procedure

In this section, we define the *scale quantization procedure*, which formalizes Nottale's approach to quantum mechanics. The terminology suggests that the quantization procedure follows ideas coming from the theory of the *scale relativity* developed by Nottale.[37]

a. The scale quantization map We define a map Q which acts on differential operators, variables and functions.

The classical variables x, v, t have quantized analogs which are denoted by $X=Q(x)$, $V=Q(v)$ and $T=Q(t)$.

In Assumption 2.1, we have the following.

Assumption 2.1: We have $Q(t)=t$.

The time variable has then a specific role, being the only variable not affected by the quantization procedure.

We denote also by

$$X(t)=Q(x(t)),\ V(t)=Q(v(t)), \tag{II.3}$$

the quantized version of the position trajectory and speed.

The main point is that we do not know for the moment the regularity of $X(t)$ or $V(t)$.

The first algebraic properties of Q is the following.

Property 2.1 (Quantization of maps): We consider a map $L:(x,v,t)\mapsto L(x,v,t)$. *The quantized map* $Q(L)=\mathcal{L}$ *is defined by*

$$\mathcal{L}:(X,V,t)\mapsto L(X,V,t). \tag{II.4}$$

As a consequence, if L is differentiable with respect to the variable x, v or t then $\mathcal{L}$ is differentiable with respect to X, V or t.

In order to use Q on differential equations, we must precise its behavior with respect to differential operators.

Property 2.2 (Operator): We consider a map of the form $f(t)=L(x(t),v(t),t)$, *where* $x(t)$ *and* $v(t)$ *are differentiable functions. The differential operator* d/dt *acts on operator* f. *By the map* Q, *we define a quantized operator* $Q(d/dt)$ *such that*

$$Q(df/dt)=Q(d/dt).Q(f),$$

where $Q(d/dt)$ *is on operator acting on* $Q(f)$, *depending on the regularity of* $Q(f)$ *with respect to* t:

(*a*) *If* $Q(f)(t)$ *is differentiable with respect to* t, *then* $Q(d/dt)=d/dt$.
(*b*) *If* $Q(f)(t)$ *is nondifferentiable with respect to* t, *then* $Q(d/dt)=\square_\epsilon/\square t$, *where* $\epsilon(X,h)>\epsilon>0$, h *being a constant.*

The constant h must be fixed by physical constraint. In the following, we consider that h has a free parameter.

As $f(t)=L(x(t),v(t),t)$, we have $Q(f)(t)=L(X(t),V(t),t)$. Hence, the regularity of $Q(f)$ with respect to t depends on the regularity of $X(t)$ and $V(t)$ with respect to t.

Moreover, as $v=dx/dt$, we have

$$V(t)=Q\left(\frac{d}{dt}\right)[X(t)]. \tag{II.5}$$

Hence, the regularity of $X(t)$ can induce a change in the form of the speed $V(t)$.

b. Scale quantization of the Euler–Lagrange equation. By the quantization procedure we give the quantized version of the Euler–Lagrange formula (II.7).

Lemma 2.1: The quantized Euler–Lagrange equation $Q(EU)$ is given by

$$Q\left(\frac{d}{dt}\right)\left[\frac{\partial \mathcal{L}}{\partial V}(X(t),V(t),t)\right]=\frac{\partial \mathcal{L}}{\partial X}. \tag{II.6}$$

Proof: The action of Q on the classical Euler–Lagrange equation (EU) gives

$$Q\left(\frac{d}{dt}\right)\left[Q\left(\frac{\partial L}{\partial v}(x(t),v(t),t)\right)\right]=Q\left(\frac{\partial L}{\partial x}\right). \tag{II.7}$$

As L is assumed to be differentiable with respect to the variables v and x, we have, using Property 2.1:

$$Q\left(\frac{d}{dt}\right)\left[\frac{\partial Q(L)}{\partial Q(v)}(Q(x)(t),Q(v)(t),t)\right]=\frac{\partial Q(L)}{\partial Q(x)}. \tag{II.8}$$

With our notations, Eq. (8) gives Eq. (6). This concludes the proof of the lemma. □

As a consequence, in order to precise the quantization procedure, we only have to precise the regularity of $Q(x(t))=X(t)$.

C. Generic trajectories of quantum mechanics

In order to precise the quantization procedure, we investigate the regularity of a quantum-mechanical path.

1. Feynman and Hibbs genericity condition

Feynman and Hibbs have already noted in Ref. 26, pp. 176–177 that the typical path of a quantum mechanical particle is continuous and nondifferentiable. More precisely, there exists a quadratic velocity, i.e., if $X(t)$ denotes the particle trajectory, then

$$\lim_{t\to t'}\frac{(X(t)-X(t'))^2}{t-t'} \text{ exists.} \qquad (FH)$$

As a consequence, we have the following result.

Lemma 3.1: Under Feynman–Hibbs characterization (FH), we have $X(t)\in H^{1/2}$.

We can deduce the following result on the Hausdorff dimension of typical paths of quantum mechanics:

Corollary 3.1: Under Feyman–Hibbs characterization (FH), the Hausdorff dimension of X is 1/2.

Proof: As $X\in H^{1/2}$, this follows from Theorem 20.6, Ref. 46, p. 310. □

On the contrary, the fractal (or Minkowski–Bouligand) dimension Δ is given by

$$\Delta(X)=2-(1/2)=3/2, \tag{II.9}$$

using (Ref. 46, pp. 154–155).

This result has been discussed in great detail by Abbott and Wise.[1]

2. Heisenberg uncertainty principle

The nondifferentiable character of typical paths of quantum mechanics can be seen as a consequence of *Heisenberg uncertainty relations*. We refer to (Ref. 37, pp. 93–95) and Ref. 14, p. 130–131 for details.

Let Δx, Δt, and Δp be the precision of the measurement of the position x, time t and *momentum* p of a given particle. The Heisenberg uncertainty relation on momentum and position is

$$\Delta p \Delta x \geqslant h. \tag{II.10}$$

We have the following relations:

$$x(t \pm \Delta t) = x(t) \pm \Delta x,$$

$$v_\epsilon(t \pm \Delta t) = (x(t+\epsilon) - x(t)/\epsilon) \pm \Delta v, \tag{II.11}$$

where $\epsilon \geqslant \Delta t$ by definition of Δt, and

$$\Delta p = m \Delta v. \tag{II.12}$$

Remark 3.1: The speed of a particle $v(t)$ is defined as the limit of the mean-speed $v_\epsilon(t) = (x(t+\epsilon) - x(t)/\epsilon)$ when ϵ goes to zero. As the time variable t is known only with precision Δt, we must have $\epsilon \geqslant \Delta t$.

What are the relations between Δv, Δx and Δt?

As $\epsilon \geqslant \Delta t$ by assumption, we have by taking the best possible value $\epsilon = \Delta t$,

$$\Delta v \sim 2 \Delta x / \Delta t. \tag{II.13}$$

As a consequence, the Heisenberg uncertainty relation (10) gives

$$m \frac{(\Delta x)^2}{\Delta t} \sim h. \tag{II.14}$$

We deduce that

$$\Delta x \sim \frac{h}{2m} \Delta t^{1/2}. \tag{II.15}$$

Hence, we deduce that the Heisenberg uncertainty relation (10) induces the fact that $X \in H^{1/2}$.

Of course, the previous reasoning can be reversed. If typical paths of quantum mechanics are assumed to be in $H^{1/2}$, then we obtain Heisenberg-like uncertainty relations.

Lemma 3.2: Let $X \in H^{1/2}$, and $0 < \Delta t \ll 1$ be a small parameter. We denote by $\mathcal{X}$ the graph of X, and by $\mathcal{X}(t) = (t, X(t))$ a point belonging to $\mathcal{X} \in \mathbb{R}^2$. We denote by $\Delta x(t) = \|\mathcal{X}(t), \mathcal{X}(t+\Delta t)\|$, where $\|.\|$ is the classical Euclidean norm on $\mathbb{R}^2$. We have

$$\Delta x \sim (\Delta t)^{1/2}, \tag{II.16}$$

for all $t \in \mathbb{R}$.

Proof: This follows from a simple computation. We have

$$\|\mathcal{X}(t), \mathcal{X}(t+\Delta t)\|^2 = (\Delta t)^2 + (X(t+\Delta t) - X(t))^2. \tag{II.17}$$

As $X \in H^{1/2}$, we obtain

$$\|\mathcal{X}(t), \mathcal{X}(t+\Delta t)\|^2 \leqslant (\Delta t)^2 + C^2 \Delta t \sim \Delta t, \tag{II.18}$$

for Δt sufficiently small. □

Of course, this result extends to arbitrary $X \in H^\alpha$, with $0 < \alpha < 1$, for which we obtain

$$\Delta x \sim (\Delta t)^\alpha. \tag{II.19}$$

D. Scale quantization of Newtonian mechanics

1. Quantization of speed

The fact that typical path of quantum mechanics belongs to $H^{1/2}$ has many implications with respect to the quantization procedure. The first one being that the quantized version of the speed v is now complex.

Lemma 4.1 (Quantized speed): Let $Q(x)=X\in H^{1/2}$; then $Q(v)=V\in\mathbb{C}$. Precisely, we have

$$V=\frac{\Box_\epsilon X}{\Box t}. \tag{II.20}$$

Proof: This follows from the quantization procedure. We have

$$v=\frac{dx}{dt}. \tag{II.21}$$

By Q, we obtain

$$V=Q\left(\frac{d}{dt}\right)(X). \tag{II.22}$$

As $X\in H^{1/2}$, we have

$$Q(d/dt)=\Box_\epsilon/\Box t, \tag{II.23}$$

which is a complex number by definition. □

2. Scale relativity and the coherence lemma

a. Scale relativity and Scale Euler–Lagrange equations. The scale-relativity theory developed by Nottale (Refs. 37, 38) extends the Einstein relativity principle to *scale*. A heuristic version of the new relativity principle can be written as follows:

"*The equations of physics keep the same form under any transformation of scale (contractions and dilatations).*"

The mathematical foundation of such a theory is difficult. The main difficulty being that space–time is now a nondifferentiable manifold. We refer to the work of Nottale[37] for more details.

The scale relativity principle has a direct consequence on the form of the equation of motion for a particle.

We first introduce the following "Scale" Euler–Lagrange equation.

Definition 4.1: Let $\mathcal{L}(V,t)$ be a quantized Lagrangian. The Scale Euler–Lagrange equation associated with $\mathcal{L}(X,V,t)$ is the equation

$$\frac{\Box_\epsilon}{\Box t}\left(\frac{\partial\mathcal{L}}{\partial V}(X(t),V(t),t)\right)=\frac{\partial\mathcal{L}}{\partial X}(X(t),V(t),t). \qquad (\mathcal{E}U)$$

We denote by $\mathcal{E}$ the mapping associating equation $(\mathcal{E}U)$ to $\mathcal{L}$.

The scale relativity principle is then equivalent to the following statement.

Statement 4.1 (Scale relativity): *The equation of motion of a quantum-mechanical particle satisfies the Scale Euler–Lagrange equation.*

The main point is that the Scale Euler–Lagrange equation does not follow from the quantization procedure, but from a first principle which fixes the form of the equation of motions.

b. Coherence lemma At this point, we can state the *coherence lemma*, which ensures us that the quantization procedure is well defined. Indeed, the scale relativity principle gives an equation of motion particle in quantum mechanics, i.e., $(\mathcal{E}U)$. But, the quantization procedure can be used

to obtain an equation of motion for the particle as a quantized version of the classical Euler–Lagrange equation, i.e., $Q(\mathrm{EU})$. The main point is that this two constructions are equivalent, i.e., $Q(\mathrm{EU})=\mathcal{E}U$. Precisely, we have the following.

Lemma 4.2 (Coherence): The following diagram commutes,

$$\begin{array}{ccc} L(x,v,t) & \overset{Q}{\rightarrow} & \mathcal{L}(X,V,t) \\ E\downarrow & & \downarrow\mathcal{E} \\ \dfrac{d}{dt}\left[\dfrac{\partial L}{\partial v}(x(t),v(t),t)\right]=\dfrac{\partial U}{\partial x} & \overset{Q}{\rightarrow} & \dfrac{\square_{\epsilon}}{\square t}\left[\dfrac{\partial \mathcal{L}}{\partial V}(X(t),V(t),t)\right]=\dfrac{\partial U}{\partial X}. \end{array} \tag{II.24}$$

Proof: This follows from a direct computation. □

In terms of mapping, the coherence lemma is then equivalent to

$$Q\circ E=\mathcal{E}\circ Q. \tag{II.25}$$

3. Action functional and wave

A basic element of Lagrangian mechanics is the action functional $A(x,t)$ which is related to speed via the equation

$$v=\frac{1}{m}\frac{\partial A}{\partial x}. \tag{II.26}$$

The function $A(x,t)$ is differentiable with respect to x and t. By the quantization procedure, we obtain the analog of the classical action functional for quantum mechanics.

Lemma 4.3 (Quantized action functional): The function $\mathcal{A}=Q(A)$ is a complex valued function $\mathcal{A}(X,t)$ which satisfies

$$V=\frac{1\partial}{m}\frac{\mathcal{A}}{\partial X}. \tag{II.27}$$

Proof: By Q the classical equation (26) gives

$$V=Q(v)=Q\left(\frac{\partial}{\partial x}\right)Q(A). \tag{II.28}$$

As the classical action $A(x,t)$ is differentiable with respect to x, the quantized version $\mathcal{A}(X,t)$ is differentiable with respect to X. As a consequence, we have

$$Q\left(\frac{\partial}{\partial x}\right)=\frac{\partial}{\partial X}. \tag{II.29}$$

This concludes the proof. □

Moreover, the quantization procedure gives us the following relation.

Lemma 4.4 (Action): The quantized action $\mathcal{A}(x,t)$ satisfies

$$\mathcal{L}=\frac{\partial \mathcal{A}}{\partial t}. \tag{II.30}$$

At this point, the main feature of quantum mechanics is to introduce complex speed and action functional. We can discuss the behavior of $\mathcal{A}$ by introducing a complex valued function, which is called the *wave function*.

Definition 4.2 (Wave function): We call wave function associated to X, the complex valued function defined by

$$\psi(X,t)=\exp\left(\frac{i\mathcal{A}(X,t)}{2m\gamma}\right), \tag{II.31}$$

where $\gamma\in\mathbb{R}$ is a constant number.

The constant γ is a normalization constant, which depends on the regularity property of $X(t)$.

The complex nature of V leads naturally to the introduction of the wave function. The wave formalism is then induced by the nondifferentiable character of typical paths of quantum mechanics.

4. The quantized Euler–Lagrange equation

The quantized Euler–Lagrange equation is given by

$$m\frac{\square_\epsilon V(t)}{\square t}=\frac{dU}{dx}(x). \tag{II.32}$$

The complex speed V is related to the wave function, so that Eq. (II.32) can be written in term of ψ.

Theorem 4.1: *Let $X(t)$ be a continuous nondifferentiable function in $H^{1/2}$ and ψ its associated wave function. The quantized Euler–Lagrange equation is of the form*

$$2i\gamma m\left[-\frac{1}{\psi}\left(\frac{\partial\psi}{\partial X}\right)^2\left(i\gamma+\frac{a_\epsilon(t)}{2}\right)+\frac{\partial\psi}{\partial t}+\frac{a_\epsilon(t)}{2}\frac{\partial^2\psi}{\partial X^2}\right]=(U(x)+\alpha(x))\psi+o(\epsilon^{1/2}), \tag{II.33}$$

where $\alpha(x)$ is an arbitrary continuous function, and

$$a_\epsilon(t)=\frac{1}{2}[(\Delta_\epsilon^+X(t))^2-(\Delta_\epsilon^-X(t))^2]-i\frac{1}{2}[(\Delta_\epsilon^+X(t))^2+(\Delta_\epsilon^-X(t))^2]. \tag{II.34}$$

The equation (33) is called the *generalized Schrodinger equation* by Nottale.[37]

Proof: We have

$$V=-i2\gamma\frac{\partial\ln(\psi)}{\partial X}. \tag{II.35}$$

The Euler–Lagrange equation is now given by

$$2i\gamma m\frac{\square_\epsilon}{\square t}\left(\frac{\partial\ln(\psi)}{\partial X}\right)=\frac{dU}{dX}. \tag{II.36}$$

We denote

$$f(X,t)=\frac{\partial\ln(\psi(X,t))}{\partial X}(X,t). \tag{II.37}$$

We apply the main lemma of Sec. I C 4 to compute $\square_\epsilon f(X(t),t)/\square t$ for complex valued functions. We have

$$\frac{\square_\epsilon}{\square t}\left(\frac{\partial \ln(\psi)}{\partial X}(X(t),t)\right)=\frac{\square_\epsilon X}{\square t}\frac{\partial}{\partial X}\left(\frac{\partial \ln(\psi(X,t))}{\partial X}\right)(X(t),t)+\frac{\partial}{\partial t}\left(\frac{\partial \ln(\psi(X,t))}{\partial X}\right)(X(t),t)$$
$$+\frac{1}{2}a_\epsilon(t)\frac{\partial^2}{\partial X^2}\left(\frac{\partial \ln(\psi(X,t))}{\partial X}\right)(X(t),t)+o(\epsilon^{1/2}). \tag{II.38}$$

Elementary calculus gives

$$\frac{\partial \ln(\psi(X,t))}{\partial X}=\frac{1}{\psi}\frac{\partial \psi}{\partial X},\quad \text{and}\quad \frac{\partial}{\partial X}\left(\frac{1}{\psi}\frac{\partial \psi}{\partial X}\right)=\frac{1}{\psi}\frac{\partial^2 \psi}{\partial^2 X}-\frac{1}{\psi^2}\left(\frac{\partial \psi}{\partial X}\right)^2. \tag{II.39}$$

Moreover, by definition of the wave function ψ and V, we have

$$V=-i2\gamma\frac{\partial \ln \psi(X,t)}{\partial X}. \tag{II.40}$$

Hence, we obtain

$$\frac{\square_\epsilon X}{\square t}=V=-i2\gamma\frac{\partial \ln \psi(X,t)}{\partial X}, \tag{II.41}$$

and

$$\frac{\square_\epsilon X}{\square t}\frac{\partial}{\partial X}\left(\frac{\partial \ln(\psi(X,t))}{\partial X}\right)(X(t),t)=-i2\gamma\frac{\partial \ln(\psi)}{\partial X}\frac{\partial}{\partial X}\left(\frac{\partial \ln(\psi)}{\partial X}\right)(X(t),t),$$
$$=-i\gamma\frac{\partial}{\partial X}\left[\left(\frac{\partial \ln(\psi)}{\partial X}\right)^2\right](X(t),t),$$
$$=-i\gamma\frac{\partial}{\partial X}\left[\frac{1}{\psi^2}\left(\frac{\partial \psi}{\partial X}\right)^2\right](X(t),t). \tag{II.42}$$

We then have

$$\frac{\square_\epsilon}{\square t}\left(\frac{\partial \ln(\psi(X,t))}{\partial X}(X(t),t)\right)=\frac{\partial}{\partial X}\left[-i\gamma\frac{1}{\psi^2}\left(\frac{\partial \psi}{\partial X}\right)^2+\frac{\partial \ln(\psi)}{\partial t}+\frac{1}{2}a_\epsilon(t)\left[\frac{1}{\psi}\frac{\partial^2 \psi}{\partial X^2}-\frac{1}{\psi^2}\left(\frac{\partial \psi}{\partial X}\right)^2\right]\right]$$
$$+o(\epsilon^{1/2}),$$
$$=\frac{\partial}{\partial X}\left[-\frac{1}{\psi^2}\left(\frac{\partial \psi}{\partial X}\right)^2\left(i\gamma+\frac{a_\epsilon(t)}{2}\right)+\frac{1}{\psi}\frac{\partial \psi}{\partial t}+\frac{a_\epsilon(t)}{2}\frac{1}{\psi}\frac{\partial^2 \psi}{\partial X^2}\right]+o(\epsilon^{1/2}). \tag{II.43}$$

As a consequence, Eq. (38) is equivalent to

$$\frac{\partial}{\partial X}\left[i2\gamma m\left[-\frac{1}{\psi^2}\left(\frac{\partial \psi}{\partial X}\right)^2\left(i\gamma+\frac{a_\epsilon(t)}{2}\right)+\frac{1}{\psi}\frac{\partial \psi}{\partial t}\right]+\frac{a_\epsilon(t)}{2}\frac{1}{\psi}\frac{\partial^2 \psi}{\partial X^2}\right]=\frac{\partial U}{\partial X}. \tag{II.44}$$

By integrating with respect to X, we obtain

$$i2\gamma m\left[-\frac{1}{\psi^2}\left(\frac{\partial \psi}{\partial X}\right)^2\left(i\gamma+\frac{a_\epsilon(t)}{2}\right)+\frac{1}{\psi}\frac{\partial \psi}{\partial t}\right]+\frac{a_\epsilon(t)}{2}\frac{1}{\psi}\frac{\partial^2 \psi}{\partial X^2}=U(X)+\alpha(X)+o(\epsilon^{1/2}), \tag{II.45}$$

where $\alpha(X)$ is an arbitrary function. This concludes the proof. □

5. Nonlinear Schrödinger equations

Many authors have suggested that the quantum mechanics based on the linear Schrödinger equation is only an approximation of some nonlinear theory with a nonlinear Schrödinger equation. Nonlinear wave mechanics was initiated by De Broglie[11] in order to have a better understanding of the relation between wave and particle (see Ref. 12, p. 227–231).

Many generalizations of the Schrödinger equation exist. We can mention, for example, the *Staruszkievicz*[42] or *Bialynicki–Birula and Mycielsky*[8] modification. All these generalizations are not a consequence of a given principle of physics. For example, the Bialynicki–Birula and Mycielsky modification can be derived, using the hydrodynamical formalism proposed by Madelung,[34] Bohm–Vigier[10] and others, by adding a *pressure term* to the Euler hydrodynamical equation (see Ref. 41, Sec. 2). Of course, one can justify *a posteriori* a given modification by the fact that it solves some relevant problems like the *collapse* of the wave function or the Schrödinger cat paradox (see Ref. 41).

Recently Castro, Mahecha and Rodriguez[13] have proposed a new nonlinear Schrödinger equation based on a generalization of Nottale reasoning.[37] In the one-dimensional case, they obtain

$$i\alpha\frac{\partial\psi}{\partial t}=-\frac{\alpha\,\mathrm{Re}(\alpha)}{2m}\frac{\partial^2\psi}{\partial x^2}+U(x)\psi-i\frac{\alpha\mathrm{Im}(\alpha)}{2m}\left(\frac{\partial\psi}{\partial x}\right)^2\frac{1}{\psi}, \tag{II.46}$$

where $\alpha\in\mathbb{C}$.

If $\mathrm{Im}(\alpha)=0$ and $\alpha=\overline{h}$, then one recovers the classical linear Schrödinger equation.

This generalization is done under two assumptions.

(i) They introduce a complex ''Planck constant'' (i.e., α) by allowing that the normalization constant γ is complex.

(ii) They consider a *complex diffusion coefficient*, which has no counterpart in our case.

The problem is that there is no geometric interpretation of a complex diffusion coefficient, nor of a complex Planck constant. As a consequence, even if Nottale's reasoning is kept in order to derive the new nonlinear Schrödinger equation (II.46), this is an *ad hoc* mathematical generalization.

On the contrary, we have to obtain a nonlinear Schrödinger equation (33) directly from the Scale relativity principle. All our constants have a clear geometrical meaning. Moreover, the nonlinear term is not an *ad hoc* term but is fixed by the theory.

E. Toward the Schrödinger equation

The generalized Schrödinger equation can be simplified in some cases, by assuming that quantum-mechanical paths satisfy special regularity properties.

Theorem 5.1: *Let $X(t)$ be a continuous nondifferentiable function belonging to $H^{1/2}$ such that*

$$a_\epsilon(t)=-i2\gamma. \tag{II.47}$$

Then, the quantized Euler–Lagrange equation takes the form

$$\gamma^2\frac{\partial^2\psi}{\partial X^2}+i\gamma\frac{\partial\psi}{\partial t}=(U(X,t)+\alpha(X))\frac{\psi}{2m}+o(\epsilon^{1/2}). \tag{II.48}$$

We can always choose a solution of Eq. (48) such that

$$\alpha(X)=0. \tag{II.49}$$

In this case, if

$$\gamma = \frac{\overline{h}}{2m}, \qquad (SC)$$

we obtain the classical Schrödinger equation

$$i\overline{h}\frac{\partial \psi}{\partial t} + \frac{\overline{h}^2}{2m}\frac{\partial^2 \psi}{\partial X^2} = U\psi. \tag{II.50}$$

Proof: The only nontrivial, but classical, part concerns the possibility of choosing a phase of the wave function such that $\alpha(X)=0$. The computations follow closely those of Ref. 4, Corollary 1.

Let ψ be a solution of (II.48). The basic idea is that we can always modify the phase of the wave function in order to obtain a solution of (II.48) such that $\alpha(X)=0$. So, let us consider the modified wave function

$$\tilde{\psi}(X,t) = \exp\left(i\frac{\mathcal{A}(X,t)}{2m\gamma} + \theta(X) \right) = \psi(X,t)\Theta(X). \tag{II.51}$$

We have

$$\frac{\partial \tilde{\psi}}{\partial X} = \frac{\partial \psi}{\partial X}\Theta + \psi\Theta',$$

$$\frac{\partial^2 \tilde{\psi}}{\partial X^2} = \frac{\partial^2 \psi}{\partial X^2}\Theta + 2\frac{\partial \psi}{\partial X}\Theta' + \psi\Theta'', \tag{II.52}$$

$$\frac{\partial \tilde{\psi}}{\partial t} = \frac{\partial \psi}{\partial t}\Theta,$$

where $\Theta'(X)$ and $\Theta''(X)$ are the first and second derivative of Θ.

By replacing in (II.48), and assuming that $\alpha(X)=0$, we obtain up to $o(\epsilon^{1/2})$ terms,

$$\Theta\left(i2\gamma m\frac{\partial \psi}{\partial t} + 2\gamma^2 m\frac{\partial^2}{\partial X^2} - U\psi \right) + 4\gamma^2 m\frac{\partial \psi}{\partial X}\Theta' + 2\gamma^2 m\psi\Theta'' = 0. \tag{II.53}$$

As $\psi(X,t)$ is a solution of (II.48) with a given value $\alpha(X)$, we deduce that $\Theta(X)$ must satisfy the following ordinary differential equation:

$$a(X,t)\Theta + b(X,t)\Theta' + c(X,t)\Theta'' = 0, \tag{II.54}$$

where

$$a(X,t) = \alpha(X)\psi, \quad b(X,t) = 4\gamma^2 m\frac{\partial \psi}{\partial X}, \quad c(X,t) = 2\gamma^2 m\psi. \tag{II.55}$$

This is a second order differential equation with nonconstant coefficients. By general theorems on linear differential equations, there always exists a solution. As a consequence, we can always choose $\Theta(X)$ such that $\phi(X,t)\Theta(X)$ satisfies (II.48) with $\alpha(X)=0$. This concludes the proof. □

Difference equations and the Schrödinger condition

The Schrödinger condition (SC) can be precise. We have the following lemma.

Lemma 5.1: The Schrödinger condition (SC) is equivalent to the difference equation

$$\Delta_\epsilon^+ X(t) = \pm\sqrt{\hbar/m}, \tag{II.56}$$

and the following relations:

$$\Delta_\epsilon^+ X(t) = \Delta_\epsilon^- X(t). \qquad (P)$$

Proof: By the definition of $a_\epsilon(t)$ in (II.34), the Schrodinger condition is equivalent to the following system:

$$(\Delta_\epsilon^+ X(t))^2 - (\Delta_\epsilon^- X(t))^2 = 0,$$

$$(\Delta_\epsilon^+ X(t))^2 + (\Delta_\epsilon^- X(t))^2 = 2\hbar/m. \tag{II.57}$$

We deduce that $(\Delta_\epsilon^+ X(t))^2 = (\Delta_\epsilon^- X(t))^2$ and $(\Delta_\epsilon^+ X(t))^2 = \hbar/m$. Hence, we have $\Delta_\epsilon^+ X(t) = \pm\sqrt{\hbar/m}$, a constant independent of t. We obtain

$$\Delta_\epsilon^- X(t) = \Delta_\epsilon^+ (t-\epsilon) = \pm\sqrt{2\hbar/m} = \Delta_\epsilon^+ X(t), \tag{II.58}$$

which concludes the proof. □

As a consequence, we are led to the study of difference equations of the form

$$\Delta_\epsilon^\sigma X(t) = a, \quad \sigma = \pm, \tag{II.59}$$

where $a \in \mathbb{R}$ is a *constant*. This kind of difference equations always have solutions of the form

$$X(t) = X^*(t) + P_\epsilon(t), \tag{II.60}$$

where $X^*(t)$ is a particular solution, and $P_\epsilon(t)$ is an *arbitrary periodic* function of t of period ϵ.

Remark 5.1: Most of the following can be generalized to general difference equations of the form $\Delta_\epsilon^\sigma X(t) = \Phi(t)$, where $\sigma = \pm$ and $\Phi(t)$ is a given function (see Ref. 35, Chap. 8).

Particular solutions always exist. Indeed, if one considers an arbitrary given function $X^*(t)$ defined on $0 \leqslant t < \epsilon$, then the difference equation defines $X^*(t)$ at every point exterior to this interval. Of course, such kinds of solutions are in general not *analytic*. We can define a special particular solution called *the principal solution* following Ref. 35, p. 200.

For (II.59) the principal solution is given by (see Ref. 35, p. 204)

$$X_c^*(t) = a\left(t - c - \frac{\epsilon}{2}\right), \tag{II.61}$$

where c is an arbitrary constant.

Remark 5.2: For $c=0$, $\omega=1$, $a=1$, we obtain the Bernouilli's polynomial $B_1(t)$.

From this section, we deduce the following *structure lemma*.

Lemma 5.2 (structure): The Schrödinger condition is satisfied by continuous functions of the form

$$X_c(t) = \pm\sqrt{\hbar/m}\left(t - c - \frac{\epsilon}{2}\right) + P_\epsilon(t), \tag{II.62}$$

where c is an arbitrary real constant, and $P_\epsilon(t)$ is an arbitrary periodic function belonging to $H^{1/2}$.

We call this set of functions the *principal Schrödinger set*. It gives the structure of typical paths of quantum mechanics in the free case.

Remark 5.3: In Ref. 4, the Schrödinger equation is obtained from a generalized equation under an assumption which is equivalent to a special fractional differential equation. In Ref. 7, we have proved that in the framework of fractional calculus, this fractional equation has no solutions.

On decoherence

Gianfausto Dell'Antonio[a)]
Interdisciplinary Centre, Accademia dei Lincei, Rome, Italy

(Received 31 March 2003; accepted 16 July 2003)

Using a quantum particle in R^3 as a toy model, and following the rules of Schrödinger's quantum mechanics, we discuss to which extent one may be able to use ''decoherence'' to view the quantum particle as a ''classical'' measuring apparatus to measure position. We discuss also very briefly the measurement of momentum and the case of quantum optics. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1616202]

I. INTRODUCTION

While Schrödinger's quantum mechanics has an undisputable extraordinary success as a model of the nonrelativistic behavior of atoms and molecules, the conceptual question ''why most of the macroscopic bodies admit a classical description'' has no satisfactory answer (and not even, perhaps, a clear mathematical formulation).

By ''classical description'' we mean here that the observables can be described as functions on a classical phase space.

On the contrary the superposition principle, which is a distinctive feature of quantum mechanics, allows for the existence of a pure state on which an observable A has no definite value.

It is sometimes stated that for large enough bodies the ''classical behavior'' should arise because the only observable one is able to measure is the mean value of observables defined at a ''microscopic'' level, and our usual perception of the world is a result of an averaging with very small statistical fluctuations, according to some version of the law of large numbers.

But the criterion of how large is the body (i.e., how many atoms it contains), fails. For example, one has manufactured a Bose–Einstein condensate made of several thousands of atoms, and which still shows a quantum mechanical behavior for comparatively large times (of the order of a few milliseconds) whereas the binding of a molecule (composed of a small number of atoms) can fairly well be described using models of rods and strings. It seems that one should make more precise the class of bodies and the class of measurements for which a classical description is legitimate.

For example, one is very far from a proof that, starting with a quantum mechanical description in terms of atoms and molecules, one is able to predict the time evolution of the macroscopic parameters so as to describe the bouncing of two ''physical'' balls. One has a further, related problem: to explain what is the physical mechanism by which some quantum systems can (for all practical purposes) act as classical apparatus. In this regard, let us remark that a solution of this problem would leave essentially untouched the measurement problem of quantum mechanics; if the apparatus can be viewed as a classical statistical Liouville ensemble, the probability of a specific outcome of a measurement is given in terms of classical probability theory.

If an actual measurement of position of a particle is taking place, and the particle is found in the domain D [with probability $p(D)$] the reduction (conditioning) of the probability distribution cannot be traced back to conditioning with respect to the state of the environment, as in classical mechanics, because when one takes into account also the environment one is lead to a theory in a bigger Hilbert space and to entangled states in which the rules of classical probability no longer

[a)]On leave from Department of Mathematics, University of Rome 1, ''La Sapienza,'' Rome, Italy.

hold. In other words, one cannot attribute to a specific final state of the environment the fact that a specific outcome of the mesurement has occured.

The more difficult (and fascinating) problem of building in the theory something that resembles classical determinism and measurement theory without wave packet reduction, is so far beyond the reach of (linear) Schrödinger quantum mechanics.

In recent years there has been a revival of interest in these issues from the part of research groups interested in the foundations of nonrelativistic quantum mechanics.

Depending on taste and past experience, one has tried a more algebraic approach, making use of the Heisenberg picture and working within the C^*-algebras framework of quantum observables (see, e.g., Refs. 1 and 2), or a more function-analytic approach using Schrödinger's quantum mechanics.

In the first approach one seeks a relevant Abelian subalgebra of operators and a suitable coupling to obtain a macroscopic measurement or otherwise a collection of ''robust'' classical states for an open quantum system to describe the appearance of environment-induced selection rules. In the second approach, one tries to describe possible mechanisms within quantum mechanics through which some specific features (e.g., the superposition principle) are somehow suppressed.

In the authors' opinion, in spite of the very interesting structures that have been constructed, especially in the algebraic context, neither of these approaches has met full success. A major contribution has come from the field of quantum optics, in which one is able to construct ''macroscopic states'' (essentially coherent states of the electromagnetic field in a cavity), to construct (experimentally) a superposition of two such states and to measure the time it takes for the system to exhibit decoherence.[3,4]

Decoherence is attributed to the interaction with the boundaries of the cavity. Although experimentally tested, this mechanism for decoherence, and therefore passage to a classical description, is very difficult to put in mathematical terms. One of the major challenges within mathematical physics is to describe it starting from the rules of quantum mechanics (or rather quantum electrodynamics).

We will come back later to the study of decoherence in quantum optics. In the following, we place ourselves within Schrödinger's quantum mechanics and describe a possible mechanism for generating at least partially some ''classical'' behavior in a quantum system.

We will take as apparatus the simplest quantum system, a particle A of mass M in R^3. This is certainly not a classical system, but we will see that, if its mass M is sufficiently large, and A undergoes scattering with sufficiently many light particles, it behaves, after the interaction has taken place, as a statistical mixture.

We shall analyze the system according to the rules of Schrödinger's approach to quantum mechanics.

In general the quantum mechanical setup will be the following: the system we are considering can be thought of as composed of three subsystems, that conventionally will be referred to as observable $\mathcal{O}$, apparatus $\mathcal{A}$, and environment $\mathcal{E}$. They are described as vectors in a product Hilbert space

$$\mathcal{H}=\mathcal{H}_o\otimes\mathcal{H}_a\otimes\mathcal{H}_e\,. \tag{1}$$

The evolution is described in general by a Hamiltonian

$$H=H_o+H_a+H_e+H^{\text{int}}_{o,a}+H^{\text{int}}_{a,e}+H^{\text{int}}_{o,e}\,, \tag{2}$$

where, for example, H_e is the Hamiltonian that describes the evolution of the environment in absence of the measuring apparatus and of the object to be measured, and $H^{\text{int}}_{a,e}$ describes the interaction between the measuring apparatus and the environment. We assume, as usual, that the interaction between the measuring apparatus and the environment is independent of the presence of the object to be measured.

Our purpose is to find the amount of ''decoherence'' that is induced in the system $\mathcal{A}$ if one neglects the information on the state of the environment (so that one has access only to the outcome of experiments that refer to the system $\mathcal{A}$).

We shall assume that neglecting the information about the system $\mathcal{E}$ can be represented mathematically by taking the trace with respect to $\mathcal{H}_e$.

Notice that if one performs this operation starting with a state which is ''entangled,'' i.e., cannot be represented by a vector $\Psi \in \mathcal{H}$ of the form

$$\phi_o \otimes \phi_a \otimes \phi_e, \quad \phi_q \in \mathcal{H}_q, \quad q = s,a,e,$$

one obtains a state which is represented by a ''density matrix'' (positive trace class operators of trace one) in $\mathcal{H}_o \otimes \mathcal{H}_a$ which is in general not a projection operator, and therefore is not associated to a vector in that space.

In this report, we shall consider first the case where the Hilbert space $\mathcal{H}_o$ is absent; we view this as corresponding to studying the decoherence induced in the (measuring) apparatus due to its interaction with the environment.

We shall be interested in the structure of the resulting density matrix, in order to see which are the ''classical features'' that can emerge.

One such classical feature could be that the resulting density matrix has (almost) diagonal kernel in a specific representation (e.g., in the space representation, or in the momentum representation). We shall comment later on whether this can be considered as an indication that in some sense the measuring apparatus can be treated as a classical ensemble for the measurement of the observable which defines the basis on which the kernel is ''almost'' diagonal.

II. A TOY MODEL OF DECOHERENCE

We will consider the case in which both the apparatus $\mathcal{A}$ and the environment $\mathcal{E}$ are systems composed of N_a, respectively, N_e particle.

The particles in the system $\mathcal{A}$ may be in a bound state (the system $\mathcal{A}$ may be a crystal). The particles in $\mathcal{E}$ are much lighter than those in $\mathcal{A}$ and are scattered by $\mathcal{A}$. Decoherence results from the scattering.

This model has been studied previously making some simplifying physical and mathematical assumptions.[5–11] It has been treated rigorously and in much detail in Ref. 12 in the case of point interactions in one dimension, and in Ref. 13 still in one dimension in the case of a point interaction superimposed to a harmonic potential.

Here we shall study in some detail the case $N_a = N_e = 1$ and $N_a = 1, N_e > 1$ with no interaction between the particles in $\mathcal{E}$ and comment briefly on the other cases.[14]

In the simplest case $N_a = N_e = 1$ one works in the tensor product of the Hilbert spaces

$$\mathcal{H}_a = L^2(R^3, \mathrm{d}x), \quad \mathcal{H}_e = L^2(R^3, \mathrm{d}y),$$

and a generic (pure) state of the system is represented by a function

$$\Psi(x,y) \in L^2(R^6, \mathrm{d}x\, \mathrm{d}y), \quad \|\Psi\| = 1.$$

The quantum mechanical evolution is given by

$$\Psi(t) = \exp\{-iHt\}\Psi(0),$$

where H is the total Hamiltonian.

Without loss of generality (the evolution equations are linear) we shall assume that Ψ has the form

$$\Psi(x,y) = \psi(x)\phi(y), \quad x,y \in R^3$$

and consider first the case

$$H_a = -\frac{1}{2M}\Delta_x, \quad H_e = -\frac{1}{2m}\Delta_y, \quad H^{\rm int}_{a,e} = V(x-y), \tag{3}$$

where Δ is the Laplacean in the indicated variable and the potential V is sufficiently regular so that $H_a + H_e + H_{\rm int}$ is self-adjoint.

We shall then discuss briefly the case $H_a = -(1/2M)\Delta_x + W(x)$. Tracing out the degrees of freedom in H_e corresponds to consider only the expectation values of the observables associated to system $\mathcal{A}$.

We prove first a simple Lemma.

Lemma 2.1: Consider the system described in (3). For any bounded operator in $\mathcal{H}_a$ one has, in the coordinate representation,

$$(e^{-iHt}\Psi, Ae^{-iHt}\Psi) = \int \psi^*(x) A_t(x,x')\psi(x') f_t^{V,\phi}(x,x')\,dx\,dx', \tag{4}$$

where

$$A_t = e^{iH_x^0 t} A e^{-iH_x^0 t}, \quad V_x(y) = V(y-x), \tag{5}$$

$$f_t^V(x,x') = (\exp\{-i(H_e + V_x)t\}\phi, \exp\{-i(H_e + V_{x'})t\}\phi). \tag{6}$$

Remark 2.1: Notice that, by construction one has $f_t^{V,\phi}(x,x) = 1$ and for a generic potential V and a generic vector ψ one has $|f_t^{V,\phi}(x,x')| < 1$ for $x \neq x'$. Moreover it is easy to prove that

$$f_t^0(x,x') = f_0^V(x,x') = 1$$

and that

$$\lim_{t\to\infty} f_t^V(x,x') = (W_+^x \phi, W_+^{x'} \phi),$$

where W_+^x is the wave operator relative to the potential $V_x(y) = V(y-x)$.

If the potential is a function which is periodic on the support of ψ with lattice period Γ one has

$$|f_t^{V,\phi}(x,x')| = 1, \quad x - x' \in \Gamma, \quad x,\ x' \in \mathrm{supp}(\psi)$$

so that if the kernel of ρ is periodic under Γ, the reduced density matrix has also this property.

One should also notice that if $A_t(x,x') = a_t(x)\delta(x-x')$ one has

$$(e^{-iHt}\Psi, Ae^{-iHt}\Psi) = (e^{-iH_x^0 t}\psi, Ae^{-iH_x^0 t}\psi)$$

and if $A = ia\cdot\nabla_x$ one has

$$(e^{-iHt}\Psi, ia\cdot\nabla_x e^{-iHt}\Psi) = (\psi, ia\nabla_x\psi) + \left(\exp\{i(H_e + V_x)t\}\phi, ia_k \frac{\partial V}{\partial x_k} \exp\{i(H_e + V_{x'})t\}\phi\right).$$

■

Proof of Lemma 2.1: Notice first that one has

$$(e^{-iHt}\Phi, Ae^{-iHt}\Phi) = (e^{-iHt}\Phi, UAU^{-1}e^{-iHt}\Phi) \tag{7}$$

for any unitary in $\mathcal{H}_e$, since A commutes with any such operator.

Next, consider the change of variables

$$\xi = x - y, \quad (M+m)\eta = Mx + my$$

with inverse

$$x=\eta-\frac{M}{m+M}\xi,\quad y=\eta-\frac{M}{m+M}\xi.$$

With the notation

$$-\frac{1}{2M}\Delta_x=H_x^0,\quad -\frac{1}{2m}\Delta_y=H_y^0,\quad -\frac{1}{2\mu}\Delta_\xi=H_\xi^0,\quad -\frac{1}{2\nu}\Delta_\eta=H_\eta^0,$$

$$\nu=M+m,\quad \mu^{-1}=m^{-1}+M^{-1},$$

one has

$$H_a^0+H_e^0=H_\xi^0+H_\eta^0.$$

Recalling that

$$H=H_x^0+H_y^0+V(x-y)=H_\xi^0+V(\xi)+H_\eta^0$$

and choosing in (6) $U=e^{-iH_y^0t}$ one has

$$e^{-iH_y^0t}e^{iHt}\Phi=e^{-iH_y^0t}e^{iH_\eta^0t}e^{i(H_\xi^0+V(\xi))t}\Phi=e^{iH_x^0t}e^{-iH_\xi^0t}e^{i(H_\xi^0+V(\xi))t}\Phi.$$

Notice that (4) can be written

$$(e^{-iHt}\Phi,Ae^{-iHt}\Phi)=\int\rho_{\mathrm{red}}(x,x')A(x,x')\,\mathrm{d}x\,\mathrm{d}x',\tag{8}$$

where $A(x,x')$ is the kernel of A in the x-representation, $\rho_{\mathrm{red}}=\rho_0(x,x';t)f(x,x';t)$ and $\rho_0(x,x';t)$ is the kernel (in the x representation) of the free evolution of the initial density matrix.

Therefore one has

$$(e^{-iHt}\Phi,Ae^{-iHt}\Phi)=(\Xi_t,e^{iH_x^0t}Ae^{-iH_x^0t}\Xi_t),\quad \Xi_t(x,y)=e^{iH_\xi^0t}e^{-i(H_\xi^0+V(\xi))t}\psi(x)\,\phi(y).$$

Using the invariance under translations of the Laplacean, changing variables (for fixed x) $\xi\to\xi+x=y$ and performing the integration over y completes the proof of Lemma 1.

□

Remark 2.2: It is easly seen that the same argument can be used in case the environment is composed of N particles which do not interact with each other and interact with the particle in $\mathcal{A}$ through potentials V_k that depend only on $x-y_k$. The analysis follows the same lines as in the previous case, with the same conclusions.

If the particles in $\mathcal{A}$ interact with each other or are acted upon by external potential forces, with smooth enough potentials, Lemma 1 [with the subsitution of $V_x(y)$ with $\Sigma_1^{N_a}V_k(y-x_k)$] holds up to terms of second order in the ratio of the mass of the particles in $\mathcal{E}$ relative to the particles in $\mathcal{A}$.

We give details of this for the case $N_e=N_a=1$ with an ''external'' potential $W(x)$. We remark that one has

$$
\begin{aligned}
&\exp\{it[H_x^0+W(x)+H_y^0+V(y-x)]\}\\
&\quad=\exp\{it[H_\eta^0+W(x)+H_x^0 i+V(\xi)]\}\\
&\quad=\exp\{it[H_\eta^0+W(\eta)+H_\xi^0-V(\xi)]\}\\
&\qquad+\int_0^1 \mathrm{d}s\,\frac{\mathrm{d}}{\mathrm{d}s}\left[\exp\left\{it\left[H_\eta^0+W\left(\eta+\frac{m}{m+M}s\xi\right)+H_\xi^0+V(\xi)\right]\right\}\right.\\
&\quad=\exp\{it[H_x^0+W(x)+H_y^0]\}\cdot\exp\left\{it\left[H_\eta^0+W\left(\eta+\frac{m}{m+M}s\xi\right)+H_\xi^0+V(\xi)\right]\right\}\\
&\qquad-\left.\exp\left\{it\left[H_x^0+W\left(\eta-\frac{m}{m+M}\xi s\right)+H_y^0\right]\right\}\exp\{-iH_\xi^0 t\}\exp\{iH_\xi^0 t+iV(\xi)t\}\right].
\end{aligned}
$$

Setting $\epsilon=m/M$ the derivative with respect to s brings down a factor ϵ and the coefficient vanishes itself at $\epsilon=0$.

Therefore in this case, under suitable regularity assumption on W one has

$$
(e^{-iHt}\Psi,Ae^{-iHt}\Psi)=\int(\psi(x)A_t(x,x')\psi(x')f_t^{V,\phi}(x,x')\psi(x')(1+O(\epsilon^2)),
$$

where

$$
A_t=e^{-i(H_x^0+W(x))t}Ae^{-i(H_x^0+W(x))t},\quad V_x(y)=V(y-x),
$$

$$
f_t^V(x,x')=(\exp\{i(H_e+V_x)t\}\phi,\exp\{i(H_e+V_{x'})t\}\phi).
$$

Repeating the steps of Lemma 2.1 one has the same result. ■

It should be emphasized that for each value of t the map

$$
\rho(x,x')\to\rho_0(x,x';t)f(x,x';t) \tag{9}
$$

is completely positive. This family of maps does not form a semigroup; whether one has a semigroup in the same limit is a very delicate issue, and we will not discuss it.

So far, the formulas we have are exact. To proceed further it is convenient to assume that the particles in $\mathcal{E}$ have a mass much smaller than those in $\mathcal{A}$.

As we shall see, this introduces two different time scales, one for $\mathcal{A}$ and one for $\mathcal{E}$. It is then seen that a partial localization of the system $\mathcal{A}$ with respect to the position variable is obtained in a time short compared with that of the natural spread of the function ψ under free evolution.

In this sense the "decoherence" process considered takes place almost instantaneously for $\mathcal{A}$ and in a very long time for $\mathcal{E}$, so that for $\mathcal{E}$ it can be regarded as a scattering event (and therefore justify the use of the scattering matrix, or rather of the wave operator used in Refs. 6, 8, and 10).

III. VERY LIGHT PARTICLES AS ENVIRONMENT

We shall assume that the particles in $\mathcal{E}$ are much lighter than the particle in $\mathcal{A}$; for concreteness we set $M=1$ for the particles in $\mathcal{A}$ and $m=\epsilon$, $\epsilon\ll 1$ for those in $\mathcal{E}$.

With the introduction of the parameter ϵ one has

$$
f_\epsilon(x,x';t)=(Y_t^x,Y_t^{x'}),\quad Y_t^x=\exp\left\{iH_y^0\frac{t}{\epsilon}\right\}\exp\left\{-i(H_y^0+\epsilon V_x)\frac{t}{\epsilon}\right\}\phi. \tag{10}
$$

It is now clear that we can choose T so small that for $0<t<T$ the effect of the free evolution on ψ is negligeable, and still $T/\epsilon\gg 1$ so that we can approximate f by a scattering regime, as suggested by the presence of t/ϵ in the exponential.

It is also evident from (10) that in the units chosen the interaction is very weak (of order ϵ) and therefore we are in need of having the environment consisting of a large number of particles (of order ϵ^{-1}) to have a decoherence effect of order one.

If the number of light particles interacting with $\mathcal{A}$ in the interval of time $[0,T]$ is still bigger, one may be able to justify the statement that the environment causes "almost instantaneous" reduction to the diagonal of the kernel of the density matrix in the position representation.

Indeed each interaction would provide a factor approximately equal to $(1-\epsilon)^f$, $f>0$ but since there are $0(M\epsilon^{-1})$ such terms their product approaches zero when $\epsilon\to 0$, $M\to\infty$. We shall comment later on the relevance of this to the statement that $\mathcal{A}$ may be used as a classical apparatus for the measurement of position.

Remark 3.1: One should remark that this limit is very singular, in the sense that the sequence of reduced density matrices converge to a state which is not represented by a density matrix for the system $\mathcal{A}$. This is a common feature of limits in which the number of particles involved tends to infinity. ■

Of course, to justify this setting requires that the initial data of the particles in $\mathcal{E}$ satisfy strong hypothesis.

In order to proceed to a more detailed analysis we shall assume that the potential $\epsilon V(y)$ satisfies the assumptions that assure the existence and unitarity of the wave operator W_+. Therefore,

$$s-\lim_{t\to\infty}\left[\exp\left\{-iH_y^0\frac{t}{\epsilon}\right\}\exp\left\{i(H_y^0+\epsilon V_x)\frac{t}{\epsilon}\right\}-W_+^x\right]\phi=0 \tag{11}$$

for any vector vector $\phi\in\mathcal{H}_e$. In (11) $W_{+,\epsilon}^x$ is the outgoing wave operator for the potential ϵV_x, $V_x(y)=V(y-x)$.

It will be convenient to introduce the subset of $\mathcal{H}_e$ consisting of vectors for which the convergence to zero in (11) is "sufficiently fast."

We define for any $\delta\geqslant 0$,

$$K_\delta\equiv\left\{\phi\in\mathcal{H}_e:\ \left\|\left[\exp\left\{-iH_y^0\frac{t}{\epsilon}\right\}\exp\left\{i(H_y^0+\epsilon V_x)\frac{t}{\epsilon}\right\}-W_{+,\epsilon}^x\right]\phi\right\|\leqslant C_\phi\epsilon^{1+\delta}\right\}, \tag{12}$$

where C_ϕ is a positive constant that may depend on ϕ and δ.

From the previous estimates one immediately has the following statement.

Lemma 3.1: If the initial state ϕ of the light particle lies in K_δ, $\delta>0$ one has

$$f\left(x,x';\frac{t}{\epsilon}\right)=(W_{+,\epsilon}^x\phi,W_{+,\epsilon}^{x'}\phi)+O(\epsilon^{1+\delta})=1+\epsilon G_V(x,x')+O(\epsilon^{1+\delta}),\quad 0<t<T, \tag{13}$$

where $G_V(x,x')$ can be computed explicitely from the first order Born expansion of the solution of the Lippmann–Schwinger equation for the potential V. □

To give an explicit expression of $G_V(x,x')$ in (13) we recall that $\phi_{\text{out}}^\epsilon$ is given by the

$$\phi_{\text{out}}^\epsilon(y)=\int \mathrm{d}k\ \phi_{\text{out}}^\epsilon(y,k)\hat{f}(k), \tag{14}$$

where $\phi_{\text{out}}^\epsilon(y,k)$ is the unique solution of the Lippman–Schwinger equation

$$\phi_{\text{out}}^\epsilon(y,k)=e^{iky}-\frac{i}{4\pi}\epsilon\int \mathrm{d}z\,\frac{e^{-i|k||y-z|}}{|y-z|}V(z)\phi_{\text{out}}^\epsilon(z,k),$$

which satisfies the condition $\lim_{|y|\to\infty}(\phi_{\text{out}}^\epsilon(y,k)-e^{i(y,k)})=0$.

Therefore, to order one in ϵ one has

$$W^x_{+,\epsilon}\phi=(\psi^\epsilon_{\rm out}(x))(y)=\phi(y)-\frac{1}{4\pi}\epsilon\int \mathrm{d}k\,\mathrm{d}z\,\frac{e^{-i|k||y-z|}}{|y-z|}V(z+x)e^{i(z,k)}\hat{\phi}(k)+o(\epsilon). \quad (15)$$

From this it is easy to deduce the formula for $G_V(x,x')$.

One can write Eq. (14) in the following form:

$$\phi^\epsilon_{\rm out}(y)=\phi(y)-\frac{\epsilon}{4\pi}\int T^x(y,y')\phi(y')+o(\epsilon)$$

with an explicit form of the kernel $T(y,y')$.

Therefore

$$(\phi^x_{{\rm out},\epsilon},\phi'^x_{{\rm out},\epsilon})=1-\frac{\epsilon}{4}[(\hat{\phi},T^x\hat{\phi})+(T^{x'}\phi,\phi)]+o(\epsilon), \quad (16)$$

where $\hat{\phi}$ is the Fourier transform of ϕ and

$$T^x=\int \mathrm{d}k\int \mathrm{d}z\,\frac{\exp\{-i|k||z-y|\}}{|z-y|}V(x+z)\exp\{i(k.z)\}.$$

Remark 3.2: A more accurate analysis, given in Ref. 12 and in Ref. 13, shows that under more stringent hypotesis on the potential one can obtain, much in the spirit of a Born–Oppenheimer (adiabatic) approximation, an asymptotic expression for the state of the full system which shows quite explicitely that if the initial state is a product state after a time of order ϵ it becomes entangled, and this produces the decoherence if one traces out the degrees of freedom of the light particle. ■

Remark 3.3: Of course, if either N_a or N_e (or both) are greater than 1, one has to deal with for N-body scattering and the expression of the wave operator becomes much more complicated, and consequently a condition analogous to that of belonging to the subspace K_ν is much more difficult to verify, unless the light particles in $\mathcal{E}$ constitute a beam of particles incident on the heavy one with a time delay sufficiently long so that the interaction can be described in terms of a succession of scattering events (in the approximation to order ϵ considered) but sufficiently small so that it is legitimate to neglect the free motion of the particle in $\mathcal{A}$ and therefore to consider that the interaction has led ''instantaneously'' to decoherence. ■

Assume that all the incoming particles in $\mathcal{E}$ belong to K_δ and if one assumes that they arrive at the location of $\mathcal{A}$ at times that are separated by $K\epsilon^{-1}$, $1\ll K<\epsilon^{-\delta}$. One has then an overall effect

$$f^\epsilon_t(x,x')=\Pi_1^N f_{t_k,\phi_k},\quad N=K\epsilon^{-1}$$

and since each of the factors for $x\neq x'$ differs is smaller than one and differs from one for a term of order ϵ one has $\lim_{K\to\infty}\lim_{\epsilon\to 0}f^\epsilon_t(x,x')=0$, $x\neq x'$ (and the convergence to zero is exponentially fast).

We comment now briefly on the conditions on the potential and the state ϕ that imply that ϕ belongs to K^V_ν, so that

$$\left\|\left[\exp\left\{-iH^0_y\frac{t}{\epsilon}\right\}\exp\left\{i(H^0_y+\epsilon V_x)\frac{t}{\epsilon}\right\}-W^x_+\right]\phi\right\|\leqslant C_\phi\epsilon^{1+\delta}.$$

It is convenient to introduce the following class W_α of potentials:

$$V(x)=(1+|x|)^{-\alpha}[V_1(x)+V_2(x)],\quad \alpha>2,\quad x\in R^3,$$

$$V_1\in L^\infty,\quad V_2\in L^2,\quad x\cdot V_1\in L^\infty+L^2,\quad (1+|x|)V_2\in L^\infty+L^2. \quad (17)$$

We also introduce the following set D_ρ of elements $f(x)$ in $L^2(R^3)$,

$$D_\rho:\{f\in L^2,\quad |x|^\rho f(x)\in L^2,\quad \rho>2,\quad f=\xi(H)f\} \tag{18}$$

for some function $\xi\in C_0^\infty(0,+\infty)$ [we have assumed, without loss of generality, that the spectrum of H is absolutely continuous and coincides with $[0,+\infty)$]. The set D_ρ is dense in L^2.

The last condition in the definition of D_ρ means that f has energy bounded away from zero, and equivalently that its asymptotic state has momentum bounded away from zero.
Then we have the following Lemma.

Lemma 3.2: Let $V\in W_\alpha$, $\alpha>2$ *and let* $\phi\in D_\rho$, $\rho>2$. *Then there is a* $\delta>0$ *such that* $f\in K_\delta$ *i.e., for some* $\delta>0$,

$$\|[\exp\{-iH^0t\}\exp\{i(H^0+V)t\}-W_+]\phi\|\leqslant C\|\phi\|t^{-(1+\delta)}. \tag{19}$$

Proof: We shall only give a sketch of the proof. One has, with $U_t^0=e^{iH^0t}$, $U_t=e^{iHt}$,

$$\begin{aligned}
&\|U_t\phi-U_t^0W_+\phi\|\\
&\quad=\|\xi(H)U_t\phi-\xi(H^0)U_t^0W_+\phi\|\|\xi(H)(U_t-U_t^0)W_+\phi+(\xi(H)-\xi(H^0))U_t^0W_+\phi\|\\
&\quad\leqslant\left\|\int_t^\infty \mathrm{d}s\; U_s\xi(H)VU_s^0W_+\phi\right\|+\|(\xi(H)-\xi(H^0))(|Q|)^\alpha\|\|(|Q|)^{-\alpha}U_t^0W_+\phi\|
\end{aligned}$$

for every $\alpha>2$.

The proof is now completed using the following estimates, which follow from geometric scattering theory (for short range potentials, the propagation outside a sufficiently large ball is essentially the same as in the free case, so that $t/|x|$ is of order one on the support of $U_t\phi$ for t very large).

Let V satisfy the hypotheses given above, $\xi\in C_0^\infty((0,+\infty)$. For every real number $\beta\in[0,\alpha]$ and each $\epsilon>0$ there is a constant $c>0$ such that, for all t, $s\in R$ the following estimates hold true:

$$\|(|x|+1)^{-\beta}\xi(H)U_t(|x|+1)^{-\beta}\|\leqslant(I+|t|)^{-\beta+\epsilon},$$

$$\|(|x|+1)^{-\beta}\xi(H)U_{t-s}U_s^0\xi(H^0)(|x|+1)^{-\beta}\|\leqslant(1+|t|)^{-\beta+\epsilon}.$$

We will not give here the proof of these inequalities (see, e.g., Refs. 15–17) but limit ourselves to some comments, that should illustrate the role of the assumptions made on the state ϕ and on the potential V.

First of all, one should remember that integration by parts provides, if $g(y)$ is a function of class C^∞ with support in $(0,\infty)$,

$$\int g(y)e^{ity}\,\mathrm{d}y=\frac{i}{t}\int g'(y)e^{ity}\,\mathrm{d}y.$$

If one uses the spectral decomposition of the free Hamiltonian, and some Sobolev inequalities, one sees that this leads to a fast decrease in time of the sup norm of $e^{iH^0t}\phi$. A convenient way to handle in the same spirit the group e^{iHt} is to introduce the generator D of the dilation group, $D=1/2\,(P\cdot Q+Q\cdot P)$ (Q and P are the vector-valued operators that represent position and momentum).

Notice that

$$[D,\xi(H^0)]=2iH^0\xi'(H^0),\quad [D,V]=\frac{i}{2}(\nabla V\quad P+P\nabla V) \tag{20}$$

for any potential V, and that by Sobolev imbedding $F(H^0+I)^{-1}$ is a bounded operator in $L^2(R^3)$ if $F \in L^2(R^3)$ (this the basis of the commutator method introduced by Mourre and which plays a crucial role in geometric scattering theory).

Therefore for elements ϕ in $L^2(R^3)$ such that $\xi(H^0)\phi=\phi$ for some smooth function ξ with support in $(0,\infty)$ one can "exchange" some decrease at infinity in $|x|$ for a better decrease in time of $(U_t^0\phi)(x)$.

The same strategy can be made to work also for the group U_t but the commutator estimates bring into play the potential V, and the conditions we have stated are required to obtain estimates (24), (25) and therefore (23), upon integration by parts in the relevant variable for the spectral densities of H^0 and of H. □

Remark 3.4: One should remark that, since the particles have mass ϵ a lower bound on the momentum implies a lower bound of order ϵ^{-1} on the velocities wich means that we can have in general $0(\epsilon^{-1})$ independent scattering events in unit time. If $\phi \in K_\delta$ there is still room for $M\epsilon^{-1}$ collisions, with M very large. ■

IV. ON THE RELEVANCE OF "ALMOST DIAGONAL SUPPORT" OF THE REPRESENTATIVE KERNEL

In the preceding section we have seen that scattering by a large number of light particles can lead to "almost total" diagonalization of the reduced density matrix in the coordinate representation. We want to comment now on the relation of this property with the fact that such reduced density matrix may exhibit some features which can be considered analogous to those of a Liouville distribution in configuration space, and therefore may be fit to describe a classical apparatus for the measurement of position.

Let us start with a simple example.

Consider a system defined in C^n by the vector $\phi=\{\phi_k\}$ corresponding to the projection operator

$$\Pi:\Pi_{k,h}=\overline{\phi}_k\phi_h\,.$$

Suppose one modifies Π in Π^ϵ defined by

$$\Pi^\epsilon:\Pi^\epsilon_{k,h}=\exp\left\{-\frac{|k-h|^2}{\epsilon^2}\right\}\Pi_{k,h}\,. \tag{21}$$

It is easy to check that Π^ϵ is a density matrix for every value of the parameter ϵ. For any density matrix ρ define the dispersion with respect to a self-adjoint operator A as

$$\Delta_A(\rho)^2=\mathrm{Tr}(\rho A^2)-(\mathrm{Tr}(\rho A))^2 \tag{22}$$

(in the case ρ is a projection operator this coincides with the usual definition of the dispersion).

Notice that $\Delta_A(\rho)$ is not a linear funcion of ρ.

It is natural to define the effective dispersion of ρ with respect to A as

$$\Delta_A^{\mathrm{eff}}(\rho)=\inf_{c_i,\rho_i}\sum c_i\Delta_A\rho_i\,,\quad \rho=\sum c_i\rho_i\,, \tag{23}$$

where $0<c_i\leqslant 1$, ρ_i are density matrices, and the infimum is taken over all such decompositons.

There is a decomposition of ρ as an orthogonal sum of projection operators which commute with A if and only if $[\rho,A]=0$.

One has then, for any diagonal matrix A for ϵ small enough,

$$\Delta_A^{\mathrm{eff}}(\Pi^\epsilon)\leqslant\epsilon.$$

We may regard the function Δ_A^{eff} as a measure of the possibility of "measuring" A with as little dispersion as possible. One has

$$[A,\rho]=0\Leftrightarrow\Delta_A^{\text{eff}}(\rho)=0.$$

It is easy to prove that for any diagonal matrix A one has

$$\Delta_A^{\text{eff}}(\Pi^\epsilon)\leqslant C\epsilon\|A\|$$

for some positive constant C, which may depend on N.

Define $\Pi^0=\lim_{\epsilon\to 0}\Pi^\epsilon$. One has

$$\Pi^0_{k,h}=|\phi_k|^2\delta_{k,h},$$

so that the density matrix Π^0 represents a statistical mixture of the states $\phi^s=\{\phi^s_{k,h}=\delta_{s,h}\delta_{s,k}\}$ with weight $|\phi_s|^2$.

Consider now a measurement made with the apparatus in the state Π^0 of an observable $\mathcal{O}$ which is represented in the basis chosen by a diagonal matrix $A_{k,h}=a_k\delta_{k,h}$.

According to the statistical interpretation of quantum mechanics, the apparatus is in the state ϕ^k with probability $|\phi_k|^2$. Let us denote by ψ the state of the system $\mathcal{O}$ and by ψ_h the eigenstate of A to the eigenvalue a_k, so that $\psi=\Sigma_i c_i\psi_i$ with $c_i\in C$.

Let us assume that during the measurement the apparatus in the state ψ^k clicks with probability $|c_k|^2$, which is the probability that $\mathcal{O}$ be in the state ϕ_k.

The joint probability will be $\Sigma_k|c_k|^2|\psi_k|^2=\text{Tr}(\Pi^0\Pi_\psi)$ where Π_ψ is the orthogonal projection on the vector ψ and the average result of the measurement of A will be $\text{Tr}\,A\Pi^0$, in accordance with the rules of quantum mechanics.

If the observable A had continuous spectrum (and therefore the corresponding Hilbert space is infinite-dimensional) one expects that a limit procedure would produce the same result.

Returning now to our toy model of decoherence, these considerations lead to the following possible "scenario" (here we follow the established definition of scenario as meaning a rough general picture in which only very few preliminary essential details have been proved or sketched).

Consider the kernel of the reduced density matrix ρ^N_{red} at time T in the coordinate representation

$$\rho^N_{\text{red}}(x,x';T)=\overline{\psi}(x)\quad\psi(x')f^N_T(x,x'),\quad x,x'\in R^3, \tag{24}$$

where the factor $f^N_T(x,x')$ is due to the scattering of N light particles as discussed in Sec. II.

Assuming that the N scattering events take place in time $0=\tau_1<\cdots<\tau_N=T$ such that $\tau_{k+1}-\tau_k=0(\epsilon)$ and that such scattering events may be considered as independent, the function f^N_T has the form

$$f^N_T(x,x')=\Pi_1^N F_{i,\tau_i}(x,x'), \tag{25}$$

where F_{i,τ_i} is a kernel by which one should multiply the reduced density matrix at time τ_i; it contains the kernel due to the decoherence effect due to the interaction with the ith particle and also the kernel which comes from the free propagation of the heavy particle between collisions (recall that in the approximation considered, the effect of each collision is instantaneous).

The explicit form of $f^N_T(x,x')$, even with the approximations we have made, is difficult to find. From the form of each $F_{i,\tau_i}(x,x')$ one can guess that it is a kernel that has value 1 when $x=x'$ and decreases fast away from the diagonal, since each of the factors is less than 1 away from the diagonal.

One may hope therefore that $\rho^N_{\text{red}}(x,x';T)$ is well approximated on S_ψ (the support of ψ) by

$$G(x,x')=C\exp\{-\epsilon^{-2}(x-x')^2\}\overline{\psi}(x)\psi(x'),$$

where C is an appropriate normalization constant [notice that away from S_ψ the "guess" cannot be true, since for each value of the index k one has $\lim_{\inf\{|x|,|x'|\}\to\infty}F_{k,\tau_k}(x,x')=1$] Define $\psi_k(x)=c\psi_k\xi(B_{x_k,\epsilon})$ where $\{x_k\}$ is a regular lattice of points with lattice spacing $\epsilon^{1+\delta}$ and ξ is the characteristic function of the ball centered in x_k and of radius ϵ. Using the explicit form of G one can prove that

$$\lim_{\epsilon\to 0}\Delta_X\rho_{\text{red}}=0$$

so that ρ_{red} is almost dispersion free with respect to the position operator X in R^3 and therefore can be considered, for all practical purposes, as a classical (Liouville) statistical ensemble with Liouville density $\|\psi(x)\|^2$.

Remark 4.1: Notice that if ρ_{red} is almost dispersion-free for the variable that represents position, it must have very large dispersion with respect to the variable that represents momentum, since Heisenberg's uncertainty principle is valid also for density matrices, being a mathematical consequence of the properties of the Fourier transform.

This is easily understood as due to the fact that, by conservation of momentum, each collision changes the momentum of the heavy particle by a finite amount of order ϵ. After $O(K\epsilon^{-1})$ scattering events, with K very large, each component of the momentum of the heavy particle can be changed by an amount which can be of order K. Therefore, if one does not keep track of the momentum of the light particles which have been scattered, the uncertainty in each component of the momentum of the heavy particles is of order K.

■

We should add another remark.

Remark 4.2: According to Heisenberg's uncertainty principle, if the localization in position of ρ_{red} is to order η the localization in momentum can be at most $\hbar/\eta$.

This suggests that one should impose the further condition $\epsilon>\sqrt{\hbar}$ if the resulting ρ_{eff} should have a dispersion of the order of $\sqrt{\hbar}$ as expected from momentum conservation and the fact that the directions of the incoming light particles are random and that each of them has dispersion both in momentum and in position of the order $\sqrt{\hbar}$.

Of course, if the dispersion in position of the incoming light particles is of the order $\hbar^\xi$ with $\xi>\frac{1}{2}$ one can allow a smaller lower bound for ϵ. ■

V. LOCALIZATION IN MOMENTUM

The construction of a reduced density matrix that may be almost diagonal in the momentum representation gives rise to serious mathematical difficulties. It requires models of the interaction of a charged quantum particle with the quantized electromagnetic field, and the construction of such models, even the ones which are only moderately realistic, presents formidable mathematical problems.

In essence, they are also scattering models, in the sense that the field is radiated to infinity in space, and is traced out; in this asymptotic regime the charged particle becomes "dressed" by a cloud of photons, and the "dress" depends on the particle's momentum. This description requires an infrared cutoff, to avoid divergences. When the cutoff is removed, in the momentum representation the kernel of the reduced density matrix becomes "almost" diagonal; this is due to the fact that in the Hilbert space representation of the joint system particle+field as direct integral over the momentum of the particle the states of the field corresponding to different momenta of the particle become "orthogonal" to each other for different values of the momentum.

In fact the representations of the canonical commutation relations assigned to the field for different values of the momentum tend to become inequivalent for different values of the momentum of the charged particle so that in the limit the reduced density matrix that describes the charged particle becomes diagonal in the momentum representation.

We give here only a bare outline of the general scheme; in fact the theory, in spite of the formidable progess made recently, is not yet in its definitive form and the conditions under which the general picture given above is valid would require an analysis which will not be given here.[18–22]

The Nelson model is a prototype for this model of interaction of a charged particle with a quantized electromagnetic field.

This model describes the interaction of a nonrelativistic spinless charged quantum particle linearly coupled to a quantized relativistic scalar Bose field, which is massless and real. The nonrelativistic scalar particles (system $\mathcal{A}$) is described by position and momentum variables x_k, p_l which satisfy the usual Heisenberg relations; the scalar field (system $\mathcal{E}$) is described in Fock space model by creation and annihilation operators $a(k)$, $a^*(k)$ which satisfy the standard commutation relations; $a(k)$ is the annihilation operator for a zero mass particle of momentum k.

Spatial translations are implemented by the total momentum operator

$$P = p + \int k a^*(k) a(k) \mathrm{d}^3 k. \tag{26}$$

The dynamics of the system is generated by the Hamiltonian

$$H = \frac{p^2}{2m} + H^{\mathrm{ph}} + g \int_0^K (a(k) e^{ikx} + a(k)^* e^{-ikx}) \xi(k) |k|^{-1/2} \mathrm{d}^3 k, \tag{27}$$

where

$$H^{\mathrm{ph}} = \int |k| a(k)^* a(k) \mathrm{d}k^3.$$

The function $\xi(k)$ is a cutoff function for low momenta necessary to define in a rigorous way the entire theory (an ultraviolet cutoff K is also needed, but in our context is irrelevant because here we shall be interested only in infrared photons).

The Hamiltonian is invariant under translations in physical space, and therefore admits a decomposition over the spectrum of the total momentum P,

$$H = \int^{\oplus} H(P) \mathrm{d}P, \quad \mathcal{H} = \int^{\oplus} \mathcal{H}_P \, \mathrm{d}P.$$

On each $\mathcal{H}_P$ the Hamiltonian can be written

$$H_P = \frac{|P^{\mathrm{ph}} - p|}{2m} + g \int_0^K (a(k) e^{ikx} + a(k)^* e^{-ikx}) \frac{\xi(k)}{\sqrt{|k|}} \mathrm{d}^3 k \tag{28}$$

and admits a ground state Ω_P.

The dressed one particle wave packets ψ_f, $f \in L^2(R^3)$ defined by

$$\psi_f(P) = f(P) \Omega_P$$

propagate according to

$$\psi_{f(t)} = \exp\{-iHt\} \psi_f, \quad f(t)(P) = f(P) \exp\{-iE(P)t\},$$

where $E(P)$ is the energy of a dressed charged particle of momentum P.

The system admits a wave operator[18,19,21] and has the property that the Hilbert space of the outgoing states [which in this case is $L^2(R^3, \mathrm{d}x) \times \mathcal{F}$, where $\mathcal{F}$ is the Fock space of the field] can be written as the integral over R^3 (momentum space of the particle) of Fock-space states of the field, $\mathcal{H} = \int^{\oplus} \mathcal{H}_p \, \mathrm{d}^3 p$.

One can prove that the asymptotic creation and annihilation operators $a_{\rm as}(k)$, $a^*_{\rm as}(k)$ of the photon field exist, satisfy the usual canonical commutation relations (CCR), and commute with the algebra of position-momentum of the dressed particle (at least in the one-particle sector).

If an infrared cutoff is present, the $a_{\rm as}$, $a^*_{\rm as}$ give a representation of the CCR which is equivalent to the representation given by the a, a^*. Define $W_{\rm as}$ to be the unitary operator that implements this unitary equivalence,

$$a_{\rm as} = W_{\rm as} a W^*_{\rm as}, \quad a^*_{\rm as} = W_{\rm as} a^* W^*_{\rm as}.$$

For the sake of simplicity, we assume that the infrared cutoff function $\xi(k)$ is chosen such that $1-\xi(k)$ is the characteristic function of the interval $|k| \leqslant \epsilon$, so that the unitary operator W depends on ϵ.

Of course, the construction of the dressed states depends on the cutoff, so that for each function f we have a family of dressed states ψ^ϵ_f, and a family of unitary operators $W^\epsilon_{\rm as}$. When the infrared cutoff is removed, i.e., in the limit $\epsilon \to 0$, the two representations become inequivalent and one has[21]

$$\lim_{\epsilon \to 0} (\psi^\epsilon_f, \psi^\epsilon_g) = 0,$$

whenever the support of f in momentum space is disjoint from the support of g.

In this sense, by tracing out the degrees of freedom of the outgoing radiation field and removing the infrared cutoff one has a reduced density matrix of the charged particles in diagonal form in the momentum representation.

This effect can be understood in a qualitative form by remarking that the Hamiltonian of our system is at most quadratic in the creation and annihilation operators of the scalar field, and therefore by a suitable Bogolijubov trasformation it can be written as the sum of a quadratic part in a new set of creation and annihilation operators $b(k), b^*(k)$ and a term which acts as the identity in the Fock space of the $b(k), b^*(k)$.

We denote by W^ϵ the unitary transformation that implements this map in Fock space (due to the presence of the infrared cutoff this unitary operator exists, but of course it depends on the cutoff chosen).

The unitary operator W^ϵ depends on the momentum of charged particle, and can be seen as a dressing trasformation, and is in general different from $W^\epsilon_{\rm as}$ obtained considering the decoupling due to the asymptotic behavior in time.

In order that W^ϵ exists for all values of p it is necessary that the following integral be finite:

$$J = \int_0^\infty |\xi(k)|^2 |k|^{-3} \, {\rm d}^3 k$$

(indeed it can be seen that if it exists for a value of the momentum p then the same is true for all the other values).

Altough the operators $W^\epsilon_{\rm as}$ and W^ϵ are not the same, it is expected that

$$(\psi^\epsilon_f, \psi^\epsilon_g) = 0(CJ^{-1})$$

when the supports of f and g are disjoint.

Therefore the situation is indeed similar to the case of localization in x-space discussed earlier, with J^{-1} playing the role of ϵ.

VI. DECOHERENCE IN QUANTUM OPTICS

We review briefly here the analysis that has been done in quantum optics, in particular in "cavity quantum electrodynamics"[3,4] about decoherence and the appearence of classical proper-

ties. The contributions of quantum optics to a better understanding of the problem are spectacular, mostly due to the fact that its predictions have been tested experimentally.

In quantum optics one defines as ''classical'' (or ''quasiclassical'') the coherent states of the quantized electromagnetic field in a cavity.[23] Since in a cavity the normal modes of the free electromagnetic field are numerable, quantization is done by associating creation and annihilation operators to each degree of freedom in the normal form of the free Hamiltonian (i.e., in the coordinates in which the free Hamiltonian is written as a sum of independent harmonic oscillators), according to the Weyl rules (since the cavity is compact, these rules should be handled with care).

For each degree of freedom, the coherent states are parametrized by a complex number α and are written explicitly as

$$|\alpha\rangle = C \exp\{(\alpha a^{\dagger} - \alpha^* a)\},$$

where $a^{\dagger}$, a are the creation and annihilation operator associated to the degree of freedom considered and C is a normalization constant.

One can verify that the average number of ''photons'' in the state α is $|\alpha|^2$ and under free evolution the coherent state $|\alpha\rangle$ evolves according to the rule $|\alpha\rangle(t) = |\alpha(t)\rangle$ where $\alpha(t) = e^{i\omega t}\alpha(0)$ with ω the frequency of the mode.

In this sense the evolution is ''classical;'' moreover one sees that the dispersion (with respect to the canonical variables) is independent of α and is identical to that of the ''vacuum'' state, defined by $\alpha = 0$.

The ''almost classical'' behavior of the field in a cavity with small value of Q ($Q = \omega\tau$ where τ is the lifetime of the mode and ω its frequency) was demonstrated in Ref. 24.

Cavites with high value of Q keep the coherent state of the electromagnetic field for a time of the order of magnitude of one second (an extremely long time by the standards of modern technology). Coherent states have the further advantage that they can be physically realized by turning on a microwave generator when the field is in the vacuum state.

The atoms are prepared in suitable states and detected after they have interacted with the field. They serve two purposes: to manipulate the field in the cavity and also to measure its state.

The method for generating a quantum superposition of the coherent states, proposed in Ref. 3 and realized in Ref. 4, involves a beam of circular polarized atoms crossing a high-Q cavity C in which a coherent state (a cat) has been previously injected (the use of circular polarized state with high angular momentum is due to their very strong coupling to microwaves and to their very long radiative decay times, due to the fact that their density has main support outside the nucleus).

On either side of the high-Q cavity C there are two cavities R_1 and R_2; these are low-Q cavities (and therefore quasiclassical, see Ref. 24). After having prepared a coherent state inside the cavity by applying a suitable microwave field to the vacuum state (recall that the vacuum state of the quantized electromagnetic field inside the cavity is the lowest energy state, but contains all vacuum fluctuations) one introduces in the system R_1, C, R_2 (in this order) a beam of circular polarized Rydberg atoms (rubidium or cesium). Their velocities are controlled precisely (so that their exit time from the cavity is known with great precision) and they are in very highly excited levels (so that they interact strongly by dipole interaction even with a very weak field).

We shall call e the level of the atoms which are injected, and we assume that there is a slightly lower level, which we shall call g, and that the two level system e, g (e for excited, g for ground) is resonating with the microwave field in R_1 and in R_2. The interaction with a resonant electromagnetic field is analogous to the interaction of a spin with a magnetic field. Denoting by $|e\rangle$ and $|g\rangle$ two representative vectors of the states e, g one can choose the intensity of the field in the cavities R_1 and in R_2 in such a way that one induces a rotation of $\pi/2$ in the ''plane'' $|e\rangle$, $|g\rangle$.

Therefore the first cavity performs the following transformation:

$$|e\rangle \to \frac{1}{\sqrt{2}}(|e\rangle + |g\rangle)$$

(the choice of the initial phases is irrelevant, since only relative phases count).

The cavity C is tuned so that if the atom crosses the cavity in the state e there is an appreciable phase shift of the field, due to a resonance between e and an ''ancilla'' state a of the atom, which resonates with e but not with g.

No appreciable phase shift is induced if the atom is in the state g.

The velocity of the atom can be selected in such a way that this phase shift is (roughly) π. After the beam has crossed the cavities R_1 and C, the entangled state of the combined system atom plus coherent state of the field is therefore

$$\frac{1}{\sqrt{2}}(|e\rangle \otimes |-\alpha\rangle + |g\rangle \otimes |\alpha\rangle).$$

Notice that one can choose for each atom the same representative (i.e., $|e\rangle$ rather then $e^{i\phi}|e\rangle$ for some ϕ that may depend on the atom in the beam) in the Hilbert space description of the state of the atoms and of the coherent state of the field, since only a change in the relative phases is significant.

After having crossed the cavity C, the beam of atoms crosses the low-Q cavity R_2 where, as explained above, there is a further action on the states of the atoms

$$|e\rangle \to \frac{1}{\sqrt{2}}(|e\rangle + |g\rangle), \quad |g\rangle \to \frac{1}{\sqrt{2}}(|g\rangle - |e\rangle).$$

Therefore, after exiting the sequence of cavities R_1, C, R_2 the combined atom-coherent state of the field is as follows:

$$\tfrac{1}{2}[|e\rangle \otimes (|-\alpha\rangle - |\alpha\rangle) + |g\rangle \otimes (|-\alpha\rangle + |\alpha\rangle). \tag{29}$$

If one now makes a measurement of the state of the atom, to find out whether it is in the state e or in the state g, one gets by reduction a quantum superposition of the two coherent states $|\alpha\rangle$ and $|-\alpha\rangle$, and therefore a quantum superposition of two ''classical'' states.

From the point of view of quantum mechanics, this is an obvious statement. The point of the experiment is that now one can determine the time it takes for the quantum superposition to ''become'' (i.e., to behave in successive measurements as) a statistical mixture, namely, a state represented by a density matrix which is not a projector.

This can be done by injecting after a time T in the same sequence of cavities an identical beam of particles.

If the state remains pure (i.e., if there has not been decoherence) one should record a perfect correlation between the measurements on the first and the second atom; if, on the other extreme, decoherence is maximal (the density matrix has eigenvalues $\frac{1}{2}$), the probability of detecting the second atom in the state e is one-half independent of the state that was detected for the first atom.

The experiment was done in 1996 by the group of Haroche in Paris[4] and the result was (in accordance with the theoretical predictions in Ref. 3) that, at least for initial states with $|\alpha| \gg 1$ (very classical from the point of view of coherent states) a sharp decay as a function of T, within an interval of time of the order of 1 millisecond, from the perfectly coherent superposition to a maximal statistical mixture.

The passage from a pure quantum mechanical state to a statistical mixture is, in the present context, attibuted to the interaction with the walls of the cavities. In fact, it is easy to see that the loss of one photon by the coherent state $|\alpha\rangle$ transforms it in the state $\alpha|-\alpha\rangle$ (since the coherent state $|\alpha\rangle$ is an eigenstate of the annihilation operator to the eigenvalue α).

In particular the coherent superposition $|\alpha\rangle+|-\alpha\rangle$ is changed in $|\alpha\rangle-|-\alpha\rangle$ and *vice versa* and therefore detecting an atom in the state e after an interaction with the wall projects the state of the electromagnetic field in a state $|\alpha\rangle+|-\alpha\rangle$ whereas if the interaction had not taken place the projected state would be $|\alpha\rangle-|-\alpha\rangle$.

Since one has no control of the interaction with the boundary, in the analysis of the outcome of the experiment with a beam of particles one ''averages'' over all possible interactions, and after a short time the outcome points to a statistical mixture.

The experiment by the Haroche group is really an impressive ''demonstration'' of the way decoherence sets in for ''macroscopic'' bodies, and points to decoherence times which are too small to be measured for a realistic ''classical'' body.

Still, the theoretical analysis carried out so far is too crude from the point of view of mathematical physics (and in general from the point of view of a clear explanation of the way in which quantum mechanical objects can be regarded as classical) and a more detailed explanation remains a challenge for the future.

VII. CONCLUSIONS

We have described three instances in which the quantum superposition of two (or more) states of a quantum ''macroscopic object'' may be destroyed by the interaction with the environment (decoherence), and thereby may lead, as far as later measurements are performed, to the fact that the state is perceived as a statistical ensemble.

The first instance was the effect of the scattering of a large number of light particles off a heavy quantum particle.

The analysis followed rigorously the lines of traditional Schrödinger's quantum mechanics, with no extra assumptions or shortcuts. The weak point of the analysis is the difficulty of handling properly the scattering by a beam of particles (as compared to the scattering by one particle); a further disturbing point is to consider as ''macroscopic object'' a single heavy quantum particle. This could be remedied by considering a bound state of very many quantum particles, but the mathematical difficulties become prohibitive.

The second instance was the interaction of a charged quantum particle with the quantized electromagnetic field. Here the observable to be measured is momentum. Only a simple model was considered, and the phenomenon of decoherence was due to the presence after the interaction of a cloud of infrared photons accompanying the particle, the cloud being different for different momentum of the asymptotic particle. Admittedly this is the weakest of the examples given, and no comment can be made on the time it takes for the decoherence to be measurable.

The third instance is the only one for which experimental results are available, and therefore to some extent the most convincing one. The ''macroscopic'' systems are the coherent states of the electromagnetic field in a cavity with perfectly conducting walls, the superposition of two coherent states is produced through a beam of atoms and the decoherence is probably due to the interaction of the electromagnetic field with the wall of the cavities. A weak point of this example could be the use of coherent states as an example of macroscopic body, and, from the formal point of view, the unsatisfactory mathematical analysis of the interaction. In view of the major interest of these experiments, a more refined description of the interaction would be welcome.

(Received 30 July 2003; accepted 2 August 2003)

We express the Hamiltonian of the quantum trigonometric Calogero–Sutherland model related to the Lie algebra D_4 in terms of a set of Weyl-invariant variables, namely, the characters of the fundamental representations of the Lie algebra. This parametrization allows us to solve for the energy eigenfunctions of the theory and to study properties of the system of orthogonal polynomials associated with them such as recurrence relations and generating functions. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1618362]

I. INTRODUCTION

Integrable models play a prominent role in theoretical physics. The reason is not only the direct phenomenological interest of some of them, but also the fact that they often provide some deep insights into the mathematical structure of the theories in which they arise and, sometimes, they even reveal unexpected relations among different physical or mathematical theories. In classical mechanics, integrability not only shows up itself in some of the most important and time-honored problems, such as the Keplerian motion or the Lagrange or Kovalevskaya top; it appears also in a plethora of new hypothetical, highly nontrivial sytems discovered mainly during the three last decades of the past century (see Refs. 1 and 2 for comprehensive reviews). Among these, the so-called Calogero–Sutherland models form a distinguished class. The first analysis of a system of this kind was performed by Calogero,[3] who studied, from the quantum standpoint, the dynamics on the infinite line of a set of particles interacting pairwise by rational plus quadratic potentials, and found that the problem was exactly solvable. Soon afterwards, Sutherland[4] arrived at similar results for the quantum problem on the circle, this time with trigonometric interaction, and Moser[5] showed that the classical version of both models enjoyed integrability in the Liouville sense. The identification of the general scope of these discoveries came with the work of Olshanetsky and Perelomov,[6,7] who realized that it was possible to associate models of this kind to all the root sytems of the simple Lie algebras, and that all these models were integrable, both in the classical and in the quantum framework.[8,9] Nowadays, there is a widespread interest in this type of integrable system, and many mathematical and physical applications for them have been found, see, for instance, Ref. 10.

The eigenfunctions of the Calogero–Sutherland Hamiltonian associated with the root system of a simple Lie algebra L are proportional to some polynomials which form a complete orthogonal system in the quantum Hilbert space. For the special values $\kappa_\alpha = 1$, where $g_\alpha = \kappa_\alpha(\kappa_\alpha - 1)$ are the coupling constants, they coincide with the irreducible characters of L. For $L = A_n$, these polynomials provide natural generalizations to n variables of the classical orthogonal polynomials in one indeterminate. In particular, for the case with a trigonometric potential, one obtains a generalized

[a)]On leave of absence from the Institute for Theoretical and Experimental Physics, 117259, Moscow, Russia; electronic mail: perelomo@mpim-bonn.mpg.de

system of Gegenbauer polynomials which can be identified with the Jack polynomials.[11] As was shown in Ref. 12 and, following a different approach, in Refs. 13–15, these generalized Gegenbauer polynomials obey a set of recurrence relations which constitute a κ-deformation of the Clebsch–Gordan series of the algebra. The finding of these recurrence relations opened the way to obtain many concrete results on the system of polynomials, such as for example explicit expressions, ladder operators, or generating functions.[16,17] The recurrence relations are also the key ingredient to formulate a perturbative approach to the most general among the Calogero–Sutherland models, that involving the Weierstrass $\wp$-function as potential.[18]

We aim to extend some of the results which have been obtained for A_n to the polynomials related to other simple algebras. For that, we will follow a constructive approach: starting with the Calogero–Sutherland Hamiltonian H, once expressed in a suitable set of independent variables (indeed, the fundamental characters of the underlying algebra), we find that the polynomial part of the solutions of the Schrödinger equation forms an orthogonal family of polynomials diagonalizing a second-order differential operator related to H; these polynomials, indexed by the highest weights of the irreducible representations of the algebra, are defined by means of a recursive formula, and some useful recurrence relations of the type character$\times$polynomial are shown. We think that it is a good idea to begin this program with a concrete case, and we choose to work in this article the problem associated with D_4 because of the triality symmetry exhibited by this algebra, which will helps us in simplifying the treatment.

The organization of the paper is as follows. In Sec. II, we explain how to express the Calogero–Sutherland Hamiltonian in terms of the fundamental characters of the algebra and how to solve the Schrödinger equation. Then, in Sec. III, we obtain the main recurrence relations among the polynomials and use them to give algorithms to calculate some subsets of them. Section IV is devoted to finding the generating functions for some classes of characters and monomials functions of D_4. More recurrence relations and some other relevant results are included in Sec. V, and finally, in Sec. VI, we give some brief conclusions. Also, we offer two appendixes. In Appendix A, for the convenience of the reader, we collect some of the basic facts about D_4 which we use in the main text. In Appendix B we list some polynomials, characters, and monomial functions.

II. THE EIGENVALUE PROBLEM

The Hamiltonian operator for the trigonometric Calogero–Sutherland model related to the root system of a simple Lie algebra of rank r has the form

$$H=\frac{1}{2}(p,p)+\sum_{\alpha\in R^+}\kappa_\alpha(\kappa_\alpha-1)\sin^{-2}(\alpha,q), \tag{1}$$

where $q=(q_1,\ldots,q_r)$, $p=(p_1,\ldots,p_r)$, $(\,,\,)$ is the usual Euclidean inner product in $\mathbf{R}^r$, R^+ is the set of positive roots of the algebra, and κ_α are constants such that $\kappa_\alpha=\kappa_\beta$ if $\|\alpha\|=\|\beta\|$. In particular, for the case of the algebra D_4 (see Appendix A), this leads to the following Schrödinger equation:

$$\begin{gathered} H\Psi^\kappa=E(\kappa)\,\Psi^\kappa,\\ H=-\frac{1}{2}\Delta+\kappa(\kappa-1)\left(\sum_{j<k}^{4}\sin^{-2}(q_j-q_k)+\sum_{j<k}^{4}\sin^{-2}(q_j+q_k)\right),\quad \Delta=\sum_{j=1}^{4}\frac{\partial^2}{\partial q_j^2}. \end{gathered} \tag{2}$$

The q coordinates are assumed to take values in the $[0,\,\pi]$ interval, and therefore the equation can be interpreted as describing the dynamics of a system of four particles moving on the circle. Let us notice, however, that there is not translational invariance. We recapitulate some important facts about this model which follow from the general structure of the quantum Calogero–Sutherland models related to Lie algebras.[9] The ground state energy and (non-normalized) wave function are

$$E_0(\kappa)=2(\rho,\rho)\,\kappa^2=28\,\kappa^2, \tag{3}$$

$$\Psi_0^\kappa(q)=\left\{\prod_{j<k}^{4}\sin(q_j-q_k)\sin(q_j+q_k)\right\}^\kappa,$$

where ρ is the standard Weyl vector, $\rho=\frac{1}{2}\Sigma_{\alpha\in R^+}\alpha$, with the sum extended over all the positive roots of D_4. The excited states depend on a four-tuple of quantum numbers $\mathbf{m}=(m_1,m_2,m_3,m_4)$,

$$H\Psi_{\mathbf{m}}^\kappa=E_{\mathbf{m}}(\kappa)\,\Psi_{\mathbf{m}}^\kappa,$$
$$E_{\mathbf{m}}(\kappa)=2(\lambda+\kappa\rho,\lambda+\kappa\rho), \tag{4}$$

where λ is the highest weight of the irreducible representation of D_4 labeled by $\mathbf{m}$, i.e., $\lambda=\Sigma_{i=1}^4 m_i\lambda_i$, and λ_i are the fundamental weights of D_4. By substitution in (4) of

$$\Psi_{\mathbf{m}}^\kappa(q)=\Psi_0^\kappa(q)\,\Phi_{\mathbf{m}}^\kappa(q), \tag{5}$$

we are led to the eigenvalue problem

$$-\Delta^\kappa\Phi_{\mathbf{m}}^\kappa=\varepsilon_{\mathbf{m}}(\kappa)\,\Phi_{\mathbf{m}}^\kappa \tag{6}$$

with

$$\Delta^\kappa=\frac{1}{2}\Delta+\kappa\sum_{j<k}^{4}\left(\operatorname{ctg}(q_j-q_k)\left(\frac{\partial}{\partial q_j}-\frac{\partial}{\partial q_k}\right)+\operatorname{ctg}(q_j+q_k)\left(\frac{\partial}{\partial q_j}+\frac{\partial}{\partial q_k}\right)\right) \tag{7}$$

and

$$\varepsilon_{\mathbf{m}}(\kappa)=E_{\mathbf{m}}(\kappa)-E_0(\kappa)=2(\lambda,\lambda+2\kappa\rho). \tag{8}$$

Introducing the inverse Cartan matrix $A_{jk}^{-1}=(\lambda_j,\lambda_k)$, we can give a more explicit expression for $\varepsilon_{\mathbf{m}}(\kappa)$:

$$\varepsilon_{\mathbf{m}}(\kappa)=2\sum_{j,k=1}^{4}A_{jk}^{-1}m_jm_k+4\kappa\sum_{j,k=1}^{4}A_{jk}^{-1}m_j=2(m_1^2+m_3^2+m_4^2)+4m_2^2+2(m_1m_3+m_1m_4+m_3m_4)+4m_2(m_1+m_3+m_4)+12\kappa(m_1+m_3+m_4)+20\kappa m_2. \tag{9}$$

The main problem is to solve Eq. (6). As has been shown for the case of the algebra A_n,[13–15] the best way to do that is to use a set of independent variables which are invariant under the Weyl symmetry of the Hamiltonian, namely, the characters of the four fundamental representations of the algebra D_4. Unfortunately, the expression of these characters in terms of the q-variables (which play the role of coordinates on the maximal torus of D_4) is not very simple. Denoting the character of the irreducible representation of maximal weight λ_j as z_j, we find

$$z_1=\sum_{j=1}^{4} x_j+\sum_{j=1}^{4} x_j^{-1},$$

$$z_2=\sum_{i<j}^{4} x_i x_j+\sum_{i<j}^{4} (x_i x_j)^{-1}+\sum_{i,j}^{4} x_i^{-1} x_j,$$

$$z_3=\overline{x}\sum_{i=1}^{4}\frac{1}{x_i}+\frac{1}{\overline{x}}\sum_{i=1}^{4} x_i,$$

$$z_4=\overline{x}+\frac{1}{\overline{x}}+\frac{1}{\overline{x}}\sum_{i<j}^{4} x_i x_j,$$

where $x_j=e^{2iq_j}$, and $\overline{x}=\sqrt{x_1x_2x_3x_4}$. These expressions make the direct change of variables from q_i to z_k quite cumbersome. We refrain from trying that approach, and choose instead an indirect route which has the further advantage of also being applicable to other algebras in which the expressions for the characters are even more involved. We can infer from (7) the structure of Δ^{κ} when written in the z-variables:

$$\Delta^{\kappa}=\sum_{j,k=1}^{4} a_{jk}(z_i)\,\partial_{z_j}\partial_{z_k}+\sum_{j=1}^{4}[b_j^{(0)}(z_i)+\kappa b_j^{(1)}(z_i)]\partial_{z_j}. \tag{10}$$

On the other hand, as is well known,[12] the $\Phi_{\mathbf{m}}^{\kappa}$ are polynomials which, with some precise partial ordering for the monomials to be described later, start as follows:

$$\Phi_{\mathbf{m}}^{\kappa}(z_i)=P_{\mathbf{m}}^{\kappa}(z_i)=z_1^{m_1}z_2^{m_2}z_3^{m_3}z_4^{m_4}+\cdots. \tag{11}$$

Therefore, making use of (9), we conclude that

$$\begin{aligned} a_{jk}(z_i)&=2\,A_{jk}^{-1}\,z_jz_k+\text{lower order terms},\\ b_j^{(r)}(z_i)&=c_j^{(r)}z_j+d_j^{(r)},\quad r=0,1. \end{aligned} \tag{12}$$

Now, to obtain the full expressions for these coefficients, we rely on the fact that, for $\kappa=1$, the $P_{\mathbf{m}}^{\kappa}$ polynomial gives the character of the irreducible representation of D_4 with maximal weight $\Sigma_{i=1}^{4} m_i\lambda_i$, while for $\kappa=0$ the same polynomial is the corresponding symmetric monomial function.[9] Both, characters and monomial functions, can be computed by using the information available in the literature (see, for instance, the ''Reference Chapter'' of Ref. 19). In fact, the following short list of polynomials

$$P_{2,0,0,0}^{(1)}(z)=z_1^2-z_2-1,$$

$$P_{1,1,0,0}^{(1)}(z)=z_1z_2-z_3z_4,$$

$$P_{1,0,1,0}^{(1)}(z)=z_1z_3-z_4,$$

$$P_{0,2,0,0}^{(1)}(z)=z_2^2-z_1z_3z_4+z_2,$$

$$P_{2,0,0,0}^{(0)}(z)=z_1^2-2z_2$$

is all we need to obtain Δ^κ. By substituting these polynomials in (6) and using (9), (10), (12) and the triality symmetry (which here implies that the final expression for Δ^κ should be invariant under permutations of the indices 1,3,4), we get enough simple linear algebraic equations to fix all the coefficients. We give here only the final result:

$$\begin{aligned}\frac{1}{2}\Delta^\kappa=&(z_1^2-2z_2-8)\partial_{z_1}^2+[2z_2^2-4(z_1^2+z_3^2+z_4^2)-2z_1z_3z_4+8z_2]\partial_{z_2}^2+(z_3^2-2z_2-8)\partial_{z_3}^2+(z_4^2\\&-2z_2-8)\partial_{z_4}^2+(2z_1z_2-6z_3z_4-8z_1)\,\partial_{z_1}\partial_{z_2}+(z_1z_3-8z_4)\,\partial_{z_1}\partial_{z_3}+(z_1z_4-8z_3)\,\partial_{z_1}\partial_{z_4}\\&+(2z_2z_3-6z_1z_4-8z_3)\,\partial_{z_2}\partial_{z_3}+(2z_2z_4-6z_1z_3-8z_4)\,\partial_{z_2}\partial_{z_4}+(z_3z_4-8z_1)\,\partial_{z_3}\partial_{z_4}+(6\kappa\\&+1)z_1\partial_{z_1}+[2(5\kappa+1)z_2+8(\kappa-1)]\,\partial_{z_2}+(6\kappa+1)z_3\partial_{z_3}+(6\kappa+1)z_4\partial_{z_4}.\end{aligned}\tag{13}$$

Once the explicit expression for the operator Δ^κ in the z variables is given, the Schrödinger equation can be solved iteratively. By direct application of Δ^κ to $z^{\mathbf{m}}\equiv z_1^{m_1}z_2^{m_2}z_2^{m_3}z_4^{m_4}$, we find

$$\begin{aligned}\Delta^\kappa z^{\mathbf{m}}=&\varepsilon_{\mathbf{m}}(\kappa)\,z^{\mathbf{m}}-\sum_{i=1}^{4}a_{\mathbf{m}}^i z^{\mathbf{m}-\alpha_i}-\sum_{j\in I}b_{\mathbf{m}}^j z^{\mathbf{m}-(\alpha_2+\alpha_j)}-\sum_{ij\in T}c_{\mathbf{m}}^{ij}z^{\mathbf{m}-(\alpha_2+\alpha_i+\alpha_j)}\\&-2a_{\mathbf{m}}^2\sum_{ij\in T}z^{\mathbf{m}-(2\alpha_2+\alpha_i+\alpha_j)}-d_{\mathbf{m}}z^{\mathbf{m}-(\alpha_1+2\alpha_2+\alpha_3+\alpha_4)}-4\sum_{j\in I}a_{\mathbf{m}}^j z^{\mathbf{m}-(\alpha_1+2\alpha_2+\alpha_3+\alpha_4+\alpha_j)},\end{aligned}\tag{14}$$

where the sets of indices are $I=\{1,3,4\}$ and $T=\{13,14,34\}$, and

$$a_{\mathbf{m}}^i=4\,m_i(m_i-1),\quad b_{\mathbf{m}}^j=12m_2m_j,$$

$$c_{\mathbf{m}}^{ij}=16\,m_i\,m_j,\qquad d_{\mathbf{m}}(\kappa)=16\,m_2\left(2-m_2-\kappa+\sum_{j\in I}m_j\right).$$

All monomials in $\Delta^\kappa z^{\mathbf{m}}$ take the form $z^{\mathbf{m}-\mu}$ with μ as a positive root. Thus, the polynomial $P_{\mathbf{m}}^\kappa$ has the form

$$P_{\mathbf{m}}^\kappa(z)=\sum_{\mu\in Q^+(\mathbf{m})}c_\mu z^{\mathbf{m}-\mu},\tag{15}$$

where we choose the normalization $c_0=1$ and, if Q^+ is the cone of positive roots,

$$Q^+(\mathbf{m})=\{\mu\in Q^+|z^{\mathbf{m}-\mu}\ \text{is well defined if}\ z_1z_2z_3z_4=0\}.\tag{16}$$

The above-mentioned partial ordering of monomials is given simply by the height of μ, i.e., $z^{\mathbf{m}-\mu_1}>z^{\mathbf{m}-\mu_2}$ if $ht(\mu_1)<ht(\mu_2)$. From (14), the coefficients c_μ obey the iterative formula

$$c_\mu=\frac{N_\mu}{\varepsilon_{\mathbf{m}-\mu}(\kappa)-\varepsilon_{\mathbf{m}}(\kappa)}\tag{17}$$

with

$$N_\mu=\sum_{i=1}^{4} a^i_{\mathbf{m}-(\mu-\alpha_i)}\, c_{\mu-\alpha_i}+\sum_{j\in I} b^j_{\mathbf{m}-(\mu-\alpha_2-\alpha_j)}\, c_{\mu-(\alpha_2+\alpha_j)}+\sum_{ij\in T} c^{ij}_{\mathbf{m}-(\mu-\alpha_2-\alpha_i-\alpha_j)}\, c_{\mu-(\alpha_2+\alpha_i+\alpha_j)}$$

$$+2\sum_{ij\in T} a^2_{\mathbf{m}-(\mu-2\alpha_2-\alpha_i-\alpha_j)}\, c_{\mu-(2\alpha_2+\alpha_i+\alpha_j)}+d_{\mathbf{m}-(\mu-\alpha_1-2\alpha_2-\alpha_3-\alpha_4)}\, c_{\mu-(\alpha_1+2\alpha_2+\alpha_3+\alpha_4)}$$

$$+4\sum_{j\in I} a^j_{\mathbf{m}-(\mu-\alpha_1-2\alpha_2-\alpha_3-\alpha_4-\alpha_j)}\, c_{\mu-(\alpha_1+2\alpha_2+\alpha_3+\alpha_4+\alpha_j)}\,.$$

Used along with the explicit expressions for the roots given in Appendix A, this formula is suitable for the implementation on a symbolic computer program. A list of polynomials obtained through the use of the formula is offered in Appendix B.

III. THE STRUCTURE OF THE RECURRENCE RELATIONS

As is well known, all the systems of orthogonal polynomials in one indeterminate z, such that $P_m(z)=z^m+\cdots$, satisfy a recursive formula $z\,P_m(z)=a_m\,P_{m+1}(z)+b_m\,P_m(z)+c_m\,P_{m-1}(z)$. In particular, the orthogonal polynomials associated with the trigonometric Calogero–Sutherland model for the case of two particles and Lie algebra A_1 are the classical Gegenbauer polynomials, whose recursive formula is known to be

$$z\,P^\kappa_m(z)=P^\kappa_{m+1}(z)+\frac{m(m-1+2\kappa)}{(m-1+\kappa)(m+\kappa)}\,P^\kappa_{m-1}(z).$$

This formula is reminiscent of the Clebsch–Gordan series for A_1. In fact, for $\kappa=1$ it reduces exactly to this Clebsch–Gordan series: the polynomials are the characters of A_1 and the coefficents are equal to one. Immediately the question arises about the existence of analogous recurrence relations, i.e., with the structure of κ-deformations of the corresponding Clebsch–Gordan series, for the polynomials related to Calogero–Sutherland models associated with other simple Lie algebras. As was shown in Ref. 13, the answer turns out to be in the affirmative for all root systems, but to obtain the expressions for the deformed coefficients it is necessary to proceed through a case-by-case analysis. Once the coefficients are known, many applications are possible. The aim of this section is to fix the structure of the basic recurrence relations for the case of D_4 and to give a simple illustration of their use.

We will study the formulas for $z_i P^\kappa_{\mathbf{m}}(z)$, $i=1,2,3,4$, in full detail. Note, however, that there are different recurrence relations, obtained in a more general context, and sometimes known as (generalized) Pieri formulas.[20] Therefore, as $P^{(1)}_{\mathbf{m}}(z)=z_i$ for $m_j=(\delta_{ji})$, and the recursive formulas are deformations of the Clebsch–Gordan series, we need to know the weights of the irreducible representations whose integral dominant weights are λ_1, λ_2, λ_3, and λ_4. For the case of λ_1, λ_3, and λ_4, these representations have dimension eight. On the other hand, if we act on the highest weight with the Weyl group in the way explained in Appendix A, we obtain eight different weights. Thus, these representations include only one orbit of the Weyl group and we are done. For the case of λ_2, the representation has dimension 28 and the orbit of the Weyl group containing λ_2 has only 24 elements. But $\lambda_2=\alpha^+_{12}$, the highest root, and thus this representation is the adjoint one and includes a second orbit: the Cartan subalgebra, with four elements of weight zero. Thus, we can summarize.

- Weights in z_1: $\pm\lambda_1$, $\pm(\lambda_1-\lambda_2)$, $\pm(\lambda_2-\lambda_3-\lambda_4)$, $\pm(\lambda_3-\lambda_4)$.
- Weights in z_2: $\pm\lambda_2$, $\pm(\lambda_2-2\lambda_j)$, $\pm(2\lambda_2-\lambda_1-\lambda_3-\lambda_4)$, $\pm(\lambda_2+\lambda_i-\lambda_j-\lambda_k)$, $\pm(\lambda_i+\lambda_j-\lambda_k)$, $\pm(\lambda_2-\lambda_1-\lambda_3-\lambda_4)$, 0, with $i,j,k\in I$.
- Weights in z_3: $\pm\lambda_3$, $\pm(\lambda_3-\lambda_2)$, $\pm(\lambda_2-\lambda_1-\lambda_4)$, $\pm(\lambda_1-\lambda_4)$.
- Weights in z_4: $\pm\lambda_4$, $\pm(\lambda_4-\lambda_2)$, $\pm(\lambda_2-\lambda_1-\lambda_3)$, $\pm(\lambda_1-\lambda_3)$.

With these weights, the structure of the recurrence relations results to be as follows:

$$z_1 P^{\kappa}_{m_1,m_2,m_3,m_4}(z) = P^{\kappa}_{m_1+1,m_2,m_3,m_4}(z) + a^1_{\mathbf{m}}(\kappa)\, P^{\kappa}_{m_1-1,m_2,m_3,m_4}(z) + b^1_{\mathbf{m}}(\kappa)\, P^{\kappa}_{m_1+1,m_2-1,m_3,m_4}(z)$$
$$+ c^1_{\mathbf{m}}(\kappa)\, P^{\kappa}_{m_1-1,m_2+1,m_3,m_4}(z) + d^1_{\mathbf{m}}(\kappa)\, P^{\kappa}_{m_1,m_2+1,m_3-1,m_4-1}(z)$$
$$+ e^1_{\mathbf{m}}(\kappa)\, P^{\kappa}_{m_1,m_2-1,m_3+1,m_4+1}(z) + f^1_{\mathbf{m}}(\kappa)\, P^{\kappa}_{m_1,m_2,m_3+1,m_4-1}(z)$$
$$+ g^1_{\mathbf{m}}(\kappa)\, P^{\kappa}_{m_1,m_2,m_3-1,m_4+1}(z),$$

$$z_2 P^{\kappa}_{m_1,m_2,m_3,m_4}(z) = P^{\kappa}_{m_1,m_2+1,m_3,m_4}(z) + A_{\mathbf{m}}(\kappa)\, P^{\kappa}_{m_1,m_2-1,m_3,m_4}(z)$$
$$+ B_{\mathbf{m}}(\kappa)^{1\pm}\, P^{\kappa}_{m_1\pm 2,m_2\mp 1,m_3,m_4}(z) + B_{\mathbf{m}}(\kappa)^{3\pm}\, P^{\kappa}_{m_1,m_2\mp 1,m_3\pm 2,m_4}(z)$$
$$+ B_{\mathbf{m}}(\kappa)^{4\pm}\, P^{\kappa}_{m_1,m_2\mp 1,m_3,m_4\pm 2}(z) + C_{\mathbf{m}}(\kappa)^{\pm}\, P^{\kappa}_{m_1\mp 1,m_2\pm 2,m_3\mp 1,m_4\mp 1}(z)$$
$$+ D_{\mathbf{m}}(\kappa)^{1\pm}\, P^{\kappa}_{m_1\pm 1,m_2\pm 1,m_3\mp 1,m_4\mp 1}(z) + D_{\mathbf{m}}(\kappa)^{3\pm}\, P^{\kappa}_{m_1\mp 1,m_2\pm 1,m_3\pm 1,m_4\mp 1}(z)$$
$$+ D_{\mathbf{m}}(\kappa)^{4\pm}\, P^{\kappa}_{m_1\mp 1,m_2\pm 1,m_3\mp 1,m_4\pm 1}(z) + E_{\mathbf{m}}(\kappa)^{1\pm}\, P^{\kappa}_{m_1\mp 1,m_2,m_3\pm 1,m_4\pm 1}(z)$$
$$+ E_{\mathbf{m}}(\kappa)^{3\pm}\, P^{\kappa}_{m_1\pm 1,m_2,m_3\mp 1,m_4\pm 1}(z) + E_{\mathbf{m}}(\kappa)^{4\pm}\, P^{\kappa}_{m_1\pm 1,m_2,m_3\pm 1,m_4\mp 1}(z)$$
$$+ F_{\mathbf{m}}(\kappa)^{\pm}\, P^{\kappa}_{m_1\pm 1,m_2\mp 1,m_3\pm 1,m_4\pm 1}(z) + G_{\mathbf{m}}(\kappa)\, P^{\kappa}_{m_1,m_2,m_3,m_4}(z),$$

$$z_3 P^{\kappa}_{m_1,m_2,m_3,m_4}(z) = P^{\kappa}_{m_1,m_2,m_3+1,m_4}(z) + a^3_{\mathbf{m}}(\kappa)\, P^{\kappa}_{m_1,m_2,m_3-1,m_4}(z) + b^3_{\mathbf{m}}(\kappa)\, P^{\kappa}_{m_1,m_2-1,m_3+1,m_4}(z)$$
$$+ c^3_{\mathbf{m}}(\kappa)\, P^{\kappa}_{m_1,m_2+1,m_3-1,m_4}(z) + d^3_{\mathbf{m}}(\kappa)\, P^{\kappa}_{m_1-1,m_2+1,m_3,m_4-1}(z)$$
$$+ e^3_{\mathbf{m}}(\kappa)\, P^{\kappa}_{m_1+1,m_2-1,m_3,m_4+1}(z) + f^3_{\mathbf{m}}(\kappa)\, P^{\kappa}_{m_1+1,m_2,m_3,m_4-1}(z)$$
$$+ g^3_{\mathbf{m}}(\kappa)\, P^{\kappa}_{m_1-1,m_2,m_3,m_4+1}(z),$$

$$z_4 P^{\kappa}_{m_1,m_2,m_3,m_4}(z) = P^{\kappa}_{m_1,m_2,m_3,m_4+1}(z) + a^4_{\mathbf{m}}(\kappa)\, P^{\kappa}_{m_1,m_2,m_3,m_4-1}(z)$$
$$+ b^4_{\mathbf{m}}(\kappa)\, P^{\kappa}_{m_1,m_2-1,m_3,m_4+1}(z) + c^4_{\mathbf{m}}(\kappa)\, P^{\kappa}_{m_1,m_2+1,m_3,m_4-1}(z)$$
$$+ d^4_{\mathbf{m}}(\kappa)\, P^{\kappa}_{m_1-1,m_2+1,m_3-1,m_4}(z) + e^4_{\mathbf{m}}(\kappa)\, P^{\kappa}_{m_1+1,m_2-1,m_3+1,m_4}(z)$$
$$+ f^4_{\mathbf{m}}(\kappa)\, P^{\kappa}_{m_1-1,m_2,m_3+1,m_4}(z) + g^4_{\mathbf{m}}(\kappa)\, P^{\kappa}_{m_1+1,m_2,m_3-1,m_4}(z),$$

where $B_{\mathbf{m}}(\kappa)^{1\pm}\, P^{\kappa}_{m_1\pm 2,m_2\mp 1,m_3,m_4}(z)$ means $B_{\mathbf{m}}(\kappa)^{1+}\, P^{\kappa}_{m_1+2,m_2-1,m_3,m_4}(z) + B_{\mathbf{m}}(\kappa)^{1-}\, P^{\kappa}_{m_1-2,m_2+1,m_3,m_4}(z)$, etc., and it is understood that all polynomials involving negative quantum numbers are zero. The recurrence relations reflect triality in the fact that not all the coefficients appearing in these formulas are independent. There are coincidences upon permutations of the quantum numbers, for instance

$$a^1_{m_1,m_2,m_3,m_4} = a^3_{m_3,m_2,m_1,m_4} = a^4_{m_4,m_2,m_3,m_1}, \tag{18}$$

and similarly for $b^j_{\mathbf{m}}, c^j_{\mathbf{m}}, d^j_{\mathbf{m}}, e^j_{\mathbf{m}}, f^j_{\mathbf{m}}, g^j_{\mathbf{m}}$. In the same fashion, we have also

$$B^{1\pm}_{m_1,m_2,m_3,m_4} = B^{3\pm}_{m_3,m_2,m_1,m_4} = B^{4\pm}_{m_4,m_2,m_3,m_1} \tag{19}$$

and similarly for $D^{j\pm}_{\mathbf{m}}, E^{j\pm}_{\mathbf{m}}$.

As an example, let us consider a simple case in which only one of the quantum numbers is nonvanishing, namely,

$$z_1 P^{\kappa}_{m,0,0,0}(z) = P^{\kappa}_{m+1,0,0,0}(z) + a_m(\kappa)\, P^{\kappa}_{m-1,0,0,0}(z) + c_m(\kappa)\, P^{\kappa}_{m-1,1,0,0}(z), \tag{20}$$

where we write $a_m(\kappa) = a^1_{m,0,0,0}(\kappa)$ and $c_m(\kappa) = c^1_{m,0,0,0}(\kappa)$. Using formulas

$$P^{\kappa}_{m,0,0,0}(z) = z_1^m - \frac{m(m-1)[4\kappa^2 + 4(m-2)\kappa + (m-1)(m-2)]}{(m-1+\kappa)(m-1+3\kappa)(m-2+\kappa)} z_1^{m-2} - \frac{m(m-1)}{m-1+\kappa} z_1^{m-2} z_2 + \cdots,$$

$$P^{\kappa}_{m,1,0,0}(z) = z_1^m z_2 + \frac{4\,\kappa(\kappa-1)(m-2+2\kappa)}{(m+1+5\kappa)(m+2\kappa)(m-1+\kappa)} z_1^m + \cdots,$$

coming from (17), we obtain the coefficients in (20):

$$a_m(\kappa) = \frac{m(m+2\kappa)(m-1+4\kappa)(m-1+6\kappa)}{(m-1+\kappa)(m-1+3\kappa)(m+3\kappa)(m+5\kappa)},$$

$$c_m(\kappa) = \frac{m(m-1+2\kappa)}{(m+\kappa)(m-1+\kappa)}.$$

As a by-product of triality, we can also write two other recurrence relations with the same coefficients:

$$\begin{aligned} z_3 P^{\kappa}_{0,0,m,0}(z) &= P^{\kappa}_{0,0,m+1,0}(z) + a_m(\kappa)\, P^{\kappa}_{0,0,m-1,0}(z) + c_m(\kappa)\, P^{\kappa}_{0,1,m-1,0}(z), \\ z_4 P^{\kappa}_{0,0,0,m}(z) &= P^{\kappa}_{0,0,0,m+1}(z) + a_m(\kappa)\, P^{\kappa}_{0,0,0,m-1}(z) + c_m(\kappa)\, P^{\kappa}_{0,1,0,m-1}(z). \end{aligned} \tag{21}$$

The first of these recurrence relations can be used to devise an algorithm for the calculation of the polynomials of the form $P^{\kappa}_{m,0,0,0}(z)$ and $P^{\kappa}_{m,1,0,0}(z)$. By multiplying (20) by the differential operator $\Delta^{\kappa} - \varepsilon_{m-1,1,0,0}(\kappa)$, the term involving $P^{\kappa}_{m-1,1,1,0}$ cancels. Using the explicit expressions (9) and (13), we find

$$\begin{aligned} P^{\kappa}_{m+1,0,0,0} = {} & \frac{1}{4(m+\kappa)} [\Delta^{\kappa}, z_1]\, P^{\kappa}_{m,0,0,0}(z) - \frac{1+4\kappa}{2(m+\kappa)} z_1 P^{\kappa}_{m,0,0,0}(z) \\ & + \frac{m(m+2\kappa)(m-1+4\kappa)(m-1+6\kappa)}{(m-1+\kappa)(m-1+3\kappa)(m+\kappa)(m+3\kappa)} P^{\kappa}_{m-1,0,0,0}(z), \end{aligned}$$

where, from (13),

$$\begin{aligned} [\Delta^{\kappa}, z_1] = {} & 4(z_1^2 - 2z_2 - 8)\partial_{z_1} + 2\,(z_1 z_3 - 8z_4)\,\partial_{z_3} + 2\,(z_1 z_4 - 8z_3)\,\partial_{z_4} \\ & + 4\,(z_1 z_2 - 3z_3 z_4 - 4z_1)\,\partial_{z_2} + 2(6\kappa+1)\, z_1. \end{aligned}$$

Once the polynomials $P^{\kappa}_{m,0,0,0}(z)$ are known, the recurrence relation (20) provides a formula for each $P^{\kappa}_{m,1,0,0}(z)$:

$$c_{m+1}(\kappa)\, P^{\kappa}_{m,1,0,0}(z) = z_1\, P^{\kappa}_{m+1,0,0,0}(z) - P^{\kappa}_{m+2,0,0,0}(z) - a_{m+1}(\kappa)\, P^{\kappa}_{m,0,0,0}(z). \tag{22}$$

IV. SOME GENERATING FUNCTIONS

We present in this section the generating functions for some characters and symmetric monomial functions. Let us consider first the case of the monomial functions with only one nonvanishing quantum number in the form $P^{(0)}_{m,0,0,0}(z)$. The generating function for this subset is

$$F_0(t,z)=\sum_{m=0}^{\infty} t^m P^{(0)}_{m,0,0,0}(z). \tag{23}$$

In terms of the x variables, the general expression for these monomial functions is

$$P^{(0)}_{m,0,0,0}(x)=\sum_{j=1}^{4} (x_j^m+x_j^{-m}), \tag{24}$$

and, in particular, we define $P^{(0)}_{0,0,0,0}(z)=8$. In these variables, the computation of $F_0(t,x)$ only requires to sum the geometric series:

$$F_0(t,x)=\sum_{j=1}^{4}\left(\frac{1}{1-tx_j}+\frac{1}{1-\dfrac{t}{x_j}}\right). \tag{25}$$

The change to the original z variables can be done by the inspection of the coefficients of the powers of t in both the numerator and denominator of this rational expression, with the result

$$F_0(t,z)=\frac{N_0(t,z)}{D(t,z)}, \tag{26}$$

where

$$\begin{aligned} N_0(t,z)=&\,8-7z_1\,t+6z_2\,t^2-5(z_3z_4-z_1)\,t^3+4(z_3^2+z_4^2-2z_2-2)\,t^4\\ &-3(z_3z_4-z_1)\,t^5+2z_2\,t^6-z_1\,t^7, \end{aligned} \tag{27}$$

$$D(t,z)=1-z_1\,t+z_2\,t^2-(z_3z_4-z_1)\,t^3+(z_3^2+z_4^2-2z_2-2)\,t^4-(z_3z_4-z_1)\,t^5+z_2\,t^6-z_1\,t^7+t^8.$$

There is an alternative approach. As the monomial functions are eigenfunctions of $\Delta^{(0)}$ with eigenvalues $\varepsilon_{m,0,0,0}(0)=2m^2$, we have

$$\frac{1}{2}\Delta^{(0)}F_0(t,z)=\sum_{m=0}^{\infty} m^2 t^m P^{(0)}_{m,0,0,0}(z),$$

and, therefore, we can write a differential equation for $F_0(t,z)$:

$$[\tfrac{1}{2}\Delta^{(0)}-(t\ \ \partial_t)^2]F_0(t,z)=0, \qquad F_0(0,z)=8. \tag{28}$$

One can verify by substitution that (26) satisfies this equation. When $F_0(t,z)$ is known, we can easily obtain the generating function

$$G_0(t,z)=\sum_{m=0}^{\infty} t^m P^{(0)}_{m,1,0,0}(z) \tag{29}$$

by only recalling (20), which for $\kappa=0$ is simply

$$z_1 P^{(0)}_{m,0,0,0}(z)=P^{(0)}_{m+1,0,0,0}(z)+P^{(0)}_{m-1,0,0,0}(z)+P^{(0)}_{m-1,1,0,0}(z). \tag{30}$$

This gives

$$G_0(t,z)=\frac{M_0(t,z)}{D(t,z)} \tag{31}$$

with

$$M_0(t,z)=z_2-4+(6\,z_1-3\,z_3z_4)\,t+(-8-2\,z_1^2-10\,z_2-z_2^2+4\,z_3^2+2\,z_1z_3z_4+4\,z_4^2)\,t^2$$
$$+(10\,z_1+5\,z_1z_2-3\,z_1z_3^2-4\,z_3z_4+z_2z_3z_4-3\,z_1z_4^2)\,t^3$$
$$+(8\,z_2-4\,z_1^2+2\,z_2^2-z_2z_3^2+4\,z_1z_3z_4-z_2z_4^2)\,t^4+(-6\,z_1-6\,z_1z_2-z_3z_4+z_2z_3z_4)\,t^5$$
$$+(8+6z_1^2+2\,z_2-z_2^2)\,t^6+(-10\,z_1+z_1z_2)\,t^7+(4-z_2)\,t^8.$$

The computation of the generating functions for the characters $P^{(1)}_{m,0,0,0}$ and $P^{(1)}_{m,1,0,0}$ goes through similar arguments. In this case, the eigenvalues are $\varepsilon_{m,0,0,0}(1)=2m^2+12m$. Hence,

$$F_1(t,z)=\sum_{m=0}^{\infty} t^m P^{(1)}_{m,0,0,0}(z)\,, \qquad P^{(1)}_{0,0,0,0}(z)\equiv 1 \tag{32}$$

is the solution of

$$[\tfrac{1}{2}\Delta^{(1)}-(t\,\partial_t)^2-6t\,\partial_t]F_1(t,z)=0, \qquad F_1(0,z)=1. \tag{33}$$

The Weyl character formula implies that the denominator of $F_1(t,z)$ should be the same $D(t,z)$ found before. Thus, we try an ansatz

$$F_1(t,z)=\frac{N_1(t,z)}{D(t,z)} \tag{34}$$

and obtain the simple answer

$$N_1(t,z)=1-t^2. \tag{35}$$

Applying the recurrence relation (20) we obtain the generating function $G_1(t,z)$ for the characters $P^{(1)}_{m,1,0,0}$:

$$G_1(t,z)=\frac{1}{D(t,z)}\{z_2-z_3z_4t+(z_3^2+z_4^2-2z_2-1)\,t^2-(z_3z_4-z_1)\,t^3+z_2\,t^4-z_1\,t^5+t^6\}. \tag{36}$$

V. MORE RECURRENCE RELATIONS AND OTHER RESULTS

In this section, we give the remaining recurrence relations involving the product of a fundamental character times a polynomial with only one nonvanishing quantum number. We also comment on the existence of some peculiar values for κ for which the polynomials associated with some special excited states are proportional to integer powers of the fundamental state wave function.

To obtain the mentioned recurrence relations, it is necessary to compute the coefficients of a limited number of terms of the polynomials involved. Once the form of these terms is known, we can obtain the coefficients in the recurrence relations solving a system of linear algebraic equations. We do not give here the full expressions for the coefficients of the required terms, because some of them are too long, and only list them:

$$P^{\kappa}_{1,0,m,0}(z)=z_1z_3^m+A\,z_3^{m-1}z_4+\cdots,$$

$$P^{\kappa}_{0,m,0,0}(z)=z_2^m+B\,z_2^{m-1}+C\,z_2^{m-2}+D\,z_1z_2^{m-2}z_3z_4+E\,z_1z_2^{m-3}z_3z_4$$
$$+F\,(z_1^2z_2^{m-2}+z_2^{m-2}z_3^2+z_2^{m-2}z_4^2)+\cdots,$$

$$P^{\kappa}_{1,m,0,0}(z)=z_1z_2^m+G\,z_1z_2^{m-1}z_4+H\,z_2^{m-1}z_3z_4+\cdots,$$

$$P^{\kappa}_{0,m,1,1}(z)=z_2^m z_3 z_4+I\,z_1 z_2^m+\cdots,$$

$$P^{\kappa}_{m,0,0,0}(z)=z_1^m+J\,z_1^{m-2}+K\,z_1^{m-2}z_2+\cdots,$$

$$P^{\kappa}_{m,1,0,0}(z)=z_1^m z_2+L\,z_1^{m-2}z_2+N\,z_1^{m-1}z_3 z_4+M\,z_1^m+\cdots,$$

$$P^{\kappa}_{m,0,1,1}(z)=z_1^m z_3 z_4+N\,z_1^{m-1}z_2+O\,z_1^{m+1}+\cdots,$$

$$P^{\kappa}_{1,m,1,1}(z)=z_1 z_2^m z_3 z_4+P\,z_2^m+Q\,z_1 z_2^{m-1}z_3 z_4+R\,(z_1^2 z_2^m+z_2^m z_3^2+z_2^m z_4^2)+S\,z_2^{m+1}+\cdots,$$

$$P^{\kappa}_{2,m,0,0}(z)=z_1^2 z_2^m+T\,z_2^m+U\,z_1 z_2^{m-1}z_3 z_4+W\,z_2^{m+1}+\cdots.$$

The use of the quantities denoted A to W in the previous formulas in the general structure of the recurrence relations give the following results:

• Formulas of type $z_1 P^{\kappa}_{0,0,m,0}(z)$:

$$z_1\,P^{\kappa}_{0,0,m,0}(z)=P^{\kappa}_{1,0,m,0}(z)+b_m(\kappa)P_{0,0,m-1,1}(z),$$

$$z_1\,P^{\kappa}_{0,0,0,m}(z)=P^{\kappa}_{1,0,0,m}(z)+b_m(\kappa)P_{0,0,1,m-1}(z),$$

$$z_3\,P^{\kappa}_{m,0,0,0}(z)=P^{\kappa}_{m,0,1,0}(z)+b_m(\kappa)P_{m-1,0,0,1}(z),$$

$$z_3\,P^{\kappa}_{0,0,0,m}(z)=P^{\kappa}_{0,0,1,m}(z)+b_m(\kappa)P_{1,0,0,m-1}(z),$$

$$z_4\,P^{\kappa}_{m,0,0,0}(z)=P^{\kappa}_{m,0,0,1}(z)+b_m(\kappa)P_{m-1,0,1,0}(z),$$

$$z_4\,P^{\kappa}_{0,0,m,0}(z)=P^{\kappa}_{0,0,m,1}(z)+b_m(\kappa)P_{1,0,m-1,0}(z)$$

with

$$b_m(\kappa)=\frac{m(m-1+4\kappa)}{(m-1+\kappa)(m+3\kappa)}\ .$$

• Formulas of type $z_1\,P^{\kappa}_{0,m,0,0}(z)$:

$$z_1\,P^{\kappa}_{0,m,0,0}(z)=P^{\kappa}_{1,m,0,0}(z)+d_m(\kappa)P_{1,m-1,0,0}(z)+e_m(\kappa)P^{\kappa}_{0,m-1,1,1}(z),$$

$$z_3\,P^{\kappa}_{0,m,0,0}(z)=P^{\kappa}_{0,m,1,0}(z)+d_m(\kappa)P_{0,m-1,1,0}(z)+e_m(\kappa)P^{\kappa}_{1,m-1,0,1}(z),$$

$$z_4\,P^{\kappa}_{0,m,0,0}(z)=P^{\kappa}_{0,m,0,1}(z)+d_m(\kappa)P_{0,m-1,0,1}(z)+e_m(\kappa)P^{\kappa}_{1,m-1,1,0}(z)$$

with

$$d_m(\kappa)=\frac{2m(m+\kappa)(m-1+3\kappa)(m-1+4\kappa)(2m-1+6\kappa)}{(m-1+\kappa)(m-1+2\kappa)(m+3\kappa)(2m-1+5\kappa)(2m+5\kappa)},$$

$$e_m(\kappa)=\frac{m(m-1+3\kappa)}{(m-1+\kappa)(m+2\kappa)}.$$

• Formulas of type $z_2\,P^{\kappa}_{m,0,0,0}(z)$:

$$z_2\,P^{\kappa}_{m,0,0,0}(z)=P^{\kappa}_{m,1,0,0}(z)+f_m(\kappa)\,P_{m-2,1,0,0}(z)+g_m(\kappa)\,P^{\kappa}_{m-1,0,1,1}(z)+h_m(\kappa)\,P^{\kappa}_{m,0,0,0}(z),$$

$$z_2\,P^{\kappa}_{0,0,m,0}(z)=P^{\kappa}_{0,1,m,0}(z)+f_m(\kappa)\,P_{0,1,m-2,0}(z)+g_m(\kappa)P^{\kappa}_{1,0,m-1,1}(z)+h_m(\kappa)\,P^{\kappa}_{0,0,m,0}(z),$$

$$z_2\,P^{\kappa}_{0,0,0,m}(z)=P^{\kappa}_{0,1,0,m}(z)+f_m(\kappa)\,P_{0,1,0,m-2}(z)+g_m(\kappa)\,P^{\kappa}_{1,0,1,m-1}(z)+h_m(\kappa)\,P^{\kappa}_{0,0,0,m}(z)$$

with

$$f_m(\kappa)=\frac{m(m-1)(m-2+2\kappa)(m+2\kappa)(m-1+4\kappa)(m-1+5\kappa)}{(m-2+\kappa)(m-1+\kappa)^2(m-1+3\kappa)(m+3\kappa)(m+4\kappa)},$$

$$g_m(\kappa)=\frac{m(m-1+3\kappa)}{(m-1+\kappa)(m+2\kappa)},$$

$$h_m(\kappa)=\frac{4[-3\kappa^3+5\kappa^2+(6m-1)\kappa+(m^2-1)]}{(m-1+\kappa)(1+3\kappa)(m+1+5\kappa)}.$$

• Formula for $z_2\,P^{\kappa}_{0,m,0,0}(z)$:

$$\begin{aligned}z_2\,P^{\kappa}_{0,m,0,0}(z)=&P^{\kappa}_{0,m+1,0,0}(z)+k_m(\kappa)\,P_{0,m-1,0,0}(z)+p_m(\kappa)\,P^{\kappa}_{1,m-1,1,1}(z)+q_m(\kappa)\,P^{\kappa}_{1,m-2,1,1}(z)\\&+r_m(\kappa)\,[P^{\kappa}_{2,m-1,0,0}(z)+P^{\kappa}_{0,m-1,2,0}(z)+P^{\kappa}_{0,m-1,0,2}(z)]+s_m(\kappa)\,P^{\kappa}_{0,m,0,0}(z)\end{aligned}$$

with

$$\begin{aligned}k_m(\kappa)=&\frac{4m(m+\kappa)^2(m+2\kappa)(m-1+3\kappa)(m-1+4\kappa)^2(2m-1+4\kappa)(m-1+5\kappa)(2m-1+6\kappa)}{(m-1+\kappa)(m-1+2\kappa)^2(m+3\kappa)^2(m+4\kappa)(2m-2+5\kappa)(2m-1+5\kappa)^2(2m+5\kappa)},\end{aligned}$$

$$p_m(\kappa)=\frac{m(m-1+2\kappa)}{(m-1+\kappa)(m+\kappa)},$$

$$q_m(\kappa)=\frac{2m(m-1)(m+\kappa)^2(m-2+2\kappa)(m-1+3\kappa)^3(2m-1+6\kappa)}{(m-2+\kappa)(m-1+\kappa)^2(m-1+2\kappa)^2(m+2\kappa)^2(2m-1+5\kappa)(2m+5\kappa)},$$

$$r_m(\kappa)=\frac{m(m+\kappa)(m-1+3\kappa)(m-1+4\kappa)}{(m-1+\kappa)(m-1+2\kappa)(m+2\kappa)(m+3\kappa)},$$

$$s_m(\kappa)=\frac{-4t_m(\kappa)}{(\kappa+1)(m-1+\kappa)(m+1+4\kappa)(2m-1+5\kappa)(2m+1+5\kappa)},$$

$$\begin{aligned}t_m(\kappa)=&(-1+5m^2-4m^4)+(2+25m-7m^2-40m^3+2m^4)\kappa+(20-35m-123m^2+20m^3)\kappa^2\\&+(-22-115m+63m^2)\kappa^3+(-19+65m)\kappa^4+20\kappa^5.\end{aligned}$$

Finally, we mention that for $\kappa=-\frac{1}{2}(n-1)$, $n\in\mathbf{N}$, the polynomials associated with the dominant weight which is n times the Weyl vector ρ are proportional to a power of the ground state wave function, namely,

$$P^{-(1/2)(n-1)}_{n\rho}=(-1)^n\,2^{12n}\left\{\prod_{j<k}^{4}\sin(q_j-q_k)\sin(q_j+q_k)\right\}^n.$$

This formula can be verified quite easily by direct application of $\Delta^{-(1/2)(n-1)}$ in the form (7) to the right-hand side: one finds that the Schrödinger equation (6) with the appropriate eigenvalue is satisfied. The most convenient way to fix the proportionality constant is by performing an analytic continuation to complex q_i and considering the region $x_i \in \mathbf{R}$ and $x_1 \gg x_2 \gg x_3 \gg x_4 \gg 0$. Then, the polynomials are dominated by the leading order term, $P_{n\rho}^{-(1/2)(n-1)} \simeq z_1^n z_2^n z_3^n z_4^n$, and, on the other hand, using the formulas for the fundamental characters displayed in Sec. II, one finds $z_1 z_2 z_3 z_4 \simeq x_1^3 x_2^2 x_3$ and $\Pi_{j<k}^4 \sin(q_j - q_k)\sin(q_j + q_k) \simeq -2^{-12} x_1^3 x_2^2 x_3$. This gives the proportionality constant written above.

VI. CONCLUSIONS

In this paper, we have shown how to solve the Schrödinger equation for the trigonometric Calogero–Sutherland model related to the Lie algebra D_4 and we have explored some properties of the energy eigenfunctions. The main point is that the use of a Weyl-invariant set of variables, the characters of the fundamental representations, leads to a formulation of the Schrödinger equation by means of a second-order differential operator with polynomial coefficients simple enough to make feasible a recursive method for the treatment of the spectral problem. The eigenfunctions provide a complete system of orthogonal polynomials in four variables, and these polynomials obey recurrence relations which are extensions of the Clebsch–Gordan series of the algebra. The structure of some of these recurrence relations has been fixed and, for particular cases, the coefficients involved have been computed. Also, some generating functions for the polynomials with parameter $\kappa = 1$ and $\kappa = 0$ have been obtained. These generating functions can give some hints about the form of the generating function for general κ, see Ref. 21.

APPENDIX A: SUMMARY OF RESULTS ON THE LIE ALGEBRA D_4

In this appendix, we review some standard facts about the root and weight systems of the Lie algebra D_4 that the reader could find useful to follow the main text. More extensive and sound treatments of these topics can be found in many excellent textbooks, see for instance Refs. 19 and 22.

The most convenient explicit representation of D_4 is

$$D_4 = \left\{ \begin{pmatrix} m & b \\ c & -m^t \end{pmatrix} \;\middle|\; m, b, c \text{ real } 4\times 4 \text{ matrices and } b^t = -b,\ c^t = -c \right\}.$$

This gives dim $D_4 = 28$. One can choose the following linear basis:

$$M_{jk} = E_{j,k} - E_{4+j,4+k}, \quad j,k = 1,2,3,4,$$

$$B_{jk} = E_{j,4+k} - E_{k,4+j}, \quad j,k = 1,2,3,4, \quad j<k,$$

$$C_{jk} = E_{4+j,k} - E_{4+k,j}, \quad j,k = 1,2,3,4, \quad j<k$$

with $(E_{i,j})_{kl} = \delta_{ik}\delta_{jl}$. The Cartan subalgebra is

$$H = \left\{ h = \sum_{i=1}^{4} c_i M_{ii} \;\middle|\; c_i \in \mathbf{R} \right\}$$

and this confirms that the rank of D_4 is four. The matrix commutators

TABLE I. Heights of positive roots.

Height	Positive roots
1	$\alpha_1,\ \alpha_2,\ \alpha_3,\ \alpha_4$
2	$\alpha_{13}=\alpha_1+\alpha_2,\ \alpha_{24}=\alpha_2+\alpha_3,\ \alpha_{24}^{+}=\alpha_2+\alpha_4$
3	$\alpha_{14}=\alpha_1+\alpha_2+\alpha_3,\ \alpha_{14}^{+}=\alpha_1+\alpha_2+\alpha_4,\ \alpha_{23}^{+}=\alpha_2+\alpha_3+\alpha_4$
4	$\alpha_{13}^{+}=\alpha_1+\alpha_2+\alpha_3+\alpha_4$
5	$\alpha_{12}^{+}=\alpha_1+2\alpha_2+\alpha_3+\alpha_4$

$$[h,M_{jk}]=(c_j-c_k)M_{jk},$$

$$[h,B_{jk}]=(c_j+c_k)B_{jk},$$

$$[h,C_{jk}]=-(c_j+c_k)C_{jk}$$

allow us to classify the 24 roots in two groups

$$\alpha_{jk}(h)=c_j-c_k,\quad j\neq k,$$

$$\alpha_{jk}^{\pm}(h)=\pm(c_j+c_k),\quad j<k.$$

One can extract the following basis of simple roots:

$$\alpha_1\equiv(1,\quad -1,\quad 0,\quad 0)=\alpha_{12},\quad \alpha_2\equiv(0,\quad 1,\quad -1,\quad 0)=\alpha_{23},$$

$$\alpha_3\equiv(0,\quad 0,\quad 1,\quad -1)=\alpha_{34},\quad \alpha_4\equiv(0,\quad 0,\quad 1,\quad 1)=\alpha_{34}^{+},$$

where we have given the decomposition of these roots in the basis of H^* dual to diag(M_{ii}), $i=1,2,3,4$. The Euclidean relations among the simple roots are

$$(\alpha_i,\alpha_i)=2,\quad i=1,2,3,4,$$

$$(\alpha_2,\alpha_i)=-1,\quad i=1,3,4,$$

$$(\alpha_i,\alpha_j)=0,\quad i=1,3,4.$$

Thus, the Cartan matrix reads

$$A=\begin{pmatrix} 2 & -1 & 0 & 0 \\ -1 & 2 & -1 & -1 \\ 0 & -1 & 2 & 0 \\ 0 & -1 & 0 & 2 \end{pmatrix}.$$

The positive roots are $\alpha_{ij},\alpha_{ij}^{+},i<j$, and they can be classified by heights as indicated in Table I. The Weyl group is easy to describe. The Weyl reflection on the hyperplane in H^* orthogonal to the root α is

$$s_\alpha(v)=v-2\frac{(\alpha,v)}{(\alpha,\alpha)}\alpha.$$

Applying this formula to $\alpha_{ij},\alpha_{ij}^{\pm}$, one readily finds that the most general Weyl reflection consists in a permutation of the components of v in the e_i basis plus an even number of changes of the signs of these components. This gives $|W|=192$ for the order of the Weyl group. The fundamental weights λ_k can be obtained from the equation $\alpha_i=\Sigma_{j=1}^{4}A_{ji}\lambda_j$. They are

$$\lambda_1=\tfrac{1}{2}(2\alpha_1+2\alpha_2+\alpha_3+\alpha_4)=\tfrac{1}{2}\ (2,\quad 0,\quad 0,\quad 0),$$

$$\lambda_2=\tfrac{1}{2}(2\alpha_1+4\alpha_2+2\alpha_3+2\alpha_4)=\tfrac{1}{2}\ (2,\quad 2,\quad 0,\quad 0),$$

$$\lambda_3=\tfrac{1}{2}(\alpha_1+2\alpha_2+2\alpha_3+\alpha_4)=\tfrac{1}{2}\ (1,\quad 1,\quad 1,\quad -1),$$

$$\lambda_4=\tfrac{1}{2}(\alpha_1+2\alpha_2+\alpha_3+2\alpha_4)=\tfrac{1}{2}\ (1,\quad 1,\quad 1,\quad 1),$$

and the geometry of the weight system is summarized by the relations

$$\|\lambda_1\|=\|\lambda_3\|=\|\lambda_4\|=1,\quad \|\lambda_2\|=\sqrt{2},$$

$$(\lambda_i,\lambda_2)=1,\ \ i=1,3,4,\quad (\lambda_i,\lambda_j)=\tfrac{1}{2},\quad i,j=1,3,4.$$

The Weyl vector is

$$\rho=\frac{1}{2}\sum_{\alpha\in R^+}\alpha=\sum_{j=1}^{4}\lambda_j=3\alpha_1+5\alpha_2+3\alpha_3+3\alpha_4=(3,\quad 2,\quad 1,\quad 0),$$

and the Weyl formula for dimensions applied to the irreducible representation associated to the integral dominant weight $\mathbf{m}=m_1\lambda_1+m_2\lambda_2+m_3\lambda_3+m_4\lambda_4$ gives

$$\dim r(\mathbf{m})=\prod_{\alpha\in R^+}\frac{(\alpha,\mathbf{m}+\rho)}{(\alpha,\rho)}=\frac{P}{1440}$$

with

$$P=\prod_{i=1}^{4}(m_i+1)\ \prod_{j}(m_2+m_j+2)\ \prod_{j<k}(m_2+m_j+m_k+3)$$
$$\times(m_1+m_2+m_3+m_4)(m_1+2m_2+m_3+m_4),$$

where the indices j,k take the values 1, 3, 4. In particular, for the fundamental representations, one finds:

$$\dim r(\lambda_1)=8,\quad \dim r(\lambda_2)=28,$$

$$\dim r(\lambda_3)=8,\quad \dim r(\lambda_4)=8.$$

APPENDIX B: SOME POLYNOMIALS, CHARACTERS, AND MONOMIAL FUNCTIONS

We list here all the polynomials, characters, and monomial functions with total degree lower or equal to three up to triality.

Polynomials:

$$P^{\kappa}_{1,0,0,0}(z)=z_1,$$

$$P^{\kappa}_{0,1,0,0}(z)=z_2+\frac{4(\kappa-1)}{5\kappa+1},$$

$$P^{\kappa}_{2,0,0,0}(z)=z_1^2-\frac{2}{1+\kappa}z_2-\frac{8\kappa}{(1+\kappa)(1+3\kappa)},$$

$$P^{\kappa}_{0,2,0,0}(z)=z_2^2-\frac{2}{1+\kappa}z_1z_3z_4-\frac{2(-1+\kappa)}{(1+\kappa)(1+2\kappa)}(z_1^2+z_3^2+z_4^2)+\frac{4(-3+5\kappa+6\kappa^2+4\kappa^3)}{(1+\kappa)(1+2\kappa)(3+5\kappa)}z_2$$
$$+\frac{16(-1+\kappa)(3+10\kappa+3\kappa^2+2\kappa^3)}{(1+\kappa)(1+2\kappa)(2+5\kappa)(3+5\kappa)},$$

$$P^{\kappa}_{1,1,0,0}(z)=z_1z_2-\frac{3}{1+2\kappa}z_3z_4+\frac{4(-1+\kappa)(-1+2\kappa)}{(1+2\kappa)(2+5\kappa)}z_1,$$

$$P^{\kappa}_{1,0,1,0}(z)=z_1z_3-\frac{4}{1+3\kappa}z_4,$$

$$P^{\kappa}_{3,0,0,0}(z)=z_1^3-\frac{6}{2+\kappa}z_1z_2+\frac{6}{(1+\kappa)(2+\kappa)}z_3z_4-\frac{12(1+2\kappa+2\kappa^2)}{(1+\kappa)(2+\kappa)(2+3\kappa)}z_1,$$

$$P^{\kappa}_{0,3,0,0}(z)=z_2^3-\frac{6}{2+\kappa}z_1z_2z_3z_4+\frac{6}{(1+\kappa)(2+\kappa)}(z_1^2z_3^2+z_1^2z_4^2+z_3^2z_4^2)-\frac{3(2+\kappa+\kappa^2)}{(1+\kappa)^2(2+\kappa)}(z_1^2z_2$$
$$+z_2z_3^2+z_2z_4^2)+\frac{6(10+17\kappa+21\kappa^2+10\kappa^3+2\kappa^4)}{5(1+\kappa)^3(2+\kappa)}z_2^2$$
$$-\frac{3(30+53\kappa+4\kappa^2-15\kappa^3+8\kappa^4)}{5(1+\kappa)^4(2+\kappa)}z_1z_3z_4-\frac{12\kappa(8+10\kappa+\kappa^2+\kappa^3)}{5(1+\kappa)^4(2+\kappa)}(z_1^2+z_3^2+z_4^2)$$
$$+\frac{12(30+119\kappa+159\kappa^2+124\kappa^3+80\kappa^4+24\kappa^5+4\kappa^6)}{5(1+\kappa)^4(2+\kappa)(4+5\kappa)}z_2$$
$$+\frac{16(-30+103\kappa+440\kappa^2+359\kappa^3+98\kappa^4+86\kappa^5+20\kappa^6+4\kappa^7)}{5(1+\kappa)^4(2+\kappa)(3+5\kappa)(4+5\kappa)},$$

$$P^{\kappa}_{2,1,0,0}(z)=z_1^2z_2-\frac{2}{1+\kappa}z_2^2-\frac{1+3\kappa}{(1+\kappa)^2}z_1z_3z_4+\frac{4(-1+\kappa)\kappa^2}{(1+\kappa)^2(3+5\kappa)}z_1^2+\frac{4}{(1+\kappa)^2}(z_3^2+z_4^2)$$
$$-\frac{4(9+27\kappa+28\kappa^2+16\kappa^3)}{(1+\kappa)^2(2+3\kappa)(3+5\kappa)}z_2-\frac{16(3+5\kappa+2\kappa^3)}{(1+\kappa)^2(2+3\kappa)(3+5\kappa)},$$

$$P^{\kappa}_{1,2,0,0}(z)=z_1z_2^2-\frac{2}{1+\kappa}z_1^2z_3z_4-\frac{1+3\kappa}{(1+\kappa)^2}z_2z_3z_4-\frac{2(-1+\kappa)}{(1+\kappa)(1+2\kappa)}z_1^3+\frac{5-\kappa}{(1+\kappa)^2}(z_1z_3^2+z_1z_4^2)$$
$$+\frac{4(-1+\kappa)(9+19\kappa+10\kappa^2+4\kappa^3)}{(1+\kappa)^2(1+2\kappa)(4+5\kappa)}z_1z_2-\frac{4(-1+\kappa)(-5+2\kappa)(1+3\kappa)}{(1+\kappa)^2(1+2\kappa)(4+5\kappa)}z_3z_4$$
$$+\frac{8(-9-57\kappa-72\kappa^2+28\kappa^3-2\kappa^4+4\kappa^5)}{(1+\kappa)^2(1+2\kappa)(3+5\kappa)(4+5\kappa)}z_1,$$

$$P^{\kappa}_{1,1,1,0}(z)=z_1z_2z_3-\frac{3}{1+2\kappa}(z_1^2z_4+z_3^2z_4)-\frac{8(-1+\kappa)}{(1+2\kappa)(2+3\kappa)}z_2z_4$$
$$+\frac{4(12+23\kappa-11\kappa^2+6\kappa^3)}{(1+2\kappa)(2+3\kappa)(3+5\kappa)}z_1z_3-\frac{8(3-22\kappa+4\kappa^2)}{(1+2\kappa)(2+3\kappa)(3+5\kappa)}z_4,$$

$$P^{\kappa}_{1,0,1,1}(z)=z_1z_3z_4-\frac{4}{1+3\kappa}(z_1^2+z_3^2+z_4^2)+\frac{12}{(1+2\kappa)(1+3\kappa)}z_2+\frac{16(1+5\kappa)}{(1+2\kappa)(1+3\kappa)^2}.$$

Characters:

$$P^{(1)}_{1,0,0,0}(z)=z_1,$$

$$P^{(1)}_{0,1,0,0}(z)=z_2,$$

$$P^{(1)}_{2,0,0,0}(z)=z_1^2-z_2-1,$$

$$P^{(1)}_{0,2,0,0}(z)=z_2^2+z_2-z_1z_3z_4,$$

$$P^{(1)}_{1,1,0,0}(z)=z_1z_2-z_3z_4,$$

$$P^{(1)}_{1,0,1,0}(z)=z_1z_3-z_4,$$

$$P^{(1)}_{3,0,0,0}(z)=z_1^3-2z_1z_2+z_3z_4-2z_1,$$

$$P^{(1)}_{0,3,0,0}(z)=z_2^3+3z_2^2+3z_2-2z_1z_2z_3z_4+z_1^2z_3^2+z_1^2z_4^2+z_3^2z_4^2-(z_1^2+z_3^2+z_4^2)z_2 -z_1z_3z_4-z_1^2-z_3^2-z_4^2+1,$$

$$P^{(1)}_{2,1,0,0}(z)=z_1^2z_2-z_2^2-z_1z_3z_4+z_3^2+z_4^2-2z_2-1,$$

$$P^{(1)}_{1,2,0,0}(z)=z_1z_2^2-z_1^2z_3z_4-z_2z_3z_4+z_1(z_3^2+z_4^2)-z_1,$$

$$P^{(1)}_{1,1,1,0}(z)=z_1z_2z_3+z_1z_3-(z_1^2+z_3^2)z_4+z_4,$$

$$P^{(1)}_{1,0,1,1}(z)=z_1z_3z_4-z_1^2-z_3^2-z_4^2+z_2+2.$$

Monomial functions:

$$P^{(0)}_{1,0,0,0}(z)=z_1,$$

$$P^{(0)}_{0,1,0,0}(z)=z_2-4,$$

$$P^{(0)}_{2,0,0,0}(z)=z_1^2-2z_2,$$

$$P^{(0)}_{0,2,0,0}(z)=z_2^2-2\,z_1z_3z_4+2\,z_1^2+2\,z_3^2+2\,z_4^2-4\,z_2-8,$$

$$P^{(0)}_{1,1,0,0}(z)=z_1z_2-3z_3z_4+2z_1,$$

$$P^{(0)}_{1,0,1,0}(z)=z_1z_3-4z_4,$$

$$P^{(0)}_{3,0,0,0}(z)=z_1^3-3z_1z_2+3z_3z_4-3z_1,$$

$$P^{(0)}_{0,3,0,0}(z)=z_2^3+6z_2^2+9z_2-3z_1z_2z_3z_4+3z_1^2z_3^2+3z_1^2z_4^2+3z_3^2z_4^2-3(z_1^2+z_3^2+z_4^2)z_2-9z_1z_3z_4-4,$$

$$P^{(0)}_{2,1,0,0}(z)=z_1^2z_2-2z_2^2-z_1z_3z_4+4z_3^2+4z_4^2-6z_2-8,$$

$$P^{(0)}_{1,2,0,0}(z)=z_1z_2^2-2z_1^2z_3z_4-z_2z_3z_4+2z_1^3+5z_1(z_3^2+z_4^2)-9z_1z_2-5z_3z_4-6z_1,$$

$$P^{(0)}_{1,1,1,0}(z)=z_1z_2z_3+8z_1z_3-3(z_1^2+z_3^2)z_4+4z_2z_4-4z_4,$$

$$P^{(0)}_{1,0,1,1}(z)=z_1z_3z_4-4z_1^2-4z_3^2-4z_4^2+12z_2+16.$$

This short note is devoted to the proof of Lifshitz tails and a Wegner estimate, and thus, band edge localization, for the random hopping model. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1616998]

I. INTRODUCTION

The model we consider in this short note is defined as follows: for $u \in \ell^2(\mathbb{Z}^d)$,

$$(H^\omega u)(x) = \sum_{|x-y|=1} \lambda^\omega((x,y))u(y), \quad x \in \mathbb{Z}^d. \tag{1.1}$$

The coefficients $\lambda^\omega((x,y))$ are real valued, bounded i.i.d. random variables satisfying the minimal symmetry requirement for H^ω to be self-adjoint. Namely, let $\mathcal{E}$ denote the set of edges $\{(x,y) \in \mathbb{Z}^d \times \mathbb{Z}^d;\ |x-y|=1\}$ (here, $|x|=|x_1|+\cdots+|x_d|$ if $x=(x_1, \ldots, x_d)$); define the set of undirected edges to be $\mathcal{E}' := \mathcal{E}/\sim$ [where $(x,y)\sim(x',y')$ if and only if $(x,y)=(x',y')$ or $(x,y)=(y',x')$]. The coefficients $\lambda^\omega(e)$, $e \in \mathcal{E}'$ are supposed to be i.i.d. random variables. Let us note here that (1.1) is a natural discrete analogue of the model studied in Ref. 4.

As H^ω is homogeneous of degree one in the variables $\lambda^\omega(e)$, $e \in \mathcal{E}'$, we may, without restriction, assume that

$$\operatorname*{ess\text{-}sup}_\omega |\lambda^\omega(e)| = 1. \tag{1.2}$$

Under these assumptions, for almost every ω, the operator H^ω is bounded and self-adjoint. Moreover, it is $\mathbb{Z}^d$-ergodic (see, e.g., Refs. 2 and 9); this guarantees that its spectrum is almost surely constant. Call it Σ. Using the classical criterion of Ref. 3, under assumption (1.2), one computes

$$\Sigma = [-2d, 2d].$$

The absolutely continuous, singular continuous and pure point components of the spectrum are also almost surely independent of ω.

The aim of the present note is to show that localization occurs near the edges of Σ.

The $\mathbb{Z}^d$-ergodicity also guarantees the existence of a density of states. In $\mathbb{Z}^d$, consider the cube of size N ($N>1$) and center 0. Denote it by Λ_N. Let Π_N be the projection (cutoff) on this cube. Then, the integrated density of states $k(E)$ of H^ω is defined by

a)Electronic mail: klopp@math.univ-paris13.fr
b)Electronic mail: shu@ms.u-tokyo.ac.jp

$$k(E) := \lim_{N \to +\infty} \frac{\#\{\text{eigenvalues of } \Pi_N H^\omega \Pi_N \text{ less than } E\}}{\#\Lambda_N}. \tag{1.3}$$

This limit exists almost surely (see Sec. II for more details); it is a nondecreasing function that takes values in $[0,1]$. Its points of growth are the points of Σ. It thus naturally defines a probability measure supported in Σ; we denote this measure by $\mathrm{d}k$.

It is well known (see, e.g., Refs. 1 and 10) that, in order to prove localization at spectral edges for models of the type (1.1), it is sufficient to prove that the integrated density of states satisfies two conditions:

(1) a regularity condition: e.g., k is Hölder continuous;
(2) a size condition: $\mathrm{d}k$ puts very little weight on the edges of the spectrum; this type of behavior is known as Lifshitz tails.

We prove the following.

Theorem 1.1: *The integrated density of states satisfies*

$$\lim_{\varepsilon \to 0^+} \frac{\log|\log k(-2d+\varepsilon)|}{\log \varepsilon} \leqslant -\frac{d}{2}$$

and

$$\lim_{\varepsilon \to 0^+} \frac{\log|\log(1-k(2d-\varepsilon))|}{\log \varepsilon} \leqslant -\frac{d}{2}. \tag{1.4}$$

To prove the regularity condition mentioned above, we need an additional assumption on the random variables. Let ν be the distribution of $\lambda^\omega(e)$. We assume the following.

$(H1)$: ν admits a locally Lipschitz continuous density, say $g(t)$.

Then, we prove the following.

Theorem 1.2: *The integrated density of states is locally Lipschitz continuous in* $\Sigma \backslash \{0\}$.

As noticed above, using multiscale analysis, Theorem 1.1 and Theorem 1.2 are sufficient to derive that the spectrum is exponentially and dynamically localized in a neighborhood of the points $2d$ and $-2d$ (see, e.g., Refs. 11 and 10).

II. SOME AUXILIARY OPERATORS

We now turn to the proofs of Theorem 1.1 and Theorem 1.2. We introduce some auxiliary periodic operators. For $N \in \mathbb{N}$, define

$$(H_N^\omega u)(x) = \sum_{|x-y|=1} \lambda_N^\omega((x,y))u(y), \quad x \in \mathbb{Z}^d, \tag{2.1}$$

where

$$\lambda_N^\omega((x,y)) = \lambda_N^\omega((x+\gamma, y+\gamma)) \quad \text{for } \gamma \in (2N+1)\mathbb{Z}^d.$$

The operator H_N^ω acting on $\ell^2(\mathbb{Z}^d)$ is $(2N+1)\mathbb{Z}^d$-periodic. Using Floquet theory (see Ref. 6 for details), we know that H_N^ω admits a density of states, say $k_N^\omega(E)$, that satisfies

$$k_N^\omega(E) = \frac{1}{(2\pi)^d} \int_{[-\pi/(2N+1), \pi/(2N+1)]^d} \#\{\text{eigenvalues of } M_N^\omega(\theta) \text{ in } [0,E]\}\mathrm{d}\theta, \tag{2.2}$$

where the $(2N+1)^d \times (2N+1)^d$-matrix $M_N^\omega(\theta)$ only differs from $\Pi_N H^\omega \Pi_N$ by an operator of rank at most CN^{d-1} (for some C independent of N, ω, and θ). Moreover, as a consequence of the $\mathbb{Z}^d$-ergodicity, one obtains, for $\varphi \in \mathcal{C}_0^\infty(\mathbb{R})$,

$$\mathbb{E}[\langle \varphi, \mathrm{d}k_N^\omega(E)\rangle] := \mathbb{E}\left(\int \varphi(\lambda)\mathrm{d}k_N^\omega(\lambda) \right) = \mathbb{E}[\langle \delta_0, \varphi(H_N^\omega)\delta_0\rangle]. \tag{2.3}$$

Equation (2.3) implies $\mathbb{E}[\mathrm{d}k_N^\omega]$ converges when $N \to +\infty$; actually, one can show that the convergence of $\mathbb{E}[\mathrm{d}k_N^\omega]$ is exponentially fast (see, e.g., Refs. 5 and 6). The limit defines a positive measure. Then, (2.2), and the remark following this last equation imply that this measure is the density of states measure of the distribution function which is defined in (1.3).

As a result of this discussion, we see that to prove Theorems 1.1 and 1.2, we only need to prove analogous statements for $\mathbb{E}[k_N^\omega(E)]$ uniformly in N for N large enough.

III. THE PROOF OF THEOREM 1.1

Let us start with the Lifshitz behavior. First, we notice that we only need to deal with the lower edge of the spectrum; indeed, the unitary transform $(Uu)(x) = (-1)^{|x|}u(x)$ conjugates H^ω to $-H^\omega$.

To prove Theorem 1.1, it suffices to prove the following local energy estimate (see, e.g., Refs. 7 and 8).

Lemma 3.1: Fix $a \in (0,1)$. For $u \in \ell^2(\mathbb{Z})$, one has

$$\langle u, H_N^\omega u\rangle \geqslant \langle u, W_N^\omega u\rangle + a\langle |u|, H_0|u|\rangle \tag{3.1}$$

where

(i) *H_0 is the free Laplace operator of $\mathbb{Z}^d$ (i.e., it is equal to $2d + H^\omega$ when $\lambda^\omega(e) = 1$, $\forall e \in \mathcal{E}$); it is non-negative;*

(ii) *the potential W_N^ω is defined by*

$$W_N^\omega(x) = \sum_{\substack{e \in \mathcal{E} \\ x \in e}} \beta(\lambda_N^\omega(e)) \quad \text{where} \quad \beta(t) = \begin{cases} -|t| & \text{if } |t| \geqslant a \\ -a & \text{if } |t| < a. \end{cases} \tag{3.2}$$

(iii) *For $e \in \mathcal{E}$, we say that $x \in e$ if $e = (x,y)$ or $e = (y,x)$ for some y.*

Indeed, we note that the random potential W_N^ω takes values in $[-2d, 2d]$, its minimum is $-2d$. One can then apply the standard argument for operators of the form $H_0 + V^\omega$ (see, e.g., Refs. 5 and 6) to obtain the desired estimate on $\mathbb{E}[k_N^\omega(E)]$ (for N not too large). The exponentially fast convergence of $\mathbb{E}[\mathrm{d}k_N^\omega]$ to $\mathrm{d}k$ then gives (1.4) exactly in the same way as in Refs. 5 and 6.

Proof of Lemma 3.1: To alleviate notations, let us drop the sub- and super-indices ω and N. One start with rewriting

$$\langle u, Hu\rangle = 2\sum_{e \in \mathcal{E}'} \lambda(e)\mathrm{Re}(\overline{u(i(e))}u(t(e))), \tag{3.3}$$

where, for an edge $e = (x,y)$, we have defined $i(e) = x$ and $t(e) = y$.

Note that

$$2\,\mathrm{Re}(\overline{u_1}u_2) = \begin{pmatrix} u_1 & u_2 \end{pmatrix}^* \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} u_1 \\ u_2 \end{pmatrix}. \tag{3.4}$$

Consider the spectrum of $\left(\begin{smallmatrix} 0 & \lambda \\ \lambda & 0 \end{smallmatrix}\right)$. Let us first assume that $\lambda = -t < 0$. Then,

$$\sigma\left[\begin{pmatrix} 0 & \lambda \\ \lambda & 0 \end{pmatrix}\right] = \{\lambda, -\lambda\} = \{-t, t\}, \tag{3.5}$$

respective eigenvectors being $\vec{e_1} = \binom{1/\sqrt{2}}{1/\sqrt{2}}$ and $\vec{e_2} = \binom{1/\sqrt{2}}{-1/\sqrt{2}}$. Let Π_1 and Π_2, respectively, be the projectors on $\vec{e_1}$ and $\vec{e_2}$; one computes

$$\Pi_1 = \frac{1}{2}\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix} \quad \text{and} \quad \Pi_1 = \frac{1}{2}\begin{pmatrix} 1 & -1 \\ -1 & 1 \end{pmatrix}. \tag{3.6}$$

Using $\beta(\cdot)$ defined in Lemma 3.1, one writes

$$\begin{pmatrix} 0 & \lambda \\ \lambda & 0 \end{pmatrix} = t\Pi_2 - t\Pi_1 \geqslant \beta(t)\Pi_1 + t\Pi_2 = \beta(t) + (t - \beta(t))\Pi_2 \geqslant \beta(t) + a\Pi_2.$$

This with (3.6) and (3.4) implies that, for $\lambda < 0$,

$$2\,\mathrm{Re}(\lambda \overline{u_1} u_2) \geqslant \beta(\lambda)(|u_1|^2 + |u_2|^2) + a\,||u_1| - |u_2||^2. \tag{3.7}$$

This relation is proved in the same way and holds for $\lambda > 0$.

