Here $\theta = \theta(x,t,\mathbf{u})$. Recent investigations by Sanders and Wang[25] suggest that the above result, Eq. (21), holds good for nonlinear PDDEs as well. For nonlinear PDDEs, the prolongation of the vector field takes the form

$$PrV_{\mathcal{D}\theta} = \sum_{\alpha,J} E^J\left(\sum_{\beta} \mathcal{D}_{\alpha\beta}\theta^{\beta}\right)\frac{\partial}{\partial E^J u^{\alpha}},$$

where E^J is the shift operator.

Let $\theta_1 = (\theta, \varsigma)^T$. Then

$$H_1\theta_1 = H_1\begin{bmatrix}\theta\\ \varsigma\end{bmatrix} = \begin{bmatrix}(uE - E^{-1}u)\theta + (E^{-1}-1)u\varsigma\\ -u\Delta\theta\end{bmatrix} = \begin{bmatrix}\Phi_1\\ \Phi_2\end{bmatrix}.$$

Next, define a bi-vector Θ of H_1 by

$$\Theta_{H_1} = \frac{1}{2}\sum[\theta \wedge \Phi_1 + \varsigma \wedge \Phi_2]$$

$$= \frac{1}{2}\sum[u\ \theta \wedge \overline{\theta} - u\ \overline{\theta} \wedge \theta + u\ \overline{\theta} \wedge \varsigma - u\ \theta \wedge \varsigma - u\ \varsigma \wedge \overline{\theta} + u\ \varsigma \wedge \theta]$$

which can be simplified, using the property of the wedge product, ($\theta \wedge \overline{\theta} = -\overline{\theta} \wedge \theta$, $\overline{\theta} \wedge \varsigma = -\varsigma \wedge \overline{\theta}$, $\theta \wedge \theta = 0$), into

$$\Theta_{H_1} = \sum[u\ \theta \wedge \overline{\theta} + u\overline{\theta} \wedge \varsigma + u\ \varsigma \wedge \theta],$$

where $\overline{\varsigma} = \varsigma_{n+1}, \overline{\theta} = \theta_{n+1}$. Now

$$PrV_{H_1\theta_1}(\Theta_{H_1}) = \sum[(-u\ \overline{\theta} + u\theta) \wedge (\theta \wedge \overline{\theta} + \overline{\theta} \wedge \varsigma + \varsigma \wedge \theta)] = 0$$

and so the skew symmetric operator H_1 is Hamiltonian. Here Σ is used to denote the equivalence classes after dividing the image of $(1-E)$. In a similar manner, we have checked that the skew symmetric operators H_2 and H_3 satisfy

$$PrV_{H_2\theta_1}(\Theta_{H_2}) = 0, \quad PrV_{H_3\theta_1}(\Theta_{H_3}) = 0$$

indicating they are Hamiltonian operators.

Next consider the skew symmetric operator H_4. Now

$$H_4\theta_1 = H_4\begin{bmatrix}\theta\\ \varsigma\end{bmatrix} = \begin{bmatrix}H_{11}^{(4)}\theta + H_{12}^{(4)}\varsigma\\ H_{21}^{(4)}\theta + H_{22}^{(4)}\varsigma\end{bmatrix} = \begin{bmatrix}\Phi_1\\ \Phi_2\end{bmatrix},$$

where $H_{11}^{(4)}$, $H_{12}^{(4)}$, $H_{21}^{(4)}$, and $H_{22}^{(4)}$ are given in Eqs. (20a) and (20b). As before we define a bi-vector Θ of H_4 as

$$\Theta_{H_4}=\frac{1}{2}\sum\ [\theta\wedge\Phi_1+\varsigma\wedge\Phi_2].$$

Proceeding further along the lines described above we find that $PrV_{H_4\theta_1}(\Theta_{H_4})$ reduce into

$$PrV_{H_4\theta_1}(\Theta_{H_4})=\sum\ (E-1)(\cdots)+\sum\ (E-E^{-1})^{-1}(\cdots). \tag{22}$$

Obviously the expression in the first summation becomes zero while the expression in the second summation does not vanish due to the presence of the inverse difference operator $(E-E^{-1})^{-1}$ and so

$$PrV_{H_4\theta_1}(\Theta_{H_4})\neq 0$$

proving that the operator H_4 is not a Hamiltonian operator. Similar conclusions can be arrived at for the remaining skew symmetric operators $H_n, n\geqslant 5$.

It is appropriate to mention here that a similar feature has been observed in the case of integrable nonlinear partial differential equations. For example, Fordy and Antonwicz[8] have shown that the two coupled Korteweg–de Vries equation admits *four* distinct operators H_1, H_2, H_3, and H_4 and pointed out that the first three operators are Hamiltonian while H_4 is not a Hamiltonian operator because the associated $PrV_{H_4\theta_1}(\Theta_{H_4})\neq 0$ since it involves integro differential operator.

Thus we conclude that the RT lattice equation (1) is only a tri-Hamiltonian system. Using a different approach Fuchssteiner *et al.*[19] have also shown that RT is a tri-Hamiltonian system.

B. VL lattice equation

1. Construction of a sequence of operators

Here

$$H_1=u(E-E^{-1})u,\quad H_2=u(Eu+uE+EuE-uE^{-1}-E^{-1}u-E^{-1}uE^{-1})u.$$

Using the operators H_1 and H_2 in Eq. (15) we obtain the following operators:

$$\begin{aligned}H_3&=\mathcal{R}H_2\\&=u(1+E+E^{-1})u[Eu+uE+EuE-E^{-1}u-uE^{-1}-E^{-1}uE^{-1}]u+u[Eu^2+EuE^{-1}u\\&\quad+Eu^2E+EuE^{-1}uE-E^{-1}u^2-E^{-1}uEu-E^{-1}u^2E-E^{-1}uEuE]u+u[Eu(E-1)^{-1}E^{-1}u\\&\quad+Eu(E-1)^{-1}u-E^{-1}u(1-E^{-1})^{-1}E^{-1}u-E^{-1}u(1-E^{-1})^{-1}u](E-E^{-1})u,\end{aligned} \tag{23}$$

$$\begin{aligned}H_4&=\mathcal{R}^2H_2\\&=[u(1+E+E^{-1})u+uEu(E-1)^{-1}-uE^{-1}u(1-E^{-1})^{-1}]\{(1+E+E^{-1})\\&\quad\times u[Eu+uE+EuE-E^{-1}u-uE^{-1}-E^{-1}uE^{-1}]u+Eu(1+E^{-1})u^2\\&\quad+Eu(1+E^{-1})uEu+Eu(E-1)^{-1}E^{-1}u(E-E^{-1})u+Eu(E-1)^{-1}u(E-E^{-1})u\\&\quad-E^{-1}u(E+1)u^2-E^{-1}u(E+1)uEu-E^{-1}u(1-E^{-1})^{-1}E^{-1}u(E-E^{-1})u\\&\quad-E^{-1}u(1-E^{-1})^{-1}u(E-E^{-1})u\},\end{aligned} \tag{24}$$

and so on.

2. Tri-Hamiltonian structure

First consider the skew symmetric operator H_1. Let

$$H_1\theta = u\ \overline{u}\ \overline{\theta} - u\ \underline{u}\ \underline{\theta},$$

where $\underline{\theta} = \theta_{n-1}$, etc. As before we define a bi-vector Θ of H_1 by

$$\Theta_{H_1} = \frac{1}{2}\sum [\theta \wedge H_1\theta] = \frac{1}{2}\sum [\theta \wedge u\ \overline{u}\,\overline{\theta} - \theta \wedge \underline{u}\ \underline{\theta}] = \frac{1}{2}\sum [u\ \overline{u}\ \theta \wedge \overline{\theta} - u\ \overline{u}\ \overline{\theta} \wedge \theta]. \tag{25}$$

Making use of the property of wedge product, the above equation can be written as

$$\Theta_{H_1} = \sum [\ u\ \overline{u}\ \theta \wedge \overline{\theta}\ ]$$

and hence

$$\begin{aligned} PrV_{H_1\theta_1}(\Theta_{H_1}) &= \sum [\ \overline{u}\ (u\overline{u}\ \overline{\theta} - u\ \underline{u}\ \underline{\theta}) \wedge \theta \wedge \overline{\theta} + u\ (\overline{u}\overline{\bar{u}}\ \bar{\bar{\theta}} - u\ \overline{u}\ \theta) \wedge \theta \wedge \overline{\theta}\ ] \\ &= \sum [\ u\ \overline{u}\ \bar{u}\ \theta \wedge \overline{\theta} \wedge \bar{\bar{\theta}} - \underline{u}\ u\ \overline{u}\ \underline{\theta} \wedge \theta \wedge \overline{\theta}\ ] \\ &= \sum [\ (E-1)\underline{u}\ u\ \overline{u}\ \underline{\theta} \wedge \theta \wedge \overline{\theta}\ ] = 0 \end{aligned}$$

and so the operator H_1 is Hamiltonian. In a similar manner, we have checked that the skew symmetric operator H_2 satisfy

$$PrV_{H_2\theta_1}(\Theta_{H_2}) = 0 \tag{26}$$

indicating that it is a Hamiltonian operator.

Next consider the skew symmetric operator H_3. As before we define a bi-vector Θ of H_3 by

$$\begin{aligned} \Theta_{H_3} = \sum [&u^3\ \overline{u}\ \overline{\theta} + u^2\ \overline{u}\overline{\bar{u}}\ \bar{\bar{\theta}} - u^2\ \underline{u}^2\ \underline{\theta} - u^3\ \underline{u}\ \underline{\theta} - u^2\ \underline{u}\ \underline{\underline{u}}\ \underline{\underline{\theta}} + u\ \overline{u\bar{u}}^2\ \bar{\bar{\theta}} + u\ \overline{u}^2\ \bar{u}\ \bar{\bar{\theta}} \\ &+ u\ \overline{u}\ \bar{\bar{\theta}} u\ \overline{\overline{\theta}} - u\ \underline{u}\ \underline{\underline{u}}^2\ \underline{\underline{\theta}} - u\ \underline{u}^2\ \underline{\underline{u}}\ \underline{\underline{\theta}} - u\underline{u}\ \underline{\underline{u}}\ \underline{\underline{\underline{u}}}\ \underline{\underline{\underline{\theta}}} + u\ \overline{u}^3\ \overline{\theta} + u^2\ \overline{u}^2\ \overline{\theta} - u\ \underline{u}^3\underline{\theta} \\ &+ uEu(E-1)^{-1}u(E-E^{-1})u\theta + uEu(E-1)^{-1}Eu(E-E^{-1})u\theta \\ &- uE^{-1}u(1-E^{-1})^{-1}E^{-1}u(E-E^{-1})u\theta - uE^{-1}u(1-E^{-1})^{-1}u(E-E^{-1})u\theta]. \end{aligned}$$

Making use of the property of wedge product and then computing the related prolongation, after a tedious calculation, we find that

$$PrV_{H_3\theta_1}(\Theta_{H_3}) = \sum (E-1)(\cdots) = 0 \tag{27}$$

provided if the field variable u is periodic with even period. Furthermore we have checked that the prolongation associated with the operators $H_n, n \geqslant 4$ does not vanish, that is

$$PrV_{H_4\theta_1}(\Theta_{H_4}) \neq 0,\ \ PrV_{H_5\theta_1}(\Theta_{H_5}), \neq 0, \ldots \tag{28}$$

even if the field variable u is periodic with even period.

Hence Vl lattice equation is a tri-Hamiltonain system only if the field variable is periodic with even period.

Using the Poisson structure technique Wadati *et al.*[22] have also shown that the VL lattice equation (2) is a tri-Hamiltonian system.

C. TL lattice equation

We have checked that the TL lattice equation (3) admits a tri-Hamiltonian structure and thus can be written as

$$\begin{bmatrix} u_t \\ v_t \end{bmatrix} = H_3 \begin{bmatrix} \frac{1}{2v} \\ 0 \end{bmatrix} = H_2 \begin{bmatrix} 0 \\ 1 \end{bmatrix} = H_1 \begin{bmatrix} 1 \\ u \end{bmatrix}.$$

Here the operators

$$H_1 = \begin{bmatrix} (E-1)v & 0 \\ 0 & v(1-E^{-1}) \end{bmatrix}, \quad H_2 = \begin{bmatrix} u(E-1)v & Ev - vE^{-1} \\ v(E-E^{-1})v & v(1-E^{-1})u \end{bmatrix} \tag{29}$$

and

$$H_3 = \mathcal{R} H_2 = \begin{bmatrix} (E-1)v^2 + (EvE - vE^{-1})v + u^2(E-1)v & u(Ev - vE^{-1}) + (Ev - vE^{-1})u \\ 2v(uE - E^{-1}u)v & v(Ev - E^{-1}vE^{-1}) + v(1-E^{-1})u^2 + v^2(1-E^{-1}) \end{bmatrix} \tag{30}$$

with the recursion operator $\mathcal{R} = H_2 H_1^{-1}$ as

$$\mathcal{R} = \begin{bmatrix} u & (Ev - vE^{-1})(1-E^{-1})^{-1}\frac{1}{v} \\ v(1+E^{-1}) & v(1-E^{-1})u(1-E^{-1})^{-1}\frac{1}{v} \end{bmatrix}. \tag{31}$$

Proceeding in a similar manner we construct a sequence of operators $(H_n,\ n \geqslant 4)$. For example, the operator H_4 is

$$H_4 = \mathcal{R}^2 H_2 = \begin{bmatrix} H_{11}^{(4)} & H_{12}^{(4)} \\ H_{21}^{(4)} & H_{22}^{(4)} \end{bmatrix}, \tag{32}$$

where

$$H_{11}^{(4)} = 2(Ev - vE^{-1})(1-E^{-1})^{-1}(uE - E^{-1}u)v + u(E-1)v^2 + u(EvE - vE^{-1})v + u^3(E-1)v,$$

$$\begin{aligned} H_{12}^{(4)} &= (Ev - vE^{-1})(1-E^{-1})^{-1}(Ev - E^{-1}vE^{-1}) + (Ev - vE^{-1})u^2 \\ &\quad + (Ev - vE^{-1})(1-E^{-1})^{-1}v(1-E^{-1}) + u^2(Ev - vE^{-1}) + u(Ev - vE^{-1})u, \end{aligned} \tag{32a}$$

$$\begin{aligned} H_{21}^{(4)} &= 2v(1-E^{-1})u(1-E^{-1})^{-1}(uE - E^{-1}u)v + v(1+E^{-1})(E-1)v^2 \\ &\quad + v(1+E^{-1})(EvE - vE^{-1})v + v(1+E^{-1})u^2(E-1)v, \end{aligned}$$

$$\begin{aligned} H_{22}^{(4)} &= v(1-E^{-1})u(1-E^{-1})^{-1}(Ev - E^{-1}vE^{-1}) + v(1-E^{-1})u^3 + v(1-E^{-1}) \\ &\quad \times u(1-E^{-1})^{-1}v(1-E^{-1}) + v(1+E^{-1})(uEv - uvE^{-1}) + v(1+E^{-1})(Ev - vE^{-1})u. \end{aligned} \tag{32b}$$

The operators $H_n, n \geqslant 5$ involve lengthy expressions; we have not presented their explicit forms here.

In order to investigate the nature of the operator H_4 Hamiltonian or not let

$$H_4 \theta_1 = H_4 \begin{bmatrix} \theta \\ \varsigma \end{bmatrix} = \begin{bmatrix} H_{11}^{(4)} \theta + H_{12}^{(4)} \varsigma \\ H_{21}^{(4)} \theta + H_{22}^{(4)} \varsigma \end{bmatrix} = \begin{bmatrix} \Phi_1 \\ \Phi_2 \end{bmatrix},$$

where $H_{11}^{(4)}$, $H_{12}^{(4)}$, $H_{21}^{(4)}$, and $H_{22}^{(4)}$ are given in Eqs. (32a) and (32b). Define a bivector Θ of H_4 as

$$\Theta_{H_4} = \frac{1}{2} \sum [\theta \wedge \Phi_1 + \varsigma \wedge \Phi_2].$$

Proceeding as before for the RT lattice equation (1) we find that the prolongation associated with H_4 does not vanish due to the presence of the inverse difference operator $(E - E^{-1})^{-1}$ and so H_4 is not a Hamiltonian operator. Similar conclusions can be arrived at for the remaining skew symmetric operators $H_n, n \geqslant 5$.

Thus we conclude that the TL lattice equation (3) is only a tri-Hamiltonian system. Similar observation has also pointed out by Oevel *et al.* using a different approach.[18]

D. BC lattice equation

A detailed but cumbersome calculation shows that BC lattice equation (4) possesses tri-Hamiltonian structure and hence can be written as

$$\begin{bmatrix} u_t \\ v_t \end{bmatrix} = H_3 \begin{bmatrix} u + \overline{u} + \underline{u} \\ -1 \end{bmatrix} = H_2 \begin{bmatrix} 0 \\ \dfrac{1}{3v} \end{bmatrix} = H_1 \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \tag{33}$$

where the Hamiltonian operators H_1, H_2, and H_3 take the form

$$H_1 = \begin{bmatrix} H_{11}^{(1)} & H_{12}^{(1)} \\ H_{21}^{(1)} & H_{22}^{(1)} \end{bmatrix}, \quad H_2 = \begin{bmatrix} H_{11}^{(2)} & H_{12}^{(2)} \\ H_{21}^{(2)} & H_{22}^{(2)} \end{bmatrix}$$

and

$$H_3 = \begin{bmatrix} R_{11} H_{11}^{(2)} + R_{12} H_{21}^{(2)} & R_{11} H_{12}^{(2)} + R_{12} H_{22}^{(2)} \\ R_{13} H_{11}^{(2)} + R_{14} H_{21}^{(2)} & R_{13} H_{12}^{(2)} + R_{14} H_{22}^{(2)} \end{bmatrix}$$

with the recursion operator $\mathcal{R}$

$$\mathcal{R} = H_2 H_1^{-1} = \begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} \end{bmatrix},$$

where

$$H_{11}^{(1)} = uEu - uE^{-1}u + E^{-1}v - vE,$$

$$H_{12}^{(1)} = -uE^{-2}v + uEv,$$

$$H_{21}^{(1)} = vE^2u - vE^{-1}u,$$

$$H_{22}^{(1)} = vE^2v + vEv - vE^{-2}v - vE^{-1}v, \tag{34}$$

$$H_{11}^{(2)}=u(uE+Eu+EuE-uE^{-1}-E^{-1}u-E^{-1}uE^{-1})u+uE^{-1}v-uEvE+E^{-1}vE^{-1}u-vE^{2}u$$
$$-uvE-vEu+E^{-1}uv+uE^{-2}v,$$

$$H_{12}^{(2)}=-u(-uE-Eu-EuE+uE^{-2}+E^{-1}uE^{-2}+E^{-1}uE^{-1})v-v(1+E+E^{2})v$$
$$+E^{-1}v(1+E^{-1}+E^{-2})v-(uE^{-1}u-uEuE^{-1})v,$$

$$H_{21}^{(2)}=-v(uE^{-1}+E^{-1}u+E^{-1}uE^{-1}-EuE-E^{2}u-E^{2}uE)u-v[(1+E+E^{2})vE$$
$$-(1+E^{-1}+E^{-2})v]-v[-uE+EuE^{-1}]u,$$

$$H_{22}^{(2)}=-v[E^{-1}uE^{-2}+uE^{-2}-uE-E^{2}uE+E^{-1}u+E^{-1}uE^{-1}$$
$$-E^{2}uE^{-1}-EuE+EuE^{-2}-E^{2}u]v, \tag{35}$$

$$R_{11}=[u(EuE-E^{-1}uE^{-1})u+uE^{-1}(1+E^{-1})v-u(1+E)vE+(E^{-1}uv-vEu)$$
$$+(u^{2}(1-E^{-1})+uE^{-1}uE^{-2}-uEuE+(1-E^{-1}))v^{2}(1+E^{-1})^{-1}u]$$
$$\times(E^{-1}v-vE-u(E^{-1}-1)(1+E^{-1})^{-1}u)^{-1}, \tag{36a}$$

$$R_{12}=\Bigg\{[u(uE+Eu+EuE-uE^{-1}-E^{-1}u-E^{-1}uE^{-1})u+uE^{-1}v-uEvE+E^{-1}vE^{-1}u-vE^{2}u$$
$$-uvE-vEu+E^{-1}uv+uE^{-2}v]+[u(-uE-Eu-EuE+uE^{-2}+E^{-1}uE^{-2}+E^{-1}uE^{-1})$$
$$+v(1+E+E^{2})-E^{-1}v(1+E^{-1}+E^{-2})v+(uE^{-1}u-uEuE^{-1})]\Bigg[(E-E^{-2})^{-1}(E-E^{-1})u$$
$$+(E-E^{-2})^{-1}\frac{1}{u}(E^{-1}v-vE)\Bigg]\Bigg\}\Bigg(v(1-E)u-(1+E)\frac{1}{u}(E^{-1}v-vE)\Bigg)^{-1}, \tag{36b}$$

$$R_{13}=\{[v(EuE-E^{-1}uE^{-1}+E^{2}uE-EuE^{-1})u-(1+E+E^{2})vE+(1+E^{-1}+E^{-2})v$$
$$+[u((1-E^{-1})+(E+E^{-1})uE^{-2}-(1+E)EuE)\}(1+E^{-1})^{-1}u](E^{-1}v-vE$$
$$-u(E^{-1}-1)(1+E^{-1})^{-1}u)^{-1}, \tag{37a}$$

$$R_{14}=\Bigg\{[-v(uE^{-1}+E^{-1}u+E^{-1}uE^{-1}-EuE-E^{2}u-E^{2}uE)v-v(1+E+E^{2})vE+v(1+E^{-1}$$
$$+E^{-2})v+v(uE-EuE^{-1})u+v(E^{-1}uE^{-2}+uE^{-2}-uE-E^{2}uE+E^{-1}u+E^{-1}uE^{-1}$$
$$-E^{2}uE^{-1}-EuE+EuE^{-2}-E^{2}u)]\Bigg[(E-E^{-2})^{-1}(E-E^{-1})u+(E-E^{-2})^{-1}\frac{1}{u}(E^{-1}v$$
$$-vE)\Bigg]\Bigg\}\Bigg(v(1-E)u-(1+E)\frac{1}{u}(E^{-1}v-vE)\Bigg)^{-1}. \tag{37b}$$

Making use of the operators H_1 and H_2 in Eq. (15) we have constructed a sequence of operators $\{H_4,H_5,H_6,\ldots\}$ which involve lengthy expressions.

We observe that the prolongation corresponding to the operator H_3 vanishes only if the field variables u and v are periodic with even period like for VL equation. Further we have checked that the prolongation associated with the operators $H_n, n\geqslant 4$ does not vanish even if the field variables are periodic with even period and so they are not Hamiltonian ones.

Thus the BC lattice equation (4) is a tri-Hamiltonian system provided if the field variables are periodic.

We find after detailed calculations that, both BM3 and BM4 lattice equations (5) and (6) admit only three distinct Hamiltonian operators and so they are tri-Hamiltonian system (brief details are given in Appendixes A and B).

IV. CONCLUSION

A systematic investigation of multi-Hamiltonian structure of certain integrable nonlinear partial differential–difference equations with two independent variables is presented. It is shown that the RT, TL, BM3, and BM4 lattice equations admit only three Hamiltonian operators while the well-known VL and BC lattice equations possess three Hamiltonian operators only if the filed variable is periodic with even period and hence they are tri-Hamiltonian systems only. It is observed that the presence of the inverse difference operators prevents one to show that the operator H_N, $N \geqslant 4$ is not Hamiltonian. A similar feature was observed for two coupled Korteweg–de Vries equations by Fordy and Antonwicz.[8]

ACKNOWLEDGMENT

One of the authors (S.K.) would like to thank the University of Madras for providing University Research Fellowship.

APPENDIX A: BM3 LATTICE EQUATION

The BM3 lattice equation (5) can be written as

$$\begin{bmatrix} u_t \\ v_t \\ w_t \end{bmatrix} = H_3 \begin{bmatrix} 0 \\ 0 \\ \dfrac{1}{w} \end{bmatrix} = H_2 \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix} = H_1 \begin{bmatrix} w \\ v \\ u \end{bmatrix}, \tag{A1}$$

where $w = w_n$ and the Hamiltonian operators H_1, H_2, H_3 takes

$$H_1 = \begin{bmatrix} (E-E^{-1}) & 0 & 0 \\ 0 & 0 & (E^{-1}-1)w \\ 0 & -w(E-1) & 0 \end{bmatrix},$$

$$H_2 = \begin{bmatrix} H_{11}^{(2)} & H_{12}^{(2)} & H_{13}^{(2)} \\ H_{21}^{(2)} & H_{22}^{(2)} & H_{23}^{(2)} \\ H_{31}^{(2)} & H_{32}^{(2)} & H_{33}^{(2)} \end{bmatrix} \quad \text{and} \quad H_3 = \begin{bmatrix} H_{11}^{(3)} & H_{12}^{(3)} & H_{13}^{(3)} \\ H_{21}^{(3)} & H_{22}^{(3)} & H_{23}^{(3)} \\ H_{31}^{(3)} & H_{32}^{(3)} & H_{33}^{(3)} \end{bmatrix}, \tag{A2}$$

where

$$H_{11}^{(2)} = Ev - vE^{-1} - u(E-1)(E-E^{-1})^{-1}(E^{-1}-1)u, \quad H_{12}^{(2)} = EwE - E^{-1}w,$$

$$H_{13}^{(2)} = u(E-1)(E-E^{-1})^{-1}(E^{-1}-1)w,$$

$$H_{21}^{(2)} = wE - E^{-1}wE^{-1}, \quad H_{22}^{(2)} = E^{-1}uw - uwE, \quad H_{23}^{(2)} = v(E^{-1}-1)w,$$

$$H_{31}^{(2)} = w(E-1)(E-E^{-1})^{-1}(E^{-1}-1)u, \quad H_{32}^{(2)} = -w(E-1)v,$$

$$H_{33}^{(2)} = w(-(E-E^{-1}) - (E-1)(E-E^{-1})^{-1}(E^{-1}-1))w, \tag{A2a}$$

$$H_{11}^{(3)} = uwE^{-1} + E^{-1}wu - wuE - Ewu + v^2E^{-1} - Ev^2,$$

$$H_{12}^{(3)}=-EwvE-EwEv+vE^{-1}w+E^{-1}wv,$$

$$H_{13}^{(3)}=(EwE-E^{-1}wE^{-1})w,$$

$$H_{21}^{(3)}=E^{-1}wvE^{-1}+vE^{-1}wE^{-1}-wEv-vwE,$$

$$H_{22}^{(3)}=E^{-1}wE^{-1}w-wEwE+uwvE+uwEv-E^{-1}uwv-vE^{-1}uw,$$

$$H_{23}^{(3)}=v^2(1-E^{-1})w+(-E^{-1}uwE^{-1}+uwE)w,$$

$$H_{31}^{(3)}=wE^{-1}wE^{-1}-wEwE-wE^{-1}uv+wEuv,$$

$$H_{32}^{(3)}=wEv^2-wv^2+wEuwE-wE^{-1}wuE-uw^2+uw^2E,$$

$$H_{33}^{(3)}=wEvw-wvE^{-1}w \tag{A2b}$$

with the recursion operator $\mathcal{R}$ for the BM3 lattice equation (5) takes the form

$$\mathcal{R}=\begin{bmatrix} (E-E^{-1})^{-1}[Ev-vE^{-1} & (E-E^{-1})^{-1}[EwE-E^{-1}w] & (E-E^{-1})^{-1}[u(E-1) \\ -u(E-1)(E-E^{-1})^{-1} & & (E-E^{-1})^{-1}(E^{-1}-1)]w \\ (E^{-1}-1)u] & & \\ -(E-E^{-1})^{-1}(E^{-1}-1)u & v & [1+E^{-1}+(E-E^{-1})^{-1} \\ & & (E^{-1}-1)]w \\ \frac{1}{w}(E^{-1}-1)^{-1} & \frac{1}{w}(E^{-1}-1)^{-1} & \frac{1}{w}(E^{-1}-1)^{-1} \\ [wE-E^{-1}wE^{-1}] & [E^{-1}uw-uwE] & [v(E^{-1}-1)w] \end{bmatrix}.$$

Making use of the operators H_1 and H_2 in Eq. (10) we have constructed a sequence of operators H_n, $n\geqslant 4$ and checked that the required prolongation does not vanish in each of the operators indicating that they are not Hamiltonian.

APPENDIX B: BM4 LATTICE EQUATION

A detailed calculation shows that the BM4 lattice equation (6) possesses a tri-Hamiltonian structure and thus can be written as

$$\begin{bmatrix} u_t \\ v_t \\ w_t \\ q_t \end{bmatrix}=H_3\begin{bmatrix} \frac{1}{u} \\ 0 \\ 0 \\ 0 \end{bmatrix}=H_2\begin{bmatrix} 0 \\ 1 \\ 0 \\ 0 \end{bmatrix}=H_1\begin{bmatrix} \underline{w} \\ \frac{v}{u} \\ 0 \end{bmatrix}, \tag{B1}$$

where $q=q_n$, $\underline{w}=w_{n-1}$,

Spectral curve and Hamiltonian structure of isomonodromic SU(2) Calogero–Gaudin system

Kanehisa Takasaki[a)]

(Received 25 November 2001; accepted 8 May 2003)

This paper presents a new approach to the Hamiltonian structure of isomonodromic deformations of a matrix system of ordinary differential equations (ODEs) on a torus. An isomonodromic analogue of the SU(2) Calogero–Gaudin system is used for a case study of this approach. A clue of this approach is a mapping to a finite number of points on the spectral curve of the isomonodromic Lax equation. The coordinates of these moving points give a new set of Darboux coordinates called the spectral Darboux coordinates. The system of isomonodromic deformations is thereby converted to a nonautonomous Hamiltonian system in the spectral Darboux coordinates. The Hamiltonians turn out to resemble those of a previously known isomonodromic system of a second-order scalar ODE. The two isomonodromic systems are shown to be linked by a simple relation. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1591053]

I. INTRODUCTION

The notion of isomonodromic deformations originates in the celebrated work of Fuchs.[1] Fuchs studied isomonodromic deformations of a second-order linear ordinary differential equation (ODE) of the form

$$\frac{\mathrm{d}^2y}{\mathrm{d}z^2}+\left(\frac{a}{z^2}+\frac{b}{(z-1)^2}+\frac{c}{(z-t)^2}+\frac{\mathrm{d}}{z(z-1)}-\frac{3}{4(z-\lambda)^2}-\frac{t(t-1)K}{z(z-1)(z-t)}+\frac{\lambda(\lambda-1)\nu}{z(z-1)(z-\lambda)}\right)y=0$$

with five regular singular points $z=0,1,\infty,t,\lambda$ on the Riemann sphere, and discovered a nonlinear ODE that is nowadays called the sixth Painlevé equation. His work was soon generalized by Garnier[2] and Schlesinger[3] in two different directions. Whereas Garnier extended the work of Fuchs to a second-order linear ODE with more singularities (including irregular ones as well), Schlesinger studied a matrix system of the form

$$\frac{\mathrm{d}Y}{\mathrm{d}z}=\sum_{j=1}^{N}\frac{A_j}{z-t_j}Y,$$

and obtained the so-called Schlesinger system

$$\frac{\partial A_k}{\partial t_j}=(1-\delta_{jk})\frac{[A_k,A_j]}{t_k-t_j}-\delta_{jk}\sum_{l\neq k}\frac{[A_k,A_l]}{t_k-t_l}$$

that characterizes isomonodromic deformations. It turned out afterwards[4] that Garnier's isomonodromic deformations with an arbitrary number of regular singular points can be reconstructed from the 2×2 Schlesinger system.

a)Electronic mail: takasaki@math.h.kyoto-u.ac.jp

The next stage of generalization is, naturally, isomonodromic deformations on a torus. This issue was first tackled by Okamoto,[5] who obtained a system of isomonodromic deformations of a second-order scalar ODE on a torus. One of his remarkable results is that the isomonodromic system on a torus can be formulated as a Hamiltonian system in much the same way as Garnier's isomonodromic system on a sphere was converted to a Hamiltonian system.[6] Iwasaki[7] extended Okamoto's work to scalar ODEs of an arbitrary order on an arbitrary compact Riemann surface, and elucidated the geometric origin of the Hamiltonian structure that Okamoto derived. The study of isomonodromic systems on a torus was further refined by Okamoto himself[8] and Kawai.[9]

As regards matrix systems, Korotkin and Samtleben[10] constructed an example of isomonodromic deformations of a 2×2 matrix system on a torus. Levin and Olshanetsky[11] developed a general framework in which the Schlesinger system and Korotkin and Samtleben's isomonodromic system are placed, along with generalizations to higher genus Riemann surfaces, in a unified way. Some more examples of matrix systems with different structures are also known.[12–15] Compared with Okamoto and Iwasaki's formulation, these ''elliptic analogues of the Schlesinger system'' are obtained on an entirely different ground, such as conformal field theories, vector bundles on a torus, KZ equations, and (classical or quantum) integrable systems. This can be seen in the structure of the matrix linear system

$$\frac{\mathrm{d}Y}{\mathrm{d}z}=L(z)Y$$

for which isomonodromic deformations are constructed. Namely, the matrix $L(z)$ (''L-matrix'') in these examples is borrowed from the isospectral Lax equation of an integrable system, though the Lax equation of isomonodromic deformations takes the nonisospectral form

$$\frac{\partial L(z)}{\partial t_j}=[L(z),M_j(z)]-\frac{\partial M_j(z)}{\partial z}.$$

Each of those isomonodromic systems is thus accompanied by an isospectral partner.

The correspondence between isospectral and isomonodromic systems will have a number of significant implications. Among them, we are particularly interested in the role of ''spectral Darboux coordinates.'' The notion of spectral Darboux coordinates was introduced by the Montreal group for isospectral systems with a rational L-matrix,[16] and extended to isomonodromic systems on a sphere.[17,18] As they demonstrated for those cases, one can construct a mapping from the Lax equation of this type of systems to a dynamical system of a finite number of points $P_1,\ldots,P_N$ on the spectral curve

$$\Gamma=\{(z,w)|\det(wI-L(z))=0\},$$

though the spectral curve itself becomes dynamical in the case of isomonodromic deformations. Spectral Darboux coordinates are the coordinates $\lambda_1,\ldots,\lambda_N,\mu_1,\ldots,\mu_N$ of the moving points $P_k=(\lambda_k,\mu_k)$. These coordinates lead to ''separation of variables'' of isospectral systems. The most classical case is the so-called Moser systems;[19] separation of variable of those systems was worked out by Moser himself. Remarkably, as Harnad and Wisse pointed out,[18] almost the same story repeats on the isomonodromic side, except that separability is lost there. In particular, this shows an algebro-geometric interpretation of Okamoto's reformulation[6] of Garnier's work[4] on the 2×2 Schlesinger system.

This paper presents a similar approach to one of the ''elliptic analogues'' of the Schlesinger systems, namely, the aforementioned isomonodromic system of Korotkin and Samtleben (in a slightly modified form). The isospectral partner of this isomonodromic system is the Calogero–Gaudin system[20,21] for the SU(2) group. Separation of variables of the usual SU(2) Calogero–Gaudin system has been developed by Brzeziński[22] and Enriquez *et al.*[23] (including ''quantum separation of variables'' in the sense of Sklyanin[24]). Our method is more or less parallel to theirs, in particular, that of Brzeziński. Actually, it is a rational (rather than elliptic) model of the SU(2)

Calogero–Gaudin system that he considered. Thus we are to extend his method in two ways—first, to an elliptic model (which is the subject of the work of Enriquez *et al.* as well), and second, to an isomonodromic system.

A main outcome of our consideration (summarized in Theorem 1, Sec. V) is that the isomonodromic SU(2) Calogero–Moser system can be converted to a nonautonomous Hamiltonian system in the spectral Darboux coordinates. The Hamiltonians of this non-autonomous system turn out to be a considerably intricate functions of the Darboux coordinates and the time variables. Remarkably, however, a very similar Hamiltonian system has been discovered by Okamoto[8] for isomonodromic deformations of a second-order scalar ODE on a torus. We shall show a natural explanation of this coincidence from our point of view.

This paper is organized as follows. Sections II and III are for preparation. In Sec. II, the Poisson structure of the L-matrix of the Calogero–Gaudin systems is reviewed. In Sec. III, the isomonodromic system is formulated in terms of two canonically conjugate ''Calogero variables'' and a set of ''spin variables.'' Sections IV and V are the main part of this paper. In Sec. IV, the spectral curve and the spectral Darboux coordinates are introduced. In Sec. V, the nonautonomous Hamiltonian system is derived. Section VI deals with the relation to isomonodromic deformations of a second-order scalar ODE. Section VII is for conclusion and supplementary remarks. Part of the technical details are collected in Appendixes.

II. *L*-MATRIX AND POISSON STRUCTURE

A. *L*-matrix

Following the idea of Korotkin and Samtleben,[10] we start from the L-matrix

$$L(z)=\begin{pmatrix} p & 0 \\ 0 & -p \end{pmatrix}+\sum_{j=1}^{N}\begin{pmatrix} \zeta(z-t_j)A_j^3 & \phi(q,z-t_j)A_j^- \\ \phi(-q,z-t_j)A_j^+ & -\zeta(z-t_j)A_j^3 \end{pmatrix}, \tag{1}$$

where q and p are Calogero variables, $A_j^{\pm}$ and A_j^3 are spin variables, $\zeta(z)$ denotes the Weierstrass ζ function, and $\phi(u,z)$ the auxiliary function that is widely used in the study of systems of the Calogero type:

$$\zeta(z)=\frac{\sigma'(z)}{\sigma(z)}, \quad \phi(u,z)=\frac{\sigma(u-z)}{\sigma(u)\sigma(z)}. \tag{2}$$

Here $\sigma(z)$ is the Weierstrass sigma function, and the prime stands for a derivative, i.e., $\sigma'(z)=\mathrm{d}\sigma(z)/\mathrm{d}z$. Let $2\omega_1$ and $2\omega_3$ denote the primitive periods of the Weierstrass functions. Throughout this paper, we assume that $t_j\neq t_k$ if $j\neq k$.

This L-matrix is slightly different from that of Korotkin and Samtleben.[10] They use Jacobi's elliptic theta function ϑ_1 rather than Weierstrass' sigma function σ. Their L-matrix is thereby more suited for formulating isomonodromic deformations against the modulus τ. We dare to modify Korotkin and Samtleben's L-matrix because this simplifies the use of interpolation formulas of elliptic functions. It should be possible to start from the L-matrix of Korotkin and Samtleben and to derive substantially the same results, though we shall not pursue it in this paper.

The Poisson structure of the dynamical variables is a standard one. The Calogero variables q,p are, in fact, the relative coordinate q_1-q_2 and momentum $(p_1-p_2)/2$ of a two body system with canonical variables (q_1,q_2,p_1,p_2), and become a canonically conjugate pair $\{q,p\}=1$ in themselves. The spin variables $A_j^{\pm},A_j^3$ obey the su(2) relations

$$\{A_j^3,A_k^{\pm}\}=\pm\delta_{jk}A_k^{\pm}, \quad \{A_j^+,A_k^-\}=2\delta_{jk}A_k^3 \tag{3}$$

with respect to the Poisson bracket.

The Poisson bracket of the spin variables is nothing but the Kostant–Killilov bracket for the residue matrix

$$A_j=\begin{pmatrix} A_j^3 & A_j^- \\ A_j^+ & -A_j^3 \end{pmatrix} \tag{4}$$

of $L(z)$ at $z=t_j$. The conjugacy class

$$\mathcal{O}_j=\{A_j|A_j\sim\mathrm{diag}(\theta_j/2,-\theta_j/2)\} \tag{5}$$

of semi-simple matrices with fixed eigenvalues $\pm\theta_j/2$ is a maximal (two-dimensional) symplectic leaf of this Poisson structure. One can use a canonically conjugate pair (x_j,ξ_j), $\{x_j,\xi_j\}=1$, to parametrize this symplectic leaf as follows:

$$A_j^+=-\frac{\xi_j^2}{2}+\frac{\theta_j^2}{2x_j^2},\quad A_j^-=\frac{x_j^2}{2},\quad A_j^3=\frac{x_j\xi_j}{2}. \tag{6}$$

Note that this parametrization is consistent with the Poisson bracket of $A_j^{\pm,3}$.

B. Poisson bracket of *L*-matrix elements

Let us write the matrix elements of $L(z)$ as

$$L(z)=\begin{pmatrix} A(u) & B(u) \\ C(u) & -A(u) \end{pmatrix}. \tag{7}$$

More explicitly,

$$A(u)=p+\sum_{j=1}^{N}\zeta(z-t_j)A_j^3,$$

$$B(u)=\sum_{j=1}^{N}\phi(q,z-t_j)A_j^-,$$

$$C(u)=\sum_{j=1}^{N}\phi(-q,z-t_j)A_j^+.$$

The nonzero Poisson brackets of these matrix elements take the form

$$\{A(z),B(w)\}=B(z)\phi(-q,z-w)-B(w)\zeta(z-w), \tag{8}$$

$$\{A(z),C(w)\}=-C(z)\phi(q,z-w)+C(w)\zeta(z-w), \tag{9}$$

$$\{B(z),C(w)\}=2(A(z)-A(w))\phi(q,z-w)+2\phi_u(q,z-w)\sum_{j=1}^{N}A_j^3, \tag{10}$$

where

$$\phi_u(u,z)=\frac{\partial\phi(u,z)}{\partial u}.$$

Thus the Poisson algebra of the matrix elements of $L(z)$ *almost closes* up to the extra term proportional to $\Sigma_{j=1}^{N}A_j^3$, which is later set to zero in order to derive the Lax equation.

These Poisson commutation relations can be easily verified by direct calculations using the functional identity

$$\phi(u,z)\phi(-u,w)+\phi(u,z-w)(\zeta(z)-\zeta(w))+\phi_u(u,z-w)=0 \tag{11}$$

of the auxiliary functions. This functional identity is a consequence of the more general one

$$\phi(u,z)\phi(v,w)+\phi(u+v,z)\phi(-v,z-w)-\phi(u+v,w)\phi(u,z-w)=0, \tag{12}$$

from which the former identity can be derived by letting $v\to -u$.

The Poisson structure of the $L(z)$-matrix elements can be cast into the compact form

$$\begin{aligned}\{L(z)\overset{\otimes}{,}L(w)\}&=\sum_{a,b,c,d}\{L_{ab}(z),L_{cd}(w)\}E_{ab}\otimes E_{cd}\\&=[L(z)\otimes I+I\otimes L(w),\ r(z-w)]+2\frac{\partial r(z-w)}{\partial q}\sum_{j=1}^{N}A_j^3,\end{aligned} \tag{13}$$

where E_{ab} denotes the matrix with the (a,b) element equal to 1 and the other elements vanishing. The r-matrix takes the form

$$\begin{aligned}r(z-w)&=\zeta(z-w)E_{11}\otimes E_{11}+\phi(q,z-w)E_{12}\otimes E_{21}+\phi(-q,z-w)E_{21}\otimes E_{12}+\zeta(z-w)E_{22}\otimes E_{22}\\&=\begin{pmatrix}\zeta(z-w)&0&0&0\\0&0&\phi(q,z-w)&0\\0&\phi(-q,z-w)&0&0\\0&0&0&\zeta(z-w)\end{pmatrix},\end{aligned} \tag{14}$$

which is a special case of the well-known dynamical r-matrix of the elliptic Calogero–Moser system.[25–27]

III. HAMILTONIANS AND LAX EQUATIONS

A. Hamiltonians

We now introduce the Hamiltonians

$$\mathcal{H}_j=\operatorname*{Res}_{z=t_j}\frac{1}{2}\operatorname{Tr}L(z)^2, \tag{15}$$

which can be written, more explicitly, as

$$\mathcal{H}_j=pA_j^3+2\sum_{k\neq j}\zeta(t_j-t_k)A_j^3A_k^3+\sum_{k\neq j}\phi(-q,t_j-t_k)A_j^-A_k^++\sum_{k\neq j}\phi(q,t_j-t_k)A_j^+A_k^-.$$

Note that these Hamiltonians depend on the time variables explicitly; the associated Hamiltonian system is thus nonautonomous. As we show in the following, these Hamiltonians *almost commute* up to a term proportional to the factor $\Sigma_j A_j$.

To this end, we use the general formula

$$\left\{\frac{1}{m}\operatorname{Tr}L(z)^m,\ \frac{1}{k}\operatorname{Tr}L(n)^n\right\}=\operatorname{Tr}(\{L(z)\overset{\otimes}{,}L(w)\}L(z)^{m-1}\otimes L(w)^{n-1}). \tag{16}$$

Inserting the Poisson commutation relations (13) into the right-hand side, we obtain the identity

$$\left\{\frac{1}{2}\operatorname{Tr}L(z)^2,\ \frac{1}{2}\operatorname{Tr}L(w)^2\right\}=2\operatorname{Tr}\left(\frac{\partial r(z-w)}{\partial q}L(z)\otimes L(w)\right)\sum_{j=1}^{N}A_j^3, \tag{17}$$

which implies that the Poisson brackets of the Hamiltonians are proportional to $\Sigma_{j=1}^N A_j^3$:

$$\{\mathcal{H}_j,\mathcal{H}_k\}\propto\sum_{j=1}^N A_j^3. \tag{18}$$

Moreover, as direct calculations show, the factor $\Sigma_{j=1}^N A_j^3$ itself commutes with the Hamiltonians:

$$\left\{\sum_{j=1}^N A_j^3,\ \mathcal{H}_k\right\}=0. \tag{19}$$

These relations ensure that one can consistently impose the constraint

$$\sum_{j=1}^N A_j^3=0, \tag{20}$$

which is preserved by the Hamiltonian flows

$$\frac{\partial q}{\partial t_j}=\{q,\mathcal{H}_j\},\quad \frac{\partial p}{\partial t_j}=\{p,\mathcal{H}_j\},\quad \frac{\partial A_k}{\partial t_j}=\{A_k,\mathcal{H}_j\}. \tag{21}$$

This constrained nonautonomous Hamiltonian system is our elliptic analogue of the Schesinger system.

B. Calculating $\{L(z),\mathcal{H}_j\}$

Our next task is to calculate the Poisson bracket

$$\{L(z),\mathcal{H}_j\}=\sum_{a,b}\{L_{ab}(z),\mathcal{H}_j\}E_{ab}$$

of the L-matrix with the Hamiltonians. To this end, one can use another general formula

$$\left\{L(z),\ \frac{1}{n}\mathrm{Tr}L(w)^n\right\}=\mathrm{Tr}_2(\{L(z)\overset{\otimes}{,}L(w)\}I\otimes L(w)^{n-1}), \tag{22}$$

where Tr_2 denotes the trace over the second component of the tensor product:

$$\mathrm{Tr}_2\left(\sum_{a,b,c,d}X_{abcd}E_{ab}\otimes E_{cd}\right)=\sum_{a,b}\left(\sum_c X_{abcc}\right)E_{ab}.$$

Plugging the Poisson commutation relation (13) into this formula, one obtains the identity

$$\left\{L(z),\ \frac{1}{2}\mathrm{Tr}L(w)^2\right\}=[L(z),\ \mathrm{Tr}_2(r(z-w)I\otimes L(w))]+2\,\mathrm{Tr}_2\left(\frac{\partial r(z-w)}{\partial q}I\otimes L(w)\right)\sum_{j=1}^N A_j^3. \tag{23}$$

The residue at $w=t_j$ should give the Poisson bracket that we have sought. The residues of the quantities on the right-hand side can be easily evaluated:

$$\operatorname*{Res}_{w=t_j}\mathrm{Tr}_2(r(z-w)I\otimes L(w))=\begin{pmatrix}\zeta(z-t_j)A_j^3 & \phi(q,z-t_j)A_j^-\\ \phi(-q,z-t_j)A_j^+ & -\zeta(z-t_j)A_j^3\end{pmatrix},$$

$$\operatorname*{Res}_{w=t_j} \mathrm{Tr}_2\left(\frac{\partial r(z-w)}{\partial q} I\otimes L(w)\right)=\begin{pmatrix} 0 & \phi_u(q,z-t_j)A_j^- \\ -\phi_u(-q,z-t_j)A_j^+ & 0 \end{pmatrix}.$$

One thus ends up with the identity

$$\{L(z),\mathcal{H}_j\}=[L(z),M_j(z)]+\text{term proportional to } \Sigma_{j=1}^N A_j^3, \tag{24}$$

where

$$M_j(z)=\begin{pmatrix} \zeta(z-t_j)A_j^3 & \phi(q,z-t_j)A_j^- \\ \phi(-q,z-t_j)A_j^+ & -\zeta(z-t_j)A_j^3 \end{pmatrix}. \tag{25}$$

C. Isomonodromic Lax equation

We are now ready to rewrite the constrained Hamiltonian system (20) and (21) into an isomonodromic Lax equation.

Let us examine what occurs if the matrix elements of $L(z)$ are differentiated against t_j. For instance, the (1,2) element reads

$$L_{12}(z)=\sum_{k=1}^N \phi(q,z-t_k)A_k^-,$$

hence the Leibniz rule yields

$$\frac{\partial L_{12}(z)}{\partial t_j}=\sum_{k=1}^N \left(\phi_u(q,z-t_k)\frac{\partial q}{\partial t_j}A_k^- + \phi(q,z-t_k)\frac{\partial A_k^-}{\partial t_j}\right)-\phi'(q,z-t_j)A_j^-,$$

where

$$\phi'(u,z)=\frac{\partial \phi(q,z)}{\partial z}.$$

Note here that the last term on the right-hand side is equal to $\partial M_{j,12}(z)/\partial z$. Since the t_j-derivatives of the dynamical variables can be expressed as the Poisson bracket with $\mathcal{H}_j$ [see (21)], the foregoing equation can be rewritten

$$\frac{\partial L_{12}(z)}{\partial t_j}=\{L_{12}(z),\mathcal{H}_j\}-\frac{\partial M_{j,12}(z)}{\partial z}.$$

Repeating similar calculations for the other matrix elements, we can eventually confirm that

$$\frac{\partial L(z)}{\partial t_j}=\{L(z),\mathcal{H}_j\}-\frac{\partial M_j(z)}{\partial z}.$$

We now turn on the constraint (20) and apply the previous calculation converting the Poisson bracket $\{L(z),\mathcal{H}_j\}$ to the commutator $[L(z),M_j(z)]$. The outcome is the isomonodromic Lax equation

$$\frac{\partial L(z)}{\partial t_j}=[L(z),M_j(z)]-\frac{\partial M_j(z)}{\partial z} \tag{26}$$

with an extra term on the right-hand side that breaks isospectrality of the L-matrix.

IV. SPECTRAL CURVE AND DARBOUX COORDINATES

A. Spectral curve

The spectral curve is defined by the eigenvalue equation

$$\det(wI - L(z)) = 0. \tag{27}$$

Since $L(z)$ is trace-free, the left-hand side can be rewritten as

$$\det(wI - L(z)) = w^2 + \det L(z) = w^2 - \tfrac{1}{2}\mathrm{Tr}\, L(z)^2. \tag{28}$$

Under the constraint (20), the matrix elements of $L(z)$ enjoy the following quasi-periodicity along the period lattice of the torus:

$$L(z + 2m\omega_1 + 2n\omega_3) = e^{-(2m\eta_1 + 2n\eta_3)Q} L(z) e^{(2m\eta_1 + 2n\eta_3)Q}, \tag{29}$$

where Q is the diagonal matrix $Q = \mathrm{diag}(q, -q)$, and η_1 and η_3 are the values of $\zeta(z)$ at $z = \omega_1, \omega_3$. The quasiperiodicity of $L(z)$ is a consequence of the quasiperiodicity of $\zeta(z)$ and $\phi(u,z)$,

$$\zeta(z + 2m\omega_1 + 2n\omega_3) = \zeta(z) + 2m\eta_1 + 2n\omega_3, \tag{30}$$

$$\phi(u, z + 2m\omega_1 + 2m\omega_3) = e^{-2m\eta_1 - 2n\eta_3} \phi(u,z), \tag{31}$$

which are easy to confirm from the property of the sigma function.

The quasiperiodicity of $L(z)$, in particular, implies the double periodicity of $\mathrm{Tr}\, L(z)^2/2$, which thereby becomes an elliptic function with poles at $z = t_1, \ldots, t_N$. Since

$$L(z) = \frac{A_j}{z - t_j} + O(1)$$

as $z \to t_j$, this elliptic function has a double pole at $z = t_j$ with the leading coefficient equal to the quadratic Casimir

$$C_j = \frac{1}{2}\mathrm{Tr}\, A_j^2 = \frac{\theta_j^2}{4} \tag{32}$$

of A_j. The residue is nothing but the Hamiltonian $\mathcal{H}_j$. Thus $\mathrm{Tr}\, L(z)^2/2$ can be expressed as

$$\frac{1}{2}\mathrm{Tr}\, L(z)^2 = \sum_{j=1}^{N} C_j \wp(z - t_j) + \sum_{j=1}^{N} \mathcal{H}_j \zeta(z - t_j) + \mathcal{H}_0, \tag{33}$$

where $\mathcal{H}_0$ is a constant term (which however depends on ω_1 and ω_3). Also note that the Hamiltonians are not linearly independent, but obey the linear constraint

$$\sum_{j=1}^{N} \mathcal{H}_j = 0. \tag{34}$$

This is a consequence of the the double periodicity of $\mathrm{Tr}\, L(z)^2/2$.

The spectral curve thus turns out to be a double covering of the torus. The branch points are located above the (possibly multiple) $2N$ zeros of $\mathrm{Tr}\, L(z)^2/2$. If these zeros are all simple, the genus of the spectral curve is equal to $N+1$. The spectral curve is time-dependent because of the extra term $\partial M_j(z)/\partial z$ on the right-hand side of the Lax equation.

B. Spectral Darboux coordinates

The construction of spectral Darboux coordinates is parallel to the case of the rational (and isospectral) model.[22] The "coordinate part" $\lambda_1,\ldots,\lambda_N$ are defined as the N zeros (modulo the period lattice) of $L_{12}(z)$,

$$L_{12}(\lambda_j)=0, \tag{35}$$

and the "momentum part" $\mu_1,\ldots,\mu_N$ are defined to be the value of $L_{11}(z)$ at these points,

$$\mu_j=L_{11}(\lambda_j)=p+\sum_{k=1}^{N}\zeta(\lambda_j-t_k)A_k^3. \tag{36}$$

In order to avoid a delicate problem, we assume throughout the following consideration that $\lambda_j \neq \lambda_k$ if $j\neq k$. It is easy to see that (λ_j,μ_j) sits on the spectral curve; $L(\lambda_j)$ takes the triangular form

$$L(\lambda_j)=\begin{pmatrix} \mu_k & 0 \\ L_{21}(\lambda_j) & -\mu_k \end{pmatrix},$$

which implies that $\pm\mu_j$ are eigenvalues of $L(\lambda_j)$.

The λ_j's are constrained by a linear relation. To see this, let us note that $L_{12}(z)$ can be factorized as

$$L_{12}(z)=\kappa\frac{\Pi_{j=1}^{N}\sigma(z-\lambda_j)}{\Pi_{j=1}^{N}\sigma(z-t_j)}, \tag{37}$$

where κ is a constant that does not depend on z. The quasiperiodicity

$$L_{12}(z+2m\omega_1+2n\omega_3)=e^{-(2m\eta_1+2n\eta_3)q}L_{12}(z)$$

of $L_{12}(z)$ implies that its zeros $\lambda_1,\ldots,\lambda_N$ are constrained as

$$\sum_{j=1}^{N}\lambda_j-\sum_{j=1}^{N}t_j\equiv q \quad \mathrm{mod}\, 2\omega_1\mathbf{Z}+2\omega_3\mathbf{Z}. \tag{38}$$

Since each λ_j is defined only up to a difference by an element of the period lattice, let us redefine λ_j's, if necessary, such that this holds without "$\mathrm{mod}\, 2\omega_1\mathbf{Z}+2\omega_3\mathbf{Z}$":

$$\sum_{j=1}^{N}\lambda_j-\sum_{j=1}^{N}t_j=q. \tag{39}$$

Of course this will be valid only for a *local* study of the system; this naive prescription has to be modified if one considers a global problem.

C. Time-dependent canonical transformation

In order to prove the canonicity of these variables λ_j,μ_j, we now restrict the spin variables onto the direct product $\mathcal{O}_1\times\cdots\times\mathcal{O}_N$ of the symplectic leaves and use the parametrization (6) by (x_j,ξ_j). Moreover, we tentatively relax the constraint (20), which now takes the form

$$\sum_{j=1}^{N}x_j\xi_j=0, \tag{40}$$

and restore it in the final stage.

The factorization relation (37) of $L_{12}(z)$ now reads

$$\frac{1}{2}\sum_{j=1}^{N}\phi(q,z-t_j)x_j^2=\kappa\frac{Q(z)}{P(z)}, \tag{41}$$

where we have introduced the two functions

$$Q(z)=\prod_{j=1}^{N}\sigma(z-\lambda_j),\quad P(z)=\prod_{j=1}^{N}\sigma(z-t_j). \tag{42}$$

This reduces to the relations

$$\frac{1}{2}x_j^2=\kappa\frac{Q(t_j)}{P'(t_j)}=\kappa\frac{\Pi_{k=1}^{N}\sigma(t_j-\lambda_k)}{\Pi_{k\neq j}\sigma(t_j-t_k)} \tag{43}$$

of the residues of both sides at $z=t_j$. These relations show how the old variables x_j are connected with the new variables λ_j (and κ). By logarithmic differentiation, these relations can be further converted to the linear relations

$$\begin{aligned}2\,\mathrm{d}\log x_j&=\mathrm{d}\log\kappa+\sum_{k=1}^{N}\mathrm{d}\log\sigma(t_j-\lambda_k)-\sum_{k\neq j}\mathrm{d}\log\sigma(t_j-t_k)\\&=\mathrm{d}\log\kappa+\sum_{k=1}^{N}\zeta(t_j-\lambda_k)(\mathrm{d}t_j-\mathrm{d}\lambda_k)-\sum_{k\neq j}\zeta(t_j-t_k)(\mathrm{d}t_j-\mathrm{d}t_k)\end{aligned} \tag{44}$$

of differential forms.

Our goal is to derive a relation between the canonical one-forms $\Sigma_{j=1}^{N}\xi_j\mathrm{d}x_j+p\,\mathrm{d}q$ and $\Sigma_{j=1}^{N}\mu_j\mathrm{d}\lambda_j$. We first multiply the both sides of the last relation by $x_j\xi_j/2$, sum over $j=1,\ldots,N$, and add $p\,\mathrm{d}q$ to both sides. We then obtain the linear relation

$$\begin{aligned}\sum_{j=1}^{N}\xi_j\,\mathrm{d}x_j+p\,\mathrm{d}q&=\frac{1}{2}\sum_{j=1}^{N}x_j\xi_j\mathrm{d}\log\kappa+\frac{1}{2}\sum_{j,k=1}^{N}x_j\xi_j\zeta(t_j-\lambda_k)(\mathrm{d}t_j-\mathrm{d}\lambda_k)\\&\quad-\frac{1}{2}\sum_{j\neq k}x_j\xi_j\zeta(t_j-t_k)(\mathrm{d}t_j-\mathrm{d}t_k)+p\,\mathrm{d}q.\end{aligned}$$

On the other hand, by differentiating (39), we have the relation

$$\mathrm{d}q=\sum_{j=1}^{N}\mathrm{d}\lambda_j-\sum_{j=1}^{N}\mathrm{d}t_j,$$

which we can use to eliminate the differential $\mathrm{d}q$ on the right-hand side of the foregoing linear relation of one-forms. The right-hand side thereby becomes a linear combination of $\mathrm{d}\log\kappa$, $\mathrm{d}\lambda_j$'s, and $\mathrm{d}t_j$'s, and the coefficient of $\mathrm{d}\lambda_j$ turns out to be equal to μ_j by (36). We thus eventually find that

$$\begin{aligned}\sum_{j=1}^{N}\xi_j\mathrm{d}x_j+p\,\mathrm{d}q&=\frac{1}{2}\sum_{j=1}^{N}x_j\xi_j\mathrm{d}\log\kappa+\sum_{j=1}^{N}\mu_j\mathrm{d}\lambda_j-p\sum_{j=1}^{N}\mathrm{d}t_j+\frac{1}{2}\sum_{j,k=1}^{N}x_j\xi_j\zeta(t_j-\lambda_k)\mathrm{d}t_j\\&\quad-\frac{1}{2}\sum_{j\neq k}x_j\xi_j\zeta(t_j-t_k)(\mathrm{d}t_j-\mathrm{d}t_k).\end{aligned} \tag{45}$$

Equation (45) shows that λ_j and μ_j are Darboux coordinates of the canonical one-form $\Sigma_{j=1}^{N}\xi_j\,dx_j+p\,dq$, and that $\log\kappa$ is a conjugate variable of the left-hand side of constraint (40). This interpretation is fully parallel to the spectral description of rational isospectral systems.[16–18]

An essential difference lies in the fact that the time variables explicitly enter the relation between the two canonical one-forms. This means that the spectral Darboux coordinates are connected with the old variables (x_j,ξ_j,q,p) by a *time-dependent* canonical transformation. Accordingly, the Hamiltonians (which is denoted by H_j in the following) in the spectral Darboux coordinates differ from the Hamiltonians $\mathcal{H}_j$ in the old variables (x_j,ξ_j,q,p). Their relation is to be determined by the fundamental formula

$$\sum_{j=1}^{N}\xi_j dx_j+p\,dq-\sum_{j=1}^{N}\mathcal{H}_j dt_j=\sum_{j=1}^{N}\mu_j d\lambda_j-\sum_{j=1}^{N}H_j dt_j, \tag{46}$$

in which we have imposed the constraint (40). More explicitly, the new Hamiltonians are defined as

$$H_j=\mathcal{H}_j+p-\frac{1}{2}x_j\xi_j\left(\sum_{k=1}^{N}\zeta(t_j-\lambda_k)-\sum_{k\neq j}\zeta(t_j-t_k)\right)+\frac{1}{2}\sum_{k\neq j}\zeta(t_j-t_k)x_k\xi_k. \tag{47}$$

The goal of Sec. V is to rewrite the right-hand side in terms of the spectral Darboux coordinates.

V. HAMILTONIAN SYSTEM IN SPECTRAL DARBOUX COORDINATES

A. Linear equations characterizing Hamiltonians

Let us recall that the pairs (λ_j,μ_j) of the spectral Darboux coordinates all sit on the spectral curve. Therefore the equations

$$\mu_k^2=\sum_{j=1}^{N}C_j\wp(\lambda_k-t_j)+\sum_{j=1}^{N}\mathcal{H}_j\zeta(\lambda_k-t_j)+\mathcal{H}_0$$

are satisfied for $k=1,\ldots,N$. These equations, along with the linear constraint (34), may be thought of as a system of linear equations that determine $\mathcal{H}_j$'s. In fact, as we shall discuss afterwards, these linear equations can be solved for $\mathcal{H}_j$'s, which thereby becomes an explicit function of the spectral Darboux coordinates (and of the time variables).

If the system in consideration were an isospectral system (such as the Moser system or the usual Calogero–Gaudin system), the time variables would not appear here explicitly, and $\mathcal{H}_j$'s would be the Hamiltonians that we have sought. The only problem would have been to solve the foregoing linear equations for $\mathcal{H}_j$. This is, actually, what Brzeziński[22] and Enriquez *et al.*[23] did in their work on separation of variables of the SU(2) Calogero–Gaudin system.

In the present case, the true Hamiltonians are *not* $\mathcal{H}_j$'s *but* H_j's. We have to rewrite the extra terms on the right-hand side of (47), too, as a function of the spectral Darboux coordinates. This is another problem that we have to solve.

To this end, let us note that the defining equation (36) of μ_j, which can be rewritten as

$$\mu_k=\sum_{j=1}^{N}\zeta(\lambda_k-t_j)\frac{x_j\xi_j}{2}+p,$$

may be thought of as a system of linear equations for p and $x_j\xi_j/2$. If one can solve these equations for p and $x_j\xi_j/2$, the solution should be an expression of p and $x_j\xi_j/2$ as a function of the spectral Darboux coordinates. Remarkably, these linear equations have the same coefficients as the foregoing linear equations for $\mathcal{H}_0$ and $\mathcal{H}_j$. Moreover, $x_j\xi_j/2$ obey the linear constraint (40), in perfect analogy with the linear constraint (34) for $\mathcal{H}_j$.

Thus the two problems, one for $\mathcal{H}_j$ and the other for the extra terms in (47), can be reduced to a single problem, namely, solving a system of linear equations of the form

$$\sum_{j=1}^{N} \zeta(\lambda_k - t_j) X_j + X_0 = b_k \quad (k=1,\dots,N),$$
$$\sum_{j=1}^{N} X_j = 0. \tag{48}$$

As we shall show in the following, this system of linear equations has a unique and explicit solution.

B. Solution of linear equations

We assume that $q \not\equiv 0 \bmod 2\omega_1\mathbf{Z} + 2\omega_3\mathbf{Z}$ or, equivalently, $\sigma(q) \neq 0$. The following ensures the uniqueness of solution of (48).

Lemma 1: If $b_j = \cdots = b_N = 0$, *then* $X_0 = X_1 = \cdots = X_N = 0$.

Proof: Consider the function

$$f(z) = \sum_{j=1}^{N} \zeta(z - t_j) X_j + X_0.$$

The first N equations of (48) imply that $f(z)$ has zeros at $z = \lambda_1, \dots, \lambda_N$. The remaining one ensures that $f(z)$ is a doubly periodic meromorphic function on the z plane. All possible poles are obviously simple and confined to $z = t_1, \dots, t_N$ and their translations by the period lattice. Therefore, if $f(z)$ is not identically zero, the zeros λ_j and the poles t_j are constrained as

$$\sum_{j=1}^{N} \lambda_j - \sum_{j=1}^{N} t_j \equiv 0 \mod 2\omega_1\mathbf{Z} + 2\omega_3\mathbf{Z},$$

but this contradicts the assumption that $q \not\equiv 0$; recall the constraint (39). Thus $f(z)$ is identically zero, and all the coefficients $X_0, X_1, \dots, X_N$ have to be zero. Q.E.D.

Having proven the uniqueness, the problem is to find a solution by any means. This can be done with the aid of an elliptic analogue of Lagrange's interpolation formula (see Appendix A).

Lemma 2: A solution of (48) is given by

$$X_j = \sum_{k=1}^{N} \frac{Q(t_j) P(\lambda_k) \sigma(t_j - \lambda_k + q) b_k}{P'(t_j) Q'(\lambda_k) \sigma(t_j - \lambda_k) \sigma(q)}, \tag{49}$$

$$X_0 = -\sum_{j,k=1}^{N} \frac{Q(t_j) P(\lambda_k) \sigma(t_j - \lambda_k + q) \zeta(\lambda_k - t_j - q) b_k}{P'(t_j) Q'(\lambda_k) \sigma(t_j - \lambda_k) \sigma(q)}. \tag{50}$$

Proof: We have only to confirm that these X_j and X_0 do satisfy (48). The last equation of (48) is indeed satisfied as (A1) shows. As regards the other equations of (48), the main task is to calculate

$$\sum_{j=1}^{N} \zeta(\lambda_l - t_j) X_j = \sum_{k=1}^{N} \left(\sum_{j=1}^{N} \frac{Q(t_j) \sigma(t_j - \lambda_k + q)}{P'(t_j) \sigma(t_j - \lambda_k)} \zeta(\lambda_l - t_j) \right) \frac{P(\lambda_k) b_k}{Q'(\lambda_k) \sigma(q)}.$$

We can use the two identities (A3) and (A4) to rewrite the sum over j on the right-hand side, and find that

$$\sum_{j=1}^{N}\zeta(\lambda_l-t_j)X_j=\sum_{k,j=1}^{N}\frac{Q(t_j)P(\lambda_k)\sigma(t_j-\lambda_k+q)\zeta(\lambda_k-t_j-q)b_k}{P'(t_j)Q'(\lambda_k)\sigma(t_j-\lambda_k)\sigma(q)}+b_l=-X_0+b_l,$$

which is nothing but the first N equations of (48). Q.E.D.

C. Writing H_j explicitly

Let us apply the foregoing formulas (49) and (50) of solution of (48) to the problem of deriving an explicit form of H_j as a function of the spectral Darboux coordinates.

If we use the formulas to the case where

$$X_j=\mathcal{H}_j,\quad X_0=\mathcal{H}_0,\quad b_k=\mu_k^2-\sum_{l=1}^{N}C_l\wp(\lambda_k-t_l),$$

we find the following expression of $\mathcal{H}_j$ and $\mathcal{H}_0$:

$$\mathcal{H}_j=\sum_{j=1}^{N}\frac{Q(t_j)P(\lambda_k)\sigma(t_j-\lambda_k+q)}{P'(t_j)Q'(\lambda_k)\sigma(t_j-\lambda_k)\sigma(q)}\left(\mu_k^2-\sum_{l=1}^{N}C_l\wp(\lambda_k-t_l)\right),\tag{51}$$

$$\mathcal{H}_0=-\sum_{j,k=1}^{N}\frac{Q(t_j)P(\lambda_k)\sigma(t_j-\lambda_k+q)\zeta(\lambda_k-t_j-q)}{P'(t_j)Q'(\lambda_k)\sigma(t_j-\lambda_k)\sigma(q)}\left(\mu_k^2-\sum_{l=1}^{N}C_l\wp(\lambda_k-t_l)\right).\tag{52}$$

Similarly, if we use the formulas in the case where

$$X_j=\tfrac{1}{2}x_j\xi_j,\quad X_0=p,\quad b_k=\mu_k,$$

we find the following expression of $x_j\xi_j/2$ and p as a function of the spectral Darboux coordinates:

$$\frac{1}{2}x_j\xi_j=\sum_{k=1}^{N}\frac{Q(t_j)P(\lambda_k)\sigma(t_j-\lambda_k+q)\mu_k}{P'(t_j)Q'(\lambda_k)\sigma(t_j-\lambda_k)\sigma(q)},\tag{53}$$

$$p=-\sum_{j,k=1}^{N}\frac{Q(t_j)P(\lambda_k)\sigma(t_j-\lambda_k+q)\zeta(\lambda_k-t_j-q)\mu_k}{P'(t_j)Q'(\lambda_k)\sigma(t_j-\lambda_k)\sigma(q)}.\tag{54}$$

Thus we have been able to rewrite each term on the right-hand side of (47) to an explicit function of the spectral Darboux coordinates.

Although the extra terms on the right-hand side of (47) still appear to be in disorder, one can see by straightforward calculations (see Appendix B) that the sum of these terms boils down to a form similar to the foregoing expression of $\mathcal{H}_j$:

$$\begin{aligned}p-\frac{1}{2}x_j\xi_j\left(\sum_{k=1}^{N}\zeta(t_j-\lambda_k)-\sum_{k\neq j}\zeta(t_j-t_k)\right)+\frac{1}{2}\sum_{k\neq j}\zeta(t_j-t_k)x_k\xi_k\\=\sum_{k=1}^{N}\frac{Q(t_j)P(\lambda_k)\sigma(t_j-\lambda_k+q)}{P'(t_j)Q'(\lambda_k)\sigma(t_j-\lambda_k)}(\zeta(t_j-\lambda_k+q)-\zeta(t_j-\lambda_k))\mu_k.\end{aligned}\tag{55}$$

Combining these results, we obtain the following expression of H_j in terms of the spectral Darboux coordinates:

$$H_j=\sum_{k=1}^{N}\frac{Q(t_j)P(\lambda_k)\sigma(t_j-\lambda_k+q)}{P'(t_j)Q'(\lambda_k)\sigma(t_j-\lambda_k)\sigma(q)}$$
$$\times\left(\mu_k^2+(\zeta(t_j-\lambda_k+q)-\zeta(t_j-\lambda_k))\mu_k-\sum_{l=1}^{N}C_l\wp(\lambda_k-t_l)\right). \tag{56}$$

Eliminating q by (39), we eventually obtain a final expression of the Hamiltonians:

$$H_j=\sum_{k=1}^{N}\frac{Q(t_j)P(\lambda_k)\sigma(\Sigma_{l\neq k}\lambda_l-\Sigma_{l\neq j}t_l)}{P'(t_j)Q'(\lambda_k)\sigma(t_j-\lambda_k)\sigma(\Sigma_{l=1}^{N}\lambda_l-\Sigma_{l=1}^{N}t_l)}$$
$$\times\left(\mu_k^2+(\zeta(t_j-\lambda_k+q)-\zeta(t_j-\lambda_k))\mu_k-\sum_{l=1}^{N}C_l\wp(\lambda_k-t_l)\right). \tag{57}$$

In summary, we have proven the following.

Theorem 1: *The isomonodromic* SU(2) *Calogero–Gaudin system can be converted to the nonautonomous Hamiltonian system*

$$\frac{\partial\lambda_k}{\partial t_j}=\frac{\partial H_j}{\partial\mu_k},\quad \frac{\partial\mu_k}{\partial t_j}=-\frac{\partial H_j}{\partial\lambda_j} \tag{58}$$

in the spectral Darboux coordinates λ_j,μ_j. *The Hamiltonians are given by (57).*

VI. RELATION TO SECOND-ORDER SCALAR ODE

A. Deriving second-order ODE

The structure of the Hamiltonians H_j is very similar to Okamoto's Hamiltonians for isomonodromic deformations of a scalar ODE on a torus.[8] This is not a coincidence, but can be explained in the same way as the case of the 2×2 Schlesinger system.[6]

A clue is the fact that any 2×2 matrix system

$$\frac{\mathrm{d}Y}{\mathrm{d}z}=L(z)Y,\quad Y=\begin{pmatrix}y_1\\y_2\end{pmatrix},$$

yields a second-order scalar ODE of the form

$$\frac{\mathrm{d}^2y_1}{\mathrm{d}z^2}+p_1(z)\frac{\mathrm{d}y_1}{\mathrm{d}z}+p_2(z)y_1=0. \tag{59}$$

The coefficients $p_1(z)$ and $p_2(z)$ of the latter are determined by the matrix $L(z)$ as follows:

$$p_1(z)=-\operatorname{Tr}L(z)-(\log L_{12}(z))', \tag{60}$$

$$p_2(z)=\det L(z)-L_{11}'(z)+L_{11}(z)(\log L_{12}(z))'. \tag{61}$$

In our case, $L(z)$ is trace-free, so that the foregoing formulas of $p_1(z)$ and $p_2(z)$ become slightly simpler: First, $p_1(z)$ can be written explicitly as

$$p_1(z)=-(\log L_{12}(z))'=-\sum_{j=1}^{N}\zeta(z-\lambda_j)+\sum_{j=1}^{N}\zeta(z-t_j), \tag{62}$$

which implies that $p_1(z)$ is doubly periodic. Second, $p_2(z)$ is also doubly periodic (as the quasiperiodicity of the matrix elements of $L(z)$ implies), and given by

$$p_2(z) = -\tfrac{1}{2}\mathrm{Tr}\, L(z)^2 - L_{11}'(z) + L_{11}(z)(\log L_{12}(z))'.$$

One can see from this formula that $p_2(z)$ has simple poles at $z=\lambda_j$ and double poles at $z=t_j$. Let us express $p_2(z)$ as

$$p_2(z) = \sum_{j=1}^{N} \alpha_j \wp(z-t_j) + \sum_{j=1}^{N} \beta_j \zeta(z-t_j) + \sum_{j=1}^{N} \gamma_j \zeta(z-\lambda_j) + \delta \tag{63}$$

and determine the coefficients by Laurent expansion at the poles.

(1) The first coefficient α_j can be read off from the $(z-t_j)^{-2}$ term of the Laurent expansion of $-\mathrm{Tr}\, L(z)^2/2$:

$$\alpha_j = -C_j = -\mathrm{Tr}\, A_j^2/2. \tag{64}$$

(2) The second coefficient β_j is the residue of $p_2(z)$ at $z=t_j$. The term $L_{11}'(z)$ does not contribute to the residue. The residue of the other terms at $z=t_j$ can be expressed as

$$-\operatorname*{Res}_{z=t_j} \tfrac{1}{2}\mathrm{Tr}\, L(z)^2 = -\mathcal{H}_j$$

and

$$\operatorname*{Res}_{z=t_j} L_{11}(z)(\log L_{12}(z))' = -p - \frac{1}{2}\sum_{k\neq j} \zeta(t_j-t_k)x_k\xi_k + \frac{1}{2}x_j\xi_j\left(\sum_{k=1}^{N} \zeta(t_j-\lambda_k) - \sum_{k\neq j} \zeta(t_j-t_k)\right).$$

As (47) shows, the sum of these two quantities is equal to $-H_j$. Therefore

$$\beta_j = \operatorname*{Res}_{z=t_j} p_2(z) = -H_j. \tag{65}$$

(3) The thrid coefficient γ_j is the residue of $p_2(z)$ at $z=\lambda_j$. Since

$$-\operatorname*{Res}_{z=\lambda_j} \tfrac{1}{2}\mathrm{Tr}\, L(z)^2 = 0$$

and

$$\operatorname*{Res}_{z=\lambda_j} L_{11}(z)(\log\, L_{12}(z))' = L_{11}(\lambda_j) = \mu_j,$$

γ_j can be expressed as

$$\gamma_j = \operatorname*{Res}_{z=\lambda_j} p_2(z) = \mu_j. \tag{66}$$

Thus the Hamiltonians H_j and the ''momenta'' μ_j can be identified with the residues of $p_2(z)$. Exactly the same relation can be seen in the case of Garnier's isomonodromic system on a sphere.[6]

B. Another form of second-order ODE

Strictly speaking, however, the second-order ODE above differs from that of Okamoto[8] and Kawai,[9] who consider a linear ODE of the form

$$\frac{\mathrm{d}^2 y}{\mathrm{d}z^2} + p(z)y = 0. \tag{67}$$

At least formally, this discrepancy can be removed by the ''gauge transformation''

$$y_1 = \exp\left(-\tfrac{1}{2}\int^z p_1(z)\mathrm{d}z \right) y. \tag{68}$$

The coefficient $p(z)$ is given by

$$p(z) = -\tfrac{1}{2}p_1'(z) - \tfrac{1}{4}p_1(z)^2 + p_2(z). \tag{69}$$

Note, however, that this is actually a delicate procedure, because the gauge transformation might spoil the isomonodromic property. Fortunately, the present case is free from this problem: The gauge transformation takes the form

$$y_1 = \left(\frac{\Pi_{j=1}^N \sigma(z-\lambda_j)}{\Pi_{j=1}^N \sigma(z-t_j)} \right)^{1/2} y, \tag{70}$$

and since the factor in front of y has constant monodromy, the isomonodromic property is preserved by the gauge transformation.

The zeroth order term $p(z)$ of the transformed ODE is a doubly periodic meromorphic function with second-order poles at $z=\lambda_j, t_j$. The residues of $p(z)$ at these poles can be readily determined:

$$\operatorname*{Res}_{z=\lambda_j} p(z) = \mu_j - 2\sum_{k=1}^N \zeta(\lambda_j - t_k) + 2\sum_{k\neq j} \zeta(\lambda_j - \lambda_k), \tag{71}$$

$$\operatorname*{Res}_{z=t_j} p(z) = -H_j - 2\sum_{k=1}^N \zeta(t_j - \lambda_k) + 2\sum_{k\neq j} \zeta(t_j - t_k). \tag{72}$$

It is rather these quantities that Okamoto[8] and Kawai[9] use as Hamiltonians and conjugate variables of λ_j's. We can indeed reformulate our Hamiltonian system in that way. Namely, if we define

$$\nu_j = \operatorname*{Res}_{z=\lambda_j} p(z), \quad K_j = -\operatorname*{Res}_{z=t_j} p(z), \tag{73}$$

these quantities satisfy

$$\sum_{j=1}^N \mu_j \mathrm{d}\lambda_j - \sum_{j=1}^N H_j \mathrm{d}t_j = \sum_{j=1}^N \nu_j \mathrm{d}\lambda_j - \sum_{j=1}^N K_j \mathrm{d}t_j + \text{exact form}. \tag{74}$$

This implies that λ_j's and ν_j's are a new set of Darboux coordinates, and that the previous Hamiltonian system is now converted to the new Hamiltonian system

$$\frac{\partial \lambda_k}{\partial t_j} = \frac{\partial K_j}{\partial \nu_k}, \quad \frac{\partial \nu_k}{\partial t_j} = -\frac{\partial K_j}{\partial \lambda_j}. \tag{75}$$

C. Reconstructing 2×2 matrix system

Let us now consider the inverse problem. Namely, given the isomonodromic deformations of the second-oder scalar ODE above, the problem is to reconstruct a 2×2 matrix system. A similar problem is discussed by Okamoto (Ref. 6, Sec. 3) in the case of isomonodromic deformations on a sphere. One can mostly follow his method. As it turns out, the L-matrix $L(z)$ can be reconstructed by an algebraic procedure once the factor κ is determined. The factor κ, on the other hand, has to be determined by a set of differential equations.

Suppose that κ has been determined. The first step of reconstruction of $L(z)$ is to reconsider (37) and (39) as *definition* of $L_{12}(z)$ and q. A_j^- and q are thus reproduced. Second, let $L_{11}(z)$ be a function of the form

$$L_{11}(z)=p+\sum_{j=1}^{N}\phi(q,z-t_j)A_j^3 \tag{76}$$

that satisfies the interpolation relations $L_{11}(\lambda_j)=\mu_j$ for $j=1,\ldots,N$. As we have seen in Sec. V, these relations can be solved for A_j^3 and p under the constraint $\Sigma_{j=1}^N A_j^3=0$. The remaining variables A_j^+ can be reproduced by

$$A_j^+=\frac{\theta_j^2-4(A_j^3)^2}{4A_j^-} \tag{77}$$

as (6) shows. One can thus reconstruct $L(z)$ from the fundamental variables λ_j,μ_j,t_j of the isomonodromic deformations of the second-order scalar ODE.

To derive a set of differential equations for κ, we start from the differential equations

$$\frac{\partial A_k}{\partial t_j}=[A_k,M_j(t_k)]\quad(j\neq k), \tag{78}$$

which is a consequence of the Lax equation (26). The (1,2) component of this matrix equation reads

$$\frac{\partial A_k^-}{\partial t_j}=2\phi(q,t_k-t_j)A_j^-A_k^3-2\zeta(t_k-t_j)A_j^3A_k^- . \tag{79}$$

After long and messy calculations (which we omit), one can derive the following intricate differential equation for κ:

$$\frac{\partial\log\kappa}{\partial t_j}=\frac{Q(t_j)}{P'(t_j)}\sum_{\ell=1}^{N}\frac{P(\lambda_\ell)\sigma(t_j-\lambda_\ell+q)}{Q'(\lambda_\ell)\sigma(t_j-\lambda_\ell)\sigma(q)}(2(\zeta(t_j-\lambda_\ell+q)-\zeta(q))\mu_\ell$$
$$+\zeta(t_j-\lambda_\ell)(\zeta(t_j-\lambda_\ell+q)-\zeta(t_j-\lambda_\ell)))-\sum_{\ell\neq j}\zeta(t_j-t_\ell)+\sum_{\ell=1}^{N}\zeta(t_j-\lambda_\ell). \tag{80}$$

VII. CONCLUSION

We have applied the method of spectral Darboux coordinates to Korotkin and Samtleben's isomonodromic system on a torus.[10] The isomonodromic system has thus been converted to a nonautonomous Hamiltonian system in the spectral Darboux coordinates. Although the Hamiltonians turn out to be a considerably intricate function, the method we have used is a rather straightforward analogue of the usual method for isomonodromic deformations on a sphere.

Our nonautonomous Hamiltonian system may be thought of as an elliptic analogue of Garnier's isomonodromic systems.[2,4,6] Almost the same system has been derived by Okamoto from isomonodromic deformations of a second-order scalar ODE on a torus.[8] We have seen how these two systems are related. Speaking differently, our approach from a 2×2 matrix system reveals a hidden algebro-geometric meaning of the Hamiltonian structure in Okamoto's work.[6]

An important lesson of the present work is that the notions of spectral curve and spectral Darboux coordinates persist to be useful and essential beyond isospectral deformations. This observation lies in the heart of the work of Harnad and Wisse.[18] We have confirmed it for an example of isomonodromic deformations on a torus.

In this respect, an interesting problem is to describe the isomonodromic SU(2) pure Gaudin system[12,14] from the same point of view. Separation of variables of the isospectral partner has been studied by Sklyanin and Takebe[28] (see also the paper of Hurtubise and Kjiri[29] for geometric aspects). The work of Sklyanin and Takebe shows that separation of variables of this system is technically far more complicated than the Calogero–Gaudin system. This will be also the case for the isomonodromic analogue.

Let us conclude the present consideration with a remark on trigonometric and rational analogues. The trigonometric and rational analogues of Korotkin and Samtleben's isomonodromic deformations can be obtained by replacing the basic functions $\sigma(z)$, $\zeta(z)$, and $\phi(u,z)$ by the following trigonometric or rational functions.

(1) Trigonometric model:

$$\sigma(z)=\sin z, \quad \zeta(z)=\frac{\cos z}{\sin z}, \quad \phi(u,z)=\frac{\cos z}{\sin z}-\frac{\cos u}{\sin u}. \tag{81}$$

(2) Rational model:

$$\sigma(z)=z, \quad \zeta(z)=\frac{1}{z}, \quad \phi(u,z)=\frac{1}{z}-\frac{1}{u}. \tag{82}$$

A hyperbolic model will be obtained if one replaces the trigonometric functions by the corresponding hyperbolic functions. These are nothing but the well-known pattern of degeneration of the Calogero–Moser systems; the Calogero–Gaudin systems, too, obey this pattern. In fact, it is the rational model in this list that Brzeziński considered in his work.[22] One can formulate an isomonodromic partner of these degenerate Calogero–Gaudin systems as in the case of the elliptic model. Presumably, those isomonodromic systems will not be known in the literature.

I am grateful to Shingo Kawai and Takashi Takebe for many useful comments. This work is partially supported by the Grant-in-Aid for Scientific Research (No. 12640169) from the Ministry of Education, Culture, Sports and Technology.

APPENDIX A: INTERPOLATION FORMULA

Let us examine the auxiliary function

$$f_k(z)=\frac{Q(z)\sigma(z-\lambda_k+q)}{P(z)\sigma(z-\lambda_k)}.$$

This is a doubly periodic meromorphic function with simple zeros at λ_j $(j\neq k)$ and λ_k-q and simple poles at t_j $(j=1,\ldots,N)$. By the residue theorem, the residues

$$\operatorname*{Res}_{z=t_j} f_k(z)=\frac{Q(t_j)\sigma(t_j-\lambda_k+q)}{P'(t_j)\sigma(t_j-\lambda_k)}$$

at the poles $z=t_j$ obey the sum-to-zero constraint

$$\sum_{j=1}^{N}\frac{Q(t_j)\sigma(t_j-\lambda_k+q)}{P'(t_j)\sigma(t_j-\lambda_k)}=0. \tag{A1}$$

Let us consider the linear combination

$$\sum_{j=1}^{N} \frac{Q(t_j)\sigma(t_j-\lambda_k+q)}{P'(t_j)\sigma(t_j-\lambda_k)}\zeta(z-t_j)$$

of $\zeta(z-t_j)$ weighted by these residues. Since this function is a doubly periodic meromorphic function with the same set of simple poles and residues as $f_k(z)$, it differs from $f_k(z)$ by at most a constant:

$$\frac{Q(z)\sigma(z-\lambda_k+q)}{P(z)\sigma(z-\lambda_k)} = \sum_{j=1}^{N} \frac{Q(t_j)\sigma(t_j-\lambda_k+q)}{P'(t_j)\sigma(t_j-\lambda_k)}\zeta(z-t_j) + \text{constant}.$$

Moreover, since the left-hand side vanishes at $z=\lambda_k-q$, the constant term on the right-hand side can be easily determined as follows:

$$\text{constant} = -\sum_{j=1}^{N} \frac{Q(t_j)\sigma(t_j-\lambda_k+q)}{P'(t_j)\sigma(t_j-\lambda_k)}\zeta(\lambda_k-t_j-q).$$

We thus obtain the interpolation formula

$$\frac{Q(z)\sigma(z-\lambda_k+q)}{P(z)\sigma(z-\lambda_k)} = \sum_{j=1}^{N} \frac{Q(t_j)\sigma(t_j-\lambda_k+q)}{P'(t_j)\sigma(t_j-\lambda_k)}(\zeta(z-t_j)-\zeta(\lambda_k-t_j-q)). \tag{A2}$$

One can derive the following three identities from this interpolation formula.

(1) Since the left-hand side of the interpolation formula vanishes at $z=\lambda_l$ $(l\neq k)$,

$$\sum_{j=1}^{N} \frac{Q(t_j)\sigma(t_j-\lambda_k+q)}{P'(t_j)\sigma(t_j-\lambda_k)}(\zeta(\lambda_l-t_j)-\zeta(\lambda_k-t_j-q)) = 0 \quad (l\neq k). \tag{A3}$$

(2) By letting $z\to\lambda_k$ in the interpolation formula,

$$\sum_{j=1}^{N} \frac{Q(t_j)\sigma(t_j-\lambda_k+q)}{P'(t_j)\sigma(t_j-\lambda_k)}(\zeta(\lambda_k-t_j)-\zeta(\lambda_k-t_j-q)) = \frac{Q'(\lambda_k)\sigma(q)}{P'(\lambda_k)}. \tag{A4}$$

(3) By replacing $k\to l$, $j\to k$ and separating a term from the sum, the interpolation formula takes the form

$$\sum_{k\neq j} \frac{Q(t_k)\sigma(t_k-\lambda_l+q)}{P'(t_k)\sigma(t_k-\lambda_l)}\zeta(z-t_k) = \frac{Q(z)\sigma(z-\lambda_l+q)}{P(z)\sigma(z-\lambda_l)} - \frac{Q(t_j)\sigma(t_j-\lambda_l+q)}{P'(t_j)\sigma(t_j-\lambda_l)}\zeta(z-t_j) + \sum_{k=1}^{N} \frac{Q(t_k)\sigma(t_k-\lambda_l+q)}{P'(t_k)\sigma(t_k-\lambda_l)}\zeta(\lambda_l-t_k-q).$$

By letting $z\to t_j$,

$$\begin{aligned}\sum_{k\neq j} &\frac{Q(t_k)\sigma(t_k-\lambda_l+q)}{P'(t_k)\sigma(t_k-\lambda_l)}\zeta(t_j-t_k) \\ &= \frac{Q(t_j)\sigma(t_j-\lambda_l+q)}{P'(t_j)\sigma(t_j-\lambda_\ell)}\left(-\frac{1}{2}\frac{P''(t_j)}{P'(t_j)} + \frac{Q'(t_j)}{Q(t_j)} - \zeta(t_j-\lambda_l) + \zeta(t_j-\lambda_l+q)\right) \\ &\quad + \sum_{k=1}^{N} \frac{Q(t_k)\sigma(t_k-\lambda_l+q)}{P'(t_k)\sigma(t_k-\lambda_l)}\zeta(\lambda_l-t_k-q).\end{aligned} \tag{A5}$$

APPENDIX B: CALCULATION OF EXTRA TERMS IN (47)

Let us use (53) to rewrite the last piece on the right-hand side of (47) as

$$\frac{1}{2}\sum_{k=1}^{N}\zeta(t_j-t_k)x_k\xi_k=\sum_{l=1}^{N}\left(\sum_{k\neq j}\frac{Q(t_k)\sigma(t_k-\lambda_l+q)}{P'(t_k)\sigma(t_k-\lambda_l)}\zeta(t_j-t_k)\right)\frac{P(\lambda_l)\mu_l}{Q'(\lambda_l)\sigma(q)}.$$

The sum over $k\neq j$ arising here has been partially calculated in (A5). Using the identities

$$\frac{1}{2}\frac{P''(t_j)}{P'(t_j)}=\sum_{k\neq j}\zeta(t_j-t_k),\quad \frac{Q'(t_j)}{Q(t_j)}=\sum_{k=1}^{N}\zeta(t_j-\lambda_k)$$

on the right-hand side of (A5), one can rewrite the foregoing quantity as

$$\begin{aligned}\frac{1}{2}\sum_{k=1}^{N}\zeta(t_j-t_k)x_k\xi_k=&\sum_{l=1}^{N}\frac{Q(t_j)P(\lambda_l)\sigma(t_k-\lambda_l+q)\mu_\ell}{P'(t_j)Q'(\lambda_l)\sigma(t_j-\lambda_l)\sigma(q)}\left(-\sum_{k\neq j}\zeta(t_j-t_k)+\sum_{k=1}^{N}\zeta(t_j-\lambda_k)\right)\\&+\sum_{l=1}^{N}\frac{Q(t_j)P(\lambda_l)\sigma(t_k-\lambda_l+q)}{P'(t_j)Q'(\lambda_l)\sigma(t_j-\lambda_l)\sigma(q)}(\zeta(t_j-\lambda_l+q)-\zeta(t_j-\lambda_l))\mu_\ell\\&+\sum_{k,l=1}^{N}\frac{Q(t_k)P(\lambda_l)\sigma(t_k-\lambda_l+q)\zeta(\lambda_l-t_k-q)\mu_l}{P'(t_k)Q'(\lambda_l)\sigma(t_k-\lambda_l)\sigma(q)}.\end{aligned}$$

By (53) and (54), the first and third lines on the right-hand side turn into the following form:

$$\text{first line}=-\frac{1}{2}x_j\xi_j\left(\sum_{\neq j}\zeta(t_j-t_k)-\sum_{k=1}^{N}\zeta(t_j-\lambda_k)\right),$$

$$\text{third line}=-p.$$

Since the sum of these two cancels the second and third pieces on the right-hand side of (47), we eventually obtain the identity

$$\begin{aligned}&p-\frac{1}{2}x_j\xi_j\left(\sum_{k=1}^{N}\zeta(t_j-\lambda_k)-\sum_{k\neq j}\zeta(t_j-t_k)\right)+\frac{1}{2}\sum_{k\neq j}\zeta(t_j-t_k)x_k\xi_k\\&\quad=\sum_{l=1}^{N}\frac{Q(t_j)P(\lambda_l)\sigma(t_j-\lambda_l+q)}{P'(t_j)Q'(\lambda_l)\sigma(t_j-\lambda_l)\sigma(q)}(\zeta(t_j-\lambda_l+q)-\zeta(t_j-\lambda_l))\mu_l,\end{aligned}$$

which is nothing but (55).

(Received 22 January 2003; accepted 20 May 2003)

The multilinear variable separation approach and the related ''universal'' formula have been applied to many $(2+1)$-dimensional nonlinear systems. Starting from the universal formula, abundant $(2+1)$-dimensional localized excitations have been found. In this paper, the universal formula is extended in two different ways. One is obtained for the modified Nizhnik–Novikov–Veselov equation such that two universal terms can be combined linearly and this type of extension is also valid for the $(2+1)$-dimensional symmetric sine-Gordon system. The other is for the dispersive long wave equation, the Broer–Kaup–Kupershmidt system, the higher order Broer–Kaup–Kupershmidt system, and the Burgers system where arbitrary number of variable separated functions can be involved. Because of the existence of the arbitrary functions in both the original universal formula and its extended forms, the multivalued functions can be used to construct a new type of localized excitations, folded solitary waves (FSWs) and foldons. The FSWs and foldons may be ''folded'' in quite complicated ways and possess quite rich structures and multiplicate interaction properties. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1598619]

I. INTRODUCTION

In nonlinear science, soliton theory plays an essential role and has been applied in almost all the natural sciences especially in all the physical branches such as fluid physics, condensed matter, biophysics, plasma physics, nonlinear optics, quantum field theory and particle physics, etc.[1–7] Most of the previous studies on soliton theory especially in high dimensions are restricted in the single valued situations. However, in various cases, the real natural phenomena are too intricate to describe only by virtue of the single valued functions. For instance, in nature, there exist very complicated folded phenomena such as the folded protein,[8] folded brain and skin surfaces, and many other kinds of folded biologic systems.[9] The simplest multivalued (folded) waves may be the bubbles on (or under) a fluid surface. Various ocean waves are really folded waves, too. Of course, at present stage, it is impossible (and we have no ambitions) to make satisfactory analytic descriptions for such complicated folded natural phenomena. But, it is still worth starting with some simpler cases.