If we now apply (3.7) to each term in the sum (3.3), we obtain

$$\begin{aligned} \langle u, Hu\rangle &= \sum_{e \in \mathcal{E}'} \beta(\lambda)(|u(i(e))|^2 + |u(t(e))|^2) + a \sum_{e \in \mathcal{E}'} ||u(i(e))| - |u(t(e))||^2 \\ &= \langle u, Wu\rangle + a\langle |u|, H_0|u|\rangle, \end{aligned}$$

where the potential W is defined by

$$W(x) = \sum_{\substack{e \in \mathcal{E} \\ x \in e}} \beta(\lambda_N^\omega(e)).$$

This completes the proof of (3.1) and thus of Lemma 3.1.

IV. THE PROOF OF THEOREM 1.2

To prove this lemma, we use the fact that H^ω, hence also $H_N^\omega = \Pi_N H^\omega \Pi_N$, is homogeneous of degree one with respect to the random variables $(\lambda^\omega(e))_{e \in \mathcal{E}'}$; indeed, one has

$$\sum_{e \in \mathcal{E}_N} \lambda^\omega(e) \frac{\partial}{\partial \lambda^\omega(e)} H_N^\omega = H_N^\omega. \tag{4.1}$$

Here, $\mathcal{E}_N$ denotes the set of edges that start and end in Λ_N [i.e., such that $i(e)$ and $t(e)$ belongs to Λ_N]. Note that $\mathcal{E}_N$ is of cardinal bounded by $C\#\Lambda_N$ (for some fixed $C > 0$).

One can use the classical argument of Wegner[12] to derive Theorem 1.2. For the reader's convenience, we detail this proof now.

Pick a compact interval $\Delta \subset (-\infty, 0)$, say, $\Delta \subset (-\infty, -c]$, $c > 0$ fixed. Let $E_N^\omega(\Delta)$ be the spectral projector of H_N^ω on the interval Δ. Then, we need to estimate

$$\#\{\text{eigenvalues of } \Pi_N H^\omega \Pi_N \text{ less than } E\} = \mathrm{tr}(E_N^\omega(\Delta)) = \mathrm{tr}\left(\int_\Delta \partial_E \mathbf{1}_{(-\infty, 0]}(H_N^\omega - E)\,\mathrm{d}E \right). \tag{4.2}$$

Here, $\mathbf{1}_A$ is the characteristic function of the set A. Using (4.1) one computes

$$\mathrm{tr}\left(\sum_{e\in\mathcal{E}_N}\lambda^{\omega}(e)\partial_{\lambda^{\omega}(e)}\mathbf{1}_{(-\infty,0]}(H_N^{\omega}-E)\right)=\mathrm{tr}(-H_N^{\omega}\partial_E\mathbf{1}_{(-\infty,0]}(H_N^{\omega}-E))).$$

For $E\in\Delta$, this gives

$$\mathrm{tr}[\partial_E\mathbf{1}_{(-\infty,0]}(H_N^{\omega}-E)]\leqslant\frac{1}{c}\mathrm{tr}\left(\sum_{e\in\mathcal{E}_N}\lambda^{\omega}(e)\partial_{\lambda^{\omega}(e)}\mathbf{1}_{(-\infty,0]}(H_N^{\omega}-E)\right)$$

hence, by (4.2),

$$c\cdot\mathrm{tr}(E_N^{\omega}(\Delta))\leqslant\int_{\Delta}\sum_{e\in\mathcal{E}_N}\mathrm{tr}(\lambda^{\omega}(e)\partial_{\lambda^{\omega}(e)}\mathbf{1}_{(-\infty,0]}(H_N^{\omega}-E)))\mathrm{d}E.$$

Taking the expectation in both sides of the previous equation, one obtains

$$c\cdot\mathbb{E}[\mathrm{tr}(E_N^{\omega}(\Delta))]\leqslant\sum_{e\in\mathcal{E}_N}\int\prod_{e'\neq e}g(\lambda^{\omega}(e'))\mathrm{d}\lambda^{\omega}(e')\int_{\Delta}\mathrm{d}E\,G_e(E,\omega),\tag{4.3}$$

where

$$G(E,\omega)=G_e(E,\omega)=\int_{-1}^{1}g(\lambda)\lambda\partial_{\lambda}\mathrm{tr}(\mathbf{1}_{(-\infty,0]}(H_N^{\omega}(\lambda,e)-E))\mathrm{d}\lambda.\tag{4.4}$$

Here, $H_N^{\omega}(\lambda,e)$ is the Hamiltonian H_N^{ω} where the random variable $\lambda_{\omega}(e)=\lambda$, and all other random variables are unchanged.

By assumption, g, the common probability density of the random variables $(\lambda^{\omega}(e))_{\gamma}$, is Lipschitz continuous. This enables us to integrate by parts in (4.4) and to obtain

$$G(E,\omega)=[g(\lambda)\lambda F(\lambda,E,\omega)]_{-1}^{1}-\int_{-1}^{1}\partial_{\lambda}(g(\lambda)\lambda)F(\lambda,E,\omega)\mathrm{d}\lambda,\tag{4.5}$$

where we have defined

$$F(\lambda,E,\omega)=\mathrm{tr}[\mathbf{1}_{(-\infty,0]}(H_N^{\omega}(1,e)-E)-\mathbf{1}_{(-\infty,0]}(H_N^{\omega}(-1,e)-E)].$$

As the single-site perturbation $\partial_{\lambda^{\omega}(e)}H^{\omega}$ is of rank 2, the function $|F(\lambda,E,\omega)|$ is bounded by 2. Hence, $|G|$ is bounded by a constant. Plugging this back into (4.3), and using equations (4.2), (4.1) and the fact that Δ is bounded away from 0, one obtains

$$\begin{aligned}&\#\{\text{eigenvalues of }\Pi_N H^{\omega}\Pi_N\text{ less than }E\}\\&=\mathbb{E}(\mathrm{tr}[E_N^{\omega}(\Delta)])\leqslant C\sum_{e\in\mathcal{E}_N}\int_{\omega'}\mathbb{P}(\mathrm{d}\omega')\int_{\Delta}\mathrm{d}E\leqslant C|\Delta||\Lambda|.\end{aligned}$$

In view of the definition of the integrated density of states (1.3), this completes the proof of Theorem 1.2.

(Received 9 July 2003; accepted 18 August 2003)

This paper deals with the dynamical system that generalizes the MIC-Kepler system. It is shown that the Schrödinger equation for this generalized MIC-Kepler system can be separated in spherical and parabolic coordinates. The spectral problem in spherical and parabolic coordinates is solved. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1619205]

I. INTRODUCTION

The system described by the Hamiltonian

$$\hat{\mathcal{H}}=\frac{1}{2}(-i\nabla-s\mathbf{A})^2+\frac{s^2}{2r^2}-\frac{1}{r}+\frac{c_1}{r(r+z)}+\frac{c_2}{r(r-z)}, \tag{1.1}$$

where c_1 and c_2 are non-negative constants, later on will be called the generalized MIC-Kepler system. (We use the system of units for which $\hbar=m=e=c=1$.)

The MIC-Kepler integrable system was constructed by Zwanziger[1] and rediscovered by McIntosh and Cisneros.[2] This system is described by the Hamiltonian

$$\hat{\mathcal{H}}_0=\frac{1}{2}(-i\nabla-s\mathbf{A})^2+\frac{s^2}{2r^2}-\frac{1}{r}, \tag{1.2}$$

where

$$\mathbf{A}=\frac{1}{r(r-z)}(y,-x,0), \quad \text{and} \quad \operatorname{rot}\mathbf{A}=\frac{\mathbf{r}}{r^3}.$$

Its distinctive peculiarity is the Coulomb hidden symmetry given by the following constants of motion (1.2):

$$\hat{\mathbf{I}}=\frac{1}{2}[(-i\nabla-s\mathbf{A})\times\hat{\mathbf{J}}-\hat{\mathbf{J}}\times(-i\nabla-s\mathbf{A})]+\frac{\mathbf{r}}{r}, \quad \hat{\mathbf{J}}=\mathbf{r}\times(-i\nabla-s\mathbf{A})-s\frac{\mathbf{r}}{r}. \tag{1.3}$$

Here, the operator $\hat{\mathbf{J}}$ defines the angular momentum of the system, while operator $\hat{\mathbf{I}}$ is the analog of the Runge–Lenz vector. These constants of motion, together with the Hamiltonian, form the quadratic symmetry algebra of the Coulomb problem. For fixed negative energy values the motion integrals make up algebra so(4), whereas for positive energy values $-$so(3.1). Due to the hidden symmetry the MIC-Kepler problem is factorized not only in the spherical but parabolic coordinates as well. Hence, the MIC-Kepler system is a natural generalization of the Coulomb problem in the presence of Dirac's monopole. In both cases the monopole number s satisfies the Dirac's rule of charge quantization $s=0,\pm 1/2,\pm 1,\ldots$.

The MIC-Kepler system could be constructed by the reduction of the four-dimensional isotropic oscillator by the use of the so-called Kustaanheimo–Stiefel transformation both on classical and quantum mechanical levels.[3] In the similar way, reducing the two- and eight-dimensional isotropic oscillator, one can obtain the two- (Ref. 4) and five-dimensional[5] analogs of the MIC-

Kepler system. An infinitely thin solenoid providing the system by the spin 1/2, plays the role of monopole in the two-dimensional case, whereas in the five-dimensional case this role is performed by the SU(2) Yang monopole,[6] endowing the system by the isospin. All the above-mentioned systems have Coulomb symmetries and are solved in spherical and parabolic coordinates both in discrete and continuous parts of the energy spectra.[7] There are generalizations of MIC-Kepler systems on the three-dimensional sphere[8] and hyperboloid[9] as well. The MIC-Kepler system has been worked out from different points of view in.[10–14]

For integer values s the MIC-Kepler system describes the relative motion of the two Dirac's dyons (charged magnetic monopoles), where vector $\mathbf{r}$ determines the position of the second dyon with respect to the first one.[1] For half-integer s the presence of the solenoid magnetic field, endowing the system with the spin 1/2, is presupposed (see, e.g., Ref. 4).

The Hamiltonian (1.1) for $s=0$ and $c_i \neq 0$ $(i=1,2)$ reduces to the Hamiltonian

$$\hat{H} = -\frac{1}{2}\Delta - \frac{1}{r} + \frac{c_1}{r(r+z)} + \frac{c_2}{r(r-z)} \tag{1.4}$$

of the generalized Kepler–Coulomb system.[15]

The potential

$$V = -\frac{\alpha}{r} + \frac{c_1}{r(r+z)} + \frac{c_2}{r(r-z)} \tag{1.5}$$

is one of the Smorodinsky–Winternitz-type potentials.[16] The Smorodinsky–Winternitz type potentials where revived and investigated in 1990 by Evans.[17] In the case where $c_1 = c_2$, the potential (1.5) reduces to the Hartmann potential that has been used for describing axially symmetric systems like ring-shaped molecules[18] and investigated from different points of view in Refs. 19–31. In particular, the (quantum mechanical) discrete spectrum for the generalized Kepler–Coulomb system (1.4) is well known,[24,27,29] even for the so-called (q,p)-analog of this system.[29] Furthermore, a path integral treatment of the potential (1.5) has been given in Refs. 23 and 27. Recently, the dynamical symmetry of the generalized Kepler–Coulomb system has been studied in Refs. 29–31, the classical motion of a particle moving in the potential (1.5) has been considered in Ref. 30, and the coefficients connecting the parabolic and spherical bases have been identified in Ref. 31 as Clebsch–Gordan coefficients of the pseudo-unitary group SU(1,1).

The purpose of the present paper is to further study the bound states of the generalized MIC-Kepler system in spherical and parabolic coordinates.

II. SPHERICAL BASIS

The Schrödinger equation with Hamiltonian (1.1) in spherical coordinates (r,θ,φ) may be solved by seeking a wave function ψ of the form

$$\psi(r,\theta,\varphi) = R(r)Z(\theta,\varphi). \tag{2.1}$$

This amounts to finding the eigenfunctions of the set $\{\hat{\mathcal{H}}, \hat{J}_z, \hat{M}\}$ of commuting operators, where the constant of motion $\hat{M}$ reads

$$\hat{M} = \hat{J}^2 + \frac{2c_1}{1+\cos\theta} + \frac{2c_2}{1-\cos\theta}. \tag{2.2}$$

Here $\hat{J}^2$ is the square of the angular momentum, $\hat{J}_z = s - i\partial/\partial\varphi$ its z-component, and $\hat{J}_z\psi = m\psi$.

After substitution the expression (2.1) the variables in the Schrödinger equation are separated and we arrive at the following system of coupled differential equations:

$$\frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial Z}{\partial\theta}\right)+\frac{1}{4\cos^2\frac{\theta}{2}}\left(\frac{\partial^2}{\partial\varphi^2}-4c_1\right)Z+\frac{1}{4\sin^2\frac{\theta}{2}}\left[\left(\frac{\partial}{\partial\varphi}+2is\right)^2-4c_2\right]Z=-\mathcal{A}Z, \tag{2.3}$$

$$\frac{1}{r^2}\frac{d}{dr}\left(r^2\frac{dR}{dr}\right)-\frac{\mathcal{A}}{r^2}R+2\left(E+\frac{1}{r}\right)R=0, \tag{2.4}$$

where $\mathcal{A}$ is a separation constant in spherical coordinates.

The solution of (2.3) is easily found to be

$$Z_{jm}^{(s)}(\theta,\varphi;\delta_1,\delta_2)=N_{jm}(\delta_1,\delta_2)\left(\cos\frac{\theta}{2}\right)^{m_1}\left(\sin\frac{\theta}{2}\right)^{m_2}P_{j-m_+}^{(m_2,m_1)}(\cos\theta)e^{i(m-s)\varphi}, \tag{2.5}$$

where $m_1=|m-s|+\delta_1=\sqrt{(m-s)^2+4c_1}$, $m_2=|m+s|+\delta_2=\sqrt{(m+s)^2+4c_2}$, $m_+=(|m+s|+|m-s|)/2$, and $P_n^{(a,b)}$ denotes a Jacobi polynomial. The quantum numbers m and j run through values: $m=-j,-j+1,\ldots,j-1,j$ and

$$j=\frac{|m+s|+|m-s|}{2},\frac{|m+s|+|m-s|}{2}+1,\ldots\ .$$

The quantum numbers j, m characterize the total momentum of the system and its projection on the axis z. For the (half)integer s j, m are (half)integers.

Furthermore, the separation constant $\mathcal{A}$ is quantized as

$$\mathcal{A}=\left(j+\frac{\delta_1+\delta_2}{2}\right)\left(j+\frac{\delta_1+\delta_2}{2}+1\right). \tag{2.6}$$

The normalization constant $N_{jm}(\delta_1,\delta_2)$ in (2.5) is given (up to a phase factor) by

$$N_{jm}(\delta_1,\delta_2)=\sqrt{\frac{(2j+\delta_1+\delta_2+1)(j-m_+)!\Gamma(j+m_++\delta_1+\delta_2+1)}{4\pi\Gamma(j-m_-+\delta_1+1)\Gamma(j+m_-+\delta_2+1)}}, \tag{2.7}$$

where $m_-=(|m+s|-|m-s|)/2$. The angular wave functions $Z_{jm}^{(s)}$ [see Eq. (2.5)] are convenient to call the ring-shaped monopole harmonics by analogy with the term ''monopole harmonics'' studied by Tamm.[32] These ring-shaped monopole harmonics generalize the functions studied by Hartmann[18] in the case $s=0,\delta_1=\delta_2$. Due to the connecting formula,[33]

$$(\lambda+\tfrac{1}{2})_n\ C_n^{\lambda}(x)=(2\lambda)_nP_n^{(\lambda-(1/2),\lambda-(1/2))}(x) \tag{2.8}$$

between the Jacobi polynomial $P_n^{(a,b)}$ and the Gegenbauer polynomial C_n^{λ}, the case $s=0$, $\delta_1=\delta_2=\delta$ yields

$$Z_{jm}^{(0)}(\theta,\varphi;\delta,\delta)=2^{|m|+\delta}\Gamma\left(|m|+\delta+\frac{1}{2}\right)\sqrt{\frac{(2j+2\delta+1)(j-|m|)!}{4\pi^2\Gamma(j+|m|+2\delta+1)}}$$
$$\times(\sin\theta)^{|m|+\delta}C_{j-|m|}^{|m|+\delta+(1/2)}(\cos\theta)e^{im\varphi}, \tag{2.9}$$

the result already obtained in Ref. 15. [In (2.8), $(a)_n$ stands for a Pochhammer symbol.] The case $\delta=0$ (i.e., $c_1=c_2=0$) can be treated by using the connecting formula

$$P_j^{|m|}(x)=\frac{(-2)^{|m|}}{\sqrt{\pi}}\Gamma\left(|m|+\frac{1}{2}\right)(1-x^2)^{|m|/2}C_{j-|m|}^{|m|+(1/2)}(x) \tag{2.10}$$

between the Gegenbauer polynomial C_n^{λ} and the associated Legandre function.[33] In fact for the $\delta=0$, Eq. (2.9) can be reduced to

$$Z_{jm}^{(0)}(\theta,\varphi;0,0)=\sqrt{\frac{(2j+1)(j-|m|)!}{4\pi(j+|m|)!}}P_j^{|m|}(\cos\theta)e^{im\varphi}, \tag{2.11}$$

an expression (up to a phase factor) that coincides with the usual (surface) spherical harmonics $Y_{lm}(\theta,\varphi)$.

Let us go now to radial equation (2.4). The introduction of (2.6) into the (2.4) leads to

$$\frac{1}{r^2}\frac{d}{dr}\left(r^2\frac{dR}{dr}\right)-\frac{1}{r^2}\left(j+\frac{\delta_1+\delta_2}{2}\right)\left(j+\frac{\delta_1+\delta_2}{2}+1\right)R+2\left(E+\frac{1}{r}\right)R=0, \tag{2.12}$$

which is reminiscent of the radial equation for the hydrogen atom except that the orbital quantum number l is replaced here by $j+(\delta_1+\delta_2)/2$. The solution of (2.12) for the discrete spectrum is

$$R_{nj}^{(s)}(r)=C_{nj}(\delta_1,\delta_2)(2\varepsilon r)^{j+[(\delta_1+\delta_2)/2]}e^{-\varepsilon r}F(-n+j+1;2j+\delta_1+\delta_2+2;2\varepsilon r), \tag{2.13}$$

where $n=|s|+1,|s|+2,\ldots$. In (2.13), the normalization factor $C_{nj}(\delta_1,\delta_2)$ reads

$$C_{nj}(\delta_1,\delta_2)=\frac{2\varepsilon^2}{\Gamma(2j+\delta_1+\delta_2+1)}\sqrt{\frac{\Gamma(n+j+\delta_1+\delta_2+1)}{(n-j-1)!}} \tag{2.14}$$

and the parameter ε is defined by

$$\varepsilon=\sqrt{-2E}=\frac{1}{n+\dfrac{\delta_1+\delta_2}{2}}. \tag{2.15}$$

The eigenvalues E are then given by

$$E\equiv E_n^{(s)}=-\frac{1}{2\left(n+\dfrac{\delta_1+\delta_2}{2}\right)^2}. \tag{2.16}$$

In the limiting case $\delta_1=\delta_2=0$, we recover the familiar results for charge-dyon bound system.[1]

III. PARABOLIC BASIS

Let us consider the generalized MIC-Kepler system in the parabolic coordinates. In the parabolic coordinates $\xi,\eta\in[0,\infty),\varphi\in[0,2\pi)$, defined by the formulas

$$x=\sqrt{\xi\eta}\cos\varphi,\quad y=\sqrt{\xi\eta}\sin\varphi,\quad z=\tfrac{1}{2}(\xi-\eta), \tag{3.1}$$

the differential elements of length and volume read

$$dl^2=\frac{\xi+\eta}{4}\left(\frac{d\xi^2}{\xi}+\frac{d\eta^2}{\eta}\right)+\xi\eta d\varphi^2,\quad dV=\tfrac{1}{4}(\xi+\eta)d\xi d\eta d\varphi, \tag{3.2}$$

while the Laplace operator looks like

$$\Delta=\frac{4}{\xi+\eta}\left[\frac{\partial}{\partial\xi}\left(\xi\frac{\partial}{\partial\xi}\right)+\frac{\partial}{\partial\eta}\left(\eta\frac{\partial}{\partial\eta}\right)\right]+\frac{1}{\xi\eta}\frac{\partial^2}{\partial\varphi^2}. \tag{3.3}$$

The substitution

$$\psi(\xi,\eta,\varphi)=\Phi_1(\xi)\Phi_2(\eta)\frac{e^{i(m-s)\varphi}}{\sqrt{2\pi}} \tag{3.4}$$

separates the variables in the Schrödinger equation and we arrive at the following system of equations:

$$\frac{d}{d\xi}\left(\xi\frac{d\Phi_1}{d\xi}\right)+\left[\frac{E}{2}\xi-\frac{m_1^2}{4\xi}+\frac{1}{2}\beta+\frac{1}{2}\right]\Phi_1=0, \tag{3.5}$$

$$\frac{d}{d\eta}\left(\eta\frac{d\Phi_2}{d\eta}\right)+\left[\frac{E}{2}\eta-\frac{m_2^2}{4\eta}-\frac{1}{2}\beta+\frac{1}{2}\right]\Phi_2=0, \tag{3.6}$$

where β is the separation constant.

These equations are analogous with the equations of the hydrogen atom in the parabolic coordinates.[34] Thus, we get

$$\psi^{(s)}_{n_1n_2m}(\xi,\eta,\varphi;\delta_1,\delta_2)=\sqrt{2}\varepsilon^2\Phi_{n_1m_1}(\xi)\Phi_{n_2m_2}(\eta)\frac{e^{i(m-s)\varphi}}{\sqrt{2\pi}}, \tag{3.7}$$

where

$$\Phi_{n_im_i}(x)=\frac{1}{\Gamma(m_i+1)}\sqrt{\frac{\Gamma(n_i+m_i+1)}{(n_i)!}}e^{-(\varepsilon x/2)}(\varepsilon x)^{(m_i/2)}F(-n_i;m_i+1;\varepsilon x). \tag{3.8}$$

Here n_1 and n_2 are non-negative integers

$$n_1=-\frac{|m-s|+\delta_1+1}{2}+\frac{\beta+1}{2\varepsilon},\quad n_2=-\frac{|m+s|+\delta_2+1}{2}-\frac{\beta-1}{2\varepsilon}. \tag{3.9}$$

From the last relations, taking into account (2.16), we get that the parabolic quantum numbers n_1 and n_2 are connected with the principal quantum number n as follows:

$$n=n_1+n_2+\frac{|m-s|+|m+s|}{2}+1. \tag{3.10}$$

Excluding the energy E from Eqs. (3.5) and (3.6), we obtain the additional integral of motion,

$$\hat{X}=\frac{2}{\xi+\eta}\left[\xi\frac{\partial}{\partial\eta}\left(\eta\frac{\partial}{\partial\eta}\right)-\eta\frac{\partial}{\partial\xi}\left(\xi\frac{\partial}{\partial\xi}\right)\right]+\frac{\xi-\eta}{2\xi\eta}\frac{\partial^2}{\partial\varphi^2}+is\frac{\xi^2+\eta^2}{\xi\eta(\xi+\eta)}\frac{\partial}{\partial\varphi}-s^2\frac{\xi-\eta}{2\xi\eta}+\frac{2c_1\eta}{\xi(\xi+\eta)}$$
$$-\frac{2c_2\xi}{\eta(\xi+\eta)}+\frac{\xi-\eta}{\xi+\eta} \tag{3.11}$$

with the eigenvalues

$$\beta=\varepsilon\left(n_1-n_2+\frac{|m-s|-|m+s|+\delta_1-\delta_2}{2}\right) \tag{3.12}$$

and eigenfunctions $\psi^{(s)}_{n_1n_2m}(\xi,\eta,\varphi;\delta_1,\delta_2)$.

In Cartesian coordinates, the operator $\hat{X}$ can be rewritten as

$$\hat{X}=z\left(\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}\right)-x\frac{\partial^2}{\partial x\partial z}-y\frac{\partial^2}{\partial y\partial z}+is\frac{r+z}{r(r-z)}\left(x\frac{\partial}{\partial y}-y\frac{\partial}{\partial x}\right)-\frac{\partial}{\partial z}-s^2\frac{r+z}{r(r-z)}+c_1\frac{r-z}{r(r+z)}$$
$$-c_2\frac{r+z}{r(r-z)}+\frac{z}{r}, \tag{3.13}$$

so that it immediately follows that $\hat{X}$ is connected to the z-component $\hat{I}_z$ of the analog of the Runge–Lenz vector (1.3) via

$$\hat{X}=\hat{I}_z+c_1\frac{r-z}{r(r+z)}-c_2\frac{r+z}{r(r-z)} \tag{3.14}$$

and coincides with $\hat{I}_z$ when $c_1=c_2=0$.

Thus we have solved the spectral problem in spherical

$$\hat{\mathcal{H}}\psi=E\psi,\quad \hat{M}\psi=\left(j+\frac{\delta_1+\delta_2}{2}\right)\left(j+\frac{\delta_1+\delta_2}{2}+1\right)\psi,\quad \hat{J}_z\psi=m\psi \tag{3.15}$$

and in parabolic coordinates

$$\hat{\mathcal{H}}\psi=E\psi,\quad \hat{X}\psi=\beta\psi,\quad \hat{J}_z\psi=m\psi, \tag{3.16}$$

where $\hat{\mathcal{H}}$, $\hat{J}_z$, $\hat{M}$, and $\hat{X}$ are defined by the expressions (1.1), (1.3), (2.2), and (3.14).

It is mentioned that all the formulas obtained for $s=0$ yield the corresponding formulas for the generalized Kepler Coulomb system.[15]

(Received 7 March 2003; accepted 15 July 2003)

We study the spectral and transport properties of Schrödinger operators on line graphs with random magnetic fields. We show that it has a pure point spectrum with exponentially decaying eigenfunctions on spectral edges, whereas there appears an eigenvalue with infinite multiplicity due to the structure of line graphs. We compute the electrical conductivity which is zero on spectral edges, but is nonzero and finite on the isolated eigenvalue mentioned above. Some related problems are also discussed. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1613377]

I. INTRODUCTION

Recently, the spectral theory of Schrödinger operators on graphs is paid much attention, and various interesting aspects, such as the relationship between the spectrum and the geometrical structure of graphs, are studied. Shirai[17] studied the spectrum of the Laplacian on d-regular infinite graphs, and found a simple formula relating the spectrum of the Laplacian on graphs to that of their line graphs. Ogurisu[15,16] gave a simple proof of results of Shirai[17] by using the notion of supersymmetry and extended them to the case where the magnetic flux is present. The subject of this paper is to consider the Schrödinger operators on line graphs with a certain random magnetic flux, where some unusual spectral properties appear. Mostly we discuss the line graph of $\mathbf{Z}^2$, but our results also apply to other graphs such as that of the triangular or hexagonal lattice discussed in Appendix A.

We first prepare notations and definitions. In this paper, a graph G is defined to be a pair $(V(G),\mathcal{E}(G))$ of a set of vertices $V(G)$ and a set of oriented edges $\mathcal{E}(G)=\{xy:x,y\in V(G)\}$. $\alpha=xy$ stands for the edge with origin x and terminus y and we write $o(\alpha)=x$, $t(\alpha)=y$. For $\alpha=xy\in\mathcal{E}(G)$, we denote the inverse edge by $\overline{\alpha}=yx$. $E(G)$ is the set of unoriented edges where $\alpha,\overline{\alpha}\in\mathcal{E}(G)$ are identified and we denote by $|\alpha|$ the corresponding element in $E(G)$ (i.e., $|\overline{\alpha}|=|\alpha|$). We denote by $l^2(G)$ the Hilbert space of complex-valued square summable functions on $V(G)$ with the inner product

$$\langle f,g\rangle_G=\sum_{x\in V(G)} m_G(x)\overline{f(x)}g(x),$$

where $m_G(x)=\sharp N_x(G)$ $(N_x(G)=\{\alpha\in\mathcal{E}(G):o(\alpha)=x\})$ is the degree of x. The line graph $L(G)$ of a graph G is defined as follows. Its vertex set is the set of edges in G: $V(L(G))=E(G)$ and $|\alpha|,|\beta|\in E(G)$ are connected by an edge $|\alpha||\beta|\in\mathcal{E}(L(G))$ if they have a vertex of G in common.

We naturally regard $\mathbf{Z}^2$ as a graph with $V(\mathbf{Z}^2)=\{x=(x_1,x_2):x_1,x_2\in\mathbf{Z}\}$, $\mathcal{E}(\mathbf{Z}^2)=\{xy:x,y\in V(\mathbf{Z}^2),|x-y|=1\}$ and let H be a bounded self-adjoint operator on $l^2(\mathbf{Z}^2)$,

b)Electronic mail: nomura@math.titech.ac.jp

$$(Hu)(x)=\sum_{\alpha\in N_x(\mathbf{Z}^2)}(u(x)-e^{iA(\alpha)}u(t(\alpha))),\quad x\in V(\mathbf{Z}^2). \tag{1.1}$$

$A:\mathcal{E}(\mathbf{Z}^2)\to\mathbf{R}$ is a vector potential satisfying $A(\alpha)=-A(\overline{\alpha}),\alpha\in\mathcal{E}(\mathbf{Z}^2)$. For $x=(x_1,x_2)\in\mathbf{Z}^2$, let $f_x=\{x_1,x_1+1\}\times\{x_2,x_2+1\}(\subset V(\mathbf{Z}^2))$ be the plaquette of $\mathbf{Z}^2$ with x as one of its vertices and let

$$\partial f_x=\{x(x+e_1),(x+e_1)(x+e_1+e_2),(x+e_1+e_2)(x+e_2),(x+e_2)x\}$$

$[\subset\mathcal{E}(\mathbf{Z}^2)]$ be the set of edges encircling the plaquette f_x counterclockwise $[e_1=(1,0),e_2=(0,1)]$. The magnetic flux on f_x is then given by

$$\Phi(f_x)=\sum_{\alpha\in\partial f_x}A(\alpha)\in[0,2\pi)\quad(\mathrm{mod}\ 2\pi).$$

The spectral properties of H is determined by $\{\Phi(f_x)\}_{x\in\mathbf{Z}^2}$ and does not depend on the choice of A with same $\{\Phi(f_x)\}_{x\in\mathbf{Z}^2}$. Given a vector potential $A:\mathcal{E}(\mathbf{Z}^2)\to\mathbf{R}$, we define the corresponding one on $L(\mathbf{Z}^2)$ by

$$A_L(|\alpha||\beta|)=\frac{A(yx)+A(xz)}{2}, \tag{1.2}$$

for $|\alpha|=|yx|$, $|\beta|=|xz|(x,y,z\in V(\mathbf{Z}^2))$. The Hamiltonian H_L on $l^2(L(\mathbf{Z}^2))$, which is the main subject of this paper, is defined by

$$(H_Lu)(|\alpha|)=\sum_{|\alpha||\beta|\in\mathcal{E}(L(\mathbf{Z}^2))}(u(|\alpha|)-e^{iA_L(|\alpha||\beta|)}u(|\beta|)),\quad|\alpha|\in\mathbf{E}(\mathbf{Z}^2). \tag{1.3}$$

The spectrum of H_L, H satisfy the following relation:[17,15,16]

$$\sigma(H_L)=\sigma(H)\cup\{8\}. \tag{1.4}$$

In this paper, we consider the case where $\{\Phi(f_x)\}_{x\in\mathbf{Z}^2}$ are random variables. Let

$$A_\omega(xy)=\begin{cases}-B_\omega(2n+1,m) & (x=(2n+1,m),y=(2n+1,m+1)),\\ B_\omega(2n+1,m) & (x=(2n+1,m+1),y=(2n+1,m));\\ 0 & (\text{otherwise})\end{cases}$$

$(n,m\in\mathbf{Z})$, with corresponding magnetic fluxes on each plaquette f_x:

$$\Phi(f_x)=\begin{cases}B_\omega(2n+1,m) & (x=(2n+1,m)),\\ -B_\omega(2n+1,m) & (x=(2n,m)).\end{cases} \tag{1.5}$$

We assume the following conditions on $\{B_\omega(2n+1,m)\}_{n,m\in\mathbf{Z}}$.

Assumption A: $\{B_\omega(2n+1,m)\}_{n,m\in\mathbf{Z}}$ *are real-valued i.i.d. random variables on a probability space* $(\Omega,\mathcal{F},\mathbf{P})$ *and the common distribution of* $\{B_\omega(2n+1,m)\}_{n,m\in\mathbf{Z}}$ *has a density* g *such that supp* $g\subset[-\pi,-c]\cup[c,\pi]$, *on which* g *is Lipshitz continuous, and* $\pm c\in supp\ g$ *for some constant* $0<c<\pi$.

The motivation to study the random flux model on line graphs is the work of Ludwig, Fisher, Shanker, and Grinstein,[10] where similar models are considered to study the transitions in the integer quantum Hall effect. In fact, H_L is one of a few examples which has an isolated eigenvalue with infinite multiplicity as is the Landau level of the Schrödinger operator on $L^2(\mathbf{R}^2)$ with a constant magnetic field. By (1.4) and the fact that[8] $\sigma(H)=[4(1-\cos c/4),4(1+\cos c/4)]$ a.s., we have

$$\sigma(H_L)=\left[4\left(1-\cos\frac{c}{4}\right),4\left(1+\cos\frac{c}{4}\right)\right]\cup\{8\},\quad \text{a.s.}$$

The integrated density of states (IDS) of H,H_L are defined as follows. Let $\mathbf{Z}^2_M=\{x=(x_1,x_2)\in\mathbf{Z}^2:|x_j|\leqslant M,j=1,2\}$ $(M\in\mathbf{N})$ and let $H^M=H|_{\mathbf{Z}^2_M},H^M_L=H_L|_{L(\mathbf{Z}^2_M)}$ be the Hamiltonian H,H_L restricted on $\mathbf{Z}^2_M,L(\mathbf{Z}^2_M)$, respectively [in other words, $\mathbf{Z}^2$ in (1.1), (1.3) is replaced by $\mathbf{Z}^2_M$]. The IDS $k(E),k_L(E)$ of H,H_L is given by

$$k(E)=\lim_{M\to\infty}\frac{1}{\sharp V(\mathbf{Z}^2_M)}\sharp\{\text{eigenvalues of } H^M\leqslant E\},$$

$$k_L(E)=\lim_{M\to\infty}\frac{1}{\sharp V(L(\mathbf{Z}^2_M))}\sharp\{\text{eigenvalues of } H^M_L\leqslant E\}.$$

It is known that $k(E),k_L(E)$ are almost surely deterministic. Our first result concerns the spectrum and the IDS of H_L.

Theorem 1.1: *Under Assumption A, we have the following.*

(1) There exists a constant $R>0$ such that the spectrum of H_L in $I_R:=[4(1-\cos c/4),4(1-\cos c/4)+R]\cup[4(1+\cos c/4)-R,4(1+\cos c/4)]$ is almost surely a pure point with exponentially decaying eigenfunctions (we say Anderson localization holds in such situations);

(2) 8 is an eigenvalue of H_L with infinite multiplicity;

(3) $k_L(E)$ is discontinuous at $E=8$: $k_L(8)-k_L(8-)=1/2$.

It is known that IDS is always continuous for Schrödinger operators on $\mathbf{Z}^d$ with metrically transitive random fields. Theorem 1.1 (1) follows from the result[8] on Anderson localization for H and the ''supersymmetric method'' discussed by Ogurisu.[15,16] The condition that supp $g\subset[-\pi,-c]\cup[c,\pi]$ is required to estimate the derivative of eigenvalues of H^M w.r.t. the magnetic fluxes, which is important to prove the Wegner estimate. To show Anderson localization for H_L, we consider an operator $\psi:l^2(\mathbf{Z}^2)\to l^2(L(\mathbf{Z}^2))_2$ [ψ and $l^2(L(\mathbf{Z}^2))_2$ are defined in Sec. II] with ψ^* its adjoint. Then we have $\sigma(\psi\psi^*)=\sigma(\psi^*\psi)\cup\{0\}$ which is the main ingredient of the proof of (1.4). We show that this relation also ''preserves'' the dense point spectrum which proves Theorem 1.1 (1). Theorem 1.1 (2), (3) is due to the structure of line graphs: there are infinite number of eigenfunctions of finite support, which is used in many areas of mathematical physics. For instance, it is essential to construct an example of the ferromagnetic ground states of the Hubbard model on line graphs.[12] Theorem 1.1 (2) holds for any configuration of magnetic fluxes $\{\Phi(f_x)\}_{x\in\mathbf{Z}^2}$ (Proposition 2.1), and Theorem 1.1 (3) holds whenever $\{\Phi(f_x)\}_{x\in\mathbf{Z}^2}$ are metrically transitive random variables on $(\Omega,\mathcal{F},\mathbf{P})$ (Proposition 2.2). On the other hand, in finite graphs, $\dim\ker(H_L-8)$ becomes different when the magnetic field is turned on (Theorem 3.1).

The next topic in this paper is to discuss the transport properties of H_L. Let

$$\sigma(E)=\lim_{\epsilon\downarrow 0}\sigma_\epsilon(E), \tag{1.6}$$

$$\sigma_\epsilon(E)=\epsilon^2\mathbf{E}\sum_{x\in L(\mathbf{Z}^2)}|x|^2|G_L(E+i\epsilon;0,x)|^2,$$

where $\mathbf{E}$ is the expectation w.r.t. $\mathbf{P}$, $G_L(z)=(H_L-z)^{-1},z\in\mathbf{C}\backslash\mathbf{R}$ is the Green's function of H_L, and $G_L(z;x,y)=\langle\delta_x,(H_L-z)^{-1}\delta_y\rangle_{l^2(L(\mathbf{Z}^2))_2}$, $x,y\in L(\mathbf{Z}^2)$ is its matrix element [$\delta_x(y)=1$ $(y=x),=0$ $(y\neq x)$]. $\sigma(E)$ may be regarded as the electrical conductivity of H_L for the Fermi energy $E\in\mathbf{R}$. A formal derivation of Eq. (1.6) is given by McKane-Stone.[11] Moreover, it is possible to derive Eq. (1.6) by the linear response theory under some technical assumptions,[2] or is

also possible to relate $\sigma(E)$ with the charge transport.[14] Our result is that $\sigma(E)$ is equal to zero, where the Anderson localization holds while $\sigma(E)$ takes a finite and nonzero value on the isolated eigenvalue with infinite multiplicity.

Theorem 1.2: *Under Assumption A, we have the following:*

(1) $\sigma(E)=0$ *for* $E\in I_R$, *where* I_R *is the closed interval appearing in Theorem 1.1;*
(2) $0<\sigma(8)<\infty$.

To prove Theorem 1.2 (1), we show two estimates on the IDS $k_L(E)$ (Wegner estimate and Lifshitz tail) by the corresponding ones on H proved by Klopp *et al.*[8] and the supersymmetric argument. Then, $\sigma(E)=0$ is the natural conclusion of the exponential decay estimate of the Green's function given by the multiscale analysis[6] [this also gives an alternative proof of Theorem 1.1 (1)]. Theorem 1.2 (2) comes from the fact that 8 is an isolated eigenvalue of H_L. We remark that σ is zero or infinity in many cases. For instance, in the case of a 1-dimensional Hamiltonian with periodic potential, we have $\sigma_\epsilon(E)\sim\epsilon^{-1}$ if $E\in\sigma(H)^\circ$ and $\sigma_\epsilon(E)\sim\epsilon^2$, if $E\in\rho(H)$.

In Secs. II, IV, we prove Theorems 1.1, 1.2, respectively. In Sec. III, we show other interesting properties of magnetic Schrödinger operators on line graphs. We study $\dim\ker\psi^*$ for finite graphs and show that it becomes different depending on whether magnetic fluxes vanish or not. This is used to show that 8 is an eigenvalue of H_L with infinite multiplicity and to study the IDS of H_L. Moreover, we show, in addition to Eq. (1.4), the nature of the spectrum is also preserved (Theorem 3.3).

In Appendix A, we discuss the extensions of results by Klopp *et al.*[8] to triangular and hexagonal lattices. Then Theorem 1.1, 1.2 also applies to these graphs, telling us the corresponding spectral and transport properties on their line graphs. In Appendix B, we study a model on a ladder which may be called ''the random graph model.'' By using ideas similar to the one for Theorem 1.1, we show that the Anderson localization holds on the whole spectrum. In Appendix C, we discuss an application of the result on $\dim\ker\psi^*$ (Theorem 3.1) to the cycles (defined in Sec. II) and show the converse of the diamagnetic inequality in some cases.

II. PROOF OF THEOREM 1.1

For a graph G, we denote by $l^2(G)_2$ the Hilbert space which is identical to $l^2(G)$ as a set but with an inner product,

$$\langle f,g\rangle_2=2\sum_{x\in V(G)}\overline{f(x)}g(x),\quad \|f\|_2=\sqrt{\langle f,f\rangle_2}.$$

Let $\psi_G: l^2(G)\to l^2(L(G))_2$ and its adjoint $\psi_G^*: l^2(L(G))_2\to l^2(G)$ be

$$(\psi_G f)(|\alpha|)=\frac{1}{2}\sum_{\beta=\alpha,\bar{\alpha}}e^{i[A(\beta)/2]}f(t(\beta)),\quad \alpha\in\mathcal{E}(G),$$

$$(\psi_G^* F)(x)=\frac{1}{m_G(x)}\sum_{\alpha\in N_x(G)}e^{i[A(\alpha)/2]}F(|\alpha|),\quad x\in V(G).$$

We write $\psi=\psi_{\mathbf{Z}^2}, \psi^*=\psi_{\mathbf{Z}^2}^*$ for simplicity. By direct computation, we have

$$\psi^*\psi=-\frac{1}{8}H+1,\quad \psi\psi^*=-\frac{1}{8}H_L+1. \tag{2.1}$$

Equation (1.2) is used here. In what follows, we say that $E\in\mathbf{R}$ is the generalized eigenvalue of H if there exists u which satisfies $Hu=Eu$ and grows at most polynomial order at infinity. In this case, we call u the generalized eigenfunction of H. Then[8] there exists $R>0$, $\Omega_0(\subset\Omega)$ with $\mathbf{P}(\Omega_0)=1$ such that for $\omega\in\Omega_0$, if $E\in I_R:=[4(1-\cos c/4),4(1-\cos c/4)+R]\cup[4(1+\cos c/4)$

$-R,4(1+\cos c/4)]$ is a generalized eigenvalue, then the corresponding generalized eigenfunction u decays exponentially at infinity. Fix $\omega\in\Omega_0$ and let $E\in I_R$, v be generalized eigenvalue of H_L and corresponding generalized eigenfunction, respectively. Then

$$\psi\psi^* v=\left(-\frac{E}{8}+1\right)v, \tag{2.2}$$

and multiplying ψ^* on both sides, we have $H(\psi^* v)=E(\psi^* v)$ with $\psi^* v$ growing at most polynomially at infinity. Therefore since $\omega\in\Omega_0$, $\psi^* v$ and hence $\psi\psi^* v$ decay exponentially. By (2.2), v also decays exponentially which concludes the proof of Theorem 1.1 (1).

To prove Theorem 1.1 (2), it suffices to show dim ker $\psi^*=\infty$ which follows from the lemma given below. We say a subgraph $C(\subset\mathbf{Z}^2)$ is a cycle of length $N(\geqslant 3)$ if there exists $x_1,x_2,\ldots,x_N\in V(\mathbf{Z}^2)$, $x_j\neq x_k$ for $j\neq k$ such that $\alpha_1=x_1x_2,\alpha_2=x_2x_3,\ldots,\alpha_j=x_jx_{j+1},\ldots,\alpha_{N-1}=x_{N-1}x_N,\alpha_N=x_Nx_1\in\mathcal{E}(\mathbf{Z}^2)$. We say C is even (resp., odd) if its length is even (resp., odd). The flux on C is given by

$$\Phi(C)=\sum_{j=1}^{N}A(\alpha_j)(\mathrm{mod}\,2\pi\,).$$

Lemma 2.1: Let $C(\subset\mathbf{Z}^2)$ be a cycle of even length N. If $\Phi(C)=0$, there exists $F\in\ker\psi^*$ which is supported on $E(C)$.

Proof: Set

$$F(|\alpha_1|)=1,\quad F(|\alpha_2|)=(-1)\exp\left[-i\frac{A(\alpha_2)}{2}-i\frac{A(\alpha_1)}{2}\right],$$

$$F(|\alpha_j|)=(-1)^{j-1}\exp\left[-i\frac{A(\alpha_j)}{2}-i(A(\alpha_2)+\cdots+A(\alpha_{j-1}))-i\frac{A(\alpha_1)}{2}\right],$$

for $3\leqslant j\leqslant N$ and $F(|\beta|)=0$ for $|\beta|\notin E(C)$. A direct computation gives $\psi^*F=0$. □

It is possible to take infinite number of even cycles in $\mathbf{Z}^2$, satisfying the assumption of Lemma 2.1. Thus we proved Theorem 1.1(2). Moreover, we have the following.

Proposition 2.1: For any configuration of $\{\Phi(f_x)\}_{x\in\mathbf{Z}^2}$, we have dim ker $\psi^*=\infty$.

Proof: Let G_x be the subgraph of $\mathbf{Z}^2$ with $V(G_x)=f_x\cup f_{x+e_1}$ and $\mathcal{E}(G_x)=\{yz:y,z\in V(G_x),|y-z|=1\}$. By Theorem 3.1, there exists a function F_x on $E(G_x)$ such that $\psi^*_{G_x}F_x=0$. Let $\tilde{F}_x(|\alpha|)=F_x(|\alpha|)$ for $|\alpha|\in E(G_x)$ and $\tilde{F}_x(|\alpha|)=0$ otherwise. Then $\psi^*\tilde{F}_x=0$. Since $\tilde{F}_x,\tilde{F}_y$ are linearly independent for $|x-y|\geqslant 2$, we have dim ker $\psi^*=\infty$. □

If we have no magnetic flux, i.e., $\Phi(f_x)=0$ for any $x\in\mathbf{Z}^2$, then ker ψ^* contains functions supported on $|\partial f_x|=\{|\alpha|:\alpha\in\partial f_x\}$.[17,15] On the other hand, if $\Phi(f_x)\neq 0$ for any $x\in\mathbf{Z}^2$, the proof of Lemma 2.1 implies that it is impossible and the supports of elements of ker ψ^* must be bigger, while Proposition 2.1 says the edges of two plaquettes $|\partial f_x|\cup|\partial f_{x+e_1}|$ are enough.

Remark 2.1: It is also possible to construct "extended states" for any configuration of magnetic fluxes. To see this, choose the gauge such that the vector potential A vanishes on edges parallel to the x_1-direction: $A(\alpha)=0$ for $\alpha=x(x+e_1)$. Let $|\alpha_{n,m}|\in E(\mathbf{Z}^2)$ be the edge connecting the vertices (n,m) and $(n+1,m)\in V(\mathbf{Z}^2)$. Then $F(|\alpha|)=(-1)^n$ for $|\alpha|=|\alpha_{n,m}|$, and $F(|\alpha|)=0$ otherwise, satisfies the desired properties.

Finally, we study the relationship between IDS of H,H_L.

Proposition 2.2: Suppose $\{\Phi(f_x)\}_{x\in\mathbf{Z}^2}$ are metrically transitive random variables on a probability space $(\Omega,\mathcal{F},\mathbf{P})$. Then IDS of H,H_L satisfy

$$k_L(E)=\begin{cases}\frac{1}{2}k(E) & (E<8),\\ \frac{1}{2}k(E)+\frac{1}{2} & (E\geqslant 8).\end{cases}$$

Proof: Define $\psi_M: l^2(\mathbf{Z}_M^2)\to l^2(L(\mathbf{Z}_M^2))_2$ as ψ restricted on $\mathbf{Z}_M^2$: $\psi_M=\chi_{L(\mathbf{Z}_M^2)}\psi\chi_{\mathbf{Z}_M^2}$ (χ_A is the characteristic function of A) and $\psi_M^*: l^2(L(\mathbf{Z}_M^2))_2\to l^2(\mathbf{Z}_M^2)$ as its adjoint. Let $\tilde{H}^M=8(1-\psi_M^*\psi_M)$, $\tilde{H}_L^M=8(1-\psi_M\psi_M^*)$ be local Hamiltonians of H,H_L, respectively. Since $\dim\ker(\psi_M^*\psi_M-E)=\dim\ker(\psi_M\psi_M^*-E)$ for $E\neq 0$, and since $\sharp V(L(\mathbf{Z}_M^2))-\sharp V(\mathbf{Z}_M^2)\leqslant\dim\ker\psi_M^*\leqslant\sharp V(L(\mathbf{Z}_M^2))-\sharp V(\mathbf{Z}_M^2)+1$ (Theorem 3.1 and Proposition 4.3 in Biggs[4]), we have

$$k_L(E)=\begin{cases}\rho k(E) & (E<8),\\ \rho k(E)+(1-\rho) & (E\geqslant 8),\end{cases}$$

where $\rho=\lim_{M\to\infty}[\sharp V(\mathbf{Z}_M^2)/\sharp V(L(\mathbf{Z}_M^2))=1/2$. □

Proposition 2.2 shows that $k_L(E)$ is discontinuous and thus proves Theorem 1.1 (3). Moreover, it also implies that H_L has an eigenvalue with infinite multiplicity a.s.

Lemma 2.2: Under the assumption of Proposition 2.2, suppose that H_L does not have eigenvalues with infinite multiplicity on an open interval $A(\subset\mathbb{R})$ a.s. Then the IDS of H_L is continuous on A.

Proof: For Borel sets $B(\subset A)$, let

$$I(B):=\lim_{M\to\infty}\frac{1}{\sharp V(L(\mathbf{Z}_M^2))}\sharp\{\text{eigenvalues of }\tilde{H}_L^M\text{ on }B\}.$$

We show $\lim_{\epsilon\to 0}I((a-\epsilon,a+\epsilon))=0$ for $a\in A$. Let $|\alpha|\in E(\mathbf{Z}^2)$. By Birkhoff's ergodic theorem,

$$I(B)=\int_\Omega d\mathbf{P}\int_B\frac{1}{6}\langle dE(\lambda)\delta_{|\alpha|},\delta_{|\alpha|}\rangle_{L(bfZ^2)},\quad\text{a.s.}$$

where $dE(\lambda)$ is the resolution of identity of H_L and

$$\delta_{|\alpha|}(|\beta|)=\begin{cases}1 & (|\beta|=|\alpha|),\\ 0 & (\text{otherwise}),\end{cases}\quad |\beta|\in E(\mathbf{Z}^2).$$

Therefore it suffices to show $I(\{a\})=0$. We consider Lebesgue's decomposition of $dE(\lambda)$ into continuous and singular parts: $dE=dE_c+dE_s$ and let $I(B)=I_c(B)+I_s(B)$ be the corresponding decomposition of $I(B)$. Since dE_c does not have an atom, $I_c(\{a\})=0$. If $a\in\sigma_p(H_L)$, let $\{f_j\}_{j=1}^N$ be the normalized eigenfunctions of H_L corresponding to the eigenvalue a. Then since $\sum_{|\alpha|\in E(\mathbf{Z}_M^2)}6|f_j(|\alpha|)|^2\leqslant 1$,

$$I_s(\{a\})=\lim_{M\to\infty}\frac{1}{\sharp V(L(\mathbf{Z}_M^2))}\sum_{|\alpha|\in E(\mathbf{Z}_M^2)}6\sum_{j=1}^N|f_j(|\alpha|)|^2=0,\quad\text{a.s.}$$

□

III. SOME PROPERTIES ON LINE GRAPHS

In this section, we show some related and interesting properties of magnetic Schrödinger operators on line graphs. First of all, we suppose G is a finite graph and consider the operator $\psi_G^*: l^2(L(G))_2\to l^2(G)$ defined in Sec. II. By definition, $\dim\ker\psi_G^*\geqslant\sharp E(G)-\sharp V(G)$. It is known, if G is bipartite or is an odd cycle and $A(\alpha)=0$ for any $\alpha\in\mathcal{E}(G)$, $\dim\ker\psi_G^*=\sharp E(G)-\sharp V(G)+1$ [Proposition 4.3 in Biggs;[4] a graph G is said to be bipartite if $V(G)$ can be

decomposed into two disjoint subsets: $V(G)=A\cup B, A\cap B=\varnothing$ such that $x,y\in V(G)$ are connected by an edge in $E(G)$ only if $x\in A, y\in B$ or $x\in B, y\in A$]. The following theorem says the situation becomes different when the magnetic flux is turned on.

Theorem 3.1: *Let G be a finite and connected graph without self-loops and multiple edges. Suppose that for some cycle C on G, $\Phi(C)\neq 0$ (resp., π) if C is even (resp., odd). Then* $\dim\ker\psi_G^*=\sharp E(G)-\sharp V(G)$.

When G is a planar graph, $\sharp E(G)-\sharp V(G)=\sharp F(G)-1$ by Euler's formula, where $F(G)$ is the set of faces on G [the faces of a finite planar graph G is the bounded connected components of $\mathbf{R}^2-(V(G)\cup E(G))$ regarding $V(G)\cup E(G)$ as a closed subset of $\mathbf{R}^2$].

Proof: We show $\operatorname{rank}\psi_G^*=\sharp V(G)$. Let $D=\{d_{jk};1\leqslant j\leqslant\sharp V(G),1\leqslant k\leqslant\sharp E(G)\}$ be the $(\sharp V(G))\times(\sharp E(G))$ matrix which is a representation of ψ_G^* on the basis $\{\delta_x\}_{x\in V(G)},\{\delta_{|\alpha|}\}_{|\alpha|\in E(G)}$, where

$$\delta_x(z)=\begin{cases}1 & (z=x),\\ 0 & (\text{otherwise}),\end{cases}\qquad \delta_{|\alpha|}(|\beta|)=\begin{cases}1 & (|\beta|=|\alpha|),\\ 0 & (\text{otherwise}),\end{cases}$$

and let $\{\mathbf{d}_j\}_{j=1}^{\sharp V(G)}(\subset\mathbf{C}^{\sharp E(G)})$ be its row vectors. In what follows, we identify $V(G)$ with the finite set $\{1,\ldots,\sharp V(G)\}$. Suppose that a linear relation is given: $\Sigma_{j=1}^{\sharp V(G)}\beta_j\mathbf{d}_j=\mathbf{0}$, $\beta_j\in\mathbf{C}$. We assume $\beta_h\neq 0$ for some $h\in\{1,\ldots,\sharp V(G)\}$ and show that, for any cycles C on G, $\Phi(C)=0$ (resp., π) if C is even (resp., odd). The supposed linear relation implies that, for $\alpha\in\mathcal{E}(G)$ with $i(\alpha)=k, t(\alpha)=l$ $(k,l\in\{1,\ldots,\sharp V(G)\})$,

$$\beta_l=-\frac{m(l)}{m(k)}e^{iA(\alpha)}\beta_k. \tag{3.1}$$

Therefore, since G is connected, $\beta_h\neq 0$ for some $h\in\{1,\ldots,\sharp V(G)\}$ implies $\beta_k\neq 0$ for any $k\in\{1,\ldots,\sharp V(G)\}$. Let C be a cycle on G of length N. We write $V(C)=\{x_1,\ldots,x_N\}$ and let $\alpha_1=x_1x_2,\ldots,\alpha_j=x_jx_{j+1},\ldots,\alpha_{N-1}=x_{N-1}x_N,\alpha_N=x_Nx_1\in\mathcal{E}(C)$. By (3.1),

$$\beta_{x_{j+1}}=-\frac{m(x_{j+1})}{m(x_j)}e^{iA(\alpha_j)}\beta_{x_j},\quad 1\leqslant j\leqslant N$$

$(x_{N+1}\equiv x_1)$. Since $\beta_k\neq 0$ for any k, we have $(-1)^Ne^{i\Phi(C)}=1$. □

Next, we come back to the case $G=\mathbf{Z}^2$ and we show that, if magnetic fluxes are uniformly away from zero, all elements of $\ker\psi^*$ can be obtained by restricting ψ^* on finite subgraph of $L(\mathbf{Z}^2)$. To be precise, let $\mathbf{Z}_M^2=\{x=(x_1,x_2)\in\mathbf{Z}^2:|x_j|\leqslant M, j=1,2\}$ be the finite box of size $2M+1$ and let

$$N=\cup_{M=1}^{\infty}\ \ker\ \psi_{\mathbf{Z}_M^2}^*$$

be the subspace of $\ker\psi^*$. By Theorem 3.1, $\dim\ker\psi_{\mathbf{Z}_M^2}^*=4M^2-1$. We denote by $\Phi(f)$ the magnetic flux penetrating the face $f\in F(\mathbf{Z}^2)$.

Theorem 3.2: *If $|\Phi(f)|\geqslant c>0$ $(f\in F(\mathbf{Z}^2))$ for some constant $c>0$, then $N=\ker\psi^*$.*

Theorem 3.2 says we can take family of finitely supported elements as a basis of $\ker\psi^*$, whose proof essentially relies on the fact that, because of the magnetic flux, 8 is an isolated point of $\sigma(H_L)$. We prepare the following notations:

$$\chi_M=\chi_{\mathbf{Z}_M^2},\quad \chi_M^L=\chi_{L(\mathbf{Z}_M^2)},$$

$$\psi_M=\chi_M^L\psi\chi_M,\quad \psi_M^*=\chi_M\psi^*\chi_M^L,$$

$$T_M^L=\psi_M\psi_M^*=\chi_M^L\psi\chi_M\psi^*\chi_M^L.$$

We regard ψ_M (resp., ψ_M^*, T_M^L) as an operator on $l^2(\mathbf{Z}_M^2)_2$ (resp. $l^2(L(\mathbf{Z}_M^2))_2$).

Lemma 3.1: For any $M \in \mathbf{N}$, $\psi_M^* \psi_M \geqslant \delta > 0$ *for some* $\delta > 0$.

Proof: By direct computation,

$$(8\psi_M^* \psi_M u)(x) = \sum_{y \in \mathbf{Z}_M^2, |y-x|=1} (u(x) - e^{iA'(x,y)} u(y)), \quad x \in \mathbf{Z}_M^2,$$

where $A'(x,y) = A(x,y) + \pi$. Then ($\mathcal{E}_M = \mathcal{E}(\mathbf{Z}_M^2)$ [resp., $\mathcal{F}_M = F(\mathbf{Z}_M^2)$] is the set of directed edges (resp., faces) on $\mathbf{Z}_M^2$),

$$\begin{aligned}\langle u, 8\psi_M^* \psi_M u \rangle_2 &= \sum_{e \in \mathcal{E}_M} |u(o(e)) - e^{iA'(e)} u(t(e))|^2 \\ &\geqslant \sum_{f \in \mathcal{F}_M} \sum_{e \in \partial f} |u(o(e)) - e^{iA'(e)} u(t(e))|^2 \\ &\geqslant 2 \sum_{f \in \mathcal{F}_M} \left(1 - \cos \frac{\Phi(f)}{4}\right) \sum_{x \in f} |u(x)|^2 = 2 \sum_{x \in \mathbf{Z}_M^2} W_\Phi(x) |u(x)|^2,\end{aligned}$$

where $W_\Phi(x) = \Sigma_{x \in \partial f, f \in \mathcal{F}_M} (1 - \cos[\Phi(f)/4]) > 0$. □

Proof of Theorem 3.2: We suppose that there exists $\varphi \in \ker \psi^*$ such that $\|\varphi\|_2 = 1$, $\varphi \perp N$ and would like to deduce a contradiction. Let

$$\epsilon = \min\left\{\frac{\delta}{2}, \frac{1}{2}\right\}, \quad \varphi_M = \chi_M^L \varphi \in l^2(L(\mathbf{Z}_M^2))_2.$$

Since $\varphi \in \ker \psi^*$ and $T_M^L \varphi_M = \chi_M^L \psi \chi_M \psi^* \chi_M^L \varphi$, $\|T_M^L \varphi_M\|_2 < \epsilon^2$ for some $M \in \mathbf{N}$. We can assume $\|\varphi_M\|_2 > 1 - \epsilon$ by taking $M \in \mathbf{N}$ sufficiently large if necessary. Let $\tilde{T}_M^L = T_M^L|_{(\ker T_M^L)^\perp}$ be the restriction of T_M^L on $(\ker T_M^L)^\perp$. Since $\varphi_M \in (\ker \psi_{\mathbf{Z}_M^2}^*)^\perp \subset (\ker T_M^L)^\perp$, we have $\|\tilde{T}_M^L \varphi_M\|_2 = \|T_M^L \varphi_M\|_2 < \epsilon^2$. Suppose $(-\epsilon, \epsilon) \subset \rho(\tilde{T}_M^L)$. Then

$$1 - \epsilon < \|(\tilde{T}_M^L)^{-1} \tilde{T}_M^L \varphi_M\|_2 \leqslant \frac{1}{\epsilon} \cdot \epsilon^2 = \epsilon,$$

which implies $1 < 2\epsilon$ and contradicts the definition of ϵ. Hence $(-\epsilon, \epsilon) \cap \sigma(\tilde{T}_M^L) \neq \varnothing$ and let $\lambda \in (-\epsilon, \epsilon) \cap \sigma(\tilde{T}_M^L)$ be an eigenvalue of $\tilde{T}_M^L$ with corresponding eigenvector $f \in (\ker T_M^L)^\perp, \|f\|_2 = 1$. We then have

$$T_M^L f = \psi_M \psi_M^* f = \lambda f, \tag{3.2}$$

$$\psi_M^* \psi_M \psi_M^* f = \lambda \psi_M^* f. \tag{3.3}$$

Because $f \in (\ker T_M^L)^\perp$, $\lambda \neq 0$. Then by (3.2), we must have $\psi_M^* f \neq 0$, which, by (3.3), contradicts Lemma 3.1. □

Remark 3.1: Theorem 3.2 can easily be extended to any planar infinite graph G satisfying [$n(f)$ *is the number of vertices in* $f \in F(G)$] *(i)* $\max_{f \in F(G)} n(f) < \infty$; *(ii) for some* $c > 0$, $|\Phi(f)| > c$ [*resp.*, $|\Phi(f) - \pi| > c$] *if* $n(f)$ *is even (resp., odd).*

In the rest of this section, we show that each component of the spectrum and the corresponding spectral subspaces are also related in Eq. (1.4), which holds in general situations. Let $\mathcal{H}^G, \mathcal{H}^L$ be Hilbert spaces and suppose that a bounded operator $\psi: \mathcal{H}^G \to \mathcal{H}^L$ is given with $\psi^*: \mathcal{H}^L \to \mathcal{H}^G$ its adjoint. Let $H_G = \psi^* \psi, H_L = \psi \psi^*$ be bounded self-adjoint operators on $\mathcal{H}^G, \mathcal{H}^L$ and let

$$\mathcal{H}^\sharp = \mathcal{H}^\sharp_{\mathrm{ac}} \oplus \mathcal{H}^\sharp_{\mathrm{sc}} \oplus \mathcal{H}^\sharp_{pp},$$

$$\mathcal{H}^\sharp_c = \mathcal{H}^\sharp_{\mathrm{ac}} \oplus \mathcal{H}^\sharp_{\mathrm{sc}}, \quad \mathcal{H}^\sharp_{\mathrm{sing}} = \mathcal{H}^\sharp_{\mathrm{sc}} \oplus \mathcal{H}^\sharp_{pp}, \quad \sharp = G, L,$$

be the decomposition of $\mathcal{H}^\sharp$ into the spectral subspaces w.r. t. $H^\sharp$ $(\sharp = G, L)$. $\mathcal{H}^\sharp_{\mathrm{ac}}$ (resp., $\mathcal{H}^\sharp_{\mathrm{sc}}, \mathcal{H}^\sharp_{pp}$) stands for the absolutely continuous (resp., singular continuous, pure point) subspace. We assume that

$$\ker\ \psi = \{0\}, \quad \ker\ \psi^* \neq \{0\},$$

which are true if $\mathcal{H}^G = l^2(G), \mathcal{H}^L = l^2(L(G))_2, \psi = \psi_G$ for an infinite graph G which is not a tree. We note that, under this assumption, ψ, ψ^* can be regarded as maps,

$$\psi : \mathcal{H}^G \to (\ker\ \psi^*)^\perp, \quad \psi^* : (\ker\ \psi^*)^\perp \to \mathcal{H}^G,$$

with bounded inverses. Our assertion is that each component of spectrum and spectral subspaces are related as follows.

Theorem 3.3:

$$(1) \quad \sigma_{\mathrm{ac}}(H_G) = \sigma_{\mathrm{ac}}(H_L), \quad \psi \mathcal{H}^G_{\mathrm{ac}} = \mathcal{H}^L_{\mathrm{ac}}, \quad \mathcal{H}^G_{\mathrm{ac}} = \psi^* \mathcal{H}^L_{\mathrm{ac}},$$

$$(2) \quad \sigma_{\mathrm{sc}}(H_G) = \sigma_{\mathrm{sc}}(H_L), \quad \psi \mathcal{H}^G_{\mathrm{sc}} = \mathcal{H}^L_{\mathrm{sc}}, \quad \mathcal{H}^G_{\mathrm{sc}} = \psi^* \mathcal{H}^L_{\mathrm{sc}},$$

$$(3) \quad \sigma_{pp}(H_L) = \sigma_{pp}(H_G) \cup \{0\}, \quad \psi \mathcal{H}^G_{pp} = \mathcal{H}^L_{pp} \cap (\ker\ \psi^*)^\perp,$$

$$\psi^* (\mathcal{H}^L_{pp} \cap (\ker\ \psi^*)^\perp) = \mathcal{H}^G_{pp},$$

where $\sigma_{pp}(H) = \overline{\{\text{eigenvalues of } H\}}$.

As a preliminary of the proof, we note the following.

Lemma 3.2: Let $P^\sharp(\cdot)$ *be the spectral projection of* $H^\sharp$ $(\sharp = G, L)$. *Then for any* $A \in \mathcal{B}$ ($\mathcal{B}$ *is the Borel set in* **R**),

$$\psi P^G(A) = P^L(A)\psi, \quad P^G(A)\psi^* = \psi^* P^L(A).$$

Proof: By definition of H^G, H^L and the boundedness of $\psi, \psi H^n_G = H^n_L \psi$. Then $\psi e^{-tH_G} = e^{-tH_L}\psi$ and by taking the Laplace transform, we have $\psi(H_G - z)^{-1} = (H_L - z)^{-1}\psi$, $z \in \mathbf{C} \setminus \mathbf{R}$. By Stone's formula and regularity of the spectral measure, we have the first assertion. The second one is proved similarly. □

Proof of Theorem 3.3:

(1) We show

$$\psi P^G_{\mathrm{ac}}(A) \mathcal{H}^G = P^L_{\mathrm{ac}}(A) \mathcal{H}^L, \tag{3.4}$$

for any $A \in \mathcal{B}$. $P^\sharp_{\mathrm{ac}}(\cdot)$ is the spectral projection of the absolutely continuous part of $H^\sharp$ [$P^\sharp_{\mathrm{sc}}(\cdot)$ is defined in the same way.] $\sigma_{\mathrm{ac}}(H_G) = \sigma_{\mathrm{ac}}(H_L)$ follows from (3.4). Let $f \in P^G_{\mathrm{ac}}(A)\mathcal{H}^G$. By Lemma 3.2,

$$\langle \psi P^G(A \cap B) f, F \rangle_L = \langle P^L(A \cap B) \psi f, F \rangle_L,$$

for any $F \in \mathcal{H}^L, B \in \mathcal{B}$. $\langle \cdot, \cdot \rangle_\sharp$ is the inner product on $\mathcal{H}^\sharp$ $(\sharp = G, L)$. By the definition of f, we have

$$\langle \psi P^G_{\mathrm{ac}}(B) f, F \rangle_L = \langle P^L(B) P^L(A) \psi f, F \rangle_L.$$

$LHS = 0$ whenever $|B| = 0$ ($|\cdot|$ is the Lebesgue measure on **R**). Letting $F = P^L(A)\psi f$,

$$\langle P^L(B)P^L(A)\psi f, P^L(A)\psi f\rangle_L = 0, \text{ if } |B| = 0.$$

Since $P^L(A)\psi f = \psi P^G(A)f = \psi f$, we have $\psi f \in P^L_{\rm ac}(A)\mathcal{H}^L$.

Conversely, let $G \in P^L_{\rm ac}(A)\mathcal{H}^L (\subset (\ker\psi^*)^\perp)$, $f = \psi^{-1}G$. For any $F \in \mathcal{H}^L, B \in \mathcal{B}$, we have

$$\langle P^L(A\cap B)G, F\rangle_L = \langle \psi P^G(A\cap B)f, F\rangle_L .$$

By the definition of G, we have

$$\langle P^L(B)\psi f, F\rangle_L = \langle P^G(B)P^G(A)f, \psi^* F\rangle_G .$$

$LHS = 0$ if $|B| = 0$. Substituting $F = (\psi^*)^{-1}P^G(A)f$, we have $P^G(A)f \in P^G_{\rm ac}(A)\mathcal{H}^G$. Since $\psi P^G(A)f = G$, we showed $G \in \psi P^G_{\rm ac}(A)\mathcal{H}^G$, proving (3.4). $\mathcal{H}^G_{\rm ac} = \psi^*\mathcal{H}^L_{\rm ac}$ follows similarly.

(2) As in the proof of (1), we show

$$\psi P^G_{\rm sc}(B)\mathcal{H}^G = P^L_{\rm sc}(B)\mathcal{H}^L, \tag{3.5}$$

for any $B \in \mathcal{B}$ which also proves $\sigma_{\rm sc}(H^G) = \sigma_{\rm sc}(H^L)$. To prove $\psi P^G_{\rm sc}(B)\mathcal{H}^G \subset P^L_{\rm sc}(B)\mathcal{H}^L$, let $f \in P^G_{\rm sc}(B)\mathcal{H}^G$. Without loss of generality, we can suppose $f \neq 0$. Let

$$\mu^f_{\rm sc}(\cdot) = \langle P^G(\cdot)f, f\rangle_G = \langle P^G(\cdot\cap B)f, f\rangle_G$$

be a singular continuous measure whose support $B' = \text{supp}\ \mu^f_{\rm sc}$ satisfies $|B'| = 0$. For any $A \in \mathcal{B}, F \in \mathcal{H}^L$,

$$\langle \psi^* P^L(A\backslash B')F, f\rangle_G = \langle P^G(A\backslash B')\psi^* F, f\rangle_G = 0.$$

Substituting $F = \psi f$ in LHS, we have $\langle P^L(A\backslash B')\psi f, \psi f\rangle_L = 0$. Moreover, substituting $G = (\psi^*)^{-1}f$, in the equality $\langle P^L(B')\psi f, G\rangle_L = \langle \psi P^G(B')f, G\rangle_L$, we have $P^L(B')\psi f \neq 0$ implying $\psi f \in \mathcal{H}^L_{\rm sing}$. On the other hand for any $b \in B'$, $P^L(\{b\})\psi f = \psi P^G(\{b\})f = 0$ implying $\psi f \in \mathcal{H}^L_c$. Thus $\psi f \in P^L_{\rm sc}(B)\mathcal{H}^L$.

Conversely, let $F \in P^L_{\rm sc}(B)\mathcal{H}^L (\subset (\ker\psi^*)^\perp)$, $F \neq 0$, $f = \psi^{-1}F$ and let

$$\mu^F_{\rm sc}(\cdot) = \langle P^L(\cdot)F, F\rangle_L = \langle P^L(\cdot\cap B)F, F\rangle_L ,$$

with supp $\mu^F_{\rm sc} = B'$, $|B'| = 0$. For any $A \in \mathcal{B}, G \in \mathcal{H}^L$,

$$\langle P^G(A\backslash B')f, \psi^* G\rangle_G = \langle P^L(A\backslash B')F, G\rangle_L = 0.$$

Substituting $G = (\psi^*)^{-1}f$, we have $\langle P^G(A\backslash B')f, f\rangle_G = 0$. Since $\langle P^G(B')f, \psi^* F\rangle_G = \langle P^L(B')F, F\rangle_L \neq 0$, $P^G(B')f \neq 0$ so that $f \in \mathcal{H}^G_{\rm sing}$. For $b \in B'$, $\psi P^G(\{b\})f = P^L(\{b\})F = 0$ and together with $\ker\psi = \{0\}$, we have $P^G(\{b\})f = 0$ which implies $f \in \mathcal{H}^G_{\rm sc}$. Thus $f \in P^G_{\rm sc}(B)\mathcal{H}^G$ proving (3.5). $\mathcal{H}^G_{\rm sc} = \psi^*\mathcal{H}^L_{\rm sc}$ follows similarly.

(3) Let

$$\sigma_p(H^\sharp) = \{\text{eigenvalues of } H^\sharp\}, \quad \mathcal{H}^\sharp_p = \{\text{eigenfunctions of } H^\sharp\}, \quad \sharp = G, L.$$

Then it is easy to see that

$$\sigma_p(H^L) = \sigma_p(H^G) \cup \{0\},$$

$$\psi\mathcal{H}^G_p = \mathcal{H}^L_p \cap (\ker\ \psi^*)^\perp, \quad \psi^*(\mathcal{H}^L_p \cap (\ker\ \psi^*)^\perp) = \mathcal{H}^G_p .$$

By taking closure, we have the desired relations. □

IV. PROOF OF THEOREM 1.2

To prove Theorem 1.2 (2), we show the Wegner estimate and Lifshitz tail to confirm the assumption of multiscale analysis. By the relation $\sigma(\psi_{\mathbf{Z}_M^2}\psi^*_{\mathbf{Z}_M^2})=\sigma(\psi^*_{\mathbf{Z}_M^2}\psi_{\mathbf{Z}_M^2})\cup\{0\}$ and the Wegner estimate proved by Klopp *et al.*,[8] we have the following: there exists a constant $C>0$ such that

$$\mathbf{P}\{\text{dist}\ (E,\sigma(H_L^M))<\epsilon\}\leqslant C\epsilon M^2, \tag{4.1}$$

for $E\in I_R=[4(1-\cos c/4),4(1-\cos c/4)+R]\cup[4(1+\cos c/4)-R,4(1+\cos c/4)]$ and for any $\epsilon>0$, $M\in\mathbf{N}$. We used the fact that the operator of rank of order M does not affect the inequality (4.1). Similarly, we can show the Lifshitz tail estimate:

$$\limsup_{E\downarrow E_0}\frac{\log(-\log k_L(E))}{\log(E-E_0)}\leqslant -1, \tag{4.2}$$

where $E_0=4(1-\cos c/4)$. Estimates (4.1), (4.2) allow us to use the standard multiscale analysis to conclude that, for $E\in I_R$ and any $p\in\mathbf{N}$,

$$\mathbf{P}\left\{\sup_{\epsilon\neq 0}|G_L^M(E+i\epsilon;0,x)|\leqslant e^{\gamma(M-|x|)}\right\}\geqslant 1-C_pM^{-p}$$

for some $\gamma>0,C_p>0$ and for any sufficiently large $M\in\mathbf{N}$. $G_L^M(z;x,y)=\langle\delta_x,(H_L^M-z)^{-1}\delta_y\rangle_2$. Then $\sigma(E)=0$ follows from Theorem 1.1 in Frölich–Spencer.[6]

To prove Theorem 1.2 (2), let P be the orthogonal projection corresponding to the eigenvalue $E_0=8$. Then (dE_λ is the resolution of the identity)

$$\sigma_\epsilon(E_0)=\epsilon^2\sum_{x\in L(\mathbf{Z}^2)}|x|^2\mathbf{E}\left|\frac{1}{-i\epsilon}\langle 0|P|x\rangle+\int_{\{\lambda\neq E_0\}}\frac{1}{\lambda-(E_0+i\epsilon)}\langle 0|dE_\lambda|x\rangle\right|^2$$

$$=\sum_{x\in L(\mathbf{Z}^2)}|x|^2\mathbf{E}|i\langle 0|P|x\rangle+\epsilon G'(E_0+i\epsilon;0,x)|^2,$$

where $G'(z)=(QH_LQ-z)^{-1},Q=I-P$. Since E_0 is an isolated eigenvalue, the matrix element $P(x,y)$ of P decays exponentially as $|x-y|\to\infty$ and so is Q. Therefore the matrix element of QH_LQ decays exponentially. Then by a version of the Combes–Thomas method[1] and by $E_0\in\rho(QH_LQ)$, $G'(E_0+i\epsilon;0,x)$ decays exponentially as $|x|\to\infty$ uniformly w.r.t. $\epsilon>0$ and $\omega\in\Omega$. Hence

$$\sigma(E_0)=\sum_{x\in L(\mathbf{Z}^2)}|x|^2\mathbf{E}|\langle 0|P|x\rangle|^2<\infty.$$

The rhs of the above equation is called the localization length[3] which is nonzero by the covariance of $P(x,y)$. Thus Theorem 1.2 (2) is proved.

APPENDIX A

In this appendix, we discuss some examples in which the argument by Klopp *et al.*[8] applies. In all cases presented below, we can prove that the Anderson localization holds on spectral edges.

Example 1 [another distribution of random vector potential on $\mathbf{Z}^2$]: In this example, we consider another distribution of the random vector potential on $\mathbf{Z}^2$ as described in Fig. 1. These vector potentials $\{\varphi_n\}$ are assumed to be i.i.d. random variables satisfying Assumption A. We then have

$$\sigma(H)=\left[4\left(1-\cos\frac{c}{4}\right),4\left(1+\cos\frac{c}{4}\right)\right],\quad \text{a.s.}$$

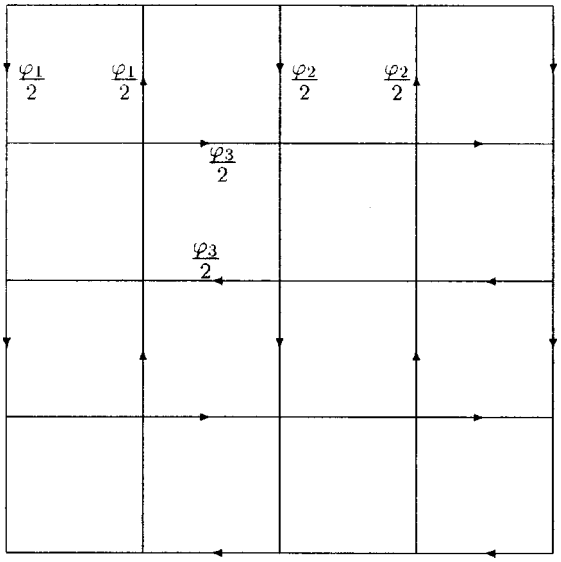

FIG. 1. Square lattice.

Example 2 [triangular lattice]: For the triangular lattice, we put the random vector potential on diagonal edges, as indicated in the Fig. 2. The Hamiltonian H is the same as defined in (1.1). Then we have the ''staggered magnetic flux'' as that on $\mathbf{Z}^2$ discussed in Sec. I. Under Assumption A, the spectrum of H is given by

$$\sigma(H)=\left[6\left(1-\cos\frac{c}{3}\right),6\left(1+\cos\frac{c}{3}\right)\right], \quad \text{a.s.}$$

Example 3 [hexagonal lattice]: To have the ''staggered magnetic flux'' on the hexagonal lattice, we put the random vector potential $\{\varphi_n\}$, as indicated in Fig. 3. Note that there are some faces with no magnetic fluxes (marked as a $\times$ in Fig. 2). Under Assumption A, we have

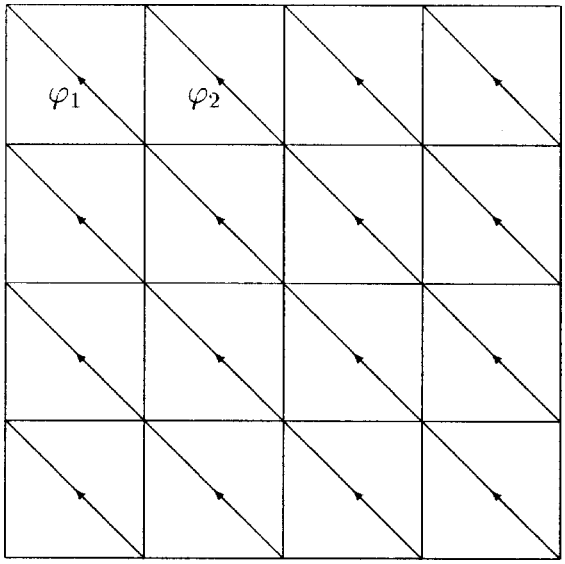

FIG. 2. Triangular lattice.

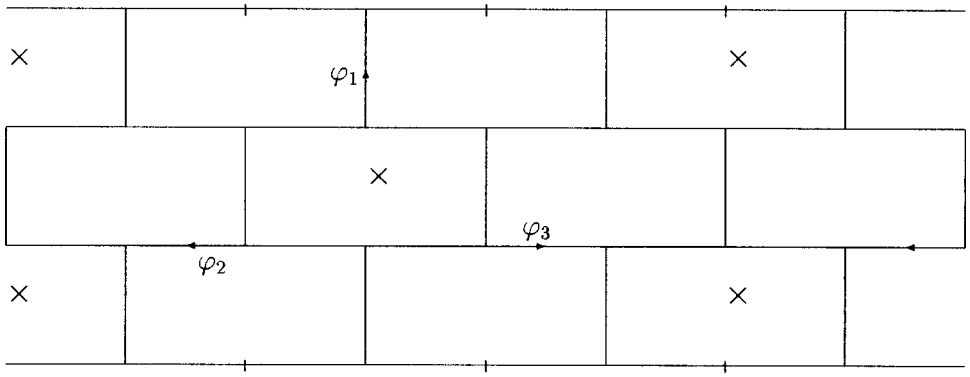

FIG. 3. Hexagonal lattice.

$$\sigma(H)=\left[3-2\sqrt{\frac{5}{4}+\cos\frac{c}{3}},3+2\sqrt{\frac{5}{4}+\cos\frac{c}{3}}\right], \quad \text{a.s.}$$

Furthermore, by using the same argument as in the proof of Theorem 1.1, we have the corresponding results for their line graphs [$d=4$ (resp., $d=6,\ 3$) for the square (resp., triangular, hexagonal) lattice]. That is,

(1) $\sigma(H_L)=\sigma(H)\cup\{2d\}$, a.s., with Anderson localization on spectral edges;
(2) $2d$ is an eigenvalue of H_L with infinite multiplicity;
(3) $k_L(E)$ is discontinuous at $E=2d$: $k_L(2d)-k_L(2d-)=1-2/d$.

APPENDIX B

In this appendix, we study a model which is different from H_L discussed in Theorem 1.1, but for which similar argument works. Let $\Lambda=\{(x_1,x_2):x_1\in\mathbf{Z},x_2=\pm 1\}$ be the ladder and let

$$(H_\Lambda u)(x)=u(x+e_1)+u(x-e_1)+a_\omega(x_1)u(x\pm e_2), \quad u\in l^2(\Lambda),x_2=\mp 1.$$

We suppose $\{a_\omega(x_1)\}_{x_1\in\mathbf{Z}}$ satisfy the following conditions.

Assumption B: $\{a_\omega(x_1)\}_{x_1\in\mathbf{Z}}$ *are real-valued i.i.d. random variables on a probability space* $(\Omega, \mathcal{F}, \mathbf{P})$ *such that the common distribution* ν *is of the Bernoulli type:*

$$\nu=t\delta(p)+(1-t)\delta(q), \quad t\in(0,1), \quad p,q\in\mathbf{R}, \quad p\neq q.$$

$\delta(a)$ is the delta measure supported on $a\in\mathbf{R}$. When $p=1,q=-1$, H_Λ can be regarded as the Bernoulli random flux model while, if $p=0,q=1$, H_Λ can be regarded as a free Hamiltonian on a random graph.

Theorem 6.1: *Under Assumption B, we have the following.*

(1) $\sigma(H_\Lambda)=J\cup(-J)$ *a.s., where* $J=[-2,2]+\{p,q\}$, *which is pure point with exponentially decaying eigenfunctions.*

(2) If $|p|$ *is sufficiently large, then the density of states* (*the Lebesgue–Stieltjes measure corresponding to IDS of* H_Λ) *has a nontrivial singular component.*

Remark 6.1: Although the one-dimensional technique is applicable to H_Λ, *the theory of Lyapunov exponent is complicated in this case.*[7]

The idea of the proof of Theorem 6.1 is to make use of the bipartite structure of Λ which allows us to reduce the problem to that in a one-dimensional Hamiltonian with a Bernoulli-type random potential. Then Theorem 6.1 follows from the result of Anderson localization on such Hamiltonians by Carmona–Klein–Martinelli.[5] It seems that this argument works only for a ladder.

Proof: For $x \in \mathbf{Z}$, we write $x_+ = (x,1), x_- = (x,-1) \in \Lambda$. Let

$$(h(\{a(x)\})f)(x) = f(x-1) + f(x+1) + a(x)f(x), \quad x \in \mathbf{Z}$$

be the Hamiltonian on $l^2(\mathbf{Z})$ with potential $a(x)$. By Theorem 2.1 in Carmona–Klein–Martinelli,[5] there exists $\Omega_0 (\subset \Omega)$ with $\mathbf{P}(\Omega_0) = 1$ such that for $\omega \in \Omega_0$, $h(\{a_\omega(x)\})$ has eigenvalues $\{E_j\}_{j \in \mathbf{N}}$ with $\overline{\{E_j\}}_{j \in \mathbf{N}} = J$ and the set of normalized and exponentially decaying eigenfunctions $\{f_j\}_{j \in \mathbf{N}}$ is a C.O.N.S. on $l^2(\mathbf{Z})$. Fix $\omega \in \Omega_0$ and define functions g_j^1, g_j^2 on Λ,

$$g_j^1(x_\pm) = f_j(x),$$

$$g_j^2(x_+) = (-1)^x f_j(x), \quad g_j^2(x_-) = (-1)^{x-1} f_j(x), \quad j \in \mathbf{N}.$$

It is straightforward to see $H_\Lambda g_j^1 = E_j g_j^1$, $H_\Lambda g_j^2 = -E_j g_j^2$, implying $E_j, -E_j$ are eigenvalues of H_Λ with exponentially decaying eigenfunctions. It suffices to show that $\{g_j^1, g_j^2\}_{j \in \mathbf{N}}$ is C.O.S. on $l^2(\Lambda)$. That they are orthogonal to each other is clear. To see that $\{g_j^1, g_j^2\}_{j \in \mathbf{N}}$ is complete, we decompose $\Lambda = A \cup B$, $A \cap B = \varnothing$ where

$$A = \{x_- : x \text{ is odd}\} \cup \{x_+ : x \text{ is even}\},$$

$$B = \{x_+ : x \text{ is odd}\} \cup \{x_- : x \text{ is even}\}.$$

Then we have

$$g_j^1(y) + g_j^2(y) = \begin{cases} 2 f_j(y_1) & (y \in A), \\ 0 & (y \in B), \end{cases}$$

$$g_j^1(y) - g_j^2(y) = \begin{cases} 0 & (y \in A), \\ 2 f_j(y_1) & (y \in B), \end{cases}$$

and from which the completeness of $\{g_j^1, g_j^2\}_{j \in \mathbf{N}}$ on $l^2(\Lambda)$ follows.

To prove Theorem 6.1 (2), let $\Lambda_M = \{x = (x_1, x_2) \in \Lambda : |x_1| \leqslant M\}$, $\mathbf{Z}_M = \{x \in \mathbf{Z} : |x| \leqslant M\}$ and let $H_{\Lambda_M} = H|_{\Lambda_M} (= \chi_{\Lambda_M} H \chi_{\Lambda_M})$, $h_M = h|_{\mathbf{Z}_M}$ be local Hamiltonians on Λ_M, $\mathbf{Z}_M$, respectively. We define the IDS of H_Λ, h as

$$k_{H_\Lambda}(E) = \lim_{M \to \infty} \frac{1}{\sharp V(\Lambda_M)} \sharp\{\text{eigenvalues of } H_{\Lambda_M} \leqslant E\},$$

$$k_h(E) = \lim_{M \to \infty} \frac{1}{2M+1} \sharp\{\text{eigenvalues of } h_M \leqslant E\}.$$

Since $\lambda \in \sigma(H_{\Lambda_M}) \Leftrightarrow \lambda \in \sigma(h_M)$ or $-\lambda \in \sigma(h_M)$, we have

$$k_{H_\Lambda}(E) = \frac{1}{2} k_h(E) - \frac{1}{2} k_h(-E) + \frac{1}{2}.$$

Theorem 6.1 (2) then follows from Theorem 2.1 in Carmona-Klein–Martinelli.[5] □

APPENDIX C

In this appendix, we consider an application of Theorem 3.1. Let C be the cycle of length N : $V(C) = \{1, \ldots, N\}$, $\mathcal{E}(C) = \{\alpha_j = j(j+1), \ \overline{\alpha_j} = (j+1)j : 1 \leqslant j \leqslant N\}$ $(N+1 \equiv 1)$ and let

$$(H_C f)(x) = t_{|\alpha_{x-1}|} e^{-iA(\alpha_{x-1})} f(x-1) + t_{|\alpha_x|} e^{iA(\alpha_x)} f(x+1) + V(x) f(x),$$

where $t_{|\alpha_x|}>0$, $V(x)\in\mathbf{R}$ $(x=1,\ldots,N,\ \ x+N\equiv x)$. Eigenvalues of H_C are determined by the magnetic flux on C: $\Phi(C)=\Sigma_{x=1}^{N}A(\alpha_x)\ \ (\mathrm{mod}\ 2\pi)$. Let $E(\Phi(C))$ be the lowest eigenvalue of H_C. Then the usual diamagnetic inequality says

$$E(\Phi(C))\geqslant E(\Phi_0),\quad \text{where}\quad \Phi_0=\begin{cases}0 & (N\text{: even}),\\ \pi & (N\text{: odd}).\end{cases}$$

Note that diamagnetic inequality is reversed on the Hubbard model in some cases because of the Fermi statistics (e.g., Lieb–Loss[9] and references therein). However, the converse statement, that is $E(\Phi(C))>E(\Phi_0)$ if $\Phi(C)\neq\Phi_0$ is not known to hold in general except the trivial case where $t_{|\alpha_x|}$ is constant and $V(x)\equiv 0$. Some examples (in the Hubbard model) in which $E(\Phi(C))=E(\Phi_0)$ for some $\Phi(C)\neq\Phi_0$ are discussed in Nakano.[13]

Theorem 7.1: *Suppose the potential V satisfies*

$$V(x)=t_{|\alpha_{x-1}|}+t_{|\alpha_x|},$$

then $E(\Phi_C)>E(\Phi_0)=0$ *if* $\Phi_C\neq\Phi_0$.

In particular, if $\{t_{|\alpha_x|}\}$ is period 2 (i.e., $t_{|\alpha_x|}=t_{|\alpha_{x+2}|}$), V is required to be constant.

Proof: We identify $L(C)$ with C and regard H_C as an operator on $l^2(L(C))_2$. Let $\psi_C^*:l^2(L(C))_2\to l^2(C)$ be

$$(\psi_C^*F)(x)=\sqrt{t_{|\alpha_{x-1}|}}\sum_{\alpha\in N_x(C)}e^{iA(\alpha)/2}F(|\alpha|),\quad F\in l^2(L(C))_2,$$

with ψ_C its adjoint. Then $\psi_C\psi_C^*$ is unitarily equivalent to H_C, for they have the same flux on C. Since $\psi_C\psi_C^*F=0\Leftrightarrow\psi_C^*F=0$, the conclusion follows from Theorem 3.1. □

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 11 NOVEMBER 2003

Radon–Nikodym derivatives of quantum operations

Maxim Raginsky[a)]
Center for Photonic Communication and Computing, Department of Electrical and Computer Engineering, Northwestern University, Evanston, Illinois 60208-3118

(Received 9 April 2003; accepted 23 July 2003)

Given a completely positive (CP) map T, there is a theorem of the Radon–Nikodym type [W. B. Arveson, Acta Math. **123**, 141 (1969); V. P. Belavkin and P. Staszewski, Rep. Math. Phys. **24**, 49 (1986)] that completely characterizes all CP maps S such that $T-S$ is also a CP map. This theorem is reviewed, and several alternative formulations are given along the way. We then use the Radon–Nikodym formalism to study the structure of order intervals of quantum operations, as well as a certain one-to-one correspondence between CP maps and positive operators, already fruitfully exploited in many quantum information-theoretic treatments. We also comment on how the Radon–Nikodym theorem can be used to derive norm estimates for differences of CP maps in general, and of quantum operations in particular. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1615697]

I. INTRODUCTION

In the mathematical framework of quantum information theory,[1] all admissible devices are modeled by the so-called quantum operations[2,3]—that is, completely positive linear contractions on the algebra of observables of the physical system under consideration. Thus it is of paramount importance to have at one's disposal a good analysis toolkit for completely positive (CP) maps.

There are many useful structure theorems for CP maps. The two best known ones, due to Stinespring[4] and Kraus,[3] are *de rigueur* in virtually all quantum information-theoretic treatments. These theorems are significant because each of them states that a given map is CP if and only if it is expressible in a certain canonical form. However, in many applications we need to consider whole families of CP maps. This necessitates the introduction of comparison tools for CP maps, e.g., when the family of CP maps in question admits some sort of (partial) order.

Mathematically, the set of all CP maps between two algebras of observables is a cone that can be partially ordered in the following natural way. If S and T are two CP maps, we write $S \leqslant T$ if $T-S$ is CP as well. This partial order comes up in, e.g., the problem of distinguishing between two known CP maps with given *a priori* probabilities under the constraint that the average probability of error is minimized.[5] A typical way of dealing with partially ordered cones is to exhibit a correspondence between the cone's order and a partial order of some ''simpler'' objects. This is accomplished by means of theorems of the Radon–Nikodym type, as in the case of, e.g., partial ordering of positive measures or positive linear functionals. There are a number of Radon–Nikodym theorems for CP maps (see, e.g., the work of Arveson,[6] Belavkin and Staszewski,[7] Davies,[2] Holevo,[8] Ozawa,[9] and Parthasarathy[10]) that differ widely in scope and in generality. Thus, the results of Davies, Ozawa, and Holevo have to do with Radon–Nikodym derivatives of CP instruments[9] with respect to scalar measures. On the other hand, ideas common to the Arveson and Belavkin–Staszewski theorems, with further developments by Parthasarathy, are directly applicable to the partial ordering of CP maps described above, and will therefore be the focus of the present article. More specifically, we will demonstrate that certain problems encountered in quantum information-theoretic settings that involve characterization and comparison of CP maps, are best understood in this Radon–Nikodym framework.

The paper is organized as follows. We summarize the salient facts on CP maps and quantum

a)Electronic mail: maxim@ece.northwestern.edu

operations in Sec. II. In Sec. III we review the Arveson–Belavkin–Staszewski formulation of the Radon–Nikodym theorem for CP maps and state several alternative, but equivalent, versions. The Radon–Nikodym machinery is then applied to the following problems: partial ordering of quantum operations (Sec. IV), characterization of quantum operations by means of positive operators (Sec. V), and estimating norms of differences of CP maps (Sec. VI). Finally some concluding remarks are made in Sec. VII.

II. PRELIMINARIES

A. Completely positive maps

1. Definitions

Let $\mathcal{A}$ and $\mathcal{B}$ be C*-algebras; denote by $\mathcal{A}^+$ the cone of positive elements of $\mathcal{A}$. A linear map $T:\mathcal{A}\to\mathcal{B}$ is called *positive* if $T(\mathcal{A}^+)\subseteq\mathcal{B}^+$. Given some $n\in\mathbb{N}$, let $\mathcal{M}_n$ be the algebra of $n\times n$ complex matrices. The map T is called *n-positive* if the induced map $T\otimes\mathrm{id}_n:\mathcal{A}\otimes\mathcal{M}_n\to\mathcal{B}\otimes\mathcal{M}_n$ is positive, and *completely positive* if it is n-positive for all $n\in\mathbb{N}$.

One typically considers maps $T:\mathcal{A}\to\mathcal{B}(\mathcal{H})$, where $\mathcal{A}$ is a C*-algebra with identity, and $\mathcal{B}(\mathcal{H})$ is the algebra of bounded operators on a complex separable Hilbert space $\mathcal{H}$. Then it can be shown[4] that T is CP if and only if, for each $n\in\mathbb{N}$,

$$\sum_{i,j=1}^{n}\langle\eta_i|T(A_i^*A_j)\eta_j\rangle\geqslant 0\quad\forall\,\eta_i\in\mathcal{H},\quad A_i\in\mathcal{A};\quad i=1,\ldots,n. \tag{1}$$

2. Theorems of Stinespring and Kraus

A fundamental theorem of Stinespring[4] states that, for any normal (i.e., ultraweakly continuous) CP map $T:\mathcal{A}\to\mathcal{B}(\mathcal{H})$, there exist a Hilbert space $\mathcal{K}$, a $*$-homomorphism $\pi:\mathcal{A}\to\mathcal{B}(\mathcal{K})$, and a bounded operator $V:\mathcal{H}\to\mathcal{K}$, such that

$$T(A)=V^*\pi(A)V\quad\forall A\in\mathcal{A}. \tag{2}$$

We will refer to any such triple $(\mathcal{K},V,\pi)$ [or, through a slight abuse of language, to the form (2) of T] as a *Stinespring dilation* of T. Given T, one can construct its Stinespring dilation in such a way that $\mathcal{K}=\pi(\mathcal{A})V\mathcal{H}$, i.e., the set $\{\pi(A)V\psi|A\in\mathcal{A},\psi\in\mathcal{H}\}$ is total in $\mathcal{K}$. With this additional property, the Stinespring dilation is unique up to unitary equivalence,[11] and is called the *minimal Stinespring dilation*.

For the special case of a CP map $T:\mathcal{B}(\mathcal{H}_1)\to\mathcal{B}(\mathcal{H}_2)$, we can always find a Hilbert space $\mathcal{E}$ and a bounded operator $V:\mathcal{H}_2\to\mathcal{H}_1\otimes\mathcal{E}$, such that

$$T(A)=V^*(A\otimes\mathbb{1}_{\mathcal{E}})V\quad\forall A\in\mathcal{A}. \tag{3}$$

This follows from the fact that any normal $*$-representation of the C*-algebra $\mathcal{B}(\mathcal{H})$ is unitarily equivalent to the *amplification map* $A\mapsto A\otimes\mathbb{1}_{\mathcal{E}}$ for some Hilbert space $\mathcal{E}$ (Ref. 12, Sec. 2.7). Any minimal Stinespring dilation of T that has the form (3) will be referred to as its *canonical Stinespring dilation*. The canonical Stinespring dilation is likewise unique up to unitary equivalence.

Another important structure theorem for CP maps is due to Kraus.[3] It says that for any CP map $T:\mathcal{A}\to\mathcal{B}(\mathcal{H})$, with $\mathcal{A}$ being a W*-algebra of operators on some Hilbert space $\mathcal{H}'$, there exists a collection of bounded operators $V_x:\mathcal{H}\to\mathcal{H}'$, such that

$$T(A)=\sum_x V_x^*AV_x, \tag{4}$$

where the series converges in the strong operator topology. If $\dim \mathcal{H}=\infty$, the set $\{V_x\}$ can be chosen in such a way that its cardinality equals the Hilbertian dimension (i.e., the cardinality of any complete orthonormal basis) of $\mathcal{H}$.[11]

The Stinespring dilation (3) and the Kraus form (4) of a CP map $T:\mathcal{B}(\mathcal{H}_1)\to\mathcal{B}(\mathcal{H}_2)$ are related to one another via the correspondence

$$V\psi=\sum_x V_x\psi\otimes e_x \quad \forall\,\psi\in\mathcal{H}_2, \tag{5}$$

where $\{e_x\}$ is an orthonormal system in $\mathcal{E}$. Note that the Kraus operators $\{V_x\}$ depend on the choice of $\{e_x\}$. The adjoint operator $V^*:\mathcal{H}_1\otimes\mathcal{E}\to\mathcal{H}_2$ acts on the elementary tensors $\psi\otimes\chi\in\mathcal{H}_1\otimes\mathcal{E}$ as

$$V^*(\psi\otimes\chi)=\sum_x \langle e_x|\chi\rangle V_x^*\psi.$$

It is not hard to see that when $\mathcal{H}_1$ and $\mathcal{H}_2$ are both finite-dimensional, any canonical Stinespring dilation of T will give rise to at most $\dim\mathcal{H}_1\cdot\dim\mathcal{H}_2$ Kraus operators. This is so because these Kraus operators must be linearly independent elements of the vector space $\mathcal{L}(\mathcal{H}_2,\mathcal{H}_1)$ of all linear operators from $\mathcal{H}_2$ into $\mathcal{H}_1$. Furthermore, the number of terms in such a Kraus decomposition is uniquely determined by T.[13]

3. Partial order of CP maps

The cone $\mathrm{CP}(\mathcal{A};\mathcal{H})$ of all normal CP maps of $\mathcal{A}$ into $\mathcal{B}(\mathcal{H})$ can be partially ordered in the following natural fashion. Given $S,\ T\in\mathrm{CP}(\mathcal{A};\mathcal{H})$, we will write $S\leqslant T$ if $T-S\in\mathrm{CP}(\mathcal{A};\mathcal{H})$. Following Belavkin and Staszewski,[7] we will say that S is *completely dominated by* T. Given a nonnegative real constant c, we will say that S is *completely c-dominated by* T if $S\leqslant cT$. Using the condition (1), we see that $S\leqslant T$ if and only if

$$\sum_{i,j=1}^{n}\langle\eta_i|S(A_i^*A_j)\,\eta_j\rangle\leqslant\sum_{i,j=1}^{n}\langle\eta_i|T(A_i^*A_j)\,\eta_j\rangle \quad \forall\,\eta_i\in\mathcal{H},\ A_i\in\mathcal{A};\ i=1,\ldots,n$$

for each $n\in\mathbb{N}$. We will use the notation $\mathrm{CP}(\mathcal{H}_1,\mathcal{H}_2)$ (note the comma) for the set of all CP maps of $\mathcal{B}(\mathcal{H}_1)$ into $\mathcal{B}(\mathcal{H}_2)$.

B. Quantum operations

Reversible dynamics of a closed quantum-mechanical system with the Hilbert space $\mathcal{H}$ is given, in the Schrödinger picture, by the mapping $\rho\mapsto U\rho U^*$, where ρ is a density operator on $\mathcal{H}$ (i.e., $\mathrm{Tr}\,\rho=1$ and $\rho\geqslant 0$), and $U:\mathcal{H}\to\mathcal{H}$ is a unitary transformation. In the dual Heisenberg picture same dynamics is described by the mapping $A\mapsto U^*AU$ for all $A\in\mathcal{B}(\mathcal{H})$. The two descriptions are equivalent as they yield the same observed statistics, $\mathrm{Tr}(U\rho U^*A)=\mathrm{Tr}(\rho U^*AU)$.

On the other hand, when the system is open because it is either coupled to an environment or is being subjected to a measurement, its most general time evolution is irreversible. This is captured mathematically by means of a *quantum operation*,[3] i.e., a completely positive normal linear map $T:\mathcal{B}(\mathcal{H})\to\mathcal{B}(\mathcal{H})$ with the additional constraint $T(\mathbb{1})\leqslant\mathbb{1}$. In terms of the Kraus form, $T(A)=\Sigma_x V_x^*AV_x$, we have the bound $\Sigma_x V_x^*V_x\leqslant\mathbb{1}$. The corresponding Schrödinger-picture map on density operators, $\rho\mapsto T_*(\rho)$, is defined[14] by

$$\mathrm{Tr}[T_*(\rho)A]=\mathrm{Tr}[\rho T(A)] \quad \forall A\in\mathcal{B}(\mathcal{H}),$$

and can then be extended to the linear span of the density operators, the trace class $\mathcal{T}(\mathcal{H})$. It follows at once that the map T_* is completely positive and trace decreasing in the sense that $\mathrm{Tr}\,T_*(X)\leqslant\mathrm{Tr}\,X$ for any $X\in\mathcal{T}(\mathcal{H})$. In order to retain proper normalization for density operators,

one usually writes the Schrödinger-picture evolution dual to T as $\rho \mapsto T_*(\rho)/\mathrm{Tr}\, T_*(\rho)$. Alternatively, one says that the transformation $\rho \mapsto T_*(\rho)$ *succeeds with probability* $\mathrm{Tr}\, T_*(\rho)$; this probability is equal to unity for all density operators ρ if and only if T is unital, i.e., $T(\mathbb{1})=\mathbb{1}$, so that T_* is trace-preserving. Unital quantum operations are also referred to as *quantum channels*.[1]

The Kraus theorem implies that we can write any quantum operation T as a sum of *pure operations* (Ref. 2, Sec. 2.3), i.e., maps of the form $A \mapsto X^*AX$ with $X^*X \leqslant \mathbb{1}$ (this is equivalent to X being a contraction, $\|X\| \leqslant 1$ where $\|\cdot\|$ is the usual operator norm, $\|X\| = \sup_{\psi \in \mathcal{H}} \|X\psi\|/\|\psi\|$). The qualification ''pure'' is usually interpreted as referring to the fact that, for any pure state $|\psi\rangle\langle\psi|$, the (un-normalized) state $X|\psi\rangle\langle\psi|X^*$ is pure as well.[5] However, as we shall see later, it is a direct consequence of the Radon–Nikodym theorem for CP maps that T is a pure operation if and only if all operations completely dominated by it are its nonnegative multiples. This is analogous to the case of pure states on a C*-algebra $\mathcal{A}$: a state ω on $\mathcal{A}$ is pure if and only if all positive linear functionals φ on $\mathcal{A}$, such that $\omega - \varphi$ is positive are nonnegative multiples of ω (Ref. 15, Sec. 2.3.2).

Given the canonical Stinespring dilation (3) of a quantum channel T (in which case V is an isometry), the Schrödinger-picture operation T_* can be cast in the so-called *ancilla form*

$$T_*(\rho) = \mathrm{Tr}_{\mathcal{E}}\, U(\rho \otimes |\xi\rangle\langle\xi|)U^*, \tag{6}$$

where $\mathrm{Tr}_{\mathcal{E}}(\cdot)$ denotes the partial trace over $\mathcal{E}$, $\xi \in \mathcal{E}$ is a fixed unit vector, and U is the unitary extension of the partial isometry $\hat{U}$ from $\mathcal{H}_2 \otimes [|\xi\rangle\langle\xi|]$ to $\mathcal{H}_1 \otimes \mathcal{E}$ defined by $\hat{U}(\psi \otimes \xi) = V\psi$.[3,16] (We use $[P]$ to denote the closed subspace corresponding to the orthogonal projection P.)

Finally, note that the input and output Hilbert spaces do not have to be the same; in general, quantum operations are completely positive normal linear maps $T: \mathcal{B}(\mathcal{H}_1) \to \mathcal{B}(\mathcal{H}_2)$ with $T(\mathbb{1}_{\mathcal{H}_1}) \leqslant \mathbb{1}_{\mathcal{H}_2}$. The corresponding Schrödinger-picture operations are completely positive trace-decreasing maps $T_*: \mathcal{T}(\mathcal{H}_2) \to \mathcal{T}(\mathcal{H}_1)$. Most of the discussion in this section carries over to this case, modulo straightforward modifications; however, one must be careful with the ancilla representation of a general Schrödinger-picture channel T_*. The key caveat here is that the initial ancillary space and the final ''traced-out'' space need not be isomorphic. This yet again underscores the advantages of working in the Heisenberg picture.

C. The norm of complete boundedness

In many information-theoretic studies of noisy quantum channels one needs a quantitative measure of the ''noisiness'' of a channel; this is, in fact, a natural departure point for various definitions of information-carrying capacities of quantum channels.[1,17,18] A good candidate for such a measure is the norm $\|T - \mathrm{id}\|_?$, where the question mark refers to the fact that we have not yet specified a suitable norm.

The choice of the proper norm turns out to be a tricky matter.[1] Let $\mathcal{A}$ and $\mathcal{B}$ be C*-algebras, and consider a linear map Λ: $\mathcal{A} \to \mathcal{B}$. We cannot adopt the operator norm, defined by

$$\|\Lambda\| = \sup\{\|\Lambda(A)\| \,|\, A \in \mathcal{A}, \|A\| \leqslant 1\}, \tag{7}$$

where $\|A\|$ is the (unique) C*-norm on $\mathcal{A}$, because the norm $\|\Lambda \otimes \mathrm{id}_n\|$ of the map $\Lambda \otimes \mathrm{id}_n : \mathcal{A} \otimes \mathcal{M}_n \to \mathcal{B} \otimes \mathcal{M}_n$ can increase with n even if Λ itself is bounded (see Chap. 3 of Ref. 19). What we need is a ''stabilized'' version of (7). A map $\Lambda: \mathcal{A} \to \mathcal{B}$ is called *completely bounded* (CB for short) if there exists some constant $C \geqslant 0$ such that all the maps $\Lambda \otimes \mathrm{id}_n : \mathcal{A} \otimes \mathcal{M}_n \to \mathcal{B} \otimes \mathcal{M}_n$ are uniformly bounded by C, i.e., $\|\Lambda \otimes \mathrm{id}_n\| \leqslant C$. The CB norm $\|\Lambda\|_{\mathrm{cb}}$ is defined to be the smallest constant C for which this holds, i.e.,

$$\|\Lambda\|_{\mathrm{cb}} = \sup_{n \in \mathbb{N}} \|\Lambda \otimes \mathrm{id}_n\|.$$

All CB maps have the property of ''factoring through a Hilbert space,'' as shown in the following key structure theorem (Theorem 3.6 in Ref. 19), given here in a slightly simplified form suitable for our needs.

Theorem II.1: *(Haagerup–Paulsen–Wittstock) Let $\mathcal{H}$ and $\mathcal{K}$ be Hilbert spaces, and let $\Lambda:\mathcal{B}(\mathcal{H})\to\mathcal{B}(\mathcal{K})$ be a CB map. Then there exist a Hilbert space $\mathcal{E}$ and operators $V_1,V_2:\mathcal{K}\to\mathcal{H}\otimes\mathcal{E}$ with $\|V_1\|\|V_2\|\leqslant\|\Lambda\|_{\rm cb}$ ($\|\cdot\|$ stands for the operator norm), such that*

$$\Lambda(A)=V_1^*(A\otimes\mathbb{1}_{\mathcal{E}})V_2\,. \tag{8}$$

Conversely, any map Λ of the form (8) satisfies $\|\Lambda\|_{\rm cb}\leqslant\|V_1\|\|V_2\|$.

Note that the Stinespring and the Haagerup–Paulsen–Wittstock theorems together imply that any CP map is automatically CB. In fact, for a CP map T, we have $\|T\|_{\rm cb}=\|T(\mathbb{1})\|$.[20] Also, the difference of two CP maps is always CB.

Theorem II.1 suggests an alternative way to define the CB norm of a map Λ, namely, as

$$\|\Lambda\|_{\rm cb}=\inf\{\|V_1\|\|V_2\|\}, \tag{9}$$

where the infimum is taken over all possible decompositions of Λ in the form (8). Moreover, the theorem guarantees that the infimum in (9) is attained.

In quantum information theory one frequently deals with both the operation $T:\mathcal{B}(\mathcal{H})\to\mathcal{B}(\mathcal{K})$ and its (pre)dual, $T_*:\mathcal{T}(\mathcal{K})\to\mathcal{T}(\mathcal{H})$. As we mentioned in Sec. II B, T and T_* are connected by the relation $\mathrm{Tr}[T(A)B]=\mathrm{Tr}[AT_*(B)]$, $A\in\mathcal{B}(\mathcal{H})$, $B\in\mathcal{T}(\mathcal{K})$. This duality holds also for any normal CB map $\Lambda:\mathcal{B}(\mathcal{H})\to\mathcal{B}(\mathcal{K})$, so that when Λ is written in the form (8), we have

$$\Lambda_*(A)=\mathrm{Tr}_{\mathcal{E}}V_2AV_1^*\quad\forall A\in\mathcal{T}(\mathcal{K}). \tag{10}$$

This motivates the definition of the dual CB norm,

$$\|\Lambda_*\|_{\rm cb}^*=\inf\{\|V_1\|\|V_2\|\}, \tag{11}$$

where the infimum is taken over all possible decompositions of Λ_* in the form (10). It is now clear that $\|\Lambda\|_{\rm cb}=\|\Lambda_*\|_{\rm cb}^*$ for any normal CB map Λ, so in the future we will always write $\|\Lambda\|_{\rm cb}$, even when working with Λ_*. In fact, the norm (11) was introduced by Kitaev[21] under the name ''diamond norm'' (Kitaev used the notation $\|\Lambda\|_\diamond$). The equivalence of the diamond norm and the CB norm has been alluded to in the literature on quantum information theory[17] but, to the best of our knowledge, no proof of the equivalence was ever presented.

The duality relation between $\Lambda:\mathcal{B}(\mathcal{H})\to\mathcal{B}(\mathcal{K})$ and $\Lambda_*:\mathcal{T}(\mathcal{K})\to\mathcal{T}(\mathcal{H})$ implies that we can also write

$$\|\Lambda\|_{\rm cb}=\sup_{n\in\mathbb{N}}\|\Lambda_*\otimes\mathrm{id}_n\|_1\,,$$

where $\|\Lambda_*\|_1=\sup\{\|\Lambda_*(A)\|_1|A\in\mathcal{T}(\mathcal{K}),\|A\|_1\leqslant1\}$ and $\|A\|_1=\mathrm{Tr}|A|\equiv\mathrm{Tr}\sqrt{A^*A}$ is the trace norm (Sec. VI.6, Ref. 22). For this purpose we can use the well-known variational characterization of the operator norm (Theorem 3.2 in Ref. 23), namely,

$$\|A\|=\sup_{\substack{B\in\mathcal{T}(\mathcal{H})\\ \|B\|_1\leqslant1}}|\mathrm{Tr}(AB)|\quad\forall A\in\mathcal{B}(\mathcal{H}).$$

Then for any normal CB map $\Lambda:\mathcal{B}(\mathcal{H})\to\mathcal{B}(\mathcal{K})$ we have

$$\|\Lambda\| = \sup_{\substack{A\in\mathcal{B}(\mathcal{H})\\ \|A\|\leq 1}} \|\Lambda(A)\| = \sup_{\substack{B\in\mathcal{T}(\mathcal{K})\\ \|B\|_1\leq 1}} \sup_{\substack{A\in\mathcal{B}(\mathcal{H})\\ \|A\|\leq 1}} |\mathrm{Tr}[\Lambda(A)B]| = \sup_{\substack{B\in\mathcal{T}(\mathcal{K})\\ \|B\|_1\leq 1}} \sup_{\substack{A\in\mathcal{B}(\mathcal{H})\\ \|A\|\leq 1}} |\mathrm{Tr}[A\Lambda_*(B)]|$$

$$= \sup_{\substack{B\in\mathcal{T}(\mathcal{K})\\ \|B\|_1\leq 1}} \|\Lambda_*(B)\|_1 = \|\Lambda_*\|_1,$$

which also implies that $\|\Lambda\otimes \mathrm{id}_n\| = \|\Lambda_*\otimes \mathrm{id}_n\|_1$ for all $n\in\mathbb{N}$. Taking the supremum of both sides with respect to n does the job. In a nutshell, the CB norm of a map between algebras of bounded operators on Hilbert spaces can be defined through a variational expression involving the operator norm, whereas the CB norm of the corresponding dual map between the trace classes is determined by a variational expression in the trace norm.

We now summarize the key properties of the CB norm. For any two CB maps $\Lambda:\mathcal{B}(\mathcal{H})\to\mathcal{B}(\mathcal{H}')$ and $\Lambda:\mathcal{B}(\mathcal{H}')\to\mathcal{B}(\mathcal{K}')$, any $A\in\mathcal{B}(\mathcal{H})$, and any $B\in\mathcal{T}(\mathcal{H}')$, we have the following:

(1) $\|\Lambda'\circ\Lambda\|_{\mathrm{cb}}\leq\|\Lambda'\|_{\mathrm{cb}}\|\Lambda\|_{\mathrm{cb}}$,
(2) $\|\Lambda\otimes\Lambda'\|_{\mathrm{cb}} = \|\Lambda\|_{\mathrm{cb}}\|\Lambda'\|_{\mathrm{cb}}$,
(3) $\|\Lambda(A)\|\leq\|\Lambda\|_{\mathrm{cb}}\|A\|$,
(4) $\|\Lambda_*(B)\|_1\leq\|\Lambda\|_{\mathrm{cb}}\|B\|_1$.

For proofs see, e.g., the article of Kitaev[21] or the monographs of Pisier[19] and Paulsen.[20]

III. THE RADON–NIKODYM THEOREM FOR COMPLETELY POSITIVE MAPS

In this section we review a theorem of the Radon–Nikodym type that allows for a complete classification of all CP maps S that are completely dominated by a given CP map T. As we have already mentioned, this theorem can be distilled from the more general results of Arveson[6] and Belavkin and Staszewski.[7] The work of Parthasarathy[10] contains further developments, in particular an analogue of the Lebesgue decomposition for CP maps. The idea is to express all maps S that satisfy $S\leq T$ in the form related to the (minimal) Stinespring dilation of T; this ''Stinespring form'' of the theorem[6,7] is stated in Sec. III A, with the proof included in order to keep the paper self-contained. Then, in Sec. III B, we state and prove two ''Kraus forms'' of the Radon–Nikodym theorem. Finally, some general remarks are given in Sec. III C.

A. The Stinespring form

Before we state and prove the Radon–Nikodym theorem, let us recall a standard piece of notation. Given a C*-algebra $\mathcal{A}$ and a $*$-homomorphism $\pi:\mathcal{A}\to\mathcal{B}(\mathcal{H})$, the set $\{B\in\mathcal{B}(\mathcal{H})\,|\,[A,B]\equiv AB-BA=0, \forall A\in\pi(\mathcal{A})\}$ is called the *commutant* of π and is denoted by $\pi(\mathcal{A})'$.

Theorem III.1: *Consider $S,T\in\mathrm{CP}(\mathcal{A};\mathcal{H})$, and let $(\mathcal{K},V,\pi)$ be the minimal Stinespring dilation of T. Then $S\leq T$ if and only if there exists an operator $\hat{F}\in\pi(\mathcal{A})'$, such that $0\leq\hat{F}\leq\mathbb{1}$ and*

$$S(A) = V^*\pi(A)\hat{F}V = V^*\hat{F}^{1/2}\pi(A)\hat{F}^{1/2}V$$

for all $A\in\mathcal{A}$. The operator $\hat{F}$ is unique in the sense that if $S(A)=V^*\pi(A)YV$ for some $Y\in\pi(\mathcal{A})'$, then $Y=\hat{F}$. We will refer to this operator $\hat{F}$ as the Radon–Nikodym derivative of S with respect to T and denote it by $\mathsf{D}_T S$.

Proof: Suppose $S\leq T$, and let $(\mathcal{K}',V',\pi')$ be the minimal Stinespring dilation of S. Define an operator $\hat{G}:\mathcal{K}\to\mathcal{K}'$ by

$$\hat{G}:\pi(A)V\eta\mapsto\pi'(A)V'\eta \quad \forall A\in\mathcal{A},\eta\in\mathcal{H},$$

and extend it to the linear span of $\pi(\mathcal{A})V\mathcal{H}$. For any finite linear combination $\Psi=\sum_{i=1}^n\pi(A_i)V\eta_i$ we have

$$\begin{aligned}\|\hat{G}\Psi\|^2 &= \sum_{i,j=1}^{n} \langle \eta_i | V'^* \pi'(A_i^* A_j) V' \eta_j \rangle \\ &= \sum_{i,j=1}^{n} \langle \eta_i | S(A_i^* A_j)\, \eta_j \rangle \\ &\leqslant \sum_{i,j=1}^{n} \langle \eta_i | T(A_i^* A_j)\, \eta_j \rangle \\ &= \sum_{i,j=1}^{n} \langle \eta_i | V^* \pi(A_i^* A_j) V \eta_j \rangle = \|\Psi\|^2.\end{aligned}$$

Thus $\hat{G}$ is a densely defined contraction, and therefore extends to a contraction from $\mathcal{K}$ into $\mathcal{K}'$. We will denote this extension also by $\hat{G}$. For the adjoint map $\hat{G}^*$, we have

$$\langle \eta | V^* \hat{G}^* \pi'(A) V' \xi \rangle = \langle \hat{G} V \eta | \pi'(A) V' \xi \rangle = \langle V' \eta | \pi'(A) V' \xi \rangle = \langle \eta | V'^* \pi'(A) V' \xi \rangle \equiv \langle \eta | S(A) \xi \rangle$$

for all $\eta, \xi \in \mathcal{H}$ and $A \in \mathcal{A}$, which implies that $V^* \hat{G}^* \pi'(A) V' \eta = S(A)\, \eta$.

The map $\hat{G}$ intertwines the representations π and π', i.e., $\hat{G}\pi(A) = \pi'(A)\hat{G}$ for any $A \in \mathcal{A}$. Indeed, for all $A, B \in \mathcal{A}$ and $\eta \in \mathcal{H}$ we have

$$\hat{G}\pi(A)\pi(B) V \eta = \hat{G}\pi(AB) V \eta = \pi'(AB) V' \eta = \pi'(A)\pi'(B) V' \eta = \pi'(A)\hat{G}\pi(B) V \eta,$$

and the desired statement follows because of the minimality of the Stinespring dilation $(\mathcal{K}, V, \pi)$. Taking adjoints, we also obtain $\pi(A)\hat{G}^* = \hat{G}^* \pi'(A)$. Letting $\hat{F} = \hat{G}^* \hat{G}$, we see that

$$\hat{F}\pi(A) = \hat{G}^* \hat{G} \pi(A) = \hat{G}^* \pi'(A) \hat{G} = \pi(A) \hat{G}^* \hat{G} = \pi(A) \hat{F},$$

which shows that $\hat{F} \in \pi(\mathcal{A})'$. Finally, for all $A \in \mathcal{A}$ and $\eta \in \mathcal{H}$ we have

$$V^* \hat{F} \pi(A) V \eta = V^* \hat{G}^* \hat{G} \pi(A) V \eta = V^* \hat{G}^* \pi'(A) V' \eta = S(A)\, \eta,$$

thus $S(A) = V^* \hat{F} \pi(A) V = V^* \pi(A) \hat{F} V = V^* \hat{F}^{1/2} \pi(A) \hat{F}^{1/2} V$. The uniqueness of $\hat{F}$ follows from the minimality of $(\mathcal{K}', V', \pi')$.

The converse is clear. ■

For the special case $S, T \in \mathrm{CP}(\mathcal{H}_1, \mathcal{H}_2)$ we can use the canonical Stinespring dilation (3) and the fact that the commutant of the algebra $\mathcal{B}(\mathcal{H}_1) \otimes \mathbb{C}\mathrm{l}_{\mathcal{E}}$ is isomorphic to $\mathbb{C}\mathrm{l}_{\mathcal{H}_1} \otimes \mathcal{B}(\mathcal{E})$ (Theorem IV.5.9 in Ref. 24), to deduce the following.

Corollary III.2: Let $S, T \in \mathrm{CP}(\mathcal{H}_1, \mathcal{H}_2)$, and let $T(A) = V^*(A \otimes \mathbb{1}_{\mathcal{E}})V$ be the canonical Stinespring dilation of T. Then $S \leqslant T$ if and only if there exists a positive contraction $F \in \mathcal{B}(\mathcal{E})$, such that $S(A) = V^*(A \otimes F)V$ for all $A \in \mathcal{B}(\mathcal{H}_1)$.

As we already mentioned, the Radon–Nikodym theorem allows one to fully appreciate the term "pure operation." Let $\mathcal{H}_1$ and $\mathcal{H}_2$ be Hilbert spaces, and consider the map $T(A) = X^* A X$, where $X: \mathcal{H}_2 \to \mathcal{H}_1$ is a contraction. Clearly, $X^* A X$ is the canonical Stinespring dilation of T so, by Theorem III.1, any $S \in \mathrm{CP}(\mathcal{H}_1, \mathcal{H}_2)$ that satisfies $S \leqslant T$ must be of the form $\lambda X^* A X$ for some $\lambda \in [0,1]$.

Theorem III.1 can also be used to characterize completely all ways to write a given $T \in \mathrm{CP}(\mathcal{A}; \mathcal{H})$ as a finite sum $\Sigma_i T_i$, with $T_i \in \mathrm{CP}(\mathcal{A}; \mathcal{H})$ for all i. It is actually the resulting theorem, stated below, that is referred to as the "Radon–Nikodym theorem for CP maps" in the quantum information literature.[18]

Theorem III.3: *Consider a map $T \in \mathrm{CP}(\mathcal{A}; \mathcal{H})$ with the canonical Stinespring dilation $(\mathcal{K}, V, \pi)$. For any finite decomposition $T = \Sigma_i T_i$ with $T_i \in \mathrm{CP}(\mathcal{A}; \mathcal{H})$ there exist unique positive operators $\hat{F}_i \in \pi(\mathcal{A})'$ that satisfy $\Sigma_i \hat{F}_i = \mathbb{1}_{\mathcal{K}}$, such that $T_i(A) = V^* \pi(A) \hat{F}_i V$.*

Proof: Apply Theorem III.1 separately to each pair (T_i, T), and let $\hat{F}_i = \mathrm{D}_T T_i$. Then $T(A) = \Sigma_i V^* \pi(A) \hat{F}_i V = V^* \pi(A) V$, and $\Sigma_i \hat{F}_i = \mathbb{1}_{\mathcal{K}}$ by the uniqueness part of Theorem III.1. ■

Remark: The decomposition $T = \Sigma_i T_i$ is a particularly simple instance of a CP instrument.[2] As such, it is not difficult to extract Theorem III.3 from more general results of Ozawa.[9] □

B. The Kraus form

Theorem III.1 can be restated in a simple way in terms of the Kraus form of a CP map. In order to do this, we need some additional machinery (Sec. II.15 in Ref. 25).

Let X be a set. Any function $K: X \times X \to \mathbb{C}$ is called a *kernel on X*. The set $\mathcal{K}(X)$ of all kernels on X is a vector space, with the corresponding algebraic operations defined pointwise on $X \times X$. We say that a kernel $K \in \mathcal{K}(X)$ is *positive-definite*, and write $K \geqslant 0$, if for each $n \in \mathbb{N}$ we have

$$\sum_{i,j=1}^{n} \overline{c}_i c_j K(x_i, x_j) \geqslant 0 \quad \forall x_i \in X, c_i \in \mathbb{C}; \;\; i = 1, \ldots, n.$$

Given a pair of kernels $K, K' \in \mathcal{K}(X)$, we will write $K \leqslant K'$ if $K' - K$ is positive-definite. Note that a positive-definite kernel is automatically Hermitian, i.e., $K(x,y) = \overline{K(y,x)}$.

According to the fundamental theorem of Kolmogorov, for any positive-definite kernel $K \in \mathcal{K}(X)$ there exist a Hilbert space $\mathcal{H}_K$ and a map $v_K: X \to \mathcal{H}_K$ such that $\langle v_K(x) | v_K(y) \rangle = K(x,y)$ for all $x, y \in X$, and the set $\{v_K(x) | x \in X\}$ is total in $\mathcal{H}_K$. The pair $(\mathcal{H}_K, v_K)$ is referred to as the *Kolmogorov decomposition* of $\mathcal{K}$ and is unique up to unitary equivalence.

After these preparations, we may state our first result.

Theorem III.4: *Consider two maps $S, T \in \mathrm{CP}(\mathcal{H}_1, \mathcal{H}_2)$. Let $\{V_x\}_{x \in X}$ be a Kraus decomposition of T induced by the canonical Stinespring dilation $T(A) = V^*(A \otimes \mathbb{1}_{\mathcal{E}})V$, as prescribed in (5). Then $S \leqslant T$ if and only if*

$$S(A) = \sum_{x,y \in X} K(x,y) V_x^* A V_y$$

for some positive-definite kernel $K \in \mathcal{K}(X)$ with $K \leqslant I$, where I is the Kronecker kernel $I(x,y) \equiv \delta_{xy}$.

Proof: Suppose $S \leqslant T$. By Corollary III.2, $S(A) = V^*(A \otimes F)V$ for some positive contraction $F \in \mathcal{B}(\mathcal{E})$. Let $\{e_x\}_{x \in X}$ be the orthonormal system in $\mathcal{E}$, determined by V and $\{V_x\}$ from (5). Then for any $\eta \in \mathcal{H}_2$ we have

$$S(A)\eta = V^*(A \otimes F)V\eta = V^*\left(\sum_{y \in X} AV_y \eta \otimes Fe_y \right) = \sum_{x,y \in X} \langle e_x | Fe_y \rangle V_x^* A V_y \eta.$$

Define the kernel $K \in \mathcal{K}(X)$ by setting $K(x,y) := \langle e_x | Fe_y \rangle$. Then $0 \leqslant F \leqslant \mathbb{1}$ implies that $0 \leqslant K \leqslant I$.

Conversely, suppose we are given

$$T(A) = \sum_{x \in X} V_x^* A V_x$$

and

$$S(A) = \sum_{x,y \in X} K(x,y) V_x^* A V_y$$

for some $K \in \mathcal{K}(X)$ such that $0 \leqslant K \leqslant I$. Let $(\mathcal{H}_K, v_K)$ be the Kolmogorov decomposition of K, and let $\mathrm{fin}(X)$ be the set of all finite subsets of X. Define an operator $G: \mathcal{E} \to \mathcal{H}_K$ by

$$G: \sum_{x \in X_0} c_x e_x \mapsto \sum_{x \in X_0} c_x v_K(x) \quad \forall c_x \in \mathbb{C},\ X_0 \in \mathrm{fin}(X).$$

It is easy to see that, for any $X_0 \in \mathrm{fin}(X)$,

$$\left\| \sum_{x \in X_0} c_x e_x \right\|^2 = \sum_{x \in X_0} |c_x|^2 = 0$$

implies $c_x = 0$ for all $x \in X_0$, and consequently

$$\left\| G\left(\sum_{x \in X_0} c_x e_x \right) \right\|^2 = \sum_{x,y \in X_0} \overline{c_x} c_y K(x,y) \leqslant \sum_{x \in X_0} |c_x|^2 = 0,$$

where the last equality above follows because $K \leqslant I$. Thus G extends to a well-defined linear operator on $\mathcal{E}$, which we will also denote by G. Let $F = G^* G$. Then $\langle e_x | F e_y \rangle = \langle v_K(x) | v_K(y) \rangle = K(x,y)$, and $0 \leqslant K \leqslant I$ implies that $0 \leqslant F \leqslant \mathbb{1}_{\mathcal{E}}$. Thus, for all $A \in \mathcal{B}(\mathcal{H}_1)$ and $\eta \in \mathcal{H}_2$ we have

$$S(A)\eta = \sum_{x,y} K(x,y) V_x^* A V_y = \sum_{x,y \in X} \langle e_x | F e_y \rangle V_x^* A V_y = V^*(A \otimes F) V,$$

so that $S \leqslant T$ by Corollary III.2. ■

Remarks: (1) When the set $\{V_x\}$ is finite, Theorem III.4 says that $S \leqslant T$ for $T(A) = \Sigma_x V_x^* A V_x$ if and only if $S(A) = \Sigma_{x,y} M_{xy} V_x^* A V_y$ for some matrix $M = [M_{xy}]$ with $0 \leqslant M \leqslant \mathbb{1}$.

(2) Since we deal only with separable Hilbert spaces, the index set X is at most countably infinite. □

Another Kraus form of the Radon–Nikodym theorem can be proved directly, without recourse to the theory of positive-definite kernels.

Theorem III.5: *Consider two maps $S,T \in \mathrm{CP}(\mathcal{H}_1, \mathcal{H}_2)$. Then $S \leqslant T$ if and only if there exist a Kraus decomposition $T(A) = \Sigma_x W_x^* A W_x$, induced by the canonical Stinespring dilation of T, and a set $\{\lambda_x | \lambda_x \in [0,1]\}$, such that $S(A) = \Sigma_x \lambda_x W_x^* A W_x$.*

Proof: Suppose $S \leqslant T$. Let $T(A) = V^*(A \otimes \mathbb{1}_{\mathcal{E}})V$ be the canonical Stinespring dilation of T. Then Corollary III.2 says that $S(A) = V^*(A \otimes F)V$ for some positive contraction $F \in \mathcal{B}(\mathcal{E})$. Write down the spectral decomposition $F = \Sigma_x \lambda_x |\phi_x\rangle\langle\phi_x|$, so that $\lambda_x \in [0,1]$ and $\langle \phi_x | \phi_y \rangle = \delta_{xy}$. Let $\{W_x\}$ be the Kraus decomposition of T determined from (5) by V and $\{\phi_x\}$. Then for any $\eta \in \mathcal{H}_2$ we have

$$S(A)\eta = V^*(A \otimes F)V\eta = V^*\left(\sum_y \lambda_y A W_y \eta \otimes \phi_y \right) = \sum_{x,y} \lambda_y \langle \phi_x | \phi_y \rangle W_x^* A W_y \eta = \sum_x \lambda_x W_x^* A W_x .$$

The converse follows readily from the fact that the map $A \mapsto \Sigma_x (1 - \lambda_x) W_x^* A W_x$ is CP for any choice of $\{W_x\}$ and $\{\lambda_x\}$ with $\lambda_x \in [0,1]$. ■

C. General remarks

Before we go on, we would like to pause and make some general comments about the significance of the Radon–Nikodym theorem for CP maps at large.

The real power of this theorem lies in the fact that it contains the ''traditional'' forms of the Radon–Nikodym theorem as special cases. In order to see this, we will need the following result (see Corollary IV.3.5 and Proposition IV.3.9 in Ref. 24): a positive map T from a C*-algebra $\mathcal{A}$ to another C*-algebra $\mathcal{B}$ is automatically completely positive whenever at least one of $\mathcal{A}$ and $\mathcal{B}$ is Abelian.

With this in mind, let us observe that any positive linear functional φ on a C*-algebra $\mathcal{A}$ is a positive map from $\mathcal{A}$ to $\mathbb{C}$, and therefore is CP. When we apply the Stinespring theorem to φ, we simply recover the GNS representations $(\mathcal{H}, \pi, \Omega)$ of $\mathcal{A}$ induced by φ, where $\mathcal{H}$ is the Hilbert space

of the representation, π is a $*$-isomorphism between $\mathcal{A}$ and a suitable C*-subalgebra of $\mathcal{B}(\mathcal{H})$, and $\Omega \in \mathcal{H}$ is cyclic for π, i.e., $\mathcal{H} = \overline{\pi(\mathcal{A})\Omega}$. Of course, we have then $\varphi(A) = \langle \Omega | \pi(A)\Omega \rangle$ for all $A \in \mathcal{A}$.

Consider first the Abelian case. Let X be a compact Hausdorff space, and let $\mathcal{A}$ be the commutative C*-algebra $\mathcal{C}(X)$ of all complex-valued continuous functions on X. Let φ be a positive linear functional on $\mathcal{C}(X)$. By the Riesz–Markov theorem [see Theorem IV.14 (Ref. 22)], there exists a unique Baire measure μ on X such that $\varphi(f) = \int_X f(x)\mathrm{d}\mu(x)$, $\forall f \in \mathcal{C}(X)$. If φ is a state [i.e., $\varphi(\mathbb{1}_X) = 1$ where $\mathbb{1}_X$ is, of course, the function on X that is identically equal to 1], then μ is a probability measure. The GNS construction yields the cyclic representation $(\mathcal{H}, \pi, \Omega)$, where $\mathcal{H} = \mathcal{L}^2(X, \mathrm{d}\mu)$, $[\pi(f)g](x) = f(x)g(x)$, and $\Omega = \mathbb{1}_X$, such that

$$\varphi(f) = \langle \Omega | \pi(f)\Omega \rangle = \int_X f(x)\mathrm{d}\mu(x).$$

This is the minimal Stinespring dilation of the CP map $\varphi: \mathcal{C}(X) \to \mathbb{C}$; more precisely, we have the isometry $V: \mathbb{C} \to \mathcal{L}^2(X, \mathrm{d}\mu)$ defined by $Vc = c\Omega$, so that $\varphi(f) = V^*\pi(f)V$. Now suppose we are given another positive linear functional η on $\mathcal{C}(X)$ such that $\eta \leqslant \varphi$, i.e., $\eta(f) \leqslant \varphi(f)$ for every non-negative $f \in \mathcal{C}(X)$. Then Theorem III.1 states that there exists a non-negative function $\rho \in \pi(\mathcal{C}(X))' \subseteq \mathcal{L}^\infty(X, \mathrm{d}\mu)$ such that $\eta(f) = V^*\pi(f)\rho V$, i.e.,

$$\eta(f) = \langle \Omega | \rho\pi(f)\Omega \rangle = \int_X \rho(x) f(x)\mathrm{d}\mu(x).$$

Again, by the Riesz–Markov theorem, there exists a unique Baire measure ν on X such that $\eta(f) = \int_X f(x)\mathrm{d}\nu(x)$. It is easy to see that the function ρ is precisely the measure-theoretic Radon–Nikodym derivative $\mathrm{d}\nu/\mathrm{d}\mu$.

The noncommutative case is dealt with in a similar manner. Namely, if φ is a state on a unital C*-algebra $\mathcal{A}$ that admits the cyclic representation $(\mathcal{H}, \pi, \Omega)$, then any positive linear functional η on $\mathcal{A}$ such that $\eta \leqslant \varphi$ has the form $\eta(A) = \langle \Omega | \pi(A)F\Omega \rangle$ for a unique positive contraction $F \in \pi(\mathcal{A})'$. This is, of course, the familiar Radon–Nikodym theorem for states on C*-algebras (see Theorem 2.3.19 in Ref. 15).

IV. PARTIAL ORDERING OF QUANTUM OPERATIONS

The first series of problems we tackle by means of the Radon–Nikodym theorems of Sec. III is connected to the partial ordering of quantum operations with respect to the relation of complete domination, defined in Sec. II.

As mentioned already, all quantum operations $T: \mathcal{B}(\mathcal{H}_1) \to \mathcal{B}(\mathcal{H}_2)$ must satisfy $T(\mathbb{1}_{\mathcal{H}_1}) \leqslant \mathbb{1}_{\mathcal{H}_2}$. It turns out that this normalization condition imposes severe restrictions on the structure of their order intervals. In particular, as shown in the following Proposition, no nontrivial difference of quantum channels can be a CP map.

Proposition IV.1: Let $S, T \in \mathrm{CP}(\mathcal{H}_1, \mathcal{H}_2)$ be quantum channels. Then $T - S \in \mathrm{CP}(\mathcal{H}_1, \mathcal{H}_2)$ if and only if $S = T$.

Proof: Suppose $T - S \in \mathrm{CP}(\mathcal{H}_1, \mathcal{H}_2)$, or, equivalently, $S \leqslant T$. Then Theorem III.5 implies that there exists a Kraus decomposition $T(A) = \Sigma_x W_x^* A W_x$ such that $S(A) = \Sigma_x \lambda_x W_x^* A W_x$ with $0 \leqslant \lambda_x \leqslant 1$. Because both S and T are channels, $S(\mathbb{1}) = T(\mathbb{1}) = \mathbb{1}$, which implies that $\Sigma_x(1 - \lambda_x)W_x^* W_x = 0$. Since each term in this sum is a positive operator, the only possibility is that $\lambda_x = 1$ for all x, or $S = T$. The converse is obvious. ■

Remark: To obtain an even simpler proof of this proposition, we can use the fact that, for a CP map T, $\|T\|_{\mathrm{cb}} = \|T(\mathbb{1})\|$ (cf. Sec. II C). Indeed, if S and T are channels, then $T(\mathbb{1}) = S(\mathbb{1}) = \mathbb{1}$, and the assumption that $T - S$ is CP yields $\|T - S\|_{\mathrm{cb}} = \|T(\mathbb{1}) - S(\mathbb{1})\| = 0$, or $S = T$. In fact, the same method shows that if S and T are two CP maps with $S(\mathbb{1}) = T(\mathbb{1})$, then $S - T$ cannot be a CP map. □

The only possible order relation between a pair of quantum channels S and T is that, say, T completely c-dominates S for some $c>1$. The latter condition follows from Proposition IV.1 and from the fact that $S\leqslant cT$ implies $\mathbb{1}\leqslant c\mathbb{1}$, which is (trivially) possible only if $c\geqslant 1$. In fact, as pointed out by Parthasarathy,[10] there are pairs of channels T, T' for which there exist constants c, $c'>1$ such that $T'\leqslant cT$ and $T\leqslant c'T'$. To show this, let S_1 and S_2 be arbitrary channels, and define $T=\lambda S_1+(1-\lambda)S_2$ and $T'=\lambda' S_1+(1-\lambda')S_2$, where $0<\lambda$, $\lambda'<1$. Then, setting $c=[\lambda(1-\lambda)]^{-1}$ and $c'=[\lambda'(1-\lambda')]^{-1}$, we see that indeed $T'\leqslant cT$ and $T\leqslant c'T'$. In Parthasarathy's terminology,[10] T and T' are *uniformly equivalent*; this is written $T\equiv_u T'$, and is an equivalence relation.

The next problem we consider has to do with an alternative way to (partially) order quantum operations by means of orthogonal projections on a suitably enlarged Hilbert space. To this end we need to recall some facts about the so-called *positive operator-valued measures* (POVM's for short) (Sec. 3.1 in Ref. 2). Let X be a topological space, Σ_X the σ-algebra of all Borel subsets of X, and $\mathcal{H}$ a Hilbert space. A map $M:\Sigma_X\to\mathcal{B}(\mathcal{H})$ is a POVM on (the Borel subsets of) X if it has the following properties:

(1) (normalization) $M(\varnothing)=0$ and $M(X)=\mathbb{1}$,
(2) (positivity) $M(\Delta)\geqslant 0$ for all $\Delta\in\Sigma_X$,
(3) (σ-additivity) if $\{\Delta_i\}$ is a countable collection of pairwise disjoint Borel sets in X, then $M(\cup_i\Delta_i)=\Sigma_i M(\Delta_i)$, where the sum converges in the weak operator topology.

A POVM that satisfies an additional requirement that each $M(\Delta)$ is an orthogonal projection, i.e., $M(\Delta)^2=M(\Delta)$, is called a *projection-valued measure* (PVM). The resulting resolution of identity is an orthogonal one. The celebrated Naimark dilation theorem (see Theorem 9.3.2 in Ref. 2) says that for every POVM $M:\Sigma_X\to\mathcal{B}(\mathcal{H})$ there exist a Hilbert space $\mathcal{K}$, a unitary $U:\mathcal{H}\to\mathcal{K}$, a Hilbert space $\widetilde{\mathcal{K}}$ containing $\mathcal{K}$ as a closed subspace, and a PVM $E:\Sigma_X\to\mathcal{B}(\widetilde{\mathcal{K}})$, such that, for any $\Delta\in\Sigma_X$, $M(\Delta)=U^*PE(\Delta)PU$, where P is the orthogonal projection from $\widetilde{\mathcal{K}}$ onto $\mathcal{K}$. Furthermore, we can define the partial isometry $V:\mathcal{H}\to\widetilde{\mathcal{K}}$ (with the final projection P) by $V=PU$, so that $M(\Delta)=V^*E(\Delta)V$.[26]

With these lengthy preliminaries out of the way, we can proceed to state and prove our result.

Theorem IV.2: *Consider quantum operations $T_i\in\mathrm{CP}(\mathcal{H}_1,\mathcal{H}_2)$, $i=1,\ldots,n$, that satisfy $T_1\leqslant T_2\leqslant\cdots\leqslant T_n$. Then there exist a Hilbert space $\mathcal{H}$, an isometry $V:\mathcal{H}_2\to\mathcal{H}_1\otimes\mathcal{H}$, and orthogonal projections $\Pi_i\in\mathcal{B}(\mathcal{H})$ such that*

(1) $T_i(A)=V^*(A\otimes\Pi_i)V$, $1\leqslant i\leqslant n$,
(2) $\Pi_1\leqslant\Pi_2\leqslant\cdots\leqslant\Pi_n$.

Conversely, if items 1 and 2 above hold for quantum operations $T_i\in\mathrm{CP}(\mathcal{H}_1,\mathcal{H}_2)$ with some $\mathcal{H}$, V, and $\{\Pi_i\}$, then $T_1\leqslant T_2\leqslant\cdots\leqslant T_n$.

Proof: Suppose that $\{T_i\}$ satisfy the hypothesis of the theorem. Without loss of generality we may take T_n to be a channel, for if not, then we can append to $\{T_i\}_{i=1}^n$ the channel $T_{n+1}(A)=M^*AM+T_n(A)$, where $M:\mathcal{H}_2\to\mathcal{H}_1$ is an operator defined, up to a unitary, through $M^*M=\mathbb{1}-T_n(\mathbb{1})$, so that the resulting collection $\{T_i\}_{i=1}^{n+1}$ still satisfies $T_1\leqslant T_2\leqslant\cdots\leqslant T_{n+1}$.

Define quantum operations S_i, $i=1,\ldots,n$, by $S_1=T_1$ and $S_i=T_i-T_{i-1}$, $1<i\leqslant n$. Then $T_k=\Sigma_{i=1}^k S_i$, $1\leqslant k\leqslant n$. If $T_n(A)=W^*(A\otimes\mathbb{1}_{\mathcal{E}})W$ is the canonical Stinespring dilation of T_n, Theorem III.3 states that there exist positive operators $F_i\in\mathcal{B}(\mathcal{E})$ such that $S_i(A)=W^*(A\otimes F_i)W$, and $\Sigma_i F_i=\mathbb{1}_{\mathcal{E}}$. By the Naimark dilation theorem there exist a Hilbert space $\mathcal{H}$, an isometry $\widetilde{V}:\mathcal{E}\to\mathcal{H}$, and a PVM $\{E_i\}_{i=1}^n$, $E_i\in\mathcal{B}(\mathcal{H})$, such that $F_i=\widetilde{V}^*E_i\widetilde{V}$, $1\leqslant i\leqslant n$. Thus we can write $S_i(A)=V^*(A\otimes E_i)V$, where the isometry $V:\mathcal{H}_2\to\mathcal{H}_1\otimes\mathcal{H}$ is defined by $V=(\mathbb{1}_{\mathcal{H}_1}\otimes\widetilde{V})W$.

For each k, $1\leqslant k\leqslant n$, let $\Pi_k=\Sigma_{i=1}^k E_i$. Since $\{E_i\}$ is an orthogonal resolution of identity, each Π_k is an orthogonal projection, and $\Pi_k\leqslant\Pi_l$ for $k\leqslant l$ by construction. Furthermore,

$$T_k(A)=\sum_{i=1}^k S_i(A)=\sum_{i=1}^k V^*(A\otimes E_i)V=V^*(A\otimes\Pi_k)V,\quad 1\leqslant k\leqslant n,$$

and the forward direction is proved. The proof of the reverse direction is straightforward. ■

It is pertinent to remark that there are situations when the correspondence between POVM's with values in a suitable Hilbert space and decompositions of a given quantum channel T into completely positive summands is not merely a nice mathematical device, but in fact acquires direct physical significance. For instance, Gregoratti and Werner[27] have exploited this correspondence in a scheme for recovery of classical and quantum information from noise by making a generalized quantum measurement (described by a POVM[28]) on the ''environment'' Hilbert space of a noisy quantum channel [the Hilbert space $\mathcal{E}$ in the ''ancilla'' form (6)].

V. CHARACTERIZATION OF QUANTUM OPERATIONS BY POSITIVE OPERATORS

The correspondence between linear maps from a matrix algebra $\mathcal{M}_m$ into a matrix algebra $\mathcal{M}_n$ and linear functionals on $\mathcal{M}_n \otimes \mathcal{M}_m$ (or, by the Riesz lemma, linear operators on $\mathbb{C}_n \otimes \mathbb{C}_m$) has been treated extensively in a variety of forms in the mathematical literature (see, e.g., Refs. 13, 29–32 for a sampling of results related to positive and completely positive maps). More recently, this correspondence has been exploited fruitfully in some quantum information-theoretic contexts, such as optimal cloning maps,[33] optimal teleportation protocols,[34] separability criteria for entangled states,[35] or entanglement generation.[36,37] In this section we will show that the one-to-one correspondence between positive operators on $\mathbb{C}_n \otimes \mathbb{C}_m$ and CP maps $T: \mathcal{M}_m \to \mathcal{M}_n$ (known as the ''Jamiolkowski isomorphism'' in the quantum information community) can be derived using the Radon–Nikodym machinery. We also comment on how this can be accomplished in the infinite-dimensional case with unbounded operators.

A. The Jamiolkowski isomorphism

In this section we consider quantum operations $T: \mathcal{B}(\mathcal{H}) \to \mathcal{B}(\mathcal{K})$ in the case of $\dim \mathcal{H} = m < \infty$ and $\dim \mathcal{K} = n < \infty$. Let $\{e_i\}_{i=1}^m$ and $\{f_\mu\}_{\mu=1}^n$ be fixed orthonormal bases of $\mathcal{H}$ and $\mathcal{K}$. (We will use italic indices for the ''input'' Hilbert space, and greek ones for the ''output'' Hilbert space.) Let τ be the tracial state on $\mathcal{M}_m$, $\tau(A) = m^{-1} \operatorname{Tr} A$, and consider the channel $\Phi(A) := \tau(A) \mathbb{1}_{\mathcal{K}}$. It is convenient to write Φ in the Krans form

$$\Phi(A) := \sum_{i=1}^{m} \sum_{\mu=1}^{n} V_{i\mu}^* A V_{i\mu},$$

where $V_{i\mu} = (1/\sqrt{m}) |e_i\rangle\langle f_\mu|$. Note that these mn Kraus operators are linearly independent, which agrees with the minimality requirement. Setting $\mathcal{E} = \mathcal{K} \otimes \mathcal{H}$, we obtain the canonical Stinespring dilation $\Phi(A) = V_\Phi^* (A \otimes \mathbb{1}_{\mathcal{E}}) V_\Phi$, where

$$V_\Phi \psi = \sum_{i=1}^{m} \sum_{\mu=1}^{n} V_{i\mu} \psi \otimes f_\mu \otimes e_i .$$

Whenever we need to specify the dimensions m and n explicitly, we will write $\Phi_{m,n}$ instead of Φ, $V_{m,n}$ instead of V_Φ, etc.

We must emphasize again that the main result of this section, stated as Theorem V.1 below, is not new. Indeed, it has appeared in numerous papers on quantum information theory.[33–37] Our contribution here is to present a new proof of this result that clearly exhibits the Jamiolkowski isomorphism in the Radon–Nikodym framework.

Theorem V.1: *In the notation described above, any CP map $T: \mathcal{B}(\mathcal{H}) \to \mathcal{B}(\mathcal{K})$ is completely m^2-dominated by Φ. There exists a unique operator $F_T \in \mathcal{B}(\mathcal{E})$ with $0 \leq F_T \leq m^2 \mathbb{1}_{\mathcal{E}}$, such that $\mathsf{D}_\Phi T = \mathbb{1}_{\mathcal{H}} \otimes F_T$, i.e., $T(A) = V_\Phi^* (A \otimes F_T) V_\Phi$. The action of T on any $A \in \mathcal{B}(\mathcal{H})$ can also be expressed in terms of F_T only, namely, as*

$$T(A) = \frac{1}{m} \operatorname{Tr}_{\mathcal{H}} [(\mathbb{1}_{\mathcal{K}} \otimes A^{\mathsf{T}}) F_T], \tag{12}$$

where A^{T} denotes the matrix transpose of A in the basis $\{e_i\}$. Furthermore, T is a quantum operation if and only if $\mathrm{Tr}_{\mathcal{H}} F_T \leqslant m\mathbb{1}_{\mathcal{K}}$.

Proof: Define $\Psi = (1/\sqrt{m})\sum_{i=1}^{m} e_i \otimes e_i$, and let $H_T = T \otimes \mathrm{id}(|\Psi\rangle\langle\Psi|)$. The matrix elements of H_T are given explicitly by

$$\langle f_\mu \otimes e_i | H_T (f_\nu \otimes e_j)\rangle = \frac{1}{m}\langle f_\mu | T(|e_i\rangle\langle e_j|) f_\nu\rangle.$$

For all $A \in \mathcal{B}(\mathcal{H})$ and $\psi \in \mathcal{K}$ we have

$$\begin{aligned} V_\Phi^*(A \otimes H_T)V_\Phi \psi &= \frac{1}{m}\sum_{i,j=1}^{m}\sum_{\mu,\nu=1}^{n} \langle e_i|Ae_j\rangle\langle f_\mu \otimes e_i | H_T(f_\nu \otimes e_j)\rangle |f_\mu\rangle\langle f_\nu|\psi\rangle \\ &= \frac{1}{m^2}\sum_{\mu,\nu=1}^{n} \langle e_i|Ae_j\rangle\langle f_\mu | T(|e_i\rangle\langle e_j|) f_\nu\rangle |f_\mu\rangle\langle f_\nu|\psi\rangle \\ &\equiv \frac{1}{m^2} T(A)\psi, \end{aligned}$$

so that $T \leqslant m^2\Phi$ and $\mathbb{1}_{\mathcal{H}} \otimes m^2 H_T = \mathsf{D}_\Phi T$ by Corollary III.2. Let $F_T = m^2 H_T$. From the uniqueness of the Radon–Nikodym derivative $\mathsf{D}_\Phi T$ it follows that F_T determines T uniquely.

To prove Eq. (12), we need the following useful identity.

Lemma V.2: For all $A \in \mathcal{B}(\mathcal{H})$ and $B \in \mathcal{B}(\mathcal{E})$, we have

$$V_\Phi^*(A \otimes B)V_\Phi = \frac{1}{m}\mathrm{Tr}_{\mathcal{H}}[(\mathbb{1}_{\mathcal{K}} \otimes A^{\mathsf{T}})B].$$

Proof: Proceed by direct computation; for an arbitrary $\psi \in \mathcal{K}$, we have

$$\begin{aligned} \mathrm{Tr}_{\mathcal{H}}[(\mathbb{1}_{\mathcal{K}} \otimes A^{\mathsf{T}})B]\psi &= \left(\mathrm{Tr}_{\mathcal{H}} \sum_{i,j,k=1}^{m}\sum_{\mu,\nu=1}^{n} \langle e_j|Ae_i\rangle\langle f_\mu \otimes e_j|B(f_\nu \otimes e_k)\rangle |f_\mu\rangle\langle f_\nu| \otimes |e_i\rangle\langle e_k|\right)\psi \\ &= \sum_{i,j=1}^{m}\sum_{\mu,\nu=1}^{n} \langle e_j|Ae_i\rangle\langle f_\mu \otimes e_j|B(f_\nu \otimes e_i)\rangle |f_\mu\rangle\langle f_\nu|\psi\rangle \\ &\equiv m V_\Phi^*(A \otimes B)V_\Phi \psi, \end{aligned}$$

and the lemma is proved. ■

This establishes Eq. (12). Finally, if T is a quantum operation, then $T(\mathbb{1}_{\mathcal{H}}) \leqslant \mathbb{1}_{\mathcal{K}}$. From Lemma V.2 it follows that $T(\mathbb{1}_{\mathcal{K}}) = (1/m)\mathrm{Tr}_{\mathcal{H}} F_T$, that is, $\mathrm{Tr}_{\mathcal{H}} F_T \leqslant m\mathbb{1}$. Conversely, if $T(\mathbb{1}_{\mathcal{H}}) = V_\Phi^*(\mathbb{1}_{\mathcal{K}} \otimes F_T)V_\Phi \leqslant \mathbb{1}_{\mathcal{K}}$, we have $\mathrm{Tr}_{\mathcal{H}} F_T \leqslant m\mathbb{1}_{\mathcal{K}}$ by Lemma V.2. The theorem is proved. ■

Let $T(A) = V^*(A \otimes \mathbb{1}_{\mathcal{F}})V$ be the canonical Stinespring dilation of T. Then it is easily shown that $\dim \mathcal{H} \cdot \dim \mathcal{F} = \mathrm{rank}\, \mathsf{D}_\Phi T$, that is $\dim \mathcal{F} = \mathrm{rank}\, F_T$. Indeed, Theorems III.5 and V.1 together imply that for any CP map $T: \mathcal{M}_m \to \mathcal{M}_n$ there exist operators $\{K_i^T\}_{i=1}^N$ from $\mathcal{M}_n$ into $\mathcal{M}_m$, such that $\Phi_{m,n}(A) = \sum_{i=1}^N (K_i^T)^* A K_i^T$ and $T(A) = \sum_{i=1}^N \lambda_i (K_i^T)^* A K_i^T$, where $\{\lambda_i\}$ are the (non-negative) eigenvalues of F_T. The Kraus operators $\{K_i^T\}_{i=1}^N$ are linearly independent, and are determined by the isometry V_Φ and the eigenvectors $\{\xi_i\}_{i=1}^N$ of F_T through $V_\Phi \psi = \sum_{i=1}^N V_i^T \psi \otimes \xi_i$. Therefore $N \equiv mn$. The number of nonzero terms in the corresponding Kraus decomposition of T is equal to $\mathrm{rank}\, F_T$, so that $\dim \mathcal{F} = \mathrm{rank}\, F_T$.

Last we would like to show how the Radon–Nikodym derivative $\mathsf{D}_\Phi T$ transforms under composition of CP maps. Consider two CP maps $T_1: \mathcal{M}_m \to \mathcal{M}_n$ and $T_2: \mathcal{M}_n \to \mathcal{M}_d$. According to Theorem V.1 we can write

$$T_1(A) = V_{m,n}^*(A \otimes F_1)V_{m,n}, \quad T_2(B) = V_{n,d}^*(B \otimes F_2)V_{n,d}$$

for uniquely determined positive operators $F_1 \in \mathcal{M}_n \otimes \mathcal{M}_m$ and F_2 on $\mathcal{M}_d \otimes \mathcal{M}_n$. For any $A \in \mathcal{M}_m$, we have

$$\begin{aligned} T_2 \circ T_1(A) &= V_{n,d}^*(T_1(A) \otimes F_2)V_{n,d} \\ &= V_{n,d}^*(V_{m,n}^*(A \otimes F_1)V_{m,n} \otimes F_2)V_{n,d} \\ &= V_{n,d}^*(V_{m,n}^* \otimes \mathbb{1}_{d\times n})(A \otimes F_1 \otimes F_2)(V_{m,n} \otimes \mathbb{1}_{d\times n})V_{n,d}, \end{aligned}$$

where $\mathbb{1}_{d\times n}$ denotes the identity operator on the dilation space $\mathbb{C}^d \otimes C^n$ of T_2. Let $\{e_i\}_{i=1}^m$, $\{f_\mu\}_{\mu=1}^n$, and $\{\phi_x\}_{x=1}^d$ be orthonormal bases of $\mathbb{C}^m$, $\mathbb{C}^n$, and $\mathbb{C}^d$, respectively. Then for any $A \in \mathcal{M}_m$ and any $\psi \in \mathbb{C}^d$ we have

$$\begin{aligned} &T_2 \circ T_1(A)\psi \\ &\quad = \frac{1}{mn}\sum_{i,j=1}^{m}\sum_{\mu,\nu=1}^{n}\sum_{x,y=1}^{d} \langle e_i|Ae_j\rangle|\phi_x\rangle\langle\phi_y|\psi\rangle\langle f_\mu \otimes e_i|F_1(f_\nu \otimes e_j)\rangle\langle\phi_x \otimes f_\mu|F_2(\phi_y \otimes f_\nu)\rangle \\ &\quad = \frac{1}{m}\sum_{i,j=1}^{m}\sum_{x,y=1}^{d}\left(\frac{1}{n}\sum_{\mu,\nu=1}^{n}\langle\phi_x \otimes f_\mu|F_2(\phi_y \otimes f_\nu)\rangle\langle f_\mu \otimes e_i|F_1(f_\nu \otimes e_j)\rangle\right)\langle e_i|Ae_j\rangle|\phi_x\rangle\langle\phi_y|\psi\rangle. \end{aligned}$$

Let $\Omega = (1/\sqrt{n})\Sigma_{\mu=1}^n f_\mu \otimes f_\mu$. Define an operator F_{21} on $\mathbb{C}^d \otimes C^m$ by

$$\langle\phi_x \otimes e_i|F_{21}(\phi_y \otimes e_j)\rangle = \langle\phi_x \otimes \Omega \otimes e_i|(F_2 \otimes F_1)(\phi_y \otimes \Omega \otimes e_j)\rangle.$$

Then it is evident from the calculations above that we can write $T_2 \circ T_1(A) = V_{m,d}^*(A \otimes F_{21})V_{m,d}$. By the uniqueness of the Radon–Nikodym derivative, $\mathbb{1}_m \otimes F_{21} = \mathsf{D}_{\Phi_{m,d}}(T_2 \circ T_1)$. Defining the conditional expectation M_Ω from $\mathcal{M}_d \otimes \mathcal{M}_n^{\otimes 2} \otimes \mathcal{M}_m$ onto $\mathcal{M}_d \otimes \mathcal{M}_m$ by

$$M_\Omega(A \otimes B \otimes C) = \langle\Omega|B\Omega\rangle(A \otimes C) \quad \forall A \in \mathcal{M}_d,\ B \in \mathcal{M}_n^{\otimes 2},\ C \in \mathcal{M}_m,$$

we can write more succinctly $F_{21} = M_\Omega(F_2 \otimes F_1)$.

B. Generalization to arbitrary faithful states

The construction described in Sec. V A also goes through if, instead of the tracial state τ, we take an arbitrary *faithful* state ω. As is well-known, for any such state there exist an orthonormal basis $\{e_i\}_{i=1}^m$ and a probability distribution $\{p_i\}_{i=1}^m$ with $p_i > 0$, such that $\omega(A) = \Sigma_{i=1}^m p_i\langle e_i|Ae_i\rangle$ for all $A \in \mathcal{B}(\mathcal{H})$. Furthermore, $\omega(A) = \langle\Omega|(A \otimes \mathbb{1})\Omega\rangle$, where $\Omega = \Sigma_{i=1}^m \sqrt{p_i}e_i \otimes e_i$. (This is, of course, the canonical Stinespring dilation of the CP map ω by means of the GNS construction.) Let $D_\omega \in \mathcal{B}(\mathcal{H})$ denote the density operator corresponding to ω, i.e., $\omega(A) = \mathrm{Tr}(D_\omega A)$. Owing to the faithfulness of ω, D_ω is invertible.

Fix an orthonormal basis $\{f_\mu\}_{\mu=1}^n$ of $\mathcal{K}$, and define the channel $\Phi_\omega : \mathcal{B}(\mathcal{H}) \to \mathcal{B}(\mathcal{K})$ through $\Phi_\omega(A) = \omega(A)\mathbb{1}_\mathcal{K}$. The Kraus form of Φ_ω is given by $\Phi_\omega(A) = \Sigma_{i=1}^m\Sigma_{\mu=1}^n V_{i\mu}^* A V_{i\mu}$, where $V_{i\mu} = \sqrt{p_i}|e_i\rangle\langle f_\mu|$, and the canonical Stinespring dilation by $\Phi_\omega(A) = V_\omega^*(A \otimes \mathbb{1}_\mathcal{E})V_\omega$, where again $\mathcal{E} \simeq \mathcal{K} \otimes \mathcal{H}$ and $V_\omega\psi = \Sigma_{i=1}^m\Sigma_{\mu=1}^n V_{i\mu}\psi \otimes f_\mu \otimes e_i$.

Consider the positive operator $F_{T,\omega} = T \otimes \mathrm{id}((D_\omega^{-1} \otimes \mathbb{1})|\Omega\rangle\langle\Omega|(D_\omega^{-1} \otimes \mathbb{1}))$, whose matrix elements are given by $\langle f_\mu \otimes e_i|F_{T,\omega}(f_\nu \otimes e_j)\rangle = (1/\sqrt{p_i p_j})\langle f_\mu|T(|e_i\rangle\langle e_j|)f_\nu\rangle$. For all $A \in \mathcal{B}(\mathcal{H})$ and $\psi \in \mathcal{K}$ we then have

$$V_\omega^*(A\otimes F_{T,\omega})V_\omega\psi=\sum_{i,j=1}^{m}\sum_{\mu,\nu=1}^{n}\sqrt{p_ip_j}\langle e_i|Ae_j\rangle\langle f_\mu\otimes e_i|F_{T,w}(f_\nu\otimes e_j)\rangle|f_\mu\rangle\langle f_\nu|\psi\rangle$$

$$=\sum_{i,j=1}^{m}\sum_{\mu,\nu=1}^{n}\langle e_i|Ae_j\rangle\langle f_\mu|T(|e_i\rangle\langle e_j|)f_\nu\rangle|f_\mu\rangle\langle f_\nu|\psi\rangle\equiv T(A)\psi,$$

so that $T\leqslant\|F_{T,\omega}\|\Phi_\omega$, with $\|F_{T,\omega}\|\leqslant\|D_\omega^{-1}\|^2\|T\|_{\mathrm{cb}}$.

Consequently, for any faithful state ω on $\mathcal{B}(\mathcal{H})$ and any CP map $T:\mathcal{B}(\mathcal{H})\to\mathcal{B}(\mathcal{K})$ there exists a positive constant c such that T is completely c-dominated by Φ_ω; thus T is uniquely determined by the Radon–Nikodym derivative $\mathsf{D}_{\Phi_\omega}T$. Note that in the special case of ω being the tracial state on $\mathcal{M}_m$ we simply recover the results of the preceding section.

C. Generalization to infinite dimensions

In the form stated above, both the Jamiolkowski isomorphism and its generalization to arbitrary faithful states are valid only for CP maps between finite-dimensional algebras. However, in many problems of quantum information theory it is necessary to consider CP maps between algebras of operators on infinite-dimensional Hilbert spaces.

Consider a normal CP map $T:\mathcal{B}(\mathcal{H})\to\mathcal{B}(\mathcal{K})$, where $\mathcal{H}$ and $\mathcal{K}$ are separable Hilbert spaces. Fix a normal faithful state ω on $\mathcal{B}(\mathcal{H})$; then there exist a complete orthonormal basis $\{e_i\}$ of $\mathcal{H}$ and a probability distribution $\{p_i\}$, $p_i>0$, such that, for any $A\in\mathcal{B}(\mathcal{H})$, $\omega(A)=\langle\Omega|(A\otimes\mathbb{1})\Omega\rangle$ with $\Omega=\Sigma_i\sqrt{p_i}e_i\otimes e_i$. Let D_ω denote the density operator corresponding to ω. Because $\mathcal{H}$ is infinite-dimensional, the inverse of D_ω is an unbounded operator defined on a dense domain, namely the linear span of $\{e_i\}$. Therefore the approach taken in the preceding section will not work; instead, we will characterize T through the Radon–Nikodym derivative of another CP map T_ω (dependent on both T and ω) with respect to the channel $\Phi_\omega=\omega(A)\mathbb{1}_\mathcal{K}$.

Choosing a complete orthonormal basis $\{f_\mu\}$ of $\mathcal{K}$, we can write Φ_ω in the Kraus form $\Phi_\omega(A)=\Sigma_{i,\mu}V_{i\mu}^*AV_{i\mu}$, $V_{i\mu}=\sqrt{p_i}|e_i\rangle\langle f_\mu|$, where the series converges in the strong operator topology. We also have the Stinespring dilation via $\Phi_\omega(A)=V_\omega^*(A\otimes\mathbb{1}_\mathcal{E})V_\omega$, where $\mathcal{E}\simeq\mathcal{K}\otimes\mathcal{H}$ and $V_\omega\psi=\Sigma_{i,\mu}V_{i\mu}\psi\otimes f_\mu\otimes e_i$. To see that this Stinespring dilation is canonical, let $A=(1/\sqrt{p_k})|e_j\rangle\langle e_k|$ and $\psi=f_\nu$. Thus

$$(A\otimes\mathbb{1}_\mathcal{E})V_\omega\psi=e_j\otimes f_\nu\otimes e_k,$$

which shows that the set $\{(A\otimes\mathbb{1}_\mathcal{E})V_\omega\psi|A\in\mathcal{B}(\mathcal{H}),\psi\in\mathcal{K}\}$ is total in $\mathcal{H}\otimes\mathcal{E}$.

Let $F_{T,\omega}=T\otimes\mathrm{id}(|\Omega\rangle\langle\Omega|)$; the matrix elements are

$$\langle f_\mu\otimes e_i|F_{T,\omega}(f_\nu\otimes e_j)\rangle=\sqrt{p_ip_j}\langle f_\mu|T(|e_i\rangle\langle e_j|)f_\nu\rangle.$$

Then for all $A\in\mathcal{B}(\mathcal{H})$ and $\psi\in\mathcal{K}$ we can write

$$V_\omega^*(A\otimes F_{T,\omega})V_\omega\psi=\sum_{i,\mu}\sum_{j,\nu}\sqrt{p_ip_j}\langle f_\mu\otimes e_i|F_{T,\omega}(f_\nu\otimes e_j)\rangle\langle e_i|Ae_j\rangle|f_\mu\rangle\langle f_\nu|\psi\rangle$$

$$=\sum_{i,\mu}\sum_{j,\nu}p_ip_j\langle e_i|Ae_j\rangle\langle f_\mu|T(|e_i\rangle\langle e_j|)f_\nu\rangle|f_\mu\rangle\langle f_\nu|\psi\rangle\equiv T(D_\omega AD_\omega)\psi.$$

We will write $T_\omega(A)$ for $T(D_\omega AD_\omega)$. From the Radon–Nikodym theorem it follows that T_ω is completely dominated by Φ_ω, and that $\mathsf{D}_{\Phi_\omega}T_\omega=\mathbb{1}_\mathcal{H}\otimes F_{T,\omega}$. We can determine the action of T on the "matrix units" $|e_i\rangle\langle e_j|$ via $T(|e_i\rangle\langle e_j|)=(p_ip_j)^{-1}T_\omega(|e_i\rangle\langle e_j|)$.

VI. NORM ESTIMATES FOR DIFFERENCES OF QUANTUM OPERATIONS

In this section we will demonstrate the use of the Radon–Nikodym theorem for CP maps in deriving several useful estimates for CB norms of differences of quantum channels.

Consider two CP maps $T_1, T_2 : \mathcal{B}(\mathcal{H}) \to \mathcal{B}(\mathcal{K})$. Suppose that there exists a CP map $T : \mathcal{B}(\mathcal{H}) \to \mathcal{B}(\mathcal{K})$, such that $T_i \leqslant T$, $i = 1, 2$, and let $T(A) = V^*(A \otimes \mathbb{1}_{\mathcal{E}})V$ be the canonical Stinespring dilation of T. By the Radon–Nikodym theorem, there exist positive contractions $F_1, F_2 \in \mathcal{B}(\mathcal{E})$ such that $T_i(A) = V^*(A \otimes F_i)V$, $i = 1, 2$. Then

$$(T_1 - T_2)(A) = T_1(A) - T_2(A) = V^*(A \otimes (F_1 - F_2))V,$$

and the Haagerup–Paulsen–Wittstock theorem immediately implies that

$$\|T_1 - T_2\|_{\mathrm{cb}} \leqslant \|V\| \|(F_1 - F_2)V\| \leqslant \|V\|^2 \|F_1 - F_2\|.$$

If T is a quantum channel, V is an isometry, so that $\|V\| = 1$. Therefore we get

$$\|T_1 - T_2\|_{\mathrm{cb}} \leqslant \|F_1 - F_2\|. \tag{13}$$

In particular, if $S \leqslant T$, then $\|S - T\|_{\mathrm{cb}} \leqslant \|\mathbb{1} - F\|$, where $\mathbb{1} \otimes F$ is the Radon–Nikodym derivative $\mathsf{D}_T S$.

Given two CP maps $T_1, T_2 : \mathcal{B}(\mathcal{H}) \to \mathcal{B}(\mathcal{K})$ with (not necessarily minimal) Stinespring dilations $T_i(A) = V_i^*(A \otimes \mathbb{1}_{\mathcal{E}})V_i$, $i = 1,2$, on the common dilation space $\mathcal{E}$, the norm $\|T_1 - T_2\|_{\mathrm{cb}}$ can be bounded from above in terms of V_1 and V_2. Indeed, denoting by π the $*$-homomorphism $\mathcal{B}(\mathcal{H}) \ni A \mapsto A \otimes \mathbb{1}_{\mathcal{E}}$, we can use the Haagerup–Paulsen–Wittstock theorem to obtain

$$\begin{aligned}
\|T_1 - T_2\|_{\mathrm{cb}} &= \|V_1^* \circ \pi \circ V_1 - V_2^* \circ \pi \circ V_2\|_{\mathrm{cb}} \\
&\leqslant \|V_1^* \circ \pi \circ V_1 - V_1^* \circ \pi \circ V_2\|_{\mathrm{cb}} + \|V_1^* \circ \pi \circ V_2 - V_2^* \circ \pi \circ V_2\|_{\mathrm{cb}} \\
&\leqslant (\|V_1\| + \|V_2\|)\|V_1 - V_2\|.
\end{aligned} \tag{14}$$

If T_1 and T_2 are channels, then V_1 and V_2 are isometries. Consequently, $\|V_1\| = \|V_2\| = 1$, and the bound (14) becomes $\|T_1 - T_2\|_{\mathrm{cb}} \leqslant 2\|V_1 - V_2\|$. As the lemma below shows, when the Hilbert spaces $\mathcal{H}$ and $\mathcal{K}$ are finite-dimensional, one can find a common dilation space $\mathcal{E}$ and maps V_1, $V_2 : \mathcal{K} \to \mathcal{H} \otimes \mathcal{E}$, such that $\|T_1 - T_2\|_{\mathrm{cb}}$ can be bounded from below.

Lemma VI.1: For any two CP maps $T_1, T_2 : \mathcal{B}(\mathcal{H}) \to \mathcal{B}(\mathcal{K})$ there exist a Hilbert space $\mathcal{E}$ and operators $V_1, V_2 : \mathcal{K} \to \mathcal{H} \otimes \mathcal{E}$ such that $T_i(A) = V_i^*(A \otimes \mathbb{1}_{\mathcal{E}})V_i$, $i = 1, 2$, and

$$\|V_1 - V_2\| \leqslant \dim \mathcal{H} \sqrt{\|T_1 - T_2\|_{\mathrm{cb}}}. \tag{15}$$

Proof: Using Theorem V.1, we can write $\mathcal{E} = \mathcal{K} \otimes \mathcal{H}$ and $V_i = \sqrt{\mathsf{D}_\Phi T_i} V_\Phi = (\mathbb{1}_{\mathcal{H}} \otimes \sqrt{F_{T_i}})V_\Phi$. Then $T_i(A) = V_i^*(A \otimes \mathbb{1}_{\mathcal{E}})V_i$. Next we prove the estimate (15). We have

$$\|V_1 - V_2\| \leqslant \|\mathbb{1}_{\mathcal{H}} \otimes \sqrt{F_{T_1}} - \mathbb{1}_{\mathcal{H}} \otimes \sqrt{F_{T_2}}\| \|V_\Phi\| = \|\sqrt{F_{T_1}} - \sqrt{F_{T_2}}\| \leqslant \sqrt{\|F_{T_1} - F_{T_2}\|}. \tag{16}$$

The last inequality in (16) holds because: (1) $x \mapsto \sqrt{x}$ is an operator monotone function on $[0,\infty)$, i.e., $\sqrt{A} \leqslant \sqrt{B}$ for all operators A, B satisfying $0 \leqslant A \leqslant B$ (Prop. V.1.8 in Ref. 38), (2) for any operator monotone function f with $f(0) = 0$ and any pair of positive operators A, B we have $\|f(A) - f(B)\| \leqslant f(\|A - B\|)$ (Theorem X.1.1 in Ref. 38), and (3) $\|X\| = \|\sqrt{X}\|^2$ for any $X \geqslant 0$ by the spectral mapping theorem. Now $F_{T_i} = (\dim \mathcal{H})^2 T_i \otimes \mathrm{id}(|\Psi\rangle\langle\Psi|)$, where $\Psi = (1/\sqrt{\dim \mathcal{H}}) \Sigma_i e_i \otimes e_i$ for some orthonormal basis $\{e_i\}$ in $\mathcal{H}$. Thus, using the properties of the CB norm, we get

$$\|F_{T_1} - F_{T_2}\| = (\dim \mathcal{H})^2 \|T_1 \otimes \mathrm{id}(|\Psi\rangle\langle\Psi|) - T_2 \otimes \mathrm{id}(|\Psi\rangle\langle\Psi|)\| \leqslant (\dim \mathcal{H})^2 \|T_1 - T_2\|_{\mathrm{cb}}. \tag{17}$$

Combining Eqs. (16) and (17) yields (15). ■

Inequality (15) was also proved by Kitaev,[21] but by quite different means. Here several warnings are in order. In the article of Kitaev[21] the ''canonical representation'' of a CP map $T:\mathcal{B}(\mathcal{H})\to\mathcal{B}(\mathcal{K})$ is defined as $T(A)=\mathrm{Tr}_{\mathcal{F}}WAW^*$ with $\mathcal{F}\simeq\mathcal{K}\otimes\mathcal{H}$. This is not to be confused with the *canonical Stinespring dilation* of T, $T(A)=V^*(A\otimes\mathbb{1}_{\mathcal{E}})V$ [or its dual, $T_*(A)=\mathrm{Tr}_{\mathcal{E}}VAV^*$] which must satisfy the requirement that $\mathcal{H}\otimes\mathcal{E}$ is (the closure of) the linear span of $\{(A\otimes\mathbb{1}_{\mathcal{E}})V\psi|A\in\mathcal{B}(\mathcal{H}),\psi\in\mathcal{K}\}$. Thus $\mathcal{E}$ is, in general, a subspace of $\mathcal{F}=\mathcal{K}\otimes\mathcal{H}$. Furthermore, Kitaev's version of the estimate (15) has $\dim\mathcal{K}$, and not $\dim\mathcal{H}$, multiplying the CB norm on its right-hand side. This is due to the fact that, whereas we cast all CP maps in the Stinespring form $T(A)=W^*(A\otimes\mathbb{1}_{\mathcal{F}})W$, Kitaev prefers to work with the dual representation $T_*(A)=\mathrm{Tr}_{\mathcal{F}}WAW^*$. Since all (bounded) operators on a finite-dimensional Hilbert space are trace-class, T_* trivially extends to a CP map from $\mathcal{B}(\mathcal{K})$ into $\mathcal{B}(\mathcal{H})$.

VII. CONCLUDING REMARKS

In this paper we have shown that the Radon-Nikodym theorem for completely positive maps[6,7,10] is an extremely powerful and versatile tool for problems involving characterization and comparison of quantum operations. The upshot is that if $T(A)=V^*(A\otimes\mathbb{1}_{\mathcal{E}})V$ is the canonical Stinespring dilation of a CP map T, then the set of all CP maps S for which $T-S$ is also CP (we say that S is *completely dominated* by T) is in a one-to-one correspondence with the positive contractions F on $\mathcal{E}$, given explicitly by $S(A)=V^*(A\otimes F)V$. As we have demonstrated, this correspondence brings many seemingly unrelated problems into a common framework.

However, many important questions still remain unanswered. For instance, it is not difficult to convert the above ''Stinespring form'' of the Radon–Nikodym theorem into an equivalent ''Kraus form'' (cf. Sec. III B). The Kraus decomposition of a CP map T involves at most countably many terms, and all maps S completely dominated by T can be characterized in terms of positive-definite kernels on the corresponding indexing set. However, it is not clear how to apply this theorem directly to CP maps given in terms of a ''continual'' Kraus decomposition (as in, e.g., the quantum operational model of Gaussian displacement noise[39]). For example, if U_g is a strongly continuous unitary representation of a compact topological group G on a Hilbert space $\mathcal{H}$, how do we describe all CP maps completely dominated by the channel

$$T(A)=\int_G U_g^*AU_g\,\mathrm{d}\mu(g),$$

where μ is the (normalized) Haar measure on G, in terms of $\{U_g\}$? A partial step in this direction has been taken by Parthasarathy,[10] who constructed a Stinespring dilation of T in terms of $\{U_g\}$ under the assumption that these operators are linearly independent μ-almost everywhere, i.e.,

$$\int_G\varphi(g)U_g\,\mathrm{d}\mu(g)=0\Leftrightarrow\varphi(g)=0\ \ \mu-\text{a.e.}$$

for any $\varphi\in\mathcal{L}^1(G,\mu)$. However, a general solution is still lacking. We hope to address this issue in a future publication.

ACKNOWLEDGMENTS

[14] Strictly speaking, one should start with the Schrödinger-picture map T_*, extend it by linearity to the trace class $\mathcal{T}(\mathcal{H})$, and then *define* the Heisenberg-picture map T by noting that, for a fixed $A \in \mathcal{B}(\mathcal{H})$, $\mathrm{Tr}[T_*(\rho)A]$ is a continuous linear functional on the trace class, and therefore has the form $\mathrm{Tr}(\rho A')$ for some $A' \in \mathcal{B}(\mathcal{H})$. We then set $T(A)=A'$. However, since we have assumed at the outset that T is normal, we do not have to worry too much about this nuance.

Harrell's modified perturbation theory [Ann. Phys. (N.Y.) **105**, 379 (1977)] is applied and extended to obtain nonpower perturbation expansions for a class of singular Hamiltonians $H=-(d^2/dx^2)+x^2+(A/x^2)+(\lambda/x^\alpha)$ $(A\geqslant 0,\alpha>2)$, known as generalized spiked harmonic oscillators. The perturbation expansions developed here are valid for small values of the coupling $\lambda>0$, and they extend the results which Harrell obtained for the spiked harmonic oscillator $A=0$. Formulas for the excited states are also developed. © *2003 American Institute of Physics.*

I. INTRODUCTION

This is a detailed extension of Harrell's modified perturbation theory[1] for the class of singular potentials

$$H=-\frac{d^2}{dx^2}+x^2+\frac{\lambda}{x^\alpha}\quad(\lambda>0,\alpha>2),\tag{1.1}$$

defined on suitable domains in the Hilbert space $L^2(0,\infty)$ with solutions satisfying Dirichlet boundary conditions. By singular we mean that the familiar Rayleigh–Schrödinger series either do not exist or do not converge. The present work, motivated by Harrell[1] and Greenlee,[2] studies a perturbative and variational analysis of the eigenvalues and eigenfunctions for the family of singular Hamiltonians

$$H=H_0+\lambda V=-\frac{d^2}{dx^2}+x^2+\frac{A}{x^2}+\frac{\lambda}{x^\alpha}\quad(A\geqslant 0)\tag{1.2}$$

known as generalized spiked harmonic oscillator Hamiltonian.[3–10] The extension lies in considering A to range over all non-negative real numbers instead of non-negative integers of the type $l(l+1)$. The main results are the extensions of Harrell's perturbative expansions[1] for the ground-state eigenvalues of the spiked harmonic oscillator Hamiltonian $A=0$. In his elegant investigation, Harrell mentioned briefly the possibility of extending his theory to the case of $A=l(l+1)$, where l is the angular-momentum quantum number; however, his results mostly concern perturbation expansions for ground-state energies of the spiked harmonic oscillator Hamiltonian (1.1). There are two principal reasons for this choice: (1) The interesting Klauder phenomenon[11–13] occurs *only* in the case $A=0$, to the effect that, for sufficiently singular potentials, the perturbation term V cannot be smoothly turned off ($\lambda\to 0$) in the Hamiltonian $H=H_0+\lambda V$ to restore the free Hamiltonian H_0; (2) Rayleigh–Schrödinger perturbation series diverge at some finite order whenever $\alpha>2$.

Klauder's phenomenon does not occur[14–16] if $A>0$. This is the case, for example, in N dimensions with $A=(l+\frac{1}{2}(N-1))(l+\frac{1}{2}(N-3))$ and $l>0$, or with $l=0$ and $N\neq 1$ or 3. In such

cases the domain of the Hamiltonian H *is* stable under the limit $\lambda \to 0$. However, a perturbative analysis for solutions that vanish at the origin is still interesting because of the divergence of the Rayleigh–Schrödinger series at some finite order for any $\alpha > 2$. We are able to conclude in the present paper that the Rayleigh–Schrödinger series will breakdown at the order $n \geqslant 2\nu(\gamma - 1)$ for $\alpha > 2$ where $\nu = 1/(\alpha - 2)$ and $\gamma = 1 + \frac{1}{2}\sqrt{1 + 4A}$. For example, $\alpha \geqslant 2\gamma$ causes the perturbation series to diverge at the first order; for $\alpha \geqslant \gamma + 1$ the second-order perturbation will diverge, etc. These results and some others concerning the convergence of Rayleigh–Schrödinger series which rely heavily of the application of Kato's criterion[17–19] will be the subject of an independent investigation. In the present paper, we concentrate on the development of nonpower perturbation expansions for the Hamiltonian (1.2).

Detwiler and Klander,[20] in their variational study of the spiked harmonic oscillator Hamiltonian (1.1), have shown that for $2 \leqslant \alpha < 3$ the eigenvalues are given by asymptotic series to first order so long as $\lambda > 0$. But for $\alpha > 3$, the ground-state eigenvalues are given by

$$E_0(\lambda) = 3 + k\lambda^{\nu} + o(\lambda^{\nu}),$$

and, for $\alpha = 3$, by

$$E_0(\lambda) = 3 + k'\lambda \log(\lambda) + O(\lambda),$$

where k and k' are to be determined by variational means.[20] Harrell, soon afterwards, modified the Rayleigh–Schrödinger series by utilizing the standard WKB-approximation technique for the lowest few orders. This proved to be quite successful, and he continued to develop a special perturbation theory, now known as singular perturbation theory, and obtained thereby the first few terms of the perturbed λ-expansion for different values of α. This turned out to be a nonpower series expansion and in fact was of exactly the same order as that of Detwiler and Klauder.[20] More specifically, Harrell[1] showed that the asymptotic series for the ground-state eigenvalues of the Hamiltonian (1.1) are explicitly given, for $\nu = 1/(\alpha - 2)$.

For $\alpha \geqslant 4$,

$$E_0(\lambda) = 3 + \frac{4\nu^{2\nu}\Gamma(1-\nu)}{\sqrt{\pi}\Gamma(1+\nu)}\lambda^{\nu} + O(\lambda^{2\nu}).$$

For $3 < \alpha < 4$,

$$E_0(\lambda) = 3 + \frac{4\nu^{2\nu}\Gamma(1-\nu)}{\sqrt{\pi}\Gamma(1+\nu)}\lambda^{\nu} - \frac{4\nu\Gamma\left(\dfrac{3-\dfrac{1}{\nu}}{2}\right)}{(1-\nu)\sqrt{\pi}}\lambda + O(\lambda^{2\nu}).$$

For $\alpha = 3$,

$$E_0(\lambda) = 3 - \frac{4}{\sqrt{\pi}}\lambda \log(\lambda) - \frac{10c}{\sqrt{\pi}}\lambda + O(\lambda^2 \log^2(\lambda))$$

$$(c = 0.577\,215\,664\,9 \text{ etc., Euler's constant}).$$

For $\frac{5}{2} < \alpha < 3$,

$$E_0(\lambda) = 3 + \frac{4\nu^{2\nu}\Gamma(1-\nu)}{\sqrt{\pi}\Gamma(1+\nu)}\lambda^{\nu} + \frac{2\Gamma\left(\dfrac{3-\alpha}{2}\right)}{\sqrt{\pi}}\lambda + O(\lambda^{2\nu}).$$

The paper is organized as follows. In Sec. II, we briefly review the regular perturbation expansions for the Hamiltonian (1.2) and we identify the conditions under which the first- and the second-order corrections of Rayleigh–Schrödinger series exists. In Sec. III, the main theorem used for the development of nonpower perturbation expansions will be introduced and proved. In Sec. IV we introduced a suitable trial wave function. In Secs. V and VI, we extend Harrell's theory to treat the generalized spiked harmonic oscillator Hamiltonians (1.2) for the cases where the Rayleigh–Schrödinger series fails and thereby we show that asymptotic series for the eigenvalues of the Hamiltonian (1.2) are explicitly given by the following.

For $\alpha \geqslant 2(2\gamma-1)$,

$$E_0(\lambda)=2\gamma+\frac{4(\gamma-1)\nu^{4\nu(\gamma-1)}\Gamma(1-2\nu(\gamma-1))}{\Gamma(\gamma)\Gamma(1+2\nu(\gamma-1))}\lambda^{2\nu(\gamma-1)}+O(\lambda^{4\nu(\gamma-1)}).$$

For $2\gamma<\alpha<2(2\gamma-1)$,

$$E_0(\lambda)=2\gamma+\frac{4(\gamma-1)\nu^{4\nu(\gamma-1)}\Gamma(1-2\nu(\gamma-1))}{\Gamma(\gamma)\Gamma(1+2\nu(\gamma-1))}\lambda^{2\nu(\gamma-1)}-\frac{2\nu\Gamma\left(\gamma-\frac{1}{2\nu}\right)}{(1-2\nu(\gamma-1))\Gamma(\gamma)}\lambda+O(\lambda^{4\nu(\gamma-1)}).$$

For $\alpha=2\gamma$,

$$E_0(\lambda)=2\gamma-\frac{1}{(\gamma-1)\Gamma(\gamma)}\lambda\log(\lambda)+\left[\frac{-c(1+\gamma)+2\log(2(\gamma-1))}{(\gamma-1)\Gamma(\gamma)}\right]\lambda+O(\lambda^2\log^2(\lambda)).$$

For $\gamma+1<\alpha<2\gamma$,

$$E_0(\lambda)=2\gamma+\frac{2\nu^{4\nu(\gamma-1)}\Gamma(1-2\nu(\gamma-1))}{\nu\Gamma(\gamma)\Gamma(2\nu(\gamma-1))}\lambda^{2\nu(\gamma-1)}+\frac{2\nu\Gamma\left(\gamma-\frac{1}{2\nu}\right)}{(2\nu(\gamma-1)-1)\Gamma(\gamma)}\lambda+O(\lambda^2),$$

where $\nu=1/(\alpha-2)$ and $\gamma=1+\frac{1}{2}\sqrt{1+4A}$. The asymptotic expansions for the case $\alpha\leqslant\gamma+1$ are discussed in Sec. VII, along with some other cases. The connection with the region $0<\alpha<5/2$, overlooked by Harrell, is also investigated. In Sec. VIII, the extension of the perturbation expansions developed in Secs. V–VII to the excited states is discussed and some explicit formulas are derived.

II. ASYMPTOTIC PERTURBATION EXPANSIONS

It is known that although many perturbation expansions diverge, they may actually be asymptotic expansions whose first few terms can yield good approximations. The class of singular Hamiltonian (1.2) affords interesting examples of this phenomenon. Indeed, by regarding the Gol'dman and Krivchenkov Hamiltonian[7] $H_0=-(d^2/dx^2)+x^2+(A/x^2)$, which admits the exact solutions

$$\psi_n(x)=(-1)^n\sqrt{\frac{2(\gamma)_n}{n!\Gamma(\gamma)}}x^{\gamma-1/2}e^{-1/2x^2}\,{}_1F_1(-n,\gamma,x^2) \tag{2.1}$$

with exact eigenenergies

$$E_n=4n+2\gamma,\quad n=0,1,2,\ldots,\quad \gamma=1+\tfrac{1}{2}\sqrt{1+4A}, \tag{2.2}$$

as the unperturbed part, and $V(x)=x^{-\alpha}$ as the perturbation potential, the first-order correction of the Rayleigh–Schrödinger series for the Hamiltonian (1.2) exists only for $\alpha<2\gamma$, while the second-order correction will required $\alpha<\gamma+1$. The first condition $\alpha<2\gamma$ follows from $E_1=(\psi_0,x^{-\alpha}\psi_0)$, while the second condition $\alpha<\gamma+1$ follows[5] from

$$E_2=\sum_{i=1}^{\infty}\frac{|(\psi_0,x^{-\alpha}\psi_i)|^2}{E_i-E_0}.$$

Under these conditions the perturbation expansions for the ground-state eigenvalues up to second-order[5] reads, for small values of λ,

$$\begin{aligned}E(\lambda,\alpha)&=E_0+E_1\lambda+E_2\lambda^2+\cdots\\&=2\gamma+\frac{\Gamma\left(\gamma-\frac{\alpha}{2}\right)}{\Gamma(\gamma)}\lambda-\lambda^2\frac{\alpha^2}{16\gamma}{}_4F_3\left(1,1,1+\frac{\alpha}{2},1+\frac{\alpha}{2};2,2,\gamma+1;1\right)+\cdots.\end{aligned}\tag{2.3}$$

In the next sections we develop nonpower perturbation expansions for the cases where the regular Rayleigh–Schrödinger series fails to exist; namely, $\alpha\geqslant 2\gamma$ and $\alpha\geqslant\gamma+1$.

Before we proceed we should note that the functions ${}_1F_1$ and ${}_4F_3$, mentioned above, are special cases of the generalized hypergeometric function[21]

$${}_pF_q(\alpha_1,\alpha_2,\ldots,\alpha_p;\beta_1,\beta_2,\ldots,\beta_q;z)=\sum_{k=0}^{\infty}\frac{\prod_{i=1}^{p}(\alpha_i)_k}{\prod_{j=1}^{q}(\beta_j)_k}\frac{z^k}{k!},\tag{2.4}$$

where p and q are non-negative integers, and none of the β_j $(j=1,2,...,q)$, is equal to zero or to a negative integer. If the series does not terminate (that is to say, none of the α_i, $i=1,2,...,p$, is a negative integer), then the series, in the case $p=q+1$, converges or diverges accordingly as $|z|<1$ or $|z|>1$. For $z=1$, the series is convergent provided $\Sigma_{j=1}^{q}\beta_j-\Sigma_{i=1}^{p}\alpha_i>0$.

Here $(a)_n$, the shifted factorial (or *Pochhammer symbol*), is defined by

$$(a)_0=1,\quad (a)_n=a(a+1)(a+2)\cdots(a+n-1)\ \text{ for }\ n=1,2,\ldots\tag{2.5}$$

and may be expressed in terms of the gamma function by $(a)_k=\Gamma(a+k)/\Gamma(a)$, when a is not a negative integer $-m$, and, in these exceptional cases, $(-m)_k=0$ if $k>m$ and otherwise $(-m)_k=(-1)^k m!/(m-k)!$

III. THE MAIN THEOREM

It is clear that the perturbation approach mentioned in Sec. II cannot apply if $\alpha\geqslant 2\gamma$, since it is clear in this case that the first-order perturbation correction diverges. We construct a modified perturbation series for the operators in this region by considering the perturbation theory of families of self-adjoint operators by an application of the variational method. This is done via Kato's generalization[22,23] of Temple's inequality,[24–26] which can understood from the following discussion. The derivation of bounds on the eigenvalues for self-adjoint operators usually starts from a consideration of the positive definite function given by

$$(\mu,\mu)=([H-\epsilon]\phi,[H-\epsilon]\phi)=(H\phi,H\phi)-(\phi,H\phi)^2+(\epsilon-(\phi,H\phi))^2\geqslant 0,\tag{3.1}$$

where μ is a function of ϕ and ϵ, i.e., $\mu=\mu(\phi,\epsilon)$, H is the operator in question, ϵ is a positive parameter, and ϕ is a suitably chosen normalized trial function. If we expand the normalized function ϕ in terms of the complete set of eigenfunctions $\{\phi_n\}$ of H with eigenvalues $E_n(\lambda)$, $\phi=\Sigma_n a_n\phi_n$, $a_n=(\phi,\phi_n)$, $(\phi,\phi)=1=\Sigma_n|a_n|^2$, we can express the positive definite function in (3.1) as

$$(\mu,\mu)=\sum_n |a_n|^2(E_n(\lambda)-\epsilon)^2\geqslant 0.$$

Let us assume that we have picked the value of ϵ for the closest approach to the ith eigenvalue E_i, i.e.,

$$(\mu,\mu)=\sum_n |a_n|^2(E_n(\lambda)-\epsilon)^2\geqslant (E_i(\lambda)-\epsilon)^2\geqslant 0. \tag{3.2}$$

By combining (3.1) and (3.2), it can be easily seen that

$$\begin{aligned}\epsilon-\sqrt{\|H\phi\|^2-(\phi,H\phi)^2+(\epsilon-(\phi,H\phi))^2}\\ \leqslant E_i(\lambda)\leqslant \epsilon+\sqrt{\|H\phi\|^2-(\phi,H\phi)^2+(\epsilon-(\phi,H\phi))^2}.\end{aligned} \tag{3.3}$$

Now, by setting[26]

$$\epsilon+[(H\phi,H\phi)-(\phi,H\phi)^2+(\epsilon-(\phi,H\phi))^2]^{1/2}=E^L_{i+1}(\lambda), \tag{3.4}$$

where $E^L_{i+1}(\lambda)$ is a lower bound estimate of $E_{i+1}(\lambda)$, we can show that Eq. (3.4) possesses the solution

$$\epsilon=\frac{1}{2}\left[E^L_{i+1}(\lambda)+(\phi,H\phi)-\frac{(H\phi,H\phi)-(\phi,H\phi)^2}{E^L_{i+1}(\lambda)-(\phi,H\phi)}\right] \tag{3.5}$$

provided $(\phi,H\phi)<E^L_{i+1}(\lambda)$. Substituting (3.5) into the lower bound expression in (3.3) yields the Kato–Temple expression for the lower bound:

$$E_i(\lambda)\geqslant(\phi,H\phi)-\frac{(H\phi,H\phi)-(\phi,H\phi)^2}{E^L_{i+1}(\lambda)-(\phi,H\phi)}. \tag{3.6}$$

Similarly, setting

$$\epsilon-[(H\phi,H\phi)-(\phi,H\phi)^2+(\epsilon-(\phi,H\phi))^2]^{1/2}=E^U_{i-1}(\lambda), \tag{3.7}$$

where $E^U_{i-1}(\lambda)$ is an upper bound estimate to the next lowest eigenvalue to $E_i(\lambda)$, yields

$$E_i(\lambda)\leqslant(\phi,H\phi)+\frac{(H\phi,H\phi)-(\phi,H\phi)^2}{(\phi,H\phi)-E^U_{i-1}(\lambda)} \tag{3.8}$$

for $E^U_{i-1}(\lambda)<(\phi,H\phi)$. We let $\eta=(\phi,H\phi)$, and the residual norm $\epsilon=\|(H-\eta)\phi\|$ (hence $\epsilon^2=\|H\phi\|^2-\eta^2$), and $\epsilon^2<(E^L_{i+1}(\lambda)-\eta)(\eta-E^U_{i-1}(\lambda))$, which follows by means of the inequalities $\eta-\epsilon^2/(E^L_{i+1}(\lambda)-\eta)>E^U_{i-1}$ or $\eta+\epsilon^2/(\eta-E^U_{i-1}(\lambda))<E^L_{i+1}(\lambda)$. This indeed ensures that the open interval $(E^U_{i-1}(\lambda),E^L_{i+1}(\lambda))$ contains a single isolated eigenvalue and no other piece of the spectrum. Then it follows from (3.6) and (3.8) that

$$\eta-\frac{\epsilon^2}{E^L_{i+1}(\lambda)-\eta}\leqslant E_i(\lambda)\leqslant\eta+\frac{\epsilon^2}{\eta-E^U_{i-1}(\lambda)}. \tag{3.9}$$

This formula is symmetric with respect to upper and lower bound, as we might expect. It should be noted that (3.9) gives $E_i(\lambda)$ within the error bound of the order ϵ^2: this is very small if ϵ is small, i.e., if ϕ is a good approximate eigenfunction. Indeed, (3.9) implies

$$|E_i(\lambda)-\eta|\leqslant\frac{\epsilon^2}{g}, \tag{3.10}$$

where $g=\min\{\eta-E_{i-1}^U(\lambda),E_{i+1}^L(\lambda)-\eta\}$. Therefore, the error in η depends on the residual norm squared, i.e., on ϵ^2, and on the gap $g>0$ for the eigenvalue is isolated.[1] If (3.9) is applied to the operator $H_0+\lambda V-E_i^\lambda$, where E_i^λ is a variational estimate for the ith eigenvalue of $H_0+\lambda V$, there results[1] the following.

Theorem 1: *If ϕ is normalized trial function for the self-adjoint operator $H=H_0+\lambda V$, where H_0 and V are self-adjoint and E_i^0 is an isolated, nondegenerate stable eigenvalue of H_0, and E_i^λ is a continuous function such that $(\phi,[H_0+\lambda V-E_i^\lambda]\phi)\to 0$ as $\lambda\to 0$, and*

$$\|[H_0+\lambda V-E_i^\lambda]\phi\|=o((\phi,[H_0+\lambda V-E_i^\lambda]\phi)^{1/2}), \tag{3.11}$$

then the eigenvalue of $H_0+\lambda V$ which converges to E_i^0 satisfies

$$E_i(\lambda)=(\phi,[H_0+\lambda V]\phi)+O(\|[H_0+\lambda V-E_i^\lambda]\phi\|^2). \tag{3.12}$$

Proof: To keep the notation simple, let us refer to $E_{i-1}^U(\lambda)$ and $E_{i+1}^L(\lambda)$ in (3.9) by α and β, respectively. Then, from the previous discussion, we have, for $\eta=(\phi,[H_0+\lambda V-E_i^\lambda]\phi)$, that $\alpha<\eta<\beta$, and $\epsilon^2<(\beta-\eta)(\eta-\alpha)$. Further, by applying the Kato–Temple inequality (3.9) to the Hamiltonian $H_0+\lambda V-E_i^\lambda$, we obtain, for normalized ϕ,

$$\eta-\frac{\epsilon^2}{\beta-\eta}\leqslant E_i(\lambda)-E_i^\lambda\leqslant\eta+\frac{\epsilon^2}{\eta-\alpha},$$

where $\epsilon^2=\|[H_0+\lambda V-E_i^\lambda]\phi\|^2-(\phi,[H_0+\lambda V-E_i^\lambda]\phi)^2$. If we divide by η, we obtain after some simplifications

$$-\frac{\left(\frac{\|[H_0+\lambda V-E_i^\lambda]\phi\|}{\eta^{1/2}}\right)^2-\eta}{\beta-\eta}\leqslant\frac{E_i(\lambda)-E_i^\lambda}{\eta}-1\leqslant\frac{\left(\frac{\|[H_0+\lambda V-E_i^\lambda]\phi\|}{\eta^{1/2}}\right)^2-\eta}{\eta-\alpha}. \tag{3.13}$$

However, since ϕ is assumed to be normalized,

$$\frac{E_i(\lambda)-E_i^\lambda}{\eta}-1=\frac{E_i(\lambda)-([H_0+\lambda V]\phi,\phi)}{\eta}=\frac{E_i(\lambda)-([H_0+\lambda V]\phi,\phi)}{\|[H_0+\lambda V-E_i^\lambda]\phi\|^2}\left(\frac{\|[H_0+\lambda V-E_i^\lambda]\phi\|}{\eta^{1/2}}\right)^2.$$

From (3.11), we have for λ sufficiently small,

$$\frac{\|[H_0+\lambda V-E_i^\lambda]\phi\|}{\eta^{1/2}}\leqslant 1.$$

Thus after dividing (3.13) by $(\|[H_0+\lambda V-E_i^\lambda]\phi\|/\eta^{1/2})^2$, we have

$$\left|\frac{E_i(\lambda)-([H_0+\lambda V]\phi,\phi)}{\|[H_0+\lambda V-E_i^\lambda]\phi\|^2}\right|\leqslant\left\{1-\frac{\eta}{\left(\frac{\|[H_0+\lambda V-E_i^\lambda]\phi\|}{\eta^{1/2}}\right)^2}\right\}\max\left\{\frac{1}{\beta-\eta},\frac{1}{\eta-\alpha}\right\}$$

$$\leqslant\max\left\{\frac{1}{\beta-\eta},\frac{1}{\eta-\alpha}\right\}\leqslant C\ \ (\text{constant}),$$

which leads to

$$E_i(\lambda)=([H_0+\lambda V]\phi,\phi)+O(\|[H_0+\lambda V-E_i^{\lambda}]\phi\|^2),$$

as required. □

IV. TRIAL WAVE FUNCTION AND SOLUTION TO A DIFFERENTIAL EQUATION

In this section we shall introduce a suitable trial function in order to obtain eigenvalue perturbation corrections by means of Theorem 1. For singular Hamiltonians of type (1.2), the trial functions are characterized by wave functions with non-integer exponent. This indeed characterizes[27–34] almost all trial functions which have been used previously to study this type of singular Hamiltonian (1.1) and (1.2). Furthermore, the trial functions have to satisfy the physical initial conditions of the problem. In the classical Rayleigh–Schrödinger perturbation theory, the lowest-order trial function for a given eigenvalue is chosen to be the unperturbed eigenfunction, i.e., the exact solutions of the unperturbed Hamiltonian. This is no longer a good choice for the perturbation λV in (1.2) with $\alpha \geqslant 2\gamma$, for

$$\int_{\epsilon}^{\infty} x^{2\gamma-\alpha-1}e^{-x^2}\,dx \approx \epsilon^{-\alpha+2\gamma},$$

which approaches ∞ as ϵ goes to zero. Intuitively, it seems that if the unperturbed eigenfunction was modified slightly near the singular point, so that the expectation value of singular term V was no longer infinite, it would become a reasonable trial function to use to estimate the perturbed eigenvalue. This was the basic idea of the trial wave function used by Detwiler *et al.* to study the Hamiltonian (1.1) and it was employed later by Harrell.[1] Using the notation of Harrell, we start with the (un-normalized) trial wave function

$$\psi(x;\lambda)=W_{\alpha}(x;\lambda)\psi_i(x), \tag{4.1}$$

where $\psi_i(x)$ is given by (2.1) and $W_{\alpha}(x;\lambda)$ is to be determined. It should be noted that far away from the singularity, we expect $\psi(x;\lambda)\sim\psi_i(x)$ for large x, since (1.2) behaves as radial harmonic oscillator Hamiltonian for large x, which, in turn, implies $\lim_{x\to\infty} W_{\alpha}(x;\lambda)=1$. Further, for an arbitrary singular point x_0, not necessarily at the origin, $\psi(x_0;\lambda)=0$, an idea that was borrowed from hard-core problems in quantum mechanics:[20] this forces $W_{\alpha}(x_0;\lambda)=0$; therefore, we must also have $\lim_{x\to 0} W_{\alpha}(x;\lambda)=0$. Using the trial function (4.1), the differential operator (1.2) leads to

$$[H_0+\lambda V-E_i]\psi(x;\lambda)=\left[-\frac{d^2W_{\alpha}(x;\lambda)}{dx^2}-2\frac{dW_{\alpha}(x;\lambda)}{dx}\frac{d}{dx}+\lambda VW_{\alpha}(x;\lambda)\right]\psi_i(x), \tag{4.2}$$

where $E_i\equiv E_i^{\lambda}$ is the variational estimate of H. It is clear from (2.1) that $[d\psi_i(x)/dx]\approx[(\gamma-1/2)/x]\psi_i(x)$ near the origin. Therefore, we may choose $W_{\alpha}(x;\lambda)$ in (4.2) such that

$$\frac{d^2W_{\alpha}(x;\lambda)}{dx^2}+\frac{2(\gamma-\frac{1}{2})}{x}\frac{dW_{\alpha}(x;\lambda)}{dx}-\lambda VW_{\alpha}(x;\lambda)=0 \tag{4.3}$$

and must satisfy the initial conditions

$$\lim_{x\to 0} W_{\alpha}(x;\lambda)=0 \quad \text{and} \quad \lim_{x\to\infty} W_{\alpha}(x;\lambda)=1. \tag{4.4}$$

Equation (4.3) allows us to write Eq. (4.2) as

$$[H_0+\lambda V-E_i]\psi(x;\lambda)=2\frac{dW_{\alpha}(x;\lambda)}{dx}\left[\frac{(\gamma-\frac{1}{2})}{x}-\frac{d}{dx}\right]\psi_i(x). \tag{4.5}$$

To solve (4.3) explicitly, we notice first that the parameter λ can be removed from the equation by a change of variable $z=\lambda^{-\nu}x$ where ν is to be determined shortly. A straightforward calculation shows that Eq. (4.3) becomes

$$\frac{d^2W_\alpha(z)}{dz^2}+\frac{2(\gamma-\frac{1}{2})}{z}\frac{dW_\alpha(z)}{dz}-\frac{\lambda^{(2-\alpha)\nu+1}}{z^\alpha}W_\alpha(z)=0.$$

So, with $\nu=1/(\alpha-2)$, independent of γ, we have

$$\frac{d^2W_\alpha(z)}{dz^2}+\frac{2(\gamma-\frac{1}{2})}{z}\frac{dW_\alpha(z)}{dz}-\frac{W_\alpha(z)}{z^\alpha}=0. \tag{4.6}$$

With another change of variable $Y(z)=z^{\gamma-1}W_\alpha(z)$, (4.6) leads to

$$\frac{d^2Y}{dz^2}+\frac{1}{z}\frac{dY}{dz}-\left[\frac{(\gamma-1)^2}{z^2}+\frac{1}{z^\alpha}\right]Y=0. \tag{4.7}$$

Finally with the further change of variable $\xi=2\nu z^{-(1/2\nu)}$, we have from (4.7),

$$\frac{d^2Y}{d\xi^2}+\frac{1}{\xi}\frac{dY}{d\xi}-\left[1+\frac{[2\nu(\gamma-1)]^2}{\xi^2}\right]Y=0, \tag{4.8}$$

which is the equation of a modified Bessel function[35] of order $2\nu(\gamma-1)$. The solution of Eq. (4.8) is

$$W_\alpha(z)=c_1z^{1-\gamma}I_{2\nu(\gamma-1)}(2\nu z^{-(1/2\nu)})+c_2z^{1-\gamma}K_{2\nu(\gamma-1)}(2\nu z^{-(1/2\nu)}),$$

where I and K denote the modified Bessel functions of the first and second kind, respectively.[35] The initial conditions $\lim_{z\to0}W_\alpha(z)=0$, and $\lim_{z\to\infty}W_\alpha(z)=1$ yields $c_1=0$ and $c_2=[2\nu^{2\nu(\gamma-1)}/\Gamma(2\nu(\gamma-1))]$ by means of

$$K_\nu(z)\approx\frac{1}{2}\Gamma(\nu)\frac{z^\nu}{2} \tag{4.9}$$

as z approach 0. Therefore, we have

$$\begin{aligned}W_\alpha(z)&=\frac{2\nu^{2\nu(\gamma-1)}}{\Gamma(2\nu(\gamma-1))}z^{1-\gamma}K_{2\nu(\gamma-1)}(2\nu z^{-(1/2\nu)}),\quad\text{or more explicitly}\\ W_\alpha(x;\lambda)&=\frac{2\nu^{2\nu(\gamma-1)}}{\Gamma(2\nu(\gamma-1))}\lambda^{\nu(\gamma-1)}x^{1-\gamma}K_{2\nu(\gamma-1)}(2\nu\sqrt{\lambda}x^{-(1/2\nu)}).\end{aligned} \tag{4.10}$$

Finally, we have for the (un-normalized) wave function (4.1) that

$$\psi(x;\lambda)=\frac{2\nu^{2\nu(\gamma-1)}}{\Gamma(2\nu(\gamma-1))}\lambda^{\nu(\gamma-1)}x^{1-\gamma}K_{2\nu(\gamma-1)}(2\nu\sqrt{\lambda}x^{-(1/2\nu)})\psi_i(x). \tag{4.11}$$

It is quite clear by means of Eq. (4.9) that $\lim_{\lambda\to0}\psi(x;\lambda)=\psi_i(x)$ as expected. Consequently, the normalization constant N_λ of $\psi(x;\lambda)$ must satisfy $\lim_{\lambda\to0}N_\lambda=1$. Some properties of the function $K_\nu(z)$ are in order.[35] The physical importance[35] of the function $K_\nu(z)$ lies in the fact that it tends exponentially to zero as $z\to\infty$. The function $K_\nu(z)$ is defined, for unrestricted values of ν, by the equation

$$K_\nu(z)=\frac{\pi}{2\sin(\nu\pi)}[I_{-\nu}(z)-I_\nu(z)], \tag{4.12}$$

where

$$I_\nu(z)=\left(\frac{z}{2}\right)^\nu\sum_{k=0}^{\infty}\frac{(\frac{1}{2}z^2)^k}{k!\Gamma(\nu+k+1)}. \tag{4.13}$$

The apparent discrepancy with (4.12) is resolved by the identity $\Gamma(\nu)\Gamma(1-\nu)=\pi/\sin(\nu\pi)$. For integer values or zero of ν in (4.12), it should be understood that $K_n(z)=\lim_{\nu\to n}K_\nu(z)$, where in this case

$$K_n(z)=\frac{1}{2}\left(\frac{z}{2}\right)^{-n}n^{n-1}\sum_{k=0}^{\infty}\frac{(n-k-1)!}{k!}\left(-\frac{z^2}{4}\right)^k+(-1)^{n+1}\log\left(\frac{z}{2}\right)I_n(z)$$
$$+(-)^n\frac{1}{2}\left(\frac{z}{2}\right)^n\sum_{k=0}^{\infty}\{\psi(k+1)+\psi(n+k+1)\}\frac{\left(\frac{z^2}{4}\right)^k}{k!(n+k)!}, \tag{4.14}$$

while

$$K_0(z)=-\left(c+\log\left(\frac{z}{2}\right)\right)I_0(z)+\sum_{r=1}^{\infty}\frac{\left(\frac{z}{2}\right)^{(2r)}}{(r!)^2}\left\{1+\frac{1}{2}+\frac{1}{3}+\cdots+\frac{1}{r}\right\}. \tag{4.15}$$

Here c is Euler's constant $c=0.577\,215\,664\,9$, etc. The following identity will also be used:

$$z\frac{dK_\nu(z)}{dz}=-\nu K_\nu(z)-zK_{\nu+1}(z). \tag{4.16}$$

V. LOWEST-ORDER ASYMPTOTIC PERTURBATION CORRECTIONS FOR $\alpha\geqslant 2\gamma$

In this section, we apply Theorem 1 and the trial function developed in Sec. IV in order to obtain the eigenvalue perturbation expansions for the Hamiltonian (1.2). We consider first the case of $\alpha\geqslant 2\gamma$ which leads to the divergence of the first-order correction of the regular Rayleigh–Schrödinger series. In a purely theoretical approach, Greenlee[2] has shown that the asymptotic perturbation expansion should take the form

$$E_0(\lambda)=E_0+E_1\lambda^{2\nu(\gamma-1)} \tag{5.1}$$

valid for $2\gamma<\alpha$ and $2\nu(\gamma-1)<1$. We note, for consistency, that we have reproduced the expression of Greenlee using our own notation. Equation (5.1) is in complete agreement with our prediction $\alpha>2\gamma$ or $2\nu(\gamma-1)<1$ for $\nu=1/(\alpha-2)$ obtained by means of Theorem 1, as we shall show in this section. In order to apply Theorem 1, we need first the normalization constant N_λ of the trial wave function $\psi(x;\lambda)$, namely Eq. (4.11). This can be found by means of the condition $\|\psi(x;\lambda)\|^2=1$ which leads to expression

$$N_\lambda^{-2}=\frac{4\nu^{4\nu(\gamma-1)}\lambda^{2\nu(\gamma-1)}}{[\Gamma(2\nu(\gamma-1)]^2}\int_0^\infty x^{2(1-\gamma)}[K_{2\nu(\gamma-1)}(2\nu\sqrt{\lambda}x^{-(1/2\nu)})]^2\psi_i(x)^2\,dx. \tag{5.2}$$

Lemma 1: For the ground-state, i.e., $i=0$, we have

$$N_\lambda^2 = 1 + \frac{2\nu^{4\nu(\gamma-1)}\Gamma(1-2\nu(\gamma-1))}{\Gamma(\gamma)\Gamma(1+2\nu(\gamma-1))}\lambda^{2\nu(\gamma-1)} + O(\lambda^{4\nu(\gamma-1)}), \tag{5.3}$$

where $\nu = 1/(\alpha-2)$ *and* $\alpha > 2\gamma$.

Proof: We note, by using (4.9) in (5.2), that $N_\lambda^2 \approx 1$. To find the order of the error term, however, we used the identity (4.12) which leads to $K_\nu(z) = [\Gamma(\nu)/2](z/2)^{-\nu} - [\Gamma(1-\nu)/2\nu] \times (z/2)^{\nu} + \cdots$. Therefore

$$\begin{aligned}[K_{2\nu(\gamma-1)}(2\nu\sqrt{\lambda}x^{-(1/2\nu)})]^2 = {} & \frac{[\Gamma(2\nu(\gamma-1))]^2}{4}(\nu\sqrt{\lambda}x^{-(1/2\nu)})^{-4\nu(\gamma-1)} \\ & - \frac{\Gamma(2\nu(\gamma-1)\Gamma(1-2\nu(\gamma-1))}{4\nu(\gamma-1)} \\ & + \frac{[\Gamma(1-2\nu(\gamma-1))]^2}{4\nu^2}(\nu\sqrt{\lambda}x^{-(1/2\nu)})^{4\nu(\gamma-1)} + \cdots . \end{aligned} \tag{5.4}$$

For the ground state, we have from (2.1) that $\psi_0(x) = \sqrt{2/\Gamma(\gamma)}x^{\gamma-1/2}e^{-x^2/2}$. Thus on substituting (5.4) into (5.2) we have, after some calculations,

$$N_\lambda^2 = \left\{ 1 - \frac{2\nu^{4\nu(\gamma-1)}\Gamma(1-2\nu(\gamma-1))}{\Gamma(\gamma)\Gamma(1+2\nu(\gamma-1))}\lambda^{2\nu(\gamma-1)} + O(\lambda^{4\nu(\gamma-1)}) \right\}^{-1}$$

and the proof of the lemma follows by a very similar argument to that for Taylor's expansion of $1/(1-\delta)$.

The reason of quoting the expansion (5.3) only up to order $\lambda^{4\nu(\gamma-1)}$ was guided by the error term in (3.12), as the following lemma indicates.

Lemma 2: For the ground-state energy of the Hamiltonian (1.2), where $\alpha > 2\gamma$ *[or* $2\nu(\gamma-1) < 1$*], we have*

$$\begin{aligned} E_0(\lambda) = {} & 2\gamma + \frac{16}{\Gamma(\gamma)}\frac{\nu^{4\nu(\gamma-1)}\lambda^{2\nu(\gamma-1)+1/2}}{[\Gamma(2\nu(\gamma-1)]^2}\int_0^\infty x^{1-(1/2\nu)}e^{-x^2}K_{2\nu(\gamma-1)}(2\nu\sqrt{\lambda}x^{-(1/2\nu)}) \\ & \times K_{1-2\nu(\gamma-1)}(2\nu\sqrt{\lambda}x^{-(1/2\nu)})dx + O(\lambda^{4\nu(\gamma-1)}). \end{aligned} \tag{5.5}$$

Proof: Equation (4.10) with (4.16) leads to

$$\frac{dW_\alpha(x;\lambda)}{dx} = \frac{2\nu^{2\nu(\gamma-1)}}{\Gamma(2\nu(\gamma-1))}\lambda^{\nu(\gamma-1)+1/2}x^{-(1/2\nu)-\gamma}K_{1-2\nu(\gamma-1)}(2\nu\sqrt{\lambda}x^{-(1/2\nu)}). \tag{5.6}$$

Furthermore, using $\psi_0(x) = \sqrt{2/\Gamma(\gamma)}x^{\gamma-1/2}e^{-x^2/2}$, we find

$$\begin{aligned} \frac{dW_\alpha(x;\lambda)}{dx}\left[\frac{(\gamma-\frac{1}{2})}{x} - \frac{d}{dx}\right]\psi_0(x) = {} & \frac{2\nu^{2\nu(\gamma-1)}\lambda^{\nu(\gamma-1)+1/2}}{\Gamma(2\nu(\gamma-1))}\sqrt{\frac{2}{\Gamma(\gamma)}}x^{1/2-(1/2\nu)}e^{-x^2/2} \\ & \times K_{1-2\nu(\gamma-1)}(2\nu\sqrt{\lambda}x^{-(1/2\nu)}), \end{aligned} \tag{5.7}$$

which leads to

$$2\left(W_\alpha(x;\lambda)\psi_0(x), \frac{dW_\alpha(x;\lambda)}{dx}\left[\frac{(\gamma-\frac{1}{2})}{x}-\frac{d}{dx}\right]\psi_0(x)\right)$$
$$=\frac{16}{\Gamma(\gamma)}\frac{\nu^{4\nu(\gamma-1)}\lambda^{2\nu(\gamma-1)+1/2}}{[\Gamma(2\nu(\gamma-1)]^2}\times\int_0^\infty x^{1-(1/2\nu)}e^{-x^2}K_{2\nu(\gamma-1)}(2\nu\sqrt{\lambda}x^{-(1/2\nu)})$$
$$\times K_{1-2\nu(\gamma-1)}(2\nu\sqrt{\lambda}x^{-(1/2\nu)})dx. \tag{5.8}$$

In order to use theorem 1, however, the trial wave function must be normalized. This is equivalent to multiplying (5.8) by the normalization constant N_λ^2, as given by (5.3). Now, since N_λ^2 is of order $\lambda^{2\nu(\gamma-1)}$, out of the second term in (5.3) the multiplication allows us to have (5.8) as quoted, plus an error term of order $\lambda^{4\nu(\gamma-1)}$ as result of using (4.9). What remains is to show that the expression $\|[H_0+\lambda V-E(\lambda)]\phi_\lambda\|$ in (3.12) is also of order $\lambda^{2\nu(\gamma-1)}$. This follows from (5.7) as follows:

$$\|[H_0+\lambda V-E_0]\psi_0\|=2\left\|\frac{dW_\alpha(x;\lambda)}{dx}\left[\frac{(\gamma-\frac{1}{2})}{x}-\frac{d}{dx}\right]\psi_0(x)\right\|$$
$$=2\left[\frac{8\nu^{4\nu(\gamma-1)}\lambda^{2\nu(\gamma-1)+1}}{\Gamma(\gamma)[\Gamma(2\nu(\gamma-1)]^2}\int_0^\infty x^{1-(1/\nu)}e^{-x^2}\right.$$
$$\left.\times[K_{1-2\nu(\gamma-1)}(2\nu\sqrt{\lambda}x^{-(1/2\nu)})]^2\,dx\right]^{1/2}$$
$$=O(\lambda^{2\nu(\gamma-1)}),$$

where we have used

$$K_{1-2\nu(\gamma-1)}(2\nu\sqrt{\lambda}x^{-(1/2\nu)})\approx\frac{\Gamma(1-2\nu(\gamma-1))}{2}(\nu\sqrt{\lambda}x^{-(1/2\nu)})^{2\nu(\gamma-1)-1}.$$

The proof of the lemma then follows by use of Theorem 1, Eq. (3.12), and the variational estimate of E_0^λ by means of (2.2). □

Because of the error term in (5.5), it is not necessary to compute the integral in (5.5) exactly but it is sufficient to estimate the integral using the asymptotic series expansions of the modified Bessel functions $K_{2\nu(\gamma-1)}(2\nu\sqrt{\lambda}x^{-(1/2\nu)})$ and $K_{1-2\nu(\gamma-1)}(2\nu\sqrt{\lambda}x^{-(1/2\nu)})$ by means of (4.12), up to the order cited. Since the order of the error term in (5.5) is $\lambda^{4\nu(\gamma-1)}$ while the integral is of order $\lambda^{2\nu(\gamma-1)}$, we may consider, for fixed α, two regions $0<2\nu(\gamma-1)\leqslant\frac{1}{2}$ and $\frac{1}{2}<2\nu(\gamma-1)<1$, or equivalently $0<4\nu(\gamma-1)\leqslant1$ and $1<4\nu(\gamma-1)<2$. For the first region, we have for the ground-state energy of the Hamiltonian (1.2)

$$E_0(\lambda)=2\gamma+\frac{4(\gamma-1)\nu^{4\nu(\gamma-1)}\Gamma(1-2\nu(\gamma-1))}{\Gamma(\gamma)\Gamma(1+2\nu(\gamma-1))}\lambda^{2\nu(\gamma-1)}+O(\lambda^{4\nu(\gamma-1)}) \tag{5.9}$$

which follows from (5.5) using the asymptotic expansions of $K_{2\nu(\gamma-1)}(2\nu\sqrt{\lambda}x^{-(1/2\nu)})$ and $K_{1-2\nu(\gamma-1)}(2\nu\sqrt{\lambda}x^{-(1/2\nu)})$ by means of (4.9). In the case $\gamma=3/2$ (i.e., $A=0$ or $\alpha\geqslant4$), Eq. (5.9) yields

$$E_0(\lambda)=3+\frac{4\nu^{2\nu}\Gamma(1-\nu)}{\sqrt{\pi}\Gamma(1+\nu)}\lambda^\nu+O(\lambda^{2\nu}), \tag{5.10}$$

where $\nu=1/(\alpha-2)$, as shown earlier by Harrell for the spiked harmonic oscillator Hamiltonian (1.1). Important conclusions follow from (5.9). For $\alpha=2(2\gamma-1)$ or $2\nu(\gamma-1)=\frac{1}{2}$, we have

$$E_0(\lambda)=2\gamma+\frac{2}{\Gamma(\gamma)}\sqrt{\lambda}+O(\lambda). \tag{5.11}$$

This provides a single ground-state approximation formula for a wide class of Hamiltonians $H=-(d^2/dx^2)+x^2+(A/x^2)+(\lambda/x^\alpha)$, where α and $\gamma=1+\frac{1}{2}\sqrt{1+4A}$ are related by $\alpha=2(2\gamma-1)$. For example, for $A=0$, i.e., $\gamma=3/2$, which yields $\alpha=4$, we have

$$E_0(\lambda)=3+\frac{4}{\sqrt{\pi}}\sqrt{\lambda}+O(\lambda),$$

as noted by Harrell. If $\alpha=6$, which implies $\gamma=2$ or $A=0.75$, we have

$$E_0(\lambda)=4+2\sqrt{\lambda}+O(\lambda).$$

For the second region $1<4\nu(\gamma-1)<2$, or $2\gamma<\alpha<2(2\gamma-1)$, by using (4.12), we can easily show that

$$\begin{aligned}&K_{2\nu(\gamma-1)}(2\nu\sqrt{\lambda}x^{-(1/2\nu)})K_{1-2\nu(\gamma-1)}(2\nu\sqrt{\lambda}x^{-(1/2\nu)})\\&\quad=\frac{\Gamma(2\nu(\gamma-1))\Gamma(1-2\nu(\gamma-1))}{2\nu\sqrt{\lambda}}x^{(1/2\nu)}\\&\qquad-\frac{[\Gamma(2\nu(\gamma-1))]^2}{4(1-2\nu(\gamma-1))}\nu^{1-4\nu(\gamma-1)}\lambda^{1/2-2\nu(\gamma-1)}x^{-(1/2\nu)+2(\gamma-1)}+\cdots.\end{aligned}$$

Consequently, (5.5) yields, for $\frac{1}{2}<2\nu(\gamma-1)<1$,

$$\begin{aligned}E_0(\lambda)=2\gamma+&\frac{4(\gamma-1)\nu^{4\nu(\gamma-1)}\Gamma(1-2\nu(\gamma-1))}{\Gamma(\gamma)\Gamma(1+2\nu(\gamma-1))}\lambda^{2\nu(\gamma-1)}-\frac{2\nu\Gamma\left(\gamma-\frac{1}{2\nu}\right)}{(1-2\nu(\gamma-1))\Gamma(\gamma)}\lambda\\&+O(\lambda^{4\nu(\gamma-1)}).\end{aligned} \tag{5.12}$$

Again the result of Harrell for the Hamiltonian (1.1) follows for the case of $\gamma=\frac{3}{2}$, i.e., $A=0$, where, in this case, $3<\alpha<4$ or $\frac{1}{2}<\nu<1$, and

$$E_0(\lambda)=3+\frac{4\nu^{2\nu}\Gamma(1-\nu)}{\sqrt{\pi}\Gamma(1+\nu)}\lambda^{\nu}-\frac{4\nu\Gamma\left(\frac{3-\frac{1}{\nu}}{2}\right)}{(1-\nu)\sqrt{\pi}}\lambda+O(\lambda^{2\nu}). \tag{5.13}$$

For the rest of this section, we consider the case of $2\nu(\gamma-1)=1$. For this specific value Eqs. (4.10) and (5.6) read, for $z=\lambda^{-\nu}x$,

$$W_\alpha(z)=\frac{z^{1-\gamma}}{\gamma-1}K_1\left(\frac{z^{1-\gamma}}{\gamma-1}\right) \tag{5.14}$$

and

$$\frac{dW_\alpha(z)}{dz}=\frac{z^{1-2\gamma}}{\gamma-1}K_0\left(\frac{z^{1-\gamma}}{\gamma-1}\right), \tag{5.15}$$

respectively. Using the asymptotic expansions

$$K_0(z)=[-c+\log(2)-\log(z)]+O(z^2),\quad K_1(z)=\frac{1}{z}+O(z) \tag{5.16}$$

which follow by means of (4.15) and (4.14), respectively, we obtain the following.

Lemma 3: For the ground state energy of the Hamiltonian (1.2), where $\alpha=2\gamma$ *[or* $2\nu(\gamma-1)=1$*], we have*

$$E_0(\lambda)=2\gamma-\frac{1}{(\gamma-1)\Gamma(\gamma)}\lambda\log(\lambda)+\left[\frac{-c(1+\gamma)+2\log(2(\gamma-1))}{(\gamma-1)\Gamma(\gamma)}\right]\lambda+O(\lambda^2\log^2(\lambda)), \tag{5.17}$$

where $c=0.577\,215\,664\,9$, etc., *is Euler's constant.*

Proof: We should note first, in this case,

$$\|[H_0+\lambda V-E(\lambda)]\psi_0\|^2=O(\lambda^2\log^2(\gamma)),$$

which follows from

$$\|[H_0+\lambda V-E(\lambda)]\psi_0\|^2=\frac{2\lambda^2}{(\gamma-1)^2\Gamma(\gamma)}\int_0^\infty x^{3-2\gamma}e^{-x^2}K_0^2\left(\frac{\sqrt{\lambda}}{\gamma-1}x^{1-\gamma}\right)dx$$

by use of (5.7). Since we are only interested in finding the order in terms of the parameter λ, the problem reduces to a search among the smallest value of $\lambda^2\log^2(\lambda)$, $-\lambda^2\log(\lambda)$, and λ^2, for small values of the parameter λ. Therefore for sufficiently small λ we have $\|[H_0+\lambda V-E(\lambda)]\psi_0\|^2=O(\lambda^2\log^2(\lambda))$ as noted. What remains is to compute

$$2\left(W_\alpha(x;\lambda)\psi_0(x),\frac{dW_\alpha(x;\lambda)}{dx}\left[\frac{(\gamma-\frac{1}{2})}{x}-\frac{d}{dx}\right]\psi_0(x)\right)$$
$$=\frac{4\lambda^{3/2}}{(\gamma-1)^2\Gamma(\gamma)}\times\int_0^\infty x^{2-\gamma}e^{-x^2}K_0\left(\frac{\sqrt{\lambda}}{\gamma-1}x^{1-\gamma}\right)K_1\left(\frac{\sqrt{\lambda}}{\gamma-1}x^{1-\gamma}\right)dx$$

by using the asymptotic expansions (5.16) up to the order $\lambda^2\log^2(\lambda)$. The lemma then follows after some straightforward calculations. It is important to note that the normalization constant N_λ, as given by (5.2), yields in this case

$$N_\lambda^{-2}=1+\left\{2\nu^2(-1+2c+2\log(\nu))+\frac{1}{2}\nu c\right\}\frac{\lambda}{\Gamma(\gamma)}+\frac{2\nu^2}{\Gamma(\gamma)}\lambda\log\lambda+\cdots$$

and will contribute to the error term in a similar manner to that mentioned in lemma 2. □

The results of Harrell, the case $\alpha=3$, follows immediately from (5.17) for the case of $A=0$ (or $\gamma=3/2$), i.e., $\nu=1$, namely,

$$E_0(\lambda)=3-\frac{4}{\sqrt{\pi}}\lambda\log(\lambda)-\frac{10c}{\sqrt{\pi}}\lambda+O(\lambda^2\log^2(\lambda)). \tag{5.18}$$

It is clear that these expressions are valid for λ much smaller than unity.

VI. LOWEST-ORDER ASYMPTOTIC PERTURBATION CORRECTIONS FOR $2\gamma>\alpha\geqslant\gamma+1$

In this section, we discuss the case of $2\gamma>\alpha\geqslant\gamma+1$ or equivalently the case of $1<2\nu(\gamma-1)\leqslant 2$. It is clear by now that, for $1<2\nu(\gamma-1)\leqslant 2$, the first-order Rayleigh–Schrödinger corrections exist but the second-order corrections diverge. Thus, the improved perturbation procedure

gives an explicit term between the first and the second order. Let us first consider the case of $1<2\nu(\gamma-1)<2$, here we rely on the asymptotic expansion of the modified Bessel function K as given by (4.12). We note from (4.5) and (5.6) that

$$\|[H_0+\lambda V-E(\lambda)]\psi_0\|^2=\frac{32\nu^{4\nu(\gamma-1)}\lambda^{2\nu(\gamma-1)+1}}{\Gamma(\gamma)[\Gamma(2\nu(\gamma-1))]^2}\int_0^\infty x^{1-(1/\nu)}e^{-x^2}K^2_{2\nu(\gamma-1)-1}(2\nu\sqrt{\lambda}x^{-(1/2\nu)})\mathrm{d}x$$

as a consequence of the known identity $K_\nu(z)=K_{-\nu}(z)$. Using (4.9) we have

$$\|[H_0+\lambda V-E(\lambda)]\psi_0\|^2=O(\lambda^2) \quad (1<2\nu(\gamma-1)<2), \tag{6.1}$$

which leads to the following lemma.

Lemma 4: For the ground-state energy of the Hamiltonian (1.2) where $\alpha>\gamma+1$ [i.e., $1<2\nu(\gamma-1)<2$], we have

$$E_0(\lambda)=2\gamma+\frac{16}{\Gamma(\gamma)}\frac{\nu^{4\nu(\gamma-1)}\lambda^{2\nu(\gamma-1)+1/2}}{[\Gamma(2\nu(\gamma-1)]^2}\int_0^\infty x^{1-(1/2\nu)}e^{-x^2}$$
$$\times K_{2\nu(\gamma-1)}(2\nu\sqrt{\lambda}x^{-(1/2\nu)})K_{2\nu(\gamma-1)-1}(2\nu\sqrt{\lambda}x^{-(1/2\nu)})\mathrm{d}x+O(\lambda^2). \tag{6.2}$$

The proof of this lemma is similar to that of lemma 3, therefore we omit it. The computation of the integral in (6.2) up to the order of λ^2 yields the perturbation expansion

$$E_0(\lambda)=2\gamma+\frac{2\nu^{4\nu(\gamma-1)}\Gamma(1-2\nu(\gamma-1))}{\nu\Gamma(\gamma)\Gamma(2\nu(\gamma-1))}\lambda^{2\nu(\gamma-1)}+\frac{2\nu\Gamma\left(\gamma-\frac{1}{2\nu}\right)}{(2\nu(\gamma-1)-1)\Gamma(\gamma)}\lambda+O(\lambda^2), \tag{6.3}$$

as the result of

$$K_{2\nu(\gamma-1)}(2\nu\sqrt{\lambda}x^{-(1/2\nu)})=\frac{\Gamma(2\nu(\gamma-1))\Gamma(1-2\nu(\gamma-1))}{2}\Bigg\{(\nu\sqrt{\lambda}x^{-(1/2\nu)})^{-2\nu(\gamma-1)}$$
$$\times\left[\frac{1}{\Gamma(1-2\nu(\gamma-1))}+\frac{(\nu\sqrt{\lambda}x^{-(1/2\nu)})^2}{\Gamma(2-2\nu(\gamma-1)}\right]-(\nu\sqrt{\lambda}x^{(1/2\nu)})^{2\nu(\gamma-1)}$$
$$\times\left[\frac{1}{\Gamma(1+2\nu(\gamma-1))}+\frac{(\nu\sqrt{\lambda}x^{-(1/2\nu)})^2}{\Gamma(2+2\nu(\gamma-1)}\right]\Bigg\}+\cdots.$$

The result of Harrell[1] follows immediately from (6.3) in the special case $A=0$, namely,

$$E_0(\lambda)=3+\frac{4\nu^{2\nu}\Gamma(1-\nu)}{\sqrt{\pi}\Gamma(1+\nu)}\lambda^\nu+\frac{2\Gamma\left(\frac{3-\alpha}{2}\right)}{\sqrt{\pi}}\lambda+O(\lambda^{2\nu}), \tag{6.4}$$

where $\nu=1/(\alpha-2)$ and $5/2<\alpha<3$.

For the case $2\nu(\gamma-1)=2$, the norm $\|[H_0+\lambda V-E(\lambda)]\psi_0\|$ can be computed easily by means of Eq. (4.5), which yields

$$\|[H_0+\lambda V-E_0]\psi_0\|^2=2\left\|\frac{dW_\alpha(x;\lambda)}{dx}\left[\frac{(\gamma-\frac{1}{2})}{x}-\frac{d}{dx}\right]\psi_0(x)\right\|^2$$
$$=\frac{16\lambda^3}{(\gamma-1)^2\Gamma(\gamma)}\int_0^\infty x^{2-\gamma}e^{-x^2}\left[K_1\left(\frac{2\sqrt{\lambda}}{\gamma-1}x^{-(1/2\nu)}\right)\right]^2 dx=O(\lambda^2),$$

as a consequence of

$$K_1(z)=\frac{1}{z}+\left(\frac{1}{4}(-1+2c)+\frac{1}{2}(-\log(2)+\log(z))\right)z+O(z^2).$$

Furthermore, since the trial wave function takes the form

$$\psi(x;\lambda)=2\nu^2\lambda x^{-(1/\nu)}K_2(2\nu\sqrt{\lambda}x^{-(1/2\nu)})\psi_0(x),$$

we may compute the normalization constant Eq. (5.2) as

$$N_\lambda^2=1+\frac{\nu\Gamma\left(\frac{1}{2\nu}\right)}{\Gamma(\gamma)}\lambda+\frac{\nu^4}{\Gamma(\gamma)}\lambda^2\log(\lambda)+O(\lambda^2)$$

in a similar fashion to the proof of lemma 1. Harrell, in his investigation, claims that the ground-state eigenvalue perturbation expansion for the spiked harmonic oscillator Hamiltonian (1.1), $\alpha=5/2$, is given by

$$E_0(\lambda)=3+\frac{2\Gamma(\frac{1}{4})}{\sqrt{\pi}}\lambda+\frac{16}{\sqrt{\pi}}\lambda^2\log(\lambda)+O(\lambda^2). \tag{6.5}$$

The following result does not confirm his claim, but shows that it is slightly different even by means of Harrell's own methodology. As our calculation will show, the ground-state perturbation expansion in the case of $\alpha=5/2$ is actually given by

$$E_0(\lambda)=3+\frac{2\Gamma(\frac{1}{4})}{\sqrt{\pi}}\lambda+\frac{32}{\sqrt{\pi}}\lambda^2\log(\lambda)+O(\lambda^2), \tag{6.6}$$

with a multiple of 2 in the log term in contrast with (6.5). In order to verify (6.6), we adopt two different approaches, first we use Harrell's method then we apply our generalization. We have for $\alpha=5/2$, the asymptotic perturbation expansion according to Harrell reads

$$E_0(\lambda)=3+2\left(W_{5/2}\psi_0,\frac{dW_{5/2}}{dx}\left(\frac{1}{x}-\frac{d}{dx}\right)\psi_0\right)+O(\lambda^2),$$

where $\psi_0(x)=(2/\pi^{1/4})xe^{-x^2/2}$. For $W_{5/2}$, Harrell used the asymptotic approximation of the modified Bessel function

$$K_2(z)=\frac{2}{z^2}-\frac{1}{2}+\left(\frac{1}{16}\left(\frac{3}{2}-2c\right)+\frac{1}{8}(\log(2)-\log(z))\right)z^2+O(z^3)$$

to show that

$$W_{5/2}(z)=1-\frac{4}{\sqrt{z}}+\frac{4\log(z)}{z}-4(4(c+\log(2))-3)z+\cdots \quad \text{for large } z.$$

If we differentiate $W_{5/2}(z)$ with respect to x, keeping in mind $z=\lambda^{-2}x$, we have, after some calculations,

$$2\left(W_{5/2}\psi_0,\frac{dW_{5/2}}{dx}\left(\frac{1}{x}-\frac{d}{dx}\right)\psi_0\right)=\frac{16\lambda}{\sqrt{\pi}}\int_0^\infty x^{3/2}e^{-x^2}\,dx+\frac{64\lambda^2\log\lambda}{\sqrt{\pi}}\int_0^\infty xe^{-x^2}\,dx+\cdots,$$

which yields (6.6), since $\int_0^\infty xe^{-x^2}\,dx=\frac{1}{2}$ and $\int_0^\infty x^{3/2}e^{-x^2}\,dx=\frac{1}{8}\Gamma(\frac{1}{4})$. Numerically, however, Eq. (6.5) is more appealing than (6.6) for a wider range of the parameter λ smaller than unity since (6.6) reduces the applicable range of λ by almost one-half.

Lemma 5: For the ground-state energy of the Hamiltonian (1.2), where $2\nu(\gamma-1)=2$, we have

$$E_0(\lambda)=2\gamma+\frac{\Gamma\left(\frac{1}{2\nu}\right)}{\Gamma(\gamma)}\lambda+\frac{2\nu^3}{\Gamma(\gamma)}\lambda^2\log(\lambda)+O(\lambda^2). \tag{6.7}$$

Proof: For $2\nu(\gamma-1)=2$, we have, using Eq. (6.2), that

$$E_0(\lambda)=2\gamma+\frac{16\nu^4\lambda^{5/2}}{\Gamma(\gamma)}\int_0^\infty x^{1-(1/2\nu)}e^{-x^2}K_2(2\nu\sqrt{\lambda}x^{-(1/2\nu)})K_1(2\nu\sqrt{\lambda}x^{-(1/2\nu)})dx+O(\lambda^2).$$

By means of the asymptotic expansions

$$K_1(z)=\frac{1}{z}+\left(\frac{1}{4}(-1+2c)+\frac{1}{2}\log\left(\frac{1}{2}z\right)\right)z+O(z^2)$$

and

$$K_2(z)=\frac{2}{z^2}-\frac{1}{2}+\left(\frac{1}{16}\left(\frac{3}{2}-2c\right)-\frac{1}{8}\log\left(\frac{1}{2}z\right)\right)z^2+O(z^4),$$

where $z=2\nu\sqrt{\lambda}x^{-(1/2\nu)}$, we have, after some calculations up to order λ^2, that

$$E_0(\lambda)=2\gamma+\frac{4\nu\lambda}{\Gamma(\gamma)}\int_0^\infty x^{1+(1/\nu)}e^{-x^2}\,dx+\frac{4\nu^3}{\Gamma(\gamma)}\lambda^2\log(\lambda)\int_0^\infty xe^{x^2}\,dx+O(\lambda^2).$$

This leads to (6.7), since $\int_0^\infty x^{1+(1/\nu)}e^{-x^2}\,dx=\frac{1}{2}\Gamma(1+(1/2\nu))$.

VII. FURTHER CASES

The expansions developed above can be extended to the case of $2\nu(\gamma-1)>2$ and the region of $\alpha<\frac{5}{2}$ which was not studied by Harrell.[1] For example, in the case of $2<2\nu(\gamma-1)<3$, the second order of the perturbation correction exists but the third order diverges. By using the modified perturbation theory we find

$$E_0(\lambda)=2\gamma+\frac{4(\gamma-1)\nu^{4\nu(\gamma-1)}\Gamma(1-2\nu(\gamma-1))}{\Gamma(\gamma)\Gamma(1+2\nu(\gamma-1))}\lambda^{2\nu(\gamma-1)}+\frac{2\nu\Gamma\left(\gamma-\frac{1}{2\nu}\right)}{(2\nu(\gamma-1)-1)\Gamma(\gamma)}\lambda$$
$$-\frac{2(3-4\nu(\gamma-1))\nu^3\Gamma\left(\gamma-\frac{1}{\nu}\right)}{(2-2\nu(\gamma-1))(1-2\nu(\gamma-1))^2\Gamma(\gamma)}\lambda^2+O(\lambda^3). \tag{7.1}$$

Again in the case of $\gamma=3/2$, Harrell's formula should read, for $7/3<\alpha<5/2$,

$$E_0(\lambda)=3+\frac{4\nu^{2\nu}\Gamma(1-\nu)}{\sqrt{\pi}\Gamma(1+\nu)}\lambda^{\nu}+\frac{4\nu\Gamma\left(\frac{3}{2}-\frac{1}{2\nu}\right)}{(\nu-1)\sqrt{\pi}}\lambda-\frac{4(3-2\nu)\nu^3\Gamma\left(\frac{3}{2}-\frac{1}{\nu}\right)}{(2-\nu)(1-\nu)^2\sqrt{\pi}}\lambda^2+O(\lambda^3), \tag{7.2}$$

where $\nu=1/(\alpha-2)$. Furthermore, for $3<2\nu(\gamma-1)<4$, we have

$$E_0(\lambda)=2\gamma+\frac{4(\gamma-1)\nu^{4\nu(\gamma-1)}\Gamma(1-2\nu(\gamma-1))}{\Gamma(\gamma)\Gamma(1+2\nu(\gamma-1))}\lambda^{2\nu(\gamma-1)}+\frac{2\nu\Gamma\left(\gamma-\frac{1}{2\nu}\right)}{(2\nu(\gamma-1)-1)\Gamma(\gamma)}\lambda$$
$$-\frac{2(3-4\nu(\gamma-1))\nu^3\Gamma\left(\gamma-\frac{1}{\nu}\right)}{(2-2\nu(\gamma-1))(1-2\nu(\gamma-1))^2\Gamma(\gamma)}\lambda^2-\frac{2\nu^5\Gamma\left(\gamma-\frac{3}{2\nu}\right)}{\Gamma(\gamma)(1-2\nu(\gamma-1))^2(2-2\nu(\gamma-1))}\lambda^3$$
$$+O(\lambda^4). \tag{7.3}$$

Similar expressions can be obtained for $n<2\nu(\gamma-1)<n+1$, $n=4,5,...$, as well for $2\nu(\gamma-1)=n$. It is important, however, to note that there are an infinite number of cases as n increases to infinity for $\alpha>2$. For example, if we restrict the value of γ to 3/2, then in this case $2<\alpha<5/2$, and obtain an infinite number of perturbation expansions consisting of analytic parts of degree λ^n in addition to one correction term in each expansion as $2+[1/(1+n)]<\alpha<2+(1/n)$. Similarly, the cases $\alpha=2+[1/(1+n)]$, $n=3,4,...$, need special treatment, as we have mentioned above. It is interesting to note that the λ-term in (7.1) or in (7.3) is identical with the corresponding λ-term in the Rayleigh–Schrödinger series. This can be easily verified by a comparison of the coefficient of λ in (7.1) or in (7.3) with the coefficient of the λ-term in (2.3). However this is clearly not the case for the λ^2-term.

VIII. EXCITED STATES

The perturbation expansions developed so far were restricted to the ground-state energy, however, it is a matter of calculation to extend these results to the excited-state energies. First, it should be noted that the exact solution of the unperturbed part of the Hamiltonian (1.2) has very little to do with the order of the error terms in the perturbation expansions. Therefore it is expected that the order of the error terms remains the same for the excited states, i.e., $i=1,2,...$. Following the discussion in Sec. III, the asymptotic expansions for the eigenvalues for excited states are given by means of Theorem 1 as

$$E_i(\lambda)=2(2i+\gamma)+2\left(W_\alpha(x;\lambda)\psi_i(x),\frac{dW_\alpha(x;\lambda)}{dx}\left[\frac{(\gamma-\frac{1}{2})}{x}-\frac{d}{dx}\right]\psi_i(x)\right)$$
$$+O(\|[H_0+\lambda V-E_i^\lambda]W_\alpha(x;\lambda)\psi_i\|^2), \tag{8.1}$$

where $\psi_i(x)$, $i=0,1,2,...$ are given by (2.1) and the energy of the unperturbed Hamiltonian E_i^{λ} is given by (2.2). In order to compute (8.1) explicitly, we notice first that

$$
\begin{aligned}
&2\left(W_\alpha(x;\lambda)\psi_i(x), \frac{dW_\alpha(x;\lambda)}{dx}\left[\frac{(\gamma-\frac{1}{2})}{x}-\frac{d}{dx}\right]\psi_i(x)\right) \\
&\quad=\frac{16(\gamma)_i}{i!\Gamma(\gamma)}\,\frac{\nu^{4\nu(\gamma-1)}\lambda^{2\nu(\gamma-1)+1/2}}{[\Gamma(2\nu(\gamma-1)]^2}\times\int_0^\infty x^{1-(1/2\nu)}e^{-x^2} \\
&\quad\times\left[\frac{2(\gamma+i)}{\gamma}\,{}_1F_1(-i;\gamma;x^2)\,{}_1F_1(-i;\gamma+1;x^2)-[{}_1F_1(-i;\gamma;x^2)]^2\right] \\
&\quad\times K_{2\nu(\gamma-1)}(2\nu\sqrt{\lambda}x^{-(1/2\nu)})K_{1-2\nu(\gamma-1)}(2\nu\sqrt{\lambda}x^{-(1/2\nu)}),dx, \qquad (8.2)
\end{aligned}
$$

where ${}_1F_1$ is the confluent hypergeometric function mentioned earlier Eq. (2.4). In producing (8.2) we have used the following identity:[35]

$$
\frac{d}{dz}\,{}_1F_1(a;b;z)={}_1F_1(a;b;z)-\frac{(b-a)}{b}\,{}_1F_1(a;b+1;z).
$$

For the case of $0<2\nu(\gamma-1)\leqslant\frac{1}{2}$ or $\alpha\geqslant 2(2\gamma-1)$, we find, by means of (4.9), that

$$
\begin{aligned}
&2\left(W_\alpha(x;\lambda)\psi_i(x), \frac{dW_\alpha(x;\lambda)}{dx}\left[\frac{(\gamma-\frac{1}{2})}{x}-\frac{d}{dx}\right]\psi_i(x)\right) \\
&\quad=\frac{4(\gamma)_i}{i!\Gamma(\gamma)}\,\frac{\Gamma(1-2\nu(\gamma-1))}{\nu\Gamma(2\nu(\gamma-1))}\,\nu^{4\nu(\gamma-1)}\lambda^{2\nu(\gamma-1)} \\
&\quad\times\int_0^\infty xe^{-x^2}\left[\frac{2(\gamma+i)}{\gamma}\,{}_1F_1(-i;\gamma;x^2)\,{}_1F_1(-i;\gamma+1;x^2)-[{}_1F_1(-i;\gamma;x^2)]^2\right]dx.
\end{aligned} \qquad (8.3)
$$

This result required the investigation of some integrals of the type

$$
\int_0^\infty xe^{-x^2}\,{}_1F_1(-i;\gamma;x^2)\,{}_1F_1(-i;\gamma+1;x^2)dx \quad\text{and}\quad \int_0^\infty xe^{-x^2}[{}_1F_1(-i;\gamma;x^2)]^2\,dx.
$$

Lemma 6: For $d>0$ and $s>0$,

$$
\begin{aligned}
&\int_0^\infty t^{d-1}e^{-st}\,{}_1F_1(a;b;kt)\,{}_1F_1(a';b';k't)dt \\
&\qquad=s^{-d}\Gamma(d)\sum_{m=0}^{\infty}\frac{(a)_m(d)_m}{(b)_m}\,\frac{\left(\frac{k}{s}\right)^m}{m!}\,{}_2F_1\left(a',d+m;b';\frac{k'}{s}\right).
\end{aligned}
$$

Proof: From the series representation, Eq. (2.4), of the confluent hypergeometric series ${}_1F_1$, namely,

$$
{}_1F_1(a;b;kt)=\sum_{m=0}^{\infty}\frac{(a)_m}{(b)_m}\,\frac{(kt)^m}{m!}\quad\text{and}\quad {}_1F_1(a';b';k't)=\sum_{n=0}^{\infty}\frac{(a')_n}{(b')_n}\,\frac{(k't)^n}{n!},
$$

we have

$$\int_0^\infty t^{d-1}e^{-st}\,{}_1F_1(a;b;kt)\,{}_1F_1(a';b';k't)\,\mathrm{d}t$$

$$=\sum_{m=0}^{\infty}\sum_{n=0}^{\infty}\frac{(a)_m(a')_n}{(b)_m(b')_n}\frac{k^m k'^n}{m!n!}\int_0^\infty e^{-st}t^{d+n+m-1}\,\mathrm{d}t$$

$$=s^{-d}\sum_{m=0}^{\infty}\sum_{n=0}^{\infty}\frac{(a)_m(a')_n}{(b)_m(b')_n}\frac{k^m k'^n}{m!n!}\left(\frac{1}{s}\right)^n\left(\frac{1}{s}\right)^m(d+m)_n\Gamma(d+m)$$

$$=s^{-d}\sum_{m=0}^{\infty}\left[\sum_{n=0}^{\infty}\frac{(a')_n(d+m)_n}{(b')_n}\frac{\left(\frac{k'}{s}\right)^n}{n!}\right]\frac{(a)_m\left(\frac{k}{s}\right)^m}{(b)_m}\Gamma(d+m)$$

$$=s^{-d}\Gamma(d)\sum_{m=0}^{\infty}\,{}_2F_1\left(a',d+m;b';\frac{k'}{s}\right)\frac{(a)_m(d)_m}{(b)_m}\frac{\left(\frac{k}{s}\right)^m}{m!}$$

with $d>0$ and $s>0$, and where we have used the series representation of ${}_2F_1$ as given by Eq. (2.4) and the Pochhammer's identity $\Gamma(d+m+n)=(d+m)_n\Gamma(d+m)=(d+m)_n(d)_m\Gamma(d)$. □

As a consequence of this lemma, we have

$$\int_0^\infty xe^{-x^2}\,{}_1F_1(-i;\gamma;x^2)\,{}_1F_1(-i;\gamma+1;x^2)\mathrm{d}x=\frac{(\gamma)_i}{2(\gamma+1)_i}\,{}_3F_2(-i,1-\gamma,1;\gamma,1-\gamma-i;1) \tag{8.4}$$

and

$$\int_0^\infty xe^{-x^2}[{}_1F_1(-i;\gamma;x^2)]^2\,\mathrm{d}x=\frac{(\gamma-1)_i}{2(\gamma)_i}\,{}_3F_2(-i,-\gamma,1;\gamma,2-\gamma-i;1), \tag{8.5}$$

where the Chu–Vandermonda identity

$${}_2F_1(-n,a;c;1)=\frac{(c-a)_n}{(c)_n}$$

has been used. Therefore, from (8.3), we have

$$2\left(W_\alpha(x;\lambda)\psi_i(x),\frac{\mathrm{d}W_\alpha(x;\lambda)}{\mathrm{d}x}\left[\frac{(\gamma-\frac{1}{2})}{x}-\frac{d}{\mathrm{d}x}\right]\psi_i(x)\right)$$

$$=\frac{4(\gamma)_i}{i!\Gamma(\gamma)}\frac{\Gamma(1-2\nu(\gamma-1))}{\nu\Gamma(2\nu(\gamma-1))}\nu^{4\nu(\gamma-1)}\lambda^{2\nu(\gamma-1)}$$

$$\times\left[{}_3F_2(-i,1-\gamma,1;\gamma,1-\gamma-i;1)-\frac{(\gamma-1)_i}{2(\gamma)_i}\,{}_3F_2(-i,-\gamma,1;\gamma,2-\gamma-i;1)\right]. \tag{8.6}$$

For $0<2\nu(\gamma-1)\leqslant\frac{1}{2}$ or $\alpha\geqslant 2(2\gamma-1)$, we have

$$E_i(\lambda)=2(2i+\gamma)+\frac{4(\gamma)_i}{i!\Gamma(\gamma)}\frac{\Gamma(1-2\nu(\gamma-1))}{\nu\Gamma(2\nu(\gamma-1))}\nu^{4\nu(\gamma-1)}\lambda^{2\nu(\gamma-1)}$$
$$\times\left[{}_3F_2(-i,1-\gamma,1;\gamma,1-\gamma-i;1)-\frac{(\gamma-1)_i}{2(\gamma)_i}{}_3F_2(-i,-\gamma,1;\gamma,2-\gamma-i;1)\right]$$
$$+O(\lambda^{4\nu(\gamma-1)}),\quad i=0,1,2,\ldots. \tag{8.7}$$

Similar expressions can be obtained for the other cases by means of lemma 6. An immediate extension of Harrell's expansions to excited states $i=1,2,\ldots$ for the Hamiltonian (1.1) can be obtained by setting $\gamma=\frac{3}{2}$ in (8.7).

IX. CONCLUSIONS

In this paper we have applied and extended Harrell's modified perturbation theory to treat a wider class of singular Hamiltonians given by (1.2). Our extensions allow us to recover Harrell's formulas for the spiked harmonic oscillator Hamiltonian (1.1) as special cases. Further, we were able to extend Harrell's results to the exited-state energies, again as special cases of our general treatment. We have also now corrected the perturbation expansion (6.5) for the case $\alpha=\frac{5}{2}$: this formula has been used without correction since the very early work of Harrell. Some interesting questions which remain to be answered are as follows. Is the modified wave function (4.11) sufficient to extend the perturbation expansions presented here to higher orders, or will further modifications need to be introduced? Why can the second-order corrections in (7.1), (7.2), and (7.3) not be recovered from the corresponding terms in the regular Rayleigh–Schrödinger series? Does this fact indicate that the trial wave function indeed requires additional modification? We hope that the present work will encourage further research into this interesting class of singular Hamiltonians.

(Received 9 June 2003; accepted 24 July 2003)

We solved the Schrödinger equation for a particle in a uniform magnetic field in the n-dimensional torus. We obtained a complete set of solutions for a broad class of problems; the torus $T^n=\mathbf{R}^n/\Lambda$ is defined as a quotient of the Euclidean space $\mathbf{R}^n$ by an arbitrary n-dimensional lattice Λ. The lattice is not necessary either cubic or rectangular. The magnetic field is also arbitrary. However, we restrict ourselves within potential-free problems; the Schrödinger operator is assumed to be the Laplace operator defined with the covariant derivative. We defined an algebra that characterizes the symmetry of the Laplacian and named it the magnetic algebra. We proved that the space of functions on which the Laplacian acts is an irreducible representation space of the magnetic algebra. In this sense the magnetic algebra completely characterizes the quantum mechanics in the magnetic torus. We developed a new method for Fourier analysis for the magnetic torus and used it to solve the eigenvalue problem of the Laplacian. All the eigenfunctions are given in explicit forms. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1616203]

I. INTRODUCTION

In this paper we solve the Schrödinger equation for a particle in a uniform magnetic field in an n-dimensional torus. The problem looks plain at first sight but actually it turns out to be a hard problem, which has not been solved before. Hence we begin this paper by a quick explanation of the problem. After that we will describe our strategy to solve it. Subsequently we will briefly mention studies by other people and describe our motivation of this study. At the end of the Introduction we will give guides for quick access to main results of this paper.

An n-dimensional torus, or n-torus, is defined as $T^n=\mathbf{R}^n/\mathbf{Z}^n$. In the coordinate a point $(t^1,\ldots,t^j+1,\ldots,t^n)$ is identified with $(t^1,\ldots,t^j,\ldots,t^n)$ for each $j=1,\ldots,n$. The eigenvalue problem of the ordinary Laplacian in the torus is the equation

$$-\Delta f=-\sum_{j=1}^{n}\left(\frac{\partial}{\partial t^j}\right)^2 f=\varepsilon f \tag{1.1}$$

with the periodic boundary condition

$$f(t^1,\ldots,t^j+1,\ldots,t^n)=f(t^1,\ldots,t^j,\ldots,t^n). \tag{1.2}$$

The eigenvalue problem can be immediately solved by Fourier expansion. A plane-wave function

a)Electronic mail: sakamoto@phys.sci.kobe-u.ac.jp
b)Present address: Graduate School of Engineering, Osaka City University, Sumiyoshi-ku, Osaka 558-8585, Japan. Electronic mail: stani@yukawa.kyoto-u.ac.jp

$$\chi_k(t^1,\ldots,t^n)=e^{2\pi i\Sigma_{j=1}^n k_j t^j} \tag{1.3}$$

with quantized momenta $k_j\in\mathbf{Z}$ is a solution. The whole set of eigenfunctions $\{\chi_k\,|\,(k_1,\ldots,k_n)\in\mathbf{Z}^n\}$ constitutes a complete orthonormal set of the space of periodic functions over the torus. This is a well-known result.

In this paper we would like to solve an eigenvalue problem of the magnetic Laplacian; the magnetic Laplacian is defined by replacing the partial derivative in the ordinary Laplacian by a covariant derivative as

$$\Delta f=\sum_{j,l=1}^n g^{jl}\left(\frac{\partial}{\partial t^j}-2\pi i A_j\right)\left(\frac{\partial}{\partial t^l}-2\pi i A_l\right)f. \tag{1.4}$$

Here A_l is a component of the $U(1)$ gauge field

$$A_l=\frac{1}{2}\sum_{j=1}^n \phi_{jl}\,t^j+\alpha_l \tag{1.5}$$

with integers $\{\phi_{jl}=-\phi_{lj}\}$ and real numbers $\{\alpha_j\}$. The gauge field $A=\Sigma_{l=1}^n A_l\,\mathrm{d}t^l$ generates a uniform magnetic field $B=\mathrm{d}A=(1/2)\Sigma_{j,l=1}^n\phi_{jl}\,\mathrm{d}t^j\wedge\mathrm{d}t^l$. Moreover, we would like to consider a general oblique torus $T^n=\mathbf{R}^n/\Lambda$; Λ is an n-dimensional lattice. Edges of the unit cell of the lattice do not necessarily cross at a right angle and they do not necessarily have a same length. Hence we introduce a metric g^{jl} in the definition of the magnetic Laplacian (1.4) to take inclined and stretched or shortened unit cells into account. The eigenvalue problem of (1.4) is accompanied by the condition

$$f(t^1,\ldots,t^j+1,\ldots,t^n)=e^{\pi i\Sigma_{k=1}^n\phi_{jk}t^k}f(t^1,\ldots,t^j,\ldots,t^n), \tag{1.6}$$

which we call a twisted periodic condition. Thus the plain problem (1.1) with (1.2) is generalized to the magnetic problem (1.4) with (1.6). At first glance it looks rather straightforward to generalize the problem in this way but it is actually highly nontrivial and difficult to generalize the solution.

Let us see where the difficulty lies. In the case of the ordinary Laplacian, the plane-wave solution (1.3) is a simultaneous eigenfunction of the momentum operators

$$p_j=-i\frac{\partial}{\partial t^j}\quad(j=1,\ldots,n) \tag{1.7}$$

as $p_j\chi_k=2\pi k_j\chi_k$. The Laplacian can be expressed in terms of the momentum operators as $-\Delta=\Sigma_{j=1}^n(p_j)^2$ and, of course, it commutes with the momentum operators. Thus integers $(k_1,\ldots,k_n)$ are good quantum numbers. Then the whole set of simultaneous eigenfunctions $\{\chi_k\}$ forms the complete solutions of the Laplacian problem. This is the way how Fourier analysis works. However, when we turn to the magnetic Laplacian, we may seek for a simultaneous eigenfunction of magnetic momentum operators

$$p_j=-i\left(\frac{\partial}{\partial t^j}-2\pi i A_j\right)\quad(j=1,\ldots,n). \tag{1.8}$$

But such a simultaneous eigenfunction does not exist because magnetic momenta do not commute with each other and instead exhibit commutators

$$[\,p_j,p_l\,]=2\pi i\,\phi_{jl}. \tag{1.9}$$

The magnetic Laplacian can be still expressed in terms of the magnetic momentum operators as $-\Delta=\Sigma_{j=1}^{n}(p_j)^2$ but it does not commute with p_j. Hence, the strategy of ordinary Fourier analysis does not work well for the magnetic Laplacian.

To solve the problem we developed a new method, which we call Fourier analysis for the magnetic torus. This is a main subject of this paper. Let us describe our strategy: First, we will find a group of operators that commute with magnetic momentum operators. We call the group a magnetic translation group. Second, we enlarge a family of operators to define an algebra, which includes magnetic momenta and magnetic translations as its elements. We call the algebra a magnetic algebra and construct its representations. Third, we show that the space of twisted periodic functions over the torus is actually an irreducible representation space of the magnetic algebra. By diagonalizing a maximal commutative subalgebra of the magnetic algebra we obtain a complete orthonormal set of twisted periodic functions. This set of orthogonal functions provides a kind of unitary transformation as the set of plane-wave functions provides the Fourier transformation which bridges between the momentum space and the real space. We note that it is easy to diagonalize the Laplacian in the momentum space. Finally, we get a whole set of eigenfunctions in the real space by applying the unitary transformation. In this procedure the third step is the hardest part and is actually accomplished by lengthy cumbersome calculations. However, the strategy is clear.

We would like to briefly review studies by other people on spectral analysis in magnetic field. Brown[1] first examined the symmetry structure of the Schrödinger equation for an electron in a lattice in a uniform magnetic field and found that the symmetry is described by a noncommutative discrete translation group. At almost the same time Zak[2] also found the same symmetry structure and named the group a magnetic translation group (MTG). Zak[3] immediately built a representation theory of the MTG in the three-dimensional lattice. From the viewpoint of functional analysis, Avron, Herbst, and Simon have been studying spectral problems of the Schrödinger operators in a magnetic field in a series of papers.[4–6] Dubrovin and Novikov[7,8] studied the spectrum of the Pauli operator in a two-dimensional lattice with a periodic magnetic field and intensively analyzed the gap structure above the ground state. Florek[9,10] constructed tensor product representations of the MTG to analyze a three-particle system in a lattice in a magnetic field. Kuwabara[11,12] has been studying quantum-classical correspondence from the viewpoint of spectral geometry. For example, he[11] proved that if the whole set of level spacings of the quantum spectrum is not dense in $\mathbf{R}$, every trajectory of the corresponding classical particle is a closed orbit. Arai[13] found a quantum plane and quantum group structure in the quantum system in a singular magnetic field. Thus we can see that quantum mechanics in a magnetic field has been an active research area. However, we do not find a literature in which the quantum mechanics in an n-torus is solved.

Our study on quantum mechanics in magnetic fields originates from studies of extra-dimension models of the space–time. In extra-dimension models the space–time is assumed to be a base space of a fiber bundle with a compact fiber or a noncompact fiber. The history of extra-dimension models is rather old, but an interest in these models is recently renewed as Arkani-Hamed, Dimopoulos, and Dvali[14] pointed out that the extra-dimension model may solve the hierarchy problem of high energy physics. Inspired with extra-dimension models we[15] built a model which has a circle S^1 as a fiber over an any-dimensional space–times $\mathbf{R}^{D-1}$. Then we found that a twisted boundary condition in the S^1-direction causes spontaneous breaking of the translational symmetry. Based on this observation, we[16] proposed a new mechanism of supersymmetry breaking. Next we[17,18] built a model which has a two-dimensional sphere S^2 as a fiber over the four-dimensional space–times $\mathbf{R}^4$. We solved dynamics in the sphere in a magnetic monopole background and then found that the monopole induces spontaneous breaking of the rotational symmetry and the CP symmetry. We also built a model which has an n-dimensional torus as a fiber and tried to analyze dynamics in the torus in a background magnetic field. However, its analysis was not a straightforward task. Then we studied the symmetry structure of quantum mechanics in the torus in the magnetic field. We[19] constructed the MTG in the n-torus and classified irreducible representations of the MTG.

Armed with these tools we are now ready to solve the spectral problem in the n-torus T^n

$=\mathbf{R}^n/\Lambda$. We decide to solve the problem exhaustively; in our treatment the dimensions of the torus is taken to be arbitrary, lengths and angles of edges of the unit cell of Λ are arbitrary, and an arbitrary constant magnetic field is applied to the torus. Thus we aim to solve the widest class of quantum mechanics in the n-torus in uniform magnetic fields.

For busy readers here we give guides for quick access to main results. In Sec. II we provide a geometric setting to define the problem. The problem to be solved is the eigenvalue problem of the magnetic Laplacian (2.13) with the twist condition (2.5). In Sec. III we find a family of operators that commute with the covariant derivative. Actually they are composition of ordinary displacements and gauge transformations as shown at (3.2). These displacement vectors form a restricted family of vectors as shown at (3.8). These displacement operators generate the magnetic translation group (MTG), which is noncommutative as shown at (3.12). Along (3.16)–(3.28) we construct irreducible representations of the MTG. In Sec. IV we introduce a coordinate system, which will be revealed to be useful later. In Sec. V we define the magnetic algebra by adding differential operators (5.2)–(5.4) and multiplicative operators (5.9) to the MTG. Then we construct and classify irreducible representations of the magnetic algebra. Section VI is devoted to calculation of simultaneous eigenfunctions (6.8) of a maximal commutative subalgebra of the magnetic algebra. Then we obtain a complete orthonormal set of functions over the magnetic torus, which provide an extension of Fourier analysis for the magnetic torus. This is one of the main products of this paper. In Sec. VII by applying this method we solve the original problem, the eigenvalue problem of the magnetic Laplacian. There we obtain a whole set of eigenfunctions (7.11) and eigenvalues (7.12). These are the main results of this paper.

II. GAUGE FIELD IN THE TORUS

Let $\mathbf{t}=(t^1,\ldots,t^n)$ denote a coordinate of an n-dimensional torus $T^n=\mathbf{R}^n/\mathbf{Z}^n$. Namely, a point $(t^1,\ldots,t^j+1,\ldots,t^n)$ is identified with $(t^1,\ldots,t^j,\ldots,t^n)$ in T^n. A uniform magnetic field is generated by the gauge field

$$A=\sum_{k=1}^{n} A_k\,\mathrm{d}t^k=\frac{1}{2}\sum_{j,k=1}^{n}\phi_{jk}\,t^j\,\mathrm{d}t^k+\sum_{k=1}^{n}\alpha_k\,\mathrm{d}t^k. \tag{2.1}$$

Here $\{\phi_{jk}=-\phi_{kj}\}$ and $\{\alpha_j\}$ are real constants. Then the magnetic field is

$$B=\mathrm{d}A=\frac{1}{2}\sum_{j,k=1}^{n}\phi_{jk}\,\mathrm{d}t^j\wedge\mathrm{d}t^k. \tag{2.2}$$

Therefore, the number ϕ_{jk} represents magnetic flux which penetrates the (t^j,t^k)-face of the torus. We call the array of numbers (ϕ_{jk}) a magnetic flux matrix.

Let us introduce a complex scalar field f in the torus. The scalar field couples to the gauge field via the covariant derivative

$$\mathrm{D}f=\mathrm{d}f-2\pi iAf. \tag{2.3}$$

We put the coefficient $2\pi i$ in front of A for later convenience. Topology of the torus imposes a boundary condition on the scalar field. The gauge field itself is not a periodic function on $\mathbf{R}^n$ but it changes its form as

$$A(t^1,\ldots,t^j+1,\ldots,t^n)=A(t^1,\ldots,t^j,\ldots,t^n)+\frac{1}{2}\sum_{k=1}^{n}\phi_{jk}\,\mathrm{d}t^k. \tag{2.4}$$

Therefore, if we make the gauge transformation

$$f(t^1,\ldots,t^j+1,\ldots,t^n)=e^{\pi i\Sigma_{k=1}^n\phi_{jk}t^k}f(t^1,\ldots,t^j,\ldots,t^n), \tag{2.5}$$

the covariant derivative (2.3) remains covariant as

$$\mathrm{D}f(t^1,\ldots,t^j+1,\ldots,t^n)=e^{\pi i\Sigma_{k=1}^n\phi_{jk}t^k}\,\mathrm{D}f(t^1,\ldots,t^j,\ldots,t^n). \tag{2.6}$$

We call the condition (2.5) a twisted periodic condition. There are two ways to bring a point $(t^1,\ldots,t^j+1,\ldots,t^k+1,\ldots,t^n)$ to $(t^1,\ldots,t^j,\ldots,t^k,\ldots,t^n)$. The first way is

$$\begin{aligned}f(t^1,\ldots,t^j+1,\ldots,t^k+1,\ldots,t^n)&=e^{\pi i\{\phi_{jk}+\Sigma_{l=1}^n\phi_{jl}t^l\}}f(t^1,\ldots,t^j,\ldots,t^k+1,\ldots,t^n)\\&=e^{\pi i\{\phi_{jk}+\Sigma_{l=1}^n\phi_{jl}t^l+\Sigma_{l=1}^n\phi_{kl}t^l\}}f(t^1,\ldots,t^j,\ldots,t^k,\ldots,t^n).\end{aligned} \tag{2.7}$$

The other way is

$$\begin{aligned}f(t^1,\ldots,t^j+1,\ldots,t^k+1,\ldots,t^n)&=e^{\pi i\{\phi_{kj}+\Sigma_{l=1}^n\phi_{kl}t^l\}}f(t^1,\ldots,t^j+1,\ldots,t^k,\ldots,t^n)\\&=e^{\pi i\{\phi_{kj}+\Sigma_{l=1}^n\phi_{kl}t^l+\Sigma_{l=1}^n\phi_{jl}t^l\}}f(t^1,\ldots,t^j,\ldots,t^k,\ldots,t^n).\end{aligned} \tag{2.8}$$

To make these two expressions coincide we need to have

$$e^{\pi i\phi_{jk}}=e^{\pi i\phi_{kj}},$$

namely,

$$e^{\pi i(\phi_{jk}-\phi_{kj})}=e^{2\pi i\phi_{jk}}=1. \tag{2.9}$$

Therefore, compatibility of the periodic conditions (2.7) and (2.8) demands that ϕ_{jk} is an integer. Hence, the magnetic flux through each face of the torus is quantized. We call the torus where the magnetic field has been introduced a magnetic torus.

Since two displacements $t^j\mapsto t^j+1$ and $t^k\mapsto t^k+1$ are commutative, we can write the twisted periodic condition (2.5) in a more general form

$$f(\mathbf{t}+\mathbf{m})=e^{\pi i\Sigma_{j,k=1}^n\phi_{jk}m^jt^k}f(\mathbf{t}) \tag{2.10}$$

with an arbitrary $\mathbf{m}=(m^1,\ldots,m^n)\in\mathbf{Z}^n$. An inner product of two twisted periodic functions $f(\mathbf{t})$ and $g(\mathbf{t})$ is defined by

$$\langle f|g\rangle=\int_0^1\mathrm{d}t^1\cdots\int_0^1\mathrm{d}t^n\,f^*(\mathbf{t})g(\mathbf{t}). \tag{2.11}$$

Equipped with this inner product the space of twisted periodic functions becomes a Hilbert space.

To define the Laplacian we need to introduce a metric into the torus. Let Λ be an n-dimensional lattice in the Euclidean space $\mathbf{R}^n$. We equip the torus T^n with a Riemannian structure by identifying T^n with the quotient space $\mathbf{R}^n/\Lambda$. Let $\{\mathbf{u}_1,\ldots,\mathbf{u}_n\}$ be a set of vectors that generates the lattice Λ. Their inner products is denoted by

$$g_{jk}=\langle\mathbf{u}_j,\mathbf{u}_k\rangle \tag{2.12}$$

and its inverse is denoted by g^{jk}. Then the magnetic Laplacian is defined as

$$\Delta f=\sum_{j,k=1}^{n} g^{jk}\left(\frac{\partial}{\partial t^j}-2\pi i A_j\right)\left(\frac{\partial}{\partial t^k}-2\pi i A_k\right)f. \tag{2.13}$$

It is also referred to as the Bochner Laplacian in the literature. The purpose of this paper is to solve the eigenvalue problem of the magnetic Laplacian accompanied by the twisted periodic condition (2.5).

III. MAGNETIC TRANSLATION GROUP

Our goal is to find a complete set of eigenvalues and eigenfunctions of the magnetic Laplacian (2.13) as announced above. A royal road to solving an eigenvalue problem is to detect symmetry. In this section we determine a group of operators that commute with the Laplacian and construct irreducible representations of the group.

The vector space $\mathbf{R}^n$ acts on the torus as isometries. However, the gauge field restricts the admissible class of vectors as seen below. An arbitrary vector $\mathbf{v}\in\mathbf{R}^n$ displaces the gauge field (2.1) as

$$A(\mathbf{t})\mapsto A(\mathbf{t}-\mathbf{v})=A(\mathbf{t})-d\left(\frac{1}{2}\sum_{j,k=1}^{n}\phi_{jk}v^j t^k\right). \tag{3.1}$$

If we perform a gauge transformation of the scalar field simultaneously with the displacement

$$f(\mathbf{t})\mapsto f'(\mathbf{t})=(U(\mathbf{v})f)(\mathbf{t})=e^{\pi i\Sigma_{j,k=1}^{n}\phi_{jk}v^j t^k}f(\mathbf{t}-\mathbf{v}), \tag{3.2}$$

then the covariant derivative is changed covariantly

$$\mathrm{D}f(\mathbf{t})\mapsto \mathrm{D}f'(\mathbf{t})=e^{\pi i\Sigma_{j,k=1}^{n}\phi_{jk}v^j t^k}(\mathrm{D}f)(\mathbf{t}-\mathbf{v}). \tag{3.3}$$

In other words, the transformation $U(\mathbf{v})$ commutes with the covariant derivative as

$$(\mathrm{D}U(\mathbf{v})f)(\mathbf{t})=(U(\mathbf{v})\mathrm{D}f)(\mathbf{t}). \tag{3.4}$$

Hence it commutes with the magnetic Laplacian, which is defined in terms of the covariant derivative. The operator $U(\mathbf{v})$ is unitary with respect to the inner product (2.11).

The displaced function (3.2) also must satisfy the twisted periodic condition. If the original function f satisfies the condition (2.10), the displaced function changes its form as

$$f'(\mathbf{t}+\mathbf{m})=e^{2\pi i\Sigma_{j,k=1}^{n}\phi_{jk}v^j m^k}e^{\pi i\Sigma_{j,k=1}^{n}\phi_{jk}m^j t^k}f'(\mathbf{t}) \tag{3.5}$$

for $\mathbf{m}\in\mathbf{Z}^n$. Thus the displaced function satisfies the condition (2.10) if and only if

$$\sum_{j,k=1}^{n}\phi_{jk}v^j m^k \tag{3.6}$$

is an integer for an arbitrary $\mathbf{m}\in\mathbf{Z}^n$. In other words,

$$\sum_{j=1}^{n}\phi_{jk}v^j \quad (k=1,\ldots,n) \tag{3.7}$$

must be an integer. We call such a restricted vector $\mathbf{v}$ a magnetic shift. The set of magnetic shifts forms an Abelian group

$$\Omega^n=\{\mathbf{v}\in\mathbf{R}^n \mid \phi\mathbf{v}\in\mathbf{Z}^n\}. \tag{3.8}$$

There is a sequence of Abelian subgroups $\mathbf{Z}^n\subset\Omega^n\subset\mathbf{R}^n$. In particular, an integer vector $\mathbf{m}\in\mathbf{Z}^n$ induces a displacement

$$(U(\mathbf{m})f)(\mathbf{t})=e^{\pi i\Sigma_{j,k=1}^n\phi_{jk}m^jt^k}f(\mathbf{t}-\mathbf{m}).$$

However, owing to the twisted periodic condition (2.10), this is reduced to the identity transformation

$$(U(\mathbf{m})f)(\mathbf{t})=f(\mathbf{t}). \tag{3.9}$$

Thus we conclude that the group G of effective transformations is generated by

$$\{U(\mathbf{v}) \mid \mathbf{v}\in\Omega^n/\mathbf{Z}^n\}. \tag{3.10}$$

We call the group G the magnetic translation group. A product of transformations is

$$U(\mathbf{v})U(\mathbf{w})=e^{\pi i\Sigma_{j,k=1}^n\phi_{jk}v^jw^k}U(\mathbf{v}+\mathbf{w}). \tag{3.11}$$

Their commutator is

$$U(\mathbf{v})U(\mathbf{w})U(-\mathbf{v})U(-\mathbf{w})=e^{2\pi i\Sigma_{j,k=1}^n\phi_{jk}v^jw^k}. \tag{3.12}$$

We can say that the MTG is a central extension of the Abelian group $\Omega^n/\mathbf{Z}^n$ by $U(1)$.

We can express the MTG in a standard form. Let $L(n,\mathbf{Z})$ denote a group of the n-dimensional matrices $\{S\}$ of integers such that $\det S=\pm1$. The matrix $S\in L(n,\mathbf{Z})$ acts on $\mathbf{t}\in\mathbf{R}^n$ by $\mathbf{t}\mapsto S\mathbf{t}$ and this action induces an automorphism of the torus $T^n=\mathbf{R}^n/\mathbf{Z}^n$. It also induces a transformation of the magnetic flux matrix as

$$\phi_{jk}\mapsto\phi'_{jk}=\sum_{l,p=1}^n\phi_{lp}S^l{}_jS^p{}_k. \tag{3.13}$$

The Frobenius lemma[20] tells that for any integral antisymmetric matrix there exists a transformation to bring it into a standard form

$$(\phi_{jk})=\begin{pmatrix}
0 & q_1 & & & & & & & & \\
-q_1 & 0 & & & & & & & & \\
 & & 0 & q_2 & & & & & & \\
 & & -q_2 & 0 & & & & & & \\
 & & & & \ddots & & & & & \\
 & & & & & 0 & q_m & & & \\
 & & & & & -q_m & 0 & & & \\
 & & & & & & & 0 & & \\
 & & & & & & & & \ddots & \\
 & & & & & & & & & 0
\end{pmatrix}, \tag{3.14}$$

where $\{q_i\}$ are positive integers and they constitute a sequence $q_1|q_2|\cdots|q_m$, which implies that q_i divides q_{i+1}. For example, we may have a sequence $3|6|12|48$. Of course, $2m\leqslant n$. The vector

subspace of the zero eigenvalue of the matrix ϕ has dimensions $n-2m$ and it is called null directions. In the following we suppose that the flux matrix is in the standard form (3.14).

Now we can write the magnetic shifts (3.8) in a more explicit form. Let $\{\mathbf{e}_1,\ldots,\mathbf{e}_n\}$ be the standard basis of $\mathbf{R}^n$ in the $(t^1,\ldots,t^n)$-coordinate. Then any magnetic shift is uniquely expressed as

$$\mathbf{v}=\sum_{j=1}^{m}\left(\frac{s_{2j-1}}{q_j}\mathbf{e}_{2j-1}+\frac{s_{2j}}{q_j}\mathbf{e}_{2j}\right)+\sum_{k=1}^{n-2m}\theta_{2m+k}\mathbf{e}_{2m+k} \tag{3.15}$$

with integers $\{s_1,\ldots,s_{2m}\}$ and real numbers $\{\theta_{2m+1},\ldots,\theta_n\}$. Namely, the magnetic shifts are generated by $\{(1/q_j)\mathbf{e}_{2j-1},(1/q_j)\mathbf{e}_{2j}\,|\,j=1,\ldots,m\}$ with integral coefficients and $\{\mathbf{e}_{2m+k}\,|\,k=1,\ldots,n-2m\}$ with real coefficients. Hence, if the flux matrix ϕ has null directions $n-2m>0$, the MTG has a continuous component. Otherwise, the MTG is a completely discrete group.

Here we summarize our discussion; the MTG is generated by the unitary operators

$$U_j=U\left(\frac{1}{q_j}\mathbf{e}_{2j-1}\right),\quad V_j=U\left(\frac{1}{q_j}\mathbf{e}_{2j}\right)\quad(j=1,\ldots,m) \tag{3.16}$$

and

$$W_k(\theta)=U(\theta\mathbf{e}_{2m+k})\quad(k=1,\ldots,n-2m). \tag{3.17}$$

According to (3.9), (3.11), (3.12), and (3.14), these generators satisfy the following relations:

$$(U_j)^{q_j}=(V_j)^{q_j}=1, \tag{3.18}$$

$$U_jV_jU_j^{-1}V_j^{-1}=e^{2\pi i/q_j}, \tag{3.19}$$

$$W_k(1)=1, \tag{3.20}$$

$$W_k(\theta)W_k(\theta')=W_k(\theta+\theta'), \tag{3.21}$$

and other trivial commutators.

To solve the eigenvalue problem of the magnetic Laplacian we need to prepare the whole set of irreducible representations of the MTG. Let $\{|r_1,\ldots,r_m;d_1,\ldots,d_{n-2m}\rangle\}$ be elements of a representation space that are labeled by

$$r_j\in\mathbf{Z}/\mathbf{Z}_{q_j}\quad(j=1,\ldots,m), \tag{3.22}$$

$$d_k\in\mathbf{Z}\quad(k=1,\ldots,n-2m). \tag{3.23}$$

Then the generators (3.16) and (3.17) are represented by

$$U_j|r_1,\ldots,r_j,\ldots,r_m;d_1,\ldots,d_{n-2m}\rangle=|r_1,\ldots,r_j+1,\ldots,r_m;d_1,\ldots,d_{n-2m}\rangle, \tag{3.24}$$

$$V_j|r_1,\ldots,r_j,\ldots,r_m;d_1,\ldots,d_{n-2m}\rangle=e^{-2\pi ir_j/q_j}|r_1,\ldots,r_j,\ldots,r_m;d_1,\ldots,d_{n-2m}\rangle, \tag{3.25}$$

$$W_k(\theta)|r_1,\ldots,r_j,\ldots,r_m;d_1,\ldots,d_{n-2m}\rangle=e^{-2\pi id_k\theta}|r_1,\ldots,r_j,\ldots,r_m;d_1,\ldots,d_{n-2m}\rangle. \tag{3.26}$$

Thus

$$\mathcal{H}_d = \bigoplus_{r_1=0}^{q_1} \cdots \bigoplus_{r_m=0}^{q_m} \mathbf{C}|r_1,\ldots,r_m;d_1,\ldots,d_{n-2m}\rangle \tag{3.27}$$

provides an irreducible representation space of the MTG. Its dimension is

$$\dim \mathcal{H}_d = q_1 \times q_2 \times \cdots \times q_m . \tag{3.28}$$

The labels r_j and d_k in (3.22) and (3.23) will become good quantum numbers for the Laplacian (2.13). The dimension (3.28) will give the degree of degeneracy of each eigenvalue.

IV. DIAGONALIZATION OF THE MAGNETIC FIELD STRENGTH

To solve the eigenvalue problem of the magnetic Laplacian we need to take the metric (2.12) into account. Remember that the basis $\{\mathbf{u}_1,\ldots,\mathbf{u}_n\}$ generates the lattice Λ in the Euclidean space $\mathbf{R}^n$ and that the torus is isometric to $\mathbf{R}^n/\Lambda$. Let $\mathbf{x}=(x^1,\ldots,x^n)$ be an orthonormal coordinate of $\mathbf{R}^n$. It is related to the normalized coordinate $\mathbf{t}=(t^1,\ldots,t^n)$ via

$$\mathbf{x} = t^1\mathbf{u}_1 + \cdots + t^n\mathbf{u}_n = U\mathbf{t}. \tag{4.1}$$

In these coordinates the magnetic field (2.2) is expressed as

$$B = \frac{1}{2}\sum_{j,k=1}^{n} B_{jk}\,\mathrm{d}x^j\wedge dx^k = \frac{1}{2}\sum_{j,k,l,p=1}^{n} B_{jk}\,u^j{}_l\,u^k{}_p\,\mathrm{d}t^l\wedge\mathrm{d}t^p = \frac{1}{2}\sum_{l,p=1}^{n}\phi_{lp}\,\mathrm{d}t^l\wedge\mathrm{d}t^p. \tag{4.2}$$

The number B_{jk} is areal density of magnetic flux which penetrates the (x^j,x^k)-plane. If we perform a coordinate transformation

$$\mathbf{x} = R\mathbf{y} \tag{4.3}$$

by an orthogonal transformation $R\in O(n,\mathbf{R})$, the components of the field strength is transformed as

$$B = \frac{1}{2}\sum_{j,k=1}^{n} B_{jk}\,\mathrm{d}x^j\wedge\mathrm{d}x^k = \frac{1}{2}\sum_{j,k,l,p=1}^{n} B_{jk}\,R^j{}_l\,R^k{}_p\,\mathrm{d}y^l\wedge\mathrm{d}y^p. \tag{4.4}$$

By a suitable orthogonal transformation the field strength matrix (B_{jk}) can be brought into a standard form

$$\nu = {}^tRB\,R = \begin{pmatrix} 0 & \nu_1 & & & & & & & \\ -\nu_1 & 0 & & & & & & & \\ & & 0 & \nu_2 & & & & & \\ & & -\nu_2 & 0 & & & & & \\ & & & & \ddots & & & & \\ & & & & & 0 & \nu_m & & \\ & & & & & -\nu_m & 0 & & \\ & & & & & & & 0 & \\ & & & & & & & & \ddots \\ & & & & & & & & & 0 \end{pmatrix}, \tag{4.5}$$

where $\{\nu_j\}$ are positive real numbers. The $(t^1,\ldots,t^n)$-coordinate system block-diagonalizes the magnetic flux in the form of (3.14) while $(y^1,\ldots,y^n)$ block-diagonalizes the magnetic field strength in the form of (4.5). The transformations (4.1) and (4.3) are combined into

$$\mathbf{y}={}^tR\mathbf{x}={}^tRU\mathbf{t}=L\mathbf{t}. \tag{4.6}$$

Then we obtain relations among the matrices

$$\phi={}^tUBU={}^tUR\,\nu\,{}^tRU={}^tL\,\nu L. \tag{4.7}$$

The phase factor in (3.2) is rewritten as

$$\begin{aligned}\sum_{j,k=1}^{n} v^j\phi_{jk}t^k&=\sum_{j,k,l,p=1}^{n} v^jL^l{}_j\nu_{lp}L^p{}_kt^k\\&=\sum_{j,l,p=1}^{n} v^jL^l{}_j\nu_{lp}y^p\\&=\sum_{j=1}^{n}\sum_{l=1}^{m} v^j(L^{2l-1}_j\nu_ly^{2l}-L^{2l}_j\nu_ly^{2l-1}).\end{aligned} \tag{4.8}$$

The gauge field (2.1) is expressed in the y-coordinate as

$$A=\frac{1}{2}\sum_{j=1}^{m}\nu_j(y^{2j-1}\,\mathrm{d}y^{2j}-y^{2j}\,\mathrm{d}y^{2j-1})+\sum_{j,k=1}^{n}\alpha_j(L^{-1})^j{}_k\,\mathrm{d}y^k. \tag{4.9}$$

We set

$$\beta_k=\sum_{j=1}^{n}\alpha_j(L^{-1})^j{}_k \tag{4.10}$$

for later use.

Actually, we can choose a transformation matrix L that has zeros in this pattern

$$L=\begin{pmatrix} L^{2i-1}_{2p-1} & L^{2i-1}_{2q} & L^{2i-1}_{2m+r}\\ L^{2j}_{2p-1} & L^{2j}_{2q} & L^{2j}_{2m+r}\\ L^{2m+k}_{2p-1} & L^{2m+k}_{2q} & L^{2m+k}_{2m+r}\end{pmatrix}=\begin{pmatrix} * & 0 & 0\\ * & * & 0\\ * & * & *\end{pmatrix} \tag{4.11}$$

with $i,j,p,q=1,\ldots,m$ and $k,r=1,\ldots,n-2m$. The inverse matrix L^{-1} also has the same pattern of zeros. This distribution of zeros is proved in Appendix A. Then we can rewrite the magnetic shift operators (3.16) and (3.17) with a help of (4.8) in the y-coordinate as

$$U_jf(y^i)=e^{\pi i\Sigma_{l=1}^{m}(1/q_j)(L^{2l-1}_{2j-1}\nu_ly^{2l}-L^{2l}_{2j-1}\nu_ly^{2l-1})}f(y^i-L^i{}_{2j-1}(1/q_j)), \tag{4.12}$$

$$V_jf(y^i)=e^{-\pi i\Sigma_{l=1}^{m}(1/q_j)L^{2l}_{2j}\nu_ly^{2l-1}}f(y^i-L^i{}_{2j}(1/q_j)), \tag{4.13}$$

$$W_k(\theta)f(y^i)=f(y^i-L^i{}_{2m+k}\theta) \tag{4.14}$$

for $j=1,\ldots,m$ and $k=1,\ldots,n-2m$. From (4.11) and (4.7) we get a formula

$$\begin{aligned}\nu_i L^{2i-1}_{2j-1} &= \sum_{l,p=1}^{m} \nu_l L^{2l-1}_{2j-1} L^{2l}_{2p} (L^{-1})^{2p}_{2i} \\ &= \sum_{l,p=1}^{m} (L^{2l-1}_{2j-1} \nu_l L^{2l}_{2p} - L^{2l}_{2j-1} \nu_l L^{2l-1}_{2p})(L^{-1})^{2p}_{2i} \\ &= \sum_{p=1}^{m} q_j \delta_{jp} (L^{-1})^{2p}_{2i} = q_j (L^{-1})^{2j}_{2i}, \end{aligned} \tag{4.15}$$

which will be repeatedly used later.

V. MAGNETIC ALGEBRA

In this section we introduce new operators which act on twisted periodic functions. These new operators and the operators in the MTG generate an algebra, which we call a magnetic algebra. We construct and classify its irreducible representations. In the next section we will prove that the space of twisted periodic functions is actually an irreducible representation of the magnetic algebra. In this sense, the magnetic algebra completely characterizes the quantum mechanics in the magnetic torus.

Now we introduce a family of Hermite operators. Expanding the covariant derivative (2.3) in terms of the y-coordinate

$$Df = i \sum_{l=1}^{n} P_l f \, \mathrm{d}y^l, \tag{5.1}$$

we define differential operators

$$P_{2j-1} = -i\left(\frac{\partial}{\partial y^{2j-1}} + \pi i \nu_j y^{2j} - 2\pi i \beta_{2j-1} \right), \tag{5.2}$$

$$P_{2j} = -i\left(\frac{\partial}{\partial y^{2j}} - \pi i \nu_j y^{2j-1} - 2\pi i \beta_{2j} \right) \quad (j = 1, \ldots, m), \tag{5.3}$$

$$P_{2m+k} = -i\left(\frac{\partial}{\partial y^{2m+k}} - 2\pi i \beta_{2m+k} \right) \quad (k = 1, \ldots, n-2m). \tag{5.4}$$

These are Hermitian with respect to the inner product (2.11). Since $(y^1, \ldots, y^n)$ is an orthonormal coordinate, the Laplacian (2.13) becomes

$$-\Delta f = \sum_{i=1}^{n} (P_i)^2 f. \tag{5.5}$$

Nontrivial commutators among P's are

$$[P_{2j-1}, P_{2j}] = 2\pi i \nu_j \quad (j = 1, \ldots, m). \tag{5.6}$$

The other commutators vanish. We call the operators $\{P_{2j-1}, P_{2j}\}$ transverse momenta while we call the operators $\{P_{2m+k}\}$ longitudinal momenta. Since the covariant derivative commutes with the magnetic shifts as seen at (3.4), the momentum operators $\{P_i\}$ commute with the shift operators $\{U_j, V_j, W_k\}$, which are defined at (3.16) and (3.17).

Next we introduce another family of unitary operators. For this purpose we need an observation; in the t-coordinate that expresses the magnetic flux matrix in the standard form (3.14), t^{2m+k} $(k=1,\ldots,n-2m)$ are genuine cyclic coordinates. That is to say, the twisted periodic function (2.5) is periodic with respect to these coordinates as

$$f(t^1,\ldots,t^{2m+k}+1,\ldots,t^n)=f(t^1,\ldots,t^{2m+k},\ldots,t^n) \quad (k=1,\ldots,n-2m) \tag{5.7}$$

and the magnetic shift (3.2) is reduced to an ordinary continuous shift

$$(W_k(\theta)f)(t^1,\ldots,t^{2m+k},\ldots,t^n)=f(t^1,\ldots,t^{2m+k}-\theta,\ldots,t^n). \tag{5.8}$$

Then we define an operator T^k for each $k=1,\ldots,n-2m$ which acts on f by multiplication

$$(T^k f)(\mathbf{t})=e^{2\pi i\, t^{2m+k}} f(\mathbf{t})=e^{2\pi i \Sigma_{i=1}^n (L^{-1})_i^{2m+k} y^i} f(\mathbf{t}). \tag{5.9}$$

Here we used the inverse L^{-1} of the coordinate transformation (4.6). The operators $\{T^k\}$ are unitary operators with respect to the inner product (2.11). They satisfy

$$W_k(\theta)T^k=e^{-2\pi i\theta}T^k W_k(\theta), \tag{5.10}$$

$$[P_i,T^k]=2\pi(L^{-1})_i^{2m+k}T^k \quad (i=1,\ldots,n;\ k=1,\ldots,n-2m) \tag{5.11}$$

and commute with the other generators of the MTG.

Combining all the operators introduced above we define an algebra $\mathcal{A}$ with the generators $\{P_i,U_j,V_j,W_k(\theta),T^k \mid i=1,\ldots,n;\ j=1,\ldots,m;\ k=1,\ldots,n-2m;\ \theta\in\mathbf{R}\}$ and with the relations (3.18)–(3.21), (5.6), (5.10), (5.11) and other trivial commutators. We call the algebra $\mathcal{A}$ a magnetic algebra. In the following we will construct all the irreducible representations of the algebra $\mathcal{A}$ and classify their unitary equivalence classes.

A subset of generators $\{P_{2j-1},P_{2m+l},V_j,W_l(\theta) \mid j=1,\ldots,m;\ l=1,\ldots,n-2m;\ \theta\in\mathbf{R}\}$ generates a maximal Abelian subalgebra of $\mathcal{A}$. Hence these generators are simultaneously diagonalizable. Their simultaneous eigenstate $|k,r,d\rangle$ is labeled by $r_j\in\mathbf{Z}/\mathbf{Z}_{q_j}$ of (3.22) and $d_l\in\mathbf{Z}$ of (3.23) with new labels

$$k_{2j-1},k_{2m+l}\in\mathbf{R}. \tag{5.12}$$

The generators $\{P_{2j-1},P_{2m+l}\}$ act on these states as

$$P_{2j-1}|k,r,d\rangle=2\pi k_{2j-1}|k,r,d\rangle, \tag{5.13}$$

$$P_{2m+l}|k,r,d\rangle=2\pi k_{2m+l}|k,r,d\rangle, \tag{5.14}$$

and $\{V_j,W_l(\theta)\}$ act as (3.25), (3.26), respectively. The coefficient 2π was set for later convenience. Other generators $\{P_{2j},T^l \mid j=1,\ldots,m;\ l=1,\ldots,n-2m\}$ act on the states as

$$\langle\psi|P_{2j}|k,r,d\rangle=i\nu_j\frac{\partial}{\partial k_{2j-1}}\langle\psi|k,r,d\rangle, \tag{5.15}$$

$$T^l|k_i,r,d_k\rangle=e^{2\pi i\{\Sigma_{j=1}^m(k_{2j-1}+\Delta^l k_{2j-1})\Delta^l k_{2j}/\nu_j+\Sigma_{p=1}^{n-2m}Z^{lp}d_p\}}|k_i+\Delta^l k_i,r,d_k+\delta_k{}^l\rangle, \tag{5.16}$$

with $\Delta^l k_i=(L^{-1})_i^{2m+l}$. We will determine the $(n-2m)\times(n-2m)$ matrix Z^{lp} later. Here $|\psi\rangle$ represents an arbitrary state. The rests $\{U_j \mid j=1,\ldots,m\}$ act as (3.24). Therefore, in an irreducible representation space the eigenvalues k_{2m+i} are linked to d_l via

$$k_{2m+i}=\sum_{l=1}^{n-2m} d_l(L^{-1})^{2m+l}_{2m+i}-\beta_{2m+i}=\sum_{l=1}^{n-2m}(d_l-\alpha_{2m+l})(L^{-1})^{2m+l}_{2m+i}\quad(i=1,\ldots,n-2m). \tag{5.17}$$

Here the real number β_{2m+i} coincides with the one that appeared in (5.4). We also used the relations (4.10) and (4.11).

The matrix Z^{lp} is determined by the condition $T^{l'}T^{l}=T^{l}T^{l'}$. The action of $T^{l'}T^{l}$ gives

$$\begin{aligned}T^{l'}T^{l}|k_i,r,d_k\rangle=&e^{2\pi i\{\Sigma_{j=1}^{m}(k_{2j-1}+\Delta^{l}k_{2j-1})\Delta^{l}k_{2j}/\nu_j+\Sigma_{p=1}^{n-2m}Z^{lp}d_p\}}\\&\times e^{2\pi i\{\Sigma_{j=1}^{m}(k_{2j-1}+\Delta^{l}k_{2j-1}+\Delta^{l'}k_{2j-1})\Delta^{l'}k_{2j}/\nu_j+\Sigma_{p=1}^{n-2m}Z^{l'p}(d_p+\delta_p{}^{l})\}}\\&\times|k_i+\Delta^{l}k_i+\Delta^{l'}k_i,r,d_k+\delta_k{}^{l}+\delta_k{}^{l'}\rangle\end{aligned} \tag{5.18}$$

while the action of $T^{l}T^{l'}$ gives

$$\begin{aligned}T^{l}T^{l'}|k_i,r,d_k\rangle=&e^{2\pi i\{\Sigma_{j=1}^{m}(k_{2j-1}+\Delta^{l'}k_{2j-1})\Delta^{l'}k_{2j}/\nu_j+\Sigma_{p=1}^{n-2m}Z^{l'p}d_p\}}\\&\times e^{2\pi i\{\Sigma_{j=1}^{m}(k_{2j-1}+\Delta^{l'}k_{2j-1}+\Delta^{l}k_{2j-1})\Delta^{l}k_{2j}/\nu_j+\Sigma_{p=1}^{n-2m}Z^{lp}(d_p+\delta_p{}^{l'})\}}\\&\times|k_i+\Delta^{l'}k_i+\Delta^{l}k_i,r,d_k+\delta_k{}^{l'}+\delta_k{}^{l}\rangle.\end{aligned} \tag{5.19}$$

To give $T^{l'}T^{l}=T^{l}T^{l'}$ the matrix $Z^{ll'}$ must satisfy

$$\sum_{j=1}^{m}(\Delta^{l}k_{2j-1}\Delta^{l'}k_{2j}/\nu_j)+Z^{l'l}=\sum_{j=1}^{m}(\Delta^{l'}k_{2j-1}\Delta^{l}k_{2j}/\nu_j)+Z^{ll'}. \tag{5.20}$$

A general solution of the above equation is

$$Z^{ll'}=\sum_{j=1}^{m}(\Delta^{l}k_{2j-1}\Delta^{l'}k_{2j}/\nu_j)+S^{ll'}. \tag{5.21}$$

Here we leave an arbitrary symmetric matrix $S^{ll'}=S^{l'l}$ yet undetermined. Actually any choice of $S^{ll'}$ results in an equivalent representation, and therefore we take $S^{ll'}=0$.

A restricted set of vectors $\{|k,r,d\rangle\}$ that are labeled by the mutually independent parameters

$$k_{2j-1}\in\mathbf{R},\quad r_j\in\mathbf{Z}/\mathbf{Z}_{q_j},\quad d_l\in\mathbf{Z}\quad(j=1,\ldots,m;\ l=1,\ldots,n-2m) \tag{5.22}$$

spans a Hilbert space $\mathcal{H}_\alpha$ for each fixed value of $(\alpha_{2m+1},\alpha_{2m+2},\ldots,\alpha_n)$. Thus we conclude that a unitary equivalence class of irreducible representations of the algebra $\mathcal{A}$ has one-to-one correspondence with the parameter $(\alpha_{2m+1},\alpha_{2m+2},\ldots,\alpha_n)\in\mathbf{R}^{n-2m}/\mathbf{Z}^{n-2m}$.

VI. FOURIER ANALYSIS FOR THE MAGNETIC TORUS

Now let us turn to the space of twisted periodic functions. It is a representation space of the magnetic algebra. We will calculate the whole family of eigenfunctions of the maximal Abelian subalgebra of the magnetic algebra. These eigenfunctions $\chi_{k,r,d}(t^1,\ldots,t^n)=\langle t|k,r,d\rangle$ satisfy

$$P_{2j-1}\chi_{k,r,d}=-i\left(\frac{\partial}{\partial y^{2j-1}}+\pi i\nu_j y^{2j}-2\pi i\beta_{2j-1}\right)\chi_{k,r,d}=2\pi k_{2j-1}\chi_{k,r,d}, \tag{6.1}$$

$$P_{2j}\chi_{k,r,d}=-i\left(\frac{\partial}{\partial y^{2j}}-\pi i\nu_j y^{2j-1}-2\pi i\beta_{2j}\right)\chi_{k,r,d}=i\nu_j\frac{\partial}{\partial k_{2j-1}}\chi_{k,r,d}, \tag{6.2}$$

$$P_{2m+l}\,\chi_{k,r,d}=-i\left(\frac{\partial}{\partial y^{2m+l}}-2\pi i\beta_{2m+l}\right)\chi_{k,r,d}=2\pi\left(\sum_{i=1}^{n-2m} d_i(L^{-1})^{2m+i}_{2m+l}-\beta_{2m+l}\right)\chi_{k,r,d}, \tag{6.3}$$

$$U_j\,\chi_{k,r,d}=e^{\pi i t^{2j}}\chi_{k,r,d}\left(t^{2j-1}-\frac{1}{q_j}\right)=\chi_{k,(r+1),d}, \tag{6.4}$$

$$V_j\,\chi_{k,r,d}=e^{-\pi i t^{2j-1}}\chi_{k,r,d}\left(t^{2j}-\frac{1}{q_j}\right)=e^{-2\pi i r_j/q_j}\chi_{k,r,d}, \tag{6.5}$$

$$W_l(\theta)\,\chi_{k,r,d}=\chi_{k,r,d}(t^{2m+l}-\theta)=e^{-2\pi i d_l\theta}\chi_{k,r,d}, \tag{6.6}$$

$$T^l\,\chi_{k,r,d}=e^{2\pi i\, t^{2m+l}}\chi_{k,r,d}=e^{2\pi i\{\Sigma_{j=1}^{m}(k_{2j-1}+\Delta k_{2j-1})\Delta k_{2j}/\nu_j+\Sigma_{p=1}^{n-2m}Z^{lp}d_p\}}\chi_{k+\Delta k,r,(d+1)}, \tag{6.7}$$

for $j=1,\ldots,m$; $l=1,\ldots,n-2m$, and $\theta\in\mathbf{R}$. Here $(r+1)$ is an abbreviation of $(r_i+\delta_{ij})$ and $(d+1)$ is an abbreviation of $(d_p+\delta_p{}^l)$. And $\Delta k_i=(L^{-1})^{2m+l}_{i}$ as given in (5.16). Then $\chi_{k,r,d}$ is a simultaneous eigenfunction of $\{P_{2j-1},P_{2m+l},V_j,W_l(\theta)\}$. In the rest of this section we will solve the set of equations (6.1)–(6.7) to get the solutions

$$\begin{aligned}\chi_{k,r,d}(y^1,\ldots,y^n)=c\,\exp&\left[2\pi i\left\{-\sum_{j=1}^{m}\sum_{l=1}^{n-2m} d_l(L^{-1})^{2m+l}_{2j-1}\beta_{2j}/\nu_j-\frac{1}{2}\sum_{j=1}^{m}\nu_j y^{2j-1}y^{2j}\right\}\right]\\
&\times\sum_{\sigma_1,\sigma_2,\ldots,\sigma_m=-\infty}^{\infty}\exp\left[2\pi i\left\{\frac{1}{2}\sum_{i,j,l=1}^{m}\nu_l L^{2l-1}_{2i-1}L^{2l}_{2j-1}(q_i\sigma_i+r_i)(q_j\sigma_j\right.\right.\\
&+r_j)/(q_iq_j)+\sum_{j=1}^{m}\beta_{2j-1}\left\{y^{2j-1}-\sum_{i=1}^{m}L^{2j-1}_{2i-1}(q_i\sigma_i+r_i)/q_i\right\}\\
&+\sum_{j,l=1}^{m}(q_j\sigma_j+r_j-\gamma_j)(L^{-1})^{2j}_{2l}\left\{y^{2l}-\sum_{i=1}^{m}L^{2l}_{2i-1}(q_i\sigma_i+r_i)/q_i\right\}\\
&+\sum_{k,l=1}^{n-2m}d_k(L^{-1})^{2m+k}_{2m+l}\left\{y^{2m+l}-\sum_{i=1}^{m}L^{2m+l}_{2i-1}(q_i\sigma_i+r_i)/q_i\right\}\\
&\left.\left.+\sum_{j=1}^{m}k_{2j-1}\left\{y^{2j-1}+\beta_{2j}/\nu_j-\sum_{i=1}^{m}L^{2j-1}_{2i-1}(q_i\sigma_i+r_i-\gamma_i)/q_i\right\}\right\}\right],\end{aligned} \tag{6.8}$$

where c is a common normalization constant. The coefficients γ_j are given later at (6.13). The fact that the eigenfunctions are uniquely determined up to the common coefficient c implies that the space of twisted periodic function is an irreducible representation space of the magnetic algebra. Consequently, the eigenfunctions (6.8) constitute a complete orthonormal set of the space of twisted periodic functions over the torus. This is one of the main results of this paper. Hence an arbitrary twisted periodic function over the torus can be expanded as

$$f(y^1,\ldots,y^n)=\sum_{k,r,d}\lambda_{k,r,d}\,\chi_{k,r,d}(y^1,\ldots,y^n) \tag{6.9}$$

with unique coefficients $\lambda_{k,r,d}$. Therefore, the complete set $\{\chi_{k,r,d}\}$ provides a new basis for Fourier analysis in the magnetic torus.

In the rest of this section we give detailed lengthy calculations to prove the above statements. The reader may skip them to the next section, where we calculate solutions of the eigenvalue problem of the magnetic Laplacian using the main result (6.8). First, a simultaneous solution of (6.1) and (6.3) is

$$\chi_{k,r,d}(y^1,y^2,\ldots,y^n)=e^{2\pi i\Sigma_{j=1}^{m}\{(k_{2j-1}+\beta_{2j-1})y^{2j-1}-(1/2)\nu_j y^{2j-1}y^{2j}\}}e^{2\pi i\Sigma_{j,l=1}^{n-2m}d_j(L^{-1})_{2m+l}^{2m+j}y^{2m+l}}\times\phi_{k,r,d}(y^2,y^4,\ldots,y^{2m}),\tag{6.10}$$

where $\phi_{k,r,d}(y^2,y^4,\ldots,y^{2m})$ is an arbitrary function to be specified later.

Next let us turn to the other equation (6.5). Using (4.13) we can rewrite (6.5) as

$$e^{-\pi i\Sigma_{l=1}^{m}(1/q_j)L^{2l}_{\ 2j}\nu_l y^{2l-1}}\chi_{k,r,d}(y^i-L^{i}_{\ 2j}/q_j)=e^{-2\pi i r_j/q_j}\chi_{k,r,d}(y^i).\tag{6.11}$$

As discussed at (4.11) we have taken the matrix L such that $L^{2l-1}_{2j}=0$. Therefore, when (6.10) is substituted, the LHS of (6.11) becomes

$$\begin{aligned}&e^{-\pi i\Sigma_{l=1}^{m}(1/q_j)L^{2l}_{\ 2j}\nu_l y^{2l-1}}\chi_{k,r,d}(y^i-L^{i}_{\ 2j}/q_j)\\&\quad=e^{2\pi i\Sigma_{l=1}^{m}\{(k_{2l-1}+\beta_{2l-1})y^{2l-1}-(1/2)\nu_l y^{2l-1}y^{2l}\}}e^{2\pi i\Sigma_{p,l=1}^{n-2m}d_p(L^{-1})_{2m+l}^{2m+p}y^{2m+l}}\\&\qquad\times e^{-2\pi i\Sigma_{p,l=1}^{n-2m}d_p(L^{-1})_{2m+l}^{2m+p}L^{2m+l}_{\ 2j}/q_j}\phi_{k,r,d}(y^{2i}-L^{2i}_{\ 2j}/q_j).\end{aligned}\tag{6.12}$$

Hence, if we set

$$\gamma_j=\sum_{p,l=1}^{n-2m}d_p(L^{-1})_{2m+l}^{2m+p}L^{2m+l}_{\ 2j},\tag{6.13}$$

(6.11) implies that

$$e^{-2\pi i\gamma_j/q_j}\phi_{k,r,d}(y^{2i}-L^{2i}_{\ 2j}/q_j)=e^{-2\pi i r_j/q_j}\phi_{k,r,d}(y^{2i}).\tag{6.14}$$

If we introduce another coordinate system $(z^1,z^2,\ldots,z^m)$ which is related to $(y^2,y^4,\ldots,y^{2m})$ via

$$y^{2i}=\sum_{j=1}^{m}L^{2i}_{\ 2j}(z^j/q_j),\tag{6.15}$$

then (6.14) is rewritten as

$$\phi_{k,r,d}(z^1,\ldots,z^j-1,\ldots,z^m)=e^{2\pi i(\gamma_j-r_j)/q_j}\phi_{k,r,d}(z^1,\ldots,z^j,\ldots,z^m).\tag{6.16}$$

Moreover, if we set

$$\psi_{k,r,d}(z^1,\ldots,z^m)=e^{2\pi i\Sigma_{j=1}^{m}(\gamma_j-r_j)z^j/q_j}\phi_{k,r,d}(z^1,\ldots,z^m),\tag{6.17}$$

then (6.16) implies that

$$\psi_{k,r,d}(z^1,\ldots,z^j-1,\ldots,z^m)=\psi_{k,r,d}(z^1,\ldots,z^j,\ldots,z^m).\tag{6.18}$$

Hence $\psi_{k,r,d}$ is a periodic function with the period 1 and can be expanded in a Fourier series

$$\psi_{k,r,d}(z^1,\ldots,z^j,\ldots,z^m)=\sum_{\sigma_1,\sigma_2,\ldots,\sigma_m=-\infty}^{\infty}c_{k,r,d,\sigma}e^{2\pi i\Sigma_{j=1}^{m}\sigma_j z^j}.\tag{6.19}$$

Note that the inverse transformation of (6.15) is given by

$$(z^j/q_j)=\sum_{i=1}^{m}(L^{-1})^{2j}_{2i}y^{2i}. \tag{6.20}$$

Combining the above equations we can write down the eigenfunction (6.10) in a more specific form as

$$\chi_{k,r,d}(y^1,y^2,\ldots,y^n)=e^{2\pi i\Sigma_{j=1}^{m}\{(k_{2j-1}+\beta_{2j-1})y^{2j-1}-(1/2)\nu_j y^{2j-1}y^{2j}\}}e^{2\pi i\Sigma_{j,l=1}^{n-2m}d_j(L^{-1})^{2m+j}_{2m+l}y^{2m+l}}$$
$$\times\sum_{\sigma_1,\sigma_2,\ldots,\sigma_m=-\infty}^{\infty}c_{k,r,d,\sigma}\,e^{2\pi i\Sigma_{j,l=1}^{m}(q_j\sigma_j+r_j-\gamma_j)(L^{-1})^{2j}_{2l}y^{2l}}. \tag{6.21}$$

Moreover, referring to (4.11) and (4.14), we can see that (6.21) satisfies (6.6). Thus we have seen that $\chi_{k,r,d}$ is a simultaneous eigenfunction of $\{P_{2j-1},P_{2m+l},V_j,W_l(\theta)\}$ as announced above.

The remaining task is to solve (6.2), (6.4), and (6.7). Let us begin with (6.2). The left-hand side (LHS) of (6.2) is

$$-i\left(\frac{\partial}{\partial y^{2j}}-\pi i\nu_j y^{2j-1}-2\pi i\beta_{2j}\right)\chi_{k,r,d}$$
$$=\sum_{\sigma_1,\sigma_2,\ldots,\sigma_m=-\infty}^{\infty}2\pi\left(-\frac{1}{2}\nu_j y^{2j-1}+\sum_{i=1}^{m}(q_i\sigma_i+r_i-\gamma_i)(L^{-1})^{2i}_{2j}-\frac{1}{2}\nu_j y^{2j-1}-\beta_{2j}\right)$$
$$\times e^{2\pi i\Sigma_{i=1}^{m}\{(k_{2i-1}+\beta_{2i-1})y^{2i-1}-(1/2)\nu_i y^{2i-1}y^{2i}\}}e^{2\pi i\Sigma_{i,l=1}^{n-2m}d_i(L^{-1})^{2m+i}_{2m+l}y^{2m+l}}c_{k,r,d,\sigma}$$
$$\times e^{2\pi i\Sigma_{i,l=1}^{m}(q_i\sigma_i+r_i-\gamma_i)(L^{-1})^{2i}_{2l}y^{2l}}.$$

On the other hand, the right-hand side (RHS) of (6.2) is

$$i\nu_j\frac{\partial}{\partial k_{2j-1}}\chi_{k,r,d}=i\nu_j\,e^{2\pi i\Sigma_{i=1}^{m}\{(k_{2i-1}+\beta_{2i-1})y^{2i-1}-(1/2)\nu_i y^{2i-1}y^{2i}\}}e^{2\pi i\Sigma_{i,l=1}^{n-2m}d_i(L^{-1})^{2m+i}_{2m+l}y^{2m+l}}$$
$$\times\sum_{\sigma_1,\sigma_2,\ldots,\sigma_m=-\infty}^{\infty}\left(\frac{\partial c_{k,r,d,\sigma}}{\partial k_{2j-1}}+2\pi i y^{2j-1}c_{k,r,d,\sigma}\right)$$
$$\times e^{2\pi i\Sigma_{i,l=1}^{m}(q_i\sigma_i+r_i-\gamma_i)(L^{-1})^{2i}_{2l}y^{2l}}.$$

Therefore, we have an equation

$$i\nu_j\frac{\partial c_{k,r,d,\sigma}}{\partial k_{2j-1}}=2\pi\left(\sum_{i=1}^{m}(q_i\sigma_i+r_i-\gamma_i)(L^{-1})^{2i}_{2j}-\beta_{2j}\right)c_{k,r,d,\sigma} \tag{6.22}$$

and get its solution

$$c_{k,r,d,\sigma}=c_{0,r,d,\sigma}\,e^{-2\pi i\{\Sigma_{i,j=1}^{m}(q_i\sigma_i+r_i-\gamma_i)(L^{-1})^{2i}_{2j}\,k_{2j-1}/\nu_j-\Sigma_{j=1}^{m}\beta_{2j}k_{2j-1}/\nu_j\}}. \tag{6.23}$$

Thus (6.21) becomes

$$\chi_{k,r,d}(y^1,y^2,\ldots,y^n)=e^{2\pi i\Sigma_{j=1}^{m}\{(k_{2j-1}+\beta_{2j-1})y^{2j-1}+k_{2j-1}\beta_{2j}/\nu_j-(1/2)\nu_j y^{2j-1}y^{2j}\}}$$
$$\times e^{2\pi i\Sigma_{j,l=1}^{n-2m}d_j(L^{-1})^{2m+j}_{\ 2m+l}y^{2m+l}}$$
$$\times\sum_{\sigma_1,\sigma_2,\ldots,\sigma_m=-\infty}^{\infty}c_{0,r,d,\sigma}\,e^{2\pi i\Sigma_{j,l=1}^{m}(q_j\sigma_j+r_j-\gamma_j)(L^{-1})^{2j}_{\ 2l}(y^{2l}-k_{2l-1}/\nu_l)}. \tag{6.24}$$

Next we turn to (6.4). With the aid of (4.12) and (4.15) the LHS of (6.4) becomes

$$e^{\pi i\Sigma_{l=1}^{m}(1/q_j)(L^{2l-1}_{\ 2j-1}\nu_l y^{2l}-L^{2l}_{\ 2j-1}\nu_l y^{2l-1})}\chi_{k,r,d}(y^i-L^{i}_{\ 2j-1}/q_j)$$
$$=e^{2\pi i\Sigma_{i=1}^{m}\{-\beta_{2i-1}L^{2i-1}_{\ 2j-1}/q_j-(1/2)(L^{-1})^{2j}_{\ 2i}L^{2i}_{\ 2j-1}/q_j\}}\,e^{-2\pi i\Sigma_{i,l=1}^{n-2m}d_i(L^{-1})^{2m+i}_{\ 2m+l}L^{2m+l}_{\ 2j-1}/q_j}$$
$$\times e^{2\pi i\Sigma_{i=1}^{m}\{(k_{2i-1}+\beta_{2i-1})y^{2i-1}+k_{2i-1}\beta_{2i}/\nu_i-(1/2)\nu_i y^{2i-1}y^{2i}\}}e^{2\pi i\Sigma_{i,l=1}^{n-2m}d_i(L^{-1})^{2m+i}_{\ 2m+l}y^{2m+l}}$$
$$\times\sum_{\sigma_1,\sigma_2,\ldots,\sigma_m=-\infty}^{\infty}c_{0,r,d,\sigma}\,e^{-2\pi i\Sigma_{i,l=1}^{m}(q_i\sigma_i+r_i-\gamma_i)(L^{-1})^{2i}_{\ 2l}L^{2l}_{\ 2j-1}/q_j}$$
$$\times e^{2\pi i\Sigma_{i,l=1}^{m}(q_i\sigma_i+r_i+\delta_{ij}-\gamma_i)(L^{-1})^{2i}_{\ 2l}(y^{2l}-k_{2l-1}/\nu_l)}. \tag{6.25}$$

To make this coincide with the RHS of (6.4) we have a recursive equation

$$e^{2\pi i\Sigma_{i=1}^{m}\{-\beta_{2i-1}L^{2i-1}_{\ 2j-1}/q_j-(1/2)(L^{-1})^{2j}_{\ 2i}L^{2i}_{\ 2j-1}/q_j\}}\,e^{-2\pi i\Sigma_{i,l=1}^{n-2m}d_i(L^{-1})^{2m+i}_{\ 2m+l}L^{2m+l}_{\ 2j-1}/q_j}$$
$$\times e^{-2\pi i\Sigma_{i,l=1}^{m}(q_i\sigma_i+r_i-\gamma_i)(L^{-1})^{2i}_{\ 2l}L^{2l}_{\ 2j-1}/q_j}\,c_{0,r,d,\sigma}=c_{0,(r+1),d,\sigma}. \tag{6.26}$$

Here $(r+1)$ means $(r_i+\delta_{ij})$. If we define an $m\times m$ matrix

$$Y_{ij}=\sum_{l=1}^{m}(L^{-1})^{2i}_{\ 2l}L^{2l}_{\ 2j-1}/q_j=\sum_{l=1}^{m}\nu_l L^{2l-1}_{\ 2i-1}L^{2l}_{\ 2j-1}/(q_iq_j), \tag{6.27}$$

it is symmetric as

$$Y_{ij}-Y_{ji}=\sum_{l=1}^{m}(L^{2l-1}_{\ 2i-1}\nu_l L^{2l}_{\ 2j-1}-L^{2l}_{\ 2i-1}\nu_l L^{2l-1}_{\ 2j-1})/(q_iq_j)=\phi_{2i-1,2j-1}/(q_iq_j)=0 \tag{6.28}$$

by virtue of (4.7). Then the solution of (6.26) is

$$c_{0,r,d,\sigma}=c_{0,0,d,\sigma}\,e^{-2\pi i\Sigma_{i,j=1}^{m}\beta_{2i-1}L^{2i-1}_{\ 2j-1}r_j/q_j}e^{-2\pi i\Sigma_{j=1}^{m}\Sigma_{i,l=1}^{n-2m}d_i(L^{-1})^{2m+i}_{\ 2m+l}L^{2m+l}_{\ 2j-1}r_j/q_j}$$
$$\times e^{-2\pi i\Sigma_{i,j,l=1}^{m}(q_i\sigma_i+(1/2)r_i-\gamma_i)(L^{-1})^{2i}_{\ 2l}L^{2l}_{\ 2j-1}r_j/q_j}. \tag{6.29}$$

Therefore, (6.24) becomes

$$\chi_{k,r,d}(y^1,y^2,\ldots,y^n)=\exp\Bigg[2\pi i\Bigg\{\sum_{j=1}^{m}\Big\{(k_{2j-1}+\beta_{2j-1})y^{2j-1}+k_{2j-1}\beta_{2j}/\nu_j-\frac{1}{2}\nu_j y^{2j-1}y^{2j}\Big\}$$
$$+\sum_{i,l=1}^{n-2m} d_i(L^{-1})^{2m+i}_{2m+l}\Big(y^{2m+l}-\sum_{j=1}^{m}L^{2m+l}_{2j-1}r_j/q_j\Big)$$
$$-\sum_{i,j=1}^{m}\beta_{2i-1}L^{2i-1}_{2j-1}r_j/q_j+\frac{1}{2}\sum_{i,j=1}^{m}Y_{ij}r_ir_j\Bigg\}\Bigg]$$
$$\times\sum_{\sigma_1,\sigma_2,\ldots,\sigma_m=-\infty}^{\infty}c_{0,0,d,\sigma}\exp\Bigg[2\pi i\sum_{j,l=1}^{m}(q_j\sigma_j+r_j-\gamma_j)(L^{-1})^{2j}_{2l}$$
$$\times\Big(y^{2l}-k_{2l-1}/\nu_l-\sum_{i=1}^{m}L^{2l}_{2i-1}r_i/q_i\Big)\Bigg]. \tag{6.30}$$

Since $(U_j)^{q_j}=1$ by (3.18), the substitution $r_j\mapsto r_j+q_j$ must leave $\chi_{k,r,d}$ invariant. This substitution gives

$$\chi_{k,(r+q),d}(\mathbf{y})=\exp\Bigg[2\pi i\Bigg\{\sum_{i=1}^{m}\Big\{(k_{2i-1}+\beta_{2i-1})y^{2i-1}+k_{2i-1}\beta_{2i}/\nu_i-\frac{1}{2}\nu_i y^{2i-1}y^{2i}\Big\}$$
$$+\sum_{i,l=1}^{n-2m}d_i(L^{-1})^{2m+i}_{2m+l}\Big(y^{2m+l}-\sum_{p=1}^{m}L^{2m+l}_{2p-1}r_p/q_p\Big)-\sum_{i,l=1}^{m}\beta_{2i-1}L^{2i-1}_{2l-1}r_l/q_l$$
$$+\frac{1}{2}\sum_{i,p=1}^{m}Y_{ip}r_ir_p-\sum_{i,l=1}^{n-2m}d_i(L^{-1})^{2m+i}_{2m+l}L^{2m+l}_{2j-1}-\sum_{i=1}^{m}\beta_{2i-1}L^{2i-1}_{2j-1}+\sum_{i=1}^{m}Y_{ij}r_iq_j$$
$$+\frac{1}{2}Y_{jj}q_jq_j\Big)\Bigg\}\sum_{\sigma_1,\sigma_2,\ldots,\sigma_m=-\infty}^{\infty}c_{0,0,d,(\sigma-1)}\exp\Bigg[2\pi i\Bigg\{-\sum_{i=1}^{m}(q_i\sigma_i+r_i-\gamma_i)Y_{ij}q_j$$
$$+\sum_{i,l=1}^{m}(q_i\sigma_i+r_i-\gamma_i)(L^{-1})^{2i}_{2l}\Big(y^{2l}-k_{2l-1}/\nu_l-\sum_{p=1}^{m}L^{2l}_{2p-1}r_p/q_p\Big)\Bigg\}\Bigg]. \tag{6.31}$$

Here $(\sigma-1)$ is an abbreviation of $(\sigma_i-\delta_{ij})$. We used (4.15). Then we have another recursive equation

$$c_{0,0,d,\sigma}=c_{0,0,d,(\sigma-1)}\exp\Bigg[2\pi i\Bigg\{-\sum_{i,l=1}^{n-2m}d_i(L^{-1})^{2m+i}_{2m+l}L^{2m+l}_{2j-1}-\sum_{i=1}^{m}\beta_{2i-1}L^{2i-1}_{2j-1}$$
$$+\sum_{i=1}^{m}Y_{ij}r_iq_j+\frac{1}{2}Y_{jj}q_jq_j-\sum_{i=1}^{m}(q_i\sigma_i+r_i-\gamma_i)Y_{ij}q_j\Bigg\}\Bigg]. \tag{6.32}$$

Remember that $q_iq_jY_{ij}=\Sigma_{l=1}^{m}\nu_lL^{2l-1}_{2i-1}L^{2l}_{2j-1}=q_jq_iY_{ji}$ is symmetric. The solution of (6.32) is

$$c_{0,0,d,\sigma}=c_{0,0,d,0}\exp\Bigg[2\pi i\Bigg\{-\sum_{i,l=1}^{n-2m}\sum_{j=1}^{m}d_i(L^{-1})^{2m+i}_{2m+l}L^{2m+l}_{2j-1}\sigma_j-\sum_{i,j=1}^{m}\beta_{2i-1}L^{2i-1}_{2j-1}\sigma_j$$
$$+\sum_{i,j=1}^{m}Y_{ij}r_iq_j\sigma_j-\sum_{i,j=1}^{m}((1/2)q_i\sigma_i+r_i-\gamma_i)Y_{ij}q_j\sigma_j\Bigg\}\Bigg]. \tag{6.33}$$

Substituting it into (6.30) and using (4.15), we get

$$\chi_{k,r,d}(\mathbf{y}) = c_{0,0,d,0}\, e^{-\pi i \Sigma_{j=1}^{m} \nu_j y^{2j-1} y^{2j}} \sum_{\sigma_1,\sigma_2,\ldots,\sigma_m=-\infty}^{\infty} \exp\Bigg[2\pi i \Bigg\{ \frac{1}{2} \sum_{i,j=1}^{m} Y_{ij}(q_i\sigma_i + r_i)(q_j\sigma_j + r_j) + \sum_{j=1}^{m} \beta_{2j-1} \Bigg\{ y^{2j-1} - \sum_{i=1}^{m} L^{2j-1}_{2i-1}(q_i\sigma_i + r_i)/q_i \Bigg\} + \sum_{j,l=1}^{m} (q_j\sigma_j + r_j - \gamma_j)(L^{-1})^{2j}_{2l} \Bigg\{ y^{2l} - \sum_{i=1}^{m} L^{2l}_{2i-1}(q_i\sigma_i + r_i)/q_i \Bigg\} + \sum_{i,l=1}^{n-2m} d_i (L^{-1})^{2m+i}_{2m+l} \Bigg\{ y^{2m+l} - \sum_{j=1}^{m} L^{2m+l}_{2j-1}(q_j\sigma_j + r_j)/q_j \Bigg\} + \sum_{j=1}^{m} k_{2j-1} \Bigg\{ y^{2j-1} + \beta_{2j}/\nu_j - \sum_{l=1}^{m} L^{2j-1}_{2l-1}(q_l\sigma_l + r_l - \gamma_l)/q_l \Bigg\} \Bigg\} \Bigg]. \tag{6.34}$$

Finally, we are going to solve (6.7). Its LHS becomes

$$\begin{aligned} & e^{2\pi i\, t^{2m+l}} \chi_{k,r,d} \\ &= c_{0,0,d,0}\, e^{-\pi i \Sigma_{j=1}^{m} \nu_j y^{2j-1} y^{2j}} \sum_{\sigma_1,\sigma_2,\ldots,\sigma_m=-\infty}^{\infty} \exp\Bigg[2\pi i \Bigg\{ \frac{1}{2} \sum_{i,j=1}^{m} Y_{ij}(q_i\sigma_i + r_i)(q_j\sigma_j + r_j) \\ &\quad + \sum_{j=1}^{m} \beta_{2j-1} \Bigg\{ y^{2j-1} - \sum_{i=1}^{m} L^{2j-1}_{2i-1}(q_i\sigma_i + r_i)/q_i \Bigg\} \\ &\quad + \sum_{j,p=1}^{m} \Bigg(q_j\sigma_j + r_j - \gamma_j + \sum_{i=1}^{m} (L^{-1})^{2m+l}_{2i} L^{2i}_{2j} \Bigg) (L^{-1})^{2j}_{2p} \Bigg\{ y^{2p} - \sum_{i=1}^{m} L^{2p}_{2i-1}(q_i\sigma_i + r_i)/q_i \Bigg\} \\ &\quad + \sum_{p,i=1}^{m} (L^{-1})^{2m+l}_{2p} L^{2p}_{2i-1}(q_i\sigma_i + r_i)/q_i \\ &\quad + \sum_{i,p=1}^{n-2m} (d_i + \delta^l_i)(L^{-1})^{2m+i}_{2m+p} \Bigg\{ y^{2m+p} - \sum_{j=1}^{m} L^{2m+p}_{2j-1}(q_j\sigma_j + r_j)/q_j \Bigg\} \\ &\quad + \sum_{p=1}^{n-2m} \sum_{j=1}^{m} (L^{-1})^{2m+l}_{2m+p} L^{2m+p}_{2j-1}(q_j\sigma_j + r_j)/q_j \\ &\quad + \sum_{j=1}^{m} (k_{2j-1} + (L^{-1})^{2m+l}_{2j-1}) \Bigg\{ y^{2j-1} + \beta_{2j}/\nu_j - \sum_{p=1}^{m} L^{2j-1}_{2p-1}(q_p\sigma_p + r_p - \gamma_p)/q_p \Bigg\} \\ &\quad - \sum_{j=1}^{m} (L^{-1})^{2m+l}_{2j-1} \Bigg\{ \beta_{2j}/\nu_j - \sum_{p=1}^{m} L^{2j-1}_{2p-1}(q_p\sigma_p + r_p - \gamma_p)/q_p \Bigg\} \Bigg\} \Bigg]. \end{aligned} \tag{6.35}$$

We set $\Delta^l k_i = (L^{-1})^{2m+l}_{i}$ as before. The change $d_p \mapsto d_p + \delta_p{}^l$ causes a change of γ_j as

$$\begin{aligned}\Delta^l\gamma_j &= \sum_{i=1}^{n-2m} (L^{-1})^{2m+l}_{2m+i} L^{2m+i}_{2j} \\ &= \sum_{i=1}^{n} (L^{-1})^{2m+l}_{i} L^{i}_{2j} - \sum_{i=1}^{m} (L^{-1})^{2m+l}_{2i-1} L^{2i-1}_{2j} - \sum_{i=1}^{m} (L^{-1})^{2m+l}_{2i} L^{2i}_{2j} \\ &= 0 - 0 - \sum_{i=1}^{m} (L^{-1})^{2m+l}_{2i} L^{2i}_{2j} \end{aligned} \tag{6.36}$$

via (6.13) with (4.11). Moreover, we can see that

$$\begin{aligned}\sum_{p=1}^{m} L^{2j-1}_{2p-1}\Delta^l\gamma_p/q_p &= -\sum_{p,i=1}^{m} L^{2j-1}_{2p-1}(L^{-1})^{2m+l}_{2i} L^{2i}_{2p}/q_p \\ &= -\sum_{p,i=1}^{m} (L^{-1})^{2p}_{2j}(L^{-1})^{2m+l}_{2i} L^{2i}_{2p}/\nu_j \\ &= -\sum_{i=1}^{m} (L^{-1})^{2m+l}_{2i}\delta^{2i}_{2j}/\nu_j \\ &= -(L^{-1})^{2m+l}_{2j}/\nu_j \\ &= -\Delta^l k_{2j}/\nu_j . \end{aligned} \tag{6.37}$$

Therefore (6.35) becomes

$$\begin{aligned} & e^{2\pi i\, t^{2m+l}}\chi_{k,r,d} \\ &= c_{0,0,d,0}\, e^{-\pi i\Sigma_{j=1}^{m}\nu_j y^{2j-1}y^{2j}} \exp\Bigg[2\pi i\Bigg\{\sum_{j=1}^{m}(k_{2j-1}+\Delta k_{2j-1})\Delta k_{2j}/\nu_j \\ &\quad -\sum_{j=1}^{m}(L^{-1})^{2m+l}_{2j-1}\Bigg(\beta_{2j}/\nu_j+\sum_{p=1}^{m}L^{2j-1}_{2p-1}\gamma_p/q_p\Bigg)\Bigg\}\Bigg] \\ &\quad \times \sum_{\sigma_1,\sigma_2,\ldots,\sigma_m=-\infty}^{\infty} \exp\Bigg[2\pi i\Bigg\{\frac{1}{2}\sum_{i,j=1}^{m} Y_{ij}(q_i\sigma_i+r_i)(q_j\sigma_j+r_j) \\ &\quad +\sum_{j=1}^{m}\beta_{2j-1}\Bigg\{y^{2j-1}-\sum_{i=1}^{m}L^{2j-1}_{2i-1}(q_i\sigma_i+r_i)/q_i\Bigg\} \\ &\quad +\sum_{j,p=1}^{m}(q_j\sigma_j+r_j-\gamma_j-\Delta\gamma_j)(L^{-1})^{2j}_{2p}\Bigg\{y^{2p}-\sum_{i=1}^{m}L^{2p}_{2i-1}(q_i\sigma_i+r_i)/q_i\Bigg\} \\ &\quad +\sum_{i,p=1}^{n-2m}(d_i+\delta^l_i)(L^{-1})^{2m+i}_{2m+p}\Bigg\{y^{2m+p}-\sum_{j=1}^{m}L^{2m+p}_{2j-1}(q_j\sigma_j+r_j)/q_j\Bigg\} \\ &\quad +\sum_{j=1}^{m}(k_{2j-1}+\Delta k_{2j-1})\Bigg\{y^{2j-1}+\beta_{2j}/\nu_j-\sum_{p=1}^{m}L^{2j-1}_{2p-1}(q_p\sigma_p+r_p-\gamma_p-\Delta\gamma_p)/q_p\Bigg\}\Bigg\}\Bigg]. \end{aligned} \tag{6.38}$$

In the course of calculation we used the fact $\Sigma_{p=1}^{n}(L^{-1})^{2m+l}_{p}L^{p}_{2i-1}=0$. With the aid of (4.15), (6.36) and the definition (5.21) we can deduce that

$$\sum_{j,p=1}^{m} (L^{-1})^{2m+l}_{2j-1} L^{2j-1}_{2p-1} \gamma_p/q_p = -\sum_{i=1}^{n-2m} Z^{li} d_i . \tag{6.39}$$

Thus we reach

$$\begin{aligned} e^{2\pi i\, t^{2m+l}} \chi_{k,r,d} = {} & e^{-2\pi i \Sigma_{j=1}^{m} (L^{-1})^{2m+l}_{2j-1} \beta_{2j}/\nu_j} c_{0,0,d,0} c^{-1}_{0,0,(d+1),0} \\ & \times e^{2\pi i \{\Sigma_{j=1}^{m} (k_{2j-1}+\Delta k_{2j-1}) \Delta k_{2j}/\nu_j + \Sigma_{i=1}^{n-2m} Z^{li} d_i\}} \chi_{k+\Delta k,r,(d+1)} . \end{aligned} \tag{6.40}$$

To satisfy (6.7) we meet another recursive equation

$$c_{0,0,(d+1),0} = e^{-2\pi i \Sigma_{j=1}^{m} (L^{-1})^{2m+l}_{2j-1} \beta_{2j}/\nu_j} c_{0,0,d,0} \tag{6.41}$$

and we get the solution

$$c_{0,0,d,0} = e^{-2\pi i \Sigma_{j=1}^{m} \Sigma_{l=1}^{n-2m} d_l (L^{-1})^{2m+l}_{2j-1} \beta_{2j}/\nu_j} c_{0,0,0,0} . \tag{6.42}$$

Substituting it into (6.34) we reach the final result

$$\begin{aligned} \chi_{k,r,d}(\mathbf{y}) = {} & c_{0,0,0,0} \exp\left[2\pi i \left\{ -\sum_{j=1}^{m} \sum_{l=1}^{n-2m} d_l (L^{-1})^{2m+l}_{2j-1} \beta_{2j}/\nu_j - \frac{1}{2} \sum_{j=1}^{m} \nu_j y^{2j-1} y^{2j} \right\} \right] \\ & \times \sum_{\sigma_1,\sigma_2,\ldots,\sigma_m=-\infty}^{\infty} \exp\left[2\pi i \left\{ \frac{1}{2} \sum_{i,j=1}^{m} Y_{ij} (q_i\sigma_i + r_i)(q_j\sigma_j + r_j) \right.\right. \\ & + \sum_{j=1}^{m} \beta_{2j-1} \left\{ y^{2j-1} - \sum_{i=1}^{m} L^{2j-1}_{2i-1} (q_i\sigma_i + r_i)/q_i \right\} \\ & + \sum_{j,l=1}^{m} (q_j\sigma_j + r_j - \gamma_j)(L^{-1})^{2j}_{2l} \left\{ y^{2l} - \sum_{i=1}^{m} L^{2l}_{2i-1} (q_i\sigma_i + r_i)/q_i \right\} \\ & + \sum_{k,l=1}^{n-2m} d_k (L^{-1})^{2m+k}_{2m+l} \left\{ y^{2m+l} - \sum_{i=1}^{m} L^{2m+l}_{2i-1} (q_i\sigma_i + r_i)/q_i \right\} \\ & \left.\left. + \sum_{j=1}^{m} k_{2j-1} \left\{ y^{2j-1} + \beta_{2j}/\nu_j - \sum_{i=1}^{m} L^{2j-1}_{2i-1} (q_i\sigma_i + r_i - \gamma_i)/q_i \right\} \right\} \right] . \end{aligned} \tag{6.43}$$

This is the result (6.8) announced previously. The eigenfunction $\chi_{k,r,d}$ is determined up to a unique normalization constant $c_{0,0,0,0}$. Thus we conclude that the space of twisted periodic functions over the torus is an irreducible representation space of the magnetic algebra $\mathcal{A}$. Finally, we have proved that the set of functions $\{\chi_{k,r,d}\}$ is a complete orthonormal set in the space of twisted periodic functions over the torus as announced at (6.9).