Similar to the single valued cases, the primary question we should (and we can) ask is: Are there any stable multivalued (folded) localized excitations? For convenience later, we define the multivalued localized excitations as folded solitary waves (FSWs). Furthermore, if the interactions

a)Electronic mail: sylou@sjtu.edu.cn

among FSWs are completely elastic, we call them foldons. In $(1+1)$-dimensional case, the simplest foldons are so-called loop solitons[10] which have been found in many $(1+1)$-dimensional integrable systems[10] and applied in some possible physical fields like the string interaction with external field,[11] quantum field theory,[12] and particle physics.[13] Nonetheless, within our knowledge, there is no study at all for the possible higher dimensional foldons.

Lately, the multilinear variable separation approach (MLVSA) has been developed well for many $(2+1)$-dimensional integrable systems[14] such as the Davey–Stewartson (DS) equation,[15,16] the Nizhnik–Novikov–Veselov (NNV) equation,[17] the asymmetric NNV (ANNV) equation,[18] the asymmetric DS (ADS) equation,[19] the dispersive long wave equation (DLWE),[20,21] the Broer–Kaup–Kupershmidt (BKK) system,[22] the higher order BKK system,[23] the nonintegrable $(2+1)$-dimensional Korteweg–de Vries (KdV) equation,[24] the long wave–short wave interaction model (LWSWIM),[25] the Maccari system,[26] the Burgers equation,[27] the $(2+1)$-dimensional sine-Gordon (2DsG) system,[28] and the general $(N+M)$-component AKNS system.[29] We call all these models the MLVSA solvable models. Using the MLVSA results, we have found that the formula,

$$U \equiv \frac{-2\Delta q_y p_x}{(a_0+a_1 p+a_2 q+a_3 pq)^2}, \quad \Delta \equiv a_0 a_3 - a_1 a_2, \tag{1}$$

is valid for suitable fields or potentials of all the above-mentioned models. In Eq. (1), $p \equiv p(x, t)$ is an arbitrary function of $\{x, t\}$, $q \equiv q(y, t)$ may be either an arbitrary function for some kinds of models such as the DS system, the NNV system, and the 2DsG system or an arbitrary solution of a Riccati equation (or heat conduction equation) for some other systems, a_0, a_1, a_2, and a_3 are constants. One of the most important results obtained from (1) is that all the known MLVSA solvable models possess quite rich localized excitations such as the solitoffs, dromions, lumps, breathers, instantons, ring solitons, peakons, compactons, localized chaotic and fractal patterns, and so on.[14]

In the universal formula (1), the appearance of the arbitrary function p (and q for some of the MLVSA solvable models) is closely related to the arbitrary boundary conditions of some types of the quantities for the related models. In some celebrated papers, the effects of arbitrary boundary conditions have been considered for some $(2+1)$-dimensional integrable systems.[30–34] For instance, Fokas and Santini[30–32] had investigated the exact solutions of the DS system with arbitrary boundary data by means of the most powerful and fruitful method, the inverse scattering transformation. The similar treatment for the 2DsG system was given by Konopelchenko and Dubrovsky.[33,34] One of the interesting results obtained by Fokas and Santini is worth mentioning again here: The localized traveling solutions, say, dromions, do not preserve their form upon interaction and hence exchange energy. Only for a special choice of the spectral parameters do these solutions preserve their forms. This kind of result had been found also for other $(2+1)$-integrable models. In fact, the non-complete elastic interaction property among the $(2+1)$-dimensional localized excitations is correct for all the MLVSA solvable models because of the validity of (1). In this paper, the necessary and sufficient conditions on the selections of the arbitrary functions appearing in the universal formula (1) (and its extended forms) for the completely elastic interaction will be given.

On the other hand, following the general ideas introduced in Ref. 30, one could, in principle, investigate the stability properties of the solutions presented in this paper and their relevance as asymptotic states for suitable initial boundary value problems. However, here, we study only the interaction behavior among the localized solutions by studying the asymptotic property of the universal formula (1) and its extensions because these formulas are valid for more than one system.

In Sec. II of this paper, the MLVSA is extended for the modified NNV (MNNV) system and the 2DsG system. Compared with the other known MLVSA solvable models, the variable separation solutions of these two systems display a new phenomenon, Two solutions expressed by the universal quantity (1) can be added linearly to generate a new solution under some special conditions. In the linear case, any number of variable separation solutions can be linearly superposed

to yield new solutions of the same system. Thus, naturally, there comes another important question, whether the ''universal'' formula can be extended in a way that more variable separated functions are included. In Sec. III A, we extend the ansatz of the MLVSA to get an extended form of the universal formula (1) for the $(2+1)$-dimensional DLWE. Whence the universal formula is extended to a general form for a particular system, one will ask whether the extended formula is valid for the other systems. In the Secs. III B, III C, and III D, the extended formula is demonstrated valid at least for three other nonlinear systems, the BKK system, the higher order BKK system, and the $(2+1)$-dimensional Burgers system. In Sec. IV, starting from the universal formula and its extended forms, a new type of localized excitations, FSWs and foldons, are discussed in detail. Section V is devoted to investigating the interaction properties both for the general localized excitations and the particular types of FSWs and foldons. The last section is a short summary and discussion. Some special results of this paper have already been reported in our previous brief report.[35]

II. THE FIRST TYPE OF EXTENSION OF THE MLVSA

A. The variable separation solution for the MNNV system

In this section, we apply the MLVSA to a new example, the MNNV system,[36]

$$u_t+u_{xxx}+u_{yyy}+\sigma^2u_x^3+\sigma^2u_y^3+3u_xv_{xx}+3u_yv_{yy}=0, \tag{2}$$

$$v_{xy}+\sigma^2u_xu_y=0, \tag{3}$$

which is a main member of the MNNV hierarchy associated with the generalized Lamé system.[37] In (2) and (3), $\sigma^2=\pm1$. We call the system (2)–(3) the MNNV I for $\sigma^2=-1$ and the MNNV II for $\sigma^2=1$. The 2DsG system is just the negative member of the MNNV I hierarchy.[38] In Ref. 39, the geometrical significance of the MNNV I system is established. The binary Darboux transformation of the MNNV I is constructed in Ref. 40.

The first step of the MLVSA is to transform the original model into a general multilinear form by means of the Painlevé Bäcklund transformation. For the MNNV system, through the standard leading order analysis and the truncated expansion approach of the Weiss–Tabor–Carnevale Painlevé analysis,[41] we find that the following Painlevé Bäcklund transformation

$$u=\pm\sigma\ln\frac{f}{g}+u_0, \tag{4}$$

$$v=-\ln(fg)+v_0, \tag{5}$$

where $\{u_0,v_0\}$ is an arbitrary known seed solution of the MNNV system, changes the model to a bilinear equation system

$$(D_t+D_x^3+D_y^3+3v_{0xx}D_x+3v_{0yy}D_y)f\cdot g+[\sigma^2(u_{0x}^2D_x+u_{0y}^2D_y)\pm\sigma^{-1}(u_{0x}D_x^2\pm u_{0y}D_y^2)]f\cdot g=0, \tag{6}$$

$$[\sigma D_xD_y\pm u_{0y}D_x\pm u_{0x}D_y]f\cdot g=0, \tag{7}$$

where the Hirota's bilinear operators D_x, D_y, D_t are defined by

$$D_x^nD_y^mD_t^kf\cdot g\equiv\partial_{\epsilon_1}^n\partial_{\epsilon_2}^m\partial_{\epsilon_3}^kf(x+\epsilon_1,y+\epsilon_2,t+\epsilon_3)g(x-\epsilon_1,y-\epsilon_2,t-\epsilon_3)|_{\epsilon_1=0,\epsilon_2=0,\epsilon_3=0}. \tag{8}$$

The second key step of the MLVSA is to take a suitable variable separation ansatz such that the space variable can be separated into different functions.

Compared with the universal formula (1) of the other MLVSA solvable models, the variable separation ansatz for the bilinear MNNV system (6) and (7) can be taken as

$$f=a_0+a_1p+a_2q+a_3pq, \tag{9}$$

$$g=b_0+b_1p+b_2q+b_3pq, \tag{10}$$

where $p\equiv p(x,\ t)$ is y-independent, $q\equiv q(y,\ t)$ is x-independent, and $a_i,\ b_i\ (i=0,\ \ldots,\ 3)$ are taken as constants here though they may be t-dependent.

The third step of the MLVSA is to select some types of seed solutions for the sake of including as many arbitrary functions as possible. It is straightforward that, for the MNNV system (2) and (3),

$$u_0=0,\quad v_0=v_1(x,\ t)+v_2(y,\ t) \tag{11}$$

with arbitrary functions $v_1(x,\ t)\equiv v_1,\ v_2(y,\ t)\equiv v_2$ is one of the appropriate seed solutions.

Now we come to the final step of obtaining the variable separation solution to the MNNV system. Substituting (9)–(11) into Eq. (7) yields a simple relation among constants $a_i,\ b_i,\ i=0,\ \ldots,\ 3$,

$$b_3a_0+a_3b_0-a_1b_2-a_2b_1=0. \tag{12}$$

Thereafter, due to (9)–(12), Eq. (6) becomes

$$\frac{q_t+q_{yyy}+3v_{2yy}q_y}{(a_3b_2-a_2b_3)q^2+2(a_3b_0-a_2b_1)q+a_1b_0-a_0b_1}$$
$$=-\frac{p_t+p_{xxx}+3v_{1xx}p_x}{(a_3b_1-a_1b_3)p^2+2(a_3b_0-a_1b_2)p+a_2b_0-a_0b_2}. \tag{13}$$

Because the left of (13) is x-independent and the right is y-independent, (13) is correct iff (if and only if)

$$p_t+p_{xxx}+3v_{1xx}p_x=-c(t)[(a_1b_3-a_3b_1)p^2+2(a_1b_2-a_3b_0)p+a_0b_2-a_2b_0], \tag{14}$$

$$q_t+q_{yyy}+3v_{2yy}q_y=c(t)[(a_3b_2-a_2b_3)q^2+2(a_3b_0-a_2b_1)q+a_1b_0-a_0b_1], \tag{15}$$

where $c(t)$ is an arbitrary function of t.

For any fixed v_1 and v_2, to solve (14) and (15) is still very difficult since the terms, q^2 and p^2, imply the nonintegrability.[42] However, thanks to the arbitrariness of the functions v_1 and v_2, we can treat the problem in an alternative way: considering p and q to be arbitrary functions, then v_1 and v_2 can be solved from (14) and (15),

$$v_{1xx}=-\frac{1}{3p_x}\{p_t+p_{xxx}+c(t)[(a_3b_1-a_1b_3)p^2+2(a_3b_0-a_1b_2)p+a_2b_0-a_0b_2]\}, \tag{16}$$

$$v_{2yy}=-\frac{1}{3q_y}\{q_t+q_{yyy}-c(t)[(a_3b_2-a_2b_3)q^2+2(a_3b_0-a_2b_1)q+a_1b_0-a_0b_1]\}. \tag{17}$$

Till now, the variable separation solution of the MNNV system is obtained

$$u=\pm\sigma\ln\frac{a_0+a_1p+a_2q+a_3pq}{b_0+b_1p+b_2q+b_3pq}, \tag{18}$$

$$v=-\ln[(a_0+a_1p+a_2q+a_3pq)(b_0+b_1p+b_2q+b_3pq)]+v_1+v_2 \tag{19}$$

with arbitrary functions p and q, the constant relation (12), and the functions v_1 and v_2 determined by (16) and (17).

It is known that the localized excitations and the universal quantity U expressed by (1) are related to the different quantities for different models. For instance, for the DS system,

$$iu_t+\tfrac{1}{2}(u_{xx}+u_{yy})+\alpha|u|^2u-uv=0, \tag{20}$$

$$v_{xx}-v_{yy}-2\alpha(|u|^2)_{xx}=0, \tag{21}$$

the universal quantity (1) is valid for the quantity $\alpha|u|^2$, i.e., $\alpha|u|^2=U$, whereas, for the NNV equation,

$$u_t-au_{xxx}-bu_{yyy}+3a(uv)_x+3b(uw)_y=0, \tag{22}$$

$$u_x=v_y, \tag{23}$$

$$u_y=w_x, \tag{24}$$

the field u itself can be expressed by the universal quantity, say, $u=U$.

As for the MNNV system (2) and (3), it is interesting to consider the potentials $F(\equiv -2u_{xy}/\sigma)$ and $G(\equiv -2v_{xy})$,

$$F=\pm\left\{\frac{2(a_1a_2-a_0a_3)p_xp_y}{(a_0+a_1p+a_2q+a_3pq)^2}-\frac{2(b_1b_2-b_0b_3)p_xp_y}{(b_0+b_1p+b_2q+b_3pq)^2}\right\}\equiv\pm(U_a-U_b), \tag{25}$$

$$G=\left\{\frac{2(a_1a_2-a_0a_3)p_xp_y}{(a_0+a_1p+a_2q+a_3pq)^2}+\frac{2(b_1b_2-b_0b_3)p_xp_y}{(b_0+b_1p+b_2q+b_3pq)^2}\right\}\equiv U_a+U_b. \tag{26}$$

In Eqs. (25) and (26), each one of U_a and U_b is rightly the universal quantity (1), which reveals two universal terms (every term is a solution of the MNNV system) can be combined linearly for the potentials F and G. The nonlinearity of the model is implied by the relation (12) among the constants in U_a and U_b and the opposite sign of the term, U_b, in Eqs. (25) and (26).

B. The variable separation solution for the 2DsG system

In Ref. 28, one of the present authors (S.-Y.L.) has shown that the variable separation solution of the 2DsG system[43,44]

$$u_{xyt}+u_yv_{xt}+u_xv_{yt}=0, \tag{27}$$

$$v_{xy}=u_xu_y, \tag{28}$$

is completely similar to that of the MNNV system. To compare the results of two models, we outline the variable separation solution of the 2DsG system here. Using the Painlevé Bäcklund transformation,

$$u=\pm i\ln\frac{f}{g}, \tag{29}$$

$$v=\ln(fg)+v_1+v_2, \tag{30}$$

where we also fix the seed solution as $\{u_0=0,\ v_0=v_1(x,t)+v_2(y,\ t)\}$ similar to the case of the MNNV system, the 2DsG system is changed to a bilinear form

$$[D_xD_yD_t+v_{1xt}D_y+v_{2yt}D_x]f\cdot g=0, \tag{31}$$

$$D_xD_yf\cdot g=0. \tag{32}$$

Adopting the ansatz (9)–(10) with the seed solution simultaneously, Eq. (32) gives the constant relation (12) and Eq. (31) becomes

$$\{[A_1p^2+2A_2p+a_2b_0-b_2a_0]v_{1xt}+2[A_1p-A_2]p_{xt}\}p_x^{-1}-2A_1p_t$$
$$=\{[B_1q^2-2A_2q+b_1a_0-a_1b_0]v_{2yt}+2[B_1q-A_2]q_{yt}\}q_y^{-1}-2B_1q_t, \tag{33}$$

where

$$A_1=a_3b_1-a_1b_3, \quad A_2=a_3b_0-b_2a_1, \quad B_1=a_2b_3-a_3b_2.$$

Likewise, taking p and q as arbitrary functions, then Eq. (33) is valid iff v_1 and v_2 satisfy

$$v_{1xt}=\frac{(c(t)+2A_1p_t)p_x-2(A_1p-A_2)p_{xt}}{A_1p^2+2A_2p+a_2b_0-b_2a_0}, \tag{34}$$

$$v_{2yt}=\frac{(c(t)+2B_1q_t)q_y-2(B_1q-A_2)q_{yt}}{B_1q^2-2A_2q+b_1a_0-a_1b_0}, \tag{35}$$

with an arbitrary function $c(t)$.

Now defining

$$F\equiv 2iu_{xy}, \quad G\equiv -2v_{xy} \tag{36}$$

for the 2DsG system, then we obtain the completely same results (25) and (26).

For the real 2DsG system and the real MNNV I system, the field u itself is important. The real condition of u tells one that g should be a complex conjugate of f,

$$g=f^*. \tag{37}$$

Under the real condition (37), the expression of u for the real MNNV I system and the 2DsG system becomes

$$u=2\arctan\frac{(a_{1r}+Aq_r-a_{3i}q_i)p_i+(a_{2r}+Ap_r)q_i+p_r(a_{1i}+a_{3i}q_r)+a_{0i}+a_{2i}q_r}{(a_{1i}+Aq_i+a_{3i}q_r)p_i+(a_{3i}p_r+a_{2i})q_i-p_r(a_{1r}+Aq_r)-a_{0r}-a_{2r}q_r}, \tag{38}$$

where the subscripts r and i express the real and imaginary parts of the related quantities, say,

$$a_{1r}=\Re(a_1), \quad a_{1i}=\Im(a_1). \tag{39}$$

Actually, expressions (4), (5), and (11) hint that for the real MNNV I system and the real 2DsG system, f and g can be simply taken as[28]

$$f=1+ipq, \quad g=1-ipq \tag{40}$$

with arbitrary real $p=p(x,t)$ and $q=q(y,t)$ by redefining the functions p, q, v_1, and v_2. Under this observation, (38) is simplified to

$$u=2\arctan(pq). \tag{41}$$

In Ref. 28, various single valued localized excitations with and without completely elastic interaction property have been discussed for quantities F, G, and u of the 2DsG system. It has also been pointed out that the variable separation solution of the real 2DsG system is equivalent to that obtained by the Moutard transformation.[28,33,34,45]

III. THE SECOND TYPE OF EXTENSIONS OF THE MLVSA

A. Extension of the variable separation solution of the DLWE

In Sec. II, we have extended the MLVSA to the MNNV and the 2DsG systems such that two universal terms can be combined linearly. However, except for some functions of time t, there are no further space variable separated functions included. In this section, we will extend the MLVSA in a quite different way for the DLWE, the BKK system, the higher order BKK system, and the Burgers equation so as to include more variable separated functions.

For the $(2+1)$-dimensional DLWE,

$$u_{yt}+\eta_{xx}+u_x u_y+u u_{xy}=0, \tag{42}$$

$$\eta_t+u_x+\eta u_x+u\eta_x+u_{xxy}=0, \tag{43}$$

the basic variable separation solution reads

$$v\equiv-\eta-1=U, \tag{44}$$

$$u=\pm\frac{2p_x(a_1+a_3q)}{a_0+a_1p+a_2q+a_3pq}+u_0, \tag{45}$$

where p is an arbitrary functions of $\{x,\ t\}$, $q=q(y,t)$ is an arbitrary solution of the Riccati equation,

$$q_t-a_0c_0-(a_1c_1+a_2c_0-a_0c_2)q-(a_3c_1-a_2c_2)q^2=0, \tag{46}$$

and the seed function u_0 is linked to p by

$$u_0=-p_x^{-1}[p_t\pm p_{xx}-a_0c_1-(a_1c_1+a_2c_0+a_0c_2)p-(a_1c_2+a_3c_0)p^2]. \tag{47}$$

The $(1+1)$-dimensional DLWE [$y=x$ of (42)–(43)] is also called the classical Boussinesq equation. There are lots of papers discussing its possible applications and exact solutions.[46] The $(2+1)$-dimensional DLWE was first obtained by Boiti *et al.*[20] as a compatibility condition for a "weak" Lax pair. In Ref. 47, Paquin and Winternitz showed that the symmetry algebra of (42)–(43) possesses the infinite-dimensional Kac–Moody–Virasoro structure. Some special similarity solutions are given in Ref. 47 by using symmetry algebra and the classical theoretical analysis. The more general symmetry algebra, W_∞ symmetry algebra, is given in Ref. 48. In Ref. 49, nine types of two-dimensional similarity reductions and thirteen types of ordinary differential equation reductions are given. Though the model is Lax or IST integrable, it does not pass the Painlevé test.[50]

To extend the universal formula to a more general form, we use the MLVSA again. For completeness, we repeat the first two steps of the MLVSA for the DLWE (42)–(43) though they have been given in our previous papers.[14,21]

To change the system to a multilinear form, by using the standard truncated Painlevé expansion, we have the following Bäcklund transformation:

$$u=\pm 2\frac{f_x}{f}+u_0, \tag{48}$$

$$\eta=2\frac{f_{xy}}{f}-2\frac{f_x f_y}{f^2}+\eta_0, \tag{49}$$

with $\{u_0,\ \eta_0\}$ being its arbitrary solution. Substituting Eqs. (48) and (49) into Eqs. (42) and (43) leads to

$$(f_{xxxx}\pm f_{xyt})f^2-[f_{xx}f_{xy}+f_yf_{xxx}+f_xf_{xxy}\pm(f_tf_{xy}+f_yf_{x,t}+f_xf_{yt})]f+2f_xf_y(f_{xx}\pm f_t)$$
$$\pm[u_0(f^2f_{xxy}-ff_yf_{xx}-2ff_xf_{xy}+2f_yf_x^2)+f(ff_{xy}-f_xf_y)u_{0x}+f(ff_{xx}-f_x^2)u_{0y}+f^2f_xu_{0xy}]=0. \tag{50}$$

$$(\eta_0+1\mp u_{0y})(ff_{xx}-f_x^2)+ff_x(\eta_{0x}\mp u_{0xy})=0. \tag{51}$$

From the DLWE (42)–(43), it is easy to see that

$$u_0=u_0(x,t), \tag{52}$$

$$\eta_0=-1, \tag{53}$$

is a trivial seed solution with u_0 being an arbitrary function of $\{x, t\}$. Under the selections (52)–(53), the bilinear equation (51) satisfies identically.

In order to solve the trilinear equation (50) with (52)–(53), one has to use some prior ansatz. The basic variable separation solution (44)–(45) results from the ansatz

$$f=a_0+a_1p+a_2q+a_3pq. \tag{54}$$

It is known that for the DLWE (42)–(43), there are two sets of infinitely many symmetries, and every symmetry possesses an arbitrary function of y or t.[48] That means infinitely many arbitrary functions of y and t can enter into the solution of (42)–(43). So, it is probable to extend the solution (44) to a more general form with more arbitrary functions. After finishing the detailed calculations, we find that the following variable separation ansatz,

$$f=q_0+\sum_{i=1}^{N}p_iq_i, \tag{55}$$

where $\{q_i, i=0, 1, 2, \ldots, N\}$, and $\{p_i, i=1, 2,\ldots, N\}$ are functions of $\{y, t\}$ and $\{x, t\}$, respectively, solves the trilinear equation (51) with (52)–(53) under the conditions

$$q_{it}=\sum_{j=0}^{N}(c_{ij}+q_iC_j)q_j, \quad i=0, 1, \ldots, N, \tag{56}$$

$$p_{it}=(c_{00}-u_0\partial_x-\partial_x^2)p_i-c_{0i}+\sum_{j=1}^{N}(c_{j0}p_i-c_{ji})p_j, \quad i=1, 2, \ldots, N, \tag{57}$$

where $\{c_{ij}, C_j, i,j=0, 1, 2, \ldots, N\}$ are arbitrary functions of t. Obviously, the general ansatz (55) will return back to the known one, Eq. (54), when $N=3, q_0=a_0, q_1=a_1, q_2=a_2q, q_3=a_3q, p_1=p_3=p, p_2=1$.

The corresponding solution for the field $v(\equiv-\eta-1)$ now reads

$$v=\frac{-2\Sigma_{i=1}^{N}p_{ix}q_{iy}}{q_0+\Sigma_{i=1}^{N}p_iq_i}+\frac{2\Sigma_{i=1}^{N}p_{ix}q_i(q_{0y}+\Sigma_{j=1}^{N}p_jq_{jy})}{(q_0+\Sigma_{i=1}^{N}p_iq_i)^2}\equiv U_E \tag{58}$$

while the quantity u is given by

$$u=\pm\frac{2\Sigma_{i=1}^{N}p_{ix}q_i}{q_0+\Sigma_{i=1}^{N}p_iq_i}+u_0. \tag{59}$$

It is clear that in addition to one $(1+1)$-dimensional arbitrary function of $\{x, t\}$ (one of u_0 and p_i), $(N+1)(N+2)-1$ arbitrary functions of t, c_{ij}, C_j have been included in the general solution. Furthermore, various arbitrary functions of y and $\{x, t\}$ will enter into (58) after the

coupled systems of (56) and (57) are solved. Because of the complexity, we have to leave these problems for our future studies. Here we just write down the simplest nontrivial case for later use. Fixing $N=1$, $c_{ij}=C_i=0$, $p_1=p$, and $q_0\to a_0+q_0$, the formula (58) is simplified to

$$v=\frac{2p_x(q_1q_{0y}-(a_0+q_0)q_{1y})}{(a_0+q_0+pq_1)^2}\equiv V \tag{60}$$

with q_0 and q_1 being arbitrary functions of y and p being an arbitrary function of $\{x,\ t\}$. It has been proven that the simplified quantity expressed by (60) does work for many other known models which allow the universal formula (1).[24,51,52]

B. Extension of the variable separation solution of the BKK system

It should be mentioned that though we have not yet proven the validity of (58) for all the models listed in Sec. I, the extended form (58) is really valid at least for some of them like the BKK system, the higher order BKK system, and the (2+1)-dimensional Burgers system.

In this section, we extend the universal formula (1) to (58) for the BKK system

$$H_{ty}-H_{xxy}+2(HH_x)_y+2G_{xx}=0, \tag{61}$$

$$G_t+G_{xx}+2(HG)_x=0. \tag{62}$$

The variable separation solution (1) for the quantity $U=-2G$ of the BKK system has been given in Ref. 22. From Ref. 22, we know that for the BKK system the corresponding Painlevé Bäcklund transformation

$$H=(\ln f)_x+H_0, \tag{63}$$

$$G=(\ln f)_{xy}+G_0, \tag{64}$$

where $\{H_0,G_0\}$ is an arbitrary known seed solution, transforms Eqs. (61) and (62) to the following trilinear and bilinear forms, respectively,

$$\begin{aligned}&2H_0(2f_x^2f_y+f^2f_{xxy}-ff_yf_{xx}-2ff_xf_{xy})+2H_{0x}f(ff_{xy}-f_xf_y)+2f^2f_xH_{0xy}-f(f_xf_{ty}+f_yf_{tx}\\&\quad+f_tf_{xy}+f_xf_{xxy}+f_yf_{xxx}+f_{xx}f_{xy})+f^2(f_{txy}+f_{xxxy})+2f_xf_y(f_t+f_{xx})+2H_{0y}f(ff_{xx}-f_x^2)=0,\end{aligned} \tag{65}$$

$$(ff_{xx}-f_x^2+ff_x\partial_x)(G_0-H_{0y})=0. \tag{66}$$

For the BKK system, the seed solution can be taken as

$$G_0=0, \tag{67}$$

$$H_0\equiv h(x,\ t)=h, \tag{68}$$

with an arbitrary function h with respect to the indicated arguments.

Now, using the ansatz (54), we can retrieve the results in Ref. 22. Whereas, taking advantage of the general ansatz (55), we have

$$q_{it}=\sum_{j=0}^{N}(c_{i,j}+q_iC_j)q_j,\quad i=0,\ 1,\ \ldots,\ N, \tag{69}$$

$$p_{it}=(c_{00}-2h\partial_x-\partial_x^2)p_i-c_{0i}+\sum_{j=1}^{N}(c_{j0}p_i-c_{ji})p_j,\quad i=1,\ 2,\ \ldots,\ N \tag{70}$$

with $\{c_{ij},\ C_j,\ i,j=0,\ 1,\ 2,\ \ldots,\ N\}$ being arbitrary functions of t. Therefore, the corresponding solutions for the fields G and H read

$$G=-\frac{1}{2}U_E, \tag{71}$$

$$H=\frac{2\Sigma_{i=1}^{N}p_{ix}q_i}{q_0+\Sigma_{i=1}^{N}p_iq_i}+h, \tag{72}$$

where the expression of U_E is exactly same as that of the DLWE expressed by (58).

C. Extension of the variable separation solution of the higher order BKK system

Though not proved yet, it is rather reasonable to believe that if one member of an integrable hierarchy is (generalized) MLVSA solvable, then the whole hierarchy may be (generalized) MLVSA solvable. For instance, in Ref. 14, the ANNV system and the ADS system, which belong to the same system, are solved by the similar MLVSA. The MLVSA solvable systems NNV and DS also belong to the same hierarchy. In Sec. II, two models, the MNNV system and the 2DsG system, existing in the same hierarchy, are MLVSA solvable in a similar way. To confirm the conclusion further, in this section, we work on the generalized MLVSA solvability of the next member of the BKK hierarchy, the higher order BKK system,[53]

$$H_{yt}+4(H_{xx}+H^3-3HH_x+3Hg_y)_{xy}+12(Hg_y)_{xx}=0, \tag{73}$$

$$g_{yt}+4(g_{xxy}+3H^2g_y+3Hg_{xy}+3g_yg_x)_x=0. \tag{74}$$

The details of the MLVSA solvability of an equivalent form of the higher order BKK system can be found in Ref. 23 and the generalized MLVSA solvability of the equivalent higher order BKK system has been given by Lin and Qian.[54]

Obviously, the higher order BKK system has a trivial seed solution

$$H=H_0\equiv H_0(x,t),\quad g=g_0\equiv g_0(x,t), \tag{75}$$

with H_0 and g_0 being arbitrary functions of $\{x,\ t\}$.

The following Painlevé Bäcklund transformation,

$$H=(\ln f)_x+H_0,\quad g=(\ln f)_x+g_0, \tag{76}$$

degenerates two equations of the higher order BKK system to a single trilinear equation

$$\begin{aligned}&12f(ff_{xy}-f_xf_y)(g_{0x}+H_0^2)_x+12[2\,f_x(f_xf_y-ff_{xy})+f^2f_{xxy}-ff_yf_{xx}](H_0^2+g_{0x})+12[2\,f_xf_yf_{xx}\\&\quad+f(ff_{xxxy}-f_yf_{xxx}-(f_xf_{xy})_x)]H_0+12f(ff_{xxy}-f_yf_{xx})H_{0x}-f(f_yf_{xt}+4f_yf_{xxxx}+4f_{xy}f_{xxx}\\&\quad+4f_xf_{xxxy}+f_tf_{xy}+f_xf_{yt})+f^2(4f_{xxxxy}+f_{xyt})+2\,f_xf_y(f_t+4f_{xxx})=0.\end{aligned} \tag{77}$$

To solve the trilinear equation (77), we use the generalized variable separation ansatz (55) again. After finishing some detailed calculations, one can find that the general variable separation ansatz (55) really solves Eq. (77) under the conditions

$$q_{it}=\sum_{j=0}^{N}(c_{ji}+C_jq_i)q_j,\quad i=0,\ 1,\ \ldots,\ N, \tag{78}$$

$$p_{it}=-4p_{ixxx}-12H_0p_{ixx}-12(g_{0x}+H_0^2)p_{ix}+c_{00}p_i-c_{0i}+\sum_{j=1}^{N}(c_{j0}p_i-c_{ji})p_j,$$

$$i=1,\ 2,\ \ldots,\ N, \tag{79}$$

where $\{c_{ij},\ C_j,\ i,j=0,\ 1,\ 2,\ \ldots,\ N\}$ are arbitrary functions of t.

For the higher order BKK system (73)–(74), the extended expression of the universal quantity U_E expressed by (58) is valid for the potential $G_1\equiv 2H_y=2g_y$, i.e.,

$$G_1=2H_y=2g_y=U_E. \tag{80}$$

D. Extension of the variable separation solution of the Burgers equation

In this section, we discuss another generalized MLVSA solvable system, the $(2+1)$-dimensional Burgers equation,

$$v_{yt}=v_yv_{yy}+av_xv_{xy}+bv_{yyy}+abv_{xxy}, \tag{81}$$

in its potential form, where a and b are arbitrary constants. An equivalent form of the potential Burgers equation (81) is derived from the generalized Painlevé integrable classification.[27]

The following transformation

$$v=2b\ln f+v_0, \tag{82}$$

with arbitrary seed solution v_0 changes the potential Burgers equation (81) to a bilinear form

$$v_{0y}(ff_{yy}-f_y^2)+av_{0x}(ff_{xy}-f_xf_y)+v_{0yy}ff_y+av_{0xy}ff_x-(f\partial_y-f_y)(f_t-bf_{yy}-abf_{xx})=0. \tag{83}$$

Evidently, Eq. (81) possesses a trivial seed solution

$$v_0=v_0(x,t) \tag{84}$$

with v_0 being an arbitrary function of the indicated variables.

The simple and direct calculations show that the generalized variable separation ansatz (55) solves the bilinear equation (83) under the conditions

$$p_{it}=\left(ab\partial_x^2+av_0\partial_x-\alpha_i+\sum_{j=1}^{N}\beta_jp_j\right)p_i,\quad i=1,\ 2,\ \ldots,\ N, \tag{85}$$

$$q_{it}=bq_{iyy}+(\alpha_0+\alpha_i)q_i,\quad i=0,\ 1,\ \ldots,\ N, \tag{86}$$

where $\{\alpha_i,\ i=0,\ 1,\ 2,\ \ldots,\ N,\ \beta_j,\ j=1,\ 2,\ldots,\ N\}$ are all arbitrary functions of t.

For the Burgers equation, the quantity $w\equiv(1/b)\,v_{xy}$ possesses the same form as the extended universal formula, i.e.,

$$w=\frac{1}{b}v_{xy}=U_E. \tag{87}$$

IV. FSWs AND FOLDONS

Starting from the ''universal'' formula (1) and using many kinds of single valued functions for p and q, plenty of localized excitations such as the solitoffs, dromions, lumps, breathers, instantons, ring solitons, peakons, and compactons have been obtained. Using $(1+1)$-dimensional chaotic and fractal functions, some kinds of $(2+1)$-dimensional localized chaotic and fractal patterns have also been found.[14]

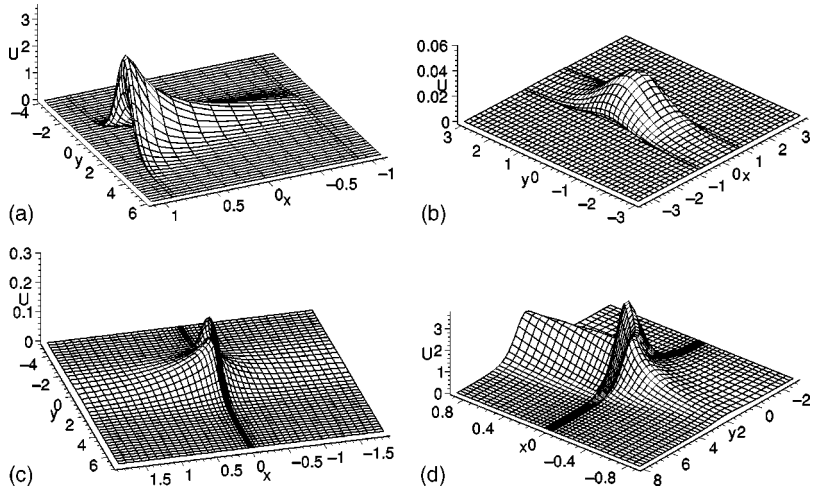

FIG. 1. Four typical FSWs for the field U expressed by (92) at $t=0$ with (93)–(98) and the related concrete parameter selections are given in (99) for the ''tent'' shape FSW (a), (100) for the ''worm'' shape FSW (b), (101) for the ''worm-dromion'' shape FSW (c), and (102) for the ''worm-solitoff'' shape FSW (d), respectively.

In this section, we focus our attention on the possible multivalued localized excitations, FSWs and foldons, constructed on the basis of the universal formula (1) and extended forms, especially, the quantity v expressed by (60) and the field u shown in (41) for the real MNNV I and 2DsG systems.

First of all, we write down a $(1+1)$-dimensional localized function, p_f, in the form

$$p_f \equiv \sum_{j=1}^{M} f_j(\xi - c_j t), \tag{88}$$

$$x = \xi + \sum_{j=1}^{M} g_j(\xi - c_j t), \tag{89}$$

where $c_1 < c_2 < \cdots < c_M$ are all arbitrary constants and $\{f_j, g_j\}$, $\forall j$ are all localized functions with the properties

$$f_j(\pm\infty) = F^{\pm}, \quad g_j(\pm\infty) = G_j^{\pm} = \text{constant}. \tag{90}$$

Judged from expression (89), ξ may be a multivalue function in certain regions of x by selecting the functions g_j suitably. Therefore, the function p_f may be a multivalue function of x in these regions though it is a single valued function of ξ. Besides, p_f is an interaction traveling solution of M localized excitations due to the property

$$\xi|_{x\to\infty} \to x \to \infty. \tag{91}$$

Indeed, most of the known $(1+1)$-dimensional multiloop solutions are the special cases of (89). Now, if all the arbitrary functions in the universal formula (1) and/or its slightly general one (60) [and/or its even more general extended one (58)] possess the forms similar to (88) with (89)–(90), then we can get various $(2+1)$-dimensional FSWs and/or foldons.

In Fig. 1, four typical FSWs are plotted for the universal quantity U expressed in its special form

$$U = \frac{2p_x q_y}{(p+q+a_0)^2}, \tag{92}$$

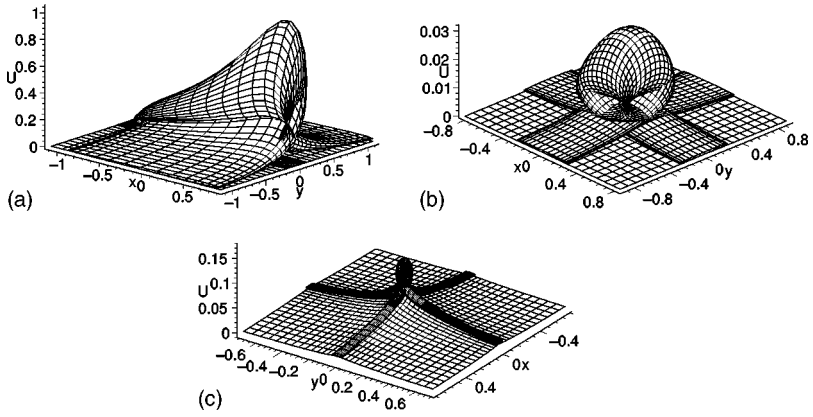

FIG. 2. Another three typical FSWs for the field U expressed by (92) at $t=0$ with (93)–(98) and the detailed parameter selections are shown in (a) (103), (b) (104), and (c) (105), respectively.

i.e., $a_3=a_1-1=a_2-1=0$ of (1), with the function selections

$$p_x=-k_1\,\mathrm{sech}^2(k_2\xi-k_3t), \tag{93}$$

$$p=-\frac{k_1}{3k_2}[3+2k_2k_4+k_2k_4\,\mathrm{sech}^2(k_2\xi-k_3t)]\tanh(k_2\xi-k_3t), \tag{94}$$

$$x=\xi+k_4\tanh(k_2\xi-k_3t), \tag{95}$$

$$q_y=-l_1\,\mathrm{sech}^2(l_2\xi), \tag{96}$$

$$q=-\frac{l_1}{3l_2}[3+2l_2l_3+l_2l_3\,\mathrm{sech}^2(l_2\eta)]\tanh(l_2\eta), \tag{97}$$

$$y=\eta+l_3\tanh(l_2\eta), \tag{98}$$

while the parameters k_1, k_2, k_3, k_4, l_1, l_2, and l_3 are selected such that p is multivalued in a small region of k_2x-k_3t and q is single valued in the whole region of y.

The detailed selections of the parameters are

$$k_1=k_2=k_3=l_1=l_2=1,\quad l_3=0,\quad k_4=-2.5,\quad a_0=1.9 \tag{99}$$

for the ''tent'' shape FSW shown in Fig. 1(a),

$$k_1=k_2=k_3=l_1=l_2=1,\quad l_3=0,\quad k_4=-2.5,\quad a_0=8 \tag{100}$$

for the ''worm'' shape FSW plotted in Fig. 1(b),

$$k_1=10,\quad k_2=k_3=l_1=l_2=l_3=1,\quad k_4=-1.15,\quad a_0=10 \tag{101}$$

for the ''worm-dromion'' shape FSW (which looks like a ''worm'' riding on a dromion) given in Fig. 1(c), and

$$k_1=k_2=k_3=l_1=l_2=l_3=1,\quad k_4=-1.15,\quad a_0=1.9 \tag{102}$$

for the ''worm-solitoff'' shape FSW (which looks like a ''worm'' riding on a solitoff's head) exhibited in Fig. 1(d).

Figure 2 shows another three typical FSWs for the same universal quantity expressed by (92)

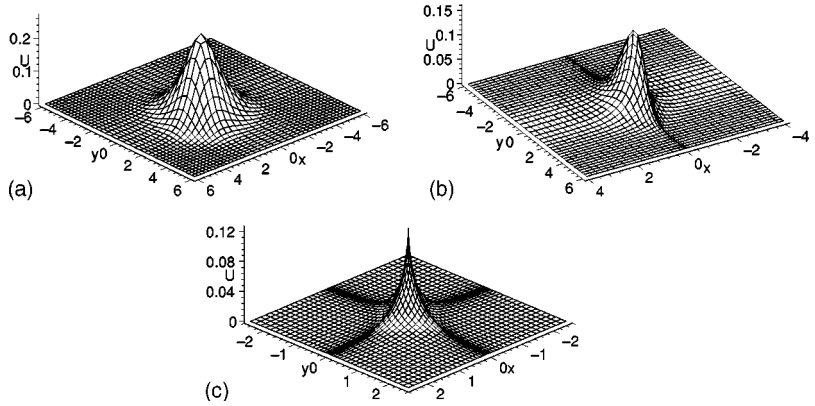

FIG. 3. Three novel single valued localized excitations for the universal quantity U shown by (92) at $t=0$ with (93)–(98) while the corresponding parameters are fixed as in (106) for the dromion (a), (110) for the first type of peakon (b), and (111) for the second type of peakon (c), respectively.

with (93)–(98). However, the parameters are chosen such that both p and q are multivalued.

For Fig. 2(a), the corresponding parameters are

$$k_1=k_2=k_3=l_1=l_2=1, \quad l_3=-1.4, \quad k_4=-2.5, \ a_0=1.9. \tag{103}$$

For Fig. 2(b), we have

$$k_1=k_2=k_3=l_1=l_2=1, \quad l_3=k_4=-1.6, \quad a_0=8. \tag{104}$$

The parameter selections

$$k_1=k_2=k_3=l_1=l_2=1, \quad l_3=k_4=-1.15, \quad a_0=4 \tag{105}$$

are related to Fig. 2(c).

In fact, the expression (92) with (93)–(98) also includes some interesting new types of single valued localized excitations by selecting the parameters appropriately such that both p and q are single valued.

In Fig. 3, three types of single valued localized excitations are plotted. Figure 3(a) shows a dromion structure and the corresponding parameters read

$$k_1=k_2=k_3=l_1=l_2=l_3=k_4=1, \quad a_0=4. \tag{106}$$

Because of the arbitrariness of the functions p and q, some types of piecewise continuous functions can be used to produce some types of $(2+1)$-dimensional peakons[14,55] and compactons.[22,56] Three special critical cases,

$$k_2k_4=-1, \quad l_2l_3\langle\ \rangle-1, \tag{107}$$

$$k_2k_4\langle\ \rangle-1, \ l_2l_3=-1, \tag{108}$$

and

$$k_2k_4=-1, \quad l_2l_3=-1, \tag{109}$$

of the expression (92) with (93)–(98) display some new types of peakon solutions.

Figure 3(b) shows a peakon structure of (92) with (93)–(98) and (107) at time $t=0$. The detailed parameters read

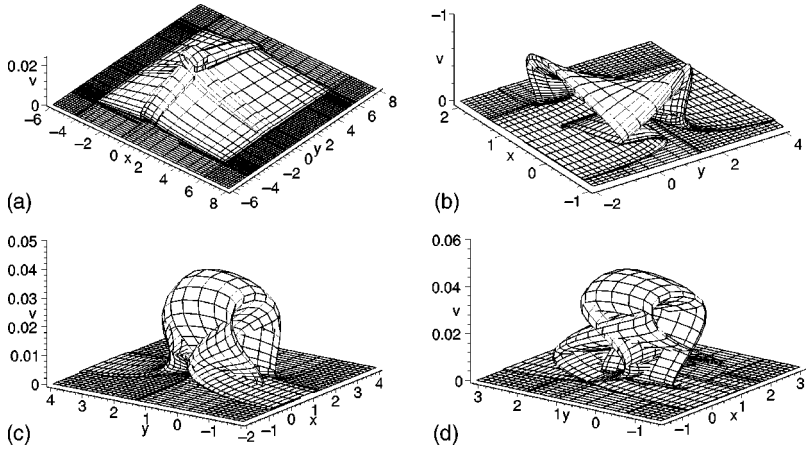

FIG. 4. Plots of the FSWs for the field v expressed by (60) at $t=0$ with (112)–(119) and the related concrete parameter selections are (120) for (a), (121) for (b), (122) for (c), and (123) for (d).

$$k_1=k_2=k_3=l_1=l_2=l_3=1, \quad k_4=-1,\ a_0=4. \tag{110}$$

Figure 3(c) shows the structure of another kind of peakon solution expressed by (92) with (93)–(98) and (109) at $t=0$ while the related parameters are

$$k_1=k_2=k_3=l_1=l_2=1, \quad l_3=-1, \quad k_4=-1, \quad a_0=4. \tag{111}$$

The more complicated FSWs and/or foldons can be constructed in two ways, selecting more complicated multivalue functions for the universal formula or using the extended forms of the universal formula with more arbitrary functions. In Fig. 4, some slightly more complex FSWs are plotted for the quantity v expressed by (60) with

$$p_x=-k_1\,\mathrm{sech}^2(k_2\xi-k_3t), \tag{112}$$

$$p=\frac{1}{2}k_1k_5(\mathrm{sech}^4(k_2\xi-k_3t)-1)-\frac{k_1}{15k_2}\{15+k_2[6k_6+10k_4+(5k_4+3k_6)\mathrm{sech}^2(k_2\xi-k_3t) -9k_6\,\mathrm{sech}^4(k_2\xi-k_3t)]\tanh(k_2\xi-k_3t)\}, \tag{113}$$

$$x=\xi+k_4\tanh(k_2\xi-k_3t)+k_5\tanh^2(k_2\xi-k_3t)+k_6\tanh^3(k_2\xi-k_3t), \tag{114}$$

$$q_{0y}=-l_1\,\mathrm{sech}^2(l_2\eta), \tag{115}$$

$$q_0=\frac{1}{2}l_1l_5[\mathrm{sech}^4(l_2\eta)-1]-\frac{l_1}{15l_2}[15+6l_2l_6+10l_2l_4+l_2(5l_4+3l_6)\mathrm{sech}^2(l_2\xi) -9l_2l_6\,\mathrm{sech}^4(l_2\xi)]\tanh(l_2\eta), \tag{116}$$

$$q_{1y}=-l_3\,\mathrm{sech}(l_2\eta), \tag{117}$$

$$q_1=\frac{l_3}{8}\mathrm{sech}(l_2\eta)\tanh(l_2\eta)[6l_6\,\mathrm{sech}^2(l_2\eta)-3l_6-4l_4]-\frac{l_3}{4l_2}(8+4l_2l_4+3l_2l_6)\arctan\exp(l_2\eta) +\frac{2}{3}l_3l_5\,\mathrm{sech}^3(l_2\eta), \tag{118}$$

$$y=\eta+l_4\tanh(l_2\eta)+l_5\tanh^2(l_2\eta)+l_6\tanh^3(l_2\eta), \tag{119}$$

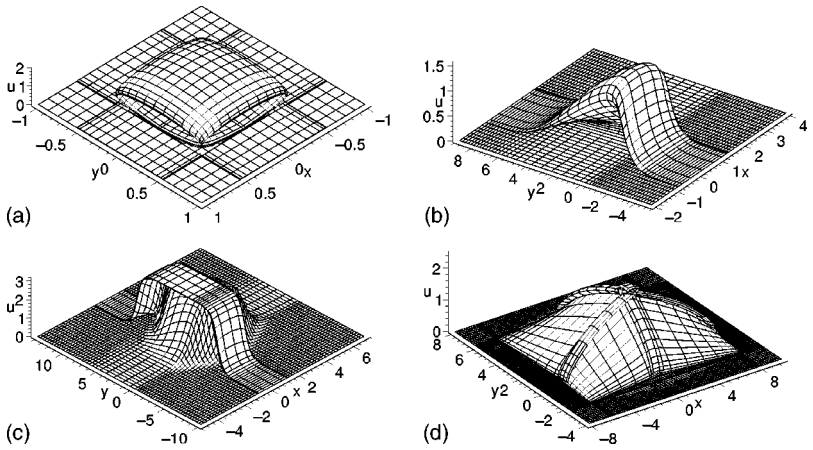

FIG. 5. Plots of the FSWs for the field u (41) with (124)–(127) for the real MNNV I and 2DsG systems at $t=0$ while the corresponding parameters are (128) for (a), (129) for (b), (130) for (c), and (131) for (d).

at time $t=0$.

The detailed selections of the parameters are

$$-k_1=k_2=k_3=k_5=l_1=l_2=l_3=l_5=1,\quad k_4=l_5=2,\quad k_6=l_6=-4,\quad a_0=50 \tag{120}$$

for Fig. 4(a),

$$k_1=72,\quad k_2=k_3=k_5=l_1=l_2=l_3=l_5=1,\quad k_4=l_4=2,\quad k_6=l_6=-4,\quad a_0=250 \tag{121}$$

for Fig. 4(b),

$$k_1=-\tfrac{6}{5},\quad k_2=k_3=k_5=l_1=l_2=l_3=l_5=1,\quad k_4=l_4=2,\quad k_6=l_6=-\tfrac{27}{5},\quad a_0=50 \tag{122}$$

for Fig. 4(c), and

$$k_1=-3,\quad k_2=k_3=k_5=l_1=l_2=l_3=l_5=1,\quad k_4=l_4=2,\quad k_6=l_6=-10,\quad a_0=250 \tag{123}$$

for Fig. 4(d).

As mentioned in Sec. II the field u is very important for the real MNNV I system and the real 2DsG system. Similar FSWs and foldons can also be constructed for the field u expressed by (38) and/or (41).

In Fig. 5, four types of FSWs are plotted for the field u of the MNNV I system and the 2DsG system expressed by (41) and the functions p and q are taken as

$$p=k_1\,\mathrm{sech}^2(k_2\xi-k_3t), \tag{124}$$

$$x=\xi+k_4\tanh(k_2\xi-k_3t)+k_5\tanh^2(k_2\xi-k_3t)+k_6\tanh^3(k_2\xi-k_3t), \tag{125}$$

$$q=l_1\,\mathrm{sech}^2(l_2\eta), \tag{126}$$

$$y=\eta+l_3\tanh(l_2\eta)+l_4\tanh^2(l_2\eta)+l_5\tanh^3(l_2\eta). \tag{127}$$

For Fig. 5(a), the related parameters are fixed as

$$k_1=1.2,\quad l_1=l_2=k_2=k_3=1,\quad l_3=k_4=-2,\quad l_4=l_5=k_5=k_6=0. \tag{128}$$

The details on the parameters of Fig. 5(b) read

$$k_1=k_2=k_3=k_5=l_1=l_2=l_3=l_5=1, \quad k_4=l_4=2, \quad k_6=-4. \tag{129}$$

For Fig. 5(c), we select

$$k_1=120, \quad k_2=k_3=k_5=l_2=l_3=l_5=1, \quad l_1=6, \; k_4=l_4=2, \quad k_6=-4. \tag{130}$$

The parameter selections

$$k_1=3, \quad k_2=k_3=k_5=l_1=l_2=l_3=1, \quad l_5=-8, \quad k_4=l_4=2, \quad k_6=-12, \tag{131}$$

are responsible for Fig. 5(d).

Fortunately, owing to the arbitrariness of the functions in the universal formula and its extension forms, we have constructed not only the single valued localized excitations but also quite rich FSWs. Now, one of the most important problems which should be discussed in the first place is whether these types of localized excitations are solitons. Particularly, are these FSWs foldons? To find the answer, we have to study the interaction properties among these types of localized excitations.

V. INTERACTION PROPERTIES OF (2+1)-DIMENSIONAL LOCALIZED EXCITATIONS

In Ref. 14, we have plotted some special interaction figures for two special types of localized excitations (saddle type of ring solitons and peakons) with and without completely interaction properties. In Ref. 22, a method is proposed to construct compact solitary waves and compactons on the basis of the universal formula (1). In Ref. 28, the method has been developed to generate general $(2+1)$-dimensional solitary waves and solitons for the quantity F expressed by (25). The complete interaction properties of the plateau type, basin type, and bowl type ring solitons for the 2DsG system are discussed in Ref. 28. In our previous short report,[35] a possible way is provided to construct foldons for the quantity given by (60) with static q_0 and q_1. In this section, as a summary and extension, we first discuss the interaction property of the localized excitations related to the universal quantity (1) and the field v (60). The possible foldon excitations are specified both for the quantities v and u expressed by (60) and (41), respectively. Then we give some concrete interaction examples of FSWs and foldons.

A. Asymptotic behaviors of the localized excitations produced from (1)

In general, if the functions p and q are selected as multi-localized solitonic excitations with

$$p|_{t\to\mp\infty}=\sum_{i=1}^{M} f_i^{\mp}, f_i^{\mp}\equiv f_i(x-c_it+\delta_i^{\mp}), \tag{132}$$

$$q|_{t\to\mp\infty}=\sum_{j=1}^{N} h_j^{\mp}, \quad h_j^{\mp}\equiv h_j(y-C_jt+\Delta_j^{\mp}), \tag{133}$$

where $\{f_i, h_j\}$ $\forall i$ and j are localized functions, then the universal quantity U expressed by (1) delivers $M\times N$ $(2+1)$-dimensional localized excitations with the asymptotic behavior

$$U|_{t\to\mp\infty}\to\sum_{i=1}^{M}\sum_{j=1}^{N}\frac{2(a_1a_2-a_3a_0)f_{ix}^{\mp}h_{jy}^{\mp}}{(a_0+a_1(f_i^{\mp}+F_i^{\mp})+a_2(h_j^{\mp}+H_j^{\mp})+a_3(f_i^{\mp}+F_i^{\mp})(h_j^{\mp}+H_j^{\mp}))^2}\equiv\sum_{i=1}^{M}\sum_{j=1}^{N}U_{ij}^{\mp}, \tag{134}$$

where

$$F_i^{\mp}=\sum_{j<i} f_j(\mp\infty)+\sum_{j>i} f_j(\pm\infty), \tag{135}$$

$$H_i^{\mp}=\sum_{j<i} h_j(\mp\infty)+\sum_{j>i} h_j(\pm\infty), \tag{136}$$

and we have assumed, without loss of generality, $C_i>C_j$ and $c_i>c_j$ if $i>j$.

It can be deduced from expression (134) that the ijth localized excitation U_{ij} preserves its shape during the interaction iff

$$F_i^{+}=F_i^{-}, \tag{137}$$

$$H_j^{+}=H_j^{-}. \tag{138}$$

Meanwhile, the phase shift of the ijth localized excitation F_{ij} reads

$$\delta_i^{+}-\delta_i^{-} \tag{139}$$

in the x direction and

$$\Delta_j^{+}-\Delta_j^{-}. \tag{140}$$

in the y direction.

The above discussions demonstrate that multiple localized solitonic excitations for the universal quantity U can be constructed without difficulties via the $(1+1)$-dimensional multiple localized excitations with the properties (132), (133), (137), and (138). As a matter of fact, any multiple localized solutions (or their derivatives) with completely elastic interaction behaviors of any known $(1+1)$-dimensional integrable models can be utilized to construct $(2+1)$-dimensional multiple localized solitonic solutions with completely elastic interaction properties for all the MLVSA models. Some detailed examples have been given in Ref. 28 for the 2DsG system based on the multi-soliton solutions of the $(1+1)$-dimensional sine-Gordon equation and the KdV equation.

If f_i and h_j of (132) and (133) are taken as $(1+1)$-dimensional localized multivalue functions (say, loop solitons), then (1) becomes multiple FSWs ($F_i^{+}\neq F_i^{-}$, $H_j^{+}\neq H_j^{-}$ at least for one of i,j) or multiple foldons ($F_i^{+}=F_i^{-}$, $H_j^{+}=H_j^{-}$ for all i, j).

B. Asymptotic properties of the localized excitations generated via (60)

If the function p is in the form (132) while q_0 and p_0 are taken as arbitrary static functions, then the field v expressed by (60) possesses the following asymptotic behavior:

$$v|_{t\to\mp\infty}\to\sum_{i=1}^{M}\frac{2f_{ix}^{\mp}[q_1q_{0y}-(a_0+q_0)q_{1y}]}{(a_0+q_0+(f_i^{\mp}+F_i^{\mp})q_1)^2}\equiv\sum_{i=1}^{M} v_j^{\mp}. \tag{141}$$

If condition (137) is satisfied, then the asymptotic property (141) reveals the solitonic property for the field v given by (60).

To get the multiple FSWs and/or foldons from (60) with p selected as (132), we have to require p and then f_i be localized multivalue functions again.

More concretely, selecting the multivalue function p of (60) as (88)–(90), $v_j^{\mp}$ of (141) will be ($z_j\equiv\xi-c_jt$),

$$v_j^{\mp}=\frac{2f_{jz_j}^{\mp}[q_1q_{0y}-(a_0+q_0)q_{1y}]}{(1+g_{jz_j}^{\mp})[a_0+q_0+q_1(f_j^{\mp}(z_j)+F_j^{\mp})]^2}, \tag{142}$$

$$x=\xi+\delta_j^{\mp}+g_j^{\mp}(z_j), \tag{143}$$

where the phase factors $\delta_j^{\mp}$ read

$$\delta_j^{\mp}=\sum_{i<j} G_i^{\mp}+\sum_{i>j} G_i^{\pm}. \tag{144}$$

From the asymptotic results (142)–(144), we discover four important facts.

(i) The jth localized excitation given by (60) with (88)–(90) is a traveling wave moving in the velocity c_j along the negative ($c_j<0$) or positive ($c_j>0$) x direction.

(ii) The multivalued properties of the jth localized excitation is only determined by g_j of (89).

(iii) The shape of the jth excitation will change if

$$F_j^{+}\neq F_j^{-}, \tag{145}$$

following the interaction. Contrarily, if

$$F_j^{+}=F_j^{-}, \tag{146}$$

it will preserve its shape.

(iv) The total phase shift for the jth excitation is

$$\delta_j^{+}-\delta_j^{-}. \tag{147}$$

C. Interaction properties of the localized excitations for the field u (41) of the real MNNV I system and the 2DsG system

For the real MNNV I system and the 2DsG systems, the important localized excitations for the field u come from (41). Selecting the functions p and q as (132) and (133) leads to

$$u|_{t\to\mp\infty}\to 2\arctan\sum_{i=1}^{M}\sum_{j=1}^{N}(f_i^{\mp}+F_i^{\mp})(h_j^{\mp}+H_j^{\mp}). \tag{148}$$

Furthermore, the most important selections for p and q may be

$$f_i(\pm\infty)=0,\ \ h_j(\pm\infty)=0,\forall i,j. \tag{149}$$

Under condition (149), we have

$$f_i^{\mp}h_j^{\mp}|_{x^2+y^2\to\infty}\to 0, \tag{150}$$

and then (148) can be simplified to

$$u|_{t\to\mp\infty}\to\sum_{i=1}^{M}\sum_{j=1}^{N}2\arctan(f_i^{\mp}h_j^{\mp})\equiv\sum_{i=1}^{M}\sum_{j=1}^{N}u_{ij}. \tag{151}$$

The asymptotic property (151) gives rise to a conclusion that when p and q possess the property (132) and (133) with (149), the interactions among the localized excitations for the field u of the MNNV I and 2DsG systems are completely elastic no matter whether the functions p and q are single valued or multivalued. In Ref. 28, some special examples for the complete interactions of the plateau type and basin type ring solitons are given.

D. Examples of the foldon interactions

In this section, we give some concrete examples on the foldon and FSW interactions.

Example 1: *Two foldon interaction of the MNNV I system and the 2DsG system.*

For the real MNNV I and 2DsG systems, a special type of multiple foldon solutions for the field u (41) can be obtained by taking

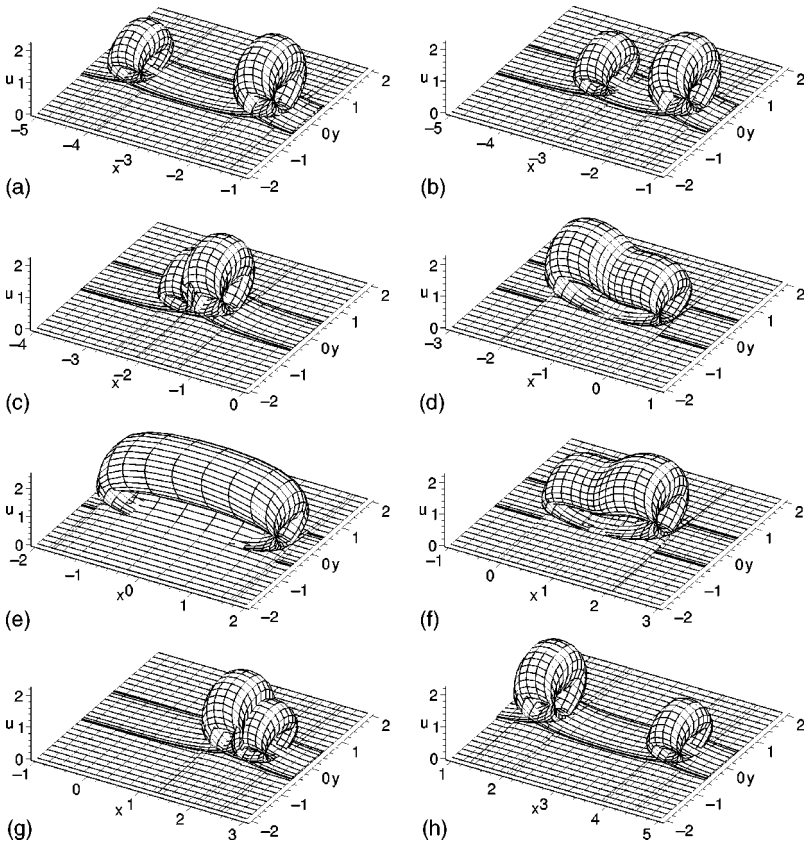

FIG. 6. Evolution plots of two foldons for the field u expressed by (41) for the MNNV I and 2DsG systems with the selections (156)–(159) at the times (a) $t=-24$, (b) $t=20$, (c) $t=-16$, (d) $t=-8$, (e) $t=0$, (f) $t=8$, (g) $t=16$, and (h) $t=24$, respectively.

$$p=\sum_{i=1}^{N} s_i \operatorname{sech}^{m_i}(k_i(\xi-c_i t)), \tag{152}$$

$$x=\xi+\sum_{i=1}^{N} y_i \tanh^{n_i}(k_i(\xi-c_i t)), \tag{153}$$

$$q=\sum_{i=1}^{M} S_i \operatorname{sech}^{M_i}(K_i(\eta-C_i t)), \tag{154}$$

$$y=\eta+\sum_{i=1}^{M} Y_i \tanh^{N_i}(K_i(\eta-C_i t)), \tag{155}$$

where s_i, y_i, S_i, Y_i, c_i, C_i, k_i, and K_i are all arbitrary constants, M, N, m_i, n_i, M_i, and N_i are positive integers.

Figure 6 shows the two-foldon interaction with

$$p=2\operatorname{sech}^2\xi+\operatorname{sech}^2(\xi-\tfrac{1}{4}t), \tag{156}$$

$$x=\xi-1.8\tanh\xi-1.7\tanh(\xi-\tfrac{1}{4}t), \tag{157}$$

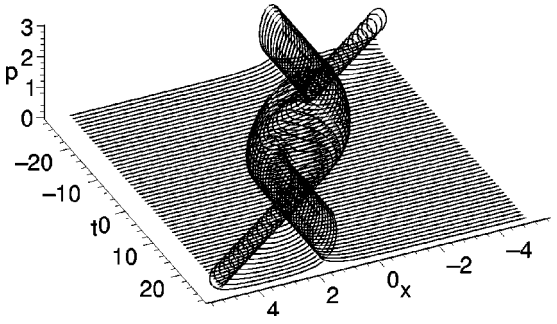

FIG. 7. Evolution plot of two loop solitons for the quantity p expressed by (156) with (157) regarding Fig. 6.

$$q=\operatorname{sech}^2\,\eta, \tag{158}$$

$$y=\eta-2\tanh\,\eta. \tag{159}$$

From Figs. 6(a)–6(h), we can see that the interaction between two foldons is completely elastic. One of the velocities of two foldons is fixed as zero, which makes it easy to survey their phase shifts. Clearly, before the interaction, the static foldon (the large one) is located at $x=-1.7$ while after the interaction, it shifts to $x=1.7$. Actually, once the conditions (149) are satisfied, the completely elastic interaction property of the multiple localized excitations for the field u expressed (41) with (132)–(133) of the MNNV I and 2DsG systems is entirely guaranteed by the completely elastic interaction property of the $(1+1)$-dimensional fields p and q. For instance, the completely elastic interaction property of the two-loop solution p expressed by (156) with (157) ensures the completely elastic interaction property of two dromions shown in Fig. 6. Figure 7 is an evolution plot of two $(1+1)$-dimensional loop solitons expressed by (156) with (157).

Example 2: Interaction among Four foldons of the MNNV I system and the 2DsG system.

Figure 8 shows a special four-foldon interaction of u expressed by (41) for the MNNV I and 2DsG systems where the functions p and q are taken as

$$p=0.6\operatorname{sech}^2\,\xi+\operatorname{sech}^2(\xi-t), \tag{160}$$

$$x=\xi-1.15\tanh\,\xi-1.15\tanh(\xi-t), \tag{161}$$

$$q=\operatorname{sech}^2\,\eta+2\operatorname{sech}^2(\eta-t), \tag{162}$$

$$y=\eta-1.15\tanh\,\eta-1.15\tanh(\eta-t). \tag{163}$$

Similar to the example shown in Fig. 6, in addition to the completely elastic interaction property among four foldons, phase shifts are observed from Fig. 8. To reveal phase shifts, it is convenient and sufficient to set the velocity of one loop soliton (either for p or q) to zero. Seen from Figs. 8(a) to 8(h), prior to interaction, the smallest foldon is static and situated at $\{x=-1.15,\ y=-1.15\}$, the largest foldon is moving with its center located at $\{x=t+1.15,\ y=t+1.15\}$, while for the other two foldons, they are static in one direction and moving in the other direction and their centers are located at $\{x=-1.15,\ \eta=t+1.15\}$ and $\{x=t+1.5,\ y=-1.15\}$, respectively; after the interaction, the static foldon remains static with shape unchanged and its center shifts to $\{x=1.15,\ y=1.15\}$, the largest foldon recovers its shape and its center shifts to $\{\xi=t-1.15,\ y=t-1.15\}$, the others preserve their shapes and velocities (static in one case) but have their centers shifted to $\{x=1.15,y=t-1.15\}$ and $\{x=t-1.15,\ y=1.15\}$, respectively.

Example 3: Interaction between two FSWs for all the MLVSA solvable systems.

The last two special examples are responsible for the real MNNV I system and the real 2DsG system. For the other MLVSA models studied in Ref. 14 and also mentioned in Sec. I, the

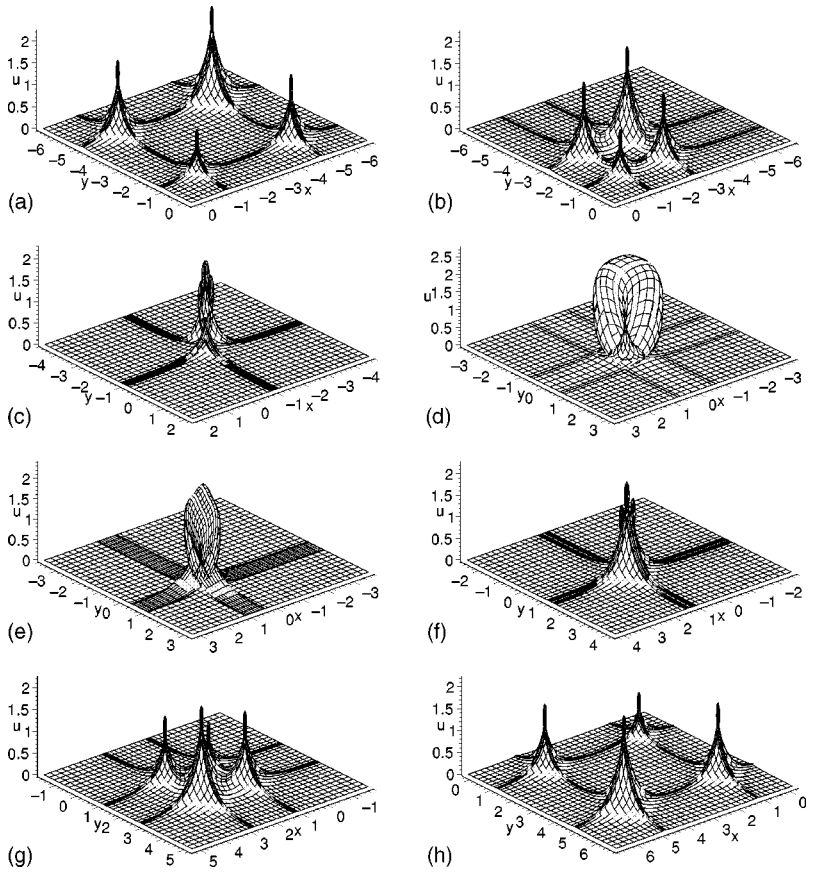

FIG. 8. Evolution plot of four foldons for the field u expressed by (41) for the MNNV I and 2DsG systems with the selections (160)–(163) at the times (a) $t=-6$, (b) $t=-4$, (c) $t=-2$, (d) $t=0$, (e) $t=1.5$, (f) $t=2.5$, (g) $t=4$, and (h) $t=6$, respectively.

universal quantity (1) [or its extend form (58)] is of more importance. Some examples of the single FSW have been discussed in the last section and the general aspect of the related multiple FSWs and foldons has been given in Secs. V A and V B. Here we write and plot down two more special two-FSW (example 3) and two-foldon (example 4) solutions for the universal quantity U.

Figure 9 is a pre- and post-interaction plot of the two FSWs for the quantity U expressed by (92) with the selections

$$p_x=-12\,\mathrm{sech}^2\,\xi-10\,\mathrm{sech}^2(\xi-t), \tag{164}$$

$$\begin{aligned} p=\frac{253}{5}\coth t\,\mathrm{csch}^2\,t\ln\frac{\alpha+1}{\alpha+\beta}+\frac{2}{15(\beta+1)^3(\beta+\alpha)^3(\alpha-1)^2}\{&(150\alpha^3+1398\alpha^2+1308\alpha\\ &+180)\beta^5+(4116\alpha^3+4134\alpha-45\alpha^4+7029\alpha^2-54)\beta^4+(35\alpha^5+1853\alpha^4+13\,175\alpha^3\\ &+13\,533\alpha^2+1722\alpha+42)\beta^3+3\alpha(1735\alpha^3+92+95\alpha^4+6457\alpha^2+1741\alpha)\beta^2\\ &+3\alpha^2(27+2493\alpha+2523\alpha^2+17\alpha^3)\beta+11\alpha^3(262\alpha+7+7\alpha^2)\}, \end{aligned} \tag{165}$$

$$\alpha\equiv\exp(2\xi),\quad \beta\equiv\exp(2t), \tag{166}$$

$$x=\xi-1.15\tanh\xi-1.15\tanh(\xi-t), \tag{167}$$

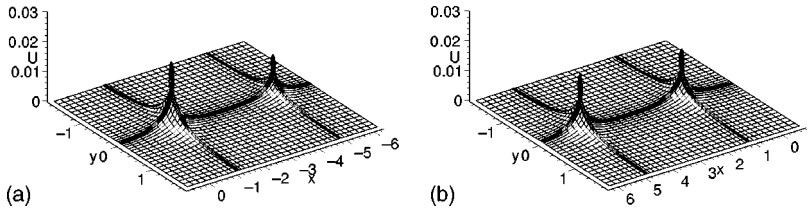

FIG. 9. Pre- and post-interaction of two FSWs at times (a) $t=-4.5$, and (b) $t=4.5$ for the universal quantity U (92) with (164)–(171).

$$q_y=-\operatorname{sech}^2\,\eta, \tag{168}$$

$$q=-\tfrac{1}{30}\tanh\,\eta(7-\tfrac{23}{2}\operatorname{sech}^2\,\eta), \tag{169}$$

$$y=\eta-1.15\tanh\,\eta, \tag{170}$$

$$a_0=30. \tag{171}$$

From Figs. 9(a) and 9(b), we know that the quantity U (92) with (164)–(171) expresses a special two-FSW solution in that the interaction between them is nonelastic. Actually, the completely elastic interaction condition (137) is not satisfied for the solution (92) with (164)–(171). For the static FSW,

$$F_1^+-F_1^-=\tfrac{14}{3}\neq 0, \tag{172}$$

and for the moving FSW,

$$F_2^+-F_2^-=-\tfrac{28}{5}\neq 0. \tag{173}$$

Though the singular factors (at $t=0$), $\coth t$, $\operatorname{csch} t$, and $1/(\alpha-1)$ appear in the expression of p (165), there is no singularity for the interaction solution (92) with (164)–(171) inasmuch

$$p|_{t=0}=\lim_{t\to 0}p=\frac{44(15\alpha^2-39\alpha-8)}{15(\alpha+1)^3}, \tag{174}$$

and

$$\max|p+q|\leqslant\max|p|+\max|q|=\tfrac{359}{30}+\tfrac{286}{345}\sqrt{299}\approx 26.3<a_0=30. \tag{175}$$

Example 4: Interaction between two foldons for the MLVSA solvable systems.

According to the general discussions in Secs. V A and V B, in order to find foldons, the functions p and q must be selected in a way that the conditions (137)–(138) or (146) are satisfied.

Figure 10 is a pre- and post-interaction plot of two foldons for the field U expressed by (92) with the selections $[\alpha\equiv\exp(2\xi),\ \beta\equiv\exp(2t)]$

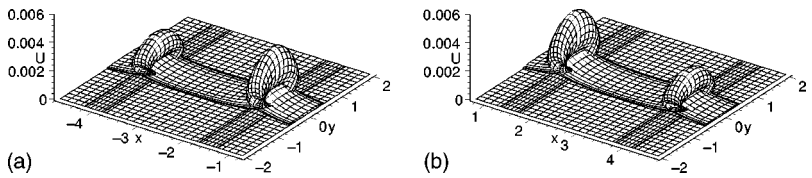

FIG. 10. Pre- and post-interaction of two foldons at times (a) $t=-5.5$, and $t=5.5$ for the universal quantity U (92) with (176)–(182).

$$p_x = -\tfrac{4}{5}\operatorname{sech}^2\xi - \tfrac{1}{2}\operatorname{sech}^2(\xi - t), \tag{176}$$

$$p = \frac{39}{10}\coth t\,\operatorname{csch}^2 t \ln\frac{\alpha+1}{\alpha+\beta} + \frac{1}{5(\beta+1)^3(\beta+\alpha)^3(\alpha-1)^2}\{(67\alpha+76\alpha^2+5\alpha^3+8)\beta^5 - (8 - 211\alpha - 205\alpha^3 - 377\alpha^2 + 5\alpha^4)\beta^4 + 3\alpha(23+243\alpha+225\alpha^2+29\alpha^3)\beta^3 + \alpha\beta^2(8\alpha^4+257\alpha^3 + 1027\alpha^2+263\alpha+5) - \alpha^2(5-401\alpha^2-392\alpha+8\alpha^3)\beta + 156\alpha^4\}, \tag{177}$$

$$x = \xi - 1.5\tanh\xi - 1.5\tanh(\xi - t), \tag{178}$$

$$q_y = -\operatorname{sech}^2\eta, \tag{179}$$

$$q = \tfrac{1}{3}\tanh\eta(1 + 2\operatorname{sech}^2\eta), \tag{180}$$

$$y = \eta - 2\tanh\eta, \tag{181}$$

$$a_0 = 20. \tag{182}$$

Since the completely elastic interaction condition (137) is really satisfied for both the static excitation and the moving one, the solution (92) with (176)–(182) is genuinely a two-foldon solution. Likewise, there is no singularity for the solution (92) with (176)–(182) thanks to

$$p|_{t=0} = \lim_{t\to 0} p = \frac{13(\alpha^2-4\alpha-1)}{5(\alpha+1)^3} \tag{183}$$

and

$$\max|p+q| \leqslant \max|p| + \max|q| = \frac{13}{10} + \frac{26}{45}\sqrt{6} + \frac{\sqrt{2}}{3} \approx 3.12 < a_0 = 20. \tag{184}$$

VI. SUMMARY AND DISCUSSIONS

The MLVSA has been successfully applied to many $(2+1)$-dimensional nonlinear systems. Utilizing the MLVSA, a universal formula is derived for all the known MLVSA solvable models. Simultaneously, a diversity of localized excitations are obtained from this universal formula via the appropriate selections of the arbitrary functions included in the formula.

In this paper, the MLVSA and the universal formula have been extended in two directions. First, the MLVSA is extended for the MNNV system and the 2DsG system where two universal terms with some suitable conditions can be superposed to generate a new exact solution of the same models. Second, by changing the basic ansatz of the MLVSA, the universal formula is extended at least for the DLWE, the BKK system, the higher order BKK system, and the Burgers system such that arbitrary number of variable separated functions are included in the variable separation solutions. The MLVSA and the universal formula may also be extended in some other ways. For instance, the MLVSA has been successfully extended to the differential-difference systems,[57] and arbitrary number of the variable separated functions can also be introduced by means of the Darboux transformations and the Bäcklund transformations[58] and so on.

Starting from the ''universal'' formula and/or its extended forms, all sorts of localized excitations with and without completely elastic interaction properties are constructed readily by suitably selecting the arbitrary functions according to the asymptotic results (134), (141), (142), and (151). Especially, a new kind of localized excitations, FSWs and foldons, is investigated both analytically and graphically. Foldons may be folded quite freely and complicatedly and then possess quite rich structures and interaction properties. The explicit phase shifts for all the localized excitations offered by the universal formula and its extended forms have also been given.

On the one hand, there are a large number of complicated ''folded'' and/or the multivalued phenomena in the real natural world. Nonetheless, there is no good analytical way to treat these kinds of complicated phenomena. This paper is only a beginning attempt to looking for some types of possible stable multivalued localized excitations, FSWs and foldons, for some real physical models including some quite ''universal'' systems like the well-known DS systems[59–61] and the DLWE.

In Refs. 30 and 62, the authors pointed out that the localized solutions of the DS equation, say, dromions, can be remote controlled by choosing a suitable motion of the boundaries. In Ref. 14, we also pointed out that though the localized excitations such as the dromions, lumps, ring solitons, peakons and foldons proposed here possess zero boundary conditions for the quantity U and its extended forms, the boundary conditions for other quantities, say, the mean flow for the DS model and v for the MNNV system, are not identically zero. The different selections of the arbitrary functions p and q in (1) correspond to the different selections of boundary conditions of those fields (or potentials) with nonzero boundary conditions and vice versa. That means, in some sense, the dromions, foldons, and other types of localized excitations for some physical quantities are remote controlled by some other quantities (or potentials). This fact hints that it is possible for one to observe the dromions, foldons, and other kinds of localized excitations from the systems governed by the MLVSA solvable models via inputting suitable boundary conditions. For foldons, the input boundaries may be selected as $(1+1)$-dimensional loop solitons.

Because the formula (60) is valid for various $(2+1)$-dimensional interesting models which are widely applied in many physical fields, we do believe that foldons are useful in the studies on the complicated ''folded'' natural world. The more about both the (extended) ''universal'' formula and the general (or special) foldons especially their possible real applications should be studied further.

(Received 2 April 2003; accepted 20 May 2003)

Closed expressions are obtained for angular and frequency radiation intensities produced by a charge moving inside the dielectric sphere S, with observations made outside S (in fact, this is a typical experimental situation when a charge moves in one medium while measurements are made in the other one). It is shown that the difference in media properties inside and outside S drastically affects angular and frequency distributions. Also, a charge motion is considered which begins and terminates in medium 2 and which passes either through the dielectric sphere filled with medium 1 or through the metallic one. The energy flux in medium 2 involves the Vavilov–Cherenkov, transition radiation and the one arising from the charge instantaneous beginning and termination of motion. The evaluated angular and frequency distributions for various charge velocities and medium properties inside and outside S show that the standard identification of the charge velocity by its radiation on the part of the charge trajectory where $\beta n > 1$ is not always valid. We analyze also the frequently used interpretation of the transition radiation in terms of instantaneous charge deceleration in one medium and its sudden acceleration in another one, and find them as to be insufficient. On the other hand, attempts to interpret the transition radiation in terms of semi-infinite motions terminating in one medium and beginning in the other one turn out to be correct if one takes into account the terms corresponding to the Vavilov–Cherenkov radiation. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1602162]

I. INTRODUCTION

This paper has a twofold aim.

First, usually, a charge moves in the one medium (1) while the measurements are made in the other one (2). For example, in the original Cherenkov experiments,[1] the electron moved in the vessel filled with water, while measurements were made outside this vessel, in air. The radiation of a charge moving inside the infinite cylindrical sample C was considered by Frank and Ginsburg[2] who shown that there is no radiation outside C if the Tamm–Frank radiation condition is not fulfilled there. It should be recalled that Frank and Ginsburg evaluated the energy flux in the direction perpendicular to the motion axis. The energy flux in the direction parallel to the motion axis was evaluated in Ref. 3. It was shown there that this component of radiation is infinitely small for all frequencies except for the infinite discrete sequence of frequencies where it is infinite.

In the same reference,[3] the geometrical optics consideration has been applied to the radiation of charge moving in the finite space interval lying completely inside the sphere S filled with a substance 1 with refractive index n_1. Observations are made outside S, in medium 2 with refractive index n_2. It was shown there that the angular spectrum broadens if $n_2 < n_1$. One of the goals of the present treatment is to make the quantitative analysis of this problem. For this, we evaluated angular and frequency radiation intensities for a number of charge velocities and media properties. In general, the presence of medium 2 outside S different from medium 1 inside S leads to the

broadening of the angular spectrum and to the appearance of additional maxima at large angles. Calculations predict the oscillations of the frequency spectrum. This could be observed experimentally.

The second problem which will be studied here is the transition and Vavilov–Cherenkov (VC) radiations on the dielectric and metallic spheres. The notion of the transition radiation was introduced by Frank and Ginsburg[4] who studied radiation arising from the uniformly moving charge passing from one medium to another. They considered the plane boundary between media 1 and 2. A thorough exposition of the transition radiation may be found in Ref. 5. In this consideration, we consider a charge motion which begins and terminates in medium 2 and which passes through the dielectric sphere filled with medium 1. The energy flux is evaluated in medium 2. As far as we know, the transition radiation only for plane interfaces was considered in physical literature. For the treated problem the angular and frequency radiation intensities are evaluated for a number of charge velocities and media properties. These expressions contain transition and VC radiations as well as the radiation from the charge instantaneous beginning and termination of motion. It is proved that the identification (frequently used by experimentalists) of the charge velocity by the Cherenkov radiation on the part of the charge trajectory where $\beta n>1$ is not always valid in the presence of boundaries.

There are analyzed attempts to explain transition radiation in terms of the charge instantaneous termination of motion in one medium and the instantaneous charge beginning of motion in another medium. It is proved that their contribution to the radiation intensity disappears if the charge motion with instantaneous velocity jumps can be considered as a limiting case of the charge smooth motion. It is considered also the interpretation of the transition radiation in terms of semi-infinite charge motions with instantaneous termination of the charge motion in one medium and with its instantaneous beginning of motion in the other one. It is shown that if the charge velocity is greater than the light velocity in medium, the terms corresponding to the VC radiation should be taken into account.

The plan of our exposition is as follows. The mathematical preliminaries are collected in Sec. II. The expansion of the electromagnetic field in terms of Legendre polynomials for the Tamm problem is given in Sec. III. In Sec. IV, a charge moving inside the dielectric sphere S filled with the substance 1 is considered. The radiation intensity is evaluated outside S, in medium 2. In Sec. V, a charge whose motion begins and terminates in the medium 2 and which passes through the dielectric sphere filled with medium 1 or through the metallic one. The energy flux is evaluated in medium 2. In Sec. VI, the review of attempts to interpret the transition radiation in terms of sudden termination of the charge motion in one medium and its sudden beginning in the other one is given. A short resume of the results obtained is presented in Sec. VII.

II. MATHEMATICAL PRELIMINARIES

We consider the charge motion in medium as to be given and intend to evaluate the electromagnetic field arising from such a motion. The solving of Maxwell equations grounds on the use of the Green functions.

For the charge motion in medium with refractive index n, the Green function is equal to

$$G_n=\exp(ik_nR)/R, \quad R=|\vec{r}-\vec{r}\,'|. \tag{2.1}$$

Here $k_n=kn$, $k=\omega/c$ and n is the medium refractive index. Its expansion in spherical coordinates is given by (see, e.g., Ref. 6)

$$G_n=2\sum_{m\geqslant 0}\epsilon_m(2l+1)\frac{(l-m)!}{(l+m)!}\cos m(\phi-\phi')G_l(r,r')P_l^m(\cos\theta)P_l^m(\cos\theta'), \tag{2.2}$$

where

$$G_l(r,r')=ik_n j_l(k_n r_<)h_l(k_n r_>), \quad j_l(x)=\sqrt{\frac{\pi}{2x}}J_{l+1/2}(x), \quad h_l(x)=\sqrt{\frac{\pi}{2x}}H^{(1)}_{l+1/2}(x),$$

$\epsilon_m=1/(1+\delta_{m,0})$; $r_>=r, r_<=r'$ if $r>r'$; $r_>=r', r_<=r$ if $r<r'$.

These equations are no longer valid if medium consists of two pieces with different refractive indices. We consider a particular case when space regions inside and outside the sphere S of the radius a are filled with the substances 1 and 2 with parameters ϵ_1,μ_1 and ϵ_2,μ_2, respectively. The Green function satisfying equations

$$(\Delta+k_1^2)G_n=-4\pi\delta^3(\vec{r}-\vec{r}')$$

for $r<a$ and

$$(\Delta+k_2^2)G_n=-4\pi\delta^3(\vec{r}-\vec{r}')$$

for $r>a$ has the same form as (2.2) but with $G_l(r,r')$ given by

$$\begin{aligned}G_l=&ik_1\Theta(a-r)\Theta(a-r')j_l(k_1r_<)h_l(k_1r_>)+ik_2\Theta(r-a)\Theta(r'-a)j_l(k_2r_<)h_l(k_2r_>)\\&+ik_1D_l\Theta(a-r)\Theta(r'-a)j_l(k_1r)h_l(k_2r')+ik_2C_l\Theta(r-a)\Theta(a-r')j_l(k_1r')h_l(k_2r).\end{aligned} \tag{2.3}$$

Here $k_1=kn_1$ and $k_2=kn_2$ ($n_1=\sqrt{\epsilon_1\mu_1}$ and $n_2=\sqrt{\epsilon_2\mu_2}$ are the refractive indices of media 1 and 2, respectively). The constants C_l and D_l are defined by the boundary conditions at $r=a$. The vector potential (VP) in the spectral representation for a charge moving along the z axis is found from the equation

$$A_z=\frac{1}{c}\int G(\vec{r},\vec{r}')\mu(r')j_z(\vec{r}')dV', \tag{2.4}$$

where $\mu=\mu_1$ for $r<a$ and $\mu=\mu_2$ for $r>a$. The integration is performed over space points where the spectral current density $j_z(\vec{r}')$ differs from zero.

III. PEDAGOGICAL EXAMPLE: THE TAMM PROBLEM IN A SPHERICAL BASIS

A. The original Tamm problem

Tamm considered the following problem.[7] A point charge is at rest at the point $z=-z_0$ of the z axis up to a moment $t=-t_0$ and at the point $z=z_0$ after the moment $t=t_0$. In the time interval $-t_0<t<t_0$, it moves uniformly along the z axis with the velocity v greater than the light velocity in medium $c_n=c/n$. The nonvanishing z component of the VP in the spectral representation is given by

$$A_z(x,y,z)=\frac{e\mu}{2\pi c}\alpha_T, \tag{3.1}$$

where

$$\alpha_T=\int_{-z_0}^{z_0}\frac{dz'}{R}\exp\left[ik\left(\frac{z'}{\beta}+nR\right)\right], \quad R=[\rho^2+(z-z')^2]^{1/2}, \quad \rho^2=x^2+y^2.$$

Imposing the conditions: (i) $R\gg z_0$ (this means that the observation distance is much larger than the motion interval); (ii) $k_nR\gg 1$, $k_n=\omega/c_n$ (this means that the observations are made in the wave zone); (iii) $nz_0^2/2R\lambda\ll 1$, $\lambda=2\pi c/\omega$ [this means that the second-order terms in the expansion of R should be small compared with π since they enter as a phase in (3.1); λ is the observed wavelength], Tamm obtained the following expression for the magnetic VP:

$$A_z=\frac{e\mu}{\pi n\omega r}\exp(iknr)q,\quad q=\frac{1}{1/\beta_n-\cos\theta}\sin\left[\frac{kLn}{2}\left(\frac{1}{\beta_n}-\cos\theta\right)\right]. \tag{3.2}$$

Here $L=2z_0$ is the motion interval and $\beta_n=\beta n$. In the limit $kL\to\infty$, one gets

$$q\to\pi\delta\left(\frac{1}{\beta_n}-\cos\theta\right),\quad A_z\to\frac{e\mu}{\omega nr}\exp(iknr)\,\delta(\cos\theta-1/\beta_n). \tag{3.3}$$

Using the vector potential (3.2), Tamm evaluated the electromagnetic field strengths and the energy flux through the sphere of the radius r for the whole time of observation

$$\mathcal{E}=R_0^2\int S_r\,\mathrm{d}\Omega\,\mathrm{d}t=\int\frac{\mathrm{d}^2\mathcal{E}}{\mathrm{d}\Omega\,\mathrm{d}\omega}\mathrm{d}\Omega\,\mathrm{d}\omega,\quad \mathrm{d}\Omega=\sin\theta\,\mathrm{d}\theta\,\mathrm{d}\phi,\quad S_r=\frac{c}{4\pi}E_\theta H_\phi,$$

where

$$\frac{\mathrm{d}^2\mathcal{E}}{\mathrm{d}\Omega\,\mathrm{d}\omega}=\frac{e^2\mu}{\pi^2nc}q^2\sin^2\theta \tag{3.4}$$

is the energy emitted into the solid angle $\mathrm{d}\Omega$, in the frequency interval $\mathrm{d}\omega$. This famous formula obtained by Tamm is frequently used by experimentalists for the identification of the charge velocity. Equation (3.4), being integrated over the solid angle, defines the frequency distribution of the radiation

$$\frac{\mathrm{d}\mathcal{E}}{\mathrm{d}\omega}=\int\frac{\mathrm{d}^2\mathcal{E}}{\mathrm{d}\Omega\,\mathrm{d}\omega}\mathrm{d}\Omega.$$

It is given by[8,9]

$$\begin{aligned}\frac{\mathrm{d}\mathcal{E}}{\mathrm{d}\omega}=&\frac{2e^2\beta}{\pi c}\left(1-\frac{1}{\beta_n^2}\right)\left\{\frac{\sin^2[kL(1-\beta_n)/2\beta]}{1-\beta_n}-\frac{\sin^2\omega[kL(1+\beta_n)/2\beta]}{1+\beta_n}-\frac{kL}{2\beta}\left[si\left(\frac{kL}{\beta}(1-\beta_n)\right)\right.\right.\\&\left.\left.-si\left(\frac{kL}{\beta}(1+\beta_n)\right)\right]\right\}-\frac{2e^2}{\pi cn^2\beta}\left[\ln\frac{|1-\beta_n|}{1+\beta_n}-ci\left(\frac{kL}{\beta}|1-\beta_n|\right)+ci\left(\frac{kL}{\beta}(1+\beta_n)\right)\right]\\&-\frac{e^2}{\pi cn^2}\left\{2n+\frac{1}{kL}\left[\sin\left(\frac{kL}{\beta}(1-\beta_n)\right)-\sin\left(\frac{kL}{\beta}(1+\beta_n)\right)\right]\right\}.\end{aligned} \tag{3.5}$$

Here $si(x)$ and $ci(x)$ are the integral sine and cosine defined by equations

$$si(x)=-\int_x^\infty\frac{\sin t}{t}dt,\quad ci(x)=-\int_x^\infty\frac{\cos t}{t}dt.$$

For $kL\gg1$, Eq. (3.5) reduces to the form given by Tamm:

$$\frac{\mathrm{d}\mathcal{E}}{\mathrm{d}\omega}=W_{BS} \tag{3.6}$$

for $v<c_n$ and

$$\frac{\mathrm{d}\mathcal{E}}{\mathrm{d}\omega}=W_{BS}+W_{Ch} \tag{3.7}$$

for $v>c_n$. Here

$$W_{BS}=\frac{2e^2\mu}{\pi c\beta n^2}\left(\ln\frac{1+\beta_n}{|1-\beta_n|}-2\beta_n\right) \quad \text{and} \quad W_{Ch}=\frac{e^2\mu kL}{c}\left(1-\frac{1}{\beta_n^2}\right).$$

Tamm identified W_{BS} with the spectral distribution of the bremsstrahlungs, arising from the charge instantaneous acceleration and deceleration at the moments $\pm t_0$, respectively. On the other hand, W_{Ch} was identified with the spectral distribution of the VC radiation. This is supported by the fact that W_{Ch} related to the charge motion interval coincides with the famous Frank-Tamm formula describing the energy radiated per unit length and per unit frequency for the charge unbounded motion[10]

$$\frac{\mathrm{d}^2\mathcal{E}}{\mathrm{d}\omega\,\mathrm{d}L}=\frac{e^2}{c^2}\left(1-\frac{1}{\beta_n^2}\right).$$

The typical experimental situations described by the Tamm formula are (i) the β decay of a nucleus at one space point accompanied by a subsequent absorption of the emitted electron at another point; (ii) a high energy electron consequently moves in vacuum, enters into the dielectric slab, leaves the slab and propagates again in vacuum. Since the electron moving uniformly in vacuum does not radiate (apart from the transition radiation arising at the boundaries of the dielectric slab), the experimentalists describe this situation via the Tamm formula, assuming that the electron is created at one side of the slab and is absorbed at the other (see, e.g., Refs. 8, 11–15).

B. Expansion of the Tamm problem in terms of Legendre polynomials

Let a charge moves in medium in a finite interval $(-z_0,z_0)$ (this corresponds to the so-called Tamm problem). Then, the current density corresponding to the Tamm problem, in the spherical coordinates, is given by

$$j_z(\omega)=\frac{e}{4\pi^2r^2\sin\theta}\left[\delta(\theta)\exp\left(\frac{ikr}{\beta}\right)+\delta(\theta-\pi)\exp\left(-\frac{ikr}{\beta}\right)\right]\Theta(z_0-r). \tag{3.8}$$

Then, using (2.2), one gets on the observation sphere of the radius $r>z_0$,

$$A_z(\omega)=\frac{ie\mu kn}{2\pi c}\sum\,(2l+1)P_l h_l(knr)J_l(0,z_0),$$

$$H_\phi(\omega)=-\frac{iek^2n^2}{2\pi c}\sum\,P_l^1 h_l(knr)\tilde{J}_l(0,z_0), \quad E_\theta(\omega)=-\frac{ek^2\mu n}{2\pi c}\sum\,P_l^1 H_l(knr)\tilde{J}_l(0,z_0). \tag{3.9}$$

Here

$$J_l(0,z_0)=\int_0^{z_0} j_l(knr')f_l(r')\mathrm{d}r', \quad \tilde{J}_l(0,z_0)=J_{l-1}(0,z_0)+J_{l+1}(0,z_0),$$

$$H_l(x)=\dot{h}_l(x)+\frac{h_l(x)}{x},$$

$$f_l(r')=\exp\left(\frac{ikr'}{\beta}\right)+(-1)^l\exp\left(-\frac{ikr'}{\beta}\right), \quad k_1=kn_1, \quad k_2=kn_2.$$

In obvious cases, we omit the arguments of the Legendre polynomials if they equal cos θ. At large distances ($kr\gg 1$) one can replace Hankel functions by their asymptotic values:

$$A_z \sim \frac{e\mu}{2\pi cr}\exp(iknr)\sum\ (2l+1)i^{-l}P_l J_l(0,z_0),$$

$$H_\phi \sim -\frac{ekn}{2\pi cr}\exp(iknr)\sum\ i^{-l}P_l^1 \tilde{J}_l(0,z_0), \quad E_\theta \sim -\frac{ek\mu}{2\pi cr}\exp(iknr)\sum\ i^{-l}P_l^1 \tilde{J}_l(0,z_0).$$

The angular radiation intensity on the sphere of the radius r

$$\frac{d^2\mathcal{E}}{d\omega\, d\Omega} = \frac{1}{2}cr^2(E_\theta H_\phi^* + \text{c.c.}) = \frac{e^2k^2n\mu}{4\pi^2 c}\left|\sum\ i^{-l}P_l^1 \tilde{J}_l(0,z_0)\right|^2$$
$$= \frac{e^2k^2n\mu\sin^2\theta}{4\pi^2 c}\left|\sum\ (2l+1)i^{-l}P_l J_l(0,z_0)\right|^2. \tag{3.10}$$

Or, in a manifest form,

$$\frac{d^2\mathcal{E}}{d\omega\, d\Omega} = \frac{e^2\mu n}{\pi^2 c}\sin^2\theta(S_1+S_2)^2, \tag{3.11}$$

where

$$S_1 = \sum_{l=0}^{\infty}(-1)^l(4l+1)P_{2l}(\cos\theta)I_{2l}^c, \quad S_2 = \sum_{l=0}^{\infty}(-1)^l(4l+3)P_{2l+1}(\cos\theta)I_{2l+1}^s,$$
$$I_{2l}^c = \int_0^{kz_0} j_{2l}(nx)\cos\left(\frac{x}{\beta}\right)dx, \quad I_{2l+1}^s = \int_0^{kz_0} j_{2l+1}(nx)\sin\left(\frac{x}{\beta}\right)dx. \tag{3.12}$$

Integrating (3.11) over the solid angle, one obtains the frequency distribution of the radiation

$$\frac{d\mathcal{E}}{d\omega} = \frac{e^2k^2n\mu}{\pi c}\sum\ \frac{l(l+1)}{2l+1}|\tilde{J}_l(0,z_0)|^2$$
$$= \frac{8e^2n\mu}{\pi c}\left[\sum\ \frac{(l+1)(2l+1)}{4l+3}(I_{2l}^c + I_{2l+2}^c)^2 + \sum\ \frac{l(2l+1)}{4l+1}(I_{2l+1}^s + I_{2l-1}^s)^2\right]. \tag{3.13}$$

These equations are valid if the radius r of the observation sphere is larger than z_0.

Numerical calculations show that Eqs. (3.11) and (3.13) coincide with the corresponding Tamm equations (3.4) and (3.5).

We concentrate now on the vector potential. For this, we rewrite it as

$$A_z = \frac{ie\mu n}{\pi c}\sum_{l=0}^{\infty}(4l+1)h_{2l}(knr)P_{2l}(\cos\theta)I_{2l}^c - \frac{e\mu n}{\pi c}\sum_{l=0}^{\infty}(4l+3)h_{2l+1}(knr)P_{2l+1}(\cos\theta)I_{2l+1}^s. \tag{3.14}$$

Usually, observations are made on large distances. For example, for $\lambda = 4\times10^{-5}$ cm and $r = 1$ m, $kr = 2\pi r/\lambda \sim 10^7$. Replacing the Hankel functions by their asymptotic values, one gets

$$A_z = \frac{e\mu}{kr\pi c}\exp(iknr)(S_1+S_2). \tag{3.15}$$

Obviously, (3.2) and (3.15) should coincide (since the same assumptions are involved in their derivation). Equating them, one gets

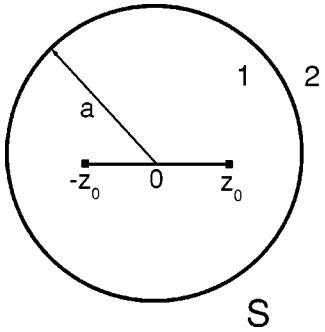

FIG. 1. A charge moves inside the dielectric sphere S filled with the medium 1. The radiation of intensity is measured outside S, in medium 2.

$$S_1+S_2=\frac{1}{n}\,\frac{\sin[kz_0n(\cos\theta-1/\beta_n)}{\cos\theta-1/\beta_n}. \tag{3.16}$$

Now we consider the coefficients I^c_{2l} and I^s_{2l+1}. In the limit $kz_0\to\infty$, the integrals

$$I^c_{2l}=\int_0^\infty j_{2l}(nx)\cos\left(\frac{x}{\beta}\right)\mathrm{d}x,\quad I^s_{2l+1}=\int_0^\infty j_{2l+1}(nx)\sin\left(\frac{x}{\beta}\right)\mathrm{d}x$$

can be evaluated in a closed form (see, e.g., Ref. 6). They are given 0 for $\beta n<1$ and

$$I^c_{2l}=\frac{\pi}{2n}(-1)^l P_{2l}(1/\beta n),\quad I^s_{2l+1}=\frac{\pi}{2n}(-1)^l P_{2l+1}(1/\beta n)$$

for $\beta n>1$. Substituting this into (3.15), one gets

$$\begin{aligned}A_\omega&=\frac{e\mu}{2nkrc}\exp(iknr)\left[\sum_{l=0}^{\infty}(4l+1)P_{2l}(\cos\theta)P_{2l}(1/\beta n)\right.\\&\quad\left.+\sum_{l=0}^{\infty}(4l+3)P_{2l+1}(\cos\theta)P_{2l+1}(1/\beta n)\right]\\&=\frac{e\mu}{2nkrc}\exp(iknr)\sum_{l=0}^{\infty}(2l+1)P_l(\cos\theta)P_l(1/\beta n)\\&=\frac{e\mu}{nkrc}\exp(iknr)\,\delta(\cos\theta-1/\beta n).\end{aligned} \tag{3.17}$$

In deriving this, we used the completeness relation

$$\sum_{l=0}^{\infty}(l+1/2)P_l(x)P_l(x')=\delta(x-x').$$

Vector potential (3.17) coincides with the one entering into (3.3).

IV. THE TAMM PROBLEM FOR A CHARGE MOVING INSIDE THE SPHERICAL SAMPLE

A. Main formulas

Let a charge move in a finite space interval $(-z_0,z_0)$ lying entirely inside the sphere S of the radius a (Fig. 1). The sphere is filled by a substance 1 with parameters ϵ_1 and μ_1. The observa-

tions are made in the medium 2 with parameters ϵ_2 and μ_2 surrounding S. The EMF strengths contributing to the radial energy flux are equal to (see Appendix A)

$$H_\phi = -\frac{iek^2n_2^2}{2\pi c}\sum \tilde{C}_l P_l^1 h_l(k_2 r),$$

$$E_\theta = -\frac{i}{\epsilon_2 kr}\frac{\mathrm{d}}{\mathrm{d}r}(rH_\phi) = -\frac{e\mu_2 n_2 k^2}{2\pi c}\sum H_l(k_2 r) P_l^1 \tilde{C}_l \tag{4.1}$$

for $r>a$ and

$$H_\phi = -\frac{iek^2n_1^2}{2\pi c}\sum P_l^1[\tilde{D}_l j_l(k_1 r)+\tilde{J}_l^{(1)}(0,z_0)h_l(k_1 r)],$$

$$E_\theta = -\frac{e\mu_1 n_1 k^2}{2\pi c}\sum P_l^1[\tilde{D}_l J_l(k_1 r)+\tilde{J}_l^{(1)}(0,z_0)H_l(k_1 r)] \tag{4.2}$$

for $z_0<r<a$. Here

$$\tilde{J}_l^{(1)}(x,y)=J_{l-1}^{(1)}(x,y)+J_{l+1}^{(1)}(x,y), \quad J_l^{(1)}(x,y)=\int_x^y j_l(k_1 r')f_l(r')\mathrm{d}r',$$

$$J_l(x)=\frac{\mathrm{d}j_l(x)}{\mathrm{d}x}+\frac{j_l(x)}{x}=\frac{1}{2l+1}[(l+1)j_{l-1}-lj_{l+1}],$$

$$H_l(x)=\frac{\mathrm{d}h_l(x)}{\mathrm{d}x}+\frac{h_l(x)}{x}=\frac{1}{2l+1}[(l+1)h_{l-1}-lh_{l+1}].$$

Imposing the continuity of H_ϕ and E_θ at $r=a$, one finds the following equations for $\tilde{C}_l$ and $\tilde{D}_l$:

$$n_2^2\tilde{C}_l h_l(2)-n_1^2\tilde{D}_l j_l(1)=n_1^2 h_l(1)\tilde{J}_l^{(1)}(0,z_0),$$

$$\mu_2 n_2\tilde{C}_l H_l(2)-\mu_1 n_1\tilde{D}_l J_l(1)=\mu_1 n_1 H_l(1)\tilde{J}_l^{(1)}(0,z_0), \tag{4.3}$$

where $1=k_1 a$ and $2=k_2 a$. From this one easily finds $\tilde{C}_l$,

$$\tilde{C}_l=\frac{i\mu_1}{n_2 k^2 a^2 \delta u p_l}\tilde{J}_l^{(1)}(0,z_0), \tag{4.4}$$

where

$$\Delta_l=\mu_2 n_1 j_l(1)H_l(2)-\mu_1 n_2 J_l(1)h_l(2).$$

At large distances ($kr\gg 1$) one can replace Hankel function by its asymptotic value. Then,

$$H_\phi = -\frac{ekn_2}{2\pi c}\frac{\exp(ik_2 r)}{r}S, \quad E_\theta = -\frac{ek\mu_2}{2\pi c}\frac{\exp(ik_2 r)}{r}S, \tag{4.5}$$

where

$$S=\sum i^{-l}P_l^1\tilde{C}_l. \tag{4.6}$$

The radiation intensity per unit frequency unit and per unit solid angle is

$$\frac{\mathrm{d}^2\mathcal{E}}{\mathrm{d}\Omega\,\mathrm{d}\omega}=\frac{1}{2}cr^2(E_\theta H_\phi^*+\text{c.c.})=\frac{e^2k^2n_2\mu_2}{4\pi^2c}|S|^2. \tag{4.7}$$

The integration over the solid angle gives the frequency distribution of radiation

$$\frac{\mathrm{d}\mathcal{E}}{\mathrm{d}\omega}=\frac{e^2k^2n_2\mu_2}{\pi c}\sum\frac{l(l+1)}{2l+1}|\tilde{C}_l|^2. \tag{4.8}$$

When the media inside and outside S are the same ($\epsilon_1=\epsilon_1=\epsilon,\ \mu_1=\mu_2=\mu$), one gets

$$\Delta_l=\frac{i\mu}{nk^2a^2}\quad\text{and}\quad\tilde{C}_l=\tilde{J}_l^{(1)}(0,z_0),$$

that is, one arrives at the one-medium Tamm problem for the space interval $(-z_0,z_0)$.

B. Numerical results

In Fig. 2, there are shown angular radiation intensities (solid lines) evaluated according (4.7) for $kz_0=10$, $ka=20$, $n_1=2$ and $n_2=1$ (that is, there is a vacuum outside S) for a number of charge velocities. Side by side with them, the Tamm angular intensities (3.4) (dotted lines) corresponding to $n=n_1$, $L=2z_0$ are shown. The distinction of (4.7) from (3.4) is due to the presence of the medium 2 outside S not coinciding with medium 1. This results in the broadening of the angular intensity distribution and in its rise at large observation angles.

The corresponding frequency distributions (4.8) (solid lines) together with the Tamm frequency distributions (3.5) (dotted lines) are shown in Fig. 3. It is seen that the frequency distribution (4.8) oscillates around the Tamm one (3.5). When evaluating $\mathrm{d}\mathcal{E}/\mathrm{d}\omega$, we implicitly assumed that the refractive index n_1 does not depend on ω in the treated frequency interval. In fact, this is a common thing in refractive media. For example, for the usual water the refractive index is almost constant in the frequency interval $6\times10^{14}<\omega<6\times10^{15}\ \mathrm{s}^{-1}$ encompassing the visible light region.

In Fig. 4, there are shown angular radiation intensities (solid lines) evaluated according (4.7) for $kz_0=10$, $ka=20$, $n_1=1$ and $n_2=2$ (that is, there is a vacuum inside S) for a number of charge velocities. Side by side with them, the Tamm angular intensities (3.4) (dotted lines) corresponding to $n=n_1$, $L=2z_0$ are shown. It is seen that the presence of medium outside S affects not so strongly as in Fig. 2.

The corresponding frequency distributions are shown in Fig. 5. Again, oscillations around the Tamm frequency distribution (3.5) are observed.

Probably, the rise of angular intensities at large angles shown in Figs. 2 and 4 is due to the reflection of the VC radiation from the internal side of S.

V. THE TAMM PROBLEM FOR A CHARGE PASSING THROUGH THE SPHERE

A. Dielectric sphere

1. Main formulas

Let a charge move with a constant velocity v in the interval $(-z_0,z_0)$. There is a sphere S of the radius $a<z_0$ with its center at the origin (Fig. 6).

The space inside S is filled by the substance with parameters ϵ_1, μ_1. Outside S there is substance with parameters ϵ_2, μ_2. The EMF strengths contributing to the radial energy flux are (see Appendix B)

$$H_\phi=-\frac{iek_2^2}{2\pi c}\sum\tilde{C}_lP_l^1h_l(k_2r),\quad E_\theta=-\frac{ek^2\mu_2n_2}{2\pi c}\sum H_l(k_2r)P_l^1\tilde{C}_l \tag{5.1}$$

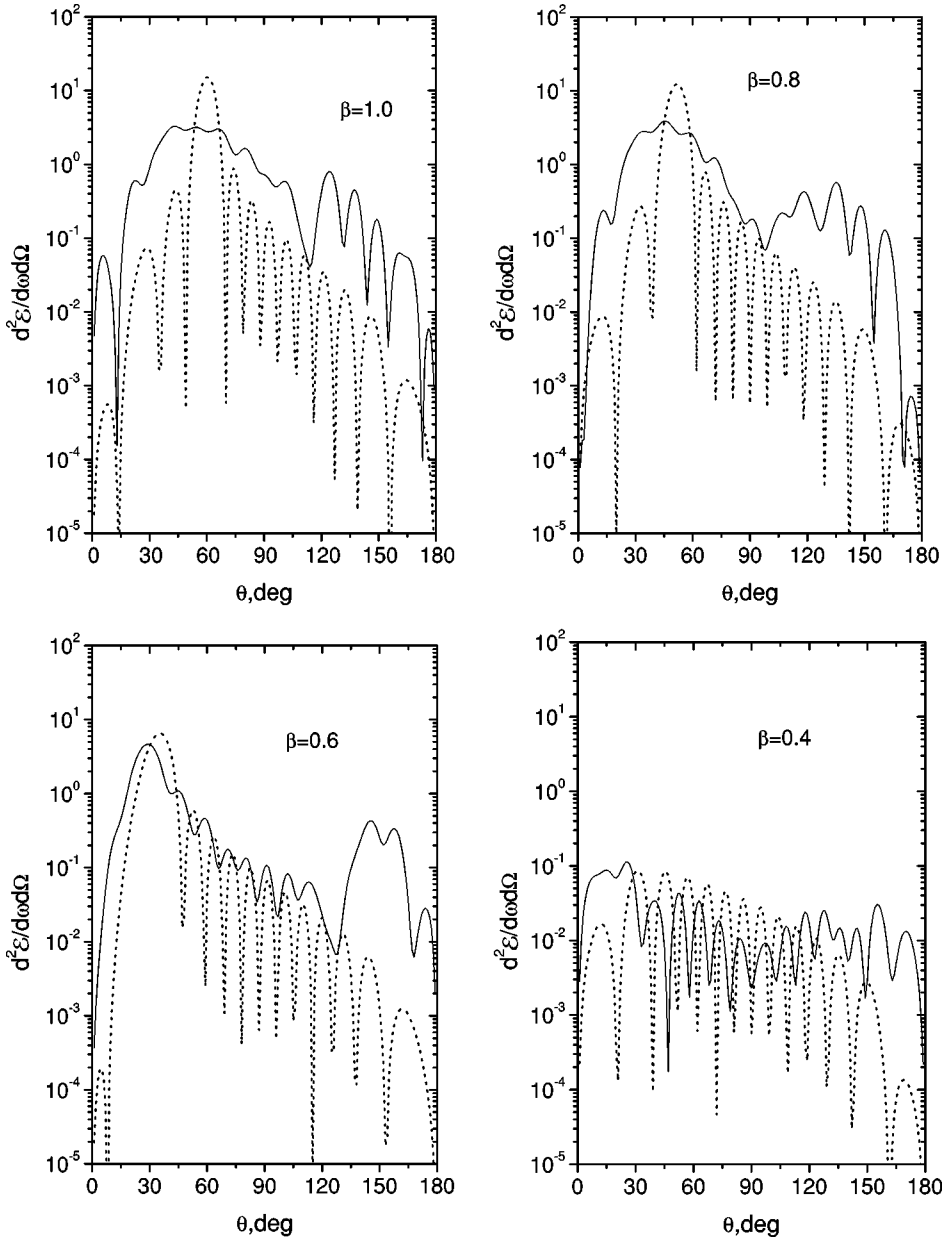

FIG. 2. Angular radiation intensities in e^2/c units (solid curves) for the charge motion shown in Fig. 1 and various charge velocities. The media parameters are $n_1=2$, $n_2=1$ (that is, there is vacuum outside the sphere S). Further, $kz_0=10$, $ka=20$. The dotted curves are the Tamm angular intensities (3.4) evaluated for $kL=2kz_0$ and $n=n_1$. The difference between these two curves is due to the fact that the medium outside S is not the same as inside S. The exact angular intensities are much broader than the corresponding Tamm ones. Probably, the rise of angular intensities at large angles is due to the reflection of the VC radiation from the internal side of S.

for $r>z_0$,

$$H_\phi=-\frac{iek_2^2}{2\pi c}\sum\ \tilde{P}_l^1[\tilde{C}_l h_l(k_2r)-h_l(k_2r)\tilde{J}_l^{(2)}(r,z_0)+j_l(k_2r)\tilde{H}_l^{(2)}(r,z_0)],$$

$$E_\theta=-\frac{ek^2\mu_2 n_2}{2\pi c}\sum\ \tilde{P}_l^1[\tilde{C}_l H_l(k_2r)-H_l(k_2r)\tilde{J}_l^{(2)}(r,z_0)+J_l(k_2r)\tilde{H}_l^{(2)}(r,z_0)] \tag{5.2}$$

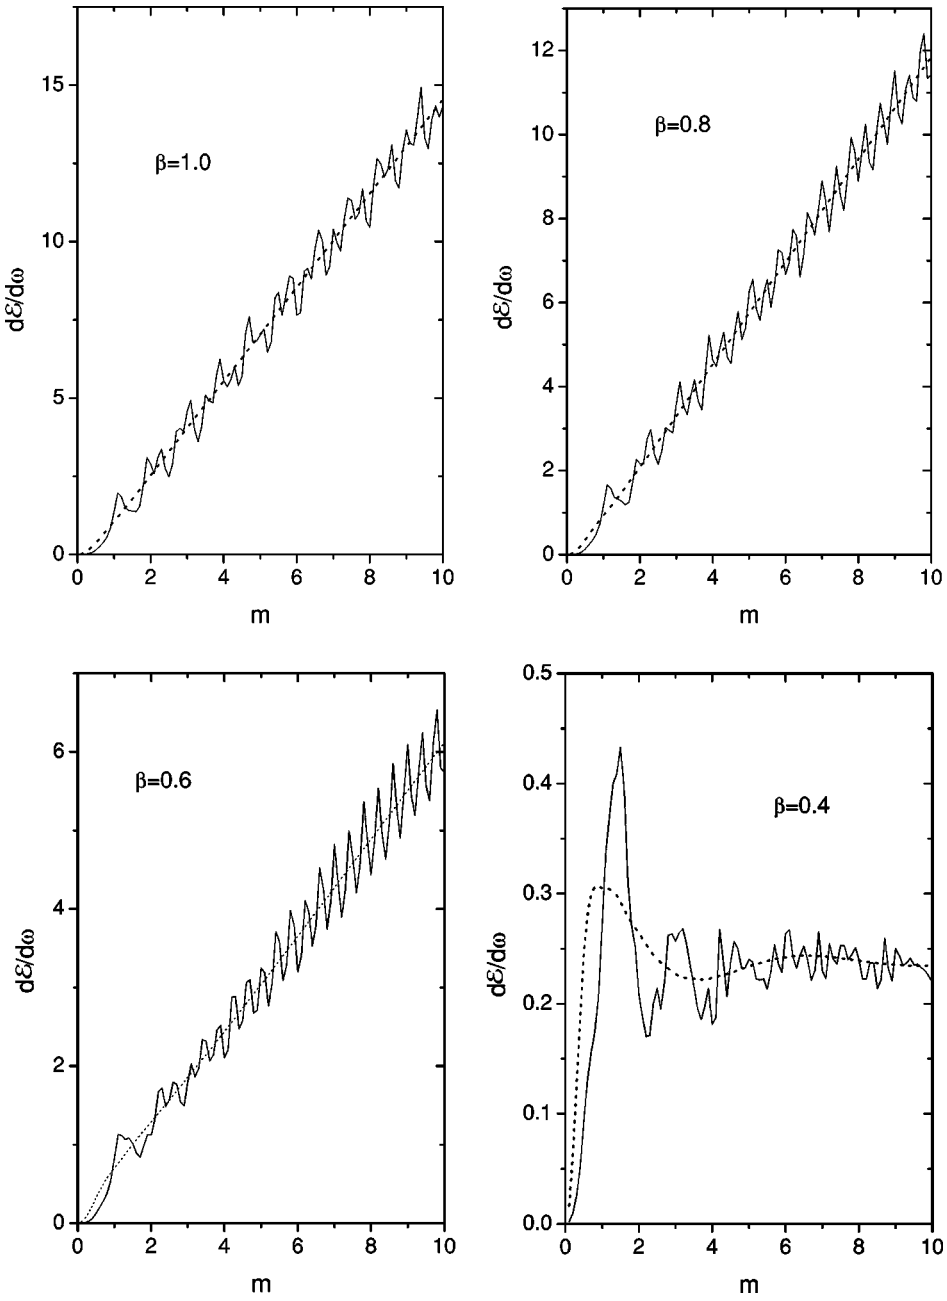

FIG. 3. Frequency radiation intensities in e^2/c units (solid curves) for the charge motion shown in Fig. 1 and various charge velocities. The media parameters are the same as in Fig. 2. Further, $kz_0=m$, $ka=2m$. The dotted curves are the Tamm frequency intensities (3.5) evaluated for $kL=2kz_0$ and $n=n_1$. It is seen that frequency intensities (4.8) oscillate around the Tamm ones.

for $a<r<z_0$ and

$$H_\phi=-\frac{iek_1^2}{2\pi c}\sum\ \tilde{P}_l^1[\tilde{D}_l j_l(k_1r)+h_l(k_1r)\tilde{J}_l^{(1)}(0,r)+j_l(k_1r)\tilde{H}_l^{(1)}(r,a)],$$

$$E_\theta=-\frac{ek^2\mu_1 n_1}{2\pi c}\sum\ \tilde{P}_l^1[\tilde{D}_l J_l(k_1r)+H_l(k_1r)\tilde{J}_l^{(1)}(0,r)+J_l(k_1r)\tilde{H}_l^{(1)}(r,a)] \tag{5.3}$$

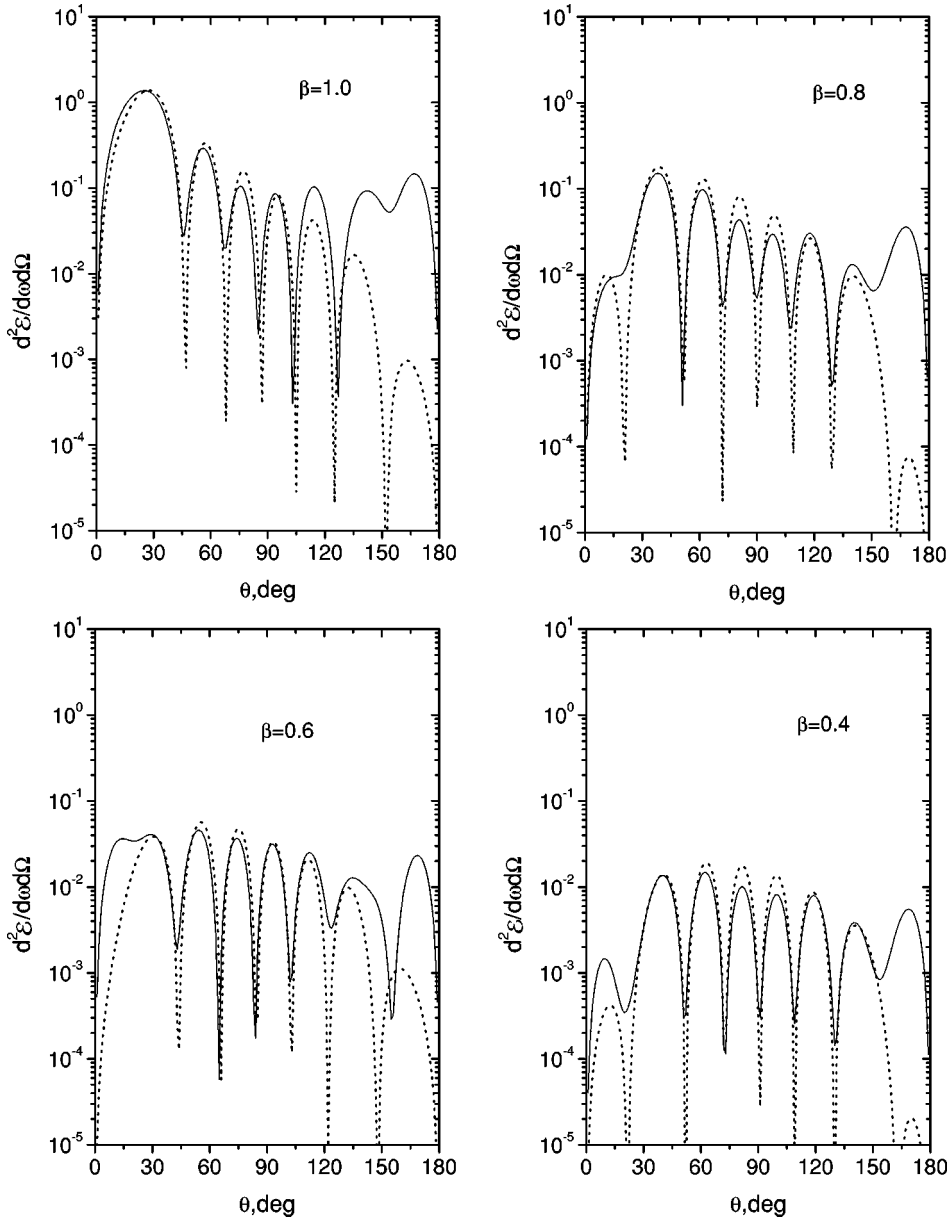

FIG. 4. The same as in Fig. 2 but for $n_1=1$, $n_2=2$ (that is, there is vacuum inside S). The dotted curves are the Tamm angular intensities (3.4) evaluated for $kL=2kz_0$ and $n=n_1$.

for $r<a$. Here

$$\tilde{H}_l^{(1)}(x,y)=H_{l-1}^{(1)}(x,y)+H_{l+1}^{(1)}(x,y), \quad \tilde{J}_l^{(2)}(x,y)=J_{l-1}^{(2)}(x,y)+J_{l+1}^{(2)}(x,y),$$

$$\tilde{H}_l^{(2)}(x,y)=H_{l-1}^{(2)}(x,y)+H_{l+1}^{(2)}(x,y), \quad H_l^{(1)}(x,y)=\int_x^y h_l(k_1r')f_l(r')\mathrm{d}r',$$

$$J_l^{(2)}(x,y)=\int_x^y j_l(k_2r')f_l(r')\mathrm{d}r', \quad H_l^{(2)}(x,y)=\int_x^y h_l(k_2r')f_l(r')\mathrm{d}r'.$$

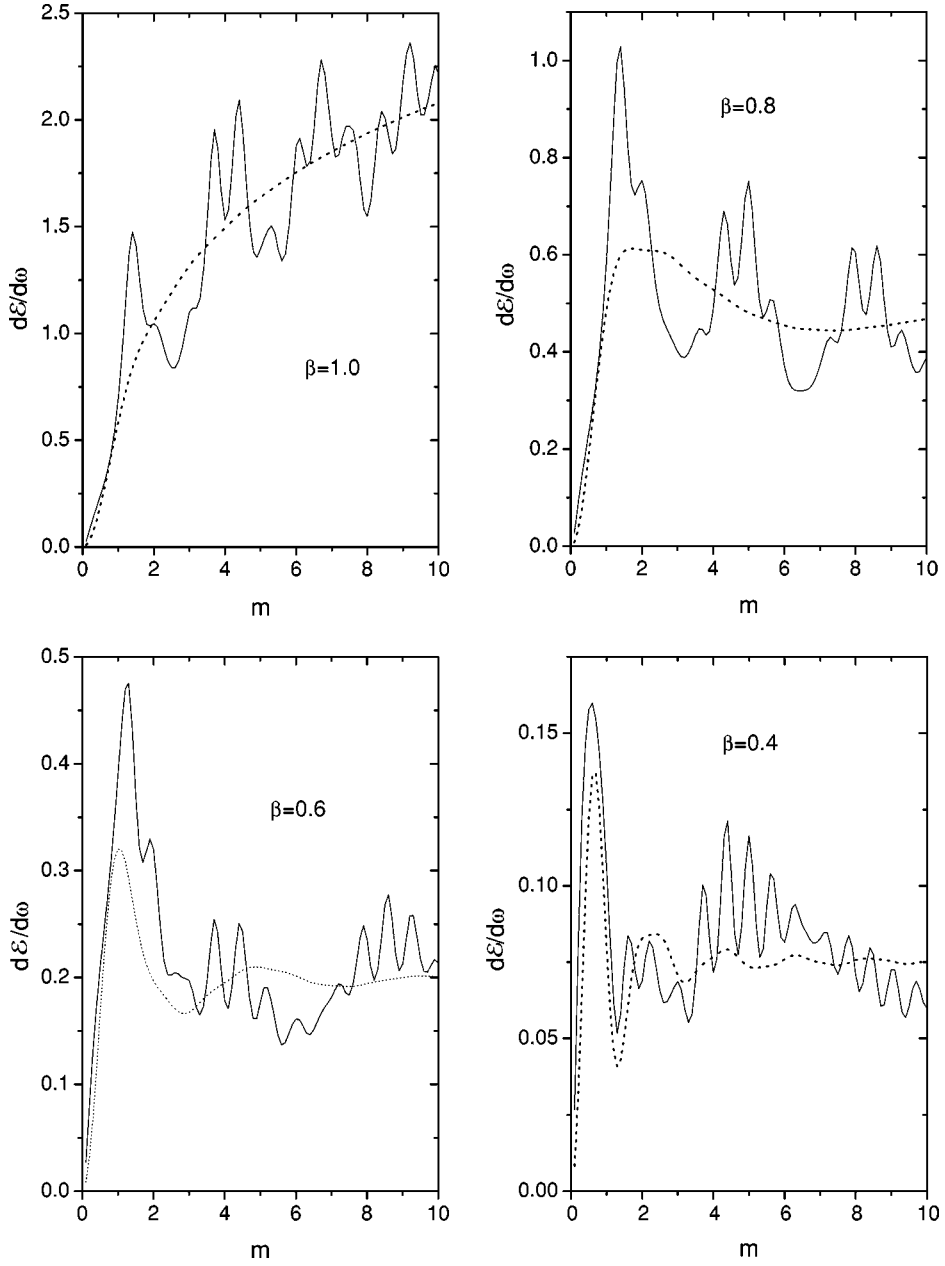

FIG. 5. The same as in Fig. 3 but for $n_1=1$, $n_2=2$ (vacuum inside S). The Tamm frequency intensities (3.5) are evaluated for $kL=2kz_0$ and $n=n_1$.

Equating E_θ and H_ϕ at $r=a$, one obtains the following equations for $\tilde{C}_l$ and $\tilde{D}_l$:

$$n_2^2 h_l(2)\tilde{C}_l - n_1^2 j_l(1)\tilde{D}_l = n_1^2 h_l(1)\tilde{J}_l^{(1)}(0,a) + n_2^2[h_l(2)\tilde{J}_l^{(2)}(a,z_0) - j_l(2)\tilde{H}_l^{(2)}(a,z_0)],$$
$$\mu_2 n_2 H_l(2)\tilde{C}_l - \mu_1 n_1 J_l(1)\tilde{D}_l = \mu_1 n_1 H_l(1)\tilde{J}_l^{(1)}(0,a) + n_2\mu_2[H_l(2)\tilde{J}_l^{(2)}(a,z_0) - J_l(2)\tilde{H}_l^{(2)}(a,z_0)]. \tag{5.4}$$

Here we set $1=k_1a$ and $2=k_2a$. For example, $j_l(1)\equiv j_l(k_1a)$, etc. From this one easily obtains $\tilde{C}_l$:

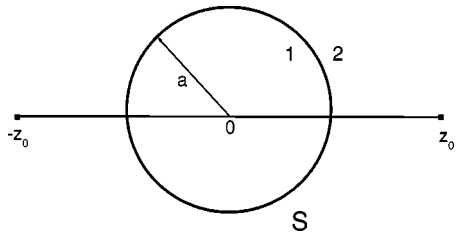

FIG. 6. A charge motion begins and terminates in medium 2. It passes through sphere S filled with the medium 1. The radiation of intensity is measured outside S, in medium 2.

$$\tilde{C}_l=\frac{1}{\Delta_l}\left\{\frac{i\mu_1}{n_2k^2a^2}\tilde{J}_l^{(1)}(0,a)+\tilde{J}_l^{(2)}(a,z_0)[\mu_2n_1j_l(1)H_l(2)-\mu_1n_2J_l(1)h_l(2)]\right.$$
$$\left.-\tilde{H}_l^{(2)}(a,z_0)[\mu_2n_1j_l(1)J_l(2)-\mu_1n_2J_l(1)j_l(2)]\right\}$$
$$=\frac{i}{\Delta_l}\left\{\frac{\mu_1}{n_2k^2a^2}\tilde{J}_l^{(1)}(0,a)+\tilde{J}_l^{(2)}(a,z_0)[\mu_2n_1j_l(1)N_l(2)-\mu_1n_2J_l(1)n_l(2)]\right.$$
$$\left.-\tilde{N}_l^{(2)}(a,z_0)[\mu_2n_1j_l(1)J_l(2)-\mu_1n_2J_l(1)j_l(2)]\right\}. \tag{5.5}$$

Here $\Delta_l=n_1\mu_2j_l(1)H_l(2)-\mu_1n_2J_l(1)h_l(2)$. At large distances ($kr\gg1$), one has

$$H_\phi\approx-\frac{ekn_2}{2\pi cr}\exp(ikn_2r)S,\quad E_\theta\approx-\frac{ek\mu_2}{2\pi cr}\exp(ikn_2r)S, \tag{5.6}$$

where

$$S=\sum\ i^{-l}\tilde{C}_lP_l^1. \tag{5.7}$$

Correspondingly, the energy flux through the sphere of the radius r is

$$\frac{\mathrm{d}^2\mathcal{E}}{\mathrm{d}\omega\,\mathrm{d}\Omega}=\frac{1}{2}cr^2(E_\theta H_\phi^*+\text{c.c.})=\frac{e^2k^2n_2\mu_2}{4\pi^2c}|S|^2. \tag{5.8}$$

Integration over the solid angle gives the frequency distribution of radiation

$$\frac{\mathrm{d}\mathcal{E}}{\mathrm{d}\omega}=\frac{e^2k^2n_2\mu_2}{\pi c}\sum\ \frac{l(l+1)}{2l+1}|\tilde{C}_l|^2. \tag{5.9}$$

The one-medium Tamm problem is obtained either in the limit $ka\to0$ or when media 1 and 2 are the same.

2. Numerical results

In Fig. 7, there are shown angular radiation intensities (solid lines) evaluated according (5.8) for $kz_0=20$, $ka=10$, $n_1=2$ and $n_2=1$ (that is, there is a vacuum outside the sphere S and a substance with $n_1=2$ inside it) for a number of charge velocities. Side by side with them, the Tamm angular intensities (3.4) (dotted lines) corresponding to $n=n_1$, $L=2a$ are shown. It is the usual thing in the VC radiation theory to associate the observed radiation with the part of the charge trajectory where $\beta n>1$ [see, e.g., Ref. 10 and (ii) item at the end of Sec. III A]. It the treated case, it lies within the sphere S. We observe a rather poor agreement of the exact

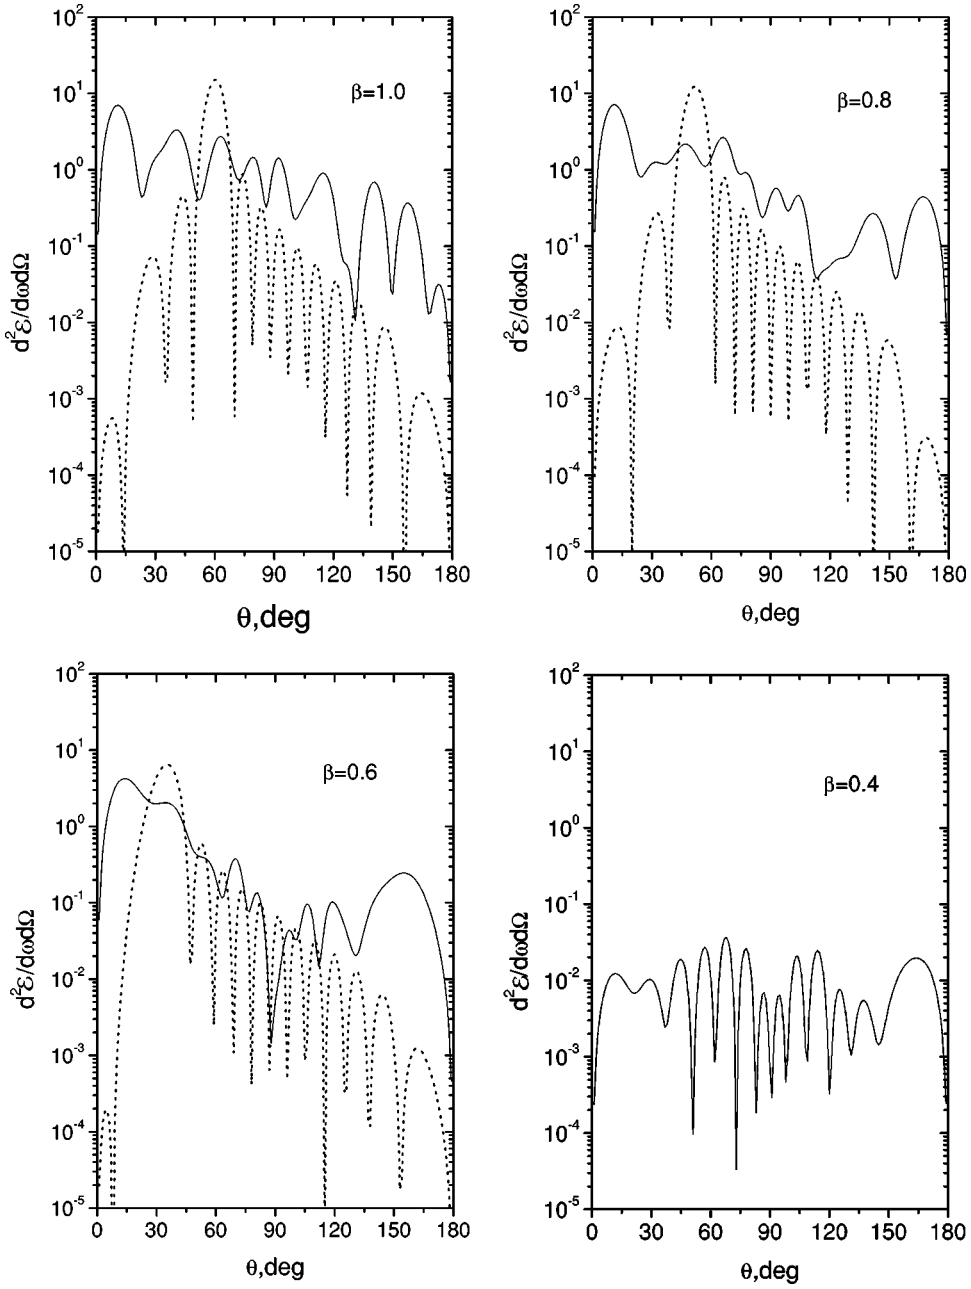

FIG. 7. Angular radiation intensities in e^2/c units (solid curves) for the charge motion shown in Fig. 6 and various charge velocities. The medium inside S is dielectric with $n_1=2$. Outside S there is vacuum ($n_2=1$). Further, $ka=10$, $kz_0=20$. The dotted curves are the Tamm angular intensities (3.4) evaluated for $kL=2ka$ and $n=n_1$. The noncoincidence of exact angular intensities with the corresponding Tamm ones and, in particular, the absence of the pronounced maximum at $\cos\theta=1/\beta n$ (especially for $\beta=1$ and $\beta=0.8$) demonstrates that the applicability of the Tamm formula for describing the radiation arising from the charge passage through the dielectric sample is rather limited.

intensity (5.8) with the Tamm one (3.4). Experimentalist studying, e.g., electron passing through the dielectric sphere S, will not see the pronounced Cherenkov maximum at $\theta=\theta_c$ ($\cos\theta_c=1/\beta n$) and, on these grounds, will not identify the charge velocity. For $\beta=0.4$ we did not present the Tamm intensity since for this velocity the Tamm intensities arising from the charge motion in $0<r<a$ (medium 1) and $a<r<z_0$ (medium 2) intervals are of the same order. It is not clear to us

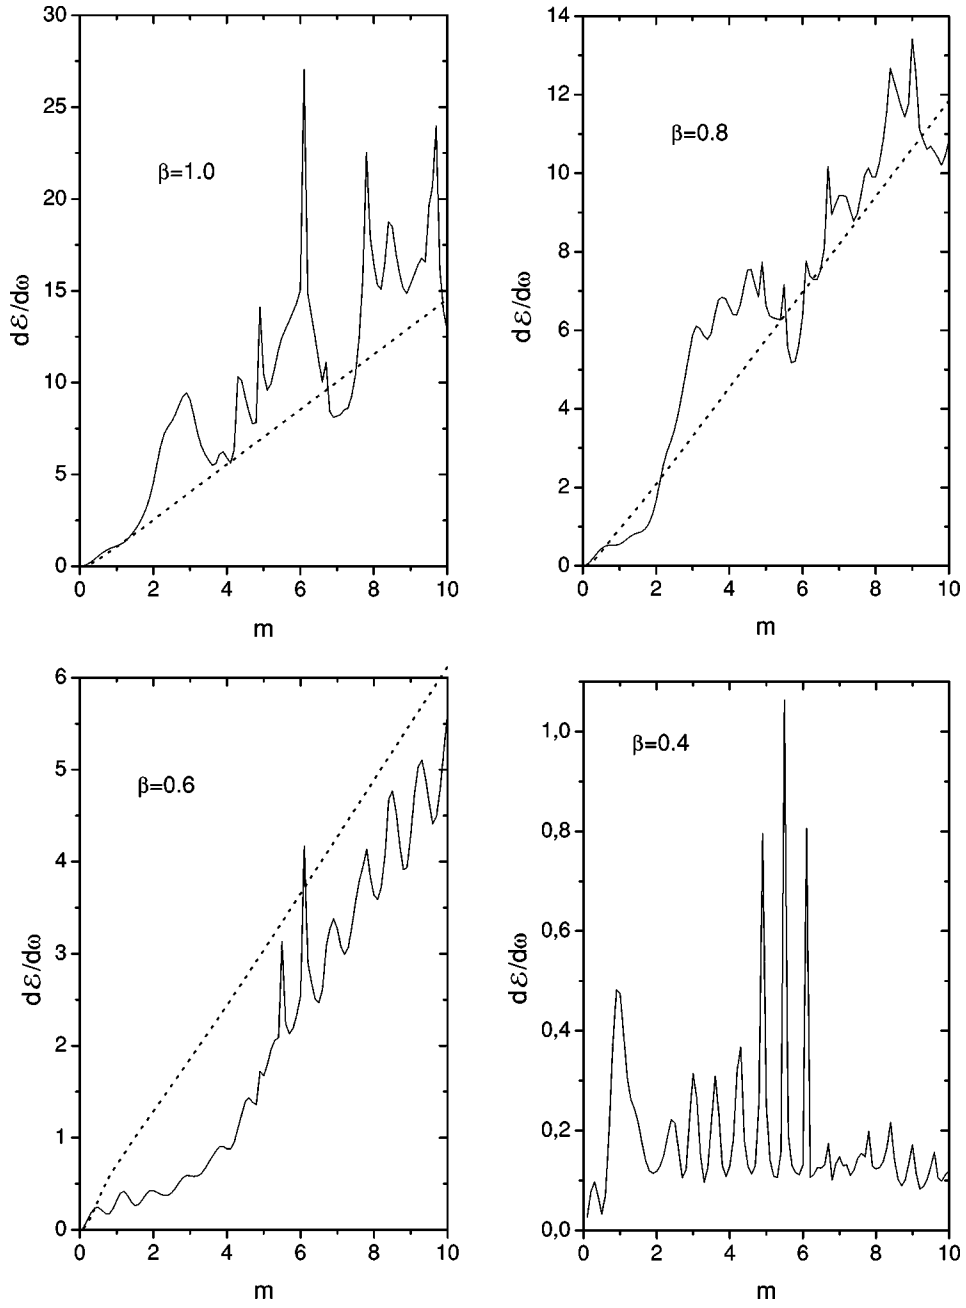

FIG. 8. Frequency radiation intensities in e^2/c units (solid curves) for the charge motion shown in Fig. 6 and various charge velocities. The media parameters are the same as in Fig. 7. Further, $ka=m$, $kz_0=2m$. The dotted curves are the Tamm frequency intensities (3.5) evaluated for $kL=2ka$ and $n=n_1$.

how to combine the corresponding Tamm amplitudes. In any case, Eqs. (5.8) and (5.9) give the exact solution of the treated problem, while the Tamm intensities are needed only for the interpretation purposes. The corresponding frequency distribution (5.9) also differs appreciably from the Tamm one (3.5) (Fig. 8).

In Fig. 9, there are shown angular radiation intensities (solid lines) evaluated according to (5.2) for $kz_0=20$, $ka=10$, $n_1=1$ and $n_2=2$ (that is, the vacuum bubble inside S surrounded by

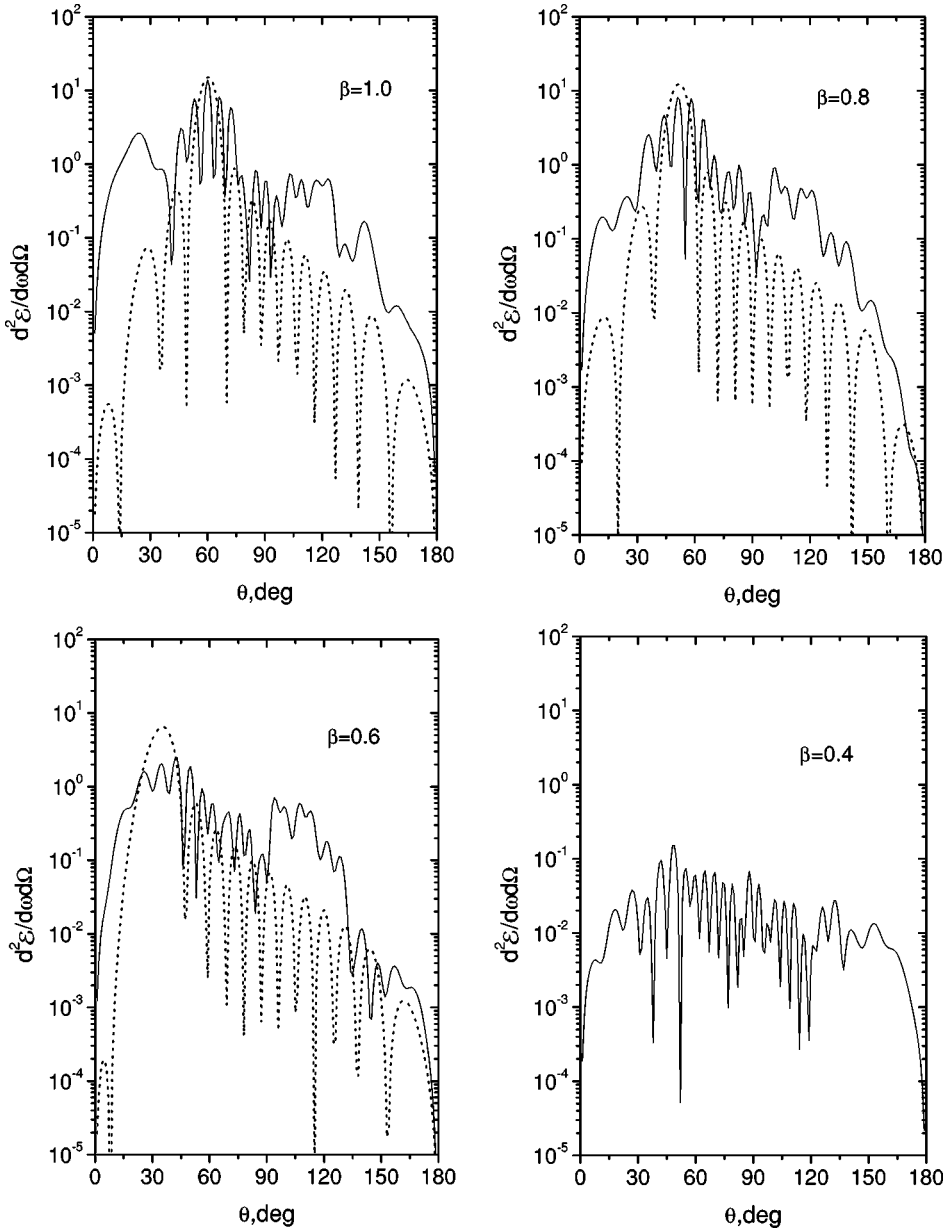

FIG. 9. The same as in Fig. 7 but for $n_1=1$, $n_2=2$ (that is, there is vacuum inside S). The dotted curves are the Tamm angular intensities (3.4) evaluated for $kL=2k(z_0-a)$ and $n=n_2$.

a substance with $n_2=2$) for a number of charge velocities. Side by side with them, the Tamm angular intensities (3.4) (dotted lines) corresponding to $n=n_2$, $L=2(z_0-a)$ are shown. In the treated case, the part of the charge trajectory where $\beta n>1$ lies outside the sphere S. We observe a satisfactory agreement of the exact intensity (5.8) with the Tamm intensity (3.4). Experimentalist studying, e.g., the electron passing through the dielectric sphere S, will see the pronounced Cherenkov maximum at $\theta=\theta_c$ ($\cos\theta_c=1/\beta n$). The corresponding frequency distribution (5.3) does not differ appreciably from the Tamm one (3.5) (Fig. 10).

B. Metallic sphere

On the surface of ideal metal, tangential components of the electric field strength vanish.[16] For the metallic sphere of the radius a, this leads to the disappearance of E_θ. This defines $\tilde{C}_l$:

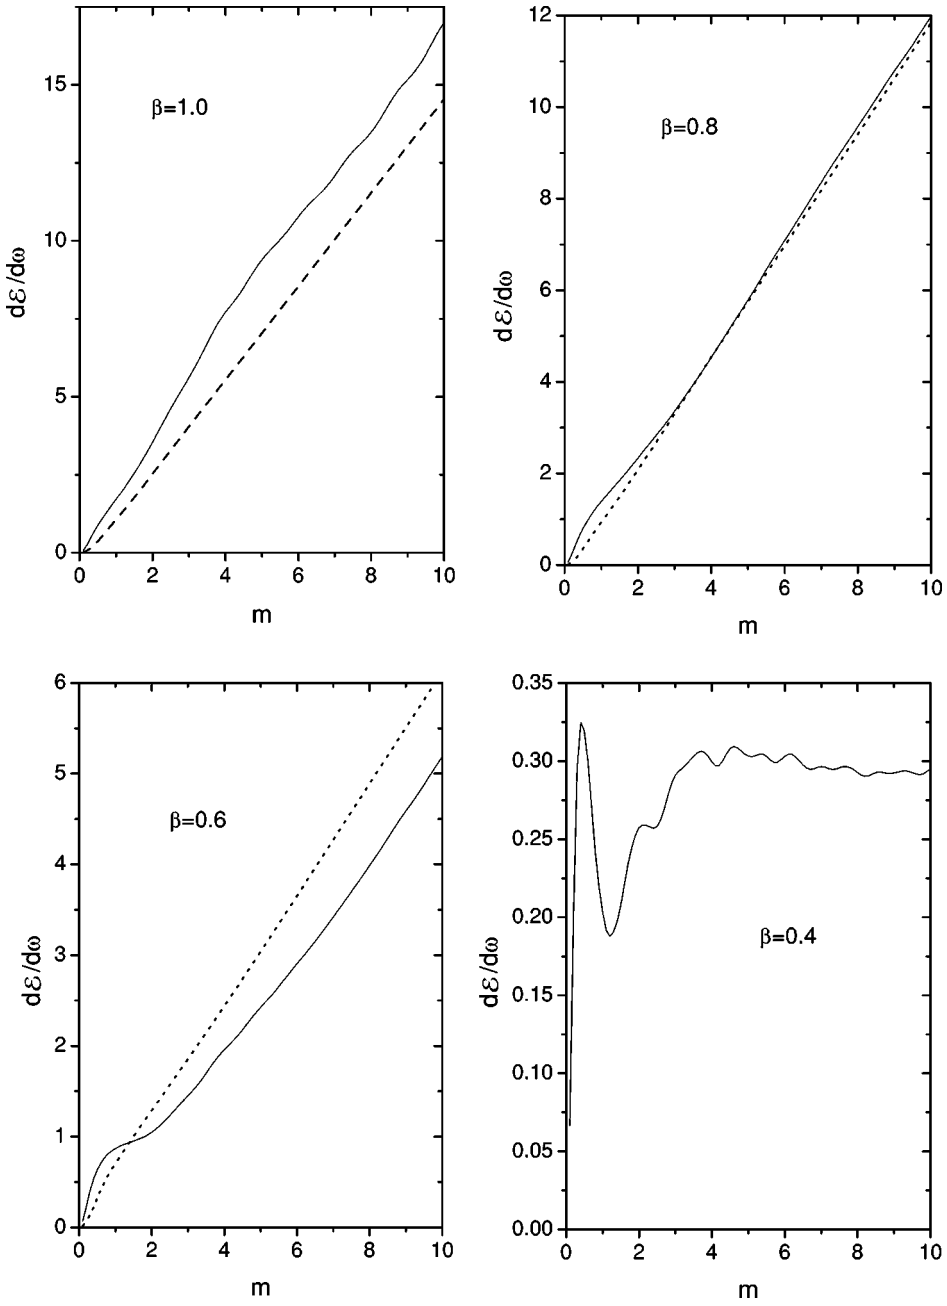

FIG. 10. The same as in Fig. 8 but for $n_1=1$, $n_2=2$ (there is vacuum inside S). The dotted curves are the Tamm frequency intensities (3.5) evaluated for $kL=2k(z_0-a)$ and $n=n_2$.

$$\widetilde{C}_l=\widetilde{J}_l^{(2)}(a,z_0)-\frac{J_l(2)}{H_l(2)}\widetilde{H}_l^{(2)}(a,z_0)=\frac{i}{H_l(2)}[N_l(2)\widetilde{J}_l^{(2)}(a,z_0)-J_l(2)\widetilde{N}_l^{(2)}(a,z_0)]. \quad (5.10)$$

Then, angular and frequency distributions are given by (5.8), (5.9) but with $\widetilde{C}_l$ defined by (5.10).

Numerical results: Let outside S be vacuum. The corresponding angular distributions (5.8) (solid lines) are compared in Fig. 11 with the Tamm angular intensities (3.4) (dotted lines) evaluated for $L=2(z_0-a)$ and $n=n_2$. Since $\beta n\leqslant 1$ outside the sphere S, the angular intensities are rather small.

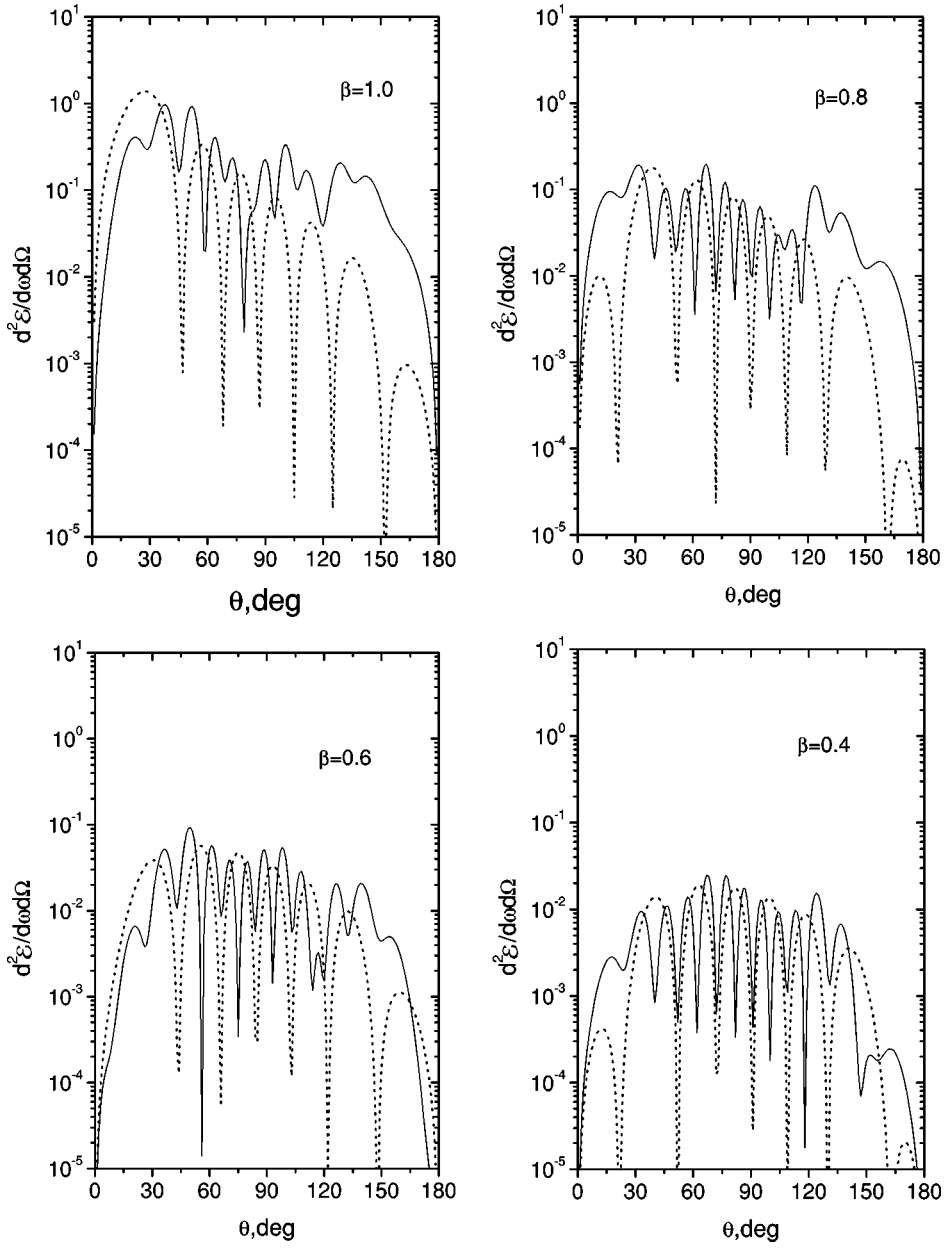

FIG. 11. Angular radiation intensities in e^2/c units (solid curves) for the charge motion shown in Fig. 6 and various charge velocities. The medium inside S is ideal metallic substance. The medium refractive index outside S is $n_2=1$ (vacuum). Further, $ka=10, kz_0=20$. The dotted curves are the Tamm angular intensities (3.4) evaluated for $kL=2k(z_0-a)$ and $n=n_2$.

The corresponding frequency distributions (5.9) (solid lines) and the Tamm ones (3.5) (dotted lines) are shown in Fig. 12. Their agreement is rather poor.

Let outside S be the medium with the refractive index $n_2=2$. The corresponding angular and frequency distributions are shown in Figs. 13 and 14, respectively. We observe the satisfactory agreement with the Tamm intensities evaluated for $L=2(z_0-a)$ and $n=n_2$.

VI. DISCUSSION

Formulas obtained in the preceding two sections describe the VC radiation, the radiation arising from the charge instantaneous acceleration and deceleration and the transition radiation arising from a charge passing from one medium to another.

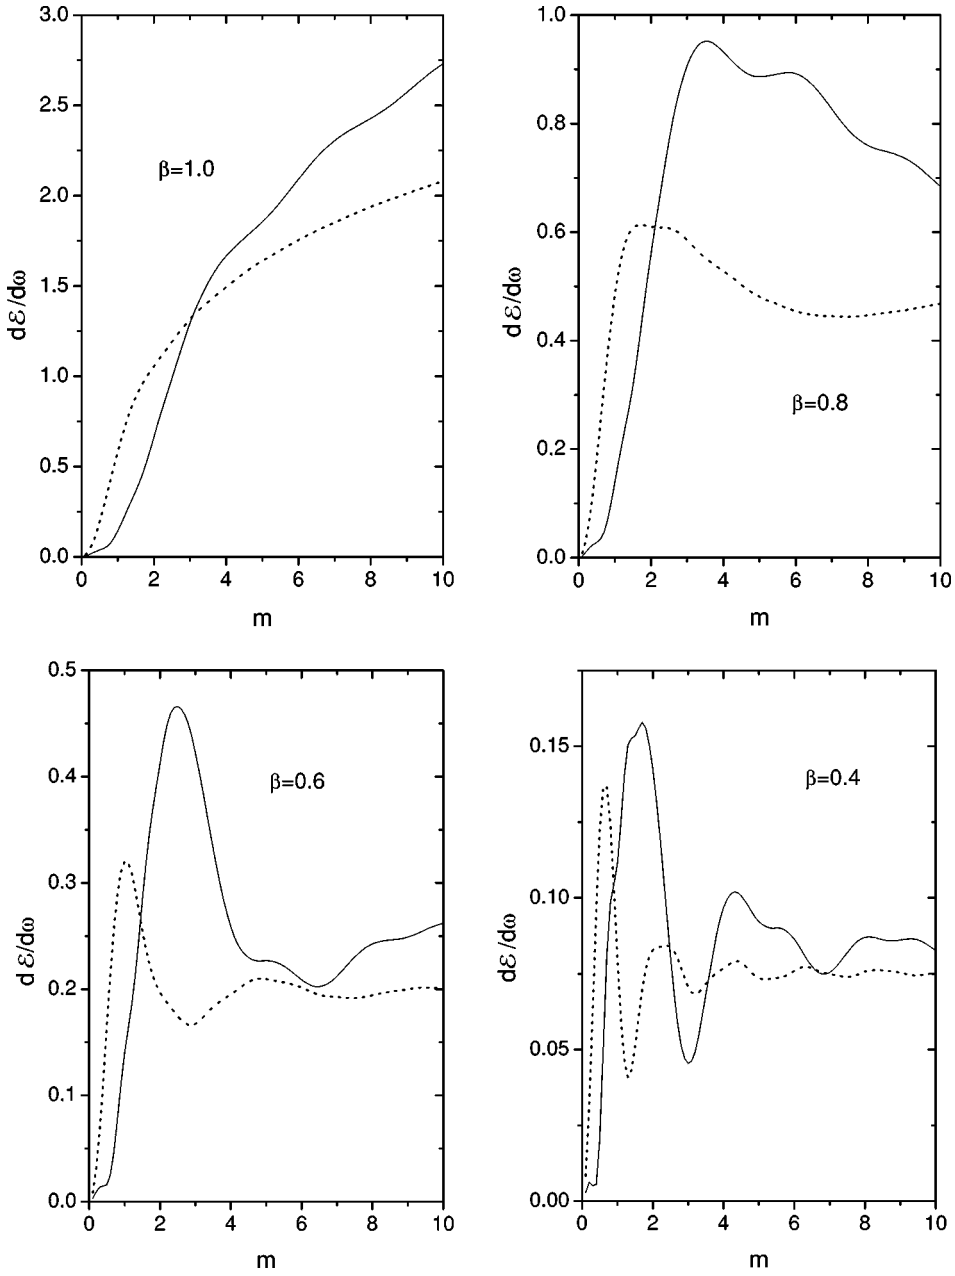

FIG. 12. Frequency radiation intensities in e^2/c units (solid curves) for the charge motion shown in Fig. 6 and various charge velocities. The medium inside S is ideal metallic substance. The medium refractive index outside S is $n_2=1$ (vacuum). Further, $ka=m, kz_0=2m$. The dotted curves are the Tamm frequency intensities (3.5) evaluated for $kL=2k(z_0-a)$ and $n=n_2$.

To separate contribution of the transition radiation, one should subtract (according, e.g., to Ref. 5 or Ref. 17) the field strengths corresponding to the inhomogenuous solution of the Maxwell equations from the total field strengths. In the treated case, the field strengths corresponding to the Tamm problem should be subtracted (they are written out in Sec. III B). This leads to the following redefinition of the $\tilde{C}_l$ coefficients:

$$\tilde{C}_l \to \tilde{C}_l - \sqrt{\frac{n_1\mu_1}{n_2\mu_2}}\tilde{J}_l^{(1)}(0,z_0)$$

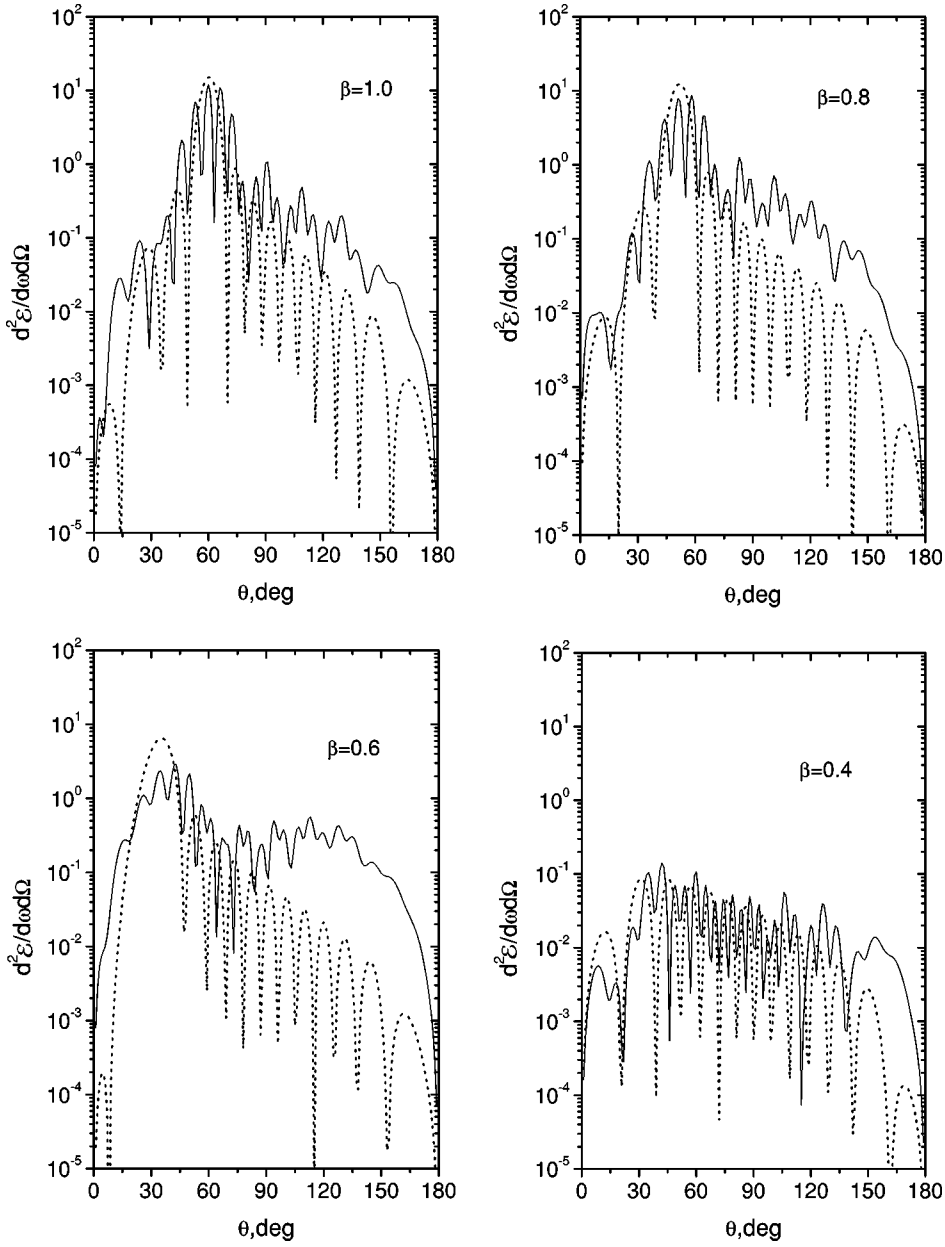

FIG. 13. The same as in Fig. 11 but for metallic substance. The medium refractive index outside S is $n_2=2$. The dotted curves are the Tamm angular intensities (3.4) evaluated for $kL=2k(z_0-a)$ and $n=n_2$.

for the motion shown in Fig. 1,

$$\tilde{C}_l \to \tilde{C}_l - \sqrt{\frac{n_1\mu_1}{n_2\mu_2}}\tilde{J}_l^{(1)}(0,a) - J_l^{(2)}(a,z_0)$$

for the charge motion through the dielectric sphere (Fig. 7) and

$$\tilde{C}_l \to \tilde{C}_l - J_l^{(2)}(a,z_0)$$

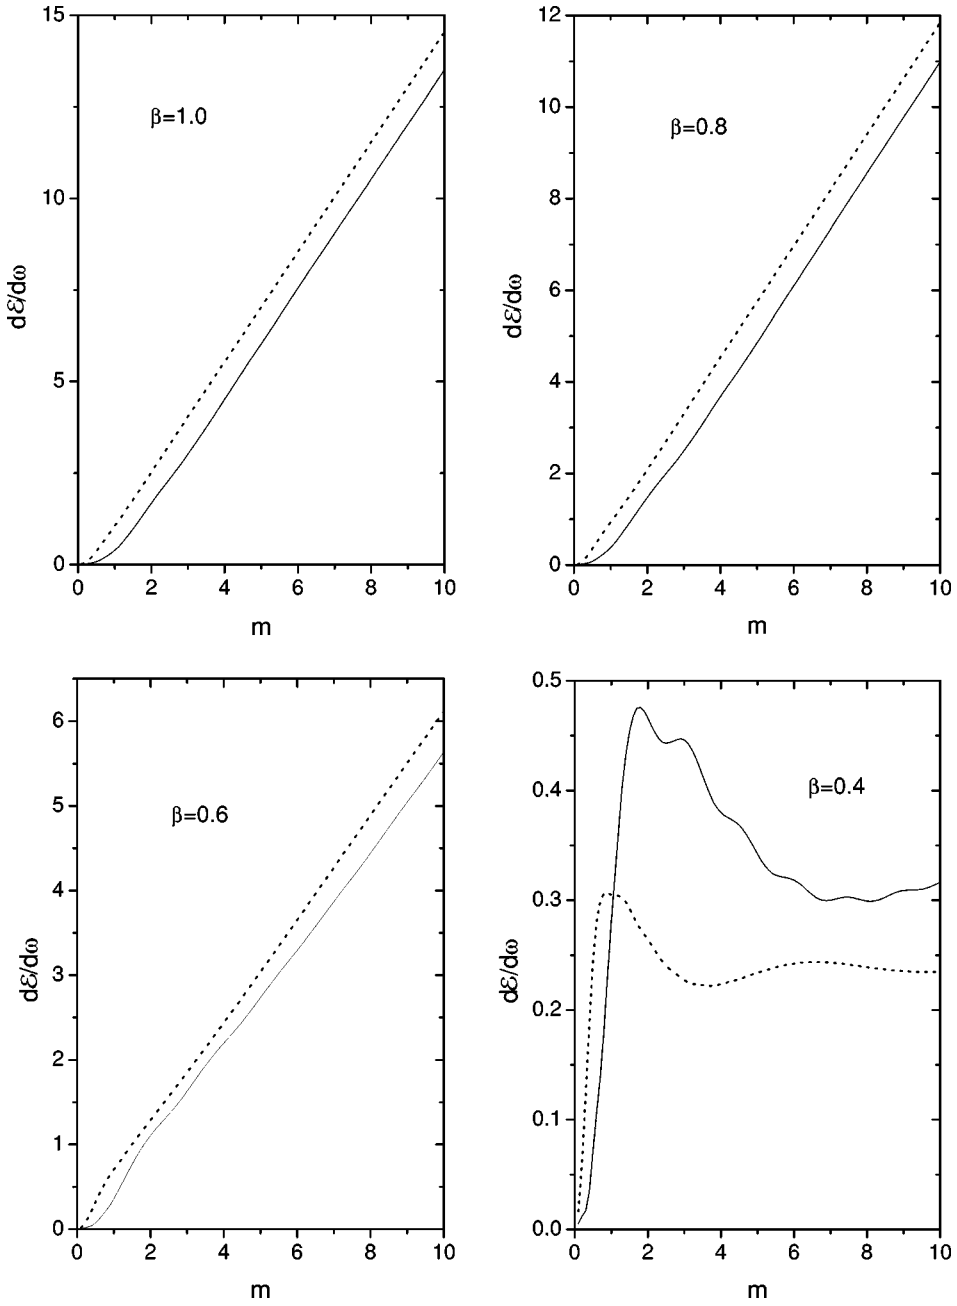

FIG. 14. The same as in Fig. 12 but for $n_2=2$. The dotted curves are the Tamm frequency intensities (3.5) evaluated for $kL=2k(z_0-a)$ and $n=n_2$.

for the charge motion through the metallic sphere (Fig. 7). These newly defined $\tilde{C}_l$ being substituted into (4.7), (4.8), (5.8), and (5.9) give transition radiation intensities. Due to the lack of space and since the observable radiation intensities are the total ones presented in Figs. 2–5 and 7–14, we do not evaluate transition radiation intensities in this paper.

In the physical literature there are semi-intuitive interpretations of the transition radiation and the one arising in the Tamm problem in terms of instantaneous acceleration and deceleration, and in terms of semi-infinite charge motion terminating at one side of the media interface and beginning at the other one. Their insufficiencies (discussed below) prevent us from their applying to the

consideration of VC and transition radiation on the spherical sample. In any case, exact solutions and numerical calculations presented in Secs. IV and V contain all necessary information for the analysis of experimental data.

A. Comment on the transition radiation

1. Interpretation of the transition radiation in terms of instantaneous velocity jumps

Sometimes the transition radiation is interpreted as a charge uniform motion with the velocity v in medium 1, its sudden stop in medium 1 at the border with medium 2, the sudden start of motion in medium 2 and the charge uniform motion in medium 2 with the velocity v (see, e.g., Refs. 18–20). It is suggested that the main contribution to the radiation intensity give the mentioned above instantaneous jumps of the charge velocity. The radiation intensity arising from the charge sudden stop in medium 1 is taken in the form

$$\frac{\mathrm{d}^2\mathcal{E}}{\mathrm{d}\omega\,\mathrm{d}\Omega}=\frac{e^2}{4\pi^2 c}\left[\frac{\vec{\beta}\times\vec{n}_r}{1-n_1(\vec{\beta}\vec{n}_r)}\right]^2, \tag{6.1}$$

where $\vec{\beta}=\vec{v}/c$, $\vec{n}_r$ is the unit radius vector of the observation point and n_1 is the refractive index of the medium 1.

On the other hand, the exact calculations were made in Ref. 21 for the following decelerated motion along the z axis:

$$z(t)=z_1+v_1(t-t_1)-\tfrac{1}{2}a(t-t_1)^2,\quad v(t)=v_1-a(t-t_1),\quad t_1<t<t_2, \tag{6.2}$$

which begins at the moment t_1 at the space point z_1 with the velocity v_1 and ends at the moment t_2 at the space point z_2 with the velocity v_2. The time motion interval t_2-t_1 and deceleration a are easily expressed through z_1, z_2, v_1, and v_2,

$$t_2-t_1=2\frac{z_2-z_1}{v_1+v_2},\quad a=\frac{1}{2}\frac{v_1^2-v_2^2}{z_2-z_1}. \tag{6.2$'$}$$

It was shown in Ref. 21 that for the fixed wavelength λ, the intensity of radiation tends to zero for $k(z_2-z_1)\to 0$ $(k=2\pi/\lambda)$. This certainly disagrees with (6.1) which differs from zero for any motion interval. To clarify the situation, we turn to the derivation of (6.1).

2. The derivation of (6.1)

For simplicity, we consider at first a charge motion in vacuum closely following Landau and Lifshitz treatise.[22] Its authors begin with the equations

$$\vec{H}=(\vec{n}_r\times\vec{E}),\quad \vec{E}=-\frac{1}{c}\dot{\vec{A}},$$

which are valid in the wave zone (the dot above the vector potential $\vec{A}$ means the differentiation over the laboratory time). For the Fourier transform of $\vec{H}$ one gets

$$\vec{H}_\omega=-\frac{1}{2\pi c}\int_{-\infty}^{\infty}(\vec{n}_r\times\dot{\vec{A}})\exp(i\omega t)\mathrm{d}t. \tag{6.3}$$

Now, if $\vec{A}\neq 0$ for $t_1<t<t_2$, then for $\omega(t_2-t_1)\ll 1$ one can set $\exp(i\omega t)\approx 1$, thus obtaining

$$\vec{H}_\omega=-\frac{1}{2\pi c}\int\vec{n}_r\times\frac{\partial\vec{A}}{\partial t}\mathrm{d}t=-\frac{1}{2\pi c}\vec{n}_r\times(\vec{A}_2-\vec{A}_1). \tag{6.4}$$

Here $\vec{A}_2=\vec{A}(t=t_2)$ and $\vec{A}_1=\vec{A}(t=t_1)$. Further, authors of Ref. 22 change $\vec{A}_1$ and $\vec{A}_2$ by the Lienard–Wiechert potentials. This gives

$$\vec{H}_\omega=\frac{e}{2\pi cr}\left[\frac{\beta_2\times n_r}{1-(\vec{\beta}_2\vec{n}_r)}-\frac{\beta_1\times n_r}{1-(\vec{\beta}_1\vec{n}_r)}\right]. \tag{6.5}$$

The radiation intensity per unit frequency and per unit solid angle is

$$\frac{\mathrm{d}^2\mathcal{E}}{\mathrm{d}\omega\,\mathrm{d}\Omega}=cr^2|\vec{H}_\omega|^2=\frac{e^2}{4\pi^2c}\left[\frac{\beta_2\times n_r}{1-(\vec{\beta}_2\vec{n}_r)}-\frac{\beta_1\times n_r}{1-(\vec{\beta}_1\vec{n}_r)}\right]^2. \tag{6.6}$$

Now if the final velocity is zero, (6.6) coincides with (6.1).

3. Resolution of paradox

We rewrite the integral entering into (6.4) in the form

$$\int\frac{\partial\vec{A}}{\partial t}\mathrm{d}t=\int\frac{\partial\vec{A}(t(t'))}{\partial t'}\mathrm{d}t'=\vec{A}_2-\vec{A}_1, \tag{6.7}$$

where t' is the charge retarded (proper) time. The laboratory times t_1 and t_2 being expressed through the retarded times for the one dimensional motion along the z axis are given by

$$t_1=t_1'+\frac{1}{c}[\rho^2+(z-z_1')^2]^{1/2},\quad t_2=t_2'+\frac{1}{c}[\rho^2+(z-z_2')^2]^{1/2}, \tag{6.8}$$

where $z_1'=z'(t_1')$ and $z_2'=z'(t_2')$ are the charge positions at the times t_1' and t_2'. Now, let the charge proper time t' be uniquely related to its position z'. Then, for $z_1'=z_2'$, one gets $t_1'=t_2'$, $t_1=t_2$ and, therefore, $\vec{A}_2=\vec{A}_1$, $\vec{H}_\omega=0$, and $\mathrm{d}^2\mathcal{E}/\mathrm{d}\omega\,\mathrm{d}\Omega=0$.

We illustrate this using the motion law (6.2) as an example [note that t and z entering into (6.2) are the charge proper time t' and its position z']. For this motion law, t' is uniquely related to z',

$$t'=t_1+2v_1\frac{z_2-z_1}{v_1^2-v_2^2}\left[1-\left(1-\frac{z'-z_1}{z_2-z_1}\,\frac{v_1^2-v_2^2}{v_1^2}\right)^{1/2}\right]. \tag{6.9}$$

According to (6.2′), $t_2=t_1$ for $z_2=z_1$. Therefore, $\vec{A}_2=\vec{A}_1$ for $t_2=t_1$ and $\vec{H}_\omega$ given by (6.4) vanishes in the $k(z_2-z_1)\to 0$ limit, in accordance with Ref. 21.

The main assumptions for the vanishing of $\vec{H}_\omega$ are (i) the discontinuous charge motion with the velocity jumps can be viewed as a limiting case of the continuous motion without the velocity jumps when the length along which the velocity changes from v_1 to v_2 tends to zero; (ii) the retarded (proper) charge time is uniquely related to its position.

We conclude the interpretation of the transition radiation in terms of the charge instantaneous acceleration and deceleration at the border of two media is not sufficient if the discontinuous charge motion can be treated as a limiting case of the continuous charge motion. In any case, the discontinuous charge motion cannot be realized in nature: it is the suitable idealization of some continuous charge motion.

In general, $\vec{A}(t_2)$ does not coincide with $\vec{A}(t_1)$ if the charge proper time is not uniquely related to its position. Consider, for example, the immovable elementary (infinitesimal) time dependent source. Then, $\vec{A}(t_2)\neq\vec{A}(t_1)$ and $\vec{H}_\omega\neq 0$. Another possibility to obtain $\vec{A}(t_2)\neq\vec{A}(t_1)$ is to take into account the internal degrees of freedom of a moving charged particle [for example, its spin flip at the fixed space point can give $\vec{A}(t_2)\neq\vec{A}(t_1)$].

4. On the interpretation of the transition radiation in terms of the charge semi-infinite motions

In Refs. 4 and 5, the transition radiation was associated with the charge radiation on the semi-infinite intervals $(-\infty,0)$ and $(0,\infty)$ lying in media 1 and 2, respectively. We analyze this situation using the vector potential as an example. VP corresponding to the charge motion in medium 1 is given by

$$A_z=\frac{e\mu_1}{2\pi c}\int_{-\infty}^{0}\frac{dz'}{R}\exp(i\psi), \tag{6.10}$$

where $\psi=kz'/\beta+k_1R$, $k_1=kn_1$, $R=\sqrt{\rho^2+(z-z')^2}$. In the quasiclassical approximation one gets

$$A_z^{(1)}=\frac{e\mu_1}{2\pi cr}\frac{1}{1-\beta_1\cos\theta} \tag{6.11}$$

for $\beta<\beta_1=1/n_1$. For $\beta>\beta_1$,

$$A_z^{(1)}=(6.11)\quad\text{for}\quad\theta<\theta_1\ ,$$

$$A_z^{(1)}=(6.11)+A_T^{(1)}\quad\text{for}\quad\theta>\theta_1.$$

Here

$$A_T^{(1)}=\frac{e\mu_1}{2\pi c}\exp\left(\frac{i\pi}{4}\right)\sqrt{\frac{2\pi\beta\gamma_1}{kr\sin\theta}}\exp\left[\frac{ikr}{\beta}\left(\cos\theta+\frac{\sin\theta}{\gamma_1}\right)\right],\quad \gamma_1=\frac{1}{\sqrt{|1-\beta_1^2|}},\quad \cos\theta_1=\frac{1}{\beta_1}. \tag{6.12}$$

Since $A_T(1)$ decreases like $1/\sqrt{kr}$, the radiation intensity is large in the $\theta>\theta_1$ angular region.

Similarly, the vector potential corresponding to the charge motion in medium 2 is given by

$$A_z^{(2)}=-\frac{e\mu_2}{2\pi cr}\frac{1}{1-\beta_2\cos\theta}\quad\text{for}\quad\beta<\beta_2=1/n_2. \tag{6.13}$$

For $\beta>\beta_2$,

$$A_z^{(2)}=(6.13)\quad\text{for}\quad\theta>\theta_2,$$

$$A_z^{(2)}=(6.13)+A_T^{(2)}\quad\text{for}\quad\theta<\theta_2.$$

Here

$$A_T^{(2)}=\frac{e\mu_2}{2\pi c}\exp\left(\frac{i\pi}{4}\right)\sqrt{\frac{2\pi\beta\gamma_2}{kr\sin\theta}}\exp\left[\frac{ikr}{\beta}\left(\cos\theta+\frac{\sin\theta}{\gamma_2}\right)\right],\quad \gamma_2=\frac{1}{\sqrt{|1-\beta_2^2|}},\quad \cos\theta_2=\frac{1}{\beta_2}. \tag{6.14}$$

Usually, the terms $A_T^{(1)}$ and $A_T^{(2)}$ are dropped in standard considerations of the transition radiation. Their interference with $A_z^{(1)}$ and $A_z^{(2)}$ given by (6.12) and (6.13), respectively, leads to the oscillations of the radiation intensity in the $\theta>\theta_1$ angular region for the charge semi-infinite motion $(-\infty,0)$ in medium 1, and in the $\theta<\theta_2$ angular region for the charge semi-infinite motion $(0,\infty)$ in medium 2.

A further procedure in obtaining the transition radiation intensities is the evaluation of EMF strengths corresponding to vector potentials in media 1 and 2 and their superposition with corresponding Fresnel coefficients. Sometimes the secondary photon rescatterings at the boundaries of media 1 and 2 (for the dielectric plate) are taken into account.

Since we have at hand the exact solution for the charge moving inside and outside the dielectric or metallic sphere, these tricks are not needed: they are automatically taken into account in closed expressions for radiation intensities.

5. On the physical meaning of $A_T^{(1)}$ and $A_T^{(2)}$ terms

To clarify the physical meaning of $A_T^{(1)}$ and $A_T^{(2)}$ terms, we consider the case when media 1 and 2 are the same. Then, the vector potential corresponding to the infinite motion $(-\infty,\infty)$ reduces to the sum of vector potentials corresponding to semi-infinite motions in media 1 and 2:

$$A_z=A_z^{(1)}+A_z^{(2)}=0$$

for $\beta<1/n$ and

$$A_z=A_T^{(1)}+A_T^{(2)}=\frac{e\mu}{2\pi c}\exp\left(\frac{i\pi}{4}\right)\sqrt{\frac{2\pi\beta\gamma_n}{kr\sin\theta}}\exp\left[\frac{ikr}{\beta}\left(\cos\theta+\frac{\sin\theta}{\gamma_n}\right)\right],\quad \gamma_n=\frac{1}{\sqrt{|1-\beta_n^2|}} \tag{6.15}$$

for $\beta>1/n$. But this is the asymptotic form $(\rho\to\infty)$ of the VC vector potential corresponding to the charge infinite motion in unbounded medium

$$A_z=\frac{e\mu}{\pi c}K_0\left(\frac{k\rho}{\beta\gamma_n}\right)\quad \text{for}\quad \beta<\frac{1}{n}\quad \text{and}\quad A_z=\frac{ie\mu}{2c}\exp\left(\frac{ikz}{\beta}\right)H_0^{(1)}\left(\frac{k\rho}{\beta\gamma_n}\right)\quad \text{for}\quad \beta>\frac{1}{n}.$$

This means that $A_T^{(1)}$ and $A_T^{(2)}$ terms describe the VC radiation for the semi-infinite charge motions in media 1 and 2. This is also confirmed by the exact solution corresponding to the semi-infinite charge motion in dispersion free medium found in Refs. 23 and 24 in the time representation. Indeed, the space regions where the VC radiation differs from zero are just the same where $A_T^{(1)}$ and $A_T^{(2)}$ terms differ from zero.

It is easy to check that the values of $A_z^{(1)}$ and $A_z^{(2)}$ are defined by the boundary point $z'=0$, while the values of $A_T^{(1)}$ and $A_T^{(2)}$ terms are defined by stationary points z' lying in the intervals $(-\infty,0)$ and $(0,\infty)$, respectively.

We see that the interpretation of the transition radiation in terms of semi-infinite motions in the intervals $(-\infty,0)$ and $(0,\infty)$ is sufficient only for $\beta<1/n$. On the other hand, for $\beta>1/n$, the Cherenkov terms $A_T^{(1)}$ and $A_T^{(2)}$ should be taken into account.

B. Comment on the Tamm problem

For the Tamm problem (uniform charge motion in a restricted space interval), the vector potential is given by (3.1). It is easily evaluated in the quasiclassical approximation. For $z<\rho\gamma_n-z_0$ and $z>\rho\gamma_n+z_0$ one gets

$$A_z^{\text{out}}=-\frac{ie\mu\beta}{2\pi ck}\left\{\frac{1}{r_2-\beta_n(z-z_0)}\exp\left[\frac{ik}{\beta}(\beta n r_2+z_0)\right]-\frac{1}{r_1-\beta_n(z+z_0)}\exp\left[\frac{ik}{\beta}(\beta n r_1-z_0)\right]\right\}. \tag{6.16}$$

Here $r_1=\sqrt{\rho^2+(z+z_0)^2}$ and $r_2=\sqrt{\rho^2+(z-z_0)^2}$. Inside the interval $\rho\gamma_n-z_0<z<\rho\gamma_n+z_0$, the vector potential equals

$$A_z^{\text{in}}=A_z^{\text{out}}+A_z^{Ch}, \tag{6.17}$$

where

$$A_z^{Ch}=\frac{e\mu}{2\pi c}\exp\left(\frac{ikz}{\beta}\right)\sqrt{\frac{2\pi\beta\gamma_n}{kr\sin\theta}}\exp\left(i\frac{\pi}{4}\right)\exp\left(\frac{ikr\sin\theta}{\beta\gamma_n}\right).$$

It is seen that A_z^{out} is infinite at $z=\rho\gamma_n\pm z_0$ (this is due to the quasiclassical approximation used). Therefore, the radiation intensity should have maxima at $z=\rho\gamma_n\pm z_0$, with a kind of plateau for $\rho\gamma_n-z_0<z<\rho\gamma_n+z_0$ and a sharp decreasing for $z<\rho\gamma_n-z_0$ and $z>\rho\gamma_n+z_0$. At the observation distances much larger than the motion length

$$r_1-\beta_n(z+z_0)\approx r(1-\beta_n\cos\theta),\quad r_2-\beta_n(z-z_0)\approx r(1-\beta_n\cos\theta),$$

$$\beta_n r_1-z_0=\beta_n r-z_0(1-\beta_n\cos\theta),\quad \beta_n r_2+z_0=\beta_n r+z_0(1-\beta_n\cos\theta).$$

Then,

$$A_z^{\text{out}}=\frac{e\mu\beta}{\pi ckr}\exp(iknr)\frac{\sin[\omega t_0(1-\beta n\cos\theta)]}{1-\beta n\cos\theta},\tag{6.18}$$

that coincides with the Tamm vector potential A_z^T entering into (3.2). Thus, inside the interval $\rho\gamma_n-z_0<z<\rho\gamma_n+z_0$,

$$A_z^{\text{in}}=A_z^T+A_z^{Ch}.\tag{6.19}$$

We observe that infinities of A_z^{out} disappeared due to the approximations involved. It is seen that for $kr\gg1$, A_z^{Ch} and A_z^T behave like $1/\sqrt{kr}$ and $1/kr$, respectively. It follows from this that the radiation intensity in space regions $z>\rho\gamma_n+z_0$ and $z<\rho\gamma_n-z_0$ is described by the Tamm formula (3.4). On the other hand, inside the space region $\rho\gamma_n-z_0<z<\rho\gamma_n+z_0$, the radiation intensity differs appreciably from the Tamm one. In fact, the second term in A_z^{in} is much larger than the first one (A_z^T) for $kr\gg1$ (since they decrease like $1/\sqrt{kr}$ and $1/kr$ for $kr\to\infty$, respectively). It is easy to check that on the surface of the sphere of the radius r, the intervals $z<\rho\gamma_n-z_0$, $\rho\gamma_n-z_0<z<\rho\gamma_n+z_0$ and $z>\rho\gamma_n+z_0$ correspond to angular intervals $\theta>\theta_1$, $\theta_2<\theta<\theta_1$ and $\theta<\theta_2$, where θ_1 and θ_2 are defined by

$$\cos\theta_1=-\frac{\epsilon_0}{\beta_n^2\gamma_n^2}+\frac{1}{\beta_n}\left[1-\left(\frac{\epsilon_0}{\beta_n\gamma_n}\right)^2\right]^{1/2}$$

and

$$\cos\theta_2=\frac{\epsilon_0}{\beta_n^2\gamma_n^2}+\frac{1}{\beta_n}\left[1-\left(\frac{\epsilon_0}{\beta_n\gamma_n}\right)^2\right]^{1/2}.\tag{6.20}$$

Here $\epsilon_0=z_0/r$. For $r\gg z_0$,

$$\theta_1=\theta_c+\frac{\epsilon_0}{\beta_n\gamma_n},\quad \theta_2=\theta_c-\frac{\epsilon_0}{\beta_n\gamma_n},$$

where θ_c is defined by $\cos\theta_c=1/\beta n$. Therefore, inside the angular interval $\theta_2<\theta<\theta_1$ the radiation intensity should have plateau with its height proportional to the observation distance r. In the limit $r\to\infty$, the above θ interval diminishes and for the radiation intensity one gets the δ-type singularity at $\cos\theta=1/\beta n$ (in addition to A_z^T). However, the θ integral from it is finite. Although $\Delta\theta=\theta_1-\theta_2=2\epsilon_0/\beta_n\gamma_n$ is very small for $r\gg z_0$, the length of arc on the observation sphere on

which the radiation intensity differs from the Tamm one is finite: it is given by $2z_0/\beta_n\gamma_n$. It would be interesting to observe this deviation experimentally (there are recent experimental indications for the existence of this plateau[25]).