VII. EIGENFUNCTIONS OF THE MAGNETIC LAPLACIAN

In this section we will write down explicitly solutions of the eigenvalue problem of the magnetic Laplacian (2.13) or (5.5), which is expressed in the y-coordinate as

$$\begin{aligned} \Delta f = {} & \sum_{j=1}^{m} \left[\left(\frac{\partial}{\partial y^{2j-1}} + \pi i \nu_j y^{2j} - 2\pi i \beta_{2j-1} \right)^2 f + \left(\frac{\partial}{\partial y^{2j}} - \pi i \nu_j y^{2j-1} - 2\pi i \beta_{2j} \right)^2 f \right] \\ & + \sum_{k=1}^{n-2m} \left(\frac{\partial}{\partial y^{2m+k}} - 2\pi i \beta_{2m+k} \right)^2 f . \end{aligned} \tag{7.1}$$

The function f must satisfy the twisted periodic condition (2.5). We will obtain solutions using the Fourier analysis that is developed in the preceding section.

Here we would like to describe the outline of our method. As mentioned in the preceding section, the Laplacian commutes with the magnetic shift operators, $\{U_j, V_j, W_k\}$. Hence the labels $(r,d)=(r_1,r_2,\ldots,r_m,d_1,d_2,\ldots,d_{n-2m})$, which are defined in (3.22)–(3.26), are good quantum numbers. Moreover, the Laplacian commutes with the longitudinal momentum operators $\{P_{2m+k}\}$. Hence the corresponding momentum eigenvalues $\{k_{2m+k}\}$ are also good quantum numbers and are related to the labels d_l via (5.17). On the other hand, the Laplacian does not commute with the transverse momentum operators $\{P_{2j-1}, P_{2j}\}$. Hence the transverse momentum eigenvalues $\{k_{2j-1}\}$ do not remain good quantum numbers. The Laplacian admits a new set of good quantum numbers $(n_1,n_2,\ldots,n_m)$, which will be introduced later. It will be revealed that eigenfunctions of the Laplacian are actually matrix elements of a unitary transformation,

$$\psi_{n,r,d}(k_1,k_3,\ldots,k_{2m-1})=\langle k,r,d|n,r,d\rangle, \tag{7.2}$$

which relates the quantum numbers n's to k's. In the k-space it is rather easy to get eigenfunctions by the standard method of a harmonic oscillator. On the other hand, the set of eigenfunctions of the momenta and magnetic shifts,

$$\chi_{k,r,d}(y^1,y^2,\ldots,y^n)=\langle y|k,r,d\rangle, \tag{7.3}$$

plays a role a unitary transformation which bridges between the momentum space and the real space like the usual Fourier transformation. Hence the Laplacian eigenfunctions are transformed into the y-coordinate representations by

$$\psi_{n,r,d}(y^1,y^2,\ldots,y^n)=\langle y|n,r,d\rangle=\int_{-\infty}^{\infty} dk_1\, dk_3\cdots dk_{2m-1}\langle y|k,r,d\rangle\,\langle k,r,d|n,r,d\rangle. \tag{7.4}$$

This will give the desired result.

Now let us carry out the program outlined above. We define creation and annihilation operators associated with the transverse momenta as

$$a_j^\dagger=\frac{1}{\sqrt{4\pi\nu_j}}(P_{2j-1}-iP_{2j}),\quad a_j=\frac{1}{\sqrt{4\pi\nu_j}}(P_{2j-1}+iP_{2j})\quad (j=1,\ldots,m). \tag{7.5}$$

It is easily verified that $[a_j,a_k^\dagger]=\delta_{jk}$. Then the Laplacian (5.5) becomes

$$-\Delta=\sum_{j=1}^{m}4\pi\nu_j\left(a_j^\dagger a_j+\frac{1}{2}\right)+\sum_{k=1}^{n-2m}(P_{2m+k})^2. \tag{7.6}$$

The eigenstate $|\Omega\rangle$ for the lowest eigenvalue satisfies

$$0=\langle k|a_j|\Omega\rangle=\frac{1}{\sqrt{4\pi\nu_j}}\langle k|(P_{2j-1}+iP_{2j})|\Omega\rangle=\frac{1}{\sqrt{4\pi\nu_j}}\left(2\pi k_{2j-1}+\nu_j\frac{\partial}{\partial k_{2j-1}}\right)\langle k|\Omega\rangle. \tag{7.7}$$

Here we used (5.13) and (5.15). The solution is

$$\langle k|\Omega\rangle=e^{-\pi\Sigma_{j=1}^{m}(k_{2j-1})^2/\nu_j}. \tag{7.8}$$

States for higher eigenvalues are generated by creation operators as

$$\begin{aligned}\langle k|n\rangle &= \frac{1}{\sqrt{n_1!\cdots n_m!}}\langle k|(a_1^\dagger)^{n_1}\cdots(a_m^\dagger)^{n_m}|\Omega\rangle \\ &= \frac{1}{\sqrt{n_1!\cdots n_m!}}\prod_{j=1}^{m}\left[\frac{1}{\sqrt{4\pi\nu_j}}\left(2\pi k_{2j-1}-\nu_j\frac{\partial}{\partial k_{2j-1}}\right)\right]^{n_j}\langle k|\Omega\rangle \\ &= \frac{1}{\sqrt{n_1!\cdots n_m!}}e^{\pi\Sigma_{j=1}^m(k_{2j-1})^2/\nu_j}\prod_{j=1}^{m}\left[\frac{1}{\sqrt{4\pi\nu_j}}\left(-\nu_j\frac{\partial}{\partial k_{2j-1}}\right)\right]^{n_j}e^{-2\pi\Sigma_{j=1}^m(k_{2j-1})^2/\nu_j} \quad (7.9)\end{aligned}$$

for $n_1,n_2,\ldots,n_m=0,1,2,\ldots$. We are suppressing other labels (r,d). In Appendix B we prove that

$$\begin{aligned}\int_{-\infty}^{\infty}\mathrm{d}k\,e^{2\pi ikz}\cdot e^{\pi k^2/\nu}\left(-\nu\frac{\partial}{\partial k}\right)^n e^{-2\pi k^2/\nu} &= \sqrt{\nu}\,e^{\pi\nu z^2}\left(-i\frac{\partial}{\partial z}\right)^n e^{-2\pi\nu z^2} \\ &= \sqrt{\nu}(i\sqrt{2\pi\nu})^n e^{-\pi\nu z^2}H_n(z\sqrt{2\pi\nu}). \quad (7.10)\end{aligned}$$

In the second line $H_n(\xi)$ is the nth Hermite polynomial. Substituting (6.43) and (7.9) into (7.4) and applying (7.10) we obtain

$$\begin{aligned}\langle y|n,r,d\rangle &= \int_{-\infty}^{\infty}\mathrm{d}k_1\,\mathrm{d}k_3\cdots\mathrm{d}k_{2m-1}\,\langle y|k,r,d\rangle\langle k,r,d|n,r,d\rangle \\ &= c\,\exp\Bigg[2\pi i\Bigg\{-\sum_{j=1}^{m}\sum_{l=1}^{n-2m}d_l(L^{-1})^{2m+l}_{2j-1}\beta_{2j}/\nu_j \\ &\quad -\frac{1}{2}\sum_{j=1}^{m}\nu_j y^{2j-1}y^{2j}\Bigg\}\Bigg]_{\sigma_1,\sigma_2,\ldots,\sigma_m=-\infty}^{\infty}\exp\Bigg[2\pi i\Bigg\{\frac{1}{2}\sum_{i,j=1}^{m}Y_{ij}(q_i\sigma_i+r_i)(q_j\sigma_j+r_j) \\ &\quad +\sum_{j=1}^{m}\beta_{2j-1}\Bigg\{y^{2j-1}-\sum_{i=1}^{m}L^{2j-1}_{2i-1}(q_i\sigma_i+r_i)/q_i\Bigg\} \\ &\quad +\sum_{j,l=1}^{m}(q_j\sigma_j+r_j-\gamma_j)(L^{-1})^{2j}_{2l}\Bigg\{y^{2l}-\sum_{i=1}^{m}L^{2l}_{2i-1}(q_i\sigma_i+r_i)/q_i\Bigg\} \\ &\quad +\sum_{k,l=1}^{n-2m}d_k(L^{-1})^{2m+k}_{2m+l}\Bigg\{y^{2m+l}-\sum_{i=1}^{m}L^{2m+l}_{2i-1}(q_i\sigma_i+r_i)/q_i\Bigg\}\Bigg\}\Bigg] \\ &\quad \times\prod_{j=1}^{m}\Bigg[\sqrt{\frac{\nu_j}{n_j!}}\left(\frac{i}{\sqrt{2}}\right)^{n_j}e^{-\pi\nu_j\{y^{2j-1}+\beta_{2j}/\nu_j-\Sigma_{i=1}^m L^{2j-1}_{2i-1}(q_i\sigma_i+r_i-\gamma_i)/q_i\}^2} \\ &\quad \times H_{n_j}\Bigg(\sqrt{2\pi\nu_j}\Bigg\{y^{2j-1}+\beta_{2j}/\nu_j-\sum_{i=1}^{m}L^{2j-1}_{2i-1}(q_i\sigma_i+r_i-\gamma_i)/q_i\Bigg\}\Bigg)\Bigg]. \quad (7.11)\end{aligned}$$

This is the main result of this paper. Using (5.17), we can calculate eigenvalues of the Laplacian (7.6) as

$$-\frac{1}{2}\Delta\psi_{n,r,d}=\Bigg[\sum_{j=1}^{m}2\pi\nu_j\left(n_j+\frac{1}{2}\right)+\frac{1}{2}\sum_{k=1}^{n-2m}\Bigg\{\sum_{l=1}^{n-2m}2\pi(d_l-\alpha_{2m+l})(L^{-1})^{2m+l}_{2m+k}\Bigg\}^2\Bigg]\psi_{n,r,d}. \quad (7.12)$$

Eigenvalues depend on quantum numbers $n_1,n_2,\ldots,n_m=0,1,2,\ldots$ and $d_1,d_2,\ldots,d_{n-2m}=0,\pm1,\pm2,\ldots$ but not on $r=(r_1,r_2,\ldots,r_m)\in\mathbf{Z}_{q_1}\times\mathbf{Z}_{q_2}\times\cdots\times\mathbf{Z}_{q_m}$. Thus each eigenvalue is degenerated by $q_1q_2\cdots q_m$ folds as predicted in (3.28). If a ratio $\nu_i/\nu_j(i\neq j)$ is rational, degeneracy happens more. On the other hand, if $\alpha_{2m+l}=0$, the eigenvalue for $-d_l$ coincides with the one for d_l. If $\alpha_{2m+l}=1/2$, the eigenvalue for $(-d_l+1)$ coincides with the one for d_l. Moreover, for specific values of $\{(L^{-1})^{2m+l}_{2m+k}\}$ we may meet more multifold degeneracy.

Let us discuss physical meanings of the eigenvalue (7.12). It is energy of an electrically charged particle moving in the magnetic field in the torus. In (7.12) we set the coefficient $-1/2$ in front of Δ to adjust the equation to the conventional Schrödinger equation. In the context of classical mechanics, the particle exhibits a cyclic motion with the frequency ν_j in the (y^{2j-1},y^{2j})-plane for each $j=1,2,\ldots,m$. And it exhibits a uniform straight motion along the y^{2m+k}-axis. The whole motion is a superposition of those cyclic and straight motions. When we turn to quantum mechanics, energy of the cyclic motion is quantized and results in the so-called Landau level $2\pi\nu_j(n_j+1/2)$. On the other hand, the longitudinal momentum P_{2m+k} associated with the straight motion is quantized to be $2\pi k_{2m+k}=2\pi\Sigma_{l=1}^{n-2m}(d_l-\alpha_{2m+l})(L^{-1})^{2m+l}_{2m+k}=2\pi\Sigma_{l=1}^{n-2m}d_l(L^{-1})^{2m+l}_{2m+k}-\beta_{2m+k}$ with integers $(d_1,d_2,\ldots,d_{n-2m})$ as explained in (5.17). Along the course of the straight motion the particle flies around the torus and picks up the so-called Aharonov–Bohm effect. Then the momentum is shifted by the Aharonov–Bohm parameters $(\beta_{2m+1},\ldots,\beta_n)$. Accordingly, the kinetic energy of the straight motion is also quantized. The total energy is then given as (7.12).

Moreover, let us examine meanings of other Aharonov–Bohm parameters $(\beta_1,\ldots,\beta_{2m})$. These do not affect the energy (7.12) and hence they have a geometric significance rather than a physical significance. To understand their meaning we rewrite the eigenfunction (6.43) as

$$\begin{aligned}\chi_{k,r,d}(\mathbf{y})=c\exp\Bigg[2\pi i\Bigg\{&\sum_{l=1}^{n-2m}\sum_{j=1}^{m}d_l\{(L^{-1})^{2m+l}_{2j}\beta_{2j-1}-(L^{-1})^{2m+l}_{2j-1}\beta_{2j}\}/\nu_j-\frac{1}{2}\sum_{j=1}^{m}\nu_jy^{2j-1}y^{2j}\\&+\sum_{j=1}^{m}\beta_{2j-1}y^{2j-1}\Bigg\}\Bigg]_{\sum_{\sigma_1,\sigma_2,\ldots,\sigma_m=-\infty}^{\infty}}\exp\Bigg[2\pi i\Bigg\{\frac{1}{2}\sum_{i,j=1}^{m}Y_{ij}(q_i\sigma_i+r_i)(q_j\sigma_j+r_j)\\&+\sum_{j,l=1}^{m}(q_j\sigma_j+r_j-\gamma_j)(L^{-1})^{2j}_{2l}\Bigg\{y^{2l}-\beta_{2l-1}/\nu_l-\sum_{i=1}^{m}L^{2l}_{2i-1}(q_i\sigma_i+r_i)/q_i\Bigg\}\\&+\sum_{k,l=1}^{n-2m}d_k(L^{-1})^{2m+k}_{2m+l}\Bigg\{y^{2m+l}-\sum_{i=1}^{m}L^{2m+l}_{2i-1}(q_i\sigma_i+r_i)/q_i\Bigg\}\\&+\sum_{j=1}^{m}k_{2j-1}\Bigg\{y^{2j-1}+\beta_{2j}/\nu_j-\sum_{i=1}^{m}L^{2j-1}_{2i-1}(q_i\sigma_i+r_i-\gamma_i)/q_i\Bigg\}\Bigg\}\Bigg].\end{aligned}\tag{7.13}$$

To get the above expression we used

$$\sum_{i=1}^{m}L^{2j-1}_{2i-1}\gamma_i/q_i=-\sum_{l=1}^{n-2m}d_l(L^{-1})^{2m+l}_{2j}/\nu_j,\tag{7.14}$$

which is easily derived from (6.36). Thus we can see that the parameters $(\beta_1,\ldots,\beta_{2m})$ induce a displacement

$$(y^{2j-1},y^{2j})\to(y^{2j-1}+\beta_{2j}/\nu_j,y^{2j}-\beta_{2j-1}/\nu_j)\tag{7.15}$$

of the profile $|\chi_{k,r,d}(\mathbf{y})|$. This is the geometric significance of the transverse Aharonov–Bohm parameters.

VIII. CONCLUSION

Here we summarize our discussions. As well-known, a $U(1)$ gauge field replaces the partial derivative by the covariant derivative and generates a magnetic field. As a natural extension of the eigenvalue problem of the ordinary Laplacian in the n-torus, we formulated the eigenvalue problem of the magnetic Laplacian. The ordinary Laplacian admits continuous Abelian symmetry and therefore the usual Fourier analysis is applicable. However, the magnetic Laplacian does not admit continuous Abelian symmetry and therefore the usual Fourier analysis is not applicable to it. Hence, we developed an alternative method, which became an extension of the usual Fourier analysis. We identified symmetry structure of the magnetic Laplacian and defined the magnetic translation group (MTG), which is discrete and non-Abelian in general. Moreover, we defined the magnetic algebra by extending the MTG. We proved that the space of functions on which the magnetic Laplacian acts is an irreducible representation space of the magnetic algebra. By diagonalizing the maximal Abelian subalgebra of the magnetic algebra we obtained a complete orthonormal set of functions $\{\chi_{k,r,d}(\mathbf{y})\}$ over the magnetic torus; those functions are labeled by a set of good quantum numbers (k,r,d). It was rather easy to diagonalize the magnetic Laplacian in the $\mathbf{k}$-space representation. Applying a unitary transformation by $\{\chi_{k,r,d}(\mathbf{y})\}$ to the eigenstate of the magnetic Laplacian, we finally obtained the eigenfunction in the $\mathbf{y}$-space representation. The eigenvalues of the magnetic Laplacian were naturally interpreted as sums of energies of cyclic motions in the transverse directions to the magnetic field and energies of linear motions in the longitudinal direction to it.

New results of this paper are the definition and representations of the magnetic algebra, the proof of irreducibility of the space of twisted periodic functions as a representation space of the magnetic algebra, the complete orthogonal set of functions (6.8) which provides a basis of the extended Fourier analysis, the eigenfunctions (7.11) of the magnetic Laplacian in explicit forms, and the eigenvalues (7.12).

Before closing this paper we would like to discuss briefly possible directions for further development. We treated only the Laplace operator in this paper but for application to physics it is more desirable to treat the Schrödinger operator

$$H = -\tfrac{1}{2}\Delta + V, \tag{8.1}$$

which has a potential energy term V. The potential V is a periodic function; in the t-coordinate it satisfies $V(t^1,\ldots,t^i+1,\ldots,t^n)=V(t^1,\ldots,t^i,\ldots,t^n)$ for each i. It acts on the twisted periodic function $f(\mathbf{t})$ by multiplication. To take the potential term into account we may introduce new operators X^k by

$$(X^j f)(\mathbf{t}) = e^{2\pi i\, t^j} f(\mathbf{t}) \quad (j=1,2,\ldots,2m), \tag{8.2}$$

which belong to the same family of operators T^k of (5.9). Then any periodic potential operator can be expanded as

$$\begin{aligned} V(t^1,\ldots,t^n) &= \sum_{\sigma_1,\sigma_2,\ldots,\sigma_n=-\infty}^{\infty} c_\sigma\, e^{2\pi i(\sigma_1 t^1+\cdots+\sigma_n t^n)} \\ &= \sum_{\sigma_1,\sigma_2,\ldots,\sigma_n=-\infty}^{\infty} c_\sigma\, (X^1)^{\sigma_1}\cdots(X^{2m})^{\sigma_{2m}}(T^1)^{\sigma_{2m+1}}\cdots(T^{n-2m})^{\sigma_n}. \end{aligned} \tag{8.3}$$

We can easily calculate commutators of X's with other operators to get an algebra which is an extension of the magnetic algebra. The resulted algebra is isomorphic to the so-called noncommutative torus[21] although we do not yet examine these relation thoroughly.

Another direction for future development is to solve an eigenvalue problem of the Dirac operator in the n-torus in the background magnetic field. We also construct supersymmetric field theory, which have both scalar and spinor fields as its constituents to pursue a new mechanism of supersymmetry breaking.

APPENDIX A: DISTRIBUTION OF ZEROS

As shown in (4.11) we prove existence of a transformation matrix L that has zeros in the pattern

$$L=\begin{pmatrix} L^{2i-1}_{2p-1} & L^{2i-1}_{2q} & L^{2i-1}_{2m+r} \\ L^{2j}_{2p-1} & L^{2j}_{2q} & L^{2j}_{2m+r} \\ L^{2m+k}_{2p-1} & L^{2m+k}_{2q} & L^{2m+k}_{2m+r} \end{pmatrix} = \begin{pmatrix} * & 0 & 0 \\ * & * & 0 \\ * & * & * \end{pmatrix} \tag{A1}$$

with $i,j,p,q=1,\ldots,m$ and $k,r=1,\ldots,n-2m$.

In $\mathbf{R}^n$ we have an antisymmetric bilinear form B. We say that a vector $\mathbf{u}$ is longitudinal with respect to B if it satisfies

$$B(\mathbf{u},\mathbf{v})=0 \tag{A2}$$

for arbitrary $\mathbf{v}\in\mathbf{R}^n$. We call

$$M^0=\{\mathbf{u}\in\mathbf{R}^n \mid \forall\mathbf{v}\in\mathbf{R}^n,\ B(\mathbf{u},\mathbf{v})=0\} \tag{A3}$$

a longitudinal vector subspace. Let $(t^1,t^2,\ldots,t^n)$ be the coordinate system that expresses B in the standard form

$$B=\frac{1}{2}\sum_{i,j=1}^{n}\phi_{ij}\,\mathrm{d}t^i\wedge\mathrm{d}t^j=\sum_{j=1}^{m}q_j\,\mathrm{d}t^{2j-1}\wedge\mathrm{d}t^{2j} \tag{A4}$$

as in (3.14). Let $(y^1,y^2,\ldots,y^n)$ be another coordinate system that is related to $(t^1,t^2,\ldots,t^n)$ by a linear transformation $y^i=\Sigma_{j=1}^{n}L^i{}_j\,t^j$. The matrix L is not yet specified. Basis vectors generated by these coordinates are related as

$$\frac{\partial}{\partial t^j}=\sum_{i=1}^{n}\frac{\partial y^i}{\partial t^j}\frac{\partial}{\partial y^i}=\sum_{i=1}^{n}L^i{}_j\frac{\partial}{\partial y^i}, \tag{A5}$$

$$\frac{\partial}{\partial y^j}=\sum_{i=1}^{n}\frac{\partial t^i}{\partial y^j}\frac{\partial}{\partial t^i}=\sum_{i=1}^{n}(L^{-1})^i{}_j\frac{\partial}{\partial t^i}. \tag{A6}$$

Define vector subspaces M^- and M^+ of $\mathbf{R}^n$ as

$$M^-=\mathbf{R}\frac{\partial}{\partial t^1}\oplus\mathbf{R}\frac{\partial}{\partial t^3}\oplus\cdots\oplus\mathbf{R}\frac{\partial}{\partial t^{2m-1}}, \tag{A7}$$

$$M^+ = \mathbf{R}\frac{\partial}{\partial t^2} \oplus \mathbf{R}\frac{\partial}{\partial t^4} \oplus \cdots \oplus \mathbf{R}\frac{\partial}{\partial t^{2m}}. \tag{A8}$$

Then $M^- \oplus M^+ \oplus M^0 = \mathbf{R}^n$. Now let us remember that $\mathbf{R}^n$ is equipped with inner product structure. Then the two-form $B: \mathbf{R}^n \times \mathbf{R}^n \to \mathbf{R}$ can be regarded as an antisymmetric operator $\hat{B}: \mathbf{R}^n \to \mathbf{R}^n$. As a square of a linear operator $\hat{B}^2$ is well-defined and becomes a symmetric operator and therefore is diagonalizable by an orthogonal transformation. $\hat{B}^2$ has nonpositive eigenvalues. The eigenspace W^0 associated with the zero eigenvalue of $\hat{B}^2$ coincides with M^0. Of course,

$$\left\{ \frac{\partial}{\partial t^{2m+1}}, \frac{\partial}{\partial t^{2m+2}}, \ldots, \frac{\partial}{\partial t^n} \right\} \tag{A9}$$

is a basis of $M^0 = W^0$. We take an orthonormal basis

$$\left\{ \frac{\partial}{\partial y^{2m+1}}, \frac{\partial}{\partial y^{2m+2}}, \ldots, \frac{\partial}{\partial y^n} \right\} \tag{A10}$$

of W^0. This implies that

$$L^{2i-1}_{2m+r} = L^{2j}_{2m+r} = (L^{-1})^{2i-1}_{2m+r} = (L^{-1})^{2j}_{2m+r} = 0 \tag{A11}$$

in (A5) and (A6).

Let us step into a difficult part of the proof. Each eigenspace associated with each nonzero eigenvalue of $\hat{B}^2$ can be decomposed into two-dimensional subspaces such that each two-dimensional subspace W_j is irreducible with respect to the action of $\hat{B}$. Thus we get an orthogonal decomposition

$$\mathbf{R}^n = W_1 \perp W_2 \perp \cdots \perp W_m \perp W^0. \tag{A12}$$

Next we define vector subspaces

$$W_j^+ = W_j \cap (M^+ \oplus M^0), \tag{A13}$$

$$W_j^- = W_j \cap (M^+ \oplus M^0)^\perp, \tag{A14}$$

then we can show that both W_j^+ and W_j^- have one dimension. First, note that $\dim W_j^+ + \dim W_j^- = \dim W_j = 2$. If $\dim W_j^+ = 2$, W_j^+ coincides with W_j itself. Since the two-form B is degenerated on $(M^+ \oplus M^0)$, it must be degenerated also on $W_j = W_j^+ \subset (M^+ \oplus M^0)$. This contradicts the fact that W_j is irreducible with respect to $\hat{B}$. On the other hand, if $\dim W_j^- = 2$, W_j^- coincides with W_j itself. Then we can take an arbitrary one-dimensional subspace $M_{-1} \subset W_j = W_j^- \subset (M^+ \oplus M^0)^\perp$. Since W_j is irreducible with respect to $\hat{B}$, B is degenerated on $M_{-1} \oplus M^+ \oplus M^0$. This contradicts the fact that $M^+ \oplus M^0$ is a maximal degenerated subspace of B. Hence we conclude that $\dim W_j^+ = \dim W_j^- = 1$.

We take a normalized vector $\partial/\partial y^{2j}$ of W_j^+. And we take another normalized vector $\partial/\partial y^{2j-1}$ of W_j^- such that $\nu_j = B(\partial/\partial y^{2j-1}, \partial/\partial y^{2j}) > 0$ for each $j = 1, \ldots, m$. Then we obtain a complete orthonormal basis $\{\partial/\partial y^i \mid i = 1,2,\ldots,n\}$ that expresses B in the standard form $B = \Sigma_{j=1}^m \nu_j \, dy^{2j-1} \wedge dy^{2j}$.

Since $\partial/\partial y^{2q} \in W_q^+ \subset M^+ \oplus M^0$, we can say that

$$(L^{-1})^{2i-1}_{2q} = 0 \tag{A15}$$

in (A6). By an elementary argument of linear algebra we can say that

$$L_{2q}^{2i-1}=0. \tag{A16}$$

The proof is over.

APPENDIX B: FOURIER TRANSFORMATION OF THE HERMITE POLYNOMIALS

In our convention the Hermite polynomial is defined as

$$H_n(\xi)=(-1)^n e^{\xi^2}\frac{d^n}{d\xi^n}e^{-\xi^2}. \tag{B1}$$

The formula (7.10) can be deduced by a partial integration and a change of variables as

$$\begin{aligned}\int_{-\infty}^{\infty} dk\, e^{2\pi ikz}\cdot e^{\pi k^2/\nu}\left(-\frac{\partial}{\partial k}\right)^n e^{-2\pi k^2/\nu} &= \int_{-\infty}^{\infty} dk\, e^{-2\pi k^2/\nu}\left(\frac{\partial}{\partial k}\right)^n e^{2\pi ikz}\cdot e^{\pi k^2/\nu}\\ &= e^{\pi\nu z^2}\int_{-\infty}^{\infty} dk\, e^{-2\pi k^2/\nu}\left(\frac{\partial}{\partial k}\right)^n e^{\pi(k+i\nu z)^2/\nu}\\ &= e^{\pi\nu z^2}\int_{-\infty}^{\infty} dk\, e^{-2\pi k^2/\nu}\left(-\frac{i}{\nu}\frac{\partial}{\partial z}\right)^n e^{\pi(k+i\nu z)^2/\nu}\\ &= e^{\pi\nu z^2}\left(-\frac{i}{\nu}\frac{\partial}{\partial z}\right)^n \int_{-\infty}^{\infty} dk\, e^{-\pi(k-i\nu z)^2/\nu-2\pi\nu z^2}\\ &= e^{\pi\nu z^2}\left(-\frac{i}{\nu}\frac{\partial}{\partial z}\right)^n \sqrt{\nu}\, e^{-2\pi\nu z^2}.\end{aligned} \tag{B2}$$

A class of vector coherent states defined over matrix domains

K. Thirulogasanthar[a] and S. Twareque Ali[b]
Department of Mathematics and Statistics, Concordia University, 7141 Sherbrooke Street West, Montreal, Quebec H4B 1R6, Canada

(Received 27 May 2003; accepted 31 July 2003)

A general scheme is proposed for constructing vector coherent states, in analogy with the well-known canonical coherent states, and their deformed versions, when these latter are expressed as infinite series in powers of a complex variable z. In the present scheme, the variable z is replaced by matrix valued functions over appropriate domains. As particular examples, we analyze the quaternionic extensions of the canonical coherent states and the Gilmore–Perelomov and Barut–Girardello coherent states arising from representations of SU(1,1). Possible physical applications are indicated. © *2003 American Institute of Physics.*

I. INTRODUCTION

One way to define conventional coherent states, over complex domains, is by constructing linear superpositions $|z\rangle$, parametrized by a single complex number z, of vectors $\{\phi_m\}_{m=0}^{\infty}$, which form an orthonormal basis in an infinite dimensional, complex, separable Hilbert space $\mathfrak{H}$:

$$|z\rangle = \mathcal{N}(|z|)^{-1/2} \sum_{m=0}^{\infty} \frac{z^m}{\sqrt{\rho(m)}} \phi_m . \tag{1.1}$$

Here $\{\rho(m)\}_{m=0}^{\infty}$ is a sequence of nonzero, positive numbers, chosen so as to ensure the convergence of the sum in a nonempty open subset $\mathcal{D}$, of the complex plane, and $\mathcal{N}(|z|)$ is a normalization constant, ensuring the condition $\langle z|z\rangle = 1$. The coherent states $|z\rangle$ are also required to satisfy a resolution of the identity condition:

$$\int_{\mathcal{D}} |z\rangle\langle z| d\mu = I \quad , \tag{1.2}$$

where $d\mu$ is an appropriately chosen measure and I is the identity operator on the Hilbert space $\mathfrak{H}$. These coherent states are known to have a large number of interesting properties, linking them to physical applications, orthogonal polynomials, generalized oscillator algebras, etc.[2,8,13,15]

In this article we extend this definition to matrix domains, thereby generating families of vector coherent states. Vector coherent states are well-known mathematical objects, particularly when they are defined as orbits of vectors under the operators of unitary representations of groups (see, for example, Refs. 2, 4, 5, and 17). However, in the present article we take a completely different route for constructing them, although in special cases the link to a group representation will also emerge.

II. VECTOR COHERENT STATES–THE GENERAL SETUP

Let $\mathcal{R}$ be a measure space, equipped with a measure $d\mathcal{R}$, and $\mathcal{K}$ a second measure space, equipped with a probability measure $d\mathcal{K}$. For $(r,k,\zeta)\in\mathcal{R}\times\mathcal{K}\times[0,2\pi)$, let

$$\mathcal{Z}=A(r)e^{i\zeta\Theta(k)}, \tag{2.1}$$

where $A(r),\Theta(k)$ are two (measurable) $n\times n$ matrix-valued functions with the following properties (assumed to hold for almost all $r\in\mathcal{R}$, with respect to the measure $d\mathcal{R}$ and almost all $k\in\mathcal{K}$, with respect to the measure $d\mathcal{K}$):

$$\Theta(k) \text{ is Hermitian, that is, } \Theta(k)=\Theta(k)^\dagger, \tag{2.2}$$

$$\Theta(k)^2=\mathbb{I}_n=n\times n \quad \text{unit matrix}, \tag{2.3}$$

$$[A(r),\Theta(k)]=A(r)\Theta(k)-\Theta(k)A(r)=0, \tag{2.4}$$

$$A(r)A(r)^\dagger=A(r)^\dagger A(r). \tag{2.5}$$

It is then straightforward to verify (e.g., by direct power series expansion) that

$$\mathcal{Z}=A(r)e^{i\zeta\Theta(k)}=A(r)[\cos\zeta+i\Theta(k)\sin\zeta]. \tag{2.6}$$

Let $\mathcal{D}=\mathcal{R}\times\mathcal{K}\times[0,2\pi)$ and define the measure $d\mu(r,k,\zeta)=d\mathcal{K}(k)d\mathcal{R}(r)d\zeta$ on it.

Let χ^j, $j=1,2,\ldots,n$, be an orthonormal basis in $\mathbb{C}^n$. Then, $\{\chi^j\otimes\phi_m\}$, $j=1,2,\ldots,n$, $m=0,1,2,\ldots,\infty$, is an orthonormal basis in $\hat{\mathfrak{H}}=\mathbb{C}^n\otimes\mathfrak{H}$. For each $\mathcal{Z}$ we define vector coherent states (VCS) as follows:

$$|\mathcal{Z},j\rangle=\mathcal{N}(|\mathcal{Z}|)^{-1/2}\sum_{m=0}^{\infty}\frac{\mathcal{Z}^m}{\sqrt{\rho(m)}}\chi^j\otimes\phi_m, \quad j=1,2,\ldots,n. \tag{2.7}$$

where, once again, $\mathcal{N}(|\mathcal{Z}|)$ is a normalization factor, which depends only on the positive part $|\mathcal{Z}|=[\mathcal{Z}\mathcal{Z}^\dagger]^{1/2}$ of the matrix $\mathcal{Z}$, and $\{\rho(m)\}_{m=0}^{\infty}$ is a sequence of nonzero positive numbers, with $\rho(0)=1$. These have to be chosen in a way such that the following two conditions are satisfied:

$$\text{normalization: } \sum_{j=0}^{n}\langle\mathcal{Z},j|\mathcal{Z},j\rangle=1, \tag{2.8}$$

$$\text{resolution of the identity: } \sum_{j=1}^{n}\int_{\mathcal{D}}W(|\mathcal{Z}|)|\mathcal{Z},j\rangle\langle\mathcal{Z},j|d\mu=\mathbb{I}_n\otimes I, \tag{2.9}$$

where $W(|\mathcal{Z}|)$ is an appropriately chosen positive weight function.

A straightforward computation, using the fact that

$$\mathcal{Z}^m=A(r)^m e^{im\zeta\Theta(k)}=A(r)^m(\cos m\zeta+i\Theta(k)\sin m\zeta),$$

shows that the normalization condition (2.8) implies the finiteness of the sum:

$$\mathcal{N}(|\mathcal{Z}|)=\sum_{m=0}^{\infty}\frac{\mathrm{Tr}|A(r)|^{2m}}{\rho(m)}, \tag{2.10}$$

($|A(r)|=[A(r)A(r)^\dagger]^{1/2}$ denoting the positive part of the matrix $A(r)$).

The resolution of the identity condition (2.9) imposes the following restriction on the weight function $W(|\mathcal{Z}|)$ and the matrices $A(r)$:

$$\int_{\mathcal{R}} \frac{2\pi W(|\mathcal{Z}|)|A(r)|^{2m}}{\mathcal{N}(|\mathcal{Z}|)} d\mathcal{R} = \rho(m)\mathbb{I}_n, \tag{2.11}$$

which can be interpreted as a sort of ''matrix moment condition.''

To see this we note that

$$\begin{aligned}
&\int_{\mathcal{D}} W(|\mathcal{Z}|)\sum_{j=1}^{n} |\mathcal{Z},j\rangle\langle\mathcal{Z},j| d\mu \\
&= \int_{\mathcal{D}} W(|\mathcal{Z}|)\sum_{j=1}^{n} \mathcal{N}(|\mathcal{Z}|)^{-1} \left| \sum_{m=0}^{\infty} \frac{\mathcal{Z}^m}{\sqrt{\rho(m)}} \chi^j \otimes \phi_m \right\rangle \left\langle \sum_{l=0}^{\infty} \frac{\mathcal{Z}^l}{\sqrt{\rho(l)}} \chi^j \otimes \phi_l \right| d\mu \\
&= \sum_{m=0}^{\infty}\sum_{l=0}^{\infty} \int_{\mathcal{D}} \frac{W(|\mathcal{Z}|)}{\mathcal{N}(|\mathcal{Z}|)\sqrt{\rho(m)\rho(l)}} A(r)^m e^{im\zeta\Theta(k)} \\
&\quad \times \left(\sum_{j=1}^{n} |\chi^j\rangle\langle\chi^j| \right) A(r)^{l\dagger} e^{-il\zeta\Theta(k)^\dagger} \otimes |\phi_m\rangle\langle\phi_l| d\mu .
\end{aligned}$$

Using

$$\sum_{j=1}^{n} |\chi^j\rangle\langle\chi^j| = \mathbb{I}_n, \quad \Theta(k)^\dagger = \Theta(k) \quad \text{and}$$

$$\int_0^{2\pi} e^{i(m-\ell)\zeta\Theta(k)} d\zeta = \begin{cases} 0 & \text{if } \ell \neq m \\ 2\pi\mathbb{I}_n & \text{if } \ell = m, \end{cases}$$

we reduce the last line to

$$\begin{aligned}
&\sum_{m=0}^{\infty} \int_{\mathcal{R}}\int_{\mathcal{K}} \frac{2\pi W(|\mathcal{Z}|)}{\mathcal{N}(|\mathcal{Z}|)\rho(m)} A(r)^m A(r)^{m\dagger} \otimes |\phi_m\rangle\langle\phi_m| d\mathcal{R} d\mathcal{K} \\
&= \sum_{m=0}^{\infty} \int_{\mathcal{R}}\int_{\mathcal{K}} \frac{2\pi W(|\mathcal{Z}|)}{\mathcal{N}(|\mathcal{Z}|)\rho(m)} |A(r)|^{2m} \otimes |\phi_m\rangle\langle\phi_m| d\mathcal{R} d\mathcal{K}.
\end{aligned}$$

Since $d\mathcal{K}$ is a probability measure, using the fact that $\Sigma_{m=0}^{\infty}|\phi_m\rangle\langle\phi_m| = I$ and imposing the condition (2.11), we immediately arrive at (2.9).

There is an associated matrix-valued reproducing kernel, $K(\mathcal{Z}^\dagger, \mathcal{Z}')$, with matrix elements,

$$\begin{aligned}
K_{j\ell}(\mathcal{Z}^\dagger, \mathcal{Z}') = \langle \mathcal{Z}, j | \mathcal{Z}', \ell \rangle &= \sum_{m=0}^{\infty} \frac{1}{\rho(m)\sqrt{\mathcal{N}(|\mathcal{Z}|)\mathcal{N}(|\mathcal{Z}'|)}} \\
&\quad \times \langle e^{-im(\zeta'\Theta(k') - \zeta\Theta(k))} A(r')^{m\dagger} A(r)^m \chi^j | \chi^\ell \rangle .
\end{aligned} \tag{2.12}$$

In view of (2.9), this kernel satisfies the reproducing condition,

$$\int_{\mathcal{D}} K(\mathcal{Z}^\dagger, \mathcal{Z}'') K(\mathcal{Z}''^\dagger, \mathcal{Z}') d\mu(k'', r'', \zeta'') = K(\mathcal{Z}^\dagger, \mathcal{Z}') . \tag{2.13}$$

III. GENERALIZED ANNIHILATION, CREATION AND NUMBER OPERATORS

There are a number of operators, associated with the coherent states (1.1), which define the so-called generalized oscillator algebras.[9,10,14,15] Similar operators can also be constructed in the

context of the VCS (2.7). In order to do that, let us first define $x_m=\rho(m)/\rho(m-1)$, for $m=1,2,3,\ldots$. Thus we write $\rho(m)=x_m x_{m-1}\cdots x_1=x_m!$ and define $x_0!=1$. The generalized annihilation or lowering operator, defined on the Hilbert space $\mathfrak{H}$, with respect to the basis $\{\phi_m\}_{m=0}^{\infty}$ is then written as

$$a\phi_m=\sqrt{x_m}\phi_{m-1} \quad \text{with} \quad a\phi_0=0\ . \tag{3.1}$$

In the case where $x_m=m$, we recover from this the standard annihilation operator for a harmonic oscillator. It is also easy to see that this operator acts on the coherent states $|z\rangle$ in the expected manner:

$$a|z\rangle=z|z\rangle\ .$$

Using a, we construct the creation or raising operator $a^\dagger$ and the number operator $N'=a^\dagger a$:

$$a^\dagger\phi_m=\sqrt{x_{m+1}}\phi_{m+1},\quad N'\phi_m=x_m\phi_m\ . \tag{3.2}$$

These three operators generate a Lie algebra (under composition given by the commutator bracket). This is the so-called generalized oscillator algebra, which we denote by $\mathfrak{A}_{\text{osc}}$. In general, the dimension of this algebra is not finite.

On the Hilbert space, $\mathbb{C}^n\otimes\mathfrak{H}$, of the VCS $|\mathcal{Z},j\rangle$, we define the corresponding operators as

$$A=\mathbb{I}_n\otimes a \quad \text{annihilation operator,} \tag{3.3}$$

$$A^\dagger=\mathbb{I}_n\otimes a^\dagger \quad \text{creation operator,} \tag{3.4}$$

$$N=\mathbb{I}_n\otimes N' \quad \text{number operator.} \tag{3.5}$$

They act on the VCS as

$$A|\mathcal{Z},j\rangle=\mathcal{Z}|\mathcal{Z},j\rangle\ , \tag{3.6}$$

$$A^\dagger|\mathcal{Z},j\rangle=\mathcal{N}(\mathcal{Z})^{-1/2}\sum_{m=0}^{\infty}\sqrt{\frac{x_{m+1}}{x_m!}}\ \mathcal{Z}^m\chi^j\otimes\phi_{m+1}\ , \tag{3.7}$$

$$N|\mathcal{Z},j\rangle=\mathcal{N}(\mathcal{Z})^{-1/2}\sum_{m=1}^{\infty}\frac{x_m}{\sqrt{x_m!}}\mathcal{Z}^m\chi^j\otimes\phi_m\ , \tag{3.8}$$

and generate the Lie algebra $\mathbb{I}_n\otimes\mathfrak{A}_{\text{osc}}$, which again is generally not finite dimensional.

Using the operators a and $a^\dagger$, we may also define the (formally) self-adjoint operators,

$$\hat{q}=\frac{a+a^\dagger}{\sqrt{2}} \quad \text{and} \quad \hat{p}=\frac{a-a^\dagger}{\sqrt{2}i}, \tag{3.9}$$

and the related operators

$$Q=\frac{A+A^\dagger}{\sqrt{2}}=\mathbb{I}_n\otimes\hat{q} \quad \text{and} \quad P=\frac{A-A^\dagger}{\sqrt{2}i}=\mathbb{I}_n\otimes\hat{p}\ . \tag{3.10}$$

We shall need these operators later, when constructing minimal uncertainty states.

To end this section, let us note that, as a consequence of the resolution of the identity (2.9), there is a natural isometric embedding of the Hilbert space of the VCS into a space of vector valued functions on the domain $\mathcal{D}$. Indeed, let $\tilde{\mathfrak{H}}=L^2(\mathcal{D},d\mu)$. Then,

$$\mathcal{W}:\mathbb{C}^n\otimes\mathfrak{H}\to\mathbb{C}^n\otimes\tilde{\mathfrak{H}},\quad \text{where}\quad (\mathcal{W}\Psi)^j(\mathcal{Z})=\langle\mathcal{Z},j|\Psi\rangle\,, \tag{3.11}$$

is easily seen to be an isometry.

IV. QUATERNIONIC CANONICAL COHERENT STATES

As a first example of our general construction, we build in this section VCS using the complex representation of quaternions by 2×2 matrices. Using the basis matrices,

$$\sigma_0=\begin{pmatrix}1&0\\0&1\end{pmatrix},\quad i\sigma_1=\begin{pmatrix}0&i\\i&0\end{pmatrix},\quad -i\sigma_2=\begin{pmatrix}0&-1\\1&0\end{pmatrix},\quad i\sigma_3=\begin{pmatrix}i&0\\0&-i\end{pmatrix},$$

where σ_1, σ_2, and σ_3 are the usual Pauli matrices, a general quaternion is written as

$$\mathfrak{q}=x_0\sigma_0+i\underline{x}\cdot\underline{\sigma}$$

with $x_0\in\mathbb{R}$, $\underline{x}=(x_1,x_2,x_3)\in\mathbb{R}^3$ and $\underline{\sigma}=(\sigma_1,-\sigma_2,\sigma_3)$. Thus,

$$\mathfrak{q}=\begin{pmatrix}x_0+ix_3&-x_2+ix_1\\x_2+ix_1&x_0-ix_3\end{pmatrix}. \tag{4.1}$$

It is convenient to introduce the polar coordinates:

$$x_0=r\cos\theta,\quad x_1=r\sin\theta\sin\phi\cos\psi,\quad x_2=r\sin\theta\sin\phi\sin\psi,\quad x_3=r\sin\theta\cos\phi\,,$$

where $r\in[0,\infty)$, $\theta,\phi\in[0,\pi]$ and $\psi\in[0,2\pi)$. In terms of these,

$$\mathfrak{q}=A(r)e^{i\theta\sigma(\hat{n})}, \tag{4.2}$$

where

$$A(r)=r\sigma_0\,,\quad \sigma(\hat{n})=\begin{pmatrix}\cos\phi&\sin\phi e^{i\psi}\\\sin\phi e^{-i\psi}&-\cos\phi\end{pmatrix},\quad \text{and}\quad \sigma(\hat{n})^2=\sigma_0\,. \tag{4.3}$$

We denote the field of quaternions by $\mathbb{H}$.

The matrices $A(r)$ and $\sigma(\hat{n})$ satisfy the conditions (2.2)–(2.5). Thus, with $\{\phi_m\}_{m=0}^{\infty}$ an orthonormal basis of an abstract Hilbert space $\mathfrak{H}$ and χ^1,χ^2 an orthonormal basis of $\mathbb{C}^2$, we can define the VCS,

$$|\mathfrak{q},j\rangle=\mathcal{N}(|\mathfrak{q}|)^{-1/2}\sum_{m=0}^{\infty}\frac{\mathfrak{q}^m}{\sqrt{x_m!}}\chi^j\otimes\phi_m\in\mathbb{C}^2\otimes\mathfrak{H}\,,\quad j=1,2, \tag{4.4}$$

where $\mathcal{N}(|\mathfrak{q}|)$ and $x_m!$ have to be chosen appropriately.

In order to determine the normalization constant $\mathcal{N}(|\mathfrak{q}|)$, and the resolution of the identity, first note that in order for the norm of the vector $|\mathfrak{q},j\rangle$ to be finite, we must have

$$\langle\mathfrak{q},j|\mathfrak{q},j\rangle=\mathcal{N}(|\mathfrak{q}|)^{-1}\sum_{m=0}^{\infty}\frac{r^{2m}}{x_m!}<\infty\,.$$

Thus if $\lim_{m\to\infty}x_m=x$, we need to restrict r to $0\leqslant r<L=\sqrt{x}$ for the convergence of the above series. In this case, we define

$$\mathcal{D}=\{(r,\theta,\phi,\psi)|0\leqslant r<L\,,\quad 0\leqslant\phi\leqslant\pi\,,\quad 0\leqslant\theta,\psi<2\pi\}\,,$$

and note that

$$\mathcal{N}(|\mathfrak{q}|)=\mathcal{N}(r)=2\sum_{m=0}^{\infty}\frac{r^{2m}}{x_m!}.$$

[In the special case when $x_m=m$, $\mathcal{N}(|\mathfrak{q}|)=2\exp[r^2]$, and $\mathcal{D}=\mathbb{R}^+\times(0,2\pi]\times S^2$, where S^2 is the surface of the unit two-sphere and (ϕ,ψ) are the angular coordinates of a point on it. Note that in this case, $\mathcal{D}$ can also be identified with TS^2, the tangent bundle of S^2.] On $\mathcal{D}$ we introduce the measure $d\mu(r,\theta,\phi,\psi)=r\ dr\,d\theta\,d\Omega(\phi,\psi)$ with $d\Omega(\phi,\psi)=(1/4\pi)\ \sin\phi\,d\phi\,d\psi$.

To obtain a resolution of the identity, we now have to find a density function $W(|q|)=W(r)$, such that

$$\int_{\mathcal{D}}|\mathfrak{q},j\rangle W(r)\langle\mathfrak{q},j|\,d\mu=\mathbb{I}_2\otimes I\,. \tag{4.5}$$

Since

$$\int_0^{2\pi}\int_0^{2\pi}\int_0^{\pi}e^{i(m-l)\theta\sigma(\hat{n})}\sin\phi\,d\phi\,d\theta\,d\psi=\begin{cases}2\pi\ \ \mathbb{I}_2 & \text{if}\ \ m=l\\ 0 & \text{if}\ \ m\neq l,\end{cases}$$

the moment condition (2.11) becomes

$$\int_0^{\infty}\frac{2\pi W(r)r^{2m+1}}{\mathcal{N}(r)}\,dr\,\mathbb{I}_2=x_m!\,\mathbb{I}_2\,.$$

Writing $W(r)=[\mathcal{N}(r)/2\pi]\lambda(r)$, this is equivalent to solving the moment problem

$$\int_0^{L}\lambda(r)r^{2m+1}dr=x_m!\,, \tag{4.6}$$

for determining the auxiliary density $\lambda(r)$. With this choice of λ the resolution of the identity (4.5) will be satisfied. As an example, if $x_m!=m!$ we have $L=\infty$ and then $W(r)=2/\pi$. We shall call the corresponding VCS,

$$|\mathfrak{q},j\rangle=\frac{e^{-r^2/2}}{\sqrt{2}}\sum_{m=0}^{\infty}\frac{\mathfrak{q}^m}{\sqrt{m!}}\chi^j\otimes\phi_m\in\mathbb{C}^2\otimes\mathfrak{H}\,, \tag{4.7}$$

quaternionic canonical coherent states. These are the natural generalizations, to quaternions, of the well known *canonical coherent states*.[2]

$$|z\rangle=e^{-r^2/2}\sum_{m=0}^{\infty}\frac{z^m}{\sqrt{m!}}\phi_m\in\mathfrak{H}\,, \tag{4.8}$$

defined over $\mathbb{C}$. Treating the vectors $|\mathfrak{q},1\rangle$ and $|\mathfrak{q},2\rangle$ as elements of a basis, we shall define a general quaternionic VCS as a linear combination,

$$|\mathfrak{q},\chi\rangle=\sum_{j=1}^{2}c_j|\mathfrak{q},j\rangle,\quad\text{where}\quad c_1,c_2\in\mathbb{C},\quad |c_1|^2+|c_2|^2=1\ ,\quad \chi=\sum_{j=1}^{2}c_j\chi^j\,. \tag{4.9}$$

V. MINIMUM UNCERTAINTY AND ANALYTICITY PROPERTIES

It is well known that the canonical coherent states (4.8) are also states of minimum uncertainty, in the sense that for any one of these states $|z\rangle$,

$$\langle\Delta\hat{q}\rangle_z\langle\Delta\hat{p}\rangle_z=\tfrac{1}{2}\quad(\text{assuming}\quad\hbar=1)\,, \tag{5.1}$$

where, for any operator A on $\mathfrak{H}$ and any vector $\phi \in \mathfrak{H}$,

$$\langle \Delta A \rangle_\phi = [\langle \phi | A^2 \phi \rangle - (\langle \phi | A \phi \rangle)^2]^{1/2}.$$

It is possible to construct quaternionic VCS with similar properties. To see this, first note that the matrix $\mathfrak{q}$ can be diagonalized as

$$\mathfrak{q} = u(\theta,\phi) \begin{pmatrix} z & 0 \\ 0 & \overline{z} \end{pmatrix} u(\theta,\phi)^\dagger, \tag{5.2}$$

where

$$u(\theta,\phi) = \begin{pmatrix} ie^{i\phi/2}\cos\frac{\theta}{2} & -e^{i\phi/2}\sin\frac{\theta}{2} \\ e^{-i\phi/2}\sin\frac{\theta}{2} & -ie^{-i\phi/2}\cos\frac{\theta}{2} \end{pmatrix} \quad \text{and} \quad z = re^{i\psi}.$$

Let $\chi^+(\theta,\phi)$ and $\chi^-(\theta,\phi)$ be the two (normalized) eigenvectors of $\mathfrak{q}$, corresponding to the eigenvalues z and $\overline{z}$, respectively. Define the two quaternionic VCS,

$$|\mathfrak{q},+\rangle = e^{-r^2/2} \sum_{m=0}^{\infty} \frac{\mathfrak{q}^m}{\sqrt{m!}} \chi^+(\theta,\phi) \otimes \phi_m = e^{-r^2/2} \sum_{m=0}^{\infty} \frac{z^m}{\sqrt{m!}} \chi^+(\theta,\phi) \otimes \phi_m, \tag{5.3}$$

$$|\mathfrak{q},-\rangle = e^{-r^2/2} \sum_{m=0}^{\infty} \frac{\mathfrak{q}^m}{\sqrt{m!}} \chi^-(\theta,\phi) \otimes \phi_m = e^{-r^2/2} \sum_{m=0}^{\infty} \frac{\overline{z}^m}{\sqrt{m!}} \chi^-(\theta,\phi) \otimes \phi_m. \tag{5.4}$$

The normalization of these states has been chosen to ensure that $\langle \mathfrak{q},\pm|\mathfrak{q},\pm\rangle = 1$. From the nature of the operators Q and P, defined in (3.10), it is then clear that these states also have minimum uncertainty:

$$\langle \Delta Q \rangle_\pm \langle \Delta P \rangle_\pm = \tfrac{1}{2}. \tag{5.5}$$

Next, let us look a little more closely at the nature of the isometry (3.11), for the quaternionic VCS. Recall that in this case, $\mathcal{D} = \mathbb{R}^+ \times (0,2\pi] \times S^2 \simeq TS^2$. Once again, let $\tilde{\mathfrak{H}} = L^2(\mathcal{D}, d\mu)$. We are interested in the isometry

$$\mathcal{W}: \mathbb{C}^2 \otimes \mathfrak{H} \to \mathbb{C}^2 \otimes \tilde{\mathfrak{H}} \quad \text{with} \quad (\mathcal{W}\mathbf{\Psi})^j(\mathfrak{q}) = \langle \mathbf{\Psi} | \mathfrak{q}, j \rangle. \tag{5.6}$$

A general vector $\mathbf{\Psi} \in \mathbb{C}^2 \otimes \mathfrak{H}$ has the form $\mathbf{\Psi} = \Sigma_{j=1}^2 \chi^j \psi_j$, with $\psi_j \in \mathfrak{H}$. We write $\mathbf{F} = \mathcal{W}\mathbf{\Psi}$ and introduce the functions

$$f_j(z) = \sum_{m=0}^{\infty} \frac{z^m}{\sqrt{m!}} \langle \phi_m | \psi_j \rangle_{\mathfrak{H}}, \quad j = 1,2, \quad \mathbf{f}(z) = \sum_{j=1}^{2} \chi^j f_j(z),$$

$$f_j(\overline{z}) = \sum_{m=0}^{\infty} \frac{\overline{z}^m}{\sqrt{m!}} \langle \phi_m | \psi_j \rangle_{\mathfrak{H}}, \quad j = 1,2, \quad \mathbf{f}(\overline{z}) = \sum_{j=1}^{2} \chi^j f_j(\overline{z}).$$

A straightforward computation then shows that the image of the isometry (5.6) consists of vector valued functions of the type

$$\mathbf{F}(z,\overline{z},\theta,\phi) = \frac{1}{\sqrt{2}} e^{-|z|^2/2} [\mathbb{P}^+(\theta,\phi)\mathbf{f}(\overline{z}) + \mathbb{P}^-(\theta,\phi)\mathbf{f}(z)], \tag{5.7}$$

where $\mathbb{P}^{\pm}(\theta,\phi)$ are eigenprojectors corresponding to the eigenvectors $\chi^{\pm}(\theta,\phi)$, respectively. Thus, for fixed (θ,ϕ), each component function $F^j(z,\overline{z},\theta,\phi)$ is a linear combination of two holomorphic functions $f_1(z), f_2(z)$ and their antiholomorphic counterparts.

VI. RELATION TO THE WEYL–HEISENBERG GROUP

The canonical coherent states (4.8) can be expressed (see, for example, Ref. 2) in the form

$$|z\rangle = e^{za^\dagger - \overline{z}a}\phi_0 = e^{i(p\hat{q}-q\hat{p})}\phi_0, \quad \text{where} \quad z=\frac{q-ip}{\sqrt{2}}. \tag{6.1}$$

We now show that the quaternionic canonical coherent states (4.7) also have the analogous representation:

$$|\mathfrak{q},j\rangle = \frac{1}{\sqrt{2}} e^{\mathfrak{q}\otimes a^\dagger - \mathfrak{q}^\dagger\otimes a}\chi^j\otimes\phi_0. \tag{6.2}$$

To see this, note that

$$[\mathfrak{q}^\dagger\otimes a, \mathfrak{q}\otimes a^\dagger] = r^2\mathbb{I}_2\otimes I.$$

Next, since for two operators A and B, the commutator of which commutes with both A and B, the Baker–Campbell–Hausdorff identity,

$$e^{A+B} = e^{-(1/2)[A,B]}e^A e^B,$$

holds, we may write

$$e^{\mathfrak{q}\otimes a^\dagger - \mathfrak{q}^\dagger\otimes a} = e^{-(1/2)[\mathfrak{q}\otimes a^\dagger, -\mathfrak{q}^\dagger\otimes a]} e^{\mathfrak{q}\otimes a^\dagger} e^{-\mathfrak{q}^\dagger\otimes a}.$$

Since $a^m\phi_0 = 0$ for all $m\geqslant 1$, we have

$$e^{-\mathfrak{q}\otimes a}\chi^j\otimes\phi_0 = \chi^j\otimes\phi_0$$

and

$$e^{\mathfrak{q}\otimes a^\dagger}(\chi^j\otimes\phi_0) = \sum_{m=0}^{\infty}\frac{(\mathfrak{q}\otimes a^\dagger)^m}{m!}\chi^j\otimes\phi_0 = \sum_{m=0}^{\infty}\frac{\mathfrak{q}^m\chi^j\otimes a^{\dagger m}\phi_0}{m!} = \sum_{m=0}^{\infty}\frac{\mathfrak{q}^m}{\sqrt{m!}}\chi^j\otimes\phi_m.$$

Thus,

$$\frac{1}{\sqrt{2}}e^{\mathfrak{q}\otimes a^\dagger - \mathfrak{q}^\dagger\otimes a}\chi^j\otimes\phi_0 = \frac{1}{\sqrt{2}}e^{-r^2/2}\sum_{m=0}^{\infty}\frac{\mathfrak{q}^m}{\sqrt{m!}}\chi^j\otimes\phi_m = |\mathfrak{q},j\rangle.$$

To develop a group theoretical interpretation for the quaternionic canonical coherent states, we go back to the canonical coherent states as written out in (6.1). The operators $\hat{q},\hat{p}$ and I generate an irreducible representation of $\mathfrak{g}_{\mathrm{W-H}}$, the Lie algebra of the Weyl–Heisenberg group $G_{\mathrm{W-H}}$, on the Hilbert space $\mathfrak{H}$. A unitary irreducible representation of $G_{\mathrm{W-H}}$ on $\mathfrak{H}$ is given by the operators $U(\vartheta,q,p) = e^{i(\vartheta I + p\hat{q} - q\hat{p})}$. Thus, $|z\rangle = U(0,q,p)\phi_0$. Turning now to the quaternionic canonical coherent states, as expressed in (6.2), we find, using (5.2),

$$\mathfrak{q}\otimes a^\dagger - \mathfrak{q}^\dagger\otimes a = u(\theta,\phi)\begin{pmatrix} za^\dagger - \overline{z}a & 0 \\ 0 & \overline{z}a^\dagger - za \end{pmatrix} u(\theta,\phi)^\dagger.$$

Thus,

$$e^{\mathfrak{q}\otimes a^\dagger-\mathfrak{q}^\dagger\otimes a}=u(\theta,\phi)\begin{pmatrix}U(0,q,p) & 0\\ 0 & U(0,q,-p)\end{pmatrix}u(\theta,\phi)^\dagger. \tag{6.3}$$

Writing

$$\tilde{U}(\vartheta,\mathfrak{q})=\tilde{U}(\vartheta,q,p,\theta,\phi):=u(\theta,\phi)\begin{pmatrix}U(\vartheta,q,p) & 0\\ 0 & U(\vartheta,q,-p)\end{pmatrix}u(\theta,\phi)^\dagger, \tag{6.4}$$

we observe that for fixed (θ,ϕ) these operators realize a unitary (reducible) representation of $G_{\mathrm{W-H}}$ on $\mathbb{C}^2\otimes\mathfrak{H}$. In terms of these operators,

$$|\mathfrak{q},j\rangle=\frac{1}{\sqrt{2}}\tilde{U}(0,\mathfrak{q})\chi^j\otimes\phi_0=\frac{1}{\sqrt{2}}\tilde{U}(0,q,p,\theta,\phi)\chi^j\otimes\phi_0, \tag{6.5}$$

in complete analogy with the case of the canonical coherent states.

VII. QUATERNIONIC VCS FROM SU(1,1) REPRESENTATIONS

As a second example of the construction of VCS using quaternions, we shall obtain analogs of the Gilmore–Perelomov[12,16] and Barut–Girardello[6] coherent states in this section. Both these families of states arise from the discrete series representations of SU(1,1). Writing $\mathcal{D}_1=\{z\in\mathbb{C}||z|<1\}$, the Gilmore–Perelomov coherent states, labeled by points of $\mathcal{D}_1$, are defined to be

$$|z;\mathrm{G-P}\rangle=(1-r^2)^\kappa\ \sum_{m=0}^{\infty}\left[\frac{(2\kappa)_m}{m!}\right]^{1/2}z^m\phi_m\in\mathfrak{H},\quad r=|z|,\quad \kappa=1,\frac{3}{2},2,\frac{5}{2},\ldots, \tag{7.1}$$

where we have used the Pochhammer symbol,

$$(a)_m=\frac{\Gamma(a+m)}{\Gamma(a)}=a(a+1)(a+2)\cdots(a+m-1),$$

and, as before, the ϕ_m constitute an orthonormal basis of the Hilbert space $\mathfrak{H}$. The index κ labels the unitary irreducible representation of SU(1,1), to which the above coherent states are associated. This representation is carried by the Hilbert space $\mathfrak{H}_{\mathrm{hol}}(\mathcal{D}_1)$, which is the subspace of all holomorphic functions in $L^2(\mathcal{D}_1,(2\kappa-1)d\mu_\kappa)$, where

$$d\mu_\kappa(z,\bar{z})=\frac{(1-r^2)^{2\kappa-2}}{\pi}rdrd\theta,\quad z=re^{i\theta}.$$

An element $g\in\mathrm{SU}(1,1)$ is a complex 2×2 matrix,

$$g=\begin{pmatrix}\alpha & \beta\\ \bar{\beta} & \bar{\alpha}\end{pmatrix},\quad \det g=|\alpha|^2-|\beta|^2=1,$$

and the unitary irreducible representation U^κ, labeled by κ, acts on vectors $f\in\mathfrak{H}_{\mathrm{hol}}(\mathcal{D}_1)$ in the manner

$$(U^\kappa(g)f)(z)=(\alpha-\bar{\beta}z)^{-2\kappa}\ f\left(\frac{\bar{\alpha}z-\beta}{\alpha-\bar{\beta}z}\right).$$

The monomials

$$u_m(z)=\left[\frac{(2\kappa)_m}{m!}\right]^{1/2} z^m$$

form an orthonormal basis in $\mathfrak{H}_{\rm hol}(\mathcal{D}_1)$. Moreover, identifying the abstract Hilbert space $\mathfrak{H}$ with $\mathfrak{H}_{\rm hol}(\mathcal{D}_1)$ and ϕ_m with u_m, it can be shown[2] that the coherent states (7.1) can also be written in the form

$$|z;\mathrm{G-P}\rangle = U^\kappa(\mathcal{Z})\phi_0\,, \quad \text{where} \quad \mathcal{Z}=\frac{1}{\sqrt{1-r^2}}\begin{pmatrix}1 & z\\ \bar z & 1\end{pmatrix}\in \mathrm{SU}(1,1)\,. \tag{7.2}$$

Observe that, in the notation introduced in (1.1), in this case we have

$$\mathcal{N}(|z|)=(1-r^2)^{-2\kappa}, \quad \rho(m)=\left[\frac{(2\kappa)_m}{m!}\right]^{-1}.$$

Thus, $x_m=m/(2\kappa+m-1)$ and since $\lim_{m\to\infty} x_m=1$, this determines the radius of convergence of the infinite series in (7.1) and hence the appearance of the unit disc.

The coherent states (7.1) satisfy the resolution of the identity,

$$\frac{2\kappa-1}{\pi}\int_{\mathcal{D}_1}|z;\mathrm{G-P}\rangle\langle z;\mathrm{G-P}|\,\frac{r\,dr\,d\theta}{(1-r^2)^2}=I\,. \tag{7.3}$$

The representation of the Lie algebra of SU(1,1) on $\mathfrak{H}_{\rm hol}(\mathcal{D}_1)$ is generated by the three operators K_+, K_- and K_3, which satisfy the commutation relations

$$[K_3,K_\pm]=\pm K_\pm\,, \quad [K_-,K_+]=2K_3\,. \tag{7.4}$$

They act on the vectors ϕ_m in the manner

$$K_-\phi_m=\sqrt{m(2\kappa+m-1)}\,\phi_{m-1}\,, \quad K_+=K_-^\dagger\,, \quad K_3\phi_m=(\kappa+m)\phi_m\,. \tag{7.5}$$

Thus $K_-\phi_0=0$ and

$$\phi_m=\frac{1}{\sqrt{m!\,(2\kappa)_m}}K_+^m\phi_0\,.$$

Furthermore, it can be shown[11] that

$$|z;\mathrm{G-P}\rangle=e^{wK_+-\bar wK_-}\phi_0\,, \quad w\in\mathbb{C}, \tag{7.6}$$

where z and w are related by

$$z=\frac{w\tanh(|w|)}{|w|}. \tag{7.7}$$

Equation (7.6) should be compared to (6.1). Note, however, that unlike in that case, the operators K_+ and K_- appearing in (7.6) are not the creation and annihilation operators naturally associated with the expansion in (7.1) [see (3.1)]. Indeed, in the present case the operator a (which we denote $a_{\mathrm{G-P}}$) has the form

$$a_{\mathrm{G-P}}|z;\mathrm{G-P}\rangle=z|z;\mathrm{G-P}\rangle\,, \quad a_{\mathrm{G-P}}\phi_m=\sqrt{\frac{m}{2\kappa+m-1}}\,\phi_{m-1}\,. \tag{7.8}$$

On the other hand, it is possible to define[6] a second set of coherent states $|w;\mathrm{B}-\mathrm{G}\rangle$ for this same representation of SU(1,1), using K_- as the generalized annihilation operator:

$$K_-|w;\mathrm{B}-\mathrm{G}\rangle := a_{\mathrm{B}-\mathrm{G}}|w;\mathrm{B}-\mathrm{G}\rangle = w|w;\mathrm{B}-\mathrm{G}\rangle, \quad w\in\mathbb{C}. \tag{7.9}$$

These states, known as the Barut–Girardello coherent states, are defined for all $w\in\mathbb{C}$ and they are of the form

$$|w;\mathrm{B}-\mathrm{G}\rangle = \frac{|w|^{2\kappa-1}}{\sqrt{I_{2\kappa-1}(2|w|)}}\sum_{m=0}^{\infty}\frac{w^m}{\sqrt{m!(2\kappa+m-1)!}}\phi_m, \tag{7.10}$$

where $I_\nu(x)$ is the order-ν modified Bessel function of the first kind. These coherent states satisfy the resolution of the identity

$$\frac{2}{\pi}\int_{\mathbb{C}}|w;\mathrm{B}-\mathrm{G}\rangle\langle w;\mathrm{B}-\mathrm{G}|K_{2\kappa-1}(2\varrho)I_{2\kappa-1}(2\varrho)\varrho\,d\varrho\,d\vartheta = I, \quad w=\varrho e^{i\vartheta}, \tag{7.11}$$

where, again, $K_\nu(x)$ is the order-ν modified Bessel function of the second kind.

It is now straightforward to write down quaternionic VCS which extend (7.1):

$$|\mathfrak{q},j;\mathrm{G}-\mathrm{P}\rangle = \frac{(1-r^2)^\kappa}{\sqrt{2}}\sum_{m=0}^{\infty}\left[\frac{(2\kappa)_m}{m!}\right]^{1/2}\mathfrak{q}^m\chi^j\otimes\phi_m, \quad r=|\mathfrak{q}|=[\mathfrak{q}\mathfrak{q}^\dagger]^{1/2}, \tag{7.12}$$

where $\mathfrak{q}$ is a quaternionic variable with domain $\mathcal{D}_1\times S^2$, and a similar set of VCS extending (7.10):

$$|\mathfrak{w},j;\mathrm{B}-\mathrm{G}\rangle = \frac{r^{2\kappa-1}}{\sqrt{2I_{2\kappa-1}(2r)}}\sum_{m=0}^{\infty}\frac{\mathfrak{w}^m}{\sqrt{m!(2\kappa+m-1)!}}\chi^j\otimes\phi_m, \quad r=|\mathfrak{w}|, \tag{7.13}$$

the quaternionic variable $\mathfrak{w}$ being defined over the domain TS^2.

In the case of the vectors (7.12), it is also possible, using (7.2), to give a representation theoretic interpretation along the lines of (6.2)–(6.5). Indeed, by virtue of (7.1), (7.2) and the decomposition (5.2) of the quaternion $\mathfrak{q}$, we can immediately rewrite (7.12) as

$$|\mathfrak{q},j;\mathrm{G}-\mathrm{P}\rangle = \frac{1}{\sqrt{2}}u(\theta,\phi)\begin{pmatrix}U^\kappa(\mathcal{Z}) & 0\\ 0 & U^\kappa(\mathcal{Z}^\dagger)\end{pmatrix}u(\theta,\phi)^\dagger\chi^j\otimes\phi_0.$$

Writing

$$\tilde{U}^\kappa(\mathfrak{q}) = u(\theta,\phi)\begin{pmatrix}U^\kappa(\mathcal{Z}) & 0\\ 0 & U^\kappa(\mathcal{Z}^\dagger)\end{pmatrix}u(\theta,\phi)^\dagger,$$

this yields

$$|\mathfrak{q},j;\mathrm{G}-\mathrm{P}\rangle = \frac{1}{\sqrt{2}}\tilde{U}^\kappa(\mathfrak{q})\chi^j\otimes\phi_0, \tag{7.14}$$

which is the analog of (6.5). Moreover, since by (7.6)

$$\tilde{U}^\kappa(\mathfrak{q})\chi^j\otimes\phi_0 = u(\theta,\phi)\begin{pmatrix}e^{wK_+-\bar{w}K_-} & 0\\ 0 & e^{\bar{w}K_+-wK_-}\end{pmatrix}u(\theta,\phi)^\dagger\chi^j\otimes\phi_0$$

with z and w being related by (7.7), we can now transform this to

$$|\mathfrak{q},j;\mathrm{G-P}\rangle=\frac{1}{\sqrt{2}}e^{\mathfrak{w}\otimes K_+-w^\dagger\otimes K_-}\chi^j\otimes\phi_0\,, \tag{7.15}$$

where now the quaternionic variables $\mathfrak{q}$ and $\mathfrak{w}$ are related by

$$\mathfrak{q}=\frac{\mathfrak{w}\tanh(|\mathfrak{w}|)}{|\mathfrak{w}|}. \tag{7.16}$$

Note that while $0\leqslant|\mathfrak{q}|<1$, for the transformed variable $\mathfrak{w}$ we have $0\leqslant|\mathfrak{w}|<\infty$.

Interestingly, there is yet another family of coherent states, again related to the SU(1,1) group, which can be constructed using the two number operators,

$$N_{\mathrm{G-P}}=a^\dagger_{\mathrm{G-P}}a_{\mathrm{G-P}}\quad\text{and}\quad N_{\mathrm{B-G}}=a^\dagger_{\mathrm{B-G}}a_{\mathrm{B-G}}.$$

Indeed, from (7.8) and (7.9),

$$N_{\mathrm{G-P}}\phi_m=\frac{m}{2\kappa+m-1}\phi_m\quad\text{and}\quad N_{\mathrm{B-G}}\phi_m=m(2\kappa+m-1)\phi_m\,. \tag{7.17}$$

Thus we define a third number operator N_{INT}, essentially as one which interpolates between these two:

$$N_{\mathrm{G-P}}N_{\mathrm{INT}}=N_{\mathrm{B-G}}\Rightarrow N_{\mathrm{INT}}\phi_m=(2\kappa+m-1)^2\phi_m\,, \tag{7.18}$$

and the related annihilation operator,

$$a_{\mathrm{INT}}\phi_m=(2\kappa+m-1)\phi_{m-1}\,. \tag{7.19}$$

The corresponding coherent states, defined for all $w\in\mathbb{C}$, are

$$|w;\mathrm{INT}\rangle=\mathcal{N}(r)^{-1/2}\sum_{m=0}^{\infty}\frac{w^m}{(2\kappa+m-1)!}\phi_m\,,\quad r=|w|\,, \tag{7.20}$$

where the normalization constant is given by

$$\mathcal{N}(r)=\frac{{}_1F_2(1;2\kappa,2\kappa;r^2)}{[\Gamma(2\kappa)]^2},$$

in terms of the hypergeometric function

$${}_1F_2(a;b,c;x)=\sum_{m=0}^{\infty}\frac{(a)_m}{(b)_m(c)_m}\cdot\frac{x^m}{m!}.$$

The moment problem for determining the resolution of the identity is now

$$\pi\int_0^\infty r^m\lambda(r)dr=[(2\kappa+m-1)!]^2\,.$$

This can be explicitly solved to yield

$$\lambda(r)=\frac{2}{\pi}r^{2\kappa-1}K_0(2\sqrt{r})\,,$$

where, once again, K_0 is the order-0 modified Bessel function of the second kind. Finally, one obtains

$$\int_{\mathbb{C}} |w;\mathrm{INT}\rangle\langle w;\mathrm{INT}|\, d\mu_{\mathrm{INT}}(w,\overline{w}) = I\,, \tag{7.21}$$

with

$$d\mu_{\mathrm{INT}}(w,\overline{w}) = \frac{2r^{4\kappa-1}}{\pi[\Gamma(2\kappa)]^2} K_0(2r)\ \ {}_1F_2(1;2\kappa,2\kappa;r^2)\, d\theta dr\,. \tag{7.22}$$

The corresponding quaternionic VCS are then

$$|\mathfrak{w},j;\mathrm{INT}\rangle = \frac{1}{\sqrt{2}}\ \frac{\Gamma(2\kappa)}{[{}_1F_2(1;2\kappa,2\kappa;r^2)]^{1/2}} \sum_{m=0}^{\infty} \frac{\mathfrak{w}^m}{(2\kappa+m-1)!}\, \chi^j \otimes \phi_m\,, \tag{7.23}$$

where $r=|\mathfrak{w}|$ and $\mathfrak{w}\in TS^2$.

The fact that the coherent states (7.20) are indeed related to the SU(1,1) group is brought out more clearly by the following observation: computing the commutator $[a_{\mathrm{INT}}, a_{\mathrm{INT}}^\dagger]$ we find

$$[a_{\mathrm{INT}}, a_{\mathrm{INT}}^\dagger]\phi_m = [2(2\kappa+m)-1]\phi_m\,.$$

Let us define a new ''number operator'' $\tilde{N}_{\mathrm{INT}}$ by the action

$$\tilde{N}_{\mathrm{INT}}\phi_m = (2\kappa+m-\tfrac{1}{2})\phi_m \tag{7.24}$$

on the basis vectors ϕ_m. Then we easily establish the commutation relations,

$$[a_{\mathrm{INT}}, a_{\mathrm{INT}}^\dagger] = 2\tilde{N}_{\mathrm{INT}}, \quad [\tilde{N}_{\mathrm{INT}}, a_{\mathrm{INT}}^\dagger] = a_{\mathrm{INT}}^\dagger, \quad [\tilde{N}_{\mathrm{INT}}, a_{\mathrm{INT}}] = -a_{\mathrm{INT}}\,. \tag{7.25}$$

Comparing with (7.4), we find that the three operators $a_{\mathrm{INT}}, a_{\mathrm{INT}}^\dagger$ and $\tilde{N}_{\mathrm{INT}}$ satisfy exactly the same commutation relations as the three generators, K_-, K_+ and K_3 of $\mathfrak{su}(1,1)$, the Lie algebra of SU(1,1). Thus, they also realize a representation of this algebra on $\mathfrak{H}$. The two number operators $\tilde{N}_{\mathrm{INT}}$ and N_{INT} are related as

$$N_{\mathrm{INT}} = \tilde{N}_{\mathrm{INT}}^2 - \tilde{N}_{\mathrm{INT}} + \tfrac{1}{4} = [\tilde{N}_{\mathrm{INT}} - \tfrac{1}{2}]^2\,. \tag{7.26}$$

A similar situation was seen to arise[3] in the case of temporally stable coherent states related to the infinite well and Pöschl–Teller potentials, where the Lie algebra $\mathfrak{su}(1,1)$ appeared as a dynamical algebra. It ought to be pointed out, however, that the representation of $\mathfrak{su}(1,1)$, generated by the operators $K_\pm, K_3$ in (7.4) and (7.5), is different from the one generated by the operators $a_{\mathrm{INT}}^\dagger$, a_{INT} and $\tilde{N}_{\mathrm{INT}}$. Indeed, computing the Casimir operators in the two cases, we find that $1/2(K_-K_+ + K_+K_-) - K_3^2 = \kappa(1-\kappa)$ while $\frac{1}{2}(a_{\mathrm{INT}}a_{\mathrm{INT}}^\dagger + a_{\mathrm{INT}}^\dagger a_{\mathrm{INT}}) - \tilde{N}_{\mathrm{INT}}^2 = \frac{1}{4}$.

VIII. CONCLUSION AND PHYSICAL APPLICATIONS

As amply evident from the above discussion, the method just elaborated for constructing vector coherent states is generic. One could in this manner associate families of VCS to almost any hypergeometric function. More interestingly, the method enables one to associate VCS to certain Clifford algebras and to reducible representations from the principal series of locally compact groups. Some of these results will be presented in a forthcoming publication.[1]

As far as physical applications are concerned, there is a range of possibilities. The quaternionic canonical VCS in (4.7) can be looked upon as amalgams of standard spin-coherent states (as described, for example, in Ref. 16) and the (scalar) canonical coherent states. Thus, $|\mathfrak{q},j\rangle$ can

be considered as a coherent state wave function for a nonrelativistic spinning particle. Suppose that such a particle is placed in a constant external magnetic field $\vec{B}=(B_1,B_2,B_3)$. Its time evolution is then governed by an interaction Hamiltonian of the type $V_I=k\vec{\sigma}\cdot\vec{B}=\omega\Theta(\hat{B})$, where k is a constant, $\vec{\sigma}=(\sigma_1,\sigma_2,\sigma_3)$, $\omega=(\sqrt{3}/2)k\|\vec{B}\|$, $\hat{B}=\vec{B}/\|\vec{B}\|$ and $\Theta(\hat{B})=(2/\sqrt{3})\,\sigma(\hat{B})$. The time evolution generated by this Hamiltonian on a state $\mathbf{\Psi}\in\mathbb{C}^2\otimes\mathfrak{H}$ is given by $\mathbf{\Psi}(t)=e^{i\omega\Theta(\hat{B})t}\mathbf{\Psi}$. Thus, the quaternionic canonical VCS

$$|\mathfrak{q}(t),j\rangle=\frac{e^{-r^2/2}}{\sqrt{2}}\sum_{m=0}^{\infty}\frac{\mathfrak{q}(t)^m}{\sqrt{m!}}\chi^j\otimes\phi_m,\quad \mathfrak{q}(t)=\|\vec{B}\|\;\; e^{i\omega\Theta(\hat{B})t}, \tag{8.1}$$

have immediate interpretation as *coherent* superpositions of time evolved basis states. The discussion in Sec. V now shows that such states have minimum uncertainty whenever the spin is either parallel or anti-parallel to the magnetic field. A second example of the use of quaternionic VCS arises in the study of two-level atoms interacting with a single mode of an electromagnetic field. This leads to coherent states resulting from a Jaynes–Cummings[7] type of Hamiltonian. A fuller description of this construction has been given in Ref. 1. One might state, with justification, that quaternionic VCS could be an extremely useful tool in the study of two-level atomic systems, placed in electromagnetic fields. As a third physical example, the creation and annihilation operators for the VCS (7.23) would generate a dynamical algebra for a spin-$\frac{1}{2}$ particle placed in a Pöschl–Teller potential, in analogy with the discussion in Ref. 3.

Phase space methods for particles on a circle

S. Zhang and A. Vourdas
Department of Computing, University of Bradford, Bradford BD7 1DP, United Kingdom

(Received 15 March 2003; accepted 29 July 2003)

The phase space $S\times Z$ for a particle on a circle is considered. Displacement operators in this phase space are introduced and their properties are studied. Wigner and Weyl functions in this context are also considered and their physical interpretation and properties are discussed. All results are compared and contrasted with the corresponding ones for the harmonic oscillator in the $R\times R$ phase space. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1616997]

I. INTRODUCTION

Since the work of Wigner[1] and Moyal,[2] phase space methods have been used extensively in quantum mechanics. A lot of this work is for the harmonic oscillator where both the position and momentum take values in the real line R and the phase space is the plane $R\times R$. There has also been work on finite quantum systems,[3,4] where both the position and momentum take values in Z_N (the integers module N) and the phase space is the lattice $Z_N\times Z_N$. The purpose of this paper is to study phase space methods for quantum particles on a circle. In this case the position takes values on a circle S and the momentum take discrete values in Z (the integers times a factor). In this case the phase space is $S\times Z$. We note that in any area where there is Fourier transform involved (e.g., in signal processing), the phase space can be $R\times R$ or $Z_N\times Z_N$ or $S\times Z$ in the sense that where one of the variables takes values in R or Z_N or S, the dual variable take values in R or Z_N or Z, correspondingly.

Quantum mechanics on a circle is the simplest example of quantum mechanics in a nontrivial topology and has been studied extensively in the literature.[5,6] Physical applications include Aharonov–Bohm phenomena,[7] mesoscopic Aharonov–Bohm rings, Floquet–Bloch wave functions in solid state systems, etc.

In Sec. II we introduce the basic formulism for position and momentum states and operators, taking into account the nontrivial topology of our system (described by the winding number). In Sec. III we introduce displacement operators and study their properties. In Sec. IV we define Wigner and Weyl functions. We show that the properties of the displacement operators lead to analogous properties for the Wigner and Weyl functions. In Sec. V we discuss an example based on a theta wave function (which is the analogue in a circle, of a Gaussian wave function in a real line). Numerical examples for the corresponding Wigner and Weyl functions are discussed. We conclude in Sec. VI with a discussion of our results.

II. POSITION AND MOMENTUM STATES

An electric charge is moving on a circle parametrized by the variable x. The winding number w_x of x is defined as the integer part of the $x/(2\pi r)$ [for negative x it is the integer part of the $x/(2\pi r)$ minus 1]. Let r be the radius of the circle. A magnetostatic flux ϕ is threading the circle in the perpendicular direction. The wave function $R(x)$ obeys the quasiperiodic boundary condition (in units $K_B=\hbar=c=1$),

$$R(x+2\pi r)=R(x)\exp(ie\phi). \tag{1}$$

Similar functions also appear in solid state physics (Bloch functions). They are normalizable within each period,

$$\frac{1}{2\pi r}\int_0^{2\pi r}|R(x)|^2\,\mathrm{d}x=1. \tag{2}$$

Since $R(x)$ is a quasiperiodic function, it can be written as the following Fourier expansion:

$$R(x)=\sum_{N=-\infty}^{\infty}R_N\exp(ip_Nx),\quad p_N=\frac{N+\sigma}{r},\quad \sigma=\frac{e\phi}{2\pi}. \tag{3}$$

The inverse Fourier transform gives

$$R_N=\frac{1}{2\pi r}\int_0^{2\pi r}\exp(-ip_Nx)R(x)\mathrm{d}x. \tag{4}$$

$R(x)$ and R_N can be, respectively, considered as the position and momentum representations of the state $|R\rangle$. So Eq. (3) and Eq. (4) can be written as

$$\langle x|R\rangle=\sum_{N=-\infty}^{\infty}\langle p_N|R\rangle\exp(ip_Nx), \tag{5}$$

$$\langle p_N|R\rangle=\frac{1}{2\pi r}\int_0^{2\pi r}\langle x|R\rangle\exp(-ip_Nx)\mathrm{d}x. \tag{6}$$

Let $|x\rangle$, $|p_N\rangle$ be position and momentum eigenstates, correspondingly. Then

$$|x\rangle=\sum_{N=-\infty}^{\infty}\exp(-ip_Nx)|p_N\rangle,\quad |p_N\rangle=\frac{1}{2\pi r}\int_0^{2\pi r}\mathrm{d}x\exp(ip_Nx)|x\rangle, \tag{7}$$

$$\langle x|y\rangle=(2\pi r)\delta[x-y+2\pi r(w_y-w_x)]\exp[-i2\pi\sigma(w_y-w_x)],\quad \langle p_M|p_N\rangle=\delta_{MN}. \tag{8}$$

It is easily seen that

$$|x+2\pi rw\rangle=\exp(-i2\pi\sigma w)|x\rangle. \tag{9}$$

The completeness can can be expressed as

$$\frac{1}{2\pi r}\int_0^{2\pi r}|x\rangle\langle x|\mathrm{d}x=\sum_{N=-\infty}^{\infty}|p_N\rangle\langle p_N|=\mathbf{1}. \tag{10}$$

Position and momentum operators are defined as

$$\hat{x}=\frac{1}{2\pi r}\int_0^{2\pi r}x|x\rangle\langle x|\mathrm{d}x,\quad \hat{p}=\sum_{N=-\infty}^{\infty}p_N|p_N\rangle\langle p_N|. \tag{11}$$

We note that a different definition of $\hat{x}$ that involves integration from τ to $\tau+2\pi r$ leads to

$$\hat{x}_\tau=\hat{x}+\Pi_\tau,\quad \Pi_\tau=\int_0^{\tau}|x\rangle\langle x|\mathrm{d}x. \tag{12}$$

The $\hat{x}_\tau$ is different from $\hat{x}$ by the projection operator Π_τ. In the special case that $\tau=2\pi rw$ where w is an integer, $\Pi_{2\pi rw}=2\pi rw\mathbf{1}$. It is easily seen that

$$\hat{x}|x\rangle=(x-2\pi rw_x)|x\rangle,\quad \hat{p}|p_N\rangle=p_N|p_N\rangle. \tag{13}$$

III. DISPLACEMENTS AND PARITY

We define displacement operators as

$$D(\alpha,K)\equiv\exp\left(-\frac{i\alpha K}{2r}\right)\exp\left(i\frac{K}{r}\hat{x}\right)\exp(-i\alpha\hat{p}), \tag{14}$$

$$D(\alpha,K)|x\rangle=\exp\left[\frac{iK}{r}\left(x+\frac{\alpha}{2}\right)\right]|x+\alpha\rangle, \tag{15}$$

$$D(\alpha,K)|p_N\rangle=\exp\left(-\frac{i\alpha K}{2r}\right)\exp(-i\alpha p_N)|p_{N+K}\rangle. \tag{16}$$

It is easily seen that

$$D(\alpha,K)D(\beta,M)=D(\alpha+\beta,K+M)\exp\left[i\left(\frac{K\beta}{2r}-\frac{M\alpha}{2r}\right)\right], \tag{17}$$

$$D(\alpha+2\pi rw,K)=(-1)^{Kw}\exp(-i2\pi\sigma w)D(\alpha,K), \tag{18}$$

$$D^{\dagger}(\alpha,K)=D(-\alpha,-K), \tag{19}$$

where w is an integer (the winding number). For later purposes we note that the $D(\alpha,K)\exp(i\alpha\sigma/r)$ is periodic in α. The period is $2\pi r$ if K is even and $4\pi r$ if K is odd number,

$$D(\alpha+2\pi r,K)\exp\left[\frac{i(\alpha+2\pi r)\sigma}{r}\right]=(-1)^{K}\exp\left(\frac{i\alpha\sigma}{r}\right)D(\alpha,K). \tag{20}$$

We also define the parity operator as

$$U_0=\frac{1}{2\pi r}\int_0^{2\pi r}|\alpha\rangle\langle-\alpha|\exp\left(\frac{i2\alpha\sigma}{r}\right)\mathrm{d}\alpha=\sum_{N=-\infty}^{\infty}|p_{-N}\rangle\langle p_N|. \tag{21}$$

The flux factor $\exp(i\alpha\sigma/r)$ has been included in the definition so that the integrand $|\alpha\rangle\langle-\alpha|\exp(i2\alpha\sigma/r)$ is periodic. The parity operator obeys the relations

$$U_0=U_0^{\dagger},\quad U_0^2=I. \tag{22}$$

The flux breaks the parity symmetry. The parity operator acting on the state $|p_{-N}\rangle$ [which has momentum $(-N+\sigma)/r$] gives the state $|p_N\rangle$ [which has momentum $(N+\sigma)/r$]; i.e., it is a parity with momentum origin σ/r. The parity operator acting on the state $|x\rangle$ gives the state $|-x\rangle\exp(-2ix\sigma/r)$. The flux factor $\exp(-2ix\sigma/r)$ corrects the quasiperiodicity caused by the flux into periodicity.

We note here that in the harmonic oscillator case the displacement operators $D(z)=\exp(za^{\dagger}-z^{*}a)$ obey the important relations[8]

$$\int_{-\infty}^{\infty}\mathrm{d}z_R\,D(z)=\sqrt{2}\pi\left|p=\frac{z_I}{\sqrt{2}}\right\rangle\left\langle p=-\frac{z_I}{\sqrt{2}}\right|, \tag{23}$$

$$\int_{-\infty}^{\infty}\mathrm{d}z_I\,D(z)=\sqrt{2}\pi\left|x=\frac{z_R}{\sqrt{2}}\right\rangle\left\langle x=-\frac{z_R}{\sqrt{2}}\right|, \tag{24}$$

$$\int \frac{d^2z}{2\pi} D(z) = U_0, \tag{25}$$

where $z = z_R + iz_I$ and U_0 is here the harmonic oscillator parity operator (defined in Ref. 8). These relations are intimately related with the marginal properties of the Wigner and Weyl functions.

Motivated by this we study here similar relations in our context of quantum mechanics on a circle. We first define the function

$$\Delta(x) = \frac{1}{2\pi}\int_0^{2\pi} \exp(i\beta x)\,d\beta = \exp(-i\pi x)\,\frac{\sin(\pi x)}{\pi x} \equiv \exp(-i\pi x)\,\mathrm{sinc}(x). \tag{26}$$

This is the sinc function (used extensively in areas like digital signal processing) with a phase factor. For integers M,N,

$$\Delta(M-N) = \delta(M,N), \tag{27}$$

where δ is Kronecker's delta. Using Eqs. (15) and (16) can prove that

$$\sum_{K=-\infty}^{\infty} D(\alpha,K) = \left|\frac{\alpha}{2}\right\rangle\left\langle -\frac{\alpha}{2}\right|, \tag{28}$$

$$\frac{1}{2\pi r}\int_0^{2\pi r} D(\alpha,K)\exp\left(\frac{i\alpha\sigma}{r}\right)d\alpha = \begin{cases} |p_{-M}\rangle\langle p_M|, & K=2M, \\ \displaystyle\sum_{N=-\infty}^{\infty} |p_{N+K}\rangle\langle p_N|\,\Delta\left(-\frac{K}{2}-N\right), & K=2M+1. \end{cases} \tag{29}$$

We have explained earlier why the integrations involve the flux factor $\exp(i\alpha\sigma/r)$. It is natural to ask what is the result in Eq. (29) if we do not include the flux factor. We can prove

$$\frac{1}{2\pi r}\int_0^{2\pi r} D(\alpha,K)\,d\alpha = \sum_{N=-\infty}^{\infty} |p_{N+K}\rangle\langle p_N|\,\Delta\left(-\frac{K}{2}-N-\sigma\right). \tag{30}$$

In Eq. (29), integration from $2\pi r$ to $4\pi r$, gives the same result for even K and the same result but with opposite sign for odd K,

$$\frac{1}{2\pi r}\int_{2\pi r}^{4\pi r} D(\alpha,K)\exp\left(\frac{i\alpha\sigma}{r}\right)d\alpha = \begin{cases} |p_{-M}\rangle\langle p_M|, & K=2M, \\ \displaystyle -\sum_{N=-\infty}^{\infty} |p_{N+K}\rangle\langle p_N|\,\Delta\left(-\frac{K}{2}-N\right), & K=2M+1. \end{cases} \tag{31}$$

This is related to the fact [Eq. (20)] that for odd K the $D(\alpha,K)\exp(i\alpha\sigma/r)$ is antiperiodic with period $2\pi r$ (it is periodic with period $4\pi r$). Therefore if we integrate from 0 to $4\pi r$ we get the same result for even K and zero for odd K.

Combining Eqs. (21) and (29) we easily show that

$$\sum_{K=\text{even}} \frac{1}{2\pi r}\int_0^{2\pi r} D(\alpha,K)\exp\left(\frac{i\alpha\sigma}{r}\right)d\alpha = U_0. \tag{32}$$

It is natural to ask what is the result in Eq. (32) if we sum over both even and odd integers. We can prove

$$\sum_{K=-\infty}^{\infty} \frac{1}{2\pi r}\int_0^{2\pi r} D(\alpha,K)\exp\left(\frac{i\alpha\sigma}{r}\right)d\alpha = U_0 + \sum_{M=-\infty}^{\infty}\sum_{N=-\infty}^{\infty} |p_{N+2M-1}\rangle\langle p_N|\,\Delta\left(-M-N+\frac{1}{2}\right). \tag{33}$$

The displaced parity operator is

$$U(\alpha,K)=D(\alpha,K)U_0D^{\dagger}(\alpha,K)=\exp\left(\frac{i\alpha\sigma}{r}\right)D(2\alpha,2K)U_0=\exp\left(-\frac{i\alpha\sigma}{r}\right)U_0D(-2\alpha,-2K). \tag{34}$$

$U(\alpha,K)$ is a periodic function of α with the period πr,

$$U(\alpha+\pi r,K)=U(\alpha,K). \tag{35}$$

We next show that

$$\sum_{K=-\infty}^{\infty}U(\alpha,K)=\tfrac{1}{2}(|\alpha\rangle\langle\alpha|+|\alpha+\pi r\rangle\langle\alpha+\pi r|), \tag{36}$$

$$\frac{1}{2\pi r}\int_0^{2\pi r}U(\alpha,K)\mathrm{d}\alpha=|p_K\rangle\langle p_K|, \tag{37}$$

$$\sum_K\frac{1}{2\pi r}\int_0^{2\pi r}U(\alpha,K)\mathrm{d}\alpha=\mathbf{1}. \tag{38}$$

Equation (36) is proved if we use Eqs. (28) and (34) in conjunction with the fact that

$$\sum_{K=\text{even}}D(\alpha,K)=\frac{1}{2}\left(\left|\frac{\alpha}{2}\right\rangle\left\langle-\frac{\alpha}{2}\right|+\left|\frac{\alpha}{2}+\pi r\right\rangle\left\langle-\frac{\alpha}{2}+\pi r\right|\right). \tag{39}$$

For completeness we also mention that

$$\sum_{K=\text{odd}}D(\alpha,K)=\frac{1}{2}\left(\left|\frac{\alpha}{2}\right\rangle\left\langle-\frac{\alpha}{2}\right|-\left|\frac{\alpha}{2}+\pi r\right\rangle\left\langle-\frac{\alpha}{2}+\pi r\right|\right). \tag{40}$$

Equation (40) can be proved using Eq. (15). We note that in Eq. (36) we have projectors to the diametrically opposite position states $|\alpha\rangle$ and $|\alpha+\pi r\rangle$. This is related to the fact that the displaced parity operator on the left-hand side of Eq. (36), has period πr. Equation (37) can be proved using Eq. (29). Summation over K in Eq. (37) gives Eq. (38).

The displacement operators are related to the displaced parity operators through a two-dimensional Fourier transform. Multiplying the left- and right-hand sides of Eq. (32) with $D(\alpha,K)$ and $[D(\alpha,K)]^{\dagger}$ correspondingly, we can prove

$$\sum_{M=\text{even}}\frac{1}{2\pi r}\int_0^{2\pi r}D(\beta,M)\exp\left(\frac{i\beta\sigma}{r}\right)\exp\left[i\frac{K\beta-M\alpha}{r}\right]\mathrm{d}\beta=U(\alpha,K). \tag{41}$$

IV. WIGNER AND WEYL FUNCTIONS

The Weyl and Wigner functions can be defined in terms of the displacement and parity operator correspondingly, as

$$\tilde{W}(\alpha,K)=\mathrm{Tr}[\hat{\rho}D(\alpha,K)], \tag{42}$$

$$W(x,p_N)=\mathrm{Tr}[\hat{\rho}U(x,N)]. \tag{43}$$

Using the fact that the density matrix is Hermitian, we easily show that the Wigner function is real. The Weyl function is in general complex. We can easily show the following formulas (which can also be used as alternative definitions):

$$\tilde{W}(\alpha,K)=\frac{1}{2\pi r}\int_0^{2\pi r}\left\langle x-\frac{\alpha}{2}\middle|\hat{\rho}\middle|x+\frac{\alpha}{2}\right\rangle \exp\left(i\frac{K}{r}x\right)\mathrm{d}x \tag{44}$$

$$=\sum_{N=-\infty}^{\infty}\langle p_{N-K}|\hat{\rho}|p_N\rangle\exp\left[-i\alpha\left(p_N-\frac{K}{2r}\right)\right]. \tag{45}$$

$$W(x,p_N)=\frac{1}{2\pi r}\int_0^{2\pi r}\langle x-\alpha|\hat{\rho}|x+\alpha\rangle\exp(i2\alpha p_N)\mathrm{d}\alpha \tag{46}$$

$$=\sum_{K=-\infty}^{\infty}\langle p_{N+K}|\hat{\rho}|p_{N-K}\rangle\exp\left(\frac{2ixK}{r}\right). \tag{47}$$

The Wigner function describes the pseudoprobability of finding the particle in phase space, in a way consistent with quantum mechanics and the uncertainty principle. The Weyl function is equal to the overlap of the displaced state with the original state. In this sense, the α,K are position and momentum *increments*. The Weyl function can be understood as a *generalized correlation function*. If we have the wave function $R(x)$ in order to find the correlation we displace it into $R(x+\alpha)$ and take the integral of $R(x)R(x+\alpha)$. In the Weyl function we perform a more general displacement in phase space i.e., a displacement in both position and momentum. Therefore the correlation is a special case of the Weyl function with $\alpha=0$ (or $K=0$). We note that the momentum takes values $(N+\sigma)/r$ and depends on σ. In contrast the momentum increments appearing on the Weyl function take values K/r and do not depend on σ.

The Wigner function is related to the Weyl function through a two-dimensional Fourier transform

$$W(x,p_N)=\frac{1}{2\pi r}\int_0^{2\pi r}\sum_{K=\text{even}}\tilde{W}(\alpha,K)\exp\left(-i\frac{K}{r}x\right)\exp(i\alpha p_N)\mathrm{d}\alpha. \tag{48}$$

This can be proved using Eq. (29) or Eq. (49). This result is intimately connected to the fact that the displacement operator and displaced parity operator are related to each other through a two-dimensional Fourier transform [Eq. (49)].

Using Eqs. (18) and (35) we easily see that the Wigner function is periodic function of x with period πr; and the Weyl function is quasiperiodic with period $2\pi r$:

$$\tilde{W}(\alpha+2\pi rw,K)=(-1)^{Kw}\exp(-i2\pi\sigma w)\tilde{W}(\alpha,K),\quad W(x+\pi r,p_N)=W(x,p_N). \tag{49}$$

The Wigner and Weyl functions depend on the magnetic flux σ although for simplicity in the notation we have not shown this dependence explicitly. They obey the relations

$$\tilde{W}_\sigma(\alpha,K)=\tilde{W}_{\sigma+1}(\alpha,K),\quad W_{\sigma+1}(x,p_N)=W_\sigma(x,p_{N+1}). \tag{50}$$

This is related to the fact that the momentum is $p_N=(N+\sigma)/r$ and as we go from σ to $\sigma+\mathbf{1}$ the momentum p_N is relabeled as p_{N+1}.

The properties of the displacement and parity operator that we proved above can be translated into properties for the Wigner and Weyl functions. Starting with the Weyl function we use Eqs. (28) and (29) to prove that

$$\sum_{K=-\infty}^{\infty}\tilde{W}(\alpha,K)=\left\langle-\frac{\alpha}{2}\middle|\rho\middle|\frac{\alpha}{2}\right\rangle, \tag{51}$$

$$\frac{1}{2\pi r}\int_0^{2\pi r}\widetilde{W}(\alpha,K)\exp\left(\frac{i\alpha\sigma}{r}\right)\mathrm{d}\alpha=\begin{cases}\langle p_M|\rho|p_{-M}\rangle, & K=2M,\\ \sum_{N=-\infty}^{\infty}\langle p_N|\rho|p_{N+K}\rangle\Delta\left(-\frac{K}{2}-N\right), & K=2M+1.\end{cases} \tag{52}$$

We can make here a similar comment to that made for Eq. (29). In Eq. (52), integration from $2\pi r$ to $4\pi r$, gives the same result for even K and the same result but with opposite sign for odd K. Therefore if we integrate from 0 to $4\pi r$ we get the same result for even K and zero for odd K. We can also show that

$$\widetilde{W}(0,0)=1, \quad \widetilde{W}(\alpha,K)=\widetilde{W}^*(-\alpha,-K), \quad |\widetilde{W}(\alpha,K)|\leqslant 1. \tag{53}$$

For the Wigner function we use Eqs. (36), (37), (38) to prove

$$\frac{1}{2\pi r}\int_0^{2\pi r}W(x,p_N)\mathrm{d}x=\langle p_N|\hat{\rho}|p_N\rangle, \tag{54}$$

$$\sum_{N=-\infty}^{\infty}W(x,p_N)=\frac{1}{2}(\langle x|\hat{\rho}|x\rangle+\langle x+\pi r|\hat{\rho}|x+\pi r\rangle), \tag{55}$$

$$\frac{1}{2\pi r}\int_0^{2\pi r}\sum_{N=-\infty}^{\infty}W(x,p_N)\mathrm{d}x=\mathbf{1}. \tag{56}$$

We can also prove that

$$\mathrm{Tr}(\hat{\rho}_1\hat{\rho}_2)=\frac{1}{2\pi r}\int_0^{2\pi r}\sum_{N=-\infty}^{\infty}W_{\rho_1}(x,p_N)W_{\rho_2}(x,p_N)\mathrm{d}x. \tag{57}$$

V. EXAMPLE

As an example, we consider a free particle descibed with the Hamiltonian

$$\hat{H}=\hat{p}^2. \tag{58}$$

We note that the particle feels a vector potential through the quasiperiodic boundary condition.

We assume that at $t=0$ the wave function is a Gaussian on a circle, i.e., a theta function. In order to explain this we introduce the Zak transform[9] on a function $S(y)$ on a real line, defined as

$$R(x,\sigma)=\mathcal{N}\sum_{w=-\infty}^{\infty}S(y=x+2\pi r w)\exp(-i2\pi\sigma w), \tag{59}$$

where $\mathcal{N}$ is used to normalize the function $R(x,\sigma)$ according to Eq. (2). If $S(y;A)$ is a Gaussian wave function

$$S(y;A)=\pi^{-1/4}\exp\left(-\frac{y^2}{2}+\sqrt{2}A\cdot y-AA_R\right), \tag{60}$$

where $A=A_R+iA_I$, then the Zak transform is

$$R(x,\sigma;A)=\mathcal{N}\cdot\pi^{-1/4}\exp\left(-\frac{x^2}{2}+\sqrt{2}Ax-AA_R\right)\Theta_3[-\pi\sigma+i\pi r(x-\sqrt{2}A);i2\pi r^2], \tag{61}$$

where $\Theta_3[u;\tau]$ is theta function,[10] defined as

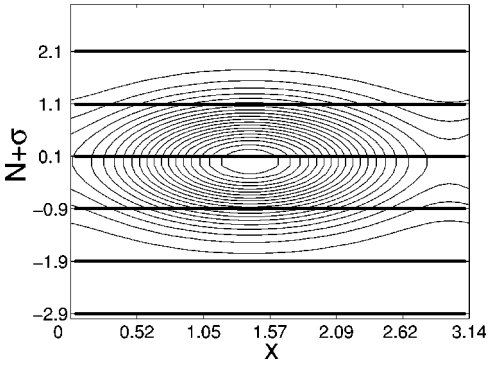

FIG. 1. A contour plot of the Wigner function at $t=0$ as a function of x and for all values of σ. The parallel black lines in the figure show the case $\sigma=0.1$.

$$\Theta_3[u;\tau]=\sum_{n=-\infty}^{\infty}\exp(i\pi\tau n^2+i2nu). \tag{62}$$

We have taken $r=1$, $A=1$ and calculated the Wigner and Weyl functions. Numerical results are shown in Figs. 1–3.

In Fig. 1 we present a contour plot of the Wigner function $W(x,N+\sigma)$ as a function of x and for all values of σ. For a given σ the Wigner function is defined only on the discrete values of the momenta $p_N=(N+\sigma)/r$ and the parallel black lines in the figure show the case $\sigma=0.1$. As expected from Eq. (49), the Wigner function is periodic function of x with period π. Also it has been explained in Eq. (50) that the plotted values of $W(x,p_1)$ for $\sigma=1$ represent the $W(x,p_2)$ for $\sigma=0$.

In Fig. 2 we present the Wigner function as a function of x at a particular momentum $p_0=\sigma$ with $\sigma=0.1$. This is really an appropriate slice of the three-dimensional version of Fig. 1.

In Fig. 3 we present a contour plot of the absolute value of the Weyl function as a function of α for $K=1$ and for all values of σ. The black line in the figure shows the case $\sigma=0.1$.

We calculate the time evolution of this system. This is easily done in the momentum representation as

$$\langle p_N|R(t)\rangle=\exp(it\hat{H})\langle p_N|R(0)\rangle. \tag{63}$$

We need the state of the system at $t=0$ in the momentum representation. If $\tilde{S}(p)$ is the Fourier transform of $S(x)$:

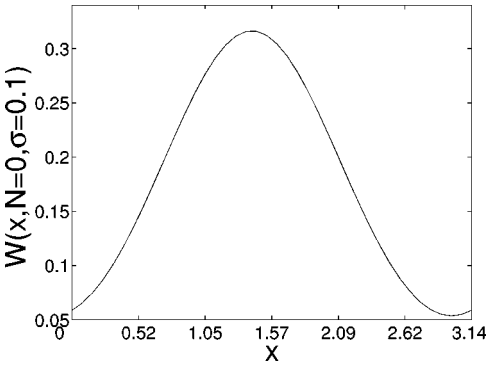

FIG. 2. A slice of the Wigner function of Fig. 1 with $\sigma=0.1$.

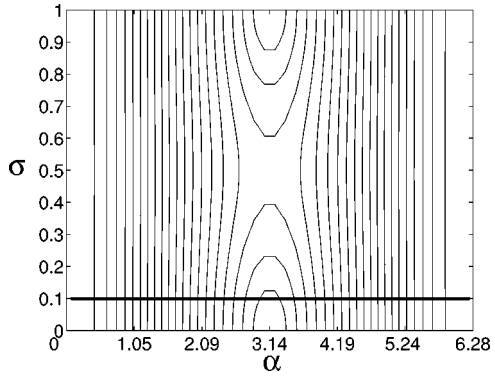

FIG. 3. A contour plot of the absolute value of the Weyl function at $t=0$ for $K=1$, as a function of α and σ. The black line in the figure shows the case $\sigma=0.1$.

$$\tilde{S}(p)=\int_{-\infty}^{+\infty} S(x)\exp(-ipx)\mathrm{d}x, \tag{64}$$

then using Eq. (4), Eq. (59), and Eq. (64) we can prove the relation

$$R_N=\frac{\mathcal{N}}{2\pi r}\tilde{S}(p_N). \tag{65}$$

Since the Fourier transform of Gaussian wave function Eq. (60) is

$$\tilde{S}(p;A)=\sqrt{2}\pi^{1/4}\exp\left(-\frac{p^2}{2}-i\sqrt{2}A\cdot p+AA_I\right), \tag{66}$$

we obtain

$$\langle p_N|R\rangle=\frac{\mathcal{N}\pi^{1/4}}{\sqrt{2}\pi r}\exp\left(-\frac{p_N^2}{2}-i\sqrt{2}A\cdot p_N+AA_I\right). \tag{67}$$

Inserting Eq. (67) into (63) we get

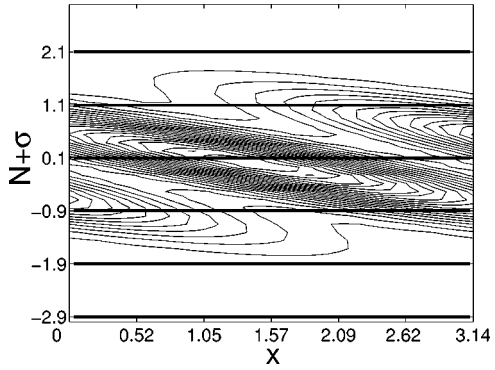

FIG. 4. A contour plot of the Wigner function at $t=1$ as a function of x and for all values of σ. The parallel black lines in the figure show the case $\sigma=0.1$.

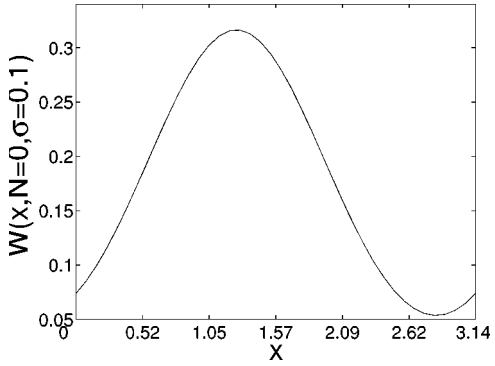

FIG. 5. A slice of the Wigner function of Fig. 4 with $\sigma=0.1$.

$$\langle p_N|R(t)\rangle=\frac{\mathcal{N}\pi^{1/4}}{\sqrt{2}\pi r}\exp\left[-\left(\frac{1}{2}-it\right)p_N^2-i\sqrt{2}A\cdot p_N+AA_I\right]. \tag{68}$$

From that we have calculated for $t=1$ the corresponding Wigner and Weyl functions to the previous ones. Results are shown in Figs. 4–6. The results show the time evolution of the system in the language of Wigner and Weyl functions.

VI. DISCUSSION

Quantum mechanics on a circle has attracted a lot of attention in the literature. It uses topological ideas in the context of quantum mechanics. In this paper we have studied phase space methods in this context. We have introduced displacement operators and studied their properties. There is clearly some analogy with the harmonic oscillator displacement operator properties [given in Eqs. (23), (24), and (25)], but there are also considerable differences. In particular the flux σ plays an important role in the properties of the displacement operators for particles on a circle. Our main results here are Eqs. (28), (29), and (32).

We also introduced Wigner and Weyl functions and discussed their physical interpreration and their properties, which are direct consequence of the displacement operator properties. A numerical example for the theta wave function of Eq. (61) (the analogue on a circle of the Gaussian function on the real line) has been discussed.

The results can be used in the context of Aharonov–Bohm devices, Floquet–Bloch solid state systems, coherent states on a circle,[11] quantum maps and classical and quantum chaos,[12] etc. Fractional Fourier transforms in this context have been discussed in Ref. 13.

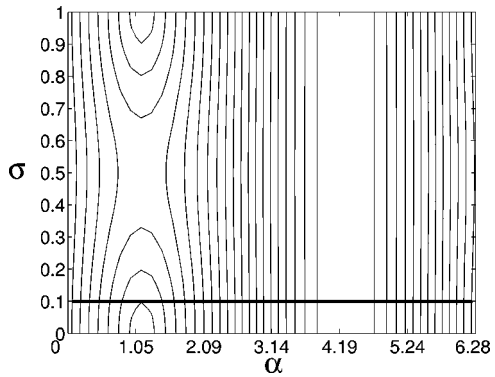

FIG. 6. A contour plot of the absolute value of the Weyl function at $t=1$ for $K=1$, as a function of α and σ. The black line in the figure shows the case $\sigma=0.1$.

The conflict between Gauss' law constraint and the existence of the propagator of the gauge fields, at the basis of contradictory proposals in the literature, is shown to lead to only two alternatives, both with peculiar features with respect to standard quantum field theory. In the positive (interacting) case, the Gauss' law holds in operator form, but only the correlations of exponentials of gauge fields exist (nonregularity) and the space translations are not strongly continuous, so that their generators do not exist. Alternatively, a Källen–Lehmann representation of the two point function of A_i satisfying locality and invariance under space–time translations, rotations and parity is derived in terms of the two point function of $F_{\mu\nu}$; positivity is violated, the Gauss' law does not hold, the energy spectrum is positive, but the relativistic spectral condition does not hold. In the free case, θ-vacua exist on the observable fields, but they do not have time translationally invariant extensions to the gauge fields; the vacuum is faithful on the longitudinal field algebra and defines a modular structure (even if the energy is positive). Functional integral representations are derived in both cases, with the alternative between ergodic measures on real random fields or complex Gaussian random fields. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1603957]

I. INTRODUCTION

In the treatment of gauge quantum field theories, even if the choice of the gauge, a basic ingredient for the control of the dynamical problem, is irrelevant for the physical conclusions, it crucially affects the mathematical structure of the formulation as well as the way the various mechanisms (mass generation, gauge symmetry breaking, θ-vacua, chiral symmetry breaking, etc.) are effectively realized. In the discussion of the nonperturbative aspects of quantum chromodynamics (QCD)[1] and of the Higgs mechanism,[2] the temporal gauge has been widely used and it is therefore worthwhile to investigate its mathematical structure.

From a technical point of view (the only relevant for the gauge choice), such a gauge has been preferred to others because it is believed to satisfy locality, positivity, and the Gauss' law constraint in operator form, at the only expense of manifest Lorentz covariance. As such, it appears as intermediate between the Coulomb gauge, where locality is lost (besides manifest Lorentz covariance), and the Feynman–Gupta–Bleuler (FGB) gauge,[3,4] where locality holds but positivity and the operator Gauss' law constraint are lost.

The aim of this article is to critically examine the mathematical structure of the temporal gauge and the status of general properties like positivity, operator Gauss' law, positivity of the energy, and relativistic spectrum condition.

The usual formulation of the temporal gauge relies either on canonical quantization as a basis

a)Author to whom correspondence should be addressed. Electronic mail: strocchi@sns.it

of the perturbative expansion or on a functional integral approach to the interacting theory, with a space lattice regularization, which also gives a (lattice regularized) canonical structure. Thus, in both cases one has a CCR algebra at equal times; actually, also in the presence of the interaction, the subalgebra generated by $\mathrm{div}\,A$ and $\mathrm{div}\,E-j_0$ remains canonical, with an interaction independent commutator also at unequal times.

Contrary to the standard case, the CCR structure of the temporal gauge does not uniquely identify its vacuum representation; as a matter of fact, the form of the propagator of the gauge potential has been debated in the literature, but a classification of the possibilities is lacking, especially in connection with basic structural properties, so that also recent textbook presentations of the temporal gauge[5] leave such basic points unsettled. The analysis of such a problem is the main content of this work: we shall classify all time translation invariant states on the CCR algebra in the free case and discuss the implications on the interacting Abelian theory.

The results are the following. Both in the free and the interacting cases positivity and time translation invariance are incompatible with the existence of the correlation functions of the field $\mathrm{div}\,A$, only its exponentials being defined. Positivity also implies that the vacuum satisfies the Gauss' law constraint in operator form and that the space translations are not strongly continuous, so that one cannot define their generators (the momentum) and the relativistic spectrum condition cannot even be defined. In the free case the condition of positivity of the energy spectrum is shown to uniquely select the (nonregular) state considered in Ref. 6 (see also Refs. 7 and 8); other time translational invariant pure states exist, which satisfy the spectral condition only on the observables.

On the other hand, the perturbative expansion and the standard functional integral approach are based on the existence of the propagator of the gauge potential, whose form has been widely discussed in the literaure, with no general sharp conclusion and with proposals often in conflict with basic principles of standard quantum field theory, even in the free case (see Ref. 5). To clarify the problem, we derive a Källen–Lehmann representation of the two point function of the gauge potential in the interacting case under the general conditions of locality and invariance under space–time translations, rotations and parity. The resulting two point function violates positivity and the relativistic spectral condition (but not the positivity of the energy spectrum) and the vacuum cannot be annihilated by the Gauss operator $\mathrm{div}\,E-j_0$ (such features are shared by the FGB gauge, where, however, there is no violation of the relativistic spectral condition). In the free field case, the quasi-free state defined by the two point function gives rise to an indefinite inner product structure which can be discussed as in the FGB gauge in terms of a Hilbert–Krein structure.

The Euclidean functional integral representation is discussed in the positive and in the indefinite case, also with the aim of clarifying the unsatisfactory proposals in the literature (which ignore the violation of Nelson positivity, involve infinite normalizations, formal Faddev–Popov ghosts, improper realization of the Gauss constraint, etc.). In the indefinite case, the representation of the Euclidean fields requires, besides real Gaussian fields $A_i^{tr}(\mathbf{x},\tau)$, $\xi(\mathbf{x},\tau)$, with $\xi(f,\tau)$ the Wiener process, a *complex* Gaussian field $z(\mathbf{x})$. In the positive case, the complex Gaussian field $z(\mathbf{x})$ is replaced by a real random field $\Xi(\mathbf{x})$ with functional measure defined by ergodic means. The correlation functions of the exponentials of the (smeared) fields are therefore represented by integration with the product of the above Gaussian measures and a measure over the spectrum of the Bohr algebra generated by the exponentials of $\Xi(g)$.

II. ALGEBRAIC STRUCTURE

At a formal level the temporal gauge is defined by the gauge condition $A_0=0$, by the canonical commutation relations (CCR)

$$[A_i(\mathbf{x}),\partial_t A_j(\mathbf{y})]=i\,\delta_{ij}\delta(\mathbf{x}-\mathbf{y}), \tag{2.1}$$

and by the CAR relations of the charged fermion fields $\psi(\mathbf{x})$, $\overline{\psi}(\mathbf{y})$. The gauge fields satisfy the following equations of motion:

$$\partial_t^2 A_i - \Delta A_i + \partial_i \operatorname{div} A = j_i, \tag{2.2}$$

where j_μ is the conserved gauge invariant electromagnetic current constructed in terms of the charged fermion fields. We shall denote by $\mathcal{F}_c$ the polynomial algebra generated by the zero time fields $A_i, \dot{A}_i, \psi, \overline{\psi}, j_\mu$, smeared with test functions in $\mathcal{S}(\mathbf{R}^3)$, hereafter called *canonical field algebra*, and by $\mathcal{F}$ the algebra generated by the fields A_i, ψ, $\overline{\psi}$, j_u, smeared with test functions in $\mathcal{S}(\mathbf{R}^4)$.

Equation (2.2) implies that $\operatorname{div} E - j_0$ is time independent so that $\forall g \in \mathcal{S}(\mathbf{R}^3)$

$$(\operatorname{div} E - j_0)(g,t) \equiv (\operatorname{div} E - j_0)(g,h), \quad h \in \mathcal{S}(\mathbf{R}), \quad \int ds\, h(s) = 1,$$

is a well defined time independent operator and therefore its equal time commutators with the fields are well defined operator valued distributions. Such commutators are fixed by the condition that $G \equiv \operatorname{div} E - j_0$ generates time independent gauge transformations; such a property follows from canonical quantization if the gauge invariant point splitting regularization of the current amounts to the addition of terms linear in A_i, $\partial_0 A_i$ to the canonical fermion current. Under such a condition one has

$$[A_i(\mathbf{x},t), G(\mathbf{y},t)] = -i\partial_i \delta(\mathbf{x}-\mathbf{y}). \tag{2.3}$$

As we shall see below, a positive realization of the temporal gauge can only be done in terms of Weyl algebras. We then introduce the algebras:

(1) $\mathcal{A} \equiv$ the polynomial algebra generated by $A(f) \equiv A_i(f_i)$, $\partial_t A(g) = E(g)$, $f_i, g_i \in \mathcal{S}(\mathbf{R}^3)$ (*gauge field algebra*), and $\mathcal{W} \equiv$ the corresponding *gauge Weyl algebra* generated by $\exp i[A(f) + E(g)] \equiv W(f,g)$;

(2) $\mathcal{A}_l \equiv$ the polynomial algebra generated by $A(\partial h) \equiv A_i(\partial_i h)$, $(\operatorname{div} E - j_0)(g)$, $h, g \in \mathcal{S}(\mathbf{R}^3)$, called the *longitudinal field algebra*, and $\mathcal{W}_l$ the corresponding *longitudinal Weyl algebra*, generated by $\exp i[A(\partial h) + (\operatorname{div} E - j_0)(g)] \equiv W_l(h,g)$.

By decomposing test functions into longitudinal and transverse (nonlocal) components and by an analysis in momentum space, it is not difficult to see that in the free case the time evolution of $\mathcal{W}$ is relativistically local, formally,

$$\alpha_t(A(f) + E(g)) = A(f_t) + E(g_t),$$

with $supp\, f_t \cup supp\, g_t$ contained in the causal shadow of $supp\, f \cup supp\, g$. The same analysis shows that Eq. (2.2) has a relativistically causal Green function, so that, in the interacting case, the relativistic locality of the gauge fields in the temporal gauge follows from the relativistic locality of the observable field j_i; this implies local commutativity for the Wightman field algebra $\mathcal{F}$, since the fermion coupling is local. In contrast, in the Coulomb gauge, the fermion coupling is nonlocal and local commutativity is lost.

The free time evolution of the longitudinal Weyl algebra is

$$\alpha_t(W_l(h,k)) = W_l(h, k + t\,h), \tag{2.4}$$

so that the longitudinal fields describe an infinite set of free nonrelativistic particles. In fact, given a complete set $\{f_n\}$ in $L^2(\mathbf{R}^3)$, with $(f_n, -\Delta f_m) = \delta_{n,m}$, the variables

$$q_n \equiv \operatorname{div} A(f_n), \quad p_n \equiv \operatorname{div} E(f_n) \tag{2.5}$$

are canonical and their time evolution is that of free particles

$$\dot{q}_n = p_n, \quad \dot{p}_n = 0.$$

The above algebraic structure follows from canonical quantization at equal times. Its validity is independent of the presence of the interaction, provided an ultraviolet regularization (e.g., by a space lattice cutoff) is introduced, so that the time evolution of the above algebras is well defined. Actually, by Eq. (2.3), $[e^{iA(\partial f,t)}, (\mathrm{div}\, E - j_0)(g,s)]$ is independent of s and therefore such a canonical commutator extends to unequal times and is independent of the interaction

$$[e^{iA_i(\partial_i h)}, (\mathrm{div}\, E - j_0)(g,s)] = -\int d^4x\, \Delta h(x)\, g(\mathbf{x})\; e^{iA_i(\partial_i h)}, \quad h \in \mathcal{S}(\mathbf{R}^4). \tag{2.6}$$

The field algebra $\mathcal{F}$ of the temporal gauge has the following infinite dimensional group of automorphisms [*time independent (small) gauge transformations*]: γ^Λ, $\Lambda(x) \in \mathcal{S}(\mathbf{R}^3)$

$$\gamma^\Lambda(A(f)) = A(f) - \int d^3x\, \Lambda\, \mathrm{div}\, f, \quad \gamma^\Lambda(E(g)) = E(g), \quad \gamma^\Lambda \psi(f) = \psi(e^{i\Lambda} f). \tag{2.7}$$

The γ^Λ commute with the time translations, as a consequence of the gauge invariance of the Lagrangian; they are generated by $G(\Lambda)$ and are unitarily implemented by elements of the longitudinal Weyl algebra.

The automorphisms of Eq. (2.7), with $\Lambda(\mathbf{x}) = \boldsymbol{\alpha}\cdot\mathbf{x}$, are called *large gauge transformations* and are still denoted by γ^Λ. They commute with the time and space translations and are locally generated by the local charges

$$G_R^\Lambda \equiv G(\Lambda f_R), \quad f_R(x) = f(|x|/R), \quad f \in \mathcal{D}(\mathbf{R}),$$

in the sense that the variations of the fields are given by

$$\delta^\Lambda B = \lim_{R\to\infty} -i\,[Q_R^\Lambda, B], \quad \forall B \in \mathcal{F}. \tag{2.8}$$

The *observable subalgebras* $\mathcal{F}_{obs}$, $\mathcal{A}_{obs}$, $\mathcal{W}_{obs}$ are characterized by pointwise invariance under all γ^Λ. $\mathcal{A}_{obs}$ is the algebra generated by $A(f)$, $\mathrm{div}\, f = 0$ and by $E(g)$; $\mathcal{F}_{obs}$ has a nontrivial center which contains the algebra generated by $G(f)$, $f \in \mathcal{S}(\mathbf{R}^3)$. The invariance of the vacuum under large gauge transformations is incompatible with the existence of the correlation functions of the field algebra $\mathcal{F}$ and, as we shall see explicitly in the free case, only holds in the nonregular positive formulation.

The gauge field algebra $\mathcal{A}$, as well as the gauge Weyl algebra $\mathcal{W}$, have the following three parameter group of automorphisms β^θ, $\theta \in \mathbf{R}^3$:

$$\beta^\theta(A(f)) = A(f), \quad \beta^\theta(E(g)) = E(g) + \theta_i \int d^3x\, g_i, \tag{2.9}$$

which generate a background constant (classical) electric field.

The automorphisms β^θ, for simplicity called θ automorphisms, commute with the space translations and have the following commutation relations with the gauge transformations and with the free time evolution

$$\beta^\theta\, \gamma^\Lambda = \gamma^\Lambda\, \beta^\theta, \quad \beta^\theta\, \alpha_t = \alpha_t\, \beta^\theta\, \gamma^{t\,\theta\cdot\mathbf{x}}, \tag{2.10}$$

so that they commute with the free time evolution on the observable algebra. The θ automorphisms are generated on $\mathcal{W}$ (and on $\mathcal{A}$) by the local charges

$$Q_R \equiv A_i(\theta_i f_R). \tag{2.11}$$

Even if the automorphisms β^θ commute with the gauge transformations, the corresponding generators do not. In conclusion, at least in the free case, such transformations have similar properties to those of the chiral transformations in quantum chromodynamics.

III. STATES AND REPRESENTATIONS

In the following we shall adopt the physicist terminology by which a linear normalized functional on a *-algebra $\mathcal{A}$ is briefly called a *state*, even if it is not positive with respect to the *-operation defined on the algebra. A state in the above sense defines a *representation* π_ω of $\mathcal{A}$ with a cyclic vector Ψ_ω and an inner product $(\pi_\omega(A)\,\Psi_\omega,\,\pi_\omega(B)\,\Psi_\omega)=\omega(A^*B)$. A semidefinite representation of a *-algebra $\mathcal{A}$ is called *irreducible* if any bounded operator which commutes with $\mathcal{A}$ is a multiple of the identity.

We shall show that the gauge condition $A_0=0$ does not uniquely fix the vacuum representation of the longitudinal algebra. We shall discuss the general obstructions which arise if, given a positive state on the observable field algebra $\mathcal{F}_{obs}$, one looks for extensions to the field algebra $\mathcal{F}$. Actually, independently of the interaction, we shall show that existence of the correlation functions of the fields requires a nonpositive vacuum state, which cannot be annihilated by the Gauss operator $\operatorname{div}E-j_0$, whereas a positive representation requires a nonregular state on the longitudinal algebra $\mathcal{L}$ generated by $\exp iA_i(\partial_i h)$, $\exp iG(h)$, $h\in\mathcal{S}(\mathbf{R}^4)$. The two alternatives are shown to have very different mathematical features and can in fact be distinguished on the basis of the structural properties that one wants to preserve.

Proposition 3.1: Let ω be a positive vacuum state on $\mathcal{F}_{obs}$, satisfying the cluster property. Then

(i) ω does not have a positive extension to $\mathcal{F}$,

(ii) any positive extension Ω to $\mathcal{L}$ is nonregular and satisfies

$$\Omega(W_l(0,g))=\omega(W_l(0,g))=1,\quad \Omega(W_l(f,g))=0,\quad \text{if}\quad f\neq 0, \tag{3.1}$$

(iii) all positive extensions of ω to an algebra containing $\mathcal{L}$ define a GNS representation π_Ω in which the space translations are not implemented by strongly continuous unitary operators $U(\mathbf{x})$, $\mathbf{x}\in\mathbf{R}^3$, and, therefore, the generator, the momentum, cannot be defined, and

(iv) all positive extensions of ω are invariant under the large (and small) gauge transformations:

$$(\gamma^\Lambda)^*\Omega=\Omega,\quad (\operatorname{div}E(\mathbf{x})-j_0(\mathbf{x}))\,\Psi_\Omega=0. \tag{3.2}$$

Proof: (i) Since $[G(h),\mathcal{F}_{obs}]=0$, by Theorem 4.4 of Ref. 9.

$$G(h)\,\Psi_\omega=c_h\,\Psi_\omega,\quad c_h\in\mathbf{C}, \tag{3.3}$$

and, by Lorentz invariance of ω on $\mathcal{F}_{obs}$, $c_h=0$. By Schwarz' inequality a positive extension Ω satisfies

$$\Omega(G(h)\,B)=0,\quad \forall\ B\in\mathcal{F}. \tag{3.4}$$

This implies

$$\Omega([\operatorname{div}A(f),G(h)])=0,\quad \forall f,h\in\mathcal{S}(\mathbf{R}^4),$$

whereas the algebraic structure, Eq. (2.6), gives

$$\Omega([\operatorname{div}A(f),G(h)])=i\int d^4x\,f(x)\,\Delta h(x).$$

(ii) In fact,

$$|c_h|^2\,\Omega(e^{iA_i(\partial_i f)})=\Omega(W_l(0,-h)\,e^{iA_i(\partial_i f)}W_l(0,h))=e^{i\int d^4x\,f\Delta h}\,\Omega(e^{iA_i(\partial_i f)}),\quad \forall f,h\in\mathcal{S}(\mathbf{R}^4),$$

and, therefore, for $f\neq 0$,

$$\Omega(e^{iA_i(\partial_i f)})=0. \tag{3.5}$$

(iii) In fact, one has

$$\Omega(e^{iA_i(\partial_i h)}\,U(-\mathbf{x})\,e^{-iA_i(\partial_i h)}\,U(\mathbf{x}))=\Omega(e^{iA_i(\partial_i h-\partial_i h_{\mathbf{x}})})$$

and the right hand side vanishes for all $\mathbf{x}\neq 0$ and it is $=1$ for $\mathbf{x}=0$.

(iv) In fact, by Eq. (2.7) one has

$$\frac{d}{d\lambda}\Omega(\gamma^{\lambda\Lambda}(B))=\lim_{R\to\infty} i\,\Omega([\,G_R^{\Lambda},\,\gamma^{\lambda\Lambda}(B)\,])=0$$

as in Eq. (3.3).

The above proposition clarifies the roots of the problems which arise in the quantization of the temporal gauge, by reducing them to very basic structures. The solutions proposed in the literature, relying on an analysis of the free case, involve a non-normalizable vacuum, or the violation of time translation invariance, etc. (for an extensive review, see Ref. 5), so that new problems are somewhat arbitrarily added, hiding the basic issues. The following analysis of the free case makes clear that general properties, like time translation invariance and either positivity or existence of the correlation functions of the fields select exactly two alternatives, yielding solutions in terms of a time translation invariant vacuum over well defined operator algebras.

In particular, the existence of the ground state correlation functions of the fields requires an indefinite inner product space as in the Gupta–Bleuler gauge; alternatively, positivity can be achieved at the price of regularity of the representation of the longitudinal Weyl algebra. A close analog of such a situation appears for free nonrelativistic particles when one asks for the existence of a ground state (see Ref. 10).

In general, given an algebra $\mathcal{A}$, a time translation automorphism α_t and a time traslationally invariant Hermitian linear functional Ω on $\mathcal{A}$, we shall say that the *energy spectral condition* holds if, $\forall A, B\in\mathcal{A}$, the expectations $G_{AB}(t)\equiv\Omega(A\,\alpha_t(B))$ are continuous in t and their Fourier transforms

$$\tilde{G}_{AB}(\omega)=(2\pi)^{-1/2}\int dt\,G_{AB}(t)e^{-i\omega t}$$

are supported in $\mathbf{R}^{+}$.

Proposition 3.2: (1) Let Ω be a state on the gauge field algebra $\mathcal{A}$ invariant under the free time evolution Then

(i) *Ω cannot be positive and*

(ii) *if the restriction ω of Ω to the observable gauge algebra $\mathcal{A}_{obs}$ is semidefinite and satisfies the energy spectral condition, then the GNS representation π_ω of $\mathcal{A}_{obs}$ is irreducible and coincides with the standard vacuum representation of the electromagnetic field algebra.*

(2) Let Ω be a state on the Weyl gauge algebra $\mathcal{W}$ invariant under the free time evolution, satisfying the energy spectral condition, and let its restriction ω to $\mathcal{W}_{obs}$ be semidefinite. Then $\pi_\Omega(\mathrm{div}\,E)=0$, the GNS representation π_ω of $\mathcal{W}_{obs}$ is irreducible and coincides with the standard vacuum representation of the free electromagnetic field (Weyl) algebra.

Proof. (1 i). In fact, by time translation invariance, $\Omega(\partial_t O)=0, \forall O\in\mathcal{A}$, and since, by the equations of motion $\partial_t\,\mathrm{div}\,E=0$, one has

$$\Omega((\mathrm{div}\,E(f))^2)=\Omega(\partial_t(\mathrm{div}\,A(f)\,\mathrm{div}\,E(f)))=0, \tag{3.6}$$

so that positivity implies that the Hilbert space vector Ψ_Ω, which represents Ω (in the GNS representation space), satisfies

$$\operatorname{div} E(f)\,\Psi_\Omega = 0, \quad \forall f \in \mathcal{S}(\mathbf{R}^3).$$

This is incompatible with the CCR since

$$\Omega([A_i(x), \operatorname{div} E(y)]) = -i\,\partial_i\,\delta(\mathbf{x}-\mathbf{y}).$$

(1 ii) By Schwarz' inequality, Eq. (3.7) gives

$$\Omega(O \operatorname{div} E(h)) = 0, \quad \forall O \in \mathcal{A}_{obs}.$$

Thus, the restriction ω of Ω to $\mathcal{A}_{obs}$ yields a representation π_ω such that $\pi_\omega(F_{\mu\nu})$ is a free electromagnetic field with energy spectral condition and the usual argument gives the standard Fock representation; the one-point function $\omega(E) = \omega(\dot{A})$ vanishes by the time translation invariance of Ω.

(2) In fact, time translation invariance implies that for $h \neq 0$, $\Omega(W_l(h,k))$ is independent of k, say $F(h)$. On the other hand, one has

$$\begin{aligned} & e^{i[(\partial h,\, \partial k') - (\partial k,\, \partial h')]/2}\, e^{i\,t\,(\partial h,\, \partial h')/2}\, \Omega(W_l(h,k)\,\alpha_t(W_l(h',k'))) \\ & \quad = F(h+h'), \quad \text{if} \quad h+h' \neq 0, \\ & \quad = \Omega(W_l(0, k+k'+t\,h')) \equiv G(k+k'+t\,h'), \quad \text{if} \quad h+h' = 0. \end{aligned}$$

Thus, the energy spectral condition requires $F(h+h') = 0$, whenever $h+h' \neq 0$, since otherwise, by taking $h = h'$, one would get a negative point of the energy spectrum. It also requires that the distributional Fourier transform $\tilde{G}(\omega)$ of $G(t\,h)$, with respect to the variable t, has support in $\omega = 0$. In fact, putting $h' = -h$, $k = k' = 0$, $d \equiv (\partial h,\, \partial h)/2$, in the above formula we have

$$G_h(\alpha\,t) \equiv G(\alpha h t) = \Omega(W_l(\alpha\,h, 0)\, W_l(-\alpha\,h, \alpha h t))\, e^{it\,\alpha^2\,d} \equiv H(t) e^{i\,t\,\alpha^2 d}.$$

Taking the Fourier transform with respect to t, and using the positive support of the Fourier transform of $H(t)$, we get

$$\operatorname{supp} \tilde{G}_h(\omega) = \operatorname{supp} \tilde{H}((\omega - \alpha^2\,d)/\alpha) \subseteq \mathbf{R}^+,$$

so that

$$\operatorname{supp}_\omega \tilde{G}((\omega + \alpha^2 d)/\alpha) \subseteq \mathbf{R}_+, \quad \operatorname{supp} \tilde{G}(\omega) \subseteq \alpha^{-1}\mathbf{R}_+ - \alpha\,d, \quad \forall \alpha \in \mathbf{R}.$$

Then $\operatorname{supp} \tilde{G} \subseteq [-\alpha\,d, \infty]$ for $\alpha > 0$, and $\operatorname{supp} \tilde{G} \subseteq [-\infty, -\alpha\,d]$ for $\alpha < 0$, which implies $\operatorname{supp} \tilde{G} = \{0\}$. Since, by positivity of Ω, $G(t)$ is bounded, one has $\tilde{G}(\omega) = \delta(\omega)$ and

$$\Omega(W_l(0, t\,k)) = 1, \tag{3.7}$$

so that $\operatorname{div} E$ is a regular variable and all its correlation functions vanish.

The above propositions imply that the representations of the temporal gauge in the free case with positive energy are the following.

A. Positive gauge invariant representation

Proposition 3.3: Invariance under free time evolution and positivity of the energy uniquely determine the positive states Ω on the Weyl field algebra to be of the following form:

$$\Omega(W(f,g)) = 0, \quad \text{if} \quad \operatorname{div}\ f \neq 0, \tag{3.8}$$

$$\Omega(W(f, g+\partial k)) = \Omega(W(f,g)), \tag{3.9}$$

$$\Omega(W(f,g)) = e^{-w(f,g)}, \quad \text{if} \quad \operatorname{div} f = 0, \tag{3.10}$$

where $k \in \mathcal{S}_{\text{real}}(\mathbf{R}^3)$ *and* $w(f,g)$ *is the standard transverse two-point function* $\langle (A(f)+E(g))\,(A(f)+E(g))\rangle_0$, $\operatorname{div} f=0$.

Proof: In fact, by Eqs. (3.7) and (2.1), one has

$$0=\Omega([W(f,g),\operatorname{div} E(k)])=-\int d^3x\, k \operatorname{div} f\, \Omega(W(f,g)),$$

which implies Eq. (3.8). Equation (2.4) and the invariance under time translation implies Eq. (3.9). The last equation follows from Proposition 3.2 which fixes the representation of the observable algebra to be the standard Fock one.

It is not difficult to see that Ω is pure[8] and coincides with the state considered in Ref. 6. Thus, as anticipated, we have a nonregular representation and the ground state correlation functions of the vector potential do not exist. Nonregularity also follows from the requirement of Gauss' law constraint by the results of Refs. 7 and 8. However, the selection of the above representation of $\mathcal{W}$, Eqs. (3.8)–(3.10), crucially depends on the condition of positive energy; in fact, one may find other (nonregular) time translationally invariant pure states which define disjoint representations in which the energy spectral condition is violated.

Proposition 3.4: In the free case, the θ *automorphisms are not unitarily implementable in the GNS representation* π_Ω *given by the state* Ω *defined above, Eqs. (3.8)–(3.10). The states* $\beta^\theta * \Omega$ *are space time translationally invariant and define disjoint nonregular representations of the Weyl field algebra, in which the energy spectral condition is violated.*

Proof: In fact, by using Eqs. (3.8)–(3.10) one has

$$\Omega(e^{i E_j(f_R)/R^3})=e^{-w(0,\, f_R/R^3)} \underset{R\to\infty}{\to} 1,$$

which implies

$$s-\lim_{R\to\infty} e^{i E_j(f_R)/R^3}\,\Psi_\Omega=\Psi_\Omega\,.$$

By the CCR, the same equation holds for any Ψ of the form $A\,\Psi_\Omega$, $A\in\mathcal{W}$, i.e., on a dense set, and therefore on any vector of the representation, since $W(0,R^{-3} f_R)$ is a unitary operator. On the other hand, by Eq. (2.10)

$$\lim_{R\to\infty} \beta^\theta * \Omega(e^{iE_j(f_R)/R^3})=e^{i\theta_j}.$$

Thus, the states $\beta^\theta * \Omega$ define disjoint representations.

Space translation invariance follows from $\beta^\theta \alpha_{\mathbf{x}}=\alpha_{\mathbf{x}}\beta^\theta$ and time translation invariance follows from Eq. (2.9),

$$\begin{aligned}(\beta^\theta * \Omega)(\alpha_t(W(f,g)))&=\Omega(\beta^\theta\,\alpha_t(W(f,g)))=\Omega(\alpha_t\,\gamma^{t\,\theta\cdot\mathbf{x}}\beta^\theta(W(f,g)))\\&=\Omega(\beta^\theta(W(f,g))=(\beta^\theta * \Omega)((W(f,g))).\end{aligned}$$

The energy spectral condition is violated as a consequence of Proposition 3.2.

A characteristic property of the θ-vacua is that they yield a nonvanishing expectation of the electric field, which is the time derivative of the vector potential. This is not incompatible with time translation invariance, because $\beta^\theta * \Omega(E(f))=0$, if $\operatorname{div} f=0$ and, if $\operatorname{div} f\neq 0$, $A(f)$ is nonregularly represented, namely its expectations do not exist, only those of its exponentials do.

Since β^θ commutes with α_t on the observable fields, the energy spectral condition holds for the correlation functions of observables and, in fact, each observable sector $\mathcal{H}_\theta$ has a unique translationally invariant state, which is the lowest energy state.

B. Indefinite regular representations

The perturbative expansion as well as the standard functional integral computations rely on the use of the field variables and therefore implicitly make use of a representation of the field algebra (otherwise the propagator of the vector potential would not exist). However, even in the free case, there is a rich literature on the possible form of the propagator of the gauge field A_i and no general agreement on the conclusion (for a review of the contributions and a detailed bibliography, see Ref. 5).

At the roots of the problem debated in the literature is the identification of gauge invariance with the vacuum being annihilated by the Gauss operator $G=\mathrm{div}\,E-j_0$ and the conflict of this condition with canonical quantization. The solutions proposed, often in conflict with basic features of standard quantum field theory, do not seem to realize that the vanishing of the Gauss operator on the vacuum is only compatible with a nonregular representation, precluding the existence of the propagator of A_i. As a consequence, see Proposition 3.1, a representation of the field algebra requires to abandon positivity, to admit that not all vectors obtained by applying the fields to the vacuum have a physical interpretation and to require the Gauss operator constraint only in expectations on the physical states (a feature common to other nonpositive gauges like the Feynman–Gupta–Bleuler gauge).

Motivated by the lack in the literature of a satisfactory characterization of the two point function of the gauge potential (even in the free case), we shall analyze it under the general condition of space–time translational invariance. In our opinion it is difficult to live without such a condition, as required by a momentum space analysis of the correlation functions or of the Feynman diagrams, according to the general wisdom of quantum field theory (e.g., the positive energy spectral condition needed for the analytic continuation to imaginary times and the functional integral representation of the so obtained Schwinger functions).

In the following, we shall characterize the two point function in the temporal gauge with interaction, under the assumption of locality discussed in Sec. II, in terms of a Källen–Lehmann representation under the additional condition of rotational and parity invariance. The result shows that *(i)* positivity of the energy spectrum is satisfied by the two point function, but not the relativistic spectral condition, *(ii)* the vacuum is a nonpositive functional on the field algebra, and *(iii)* the Gauss' law constraint does not hold as an operator equation on the physical states and can only be required to hold in expectations on such states.

Proposition 3.5: Let Ω be a state on the local field algebra $\mathcal{F}$ invariant under space–time translations, rotations and parity, whose restriction to the observable field algebra satisfies the standard Wightman axioms for vacuum expectation values. Then the two point function of the gauge potential has the following representation ($y\equiv x'-x$):

$$\begin{aligned}\langle A_i(x)\,A_j(x')\rangle &\equiv \Omega(A_i(x)\,A_j(x'))\\ &= \int d^4k\, e^{iky}\int d\rho(m^2)\left(\delta_{ij}-\frac{k_i\,k_j}{\mathbf{k}^2+m^2}\right)\delta(k^2+m^2)\;\theta(k_0)\\ &\quad+\frac{1}{2}iy_0\left[\partial_i\partial_j\,\mathcal{P}(\Delta)\,\delta(\mathbf{y})+\int d^3k\, e^{-i\mathbf{k}\,\mathbf{y}}\int d\rho(m^2)\,k_ik_j(\mathbf{k}^2+m^2)^{-1}\right]\\ &\quad+\partial_i\partial_j a(\mathbf{x}^2),\end{aligned}\tag{3.11}$$

where $\mathcal{P}$ is a polynomial and $d\rho$ is the spectral measure of the two point function of the electromagnetic field

$$\begin{aligned}\langle F_{\mu\rho}F_{\nu\sigma}\rangle(y)&=(g_{\rho\sigma}\,\partial_\mu\partial_\nu+g_{\mu\nu}\partial_\rho\partial_\sigma-g_{\rho\nu}\partial_\mu\partial_\sigma-g_{\mu\sigma}\partial_\nu\partial_\rho)F(y),\\ \widetilde{F}(k)&=\int d\rho(m^2)\;\delta(k^2+m^2)\,\theta(k_0).\end{aligned}\tag{3.12}$$

The condition of a canonical structure at equal times, apart from renormalization constants, requires

$$\mathcal{P}=\text{const}\equiv Z.$$

The arbitrary function $a(\mathbf{x})$ *can be removed by a time independent operator gauge transformation.*

Such a two point function satisfies the positive energy but not the relativistic spectral condition.

In particular, in the free field case, we have

$$\langle A_i A_j\rangle(y)=(\delta_{ij}-\partial_i\partial_j(\Delta)^{-1})D^+(y)+\tfrac{1}{2}i\,y_0\,\partial_i\partial_j(\Delta)^{-1}\delta(\mathbf{y}). \tag{3.13}$$

Proof: Invariance under space–time translation, rotations and parity implies that the two point function can be written in the form

$$\langle A_i A_j\rangle(x)=\delta_{ij}H(x)+\partial_i\partial_j L(x), \tag{3.14}$$

with H, L rotationally invariant distributions; such a decomposition is unique up to a redefinition $H\to H+h(x_0)$, $L\to L-\frac{1}{2}h(x_0)\mathbf{x}^2$, L being defined up to constants. A comparison between the two point function of the electric field given by Eq. (3.12) and that derived from Eq. (3.14) (using $E_i=\partial_0 A_i$) yields

$$\delta_{ij}\partial_0^2(H-F)+\partial_i\partial_j(F+\partial_0^2 L)=0.$$

Such an equation implies

$$H=F+h(t),\quad \partial_i\partial_j\partial_0^2 L=-\partial_i\partial_j F-\delta_{ij}h(t),$$

and one can use the arbitrariness in the definition of H, L to remove $h(t)$. Hence one can write

$$\partial_i\partial_j L=-(\partial_i\partial_j/\partial_0^2)F+a_{ij}(\mathbf{x})+i\,t\,b_{ij}(\mathbf{x}),$$

since the operator $\partial_i\partial_j/\partial_0^2$ is well defined in momentum space, where it corresponds to multiplication of the spectral measure by the bounded function $k_i k_j(\mathbf{k}^2+m^2)^{-1}$; furthermore, by taking the curl one gets $a_{ij}(\mathbf{x})=\partial_i\partial_j a(\mathbf{x}^2)$, $b_{ij}(\mathbf{x})=\partial_i\partial_j b(\mathbf{x}^2)$.

Locality of the commutator $\langle[A_i(x),\partial_0 A_j(y)]\rangle$ requires

$$2\tilde{b}(\mathbf{k})=\int d\rho(m^2)(\mathbf{k}^2+m^2)^{-1}+\mathcal{P}(\mathbf{k}^2),$$

and a canonical structure at equal times requires $\mathcal{P}(\mathbf{k}^2)=Z$. The residual gauge invariance of the equations of motion and of the CCRs under time independent operator gauge transformations

$$A_i(x)\to A_i(x)+\partial_i\varphi(\mathbf{x}),\quad \psi(x)\to :e^{ie\varphi}:(\mathbf{x})\,\psi(x)$$

allows us to eliminate the function $a(\mathbf{x}^2)$.

The Fourier transform of the term linear in time has support on the plane $\omega=0$, $\mathbf{k}$ arbitrary, so that the posivitity of the energy spectrum is satisfied, but not the relativistic spectral condition.

In the free field case both $\operatorname{div} A\Psi_0$ and $\operatorname{div} E\Psi_0$ are vectors of zero indefinite product with themselves, briefly of zero norm or null vectors, which however cannot vanish.

As one should *a priori* expect, whenever a state yields a nontrivial representation of a gauge dependent field algebra,[11] the above indefinite states on the field algebra are not gauge invariant. In fact, one has $\Omega(\gamma^\Lambda(A_i))\neq\Omega(A_i)=0$.

Proposition 3.6: In the free case, the states $\beta^\theta * \Omega$, *with* Ω *any quasi-free (indefinite) state defined by Eq. (3.13) are space translationally invariant on the field algebra, but not time translationally invariant. Only their restrictions to the gauge invariant field algebra are time translationally invariant.*

Proof: In fact, $\forall f \in \mathcal{S}(\mathbf{R}^3)$, one has

$$\beta^\theta * \Omega(\alpha_t(A(f))) = \Omega(A(f)) + t \int d^3x\ \theta_i f_i(\mathbf{x})$$

and, if $\operatorname{div} f = 0$, $\int dx\ \theta_i f_i(\mathbf{x}) = -\int dx\ \boldsymbol{\theta}\cdot\mathbf{x} \operatorname{div} f(\mathbf{x}) = 0$.

In conclusion, the space and time translationally invariant θ-states on the observable field algebra do not have regular time translationally invariant extensions to the field algebra (the time invariant extension are nonregular); in this sense they display a mechanism which is crucial for solving the problem arising in the Ward identities of chiral symmetry breaking in quantum chromodynamics.[11,12]

Since the new structures emerging with respect to the standard case are connected with the longitudinal algebra, it is worthwhile to have a better mathematical control on the properties of its GNS representation given by the state Ω of Proposition 3.5, at least in the free case. As mentioned in Sec. II, Eqs. (2.5), the longitudinal algebra can be discussed in terms of the field variables $\operatorname{div} A_l(f_n)$, $\operatorname{div} \dot{A}_l(f_n)$, $f_n \in \mathcal{S}(\mathbf{R}^3)$. The problem is then reduced to the unique ground state (indefinite) representation of the Heisenberg algebra associated to a countable number of free particles. Such GNS representation has been analyzed in Ref. 10 and the result is the following.

Proposition 3.7: In the free case the quasi-free (indefinite) state Ω *defined by Eq. (3.13) is faithful on the longitudinal algebra* $\mathcal{A}_l$ *generated by* $\operatorname{div} A$, $\operatorname{div} E$, *and the commutant of* $\mathcal{A}_l$ *in the corresponding GNS representation is isomorphic to* $\mathcal{A}_l$.

The GNS representation is given as an infinite tensor product of Fock and anti-Fock representations[13,14] *of the canonical variables*

$$Q_{n,\pm} \equiv (q_n \pm p'_n)/\sqrt{2}, \quad P_{n,\pm} \equiv (\pm p_n + q'_n)/\sqrt{2},$$

with

$$q'_n \equiv i S\, q_n\, S, \quad p'_n \equiv -i\, S\, p_n\, S, \quad \forall n,$$

and S *the antiunitary KMS operator defined by*

$$S\, A\, \Psi_0 = A^* \Psi_0, \quad \forall A \in \mathcal{A}_l.$$

Proof: The proof is the same as for a single free particle.[10]

IV. FUNCTIONAL INTEGRAL REPRESENTATION

We start by discussing the functional integral representation of the temporal gauge in the indefinite case with free time evolution.