From the previous consideration it follows that A_z^{Ch} is a part of the Cherenkov shock wave enclosed between straight lines $z=-z_0+\rho\gamma_n$ and $z=z_0+\rho\gamma_n$ with its normal inclined under the angle θ_c towards the motion axis. In the quasiclassical approximation, the stationary point $z'=z-\rho\gamma_n$ of the integral α_T entering in (3.1) lies inside the motion interval $(-z_0,z_0)$ and defines the value of A_z^{Ch}. On the other hand, for the A_z^{out} the stationary point of α_T lies outside the charge motion interval and the value of α_T is defined by initial and final points of the motion interval. Therefore, A_z^{out} is somehow related to the beginning and the end of motion. In Refs. 26 and 27 the radiation intensity in the Tamm problem was associated with the interference of bremsstrahlung shock waves arising from the instantaneous velocity jumps at the beginning and the end of motion. However, if one replaces the instantaneous velocity jumps by the smoothed ones and then tends the width of the transition region (where the velocity smoothly changes) to zero then the contribution of this region to the radiation intensity also tends to zero.[21] There are no velocity jumps for this smoothed motion and, therefore, the radiation intensity in the Tamm problem cannot be attributed to them. However, there are acceleration jumps at the beginning and the end of motion and at the moments when the accelerated motion meets the uniform one. Thus, the above intensity can be still associated with acceleration jumps. To clarify the situation, the Tamm problem with absolutely continuous charge motion (for which the velocity itself and all its time derivatives are absolutely continuous functions of time) was considered in Ref. 28. It was shown that the relatively slow decreasing of the radiation intensity outside the plateau is replaced by its exponential damping. This means that the discontinuities of higher derivatives of the charge velocity contribute to the asymptotic behavior of the radiation intensities as well. Formerly, for the charge motion in vacuum, the exponential damping for all angles was recognized in Refs. 29–32. We conclude: the instantaneous velocity jumps at the beginning and the end of motion do not contribute to the radiation intensity provided they can be viewed as the limiting cases of the smooth charge motion in the limit when the lengths of accelerated (decelerated) pieces of the charge trajectory tend to zero. This means that attempts to interpret the radiation intensity given by the Tamm formula (3.4) in terms of the charge instantaneous acceleration and deceleration are insufficient.

We summarize:

(1) The interpretation of the transition radiation and the Tamm problem in terms of instantaneous acceleration and deceleration is not sufficient;
(2) the usual interpretation of the transition radiation arising when the charge crosses the boundary between two media in terms of semi-infinite charge motions is valid only if $\beta<1/n_1$ and $\beta<1/n_2$. Otherwise, this interpretation should be supplemented by the Cherenkov-type terms;
(3) there is no need in artificial means mentioned in previous two items in the treated exactly solvable case corresponding to the transition and VC radiations on a spherical sample.

VII. CONCLUSION

We briefly review the main results obtained.

(1) The electromagnetic field strengths and angular radiation intensity corresponding to the Tamm problem are developed in terms of Legendre polynomials. The corresponding representation for the frequency distributions is also found.

(2) We found closed expressions for the electromagnetic field arising from the charge motion confined to the dielectric sphere S which is surrounded by another dielectric medium with dielectric properties different from those inside S. It is studied how differences of media properties inside and outside S affect the angular and frequency radiation intensities for various charge velocities. In general, these differences lead to the broadening of the angular spectrum, to the rise of angular intensities at large angles, and to the appearance of oscillations in the frequency spectrum.

(3) It is considered how radiates a charge whose motion begins and terminates in medium 2 and which passes through the dielectric sphere S filled with medium 1 or through the metallic sphere. The evaluated energy flux includes the VC and transition radiations as well as ones originating from the beginning and termination of motion. It is shown that when the medium 2 outside S is vacuum and medium 1 inside S has refractive index n_1 satisfying $\beta n_1 > 1$, the angular and frequency radiation intensities cannot be always interpreted in terms of the Tamm formula (3.4) corresponding to the charge motion inside S (as it is usually believed).

(4) It is proved that the interpretation of the transition radiation in terms of the instantaneous termination of the charge motion in one medium and its instantaneous beginning in the other one is not valid if the above motion with sudden velocity jumps can be considered as a limiting case of the smooth charge motion. It is shown that the interpretation of the transition radiation in terms of semi-infinite motions with instantaneous termination of the charge motion in one medium and with its instantaneous beginning in the other one, should be supplemented with the VC radiation terms. Certainly, these remarks are related only to the interpretation of the transition radiation, not to the exact solutions obtained for the plane interface, e.g., in Refs. 5 and 17.

APPENDIX A

Using (2.3), (2.4), and (3.8) we find that the magnetic vector potential corresponding to Fig. 1 equals

$$A_z = \frac{iek_2\mu_2}{2\pi c} \sum (2l+1) P_l(\cos\theta) h_l(k_2 r) C_l$$

for $r > a$,

$$A_z = \frac{iek_1\mu_1}{2\pi c} \sum (2l+1) P_l(\cos\theta) [j_l(k_1 r) D_l + h_l(k_1 r) J_l^{(1)}(0, z_0)]$$

for $z_0 < r < a$, and

$$A_z = \frac{iek_1\mu_1}{2\pi c} \sum (2l+1) P_l(\cos\theta) [j_l(k_1 r) D_l + h_l(k_1 r) J_l^{(1)}(0, r) + j_l(k_1 r) H_l^{(1)}(r, z_0)]$$

for $r < z_0$. Here we set

$$J_l^{(1)}(x,y) = \int_x^y j_l(k_1 r') f_l(r') \mathrm{d}r', \quad H_l^{(1)}(x,y) = \int_x^y h_l(k_1 r') f_l(r') \mathrm{d}r'.$$

Differentiating A_z, one finds EMF strengths (4.1), (4.2) in which

$$\tilde{C}_l = C_{l-1} + C_{l+1} \quad \text{and} \quad \tilde{D}_l = D_{l-1} + D_{l+1}.$$

Since EMF strengths contain only $\tilde{C}_l$ and $\tilde{D}_l$, the coefficients C_l and D_l entering into electromagnetic potentials are not needed.

APPENDIX B

The magnetic vector potential satisfying equations $(\Delta + k_2^2) A_z = 0$ for $r > z_0$, $(\Delta + k_2^2) A_z = -4\pi\mu_2 j_z / c$ for $a < r < z_0$ and $(\Delta + k_1^2) A_z = -4\pi\mu_1 j_z / c$ for $r < a$ is given by

$$A_z = \frac{iek_2\mu_2}{2\pi c} \sum (2l+1) P_l h_l(k_2 r) \left[C_l \frac{\mu_1}{\mu_2} J_l^{(1)}(0, a) + J_l^{(2)}(a, z_0) \right]$$

for $r > z_0$,

$$A_z=\frac{iek_2\mu_2}{2\pi c}\sum\ (2l+1)P_l\left[h_l(k_2r)C_l\frac{\mu_1}{\mu_2}J_l^{(1)}(0,a)+h_l(k_2r)J_l^{(2)}(a,r)+j_l(k_2r)H_l^{(2)}(r,z_0)\right]$$

for $a<r<z_0$, and

$$A_z=\frac{iek_1\mu_1}{2\pi c}\sum\ (2l+1)P_l(\cos\theta)\left[j_l(k_1r)\frac{\mu_2}{\mu_1}D_lH_l^{(2)}(a,z_0)+h_l(k_1r)J_l^{(1)}(0,r)\right.$$
$$\left.+j_l(k_1r)H_l^{(1)}(r,a)\right]$$

for $r<a$. Here

$$J_l^{(2)}(x,y)=\int_x^y j_l(k_2r')f_l(r')\mathrm{d}r',\quad H_l^{(2)}(x,y)=\int_x^y h_l(k_2r')f_l(r')\mathrm{d}r'.$$

It is convenient to redefine C_l and D_l:

$$C_l'=C_l\frac{\mu_1}{\mu_2}J_l^{(1)}(0,a)+J_l^{(2)}(a,z_0),\quad D_l'=D_l\frac{\mu_2}{\mu_1}H_l^{(2)}(a,z_0).$$

Then,

$$A_z=\frac{iek_2\mu_2}{2\pi c}\sum\ (2l+1)P_lh_l(k_2r)C_l'$$

for $r>z_0$,

$$A_z=\frac{iek_2\mu_2}{2\pi c}\sum\ (2l+1)P_l(\cos\theta)[C_l'h_l(k_2r)-h_l(k_2r)J_l^{(2)}(r,z_0)+j_l(k_2r)H_l^{(2)}(r,z_0)]$$

for $a<r<z_0$, and

$$A_z=\frac{iek_1\mu_1}{2\pi c}\sum\ (2l+1)P_l(\cos\theta)[D_l'j_l(k_1r)+h_l(k_1r)J_l^{(1)}(0,r)+j_l(k_1r)H_l^{(1)}(r,a)]$$

for $r<a$. Differentiating A_z, one recovers EMF strengths (5.1)–(5.3) where

$$\tilde{C}_l=C_{l-1}'+C_{l+1}',\quad \tilde{D}_l=D_{l-1}'+D_{l+1}'.$$

Again, we do not need coefficients C_l and D_l entering into the vector potential since EMF field strengths (and the radiation intensity) depend only on $\tilde{C}_l$ and $\tilde{D}_l$.

Classical transport of charged particles in a magnetic field

Noel Corngold[a)]
Watson Laboratories, California Institute of Technology, Pasadena, California 91125

(Received 8 September 2002; accepted 23 April 2003)

We examine the traditional transport equation for classical, charged particles diffusing in a cold, absorbing medium subject to a uniform magnetic field and in which scattering is isotropic. Steady-state solutions in plane geometry are examined in some detail; we make no expansion about an isotropic angular distribution. Restricting the motion to two dimensions captures most of the interesting features; there is some discussion of the three-dimensional case. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1591994]

I. INTRODUCTION

The motion of ions and electrons in a weakly ionized gas subjected to external electric and magnetic fields is an ancient and ''classical'' problem in kinetic theory.[1,2] The analysis of these systems (''swarms'') is based, almost always, upon a linear ''Boltzmann,'' or transport equation. The equation is treated in its most general form so that one can be as faithful as possible to the experiments. Most often the velocity variation of the distribution function is expressed in terms of a series of tensorial spherical harmonics, and the evolution of the density described in ''hydrodynamic'' and ''nonhydrodynamic'' terms. (Here, the interested reader should consult the impressive publications of Australian physicists.[3–6]) Such expansions—which may be viewed as a generalization of the traditional, Chapman–Enskog treatment of Boltzmann's equation—generate an infinite hierarchy of ''moment-equations,'' a hierarchy which is truncated at some level, for reasons which are physical or practical. This procedure, with its advantages and its limitations, has been part of transport theory almost since its creation. Since these expansions are usually asymptotic, at best, one welcomes comparison with exact solutions of related transport equations which are not trivial.

This paper is concerned with the solution of such a relevant model—it describes the time-independent transport of charged test-particles in a cold medium which scatters isotropically, may capture particles, and is immersed in a uniform magnetic field. Since no electric field is present, the distribution in velocity is simpler, but still interesting. In the solution, the most important dimensionless parameter is ω, the ratio of cyclotron frequency to collision frequency. If one wishes to go beyond treating the analysis as a mathematical exercise, merely, one notes that ω is trivially small for ions in realistic situations, but can be interestingly large for electrons. Then, the (asymptotic) velocity distribution deviates considerably from the isotropic form about which the simplest ''hydrodynamic'' models are centered. Other results are—apart from an array of attractive equations involving Bessel functions—(1) that the magnetic field shatters the famous continuous spectrum associated with the ''one-speed transport equation[7]'' into an infinity of discrete eigenvalues. (We discuss the behavior of these eigenvalues as field and absorption strength are varied; the limit $\omega \to 0$ is quite singular.) (2) The magnetic field induces a flow parallel to the source plane. This ''diamagnetic drift'' is well known to plasma physicists.[8] Here we treat it in some detail. Most important is that none of our results rely upon an assumption of ''small gradients.''

Justifying the irreversible, transport—rather than the reversible, Liouville treatment of a problem in kinetic theory—poses famous and delicate problems. In the case of an isolated and simple gas one justifies mathematically the transition from Liouville to transport by a limiting

a)Electronic mail: nrdc@caltech.edu

process—by invoking the ''Grad-limit.[9]'' To the physicist, this means, roughly, that the gas should be sufficiently dilute for transport theory to be useful. When the system is subject to external fields, matters become more difficult. Recently, a group of scholars[10] has analyzed the limiting process for the Lorentz model—which describes charged particles diffusing through a static array of scatterers—immersed in a magnetic field. Their analysis considers how unusual trajectories—a particle whirling in circular orbit in the space between two scatterers, for example—are to be treated in the construction of the ''correct,'' coarse-grained transport equation. Our paper avoids these difficult issues. We simply study the ''traditional'' transport equation as a mathematical object, acknowledging that it describes the physics correctly in some regime where the magnetic field is not too strong and that often, continuing results obtained from a sanctioned region, say $\omega<1$, into a questionable one, say $\omega\gg 1$, has some value.

Most of the paper is devoted to motion in two dimensions (2D)—in a plane perpendicular to the uniform magnetic field. We give, briefly, expressions for densities and currents in the three-dimensional case as well. In treating the equation, its features and consequences, we allow the strength of the uniform magnetic field to vary arbitrarily. The fact that a steady source of particles in an absorbing medium produces a steady distribution indicates that the traditional equation gives no weight to particles whirling, collisionless in tight circles,

II. ANALYSIS OF A SIMPLE MODEL

We begin with a simple model: noninteracting charged particles of fixed kinetic energy move in a plane perpendicular to an uniform magnetic field. The particles scatter elastically and isotropically from host atoms (''neutrals.'') We are in steady state, there is a plane source ($y-z$ plane) at the origin, and the medium, which is unbounded, may absorb particles. The distribution function for position and velocity, $F(x,\phi)$, depends then upon two variables, and we face the kinetic equation

$$\mu\frac{\partial}{\partial x}F(x,\phi)-\omega\frac{\partial}{\partial\phi}F(x,\phi)=\frac{c}{2\pi}\int_0^{2\pi}\mathrm{d}\phi\,F(x,\phi)-F(x,\phi)+Q(\phi)\,\delta(x). \tag{1}$$

This familiar equation, with $(v\cdot x)=\mu=\cos\phi$, is written in dimensionless variables. The constant speed is taken to be unity, distance is scaled by the total mean-free-path for encounters, time by the corresponding mean-free-time, and ω represents the cyclotron frequency qB/mc divided by the collision frequency. ω may also be seen as the ratio of mean-free-path to Larmor radius. c, the number of secondaries produced per collision, is limited to $1>c\geqslant 0$. As we see later, transport in three dimensions—with plane symmetry—is not that much more difficult.

After Fourier transformation in x we have

$$\mathcal{O}f(k,\phi)=-\omega\frac{\partial}{\partial\phi}f(k,\phi)+(1+ik\mu)f(k,\phi)=\frac{c}{2\pi}\int_0^{2\pi}\mathrm{d}\phi\,f(k,\phi)+Q(\phi) \tag{2}$$

or

$$(\mathcal{O}-c\mathcal{P})f(k,\phi)=Q(\phi).$$

A new notation, Dirac-like, helps. Our operators act in function spaces whose elements are distribution functions $|f\rangle$. and $\langle g|$. There is a complex inner product. Thus,

$$\langle g|f\rangle\equiv\int_0^{2\pi}\mathrm{d}\phi\,g^*(\phi)f(\phi)=\langle f|g\rangle^*$$

and

$$(\mathcal{O}-c\mathcal{P})|f\rangle=|Q\rangle. \tag{3}$$

$\mathcal{P}$ is the projection operator,

$$\mathcal{P}|f\rangle \equiv |a\rangle\langle a|f\rangle, \quad \langle a|a\rangle = 1$$

with

$$|a\rangle = \frac{1}{\sqrt{2\pi}}, \quad \langle a|f\rangle = \int_0^{2\pi} \mathrm{d}\phi \frac{1}{\sqrt{2\pi}} f(\phi).$$

We may also use $|1\rangle = \sqrt{2\pi}|a\rangle$, so that $\langle 1|f\rangle = \int_0^{2\pi} \mathrm{d}\phi\, f(k,\phi)$ gives $n(k)$, the angle-integrated density. The particle currents are

$$\mathcal{J}_{x,y}(k) = \int_0^{2\pi} \mathrm{d}\phi [\cos\phi, \sin\phi] \;\; f(k,\phi).$$

We use the special notation $\mathcal{J}_{x,y}(k) = \langle j_{x,y}|f\rangle$ for the currents.

Two results follow quickly; the solution to the kinetic equation, Eq. (3), is

$$|f\rangle = \frac{1}{\mathcal{O}}|Q\rangle + c\frac{1}{\mathcal{O}}|a\rangle \frac{\langle a|\dfrac{1}{\mathcal{O}}|Q\rangle}{\left[1 - c\langle a|\dfrac{1}{\mathcal{O}}|a\rangle\right]}, \tag{4}$$

and if we take the particularly simple case of an isotropic source of strength $|Q\rangle = |a\rangle$ we find

$$\begin{aligned} |f\rangle &= \frac{1}{\left[1 - c\langle a|\dfrac{1}{\mathcal{O}}|a\rangle\right]} \frac{1}{\mathcal{O}}|a\rangle = \frac{1}{\mathcal{D}(k,c)} \frac{1}{\mathcal{O}}|a\rangle, \\ \langle a|f\rangle &= \frac{1}{\left[1 - c\langle a|\dfrac{1}{\mathcal{O}}|a\rangle\right]} \langle a|\frac{1}{\mathcal{O}}|a\rangle = \frac{1}{\mathcal{D}(k,c)}\langle a|\frac{1}{\mathcal{O}}|a\rangle. \end{aligned} \tag{5}$$

The last equation also states that with unit source, $|Q_1\rangle = 1/2\pi$,

$$n(k) = \frac{1}{\mathcal{D}(k,c)}\langle a|\frac{1}{\mathcal{O}}|a\rangle = \frac{\mathcal{K}(k)}{\mathcal{D}(k,c)} = \frac{\mathcal{K}(k)}{1 - c\mathcal{K}(k)}.$$

There are corresponding expressions for the currents,

$$\mathcal{J}_{x,y}(k) = \frac{1}{\mathcal{D}(k,c)}\langle j_{x,y}|\frac{1}{\mathcal{O}}|a\rangle$$

for source $|Q\rangle = |a\rangle$.

An alternative expression for $\mathcal{J}_x(k)$ appears if we integrate Eq. (1) directly, to get the equation of continuity,

$$\frac{\partial}{\partial x}\mathcal{J}_x(x) + (1-c)n(x) = Q\delta(x).$$

We find

$$ik\mathcal{J}_x(k,c)=\frac{1-\mathcal{K}(k)}{1-c\mathcal{K}(k)}=\frac{\mathcal{D}(k,1)}{\mathcal{D}(k,c)}, \tag{6}$$

for unit source $|Q_1\rangle$. That the various expressions are related by partial integration will be evident later, as will the expression

$$i\mathcal{J}_y(k,c)=\frac{\omega}{2}\frac{1}{\mathcal{D}(k,c)}\frac{\partial}{\partial k}\mathcal{K}(k). \tag{7}$$

The quantity

$$\mathcal{K}(k)=\langle a|\frac{1}{\mathcal{O}}|a\rangle$$

contains the essence of the system, generating the relaxation lengths, for example. This kernel is the Fourier transform of the kernel controlling the Peierls integral equation[11] for $n(x)$ (see the following). We shall refer to $\mathcal{D}(k,c)=1-c\mathcal{K}$ as the dispersion function. This article is concerned with the features of density and current. To get at them, we learn as much as we can about $\mathcal{K}(k)$ and $\mathcal{D}(k,c)$.

A. Evaluating the kernel

Of the several ways to evaluate the kernel; two are particularly helpful. In the first, we make use of the eigen-vectors of the operator $\mathcal{O}$,

$$\mathcal{O}|n\rangle=\lambda_n|n\rangle.$$

One finds

$$|n\rangle=\frac{1}{\sqrt{2\pi}}\exp[in\phi]\exp\left[i\frac{k}{\omega}\sin\phi\right],$$
$$\lambda_n=1-in\omega. \tag{8}$$

The $|n\rangle$ are complete and orthonormal, with the usual complex inner product. The wave number k appears parametrically in the eigenvector but not in the eigenvalue. The $|n\rangle$ form a useful basis for expansion. Since

$$\langle a|n\rangle=\frac{1}{2\pi}\int_0^{2\pi}\mathrm{d}\phi\exp[in\phi]\exp\left[i\frac{k}{\omega}\sin\phi\right]=(-)^nJ_n\left(\frac{k}{\omega}\right)=\langle n|a\rangle. \tag{9}$$

Bessel functions make their expected appearance. A quite straightforward calculation leads then to the first of several expressions for the kernel,

$$\langle a|\frac{1}{\mathcal{O}}|a\rangle=\left[J_0\left(\frac{k}{\omega}\right)\right]^2+2\sum_{n=1}^{\infty}\left[J_n\left(\frac{k}{\omega}\right)\right]^2\Big/(1+n^2\omega^2). \tag{10}$$

(In the following text, we may denote k/ω by κ, which is proportional to the ratio of cyclotron radius to wavelength of the k mode.)

Another straightforward calculation, making use of $\mathcal{J}_{\pm}=\mathcal{J}_x\pm i\mathcal{J}_y$ and recursion relations, leads to Eq. (7) for the transverse current—the ''diamagnetic drift'' of the plasma physicists. We note an alternate derivation ahead.

A more powerful and elastic representation of the kernel stems from an ''algebraic'' method, which is a simplified version of the method of characteristics.

Write

$$\frac{1}{\mathcal{O}}|f\rangle=\int_0^\infty \mathrm{d}t\, e^{-t}e^{-t(A+B)}|f\rangle,$$
$$(A+B)=ik\cos\phi-\omega\frac{\partial}{\partial\phi}=e^{i\kappa\sin\phi}\left(-\omega\frac{\partial}{\partial\phi}\right)e^{-i\kappa\sin\phi}. \tag{11}$$

Multiplication by t and constructing the exponential series gives

$$e^{-t(A+B)}=e^{i\kappa\sin\phi}\exp\left(\omega t\frac{\partial}{\partial\phi}\right)e^{-i\kappa\sin\phi},$$

and we can write, quite generally,

$$\langle g|\frac{1}{\mathcal{O}}|Q\rangle=\int_0^\infty \mathrm{d}t\, e^{-t}\int_0^{2\pi}\mathrm{d}\phi\, g(\phi)^* e^{i\kappa[\sin\phi-\sin(\phi+\omega t)]}Q(\phi+\omega t). \tag{12}$$

In particular, our kernel is

$$\langle a|\frac{1}{\mathcal{O}}|a\rangle=\frac{1}{2\pi}\int_0^\infty \mathrm{d}t\, e^{-t}\int_0^{2\pi}\mathrm{d}\phi\, e^{i\kappa[\sin\phi-\sin(\phi+\omega t)]}, \tag{13}$$

and inversion of the Fourier transform gives the Peierls integral equation which corresponds to Eq. (1). One finds—for an isotropic source—

$$n(x)=\frac{1}{2\pi}\int_{-\infty}^{\infty}\mathrm{d}x'\,\mathcal{K}(x-x')[n(x')+q(x')]$$

with

$$\mathcal{K}(x-x')=\int_0^\infty \mathrm{d}t\, e^{-t}\int_0^{2\pi}\mathrm{d}\phi\,\delta(x-x'+[\sin\phi-\sin(\phi+\omega t)]).$$

After some reduction, using the fact that the integral of a periodic function over its period is unaltered by a shift in the variable of integration, we find

$$\mathcal{K}(x-x')=\frac{1}{1-e^{-4\pi/\omega}}\int_0^{2\pi}\mathrm{d}\theta\int_0^{2\pi}\mathrm{d}\phi\, e^{-2\theta/\omega}\delta\left(\frac{\omega}{2}(x-x')-\sin\theta\sin\phi\right).$$

$\mathcal{K}$ is even, in its argument. In our dimensionless units ω, the ratio of cyclotron frequency to collision frequency is the reciprocal of the ratio of cyclotron radius to mean-free-path. Thus, the constraint expressed by the δ-function, that $|x-x'|\leqslant 2/\omega$, is precisely the statement that the farthest-ranging particle is found at one ''cyclotron-diameter'' from a plane source, having left the source traveling parallel to it. The Peierls' kernel, $\mathcal{K}(x)$, has ''compact support''; it has no exponential tail. Further reduction will be remarked upon later. [See Eq. (24).]

Returning to the kernel, note the limit $\omega\to 0$ when

$$\langle a|\frac{1}{\mathcal{O}}|a\rangle\to\frac{1}{2\pi}\int_0^{2\pi}\mathrm{d}\phi\,\frac{1}{1+ik\cos\phi}=\frac{1}{\sqrt{1+k^2}}. \tag{14}$$

In the field-free case, the kernel and the dispersion function are analytic in a cut, complex-k plane, and spatial relaxation is described by a discrete and a continuous spectrum of relaxation lengths. The Fourier inverse of the kernel,

$$\frac{1}{2\pi}\int_{-\infty}^{\infty} \mathrm{d}k\, e^{ikx}\langle a|\frac{1}{\mathcal{O}}|a\rangle = \frac{1}{\pi}K_0(|x|),$$

expresses the density of uncollided particles as a Bessel function. Another useful limiting expression holds when $\omega \gg 1$. Then Eq. (10) informs us that

$$\langle a|\frac{1}{\mathcal{O}}|a\rangle \to \left[J_0\left(\frac{k}{\omega}\right)\right]^2. \tag{15}$$

The kernel, as expressed by Eq. (13), may be simplified if we expand the exponential, noting that only even powers survive the angle-averaging. One finds that when $n=2m$,

$$\frac{1}{2\pi}\int_0^{2\pi} \mathrm{d}\phi[\sin\phi - \sin(\phi+\omega t)]^n = \binom{2m}{m}\left[\sin\left(\frac{\omega t}{2}\right)\right]^{2m}.$$

Now, two paths are open; one can use

$$\frac{1}{(2m)!}\int_0^{\infty} \mathrm{d}t\, e^{-t}\left(\sin\frac{\omega}{2}t\right)^{2m} = \omega^{2m}\prod_{r=1}^{m}\frac{1}{1+r^2\omega^2},$$

to get the useful series

$$\langle a|\frac{1}{\mathcal{O}}|a\rangle = 1+\sum_{m=1}^{\infty}(-)^m\binom{2m}{m}\left(\frac{k^2}{4}\right)^m\prod_{r=1}^{m}\frac{1}{1+r^2\omega^2}, \tag{16}$$

or eschew the t-integration, recognizing the series as generating the Bessel function J_0, and hence that

$$\mathcal{K}(k) = \langle a|\frac{1}{\mathcal{O}}|a\rangle = \int_0^{\infty}\mathrm{d}t\, e^{-t}J_0\left(2\frac{k}{\omega}\sin\frac{\omega t}{2}\right). \tag{17}$$

(The Appendix contains a shorter derivation of this result.)

Equation (17) may be rearranged by exploiting periodicity, and using

$$\int_0^{\pi}\mathrm{d}\phi\, g(\phi)F(\sin\phi) = \int_0^{\pi/2}\mathrm{d}\phi\left[g\left(\frac{\pi}{2}-\phi\right)+g\left(\frac{\pi}{2}+\phi\right)\right]F(\cos\phi),$$

to get

$$\mathcal{K}(k) = \frac{2}{\omega}\frac{1}{1-e^{-2\pi/\omega}}\int_0^{\pi}\mathrm{d}\phi\, e^{-2\phi/\omega}J_0\left(2\frac{k}{\omega}\sin\phi\right) \tag{18}$$

$$= \frac{2}{\omega}\frac{1}{\sinh\left(\frac{\pi}{\omega}\right)}\int_0^{\pi/2}\mathrm{d}\phi\cosh\left(\frac{2\phi}{\omega}\right)J_0\left(2\frac{k}{\omega}\cos\phi\right), \tag{19}$$

all of which have been found useful. A nice connection with the eigenfunction expansion, Eq. (10), is made via Neumann's addition formula

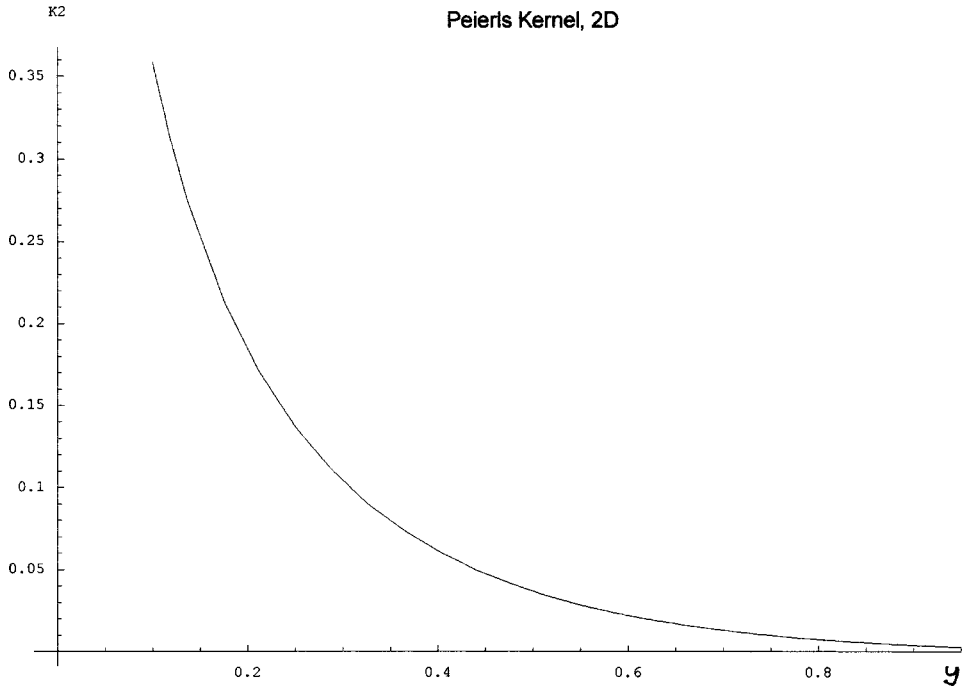

FIG. 1. $\mathcal{K}_2$, the 2D kernel (Peierls) for the integral equation for density, $n(x)$, with $\omega=0.5$, shown as a function of its argument, $y=\omega|x|/2$. The kernel is zero when $y>1$ while $\mathcal{K}_2(1^-)=1/[2\sinh(\pi/\omega)]$.

$$J_0(2t\sin\psi)=J_0(t)^2+2\sum_{n=1}^{\infty}J_n(t)^2\cos 2n\psi$$

in concert with Eq. (17).

Finally, we may Fourier-invert Eq. (19) to get another representation of the Peierls kernel, namely

$$\mathcal{K}(x)=\frac{1}{\pi}\frac{1}{\sinh\left(\frac{\pi}{\omega}\right)}\int_0^{\phi_*(\omega x)}d\phi\,\frac{\cosh\left(\frac{2\phi}{\omega}\right)}{\sqrt{\cos^2\phi-\cos^2\phi_*(\omega x)}},\quad 0<x<\frac{2}{\omega}$$

$$=0,\quad x>\frac{2}{\omega},\tag{20}$$

where ϕ_* is defined through $\cos\phi_*=(\omega/2)x$. (See Fig. 1.)

A final comment for this section: There is still another way to solve our transport equation, Fourier expansion in ϕ. That approach, which is more natural when the scattering is anisotropic, leads to difference equations, to solutions in terms of continued fractions and to the traditional, truncated solutions which we wish to avoid.

B. The complex *k* plane

The Fourier inversion of $\langle a|f\rangle$ and $\langle j_{x,y}|f\rangle$ will be controlled by singularities in the complex k plane. The series in Eq. (16) converges throughout the k plane for all nonzero ω, assuring us that our kernel is an entire function of k. Thus, the only singularities are the zeros of the dispersion function. The magnetic field has shattered the continuous spectrum and it is to the zeros that we turn. They will describe the relaxation lengths which characterize the system. Since their location

depends upon both magnetic field and absorption, $0 \leqslant \omega < \infty$ and $0 \leqslant c \leqslant 1$, the picture, overall, is complicated. But the analysis is eased somewhat by the fact that c and ω occur separately in the dispersion function. We begin by observing the following.

(1) Since $\mathcal{D}$ is a real function of k^2, a complex root of the dispersion equation will generate four zeros in the k plane, of the form $\pm(\xi \pm i\eta)$. Thus we may limit our discussion to a single quadrant of the complex k plane, with the understanding that the other three will be filled by reflection.

(2) If the particle distribution is to be bounded at infinity we expect that $\mathcal{D}$ has no zeros on the real axis of k. (The exceptional case $c=1$ produces a second-order zero at the origin, and is "physical" when the source is moved to infinity—the Milne case.) And inspection of the series for $\mathcal{D}$ shows that when $c=1$, there are no zeros (poles) on the imaginary axis.

(3) *The dominant zero*. When $0<c<1$ there is a dominant zero (pole) on the positive (and the negative) sections of the imaginary axis, where $k=i\eta$. This pole, with its associated residue, describes the dominant, large-x, "asymptotic" behavior of the distribution. There is no other zero on the axis because the kernel is a function of η which increases smoothly. (The zeros which are off-axis and are discussed later, give oscillatory contributions which cannot dominate, asymptotically.) Then, for the dominant zero, we have four regimes as follows.

(i) *Strong field* ($\omega \gg 1$, c arbitrary). Here, Eq. (15) enables us to write

$$\eta_0 = \omega y(c),$$

where

$$1 - cI_0(y)^2 = 0 \tag{21}$$

for all c. (In practice, the estimate is valuable even at $\omega \approx 1$.)

(ii) *Weak absorption* ($1-c \ll 1$, ω arbitrary). Here, the zero lies close to the origin, and the series, Eq. (16) yields

$$\eta_0 \simeq \sqrt{2(1-c)(1+\omega^2)}, \tag{22}$$

a result which emerges from Eq. (21), too. It describes a simple, exponential attenuation, which has been increased by the magnetic field. In the field-free case $\eta_0 = \sqrt{1-c^2}$ exactly.

(iii) *Strong absorption* ($c \to 0$, ω arbitrary). When field is absent the kernel displays branch points, and the zero falls into the branch singularity when $c=0$. With field present, there are no branch points and matters are quite different. The dominant zero moves along the imaginary axis to infinity as $c \to 0$, the dominant relaxation length becoming arbitrarily small. It is the magnetic field, rather than the mean free-path, which is in control. Equation (21) yields an easy estimate, when the field is large,

$$\eta_0 \simeq \frac{\omega}{2} \log\left(\frac{1}{c}\right). \tag{23}$$

In the limit, $c=0$, the distribution becomes that of uncollided particles proceeding from a plane, isotropic source. It is simply the Peierls kernel, Eq. (20). It helps to write the symmetric distribution as ($x>0$)

$$n_0(x)=\mathcal{K}(x)=\frac{1}{\pi}\frac{\cosh\left(\frac{2\phi_*(\omega x)}{\omega}\right)}{\sinh\left(\frac{\pi}{\omega}\right)}\int_0^{\phi_*(\omega x)}d\phi\,\frac{1}{\sqrt{\cos^2\phi-\cos^2\phi_*(\omega x)}}$$

$$+\frac{1}{\pi}\frac{1}{\sinh\left(\frac{\pi}{\omega}\right)}\int_0^{\phi_*(\omega x)}d\phi\,\frac{\cosh\left(\frac{2\phi}{\omega}\right)-\cosh\left(\frac{2\phi_*(\omega x)}{\omega}\right)}{\sqrt{\cos^2\phi-\cos^2\phi_*(\omega x)}},\quad 0<x<\frac{2}{\omega}$$

$$=0,\quad x>\frac{2}{\omega}. \tag{24}$$

The key quantity in its description is $\phi_*(\omega x)$, which descends from $(\pi/2)$ at the plane source to zero at the edge of the distribution. We note further that (a) the second term in Eq. (24) is bounded for all $\phi_*(x)$, vanishing at the edge of the distribution, while (b) the integral appearing in the first term may be transformed into the complete elliptical integral $K(\sin^2\phi_*)$. It diverges, logarithmically at the source plane, and is $(\pi/2)$ at the edge. Thus, the distribution of uncollided particles is discontinuous at its edge. We have the limits (see Fig. 1)

$$n_0(x)=\mathcal{K}(x)\to\frac{1}{2\sinh\left(\frac{\pi}{\omega}\right)},\quad x\to\frac{2}{\omega},$$

$$n_0(x)=\mathcal{K}(x)\sim\frac{1}{\pi}\coth\left(\frac{\pi}{\omega}\right)\log\left(\frac{1}{x}\right)+\cdots,\quad x\to 0. \tag{25}$$

The size of the step-discontinuity vanishes, conveniently, as $\omega\to 0$, while the leading behavior at the source plane coincides with that of the field-free case.

(iv) *Weak field* ($\omega\to 0$, c arbitrary). While the large-ω limit is relatively simple, the small-ω limit is not. Since singularities which are absent when $\omega\neq 0$ appear (at $\eta=\pm 1$) when $\omega=0$, the behavior in the neighborhood of these points cannot be analytic. The simple expression, Eq. (22), does not tell the full story. We begin by studying

$$\mathcal{I}(\phi,\eta)=\cosh\left(\frac{2}{\omega}\phi\right)I_0\left(\frac{2}{\omega}\eta\cos\phi\right),$$

the integrand appearing in Eq. (19), in the regime $(2/\omega)\equiv\lambda\gg 1$. At the limits of integration we have

$$\mathcal{I}(0,\eta)=I_0(\lambda\eta),\quad \mathcal{I}\left(\frac{\pi}{2},\eta\right)=\cosh\left(\lambda\frac{\pi}{2}\right),$$

and behavior will be different in different intervals of η, for absorption may cause η_0 to be large. It is no surprise that $\eta=1$, and $\eta=\pi/2$, play important roles in the analysis.

(a) When $\eta<1$, $\mathcal{I}(\phi,\eta)$ is seen to be an increasing function of ϕ in $(0,\pi/2)$ and the integral is controlled by the behavior of $\mathcal{I}$ near its maximum—at the edge. If we rearrange Eq. (19) to place the maximum at the origin we obtain

$$\mathcal{K}(i\eta)=\frac{1}{2}\int_0^{\Lambda}dt\,I_0\left(\lambda\eta\sin\left(\frac{t}{\lambda}\right)\right)\{(\coth(\Lambda)-1)e^{t}+(\coth(\Lambda)+1)e^{-t}\},$$

where

TABLE I. $1/\eta_0$ is the relaxation length, in units of mean-free-path, for the particle distribution far from its plane source, in the presence of various amounts of capture and various magnetic field strengths.

	Dominant zero, η_0				
ω	$c=0.9$	$c=0.7$	$c=0.5$	$c=0.3$	$c=0.1$
0.25	0.46	0.78	1.0	1.2	1.5
0.5	0.50	0.89	1.2	1.5	2.0
1	0.65	1.2	1.6	2.1	3.0

$$\Lambda=\frac{\pi}{\omega}=\frac{\pi}{2}\lambda.$$

A little consideration shows that when λ is very large we may write

$$\mathcal{K}(i\eta)\simeq\int_0^\infty \mathrm{d}t\, I_0\left(\lambda\eta\sin\left(\frac{t}{\lambda}\right)\right)e^{-t}$$

with exponentially small error, $O(e^{-(1-\eta)\Lambda})$. Then, expansion about $t=0$, aided by the relation

$$\frac{1}{n!}\int_0^\infty \mathrm{d}t\, e^{-t}t^n J_0(kt)=\frac{1}{(1+k^2)^{(n+1/2)}}P_n\left(\frac{1}{\sqrt{1+k^2}}\right) \tag{26}$$

(P_n is the Legendre polynomial) yields

$$\mathcal{K}(i\eta)=\langle a|\frac{1}{\mathcal{O}}|a\rangle=\frac{1}{\sqrt{1-\eta^2}}\left[1-\frac{1}{2}\left(\frac{\omega}{2}\right)^2\eta^2\frac{4+\eta^2}{(1-\eta^2)^3}+\cdots\right], \tag{27}$$

in which the singular nature of the small-ω behavior is displayed.

In the complimentary situation, when $\eta>1$, $\mathcal{I}(\phi,\eta)$ posesses a maximum inside the interval $(0,\pi/2)$. When that sharp maximum dominates the contribution from the edge, expansion produces

$$\mathcal{K}(i\eta)\simeq\frac{1}{\sqrt{\eta^2-1}}\exp\left[\left(\frac{2}{\omega}\right)\left(\sin^{-1}\frac{1}{\eta}-\frac{\pi}{2}+\sqrt{\eta^2-1}\right)\right], \tag{28}$$

as $(2/\omega)\to\infty$. Thus, when $\eta\gg1$ as well,

$$\mathcal{K}(i\eta)\simeq\frac{1}{\eta}\exp\left[\frac{2}{\omega}\left(\eta-\frac{\pi}{2}\right)\right], \tag{29}$$

which leads easily to the estimate

$$\eta_0\simeq\frac{\omega}{2}\log\left(\frac{1}{c}\right)\quad\text{for } c\to0\quad\text{and }\omega\text{ ``small,''} \tag{30}$$

familiar, and in agreement with Eq. (23).

Some dominant zeros are displayed in Table I.

(4) *Transients*. The other zeros, or relaxation lengths, form a complex pattern. They produce transient, oscillating terms in the spatial distribution. We would like a picture of the pattern, and how it alters as the magnetic field is altered. In particular, we are interested in the limit $\omega\to0$. Ultimately, we rely on the summation, numerically, of Eq. (16). But the search for zeros is helped greatly by asymptotic estimates, to which we turn.

(i) *Strong field* ($\omega \gg 1$, $|\kappa|$ arbitrary) ($\kappa \equiv k/\omega$). We begin with the simplest estimate, $\omega \gg 1$, when a different approach yields a familiar result,

$$\mathcal{K}(k) \simeq 1 + \sum_{m=1}^{\infty} \binom{2m}{m} \left(-\frac{k^2}{4\omega^2} \right)^m \frac{1}{(m!)^2} = \frac{2}{\pi} \int_0^{\pi/2} d\phi \, J_0\left(2\frac{k}{\omega} \sin\phi \right) = J_0\left(\frac{k}{\omega} \right)^2. \tag{31}$$

Then, the ω dependence is simple, $k_n = \omega \kappa_n$, where $\kappa_n(c)$ is one of the complex zeros of $1 - cJ_0(\kappa)^2$. (In practice, the estimate is valuable even at $\omega \approx 1$.) Among these, the "higher harmonics" ($|\kappa| \gg 1$) obey

$$\frac{\sin 2x}{2x} e^{2y} = \frac{\pi}{c}, \quad \cos 2x = 2y e^{-2y} \frac{\pi}{c}, \tag{32}$$

where $\kappa = x + iy$. From these, we infer

$$k_n \approx \omega \left\{ n\pi + i\frac{1}{2} \log\left[\left(2n + \frac{1}{2} \right) \frac{\pi^2}{c} \right] \right\}, \quad n = 0,1,2,... \tag{33}$$

for the regime $\omega \gg 1$ and $|k| \gg \omega$. The real parts of the relaxation constants increase only logarithmically, the imaginary parts linearly. Note that the dominant zero is contained here, associated with $c \ll 1$, and behaves as

$$k_0 \simeq i\frac{\omega}{2} \log\left(\frac{1}{c} \right).$$

(ii) *Weak field* is included in the regime ($|\kappa| \gg 1$, ω arbitrary). We begin with the estimate

$$\int_0^{\pi} d\phi \, e^{-2\phi/\omega} J_0(2\kappa \sin\phi) \sim \frac{1}{2\kappa} [1 + e^{-2\pi/\omega} + 2e^{-\pi/\omega} \sin 2\kappa], \quad |\kappa| \to \infty, \tag{34}$$

derived by the method of stationary phase, including end-point corrections. The derivation proceeds with the assumption that k is real, but suggests strongly that the result holds throughout the quadrant when $\mathrm{Re}(\kappa) > 0$. This conjecture is supported by the fact that Eqs. (34) and (31) are identical, namely,

$$\mathcal{K}(k) \approx \frac{i}{2\pi\kappa} e^{-2i\kappa}$$

when their domains overlap, and by numerical experience. We have, then, the approximate dispersion equation,

$$1 + \left(\frac{2e^{-\pi/\omega}}{1 + e^{-2\pi/\omega}} \right) \sin 2\kappa = \frac{\kappa\omega}{c} \left(\frac{1 - e^{-2\pi/\omega}}{1 + e^{-2\pi/\omega}} \right). \tag{35}$$

For field strengths $e^{-2\pi/\omega} \ll 1$, and for κ large, further simplification enables us to write the estimate as

$$\begin{aligned} c\xi &= 1 + \exp\left[\frac{2}{\omega} \left(\eta - \frac{\pi}{2} \right) \right] \sin\frac{2\xi}{\omega}, \\ c\eta &= \exp\left[\frac{2}{\omega} \left(\eta - \frac{\pi}{2} \right) \right] \cos\frac{2\xi}{\omega} \end{aligned} \tag{36}$$

(recall that $k=\xi+i\,\eta$).

When ω is small these expressions are useful when $\eta>\pi/2$. Then, with

$$\eta=\frac{\pi}{2}+\frac{\omega}{2}\,\eta_1(\omega)$$

and

$$\xi=\frac{\omega}{2}\,\xi_1(\omega).$$

the new functions assumed to be regular, we are led to

$$k_n=\omega[n\pi-\xi_*]+i\left[\frac{\pi}{2}+\frac{\omega}{4}\log\left\{1+\left(\frac{\pi c}{2}\right)^2\right\}\right]+o(\omega),$$

where $(n\pi-\xi_*)=2\xi_1(0)$ is the solution to

$$\tan\{2\xi_1(0)\}=-\frac{2}{\pi c},$$

and $n=1,2,...$ is not too large. This pattern of zeros, differing little in their imaginary parts, and marching into a point on the imaginary axis, is roughly (''semiquantitatively'') correct. The numerical values it yields are helpful, even though the true point of accumulation is $k=i$ rather than $k=i(\pi/2)$. Of course, the asymptotic expansion fails on the imaginary axis. There, and in an unknown strip containing it, we return to the expansion used in connection with Eq. (27) to obtain

$$\mathcal{K}(k)=\langle a|\,\frac{1}{\mathcal{O}}\,|a\rangle=\frac{1}{\sqrt{k^2+1}}\left[1-\frac{1}{2}\left(\frac{\omega}{2}\right)^2 k^2\frac{k^2-4}{(k^2+1)^3}+\cdots\right], \tag{37}$$

a complicated series which exhibits clearly the branch-point singularity and omits exponentially small terms (in ω). Before Eq. (37) is used to estimate zeros computation of the winding-number suggests that if we consider a small circular region about $k=i$, the number of zeros (poles) present in the region increases without limit as $\omega\to 0$. Analysis of the series suggests that the zeros do not follow distinct, ray-like paths as they fall into the (nascent) branch point. Rather, their paths merge. For example the first few terms of Eq. (37) yield a pair of roots and a merged path described by

$$k-i\approx\alpha\omega^{2/3}\exp\left(\frac{\pi}{6}i\right)\left[1\mp\frac{1}{3}\sqrt{2\alpha}\;\omega^{1/3}\exp\left(\frac{\pi}{3}i\right)\right], \tag{38}$$

$$\alpha=\frac{1}{4}(5)^{1/3}$$

in the first quadrant. The dependence upon $\omega^{2/3}$ is borne out to a fraction of a percent by numerical calculation, and the $\pi/6$, which characterizes the asymptote, appears to be correct, but the numerical coefficients need improvement. Overall the dependence upon ω is quite singular, for we have omitted exponentially singular factors. See Fig. 2.

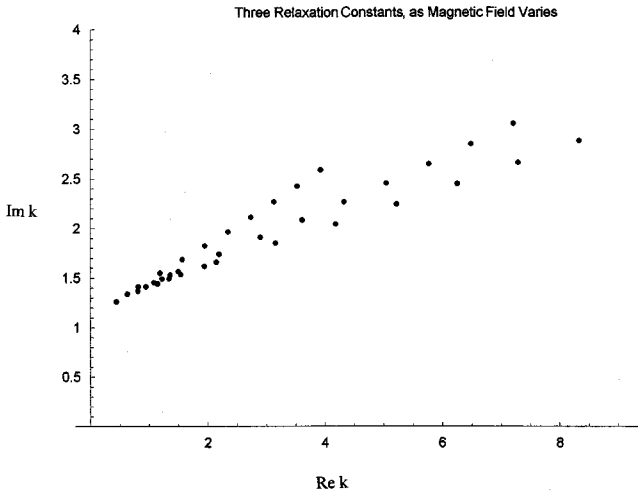

FIG. 2. Three zeros (poles) and their "motion" in the k plane as the magnetic field (ω) is altered. $\omega\to 0$ brings them to $k=i$.

C. Densities and currents

The currents $\mathcal{J}_{x,y}(k)$ may be obtained from the kernel via Eqs. (6) and (7) or directly, from

$$\frac{1}{\sqrt{2\pi}}\langle j_{\pm}|\frac{1}{\mathcal{O}}|a\rangle=\int_0^{\infty}\mathrm{d}t\,e^{-t}\int_0^{2\pi}\frac{\mathrm{d}\phi}{2\pi}e^{\pm i\phi}e^{i\kappa[\sin\phi-\sin(\phi+\omega t)]},$$

which yields, for $|Q_1\rangle$ (unit source),

$$\begin{aligned} i\mathcal{J}_x(k)&=\frac{1}{\mathcal{D}(k,c)}\int_0^{\infty}\mathrm{d}t\,e^{-t}\cos\frac{\omega t}{2}J_1\left(2\kappa\sin\frac{\omega t}{2}\right),\\ -i\mathcal{J}_y(k)&=\frac{1}{\mathcal{D}(k,c)}\int_0^{\infty}\mathrm{d}t\,e^{-t}\sin\frac{\omega t}{2}J_1\left(2\kappa\sin\frac{\omega t}{2}\right), \end{aligned} \tag{39}$$

as symmetric alternatives to Eqs. (6) and (7). Also, there is Eq. (17),

$$n(k)=\frac{1}{\mathcal{D}(k,c)}\int_0^{\infty}\mathrm{d}t\,e^{-t}J_0\left(2\frac{k}{\omega}\sin\frac{\omega t}{2}\right).$$

Equations (6) and (7) follow easily from Eq. (39) by integration by parts.

Since $\mathcal{D}(k,c)$ is even in k, we conclude that the components of current change sign when x is replaced by $-x$. Since $\mathcal{D}(k,c)$ diminishes with increasing k [see Eq. (34)], the behavior of density and current near the source is linked to the behavior of the integrals in Eq. (39). These, which describe the uncollided particles, may be inverted and reduced to

$$\begin{aligned} \mathcal{J}_{0x}(x)&=\frac{1}{\pi}\frac{\cos\phi_*(x)}{\sinh\left(\frac{\pi}{\omega}\right)}\int_0^{\phi_*(x)}\mathrm{d}\phi\,\sinh\left(\frac{2\phi}{\omega}\right)\frac{\tan\phi}{\sqrt{\cos^2\phi-\cos^2\phi_*(x)}}\\ &=\tfrac{1}{2}-(1-c)x\;n_0(x)+\cdots, \end{aligned} \tag{40}$$

$$\mathcal{J}_{0y}(x)=-\frac{1}{\pi}\frac{\cos\phi_*(x)}{\sinh\left(\frac{\pi}{\omega}\right)}\int_0^{\phi_*(x)}d\phi\frac{\cosh\left(\frac{2\phi}{\omega}\right)}{\sqrt{\cos^2\phi-\cos^2\phi_*(x)}}$$

$$=-\frac{\omega}{2}x\,n_0(x) \tag{41}$$

near the source-plane. For the behavior (''asymptotic'') far from the plane, we turn to inversion by contour integration to get

$$\mathcal{J}_y(x)=-\frac{\omega}{2c}\sum_n e^{ik_nx},$$

$$\mathcal{J}_x(x)=-\left(\frac{1-c}{c}\right)\sum_n\frac{1}{k_nD_n}e^{ik_nx}, \tag{42}$$

$$n(x)=\frac{i}{c}\sum_n\frac{1}{D_n}e^{ik_nx},$$

with $D_n\equiv(\partial/\partial k)D(k_n,c)$. Though the summation is over all zeros in the upper half-plane, we are most interested in the contribution from the dominant zero. Note that the equation of continuity is satisfied, ''mode by mode,'' and observe the strangely simple expression for $\mathcal{J}_y(x)$, as well as the singular behavior at $x=0$.

The transverse current, $\mathcal{J}_y(x)$, which is zero at the source plane, grows as one proceeds away. The ratio $\mathcal{J}_y(x)/\mathcal{J}_x(x)$ is then of some interest. The ratio assumes the value $\frac{1}{2}[k_0D_0/(1-c)]\omega$ asymptotically. One may compute the quantity easily in two limiting cases. In the first, very weak capture, $c\gg1-c$, the ratio is simply $(-\omega)$. In the second, very high frequency, $\omega\gg1$ [see Eqs. (16) and (31)] the ratio is $(-\omega\mathcal{F}(c))$, where

$$\mathcal{F}(c)=\frac{\sqrt{c}}{1-c}\kappa_0J_1(\kappa_0),\quad J_0(\kappa_0)=\frac{1}{\sqrt{c}}. \tag{43}$$

Diffusion: $(k_0=i\eta_0=\omega\kappa_0)$. The question of diffusion and diffusion constant may be viewed in two ways. One can note that far from the source the density follows $n_{xx}+k_0^2n=0$, an equation suggesting steady-state diffusion with diffusion coefficient

$$\mathbb{D}_{xx}=\frac{(1-c)}{\eta_0^2}.$$

More generally,

$$\mathbb{D}_{xx}=\mathbb{D}_{yy}=\frac{(1-c)}{\eta_0^2},\quad \mathbb{D}_{yx}=-\mathbb{D}_{xy}=\frac{\omega}{2k_0}\frac{\partial}{\partial k}\mathcal{D}(k,\omega)|_{k_0}, \tag{44}$$

the tensor components depending upon field strength and capture. This view is surely more helpful to the experimenter than is the traditional attitude that ''Fick's law'' holds throughout, that there is everywhere a proportionality between density gradient and current. In fact, the law holds only when spatial variations are so gentle (''long-ranged'') that only the lowest powers in an expansion in k need be retained. Then, Eq. (16) leads to

$$\begin{pmatrix} \mathcal{J}_x \\ \mathcal{J}_y \end{pmatrix} = -\frac{1}{2}(ik)\frac{1}{1-c}\frac{1}{1+\omega^2}\begin{pmatrix} 1 \\ -\omega \end{pmatrix}, \tag{45}$$

describing ''classical'' anisotropic diffusion, with diffusion tensor

$$\mathbb{D}_{ij} = \frac{1}{2}\frac{1}{1+\omega^2}\begin{pmatrix} 1 & \omega \\ -\omega & 1 \end{pmatrix}. \tag{46}$$

This simple picture, found in most textbooks, displays a ''normal'' diffusion, inhibited by the magnetic field, and transverse diffusion, induced by the field. The tensor multiplication may also be written

$$\mathbb{D}\cdot\nabla n = \frac{1}{2}\frac{1}{1+\omega^2}[1-\omega\hat{z}\times]\nabla n.$$

The two treatments differ little when capture is almost negligible and k_0 is small. The case of large field (''high frequency'') is accessible through Eqs. (16) and (31) when Eq. (44) yields

$$\mathbb{D}_{yx} = -\mathbb{D}_{xy} = -\frac{1}{\omega\sqrt{c}}\frac{J_1(\kappa_0)}{\kappa_0}.$$

Thus, for fixed capture, the transverse diffusion is—again—inhibited by the magnetic field when the field is large. D_{yx} rises, proportionally to ω when ω is small, reaches some peak value, then decreases, as $1/\omega$.

D. The distribution in angle

The angular distribution in the dominant, asymptotic mode is of particular interest. In the notation of Eq. (44) that quantity, $F_\infty(x,\phi)$, is

$$F_\infty(x,\phi) = \frac{i}{D_0}e^{ik_0x}\Phi_0(\phi)$$

with

$$\Phi_0(\phi) = \frac{1}{2\pi}\int_0^\infty \mathrm{d}t\, e^{-t}\exp\left(i\left(\frac{k_0}{\omega}\right)[\sin\phi - \sin(\phi+\omega t)]\right) \tag{47}$$

for unit source. The transient modes have a similar appearance. One of the many possible rearrangements brings us to the convenient form,

$$\Phi_0(\phi) = \frac{1}{2\pi\omega}\frac{1}{1-e^{-2\pi/\omega}}e^{(1/\omega)\mathcal{F}(\phi)}\int_\phi^{\phi+2\pi}\mathrm{d}\alpha\, e^{-(1/\omega)\mathcal{F}(\alpha)} \tag{48}$$

with $\mathcal{F}(\phi) = \phi - \eta_0\sin\phi$ $[k_0 = i\eta_0(\omega,c)]$. And there is always the differential equation

$$-\omega\frac{\partial}{\partial\phi}z(\phi) + (1-\eta_0\cos\phi)z(\phi) = \frac{1}{2\pi}$$

which, when solved (numerically) under the condition that $z(\phi) = z(\phi+2\pi)$, yields a function proportional to $\Phi_0(\phi)$.

Once again, the question of $\eta_0 < 1$ or $\eta_0 > 1$ enters. In the former case $\mathcal{F}(\phi)$ is positive and increasing, in the latter, not so, and one encounters more dramatic behavior. Analytical information

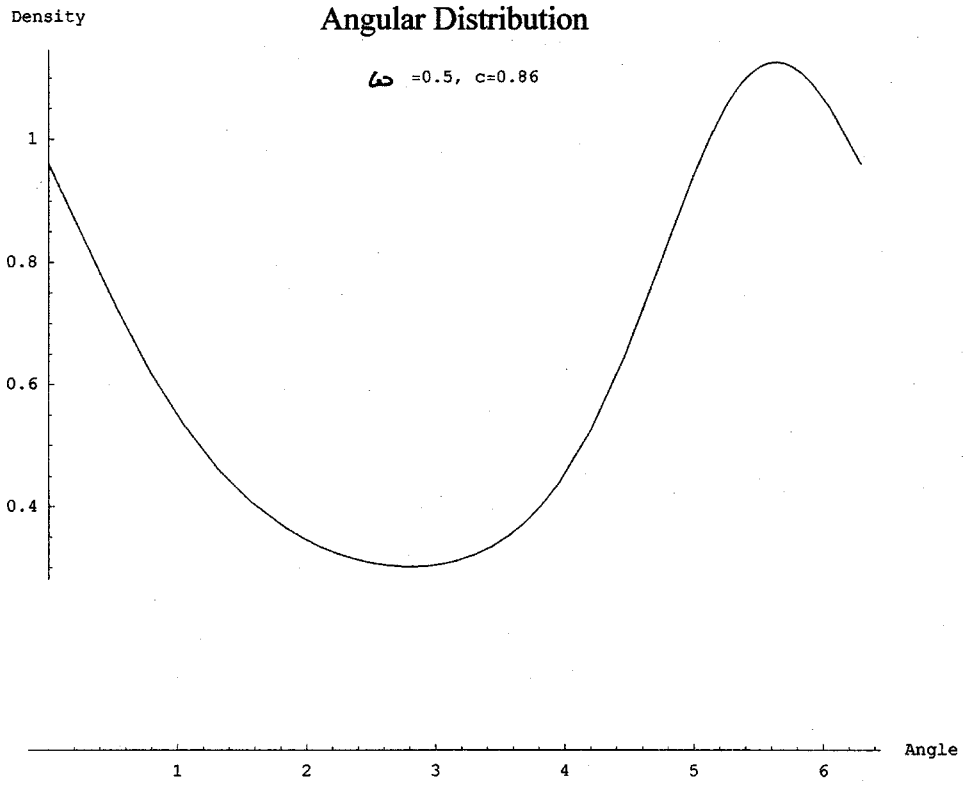

FIG. 3. Asymptotic angular distribution (2D) for $\omega=0.5$, $c=0.86$. Arbitrary normalization. Capture moderate, field strong.

is available when ω is small, when familiar ideas from ''asymptotics'' enter.[12] For example, as $\omega\to 0$ the dominant contribution from the integral in Eq. (48) comes from the interval where $\mathcal{F}(\alpha)$ is minimum. In the case $\eta_0<1$ the minimum is at $\alpha=\phi$ and expansion about that (edge-) value yields

$$\Phi_0(\phi)=\frac{1}{2\pi}\,\frac{1}{(1-\eta_0\cos\phi)}\left[1-\omega\,\frac{\eta_0\sin\phi}{(1-\eta_0\cos\phi)^2}+\cdots\right],$$

precisely the ''outer expansion'' of the solution to the differential equation. Since the outer solution satisfies the boundary condition, there is no need for a boundary layer. This simple expression displays an interesting feature of the angular distribution—a small peak centered at a small angle. The disturbance, vanishing with ω, generates the transverse current.

When $\eta_0>1$ the situation is different. $\mathcal{F}(\alpha)$ is oscillatory, and has a single minimum, at $0\leqslant\phi_*<\pi/2$ where $\cos\phi_*=(1/\eta_0)$. In a subinterval of $(-\pi<\phi\leqslant\pi)$, namely, $(\phi_{**}<0<\phi<\phi_*)$, where $\mathcal{F}(\phi_{**})=\mathcal{F}(\phi_*)$, the minimum lies inside the integration of Eq. (48) and produces boundary layer behavior. $\Phi(\phi)$ rises rapidly, proportional to $\exp[(1/\omega)(\mathcal{F}(\phi)-\mathcal{F}(\phi_*))]$ then falls and passes to the nonexponential ''outer''-behavior for the remainder of the interval. These features are displayed in Figs. 3 and 4. Clearly, these angular distributions are not represented well by an expansion-in-angle that is near-isotropic. The distributions associated with $\eta_0>1$ become quite singular in the limit of vanishing field—the continuum limit.

E. Transport in three dimensions (3D)

Since the key features are captured in the 2D case, we treat 3D briefly. We remain with plane symmetry. Then, the modifications are relatively minor. It is convenient to use two sets of angle variables. In one, the x axis is the polar axis and the polar and azimuthal angles are denoted (θ,ψ);

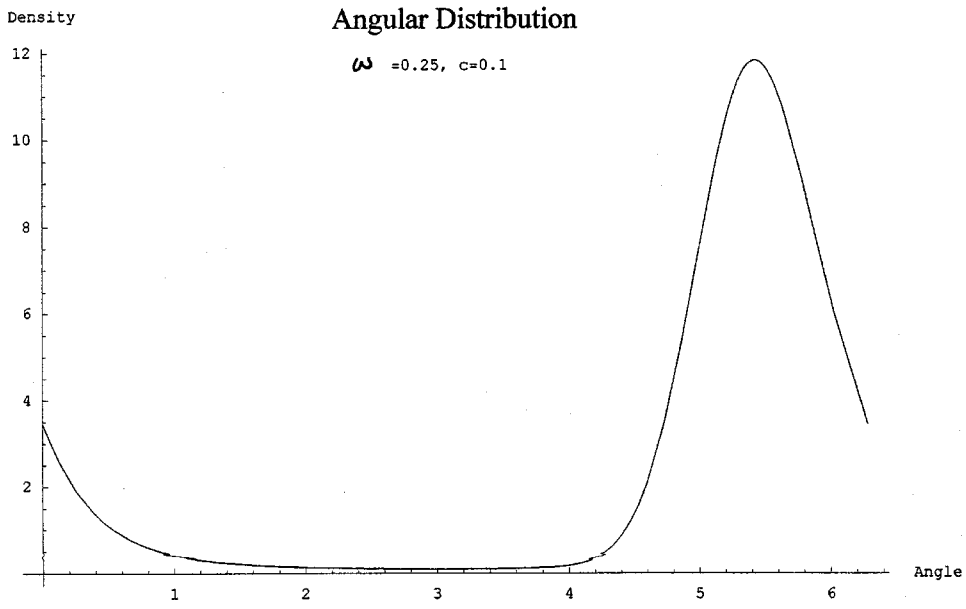

FIG. 4. Asymptotic angular distribution (2D) for $\omega=0.25$, $c=0.1$. Arbitrary normalization. Capture very strong, field moderate.

in the other, the z axis, to which the field is parallel, is the polar axis and the angles are (χ,ϕ). The streaming portion of the transport equation is altered only in that "$\mu=\cos\phi$" is replaced by $\mu=\sin\chi\cos\phi$. Since χ enters the equation only "parametrically," it may be absorbed through much of the subsequent calculation by simply replacing the Fourier transform variable "k" by $k_\perp=k\sin\chi$. The density is now a function of two angles, (χ,ϕ). The in-scattering term is altered through the replacement,

$$\frac{1}{2\pi}\int_0^{2\pi} d\phi \rightarrow \frac{1}{4\pi}\int d\Omega = \frac{1}{4\pi}\int_0^{2\pi} d\phi \int_0^{\pi} d\chi \sin\chi.$$

The vector space is now a space of functions defined on the unit sphere, and we may use (θ,ψ) or (χ,ϕ) in place of the variable, ϕ. The inner product is now

$$\langle g|f\rangle \equiv \int d\Omega\, g^*(\Omega) f(\Omega) = \langle f|g\rangle^*$$

and the ubiquitous

$$\langle \phi|a\rangle = \frac{1}{\sqrt{2\pi}}, \quad \langle a|f\rangle = \int_0^{2\pi} d\phi \frac{1}{\sqrt{2\pi}} f(\phi)$$

become

$$\langle \Omega|a\rangle = \frac{1}{\sqrt{4\pi}}, \quad \langle a|f\rangle = \int d\Omega \frac{1}{\sqrt{4\pi}} f(\Omega).$$

With these reinterpretations, most of the equations of the 2D case may be carried over, easily, to 3D, turning Bessel functions into spherical Bessel functions. We begin with the kernel,

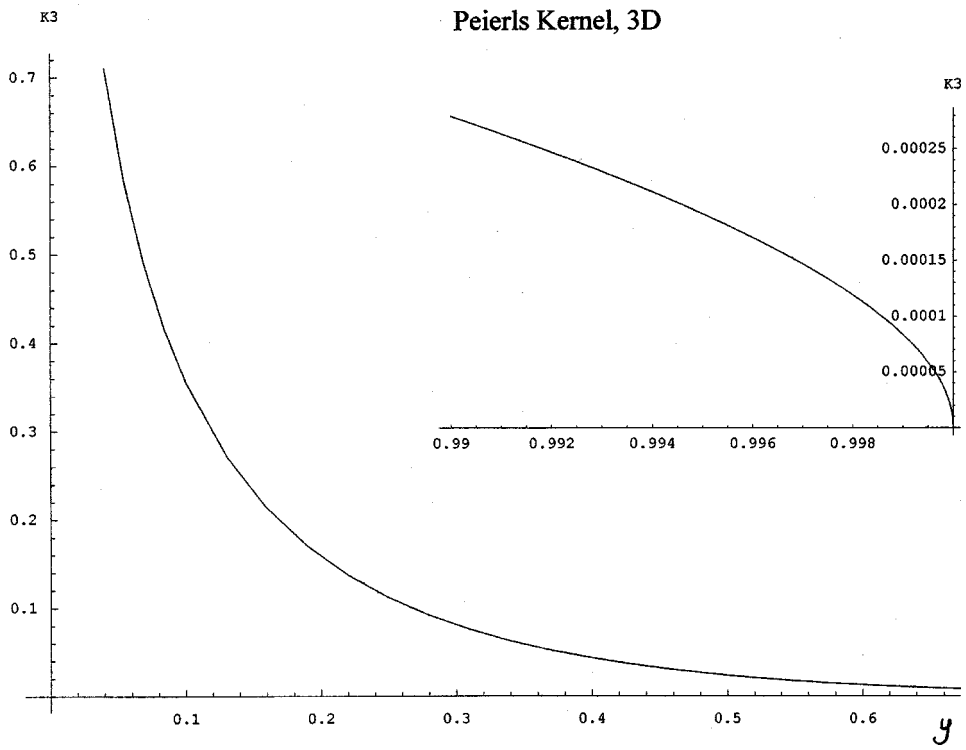

FIG. 5. $\mathcal{K}_3$, the 3D kernel (Peierls) for the integral equation for density, $n(x)$, with $\omega=0.5$, shown as a function of its argument, $y=\omega|x|/2$. The kernel is zero when $y\geqslant 1$.

$$\langle a|\frac{1}{\mathcal{O}}|a\rangle \to \frac{1}{4\pi}\int_0^\infty \mathrm{d}t\, e^{-t}\int \mathrm{d}\Omega\, e^{i\kappa_\perp[\sin\phi-\sin(\phi+\omega t)]}$$
$$=\int_0^\infty \mathrm{d}t\, e^{-t}\frac{1}{2}\int_0^\pi \mathrm{d}\chi \sin\chi \;\; J_0\left(2\kappa\sin\frac{\omega t}{2}\sin\chi\right). \tag{49}$$

Here, and in the discussion of currents, the relation

$$\int_0^{\pi/2}\mathrm{d}\chi \sin^{n+1}\chi \;\; J_n(z\sin\chi)=j_n(z),$$

between ordinary and spherical Bessel functions is useful. Then,

$$\mathcal{K}_3(k,\omega)\equiv\langle a|\frac{1}{\mathcal{O}}|a\rangle=\int_0^\infty \mathrm{d}t\, e^{-t}j_0\left(2\kappa\sin\frac{\omega t}{2}\right)=\frac{2}{\omega}\frac{1}{\sinh\left(\frac{\pi}{\omega}\right)}\int_0^{\pi/2}\mathrm{d}\phi\cosh\left(\frac{2\phi}{\omega}\right)j_0\left(2\frac{k}{\omega}\cos\phi\right), \tag{50}$$

with $j_0(z)=\sin z/z$.

Upon expansion to produce a power series in k, one finds

$$\mathcal{K}_3(k,\omega)=\left[1+\sum_{m=1}^{\infty}\frac{(-k^2)^m}{2m+1}\prod_{r=1}^{m}\frac{1}{1+r^2\omega^2}\right]. \tag{51}$$

Setting $\omega=0$ gives the familiar logarithm of the field-free case, and expanding for small ω in the manner given earlier [e.g., Eqs. (27) and (37)] yields the singular and asymptotic sequence

$$\mathcal{K}_3(k,\omega)=\frac{1}{2ik}\log\frac{1+ik}{1-ik}+\frac{1}{3}\omega^2\frac{k^2}{(k^2+1)^3}+\cdots+\text{exponentially small terms.} \tag{52}$$

The regime $\omega\gg 1$ is dealt with best via the series, Eq. (49), giving

$$\mathcal{K}_3(k,\omega)\asymp\frac{\omega}{2k}\int_0^{2k/\omega}\mathrm{d}z\,J_0(z). \tag{53}$$

These expressions are helpful in determining the zeros of $\mathcal{D}_3(k,\omega,c)$, which, like its predecessor, is entire-in-k. The behavior of these zeros is quite similar to their 2D counterparts. Turning to the picture in x coordinates, we note that the Peierls kernel may be obtained by Fourier-inverting Eq. (49) to get a pretty, ''3-Sine'' formula for the even function,

$$\mathcal{K}_3(x-x',\omega)=\frac{1}{1-e^{-4\pi/\omega}}\int_0^{2\pi}\mathrm{d}\theta\int\mathrm{d}\Omega\,e^{-2\theta/\omega}\delta\left(\frac{\omega}{2}(x-x')-\sin\theta\sin\phi\sin\chi\right). \tag{54}$$

Comments made earlier about its compact support continue to hold. On the other hand, we may Fourier-invert Eq. (50) to get quite a different compact form,

$$\mathcal{K}_3(x,\omega)=\frac{1}{2\sinh\left(\dfrac{\pi}{\omega}\right)}\int_0^{\phi_*(\omega x)}\frac{\mathrm{d}\phi}{\cos\phi}\cosh\frac{2\phi}{\omega} \tag{55}$$

($\cos\phi_*=(\omega/2)x$, and $|(\omega/2)x|<1$). In fact, $\mathcal{K}_3$ may be shown to vanish with vertical tangent. (See Fig. 5.) That this rather peculiar expression does become the familiar exponential integral when $\omega\to 0$ may be seen by setting

$$\phi=\left(\frac{\pi}{2}-\psi\right),$$

expanding the cosh, and passing to the limit.

Currents. We have, generally,

$$\mathcal{J}_{x,y,z}(k)\equiv\mathcal{J}(k)=\langle j|\frac{1}{\mathcal{O}}|Q\rangle+\frac{c}{\mathcal{D}(k,c)}\langle j|\frac{1}{\mathcal{O}}|a\rangle\langle a|\frac{1}{\mathcal{O}}|Q\rangle. \tag{56}$$

When the source is isotropic, and normalized to $\sqrt{4\pi}$,

$$\mathcal{J}(k)=\frac{1}{\mathcal{D}(k,c)}\langle j|\frac{1}{\mathcal{O}}|a\rangle, \tag{57}$$

and we discuss the numerator of this expression,

$$\frac{1}{\sqrt{4\pi}}\langle j_{x,y}|\frac{1}{\mathcal{O}}|a\rangle=\frac{1}{4\pi}\int_0^\infty\mathrm{d}t\,e^{-t}\int\mathrm{d}\Omega\sin\chi[\cos\phi,\sin\phi]e^{i\kappa_\perp[\sin\phi-\sin(\phi+\omega t)]}, \tag{58}$$

$$\frac{1}{\sqrt{4\pi}}\langle j_z|\frac{1}{\mathcal{O}}|a\rangle=\frac{1}{4\pi}\int_0^\infty \mathrm{d}t\, e^{-t}\int \mathrm{d}\Omega\cos\chi e^{i\kappa_\perp[\sin\phi-\sin(\phi+\omega t)]}$$

$$=\int_0^\infty \mathrm{d}t\, e^{-t}\frac{1}{2}\int_0^\pi \mathrm{d}\chi\sin\chi\cos\chi J_0\left(2\kappa\sin\chi\sin\frac{\omega t}{2}\right)=0,\quad \text{by symmetry.} \tag{59}$$

Thus, quite generally,

$$\mathcal{J}_z(k)=\langle j_z|\frac{1}{\mathcal{O}}|Q\rangle,$$

an expression which is, at first sight, puzzling, for the current appears to be independent of capture. A moment's thought convinces one of its correctness, and that J_z is, in any case, trivial. We merely note that with isotropic scattering, a beam becomes distributed isotropically at the first collision. After that collision, only a density gradient will drive a current. But in our problem, there are no gradients in the z direction; J_z exists only in the interval from birth to first collision when the value of "c" is irrelevant. This argument holds for particles immersed in an arbitrary external field that is independent of z. The z current is carried only by uncollided particles. Adding a bit of anisotropy to the scattering changes the result significantly.

The current components, $\mathcal{J}_{x,y}(k)$, are simply the weighted χ average of their counterparts in two dimensions, Eq. (39). The connection between ordinary and spherical Bessel functions then gives the concise result,

$$i\mathcal{J}_x(k)=\frac{1}{\mathcal{D}_3(k,c)}\int_0^\infty \mathrm{d}t\, e^{-t}\cos\frac{\omega t}{2}\; j_1\left(2\kappa\sin\frac{\omega t}{2}\right),$$

$$-i\mathcal{J}_y(k)=\frac{1}{\mathcal{D}_3(k,c)}\int_0^\infty \mathrm{d}t\, e^{-t}\sin\frac{\omega t}{2}\; j_1\left(2\kappa\sin\frac{\omega t}{2}\right), \tag{60}$$

for currents in three dimensions.

Angular distributions. Expressions for the angular distribution associated with dominant and transient modes may be obtained easily. One simply replaces k_0 with $k_0\sin\chi$ in Eq. (47). The distributions are then symmetric with respect to the $(x-y)$ plane and fixing a value of χ is equivalent to selecting one of the 2D distributions we have described earlier. As χ decreases from its in-plane value of $\pi/2$, the effective η_0 diminishes and the corresponding distribution is smoother. Overall, angular distributions in 3D appear to be smoother than those in 2D.

One can proceed further with details of the 3D case, in a manner similar to that of 2D but it is clear that the 2D case displays almost everything that is interesting about the problem. The next step should be an attack upon the time-dependent problem, which is simple enough after Laplace-transform, but whose inversion is a complicated matter.

ACKNOWLEDGMENTS

The author is grateful for a friendly and helpful correspondence with Professor R. E Robson and Professor K. Kumar, during the early phase of this research.

APPENDIX

An alternative, easier way to evaluate the key quantity,

$$\langle a|\frac{1}{\mathcal{O}}|a\rangle=\frac{1}{2\pi}\int_0^\infty \mathrm{d}t\, e^{-t}\int_0^{2\pi}\mathrm{d}\phi\, e^{i\kappa[\sin\phi-\sin(\phi+\omega t)]}$$

is to notice that $[\sin\phi-\sin(\phi+\omega t)]=-2\sin(\omega t/2)\cos(\phi+\omega t/2)$, and that the replacement of $(\phi+\omega t/2)$ by ϕ does not alter the value of the integral. The expression

$$\langle a|\frac{1}{\mathcal{O}}|a\rangle=\int_0^\infty \mathrm{d}t\, e^{-t}J_0\left(2\kappa\sin\frac{\omega t}{2}\right)$$

follows at once. In fact, evaluation of the matrix element in the expression for the current induced by an isotropic source

$$J_{x,y}(k)=\frac{1}{\mathcal{D}(k)}\langle j_{x,y}|\frac{1}{\mathcal{O}}|a\rangle,$$

$$\frac{1}{\sqrt{2\pi}}\langle j_{x,y}|\frac{1}{\mathcal{O}}|a\rangle=\frac{1}{2\pi}\int_0^\infty \mathrm{d}t\, e^{-t}\int_0^{2\pi}\mathrm{d}\phi[\cos\phi,\sin\phi]e^{i\kappa[\sin\phi-\sin(\phi+\omega t)]}$$

is made easy by the same approach. The change of variable $(\phi+\omega t/2)\rightarrow\phi$ and integration by parts produces the results noted earlier.

The three-body problem with an inverse square law potential

Lidia Jiménez-Lara[a] and Eduardo Piña[b]

(Received 2 April 2003; accepted 14 April 2003)

We study the motion of three masses in a plane interacting with a central potential proportional to $1/r^2$ using the coordinates introduced recently by Piña. We show that this problem with four degrees of freedom (three angles and a distance related to the inertia moment of the system in these coordinates) is partially separable, and can be reduced to a problem with two degrees of freedom (two angles) with a new constant of motion. We find a symmetry of reflection (an involution) for this system and we use the symmetry lines to find periodic orbits in the angular coordinates. These orbits will not be periodic in general on the whole phase space because the coordinate of distance type grows as t when $t\to\infty$ and it is unbounded. However, if the inertia moment of the system remains constant, they will be periodic on the whole phase space. © *2003 American Institute of Physics.*

I. INTRODUCTION

We consider three masses $m_1 \geqslant m_2 \geqslant m_3$ moving in a plane and interacting with a central potential k/r^2, k constant. Poincaré studied this problem at the end of the 19th century[1] and he showed by the minimum action principle that there exist periodic orbits for this problem. Sbano[2] consider Newtonian-type potentials k/r^n when the total angular momentum vanishes, and he proves the existence of a periodic orbit. We use the coordinates introduced in Ref. 3 in the way of Ref. 4 to show that for a potential k/r^2 there is an extra constant of motion that allows us to separate the motion of the total inertia moment. We then introduce appropriate dimensionless variables in order to reduce the number of parameters, and we give a global description of the total inertia moment variable. We then reduce the problem to an equivalent two degrees of freedom one with a constant of motion, and we obtain a symmetry of involution. By means of the symmetry lines of the problem we find explicitly periodic orbits.

The main idea introducing the new coordinates is to choose the origin of coordinates at the center of mass, and to select the frame of principal axes of the three particles. Since the motion is in a plane, it is sufficient to take into account only one rotation angle ψ (instead of three Euler angles) in order to transform from the principal axes frame to the inertial one. Two distances R_1 and R_2 (associated with the two independent inertia moments), and an extra angle σ are defined in these coordinates. In the Appendix we show explicitly the change of coordinates from the six coordinates (x_i, y_i), $i=1,2,3$ to the four generalized coordinates ψ, R_1, R_2, σ and the relation of the last three with the distances between particles.

II. EQUATIONS OF MOTION

The Hamiltonian $\mathcal{H}=T+V$ of these problem results in[5]

$$\mathcal{H}=\frac{1}{2\mu}\left(P_1^2+P_2^2+\frac{(R_1^2+R_2^2)(P_\sigma^2+P_\psi^2)+4R_1R_2P_\sigma P_\psi}{(R_1^2-R_2^2)^2}\right)-\frac{k}{2}\left(\frac{1}{r_{23}^2}+\frac{1}{r_{13}^2}+\frac{1}{r_{12}^2}\right),$$

[a]Electronic mail: lidia@xanum.uam.mx
[b]Electronic mail: pge@xanum.uam.mx

where $\mu=\sqrt{(m_1 m_2 m_3)/(m_1+m_2+m_3)}$, P_i, $i=1,2,\sigma,\psi$ are the canonical momenta, r_{jl}, $j,l=1,2,3$ are the distances between m_j and m_l, k is a constant and the two independent inertia moments are related with R_1 and R_2 by $I_1=\mu R_1^2$ and $I_2=\mu R_2^2$. Note that if $R_1=R_2$, the Hamiltonian is not well defined, because the change of variables is not well defined there, then we will avoid those values.

It is convenient to change the variables R_1 and R_2 for the polar variables R, θ,

$$R_1=R\cos\theta,$$

$$R_2=R\sin\theta$$

with $R\in\mathbb{R}^+$, $\theta\in\mathbb{S}^1$. Now $\mu R^2=I$ is the inertia moment of the system, $I=\Sigma_{i=1}^3 m_i\mathbf{r}_i^2$. The Hamiltonian goes over to

$$\mathcal{H}=\frac{1}{2\mu}\left(P_R^2+\frac{P_\theta^2}{R^2}+\frac{(P_\sigma^2+P_\psi^2)+2\sin 2\theta P_\sigma P_\psi}{R^2\cos^2 2\theta}\right)-\frac{k}{2}\left(\frac{1}{r_{23}^2}+\frac{1}{r_{13}^2}+\frac{1}{r_{12}^2}\right),$$

where the distances between particles r_{jl} become

$$\begin{pmatrix} r_{23}^2 \\ r_{13}^2 \\ r_{12}^2 \end{pmatrix}=\mathbf{B}\,R^2\begin{pmatrix} \cos^2\theta\sin^2\sigma+\sin^2\theta\cos^2\sigma \\ \cos^2\theta\cos^2\sigma+\sin^2\theta\sin^2\sigma \\ -\cos 2\theta\sin 2\sigma \end{pmatrix}, \tag{1}$$

with $\mathbf{B}$ being the constant dimensionless matrix, depending only on the masses, given in the appendix, Eq. (A8). If we define the dimensionless distances $s_{ij}=r_{ij}/R$, divide (1) by R^2 and simplify, we obtain

$$\begin{pmatrix} s_{23}^2 \\ s_{13}^2 \\ s_{12}^2 \end{pmatrix}=\mathbf{B}\begin{pmatrix} (1-\cos 2\sigma\cos 2\theta)/2 \\ (1+\cos 2\sigma\cos 2\theta)/2 \\ -\sin 2\sigma\cos 2\theta \end{pmatrix}, \tag{2}$$

and then the Hamiltonian results in

$$\mathcal{H}=\frac{P_R^2}{2\mu}+\frac{1}{2\mu R^2}\left(P_\theta^2+\frac{(P_\sigma^2+P_\psi^2)+2\sin 2\theta P_\sigma P_\psi}{\cos^2 2\theta}-\mu k\left[\frac{1}{s_{23}^2}+\frac{1}{s_{13}^2}+\frac{1}{s_{12}^2}\right]\right). \tag{3}$$

The equations of motion derived from this Hamiltonian function have three constants of motion: the energy with the value E,

$$\mathcal{H}=T+V=E, \tag{4}$$

the angular momentum with the value p_ψ,

$$P_\psi=\mu R^2[\dot{\psi}-\sin 2\theta\dot{\sigma}]=p_\psi, \tag{5}$$

and a third constant,

$$\mathcal{K}=\frac{P_\theta^2}{2}+\frac{P_\sigma^2+P_\psi^2+2\sin 2\theta P_\sigma P_\psi}{2\cos^2 2\theta}-\frac{\mu k}{2}\left[\frac{1}{s_{23}^2}+\frac{1}{s_{13}^2}+\frac{1}{s_{12}^2}\right]=K. \tag{6}$$

III. SEPARATION OF VARIABLES

The Hamiltonian (3) is separable in t, ψ, and R variables, with constants of separation $\mathcal{H}=E$, $P_\psi=p_\psi$ and $\mathcal{K}=K$, respectively. The Hamiltonian reduces to

$$\mathcal{H}=\frac{P_R^2}{2\mu}+\frac{\mathcal{K}}{\mu R^2}, \tag{7}$$

then the $R(t)$ variable can be solved independently of the other ones by using the first integrals $\mathcal{H}=E$ and $\mathcal{K}=K$ with the solution

$$\mu R^2=2Et^2+At+B, \tag{8}$$

A, B constants of integration.

For the angular variables the Hamilton equations are given by

$$-\frac{\partial\mathcal{H}}{\partial\beta}=-\frac{1}{\mu R^2}\frac{\partial\mathcal{K}}{\partial\beta}=\frac{dP_\beta}{dt},$$

$$\frac{\partial\mathcal{H}}{\partial P_\beta}=\frac{1}{\mu R^2}\frac{\partial\mathcal{K}}{\partial P_\beta}=\frac{d\beta}{dt}$$

with $\beta=\theta,\sigma,\psi$. These equations suggest that we introduce a new time rescaled by R^{-2} to obtain Hamilton equations, with $\mathcal{K}$ the ''Hamiltonian'' of a reduced system without the R variable. Before doing this, we introduce dimensionless variables in order to reduce the number of parameters.

IV. DIMENSIONLESS VARIABLES

We simplify the study of this problem introducing dimensionless variables denoted by a prime. This reduces the study to a few cases depending on whether E or K are equal or different from zero.

We first define

$$\mathcal{K}'=\frac{\mathcal{K}}{\mu k},\quad P_i'=\frac{P_i}{\sqrt{\mu k}},\quad i=\theta,\sigma,\psi,$$

where we are assuming an attractive potential, i.e., $k>0$, but this is not restrictive. Equation (6) becomes

$$\mathcal{K}'=\frac{P_\theta'^2}{2}+\frac{P_\sigma'^2+P_\psi'^2+2\sin 2\theta P_\sigma' P_\psi'}{2\cos^2 2\theta}+\mathcal{V}(\theta,\sigma), \tag{9}$$

where the ''potential'' $\mathcal{V}$ is

$$\mathcal{V}(\theta,\sigma)=-\frac{1}{2}\left[\frac{1}{s_{23}^2}+\frac{1}{s_{13}^2}+\frac{1}{s_{12}^2}\right],$$

and the dimensionless square distances are given by (2). Now we consider the energy equation (7) with two cases.

(1) $E\neq 0$. Now let

$$\mathcal{H}'=\frac{\mathcal{H}}{|E|},\quad P_R'=\frac{P_R}{\sqrt{\mu|E|}},\quad R'=R\sqrt{\frac{|E|}{k}},\quad t'=t\frac{|E|}{\sqrt{\mu k}}, \tag{10}$$

be the dimensionless Hamiltonian, momentum, distance, and time, respectively. Then we have only two values for $\mathcal{H}'=\pm 1$, depending on whether E is positive or negative. The first integral of energy reduces to

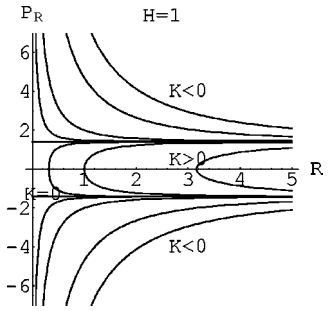

FIG. 1. Motion on the (R, P_R) plane for $\mathcal{H}=1$, $\mathcal{K}\in\mathbb{R}$.

$$\mathcal{H}'=\frac{P_R'^2}{2}+\frac{\mathcal{K}'}{R'^2}=\pm 1\,. \tag{11}$$

(2) $E=0$. We define $R_0=R(0)$ and

$$\mathcal{H}'=\frac{\mathcal{H}R_0^2}{k},\quad P_R'=\frac{P_R R_0}{\sqrt{\mu k}},\quad R'=\frac{R}{R_0},\quad t'=\frac{t}{R_0^2}\sqrt{\frac{k}{\mu}}. \tag{12}$$

Then the energy equation is the same as that in the $E\neq 0$ case but now it has the numerical value zero,

$$\mathcal{H}'=\frac{P_R'^2}{2}+\frac{\mathcal{K}'}{R'^2}=0\,, \tag{13}$$

and then

$$P_R'=\pm\frac{\sqrt{-2\mathcal{K}'}}{R'},$$

with $\mathcal{K}'\leqslant 0$.

In this way, we have to consider essentially three cases for the energy: $\mathcal{H}'=-1$, $\mathcal{H}'=0$ and $\mathcal{H}'=1$. From now on, we will work with the dimensionless variables but we drop the prime in order to make easier the notation.

V. SOLUTION OF THE *R* VARIABLE

As we have shown in Sec. IV, the dimensionless energy equation (11) or (13) gives the solution for the R variable

$$\mathcal{H}=\frac{P_R^2}{2}+\frac{\mathcal{K}}{R^2} \tag{14}$$

with $\mathcal{H}=\pm 1$ in case (1) and $\mathcal{H}=0$ in case (2). Solving for P_R^2 we have

$$\mathcal{H}R^2\geqslant\mathcal{K}$$

then the total inertia moment must be greater or equal to $\mathcal{K}/\mathcal{H}$. In Figs. 1, 2, and 3 we show the projection of the phase portrait on the (R, P_R) plane when $\mathcal{H}=1$, $\mathcal{H}=0$ and $\mathcal{H}=-1$, respectively. Now we consider these three values separately.

(a) $\mathcal{H}=1$. From Eq. (14), we see that $\mathcal{K}\in\mathbb{R}$. When $\mathcal{K}=0$, the solution has constant momentum $P_R=\pm\sqrt{2}$. The R variable comes from infinity, and then the system goes to total collision R

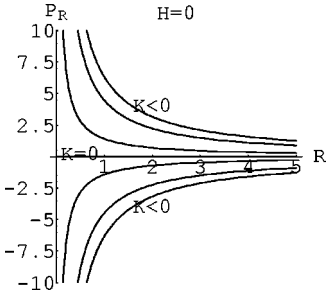

FIG. 2. Motion on the (R, P_R) plane for $\mathcal{H}=0$, $\mathcal{K}\leqslant 0$.

$=0$, or the system comes from total collision and then R escapes to infinity hyperbolically. Note that $R\to\infty$ means that at least two of the particles escape to infinity. This solution gives the asymptote that divides the other two cases $\mathcal{K}>0$ or $\mathcal{K}<0$. If $\mathcal{K}>0$, the inertia moment comes from infinity with $P_R<0$, reaches a minimum value at $R=\sqrt{K}$ when $P_R=0$, and then escapes to infinity with $P_R>0$ (hyperbolic solutions). If $\mathcal{K}<0$, then the system goes out from total collision and escapes to infinity with $P_R>0$, or comes from infinity and goes to total collision. See Fig. 1.

(b) $\mathcal{H}=0$. Then we have that $\mathcal{K}\leqslant 0$. If $\mathcal{K}=0$, all the solutions are equilibrium points. Then, if we find periodic solutions in the angular variables when $\mathcal{K}=0$, they will be periodic also in R if we put $\mathcal{H}=0$. If $\mathcal{K}<0$, the system goes out from total collision and escapes to infinity with $P_R=0$ (parabolic solutions), or comes from infinity and goes to total collision. See Fig. 2.

(c) $\mathcal{H}=-1$. Then $\mathcal{K}<0$ and all the solutions come from total collision, reach a maximum value of the inertia moment at $R=\sqrt{-K}$, and then return to total collision. See Fig. 3.

VI. THE ANGULAR MOTION

We have seen that the R variable can be separated and the study of this problem reduced to a few cases: (a) $\mathcal{H}=1$, $\mathcal{K}\in\mathbb{R}$; (b) $\mathcal{H}=0$, $\mathcal{K}\leqslant 0$; (c) $\mathcal{H}=-1$, $\mathcal{K}\in\mathbb{R}^-$ (remember we are using the dimensionless variables of Sec. IV dropping the primes). At any rate, the Hamilton equations for the angular variables result in

$$-\frac{\partial\mathcal{H}}{\partial\beta}=-\frac{1}{R^2}\frac{\partial\mathcal{K}}{\partial\beta}=\frac{dP_\beta}{dt}, \tag{15}$$

$$\frac{\partial\mathcal{H}}{\partial P_\beta}=\frac{1}{R^2}\frac{\partial\mathcal{K}}{\partial P_\beta}=\frac{d\beta}{dt}, \tag{16}$$

with $\beta=\theta,\sigma,\psi$. These equations suggest that we define a new (dimensionless) time

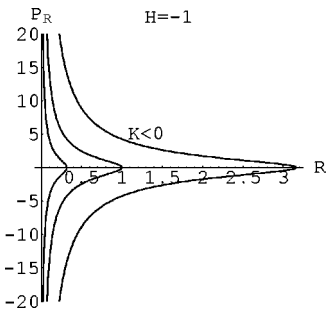

FIG. 3. Motion on the (R, P_R) plane for $\mathcal{H}=-1$, $\mathcal{K}<0$.

$$d\tau = \frac{dt}{R^2}$$

and consider $\mathcal{K}$ as a "Hamiltonian," with τ its canonical coordinate

$$\frac{dP_\beta}{d\tau} = -\frac{\partial \mathcal{K}}{\partial \beta},$$

$$\frac{d\beta}{d\tau} = \frac{\partial \mathcal{K}}{\partial P_\beta},$$

where $\beta = \theta, \sigma, \psi$.

As P_ψ is a first integral, we will assume it to be a constant parameter with value p_ψ in all the calculations. Coordinate ψ can be ignored until the other coordinates are known as functions of time, then the quadrature for ψ can be used to obtain the complete solution

$$\dot{\psi} = \frac{p_\psi + \sin 2\theta P_\sigma}{\mu R^2 \cos^2 2\theta}. \tag{17}$$

This quadrature reduces the number of variables from three to two. From now on, $P_\psi = p_\psi$ will be an extra constant parameter.

For θ and σ variables we obtain

$$\begin{aligned} \frac{dP_\theta}{d\tau} &= -\frac{2(P_\sigma^2 + p_\psi^2 + 2\sin 2\theta P_\sigma p_\psi)\tan 2\theta}{\cos^2 2\theta} - \frac{2P_\sigma p_\psi}{\cos 2\theta} - \frac{\partial \mathcal{V}}{\partial \theta}, \\ \frac{dP_\sigma}{d\tau} &= -\frac{\partial \mathcal{V}}{\partial \sigma}, \\ \frac{d\theta}{d\tau} &= P_\theta, \\ \frac{d\sigma}{d\tau} &= \frac{P_\sigma + \sin 2\theta p_\psi}{\cos^2 2\theta}. \end{aligned} \tag{18}$$

This Hamiltonian system is not defined at $\theta = \pm \pi/4, \pm 3\pi/4$, because the change of variables is not well defined there. Furthermore, the potential $\mathcal{V}(\theta, \sigma)$ is a function of 2θ and 2σ. Thus the dominium of σ and θ is $\sigma \in [0, \pi)$ and $\theta \in (-\pi/4, \pi/4) \cup (\pi/4, 3\pi/4)$.

We have reduced the original problem with four degrees of freedom and Hamiltonian (3) to a two degrees of freedom problem with Hamiltonian $\mathcal{K}$ and a parameter p_ψ.

VII. SYMMETRIES AND POINCARÉ MAPS

The Hamiltonian system obtained by (3) is invariant under the involution

$$(R, \theta, \sigma, \psi, P_R, P_\theta, P_\sigma, p_\psi, t) \to (R, -\theta, \sigma, -\psi, -P_R, P_\theta, -P_\sigma, p_\psi, -t).$$

Upon restricting it to two degrees of freedom and calling it I_0, we get

$$I_0(\theta, \sigma, P_\theta, P_\sigma, \tau) = (-\theta, \sigma, P_\theta, -P_\sigma, -\tau).$$

Let $\Pi = \{(\theta, \sigma) : \theta \in (-\pi/4, \pi/4) \cup (\pi/4, 3\pi/4)$ and $\sigma \in [0, \pi)\}$ and $\Omega = \{(\theta, \sigma, P_\theta, P_\sigma) : (\theta, \sigma) \in \Pi, (P_\theta, P_\sigma) \in \mathbb{R}^2\}$ be the configuration and phase space in the reduced problem, respectively. Let $\mathcal{E} = \{x \in \Omega : \mathcal{K} = K\}$, $K \in \mathbb{R}$ be the level of constant "energy." We introduce a Poincaré section $\Sigma = \{x \in \mathcal{E} : \theta = 0\}$ and the Poincaré map $T : \Sigma \to \Sigma$ induced by the Hamiltonian flow. We observe

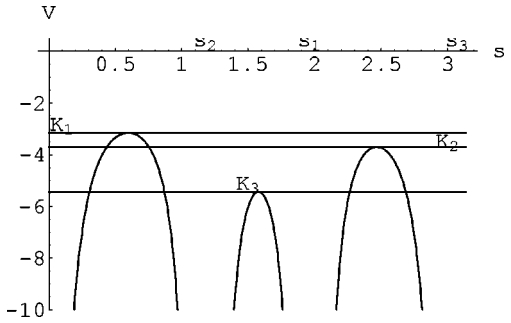

FIG. 4. The potential $\mathcal{V}(0,\sigma)$ (we used s instead of σ in the graph) for $m_1=3$, $m2=2$, $m_3=1$, and $p_\psi=0$. We also show its maximum values $K_1=-3.1561$, $K_2=-3.7003$, and $K_3=-5.4352$, and the values $\sigma_1=1.963\,49$, $\sigma_2=1.178\,09$, $\sigma_3=3.070\,64$ where a double collision takes place and the potential tends to $-\infty$.

that $I_0\Sigma=\Sigma$, i.e., the Poincaré section is invariant under the involution I_0. From Eq. (9) with $\theta=0$ we see that every point in Σ and their iterations with T must be in the interior of the region

$$P_\sigma^2 \leqslant 2K-2\mathcal{V}(0,\sigma)-p_\psi^2, \tag{19}$$

We next fix the values $p_\psi=0$, $m_1=3$, $m_2=2$, and $m_3=1$ to show some numerical results. The vectors **a** and **b** become $\mathbf{a}=(0.377\,172,-0.533\,402,-0.064\,712\,5)$ and $\mathbf{b}=(0.156\,230,0.220\,942,-0.910\,574)$; then relation (19) implies $K\geqslant\mathcal{V}(0,\sigma)$. In Fig. 4 we plot $\mathcal{V}(0,\sigma)$. The three values $\sigma_1=1.963\,495$, $\sigma_2=1.178\,097$, and $\sigma_3=3.070\,644$ correspond to the double collisions $s_{23}=0$, $s_{13}=0$ and $s_{12}=0$ on the Σ section, respectively, where $\mathcal{V}(0,\sigma_i)\to-\infty$, $i=1,2,3$. The potential has three maximum values $K_1=-3.156\,102$, $K_2=-3.700\,327$, and $K_3=-5.435\,221$. For values $K>K_1$, all the values of σ are allowed in the Poincaré region. If $K_1>K>K_2$, there is a forbidden region of σ. If $K_2>K>K_3$, there are two forbidden regions and if $K<K_3$, there are three forbidden regions in the Poincaré region.

The Poincaré maps for $\mathcal{K}=-1,0$ do not seem to have islands. In Fig. 5 the Poincaré map for $\mathcal{K}=10$ is shown, where two islands are evident. For this value of $\mathcal{K}$ there are stable periodic orbits at the center of the islands.

In what follows, symmetrical periodic orbits will be found.

VIII. PERIODIC ORBITS

A survey of the state of the art on the theory of reversible dynamical systems and the results on symmetrical periodic orbits is given in Ref. 6. Here we use the symmetry lines to find periodic orbits. Let $\Gamma_0=\{x\in\Sigma: I_0x=x\}=\{x\in\Sigma: P_\sigma=0\}$ be the set of invariant points of I_0, called the

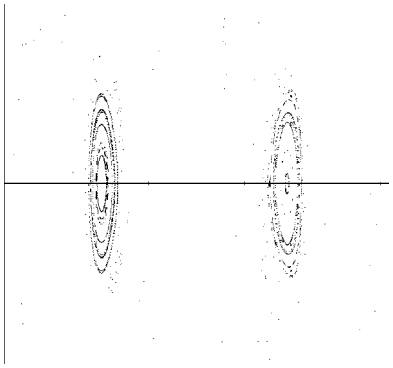

FIG. 5. Poincaré map for $m_1=3$, $m2=2$, $m_3=1$, $p_\psi=0$, and $\mathcal{K}=10$. The horizontal axis is $\sigma\in[0,\pi]$, and the vertical one is $P_\sigma\in[-\pi,\pi]$.

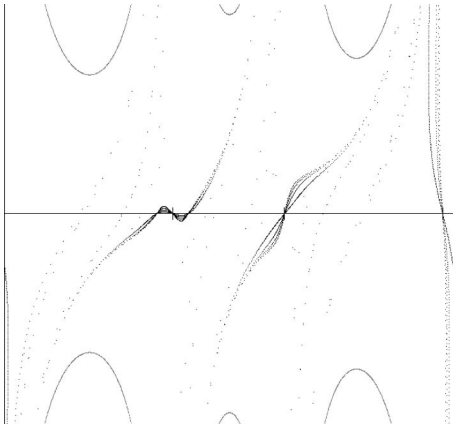

FIG. 6. Γ_0, Γ_2, Γ_4, Γ_6, and Γ_8 symmetry lines for $m_1=3$, $m2=2$, $m_3=1$, $p_\psi=0$, and $\mathcal{K}=-1$. The horizontal axis is $\sigma\in[0,\pi]$, and the vertical one is $P_\sigma\in[-\pi,\pi]$.

fundamental symmetry line, and $\Gamma_{2j}=T^j\Gamma_0$, $j\in\mathbb{Z}$ the symmetry lines obtained by the Poincaré map of Γ_0. It can be shown[7,8] that the intersections of these symmetry lines are periodic orbits, i.e., if

$$x\in\Gamma_{2j}\cap\Gamma_{2i} \quad \text{then} \quad T^{2|j-i|}x=x, \quad i\neq j \ .$$

If x is at the intersection of Γ_{2j} and Γ_{2i}, then it is a periodic orbit of T and its period divides $2|j-i|$, $j,i\in\mathbb{Z}$.

We have integrated the Hamiltonian system (18) by a Runge–Kutta method order 7–8 with initial conditions $(\sigma,P_\sigma)=(\sigma,0)$ on the fundamental symmetry line Γ_0 and we calculated the Γ_2, Γ_4, Γ_6, and Γ_8 lines. In Figs. 6, 7, and 8 are shown these lines for $p_\psi=0$, $m_1=3$, $m_2=2$, $m_3=1$ and $\mathcal{K}=-1,0,10$, respectively. The intersections of the symmetry lines are periodic orbits in Σ. We show in Fig. 9 three periodic orbits in the configuration space Π, obtained by the intersection of the symmetry lines for three different values of $\mathcal{K}=-1,0,10$, and in Figs. 10, 11, and 12 the respective orbits of the three bodies in the Cartesian rotating frame moving with ψ for each case of $\mathcal{K}$. In general, they will not be periodic in all the variables because R is not a periodic variable, except for the case $\mathcal{K}=0$ and $\mathcal{H}=0$ where R becomes constant. In addition we must choose the p_ψ parameter properly to have a periodic orbit with the same frequency of the ψ

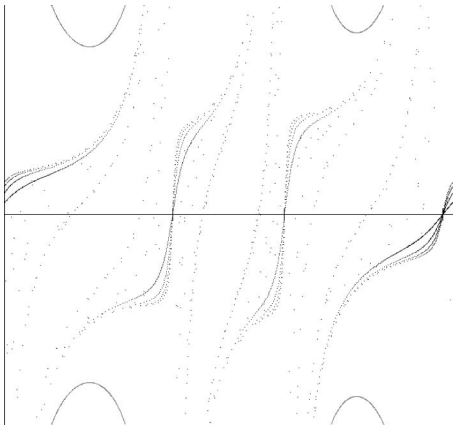

FIG. 7. Γ_0, Γ_2, Γ_4, Γ_6, and Γ_8 symmetry lines for $m_1=3$, $m2=2$, $m_3=1$, $p_\psi=0$, and $\mathcal{K}=0$. The horizontal axis is $\sigma\in[0,\pi]$, and the vertical one is $P_\sigma\in[-\pi,\pi]$.

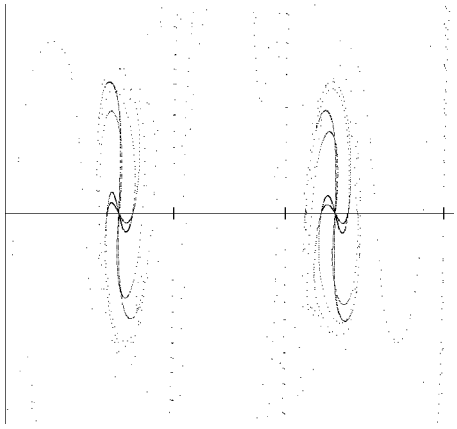

FIG. 8. Γ_0, Γ_2, Γ_4, Γ_6, and Γ_8 symmetry lines for $m_1=3$, $m2=2$, $m_3=1$, $p_\psi=0$, and $\mathcal{K}=10$. The horizontal axis is $\sigma\in[0,\pi]$, and the vertical one is $P_\sigma\in[-\pi,\pi]$.

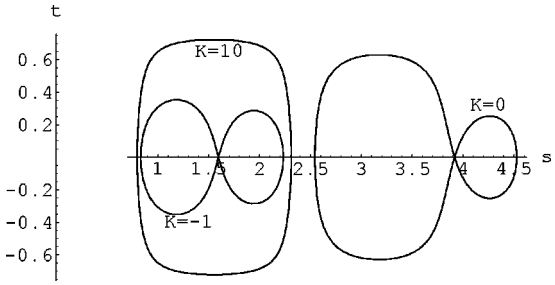

FIG. 9. Three different periodic orbits in the reduced configuration space (σ,θ) for $\mathcal{K}=-1,0,10$ (we used s and t instead of σ and θ in the graph). The respective periodic orbits of the three bodies in Cartesian coordinates are shown in Figs. 10–12.

motion, which we are not describing here. The periodic solutions here obtained are in general periodic up to a rotation and a homothetic transformation by ψ and R variables, respectively.

IX. CONCLUSIONS

We have introduced suitable coordinates to separate partially the problem of four degrees of freedom by means of three first integrals. We thus studied the motion in the (R,P_R) plane and we showed that generically, at least two particles will escape to infinity increasing continuously their inertia moment, or the three particles will collide.

We therefore have reduced the problem to a two degrees of freedom one with an extra constant of motion $\mathcal{K}$, and we have been able to find periodic orbits for these reduced problems. These solutions will be in general periodic up to a rotation and homothetic transformation in the whole space. For special values of the constants of motion ($E=0$, $K=0$), the periodic orbits will also be periodic in the R variable. If we properly select p_ψ, the solution will be completely periodic.

Generically, the three bodies either collide, or their total inertia moment tends to infinity, which means that at least two of them escape to infinity.

ACKNOWLEDGMENTS

We thank Professor Jaume Llibre for important remarks and also for providing us with the subroutine developed by his group at the University of Barcelona that makes the numerical integration by the Runge–Kutta 7–8 method. We also thank Professor Florin Diacu for providing us the reference of Poincaré and Dr. Teresa de la Selva for helpful discussions.

APPENDIX

In this appendix we give the explicit change of coordinates from the coordinates in Ref. 4 to the Cartesian inertial frame. First, we put the origin of coordinates at the center of mass of the three particles, and we choose the third coordinate of each particle to be zero. In addition to the ψ coordinate that rotates from the principal axes frame to the inertial frame, three other coordinates are introduced: σ, R_1, and R_2. The last two are distances closely related to the two independent inertia moments $I_1=\mu R_1^2$ and $I_2=\mu R_2^2$, where μ is the mass

$$\mu=\sqrt{\frac{m_1 m_2 m_3}{m_1+m_2+m_3}}.$$

The Cartesian inertial coordinates in the plane of motion (x_i,y_i) for each m_i, written in terms of the new coordinates are

$$\mathbf{r}_j=\begin{pmatrix} x_j \\ y_j \end{pmatrix}=\mathbf{C}\begin{pmatrix} a_j \\ b_j \end{pmatrix}, \quad i=1,2,3, \tag{A1}$$

where

$$\mathbf{C}=\begin{pmatrix} R_2\cos\sigma\cos\psi+R_1\sin\sigma\sin\psi & R_2\sin\sigma\cos\psi-R_1\cos\sigma\sin\psi \\ R_2\cos\sigma\sin\psi-R_1\sin\sigma\cos\psi & R_2\sin\sigma\sin\psi+R_1\cos\sigma\cos\psi \end{pmatrix}.$$

The vectors **a** and **b** are constant, perpendicular, and orthogonal to the vector $\mathbf{m}=(m_1,m_2,m_3)$ in the mass space,

$$\mathbf{a}\cdot\mathbf{m}=\mathbf{b}\cdot\mathbf{m}=\mathbf{a}\cdot\mathbf{b}=0\,. \tag{A2}$$

If we denote the matrix $\mathbf{M}=\mathrm{diag}\{m_1,m_2,m_3\}$, we can complete the definition of vectors **a** and **b** assuming

$$\mathbf{b}\,\mathbf{M}\,\mathbf{a}^T=0, \tag{A3}$$

and the normalization conditions

$$\mathbf{a}\,\mathbf{M}\,\mathbf{a}^T=\mathbf{b}\,\mathbf{M}\,\mathbf{b}^T=\mu\,, \tag{A4}$$

that define the vectors **a** and **b** with no dimensions. The transformation (A1) is well defined when $(a_ib_j-a_jb_i)(R1^2-R_2^2)\neq 0$, $i\neq j$. In the case of $m_1>m_2>m_3$ the **a** and **b** vectors result in[4]

$$\mathbf{a}=y_a\left(\frac{m_1}{m_1-x_a},\frac{m_2}{m_2-x_a},\frac{m_3}{m_3-x_a}\right) \tag{A5}$$

and

$$\mathbf{b}=y_b\left(\frac{m_1}{m_1-x_b},\frac{m_2}{m_2-x_b},\frac{m_3}{m_3-x_b}\right), \tag{A6}$$

where x_a and x_b are the roots (with $x_a>x_b$) of the quadratic equation

$$x^2(m_1^2+m_2^2+m_3^2)-x[(m_1+m_2+m_3)(m_1m_2+m_1m_3+m_2m_3)-3m_1m_2m_3]$$
$$+(m_1+m_2+m_3)m_1m_2m_3=0\,,$$

and y_a and y_b are normalization factors given by

$$y_i^2\left(\frac{m_1^3}{(m_1-x_i)^2}+\frac{m_2^3}{(m_2-x_i)^2}+\frac{m_3^3}{(m_3-x_i)^2}\right)=\mu\,,$$

with $i=a,b$.

If two or three masses are equal, vectors **a** and **b** must be redefined and constructed by using the properties (A2)–(A4). For instance, for $m1\geqslant m2=m3$ we choose

$$\mathbf{a}=\frac{1}{\sqrt{2}}(0,1,-1)\,,$$

and

$$\mathbf{b}=\frac{1}{\sqrt{2(1+2m_2/m_1)}}(-2m_2/m_1,1,1)\,,$$

where the factor of normalization is m_2 instead of μ in (A4).

Finally, the relation among the distance between particles and the new coordinates is

$$\begin{pmatrix} r_{23}^2 \\ r_{13}^2 \\ r_{12}^2 \end{pmatrix} = \mathbf{B} \begin{pmatrix} R_1^2 \sin^2\sigma + R_2^2 \cos^2\sigma \\ R_1^2 \cos^2\sigma + R_2^2 \sin^2\sigma \\ (R_2^2 - R_1^2) 2 \sin\sigma \cos\sigma \end{pmatrix}, \tag{A7}$$

where **B** is the constant matrix, depending only on the masses,

$$\mathbf{B} = \frac{1}{\mu^2} \begin{pmatrix} m_1^2 b_1^2 & m_1^2 a_1^2 & -m_1^2 a_1 b_1 \\ m_2^2 b_2^2 & m_2^2 a_2^2 & -m_2^2 a_2 b_2 \\ m_3^2 b_3^2 & m_3^2 a_3^2 & -m_3^2 a_3 b_3 \end{pmatrix}. \tag{A8}$$

In the case of two or three equal masses, the factor $1/\mu^2$ in B must be changed by

$$\frac{1}{m_2^2} + \frac{2}{m_1 m_2}.$$

(Received 12 July 2002; accepted 28 March 2003)

The expression of the components of the equation of motion of the classical Kepler problem in terms of the natural variables associated with the Ermanno–Bernoulli constants leads naturally to the same equations as are obtained by the technique of reduction of order developed by Nucci [J. Math. Phys. **37**, 1772 (1996)], reported by Nucci and Leach [J. Math. Phys. **42**, 746 (2001)]. Three representations of the complete symmetry group of the Kepler problem are obtained from the three standard representations of the complete symmetry group of the simple harmonic oscillator. The algebra of the complete symmetry group of the two-dimensional Kepler problem is identified to be $A_1 \oplus \{A_{3,3}\}$. The applicability of the results to other classes of problem, such as the Kepler problem with drag, which possess a conserved vector of Laplace–Runge–Lenz type, is indicated. The three-dimensional Kepler problem is shown to be completely specified by six symmetries rather than the eight previously reported by Krause [J. Math. Phys. **35**, 5734 (1994)]. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1576903]

I. INTRODUCTION

When studies of the Lie point symmetries of various ordinary differential equations and systems of ordinary differential equations were being reported in the late 1970s, it was customary to describe the set of point symmetries obtained by the Lie method as the complete symmetry group of the differential equation (or system of differential equations). This was a reaction to some earlier results obtained using Noether's theorem for which, in the case of a linear second order ordinary differential equation, five point symmetries were reported. The expression fell out of use during the 1980s. In 1994 Krause[15] revived the usage of the expression in a context for which it was a much more suitable descriptor. Krause's concept of a complete symmetry group of a differential equation is the group associated with the set of symmetries, be they point, contact, generalized or nonlocal, required to specify the equation or system completely. Specifically he required that the elements of the group have the two properties that the manifold of solutions be an homogeneous space of the group and the group be specific to the system, i.e., no other system admits it. Subsequently a requirement of minimality was added after Andriopoulos *et al.*[1,2] showed that not only was the group not unique but also the dimensionality could vary. The completeness of the specification was up to a scaling factor in the example used by Krause as the vehicle for his discussion and up to an arbitrary translation in an example discussed by Leach *et al.*[21]

As a vehicle to illustrate the concept of a complete symmetry group Krause used the Kepler problem, which is probably the central paradigm of mechanics. The Kepler problem possesses the first integrals of the conservation of the scalar energy, the vector of angular momentum and

[a]Permanent address: School of Mathematical and Statistical Sciences, University of Natal, Durban 4041, Republic of South Africa.

vectors in the plane of the orbit known as Hamilton's vector[13] and the Laplace–Runge–Lenz vector.[5,14,3,16,31,22] The invariance Lie algebra of the first integrals under the operation of taking the Poisson bracket is so(4) (in the case of negative energy) and the Lie algebra of the five Lie point symmetries of the equation of motion $A_2 \oplus \mathrm{so}(3)$. The algebra of the complete symmetry group has not been given. The elements of the five-dimensional algebra are

$$X_1=\partial_t, \quad X_3=x_2\partial_{x_3}-x_3\partial_{x_2},$$

$$X_2=t\partial_t+\tfrac{2}{3}r\partial_r, \quad X_4=x_3\partial_{x_1}-x_1\partial_{x_3}, \tag{1.1}$$

$$X_5=x_1\partial_{x_2}-x_2\partial_{x_1}$$

in which x_1, x_2, and x_3 are the usual Cartesian components of the position vector $\mathbf{r}$ of magnitude r. These five point symmetries of the equation of motion are insufficient to specify the equation completely. To overcome the deficiency in the number of symmetries Krause introduced a nonlocal symmetry of specific structure defined by

$$Y=\left[\int \xi(t,x_1,\ldots,x_N)\mathrm{d}t\right]\partial_t+\sum_{i=1}^{N} \eta_i(t,x_1,\ldots,x_N)\partial_{x_i} \tag{1.2}$$

and obtained three symmetries of this form, *videlicet*

$$Y_1=2\left(\int x_1\mathrm{d}t\right)\partial_t+x_1r\partial_r,$$

$$Y_2=2\left(\int x_2\mathrm{d}t\right)\partial_t+x_2r\partial_r, \tag{1.3}$$

$$Y_1=2\left(\int x_3\mathrm{d}t\right)\partial_t+x_3r\partial_r,$$

which has the compact form

$$\mathbf{Y}=2\left(\int \mathbf{r}\,\mathrm{d}t\right)\partial_t+\mathbf{r}\,r\partial_r, \tag{1.4}$$

in which $r^2=x_1^2+x_2^2+x_3^2$, for the Kepler problem. With these three additional symmetries he was able to specify completely the three second order equations of the equation of motion, up to the value of the gravitational constant in the radial equation which, as was noted above, is scalable.

Despite Krause's belief that the necessary number of symmetries for the complete symmetry group of the Kepler problem could not the obtained by means of the standard Lie point symmetry analysis, Nucci[28] was able to obtain all of the elements of the complete symmetry group by means of Lie point symmetry analysis—to be fair to Krause one must omit the word standard—so that the determination of the symmetries could be determined by the use of her interactive code.[26,27] The technique of reduction of order introduced by Nucci[28] was successfully used by Nucci and Leach[29] on a number of problems, both real and imaginary, for which conserved vectors of the type of the Laplace–Runge–Lenz had been found, mainly in the 1980s.[7,8,10,11,18,17] Just as the Laplace–Runge–Lenz vector provides a direct route to the equation of the orbit of the classical Kepler problem, the corresponding vectors of the generalized Kepler problems provide the same direct route to the equations of their orbits.

Nucci and Leach[29] showed that there were more nonlocal symmetries of the structure adopted by Krause (1.2), obtainable as point symmetries by the reduction method of Nucci, than Krause had reported. One of the intentions of this paper is to show that these additional nonlocal sym-

metries have a place in the discussion of the complete symmetry group. We find that there are three equivalent representations of the complete symmetry group, which we also described, for the Kepler problem. All symmetries are found by point methods. We find that there is no need to use the method of reduction of order introduced by Nucci since there is a natural variable available—its existence was demonstrated using the method of reduction of order in Nucci and Leach[29]—to write the system as the equation of a one-dimensional simple harmonic oscillator plus a conservation law. (This is in the case of a two-dimensional treatment. For three dimensions the corresponding result is one differential equation plus two conservation laws. We confine our attention to two dimensions for purposes of simplicity of presentation.) The equivalence of the Kepler problem to the simple harmonic oscillator plus a conservation law is carried over in the group properties. Some years ago Mahomed and Leach[20] showed that the three first integrals of the simple harmonic oscillator, $\ddot{x}+x=0$,

$$I_1=x\cos t-\dot{x}\sin t,$$

$$I_2=x\sin t+\dot{x}\cos t, \tag{1.5}$$

$$I_3=\frac{x\cos t-\dot{x}\sin t}{x\sin t+\dot{x}\cos t}$$

each possessed three Lie point symmetries with the same algebra. More recently Andriopoulos *et al.*[1] showed that this very algebra provided the elements of the complete symmetry group of the equation of motion for the simple harmonic oscillator. We see that these three equivalent representations lead to three equivalent representations of the complete symmetry group of the Kepler problem.

By analogy these results apply to all other systems for which one can obtain a Laplace–Runge–Lenz vector.

In the next section we summarize the determination and properties of the integrals of the Kepler problem, show how this leads naturally to the simple harmonic oscillator and consider the properties of the symmetries of the latter. In the following section we provide an explicit demonstration that the sets of symmetries obtained are indeed the elements of the complete symmetry group of the two-dimensional Kepler problem. In Sec. IV we consider the connection between the simple harmonic oscillator and the Kepler problem in three dimensions. We present some observations in Sec. V.

II. THE CONSERVATION LAWS OF THE KEPLER PROBLEM

The reduced equation for the Kepler problem is

$$0=\ddot{\mathbf{r}}+\frac{\mu\mathbf{r}}{r^3}. \tag{2.1}$$

The vector product of $\mathbf{r}$ with (2.1), *videlicet*

$$0=\mathbf{r}\times\ddot{\mathbf{r}}+\frac{\mu\mathbf{r}\times\mathbf{r}}{r^3}, \tag{2.2}$$

gives that

$$\mathbf{L}:=\mathbf{r}\times\dot{\mathbf{r}} \tag{2.3}$$

is a conserved vector, essentially the angular momentum. (One could imagine that we set the effective mass of the system at unity by rescaling.)

The vector product of (2.1) with $\mathbf{L}$ gives

$$0=(\dot{\mathbf{r}}\times\mathbf{L})^{\cdot}+\frac{\mu\mathbf{r}\times\mathbf{L}}{r^3}. \tag{2.4}$$

With the use of the decomposition

$$\dot{\mathbf{r}}=\dot{r}\hat{\mathbf{r}}+r\dot{\hat{\mathbf{r}}} \tag{2.5}$$

we may write the vector product in the numerator of the second term of (2.4) as

$$\mathbf{r}\times\mathbf{L}=r\dot{r}\mathbf{r}-r^2(\dot{r}\hat{\mathbf{r}}+r\dot{\hat{\mathbf{r}}})=-r^3\dot{\hat{\mathbf{r}}} \tag{2.6}$$

so that (2.4) becomes

$$0=(\dot{\mathbf{r}}\times\mathbf{L})^{\cdot}-\mu\dot{\hat{\mathbf{r}}} \tag{2.7}$$

and we obtain a second conserved vector, *videlicet*

$$\mathbf{J}:=\dot{\mathbf{r}}\times\mathbf{L}-\mu\hat{\mathbf{r}} \tag{2.8}$$

which is the renowned Laplace–Runge–Lenz vector, presumably so-called because it was discovered by Ermanno and Bernoulli at the beginning of the eighteenth century.

There is a third conserved vector which was obtained by Hamilton in 1845. Trivially it may be obtained by taking the vector product of **L** and **J**. However, as it arises from a direct integration of the equation of motion (2.1), such a derivation from integrals which require the use of integrating factors applied to the equation of motion does seem to be a little lacking in fundamentalism. We define a unit vector, $\hat{\boldsymbol{\omega}}$, as the unit vector in the instantaneous direction of the angular velocity, i.e., in the direction of $\dot{\hat{\mathbf{r}}}$. With $\hat{\mathbf{r}}$ and $\hat{\mathbf{L}}$ it forms an orthogonal triad. Specifically we have

$$\hat{\boldsymbol{\omega}}=\hat{\mathbf{L}}\times\hat{\mathbf{r}}, \tag{2.9}$$

so that

$$\dot{\hat{\boldsymbol{\omega}}}=\hat{\mathbf{L}}\times\dot{\hat{\mathbf{r}}}, \tag{2.10}$$

since the direction of **L** is constant. We consider the vector product on the right of (2.10). From the definition of the angular momentum we have

$$\hat{\mathbf{L}}\frac{L}{r^2}=\hat{\mathbf{r}}\times\dot{\hat{\mathbf{r}}}. \tag{2.11}$$

Taking the vector product of this with $\dot{\hat{\mathbf{r}}}$ we have

$$\hat{\mathbf{L}}\times\dot{\hat{\mathbf{r}}}\,\frac{L}{r^2}=-\dot{\hat{\mathbf{r}}}.\dot{\hat{\mathbf{r}}}\hat{\mathbf{r}}$$

$$\Leftrightarrow\quad \hat{\mathbf{r}}=-\frac{L}{r^2}\frac{1}{\dot{\hat{\mathbf{r}}}.\dot{\hat{\mathbf{r}}}}\hat{\mathbf{L}}\times\dot{\hat{\mathbf{r}}}$$

$$=-\frac{L}{r^2}\frac{1}{\dot{\hat{\mathbf{r}}}.\dot{\hat{\mathbf{r}}}}\dot{\hat{\boldsymbol{\omega}}} \tag{2.12}$$

and so the equation of motion (2.1) becomes

$$0=\ddot{\mathbf{r}}-\frac{\mu}{r^2}\frac{L}{r^2}\frac{1}{\dot{\hat{\mathbf{r}}}.\dot{\hat{\mathbf{r}}}}\dot{\hat{\boldsymbol{\omega}}}. \tag{2.13}$$

Since $\mathbf{L}=r^2\hat{\mathbf{r}}\times\dot{\hat{\mathbf{r}}}$, Eq. (2.13) is trivially integrated to give

$$\mathbf{K}:=\dot{\mathbf{r}}-\frac{\mu\hat{\boldsymbol{\omega}}}{L}, \tag{2.14}$$

which is Hamilton's vector.

We note that in the above derivation we have not made use of the fact that the orbit is in a plane due to the conservation of the angular momentum. When we reduce the motion to motion in a plane, we may use plane polar coordinates, (r,θ), and replace $\hat{\boldsymbol{\omega}}$ with $\hat{\boldsymbol{\theta}}$.

The vectors **J**, **K**, and **L** constitute an orthogonal triad.

The explicit expression for **J** in plane polar coordinates is

$$\mathbf{J}=(r^3\dot{\theta}^2-\mu)\hat{\mathbf{r}}-r^2\dot{r}\dot{\theta}\hat{\boldsymbol{\theta}}. \tag{2.15}$$

Since $\hat{\mathbf{r}}=\hat{\mathbf{i}}\cos\theta+\hat{\mathbf{j}}\sin\theta$ and $\hat{\boldsymbol{\theta}}=-i\sin\theta+\hat{\mathbf{j}}\cos\theta$, the Cartesian components of **J** are

$$J_x=(r^3\dot{\theta}^2-\mu)\cos\theta+r^2\dot{r}\dot{\theta}\sin\theta, \tag{2.16}$$

$$J_y=(r^3\dot{\theta}^2-\mu)\sin\theta-r^2\dot{r}\dot{\theta}\cos\theta. \tag{2.17}$$

From the combination

$$J_x\pm iJ_y=(r^3\dot{\theta}^2-\mu)e^{\pm i\theta}\pm ir^2\dot{r}\dot{\theta}e^{\pm i\theta}=L^2\left(\frac{1}{r}-\frac{\mu}{L^2}\pm i\frac{\dot{r}}{r^2\dot{\theta}}\right)=\mp iL^2\left(\left(\frac{1}{r}\right)'\pm i\left(\frac{1}{r}-\frac{\mu}{L^2}\right)\right)e^{\pm i\theta}, \tag{2.18}$$

where $L:=r^2\dot{\theta}$ is the magnitude of the angular momentum and the prime denotes differentiation with respect to θ, we define the Ermanno–Bernoulli constants as

$$J_\pm=(v_1'\pm iv_1)e^{\pm i\theta}, \tag{2.19}$$

where $v_1=1/r-\mu/L^2$. The reason for the rescaling is to be found in the radial equation of motion which has the simple form

$$v_1''+v_1=0, \tag{2.20}$$

i.e., the equation for a one-dimensional simple harmonic oscillator. Of course, the reduction of the radial equation to that of a linear oscillator equation is scarcely novel [see, for example, Whitaker (Ref. 32, p. 83)], but its group theoretical derivation and the identification of the new variable as being derived from the Laplace–Runge–Lenz vector is more recent.[29] Note that we can write the Laplace–Runge–Lenz vector in terms of v_1 as

$$\mathbf{J}=L^2(v_1\hat{\mathbf{r}}+v_1'\hat{\boldsymbol{\theta}}). \tag{2.21}$$

For the sake of completion we note that the scalar product of $\dot{\mathbf{r}}$ with (2.1) is easily integrated to give the energy integral, *videlicet*

$$E:=\frac{1}{2}\dot{\mathbf{r}}.\dot{\mathbf{r}}-\frac{\mu}{r}. \tag{2.22}$$

The various first integrals are related according to

$$L^4 J_+ J_- = 2L^2 E + \mu^2. \tag{2.23}$$

III. THE THREE REPRESENTATIONS OF THE COMPLETE SYMMETRY GROUP OF THE KEPLER PROBLEM

In terms of the dependent variables v_1 and v_2 and the independent variable θ the two-dimensional Kepler problem is defined by the system of differential equations

$$v_1'' + v_1 = 0, \tag{3.1}$$

$$v_2' = 0, \tag{3.2}$$

which correspond to the radial and angular components of the equation of motion (2.1). As a linear second order ordinary differential equation (3.1) possesses eight Lie point symmetries. The Lie point symmetries of the system (3.1) and (3.2) can be written as

$$\begin{gathered}\Gamma_1 = \partial_{v_2}, \quad \Gamma_{4\pm} = e^{\pm i\theta}\partial_{v_1}, \\ \Gamma_2 = \partial_\theta, \quad \Gamma_{5\pm} = e^{\pm 2i\theta}(\partial_\theta \pm i v_1 \partial_{v_1}), \\ \Gamma_3 = v_1 \partial_{v_1}, \quad \Gamma_{6\pm} = e^{\pm i\theta}(v_1 \partial_\theta \pm i v_1^2 \partial_{v_1}).\end{gathered} \tag{3.3}$$

These nine point symmetries plus ∂_t which is implicit in the change of independent variable from t to θ constitute the set of symmetries at our disposal for the determination of the complete symmetry group of the Kepler problem.

In 1988 Mahomed and Leach[20] showed that to each of three specific invariants of a second order equation possessing eight Lie point symmetries there were three point symmetries with the same algebra, *videlicet* $D \oplus_s T_2$. Recently, Andriopoulos *et al.*[1] showed that the same three symmetries completely specified the equation and so the complete symmetry group was the semidirect product of dilations and translations in the plane. In our format, which differs somewhat from the earlier literature, the invariants, I_A, I_B, and I_C, and the symmetries A_i, B_i, and C_i, $i=1,3$, are

$$I_A = (v_1 + i v_1') e^{i\theta} \begin{cases} A_1 = e^{i\theta}\partial_{v_1}, \\ A_2 = \partial_\theta - i v_1 \partial_{v_1}, \\ A_3 = e^{2i\theta}(\partial_\theta + i v \partial_{v_1}), \end{cases} \tag{3.4}$$

$$I_B = (v_1 - i v_1') e^{-i\theta} \begin{cases} B_1 = e^{-i\theta}\partial_{v_1}, \\ B_2 = \partial_\theta + i v_1 \partial_{v_1}, \\ B_3 = e^{-2i\theta}(\partial_\theta - i v \partial_{v_1}), \end{cases} \tag{3.5}$$

$$I_C = \frac{v_1 + i v_1'}{v_1 - i v_1'} e^{2i\theta} \begin{cases} C_1 = v_1 \partial_{v_1}, \\ C_{2\pm} = e^{\pm i\theta}(v_1 \partial_\theta \pm i v_1^2 \partial_{v_1}). \end{cases} \tag{3.6}$$

We note the typical variation of the appearance of combinations of Γ_2 and Γ_3, both of which are rescaling symmetries, in the algebras of the invariants.[6,19]

Proposition: The complete symmetry group of the two-dimensional Kepler problem given by the equation of motion (2.1) has three (equivalent) representations given by the sets A, B or C plus ∂_t.

To demonstrate the correctness of the proposition we first express the symmetries in terms of the variables found in (2.1). A (t, r, θ) symmetry becomes a (θ, v_1, v_2) symmetry according to

$$\tau\partial_t+\eta\partial_r+\zeta\partial_\theta\rightarrow\zeta\partial_\theta+\Omega\partial_{v_1}+\Sigma\partial_{v_2}, \tag{3.7}$$

where

$$v_2=r^2\dot{\theta},\quad v_1=\frac{1}{r}-\frac{\mu}{v_2^2},$$

$$\Sigma=2\eta r\dot{\theta}+r^2(\dot{\zeta}-\dot{\theta}\dot{\tau}), \tag{3.8}$$

$$\Omega=-\frac{\eta}{r^2}+\frac{2\mu}{v_2^3}\Sigma.$$

For A_1 we have $\zeta=0$, $\Omega=e^{i\theta}$ and $\Sigma=0$. We use the relations in (3.8) to determine that $\eta=-r^2e^{i\theta}$ and $\tau=-2\int re^{i\theta}\,\mathrm{d}t$. The same procedure is followed for A_2 and A_3. In (t,r,θ) coordinates we obtain

$$A_1=\left(2\int re^{i\theta}\,\mathrm{d}t\right)\partial_t+r^2e^{i\theta}\partial_r,$$

$$A_2=2\left(t-\frac{\mu}{L^2}\int r\,\mathrm{d}t\right)+r\left(1-\frac{\mu r}{L^2}\right)\partial_r-i\partial_\theta, \tag{3.9}$$

$$A_3=\left(\frac{2i\mu}{L^2}\int re^{2i\theta}\,\mathrm{d}t\right)\partial_t-ir\left(1-\frac{\mu r}{L^2}\right)e^{2i\theta}\partial_r+e^{2i\theta}\partial_\theta.$$

The general radial and angular components of the equation of motion can be written as the system

$$\ddot{r}=f(t,r,\theta,\dot{r},\dot{\theta}),$$

$$\ddot{\theta}=g(t,r,\theta,\dot{r},\dot{\theta}),$$

and invariance under the symmetry ∂_t immediately enables us to write this in the simpler form

$$\ddot{r}=f(r,\theta,\dot{r},\dot{\theta}), \tag{3.10}$$

$$\ddot{\theta}=g(r,\theta,\dot{r},\dot{\theta}). \tag{3.11}$$

The actions of the second extensions of A_1, A_2, and A_3 on (3.10) and (3.11) give, respectively,

$$r\frac{\partial f}{\partial r}+ir\dot{\theta}\frac{\partial f}{\partial\dot{r}}-2\dot{\theta}\frac{\partial f}{\partial\dot{\theta}}=irg-2f+2i\dot{r}\dot{\theta}-r\dot{\theta}^2, \tag{3.12}$$

$$r\frac{\partial g}{\partial r}+ir\dot{\theta}\frac{\partial g}{\partial\dot{r}}-2\dot{\theta}\frac{\partial g}{\partial\dot{\theta}}=-4g-\frac{2\dot{r}\dot{\theta}}{r}-2i\dot{\theta}^2, \tag{3.13}$$

$$r\left(1-\frac{\mu r}{L^2}\right)\frac{\partial f}{\partial r}-i\frac{\partial f}{\partial\theta}-\dot{r}\frac{\partial f}{\partial\dot{r}}-2\dot{\theta}\left(1-\frac{\mu r}{L^2}\right)\frac{\partial f}{\partial\dot{\theta}}=-3f+2\frac{\mu r}{L^2}f, \tag{3.14}$$

$$r\left(1-\frac{\mu r}{L^2}\right)\frac{\partial g}{\partial r}-i\frac{\partial g}{\partial\theta}-\dot r\frac{\partial g}{\partial\dot r}-2\dot\theta\left(1-\frac{\mu r}{L^2}\right)\frac{\partial g}{\partial\dot\theta}=-4g\left(1-\frac{\mu r}{L^2}\right)+\frac{2\mu\dot r\dot\theta}{L^2}, \tag{3.15}$$

$$-r\left(1-\frac{\mu r}{L^2}\right)\frac{\partial f}{\partial r}+\frac{\partial f}{\partial\theta}-\left[\dot r+2ir\dot\theta\left(1-\frac{\mu r}{L^2}\right)\right]\frac{\partial f}{\partial\dot r}+2\dot\theta\left(1-\frac{\mu r}{L^2}\right)\frac{\partial f}{\partial\dot\theta}$$
$$=-f\left(1+\frac{2\mu r}{L^2}\right)-2igr\left(1-\frac{\mu r}{L^2}\right)+4r\dot\theta^2\left(1-\frac{\mu r}{L^2}\right)-4i\dot r\dot\theta\left(1-\frac{\mu r}{L^2}\right), \tag{3.16}$$

$$-r\left(1-\frac{\mu r}{L^2}\right)\frac{\partial g}{\partial r}+\frac{\partial f}{\partial\theta}-\left[\dot r+2ir\dot\theta\left(1-\frac{\mu r}{L^2}\right)\right]\frac{\partial g}{\partial\dot r}+2\dot\theta\left(1-\frac{\mu r}{L^2}\right)\frac{\partial g}{\partial\dot\theta}$$
$$=2g\left(1-\frac{2\mu r}{L^2}\right)+4i\dot\theta^2\left(1-\frac{\mu r}{L^2}\right)-\frac{2\mu\dot r\dot\theta}{L^2}, \tag{3.17}$$

after division by $e^{i\theta}$ in (3.12) and (3.13) and $e^{2i\theta}$ in (3.16) and (3.17), respectively.

We observe that the right-hand sides of the angular equations contain only g whereas those of the radial equations contained both f and g. We work with the former set of equations. Adding (3.15) and (3.17) we obtain

$$-2\left[\dot r+ir\dot\theta\left(1-\frac{\mu r}{L^2}\right)\right]\frac{\partial g}{\partial\dot r}=-2g+4i\dot\theta^2\left(1-\frac{\mu r}{L^2}\right). \tag{3.18}$$

The combination $-(1-\mu r/L^2)$ (3.13) and (3.15) gives

$$-\left[\dot r+ir\dot\theta\left(1-\frac{\mu r}{L^2}\right)\right]\frac{\partial g}{\partial\dot r}=\frac{2\mu\dot r\dot\theta}{L^2}+2\left(1-\frac{\mu r}{L^2}\right)\left(\frac{\dot r\dot\theta}{r}+i\dot\theta^2\right). \tag{3.19}$$

We eliminate all derivatives of g by means of the combination (3.18) and (3.19) to obtain

$$g=-\frac{2\dot r\dot\theta}{r}. \tag{3.20}$$

We further observe that the left-hand sides of the radial equations contain the same terms as those of the angular equations with f in place of g and take the same combinations as in the preceding paragraph to obtain

$$f=r\dot\theta^2\left(1-\frac{\mu r}{L^2}\right) \tag{3.21}$$

which, on the replacement of L by $r^2\dot\theta$ becomes

$$f=r\dot\theta^2-\frac{\mu}{r^2}. \tag{3.22}$$

Hence the A-set of symmetries, together with ∂_t, provides a representation of the complete symmetry group of the Kepler problem in the two-dimensional form considered here. As the B-set of symmetries is the complex conjugate of the A-set, it is evident that this set also leads to a representation of the complete symmetry group. We need only consider now the C-set.

In terms of (t,r,θ) coordinates the C-set symmetries are

$$C_1=\left(-2\int x\,\mathrm{d}t\right)\partial_t-rx\partial_r, \tag{3.23}$$

$$C_{2\pm}=\left[\int\left(-\frac{\dot r}{L}\pm\frac{ix}{r}\mp 2i\frac{x^2}{r}\right)e^{\pm i\theta}\,\mathrm{d}t\right]\partial_t\mp ix^2e^{\pm i\theta}\partial_r+\frac{x}{r}e^{\pm i\theta}\partial_\theta, \tag{3.24}$$

in which we have introduced the notation

$$x=1-\frac{\mu r}{L^2},\quad \dot x=-\frac{\mu\dot r}{L^2} \tag{3.25}$$

in an attempt to compactify the expressions.

From our experience with the A-set of symmetries we know that the right-hand sides of the equations will be the same, apart from an interchange of f and g, for both the radial and angular components of (3.10) and (3.11). We also expect the angular equation to be simpler and so commence with these. We obtain

$$C_1,\quad -rx\frac{\partial g}{\partial r}+(\dot r x-r\dot x)\frac{\partial g}{\partial\dot r}+2x\dot\theta\frac{\partial g}{\partial\dot\theta};$$

$$C_{2\pm},\quad \left[\mp ix^2\frac{\partial g}{\partial r}+\frac{x}{r}\frac{\partial g}{\partial\theta}+\left(\mp 2ix\dot x+x^2\dot\theta+\frac{\dot r^2}{L}\mp\frac{i\dot r x}{r}\pm\frac{2i\dot r x^2}{r}\right)\frac{\partial g}{\partial\dot r}\pm 2i\frac{x^2\dot\theta}{r}\frac{\partial g}{\partial\dot\theta}\right]e^{\pm i\theta}. \tag{3.26}$$

By means of some obvious manipulations we find that

$$2ixC_1-r(C_{2+}e^{-i\theta}-C_{2-}e^{i\theta})=0 \tag{3.27}$$

and so must use this combination on the left-hand sides to obtain g. The left-hand sides are

$$\begin{aligned}&C_1,\quad 4gx+2\dot x\dot\theta;\\ &C_{2\pm},\quad \pm\frac{4ix\dot x\dot\theta}{r}\mp\frac{2ix^2\dot r\dot\theta}{r^2}+g\left(\frac{\dot r}{L}\mp\frac{ix}{r}\pm\frac{4ix^2}{r}\right);\end{aligned} \tag{3.28}$$

from the latter of which a common factor of $\exp[\pm i\theta]$ has been removed. After a little manipulation of these expressions in (3.27) we regain (3.20).

The left-hand sides of the radial equations are

$$C_1,\quad f\left(3x+\frac{\mu r}{L^2}\right);$$

$$\begin{aligned}C_{2\pm},\quad &f\left(3\frac{\dot r}{L}\pm 2i\frac{\mu x}{L^2}\mp 2i\frac{x}{r}\pm 4i\frac{x^2}{r}\right)\mp 2i\dot x^2+4x\dot x\dot\theta+x^2g\pm ix^2\dot\theta^2\pm i\frac{\dot r^2\dot\theta}{L}\\ &-\dot r\left(\pm\frac{i\dot x}{r}\mp\frac{ix\dot r}{r^2}\mp\frac{4ix\dot x}{r}\pm\frac{2ix^2\dot r}{r^2}-\frac{x\dot\theta}{r}+\frac{2x^2\dot\theta}{r}\right);\end{aligned}$$

and, when we substitute these expressions in (3.27) and simplify, we obtain

$$2ix\left(f-r\dot\theta^2+\frac{\mu}{r^2}\right) \tag{3.29}$$

and so the radial equation of motion is regained.

Thus we have proven the proposition by explicit demonstration.

We observe that the symmetry, ∂_t, is necessary to enable the manipulations with the terms in $e^{\pm i\theta}$ above. Without this symmetry we would have to include the nonlocal coefficients of the ∂_t and so the exponential terms could not be eliminated. *A priori* one would have expected five symmetries from general considerations of the number of symmetries needed for an nth order system[1] and it is evident that the first order equation, representing the conservation of angular momentum, does not lead to the requirement of an additional symmetry.

It remains to consider the algebra of these representations of the complete symmetry group. The Lie brackets of the three representations are

$$\begin{gathered}
[A_1,A_2]_{\mathrm{LB}}=-2iA_1,\quad [B_1,B_2]_{\mathrm{LB}}=2iB_1,\quad [C_1,C_{2\pm}]_{\mathrm{LB}}=C_{2\pm},\\
[A_1,A_3]_{\mathrm{LB}}=0,\quad [B_1,B_3]_{\mathrm{LB}}=0,\quad [C_{2+},C_{2-}]_{\mathrm{LB}}=0,\\
[A_2,A_3]_{\mathrm{LB}}=2iA_3,\quad [B_2,B_3]_{\mathrm{LB}}=-2iB_3,\\
[\partial_t,A_i]_{\mathrm{LB}}=0,\quad [\partial_t,B_i]_{\mathrm{LB}}=0,\quad [\partial_t,C_i]_{\mathrm{LB}}=0.
\end{gathered}\tag{3.30}$$

The differences in the brackets can be rectified by suitable rescaling of the symmetries and renumbering. We note that ∂_t has zero Lie brackets with all other symmetries. Taking the C-set as an example we see that subalgebra C_1 acts semidirectly on the pair, $C_{2\pm}$, which is an Abelian subalgebra. Thus the structure of the algebra is $A_1\oplus\{A_1\oplus_s 2A_1\}$, where we use the standard notation of the Mubarakzyanov classification,[23–25] in which the algebras within braces constitute the semidirect sum of dilations and translations in the plane, also known as $A_{3,3}$.

The reduction of (2.1) to (3.1) and (3.2) is essentially a reduction of order using the symmetry ∂_t of the system (2.1). We have noted that all of the elements of the algebra of the complete symmetry group have zero Lie bracket with this symmetry. It is a commonplace [see, for example, Olver (Ref. 30, p. 185)] that, if a point symmetry has zero Lie bracket with the symmetry used for the reduction, it remains as a point symmetry of the reduced system. If it does not, then it becomes an exponential nonlocal symmetry of the reduced system. Here we have an interesting situation in that a nonlocal symmetry having zero Lie bracket with the reducing symmetry becomes a point symmetry of the reduced system. This is a hitherto unexplored aspect of the subject of nonlocal symmetries and may well bear fruitful investigation.

As a final point in connection with the representations of the complete symmetry group of the two-dimensional Kepler problem we note that it is not necessary to express these in terms of nonlocal symmetries. If we consider the three A symmetries by way of example, we have

$$\begin{aligned}
A_1&=\left(2\int re^{i\theta}\,\mathrm{d}t\right)\partial_t+r^2e^{i\theta}\partial_r,\\
A_2&=2\left(t-\frac{\mu}{L^2}\int r\,\mathrm{d}t\right)\partial_t+r\left(1-\frac{\mu r}{L^2}\right)\partial_r-i\partial_\theta,\\
A_3&=\left(\frac{2i\mu}{L^2}\int re^{2i\theta}\,\mathrm{d}t\right)\partial_t-ir\left(1-\frac{\mu r}{L^2}\right)e^{2i\theta}\partial_r+e^{2i\theta}\partial_\theta.
\end{aligned}\tag{3.31}$$

In each case the nonlocality comes from the integral in the coefficient function of ∂_t. In the case of A_2 we may manipulate the integral as follows:

$$\int r\,\mathrm{d}t=\int r\frac{\mathrm{d}\theta}{\dot\theta}=\int\frac{r^3}{L}\mathrm{d}\theta=L^5\int\frac{\mathrm{d}\theta}{(\mu+J\cos\theta)^3},\tag{3.32}$$

in which we have used the equation, $r(\theta)$, of the orbit. Similarly we have

$$\int re^{i\theta}\,\mathrm{d}t = L^5\int\frac{e^{i\theta}\,\mathrm{d}\theta}{(\mu+J\cos\theta)^3},$$
$$\int re^{2i\theta}\,\mathrm{d}t = L^5\int\frac{e^{2i\theta}\,\mathrm{d}\theta}{(\mu+J\cos\theta)^3}, \tag{3.33}$$

for A_1 and A_3, respectively. The integrals may be evaluated using standard integrals (Ref. 12, pp. 179, 180). In the case of negative energy as generalized symmetries we have

$$A_1=\left[\frac{ir^2L}{J}+\frac{\mu r^2\sin\theta}{2(-2E)L}+\frac{r(\mu^2+2J^2)\sin\theta}{2(-2E)^2L}-\frac{6\mu J}{(-2E)^{5/2}}\arctan\left(\frac{\mu-J}{\mu+J}\right)^{1/2}\tan\frac{\theta}{2}\right]\partial_t+r^2e^{i\theta}\partial_r,$$

$$A_2=2\left[t-\frac{\mu}{L^2}\left(\frac{r^2J\sin\theta}{4EL}-\frac{3\mu rJ\sin\theta}{8E^2L}+\frac{2\mu^2+J^2}{(-2E)^{5/2}}\arctan\left(\frac{\mu-J}{\mu+J}\right)^{1/2}\tan\frac{\theta}{2}\right)\right]\partial_t+r\left(1-\frac{\mu r}{L^2}\right)\partial_r$$
$$+\partial_\theta, \tag{3.34}$$

$$A_3=\frac{2i\mu}{L^2}\left[\frac{(2\mu^2-J^2)\mu r^2\sin\theta}{2J^2(-2E)L}+\frac{2\mu^4+3\mu^2J^2-2J^4-8\mu J^3+8\mu^3J}{2J^2L(-2E)^2}r\sin\theta\right.$$
$$\left.-\frac{4\mu^4+12\mu^3J-6\mu J^3-4J^4}{J^2(-2E)^{5/2}}\arctan\sqrt{\frac{\mu-J}{\mu+J}}\tan\frac{1}{2}\theta\right]\partial_t-ir\left(1-\frac{\mu r}{L^2}\right)e^{2i\theta}\partial_r+e^{2i\theta}\partial_\theta,$$

in which we have used the well-known relationship $J^2=2EL^2+\mu^2$. (The forms of the symmetries for the cases of positive and zero energy are calculated similarly.) The symmetries are generalized since L, E, and J are functions of $\dot r$ and $\dot\theta$. We note that the appearances of the generalized symmetries are complicated and not particularly intuitive. One is inclined to the opinion that the nonlocal representation is to be preferred.

IV. THE KEPLER PROBLEM IN THREE DIMENSIONS

The radial, polar and azimuthal components of the equation of motion for the Kepler problem, (2.1), are

$$\ddot r-r\dot\theta^2-r\sin^2\theta\dot\phi^2=-\frac{\mu}{r^2}, \tag{4.1}$$

$$r\ddot\theta+2\dot r\dot\theta-r\dot\phi^2\sin\theta\cos\theta=0, \tag{4.2}$$

$$(r\ddot\phi+2\dot r\dot\phi)\sin\theta+2r\dot\theta\dot\phi\cos\theta=0, \tag{4.3}$$

respectively. The Laplace–Runge–Lenz vector, (2.8), has the three Cartesian components

$$J_x=\left(\frac{L^2}{r}-\mu\right)\sin\theta\cos\phi-r^2\dot r(\dot\theta\cos\theta\cos\phi-\dot\phi\sin\theta\sin\phi), \tag{4.4}$$

$$J_y=\left(\frac{L^2}{r}-\mu\right)\sin\theta\sin\phi-r^2\dot r(\dot\theta\cos\theta\sin\phi+\dot\phi\sin\theta\cos\phi), \tag{4.5}$$

$$J_z=\left(\frac{L^2}{r}-\mu\right)\cos\theta+r^2\dot r\dot\theta\sin\theta, \tag{4.6}$$

and we combine the first two to obtain

$$J_{\pm}=J_x\pm iJ_y=\left[\left(\frac{L^2}{r}-\mu\right)\sin\theta-r^2\dot{r}\dot{\theta}\cos\theta\mp ir^2\dot{r}\dot{\phi}\sin\theta\right]e^{\pm i\phi}. \tag{4.7}$$

By analogy with the two-dimensional Kepler problem the real part of the expression within the crochets is the obvious candidate for one of the new variables.

The matter of identifying a third variable—the z-component of the angular momentum which comes from direct integration of the azimuthal inflation makes an obvious second variable—requires a little ingenuity. From the azimuthal equation, (4.3), we have

$$\dot{r}=-r\dot{\theta}\cot\theta-\frac{r\ddot{\phi}}{2\dot{\phi}}. \tag{4.8}$$

With this and following division by the common r the polar equation becomes

$$\ddot{\theta}-2\dot{\theta}^2\cot\theta-\frac{\ddot{\phi}\dot{\theta}}{\dot{\phi}}-\dot{\phi}^2\sin\theta\cos\theta=0. \tag{4.9}$$

We take ϕ to be the new independent variable. Then (4.9) is

$$\theta''-2\theta'^2\cot\theta-\sin\theta\cos\theta=0, \tag{4.10}$$

where the prime denotes differentiation with respect to the new independent variable ϕ. A second oscillator is obtained after the change of variable $v_2=\cot\theta$.

Thus we obtain a two-dimensional oscillator plus a conservation law, *videlicet*

$$\begin{gathered}v_1''+v_1=0,\quad v_1=\left(\frac{L^2}{r}-\mu\right)\sin\theta-r^2\dot{r}\dot{\theta}\cos\theta,\\ v_2''+v_2=0,\quad v_2=\cot\theta,\\ v_3'=0,\quad v_3=r^2\dot{\phi}\sin^2\theta,\end{gathered} \tag{4.11}$$

where the independent variable is ϕ.

The Lie point symmetries of (4.11) are those of the two-dimensional linear system plus ∂_{v_3} and are[9]

$$\begin{gathered}\Gamma_{1\pm}=e^{\pm i\phi}\partial_{v_1},\quad \Gamma_{2\pm}=e^{\pm i\phi}\partial_{v_2},\\ \Gamma_{3\pm}=v_1e^{\pm i\phi}[\partial_\phi\pm(v_1\partial_{v_1}+v_2\partial_{v_2})],\quad \Gamma_{4\pm}=v_2e^{\pm i\phi}[\partial_\phi\pm(v_1\partial_{v_1}+v_2\partial_{v_2})],\\ \Gamma_{5\pm}=e^{\pm i\phi}[\partial_\phi\pm(v_1\partial_{v_1}+v_2\partial_{v_2})],\\ \Gamma_6=v_1\partial_{v_1},\quad \Gamma_7=v_1\partial_{v_2},\\ \Gamma_8=v_2\partial_{v_1},\quad \Gamma_9=v_2\partial_{v_2},\\ \Gamma_{10}=\partial_\phi,\quad \Gamma_{11}=\partial_{v_3}.\end{gathered} \tag{4.12}$$

The algebra of these 16 symmetries is $A_1\oplus\mathrm{sl}(4,R)$, where the $\mathrm{sl}(4,R)$ is the algebra of the point symmetries of the two-dimensional simple harmonic oscillator.

The two-dimensional oscillator is completely specified by the five symmetries[2] $\Gamma_{1\pm}$, $\Gamma_{2\pm}$, and $\Gamma_6+\Gamma_9$ which has the algebra $A_1\oplus_s\{2A_1\oplus 2A_1\}$, being a representation of the semidirect product of dilations and translations in the four-plane. This algebra completely specifies the system (4.11). Consequently the three-dimensional Kepler problem is completely specified by the six-dimensional algebra $A_1\oplus\{A_1\oplus_s\{2A_1\oplus 2A_1\}\}$.

Krause[15] reported that eight symmetries were needed to specify the three-dimensional Kepler problem. Evidently he did not make the correct choice of symmetries. If one considers the representation of, say, $\Gamma_{1\pm}$ in terms of spherical polar coordinates, one obtains

$$\Gamma_{1\pm}=\left\{\int 2r\cos\theta\exp\left[-\int\frac{\dot\phi^2\sin^3\theta}{\dot\theta\cos\theta}\mathrm{d}t\right]\left[\int\frac{\exp(\pm i\phi)}{r^4\dot\theta\cos^2\theta}\exp\left(\int\frac{\dot\phi^2\sin^3\theta}{\dot\theta\cos\theta}\mathrm{d}t\right)\mathrm{d}t\right]\mathrm{d}t\right\}\partial_t$$
$$+\left\{r^2\cos\theta\exp\left[-\int\frac{\dot\phi^2\sin^3\theta}{\dot\theta\cos\theta}\mathrm{d}t\right]\left[\int\frac{\exp(\pm i\phi)}{r^4\dot\theta\cos^2\theta}\exp\left(\int\frac{\dot\phi^2\sin^3\theta}{\dot\theta\cos\theta}\mathrm{d}t\right)\mathrm{d}t\right]\right\}\partial_r. \tag{4.13}$$

The structure of this symmetry is scarcely intuitive and it is unlikely that anyone could make an Anzatz for a structure of this type.

V. CONCLUSION

In this paper we have shown that there are three representations of the complete symmetry group for the Kepler problem. These three representations followed directly from the three representations of the complete symmetry group for the simple harmonic oscillator. As Nucci and Leach[29] have shown that a number of related problems, all characterized by the possession of a conserved vector of Laplace–Runge–Lenz type, may be reduced to the simple harmonic oscillator, we may infer that these systems also have three representations for their complete symmetry groups. Indeed, one expects that the algebra be the same.

Given that the algebra is the same, there should exist a transformation of coordinates between any two of these systems. We illustrate this in the case of the Kepler problem with drag, the problem of a low altitude satellite modelled by Danby,[4] with the equation of motion

$$\ddot r+\frac{\alpha}{r^2}\dot r+\frac{\mu}{r^3}r=0, \tag{5.1}$$

where α and μ are constants. Since the direction of the angular momentum is a constant, we may analyze the problem in two dimensions using plane polar coordinates, (r,θ). The radial and angular components of the equation of motion are

$$\ddot r-r\dot\theta^2+\frac{\alpha\dot r}{r^2}+\frac{\mu}{r^2}=0, \tag{5.2}$$

$$r\ddot\theta+2\dot r\dot\theta+\frac{\alpha\dot\theta}{r}=0. \tag{5.3}$$

The reduction to the simple harmonic oscillator and a first-order conservation law is achieved by the change of variables

$$v_1=\frac{1}{r}-\mu z(\theta),$$
$$v_2=r^2\dot\theta+\alpha\theta, \tag{5.4}$$

where the function $z(\theta)$ is defined by

$$z(\theta)=\int^{\theta}\frac{\sin(\theta-\eta)\,\mathrm{d}\eta}{(\beta-\alpha\eta)^2}$$

$$\Leftrightarrow z''(\theta)+z(\theta)=\frac{1}{(\beta-\alpha\eta)^2} \tag{5.5}$$

and β is the value of the conservation law $L+\alpha\theta$ which replaces the conservation of the magnitude of the angular momentum found for the standard Kepler problem. The Ermanno–Bernoulli constants are

$$J_{\pm}=\left[\left(\frac{1}{r}-\mu z\right)'\pm i\left(\frac{1}{r}-\mu z\right)\right]. \tag{5.6}$$

In line with the treatment of the Kepler problem we would expect the system (5.2) and (5.3) to be completely specified by the symmetry ∂_t plus any one of the triplets which completely specify the equation for the oscillator, say the A-set. We can incorporate the symmetry ∂_t into the definition of the system to be tested, *videlicet*

$$\ddot{r}=f(r,\theta,\dot{r},\dot{\theta}), \tag{5.7}$$

$$\ddot{\theta}=g(r,\theta,\dot{r},\dot{\theta}). \tag{5.8}$$

In terms of the variables t, r, and θ the three A symmetries are

$$A_1=\left(2\int re^{i\theta}\,\mathrm{d}t\right)\partial_t+r^2e^{i\theta}\partial_r, \tag{5.9}$$

$$A_2=\left[\int\left(2i-2\mu r(z'+iz)\frac{\alpha}{L}\right)\mathrm{d}t\right]\partial_t+ir[1+i\mu r(z'+iz)]\partial_r+\partial_\theta, \tag{5.10}$$

$$A_3=\left[\int\left(-2\mu r(z'-iz)+\frac{\alpha}{L}\right)e^{2i\theta}\,\mathrm{d}t\right]\partial_t-ir[1-\mu ir(z'-iz)]e^{2i\theta}\partial_r+e^{2i\theta}\partial_\theta. \tag{5.11}$$

The actions of the second extensions of these three symmetries on the pair of equations (5.7) and (5.8) produce the following set of equations to be solved to determine f and g. The equations alternate from radial to angular in turn,

$$ir^2g+2ir\dot{r}\dot{\theta}-r^2\dot{\theta}^2-2rf=r^2\frac{\partial f}{\partial r}+ir^2\dot{\theta}\frac{\partial f}{\partial\dot{r}}-2r\dot{\theta}\frac{\partial f}{\partial\dot{\theta}}, \tag{5.12}$$

$$-4rf-2r\dot{\theta}-2ir\dot{\theta}^2=r^2\frac{\partial g}{\partial r}+ir^2\dot{\theta}\frac{\partial g}{\partial\dot{r}}-2r\dot{\theta}\frac{\partial g}{\partial\dot{\theta}}, \tag{5.13}$$

$$-3if-2\frac{\alpha}{L}f-\mu(r^2g+2r\dot r\dot\theta)(z''+iz')-\mu r^2\dot\theta^2(z'''+iz'')+2\mu rf(z'+iz)$$
$$=ir[1+\mu ir(z'+iz)]\frac{\partial f}{\partial r}+\frac{\partial f}{\partial\theta}+\left[-i\dot r-\mu r^2\dot\theta(z''+iz')-\frac{\alpha\dot r}{L}\right]\frac{\partial f}{\partial\dot r}$$
$$+\left[-2i\dot\theta+2\mu r\dot\theta(z'+iz)-\frac{\alpha\dot\theta}{L}\right]\frac{\partial f}{\partial\dot\theta}, \tag{5.14}$$

$$-4ig+2\mu(2rg+\dot r\dot\theta)(z'+iz)+2\mu r\dot\theta^2(z''+iz')+\frac{2\alpha\dot r}{r^3}-\frac{\alpha g}{L}$$
$$=ir[1+\mu ir(z'+iz)]\frac{\partial g}{\partial r}+\frac{\partial g}{\partial\theta}+\left[-i\dot r-\mu r^2\dot\theta(z''+iz')-\frac{\alpha\dot r}{L}\right]\frac{\partial g}{\partial\dot r}$$
$$+\left[-2i\dot\theta+2\mu r\dot\theta(z'+iz)-\frac{\alpha\dot\theta}{L}\right]\frac{\partial g}{\partial\dot\theta}, \tag{5.15}$$

$$-if-\mu(r^2g+2r\dot r\dot\theta)(z''+iz'+2z)+2(r\ddot\theta+2\dot r\dot\theta)-\mu r^2\dot\theta^2(z'''-iz'')-4i\mu r^2\dot\theta^2(z''-iz')$$
$$-\frac{\alpha f}{L}+\frac{\alpha\dot rL}{L^2}+4ir\dot\theta^2+2\mu(rf+2r^2\dot\theta^2)(z'-iz)-\frac{2i\alpha\dot r\dot\theta}{L}-\frac{\alpha f}{L}$$
$$=-ir[1-\mu ir(z'-iz)]\frac{\partial f}{\partial r}+\frac{\partial f}{\partial\theta}+\left[2r\dot\theta-\mu r\dot\theta(z''+iz'+2z)-\frac{\alpha\dot r}{L}\right]\frac{\partial f}{\partial\dot r}$$
$$+\left[2i\dot\theta+2\mu r\dot\theta(z'-iz)-\frac{\alpha\dot\theta}{L}\right]\frac{\partial f}{\partial\dot\theta}, \tag{5.16}$$

$$2ig+2\mu(2rg+\dot r\dot\theta)(z'-iz)+2\mu r\dot\theta^2(z''+iz'+2z)+\frac{2\alpha\dot r}{r^3}-4\dot\theta^2-\frac{2i\alpha\dot\theta}{r^2}\frac{\alpha g}{L}$$
$$=-ir[1-\mu ir(z'-iz)]\frac{\partial g}{\partial r}+\frac{\partial g}{\partial\theta}+\left[2r\dot\theta-\mu r\dot\theta(z''+iz'+2z)-\frac{\alpha\dot r}{L}\right]\frac{\partial g}{\partial\dot r}$$
$$+\left[2i\dot\theta+2\mu r\dot\theta(z'-iz)-\frac{\alpha\dot\theta}{L}\right]\frac{\partial g}{\partial\dot\theta}. \tag{5.17}$$

We observe that the combinations $r[(5.17)-(5.15)]+2i(1-\mu rz)(5.13)$ and the same with (5.16), (5.14), and (5.12) give zero on the right-hand side and so the system of partial differential equations to determine f and g reduces to an algebraic equation. From the combination of the angular equations we verify that

$$g=-\frac{2\dot r\dot\theta}{r}-\frac{\alpha\dot\theta}{r^2}. \tag{5.18}$$

With this and the combination of the radial equations we then verify that

$$f = r\dot{\theta}^2 - \frac{\alpha \dot{r}}{r^2} - \frac{\mu}{r^2} \tag{5.19}$$

provided the function $z(\theta)$ is a solution of the equation

$$z'' + z = \frac{1}{L^2}. \tag{5.20}$$

Since the sets of symmetries B and C are related to those of A by means of a point transformation which preserves the differential equation, it is evident that the same result applies for the sets B and C.

In this paper we have demonstrated that the Kepler problem can be recast as a simple harmonic oscillator plus a conservation law. By contrast with other literature on the relationship between the Kepler problem and the simple harmonic oscillator in which the Kepler problem is embedded in an oscillator of higher dimension we have shown that the Kepler problem in two dimensions has a natural representation in terms of a one-dimensional oscillator plus a first-order equation which represents the conservation of angular momentum. In the case of the Kepler problem in three dimensions the natural representation is in terms of a two-dimensional oscillator and the conservation of the z component of the angular momentum. Because of this relationship between the Kepler problem and the simple harmonic oscillator and the well-established results for the complete symmetry group of the latter it has been a relatively easy matter to determine the complete symmetry group for the Kepler problem in its two- and three-dimensional forms. The former requires four symmetries to specify it completely and the latter six. In both cases the number of symmetries required is one less than would have been expected, that being five for the two-dimensional case and seven for the three-dimensional case.

We recall that Krause[15] reported that the complete symmetry group of the three-dimensional Kepler problem consists of eight elements which is considerably in excess of the number reported here. It is known[1] that an inappropriate choice of symmetries can result in more symmetries being required to specify the equation than the minimal number. Apparently this is what happened in the case of Krause's work. That it should happen is quite understandable since he was working in a vacuum, as it were. In the case of the present work we had the advantage of the results for oscillator systems[2] and the relationship between the Kepler problem and the oscillator which we have shown for the three-dimensional problem. Furthermore, as we saw in the case of the three-dimensional Kepler problem, the representation of the elements of the complete symmetry algebra in terms of the original variables of the Kepler problem is extremely nonlocal and most nonintuitive.

Lorenz integrable system moves à la Poinsot

M. C. Nucci[a)]

(Received 12 February 2003; accepted 20 May 2003)

A transformation is derived which takes the Lorenz integrable system into the well-known Euler equations of a torque-free rigid body about a fixed point, i.e., the famous motion à la Poinsot. The proof is based on Lie group analysis applied to two third-order ordinary differential equations admitting the same two-dimensional Lie symmetry algebra. Lie's classification of two-dimensional symmetry algebras in the plane is used. If the same transformation is applied to the Lorenz system with any values of the parameters, then one obtains Euler equations of a rigid body about a fixed point subjected to a torsion depending on time and angular velocity. The numerical solution of this system yields a three-dimensional picture which looks like a ''tornado'' the cross-section of which has a butterfly-shape. Thus Lorenz's *butterfly* has been transformed into a *tornado*. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1599955]

I. INTRODUCTION

The motion of a heavy rigid body about a fixed point is one of the most famous problems of classical mechanics.[1] In 1750 Euler[2] derived the equations of motion, which now bear his name, and described what is nowadays known as the Euler–Poinsot case because of the geometrical description given by Poinsot about 100 years later.[3] It was Jacobi[4] who integrated this case by using the elliptic functions which he had developed (along with Legendre, Abel, and Gauss[5]) and mastered[6]—we have translated this fundamental text into Italian and commented extensively.[7]

More than 200 years later, in 1963, a paper was published[8] in which was presented a system of three ordinary differential equations. The author considered a hydrodynamical system developed by Rayleigh[9] and reduced it by applying a double Fourier series as in Ref. 10. Thus he obtained what nowadays is the famous Lorenz system.[11] Three parameters are part of the Lorenz system. For particular values of those parameters the Lorenz system can be integrated in closed form by means of Jacobi elliptic functions.[12] We call this system the Lorenz integrable system.

In January 2001 the first Whiteman prize for notable exposition on the history of mathematics was awarded to Thomas Hawkins by the American Mathematical Society. In the citation, published in the Notices of AMS **48**, 416-417 (2001), one reads that Thomas Hawkins ''... has written extensively on the history of Lie groups. In particular he has traced their origins to [Lie's] work in the 1870s on differential equations ... the *idée fixe* guiding Lie's work was the development of a Galois theory of differential equations ... (Hawkins's book[13]) highlights the fascinating interaction of geometry, analysis, mathematical physics, algebra and topology ...'' Also Hawkins had established ''the nature and extent of Jacobi's influence upon Lie.'' [14]

In the Introduction of his book[15] Olver wrote that ''it is impossible to overestimate the importance of Lie's contribution to modern science and mathematics. Nevertheless anyone who is already familiar with [it] ... is perhaps surprised to know that its original inspirational source was the field of differential equations.''

Lie's monumental work on transformation groups,[16–18] and in particular contact transformations,[19] led him to achieve his goal.[20]

Many books have been dedicated to this subject and its generalizations (Refs. 21–23, 15, 24–29).

Lie group analysis is indeed the most powerful tool to find the general solution of ordinary differential equations. Any known integration technique can be shown to be a particular case of a general integration method based on the derivation of the continuous group of symmetries admitted by the differential equation, i.e., the Lie symmetry algebra. In particular Bianchi's theorem (Refs. 30 and 15) states that, if an admitted n-dimensional solvable Lie symmetry algebra is found, then the general solution of the corresponding nth-order system of ordinary differential equations can be obtained by quadratures. The admitted Lie symmetry algebra can be easily derived by a straightforward although lengthy procedure. As computer algebra software becomes widely used, the integration of systems of ordinary differential equations by means of Lie group analysis is becoming easier to perform. A major drawback of Lie's method is that it is useless when applied to systems of n first-order equations, because they admit an infinite number of symmetries, and there is no systematic way to find even a one-dimensional Lie symmetry algebra, apart from trivial groups like translations in time admitted by autonomous systems. One may try to derive an admitted n-dimensional solvable Lie symmetry algebra by making an ansatz on the form of its generators.

However, in Ref. 31 we have remarked that any system of n first-order equations could be transformed into an equivalent system where at least one of the equations is of second order. Then the admitted Lie symmetry algebra is no longer infinite-dimensional, and nontrivial symmetries of the original system could be retrieved.[31] This idea has been successfully applied in several instances (Refs. 31–34). Also in Ref. 35 we have have shown that first integrals can be obtained by Lie group analysis, even if the system under study does not come from a variational problem, i.e., without making use of Noether's theorem.[36] If we consider a system of first-order equations and, by eliminating one of the dependent variables, derive an equivalent system which has one equation of second-order, then Lie group analysis applied to that equivalent system yields the first integral(s) of the original system which do(es) not contain the eliminated dependent variable. Of course this requires that such first integrals exist. The procedure should be repeated as many times as there are dependent variables in order to find all such first integrals. The first integrals correspond to the characteristic curves of determining equations of parabolic type which are constructed by the method of Lie group analysis. We remark that interactive (not automatic) programs for calculating Lie symmetries such as Refs. 37 and 38 are more appropriate for performing this task.

We have briefly sketched three apparently unrelated subjects. In this paper we show that the Lorenz system and the Euler equations are actually related by means of Lie group analysis. In Ref. 39 we applied Lie group analysis to a third-order differential equation, which is equivalent to the Lorenz integrable system, and obtained a two-dimensional Lie symmetry algebra, which we then used to integrate the Lorenz integrable system in terms of Jacobi elliptic functions. Here we show that the same Lie symmetry algebra is admitted by a third-order differential equation which is equivalent to the Euler equations of a torque-free rigid body moving about a fixed point. Then a transformation is easily derived by which the Lorenz integrable system becomes the Euler equations of a torque-free rigid body moving about a fixed point. Thus, it can be stated that ''the Lorenz integrable system moves à la Poinsot.'' If the same transformation is applied to the Lorenz system with any value of parameters, then one obtains the Euler equations of a rigid body moving about a fixed point and subjected to a torsion depending on time and angular velocity. The numerical solution of this system yields a three-dimensional picture which resembles a ''tornado'' the cross-section of which has a butterfly-shape. By means of our transformation Lorenz's *butterfly* becomes a *tornado*.

In the last section the relationship between Lie group analysis and first integrals[35] is exemplified by considering the Euler equations of a torque-free rigid body about a fixed point and the Lorenz integrable system.

II. BUTTERFLIES AND TORNADOES

Consider the Lorenz system:[8]

$$x' = \tilde{\sigma}(y-x), \tag{1}$$

$$y' = -xz + \tilde{r}x - y, \tag{2}$$

$$z' = xy - \tilde{b}z, \tag{3}$$

where $\tilde{\sigma}$, $\tilde{b}$, and $\tilde{r}$ are parameters (a prime denotes differentiation with respect to τ). This system can be reduced to a single third-order ordinary differential equation for x,[41] which admits a two-dimensional Lie symmetry algebra if $\tilde{\sigma}=1/2$, $\tilde{b}=1$, and $\tilde{r}=0$. System (1)–(3) becomes

$$x' = \frac{(y-x)}{2}, \tag{4}$$

$$y' = -xz - y, \tag{5}$$

$$z' = xy - z. \tag{6}$$

The corresponding third-order equation is

$$2xx''' - 2x'x'' + 5xx'' - 3x'^2 + 2x^3x' + 3xx' + x^4 + x^2 = 0, \tag{7}$$

and admits a two-dimensional Lie symmetry algebra L_2 with basis:

$$X_1 = \partial_\tau, \qquad X_2 = e^{\tau/2}\left(\partial_\tau - \frac{1}{2}x\partial_x\right). \tag{8}$$

A basis of its differential invariants of-order $\leqslant 2$ is given by

$$\phi = \left(x' + \frac{x}{2}\right)x^{-2}, \qquad \psi = \left(x'' + \frac{3}{2}x' + \frac{x}{2}\right)x^{-3}. \tag{9}$$

Equation (7) is reduced to the following first-order equation:

$$(\psi - 2\phi^2)\frac{\mathrm{d}\psi}{\mathrm{d}\phi} = -2\psi\phi - \phi, \tag{10}$$

which can be easily integrated[40] to give

$$\frac{1+4\psi-4\phi^2}{(1+2\psi)^2} = c_1, \tag{11}$$

where c_1 is an arbitrary constant. The substitution of x and its derivatives into (11) yields a second-order ordinary differential equation,

$$\frac{1+4\left(x''+\frac{3}{2}x'+\frac{1}{2}x\right)x^{-3}-4\left(x'+\frac{1}{2}x\right)^2x^{-4}}{(x^3+2x''+3x'+x)^2x^{-6}} = c_1, \tag{12}$$

which admits the Lie symmetry algebra L_2. Lie's classification of two-dimensional algebras into four canonical types[20] allows us to integrate (12) by quadrature if we introduce the canonical variables:

$$v=-2e^{-\tau/2}, \qquad u=\frac{e^{-\tau/2}}{x}, \tag{13}$$

which transform Eq. (12) into

$$\frac{1+4\left(\frac{du}{dv}\right)^2-4u\frac{d^2u}{dv^2}}{\left[2u\frac{d^2u}{dv^2}-4\left(\frac{du}{dv}\right)^2-1\right]^2}=c_1, \tag{14}$$

and operators (8) into

$$\overline{X}_1=\partial_v, \qquad \overline{X}_2=v\partial_v+u\partial_u. \tag{15}$$

Then the general solution of (14) can be easily derived[20] to be

$$\int (-c_1\mp 2c_2u^2-c_2^2u^4)^{-1/2}du=\pm\frac{v}{2\sqrt{c_1}}+c_3, \tag{16}$$

with c_2 and c_3 arbitrary constants. This solution which involves an elliptic integral has already been obtained by Sen and Tabor[41] by means of a lengthier analysis.

The Euler equations describing the motion of a heavy rigid body about a fixed point with no torsion are

$$\dot{p}=\frac{(B-C)}{A}qr, \tag{17}$$

$$\dot{q}=\frac{(C-A)}{B}pr, \tag{18}$$

$$\dot{r}=\frac{(A-B)}{C}pq, \tag{19}$$

with A, B, and C being the principal moments of inertia, and $p(t)$, $q(t)$, and $r(t)$ the components of the angular velocity (a dot denotes differentiation with respect to t). This system can be reduced to a single third-order ordinary differential equation for, say, p, viz.,

$$p\frac{d^3p}{dt^3}-\frac{dp}{dt}\frac{d^2p}{dt^2}-\frac{4(C-A)(A-B)}{BC}p^3\frac{dp}{dt}=0, \tag{20}$$

which admits a two-dimensional Lie symmetry algebra $\mathcal{L}_2$ with basis:

$$\Gamma_1=\partial_t, \qquad \Gamma_2=t\partial_t-p\partial_p. \tag{21}$$

The two Lie symmetry algebras L_2 and $\mathcal{L}_2$ that we have found are actually the same, i.e., Type IV in Lie's classification.[20] Therefore they are linked by a transformation which takes (τ,x) into (t,p). Prolongation to the second-order of the two equivalent Lie symmetry algebras yields a transformation which takes the system (17)–(19) into the system (4)–(6) as

$$\tau=\log\left(\frac{4}{t^2}\right),$$

$$x=\frac{p\,t}{2},$$

$$y=\frac{C-B}{2A}qrt^2, \tag{22}$$

$$z=\frac{C-B}{2A}\left[\frac{(C-A)}{B}r^2+\frac{(A-B)}{C}q^2\right]t^2,$$

with the following condition on the momenta of inertia:

$$\frac{(A-B)(A-C)}{BC}=\frac{1}{4}. \tag{23}$$

A slightly more general condition could have been considered if one replaces 1/4 with $k/4$ (k an arbitrary parameter). If one derives B from (23) by assuming $A-C>0$ and $4A-3C>0$, i.e.,

$$B=\frac{4A(A-C)}{4A-3C}, \tag{24}$$

then the transformation (22) turns into the following:

$$\tau=\log\left(\frac{4}{t^2}\right),$$

$$x=\frac{p\,t}{2},$$

$$y=-\frac{(2A-C)(2A-3C)}{2A(4A-3C)}qrt^2, \tag{25}$$

$$z=-\frac{(2A-C)(2A-3C)[4A^2q^2-(4A-3C)^2r^2]}{8A^2(4A-3C)^2}t^2,$$

and the system (17)–(19) assumes the form

$$\dot{p}=\frac{(2A-C)(2A-3C)}{A(4A-3C)}qr, \tag{26}$$

$$\dot{q}=\frac{3C-4A}{4A}pr, \tag{27}$$

$$\dot{r}=\frac{A}{4A-3C}pq. \tag{28}$$

We also derive the inverse transformation, i.e.,

$$t=2e^{-\tau/2},$$

$$p=xe^{\tau/2}, \tag{29}$$

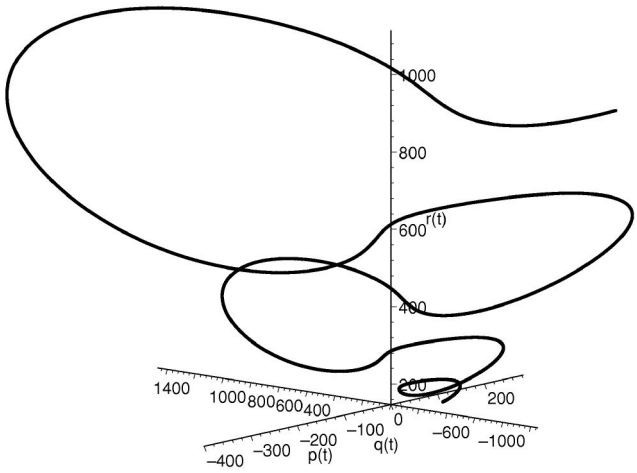

FIG. 1. The 3-dim plot of the ''tornado.''

$$q=-\frac{(4A-3C)ye^{\tau/2}}{2\sqrt{(2A-C)(2A-3C)(\sqrt{y^2+z^2}+z)}},$$

$$r=\frac{Ae^{\tau/2}\sqrt{\sqrt{y^2+z^2}+z}}{\sqrt{(2A-C)(2A-3C)}},$$

which takes the system (4)–(6) into the system (17)–(19) after substituting B as in (24).

If one applies the transformation (29) to the general Lorenz system (1)–(3), then the following equations are obtained:

$$\dot{p}=\frac{2(2A-C)(2A-3C)\tilde{\sigma}}{A(4A-3C)}qr+(2\tilde{\sigma}-1)\frac{p}{t}, \tag{30}$$

$$\dot{q}=\frac{3C-4A}{4A}pr+(\tilde{b}-1)\frac{4A^2q^2-(4A-3C)^2r^2}{4A^2q^2+(4A-3C)^2r^2}\frac{q}{t}+\tilde{r}\frac{2(4A-3C)^3A}{(2A-C)(2A-3C)[4A^2q^2+(4A-3C)^2r^2]}\frac{pr}{t^2}, \tag{31}$$

$$\dot{r}=\frac{A}{4A-3C}pq-(\tilde{b}-1)\frac{4A^2q^2-(4A-3C)^2r^2}{4A^2q^2+(4A-3C)^2r^2}\frac{r}{t}+\tilde{r}\frac{8(4A-3C)A^3}{(2A-C)(2A-3C)[4A^2q^2+(4A-3C)^2r^2]}\frac{pq}{t^2}. \tag{32}$$

They can be interpreted as the Euler equations of a rigid body moving about a fixed point and subjected to a torsion which depends on time t and angular velocity (p,q,r) in the body-frame reference. Also the momenta of inertia are linked by relation (24). To our knowledge such a system has never been described.

If we use Maple V in order to draw a three-dimensional plot of system (30)–(32), then a ''tornado,'' the cross-section of which resembles a butterfly, is obtained (Fig. 1). The usual values

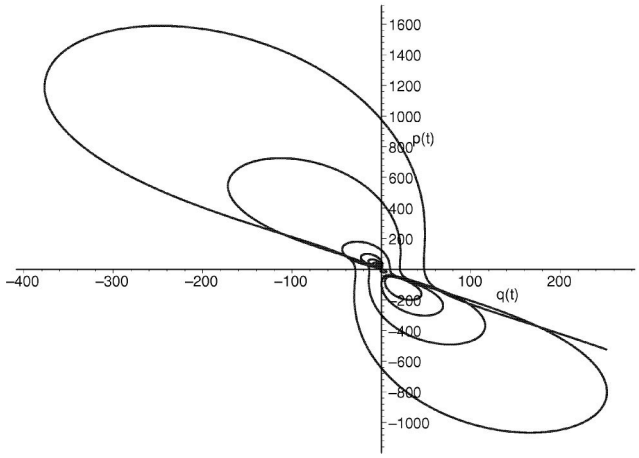

FIG. 2. The 2-dim plot of p vs q.

for the Lorenz parameters, $\tilde{\sigma}=10$, $\tilde{b}=8/3$, $\tilde{r}=28$, are imposed. Also we assume $A=2$ and $C=1$. We consider t as it varies in the interval $[2,0.015]$, which corresponds to $\tau\in[0,9.8]$ approximately. The step size used is 0.00005.

The butterfly-shape curve is better seen in Fig. 2, which shows the two-dimensional plot of p versus q.

A clearer view of the ''tornado'' is given in Fig. 3, which shows the two-dimensional plot of r versus q. Another view can be found in Fig. 4 which shows the two-dimensional plot of r versus p.

In Figs. 5 and 6 the plot of p versus t is given for two different but close initial values (1 and 1.01). For relatively large values of t, say $t\in[2,0.5]$, the solutions are the same (Fig. 5). For small t, say $t\in[0.05,0.015]$, a dramatic difference appears (Fig. 6).

In Ref. 42 it was found that one could explicitly derive a first integral of the Lorenz system (1)–(3) in six different instances which correspond to particular values of the Lorenz parameters. It is a trivial task to apply those findings to system (30)–(32) by using the transformation (22). The following is the list of the six cases with a relative first integral F for the system (30)–(32).

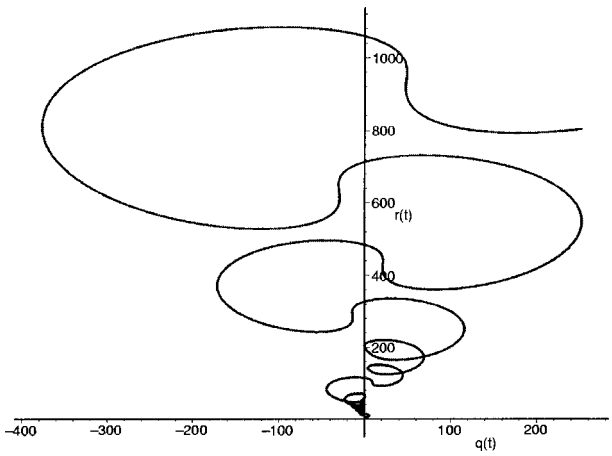

FIG. 3. The 2-dim plot of r vs q.

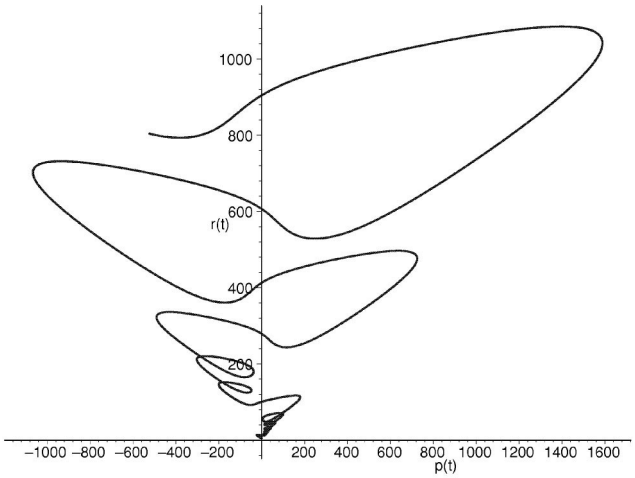

FIG. 4. The 2-dim plot of r vs p.

(1) $\tilde{b}=2\tilde{\sigma}$, $\tilde{r}$ arbitrary,

$$F=4^{2\tilde{\sigma}-1}t^{2(1-2\tilde{\sigma})}\left(p^2+\frac{[4A^2q^2-(4A-3C)^2r^2](2A-C)(2A-3C)\tilde{\sigma}}{A^2(4A-3C)^2}\right).$$

(2) $\tilde{b}=0$, $\tilde{\sigma}=1/3$, $\tilde{r}$ arbitrary,

$$F=4^{1/3}t^{-2/3}\left(-p^2\tilde{r}-2\frac{(2A-C)(2A-3C)}{3A(4A-3C)}pqrt-\frac{3}{16}p^4t^2\right.$$
$$\left.-\frac{(4A^2q^2-(4A-3C)^2r^2)(2A-C)(2A-3C)}{8A^2(4A-3C)^2}p^2t^2+\frac{(2A-C)^2(2A-3C)^2}{3A^2(4A-3C)^2}q^2r^2t^2\right).$$

(3) $\tilde{b}=1$, $\tilde{r}=0$, $\tilde{\sigma}$ arbitrary,

$$F=\frac{(4A^2q^2+(4A-3C)^2r^2)^2(2A-C)^2(2A-3C)^2}{4A^4(4A-3C)^4}.$$

(4) $\tilde{b}=4$, $\tilde{\sigma}=1$, $\tilde{r}$ arbitrary,

$$F=4t^{-6}\left(16p^2\tilde{r}+32\tilde{r}\frac{(4A^2q^2-(4A-3C)^2r^2)(2A-C)(2A-3C)}{A^2(4A-3C)^2}-p^4t^2\right.$$

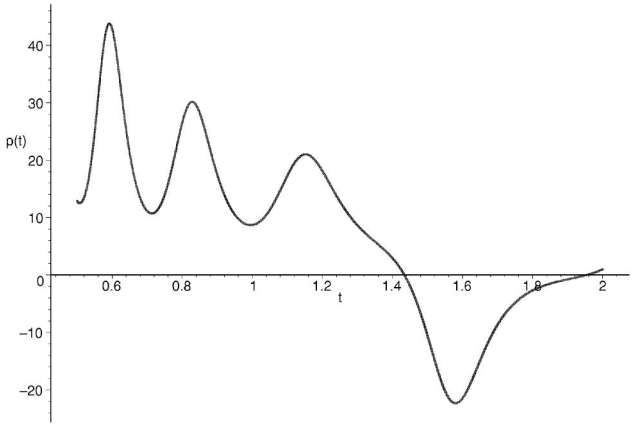

FIG. 5. Varying the initial condition of p in $t=2$ by 0.01. The two plots of $p(t), t\in[2,0.5]$ are indistinguishable.

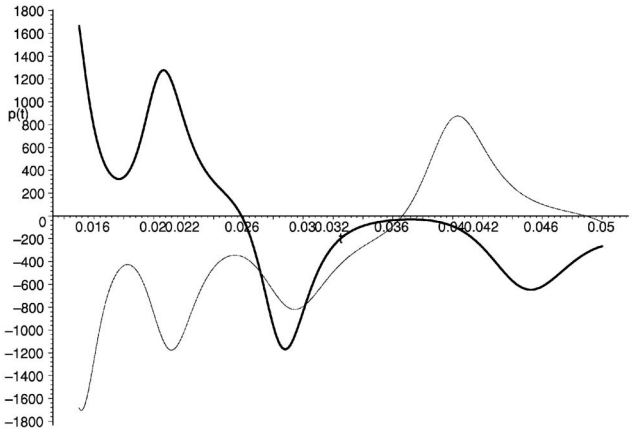

FIG. 6. Varying the initial condition of p in $t=2$ by 0.01. There are two different plots of $p(t), t\in[0.05,0.015]$: the darker line represents the plot of $p(t)$ with initial condition $p=1$ in $t=2$, and the lighter line the plot of $p(t)$ with initial condition $p=1.01$ in $t=2$.

$$-2\frac{(4A^2q^2-(4A-3C)^2r^2)(2A-C)(2A-3C)}{A^2(4A-3C)^2}p^2t^2+32\frac{(2A-C)(2A-3C)}{A(4A-3C)}pqrt$$
$$+16\frac{(2A-C)^2(2A-3C)^2}{A^2(4A-3C)^2}q^2r^2t^2-32\frac{(4A^2q^2-(4A-3C)^2r^2)(2A-C)(2A-3C)}{A^2(4A-3C)^2}\Bigg).$$

(5) $\tilde{b}=1$, $\tilde{\sigma}=1$, $\tilde{r}$ arbitrary,

$$F=-\frac{4}{t^2}p^2\tilde{r}+\frac{(4A^2q^2+(4A-3C)^2r^2)^2(2A-C)^2(2A-3C)^2}{4A^4(4A-3C)^4}.$$

(6) $\tilde{b}=6\tilde{\sigma}-2$, $\tilde{r}=2\tilde{\sigma}-1$

$$F=4^{4\tilde{\sigma}}t^{2(1-4\tilde{\sigma})}\Bigg(-\frac{p^4t^2}{64\tilde{\sigma}}-\tilde{\sigma}\frac{(4A^2q^2-(4A-3C)^2r^2)(2A-C)(2A-3C)}{32A^2(4A-3C)^2}p^2t^2+\frac{(2\tilde{\sigma}-1)^2}{4\tilde{\sigma}}p^2$$
$$+\frac{(2A-C)(2A-3C)(2\tilde{\sigma}-1)}{2A(4A-3C)}pqrt+\frac{(2A-C)^2(2A-3C)^2\tilde{\sigma}}{4A^2(4A-3C)^2}q^2r^2t^2\Bigg).$$

III. LIE GROUP ANALYSIS AND FIRST INTEGRALS

In Ref. 35 we showed the application of Lie group analysis in order to obtain first integrals with at least one missing variable. Consider Euler equations (17)–(19). There exist two well-known first integrals, i.e., the conservation of kinetic energy and the conservation of angular momentum:

$$Ap^2+Bq^2+Cr^2=I_1, \tag{33}$$

$$A^2p^2+B^2q^2+C^2r^2=I_2. \tag{34}$$

We derive p from (19) (the method works independently of the chosen equation) as

$$p=\frac{C\dot{r}}{(A-B)q},$$

in order to obtain the following two differential equations in q and r, one of first-order and one second-order, respectively:

$$\dot{q}=\frac{C(C_A)r\dot{r}}{B(A-B)q}, \tag{35}$$

$$\ddot{r}=\frac{C(C-A)}{B(A-B)q^2}r\dot{r}^2+\frac{(B-C)(A-B)}{AC}rq^2. \tag{36}$$

When Lie group analysis of the system (35)–(36) is performed, a linear partial differential equation of a parabolic structure is generated. Its characteristic curve is given by

$$B(A-B)q^2+C(A-C)r^2,$$

which is a combination of the two first integrals (33) and (34). Consequently we introduce the new dependent variable s such that

$$q=\sqrt{\frac{C(C-A)r^2+s}{B(A-B)}}, \tag{37}$$

in order to obtain the following system:

$$\dot{s}=0, \tag{38}$$

$$\ddot{r}=\frac{C(C-A)r\dot{r}^2}{C(C-A)r^2+s}+\frac{(C-A)(B-C)r^3}{AB}+\frac{(B-C)sr}{ABC}. \tag{39}$$

Equation (39) admits an eight-dimensional Lie symmetry algebra (i.e., it is linearizable) if either $A=C$ or $B=C$, i.e., the case of the torque-free Lagrange top (uniform precession). If either q or r, one at a time, is eliminated from system (17)–(19), then a similar result is obtained, i.e., the other two combinations of the first integrals (33) and (34). Indeed the elimination of q yields the first integral,

$$A(A-B)p^2+C(B-C)r^2,$$

and the elimination of r yields the first integral

$$B(B-C)q^2+A(A-C)p^2.$$

If the same method is applied to the Lorenz integrable system (4)–(6), then the following two first integrals are obtained:

$$(y^2+z^2)\,e^{2\tau}, \tag{40}$$

$$(z-x^2)\,e^{\tau}. \tag{41}$$

Those first integrals were found in Ref. 12 by using the Painlevé analysis.