By analytic continuation to imaginary time the two point correlation function, Eq. (3.13), gives rise to the following Schwinger function,

$$S_{ij}(x-y) = (\delta_{ij} - \Delta^{-1}\, \partial_i\, \partial_j)\, S(x-y) - \partial_i\, \partial_j\, \Delta^{-1}\, \delta(\mathbf{x}-\mathbf{y})\ |x_0 - y_0|/2, \tag{4.1}$$

where S is the standard Schwinger function of a scalar field. The Schwinger function Eq. (4.1) defines an inner product in $\mathcal{S}^3_{\text{real}}(\mathbf{R}^4)$,

$$\langle f, f\rangle = \langle f, f\rangle_{tr} + \langle f, f\rangle_l,$$

$$\langle f, f\rangle_{tr} \equiv \int d^4x\, d^4y\, f_i(x)(\delta_{ij} - \Delta^{-1}\partial_i\partial_j)\, f_j(y)\, S(x-y), \tag{4.2}$$

$$\langle f, \ f\rangle_l \equiv \int d^4x\, d^4y\, \partial f(x)\, \partial f(y)\, \Delta^{-1}\, \delta(\mathbf{x}-\mathbf{y})\, |x_0 - y_0|/2. \tag{4.3}$$

The transverse inner product $\langle ., .\rangle_{tr}$ is semidefinite and therefore it defines a Gaussian integral with measure $d\mu(A^{tr}(\mathbf{x},\tau))$ and a Euclidean Gaussian field $A_i^{tr}(\mathbf{x},\tau)$.

The longitudinal inner product $\langle ., .\rangle_l$ is indefinite but not degenerate on $\mathcal{S}_l(\mathbf{R}^4) \equiv \{h = \partial_i g_i\,,\ g_i \in \mathcal{S}_{\text{real}}(\mathbf{R}^4)\}$. Therefore, the longitudinal inner product defines the two point Schwinger function of a Gaussian vector field $\partial_i\phi(\mathbf{x},\tau)$ with

$$\langle \phi(\mathbf{x},\tau)\ \phi(\mathbf{y},\sigma)\rangle = \Delta^{-1}\delta(\mathbf{x}-\mathbf{y})\, |\tau-\sigma|/2. \tag{4.4}$$

Thus, $\forall f \in \mathcal{S}(\mathbf{R}^3)$, $\phi(f,\tau)$ is the analog of the variable $q(\tau)$ describing the position of a free particle and Eq. (4.4) corresponds to the ground state Euclidean representation of the Heisenberg algebra with free evolution.[10] Following the results of Ref. 10, a functional integral representation is obtained by introducing the random field

$$A_i(\mathbf{x},\tau) = A_i^{tr}(\mathbf{x},\tau) + \partial_i[\ \xi(\mathbf{x},\tau) + z(\mathbf{x}) - \overline{z}(\mathbf{x})|\tau|], \tag{4.5}$$

where $z(\mathbf{x})$ is a complex Gaussian field with the following expectations

$$\langle z(\mathbf{x})\, z(\mathbf{y})\rangle = 0,\ \langle z(\mathbf{x})\, \overline{z}(\mathbf{y})\rangle = -\tfrac{1}{2}\Delta^{-1}\delta(\mathbf{x}-\mathbf{y}),$$

corresponding to $z = z_1 + iz_2,\ z_1, z_2$ independent real Gaussian fields with

$$\langle z_1^2\rangle = \langle z_2^2\rangle = -\Delta^{-1}\delta(\mathbf{x}-\mathbf{y})/4,$$

and $\xi(\mathbf{x},\tau)$ is a real Gaussian field with

$$\langle \xi(\mathbf{x},\tau)\ \xi(\mathbf{y},\sigma)\rangle = -\tfrac{1}{2}\Delta^{-1}\delta(\mathbf{x}-\mathbf{y})\ (-|\tau-\sigma| + |\tau| + |\sigma|).$$

Clearly, the covariance of ξ is a positive kernel, being the product of the positive kernel $-\Delta^{-1}\,\delta$ and of the Wiener kernel. Hence, the Schwinger functions are represented by

$$\langle A_{i_1}(\mathbf{x}_1,\tau_1)\cdots A_{i_n}(\mathbf{x}_n,\tau_n)\rangle = \int d\mu(A^{tr}(\mathbf{x},\tau))\, dw(\xi(\mathbf{x},\tau))\, d\nu(z(\mathbf{x})) \times \prod_{k=1}^{n}\ (A_i^{tr}(\mathbf{x}_k,\tau_k) + \partial_i(\xi(\mathbf{x}_k,\tau_k) + z(\mathbf{x}_k) - \overline{z}(\mathbf{x}_k)|\tau_k|)), \tag{4.6}$$

where $d\mu, d\nu, dw$ are the functional measures defined by the processes introduced above.

In the positive (nonregular) formulation of Sec. III A the construction of a functional integral representation for the Euclidean correlation functions essentially reduces to the case of the Euclidean correlation functions given by the (nonregular) positive ground state of a nonrelativistic particle, discussed in Ref. 10. In fact, the Euclidean correlation functions of exponentials of fields

$$\Omega(e^{iA(f_1,\tau_1)}\cdots e^{iA(f_n,\tau_n)})$$

obtained from Eqs. (3.8)–(3.10) have the same form as in Ref. 10, Eq. (C.2), with α_k replaced by $\partial_i\phi(f_k)$ and vanish unless

$$\partial_i f_1^i(\mathbf{x}) + \cdots + \partial_i f_n^i(\mathbf{x}) = 0. \tag{4.7}$$

If this condition is satisfied, by Proposition 3.3 and Eqs. (4.2) and (4.3) they coincide with the correlation functions of the indefinite case. Moreover, Eq. (4.7) implies that in the exponential the variable z is smeared with a vanishing test function, and the two point function of $\overline{z}$ vanishes. Therefore, as in Ref. 10, the above correlation functions coincide with those of the exponentials of Gaussian fields

$$A_i^{tr}(f^i,\tau)+\xi(-\partial_i f^i,\tau) \tag{4.8}$$

with the measures $d\mu$, dw introduced above in Eq. (4.6).

As for a free particle, the above correlation functions are therefore given by the ergodic mean over the real variables $\Xi(g)$, $\Xi\in\mathcal{S}'_{\text{real}}(\mathbf{R}^3)$ of the correlation functions of exponentials

$$\exp i\,A_i^{tr}(f^i,\tau)\exp -i\,(\xi(\partial_i f^i,\,\tau)+\Xi(\partial_i f^i)) \tag{4.9}$$

and, therefore, by the Riesz–Markov theorem, they can be represented as integrals over the spectrum Σ of the C^*-algebra generated by $\exp i\,\Xi(g)$, $g\in\mathcal{S}_{\text{real}}(\mathbf{R}^3)$. Σ is the generalization of the spectrum of the Bohr algebra,[15] generated by $\exp i\alpha x$, $x\in\mathbf{R}$, with Ξ corresponding to x and g to α.

In conclusion,

$$\Omega(e^{iA(f_1,\tau_1)}\cdots e^{iA(f_n,\tau_n)})=\int d\mu\,(A^{tr}(\mathbf{x},\tau))\,dw\,(\xi(\mathbf{x},\tau))$$
$$\times\int d\nu_\Sigma(\Xi(g))\prod_{s=1}^{n} e^{i\,A_i^{tr}(f_j^i,\tau_j)}\,e^{-i\,\xi(\partial_i f_j^i,\tau_j)}\,e^{-i\,\Xi(\partial_i f_j^i)}$$

with $d\nu_\Sigma$ the measure on Σ representing the ergodic mean in all the variables $\Xi(g)$;[10] the integral vanishes if Eq. (4.7) does not hold and otherwise coincides with the expectation of a product of exponentials of fields of the form (4.8).

(Received 27 November 2001; accepted 21 July 2003)

The extension of the Campbell–Magaard embedding theorem to general relativity with minimally coupled scalar fields is formulated and proven. The result is applied to the case of a self-interacting scalar field for which new embeddings are found, and to Brans–Dicke theory. The relationship between the Campbell–Magaard theorem and the General Relativity Cauchy and initial value problems is outlined. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1610237]

I. INTRODUCTION

There is currently a high level of interest in higher dimensional theories of gravity, motivated in part by recent developments in both string theory and early universe cosmology. There is a growing body of evidence[1] supporting the conjecture that the five perturbative, 10D string theories may correspond to different limiting cases of a more fundamental, nonperturbative, 11D ''M theory,'' which reduces to 11D supergravity in the infrared limit. (For recent reviews, see, e.g., Ref. 2.) Inspired by these advances, the proposal that our observable universe may be regarded as a domain wall or ''brane'' that is embedded in a higher-dimensional space–time has recently become popular in early universe cosmology.[3–6] In the braneworld scenario, the backreaction of the brane results in a higher-dimensional geometry that is nonfactorizable. Consequently this scenario is clearly distinct from the standard Kaluza–Klein compactification scheme. Indeed, in the five-dimensional Randall–Sundrum models, the extra dimension need not be compact.[6]

An important question that arises in such braneworld scenarios is the relationship between the geometry of the apparent, lower-dimensional world and that of the embedding, higher-dimensional space–time. It is therefore important, in view of the above discussion, to develop embedding theorems that enable such questions to be concretely addressed (for an overview and extensive bibliography, see Ref. 7). An important theorem is due to Campbell and Magaard (CM)[8,9] and states that any n-dimensional, (semi-)Riemannian manifold (M^n,g) can be locally and isometrically embedded in an $(n+1)$-dimensional manifold $(N^{n+1},\tilde{g})$, where the Ricci curvature of N^{n+1} vanishes.[8,9] The theorem was suggested by Campbell[8] and a proof was later offered by Magaard.[9] The theorem has been discussed in a number of contexts in the literature.[10–19]

Recently, we showed[16,17] how to extend this theorem to the class of embeddings where $(N^{n+1},\tilde{g})$ is an Einstein space, with a nonzero Ricci tensor that is directly proportional to the metric, $\tilde{g}$. Specific classes of embeddings, such as those of Einstein spaces within Einstein spaces, were established.[16]

a)Electronic mail: j.e.lidsey@qmul.ac.uk

Einstein spaces can be viewed as solutions to General Relativity (GR), where the Ricci curvature is generated by a particular source—the cosmological constant. A natural question to address is whether further extensions of the CM theorem are possible and, in particular, to investigate embeddings in spaces that are sourced by dynamical matter fields. One of the simplest models for matter is a scalar field. In this paper, we extend the CM analysis to include a minimally coupled scalar field with a general potential energy arising through its self-interactions, and for Brans–Dicke theory.[20]

The paper is organized as follows. In Sec. II we extend the CM theorem to spaces sourced by a scalar field, identifying the mathematical conditions that must be satisfied by such a field in order for the embedding of a given manifold to be possible in principle. In Sec. III A, it is shown that minimally coupled, self-interacting scalar fields satisfy these conditions. Examples of such embeddings are given in Sec. III B. The Brans–Dicke field is then considered in Sec. III C. We then outline the clarifying relation between the CM theorem and the GR Cauchy[21–23] and initial value[24–26] problems in Sec. IV. We conclude in Sec. V.

II. CAMPBELL–MAGAARD THEOREM WITH SCALAR FIELD

The proof of the Campbell–Magaard (CM) theorem[8–10] and of its extension to the case when the embedding manifold is an Einstein space[16,17] follows a scheme similar to the methods employed when investigating the GR Cauchy problem, i.e., once the initial conditions for the metric in a three-dimensional hypersurface are given, one would like to know whether the Einstein field equations (EFEs) with a nontrivial source admit a unique solution.

In GR, the space–time metric is determined by the Einstein equations

$$G_{\mu\nu} = -\kappa T_{\mu\nu}, \tag{1}$$

where κ is the Einstein constant and $T_{\mu\nu}$ is the energy–momentum tensor, which is a function of the matter fields and the metric. We consider a scalar field $\overline{\chi}$ defined in a semi-Riemannian manifold $(N^{n+1}, \tilde{g}_{\alpha\beta})$. (In this paper, Latin and Greek indices run from 1 to n and from 1 to $n+1$, respectively.) We assume that the energy–momentum tensor of this field is an analytic function of the field $\overline{\chi}$, its first derivatives, and the metric tensor $\tilde{g}_{\alpha\beta}$:

$$\tilde{T}_{\mu\nu} = \tilde{T}_{\mu\nu}\left(\overline{\chi}, \frac{\partial\overline{\chi}}{\partial x^{\alpha}}, \tilde{g}_{\alpha\beta}\right). \tag{2}$$

Let us choose a coordinate system in which the metric $\tilde{g}_{\alpha\beta}$ has the line element

$$ds^2 = \overline{g}_{ik}\, dx^i\, dx^k + \varepsilon\, \overline{\phi}^2\, dy^2, \tag{3}$$

where $y = x^{n+1}$, $\overline{\phi} = \overline{\phi}(x^1, \ldots, x^n, y)$, $\overline{g}_{ik} = \overline{g}_{ik}(x^1, \ldots, x^n, y)$ and $\varepsilon = \pm 1$.

We suppose that the evolution of $\overline{\chi}$ is governed by a second-order p.d.e. which may be written in the form

$$\frac{\partial^2\overline{\chi}}{\partial y^2} = P\left(\overline{\chi}, \frac{\partial\overline{\chi}}{\partial x^i}, \frac{\partial\overline{\chi}}{\partial y}, \overline{g}_{\alpha\beta}, \frac{\partial\overline{g}_{\alpha\beta}}{\partial x^i}, \frac{\partial\overline{g}_{\alpha\beta}}{\partial y}, \frac{\partial^2\overline{\chi}}{\partial x^i \partial x^k}\right), \tag{4}$$

where P is analytic with respect to each of its arguments. We also make the physically reasonable assumption of energy–momentum conservation:

$$\tilde{\nabla}_{\mu}\tilde{T}^{\mu\nu} = 0, \tag{5}$$

where $\tilde{\nabla}_{\mu}$ is the covariant derivative with respect to $\tilde{g}_{\mu\nu}$.

We now claim that if conditions (2), (4), and (5) hold, it is possible to locally embed any n-dimensional, (semi-)Riemannian manifold (M^n,g) in an $(n+1)$-dimensional space sourced by the scalar field $\overline{\chi}$.

In the coordinates (3), the EFEs take the form

$$\tilde{R}_{ik}=\overline{R}_{ik}+\varepsilon\overline{g}^{jm}(\overline{\Omega}_{ik}\overline{\Omega}_{jm}-2\overline{\Omega}_{jk}\overline{\Omega}_{im})-\frac{\varepsilon}{\overline{\phi}}\frac{\partial\overline{\Omega}_{ik}}{\partial y}+\frac{1}{\overline{\phi}}\overline{\nabla}_i\overline{\nabla}_k\overline{\phi}=-\kappa\left(\tilde{T}_{ik}-\frac{1}{n-1}g_{ik}\tilde{T}\right), \quad (6)$$

$$\tilde{R}^y_i=\frac{\varepsilon}{\overline{\phi}}\overline{g}^{jk}(\overline{\nabla}_j\overline{\Omega}_{ik}-\overline{\nabla}_i\overline{\Omega}_{jk})=-\kappa\tilde{T}^y_i\,, \quad (7)$$

$$\tilde{G}^y_y=-\tfrac{1}{2}\overline{g}^{ik}\overline{g}^{jm}(\overline{R}_{ijkm}+\varepsilon(\overline{\Omega}_{ik}\overline{\Omega}_{jm}-\overline{\Omega}_{jk}\overline{\Omega}_{im}))=-\kappa\tilde{T}^y_y\,, \quad (8)$$

where

$$\overline{\Omega}_{ik}=-\frac{1}{2\overline{\phi}}\frac{\partial\overline{g}_{ik}}{\partial y} \quad (9)$$

and the barred terms are calculated with the metric $\overline{g}_{ik}$ induced on the hypersurface Σ_c of constant $y=c$.

We now state the following lemma:

Lemma 1: Let the functions $\overline{g}_{ik}(x^1,\ldots,x^n,y)$, $\overline{\phi}(x^1,\ldots,x^n,y)$ *and* $\overline{\chi}(x^1,\ldots,x^n,y)$ *be analytic at* $(0,\ldots,0)\in\Sigma_0\subset\Re^{n+1}$. *Assume that the following conditions hold:*

(i) $\overline{g}_{ik}=\overline{g}_{ki}$;

(ii) $\det(\overline{g}_{ik})\neq 0$;

(iii) $\overline{\phi}\neq 0$.

Assume further that $\overline{g}_{ik}$ *and* $\overline{\chi}$ *satisfy Eqs. (4) and (6) in the open set* $U\subset\Re^{n+1}$ *which contains* $0\in\Re^{n+1}$ *and (7) and (8) at* Σ_0. *Then,* $\overline{g}_{ik}$, $\overline{\phi}$, *and* $\overline{\chi}$ *satisfy (7) and (8) in a neighborhood of* $0\in\Re^{n+1}$.

Proof: The key point of the proof is given by (5). First, let us define the tensor $\tilde{F}_{\alpha\beta}=\tilde{G}_{\alpha\beta}+\kappa\tilde{T}_{\alpha\beta}$. By assumption, $\overline{\chi}$ satisfies (4) in a neighborhood $V\subset\Re^{n+1}$ of $0\in\Re^{n+1}$, whence (5) also holds in V. It then follows that $\tilde{F}_{\alpha\beta}$ has vanishing divergence, so

$$\frac{\partial\tilde{F}^y_\beta}{\partial y}=-\frac{\partial\tilde{F}^i_\beta}{\partial x^i}-\tilde{\Gamma}^\mu_{\mu\lambda}\tilde{F}^\lambda_\beta+\tilde{\Gamma}^\mu_{\lambda\beta}\tilde{F}^\lambda_\mu\,.$$

On the other hand, by expressing the Einstein tensor in terms of the Ricci tensor, we can write

$$\tilde{F}^i_k=\tilde{R}^i_k-\delta^i_k(\tilde{R}^j_j+\tilde{G}^y_y)+\kappa\tilde{T}^i_k\,.$$

Again, by assumption,

$$\tilde{R}^i_k=-\kappa\left[\tilde{T}^i_k-\frac{\delta^i_j}{n-1}(\tilde{T}^j_j+\tilde{T}^y_y)\right]$$

holds in $V\subset\Re^{n+1}$ and it then follows that $\tilde{F}^i_k=-\delta^i_k\tilde{F}^y_y$ in V. After some algebra we may then deduce that

$$\frac{\partial\tilde{F}^y_y}{\partial y}=-\varepsilon\overline{\phi}^2\overline{g}^{ij}\frac{\partial\tilde{F}^y_i}{\partial x^j}-2\tilde{\Gamma}^i_{iy}\tilde{F}^y_y+\left(-\varepsilon\frac{\partial(\overline{\phi}^2\overline{g}^{ij})}{\partial y^j}-\varepsilon\overline{\phi}^2\overline{g}^{ij}\tilde{\Gamma}^k_{kj}+\tilde{\Gamma}^i_{yy}\right)\tilde{F}^y_i\,,$$

$$\frac{\partial \tilde{F}^y_i}{\partial y} = \frac{\partial \tilde{F}^y_y}{\partial x^i} + 2\tilde{\Gamma}^y_{yi}\tilde{F}^y_y + (\tilde{\Gamma}^k_{yi} + \varepsilon\overline{\phi}^2\overline{g}^{kj}\tilde{\Gamma}^y_{ij} - \tilde{\Gamma}^\mu_{y\mu}\delta^k_i)\tilde{F}^y_k$$

and since (7) and (8) hold at the hypersurface Σ_0, it follows that $\tilde{F}^y_\beta = 0$ and hence that $\partial\tilde{F}^y_\beta/\partial y|_{y=0} = 0$.

It is not difficult to show by mathematical induction that all the derivatives of $\tilde{F}^y_\beta$ (to any order) vanish at $y=0$. As $\tilde{F}^y_\beta$ is analytic, we may therefore conclude that $\tilde{F}^y_\beta = 0$ in an open set of $\Re^{n+1}$. Thus, (7) and (8) also hold in an open set of $\Re^{n+1}$ which includes the origin and this proves the lemma. □

To proceed, we must now establish that the solutions $\overline{g}_{ik}$, $\overline{\phi}$, and $\overline{\chi}$ do indeed exist. With this in mind, let us now recall the Cauchy–Kowalewski (CK) theorem:[27]

Theorem [Cauchy–Kowalewski]: *Consider the set of partial differential equations*

$$\frac{\partial^2 u^A}{\partial (y^{n+1})^2} = F^A\left(y^\alpha, u^B, \frac{\partial u^B}{\partial y^\alpha}, \frac{\partial^2 u^B}{\partial y^\alpha \partial y^i}, \right), \quad A = 1, \ldots, m, \tag{10}$$

where $u^1, .., u^m$ *are* m *unknown functions of the* $n+1$ *variables* $y^1, \ldots, y^n, y^{n+1}$, $\alpha = 1, \ldots, n+1$, $i = 1, \ldots, n$, $B = 1, \ldots, m$. *Also, let* $\xi^1, \ldots, \xi^m, \eta^1, \ldots, \eta^m$, *be functions of the variables* $y^1, \ldots, y^n$, *and be analytic at* $0 \in \Re^n$. *If the functions* F^A *are analytic with respect to each of their arguments around the values evaluated at the point* $y^1 = \cdots = y^n = 0$, *there exists a unique solution of Eq. (10) which is analytic at* $0 \in \Re^{n+1}$ *and that satisfies the initial conditions*

$$u^A(y^1, \ldots, y^n, 0) = \xi^A(y^1, \ldots, y^n), \tag{11}$$

$$\frac{\partial u^A}{\partial y^{n+1}}(y^1, \ldots, y^n, 0) = \eta^A(y^1, \ldots, y^n), \quad A = 1, \ldots, m. \tag{12}$$

After solving (6) for the second-order derivative of $\overline{g}_{ik}$ with respect to y we find that

$$\frac{\partial^2 \overline{g}_{ik}}{\partial y^2} = -2\varepsilon\kappa\overline{\phi}^2\left(T_{ik} - \frac{1}{n-1}g_{ik}T\right) + \frac{1}{\overline{\phi}}\frac{\partial\overline{\phi}}{\partial y}\frac{\partial\overline{g}_{ik}}{\partial y}$$
$$- \frac{1}{2}\overline{g}^{jm}\left(\frac{\partial\overline{g}_{ik}}{\partial y}\frac{\partial\overline{g}_{jm}}{\partial y} - 2\frac{\partial\overline{g}_{im}}{\partial y}\frac{\partial\overline{g}_{jk}}{\partial y}\right) - 2\varepsilon\overline{\phi}\left(\frac{\partial^2\overline{\phi}}{\partial x^i \partial x^k} - \frac{\partial\overline{\phi}}{\partial x^j}\overline{\Gamma}^j_{ik}\right) - 2\varepsilon\overline{\phi}^2\overline{R}_{ik}. \tag{13}$$

Due to the symmetry of the tensors, $\overline{g}_{ik}$ and T_{ik}, we can rewrite (13) in terms of the components of g_{ik} with $i \leqslant k$. This equation, together with the field equation (4), form a set of $1 + n(n+1)/2$ p.d.e's for the $1 + n(n+1)/2$ unknown functions, $\overline{g}_{ik}$ $(i \leqslant k)$ and $\overline{\chi}$. (Note that $\overline{\phi}$ is a nonzero analytic function that is treated as a known.)

Thus, the p.d.e. system we have just obtained has the canonical form of (10) and, moreover, it satisfies all of the conditions required for the use of the CK theorem. Indeed, by virtue of the properties (2) and (4) imposed on $T_{\alpha\beta}$ and P, the right-hand side of the equations is comprised of functions of the variables

$$x^1, \ldots, x^n, y; \overline{g}_{ik}, \overline{\chi}, \frac{\partial\overline{g}_{ik}}{\partial x^j}, \frac{\partial\overline{g}_{ik}}{\partial y}, \frac{\partial\overline{\chi}}{\partial x^j}, \frac{\partial\overline{\chi}}{\partial y}; \frac{\partial^2\overline{g}_{ik}}{\partial x^j \partial x^m}, \frac{\partial^2\overline{\chi}}{\partial x^j \partial x^m},$$

which are analytic with respect to each of their arguments at

$$x^1 = 0, \ldots, x^n = 0, y = 0; \overline{g}_{ik}|_0, \overline{\chi}|_0, \left.\frac{\partial\overline{g}_{ik}}{\partial x^j}\right|_0, \left.\frac{\partial\overline{g}_{ik}}{\partial y}\right|_0, \left.\frac{\partial\overline{\chi}}{\partial x^j}\right|_0, \left.\frac{\partial\overline{\chi}}{\partial y}\right|_0; \left.\frac{\partial^2\overline{g}_{ik}}{\partial x^j \partial x^m}\right|_0, \left.\frac{\partial^2\overline{\chi}}{\partial x^j \partial x^m}\right|_0,$$

if $|\overline{g}_{ik}|_0 \neq 0$. Therefore, given analytic initial conditions

$$\overline{g}_{ik}(x^1,\ldots,x^n,0)=g_{ik}(x^1,\ldots,x^n), \quad \frac{\partial \overline{g}_{ik}}{\partial y}(x^1,\ldots,x^n,0)=\overline{\phi}(x^1,\ldots,x^n,0)\Omega_{ik}(x^1,\ldots,x^n),$$

$$\overline{\chi}(x^1,\ldots,x^n,0)=\xi(x^1,\ldots,x^n), \quad \frac{\partial \overline{\chi}}{\partial y}(x^1,\ldots,x^n,0)=\eta(x^1,\ldots,x^n), \tag{14}$$

which satisfy $|g_{ik}| \neq 0$, there exists a unique set of functions $\overline{g}_{ik}$ and $\overline{\chi}$ which solve Eqs. (4) and (6) which are analytic at the origin. It should be noted that an important feature of these solutions is the property $|\overline{g}_{ik}| \neq 0$ in some neighborhood of $0 \in \mathfrak{R}^{n+1}$.

If we take the initial conditions g_{ik} as being the metric components of a (semi-)Riemannian space M^n written in some coordinate system, then we can state the following theorem:

Theorem 1: *Let M^n be an n-dimensional, semi-Riemaninan manifold with metric given by $ds^2=g_{ik}dx^i dx^k$, in a coordinate system $\{x^i\}$ of M^n. Let $p \in M^n$ have coordinates $x_p^1=\cdots=x_p^n=0$. Then M^n has a local isometric and analytic embedding (at the point p) in an $(n+1)$-dimensional space sourced by any arbitrary scalar field $\overline{\chi}$ that is characterized by the properties (2), (4), and (5) iff there exist functions $\Omega_{ik}(x^1,\ldots,x^n)$ $(i,k=1,...,n)$, $\xi(x^1,\ldots,x^n)$, $\eta(x^1,\ldots,x^n)$ and $\phi(x^1,\ldots,x^n) \neq 0$ that are analytic at $0 \in \mathfrak{R}^n$ such that*

$$\Omega_{ik}=\Omega_{ki}, \tag{15}$$

$$g^{jk}(\nabla_j \Omega_{ik}-\nabla_i \Omega_{jk})=-\varepsilon \kappa \phi T_i^y(\xi,\eta,g_{ij}), \tag{16}$$

$$g^{ik}g^{jm}(R_{ijkm}+\varepsilon(\Omega_{ik}\Omega_{jm}-\Omega_{jk}\Omega_{im}))=2\kappa T_y^y(\xi,\eta,g_{ij}). \tag{17}$$

Proof: ($\Rightarrow$) If M^n has an embedding in some arbitrary space sourced by a scalar field, then it can be proved[17,28] that there exists a coordinate system in which the metric of the embedding space has the form $ds^2=\overline{g}_{ik}dx^i dx^k+\varepsilon \overline{\phi}^2 dy^2$, where the analytic functions $\overline{g}_{ik}(x^1,\ldots,x^n,y)$ and $\overline{\phi}(x^1,\ldots,x^n,y)$ are such that $\overline{\phi}(x^1,\ldots,x^n,y) \neq 0$ and $\overline{g}_{ik}(x^1,\ldots,x^n,0)=g_{ik}(x^1,\ldots,x^n)$ in an open set of $\mathfrak{R}^n$ which contains the origin. Given that the embedding space is, by assumption, generated by a scalar field $\overline{\chi}$, it follows that $\overline{g}_{ik}$ and $\overline{\phi}$ necessarily satisfy Eqs. (4), (6), and (8) for some field $\overline{\chi}(x^1,\ldots,x^n,y)$ in a neighborhood of $0 \in \mathfrak{R}^{n+1}$. In particular, Eqs. (7) and (8) hold for $y=0$. Therefore, the functions $\Omega_{ik}(x^1,\ldots,x^n)$ $(i,k=1,...,n)$, $\xi(x^1,\ldots,x^n)$, $\eta(x^1,\ldots,x^n)$ and $\phi(x^1,\ldots,x^n)$, as defined by

$$\Omega_{ik}=\overline{\Omega}_{ik}(x^1,\ldots,x^n,0), \quad \xi=\overline{\chi}(x^1,\ldots,x^n,0)\,\eta=\left.\frac{\partial \overline{\chi}}{\partial y}\right|_{y=0}, \quad \phi(x^1,\ldots,x^n)=\overline{\phi}(x^1,\ldots,x^n,0) \tag{18}$$

satisfy Eqs. (15), (16) and (17).

($\Leftarrow$) Suppose that there exist functions $\Omega_{ik}(x^1,\ldots,x^n)$, $\xi(x^1,\ldots,x^n)$, $\eta(x^1,\ldots,x^n)$ and $\phi(x^1,\ldots,x^n) \neq 0$ which satisfy (15), (16), and (17). Choose an analytic function given by $\overline{\phi}(x^1,\ldots,x^n,y) \neq 0$ such that $\overline{\phi}(x^1,\ldots,x^n,0)=\phi(x^1,\ldots,x^n)$. By virtue of the CK theorem, there exists a unique set of analytic functions $\overline{g}_{ik}(x^1,\ldots,x^n,y)$ and $\overline{\chi}(x^1,\ldots,x^n,y)$ that satisfy Eqs. (4) and (6) and the initial conditions (14). Since, by assumption, the initial conditions satisfy Eqs. (15), (16), and (17), Eqs. (7) and (8) are satisfied at $y=0$ by $\overline{g}_{ik}$, $\overline{\phi}$ and $\overline{\chi}$. It follows from Lemma 1 that $\overline{g}_{ik}$, $\overline{\phi}$, and $\overline{\chi}$ also satisfy Eqs. (4), (6), and (8) in an open set of $\mathfrak{R}^{n+1}$ which contains the origin. We conclude, therefore, that the $(n+1)$-dimensional manifold whose line element (3) is expressed in terms of the solutions $\overline{g}_{ik}$ and $\overline{\phi}$ is a space generated by a scalar field. Thus, the (semi-)Riemannian manifold (M^n,g) can indeed be embedded in a space sourced by a scalar field. □

According to Theorem 1, the existence of solutions to Eqs. (15)–(17) is sufficient to ensure that the local, analytic embedding of M^n is possible. The proof that these solutions do in fact exist consists in showing that Eqs. (15)–(17) can be expressed in the canonical form required by the CK theorem (here in its first-derivative version). This can be done by following the method presented in Ref. 10 with no significant modifications, and so we omit the details here. The idea is to use (17) to isolate Ω_{11} which is then substituted into (16) which is to be regarded as a system of p.d.e.'s for n unknown functions: the $n-1$ Ω_{1k} for $k\geqslant 2$ and one other component of Ω, which we call Θ. These p.d.e.'s are in the correct canonical form to employ the CK theorem. Thus, if the analytic functions g_{ik} are given, there exist analytic functions Ω_{ik} which solve Eqs. (15)–(17) and this leads us to the following theorem:

Theorem 2: *Let M^n $(n>1)$ be a piece of a (semi-)Riemannian space with line element $\mathrm{d}s^2=g_{ik}\mathrm{d}x^i\mathrm{d}x^k$, expressed in a coordinate system which covers a neighborhood of a point $p\in M^n$ whose coordinates are $x_p^1=\cdots=x_p^n=0$. If g_{ik} are analytic functions at $0\in\Re^n$, then M^n can be embedded at p in some $(n+1)$-dimensional space sourced by any arbitrary scalar field satisfying conditions (2), (4), and (5). Moreover, the line element of the embedding space is unique if the arbitrary functions to be chosen obey the following conditions:*

(i) *the $[n(n-1)/2]-1$ functions Ω_{ik} $(i\leqslant k, i>1$, and excluding the component $\Theta)$ are analytic at $0\in\Re^n$;*

(ii) *the n functions $\Omega_{1k}(0,x^2,\ldots,x^n)=f_k(x^2,\ldots,x^n)$ $(k>1)$ and $\Theta(0,x^2,\ldots,x^n)=f_1(x^2,\ldots,x^n)$ are analytic at $0\in\Re^{n-1}$, with the coefficient of Ω_{11} in (17) nonzero (to permit the elimination of Ω_{11} in order to set up the p.d.e. system),*

(iii) *a function $\phi(x^1,\ldots,x^{n+1})\neq 0$, analytic at $0\in\Re^{n+1}$, is chosen;*

(iv) *two functions $\xi(x^1,\ldots,x^n)$ and $\eta(x^1,\ldots,x^n)$, analytic at $0\in\Re^n$, are chosen.*

Note that when we refer to a space generated by a scalar field we have in mind a nontrivial solution of the Einstein-scalar system. In other words, we are implicitly considering a solution such that the associated energy–momentum tensor is nonzero. The exclusion of trivial solutions is possible because the initial conditions of the field (the functions ξ and η) are arbitrary and this implies that they can be chosen in such a way that $T_{\alpha\beta}\neq 0$ at Σ_0 (for some α and β). Consequently, continuity requirements imply that the energy–momentum tensor does not vanish in some neighborhood of $0\in\Re^{n+1}$.

We proceed in Sec. III to employ this theorem to establish specific classes of embeddings.

III. APPLICATIONS

A. Self-interacting scalar fields

In this section we consider a real scalar field, χ, minimally coupled to Einstein gravity and self-interacting through a potential, $W(\chi)$. We assume that the potential is a well-behaved, analytic function of the field. The energy–momentum tensor of such a field is given by

$$T_{\alpha\beta}=\nabla_\alpha\chi\nabla_\beta\chi-\tfrac{1}{2}g_{\alpha\beta}(\nabla^\gamma\chi\nabla_\gamma\chi)-g_{\alpha\beta}W(\chi). \tag{19}$$

It easily follows that the energy–momentum tensor (19) has vanishing divergence if χ solves the field equation

$$\nabla^\alpha\nabla_\alpha\chi-\frac{\mathrm{d}W}{\mathrm{d}\chi}=0. \tag{20}$$

In the coordinate system (3) the field equation (20) takes the form of Eq. (4) with

$$P=\varepsilon\phi^2\left(-g^{ik}\frac{\partial^2\chi}{\partial x^i\partial x^k}-g^{\alpha\beta}\Gamma^\gamma_{\alpha\beta}\frac{\partial\chi}{\partial x^\gamma}+\frac{\mathrm{d}W}{\mathrm{d}\chi}\right). \tag{21}$$

Note that the function P, which depends on χ, $\partial\chi/\partial x^i$, $\partial\chi/\partial y$, $g_{\alpha\beta}$, $\partial g_{\alpha\beta}/\partial x^i$, $\partial g_{\alpha\beta}/\partial y$, and $\partial^2\chi/\partial x^i\partial x^k$, is analytic with respect to each of these arguments.

Since conditions (2), (4), and (5) are satisfied by a minimally coupled, self-interacting scalar field, we may conclude the following:

Corollary 1: Let $M^n(n>1)$ *be a piece of a (semi-)Riemannian space with line element* $\mathrm{d}s^2=g_{ik}\mathrm{d}x^i\mathrm{d}x^k$, *expressed in a coordinate system which covers a neighborhood of a point* $p\in M^n$ *whose coordinates are* $x_p^1=\cdots=x_p^n=0$. *If* g_{ik} *are analytic functions at* $0\in\Re^n$, *then* M^n *can be embedded at* p *in some* $(n+1)$*-dimensional space generated by any arbitrary, minimally coupled, self-interacting scalar field.*

Note that M^n is truly Riemannian for $\varepsilon=-1$ and semi-Riemannian for $\varepsilon=+1$.

B. Examples of embeddings with self-interacting scalar fields

We now employ this result to construct embeddings for a class of space–times into higher-dimensional space–times sourced by such a scalar field. We begin with the ansatz

$$\overline{\Omega}_{ij}=C\overline{g}_{ij}, \tag{22}$$

where $C=C(x^\alpha)$ is a scalar function of the coordinates of the embedding metric. We further assume that the scalar field is independent of the embedded metric coordinates, i.e., $\chi=\chi(y)$, and specify $\kappa=1$ and $\varepsilon=1$ for simplicity.

Substituting (22) into (16) implies that $\nabla_i C=0$ and, consequently, that C must be a function of the extra coordinate y alone. Choosing the normal coordinate form for ϕ:

$$\phi=1, \tag{23}$$

then implies that (9) can be integrated to yield the solution

$$\overline{g}_{ij}=a^2(y)g_{ij}, \tag{24}$$

where $C\equiv-\mathrm{d}\ln a/\mathrm{d}y$.

When (22) and (23) are valid, the scalar field equation (20) simplifies to

$$\frac{\mathrm{d}^2\chi}{\mathrm{d}y^2}+\frac{n}{a}\frac{\mathrm{d}a}{\mathrm{d}y}\frac{\mathrm{d}\chi}{\mathrm{d}y}-\frac{\mathrm{d}V}{\mathrm{d}\chi}=0 \tag{25}$$

and by substituting the appropriate components of the energy–momentum tensor (19) into (6) and (8), we find that

$$\overline{R}_{ik}+\overline{\Omega}\overline{\Omega}_{ik}-2\overline{\Omega}_{im}\overline{\Omega}_k^m-\frac{\partial\overline{\Omega}_{ik}}{\partial y}=-\frac{2V}{n-1}\overline{g}_{ik}, \tag{26}$$

$$\overline{R}+\overline{\Omega}^2-\overline{\Omega}_j^i\overline{\Omega}_i^j=\left(\frac{d\chi}{dy}\right)^2-2V. \tag{27}$$

Furthermore, subtracting (27) from the trace of (26) and substituting for the ansatz (22) implies that

$$\frac{n}{a}\frac{\mathrm{d}^2a}{\mathrm{d}y^2}=-\left(\frac{\mathrm{d}\chi}{\mathrm{d}y}\right)^2-\frac{2V}{n-1}. \tag{28}$$

We may solve (28) and (25) for an unknown self-interaction potential, by specifying the functional forms of $a(y)$ and $\chi(y)$:

$$a\equiv(1+\lambda y)^p, \tag{29}$$

$$\chi \equiv q \ln(1+\lambda y), \tag{30}$$

where p, q, and λ are constants. Substituting (29) and (30) into (28) implies that this is consistent if the scalar field potential has an exponential (Liouville) form:

$$V = -\lambda^2\left(\frac{n-1}{2}\right)[np(p-1)+q^2]\exp\left(-\frac{2}{q}\chi\right), \tag{31}$$

and it then follows that the scalar field equation (25) is solved if

$$(p-1)[q^2-p(n-1)]=0. \tag{32}$$

Thus, the embedding is established by solving (26) for the two cases, where $q^2=p(n-1)$ or $p=1$. In the first case, substituting for (29)–(31) implies that the embedding metric, g_{ij}, must have vanishing Ricci tensor. We conclude, therefore, that there is an embedding of n-D Ricci-flat manifolds with metric g_{ij}, in an $(n+1)$-D manifold sourced by a scalar field, with metric given by

$$ds^2=(1+\lambda y)^p g_{ik}dx^i dx^k + dy^2, \tag{33}$$

where the scalar field (30) self-interacts through the exponential potential (31). This generalizes the 4D result of Ref. 29 to arbitrary dimension.

In the second case, where $p=1$, the above-mentioned procedure implies that (26) is solved if

$$R_{ik}=\frac{(q^2-n+1)\lambda^2}{(1+\lambda y)^2}g_{ik} \tag{34}$$

and it follows that the embedded metric is an Einstein space with a nonzero Ricci curvature. The sign and magnitude of the effective cosmological constant of the embedded manifold determine the self-interaction coupling, q, of the scalar field. Indeed, the potential (31) is negative-definite for this embedding. An embedding of this type has been considered within the context of dilatonic braneworld scenarios.[30] It is interesting that the functional form of the potential (31) is the same for the two different classes of embedding. Moreover, potentials of this form arise in compactified supergravity theories.[31]

The above-given embeddings are specific in the sense that for the assumed form of Ω_{ik} given in (22), the embedding is only consistent if the scalar field has an exponential potential. However, Corollary 1 states that an embedding is possible for any analytic potential. This would require some other form for Ω_{ik} to be chosen.

C. Brans–Dicke theory

The Brans–Dicke theory of gravity[20] represents a natural extension of GR, where a nonminimally coupled (''dilatonic'') scalar field parametrizes the space–time dependence of Newton's ''constant.'' Nevertheless, it is well known that this theory is conformally equivalent to GR with a minimally coupled scalar field. Therefore, the following corollary to the above-mentioned theorems is deduced if one is prepared to work within the context of the conformally transformed fields.

Corollary 2: Let $M^n(n>1)$ *be a piece of a (semi-)Riemannian space with line element* $ds^2=g_{ik}dx^i dx^k$, *expressed in a coordinate system which covers a neighborhood of a point* $p\in M^n$ *whose coordinates are* $x_p^1=\cdots=x_p^n=0$. *If* g_{ik} *are analytic functions at* $0\in\Re^n$, *then* M^n *can be embedded at* p *in some* $(n+1)$*-dimensional space which is a solution of the vacuum, Brans–Dicke field equations.*

IV. CAMPBELL–MAGAARD AND THE GR CAUCHY AND INITIAL VALUE PROBLEMS

In Sec. II, we referred to the close relationship between the CM theorem and the GR Cauchy and initial value problems (CP and IVP, respectively). There is a wealth of literature on the latter problems within the context of $(3,0)\rightarrow(3,1)$ embeddings [we denote by (p,q) a manifold with p spacelike and q timelike coordinates], which makes it a valuable source of ideas for embedding theorems. The first idea is to show how the CM theorem follows from a collection of known results. The second idea will be to question whether any of the dimension- or signature-dependent results of the GR CP have useful generalizations. This will lead to possible limitations of the usual methods of constructing higher-dimensional solutions from lower-dimensional ones. We begin by outlining the GR CP and IVP.

By use of the $(3+1)$ split of the space–time line element (here, N is the lapse, N^i is the shift, and h_{ij} is the induced 3-metric)

$$ds^2 = h_{ij}(N\,dx^i + N^i dt)(N\,dx^j + N^j\,dt) - (N\,dt)^2, \tag{35}$$

the ten EFEs may be rewritten as six evolution equations and the four Gauss–Codazzi constraints. The mathematics of this split is the same, up to the signature, as that of splitting the EFEs into Eq. (6) and into Eqs. (7) and (8), if one identifies the lapse to be ϕ and imposes the partial gauge condition that the shift be zero. The GR CP is then the study of the evolution equations given some initial data that obeys the constraints.

It is standard knowledge[21,22] that these evolution equations can be written in the correct form required by the CK theorem, and so we are guaranteed that a solution exists locally and that it is unique. Whereas self-consistency requires the evolution equations to propagate the constraints off the initial hypersurface, it is immediately evident that this follows from the Bianchi identities.

There are additional results about the GR CP having a number of physically desirable features. First, it is Hadamard well-posed[27,21] so that in addition to the existence of a unique solution, the solution depends continuously on the prescribed data. Without this, an arbitrarily small change in the data set could give rise to an arbitrarily large change in the form of the solution which prevents physical predictability. Second, it possesses the ''domain of dependence'' property, i.e., the data can only affect the evolution in regions that are in causal contact with that data, which is a necessary criterion for the good behavior of hyperbolic systems.[21,23] The continuous dependence and domain of dependence properties follow in harmonic coordinates from Leray's theorem,[32,21] which is specific to hyperbolic operators. Finally, it is standard knowledge that the GR CP is well-posed in the presence of scalar fields, electromagnetism, perfect fluids, Brans–Dicke theory, and certain higher-derivative theories.[21]

The IVP or data construction problem (solving the Gauss–Codazzi constraints) is considered to be the most difficult step in the $(3+1)$ formalism of GR.[33] This problem is underdetermined, because there are twelve unknown functions (the components of the 3-metric h_{ik} and the second fundamental form Ω_{ik}), but only four equations. Hawking and Ellis[34] apparently refer to a general result stating that if eight of the unknown functions are specified for a space–time with an arbitrary matter content, the constraint equations may be solved for the remaining four. However, the work they refer to, Ref. 22, considers only two methods (the thin sandwich method and the usual conformal method), neither of which resemble Magaard's method.

We now consider the CM theorem piece by piece. The structure of none of the above-mentioned results is dependent on the dimension. Neither the CK theorem nor the method of expressing the GR evolution equations in the correct form to invoke the CK theorem are affected by the signature. Furthermore the Bianchi identity which guarantees constraint propagation is geometrical and hence equally valid regardless of the signature. Hence, the first part of the proof of the CM theorem (existence, uniqueness, and constraint propagation) follows directly from these results holding for the $(3+1)$-D GR CP.

The second part of the proof, due to Magaard, is a subcase of the result in Hawking and Ellis[34] generalized to arbitrary dimension. However, we emphasize that Magaard's approach differs from that of the usual conformal data construction.[24–26] The former considers the lower-dimensional

metric to be a known function, but the latter considers it to be known only up to a conformal factor. The former is of interest following the new motivation for studying higher-dimensional space–times, whereas the latter has only been employed for three spacelike dimensions using largely signature-dependent (that is, elliptical) methods.

If we are to interpret the CM theorem from a physical point of view, we are well-motivated to demand that the procedure for constructing embeddings is a well-posed problem. The types of embeddings of interest are $(n,1)\rightarrow(n+1,1)$ and $(n,1)\rightarrow(n,2)$, which are forms which are not known to exhibit continuous dependence, respectively. (There is no simple way of investigating whether theorems that hold for one particular signature hold for any other. This is due to significant mathematical differences between elliptic and ''hyperbolic'' operators. From the point of view of the function spaces that underly the analysis, Holder spaces are natural for the study of elliptic operators while Sobolev spaces are natural for the study of hyperbolic operators.) The former is termed the ''sideways problem for a hyperbolic system,'' and arises in a number of nonrelativistic contexts, as summarized by Ames and Straughan.[35] The only general result known for simple examples of such problems is that, given certain bounds, the solution is Holder-stable in some region,[36] but this is not considered to amount to a sufficiently strong theorem to guarantee continuous dependence. The latter is an ultrahyperbolic problem. These remain largely unexplored since they were traditionally considered to be physically irrelevant (see, however, Ref. 37). This implies, for example, that there are problems with the physical interpretation of models based on GR with two timelike dimensions[38] (as also pointed out in $(10+2)$-D supergravity[39]).

If we exclude this second possibility, it may be more promising to approach higher-dimensional embeddings with a two-step procedure of the form $(3,0)\rightarrow(4,0)\rightarrow(4,1)$. The first step could be a boundary problem along the lines considered in Ref. 40, while the second step is a higher-dimensional version of the GR CP. This procedure would allow the bulk to influence the hypersurface in a causal way (in the usual GR sense), which is not possible in a $(3,1)\rightarrow(4,1)$ type of embedding (except perhaps in a perturbative treatment). It is clearly of interest to construct models in which the bulk does play a role that is, in principle, observable and testable. Although the nature of causality in higher-dimensional theories may be substantially different to that of $(3+1)$-D GR,[41] such models would be consistent with a direct extension of GR.

V. CONCLUSION

In this paper, we have proved an extension of the CM embedding theorem,[8,9] where the embedding metric is sourced by one or more scalar fields minimally coupled to GR. We employed this theorem to establish classes of embeddings where the scalar field self-interacts through an exponential potential. The relationship between the CM theorem and the Cauchy and initial value problems of GR was highlighted. This relationship will certainly permit CP and IVP techniques to be adapted to provide further space–time into space–time embeddings.

Embedding theorems are important from both the mathematical and physical points of view. They allow classification schemes for different space–times to be developed as well as providing algorithms for generating new solutions.[42] The primary physical motivation for developing mathematical embedding theorems arises from the resurgence of interest in higher-dimensional theories of gravity and cosmology, most notably the braneworld scenarios.[3–6] In particular, the Randall–Sundrum ''type II'' (RSII) scenario,[6] where a codimension one brane is embedded in five-dimensional anti-de Sitter (AdS_5) space, has attracted considerable attention. Embeddings are also of relevance to the induced ''space–time–matter'' (STM) theory, whereby the 4D universe is viewed as a slice of a 5D universe.[43,44,19] (For reviews, see, e.g., Refs. 14 and 45.) The CM theory was recently employed within the context of both the RSII scenario and STM theory, where the close similarities between the two approaches were highlighted and algorithms for employing the theorem in practice were outlined.[19] The relationship between the two pictures has also been emphasized in Ref. 44.

Although the RSII model was motivated in part by the Horăva–Witten theory for the strongly coupled limit of the $E_8\times E_8$ heterotic string theory,[4] it is an idealized system, in the sense that the higher-dimensional space is assumed to be an Einstein space. It is therefore important to consider

more general settings that are inspired by string theoretic considerations. For example, the supergravity actions contain, in addition to the scalar dilaton field, a number of antisymmetric form-fields. Up on compactification from ten or eleven dimensions, the degrees of freedom associated with these fields can manifest themselves as scalar fields that self-interact through one or more potentials. In particular, scalar fields arise when the form fields have a nontrivial flux over the compactifying dimensions that is able to support a solitonic brane configuration. A specific example is the compactification of the Horăva–Witten theory to five dimensions,[5] where a scalar field arises in the fifth (bulk) dimension with an exponential potential of the form considered in Sec. III B.

In view of the above discussion, it is important to develop the mathematical framework through embedding theorems for studying braneworld models containing scalar fields in the higher dimensions. Unlike almost all current analyses, our treatment in the present work is for the *full* Einstein-scalar field system rather than for some highly symmetric case. This general treatment is appropriate because we are establishing an existence and uniqueness theorem for embeddings into space–times sourced by scalar fields. (This is also the starting point of the perturbative 4D treatment of domain walls presented in Ref. 46.)

It is worth emphasizing that by including scalar fields in our extension of the CM theory, we mean additional, bulk scalar fields, $\overline{\chi}$, and not the higher-dimensional metric component, $\overline{\phi}$, which is an effective scalar field in the Kaluza–Klein and STM approaches. The theorem we have proved therefore provides a starting point for considering a number of open physical questions, such as the possible restrictions that may arise on the energy–momentum tensor of the brane matter fields once the junction conditions are imposed. A related question is whether plausible 4D physics can generically be recovered and whether there are testable corrections to Newton gravity such as those in the RSII scenario.[6] It would be interesting to consider these questions further.

Finally, our generalization in this paper of the CM theorem implies that for a given 4D space–time, there are an infinite number of embedding space–times with one extra dimension, in the sense that there is at least one possible embedding for each functional form of the higher-dimensional energy–momentum tensor, in particular, one per scalar interaction potential of the surrounding 5D space–time. (In the embedding procedure, the energy–momentum tensor is viewed as a function of the coordinates and not as a function of the fields. This implies that the higher-dimensional models are merely encoding solutions rather than specific physical laws. Compare with how Kaluza–Klein theory offered further predictions as a result of the geometrization of the electromagnetic field.) This is arguably an undersirable feature for higher-dimensional theories, since it implies that unique physical predictions cannot be made in the absence of well-founded principles that *select* a particular higher-dimensional space–time. This is similar to the well-known problem in string theory phenomenology, where different particle spectra arise for different Calabi–Yau compactifications.[47] The introduction of discontinuities or branes is unlikely to remove this nonuniqueness property, since there are many possible brane configurations (single, parallel, or intersecting) that could be considered and many possible forms for the higher dimensional bulk space–time, but presently no established way to distinguish between them from a physical point of view. Perhaps, the number of fields and the form of the potential would be restricted in some higher-dimensional theory and by requiring the recovery of (possibly corrected) 4D physics as discussed earlier. Our theorem provides a framework within which these and related questions can be addressed.

(Received 9 December 2002; accepted 18 August 2003)

We establish exactly solvable models for the motion of neutral particles, electrically charged point and spin particles [U(1) symmetry], isospin particles [SU(2) symmetry], and particles with color charges [SU(3) symmetry] in a gravitational wave background. Special attention is devoted to parametric effects induced by the gravitational field. In particular, we discuss parametric instabilities of the particle motion and parametric oscillations of the vectors of spin, isospin, and color charge. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1617364]

I. INTRODUCTION

Periodic external fields are known to induce parametric phenomena in physical systems. This includes such effects as parametric oscillations (the oscillation frequency becomes a periodic function of time) and parametric instabilities (exponential growth of certain dynamical quantities).[1–3] Classical examples are the parametric resonance in vibrations of mechanical and electrical systems[1–3] and plasma instabilities in external electromagnetic fields.[4,5] From a mathematical point of view, such phenomena are described by differential equations with periodic coefficients which are subject to Floquet's theory.[2,3,6–9] As we shall demonstrate here, equations of this type naturally appear if one considers the motion of different kinds of particles in a gravitational wave (GW) background. The gravitational wave may play the role of an external periodic pumping field. In fact, most of the attempts for a direct detection of gravitational waves rely on this concept. The mathematical similarity to dynamical equations which are known to describe parametric oscillations and resonances then naturally suggests the possibility of gravitationally induced parametric effects.

The idea of parametric phenomena in GW fields is not new. For a linearized GW field it was discussed in Ref. 10. The first exactly solvable model for the evolution of a kinetic system in a *nonlinear* GW field, demonstrating explicitly the possibility of parametric excitation of a relativistic plasma by a periodic GW, has been established in Ref. 11. At the same time, in the nineties, the problem of parametric resonance during the reheating phase of inflationary models has become an intensely elaborated topic in a cosmological context (see, e.g., Refs. 12–16). More recently, investigations, concerning parametric phenomena in a GW field, have attracted attention again (see, e.g., Refs. 17–19).

The purpose of the present paper is to clarify characteristic features of gravitationally induced parametric effects for simple dynamical configurations. As a first example we consider the motion of an electrically charged point particle which is simultaneously exposed to a constant magnetic field and a gravitational wave with front plane orthogonal to the magnetic field. In the second example we include an additional spin degree of freedom which is described by the Bargmann–

Michel–Telegdi (BMT) equations.[20] In the third case the electrically charged spin-particle is replaced by a particle with isospin and the magnetic field is replaced by a corresponding Yang–Mills field. The isospin dynamics is governed by Wong's equation[21] for the three-dimensional isospin vector. Finally, we consider the motion of particles with color charge, described by Wong's equation for the eight color degrees of freedom. Using suitably specified Yang–Mills fields, we establish a general scheme which allows a unified treatment of the particle dynamics for all four cases. We show that on a periodic GW background this dynamics is characterized by Hill and Mathieu equations. Well-known stability properties of the latter allow us to classify the particle motion accordingly. This implies parametric oscillations and/or parametric instabilities as generic phenomena. The precession dynamics of the vectors of spin, isospin, and color charge is coupled to the particle motion and parametrically driven as well.

The paper is organized as follows. In Sec. II we establish the basic dynamic equations for the Abelian and non-Abelian subcases to be discussed in the following. In Sec. III the Yang–Mills fields for the latter cases are specified. The (exact) gravitational background is characterized in Sec. IV. Section V is devoted to a compact, general solution for the particle dynamics. A ''sandwich'' GW is considered as a special case. The spin precession for an electrically charged particle is the subject of Sec. VI. Sections VII and VIII discuss the dynamics in the spaces of isospin and color charge, respectively. In Sec. IX we summarize our main results. We use units in which $\hbar = c = 1$.

II. PARTICLE DYNAMICS: BASIC EQUATIONS

Let us consider the evolution of relativistic point particles with either an electric charge and a spin-vector, or an isospin, or a color charge. The concepts of classical particles with isospin [for the SU(2) symmetry] or color charge [for the SU(3) symmetry] are generalizations of the electrically charged particles to the non-Abelian case (see, e.g., Ref. 22). The dynamical equations for the particle momentum p^i, for the spin-vector S^i, and for the charge $Q^{(A)}$, where (A) is a group index, are

$$\frac{Dp^i}{D\tau} = \mathcal{F}^i, \quad \frac{DS^i}{D\tau} = \mathcal{G}^i, \quad \frac{DQ^{(A)}}{D\tau} = \mathcal{G}^{(A)}\ , \tag{1}$$

respectively. Here, D denotes the covariant differential, τ is a parameter along the particle world-line, and $\mathcal{F}^i$ is the force four vector which is orthogonal to the particle momentum $p^i = m\mathrm{d}x^i/\mathrm{d}\tau$, i.e., $p_i\mathcal{F}^i = 0$. The quantity $\mathcal{G}^i$ describes the spin rotation within the BMT theory. The quantity $\mathcal{G}^{(A)}$ is a vector in the group space which determines the non-Abelian charge evolution and plays a similar role for the charge as $\mathcal{F}^i$ plays for the momentum. The limiting case of neutral particles is characterized by $\mathcal{F}^i = \mathcal{G}^i = \mathcal{G}^{(A)} = 0$.

A. Electrically charged point particles

In this case the relevant force is the Lorentz force

$$\mathcal{F}^i = \frac{e}{m} F^i{}_{\cdot k}\, p^k \tag{2}$$

with

$$F_{ik} = \nabla_i A_k - \nabla_k A_i\,, \quad \nabla_k F^{ik} = 0, \tag{3}$$

where F_{ik} is the Maxwell tensor. The particle under consideration is regarded here as a test particle. Moreover, the charge is constant which renders the third equation in (1) irrelevant.

B. Electrically charged spin particles

According to Ref. 20 the evolution of classical relativistic spin particles is governed by

$$\frac{Dp^i}{D\tau}=\frac{e}{m}F^i_{\cdot k}\ p^k \tag{4}$$

and

$$\frac{DS^i}{D\tau}=\frac{e}{2m}\left[gF^i_{\cdot k}S^k+\frac{(g-2)}{m^2}p^iF_{kl}S^kp^l\right]. \tag{5}$$

Here, S^i is the spin four-vector and g is the gyromagnetic ratio. Equation (5) describes the precession of the magnetic moment. It generalizes earlier nonrelativistic equations by Thomas[23] and Bloch,[24] which rely on the circumstance that the ''expectation value of the vector operator representing the 'spin' will necessarily follow the same time dependence as one would obtain from a classical equation of motion'' (cf. Ref. 20). While the particle momentum according to Eq. (4) is independent of the spin vector, the dynamics of the latter is coupled (at least via the covariant derivative) to the particle motion.

C. Isospin particles

Here we have a triplet $I^{(A)}$ of scalar fields representing a vector in the three-dimensional isospin space, i.e., $(A)=(1),(2),(3)$. This space has an Euclidean metric $G_{(A)(B)}$. The relevant force

$$\mathcal{F}^i=\frac{g}{m}F^{(A)i}_{\cdot\ k}\ p^kI^{(B)}G_{(A)(B)}, \tag{6}$$

where g is the interaction constant, has been obtained by Kerner[25] and Wong.[21] The isospin dynamics is determined by Wong's equation[21]

$$\frac{D}{D\tau}I^{(A)}=-\frac{g}{m}\varepsilon^{(A)}_{\cdot(B)(C)}A^{(B)}_ip^iI^{(C)}, \tag{7}$$

where we have used that the structure constants for the SU(2) group coincide with the three-dimensional Levi–Civita symbol $\varepsilon^{(A)}_{\cdot(B)(C)}$. The quantities $A^{(A)}_i$ are the vector potentials in terms of which the Yang–Mills field strength tensor $F^{(B)}_{jk}$ is given by

$$F^{(B)}_{jk}=\nabla_jA^{(B)}_k-\nabla_kA^{(B)}_j+g\varepsilon^{(B)}_{\cdot(K)(L)}A^{(K)}_jA^{(L)}_k. \tag{8}$$

The Yang–Mills field equations are

$$g^{ij}[\nabla_iF^{(A)}_{jk}+g\varepsilon^{(A)}_{\cdot(B)(C)}A^{(B)}_iF^{(C)}_{jk}]=0. \tag{9}$$

Again we consider the particle motion in a given external field. Wong's equation represents a non-Abelian generalization of the equation of motion for electrically charged point particles. It can be obtained as the classical limit from quantum field theory for the case of sufficiently localized quantum states of the matter fields with characteristic length scales much smaller than those associated with the Yang–Mills fields.[26,22]

D. Particles with color charge

For test particles with color charge the force $\mathcal{F}^i$ is given by

$$\mathcal{F}^i=\frac{g}{m}F^{(A)i}_{\cdot k}\ p^k Q^{(B)}G_{(A)(B)}, \tag{10}$$

with the field strength tensor

$$F^{(B)}_{jk}=\nabla_j A^{(B)}_k-\nabla_k A^{(B)}_j+g f^{(B)}_{\cdot\,(K)(L)}A^{(K)}_j A^{(L)}_k, \tag{11}$$

where the $f^{(B)}_{\cdot\,(K)(L)}$ are the structure constants of the SU(3)group. The field equations are

$$g^{ij}[\nabla_i F^{(A)}_{jk}+g f^{(A)}_{\cdot\,(B)(C)}A^{(B)}_i F^{(C)}_{jk}]=0. \tag{12}$$

The quantity $Q^{(A)}$ is the color charge with $(A)=(1)-(8)$. Wong's equation in this case reads

$$\frac{D}{D\tau}Q^{(A)}=-\frac{g}{m}f^{(A)}_{\cdot\,(B)(C)}A^{(B)}_i p^i\ Q^{(C)}. \tag{13}$$

The structure constants $f^{(A)}_{\cdot\,(B)(C)}$ are characterized by the commutator relations

$$[\lambda_{(A)},\lambda_{(B)}]=2i f_{(A)(B)(C)}\lambda^{(C)}, \tag{14}$$

where $\lambda_{(A)}$ are the traceless, Hermitian Gell–Mann matrices (see, e.g., Refs. 27 and 28). In detail we have

$$\begin{gathered} f_{(1)(2)(3)}=1,\quad f_{(4)(5)(8)}=f_{(6)(7)(8)}=\frac{\sqrt{3}}{2},\\ f_{(1)(4)(7)}=f_{(2)(4)(6)}=f_{(2)(5)(7)}=f_{(3)(4)(5)}=-f_{(3)(6)(7)}=-f_{(1)(5)(6)}=\tfrac{1}{2}. \end{gathered} \tag{15}$$

In the following we shall also use the completely symmetric coefficients $d_{(A)(B)(C)}$ of the basic representation which are given by the anti-commutation relations

$$\{\lambda_{(A)},\lambda_{(B)}\}=\tfrac{4}{3}\delta_{(A)(B)}+2d_{(A)(B)(C)}\lambda^{(C)}, \tag{16}$$

where[29,22]

$$\begin{aligned} d_{(1)(4)(6)}&=d_{(1)(5)(7)}=d_{(2)(5)(6)}=d_{(3)(4)(4)}=d_{(3)(5)(5)}=-d_{(2)(4)(7)}=-d_{(3)(6)(6)}\\ &\quad=-d_{(3)(7)(7)}=\tfrac{1}{2},\\ d_{(1)(1)(8)}&=d_{(2)(2)(8)}=d_{(3)(3)(8)}=-d_{(8)(8)(8)}=-2d_{(4)(4)(8)}=-2d_{(5)(5)(8)}\\ &\quad=-2d_{(6)(6)(8)}=-2d_{(7)(7)(8)}=\frac{1}{\sqrt{3}}. \end{aligned} \tag{17}$$

III. YANG–MILLS FIELDS WITH "PARALLEL" POTENTIALS

It is known that for each solution of the general relativistic source free Maxwell equations one can construct a set of solutions of the general relativistic Yang–Mills equations.[30] Following Gal'tsov[31] we will refer to the corresponding Yang–Mills potentials as ''parallel'' potentials. The latter are characterized by

$$A^{(B)}_i=q^{(B)}A_i,\quad F^{(A)}_{ik}=q^{(A)}F_{ik},\quad q^{(B)}q_{(B)}=1,\quad q^{(B)}=\text{const.} \tag{18}$$

Due to the antisymmetry of the structure coefficients the relations (8) and (11) as well as Eqs. (9) and (12) reduce to the linear Maxwell-type forms (3). Nevertheless, compared with Maxwell's theory there exists an additional degree of freedom, namely, the direction of the vector $q^{(A)}$ in the group space.[30] Additionally, the structure coefficients $f^{(B)}_{\cdot\,(K)(L)}$ are different from zero which will result in a qualitatively different dynamics.

A. Isospin particles

In this case the ansatz (18) transforms the first of equations (1) with (6) into

$$\frac{Dp^i}{D\tau}=\frac{gI^{(A)}q_{(A)}}{m}F^i_{\cdot\,k}p^k, \tag{19}$$

which has the structure of the equations of motion of a particle with charge $e\equiv gI^{(A)}q_{(A)}$ under the influence of the Lorentz force (2). Analogously, one can rewrite Eq. (7) for the isospin evolution,

$$\frac{\mathrm{d}}{\mathrm{d}\tau}I^{(A)}=-\Omega\varepsilon^{(A)}_{\cdot\,(B)(C)}q^{(B)}I^{(C)},\quad \Omega\equiv\frac{g}{m}A_ip^i. \tag{20}$$

Because of the antisymmetry of the Levi–Civita symbols, Eq. (20) admits a quadratic integral of motion $I^{(A)}I_{(A)}=\text{const}$, which is a Casimir invariant,[22] normalizable to $I^{(A)}I_{(A)}=1$. In addition, we obtain from (20)

$$q_{(A)}\frac{\mathrm{d}I^{(A)}}{\mathrm{d}\tau}\equiv 0\ ,\ \rightarrow\ \ I^{(A)}q_{(A)}\equiv I=\text{const}. \tag{21}$$

Using the standard definition

$$[\vec{I},\vec{\Omega}]^{(A)}\equiv\varepsilon^{(A)}_{\cdot\,(B)(C)}I^{(B)}\Omega^{(C)},\quad \Omega^{(C)}\equiv\Omega q^{(C)}, \tag{22}$$

of the vector product, Eq. (20) may be written as an equation for the precession of $\vec{I}$,

$$\frac{\mathrm{d}}{\mathrm{d}\tau}\vec{I}=[\vec{I},\vec{\Omega}]. \tag{23}$$

The "longitudinal" component $I^{(A)}q_{(A)}$, the projection of the dynamical variable $I^{(A)}$ on the "rotation axis" $q^{(A)}$, remains constant according to (21).

B. Colored particles

Similar to the previous isospin case the color charge evolution equation (13) admits the existence of a quadratic integral of motion $Q^{(A)}Q_{(A)}=\text{const}$ which is the first Casimir invariant.[22] The condition (18) of parallelism in the color space provides a second integral of motion $Q^{(A)}q_{(A)}=\text{const}$, as well. However, the corresponding eight-dimensional evolution equations,

$$\frac{\mathrm{d}}{\mathrm{d}\tau}Q^{(A)}=-\Omega H^{(A)}_{\cdot\,(C)}Q^{(C)},\quad \Omega\equiv\frac{g}{m}A_ip^i\ ,\quad H^{(A)}_{\cdot\,(C)}\equiv f^{(A)}_{\cdot\,(B)(C)}q^{(B)}\ , \tag{24}$$

are more complicated than Eq. (23) for the isospin precession. Different from the SU(2) model there exists a second Casimir invariant

$$\mathcal{Q}=d_{(A)(B)(C)}Q^{(A)}Q^{(B)}Q^{(C)}\,, \tag{25}$$

where $d_{(A)(B)(C)}$ are the totally symmetric group coefficients (17) of the given basic representation of the SU(3) group. In detail it reads

$$\mathcal{Q}=-\frac{1}{\sqrt{3}}(Q^{(8)})^3+\sqrt{3}Q^{(8)}[(Q^{(1)})^2+(Q^{(2)})^2+(Q^{(3)})^2]-\frac{\sqrt{3}}{2}Q^{(8)}[(Q^{(4)})^2+(Q^{(5)})^2+(Q^{(6)})^2$$
$$+(Q^{(7)})^2]+3Q^{(1)}[Q^{(4)}Q^{(6)}+Q^{(5)}Q^{(7)}]+3Q^{(2)}[-Q^{(4)}Q^{(7)}+Q^{(5)}Q^{(6)}]+\tfrac{3}{2}Q^{(3)}[(Q^{(4)})^2$$
$$+(Q^{(5)})^2-(Q^{(6)})^2-(Q^{(7)})^2]. \tag{26}$$

IV. GRAVITATIONAL WAVE BACKGROUND

Our aim in this paper is to study the general dynamics outlined so far in the field of a plane-fronted GW with parallel rays (PP wave). We assume the latter to be an exact solution of Einstein's vacuum field equations with a five-parametric group of isometries G_5, including a covariantly constant null Killing vector (KV).[32] Gravitational waves are usually described either in Fermi coordinates or in the transverse-traceless (TT) gauge. For the merits of each of these choices and for issues of gauge-invariance in the linearized theory see, e.g., Ref. 33. In order to establish a comprehensive picture we start by sketching our basic setting for both cases. For computational ease most of the analysis will then be done in TT coordinates.

A. PP wave in Fermi coordinates

The corresponding line element

$$\mathrm{d}s^2=2\mathrm{d}\bar{u}\,\mathrm{d}\bar{v}-\mathrm{d}y^2-\mathrm{d}z^2-2\mathcal{H}(\bar{u},y,z)\mathrm{d}\bar{u}^2,\quad \bar{u}=\frac{t-x}{\sqrt{2}},\quad \bar{v}=\frac{t+x}{\sqrt{2}}, \tag{27}$$

contains a harmonic function $\mathcal{H}$, obeying

$$\frac{\partial^2\mathcal{H}}{\partial y^2}+\frac{\partial^2\mathcal{H}}{\partial z^2}=0, \tag{28}$$

which is quadratic in y and z for a G_5 symmetry group. Explicitly, we have[32]

$$2\mathcal{H}(\bar{u},y,z)=A(\bar{u})(y^2-z^2)+2B(\bar{u})yz, \tag{29}$$

where $A(\bar{u})$ and $B(\bar{u})$ are arbitrary functions of the retarded time $\bar{u}$. We may define a periodic GW by assuming the variables A and B to be periodic functions of $\bar{u}$. All nonvanishing components of the Riemann tensor, $R_{z\bar{u}z\bar{u}}=-R_{y\bar{u}y\bar{u}}=A(\bar{u})$ and $R_{y\bar{u}z\bar{u}}=-B(\bar{u})$, are periodic for this case. The GW metric in Fermi coordinates is nonsingular for arbitrary retarded times because $\det(g_{ik})\equiv-1\neq0$. However, the weak field approximation $\max|g_{ik}|\ll1$ is correct only close to $y=0$, $z=0$.

B. PP wave in TT gauge

The line element in TT gauge has the form

$$\mathrm{d}s^2=2\mathrm{d}u\,\mathrm{d}v-L^2[\cosh 2\gamma(e^{2\beta}(\mathrm{d}x^2)^2+e^{-2\beta}(\mathrm{d}x^3)^2)+2\sinh 2\gamma\mathrm{d}x^2\,dx^3], \tag{30}$$

where $u=(t-x^1)/\sqrt{2}$ and $v=(t+x^1)/\sqrt{2}$ are the retarded and the advanced times, respectively. For this metric the three KVs which form an Abelian subgroup of G_5 are

$$\xi^i_{(v)}=\delta^i_v,\quad \xi^i_{(2)}=\delta^i_2,\quad \xi^i_{(3)}=\delta^i_3. \tag{31}$$

The KV $\xi^i_{(v)}$ is a covariantly constant null vector, orthogonal to $\xi^i_{(2)}$ and $\xi^i_{(3)}$. The functions $\beta(u)$ and $\gamma(u)$ are arbitrary. We shall focus here on the case of periodic functions $\beta(u)$ and $\gamma(u)$. This definition of periodicity does not, in general, coincide with the definition in Fermi coordinates

given above. However, both concepts of a periodic GW have the same weak-field limit, which in the TT gauge is characterized by $L=1$, $|\beta(u)|\ll 1$ and $|\gamma(u)|\ll 1$. Generally, the function $L(u)$ satisfies the Einstein equation:[33]

$$\ddot{L}+L((\dot{\beta})^2\cosh^2 2\gamma+(\dot{\gamma})^2)=0, \tag{32}$$

where a dot denotes the derivative with respect to the retarded time u. We assume the hypersurface $u=0$ to be the leading front of the GW with

$$\beta(0)=\gamma(0)=0, \quad L(0)=1, \quad \dot{\beta}(0)=\dot{\gamma}(0)=\dot{L}(0)=0. \tag{33}$$

For the special case $\gamma(u)\equiv 0$ [equivalent to $B(\overline{u})\equiv 0$], corresponding to only one polarization direction, the transformation relations between Fermi and TT coordinates are

$$\begin{gathered}\overline{u}=u, \quad \overline{v}=v+\tfrac{1}{4}[(x^2)^2(L^2e^{2\beta})^{\cdot}+(x^3)^2(L^2e^{-2\beta})^{\cdot}], \\ y=Le^{\beta}\cdot x^2, \quad z=Le^{-\beta}\cdot x^3, \quad A(u)=\ddot{\beta}+2\dot{\beta}\frac{\dot{L}}{L}.\end{gathered} \tag{34}$$

The last formula clarifies the relation between the different periodicity definitions given above. For the physically relevant situation where the background factor L changes only slowly compared with the change of the wave factor β (cf. Ref. 33) the last term in the formula for $A(u)$ in Eq. (34) can be neglected. Then we have $A(u)=\ddot{\beta}$ and both periodicity definitions coincide.

V. PARTICLE DYNAMICS: SOLUTIONS

We are interested here in the particle dynamics in given external gravitational and Yang–Mills fields. The restriction (18) to Yang–Mills fields with ''parallel potentials'' simplifies the Kerner–Wong equations since the quantities $I^{(A)}q_{(A)}$ and $Q^{(A)}q_{(A)}$ remain constant. We introduce the cumulative symbol σ for either e, or $gI^{(A)}q_{(A)}$, or $gQ^{(A)}q_{(A)}$, which allows us to write the equation of motion with either (2), or (6), or (10) in the unified form

$$\frac{Dp^i}{D\tau}=\frac{\sigma}{m}F^i{}_{\cdot k}p^k, \quad \frac{\mathrm{d}x^i}{\mathrm{d}\tau}=\frac{p^i}{m}. \tag{35}$$

The orthogonality of the force to the particle momentum corresponds to the quadratic integral

$$g^{ik}p_ip_k=m^2. \tag{36}$$

One may solve this relation for one of the components of the momentum. In Fermi coordinates we have

$$p_{\overline{u}}=\frac{1}{2p_{\overline{v}}}[m^2+p_y^2+p_z^2-2\mathcal{H}(\overline{u},y,z)p_{\overline{v}}^2]. \tag{37}$$

The analogous formula in TT coordinates is

$$p_u=\frac{1}{2p_v}[m^2-g^{\alpha\beta}(u)p_{\alpha}p_{\beta}], \tag{38}$$

where greek indices run from 2 to 3. Both in Fermi and in TT coordinates the covariantly constant null KV has the form $\xi^i_{(\overline{v})}=\delta^i_{\overline{v}}$ and $\xi^i_{(v)}=\delta^i_v$, respectively. In the following we shall restrict ourselves to fields which satisfy

$$\xi^i_{(\bar{v})}F_{ik}=\xi^i_{(v)}F_{ik}=0. \tag{39}$$

This implies that the quantities $\xi^i_{(\bar{v})}p_i$ and $\xi^i_{(v)}p_i$ are integrals of motion (see e.g., Ref. 33),

$$\xi^i_{(\bar{v})}p_i=\xi^i_{(v)}p_i=p_v=C_v=\text{const.} \tag{40}$$

Using the general relationship

$$m\frac{du}{d\tau}=p^u=p^{\bar{u}}=p_v=C_v, \tag{41}$$

one can reparametrize the remaining equations for $C_v\neq 0$, by means of the linear formula (notice that $\bar{u}=u$ [cf. Eq. (34)] holds also in the general case)

$$\tau=\tau_0+\frac{m}{C_v}u. \tag{42}$$

We start our solution procedure by first recalling the reference case of neutral particles.

A. Neutral particles

For a vanishing generalized charge σ the equations of motion in TT coordinates are immediately integrated. The result is

$$p_v(u)=C_v,\quad p_2(u)=C_2,\quad p_3(u)=C_3,\quad p_u=\frac{1}{2C_v}[m^2-g^{\alpha\beta}(u)\;\; C_\alpha C_\beta], \tag{43}$$

where C_2 and C_3 are constants. A particle moving in direction of the GW propagation before the infall of the latter, i.e., $p_2=p_3=0$, will not change its direction. If we additionally have $C_v=mc/\sqrt{2}$, the particle is at rest both before and after the GW infall, since $p_1(u)=p_2(u)=p_3(u)=0$ and $p_0=mc$. An observer at rest, characterized by a four-velocity $V^i=(1/\sqrt{2})(\delta^i_u+\delta^i_v)\equiv\delta^i_0$, would measure the (invariant) particle energy $\mathcal{E}\equiv p^kV_k=(1/\sqrt{2})(p_u+p_v)$. For neutral particles p_v and p_u are given in Eq. (43). Corresponding expressions for charged particles will be obtained in the following.

In Fermi coordinates the situation is as follows. The system (35) reduces to the set of equations

$$\begin{gathered}\dot{y}=-C_v^{-1}p_y,\quad \dot{z}=-C_v^{-1}p_z,\\ C_v^{-1}\dot{p}_y=-A(u)y-B(u)z,\quad C_v^{-1}\dot{p}_z=A(u)z-B(u)y,\end{gathered} \tag{44}$$

for y, z, p_y, and p_z. If the latter set of quantities is known, the component p_u follows via (37). The quantity $\bar{v}(u)$ may be found by solving

$$\dot{\bar{v}}=C_v^{-1}p_u+2\mathcal{H}(u,y,z). \tag{45}$$

The set (44) is a linear, homogeneous first-order system of differential equations. For a GW field with polarization $B(u)\equiv 0$ and with A depending on the retarded time via the dimensionless variable ku, it can be written as

$$y''-\mathcal{A}(ku)y=0,\quad z''+\mathcal{A}(ku)z=0\ . \tag{46}$$

Differentiation with respect to ku is denoted by a prime and $\mathcal{A}(ku)\equiv A(u)/k^2$. For $A(u)\equiv 0$, i.e., in the absence of a gravitational field, $y(u)$ and $z(u)$ are linear functions of the retarded time (and of the affine parameter τ), and the particle has constant momentum. For a periodic function $A(u)$,

Eq. (46) is of the type of Hill's equation.[2,7,8] The solutions are Hill functions. For a dependence $\mathcal{A}(ku)=\delta+\varepsilon\cos(ku)$ where δ and ε are constants, Eq. (46) reduces to Mathieu equations which have solutions of the type[2,3,8]

$$y\propto\exp[\mu ku]\phi(ku)+\exp[-\mu ku]\psi(ku)\,, \tag{47}$$

where ϕ and ψ are periodic functions with the period of $\mathcal{A}(ku)$, i.e., in the present case, $\phi(ku+2\pi)=\phi(ku)$ and $\psi(ku+2\pi)=\psi(ku)$. The solutions consist of products of an exponential function and a periodic function of period 2π. The characteristic exponent μ is a complex constant. For $\mathrm{Re}(\mu)=0$ the solution is stable. In general, it is not periodic again but it is oscillating (Ref. 7, p. 115). For $\mathrm{Re}(\mu)\neq 0$ either the first or the second exponential function in (47) is unbounded and the solution is unstable. The stability properties of Mathieu's equations are well known in the literature and may be visualized by stability regions in an δ–ε diagram [see Ref. 2, Eq. (4.1) and Fig. 5.1]. Let us consider the stability region which is closest to the origin $\delta=\varepsilon=0$. For small positive values of δ and ε the boundary of this region is determined by the line $\delta=\frac{1}{4}-\frac{1}{2}\varepsilon$. Applied to the case $A(u)=A_0\cos(ku)$, i.e., $\delta=0$ and $\varepsilon=A_0/k^2$, this means stable solutions for $\varepsilon=A_0/k^2<1/2$. Since $A_0=\ddot{\beta}(0)=\beta_0 k^2$, we have also $\beta_0<1/2$. Under this condition neutral particles are parametrically oscillating in Fermi coordinates.

While equations of the type of Mathieu's equation and questions of stability will play an essential role in the following investigations of the dynamics of charged particles (see Sec. V B 2), it is obvious that the description for neutral particles is more involved in Fermi coordinates. Therefore, for computational ease and in order to separate charge effects from the neutral particle motion we shall perform the following analysis in TT coordinates.

B. Charged particles

To obtain exactly solvable models for the particle motion we resort to simple field configurations $F^{(A)}_{ik}$. For particles with electric charge we focus on the motion of the latter in a constant homogeneous magnetic field H_0 orthogonal to the GW front plane, which corresponds to a Maxwell tensor

$$F_{jk}=H_0(\delta^2_j\delta^3_k-\delta^3_j\delta^2_k). \tag{48}$$

A corresponding generalization for non-Abelian fields with parallel potentials according to (18) is

$$F^{(A)}_{jk}=q^{(A)}M(\delta^2_j\delta^3_k-\delta^3_j\delta^2_k),\quad M=\mathrm{const}. \tag{49}$$

Both (48) and (49) satisfy (39) with (31). This constitutes a model in which the gravitational wave and the fields (48) or (49) are given, external fields which are independent of each other. It may provide the basis of a perturbative treatment with respect to the GW amplitude within a linearized theory. It is worth mentioning that expressions (48) and (49) are also solutions of the Maxwell- and Yang–Mills equations, respectively, on the background of the exact GW (30) [or (27)]. This allows a study of the corresponding field dynamics on a GW background, which, however, is not the purpose of the present paper.

For the equations of motion in TT coordinates we obtain

$$\frac{\mathrm{d}p_2}{\mathrm{d}\tau}=\frac{M\sigma}{m}(g^{32}p_2+g^{33}p_3),\quad \frac{\mathrm{d}p_3}{\mathrm{d}\tau}=-\frac{M\sigma}{m}(g^{22}p_2+g^{23}p_3). \tag{50}$$

Equivalent second-order equations are

$$\frac{\mathrm{d}^2p_2}{\mathrm{d}u^2}+R_2(u)\frac{\mathrm{d}p_2}{\mathrm{d}u}+W_2(u)p_2=0,\quad p_3=\frac{1}{g^{33}}\left(\frac{1}{\Pi}\dot{p}_2-g^{23}p_2\right), \tag{51}$$

or

$$\frac{d^2p_3}{du^2}+R_3(u)\frac{dp_3}{du}+W_3(u)p_3=0,\quad p_2=\frac{1}{g^{22}}\left(-\frac{1}{\Pi}\dot{p}_3-g^{23}p_3\right), \tag{52}$$

where we have introduced the notations

$$\begin{aligned} R_2(u)&=-\frac{\dot{g}^{33}(u)}{g^{33}(u)}=2\left(\frac{\dot{L}}{L}-\dot{\beta}-\dot{\gamma}\tanh(2\gamma)\right),\\ R_3(u)&=-\frac{\dot{g}^{22}(u)}{g^{22}(u)}=2\left(\frac{\dot{L}}{L}+\dot{\beta}-\dot{\gamma}\tanh(2\gamma)\right), \end{aligned} \tag{53}$$

and

$$\begin{aligned} W_2(u)&=\frac{\Pi^2}{L^4}+\frac{2\Pi}{L^2}\left(\dot{\beta}\sinh(2\gamma)-\frac{\dot{\gamma}}{\cosh(2\gamma)}\right),\\ W_3(u)&=\frac{\Pi^2}{L^4}+\frac{2\Pi}{L^2}\left(\dot{\beta}\sinh(2\gamma)+\frac{\dot{\gamma}}{\cosh(2\gamma)}\right), \end{aligned} \tag{54}$$

with

$$\Pi=\frac{M\sigma}{C_v}=\text{const.} \tag{55}$$

The substitution $\beta\to-\beta$ converts R_3 into R_2 and vice versa, while W_3 is obtained from W_2 by $\beta\to-\beta$ and simultaneously $\Pi\to-\Pi$.

By the substitution

$$p_\alpha=Z_\alpha(u)\exp\left\{-\frac{1}{2}\int_0^u R_\alpha(\zeta)d\zeta\right\} \tag{56}$$

Eqs. (51) and (52) may be transformed into the Hill equations

$$\ddot{Z}_\alpha+F_\alpha(u)Z_\alpha=0, \tag{57}$$

where

$$F_\alpha=W_\alpha-\frac{R_\alpha^2}{4}-\frac{\dot{R}_\alpha}{2}. \tag{58}$$

The detailed form of relations (56) and (58) is

$$p_2=Z_2(u)\sqrt{\cosh(2\gamma)}\frac{e^{\beta}}{L},\quad p_3=Z_3(u)\sqrt{\cosh(2\gamma)}\frac{e^{-\beta}}{L},\quad p_\alpha(0)=Z_\alpha(0)\equiv C_\alpha, \tag{59}$$

and

$$\begin{aligned} F_2(u)=&\frac{\Pi^2}{L^4}+\frac{2\Pi}{L^2}\left(\dot{\beta}\sinh(2\gamma)-\frac{\dot{\gamma}}{\cosh(2\gamma)}\right)+\ddot{\beta}+\ddot{\gamma}\tanh(2\gamma)+\frac{3(\dot{\gamma})^2}{(\cosh(2\gamma))^2}\\ &+(\dot{\beta})^2(\sinh(2\gamma))^2+2\frac{\dot{L}}{L}\dot{\beta}+2\frac{\dot{L}}{L}\dot{\gamma}\tanh(2\gamma)-2\dot{\gamma}\dot{\beta}\tanh(2\gamma), \end{aligned} \tag{60}$$

$$F_3(u)=\frac{\Pi^2}{L^4}+\frac{2\Pi}{L^2}\left(\dot\beta\sinh(2\gamma)+\frac{\dot\gamma}{\cosh(2\gamma)}\right)-\ddot\beta+\ddot\gamma\tanh(2\gamma)+\frac{3(\dot\gamma)^2}{(\cosh(2\gamma))^2}$$
$$+(\dot\beta)^2(\sinh(2\gamma))^2-2\frac{\dot L}{L}\dot\beta+2\frac{\dot L}{L}\dot\gamma\tanh(2\gamma)+2\dot\gamma\dot\beta\tanh(2\gamma), \tag{61}$$

respectively. In a next step we have to solve Hill's equations (57).

1. General solution of Hill's equation

The structure of the solutions of the linear, second-order differential equations (57) is[2,3,7–9]

$$Z_2(u)=C_2H_2(u)-\Pi C_3H_3(u). \tag{62}$$

The functions $H_\alpha(u)$ satisfy the initial conditions

$$H_2(0)=1,\quad \dot H_2(0)=0,\quad H_3(0)=0,\quad \dot H_3(0)=1, \tag{63}$$

and represent the fundamental solutions of Hill's equation (57) with unitary Wronsky determinant. For $Z_3(u)$ we have

$$Z_3(u)=C_3H_3^*+C_2\Pi H_2^*, \tag{64}$$

where

$$H_2^*=-\frac{L^2}{\Pi^2\cosh 2\gamma}\left[\dot H_2+H_2\left(\dot\gamma\tanh 2\gamma+\dot\beta-\frac{\dot L}{L}-\frac{\Pi}{L^2}\sinh 2\gamma\right)\right], \tag{65}$$

$$H_3^*=\frac{L^2}{\cosh 2\gamma}\left[\dot H_3+H_3\left(\dot\gamma\tanh 2\gamma+\dot\beta-\frac{\dot L}{L}-\frac{\Pi}{L^2}\sinh 2\gamma\right)\right], \tag{66}$$

$$H_2^*(0)=\dot H_2(0)=0\,,\quad H_3^*(0)=\dot H_3(0)=1\,. \tag{67}$$

In the absence of gravitational radiation, i.e., for $\beta=\gamma\equiv 0$, $L\equiv 1$, the functions F_α in Eq. (58) reduce to

$$F_2(u)=F_3(u)=\text{const}=\Pi^2\,. \tag{68}$$

Equation (57) then describes harmonic oscillations with

$$H_2=H_3^*\equiv\cos\Pi u,\quad H_3=H_2^*\equiv\frac{1}{\Pi}\sin\Pi u. \tag{69}$$

Since with (42) and (55) we have $\Pi u\to\Omega_H\tau$ where $\Omega_H\equiv eH_0/mc$ is the Larmor frequency, we recover the corresponding particle rotation in flat space–time. Generally, the functions H_2, H_3, H_2^*, and H_3^* cannot be written in terms of elementary functions but are given as series representations. In the following section we shall be interested in expressions for F_2 and F_3 for which the Hill equations (57) specify to Mathieu equations. Then the functions H_α can be expanded in powers of the GW amplitude, where the zeroth order is given by (69).

The analysis so far may be summarized by writing the solution of the equations of motion (51) and (52) in the compact and elegant matrix form

$$\begin{pmatrix}p_2\\p_3\end{pmatrix}=\mathbf{H}(u)\cdot\begin{pmatrix}C_2\\C_3\end{pmatrix}, \tag{70}$$

where

$$\mathbf{H}(u)\equiv\frac{\sqrt{\cosh 2\gamma}}{L}\begin{pmatrix} e^{\beta} & 0 \\ 0 & e^{-\beta}\end{pmatrix}\cdot\begin{pmatrix} H_2(u) & -\Pi H_3(u) \\ \Pi H_2^*(u) & H_3^*(u)\end{pmatrix}. \tag{71}$$

The set of equations (70) and (71) represents the general solution for the momentum of the charged particle in the GW field (30) and the Yang–Mills field (49).

2. A simple model

Now we apply the general formalism to a ''sandwich'' GW (see, e.g., Ref. 33) with polarization $\gamma=0$. Let β be different from zero during a finite retarded time interval T, i.e., $\beta=0$ for $u\leqslant 0$ and $u\geqslant T$. Within the interval $0<u<T$ we assume β to be periodic according to

$$\beta(u)=\beta_0(1-\cos(ku)),\quad (0<u<T). \tag{72}$$

This implies $\beta(0)=\beta(2\pi/k)=0$ and $\dot{\beta}(0)=\dot{\beta}(2\pi/k)=0$. Furthermore, the time scale T is assumed to be small compared with the scale on which the background factor L changes.[33] Under these conditions we may neglect the $\dot{L}/L$ terms in (60) and (61) and use the latter expressions with $L=1$. For this situation the potentials F_2 and F_3 reduce to

$$\begin{aligned} F_2&=\Pi^2+\beta_0k^2\cos(ku)=\Pi^2-R^2_{\cdot u2u},\\ F_3&=\Pi^2-\beta_0k^2\cos(ku)=\Pi^2-R^3_{\cdot u3u}\end{aligned} \tag{73}$$

in the interval $0<u<T$. Replacing now the variable u by ku and denoting the derivative with respect to ku again by a prime, Eq. (57) with (73) specify to

$$\begin{aligned} Z_2''+\left(\frac{\Pi^2}{k^2}+\beta_0\cos(ku)\right)Z_2&=0,\\ Z_3''+\left(\frac{\Pi^2}{k^2}-\beta_0\cos(ku)\right)Z_3&=0.\end{aligned} \tag{74}$$

Both Z_2 and Z_3 obey Mathieu equations. In the absence of the GW, i.e., for $\beta\equiv 0$, we have $F_\alpha(ku)=\Pi^2/k^2=\text{const}$ [here we have used the redefinition $F_\alpha(ku)\equiv F_\alpha(u)/k^2$] and the equations of motion reduce to harmonic oscillator equations with solutions

$$Z_2=p_2=C_2\cos(\Pi u)-C_3\sin(\Pi u), \tag{75}$$

$$Z_3=p_3=C_3\cos(\Pi u)+C_2\sin(\Pi u). \tag{76}$$

Replacing here Π and u according to (55) and (42), we find a particle rotation in the x^20x^3 plane with the angular velocity $\Omega_M\equiv M\sigma/m$, which is, of course, the analogue of the Larmor frequency. Immediately after the wave front, i.e., at $u=0_{+0}$, we have

$$F_2(0)=\frac{\Pi^2}{k^2}+\beta_0,\quad F_3(0)=\frac{\Pi^2}{k^2}-\beta_0. \tag{77}$$

The jump β_0k^2 of the curvature tensor at the front makes the evolutions of the p_2 and p_3 components different. They begin to oscillate with different frequencies and the particle trajectory is no longer circular. Corresponding features hold for the second polarization $\beta\equiv 0$ and $\gamma\neq 0$, for which F_2 and F_3 differ in the term linear in Π [cf. Eqs. (60) and (61)].

The general solutions of Eq. (74) are of the type of "cosine elliptic" and "sine elliptic" functions (see Refs. 7 and 9). As already mentioned, the latter may be expanded in powers of β_0 with the zeroth-order terms (75) and (76).

Equation (74) is of the same type as Eq. (46). With the identifications $\delta \to \Pi^2/k^2$ and $\varepsilon \to \beta_0$, the stability discussion mentioned in Sec. V A may be applied here as well [see Ref. 2, Eq. (4.1) and Fig. 5.1]. Depending on the parameter combinations the solutions may be stable or unstable. Within the stable regions the functions Z_2 and Z_3 are parametrically oscillating which, according to (59), implies a corresponding behavior of the particle momenta. The regions of stable solutions are characterized by stability zones in a $(\Pi/k)^2 \times \beta_0$ plane which are connected together at the points $(\Pi/k)^2 = n^2/4$, $\beta_0 = 0$, where n is an integer.[2]

The analysis of the neutral particle motion in Sec. V A corresponds to the case $\Pi = n = 0$. For $\Pi \neq 0$ the relevant values for the transition points are $n = 1,2,\ldots$. For $n = 1$ we have $\Pi/k = 1/2$. These points on the axis $\beta_0 = 0$ (which corresponds to the absence of the GW) are the only transition points between stable regions which also belong to the stable region. All other boundary points of the stable regions are unstable points. Consequently, any deviation from $\beta_0 = 0$, i.e., even a GW with arbitrary weak amplitude β_0, induces an instability in these critical points. In particular, this is true for the point $\Pi/k = 1/2$ (see Ref. 2, Fig. 5.1). This demonstrates that parametric instabilities are a generic phenomenon for the motion of particles in all the cases considered here. While we have obtained this result in TT coordinates, the transformations (34) allow us to find the corresponding particle momenta in Fermi coordinates as well. The relevant transformations are

$$p_{\bar{v}} = p_v = C_v\,, \quad p_y = p_2(u)\frac{e^{-\beta}}{L} - C_v\left(\frac{\dot{L}}{L} + \dot{\beta}\right) y(u)\,,$$
$$p_z = p_3(u)\frac{e^{\beta}}{L} - C_v\left(\frac{\dot{L}}{L} - \dot{\beta}\right) z(u)\,, \tag{78}$$

where

$$y(u) = L e^{\beta}\left[y(0) - \int_0^u d\zeta\, p_2(\zeta) L^{-2}(\zeta) e^{-2\beta(\zeta)}\right],$$
$$z(u) = L e^{-\beta}\left[z(0) - \int_0^u d\zeta\, p_3(\zeta) L^{-2}(\zeta) e^{2\beta(\zeta)}\right]. \tag{79}$$

It is interesting to realize that there are astrophysical situations for which the existence of such kind of instabilities might be relevant. This can be seen with the help of the following order-of-magnitude estimates. Equation (55) may be written as $\Pi = \Omega_M m/C_v$ with $\Omega_M = M\sigma/m$. For the electromagnetic case one has $\sigma = e$ and $M = H_0$. The interstellar magnetic field is of the order $3-6\times 10^{-6}$ Oe.[34] The integral of motion C_v is equal to $C_v = (\sqrt{m^2 + \vec{p}^2(0)} - p^1(0))/\sqrt{2}$. For nonrelativistic particles $C_v \propto m/\sqrt{2}$ and $\Pi \propto \omega_H \sqrt{2}$. (The coefficient $\sqrt{2}$ disappears if we use the natural parameter τ instead of retarded time u). Using the estimate[34] $\omega_H \propto 10^7 \cdot H_0(\mathrm{Hz})$ we find $\omega_H \approx 10^1 - 10^2$ Hz. This is well within the typical range $1-10^3$ Hz for the frequency k of a GW, generated by rapidly rotating neutron stars (pulsars). Thus, for nonrelativistic particles Π may be of the same order as the GW frequency k. The situation is different for ultrarelativistic particles. Since for particles that move in propagation direction of the GW ($p^1(0) > 0$), we have $C_v \to 0$ for $m \to 0$. Consequently, the quantity Π becomes very large [cf. Eq. (55)], such that $\Pi \gg k$. However, if the particles move in the opposite direction, i.e., $p^1(0) < 0$, any value of C_v is possible. In particular, Π is not excluded to be in the range of about 10^{-3} Hz which is typical for infra-low-frequency GW from relativistic compact binaries.

Since an ensemble of particles will generally not be characterized by a single value of C_v but by a distribution, the quantity C_v may play the role of a tuning parameter in the following sense.

Let us associate a mean value $\langle C_v \rangle$ for the system as a whole and let the system be outside the resonance $\omega_H/k=n/2$ for this $\langle C_v \rangle$, but not very far from it. Since $\Pi=\omega_H m/C_v$, we will very likely find a particular particle with a specific C_v such that for this particle $\Pi/k=n/2$ exactly. Consequently, certain particles of the ensemble might be resonant under these conditions.

VI. EVOLUTION OF THE SPIN FOUR-VECTOR

In this section we focus on the solution of Eq. (5) in external gravitational and magnetic fields. Equations (4) and (5) admit two integrals of motion, namely $p_i S^i=0$ and $S_i S^i=-E_0^2=\text{const}$.[20] In the present context this amounts to

$$p_v S_u+p_u S_v+p_\alpha S^\alpha=0, \quad 2S_u S_v+S_\alpha S^\alpha=-E_0^2, \tag{80}$$

which may be used to eliminate the components S_v and S_u according to

$$S_u=\frac{1}{2p_v}[-p_\alpha S^\alpha \mp \sqrt{(p_\alpha S^\alpha)^2+(m^2-p_\alpha p^\alpha)(E_0^2+S_\alpha S^\alpha)}], \tag{81}$$

and

$$S_v=\frac{1}{2p_u}[-p_\alpha S^\alpha \pm \sqrt{(p_\alpha S^\alpha)^2+(m^2-p_\alpha p^\alpha)(E_0^2+S_\alpha S^\alpha)}], \tag{82}$$

respectively. After the reparametrization (42) the remaining equations are

$$\frac{dS_\alpha}{du}=\frac{1}{2}g^{\sigma\rho}\dot{g}_{\rho\alpha}\left(S_\sigma-p_\sigma\frac{S_v}{C_v}\right)+\frac{e}{2C_v}\left[\ gF_{\alpha k}S^k+\frac{(g-2)}{m^2}p_\alpha F_{kl}S^k p^l\right]. \tag{83}$$

Furthermore, the equation for S_v is

$$\frac{dS_v}{du}=\frac{e(g-2)}{2m^2}F_{kl}S^k p^l. \tag{84}$$

In the following we shall restrict ourselves to the exactly integrable case $g=2$. Under this condition we find from (84) that

$$S_v=\text{const}=E_v. \tag{85}$$

After the substitution

$$S_\alpha=X_\alpha+\frac{E_v}{C_v}p_\alpha, \tag{86}$$

where p_α is assumed to be given by Eq. (70) in terms of Hill (or Mathieu) functions, we obtain a homogeneous equation for the new variable X_α,

$$\frac{\mathrm{d}X_\alpha}{\mathrm{d}u}=\frac{1}{2}g^{\sigma\rho}\dot{g}_{\rho\alpha}X_\sigma+\frac{e}{C_v}F_{\alpha\sigma}g^{\sigma\lambda}X_\lambda. \tag{87}$$

It is convenient to write this equation in the matrix form

$$\frac{\mathrm{d}}{\mathrm{d}u}\mathbf{X}=\left(\mathbf{A}+\frac{\Pi}{L^2}\mathbf{B}\right)\cdot\mathbf{X}, \tag{88}$$

where $\mathbf{X}$ is a column vector with elements X_2 and X_3. The two-dimensional matrices $\mathbf{A}$ and $\mathbf{B}$ have the structures

$$\mathbf{A}=\begin{pmatrix} \dfrac{\dot{L}}{L}+\cosh^2(2\gamma)\dot{\beta} & e^{2\beta}(\dot{\gamma}-\sinh(2\gamma)\cosh(2\gamma)\dot{\beta}) \\ e^{-2\beta}(\dot{\gamma}+\sinh(2\gamma)\cosh(2\gamma)\dot{\beta}) & \dfrac{\dot{L}}{L}-\cosh^2(2\gamma)\dot{\beta} \end{pmatrix}, \tag{89}$$

and

$$\mathbf{B}\equiv\begin{pmatrix} \sinh 2\gamma & -e^{2\beta}\cosh 2\gamma \\ e^{-2\beta}\cosh 2\gamma & -\sinh 2\gamma \end{pmatrix}, \tag{90}$$

respectively. Equation (50) may be written in matrix form as well:

$$\begin{pmatrix} p_2 \\ p_3 \end{pmatrix}^{\cdot}=\frac{\Pi}{L^2}\mathbf{B}\cdot\begin{pmatrix} p_2 \\ p_3 \end{pmatrix}. \tag{91}$$

For the derivative of the combination $p_2^2+p_3^2$ we obtain

$$\frac{\mathrm{d}}{\mathrm{d}u}(p_2^2+p_3^2)=\frac{2\Pi}{L^2}[(p_2^2-p_3^2)\sinh 2\gamma-2p_2p_3\cosh 2\gamma\sinh 2\beta]. \tag{92}$$

In general, the right-hand side of this equation is different from zero, i.e., the particle motion is no longer circular in the GW field.

Equation (88) may be further simplified by changing to a new variable **Y**, defined by

$$\mathbf{X}=\mathbf{T}\cdot\mathbf{Y}, \tag{93}$$

where **T** is supposed to satisfy the differential equation

$$\frac{\mathrm{d}}{\mathrm{d}u}\mathbf{T}=\mathbf{A}\cdot\mathbf{T}. \tag{94}$$

This procedure (cf. Refs. 35 and 36) removes the **A** term in Eq. (88) and gives rise to

$$\frac{\mathrm{d}}{\mathrm{d}u}\mathbf{Y}=\frac{\Pi}{L^2}\hat{\mathbf{B}}\cdot\mathbf{Y} \tag{95}$$

for **Y** with

$$\hat{\mathbf{B}}\equiv\mathbf{T}^{-1}\cdot\mathbf{B}\cdot\mathbf{T}. \tag{96}$$

By direct calculation one checks that the matrix

$$\mathbf{T}=L\cdot\begin{pmatrix} e^{\beta} & 0 \\ 0 & e^{-\beta} \end{pmatrix}\cdot\begin{pmatrix} \cosh\gamma & \sinh\gamma \\ \sinh\gamma & \cosh\gamma \end{pmatrix}\cdot\begin{pmatrix} \cos\psi & -\sin\psi \\ \sin\psi & \cos\psi \end{pmatrix}, \tag{97}$$

where

$$\psi\equiv\int_0^u\dot{\beta}\sinh 2\gamma\,\mathrm{d}u \tag{98}$$

satisfies Eq. (94). The determinants of each of the three two-dimensional matrices in (97) are equal to one. In the absence of the GW field all of them are identical to **I**, i.e.,

$$\mathbf{T}(0)=\mathbf{I}\equiv\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}. \tag{99}$$

The structure of the third matrix on the right-hand side of Eq. (97) suggests the interpretation as a gravitationally induced rotation with phase $\psi(u)$ and frequency $\dot{\psi}(u)$. For either of the polarizations $\gamma=0$ or $\beta=0$, however, we have $\psi=0$ and the third matrix reduces to $\mathbf{I}$.

Direct calculation of the matrix $\hat{\mathbf{B}}$ in (96) with the help of expressions (90), (97), and (98) yields the surprisingly simple result

$$\hat{\mathbf{B}}\equiv\mathbf{T}^{-1}\cdot\mathbf{B}\cdot\mathbf{T}=\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}. \tag{100}$$

It is remarkable, that the matrix $\hat{\mathbf{B}}$, different from $\mathbf{B}$, does *not* depend on retarded time. This property allows us to find the solution of Eq. (95) in terms of elementary functions as

$$\begin{pmatrix}Y_2(u)\\ Y_3(u)\end{pmatrix}=\mathbf{R}(u)\cdot\begin{pmatrix}Y_2(0)\\ Y_3(0)\end{pmatrix},\quad \mathbf{R}(u)\equiv\begin{pmatrix}\cos\Phi(u) & -\sin\Phi(u)\\ \sin\Phi(u) & \cos\Phi(u)\end{pmatrix}, \tag{101}$$

where

$$\Phi(u)\equiv\Pi\int_0^u\frac{du}{L^2(u)}. \tag{102}$$

The combination

$$Y_2^2(u)+Y_3^2(u)=Y_2^2(0)+Y_3^2(0) \tag{103}$$

is preserved, i.e., the dynamics of $\mathbf{Y}$ represents a rotation in the x^20x^3 plane. The functions $S_2(u)$ and $S_3(u)$ in (86) can now be expressed in terms of the three matrices $\mathbf{H}(u)$, $\mathbf{T}(u)$, and $\mathbf{R}(u)$, given by expressions (71), (97), and (101), respectively:

$$\begin{pmatrix}S_2(u)\\ S_3(u)\end{pmatrix}=\mathbf{T}(u)\cdot\mathbf{R}(u)\cdot\begin{pmatrix}S_2(0)\\ S_3(0)\end{pmatrix}+\frac{E_v}{C_v}[\,\mathbf{H}(u)-\mathbf{T}(u)\cdot\mathbf{R}(u)]\begin{pmatrix}C_2\\ C_3\end{pmatrix}. \tag{104}$$

While the matrices $\mathbf{T}(u)$ and $\mathbf{R}(u)$ are constructed out of elementary functions, the matrix $\mathbf{H}(u)$, according to Eq. (71), consists of Hill functions, which for the special case of Sec. V B 2 reduce to Mathieu functions. The latter, in turn, can be expressed via ''cosine elliptic'' and ''sine elliptic'' functions [see the discussion following Eq. (77)]. All these functions are assumed to be known here. In the absence of the GW,

$$\mathbf{T}(u)\equiv\mathbf{I},\quad \mathbf{H}(u)=\mathbf{R}(u)\equiv\mathbf{R}_0(\tau)=\begin{pmatrix}\cos\Omega_H\tau & -\sin\Omega_H\tau\\ \sin\Omega_H\tau & \cos\Omega_H\tau\end{pmatrix}, \tag{105}$$

and we recover the standard flat space–time rotation of the spin particle,

$$\begin{pmatrix}p_2(\tau)\\ p_3(\tau)\end{pmatrix}=\mathbf{R}_0(\tau)\cdot\begin{pmatrix}C_2\\ C_3\end{pmatrix},\quad \begin{pmatrix}S_2(\tau)\\ S_3(\tau)\end{pmatrix}=\mathbf{R}_0(\tau)\cdot\begin{pmatrix}S_2(0)\\ S_3(0)\end{pmatrix}. \tag{106}$$

Equation (104) represents the general solution for the spin dynamics in the GW field (30) and the magnetic field (48). The structure of the solution (104) allows us to interpret the spin dynamics as composed of three separate contributions, characterized by the matrices $\mathbf{R}(u)$, $\mathbf{T}(u)$, and $\mathbf{H}(u)$. The matrix $\mathbf{R}$ represents a Larmor type precession with the frequency $\Pi/L^2(u)$. As already

mentioned, the matrix **T** describes a gravitationally induced rotation with phase $\psi(u)$ and frequency $\dot{\psi}(u)$, and finally, the matrix **H** accounts for the coupling of the particle motion (70) to the spin dynamics.

VII. ISOSPIN EVOLUTION

In this section as well as in the subsequent one we discuss the dynamics of non-Abelian charges under the influence of external gravitational and Yang–Mills fields. Let us consider Eq. (20) for the SU(2) symmetry group. Since the structure constants for this group coincide with the Levi–Civita symbol, all three directions in the isospin space are equivalent. With the choice $I^{(3)}=I_{(A)}q^{(A)}$ we obtain the following equations for the isospin evolution:

$$\frac{\mathrm{d}I^{(1)}}{\mathrm{d}\tau}=\Omega\cdot I^{(2)},\quad \frac{\mathrm{d}I^{(2)}}{\mathrm{d}\tau}=-\Omega\cdot I^{(1)}. \tag{107}$$

The precession frequency Ω in Eq. (20) is calculated on the particle worldline with p^i from (70) and the potential

$$A_i(u)=\frac{1}{2}M\left[\left(x^2(u)-x^2(0)-\frac{C_2}{\Pi C_v}\right)\delta_i^3-\left(x^3(u)-x^3(0)-\frac{C_3}{\Pi C_v}\right)\delta_i^2\right], \tag{108}$$

corresponding to the constant solution $F_{23}=M$. Differentiating expression (108), we recover the field strength (49). The frequency $\Omega(u)$ in (20) is given by

$$\Omega(u)=\frac{g}{m}(A_2p^2+A_3p^3). \tag{109}$$

Here, the arbitrary constant was chosen such that $\Omega(u=0)=0$. In order to find the terms $x^2(u)-x^2(0)$ and $x^3(u)-x^3(0)$ which are needed in (108), we have to integrate the second equation in (35). The formal solution is

$$x^\alpha(u)-x^\alpha(0)=\frac{1}{C_v}\int_0^u d\xi g^{\alpha\beta}(\xi)p_\beta(\xi), \tag{110}$$

which provides us with

$$\Omega(u)=\frac{gM}{2mC_v}\left\{\int_0^u \mathrm{d}\xi[p^2(\xi)p^3(u)-p^3(\xi)p^2(u)]-\frac{1}{\Pi}[C_2p^3(u)-C_3p^2(u)]\right\}. \tag{111}$$

Again we assume here $p^2(u)$ and $p^3(u)$ to be known, i.e., the particle dynamics is considered to be solved [cf. Eqs. (70) and (71)]. The solution of the system (107) then becomes

$$I^{(1)}=I\cos\Psi(u),\quad I^{(2)}=-I\sin\Psi(u),\quad \Psi(u)=\Psi(0)+\frac{m}{C_v}\int_0^u\Omega(u)\mathrm{d}u. \tag{112}$$

The function $\Psi(u)$ plays the role of the (generally u-dependent) phase of the isospin precession in the external Yang–Mills field.[37] The set of equations (112) with (111) provides a complete description for the isospin dynamics under the influence of the GW (30) and the Yang–Mills field (49).

VIII. COLOR CHARGE EVOLUTION

The SU(3) case may be studied along similar lines although it is technically more extended since more degrees of freedom are involved. As a result, we shall find a richer dynamical structure than in the SU(2) case. With the ansatz (18) and expression (15), Eq. (24) for the color charge dynamics becomes

$$
\begin{aligned}
\frac{dQ^{(1)}}{d\tau} &= -\Omega\left[(q^{(2)}Q^{(3)}-q^{(3)}Q^{(2)})+\frac{1}{2}(q^{(4)}Q^{(7)}-q^{(7)}Q^{(4)})-\frac{1}{2}(q^{(5)}Q^{(6)}-q^{(6)}Q^{(5)})\right],\\
\frac{dQ^{(2)}}{d\tau} &= -\Omega\left[(q^{(3)}Q^{(1)}-q^{(1)}Q^{(3)})+\frac{1}{2}(q^{(4)}Q^{(6)}-q^{(6)}Q^{(4)})+\frac{1}{2}(q^{(5)}Q^{(7)}-q^{(7)}Q^{(5)})\right],\\
\frac{dQ^{(3)}}{d\tau} &= -\Omega\left[(q^{(1)}Q^{(2)}-q^{(2)}Q^{(1)})+\frac{1}{2}(q^{(4)}Q^{(5)}-q^{(5)}Q^{(4)})-\frac{1}{2}(q^{(6)}Q^{(7)}-q^{(7)}Q^{(6)})\right],\\
\frac{dQ^{(4)}}{d\tau} &= -\frac{\Omega}{2}[(q^{(7)}Q^{(1)}-q^{(1)}Q^{(7)})+(q^{(6)}Q^{(2)}-q^{(2)}Q^{(6)})+(q^{(5)}Q^{(3)}-q^{(3)}Q^{(5)})]\\
&\quad -\frac{\sqrt{3}\Omega}{2}[q^{(5)}Q^{(8)}-q^{(8)}Q^{(5)}],\\
\frac{dQ^{(5)}}{d\tau} &= -\frac{\Omega}{2}[(q^{(1)}Q^{(6)}-q^{(6)}Q^{(1)})+(q^{(7)}Q^{(2)}-q^{(2)}Q^{(7)})+(q^{(3)}Q^{(4)}-q^{(4)}Q^{(3)})]\\
&\quad -\frac{\sqrt{3}\Omega}{2}[q^{(8)}Q^{(4)}-q^{(4)}Q^{(8)}],\\
\frac{dQ^{(6)}}{d\tau} &= -\frac{\Omega}{2}[(q^{(5)}Q^{(1)}-q^{(1)}Q^{(5)})+(q^{(2)}Q^{(4)}-q^{(4)}Q^{(2)})+(q^{(3)}Q^{(7)}-q^{(7)}Q^{(3)})]\\
&\quad -\frac{\sqrt{3}\Omega}{2}[q^{(7)}Q^{(8)}-q^{(8)}Q^{(7)}],\\
\frac{dQ^{(7)}}{d\tau} &= -\frac{\Omega}{2}[(q^{(1)}Q^{(4)}-q^{(4)}Q^{(1)})+(q^{(2)}Q^{(5)}-q^{(5)}Q^{(2)})+(q^{(6)}Q^{(3)}-q^{(3)}Q^{(6)})]\\
&\quad -\frac{\sqrt{3}\Omega}{2}[q^{(8)}Q^{(6)}-q^{(6)}Q^{(8)}],\\
\frac{dQ^{(8)}}{d\tau} &= -\frac{\sqrt{3}\Omega}{2}[(q^{(4)}Q^{(5)}-q^{(5)}Q^{(4)})+(q^{(6)}Q^{(7)}-q^{(7)}Q^{(6)})].
\end{aligned}
\tag{113}
$$

The space of color charges may be split into three different subspaces, which correspond to the structures of the SU(2), SU(2)×U(1) and U(1) subgroups of the total group SU(3) (see, e.g., Ref. 38). In the following we consider the vector $q^{(A)}$ to lie in the first, second, and third subspaces, respectively.

A. First special case

Let the vector $q^{(A)}$ have only the three nonzero components $q^{(1)}$, $q^{(2)}$, and $q^{(3)}$. It is then evident that

$$
(Q^{(1)})^2+(Q^{(2)})^2+(Q^{(3)})^2=\text{const}\,, \tag{114}
$$

$$(Q^{(4)})^2+(Q^{(5)})^2+(Q^{(7)})^2+(Q^{(7)})^2=\text{const}, \tag{115}$$

and

$$Q^{(8)}=\text{const}. \tag{116}$$

For the color charges $Q^{(1)}$, $Q^{(2)}$, and $Q^{(3)}$, which correspond to a SU(2) subgroup of the total SU(3) group, the combination (114) is preserved. A similar relation holds for the set $Q^{(4)}$, $Q^{(5)}$, $Q^{(6)}$, and $Q^{(7)}$, while $Q^{(8)}$ is separately conserved. Relations (114)–(116) are also obtained for the case that the only nonvanishing components are $q^{(4)}$, $q^{(5)}$, $q^{(6)}$, and $q^{(7)}$, as well as for the choice $q^{(1)}=q^{(2)}=\cdots=q^{(7)}=0$ and $q^{(8)}\neq 0$. Let us now further specify to the case $q^{(A)}=\delta^{(A)}_{(1)}$. Then the system (113) takes the form

$$\begin{gathered}
\frac{dQ^{(1)}}{d\tau}=0\,,\quad \frac{dQ^{(8)}}{d\tau}=0\,,\\
\frac{dQ^{(2)}}{d\tau}=\Omega Q^{(3)},\quad \frac{dQ^{(3)}}{d\tau}=-\Omega Q^{(2)},\\
\frac{dQ^{(4)}}{d\tau}=\frac{1}{2}\Omega Q^{(7)},\quad \frac{dQ^{(7)}}{d\tau}=-\frac{1}{2}\Omega Q^{(4)},\\
\frac{dQ^{(5)}}{d\tau}=-\frac{1}{2}\Omega Q^{(6)},\quad \frac{dQ^{(6)}}{d\tau}=\frac{1}{2}\Omega Q^{(5)}.
\end{gathered} \tag{117}$$

The color charge $Q^{(1)}$ remains constant because it is the projection $Q^{(A)}q_{(A)}$ of the vector $Q^{(A)}$ on the given preferred direction $q_{(A)}$. The charge $Q^{(8)}$ does not evolve, because for such a $q_{(A)}$ the antisymmetric tensor $H_{(A)(B)}$ in (24) does not contain a nonvanishing component with $(A)=(8)$. The equations for $Q^{(2)},\ldots,Q^{(7)}$ split into *three two-dimensional* subsystems with the pairs $Q^{(2)}$ and $Q^{(3)}$, $Q^{(4)}$ and $Q^{(7)}$, $Q^{(5)}$, and $Q^{(6)}$. The evolution of the first pair ($Q^{(2)}$ and $Q^{(3)}$) corresponds to a precession in the group space with the frequency Ω. It has a solution of the type (112). The dynamics of the pairs $Q^{(4)}$, $Q^{(7)}$ and $Q^{(5)}$, $Q^{(6)}$ is a precession with the frequency $\Omega/2$.

B. Second special case: $q^{(A)}=\delta^{(A)}_{(4)}$

Now we assume $q^{(A)}$ to lie in the second subspace. As an example we consider the case $q^{(A)}=\delta^{(A)}_{(4)}$. For this choice the set of equations (113) can be transformed into

$$\begin{gathered}
\frac{dQ^{(4)}}{d\tau}=0,\quad \frac{d}{d\tau}\left(-\frac{\sqrt{3}}{2}Q^3+\frac{1}{2}Q^8\right)=0\,,\\
\frac{dQ^{(5)}}{d\tau}=\Omega Q^*,\quad \frac{dQ^*}{d\tau}=-\Omega Q^{(5)},\quad Q^*\equiv\frac{1}{2}(Q^{(3)}+\sqrt{3}Q^{(8)}),\\
\frac{dQ^{(1)}}{d\tau}=-\frac{1}{2}\Omega Q^{(7)},\quad \frac{dQ^{(7)}}{d\tau}=\frac{1}{2}\Omega Q^{(1)},\\
\frac{dQ^{(2)}}{d\tau}=-\frac{1}{2}\Omega Q^{(6)},\quad \frac{dQ^{(6)}}{d\tau}=\frac{1}{2}\Omega Q^{(2)}.
\end{gathered} \tag{118}$$

The quantities $Q^{(4)}$ and $-(\sqrt{3}/2)Q^3+\frac{1}{2}Q^8$ remain constant, the projections $Q^{(5)}$ and $Q^*\equiv\frac{1}{2}(Q^{(3)}+\sqrt{3}Q^{(8)})$ precess with the frequency Ω, the pairs $Q^{(1)}$, $Q^{(7)}$ and $Q^{(2)}$, $Q^{(6)}$ precess with $\Omega/2$. Furthermore, one has

$$(Q^{(1)})^2+(Q^{(7)})^2=\text{const}\,,\quad (Q^{(2)})^2+(Q^{(6)})^2=\text{const},$$
$$(Q^{(3)})^2+(Q^{(5)})^2+(Q^{(8)})^2=\text{const}. \tag{119}$$

C. Third special case: $q^{(A)}=\delta^{(A)}_{(8)}$

Finally, let $q^{(A)}$ be parallel to the basis vector in the U(1) subspace, i.e., $q^{(A)}=\delta^{(A)}_{(8)}$. Here we obtain

$$\frac{dQ^{(1)}}{d\tau}=0,\quad \frac{dQ^{(2)}}{d\tau}=0,\quad \frac{dQ^{(3)}}{d\tau}=0,\quad \frac{dQ^{(8)}}{d\tau}=0,$$

as well as

$$\frac{dQ^{(4)}}{d\tau}=\frac{\sqrt{3}}{2}\Omega Q^{(5)},\quad \frac{dQ^{(5)}}{d\tau}=-\frac{\sqrt{3}}{2}\Omega Q^{(4)},$$
$$\frac{dQ^{(6)}}{d\tau}=\frac{\sqrt{3}}{2}\Omega Q^{(7)},\quad \frac{dQ^{(7)}}{d\tau}=-\frac{\sqrt{3}}{2}\Omega Q^{(6)}. \tag{120}$$

The pairs $Q^{(4)}$, $Q^{(5)}$ and $Q^{(6)}$, $Q^{(7)}$ precess with the frequency $(\sqrt{3}/2)\,\Omega$, while $Q^{(1)}$, $Q^{(2)}$, $Q^{(3)}$, and $Q^{(8)}$ are constant.

D. Remarks on the general case

In the general case one expects the color vector $Q^{(A)}$ to rotate in the hypersurface orthogonal to $q^{(A)}$ in the group space. This is illustrated by the following analogy. Let us consider the standard decomposition of the Maxwell tensor with respect to a four-velocity vector V^i of an arbitrary observer,

$$F_{ik}=E_iV_k-E_kV_i-\varepsilon_{ikjl}H^jV^l, \tag{121}$$

where E^i and H^k are the corresponding four-vectors for the electric and magnetic fields, respectively. For $F_{ik}V^k=0$ the comoving observer experiences a magnetic field only which, via the Lorentz force, generates a spatial particle rotation, i.e., a rotation in the hypersurface orthogonal to V^i.

In the present case the vector $q^{(A)}$ plays the role of V^i. Instead of Maxwell's tensor we have to consider [cf. Eq. (24)] the antisymmetric tensor $H_{(A)(C)}=f_{(A)(B)(C)}q^{(B)}$. Since $H_{(A)(C)}q^{(C)}=0$, this represents a group space analogue to the previous case of a pure magnetic field in space–time. Consequently, the color vector rotates in the group space analogously to the momentum vector of a charged particle in a pure magnetic field.

IX. CONCLUSIONS

Charged particles in electromagnetic fields are known to be parametrically influenced by gravitational waves. Typical phenomena are parametric resonances and parametric oscillations. In the present paper we have generalized and extended work in this field to include classical spin particles and particles with non-Abelian charges in specific Yang–Mills fields. Moreover, no weak field approximation was used for the GW. The electrically charged spin particle was described by the Bargmann–Michel–Telegdi equations. For the dynamics of the non-Abelian charges we used Wong's equations for the isospin [SU(2)-symmetry] and for the color charges [SU(3) symmetry]. We derived exact general solutions for the parametric influence of the GW on the particle motion in each of the mentioned cases, including the dynamics of spin, isospin, and color charge. For the case of a special sandwich GW the particle dynamics was reduced to a set of Mathieu equations. Using well-known stability properties of the latter we found that parametric instabilities are a

generic phenomenon for such kind of particle motion. Since spin, isospin, and color charge are coupled to this motion, their dynamics is affected correspondingly. The spin dynamics was shown to be composed of three elements, namely a gravitationally modified Larmor precession, a part due to the coupling to the particle motion, and a pure gravitational part. The vectors of isospin and color charge carry out gravitationally influenced precession motions in their group spaces which we have classified for several cases.

(Received 7 May 2003; accepted 27 June 2003)

Matter collineations of spherically symmetric Lorentzian manifolds are considered. These are investigated when the energy–momentum tensor is nondegenerate and also when it is degenerate. We have classified space–times admitting higher symmetries and space–times admitting SO(3) as the maximal isometry group. For the nondegenerate case, we obtain either *four*, *six*, *seven*, or *ten* independent matter collineations in which *four* are isometries and the rest are proper. The results of the previous paper [Sharif and Sehar (Gen. Relativ. Gravit. **35**, 1091 (2003)] are recovered as a special case. It is worth noting that we have also obtained two cases where the energy–momentum tensor is degenerate but the group of matter collineations is finite-dimensional, i.e., *four* or *ten*. © *2003 American Institute of Physics.*

I. INTRODUCTION

Since the pioneering work of Katzin, Levine, Davis and their collaborators,[1–5] the study of symmetries has played an important role in the classification of space–times, giving rise to many interesting results with useful applications. The theory of General Relativity (GR), described by Einstein's field equations (EFEs), is highly nonlinear. Due to its nonlinearity, it becomes difficult to find the exact solutions of the EFEs, in particular, if the metric depends on all coordinates.[6] However, this problem can be overcome to some extent if it is assumed that the space–time has some geometric symmetry properties. These symmetry properties are given by Killing vectors (KVs), which then lead to conservation laws.[7–9] A large number of solutions of the EFEs with different symmetry structures have been found[8] and classified according to their properties.[10]

As given by the pioneers, curvature and Ricci tensors play a significant role (in terms of curvature and Ricci collineations) in understanding the geometric structure of metrics. They have provided a detailed study of curvature and Ricci collineations in the context of the related particle and field conservation laws. For a given distribution of matter, the contribution of gravitational potential satisfying EFEs is the principal aim of all investigations in gravitational physics. This has been achieved by imposing symmetries on the geometry compatible with the dynamics of the chosen distribution of matter. In an attempt to study the geometric and physical properties of the electromagnetic fields, different types of collineations have been investigated[11,12] along with many other interesting results. Symmetries of the energy–momentum tensor (also called matter collineations) provide conservation laws on matter fields. These enable us to know how the physical fields, occupying in certain region of space–times, reflect the symmetries of the metric.[13]

There is a large body of recent literature which shows interest in the study of matter collineations (MCs).[14–22] In a recent paper,[14] the study of MCs has been taken for static spherically symmetric space–times (SSS) and some interesting results have been obtained. However, it was incomplete in the sense that (i) only the static case was considered and (ii) some cases were missing, in particular, for finite-dimensional MCs. In this paper, we extend the procedure to

[a)]Present address: Department of Mathematical Sciences, University of Aberdeen, Kings College, Aberdeen AB24 3UE Scotland, UK; electronic mail: msharif@maths.abdn.ac.uk

calculate MCs of SSS both for nondegenerate and also for degenerate cases with special emphasis on the metrics admitting higher symmetries and also SO(3) as the maximal symmetry. We relate them with RCs and isometries. The rest of the paper is organized as follows. Section II contains a brief review of MCs and we write down MC equations for SSS. In Sec. III, we shall solve these MC equations when the energy–momentum tensor is nondegenerate and in Sec. IV MC equations are solved for the degenerate energy–momentum tensor. Section V contains a summary and discussion of the results obtained.

II. MATTER COLLINEATIONS AND ITS EQUATIONS

Let (M,g) be a space–time, where M is a smooth, connected, Hausdorff four-dimensional manifold and g is smooth Lorentzian metric of signature $(+---)$ defined on M. The manifold M and the metric g are assumed smooth (C^{∞}). We shall use the usual component notation in local charts, and a covariant derivative with respect to the symmetric connection Γ associated with the metric g will be denoted by a semicolon and a partial derivative by a comma.

The geometry and matter of a space–time are related through the EFEs given in each coordinate system of M by

$$R_{ab}-\tfrac{1}{2}Rg_{ab}\equiv G_{ab}=\kappa T_{ab} \quad (a,b=0,1,2,3), \tag{1}$$

where κ is the gravitational constant, G_{ab} is the Einstein tensor, R_{ab} is the Ricci and T_{ab} is the matter (energy–momentum) tensor. Also, $R=g^{ab}R_{ab}$ is the Ricci scalar. We have assumed here that the cosmological constant $\Lambda=0$. Using the Bianchi identities, it can easily be shown that

$$G^{ab};b=0 \ (\Leftrightarrow T^{ab};b=0). \tag{2}$$

A smooth vector field ξ is said to preserve a matter symmetry[23] on M if, for each smooth local diffeomorphism ϕ_t associated with ξ, the tensor T and ϕ_t^*T are equal on the domain U of ϕ_t, i.e., $T=\phi_t^*T$. Equivalently, a vector field ξ^a is said to generate a MC if it satisfies

$$\pounds_{\xi}T_{ab}=0 \quad \Leftrightarrow \quad \pounds_{\xi}G_{ab}=0, \tag{3}$$

where £ is the Lie derivative operator, ξ^a is the symmetry or collineation vector. Every KV is a MC but the converse is not true, in general. Collineations can be proper (nontrivial) or improper (trivial). We define a proper MC to be a MC which is not a KV, or a homothetic vector (HV). The MC Eq. (3) can be written in component form as

$$T_{ab,c}\xi^c+T_{ac}\xi^c_{,b}+T_{cb}\xi^c_{,a}=0. \tag{4}$$

The most general form of the metric for a spherically symmetric Lorentzian manifold is given by

$$\mathrm{d}s^2=e^{\nu(t,r)}\mathrm{d}t^2-e^{\mu(t,r)}\mathrm{d}r^2-e^{\lambda(t,r)}\mathrm{d}\Omega^2, \tag{5}$$

where $\mathrm{d}\Omega^2=\mathrm{d}\theta^2+\sin^2\theta\,\mathrm{d}\phi^2$. The surviving components of the energy–momentum tensor, given in Appendix A, are T_{00}, T_{01} T_{11}, T_{22}, T_{33}, where $T_{33}=\sin^2\theta T_{22}$.

The MC equations can be written as follows:

$$T_{00,0}\xi^0+T_{00,1}\xi^1+2T_{00}\xi^0_{,0}+2T_{01}\xi^1_{,0}=0, \tag{6}$$

$$T_{01,0}\xi^0+T_{01,1}\xi^1+T_{01}\xi^0_{,0}+T_{11}\xi^1_{,0}+T_{01}\xi^1_{,1}+T_{00}\xi^0_{,1}=0, \tag{7}$$

$$T_{00}\xi^0_{,2}+T_{01}\xi^1_{,2}+T_{22}\xi^2_{,0}=0, \tag{8}$$

$$T_{00}\xi^0_{,3}+T_{01}\xi^1_{,3}+\sin^2\theta T_{22}\xi^3_{,0}=0, \tag{9}$$

$$T_{11,0}\xi^0+T_{11,1}\xi^1+2T_{01}\xi^0_{,1}+2T_{11}\xi^1_{,1}=0, \tag{10}$$

$$T_{01}\xi^0_{,2}+T_{11}\xi^1_{,2}+T_{22}\xi^2_{,1}=0, \tag{11}$$

$$T_{01}\xi^0_{,3}+T_{11}\xi^1_{,3}+\sin^2\theta T_{22}\xi^3_{,1}=0, \tag{12}$$

$$T_{22,0}\xi^0+T_{22,1}\xi^1+2T_{22}\xi^2_{,2}=0, \tag{13}$$

$$T_{22}\xi^2_{,3}+\sin^2\theta T_{22}\xi^3_{,2}=0, \tag{14}$$

$$T_{22,0}\xi^0+T_{22,1}\xi^1+2\cot\theta T_{22}\xi^2+2T_{22}\xi^3_{,3}=0. \tag{15}$$

These are the first-order nonlinear partial differential equations in four variables $\xi^a(x^b)$. We solve these equations for the nondegenerate case, when

$$\det(T_{ab})=T_{22}^2(T_{00}T_{11}-T_{01}^2)\sin^2\theta\neq 0 \tag{16}$$

and for the degenerate case, where $\det(T_{ab})=0$. It is noticed that when $T_{01}=0$ we shall use the notation $T_{aa}=T_a$ for the sake of brevity.

III. MATTER COLLINEATIONS IN THE NONDEGENERATE CASE

In this section, we shall evaluate MCs only for those cases which have nondegenerate energy–momentum tensor, i.e., $\det(T_{ab})\neq 0$. This will be done as two cases; one when M admits higher symmetries and one when SO(3) is the maximal isometry group of M. To this end, we set up the general conditions for the solution of MC equations for the nondegenerate case.

When we solve Eqs. (6)–(15) simultaneously, after some tedious algebra, we get the following solution:

$$\xi^0=\frac{T_{22}}{T_{00}T_{11}-T_{01}^2}[\{(\dot{A}_1T_{11}-A_1'T_{01})\sin\phi-(\dot{A}_2T_{11}-A_2'T_{01})\cos\phi\}\sin\theta + (\dot{A}_3T_{11}-A_3'T_{01})\cos\theta+A_4T_{11}-A_5T_{01}], \tag{17}$$

$$\xi^1=\frac{-T_{22}}{T_{00}T_{11}-T_{01}^2}[\{(\dot{A}_1T_{01}-A_1'T_{00})\sin\phi-(\dot{A}_2T_{01}-A_2'T_{00})\cos\phi\}\sin\theta + (\dot{A}_3T_{01}-A_3'T_{00})\sin\theta+A_4T_{01}-A_5T_{00}], \tag{18}$$

$$\xi^2=-(A_1\sin\phi-A_2\cos\phi)\cos\theta+A_3\sin\theta+c_1\sin\phi-c_2\cos\phi+c_4\ln\left(\tan\frac{\theta}{2}\right)\sin\theta, \tag{19}$$

$$\xi^3=-(A_1\cos\phi+A_2\sin\phi)\csc\theta+(c_1\cos\phi+c_2\sin\phi)\cot\theta+c_4\phi+c_3, \tag{20}$$

where c_1,c_2,c_3,c_4 are arbitrary constants and $A_\nu=A_\nu(t,r)$, $\nu=1,2,3,4,5$. Here dot and prime indicate the differentiation with respect to time and r coordinate, respectively. When we replace these values of ξ^a in MC Eqs. (6)–(15), we obtain the following differential constraints on A_ν with $c_4=0$:

$$2(T_{00}T_{11}-T_{01}^2)(T_{22}\dot{A}_i)^{\cdot}+T_{22}[(2T_{01}\dot{T}_{01}-T_{11}\dot{T}_{00}-T_{01}T_{00}')\dot{A}_i-(2T_{00}\dot{T}_{01}-T_{01}\dot{T}_{00}-T_{00}T_{00}')A_i'] = 0, \quad (i=1,2,3), \tag{21}$$

$$(T_{00}T_{11}-T_{01}^2)[(T_{22}\dot{A}_i)'+(T_{22}A_i')^{\cdot}]+T_{22}[(T_{01}\dot{T}_{11}-T_{11}T_{00}')\dot{A}_i+(T_{01}T_{00}'-T_{00}\dot{T}_{11})A_i']=0, \tag{22}$$

$$2(T_{00}T_{11}-T_{01}^2)(T_{22}A_i')'+T_{22}[(2T_{01}T_{01}'-T_{00}T_{11}'-T_{01}\dot{T}_{11})-(2T_{11}T_{01}'-T_{11}\dot{T}_{11}-T_{01}T_{11}')\dot{A}_i]=0, \tag{23}$$

$$(T_{11}\dot{T}_{22}-T_{01}T_{22}')\dot{A}_i+(T_{00}T_{22}'-T_{01}\dot{T}_{22})A_i'+2A_i=0, \tag{24}$$

$$2(T_{00}T_{11}-T_{01}^2)(T_{22}A_4)^{\cdot}+T_{22}[(2T_{01}\dot{T}_{01}-T_{11}\dot{T}_{00}-T_{01}T_{00}')A_4-(2T_{00}\dot{T}_{01}-T_{01}\dot{T}_{00}-T_{00}T_{00}')A_5]=0, \tag{25}$$

$$(T_{00}T_{11}-T_{01}^2)[(T_{22}A_4)'+(T_{22}A_5)^{\cdot}]+T_{22}[(T_{01}\dot{T}_{11}-T_{11}T_{00}')A_4+(T_{01}T_{00}'-T_{00}\dot{T}_{11})A_5]=0, \tag{26}$$

$$2(T_{00}T_{11}-T_{01}^2)(T_{22}A_5)'+T_{22}[(2T_{01}T_{01}'-T_{00}T_{11}'-T_{01}\dot{T}_{11})A_5-(2T_{11}T_{01}'-T_{11}\dot{T}_{11}-T_{01}T_{11}')A_4]=0, \tag{27}$$

$$(T_{11}\dot{T}_{22}-T_{01}T_{22}')A_4+(T_{00}T_{22}'-T_{01}\dot{T}_{22})A_5=0. \tag{28}$$

Thus the problem of working out MCs for all possibilities of A_i, A_4, A_5 is reduced to solving the set of Eqs. (17)–(20) subject to the above-given constraints. We would solve these to classify MCs of the manifolds admitting higher symmetries than SO(3) and SO(3) as the maximal isometry group.

A. MCs of the space–times admitting higher symmetries

Here we use the constraint equations (21)–(28) to evaluate MCs of the space–times given by Eq. (5) which admit higher symmetries than SO(3). The six cases admitting symmetry groups larger than SO(3) are the following:

(1) $SO(3)\otimes\mathbf{R}$, where $\mathbf{R}=\partial_t$ if and only if
(a) $\nu=\nu(r)$, $\mu=\mu(r)$, $\lambda=2\ln r$ or (b) $\nu=\nu(r)$, $\mu=0$, $\lambda=2\ln a$,
where a is an arbitrary constant,
(2) $SO(3)\otimes\mathbf{R}$, where $\mathbf{R}=\partial_r$ if and only if
(a) $\nu=\nu(t)$, $\mu=\mu(t)$, $\lambda=2\ln t$ or (b) $\nu=0$, $\mu=\mu(t)$, $\lambda=2\ln a$,
(3) $SO(3)\otimes\mathbf{R}$, where $\mathbf{R}=\partial_t+e\partial_r$ if and only if
$\nu=0=\mu$, $\lambda=\lambda(t+er)$ with $e=\pm1$,
(4) SO(4) if and only if $\nu=0$, $\mu=2\ln R(t)$, $\lambda=2\ln R(t)\sin r$ such that
$R\ddot{R}-\dot{R}^2-1\neq0$,
(5) $SO(3)\times\mathbf{R}^3$ if and only if $\nu=0$, $\mu=2\ln R(t)$, $\lambda=2\ln R(t)r$ such that
$R\ddot{R}-\dot{R}^2\neq0$,
(6) SO(1,3) if and only if
(a) $\nu=0$, $\mu=2\ln R(t)$, $\lambda=2\ln R(t)\sinh r$ such that
$R\ddot{R}-\dot{R}^2+1\neq0$, or
(b) $\nu=2\ln Q(r)$, $\mu=0$, $\lambda=2\ln Q(r)\cosh t$ such that
$QQ''-Q'^2+1\neq0$.

Case (1): In this case, we have $T_{01}=0$ and also $\dot{T}_{ab}=0$. Using these values, Eqs. (17)–(28) reduce to

$$\xi^0=\frac{T_2}{T_0}[(\dot{A}_1\sin\phi-\dot{A}_2\cos\phi)\sin\theta+\dot{A}_3\cos\theta+A_4], \tag{29}$$

$$\xi^1=\frac{T_2}{T_1}[(A_1'\sin\phi-A_2'\cos\phi)\sin\theta+A_3'\cos\theta+A_5], \tag{30}$$

$$\xi^2=-(A_1\sin\phi-A_2\cos\phi)\cos\theta+A_3\sin\theta+c_1\sin\phi-c_2\cos\phi, \tag{31}$$

$$\xi^3=-(A_1\cos\phi+A_2\sin\phi)\csc\theta+(c_1\cos\phi+c_2\sin\phi)\cot\theta+c_3, \tag{32}$$

where we have used the notation $T_{aa}=T_a$ for the sake of simplicity. These ξ^a are satisfied subject to the following differential constraints on A_ν:

$$T_1\dot{A}_4+T_0'A_5=0,\quad \left(\frac{T_2}{T_0}A_4\right)'+\frac{T_2}{T_0}\dot{A}_5=0,$$
$$\left(\frac{T_2}{\sqrt{T_1}}A_5\right)'=0,\quad T_2'A_5=0, \tag{33}$$

$$2T_1\ddot{A}_i+T_0'A_i'=0,\quad \left(\sqrt{\frac{T_2}{T_0}}\dot{A}_i\right)'=0,$$
$$\left(\frac{T_2}{\sqrt{T_1}}A_i'\right)'=0,\quad 2T_1A_i+T_2'A_i'=0. \tag{34}$$

It is interesting to note that this case reduces to the nondegenerate case of Ref. 14. However, the possibility of seven MCs is recovered here which was missing there. Now the evaluation of MCs for all possibilities of A_i, A_4, A_5 is reduced to solving the set of Eqs. (29)–(32) subject to the constraints given by Eqs. (33) and (34). A complete solution of these equations is obtained by considering different possibilities of T_2. The last equation of Eq. (33) implies that either

$$\text{(a)}\ \ T_2'=0,\ \ \textit{or}\ \ \text{(b)}\ \ T_2'\neq 0.$$

The first case when $T_2=\beta$, where β is an arbitrary constant, Eq. (34) gives $A_i=0$ and consequently Eqs. (29)–(32) yield

$$\xi^0=A_4(t,r),\ \ \xi^1=A_5(t,r),$$
$$\xi^2=c_1\sin\phi-c_2\cos\phi,\quad \xi^3=(c_1\cos\phi+c_2\sin\phi)\cot\theta+c_3. \tag{35}$$

Further, if we assume that

$$\left[\frac{T_0}{\sqrt{T_1}}\left(\frac{T_0'}{2T_0\sqrt{T_1}}\right)'\right]'\neq 0,$$

we obtain four MCs identical to the usual KVs of spherical symmetry given by

$$\xi=c_0\frac{T_0}{\beta}\partial_t+c_1(\sin\phi\partial_\theta+\cot\theta\cos\phi\partial_\phi)+c_2(\cos\phi\partial_\theta-\cot\theta\sin\phi\partial_\phi)+c_3\partial_\phi. \tag{36}$$

When

$$\left[\frac{T_0}{\sqrt{T_1}}\left(\frac{T_0'}{2T_0\sqrt{T_1}}\right)'\right]'=0,$$

this implies that

$$\frac{T_0}{\sqrt{T_1}}\left[\frac{T_0'}{2T_0\sqrt{T_1}}\right]'=\alpha,$$

where α is an arbitrary constant which may be positive, zero, or negative. In each case, we have six MCs.

For $\alpha>0$, we obtain

$$\begin{aligned}\xi=&c_0\frac{T_0}{\beta}\partial_t+c_1(\sin\phi\partial_\theta+\cot\theta\cos\phi\partial_\phi)+c_2(\cos\phi\partial_\theta-\cot\theta\sin\phi\partial_\phi)+c_3\partial_\phi\\&+c_4\left(-\frac{T_0'}{2\beta\sqrt{\alpha T_1}}\sinh\sqrt{\alpha}t\partial_t+\frac{\sqrt{T_1}}{\beta}\cosh\sqrt{\alpha}t\partial_r\right)\\&+c_5\left(-\frac{T_0'}{2\beta\sqrt{\alpha T_1}}\cosh\sqrt{\alpha}t\partial_t+\frac{\sqrt{T_1}}{\beta}\sinh\sqrt{\alpha}t\partial_r\right).\end{aligned}\tag{37}$$

If $\alpha=0$, we have

$$\begin{aligned}\xi=&c_0\frac{T_0}{\beta}\partial_t+c_1(\sin\phi\partial_\theta+\cot\theta\cos\phi\partial_\phi)+c_2(\cos\phi\partial_\theta-\cot\theta\sin\phi\partial_\phi)+c_3\partial_\phi\\&+c_4\left[-\frac{T_0}{\beta}\left(\frac{\gamma}{2}t^2+\frac{1}{\beta}\int\sqrt{T_1}dr\right)\partial_t+\frac{\sqrt{T_1}}{\beta}t\partial_r\right]+c_5\left(\frac{T_0}{\beta}\gamma t\partial_t+\frac{\sqrt{T_1}}{\beta}\partial_r\right),\end{aligned}\tag{38}$$

where

$$\frac{T_0'}{2T_0\sqrt{T_1}}=\gamma,$$

an arbitrary constant. The case $\alpha<0$ yields

$$\begin{aligned}\xi=&c_0\frac{T_0}{\beta}\partial_t+c_1(\sin\phi\partial_\theta+\cot\theta\cos\phi\partial_\phi)+c_2(\cos\phi\partial_\theta-\cot\theta\sin\phi\partial_\phi)\\&+c_3\partial_\phi+c_4\left(-\frac{T_0'}{2\beta\sqrt{-\alpha T_1}}\sin\sqrt{-\alpha}t\partial_t+\frac{\sqrt{T_1}}{\beta}\cos\sqrt{-\alpha}t\partial_r\right)\\&+c_5\left(\frac{T_0'}{2\beta\sqrt{-\alpha T_1}}\cos\sqrt{-\alpha}t\partial_t+\frac{\sqrt{T_1}}{\beta}\sin\sqrt{-\alpha}t\partial_r\right).\end{aligned}\tag{39}$$

In case (b), when $T_2'\neq0$, it follows from Eqs. (33) and (34) that for

$$\frac{T_2}{\sqrt{T_1}}\left(\frac{T_2'}{2T_2\sqrt{T_1}}\right)'+1\neq0,$$

we obtain the same MCs as the usual minimal KVs for spherically symmetry.

If

$$\frac{T_2}{\sqrt{T_1}}\left(\frac{T_2'}{2T_2\sqrt{T_1}}\right)'+1=0$$

and

$$\left(\frac{T_2'}{\sqrt{T_0T_1T_2}}\right)'\neq 0,$$

we have seven MCs given by

$$\begin{aligned}\xi=&c_0\partial_t+c_1(\sin\phi\partial_\theta+\cot\theta\cos\phi\partial_\phi)+c_2(\cos\phi\partial_\theta-\cot\theta\sin\phi\partial_\phi)+c_3\partial_\phi\\&+c_4\left(-\frac{1}{\sqrt{T_1}}\sin\phi\sin\theta\partial_r-X\sin\phi\cos\theta\partial_\theta-X\cos\phi\csc\theta\partial_\phi\right)\\&+c_5\left(\frac{1}{\sqrt{T_1}}\cos\phi\sin\theta\partial_r+X\cos\phi\cos\theta\partial_\theta-X\sin\phi\csc\theta\partial_\phi\right)\\&+c_6\left(-\frac{1}{\sqrt{T_1}}\cos\theta\partial_r-X\sin\theta\partial_\theta\right),\end{aligned}\tag{40}$$

where $X=T_2'/2T_2\sqrt{T_1}$. If we have $(T_2/\sqrt{T_1})(T_2'/2T_2\sqrt{T_1})'+1=0$, $(T_2'/\sqrt{T_0T_1T_2})'=0$, and $(T_0'/T_2')'\neq 0$, then we get four MCs.

When $(T_2/\sqrt{T_1})(T_2'/2T_2\sqrt{T_1})'+1=0$, $(T_2'/\sqrt{T_0T_1T_2})'=0$, and $T_0'/T_2'=\delta$, an arbitrary constant. For $\delta>0$, we obtain

$$\begin{aligned}\xi=&c_0\partial_t+c_1(\sin\phi\partial_\theta+\cot\theta\cos\phi\partial_\phi)+c_2(\cos\phi\partial_\theta-\cot\theta\sin\phi\partial_\phi)+c_3\partial_\phi\\&+c_4\left[\left(\frac{T_2}{T_0}X\sqrt{\delta}\sinh\sqrt{\delta}t\partial_t-\frac{1}{\sqrt{T_1}}\cosh\sqrt{\delta}t\partial_r\right)\sin\theta\sin\phi-(\cos\theta\sin\phi\partial_\theta\right.\\&\left.+\csc\theta\cos\phi\partial_\phi)X\cosh\sqrt{\delta}t\right]+c_5\left[\left(-\frac{T_2}{T_0}X\sqrt{\delta}\sinh\sqrt{\delta}t\partial_t+\frac{1}{\sqrt{T_1}}\cosh\sqrt{\delta}t\partial_r\right)\sin\theta\cos\phi\right.\\&\left.+(\cos\theta\cos\phi\partial_\theta-\csc\theta\sin\phi\partial_\phi)X\cosh\sqrt{\delta}t\right]+c_6\left[\left(\frac{T_2}{T_0}X\sqrt{\delta}\sinh\sqrt{\delta}t\partial_t\right.\right.\\&\left.\left.-\frac{1}{\sqrt{T_1}}\cosh\sqrt{\delta}t\partial_r\right)\cos\theta+X\cosh\sqrt{\delta}t\sin\theta\partial_\theta\right]+c_7\left[\left(\frac{T_2}{T_0}X\sqrt{\delta}\cosh\sqrt{\delta}t\partial_t\right.\right.\\&\left.\left.-\frac{1}{\sqrt{T_1}}\sinh\sqrt{\delta}t\partial_r\right)\sin\theta\sin\phi-(\cos\theta\sin\phi\partial_\theta+\csc\theta\cos\phi\partial_\phi)X\sinh\sqrt{\delta}t\right]\\&+c_8\left[-\left(\frac{T_2}{T_0}X\sqrt{\delta}\cosh\sqrt{\delta}t\partial_t+\frac{1}{\sqrt{T_1}}\sinh\sqrt{\delta}t\partial_r\right)\sin\theta\cos\phi+(\cos\theta\cos\phi\partial_\theta\right.\\&\left.-\csc\theta\sin\phi\partial_\phi)X\sinh\sqrt{\delta}t+c_9\left(\frac{T_2}{T_0}X\sqrt{\delta}\cosh\sqrt{\delta}t\partial_t-\frac{1}{\sqrt{T_1}}X\sinh\sqrt{\delta}t\partial_r\right)\cos\theta\right.\\&\left.+X\sinh\sqrt{\delta}t\sin\theta\partial_\theta\right].\end{aligned}\tag{41}$$

If $\delta=0$, we have

$$\begin{aligned}\xi=&c_0\partial_t+c_1(\sin\phi\partial_\theta+\cot\theta\cos\phi\partial_\phi)+c_2(\cos\phi\partial_\theta-\cot\theta\sin\phi\partial_\phi)+c_3\partial_\phi\\&+c_4\left[\left(\frac{T_2}{T_0}X\partial_t-\frac{1}{\sqrt{T_1}}t\partial_r\right)\sin\theta\sin\phi-(\cos\theta\sin\phi\partial_\theta+\csc\theta\cos\phi\partial_\phi)tX\right]\\&+c_5\left[\left(-\frac{T_2}{T_0}X\partial_t+\frac{1}{\sqrt{T_1}}t\partial_r\right)\sin\theta\cos\phi+(\cos\theta\cos\phi\partial_\theta-\csc\theta\sin\phi\partial_\phi)tX\right]\\&+c_6\left[\left(\frac{T_2}{T_0}X\partial_t-\frac{1}{\sqrt{T_1}}t\partial_r\right)\cos\theta+tX\sin\theta\right]\\&+c_7\left[\left(-\frac{1}{\sqrt{T_1}}\sin\theta\partial_r-X\cos\theta\partial_\theta\right)\sin\phi-X\csc\theta\cos\phi\partial_\phi\right]\\&+c_8\left[\left(\frac{1}{\sqrt{T_1}}\sin\theta\partial_r+X\cos\theta\partial_\theta\right)\cos\phi-X\csc\theta\sin\phi\partial_\phi\right]\\&+c_9\left(-\frac{1}{\sqrt{T_1}}\cos\theta\partial_r+X\sin\theta\partial_\theta\right).\end{aligned}\tag{42}$$

For $\delta<0$, MCs are given by

$$\begin{aligned}\xi=&c_0\partial_t+c_1(\sin\phi\partial_\theta+\cot\theta\cos\phi\partial_\phi)+c_2(\cos\phi\partial_\theta-\cot\theta\sin\phi\partial_\phi)+c_3\partial_\phi\\&+c_4\left[\left(-\frac{T_2}{T_0}X\sqrt{-\delta}\sin\sqrt{-\delta}t\partial_t-\frac{1}{\sqrt{T_1}}\cos\sqrt{-\delta}t\partial_r\right)\sin\theta\sin\phi-(\cos\theta\sin\phi\partial_\theta\right.\\&\left.+\csc\theta\cos\phi\partial_\phi)X\cos\sqrt{-\delta}t\right]+c_5\left[\left(\frac{T_2}{T_0}X\sqrt{-\delta}\sin\sqrt{-\delta}t\partial_t+\frac{1}{\sqrt{T_1}}\cos\sqrt{-\delta}t\partial_r\right)\sin\theta\cos\phi\right.\\&\left.+(\cos\theta\cos\phi\partial_\theta-\csc\theta\sin\phi\partial_\phi)X\cos\sqrt{-\delta}t\right]+c_6\left[\left(-\frac{T_2}{T_0}X\sqrt{-\delta}\sin\sqrt{-\delta}t\partial_t\right.\right.\\&\left.\left.-\frac{1}{\sqrt{T_1}}\cos\sqrt{-\delta}t\partial_r\right)\cos\theta+X\cos\sqrt{-\delta}t\sin\theta\partial_\theta\right]+c_7\left[\left(\frac{T_2}{T_0}X\sqrt{-\delta}\cos\sqrt{-\delta}t\partial_t\right.\right.\\&\left.\left.-\frac{1}{\sqrt{T_1}}\sin\sqrt{-\delta}t\partial_r\right)\sin\theta\sin\phi-(\cos\theta\sin\phi\partial_\theta+\csc\theta\cos\phi\partial_\phi)X\sin\sqrt{-\delta}t\right]\\&+c_8\left[-\left(\frac{T_2}{T_0}X\sqrt{\delta}\cos\sqrt{-\delta}t\partial_t+\frac{1}{\sqrt{T_1}}\sin\sqrt{-\delta}t\partial_r\right)\sin\theta\cos\phi+(\cos\theta\cos\phi\partial_\theta\right.\\&\left.-\csc\theta\sin\phi\partial_\phi)X\sin\sqrt{-\delta}t+c_9\left(\frac{T_2}{T_0}X\sqrt{-\delta}\cos\sqrt{-\delta}t\partial_t-\frac{1}{\sqrt{T_1}}X\sin\sqrt{-\delta}t\partial_r\right)\cos\theta\right.\\&\left.+X\sin\sqrt{-\delta}t\sin\theta\partial_\theta\right].\end{aligned}\tag{43}$$

From Eqs. (41) to (43), it follows that for each value of δ, we obtain ten independent MCs.

Case (2): In this case, we have $T_{01}=0$ and $T_a'=0$. If we use the transformations $t\leftrightarrow r$, $\xi^0\leftrightarrow\xi^1$, $T_0\leftrightarrow T_1$, the solution of this case can be trivially obtained as in case (1).

Cases (4), (5), (6): The cases (4), (5) and (6a) describe Friedmann Robertson (FRW) space–times whereas case (6b) describes FRW like space–times. For these metrics, the nonvanishing components of Ricci and energy–momentum tensors are given in Appendix B. If any of T_a is zero, we get infinte dimensional MCs. For the nondegenerate case, we have $T_a\neq 0$, which implies the following possibilities:

$$\text{(a)}\quad \frac{T_1}{\sqrt{T_0}}\left(\frac{\dot{T}_2}{2T_1\sqrt{T_0}}\right)-k=0,\quad \text{(b)}\quad \frac{T_1}{\sqrt{T_0}}\left(\frac{\dot{T}_2}{2T_1\sqrt{T_0}}\right)-k\neq 0$$

with

$$\text{(i)}\quad \dot{T}_1=0,\quad \text{(ii)}\quad \dot{T}_1\neq 0,$$

where k has the values $1,0,-1$ for closed, flat, and open FRW space–times, respectively.

In case (ai), we must have $k=0$ and $T_1=a\neq 0$, a is an arbitrary constant. Thus, in addition to the nonproper MCs $\xi_{(1)},\xi_{(2)},\xi_{(3)},\xi_{(4)},\xi_{(5)},\xi_{(6)}$ given in Appendix C, we obtain the following proper MCs:

$$\begin{aligned}
\xi_{(7)}&=\frac{1}{\sqrt{T_0}}\partial_t,\\
\xi_{(8)}&=r\left(\frac{1}{\sqrt{T_0}}\partial_t-Y\partial_r\right)\sin\theta\sin\phi-(\cos\theta\sin\phi\partial_\theta+\csc\theta\cos\phi\partial_\phi)Y,\\
\xi_{(9)}&=r\left(\frac{1}{\sqrt{T_0}}\partial_t-Y\partial_r\right)\sin\theta\cos\phi-(\cos\theta\cos\phi\partial_\theta-\csc\theta\sin\phi\partial_\phi)Y,\\
\xi_{(10)}&=r\left(\frac{1}{\sqrt{T_0}}\partial_t-Y\partial_r\right)\cos\theta+Y\sin\theta\partial_\theta,
\end{aligned}\tag{44}$$

where $Y=(1/ar)\int\sqrt{T_0}dt$. This gives ten independent MCs in which six are the usual KVs of of closed FRW metric and the rest are the proper MCs.

Case (aii) also yields ten independent MCs for each value of k. For the value of $k=1$, the proper MCs are given by

$$\begin{aligned}
\xi_{(7)}&=\left(\frac{\sqrt{T_0}}{T_1}\cot r\partial_t-Z\sin^2 r\partial_r\right)\csc r,\\
\xi_{(8)}&=\left[\left(\frac{T_2}{T_0}\dot{Z}\partial_t-Z\sin r\cos r\partial_r\right)\sin\theta\sin\phi-Z(\cos\theta\sin\phi\partial_\theta+\csc\theta\cos\phi\partial_\phi)\csc r\right],\\
\xi_{(9)}&=\left[\left(\frac{T_2}{T_0}\dot{Z}\partial_t-Z\sin r\cos r\partial_r\right)\sin\theta\cos\phi-Z(\cos\theta\cos\phi\partial_\theta-\csc\theta\sin\phi\partial_\phi)\csc r\right],\\
\xi_{(10)}&=\left[\left(\frac{T_2}{T_0}\dot{Z}\partial_t-Z\sin r\cos r\partial_r\right)\cos\theta-Z\partial_\theta\right]\csc r,
\end{aligned}\tag{45}$$

where $Z=T_2/2T_1\sqrt{T_0}$. For $k=0$, we have the following proper MCs:

$$\xi_{(7)}=\left(\frac{1}{\sqrt{T_0}}\partial_t-rZ\partial_r\right),$$

$$\begin{aligned}\xi_{(8)}=&\left[\left\{\left(\frac{rT_2}{2T_0}\dot{Z}-\frac{r}{\sqrt{T_0}}\right)\partial_t+\left(\frac{r^2Z}{2}+\int\frac{\sqrt{T_0}}{T_1}\mathrm{d}t\,\partial_r\right)\right\}\sin\theta\sin\phi\right.\\&\left.-\left(\frac{r}{2}Z-\frac{1}{r}\int\frac{\sqrt{T_0}}{T_1}\mathrm{d}t\right)(\cos\theta\sin\phi\partial_\theta+\csc\theta\cos\phi\partial_\phi)\right],\\ \xi_{(9)}=&\left[\left\{\left(\frac{rT_2}{2T_0}\dot{Z}-\frac{r}{\sqrt{T_0}}\right)\partial_t+\left(\frac{r^2Z}{2}+\int\frac{\sqrt{T_0}}{T_1}\mathrm{d}t\partial_r\right)\right\}\sin\theta\cos\phi\right.\\&\left.-\left(\frac{r}{2}Z-\frac{1}{r}\int\frac{\sqrt{T_0}}{T_1}\mathrm{d}t\right)(\cos\theta\cos\phi\partial_\theta-\csc\theta\sin\phi\partial_\phi)\right],\end{aligned}\tag{46}$$

$$\xi_{(10)}=\left[\left\{\left(\frac{rT_2}{2T_0}\dot{Z}-\frac{r}{\sqrt{T_0}}\right)\partial_t+\left(\frac{r^2Z}{2}+\int\frac{\sqrt{T_0}}{T_1}\mathrm{d}t\,\partial_r\right)\right\}\cos\theta-\left(\frac{r}{2}Z-\frac{1}{r}\int\frac{\sqrt{T_0}}{T_1}\mathrm{d}t\right)\sin\theta\partial_\theta\right].$$

For the value of $k=-1$, the four proper MCs are

$$\xi_{(7)}=\frac{1}{T_1}(\sqrt{T_0}\coth r\partial_t-T_2Z\partial_r)\csc hr,$$

$$\begin{aligned}\xi_{(8)}=&\left[\left(\frac{T_2}{T_0}\dot{Z}\partial_t+Z\sinh r\cosh r\partial_r\right)\sin\theta\sin\phi-Z(\cos\theta\sin\phi\partial_\theta+\csc\theta\cos\phi\partial_\phi)\right]\csc hr,\\ \xi_{(9)}=&\left[\left(\frac{T_2}{T_0}\dot{Z}\partial_t+Z\sinh r\cosh r\partial_r\right)\sin\theta\cos\phi-Z(\cos\theta\cos\phi\partial_\theta-\csc\theta\sin\phi\partial_\phi)\right]\csc hr,\end{aligned}\tag{47}$$

$$\xi_{(10)}=\left[\left(\frac{T_2}{T_0}\dot{Z}\partial_t+Z\sinh r\cosh r\partial_r\right)\cos\theta-Z\partial_\theta\right]\csc hr.$$

Thus we obtain ten independent MCs for each value of k in which six are the usual isometries of FRW metric and the the remaining four are the proper MCs.

For the case (bi), we must require that $k\neq 0$. When $k=1$, we obtain one proper MC given by

$$\xi_{(7)}=\frac{T_2}{\sqrt{T_0}a}\csc^2 r\partial_t.\tag{48}$$

For $k=-1$, proper MC is

$$\xi_{(7)}=\frac{T_2}{\sqrt{T_0}a}\csc h^2 r\partial_t.\tag{49}$$

This case gives seven independent MCs in which six are nonproper and one is proper MC. It can be checked that the case (bii) gives six independent MCs for each value of k which are usual KVs of FRW space–times. Similarly, case (6b) can be solved to give either six, seven, or ten MCs.

B. MCs of the space–times admitting SO(3) as the maximal isometry group

In this section, we evaluate MCs of the spherically symmetric space–times which admit SO(3) as the maximal isometry group. In these solutions, we take any additional MC (if it exists) to be orthogonal to the SO(3) orbit. For this we must require that $A_i \equiv 0$ and consequently, it follows from Eqs. (17) to (20) that $\xi^0 = \xi^0(t,r)$, $\xi^1 = \xi^1(t,r)$, $\xi^2 = 0$, $\xi^3 = 0$. It is mentioned here that we are considering only diagonal metrics for this case. The nondiagonal metrics can be solved in a similar way. If we make use of the following substitutions

$$\frac{T_2}{T_0}A_4 = C(t,r), \quad \frac{T_2}{T_1}A_5 = D(t,r), \quad \sqrt{T_0} = A(t,r), \quad \sqrt{T_1} = B(t,r)$$

in the constraint Eqs. (21)–(28), then it follows that

$$\dot{C} = -\dot{A}C - A'D, \tag{50}$$

$$A^2C' + B^2\dot{D} = 0, \tag{51}$$

$$D' = -\dot{B}C - B'D, \tag{52}$$

$$\dot{T}_2 C + T_2' D = 0. \tag{53}$$

To solve this system of equations, we have the following possibilities:

$$\text{(i)} \quad \dot{T}_2 = 0, \quad T_2' \neq 0, \quad \text{(ii)} \quad \dot{T}_2 \neq 0, \quad T_2' = 0,$$

$$\text{(iii)} \quad \dot{T}_2 \neq 0, \quad T_2' \neq 0, \quad \text{(iv)} \quad \dot{T}_2 = 0, \quad T_2' = 0.$$

The first possibility does not provide any proper MC if we assume that $\dot{T}_1 \neq 0$. However, the assumption $\dot{T}_1 = 0$, $\dot{T}_0 \neq 0$ gives infinite dimensional MCs.

The second case shows that there does not exist a proper MC with the constraint $T_0' \neq 0$ but the constraints $T_0' = 0$, $T_1' \neq 0$ provide infinite dimensional MCs.

In the third case, when

$$T_0 T_2' \left[\frac{T_1' \dot{T}_2 - \dot{T}_1 T_2'}{2\sqrt{T_1}\dot{T}_2} + \left\{ \ln\left(\frac{\dot{T}_2}{T_2'} \right) \right\}' \right] + T_1 \dot{T}_2 \left[\frac{T_0' \dot{T}_2 - \dot{T}_0 T_2'}{2\sqrt{T_0}T_2'} + \left\{ \ln\left(\frac{\dot{T}_2}{T_2'} \right) \right\}^{\cdot} \right] \neq 0,$$

we do not have a proper MC. However, if

$$T_0 T_2' \left[\frac{T_1' \dot{T}_2 - \dot{T}_1 T_2'}{2\sqrt{T_1}\dot{T}_2} + \left\{ \ln\left(\frac{\dot{T}_2}{T_2'} \right) \right\}' \right] + T_1 \dot{T}_2 \left[\frac{T_0' \dot{T}_2 - \dot{T}_0 T_2'}{2\sqrt{T_0}T_2'} + \left\{ \ln\left(\frac{\dot{T}_2}{T_2'} \right) \right\}^{\cdot} \right] = 0.$$

and

$$\left(\frac{T_0' \dot{T}_2 - \dot{T}_0 T_2'}{2\sqrt{T_0}\dot{T}_2} \right)' = \left[\frac{T_2'}{\dot{T}_2} \left\{ \frac{\dot{T}_1 T_2' - T_1' \dot{T}_2}{2\sqrt{T_1}T_2'} - \left(\frac{\dot{T}_2}{T_2'} \right)' \right\} \right]^{\cdot}$$

then there exists a proper MC given by

$$\exp\left(\int \frac{T_0' \dot{T}_2 - \dot{T}_0 T_2'}{2\sqrt{T_0}\dot{T}_2} \mathrm{d}t \right) \left(\partial_t - \frac{\dot{T}_2}{T_2'} \partial_r \right). \tag{54}$$

If

$$\left(\frac{T_0'\dot{T}_2-\dot{T}_0T_2'}{2\sqrt{T_0}\dot{T}_2}\right)'\neq\left[\frac{T_2'}{\dot{T}_2}\left\{\frac{\dot{T}_1T_2'-T_1'\dot{T}_2}{2\sqrt{T_1}T_2'}-\left(\frac{\dot{T}_2}{T_2'}\right)'\right\}\right]^{\cdot}$$

then this case gives infinite number of MCs.

In the last case, we solve Eqs. (50)–(52), which imply that $\dot{A}B'-A'\dot{B}\equiv\psi(t,r)$. If $\psi=0$, then we must have $\dot{C}=0=D'$ for a nontrivial solution. Thus the constraints $\dot{T}_0T_1'-T_0'\dot{T}_1=0$ together with

$$T_0'\neq 0,\ \left[\frac{T_1}{T_0}\left(\frac{\dot{T}_1}{T_0'}\right)^{\cdot}\right]^{\cdot}=0,$$

yield the following proper MC:

$$\exp\left(\int\frac{T_1}{T_0}\left(\frac{\dot{T}_0}{T_0'}\right)^{\cdot}dr\right)\left(\partial_t-\frac{\dot{T}_0}{T_0'}\partial_r\right). \tag{55}$$

However, for $\dot{T}_0T_1'-T_0'\dot{T}_1=0$ together with

$$T_0'=0,\ T_1'\neq 0,\ \left[\frac{T_1}{T_0}\left(\frac{\dot{T}_1}{T_1'}\right)^{\cdot}\right]^{\cdot}=0,$$

we obtain the proper MC given by

$$\exp\left(\int\frac{T_1}{T_0}\left(\frac{\dot{T}_1}{T_1'}\right)^{\cdot}dr\right)\left(\partial_t-\frac{\dot{T}_1}{T_1'}\partial_r\right). \tag{56}$$

The constraint $\dot{T}_0T_1'-T_0'\dot{T}_1=0$ along with $T_0'=0$, $T_1'=0=\dot{T}_1$, $\dot{T}_0\neq 0$ gives infinite many MCs.

For $\psi\neq 0$, we must have $\dot{C}\neq 0$, $D'\neq 0$ for a nontrivial solution. Let us express $\dot{C}$ and D' as E and F, respectively, so that

$$C=-\frac{B'}{\psi}E(t,r)+\frac{A'}{\psi}F(t,r), \tag{57}$$

$$D=\frac{\dot{B}}{\psi}E(t,r)-\frac{\dot{A}}{\psi}F(t,r). \tag{58}$$

We obtain two linearly independent MCs which are orthogonal to $T_e(\mathrm{SO}(3))$ and are given by

$$X_1=\frac{E}{\psi}(-B'\partial_t+\dot{B}\partial_r), \tag{59}$$

$$X_2=\frac{F}{\psi}(A'\partial_t-\dot{A}\partial_r). \tag{60}$$

The Lie bracket of these vector fields is

$$[X_1,X_2]=\frac{F(\dot{A}E'-A'\dot{E})}{E\psi}X_1+\frac{E(\dot{B}F'-B'\dot{F})}{F\psi}X_2. \tag{61}$$

For its closedness, we must have $F(\dot{A}E'-A'\dot{E})/E\psi=a_1$ and $E(\dot{B}F'-B'\dot{F})/F\psi=a_2$, where a_1 and a_2 are constants. From here we have either (i) $a_1\neq 0$, $a_2=0$, or (ii) $a_1=0$, $a_2\neq 0$ or (iii) $a_1=0=a_2$. The first two possibilities contradict the assumption that $\psi\neq 0$. This shows that the third possibility closes the Lie algebra. Thus we have

$$C'=\frac{B^2}{A^2A'^2+B^2\dot{A}^2}[\{A'(\ddot{A}-\dot{A}^2)-\dot{A}(\dot{A}'-A'\dot{B})\}C+\{A'(\dot{A}'-\dot{A}A')-\dot{A}(A''-A'B')\}D], \tag{62}$$

$$\dot{D}=-\frac{A^2}{A^2A'^2+B^2\dot{A}^2}[\{A'(\ddot{A}-\dot{A}^2)-\dot{A}(\dot{A}'-A'\dot{B})\}C+\{A'(\dot{A}'-\dot{A}A')-\dot{A}(A''-A'B')\}D], \tag{63}$$

along with the compatibility constraint in the components T_0 and T_1 of the energy–momentum tensor given by

$$\left(\ln\frac{A'}{\dot{A}}e^{A-B}\right)'\left(\ln\frac{\dot{B}}{B'}e^{B-A}\right)-\left(\ln\frac{A'}{\dot{A}}e^{A-B}\right)\left(\ln\frac{\dot{B}}{B'}e^{B-A}\right)'=0. \tag{64}$$

IV. MATTER COLLINEATIONS IN THE DEGENERATE CASE

In this section only those cases will be considered for which the energy–momentum tensor is degenerate, i.e., $\det(T_{ab})=0$.

A. MCs of the manifolds admitting higher symmetries

Here we would discuss the MCs of the manifolds admitting higher symmetries than SO(3). For higher symmetries, all metrics have $T_{01}=0$ except the case (3) of the last section. Thus we would discuss the space–times for which $T_{01}=0$ and $\det(T_{ab})=0$, i.e., when at least one of the T_a or their combination is zero. It can be shown that for $T_1=0$, $T_k\neq 0$, $k=0,2$ [case (1) of Sec. III], we obtain infinite dimensional MCs. The solution for $T_0=0$, $T_l\neq 0$, $l=1,2$ [case (2) of Sec. III] also gives infinite dimensional MCs. These have been discussed in detail elsewhere.[14] Here we are interested in exploring the possibilities of finite MCs.

When $T_k'\neq 0$, $(T_0/T_2)'\neq 0$, we obtain four MCs which are the usual KVs of the spherical symmetry. For $T_k'\neq 0$, $(T_0/T_2)'=0$, we obtain ten independent MCs. These are

$$\begin{aligned}\xi^0&=\beta[(\dot{g}_1\sin\phi-\dot{g}_2\cos\phi)\sin\theta+\dot{g}_3\cos\theta]+c_0, \quad \xi^1=0,\\ \xi^2&=-(g_1\sin\phi-g_2\cos\phi)\cos\theta+g_3\sin\theta+c_1\sin\phi-c_2\cos\phi,\\ \xi^3&=-(g_1\cos\phi+g_2\sin\phi)\csc\theta+(c_1\cos\phi+c_2\sin\phi)\cot\theta+c_3,\end{aligned} \tag{65}$$

where $\beta=T_2/T_0\neq 0$ is an arbitrary constant and the function g satisfies the following constraint:

$$\beta\ddot{g}_i(t)-g_i(t)=0. \tag{66}$$

The solution for the nonstatic case can be obtained trivially, which turns out to be the same with different constraints.

B. MCs of the manifolds admitting SO(3) as the maximal isometry group

The metrics which admit SO(3) as the maximal symmetry group yield $\xi^2=0=\xi^3$ and the MC equations reduce to six independent equations which involve

TABLE I. MCs of case (1) for the nondegenerate case admitting higher symmetries. Notice that MCs for the case (2) are the same as for the case (1) which can be obtained trivially by using the transformations given in the Sec. III.

Cases	MCs	Constraints
1ai	4	$\left[\frac{T_0}{\sqrt{T_1}}\left(\frac{T_0'}{2T_0\sqrt{T_1}}\right)'\right]'\neq 0$
1aii	6	$\left[\frac{T_0}{\sqrt{T_1}}\left(\frac{T_0'}{2T_0\sqrt{T_1}}\right)'\right]'=0$
1bi	4	$\frac{T_2}{\sqrt{T_1}}\left(\frac{T_2'}{2T_2\sqrt{T_1}}\right)'+1\neq 0$
1bii	7	$\frac{T_2}{\sqrt{T_1}}\left(\frac{T_2'}{2T_2\sqrt{T_1}}\right)'+1=0,\quad \left(\frac{T_2'}{\sqrt{T_0T_1T_2}}\right)'\neq 0$
1biii	4	$\frac{T_2}{\sqrt{T_1}}\left(\frac{T_2'}{2T_2\sqrt{T_1}}\right)'+1=0,\quad \left(\frac{T_2'}{\sqrt{T_0T_1T_2}}\right)'=0,\quad \left(\frac{T_0'}{T_2}\right)'\neq 0$
1biv	10	$\frac{T_2}{\sqrt{T_1}}\left(\frac{T_2'}{2T_2\sqrt{T_1}}\right)'+1=0,\quad \left(\frac{T_2'}{\sqrt{T_0T_1T_2}}\right)'=0,\quad \left(\frac{T_0'}{T_2}\right)'=0$

$$\dot{T}_{22}\xi^0+T_{22}'\xi^1=0. \tag{67}$$

This gives rise to the following four cases:

$$\text{(i)}\quad \dot{T}_{22}=0,\ T_{22}'\neq 0,\quad \text{(ii)}\quad \dot{T}_{22}\neq 0,\ T_{22}'=0,$$

$$\text{(iii)}\quad \dot{T}_{22}\neq 0,\ T_{22}'\neq 0,\quad \text{(iv)}\quad \dot{T}_{22}=0,\ T_{22}'=0.$$

If we solve these cases, we may have interesting physical consequences. These will be discussed somewhere else.

V. CONCLUSION

In this paper, we have attempted to classify the most general spherically symmetric space–times according to their MCs. We have found a general solution of the MC equations for the nondegenerate, diagonal, and nondiagonal energy–momentum tensor. Further, we have classified space–times admitting higher symmetries than SO(3) and those which admit SO(3) as the maximal isometry group for both nondegenerate and degenerate cases. It is found that for the nondegenerate and degenerate cases, we recover the earlier known results[14] as a special case. We also obtain some interesting missing results in the earlier work. It is mentioned here that MCs found here coincide with *RCs* but the constraints are entirely different. The summary of the results can be given below in Tables I–IV.

It can be seen from Tables I–IV that each case has different constraints on the energy–momentum tensor. It would be interesting to solve these constraints or at least examples should be constructed to check the dimensions of the MCs. We are able to classify MCs of the space–times with SO(3) as the maximal isometry group only for the nondegenerate case. However, it needs to be completed for the degenerate case. Also, case (3) of Sec. III admitting higher symmetries is kept open. These would be discussed in a separate work.

TABLE II. MCs of cases (4), (5), (6) for the nondegenerate case admitting higher symmetries. It is noted here that the cases (4), (5) and (6a) describe FRW metrics and (6b) FRW-like metrics and have the same MCs in all cases as given below.

Cases	MCs	Constraints
4ai	10	$\frac{T_1}{\sqrt{T_0}}\left(\frac{\dot{T}_2}{2T_1\sqrt{T_0}}\right)^{\cdot}-k=0, \quad \dot{T}_1=0$
4aii	10	$\frac{T_1}{\sqrt{T_0}}\left(\frac{\dot{T}_2}{2T_1\sqrt{T_0}}\right)^{\cdot}-k=0, \quad \dot{T}_1\neq 0$
4bi	7	$\frac{T_1}{\sqrt{T_0}}\left(\frac{\dot{T}_2}{2T_1\sqrt{T_0}}\right)^{\cdot}-k\neq 0, \quad \dot{T}_1\neq 0$
4bii	6	$\frac{T_1}{\sqrt{T_0}}\left(\frac{\dot{T}_2}{2T_1\sqrt{T_0}}\right)^{\cdot}-k\neq 0, \quad \dot{T}_1\neq 0$

I would like to thank the Ministry of Science and Technology (MOST), Pakistan for providing a postdoctoral fellowship at the University of Aberdeen, UK. I also appreciate the comments given by Professor G.S. Hall during its write up.

APPENDIX A

The surviving components of the Ricci tensor are

$$R_{00}=\tfrac{1}{4}e^{\nu-\mu}(2\nu''+\nu'^2-\nu'\mu'+2\nu'\lambda')-\tfrac{1}{4}(2\ddot{\mu}+\dot{\mu}^2-\dot{\nu}\dot{\mu}+4\ddot{\lambda}+2\dot{\lambda}^2-2\dot{\nu}\dot{\lambda}),$$

$$R_{01}=-\tfrac{1}{2}(2\dot{\lambda}'+\dot{\lambda}\lambda'-\nu'\dot{\lambda}-\dot{\mu}\lambda'),$$

$$R_{11}=\tfrac{1}{4}e^{\mu-\nu}(2\ddot{\mu}+\dot{\mu}^2-\dot{\nu}\dot{\mu}+2\dot{\mu}\dot{\lambda})-\tfrac{1}{4}(2\nu''+\nu'^2-\nu'\mu'+4\lambda''+2\lambda'^2-2\mu'\lambda'), \quad \text{(A1)}$$

$$R_{22}=\tfrac{1}{4}e^{\lambda-\nu}(2\ddot{\lambda}+2\dot{\lambda}^2-\dot{\nu}\dot{\lambda}+\dot{\mu}\dot{\lambda})-\tfrac{1}{4}e^{\lambda-\mu}(2\lambda''+2\lambda'^2-\mu'\lambda'+\nu'\lambda')+1,$$

$$R_{33}=R_{22}\sin^2\theta.$$

The Ricci scalar is given by

$$R=\tfrac{1}{2}e^{-\mu}(2\nu''+\nu'^2-\nu'\mu'+2\nu'\lambda'-2\mu'\lambda'+3\lambda'^2+4\lambda'')-2e^{-\lambda}$$
$$-\tfrac{1}{2}e^{-\nu}(2\ddot{\mu}+\dot{\mu}^2-\dot{\nu}\dot{\mu}-2\dot{\nu}\dot{\lambda}+2\dot{\mu}\dot{\lambda}+3\dot{\lambda}^2+4\ddot{\lambda}). \quad \text{(A2)}$$

Using Einstein field equations (1), the nonvanishing components of energy–momentum tensor T_{ab} are

$$T_{00}=\tfrac{1}{4}(\dot{\lambda}^2+2\dot{\mu}\dot{\lambda})-\tfrac{1}{4}e^{\nu-\mu}(4\lambda''+3\lambda'^2-2\mu'\lambda')+e^{\nu-\lambda}, \quad T_{01}=R_{01},$$

$$T_{11}=\tfrac{1}{4}(\lambda'^2+2\nu'\lambda')-\tfrac{1}{4}e^{\mu-\nu}(4\ddot{\lambda}+3\dot{\lambda}^2-2\dot{\nu}\dot{\lambda})-e^{\mu-\lambda},$$
$$T_{22}=\tfrac{1}{4}e^{\lambda-\mu}(2\nu''+\nu'^2-\nu'\mu'+\nu'\lambda'-\mu'\lambda'+\lambda'^2+2\lambda'') \quad \text{(A3)}$$
$$-\tfrac{1}{4}e^{\lambda-\nu}(2\ddot{\mu}+\dot{\mu}^2-\dot{\nu}\dot{\mu}-\dot{\nu}\dot{\lambda}+\dot{\mu}\dot{\lambda}+\dot{\lambda}^2+2\ddot{\lambda}),$$

$$T_{33}=T_{22}\sin^2\theta.$$

APPENDIX B

The nonvanishing components of the Ricci tensor for FRW space–times are given by

$$R_0=-3\frac{\ddot{R}}{R},$$

$$R_1=\frac{(R^3)^{\cdot\cdot}}{3R}-2k,$$

$$R_2=R_1\Sigma^2(k,r), \quad \text{(B1)}$$

$$R_3=R_2\sin^2\theta,$$

where

$$\Sigma(k,r)=\sin r, \quad \text{for } k=1,$$
$$=r, \quad \text{for } k=0,$$
$$=\sinh r, \quad \text{for } k=-1.$$

The Ricci scalar is given by

$$R=-\frac{6}{R^2}(R\ddot{R}+\dot{R}^2-k). \tag{B2}$$

Now, the surviving components of energy–momentum tensor for FRW space–times are given by

$$T_0=\frac{3}{R^2}(\dot{R}^2-k),$$
$$T_1=-(2R\ddot{R}+\dot{R}^2)+k,$$
$$T_2=T_1\Sigma^2(k,r), \tag{B3}$$
$$T_3=T_2\sin^2\theta.$$

APPENDIX C

Linearly independent KVs associated with the FRW space–times are given by Ref. 24 for $k=1$,

$$\xi_{(1)}=\sin\phi\partial_\theta+\cot\theta\cos\phi\partial_\phi,$$
$$\xi_{(2)}=\cos\phi\partial_\theta-\cot\theta\sin\phi\partial_\phi,$$
$$\xi_{(3)}=\partial_\phi,$$
$$\xi_{(4)}=(\sin\theta\partial_r+\cot r\cos\theta\partial_\theta)\sin\phi+\cot r\csc\theta\cos\phi\partial_\phi, \tag{C1}$$
$$\xi_{(5)}=(\sin\theta\partial_r+\cot r\cos\theta\partial_\theta)\cos\phi-\cot r\csc\theta\sin\phi\partial_\phi,$$
$$\xi_{(6)}=\cos\theta\partial_r-\cot r\sin\theta\partial_\theta.$$

For $k=0$, we have

$$\xi_{(1)}=\sin\phi\partial_\theta+\cot\theta\cos\phi\partial_\phi,$$
$$\xi_{(2)}=\cos\phi\partial_\theta-\cot\theta\sin\phi\partial_\phi,$$
$$\xi_{(3)}=\partial_\phi,$$
$$\xi_{(4)}=\left(\sin\theta\partial_r+\frac{1}{r}\cos\theta\partial_\theta\right)\sin\phi+\frac{1}{r}\csc\theta\cos\phi\partial_\phi, \tag{C2}$$
$$\xi_{(5)}=\left(\sin\theta\partial_r+\frac{1}{r}\cos\theta\partial_\theta\right)\cos\phi-\frac{1}{r}\csc\theta\sin\phi\partial_\phi,$$
$$\xi_{(6)}=\left(\cos\theta\partial_r-\frac{1}{r}\sin\theta\partial_\theta\right).$$

For $k=-1$,

$$\xi_{(1)}=\sin\phi\partial_\theta+\cot\theta\cos\phi\partial_\phi,$$

$$\xi_{(2)}=\cos\phi\partial_\theta-\cot\theta\sin\phi\partial_\phi,$$

$$\xi_{(3)}=\partial_\phi,$$

$$\xi_{(4)}=(\sin\theta\partial_r+\coth r\cos\theta\partial_\theta)\sin\phi+\coth r\csc\theta\cos\phi\partial_\phi, \tag{C3}$$

$$\xi_{(5)}=(\sin\theta\partial_r+\coth r\cos\theta\partial_\theta)\cos\phi-\coth r\csc\theta\sin\phi\partial_\phi,$$

$$\xi_{(6)}=\cos\theta\partial_r-\coth r\sin\theta\partial_\theta.$$

(Received 11 April 2003; accepted 1 July 2003)

The solution is provided of a three-body problem in the plane, which is the third of a trio recently identified as likely to display a particularly simple time-evolution hence to be amenable to exact treatment. This conjecture, already validated by providing the solution of the first two of these three models, is now completely proven by exhibiting the solution of the third. This finding also demonstrates the conjectured super-Painlevé character of certain nonlinear ordinary differential equations, namely, the fact that their *general* solution is an *entire* function of the independent variable. © *2003 American Institute of Physics.*

I. INTRODUCTION

Recently the N-body problem in the plane characterized by the Newtonian equations of motion

$$\ddot{\vec{r}}_n = \omega \hat{k} \wedge \dot{\vec{r}}_n + 2 \sum_{m=1, m \neq n}^{N} r_{nm}^{-2} (\alpha_{nm} + \tilde{\alpha}_{nm} \hat{k} \wedge) \cdot [\dot{\vec{r}}_n (\dot{\vec{r}}_m \cdot \vec{r}_{nm}) + \dot{\vec{r}}_m (\dot{\vec{r}}_n \cdot \vec{r}_{nm}) - \vec{r}_{nm} (\dot{\vec{r}}_m \cdot \dot{\vec{r}}_m)] \quad (1)$$

has been much investigated.[1–7] Here the N two-vectors $\vec{r}_n \equiv \vec{r}_n(t)$ identify the positions, as funtions of the (real) time variable t, of the moving point-particles in a plane which for notational convenience is immersed in three-dimensional space, so that $\vec{r}_n \equiv (x_n, y_n, 0)$; $\hat{k}$ is the unit three-vector orthogonal to that plane, $\hat{k} \equiv (0,0,1)$, so that $\hat{k} \wedge \vec{r}_n \equiv (-y_n, x_n, 0)$; $\vec{r}_{nm} \equiv \vec{r}_n - \vec{r}_m$, hence $r_{nm}^2 \equiv \vec{r}_{nm} \cdot \vec{r}_{nm} \equiv (x_n - x_m)^2 + (y_n - y_m)^2$; superimposed dots denote of course time derivatives; ω is a *positive* constant, which sets the time scale and to which we associate the period

$$T = \frac{2\pi}{\omega}; \quad (2)$$

and the "coupling constants" $\alpha_{nm}, \tilde{\alpha}_{nm}$ are *a priori* arbitrary (of course *real*; a sufficient condition for this system to be Hamiltonian[2] is the requirement that these constants be symmetrical in their two indices, $\alpha_{nm} = \alpha_{mn}, \tilde{\alpha}_{nm} = \tilde{\alpha}_{mn}$, as we hereafter assume). Note that, in the special case without two-body forces ($\alpha_{nm} = \tilde{\alpha}_{nm} = 0$) this N-body problem describes N (equal) charged particles, not interacting among themselves, moving on a plane in the presence of a constant magnetic field

a)Electronic mail: francesco.calogero@roma1.infn.it
b)Electronic mail: jpf@ccr.jussieu.fr
c)Electronic mail: adolfo@matcuer.unam.mx

orthogonal to that plane (''cyclotron''); all solutions are then *completely periodic* with period T, see (2), since each particle moves with such a period on its circular trajectory (the center and radius of which are determined by its initial position and velocity).

To treat the N-body problem (1) it is generally convenient to identify the *real* ''physical'' plane on which the N points $\vec{r}_n \equiv (x_n, y_n, 0)$ move, with the *complex* plane in which the complex numbers $z_n \equiv x_n + i\, y_n$ move. Indeed via this correspondence these equations of motion (1) take the following neater form:

$$\ddot{z}_n - i\,\omega\,\dot{z}_n = 2 \sum_{m=1, m\neq n}^{N} a_{nm} \frac{\dot{z}_n\,\dot{z}_m}{z_n - z_m} \tag{3}$$

with

$$a_{nm} = \alpha_{nm} + i\,\tilde{\alpha}_{nm}\,. \tag{4}$$

Then one notes that, via the change of independent variable

$$z_n(t) = \zeta_n(\tau), \tag{5a}$$

$$\tau \equiv \tau(t) = \frac{\exp(i\omega t) - 1}{i\,\omega}, \tag{5b}$$

the equations of motion (3) become

$$\zeta_n'' = 2 \sum_{m=1, m\neq n}^{N} a_{nm} \frac{\zeta_n'\,\zeta_m'}{\zeta_n - \zeta_m}. \tag{6}$$

Here and generally below primes denote of course differentiations with respect to the (complex) independent variable τ. Note that this change of independent variable (5) implies that the *complex* variable $\tau(t)$ is a periodic function of the *real* variable t (time) with period T [see (2)], and moreover it entails the following very simple relations among the initial data for z_n and ζ_n:

$$z_n(0) = \zeta_n(0), \quad \dot{z}_n(0) = \zeta_n'(0). \tag{7}$$

Hence to obtain the solution of the equations of motion (3), namely of the Newtonian equations of motion (1), one can instead solve, with the *same* initial conditions [see (7)], the equations of motion (6), and then use the change of independent variable (5) to obtain the desired solution of the equations of motion (3). And this clearly implies that, if the solution $\zeta_n(\tau)$ of the equations of motion (6) is *meromorphic* in the complex variable τ, the corresponding solution $z_n(t)$ of the equations of motion (3), namely of the Newtonian equations of motion (1), is *completely periodic* with period T, see (2); unless one of the poles of the meromorphic solution $\zeta_n(\tau)$ of the equations of motion (6) happens to fall exactly on the circle with center at $\tau = i/\omega$ and radius $1/\omega$ in the complex τ-plane, which is traveled counterclockwise by the complex variable τ as the real variable t evolves from the initial condition at $t = 0$, in which case the time evolution hits a singularity: this corresponds to the (special) motions of the N-body problem in the plane characterized by the Newtonian equations of motion (1) in which a singularity occurs in the time evolution, generally corresponding to a particle collision.

It is therefore of interest to identify the particular N-body systems of type (3), characterized by a special choice of the number of particles N and of the coupling constants a_{nm}, see (4), such that the corresponding equations (6) *only* possess solutions $\zeta_n(\tau)$ that are *meromorphic* in τ, or even more remarkably, that *only* possess solutions which are *entire* in τ. In the first case [''*all* solutions $\zeta_n(\tau)$ of (6) are *meromorphic*''] one can then assert that these equations of motion (6) are endowed with the *Painlevé property*; in the second case [''*all* solutions $\zeta_n(\tau)$ of (6) are *entire*''] one can then assert that the equations of motion (6) are endowed with the *super-Painlevé property*.[3]

Note that the corresponding "physical" N-body systems in the plane (1) *only* possess solutions which are *completely periodic* with period T, see (2), except for the special cases of motions that run into singularities (generally due to particle collisions) in the first case, without any exception in the second case. Hence such systems (1) provide examples of *nonlinear harmonic oscillators*.[7]

On the basis of the local analysis of the singularities of the solutions $\zeta_n(\tau)$ of the equations of motion (6) made in Ref. 6, the conjecture has been proffered[3] that, in the context of the three-body problem ($N=3$), and excluding the cases in which two of the three constants a_{nm} vanish (when the three-body problem reduces to a two-body problem), there are altogether 11 cases (corresponding, up to permutations, to 11 different assignments of the triple of coupling constants $a_{12}=a_{21}$, $a_{23}=a_{32}$, $a_{31}=a_{13}$) in which the equations of motion (6) are *Painlevé*, and out of these 11 cases there are three which are *super-Painlevé*. In this paper we focus on the latter three cases, in particular on the one not hitherto solved.

The first *super-Painlevé* case is characterized by equations of motion (6) (with $N=3$) with one vanishing coupling constant and the other two equal to minus one-half, say (of course up to permutations) $a_{12}=a_{21}=0$, $a_{23}=a_{32}=a_{31}=a_{13}=-1/2$. In this case *all* solutions $\zeta_n(\tau)$ of the equations of motion (6) (have been obtained[3] and) are indeed *polynomial* in τ.

The second *super-Painlevé* case is characterized by equations of motion (6) (with $N=3$) with all three coupling constants equal to minus one-half, $a_{12}=a_{21}=a_{23}=a_{32}=a_{31}=a_{13}=-1/2$. In this case *all* solutions $\zeta_n(\tau)$ of the equations of motion (6) (have as well been obtained[4] and) are indeed *exponential* in τ [up to degeneracies, which yield a *polynomial* behavior, and up to the center-of-mass motion, which is of course uniform, see (6)].

The third case is characterized by equations of motion (6) (with $N=3$) with one vanishing coupling constant, one equal to minus one-half and one equal to minus unity, say (of course up to permutations)

$$a_{12}=a_{21}=0, \quad a_{23}=a_{32}=-1/2, \quad a_{31}=a_{13}=-1. \tag{8}$$

This is the case treated in this paper, where we obtain in rather explicit form its *general* solution $\zeta_n(\tau)$, and we prove that it is indeed *entire* in the complex variable τ. These results are detailed in the following Sec. II. The proof of these results is provided in Sec. III, and some final remarks are in Sec. IV.

Let us end this introductory section by recalling that, in the case with all coupling constants equal to unity, $a_{nm}=1$, the N-body problem characterized by the equations of motion (6)—hence as well that characterized by the equations of motion (3) [or equivalently by (1) with $\alpha_{nm}=1$, $\tilde{\alpha}_{nm}=0$, see (4)]—is *completely integrable* indeed *solvable*;[2] in this case the solutions $\zeta_n(\tau)$ of the equations of motion (6) feature however a finite number of square-root branch points, hence this integrable case is not Painlevé. The remarkable characteristics of this *integrable*, indeed *solvable* (see, for instance, Ref. 2), model suggested to call it a "goldfish,"[1] and it was subsequently suggested that this name be attributed to the general model (1) with arbitrary coupling constants, which also displays a very interesting phenomenology.[6]

II. RESULTS

In this section we exhibit the solution of the initial-value problem for the equations of motion (6) with $N=3$ and the assignment (8) of the coupling constants.

Let

$$\zeta_1(\tau)=x(\tau)+Z(\tau), \quad \zeta_2(\tau)=y(\tau)+Z(\tau), \quad \zeta_3(\tau)=-x(\tau)-y(\tau)+Z(\tau), \tag{9}$$

which entails that Z is the center-of-mass coordinate,

$$Z=\tfrac{1}{3}(\zeta_1+\zeta_2+\zeta_3), \tag{10}$$

hence, as clearly implied by the equations of motion (6), it moves uniformly

$$Z''=0, \quad Z(\tau)=Z(0)+Z'(0)\,\tau=Z(0)+V\,\tau. \tag{11}$$

Here and hereafter we indicate with

$$V=\tfrac{1}{3}[\zeta_1'(0)+\zeta_2'(0)+\zeta_3'(0)] \tag{12}$$

the (of course τ-independent) center-of-mass speed.

We now assert (and in the following section we prove) that $x(\tau)$ is given, in terms of $y(\tau)$, by the following formula:

$$x(\tau)=-2\,y(\tau)+[y'(\tau)+V]\,(\tau-\tau_0), \tag{13}$$

with the constant τ_0 (here and below) given in terms of the initial data by the formula

$$\tau_0=\frac{\zeta_3(0)-\zeta_2(0)}{\zeta_2'(0)}. \tag{14}$$

We moreover assert (and in the following section we prove) that $y(\tau)$ is given by the following formulas:

$$y(\tau)=2\,V\,(\tau-\tau_0)+F(\alpha_0,\alpha_1,\alpha_2;K;\tau-\tau_0), \tag{15a}$$

$$F(\alpha_0,\alpha_1,\alpha_2;K;z)=\alpha_0\,F^{(0)}(K;z)+\alpha_1\,F^{(1)}(K;z)+\alpha_2\,F^{(2)}(K;z), \tag{15b}$$

where the three constants $\alpha_0,\alpha_1,\alpha_2$ can be adjusted to fit the initial data, the constant K is given in terms of these data as follows:

$$K=\frac{\zeta_1'(0)\;\zeta_2'(0)\;\zeta_3'(0)}{[\zeta_3(0)-\zeta_2(0)][\zeta_3(0)-\zeta_1(0)]^2}, \tag{16}$$

and the three functions $F^{(j)}(K;z)$ are defined by the following formulas:

$$F^{(j)}(K;z)=z^j\sum_{m=0}^{\infty} c_m^{(j)}\,(2K)^m\,z^{3m}, \tag{17a}$$

$$c_0^{(0)}=1, \quad c_m^{(0)}=-\frac{(6m-6)!}{2\,(3m)!\,(3m-1)!\,(3m-2)!}, \quad m=1,2,3,\ldots, \tag{17b}$$

$$c_0^{(1)}=1, \quad c_m^{(1)}=-\frac{(6m-4)!}{24\,(3m+1)!\,(3m)!\,(3m-1)!}, \quad m=1,2,3,\ldots, \tag{17c}$$

$$c_0^{(2)}=\frac{1}{2}, \quad c_m^{(2)}=\frac{(6m-2)!}{120\,(3m+2)!\,(3m+1)!\,(3m)!}, \quad m=1,2,3,\ldots. \tag{17d}$$

These formulas provide the *general* solution of the equations of motion (6) with $N=3$ and the assignment (8) of the coupling constants, since they contain the six constants $Z(0)$, V, τ_0, α_1, α_2, α_3, which can be adjusted to fit the six initial conditions $\zeta_n(0)$, $\zeta_n'(0)$, $n=1,2,3$. Expressions of the first three of these constants [as well as of the constant K, see (16)] in terms of the initial data are already written above, see (10), (12), (14), while the other three, α_1, α_2, α_3, can be easily obtained from the following system of three linear equations (which is always solvable, since the determinant of the coefficients in its left-hand side is unity, as proven below):

$$\alpha_0 F^{(0)}(K;-\tau_0)+\alpha_1 F^{(1)}(K;-\tau_0)+\alpha_2 F^{(2)}(K;-\tau_0)$$
$$=\frac{1}{3}[-\zeta_1(0)+2\zeta_2(0)-\zeta_3(0)]+\frac{2V[\zeta_3(0)-\zeta_2(0)]}{\zeta_2'(0)}, \tag{18a}$$

$$\alpha_0 F^{(0)\prime}(K;-\tau_0)+\alpha_1 F^{(1)\prime}(K;-\tau_0)+\alpha_2 F^{(2)\prime}(K;-\tau_0)$$
$$=\tfrac{1}{3}[-\zeta_1'(0)+2\zeta_2'(0)-\zeta_3'(0)]-2V, \tag{18b}$$

$$\alpha_0 F^{(0)\prime\prime}(K;-\tau_0)+\alpha_1 F^{(1)\prime\prime}(K;-\tau_0)+\alpha_2 F^{(2)\prime\prime}(K;-\tau_0)=\frac{\zeta_2'(0)\,\zeta_3'(0)}{\zeta_3(0)-\zeta_2(0)}. \tag{18c}$$

This concludes our display of the *general* solution $\zeta_n(\tau)$ of the equations of motion (6) with $N=3$ and the assignment (8) of the coupling constants, and as well of the solution of the corresponding *initial-value* problem. The fact that these solutions $\zeta_n(\tau)$ are *entire* is plain, see (15) and (especially) (17).

These findings provide an explicit solution of the two nonlinear third-order ODEs satisfied by $y(\tau)$ and $x(\tau)$, obtained in Ref. 3 and conjectured there to be *super-Painlevé*. This conjecture is thereby validated; but the fact that the solutions of these nonlinear ODEs also satisfy *linear* (nonautonomous, third order) ODEs (as shown in the following section) presumably decreases the interest of those nonlinear ODEs, at least for the aficionados of Painlevé lore.

III. PROOFS

Let us begin by reformulating, following Ref. 3, the equations of motion (6) with $N=3$ in a more convenient form.

First of all we introduce for notational convenience the three coupling constants a, b, c by setting

$$a_{12}=a_{21}=a, \quad a_{23}=a_{32}=b, \quad a_{31}=a_{13}=c. \tag{19}$$

Next we point out that, as clearly implied by the equations of motion (6), the center of mass, see (10), moves uniformly.

We then introduce the coordinates u_n relative to the center of mass,

$$u_n=\zeta_n-Z, \quad n=1,2,3, \tag{20}$$

which clearly satisfy the restriction

$$u_1+u_2+u_3=0, \tag{21}$$

and we set [for notational convenience, and of course consistently with (21) as well as (9)]

$$u_1=x, \quad u_2=y, \quad u_3=-x-y. \tag{22}$$

It is then a matter of trivial algebra to write the equations of motion (6) (with $N=3$) in terms of the two variables x and y,

$$x''=2\,a\,\frac{(x'+V)\,(y'+V)}{x-y}-2\,c\,\frac{(x'+V)\,(x'+y'-V)}{2x+y}, \tag{23}$$

$$y''=-2\,a\,\frac{(x'+V)\,(y'+V)}{x-y}-2\,b\,\frac{(y'+V)\,(x'+y'-V)}{2y+x}. \tag{24}$$

Let us also note the existence (implied by these equations of motion[6]) of the constant of motion K,

$$K=(x'+V)\,(y'+V)\,(x'+y'-V)\,(x-y)^{2a}\,(2y+x)^{2b}\,(2x+y)^{2c}, \tag{25}$$

where of course $V=Z'(0)$ [see (11)].

We now restrict attention to the coupling constants assignment $a=0$, $b=-1/2$, keeping temporarily still free the option to assign the third coupling constant, c [eventually, to be completely consistent with the assignment (8), we shall set $c=-1$]. Hence the equations of motion now read as follows:

$$x''=-2\,c\,\frac{(x'+V)\,(x'+y'-V)}{2x+y}, \tag{26}$$

$$y''=\frac{(y'+V)\,(x'+y'-V)}{2y+x}, \tag{27}$$

and the associated constant of integration K reads as follows:

$$K=(x'+V)\,(y'+V)\,(x'+y'-V)\,(2y+x)^{-1}\,(2x+y)^{2c}. \tag{28}$$

We now introduce the auxiliary variable

$$\eta(\tau)=\frac{2y(\tau)+x(\tau)}{y'(\tau)+V}, \tag{29}$$

and we note that, as a consequence of (27), there holds the remarkable relation

$$\eta'(\tau)=1, \tag{30}$$

which of course entails

$$\eta(\tau)=\tau-\tau_0 \tag{31}$$

[and note the consistency of the expression (14) of τ_0 with this formula (31), via (29) with (9) and (11)].

We now note that (29) with (31) yield (13), which is therefore now proven, while clearly via (28) and (29) with (31) we can rewrite (26) as follows:

$$x''=-2\,c\,K\,(\tau-\tau_0)\,(2x+y)^{-2c-1}. \tag{32}$$

And the insertion of the expression (13) of x in this equation yields the following third-order ODE for $y(\tau)$:

$$y'''=-2\,c\,K\,[2\,(\tau-\tau_0)\,(y'+V)-3\,y]^{-2c-1}. \tag{33}$$

This ODE becomes particularly simple for two choices of the coupling constant c: for $c=-1/2$, which corresponds to the case treated in Ref. 3; and for $c=-1$, which is the case treated in this paper, to which attention is hereafter restricted. Then this ODE becomes *linear*,

$$y'''=2\,K\,[2\,(\tau-\tau_0)\,(y'+V)-3\,y]. \tag{34}$$

To solve it we now set

$$y(\tau)=2\,V\,(\tau-\tau_0)+F(K;\tau-\tau_0), \tag{35}$$

and we thereby obtain for $F(K;z)$ the neat ODE

$$F'''=2\,K\,[2\,z\,F'-3\,F], \tag{36}$$

where of course the primes denote, here and hereafter, differentiation with respect to the new independent variable $z=\tau-\tau_0$. It is now easy to check that the *general* solution of this linear third-order ODE is provided by (15b) with (17). And it is moreover plain that the three independent solutions $F^{(j)}(K;z)$, $j=1,2,3$, see (17), of this ODE (36) are characterized by the conditions

$$F^{(0)}(K;0)=1, \quad F^{(0)\prime}(K;0)=0, \quad F^{(0)\prime\prime}(K;0)=0, \tag{37a}$$

$$F^{(1)}(K;0)=0, \quad F^{(1)\prime}(K;0)=1, \quad F^{(1)\prime\prime}(K;0)=0, \tag{37b}$$

$$F^{(2)}(K;0)=0, \quad F^{(2)\prime}(K;0)=0, \quad F^{(2)\prime\prime}(K;0)=1, \tag{37c}$$

that clearly guarantee their linear independence, and moreover entail that their Wronskian, which is of course z-independent [thanks to (36)], equals unity,

$$\det\begin{pmatrix} F^{(0)}(K;z) & F^{(1)}(K;z) & F^{(2)}(K;z) \\ F^{(0)\prime}(K;z) & F^{(1)\prime}(K;z) & F^{(2)\prime}(K;z) \\ F^{(0)\prime\prime}(K;z) & F^{(1)\prime\prime}(K;z) & F^{(2)\prime\prime}(K;z) \end{pmatrix}=1. \tag{38}$$

The proof of all the results reported in the preceding section is thereby completed.

It will remain to be seen whether the approach used herein can be exploited to solve other three-body problems of type (6), and in particular some of those singled out in Ref. 3; an obvious candidate is the model characterized by the coupling constants $a_{12}=a_{21}=a=0$, $a_{23}=a_{32}=b=-1/2$, $a_{31}=a_{13}=c=-3/2$, to which the treatment given in this section is still applicable, leading again to the ODE (33), but with a value of c that causes the right-hand side of this ODE to be quadratic [rather than being linear, as is the case, see (34), for the model treated in this paper].

ACKNOWLEDGMENTS

(Received 6 November 2002; accepted 27 May 2003)

The minimal coupling principle is revisited under the quantum perspectives of the space–time symmetry. This revision is better realized on a group approach to quantization (GAQ) where group cohomology and extensions of groups play a preponderant role. We first consider the case of the electromagnetic potential; the Galilei and/or Poincaré group is (noncentrally) extended by the ''local'' U(1) group. The resulting group can also be seen as a central extension, parametrized by both the mass and the electric charge, of an infinite-dimensional group, on which GAQ leads to the dynamics of a particle moving in the presence of an electromagnetic field. Then we try the gravitational interaction of a particle by making the space–time translations ''local.'' However, promoting to ''local'' the space–time subgroup of the true symmetry of the quantum free relativistic particle, i.e., the centrally extended by U(1) Poincaré group, results in a new electromagneticlike force of pure gravitational origin. This is a consequence of the space–time translations not being an invariant subgroup of the extended Poincaré group and constitutes a preliminary attempt to a nontrivial mixing of space–time and internal gauge interactions. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1604183]

I. INTRODUCTION

In the Lagrangian formalism, formulated on the one-jet bundle, $J^1(E)$ of a vector bundle E on Minkowski space–time M,[1,2] promoting a given underlying rigid symmetry to ''local,'' i.e., extending the corresponding Lie algebra by taking the tensor product of it by the algebra of real analytic functions on M, requires the introduction of a derivation law on the module of sections of E, $\Gamma(E)$, which is eventually interpreted as a potential providing the corresponding gauge interaction. This is essentially the formulation of the so-called minimal coupling principle, which culminates in Utiyama's theory.[3] Internal gauge invariance had originally led successfully to electromagnetic interaction associated with U(1), then to Yang–Mills associated with isospin SU(2) (valid only at the ''very strong'' limit), electroweak with $(\mathrm{SU}(2)\otimes\mathrm{U}(1))/Z_2$, and finally to strong interaction associated with color SU(3). The same spirit is shared by later attempts to unify all of these into gauge groups such as SU(5). On the other hand, the ''local'' invariance under external (space–time) symmetries, such as a subgroup of the Poincaré group, has been used to provide a gauge framework for gravity,[4] although fully disconnected from the other (internal) interactions. In fact, a unification of gravity and the other interactions would have supposedly required the nontrivial mixing of the space–time group and some internal symmetry, a task

[a]Electronic mail: valdaya@iaa.es

explicitly forbidden by the so-called *no-go theorems* by O'Raifeartaigh, Coleman, Mandula, Michel, etc.[5–8] long ago, which stated that there is no finite-dimensional Lie group containing the Poincaré group acting as diffeomorphisms of the base manifold M, the Minkowski space–time, and any internal SU(n) group acting linearly on the fiber of E, except for the direct product. It is worth mentioning that supersymmetry was originally developed in the 1970s, mainly by Salam and Strathdee,[9] in an unsuccessful attempt to invalidate the no-go theorems.

However, the current skill in dealing with Lie group extensions and irreducible representations of (even infinite-dimensional) Lie groups tempts us into revisiting the question of the mixing of symmetries and, accordingly, the unification of interactions in terms of ordinary Lie groups. We propose a simple, yet nontrivial, way of facing the problem of interaction mixing. This consists in identifying one of the U(1) Cartan subgroups in the internal symmetry with the U(1) phase invariance in quantum mechanics. Then, turning the space–time translation subgroup of a centrally extended Poincaré group[10–13] into a ''local'' group automatically promotes the original rigid internal symmetry to the gauge level in a nontrivial way from the physical standpoint. This provides a nontrivial mixing of gravity and the already introduced internal interaction associated with the given unitary symmetry. Here, we seek to demonstrate explicitly the ocurrence of this new phenomenon at least at a given approximation without exhausting all possibilities of the proposed algorithm. This means that our present computational outputs must be understood as being partial, although, at the nonrelativistic limit, they are exact and reveal with precision the mixing effect.[14]

As is well known, the minimal coupling principle can also be formulated on a bundle E of the form $E=\mathbb{R}^3\times\mathbb{R}\to\mathbb{R}$, as corresponding to the case of mechanics, thus making the problem technically easier while keeping the essential point to be discussed here. In this framework, to be followed in the present article, the gauge principle will be revisited by simply substituting the quantum mechanical space–time symmetry for the standard (classical) one. In fact, in a previous letter,[14] we sketched an approach to the problem in this simple and economical way, i.e., in a particle mechanics (versus field theory) framework, and we now undertake a more detailed and formal presentation. A much more involved generalization to quantum field theory is under way.[15]

Since the revision we attempt here lies entirely on symmetry grounds, a (quantum) mechanical formulation tightly attached to a group structure is better suited. There is, in fact, a way of associating physical dynamics with a specific symmetry group. This could be accomplished by means of the rather standard co-adjoint-orbits method of Kirillov,[16] where the Lagrangian is seen as the local potential of the corresponding symplectic form. However, we shall proceed through a group approach to quantization (GAQ),[17,18] which is directly related to the co-homological structure of the symmetry group, and leads directly to the quantum theory, a fact that can be of capital relevance in the near future in passing to the quantum-field-theory level. Co-homology parameters will be directly identified with the physical coupling constants. In this sense, the association of the parameter of the (symplectic) co-homology group of the Galilei group with the particle mass has been emphasized by Souriau.[19]

As an intermediate step between the more standard Lagrangian version of the minimal interaction principle and the one to be presented here, we shall formulate a version ''à la Cartan,'' i.e., in terms of the invariance of the Poincaré–Cartan form[20–23] rather than the Lagrangian, of the part of Utiyama's theory concerning the particle in interaction with the field. Indeed, as mentioned above, the dynamics of the gauge fields themselves will be considerd elsewhere.

The article is organized as follows. Section II is a thorough presentation of basic geometrical aspects of classical and quantum mechanics, mainly those fundamental to the development of the present work. Section III is devoted to the Cartan-like analysis of the minimal coupling principle particularized for the case of electromagnetism and nonrelativistic gravity. In Sec. IV we present explicitly the GAQ with the example of a particle moving in an electromagnetic field. Finally, in Sec. V, we directly present the chief problem of gauging the translation subgroup of the centrally extended Poincaré group giving rise to the new phenomenon of an extra coupling constant mixing nontrivially the geodesic force and the Lorentz one. Some outlooks are included at the end.

II. PHASE INVARIANCE IN QUANTUM MECHANICS

According to the standard approach to quantum mechanics (see, for instance, Ref. 24) a state of the system is characterized by a *ray*, rather than a vector, of a Hilbert space, i.e., normalized wave functions are determined up to a complex number of module 1 or phase. This is a direct consequence of the definition of probability and constitutes a symmetry to be referred to as U(1) or phase invariance in quantum mechanics. Let us approach this symmetry from quite different perspectives to highlight its fundamental features.

A. Behavior of the Schrödinger equation

We shall consider the behavior of the Schrödinger equation corresponding to the free quantum particle

$$i\hbar \frac{\partial}{\partial t}\Psi = -\frac{\hbar^2}{2m}\nabla^2\Psi, \tag{1}$$

under the Galilei transformations

$$\begin{aligned} t' &= t + b, \\ \vec{x}' &= R\vec{x} + \vec{a} + \vec{V}t, \\ \vec{v}' &= R\vec{v} + \vec{V}. \end{aligned} \tag{2}$$

where R represents rotations, $b \in \mathbb{R}$ and $\vec{a} \in \mathbb{R}^3$ time and space translations, respectively, and $\vec{V} \in \mathbb{R}^3$ Galilean boosts.

Equation (1) acquires an extra term,

$$i\hbar \frac{\partial}{\partial t'}\Psi + i\hbar \vec{V}\cdot \frac{\partial \Psi}{\partial \vec{x}'} = -\frac{\hbar^2}{2m}\nabla'^2\Psi, \tag{3}$$

which can be compensated only by also transforming the wave function. Allowing for a nontrivial phase factor in front of the transformed wave function, of the form

$$\Psi' = e^{(im/\hbar)(\vec{V}\cdot R\vec{x} + (1/2)\vec{V}^2 t)}\Psi, \tag{4}$$

the Schrödinger equation becomes strictly invariant:

$$i\hbar \frac{\partial}{\partial t'}\Psi' = -\frac{\hbar^2}{2m}\nabla'^2\Psi'. \tag{5}$$

The need for a transformation such as (4) accompanying the space–time transformation (2) to accomplish full invariance strongly suggests the adoption of a central extension of the Galilei group as the basic (quantum-mechanical) space–time symmetry for the free particle.[25] The constant $\hbar$ is required to keep the exponent in (4) dimensionless.

The successive composition of two transformations in the extended Galilei group $\tilde{G}$ immediately leads to the group law:

$$\begin{aligned} b'' &= b' + b, \\ \vec{a}'' &= \vec{a}' + R(\vec{\epsilon}')\vec{a} + \vec{V}'b, \\ \vec{V}'' &= \vec{V}' + R(\vec{\epsilon}')\vec{V}, \end{aligned} \tag{6}$$

$$\vec{\epsilon}''=\sqrt{1-\frac{\vec{\epsilon}^{\,2}}{4}}\,\vec{\epsilon}'+\sqrt{1-\frac{\vec{\epsilon}'^{\,2}}{4}}\,\vec{\epsilon}+\frac{1}{2}\,\vec{\epsilon}'\wedge\vec{\epsilon},$$

$$e^{i\phi''}=e^{i\phi'}e^{i\phi}e^{(im/\hbar)[\vec{V}'R'\vec{a}+(1/2)\,b\vec{V}'^{2}]},$$

where $e^{i\phi}\in \mathrm{U}(1)$, and we have made the rotation parameters $\vec{\epsilon}\in\mathbb{R}^3$ explicit, which are restricted to $2\sin(\chi/2)=|\vec{\epsilon}|$, χ being the rotation angle.

B. Semi-invariance in classical mechanics

This phenomenon of extending the space–time symmetry, although conceptually pure quantum mechanical, can also be recast within a (semi-)classical formalism, by requiring the simultaneous extension of the classical phase space by a new variable ϕ, transforming in a nontrivial way under the U(1)-extended symmetry group. The need for such an extension is motivated by the lack of strict invariance of the Poincaré–Cartan form associated with the free particle ($H=p_i\dot{x}^i-L=\vec{p}^{\,2}/2m$),

$$\Theta_{PC}\equiv p_i dx^i-Hdt=\left(\frac{\partial L}{\partial\dot{x}^i}(dx^i-\dot{x}^i dt)+L dt\right)=p_i dx^i-\frac{\vec{p}^{\,2}}{2m}dt \tag{7}$$

under the Galilei group. In fact, it is left only semi-invariant by the infinitesimal transformations associated with (2) in the sense that the Lie derivative of Θ_{PC} with respect to those generators is the differential of a function not necessarily zero:

$$\begin{aligned}
&X_b=\frac{\partial}{\partial t}\Rightarrow L_{X_b}\Theta_{PC}=0,\\
&X_{\vec{a}}=\frac{\partial}{\partial\vec{x}}\Rightarrow L_{X_{\vec{a}}}\Theta_{PC}=0,\\
&X_{\vec{V}}=t\frac{\partial}{\partial\vec{x}}+m\frac{\partial}{\partial\vec{p}}\Rightarrow L_{X_{\vec{V}}}\Theta_{PC}=d(m\vec{x}),\\
&X_{\vec{\epsilon}}=\vec{x}\wedge\frac{\partial}{\partial\vec{x}}+\vec{p}\wedge\frac{\partial}{\partial\vec{p}}\Rightarrow L_{X_{\vec{\epsilon}}}\Theta_{PC}=0.
\end{aligned} \tag{8}$$

The pathology of semi-invariance is parallel to the absence of a clean quotient by the equations of motion. Let us see in some detail the quotient process in going to the solution manifold. In the Cartan formalism the trajectories of a general physical system are the orbits of the kernel of $d\Theta_{PC}$:

$$\begin{aligned}
&\Theta_{PC}\equiv p_i dx^i-Hdt,\\
&\Omega\equiv d\Theta_{PC}=dp_i\wedge dx^i-\frac{\partial H}{\partial x^i}dx^i\wedge dt-\frac{\partial H}{\partial p_i}dp_i\wedge dt.
\end{aligned} \tag{9}$$

Ω has a one-dimensional kernel generated by $X^H\in\mathrm{Ker}\,d\Theta_{PC}$ such that $dt(X^H)=1$,

$$X^H=\frac{\partial}{\partial t}+\frac{\partial H}{\partial p_i}\frac{\partial}{\partial x^i}-\frac{\partial H}{\partial x^i}\frac{\partial}{\partial p_i}, \tag{10}$$

and the associated equations of motion are the Hamilton equations:

$$\frac{dt}{d\tau}=1,$$

$$\frac{dx^i}{d\tau}=\frac{\partial H}{\partial p_i}, \tag{11}$$

$$\frac{dp_i}{d\tau}=-\frac{\partial H}{\partial x^i}.$$

The vector field X^H defines a one-parameter group which divides the *space of movements* $\mathbb{R}\times\mathbb{R}^3\times\mathbb{R}^3$, parametrized by $(t,\vec{x},\vec{p})$, into classes, and $M\equiv\{\mathbb{R}\times\mathbb{R}^3\times\mathbb{R}^3\}/X^H$ constitutes the symplectic *phase space* of the system characterized by the Hamiltonian H; the symplectic form is obtained by the projection of Ω. The change of variables under which the equations of motion on the quotient become trivial is the Hamilton–Jacobi transformation. For the example $H=\vec{p}^2/2m$, corresponding to a free particle, this transformation is

$$\begin{cases} x^i=\dfrac{P^i}{m}\tau+K^i \\ p_i=P_i \\ t=\tau \end{cases} \Leftrightarrow \begin{cases} K^i=x^i-\dfrac{p^i}{m}t, \\ P_i=p_i, \\ \tau=t, \end{cases} \tag{12}$$

where the constants of motion K^i,P_j parametrize the solution manifold M. However, the form Θ_{PC} goes to the quotient except for a total differential:

$$\Theta_{PC}\rightarrow P_i dK^i+d\left(\frac{\vec{P}^2}{2m}\tau\right),$$

$$\omega=dP_i\wedge dK^i. \tag{13}$$

C. Poisson algebra realization

Another equivalent analytical mechanics breakdown claiming a ''generalization'' is the unfair relationship between the Lie brackets of basic symmetries and the corresponding Poisson brackets of the associated Noether invariants. The symplectic form[21–23] is a skew-symmetric ''metric'' and defines an isomorphism $\omega^\flat:\mathcal{X}(M)\leftrightarrow\Lambda^1(M)$ between the vector space of vector fields on M and that of one-forms on M,

$$X\in\mathcal{X}(M)\mapsto\omega(X,\cdot)\equiv i_X\omega\in\Lambda^1(M), \tag{14}$$

associating a bracket $\{,\}$ on $\Lambda^1(M)$ with the Lie bracket of vector fields. In particular, given functions $f,g\in C^\infty(M)$, their differentials are associated with *Hamiltonian vector fields* X_f,X_g.[26] This permits the definition of a Poisson bracket between functions, rather than one-forms, but this time the correspondence $\{,\}\rightarrow[,]$,

$$\{,\}:f,g\mapsto\{f,g\}/d\{f,g\}=-i_{[X_f,X_g]}\omega, \tag{15}$$

is no longer an isomorphism because constant functions have trivial Hamiltonian vector fields. In particular, with regard to the example $H=\vec{p}^2/2m$, and considering K^i,P_j as the basic coordinates for M, we find

$$\{K^i,P_j\}=\delta^i_j\cdot 1\mapsto[X_{K^i},X_{P_j}]=0, \tag{16}$$

that is, a Lie algebra homomorphism whose kernel is the central subalgebra of constant functions, $\mathbb{R}$, generated by 1. It is easy to realize that X_{K^i}, X_{P_j} are nothing other than the generators X_{V^i}, X_{a^j}, respectively, of the action (2) of the unextended Galilei group on the space of movements, written on the solution manifold.[27]

The extension of phase space is required to represent faithfully the (classical) Poisson algebra by means of the generators of the extended symmetry as first-order differential operators, a fact that constitutes the Bohr–Sommerfeld approximation to quantization or prequantization, in the language of geometric quantization.[19,28–30] Let us look at the preliminary steps towards the geometric attempts at quantization.

D. Geometric and group approach to quantization

The existence of a nontrivial kernel in the correspondence between functions and Hamiltonian vector fields is an essential failure of the naive geometric approach to quantization $\hat{}: f \mapsto \hat{f} \equiv X_f$, which would associate the trivial operator to any constant. The simplest way of avoiding this problem consists of enlarging phase space (and/or movements space) with one extra variable providing one extra component to X_f, and generalizing accordingly the equation $i_{X_f} d\Theta_{PC} = -df$ so as to get a nontrivial new component even though f is a constant. On a quantum manifold P, locally isomorphic to $M \times S^1$, with connection form Θ such that the curvature two-form $(d\Theta)$ coincides with $d\Theta_{PC}$, the equation above can be replaced by the set of equations[19]

$$\begin{aligned} i_{\tilde{X}_f} d\Theta &= -df, \\ i_{\tilde{X}_f} \Theta &= f, \end{aligned} \tag{17}$$

generalizing in this way the quantization map which now reads (except perhaps for a minus sign)

$$\hat{}: f \mapsto i\tilde{X}_f. \tag{18}$$

Note that Eq. (17) immediately implies the strict invariance of Θ under $\tilde{X}_f$:

$$L_{\tilde{X}_f} \Theta = d i_{\tilde{X}_f} \Theta + i_{\tilde{X}_f} d\Theta = df - df = 0. \tag{19}$$

Locally, we can write $\Theta = \Theta_{PC} + dz/iz$, $z = e^{i\Phi} \in S^1$, and then $\tilde{X}_f = X_f + [f - \Theta_{PC}(X_f)] \times (iz(\partial/\partial z) - iz^*(\partial/\partial z^*))$, and we immediately see that (17) has a unique solution associating the fundamental (vertical) vector field $\Xi \equiv iz(\partial/\partial z) - iz^*(\partial/\partial z^*) = \partial/\partial\Phi$, dual to dz/iz, with the unity of $\mathbb{R}$.

The quantization map $\hat{}$ is now an isomorphism between the Poisson algebra on M and the Lie subalgebra of vector fields on P that are solutions to (17). For the basic functions, we have

$$\{K^i, P_j\} = \delta^i_j \cdot 1 \leftrightarrow [\tilde{X}_{K^i}, \tilde{X}_{P_j}] = \delta^i_j \cdot \Xi. \tag{20}$$

It is again easy to realize that, in the case of the free particle, the operators $\tilde{X}_{K^i}, \tilde{X}_{P_j}$ are nothing other than the generators $\tilde{X}_{V^i}, \tilde{X}_{a^j}$ of the action (2) and (4) on the extended space of movements (with $\zeta \equiv e^{i\phi} \in S^1$) of the extended Galilei group, that is to say,

$$\begin{aligned} \tilde{X}_b &= X_b, \\ \tilde{X}_{\vec{a}} &= X_{\vec{a}}, \\ \tilde{X}_{\vec{v}} &= X_{\vec{v}} - \frac{1}{\hbar} m\vec{x} \frac{\partial}{\partial \phi}, \end{aligned} \tag{21}$$

$$\tilde{X}_{\vec{\epsilon}} = X_{\vec{\epsilon}},$$

written on the solution manifold.

To pass to the solution manifold, we must take into account the evolution of the new variable $\zeta \in \mathrm{U}(1)$. In fact, the equations of motion in the extended [by U(1)] movement space are given by the vector field $\check{X}$ in the kernel of $d\Theta$ and Θ, simultaneously, satisfying $dt(X)=1$. Locally, and for the choice $\Theta_{PC} = p_i dx^i - H dt$, we find

$$\check{X}^H = X^H + \left\{ H - p_i \frac{\partial H}{\partial p_i} \right\} \Xi. \tag{22}$$

For the free particle, $\check{X}^H$ provides the following new equation, to be added to de Hamilton–Jacobi set (12),

$$\zeta = z e^{-(i/\hbar)(\vec{P}^2/2m)\,t} \Leftrightarrow z = \zeta e^{(i/\hbar)(\vec{p}^2/2m)\,t}. \tag{23}$$

Now the form Θ, originally written in the space of movements as

$$\Theta = p_i dx^i - \frac{\vec{p}^2}{2m} dt + \hbar \frac{d\zeta}{i\zeta}, \tag{24}$$

goes to the quotient, by applying the extended Hamilton–Jacobi transformation (12) and (23), giving

$$\Theta = P_i dK^i + \hbar \frac{dz}{iz}. \tag{25}$$

The space of wave functions Ψ is constituted by the complex functions on P that satisfy the U(1)-equivariance condition, turning Ψ into a section of the principal bundle $P \to M$:[31]

$$\Xi \tilde{\Psi} = i\tilde{\Psi} \leftrightarrow \tilde{\Psi}(K,P,z) = z\Psi(K,P), \tag{26}$$

on which the vector fields $\tilde{X}_f$ act, defining the *prequantum operators*.

Unfortunately, the quantization map $\hat{}$ is faithful but not irreducible as a representation of the Lie algebra of classical functions. At this prequantization level, we are able to reproduce only the Bohr–Sommerfeld–Wilson quantization rules.[30] We know that this representation is reducible because of the existence of nontrivial operators commuting with the basic quantum generators $\hat{K}^i \equiv i\hbar \tilde{X}_{K^i}, \hat{P}_j \equiv -i\hbar \tilde{X}_{P_j}$. In fact, thinking of the simplest case, that of the free particle for example, and adopting for Θ the local expression (25), we get the following basic operators acting on the untilded wave functions Ψ:

$$\hat{K}^i = i\hbar \frac{\partial}{\partial P_i} + K^i, \qquad \hat{P}_j = -i\hbar \frac{\partial}{\partial K^j}, \tag{27}$$

and it is clear that the operators $\check{K}^i \equiv \partial/\partial P_i$ do commute with them.

True quantization requires that all nontrivial operators commuting with basic quantum generators should be trivialized. We must then impose a maximal set of mutually compatible conditions in the form $X\Psi = 0$, for X in some maximal vector space called *polarization*. For instance, in the example above the operator $\partial/\partial P_i$ would be trivial had we imposed the polarization condition $(\partial/\partial P_i)\,\Psi = 0 \to \Psi \neq \Psi(P)$. Finding a polarization, however, is a nontrivial task in general, because two polarization conditions $\hat{a}\Psi = 0$, $\hat{b}\Psi = 0$ are inconsistent if $[\hat{a},\hat{b}] = \hat{1}$ and, once a certain

polarization has been imposed, the set of physical operators that preserve the polarization is severely restricted. Even more, the existence of an invariant polarization, i.e., a polarization preserved by the basic operators, is by no means guaranteed.

A stylish and even practical (at least for fundamental systems) solution to this and other problems comes from the structure itself of the (classical) Poisson algebra seen as a fundamental symmetry of the physical system to be quantized or, more precisely, the (quantum) physical system to be studied. Looking again at the quantum symmetry of the free particle, the extended Galilei group (2), we can adopt its structure as the basic block to provide the whole physical system, including the space and time where the evolution takes place.[17,18] The chief idea is to replace the quantum manifold P with a Lie group $\tilde{G}$ bearing the structure of a principal bundle with structure group U(1) and a connection one-form Θ selected from the canonical invariant forms on the group. The simplest, though sufficiently broad, example of such a class of Lie groups is the case of a central extension of a given group G by U(1).[25] In this situation, the central extensions are parametrized by the second co-homology group of G in U(1), $H^2(G,\mathrm{U}(1))$, and the coordinates in this (vector) space are associated with fundamental constants such as the mass[19] or the electric charge (see Sec. IV). Each co-homology constant is in turn associated with a Lie subalgebra of even dimension (in fact, a symplectic vector space) which will provide a set of canonically conjugate pairs of operators. We shall call them *dynamical* quantities, or the corresponding parameters in the group (classical) dynamical variables.

The virtues of working on a Lie group are multiple, but, for the time being, let us point out that of possessing two sets of natural, mutually commuting operators, that is, the left- and right-invariant vector fields, the latter of which can provide a unitary representation to be reduced by polarization conditions imposed by a subalgebra of the former. With this choice, the connection one-form Θ is the U(1) component of the left-invariant canonical one-form on the group, which is automatically invariant under the right-invariant vector fields. The only apparent drawback of doing so is that the quotient $\tilde{G}/\mathrm{U}(1)$ is not necessarily a symplectic manifold since the curvature two-form $d\Theta$ may have a nontrivial kernel. However, this apparent problem is solved by including in the polarization conditions, formulated in terms of a maximal horizontal subalgebra $\mathcal{P}$ of left-invariant vector fields, the subalgebra of (left-invariant) vector fields $\mathcal{G}_\Theta$ generating the characteristic module of Θ, i.e., $\mathrm{Ker}\Theta \cap \mathrm{Ker}d\Theta$.

It should be stressed that, far from being a drawback, working on the precontact manifold $\tilde{G}$ instead of a proper quantum manifold P allows us to deal with quantum systems without classical limit. In fact, the trajectories of the vector fields in the characteristic subalgebra generalize the classical motion, and the solution of the corresponding equations can be bypassed by including this subalgebra in the polarization as generalized Schrödinger equations.

III. CARTAN-LIKE VERSION OF THE MINIMAL-COUPLING PRINCIPLE: THE ELECTROMAGNETIC AND NONRELATIVISTIC GRAVITATIONAL FORCES

Once the symmetry of the free particle has been posed through the strict invariance of the corresponding extended Poincaré–Cartan (or quantization) form Θ (24) under the action of extended Galilei group, we may postulate the requirement of invariance of a generalized Θ under the Galilei group (noncentrally) extended by the ''local'' group $\mathrm{U}(1)(\vec{x},t)$ (of local phase transformations $e^{i\phi(\vec{x},t)}$). This requirement, along with the minimal substitution in Θ to achieve strict invariance, constitutes the Cartan-like version of the minimal coupling principle for the U(1) rigid symmetry and will lead to the motion of a particle in the presence of an electromagnetic field.

Let us consider the Lie algebra $\tilde{\mathcal{G}}$ of the centrally extended Galilei group $\tilde{G}$ (only nonzero commutators):

$$
\begin{gathered}
[\tilde{X}_{V^i},\tilde{X}_b]=\tilde{X}_{a^i},\quad [\tilde{X}_{V^i},\tilde{X}_{a^j}]=\frac{m}{\hbar}\delta_{ij}\tilde{X}_\phi,\\
[\tilde{X}_{\epsilon^i},\tilde{X}_{\epsilon^j}]=\epsilon_{ij.}{}^k\tilde{X}_{\epsilon^k},\quad [\tilde{X}_{\epsilon^i},\tilde{X}_{V^j}]=\epsilon_{ij.}{}^k\tilde{X}_{V^k},\quad [\tilde{X}_{\epsilon^i},\tilde{X}_{a^j}]=\epsilon_{ij.}{}^k\tilde{X}_{a^k},
\end{gathered}
\tag{28}
$$

which, as mentioned above, leaves strictly invariant the extended Poincaré–Cartan form $\Theta = p_i dx^i - (\vec{p}^2/2m) + \hbar d\phi$, that is, $L_{\tilde{X}_a}\Theta = 0, \forall \tilde{X}_a \in \tilde{\mathcal{G}}$.

Local U(1) transformations generated by $f \otimes X_\phi$, f being a real function $f(\vec{x},t)$, are incorporated into the scheme by adding to (28) the extra commutators:[32]

$$[\tilde{X}_a, f \otimes X_\phi] = (L_{\tilde{X}_a} f) \otimes X_\phi . \tag{29}$$

The Lie derivative of (24) with respect to $f \otimes X_\phi$ gives

$$L_{f \otimes X_\phi}\Theta = d(i_{fX_\phi}\Theta) + i_{fX_\phi} d\Theta = df.$$

Keeping the strict invariance requires modifying Θ by adding a connection term $\Gamma = \Gamma_i dx^i + \Gamma_0 dt$ whose components transform under $\mathrm{U}(1)(\vec{x},t)$ as the space–time gradient of the function f.[33] Additional conditions on Γ will be obtained by requiring strict invariance of $\Theta' \equiv \Theta + \Gamma$ under the complete group. The generators of the action of the whole group on the variables $(t, \vec{x}, \vec{p}, \vec{\Gamma}, \Gamma_0, \phi)$ are

$$\begin{aligned}
\tilde{X}_b &= \frac{\partial}{\partial t}, \\
\tilde{X}_{\vec{a}} &= \frac{\partial}{\partial \vec{x}}, \\
\tilde{X}_{\vec{V}} &= t\frac{\partial}{\partial \vec{x}} + m\frac{\partial}{\partial \vec{p}} + \vec{\Gamma}\frac{\partial}{\partial \Gamma_0} + \frac{m}{\hbar}\vec{x}\frac{\partial}{\partial \phi}, \\
\tilde{X}_{\vec{\epsilon}} &= \vec{x} \wedge \frac{\partial}{\partial \vec{x}} + \vec{p} \wedge \frac{\partial}{\partial \vec{p}} + \vec{\Gamma} \wedge \frac{\partial}{\partial \vec{\Gamma}}, \\
f \otimes X_\phi &= -\vec{\nabla} f \frac{\partial}{\partial \vec{\Gamma}} + \frac{\partial f}{\partial t}\frac{\partial}{\partial \Gamma_0} - \frac{f}{\hbar}\frac{\partial}{\partial \phi}.
\end{aligned} \tag{30}$$

Then, the infinitesimal condition

$$L_X(\Theta') = 0$$

implies the following finite transformation properties of the components of Γ:

$$\begin{aligned}
\vec{\Gamma}' &= R\vec{\Gamma}, \\
\Gamma_0' &= \Gamma_0 + \vec{V} \cdot R\vec{\Gamma},
\end{aligned} \tag{31}$$

under a rotation and a boost, and

$$\begin{aligned}
\vec{\Gamma}' &= \vec{\Gamma} + \vec{\nabla} f, \\
\Gamma_0' &= \Gamma_0 + \frac{\partial f}{\partial t},
\end{aligned} \tag{32}$$

under an element of $\mathrm{U}(1)(\vec{x},t)$.

Let us now compute the simultaneous kernel of Θ' and $d\Theta'$ and write the equations of motion, rewriting the connection Γ as $\Gamma \equiv qA_i dx^i - qA_0 dt$. We then have (omitting the prime over Θ')

$$\Theta = m\vec{v}\cdot d\vec{x} - \tfrac{1}{2}m\vec{v}^2 dt + q\vec{A}\cdot d\vec{x} - qA^0 dt + \hbar\, d\phi, \tag{33}$$

$$\check{X} = \frac{\partial}{\partial t} + \vec{v}\cdot\frac{\partial}{\partial \vec{x}} + \frac{q}{m}\left[\left(\frac{\partial A_j}{\partial x^i} - \frac{\partial A_i}{\partial x^j}\right)v^j - \frac{\partial A^0}{\partial x^i} - \frac{\partial A_i}{\partial t}\right]\frac{\partial}{\partial v_i} - \frac{1}{\hbar}\left[\frac{1}{2}m\vec{v}^2 + q(\vec{v}\cdot\vec{A} - A^0)\right]\frac{\partial}{\partial \phi}. \tag{34}$$

It states the equations of motion of a charged particle of charge q in an electromagnetic field:

$$\frac{d\vec{x}}{dt} = \vec{v},$$

$$m\frac{d\vec{v}}{dt} = q\left[\vec{v}\wedge(\vec{\nabla}\wedge\vec{A}) - \vec{\nabla}A^0 - \frac{\partial\vec{A}}{\partial t}\right], \tag{35}$$

$$\frac{d\phi}{dt} = -\frac{1}{\hbar}\left(\frac{\vec{p}^2}{2m} - \frac{q}{m}\vec{A}\cdot\vec{p}\right).$$

The minimal coupling principle can also be applied to the case of Newtonian gravity by requiring the space and time translation parameters to depend on time. Unlike the electromagnetic gauge principle, which can be directly extended to the relativistic situation, relativistic gravity is much more involved and will be analyzed in Sec. V, mixed with electromagnetism as our central task.

For brevity, let us consider the 1+1-dimensional case. Starting with the unextended Galilei group, we promote the space and time translations to local in the more economical way, that is, turning the corresponding group parameters into functions of time. The gauge algebra is then

$$[f(t)\otimes X_b, X_b] = -\frac{\partial f}{\partial t}\otimes X_b,$$

$$[f(t)\otimes X_b, X_a] = 0, \tag{36}$$

$$[f(t)\otimes X_b, X_V] = f(t)\otimes X_a.$$

According to the minimal prescription, we introduce a connection $\Gamma \equiv h\,dt$ to be added to the free Poincaré–Cartan form, and an extra component in $\partial/\partial h$ to the Galilei generators for nontrivial realization of the current algebra (36). Then the semi-invariance of

$$\Theta'_{PC} = p\,dx - \frac{p^2}{2m}dt + h\,dt \tag{37}$$

under the current algebra (36) fixes the new components in h, so that the complete expression of the Lie algebra of the *unextended* Galilei group with local (depending only on time) space and time translation subgroup becomes

$$f(t)\otimes X_b = f\frac{\partial}{\partial t} + \left(\frac{p^2}{2m} - h\right)\frac{df}{dt}\frac{\partial}{\partial h},$$

$$f(t)\otimes X_a = f\frac{\partial}{\partial x} - p\frac{df}{dt}\frac{\partial}{\partial h},$$

$$X_V = t\frac{\partial}{\partial x} + m\frac{\partial}{\partial p}, \tag{38}$$

$$f(t)\otimes X_h = f\frac{\partial}{\partial h},$$

where we have had to introduce the new local generator $f(t)\otimes X_h$ in order to close the current algebra. The new generator also leaves the form (37) semi-invariant. Strict invariance is now achieved by adding to generators X new components in $\partial/\partial\phi$ with coefficients equal to $-g$, g being such that $i_X d\Theta' = dg$. This results in

$$\begin{aligned}
\widetilde{f(t)\otimes X_b} &= f\frac{\partial}{\partial t} + \left(\frac{p^2}{2m} - h\right)\frac{df}{dt}\frac{\partial}{\partial h} - \frac{f}{\hbar}\left(\frac{p^2}{2m} - h\right)\frac{\partial}{\partial \phi},\\
\widetilde{f(t)\otimes X_a} &= f\frac{\partial}{\partial x} - p\frac{df}{dt}\frac{\partial}{\partial h} + \frac{1}{\hbar}fp\frac{\partial}{\partial \phi},\\
\tilde{X}_V &= t\frac{\partial}{\partial x} + m\frac{\partial}{\partial p} - \frac{m}{\hbar}\left(x - \frac{p}{m}t\right)\frac{\partial}{\partial \phi},\\
\widetilde{f(t)\otimes X_h} &= f\frac{\partial}{\partial h} - \frac{f}{\hbar}\frac{\partial}{\partial \phi}.
\end{aligned} \tag{39}$$

The reason for U(1)-extending after gauging is clear: both processes definitely do not commute. Proceeding the other way round leads, precisely, to the new results of Sec. V.

The Cartan-like equations associated with (37) lead directly to the Newtonian gravity equations if we identify h with the gravitational potential. This potential can be related to the component g_{00} of a metric in the Newtonian limit of general relativity via the expression $g_{00}\approx 1+h$.

IV. GROUP APPROACH TO THE QUANTIZATION OF A PARTICLE MOVING IN AN ELECTROMAGNETIC FIELD

In this and the next section, we shall adopt the GAQ formalism as a generalization of the geometrical approach to quantum mechanics, although we shall be interested, for now, primarily in the classical equations of motion. As mentioned above, we seek to reproduce any dynamical or kinematical quantity or variable out of a Lie group so that notation such as $t,\vec{x},\vec{p}$, etc. will refer to group variables (although directly identifiable with ''physical'' ones once the equations of motion are written).

Let us start by exponentiating the algebra (28)+(29), originally performed on a given movement space, in order to arrive at an abstract Lie group from which to obtain all physical structures. This algebra is infinite dimensional but, for real analytic functions f, the dynamical-variable content of it, in the sense of Sec. II D, is addressed by the (co-homological) structure of the finite-dimensional subalgebra generated by $\tilde{\mathcal{G}}$ along with those generators $f\otimes X_\phi$ with only linear functions, $t\otimes X_\phi$ and $x^i\otimes X_\phi$, to be called X_{A^0} and X_{A^i}, respectively. The rest of the functions contribute only to the characteristic (nondynamical) subalgebra and can be decoupled from the theory. Let us call $\tilde{G}_E$ this finite-dimensional group. It proves to be enough to describe the dynamics of a particle moving in an electromagnetic field if we resort to the trick (see below) of assuming an explicit dependence $A^\mu = A^\mu(\vec{x},t)$ once the one-form Θ will be found. [This procedure is suggested by the possibility of writing an analytic function in the form $f(\vec{x},t)=\phi + A_\mu(\vec{x},t)x^\mu$, where $\phi = f(\vec{0},0)$.] We shall not be involved here with the corresponding quantum field theory.

The group $\tilde{G}_E$ can be given the following group law which extends that of the Galilei group (with parameters $t,\vec{x},\vec{v}\equiv\vec{p}/m$ instead of $b,\vec{a},\vec{V}$, respectively) and agrees with the finite transformation (31) and (32):

$$t'' = t' + t,$$

$$\vec{x}'' = \vec{x}' + R'\vec{x} + \vec{v}'t,$$

$$\vec{v}''=\vec{v}'+R'\vec{v},$$

$$R''=R'R,$$

$$\vec{A}''=\vec{A}'+R'\vec{A}, \tag{40}$$

$$A_0''=A_0'+A_0+\vec{v}'\cdot R'\vec{A},$$

$$\zeta''=\zeta'\zeta e^{i\xi_m(g',g)}e^{i\xi_q(g',g)},$$

$$\xi_m(g',g)\equiv-\frac{m}{\hbar}\left[\vec{v}'\cdot R'\vec{x}+\frac{1}{2}t\vec{v}'^2\right],$$

$$\xi_q(g',g)\equiv-\frac{q}{\hbar}[\vec{A}'\cdot R'\vec{x}+t(\vec{v}'\cdot\vec{A}'-A_0')],$$

where $\xi_m(g',g)$ is a standard Bargmann-like cocycle associated with the Galilei (sub)group, in particular with the symplectic submanifold of coordinates (x^i,v_j), and $\xi_q(g',g)$ is a new cocycle, parametrized by the electric charge, as we shall see, associated with the symplectic submanifold of coordinates (x^i,A_j). Both satisfy the cocycle conditions

$$\xi(g',g)+\xi(g'*g,g'')=\xi(g',g*g'')+\xi(g,g''),$$

$$\xi(0,g)=\xi(g',0)=0$$

intended to maintain the structure of group law after the extension. Since both cocycles are associated with intersecting symplectic submanifold ($\vec{x}$ is in both) we should expect a mixed momentum variable conjugated to $\vec{x}$, to be identified with the minimally coupled momentum. This is the essence of minimal coupling in GAQ.

From (40) we derive left- and right-invariant vector fields and from the former the ζ-component of the left-invariant canonical one-form:

$$\tilde{X}_t^L=\frac{\partial}{\partial t}+\vec{v}\cdot\frac{\partial}{\partial\vec{x}}-\frac{1}{\hbar}\left[\frac{1}{2}m\vec{v}^2+q(\vec{v}\cdot\vec{A}-A_0)\right]\Xi,$$

$$\tilde{X}_{\vec{x}}^L=R\left(\frac{\partial}{\partial\vec{x}}-\frac{1}{\hbar}[m\vec{v}+q\vec{A}]\Xi\right),$$

$$\tilde{X}_{\vec{v}}^L=R\left(\frac{\partial}{\partial\vec{v}}\right),$$

$$\tilde{X}_{\vec{\epsilon}}^L=\sqrt{1-\frac{\vec{\epsilon}^2}{4}}\frac{\partial}{\partial\vec{\epsilon}}-\frac{1}{2}\vec{\epsilon}\wedge\frac{\partial}{\partial\vec{\epsilon}}, \tag{41}$$

$$\tilde{X}_{\vec{A}}^L=R\left(\frac{\partial}{\partial\vec{A}}+\vec{v}\frac{\partial}{\partial\vec{A}_0}\right),$$

$$\tilde{X}_{A_0}^L=\frac{\partial}{\partial A_0},$$

$$\tilde{X}^L_{\zeta}=i\left(\zeta\frac{\partial}{\partial\zeta}-\zeta^*\frac{\partial}{\partial\zeta^*}\right)\equiv\frac{\partial}{\partial\phi}\equiv\Xi,$$

$$\tilde{X}^R_t=\frac{\partial}{\partial t},$$

$$\tilde{X}^R_{\vec{x}}=\frac{\partial}{\partial\vec{x}},$$

$$\tilde{X}^R_{\vec{v}}=\frac{\partial}{\partial\vec{v}}+t\frac{\partial}{\partial\vec{x}},$$

$$\tilde{X}^R_{\vec{\epsilon}}=\sqrt{1-\frac{\vec{\epsilon}^2}{4}}\frac{\partial}{\partial\vec{\epsilon}}+\frac{1}{2}\vec{\epsilon}\wedge\frac{\partial}{\partial\vec{\epsilon}},\tag{42}$$

$$\tilde{X}^R_{\vec{A}}=\frac{\partial}{\partial\vec{A}}-q\vec{x}\Xi,$$

$$\tilde{X}^R_{A_0}=\frac{\partial}{\partial A_0}+qt\Xi,$$

$$\tilde{X}^R_{\zeta}=i\left(\zeta\frac{\partial}{\partial\zeta}-\zeta^*\frac{\partial}{\partial\zeta^*}\right)\equiv\frac{\partial}{\partial\phi}\equiv\Xi,$$

$$\Theta\equiv\hbar\,\theta^{(\zeta)L}=m\vec{v}\cdot d\vec{x}-\frac{1}{2}m\vec{v}^2dt+q\vec{A}\cdot d\vec{x}-qA_0dt+\hbar\frac{d\zeta}{i\zeta}.\tag{43}$$

The commutation relations of (let us say) left generators (omitting rotations, which operate in the standard way) are

$$[\tilde{X}^L_t,\tilde{X}^L_{x^i}]=0,\quad[\tilde{X}^L_t,\tilde{X}^L_{v^i}]=-\tilde{X}^L_{x^i},\quad[\tilde{X}^L_{x^i},\tilde{X}^L_{v^j}]=\frac{m}{\hbar}\delta_{ij}\Xi,$$

$$[\tilde{X}^L_t,\tilde{X}^L_{Ai}]=0,\quad[\tilde{X}^L_t,\tilde{X}^L_{A0}]=-\frac{q}{\hbar}\Xi,\quad[\tilde{X}^L_{x^i},\tilde{X}^L_{Aj}]=\frac{q}{\hbar}\delta_{ij}\Xi,\tag{44}$$

$$[\tilde{X}^L_{x^i},\tilde{X}^L_{A^0}]=0,\quad[\tilde{X}^L_{v^i},\tilde{X}^L_{Aj}]=\delta_{ij}\tilde{X}^L_{A^0},\quad[\tilde{X}^L_{v^i},\tilde{X}^L_{A^0}]=0.$$

If we compute the characteristic module of Θ, i.e., $\mathrm{Ker}d\Theta\cap\mathrm{Ker}\Theta$ for $q=0$, as corresponding to the free particle, we find that it is generated by a left subalgebra

$$\mathcal{G}_\Theta|_{q=0}=\langle\tilde{X}^L_t,\tilde{X}^L_{\vec{\epsilon}},\tilde{X}^L_{\vec{A}},\tilde{X}^L_{A_0}\rangle,\tag{45}$$

leading to the trajectories (12) and (23) for the dynamical (symplectic) variables $\vec{x}$ and $\vec{p}$, and additional ones for the kinematical (nonsymplectic) variables $\vec{\epsilon},\vec{A},A_0$ which decouple from the theory. The quotient of $\tilde{G}_E/\mathrm{U}(1)$ by the generalized equations of motion is a symplectic manifold (the solution manifold) of dimension $3+3$. However, for nonzero q, we have

$$\mathcal{G}_\Theta=\left\langle\tilde{X}^L_{\vec{\epsilon}},\ \tilde{X}^L_{\vec{A}}-\frac{q}{m}\tilde{X}^L_{\vec{v}}\right\rangle,\tag{46}$$

leading to a symplectic manifold of dimension 4+4. We should note that no time evolution appears as an equation of motion. This is because the electromagnetic cocycle lends dynamical character to t as conjugate to A_0. The only characteristic vector field, apart from $\tilde{X}^L_{\vec{\epsilon}}$, which again simply decouples the variables $\vec{\epsilon}$, is the one defining the minimal coupling. In fact, the Noether invariants $i_{\tilde{X}}\Theta$ are

$$i_{\tilde{X}^R_t}\Theta = -\left(\tfrac{1}{2}m\vec{v}^2 + qA_0\right),$$

$$i_{\tilde{X}^R_{\vec{x}}}\Theta = m\vec{v} + q\vec{A} \equiv \vec{P},$$

$$i_{\tilde{X}^R_{\vec{v}}}\Theta = -m(\vec{x} - \vec{v}t) + q\vec{A}t,$$

$$i_{\tilde{X}^R_{\vec{A}}}\Theta = -q\vec{x},$$

$$i_{\tilde{X}^R_{A_0}}\Theta = qt,$$

reproducing, in particular the "canonical momentun" $\vec{P} \equiv m\vec{v} + q\vec{A}$.

Real dynamics appear when we impose the "constraint" $A_{0,i} = A_{0,i}(\vec{x},t)$ on Θ, whose characteristic module turns out now to be generated by $\check{X}$ in (34), thus reproducing the standard equations of motion. The trick of introducing this constraint after the form Θ associated with $\tilde{G}_E$ has been computed can in fact be justified in mathematical terms, although at the price of introducing an explicit infinite parametrization of the field A_μ by means of, for instance, Fourier coefficients $a_\mu(\vec{k})$, $a^*_\nu(\vec{k})$, and, very importantly, an extra space–time translation group associated with this field, let us say χ_μ. That is, the general space–time position on which the field lies conceptually differs from the space–time position of the particle. Under these conditions a cocycle of this infinite-dimensional group can be introduced, contributing the form Θ with the term $q\vec{A}(\vec{x},t) \cdot d\vec{x} - qA_0(\vec{x},t)dt$ where

$$A_\mu(\vec{x},t) = \int \frac{d^3\vec{k}}{2k^o}\{a_\mu(\vec{k})e^{-ik\cdot x} + a^*_\mu(\vec{k})e^{ik\cdot x}\}, \tag{47}$$

that is, the electromagnetic field evaluated on the trajectories of the particle. Now, the above-mentioned constraint proves to be as natural as stating that, on a trajectory, the particle sees the field A_μ evaluated on x_μ rather than on χ_μ. This precise construction, along with the (also infinite-dimensional) cocycle providing dynamical content to the field variables $a_\mu(\vec{k})$, $a^*_\nu(\vec{k})$ themselves, deserves a separate work, which is in progress.

We should say to conclude this section that this study can be repeated with the centrally extended Poincaré group $\tilde{P}$[10,11] (see also Refs. 13 and 14) by promoting to *local* the U(1) transformations and considering the finite-dimensional subgroup $\tilde{P}_E$ analogous to $\tilde{G}_E$.

V. MIXING THE ELECTROMAGNETIC AND GRAVITATIONAL FORCES

Let us now consider the gravitational interaction from our group-theoretical viewpoint (we shall omit $\hbar$ in this section). To this end, we start directly with the centrally extended Poincaré group $\tilde{P}$ and see how the fact that the translation generators produce the central term under commutation with some other generators (boosts) plays a singular role in the relationship between local space–time translations and local U(1) transformations. Symbolically denoting the generators of translations by P, P_0, those of boosts by K and the central one by Ξ, we find

$$[K, f\otimes P] \simeq (L_K f)\otimes P + f\otimes(P_0 + \Xi). \tag{48}$$

This means that turning the translations into *local* symmetry also entails the *local* nature of the U(1) phase. We thus expect a nontrivial mixing of gravity and electromagnetism into an infinite-dimensional electro-gravitational group.

We shall follow steps identical to those given in the former example. In turning the parameters of space–time translations *local*, we replace x^μ with $x^\mu + h^\mu_\nu(\vec{x},x^0)x^\nu$, write a finite-dimensional algebra $\mathcal{P}_{EG}$ keeping only the linear part of local space–time translations ($x^\mu + h^\mu_\nu x^\nu$, with constant $h_{\mu\nu}$), the generators of which will be called $X_{h^{\mu\nu}}$, apply the GAQ formalism and impose the "constraint" $h^{\mu\nu}=h^{\mu\nu}(\vec{x},x^0)$, on the symplectic submanifolds (solution manifolds). However, the co-homological structure of this finite-dimensional electro-gravitational subgroup, $\tilde{P}_{EG}$, is richer than that of $\tilde{P}_E$ and the exponentiation of the Lie algebra $\tilde{\mathcal{P}}_{EG}$ is by far more involved. As mentioned in the Introduction, we attempt only a basic description of the new phenomenology which results from the present revisited gauge principle, although we seek, apart from the exact Lorentz force, an approximate expression for the geodesic force in terms of the metric $g^{\mu\nu} \equiv \eta^{\mu\nu}+h^{\mu\nu}$. Thus, we shall resort only to what seems to be the basic co-homological (fundamental) constants corresponding to the inertial mass m, the electric charge q, the gravitational mass g and the *mixing vertex* coupling constant κ.

Let us write the algebra $\tilde{\mathcal{P}}_{EG}$ in an almost covariant way (the central extensions and induced deformations are necessarily non-covariant). To this end, we parametrize the Lorentz transformations with $\epsilon^{\mu\nu}$ as usual. The proposed explicit algebra is

$$
\begin{aligned}
&[\tilde{X}^L_{x^\mu},\tilde{X}^L_{\epsilon^{\nu\rho}}] = -\eta_{\nu\mu}\tilde{X}^L_{x^\rho}+\eta_{\rho\mu}\tilde{X}^L_{x^\nu}-(m+\kappa q)c(\eta_{\rho\mu}\delta^0_\nu-\eta_{\nu\mu}\delta^0_\rho)\Xi,\\
&[\tilde{X}^L_{x^\mu},\tilde{X}^L_{h^{\nu\rho}}] = -\eta_{\nu\mu}\tilde{X}^L_{x^\rho}-\eta_{\rho\mu}\tilde{X}^L_{x^\nu}+[2(g-mc)\eta_{0\mu}\delta^0_\nu\delta^0_\rho+mc(\eta_{\rho\mu}\delta^0_\nu+\eta_{\nu\mu}\delta^0_\rho)]\Xi,\\
&[\tilde{X}^L_{x^\mu},\tilde{X}^L_{A^\nu}] = -q\,\eta_{\nu\mu}\Xi,\\
&[\tilde{X}^L_{\epsilon^{\mu\nu}},\tilde{X}^L_{\epsilon^{\alpha\beta}}] = -\eta_{\alpha\nu}\tilde{X}^L_{\epsilon^{\mu\beta}}+\eta_{\beta\nu}\tilde{X}^L_{\epsilon^{\mu\alpha}}+\eta_{\alpha\mu}\tilde{X}^L_{\epsilon^{\nu\beta}}-\eta_{\mu\beta}\tilde{X}^L_{\epsilon^{\nu\alpha}},\\
&[\tilde{X}^L_{\epsilon^{\mu\nu}},\tilde{X}^l_{h^{\alpha\beta}}] = -\eta_{\alpha\nu}\tilde{X}^L_{h^{\mu\beta}}-\eta_{\beta\nu}\tilde{X}^L_{h^{\mu\alpha}}+\eta_{\alpha\mu}\tilde{X}^L_{h^{\nu\beta}}+\eta_{\mu\beta}\tilde{X}^L_{h^{\nu\alpha}}+\frac{1}{q}\{\kappa qc(\eta_{\alpha\nu}\delta^\rho_\beta\delta^0_\mu-\eta_{\mu\alpha}\delta^\rho_\beta\delta^0_\nu\\
&\quad+\eta_{\nu\beta}\delta^\rho_\alpha\delta^0_\mu-\eta_{\mu\beta}\delta^\rho_\alpha\delta^0_\nu)-2(g-mc)[(\eta_{\alpha\nu}\delta^\rho_\beta\delta^0_\mu-\eta_{\mu\alpha}\delta^\rho_\beta\delta^0_\nu+\eta_{\nu\beta}\delta^\rho_\alpha\delta^0_\mu\\
&\quad-\eta_{\mu\beta}\delta^\rho_\alpha\delta^0_\nu)\delta^\rho_0+\delta^0_\alpha\delta^0_\beta(\eta_{0\nu}\delta^0_\mu-\eta_{0\mu}\delta^\rho_\nu)]\}\tilde{X}^L_{A^\rho},\\
&[\tilde{X}^L_{\epsilon^{\mu\nu}},\tilde{X}^L_{A^\rho}] = -\eta_{\rho\nu}\tilde{X}^L_{A^\mu}+\eta_{\rho\mu}\tilde{X}^L_{A^\nu},\\
&[\tilde{X}^L_{h^{\mu\nu}},\tilde{X}^L_{h^{\alpha\beta}}] = -\eta_{\alpha\nu}\tilde{X}^L_{\epsilon^{\mu\beta}}-\eta_{\beta\nu}\tilde{X}^L_{\epsilon^{\mu\alpha}}-\eta_{\alpha\mu}\tilde{X}^L_{\epsilon^{\nu\beta}}-\eta_{\mu\beta}\tilde{X}^L_{\epsilon^{\nu\alpha}}\\
&\quad+\frac{1}{q}\{-\kappa qc[\eta_{\alpha\nu}\delta^{0\rho}_{\beta\mu}+\eta_{\beta\nu}\delta^{0\rho}_{\alpha\mu}+\eta_{\alpha\mu}\delta^{0\rho}_{\beta\nu}+\eta_{\beta\mu}\delta^{0\rho}_{\alpha\nu}]\\
&\quad+2(g-mc)[\delta^0_\alpha\delta^0_\beta(\eta_{0\nu}\delta^\rho_\mu+\eta_{0\beta}\delta^\rho_\nu)-\delta^0_\mu\delta^0_\nu(\eta_{0\beta}\delta^\rho_\beta+\eta_{0\alpha}\delta^\rho_\beta)]\}\tilde{X}^L_{A^\rho},\\
&[\tilde{X}^L_{h^{\mu\nu}},\tilde{X}^L_{A^\rho}] = -\eta_{\rho\nu}\tilde{X}^L_{A^\mu}-\eta_{\rho\mu}\tilde{X}^L_{A^\nu},
\end{aligned}
\tag{49}
$$

where $\delta^{0\rho}_{\beta\mu}\equiv\delta^0_\beta\delta^\rho_\mu-\delta^0_\mu\delta^\rho_\beta$ is the Kronecker tensor.

It bears mentioning that one of the central extension parameters, actually g, is really free at the Lie algebra level but must acquire the value $g=mc$ if the present theory is intended to reproduce the standard disconnected electromagnetic and gravitational forces for $\kappa=0$, i.e., when the constant responsible for the mixing of both interactions is switched off. The appearance of

relationships between two co-homology constants, such as $g=mc$, indicates the compatibility of further extensions of the algebra $\mathcal{P}_{EG}$ with the constants already introduced. Such further extensions could generalize the present results.

This algebra must be exponentiated in order to have a group law from which to compute left- and right-invariant vector field and the quantization one-form Θ, just as in the pure electromagnetic example. As stated above, such a process is much more involved and, in principle, a ''perturbative'' algorithm is in order. We shall resort to an approximation formula[34] up to a given order (order 3 in the fully relativistic case and 4 in the nonrelativistic limit given in Ref. 14, although in the latter the expressions obtained prove to be exact already at this order), inspired in the theory of formal groups,[35] which generalizes that of Campbell–Hausdorff in the sense that it allows for expressions which more directly fit actual physical formulas (although the latter is as well valid). In fact, it has been used in a parallel calculation carried out with REDUCE. Here is the approximate group law:

$$x''^{\alpha}=x^{\alpha}+x'^{\alpha}+\eta_{\mu[\nu}\delta_{\rho]}{}^{\alpha}\epsilon'^{\nu\rho}x^{\mu}+\eta_{\mu(\nu}\delta_{\rho)}{}^{\alpha}h'^{\nu\rho}x^{\mu}+\cdots,$$

$$\epsilon''^{\omega\rho}=\epsilon^{\omega\rho}+\epsilon'^{\omega\rho}-\tfrac{1}{4}\eta_{[\alpha[\nu}\delta_{\mu]}{}^{[\omega}\delta^{\rho]}{}_{\beta]}\epsilon'^{\mu\nu}\epsilon^{\alpha\beta}-\tfrac{1}{4}\eta_{(\alpha(\nu}\delta_{\mu)}{}^{[\omega}\delta^{\rho]}{}_{\beta)}h'^{\mu\nu}h^{\alpha\beta}+\cdots,$$

$$h''^{\omega\rho}=h^{\omega\rho}+h'^{\omega\rho}-\tfrac{1}{2}\eta_{(\alpha[\nu}\delta_{\mu]}{}^{(\omega}\delta^{\rho)}{}_{\beta)}\epsilon'^{\mu\nu}h^{\alpha\beta}+\cdots, \tag{50}$$

$$\begin{aligned}A''^{\rho}=&A^{\rho}+A'^{\rho}+(\kappa c\,\eta_{(\alpha[\nu}\delta_{\mu]}{}^{0}\delta_{\beta)}{}^{\rho})\epsilon'^{\mu\nu}h^{\alpha\beta}+\eta_{\rho[\mu}\delta_{\nu]}{}^{\alpha}\epsilon'^{\mu\nu}A^{\rho}\\&+\tfrac{1}{2}(\kappa c\,\eta_{(\alpha(\nu}\delta_{\mu)}{}^{[0}\delta^{\rho]}{}_{\beta)})h'^{\mu\nu}h^{\alpha\beta}-\eta_{\rho(\mu}\delta_{\nu)}{}^{\alpha}h'^{\mu\nu}A^{\rho}+\cdots,\end{aligned}$$

$$\begin{aligned}\varphi''=&\varphi'+\varphi-(m+\kappa q)c\,\eta_{\mu[\nu}\delta_{\rho]}{}^{0}\epsilon'^{\mu\nu}x^{\rho}-mc\,\eta_{\mu(\nu}\delta_{\rho)}{}^{0}h'^{\nu\rho}x^{\mu}+q\,\eta_{\nu\mu}A'^{\nu}x^{\mu}\\&+\tfrac{1}{2}\{(-\tfrac{1}{4}(m+\kappa q)c\,\eta_{\rho[\sigma}\delta_{\gamma]}{}^{0}\eta_{\alpha[\nu}\delta_{\mu]}{}^{[\sigma}\delta^{\gamma]}{}_{\beta]}-(m+\kappa q)c\,\eta_{\sigma[\mu}\delta_{\nu]}{}^{0}\eta_{\rho[\alpha}\delta_{\beta]}{}^{\sigma}))\epsilon'^{\mu\nu}\epsilon'^{\alpha\beta}x^{\rho}\\&-mc\,\eta_{\sigma(\mu}\delta_{\nu)}{}^{\sigma}\eta_{\rho[\alpha}\delta_{\beta]}{}^{\sigma}h'^{\mu\nu}\epsilon'^{\alpha\beta}x^{\rho}+q\,\eta_{\sigma\mu}\eta_{\rho[\alpha}\delta_{\beta]}{}^{\sigma}A'^{\mu}\epsilon'^{\alpha\beta}x^{\rho}\\&+[-\tfrac{1}{4}(m+\kappa q)c\,\eta_{\rho[\sigma}\delta_{\gamma]}{}^{0}\eta_{\alpha(\nu}\delta_{\mu)}{}^{[\sigma}\delta^{\gamma]}{}_{\beta)}-\tfrac{1}{2}\eta_{\rho\sigma}(-\kappa qc\,\eta_{(\alpha(\nu}\delta_{\mu)}{}^{[0}\delta^{\sigma]}{}_{\beta)})]h'^{\mu\nu}h'^{\alpha\beta}x^{\rho}\\&+q\,\eta_{\sigma\mu}\eta_{\rho(\alpha}\delta_{\beta)}{}^{\sigma}A'^{\mu}h'^{\alpha\beta}x^{\rho}\}+\cdots.\end{aligned}$$

From this law we can proceed following identical steps as in the pure electromagnetic case and derive the approximate quantization form Θ, approximate Noether invariants, Poincaré–Cartan form, Lagrangian, etc. Let us write explicitly Θ,

$$\begin{aligned}\Theta=d\varphi+\Big\{&(m+\kappa q)c\,\eta_{\rho[\alpha}\delta_{\beta]}{}^{0}\epsilon^{\alpha\beta}+mc\,\eta_{\rho(\alpha}\delta_{\beta)}{}^{0}h^{\alpha\beta}-q\,\eta_{\alpha\rho}A^{\alpha}\\&+\frac{1}{4}(m+\kappa q)c(\eta_{\sigma[\mu}\delta_{\nu]}{}^{0}\eta_{\rho[\beta}\delta_{\alpha]}{}^{\sigma}+\eta_{\sigma[\alpha}\delta_{\beta]}{}^{0}\eta_{\rho[\nu}\delta_{\mu]}{}^{\sigma})\epsilon^{\mu\nu}\epsilon^{\alpha\beta}-\frac{1}{4}mc(\eta_{\sigma(\mu}\delta_{\nu)}{}^{0}\eta_{\rho(\beta}\delta_{\alpha)}{}^{\sigma}\\&+\eta_{\sigma(\alpha}\delta_{\beta)}{}^{0}\eta_{\rho(\nu}\delta_{\mu)}{}^{\sigma})h^{\mu\nu}h^{\alpha\beta}+\frac{1}{2}[2(m+\kappa q)c\,\eta_{\rho(\mu}\eta_{\nu)[\alpha}\delta_{\beta]}{}^{0}+mc\,\eta_{\rho[\alpha}\eta_{\beta](\mu}\delta_{\nu)}{}^{0}]\\&+\frac{q}{2}\eta_{\nu\rho}\eta_{\omega[\alpha}\delta_{\beta]}{}^{\nu}\epsilon^{\alpha\beta}A^{\omega}-\frac{q}{2}\eta_{\nu\rho}\eta_{\omega(\alpha}\delta_{\beta)}{}^{\nu}h^{\alpha\beta}A^{\omega}\Big\}dx^{\rho}+\cdots,\end{aligned}$$

and, before writing $d\Theta$, perform a change of variables in order to take this presymplectic two-form to almost ''canonical'' (or standard) form:[36]

$$A^{\alpha}\rightarrow A^{\alpha}+\eta_{\sigma\gamma}(\epsilon^{\alpha\sigma}+h^{\alpha\sigma})A^{\gamma}\cdots,$$

$$\begin{aligned}(m+\kappa q)c\,\epsilon^{0i}\rightarrow{}&(m+\kappa q)c\,\epsilon^{0i}+\Sigma_j\{\tfrac{1}{2}(m+\kappa q)c(\epsilon^{ij}-\epsilon^{ji})\epsilon^{0j}+g\,\delta_{ij}h^{00}\epsilon^{0j}-2(m+\kappa q)ch^{ij}\epsilon^{0j}\\&+\cdots\},\\ h^{0j}\rightarrow{}&h^{0j}+\Sigma_i\,\tfrac{1}{2}(\epsilon^{ij}-\epsilon^{ji})h^{0i},\\ h^{00}\rightarrow{}&h^{00}-\tfrac{1}{4}\delta_{ij}h^{0i}\epsilon^{0j}.\end{aligned}\tag{51}$$

After this change $d\Theta$ acquires the expression

$$\begin{aligned}d\Theta={}&d\,\epsilon^{0i}\wedge dx^0(-(m+\kappa q)c(\epsilon^{0i}+h^{0i}))+(m+\kappa q)c\,d\,\epsilon^{0i}\wedge dx^i+d\,h^{00}\wedge dx^0 2mc(1-2\,h^{00})\\&+d\,h^{0i}\wedge dx^0(mch^{0i}-(m+\kappa q)c\,\epsilon^{0i})+d\,h^{00}\wedge dx^i mch^{0i}+d\,h^{0j}\wedge dx^i mc((-1+h^{00})\\&\times\delta_{ij}-h^{ji})-mc\,d\,h^{ij}\wedge dx^i h^{0j}-qdA^0\wedge dx^0+qdA^i\wedge dx^i+\cdots.\end{aligned}$$

The equations of motion can now be obtained à la Cartan by finding the kernel of this Poincaré–Cartan-like form. Then, we have

$$\begin{aligned}(m+\kappa q)c\frac{d^2\vec{x}}{dt^2}={}&q\left[\frac{d\vec{x}}{dt}\wedge\vec{\nabla}\wedge\vec{A}-\partial_0\vec{A}-\vec{\nabla}A^0\right]\\&+mc\Bigg[\partial_0\vec{h}+\vec{\nabla}h^{00}-\frac{d\vec{x}}{dt}\wedge\vec{\nabla}\wedge\vec{h}\\&+\frac{1}{4}\Bigg\{-\partial_0(h^{00}\vec{h})+\frac{d\vec{x}}{dt}\wedge\vec{\nabla}\wedge(h^{00}\vec{h})+\partial_0(\vec{\vec{h}}\cdot\vec{h})-\frac{d\vec{x}}{dt}\wedge\vec{\nabla}\wedge(\vec{\vec{h}}\cdot\vec{h})\\&-2\vec{\nabla}(h^{00^2})+\vec{\nabla}(\vec{h}\cdot\vec{h})\Bigg\}+\cdots\Bigg]\\&+\frac{\kappa qc}{2}\left[\frac{1}{4}\vec{\nabla}(\vec{h}\cdot\vec{h})+\partial_0\vec{h}-\frac{d\vec{x}}{dt}\wedge\vec{\nabla}\wedge\vec{h}+\cdots\right].\end{aligned}\tag{52}$$

The first line in (52) corresponds to the standard (exact) motion of a particle in the presence of an electromagnetic field, except for the value of the inertial mass, which is corrected by κq. The second one reproduces the standard gravito-electromagnetic force,[37] i.e., the approximation in which the gravitational field looks like an electromagnetic one. The third and fourth are the first nonlinear corrections to gravity. The fifth, however, is quite new and represents a force that looks also like the Lorentz force, at the present approximation, but generated by the gravitational potentials, although proportional to q; it should not be confused with the above-mentioned gravito-electromagnetic one. As far as the magnitude of the new Lie algebra co-homology constant κ is concerned, it is limited by experimental clearance for the difference between particle and anti-particle mass, which for the electron is about $10^{-8}m_e$. Even though this is a small value, extremely dense rotating bodies could be able to produce measurable forces. Conversely, a mixing of electromagnetism and gravity predicts a mass difference between charged particles and anti-particles, which could be experimentally tested, by measuring, for instance, the Rydberg constant

$$\left(\sim\frac{M_{\text{antiproton}}\times M_{\text{positron}}}{M_{\text{antiproton}}+M_{\text{positron}}}\right)$$

through the Lamb shift in anti-hydrogen.[38,39]

Let us remark the above-mentioned fact that one of the allowed Lie-algebra co-homology extension parameters, that is g, has been fixed to the particular value $g=mc$ in order to recover

the standard theory for $\kappa=0$. We might say that this requirement, along with another condition of ''analyticity in q'' in the group law, constitutes a group-theoretical setting of the (weak) *equivalence principle*.

Since the present theory has been formulated on the basis of our group approach to quantization, the quantum version of it would proceed in a rather straightforward manner. We shall not insist any more on this particle mechanical study while waiting for a wide generalization allowing for field degrees of freedom. In fact, a natural yet highly nonelementary attempt at an extension of the present theory to quantum field theory is in progress.[15] A further generalization of the present work in which the U(1) subgroup of phase invariance is considered as a Cartan subgroup of a larger internal symmetry group is also in order. Notice that including the phase invariance in, for instance $\mathrm{SU}(2)\otimes\mathrm{U}(1)$, would result in additional phenomenology such as the production of Z_0 particles out of gravity.

ACKNOWLEDGMENT

This work was partially supported by the DGICYT. We desire to thank G. Gibbons for pointing out a relevant misprint in the statement of the ''no-go theorems'' in a preliminary version of this paper. We also thank C. Barceló for valuable comments on the Equivalence Principle and S. Vinitsky for exciting comments on the experimental test for the new constant.

[36] This change might have been made in the group law by choosing a more appropriate Campbell–Hausdorff-like formula but that choice is by no means a trivial task. We must stress on the fact that the quantum theory according to GAQ is free of these requirements as we associate quantum operators directly with group generators and the final output, i.e., the quantum representation is fully independent of any choice of coordinates in the group manifold. Even more, the classical theory can also be formulated in a fully invariant manner by using the Noether invariants as coordinates, but in this way the classical evolution is apparently hidden.

In this paper, we consider the supercritical complex Ginzburg–Landau equation. We discuss the existence of suitable weak solution in Ω, where Ω is a bounded domain in $\mathbb{R}^n$ or the whole space. We also discuss the properties of the set of the singular points of the suitable weak solution in $\mathbb{R}^n$, which means that the possible singular points are located in a bounded ball for any given time and there is no singular point on the whole space after limited time. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1618360]

I. INTRODUCTION AND RESULTS

In this paper we consider the following supercritical complex Ginzburg–Landau (CGL) equations:

$$\begin{aligned} &u_t=(1+i\mu)\Delta u-(1+i\nu)|u|^{2\sigma}u+Ru \quad \text{in } \Omega\times[0,T),\\ &u(x,0)=u_0(x), \quad x\in\Omega,\\ &u(x,t)=0, \quad x\in\partial\Omega, \quad 0<t<T, \end{aligned} \tag{1}$$

where $u(x,t)$ is a complex-valued field, the initial data $u_0\in L^2$, $R>0$, $\mu,\nu\in\mathbb{R}$ and $2/n<\sigma<(n+4)/2n$, Ω is a bounded domain in $\mathbb{R}^n$ or the whole space. When $\Omega=\mathbb{R}^n$, the third line of (1) should be replaced by $u(x,t)\to 0$ as $|x|\to\infty$ for $0<t<T$. This equation, most often considered with a cubic nonlinearity and $n=3$, has a long history in physics as a generic amplitude equation near the onset of instabilities in fluid mechanical systems, as well as in the theory of phase transitions and superconductivity. In this paper, we concentrate on mathematical questions related to the regularity of weak solutions. In the case $\sigma=1$, solutions of (1) have similar scaling properties as solutions of the Navier–Stokes equations. It might be a good model problem in connection with regularity questions regarding the Navier–Stokes equations.

For Eq. (1) in the periodic case, the existence of weak solutions in all cases was obtained in Ref. 1. It is pointed out in Ref. 1 that in the subcritical case ($\sigma n<2$), all weak solutions are regular. When $\sigma n=2$, it is known that singularities cannot develop from sufficiently regular initial data (see Ref. 2 for case $\sigma=2$, $n=2$ and Ref. 1 for the general case). When $\sigma n>2$, regularity results are available only for special values of μ and ν (see Ref. 1).

For Eq. (1), the existence of a weak solution can be obtained by the Galerkin approximation. The full regularity for weak solutions of (1) in the subcritical and critical cases can be obtained by

[a)]Electronic mail: lxfn2@263.net
[b)]Electronic mail: mjhy@zju.edu.cn

the usual bootstrap argument and a refined version of the standard bootstrap argument, respectively. In the supercritical case ($\sigma n>2$) it is not known whether weak solutions are regular for general values of μ and ν.

In Ref. 3, the following version of CGL was considered:

$$u_t=(1+i\mu)\Delta u-i\nu|u|^{2\sigma}u+Ru \quad \text{in } \Omega\times[0,T),$$

$$u(x,0)=u_0(x), \quad x\in\Omega, \tag{2}$$

$$u(x,t)=0, \quad x\in\partial\Omega, \quad 0<t<T.$$

The partial regularity of the suitable weak solution was discussed and the existence of the suitable weak solution was mentioned but without proof in Ref. 3. In this paper we prove the existence of the suitable weak solution of (1). Actually, it also works for (2). For more details on (1) and (2), see Refs. 3, 1, and 2.

Now we give some notations. Let $D=\Omega\times(0,T)$, B_r be the ball in $\mathbb{R}^n$ with radius r, $Q_r=Q_r(x,t)=\{(y,s):|y-x|\leqslant r, t-r^2\leqslant s<t\}$. Let $E_0(u)=\sup_{0<t<T}1/2\int_\Omega|u|^2\mathrm{d}x$, $E_1(u)=\int_0^T\int_\Omega|\nabla u|^2\mathrm{d}x\,\mathrm{d}t$, and $E=E_0+E_1$. Let $H^1(\Omega)=\{u\in L^2(\Omega):\nabla u\in L^2(\Omega)\}$ and $H_0^1(\Omega)$ be the completion of $C_0^\infty(\Omega)$ in $H^1(\Omega)$ and $H^{-1}(\Omega)$ be the dual of $H_0^1(\Omega)$. We omit Ω if there is no confusion.

The definition of suitable weak solution is the following.

Definition 1.1: We say u is a suitable weak solution of (1) on D, if the following conditions are satisfied:

(i) $u\in L^\infty(0,T;L^2(\Omega))\cap L^2(0,T;H^1(\Omega))$.
(ii) u satisfies (1) in the sense of distributions on D.
(iii) (Generalized energy inequality) For each real-valued $\phi\in C_0^\infty(D)$ with $\phi\geqslant 0$, the following inequality holds:

$$2\int\int|\nabla u|^2\phi\,\mathrm{d}x\,\mathrm{d}t+\int\int|u|^{2\sigma+2}\phi\,\mathrm{d}x\,\mathrm{d}t$$
$$\leqslant\int\int|u|^2(\phi'+2\Delta\phi)\mathrm{d}x\,\mathrm{d}t+2\Re\left\{(1+i\mu)\int\int u\nabla\bar{u}\nabla\phi\,\mathrm{d}x\,\mathrm{d}t\right\}+2R\int\int|u|^2\phi\,\mathrm{d}x\,\mathrm{d}t. \tag{3}$$

We have the following existence result.

Theorem 1.1: *Let $u_0\in L^2(\Omega)$. Then there exists a weak solution u of (1) on D satisfying*

$$u\in L^2(0,T;H_0^1)\cap L^\infty(0,T;L^2), \tag{4}$$

$$u(t)\to u_0 \ \text{ weakly in } L^2 \text{ as } t\to 0, \tag{5}$$

and if $\phi\in C^\infty(\overline{D})$, $\phi\geqslant 0$, and $\phi=0$ near $\partial\Omega\times(0,T)$, then for $0<t<T$,

$$\int_{\Omega\times\{t\}}|u|^2\phi+2\int_0^t\int_\Omega|\nabla u|^2\phi+\int_0^t\int_\Omega|u|^{2\sigma+2}\phi$$
$$\leqslant\int_\Omega|u_0|^2\phi(x,0)+\int_0^t\int_\Omega|u|^2(\phi'+2\Delta\phi)+2\Re\left\{(1+i\mu)\int_0^t\int_\Omega u\nabla\bar{u}\nabla\phi\right\}+2R\int_0^t\int_\Omega|u|^2\phi. \tag{6}$$

By the motivation of Ref. 4, we consider the property of the set of singular points of the suitable weak solution with more assumptions on the initial data. We consider (2) for simplicity and have the following theorem.

Theorem 1.2: *Suppose* $u_0 \in L^2(\mathbb{R}^n)$, *and*

$$\frac{1}{2}\int_{\mathbb{R}^n}|u_0|^2|x|\mathrm{d}x = G < \infty. \tag{7}$$

Then there exists a weak solution of the initial value problem of (2) which is regular in the region $\{(x,t):|x|^2 t^{n-2/\sigma} > K_1\}$, *where* $K_1 = K_1(E,G)$ *is a constant depending on* E *and* G.

Remark 1.1: The above theorem means that the set of singular points is restricted in a bounded domain for every time. Actually, there is no singular point in $\mathbb{R}^n$ *after a limited time, see Lemma 3.1.*

The following interpolation inequality is useful in our following proofs.

Lemma 1.1: If $u \in H^1(B_r)$, *then*

$$\int_{B_r}|u|^q \mathrm{d}x \leqslant C\left(\int_{B_r}|\nabla u|^2 \mathrm{d}x\right)^a \left(\int_{B_r}|u|^2\right)^{(q/2)-a} + \frac{C}{r^{2a}}\left(\int_{B_r}|u|^2\right)^{q/2}, \tag{8}$$

where $a = (n/4)(q-2)$, $2 \leqslant q \leqslant 2n/(n-2)$, C *independent of* r. *Moreover, if* u *has mean zero on* B_r *or if* B_r *is replaced by all of* $\mathbb{R}^n$, *then the second term on the right-hand side in (8) may be omitted.*

In the remainder of this paper we prove these two theorems, respectively.

II. PROOF OF THE THEOREM 1.1

We begin with some lemmas concerning the relevant linear systems.

Lemma 2.1: Suppose $f \in L^2(0,T;H^{-1})$, $u \in L^2(0,T;H_0^1)$, *and*

$$u_t = (1+i\mu)\Delta u + f \tag{9}$$

in the sense of distributions on D. *Then* $u_t \in L^2(0,T;H^{-1})$,

$$\frac{\mathrm{d}}{\mathrm{d}t}\int_\Omega |u|^2 \mathrm{d}x = 2\Re\int_\Omega u_t \overline{u}\,\mathrm{d}x \tag{10}$$

in the sense of distributions on $(0,T)$, *and* $u \in C([0,T];L^2)$ *after modification on a set of measure zero. Solution of (9) is unique in* $L^2(0,T;H_0^1)$ *for given initial data* $u_0 \in L^2$.

Proof: The proof is standard, see Refs. 4 and 5.

Lemma 2.2: Let $u_0 \in L^2$ *and* $w \in C^\infty(\overline{D};\mathbb{R})$ *with* $w \geqslant 0$. *Then there exists unique function* $u \in C([0,T];L^2) \cap L^2(0,T;H_0^1)$ *such that*

$$u_t = (1+i\mu)\Delta u - (1+i\nu)wu + Ru \tag{11}$$

in the sense of distributions on D *and* $u(0) = u_0$.

Proof: The proof is similar to Ref. 4, and for the proof of uniqueness of solution we need the Grownwall inequality.

Lemma 2.3: Let $u_0 \in L^2$, $w \in C^\infty(\overline{D};\mathbb{R})$ *with* $w \geqslant 0$ *and* u *be a solution of (11). Then for any* $\phi \in C_0^\infty(\overline{D})$ *with* $\phi = 0$ *near* $\partial\Omega \times (0,T)$, *for all* $t \in (0,T)$,

$$\int_{\Omega\times\{t\}}|u|^2\phi+2\int_0^t\int_\Omega|\nabla u|^2\phi+\int_0^t\int_\Omega w|u|^2\phi$$
$$=\int_\Omega|u_0|^2\phi(x,0)+\int_0^t\int_\Omega|u|^2(\phi'+2\Delta\phi)+2\Re\left\{(1+i\mu)\int_0^t\int_\Omega u\nabla\bar{u}\nabla\phi\right\}$$
$$+2R\int_0^t\int_\Omega|u|^2\phi. \tag{12}$$

Proof: Suppose for the moment that ϕ also vanishes near $t=0$; choose Ω_1 so that $\bar{\Omega}_1\subset\Omega$ and supp $\phi\subset\Omega_1\times(0,T)$. Writing $F=-(1+i\nu)wu+Ru\in L^2(D)$, we have

$$u_t=(1+i\mu)\Delta u+F. \tag{13}$$

Mollifying (in $\mathbb{R}^{n+1}$) each term of (13), we obtain sequences of smooth functions $\{u_m\}$ and $\{F_m\}$ such that

$$\frac{\mathrm{d}}{\mathrm{d}t}u_m=(1+i\mu)\Delta u_m+F_m, \tag{14}$$

with $u_m\to u$ in $L^2(D)$, $\nabla u_m\to\nabla u$ in $L^2(D)$, and $F_m\to F$ in $L^2(D)$. Multiplying (14) by $\bar{u}_m\phi$, integrating by part on D, and taking the real part, by Lemma 2.1, we have

$$-\int\int|u_m|^2\phi'=2\Re\left\{(1+i\mu)\left[-\int\int|\nabla u_m|^2\phi+\int\int u_m\nabla\bar{u}_m\nabla\phi+\int\int|u_m|^2\Delta\phi\right]\right\}$$
$$+2\Re\int\int F_m\bar{u}_m\phi.$$

We pass to the limit as $m\to\infty$ and obtain

$$-\int\int|u|^2\phi'=-2\int\int|\nabla u|^2\phi+2\Re\left\{(1+i\mu)\int\int u\nabla\bar{u}\nabla\phi\right\}+2\int\int|u|^2\Delta\phi$$
$$+2\Re\int\int F\bar{u}\phi.$$

On the other hand,

$$2\Re\int\int F\bar{u}\phi=2\Re\left(\int\int-(1+i\nu)w|u|^2\phi+R|u|^2\phi\right)=-2\int\int w|u|^2\phi+2R\int\int|u|^2\phi.$$

So we have

$$2\int\int|\nabla u|^2\phi+\int\int w|u|^2\phi=\int\int|u|^2(\phi'+2\Delta\phi)+2R\int\int|u|^2\phi$$
$$+2\Re\left\{(1+i\mu)\int\int u\nabla\bar{u}\nabla\phi\right\}. \tag{15}$$

For the general $\phi\in C^\infty(\bar{D})$, $\phi\geqslant 0$, by the argument in Ref. 4, we obtain (12).

Utilize the "retard mollifier" $\Psi_\delta(u)$ as in Ref. 4, we have the following lemma.

Lemma 2.4: For any $u\in L^\infty(0,T;L^2)\cap L^2(0,T;H_0^1)$,

$$\sup_{0<t<T}\int_\Omega|\Psi_\delta(u)|^2(x,t)\mathrm{d}x\leqslant CE_0(u), \tag{16}$$

$$\int \int_D |\nabla \Psi_\delta(u)|^2 \mathrm{d}x\, \mathrm{d}t \leqslant C E_1(u), \tag{17}$$

where C denotes an universal constant.

Now we are ready to prove Theorem 1.1. For any large integer N, let $\delta = T/N$, and solve

$$\frac{\mathrm{d}}{\mathrm{d}t} u_N = (1+i\mu)\nabla u_N - (1+i\nu)\Psi_\delta(|\Psi_\delta(u_N)|^{2\sigma})u_N + R u_N, \tag{18}$$

$$u_N \in L^2(0,T;H_0^1) \cap C([0,T];L^2), \tag{19}$$

$$u_N(0) = u_0. \tag{20}$$

By induction, due to Lemma 2.2, such u_N exist on each $(m\delta,(m+1)\delta)$, $0 \leqslant m \leqslant N-1$. By (10), we have

$$\int_{\Omega\times\{t\}} |u_N|^2 + 2\int_0^t \int_\Omega |\nabla u_N|^2 + 2\int_0^t \int_\Omega \Psi_\delta(|\Psi_\delta(u_N)|^{2\sigma})|u_N|^2 = \int_\Omega |u_0|^2 + 2R\int_0^t \int_\Omega |u_N|^2,$$

then

$$\int_{\Omega\times\{t\}} |u_N|^2 \leqslant \int_\Omega |u_0|^2 + 2R\int_0^t \int_\Omega |u_N|^2.$$

By the Grownwall inequality, for $t \in (0,T)$,

$$\int_{\Omega\times\{t\}} |u_N|^2 \mathrm{d}x \leqslant \exp(2RT)\int_\Omega |u_0|^2,$$

then for $t \in (0,T)$,

$$\int_{\Omega\times\{t\}} |u_N|^2 + 2\int_0^t \int_\Omega |\nabla u_N|^2 + 2\int_0^t \int_\Omega \Psi_\delta(|\Psi_\delta(u_N)|^{2\sigma})|u_N|^2 \leqslant (1+2RT\exp(2RT))\int_\Omega |u_0|^2,$$

so we have

$$\{u_N\} \text{ is bounded in } L^\infty(0,T;L^2) \cap L^2(0,T;H_0^1). \tag{21}$$

We claim that

$$\frac{\mathrm{d}}{\mathrm{d}t} u_N \in L^p(0,T;H^{-s}), \tag{22}$$

where $s > n/2$ for some $1 < p < \infty$.

By (18) and (21), it is sufficient to check that $\Psi_\delta(|\Psi_\delta(u_N)|^{2\sigma})u_N \in L^p(0,T;H^{-s})$. By Lemma 1.1, we have

$$\int_\Omega |u_N|^{2\sigma+1} \leqslant C\left(\int_\Omega |\nabla u_N|^2\right)^a \left(\int_\Omega |u_N|^2\right)^{(2\sigma+1)/2-a} + \frac{C}{r^{2a}}\left(\int_\Omega |u_N|^2\right)^{(2\sigma+1)/2},$$

where

$$a = \frac{n(2\sigma-1)}{4}.$$

For $\sigma<(4+n)/2n$, let $p=4/[n(2\sigma-1)]>1$, we have

$$\int_0^T\left(\int_\Omega |u_N|^{2\sigma+1}\mathrm{d}x\right)^p \mathrm{d}t\leqslant C(E_0^{(2\sigma+1)/2-a})^p E_1+\frac{CT}{r^{2ap}}E_0^{[(2\sigma+1)p]/2}<\infty,$$

so $\Psi_\delta(|\Psi_\delta(u_N)|^{2\sigma})u_N\in L^p(0,T;H^{-s})$.

When Ω is bounded in $\mathbb{R}^n$, by (21), (22) and Theorem 2.1 in Chap. III in Ref. 5, $\{u_N\}$ stays in a compact set of $L^2(0,T;L^2)$, then there exists a strongly convergent subsequence of $\{u_N\}$, still denoted by $\{u_N\}$, and u^* with

$$u_N\to u^* \text{ in } L^2(0,T;L^2). \tag{23}$$

By Lemma 1.1, let $r_0=\mathrm{diam}(\Omega)$,

$$\int_\Omega |u_N|^{[2(n+2)]/n}\mathrm{d}x\leqslant C\left(\int_\Omega|\nabla u_N|^2\mathrm{d}x\right)\left(\int_\Omega|u_N|^2\mathrm{d}x\right)^{2/n}+\frac{C}{r_0^2}\left(\int_\Omega|u_N|^2\mathrm{d}x\right)^{(n+2)/n},$$

then integrate from 0 to T,

$$\int_0^T\int_\Omega|u_N|^{[2(n+2)]/n}\mathrm{d}x\mathrm{d}t\leqslant CE_1E_0^{2/n}+\frac{CT}{r_0^2}E_0^{(n+2)/n}<\infty,$$

so $\{u_N\}$ is bounded in $L^{[2(n+2)]/n}(D)$. By (23), for $2\leqslant q<[2(n+2)]/n$,

$$u_N\to u^* \text{ in } L^q(0,T;L^q). \tag{24}$$

When $\Omega=\mathbb{R}^n$, we can only obtain that there exists a subsequence, still denoted by $\{u_N\}$, and u^* satisfying $u_N\to u^*$ strongly in $L^2(0,T;L^2_{\mathrm{loc}})$, $\{u_N\}$ is bounded in $L^{[2(n+2)]/n}(D)$ and then $u_N\to u^*$ strongly in $L^q(0,T;L^q_{\mathrm{loc}})$ for $2\leqslant q<[2(n+2)]/n$, which is enough to get our results.

By (21),

$$u_N\to u^* \text{ weakly in } L^2(0,T;H_0^1), \tag{25}$$

and

$$u_N\to u^* \text{ weak-star in } L^\infty(0,T;L^2). \tag{26}$$

By the definition of Ψ_δ, for some $r<(n+2)/n\sigma$,

$$\Psi_\delta(|\Psi_\delta(u_N)|^{2\sigma})\to|u^*|^{2\sigma} \text{ in } L^r(0,T;L^r), \tag{27}$$

and

$$\Psi_\delta(u_N)\to u^* \textit{ strongly in } L^q(D). \tag{28}$$

So u^* is the solution of (18) in the sense of distributions. From now on, the proof is similar to that in Ref. 4.

III. PROOF OF THE THEOREM 1.2

In this section, we consider the initial value problem of (2) for simplicity. Let $\Omega=\mathbb{R}^n$ and u be a suitable weak solution of (2) on $\mathbb{R}^n\times(0,\infty)$ with initial data $u_0\in L^2$, and for $\phi\in C_0^\infty(\mathbb{R}^n\times\mathbb{R})$ with $\phi\geqslant 0$,

$$\int_{\Omega\times\{t\}}|u|^2\phi+2\int_0^t\int_\Omega|\nabla u|^2\phi\leqslant\int_\Omega|u_0|^2\phi(x,0)+2R\int_0^t\int_\Omega|u|^2\phi+\int_0^t\int_\Omega|u|^2(\phi'+2\Delta\phi)$$
$$+2\Re\left\{(1+i\mu)\int_0^t\int_\Omega u\nabla\bar{u}\nabla\phi\right\}. \tag{29}$$

Here we need a corollary in Ref. 3.

Proposition 3.1: Let $\alpha>2$, $2\sigma+1<\alpha<[2(n+2)]/n$, there exists $\epsilon_0>0$, if u is a suitable weak solution of (2) on Q_r, and moreover,

$$\frac{1}{r^{n+2-\alpha/\sigma}}\int\int_{Q_r}|u|^\alpha\leqslant\epsilon_0, \tag{30}$$

then u is C^{α_0} in $Q_{r/4}$ for some $\alpha_0\in(0,1/2)$.

By the same idea in Ref. 3, we let $v=e^{-Rt}u$, if u is a suitable weak solution of (2), then v is a suitable weak solution of the following problem:

$$v_t=(1+i\mu)\Delta v-i\nu e^{2\sigma Rt}|v|^{2\sigma}v \quad \text{in } \Omega\times(0,T),$$
$$v(x,0)=v_0(x), \quad x\in\Omega, \tag{31}$$
$$v(x,t)=0, \quad x\in\partial\Omega,\ t\in(0,T),$$

and the corresponding generalized energy inequality

$$\int_{\Omega\times\{t\}}|v|^2\phi+2\int_0^t\int_\Omega|\nabla v|^2\phi\leqslant\int_\Omega|v_0|^2\phi(x,0)+\int_0^t\int_\Omega|v|^2(\phi'+2\Delta\phi)$$
$$+2\Re\left\{(1+i\mu)\int_0^t\int_\Omega v\nabla\bar{v}\nabla\phi\right\} \tag{32}$$

holds for any real-valued $\phi\in C^\infty(D)$ with $\phi\geqslant0$ and $\phi(t)\in C_0^\infty(\mathbb{R}^n)$ for each $t\in[0,T]$.

To prove Theorem 1.2, we need the following lemmas.

Lemma 3.1: There exists an absolute constant C such that if $t\geqslant CE^{2\sigma/(n\sigma-2)}$, then u is regular at (x,t).

Proof: By Lemma 1.1,

$$\int_{\mathbb{R}^n}|u|^\alpha dx\leqslant C\left(\int_{\mathbb{R}^n}|u|^2dx\right)^{(\alpha/2)(1-n(1/2-1/\alpha))}\left(\int_{\mathbb{R}^n}|\nabla u|^2dx\right)^{(n\alpha/2)(1/2-1/\alpha)},$$

then

$$\int_0^T\int_{\mathbb{R}^n}|u|^\alpha dx\,dt\leqslant C\left(\sup_t\int_{\mathbb{R}^n}|u|^2dx\right)^{(\alpha/2)(1-n(1/2-1/\alpha))}\int_0^T\left(\int_{\mathbb{R}^n}|\nabla u|^2dx\right)^{(n\alpha/2)(1/2-1/\alpha)}dt$$
$$\leqslant CE_0^{(\alpha/2)(1-n(1/2-1/\alpha))}E_1^{(n\alpha/2)(1/2-1/\alpha)}T^{1-(n\alpha/2)(1/2-1/\alpha)}$$
$$\leqslant CE^{\alpha/2}T^{1-(n\alpha/2)(1/2-1/\alpha)}.$$

When $E\leqslant(\epsilon_0/C)^{2/\alpha}T^{n/2-1/\sigma}$, i.e., $T\geqslant C(\epsilon_0,\alpha)E^{2\sigma/(n\sigma-2)}$,

$$\int_0^T\int_{\mathbb{R}^n}|u|^\alpha dx\,dt\leqslant\epsilon_0T^{(n+2)/2-\alpha/2\sigma}.$$

By Proposition 3.1, if

$$\int \int_{Q_r} |u|^{\alpha} dx\, dt \leqslant \epsilon_0 r^{n+2-\alpha/\sigma},$$

then u is regular in $Q_{r/4}$, so Lemma holds.

Lemma 3.2: Let $\tau = \epsilon + |x|$, $\epsilon \geqslant 0$. *If*

(i) $r \geqslant 2$, $\gamma + n/r > 0$, $\alpha + n/2 > 0$, $\beta + n/2 > 0$, $1/2 \leqslant a \leqslant 1$,

(ii) $\gamma + n/r = a(\alpha + (n-2)/2) + (1-a)(\beta + n/2)$,

(iii) $a(\alpha - 1) + (1-a)\beta \leqslant \gamma \leqslant a\alpha + (1-a)\beta$,

then

$$|\tau^{\gamma} u|_{L^2} \leqslant C |\tau^{\alpha} |\nabla u||_{L^2}^{a} |\tau^{\beta} u|_{L^2}^{1-a}. \tag{33}$$

For $n = 3$, the proof of the lemma has been given in Ref. 4; for the general case, the proof is similar.

Lemma 3.3: Let u *be a suitable weak solution of (2) with (29) holds and* $G < \infty$. *Then for a.e.* $t > 0$,

$$\frac{1}{2} \int_{\mathbb{R}^n} |u|^2 |x| dx + \int_0^t \int_{\mathbb{R}^n} |\nabla u|^2 |x| dx\, dt \leqslant A(t), \tag{34}$$

where $A(t) = G + Ct^{1/2}E$.

Proof: By Lemma 3.2,

$$\int_{\mathbb{R}^n} \frac{|u|^2}{|x|} dx \leqslant C \left(\int_{\mathbb{R}^n} |u|^2 dx \right)^{1/2} \left(\int_{\mathbb{R}^n} |\nabla u|^2 dx \right)^{1/2},$$

then

$$\int_0^t \int_{\mathbb{R}^n} \frac{|u|^2}{|x|} dx\, dt \leqslant C E_0^{1/2} E_1^{1/2} t^{1/2} \leqslant C E t^{1/2}.$$

Let $\chi(t)$ be C^{∞} on $s \geqslant 0$ with $0 \leqslant \chi \leqslant 1$, $\chi = 1$ for $s \leqslant 1$ and $\chi = 0$ for $s \geqslant 2$. For constants $1 > \lambda \gg \epsilon > 0$, we use the test function $\phi(x) = 1/2\,(\lambda^2 - |x|^2)^{1/2} \chi(\epsilon/\lambda\,|x|)$ in the energy inequality (32). It is easy to verify that $|\nabla \phi| \leqslant C$, $|\Delta \phi| \leqslant C|x|^{-1}$, with C independent of λ and ϵ. Then

$$\int_{\mathbb{R}^n \times \{t\}} |u|^2 \phi\, dx + 2 \int_0^t \int_{\mathbb{R}^n} |\nabla u|^2 \phi dx\, dt \leqslant \int_{\mathbb{R}^n} |u_0|^2 |x| dx + C \int_0^t \int_{\mathbb{R}^n} \left\{ \frac{|u|^2}{|x|} + |u||\nabla u| \right\} dx\, dt.$$

Let $\epsilon \to 0$ and then $\lambda \to 0$,

$$\int_{\mathbb{R}^n \times \{t\}} |u|^2 |x| dx + 2 \int_0^t \int_{\mathbb{R}^n} |\nabla u|^2 |x| dx\, dt \leqslant G + C E t^{1/2}.$$

Now we prove Theorem 1.2. Let S be the set of singular points of u. By Lemma 3.1, if $(x,t) \in S$, then

$$t < C E^{2\sigma/(n\sigma - 2)}. \tag{35}$$

Let $r^2 = 5/4\,t$, $Q = Q_r(x, r^2)$, by Proposition 3.1,

$$\int \int_{Q} |u|^{\alpha} dx\, dt > C \epsilon_0 t^{n+2/2-\alpha/2\sigma}. \tag{36}$$

Let $R=|x|$ and suppose for the moment that $R\geqslant 2r$. Take $\gamma=\alpha=\beta=1/2$, $a=n/(n+2)$, and $p=[2(n+1)]/n$, by Lemma 3.2,

$$||x|^{1/2}|u||_{L^p}^p\leqslant C||x|^{1/2}|\nabla u||_{L^2}^2||x|^{1/2}|u||_{L^2}^{4/n}. \tag{37}$$

Integrate from 0 to t,

$$\int_0^t\int_{\mathbb{R}^n}|x|^{(n+2)/n}|u|^{[2(n+2)]/n}\mathrm{d}x\,\mathrm{d}t\leqslant CA(t)^{2/n}\int_0^t\int_{\mathbb{R}^n}|x||\nabla u|^2\mathrm{d}x\,\mathrm{d}t\leqslant CA(t)^{(2+n)/n}.$$

By (36) and the Hölder inequality,

$$\begin{aligned}C\epsilon_0 t^{n+2/2-\alpha/2\sigma}&\leqslant\int\int_Q|u|^\alpha\mathrm{d}x\,\mathrm{d}t\leqslant r^{n+2-\alpha n/2}\left(\int\int_Q|u|^{[2(n+2)]/n}\mathrm{d}x\,\mathrm{d}t\right)^{\alpha n/[2(n+2)]}\\&\leqslant Cr^{n+2-\alpha n/2}R^{-\alpha/2}A(t)^{\alpha/2}\leqslant K(E,G)t^{n+2/2-\alpha n/4}R^{-\alpha/2},\end{aligned}$$

so

$$R^2t^{n-2/\sigma}\leqslant K_0(E,G,\alpha).$$

For $R\leqslant 2r$,

$$R^2t^{n-2/\sigma}\leqslant 5t^{n+1-2\sigma}\leqslant C(E^{2\sigma/(n\sigma-2)})^{n+1-2/\sigma}.$$

Therefore, Theorem 1.2 holds with $K_1=C\max(K_0,E^{2\sigma/n\sigma-2(n+1-2/\sigma)})$.

Multiplicative noise: A mechanism leading to nonextensive statistical mechanics

Celia Anteneodo and Constantino Tsallis
Centro Brasileiro de Pesquisas Fisicas, Dr Xavier Sigaud 150, 22290-180, Rio de Janeiro-RJ, Brazil

(Received 10 January 2003; accepted 12 August 2003)

A large variety of microscopic or mesoscopic models lead to generic results that accommodate naturally within Boltzmann–Gibbs statistical mechanics [based on $S_1 \equiv -k\int du\, p(u)\ln p(u)$]. Similarly, other classes of models point toward nonextensive statistical mechanics [based on $S_q \equiv k[1-\int du[p(u)]^q]/[q-1]$, where the value of the entropic index $q \in \Re$ depends on the specific model]. We show here a family of models, with multiplicative noise, which belongs to the nonextensive class. More specifically, we consider Langevin equations of the type $\dot{u} = f(u) + g(u)\xi(t) + \eta(t)$, where $\xi(t)$ and $\eta(t)$ are independent zero-mean Gaussian white noises with respective amplitudes M and A. This leads to the Fokker–Planck equation $\partial_t P(u,t) = -\partial_u[f(u)P(u,t)] + M\partial_u\{g(u)\partial_u[g(u)P(u,t)]\} + A\partial_{uu}P(u,t)$. Whenever the deterministic drift is proportional to the noise induced one, i.e., $f(u) = -\tau g(u)g'(u)$, the stationary solution is shown to be $P(u,\infty) \propto \{1-(1-q)\beta[g(u)]^2\}^{1/(1-q)}$ [with $q \equiv (\tau+3M)/(\tau+M)$ and $\beta = (\tau+M/2A)$]. This distribution is precisely the one optimizing S_q with the constraint $\langle[g(u)]^2\rangle_q \equiv \{\int du\,[g(u)]^2[P(u)]^q\}/\{\int du\,[P(u)]^q\} = \text{const}$. We also introduce and discuss various characterizations of the width of the distributions. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1617365]

Ubiquitous systems can be naturally described within Boltzmann–Gibbs (BG) statistical mechanics [based on the entropy $S_1 \equiv -k\int du\, p(u)\ln p(u)$]. These systems have in common the fact that they like *equally* to live everywhere they are allowed to, that is, they are ergodic in the entire phase space. However, there are other systems that, depending on the initial conditions, may prefer a particular subspace. The BG scenario may not be appropriate any longer and an extension of the usual thermostatistical description, taking into account the features of such subspace, would be required. If that subspace has a scale invariant geometry, a hierarchical or multifractal structure, then the model points toward nonextensive statistical mechanics [based on the entropic form $S_q \equiv k\,[1-\int du\,[p(u)]^q]/[q-1]\,,\ \ q \in \Re$][1] (see Ref. 2 for reviews). Among the models which belong to this category, one finds low-dimensional dissipative and conservative maps,[3] fractional and nonlinear Fokker–Planck equations,[4] Langevin dynamics with fluctuating temperature,[5] growth of many-body scale-free networks[6] and long-range many-body classical Hamiltonians.[7] The corresponding value of the entropic index q depends on the specific model, or, more precisely, on the nonextensivity universality class of the model. It is our purpose here to show a large family of models with multiplicative noise which belongs to the nonextensive class.

Microscopic dynamics, containing multiplicative noise, may be encountered in many dynamical processes, such as in stochastic resonance,[8] noise induced phase transitions,[9] granular packings,[10] and others.[11,12] Due to its significance, stochastic processes with multiplicative noise have been the subject of numerous studies in the last decades.[13–15] Here we will consider processes subject to both additive and multiplicative noises and described by the dimensionless stochastic differential equation of the form

$$\dot{u} = f(u) + g(u)\xi(t) + \eta(t), \tag{1}$$

where $u(t)$ is a stochastic variable, f,g are arbitrary functions $[g(0)=0]$, and $\xi(t), \eta(t)$ are uncorrelated and Gaussian-distributed zero-mean white noises, hence satisfying

$$\langle \xi(t)\xi(t')\rangle = 2M\delta(t-t'), \quad \langle \eta(t)\eta(t')\rangle = 2A\delta(t-t'), \tag{2}$$

where $M,A>0$ are the noise amplitudes and stand for "multiplicative" and "additive," respectively. Clearly, some degree of correlation between the two noises can be of physical relevance, however, this remains out of the present scope. The deterministic drift $f(u)$ can be interpreted either as a damping force (whenever u is a velocity-like quantity) or as an external force (when motion is overdamped and u represents a position coordinate). Other interpretations are possible as well, depending on the particular system treated.

It is interesting to note that additive and multiplicative terms in Eq. (1) could be gathered in an effective multiplicative noise term,[16] however we prefer to keep track of both sources independently.

The stochastic differential equation (1) is not completely defined and must be complemented by an additional rule. This is due to the fact that each pulse of the stochastic noise produces a jump in u, then the question arises: which is the value of u to be used in $g(u)$? This is the well-known Itô–Stratonovich controversy.[15,17] In the Itô definition, the value before the pulse must be used, whereas in the Stratonovich definition the values before and after the pulse contribute in a symmetric way. If noise were purely additive, then both definitions agree.

The Fokker–Planck equation for the probability density $P(u,t)$, associated to Eq. (1), can be obtained from the Kramers–Moyal expansion $\partial_t P = \Sigma_{n\geqslant 1}(-\partial_u)^n[D^{(n)}P]$, where the coefficients are given by

$$D^{(n)}(x,t) = \frac{1}{n!}\lim_{\tau\to 0}\frac{[u(t+\tau)-x]^n}{\tau}\bigg|_{u(t)=x}.$$

These coefficients can be readily obtained following the standard lines found for instance in Ref. 15. Using the Stratonovich definition of stochastic integral, one gets

$$D^{(1)}(u,t) = f(u) + Mg(u)g'(u) \equiv J(u), \tag{3}$$

$$D^{(2)}(u,t) = A + M[g(u)]^2 \equiv D(u), \tag{4}$$

while $D^{(n)}(u,t)=0$ for $n\geqslant 3$. Then, one arrives straightforwardly at

$$\partial_t P = -\partial_u j(u), \tag{5}$$

where $j(u)\equiv J(u)P - \partial_u[D(u)P]$ is the current. In the Itô calculation, Eq. (3) becomes $J(u) = f(u)$, that is, the noise-induced (or spurious) drift is missing. In what follows we will adopt the Stratonovich definition. However, this choice will not affect the present discussion excepting for a redefinition of some of the parameters that are involved.

Equation (5) can also be written as

$$\partial_t P = -\partial_u(f(u)P) + M\partial_u(g(u)\partial_u[g(u)P]) + A\partial_{uu}P. \tag{6}$$

In some processes, the deterministic and noise-induced drifts may have the same functional form. Let us set this condition as follows:

$$f(u) = -\tau g(u)g'(u), \tag{7}$$

τ being a proportionality constant. In other words, $f(u)$ is derived from a potential-like function $V(u) = (\tau/2)[g(u)]^2$. Let us note that the particular case $g(u)\propto f(u)\propto u$, which is a natural first choice for a physical system, verifies this condition. However, since no extra calculational difficulties emerge, we will discuss here the more general case (7). Notice that in the absence of deterministic forcing, condition (7) is trivially satisfied for any g by setting $\tau=0$.

In the present paper we will restrict to the stationary solutions for no flux boundary conditions [i.e., such that $j(-\infty)=j(\infty)=j(u)=0$], although more general conditions could in principle also

be considered. If (7) is verified, then, the stationary solution $P_s(u)$ is of the q-exponential form appearing in nonextensive statistical mechanics.[1] More precisely, in that case, one obtains

$$P_s(u) \propto [1+(q-1)\beta[g(u)]^2]^{1/(1-q)}, \tag{8}$$

where $\beta \equiv 1/kT = (\tau+M)/2A$ (where by T we generically mean the amplitude of an effective noise) and

$$q = \frac{\tau+3M}{\tau+M} \quad . \tag{9}$$

As an aside comment let us mention that if we had used the Itô convention we would have obtained $q=(\tau+4M)/(\tau+2M)$. Let us now go back to our Stratonovich choice.

P_s is normalizable if $|g(u)|$ grows with $|u|$ faster than $|u|^{1/(1+\tau/M)}$ $(\tau > -M)$. This probability distribution function (pdf) optimizes

$$S_q \equiv k \frac{1-\int \mathrm{d}u \ \ [P(u)]^q}{q-1}, \tag{10}$$

with the constraint

$$\langle [g(u)]^2 \rangle_q \equiv \frac{\int \mathrm{d}u \ \ [g(u)]^2 [P(u)]^q}{\int \mathrm{d}u [P(u)]^q} = \text{const.} \tag{11}$$

The condition (7) is not necessary for having solutions of the q-exponential form, as it follows along the lines of Refs. 18 and 19, in spite of the fact that the models therein considered are different from the present one.

Let us consider in more detail the case when both the forcing and the multiplicative noise depend on the stochastic variable u as a power law, that is, when the Langevin Eq. (1) becomes

$$\dot{u} = -\gamma u|u|^{r-1} + u|u|^{s-1}\xi(t) + \eta(t), \tag{12}$$

with $r,s \geqslant 0$ and a drift coefficient γ typically positive. In this case, the deterministic drift is derived from a confining potential-like function of the form $V(u)=\gamma|u|^{r+1}/(r+1)$. The corresponding Fokker–Planck equation becomes

$$\partial_t P = -\partial_u(-\gamma u|u|^{r-1}P) + M\partial_u(|u|^s \partial_u[|u|^s P]) + A\partial_{uu}P. \tag{13}$$

Hence, its stationary solution $P_s(u)$ is given by

$$P_s(u) = \frac{P_0 \, \mathrm{e}^{-h(u)}}{\left(1+\dfrac{M}{A}|u|^{2s}\right)^{1/2}} \quad , \tag{14}$$

P_0 being the normalization constant and

$$h(u) \equiv \frac{\gamma|u|^{1+r}}{A[1+r]} \ {}_2F_1\left(\frac{1+r}{2s},1;1+\frac{1+r}{2s};-\frac{M}{A}|u|^{2s}\right), \tag{15}$$

where ${}_2F_1$ is the hypergeometric function.

We shall analyze now some limiting cases.

(A) For vanishing deterministic forcing $(\gamma \to 0)$, Eq. (14) becomes

$$P_s(u) = \frac{P_0}{\left(1+\frac{M}{A}|u|^{2s}\right)^{1/2}}, \tag{16}$$

with

$$P_0 = \frac{(M/A)^{1/(2s)}\ \Gamma\left(\frac{1}{2}\right)}{2\,\Gamma\left(1+\frac{1}{2s}\right)\ \Gamma\left(\frac{1}{2}-\frac{1}{2s}\right)} \quad \text{for } s>1. \tag{17}$$

This pdf is of the q-exponential form (with $q=3$) as expected because, in this case, condition (7) is trivially true since it corresponds to $\tau=0$. Interestingly, in the presence of multiplicative noise, the steady state P_s is normalizable *even in the absence of a confining potential*, as long as $s>1$. The so-called spurious drift which originates from the multiplicative noise term in the Langevin equation is responsible for kicking the system back close to the origin, where fluctuations are smaller. On the other hand, the additive noise plays an essential role, providing fluctuations which avoid the full concentration (at the origin) that would occur otherwise. This type of stabilizing effect of the multiplicative noise is long known.[20]

(B) In the limit $M\to 0$, all other parameters being fixed, i.e., when no multipliciative noise is present, Eq. (14) becomes of the following stretched exponential form:

$$P_s(u) = \frac{\left[\frac{\gamma}{A[1+r]}\right]^{1/(1+r)}}{2\,\Gamma\left(1+\frac{1}{1+r}\right)}\ e^{-(\gamma/A[1+r])|u|^{1+r}}. \tag{18}$$

In particular, for the linear forcing $(r=1)$, the Gaussian pdf is recovered.

(C) In the limit $A\to 0$, i.e., for vanishing strength of the additive noise, the steady state is normalizable for $s<1$ and $p\equiv r+1-2s>0$. The condition $p>0$ implies that the potential of the drift has to be steep enough to confine the system and yield a steady state. Then, we have

$$P_s(u) = \frac{p\ \left[\frac{\gamma}{Mp}\right]^{(1-s)/p}}{2\ \Gamma\left(\frac{1-s}{p}\right)}\ \frac{e^{-(\gamma/Mp)\,|u|^p}}{|u|^s}\ . \tag{19}$$

Vanishing A concentrates the probability at the origin. Again, the Gaussian distribution is recovered for $r=1$ (harmonic forcing) and $s=0$ (additive noise).

The limits analyzed above are not generically interchangeable, that is, convergence is not necessarily uniform.

In the general case where (A,M,γ) are all finite, the same dependence on u as that in Eq. (19) is obtained for sufficiently large $|u|$. In fact, if one defines the dimensionless variable $\overline{u}=u/\lambda$ with $\lambda\equiv(A/M)^{1/2s}$, it is clear that the asymptotic expression of Eq. (14) for $|\overline{u}|\to\infty$ corresponds to both limits $|u|\to\infty$ and $A\to 0$.

For finite (A,M,γ), in the $p=0$ marginal case where the drift and multiplicative-noise exponents are related through $1+r=2s$ [hence condition (7) is verified with $\tau=\gamma/s$], a q-exponential pdf emerges at asymptotically long time. In fact, in that case, the hypergeometric in Eq. (15) becomes ${}_2F_1(1,1;2;-z)=\ln(1+z)/z$ and one gets

$$P_s(u) = \frac{P_0}{(1+|u/\lambda|^{2s})^{1/(q-1)}}\ , \tag{20}$$

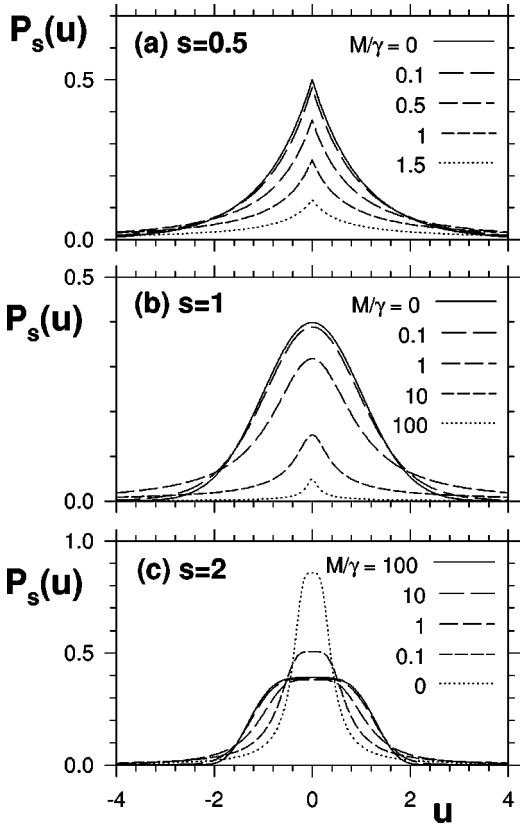

FIG. 1. Steady state pdfs for $s=0.5$ (a), 1 (b), and 2 (c), with $r=2s-1$, $A/\gamma=1$ and different values of M/γ indicated in the figure. Notice that the alternative representation $\lambda\, P_s(u)$ vs u/λ with $\lambda=(A/M)^{1/2s}$ would give profiles independent on the particular choice of A/γ.

with

$$q=\frac{(\gamma/s)+3M}{(\gamma/s)+M} \tag{21}$$

and

$$P_0=\frac{\Gamma\left(\frac{1}{2}+\frac{\gamma}{2sM}\right)}{2\lambda\,\Gamma\left(1+\frac{1}{2s}\right)\,\Gamma\left(\frac{1}{2}+\frac{\gamma}{2sM}-\frac{1}{2s}\right)} \quad . \tag{22}$$

$P_s(u)$ is normalizable for $s+\gamma/M>1$. Notice that q-exponential pdf's can appear even for negative γ (i.e., for repulsive deterministic forces). The $1+r=2s$ class includes the particular linear case $r=s=1$, that has already been treated in the literature.[11,21] In Fig. 1 we exhibit the steady state pdf (20) for several values of the system parameters.

Assuming that $\langle u\rangle=0$, the width of $P(u,t)$ can be characterized in many ways, such as (i) the inverse of the height at the origin, namely, $1/P(0,t)$; (ii) the width at half height, Δ; (iii) the square root of the mean value of u^2; (iv) the $2s$-root of the mean value of $|u|^{2s}$; (v) the square root of the q-expectation values of u^2; (vi) the $2s$-root of the q-expectation value of $|u|^{2s}$, or even combinations of these, for instance, (vii) $\sqrt{\Delta/P(0,t)}$ (see also Ref. 22). Let us recall that the normalized q-expectation of ψ is defined as

$$\langle \psi \rangle_q(t) \equiv \frac{\int \mathrm{d}u\ \psi(u)[P(u,t)]^q}{\int \mathrm{d}u\ \ [P(u,t)]^q}, \tag{23}$$

hence, $\langle \psi \rangle_1$ equals the usual mean value $\langle \psi \rangle$.

For the usual case where $P(u,t)$ is a Gaussian, all these definitions basically coincide. This is not so in general, as we shall illustrate in what follows for the stationary state of Eq. (20).

(i) The inverse of the height at the origin

$$\frac{1}{P_s(0)} = \lambda\ \frac{2\,\Gamma\left(1+\frac{1}{2s}\right)\ \Gamma\left(\frac{1}{2}+\frac{\gamma}{2sM}-\frac{1}{2s}\right)}{\Gamma\left(\frac{1}{2}+\frac{\gamma}{2sM}\right)}. \tag{24}$$

(ii) The width at half height

$$\Delta = 2\lambda\ (2^{1/[(\gamma/2sM)\ +\ 1/2]}-1)^{1/2s}. \tag{25}$$

(iii) The square root of the mean value of u^2,

$$\langle u^2 \rangle^{1/2} = \lambda\ \sqrt{\frac{\Gamma\left(\frac{3}{2s}\right)\ \Gamma\left(\frac{1}{2}+\frac{\gamma}{2sM}-\frac{3}{2s}\right)}{\Gamma\left(\frac{1}{2s}\right)\ \Gamma\left(\frac{1}{2}+\frac{\gamma}{2sM}-\frac{1}{2s}\right)}}, \tag{26}$$

for $\gamma/M > 3-s$ (otherwise it diverges).

(iv) The $2s$-root of the mean value of $|u|^{2s}$,

$$\langle |u|^{2s} \rangle^{1/2s} = \frac{\lambda}{(\gamma/M-s-1)^{1/2s}} \tag{27}$$

for $\gamma/M > 1+s$ (otherwise it diverges).

(v) The square root of the q-expectation value of u^2,

$$\langle u^2 \rangle_q^{1/2} = \lambda\ \sqrt{\frac{\Gamma\left(\frac{3}{2s}\right)\ \Gamma\left(\frac{3}{2}+\frac{\gamma}{2sM}-\frac{3}{2s}\right)}{\Gamma\left(\frac{1}{2s}\right)\ \Gamma\left(\frac{3}{2}+\frac{\gamma}{2sM}-\frac{1}{2s}\right)}}, \tag{28}$$

for $\gamma/M > 3(1-s)$ (otherwise it diverges).

(vi) The $2s$-root of the q-expectation value of $|u|^{2s}$,

$$\langle |u|^{2s} \rangle_q^{1/2s} = \frac{\lambda}{(\gamma/M+s-1)^{1/2s}}, \tag{29}$$

for $\gamma/M > 1-s$. Notice that this condition has already been encountered. Indeed, it is necessary for normalizability. An important remark is mandatory: of all the above characterizations of width which are based on expectation values (i.e., $\langle u^2 \rangle^{1/2}$, $\langle |u|^{2s} \rangle^{1/2s}$, $\langle u^2 \rangle_q^{1/2}$, and $\langle |u|^{2s} \rangle_q^{1/2s}$), *only the last one does not diverge in any admissible (i.e., normalizable) case*. This is particularly remarkable because this generalized expectation value is, as already seen, precisely the one to be used as constraint in the optimization of S_q. In addition to this, it is worthy noticing that $\langle |u|^{2s} \rangle_q^{1/2s}$ is in all cases comparable to $\sqrt{\Delta/P_s(0)}$, a semiempirical quantity which takes into account the contributions of both body and tails.

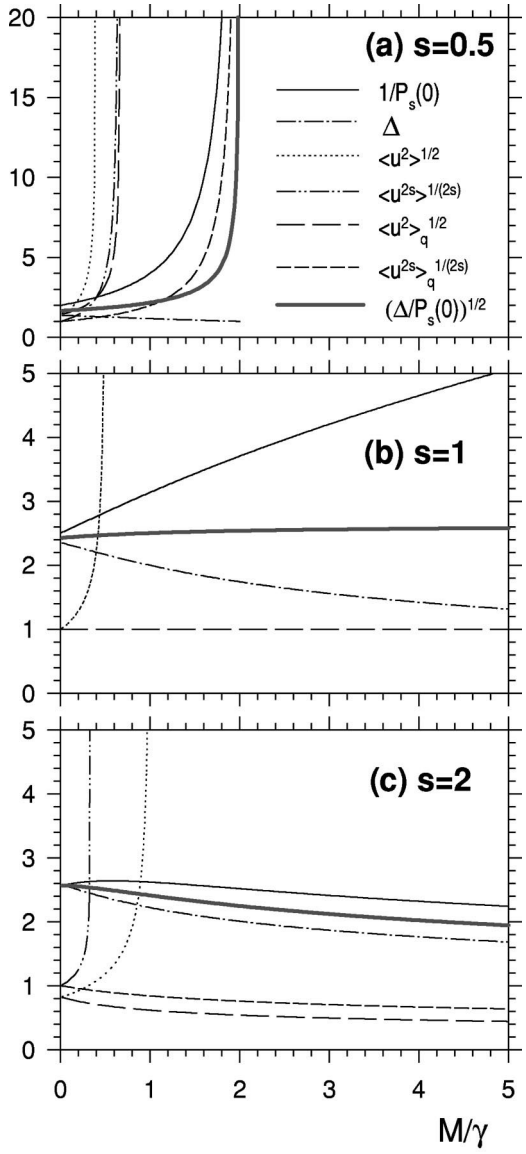

FIG. 2. Different parameters characterizing the ''width'' of the distribution as a function of M/γ for $s=0.5$ (a), 1 (b), and 2 (c), with $r=2s-1$ and $A/\gamma=1$. For $\gamma>0$, normalizability implies $M/\gamma<1/(1-s)$ if $s<1$; for $s\geqslant 1$, the physical region of M/γ extends up to infinity.

In Fig. 2 we exhibit all these quantities as a function of M/γ for typical values of s with $r=2s-1$. As M/γ increases, in all cases, $P_s(u)$ becomes more peaky around the origin (Δ decreases). Moreover, for increasing M/γ and $s=1$, the tail tends to $1/|u|$ [hence $P_s(0)\to 0$]. Also for $s=1/2$, $P_s(0)\to 0$ as the pdf becomes more tailed, but M/γ has the upper bound 2. Contrarily to the previous cases, for $s>1$, as M/γ increases, $P_s(0)$ also increases.

The q-exponential character is not exclusive of the steady state but it also emerges along the time evolution of the pdf, as illustrated in Fig. 3. In this figure we employ the semi-$\ln_q$ representation, where $\ln_q x=(x^{1-q}-1)/(q-1)$. Notice in Figs. 3(b) and 3(c) that the curve for $t\to\infty$ is a straight line. In Fig. 3(c), curves are almost straight lines, thus indicating that the pdf's are very close to q-exponentials along time.