From (6) we have

$$x=\frac{z'+z}{y},$$

in order to obtain the following two differential equations in y and z: one of first-order and one second-order, respectively:

$$y'=-\frac{y^2+z^2+zz'}{y}, \tag{42}$$

$$z''=\frac{y^4-3y^2z-5y^2z'-2z^3-4z^2z'-2zz'^2}{2y^2}. \tag{43}$$

When the Lie group analysis of the system (42)–(43) is performed, a linear partial differential equation of a parabolic structure is generated. Its characteristic curve is given by

$$y^2+z^2.$$

Consequently we introduce the new dependent variable Y such that

$$y=\sqrt{Y-z^2}, \tag{44}$$

in order to obtain the following system:

$$Y'=-2Y, \tag{45}$$

$$z''=\frac{Y^2-2Yz^2-3Yz-5Yz'+z^4+z^3+z^2z'-2zz'^2}{2(Y-z^2)}. \tag{46}$$

The first equation can be easily integrated to yield the first integral (40). If we eliminate y from system (4)–(6), a similar procedure provides the first integral (41).

(Received 2 February 2003; accepted 24 April 2003)

In this article we consider a family of minimization problems whose solutions represent the vortices of two dimensional flows. We prove that if we consider an admissible sequence of vortices, then the corresponding centroids converge to the global minimizer of the Routh function associated with an appropriate energy functional. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1597947]

I. INTRODUCTION

It is well known that for isochoric (volume-preserving) plane motion of a fluid, the velocity field $\mathbf{u}(x_1,x_2)$ satisfies the continuity equation $\nabla\cdot\mathbf{u}=0$, which is identically satisfied if we write

$$\mathbf{u}=\left(\frac{\partial\psi}{\partial x_2},-\frac{\partial\psi}{\partial x_1}\right),$$

where ψ is the stream function, which is constant on any curve everywhere tangent to the velocity field. It is also well known that for an incompressible fluid, the dynamical equations of plane motion can be reduced to the vorticity equation

$$\frac{\partial\omega}{\partial t}+\mathbf{u}\cdot\nabla\omega=0,$$

where $\omega=-\Delta\psi$ is the (scalar) vorticity (i.e., the nonzero component of $\nabla\times\mathbf{u}$). Note that when $\omega=0$, the flow is said to be irrotational. It follows that for steady motion (no time dependence) the Jacobian determinant of ψ and ω vanishes; that is,

$$[\psi,\omega]=0, \tag{1}$$

and so ψ and ω are functionally dependent. Inserting $\omega=-\Delta\psi$ into (1) we derive

$$[\psi,-\Delta\psi]=0. \tag{2}$$

Therefore, if ϕ is any real valued function and ψ is a solution of the semilinear equation

$$-\Delta\psi=\phi(\psi), \tag{3}$$

[a)]Electronic mail: b_emamizadeh@yahoo.com
[b)]Address to be used for correspondence

then ψ is also a solution of (2). So, a solution of (3) would represent the stream function of a two dimensional ideal fluid. For the mathematical background in fluid dynamics the reader is referred to Ref. 15.

In Ref. 11, it was proved that the following inverse (the nonlinearity ϕ was not known *a priori*) problem,

$$\begin{gathered} -\Delta\psi=\phi(\psi) \quad \text{in } \Omega, \\ \psi=0 \quad \text{on } \partial\Omega, \\ -\Delta\psi\in\mathcal{F}, \\ \psi\to\lambda x_1x_2 \quad \text{at infinity,} \end{gathered} \tag{4}$$

has a solution, where Ω was a set obtained by excluding a region containing the origin and $\mathcal{F}$ was the set of rearrangements of a given function (see the next section for definition). Any solution of (4), recalling the above discussion, represents a planar ideal fluid in Ω which is tangential to $\partial\Omega$ ($\psi=0$ on $\partial\Omega$), its vorticity belongs to $\mathcal{F}$, and behaves as an irrotational flow at long range points ($\psi\to\lambda x_1x_2$). The proof was based on the extensively developed rearrangement variational principles for strictly convex functionals which are weakly sequentially continuous. More precisely, it was shown that for $\Psi_\lambda=\Psi-\lambda\mathcal{I}$, the difference of a quadratic and a linear integral functional over Ω, the variational problem

$$P_\lambda: \quad \sup_{\zeta\in\mathcal{F}}\Psi_\lambda(\zeta) \tag{5}$$

is solvable for small positive values of λ. The corresponding Euler–Lagrange equation at a solution of (5) would then provide a solution for (4). It was shown that using a standard rescaling $[\zeta(x)\to c\zeta(c^{1/2}x)]$, one converts (5) into a new parametrized family of variational problems

$$\hat{P}_c: \quad \sup_{\zeta\in\mathcal{F}_c}\hat{\Psi}_c(\zeta), \tag{6}$$

which are easier to deal with essentially because the rescaling would elliminate the λ in front of the linear part of Ψ_λ at the price of having all the integrals involved in $\hat{\Psi}_c$ over the rescaled Ω, denoted Ω_c (see the next section for definitions). It was proved in Ref. 11 that (6) is solvable provided $c\gg1$; this implies that (5) is solvable when λ is small enough. Since solutions of (6) also represent steady flows, in this article we would like to consider (6) independent of (5), and prove an asymptotic result concerning the centroids of the solutions of (6). We will show that if c_n is an admissible sequence, and if ζ_{c_n} is any solution of $\hat{P}_{c_n}$, then the sequence of centroids of ζ_{c_n} will converge to the global maximizer of the Routh function

$$H(x)=\frac{1}{4\pi}\log\frac{|x|}{2x_1x_2}+x_1x_2.$$

This result is stated in Theorem 3 of the next section.

Badiani[1] considered a similar situation where Ω in his case was the upper half plane excluding a region containing the origin. Since the upper half plane is symmetric with respect to the x_2-axis, the author of Ref. 1 could make effective use of Steiner symmetrization techniques. However, in our case, due to lack of symmetry of the quarter plane, we are unable to use Steiner symmetrization, so we need to obtain novel estimates in order to make up for this deficiency. Moreover, these estimates can be similarly reproduced for the upper half plane case and in fact for any wedge type domains in general.

The main mathematical difficulty in proving solvability of problems like $\hat{P}_c$ is the unboundedness of the domain of the problem which makes the usual direct method of calculus of variations *unavailable*. However, it is well known that essential information can be extracted from considering $\hat{P}_c$ first on bounded domains (see Ref. 2). Therefore, for the convenience of the reader we end this section with a brief review of the variational principle suitable for proving solvability of variational problems similar to $\hat{P}_c$. For a complete treatment the reader is referred to Ref. 11.

Let Ω be a bounded domain in $\mathbb{R}^2$; let p and q be conjugate exponents, that is, $1/p+1/q=1$, for $2<p<\infty$. Suppose that $\Phi: L^p(\Omega)\to\infty$ is a convex functional and $\mathcal{F}(\Omega)$ is the set of rearrangements of a given function $f_0\in L^p(\Omega)$. Then the following result was obtained by Burton:[4] *If Φ is weakly sequentially continuous, then Φ attains a maximum relative to $\mathcal{F}(\Omega)$. In addition, if Φ is strictly convex and f^* is a maximizer relative to $\mathcal{F}(\Omega)$ and $g\in\partial\Phi(f^*)$, subdifferential of Φ at f^*, then*

$$f^*=\phi\circ g, \tag{7}$$

almost everywhere in Ω for some increasing function ϕ.

Note that in case Φ is differentiable, which is indeed the case we are interested in, then $\partial\Phi(f^*)=\{\Phi'(f^*)\}$. Therefore (7) turns into

$$f^*=\phi\circ\Phi'(f^*), \tag{8}$$

almost everywhere in Ω. Equation (8) will prove to be the main ingredient in our analysis; in particular it is very helpful in deriving essential estimates.

Rearrangement variational problems have been an active field of research in recent years; see Refs. 1, 5, 6, and 9–12 for theoretical results and Refs. 7 and 8 for numerical results.

II. NOTATION, DEFINITIONS AND THE STATEMENT OF THE MAIN RESULTS

Henceforth p is an arbitrary fixed number in $(2,\infty)$. For any number $r\geqslant 1$, r^* denotes the conjugate exponent, $1/r+1/r^*=1$. For a measurable set $E\subseteq\mathbb{R}^2$, $|E|$ denotes the Lebesgue measure of E. The ball centered at x with radius ξ is denoted $B_\xi(x)$; in the case where the center is the origin we write B_ξ. Given a measurable set $A\subseteq\mathbb{R}^2$, $x\in\mathbb{R}^2$ is called a density point of A whenever

$$|B_\epsilon(x)\cap A|>0,$$

for every $\epsilon>0$. The set of all density points of A is denoted $\mathrm{den}(A)$. The essential diameter of A, denoted $\mathrm{diam}(A)$, is defined by

$$\mathrm{diam}(A)=\sup\{|x-y|:\ \ x,y\in\mathrm{den}(A)\}.$$

Let D be an open, bounded, simply connected set containing the origin and assume $\overline{D}\subset B_1$. Let Π_+ denote the open first quadrant; let $\Omega=\Pi_+\backslash\overline{D}$ such that $\partial\Omega\in C^2$. For $c>0$ we set

$$\Omega_c=\{x\in\Pi_+|\ \ c^{1/2}x\in\Omega\}.$$

The symbols G_+, G, G_B and G_c denote the Green's functions for $-\Delta$ with homogeneous Dirichlet boundary conditions in Π_+, Ω, $\Pi_+\backslash\overline{B_1}$ and Ω_c, respectively. It is well known that

$$G_+(x,y)=\frac{1}{2\pi}\log\frac{|x-\overline{y}|\ \ |x-\underline{y}|}{|x-y|\ \ |x-\underline{\overline{y}}|},\qquad x,y\in\Pi_+,\ \ x\neq y,$$

where the overline and the underline signs designate the reflections with respect to x_1 and x_2 axes, respectively. We also have the following identity:

$$G_c(x,y)=G(c^{1/2}x,c^{1/2}y), \quad x,y\in\Omega_c, \quad x\neq y.$$

By applying the maximum principle we readily obtain

$$G_B(x,y)\leqslant G_c(x,y)\leqslant G_+(x,y), \tag{9}$$

where each inequality holds in the positive domain. For a measurable function ζ and $x\in\mathbb{R}^2$ we define

$$K_+\zeta(x)=\int_{\Pi_+} G_+(x,y)\quad \zeta(y)dy,$$

$$K\zeta(x)=\int_{\Omega} G(x,y)\quad \zeta(y)dy,$$

$$K_c\zeta(x)=\int_{\Omega_c} G_c(x,y)\quad \zeta(y)dy,$$

whenever the integrals exist.

We let $\eta\in C^2(\Omega)\cap C^1(\overline{\Omega})$ be a function satisfying

$$\Delta\eta=0 \quad \text{in} \quad \Omega,$$

$$\eta=0 \quad \text{on} \quad \partial\Omega,$$

$$\eta=x_1x_2+O(|x|^{-2}) \quad \text{as} \quad |x|\to\infty,$$

$$\nabla\eta=(x_2,x_1)+O(|x|^{-3}), \quad \text{as} \quad |x|\to\infty,$$

and

$$x_1x_2-\frac{x_1x_2}{|x|^4}\leqslant\eta\leqslant x_1x_2, \quad x\in\Omega. \tag{10}$$

Let us fix $\zeta_0\in L^p(\Omega)$, a non-negative, nontrivial function with compact support and assume $|\text{supp}(\zeta_0)|=\pi a^2$, for some $a>0$. In addition, we suppose that $\|\zeta_0\|_1=1$. A measurable function ζ is said to be a rearrangement of ζ_0 on Ω whenever

$$|\{x\in\Omega|\quad \zeta(x)\geqslant\alpha\}|=|\{x\in\Omega|\quad \zeta_0(x)\geqslant\alpha\}|,$$

for every $\alpha\in\mathbb{R}$. The set of all rearrangements of ζ_0 on Ω, with compact support, is denoted $\mathcal{F}$. For $c>0$ and a measurable function ζ we define

$$\mathcal{C}_c(\zeta)(x)=c\,\zeta(c^{1/2}x), \quad x\in\Omega_c. \tag{11}$$

The mapping $\mathcal{C}_c$ as defined in (11) takes measurable functions on Ω to measurable functions on Ω_c. By $\mathcal{F}_c$ we denote the set of all rearrangements of $\mathcal{C}_c(\zeta_0)$ on Ω_c with compact support. Given a measurable function ζ on Ω_c, $c>0$, we define the energy functional

$$\hat{\Psi}_c(\zeta)=\frac{1}{2}\int_{\Omega_c}\zeta\quad K_c\zeta-\int_{\Omega_c}\eta_c\zeta, \tag{12}$$

where $\eta_c(x)=c^{-1}\quad \eta(c^{1/2}x)$, whenever the integrals exist. For $c>0$ we set

$$\hat{P}_c: \quad \sup_{\zeta \in \mathcal{F}_c} \hat{\Psi}_c(\zeta).$$

The solution set for $\hat{P}_c$ is denoted Σ_c. Let us note that from (10) we infer

$$x_1x_2 - \frac{x_1x_2}{c^2|x|^4} \leqslant \eta_c(x) \leqslant x_1x_2, \qquad x \in \Omega_c. \tag{13}$$

We end this section with a result from Ref. 11 (Theorem 1) followed by the main results of this article (Theorems 2 and 3).

Theorem 1: *There exists $c^0>0$ such that for $c \geqslant c^0$, $\hat{P}_c$ is solvable. Moreover, if $\zeta \in \Sigma_c$, then*

$$\mathrm{supp}(\zeta) \subset B_{R(c)},$$

where $R(c)$ is a constant merely depending on c which satisfies

$$R(c) \leqslant Ac^{1/2}, \tag{14}$$

for some $A>0$. In addition we have

$$\mathrm{supp}(\zeta) = \{x \in \Omega_c : K_c\zeta(x) - \eta_c(x) \geqslant \gamma_c\}, \tag{15}$$

where γ_c is a constant depending on c satisfying the following inequality:

$$\gamma_c \geqslant \frac{1}{2\pi} \log \frac{c^{1/2}}{2a} + C. \tag{16}$$

Theorem 2: *There exist $c^1 \geqslant c^0$ and $R>0$ such that if $c \geqslant c^1$ and $\zeta \in \Sigma_c$, then*

$$\mathrm{supp}(\zeta) \subseteq B_R, \tag{17}$$

modulo a set of measure zero.

Before stating our last result we need the following definitions.

Definition 1: For a measurable function f on $S \subseteq \mathbb{R}^2$, the centroid of f, denoted $\mathrm{cent}(f)$, is defined by

$$\mathrm{cent}(f) = \int_S x \quad f(x)dx.$$

Definition 2: Suppose $\{c_j\}$ is a sequence of real numbers and ζ_{c_j} is a measurable function on Ω_{c_j}, for $j \in \mathbb{N}$. We say the sequence $\{\zeta_{c_j}\}$ is admissible whenever $\{\mathrm{cent}(\zeta_{c_j})\}$ is a convergent sequence in $\mathbb{R}^2$.

Remark: Let us point out that if $\{c_j\}$ is a sequence with $c_j \geqslant c^1$, and $\zeta_{c_j} \in \Sigma_{c_j}$, $j \in \mathbb{N}$, then by Theorem 2, $\{\zeta_{c_j}\}$ contains a subsequence which is admissible.

Theorem 3: *Suppose $\{c_j\}$ is a sequence of real numbers tending to infinity. Suppose $\zeta_{c_j} \in \Sigma_{c_j}$, and $\{\zeta_{c_j}\}$ is admissible. Then*

$$\mathrm{cent}(\zeta_{c_j}) \to \hat{x}, \tag{18}$$

as $j \to \infty$.

Throughout the article the symbol C always indicates a universal constant which may appear in consecutive steps with different values.

III. PRELIMINARIES

In this section we recall some results from Ref. 11. We begin with the following identities:

$$G(x,y)=\frac{1}{2\pi}\log\frac{1}{|x-y|}-h(x,y),$$

$$G_+(x,y)=\frac{1}{2\pi}\log\frac{1}{|x-y|}-h_+(x,y),$$

$$G_B(x,y)=\frac{1}{2\pi}\log\frac{1}{|x-y|}-h_B(x,y),$$

where h, h_+, and h_B are harmonic functions, for fixed y, in their respective domains. From (9) it follows that

$$h_+(x,y)\leqslant h(x,y)\leqslant h_1(x,y), \tag{19}$$

where the inequalities are understood to hold in the positive domains. We set $\hat{h}=h-h_+$ and $\hat{h}_1=h_1-h_+$. Then from (19) we infer $0\leqslant\hat{h}\leqslant\hat{h}_1$; also elementary calculations verify that

$$\hat{h}_1(x,y)\leqslant\frac{x_2y_2}{\pi(|x||y|-1)^2}\ , \tag{20}$$

provided $x,y\in\Pi_+\backslash\overline{B}_1$. Similarly, we obtain

$$0\leqslant\hat{h}_1(x,y)\leqslant\frac{x_1y_1}{\pi(|x||y|-1)^2}\ , \tag{21}$$

provided $x,y\in\Pi_+\backslash\overline{B}_1$.

Let $\zeta\in L^p(\Omega)$ have compact support. Then $K_+\zeta(x)$ is defined at every point $x\in\mathbb{R}^2$ (see Ref. 9). Thus from

$$|K\zeta(x)|\leqslant K|\zeta|(x)\leqslant K_+|\zeta|(x),$$

it follows that $K\zeta(x)$ is defined at every $x\in\mathbb{R}^2$.

For $c>0$, let $\mathcal{C}_c:\mathcal{F}\to\mathcal{F}_c$ be defined as in (11). Then $\mathcal{C}_c$ is a bijection. Moreover, if $\zeta\in\mathcal{F}$, then

(i) $\|\mathcal{C}_c(\zeta)\|_p=c^{1/p^*}\ \|\zeta\|_p$ and
(ii) $|\mathrm{supp}(\mathcal{C}(\zeta))|=c^{-1}\ |\mathrm{supp}(\zeta)|$, where $\mathrm{supp}(\cdot)$ denotes the usual support of a function.

The Routh function associated with $\hat{P}_c$ is denoted $H(x)=H_1(x)+H_2(x)$, $x\in\Pi_+$, where

$$H_1(x)=\frac{1}{4\pi}\log\frac{|x|}{2x_1x_2},$$

$$H_2(x)=x_1x_2.$$

Observe that for $z\in\partial\Pi_+$ we have $\lim_{x\to z}H(x)=\infty$. Elementary calculations prove that H has a unique global minimum at $\hat{x}=(\hat{x}_1,\hat{x}_2):=(1/(2\sqrt{2\pi}),1/(2\sqrt{2\pi}))$. For more information on the Routh function the reader is referred to the classic monograph, Ref. 14.

IV. AN AUXILIARY LEMMA

The main feature of this section is the following support lemma which is a crucial tool in the analysis to follow. We first need the following result from Ref. 1.

Proposition: Suppose $Q \geqslant 1$ and $c \geqslant 4a^2$. Let $v \in L^p(\Pi_+)$ be a non-negative function vanishing outside a set of measure πa^2 and define $v_c(x) = C_c(v)(x)$. For $x \in \Pi_+$, we set $\hat{B}(x) = B_{Qa/c^{1/2}}(x)$ and

$$I(x) = \int_{\hat{B}(x)} \log\left(\frac{2a|x-\overline{y}|}{c^{1/2}|x-y|}\right) \; v_c(y)dy,$$

$$\overline{I}(x) = \int_{\hat{B}(x)} \log\left(\frac{2a|x-\underline{y}|}{c^{1/2}|x-y|}\right) \; v_c(y)dy.$$

Then there exist constants N_1, N_2, N_3, N_1', N_2' and N_3' such that

$$I(x) \leqslant \begin{cases} (N_1 + N_2|\log x_2|)\|v\|_p, & x_2 \geqslant a, \\ N_3\|v\|_p, & 0 < x_2 \leqslant a, \end{cases} \tag{22}$$

and

$$\overline{I}(x) \leqslant \begin{cases} (N_1' + N_2'|\log x_1|)\|v\|_p, & x_1 \geqslant a, \\ N_3'\|v\|_p, & 0 < x_1 \leqslant a. \end{cases} \tag{23}$$

Lemma (support lemma): Let c^0 be as in Theorem 1. Then there exist $\check{c} > c^0$ and $d > 0$ such that if $c \geqslant \check{c}$, then

$$\operatorname{diam}(\operatorname{supp}(\check{\zeta}_c)) \leqslant d, \tag{24}$$

for all $\check{\zeta}_c \in \Sigma_c$.

Proof: It suffices to set $\check{c} = \max\{c^0, 4a^2\}$. Fix $c \geqslant \check{c}$ and $\check{\zeta}_c \in \Sigma_c$. From (15) and (16) we infer

$$K_c\check{\zeta}_c(x) - \eta_c(x) \geqslant \frac{1}{2\pi}\log\frac{c^{1/2}}{2a} + C,$$

for almost every $x \in \operatorname{supp}(\check{\zeta}_c)$. Since $K_c\check{\zeta}_c(x) \leqslant K_+\check{\zeta}_c(x)$ we deduce

$$\eta_c(x) + C \leqslant K_+\check{\zeta}_c(x) - \frac{1}{2\pi}\log\frac{c^{1/2}}{2a} = \frac{1}{2\pi}\int_{\Omega_c} \log\frac{2a|x-\overline{y}||x-\underline{y}|}{c^{1/2}|x-y||x-\overline{\underline{y}}|}\,\check{\zeta}_c(y)dy, \tag{25}$$

for almost every $x \in \operatorname{supp}(\check{\zeta}_c)$. Let us set $S = \{x \in \Pi_+ \mid \min\{x_1, x_2\} > a\}$ and for $x \in \Pi_+$ define

$$J(x) = \frac{1}{2\pi}\int_{\hat{B}(x)} \log\frac{2a|x-\overline{y}||x-\underline{y}|}{c^{1/2}|x-y||x-\overline{\underline{y}}|}\;\check{\zeta}_c(y)dy,$$

where $\hat{B}(x)$ is defined as in the proposition. Observe that for x, $y \in \Pi_+$ we have $|x-\overline{y}|/|x-\overline{\underline{y}}| < 1$ and $|x-\underline{y}|/|x-\overline{\underline{y}}| < 1$. Hence, for $x \in \Pi_+ \backslash S$ we can apply (22) and (23) to obtain

$$J(x) \leqslant N_3''\|\zeta_0\|_p, \tag{26}$$

where $N'' = \max\{N_3, N_3'\}$. Also, for $x \in S$ we have

$$J(x) \leqslant I(x) \leqslant (N_1 + N_2|\log x_2|) \;\; \|\zeta_0\|_p. \tag{27}$$

Therefore, from (25)–(27) we infer that for almost every $x \in \mathrm{supp}(\check{\zeta}_c)$ we have

$$\eta_c(x)+C \leqslant \frac{1}{2\pi}\int_{\Omega_c\setminus\hat{B}(x)} \log\left(\frac{2a|x-\overline{y}|}{c^{1/2}|x-y|}\right)\ \check{\zeta}_c(y)dy+\begin{cases}(N_1+N_2|\log x_2|)\|\zeta_0\|_p, & x\in S,\\ N_3''\|\zeta_0\|_p, & x\in \Pi_+\setminus S.\end{cases} \tag{28}$$

Since $\mathrm{supp}(\check{\zeta}_c)$ is essentially contained in $B_{R(c)}$ and $R(c)\leqslant Ac^{1/2}$, by (14), we obtain

$$\frac{1}{2\pi}\int_{\Omega_c\setminus\hat{B}(x)} \log\left(\frac{2a|x-\overline{y}|}{c^{1/2}|x-y|}\right)\ \check{\zeta}_c(y)dy \leqslant \frac{1}{2\pi}\log\frac{4R(c)}{Q}\int_{\Omega_c\setminus\hat{B}(x)}\check{\zeta}_c(y)dy, \tag{29}$$

for every $x\in\Pi_+$. Therefore by (29) and rearranging the terms in (28) we infer that for almost every $x\in\mathrm{supp}(\check{\zeta}_c)$ we have

$$\frac{1}{2\pi}\log\frac{Q}{4R(c)}\int_{\Omega_c\setminus\hat{B}(x)}\check{\zeta}_c(y)dy\leqslant\begin{cases}N_3''\|\zeta_0\|_p+C-\eta_c(x), & x\in\Pi_+-S,\\ (N_1+N_2|\log x_2|)\|)\|\zeta_0\|_p+C-\eta_c(x), & x\in S.\end{cases}$$

From this we deduce the existence of a positive constant ν such that

$$\log\frac{Q}{4R(c)}\int_{\Omega_c\setminus\hat{B}(x)}\check{\zeta}_c(y)dy<\nu. \tag{30}$$

Let us now set $Q=4R(c)e^{2\nu}$. Then, from (30) we obtain

$$\int_{\Omega_c\setminus\hat{B}(x)}\check{\zeta}_c(y)dy<\frac{1}{2}, \tag{31}$$

for almost every $x\in\mathrm{supp}(\check{\zeta}_c)$. We now claim that

$$\mathrm{diam}(\mathrm{supp}(\check{\zeta}_c))\leqslant 8aR(c)e^{2\nu}/c^{1/2}. \tag{32}$$

To seek a contradiction suppose this is not true, that is, $\mathrm{diam}(\mathrm{supp}(\check{\zeta}_c))>8aR(c)e^{2\nu}/c^{1/2}$. In this case, there exist x and y in $\mathrm{den}(\mathrm{supp}(\check{\zeta}_c))$ such that $|x-y|>8aR(c)e^{2\nu}/c^{1/2}$. Hence $B_{8aR(c)e^{2\nu}/c^{1/2}}(x)$ and $B_{8aR(c)e^{2\nu}/c^{1/2}}(y)$ are disjoint. Thus, by (31), we obtain

$$1<\int_{B_{8aR(c)e^{2\nu}/c^{1/2}}(x)}\check{\zeta}_c(w)dw+\int_{B_{8aR(c)e^{2\nu}/c^{1/2}}(y)}\check{\zeta}_c(w)dw\leqslant 1,$$

which is a contradiction, hence from (14) and (32) we obtain (24). □

V. PROOFS OF THEOREMS 2 AND 3

Proof of Theorem 2: The proof consists of three assertions.

Assertion 1: Let $\check{c}$ be as in the lemma. Then there exist $c_1'\geqslant\check{c}$ and $\overline{R}>0$ such that if $c\geqslant c_1'$ and $\check{\zeta}_c\in\Sigma_c$, then

$$\mathrm{supp}(\check{\zeta}_c)\subset L(2d)\cup(\Pi_+\cap B_{\overline{R}}), \tag{33}$$

modulo a set of measure zero. Here

$$L(2d)=\{x\in\Pi_+|\ \ \min\{x_1,x_2\}\leqslant 2d\}, \tag{34}$$

where d is the bound stated in the lemma.

Proof of Assertion 1: Suppose the assertion is false. Hence there exist sequences $\{c_j\}$, $\{\check{\zeta}_{c_j}\}$ and $\{x_j\}$ such that

(a) $\check{c} \leqslant c_j \to \infty$, as $j \to \infty$,
(b) $\check{\zeta}_{c_j} \in \Sigma_{c_j}$, for all j, and
(c) $x_j = (x_{j,1}, x_{j,2}) \in \mathrm{den}(\mathrm{supp}(\check{\zeta}_{c_j}))$, for all j, and $|x_j| \to \infty$, as $j \to \infty$.

For simplicity, when appropriate, we replace c_j by j, thus we write $\hat{\Psi}_j$ for $\hat{\Psi}_{c_j}$, $\check{\zeta}_j$ for $\check{\zeta}_{c_j}$. The Schwarz-symmetrization of $\check{\zeta}_j$ with respect to $\hat{x}$ is denoted by ζ_j^*. Without loss of generality we may assume that $\mathrm{supp}(\zeta_j^*) \subset B_{1/4\sqrt{2\pi}}(\hat{x})$ for all j. Fixing j, we observe, from the lemma, that $\mathrm{supp}(\check{\zeta}_j)$ is essentially contained in $\Pi_+ \backslash L(d)$, where

$$L(d) = \{x \in \Pi_+ | \quad \min\{x_1, x_2\} \leqslant d\}.$$

Therefore

$$\begin{aligned}\hat{\Psi}_j(\zeta_j^*) - \hat{\Psi}_j(\check{\zeta}_j) \geqslant & \int_{\Omega_j}\int_{\Omega_j}\left(\frac{1}{2}h(c_j^{1/2}x, c_j^{1/2}y) - \frac{1}{4\pi}\log\frac{1}{c_j^{1/2}} + \eta_j(x)\right) \quad \check{\zeta}_j(x)\check{\zeta}_j(y)dxdy \\ & - \int_{\Omega_j}\int_{\Omega_j}\left(\frac{1}{2}h(c_j^{1/2}x, c_j^{1/2}y) - \frac{1}{4\pi}\log\frac{1}{c_j^{1/2}} + \eta_j(x)\right) \quad \zeta_j^*(x)\zeta_j^*(y)dxdy,\end{aligned} \tag{35}$$

where we have applied an n-dimensional generalization of an inequality of F. Riesz on rearrangements to the logarithmic parts (see, for example, Ref. 3). Since $h \geqslant h_+$ we infer

$$\begin{aligned}\frac{1}{2}h(c_j^{1/2}x, c_j^{1/2}y) - \frac{1}{4\pi}\log\frac{1}{c_j^{1/2}} + \eta_j(x) &\geqslant \frac{1}{4\pi}\log\frac{|x-\overline{y}|}{c_j^{1/2}|x-\overline{y}||x-\underline{y}|} - \frac{1}{4\pi}\log\frac{1}{c_j^{1/2}} + x_1x_2 - \frac{x_1x_2}{c_j^2|x|^4} \\ &\geqslant \frac{1}{4\pi}\log\frac{|x-\overline{y}|}{|x-\overline{y}||x-\underline{y}|} + \frac{1}{2}x_1x_2,\end{aligned} \tag{36}$$

for all x, $y \in \mathrm{den}(\mathrm{supp}(\check{\zeta}_j))$. Also, note that for x, $y \in \mathrm{supp}(\zeta_j^*) \subset B_{1/4\sqrt{2\pi}}(\hat{x})$ we have

$$\begin{aligned}\frac{1}{2}h(c_j^{1/2}x, c_j^{1/2}y) - \frac{1}{4\pi}\log\frac{1}{c_j^{1/2}} + \eta_j(x) &\leqslant \frac{1}{2}\hat{h}(c_j^{1/2}x, c_j^{1/2}y) + \frac{1}{2}h_+(c_j^{1/2}x, c_j^{1/2}y) - \frac{1}{4\pi}\log\frac{1}{c^{1/2}} + x_1x_2 \\ &\leqslant \frac{1}{2}\hat{h}_1(c_j^{1/2}x, c_j^{1/2}y) + \frac{1}{4\pi}\log\frac{|x-\overline{y}|}{|x-\overline{y}||x-\underline{y}|} + x_1x_2 \\ &\leqslant \frac{c_jx_1x_2}{2\pi(c_j|x||y|-1)^2} + \frac{1}{4\pi}\log\frac{|x-\overline{y}|}{|x-\overline{y}||x-\underline{y}|} + x_1x_2 \leqslant K_1,\end{aligned} \tag{37}$$

provided j is sufficiently large; here, K_1 is positive constant.

Let us assume that $x_{j,2} \to \infty$, as $j \to \infty$ (the case where $x_{j,1} \to \infty$ can be treated similarly); moreover we may assume that for almost every $x = (x_1, x_2) \in \mathrm{supp}(\check{\zeta}_j)$ we have $x_2 \leqslant x_{j,2}$. Therefore, by (36), for x, $y \in \mathrm{den}(\mathrm{supp}(\check{\zeta}_j))$ we find

$$\frac{1}{2}h(c_j^{1/2}x,c_j^{1/2}y)-\frac{1}{4\pi}\log\frac{1}{c_j^{1/2}}+\eta_j(x)\geqslant\frac{1}{4\pi}\log\frac{1}{|x-\bar{y}|}+\frac{1}{2}d(x_{j,2}-d)$$
$$\geqslant\frac{1}{4\pi}\log\frac{1}{2x_{j,2}}+\frac{1}{2}d(x_{j,2}-d)\to\infty, \tag{38}$$

as $j\to\infty$. Hence from (35), (37), and (38) we deduce

$$\hat{\Psi}_{j_0}(\zeta_{j_0}^*)-\hat{\Psi}_{j_0}(\check{\zeta}_{j_0})>0,$$

for some j_0 sufficiently large. This contradicts the maximality of $\check{\zeta}_{j_0}$. Hence the assertion is proved.

Assertion 2: Let c_1' be as in Assertion 1. Then there exists $\mu>0$ such that if $c\geqslant c_1'$ and $\check{\zeta}_c\in\Sigma_c$, then

$$\mathrm{supp}(\check{\zeta}_c)\subset\{x\in\Pi_+|\ \ x_1x_2<\mu\}, \tag{39}$$

modulo a set of measure zero.

Proof of Assertion 2: Let us fix $c\geqslant c_1'$ and consider $\check{\zeta}_c\in\Sigma_c$. From Assertion 1 it follows that there exists $\tau>a$ such that $\mathrm{supp}(\check{\zeta}_c)$ is essentially contained in $\mathbb{R}^+\times(0,\tau)$ or $(0,\tau)\times\mathbb{R}^+$. Let us first suppose that $\mathrm{supp}(\check{\zeta}_c)$ is essentially contained in $\mathbb{R}^+\times(0,\tau)$. Then for almost every $x=(x_1,x_2)\in\mathrm{supp}(\check{\zeta}_c)$, with $x_1>\tau$, we can apply the estimate (13) to obtain

$$K_+\check{\zeta}_c(x)-\frac{1}{2}x_1x_2\geqslant K_c\check{\zeta}_c(x)-\eta_c(x)\geqslant\frac{1}{2\pi}\log\frac{c^{1/2}}{2a}-C. \tag{40}$$

Therefore from (40) we infer

$$x_1x_2\leqslant 2K_+\check{\zeta}_c(x)-\frac{1}{\pi}\log\frac{c^{1/2}}{2a}+C=\frac{1}{\pi}\int_{\Omega_c}\log\frac{2a|x-\bar{y}||x-y|}{c^{1/2}|x-y||x-\bar{y}|}\check{\zeta}_c(y)dy+C. \tag{41}$$

The integral in (41) is dominated by $\int_{\Omega_c}\log(2a|x-\bar{y}|/c^{1/2}|x-y|)\ \ \check{\zeta}_c(y)dy$. Now we write

$$\int_{\Omega_c}\log\frac{2a|x-\bar{y}|}{c^{1/2}|x-y|}\check{\zeta}_c(y)dy=\int_{B_{a/c^{1/2}}(x)}\log\frac{2a|x-\bar{y}|}{c^{1/2}|x-y|}\check{\zeta}_c(y)dy$$
$$+\int_{\Omega_c\setminus B_{a/c^{1/2}}(x)}\log\frac{2a|x-\bar{y}|}{c^{1/2}|x-y|}\check{\zeta}_c(y)dy.$$

Applying (22), with $Q=1$, we find $\bar{\eta}>0$ such that

$$\int_{B_{a/c^{1/2}}(x)}\log\frac{2a|x-\bar{y}|}{c^{1/2}|x-y|}\check{\zeta}_c(y)dy\leqslant\bar{\eta}. \tag{42}$$

We also have

$$\int_{\Omega_c\setminus B_{a/c^{1/2}}(x)}\log\frac{2a|x-\bar{y}|}{c^{1/2}|x-y|}\check{\zeta}_c(y)dy\leqslant\log(4\tau). \tag{43}$$

Hence from (42) and (43) we conclude that for almost every $x\in\mathrm{supp}(\check{\zeta}_c)$ we have

$$x_1 x_2 \leqslant \frac{1}{\pi}(\overline{\eta}+\log(4\tau))+C. \tag{44}$$

From (44) we readily deduce (39).

The case where $\mathrm{supp}(\check{\zeta}_c)$ is essentially contained in $(0,\tau)\times\mathbb{R}^+$ can be treated similarly [in the proof we make use of (23)]. Therefore the proof of Assertion 2 is complete.

Assertion 3: Let c_1' be as in Assertion 1. Then there exist $c^1 \geqslant c_1'$, $R>0$, such that if $c \geqslant c^1$ and $\check{\zeta}_c \in \Sigma_c$, then

$$\mathrm{supp}(\check{\zeta}_c) \subset B_R,$$

modulo a set of measure zero.

Proof of Assertion 3: To seek a contradiction, suppose the assertion is false. Then by Assertion 2, there exist sequences $\{c_j\}$, $\{\check{\zeta}_j\}$ and $\{x_j\}$ such that the following hold.

(i) $c_1' \leqslant c_j \to \infty$, as $j \to \infty$.

(ii) $\check{\zeta}_j \in \Sigma_j$ such that $\mathrm{supp}(\check{\zeta}_j)$ is essentially contained in $\mathbb{R}^+\times(0,1/j)$, for all j; the case where $\mathrm{supp}(\check{\zeta}_j)$ is essentially contained in $(0,1/j)\times\mathbb{R}^+$ can be treated similarly.

(iii) $x_j \in \mathrm{den}(\mathrm{supp}(\check{\zeta}_j))$, for every j, and $|x_j| \to \infty$ as $j \to \infty$.

Notice that we have again replaced c_j by j, when appropriate.

We claim that $\mathrm{diam}(\mathrm{supp}(\check{\zeta}_j)) \to 0$, as $j \to \infty$. To prove the claim we fix j. Then for almost every $x \in \mathrm{supp}(\check{\zeta}_j)$ we have

$$\frac{1}{2\pi}\log\frac{c_j^{1/2}}{2a}+C \leqslant K_j\check{\zeta}_j(x)-\eta_j(x) \leqslant K_+\check{\zeta}_j(x) \leqslant \frac{1}{2\pi}\int_{\Omega_j}\log\frac{|x-\overline{y}|}{|x-y|}\check{\zeta}_j(y)dy,$$

since η_j is positive and $K_j\check{\zeta}_j(x) \leqslant K_+\check{\zeta}_j(x)$ for almost every $x \in \Omega_j$. Therefore,

$$C \leqslant \frac{1}{2\pi}\int_{\Omega_j}\log\frac{2a|x-\overline{y}|}{c_j^{1/2}|x-y|}\check{\zeta}_j(y)dy.$$

Let $Q>1$ and set $\hat{B}(x) := B_{Qa/c_j^{1/2}}(x)$. Then

$$C \leqslant \frac{1}{2\pi}\int_{\hat{B}(x)}\log\frac{2a|x-\overline{y}|}{c_j^{1/2}|x-y|}\check{\zeta}_j(y)dy+\frac{1}{2\pi}\int_{\Omega_j\setminus\hat{B}(x)}\log\frac{2a|x-\overline{y}|}{c_j^{1/2}|x-y|}\check{\zeta}_j(y)dy.$$

Applying (22) we find that

$$\frac{1}{2\pi}\int_{\hat{B}(x)}\log\frac{2a|x-\overline{y}|}{c_j^{1/2}|x-y|}\check{\zeta}_j(y)dy \leqslant K_2,$$

where K_2 is a positive constant. Also

$$\frac{1}{2\pi}\int_{\Omega_j\setminus\hat{B}(x)}\log\frac{2a|x-\overline{y}|}{c_j^{1/2}|x-y|}\check{\zeta}_j(y)dy \leqslant \frac{1}{2\pi}\log\frac{2(d+2)}{Q}\int_{\Omega_j\setminus\hat{B}(x)}\check{\zeta}_j(y)dy,$$

where we have used the fact that for $x,\ y \in \mathrm{supp}(\check{\zeta}_j)$,

$$|x-\overline{y}| \leqslant |x-y|+|y-\overline{y}| \leqslant \mathrm{diam}(\mathrm{supp}(\check{\zeta}_j))+2y_2 \leqslant \mathrm{diam}(\mathrm{supp}(\check{\zeta}_j))+2/j, \tag{45}$$

and that $\mathrm{diam}(\mathrm{supp}(\check{\zeta}_j))+2/j \leqslant d+2$. Therefore, we obtain

$$C \leqslant K_2 + \frac{1}{2\pi}\log\frac{2(d+2)}{Q}\int_{\Omega_j \setminus \hat{B}(x)} \check{\zeta}_j(y)\,dy.$$

Hence by rearranging we derive

$$\log\frac{Q}{2(d+2)}\int_{\Omega_j \setminus \hat{B}(x)} \check{\zeta}_j(y)\,dy \leqslant 2\pi(C+K_2) < \hat{\nu},$$

for some $\hat{\nu} > 0$. Let us now set $Q = 2(d+2)e^{2\hat{\nu}}$ to obtain

$$\int_{\Omega_j \setminus \hat{B}(x)} \check{\zeta}_j(y)\,dy < \frac{1}{2}, \tag{46}$$

for almost every $x \in \mathrm{supp}(\check{\zeta}_j)$. From (46), applying the same argument as in the lemma, we find

$$\mathrm{diam}(\mathrm{supp}(\check{\zeta}_j)) < \frac{4a(d+2)e^{2\hat{\nu}}}{c_j^{1/2}}. \tag{47}$$

The proof of the claim is complete when we let $j \to \infty$ in (47).

Let ζ_j^* denote the Schwarz symmetrization of $\check{\zeta}_j$ with respect to $\hat{x}$. We intend to show that $\hat{\Psi}_{j_1}(\zeta_{j_1}^*) - \hat{\Psi}_{j_1}(\check{\zeta}_{j_1}) > 0$, for some j_1, which is a contradiction to the maximality of $\check{\zeta}_{j_1}$, and hence the desired result follows. However, this is easily proved using the same method employed in Assertion 1, the key step being a result similar to (38) which is explained here. For x, $y \in \mathrm{den}(\mathrm{supp}(\check{\zeta}_j))$ we have

$$\begin{aligned}\frac{1}{2}h(c_j^{1/2}x, c_j^{1/2}y) - \frac{1}{4\pi}\log\frac{1}{c_j^{1/2}} + \eta_j(x) &\geqslant \frac{1}{2}h_+(c_j^{1/2}x, c_j^{1/2}y) - \frac{1}{4\pi}\log\frac{1}{c_j^{1/2}} \\ &= \frac{1}{4\pi}\log\frac{|x-\overline{y}|}{|x-\overline{y}||\bar{x}-\underline{y}|} \\ &\geqslant \frac{1}{4\pi}\log\frac{1}{|x-\overline{y}|};\end{aligned} \tag{48}$$

now by using (45) we obtain

$$\frac{1}{4\pi}\log\frac{1}{|x-\overline{y}|} \geqslant \frac{1}{4\pi}\log\frac{1}{\mathrm{diam}(\mathrm{supp}(\check{\zeta}_j)) + 2/j} \to 0, \tag{49}$$

as $j \to \infty$. This finishes the proof of Assertion 3, hence the proof of the theorem is complete. □

Proof of Theorem 3: We again replace c_j by j to simplify notation. Let us also set $\mathrm{cent}(\zeta_j) = z_j = (z_{j,1}, z_{j,2})$ and assume that $z_j \to z$, as $j \to \infty$. By maximality of $\check{\zeta}_j$ we have

$$\hat{\Psi}_j(\check{\zeta}_j) \geqslant \hat{\Psi}_j(\zeta_j^*), \tag{50}$$

where ζ_j^* denotes the Schwarz symmetrization of $\check{\zeta}_j$ with respect to $\hat{x}$. From (50) and an application of Riesz's inequality we obtain

$$T_j(\check{\zeta}_j) := \int_{\Omega_j}\int_{\Omega_j}\left(\frac{1}{2}h(c_j^{1/2}x,c_j^{1/2}y)-\frac{1}{4\pi}\log\frac{1}{c_j^{1/2}}+\eta_j(x)\right)\check{\zeta}_j(x)\check{\zeta}_j(y)dxdy$$
$$\leqslant \int_{\Omega_j}\int_{\Omega_j}\left(\frac{1}{2}h(c_j^{1/2}x,c_j^{1/2}y)-\frac{1}{4\pi}\log\frac{1}{c_j^{1/2}}+\eta_j(x)\right)\zeta_j^*(x)\zeta_j^*(y)dxdy = T_j(\zeta_j^*). \quad (51)$$

We now fix $0<\epsilon<1/(2\sqrt{2\pi})$. Then there exists $j_0(\epsilon)\in\mathbb{N}$ such that if $j\geqslant j_0(\epsilon)$, then $\mathrm{supp}(\zeta_j^*)\subset B_\epsilon(\hat{x})$. For $j\geqslant j_0(\epsilon)$ and $x,\ y\in B_\epsilon(\hat{x})$ we have

$$\left|\frac{1}{2}h(c_j^{1/2}x,c_j^{1/2}y)-\frac{1}{4\pi}\log\frac{1}{c_j^{1/2}}-H_1(\hat{x})\right|$$
$$\leqslant \frac{1}{2}\hat{h}_1(c_j^{1/2}x,c_j^{1/2}y)+\frac{1}{4\pi}\left|\log\frac{2\hat{x}_1\hat{x}_2|x-\overline{y}|}{|x-\overline{y}||x-\underline{y}||\hat{x}|}\right|$$
$$\leqslant \frac{c_jx_2y_2}{2\pi(c_j|x||y|-1)^2}+\frac{1}{4\pi}\left|\log\frac{2\hat{x}_1\hat{x}_2|x-\overline{y}|}{|x-\overline{y}||x-\underline{y}||\hat{x}|}\right|$$
$$\leqslant \frac{c_j(\hat{x}_1+\epsilon)(\hat{x}_2+\epsilon)}{2\pi(c_j(|\hat{x}|-\epsilon)^2-1)^2}+\frac{1}{4\pi}\sup_{x,y\in B_\epsilon(\hat{x})}\left|\log\frac{2\hat{x}_1\hat{x}_2|x-\overline{y}|}{|x-\overline{y}||x-\underline{y}||\hat{x}}\right|\to 0,$$

as $j\to\infty$. This implies

$$\int_{\Omega_j}\int_{\Omega_j}\left(\frac{1}{2}h(c_j^{1/2}x,c_j^{1/2}y)-\frac{1}{4\pi}\log\frac{1}{c_j^{1/2}}\right)\zeta_j^*(x)\zeta_j^*(y)dxdy\to H_1(\hat{x}), \quad (52)$$

as $j\to\infty$. Also, from (13), we have

$$|\eta_j(x)-H_2(\hat{x})|\leqslant|x_1x_2-\hat{x}_1\hat{x}_2|+\frac{1}{c_j^2|x|^2},$$

for $x\in B_\epsilon(\hat{x})$,

$$\sup_{x\in B_\epsilon(\hat{x})}|\eta_j(x)-H_2(\hat{x})|\to 0, \quad (53)$$

as $j\to\infty$. From (52) and (53) we deduce that $T_j(\zeta_j^*)\to H(\hat{x})$, as $j\to\infty$.

We now claim that

$$T_j(\check{\zeta}_j)\to H(z), \quad \text{as } j\to\infty. \quad (54)$$

Note that by proving (54) we will have completed the proof of the theorem; indeed, if (54) is true, then from (51) we infer $H(z)\leqslant H(\hat{x})$, hence $\hat{z}=\hat{x}$. To prove the claim we first show that $z\notin\partial\Pi_+$. Seeking a contradiction we suppose $z\in\partial\Pi_+$. Setting $z=(z_1,z_2)$, we may assume that $z_2=0$. Fix $\epsilon>0$; then there exists $\overline{j}(\epsilon)\in\mathbb{N}$ such that if $j\geqslant\overline{j}(\epsilon)$, then

$$|x-z|\leqslant|x-z_j|+|z_j-z|\leqslant\mathrm{diam}(\mathrm{supp}(\check{\zeta}_j))+\epsilon, \quad (55)$$

for almost every $x\in\mathrm{supp}(\check{\zeta}_j)$. Now, similarly to (48) and (49) we derive

$$\frac{1}{2}h(c_j^{1/2}x,c_j^{1/2}y)-\frac{1}{4\pi}\log\frac{1}{c_j^{1/2}}+\eta_j(x)\geqslant\frac{1}{4\pi}\log\frac{1}{|x-\overline{y}|}\geqslant\frac{1}{4\pi}\log\frac{1}{\mathrm{diam}(\mathrm{supp}(\check{\zeta}_j))+2y_2},$$

for $x,\ y\in \mathrm{den}(\mathrm{supp}(\check{\zeta}_j))$ and $j\geqslant \overline{j}(\epsilon)$. If $j\geqslant \overline{j}(\epsilon)$ and $y\in \mathrm{supp}(\check{\zeta}_j)$, we can apply (55) to derive

$$y_2\leqslant |y-z|\leqslant \mathrm{diam}(\mathrm{supp}(\check{\zeta}_j))+\epsilon.$$

Therefore if $j\geqslant \overline{j}(\epsilon)$ and $x,\ y\in \mathrm{den}(\mathrm{supp}(\check{\zeta}_j))$, then

$$\frac{1}{2}h(c_j^{1/2}x,c_j^{1/2}y)-\frac{1}{4\pi}\log\frac{1}{c_j^{1/2}}+\eta_j(x)\geqslant \frac{1}{4\pi}\log\frac{1}{3\mathrm{diam}(\mathrm{supp}(\check{\zeta}_j))+2\epsilon}.$$

This in conjunction with the fact that $\mathrm{diam}(\mathrm{supp}(\check{\zeta}_j))\to 0$, as $j\to\infty$, implies

$$\limsup_{j\to\infty} T_j(\check{\zeta}_j)\geqslant \frac{1}{4\pi}\log\frac{1}{2\epsilon},$$

hence $\limsup_{j\to\infty} T_j(\check{\zeta}_j)=\infty$, since $\epsilon>0$ was arbitrary. However, this contradicts (51), since $T_j(\zeta_j^*)$ is bounded from above for all sufficiently large j [see (37)]. Hence, $z\notin \partial\Pi_+$.

We now set $\varepsilon=\mathrm{dist}(z,\partial\Pi_+)$, the distance from z to $\partial\Pi_+$. We showed above that $\varepsilon>0$. Observe that there exists $\check{j}(\varepsilon)\in\mathbb{N}$ such that if $j\geqslant \check{j}(\varepsilon)$, then $\mathrm{supp}(\check{\zeta}_j)$ is essentially contained in $B_{\varepsilon/2}(z)$. We next define the real valued function D on $\Omega\times\Omega\subset\mathbb{R}^4$ by

$$D(x,y)=D(x_1,x_2,y_1,y_2)=h_+(x,y).$$

Note that ∇D is bounded on $B_{\varepsilon/2}(z)\times B_{\varepsilon/2}(z)$, hence, there exists a positive constant, say K_3, such that $\|\nabla D\|_{\infty,B_{\varepsilon/2}(z)\times B_{\varepsilon/2}(z)}\leqslant K_3$. Now, for $j\geqslant \check{j}(\varepsilon)$ and $x,\ y\in B_{\varepsilon/2}(z)$ we can apply the mean value inequality to deduce

$$\begin{aligned}\left|\frac{1}{2}h(c_j^{1/2}x,c_j^{1/2}y)-\frac{1}{4\pi}\log\frac{1}{c_j^{1/2}}-H_1(z)\right| &\leqslant \frac{1}{2}\hat{h}_1(c_j^{1/2}x,c_j^{1/2}y)+\frac{1}{4\pi}|D(x,y)-D(z,z)|\\ &\leqslant \frac{1}{2}\hat{h}_1(c_j^{1/2}x,c_j^{1/2}y)+\frac{1}{4\pi}K_3|(x,y)-(z,z)|_{\mathbb{R}^4}\\ &= o(1)+\frac{1}{4\pi}K_3|(x,y)-(z,z)|_{\mathbb{R}^4},\end{aligned}\tag{56}$$

as $j\to\infty$, uniformly in x and y, where $|\cdot|_{\mathbb{R}^4}$ denotes the usual Euclidean distance in $\mathbb{R}^4$. Note that for $j\geqslant \check{j}(\varepsilon)$ and $x,\ y\in B_{\varepsilon/2}(z)$ we have

$$|(x,y)-(z,z)|_{\mathbb{R}^4}\leqslant 4(\mathrm{diam}(\mathrm{supp}(\check{\zeta}_j))+|\hat{z}_j-z|)=o(1),\tag{57}$$

as $j\to\infty$. Whence by (56) and (57) we obtain

$$\frac{1}{2}h(c_j^{1/2}x,c_j^{1/2}y)-\frac{1}{4\pi}\log\frac{1}{c_j^{1/2}}-H_1(z)=o(1),$$

as $j\to\infty$, uniformly in $x,\ y\in B_{\varepsilon/2}(z)$. This, in turn, shows that

$$\int_{\Omega_j}\int_{\Omega_j}\left(\frac{1}{2}h(c_j^{1/2}x,c_j^{1/2}y)-\frac{1}{4\pi}\log\frac{1}{c_j^{1/2}}\right)\check{\zeta}_j(x)\check{\zeta}_j(y)dxdy\to H_1(z),$$

as $j\to\infty$. To complete the proof it remains to show that

$$\eta_j(x)-H_2(z)=o(1),\tag{58}$$

as $j\to\infty$, uniformly in $x\in B_{\varepsilon/2}(z)$. So let us fix $x\in B_{\varepsilon/2}(z)$ and suppose $j\geqslant\check{j}(\varepsilon)$. Then

$$|\eta_j(x)-H_2(z)|\leqslant|x_1x_2-z_1z_2|+\frac{1}{c_j^2|x|^2}.$$

It is easy to verify that

$$|x_1x_2-z_1z_2|\leqslant|x_2|\mathrm{diam}(\mathrm{supp}(\check{\xi}_j))+|z_{j,1}|\mathrm{diam}(\mathrm{supp}(\check{\xi}_j))+|z_{j,1}z_{j,2}-z_1z_2|\to 0,$$

as $j\to\infty$, uniformly in x. Therefore (58) follows, so we infer

$$\int_{\Omega_j}\eta_j(x)\check{\xi}_j(x)dx\to H_2(z),$$

as $j\to\infty$. Thus the proof of the theorem is complete. □

(Received 16 January 2003; accepted 17 April 2003)

A new approach for derivation of Benney-type moment chains and integrable hydrodynamic type systems is presented. New integrable hydrodynamic chains are constructed; all their hydrodynamical reductions are described and integrated. New $(2+1)$ integrable hydrodynamic type systems are found. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1597946]

I. INTRODUCTION

The integrable hydrodynamic chain

$$\partial_t A_k = \partial_x A_{k+1} + k A_{k-1} A_{0,x}, \quad k = 0,1,\ldots, \tag{1}$$

for the first time was introduced by D. J. Benney in a theory of finite-depth fluid (see Ref. 5). Here the moments A_k are an infinite number of field variables. Later, it was shown that these moments satisfy a dispersionless limit of KP hierarchy determined by the Sato pseudo-differential operator

$$\hat{L} = \partial_x + A_0 \partial_x^{-1} + A_1 \partial_x^{-2} + \cdots,$$

which in dispersionless limit is reduced to

$$\lambda = \mu + \frac{A_0}{\mu} + \frac{A_1}{\mu^2} + \cdots. \tag{2}$$

The Benney moment chain can be written in the equivalent form (see Ref. 20)

$$\lambda_t - \mu \lambda_x = \frac{\partial \lambda}{\partial \mu}\left[\mu_t - \partial_x\left(\frac{\mu^2}{2} + A_0\right)\right]. \tag{3}$$

If $\lambda = \text{const}$, then μ is a generating function (with respect to the parameter λ) of the conservation law densities

$$\mu_t = \partial_x\left(\frac{\mu^2}{2} + A_0\right). \tag{4}$$

In the case, when only the first N moments A_k are functionally independent ($k = 0, 1, \ldots, N-1$), all A_k with $k \geqslant N$ can be consistently expressed as functions of the first N moments. This is called a hydrodynamical reduction. More generally, we can define ''differential reductions,'' in which all A_k with $k \geqslant N$ can be consistently expressed as functions of the first N moments and their derivatives. However, we are only concerned with hydrodynamical reductions here (in the spirit of Ref. 21). Then these hydrodynamical reductions are the hydrodynamic type systems written in Riemann invariants r^i,

$$r_t^i = \mu_i(\mathbf{r}) r_x^i, \quad i = 1,2,\ldots,N, \tag{5}$$

a)Electronic mail: maxim.pavlov@mtu-net.ru

i.e., a hydrodynamic type system has diagonal form in these field variables and there is no summation over each repeated index (see, for instance, Ref. 36). The Riemann invariants r^i and the characteristic velocities $\mu_i(\mathbf{r})$ are determined by conditions

$$r^i=\mu_i+\frac{A_0}{\mu_i}+\frac{A_1}{\mu_i^2}+\frac{A_2}{\mu_i^3}+\cdots, \quad 1=\frac{A_0}{\mu_i^2}+2\frac{A_1}{\mu_i^3}+3\frac{A_2}{\mu_i^4}+\cdots.$$

[See (2) and (3). Of course, defining the Riemann invariants and characteristic speeds in terms of formal series is apparently risky—at least we should emphasize that these series will converge to analytic functions in all cases considered, see Ref. 21.] These hydrodynamic type systems are integrable, too (all moments A_k are some functions of r^i, which are determined by compatibility conditions with whole Benney moment chain, see Ref. 21). These hydrodynamic type systems have the same generating functions of conservation laws [see (4)] and the commuting flows (see Ref. 33; the "commuting flows" means that the Riemann invariants r^i simultaneously are functions of an infinite number of independent variables t_k, $k=0,1,\ldots$, here $t_0\equiv x$, $t_1\equiv t$),

$$\mu(\lambda)_{\tau(\tilde{\lambda})}=\partial_x \ln[\mu(\lambda)-\mu(\tilde{\lambda})], \tag{6}$$

where

$$\partial_{\tau(\tilde{\lambda})}=\partial_{t_0}+\frac{1}{\tilde{\lambda}}\partial_{t_1}+\frac{1}{\tilde{\lambda}^2}\partial_{t_2}+\cdots.$$

Moreover, the generating function (with respect to the parameter $\tilde{\lambda}$) of solutions for any reduction (5) can be found by the Tsarev generalized hodograph method (Ref. 36, also see Ref. 33)

$$x+\mu_i(\mathbf{r})t=\frac{1}{\mu_i(\mathbf{r})-\mu(\tilde{\lambda})}, \quad i=1,2,\ldots,N. \tag{7}$$

Thus, if some hydrodynamic type system is recognized as a reduction of the Benney moment chain, it means that this system has most properties of the Benney moment chain.

The idea presented in this article is the following: if one can introduce the moments A_k for given integrable hydrodynamic type system (5), then **one can ignore the origin** (i.e., given hydrodynamic type system) of this *hydrodynamic chain*

$$\partial_t A=F(\mathbf{A})A_x,$$

where A is an infinite-number component vector and $F(\mathbf{A})$ is an infinite-number component matrix. The next step is a description of all possible integrable hydrodynamical reductions [one of them, of course, must be the original hydrodynamic type system (5)],

$$r^i_t=V_i(\mathbf{r})r^i_x, \quad i=1,2,\ldots,M, \tag{8}$$

where M is not connected with N [see (5)], and V_i satisfy some nonlinear system of partial differential equations (PDE's) (see below). Also, we assume that $V_i\neq V_k$ for any $i\neq k$ (this is a necessary condition for the application of the Tsarev generalized hodograph method). Thus, every hydrodynamic chain constructed in this way can be regarded as a *huge box* for some variety of the integrable hydrodynamic type systems.

For instance, the particular case of gas dynamics

$$u_t=\partial_x\left[\frac{u^2}{2}+\frac{\eta^{\gamma-1}}{\gamma-1}\right], \quad \eta_t=\partial_x(u\eta), \tag{9}$$

for $\gamma=2$ (shallow water equations),

$$u_t=\partial_x\left[\frac{u^2}{2}+\eta\right],\quad \eta_t=\partial_x(u\eta), \tag{10}$$

satisfies the Benney moment chain (1) if one introduces the moments $A_k=u^k\eta$.

It is easy to check that the Benney moment chain has a more general (the Zakharov) reduction $A_k=\Sigma_{i=1}^N u_i^k\eta_i$ (see Ref. 38), which creates the dispersionless limit of the vector nonlinear Schrödinger equation (VNLS)

$$\partial_t u_i=\partial_x\left[\frac{u_i^2}{2}+\sum_{k=1}^N \eta_k\right],\quad \partial_t\eta_i=\partial_x(u_i\eta_i),\quad i=1,2,\ldots,N. \tag{11}$$

Remark: Under this Zakharov reduction infinite series (2) yields a more compact expression (see Ref. 38)

$$\lambda=\mu+\sum_{k=1}^N \frac{\eta_k}{\mu-u_k}. \tag{12}$$

It is easy to check that the dispersionless limit of VNLS satisfies equation (3) with respect to the equation of Riemann surface (12).

Obviously, in both above-mentioned cases, corresponding hydrodynamic type systems (10) and (11) have the same generating functions of conservation law densities (4) and commuting flows (6) as whole Benney moment chain (1). Here we demonstrate this approach on an example of a new hydrodynamic chain, which contains some important reductions well known in mathematics, fluid dynamics, nonlinear optics, biology and chemistry.

The main classification problem in the theory of integrable hydrodynamic type systems can be reformulated as the problem of description of all possible integrable hydrodynamic chains. For simplicity, we restrict our consideration to the case, when any hierarchy of the hydrodynamic chains can be written in a conservative form [see, for instance, (30) below]:

$$\partial_{t_n}A_k=\partial_x F_{k,n}(A_{k+n},A_{k+n-1},\ldots,A_0),\quad k,n=0,1,2\ldots$$

If one can classify all possible functions F_k, it means that all the hydrodynamic type systems embedded in such hydrodynamic chains by different reductions are classified, too. In the simplest case $(N=2)$,

$$\partial_t A_0=\partial_x F_{01}(A_0,A_1),\quad \partial_t A_1=\partial_x F_{11}(A_0,A_1,A_2),$$

where $A_2(A_0,A_1)$ is a conservation law density of the reduced hydrodynamic type system. Then the governing equation for function A_2 is quasilinear,

$$f_v w_{uu}=[f_u-\varphi_v-\varphi_w w_v]w_{uv}+[\varphi_u+\varphi_w w_u]w_{vv},$$

where

$$u\equiv A_0,\quad v\equiv A_1,\quad w\equiv A_2,\quad f\equiv F_{01},\quad \varphi\equiv F_{11}.$$

When $F_{01}=v$ and $F_{11}=w(u,v)-u^2/2$, this is the two-component reduction of the Benney moment chain (see Ref. 21),

$$w_{uu}=-w_v w_{uv}+(w_u-u)w_{vv}.$$

If $F_{01}=v-u^2$ and $F_{11}=w(u,v)-uv$, then the corresponding equation,

$$w_{uu}=-(u+w_v)w_{uv}+(w_u-v)w_{vv},$$

can be solved in the parametric form

$$w=\tfrac{1}{6}[A''(s)+B''(r)]^3+[A''(s)+B''(r)][A'(s)-sA''(s)+B'(r)-rB''(r)]+s^2A''(s)-2sA'(s)$$
$$+2A(s)+r^2B''(r)-2rB'(r)+2B(r),$$

$$v=\tfrac{1}{2}[A''(s)+B''(r)]^2+A'(s)-sA''(s)+B'(r)-rB''(r),\quad u=A''(s)+B''(r),$$

where $A(s)$ and $B(r)$ are arbitrary functions. Thus, the two-component reduced (hydrodynamic type) system in Riemann invariants is

$$r_t=(A''(s)+B''(r)+r)r_x,\quad s_t=(A''(s)+B''(r)+s)s_x.$$

This system is the natural two-parametric generalization of gas dynamics (9) (see below).

The goal of this article is a complete description of the N-component generalization of the above-mentioned formulas.

In Sec. II of this paper, so-called the "ε-systems" are introduced. All their properties such as conservation laws and commuting flows are described. The corresponding hydrodynamic chain is found by the natural introduction of moments.

In Sec. III, some properties of such transformations between different representations of this hydrodynamic chain are obtained.

In Sec. IV, all possible hydrodynamical reductions are found. Particular and important reductions of this hydrodynamic chain are emphasized.

In Sec. V, generating functions of conservation law densities, commuting flows and solutions (by the Tsarev generalized hodograph method) for these hydrodynamical reductions are constructed.

In Sec. VI, a general solution of these hydrodynamic type systems is presented.

In Sec. VII, new $(2+1)$ integrable hydrodynamic type systems are found.

In Sec. VIII, another hydrodynamic chain is presented and all its hydrodynamical reductions are described.

In Sec. IX, we discuss some still open problems: Hamiltonian structures and integrable dispersive extensions of hydrodynamic chains and their reductions.

In Sec. X (Conclusion), we describe a general situation in a theory of hydrodynamic chains.

II. "ε-SYSTEMS"

This class of integrable hydrodynamic type systems

$$r^i_t=\left[r^i-\varepsilon\sum_{m=1}^{N}r^m\right]r^i_x,\quad i=1,2,\ldots,N, \tag{13}$$

where ε is an arbitrary constant, was established in Ref. 29 (also see Refs. 17 and 30–32). These hydrodynamic type systems (13) and its commuting flows (see below) we shall call the "ε-systems." The particular case $N=2$ plays an important role in gas dynamics [see (9), where the adiabatic index $\gamma=(3-2\varepsilon)/(1-2\varepsilon)$], in field theory ($\gamma=-1$, the Born–Infeld equation), in nonlinear optics [$\gamma=2$, the dispersionless limit of the nonlinear Schrödinger equation, see (9)] and in fluid dynamics ($\gamma=4$, the dispersionless limit of the second commuting flow to the Boussinesq equation). Also, the "ε-systems" (for arbitrary N) are well known in differential geometry ($\varepsilon=-\frac{1}{2}$, elliptic coordinates, see, for instance, Ref. 32; the dispersionless limit of Coupled KdV, see, for instance, Ref. 16), in soliton theory ($\varepsilon=1$, some particular solutions of linearly degenerated systems are multi-gap solutions of KdV, see Ref. 11), in biology and chemistry ($\varepsilon=-1$, chromatography, electrophoresis, isotahophoresis). Moreover, a general solution can be found explicitly (see Ref. 31), for instance, in one-atomic ($\gamma=\frac{5}{3}$, $\varepsilon=-1$) and two-atomic ($\gamma=\frac{7}{5}$, $\varepsilon=-2$) gases

[see (13)] and their generalization for an arbitrary N and an arbitrary **integer** ε. Thus, the obvious aim is to extend a class of integrable hydrodynamic type systems starting from (13) with preservation of some properties.

The hydrodynamic type system (13) has a generation function μ of conservation law densities; when $\lambda \to \infty$,

$$\mu \equiv \prod_{m=1}^{N} (1 - r_m/\lambda)^{-\varepsilon} = 1 + a_1/\lambda + a_2/\lambda^2 + \cdots, \tag{14}$$

when $\lambda \to 0$ (up to constant multiplier)

$$\mu \equiv \prod_{m=1}^{N} (r_m - \lambda)^{-\varepsilon} = b_0 + b_1\lambda + b_2\lambda^2 + \cdots. \tag{15}$$

The first series (14) is a series of polynomial conservation law densities a_k with respect to Riemann invariants (this is analog of the Kruskal series of conservation law densities for integrable dispersive systems like the Korteweg–de Vries equation). We shall call them as ''higher'' (or ''positive'') conservation law densities and correspondingly their homogeneity. The coefficients b_k we shall call as ''lower'' (or ''negative'') conservation law densities (they play a role as ''new'' conservation law densities appearing under Miura type transformation in the theory of integrable dispersive systems).

It is easy to check that any commuting flow (so, every Riemann invariant r^i is a function of three independent variables x, t, τ)

$$r^i_\tau = w^i_{(\varepsilon)}(\mathbf{r}) r^i_x \tag{16}$$

to hydrodynamic type system (13) has velocities

$$w^i_{(\varepsilon)}(\mathbf{r}) = \partial_i h_{(-\varepsilon)}, \tag{17}$$

where $h_{(-\varepsilon)}$ is some conservation law density of the ''$(-\varepsilon)$-system,''

$$r^i_t = \left[r^i + \varepsilon \sum_{m=1}^{N} r^m \right] r^i_x, \quad i = 1,2,\ldots,N.$$

Since the ''ε-systems'' and ''$(-\varepsilon)$-systems'' have generating functions of conservation law densities such that

$$\mu_{(\varepsilon)} \cdot \mu_{(-\varepsilon)} = 1, \tag{18}$$

then a generating function of commuting flows to (13) in Riemann invariants is [see (16) and (17)]

$$r^i_{\tau(\tilde{\lambda})} = \frac{1}{(1 - r^i/\tilde{\lambda})\tilde{\mu}} r^i_x, \tag{19}$$

and in the conservative form [cf. (6)] is

$$\mu_{\tau(\tilde{\lambda})} = \frac{\tilde{\lambda}}{\tilde{\lambda} - \lambda} \partial_x \left(\frac{\mu}{\tilde{\mu}} \right), \tag{20}$$

where $\tilde{\mu} \equiv \mu(\tilde{\lambda})$ [see (14) and (15)].

Higher commuting flows can be obtained from [see (14)]

$$\tilde{\mu}\equiv\prod_{m=1}^{N}(1-r_m/\tilde{\lambda})^{-\varepsilon}=1+a_1/\tilde{\lambda}+a_2/\tilde{\lambda}^2+\cdots$$

and formal series

$$\partial_{\tau(\tilde{\lambda})}=\partial_{t_0}+\frac{1}{\tilde{\lambda}}\partial_{t_1}+\frac{1}{\tilde{\lambda}^2}\partial_{t_2}+\cdots$$

when $\tilde{\lambda}\to\infty$. The corresponding generating functions of conservation laws are

$$\partial_{t_k}\mu=\partial_x\left[\mu\sum_{m=0}^{k}\tilde{a}_m\lambda^{k-m}\right],\qquad k=0,1,2,\ldots, \tag{21}$$

where

$$\tilde{a}_0=a_0=1,\quad \tilde{a}_1=-a_1,\quad \tilde{a}_n=-a_n-\sum_{m=1}^{n-1}\tilde{a}_m a_{n-k},\quad n=2,3,\ldots.$$

The corresponding *higher* commuting flows (in Riemann invariants) are

$$\partial_{t_k}r^i=\left[\sum_{m=0}^{k}\tilde{a}_m(r^i)^{k-m}\right]r_x^i,\qquad k=0,1,2,\ldots. \tag{22}$$

Lower commuting flows can be obtained from [see (15)]

$$\tilde{\mu}\equiv\prod_{m=1}^{N}(r_m-\tilde{\lambda})^{-\varepsilon}=b_0+b_1\tilde{\lambda}+b_2\tilde{\lambda}^2+\cdots$$

and formal series

$$\partial_{\tau(\tilde{\lambda})}=\tilde{\lambda}\partial_{t_{-1}}+\tilde{\lambda}^2\partial_{t_{-2}}+\tilde{\lambda}^3\partial_{t_{-3}}+\cdots,$$

when $\tilde{\lambda}\to 0$. The corresponding generating functions of conservation laws are

$$\partial_{t_{-k-1}}\mu=\partial_x\left[\mu\sum_{m=0}^{k}\tilde{b}_m\lambda^{m-k-1}\right],\quad k=0,1,2,\ldots, \tag{23}$$

where

$$\tilde{b}_0=\frac{1}{b_0},\quad \tilde{b}_k=-\frac{1}{b_0}\sum_{m=0}^{k-1}\tilde{b}_m b_{k-m},\quad k=1,2,\ldots.$$

The corresponding *lower* commuting flows (in Riemann invariants) are

$$\partial_{t_{-k-1}}r^i=\left[\sum_{m=0}^{k}\tilde{b}_m(r^i)^{m-k-1}\right]r_x^i,\quad k=0,1,2,\ldots. \tag{24}$$

If $\lambda\to\infty$ and $\tilde{\lambda}\to\infty$, all the *higher* conservation laws for the *higher* commuting flows are

$$\partial_{t_k}a_m=\partial_x\left[\sum_{s=0}^{k}\tilde{a}_s a_{k+m-s}\right],\quad k=0,1,2,\ldots. \tag{25}$$

If $\lambda\to 0$ and $\tilde{\lambda}\to\infty$, all the *lower* conservation laws for the *higher* commuting flows are

$$\partial_{t_n} b_k=\partial_x\left[\sum_{s=0}^{k} b_s\tilde{a}_{n+s-k}\right],\quad k\leqslant n,\quad \partial_{t_n} b_k=\partial_x\left[\sum_{s=0}^{n}\tilde{a}_s b_{k+s-n}\right],\quad k\geqslant n. \tag{26}$$

If $\lambda\to 0$ and $\tilde{\lambda}\to 0$, all the *lower* conservation laws for the *lower* commuting flows are

$$\partial_{t_{-n-1}} b_m=\partial_x\left[\sum_{k=0}^{n}\tilde{b}_k b_{n+m+1-k}\right],\quad n=0,1,2,\ldots. \tag{27}$$

If $\lambda\to\infty$ and $\tilde{\lambda}\to 0$, all the *higher* conservation laws for the *lower* commuting flows are

$$\partial_{t_{-n-1}} a_{m+1}=\partial_x\left[\sum_{k=0}^{m} a_s\tilde{b}_{n+s-m}\right],\ m\leqslant n,\ \partial_{t_{-n-1}} a_{m+1}=\partial_x\left[\sum_{k=0}^{n}\tilde{b}_s a_{m+s-n}\right],\ m\geqslant n. \tag{28}$$

All these above formulas can be easily checked by direct calculations.

For instance, the initial system (13) has the generating function of conservation laws

$$\partial_t\mu=\partial_x[(\lambda-a_1)\mu], \tag{29}$$

where an infinite set of the *positive* (polynomial) conservation laws is

$$\partial_{t_1} a_k=\partial_x[a_{k+1}-a_1 a_k],\quad k=1,2,\ldots, \tag{30}$$

and an infinite set of the *negative* conservation laws is

$$\partial_{t_1} b_0=\partial_x(-a_1 b_0),\quad \partial_{t_1} b_k=\partial_x[b_{k-1}-a_1 b_k],\quad k=1,2,\ldots. \tag{31}$$

The second commuting flow [see (13) and (22)]

$$r^i_{t_2}=\left[(r^i)^2-\varepsilon r^i\sum_{m=1}^{N} r^m+\frac{\varepsilon^2}{2}\left(\sum_{m=1}^{N} r^m\right)^2-\frac{\varepsilon}{2}\sum_{m=1}^{N}(r^m)^2\right]r^i_x,\quad i=1,2,\ldots,N,$$

has the generating function of conservation laws [see (21)]

$$\mu_{t_2}=\partial_x[(\lambda^2-a_1\lambda+a_1^2-a_2)\mu],$$

where an infinite set of the *positive* (polynomial) conservation laws is [see (25)]

$$\partial_{t_2} a_k=\partial_x[a_{k+2}-a_1 a_{k+1}+(a_1^2-a_2)a_k]. \tag{32}$$

An infinite set of the *negative* conservation laws is [see (26)]

$$\partial_{t_2} b_0=\partial_x[b_0(a_1^2-a_2)],\quad \partial_{t_2} b_1=\partial_x[b_1(a_1^2-a_2)-a_1 b_0],$$

$$\partial_{t_2} b_k=\partial_x[b_k(a_1^2-a_2)-a_1 b_{k-1}+b_{k-2}],\quad k=2,3,\ldots.$$

The first *negative* ($\tilde{\lambda}\to 0$) commuting flow is [see (24)]

$$r^i_{t_{-1}}=\frac{1}{b_0 r^i}r^i_x=\frac{\Pi_{m=1}^{N}(r^m)^{\varepsilon}}{r^i}r^i_x, \tag{33}$$

where the generating function of conservation laws is [see (23)]

$$\mu_{t_{-1}}=\partial_x\frac{\mu}{\lambda b_0}, \tag{34}$$

where an infinite set of *negative* conservation laws is [see (27)]

$$\partial_{t_{-1}}b_k=\partial_x\frac{b_{k+1}}{b_0},\quad k=0,1,2,\ldots, \tag{35}$$

and an infinite set of *positive* conservation laws is [see (28)]

$$\partial_{t_{-1}}a_1=\partial_x\frac{1}{b_0},\quad \partial_{t_{-1}}a_{k+1}=\partial_x\frac{a_k}{b_0},\quad k=1,2,\ldots. \tag{36}$$

Remark: The reciprocal transformation [see the first equation in (31)]

$$dy_{-1}=b_0dx-a_1b_0dt_1,\quad dz=dt_1,$$

connects system (13) [also, see (30) and (31)] and its commuting flow (33) [also, see (35) and (36)].

The reciprocal transformation [see (29)]

$$dy=\mu[dx+(\lambda-a_1)dt_1],\quad dz=dt_1,$$

connects system (13) and the generating function of its commuting flows [see (16)–(20)]

$$\partial_t a_1=-\lambda\partial_x(1/\mu).$$

III. NEW HYDRODYNAMIC CHAIN

The hydrodynamic type system (13) can be rewritten as the infinite moment chain

$$\partial_t c_k=\partial_x c_{k+1}-c_1\partial_x c_k,\quad k=0,\pm1,\pm2,\ldots, \tag{37}$$

where the first N moments c_k $(k=1,2,\ldots,N)$ are functionally independent:

$$c_0=\varepsilon\sum_{m=1}^{N}\ln r^m,\quad c_k=\frac{\varepsilon}{k}\sum_{m=1}^{N}(r^m)^k,\quad k=\pm1,\pm2,\ldots. \tag{38}$$

Thus, all a_k, b_k and c_k can be expressed via each other (see below). This is an invertible transformation.

However, now we can start our investigation namely from a hydrodynamic chain written in form (37) or, for instance, in form (30) without any reference on the original hydrodynamic type system (13) [and the explicit expressions (38)]. If now we restrict our infinite moment chain to the N-component case, then just one particular solution obviously is exactly the hydrodynamic type system (13) [also, see (38)]. How to find all other possible reductions? The answer will be done in next section.

Remark: For the first time, this hydrodynamic chain (30) has been derived (in another terms) by S. J. Alber (see Ref. 2; also it has been independently obtained in another context by V. G. Mikhalev, see Ref. 27), and recently by L. M. Alonso and A. B. Shabat (see Ref. 4; they describe mostly differential reductions and very particular hydrodynamical reductions; in our article we describe all possible hydrodynamical reductions). Actually, the starting point of their investigations was the hydrodynamic type "ε-system," when $\varepsilon=-\frac{1}{2}$, related by generalized reciprocal transformation with averaged (by the Whitham method) integrable systems (determined by scalar second order spectral transform with energy-dependent potential, see also mentioned references) related with hyperelliptic surfaces.

The generating function of conservation laws for the hydrodynamic chain (37) is exactly (29), where [cf. (14)]

$$\mu=1+\sum_{k=1}^{\infty} a_k\lambda^{-k}=\exp\left[\sum_{k=1}^{\infty} c_k\lambda^{-k}\right], \quad c_1\equiv a_1, \tag{39}$$

and $\lambda\to\infty$. The hydrodynamic chain (31) satisfies the same generating function (29), where [cf. (15)]

$$\mu=\sum_{k=0}^{\infty} b_k\lambda^{k}=\exp\left[-\sum_{k=0}^{\infty} c_{-k}\lambda^{k}\right], \quad c_0\equiv-\ln b_0, \tag{40}$$

and $\lambda\to 0$.

All the *positive* commuting flows in field variables c_k are

$$\partial_{t_n} c_k=\sum_{m=0}^{n} \tilde{a}_m c_{k+n-m,x}, \quad k=0,\pm 1,\pm 2,\ldots,$$

where the generating function of conservation law densities for an arbitrary *positive* commuting flow is (21); all *negative* flows are

$$\partial_{t_{-n-1}} c_k=\sum_{m=0}^{n} \tilde{b}_m c_{k+m-n,x}, \quad k=0,\pm 1,\pm 2,\ldots,$$

where the generating function of conservation law densities for an arbitrary *negative* commuting flow is (23). All these *negative* flows can be obtained from *positive* commuting flows (see above) by the reciprocal transformation (see the Remark of the previous section). For instance, the first *negative* flow is

$$\partial_{t_{-1}} c_k=e^{c_0}\partial_x c_{k-1}, \quad k=0,\pm 1,\pm 2,\ldots. \tag{41}$$

Remark: Obviously, the values $\tilde{a}_k$ and $\tilde{b}_k$ can be expressed from analogs of (39) and (40) [see (20)],

$$\frac{1}{\mu}=1+\sum_{k=1}^{\infty} \tilde{a}_k\lambda^{-k}=\exp\left[-\sum_{k=1}^{\infty} c_k\lambda^{-k}\right], \quad \tilde{a}_1\equiv -c_1, \quad \lambda\to\infty.$$

$$\frac{1}{\mu}=\sum_{k=0}^{\infty} \tilde{b}_k\lambda^{k}=\exp\left[\sum_{k=0}^{\infty} c_{-k}\lambda^{k}\right], \quad \tilde{b}_0\equiv e^{c_0}, \quad \lambda\to 0.$$

Thus, the hydrodynamic chain (37) can be expressed via the different moments (a_k, b_k), see, for instance, the Remark in Sec. VI.

The relationship (39) between the *positive* moments c_k and the *positive* conservation law densities a_k can be expressed explicitly by the next four recursive formulas, where the first of them,

$$da_{k+1}=\sum_{m=1}^{k} a_m dc_{k+1-m}+dc_{k+1}, \quad k=0,1,2,\ldots,$$

is a consequence of the three local symmetry operators acting on a space of the conservation law densities a_k: the shift operator

$$\hat{\delta}a_{k+1}=\frac{\partial a_{k+1}}{\partial c_1}=a_k, \quad k=0,1,2,\ldots;$$

the scaling operator

$$\hat{R}a_k=\sum_{m=1}^{\infty} mc_m\frac{\partial a_k}{\partial c_m}=ka_k, \quad k=0,1,2,\ldots;$$

and the projective operator

$$\hat{S}a_k=\left[c_1+\sum_{m=1}^{\infty}(m+1)c_{m+1}\frac{\partial}{\partial c_m}\right]a_k=(k+1)a_{k+1}, \quad k=0,1,2,\ldots.$$

IV. FINITE-COMPONENT REDUCTIONS

Theorem 1: *The hydrodynamic type system (8) with an arbitrary number of components is embedded into the hydrodynamic chain (37) if and only if*

$$V_i=f_i(r^i)-c_1, \quad c_1=\sum_{m=1}^{N}\psi_m(r^m), \tag{42}$$

where $f_i(r^i)$ *and* $\psi_k(r^k)$ *are arbitrary functions.*

Proof: Any reductions are compatible with given hydrodynamic chain (37) if every moment c_k can be expressed as a function of just N independent Riemann invariants r^i. Then one obtains

$$V_i\partial_i c_k=\partial_i c_{k+1}-c_1\partial_i c_k, \quad i=1,2,\ldots,,N,k=0,\pm 1,\pm 2,\ldots,$$

It is easy to see, that

$$\partial_i c_{k+1}=(V_i+c_1)^k\partial_i c_1, \quad i=1,2,\ldots,N, \quad k=0,\pm 1,\pm 2,\ldots.$$

Thus, the second derivatives

$$\partial_j[(V_i+c_1)^k\partial_i c_1]=\partial_i[(V_j+c_1)^k\partial_j c_1], \quad i=1,2,\ldots,N, \quad k=0,\pm 1,\pm 2,\ldots,$$

yield the general reduction (42). ■

Thus, all moments are

$$c_k=\sum_{m=1}^{N}\int^{r^m}[f_m(\lambda)]^{k-1}d\psi_m(\lambda), \quad k=0,\pm 1,\pm 2,\ldots.$$

Remark: The hydrodynamic type systems

$$r^i_{t_{-1}}=W^i(\mathbf{r})r^i_x, \quad i=1,2,\ldots,N, \tag{43}$$

embedded into first negative flow (41) [see (37)] can be found in the same way [see (42)]: from $W^i\partial_i c_k=e^{c_0}\partial_i c_{k-1}$ *one can obtain* $\partial_i c_k=(e^{c_0}/W^i)^k\partial_i c_0$. *In comparison with* $\partial_i c_k=(V_i+c_1)^k\partial_i c_0$ *one can obtain*

$$W^i=\frac{1}{f_i(r^i)}\exp\left[\sum_{m=1}^{N}\int^{r^m}\frac{d\psi_m(\lambda)}{f_m(\lambda)}\right]. \tag{44}$$

The next task is how to write hydrodynamical reductions in *closed* form via special variables like conservation law densities [see, e.g., (30)]. It means that all higher moments a_{N+k} (k

$=1,2,\dots$) must be expressed via lower moments a_k ($k=1,2,\dots,N$). In the particular case (13), all higher moments a_{N+k} are polynoms, which can be found from the relations [see (14)]

$$0=[(1+\lambda a_1+\lambda^2 a_2+\cdots+\lambda^N a_N+\lambda^{N+1}a_{N+1}+\cdots)^{-1/\varepsilon}]^{(N+k)}, \quad k=1,2,\dots.$$

For example, the first higher moment a_{N+1} can be found from the more compact recursive relation

$$\sum_{k=1}^{N+1}\frac{\Gamma(1-1/\varepsilon)z_k^{(N+1)}}{\Gamma(1-k-1/\varepsilon)\Gamma(k+1)}=0,$$

where $z_k^{(N+1)}$ is a coefficient of the series

$$[a_1+a_2\lambda+a_3\lambda^2+\cdots+a_{N+2-k}\lambda^{N+1-k}]^k=a_1^k+\lambda k a_1^{k-1}a_2+\cdots+\lambda^{N+1-k}z_k^{(N+1)}+\cdots.$$

All higher moments a_{N+k} are polynoms of lower moments a_k, e.g.,

$$a_3=\frac{1+\varepsilon}{\varepsilon}a_1a_2-\frac{(1+\varepsilon)(1+2\varepsilon)}{6\varepsilon^2}a_1^3, \quad N=2,$$

$$a_4=\frac{1+\varepsilon}{2\varepsilon}(2a_1a_3+a_2^2)-\frac{(1+\varepsilon)(1+2\varepsilon)}{2\varepsilon^2}a_1^2a_2+\frac{(1+\varepsilon)(1+2\varepsilon)(1+3\varepsilon)}{24\varepsilon^3}a_1^4, \quad N=3,$$

$$a_5=\frac{1+\varepsilon}{\varepsilon}(a_1a_4+a_2a_3)-\frac{(1+\varepsilon)(1+2\varepsilon)}{2\varepsilon^2}(a_1^2a_3+a_1a_2^2)+\frac{(1+\varepsilon)(1+2\varepsilon)(1+3\varepsilon)}{6\varepsilon^3}a_1^3a_2$$
$$-\frac{(1+\varepsilon)(1+2\varepsilon)(1+3\varepsilon)(1+4\varepsilon)}{120\varepsilon^4}a_1^5, \quad N=4,$$

and so on. The first exceptional case is the chromatography phenomena ($\varepsilon=-1$). Then

$$a_3=-a_1a_2+\tfrac{1}{6}a_1^3, \quad N=2,$$

$$a_4=-\tfrac{1}{2}(2a_1a_3+a_2^2)+\tfrac{1}{2}a_1^2a_2-\tfrac{1}{12}a_1^4, \quad N=3,$$

$$a_5=-(a_1a_4+a_2a_3)+\tfrac{1}{2}(a_1^2a_3+a_1a_2^2)-\tfrac{1}{3}a_1^3a_2+\tfrac{1}{20}a_1^5, \quad N=4;$$

the second exceptional case is (dispersionless limits of coupled KdV and coupled Harry Dym) $\varepsilon=-\frac{1}{2}$, then first higher moment a_{N+1} is just a quadratic expression via lower moments a_k. It means that corresponding hydrodynamic type systems have at least one local Hamiltonian structure (see Ref. 34); actually, the largest number of local Hamiltonian structures is $(N+1)$, *iff* $\varepsilon=-\frac{1}{2}$, see Ref. 16. The third exceptional case is $\varepsilon=-1/M$, where $M=3,4,\dots$. Then all expressions for the higher moments a_k will be quickly truncated (see above; it means that just few terms will survive in corresponding sums).

V. COMMUTING FLOWS AND REDUCTIONS

The corresponding linear system for conservation law densities (see Ref. 36) is

$$\partial_{ik}h=\frac{\psi_k'(r^k)}{f_i(r^i)-f_k(r^k)}\partial_i h-\frac{\psi_i'(r^i)}{f_i(r^i)-f_k(r^k)}\partial_k h, \quad i\neq k. \tag{45}$$

The general solution of such a system is determined by N functions of a single variable (also, see Ref. 36). In a particular, but very important, case of the "ε-systems" [see, for example, (13)] this linear system (45) is exactly the N-component generalization of the Euler–Darboux–Poisson system (see Ref. 31)

$$\partial_{ik}h=\frac{\varepsilon}{r^i-r^k}[\partial_i h-\partial_k h],\quad i\neq k. \tag{46}$$

At first, it is necessary to find a generating function of conservation law densities μ, which can be found in comparison with (29) and (42)

$$\mu(\mathbf{r},\lambda)=\exp\left(\sum_{k=1}^{N}\int^{r^k}\frac{d\psi_k(\tilde{\lambda})}{\lambda-f_k(\tilde{\lambda})}\right). \tag{47}$$

This formula (47) simplifies in the case of the "ε-systems" [see (14) and (15), that was well known in the case $N=2$, for example, see Ref. 7]. The velocities w^i of the commuting flows (i.e., Riemann invariants r^i are considered as the functions simultaneously of three independent variables x, t, τ),

$$r^i_\tau=w^i(\mathbf{r})r^i_x,\quad i=1,2,\ldots,N, \tag{48}$$

can be found as the solutions of another linear system (also see Ref. 36):

$$\partial_i w^k=-\frac{\psi_i'}{f_i(r^i)-f_k(r^k)}(w^i-w^k),\quad i\neq k. \tag{49}$$

Theorem 2: *Any solutions of the linear system (49) are connected with the solutions of another linear system [cf. (45)],*

$$\partial_{ik}\tilde{h}=-\frac{\psi_k'(r^k)}{f_i(r^i)-f_k(r^k)}\partial_i\tilde{h}+\frac{\psi_i'(r^i)}{f_i(r^i)-f_k(r^k)}\partial_k\tilde{h},\quad i\neq k,$$

by the differential substitution of the first order

$$w^i=\frac{1}{\psi_i'}\partial_i\tilde{h}.$$

Thus, the generating function of solutions [for the hydrodynamic type systems (8) and (42)–(44); cf. (13) and (33)] by the Tsarev generalized hodograph method (also see Ref. 36) is

$$\begin{aligned}x+\left[f_i(r^i)-\sum_{k=1}^{N}\psi_k(r^k)\right]t_1+\frac{1}{f_i(r^i)}\exp\left[\sum_{m=1}^{N}\int^{r^m}\frac{d\psi_m(\lambda)}{f_m(\lambda)}\right]t_{-1}\\ =-\frac{1}{\lambda-f_i(r^i)}\exp\left[-\sum_{k=1}^{N}\int^{r^k}\frac{d\psi_k(\tilde{\lambda})}{\lambda-f_k(\tilde{\lambda})}\right],\end{aligned} \tag{50}$$

where the generating function of commuting flows [see (19)] in Riemann invariants is

$$r^i_{\tau(\tilde{\lambda})}=\frac{1}{(1-f_i(r^i)/\tilde{\lambda})\tilde{\mu}}r^i_x.$$

Remark: If one selects the monoms

$$\psi_i(r^i)=\varepsilon_i r^i,$$

where ε_k are arbitrary constants, then the generalized "ε-systems"

$$r_t^i=\left[r^i-\sum_{m=1}^{N}\varepsilon_m r^m\right]r_x^i \tag{51}$$

have the generating function of conservation law densities [cf. (14) and (47)]

$$\mu=\prod_{m=1}^{N}(1-r_m/\lambda)^{-\varepsilon_m}.$$

In the general case (N *is arbitrary) the hydrodynamic type system (51) is the natural* N*-parametric reduction of the hydrodynamic chain (37). When* $N=2$ *this system (51) is the natural two-parametric generalization of gas dynamics (9). If we choose [cf. (38)]*

$$c_0=\sum_{m=1}^{N}\varepsilon_m\ln r^m,\quad c_k=\frac{1}{k}\sum_{m=1}^{N}\varepsilon_m(r^m)^k,\quad k=\pm1,\pm2,\ldots,$$

then the hydrodynamic type system (51) satisfies hydrodynamic chain (37).

Remark: In the particular case $f_i(r^i)=\varepsilon_i$ (ε_i *are arbitrary constants and* $\varepsilon_i\neq\varepsilon_k$ *for* $i\neq k$; *this is the* N*-component generalization of gas dynamics, when the adiabatic index* $\gamma=1$*) the hydrodynamic type system (42)*

$$r_t^i=\left[\varepsilon_i-\sum_{m=1}^{N}\psi_m(r^m)\right]r_x^i$$

is "trivial" [also $\psi_i(r^i)\neq\text{const}$*]. In this case, the linear system (45) has constant coefficients*

$$\frac{\partial^2 h}{\partial R^i\partial R^k}=\frac{1}{\varepsilon_i-\varepsilon_k}\left[\frac{\partial h}{\partial R^i}-\frac{\partial h}{\partial R^k}\right],\quad i\neq k,$$

where $R^i=\psi_i(r^i)$.