In the presence of multiplicative noise, the system variables directly couple to noise. Therefore, behaviors are observed that can not occur in the presence of additive noise alone. In particu-

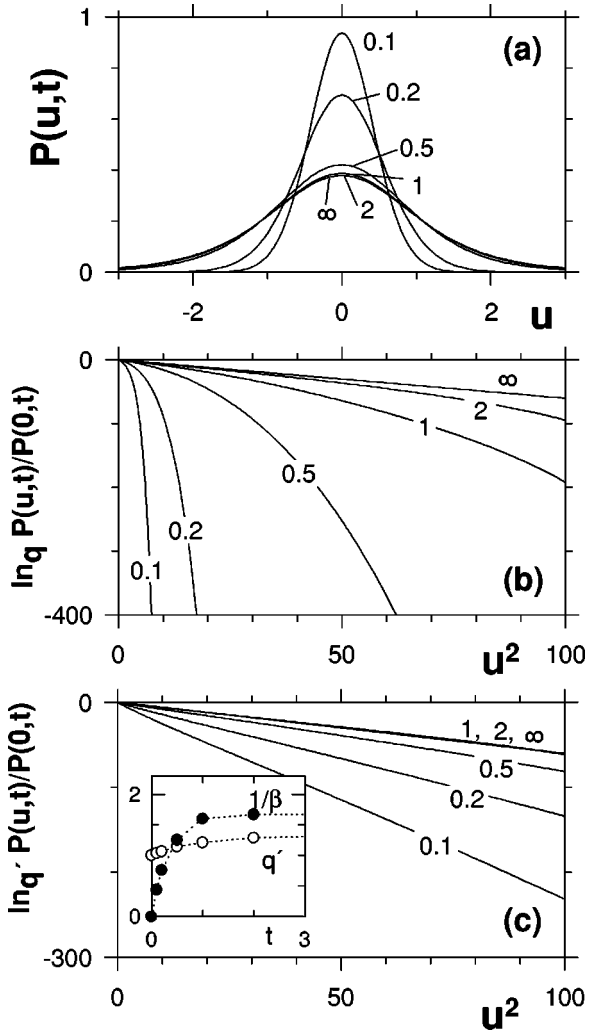

FIG. 3. Time evolution of the pdf for $r=s=1$, $A=\gamma=1$, and $M=0.2$ at different times indicated in the figure, in different representations: linear (a), semi-$\ln_q$ with $q=(\gamma+3M)/(\gamma+M)$ (b), and semi-$\ln_{q'}$, with time dependent q' (c). We used the ansatz $P=P_0(1+(q'-1)\beta u^2)^{1/(1-q')}$, with $P_0=\sqrt{\pi/\beta(q'-1)}\,\Gamma([1/(q'-1)]-\frac{1}{2})/\Gamma(1/(q'-1))$. In the inset we present q' and β vs t. In particular, $q(0)=1$, $1/\beta(0)=0$, $q(\infty)=4/3$, and $1/\beta(\infty)=5/3$.

lar, q-exponential pdf's of the form given by Eq. (8) can arise. For the present processes, q-exponentials do occur either in the absence of forcing ($\gamma=0$) or for drifts verifying Eq. (7), which, for the power-law case, becomes $r=2s-1$. The deterministic forcing does not need to be confining (i.e., $\gamma<0$ is allowed) for the formation of a q-exponential stationary pdf, provided $\gamma/M>1-s$. In any case, if a repulsive effective force prevails for some period of time, the variable u can take large values and power law tails can arise. In particular, a q-exponential occurs when the stochastic forcing is proportional to the deterministic one. Alternatively, during the intervals when the effective force is attractive, the probability tends to concentrate at the origin. Then, at this stage, the additive noise plays a fundamental role allowing the existence of a normalizable steady state by avoiding collapse of the pdf at the origin. When both kinds of noise occur simultaneously, the presence of multiplicative noise can not be formally avoided by a simple transformation of variables. The particular interplay between additive and multiplicative noises as well as that between deterministic and stochastic drifts can lead to the appearance of q-exponentials.

It is worthy to emphasize at this point that the stationary solutions of the present problem have

the general form given by Eq. (14). The q-exponential pdf's represent a special case, which in turn includes the Boltzmann–Gibss pdf as an even more special one, corresponding to the standard thermal equilibrium. Furthermore, the q-exponential pdf's are unique in the sense that they optimize, under appropriate constraints, the entropy functional S_q [Eq. (10)]. This entropic form is in turn unique in the sense that it is the only one which satisfies[23] a set of conditions naturally generalizing both the Shannon and the Kinchin axioms. Also, S_q is consistent with stability (or robustness) of the q-exponential pdf's in the sense described by Abe,[24] whereas Renyi entropy and the normalized version of S_q are not.

Let us conclude by stressing that q-exponentials have also been observed in a variety of similar processes.[5,18,25] The mechanism leading to such distributions is expected to be present in systems with long-range memory, long-range interactions, fractal or hierarchical structures and similar scenarios.

In what concerns the model defined by Eqs. (3)–(5), it is clear that $f(u)$ and $g(u)$ are generically independent functions. However, it does occur that when they are connected through Eq. (7), the q-exponential form emerges naturally. It would no doubt be very interesting if we had a geometrical interpretation of this fact. Hints along this line would be welcome.

As illustrated in Fig. 3 (deterministic drift proportional to the stochastic one), the q-exponential is exact for $t\to\infty$ and it is an excellent approximation $\forall t$.

The best characterizations of the width of the pdf's clearly are those which remain finite under generic circumstances. In our case, this happens for $1/P(0,t)$, Δ, $\langle|u|^{2s}\rangle_q^{1/2s}$ or combinations such as $\sqrt{\Delta/P(0,t)}$. The latter two are preferable since they contain attributes of both body and tails of the pdf. For a mathematically convenient and generic characterization, clearly $\langle|u|^{2s}\rangle_q^{1/2s}$ is the most appropriate.

We are grateful to C.F. Moukarzel for useful remarks and to H. Wio with regard to the comment in Ref. 16. We also acknowledge PRONEX, FAPERJ, and CNPq (Brazilian agencies) for partial financial support.

(Received 23 March 2003; accepted 15 July 2003)

In this paper we formulate the generalized problem of the Boltzmann equation based on the kinetic entropy balance equation in conjunction with the maximum entropy principle. First we prove that the solution of this generalized problem is unique. We then prove that the entropy balance equation obtained by Eu in extended irreversible thermodynamics is valid, if, and only if, the one-particle distribution function f_a is the solution of this generalized problem. As a by-product of this result, we also obtain a statistical expression of the thermodynamic entropy balance equation that shares the same formula as the kinetic entropy balance equation. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1615696]

I. INTRODUCTION

In 1949 Grad constructed a formal solution of the Boltzmann equation (BE) by expanding the one-particle distribution function as a generalized Fourier series in terms of a complete orthonormal system of tensor Hermite polynomials.[1] Since then Grad's moment method has been employed as the kinetic foundation of extended irreversible thermodynamics. However the results are satisfactory only in the first order approximation. On the other hand, several different approaches to extended irreversible thermodynamics (EIT) have been proposed in the past, particularly, the theory of EIT by Jou, Casas-Vazquez, and Lebon,[2] the extended thermodynamics (ET) by Müller and Ruggeri,[3] and the modified moment method by Eu.[4] The theories by Jou *et al.*, and by Müller and Ruggeri in particular, are based on the exploitation of the thermodynamic entropy balance equation, where the dynamical equations of the moments are constructed in accordance with the macroscopic entropy principle, while the statistical foundation of the theory is based on the method of maximum entropy principle (MEP).[5] Recently Boillat and Ruggeri[6] further proved the equivalence between the entropy principle and the closure of the moments by the method of MEP. The kinetic foundation of EIT has been a challenging open problem, especially a complete analyis on the relation between kinetic entropy balance equation and thermodynamic entropy balance equation is still lacking in the literature.

The main objective of this paper is to investigate the relationship between the entropy balance equation (EBE) and the moment method from the standpoint of kinetic theory based on the Boltzmann equation. First we formulate the generalized problem of BE in terms of kinetic EBE and the maximum entropy principle. This generalized problem is equivalent to the Boltzmann equation if the entire set of moments are considered. We then prove that the solution of this generalized problem is unique. Next, we apply the solution of the generalized problem to EIT and prove that the thermodynamic EBE obtained by Eu is valid if and only if the one-particle distribution function is the solution of the generalized problem of BE. As a byproduct of this result we show that thermodynamic EBE is equivalent to kinetic EBE. Although there appears to be some overlaps between our work and those in Refs. 2–4 and 6, where MEP is employed to determine the structure of the one-particle distribution function in terms of the moments, however, the ultimate goal of this work is to investigate the relationship between kinetic EBE and thermodynamic EBE in terms of the thermodynamic variables via the Boltzmann equation. This problem has not yet been explored in the literature.

Consider a system of molecules in r components in a region of R^3 with volume V, where no

chemical reactions take place. Let f_a be the one-particle distribution function of species a at space–time $(\vec{r},t)$ with molecular velocity $\vec{v}_a$. The Boltzmann equation of the system can be written as

$$\partial_t f_a + \vec{v}_a \cdot \nabla f_a = \sum_b C(f_a, f_b), \tag{1}$$

where $C(f_a, f_b)$ is the Boltzmann collision integral.

In kinetic theory the entropy density S, the entropy current $\vec{J}_s$ and the entropy production σ, respectively, are defined by

$$\rho S = -\sum_a \int f_a \ [\ell n \ (f_a) - 1] \mathrm{d}\vec{v}_a = -\sum_a \langle f_a, \ \ell n \ (f_a) - 1 \rangle, \tag{2}$$

$$\vec{J}_s = -\sum_a \int f_a \vec{c}_a \ [\ell n \ (f_a) - 1] \mathrm{d}\vec{v}_a = -\sum_a \langle f_a, \vec{c}_a \ [\ell n \ (f_a) - 1] \rangle, \tag{3}$$

$$\sigma = -\sum_{a,b} \int C(f_a, f_b) \ \ell n \ (f_a) \mathrm{d}\vec{v}_a = -\sum_{a,b} \langle C(f_a, f_b), \ell n \ (f_a) \rangle, \tag{4}$$

where we have set the Boltzmann constant $k=1$, and $\vec{c}_a = \vec{v}_a - \vec{v}$ is the peculiar velocity with $\vec{v}$ as the mean velocity. Furthermore, we have adopted the notation $\langle A, B \rangle = \int AB \, \mathrm{d}\vec{v}_a$.

By (1)–(4) we can easily obtain the kinetic EBE,

$$\rho \, \mathrm{d}_t S + \nabla \cdot \vec{J}_s - \sigma = -\sum_a \langle B(f_a), \ell n \ (f_a) \rangle = 0, \tag{5a}$$

$$\sigma \geqslant 0, \tag{5b}$$

where $\mathrm{d}_t = \partial_t + \vec{v} \cdot \nabla$ is the substantial differentation, and $B(f_a) = (\partial_t + \vec{v}_a \cdot \nabla) f_a - \Sigma_b C(f_a, f_b)$. Although (5a) and (5b) are rigorous results of BE; however, they are void of thermodynamic information since S, $\vec{J}_s$, and σ are functions of $(\vec{r},t)$. In order to study irreversible thermodynamics, these quantities must be expressed as functions of the thermodynamic variables. Thus we define the following central moments of the molecular velocity $\vec{v}_a$:

$$\rho_a = \langle f_a, m_a \rangle, \quad c_a = \rho_a \rho^{-1}, \quad \rho = \sum_a \rho_a, \tag{6}$$

$$\rho \vec{v} = \sum_a \langle f_a, m_a \vec{v}_a \rangle, \tag{7}$$

$$\rho e = \sum_a \langle f_a, \tfrac{1}{2} m_a \vec{c}_a \cdot \vec{c}_a \rangle, \tag{8}$$

$$\rho \hat{\phi}^{(m)}_{a,i} = \langle f_a, h^{(m)}_{a,i} \rangle. \tag{9}$$

Here e is the internal energy density, $\{h^{(m)}_{a,i}\}$ is a set of tensor Hermite polynomials constructed by Eu.[4] Notice that $h^{(m)}_{a,i}$, $i=(i_1,\ldots,i_m)$, $1 \leqslant i_k \leqslant 3$, is a tensor of order m as well as a polynomial of degree m. Moreover, $h^{(m)}_{a,i}$ is a linear combination of the tensor Hermite polynomials $H^{(n)}_{a,i}, n \leqslant m$, constructed by Grad.[1] The detailed expressions of $H^{(m)}_{a,i}$ and $h^{(m)}_{a,i}$ can be found in Refs. 1 and 4, respectively. For simplicity, hereafter we drop the tensor index i and denote $h^{(m)}_{a,i} = h^{(m)}_a$, $\hat{\phi}^{(m)}_{a,i} = \hat{\phi}^{(m)}_a$. For future reference we set $\hat{h}^{(0)}_a = m_a$, $\hat{h}^{(m)}_a = m_a \vec{v}_a$, $\hat{h}^{(e)}_a = \frac{1}{2} m_a \vec{c}_a \cdot \vec{c}_a$, $\hat{h}^{(i)}_a$

$=h_a^{(i)}$, $i\geqslant 1$. Thus $\hat{\phi}_a^{(1)}=\vec{J}_a$ is the diffusion flux, $\hat{\phi}_a^{(2)}=\vec{\vec{\pi}}_a$ is the symmetric traceless pressure tensor, $\hat{\phi}_a^{(3)}=\vec{Q}_a$ is the heat flux, etc. We call $\hat{\phi}_a^{(i)}, i\geqslant 1$, the generalized fluxes.

In the classical theory of irreversible thermodynamics,[7] the thermodynamic states are described by the conserved variables $(e,v=\rho^{-1},c_a)$. In order to consider some nonequilibrium phenomena such as ultrasound propagation, light or neutron scattering, etc., it is necessary to include the dissipative fluxes $\hat{\phi}_a^{(i)}$ in addition to the conserved variables e,v,c_a. Let $x=\{e,v,c_a,\hat{\phi}_a^{(i)};\ 1\leqslant a\leqslant r,\ 1\leqslant i\leqslant n\}=(x^1,x^2,\ldots,x^N)$. Depending on the particular problem under consideration, n can be taken as large as necessary. Henceforth we consider x as the set of thermodynamic variables in EIT.

By the definition $B(f_a)=\partial_t f_a+\vec{v}_a\cdot\nabla f_a-\Sigma_b C(f_a,f_b)$, and (6)–(9) we can easily prove the following.

Lemma: The dynamical equations of the thermodynamical variables $x=(e,v,c_a,\hat{\phi}_a^{(k)})$ can be written as

$$\sum_a \langle B(f_a),\hat{h}_a^{(o)}\rangle=\mathrm{d}_t\rho+\rho\nabla\cdot\vec{v}=0, \tag{10}$$

$$\langle B(f_a),\hat{h}_a^{(o)}\rangle=\rho\,\mathrm{d}_t c_a+\nabla\cdot\vec{J}_a=0, \tag{11}$$

$$\sum_a \langle B(f_a),\hat{h}_a^{(m)}\rangle=\rho\,\mathrm{d}_t\vec{v}+\nabla\cdot\vec{\vec{P}}=0, \tag{12}$$

$$\sum_a \langle B(f_a),\hat{h}_a^{(e)}\rangle=\rho\,\mathrm{d}_t e+\nabla\cdot\vec{Q}+\vec{\vec{\pi}}:[\nabla\vec{v}]^{(2)}+p\nabla\cdot\vec{v}=0, \tag{13}$$

$$\langle B(f_a),\hat{h}_a^{(k)}\rangle=\rho\,\mathrm{d}_t\hat{\phi}_a^{(k)}+\nabla\cdot\Psi_a^{(k+1)}-\mathcal{Z}_a^{(k)}-\Lambda_a^{(k)}=0,\quad k\geqslant 1, \tag{14}$$

$$\mathcal{Z}_a^{(k)}=\langle f_a,(\mathrm{d}_t+\vec{c}_a\cdot\nabla)\hat{h}_a^{(k)}\rangle,\quad \Lambda_a^{(k)}=\sum_b \langle C(f_a,f_b),\hat{h}_a^{(k)}\rangle.$$

In (10)–(14), $\vec{\vec{P}}=\vec{\vec{\pi}}+p\hat{I}$ is the pressure tensor, $\hat{I}$ is the unit second order tensor, $[\nabla\vec{v}]^{(2)}$ is the traceless symmetric part of $\nabla\vec{v}$, and "$:$" denotes the scalar product of tensors. Furthermore, $\Psi_a^{(k+1)}=\langle f_a,\vec{c}_a\hat{h}_a^{(k)}\rangle$ is the flux of $\hat{\phi}_a^{(k)}$, $\mathcal{Z}_a^{(k)}$ and $\Lambda_a^{(k)}$ are the kinematic component and the collisional component of the dynamics of $\hat{\phi}_a^{(k)}$.

The proofs of (10)–(14) are cumbersome but straightforward. It should be noted that (10)–(14) do not require $B(f_a)=0$ although $B(f_a)=0$ does emerge as $k\to\infty$. This viewpoint will be further elucidated in the next section. The advantage of adopting $\hat{h}_a^{(0)},\hat{h}_a^{(m)},\hat{h}_a^{(e)}$, and $\hat{h}_a^{(k)}$ is mainly due to the fact that they are directly associated with the thermodynamic variables. Equation (14) is due to Eu, however, similar expressions have also been obtained by Jou *et al.*, and by Müller–Ruggeri.

II. FORMULATION OF THE GENERALIZED PROBLEM OF BE

In this section we formulate the generalized problem of BE. Let $R^+=[0,\infty)$, and G_1,G_2 be open subsets of the velocity space $\mathbb{R}^3$ and the spatial space $\mathbb{R}^3$, respectively. Consider $(\vec{r},t)\in G_2\times\mathbb{R}^+$ as continous parameters. Following the general theory in solving nonlinear problems in PDE's,[8] we first formulate the equivalent problem of BE as follows.

Suppose $f_a,\ \partial_t f_a,\nabla f_a\in L_2(G_1\times G_2\times\mathbb{R}^+)$. If

$$\int_{G_1} B(f_a)u(\vec{v}_a)d\vec{v}_a=\langle B(f_a),u(\vec{v}_a)\rangle=0 \tag{15a}$$

for all $u(\vec{v}_a) \in C^\infty(G_1)$, then $B(f_a)=0$ for every $(\vec{r},t)$ and a.e. for $\vec{v}_a \in G_1$. In particular, let $\{u_n\}$ be a complete orthonormal system of functions in $L_2(G_1)$. Suppose

$$\langle B(f_a), u_n \rangle = 0 \tag{15b}$$

for all n. Then $B(f_a)=0$ for every $(\vec{r},t)$.

Consider $u_n \in \{H_a^{(n)}\}_{n=0}^N$ in (15b), and set

$$f_a^N = f_a^{(0)} \sum_{n=0}^{N} \frac{1}{n!} A_a^n(\vec{r},t)\ H_a^{(n)}(\vec{v}_a),$$

where $f_a^{(0)}$ is the Maxwell Boltzmann distribution. By the orthonormality condition of $H_a^{(i)}$, $A_a^{(n)}$ can be determined by the following procedure:

$$\begin{aligned} \langle B(f_a^N), H_a^{(m)} \rangle &= 0, \quad m \leqslant N, \\ A_a^{(n)} &= 0, \quad n > N, \end{aligned} \tag{16}$$

where $A_a^{(n)}$ are functions of the thermodynamic variables. Thus Grad's moment method can be formulated as a Galerkin scheme given by (16) for any finite N.[8] It is evident that (16) yields a formal solution of BE as $N \to \infty$.

Due to the term $\ell n f_a$ in (2) and (3), it is difficult to obtain simple expressions for S, $\vec{J}_s$, and σ in terms of the thermodynamic variables. In order to overcome this difficulty we resort to the kinetic entropy balance equation (kinetic EBE) (5a) and consider

$$\langle B(f_a), \ell n f_a \rangle = 0. \tag{17}$$

Define

$$\hat{h}_a = (\hat{h}_a^{(0)}, \hat{h}_a^{(m)}, \hat{h}_a^{(e)}, \hat{h}_a^{(k)}), \quad k=1,\ 2,\ldots,n,$$

$$\lambda_a = (\lambda_a^{(0)}, \vec{\lambda}_{(m)}, \lambda_e, \lambda_a^{(k)}), \quad k=1,\ 2,\ldots,n.$$

Here $\lambda_a^{(0)}$ and λ_e are scalar functions, $\vec{\lambda}_{(m)}$ is a vector function, while $\lambda_a^{(k)}$ is a kth order tensor function. These functions are functions of $(\vec{r},t)$. We look for f_a that satisfies (17) under the constraints (6)–(9). In view of (10)–(14) we set

$$\ell n f_a = \lambda_a^{(0)} \hat{h}_a^{(0)} + \vec{\lambda}_{(m)} \cdot \hat{h}_a^{(m)} + \lambda_e \hat{h}_a^{(e)} + \sum_{k=1} \lambda_a^{(k)} : \hat{h}_a^{(k)} = \lambda_a \cdot \hat{h}_a \ \in \ \mathrm{Span}\{\hat{h}_a^{(0)}, \hat{h}_a^{(m)}, \hat{h}_a^{(e)}, \hat{h}_a^{(k)}\}_{k=1}^n. \tag{18}$$

Thus we solve (17) with $\ell n f_a$ given by (18) for appropriate choices of λ_a. Since both λ_a and $\hat{h}_a$ are linearly independent sets, by (17) we have $\langle B(f_a), \hat{h}_a \rangle = 0$. This in turn gives rise to the dynamical equations of the thermodynamic variables (10)–(14). On the other hand, λ_a can be determined by the constraint conditions (6)–(9) that maximize the entropy density function (maximum entropy principle). In analogy with Grad's moment method, we now formulate the generalized problem of BE as follows:

(i) Solve $\langle B(f_a), \ell n f_a \rangle = 0$ with $\ell n f_a$ given by (18).
(ii) Determine λ_a by the constraint conditions (6)–(9) that maximizes the entropy density function.

Notice that step (i) is equivalent to the dynamical equations (10)–(14), while step (ii) determines the structure f_a that satisfies the maximum entropy principle. Since $\{h_a^{(m)}\}$ also forms a

complete orthonormal system of functions in $L_2(G_1)$, by (15b), the solution of this generalized problem also yields a formal solution of BE as $n\to\infty$. The advantage of this method is that EBE is satisfied for any finite n. In the next section we further consider the solution of this generalized problem and its consequences.

III. RELATIONSHIP BETWEEN KINETIC EBE AND THERMODYNAMIC EBE

By (18) f_a can be expressed as

$$f_a(\vec{v}_a,\vec{r},t)=\exp\ [\lambda_a(\vec{r},t)\cdot\hat{h}_a(\vec{c}_a)-\epsilon(\vec{c}_a\cdot\vec{c}_a)^n], \tag{19}$$

where ϵ is an infinitesimal positive real number which is required to ensure that $F_a=\lim_{\epsilon\to0}\int f_a d\vec{v}_a$ is finite. Then $w_a=(F_a)^{-1}f_a$ can be considered as a probability density function. Next we determine the coefficient functions λ_a as follows:

$$\rho_a=\lim_{\epsilon\to0}\langle f_a,\hat{h}_a^{(0)}\rangle=\lim_{\epsilon\to0}\langle f_a^{(0)},\hat{h}_a^{(0)}\rangle,\quad \rho=\sum_a\ \rho_a, \tag{20a}$$

$$\rho\vec{v}=\lim_{\epsilon\to0}\sum_a\ \langle f_a,\hat{h}_a^{(m)}\rangle=\lim_{\epsilon\to0}\sum_a\ \langle f_a^{(0)},\hat{h}_a^{(m)}\rangle, \tag{20b}$$

$$\rho e=\lim_{\epsilon\to0}\sum_a\ \langle f_a,\hat{h}_a^{(e)}\rangle=\lim_{\epsilon\to0}\sum_a\ \langle f_a^{(0)},\hat{h}_a^{(e)}\rangle, \tag{20c}$$

$$\rho\hat{\phi}_a^{(k)}=\lim_{\epsilon\to0}\langle f_a,\hat{h}_a^{(k)}\rangle. \tag{20d}$$

Consequently the solution of the generalized problem of BE can be written as

$$\begin{aligned} f_a^{(M)}&=\exp\left\{(\mu_aT^{-1})\hat{h}_a^{(0)}-T^{-1}\hat{h}_a^{(e)}-\sum_{k=1}^{n}\ (X_a^{(k)}T^{-1}):\hat{h}_a^{(k)}-\epsilon(\vec{c}_a\cdot\vec{c}_a)^n\right\}\\ &=\exp\left\{-T^{-1}\left[-m_a\mu_a+\frac{1}{2}m_a\vec{c}_a\cdot\vec{c}_a+\sum_{k=1}^{n}X_a^{(k)}:\hat{h}_a^{(k)}\right]-\epsilon(\vec{c}_a\cdot\vec{c}_a)^n\right\}, \end{aligned} \tag{21}$$

where T is the local thermodynamics temperature, μ_a the chemical potential of molecular species a,[7] and $X_a^{(k)}=T^{-1}\lambda_a^{(k)}$ determined by (20d) is the generalized potential conjugate to the generalized fluxes $\hat{\phi}_a^{(k)}$. Here T, μ_a and $X_a^{(k)}$ are now functions of the thermodynamic variables that are governed by (10)–(14).

In terms of $f_a^{(M)}$ and the definitions of the entropy density function as well as the entropy current function, we have

$$S_M=T^{-1}\left[e+p\nu-\sum_a\ \mu_ac_a+\sum_k\ X_a^{(k)}:\hat{\phi}_a^{(k)}\right]+0(\epsilon), \tag{22a}$$

$$\vec{J}_M=T^{-1}\left[\vec{Q}-\sum_a\ \mu_a\vec{J}_a+\sum_k\ X_a^{(k)}\cdot\Psi_a^{(k+1)}\right]+0(\epsilon)=T^{-1}\vec{Q}_c+0(\epsilon). \tag{22b}$$

Since the term $0(\epsilon)$ does not contain any physical significance, hereafter we drop this term for simplicity. In general it is rather difficult to find exact solutions for $X_a^{(k)}$ from (22d),[9] however, approximate solutions for $X_a^{(k)}$ can be found in Refs. 2–4. It is well known in probability theory that different probability density functions can have the same set of moments. Thus it is inappropriate to find $X_a^{(k)}$ via $A_a^{(k)}$ in (16).[10]

The exponential form of $f_a^{(M)}$ in (21) has been proposed by Eu. Similar expression of $f_a^{(M)}$ has also been proposed by Müller–Ruggeri. As S_M and $\vec{J}_M$ are functions of the thermodynamic variables, we call S_M and $\vec{J}_M$ the thermodynamic entropy density function and entropy current function, respectively.[11] Now we prove that $f_a^{(M)}$ is the unique solution of the generalized problem of BE. To this end, we assume that f_a is another one-particle distribution function that satisfies (17) and (6)–(9). With the aid of the inequality $\ell n \mathcal{Z} \leqslant \mathcal{Z}-1$, we can easily prove

$$\begin{aligned}\rho S-\rho S_M &= -\sum_a \langle f_a, \ell n f_a - 1\rangle + \lim_{\epsilon\to 0}\sum_a \langle f_a^{(M)}, \ell n f_a^{(M)} - 1\rangle \\ &= \lim_{\epsilon\to 0}\sum_a \left\{ \int f_a \ell n\left(\frac{f_a^{(M)}}{f_a}\right) \mathrm{d}\vec{v}_a + \int (f_a - f_a^{(M)})\mathrm{d}\vec{v}_a \right\} \\ &\leqslant \lim_{\epsilon\to 0}\sum_a \int [(f_a^{(M)} - f_a) + (f_a - f_a^{(M)})]\ \mathrm{d}\vec{v}_a = 0,\end{aligned}$$

where equality holds if and only if $f_a = f_a^{(M)}$. Therfore, among all f_a's that satisfy (17) and the constraint conditions (6)–(9), $f_a^{(M)}$ is the unique one-particle distribution function that maximizes the entropy density function.

Theorem 1: The solution of the generalized problem of the Boltzmann equation is uniquely given by (21).

Next we consider the thermodynamics EBE. By (22b) and the dynamical equations of the thermodynamic variables x in (10)–(14), we can obtain the following equation:[4]

$$\rho T^{-1}\left\{ \mathrm{d}_t e + p\,\mathrm{d}_t \nu - \sum_a \mu_a \mathrm{d}_t c_a + \sum_{a,k} X_a^{(k)} : \mathrm{d}_t \hat{\phi}_a^{(k)} \right\} + \nabla\cdot\vec{J}_M = \Sigma_M, \tag{23a}$$

$$\begin{aligned}\Sigma_M = -T^{-1}\Big\{ &\vec{Q}_c\cdot\nabla \ell n T + \vec{\vec{\pi}} : [\nabla\vec{v}]^{(2)} + \sum_a \vec{J}_a\cdot\nabla\mu_a \\ &- \sum_{a,k} \Psi_a^{(k+1)}\cdot(\nabla X_a^{(k)}) - \sum_{a,k} X_a^{(k)} : (\mathcal{Z}_a^{(k)} + \Lambda_a^{(k)}) \Big\}.\end{aligned} \tag{23b}$$

In order to identify (23a) with thermodynamic EBE and Σ_M with thermodynamic entropy production, we follow the method by Müller–Ruggeri and consider the inequality

$$\rho\,\mathrm{d}_t S_M + \nabla\cdot\vec{J}_M \geqslant 0. \tag{24}$$

The minimization of (24) can be carried out by introducing a function $\Sigma \geqslant 0$ subject to the constraint conditions (10)–(14). Then we have

$$\begin{aligned}\rho\,\mathrm{d}_t S_M + \nabla\cdot\vec{J}_M - \Big\{ \Sigma - \sum_a \alpha_a(\rho\,\mathrm{d}_t c_a + \nabla\cdot\vec{J}_a) - \vec{\alpha}_m\cdot(\rho\,\mathrm{d}_t\vec{v} + \nabla\cdot\vec{\vec{P}}) - \alpha_e(\rho\,\mathrm{d}_t e + \rho p\,\mathrm{d}_t\nu + \nabla\cdot\vec{Q} \\ + \vec{\vec{\pi}} : [\nabla\vec{v}]^{(2)}) - \sum_{a,k} \alpha_a^{(k)} : (\rho\,\mathrm{d}_t\hat{\phi}_a^{(k)} + \nabla\cdot\Psi_a^{(k+1)} - \mathcal{Z}_a^{(k)} - \Lambda_a^{(k)}) \Big\} = 0,\end{aligned} \tag{25a}$$

where α_a, $\vec{\alpha}_m$, α_e, and $\alpha_a^{(k)}$ are Lagrange multipliers. On the other hand, (25a) can be recast as

$$\rho\,\mathrm{d}_t S_M + \nabla\cdot\vec{J}_M - \Sigma = -\sum_a \int B(f_a)\left\{ \alpha_a\hat{h}_a^{(0)} + \vec{\alpha}_m\cdot\ \hat{h}_a^{(m)} + \alpha_e\hat{h}_a^{(e)} + \sum_k \alpha_a^{(k)} :\ \hat{h}_a^{(k)} \right\} \mathrm{d}\vec{v}_a = 0. \tag{25b}$$

But the right-hand side of (25b) is the same as (17) with $\ell n f_a = \hat{\alpha}_a \cdot \hat{h}_a$, $\hat{\alpha}_a = (\alpha_a, \vec{\alpha}_m, \alpha_e, \alpha_a^{(k)})$. By (20a)–(20d) we obtain $\alpha_a = \mu_a T^{-1}$, $\vec{\alpha}_m = 0$, $\alpha_e = -T^{-1}$, and $\alpha_a^{(k)} = -T^{-1} X_a^{(k)}$. Henceforth $\Sigma_M = \Sigma \geqslant 0$, $\vec{J}_M = T^{-1} \vec{Q}_c$, and the evolution of S_M is given by

$$T\, \mathrm{d}_t S_M = \mathrm{d}_t e + p\, \mathrm{d}_t \nu - \sum_a \mu_a \mathrm{d}_t c_a + \sum_{a,k} X_a^{(k)} : \mathrm{d}_t \hat{\phi}_a^{(k)}, \tag{26a}$$

that can be transformed into the well-known Gibbs one-form[2–4]

$$T\, \mathrm{d}S = \mathrm{d}e + p\, \mathrm{d}\nu - \sum_a \mu_a\, \mathrm{d}c_a + \sum_{a,k} X_a^{(k)} : \mathrm{d}\hat{\phi}_a^{(k)}. \tag{26b}$$

Therefore, if $f_a = f_a^{(M)}$, then thermodynamic EBE is given by (23a) and (23b). For the converse, assume (23a) and (23b). Then $f_a = f_a^{(M)}$ follows from (24), (25a), and (25b).

Theorem 2: The thermodynamic entropy balance equation $\rho\, \mathrm{d}_t S_M + \nabla \cdot \vec{J}_M - \Sigma_M = 0$ with $\Sigma_M \geqslant 0$ is given by (23a) and (23b) if and only if f_a is the solution of the generalized problem of the Boltzmann equation.

As a consequence of (25b) and Theorem 2 we have the following.

Corollary: The statistical expression of the thermodynamic entropy balance equation is given by

$$\rho\, \mathrm{d}_t S_M + \nabla \cdot \vec{J}_M - \Sigma_M = -\sum_a \langle B(f_a^M),\ \ell n(f_a^M) \rangle = 0.$$

In other words, thermodynamic EBE and kinetic EBE share the same microscopic formula.

We could have obtained the thermodynamic EBE (23a) from (22a) in conjunction with the dynamical equations of the thermodynamic variables (10)–(14). However this approach relies on finding the integral manifold of the Pfaffian equation $\xi = 0$ under the inaccessibility condition $\xi \Lambda d\xi = 0$,[12] where

$$\xi = \mathrm{d}e + p\, \mathrm{d}\nu - \sum_a \mu_a\, \mathrm{d}c_a + \sum_{a,k} X_a^{(k)} : \mathrm{d}\hat{\phi}_a^{(k)}.$$

Finally we examine the relationship between σ and Σ_M. By (23b) it is evident that Σ_M contains σ as well as other dissipative energies attributable to the dynamics of the moments via the evolution equations (10)–(14). On the other hand, molecular collisions are the only contributor of σ. Therefore Σ_M cannot be obtained from (4) by direct substitution of $f_a = f_a^{(M)}$.

IV. CONCLUSION

Extended irreversible thermodynamics is a phenomenological science. The foundation of EIT constructed by Jou *et al.* and by Müller–Ruggeri is based on the exploitation of the thermodynamic entropy balance equation, while the theory of EIT developed by Eu is based on the modified moment method closely related to the theory of Grad. According to Jou *et al.* and Müller–Ruggeri, the dynamical equations of the moments are constructed such that the thermodynamic EBE is satisified. In the meanwhile, the statistical foundation of the theory is based on the maximum entropy principle that determines the structure of the one-particle distribution function in terms of the moments. Following the general theory in solving nonlinear problems in PDEs, first we formulate the generalized problem of the Boltzmann equation in terms of kinetic EBE in conjunction with the maximum entropy principle. This generalized problem ultimately gives rise to a formal solution of the Boltzmann equation if the entire set of moments are considered. Notice that there are many different f_a's that satisfy the kinetic entropy balance equation (5a). However the maximum entropy principle can be satisfied if and only if $f_a = f_a^{(M)}$. Thus the solution of the generalized problem of BE is uniquely given by (21). We then apply this result to EIT and prove

that thermodynamic EBE given by (23a) and (23b) holds if and only if f_a is the solution of the generalized problem of the Boltzmann equation. As a byproduct of Theorem 2 we obtain a statistical expression of thermodynamic EBE that shares the same formula as the kinetic EBE in (5a). In other words, kinetic EBE is equivalent to thermodynamic EBE if and only if $f_a = f_a^{(M)}$.

(Received 18 November 2002; accepted 21 July 2003)

We derive the stochastic dynamics of the complex valued amplitude resulting from coherent scattering from a random population of scatterers when this becomes asymptotically large. Considerations of a random walk model, introduced by Jakeman, are used to derive stochastic differential equations for the amplitude and corresponding intensity and phase stochastic processes. An analysis of the correlation structure in the fluctuations is provided and interpreted geometrically in terms of the gauge invariant properties of the field and the Markov property. A Fokker–Planck description for the evolution of the probability density is given and the equilibrium and detailed balance conditions shown to hold. Expressions for the intensity autocorrelation function and power spectral density are provided in closed form. The practical implications of the stochastic theory are discussed. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1611264]

I. INTRODUCTION

Recent developments in the diffusion based analysis of scattering from random media, reported in Field and Tough (2003), have led to significant results that enable the identification of *K*-distributed noise processes in electromagnetic scattering. The results comprise various stochastic differential equations (SDEs) for the scattered amplitude, intensity, phase and scattering cross section motivated by a combination of theoretical considerations and analysis of empirical data.

The purpose of the present paper is to formulate the stochastic dynamics of the electromagnetic field, scattered from a random medium that consists of a collection of independent component scatterers, whose population size has fluctuations in accordance with the birth–death–immigration (BDI) model (Bartlett, 1966). This is achieved from first principles via considerations of the complex random walk model introduced by Jakeman (Jakeman, 1980). Our results thus provide the theoretical foundation of the anomaly detection technique reported earlier (Field and Tough, 2003), and extend the model to include a detailed description of the intensity autocorrelation function and power spectral density.

The paper is organized as follows. Section II begins with a derivation of the complex amplitude SDE in the case of a constant scattering cross section, i.e., Rayleigh scattering, from considerations of a complex random walk model, and extends this to the *K*-distributed case via the insertion of step number fluctuations. The resulting SDE for the amplitude process is used to derive corresponding SDEs for the intensity and phase processes, and expressions for the squared volatilities of each of these processes are provided. This framework is used to explain the geometrical structure of the correlations in the fluctuations of the complex amplitude.

In Sec. III we provide a Fokker–Planck description for the joint probability density of the scattering cross section and intensity processes and study the asymptotic behavior. It is verified that the model possesses the joint probability appropriate to the *K*-distribution, and that the condition for detailed balance is also satisfied.

Section IV provides a detailed analysis of the finite-time correlation properties of the stochastic model. The Green's functions arising from the Fokker–Planck description are computed and

expressions for the intensity autocorrelation function and power spectral density are provided in closed form. We conclude in Sec. V with an account of the interpretation and practical implications of the theoretical framework proposed.

II. STOCHASTIC DYNAMICS OF AMPLITUDE PROCESS

A. Amplitude

We develop the random walk model with step number fluctuations due to Jakeman (see Jakeman, 1980; Jakeman and Tough, 1988) as a continuous time diffusion process. It is shown in the Rayleigh case of a fixed step number that the amplitude obeys a complex Ornstein–Uhlenbeck equation, and a corresponding SDE in the K-distributed case is derived.

1. Rayleigh scattering

In the Rayleigh case consider the random walk model for the scattered electric field (cf. Jakeman, 1980; Tough, 1987; Jakeman and Tough, 1988),

$$\mathcal{E}_t^{(N)} = \sum_{j=1}^{N} \exp[i\varphi_t^{(j)}] \tag{2.1}$$

for constant population size N. Since Maxwell's equations for the electromagnetic field possess U(1) gauge invariance with respect to duality rotations, i.e., multiplication by $\exp(i\Lambda)$ for constant Λ (cf. Penrose and Rindler, 1984), the assumption of independence of $\{\varphi^{(j)}\}$ implies that these phases are uniformly distributed. Accordingly in (2.1) the phase factors $\{\exp[i\varphi_t^{(j)}]\}$ are independent and uniformly distributed on the unit circle in $\mathbb{C}$. Our (phase) diffusion model therefore takes $\{\varphi_t^{(j)}\}$ as a collection of (displaced) Wiener processes on a suitable time scale, $\varphi_t^{(j)} = \Delta^{(j)} + \mathcal{B}^{1/2} W_t^{(j)}$, with the random initializations $\{\Delta^{(j)}\}$ a set of independent random variables uniformly distributed on the interval $[0,2\pi)$, and thus $\mathrm{d}\varphi_t^{(j)} = \mathcal{B}^{1/2}\,\mathrm{d}W_t^{(j)}$, $\mathrm{d}\varphi_t^{(j)2} = \mathcal{B}\,\mathrm{d}t$. From Ito's formula (e.g., Oksendal, 1998; Karatzas and Shreve, 1988) the Ito differential of (2.1) is

$$\mathrm{d}\mathcal{E}_t^{(N)} = \sum_{j=1}^{N} \left(i\,\mathrm{d}\varphi_t^{(j)} - \frac{1}{2}\,\mathrm{d}\varphi_t^{(j)2} \right) \exp[i\varphi_t^{(j)}]. \tag{2.2}$$

The first term $\Sigma_{j=1}^{N} i\,\mathrm{d}\varphi_t^{(j)} \exp[i\varphi_t^{(j)}]$ on the right-hand side of (2.2) consists of a sum of independent randomly phased Wiener processes, with variance equal to $\mathcal{B}N\,\mathrm{d}t$, while the second term is independent of the scatterer label j. Thus from (2.2) we can write

$$\mathrm{d}\mathcal{E}_t^{(N)} = -\tfrac{1}{2}\mathcal{B}\mathcal{E}_t^{(N)}\,\mathrm{d}t + (\mathcal{B}N)^{1/2}\,\mathrm{d}\xi_t, \tag{2.3}$$

where ξ_t is a complex Wiener process satisfying $|\mathrm{d}\xi_t|^2 = \mathrm{d}t$, $\mathrm{d}\xi_t^2 = 0$. The process ξ_t is adapted to the filtration $\mathcal{F}^{(\varphi)} = \cup_j \mathcal{F}^{(j)}$, where $\mathcal{F}^{(j)}$ is the filtration appropriate to the component scatterer phase $\varphi_t^{(j)}$. The amplitude process Ψ_t is then defined by $\Psi_t = \lim_{N\to\infty}[\mathcal{E}_t^{(N)}/\overline{N}^{1/2}]$ and satisfies the SDE,

$$\mathrm{d}\Psi_t = -\tfrac{1}{2}\mathcal{B}\Psi_t\,\mathrm{d}t + (\mathcal{B}x)^{1/2}\,\mathrm{d}\xi_t, \tag{2.4}$$

where the continuous valued random variable x, the average scattering power, arises from an asymptotically large population via $x = \lim_{N\to\infty}[N/\overline{N}]$.

2. K-distributed noise

In the case of step number fluctuations in the random walk model (2.1), we define the amplitude Ψ_t in a similar manner to the Rayleigh case above, with the modification that we employ a time dependent N_t such that $x_t = \lim_{N_t\to\infty}[N_t/\overline{N}]$. Thus

$$\Psi_t = \lim_{N_t\to\infty}\left\{\frac{1}{\overline{N}^{1/2}}\sum_{j=1}^{N_t}\exp[i\varphi_t^{(j)}]\right\} \tag{2.5}$$

$$= \lim_{N_t\to\infty}\left\{\left(\frac{N_t}{\overline{N}}\right)^{1/2}\frac{1}{N_t^{1/2}}\sum_{j=1}^{N_t}\exp[i\varphi_t^{(j)}]\right\} \tag{2.6}$$

$$= x_t^{1/2}\gamma_t, \tag{2.7}$$

where $\gamma_t = \lim_{N\to\infty}[\mathcal{E}_t^{(N_t)}/N_t^{1/2}]$. According to the arguments given in the Rayleigh case above, γ_t is a complex Ornstein–Uhlenbeck process which obeys the SDE

$$\mathrm{d}\gamma_t = -\tfrac{1}{2}\mathcal{B}\gamma_t\,\mathrm{d}t + \mathcal{B}^{1/2}\,\mathrm{d}\xi_t. \tag{2.8}$$

Observe from (2.4), therefore, that γ_t is a unit power Rayleigh process. The above equation for γ_t can be solved by considering the stochastic differential $\mathrm{d}[\exp(\frac{1}{2}\mathcal{B}t)\gamma_t]$, which leads to the solution

$$\gamma_t = \exp\left(-\frac{1}{2}\mathcal{B}t\right)\left\{\gamma_0 + \mathcal{B}^{1/2}\int_0^t \exp\left(\frac{1}{2}\mathcal{B}s\right)\mathrm{d}\xi_s\right\}. \tag{2.9}$$

We deduce the expectation formulas

$$\mathbb{E}[\gamma_t] = \exp(-\tfrac{1}{2}\mathcal{B}t)\gamma_0, \tag{2.10}$$

$$\mathbb{E}[|\gamma_t|^2] = 1 + \exp(-\mathcal{B}t)(|\gamma_0|^2 - 1). \tag{2.11}$$

From (2.11) it follows that $\lim_{t\to\infty}\mathbb{E}[|\gamma_t|^2] = 1$ and so from (2.7) we find the intensity process, defined by $z_t = |\Psi_t|^2$, satisfies $\mathbb{E}[z_t] = x_t$. The SDE for Ψ_t, as determined by (2.7), can now be derived, via the Ito product formula $\mathrm{d}(X_tY_t) \equiv X_t\,\mathrm{d}Y_t + Y_t\,\mathrm{d}X_t + \mathrm{d}X_t\,\mathrm{d}Y_t$. For this purpose it is convenient to introduce the square-root cross section $r_t = x_t^{1/2}$ and thus, from (2.7), we find $\mathrm{d}\Psi_t = r_t\,\mathrm{d}\gamma_t + \gamma_t\,\mathrm{d}r_t$. Observe that the cross term $\mathrm{d}r_t\,\mathrm{d}\gamma_t$ does not feature in this relation owing to the independence of $W_t^{(x)}$ and $\xi_t^{(\varphi)}$, which originate from the intrinsic scattering population and the scattered electromagnetic field, respectively.

The BDI model (Bartlett, 1966) posits a first order master equation for the population N_t, with respective generation and recombination rates $G = \lambda N + \nu$, $R = \mu N$. For an asymptotically large population, $N\to\infty$, we deduce (Tough, 1987; Jakeman and Tough, 1988; Field and Tough, 2003) that the re-scaled population variate $x \mapsto \alpha x$ satisfies the SDE

$$\mathrm{d}x_t = \mathcal{A}(\alpha - x_t)\mathrm{d}t + (2\mathcal{A}x_t)^{1/2}\,\mathrm{d}W_t^{(x)} \tag{2.12}$$

for an independent Wiener process $W_t^{(x)}$, where $\alpha = \nu/\lambda$. This leads to the asymptotic Γ-distribution for x_t,

$$\Gamma_\alpha(x) = \frac{x^{\alpha-1}\exp(-x)}{\Gamma(\alpha)}, \tag{2.13}$$

so that $\mathrm{Var}[x] = \langle x\rangle = \alpha$. From Ito's formula applied to $r_t = x_t^{1/2}$ we find $\mathrm{d}r_t = \mathrm{d}x_t/2x_t^{1/2} - \mathrm{d}x_t^2/8x_t^{3/2}$, and thus from (2.12),

$$\mathrm{d}r_t = \mathcal{A}\left(\frac{2(\alpha - x_t) - 1}{4r_t}\right)\mathrm{d}t + \left(\frac{\mathcal{A}}{2}\right)^{1/2}\mathrm{d}W_t^{(x)}. \tag{2.14}$$

This leads to the following result.

Proposition 2.1: In the K-distributed case the scattered amplitude is governed by the SDE,

$$\frac{d\Psi_t}{\Psi_t} = -\frac{1}{2}\mathcal{B}\,dt + \frac{\mathcal{B}^{1/2}}{\gamma_t}d\xi_t + \mathcal{A}\left(\frac{2(\alpha - x_t) - 1}{4x_t}\right)dt + \left(\frac{\mathcal{A}}{2x_t}\right)^{1/2} dW_t^{(x)}. \tag{2.15}$$

This evolution is invariant under the U(1) gauge transformation $\Psi_t \mapsto \exp(i\Lambda)\Psi_t$*, for constant* Λ.

In the above expression $\mathcal{A}$ and $\mathcal{B}$ are independent constants with the dimension of frequency. In most situations of interest, however, such as those reported in Field and Tough (2003), the wavelength of the illuminating radiation is such that the two corresponding reciprocal correlation time scales satisfy $\mathcal{A}^{-1} \gg \mathcal{B}^{-1}$. The description of Rayleigh scattering (i.e., constant scattering cross section) is recovered when $\mathcal{A} = 0$. Proposition 2.1 implies the following result.

Corollary 2.2: The squared volatility of the amplitude process Ψ_t *is given by*

$$|d\Psi_t|^2 = \left(\mathcal{B}x_t + \frac{\mathcal{A}z_t}{2x_t}\right)dt. \tag{2.16}$$

It is the *linearity* of the right-hand side above in z_t that enables the anomaly detection mechanism, reported in Field and Tough (2003).

B. Intensity

The stochastic differential of the intensity process z_t can be expressed in terms of the amplitude via the identity

$$dz_t = \Psi_t^*\, d\Psi_t + \Psi_t\, d\Psi_t^* + |d\Psi_t|^2 \tag{2.17}$$

which follows from $z_t = |\Psi_t|^2$. From (2.8) we find

$$\begin{aligned}\Psi_t^*\, d\Psi_t + \Psi_t\, d\Psi_t^* &= x_t(\gamma_t^*\, d\gamma_t + \gamma_t\, d\gamma_t^*) + 2|\gamma_t|^2 r_t\, dr_t \\ &= -\mathcal{B}z_t\, dt + \mathcal{B}^{1/2}x_t(\gamma_t^*\, d\xi_t + \gamma_t\, d\xi_t^*) + \frac{2z_t}{r_t}dr_t.\end{aligned} \tag{2.18}$$

The terms involving $d\xi_t$ above can be combined in terms of a real-valued Wiener process $W_t^{(\varphi)}$ according to

$$\gamma_t^*\, d\xi_t + \gamma_t\, d\xi_t^* \equiv \left(\frac{2z_t}{x_t}\right)^{1/2} dW_t^{(\varphi)}. \tag{2.19}$$

We deduce from (2.16), (2.17), (2.18) that

$$dz_t = -\mathcal{B}z_t\, dt + (2\mathcal{B}z_t x_t)^{1/2}\, dW_t^{(\varphi)} + \frac{2z_t}{r_t}dr_t + \left(\mathcal{B}x_t + \frac{\mathcal{A}z_t}{2x_t}\right)dt. \tag{2.20}$$

In combination with (2.14) this leads to the following result.

Proposition 2.3: The intensity SDE is given by

$$dz_t = \left[\mathcal{B}(x_t - z_t) + \frac{\mathcal{A}z_t(\alpha - x_t)}{x_t}\right]dt + \left(2\mathcal{B}x_t z_t + \frac{2\mathcal{A}z_t^2}{x_t}\right)^{1/2} dW_t^{(z)} \tag{2.21}$$

in which $W_t^{(z)}$ *is correlated with* $W_t^{(x)}$ *of (2.12), and satisfies*

$$\left(\mathcal{B}x_t z_t + \frac{\mathcal{A}z_t^2}{x_t}\right)^{1/2} dW_t^{(z)} = (\mathcal{B}x_t z_t)^{1/2}\, dW_t^{(\varphi)} + \left(\frac{\mathcal{A}}{x_t}\right)^{1/2} z_t\, dW_t^{(x)}. \tag{2.22}$$

The filtration of $W_t^{(\varphi)}$ arises from the constituent phases $\varphi_t^{(j)}$ in the random walk according to (2.19), while that of $W_t^{(x)}$ stems solely from the fluctuations in the endogenously specified population model. Observe that, if $\mathcal{B}=0$, (2.22) implies $W^{(z)}=W^{(x)}$, and from (2.8) γ_t is constant, so $|\gamma_t|^2=\mathbb{E}[|\gamma_t|^2]=1$. Accordingly $z_t=x_t$ is a solution of (2.21), as required by (2.7). From Proposition 2.3 we obtain the following result.

Corollary 2.4: The squared intensity volatility is determined by

$$\mathrm{d}z_t^2=\left(2\mathcal{B}x_tz_t+\frac{2\mathcal{A}z_t^2}{x_t}\right)\mathrm{d}t. \tag{2.23}$$

Alternatively, in terms of the amplitude process Ψ_t, the squared volatility in the intensity z_t can be expressed as

$$\mathrm{d}z_t^2\equiv\Psi_t^2\,\mathrm{d}\Psi_t^{*2}+\Psi_t^{*2}\,\mathrm{d}\Psi_t^2+2z_t|\mathrm{d}\Psi_t|^2 \tag{2.24}$$

which, from (2.15), leads to the above expression for $\mathrm{d}z_t^2$. Observe that for $\mathcal{A}\ll\mathcal{B}$ the dominant contribution to the squared intensity volatility is proportional to the instantaneous value of the intensity. Thus for a Rayleigh time scale $\mathcal{B}^{-1}$, over which x_t remains approximately constant, the time series data for $\mathrm{d}z_t^2$ and z_t should exhibit strong correlation. This feature has been experimentally verified in a case of optical scattering, and is reported in Sec. IV A of Field and Tough (2003).

In terms of the square-root intensity $R_t=\sqrt{z_t}$ an application of Ito's formula to (2.23) yields the following result.

Corollary 2.5: The squared volatility in the modulus amplitude is determined by

$$\mathrm{d}R_t^2=\frac{1}{2}\left(\mathcal{B}x_t+\frac{\mathcal{A}z_t}{x_t}\right)\mathrm{d}t. \tag{2.25}$$

C. Phase

The complex amplitude process can be expressed in polar form $\Psi_t=R_t\exp(i\theta_t)$ and thus, writing $i\,\theta_t=\log(\Psi_t/R_t)$, we deduce from Ito's formula that

$$i\,\mathrm{d}\theta_t=\frac{\mathrm{d}\Psi_t}{\Psi_t}-\frac{1}{2}\left(\frac{\mathrm{d}\Psi_t}{\Psi_t}\right)^2-\frac{\mathrm{d}R_t}{R_t}+\frac{1}{2}\left(\frac{\mathrm{d}R_t}{R_t}\right)^2. \tag{2.26}$$

Since the left-hand side is purely imaginary we can express $\mathrm{d}\theta_t$ in terms of Ψ_t alone as

$$\mathrm{d}\theta_t=\frac{1}{2i}\left[\left(\frac{\mathrm{d}\Psi_t}{\Psi_t}-\frac{1}{2}\left(\frac{\mathrm{d}\Psi_t}{\Psi_t}\right)^2\right)-\left(\frac{\mathrm{d}\Psi_t^*}{\Psi_t^*}-\frac{1}{2}\left(\frac{\mathrm{d}\Psi_t^*}{\Psi_t^*}\right)^2\right)\right]. \tag{2.27}$$

Accordingly, the squared phase volatility is determined by the identity

$$\mathrm{d}\theta_t^2\equiv\frac{|\mathrm{d}\Psi_t|^2}{2z_t}-\frac{\mathrm{d}\Psi_t^2}{4\Psi_t^2}-\frac{\mathrm{d}\Psi_t^{*2}}{4\Psi_t^{*2}}. \tag{2.28}$$

From (2.15) we have

$$\frac{\mathrm{d}\Psi_t}{\Psi_t}-\frac{1}{2}\left(\frac{\mathrm{d}\Psi_t}{\Psi_t}\right)^2=\left(\frac{\mathcal{A}(\alpha-x_t-1)}{2x_t}-\frac{1}{2}\mathcal{B}\right)\mathrm{d}t+\left(\frac{\mathcal{A}}{2x_t}\right)^{1/2}\mathrm{d}W_t^{(x)}+\frac{\mathcal{B}^{1/2}}{\gamma_t}\mathrm{d}\xi_t. \tag{2.29}$$

Hence, from (2.27), θ_t obeys the SDE,

$$\mathrm{d}\theta_t=\frac{\mathcal{B}^{1/2}}{2i|\gamma_t|^2}(\gamma_t^*\,\mathrm{d}\xi_t-\gamma_t\,\mathrm{d}\xi_t^*). \tag{2.30}$$

As in the derivation of the SDE for the intensity, we can express the terms involving ξ_t in (2.30) as a distinct real-valued Wiener process $W_t^{(\theta)}$ according to

$$\frac{1}{2i}(\gamma_t^* \, \mathrm{d}\xi_t - \gamma_t \, \mathrm{d}\xi_t^*) \equiv \left(\frac{z_t}{2x_t}\right)^{1/2} \mathrm{d}W_t^{(\theta)}. \tag{2.31}$$

Thus we obtain the following result.

Proposition 2.6: The total phase θ_t of the complex amplitude process Ψ_t obeys the SDE,

$$\mathrm{d}\theta_t = \left(\frac{\mathcal{B}x_t}{2z_t}\right)^{1/2} \mathrm{d}W_t^{(\theta)}, \tag{2.32}$$

which has vanishing drift.

The result has the following consequence.

Corollary 2.7: The squared total phase volatility is given by

$$\mathrm{d}\theta_t^2 = \frac{\mathcal{B}x_t}{2z_t}\mathrm{d}t. \tag{2.33}$$

Alternatively (2.33) can be derived by applying (2.28) to (2.15). This result accords with the general scaling and symmetry arguments for the behavior of the squared phase volatility put forward in Sec. IV of Field and Tough (2003). The situation should be contrasted with the differentiable model for the process Ψ_t (Jakeman *et al.*, 2001) for which the intensity-weighted phase derivative, instead of its square, has minimal variance.

These relations lead to expressions for the frequency constants $\mathcal{A}$, $\mathcal{B}$ as follows. With respect to an average over the phase fluctuations $\mathrm{d}\varphi_t^{(j)}$ there exists a *residual constant term* in the squared phase volatility, i.e.,

$$\mathbb{E}[\mathrm{d}\theta_t^2/\mathrm{d}t|\mathcal{F}^{(\varphi)}] = \tfrac{1}{2}\mathcal{B}. \tag{2.34}$$

In principle this enables the Rayleigh constant $\mathcal{B}$ to be deduced from scattering data (alternatively an estimate of the Rayleigh correlation time scale $\mathcal{B}^{-1}$ can be found from measuring the time difference between successive peaks in the intensity time series data $\{z_t\}$). Expression (2.33) implies that $x_t = 2\mathcal{B}^{-1} z_t \, \mathrm{d}\theta_t^2/\mathrm{d}t$ and so the instantaneous values of the cross section x_t (and therefore r_t) are observable through the squared phase fluctuations. Consequently, the constant $\mathcal{A}$ can be deduced from the phase fluctuations through the square of (2.14),

$$\frac{\mathrm{d}r_t^2}{\mathrm{d}t} = \frac{1}{2}\mathcal{A}. \tag{2.35}$$

(Cf. Sec. III in Field and Tough, 2003, for an account of the observability of the squared volatilities for discretely sampled time series data.)

D. Correlation of fluctuations

The stochastic dynamics presented in Proposition 2.1 enable one to deduce the correlation structure in the fluctuations of the complex amplitude process Ψ_t.

A geometric insight into these properties can be gained from the symmetry properties of the process Ψ_t. Proposition 2.1 shows that the SDE for Ψ_t is invariant under the U(1) gauge transformation $\Psi_t \mapsto \exp(i\Lambda)\Psi_t$. Since the drift in (2.15) is real valued, the identity (2.27) implies that θ_t has vanishing drift, as seen explicitly from Proposition 2.6. The resulting asymptotic probability distribution is therefore U(1) symmetric.

In respect of time evolution, the SDE (2.15) has the Markov property, that the evolution it determines depends on the instantaneous value of Ψ_t and is independent of the history of the

process $\{\Psi_{t'}|t'<t\}$. This feature yields a preferred symmetry, namely the instantaneous radial direction determined by Ψ_t. The diffusion tensor σ^{ij}, determined by $d\Psi^i\, d\Psi^j=\sigma^{ij}\, dt$ is real and symmetric and therefore diagonalizes over $\mathbb{C}$. In the nondegenerate case its eigenvectors constitute a unique orthogonal pair corresponding to the directions in which the component Wiener increments are independent. On grounds of the above symmetry we anticipate that the space of eigendirections contains the instantaneous radial (and attendant orthogonal θ) direction. This geometrical property can be verified explicitly from (2.19), (2.22), and (2.31), which imply the following.

Proposition 2.8: The cross-correlation between $W_t^{(z)}$, $W_t^{(\theta)}$ vanishes identically, i.e., $dW_t^{(z)}\, dW_t^{(\theta)}=0$. Correspondingly $dR_t\, d\theta_t=0$, i.e., the fluctuations in R_t, θ_t are statistically independent.

In terms of the I,Q component representation the coordinate transformations $I=R\cos\theta$, $Q=R\sin\theta$ and the property $dR_t\, d\theta_t=0$ imply the geometric relation

$$dI_t\, dQ_t=\cos\theta_t\sin\theta_t(dR_t^2-R_t^2\, d\theta_t^2). \tag{2.36}$$

This leads to the following result.

Proposition 2.9: The I_t, Q_t components of Ψ_t are independent if and only if $\sigma_{(R)}=R\sigma_{(\theta)}$, i.e., $\sigma_{(z)}=2z\sigma_{(\theta)}$. A departure from this relation induces a correlation between the Wiener increments in I_t, Q_t.

Alternatively, this result can be derived using the contravariance of the diffusion tensor σ^{ij}, which enables one to translate between its I,Q and R,θ components via the above coordinate transformation (e.g., Risken, 1989). In the general case we find from (2.23), (2.33) that

$$\frac{\sigma_{(z)}^2}{\sigma_{(\theta)}^2}=4z^2+\frac{4\mathcal{A}z^3}{\mathcal{B}x^2}. \tag{2.37}$$

This relation can be used to characterize the geometry of the fluctuations as follows.

Proposition 2.10: In the K-distributed case, $\mathcal{A}\neq 0$, the diffusion tensor is nondegenerate, and the fluctuations δI_t, δQ_t are correlated. The (comoving) error surface S of $\delta\Psi_t$, defined by the quadratic form $\sigma^{II}\delta I_t^2+2\sigma^{IQ}\delta I_t\delta Q_t+\sigma^{QQ}\delta Q_t^2=1$, is an ellipse whose major axis lies in the instantaneous radial direction defined by Ψ_t. Degeneracy occurs only in the Rayleigh case, $\mathcal{A}=0$, for which S is a circle, i.e., the fluctuations in Ψ_t are isotropic.

We remark in general that the random variables I_t, Q_t possess a joint probability distribution that is U(1) symmetric, i.e., given by a surface of revolution about the perpendicular axis to the origin in the I,Q-plane. Nevertheless I_t, Q_t are correlated in general, and become independent only in the Rayleigh case, $\mathcal{A}=0$, for which the surface of revolution is Gaussian. In this case the component I_t, Q_t processes can be described by the pair of (uncoupled) Ornstein–Uhlenbeck processes determined as the real and imaginary parts of (2.4).

III. ASYMPTOTIC BEHAVIOR

A. Equilibrium distribution

We recall the covariant form of the Fokker–Planck equation (FPE) for the asymptotic joint distribution $\mathcal{P}(x,z,t)$ (e.g., Risken, 1989)

$$\frac{\partial\mathcal{P}}{\partial t}=-\sum_i\,\partial_i(b^i\mathcal{P})+\frac{1}{2}\sum_{i,j}\,\partial_i\partial_j(\sigma^{ij}\mathcal{P}). \tag{3.1}$$

From (2.12), (2.21), (2.22) the components of the diffusion tensor in the x,z coordinate representation are given by

$$\sigma^{\mathbf{ij}}=2\begin{pmatrix}\mathcal{A}x & \mathcal{A}z\\ \mathcal{A}z & \mathcal{B}xz+\mathcal{A}z^2/x\end{pmatrix} \tag{3.2}$$

while the drift vector has components

$$b^{\mathbf{i}}=2\begin{pmatrix}\mathcal{A}(\alpha-x)\\ \mathcal{B}(x-z)+\mathcal{A}z(\alpha-x)/x\end{pmatrix}. \tag{3.3}$$

From (3.1), therefore, we deduce the following.

Proposition 3.1: The FPE for the joint distribution of the cross section x_t and intensity z_t is

$$\frac{\partial\mathcal{P}}{\partial t}=\mathcal{B}\{-\partial_z[(x-z)\mathcal{P}]+x\partial_z^2[z\mathcal{P}]\}+\mathcal{A}\left\{-\partial_z\left(\frac{z(\alpha-x)\mathcal{P}}{x}\right)-\partial_x((\alpha-x)\mathcal{P})\right\}$$
$$+\mathcal{A}\left\{\partial_z^2\left(\frac{z^2\mathcal{P}}{x}\right)+2\partial_x\partial_z(z\mathcal{P})+\partial_x^2(x\mathcal{P})\right\}. \tag{3.4}$$

This admits the asymptotic joint distribution

$$\mathcal{P}=\frac{x^{\alpha-2}\exp(-x-z/x)}{\Gamma(\alpha)}. \tag{3.5}$$

Proof: The derivation of (3.4) follows immediately from (3.1), (3.2), and (3.3), while the following identities for the derivatives of the joint distribution:

$$\partial_z\mathcal{P}=-\mathcal{P}/x,$$
$$\partial_z(z\mathcal{P})=(1-z/x)\mathcal{P},$$
$$\partial_z^2(z\mathcal{P})=\left(-\frac{2}{x}+\frac{z}{x^2}\right)\mathcal{P}, \tag{3.6}$$
$$\partial_x\mathcal{P}=\left(\frac{\alpha-1}{x}+\frac{z}{x^2}-1\right)\mathcal{P},$$
$$\partial_x^2\mathcal{P}=\left\{\left(\frac{\alpha-1}{x}+\frac{z}{x^2}-1\right)^2-\frac{\alpha-1}{x^2}-\frac{2z}{x^3}\right\}\mathcal{P},$$

enable one to verify that (3.5) is an asymptotic solution of (3.4). □

Observe from (2.12) and (3.4) that the model behavior of the scattering cross section is *endogenously specified*, i.e., the parameters involved arise from the population alone, independently of the electromagnetic field. Thus (2.12) is independent of z_t. Nevertheless there exists a nonlinear coupling between the x_t, z_t variables, owing to the presence of x_t in (2.21) and the correlation of $W_t^{(x)}$, $W_t^{(z)}$ according to (2.22). Therefore x_t, z_t are statistically dependent random variables, which relation is symmetric. The situation in regard to the endogenous specification of the evolution of the cross section through (2.12) should be contrasted with the previous discussion given in Tough (1987), and its generalizations in Field and Tough (2003) in which it is necessary that the SDE for x_t has an explicit z_t dependence, and in which the Wiener processes $W_t^{(x)}$, $W_t^{(z)}$ are considered to be independent. Although these analyses preserve the joint distribution appropriate to *K*-distributed noise, these models are not so natural from a physical point of view.

B. Detailed balance

The covariant Fokker–Planck equation (3.1) can be re-expressed as the equation of continuity

$$\frac{\partial\mathcal{P}}{\partial t}+\sum_i\partial_i(\mathcal{P}v^i)=0, \tag{3.7}$$

where the *current* v^i is defined by $v^i = b^i - \frac{1}{2}\mathcal{P}^{-1}\Sigma_j \partial_j(\sigma^{ij}\mathcal{P})$. In addition to the the equilibrium condition $\partial\mathcal{P}/\partial t = 0$, the condition for detailed balance states that $v^i = 0$. Explicit calculation using (3.6) shows that v^i vanishes asymptotically. Alternatively, a more intuitive argument for this property is as follows. From (2.7) we have the factorization $z_t = x_t u_t$, where $u_t = |\gamma_t|^2$, in which the factors x_t, u_t are independent random variables. The coordinate transformation $x^{\mathbf{i}} \mapsto x^{\mathbf{i}'}: (x,z) \mapsto (x,u)$ recasts the joint distribution (3.5) and SDEs (2.12), (2.21) such that

$$b^{\mathbf{i}'} = \begin{pmatrix} \mathcal{A}\beta^{\mathbf{1}'}(x) \\ \mathcal{B}\beta^{\mathbf{2}'}(u) \end{pmatrix}, \quad \sigma^{\mathbf{i}'\mathbf{j}'} = \begin{pmatrix} \mathcal{A}\Sigma^{\mathbf{1}'\mathbf{1}'}(x) & 0 \\ 0 & \mathcal{B}\Sigma^{\mathbf{2}'\mathbf{2}'}(u) \end{pmatrix},$$

where the functions $\beta^{\cdot}(\cdot)$, $\Sigma^{\cdot}(\cdot)$ are determined from (2.8), (2.12) and are independent of $\mathcal{A}$, $\mathcal{B}$. The equilibrium condition in the (x,u) representation, obtained by setting the left-hand side of (3.1) equal to zero, implies detailed balance, since this condition holds for arbitrary values of the constants $\mathcal{A}$, $\mathcal{B}$. Consequently, $v^{\mathbf{i}}$ in the (x,z) representation also vanishes, since $v^{\mathbf{i}}$ transforms homogeneously (i.e., tensorially) under coordinate transformations (see, e.g., Risken, 1989).

IV. CORRELATION PROPERTIES

For simplicity we adopt a timescale such that the constant $\mathcal{B}$ of (2.8) is equal to unity. The independent constant $\mathcal{A}$ will then satisfy $\mathcal{A} \ll 1$ in most practical situations of interest (e.g., scattering at radar wavelength), although this condition is not necessary for the validity of the expressions that follow in this section.

A. Intensity autocorrelation

It is convenient to write the intensity process in the product representation $z_t = u_t x_t$. From (2.8) the process $u_t = |\gamma_t|^2$ satisfies the SDE,

$$\mathrm{d}u_t = (1 - u_t)\mathrm{d}t + \sqrt{2u_t}\,\mathrm{d}W_t^{(u)}, \tag{4.1}$$

where $\gamma_t\,\mathrm{d}\xi_t^* + \gamma_t^*\,\mathrm{d}\xi_t = \sqrt{2u_t}\,\mathrm{d}W_t^{(u)}$. The propagator (i.e., Green's function for the corresponding FPE) for the process u_t is given by

$$P(u,t|u_0) = \frac{1}{1-\exp(-t)}\exp\left(-\frac{u + u_0\exp(-t)}{1-\exp(-t)}\right) I_0\left(\frac{2\exp(-t/2)\sqrt{uu_0}}{1-\exp(-t)}\right), \tag{4.2}$$

where I_α denotes the modified Bessel function (e.g., Jeffreys and Jeffreys, 1966). In a similar manner the propagator for (2.12) is given by

$$P(x,t|x_0) = \frac{1}{1-\exp(-\mathcal{A}t)}\left(\frac{x\exp(\mathcal{A}t)}{x_0}\right)^{(\alpha-1)/2} \exp\left(-\frac{(x + x_0\exp(-\mathcal{A}t))}{1-\exp(-\mathcal{A}t)}\right) \times I_{\alpha-1}\left(\frac{2\exp(-\mathcal{A}t/2)\sqrt{xx_0}}{1-\exp(-\mathcal{A}t)}\right). \tag{4.3}$$

This can be re-expressed as a series expansion

$$P(x,t|x_0) = x^{\alpha-1}\exp(-x)\sum_{n=0}^{\infty}\frac{n!}{\Gamma(n+\alpha)}\exp(-\mathcal{A}nt)L_n^{\alpha-1}(x)L_n^{\alpha-1}(x_0), \tag{4.4}$$

where the Laguerre polynomials L_n^α are defined by

$$L_n^\alpha(x) = \frac{x^{-\alpha}\exp(x)}{n!}\left(\frac{\mathrm{d}}{\mathrm{d}x}\right)^n (x^{\alpha+n}\exp(-x)) \tag{4.5}$$

(cf. Wong, 1963 for corresponding derivations). Combining (4.2), (4.4) leads to the following result.

Proposition 4.1: The propagator for (3.4) is given by

$$P(z,x,t|z_0,x_0)=\frac{1}{x(1-\exp(-t))(1-\exp(-\mathcal{A}t))}\left(\frac{x\exp(\mathcal{A}t)}{x_0}\right)^{(\alpha-1)/2}$$
$$\times\exp\left(-\frac{z/x+z_0\exp(-t)/x_0}{1-\exp(-t)}\right)\exp\left(-\frac{x+x_0\exp(-\mathcal{A}t)}{1-\exp(-\mathcal{A}t)}\right)$$
$$\times I_0\left(\frac{2\exp(-t/2)}{1-\exp(-t)}\sqrt{\frac{zz_0}{xx_0}}\right)I_{\alpha-1}\left(\frac{2\exp(-\mathcal{A}t/2)\sqrt{xx_0}}{1-\exp(-\mathcal{A}t)}\right). \tag{4.6}$$

Thus a general two-point correlation function can be expressed as the integral

$$\langle F_1(x_t,z_t)F_2(x_0,z_0)\rangle=\int_0^\infty \mathrm{d}x\,\mathrm{d}z\,\mathrm{d}x_0\,\mathrm{d}z_0\,F_1(x,z)F_2(x_0,z_0)P(x,z,t|x_0,z_0)$$
$$\times\frac{x_0^{\alpha-2}\exp(-z_0/x_0-x_0)}{\Gamma(\alpha)}. \tag{4.7}$$

As a consequence we have the following result.

Corollary 4.2: The intensity autocorrrelation function is given by

$$\langle z_t z_0\rangle=\langle u_t u_0\rangle\langle x_t x_0\rangle=\alpha(\alpha+\exp(-\mathcal{A}t))(1+\exp(-t)). \tag{4.8}$$

B. Power spectral density

In the additional presence of a Doppler frequency shift ω_0 (the presence of $\omega_0\neq 0$ is important in radar applications; see, e.g., Helmstrom, 1960) the process γ_t of Sec. II is modified to obey the SDE,

$$\mathrm{d}\gamma_t=(-\tfrac{1}{2}+i\omega_0)\gamma_t\,\mathrm{d}t+\mathrm{d}\xi_t. \tag{4.9}$$

The amplitude process Ψ_t determined by (2.15) is *stationary*, since there is no explicit time dependence in (2.15), the phase distribution is uniform, and the modulus amplitude R_t has a stationary distribution in accordance with the stationary K-distribution for the intensity (it is assumed that the distributions of the *initial* values of Ψ and its associated processes are given by their asymptotic stationary distributions). Therefore, we apply the *Wiener–Khintchine theorem* which asserts that the *power spectral density* $S(\omega)$ is equal to the Fourier transform (denoted by a tilde) of the autocorrelation function, i.e., $\langle\tilde{\Psi}(\omega)\tilde{\Psi}(\omega')\rangle=\pi\delta(\omega-\omega')S(\omega)$ where $S(\omega)=\widetilde{\langle\Psi_t\Psi_0^*\rangle}$. The amplitude autocorrelation function satisfies

$$\langle\Psi_t\Psi_0^*\rangle=\langle\sqrt{x_t x_0}\rangle\exp(-|t|/2-i\omega_0 t). \tag{4.10}$$

Using the propagator expansion (4.4), the evaluation of the factor $\langle\sqrt{x_t x_0}\rangle$ proceeds according to

$$\langle \sqrt{x_t x_0}\rangle = \int_0^\infty dx \int_0^\infty dx_0 \frac{x_0^{\alpha-1}\exp(-x_0)}{\Gamma(\alpha)} P(x,t|x_0)\sqrt{x x_0} = \frac{1}{\Gamma(\alpha)}\sum_{n=0}^{\infty}\frac{n!}{\Gamma(n+\alpha)}\exp(-\mathcal{A}nt)$$
$$\times\left(\int_0^\infty x^{\alpha-1/2}\exp(-x)L_n^{\alpha-1}(x)dx\right)^2 = \frac{1}{\Gamma(\alpha)}\sum_{n=0}^{\infty}\frac{n!}{\Gamma(n+\alpha)}\exp(-\mathcal{A}nt)$$
$$\times\left(\frac{\Gamma(\alpha+\frac{1}{2})\Gamma(n-\frac{1}{2})}{n!\,2\sqrt{\pi}}\right)^2 = \frac{\Gamma(\alpha+\frac{1}{2})^2}{\Gamma(\alpha)^2}\,{}_2F_1(-1/2,-1/2,\alpha,\exp(-\mathcal{A}t)). \tag{4.11}$$

Here the hypergeometric function ${}_2F_1$ is identified from its series expansion. When $t\to\infty$, (4.11) approaches $\langle\sqrt{x}\rangle^2$, as anticipated from the decorrelation of x_t, x_0 over large times. As $t\to 0$ we find, from the identity due to Gauss,

$${}_2F_1(a,b,c,1) = \frac{\Gamma(c)\Gamma(c-a-b)}{\Gamma(c-a)\Gamma(c-b)}, \tag{4.12}$$

that (4.11) reduces to the anticipated form

$$\lim_{t\to 0}\langle\sqrt{x_t x_0}\rangle = \frac{\Gamma(\alpha+1)}{\Gamma(\alpha)} = \alpha = \langle x\rangle. \tag{4.13}$$

Expressions (4.10), (4.11) lead to the following result.

Proposition 4.3: The autocorrelation function of the complex amplitude process Ψ_t is given by

$$\langle \Psi_t \Psi_0^*\rangle = \frac{\Gamma(\alpha+\frac{1}{2})^2}{\Gamma(\alpha)^2}\,{}_2F_1(-1/2,-1/2,\alpha,\exp(-\mathcal{A}t))\exp(-|t|/2 - i\omega_0 t). \tag{4.14}$$

According to the Wiener–Khintchine theorem, a Fourier transform of this result has the following consequence.

Corollary 4.4: The power spectral density of the K-distributed noise process characterized by (2.15) is given by

$$S(\omega) = 2\,\frac{\Gamma(\alpha+\frac{1}{2})^2}{\Gamma(\alpha)^2}\int_0^\infty {}_2F_1(-1/2,-1/2,\alpha,\exp(-\mathcal{A}t))\exp(-t/2)\cos((\omega-\omega_0)t). \tag{4.15}$$

Expanding the hypergeometric function ${}_2F_1$ as a series and integrating term by term, the resulting series is recognized as a generalized hypergeometric function of unit argument. Thus

$$S(\omega) = 2\Re\left\{\frac{{}_3F_2(-1/2,-1/2,(1/2+i(\omega-\omega_0))/\mathcal{A};\alpha,1+(1/2+i(\omega-\omega_0))/\mathcal{A};1)}{1/2+i(\omega-\omega_0)}\right\}\frac{\Gamma(\alpha+\frac{1}{2})^2}{\Gamma(\alpha)^2}. \tag{4.16}$$

These calculations illustrate how the product representation of the amplitude (2.7) facilitates the analysis of the associated FPE (3.4).

V. INTERPRETATION AND IMPLICATIONS

The study provides the first theoretical account of *K*-distributed noise processes in which the continuous time dynamical features of the electromagnetic scattering process are fully captured. This has been achieved via the formulation of stochastic differential equations for the scattered amplitude, using the primitive assumptions of the complex random walk model.

The results substantiate an earlier proposal for anomaly detection in the context of such processes (Field and Tough, 2003) based on the concept of observability in the fluctuations of the

complex amplitude process over a sample path. In this respect, Corollary 2.2 leads to a correlation between the observed $|d\Psi_t|^2$ and its predicted value of the form $c(|d\Psi_t|^2, z_t)$, which should approximate unity within the domain of validity of the model. This feature enables an anomaly detection mechanism for K-distributed noise processes, which has been successfully tested on experimental data, and is reported in Sec. IV B of Field and Tough (2003). It is of considerable importance that (2.16) can be derived from theoretical considerations alone.

The formulation of the continuous time dynamics is more fundamental than knowledge of certain statistical properties of a model and, moreover, implies the form of all correlation functions and higher order statistics. In this respect we have provided closed form expressions for the intensity autocorrelation function and the power spectral density, which should be applicable in situations of radar and laser physics. The tractability of such expressions is facilitated by the use of computational tools such as *Mathematica* (Wolfram, 1999).

The methodology we have described admits the generalization of the SDE for the scattering cross section (2.12) to more general endogenous models of population processes, such as described in Sec. II of Field and Tough (2003). This could include corresponding descriptions of the electromagnetic scattering processes that lead, e.g., to the Weibull distribution (applied to scatter from land clutter), the intensity compound K-distribution for various radar parameters (e.g., applied to synthetic aperture radar) and other examples (cf. Jakeman and Tough, 1988).

Corollary 2.7 implies that the instantaneous value of the scattering cross section is observable from the scattered amplitude. The cross section is of primary significance in anomaly detection within a random scattering medium (e.g., the sea-surface, heterogeneous media), which had previously been regarded as a hidden physical variable whose instantaneous values were not deducible from the scattering data. The expression (2.25) for the squared volatility in the modulus amplitude should find application to problems in incoherent radar detection where the total scattered phase information is not available.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 11 NOVEMBER 2003

Interacting squares in arbitrary external field

Christian Tutschka
Departamento de Matemáticas, Universidad Carlos III de Madrid, 28911 Leganés, Spain

(Received 16 June 2003; accepted 14 July 2003)

A model of a many-body system composed of squares with contact pair interactions in an arbitrary external field is presented. The formulation uses a mapping of the system onto polydisperse hard core mixtures. On the polydisperse level then, a simplified Hamiltonian function is specified. This assumption together with a further one about the global free energy functional for the pure hard core part of the idealized mixture make the model solvable. It is expected to hold for high temperatures, low densities, or low temperatures. The validity of the method of construction in the latter case is illustrated by a further application to a corresponding lattice system, for which exact results to compare with are readily available when the temperature is sufficiently low. © *2003 American Institute of Physics.*

I. INTRODUCTION

In the catalogues of solvable models in statistical mechanics (see, e.g., Refs. 1 and 2), calculations of free energies in the presence of external fields are rarely listed. For example, even the prominent Ising model on $\mathbb{Z}^2$ has only been solved in zero field. As a consequence of the difficulty of the problem, the analysis of many-body systems in external fields developed into a subdiscipline of statistical mechanics, with density functional theory as unifying approach. The basic idea of density functional theory (for a review, see, e.g., Ref. 3) consists in representing thermodynamic potentials in terms of the local particle density ϱ. Besides this well-known transformation to ϱ as new free variable, another profound idea emerged only recently, namely the concept of overcomplete density functional description. This method was introduced by Percus.[4] In such a representation of thermodynamic potentials, use is made of additional variables other than the local particle density to both clarify and better control the structure of the functionals.[3] So far, several overcomplete representations of the statistical mechanics of $D=1$ particle systems with next neighbor interactions in an arbitrary external field have been deduced[5,4,6] (for a historic overview see, e.g., Ref. 6). The purpose of this communication is to initiate the extension of the overcompleteness technique of Cuesta and Tutschka[6] by considering a suitable chosen interacting particle system in $\mathbb{R}^2$ (and on $\mathbb{Z}^2$).

From a physical point of view, their approach is that of introducing the sequence of local densities $\{\varrho_i\}_{i\geqslant 1}$ of blocks (clusters, superparticles,[5] or units) containing i particles connected (bounded or associated[7]) due to the attractive part of the interaction as set of redundant variables. Since then the pair interaction among the blocks is per construction a hard core potential, the resulting free energy functional takes on the polydisperse, additive hard rods mixture form. Consequently, the functional is parameterized by few sums (over the local block densities ϱ_i), which, in turn, can be evaluated (for the $D=1$ next neighbor case) in closed form. Based on this observation, Cuesta and Tutschka[6] show (though indirectly) that the thermodynamic potentials of $D=1$ particle systems with next neighbor interactions in an arbitrary external field are—analogous to the well-known uniform isothermal–isobaric technique (see, e.g., Ruelle[8])—completely characterized by pressure-like quantities $p^{\pm}$, termed effective pressures.[9,10]

From a mathematical viewpoint, they lifted the representation of positive integers n (physically interpreted as number of particles) as sums of other positive integers, known as partitions of n (see, e.g., Andrews[11,12]), to the thermodynamic level. Here, the central observation is that the

number of partitions of n is exponentially bounded (Hardy–Ramanujan formula—see, e.g., Andrews[11,12]).

Cuesta and Tutschka[6] developed these ideas along two examples, the sticky core model, in which the interaction has a 0-range attractive component at the edge of the core, and the prototypical square-well potential. In particular, the full and explicit analysis of the former system was possible because of the contact nature of the adhesive interaction. That is, the particles of a unit are forced to lie, in relative coordinates, on the linear lattice.

While the logic of the overcompleteness scheme of Cuesta and Tutschka,[6] with its resemblance to the isothermal–isobaric method, not only works for the simplified $D=1$ setup, a mathematical analysis of the direct extension of the format to $D>1$ is not within reach. Correspondingly, this communication starts the extension of the overcomplete representation of Cuesta and Tutschka[6] by looking at $D=2$ examples with type of contact pair interactions. This choice of course is based on the very handy properties of the $D=1$ sticky core model. Furthermore, we are going to restrict ourselves to oriented hard square cores.

Our program consists of three steps. First, in Sec. II A, we shall give a reformulation of the sticky rods free energy functional. The topic will be the abstraction from the $D=1$ nature of the solution. Namely, that we are going to work backwards from the elegant and compact effective pressures representation. In particular, we will avoid the closed-form evaluation of the sums over the local block densities (which will most likely not be possible in $D=2$), as well as infer the relation between ϱ and the local block densities $\{\varrho_i\}_{i\geqslant 1}$ directly from the lattice structure of the units (instead from an identity of functional analysis as within the $p^{\pm}$ format)—see formula (2.7). With these preliminary considerations in mind, we shall turn to the crucial part of our program (step two), the extension to $D=2$, pursued in Sec. II B. Following the logic of the Cuesta–Tutschka format, the central theme will be the control of the block configurations. Whereas for the $D=1$ case, the units are completely characterized by the number of connected particles i, in the $D=2$ case, the shape functions of the units are no longer defined by a single integer parameter. This means that while the mapping of our many-body system of squares with contact interactions onto a polydisperse, additive hard core mixture is formally possible, the Hamiltonian function of this mixture will be, foremost due to the geometry of the hard cores (i.e., the units or blocks), hopelessly complicated, and therefore the evaluation of its free energy functional far beyond reach. Hence, in order to set up an analytically tractable scheme, we are forced to specify a sufficiently simple polydisperse hard core mixture type Hamiltonian such that its thermodynamic potentials can be calculated. The idealization we are going to use will restrict the spatial structure of the units to a certain class of compact configurations. Clearly, this simplifying condition means that the model will have a limited domain. In fact it will be easy to guess the thermodynamic region for which the approach is valid. But somewhat more quantitative estimates would certainly be preferable. This question provides the focus of the last step of our program. In Sec. III, the procedure of Sec. II B will be applied to an interacting particle system with next neighbor interactions on $\mathbb{Z}^2$, for which the coexistence curve is well-known (see, e.g., Refs. 1 and 2). This will provide us finally, at least for low temperatures, with an explicit comparison of our idealization with exact results.

II. NONUNIFORM CONTINUOUS SYSTEMS

A. One-dimensional sticky cores

This model is to be interpreted as meaning a system of $D=1$ hard balls with an additional, zero-range attractive interaction at the edge of the core. It can be regarded as a limiting case of a $D=1$ particle system with square-well potential. In the latter system, the pair interaction V between two particles at distance q is (selecting units such that the hard core diameter equals 1)

$$V(q)=\begin{cases} -\mathcal{E} & \text{if } q\in[1,1+d), \\ 0 & \text{if } q\in[1+d,\infty), \\ +\infty & \text{otherwise,} \end{cases} \tag{2.1}$$

where $d \leqslant 1$ is the width of the well and $\mathcal{E} \in \mathbb{R}_+$ the interaction strength. Upon introducing the pair interaction Boltzmann factor

$$e(y,x) = \begin{cases} \exp[-\beta V(y-x)] & \text{if } y \geqslant x, \\ 0 & \text{otherwise,} \end{cases} \tag{2.2}$$

with $x,y \in \mathbb{R}$ as the positions of two neighboring particles and $\beta \in \mathbb{R}_+$ the reciprocal temperature, the pair interaction energy of $D=1$ adhesive systems is characterized through (2.1) as well as (2.2) by the limit

$$\lim_{\substack{\mathcal{E} \to +\infty \\ d \to 0^+}} e(y,x)\big|_{d \exp(\beta\mathcal{E}) \to \lambda} = h_1(y-x) + \lambda\, \delta_1(y-x), \tag{2.3a}$$

where $\delta_a = h_a'$, h_a being the Heaviside function shifted to the right by a, and $\lambda \in \mathbb{R}_+$ the stickiness (coupling or bonding[7]) parameter.

The formulation of the Hamiltonian function is completed via the definition of the local activity

$$z(x) = \exp\{\beta[\mu - U(x)]\}. \tag{2.3b}$$

This term of the Hamiltonian gives the interaction energy between the external field U (and the chemical potential $\mu \in \mathbb{R}$, respectively) and the particle at x.

For the Hamiltonian (2.3), the free energy was first obtained by Percus in 1982 through the inverse operator format.[13] Later on, Cuesta and Tutschka[6] gave an alternative derivation, leading to a physically more transparent representation of the thermodynamic potentials in terms of effective pressures $p^{\pm}$. They also showed the equivalence of the two schemes.

The aim of this section is to infer a reformulation of the sticky rods functional most suitable for the transition to $D=2$. We are going to avoid simplifications specific to the $D=1$ nature of the system. The emphasis will be on the geometric properties of the units. Thus, the functional will be less simple than in the $p^{\pm}$ representation, and therefore, most notably, computationally less efficient, too.

Our reasoning is based on the transformation technique due to Cuesta and Tutschka.[6] This method consists of three stages.

The analysis starts with a decomposition of the $D=1$ sticky core system into units (monomers, dimers, trimers,...) of i, via the attractive part of the pair interaction Boltzmann factor (2.3a), connected particles. By the contact nature of the adhesive interaction, these units have diameter i. Furthermore, the pair interaction among them is per construction a hard core potential. Thus, the original system is mapped onto a polydisperse, additive hard rods mixture with pair interaction Boltzmann factor between component i and j given as [cf. (3.6) of Cuesta and Tutschka[6]]

$$e_{ij}(y,x) = h_{(i+j)/2}(y-x). \tag{2.4a}$$

In the second stage, the composition of the units is incorporated. That is, the partition function of an i-particle unit at x is represented by the local activity $z_i(x)$ of component i of the mixture. The total isothermal measure of a unit of i particles (numbered from left to right, i.e., $x_1 \leqslant x_2 \leqslant x_3 \cdots \leqslant x_i$), centered at x, is via (2.3) given by

$$z(x_i) \int_{\mathbb{R}^{i-1}} \prod_{k=1}^{i-1} \delta_1(x_{k+1} - x_k)\, z(x_k)\, \mathrm{d}(x_1, \ldots, x_{i-1})\big|_{x_i = x + n_i},$$

where $n_i = (i-1)/2$, $i \in \mathbb{N}_+$. Upon using the properties of Dirac's δ-distribution, we therefore have that [cf. (3.5) of Cuesta and Tutschka[6]]

$$z_i(x)=\lambda^{i-1}\prod_{|j|\leqslant n_i} z(x+j),$$

which transcribes via (2.3b) to the completely polydisperse form

$$z_i(x)=C_i(\lambda)\exp\{\beta[\mu_i-U_i(x)]\} \tag{2.4b}$$

with $C_i(\lambda)=\lambda^{i-1}$, the chemical potential μ_i of component i equal to $i\mu$, and the external field given as

$$U_i(x)=\sum_{|j|\leqslant n_i} U(x+j). \tag{2.5}$$

This shows the basic underlying lattice structure of sticky core units most clearly.

On following Percus,[13,4] the local partial (or block) densities $\varrho_i\in L^1(\mathbb{R})$ are now obtainable by

$$\varrho_i(x)=\frac{\delta\ln\Xi}{\delta\ln z_i(x)},$$

where Ξ is the total Gibbs measure of (2.4) with the indices of the blocks determined statistically,[14,4] or, equivalently, of (2.3).

The main property that makes the calculation of the free energy functional $\mathfrak{F}$ of the Hamiltonian function (2.4) rather straightforward is the close resemblance of the latter to the polydisperse additive pure hard rods mixture Hamiltonian, for which the free energy is known.[14,4] Indeed, for $C_i(\lambda)\equiv 1$ the Hamiltonian (2.4) defines a $D=1$ additive mixture of pure hard cores in an external field U_i. Therefore, upon writing $\mathfrak{F}[\{\varrho_i\}_{i\geqslant 1}]=\Sigma_{i\geqslant 1}\int_{\mathbb{R}}\varrho_i(x)U_i(x)\,dx+\bar{\mathfrak{F}}[\{\varrho_i\}_{i\geqslant 1}]$, so that $\bar{\mathfrak{F}}$ denotes the intrinsic free energy functional (see, e.g., Percus[3]), we have due to Vanderlick, Davis, and Percus[14] at once

$$\beta\bar{\mathfrak{F}}[\{\varrho_i\}_{i\geqslant 1}]|_{C_i(\lambda)\equiv 1}=\int_{\mathbb{R}}\left\{\sum_{i\geqslant 1}\varrho_i(x)[\ln\varrho_i(x)-1]-\sigma(x)\ln[1-\tau(x)]\right\}dx$$

with the linear transforms of the densities (cf. Percus[13])

$$\sigma(x)=\sum_{i\geqslant 1}\int_{\mathbb{R}}\sigma^{(i)}(x-x')\varrho_i(x')\,dx',\quad \tau(x)=\sum_{i\geqslant 1}\int_{\mathbb{R}}\tau^{(i)}(x-x')\varrho_i(x')\,dx',$$

and ($h\equiv h_0$)

$$\tau^{(i)}(x)=h\left(\frac{i}{2}-|x|\right),\quad \sigma^{(i)}(x)=\frac{1}{2}|\partial_x\tau^{(i)}(x)|,\quad x\in\mathbb{R}. \tag{2.6}$$

Thus we conclude using definition (2.4b) that

$$\beta\bar{\mathfrak{F}}[\{\varrho_i\}_{i\geqslant 1}]=\int_{\mathbb{R}}\left\{\sum_{i\geqslant 1}\varrho_i(x)\left[\ln\frac{\varrho_i(x)}{C_i(\lambda)}-1\right]-\sigma(x)\ln[1-\tau(x)]\right\}dx.$$

The calculus ends (third stage) by projecting the functional $\mathfrak{F}$ onto the sought free energy F of $D=1$ sticky cores. This transform inverse is accomplished by means of a variational principle. The free energy functional of the original system occurs via an evaluation of the variational formula at the set of minimizing local partial densities.

Again upon using the discrete geometrical nature of the units, we obtain the partition of the local particle density [cf. (3.36) of Cuesta and Tutschka[6]]

$$\varrho(x)=\sum_{i\geqslant 1}\sum_{|j|\leqslant n_i}\varrho_i(x+j). \tag{2.7}$$

This yields

$$\tau(x)=\sum_{i\geqslant 1}\int_{x-\,i/2}^{x+\,i/2}\varrho_i(y)\,\mathrm{d}y=\int_{x-\,1/2}^{x+\,1/2}\varrho(y)\,\mathrm{d}y$$

as well as

$$\sum_{i\geqslant 1}\int_{\mathbb{R}}\varrho_i(x)U_i(x)\,\mathrm{d}x=\int_{\mathbb{R}}\varrho(x)U(x)\,\mathrm{d}x$$

by (2.5). Hence $\mathfrak{F}$ becomes

$$\beta\mathfrak{F}[\varrho,\{\varrho_i\}_{i\geqslant 1}]=\int_{\mathbb{R}}\left\{\varrho(x)\beta U(x)+\sum_{i\geqslant 1}\varrho_i(x)\left[\ln\frac{\varrho_i(x)}{C_i(\lambda)}-1\right]-\sigma(x)\ln[1-\tau(x)]\right\}\mathrm{d}x.$$

From this our overcomplete format free energy F of $D=1$ sticky balls in an external field U is found through the usual minimum principle of classical density functional theory (see, e.g., Refs. 15 and 3). If we evaluate the minimum in two steps, then we infer that

$$\beta F[U]=\min_{\varrho\in D_n}\min\left\{\beta\mathfrak{F}[\varrho,\{\varrho_i\}_{i\geqslant 1}]\colon L^1(\mathbb{R})\ni\varrho_i(x)\geqslant 0\wedge\sum_{i\geqslant 1}\sum_{|j|\leqslant n_i}\varrho_i(x+j)=\varrho(x)\right\} \tag{2.8}$$

with $D_n=\{t\in L^1(\mathbb{R})\colon t(x)\geqslant 0\wedge\int_{\mathbb{R}}t(x)\,\mathrm{d}x=n\}$, n fixed.

Given $\lambda\in\mathbb{R}_+$ and $\varrho\in D_n$, $\mathfrak{F}$ is convex in the local partial densities $\{\varrho_i\}_{i\geqslant 1}$. Thus the minimum in (2.8) with respect to $\{\varrho_i\}_{i\geqslant 1}$ is attained at (setting $m_i=n_i-\frac{1}{2}$)

$$\varrho_i(x)=C_i(\lambda)\frac{\Pi_{|j|\leqslant n_i}\varrho_1(x+j)}{\Pi_{|j|\leqslant m_i}[1-\tau(x+j)]},\quad i>1,$$

and ϱ_1 is found via (2.7). Therefore F simplifies to

$$\beta F[U]=\min_{\varrho\in D_n}\int_{\mathbb{R}}\left\{\varrho(x)[\beta U(x)+\ln\varrho_1(x)]-\sum_{i\geqslant 1}\varrho_i(x)-\frac{1}{2}\left[\varrho\left(x-\frac{1}{2}\right)+\varrho\left(x+\frac{1}{2}\right)\right]\right.$$
$$\left.\times\ln[1-\tau(x)]\right\}\mathrm{d}x, \tag{2.9}$$

which generalizes the findings in Sec. 2.2 of Kierlik and Rosinberg[7] for dimerizing hard rods, controlled by ϱ_1 and ϱ_2, to systems characterized by an arbitrary number of local partial densities. The equivalence of (2.9) and the inverse operator format sticky rods free energy functional[13] can be established through results shown in Sec. 3.2.1 of Cuesta and Tutschka.[6]

B. Plane case

At the outset we have to say what is meant by a many-body system of squares (having only translational degrees of freedom) with ''contact pair interactions.'' Clearly, one would like to go on with a system of sticky squares, in which the attractive part of the pair interaction Boltzmann factor is compressed to a Dirac δ-distribution on the boundary of the hard square core. But this

particle system is not thermodynamically stable. The proof of divergence of the partition function of sticky squares parallels that for sticky discs given by Stell,[16] except that for the quadratic case a particle can interact simultaneously with at most eight neighbors.

As a remedy, we back away from the sticky limit. We look at a system of squares with square-well attraction of well-width $d \in \mathbb{R}_+$ as well as interaction strength $\mathcal{E} \in \mathbb{R}_+$, and let $\mathcal{E}$ depend on d in such a way that $\lambda = d[\exp(\beta\mathcal{E}) - 1]$ remains finite as d tends to zero. Then, for $\lambda \in \mathbb{R}_+$ and sufficiently small $d > 0$ (see below), we define the pair interaction Boltzmann factor of a particle system of squares with ''contact pair interactions'' as given by (selecting units so that the side length of the hard square core equals 1)

$$e(x,y) = h_1(|x-y|_\infty) + \frac{\lambda}{d} h_{1,d}(|x-y|_\infty) \tag{2.10a}$$

with $x,y \in \mathbb{R}^2$ specifying the positions of the particles and $h_{a,b} = h_a - h_{a+b}$. That is, instead of taking the limit $d \to 0$ (the standard sticky limit—see, e.g., Stell[16]), we consider a related pair interaction function with arbitrarily small but fixed $d \neq 0$. The reason for the term ''contact interaction'' is that for sufficiently small $d > 0$ the range of the attraction in (2.10a) is negligible compared to the size of the particles.

The definition of the Hamiltonian function is finished via the local activity z, which generalizes without change to

$$z(x) = \exp\{\beta[\mu - U(x)]\}, \tag{2.10b}$$

where U is again the external field and μ the chemical potential (implicitly including the momentum contributions).

1. Overcompleteness technique

Now we will extend the particular overcomplete form deduced in Sec. II A to $D = 2$. There is no difference at all between the strategy we will use for the planar problem and the logic followed above. There are significant differences in the realizations, however. The central theme of the $D = 1$ analysis is the one-sided nature of the pair interaction Boltzmann factor (2.2). That is, the main properties that make the setup easier in the $D = 1$ context are

(a) the units are defined by a single integer variable, and
(b) the intrinsic free energy functional at $C_i(\lambda) \equiv 1$ is exact.

The $D = 2$ case does not share these properties. Still, there are units in the planar problem that can be characterized by two integer variables, and there is a functional that extrapolates from the polydisperse hard rod mixture functional to that of similar $D = 2$ particle systems. When we want our scheme to be analytically tractable, some suitable assumptions are needed. The guiding principle will be that of simplicity.

We begin again by mapping the given system (2.10) onto an additive polydisperse hard core mixture. This transformation partitions the original system into units of connected particles. Then these units are, in turn, regarded as components of a mixture, in which the interaction among the components is of hard core type. Thus the transformation maps configurations of connected particles of the original system onto components of the mixture. Correspondingly, the Hamiltonian function of this mixture is hopelessly complicated. In order to define a suitable idealization thereof, we restrict ourselves first to configurations of maximal connected particles. That is, via the contact nature of the interaction, we are left with units of square lattice type geometry. But this is not enough. Moreover, in analogy with the characterization of $D = 1$ units by a single integer parameter, we allow only for $D = 2$ units of rectangle-like shapes. Hence we specify units as $D = 2$ arrays of $i_1 \times i_2$ (with $i_1, i_2 \in \mathbb{N}_+$ interpreted as numbers of row and column particles, respectively) maximal connected particles. This extension of (a) to the $D = 2$ level is summarized in the following rule.

Assumption 2.1: The polydisperse representation of a nonuniform system of squares with contact interactions is completely characterized by rectangular arrays of maximal connected particles.

Here some comments are in order.

(1) The cases $(i_1=1)\vee(i_2=1)$ are to be interpreted as essentially one-dimensional, so that we are back to (a) when we specialize Assumption 2.1 to $D=1$. Then, through Assumption 2.1 and the contact nature of the interaction, the units become asymptotically as $d\to 0^+$ rectangles $R_i=\{(x_1,x_2)\in\mathbb{R}^2: |x_k|\leqslant i_k/2,\ k=1,2\}$, where we introduced a double-index $i=(i_1,i_2)$.
(2) Assumption 2.1 cannot possibly be exact. Only a certain class of configurations of connected particles is included.
(3) On the other hand, it is expected to be a good approximation whenever monomers are predominantly present in the system. That is, Assumption 2.1 holds for sufficiently high temperatures and sufficiently dilute states.
(4) At sufficiently low temperatures, there is only a vanishing proportion of units of connected but not maximal connected particles. Furthermore, by the contact nature of the interaction, the dominant units of maximal connected particles tend to minimize their surfaces. Then we may think of the particle system as being composed of compact, quasi close-packed units. Consequently, Assumption 2.1 is expected to be a good approximation for sufficiently low temperatures.
(5) The high density limit has to be treated separately since there will be ''percolation'' of arbitrarily long chains. So that at sufficiently high densities one can expect to enter a regime in which the validity of Assumption 2.1 is very questionable.

Thus, upon combing Assumption 2.1 with (2.10a) we have that the pair interaction Boltzmann factor between components i and j of the mixture is asymptotically as $d\to 0^+$ given by

$$e_{ij}(x,y)\asymp\chi_{\mathbb{R}^2\setminus R_{i+j}}(x-y), \tag{2.11a}$$

where χ_A is the characteristic function of the set A.

In the second stage, the definition of the model Hamiltonian on the polydisperse level is completed. Namely, the local activity $z_i(x)$ is used to encode the partition function of the $i_1\times i_2$ particle unit at x. Again through Assumption 2.1 and the d-range of the attractive part of the pair interaction, the local activity becomes as $d\to 0^+$,

$$z_i(x)\asymp C_i(\lambda,d)\exp\{\beta[\mu_i-U_i(x)]\}. \tag{2.11b}$$

Here, the combinatorial part is given by

$$C_i(\lambda,d)\asymp\frac{\lambda^{q(i)}}{(i_1 i_2)!\, d^{r(i)}}$$

with $q(i)=4i_1i_2-3(i_1+i_2)+2$, as well as $r(i)=0$ if $(i_1=1)\vee(i_2=1)$ and $2i_1i_2-3(i_1+i_2)+4$ otherwise. Moreover, the chemical potential of component i is found as $\mu_i=i_1i_2\,\mu$, and the external field is prescribed by the formula

$$U_i(x)\asymp\sum_{|j_1|\leqslant n_{i_1},|j_2|\leqslant n_{i_2}} U(x_1+j_1,x_2+j_2) \tag{2.12}$$

as $d\to 0^+$.

Accordingly, the local partial density $\varrho_{i_1i_2}$ of the original system is identified with the local particle density of component i of the mixture. Through this interpretation the partial densities can again be used variationally for the original system—see below.

Next we will turn to the calculation of the intrinsic free energy functional of (2.11). In two dimensions, exact solutions are in very short supply, even for pure hard core particle systems. One is therefore forced to evaluate the free energy at $C_i(\lambda,d)\equiv 1$ by means of some extrapolation type of scheme.

Several years ago, Zhang[10] reexamined hard rods in an external field by extending the Reiss–Frisch–Lebowitz (RFL) scaled particle format to the nonuniform case. He showed that the RFL reasoning is exact for nonuniform $D=1$ hard balls and constructed the ''global free energy functional'' which serves as generating functional for all hard rods intrinsic free energy density functionals. The physics of the nonuniform RFL approach is that locally the probability measure of creating a core of diameter a at x, $\mu_a(x)$, characterizes the equilibrium state of the system completely. Hence the excess global free energy functional is equal to the intrinsic ideal gas free energy functional of μ_a. Later on, the scope of global free energy functionals was expanded.[17,18] Cuesta and Martínez-Ratón[17] generalized Zhang's functional to hard rod mixtures. They also observed that for any additive mixture of hard rectangles an intrinsic free energy functional can be extrapolated from the hard rod mixtures global functional and related it to $D=2$ RFL scaled-particle-type arguments. We apply their extrapolation technique in our extension of (b) to $D=2$.

Assumption 2.2: The global free energy functional is the same for additive polydisperse hard rod and hard rectangle mixtures.

We note some properties of the assumption (cf. Cuesta and Martínez-Ratón[17])

(1) Assumption 2.2 is exact for sufficiently rarefied gases.[17]
(2) It is believed that the hard rod mixtures global functional gives the correct order of the thermodynamic potentials for hard rectangle mixtures. Of course this does not mean that the relative errors are small on the whole thermodynamic domain. Assumption 2.2 is expected to be a good approximation up to (at least) intermediate densities. For numerical tests passed by RFL type functionals see, e.g., Ref. 17.

So let us write $\mathfrak{F}[\{\varrho_{i_1i_2}\}]=\Sigma_{i_1,i_2\geqslant 1}\int_{\mathbb{R}^2}\varrho_{i_1i_2}(x)U_{i_1i_2}(x)\,dx+\bar{\mathfrak{F}}[\{\varrho_{i_1i_2}\}]$, such that $\bar{\mathfrak{F}}$ is the intrinsic free energy functional of Hamiltonian (2.11). Then, on using Assumption 2.2, we have due to Zhang[10] (as well as Cuesta and Martínez-Ratón[17]) immediately that

$$\beta\bar{\mathfrak{F}}[\{\varrho_{i_1i_2}\}_{i_1,i_2\geqslant 1}]|_{C_{i_1i_2}(\lambda,d)\equiv 1}$$
$$\asymp\int_{\mathbb{R}^2}\left\{\sum_{i_1,i_2\geqslant 1}\varrho_{i_1i_2}(x)[\ln\varrho_{i_1i_2}(x)-1]-\sigma(x)\ln[1-\tau(x)]+\frac{\nu_1(x)\,\nu_2(x)}{1-\tau(x)}\right\}dx,$$

where

$$\sigma(x)=\sum_{i_1,i_2\geqslant 1}\int_{\mathbb{R}^2}\sigma^{(i_1)}(x_1-x_1')\sigma^{(i_2)}(x_2-x_2')\varrho_{i_1i_2}(x_1',x_2')\,d(x_1',x_2'),$$

$$\nu_1(x)=\sum_{i_1,i_2\geqslant 1}\int_{\mathbb{R}^2}\sigma^{(i_1)}(x_1-x_1')\tau^{(i_2)}(x_2-x_2')\varrho_{i_1i_2}(x_1',x_2')\,d(x_1',x_2'),$$

$$\nu_2(x)=\sum_{i_1,i_2\geqslant 1}\int_{\mathbb{R}^2}\tau^{(i_1)}(x_1-x_1')\sigma^{(i_2)}(x_2-x_2')\varrho_{i_1i_2}(x_1',x_2')\,d(x_1',x_2'),$$

$$\tau(x)=\sum_{i_1,i_2\geqslant 1}\int_{\mathbb{R}^2}\tau^{(i_1)}(x_1-x_1')\tau^{(i_2)}(x_2-x_2')\varrho_{i_1i_2}(x_1',x_2')\,d(x_1',x_2')$$

with $\sigma^{(i)}$ and $\tau^{(i)}$ brought in via (2.6). Correspondingly we find through definition (2.11b) that

$$\beta\bar{\mathfrak{F}}[\{\varrho_{i_1i_2}\}_{i_1,i_2\geqslant 1}]$$
$$\asymp\int_{\mathbb{R}^2}\left\{\sum_{i_1,i_2\geqslant 1}\varrho_{i_1i_2}(x)\left[\ln\frac{\varrho_{i_1i_2}(x)}{C_{i_1i_2}(\lambda,d)}-1\right]-\sigma(x)\ln[1-\tau(x)]+\frac{\nu_1(x)\nu_2(x)}{1-\tau(x)}\right\}\mathrm{d}x.$$

We end (third stage) as in the $D=1$ context by projecting the polydisperse functional $\mathfrak{F}$ onto the desired free energy F of the original system. The transform inverse is obtained via the minimization of $\mathfrak{F}$ with respect to all the $\varrho_{i_1i_2}$ subject to the constraint

$$\varrho(x)\asymp\sum_{i_1,i_2\geqslant 1}\sum_{|j_1|\leqslant n_{i_1},|j_2|\leqslant n_{i_2}}\varrho_{i_1i_2}(x_1+j_1,x_2+j_2),\tag{2.13}$$

which follows from the discrete geometry of the units as $d\to 0^+$. Thus,

$$\tau(x)=\sum_{i_1,i_2\geqslant 1}\int_{x_1-i_1/2}^{x_1+i_1/2}\int_{x_2-i_2/2}^{x_2+i_2/2}\varrho_{i_1i_2}(x_1',x_2')\,\mathrm{d}(x_1',x_2')\asymp\int_{x_1-1/2}^{x_1+1/2}\int_{x_2-1/2}^{x_2+1/2}\varrho(x_1',x_2')\,\mathrm{d}(x_1',x_2'),$$

as well as upon processing (2.12),

$$\sum_{i_1,i_2\geqslant 1}\int_{\mathbb{R}^2}\varrho_{i_1i_2}(x)U_{i_1i_2}(x)\,\mathrm{d}x\asymp\int_{\mathbb{R}^2}\varrho(x)U(x)\,\mathrm{d}x.$$

Therefore $\mathfrak{F}$ takes on the form

$$\beta\mathfrak{F}[\varrho,\{\varrho_{i_1i_2}\}_{i_1,i_2\geqslant 1}]$$
$$\asymp\int_{\mathbb{R}^2}\left\{\varrho(x)\beta U(x)+\sum_{i_1,i_2\geqslant 1}\varrho_{i_1i_2}(x)\left[\ln\frac{\varrho_{i_1i_2}(x)}{C_{i_1i_2}(\lambda,d)}-1\right]-\sigma(x)\ln[1-\tau(x)]\right.$$
$$\left.+\frac{\nu_1(x)\nu_2(x)}{1-\tau(x)}\right\}\mathrm{d}x,$$

so that we finally infer from Assumptions 2.1 and 2.2 for the free energy of a nonuniform system of squares with contact interactions

$$\beta F[U]\asymp\min_{\varrho\in D_n}\min\left\{\beta\mathfrak{F}[\varrho,\{\varrho_{i_1i_2}\}_{i_1,i_2\geqslant 1}]:L^1(\mathbb{R}^2)\ni\varrho_{i_1i_2}(x)\geqslant 0\right.$$
$$\left.\wedge\sum_{i_1,i_2\geqslant 1}\sum_{|j_1|\leqslant n_{i_1},|j_2|\leqslant n_{i_2}}\varrho_{i_1i_2}(x_1+j_1,x_2+j_2)=\varrho(x)\right\}\tag{2.14}$$

with $D_n=\{t\in L^1(\mathbb{R}^2):t(x)\geqslant 0\wedge\int_{\mathbb{R}^2}t(x)\,\mathrm{d}x=n\}$, n fixed.

Given $\lambda\in\mathbb{R}_+$, sufficiently small $d>0$, and $\varrho\in D_n$, the functional appearing on the right-hand side (RHS) of (2.14) is convex in the local partial densities. Hence it attains its minimum with respect to $\{\varrho_{i_1i_2}\}_{i_1,i_2\geqslant 1}$ at

$$\varrho_{i_1 i_2}(x) \asymp C_{i_1 i_2}(\lambda,d)\,\frac{\Pi_{|j_1|\leqslant n_{i_1},|j_2|\leqslant n_{i_2}}\varrho_{11}(x_1+j_1,x_2+j_2)}{\Pi_{|j_1|\leqslant m_{i_1},|j_2|\leqslant m_{i_2}}[1-\tau(x_1+j_1,x_2+j_2)]}$$

$$\times \prod_{|j_1|\leqslant m_{i_1}} \frac{\exp[\mu_2^{(i_2)}(x_1+j_1,x_2)]}{\Pi_{s\in\{-,+\}}\left[1-\tau\left(x_1+j_1,x_2+s\frac{i_2}{2}\right)\right]^{1/2}}$$

$$\times \prod_{|j_2|\leqslant m_{i_2}} \frac{\exp[\mu_1^{(i_1)}(x_1,x_2+j_2)]}{\Pi_{s\in\{-,+\}}\left[1-\tau\left(x_1+s\frac{i_1}{2},x_2+j_2\right)\right]^{1/2}} \quad (i_1\neq 1)\wedge(i_2\neq 1).$$

Here we introduced for $k\in\mathbb{N}$

$$\mu_1^{(k)}(x)=\int_{x_1-(k/2)}^{x_1+(k/2)}\frac{\nu_1(x_1',x_2)}{1-\tau(x_1',x_2)}\,\mathrm{d}x_1', \quad \mu_2^{(k)}(x)=\int_{x_2-(k/2)}^{x_2+(k/2)}\frac{\nu_2(x_1,x_2')}{1-\tau(x_1,x_2')}\,\mathrm{d}x_2',$$

and $m_i=n_i-\frac{1}{2}$, $i\in\mathbb{N}_+$ [remember that we have let $n_i=(i-1)/2$)]. The local monomer density ϱ_{11} is determined through (2.13). Thus F simplifies to

$$\beta F[U]\asymp \min_{\varrho\in D_n}\int_{\mathbb{R}^2}\Bigg\{\varrho(x_1,x_2)[\beta U(x_1,x_2)+\ln\varrho_{11}(x_1,x_2)]-\sum_{i_1,i_2\geqslant 1}\varrho_{i_1 i_2}(x_1,x_2)$$

$$-\frac{1}{4}\sum_{s_1,s_2\in\{-,+\}}\varrho\left(x_1+\frac{s_1}{2},x_2+\frac{s_2}{2}\right)\ln[1-\tau(x_1,x_2)]+\frac{1}{2}\sum_{s\in\{-,+\}}\left[\varrho\left(x_1+\frac{s}{2},x_2\right)\right.$$

$$\left.\times\mu_2^{(1)}(x_1,x_2)+\varrho\left(x_1,x_2+\frac{s}{2}\right)\mu_1^{(1)}(x_1,x_2)\right]-\frac{1}{2}\sum_{i_1,i_2\geqslant 1}\sum_{s\in\{-,+\}}\left[\varrho_{i_1 i_2}\left(x_1+s\frac{i_1}{2},x_2\right)\right.$$

$$\left.\times\mu_2^{(i_2)}(x_1,x_2)+\varrho_{i_1 i_2}\left(x_1,x_2+s\frac{i_2}{2}\right)\mu_1^{(i_1)}(x_1,x_2)\right]+\frac{\nu_1(x_1,x_2)\,\nu_2(x_1,x_2)}{1-\tau(x_1,x_2)}\Bigg\}\,\mathrm{d}(x_1,x_2).$$

2. Uniform limit

Suppose we have a field-free situation with particle density ρ and partial densities $\{\rho_{i_1 i_2}\}_{i_1,i_2\geqslant 1}$. Then it follows from the above that the thermodynamic pressure p and specific free energy f are

$$\beta p(\beta,\rho)\asymp\frac{\xi_0}{1-\rho}+\left(\frac{\xi_1}{1-\rho}\right)^2, \tag{2.15}$$

$$\beta f(\beta,\rho)\asymp\rho\left[\ln\rho_{11}-\ln(1-\rho)+\frac{2\xi_1}{1-\rho}\right]-\xi_0-\frac{\xi_1^2}{1-\rho}, \tag{2.16}$$

where for $(i_1\neq 1)\wedge(i_2\neq 1)$

$$\rho_{i_1 i_2}\asymp C_{i_1 i_2}(\lambda,d)\,\rho_{11}\left(\frac{\rho_{11}}{1-\rho}\right)^{i_1 i_2-1}\left[\exp\left(\frac{\xi_1}{1-\rho}\right)\right]^{2i_1 i_2-(i_1+i_2)}$$

with $\rho=\Sigma_{i_1,i_2\geqslant 1} i_1 i_2\,\rho_{i_1 i_2}$, $\xi_1=\Sigma_{i_1,i_2\geqslant 1} i_2\,\rho_{i_1 i_2}=\Sigma_{i_1,i_2\geqslant 1} i_1\,\rho_{i_1 i_2}$, as well as $\xi_0=\Sigma_{i_1,i_2\geqslant 1}\rho_{i_1 i_2}$.

It is natural to ask whether the model exhibits a phase transition (see, e.g., Ruelle[8]) at sufficiently small d if λ is large enough. Even more so since Lebowitz and Percus[19] showed that

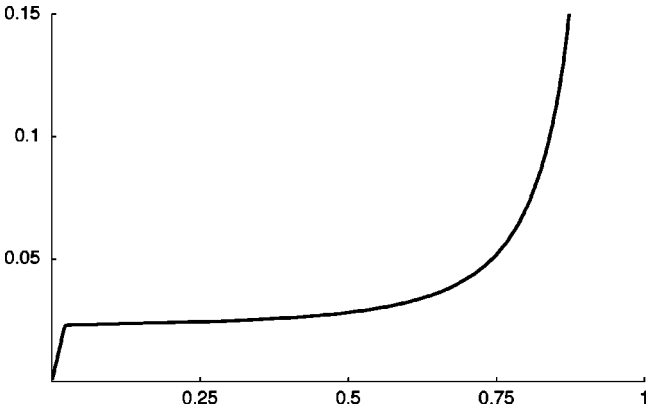

FIG. 1. Finite approximation isotherm for the interacting squares model (2.15): βp as a function of $\rho \in (0,1)$ for $\lambda = 0.15$ and $d = 0.0001$. The upper summation limits of the sums in (2.15) were set equal to 25.

already for a related $D=1$ particle system a first-order phase transition occurs. A curve showing βp as a function of $\rho \in (0,1)$ for $\lambda = 0.15$ and $d = 0.0001$ is depicted in Fig. 1 for which $\rho_{i_1 i_2} = 0$, $(i_1 > n) \vee (i_2 > n)$, $n = 25$. Also from this numerical evaluation one might reasonably expect the existence of a first-order phase transition as n tends to infinity. Up to now we have no proof of this conjecture.

III. LATTICE SYSTEMS

It would also be useful to have the transformation technique for lattice systems since they arise naturally in statistical mechanics. In this section we shall show that the method applies equally well to the prototypical particle system with next neighbor interactions on $\mathbb{Z}^2$. One reason for this choice is that for this system the phase separation line is known (see, e.g., Refs. 1 and 2). This will allow us to compare our polydisperse modeling with exact results. Another notable one is the fact that the restriction of the particle positions to $\mathbb{Z}^2$ makes the system a perfectly reasonable ''toy model'' of squares with contact pair interactions if β is large enough. Namely that the units of maximal connected particles are now by definition of square lattice geometry such that the next neighbor system on $\mathbb{Z}^2$ mimics the continuous one with contact interactions in $\mathbb{R}^2$ modulo the discretized positions of the units.

As a preliminary we are going to start from the $D=1$ case in Sec. III A. The corresponding specific free energy will be calculated by means of elementary combinatorics and through a mapping onto polydisperse hard rod mixtures. In analogy with the above development, the transformation technique will then be lifted to $\mathbb{Z}^2$ in Sec. III B. To see that it indeed gives sensible thermodynamic properties, at least for sufficiently low temperatures, we will finally compare those with exact results.

A. Next neighbor interacting particles on $\mathbb{Z}$

Throughout this subsection we will work in the ''particle'' representation of lattice systems (as opposed to the ''spin'' representation or the ''alloy'' interpretation—see, e.g., Ruelle[8]). Correspondingly, we consider an interval $\Lambda \subset \mathbb{Z}$ of n integers (points or sites), numbered from left to right, and assign to each site i of Λ a variable x_i which takes the value 1 (occupied site) or 0 (empty site). This means that each lattice site can be occupied by at most one particle. The number of particles of a configuration $x = \{x_i : i \in \Lambda\}$ is defined by $N(x) = \#\{i \in \Lambda : x_i = 1\}$. Furthermore, we associate with each configuration x a Hamiltonian or pair interaction energy (cf. Baxter[1])

$$H(x) = -\mathcal{E} \sum_{i=1}^{n-1} x_i x_{i+1},$$

where $\mathcal{E}\in\mathbb{R}_+$ is again the interaction strength. Then the total Gibbs measure for a particle system with next neighbor interactions on Λ is given by (cf. Ruelle[8])

$$Z(\beta,\mu,n)=\sum_{m=0}^{n}\exp(m\beta\mu)\sum_{\substack{x\in\{0,1\}^n\\ N(x)=m}}\exp[-\beta H(x)]$$

and the thermodynamic pressure as

$$\beta p(\beta,\mu)=\lim_{n\to\infty}\frac{1}{n}Z(\beta,\mu,n).$$

1. Partition of the particle density

To evaluate these, we decompose the system into units of i by the negative, i.e., attractive part of the pair interaction connected particles. Consider an arbitrary n-site configuration $x\in\{0,1\}^n$ such that $N(x)=m\geqslant 1$. Denote by k_i the number of times a unit of i connected particles appears in x. Define correspondingly the set

$$A_m=\left\{k=(k_1,\ldots,k_m):\, k_i\in\{0,\ldots,m\}\wedge\sum_{i=1}^{m}k_i i=m\right\}$$

and let for fixed $k\in A_m$

$$C(n,m,k)=\frac{(\Sigma_{i=1}^{m}k_i)!}{k_1!\cdots k_m!}\binom{n-m+1}{\sum_{i=1}^{m}k_i}. \tag{3.1}$$

There are $C(n,m,k)$ (n,m,k)-configurations x with the same energy $H(x)$. Hence the total Gibbs measure becomes

$$Z(\beta,\mu,n)=1+\sum_{m=1}^{n}\exp(m\beta\mu)\sum_{k\in A_m}C(n,m,k)\,\lambda^{\Sigma_{i=1}^{m}(i-1)k_i}, \tag{3.2}$$

where we introduced $\lambda=\exp(\beta\mathcal{E})\geqslant 1$.

We observe that the empty configuration has one partition, the empty partition.

We also observe the close resemblance of (3.1) to the corresponding formula for sticky rods in Sec. 2.1 of Cuesta and Tutschka.[6] The additional binomial coefficient in (3.1) controls the number of empty sites between successive units.

Since there are no more than n terms in the first sum, and since also the number of summands of the second sum is exponentially bounded (cf. the theorem due to Hardy and Ramanujan on the number of partitions of a positive integer—see, e.g., Andrews[11,12]), the leading order asymptotic behavior of Z is determined by the largest summands in (3.2) (see, e.g., Ellis[20]).

A weak form of Stirling's formula, $\ln(n!)=n\ln n-n+O(\ln n)$, gives as n tends to infinity

$$\frac{1}{n}\ln C(n,m,k)=\left(1-\frac{m}{n}\right)\ln\left(1-\frac{m}{n}\right)-\left(1-\frac{m}{n}-\sum_{i=1}^{m}\frac{k_i}{n}\right)\ln\left(1-\frac{m}{n}-\sum_{j=1}^{m}\frac{k_j}{n}\right)$$
$$-\sum_{i=1}^{m}\frac{k_i}{n}\ln\frac{k_i}{n}+O\left(\frac{\ln n}{n}\right).$$

Here the uniform bound of the reminder can be proved via a binary partition of the sum in $\Sigma_{i=1}^{m} O(\ln k_i)$. Therefore, upon introducing the particle density $\rho = m/n$ and the partial densities $\rho_i = k_i/n$ as $n \to \infty$, we infer that

$$\beta p(\beta,\mu) = \max_{\rho \in (0,1)} [\rho\,\beta\mu - \beta f(\beta,\rho)],$$

where the specific free energy is found to be

$$\beta f(\beta,\rho) = \min_{(\rho_1,\ldots)\in A_\rho} \left[\sum_{i\geqslant 1} \rho_i \ln \frac{\rho_i}{\lambda^{i-1}} + \left(1-\rho-\sum_{i\geqslant 1}\rho_i\right) \ln\left(1-\rho-\sum_{i\geqslant 1}\rho_i\right) - (1-\rho)\ln(1-\rho) \right] \tag{3.3}$$

with $A_\rho = \{(r_1,\ldots): r_i \geqslant 0 \wedge \Sigma_{i\geqslant 1} r_i i = \rho\}$.

Fix $\lambda \geqslant 1$ and $\rho \in (0,1)$. Then the function appearing on the RHS of the overcomplete free energy (3.3) is convex in all the ρ_i. Thus it attains its minimum at the unique value

$$\rho_i = \begin{cases} \dfrac{\rho}{[1+\lambda(\theta-1)]^2} & \text{if } i=1, \\ \dfrac{\rho_1}{\left[1+\dfrac{1}{\lambda(\theta-1)}\right]^{i-1}} & \text{otherwise,} \end{cases}$$

where $\theta \equiv \exp[\beta p(\beta,\rho)]$. Through

$$\sum_{i\geqslant 1} \rho_i = \frac{\rho}{1+\lambda(\theta-1)} \tag{3.4}$$

we have that

$$\left(1-\frac{1}{\theta}\right)[1+\lambda(\theta-1)] = \frac{1}{\rho^{-1}-1}, \tag{3.5a}$$

or explicitly

$$\theta = \frac{1}{2\lambda}\left[-1+\frac{1}{\rho^{-1}-1}+2\lambda+\sqrt{\left(1-\frac{1}{\rho^{-1}-1}\right)^2+\frac{4\lambda}{\rho^{-1}-1}}\right], \tag{3.5b}$$

which is the known result (see, e.g., Lavis and Bell[2]). Hence f simplifies to

$$\beta f(\beta,\rho) = \rho\ln(\theta-1) - \rho\ln[1+\lambda(\theta-1)] - (1-\rho)\ln\theta.$$

Note the formal resemblance of these results to those for $D=1$ sticky balls deduced in Sec. 2.1 of Cuesta and Tutschka.[6] This shows that the discrete geometrical nature of the units is the central property linking next neighbor interacting particles on $\mathbb{Z}$ and sticky rods. One could go ahead and convert the treatment of nonuniform $D=1$ sticky cores as presented in Ref. 6 to the discrete case. Then this picture leads to the conjecture that there is a hard rods mixture form free energy functional for $D=1$ next neighbor lattice gases which is completely characterized by effective pressures $p^{\pm}$.[9,10,6] These pressure-like quantities are determined by quadratic equations [cf. (3.47) of Cuesta and Tutschka[6] as well as (3.5)]. The argument may be ended by noting that in the original derivation of the free energy functional for this system by Percus,[21] the solution of the inverse problem is reduced to a quadratic equation, too.

2. Mapping onto a polydisperse mixture

We end this section by adopting the transformation method of Cuesta and Tutschka[6] to the $D=1$ discrete case.

First we observe that an i-particle unit is of "effective" size $a_i=i+1$, $i\in\mathbb{N}_+$, since a unit of i connected particles starts and terminates by definition with an empty site. Again these units interact through hard core potentials, so that a next neighbor lattice gas on $\mathbb{Z}$ can be mapped onto an additive polydisperse hard rods mixture in which the diameter of component i equals $i+1$.

In the second stage, the internal partition function of an i-particle unit, λ^{i-1}, is incorporated. As above, this amounts of encoding λ^{i-1} into the activity of component i. This completes the transformation to a $D=1$ polydisperse hard core mixture. Let us call this mixture for future reference "original" polydisperse mixture. However, in contrast to the continuous case, we cannot directly evaluate the free energy of this mixture at $\lambda=1$. The complication being that the centers of the hard rods do not necessarily lie on $\mathbb{Z}$. To account for this, we go over to a suitable rescaled additive polydisperse hard rods mixture.

So suppose we have a $D=1$ additive polydisperse hard core mixture in an external field. Let the pair interaction Boltzmann factor between component i and j be given by [in the following a bar signifies a quantity of the "rescaled" polydisperse mixture]

$$\overline{e_{ij}}(y,x)=\chi_{\mathbb{N}}(y-x-(i+j+2)) \tag{3.6}$$

with $x,y\in\mathbb{Z}$ denoting the positions of the hard rods. That is, we consider a mixture with even hard core diameters $\overline{a_i}=2(i+1)$. As usual, the influence of the chemical potential $\overline{\mu_i}$ and the external field $\overline{U_i}$ is represented via the local activity $\overline{z_i}$ of component i (see, e.g., Refs. 14 and 18). The setup is ended by introducing all the local partial densities $\overline{\varrho_i}$ accordingly.

For such a polydisperse mixture, the free energy density functional is known exactly.[14,18] Hence, on taking the uniform limit, we would immediately obtain, say, the equation of state for the $D=1$ next neighbor lattice gas if we would be able to project the excess free energy for the rescaled hard rods mixture onto that for the original one at $\lambda=1$.

To do so, we first exclude certain configurations from the configuration space of the rescaled polydisperse system. Let us introduce the predicate $P(i)\Leftrightarrow i$ even. Then the configurations of the original and the rescaled mixture are equivalent by the following rule. The local partial density $\overline{\varrho_i}$ at $x\in\mathbb{Z}$ is equal to 0 whenever

(I) $\neg P(i)\wedge\neg P(x)$ or $P(i)\wedge P(x)$.

In order to have full equivalence between the two systems, we furthermore restrict the domain of the observables for the rescaled mixture to the set

(II) $\{x\in\mathbb{Z}\colon P(x)\}$.

Now let us put everything together. We start from the excess free energy density functional for the rescaled pure hard rods mixture as characterized by the pair interaction Boltzmann factor (3.6). Imposing the boundary conditions (I) and (II), one gets an excess free energy functional which reduces in the uniform limit to the excess free energy for the original $D=1$ polydisperse hard core mixture at $\lambda=1$. From this, upon incorporating the partition functions of the units, λ^{i-1}, the function on the RHS of (3.3) is reproduced, as must be the case.

Finally it may be noted that an alternative form of the equation of state follows most readily from (3.3) through one of the well-known thermodynamic relations (see, e.g., Ruelle[8]). We find that [cf. (2.23) of Lafuente and Cuesta[18]]

$$\beta p(\beta,\rho)=\ln\left[\frac{1-\Sigma_{i\geqslant 1} i\rho_i}{1-\Sigma_{i\geqslant 1}(i+1)\rho_i}\right],$$

which is via $\Sigma_{i\geqslant 1} i\rho_i=\rho$ and (3.4) equivalent to (3.5).

B. Extension to $\mathbb{Z}^2$

We consider the standard example[1] of a system with next neighbor interactions on the square lattice. As before, we use the "particle" representation, so that with every site $i \in \mathbb{Z}^2$ a state variable $x_i \in \{0,1\}$ is associated. Then the lattice energy is[1]

$$H = -\mathcal{E} \sum_{(i,j)} x_i x_j ,$$

where (i,j) signifies an unordered next neighbor pair and $\mathcal{E}$ is as above the interaction strength.

For such a system, several thermodynamic properties are known exactly. Our objective is to transcribe the procedure of Sec. II B to this case, allowing us to study the validity of idealizations such as Assumptions 2.1 and 2.2. The development goes through modulo changes due to the discrete nature of the system. Therefore, there is probably no need to be too detailed in what follows.

1. Restricted overcomplete representation

As in the continuous case, we begin the construction with a decomposition of the system into units of connected particles. Here, two particles are said to be connected if their pair interaction energy equals $-\mathcal{E}$. By applying the transformation technique of Cuesta and Tutschka,[6] this partition of the system can be turned into a mapping onto polydisperse hard core mixtures. However, as was argued in Sec. II B, a mathematical analysis of such a polydisperse mixture is beyond reach. Thus, in order to build a solvable model, we restrict ourselves to a certain class of compact unit configurations. The lattice analogue of Assumption 2.1 reads as follows.

Assumption 3.1: The polydisperse representation of a particle system with next neighbor interactions on $\mathbb{Z}^2$ is completely characterized by rectangular arrays of connected particles.

Recall that this idealization cannot possibly be exact, but that it is expected to be valid at sufficiently high temperatures, low densities, or low temperatures. Again, the high density limit has to be examined separately.

The units interact with each other via hard core potentials. Next the precise nature of these pair interactions will be defined. For $i=(i_1,i_2)$, $i_1,i_2 \in \mathbb{N}_+$, denote by $R_i \subset \mathbb{Z}^2$ a rectangle of side lengths i_1 and i_2, respectively, as well as by $A_i \subset \mathbb{Z}^2$ the "effective" shape of an $i_1 \times i_2$ array of connected particles. Then, in analogy with the $D=1$ case, the interior of the set A_i is given by R_{i-1}; the boundary of A_i represents again the coat of empty sites on the circumference of each unit. Since every site has four next neighbors, A_i is equal to R_{i+1} only modulo the sites on the corners of R_{i+1}. Clearly, we cannot proceed analytically with a polydisperse mixture composed of particles of sorts A_i. So that in contrast to the continuous case, Assumption 3.1 is not strong enough to specify a mathematically tractable polydisperse Hamiltonian. We therefore make the following additional simplification.

Assumption 3.2: An $i_1 \times i_2$ array of connected particles has effective shape R_{i+1}.

The consequences of the assumption may be described as follows. If the system is in a sufficiently dilute state, then the additional excluded volume is negligible compared to the total free volume of the system. Hence Assumption 3.2 holds for sufficiently low densities. On the other hand, Assumption 3.2 should also be a good approximation whenever the predominant units are sufficiently large, since the boundary of A_i is of no consequence in the limit $i_1,i_2 \to \infty$. This means that Assumption 3.2 is expected to be valid for intermediate and high densities if β is sufficiently large, too.

With Assumptions 3.1 and 3.2, the first stage of the transformation can be ended. By now, the next neighbor square lattice gas is mapped onto an additive polydisperse mixture of hard rectangles with side lengths i_1+1 and i_2+1, respectively.

In the second stage, the partition function of an i-unit is appended to the activity of component i of the mixture. Through the next neighbor nature of the interaction, the total isothermal measure of an $i_1 \times i_2$ array of connected particles is found to be $C_{i_1 i_2}(\lambda) = \lambda^{2i_1 i_2 - (i_1 + i_2)}$. This completes the polydisperse setting.

Next we will construct the free energy for this polydisperse mixture at $\lambda = 1$. Once this, say, "level-2" free energy is known, the free energy for the next neighbor interacting particle system on $\mathbb{Z}^2$ (the "level-1" free energy, then) is obtainable via a variational formula (stage three of the transformation technique—see above).

To simplify the computation of the level-2 excess free energy, we can follow the same procedure as in Sec. III A 2. That is, we introduce a nonuniform additive polydisperse mixture of pure hard rectangles with even side lengths $2(i_1+1)$ and $2(i_2+1)$, respectively. This is our "level-3" system. Then the following four disjunctive rules guarantee that all with respect to the level-2 system spurious configurations are excluded from the level-3 configuration space. Depending on the shape of the units, the local partial density of component i of the level-3 system vanishes at $(x_1, x_2) \in \mathbb{Z}^2$ whenever

(I) $(\neg P(i_1) \wedge \neg P(i_2)) \wedge (\neg P(x_1) \vee \neg P(x_2))$,

(II) $(P(i_1) \wedge \neg P(i_2)) \wedge (P(x_1) \vee \neg P(x_2))$,

(III) $(\neg P(i_1) \wedge P(i_2)) \wedge (\neg P(x_1) \vee P(x_2))$, or

(IV) $(P(i_1) \wedge P(i_2)) \wedge (P(x_1) \vee P(x_2))$.

There is a further condition for full equivalence. The domain of the observables is to be restricted to the set

(V) $\{(x_1, x_2) \in \mathbb{Z}^2 : P(x_1) \wedge P(x_2)\}$.

These rules relate the level-3 excess properties and the sought level-2 excess thermodynamic functions at $\lambda = 1$.

Like in the $D = 2$ continuous case, we are forced to evaluate the level-3 excess free energy functional by means of some extrapolation type of scheme. Recently, Lafuente and Cuesta[18] wrote down the discrete version of Zhang's global free energy functional for continuous hard rod mixtures. This RFL scaled-particle-type functional serves as our basic underlying level-3 excess free energy model.

Assumption 3.3: The global free energy functional is the same for additive polydisperse hard rod mixtures on $\mathbb{Z}$ and additive polydisperse hard rectangle mixtures on $\mathbb{Z}^2$.

The same comments as above can be made. Assumption 3.3 is exact for sufficiently low densities, and it is believed to hold up to (at least) intermediate or moderately high densities.[18]

We are now ready to deduce the free energy for next neighbor square lattice gases under Assumptions 3.1–3.3. First take the global free energy functional (Assumption 3.3) and generate the excess free energy density functional for an additive mixture of rectangles with even side lengths $2(i_1+1)$ and $2(i_2+1)$, respectively. Next, introduce a related functional by applying projection (I)–(V). By construction, this functional gives in the uniform limit the excess part of [cf. (3.13) of Lafuente and Cuesta[18]]

$$\beta f^*(\beta, \rho, \{\rho_{i_1 i_2}\}_{i_1, i_2 \geqslant 1})\big|_{C_{i_1 i_2}(\lambda) \equiv 1} = \sum_{i_1, i_2, \geqslant 1} \rho_{i_1 i_2} \ln \rho_{i_1 i_2} + (1-\xi)\ln(1-\xi) - (1-\nu_1)\ln(1-\nu_1) - (1-\nu_2)\ln(1-\nu_2) + (1-\rho)\ln(1-\rho),$$

the specific free energy at $\lambda = 1$ associated with the polydisperse Hamiltonian function specified through Assumption 3.1 and 3.2. Here, the sequence $\{\rho_{i_1 i_2}\}_{i_1, i_2 \geqslant 1}$ represents the partial densities

of the system, $\rho=\Sigma_{i_1,i_2\geqslant 1} i_1 i_2\, \rho_{i_1 i_2}$ is the particle density, $\nu_1=\Sigma_{i_1,i_2\geqslant 1}(i_1+1) i_2\, \rho_{i_1 i_2}$, $\nu_2=\Sigma_{i_1,i_2\geqslant 1} i_1(i_2+1)\, \rho_{i_1 i_2}$, and $\xi=\Sigma_{i_1,i_2\geqslant 1}(i_1+1)(i_2+1)\, \rho_{i_1 i_2}$. Moreover, processing the ideal gas part we conclude that

$$\beta f^*(\beta,\rho,\{\rho_{i_1 i_2}\}_{i_1,i_2\geqslant 1}) = \sum_{i_1,i_2,\geqslant 1} \rho_{i_1 i_2} \ln \frac{\rho_{i_1 i_2}}{C_{i_1 i_2}(\lambda)} + (1-\xi)\ln(1-\xi) - (1-\nu_1)\ln(1-\nu_1) - (1-\nu_2)\ln(1-\nu_2) + (1-\rho)\ln(1-\rho).$$

Finally recall that a variational principle relates the level-1 and level-2 free energy functions (stage three of the transformation technique), so that we infer from Assumptions 3.1–3.3 for the specific free energy of a classical next neighbor square lattice gas

$$\beta f(\beta,\rho) = \min_{(\rho_{11},\ldots)\in A_\rho} \beta f^*(\beta,\rho,\{\rho_{i_1 i_2}\}_{i_1,i_2\geqslant 1})$$

with $A_\rho=\{(r_{11},\ldots): r_{i_1 i_2}\geqslant 0 \wedge \Sigma_{i_1,i_2\geqslant 1} i_1 i_2\, r_{i_1 i_2}=\rho\}$.

Fix $\lambda\geqslant 1$ and suitable $\rho\in(0,1)$ (cf. Assumption 3.2). Then f^* is convex in all the partial densities. Hence the minimum is attained at

$$\rho_{i_1 i_2} = \rho_{11}\left(\frac{\rho_{11}}{1-\xi}\right)^{i_1 i_2 - 1}\left[\frac{\lambda(1-\eta)}{1-\xi}\right]^{2 i_1 i_2 - (i_1+i_2)} \qquad (i_1\neq 1)\wedge(i_2\neq 1),$$

where $\nu_1=\nu_2\equiv\eta$ via spatial symmetry. Therefore f simplifies to

$$\beta f(\beta,\rho) = \rho\ln\rho_{11} + (1-4\rho)\ln(1-\xi) - 2(1-2\rho)\ln(1-\eta) + (1-\rho)\ln(1-\rho).$$

Furthermore, we have for the thermodynamic pressure

$$\beta p(\beta,\rho) = \ln\left[\frac{(1-\eta)^2}{(1-\xi)(1-\rho)}\right]. \tag{3.7}$$

2. Exact coexistence curve

We come now to the final step (step three) in our program. Also for a feeling as to what to expect for the continuous case if β is sufficiently large, we will compare the pressure function (3.7) with the exact equation of state in the two-phase thermodynamic region of the system.

In order to keep things simple, we take $\mathcal{E}=1$, so that the phase separation line can be parametrized by $\lambda=\lambda(\beta)=\exp\beta$ [remember that we have set $\lambda=\exp(\beta\mathcal{E})$]. Then the exact thermodynamic pressure at phase equilibrium for a classical next neighbor square lattice gas is[1,2]

$$\beta p(\beta) = \ln\left(1+\frac{1}{\lambda}\right) + \frac{1}{\pi}\int_0^{\pi/2} \ln\left[\frac{1}{2}(1+\sqrt{1-k_1^2\sin^2\theta})\right] d\theta, \quad \lambda\geqslant\lambda_c, \tag{3.8a}$$

where

$$k_1=\frac{2\sqrt{k}}{1+k}, \quad k=\frac{4\lambda}{(\lambda-1)^2},$$

and λ_c denotes the "critical" value of λ, determined by the quadratic equation $k=1$. This yields via the condition $\lambda\geqslant 1$ the number $\lambda_c=3+2\sqrt{2}$. The exact "conjugate" particle densities at phase equilibrium are found to be[1,2]

$$\rho_\pm(\beta) = \tfrac{1}{2}(1\pm\sqrt[8]{1-k^2}), \quad \lambda\geqslant\lambda_c. \tag{3.8b}$$

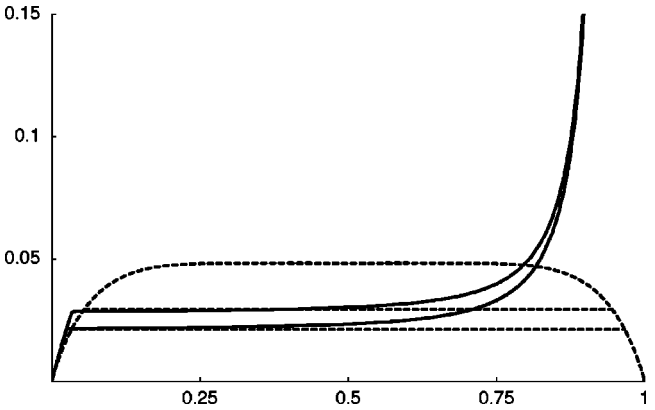

FIG. 2. Finite approximation isotherms (full lines) for the classical next neighbor square lattice gas model (3.7): βp as a function of $\rho \in (0,1)$ for $\lambda = 7$ (upper curve) and $\lambda = 8$ (lower graph). The upper summation limit n of the sums in (3.7) was picked to be 35. The broken lines are the exact phase separation line (3.8) and the corresponding exact pressures at phase equilibrium (3.8a), respectively.

Two $(\beta p, \rho)$ isotherms of (3.7) (full lines) for λ greater than λ_c are shown in Fig. 2. Notice that the upper summation limit n of the sums in (3.7) was set to 35. The broken curve is the exact coexistence curve (3.8) and the broken horizontal lines are the corresponding exact phase equilibrium pressures (3.8a).

While incrementing the summation limit n, the flattish part of the isotherms becomes both flatter and longer. Since the proportion of small units decreases when n increases, the pressure is lower for $n+1$, too. Thus one may conjecture that for sufficiently large n the pressure function (3.7) is a good approximation over a wide range of densities if λ is large enough; according to Fig. 2, an estimate is $\lambda \geqslant 8$. Clearly, what remains to be checked is that the error brought in via Assumption 3.3 will only be felt when ρ is high. It may also be noted that for, say, $\lambda < 8$, at least the ρ_- part of the phase separation line is overestimated. This defect of our model is not uncommon: it affects for example also the well-known mean field square lattice gas (see, e.g., Lavis and Bell[2]).

In summary, the numerical evaluation indicates that the lattice scheme behaves precisely as expected when β is sufficiently large. And this also gives—indirectly—some confidence in the soundness of the continuous $D=2$ extension developed in Sec. II B.

IV. CONCLUDING REMARKS

The construction of the model in $\mathbb{R}^2$ carries over to $\mathbb{R}^D$, where $D \geqslant 3$, essentially without change. But it shall ease the process if from the start we handle the model by symbolic means, since the calculations get a little involved, though, under passage to arbitrary D. While for $D=2$, the characteristic spatial structures are rectangles (cf. Assumption 2.1), for general D, these sets generalize to $(i_1, \ldots, i_D)$ type cuboids in D-dimensional space $\{(x_1, \ldots, x_D) \in \mathbb{R}^D: |x_k| \leqslant i_k/2 \text{ for } k = 1, \ldots, D\}$, where $i_1, \ldots, i_D \in \mathbb{N}_+$. Then, in analogy with Assumption 2.2, the basic underlying free energy model for an additive polydisperse mixture of pure D-cuboids is obtained via the global free energy functional for hard rod mixtures (cf. Cuesta and Martínez-Ratón[17]).

Clearly, to proceed to increasingly complex solvable models, ''less'' compact unit configurations are to be included in a systematic fashion. The point here is not so much that a larger class of unit configurations is introduced, i.e., that of expanding Assumption 2.1, but rather that the new configurations give rise to a polydisperse Hamiltonian function for which Zhang's global free energy functional is no longer applicable (cf. Cuesta and Martínez-Ratón[17]). This means that improvements in the polydisperse representation depend largely on the future development in density functional theory for additive polydisperse pure hard core mixtures.

Yet another obvious question to be considered is whether one can analyze systems with square-well interactions under the milder condition of non-vanishing attraction ranges. The most interesting feature of this class of potentials is that we may now not merely forget the range parameter d of the interactions. Still, the construction proceeds as above when we are willing to start from a $D=1$ particle system with square-well interactions in which the size of connected next neighbor pairs is restricted to finitely many values. Thereafter, the deduction of the free energy for such a ''discretized'' square-well potential follows the method developed in Sec. II A. Like for the asymptotic $d\to 0^+$ case, the extension to $\mathbb{R}^2$ is then carried out by lifting this particular $D=1$ density functional representation to $D=2$ and combining it with suitable idealizations in order to make the model solvable (cf. Assumptions 2.1 and 2.2). Once the discrete version is sufficiently well understood, we get what we really want by taking the continuum limit.

The main theme will be again the incorporation of the unit partition functions into the additive polydisperse hard core mixture format, only that now an asymptotic analysis of these total isothermal measures as $d\to 0^+$ does not suffice. Progress in this direction will be reported in due course.

The existence of ring-like structures in exact Hopfion solutions is shown. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1612897]

I. INTRODUCTION

Extended solutions are of central importance in different applications of modern field theory, from high energy to condensed matter physics. Their relevance is parallel to the difficulty in the analysis of the nonlinear theories which encode them and the scarce exact results in higher dimensions. To circumvent one of the main problems, the scaling instablity for scalar fields beyond one spatial dimension found by Skyrme[1] and formalized by Derrick,[2] one obvious possibility is nonpolynomial Lagrangians, which are not unfamiliar. Among those attempts the work by Deser, Duff, and Isham,[3] where the simplest choice of just the power required to balance the scaling is analyzed, is of special interest. As the authors discuss, such models have, of course, no free field expansion around a trivial vacuum. But they can have a semiclassical formulation around nontrivial solutions and eventually a small time dependent perturbation of the static solutions. One solution was found and the importance of global transformations was emphasized. This model was further extended by Nicole[4] and put in a more general framework by Kundu.[5] It was rediscovered independently in a series of papers[6] in the context of a new proposal for a generalized integrability,[7] finding infinitely many analytic solutions with general Hopf indices. This was an unsolved problem, which is important for soliton physics and because of the many applications of those maps, combining topology and geometry. In their last paper,[8] a new feature of the Hopfion solutions was discovered, namely, a line singularity in an infinitely thin tube along the z axis from a special current with a nonconserved charge, provided by the geometric method.

In this article we extend the analysis to find that there is in fact another solution of the ring type, which is interesting, as ring structures are typical in higher dimensional soliton analysis, both in numerical[9] and analytical approximations.[10] In fact, these currents and solutions should be relevant for the analytical study of soliton scattering. We also pay special attention to the symmetries, including global aspects of the solution, as many aspects of the model are generic to other local formulations of topological degrees of freedom. Time dependence analysis is also a natural possiblity in the generalized zero curvature approach, as it preserves Lorentz covariance.

II. THE RING-LIKE SOLUTIONS

As shown in Ref. 8, the only models involving the antisymmetric tensor in the complex field u,

$$h_{\mu\nu} = -i\,(\partial_\mu u \partial_\nu u^* - \partial_\nu u \partial_\mu u^*), \tag{1}$$

a)Electronic mail: adam@mat.univie.ac.at

which satisfy without constraints the integrability criterion of the geometric approach of Ref. 7 (i.e., infinitely many conserved currents) and which can be derived from an action principle, are those where the Lagrangian is a functional of h^2/f^2, where f is a real function of u and u^*. If one further asks for scaling invariance to allow for stable static solutions, we are lead to the class of models given by the Lagrangian density

$$\mathcal{L}\equiv\left(\frac{h_{\mu\nu}^2}{2\,f^2}\right)^{3/4}, \tag{2}$$

which generalizes and explains choices and solutions found before.[3–6]

We assume from now on that f only depends on uu^*. If $\lim_{|\vec{x}|\to\infty}u(\vec{x})=u_0=\text{const}$ is assumed, then the domain space $\mathbb{R}^3$ has the topology of the three-sphere S^3. If, in addition, the target space may be identified with the two-sphere S^2 via stereographic projection, then u may be interpreted as a map $S^3\to S^2$, which is characterized by an integer winding number (the Hopf index). In this case there exists an infinite number of static, soliton-like solutions to the equations of motion of the model, and these all have integer Hopf index. These solutions were first found in Ref. 6 and they are obtained by inserting into the static equations of motion

$$-h_{ij}\partial^j u\,\partial^i h^2+4h^2\partial^i h_{ij}\partial^j u+i(h^2)^2\partial_{u^*}f=0 \tag{3}$$

(where $h^2\equiv h_{ij}h^{ij}$) the product ansatz

$$u(\eta,\xi,\varphi)\equiv R(\eta)e^{i(m\xi+n\varphi)} \tag{4}$$

in toroidal coordinates

$$\begin{gathered}x=q^{-1}\sinh\eta\cos\varphi,\quad y=q^{-1}\sinh\eta\sin\varphi,\\ z=q^{-1}\sin\xi;\quad q=\cosh\eta-\cos\xi.\end{gathered} \tag{5}$$

As explained elegantly in Ref. 8, the ansatz (4) follows from the conformal symmetry of the equations of motion. If one assumes that f is a function of $T\equiv R^2\equiv uu^*$ only, $\partial_{u^*}f$ simplifies to $\partial_{u^*}f=f_{,T}\,u$. With the ansatz (4), this results in an ordinary differential equation for $R(\eta)$, which may be conveniently expressed in terms of $T\equiv R^2\equiv uu^*$ as

$$\left(\ln\frac{T_{,\eta}}{f}\right)_{,\eta}=\frac{\cosh\eta}{\sinh\eta}\,\frac{n^2-2m^2\sinh^2\eta}{n^2+m^2\sinh^2\eta} \tag{6}$$

and $X_{,\eta}$ denotes derivative of X with respect to η. Further, we assume $m^2>n^2$ in the sequel. A first integral may be found easily,

$$\frac{T_{,\eta}}{f}=k_1\frac{\sinh\eta}{(n^2+m^2\sinh^2\eta)^{3/2}} \tag{7}$$

(here k_1 is a constant of integration), whereas for a further integration the explicit form of the function $f(T)$ is needed.

In the end, we shall choose $f=(1+T)^2$, because we are referring to the solutions of Babelon and Ferreira,[8] but let us briefly mention a class of functions $f(T)$ that leads to a target space with the topology of the two-sphere and, therefore, to genuine Hopf solitons, which can have useful applications. For $f=(1+T)^2$, the expression h_{ij}/f in the Lagrangian density (2) is, in fact, just the pull-back under the map u of the area two-form

$$d\Omega=-i\frac{\mathrm{d}z\,\mathrm{d}z^*}{(1+zz^*)^2} \tag{8}$$

on the two-sphere. A pull-back of this two-form under maps $S^2 \to S^2$ will lead to further acceptable area two-forms (i.e., area two-forms respecting the topology of the target space). If we want to maintain the simple dependence $f=f(T)$, then a class of allowed maps is

$$\phi: \ z \to \sqrt{g(zz^*)}e^{il\ \arg(z)}. \tag{9}$$

These are indeed maps $S^2 \to S^2$ provided that $g(0)=0$ and $g(\infty)=\infty$. Further, l must be an integer. The pullback of the area two-form (8) is

$$\phi_*(d\Omega) = -i\frac{\mathrm{dz}\ \mathrm{dz}^* l g'}{(1+g)^2}, \tag{10}$$

therefore any function f of the type

$$f(T) = \frac{(1+g(T))^2}{l\, g_{,T}} \tag{11}$$

leads to a theory (2) with genuine Hopf solitons.

In the sequel we restrict to the simplest case $f=(1+T)^2$ (the area two-form on the two-sphere). Then the first integral (7) may be easily integrated to yield

$$\frac{1}{1+T} = \frac{k_1}{(m^2-n^2)}\frac{\cosh\eta}{(n^2+m^2\sinh^2\eta)^{1/2}} + k_2, \tag{12}$$

where k_1 and k_2 are two constants of integration. These constants have to be fixed by imposing some boundary conditions on the field u. For this purpose let us introduce the unit vector $\vec{n}$ related to u via stereographic projection

$$\vec{n} = \frac{1}{1+|u|^2}(u+u^*, -i(u-u^*), |u|^2-1) \quad , \quad u = \frac{n_1+in_2}{1-n_3}. \tag{13}$$

If u is supposed to be a true Hopf map, then the number of allowed boundary conditions is, in fact, very restricted. The point is that a true Hopf map should cover the whole target S^2, including the north pole ($\vec{n}=(0,0,1)$, or $T=\infty$) and the south pole ($\vec{n}=(0,0,-1)$, or $T=0$). Therefore, the boundary conditions should be chosen such that T varies between $T=0$ and $T=\infty$. Further, the pre-images of the north pole and the south pole should be one-dimensional lines in $\mathbb{R}^3$. However, the only values of η which define one-dimensional lines (instead of two-dimensional tori, as is the general case), are $\eta=0$, which defines the z axis (together with spatial infinity), and $\eta=\infty$, which defines the circle

$$C = \{\vec{x}\in\mathbb{R}^3: \ z=0 \ \wedge \ r^2=1\}. \tag{14}$$

Therefore, there are two possible choices for the boundary conditions, namely, $T(\eta=0)=0$, $T(\eta=\infty)=\infty$, or $T(\eta=0)=\infty$, $T(\eta=\infty)=0$.

In Ref. 8 the second option was chosen (which we call $T^{(2)}$ for convenience),

$$T^{(2)} = \frac{\cosh\eta - \sqrt{n^2/m^2+\sinh^2\eta}}{\sqrt{1+m^2/n^2\sinh^2\eta}-\cosh\eta}, \quad T^{(2)}(\eta=0)=\infty \quad , \quad T^{(2)}(\eta=\infty)=0. \tag{15}$$

Let us now investigate our first option, for which we get

$$T^{(1)} = (T^{(2)})^{-1}, \quad T^{(1)}(\eta=0)=0 \quad , \quad T^{(1)}(\eta=\infty)=\infty. \tag{16}$$

Now one could simply identify the solitons with the position of their singular value $|u|=\infty$, then the solitons of type $T^{(2)}$ would be identified with the straight line $x=0,y=0$ (the z axis), and the solitons of type $T^{(1)}$ would be ascribed to the circle C. However, this identification is in principle quite arbitrary, and requires a physical motivation.

In Ref. 8 it was shown that the solitions of type $T^{(2)}$ can indeed be identified with the z axis in a well-defined manner. More precisely, there exists a conserved current J_μ which has the property that for solitons of type $T^{(2)}$ it is singular along the z axis. Moreover, a constant flow of this current is emerging from the singular line (the z axis). Here we want to investigate the equivalent problem for solitons of type $T^{(1)}$, which is relevant as rings are common in higher dimensional solitons.[9,10]

So let us briefly review and further develop some results of Ref. 8 on the above-mentioned conserved current, with some more details required for our purposes. There exists (among other symmetries) a symmetry of the action under a transformation which is a combination of a dilatation on three-dimensional domain space plus a specific transformation on target space. The infinitesimal version of this symmetry transformation is given in Ref. 8, but it is, in fact, not difficult to obtain the transformation for finite transformation parameter. Under a dilatation transformation $x\to\Lambda^3 x\equiv e^{3\lambda}x$ (the power three of the dilatation parameter is chosen for later convenience) the action of the theory scales like

$$S\to\Lambda^{-3}S, \tag{17}$$

therefore the theory is invariant if the dilatation is combined with a transformation of the target space variable, $u\to v(u,\overline{u})$, such that

$$\frac{\mathrm{d}u\,\mathrm{d}\overline{u}}{(1+\overline{u}u)^2}\to\frac{\mathrm{d}v\,\mathrm{d}\overline{v}}{(1+\overline{v}v)^2}=\Lambda^2\frac{\mathrm{d}u\,\mathrm{d}\overline{u}}{(1+\overline{u}u)^2}. \tag{18}$$

If we introduce the real coordinates on target space $u=T^{1/2}e^{i\phi}$ (angle and radius squared on the Euclidean plane) and assume that $v=(\tilde{T})^{1/2}(T)e^{i\phi}$ (i.e., u and v have the same argument, and the modulus of v is a function of the modulus T only) then we get

$$\frac{\tilde{T}'(T)\mathrm{d}T\,\mathrm{d}\phi}{(1+\tilde{T})^2}=\Lambda^2\frac{\mathrm{d}T\,\mathrm{d}\phi}{(1+T)^2} \tag{19}$$

or

$$\frac{\tilde{T}'}{(1+\tilde{T})^2}=\frac{\Lambda^2}{(1+T)^2} \tag{20}$$

with the solution

$$\frac{1}{1+\tilde{T}}=\frac{\Lambda^2}{1+T}+c, \tag{21}$$

where c is a constant of integration. If we require the boundary condition $\tilde{T}(0)=0$ then we get

$$\tilde{T}=\frac{\Lambda^2 T}{\Lambda^2+(1+T)(1-\Lambda^2)} \tag{22}$$

or

$$v=\frac{\Lambda u}{[\Lambda^2+(1+\overline{u}u)(1-\Lambda^2)]^{1/2}}. \tag{23}$$

This v indeed fulfills Eq. (18) as may be checked easily. In addition, it reduces to the transformation of Babelon and Ferreira[8] for infinitesimal λ (i.e., $\Lambda=1+\lambda$). Therefore Eq. (23) is the required symmetry transformation on target space. (Observe that this transformation has the funny property that it is well-defined only for $\Lambda^2\leqslant 1$, i.e., for scaling transformations which shrink distances.)

The conserved Noether current related to this symmetry transformation is

$$J_\mu=x^\nu\Theta_{\mu\nu}+j_\mu, \tag{24}$$

where $\Theta_{\mu\nu}$ is the canonical energy–momentum tensor of the theory, and j_μ is

$$j_\mu=-i\left(\frac{h^2}{2(1+T)^4}\right)^{-1/4}\frac{1}{2(1+T)^3}h_{\mu\nu}(u\partial^\nu u^*-u^*\partial^\nu u). \tag{25}$$

Here, the first term of J_μ (containing the energy–momentum tensor) is due to the space dilatation, whereas the second term, j_μ, is due to the specific target space transformation (23). The current obeys the conservation equation $\partial^\mu J_\mu=0$. For static configurations $u(\vec{x})$ this conservation equation may be used to derive the relation

$$E\equiv\partial_t\int d^3xJ^0=\int_\Sigma d\vec{f}\cdot\vec{J}, \tag{26}$$

where E is the static energy of the static configuration,

$$E=4\pi^2\sqrt{|m||n|(|m|+|n|)}, \tag{27}$$

and the integral on the right-hand side of (26) is an integral over surfaces Σ which surround the singularities of the current $\vec{J}$. It turns out that the first term of the current for static fields, $x^j\Theta_{ij}$, is regular everywhere and may, therefore, be ignored in the surface integral of (26) provided that the integration surfaces are chosen such that the enclosed volume is infinitesimal. For the current $\vec{j}$ we find after some calculation

$$\vec{j}=\left(\left|\frac{T_{,\eta}}{(1+T)^2}\right|\right)^{1/2}\frac{T}{1+T}\left(\frac{n^2}{\sinh^2\eta}+m^2\right)^{3/4}(\cosh\eta-\cos\xi)^2\vec{e}_\eta, \tag{28}$$

where $\vec{e}_\eta=(\cosh\eta-\cos\xi)^{-1}\nabla\eta$ is a vector of unit length which is perpendicular to the surfaces of constant η (tori). Observe that $\vec{e}_\eta$ is pointing into the interior of the tori, because η is growing in this direction. We may use the first integral of the equations of motion, (7), for the first factor on the right-hand side containing $T_{,\eta}$, and find

$$\vec{j}=\sqrt{|m||n|(|m|+|n|)}\,\frac{T}{1+T}\,\frac{(\cosh\eta-\cos\xi)^2}{\sinh\eta}\,\vec{e}_\eta. \tag{29}$$

If we ignore the factor $T/(1+T)$ for the moment, then we see that the remaining expression is singular both for $\eta=0$ (along the z axis) and for $\eta=\infty$ (along the circle C). Depending on whether we choose $T^{(1)}$ or $T^{(2)}$ for T, one of the two singularities gets canceled, whereas the other remains. For $T=T^{(2)}$ (the case which was studied in Ref. 8), the singularity along the z axis remains. In this case we choose a very large torus $\eta\ll 1$ as integration surface. For the regular terms the limit $\eta\to 0$ may be performed, such that the integration is extended to the whole space. For the singular $\vec{j}$ the surface integral should be performed for a finite η and the limit $\eta\to 0$ should be taken afterwards. The surface element on the torus surface $\eta=\text{const}$ is

$$\mathrm{d}\vec{f}=\vec{e}_{\eta}\frac{\sinh\eta}{(\cosh\eta-\cos\xi)^2}\mathrm{d}\varphi\,\mathrm{d}\xi, \tag{30}$$

therefore the surface integral is

$$\int_{\eta=\mathrm{const}}\vec{j}\cdot\mathrm{d}\vec{f}=\sqrt{|m||n|(|m|+|n|)}\,\frac{T}{1+T}\int\mathrm{d}\varphi\,\mathrm{d}\xi=4\pi^2\sqrt{|m||n|(|m|+|n|)}\,\frac{T}{1+T}. \tag{31}$$

For $T=T^{(2)}$ this should be evaluated in the limit $\eta\to 0$ for which $T^{(2)}/(1+T^{(2)})$ is equal to one. Therefore the total flux emerging from the singular line (the z axis) is

$$\mathrm{flux}=4\pi^2\sqrt{|m||n|(|m|+|n|)}=E, \tag{32}$$

where E is the static energy (27).

On the other hand, for $T=T^{(1)}$ the singularity is located at the circle C, therefore a tiny torus (large η) should be excluded from the integration region. So we take the limit $\eta\to\infty$ now in the surface integral (31). But $T^{(1)}/(1+T^{(1)})$ is equal to one in this limit, so we find again for the flux the same previous expression (32).

Therefore, for solutions of the type $T^{(1)}$ the singular line is the circle C and a nonzero flux of total amount given in (32) emerges from this singular circle. As a consequence, the solutions of type $T^{(1)}$ are characterized by a ring-like structure, where the ring is located at the position of the circle C, which, as said, is relevant for their physics and especially for the scattering.

III. DISCUSSION

So we indeed found that in addition to the solutions of type $T^{(2)}$ originally obtained by Aratyn, Ferreira, and Zimerman (AFZ) in Ref. 6, which are characterized by a straight line of singular flux according to Babelon and Ferreira, there exist solutions where the singular flux is located along the circle C, forming thereby a ring-like structure. In hindsight, this result is not so surprising, and the ring-like structure is, in fact, the generic case. To see this, let us invoke a further symmetry of the model, namely, constant rotations of the target space S^2. In domain space $\mathbb{R}^3$ such a rotation rotates different level curves (i.e., curves of constant $u=u_0$ for different values of u_0) into each other, because these level curves are the pre-images of points of the target S^2 under the map u. Generically, these level curves are circles, with the only exception of the z axis. Therefore, any rotation on target space which moves the north pole and the south pole will transform a solution of type $T^{(2)}$ into a new solution where the line of singular flux is located along a circle.

On the target space coordinate u such rotations are represented by modular transformations $u\to(a+bu)/(c+du)$, where $ad-bc=1$. A general modular transformation is, however, not compatible with the simple ansatz (4) which was used by AFZ to find solutions. The only nontrivial modular transformation compatible with the ansatz (4) is the inversion map $u\to(1/u)$. And indeed, the composition of the inversion map with the map $(m,n)\to(-m,-n)$ (which again maps a solution to another solution with the same energy) precisely maps the AFZ solutions $T^{(2)}$ to the solutions of type $T^{(1)}$ discussed in this paper.

Besides their interest for the scattering, the results can also be useful—given the generic features of the theory considered—for other higher dimensional models on the sphere and/or using similar scaling arguments, like Skyrme theory and its restriction to the SU(2)/U(1) coset, proposed by Faddeev as an effective theory of QCD at long distances.[11]

(Received 16 July 2003; accepted 24 July 2003)

We investigate the weak Hopf algebras of Li based on $U_q[sl_n]$ and Sweedler's finite dimensional example. We give weak Hopf algebra isomorphisms between the weak generalizations of $U_q[sl_n]$ which are ''upgraded'' automorphisms of $U_q[sl_n]$ and hence give a classification of these structures as weak Hopf algebras. We also show how to decompose these examples into a direct sum which leads to unexpected isomorphisms between their algebraic structure. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1616999]

I. INTRODUCTION

Since the introduction of quantum groups,[1] the importance of Hopf algebras has been widely recognized in both mathematics and physics. Generalizations of Hopf algebras have been considered, usually motivated by some application in mathematical physics. The most well-known example of the generalizations may be quasi-Hopf algebras where the coassociativity of a Hopf algebra is relaxed,[2] but at the same time keeping the category of modules monoidal. A similar type of relaxation of coassociativity is also found in truncated quasi-Hopf algebras[3] and rational Hopf algebras.[4] This is where the notion of a weak coproduct was introduced, such that $\Delta(1) \neq 1 \otimes 1$, and was motivated by the study of symmetries in low dimensional quantum field theory. One problem that arose was the fact that the dual of these structures was not associative, which led to further problems in defining crossed products and a double construction.[5] Although these issues have already been addressed in Refs. 6 and 7, the question still arose as to the possibility of defining a structure which could still provide nonintegral dimensions for the quantum field theories in a similar way to the weak quasi-Hopf algebras,[3] but at the same time be coassociative. This was the motivation behind defining the weak Hopf algebras of Refs. 5, 8, and 9. Since these are not bialgebras, but *almost* bialgebras,[10] there were also axioms required to define a weak antipode, differing slightly from the usual ones of a Hopf algebra such that the category of finite dimensional modules was still monoidal, and also with a rigidity structure defined through a generalized antipode.[9] Another question then arose as to the possibility of defining a weak antipode on bialgebras. Li has introduced the notion of a weak Hopf algebra to mean a bialgebra on which is defined such a weak antipode.[10,11] In this paper, we investigate these weak Hopf algebras as defined by Li.

The concept of a weak Hopf algebra is rather new. There are not many examples known, though several have appeared in the literature. One example is given by the semigroup algebra of any regular monoid which gives a generalization of the well-known group algebra.[11] The other known examples were given in Ref. 12 where the authors presented two weak Hopf generalizations of the quantized enveloping algebra $U_q[sl_2]$.

The purpose of this paper is twofold. First, we wish to propose some minor adjustments to the examples given in Ref. 12. Second, we extend the construction to the case of other known Hopf algebras such as $U_q[sl_n]$[13] and Sweedler's Hopf algebra.[14,15] It is also evident that we can define weak extensions of quantum superalgebras in a similar way. As a consequence, we shall have a lot of new nontrivial examples of weak Hopf algebras. We believe that for a deeper understanding

of weak Hopf algebras as well having some insight into their applications, it is important to have various examples.

The paper is organized as follows. In Sec. II we give a brief summary of the definition of weak Hopf algebra. Following that, Sec. III has a closer look at the examples given in Ref. 12 and we propose slightly modified versions of these examples. We then realize in Sec. IV that for $U_q[sl_n]$ there is a plethora of examples which leads us to finding isomorphisms between structures, thus giving a classification in some sense of weak Hopf algebras corresponding to $U_q[sl_n]$. The following section looks at weak extensions of Sweedler's famous finite dimensional Hopf algebra, where we also show that with our construction, in general we can decompose the weak Hopf algebra into a direct sum of the original bialgebra with some other subalgebra. This leads to ''unexpected'' algebra isomorphisms between structures in some cases.

II. WEAK HOPF ALGEBRAS

For the reader's convenience we recall the definition of a weak Hopf algebra in the sense of Li and Duplij.[10,12] Let $(H,\Delta,\varepsilon,m,u)$ be a bialgebra over a field K, where $\Delta:H\to H\otimes H$ is the coproduct, $\varepsilon:H\to K$ is the counit, $m:H\otimes H\to H$ the product and $u:K\to H$ the unit of H. The following properties define H:

$$m(m\otimes \mathrm{id})=m(\mathrm{id}\otimes m),$$

$$m(u\otimes \mathrm{id})=\mathrm{id}=m(\mathrm{id}\otimes u),$$

$$(\mathrm{id}\otimes\Delta)\Delta=(\Delta\otimes\mathrm{id})\Delta,$$

$$(\varepsilon\otimes\mathrm{id})\Delta=\mathrm{id}=(\mathrm{id}\otimes\varepsilon)\Delta,$$

$$(m\otimes m)(\mathrm{id}\otimes\sigma\otimes\mathrm{id})(\Delta\otimes\Delta)=\Delta\circ m,$$

$$\varepsilon\otimes\varepsilon=\varepsilon\circ m.$$

Here $\sigma:H\otimes H\to H\otimes H$ is the flip operator $\sigma(h_1\otimes h_2)=h_2\otimes h_1$ for all $h_1,h_2\in H$.

H is a weak Hopf algebra if there is a weak antipode $T:H\to H$ which is an algebra homomorphism satisfying the two conditions

$$T*\mathrm{id}*T=T, \tag{2.1}$$

$$\mathrm{id}*T*\mathrm{id}=\mathrm{id}, \tag{2.2}$$

with the convolution product $*$ defined over maps on H by

$$a*b\equiv m(a\otimes b)\Delta:H\to H.$$

Note that the antipode of a Hopf algebra is a weak antipode due to the fact that $u\circ\varepsilon:H\to H$ is the identity of the convolution product $*$. Recall that $S:H\to H$ is an antipode if it satisfies

$$S*\mathrm{id}=u\circ\varepsilon, \tag{2.3}$$

$$\mathrm{id}*S=u\circ\varepsilon. \tag{2.4}$$

For example, we see that

$$S*\mathrm{id}=u\circ\varepsilon$$

$$\Rightarrow \mathrm{id}*S*\mathrm{id}=\mathrm{id}*u\circ\varepsilon$$

$$\Rightarrow \mathrm{id}*S*\mathrm{id}=\mathrm{id}.$$

In fact S needs only be a left or right antipode, meaning it satisfies only one of the two equalities (2.3) or (2.4), in order for it to be a weak antipode.

III. WEAK $U_q[sl_2]$

In this section we give a summary of the examples of weak $U_q[sl_2]$ presented in Ref. 12. It is notable that the defining relations of the "J-weak" quantum algebra $v\mathfrak{sl}_q(2)$ given in that paper can be simplified, and we give a minor adjustment to this example and show that it is in fact a weak Hopf algebra. We also give one other example generalizing $U_q[sl_2]$ which uses a mixture of the two examples from Ref. 12.

We remind the reader that the usual $U_q[sl_2]$ relations to which we refer, in terms of the four generators E,F,K,K^{-1}, are as follows:

$$K^{-1}K=KK^{-1}=1, \tag{3.1}$$

$$KEK^{-1}=q^2E, \tag{3.2}$$

$$KFK^{-1}=q^{-2}F, \tag{3.3}$$

$$EF-FE=\frac{K-K^{-1}}{q-q^{-1}}. \tag{3.4}$$

The coalgebra structure (coproduct Δ, counit ε) is given by

$$\Delta(K^{\pm 1})=K^{\pm 1}\otimes K^{\pm 1},$$

$$\Delta(E)=E\otimes K+1\otimes E,$$

$$\Delta(F)=F\otimes 1+K^{-1}\otimes F,$$

$$\varepsilon(E)=\varepsilon(F)=0,$$

$$\varepsilon(K^{\pm 1})=1.$$

It is clear that when we wish to determine the explicit action of the antipode, we apply the definition (2.3) and (2.4) to an arbitrary element in the algebra and solve. In all cases we can solve explicitly due to the existence of the invertible group-like elements $1,K,K^{-1}$. The obvious first step in generalization to the weak Hopf case would be to attempt to remove the invertibility of these elements. This was the main idea in Ref. 12 when generalizing the above definition.

First, all weak extensions of $U_q[sl_2]$ have generators $E,F,K,\overline{K}$ satisfying

$$K\overline{K}=\overline{K}K\equiv J, \tag{3.5}$$

$$K\overline{K}K=K, \quad \overline{K}K\overline{K}=\overline{K}, \tag{3.6}$$

$$EF-FE=\frac{K-\overline{K}}{q-q^{-1}}. \tag{3.7}$$

In what follows we usually write the generators with subscripts (following Ref. 12) to differentiate the definitions.

Definition 1 (from Ref. 12): $w\mathfrak{sl}_q(2)$ is the algebra generated by the four elements E_w, F_w, K_w, $\overline{K}_w$ satisfying (3.5), (3.6), (3.7) along with the relations

$$K_w E_w = q^2 E_w K_w, \tag{3.8}$$

$$\overline{K}_w E_w = q^{-2} E_w \overline{K}_w, \tag{3.9}$$

$$K_w F_w = q^{-2} F_w K_w, \tag{3.10}$$

$$\overline{K}_w F_w = q^2 F_w \overline{K}_w. \tag{3.11}$$

Here the invertibility of K and $\overline{K}$ has been relaxed, and instead of the identity, the element J_w has been introduced. It can be seen that this element J_w satisfies

$$aJ_w = J_w a, \quad \forall a \in w\mathfrak{sl}_q(2).$$

To demonstrate this we check

$$E_w J_w \overset{(3.5)}{=} E_w K_w \overline{K}_w \overset{(3.8)}{=} q^{-2} K_w E_w \overline{K}_w \overset{(3.9)}{=} K_w \overline{K}_w E_w \overset{(3.5)}{=} J_w E_w. \tag{3.12}$$

A similar calculation is performed for F_w and the calculations for K_w and $\overline{K}_w$ are trivial.

Also note that due to the relations (3.6), J_w is an idempotent. Namely,

$$J_w^2 = J_w.$$

The coalgebra structure is defined as follows. The coproduct and counit are, respectively, given by

$$\Delta_w(E_w) = 1 \otimes E_w + E_w \otimes K_w,$$

$$\Delta_w(F_w) = F_w \otimes 1 + \overline{K}_w \otimes F_w,$$

$$\Delta_w(K_w) = K_w \otimes K_w,$$

$$\Delta_w(\overline{K}_w) = \overline{K}_w \otimes \overline{K}_w,$$

$$\varepsilon_w(E_w) = \varepsilon_w(F_w) = 0,$$

$$\varepsilon_w(K_w) = \varepsilon_w(\overline{K}_w) = 1.$$

It can be verified that they are both algebra homomorphisms so that

$$\Delta_w(xy) = \Delta_w(x)\Delta_w(y)$$

and

$$\varepsilon_w(xy) = \varepsilon_w(x)\varepsilon_w(y)$$

for all $x,y \in w\mathfrak{sl}_q(2)$, thus preserving the defining relations. With this coproduct a corresponding weak antipode can be determined by solving equations (2.1) and (2.2) with the above coproduct. The only possible weak antipode in this case is

$$T_w(1) = 1,$$

$$T_w(K_w) = \overline{K}_w,$$

$$T_w(\overline{K}_w) = K_w, \tag{3.13}$$

$$T_w(E_w) = -E_w\overline{K}_w,$$

$$T_w(F_w) = -K_wF_w.$$

It can be shown that T_w is an algebra antihomomorphism, that is, $T(ab)=T(b)T(a)$. Note that with the above bialgebra structure it is not possible to determine an antipode in the usual sense. As we mentioned previously, this was the motivation for relaxing (3.1) to (3.5) in order to provide weak antipodes which are not antipodes. For example, to solve the equation

$$S*\mathrm{id}(K)=\varepsilon(K)1 \Rightarrow S(K)K=1,$$

we would need an inverse of the element K.

Another possible definition given in Ref. 12 is the following.

Definition 2 (from Ref. 12): $v\mathfrak{sl}_q(2)$ is the algebra generated by the four elements E_v, F_v, K_v, $\overline{K}_v$ satisfying (3.5), (3.6), (3.7) along with the relations

$$K_vE_v\overline{K}_v = q^2E_v, \tag{3.14}$$

$$K_vF_v\overline{K}_v = q^{-2}F_v. \tag{3.15}$$

In this case, $J_v=K_v\overline{K}_v$ satisfies the relation

$$J_va = aJ_v = a, \tag{3.16}$$

for $a=E_v$, F_v, K_v, $\overline{K}_v$ (and hence J_v). To demonstrate, we have

$$E_vJ_v \overset{(3.5)}{=} E_vK_v\overline{K}_v \overset{(3.14)}{=} q^{-2}K_vE_v\overline{K}_vK_v\overline{K}_v \overset{(3.6)}{=} q^{-2}K_vE_v\overline{K}_v \overset{(3.14)}{(=E_v)} \overset{(3.6)}{=} q^{-2}K_v\overline{K}_vK_vE_v\overline{K}_v$$
$$\overset{(3.14)}{=} K_v\overline{K}_vE_v \overset{(3.5)}{=} J_vE_v.$$

For the generator F_v, a similar calculation can be done. For the cases K_v and $\overline{K}_v$, the calculation is trivial. The most remarkable consequence of this property is that the analogue of defining relation (3.7) presented in Ref. 12 which was in the form

$$E_vJ_vF_v - F_vJ_vE_v = \frac{K_v-\overline{K}_v}{q-q^{-1}},$$

reduces to (3.7) by the above argument. Therefore in what follows we shall always use relation (3.7) and not the relation above.

The coalgebra structure for this second definition is as follows:

$$\begin{aligned}\Delta_v(E_v) &= J_v\otimes E_v + E_v\otimes K_v,\\ \Delta_v(F_v) &= F_v\otimes J_v + \overline{K}_v\otimes F_v,\end{aligned} \tag{3.17}$$

with the remaining actions coinciding precisely with the case of definition 1.

Moreover, relations (3.14) and (3.15) can be manipulated to those of definition 1. We demonstrate that

$$K_vE_v \overset{(3.6)}{=} K_v\overline{K}_vK_vE_v \overset{(3.5),(3.16)}{=} K_vE_v\overline{K}_vK_v \overset{(3.14)}{=} q^2E_vK_v.$$

The other relations can be verified in a similar way. Although the coproduct is different to that of definition 1, there exists a weak antipode which is the same as (3.13) in the case of definition 1.

This indicates that much of the discussion in Ref. 12 relating to $v\mathfrak{sl}_q(2)$ is redundant. However, we would like to make it clear that we consider the paper[12] rich in ideas and an inspiration to our current investigations.

There are other possibilities for defining weak extensions of $U_q[sl_2]$. These involve mixtures of definition 1 and definition 2 over the generators E,F. For example, we can say that one case is where E satisfies the relations (3.8), (3.9) and F satisfies (3.15), along with all the other relations common to both definition 1 and definition 2. The coproduct would then have the action

$$\Delta(E)=1\otimes E+E\otimes K,$$

$$\Delta(F)=F\otimes J+\overline{K}\otimes F,$$

along with the usual group-like coproduct for K and $\overline{K}$. The weak antipode would still be the same as in definitions 1 and 2.

We can also swap this mixture of definitions and say that E satisfies those relations of definition 2, but F satisfies the relations of definition 1. This case is actually isomorphic to the first mixture, as we shall see later. In the section on weak $U_q[sl_n]$ we give a more formal way of notating such mixtures.

So we now have some clues as to how we may approach the problem of defining weak extensions of $U_q[sl_n]$. It is clear that there will be many possible combinations of generators satisfying either of the two definitions in the general case. This then begs the question: how would we know which mixtures of the two definitions lead to isomorphic algebras? To this end we have an important observation regarding some of the automorphisms of the original quantum algebra $U_q[sl_n]$ which "lift up" to isomorphisms between weak Hopf structures. We shall look at these isomorphisms in more detail in the next section.

In general, we say that a generator satisfying the relations of definition 1 is of type 1, and is type 2 if it satisfies the relations of definition 2.

IV. WEAK $U_q[sl_n]$

A. Mixing definitions

For the case of $w\mathfrak{sl}_q(n)$, which has simple generators E_i, F_i, K_i and $\overline{K_i}$ $(i=1,\ldots,n-1)$, we can choose either definition 1 or 2 to describe the relations between any E_i and the $K_j/\overline{K_j}$ and similarly for any F_i. This is what is meant by the word "mixture." The relations satisfied by the generators are as follows, for all i,j unless specified otherwise:

$$\begin{gathered}
K_iK_j=K_jK_i,\ \ \overline{K_i}\,\overline{K_j}=\overline{K_j}\,\overline{K_i},\ \ K_i\overline{K_j}=\overline{K_j}K_i,\quad K_i\overline{K_i}=J,\\
JK_j=K_jJ=K_j,\ \ J\overline{K_j}=\overline{K_j}J=\overline{K_j},\\
E_iF_j-F_jE_i=\delta_{ij}\frac{K_i-\overline{K_i}}{q-q^{-1}},\\
E_i^2E_{i\pm1}-(q+q^{-1})E_iE_{i\pm1}E_i+E_{i\pm1}E_i^2=0,\\
F_i^2F_{i\pm1}-(q+q^{-1})F_iF_{i\pm1}F_i+F_{i\pm1}F_i^2=0,\\
E_iE_j=E_jE_i,\ \ F_iF_j=F_jF_i,\ \ |i-j|\geqslant 2.
\end{gathered}\tag{4.1}$$

We also need to specify the relations between the E_i and the K_j, for example. Let a_{ij} denote the Cartan matrix for $sl(n)$, $a_{ii}=2$, $a_{i,i\pm1}=-1$ and zero otherwise. If E_i satisfies

$$K_jE_i=q^{a_{ij}}E_iK_j,\quad E_i\overline{K_j}=q^{a_{ij}}\overline{K_j}E_i,\quad \forall j,\tag{4.2}$$

we say E_i satisfies definition 1, or simply E_i is type 1. However, if E_i satisfies

$$K_j E_i \overline{K}_j = q^{a_{ij}} E_i, \quad \forall j, \tag{4.3}$$

we say E_i satisfies definition 2, or simply E_i is type 2. The same convention holds for F_i by replacing E_i with F_i and a_{ij} with $-a_{ij}$ in the above relation. Notice also that J is defined for all i, so, for example,

$$J = K_i \overline{K}_i = K_j \overline{K}_j, \quad i \neq j.$$

The coproduct has the following action:

$$\begin{aligned}
\Delta(K_i) &= K_i \otimes K_i, \\
\Delta(\overline{K}_i) &= \overline{K}_i \otimes \overline{K}_i, \\
\Delta(E_i) &= \begin{cases} 1 \otimes E_i + E_i \otimes K_i, & E_i \text{ is type } 1 \\ J \otimes E_i + E_i \otimes K_i, & E_i \text{ is type } 2, \end{cases} \\
\Delta(F_i) &= \begin{cases} F_i \otimes 1 + \overline{K}_i \otimes F_i, & F_i \text{ is type } 1 \\ F_i \otimes J + \overline{K}_i \otimes F_i, & F_i \text{ is type } 2, \end{cases}
\end{aligned} \tag{4.4}$$

while the action of the counit is

$$\varepsilon(1) = \varepsilon(K_i) = \varepsilon(\overline{K}_i) = 1, \quad \varepsilon(E_i) = \varepsilon(F_i) = 0.$$

The weak antipode T will always have the form

$$\begin{aligned}
T(1) &= 1, \\
T(K_i) &= \overline{K}_i, \\
T(\overline{K}_i) &= K_i, \\
T(E_i) &= -E_i \overline{K}_i, \\
T(F_i) &= -K_i F_i,
\end{aligned}$$

regardless of the type of the generators E_i and F_i.

In order to notate these mixtures for $w\mathfrak{sl}_q(n)$ we use a binary notation, where a 1 indicates the use of a type 1 generator and a 0 indicates the use of a type 2 generator. We list the $2(n-1)$ simple generators E_i and F_i, starting with the E_i followed by the F_i. We then write down a list of 0's and 1's in the order corresponding to the generators determined by their type. This then gives an integer from 0 to $2^{2(n-1)}-1$ in binary representation which contains all the information as to which particular mixture of definition we are using for the relations between the generators E_i and F_i and all the $K_j/\overline{K}_j$. We denote this integer d and the algebra is expressed as $w\mathfrak{sl}_q^d(n)$. In total there are $2^{2(n-1)}$ possible mixtures for $w\mathfrak{sl}_q^d(n)$.

Note that we cannot have different definitions for the relations between the same generator with different K_i's because the coproduct could not possibly be consistent with those defining relations.

For example, in the case of $w\mathfrak{sl}_q(4)$ we have the simple generators (not including the K_i), $E_1, E_2, E_3, F_1, F_2, F_3$. Hence there are $2^6 = 64$ different possibilities for relations with the K_i. The notation $w\mathfrak{sl}_q^{43}(4)$ has the following meaning. Since the number 43 has the binary represen-

tation 101011, this is interpreted to mean that the simple generators E_1, E_3, F_2, F_3 are type 1 with the remaining ones E_2, F_1 being type 2. This information is determined by superimposing the list of binary digits $\{1,0,1,0,1,1\}$ with the list of simple generators in the order $\{E_1, E_2, E_3, F_1, F_2, F_3\}$.

It should also be noted that the algebra $w\mathfrak{sl}_q^3(2)$ coincides with $w\mathfrak{sl}_q(2)$ given in Ref. 12 (and in section III above) and the example $v\mathfrak{sl}_q(2)$ of Ref. 12 is precisely $w\mathfrak{sl}_q^0(2)$ in our notation.

B. Isomorphic structures

Now we look in more detail at the weak Hopf algebras of type $U_q[sl_n]$ using mixtures of the two types of generators. In some cases where $d_1 \neq d_2$, there exists a weak Hopf algebra isomorphism $w\mathfrak{sl}_q^{d_1}(n) \simeq w\mathfrak{sl}_q^{d_2}(n)$. It is therefore worth investigating all possible isomorphisms in order to classify the weak extensions based on our criteria. As we shall see in this section, the isomorphisms are derived from a subset of the set of automorphisms on the algebra $U_q[sl_n]$. In other words, a subset of the automorphisms on $U_q[sl_n]$ "lift up" to isomorphisms between the weak Hopf extensions. The reason only a subset can be considered, as we shall see later, is because some of the automorphisms of $U_q[sl_n]$ lose their invertibility when upgraded to act on the weak $w\mathfrak{sl}_q^d(n)$, so therefore cannot be isomorphisms.

If $(A, \Delta, \varepsilon, T)$ and $(B, \Delta', \varepsilon', T')$ are weak Hopf algebras, then a weak Hopf algebra isomorphism $\psi: A \to B$ is an invertible algebra homomorphism satisfying

$$(\psi \otimes \psi) \circ \Delta = \Delta' \circ \psi, \tag{4.5}$$

$$\varepsilon = \varepsilon' \circ \psi, \tag{4.6}$$

$$\psi \circ T = T' \circ \psi. \tag{4.7}$$

For example, consider the algebra $w\mathfrak{sl}_q^1(2)$. This has generators $E^{(1)}, F^{(1)}, K^{(1)}, \overline{K}^{(1)}$ (and $1^{(1)}$) satisfying

$$K^{(1)}\overline{K}^{(1)} = \overline{K}^{(1)}K^{(1)} \equiv J^{(1)},$$

$$K^{(1)}\overline{K}^{(1)}K^{(1)} = K^{(1)}, \quad \overline{K}^{(1)}K^{(1)}\overline{K}^{(1)} = \overline{K}^{(1)},$$

$$K^{(1)}F^{(1)} = q^{-2}F^{(1)}K^{(1)}, \quad \overline{K}^{(1)}F^{(1)} = q^2F^{(1)}\overline{K}^{(1)},$$

$$K^{(1)}E^{(1)}\overline{K}^{(1)} = q^2E^{(1)},$$

$$E^{(1)}F^{(1)} - F^{(1)}E^{(1)} = \frac{K^{(1)} - \overline{K}^{(1)}}{q - q^{-1}},$$

since the binary representation of $1 = \{0,1\}$ is superimposed with the list of generators $\{E^{(1)}, F^{(1)}\}$ and so $E^{(1)}$ is type 2 and $F^{(1)}$ is type 1. Let us now consider the coalgebra structure of this algebra. The coproduct Δ and counit ε are, respectively, given by

$$\Delta(K^{(1)}) = K^{(1)} \otimes K^{(1)},$$

$$\Delta(\overline{K}^{(1)}) = \overline{K}^{(1)} \otimes \overline{K}^{(1)},$$

$$\Delta(E^{(1)}) = J^{(1)} \otimes E^{(1)} + E^{(1)} \otimes K^{(1)},$$

$$\Delta(F^{(1)}) = F^{(1)} \otimes 1^{(1)} + \overline{K}^{(1)} \otimes F^{(1)},$$

$$\varepsilon(E^{(1)})=\varepsilon(F^{(1)})=0,$$

$$\varepsilon(K^{(1)})=\varepsilon(\overline{K}^{(1)})=1.$$

Now consider the map $\psi: w\mathfrak{sl}_q^1(2)\to w\mathfrak{sl}_q^2(2)$ defined by the action

$$\psi(E^{(1)})=F^{(2)},$$

$$\psi(F^{(1)})=E^{(2)},$$

$$\psi(K^{(1)})=\overline{K}^{(2)},$$

$$\psi(\overline{K}^{(1)})=K^{(2)},$$

where we have employed an obvious notation with superscripts. This map derives from the so-called Cartan involution on $U_q[sl_2]$. In the weak case it can be seen to be a weak Hopf algebra isomorphism since it preserves the generator type (that is, it is consistent with the defining relations) and is also consistent with Eqs. (4.5)–(4.7).

In general the rule is that such an isomorphism must map a type 1 generator into a type 1 generator and similarly for type 2. We demonstrate the sort of calculation required to show consistency with the relations. Take, for example,

$$\begin{aligned}\text{lhs}&=\psi(K^{(1)})\psi(E^{(1)})\psi(\overline{K}^{(1)})=\overline{K}^{(2)}F^{(2)}K^{(2)}=q^2\overline{K}^{(2)}(K^{(2)}F^{(2)}\overline{K}^{(2)})K^{(2)}\\&=q^2F^{(2)}=q^2\psi(E^{(1)})=\text{rhs}.\end{aligned}$$

The other relations can be realized in a similar fashion. To demonstrate consistency with the coproduct, we can use Eq. (4.5) to determine Δ' in this case. For example, applying both sides of (4.5) to $E^{(1)}$ gives

$$(\psi\otimes\psi)\Delta(E^{(1)})=(\psi\otimes\psi)(J^{(1)}\otimes E^{(1)}+E^{(1)}\otimes K^{(1)})=J^{(2)}\otimes F^{(2)}+F^{(2)}\otimes\overline{K}^{(2)},$$

$$\Delta'(\psi(E^{(1)}))=\Delta'(F^{(2)}).$$

This then gives the action of Δ' on $F^{(2)}$. The remaining actions are

$$\Delta'(E^{(2)})=E^{(2)}\otimes 1^{(2)}+K^{(2)}\otimes E^{(2)},$$

$$\Delta'(K^{(2)})=K^{(2)}\otimes K^{(2)},$$

$$\Delta'(\overline{K}^{(2)})=\overline{K}^{(2)}\otimes\overline{K}^{(2)}.$$

Note that this is not the coproduct given in Eqs. (4.4), but it is in fact the opposite coproduct, $\Delta^{\sigma}=\sigma\circ\Delta$ (σ being the flip operator), which we know from the theory of bialgebras is a perfectly acceptable one. It is also straightforward to verify (4.6) holds. Because the action of the weak antipode is dependent on the coproduct, T' will be different to the one presented earlier. It is straightforward to verify that it does indeed exist, and that Eq. (4.7) is satisfied.

Although there are undoubtedly many other possibilities to extend $U_q[sl_2]$ to a weak structure, the extensions presented in this paper based on that of Ref. 12 total three, namely, $w\mathfrak{sl}_q^0(2)$, $w\mathfrak{sl}_q^1(2)\simeq w\mathfrak{sl}_q^2(2)$, and $w\mathfrak{sl}_q^3(2)$. In each case the weak antipode has the same action, that of (3.13).

C. Number of unique structures

We now address the question of the number of possible weak Hopf algebra isomorphisms $\psi: w\mathfrak{sl}_q^d(n) \to w\mathfrak{sl}_q^{d'}(n),\ d \neq d'$.

It is well known that for $U_q[sl_n]$ there are several types of automorphisms.[16] The most relevant to this paper are the Dynkin diagram automorphisms and the Cartan involution, since they give rise to Hopf algebra automorphisms and antiautomorphisms, respectively. We consider maps ρ_d and ω_d which have the same actions as the Dynkin diagram automorphism and the Cartan involution, respectively, but applied to the weak Hopf algebra $w\mathfrak{sl}_q^d(n)$. These maps then become isomorphisms between weak Hopf structures. Their actions are given by

$$\rho_d(E_i^{(d)}) = E_{n-i}^{(d')}, \quad \rho_d(F_i^{(d)}) = F_{n-i}^{(d')}, \quad \rho_d(K_i^{(d)}) = K_{n-i}^{(d')}, \quad \rho_d(\overline{K}_i^{(d)}) = \overline{K}_{n-i}^{(d')},$$

$$\omega_d(E_i^{(d)}) = F_i^{(d'')}, \quad \omega_d(F_i^{(d)}) = E_i^{(d'')}, \quad \omega_d(K_i^{(d)}) = \overline{K}_i^{(d'')}, \quad \omega_d(\overline{K}_i^{(d)}) = K_i^{(d'')},$$

where the indices d (corresponding to the source), d' and d'' (corresponding to the targets) are used to differentiate between the structures. Note that ρ_d and ω_d map into different spaces which justifies the use of the different indices d' and d''. With these actions, it can be easily verified that

$$\rho_{d'} \circ \rho_d = \mathrm{id}, \quad \omega_{d''} \circ \omega_d = \mathrm{id}.$$

Lusztig[17] has also given a set of algebra automorphisms defined on the quantized enveloping algebras. However, when applied to our weak generalizations, they are found to be noninvertible and therefore are not isomorphisms between weak Hopf algebras.

Although we know of the existence of other algebra isomorphisms which exist between structures, the only known weak Hopf algebra isomorphisms are ρ_d and ω_d. We will comment more on these algebra isomorphisms in Sec. V.

One important point is that ρ_d and ω_d both preserve the generator type, so for example if $E_i^{(d)}$ is a type 1 generator, so are $E_{n-i}^{(d')}$ and $F_i^{(d'')}$. Therefore ρ_d and ω_d must correspond to maps (say r_d and w_d, respectively) defined on the non-negative integers such that

$$\rho_d : w\mathfrak{sl}_q^d(n) \to w\mathfrak{sl}_q^{r_d(d)}(n),$$

$$\omega_d : w\mathfrak{sl}_q^d(n) \to w\mathfrak{sl}_q^{w_d(d)}(n).$$

Once we know the action of the maps r_d and w_d, this should allow us to be able to determine which structures are isomorphic and hence lead to a classification.

To this end, we write d in terms of its binary expansion

$$d = (d_0, d_1, \ldots, d_{n-2} | d_{n-1}, \ldots, d_{2n-3}),$$

where the bar separates the values representing the E_i and F_i, and where the d_i have values of either 0 or 1. Then $r_d(d)$ and $w_d(d)$ have the expansions

$$w_d(d) = (d_{n-1}, \ldots, d_{2n-3} | d_0, \ldots, d_{n-2}),$$

$$r_d(d) = (d_{n-2}, \ldots, d_0 | d_{2n-3}, \ldots, d_{n-1}).$$

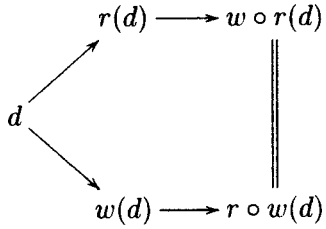
In terms of the components of the binary expansion we have

$$w_d(d_k) = d'_{3n-4-k \bmod 2(n-1)},$$

$$r_d(d_k) = d''_{n-1+k \bmod 2(n-1)}.$$

This simplifies the problem of determining isomorphic structures and allows us to explicitly count the number of unique structures for each n.

It is worth noting that $\rho\circ\omega=\omega\circ\rho$, so the only isomorphisms we need to consider are ρ, ω and $\rho\circ\omega$ (we have dropped the subscripts for convenience). According to this prescription, there can only be at most four structures which are isomorphic. In some cases there could be two and in others there could be no isomorphisms. These cases are referred to below as degenerate. The situation can be summarized in the following diagram



where in some cases the arrows could be equalities, in which case there would be one of the aforementioned degeneracies. In order to count the number of unique (nonisomorphic) weak extensions of $ws\mathfrak{l}_q^d(n)$, we list all the possible degenerate cases;

(1) $w(d)=d$,
(2) $r(d)=d$,
(3) $r(d)=w(d)$,

and consider their intersection $(1)\cap(2)\cap(3)$, union $(1)\cup(2)\cup(3)$ and their union's complement $\overline{(1)\cup(2)\cup(3)}$ in order to count the total number of unique cases. We note that some of these cases will lead to exactly two isomorphic structures, and combinations of the above cases will lead to no isomorphic structures. We aim to separate each of these situations and then add the number of structures relating to each.

Case (1): The only d satisfying $w(d)=d$ is of the form

$$d=(d_0,d_1,\ldots,d_{n-2}|d_0,d_1,\ldots,d_{n-2}).$$

Therefore the total number of cases satisfying case (1) is 2^{n-1}.

Case (2): We separate this case into two cases corresponding to n being odd and even. For $n=2m+1$ the only d satisfying case (2) is of the form

$$d=(d_0,d_1,\ldots,d_{m-1},d_{m-1},\ldots,d_0|d_{2m},d_{2m+1},\ldots,d_{3m-1},d_{3m-1},\ldots,d_{2m}),$$

so there are $2^{2m}=2^{n-1}$ possibilities. For $n=2m$ the only d satisfying case (2) has the form

$$d=(d_0,\ldots,d_{m-2},d_{m-1},d_{m-2},\ldots,d_0|d_{2m-1},\ldots,d_{3m-3},d_{3m-2},d_{3m-3},\ldots,d_{2m-1}),$$

so there are $2^{2(m-1)+2}=2^{2m}=2^n$ possibilities.

Case (3): The only d satisfying this case is of the form

$$d=(d_0,d_1,\ldots,d_{n-2}|d_{n-2},\ldots,d_0),$$

so there are 2^{n-1} possibilities.

$(1)\cap(2)\cap(3)$: Once again we treat the case for n is even and odd separately. For $n=2m+1$, d is of the form

$$d=(d_0,d_1,\ldots,d_{m-1},d_{m-1},\ldots,d_0|d_0,d_1,\ldots,d_{m-1},d_{m-1},\ldots,d_0),$$

so there are $2^m=2^{(n-1)/2}$ possibilities. For $n=2m$, d is of the form

$$d=(d_0,\ldots,d_{m-2},d_{m-1},d_{m-2},\ldots,d_0|d_0,\ldots,d_{m-2},d_{m-1},d_{m-2},\ldots,d_0),$$

giving $2^m=2^{n/2}$ possibilities.

$(1)\cup(2)\cup(3)$: Combining the above three cases and subtracting twice their intersection gives the union, for which there are $3.2^{2m}-2^{m+1}$ possibilities for $n=2m+1$ and $2^{2m+1}-2^{m+1}$ possibilities for $n=2m$. The compliment of the union then has $2^{4m}-3.2^{2m}+2^{m+1}$ possibilities for $n=2m+1$ and $2^{4m-2}-2^{2m+1}+2^{m+1}$ possibilities for $n=2m$.

To calculate the exact number of unique structures we consider the fact that case (1) without cases (2) or (3) (and permutations) will have precisely two structures which are isomorphic, or put another way, isomorphic structures in these cases come in pairs. Therefore we need to half the number obtained above when counting the total number of structures. Similarly for the structures which do not fall into these degenerate cases. There will be exactly four isomorphic structures so we need to divide the number corresponding to $(1)\cup(2)\cup(3)$ by 4.

Therefore the number of nonisomorphic structures, say Z_n, is

$$Z_{2m+1}=\frac{2^{2m}-2^m}{2}+\frac{2^{2m}-2^m}{2}+\frac{2^{2m}-2^m}{2}+2^m+\frac{2^{4m}-3.2^{2m}+2^{m+1}}{4}=2^{4m-2}+\frac{3}{4}.2^{2m},$$

$$Z_{2m}=\frac{2^{2m-1}-2^m}{2}+\frac{2^{2m}-2^m}{2}+\frac{2^{2m-1}-2^m}{2}+2^m+\frac{2^{4m-2}-2^{2m+1}+2^{m+1}}{4}=2^{4m-4}+2^{2m-1}.$$

Putting these two cases together gives

$$Z_n=2^{n-4}(7+(-1)^n+2^n),$$

which is the number of unique weak Hopf structures corresponding to $w\mathfrak{sl}_q^d(n)$.

This formula for Z_n has been verified up to $n=10$ by directly applying the maps ρ, ω and $\rho\circ\omega$ and then counting the number of unique structures. To give the reader an idea of the number of structures, we have the table below.

n	2	3	4	5	6	7	8	9	10
Z_n	3	7	24	76	288	1072	4224	16 576	66 048

We also list for $n\leqslant 4$ all the values of d, putting isomorphic values in brackets $\{,\}$. For $n=2$ we have already determined that the values

$$d=0,\{1,2\},3$$

give the three unique structures. For $n=3$ the values of d for the seven structures are

$$d=0,\{1,2,4,8\},\{3,12\},\{5,10\},\{6,9\},\{7,11,13,14\},15.$$

For $n=4$ the 24 values of d are

$$d=0,\{1,4,8,32\},\{2,16\},\{3,6,24,48\},\{5,40\},\{7,56\},\{9,36\},\{10,17,20,34\},\{11,25,38,52\},\{12,33\},$$
$$\{13,37,41,44\},\{14,28,35,49\},\{15,39,57,60\},18,\{19,22,26,50\},\{21,42\},\{23,58\},\{27,54\},$$
$$\{29,43,46,53\},\{30,51\},\{31,55,59,62\},45,\{47,61\},63.$$

All cases up to $n=10$ have been calculated, but are obviously too unwieldy to include in the article.

V. DIRECT SUM DECOMPOSITION AND SWEEDLER'S EXAMPLE

We now look in more detail at the algebraic structure and show that the upgraded quantized enveloping algebra automorphisms are not the only algebra isomorphisms between the various $w\mathfrak{sl}_q^d(n)$.

First recall Sweedler's example[14] of a finite dimensional Hopf algebra, denoted H. H is generated by elements I,G,X (where I is the identity element) satisfying the relations

$$G^2=I,$$

$$GX=-XG,$$

$$X^2=0.$$

The coproduct is given by

$$\Delta(G)=G\otimes G,$$

$$\Delta(X)=X\otimes G+I\otimes X,$$

and the counit given by

$$\varepsilon(G)=1=\varepsilon(I), \quad \varepsilon(X)=0.$$

The antipode S is given by the action

$$S(G)=G, \quad S(I)=I, \quad S(X)=GX.$$

Clearly H is four dimensional with basis $\{I,G,GX,X\}$.

In order to give an example of a weak Hopf algebra based on this structure with generators $\{1,g,x\}$ (we now use lower case symbols), instead of using the relation $g^2=1$, we impose the relation $g^3=g$. Moreover, we can choose either the relation $gx=-xg$, in which case we refer to x as a type 1 generator (analagous to the notion discussed at the end of Sec. III), or we can choose the relation $gxg=-x$, in which case we call x a type 2 generator. A type 2 generator is also a type 1 generator, but not conversely, since $g^2\neq 1$.

For the first case, we choose x to be type 1. Denote the algebra by H_1. The following relations are satisfied:

$$g^3=g,$$

$$gx=-xg,$$

$$x^2=0,$$

along with the same coproduct and counit as in the usual Hopf case (given above). Solving Eqs. (2.1) and (2.2) gives the weak antipode

$$T(1)=1,$$

$$T(g)=g,$$

$$T(x)=gx,$$

which has the same action as the antipode from the Hopf case but nevertheless is not an antipode. The defining relations imply that H_1 is six dimensional with basis

$$\{1,g,g^2,x,gx,g^2x\}.$$

Note that the element g^2 is a central idempotent. This is easily verified with the defining relations.

It is with this example that we demonstrate explicitly how to obtain a direct sum decomposition for an algebra with a central idempotent. This procedure will then be extended to the case of $w\mathfrak{sl}_q^d(n)$.

H_1 has a direct sum decomposition

$$H_1 = H_1^0 \oplus H_1^1,$$

where H_1^0 is the subalgebra with basis $\{(1-g^2)x, 1-g^2\}$, on which multiplication by g^2 is zero (indicated in the superscript), and H_1^1 is the subalgebra with basis $\{g, g^2, gx, g^2x\}$ on which multiplication by g^2 is the identity (also indicated in the superscript). In fact, these two subalgebras are determined by setting

$$\begin{aligned} H_1^0 &= (1-g^2)H_1, \\ H_1^1 &= g^2 H_1. \end{aligned} \tag{5.1}$$

It is straightforward to verify that the map $\psi: H_1^1 \to H$ with the action

$$\psi(g) = G,$$

$$\psi(g^2) = I,$$

$$\psi(gx) = GX,$$

$$\psi(g^2x) = X,$$

defines a weak Hopf algebra isomorphism, where I, G, X are the generators of the original Sweedler Hopf algebra H. Since H appears as a subalgebra of H_1, we can simply apply $\psi^{-1} \otimes \psi^{-1}$ to the R-matrix of H (see Ref. 15) to obtain an R-matrix $\mathcal{R}$ of H_1 satisfying

$$\mathcal{R}\Delta(a) = \sigma \circ \Delta(a)\mathcal{R}, \quad \forall a \in H_1,$$

$$\mathcal{R}_{13}\mathcal{R}_{23} = (\Delta \otimes \mathrm{id})(\mathcal{R}),$$

$$\mathcal{R}_{13}\mathcal{R}_{12} = (\mathrm{id} \otimes \Delta)(\mathcal{R}).$$

Such an R-matrix is then given by

$$\mathcal{R} = g^2 \otimes g^2 - 2p \otimes p + \alpha(g^2x \otimes g^2x - 2g^2x \otimes px + 2px \otimes px),$$

where $p = (g^2 - g)/2$ and α is an arbitrary parameter. This $\mathcal{R}$ is not invertible, but it satisfies the regularity condition[12]

$$\mathcal{R}\hat{\mathcal{R}}\mathcal{R} = \mathcal{R}, \tag{5.2}$$

$$\hat{\mathcal{R}}\mathcal{R}\hat{\mathcal{R}} = \hat{\mathcal{R}}, \tag{5.3}$$

where

$$\hat{\mathcal{R}} = g^2 \otimes g^2 - 2p \otimes p + \alpha(g^2x \otimes g^2x - 2px \otimes g^2x + 2px \otimes px).$$

It should also be noted that the Sweedler Hopf algebra H also appears as a subalgebra of H_1 with its generators defined by

$$I = 1,$$

$$G=1+g-g^2,$$

$$X=(1+\alpha g)gx,$$

where α is an an arbitrary constant. However, this is just an observation and has no consequence to the results of our paper, since this subalgebra is only isomorphic to H as an algebra, not a bialgebra.

Now we look at the algebra H_2, which corresponds to the choice of the generator x to be of type 2. This implies the following relations:

$$g^3=g,$$

$$gxg=-x,$$

$$x^2=0.$$

The only difference with the coproduct in this case is with the action defined on the generator x, which is now given by

$$\Delta(x)=x\otimes g+g^2\otimes x,$$

and the counit is the same as usual. The algebra H_2 is five dimensional with basis $\{1,g,x,gx,g^2\}$. Note that g^2 is a central idempotent. Defining

$$H_2^0=(1-g^2)H_2,$$

$$H_2^1=g^2H_2,$$

the decomposition

$$H_2=H_2^0\oplus H_2^1$$

still holds, where the superscripts still refer to the action of g^2, but now H_2^0 has basis $\{1-g^2\}$ and H_2^1 has basis $\{g^2,g,x,gx\}$.

Once again it is possible to verify that there exists a weak Hopf algebra isomorphism $\varphi:H_2^1\rightarrow H$ with the following action:

$$\varphi(g^2)=I,$$

$$\varphi(g)=G,$$

$$\varphi(x)=X,$$

$$\varphi(gx)=GX.$$

In a similar way to both of the examples above, for a quantized enveloping algebra $U\equiv U_q[sl_n]$, its weak extension U_w and some other algebraic structure U_0, a decomposition of the form

$$U_w=U_0\oplus U=(1-J)U_w\oplus JU_w$$

exists due to there being a central idempotent J whose existence derives from the relaxation of the invertibility of group-like elements in the algebra. In fact it is straightforward to prove the fact that for any d,

$$U_q[sl_n]\simeq J.w\mathfrak{sl}_q^d(n).$$

This result is another way of stating Proposition 1 from the paper.[12]

From another point of view, we could say that a weak extension is nothing but the original Hopf algebra plus some other algebra in which is contained all the information regarding the weak structure. In this case, it would help to know what conditions U_0 would have to satisfy in order that U_w has a weak Hopf structure. This has not been the approach of this paper as we saw in the last section. Since there are no other weak Hopf algebra isomorphisms on the weak $w\mathfrak{sl}_q^d(n)$, the classification *as weak Hopf algebras* is complete. However, if we were to consider all possible algebra isomorphisms, this direct sum decomposition is important since it leads to discovering several ''unexpected'' isomorphisms which do not arise from the action of the automorphisms in the quantised enveloping algebra case.

Since we only need the presence of a central idempotent to achieve this direct sum decomposition, we can apply this idea to the weak extensions of $U_q[sl_n]$ from the previous section, since the element J is always a central idempotent. However, it does not affect our classification of the weak Hopf algebra structure from the previous section. To demonstrate, we show that, rather unexpectedly, there is an algebra isomorphism $\psi: w\mathfrak{sl}_q^{10}(3)\rightarrow w\mathfrak{sl}_q^{9}(3)$.

We first apply the direct sum decomposition to $U=w\mathfrak{sl}_q^{10}(3)$ and $V=w\mathfrak{sl}_q^{9}(3)$ such that

$$U=(1-J)U\oplus JU\equiv U_0\oplus U_1$$

and similarly

$$V=(1-J')V\oplus J'V\equiv V_0\oplus V_1.$$

Explicitly we have U_0 generated by $\langle(1-J)E_1,(1-J)F_1,1-J\rangle$ and U_1 generated by $\langle J,JE_1,JF_1,E_2,F_2,K_1,K_2,\overline{K}_1,\overline{K}_2\rangle$. For V, denoting its generators by a prime, we have V_0 generated by $\langle(1-J')E_1',(1-J')F_2',1-J'\rangle$ and V_1 generated by $\langle J',J'E_1',E_2',F_1',J'F_2',K_1',K_2',\overline{K}_1',\overline{K}_2'\rangle$. It is straightforward to show that both U_1 and V_1 are isomorphic as (weak) Hopf algebras to $U_q[sl(3)]$. It is also easy to verify that U_0 and V_0 are both Abelian with the same number of generators and are therefore isomorphic as algebras. Combining these two facts leads to the isomorphism $\psi: U\rightarrow V$, the action of which is given by

$$\psi(1)=1,$$

$$\psi(E_1)=(1-J')F_2'+F_1',$$

$$\psi(E_2)=J'F_2',$$

$$\psi(F_1)=E_1',$$

$$\psi(F_2)=E_2',$$

$$\psi(K_i)=\overline{K}_i',$$

$$\psi(\overline{K}_i)=K_i'.$$

The map ψ is consistent with all the defining relations so is therefore an algebra homomorphism and it can be shown to have inverse

$$\psi^{-1}(E_1')=F_1,$$

$$\psi^{-1}(E_2')=F_2,$$

$$\psi^{-1}(F_1')=JE_1,$$

$$\psi^{-1}(F_2')=(1-J)E_1+E_2,$$

$$\psi^{-1}(K_i')=\overline{K}_i,$$

$$\psi^{-1}(\overline{K}_i')=K_i.$$

Therefore ψ is an isomorphism.

If we set the action of the coproduct Δ for U and allow the freedom to choose the coproduct Δ' of V consistently with ψ, then we end up having to compare the action of $(\psi\otimes\psi)\circ\Delta$ with $\Delta'\circ\psi$. Applying both of these maps to the generators will clearly give a noncoassociative Δ'. Therefore the ψ only can be considered as an algebra isomorphism. However, it is uncertain whether or not this coproduct Δ' would define a quasibialgebra.[2] This certainly raises some interesting questions relating to whether or not these isomorphisms could correspond to some kind of Drinfeld twist. If so, then perhaps our classification is only a much smaller classification of the structures as quasibialgebras. This idea may warrant further investigation.

VI. CONCLUDING REMARKS

We have seen that it is possible to define weak extensions of $U_q[sl_n]$ by only relaxing some of the relations in the original algebra. As we saw in the work of Li and Duplij,[12] one nice way of doing this is to relax invertibility of the group-like elements to a more general regularity condition and also to impose one of two relations on the other generators. This allows us to define many examples.

One observation is that it is also possible to extend the definition of a quantized superalgebra[18] to the weak case by using the same idea of relaxing the invertibility of the generators K and $\overline{K}$. We demonstrate with the algebra $w\mathfrak{osp}_q^d(2|1)$ which has generators $\{K,\overline{K},V_+,V_-\}$. We define the parity of these generators to be $p(K)=p(\overline{K})=0$, $p(V_\pm)=1$.

The following relations are satisfied:

$$K\overline{K}=\overline{K}K,\quad K\overline{K}K=K,\quad \overline{K}K\overline{K}=\overline{K},$$

$$KV_\pm=q^{\pm1}V_\pm K,\quad \overline{K}V_\pm=q^{\mp1}V_\pm\overline{K}, \tag{6.1}$$

$$\{V_+,V_-\}=-\frac{1}{4}\frac{K-\overline{K}}{q-q^{-1}}.$$

Keeping in theme with the preceding sections, if in addition the following relations are satisfied:

$$KX\overline{K}=q^{\pm1}X,$$

where $X=V_+$ or V_-, then we call X a type 2 generator. Otherwise we call X a type 1 generator. This example is almost exactly like the case of $w\mathfrak{sl}_q^d(2)$ in that we have the same notion of generators of type 1 and 2. The coalgebra structure is of the same form, and the only real difference is that the weak antipode is a graded algebra antihomomorphism, so it satisfies $T(ab)=(-1)^{p(a)p(b)}T(b)T(a)$.

All the weak Hopf algebras given in this paper have noncocommutative coproducts. This implies existence of universal R-matrices that could give new solutions of quantum Yang–Baxter equations as mentioned in Refs. 10 and 12. One direction for future work is to investigate the form of such R-matrices. We expect the expressions would not be that different to those of the original Hopf algebra due to the direct sum decomposition of Sec. V. In fact, in Sec. V we gave one possible R-matrix for the finite dimensional weak Hopf generalization of Sweedler's well-known example using these facts.

Section V also demonstrates the fact that there are many algebra isomorphisms between structures. In this paper we did not investigate all possible isomorphisms, but instead gave a small existence proof that such isomorphisms do indeed exist. It would be interesting to classify these structures as algebras using this observation.

A question that arose during our investigation is one related to automorphisms and twisting, especially in the usual quantized enveloping algebra case. As we have already mentioned, the algebra automorphisms are well known for the quantized enveloping algebras, some of which are also bialgebra automorphisms. We are currently unaware of whether or not, corresponding to every algebra automorphism $\psi: A \rightarrow A$, there exists a twist element $F \in A \otimes A$ such that

$$(\psi \otimes \psi)\Delta(a) = F.\Delta(\psi(a)).F^{-1}, \quad \forall a \in A.$$

Givental formula in terms of Virasoro operators

A. Alexandrov[a)]
ITEP, Moscow, Russia

(Received 26 February 2003; accepted 22 May 2003)

We present a conjecture that the universal enveloping algebra of differential operators $\partial/\partial t_k$ over $\mathbb{C}$ coincides in the origin with the universal enveloping algebra of the (Borel subalgebra of) Virasoro generators from the Kontsevich model. Thus, we can decompose any (pseudo)differential operator to a combination of the Virasoro operators. Using this decomposition we present the right-hand side of the Givental formula [math.AG/0008067] as a constant part of the differential operator we introduce. In the case of $\mathbb{CP}^1$ studied in the paper by Song and Song [hep-th/0103254], the left-hand side of the Givental formula is a unit, which imposes certain constraints on this differential operator. We explicitly check that these constraints are correct up to $O(q^4)$. We also propose a conjecture of factorization modulo Hirota equation of the differential operator introduced and check this conjecture with the same accuracy. © *2003 American Institute of Physics.*

I. INTRODUCTION

It is well known that $\mathcal{N}=2$ supersymmetric sigma-model with target space M, defined on the genus g Riemann surface, through twisting, leads to the topological field theory.[1] For $D=2$ sigma-model, the correlation functions of such topological field theory are known to be some intersection numbers on the target space, and the fields of this theory, which we call primary fields, are in one-to-one correspondence with the elements of $H^*(M)$ (see, for example, Ref. 2). Thus, for any genus g, the free energy $F_M^g(s)$ of the theory, as a function of couplings s to primary fields (the space of such couplings is called small phase space) is a generating function for such intersection numbers on the target space. The genus zero free energy $F_M^0(s)$ is described by associativity—WDVV equations.[2,3]

Coupling of the topological field theory to the topological gravity leads to the so-called topological string theory. The genus g free energy $\mathcal{F}_M^g(t)$ of this theory, which depends on infinitely many coupling constants t (couplings to gravitational descendants), describes intersection theory on the compactified moduli spaces of genus g punctured Riemann surfaces. We will denote coordinates on the big phase space as t, while on the small phase space, subspace of the big one, as s. Combining $\mathcal{F}_M^g(t)$ for all g into the sum and exponentiating $\tau_M(t)=\exp\Sigma_{g=0}\hbar^{g-1}\mathcal{F}_M^g(t)$, one gets a general object which depends on the manifold and is the function of infinitely many coupling constants. We call it τ-function.[4] This function can be considered from many different points of view, which lead to different conditions on $\tau_M(t)$ (Refs. 2, 5–7) (Virasoro constraints, dilaton and divisor equations). However, in general, they do not seem to be restrictive enough to determine $\tau_M(t)$ completely.

In fact, there are at least two examples of the manifold M when the function τ_M for topological field theory with the target space M turns out to be the τ-function of integrable hierarchy. The first example is the point. Its function $\tau_\bullet$, which corresponds to the pure topological gravity,[2] is the τ-function for the KdV hierarchy.[8,9] It can be realized as the matrix integral (famous Kontsevich model[10])

[a)]Electronic mail: alex@gate.itep.ru

$$\tau_\bullet(T)=\frac{\int \mathrm{d}H\, e^{-1/3\mathrm{Tr}\,H^3+\mathrm{Tr}\,M^2H}}{\int \mathrm{d}H\, e^{-\mathrm{Tr}MH^2}}, \tag{1}$$

over $N\times N$ Hermitian matrix, the coupling constants, i.e., the times from the integrable point of view, are defined as follows:

$$T_k=-\frac{1}{k}\mathrm{Tr}\,M^{-k}. \tag{2}$$

Invariance of this matrix integral with respect to the change of variables,[11] namely,

$$H\to H+\epsilon_p\,, \tag{3}$$

with $\epsilon_p=M^{2p}$ leads to the Virasoro constraints $L_n\tau_\bullet(T_k)=0$, $n\geqslant -1$ (see, for instance, Refs. 12–14 with Ref. 15),

$$L_n=\frac{1}{2}\sum_{k\ odd} kT_k\frac{\partial}{\partial T_{k+2n}}+\frac{1}{4}\sum_{\substack{a+b=2n\\ a,b\ \ odd\ \ and>0}}\frac{\partial^2}{\partial T_a\partial T_b}+\frac{T_1^2}{4}\delta_{n,-1}+\frac{1}{16}\delta_{n,0}-\frac{\partial}{\partial T_{3+2n}},\quad n\geqslant -1. \tag{4}$$

These Virasoro operators form the Borel subalgebra of the Virasoro algebra,

$$[L_n\,,L_m]=(n-m)L_{n+m}\,. \tag{5}$$

The second example, $M=\mathbb{CP}^1$, conjectured to correspond to the Toda hierarchy,[6,16] has been proved in the interesting paper.[17] The τ-function for it can also be represented as some matrix integral. By analogous consideration, this representation leads to the Borel subalgebra of some other Virasoro algebra which annihilates the τ-function. Therefore, one could expect that the function τ_M associated with any manifold, is the τ-function for some integrable hierarchy. This is one of the reasons why we generally call it τ-function.

For several particular manifolds there exist some explicit formulas for F_M^g. The example, of $M=\mathbb{CP}^1$ is, in a sense, the only foreseeable: its whole free energy vanishes on the small phase space, except genus zero and genus one, which are, correspondingly,[18]

$$F^0_{\mathbb{CP}^1}=\tfrac{1}{2}(s_P)^2s_Q+e^{s_Q} \tag{6}$$

and

$$F^1_{\mathbb{CP}^1}=-s_Q/24. \tag{7}$$

For $\mathbb{CP}^2$ the genus zero free energy is of the form

$$F^0_{\mathbb{CP}^2}=\frac{1}{2}s_P(s_Q)^2+\frac{1}{2}(s_P)^2s_R+\sum_{d=1}N_d^{(0)}\frac{(s_R)^{3d-1}}{(3d-1)!}\exp(s_Qd), \tag{8}$$

and for the expansion coefficients $N_d^{(0)}$ there is the recursive relation[5]

$$N_d^{(0)}=(3d-4)!\sum_{l+k=d}\frac{N_l^{(0)}N_k^{(0)}}{(3l-1)!(3k-1)!}k^2l[3kl+l-2k]. \tag{9}$$

Here the numbers $N_d^{(0)}$ and $N_d^{(1)}$ are numbers of degree d rational (elliptic) curves passing through $3d-1$ (respectively, $3d$) points.

For the genus one free energy

$$F^1_{\mathbb{CP}^2}=\frac{-s_Q}{8}+\sum_{d=1} N^{(1)}_d \frac{(s_R)^{3d}}{(3d)!}\exp(ds_Q), \tag{10}$$

analogous recursion relation was derived in Ref. 19, using Virasoro constraints for $\mathbb{CP}^n$ and the topological recursion relations (see also Ref. 20)

$$N^{(1)}_n=N^{(0)}_n\frac{1}{72}n(n-1)(n-2)+\sum_{k+l=n}(3n-1)!\,\frac{N^{(0)}_k}{(3k-1)!}\,\frac{N^{(1)}_l}{(3l)!}\,\frac{l}{9}(3k^2-2k). \tag{11}$$

However, in general, there are no expressions for higher genera similar to (9), (11), and only a few first terms in the series like (8), (10) are found.

The problem is to construct a regular procedure for finding $F^M_g(s)$. In this paper, we make a modest contribution to solving this problem. It is based on the remarkable formula which was proposed in Ref. 21 with the help of the localization technique, and connects the Kontsevich τ-function ($\tau_\bullet$, function for the point on the big phase space) with the τ-function for some (for instance, projective) manifold M on the small phase space, with the genus zero and one contributions omitted[22]

$$e^{\Sigma_{g>1}\hbar^{g-1}F^g_M(s)}=\left[e^{D_M(s)}\prod_j \tau_\bullet(\hbar\Delta_j;t^{(j)}_0,t^{(j)}_1,\ldots)\right]_{t^{(i)}_k=T^i_k(s)}. \tag{12}$$

Here s_i are coordinates on the small phase space for the manifold M, indices i,j run from 1 to $K=\dim(H^*(M))$, and $D_M(s)$ is the bilinear pseudodifferential[23] operator acting on $t^{(i)}_k$,

$$D_M(s)=\frac{\hbar}{2}\sum_{k,l=0}^{\infty}\sum_{i,j} V^{ij}_{kl}(s)\Delta^{1/2}_i(s)\Delta^{1/2}_j(s)\partial_{t^{(i)}_k}\partial_{t^{(j)}_l}, \tag{13}$$

$V^{ij}_{kl}(s)$, $\Delta_i(s)$, and $T^i_k(s)$ being some functions which can be presented in terms of the genus zero potential $F^0_M(s)$, more precisely on its third derivatives (Refs. 21 and 24).

Formula (12) was studied in Ref. 24 for the first nontrivial example of the manifold M, $\mathbb{CP}^1$.

Since, as we know from the explicit form of the free energy on the small phase space for $\mathbb{CP}^1$ the lhs of (12) is unity, formula (12) can be considered as an equation imposed on the Kontsevich τ-function. We call it the Song equation.[25]

In Ref. 24 all the necessary coefficients Δ,V, and T were calculated, and (12) was checked extensively using the expansion in $\hbar$ with the accuracy of $O(\hbar^4)$. This calculation involves the explicit form of $\tau_\bullet(t)$ as a series in times.

In our paper, we reformulate the problem of calculation on the right-hand side (rhs) of (12) for given V and T realizing some particular differential operator D'_M easily connected with D_M [see (15)] via Virasoro operators.

Namely, the shift operator

$$\exp\sum_{i=1}^{K}\sum_{k=2}^{\infty} T^i_k(s)\partial_{t^{(i)}_k} \tag{14}$$

obviously commutes with $D_M(s)$, and for the operator

$$D'_M(s)=D_M(s)+\sum_{i=1}^{K}\sum_{k=2}^{\infty} T^i_k(s)\partial_{t^{(i)}_k} \tag{15}$$

we have the equality

$$\left[e^{D_M(s)}\prod_j \tau_\bullet(\hbar\Delta_j;t_0^{(j)},t_1^{(j)},\ldots)\right]_{t_k^{(i)}=T_k^i(s)}=\left[e^{D'_M(s)}\prod_j \tau_\bullet(\hbar\Delta_j;t_0^{(j)},t_1^{(j)},\ldots)\right]_{t_k^{(i)}=0}. \quad (16)$$

The general idea of the paper is to present the operator $e^{D'_M}$ in the origin of the space of times $t_k^{(i)}$ in terms of the Virasoro operators (this means, that we consider rhs modulo term, proportional to the positive powers of the times t) (4),

$$e^{D'_M}\Big|_{t=0}=\sum_{[l_1],[l_2],\ldots,[l_K]}^{\infty} P^M_{[l_1],[l_2],\ldots,[l_K]}(s)L_{[l_1]}\otimes L_{[l_2]}\otimes\cdots\otimes L_{[l_K]}\Big|_{t=0}. \quad (17)$$

Here $L_{[l]}$ are products of the Virasoro operators with the non-negative multiplicities m_i, given by multi-indices $[l]$: for $[l]=(m_{-1},m_0,\ldots,m_r)$ we define

$$L_{[l]}:=L_r^{m_r}\cdots L_0^{m_0}L_{-1}^{m_{-1}}, \quad (18)$$

and, if all multiplicities m_i vanish,

$$L_{[0]}=1, \quad (19)$$

where we denote $[0]:=(0,0,\ldots,0)$. Since all the Virasoro operators of the Borel subalgebra annihilate the Kontsevich τ-function, the action of the operator presented in this way on the $\tau_\bullet$'s at the point $t=0$ is trivial, that is, the only nonvanishing contribution to the left-hand side (lhs) of (12) is given by the constant term proportional to (19):

$$e^{\Sigma_{g>1}\hbar^{g-1}F^g_M(s)}=P^M_{[0],[0],\ldots,[0]}(s). \quad (20)$$

In particular, the Song equation in terms of D' is

$$\exp[D'_{\mathbb{CP}^1}]\tau(\hbar,x)\tau(\hbar,y)|_{x_n=y_n=0}=1. \quad (21)$$

In the case of $\mathbb{CP}^1$, one can expand the operator $D'_{\mathbb{CP}^1}$ in the series in $q:=\exp(-s_Q/2)$,

$$e^{D'_{\mathbb{CP}^1}}=1+\sum_{n=1}^{\infty} q^n\sum_{[l_1],[l_2]} P^{\mathbb{CP}^1(n)}_{[l_1],[l_2]}(\hbar)L_{[l_1]}\otimes L_{[l_2]}\Big|_{t=0}. \quad (22)$$

Since for $\mathbb{CP}^1$ the lhs of (12) is equal to 1, the Song equation is equivalent to the condition

$$P^{\mathbb{CP}^1(n)}_{[0],[0]}=0, \quad n\geqslant 1. \quad (23)$$

In this paper, we check this condition with the accuracy of $O(q^4)$.

The paper contains two conjectures. The first conjecture which states that any differential operator in times t with constant coefficients can be presented as a combination of the Virasoro operators with some multiplicities at the origin helps to deal with the Givental formula. The second conjecture, whose general structure is still unknown, in particular the case of $M=\mathbb{CP}^1$ claims that the operator $D'_{\mathbb{CP}^1}$ (22) can be factorized into the sum of two parts, which are tensor squares of differential operators, modulo Hirota equations. Both of these conjectures are checked perturbatively in the example of $\mathbb{CP}^1$ with the accuracy of $O(q^4)$.

The paper is organized as follows: in Sec. II we represent the main results of Ref. 24 and explicitly present the Virasoro and Hirota constraints which we use in our calculations. Sections III and IV are devoted to our two conjectures, while Sec. V contains some concluding remarks.

II. MAIN INGREDIENTS

In Ref. 24 it was shown that, denoting $t_n^{(+)}=x_n$ and $t_n^{(-)}=y_n$, one has the following differential operator:

$$D_{\mathbb{CP}^1}:=\frac{\hbar}{2}\sum_{k,l\geqslant 0}\left(V_{kl}^{++}(\partial_{x_k}\partial_{x_l}+\partial_{y_k}\partial_{y_l})+2i(-1)^{l-1}V_{kl}^{+-}\partial_{x_k}\partial_{y_l}\right), \tag{24}$$

and introducing α being c-numbers

$$\alpha_{m+1}=-\frac{(2m+1)^2}{8(m+1)}\alpha_m, \quad \alpha_0=1, \tag{25}$$

we can represent times[26] T^+

$$T_n^+=\begin{cases}0, & n=0,1\\ -\dfrac{\alpha_{n-1}}{2^{n-1}}\exp\left[\dfrac{-(n-1)s_Q}{2}\right], & n\geqslant 2.\end{cases} \tag{26}$$

In the case of $\mathbb{CP}$ we have two times on the small phase space but third derivatives of the free energy depend only on one coordinate, s_Q. This means that all components of our construction depend on this one coordinate. α being c-numbers,

$$\alpha_{m+1}=-\frac{(2m+1)^2}{8(m+1)}\alpha_m, \quad \alpha_0=1. \tag{27}$$

Coefficients V^{++} and V^{+-} in (24) can be presented as bilinear combinations of T_k^+ similar to those in the paper (the proper formula has a slight mistake therein):[24]

$$V_{kl}^{++}=\sum_{n=0}^{k-1}\frac{(-1)^n(4(l+n+1)(k-n)-1)}{(2l+2n+1)(2k-2n-1)}T_{l+n+2}^+T_{k-n+1}^++(-1)^{k+1}\frac{T_{l+k+2}^+}{2l+2k+1},$$

$$V_{kl}^{+-}=i(-1)^l\left[\sum_{n=0}^{k-1}\frac{2(l+2n+1-k)}{(2l+2n+1)(2k-2n-1)}T_{l+n+2}^+T_{k-n+1}^++2(l+k+1)\frac{T_{l+k+2}^+}{2l+2k+1}\right]. \tag{28}$$

Taking into account that, in (26) $T_0^+=T_1^+=0$, one can explicitly substitute the Kontsevich τ-function to (12) in the case $M=\mathbb{CP}^1$, and check the equality, expanding the operator and τ-functions in the $\hbar$-series,

$$\exp[D_{\mathbb{CP}^1}]\tau_\bullet(\hbar,x)\tau_\bullet(\hbar,y)|_{x_n=y_n=T_n^+}=:1+\sum_{n=1}^{\infty}a_n\hbar^n. \tag{29}$$

In this way, one gets an infinite family of equations on the coefficients of the decomposition of $\tau_\bullet(\hbar,t)$,

$$a_n=0, \quad \forall n>0. \tag{30}$$

In Ref. 24, the first three equations were explicitly checked.

The Virasoro operators corresponding to our normalization of times, are (see, for example, Ref. 27)

$$L_n=\begin{cases}\displaystyle\sum_{m=1}^{\infty}\tilde{t}_m\partial_{m-1}+\frac{1}{2\hbar}t_0^2, & n=-1\\ \displaystyle\sum_{m=0}^{\infty}\left(m+\frac{1}{2}\right)\tilde{t}_m\partial_m+\frac{1}{16}, & n=0\\ \displaystyle\sum_{m=0}^{\infty}\frac{\Gamma(n+m+\frac{3}{2})}{\Gamma(m+\frac{1}{2})}\tilde{t}_m\partial_{m+n}+\frac{\hbar}{2}\sum_{m=0}^{n-1}(-1)^{m+1}\frac{\Gamma(n-m+\frac{1}{2})}{\Gamma(-m-\frac{1}{2})}\partial_m\partial_{n-m-1}, & n>0,\end{cases} \tag{31}$$

with $\tilde{t}_m:=t_m-\delta_{m,1}$, $\partial_m=\partial/\partial t_m$. They annihilate the Kontsevich τ-function,

$$L_n\tau_*(\hbar,t)=0,\ \ n\geqslant -1. \tag{32}$$

It is also known that any KdV τ-function, in particular, the Kontsevich one, solves the Hirota bilinear equations, the first three of which being (see, for instance, Ref. 28)

$$\begin{aligned}&(\hbar D_0^4-12D_0D_1)\tau(t)\cdot\tau(t)=0,\\ &\left(-24D_1^2+\hbar D_0^3D_1+\frac{\hbar^2}{12}D_0^6\right)\tau(t)\cdot\tau(t)=0,\\ &\left(-D_1^2+\frac{\hbar^2}{360}D_0^6+D_0D_2\right)\tau(t)\cdot\tau(t)=0,\end{aligned} \tag{33}$$

which we denote for the sake of brevity as

$$\mathbf{H}_i=0,\ \ i=1,2,3. \tag{34}$$

III. CONNECTION BETWEEN SONG AND VIRASORO EQUATIONS

Consider an arbitrary operator of the form

$$B:=\partial_1^{n_1}\partial_2^{n_2}\cdots\partial_k^{n_k},\quad n_i\geqslant 0,\quad \sum_{i=1}^{k}n_k>0, \tag{35}$$

for some finite k. We experimentally check for small k and n that this operator can be presented as a combination of the Virasoro operators (31) at the origin of the space of times t,

$$B=\sum_{m_{-1},\ldots,m_r=0}^{\infty}c_{m_r,\ldots,m_0,m_{-1}}L_r^{m_r}\cdots L_0^{m_0}L_{-1}^{m_{-1}}\Big|_{t=0}=:\sum_{[l]}c_{[l]}L_{[l]}\Big|_{t=0}, \tag{36}$$

for some finite r, dependent on n and k, where we introduced multi-index $[l]=(m_{-1},m_0,\ldots,m_r)$. Some of the multiplicities m_i, and even all of them, can vanish. Namely, we expressed 27 derivatives, which are necessary for our perturbative calculation (see below), in terms of the Virasoro operators. Using explicit form of the Virasoro operators we can get some answers for actions of the differetial operators on the tau-function, not representing them as a combination of Virasoro operators, for example,

$$\frac{\partial}{\partial T_1}^{n_0}\frac{\partial}{\partial T_3}^{n_1}\tau_*(T_1,T_3,\ldots)\Big|_{T_1=T_3=\cdots=0}=\frac{1}{3}\left(\frac{3}{2}\right)^{n_1}\left(\frac{1}{6\hbar}\right)^{n_0/3}\frac{\Gamma\left(-\frac{n_0}{3}\right)}{\Gamma(-n_0)}\frac{\Gamma(n_1+\frac{1}{3}n_0+\frac{1}{24})}{\Gamma(\frac{1}{3}n_0+\frac{1}{24})}. \tag{37}$$

For example,

$$\begin{aligned}\partial_0 &= -L_{-1}|_{t=0},\\ \partial_0^2 &= L_{-1}^2|_{t=0},\\ \partial_0^3 &= -L_{-1}^3|_{t=0}+\frac{1}{\hbar},\\ \partial_2 &= \frac{1}{30}\hbar L_{-1}^2\Big|_{t=0}-\frac{4}{15}L_1\Big|_{t=0}.\end{aligned} \tag{38}$$

If this is correct for arbitrary B, one can present any pseudodifferential operator as a combination of the Virasoro operators at the origin of the space of times t. Thus, one can present any tensor product of N differential operators as a sum of tensor products of combinations of the Virasoro operators

$$\sum_{[l_1],[l_2],\ldots,[l_N]}^{\infty} P_{[l_1],[l_2],\ldots,[l_N]} L_{[l_1]}\otimes L_{[l_2]}\otimes\cdots\otimes L_{[l_N]}\Big|_{t=0}, \tag{39}$$

with P being some coefficients.

This representation can be appropriate for our consideration. In particular, one has

$$e^{D'_M}=\sum_{[l_1],[l_2],\ldots,[l_K]}^{\infty} P^M_{[l_1],[l_2],\ldots,[l_K]}(s) L_{[l_1]}\otimes L_{[l_2]}\otimes\cdots\otimes L_{[l_K]}\Big|_{t=0}. \tag{40}$$

Here the operator

$$D'_M(s)=D_M(s)+\sum_{i=1}^{K}\sum_{k=2}^{\infty} T^i_k(s)\partial_{t^{(i)}_k} \tag{41}$$

is the combination of the D_M and the operator, which shifts the times $t^{(i)}_k=T^i_k$ to zero.

Since all the Virasoro operators of the Borel subalgebra annihilate $\tau_\bullet$, calculation of the action of the operator on the product of $\tau_\bullet$'s in the origin is equivalent to calculating $P_{[0],[0],\ldots,[0]}$. One observes that the lhs of (12) is equal to the identity component of the decomposition of operator $e^{D'_M}$ in terms of Virasoro operators

$$e^{\Sigma_{g>1}\hbar^{g-1}F^g_M(s)}=P^M_{[0],[0],\ldots,[0]}(s). \tag{42}$$

In our particular case, moving our times to the origin is equivalent to changing the operator D: for the operator

$$D'_{\mathbb{CP}^1}=D_{\mathbb{CP}^1}+\sum_{n=2}^{\infty} T^+_n\left(\frac{\partial}{\partial x_n}+\frac{\partial}{\partial y_n}\right), \tag{43}$$

the Song equation is

$$\exp[D']\tau_\bullet(\hbar,x)\tau_\bullet(\hbar,y)|_{x=y=0}=1. \tag{44}$$

Now we can check the Song equation perturbatively, not specifying the explicit form of $\tau_\bullet$. This is the advantage of our approach, since the approach of Ref. 24 required the explicit form of $\tau_\bullet$. To study this equation perturbatively, we can expand the operator in the series in q,

$$\exp[D'_{\mathbb{CP}^1}]=:1+\sum_{n=1}^{\infty} q^n \sum_{[l_1],[l_2]} P^{\mathbb{CP}^1(n)}_{[l_1],[l_2]}(\hbar) L_{[l_1]}\otimes L_{[l_2]}\Big|_{t=0}, \tag{45}$$

and all we must check is that

$$P^{\mathbb{CP}^1(m)}_{[0][0]}=0 \quad \forall m>0. \tag{46}$$

We check this up to $n=3$.

The explicit expression for the operator $e^{D'_{\mathbb{CP}^1}}|_{x=y=0}$ acting on $\tau_\bullet$'s looks like

$$\begin{aligned}
e^{D'_{\mathbb{CP}^1}}\tau\otimes\tau|_{x=y=0}=1+([&-\tfrac{1}{30}L_1\tau+(-\tfrac{7}{120}L_{-1}^2\tau+\tfrac{1}{8}(L_{-1}\tau)^2)\hbar]q+[(\tfrac{1}{3600}(L_1\tau)^2+\tfrac{1}{3600}L_1^2\tau\\
&+\tfrac{1}{504}L_2\tau)+(\tfrac{109}{50\,400}L_{-1}\tau+\tfrac{53}{8400}L_{-1}L_0\tau-\tfrac{1}{240}L_{-1}\tau L_{-1}L_1\tau+\tfrac{7}{7200}L_{-1}^2L_1\tau\\
&-\tfrac{7}{240}L_{-1}\tau L_0\tau+\tfrac{7}{7200}L_{-1}^2\tau L_1\tau)\hbar+(\tfrac{49}{57\,600}L_{-1}^4\tau-\tfrac{7}{960}L_{-1}\tau L_{-1}^3\tau\\
&+\tfrac{499}{57\,600}(L_{-1}^2\tau)^2)\hbar^2]q^2+[(-\tfrac{97}{453\,600}L_3\tau-\tfrac{1}{648\,000}L_1^3\tau-\tfrac{1}{30\,240}L_1L_2\tau\\
&-\tfrac{1}{216\,000}L_1^2\tau L_1\tau-\tfrac{1}{30\,240}L_2\tau L_1\tau)+(\tfrac{31}{7200}(L_0\tau)^2+\tfrac{14\,951}{3\,024\,000}L_{-1}\tau L_1\tau\\
&-\tfrac{53}{504\,000}L_{-1}L_0\tau L_1\tau-\tfrac{53}{504\,000}L_{-1}L_0L_1\tau+\tfrac{1}{4032}L_{-1}\tau L_{-1}L_2\tau-\tfrac{7}{864\,000}L_1^2\tau L_{-1}^2\tau\\
&+\tfrac{1}{28\,800}L_{-1}\tau L_{-1}L_1^2\tau+\tfrac{1}{28\,800}(L_{-1}L_1\tau)^2-\tfrac{1}{17\,280}L_{-1}^2L_2\tau-\tfrac{1}{17\,280}L_2\tau L_{-1}^2\tau\\
&-\tfrac{61}{252\,000}L_0^2\tau-\tfrac{1319}{1\,814\,400}L_{-1}L_1\tau+\tfrac{7}{14\,400}L_{-1}\tau L_0L_1\tau-\tfrac{7}{864\,000}L_{-1}^2L_1^2\tau\\
&-\tfrac{151}{324\,000}L_0\tau-\tfrac{7}{432\,000}L_{-1}^2L_1\tau L_1\tau+\tfrac{7}{14\,400}L_{-1}L_1\tau L_0\tau)\hbar+(\tfrac{7}{57\,600}L_{-1}L_1\tau L_{-1}^3\tau\\
&+\tfrac{1121}{1\,728\,000}L_{-1}\tau L_{-1}^2\tau-\tfrac{53}{288\,000}L_{-1}^3L_0\tau+\tfrac{49}{57\,600}L_{-1}^3\tau L_0\tau-\tfrac{4567}{12\,0960\,000}L_{-1}^3\tau\\
&-\tfrac{1103}{288\,000}L_{-1}L_0\tau L_{-1}^2\tau+\tfrac{7}{57\,600}L_{-1}\tau L_{-1}^3L_1\tau+\tfrac{661}{403\,200}L_{-1}\tau L_{-1}^2L_0\tau\\
&-\tfrac{499}{1\,728\,000}L_{-1}^2L_1\tau L_{-1}^2\tau-\tfrac{49}{3\,456\,000}L_{-1}^4L_1\tau-\tfrac{49}{3\,456\,000}L_{-1}^4\tau L_1\tau)\hbar^2\\
&+(-\tfrac{6643}{13\,824\,000}L_{-1}^4\tau L_{-1}^2\tau+\tfrac{199}{460\,800}(L_{-1}^3\tau)^2+\tfrac{49}{460\,800}L_{-1}\tau L_{-1}^5\tau\\
&-\tfrac{343}{41\,472\,000}L_{-1}^6\tau)\hbar^3]q^3)|_{t=0}+O(q^4).
\end{aligned} \tag{47}$$

This form seems to be convenient, since the operator $D'_{\mathbb{CP}^1}$ is symmetric in x and y. Now, if one uses the explicit expression for the τ-function $\tau_\bullet$, conditions (46) for $m=3n$ reproduce the conditions $a_n=0$ from (30). They are only those conditions that restrict the coefficients V^{++}, V^{+-}, and T^+.

IV. LINEAR EQUATION FROM THE BILINEAR ONE

The Song equation is quadratic in $\tau_\bullet$. Thus, if one manages to presents the operator $e^{D'_{\mathbb{CP}^1}}$ as

$$e^{D'_{\mathbb{CP}^1}}=f(\hbar,q,L)^{\otimes 2}+2\hbar q g(\hbar,q,L)^{\otimes 2}, \tag{48}$$

the Song equation is equivalent to the system of two linear equations

$$\begin{aligned}
f(\hbar,q,L)\tau_\bullet|_{t=0}&=1,\\
g(\hbar,q,L)\tau_\bullet|_{t=0}&=0.
\end{aligned} \tag{49}$$

Here f and g are some operators expressed in terms of the Virasoro operators at the origin.

It turns out that the conjecture (48) is slightly incorrect, instead, with the accuracy of $O(q^4)$, one gets

$$[e^{D'_{\mathbb{CP}^1}} - f(\hbar,q,L)^{\otimes 2} - 2\hbar q g(\hbar,q,L)^{\otimes 2}]\tau\otimes\tau|_{t=0} = \left[\frac{\hbar}{768}q^2\mathbf{H}_1 - \left(\frac{11}{12\,288}\mathbf{H}_2 + \frac{21}{1024}\mathbf{H}_3 + \frac{17}{737\,280}\hbar^2 L_{-1}^2\mathbf{H}_1 - \frac{1}{46\,080}\hbar L_1\mathbf{H}_1\right)q^3\right]\Big|_{t=0}, \tag{50}$$

where $\mathbf{H}$'s are combinations bilinear in τ which correspond to the Hirota equations

$$\mathbf{H}_1(t=0) = ((2L_{-1}^4\tau - 8L_{-1}\tau L_{-1}^3\tau + 6(L_{-1}^2\tau)^2)\hbar + 8L_{-1}\tau - 16L_{-1}L_0\tau + 16L_{-1}\tau L_0\tau)|_{t=0},$$

$$\begin{aligned}\mathbf{H}_2(t=0) = (&32L_0\tau - \tfrac{64}{3}L_0^2\tau + \tfrac{64}{3}(L_0\tau)^2 + (-2L_{-1}^3\tau + \tfrac{4}{3}L_{-1}^3L_0\tau + 2L_{-1}\tau L_{-1}^2\tau - 4L_{-1}\tau L_{-1}^2L_0\tau \\ &+ 4L_{-1}L_0\tau L_{-1}^2\tau - \tfrac{4}{3}L_{-1}^3\tau L_0\tau)\hbar + (-L_{-1}\tau L_{-1}^5\tau + \tfrac{1}{6}L_{-1}^6\tau + \tfrac{5}{2}L_{-1}^4\tau L_{-1}^2\tau \\ &- \tfrac{5}{3}(L_{-1}^3\tau)^2)\hbar^2)|_{t=0},\end{aligned}$$

$$\begin{aligned}\mathbf{H}_3(t=0) = ((&\tfrac{16}{15}L_0\tau + \tfrac{8}{15}L_{-1}L_1\tau - \tfrac{8}{15}L_{-1}\tau L_1\tau - \tfrac{8}{9}L_0^2\tau + \tfrac{8}{9}(L_0\tau)^2) \\ &+ (-\tfrac{1}{15}L_{-1}^3\tau + \tfrac{1}{15}L_{-1}\tau L_{-1}^2\tau)\hbar + (\tfrac{1}{180}L_{-1}^6\tau - \tfrac{1}{30}L_{-1}\tau L_{-1}^5\tau \\ &+ \tfrac{1}{12}L_{-1}^4\tau L_{-1}^2\tau - \tfrac{1}{18}(L_{-1}^3\tau)^2)\hbar^2)|_{t=0}.\end{aligned} \tag{51}$$

The operators f and g are, respectively,

$$\begin{aligned}f(\hbar,q,L) = 1 + (&-\tfrac{1}{60}L_1 - \tfrac{7}{240}\hbar L_{-1}^2)q + (-\tfrac{13}{3150}\hbar L_{-1} + \tfrac{19}{1400}\hbar L_{-1}L_0 + \tfrac{1}{1008}L_2 + \tfrac{7}{14\,400}\hbar L_{-1}^2L_1 \\ &+ \tfrac{1}{7200}L_1^2 - \tfrac{101}{57\,600}\hbar^2L_{-1}^4)q^2 + \tfrac{1}{2}((-\tfrac{97}{453\,600}L_3 - \tfrac{1}{648\,000}L_1^3 - \tfrac{1}{30\,240}L_1L_2) \\ &+ (-\tfrac{19}{42\,000}L_{-1}L_0L_1 - \tfrac{59}{63\,000}L_0^2 - \tfrac{7}{864\,000}L_{-1}^2L_1^2 - \tfrac{1}{17\,280}L_{-1}^2L_2 + \tfrac{937}{162\,000}L_0 \\ &- \tfrac{311}{28\,350}L_{-1}L_1)\hbar + (\tfrac{101}{3\,456\,000}L_{-1}^4L_1 - \tfrac{187}{756\,000}L_{-1}^3 + \tfrac{31}{24\,000}L_{-1}^3L_0)\hbar^2 \\ &- \tfrac{793}{41\,472\,000}L_{-1}^6\hbar^3)q^3 + O(q^4),\end{aligned} \tag{52}$$

$$\begin{aligned}g(\hbar,q,L) = \tfrac{1}{4}L_{-1} + (&-\tfrac{1}{240}L_{-1}L_1 + \tfrac{1}{320}\hbar L_{-1}^3 - \tfrac{1}{20}L_0)q + ((\tfrac{97}{6300}L_1 + \tfrac{1}{1200}L_0L_1 \\ &+ \tfrac{1}{4032}L_{-1}L_2 + \tfrac{1}{28\,800}L_{-1}L_1^2) + (-\tfrac{1}{2400}L_{-1}^2 - \tfrac{47}{33\,600}L_{-1}^2L_0 - \tfrac{1}{19\,200}L_{-1}^3L_1)\hbar \\ &- \tfrac{1}{460\,800}L_{-1}^5\hbar^2)q^2 + O(q^3).\end{aligned} \tag{53}$$

V. CONCLUSION

In this paper, we presented two conjectures, which could help in the ''experimental'' work with the Givental formula (12), and perturbatively checked them for the simplest example of the manifold $\mathbb{CP}^1$. In spite of the lack of the complete proof for these conjectures, and even clear formulation of the second one, they could be of some use. One way to use them is to present the differential operator corresponding to the manifold M, completely in terms of the Virasoro operators with the constant coefficients $P^M_{[l_1],[l_2],\ldots,[l_N]}$ [we should mention, that this is not equivalent to present $D'_M(s)$ in such form],

$$e^{D'_M(s)}=\left[\exp\sum_{[l_1],[l_2],\ldots[l_N]}^{\infty}P^M_{[l_1],[l_2],\ldots,[l_N]}L_{[l_1]}\otimes L_{[l_2]}\otimes\cdots\otimes L_{[l_N]}\right]\Bigg|_{t=0}. \tag{54}$$

This is equivalent to finding the τ-function of the manifold M on the small phase space, if one additionally knows the genus 1 free energy (the genus zero free energy explicitly enters the coefficients on the rhs). We do not know how to do this nonperturbatively, even for $M=\mathbb{CP}^1$. The other way is to proceed with perturbative calculations of free energies, for example, in the case of $M=\mathbb{CP}^2$, using formula (12) and ideas of this paper.

Another interesting way to go is to study the formula analogous to (12) such that its lhs contains the free energy (with genus 0 and 1 contributions subtracted) on the big phase space.[1] It gives almost τ_M, modulo genus zero and genus one contributions. However, the structure of the rhs is far less transparent in this case.

One also can approach to the Givental formula (12) from another side. Namely, one can take some known τ-function, insert it on the lhs and study the structure of the differential operator on the rhs. The interesting example to deal with is provided by the τ-function for the generalized Kontsevich model.[14]

Geometric phase and modulus relations for probability amplitudes as functions on complex parameter spaces

Alonso Botero[a)]
Department of Physics and Astronomy, University of South Carolina, Columbia, South Carolina 29208 and Centro Internacional de Física, Ciudad Universitaria, Bogotá, Colombia

(Received 28 May 2002; accepted 29 July 2003)

We investigate general differential relations connecting the respective behaviors of the phase and modulus of probability amplitudes of the form $\langle \psi_f | \psi \rangle$, where $|\psi_f\rangle$ is a fixed state in Hilbert space and $|\psi\rangle$ is a variable state, treated as a section of a U(1) bundle over a complex subspace of the corresponding ray space $\mathcal{R}=\mathbb{C}P^n$. Amplitude functions on such holomorphic line bundles, while not strictly holomorphic, nevertheless satisfy generalized Cauchy–Riemann conditions involving the U(1) Berry–Simon connection on the parameter space. These conditions entail invertible relations between the gradients of the phase and modulus, therefore allowing for the reconstruction of the phase from the modulus (or vice versa) and other conditions on the behavior of either polar component of the amplitude. As a special case, we consider amplitude functions valued on the space of pure states, the ray space $\mathcal{R}=\mathbb{C}P^n$, where transition probabilities have a geometric interpretation in terms of geodesic distances as measured with the Fubini–Study metric. In conjunction with the generalized Cauchy–Riemann conditions, this geodesic interpretation leads to additional relations, in particular, a novel connection between the modulus of the amplitude and the phase gradient, somewhat reminiscent of the WKB formula. Finally, a connection with geometric phases is established. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1612895]

I. INTRODUCTION

The study of correlations between the behavior of the phase and modulus of complex probability amplitudes is a relevant topic in a number of physical problems such as the ''phase problem'' in diffraction theory,[1] the study of phase singularities[2] and the semiclassical or WKB approximation[3] to name a few. In the phase problem, for instance, the aim is to infer phase information in the diffracted wave from the observed cross section, which only involves the magnitude of the wave. In the study of phase dislocations, it is known that regions of vanishing amplitude are characterized by surrounding regions of generally nonuniform vortex-type phase singularities. Finally, in the semiclassical approximation, the phase gradient is in correspondence with the classical momentum and the behavior of the magnitude of the amplitude is correlated to the phase gradient by Liouville's theorem.

From a different standpoint, significant insight into the geometrical meaning of both the modulus and the phase of probability amplitudes has emerged from the study of the ray space $\mathcal{R}$ (also known as projective Hilbert space), particularly in connection with geometric phases,[4–7] quantum information theory,[8,9] and other topics falling under the general category of geometric quantum mechanics.[10,11] From the work of Berry,[4] Simon,[5] and Aharonov and Anandan[6] amongst others, it is known that under cyclic evolution a geometric phase factor is acquired by the ampli-

tude, which is interpreted as the holonomy associated with a natural connection (the so-called Berry–Simon connection) on the U(1) bundle over $\mathcal{R}$, and which is proportional to the symplectic area enclosed by the circuit in $\mathcal{R}$. Samuel and Bhandari[7] have also shown that the so-called Pancharatnam phase difference between any two states can be expressed as a line integral of the Berry–Simon connection along the geodesic connecting the two states, as measured with the Fubini–Study metric, the natural metric on $\mathcal{R}$. Finally, there exists a natural geometric interpretation to transition probabilities in the ray space as the cosine of the geodesic distance with respect to the Fubini–Study metric,[10] a measure that is intimately related to information-theoretic measures of statistical distance between two probability distributions.[8,9]

In the present paper, the aim is to shed additional insight into the correlation between the phase and magnitude of transition probability amplitudes from the point of view of geometric quantum mechanics. Specifically, we study amplitudes of the form $\langle \psi_f|\psi\rangle$, where $|\psi_f\rangle$ is any fixed state in Hilbert space and $|\psi\rangle$ is parametrized on a complex parameter subspace $\mathcal{M}$ of the ray space $\mathcal{R}$, or, in particular, the ray space itself. We then obtain general geometric relations between the two polar components of the amplitude arising from holomorphicity and metric constraints natural to such complex parameter spaces. We note that a number of state families of broad physical interest are valued on complex parameter spaces, including the family of coherent and more generally squeezed states, the Bloch sphere of spin-1/2 states, as well as complex extensions of real parameter families.

A brief summary of the main results and the structure of the paper is in order. In Sec. II we spell out in greater detail the geometric setting involved, which is more precisely that of *holomorphic line bundles* over the complex parameter space $\mathcal{M}$. Such bundles share with the more general line bundles over arbitrary parameter spaces (arising, for instance, in connection with Berry phases) two important geometric objects, namely, the Berry–Simon connection $\mathbf{A}=-i\langle\psi|\mathbf{d}\psi\rangle$ and the quantum geometric tensor $\mathbf{H}\propto\langle\mathbf{d}\psi|\otimes|\mathbf{d}\psi\rangle-\langle\psi|\mathbf{d}\psi\rangle\otimes\langle\mathbf{d}\psi|\psi\rangle$. The symmetric part of $\mathbf{H}$ gives rise to a ''quantum'' metric on $\mathcal{M}$ (the Fubini–Study metric when $\mathcal{M}=\mathcal{R}$), while the antisymmetric part, here denoted by Ω, is proportional to the field-strength tensor associated with the connection. There are, however, additional constraints that follow from the fact that $\mathcal{M}$ is a complex submanifold of $\mathcal{R}$. In particular, state sections of the corresponding line bundle satisfy generalized holomorphicity conditions and the base manifold inherits from the ray space its Kähler structure. These constraints are then used in Sec. III to show that the polar components of $\langle\psi_f|\psi\rangle=\sqrt{p}\,e^{i\eta}$ satisfy a generalized version of Cauchy–Riemann conditions on the logarithm of $\langle\psi_f|\psi\rangle$, the relations

$$\nabla\log\sqrt{p}=\mathbf{\Omega}\cdot(\nabla\eta-\mathbf{A}),$$

$$(\nabla\eta-\mathbf{A})=-\mathbf{\Omega}\cdot\nabla\log\sqrt{p},$$

where the inner product is with respect to the quantum metric on $\mathcal{M}$. With the aid of these conditions, it is then possible to reconstruct either polar component of the amplitude from the parametric dependence of the other, as well as to obtain additional constraints on the behavior of p and η. A brief illustration of the the generalized Cauchy–Riemann conditions on the Bloch sphere is given in Sec. IV. In Sec. V we turn to the case when $\mathcal{M}=\mathcal{R}$, where we explore the consequences of previously obtained results in conjunction with an additional geometric relation that exists between the transition probability p and geodesic distances as measured by the Fubini–Study metric. In particular, we give a generalization of the Samuel and Bhandari result for the Pancharatnam phase for nongeodesic paths. More importantly, it is shown that the transition amplitude can be parametrized entirely in terms of its phase according to the formula

$$\langle\psi_f|\psi\rangle=\frac{e^{i\eta}}{\sqrt{1+q\|\nabla\eta-\mathbf{A}\|^2}},\tag{1.1}$$

where q is an arbitrary parameter in the definition of the metric. Prompted by a certain resemblance to the WKB formula $\psi_{\mathrm{WKB}}(x)=e^{i\eta(x)}/\sqrt{|\nabla\eta|}$, a trajectory interpretation to the phase gradient on $\mathcal{R}$ is obtained. Finally, in Sec. VI, we establish a connection between our results and the geometric phase acquired during cyclic and noncyclic evolutions.

II. GEOMETRY OF HOLOMORPHIC LINE BUNDLES

We devote some time to introduce the relevant geometric aspects that are involved. Let the map $\tilde{\psi}:\mathcal{M}\to\mathcal{H}$ define a family of unnormalized state vectors $|\,\tilde{\psi}(z)\,\rangle\in\mathcal{H}$, which only depend on a set of local holomorphic coordinates z^a on $\mathcal{M}$. The family $|\psi\rangle$ is then obtained by projecting $|\tilde{\psi}\rangle$ onto the set of pure normalized state vectors according to

$$|\psi(z,\overline{z})\rangle=\frac{e^{i\gamma(z,\overline{z})}}{\sqrt{\langle\tilde{\psi}(\overline{z})|\tilde{\psi}(z)\rangle}}|\tilde{\psi}(z)\rangle\,, \tag{2.1}$$

where γ is some (real) phase factor that for the moment will be assumed to be an arbitrary function of z and $\overline{z}$.

It will also be convenient to keep in mind alternative parametrizations of $|\psi\rangle$ in terms of the set of real coordinates (x^a,y^a) related to z^a $(\overline{z}^a)$ as usual by $z^a=x^a+iy^a$ $(\overline{z}^a=x^a-iy^a)$, and more generally in terms of arbitrary real coordinates on $\mathcal{M}$ which will be denoted by ξ^μ with the index μ ranging from 1 to $2k$ [throughout the section we use italic indices $a,b,\ldots$ (ranging from 1 to k) to denote complex coordinates or their real and imaginary components and greek indices to denote general coordinates].

Neglecting for the moment the fact that $\mathcal{M}$ is a complex manifold, we see that there is a correspondence between a point in $\mathcal{M}$ and a pure-state density matrix $|\psi\rangle\langle\psi|$, and therefore a point in the ray space $\mathcal{R}$, the equivalence class of states under the equivalence relation $|\psi\rangle\sim e^{i\phi}|\psi\rangle$. The geometric setting is therefore that of the U(1) or line bundle $P(\mathcal{M},\mathrm{U}(1))$ over the parameter space $\mathcal{M}$,[5,12,13] on which a choice of $|\psi\rangle$ with a given phase factor γ corresponds to a particular choice of local section.

Now, as is well known in the context of geometric phases,[14] there is a natural geometric connection that can be defined on the line bundle over a parameter space $\mathcal{M}$, which is expressed locally by the so-called Berry–Simon (BS) connection one-form $\mathbf{A}=A_\mu\mathrm{d}\xi^\mu$, with components

$$A_\mu=-i\langle\psi|\partial_\mu\psi\rangle\,, \tag{2.2}$$

where $\partial_\mu=\partial/\partial\xi^\mu$ in arbitrary coordinates. This connection is naturally induced by the Dirac inner product on Hilbert space $\langle\phi|\psi\rangle$ in the sense that the horizontal motion defined by this connection corresponds to infinitesimal variations orthogonal to $|\psi\rangle$, i.e., $\langle\psi|\,\delta_{\mathrm{Horiz}}\psi\rangle=0$. The resulting covariant derivative of a section $|\psi\rangle$,

$$D_\mu|\psi\rangle\equiv[\partial_\mu-iA_\mu]|\psi\rangle\,, \tag{2.3}$$

therefore satisfies $\langle\psi|D_\mu\psi\rangle=0$. By virtue of Eq. (2.1), it is clear that under a U(1) gauge transformation $|\psi\rangle\to e^{i\delta\gamma}|\psi\rangle$, A_μ transforms as $A_\mu\to A_\mu+\partial_\mu\delta\gamma$, in such a way that $D_\mu|\psi\rangle$ transforms homogeneously as $D_\mu|\psi\rangle\to e^{i\delta\gamma}D_\mu|\psi\rangle$. Furthermore, a U(1) gauge transformation may always be introduced so that the connection form is set to zero at least at one point in $\mathcal{M}$. As usual, the failure of the covariant derivative to commute in different directions is measured by the curl of $\mathbf{A}$.

When $\mathcal{M}$ is a complex manifold as is the case in question, there is added richness brought about by the complex nature of the base space. In particular, it is possible to construct a more refined notion of the line bundle over $\mathcal{M}$, namely a *Holomorphic line bundle*.[12,13,15,16] The notion of such bundles rests on a generalization of the concept of a holomorphic function, in the sense that by a suitable gauge transformation it is possible to have a section satisfy, *at a given point*, the

standard holomorphic condition $(\partial/\partial\overline{z^a})\,|\psi\rangle = 0$. Let us see how this comes about with the parametrization in Eq. (2.1). By construction we have that the un-normalized vector $|\tilde{\psi}\rangle$ satisfies the holomorphic condition,

$$\frac{\partial}{\partial\overline{z^a}}|\,\tilde{\psi}(z)\,\rangle = 0\,, \tag{2.4}$$

with $\overline{z^\alpha} = x^a - iy^a$. It is clear however, that $|\psi\rangle$ is not strictly holomorphic, as the antiholomorphic coordinates $\overline{z^a}$ appear not only in the phase factor γ, but more importantly in the normalization factor which involves the antiholomorphic map $\langle\tilde{\psi}(\overline{z})|$. Thus we have in general that

$$\frac{\partial}{\partial\overline{z^a}}|\,\psi\rangle = \left[\frac{\partial}{\partial\overline{z^a}}\log\frac{e^{i\gamma}}{\sqrt{\langle\tilde{\psi}|\tilde{\psi}\rangle}}\right]|\,\psi\rangle\,. \tag{2.5}$$

Now, taking the inner product of this expression with $|\psi\rangle$ itself, we find that

$$\langle\,\psi|\,\frac{\partial}{\partial\overline{z^a}}|\,\psi\rangle = \left[\frac{\partial}{\partial\overline{z^a}}\log\frac{e^{i\gamma}}{\sqrt{\langle\tilde{\psi}|\tilde{\psi}\rangle}}\right]. \tag{2.6}$$

Expressing the BS one-form in the complex basis as $\mathbf{A} = A_a\mathbf{d}z^a + A_{\overline{a}}\mathbf{d}\overline{z}^a$, with

$$A_a = -i\langle\,\psi|\partial_a\psi\rangle\,,\quad A_{\overline{a}} = -i\langle\,\psi|\partial_{\overline{a}}\psi\rangle \tag{2.7}$$

[where $\partial_a = (\partial/\partial z^a)$, $\partial_{\overline{a}} = (\partial/\partial\overline{z^a})$], and finally splitting the covariant derivative D into holomorphic and antiholomorphic components, we have

$$D_a = \frac{\partial}{\partial z^a} - iA_a\,,\quad D_{\overline{a}} = \frac{\partial}{\partial\overline{z^a}} - iA_{\overline{a}}.$$

Thus, we find from Eqs. (2.5) and (2.6) that the section $|\psi\rangle$ satisfies a generalized ''gauge covariant'' holomorphic condition

$$D_{\overline{a}}|\,\psi\rangle = 0. \tag{2.8}$$

However, it is always possible to ''gauge away'' the BS connection at least at one point. At that point then, the section satisfies the usual holomorphic condition $\partial_{\overline{a}}|\,\psi\rangle = 0$. Thus, modulo a U(1) gauge transformation, $|\psi\rangle$ is a locally holomorphic section. For future reference, we shall also need the dual, now antiholomorphic condition, on the bra $\langle\psi|$. This is given by

$$\langle D_a\psi| = [\,\partial_a + iA_a]\langle\psi| = 0\,. \tag{2.9}$$

We now consider geometric aspects of the base space $\mathcal{M}$ and introduce additional objects that will be of use later. The horizontal motion associated with the BS connection on the line bundle over $\mathcal{M}$ induces naturally on the base space $\mathcal{M}$ a gauge-invariant rank-2 Hermitian tensor

$$H_{\mu\nu} = q\,\langle D_\mu\psi|D_\nu\psi\rangle\,, \tag{2.10}$$

which Berry[17] has named the *quantum geometric tensor*. Here, q is any strictly positive real number to be adjusted for convenience. The real part of $H_{\mu\nu}$ is positive definite and symmetric, and thus defines a metric $g_{\mu\nu}$ on $\mathcal{M}$, the *quantum metric*, with line element

$$\mathrm{d}s^2 = g_{\mu\nu}\,\mathrm{d}\xi^\mu\,\mathrm{d}\xi^\nu = q[\,\langle\mathrm{d}\psi|\mathrm{d}\psi\rangle - \langle\mathrm{d}\psi|\,\psi\rangle\langle\,\psi|\mathrm{d}\psi\rangle\,]\,. \tag{2.11}$$

In turn, the imaginary part of H is antisymmetric and is closely related to the curl of the BS connection one-form $\mathbf{A}$:

$$\mathbf{\Omega} = \mathrm{Im}\, H = \frac{q}{2}\langle \mathbf{d}\psi| \wedge |\mathbf{d}\psi\rangle = \frac{q}{2}\mathbf{dA}\,. \tag{2.12}$$

Since $\mathbf{d}^2 = 0$ it follows that $\mathbf{\Omega}$ is automatically closed.

When $\mathcal{M}$ is the base space for the Hermitian line bundle, considerable simplifications follow. First of all, from the generalized holomorphic condition $|D_{\bar{a}}\psi\rangle = 0$ and its dual, we have that in complex coordinates the quantum geometric tensor takes as components

$$H_{\bar{a}b} = \langle D_{\bar{a}}\psi | D_b \psi\rangle\,, \quad H_{ab} = 0\,. \tag{2.13}$$

This implies that the metric, as well as the two-form $\mathbf{\Omega}$ may be written out as

$$\begin{aligned} \mathbf{g} &= g_{a\bar{b}}\,\mathbf{dz}^a \otimes \mathbf{d\bar{z}}^b + g_{\bar{a}b}\,\mathbf{d\bar{z}}^a \otimes \mathbf{dz}^b\,, \\ \mathbf{\Omega} &= i g_{a\bar{b}}\,\mathbf{dz}^a \wedge \mathbf{d\bar{z}}^b\,, \end{aligned} \tag{2.14}$$

where $g_{a\bar{b}} = g_{\bar{b}a} = \frac{1}{2}H_{a\bar{b}}$. Note that if the metric is nondegenerate (as we shall assume henceforth), it then follows, on the one hand, that the U(1) connection $\mathbf{A}$ is nontrivial, and on the other, that both $\mathbf{g}$ and $\mathbf{\Omega}$ admit inverses. In particular, the inverse metric takes the form

$$\mathbf{g}^{-1} = g^{a\bar{b}}\partial_a \otimes \partial_{\bar{b}} + g^{\bar{a}b}\partial_{\bar{a}} \otimes \partial_b\,, \tag{2.15}$$

where $g^{\bar{a}b} = g^{b\bar{a}}$ satisfies $g_{a\bar{b}}g^{\bar{b}c} = \delta_a^c$.

To understand the significance of Eq. (2.14), we now introduce the so-called complex structure, the defining tensorial object for a complex manifold. In complex coordinates, the complex structure tensor J takes the canonical form

$$J^a{}_b = i\,\delta^a{}_b\,, \quad J^{\bar{a}}{}_{\bar{b}} = -i\,\delta^{\bar{a}}{}_{\bar{b}} \tag{2.16}$$

with the remaining components vanishing. The complex structure satisfies $J^\mu{}_\lambda J^\lambda{}_\nu = -\delta^\mu{}_\nu$ (i.e., $J^2 = -1$) and implements the multiplication by i $(-i)$ on vector fields with holomorphic (antiholomorphic) indices. In terms of J, it is readily verified that the metric satisfies

$$g_{\mu\nu} = J^\gamma{}_\mu J^\lambda{}_\nu g_{\gamma\lambda}\,. \tag{2.17}$$

In this case one says that the metric is *Hermitian*. In turn, the two-form $\mathbf{\Omega}$ is what is known as the *Kähler form* of the metric, defined by

$$\Omega_{\mu\nu} = g_{\lambda\nu}J^\lambda{}_\mu\,, \tag{2.18}$$

i.e., $\Omega_{\mu\nu} = -J_{\mu\nu}$. The expressions for $\mathbf{g}$ and $\mathbf{\Omega}$ in Eq. (2.14), where $g_{ab} = g_{\bar{a}\bar{b}} = \Omega_{ab} = \Omega_{\bar{a}\bar{b}} = 0$, are the canonical forms that a Hermitian metric and its Kähler form take in complex coordinates.

When the Kähler form $\mathbf{\Omega}$ is closed, as in our case, $\mathcal{M}$ is known as a Kähler manifold and the metric a Kähler metric. The offshoot of this is a compatibility between the Hemitian and Riemannian structures of the manifold, embodied by the fact that

$$\mathbf{d}\Omega = 0 \Leftrightarrow \nabla_\mu J^\nu{}_\lambda = 0\,, \tag{2.19}$$

where ∇_μ denotes covariant differentiation of ordinary tensor fields on $\mathcal{M}$ with respect to the affine connection associated with the metric g. The condition $d\mathbf{\Omega} = 0$ entails that the Hermitian components $g_{a\bar{b}}$ of the metric and the Kähler form satisfy in complex coordinates the symmetry conditions

$$\partial_c g_{a\bar{b}} = \partial_a g_{c\bar{b}}, \quad \partial_{\bar{c}} g_{\bar{a}b} = \partial z^{\bar{a}} \partial g_{\bar{c}b}. \tag{2.20}$$

From the definition of the affine connection in arbitrary coordinates, $\Gamma^{\mu}_{\nu\lambda} = \frac{1}{2} g^{\mu\gamma}(\partial_\mu g_{\nu\gamma} + \partial_\nu g_{\mu\gamma} - \partial_\gamma g_{\mu\nu})$, it is then straightforward to verify that in complex coordinates the affine connection takes the form

$$\Gamma^{a}{}_{bc} = g^{\bar{d}a} \partial_b g_{c\bar{d}}, \quad \Gamma^{\bar{a}}{}_{\bar{b}\bar{c}} = g^{\bar{a}d} \partial_{\bar{b}} g_{d\bar{c}}, \tag{2.21}$$

with the symbols mixing holomorphic and antiholomorphic indices vanishing. Covariant differentiation with respect to a holomorphic (antiholomorphic) coordinate therefore acts like regular differentiation on antiholomorphic (holomorphic) indices. Another way of saying this is that the *affine* connection preserves the separation between holomorphic and antiholomorphic tensor fields. We remark that in complex manifolds that are not Kähler, it is still possible to define a Hermitian connection taking the form of Eq. (2.21) and satisfying $\nabla J = 0$, but this connection will not coincide with the affine connection.

A second consequence of the symmetry conditions in Eq. (2.20) is that the Kähler metric may be derived locally from a scalar potential function, the so-called *Kähler potential*, according to $g_{a\bar{b}} = \partial_a \partial_{\bar{b}} K(z,\bar{z})$. This can be seen by noting from Eq. (2.6) that

$$\mathbf{A} = \mathbf{d}\gamma + \frac{1}{2i} \partial_a \log\langle\tilde{\psi}|\tilde{\psi}\rangle \, \mathbf{d}z^a - \frac{1}{2i} \partial_{\bar{a}} \log\langle\tilde{\psi}|\tilde{\psi}\rangle \mathbf{d}\bar{z}^a, \tag{2.22}$$

from which we see that

$$\mathbf{\Omega} = \frac{q}{2} \mathbf{dA} = \frac{iq}{2} \partial_a \partial_{\bar{b}} \log\langle\tilde{\psi}|\tilde{\psi}\rangle \mathbf{d}z^a \wedge \mathbf{d}\bar{z}^b. \tag{2.23}$$

Consequently, from Eq. (2.14), we have that

$$g_{a\bar{b}} = \frac{q}{2} \partial_a \partial_{\bar{b}} \log\langle\tilde{\psi}|\tilde{\psi}\rangle, \tag{2.24}$$

so that an appropriate *Kähler* potential is given by

$$\tilde{K} = (q/2) \log\langle\tilde{\psi}|\tilde{\psi}\rangle. \tag{2.25}$$

Note however that this potential is not uniquely defined, since one is free to add to $K(z,\bar{z})$ any function of the form $f_1(z) + f_2(\bar{z})$ without changing $g_{a\bar{b}}$. Note finally that a choice of gauge in which $\gamma(z,\bar{z}) = \mathrm{Re}[f(z)] = \frac{1}{2}[f(z) + f^*(\bar{z})]$ for some arbitrary holomorphic function $f(z)$, is equivalent to a reparametrization of $|\psi\rangle$ in which in Eq. (2.1), the phase γ is set to zero and the un-normalized vector $|\tilde{\psi}\rangle$ gets replaced by $|\tilde{\psi}'\rangle = e^{f(z)}|\tilde{\psi}\rangle$. In such case, all geometric objects of interest for us, namely, the Berry–Simon connection and the second-rank tensors obtained from the quantum geometric tensor, can be derived from the Kähler potential $\tilde{K}' = (q/2)\log\langle\tilde{\psi}'|\tilde{\psi}'\rangle$.[18] The freedom that remains in the choice of f corresponds to the freedom in the definition of the Kähler potential.

III. GENERALIZED CAUCHY–RIEMANN CONDITIONS

We now explore the consequences on the behavior of the polar components of any transition amplitude

$$\langle\psi_f|\psi(\xi)\rangle = \sqrt{p(\xi)}\, e^{i\eta(\xi)},$$

where $|\psi(\xi)\rangle$ is a section of a holomorphic line bundle over a complex submanifold $\mathcal{M}\in\mathcal{R}$, i.e., of the form of Eq. (2.1), as described in the preceding section, and ξ are arbitrary real coordinates on $\mathcal{M}$.

The first thing to note is that due to the arbitrariness in the definition of the phase γ in Eq. (2.5), the notion of phase $\langle\psi_f|\psi\rangle$ is tied to the choice of gauge. Specifically, the phase $\eta\equiv\arg\langle\psi_f|\psi\rangle$, transforms under the U(1) gauge transformations $|\psi\rangle\rightarrow e^{i\delta\gamma}|\psi\rangle$ as

$$\eta\rightarrow\eta+\delta\gamma.$$

It then becomes convenient to introduce a gauge-invariant notion of phase variation by means of the *BS*-connection This is done by defining a *gauge invariant phase gradient*

$$V_\mu\equiv\partial_\mu\eta-A_\mu\,. \tag{3.1}$$

Clearly, the one-form $\mathbf{V}=V_\mu\mathbf{d}\xi^\mu$ is not closed but rather satisfies $\mathbf{dV}=-\mathbf{dA}=-(2/q)\mathbf{\Omega}$. The modulus of $\langle\psi_f|\psi\rangle$, $\sqrt{p}\equiv|\langle\psi_f|\psi\rangle|$, is of course gauge invariant.

Now, since $|\psi_f\rangle$ is assumed to be a constant vector, it follows from Eq. (2.8) that the amplitude $\langle\psi_f|\psi\rangle$ is as well subject to the generalized holomorphic (antiholomorphic) conditions when expressed in local complex coordinates

$$\left[\frac{\partial}{\partial\bar{z}^a}-iA_{\bar{a}}\right]\langle\psi_f|\psi\rangle=0\,, \tag{3.2}$$

$$\left[\frac{\partial}{\partial z^a}+iA_a\right]\langle\psi|\psi_f\rangle=0\,. \tag{3.3}$$

Assuming then that $\langle\psi_f|\psi\rangle\neq0$, the logarithm of the amplitude can be defined analytically, and we find that

$$\begin{aligned} i[\partial_{\bar{a}}\eta-A_{\bar{a}}]+\partial_{\bar{a}}\log\sqrt{p}=0,\\ -i[\partial_a\eta-A_a]+\partial_a\log\sqrt{p}=0\,. \end{aligned} \tag{3.4}$$

As mentioned earlier, by a suitable choice of gauge it is possible to have the section $|\psi\rangle$ satsify ordinary Cauchy–Riemann conditions at a specified point. Correspondingly, the above conditions can be brought locally to the form of ordinary Cauchy–Riemann conditions.

For our purposes, it will be more convenient to cast the above expression in terms of the Kähler form $\mathbf{\Omega}$ which has a more immediate interpretation in terms of the Berry–Simon connection $\mathbf{A}$ (recall that $\mathbf{\Omega}=(q/2)\mathbf{dA}$). Using the facts that $J^\nu{}_\mu V_\nu=J_{\nu\mu}V^\nu=\Omega_{\mu\nu}V^\nu=\Omega_\mu{}^\nu V_\nu$ and that in mixed-rank form $J^2=\Omega^2=-1$, we then have the following alternative expressions:

$$\partial_\mu\log\sqrt{p}=\Omega_\mu{}^\nu[\,\partial_\nu\eta-A_\nu]\,, \tag{3.5a}$$

$$\partial_\mu\eta=A_\mu-\Omega_\mu{}^\nu\partial_\nu\log\sqrt{p}\,. \tag{3.5b}$$

We shall refer to these as the *generalized Cauchy Riemann conditions* satisfied by the polar components of the amplitude $\langle\psi_f|\psi\rangle$. These conditions constitute the first important result of the paper, and will serve as a starting point for a number of additional relations that will be derived in the forthcoming.

The most important consequence of Eq. (3.5) is the existence of the reconstruction formulas on $\mathcal{M}$,

$$\eta(\xi)-\eta(\xi_0)=\int_{\xi_0}^{\xi}\mathrm{d}\xi^\mu[A_\mu-\Omega_\mu{}^\nu\partial_\nu\log\sqrt{p}\,] \tag{3.6}$$

and

$$\sqrt{\frac{p(\xi)}{p(\xi_0)}}=\exp\left[\int_{\xi_0}^{\xi} d\xi^{\mu}\,\Omega_{\mu}{}^{\nu}[\,\partial_{\nu}\eta-A_{\nu}]\right], \tag{3.7}$$

by means of which one polar component of the amplitude $\langle\psi_f|\psi\rangle$ can be obtained from the other by line integration once the connection is specified. Since both formulas arise from exact differentials, the choice of integration path can be left arbitrary as long as any two paths may be deformed continuously into one another within a simply connected region excluding singularities. However, since the individual terms in the integrands are not generally exact, all terms must be evaluated along the same path. This path independence must reflect itself, therefore, in ancillary relations that both p and η have to satisfy in order to guarantee that the left-hand sides of Eqs. (3.5a) and (3.5b) are exact differentials, conditions that will be examined in more detail shortly.

Before doing so, we use the fact that the quantum metric in Eq. (2.11) on $\mathcal{M}$ is a Hermitian metric to establish relations on the magnitude and angle between the gauge invariant gradients $\nabla\eta-\mathbf{A}$ and $\nabla\log\sqrt{p}$ on $\mathcal{M}$. The Hermitian condition on the metric is that the complex structure should preserve the inner product, i.e., $\mathbf{X}\cdot\mathbf{Y}=(J\mathbf{X})\cdot(J\mathbf{Y})$. This implies from the generalized Cauchy–Riemann conditions that the gauge invariant gradients have the same magnitude as defined in terms of the quantum metric,

$$|\nabla\log\sqrt{p}\,|=|\nabla\eta-\mathbf{A}|\,. \tag{3.8}$$

A second property of a Hermitian metric is that $\mathbf{X}\cdot\mathbf{J}\mathbf{X}=0$, a property that in a Kähler manifold follows automatically from the antisymmetry of the Kähler form $\mathbf{\Omega}$. It follows therefore from Eq. (3.5) that

$$\nabla p\cdot(\nabla\eta-\mathbf{A})=0\,. \tag{3.9}$$

A particular consequence is therefore that lines of constant phase and constant transition probability necessarily meet at right angles wherever $\mathbf{A}$ is made to to vanish by a choice of gauge.

Next, we turn to the previously mentioned integrability conditions. The most evident one comes from rearranging Eq. (3.5b) to read $\Omega_{\mu}{}^{\nu}\partial_{\nu}\log\sqrt{p}=A_{\mu}-\partial_{\mu}\eta$, in which case we see that the one-form $\mathbf{\Omega}\cdot\mathbf{d}\log\sqrt{p}$ is equivalent to the BS connection up to the gauge term $\mathbf{d}\eta$. Correspondingly, the curl of $\Omega_{\mu}{}^{\nu}\partial_{\nu}\log\sqrt{p}$ must lead to the same curl of A_{μ}, which, up to a constant, is nothing more than the Kähler form. Using the fact that the Kähler form is covariantly constant, we then have

$$\Omega_{\nu}{}^{\gamma}\nabla_{\mu}\nabla_{\gamma}\log\sqrt{p}-\Omega_{\mu}{}^{\gamma}\nabla_{\nu}\nabla_{\gamma}\log\sqrt{p}=\frac{2}{q}\Omega_{\mu\nu}\,.$$

Multiplying on both sides by the Kähler form and using $\Omega^2=-1$, the equation can then be transformed to

$$[\nabla_{\mu}\nabla_{\nu}+\Omega_{\mu}{}^{\alpha}\Omega_{\nu}{}^{\beta}\nabla_{\alpha}\nabla_{\beta}]\log\sqrt{p}=-\frac{2}{q}g_{\mu\nu}\,. \tag{3.10}$$

The interpretation of this equation becomes more straightforward in complex coordinates, in which case it reads

$$q\nabla_{a}\nabla_{\bar{b}}\log\sqrt{p}=-g_{a\bar{b}}\,. \tag{3.11}$$

Since $\nabla_{a}\nabla_{\bar{b}}\log\sqrt{p}=\partial_{a}\partial_{\bar{b}}\log\sqrt{p}$, we further see that the condition *is that* $-q\log\sqrt{p}$ *is a Kähler potential for the quantum metric on* $\mathcal{M}$. This can be seen more clearly by noting from Eq. (2.1) that

$$q \log \sqrt{p} = \frac{q}{2} \log[\langle \psi_f | \psi \rangle \langle \psi | \psi_f \rangle] = -\frac{q}{2} \log \langle \tilde{\psi} | \tilde{\psi} \rangle + q \log \langle \psi_f | \tilde{\psi} \rangle + q \log \langle \tilde{\psi} | \psi_f \rangle .$$

Apart from the purely holomorphic and antiholomorphic functions $\log\langle\psi_f|\tilde{\psi}\rangle$ and $\log\langle\tilde{\psi}|\psi_f\rangle$, respectively, this is nothing more than minus the Kähler potential $\tilde{K} = (q/2) \log\langle\tilde{\psi}|\tilde{\psi}\rangle$ mentioned in Sec. II.

Concerning the second integrability condition, we can use the fact that $\partial_\mu \log \sqrt{p}$ is a gradient to obtain from (3.5a) that

$$[\nabla_\mu \delta^\beta_\nu + \Omega_\mu{}^\alpha \Omega_\nu{}^\beta \nabla_\alpha](\nabla_\beta \eta - A_\beta) = 0 , \tag{3.12}$$

a condition that in complex coordinates takes the form

$$\nabla_a(\nabla_{\bar{b}} \eta - A_{\bar{b}}) + \nabla_{\bar{b}}(\nabla_a \eta - A_a) = 0 . \tag{3.13}$$

Further insight into this condition is obtained from Eq. (2.22) in which case we see that $\nabla_a A_{\bar{b}} + \nabla_{\bar{b}} A_a$ is nothing more than $2\partial_a \partial_{\bar{b}} \gamma$. Therefore, under the restricted choice of $\gamma = \frac{1}{2}[f(z) + \overline{f(z)}]$ mentioned previously as the condition in which all geometric quantities can be derived from the Kähler potential, we have that $\partial_a \partial_{\bar{b}} \gamma = 0$ and therefore that

$$\nabla_a \nabla_{\bar{b}} \eta = 0 .$$

In other words, the second condition expresses the fact that modulo a gauge term mixing holomorphic and antiholomorphic coordinates, the phase η is a linear combination of a purely holomorphic and a purely antiholomorphic function. This can be seen most clearly by noting from Eq. (2.1) that

$$\eta = \gamma + \frac{1}{2i} \log\langle \psi_f | \tilde{\psi} \rangle - \frac{1}{2i} \log\langle \tilde{\psi} | \psi_f \rangle .$$

We see therefore that the integrability conditions, Eqs. (3.10) and (3.12), ensuring the consistency of the generalized Cauchy–Riemann conditions in Eq. (3.5) are rather trivial consequences of the parametrization of state sections on a holomorphic line bundle. Still, they lead to nontrivial constraints on the behavior of the phase and modulus of the amplitude when the parameter space is viewed as a general Riemannian manifold.

In particular, by contracting indices in Eqs. (3.10) and (3.12) we determine that the phase and modulus of $\langle \psi_f | \psi \rangle$ satisfy locally the scalar conditions

$$\nabla \cdot (\nabla \eta - \mathbf{A}) = 0, \tag{3.14a}$$

$$\nabla^2 \log \sqrt{p} = -\frac{2k}{q}, \tag{3.14b}$$

where k is the complex dimension of $\mathcal{M}$ and $\nabla\cdot$ and ∇^2 are the divergence and Laplacian operators on $\mathcal{M}$ associated with the quantum metric. Note that since it is always possible to choose $\nabla \cdot \mathbf{A} = 0$ (for instance, with the restricted choice of gauge mentioned previously), the first condition can always be brought to the form $\nabla^2 \eta = 0$.

Finally, it is interesting to note that from the scalar conditions [Eq. (3.14)] and Eqs. (3.8) and (3.9), one obtains

$$\nabla \cdot [p\,(\nabla \eta - \mathbf{A})] = 0, \tag{3.15}$$

$$\frac{1}{2} |\nabla \eta - \mathbf{A}|^2 - \frac{1}{2} \frac{\nabla^2 \sqrt{p}}{\sqrt{p}} = \frac{k}{q}, \tag{3.16}$$

a set of equations analogous to the generalized Hamilton–Jacobi equation and the probability conservation equation arising from the time-independent Schrödinger equation a free particle in a magnetic field. That the probability amplitude $\langle \psi_f | \psi \rangle$ therefore satisfies on $\mathcal{M}$ the corresponding Schödinger equation

$$-\frac{1}{2}(\nabla - i\mathbf{A}) \cdot (\nabla - i\mathbf{A}) \langle \psi_f | \psi \rangle = \frac{k}{q} \langle \psi_f | \psi \rangle$$

can be verified by noting that in complex coordinates $g^{a\bar{b}} D_a D_{\bar{b}} \langle \psi_f | \psi \rangle = 0$ and using the commutation relation

$$[D_a, D_{\bar{b}}] = -\frac{2i}{q} \Omega_{a\bar{b}} = \frac{2}{q} g_{a\bar{b}}.$$

The analogy between $(\nabla \eta - \mathbf{A})$ and a velocity field suggests that it may be possible to establish a trajectory interpretation for the invariant phase gradient. We shall see in Sec. V that such an interpretation is indeed possible on the ray space.

IV. PHASE/MODULUS RELATIONS ON THE BLOCH SPHERE

Let us for the moment flesh out the preceding results with a simple concrete illustration. Consider the family of spin-1/2 states $|\hat{n}\rangle$ represented by points on the Bloch sphere labeled by the usual polar angles θ, ϕ,

$$|\hat{n}\rangle = \begin{pmatrix} \cos\dfrac{\theta}{2} \\ \sin\dfrac{\theta}{2} e^{i\phi} \end{pmatrix}, \tag{4.1}$$

where the basis used is the standard $|\pm\rangle$ eigenbasis of σ_3. As is well known, the two-sphere is in fact a complex manifold, namely the complex projective space $\mathbb{C}P^1$. To see this, note that the parametrization of the unnormalized state $|\tilde{\psi}\rangle$,

$$|\tilde{\psi}(z)\rangle = \begin{pmatrix} 1 \\ z \end{pmatrix}, \tag{4.2}$$

maps, according to Eq. (2.1), to the quantum state section [Eq. (4.1)] after the identification

$$z = \tan\frac{\theta}{2} e^{i\phi}, \quad \gamma = 0. \tag{4.3}$$

The map corresponds to a stereographic projection of the sphere to the complex plane, mapping the south pole into $z = \infty$.

We proceed by calculating the geometric objects of interest. From the Kähler potential, $\tilde{K} = (q/2) \log\langle\tilde{\psi}|\tilde{\psi}\rangle = (q/2) \log(1 + z\bar{z})$, it is straightforward to compute the metric element, i.e.,

$$\mathrm{ds}^2 = q \frac{\mathrm{dz}\, \mathrm{d}\bar{z}}{(1+|z|^2)^2} = \frac{q}{4}[\mathrm{d}\theta^2 + \sin^2\theta\, \mathrm{d}\phi^2]. \tag{4.4}$$

Choosing $q = 4$ for this example, the quantum metric reduces to the usual metric on the unit sphere, with nonvanishing components

$$g_{\theta\theta} = 1, \quad g_{\phi\phi} = \sin^2\theta.$$

The BS connection form is more straightforward to calculate from Eq. (4.1) and we find that

$$\mathbf{A}=\sin^2\frac{\theta}{2}\,\mathbf{d}\phi=\frac{1}{2}(1-\cos\theta)\,\mathbf{d}\phi\,. \tag{4.5}$$

The BS connection leads therefore to the Kähler form

$$\mathbf{\Omega}=\frac{q}{2}\,\mathbf{dA}=\sin\theta\,\mathbf{d}\theta\wedge\mathbf{d}\phi\,, \tag{4.6}$$

which is immediately recognized as the volume form for the unit two-sphere.

With this, it is then possible to express the generalized Cauchy–Riemann conditions for the polar components of some amplitude $\langle\psi_f|\hat{n}\rangle$ in a more conventional form by embedding them in three-dimensional space. Letting $\hat{n}$ now stand for $\vec{r}/r$ and using standard vector notation, the connection becomes

$$\vec{A}=\frac{1}{2r}\left[\frac{1-\cos\theta}{\sin\theta}\right]\hat{\phi}\,, \tag{4.7}$$

which is the usual ''Dirac string'' vector potential for a magnetic charge 1/2 located at the origin and with the string singularity along the south pole. Equations (3.5a) and (3.5b) now read

$$\vec{\nabla}\log\sqrt{p}=-\hat{n}\times(\vec{\nabla}\eta-\vec{A}),$$

$$\vec{\nabla}\eta=\vec{A}+\hat{n}\times\vec{\nabla}\log\sqrt{p}\,, \tag{4.8}$$

where p and η are assumed to depend only on the polar angles. We verify this in a simple example. Take

$$\langle-|\hat{n}\rangle=\sin\frac{\theta}{2}e^{i\phi}\,, \tag{4.9}$$

where from we see that $\sqrt{p}=\sin(\theta/2)$ and $\eta=\phi$ so that

$$\vec{\nabla}\log\sqrt{p}=\frac{1}{2r}\cot\frac{\theta}{2},\hat{\theta}$$

and $\vec{\nabla}\eta=(1/r\sin\theta)\hat{\phi}$. The gauge invariant phase gradient is therefore

$$\vec{\nabla}\eta-\vec{A}=\frac{1}{2r\sin\theta}\left[1-\frac{1}{2}(1-\cos\theta)\right]\hat{\phi}=\frac{1}{2r}\cot\frac{\theta}{2}\,\hat{\phi}$$

and thus we verify that $\vec{\nabla}\log\sqrt{p}=-\hat{n}\times(\vec{\nabla}\eta-\vec{A})$.

More generally, we obtain a coordinate-independent geometric interpretation of the phase gradient for a transition amplitude $\langle\hat{m}|\hat{n}\rangle$ for fixed $|\hat{m}\rangle$ not necessarily on the same section as $|\hat{n}\rangle$. Since the transition probability is

$$p=|\langle\hat{m}|\hat{n}\rangle|^2=\tfrac{1}{2}(1+\hat{n}\cdot\hat{m})\,, \tag{4.10}$$

using $\vec{\nabla}(\hat{n}\cdot\hat{m})=(\hat{m}-(\hat{m}\cdot\hat{n})\hat{n})/r$ we obtain

$$\hat{n}\times\vec{\nabla}\log\sqrt{p}=\left(\frac{1}{2r}\right)\frac{\hat{n}\times\hat{m}}{1+\hat{n}\cdot\hat{m}}\,. \tag{4.11}$$

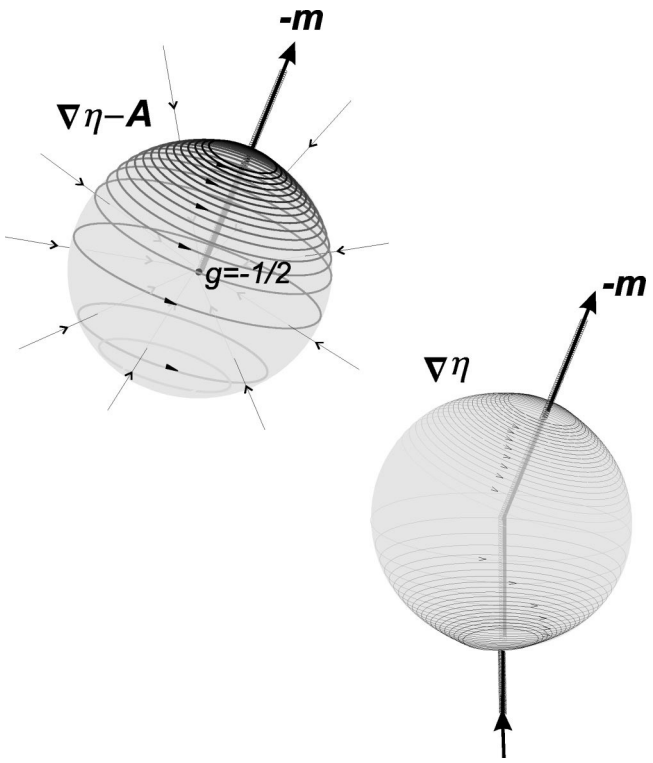

FIG. 1. Interpretation of the gauge invariant phase gradient as the vector potential on the unit sphere for a magnetic charge $-1/2$, and the phase gradient as the vector potential on the sphere for a trapped flux line of flux 2π.

But noting that the vector potential may also be expressed as $\vec{A}=(1/2r)\,[\hat{z}\times\hat{n}/(1+\hat{n}\cdot\hat{z})]$, we see by comparison that $\hat{n}\times\vec{\nabla}\log\sqrt{p}$, and hence the invariant phase gradient $\vec{\nabla}\eta-\vec{A}$, is the vector potential in a *fixed* gauge [specified by Eq. (4.11)] for a magnetic monopole of charge $-1/2$ centered at the origin with the string singularity running along the $-\hat{m}$ axis. Thus, the phase gradient $\vec{\nabla}\eta$ is nothing more than the sum of two vector potentials for two magnetic charges of opposite sign at the origin, with the respective Dirac flux strings running along the directions $-\hat{z}$ and $-\hat{m}$. Equivalently, we can say that the phase gradient $\vec{\nabla}\eta$ is the local vector potential at the exterior of single trapped-flux-line running along $-\hat{z}$ axis into the origin and exiting along the $-\hat{m}$ axis (Fig. 1), with the flux enclosed being $1/2\times 4\pi=2\pi$.

Some global properties of the phase dependence now become evident. First, the invariant phase gradient has only one vortex-like singularity at $\hat{n}=-\hat{m}$, where the amplitude $\langle\hat{m}|\hat{n}\rangle$ vanishes, with a circulation $\oint(\vec{\nabla}\eta-\vec{A})\cdot d\vec{l}=2\pi$. On the other hand, the actual phase gradient has, generically, two such singularities with circulation $\oint\vec{\nabla}\eta\cdot\mathrm{d}\vec{l}=\pm 2\pi$ at the two points on the unit sphere where the flux line crosses. One of these points is fixed to be $\hat{n}=-\hat{m}$ corresponding to the actual singularity at $\langle\hat{m}|\hat{n}\rangle=0$; the other point reflects the string singularity in the connection and is therefore dependent on the choice of section $|\hat{n}\rangle$. Note that while additional singularities may be created by means of singular gauge transformations, the string singularity associated with the connection cannot be removed. The exception is when the string singularity happens to be precisely at $\hat{n}=-\hat{m}$, in which case both singular points disappear and the phase is essentially a constant up to nonsingular gauge transformations.

V. ADDITIONAL PHASE/MODULUS RELATIONS ON THE RAY SPACE

So far, we have considered phase/modulus relations for transition amplitudes of the form $\langle\psi_f|\psi\rangle$ where $|\psi\rangle$ is a section of the holomorphic bundle over an arbitrary complex pure quantum

state manifold. Any such space is itself a complex submanifold of the so-called ray space $\mathcal{R}$, the entire space of pure quantum states modulo a phase transformation. If $n+1$ is the dimensionality of the Hilbert space of the quantum system, then the ray space is the complex projective space $\mathbb{C}P^{n-1}$. A state section $|\psi\rangle$ over $\mathcal{R}$ is therefore a section over a holomorphic line bundle as well, and hence the results of the preceding section hold without change. However, on the ray space, it is possible to establish an additional geometric relation between the transition probability $p=|\langle\psi_f|\psi\rangle|^2$ and geodesic distances on $\mathcal{R}$ as measured with the quantum metric. By virtue of the generalized Cauchy–Riemann conditions (3.5), this new relation has far-reaching consequences, as we now show.

On the ray space, the quantum metric $ds^2=q[\,\langle d\psi|d\psi\rangle-\langle d\psi|\psi\rangle\langle\psi|d\psi\rangle\,]$ is known as the *Fubini–Study* metric, and is the most natural Riemannian metric on the ray space as it the only one invariant under unitary transformations. Geometrically, the metric arises quite naturally by defining for two arbitrary rays in Hilbert space $[\,|\phi\rangle\,]$ and $[\,|\psi\rangle\,]$ (represented by the normalized states $|\phi\rangle$ and $|\psi\rangle$), the distance function[10]

$$s(\phi,\psi)=\sqrt{q}\cos^{-1}|\langle\psi|\phi\rangle|\,. \tag{5.1}$$

The Fubini–Study metric is then obtained by choosing $|\phi\rangle$ and $|\psi\rangle$ on the same section and taking the limit when $|\phi\rangle$ goes to $|\psi\rangle$, in which case

$$|\phi\rangle\simeq|\psi\rangle+|d\psi\rangle+\tfrac{1}{2}|d^2\psi\rangle\,,$$

thus yielding the infinitesimal distance function $ds(\phi,\psi)=\sqrt{q}\sqrt{\langle d\psi|d\psi\rangle-\langle d\psi|\psi\rangle\langle\psi|d\psi\rangle}$.

From the above considerations it holds, therefore, that the modulus of the amplitude $\langle\psi_f|\psi(\xi)\rangle$ can be expressed as a function of the Fubini–Study geodesic distance $s(\xi)$ between the rays $[\,|\psi\rangle\,]$ and the fixed state $[\,|\psi_f\rangle\,]$, according to

$$\sqrt{p(\xi)}=\cos\left(\frac{s(\xi)}{\sqrt{q}}\right). \tag{5.2}$$

From this, we deduce that the gradient of $\log\sqrt{p}$ is given by

$$\nabla\log\sqrt{p}=-\frac{1}{\sqrt{q}}\tan\left(\frac{s}{\sqrt{q}}\right)\nabla s\,.$$

Now, since the modulus of the gradient measures the rate of change with respect to the metric length, it is clear that

$$|\nabla s|^2=1\,. \tag{5.3}$$

Translated in terms of $\sqrt{p}$, we then have that

$$q|\nabla\log\sqrt{p}\,|^2=\tan^2\left(\frac{s}{\sqrt{q}}\right)=\frac{1}{p}-1\,. \tag{5.4}$$

A brief comment on the statistical interpretation of this expression is in order. On the ray space, we may define for any observable $\hat{A}$, the corresponding expectation value function $A(\xi)=\langle\psi|\hat{A}|\psi\rangle$. It is then possible to show (see, e.g., Ref. 11) that the uncertainty $\langle\Delta A^2\rangle=\langle\psi|\hat{A}^2|\psi\rangle-A(\xi)^2$ is related to the gradient of $A(\xi)$ by

$$\frac{4}{q}\langle\Delta A^2\rangle=g^{\mu\nu}(\nabla_\mu A)(\nabla_\nu A)=|\nabla A|^2\,,$$

where $g^{\mu\nu}$ is the inverse to the Fubini–Study metric. Taking $\hat{A}$ to be the projection operator $\hat{\Pi} = |\psi_f\rangle\langle\psi_f|$, we obtain $\langle\Pi\rangle = p$ and $\langle\Delta\Pi^2\rangle = p(1-p)$. Thus,

$$|\nabla p\,|^2 = \frac{4}{q}\langle\Delta\Pi^2\rangle = \frac{4}{q}p(1-p)\,, \tag{5.5}$$

which can be seen to follow directly from Eq. (5.4). Therefore, the connection between the transition probability and the Fubini–Study metric is such that the variation of p with respect to the geodesic distance is, up to a proportionality constant, the variance in the frequency with which $|\psi_f\rangle$ is obtained given $|\psi\rangle$.[8]

Let us then proceed to explore a number of consequences that follow from this connection in conjunction with previously obtained results stemming from the generalized Cauchy–Riemann conditions in Eq. (3.5). Thus far we have seen that from the phase of $\langle\psi_f|\psi\rangle$ it is possible to recover the functional dependence of its modulus by means of line integration. It is now easy to show that in the ray space, the modulus of the amplitude can also be obtained by *differentiation* of the phase. For this we note, as shown earlier, that from the generalized Cauchy–Riemann conditions and the definition of the quantum metric it follows that $|\nabla \log\sqrt{p}|^2 = |\nabla\eta - \mathbf{A}|^2$. Using Eq. (5.4) we see therefore that

$$|\nabla\eta - \mathbf{A}|^2 = 1/p - 1\,,$$

and hence that the transition probability can also be expressed as

$$p = \frac{1}{1+q\,|\nabla\eta - \mathbf{A}|^2}\,. \tag{5.6}$$

With this, the following expression for the amplitude emerges:

$$\langle\psi_f|\psi\rangle = \frac{e^{i\eta}}{\sqrt{1+q\,|\nabla\eta - \mathbf{A}|^2}}\,, \tag{5.7}$$

signifying that, in a sense, all the information in the amplitude $\langle\psi_f|\psi\rangle$ is already contained in its phase factor.

It is also interesting to note that if the invariant phase gradient is treated as some velocity field as in semiclassical physics, then Eq. (5.7) for the amplitude bears a slight resemblance to the WKB formula $\psi(x) \propto e^{i\eta}/\sqrt{|\eta'|}$ in one dimension (note however the different powers of η' in the radical). The resemblance is sufficiently intriguing to motivate an interpretation of the invariant phase gradient as a sort of velocity field of certain trajectories on the ray space. This can be done as follows. From the generalized Cauchy–Riemann condition, Eq. (3.5), we have that

$$\nabla_\mu \log\sqrt{p} = \Omega_{\mu\nu}V^\nu\,. \tag{5.8}$$

Using Eq. (5.6), we substitute $p = (1+qV_\lambda V^\lambda)^{-1}$ to obtain

$$-\frac{q}{2}\frac{\nabla_\mu(V_\nu V^\nu)}{1+qV_\lambda V^\lambda} = \Omega_{\mu\nu}V^\nu. \tag{5.9}$$

We now use the fact that

$$\frac{1}{2}\nabla_\mu(V_\nu V^\nu) = V^\nu\nabla_\mu V_\nu = V^\nu\nabla_\nu V_\mu + V^\nu(\nabla_\mu V_\nu - \nabla_\nu V_\mu) = V^\nu\nabla_\nu V_\mu - \frac{2}{q}V^\nu\Omega_{\mu\nu}\,, \tag{5.10}$$

where we have used the fact that $\mathbf{dV} = \mathbf{d}(\mathbf{d}\eta - \mathbf{A}) = -\mathbf{dA} = -(2/q)\boldsymbol{\Omega}$. Hence we have that

$$\nabla_{\mathbf{V}} V^{\mu} = \frac{1}{q}(1 - q|\mathbf{V}|^2)\, \Omega^{\mu}{}_{\nu} V^{\nu}, \tag{5.11}$$

where $\nabla_{\mathbf{V}} = V^{\nu}\nabla_{\nu}$ is the covariant derivative along the vector field V^{μ}. Now note that because of the antisymmetry of $\mathbf{\Omega}$, the magnitude of $\mathbf{V}$ is preserved along its integral lines, i.e., $\nabla_{\mathbf{V}}|\mathbf{V}|^2 = 0$, in consistency with the the fact that the transition probability is constant in the direction of $\mathbf{V}$. Parametrizing the integral curves of $\mathbf{V}$ in terms of the geodesic distance along the curve as $V^{\mu} = |\mathbf{V}|\,(d\xi^{\mu}/ds)$, we obtain the equation

$$\frac{\mathrm{d}^2\xi^{\mu}}{\mathrm{d}s^2} + \Gamma^{\mu}_{\nu\lambda}\frac{\mathrm{d}\xi^{\nu}}{\mathrm{d}s}\frac{\mathrm{d}\xi^{\lambda}}{\mathrm{d}s} = e_{|\mathbf{V}|}F^{\mu}{}_{\nu}\frac{\mathrm{d}\xi^{\mu}}{\mathrm{d}s}, \tag{5.12}$$

where $e_{|\mathbf{V}|}$ is a specific constant to each curve given by

$$e_{|\mathbf{V}|} = \frac{1 - q|\mathbf{V}|^2}{2|\mathbf{V}|},$$

and $F^{\mu}{}_{\nu}$ is the field strength associated with the Berry–Simon connection ($\mathbf{F} = \mathbf{dA}$). From this we see that integral curves of the invariant phase gradient vector field V^{μ} are in correspondence with trajectories on the ray space of charged particles subject to the magnetic field associated with the Berry–Simon connection. The significance of these trajectories will not be explored in the present paper. Still, these results in conjunction with Eq. (5.7) suggest a procedure by which the whole transition amplitude may be obtained from the solution to a corresponding mechanical problem on the ray space.

To conclude this section, it is worth noting a simplification on the ray space of the scalar integrability condition, Eq. (3.14b), that follows from Eq. (5.4), namely,

$$\nabla^2 p = -\frac{4(k+1)}{q}\left[p - \frac{1}{k+1}\right]. \tag{5.13}$$

Since the ray space is compact, $\int_{\mathcal{R}} \mathrm{d}\mu\, \nabla^2 p = 0$, and therefore a volume integration over the entire space of this equation entails that

$$\langle p \rangle_{\mathcal{R}} = \frac{\int_{\mathcal{R}} \mathrm{d}\mu\, p}{\int_{\mathcal{R}} \mathrm{d}\mu} = \frac{1}{k+1},$$

in consistency with the fact that the average of $|\psi\rangle\langle\psi|$ over the entire ray space should be the completely mixed density matrix of a $k+1$ dimensional Hilbert space. Equation (5.13) then tells us that the deviation of the transition probability from its average value on the ray space is an eigenfunction of the Laplacian operator with eigenvalue $-(4/q)(k+1)$. This is easily verified for the Bloch sphere ($k=1$ and choosing $q=4$), in which case $p - \frac{1}{2} = \frac{1}{2}\hat{n}\cdot\hat{m}$ is made up of spherical harmonics of order $l=1$.

VI. GEOMETRIC PHASES

To conclude, we connect the present results with known results on geometric phases. As a first application we make a connection with a result of Samuel and Bhandari on the Pancharatnam phase. Pancharatnam[19] suggested that an operational definition of what it meant for two quantum states to be ''in'' or ''out of'' phase was naturally provided by the inner product between the two states. The phase $\eta = \arg\langle\psi_f|\psi\rangle$ is therefore also called the *Pancharatnam phase difference*. Samuel and Bhandari[7] have shown that this phase has an intrinsic geometric meaning as it can be obtained from the Berry–Simon connection using the geodesic rule, i.e.,

$$\eta = \int \mathrm{d}\xi'^{\mu} A_{\mu}, \tag{6.1}$$

where the integral is evaluated along the geodesic connecting the ray $[|\psi_f\rangle]$ with $[|\psi\rangle]$ and where it is assumed that $|\psi_f\rangle$ is an element of the same state section as $|\psi\rangle$. With the aid of the Cauchy–Riemann and the relationship between p and the geodesic distance, it is now seen that for an arbitrary integration path between the two rays Eq. (6.1) generalizes to

$$\eta = \eta_o + \int \mathrm{d}\xi^{\mu} A_{\mu} + \frac{1}{\sqrt{q}} \int \mathrm{d}\xi^{\mu} \Omega_{\mu}{}^{\nu} \partial_{\nu} s \tan \frac{s}{\sqrt{q}}, \tag{6.2}$$

where s denotes the geodesic distance from the initial ray to point of integration. If the path of integration is chosen along the geodesic, then from the antisymmetry of the Kähler form, the differential $\mathrm{d}\xi^{\mu} \Omega_{\mu}^{\nu} \partial_{\nu} s$ vanishes and equation is obtained up to the phase relating $|\psi_f\rangle$ with the element of the section $|\psi\rangle$ at $[\,|\psi_f\rangle\,]$.

Next, we turn to geometric phases under time evolution. As is well known, in the course of time evolution the amplitude between the instantaneous state of a system $|\psi;t\rangle$, and the initial state $|\psi;0\rangle$ acquires a total phase that can be decomposed into dynamical and geometric parts. It has been shown by Aharonov and Anandan[6] that when the system undergoes a cyclic evolution so that the state returns to the initial ray, the geometric contribution to the phase difference acquired is given by $-\oint \mathbf{A}$. The result generalizes a previous result by Berry,[4] in which the same geometric phase difference is acquired in the course of adiabatic evolution if the initial state is initially an eigenstate of an adiabatically varying Hamiltonian.

We now wish to generalize the above results by showing that the phase difference between the exact state $|\psi;t\rangle$ and any arbitrary state $|\psi_f\rangle$ can also be separated into dynamic and geometric contributions and give explicit formulas for the geometric component. The idea then is to consider the phase of an amplitude $\langle \psi_f|\psi;t\rangle$,

$$\beta = \arg\langle \psi_f|\psi;t\rangle,$$

where the state $|\psi;t\rangle$ satisfies the evolution equation

$$i\partial_t|\psi;t\rangle = \hat{H}(t)|\psi;t\rangle\,.$$

We consider, as an intermediate step, some arbitrary state section $|\psi(\xi)\rangle$ on the U(1) bundle over the ray space, so that at any given time the time evolved state may be written as

$$|\psi;t\rangle = e^{i\phi(t)}|\psi(\xi(t))\rangle\,.$$

Substituting into the Schrödinger equation and taking the inner product with $|\psi;t\rangle$, we then find that the phase factor $\phi(t)$ satisfies

$$\dot{\phi} = -\langle \psi|\hat{H}(t)|\psi\rangle + i\langle \psi(\xi)|\partial_t|\psi(\xi)\rangle = -\langle \hat{H}(t)\rangle - A_{\mu}\dot{\xi}^{\mu}\,.$$

Now, letting $\eta = \arg\langle\psi_f|\psi\rangle$, we then have

$$\dot{\beta} = \dot{\phi} + \dot{\eta} \tag{6.3}$$

$$= -\langle \hat{H}(t)\rangle - A_{\mu}\dot{\xi}^{\mu} + \eta_{,\mu}\dot{\xi}^{\mu}\,. \tag{6.4}$$

Thus we recognize the term $\eta_{,\mu} - A_{\mu}$ as the invariant phase gradient for the transition amplitude corresponding to the state section in question. We can then apply the generalized Cauchy–Riemann conditions to deduce finally that

$$\dot{\beta} = -\langle \hat{H}(t) \rangle - \dot{\xi}^{\mu} \Omega_{\mu}{}^{\nu} \partial_{\nu} \log \sqrt{p(\xi)} \ . \tag{6.5}$$

The result shows that in the course of time evolution, the amplitude $\arg\langle \psi_f | \psi; t \rangle$ acquires aside from the dynamical phase, a geometric component

$$\beta_g = -\int \mathrm{d}\xi^{\mu} \Omega_{\mu}{}^{\nu} \partial_{\nu} \log \sqrt{p(\xi)} \, . \tag{6.6}$$

To see the connection between this result and the cyclic geometric phase we recall that the curl of $\Omega_{\mu}{}^{\nu} \partial_{\nu} \log \sqrt{p(\xi)} \mathbf{d}\xi^{\mu}$ is the same curl as the curl of $\mathbf{A}$. Thus, when the evolution on the ray space is cyclic, we obtain the usual geometric phase $-\oint \mathbf{A}$. Note also that the present results can be extended to any complex submanifold of $\mathcal{R}$ if under time evolution the state remains on the manifold, for instance by virtue of adiabatic time evolution.

ACKNOWLEDGMENTS

This paper is dedicated to the memory of Jeeva Anandan from whom the author benefited in many stimulating discussions of the ideas presented herein. The author would also like to thank Y. Aharonov, P. Mazur, and E.C.G. Sudarshan for helpful discussions. This work was supported in part by the Office of Naval Research under Grant No. N00014-00-1-0383. A short review of the plethysm technique aiming to its application in finding branching rules for the reduction of an irreducible representation of a group under the restriction to one of its subgroups is given. The algebraic structure of the interacting boson model and some of its extensions is given together with the branching rules needed to classify their basis states, obtained by the use of plethysms. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1611265]

I. INTRODUCTION

In the study of irreducible representations (irreps) of the full linear group GL(n) in n dimensions an important role is played by the so called Schur functions.[1–3] In a given irrep $\{\lambda\}$ of GL(n) the character of each of its elements A is the Schur function $\{\lambda\}$ evaluated with the eigenvalues of A.

A Schur function is expressed in terms of *fundamental symmetrical quantities* a_i, h_i, and s_i,[4] polynomials in n unknowns that are left invariant under permutations of these unknowns. The plethysm of Schur functions turned out a powerful tool to determine branching rules for the reduction of irreps of GL(n) subgroups under restriction to some of their subgroups.[4,5] The plethysm operation of Schur functions was discovered by Littlewood[6] as a third way of combining two Schur function to obtain a linear combination of Schur functions of a same degree. With few exceptions,[4,7,8] it remainded almost unknown to physicists due to the great difficulties involved in its calculation. With the appearence of powerful computers the tedious labor of computing plethysms was no more a problem and new efforts were made in order to find algorithms for computing them.[5,9–13]

In most applications to physical problems such as in nuclear structure[5,7] and in the present work only a particular class of plethysm is needed, namely that in which the left factor is a symmetric Schur function and in the expansion only those Schur functions with no more than a given number of rows are considered. In that case, using an induction formula for computing plethysms with both factors being symmetric Schur functions given in Ref. 13, we developed an algorithm[5] to compute plethysms with a symmetric Schur function in the left and all Schur functions of a given degree at right.

A field in which the plethysm technique can show all its power is the interacting boson model (IBM) and its generalizations.

The IBM when originally introduced by Arima and Iachello[14] is 1975 takes the nucleons outside a core of an even–even nucleus couple then into pairs to form bosons with angular momentum 2(d-bosons) and 0(s-bosons), no other degree of freedom, besides their z-component being taken into account. To work in the second quantization formalism they introduce 5 (for d-bosons) $+1$(for s-bosons)$=6$ creation and annihilation boson operators. The space of states is taken as polynomials of degree N (number of boson pairs) in creation operators acting on a vacuum realizing in this way the basis states of irreducible symmetric representations of U(6).

These bosons interact among themselves by interactions that preserve angular momentum and number of boson pairs so that their Hamiltonian can be written in terms of Casimir invariants of U(6) subgroups.

This original verson is nowadays referred to as IBM-1. Some extensions of the model appeared[15] in order to account for other degrees of freedom and the inclusion of bosons with other angular momenta. The unitary group is enlarged and a very rich algebraic structure arises. The basis states of the irreps of these unitary groups are labeled by labels of irreps of their subgroups in chains ending with $O^+(3)$, the rotation group in three dimensions. To this end one needs to know how an irrep of a group branches into irreps of some of its subgroups. We will show in this paper how plethysms can be used to find these branching rules. Besides, the cases here studied can serve as examples for applications in other areas.

II. SUMMARY OF PLETHYSMS

A partition $(\lambda)\equiv(\lambda_1,\lambda_2,\ldots,\lambda_n)$ is a set of nonnegative integers (parts) λ_i such that $\lambda_1+\lambda_2+\cdots+\lambda_n=n$. If, in addition, they satisfy $\lambda_1\geqslant\lambda_2\geqslant\cdots\geqslant\lambda_n$, the partition is called *standard*. Since we will deal only with standard partitions we will omit the word standard. Usually in a partition the null parts are omitted and the repeated ones are exponentiated. We will use greek letters to denote a partition and italic letters to denote a single part of a partition. To each partition one associates a Young diagram, an array of n boxes with λ_1 boxes in the first row, λ_2 in the second and so on. Due to that the nonzero parts of a partition are referred to as *rows* and the conjugate partition of a given partition $(\lambda_1,\lambda_2,\ldots,\lambda_p,0,\ldots,0)$ is defined as the partition whose Young diagram is obtained from that of (λ) by interchange of rows and columns, i.e.,

$$(\tilde{\lambda})=(p^{\lambda_p},(p-1)^{\lambda_{p-1}-\lambda_p},\ldots,2^{\lambda_2-\lambda_3},1^{\lambda_1-\lambda_2}). \tag{1}$$

Given a set of n variables $x_1,x_2,\ldots,x_n$ and a partition (λ) of r, the Schur function $\{\lambda\}$ associated to (λ) is defined as[4,6]

$$\{\lambda\}=\frac{1}{r!}|Z_r|^{[\lambda]}, \tag{2}$$

where Z is the matrix

$$Z_r=\begin{pmatrix} s_1 & 1 & 0 & 0 & \ldots & \ldots & \ldots & 0 \\ s_2 & s_1 & 2 & 0 & \ldots & \ldots & \ldots & 0 \\ s_3 & s_2 & s_1 & 3 & 0 & \ldots & \ldots & 0 \\ \ldots & \ldots & \ldots & .. & \ldots & \ldots & \ldots & 0 \\ s_{r-1} & s_{r-2} & \ldots & \ldots & \ldots & \ldots & s_1 & r-1 \\ s_r & s_{r-1} & \ldots & \ldots & \ldots & \ldots & s_2 & s_1 \end{pmatrix} \tag{3}$$

and $s_i\equiv s_i(x_1,x_2,\ldots,x_n)$ is the sum of ith powers of each variable $x_1,x_2,\ldots,x_n$. In this notation of Schur function the variables and their number n are implied while r, called its *degree*, is obtained by $r=\lambda_1+\lambda_2+\cdots+\lambda_r$.

In (2), $|Z|^{(\lambda)}$ is the immanant of Z, an extension of the concept of determinant, given by

$$|Z|^{(\lambda)}=\sum_P \chi^{[\lambda]}(P)z_{1p_1}z_{2p_2}\cdots z_{rp_r}, \tag{4}$$

where the sum is over all permutations $P=(p_1,p_2,\ldots,p_r)$ of the integers $1,2,\ldots,r$ and $\chi^{[\lambda]}(P)$ is the character of permutation P in the irrep $[\lambda]$ of the symmetric group $S(r)$.

As a consequence of definition (2) a Schur function is an homogeneous polynomial of degree r in the variables $x_1, x_2, \ldots, x_n$, being identically null for partitions (λ) of r into more than n nonzero parts.

Expression (2) can be worked out to produce an alternative definition[6,9] of the Schur function

$$\{\lambda\} = \frac{|(x_i)^{\lambda_j + n - j}|}{|(x_i)^{n-j}|}, \tag{5}$$

where $|f_j(x_i)|$ denotes the determinant of a matrix M with elements $M_{i,j} = f_j(x_i)$.

A pair of Schur functions $\{\lambda'\}$, $\{\lambda''\}$ of degrees r' and r'' can be combined into three different ways to produce linear combination of Schur functions $\{\lambda'''\}$ of degree r''': inner (or direct) product, outer product and plethysm. These three operations will be denoted, respectively, as

$$\begin{aligned}
\{\lambda'\} \times \{\lambda''\} &= \sum_{\lambda'''} \alpha(\{\lambda'\} \times \{\lambda''\} \to \{\lambda'''\})\{\lambda'''\}, \\
\{\lambda'\}\{\lambda''\} &= \sum_{\lambda'''} \alpha(\{\lambda'\}\{\lambda''\} \to \{\lambda'''\})\{\lambda'''\}, \\
\{\lambda'\} \otimes \{\lambda''\} &= \sum_{\lambda'''} \alpha(\{\lambda\} \otimes \{\lambda''\} \to \{\lambda'''\})\{\lambda'''\},
\end{aligned} \tag{6}$$

where $\alpha(\cdots)$ is a non-negative integer denoting the multiplicity of $\{\lambda'''\}$ in the expansion. For clarity we attach to it an argument denoting the kind of operation that produced it.

In the inner product the degrees of the Schur functions involved are all equal, i.e., $r''' = r' = r'' = n$, and the expansion coefficients α are the coefficients of reduction of the Kronecker product of $S(n)$ irreps $[\lambda']$ and $[\lambda'']$.

In the outer product one has $r''' = r' + r''$ and the coefficients α are obtained by making the product of a Schur function in variables $(x_1, x_2, \ldots, x_{n'})$ by another in variables $(y_1, y_2, \ldots, y_{n''})$ and expressing it as a linear combination of Schur functions in variables $(z_1, z_2, \ldots, z_{n'''})$ with $z_i = x_i$ for $1 \leqslant i \leqslant n'$ and $z_{n'+i} = y_i$ for $1 \leqslant i \leqslant n''$. Littlewood obtained a procedure to find the coefficients of the outer product known in the literature as ''Littlewood's rules.''

To define plethysm one needs first to introduce the concept of *invariant matrix*.

Let $T(A)$ be an $m \times m$ matrix whose elements t_{ij} are given homogeneous polynomials of degree r in the elements of A. Let $T(B)$ be a matrix built with the *same* polynomials t_{ij} now in the elements of B. If

$$T(A)T(B) = T(AB) \tag{7}$$

for any nonsingular $m \times m$ matrices A, B then the matrix $T(A)$ is called an invariant matrix(of degree r) of A.

It follows from (7) that, once the set of polynomial t_{ij} is fixed, the set of matrices $\mathcal{D}^T(A) \equiv T(A)$ is a representation of $\mathrm{GL}(n)$.

As the Kronecker product of two representations of a group is also a representation of this group, the Kronecker product of invariant matrices is also an invariant matrix, in general reducible. Schur[1] demonstrated that *if A is an $n \times n$ matrix, there are as many irreducible invariant matrices of A of degree r as are the partitions of r with no more than n nonzero parts and the trace of them are the Schur functions of degree r in the eigenvalues of A*. These irreducible invariant matrices are then labeled by those partitions and denoted by $A^{[\mu]}$. The details of construction of irreducible invariant matrices can be found in Refs. 16 and 17.

Since an invariant matrix of an invariant matrix is also an invariant matrix of the original matrix, it can be decomposed into irreducible components

$$[A^{[\mu]}]^{[\nu]}=\sum_{\lambda}\ \kappa_{\lambda\mu\nu}A^{[\lambda]}. \tag{8}$$

Let us denote by r_μ, r_ν, and r_λ, the degrees of $\{\mu\}$, $\{\nu\}$, and $\{\lambda\}$, respectively. Since the elements of $A^{[\mu]}$ are polynomials of degree r_μ in the elements of A and those of $[A^{[\mu]}]^{[\nu]}$ are polynomials of degree r_ν in the components of $A^{[\mu]}$, it follows that $r_\lambda=r_\mu r_\nu$.

Equation (8) led Littlewood[6] to define a third composition rule of Schur functions denoted by the symbol $\otimes$ and defined as

$$\{\mu\}\otimes\{\nu\}=\sum_{\lambda}\ \kappa_{\lambda\mu\nu}\{\lambda\}, \tag{9}$$

where the Schur functions $\{\lambda\}$ and the numerical coefficients $\kappa_{\lambda\mu\nu}$ are those given in (8). This operation was later on named *plethysm*.

The plethysm operation has the following properties:[4,6,8]

$$\{\lambda\}\otimes(\{\mu\}\otimes\{\nu\})=(\{\lambda\}\otimes\{\mu\})\otimes\{\nu\}, \tag{10}$$

$$\{\lambda\}\otimes(\{\mu\}\pm\{\nu\})=\{\lambda\}\otimes\{\mu\}\pm\{\lambda\}\otimes\{\nu\}, \tag{11}$$

$$(\{\lambda\}+\{\mu\})\otimes\{\nu\}=\sum_{\lambda'\lambda''}\ \alpha(\{\lambda'\}\{\lambda''\}\rightarrow\{\nu\})(\{\lambda\}\otimes\{\lambda'\})(\{\mu\}\otimes\{\lambda''\}), \tag{12}$$

$$(\{\lambda\}-\{\mu\})\otimes\{\nu\}=\sum_{\lambda'\lambda''}\ (-)^{r''}\alpha(\{\lambda'\}\{\lambda''\}\rightarrow\{\nu\})(\{\lambda\}\otimes\{\lambda'\})(\{\mu\}\otimes\{\tilde{\lambda}''\}), \tag{13}$$

$$\{\lambda\}\otimes(\{\mu\}\{\nu\})=(\{\lambda\}\otimes\{\mu\})(\{\lambda\}\otimes\{\nu\}), \tag{14}$$

$$(\{\lambda\}\{\mu\})\otimes\{\nu\}=\sum_{\lambda'\lambda''}\ \alpha(\{\lambda'\}\times\{\lambda''\}\rightarrow\{\nu\})(\{\lambda\}\otimes\{\lambda'\})(\{\mu\}\otimes\{\lambda''\}), \tag{15}$$