VI. GENERAL SOLUTION

Description of the general solution for the linear system (45) is a very complicated task. Construction of the general solution has been made only in the case of the "ε-systems" (see Ref. 31), when N is arbitrary; cases $N=2$ and $N=3$ were completely investigated by G. Darboux, L. P. Eisenhart, and T. H. Gronwall (see Refs. 7 and 10). The basic idea of how to construct a general solution (parametrized by N functions of a single variable, see Ref. 36) of any overdetermined linear systems like (45) was presented in Ref. 36 by recursive application of symmetry operators compatible with such systems. However, here we establish an alternative approach in the spirit of G. Darboux (see Ref. 36; also, see the section concerning elliptic coordinates in Ref. 7). Elliptic coordinates μ_α ($\alpha=1,2,\ldots,N$) appear in the theory of integrable hydrodynamic type systems associated with hyperelliptic curves, i.e., with the "ε-systems," where $\varepsilon=-\frac{1}{2}$. G. Darboux suggested to introduce special variables r^k ($k=1,2,\ldots,N$) for separation of coordinates in the Laplace equation by the following rule [see (15), when $\varepsilon=-\frac{1}{2}$]

$$\mu_\alpha^2=\frac{\Pi_{k=1}^{N}(\gamma_\alpha-r^k)}{\Pi_{\beta\neq\alpha}(\gamma_\alpha-\gamma_\beta)},\quad g^{ii}=\frac{\Pi_{\beta=1}^{N}(r^i-\gamma_\beta)}{\Pi_{k\neq i}(r^i-r^k)},$$

where γ_α are arbitrary constants [the denominator $\Pi_{\beta\neq\alpha}(\gamma_\alpha-\gamma_\beta)$ in the first expression is just a constant multiplier, which does not affect the property to be a conservation law density, also see (29)] and the flat (not constant) metric $g^{ii}(\mathbf{r})$ determined by

$$ds^2=\sum_{\alpha=1}^{N}(d\mu_\alpha)^2=\sum_{k=1}^{N}g_{kk}(dr^k)^2.$$

Thus, elliptic coordinates coincide with the Riemann invariants for "ε-systems," where $\varepsilon=-\frac{1}{2}$. It is easy to generalize the Darboux coordinates μ_α to an arbitrary ε:

$$(\mu_\alpha)^{-1/\varepsilon}=\frac{\Pi_{k=1}^{N}(\gamma_\alpha-r^k)}{\Pi_{\beta\neq\alpha}\Pi(\gamma_\alpha-\gamma_\beta)},\quad \alpha=1,2,\ldots,N.$$

In this case, all the "ε-systems," for instance, (13) and (33), can be written explicitly via μ_α in the conservative form [see (30) and (35) in the particular case $\varepsilon=-\frac{1}{2}$]

$$\begin{aligned}&\partial_t\mu_\alpha=\partial_x\left[\left(\varepsilon\sum_{\beta=1}^{N}(\mu_\beta)^{-1/\varepsilon}+\gamma_\alpha-\varepsilon\sum_{\beta=1}^{N}\gamma_\beta\right)\mu_\alpha\right],\\ &\partial_{t_{-1}}\mu_\alpha=\frac{\Pi_{\beta=1}^{N}(\gamma_\beta)^{\varepsilon}}{\gamma_\alpha}\partial_x\left[\left(1-\sum_{\beta=1}^{N}\frac{(\mu_\beta)^{-1/\varepsilon}}{\gamma_\beta}\right)^{\varepsilon}\mu_\alpha\right],\quad \alpha=1,2,\ldots,N.\end{aligned}\tag{52}$$

Remark: The hydrodynamic type systems (13) and (33) for another set of the moments $E_k=\Sigma_{\beta=1}^{N}(\gamma_\beta)^k(\mu_\beta)^{-1/\varepsilon}$ *[see (52)] can be written as the following hydrodynamic chains:*

$$\partial_{t_1}E_k=\partial_xE_{k+1}+\varepsilon\left[E_0-\sum_{\beta=1}^{N}\gamma_\beta\right]E_{k,x}-E_kE_{0,x},\quad k=0,\pm1,\pm2,\ldots,\tag{53}$$

$$\partial_{t_{-1}}E_k=\prod_{\beta=1}^{N}(\gamma_\beta)^{\varepsilon}[(1-E_{-1})^{\varepsilon}\partial_xE_{k-1}+(1-E_{-1})^{\varepsilon-1}E_{k-1}E_{-1,x}],\tag{54}$$

where

$$a_1=\varepsilon\left(\sum_{\beta=1}^{N}\gamma_\beta-E_0\right),\quad b_0=\prod_{\beta=1}^{N}(\gamma_\beta)^{-\varepsilon}(1-E_{-1})^{-\varepsilon}.$$

Remark: The hydrodynamic chain (53) is the same as the hydrodynamic chain (30), because these two chains are connected by the invertible transformation [see (29) and (39)]

$$\mu^{-1/\varepsilon}=1+\sum_{k=0}^{\infty}E_k\lambda^{-(k+1)},\tag{55}$$

where $\lambda\to\infty$. *The hydrodynamic chain (54) is the same as the hydrodynamic chain (35), because these two chains are connected by the invertible transformation [see (34) and (40)]*

$$\mu^{-1/\varepsilon}=1-\sum_{k=1}^{\infty}E_{-k}\lambda^{k-1},$$

where $\lambda\to0$.

Thus, our approach is the following: we mark N arbitrary points $\lambda=\gamma_\alpha$ (N distinct punctures) on the Riemann surface $F(\lambda,\mu)=0$ [see (47) and cf. (12)]; then we obtain special set of coordinates

$$\mu_\alpha=\exp\left(\sum_{k=1}^{N}\int_{\gamma_\alpha}^{r^k}\frac{d\psi_k(\tilde\lambda)}{\gamma_\alpha-f_k(\tilde\lambda)}\right),\tag{56}$$

which in fact is *the fundamental basis of linearly independent solutions* for the corresponding linear system (45). It means that any solution of the linear system (45) can be presented as a linear combination of the basis solutions (56) with some coefficients. Finally, we just mention that any overdetermined linear system like (45) must have a general solution which depends on N arbitrary parameters γ_α. In our case, we should take N infinite series of the conservation law densities $\mu_{\alpha,k}$ $(k=1,2,\dots)$ starting near already fixed punctures γ_α:

$$\mu^{(\alpha)}=\mu_\alpha+(\lambda-\gamma_\alpha)\mu_{\alpha,1}+(\lambda-\gamma_\alpha)^2\mu_{\alpha,2}+\cdots, \quad \lambda\to\gamma_\alpha, \quad \alpha=1,2,\dots,N.$$

Thus, the general solution of the linear system (45) is

$$h(\mathbf{r})=\sum_{\beta=1}^{N}\int_{\gamma_\beta}^{r^\beta}\varphi_\beta(\lambda)\mu^{(\beta)}(\lambda)d\lambda,$$

where $\varphi_\beta(\lambda)$ are arbitrary functions, and the general solution of the hydrodynamic type systems is given in the implicit form [see (8), (42)–(44), and (50)]:

$$x+\left[f_i(r^i)-\sum_{k=1}^{N}\psi_k(r^k)\right]t_1+\frac{1}{f_i(r^i)}\exp\left[\sum_{m=1}^{N}\int^{r^m}\frac{d\psi_m(\lambda)}{f_m(\lambda)}\right]t_{-1}$$
$$=\frac{1}{\psi_i'(r^i)}\partial_i\left[\sum_{\beta=1}^{N}\int_{\gamma_\beta}^{r^\beta}\varphi_\beta(\lambda)\tilde{\mu}^{(\beta)}(\lambda)d\lambda\right], \tag{57}$$

where

$$\tilde{\mu}_\alpha=\exp\left[-\sum_{k=1}^{N}\int_{\gamma_\alpha}^{r^k}\frac{d\psi_k(\tilde{\lambda})}{\gamma_\alpha-f_k(\tilde{\lambda})}\right], \quad \tilde{\mu}(\mathbf{r},\lambda)=\exp\left[-\sum_{k=1}^{N}\int^{r^k}\frac{d\psi_k(\tilde{\lambda})}{\lambda-f_k(\tilde{\lambda})}\right],$$

$$\tilde{\mu}^{(\alpha)}=\tilde{\mu}_\alpha+(\lambda-\gamma_\alpha)\tilde{\mu}_{\alpha,1}+(\lambda-\gamma_\alpha)^2\tilde{\mu}_{\alpha,2}+\cdots, \quad \lambda\to\gamma_\alpha, \quad \alpha=1,2,\dots,N.$$

The general solution of the linear system (45) can be presented in the most possible explicit form in special case, when values ε are *integers* for the "ε-systems." The case $N=2$ (namely, Euler–Darboux–Poisson equation) was completely investigated (see, for instance, Ref. 35). Its generalization on the N-component case (46), or moreover on the case of arbitrary *integers* ε_m [see (51)],

$$\partial_{ik}h=\frac{1}{r^i-r^k}[\varepsilon_k\partial_i h-\varepsilon_i\partial_k h], \quad i\neq k, \tag{58}$$

can be made in the same way as in Ref. 35. For simplicity, here we shall restrict our consideration to the case of (46) (see Ref. 31).

The general solution of (46) (if $\varepsilon=\pm n$, $n=1,2,\dots$) is

$$h_{(n)}=\sum_{k=1}^{N}\frac{d^n}{d(r^k)^n}\left[\frac{\varphi_k(r^k)}{\sum_{m\neq k}(r^k-r^m)^n}\right], \quad h_{(-n)}=\sum_{k=1}^{N}\int^{r^k}\varphi_k(\lambda)\prod_{m=1}^{N}(\lambda-r^m)^n d\lambda,$$

where $\varphi_k(r^k)$ are N arbitrary functions of a single variable [if we replace $\varphi_k(\lambda)\to\varphi_k^{(nN+1)}(\lambda)$ in second *negative* case, then all integrals can be expressed via finite number of derivatives only]. Thus, indeed, these solutions are general (see Ref. 36) for *positive* and *negative integers* ε [see (13) and (46)]. The general solutions for (58) can be obtained by recursive application of Laplace transformations (see Ref. 11) to the above formulas (also, see Ref. 1).

If ε is negative and $\varepsilon\neq -n$, $n=1,2,\dots$, then the above-mentioned solution (right) easily generalizes to

$$h_\varepsilon=\sum_{k=1}^{N}\int_{\gamma_k}^{r^k}\varphi_k(\lambda)\prod_{m=1}^{N}(\lambda-r^m)^{-\varepsilon}d\lambda,$$

where γ_k $(k=1,2,\ldots,N)$ are arbitrary constants. If ε is positive and $\varepsilon\neq n$, $n=1,2,\ldots$, then the above-mentioned solution (left) easily generalizes to just the case when εN is integer. Then

$$h_\varepsilon=\sum_{k=1}^{N}\oint_{C_k}\frac{\varphi_k(\lambda)d\lambda}{\Pi_{m=1}^{N}(\lambda-r^m)^{\varepsilon}},$$

where C_k $(k=1,2,\ldots,N)$ are simple small contours surrounding the points $\lambda=r^k$ $(k=1,2,\ldots,N)$. However, in a general case (when ε is positive and εN is not integer) these contours C_k could not be closed on corresponding Riemann surface, because a sum of all phase shifts (for every point) will not be proportional to $2\pi M$, where M is some integer. For avoiding this problem one can introduce another set of contour-dumbbell-shaped figures $C_{k,k+1}$ surrounding every two neighbor points $\lambda=r^k$ and $\lambda=r^{k+1}$ $(k=1,2,\ldots,N)$. So, the integration must change sign twice from clockwise to anticlockwise, then every time a phase shift will be 2π exactly. However, the number of contours must be equal to $N-1$, because in the opposite case (if the number is N) all contours became linearly dependent. Thus, in this general case a general solution of (46) parametrized by the N arbitrary functions of a single variable is

$$h_\varepsilon=\sum_{k=1}^{N-1}\oint_{C_{k,k+1}}\frac{\varphi_k(\lambda)d\lambda}{\Pi_{m=1}^{N}(\lambda-r^m)^{\varepsilon}}+\int_{-\infty}^{0}\frac{\varphi_N(\lambda)d\lambda}{\Pi_{m=1}^{N}(\lambda-r^m)^{\varepsilon}},$$

where for simplicity we assume (without lost of generacy) that real parts of Riemann invariants r^k (branch points on a complex Riemann surface) are numerated as follows:

$$0<\mathrm{Re}r^1<\mathrm{Re}r^2<\cdots<\mathrm{Re}r^N.$$

VII. (2+1)-INTEGRABLE HYDRODYNAMIC TYPE SYSTEMS

The Benney moment chain (1) is equivalent to the hierarchy of $(2+1)$ hydrodynamic type systems embedded in the dispersionless KP hierarchy as the Khohlov–Zabolotskaya equation

$$(u_{t_2}-uu_x)_x=u_{t_1t_1}, \tag{59}$$

which can be obtained from the coupled equations of the Benney moment chain (1) and one equation of its first nontrivial commuting flow (see Sec. IX)

$$\partial_{t_2}A_k=\partial_xA_{k+2}+A_0A_{k,x}+(k+1)A_kA_{0,x}+kA_{k-1}A_{1,x},\quad k=0,1,2,\ldots, \tag{60}$$

by eliminating the moments A_1 and A_2:

$$\partial_{t_1}A_0=\partial_xA_1,\quad \partial_{t_1}A_1=\partial_x[A_2+\tfrac{1}{2}A_0^2],\quad \partial_{t_2}A_0=\partial_x[A_2+A_0^2],$$

where $u=A_0$.

Let us start now with the hydrodynamic chains (30) and (32), eliminate the field variable a_3 from couple equations from the first hydrodynamic chain (30) and one equation from the second hydrodynamic chain (60),

$$\partial_{t_1}a_1=\partial_x[a_2-a_1^2],\quad \partial_{t_1}a_2=\partial_x[a_3-a_1a_2],\quad \partial_{t_2}a_1=\partial_x[a_3-2a_1a_2+a_1^3].$$

Then we came to the new integrable $(2+1)$ hydrodynamic type system

$$u_{t_1}=w_x, \quad u_{t_2}=w_{t_1}+uw_x-wu_x, \tag{61}$$

where

$$u=a_1, \quad w=a_2-a_1^2.$$

It is easy to check that all possible hydrodynamical reductions of this system (61) (see, for instance, the approach in Ref. 15):

$$r^i_{t_1}=\mu_i(\mathbf{r})r^i_x, \quad r^i_{t_2}=\zeta_i(\mathbf{r})r^i_x, \quad i=1,2,\ldots,N,$$

are exactly the same as those found already [see (42)], where

$$\zeta_i=f_i^2(r^i)-f_i(r^i)\sum_{k=0}^{N}\psi_m(r^m)+\frac{1}{2}\left(\sum_{k=0}^{N}\psi_m(r^m)\right)^2-\sum_{k=0}^{N}\int^{r^k}f_k(\lambda)d\psi_k(\lambda).$$

Moreover, one can obtain a whole hierarchy of such integrable $(2+1)$ hydrodynamic type systems like (61) by eliminating some other field variables a_k in combination with other commuting flows of the hydrodynamic chain (30). For example, two other equations [see (37) and (41)],

$$\partial_{t_1}e^{-c_0}=\partial_x[-c_1e^{-c_0}], \quad \partial_{t_{-1}}c_1=\partial_x e^{c_0}, \tag{62}$$

yield a new integrable $(2+1)$ hydrodynamic type system [its $(1+1)$ hydrodynamical reductions are exactly (43) and (44)].

VIII. ANOTHER HYDRODYNAMIC CHAIN

Now we start with the integrable hydrodynamic type system[18]

$$r^i_t=\left[\sum_{m=1}^{N}\varepsilon_m r^m-\varepsilon_i\sum_{m=1}^{N}r^m\right]r^i_x, \quad i=1,2,\ldots,N, \tag{63}$$

when ε_k are arbitrary constants. This system can be rewritten as the hydrodynamic chain

$$\partial_t c_k=c_1\partial_x c_k-c_0\partial_x c_{k+1}, \quad k=0,\pm1,\pm2,\ldots, \tag{64}$$

where the moments

$$c_k=\sum_{m=1}^{N}r^m(\varepsilon_m)^k.$$

Theorem 3: *Under the reciprocal transformation*

$$dz=\frac{1}{c_0}dx+\frac{c_1}{c_0}dt, \quad dy=dt,$$

this hydrodynamic chain linearizes

$$\partial_y c_k+\partial_z c_{k+1}=0, \quad k=0,\pm1,\pm2,\ldots. \tag{65}$$

It means that any reductions such as (63) of the hydrodynamic chain (64) linearizes under above reciprocal transformation. The solution of the hydrodynamic chain (65) is a set of the separate Riemann–Monge–Hopf equations

$$r^i_y+f_i(r^i)r^i_z=0, \quad i=1,2,\ldots,N,$$

where $f_i(r^i)$ are arbitrary functions. Thus, every integrable reduction of hydrodynamic chain (64) has the simple form

$$r^i_t=[c_0 f_i(r^i)-c_1]r^i_x,$$

where

$$c_k=\sum_{m=1}^{N}\int^{r^m}[f_m(\lambda)]^k d\psi_m(\lambda),\quad k=0,\pm 1,\pm 2,\ldots,$$

and $\psi_m(r^m)$ are arbitrary functions [by scaling $\psi_m(r^m)\to R_m$ integrable hydrodynamical reductions are parametrized by N arbitrary functions of a single variable only].

IX. OPEN PROBLEMS

The Benney moment chain (the Zakharov reduction) is a dispersionless limit of the vector nonlinear Schrödinger equation [see (11), (12), and Ref. 38]. The inverse problem is how to reconstruct a *dispersive* integrable analog of given hydrodynamic type system. A *dispersive* analog is known [coupled KdV is a *dispersive* analog of system (13); couple Harry Dym is a *dispersive* analog of system (33), see, e.g., Refs. 22 and 16] just in the case of the "ε-systems" with $\varepsilon=-\frac{1}{2}$. The KP hierarchy is a *dispersive* analog for the *whole* Benney moment chain (1) [as the KP equation is a *dispersive* analog of the Khohlov–Zabolotzkaya system (59)], but similar *dispersive* $(2+1)$ analogs for the whole hydrodynamic chain (37) or for the $(2+1)$ hydrodynamic type systems (61) or (62) still are unknown.

Local Hamiltonian structures for the hydrodynamic type system (13) were completely investigated in Ref. 29 and 16. It was proved that, if $N=2$, then the hydrodynamic type system (13) for any ε has three local Hamiltonian structures (also, see Refs. 28 and 12); if $N=3$ and $\varepsilon=-\frac{1}{2}$, then it has four local Hamiltonian structures; if $N=3$ and $\varepsilon=1$, then it has two-parametric family of local Hamiltonian structures (also see Refs. 30 and 17); if $N>3$, then $\varepsilon=-\frac{1}{2}$ and it has $(N+1)$-local Hamiltonian structures.

Hamiltonian structures of integrable hydrodynamic type systems are determined by a metric g_{ii} (see, Ref. 9). The metric

$$g^{ii}=\zeta_i(r^i)\exp\left[-2\sum_{k\neq i}\int^{r^k}\frac{d\psi_k(\lambda)}{f_i(r^i)-f_k(\lambda)}\right]$$

with arbitrary functions $\zeta_i(r^i)$ determines a nonlocal Hamiltonian formalism (see Ref. 13 and 36) of hydrodynamic type systems (8) and (42)–(44) and their commuting flows. Unfortunately, local and nonlocal Hamiltonian formalism has been done just for the hydrodynamic type systems (13) when $\varepsilon=\pm 1$ and $\varepsilon=-\frac{1}{2}$ (see, for instance Refs. 17 and 13). However, the problem of a description of local and nonlocal Hamiltonian structures in general case (42) still is open. Nevertheless, this problem can be solved by the Dirac restriction of a Hamiltonian structure (see for the beginning Ref. 13) known for the whole hydrodynamic chain, as it was already done in Ref. 6 for other hydrodynamic chains.

The starting point of such an investigation is a Lax-type representation. For instance, the Lax-type representation [see (2)] for the dispersionless KP hierarchy [i.e., the Benney moment chain (1)] is well known (see Ref. 26)

$$\partial_{t_n}\lambda=\{Q_n,\lambda\}=\frac{\partial Q_n}{\partial\mu}\frac{\partial\lambda}{\partial x}-\frac{\partial Q_n}{\partial x}\frac{\partial\lambda}{\partial\mu},\quad n=0,1,2,\ldots, \tag{66}$$

where Q_n is the part, polynomial in μ, of λ^n. Also, the first local Hamiltonian structure for whole Benney moment chain (1),

$$\partial_{t_n} A_k = \sum_{m \geqslant 0} \left[k A_{k+m-1} \partial_x \frac{\delta H_{n+1}}{\delta A_m} + \left(m A_{k+m-1} \frac{\delta H_{n+1}}{\delta A_m} \right)_x \right], \tag{67}$$

where the Hamiltonian is $H_2 = \frac{1}{2}\int [A_2 + A_0^2] dx$, was constructed in Ref. 25 [the relationship between formulas (66) and (67) was found in Ref. 26, too; first nontrivial commuting flow [see (60)] is determined by the next Hamiltonian $H_3 = \frac{1}{3}\int [A_3 + 3A_0 A_1] dx$; functional $H_0 = \int A_0 dx$ is a Casimir of this Hamiltonian structure, the functional $H_1 = \int A_1 dx$ is a momentum of this Hamiltonian structure].

Similar Lax type representation for the hydrodynamic chain (37) was established in Ref. 4 [cf. (66)]

$$\partial_{t_n} L = \langle Q_n, L \rangle = Q_n \frac{\partial L}{\partial x} - \frac{\partial Q_n}{\partial x} L, \quad n = 0,1,2,\ldots, \tag{68}$$

where

$$Q_n = (\lambda^n L)_+, \quad L = 1 + G_0/\lambda + G_1/\lambda^2 + G_2/\lambda^3 + \cdots.$$

The corresponding first hydrodynamic chain

$$\partial_{t_1} G_k = \partial_x G_{k+1} + G_0 G_{k,x} - G_k G_{0,x}, \quad k = 0,1,2,\ldots,$$

is exactly the hydrodynamic chain (53), where $\varepsilon = 1$, and the linear term $-\varepsilon(\Sigma_{\beta=1}^N \gamma_\beta) E_{k,x}$ is removed by a shift of the independent variable $[x \to x - \varepsilon(\Sigma_{\beta=1}^N \gamma_\beta) t]$. Thus, a generating function of these moments is [see (53), (55), and (68)]

$$\mu^{-1} \equiv L = 1 + \sum_{k=0}^{\infty} G_k \lambda^{-(k+1)}.$$

The alternative Lax type representations are

$$\partial_{t_k} \rho = \left[\sum_{m=0}^{k} \tilde{a}_m \lambda^{k-m} \partial_x, \rho \right], \quad \partial_{t_{-k-1}} \rho = \left[\sum_{m=0}^{k} \tilde{b}_m \lambda^{m-k-1} \partial_x, \rho \right], \quad k = 0,1,2,\ldots,$$

where $\mu = \rho_x$ [see (21) and (23)].

We suppose that the hydrodynamic chain (37) and its commuting flows have local Hamiltonian structure [cf. (67)]

$$\partial_{t_n} c_k = \sum_{k=1}^{\infty} [\beta_{k,m}(\mathbf{c}) \partial_x + \partial_x \beta_{m,k}(\mathbf{c})] \frac{\delta H_{n+1}}{\delta c_m},$$

where $\beta_{k,m}$ are some functions.

The Hamiltonian structures of integrable hydrodynamic type systems can be successfully investigated by application of methods from the differential (see, for example, Refs. 36, 29–33, 12,16, 13, and 17) and algebraic geometries (see, for instance, Refs. 8 and 24). An alternative way is following: assume that our given integrable hydrodynamic type system (N components) is a some reduction of some ''bigger'' integrable hydrodynamic type system ($N+M$ components); assume that Hamiltonian structure of such ''bigger'' integrable hydrodynamic type system is already known. Then the direct application of the Dirac restriction to this Hamiltonian structure [the first step in such procedure (see Ref. 13) is the choice of some Riemann invariants $r^k = \text{const}$, $k = 1,2,\ldots,M$] yields the transformed Hamiltonian structure of a ''restricted'' hydrodynamic type system. The Dirac restriction of Hamiltonian structures (in algebraic language) was developed in application to hydrodynamic chains and their reductions (see Ref. 6). The first step

in such a procedure is the recalculation of the Lax type representation [such as (66) or (68)] to the Hamiltonian structure of a whole hydrodynamic chain [see, for instance, (67)].

X. CONCLUSION

In this article we present a recipe: how to construct a hydrodynamic chain starting from any given hydrodynamic type system with *polynomial* (or *rational*) velocities with respect to their field variables [for simplicity we have mentioned just two cases: namely Benney moment chain, whose moments are connected directly with some *conservation law densities* (u_k, η_k) and the hydrodynamic chain (37), whose moments are connected directly with *Riemann invariants*]. In fact, it means that **any integrable hydrodynamic type system (written in Riemann invariants) with such *polynomial* velocities is embedded in hydrodynamic chain (37) or its higher (or lower) commuting flows**. Any integrable hydrodynamic type system written in Riemann invariants with *rational* velocities

$$r^i_t = g_0 \frac{(r^i)^M + g_1 (r^i)^{M-1} + \cdots + g_M}{(r^i)^K + e_1 (r^i)^{K-1} + \cdots + e_K} r^i_x, \quad i = 1,2,\ldots,N, \tag{69}$$

has the generating function of conservation laws

$$\mu_t = \partial_x \left[g_0 \frac{\lambda^M + g_1 \lambda^{M-1} + \cdots + g_M}{\lambda^K + e_1 \lambda^{K-1} + \cdots + e_K} \mu \right]. \tag{70}$$

For simplicity we assume that the coefficients e_k and g_k of such *rational* velocities are some *symmetric* (not necessary to be *polynomials*!) functions of Riemann invariants; K, M, and N are arbitrary natural numbers. As example, we can take any integrable systems embedded into 2×2 spectral transform like the Korteweg–de Vries equation, the Bonnet equation (the sine-Gordon equation) and the nonlinear Schrödinger equation. All their Whitham deformations [i.e., hydrodynamic type systems, see, for instance, Refs. 8 and 24] have such representation (69) as consequence (70) written in Abelian differentials on hyperelliptic surfaces

$$\partial_t dp = \partial_x dq,$$

where

$$dp = \frac{\lambda^K + e_1 \lambda^{K-1} + \cdots + e_K}{\sqrt{\Pi_{m=1}^N (r_m - \lambda)}} d\lambda, \quad dq = g_0 \frac{\lambda^M + g_1 \lambda^{M-1} + \cdots + g_M}{\sqrt{\Pi_{m=1}^N (r_m - \lambda)}} d\lambda,$$

and velocities of (69) are

$$g_0 \frac{(r^i)^M + g_1 (r^i)^{M-1} + \cdots + g_M}{(r^i)^K + e_1 (r^i)^{K-1} + \cdots + e_K} = \left. \frac{dq}{dp} \right|_{\lambda = r^i}.$$

Substituting [cf. (39)]

$$\mu = 1 + \sum_{k=1}^{\infty} a_k \lambda^{-k}$$

into the generating function (70) one can obtain similar formulas and results as it was done in this article. The next step is a *replication* of integrable hydrodynamic type systems as different hydrodynamical reductions of hydrodynamic chains. The *main advantage* of such *replicated* systems is a *preservation* of some properties of original hydrodynamic type systems like *generating functions of conservation laws and commuting flows* [see (2), (4), and (6) for the Benney moment chain (1); see (14), (29), and (20) for the hydrodynamic chain (37)]. Thus, a problem of integrability is much

simpler—all that necessary to do: to construct a general solution [starting from already obtained generating function, see (7), (50), and (57)], parametrized by N functions of a single variable (see Ref. 36) and to solve Cauchy problem, that in fact is done to this moment just for four cases (the Zakharov reduction of the Benney moment chain, see Ref. 19; linearly degenerate system, see Ref. 37; this particular class is the "ε-systems" with $\varepsilon=1$; hydrodynamic type systems of the Tample class, this particular class is the "ε-systems" with $\varepsilon=-1$, see Ref. 29; Whitham hydrodynamic type systems related with hyperelliptic surfaces such averaged N-phase solutions of Korteweg–de Vries equation (KdV) or nonlinear Schrödinger equation (NLS), it was done in articles of G. El, T. Grava, B.A. Dubrovin, F. R. Tian, J. Gibbons and many others).

Moreover, any two commuting flows of (29), for example, (21),

$$dz=\mu\left[dx+\sum_{m=0}^{k}\tilde{a}_m\lambda^{k-m}dt^k+\sum_{m=0}^{n}\tilde{a}_m\lambda^{n-m}dt^n\right],\qquad k,n=1,2,\ldots,$$

yield the hydrodynamic type systems with *rational* velocities

$$r^i_{t_k}=\frac{\sum_{m=0}^{k}\tilde{a}_m(r^i)^{k-m}}{\sum_{m=0}^{n}\tilde{a}_m(r^i)^{n-m}}r^i_{t_n},\quad k\neq n,\qquad i=1,2,\ldots,N.$$

A more complicated *rational* dependence can be obtained by application of a generalized reciprocal transformation (see, for instance, Ref. 11 and 17), starting from (29) and its commuting flows.

Thus, this is a *powerful tool for classification* of integrable hydrodynamic type systems and their *integrability*. Moreover, if any given hydrodynamic type system has a generating function of conservation laws [see, for instance, (4) or (29)], it means that the corresponding hydrodynamic chain has the same generating function. For example, if a some hydrodynamic type system has the same generating function as the Benney moment chain (4), it means that this hydrodynamic type system is some reduction of the Benney moment chain. Thus, this is a wonderful symptom in a recognition of an immersion of any unknown hydrodynamic type systems into already known hydrodynamic chains. Thus, *if one can construct a generating function of conservation laws for some hydrodynamic type system, it means that, in fact, the hydrodynamic chain is already constructed* (and may be recognized, because, obviously, the number of hydrodynamic chains is much smaller than the number of integrable hydrodynamic type systems).

However, the problem of a description of all possible reductions is very complicated. For instance, this problem for the Benney moment chain is still open (see Ref. 21). However, this problem for the Boyer–Finley moment chain (continuum limit of the Darboux–Laplace chain, which also is known as two-dimensional Toda lattice, see Refs. 3, 15, and 24) in fact does *not exist*, because both mentioned hydrodynamic chains are related by special exchange of independent variables (see Ref. 23). Thus, we are lucky to solve this problem for the hydrodynamic chain (37).

ACKNOWLEDGMENTS

I am grateful to my friends and colleagues Eugeni Ferapontov for his suggestions in improvement of my calculations and Yuji Kodama for useful discussions. Also I would like to thank Gennady El' and Anatoly Kamchatnov for carefully reading the manuscript.

(Received 30 January 2003; accepted 12 May 2003)

The density matrix for the impenetrable Bose gas in Dirichlet and Neumann boundary conditions can be written in terms of $\langle \Pi_{l=1}^{n} |\cos\phi_1 - \cos\theta_l||\cos\phi_2 - \cos\theta_l| \rangle$, where the average is with respect to the eigenvalue probability density function for random unitary matrices from the classical groups $\mathrm{Sp}(n)$ and $\mathrm{O}^+(2n)$, respectively. In the large n limit log-gas considerations imply that the average factorizes into the product of averages of the form $\langle \Pi_{l=1}^{n} |\cos\phi - \cos\theta_l| \rangle$. By changing variables this average in turn is a special case of the function of t obtained by averaging $\Pi_{l=1}^{n} |t - x_l|^{2q}$ over the Jacobi unitary ensemble from random matrix theory. The latter task is accomplished by a duality formula from the theory of Selberg correlation integrals, and the large n asymptotic form is obtained. The corresponding large n asymptotic form of the density matrix is used, via the exact solution of a particular integral equation, to compute the asymptotic form of the low lying effective single particle states and their occupations, which are proportional to $\sqrt{N}$. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1599954]

I. INTRODUCTION

The probability density functions (p.d.f.'s)

$$\frac{1}{n!}\left(\frac{1}{2\pi}\right)^n \prod_{l=1}^{n} 4\sin^2(\theta_l) \prod_{1\leqslant j<k\leqslant n} 4(\cos\theta_k - \cos\theta_j)^2, \tag{1}$$

$$\frac{2}{n!}\left(\frac{1}{2\pi}\right)^n \prod_{1\leqslant j<k\leqslant n} 4(\cos\theta_k - \cos\theta_j)^2, \tag{2}$$

where $0 \leqslant \theta_j \leqslant \pi$ $(j=1,\ldots,n)$ occur in both random matrix theory and the quantum many body problem. In the former they are eigenvalue p.d.f.'s for classical groups with the Haar (uniform) measure—the group $\mathrm{Sp}(n)$ of $n\times n$ unitary matrices with real quaternion elements (which are themselves 2×2 matrices), and the group $\mathrm{O}^+(2n)$ of $2n\times 2n$ unitary matrices with real elements (real orthogonal matrices) and determinant equal to $+1$, for (1) and (2), respectively. A self-contained derivation of these facts can be found in Ref. 1, Chap. 2. In the latter they are the absolute value squared of the ground state wave function for n free fermions on the interval $[0, \pi]$ with Dirichlet and Neumann boundary conditions, respectively. As is similarly well known, and revised from first principles in our work,[2] they are also the absolute value squared of the ground

[a)]Electronic mail: P.Forrester@ms.unimelb.edu.au
[b)]Electronic mail: n.frankel@physics.unimelb.edu.au
[c)]Electronic mail: t.garoni@physics.unimelb.edu.au

state wave function for n impenetrable bosons on the interval $[0, \pi]$—in one-dimension the ground state wave function of the impenetrable Bose system is equal to the absolute value of the corresponding free Fermi system.

In studies relating to both these seemingly disparate interpretations of the p.d.f.'s (1) and (2) there is cause to investigate the function of (ϕ, m, n) defined by averaging

$$\prod_{l=1}^{n} (\cos\phi - \cos\theta_l)^m \tag{3}$$

with respect to these p.d.f.'s. In the random matrix interpretation this comes about in applications to L-function theory.[3–5] Briefly, there are families of L-functions with special symmetries which are known to have their nontrivial zeros well described by eigenvalues of random matrices from the classical group corresponding to that symmetry. For $\cos\phi = 1$ and small values of m the expected value of (3) can be computed with $\{\theta_l\}$ corresponding to the zeros of particular families of L-functions, and it can also be computed—with m a general non-negative integer—for the random matrix ensembles. This then allows for both a test of the original hypothesis relating L-functions to random matrices, and provides specific conjectures for the statistical properties of the zeros of the L-function families.

In the quantum many body interpretation the immediate interest is not in the average of (3), but rather the average of

$$\prod_{l=1}^{n} |\cos\phi_1 - \cos\theta_l||\cos\phi_2 - \cos\theta_l|. \tag{4}$$

This gives the ground state density matrix of the corresponding impenetrable Bose gas system (if the absolute value signs are removed, the average gives the ground state density matrix for the free Fermi system).[2] However the study of (4) leads back to the computation of (3). Thus as noted in Refs. 6 and 7 for the problem of computing the asymptotic behavior of the ground state density matrix for the impenetrable bosons in the bulk and in an harmonic trap respectively, for large n and ϕ_1 and ϕ_2 fixed the average (4) is expected to factorize, and be proportional to the average of the product involving ϕ_1 times the average of the product involving ϕ_2. The latter are then the continuation in m of (3) from the even positive integers to the value $m = 1$ [this being a way to effectively study the average of the absolute value of (3)].

We remark that in the case of the density matrix for the impenetrable bosons in periodic boundary conditions the analogous task is to compute the average of

$$\prod_{l=1}^{n} |e^{i\phi_1} - e^{i\theta_l}|\,|e^{i\phi_2} - e^{i\theta_l}| \tag{5}$$

with respect to the p.d.f.,

$$\frac{1}{n!}\left(\frac{1}{2\pi}\right)^n \prod_{1 \leqslant j < k \leqslant n} |e^{i\theta_k} - e^{i\theta_j}|^2, \tag{6}$$

where $-\pi < \theta_j \leqslant \pi$ $(j = 1, \ldots, n)$. In this case the asymptotic form for large n with ϕ_1 and ϕ_2 fixed is a special case of known asymptotic forms for Toeplitz determinants with singular generating functions of the so-called Fisher–Hartwig-type (for an extended discussion on this point and references to the relevant literature, see Ref. 2). The average of (4) with respect to (1) or (2) can readily be written as a Hankel determinant, but there is no known analog of the Fisher–Hartwig asymptotic form.

In Sec. II we show how, for m an even positive integer, the average of (3) with respect to the p.d.f.'s (1) and (2), which is by definition an n-dimensional integral, can be written as an m-dimensional integral. From the latter the large n asymptotic form of the average is deduced. In

Sec. III the result of Sec. II is used to deduce the large n asymptotic form of the average (4) with respect to the p.d.f.'s (1) and (2) and thus of the ground state density matrix. We conclude in Sec. IV by applying our result for the asymptotic form of the density matrix to the computation of the occupations of the effective single particle states. We also make some remarks in relation to the wider setting of our asymptotic analysis, in which we use Coulomb gas arguments to formulate an analog of the Fisher–Hartwig asymptotic form for a class of Jacobi unitary ensemble averages.

II. DUALITY FORMULAS FOR MULTIPLE INTEGRALS AND ASYMPTOTIC ANALYSIS

A. The duality formula

The change of variables,

$$x_j=\tfrac{1}{2}(\cos\theta_j+1) \quad (0\leqslant x_j\leqslant 1, \quad j=1,\dots,n) \tag{7}$$

transforms (1) and (2) into p.d.f.'s which are proportional to

$$\prod_{l=1}^{n}(x_l(1-x_l))^{1/2}\prod_{1\leqslant j<k\leqslant n}(x_k-x_j)^2, \tag{8}$$

$$\prod_{l=1}^{n}(x_l(1-x_l))^{-1/2}\prod_{1\leqslant j<k\leqslant n}(x_k-x_j)^2, \tag{9}$$

respectively. These p.d.f.'s in turn are special cases of the class of p.d.f.'s proportional to

$$\prod_{l=1}^{n}x_l^{\lambda_1}(1-x_l)^{\lambda_2}\prod_{1\leqslant j<k\leqslant n}(x_k-x_j)^2 \tag{10}$$

known in random matrix theory as the Jacobi unitary ensemble. Also, under the change of variables (7) the task of computing the average of (3) becomes the task of computing the average of

$$\prod_{l=1}^{n}(t-x_l)^m \tag{11}$$

with respect to (8) and (9), or more generally with respect to (10).

In fact there is an advantage in further generalizing the setting of the computation of the average of (11) and considering the class of multiple integrals known as Selberg correlation integrals, defined by

$$\begin{aligned}S_{n,m}(\lambda_1,\lambda_2,\lambda;t_1,\dots,t_m)&:=\frac{1}{C}\int_{[0,1]^n}dx_1\cdots dx_n\prod_{l=1}^{n}\left(x_l^{\lambda_1}(1-x_l)^{\lambda_2}\prod_{i=1}^{m}(t_i-x_l)\right)\\&\quad\times\prod_{1\leqslant j<k\leqslant n}|x_k-x_j|^{2\lambda}\\&=\left\langle\prod_{l=1}^{n}\prod_{i=1}^{m}(t_i-x_l)\right\rangle_{\mathrm{J}(2\lambda)\mathrm{E}_n}.\end{aligned} \tag{12}$$

Here,

$$C=S_n(\lambda_1,\lambda_2,\lambda)=\int_{[0,1]^n}dx_1\cdots dx_n\prod_{l=1}^{n}x_l^{\lambda_1}(1-x_l)^{\lambda_2}\prod_{1\leqslant j<k\leqslant n}|x_k-x_j|^{2\lambda}, \tag{13}$$

known as the Selberg integral, is the normalization chosen so that the coefficient of $\Pi_{i=1}^m t_i^n$ is unity, and the average over $\mathrm{J}(2\lambda)\mathrm{E}_n$ refers to the p.d.f.,

$$\frac{1}{S_n(\lambda_1,\lambda_2,\lambda)}\prod_{l=1}^n x_l^{\lambda_1}(1-x_l)^{\lambda_2}\prod_{1\leqslant j<k\leqslant n}|x_k-x_j|^{2\lambda} \tag{14}$$

[the notation $\mathrm{J}(2\lambda)\mathrm{E}_n$ denotes the Jacobi-(2λ) ensemble, which with $\lambda=1$ corresponds to the Jacobi unitary ensemble (10)]. Setting $t_1=\cdots=t_m=t$ in (12) gives the average of (11) with respect to (14). The advantage in studying (12) is that we can put to use the discovery of Ref. 8, relating the Selberg correlation integrals to the theory of Jack polynomials (in the case $\lambda=1$ the Jack polynomials coincide with the Schur polynomials[9]). In particular the Selberg correlation integrals were evaluated in terms of a generalization of the Gauss hypergeometric function ${}_2F_1$ based on the Jack polynomials. It was realized by one of the present authors[10–15] that theory initiated in Ref. 8 could be further developed and used to express the average of (9) with respect to (14) and its limiting forms as the Laguerre—(2λ) ensemble and the Gaussian—(2λ) ensemble, as m-dimensional integrals. Because the role of n and m is effectively interchanged, these integration identities have been referred to as duality formulas.[16–18] One of their uses, as we will demonstrate in the case of the average of (11) with respect to (10), is in the computation of the large n asymptotics.

The particular duality formula of interest to us is given explicitly in Ref. 15. To state the result we must introduce the generalized circular ensemble, $\mathrm{C}\beta\mathrm{E}_N$, as the p.d.f. proportional to

$$\prod_{1\leqslant j<k\leqslant N}|z_k-z_j|^\beta \quad (z_j=e^{i\theta_j},\ -\pi<\theta_j<\pi,\ j=1,\dots,N). \tag{15}$$

With this notation, we read off from Ref. 15, Eq. (3.41) that

$$\left\langle\prod_{l=1}^N z_l^{(\eta_1-\eta_2)/2}|1+z_l|^{\eta_1+\eta_2}(1+tz_l)^m\right\rangle_{\mathrm{C}\beta\mathrm{E}_N}\propto\left\langle\prod_{l=1}^m[1-(1-t)x_l]^N\right\rangle_{\mathrm{J}(4/\beta)\mathrm{E}_m}\Bigg|_{\substack{\lambda_1=2(\eta_2-m+1)/\beta-1\\ \lambda_2=2(\eta_1+1)/\beta-1}}. \tag{16}$$

But we want to make $\langle\Pi_{l=1}^n(t-x_l)^m\rangle_{\mathrm{J}(2\lambda)\mathrm{E}_n}$ the quantity being transformed, so (16) requires manipulation. For this we write

$$t\mapsto 1-\frac{1}{t},\quad m\leftrightarrow N,\quad \frac{2}{\beta}=\lambda,\quad N=n. \tag{17}$$

Noting that then

$$\eta_1=\frac{1}{\lambda}(\lambda_2+1)-1,\quad \eta_2=\frac{1}{\lambda}(\lambda_1+1)+n-1, \tag{18}$$

multiplying both sides of (16) by t^{mN} and taking the complex conjugate of the left-hand side of (16) shows

$$\left\langle\prod_{l=1}^n(t-x_l)^m\right\rangle_{\mathrm{J}(2\lambda)\mathrm{E}_n}$$
$$=A\left\langle\prod_{l=1}^m z_l^{([(\lambda_1-\lambda_2)/\lambda]-n)/2}|1+z_l|^{[(\lambda_1+\lambda_2+2)/\lambda]+n-2}[t(1+z_l)-1]^n\right\rangle_{\mathrm{C}(2/\lambda)\mathrm{E}_m}, \tag{19}$$

where A, the proportionality constant, is independent of t. To specify A requires, in addition to the Selberg integral (13), the so-called Morris integral,

$$M_n(a,b,\lambda) := \left(\frac{1}{2\pi}\right)^n \int_{-\pi}^{\pi} d\theta_1 \cdots \int_{-\pi}^{\pi} d\theta_n \prod_{l=1}^{n} z_l^{(a-b)/2} |1+z_l|^{a+b} \prod_{1\le j<k\le n} |z_k - z_j|^{2\lambda}. \quad (20)$$

Then setting $t=1$ in (19) shows that

$$A = \frac{S_n(\lambda_1,\lambda_2+m,\lambda)}{S_n(\lambda_1,\lambda_2,\lambda)} \frac{M_m(0,0,1/\lambda)}{M_m(\eta_2,\eta_1,1/\lambda)}, \quad (21)$$

where η_1 and η_2 are given by (18). Both the Selberg integral and Morris integral have exact evaluations in terms of products of gamma functions (see, e.g., Ref. 1). In the case $\lambda=1$ these read

$$\begin{aligned} S_n(a,b,1) &= \prod_{j=0}^{n-1} \frac{\Gamma(a+1+j)\Gamma(b+1+j)\Gamma(2+j)}{\Gamma(a+b+1+n+j)} \\ &= \frac{G(n+1+a)}{G(1+a)} \frac{G(n+1+b)}{G(1+b)} \frac{G(n+1+a+b)}{G(2n+1+a+b)} G(n+2), \end{aligned} \quad (22)$$

$$\begin{aligned} M_n(a,b,1) &= \prod_{j=0}^{n-1} \frac{\Gamma(a+b+1+j)\Gamma(2+j)}{\Gamma(a+1+j)\Gamma(b+1+j)} \\ &= \frac{G(n+1+a+b)}{G(1+a+b)} \frac{G(1+a)}{G(n+1+a)} \frac{G(1+b)}{G(n+1+b)} G(n+2), \end{aligned} \quad (23)$$

where $G(z)$ denotes the Barnes G-function, related to the gamma function by the functional equation,

$$G(z+1) = \Gamma(z) G(z). \quad (24)$$

B. Asymptotics

Our interest is in the asymptotic form of the $\mathrm{J}(2\lambda)\mathrm{E}_n$ average in (19) in the case $\lambda=1$ and m even. The experience of our previous study,[7] in which we studied the same product averaged over the Gaussian unitary ensemble (eigenvalue p.d.f. of complex Hermitian matrices with Gaussian entries) using a result known in the literature[19] (see also Ref. 20), tells us the related quantity,

$$\frac{Z_{n,\lambda_1,\lambda_2}((X,q))}{Z_{n+q,\lambda_1,\lambda_2}((\cdot,0))}, \quad (25)$$

where

$$\begin{aligned} Z_{n,\lambda_1,\lambda_2}((X,q)) &= X^{\lambda_1 q}(1-X)^{\lambda_2 q} \int_0^1 dX_1 \cdots \int_0^1 dX_n \prod_{l=1}^{n} X_l^{\lambda_1} (1-X_l)^{\lambda_2} |X-X_l|^{2q} \\ &\times \prod_{1\le j<k\le n} |X_k - X_j|^2 \end{aligned} \quad (26)$$

is better suited for the purpose. In addition to multiplying the JUE_n average in (19) by the t-dependent factor $t^{\lambda_1 m/2}(1-t)^{\lambda_2 m/2}$, a key feature of (25) is the normalization chosen so that in the interpretation of (26) as the configuration integral for a log-potential Coulomb gas the normalization has the same total charge.

It follows from (19), (21), and noting

$$Z_{n+q,\lambda_1,\lambda_2}((\cdot,0))=S_{n+q}(\lambda_1,\lambda_2,1), \tag{27}$$

that we have the duality formula for (25) with $q=m/2$, m even

$$\begin{aligned}
&\frac{Z_{n,\lambda_1,\lambda_2}((t,m/2))}{Z_{n+m/2,\lambda_1,\lambda_2}((\cdot,0))} \\
&\quad=\frac{S_n(\lambda_1,\lambda_2+m,1)}{S_{n+m/2}(\lambda_1,\lambda_2,1)M_m(\lambda_1+n,\lambda_2,1)}t^{\lambda_1 m/2}(1-t)^{\lambda_2 m/2} \\
&\quad\quad\times\left(\frac{1}{2\pi}\right)^m\int_{-\pi}^{\pi}d\theta_1\cdots\int_{-\pi}^{\pi}d\theta_m\prod_{l=1}^{m}z_l^{(\lambda_1-\lambda_2-n)/2}|1+z_l|^{\lambda_1+\lambda_2+n}[t(1+z_l)-1]^n \\
&\quad\quad\times\prod_{1\le j<k\le m}|z_k-z_j|^2 \\
&\quad=\frac{S_n(\lambda_1,\lambda_2+m,1)}{(2\pi)^m S_{n+m/2}(\lambda_1,\lambda_2,1)M_m(\lambda_1+n,\lambda_2,1)}I_n(t),
\end{aligned} \tag{28}$$

where

$$\begin{aligned}
I_n(t)&:=t^{\lambda_1 m/2}(1-t)^{\lambda_2 m/2}\int_{\mathcal{C}^m}dx_1\cdots dx_m\prod_{l=1}^{m}(x_l)^{\lambda_1+\lambda_2+n}(x_l-1)^{-(\lambda_2+n+m)}(tx_l-1)^n \\
&\quad\times\prod_{1\le j<k\le m}(x_k-x_j)^2.
\end{aligned} \tag{29}$$

In (29), $\mathcal{C}$ is any simple closed contour starting at $x_j=0$ in the complex plane and encircling $x_j=1$ anticlockwise without crossing the interval $x_j\in(0,1)$. We obtain the second equality in (28) by writing the integrand in a form without absolute value signs, changing variables

$$d\theta_j=\frac{1}{iz_j}dz_j, \tag{30}$$

then changing variables $z_j\mapsto x_j-1$.

The large n, fixed $t\in(0,1)$ asymptotic analysis of an integral very similar to (29) has been detailed in Ref. 14, and that analysis in turn follows the stationary phase analysis of a related multiple integral given in Ref. 11. Now, the n-dependent terms in the integrand of $I_n(t)$ are

$$x_j^n(1-x_j)^{-n}(1-tx_j)^n=\exp[n(\log x_j-\log(1-x_j)+\log(1-tx_j))]. \tag{31}$$

As noted in Ref. 14, a simple calculation shows that the stationary point of the exponent occurs when

$$x_j=1\pm i\left[\frac{1}{t}(1-t)\right]^{1/2}=:x_\pm. \tag{32}$$

This suggests we deform the contours so that $m/2$ integration variables, $(x_1,\ldots,x_{m/2})$ say, pass through x_+, and the remaining pass through x_-. We must then expand the integrand in the neighborhood of these stationary points. Because we have made a definite choice of the $m/2$ variables, we must multiply by the combinatorial factor $\binom{m}{m/2}$. Another factor of $(-1)^{m/2}$ comes from the sense of the deformed contour being opposite for x_+ and x_-. From Ref. 14 we know that expanding the exponent in (31) to second order in $(x_\pm-x_j)$ gives

$$\exp[n(\log x_j-\log(1-x_j)+\log(1-tx_j))]\sim\exp\left[-\frac{n\alpha}{2}(x_j-x_\pm)^2\right], \tag{33}$$

where

$$\alpha = \frac{t^2}{(1-tx_\pm)^2} + \frac{1}{x_\pm^2} - \frac{1}{(1-x_\pm)^2}. \tag{34}$$

Regarding the leading order expansion of the other terms in the integrand we have

$$\prod_{1\leqslant j<k\leqslant m} (x_k - x_j)^2 \sim (x_+ - x_-)^{2(m/2)^2} \prod_{1\leqslant j<k\leqslant m/2} (x_k - x_j)^2 \prod_{m/2+1\leqslant j<k\leqslant m} (x_k - x_j)^2, \tag{35}$$

$$\prod_{j=1}^{m} (x_j)^{\lambda_1+\lambda_2} (x_j - 1)^{-(\lambda_2+m)} \sim |x_+|^{(\lambda_1+\lambda_2)m} |1-x_+|^{-(\lambda_2+m)m}. \tag{36}$$

Hence,

$$\begin{aligned} I_n(t) &\sim (-1)^{m/2} \binom{m}{m/2} [t^{\lambda_1}(1-t)^{\lambda_2}]^{m/2} (x_+ - x_-)^{2(m/2)^2} |x_+|^{(\lambda_1+\lambda_2)m} |1-x_+|^{-(\lambda_2+m)m} \\ &\quad \times \left| \int_{-\infty}^{\infty} dx_1 \cdots \int_{-\infty}^{\infty} dx_{m/2} \prod_{l=1}^{m/2} \exp\left[\frac{-n\alpha}{2} x_l^2 \right] \prod_{1\leqslant j<k\leqslant m/2} (x_k - x_j)^2 \right|^2 \\ &= (-1)^{m/2} \binom{m}{m/2} [t^{\lambda_1}(1-t)^{\lambda_2}]^{m/2} (x_+ - x_-)^{2(m/2)^2} |x_+|^{(\lambda_1+\lambda_2)m} |1-x_+|^{-(\lambda_2+m)m} \\ &\quad \times |n\alpha|^{-(m/2)^2} (V_{m/2})^2, \end{aligned} \tag{37}$$

where

$$V_{m/2} := \int_{-\infty}^{\infty} dx_1 \cdots \int_{-\infty}^{\infty} dx_{m/2} \prod_{l=1}^{m/2} \exp\left[-\frac{1}{2} x_l^2 \right] \prod_{1\leqslant j<k\leqslant m/2} (x_k - x_j)^2. \tag{38}$$

From Ref. 14,

$$|x_+| = \sqrt{\frac{1}{t}}, \quad |1-x_+| = \sqrt{\frac{1-t}{t}}, \quad |x_+ - x_-| = 2\sqrt{\frac{1-t}{t}}, \quad |\alpha| = \frac{2t^{3/2}}{(1-t)^{1/2}}, \tag{39}$$

so (37) simplifies to read

$$I_n(t) \sim \binom{m}{m/2} 2^{(m/2)^2} n^{-(m/2)^2} [t(1-t)]^{-m^2/8} (V_{m/2})^2. \tag{40}$$

Furthermore, we recognize $V_{m/2}$ as a limiting case of the Selberg integral known as the Mehta integral,[21] which has the evaluation,

$$V_{m/2} = (2\pi)^{m/4} \prod_{j=0}^{m/2-1} \Gamma(2+j) = (2\pi)^{m/4} G(m/2+2). \tag{41}$$

Recalling (28), our remaining task is to compute the asymptotic form of the combination of Selberg integrals and the Morris integral therein. According to (22) and (23), for this we require knowledge of the asymptotic expansion of the Barnes G-function. In fact Barnes himself showed[22]

$$\log\left(\frac{G(n+a+1)}{G(n+b+1)} \right) \underset{n\to\infty}{\sim} (b-a)n + \frac{a-b}{2} \log(2\pi) + \left((a-b)n + \frac{a^2-b^2}{2} \right) \log n + o(1). \tag{42}$$

Using this we find

$$\frac{S_n(\lambda_1,\lambda_2+m,1)}{S_{n+m/2}(\lambda_1,\lambda_2,1)M_m(\lambda_1+n,\lambda_2,1)}\sim\frac{n^{m^2/2-m/2}}{G(m+2)}. \tag{43}$$

Substituting (41) in (40), then substituting the result together with (43) in (28) we obtain the sought asymptotic formula,

$$\frac{Z_{n,\lambda_1,\lambda_2}((t,q))}{Z_{n+q,\lambda_1,\lambda_2}((\cdot,0))}\sim\frac{1}{\pi^q}\frac{G^2(q+1)}{G(2q+1)}(2n)^{-q+q^2}[t(1-t)]^{-q^2/2}, \tag{44}$$

where we have set $m/2=q$ and use has been made of the functional equation (24). We note that the right-hand side of (44) is independent of the parameters λ_1 and λ_2.

A check on our workings to this stage is the special case $q=1$. Then (25) coincides with the eigenvalue density in the JUE, $\rho^{\mathrm{JUE}}(X)$, normalized so that its integral on $[0, 1]$ is unity. Setting $q=1$ in (44) we read off that

$$\rho^{\mathrm{JUE}}(X)\sim\frac{1}{\pi}(X(1-X))^{-1/2}, \tag{45}$$

which is indeed the known functional form (see, e.g., Ref. 1).

III. ASYMPTOTIC FORM OF THE DENSITY MATRICES

Consider the impenetrable Bose gas of $N+1$ particles confined to the interval $[0,L]$ with Dirichlet boundary conditions. We know from Ref. 2 that the ground state density matrix $\rho^D_{N+1}(x,y)$ is given by

$$\rho^D_{N+1}(x,y)=\frac{(N+1)}{C}\left(\sin\frac{\pi x}{L}\right)\left(\sin\frac{\pi y}{L}\right)\int_0^L dx_1\cdots\int_0^L dx_N\prod_{l=1}^{N}\sin^2\frac{\pi x_l}{L}$$
$$\times\left|\cos\frac{\pi x}{L}-\cos\frac{\pi x_l}{L}\right|\left|\cos\frac{\pi y}{L}-\cos\frac{\pi x_l}{L}\right|\prod_{1\le j<k\le N}\left|\cos\frac{\pi x_k}{L}-\cos\frac{\pi x_j}{L}\right|^2, \tag{46}$$

where

$$C=\int_0^L dx_1\cdots\int_0^L dx_{N+1}\prod_{l=1}^{N+1}\sin^2\frac{\pi x_l}{L}\prod_{1\le j<k\le N+1}\left|\cos\frac{\pi x_k}{L}-\cos\frac{\pi x_j}{L}\right|^2. \tag{47}$$

Let us now change variables,

$$\cos\frac{\pi x_j}{L}=2X_j-1 \tag{48}$$

in both (46) and (47), and let us define

$$\rho^D_{N+1}(X,Y):=\rho^D_{N+1}(x,y)\big|_{\substack{\cos \pi x/L=2X-1\\ \cos \pi y/L=2Y-1}}. \tag{49}$$

Then in terms of the generalization of (26),

$$Z_{n,\lambda_1,\lambda_2}((X,q_1),(Y,q_2))=|X-Y|^{2q_1q_2}X^{\lambda_1q_1}(1-X)^{\lambda_2q_1}Y^{\lambda_1q_2}(1-Y)^{\lambda_2q_2}\int_0^1 dX_1\cdots\int_0^1 dX_n$$
$$\times\prod_{l=1}^{n} X_l^{\lambda_1}(1-X_l)^{\lambda_2}|X-X_l|^{2q_1}|Y-X_l|^{2q_2}\prod_{1\leq j<k\leq n}|X_k-X_j|^2 \quad (50)$$

we have

$$\rho^D_{N+1}(X,Y)=\frac{\pi\rho}{|X-Y|^{1/2}}[X(1-X)]^{1/4}[Y(1-Y)]^{1/4}\frac{Z_{N,1/2,1/2}((X,1/2),(Y,1/2))}{Z_{N+1,1/2,1/2}((\cdot,0),(\cdot,0))}, \quad (51)$$

where $\rho:=N/L$.

Similar considerations apply to the impenetrable Bose gas of $N+1$ particles confined to the interval $[0,L]$ with Neumann boundary conditions. Again from Ref. 2 we know that the ground state density matrix $\rho^N_{N+1}(x,y)$ is given by

$$\rho^N_{N+1}(x,y)=\frac{(N+1)}{C}\int_0^L dx_1\cdots\int_0^L dx_N\prod_{l=1}^{N}\left|\cos\frac{\pi x}{L}-\cos\frac{\pi x_l}{L}\right|\left|\cos\frac{\pi y}{L}-\cos\frac{\pi x_l}{L}\right|$$
$$\times\prod_{1\leq j<k\leq N}\left|\cos\frac{\pi x_k}{L}-\cos\frac{\pi x_j}{L}\right|^2, \quad (52)$$

where

$$C=\int_0^L dx_1\cdots\int_0^L dx_{N+1}\prod_{1\leq j<k\leq N+1}\left|\cos\frac{\pi x_k}{L}-\cos\frac{\pi x_j}{L}\right|^2. \quad (53)$$

Defining

$$\rho^N_{N+1}(X,Y):=\rho^N_{N+1}(x,y)\big|_{\substack{\cos \pi x/L=2X-1\\ \cos \pi y/L=2Y-1}} \quad (54)$$

and changing variables according to (48) in (52) and (53) shows

$$\rho^N_{N+1}(X,Y)=\frac{\pi\rho}{|X-Y|^{1/2}}[X(1-X)]^{1/4}[Y(1-Y)]^{1/4}\frac{Z_{N,-1/2,-1/2}((X,1/2),(Y,1/2))}{Z_{N+1,-1/2,-1/2}((\cdot,0),(\cdot,0))}. \quad (55)$$

As already noticed in Refs. 6, 7, the log-gas interpretation of (50) allows us to predict that for large n it factorizes into a function of X and the same function of Y, which are themselves of the form (26). Explicitly, we expect

$$\frac{Z_{n,\lambda_1,\lambda_2}((X,q_1),(Y,q_2))}{Z_{n+q_1+q_2,\lambda_1,\lambda_2}((\cdot,0),(\cdot,0))}\sim\frac{Z_{n,\lambda_1,\lambda_2}((X,q_1))}{Z_{n+q_1,\lambda_1,\lambda_2}((\cdot,0))}\frac{Z_{n,\lambda_1,\lambda_2}((Y,q_2))}{Z_{n+q_2,\lambda_1,\lambda_2}((\cdot,0))}. \quad (56)$$

As in (26), the key to choosing the correct normalizations is to balance the total charge in the log-gas interpretation. Setting $q_1=q_2=q$ as required by (51) and (55) it follows from (56) that

$$\frac{Z_{n,\lambda_1,\lambda_2}((X,q),(Y,q))}{Z_{n+2q,\lambda_1,\lambda_2}((\cdot,0),(\cdot,0))}\sim\left(\frac{1}{\pi^q}\frac{G^2(q+1)}{G(2q+1)}(2n)^{-q+q^2}\right)^2[X(1-X)]^{-q^2/2}[Y(1-Y)]^{-q^2/2}. \quad (57)$$

Substituting this asymptotic form with $q=1/2$ in (51) and (55) we obtain that for large N and fixed $X,Y\in(0,1)$,

$$\rho_{N+1}^{D}(X,Y)\sim\rho_{N+1}^{N}(X,Y)\sim\rho\frac{G^4(3/2)}{\sqrt{2N}}\frac{[X(1-X)]^{1/8}[Y(1-Y)]^{1/8}}{|X-Y|^{1/2}}. \tag{58}$$

It is of interest to compare the asymptotic formula (58) against a numerical determination of say $\rho_{N+1}^{D}(X,Y)$ or more conveniently $\rho_{N+1}^{D}(X,1-X)$. To compute the latter we write it as a random matrix average. Thus it follows from the various definitions that

$$\rho_{N+1}^{D}(X,1-X)=\frac{8\rho}{N+1}X(1-X)\left\langle\prod_{l=1}^{N}(|4(1-X)-4X_l|)(|4X-4X_l|)\right\rangle_{\mathrm{JUE}_N}\Bigg|_{\lambda_1=\lambda_2=1/2}. \tag{59}$$

For each $k=1,2,\ldots,M$ suppose we sample from $\mathrm{JUE}_N|_{\lambda_1=\lambda_2=1/2}$ obtaining the N-tuple $(X_1^{(k)},X_2^{(k)},\ldots,X_N^{(k)})$. Then the method of Monte Carlo integration tells us that

$$\rho_{N+1}^{D}(X,1-X)=\frac{8\rho}{N+1}X(1-X)\frac{1}{M}\sum_{k=1}^{M}\prod_{l=1}^{N}(|4(1-X)-4X_l^{(k)}|)(|4X-4X_l^{(k)}|)+O\left(\frac{1}{\sqrt{M}}\right). \tag{60}$$

Fortuitously, we have available a recently discovered[23] random three term recurrence which generates a polynomial, the zeros of which have the p.d.f. $\mathrm{J}(2\lambda)\mathrm{E}_n$. In the case of interest ($\lambda_1=\lambda_2=1/2$, $\lambda=1$) the recurrence states

$$A_0(x)=1,$$

$$A_1(x)=x-\mathrm{BD}[n+1/2,n+1/2],$$

$$A_j(x)=(w_2(x-1)+w_0x)A_{j-1}(x)+w_1x(x-1)A_{j-2}(x)\quad(j=2,\ldots,n), \tag{61}$$

where with

$$a\in\mathrm{GD}[n+1-j+1/2,1],\quad b\in\mathrm{GD}[j-1,1/2],\quad c\in\mathrm{GD}[n+1-j+1/2,1], \tag{62}$$

and $d:=a+b+c$ we have

$$w_0=\frac{a}{d},\quad w_1=\frac{b}{d},\quad w_2=1-w_0-w_1. \tag{63}$$

Here $\mathrm{BD}[a,b]$ denotes the classical beta distribution, while $\mathrm{GD}[m,\sigma]$ denotes the classical gamma distribution. The theory of Ref. 23 tells us that $A_n(x)$ has its zeros distributed according to $\mathrm{JUE}_n|_{\lambda_1=\lambda_2=\lambda}$. Implementing (61) for fixed n we thus computed the samples required in (60) for the Monte Carlo evaluation of $\rho_{N+1}^{D}(X,1-X)$. Forming the ratio then with the asymptotic form (58) gave the data in Table I.

IV. PHYSICAL AND MATHEMATICAL IMPLICATIONS

A. Ground state occupation of effective single particle states

The ground state density matrix is the theoretical quantity which quantifies the condensation of a Bose system. Thus if we decompose the density matrix

$$\rho_N(x,y)=\sum_{j=0}^{\infty}\lambda_j\phi_j(x)\phi_j(y), \tag{64}$$

where the λ_j,ϕ_j are the eigenvalues and normalized eigenfunctions in the eigenvalue problem

TABLE I. The ratio $\rho_{N+1}^{D,\mathrm{MC}}(X,1-X)/\rho_{N+1}^{D}(X,1-X)$ where $\rho_{N+1}^{D,\mathrm{MC}}(X,1-X)$ refers to the Monte Carlo expression (60), while $\rho_{N+1}^{D}(X,1-X)$ is the asymptotic form (58). We chose $N=14$, and evaluated (60) with $M=5000$.

X	$\rho_{N+1}^{D,\mathrm{MC}}(X,1-X)/\rho_{N+1}^{D}(X,1-X)$
0.025	1.0958
0.075	1.0039
0.125	1.0363
0.175	1.0098
0.225	0.9439
0.275	1.0080
0.325	0.9692
0.375	1.0338
0.425	0.9706
0.475	1.1309

$$\int \rho_N(x,y)\phi_j(y)\,dy=\lambda_j\phi_j(x), \tag{65}$$

then by analogy with the free Fermi system in which (64) holds with $\lambda_j=1$ $(j=0,\ldots,N-1)$, $\lambda_j=0$ $(j\geqslant N)$, we see that the λ_j have the physical interpretation as the occupation numbers of effective single particle states $\phi_j(x)$. For Bose–Einstein condensation to occur we must have λ_0 proportional to N.

To study (65) in the case of the impenetrable Bose gas in Dirichlet or Neumann boundary conditions we restrict ourselves to large N where use can be made of the asymptotic form of the density matrices (58). Before making the substitution, recalling the definitions (49) and (54) we must first change variables in (65) and redefine the eigenfunctions so that

$$\cos \pi y/L=2Y-1, \quad \phi_j(Y)=\phi_j(y)|_{\cos \pi y/L=2Y-1}, \quad \phi_j(X)=\phi_j(x)|_{\cos \pi x/L=2X-1}. \tag{66}$$

Doing this we obtain, for large N, the integral equation

$$\sqrt{\frac{N}{2}}\frac{G^4(3/2)}{\pi}\int_0^1 \frac{[X(1-X)]^{1/8}[Y(1-Y)]^{1/8}}{|X-Y|^{1/2}}\phi_j(Y)\frac{dY}{\sqrt{Y(1-Y)}}=\lambda_j\phi_j(X). \tag{67}$$

It follows immediately that

$$\lambda_j\propto\sqrt{N}. \tag{68}$$

As noted in Ref. 7 this conclusion requires that j be fixed—for $j\geqslant N$ we expect $\lambda_j\propto(N/j)^4$ in keeping with the corresponding result in periodic boundary conditions, since in this regime the boundary conditions are not expected to play a role.

Setting

$$\lambda_j=\frac{G^4(3/2)}{\sqrt{2}\pi}\sqrt{N}\overline{\lambda}_j \tag{69}$$

and rearranging, (67) reads

$$\int_0^1 \frac{\phi_j(Y)}{|X-Y|^{1/2}}\frac{dY}{[Y(1-Y)]^{3/8}}=\overline{\lambda}_j\frac{\phi_j(X)}{[X(1-X)]^{1/8}}. \tag{70}$$

Remarkably the effective single particle ground state $\phi_0(X)$, and the corresponding scaled occupation number $\overline{\lambda}_0$ can be computed exactly from (70). To see this requires knowledge of a piece of integral equation theory presented in Porter and Stirling.[24] The relevant theory tells us that the solution of the integral equation,

$$\int_0^1 \frac{\phi(t)}{|x-t|^\nu} dt = 1, \qquad \nu < 1 \tag{71}$$

is

$$\phi(x) = \frac{1}{\pi}\left(\cos\frac{\pi\nu}{2}\right)[x(1-x)]^{(\nu-1)/2}. \tag{72}$$

Setting $\nu = 1/2$, it follows immediately that

$$\phi_0(X) = \frac{1}{\sqrt{A}}[X(1-X)]^{1/8}, \quad \overline{\lambda}_0 = \pi\sqrt{2} \tag{73}$$

satisfies (71), where the normalization A is determined by the requirement that

$$\frac{L}{\pi}\int_0^1 (\phi_0(X))^2 \frac{dX}{\sqrt{X(1-X)}} = 1, \tag{74}$$

and so

$$A = \frac{L}{\pi}B(3/4,3/4), \tag{75}$$

where $B(a,b)$ denotes the beta function. Substituting the exact evaluation of $\overline{\lambda}_0$ in (69) shows that in the large N limit,

$$\lambda_0 = G^4(3/2)\sqrt{N} = 1.3069\sqrt{N}. \tag{76}$$

To compute the higher order single particle states and their corresponding occupations we make the ansatz,

$$\phi_j(X) \propto \phi_0(X) p_j(X), \tag{77}$$

where $p_j(X)$ is a polynomial of degree j. Now $\{\phi_j(X)\}$ can always be chosen to be orthogonal (note that the measure is $dX/\sqrt{X(1-X)}$ on [0, 1]) so recalling (73) we require

$$\int_0^1 \frac{p_j(X)p_k(X)}{(X(1-X))^{1/4}} dX = 0, \quad j \neq k. \tag{78}$$

Up to normalization, the unique polynomials with this property are the particular Gegenbauer polynomials

$$p_j(X) = C_j^{1/4}(2X-1), \tag{79}$$

which we note are proportional to the particular Jacobi polynomials $P_j^{-1/4,-1/4}(2X-1)$. Normalizing (77) with the substitution (79) as in (74) shows

$$\phi_j(X) = \sqrt{\frac{1}{L}}\sqrt{\frac{j!(j+1/4)\Gamma^2(1/4)}{\Gamma(j+1/2)}}(X(1-X))^{1/8}C_j^{1/4}(2X-1). \tag{80}$$

Now substituting (80) in (70) and setting $X=1$ we obtain a definite integral for $\overline{\lambda_j}$ which can be found in Ref. 25, giving us the evaluation

$$\overline{\lambda_j}=\sqrt{2\pi}\frac{\Gamma(j+1/2)}{j!} \tag{81}$$

and hence

$$\lambda_j=G^4(3/2)\frac{\Gamma(j+1/2)}{\sqrt{\pi}j!}\sqrt{N}. \tag{82}$$

To arrive at (80) we have made the ansatz (77). In fact a different approach can be taken to the problem, in which it is shown that an integral operator following from (70) commutes with the differential operator determining the polynomials $\{C_j^{1/4}(2X-1)\}_{j=0,1,2,\ldots}$. This is done in the Appendix.

Finally, we note that substituting (58), (80), and (81) in (64) gives the following interesting identity:

$$\frac{1}{|X-Y|^{1/2}}=\sqrt{\frac{2}{\pi}}\Gamma^2(1/4)\sum_{j=0}^{\infty}(j+1/4)C_j^{1/4}(2X-1)C_j^{1/4}(2Y-1). \tag{83}$$

B. Generalized Fisher–Hartwig-type asymptotics

One viewpoint of our asymptotic analysis of multiple integrals of the form (50) is that we are studying asymptotic problems of the Fisher–Hartwig class. Let us recall that the latter refers literally to Toeplitz determinants with both zeros and jump discontinuities is its generating function,

$$D_N[e^{a(\theta)}]:=\det[a_{i-j}]_{i,j=1,\ldots,N},\quad e^{a(\theta)}=\sum_{p=-\infty}^{\infty}a_p e^{ip\theta}, \tag{84}$$

where

$$a(\theta)=g(\theta)-i\sum_{r=1}^{R}b_r[\pi-(\theta-\phi_r)]\bmod 2\pi+\sum_{r=1}^{R}a_r\log|2-2\cos(\theta-\phi_r)| \tag{85}$$

with

$$g(\theta)=\sum_{p=-\infty}^{\infty}g_p e^{ip\theta},\qquad \sum_{p=-\infty}^{\infty}|p||g_p|^2<\infty. \tag{86}$$

Thus $g(\theta)$ is a regular term, while at ϕ_r $(r=1,\ldots,R)$ there is a jump discontinuity of strength b_r and a zero of order a_r. To see the relationship with (50) we set $b_r=0$ $(r=1,\ldots,R)$ thus eliminating the jump discontinuities, and recall the general formula relating a Toeplitz determinant to a multiple integral,

$$\begin{aligned}D_N[e^{a(\theta)}]&=\frac{1}{N!}\int_0^{2\pi}d\theta_1\cdots\int_0^{2\pi}d\theta_N\prod_{l=1}^{N}e^{a(\theta_l)}\prod_{1\leqslant j<k\leqslant N}|e^{i\theta_k}-e^{i\theta_j}|^2\\&=\frac{1}{N!}\int_0^{2\pi}d\theta_1\cdots\int_0^{2\pi}d\theta_N\prod_{l=1}^{N}e^{g(\theta_l)}\left(\prod_{r=1}^{R}|e^{i\theta_l}-e^{i\phi_r}|^{2a_r}\right)\prod_{1\leqslant j<k\leqslant N}|e^{i\theta_k}-e^{i\theta_j}|^2.\end{aligned} \tag{87}$$

Fisher and Hartwig[26] conjectured that in the case (87),

$$D_N[e^{a(\theta)}] \sim e^{g_0 N} e^{\sum_{r=1}^R a_r^2 \log N} E, \tag{88}$$

where E is independent of N. This was subsequently proved, and it was furthermore shown

$$E = e^{\sum_{k=1}^\infty k g_k g_{-k}} \prod_{r=1}^R e^{-a_r(g(\phi_r)-g_0)} \prod_{1\le j<k\le R} |e^{i\phi_k} - e^{i\phi_j}|^{-2a_k a_j} \prod_{r=1}^R \frac{G^2(1+a_r)}{G(1+2a_r)} \tag{89}$$

(see, for example, the monograph[27] and references therein).

As noted by one of the present authors some years ago,[28] it is straightforward to reproduce the structure of (88) using the analogous log-gas argument to that used here in the analysis of (50). Now the (normalized) multiple integral corresponding to (87) which relates to (50) is

$$\frac{H_{n,\lambda_1,\lambda_2}[e^{h(x)} \Pi_{r=1}^R |y_r - x|^{2q_r}]}{H_{n,\lambda_1,\lambda_2}[1]}, \tag{90}$$

$$H_{n,\lambda_1,\lambda_2}[f(x)] := \int_0^1 dx_1 \cdots \int_0^1 dx_n \prod_{l=1}^n f(x_l) x_l^{\lambda_1} (1-x_l)^{\lambda_2} \prod_{1\le j<k\le n} |x_k - x_j|^2, \tag{91}$$

where $h(x)$ is analytic on (0,1). As our final issue, we would like to extend the log-gas argument used in the analysis of (50) to predict the large n asymptotic form of (90).

From the log-gas perspective, the natural quantity to analyze is

$$\prod_{1\le j<k\le r} |y_k - y_j|^{2q_j q_k} \frac{H_{n,\lambda_1,\lambda_2}[e^{h(x)} \Pi_{r=1}^R |y_r - x|^{2q_r}]}{H_{n+\sum_{r=1}^R q_r,\lambda_1,\lambda_2}[e^{h(x)}]}. \tag{92}$$

Analogous to (56) we expect for large n (92) to factorize as

$$\frac{H_{n,\lambda_1,\lambda_2}[e^{h(x)} \Pi_{r=1}^R |y_r - x|^{2q_r}]}{H_{n+\sum_{r=1}^R q_r,\lambda_1,\lambda_2}[e^{h(x)}]} \sim \prod_{r=1}^R e^{-q_r h(y_r)} \frac{H_{n,\lambda_1,\lambda_2}[|y_r - x|^{2q_r}]}{H_{n+q_r,\lambda_1,\lambda_2}[1]}, \tag{93}$$

where the second expression is motivated by inspection of the known results (88) and (89) for (87).

Thus we expect

$$\frac{H_{n,\lambda_1,\lambda_2}[e^{h(x)} \Pi_{r=1}^R |y_r - x|^{2q_r}]}{H_{n,\lambda_1,\lambda_2}[1]} \sim \prod_{1\le j<k\le r} |y_k - y_j|^{-2q_j q_k} \frac{H_{n+\sum_{r=1}^R q_r,\lambda_1,\lambda_2}[e^{h(x)}]}{H_{n,\lambda_1,\lambda_2}[1]} \times \prod_{r=1}^R e^{-q_r h(y_r)} \frac{H_{n,\lambda_1,\lambda_2}[|y_r - x|^{2q_r}]}{H_{n+q_r,\lambda_1,\lambda_2}[1]}. \tag{94}$$

But according to (44),

$$\frac{H_{n,\lambda_1,\lambda_2}[|y_r-x|^{2q_r}]}{H_{n+q_r,\lambda_1,\lambda_2}[1]} \sim \frac{1}{\pi^{q_r}} \frac{G^2(q_r+1)}{G(2q_r+1)} (2n)^{-q_r+q_r^2} (y_r(1-y_r))^{-q_r^2/2}. \tag{95}$$

Also, for the first ratio on the right hand side of (94) we have available both rigorous results[29,30] as well as log-gas type arguments[31] which together tell us that

$$\frac{H_{n+Q,\lambda_1,\lambda_2}[e^{h(x)}]}{H_{n,\lambda_1,\lambda_2}[1]} \sim \exp\left[\frac{n+Q+(\lambda_1+\lambda_2)/2}{\pi} \int_0^1 \frac{h(x)}{[x(1-x)]^{1/2}} dx\right] \exp\left[-\frac{\lambda_1+\lambda_2}{4}(h(0)+h(1))\right]$$
$$\times \exp\left[\frac{1}{4\pi^2} \int_0^1 dx \frac{h(x)}{[x(1-x)]^{1/2}} \int_0^1 dy \frac{h'(y)[y(1-y)]^{1/2}}{x-y}\right]. \tag{96}$$

Substituting (95) and (96) in (93) gives the analog of (88),

$$\frac{H_{n,\lambda_1,\lambda_2}[e^{h(x)} \Pi_{r=1}^R |y_r-x|^{2q_r}]}{H_{n,\lambda_1,\lambda_2}[1]} \sim \exp\left[\frac{n+\Sigma_{r=1}^R q_r+(\lambda_1+\lambda_2)/2}{\pi} \int_0^1 \frac{h(x)}{[x(1-x)]^{1/2}} dx\right]$$
$$\times \exp\left[\sum_{r=1}^R (-q_r+q_r^2)\log 2n\right] K, \tag{97}$$

where

$$K = \prod_{1\leqslant j<k\leqslant R} |y_k-y_j|^{-2q_jq_k} e^{-(\lambda_1+\lambda_2)[h(0)+h(1)]/4} e^{-\Sigma_{r=1}^R q_r h(y_r)}$$
$$\times \exp\left[\frac{1}{4\pi^2} \int_0^1 dx \frac{h(x)}{[x(1-x)]^{1/2}} \int_0^1 dy \frac{h'(y)[y(1-y)]^{1/2}}{x-y}\right]$$
$$\times \prod_{r=1}^R [y_r(1-y_r)]^{-q_r^2/2} \prod_{r=1}^R \frac{1}{\pi^{q_r}} \frac{G^2(q_r+1)}{G(2q_r+1)}. \tag{98}$$

C. Concluding remarks

In our first paper on the impenetrable Bose gas[2] we set ourselves the goal of providing the leading asymptotic form of the density matrix for the impenetrable Bose gas in a harmonic trap and in Dirichlet and Neumann boundary conditions. It was noted in Ref. 2 that for the impenetrable Bose gas in periodic boundary conditions, the Fisher–Hartwig formula gave the asymptotic form,

$$\rho_{N+1}^C(x;0) \sim \rho \frac{G^4(3/2)}{\sqrt{2\pi}} \left(\frac{\pi}{N \sin(\pi\rho x/N)}\right)^{1/2}. \tag{99}$$

In Ref. 7, it was shown that for the harmonic well

$$(2N)^{1/2} \rho_{N+1}^H(\sqrt{2N}X, \sqrt{2N}Y) \sim N^{1/2} \frac{G^4(3/2)}{\pi} \frac{(1-X^2)^{1/8}(1-Y^2)^{1/8}}{|X-Y|^{1/2}}, \tag{100}$$

while in the present paper, after changing variables according to (49), the asymptotic form of the density matrix is shown to have the leading asymptotic form (58). As a consequence of the scaling properties of these asymptotic forms, the occupation number of the low lying effective single particle states are all proportional to $\sqrt{N}$, but with a proportionality constant dependent on the particular system.

To obtain the asymptotic forms we have used a combination of exact analysis, made possible by the theory of Selberg correlation integrals, and physical reasoning based on log-gas analogies. Taking this argument to its logical conclusion leads to a conjectured exact asymptotic formula, given by (97) and (98) for a Jacobi weight analog of the Fisher–Hartwig formula.

APPENDIX: PROOF THAT $\{\phi_0(X)C_j^{1/4}(2X-1)\}_{j=0,1,2,\ldots}$ ARE SOLUTIONS OF THE INTEGRAL EQUATION (70)

The assertion that the $\phi_j(X)$ given by (77) are solutions of (70) is equivalent to stating that the Gegenbauer polynomials are eigenfunctions of the integral operator,

$$K[f(\xi)] := \int_{-1}^{1} \frac{d\psi}{|\xi-\psi|^{1/2}(1-\psi^2)^{1/4}} f(\psi), \tag{A1}$$

where for convenience we are working on the interval $-1 \leqslant \xi \leqslant 1$. In this appendix we prove that K commutes with the differential operator, L, which determines the Gegenbauer polynomials,

$$L := (1-\xi^2)\frac{d^2}{d\xi^2} - \frac{3}{2}\xi\frac{d}{d\xi}, \tag{A2}$$

with

$$LC_j^{1/4}(\xi) = -j(j+1/2)C_j^{1/4}(\xi). \tag{A3}$$

We begin by identifying $K[C_j^{1/4}(\xi)]$ with the following finite sum of hypergeometric functions:

$$\begin{aligned} K[C_j^{1/4}(\xi)] = {} & \Omega_j \sum_{k=0}^{j} \frac{(-j)_k (j+1/2)_k}{k!(3/4)_k} \left(\frac{1+\xi}{2}\right)^{1/4} {}_2F_1\left(\frac{1}{4}-k, \frac{3}{4}; \frac{5}{4}; \frac{1+\xi}{2}\right) \\ & + (-1)^j \Omega_j \sum_{k=0}^{j} \frac{(-j)_k (j+1/2)_k}{k!(3/4)_k} \left(\frac{1-\xi}{2}\right)^{1/4} {}_2F_1\left(\frac{1}{4}-k, \frac{3}{4}; \frac{5}{4}; \frac{1-\xi}{2}\right), \end{aligned} \tag{A4}$$

where

$$\Omega_j := \frac{\Gamma(3/4)}{\Gamma(5/4)} \frac{\Gamma(j+1/2)}{j!}. \tag{A5}$$

To derive (A4) we break up the interval of integration in $K[C_j^{1/4}(\xi)]$ into two regions, thus removing the need for the modulus, which gives

$$\begin{aligned} K[C_j^{1/4}(\xi)] &= \int_{\xi}^{1} (1-\psi^2)^{-1/4} C_j^{1/4}(\psi) \frac{d\psi}{\sqrt{\psi-\xi}} + (-1)^j \int_{-\xi}^{1} (1-\psi^2)^{-1/4} C_j^{1/4}(\psi) \frac{d\psi}{\sqrt{\psi+\xi}} \\ &= z_-^{1/4} \int_0^1 d\psi\, \psi^{-1/4} (1-\psi)^{-1/2} (1-z_-\psi)^{-1/4} C_j^{1/4}(1-2z_-\psi) \\ &\quad + (-1)^j z_+^{1/4} \int_0^1 d\psi\, \psi^{-1/4} (1-\psi)^{-1/2} (1-z_+\psi)^{-1/4} C_j^{1/4}(1-2z_+\psi), \end{aligned} \tag{A6}$$

where we have defined

$$z_{\pm} := \frac{1 \pm \xi}{2} \tag{A7}$$

and in obtaining the second equality we have changed integration variables from ψ to $(1-\psi)/(1-\xi)$ and $(1-\psi)/(1+\xi)$ in the first and second integrals respectively. Substituting the following known[25] expansion for the Gegenbauer polynomials

$$C_j^{1/4}(\psi) = \frac{(-1)^j \Gamma(j+1/2)}{j!\sqrt{\pi}} \sum_{k=0}^{j} \frac{(-j)_k (j+1/2)_k}{k!(3/4)_k} \left(\frac{1+\psi}{2} \right)^k \tag{A8}$$

into (A6), and using the standard integral representation of the ${}_2F_1$ function,

$$\int_0^1 d\psi \frac{\psi^{-1/4}(1-\psi)^{-1/2}}{(1-z\psi)^{-k+1/4}} = B(3/4,1/2)\, {}_2F_1\left(\frac{1}{4}-k, \frac{3}{4}; \frac{5}{4}; z \right), \tag{A9}$$

then results in (A4).

We can now utilize known hypergeometric identities to facilitate the operation of the differential operator L on the expression for $K[C_j^{1/4}(\xi)]$ given by (A4). We note that the structure of (A4) is of the form,

$$K[C_j^{1/4}(\xi)] = \Omega_j S_j(z_+) + (-1)^j \Omega_j S_j(z_-), \tag{A10}$$

where

$$S_j(z) := \sum_{k=0}^{j} \frac{(-j)_k (j+1/2)_k}{k!(3/4)_k} z^{1/4}\, {}_2F_1\left(\frac{1}{4}-k, \frac{3}{4}; \frac{5}{4}; z \right). \tag{A11}$$

In terms of both the variables $z = z_+$ and $z = z_-$ the differential operator L has the form

$$L = z(1-z)\frac{d^2}{dz^2} - \frac{3}{4}(2z-1)\frac{d}{dz}. \tag{A12}$$

Utilizing the identity[32]

$$\frac{d^n}{dz^n}\left[z^{\delta}\, {}_pF_q\left(\begin{matrix} \alpha_1, \ldots, \alpha_p \\ \rho_1, \ldots, \rho_q \end{matrix} \middle| z \right) \right] = (\delta - n + 1)_n z^{\delta - n}\, {}_{p+1}F_{q+1}\left(\begin{matrix} \delta+1, \alpha_1, \ldots, \alpha_p \\ \delta+1-n, \rho_1, \ldots, \rho_q \end{matrix} \middle| z \right), \tag{A13}$$

we find that

$$\begin{aligned} L z^{1/4}\, {}_2F_1\left(\frac{1}{4}-k, \frac{3}{4}; \frac{5}{4}; z \right) &= \frac{z^{1/4}}{z}\left(-\frac{3}{16} \right)(1-z)\, {}_2F_1\left(\frac{1}{4}-k, \frac{3}{4}; -\frac{3}{4}; z \right) \\ &\quad + \frac{z^{1/4}}{z}\left(-\frac{3}{16} \right)(2z-1)\, {}_2F_1\left(\frac{1}{4}-k, \frac{3}{4}; \frac{1}{4}; z \right), \end{aligned} \tag{A14}$$

$$L z^{1/4}\, {}_2F_1\left(\frac{1}{4}-k, \frac{3}{4}; \frac{5}{4}; z \right) = -\frac{1}{2} z^{1/4} k\, {}_2F_1\left(\frac{1}{4}-k, \frac{3}{4}; \frac{5}{4}; z \right) - \frac{1}{4} z^{1/4} k\, {}_2F_1\left(\frac{1}{4}-k, \frac{3}{4}; \frac{1}{4}; z \right), \tag{A15}$$

$$Lz^{1/4}{}_2F_1\left(\frac{1}{4}-k,\frac{3}{4};\frac{5}{4};z\right)=-z^{1/4}k\left(k+\frac{1}{2}\right)\,{}_2F_1\left(\frac{1}{4}-k,\frac{3}{4};\frac{5}{4};z\right)$$
$$-z^{1/4}k\left(\frac{1}{4}-k\right)\,{}_2F_1\left(\frac{1}{4}-(k-1),\frac{3}{4};\frac{5}{4};z\right), \tag{A16}$$

where the equalities in (A15) and (A16), respectively, follow from the two particular contiguity relations,[32]

$$\left(-\frac{3}{16}\right)(1-z)_2F_1\left(\frac{1}{4}-k,\frac{3}{4};-\frac{3}{4};z\right)=\frac{1}{16}[(6-4k)z-3]_2F_1\left(\frac{1}{4}-k,\frac{3}{4};\frac{1}{4};z\right)$$
$$-\frac{kz}{2}\,{}_2F_1\left(\frac{1}{4}-k,\frac{3}{4};\frac{5}{4};z\right), \tag{A17}$$

and

$$-\frac{1}{4}\,{}_2F_1\left(\frac{1}{4}-k,\frac{3}{4};\frac{1}{4};z\right)=-k\,{}_2F_1\left(\frac{1}{4}-k,\frac{3}{4};\frac{5}{4};z\right)-\left(\frac{1}{4}-k\right)\,{}_2F_1\left(\frac{1}{4}-(k-1),\frac{3}{4};\frac{5}{4};z\right). \tag{A18}$$

Hence from (A16) we obtain

$$LS_j(z)=-z^{1/4}\sum_{k=0}^{j}\frac{(-j)_k(j+1/2)_k}{k!(3/4)_k}k\left(\frac{1}{2}+k\right)\,{}_2F_1\left(\frac{1}{4}-k,\frac{3}{4};\frac{5}{4};z\right)$$
$$-z^{1/4}\sum_{k=0}^{j}\frac{(-j)_k(j+1/2)_k}{k!(3/4)_k}k\left(\frac{1}{4}-k\right)\,{}_2F_1\left(\frac{1}{4}-(k-1),\frac{3}{4};\frac{5}{4};z\right). \tag{A19}$$

Changing summation index in the second sum in (A19) from k to $k-1$ and simplifying we deduce finally that

$$LS_j(z)=-j(j+1/2)\sum_{k=0}^{j}\frac{(-j)_k(j+1/2)_k}{k!(3/4)_k}z^{1/4}\,{}_2F_1\left(\frac{1}{4}-k,\frac{3}{4};\frac{5}{4};z\right)=-j(j+1/2)S_j(z), \tag{A20}$$

which then implies that

$$LKC_j^{1/4}(\xi)=-j(j+1/2)KC_j^{1/4}(\xi) \tag{A21}$$
$$=KLC_j^{1/4}(\xi)\qquad(j=0,1,2,\dots) \tag{A22}$$

and so

$$[K,L]=0. \tag{A23}$$

Entropy production fluctuations of finite Markov chains

Da-Quan Jiang,[a] Min Qian, and Fu-Xi Zhang[b]
LMAM, School of Mathematical Sciences, Peking University, Beijing 100871, People's Republic of China

(Received 6 September 2002; accepted 14 April 2003)

For almost every trajectory segment over a finite time span of a finite Markov chain with any given initial distribution, the logarithm of the ratio of its probability to that of its time-reversal converges exponentially to the entropy production rate of the Markov chain. The large deviation rate function has a symmetry of Gallavotti–Cohen type, which is called the fluctuation theorem. Moreover, similar symmetries also hold for the rate functions of the joint distributions of general observables and the logarithmic probability ratio. © *2003 American Institute of Physics.*

I. INTRODUCTION

Stationary nonequilibrium states play an important role in statistical physics and have been studied since Boltzmann's time. In 1993, Evans, Cohen, and Morriss[1] found in computer simulations that the natural invariant measure of a stationary nonequilibrium system has a symmetry which, being called later the fluctuation theorem by Gallavotti and Cohen,[2–5] gives a general formula for the probability ratio of observing trajectories that satisfy or violate the second law of thermodynamics. Since then there have been many derivations and generalizations of the fluctuation theorem. Motivated by the result in Ref. 1, Gallavotti and Cohen[6] gave the first mathematical presentation of the fluctuation theorem for stationary nonequilibrium systems modelled by hyperbolic dynamical systems: Provided that the dynamics is invariant under time reversal and is sufficiently chaotic, the probability distributions of the phase space contraction averaged over large time spans have a large deviation property and the large deviation rate function has a symmetry. Evans and Searles[7–13] considered transient, rather than stationary, nonequilibrium systems and employed a known equilibrium state (such as the Liouville measure) as the initial distribution to derive a transient fluctuation theorem. Gallavotti[14] and Evans *et al.*[13,15] proposed a local version of the fluctuation theorem. Kurchan[16] pointed out that the fluctuation theorem also holds for certain diffusion processes. Lebowitz and Spohn[17] extended Kurchan's results to general Markov processes, and Maes[18] thought of the fluctuation theorem as a property of space–time Gibbs measures. Searles and Evans[19] derived the transient fluctuation theorem for non-stationary stochastic systems.

For systems close to equilibrium, the distribution of trajectories over a finite time interval has little difference from that of their time reversals, and the fluctuation theorem yields the well-known Green–Kubo formula and the Onsager reciprocity relations,[3,17,18,20,21] i.e., the symmetry of the transport coefficients matrix which relate thermodynamic ''forces'' and ''fluxes.'' Surprisingly, the fluctuation theorem is also valid for systems in the nonlinear response regime far from equilibrium. In this sense, the fluctuation theorem can be thought of as an extension of the fluctuation-dissipation theorem, which holds for systems in the linear response regime close to equilibrium.

The concept of entropy production was first put forward in nonequilibrium statistical physics to describe how far a specific state of a system is away from its equilibrium state.[22–24] In Refs. 25–27, a measure-theoretic definition of entropy production rate is proposed for stochastic processes, unifying different entropy production formulas in various concrete cases. Suppose that ξ

[a]Electronic mail: jiangdq@math.pku.edu.cn
[b]Electronic mail: zhangfxi@math.pku.edu.cn

$=\{\xi_n\}_{n\in\mathbf{Z}}$ is a stationary, irreducible and positive recurrent Markov chain with finite state space S, transition probability matrix $P=(p_{ij})_{i,j\in S}$, and invariant distribution $\Pi=\{\pi_i\}_{i\in S}$. Let $\mathbf{P}$ and $\mathbf{P}^-$ be the distributions of the Markov chain and its time-reversal respectively, and denote their restrictions on $\mathcal{F}_0^n=\sigma(\xi_i,0\leqslant i\leqslant n)$ by $\mathbf{P}_{[0,n]}$ and $\mathbf{P}^-_{[0,n]}$. The entropy production rate of ξ is defined as

$$e_p \overset{\text{def}}{=} \lim_{n\to+\infty}\frac{1}{n}H(\mathbf{P}_{[0,n]},\mathbf{P}^-_{[0,n]}),$$

where $H(\mathbf{P}_{[0,n]},\mathbf{P}^-_{[0,n]})$ is the relative entropy of $\mathbf{P}_{[0,n]}$ with respect to $\mathbf{P}^-_{[0,n]}$. A sufficient and necessary condition for $\mathbf{P}_{[0,n]}$ and $\mathbf{P}^-_{[0,n]}$ being mutually absolutely continuous is that $p_{ij}>0\Leftrightarrow p_{ji}>0$ for any i,j. Under this assumption,

$$e_p=E^{\mathbf{P}_{[0,n]}}\log\frac{d\mathbf{P}_{[0,n]}}{d\mathbf{P}^-_{[0,n]}}=\frac{1}{2}\sum_{i,j\in S}(\pi_i p_{ij}-\pi_j p_{ji})\log\frac{\pi_i p_{ij}}{\pi_j p_{ji}}. \tag{1}$$

For a stationary Markov process, its entropy production rate can be defined similarly. In Refs. 25 and 28–30, the entropy production rate e_p of a stationary finite Markov chain is expressed in terms of cycles, which occur along almost all sample paths, and their weights. Recently, Jiang *et al.*[31] gave a measure-theoretic exposition of the entropy production rate for hyperbolic dynamical systems, which was defined by Ruelle[32] from the physical point of view. Maes *et al.*[33] presented a definition of entropy production rate for some classes of deterministic and stochastic dynamics in the context of Gibbs measures.

In this paper, we prove the following strong limit theorem for a stationary irreducible finite Markov chain with discrete or continuous time parameter:

$$\lim_{t\to+\infty}\frac{1}{t}\log\frac{d\mathbf{P}_{[0,t)}}{d\mathbf{P}^-_{[0,t)}}(\omega)=e_p,\quad \mathbf{P}-\text{a.s.}$$

Furthermore, the convergence of the corresponding distributions is shown to be exponential, and the large deviation rate function $I(z)$ satisfies a symmetry: $I(z)=I(-z)-z$ for any $z\in\mathbf{R}$; this is actually the fluctuation theorem of Gallavotti–Cohen type for finite Markov chains. The proof is based on the well-known Perron–Frobenius theorem.[34–37] The statement of the theorem appeared in the pioneering paper Lebowitz and Spohn,[17] which also contained a proof. Here we present a mathematically strict proof. Part of the idea and techniques in our paper comes from Ref. 17, to which it is sincerely acknowledged. Moreover, we give a strict but very simple proof to the fluctuation theorem for the logarithmic probability ratios and for the joint distributions of them with general observables. We also discuss the transient fluctuation theorem for nonstationary Markov chains with discrete or continuous time parameter.

II. FINITE MARKOV CHAINS WITH DISCRETE TIME PARAMETER

To bring the main ideas into eminence, in this section we first treat the simplest case. $\xi=\{\xi_n:n\in\mathbf{Z}\}$ will be from now on a stationary irreducible discrete time Markov chain on probability space $(\Omega,\mathcal{F},\mathbf{P})$ with finite state space $S=\{1,2,\ldots,d\}$, transition probability matrix $P=(p_{ij})_{i,j\in S}$, and invariant probability distribution $\Pi=\{\pi_i\}_{i\in S}$. Without loss of generality, we assume that ξ is a coordinate process on its canonical trajectory space $(\Omega,\mathcal{F},\mathbf{P})$. That is, $\Omega=S^{\mathbf{Z}}$, $\mathcal{F}=\sigma\{\xi_n:n\in\mathbf{Z}\}$ and $\mathbf{P}$ is the distribution of ξ. Now we introduce two transformations: the time-reversal transformation

$$r:\Omega\to\Omega,\quad \xi_n(r\omega)=\xi_{-n}(\omega),\quad \forall n\in\mathbf{Z};$$

and the shift operator

$$\theta:(\Omega,\mathcal{F})\to(\Omega,\mathcal{F}),\quad \xi_n(\theta\omega)=\xi_{n+1}(\omega),\quad \forall n\in\mathbf{Z}.$$

It is easy to see that r and θ are $\mathcal{F}$-measurable and invertible with $r^{-1}=r$. Since ξ is stationary, $\theta^n\mathbf{P}=\mathbf{P}$, which yields $\theta^n\mathbf{P}^-=\mathbf{P}^-$ because $r\theta=\theta^{-1}r$, where $\mathbf{P}^-=r\mathbf{P}$ is the distribution of ξ's time reversal. The stationary Markov chain ξ is said to be reversible if $\mathbf{P}=\mathbf{P}^-$. As is well known, ξ is reversible if and only if the entropy production rate e_p of ξ vanishes, or iff $\pi_i p_{ij}=\pi_j p_{ji}$ for any $i,j\in S$, i.e. ξ is in detailed balance.[25–27]

For each $n\in\mathbf{Z}$ and $k\in\mathbf{N}$, denote by $\mathbf{P}_{[n,n+k]}$ and $\mathbf{P}^-_{[n,n+k]}$, respectively, the restrictions of $\mathbf{P}$ and $\mathbf{P}^-$ on $\mathcal{F}_n^{n+k}=\sigma(\xi_m:n\leqslant m\leqslant n+k)$. We assume that the transition matrix P satisfies the condition

$$p_{ij}>0\Leftrightarrow p_{ji}>0,\quad \forall i,j\in S. \tag{2}$$

Otherwise, $\mathbf{P}_{[0,n]}$ is not absolutely continuous with respect to $\mathbf{P}^-_{[0,n]}$, and by the definition of relative entropy, $H(\mathbf{P}_{[0,n]},\mathbf{P}^-_{[0,n]})$ is infinite for all $n\in\mathbf{N}$, hence $e_p=+\infty$. This is a trivial case.

Proposition 2.1: Under the condition (2), $\mathbf{P}_{[n,n+k]}$ and $\mathbf{P}^-_{[n,n+k]}$ are absolutely continuous with respect to each other, and the Radon–Nikodym derivative is given by

$$\frac{\mathrm{d}\mathbf{P}_{[n,n+k]}}{\mathrm{d}\mathbf{P}^-_{[n,n+k]}}(\omega)=\frac{\pi_{\xi_n(\omega)}p_{\xi_n(\omega)\xi_{n+1}(\omega)}\cdots p_{\xi_{n+k-1}(\omega)\xi_{n+k}(\omega)}}{\pi_{\xi_{n+k}(\omega)}p_{\xi_{n+k}(\omega)\xi_{n+k-1}(\omega)}\cdots p_{\xi_{n+1}(\omega)\xi_n(\omega)}},\quad \mathbf{P}-\text{a.s.}$$

Notice that $(1/n)\,E^{\mathbf{P}}\log(\mathrm{d}\mathbf{P}_{[0,n]}/\mathrm{d}\mathbf{P}^-_{[0,n]})$ converges to the entropy production rate e_p of ξ, which is given in (1). In fact, we can get a stronger result.

Proposition 2.2: Under the condition (2),

$$\lim_{n\to+\infty}\frac{1}{n}\log\frac{\mathrm{d}\mathbf{P}_{[0,n]}}{\mathrm{d}\mathbf{P}^-_{[0,n]}}(\omega)=e_p,\quad \mathbf{P}-\text{a.s. or } L^1(\mathrm{d}\mathbf{P}).$$

Proof: Let

$$f(\omega)=\log\frac{\pi_{\xi_0(\omega)}p_{\xi_0(\omega)\xi_1(\omega)}}{\pi_{\xi_1(\omega)}p_{\xi_1(\omega)\xi_0(\omega)}},$$

then

$$\begin{aligned}\frac{1}{n}\log\frac{\mathrm{d}\mathbf{P}_{[0,n]}}{\mathrm{d}\mathbf{P}^-_{[0,n]}}(\omega)&=\frac{1}{n}\log\frac{\pi_{\xi_0(\omega)}p_{\xi_0(\omega)\xi_1(\omega)}\cdots p_{\xi_{n-1}(\omega)\xi_n(\omega)}}{\pi_{\xi_n(\omega)}p_{\xi_n(\omega)\xi_{n-1}(\omega)}\cdots p_{\xi_1(\omega)\xi_0(\omega)}}\\&=\frac{1}{n}\sum_{k=0}^{n-1}\log\frac{\pi_{\xi_k(\omega)}p_{\xi_k(\omega)\xi_{k+1}(\omega)}}{\pi_{\xi_{k+1}(\omega)}p_{\xi_{k+1}(\omega)\xi_k(\omega)}}\\&=\frac{1}{n}\sum_{k=0}^{n-1}f(\theta^k\omega),\quad \mathbf{P}-\text{a.s.}\end{aligned}$$

By the Birkhoff ergodic theorem,[38]

$$\lim_{n\to+\infty}\frac{1}{n}\log\frac{\mathrm{d}\mathbf{P}_{[0,n]}}{\mathrm{d}\mathbf{P}^-_{[0,n]}}(\omega)=\lim_{n\to+\infty}\frac{1}{n}\sum_{k=0}^{n-1}f(\theta^k\omega)=\int f\,\mathrm{d}\mathbf{P}=e_p,\quad \mathbf{P}-\text{a.s. or } L^1(\mathrm{d}\mathbf{P}).\qquad\square$$

There will naturally arise the question what is the convergence rate. The large deviation theory provides us a way to calculate this rate. Let $W_n(\omega)=\log(\mathrm{d}\mathbf{P}_{[0,n]}/\mathrm{d}\mathbf{P}^-_{[0,n]})(\omega)$ and $c_n(\lambda)=(\log Ee^{\lambda W_n})/n$. It is not difficult to see that W_n/n takes finitely many values and $e^{\lambda W_n(\omega)}>0$,

$\mathbf{P}-$a.s. Thus, according to Theorem II.6.1 in Ellis,[39] in order to verify $\{\mu_n : n \in \mathbf{Z}^+\}$, where μ_n is the distribution of W_n/n, has a large deviation property, we only need to verify the free energy function $c(\lambda) \overset{\text{def}}{=} \lim_{n\to+\infty} c_n(\lambda)$ of $\{W_n : n \in \mathbf{Z}^+\}$ exists and is differentiable.

Theorem 2.3: *For all* $\lambda \in \mathbf{R}$, $\lim_{n\to+\infty} c_n(\lambda)$ *exists and the free energy function* $c(\lambda)$ *of* $\{W_n : n \in \mathbf{Z}^+\}$ *is differentiable.*

Proof: From Proposition 2.1,

$$Ee^{\lambda W_n} = \sum_{\substack{i_0,i_1,\cdots,i_n: \\ p_{i_0i_1}\cdots p_{i_{n-1}i_n}>0}} \pi_{i_0} p_{i_0i_1}\cdots p_{i_{n-1}i_n} \left(\frac{\pi_{i_0} p_{i_0i_1}\cdots p_{i_{n-1}i_n}}{\pi_{i_n} p_{i_1i_0}\cdots p_{i_ni_{n-1}}}\right)^{\lambda}$$

$$= \sum_{i_0,i_1,\cdots,i_n} \pi_{i_0} a_{i_0i_1}(\lambda)\cdots a_{i_{n-1}i_n}(\lambda)\left(\frac{\pi_{i_0}}{\pi_{i_n}}\right)^{\lambda},$$

where

$$a_{ij}(\lambda) = \begin{cases} p_{ij}^{1+\lambda} p_{ji}^{-\lambda}, & p_{ij}>0, \\ 0, & p_{ij}=0. \end{cases}$$

It is obvious that $p_{ij}>0 \Leftrightarrow a_{ij}(\lambda)>0$. Hence $\mathbf{A}(\lambda)=(a_{ij}(\lambda))$ is an irreducible nonnegative matrix. By the Perron–Frobenius theorem, the spectral radius $e(\lambda)$ of $\mathbf{A}(\lambda)$ is a positive eigenvalue of $\mathbf{A}(\lambda)$ with one-dimensional eigenspace $\{k\vec{\alpha} : k \in \mathbf{R}\}$, where $\vec{\alpha}=(\alpha_1,\alpha_2,\ldots,\alpha_d)^T$ and $\alpha_i>0$ for all $i \in S$.

For any given $\lambda>0$, denote

$$C_0 = \max_{i,j}\left(\frac{\pi_i}{\pi_j}\right)^{\lambda}, \quad \alpha_{\min} = \min_i \alpha_i, \quad \alpha_{\max} = \max_i \alpha_i.$$

Then

$$\frac{1}{C_0\alpha_{\max}} \vec{\pi}\mathbf{A}(\lambda)^n\vec{\alpha} \leqslant Ee^{\lambda W_n} \leqslant \frac{C_0}{\alpha_{\min}} \vec{\pi}\mathbf{A}(\lambda)^n\vec{\alpha},$$

where $\vec{\pi}=(\pi_1,\pi_2,\ldots,\pi_d)$. Hence

$$\lim_{n\to+\infty}\frac{1}{n}\log Ee^{\lambda W_n} = \lim_{n\to+\infty}\frac{1}{n}\log \vec{\pi}\mathbf{A}(\lambda)^n\vec{\alpha} = \log e(\lambda),$$

where $e(\lambda)$ is differentiable because it is the simple eigenvalue of a differentiable matrix $\mathbf{A}(\lambda)$ (see Ref. 37 for details). □

By now, we have verified the fact that $\{\mu_n : n \in \mathbf{Z}^+\}$ has a large deviation property with rate function $I(z)=\sup_{\lambda\in\mathbf{R}}\{\lambda z - c(\lambda)\}$. Since $c_n(\cdot)$, $n \in \mathbf{N}$, and $c(\cdot)$ are all finite, and $c(\cdot)$ is differentiable at $\lambda=0$, by Theorem II.6.3 in Ellis,[39] W_n/n converges exponentially to the constant $c'(0)$. From Proposition 2.2, $c'(0)$ equals the entropy production rate e_p of the stationary Markov chain ξ. Furthermore, the innate symmetry of $\{W_n\}$ implies the symmetry of its free energy function and rate function.

Theorem 2.4: *(Fluctuation theorem) The free energy function* $c(\lambda)$ *and the large deviation rate function* $I(z)$ *of* $\{W_n : n \in \mathbf{Z}^+\}$ *have the following properties:*

$$c(\lambda) = c(-(1+\lambda)), \ \forall \lambda \in \mathbf{R}, \quad I(z) = I(-z) - z, \ \forall z \in \mathbf{R}.$$

Proof: Since $\mathbf{P}$ and $\mathbf{P}^-$ are reciprocal under the time-reversal transformation,

$$\frac{d\mathbf{P}_{[0,n]}}{d\mathbf{P}^-_{[0,n]}}(r\omega)=\frac{d\mathbf{P}^-_{[-n,0]}}{d\mathbf{P}_{[-n,0]}}(\omega)=\frac{d\mathbf{P}^-_{[0,n]}}{d\mathbf{P}_{[0,n]}}(\theta^{-n}\omega)=\left(\frac{d\mathbf{P}_{[0,n]}}{d\mathbf{P}^-_{[0,n]}}(\theta^{-n}\omega)\right)^{-1}.$$

Thus

$$\begin{aligned}Ee^{\lambda W_n}&=\int\left(\frac{d\mathbf{P}_{[0,n]}}{d\mathbf{P}^-_{[0,n]}}(\omega)\right)^{\lambda}d\mathbf{P}(\omega)\\&=\int\left(\frac{d\mathbf{P}_{[0,n]}}{d\mathbf{P}^-_{[0,n]}}(r\omega)\right)^{\lambda}d\mathbf{P}^-(\omega)\\&=\int\left(\frac{d\mathbf{P}_{[0,n]}}{d\mathbf{P}^-_{[0,n]}}(\theta^{-n}\omega)\right)^{-\lambda}d\mathbf{P}^-(\omega)\\&=\int\left(\frac{d\mathbf{P}_{[0,n]}}{d\mathbf{P}^-_{[0,n]}}(\omega)\right)^{-(1+\lambda)}d\mathbf{P}(\omega)=Ee^{-(1+\lambda)W_n}.\end{aligned}$$

This yields $c(\lambda)=c(-(1+\lambda))$, and hence

$$\begin{aligned}I(z)&=\sup_{\lambda\in\mathbf{R}}\{\lambda z-c(\lambda)\}=\sup_{\lambda\in\mathbf{R}}\{\lambda z-c(-(1+\lambda))\}\\&=\sup_{\lambda\in\mathbf{R}}\{-(1+\lambda)z-c(\lambda)\}=\sup_{\lambda\in\mathbf{R}}\{\lambda\cdot(-z)-c(\lambda)\}-z=I(-z)-z.\end{aligned}$$ □

We could regard $W_n(\omega)/n=(1/n)\log(d\mathbf{P}_{[0,n]}/d\mathbf{P}^-_{[0,n]})(\omega)$ as the time-averaged entropy production rate of the sample trajectory ω of the stochastic system modelled by the Markov chain ξ. Roughly speaking, the fluctuation theorem gives a formula for the probability ratio that the sample entropy production rate W_n/n takes a value z to that of $-z$, and the ratio is roughly e^{nz}. If the Markov chain ξ is reversible, $I(0)=0$ and $I(z)=+\infty$ for any $z\neq 0$. In this case the fluctuation theorem gives a trivial result. However, if the Markov chain ξ is not reversible, for $z>0$ in a certain range, the sample entropy production rate W_n/n has a positive probability to take the value $z>0$ as well as the value $-z$. The fluctuation theorem tells that the former probability is greater, which accords with the second law of thermodynamics.

Now we discuss the transient fluctuation theorem for non-stationary Markov chains. Assume that $\tilde{\xi}=\{\tilde{\xi}_n:n\in\mathbf{Z}^+\}$ is an irreducible finite Markov chain on its canonical trajectory space $(\tilde{\Omega},\tilde{\mathcal{F}},\tilde{\mathbf{P}})$ with finite state space S and transition probability matrix $P=(p_{ij})_{i,j\in S}$ as ξ. Suppose that the initial distribution ν (not necessarily invariant) satisfies $\nu_i>0$ for any $i\in S$. Denote the distributions of the trajectory segments of ξ over a finite time interval $[0,n]$ and their time reversals by $\tilde{\mathbf{P}}_{[0,n]}$ and $\tilde{\mathbf{P}}^-_{[0,n]}$, respectively. Let $\tilde{W}_n=\log(d\tilde{\mathbf{P}}_{[0,n]}/d\tilde{\mathbf{P}}^-_{[0,n]})$. From the above presentation, one can easily see that $\{\tilde{\mu}_n:n\geqslant 0\}$, the family of distributions of $\{\tilde{W}_n/n:n\geqslant 0\}$, also has a large deviation property and $\{\tilde{W}_n\}$ has the same free energy function as $\{W_n\}$, which yields that $\{\tilde{\mu}_n\}$ has the same large deviation rate function as $\{\mu_n\}$ and thus the rate function has a symmetry. Moreover, for any $n>0,z\in\mathbf{R}$, it holds that

$$\begin{aligned}\tilde{\mathbf{P}}\left(\frac{\tilde{W}_n}{n}=z\right)&=\tilde{\mathbf{P}}\left(\frac{d\tilde{\mathbf{P}}_{[0,n]}}{d\tilde{\mathbf{P}}^-_{[0,n]}}=e^{nz}\right)=\tilde{\mathbf{P}}_{[0,n]}\left(\frac{d\tilde{\mathbf{P}}_{[0,n]}}{d\tilde{\mathbf{P}}^-_{[0,n]}}=e^{nz}\right)=e^{nz}\tilde{\mathbf{P}}^-_{[0,n]}\left(\frac{d\tilde{\mathbf{P}}_{[0,n]}}{d\tilde{\mathbf{P}}^-_{[0,n]}}=e^{nz}\right)\\&=e^{nz}\tilde{\mathbf{P}}_{[0,n]}\left(\frac{d\tilde{\mathbf{P}}^-_{[0,n]}}{d\tilde{\mathbf{P}}_{[0,n]}}=e^{nz}\right)=e^{nz}\tilde{\mathbf{P}}\left(\frac{\tilde{W}_n}{n}=-z\right).\end{aligned}$$

Since S is finite, $\tilde{W}_n/n$ only takes a finite number of values and both sides of the above equality may simultaneously be equal to zero. However, in case one can divide over, the above equality can be written as

$$\frac{\tilde{\mathbf{P}}\left(\frac{\tilde{W}_n}{n}=z\right)}{\tilde{\mathbf{P}}\left(\frac{\tilde{W}_n}{n}=-z\right)}=e^{nz}.$$

Such an equality is called the transient fluctuation theorem by Evans *et al.*[7–13,19]

III. FINITE MARKOV CHAINS WITH CONTINUOUS TIME PARAMETER

In this section, we will discuss the same problem in the case of continuous time. The emphasis is much more oriented to detailed mathematical analysis and estimates. Let $\xi=\{\xi_t:t\in\mathbf{R}\}$ be a stationary, irreducible Markov chain on a probability space $(\Omega,\mathcal{F},\mathbf{P})$ with finite state space $S=\{1,\ldots,d\}$, conservative Q-matrix $Q=(q_{ij})_{i,j\in S}$, and invariant distribution $\Pi=\{\pi_i\}_{i\in S}$. Without loss of generality, we suppose that $(\Omega,\mathcal{F},\mathbf{P})$ is the canonical trajectory space of ξ, and its trajectories are right continuous having left limits. Since the time-reversed trajectories are left continuous having right limits, we should modify them. Define the time-reversal transformation and the shift operator as

$$r:(\Omega,\mathcal{F})\to(\Omega,\mathcal{F}),\quad \xi_t(r\omega)=\lim_{s\uparrow -t}\xi_s(\omega),\quad \forall t\in\mathbf{R},$$

$$\theta^t:(\Omega,\mathcal{F})\to(\Omega,\mathcal{F}),\quad \xi_s(\theta^t\omega)=\xi_{s+t}(\omega),\quad \forall s,t\in\mathbf{R}.$$

r,θ^t are $\mathcal{F}$-measurable and invertible with $r^{-1}=r$, $r\theta^t=\theta^{-t}r$, $\theta^t\mathbf{P}=\mathbf{P}$ and $\theta^t\mathbf{P}^-=\mathbf{P}^-$, where $\mathbf{P}^-=r\mathbf{P}$. The stationary Markov chain ξ is said to be reversible if $\mathbf{P}=\mathbf{P}^-$. As is well known, ξ is reversible if and only if the entropy production rate e_p of ξ vanishes, or iff $\pi_i q_{ij}=\pi_j q_{ji}$ for any $i,j\in S$.[26,27,29] Similarly as in the discrete time case, we assume that the Q-matrix satisfies the condition

$$q_{ij}>0\Leftrightarrow q_{ji}>0,\quad \forall i,j\in S. \tag{3}$$

For each $s\in\mathbf{R}$ and $t\in\mathbf{R}^+$, denote by $\mathbf{P}_{[s,s+t)}$ and $\mathbf{P}^-_{[s,s+t)}$, respectively, the restrictions of $\mathbf{P}$ and $\mathbf{P}^-$ on $\mathcal{F}_s^{s+t}=\sigma(\xi_u:s\leqslant u<s+t)$, then we have the following proposition.

Proposition 3.1: Under the condition (3), $\mathbf{P}_{[s,s+t)}$ and $\mathbf{P}^-_{[s,s+t)}$ are absolutely continuous with respect to each other, and the Radon–Nikodym derivative is given by

$$\left.\frac{\mathrm{d}\mathbf{P}_{[s,s+t)}}{\mathrm{d}\mathbf{P}^-_{[s,s+t)}}\right|_{A_{i_0i_1\cdots i_n}(t)}=\frac{\pi_{i_0}q_{i_0i_1}\cdots q_{i_{n-1}i_n}}{\pi_{i_n}q_{i_ni_{n-1}}\cdots q_{i_1i_0}},\quad \mathbf{P}-\text{a.s.},$$

where

$$A_{i_0i_1\cdots i_n}(t)=\{\omega\in\Omega:\omega \textit{ jumps } n \textit{ times in } [s,s+t),\ \textit{and the states are } i_0,\ldots,i_n \textit{ in turn}\}.$$

Proof: Denote $T_0=s$ and the jump times in the interval $[s,s+t)$ by $T_1(\omega),T_2(\omega),\ldots$ in turn. For any $n\geqslant 0$, $i_0,i_1,\ldots,i_n\in S$, $0<s_1<\cdots<s_n<s_{n+1}=t$ and small $\delta s_1,\ldots,\delta s_n>0$ (such that $s_k+\delta s_k<s_{k+1}$, $k=1,\ldots,n$), denote

$$A=\{\omega\in A_{i_0i_1\cdots i_n}(t):s_k\leqslant T_k(\omega)<s_k+\delta s_k,\ k=1,\ldots,n\}.$$

Then

$$\begin{aligned}\mathbf{P}(A)=&\int_{s_1}^{s_1+\delta s_1}\mathrm{d}t_1\int_{s_2}^{s_2+\delta s_2}\mathrm{d}t_2\cdots\int_{s_n}^{s_n+\delta s_n}\mathrm{d}t_n\\&\times\int_t^{+\infty}\mathrm{d}t_{n+1}\pi_{i_0}q_{i_0i_1}\cdots q_{i_{n-1}i_n}q_{i_n}e^{-q_{i_0}t_1}e^{-q_{i_1}(t_2-t_1)}\cdots e^{-q_{i_n}(t_{n+1}-t_n)}\\=&\int_{s_1}^{s_1+\delta s_1}\mathrm{d}t_1\int_{s_2}^{s_2+\delta s_2}\mathrm{d}t_2\cdots\int_{s_n}^{s_n+\delta s_n}\mathrm{d}t_n\pi_{i_0}q_{i_0i_1}\cdots q_{i_{n-1}i_n}\\&\times e^{-q_{i_0}t_1}e^{-q_{i_1}(t_2-t_1)}\cdots e^{-q_{i_{n-1}}(t_n-t_{n-1})}e^{-q_{i_n}(t-t_n)}.\end{aligned}$$

Since

$$rA=\{\omega\in A_{i_ni_{n-1}\cdots i_0}(t):t-(s_{n+1-k}+\delta s_{n+1-k})\leqslant T_k(\omega)<t-s_{n+1-k},\ \ k=1,\ldots,n\},$$

it follows that

$$\begin{aligned}\mathbf{P}^-(A)=\mathbf{P}(rA)=&\int_{t-(s_n+\delta s_n)}^{t-s_n}\mathrm{d}t_1\int_{t-(s_{n-1}+\delta s_{n-1})}^{t-s_{n-1}}\mathrm{d}t_2\cdots\int_{t-(s_1+\delta s_1)}^{t-s_1}\mathrm{d}t_n\pi_{i_n}q_{i_ni_{n-1}}\cdots q_{i_1i_0}\\&\times e^{-q_{i_n}t_1}e^{-q_{i_{n-1}}(t_2-t_1)}\cdots e^{-q_{i_1}(t_n-t_{n-1})}e^{-q_{i_0}(t-t_n)}\\=&\int_{s_1}^{s_1+\delta s_1}\mathrm{d}t_1\int_{s_2}^{s_2+\delta s_2}\mathrm{d}t_2\cdots\int_{s_n}^{s_n+\delta s_n}\mathrm{d}t_n\pi_{i_n}q_{i_ni_{n-1}}\cdots q_{i_1i_0}\\&\times e^{-q_{i_0}t_1}e^{-q_{i_1}(t_2-t_1)}\cdots e^{-q_{i_{n-1}}(t_n-t_{n-1})}e^{-q_{i_n}(t-t_n)}\\=&\frac{\pi_{i_n}q_{i_ni_{n-1}}\cdots q_{i_1i_0}}{\pi_{i_0}q_{i_0i_1}\cdots q_{i_{n-1}i_n}}\mathbf{P}(A).\end{aligned}$$

Notice that such A's as above generate $\mathcal{F}_{[s,s+t)}$, then one obtains the desired result immediately. □

The entropy production rate e_p of the stationary Markov chain ξ can be defined by

$$e_p\overset{\text{def}}{=}\lim_{t\to+\infty}\frac{1}{t}H(\mathbf{P}_{[0,t)},\mathbf{P}^-_{[0,t)})=\lim_{t\to+\infty}\frac{1}{t}E^{\mathbf{P}}\log\frac{\mathrm{d}\mathbf{P}_{[0,t)}}{\mathrm{d}\mathbf{P}^-_{[0,t)}},$$

or equivalently, as in Refs. 26 and 27, by

$$e_p\overset{\text{def}}{=}\lim_{t\downarrow0+}\frac{1}{t}H(\mathbf{P}_{[s,s+t)},\mathbf{P}^-_{[s,s+t)})=\lim_{t\downarrow0+}\frac{1}{t}E^{\mathbf{P}}\log\frac{\mathrm{d}\mathbf{P}_{[s,s+t)}}{\mathrm{d}\mathbf{P}^-_{[s,s+t)}},$$

where $s\in\mathbf{R}$. The equivalence is a direct consequence of Theorem 10.4 in Varadhan.[40] In Refs. 26, 28, and 29, an entropy production formula was given for ξ:

$$e_p=\frac{1}{2}\sum_{i,j\in S}(\pi_iq_{ij}-\pi_jq_{ji})\log\frac{\pi_iq_{ij}}{\pi_jq_{ji}}.\tag{4}$$

Employing Proposition 3.1 and (6), (7) below, it is not difficult to prove this formula strictly.

Proposition 3.2: Under the condition (3),

$$\lim_{t\to+\infty}\frac{1}{t}\log\frac{d\mathbf{P}_{[s,s+t)}}{d\mathbf{P}^{-}_{[s,s+t)}}(\omega)=e_p,\quad \mathbf{P}-\text{a.s.}$$

Proof: Let $N_t(\omega)$ be the number of jumps of ω in the interval $[s,s+t)$, $N_t(i,j,\omega)$ be the number of jumps from i to j of ω in the interval $[s,s+t)$ and $\{X_k\}_{k\in\mathbf{Z}^+}$ be the embedded chain of ξ defined by $X_k=\xi_{T_k}$. By Proposition 3.1,

$$\begin{aligned}\frac{1}{t}\log\frac{d\mathbf{P}_{[s,s+t)}}{d\mathbf{P}^{-}_{[s,s+t)}}(\omega)&=\frac{1}{t}\sum_{n=0}^{+\infty}\left(\log\frac{\pi_{X_0(\omega)}}{\pi_{X_n(\omega)}}+\sum_{k=0}^{n-1}\log\frac{q_{X_k(\omega)X_{k+1}(\omega)}}{q_{X_{k+1}(\omega)X_k(\omega)}}\right)1_{\{N_t=n\}}(\omega)\\&=\frac{1}{t}\sum_{n=0}^{+\infty}1_{\{N_t=n\}}(\omega)\log\frac{\pi_{X_0(\omega)}}{\pi_{X_n(\omega)}}\\&\quad+\sum_{i,j\in S}\sum_{n=0}^{+\infty}\sum_{k=0}^{n-1}\frac{1}{t}1_{\{N_t=n\}}(\omega)1_{\{X_k=i,X_{k+1}=j\}}(\omega)\log\frac{q_{ij}}{q_{ji}}\\&=\frac{1}{t}\sum_{n=0}^{+\infty}1_{\{N_t=n\}}(\omega)\log\frac{\pi_{X_0(\omega)}}{\pi_{X_n(\omega)}}+\sum_{i,j\in S}\frac{1}{t}N_t(i,j,\omega)\log\frac{q_{ij}}{q_{ji}},\end{aligned}\tag{5}$$

where $1_A(\cdot)$ is the indicator function of the event $A\in\mathcal{F}$. For any $t_1,t_2\geqslant 0$ and $i,j\in S$, $N_{t_1+t_2}(i,j,\omega)=N_{t_1}(i,j,\omega)+N_{t_2}(i,j,\theta^{t_1}\omega)$, $\mathbf{P}-$a.s. By the subadditive ergodic theorem,[38] for any $\delta>0$, it holds that

$$\lim_{n\to+\infty}\frac{1}{n\delta}N_{n\delta}(i,j,\omega)=\inf_n\frac{1}{n\delta}EN_{n\delta}(i,j,\cdot)=\frac{1}{\delta}EN_\delta(i,j,\cdot),\quad \mathbf{P}-\text{a.s.}$$

For any t, there exist $n(t)\in\mathbf{Z}^+$ and $r(t)\in[0,\delta)$ such that $t=n(t)\delta+r(t)$, thus

$$\frac{1}{t}N_t(i,j,\omega)=\frac{1}{t}N_{n(t)\delta}(i,j,\omega)+\frac{1}{t}N_{r(t)}(i,j,\theta^{n(t)\delta}\omega),\quad \mathbf{P}-\text{a.s.}$$

Consequently,

$$\lim_{t\to+\infty}\frac{1}{t}N_{n(t)\delta}(i,j,\omega)=\frac{1}{\delta}EN_\delta(i,j,\cdot),\quad \mathbf{P}-\text{a.s.}$$

Now we would like to prove that $\lim_{t\to+\infty}N_{r(t)}(i,j,\theta^{n(t)\delta}\omega)/t=0$, $\mathbf{P}-$a.s. For any given $i_0,i_1,\ldots,i_n\in S$,

$$\begin{aligned}\mathbf{P}(A_{i_0i_1\cdots i_n}(t))&=\int_0^t dt_n\int_{0<t_1<t_2<\cdots<t_n}dt_1\,dt_2\cdots dt_{n-1}\pi_{i_0}q_{i_0i_1}\cdots q_{i_{n-1}i_n}e^{-q_{i_n}t}\prod_{k=1}^{n}e^{(q_{i_k}-q_{i_{k-1}})t_k}\\&\leqslant\pi_{i_0}q_{i_0i_1}\cdots q_{i_{n-1}i_n}\frac{t^n}{n!}.\end{aligned}\tag{6}$$

Hence for any n,

$$\mathbf{P}(N_t(\omega)=n)\leqslant\sum_{\substack{i_0,\cdots,i_n\\ i_k\neq i_{k+1}}}\pi_{i_0}q_{i_0i_1}\cdots q_{i_{n-1}i_n}\frac{t^n}{n!}\leqslant\frac{(\max_i q_i t)^n}{n!}.\tag{7}$$

For any $\varepsilon>0$,

$$\begin{aligned}\sum_{n=0}^{+\infty}\mathbf{P}(N_\delta(i,j,\omega)>n\varepsilon)&\leqslant\sum_{n=0}^{+\infty}\mathbf{P}(N_\delta(\omega)>n\varepsilon)\\&=\sum_{n=0}^{+\infty}\sum_{k>n\varepsilon}\mathbf{P}(N_\delta(\omega)=k)\\&=\sum_{k=1}^{+\infty}\sum_{0\leqslant n<k\varepsilon^{-1}}\mathbf{P}(N_\delta(\omega)=k)\\&\leqslant\sum_{k=1}^{+\infty}\mathbf{P}(N_\delta(\omega)=k)(k\varepsilon^{-1}+1)<+\infty.\end{aligned}$$

Since the process is stationary, $\mathbf{P}(N_\delta(i,j,\theta^{n\delta}\omega)>n\varepsilon)=\mathbf{P}(N_\delta(i,j,\omega)>n\varepsilon)$ for any $n>0$. This together with the Borel–Cantelli lemma yields that

$$\begin{aligned}&\mathbf{P}\left(\exists\ \text{a sequence}\ \{t_k\geqslant 0\}_{k\in\mathbf{N}}\ \text{s.t.}\ t_k\uparrow+\infty\ \text{and}\ \frac{1}{t_k}N_{r(t_k)}(i,j,\theta^{n(t_k)\delta}\omega)>\varepsilon,\forall k\in\mathbf{N}\right)\\&\qquad\leqslant\mathbf{P}[N_\delta(i,j,\theta^{n\delta}\omega)>n\varepsilon\ \text{ infinitely often}]=0.\end{aligned}$$

Hence $\mathbf{P}-$a.s., $\lim_{t\to+\infty}(1/t)\,N_{r(t)}(i,j,\theta^{n(t)\delta}\omega)=0$. So for any given $\delta>0$, it holds that

$$\lim_{t\to+\infty}\frac{1}{t}N_t(i,j,\omega)=\frac{1}{\delta}EN_\delta(i,j,\cdot),\quad\mathbf{P}-\text{a.s.},\tag{8}$$

where $EN_\delta(i,j,\cdot)=\Sigma_{n=1}^{+\infty}EN_\delta(i,j,\cdot)1_{\{N_\delta=n\}}(\cdot)$. On one hand,

$$\begin{aligned}\frac{1}{\delta}EN_\delta(i,j,\cdot)1_{\{N_\delta=1\}}(\cdot)&=\frac{1}{\delta}P(N_\delta(\omega)=1,N_\delta(i,j,\omega)=1)\\&=\frac{1}{\delta}\int_0^\delta\pi_iq_{ij}e^{-q_j\delta}e^{(q_j-q_i)\tau}\,\mathrm{d}\tau\to\pi_iq_{ij},\quad\text{as}\ \ \delta\to0+.\end{aligned}$$

On the other hand, from (7)

$$\frac{1}{\delta}\sum_{n=2}^{+\infty}EN_\delta(i,j,\cdot)1_{\{N_\delta=n\}}(\cdot)\leqslant\frac{1}{\delta}\sum_{n=2}^{+\infty}nP(N_\delta(\omega)=n)\to0,\quad\text{as}\ \ \delta\to0+.$$

Hence $(1/\delta)\,EN_\delta(i,j,\cdot)=\pi_iq_{ij}$, which together with (5) and (8) yields that

$$\lim_{t\to+\infty}\frac{1}{t}\log\frac{\mathrm{d}\mathbf{P}_{[s,s+t)}}{\mathrm{d}\mathbf{P}^-_{[s,s+t)}}(\omega)=\sum_{i,j}\pi_iq_{ij}\log\frac{\pi_iq_{ij}}{\pi_jq_{ji}}=e_p,\quad\mathbf{P}-\text{a.s.}\qquad\square$$

Let $W_t(\omega)=\log(\mathrm{d}\mathbf{P}_{[0,t)}/\mathrm{d}\mathbf{P}^-_{[0,t)})(\omega)$, μ_t be the distribution of W_t/t and $c_t(\lambda)=(\log Ee^{\lambda W_t})/t$. According to Theorem II.6.1 in Ellis[39] (modified for continuous time parameter), in order to verify $\{\mu_t:t\in\mathbf{R}^+\}$ has a large deviation property, we only need to prove $c_t(\lambda)$ is finite and the free energy function $c(\lambda)\overset{\text{def}}{=}\lim_{t\to+\infty}c_t(\lambda)$ of $\{W_t:t\in\mathbf{R}^+\}$ exists and is differentiable.

Proposition 3.3: For any $t>0$ and $\lambda\in\mathbf{R}$, $c_t(\lambda)$ is finite.

Proof: For any $i\in S$, by Proposition 3.1, it holds that

$$E_i(t,\lambda)\overset{\text{def}}{=}E(e^{\lambda W_t}|\xi_0=i)=\sum_{n=0}^{+\infty}\sum_{\substack{i_1,\cdots,i_n:\\ q_{ii_1}q_{i_1i_2}\cdots q_{i_{n-1}i_n}>0}}\left(\frac{\pi_i q_{ii_1}q_{i_1i_2}\cdots q_{i_{n-1}i_n}}{\pi_{i_n}q_{i_ni_{n-1}}\cdots q_{i_2i_1}q_{i_1i}}\right)^{\lambda}\mathbf{P}(A_{ii_1\ldots i_n}(t)|\xi_0=i). \tag{9}$$

From (6) and (7),

$$\sum_{\substack{i_1,\cdots,i_n:\\ q_{ii_1}q_{i_1i_2}\cdots q_{i_{n-1}i_n}>0}}\left(\frac{\pi_i q_{ii_1}q_{i_1i_2}\cdots q_{i_{n-1}i_n}}{\pi_{i_n}q_{i_ni_{n-1}}\cdots q_{i_2i_1}q_{i_1i}}\right)^{\lambda}\mathbf{P}(A_{ii_1\ldots i_n}(t)|\xi_0=i)\leqslant B^{\lambda}\frac{(C^{\lambda}Dt)^n}{n!},$$

where $B=\max_{i,j}\pi_i/\pi_j$, $C=\max\{q_{ij}/q_{ji}:q_{ij}>0\}$ and $D=\max_i q_i$. Hence $E_i(t,\lambda)<+\infty$ and $Ee^{\lambda W_t}=\Sigma_i\pi_iE_i(t,\lambda)<+\infty$. On the other hand, it is easy to see $Ee^{\lambda W_t}>0$. Thus $c_t(\lambda)=(1/t)\log Ee^{\lambda W_t}$ is finite. □

Theorem 3.4: *For all* $\lambda\in\mathbf{R}$, $\lim_{t\to+\infty}c_t(\lambda)$ *exists and the free energy function* $c(\lambda)$ *of* $\{W_t:t\in\mathbf{R}^+\}$ *is differentiable.*

Proof: From (6),

$$\frac{\mathrm{d}}{\mathrm{d}t}\mathbf{P}(A_{i_0i_1\cdots i_n}(t))=-q_{i_n}\mathbf{P}(A_{i_0i_1\cdots i_n}(t))+q_{i_{n-1}i_n}\mathbf{P}(A_{i_0i_1\cdots i_{n-1}}(t)). \tag{10}$$

By Proposition 3.1 and $\mathbf{P}^-=r\mathbf{P}$, it holds that

$$\mathbf{P}(A_{i_0i_1\cdots i_n}(t))=\frac{\pi_{i_0}q_{i_0i_1}\cdots q_{i_{n-1}i_n}}{\pi_{i_n}q_{i_ni_{n-1}}\cdots q_{i_1i_0}}\mathbf{P}(A_{i_ni_{n-1}\cdots i_0}(t)).$$

This together with (10) yields that

$$\frac{\mathrm{d}}{\mathrm{d}t}\mathbf{P}(A_{i_0i_1\cdots i_n}(t))=-q_{i_0}\mathbf{P}(A_{i_0i_1\cdots i_n}(t))+\frac{\pi_{i_0}q_{i_0i_1}}{\pi_{i_1}}\mathbf{P}(A_{i_1i_2\cdots i_n}(t)),$$

and it follows that

$$\frac{\mathrm{d}}{\mathrm{d}t}\mathbf{P}(A_{i_0i_1\cdots i_n}(t)|\xi_0=i_0)=-q_{i_0}\mathbf{P}(A_{i_0i_1\cdots i_n}(t)|\xi_0=i_0)+q_{i_0i_1}\mathbf{P}(A_{i_1\cdots i_n}(t)|\xi_0=i_1).$$

Taking differentials on both sides of (9) with respect to t, we get

$$\frac{\mathrm{d}}{\mathrm{d}t}E_i(t,\lambda)=-q_iE_i(t,\lambda)+\sum_{j:q_{ij}>0}q_{ij}\left(\frac{\pi_iq_{ij}}{\pi_jq_{ji}}\right)^{\lambda}E_j(t,\lambda). \tag{11}$$

Let

$$\mathbf{E}(t,\lambda)=\begin{pmatrix}E_1(t,\lambda)\\ \cdots\\ E_d(t,\lambda)\end{pmatrix},\quad l_{ij}(\lambda)=\begin{cases}-q_i, & \text{if } i=j,\\ q_{ij}\left(\dfrac{\pi_iq_{ij}}{\pi_jq_{ji}}\right)^{\lambda}, & \text{if } q_{ij}>0,\\ 0, & \text{if } q_{ij}=0.\end{cases}\quad \mathbf{1}=\begin{pmatrix}1\\ \vdots\\ 1\end{pmatrix}.$$

Since $\mathbf{E}(0,\lambda)=\mathbf{1}$, (11) yields $\mathbf{E}(t,\lambda)=e^{\mathbf{L}(\lambda)t}\mathbf{1}$, where $\mathbf{L}(\lambda)=(l_{ij}(\lambda))$. Thus

$$c_t(\lambda)=\frac{1}{t}\log Ee^{\lambda W_t}=\frac{1}{t}\log\sum_i\pi_iE_i(t,\lambda)=\frac{1}{t}\log\vec{\pi}e^{\mathbf{L}(\lambda)t}\mathbf{1}, \tag{12}$$

where $\vec{\pi}=(\pi_1,\pi_2,\ldots,\pi_d)$. It is easy to see that $q_{ij}>0\Leftrightarrow l_{ij}(\lambda)>0$ and $q_{ij}=0\Leftrightarrow l_{ij}(\lambda)=0$. Since Q is irreducible, the Taylor expansion of $e^{\mathbf{L}(\lambda)t}$ at $t=0$,

$$e^{\mathbf{L}(\lambda)t}=\mathbf{I}+\mathbf{L}(\lambda)t+\frac{1}{2!}\mathbf{L}(\lambda)^2t^2+\cdots+\frac{1}{n!}\mathbf{L}(\lambda)^nt^n+\mathbf{o}(t^n),$$

tells that for any $i,j\in S$, there is a $\delta(i,j)>0$ such that $[e^{\mathbf{L}(\lambda)t}]_{ij}>0$ for any $t\in(0,\delta(i,j)]$. Hence $e^{\mathbf{L}(\lambda)\delta}>0$ for any sufficiently small δ, which yields that it holds for all $\delta>0$. For a fixed $\delta>0$, by the Perron–Frobenius theorem, the spectral radius $e(\lambda,\delta)$ of $e^{\mathbf{L}(\lambda)\delta}$ is a positive eigenvalue of $e^{\mathbf{L}(\lambda)\delta}$ with one-dimensional eigenspace. This together with (12) yields that

$$c(\lambda)=\lim_{t\to+\infty}c_t(\lambda)=\delta^{-1}\log e(\lambda,\delta).$$

$c(\lambda)$ is differentiable because $\mathbf{L}(\lambda)$ is differentiable and so are $e^{\mathbf{L}(\lambda)\delta}$ and $e(\lambda,\delta)$. □

Also the innate symmetry of $\{W_t\}$ implies symmetries of its free energy function and rate function. The proof is exactly the same as that of Theorem 2.4.

Theorem 3.5: *(Fluctuation theorem) The free energy function $c(\cdot)$ and the large deviation rate function $I(\cdot)$ of $\{W_t:t\in\mathbf{R}^+\}$ satisfy*

$$c(\lambda)=c(-(1+\lambda)),\quad \forall\lambda\in\mathbf{R},\quad I(z)=I(-z)-z,\quad \forall z\in\mathbf{R}.$$

As in the discrete-time case, the transient fluctuation theorem holds for nonstationary Markov chains with continuous-time parameter. Suppose that $\tilde{\xi}=\{\tilde{\xi}_t:t\geqslant 0\}$ is a Markov chain on its canonical trajectory space $(\tilde{\Omega},\tilde{\mathcal{F}},\tilde{\mathbf{P}})$ with the same state space S and the same Q-matrix Q as those of ξ. Assume that the initial distribution ν (may not invariant) satisfies $\nu_i>0$ for all $i\in S$. Denote the distributions of the trajectory segments of ξ over a finite time interval $[0,t)$ and their time reversals by $\tilde{\mathbf{P}}_{[0,t)}$ and $\tilde{\mathbf{P}}^-_{[0,t)}$, respectively. Let $\tilde{W}_t=\log(\mathrm{d}\tilde{\mathbf{P}}_{[0,t)}/\mathrm{d}\tilde{\mathbf{P}}^-_{[0,t)})$. From the above presentation, one can see that $\{\tilde{\mu}_t:t\geqslant 0\}$, the family of the distributions of $\{\tilde{W}_t/t:t\geqslant 0\}$, also has a large deviation property and $\{\tilde{W}_t\}$ has the same free energy function as $\{W_t\}$, which yields that $\{\tilde{\mu}_t\}$ has the same large deviation rate function as $\{\mu_t\}$ and thus the rate function has a symmetry. We also have

$$\tilde{\mathbf{P}}\left(\frac{\tilde{W}_t}{t}=z\right)=e^{tz}\tilde{\mathbf{P}}\left(\frac{\tilde{W}_t}{t}=-z\right),\quad \forall t>0,z\in\mathbf{R}.$$

IV. FLUCTUATIONS OF GENERAL OBSERVABLES

With the assumptions and notation of the stationary case in Sec. II, let $\varphi:S\to\mathbf{R}$ be an observable and $\Phi_n(\omega)=\Sigma_{k=0}^n\varphi(\xi_k(\omega))=\Sigma_{k=0}^n\varphi(\xi_0(\theta^k\omega))$. Clearly, Φ_n satisfies $\Phi_n(r\omega)=\Phi_n(\theta^{-n}\omega)$ for any $\omega\in\Omega$. From the Birkhoff ergodic theorem, it follows that $\lim_{n\to+\infty}\Phi_n/n=E^{\mathrm{II}}\varphi$. Use the Perron–Frobenius theorem, then one sees that

$$c(\lambda_1,\lambda_2)\overset{\text{def}}{=}\lim_{n\to+\infty}\frac{1}{n}\log Ee^{\lambda_1W_n+\lambda_2\Phi_n}$$

exists and is differentiable with respect to λ_1,λ_2. Thus $\{\mu_n:n\geqslant 0\}$, the family of the distributions of $\{(W_n/n,\Phi_n/n):n\geqslant 0\}$, has a large deviation property with rate function $I(z_1,z_2)=\sup_{\lambda_1,\lambda_2\in\mathbf{R}}\{\lambda_1z_1+\lambda_2z_2-c(\lambda_1,\lambda_2)\}$. It is not difficult to find that $c(\lambda_1,\lambda_2)=c(-(1+\lambda_1),\lambda_2)$ and $I(z_1,z_2)=I(-z_1,z_2)-z_1$. In general, let $\{\vec{\Phi}_n:n\geqslant 0\}$ and $\{\vec{\Psi}_n:n\geqslant 0\}$ be two sets of random vectors on $(\Omega,\mathcal{F},\mathbf{P})$, where $\vec{\Phi}_n$ and $\vec{\Psi}_n$ are $\mathcal{F}_0^n$ measurable. Provided that the free energy function

$$c(\lambda,\vec{\nu},\vec{\gamma})\overset{\text{def}}{=}\lim_{n\to+\infty}\frac{1}{n}\log Ee^{\lambda W_n+\langle\vec{\nu},\vec{\Phi}_n\rangle+\langle\vec{\gamma},\vec{\Psi}_n\rangle}$$

exists and is differentiable, it holds that $\{\mu_n:n\geqslant 0\}$, the family of the distributions of $\{(1/n)(W_n,\vec{\Phi}_n,\vec{\Psi}_n):n\geqslant 0\}$, has a large deviation property with rate function $I(z,\vec{u},\vec{v})=\sup_{\lambda,\vec{\nu},\vec{\gamma}}\{\lambda z+\langle\vec{\nu},\vec{u}\rangle+\langle\vec{\gamma},\vec{v}\rangle-c(\lambda,\vec{\nu},\vec{\gamma}\}$.

Theorem 4.1: *If* $\vec{\Phi}_n(r\omega)=\vec{\Phi}_n(\theta^{-n}\omega)$ *and* $\vec{\Psi}_n(r\omega)=-\vec{\Psi}_n(\theta^{-n}\omega)$ *for any* $n\geqslant 0$ *and* $\omega\in\Omega$, *it holds that*

$$c(\lambda,\vec{\nu},\vec{\gamma})=c(-(1+\lambda),\vec{\nu},-\vec{\gamma}),\quad I(z,\vec{u},\vec{v})=I(-z,\vec{u},-\vec{v})-z.$$

Proof: For any given $\lambda,\vec{\nu},\vec{\gamma}$,

$$\begin{aligned}Ee^{\lambda W_n+\langle\vec{\nu},\vec{\Phi}_n\rangle+\langle\vec{\gamma},\vec{\Psi}_n\rangle}&=\int\left(\frac{d\mathbf{P}_{[0,n]}}{d\mathbf{P}^{-}_{[0,n]}}(\omega)\right)^{\lambda}e^{\langle\vec{\nu},\vec{\Phi}_n(\omega)\rangle+\langle\vec{\gamma},\vec{\Psi}_n(\omega)\rangle}\,d\mathbf{P}(\omega)\\&=\int\left(\frac{d\mathbf{P}_{[0,n]}}{d\mathbf{P}^{-}_{[0,n]}}(r\omega)\right)^{\lambda}e^{\langle\vec{\nu},\vec{\Phi}_n(r\omega)\rangle+\langle\vec{\gamma},\vec{\Psi}_n(r\omega)\rangle}\,d\mathbf{P}^{-}(\omega)\\&=\int\left(\frac{d\mathbf{P}_{[0,n]}}{d\mathbf{P}^{-}_{[0,n]}}(\theta^{-n}\omega)\right)^{-\lambda}e^{\langle\vec{\nu},\vec{\Phi}_n(\theta^{-n}\omega)\rangle+\langle\vec{\gamma},-\vec{\Psi}_n(\theta^{-n}\omega)\rangle}\,d\mathbf{P}^{-}(\omega)\\&=Ee^{-(1+\lambda)W_n+\langle\vec{\nu},\vec{\Phi}_n\rangle+\langle-\vec{\gamma},\vec{\Psi}_n\rangle}.\end{aligned}$$

The desired result follows immediately. □

Remark: The same result still holds for the continuous time case.

A direct calculation of the free energy from the Bethe ansatz equation for the Heisenberg model

Go Kato[a] and Miki Wadati[b]

(Received 18 November 2002; accepted 14 April 2003)

Thermodynamics of the XXX Heisenberg model is studied. The trace of the Boltzmann weight with respect to the Hilbert space is taken in the thermodynamic limit with the number of up-spins being fixed. The expression of the trace gives an explanation why the correct thermodynamic quantities are derived from the string hypothesis. A combination of this with the previous result leads to a conclusion that the free energy can be calculated only from the Bethe ansatz equation. The method is more direct than other known methods which were used to derive the free energy. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1592610]

I. INTRODUCTION

There are two well-known methods to calculate the free energy for quantum integrable systems. One is the thermodynamic Bethe ansatz (TBA) method,[1] and the other is the quantum transfer matrix (QTM) method.[2–6] Both methods, however, are still unsatisfactory. In TBA case, we assume the form of the entropy. And we use the string hypothesis[7,8] for some models, whose validity is not yet proved. While QTM is a general formulation, it is difficult to analyze the resultant equations. We solve them asymptotically or numerically. In this paper, we present a direct method whereby the free energy is derived without logical jumps, assumptions and numerical supports.

We treat the spin-half XXX Heisenberg chain. The Hamiltonian of the system is

$$H=-J\sum_{j=1}^{L}(S_j^xS_{j+1}^x+S_j^yS_{j+1}^y+S_j^zS_{j+1}^z)-h\sum_{j=1}^{L}S_j^z+\text{constant}, \tag{1.1}$$

where L is the total number of sites, J is the coupling constant and h expresses the external field. This model is interesting since it has bound states, and correspondingly the Bethe equations have complex solutions. Throughout the paper, we assume periodic boundary condition, and use a unit which makes $J=1$.

We briefly summarize our previous work[9] on this system. We suppose the expression of Z_M, the trace of the Boltzmann weight with respect to the Hilbert space in which the number of up-spins is fixed to be M. An infinite sum $\Sigma_M Z_M$ defined by the expression is analyzed by use of combinatorial relations. Then, it is proved that the free energy $-k_BT\log\Sigma_M Z_M$ can be expressed in term of the function which satisfies an integral equation. The result perfectly agrees with the free energy derived from a different method.[10]

Our purpose is to derive directly the expression

$$Z_M\equiv\mathrm{Tr}\,e^{-\beta H_M},\quad \beta=1/k_BT \tag{1.2}$$

$$=\frac{e^{hM}}{M!}\sum_{\theta\in\Theta_M}\left[\prod_{\sigma\in\theta}N_\sigma!\right]\sum_{\zeta\in\Theta(\theta)}\mu(\hat{0}_\theta,\zeta)\left[\prod_{\theta'\in\zeta}\int_{-\infty}^{\infty}\mathrm{d}x_{\theta'}\right]\left|\frac{\partial I}{\partial x}\right|_{L,\zeta}e^{-\beta E(\zeta)} \tag{1.3}$$

[a]Electronic mail: kato@monet.phys.s.u-tokyo.ac.jp
[b]Electronic mail: wadati@phys.s.u-tokyo.ac.jp

in the thermodynamic limit $L\to\infty$. All the notation in (1.3) are explained in the following sections. Here, H_M denotes the Hamiltonian (1.1) acting on the Hilbert space in which the number of up-spins is restricted to a constant M. In this paper, we use only the Bethe ansatz; the eigenenergy E of H_M is given by

$$E+hM=\sum_{m=1}^{M}\frac{2}{x_m^2+1}, \tag{1.4}$$

where $\{x_m\}$ satisfies the Bethe equations,

$$\left[\frac{x_m+i}{x_m-i}\right]^L=\prod_{m'\neq m}\frac{x_m-x_{m'}+2i}{x_m-x_{m'}-2i}, \tag{1.5}$$

which are due to periodic boundary condition. Note that (1.3) is the expression of Z_M supposed in the previous paper.[9] We thus complete a new method to derive the free energy of this system independent of TBA and QTM.

The derivation goes as follows. First, we express the trace in a series with respect to solutions of the Bethe equations, which constitute a complete set of the system. Next, the series are replaced by integrals over pseudomomenta. The replacement, however, has a difficulty, because the Bethe equations have complex solutions. The difficulty is resolved by taking a ''good'' integral path. Finally, changing the integral path into a straight line on the complex plane, Z_M in (1.3) is obtained.

We also show that the expression of Z_M gives a reason why the string hypothesis, that is, the substitution of the Bethe equations for string center equations, is appropriate. The substitution is a critical procedure when we apply the thermodynamic Bethe ansatz to an integrable system which has bound states.

The outline of this paper is the following. In Sec. II, we derive the expression (1.3) under the condition $M=2$ only from the Bethe ansatz. In Sec. III, we outline the derivation of Z_M in arbitrary M case. In Sec. IV, we reformulate the results in graphical expressions. In Sec. V, we examine the string hypothesis by use of thus proved expression of Z_M. The last section is devoted to the concluding remarks. Technical details of calculations and proofs are very complicated and therefore we write them in a separate paper.

II. DERIVATION OF Z_2 FROM BETHE EQUATIONS

To explain the essence of the method, we consider the $M=2$ case. With the eigenenergies E (1.4) for $M=2$, Z_2 becomes

$$2Z_2e^{-\beta h2}=\sum\ \exp\left(-\beta\sum_{m=1}^{2}\frac{2}{x_m^2+1}\right). \tag{2.1}$$

Here, Σ without subscript means a summation over all the different physical solutions of the Bethe equations. It is interpreted as a summation with respect to a set of integers $\{I_1,I_2\}$ corresponding to a physical solution, where $\{I_1,I_2\}$ is related to $\{x_1,x_2\}$ by

$$\left[\frac{x_1+i}{x_1-i}\right]^L=e^{-2\pi iI_1}\left[\frac{x_1-x_2+2i}{x_1-x_2-2i}\right]\quad\text{and}\qquad(1\leftrightarrow2). \tag{2.2}$$

Note that I_1, I_2 are so-called quantum numbers and they are usually used when Eqs. (2.2) are written in logarithm forms. They are included in (2.2) to show explicitly I_1, I_2-dependences of x_1, x_2. We say that a solution of the Bethe equations is a ''physical solution'' if and only if the two

pseudomomenta x_1, x_2 of the solution do not have ''same value.'' The words ''different'' and ''same value'' will be explained later.

Equation (2.1) can be written as

$$2Z_2 e^{-\beta h 2} = \sum_{I_1, I_2} \exp\left(-\beta \sum_{m=1}^{2} \frac{2}{x_m^2 + 1} \right) - \sum_{I} \exp\left(-\beta \frac{4}{x^2+1} \right), \tag{2.3}$$

where $x_1 = x_1(I_1, I_2)$, $x_2 = x_2(I_1, I_2)$ are functions of I_1 and I_2. The first double summations are over all the solutions of the Bethe equations (2.2) and the second summation is over the solutions of the following equation:

$$\left[\frac{x+i}{x-i} \right]^L = -e^{-2\pi i I}. \tag{2.4}$$

In (2.3), extinction of nonphysical states from the sum is realized by the subtraction of the second term.

By using the Poisson formula

$$\sum_n f(n) = \sum_{m=-\infty}^{\infty} \int f(n) e^{2\pi i n m} \, \mathrm{d}n, \tag{2.5}$$

we express (2.3) as

$$\begin{aligned} 2Z_2 e^{-\beta h 2} = & \sum_{m_1, m_2 = -\infty}^{\infty} \int \int \exp\left(-\beta \sum_{m=1}^{2} \frac{2}{x_m^2+1} + 2\pi i (m_1 I_1 + m_2 I_2) \right) \mathrm{d}I_1 \, \mathrm{d}I_2 \\ & - \sum_{m=-\infty}^{\infty} \int \exp\left(-\beta \frac{4}{x^2+1} + 2\pi i (mI) \right) \mathrm{d}I. \end{aligned} \tag{2.6}$$

The most important matter in (2.6) is the definition of the paths of the multiple integrals. For the Poisson formula we define the paths as follows: The paths are manifolds on which I_1, I_2, I is a set of real numbers and x_1, x_2, x are continuously distributed. The orientation of the integral paths are chosen so that the values of integrals $\int \mathrm{d}I_1 \, \mathrm{d}I_2$ and $\int \mathrm{d}I$ for any part of the integral path are positive. The above definition explicitly characterizes the second integral in (2.6): we may take the integral path with respect to x to be $(-\infty, \infty)$.

For rewriting (2.1) into (2.6), it is necessary to define the words ''different'' and ''same value.'' We regard $\{x_1, x_2 \in \mathbb{C} \text{ or } \infty\}$ in Eq. (2.2) as a multivalued vector function of $\{e^{2\pi i I_1}, e^{2\pi i I_2} \neq 0, \infty\}$. Whether x_1 and x_2 take the ''same value'' or not depends on neighborhoods of the point $\{x_1, x_2\}$ on the Riemann surface defined by the function. We call that x_1 and x_2 take the ''same value'' if and only if there is a point $\{x_1', x_2'\}$ in any neighborhood where $x_1' = x_2'$ and $x_{1,2} \neq x_{1,2}'$. In case $x_1 = x_2 \neq \infty, \pm i$, this definition indicates that x_1 and x_2 take the ''same value.'' Therefore, in almost all the region of variables $\{x_1, x_2\}$, this definition leads to a valid definition of the ''physical solution.'' Next, ''different'' is defined as follows. Solutions of (2.2) corresponding to different points on the Riemann surface are ''different,'' where we regard (2.2) as an equation for $\{x_1, x_1\}$ fixing $\{e^{2\pi i I_1}, e^{2\pi i I_2}\}$ to be constants. At any point on the Riemann surface, the number of ''different'' solutions is estimated by

$$\lim_{\epsilon \to 0} \max \text{ number of points on } R_\epsilon \text{ corresponding to the same } \{e^{2\pi i I_1'}, e^{2\pi i I_2'}\}, \tag{2.7}$$

where R_ϵ is an ϵ-neighborhood of the point on the Riemann surface. Summarizing the above

considerations, we can say that the point on the Riemann surface $x_1, x_2 = \infty$, $I_1, I_2 =$ integer corresponds to two ''different'' solutions, and to two ''physical solutions.'' But, there is only one eigenstate corresponding to the point. We interpret this as follows. The ''values'' x_1 and x_2 are not the ''same value,'' and one of the ''physical solutions'' is given by exchanging the ''values'' x_1, x_2 of the other ''physical solution.''

We consider an integral, that is the first term in (2.6),

$$\sum_{m_1,m_2=-\infty}^{\infty} \int\int \exp\left(-\beta \sum_{m=1}^{2} \frac{2}{x_m^2+1} + 2\pi i(m_1 I_1 + m_2 I_2) \right) \mathrm{d}I_1 \, \mathrm{d}I_2 \tag{2.8}$$

along the integral path

$$\left| \left(\frac{x_1 - i}{x_1 + i} \right)^L \left(\frac{x_1 - x_2 + 2i}{x_1 - x_2 - 2i} \right) \right| = A_1 \quad \text{and} \ (1 \leftrightarrow 2), \tag{2.9}$$

where A_1 and A_2 are constants. The integral (2.8) does not depend on $A_{1,2}$ in case $0 < A_{1,2} < \infty$. The reason is that the integrand on the path is bounded, and the dimension of the nonanalytic region, i.e., $x_1, x_2 = \pm i$ or ∞, on the Riemann surface $\{e^{2\pi i I_1}, e^{2\pi i I_2}\}$ is sufficiently small. It is to be noted that we define the orientation of the path so that an integral $\int\int \mathrm{d}I_1 \, \mathrm{d}I_2$ for any part of the path is positive.

Using the above fact, we can change the integral path of the multiple integral (2.8) into the path (2.9). Defining $A_{1,2}$ as a set of sufficiently small real numbers, we have

$$\begin{aligned} (2.8) = \sum_{m_1,m_2=-\infty}^{\infty} & \int_{|x_2 - i| = 0+} \int_{|x_1 - i| = 0+} \left| \frac{\partial(I_1, I_2)}{\partial(x_1, x_2)} \right| \exp\left(-\beta \sum_{m=1}^{2} \frac{2}{x_m^2+1} \right) \\ & \times \left(\frac{x_1 - i}{x_1 + i} \right)^{m_1 L} \left(\frac{x_2 - i}{x_2 + i} \right)^{m_2 L} \left(\frac{x_1 - x_2 + 2i}{x_1 - x_2 - 2i} \right)^{m_1 - m_2} \mathrm{d}x_1 \, \mathrm{d}x_2, \end{aligned} \tag{2.10}$$

where $|x_{1,2} - i| = 0+$ indicates the integral path that $x_{1,2}$ turns around a point i anticlockwise. The Jacobian from (I_1, I_2) to (x_1, x_2) is denoted by $|\partial(I_1, I_2)/\partial(x_1, x_2)|$. This expression (2.10) enables us to evaluate the upper bound for the absolute value of the sum without the term corresponding to $m_1, m_2 = 0$. The upper bound is estimated as Ce^{-cL} where C and c do not depend on L. Then, in the thermodynamic limit the terms corresponding to $m_1 \neq 0$ or $m_2 \neq 0$ can be neglected. Hereafter, we drop these terms.

We change the integral path from $|x_\sigma - i| = 0+$ into $(-\infty, \infty)$. From (2.10), we have

$$\begin{aligned} (2.8) = & \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \left| \frac{\partial(I_1, I_2)}{\partial(x_1, x_2)} \right| \exp\left(-\beta \sum_{m=1}^{2} \frac{2}{x_m^2+1} \right) \mathrm{d}x_1 \, \mathrm{d}x_2 + \int_{-\infty}^{\infty} \left(\frac{8L}{(x+i)^2+4} \right) \\ & \times \exp\left(-\beta \frac{4}{(x+i)^2+4} \right) \frac{\mathrm{d}x}{2\pi}. \end{aligned} \tag{2.11}$$

The second term in the above represents a residue which the modification of the integral path generates.

We shift the integral path of the variables x in (2.11) from $(-\infty, \infty)$ to $(-\infty - i, \infty - i)$, and rewrite variables x into $x - i$,

$$(2.8) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \left| \frac{\partial(I_1, I_2)}{\partial(x_1, x_2)} \right| \exp\left(-\beta \sum_{m=1}^{2} \frac{2}{x_m^2+1} \right) \mathrm{d}x_1 \, \mathrm{d}x_2 + \int_{-\infty}^{\infty} \left(\frac{8L}{x^2+4} \right) \exp\left(-\beta \frac{4}{x^2+4} \right) \frac{\mathrm{d}x}{2\pi}. \tag{2.12}$$

We purposely write this obvious modification in order to compare this procedure with that in case $M \geqslant 3$.

Using the expression (2.12) in (2.6) and substituting the Jacobian explicitly, we obtain

$$2Z_2 e^{-\beta h 2} = \int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\left|\frac{\partial(I_1,I_2)}{\partial(x_1,x_2)}\right|\exp\left(-\beta\sum_{m=1}^{2}\frac{2}{x_m^2+1}\right)dx_1\,dx_2+\int_{-\infty}^{\infty}\left(\frac{8L}{x^2+4}\right)\exp\left(-\beta\frac{4}{x^2+4}\right)\frac{dx}{2\pi}$$
$$-\int_{-\infty}^{\infty}\left(\frac{2L}{x^2+1}\right)\exp\left(-\beta\frac{4}{x^2+1}\right)\frac{dx}{2\pi}.$$

$$=\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{2L}{x_1^2+1}\,\frac{2L}{x_2^2+1}\exp\left(-\beta\sum_{m=1}^{2}\frac{2}{x_m^2+1}\right)dx_1\,dx_2+\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\left(\frac{2L}{x_1^2+1}\right.$$
$$\left.+\frac{2L}{x_2^2+1}\right)\frac{-4L}{(x_1^2-x_2^2)+4}\exp\left(-\beta\sum_{m=1}^{2}\frac{2}{x_m^2+1}\right)dx_1\,dx_2+2\int_{-\infty}^{\infty}\left(\frac{4L}{x^2+4}\right)$$
$$\times\exp\left(-\beta\frac{4}{x^2+4}\right)\frac{dx}{2\pi}-\frac{1}{2}\int_{-\infty}^{\infty}\left(\frac{4L}{x^2+1}\right)\exp\left(-\beta\frac{4}{x^2+1}\right)\frac{dx}{2\pi}. \tag{2.13}$$

This formula corresponds to (1.3) for $M=2$. A remark is in order: Because of the same reason as we neglect the terms corresponding to $m_1 \neq 0$ or $m_2 \neq 0$, we drop the terms corresponding to $m \neq 0$ in the second term of (2.6) by taking the thermodynamic limit.

III. DERIVATION OF Z_M FROM BETHE EQUATIONS

In order to explain our analysis of (1.2) for arbitrary M case, we need several symbols and notations. Definitions of symbols are placed before we first use them. To make clear the extension from $M=2$, we refer to the corresponding expression by writing, for instance, cf. (2.8).

With the eigenenergies E (1.4), Z_M is written as

$$M!Z_M e^{-\beta h M} = \sum \exp\left(-\beta\sum_{m=1}^{M}\frac{2}{x_m^2+1}\right) \tag{3.1}$$

[cf. (2.1)]. Here, Σ without subscript means a summation over all the different physical solutions of the Bethe equations (1.5). It is interpreted as a summation with respect to a set of integers $\{I_m\}$ corresponding to a physical solution, where $\{I_m\}$ is related to $\{x_m\}$ by

$$\left[\frac{x_m+i}{x_m-i}\right]^L = e^{-2\pi i I_m}\prod_{m'\neq m}\left[\frac{x_m-x_{m'}+2i}{x_m-x_{m'}-2i}\right] \tag{3.2}$$

[cf. (2.2)]. We call that a solution of the Bethe equation is a physical solution if and only if any two pseudomomenta x_m of the solution do not take same value. The words different, and same value are defined in the same way as in $M=2$ case.

Definition $\Theta(\sigma)$*:* Let σ be a set which has a finite number of elements. $\Theta(\sigma)$ denotes all the patterns of division of a set σ. A pattern of division θ is a set with elements each of which is a cluster. The cluster σ' is one of the pieces into which a set σ is divided, and the cluster is also regarded as a set

$$\Theta(\sigma)=\left\{\ \theta\ \middle|\ \sigma=\bigoplus_{\sigma'\in\theta}\sigma'\ \right\}. \tag{3.3}$$

In case of $\sigma=\{1,2,\ldots,n\}$, we write Θ_n for $\Theta(\{1,2,\ldots,n\})$ for simplicity.

Definition N_σ*:* Let σ be a set or a sequence which has a finite number of elements. The number of elements of a set or a sequence σ is denoted by N_σ.

By use of the above symbols, (3.1) can be rewritten as

$$M!Z_M e^{-\beta hM} = \sum_{\theta \in \Theta_M} \mu(\hat{0}_M, \theta) \sum_{\{I_\sigma\}} e^{-\beta E_\theta} \tag{3.4}$$

[cf. (2.3)], where $\mu(\hat{0}_M, \theta)$ and E_θ are, respectively, defined as

$$\mu(\hat{0}_M, \theta) \equiv \prod_{\sigma \in \theta} (-)^{N_\sigma - 1}(N_\sigma - 1)!, \tag{3.5}$$

$$E_\theta \equiv \sum_{\sigma \in \theta} \frac{2N_\sigma}{x_\sigma^2 + 1}, \quad \theta \in \Theta_M. \tag{3.6}$$

In (3.4), $\Sigma_{\{I_\sigma\}}$ means a summation over all the solutions of equations

$$\left[\frac{x_\sigma + i}{x_\sigma - i}\right]^L = e^{-2\pi i I_\sigma} \prod_{\sigma' \in \theta, \neq \sigma} \left[\frac{x_\sigma - x_{\sigma'} + 2i}{x_\sigma - x_{\sigma'} - 2i}\right]^{N_{\sigma'}}, \quad \sigma \in \theta. \tag{3.7}$$

We note that Eqs. (3.7) are Eqs. (3.2) with the restrictions

$$x_m = x_\sigma, \quad I_m = I_\sigma, \quad m \in \sigma. \tag{3.8}$$

In other words, (3.7) for θ which satisfies $N_\theta = M$ is equivalent to (3.2). Then, the difference between (3.1) and the term corresponding to the θ in (3.4) is the sum over nonphysical states with respect to (3.2). And, extinction of nonphysical states from the sum is realized by the coefficients $\Sigma_{\theta \in \Theta_M} \mu(\hat{0}_M, \theta)$. The function $\mu(\hat{0}_M, \theta)$ is a special case of the Möbius function $\mu(\theta', \theta)$ which comes from a natural definition of partial order among elements in Θ_M. In this way, the equivalence of (3.1) and (3.4) can be regarded as the Möbius inversion formula.[11,12]

The sum in (3.4) is replaced by integrals

$$M!Z_M e^{-\beta hM} = \sum_{\theta \in \Theta_M} \mu(\hat{0}_M, \theta) \int e^{-\beta E_\theta} \prod_{\sigma \in \theta} \mathrm{d}I_\sigma \tag{3.9}$$

[cf. (2.6)]. Here, we have applied the Poisson formula, and neglected higher order terms of the form e^{-cL} which do not contribute to Z_M in the thermodynamic limit. It is important to pay attention to the integral paths. We define the path of the multiple integral in (3.9) depending on θ. The integral path is a manifold on which $\{I_\sigma\}$ is a set of real numbers and $\{x_\sigma\}$ are continuously distributed. Concretely, the integral path for θ is an N_θ-dimensional surface defined by conditions,

$$\left| \left(\frac{x_\sigma - i}{x_\sigma + i}\right)^L \prod_{\sigma' \in \theta, \neq \sigma} \left(\frac{x_\sigma - x_{\sigma'} + 2i}{x_\sigma - x_{\sigma'} - 2i}\right)^{N_{\sigma'}} \right| = 1. \tag{3.10}$$

The orientation of the integral path is chosen so that the value of an integral $\int \Pi \mathrm{d}I_\sigma$ for any part of the integral path is positive.

We introduce integrals

$$\int e^{-\beta E_\theta} \prod_{\sigma \in \theta} \mathrm{d}I_\sigma, \tag{3.11}$$

along the integral path

$$\left|\left(\frac{x_\sigma - i}{x_\sigma + i}\right)^L \prod_{\sigma' \in \theta, \neq \sigma} \left(\frac{x_\sigma - x_{\sigma'} + 2i}{x_\sigma - x_{\sigma'} - 2i}\right)^{N_{\sigma'}}\right| = A_\sigma, \quad \sigma \in \theta \tag{3.12}$$

[cf. (2.8) and (2.9)]. The relation between x_σ and I_σ is defined by (3.7) and E_θ is defined by (3.6). The integrals (3.11) do not depend on A_σ in case $0 < A_\sigma < \infty$ due to the same reason as in the case $M = 2$. Note again that we define the orientation of the path so that an integral $\int \Pi \mathrm{d}I_\sigma$ for any part of the path is positive.

Therefore, we can change the integral path (3.10) in the multiple integral (3.9) into the path (3.12). By defining A_σ as a set of sufficiently small real numbers, we can rewrite (3.9) as

$$(3.9) = \sum_{\theta \in \Theta_M} \mu(\hat{0}_M, \theta) \left[\prod_{\sigma \in \theta} \int_{|x_\sigma - i| = 0+} \mathrm{d}x_\sigma\right] \left|\frac{\partial I_\sigma}{\partial x_\sigma}\right|_{L,\theta} e^{-\beta E_\theta} \tag{3.13}$$

[cf. (2.10)], where $|x_\sigma - i| = 0+$ indicates the integral path that x_σ turns around a point i anticlockwise. To be precise, there remain other integral paths in the limit $A_\sigma \to 0$, but all the integrals for these paths cancel out each other.

Definition $\Lambda(\theta)$: Let θ be a set with a finite number of elements. We denote by $\Lambda(\theta)$ all the patterns of connection of the set θ. What we call a pattern of connection satisfies the following two conditions. (1) Any two elements of θ are connected or not. Simply, there is no multiple connection. (2) There is no closed path in the connections. Then, a pattern of connection λ is a set of elements each of which corresponds to a connection η. To summarize, $\Lambda(\theta)$ satisfies conditions,

$$\text{if} \quad \eta \in \lambda \in \Lambda(\theta), \quad \text{then} \quad \eta = \{\sigma, \sigma'\}, \quad \sigma, \sigma' \in \theta,$$

$$\text{if} \quad \{\sigma_1, \sigma_2\}, \{\sigma_2, \sigma_3\}, \ldots, \{\sigma_{m-1}, \sigma_m\} \in \lambda \in \Lambda(\theta), \quad \text{then} \quad \{\sigma_1, \sigma_m\} \notin \lambda, \tag{3.14}$$

and has the most elements of all sets which satisfy the above conditions.

Definition $G_\theta(\lambda)$: Let θ be a set with a finite number of elements, and $\lambda \in \Lambda(\theta)$. $G_\theta(\lambda)$ is an element of $\Theta(\theta)$. In other words, $G_\theta(\lambda)$ is a pattern of division of θ. We call that σ and σ' in θ are indirectly connected by λ when σ is linked to σ' through one or some connections in λ. Two elements in θ are indirectly connected by λ if and only if there is a cluster $\theta' \in G_\theta(\lambda)$ containing the two elements. Precisely, $G_\theta(\lambda)$ satisfies the conditions,

$$G_\theta(\lambda) \in \quad \Theta(\theta)$$

$$\text{if} \quad \{\sigma, \sigma'\} \in \lambda, \quad \text{then} \quad \sigma, \sigma' \in \theta' \in G_\theta(\lambda), \tag{3.15}$$

and has the most elements of all sets which satisfy the conditions.

Definition $\tilde{\Theta}(\theta)$: Let θ be a set with a finite number of elements. A set $\tilde{\Theta}(\theta)$ consists of all elements $\tilde{\zeta}$ satisfying the following conditions. First, $\tilde{\zeta}$ is a set of sequences as elements. Second, all the elements in the sequences are in θ. Third, a set of sets ζ derived from $\tilde{\zeta}$ is in $\Theta(\theta)$. Here, ζ is derived from $\tilde{\zeta}$ when we replace sequences in $\tilde{\zeta}$ with sets by ignoring the order of the sequences. Note that the number of $\tilde{\zeta}$'s which become a ζ by the above procedure is $\Pi_{\theta' \in \zeta} N_{\theta'}!$.

Using these symbols, we can change the integral path in (3.13) from $|x_\sigma - i| = 0+$ into $[-\infty + i \min(\sigma_1)\delta, \infty + i \min(\sigma_1)\delta]$;

$$
\begin{aligned}
(3.9)=&\sum_{\theta\in\Theta_M}\sum_{\tilde{\zeta}\in\tilde{\Theta}(\theta)}\sum_{\lambda\in\Lambda(\tilde{\zeta})}\left[\prod_{(\sigma_1,\sigma_2,\ldots)=\tilde{\theta}\in\tilde{\zeta}}\int_{-\infty+i\min(\sigma_1)\delta}^{+\infty+i\min(\sigma_1)\delta}\frac{dx_{\tilde{\theta}}}{2\pi}\right]\\
&\times\left[\prod_{\tilde{\zeta}'\in G_{\tilde{\zeta}}(\lambda)}\left(\sum_{\tilde{\theta}\in\tilde{\zeta}'}\sum_{\sigma_m\in\tilde{\theta}=(\sigma_1,\ldots)}\frac{2N_{\sigma_m}L}{(x_{\tilde{\theta}}+2(m-1)i)^2+1}\right)\right]\\
&\times\left[\prod_{\{\tilde{\theta},\tilde{\theta}'\}\in\lambda}\left(\sum_{\sigma_m\in\tilde{\theta}=(\sigma_1,\ldots)}\sum_{\sigma'_{m'}\in\tilde{\theta}'=(\sigma'_1,\ldots)}\frac{-4N_{\sigma_m}N_{\sigma'_{m'}}}{(x_{\tilde{\theta}}-x_{\tilde{\theta}'}+2(m-m')i)^2+4}\right)\right]\\
&\times\exp\left(-\beta\sum_{\tilde{\theta}\in\tilde{\zeta}}\sum_{\sigma_m\in\tilde{\theta}=(\sigma_1,\ldots)}\frac{2N_{\sigma_m}}{(x_{\tilde{\theta}}+2(m-1)i)^2+1}\right)\\
&\times\prod_{(\sigma_1,\ldots)=\tilde{\theta}\in\tilde{\zeta}}\left[(-)^{N_{\sigma_1}-1}(N_{\sigma_1}-1)!N_{\sigma_1}^{-1}\prod_{\sigma_{m>1}\in\tilde{\theta}}\right.\\
&\left.\times\left[\sum_{\theta'\in\Theta(\sigma_m)}N_{\sigma_{m-1}}^{N_{\theta'}}\prod_{\sigma'\in\theta'}(-)^{N_{\sigma'}-1}(N_{\sigma'}-1)!\right]\right]
\end{aligned}
\tag{3.16}
$$

[cf. (2.11)], where $\min(\sigma_1)$ means the smallest integer in the set σ_1. In (3.16), we have substituted an explicit expression of the Jacobian,

$$
(2\pi)^{N_\theta}\left|\frac{\partial I_\sigma}{\partial x'_\sigma}\right|_{L,\theta}\equiv\left[\prod_{\sigma\in\theta}N_\sigma\right]^{-1}\sum_{\lambda\in\Lambda(\theta)}\left[\prod_{\{\sigma,\sigma'\}\in\lambda}-\frac{4N_\sigma N_{\sigma'}}{(x_\sigma-x_{\sigma'})^2+4}\right]\prod_{\theta'\in G_\theta(\lambda)}\left[\sum_{\sigma\in\theta'}\frac{2N_\sigma L}{x_\sigma^2+1}\right].
\tag{3.17}
$$

A remark is in order. In (3.16), the series $\Sigma_{\tilde{\zeta}\ldots}$ with respect to $\tilde{\zeta}$ can be divided into two parts. One is a set in which all elements have only one element, and the other contains the rest. The former is a set of terms corresponding to (3.13) with an integral path $(-\infty,\infty)$. The latter is a set of terms corresponding to residues which the modification of the integral path generates.

Definition $\bar{\Theta}(\theta)$*:* Let θ be a set which has a finite number of sets as elements. $\bar{\Theta}(\theta)$ consists of all elements ζ satisfying the following two conditions. First, ζ is in $\Theta(\theta)$. Second, any set θ' in ζ satisfies the condition that all sets as elements in the set θ' have the same number of elements. Then,

$$
\bar{\Theta}(\theta)=\{\zeta\in\Theta(\zeta)|N_\sigma=N_{\sigma'},\quad \sigma,\sigma'\in\theta'\in\zeta\}.
\tag{3.18}
$$

We transform the integral path of a variable $x_{\tilde{\theta}}$ in (3.16) from $[-\infty+i\min(\sigma_1)\delta,+\infty+i\min(\sigma_1)\delta]$ to $[-\infty-(N_{\tilde{\theta}}-1)i,+\infty-(N_{\tilde{\theta}}-1)i]$, and change variables $x_{\tilde{\theta}}$ into $x_{\tilde{\theta}}-(N_{\tilde{\theta}}-1)i$. Then, we obtain

$$
M!Z_M e^{-hM}=\sum_{\theta\in\Theta_M}\left[\prod_{\sigma\in\theta}N_\sigma!\right]\sum_{\zeta\in\Theta(\theta)}\mu(\hat{0}_\theta,\zeta)\left[\prod_{\theta'\in\zeta}\int_{-\infty}^{\infty}dx_{\theta'}\right]\left|\frac{\partial I}{\partial x}\right|_{L,\zeta}e^{-\beta E(\zeta)}
\tag{3.19}
$$

[cf. (2.12)] and then [cf. (2.13)] where

$$
\mu(\hat{0}_\theta,\zeta)\equiv\prod_{\theta'\in\zeta}(-)^{N_{\theta'}-1}(N_{\theta'}-1)!,
\tag{3.20}
$$

$$
E(\zeta)\equiv\sum_{\theta'\in\zeta}\frac{2N_{\theta'}M_{\theta'}}{x_{\theta'}^2+M_{\theta'}^2},
\tag{3.21}
$$

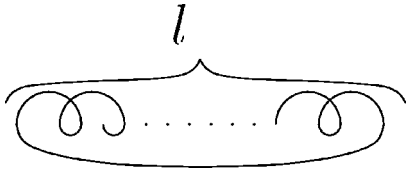

FIG. 1. l-toron.

$$(2\pi)^{N_\zeta}\left|\frac{\partial I}{\partial x}\right|_{L,\zeta} \equiv \left[\prod_{\theta'\in\zeta} N_{\theta'}^{-1}\right]\sum_{\lambda\in\Lambda(\zeta)}\left[\prod_{\zeta'\in G_\zeta(\lambda)}\left(\sum_{\theta'\in\zeta'}\frac{2N_{\theta'}M_{\theta'}L}{x_{\theta'}^2+M_{\theta'}^2}\right)\right] \times\left[\prod_{\{\theta',\theta''\}\in\lambda}(-N_{\theta'}N_{\theta''})K_{M_{\theta'},M_{\theta''}}(x_{\theta'}-x_{\theta''})\right], \tag{3.22}$$

with

$$K_{n,m}(x)\equiv\begin{cases}\kappa_{|n-m|}(x)+2\kappa_{|n-m|+2}(x)+\cdots+2\kappa_{n+m-2}(x)+\kappa_{n+m}(x), & n\neq m,\\ 2\kappa_2(x)+\cdots+2\kappa_{2n-2}(x)+\kappa_{2n}(x), & n=m,\end{cases} \tag{3.23}$$

and

$$\kappa_n(x)\equiv\frac{2n}{x^2+n^2}. \tag{3.24}$$

Contrary to the $M=2$ case, this modification of the integral paths is not trivial in general M case, because many residues are generated by the modification. In this way, we have shown the equivalence of (3.9) and (3.19), and therefore have proved (1.3). This completes the main purpose of this paper. We remark that (3.19) is the expression which we suppose Z_M to be in the previous paper.[9]

IV. GRAPH REPRESENTATION

We further develop a graphical representation of Z_M. We call an l times rolled coil an *l-toron* (Fig. 1), and call an m times repeated l-toron an l^m-toron (Fig. 2). Therefore, l^1-toron is simply an l-toron. The terminology ''toron'' has been introduced in the theory of quantum cluster expansions.[13,14] We call a connection of two torons a *branch*. The *tree* consists of a toron or torons connected by branches. The *forest* consists of the trees. We denote by $\mathcal{W}_M$ a set of all the forests which satisfy the condition that M is the sum of the number of rolls multiplied by the number of repetitions for torons. Figure 3 illustrates all the elements in $\mathcal{W}_2$. Remark that there are four types of forest in $\mathcal{W}_2$. It turns out that each forest in $\mathcal{W}_2$ corresponds to a term in (2.13).

In terms of these terminologies, we may rewrite (3.19) as

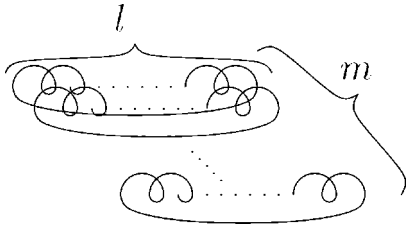

FIG. 2. l^m-toron.

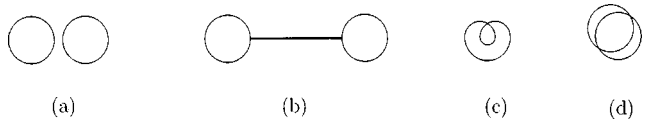

FIG. 3. A set of the forests, $\mathcal{W}_2$. (a) Two trees each of which consists of a 1-toron. (b) A tree where two 1-torons are connected by a branch. (c) A 2-toron, (d) 1^2-toron.

$$Z_M e^{-\beta h M} = \sum_{f \in \mathcal{W}_M} \frac{\mathrm{Sym}(f)}{M!} \prod_{t \text{ in the forest } f} \mathcal{S}(t). \tag{4.1}$$

Here, $\mathrm{Sym}(f)$ indicates a symmetrical factor of the forest. That is, $\mathrm{Sym}(f)$ means the number of different ways in which a set $\{1,\ldots,M\}$ can be distributed to all the torons of f at a time, on the condition that ml elements are placed in an l^m-toron. For example,

$$\mathrm{Sym}(\circ) = 1, \quad \mathrm{Sym}(\circ\!-\!\circ) = 1, \quad \mathrm{Sym}(\text{⊙}) = 1, \quad \mathrm{Sym}(\text{◎}) = 1. \tag{4.2}$$

From (3.19), we can show that $\mathcal{S}(t)$ in (4.1) is given as follows:

$$\mathcal{S}(t) \equiv \left(\prod_{\omega} (M_\omega N_\omega)! (-1)^{N_\omega - 1} N_\omega^{n(\omega,t)-2} \right) \int \prod_{\omega} \frac{dx_\omega}{2\pi} L \left(\sum_{\omega} \frac{2N_\omega M_\omega}{x_\omega^2 + M_\omega^2} \right) \left(\prod_{b \in \Xi(t)} - K_{M_{\omega_\alpha(b)}, M_{\omega_\beta(b)}} (x_{\omega_\alpha(b)} - x_{\omega_\beta(b)}) \right) e^{-\beta(\Sigma_\omega [2N_\omega M_\omega / (x_\omega^2 + M_\omega^2)])}. \tag{4.3}$$

We explain notations in (4.3): M_ω denotes the number of repetitions for toron ω, N_ω the number of rolls for toron ω, and $\Xi(t)$ a set of all the branches contained in a tree t. $n(\omega,t)$ is the number of branches with which the toron ω is connected in the tree t. $\omega_\alpha(b)$ and $\omega_\beta(b)$ denote two end-torons connected by a branch b. And Σ_ω (or Π_ω) indicates a sum (or a product) with respect to all the torons ω in the tree t. For example,

$$\text{(a)} \quad [\mathcal{S}(\text{●})]^2 = \left[((1\times 1)!(-1)^0 1^{-2}) \times \int \frac{dx_\omega}{2\pi} L \times \frac{2}{x_\omega^2 + 1} \times e^{-\beta[2/(x_\omega^2+1)]} \right]^2, \tag{4.4}$$

$$\text{(b)} \quad \mathcal{S}(\circ\!-\!\circ) = ((1\times 1)!(-1)^0 1^{-1} \times (1\times 1)!(-1)^0 1^{-1}) \times \int \frac{dx_{\omega_1}}{2\pi} \frac{dx_{\omega_2}}{2\pi} L \times \left(\frac{2}{x_{\omega_1}^2 + 1} + \frac{2}{x_{\omega_2}^2 + 1} \right) \times (-K_{11}(x_{\omega_1} - x_{\omega_2})) e^{-\beta([2/(x_{\omega_1}^2+1)] + [2/(x_{\omega_2}^2+1)])}, \tag{4.5}$$

$$\text{(c)} \quad \mathcal{S}(\text{⊙}) = ((1\times 2)!(-1)^1 2^{-2}) \times \int \frac{dx_\omega}{2\pi} L \times \frac{4}{x_{\omega_1}^2 + 1} \times e^{-\beta([4/(x_{\omega_1}^2+1)])}, \tag{4.6}$$

$$\text{(d)} \quad \mathcal{S}(\text{◎}) = ((2\times 1)!(-1)^0 1^{-2}) \times \int \frac{dx_\omega}{2\pi} L \times \frac{4}{x_{\omega_1}^2 + 4} \times e^{-\beta([4/(x_{\omega_1}^2+4)])}. \tag{4.7}$$

Substitution of (4.2) and the above expressions into (4.1) gives Eq. (2.13).

As examples, we list graphical representations of $Z_1 \sim Z_4$,

$$Z_1 e^{-\beta h} = \bigcirc, \tag{4.8}$$

$$Z_2 e^{-\beta h 2} = \tfrac{1}{2}\bigcirc\bigcirc + \tfrac{1}{2}\bigcirc\!\!-\!\!\bigcirc - \tfrac{1}{4}\,\textcircled{\scriptsize 0} + \textcircled{\scriptsize 0}, \tag{4.9}$$

$$Z_3 e^{-\beta h 3} = \tfrac{1}{6}\,\bigcirc\bigcirc\bigcirc + \tfrac{1}{2}\,\bigcirc\!\!-\!\!\bigcirc\bigcirc - \tfrac{1}{4}\,\textcircled{\scriptsize 0}\bigcirc + \textcircled{\scriptsize 0}\textcircled{\scriptsize 0} + \tfrac{1}{2}$$
$$- \tfrac{1}{2}\,\textcircled{\scriptsize 0}\!\!-\!\!\bigcirc + \textcircled{\scriptsize 0}\!\!-\!\!\bigcirc + \tfrac{1}{9}\,\textcircled{\scriptsize 00} + \textcircled{\scriptsize 0}\textcircled{\scriptsize 0}\ . \tag{4.10}$$

The coefficients of trees are $\mathrm{Sym}(f)/M!$ multiplied by the coefficients of $\mathcal{S}(t)$, i.e.,

$$\left(\prod_{\omega} (M_\omega N_\omega)! (-1)^{N_\omega - 1} N_\omega^{n(\omega,t)-2} \right). \tag{4.11}$$

V. A RELATION BETWEEN Z_M AND THE STRING HYPOTHESIS

The function (3.22) is the Jacobian between $\{x_\theta\}$ and $\{I_\theta\}$ defined by the relations,

$$\left[\frac{x_{\theta'} + M_{\theta'} i}{x_{\theta'} - M_{\theta'} i} \right]^L = e^{-2\pi i I_{\theta'}} \prod_{\theta'' \in \zeta, \neq \theta'} E_{M_{\theta'}, M_{\theta''}}(x_{\theta'} - x_{\theta''})^{N_{\theta''}}, \tag{5.1}$$

where $\theta \in \Theta_M$, $\zeta \in \overline{\Theta}(\theta)$, and

$$E_{n,m}(x) \equiv \frac{[x-(n+m)i][x-|n-m|i]}{[x+(n+m)i][x+|n-m|i]} \prod_{k=1}^{\min(n,m)} \left[\frac{x+(n+m-2k)i}{x-(n+m-2k)i} \right]^2. \tag{5.2}$$

We emphasize the following: We regard the variable I_θ as an integer and interpret the value $x_{\theta'}$ as an $M_{\theta'}$-string center. The relations (5.1) are indeed the equations which are introduced by the string hypothesis on condition that all $N_{\theta' \in \zeta} = 1$. And, each term of (3.21) is the energy corresponding to an $M_{\theta'}$-string in the string hypothesis.

Now, we study Eq. (3.19) again. As we have shown in the previous paper,[9] the expression (3.19) can be derived by summing up the string center equation formally. The derivation is summarized as follows. From the string hypothesis, we have

$$M! Z_M e^{-hM} = \sum_{\theta \in \Theta_M} \left[\prod_{\sigma \in \theta} N_\sigma! \right] \sum_{\zeta \in \overline{\Theta}(\theta)} \mu(\hat{0}_\theta, \zeta) \sum_{\{I_\theta\}} e^{-\beta E(\zeta)}, \tag{5.3}$$

where $\Sigma_{\{I_\theta\}}$ means a summation over all the real number solutions of (5.1) on condition that $\{I_\theta\}$ are integers. Note that the coefficients are derived from the symmetry of the quasiparticles. We can derive

$$\begin{aligned} M! Z_M e^{-hM} &= \sum_{\theta \in \Theta_M} \left[\prod_{\sigma \in \theta} N_\sigma! \right] \sum_{\zeta \in \overline{\Theta}(\theta)} \mu(\hat{0}_\theta, \zeta) \left[\prod_{\theta' \in \zeta} \int \mathrm{d}I_{\theta'} \right] e^{-\beta E(\zeta)} \\ &= \sum_{\theta \in \Theta_M} \left[\prod_{\sigma \in \theta} N_\sigma! \right] \sum_{\zeta \in \overline{\Theta}(\theta)} \mu(\hat{0}_\theta, \zeta) \left[\prod_{\theta' \in \zeta} \int_{-\infty}^{\infty} \mathrm{d}x_{\theta'} \right] \left| \frac{\partial I}{\partial x} \right| e^{-\beta E(\zeta)}, \end{aligned} \tag{5.4}$$

from (5.3) by formally using the formula (2.5), and neglecting the terms which correspond to $m \neq 0$ in the formula (2.5) in the thermodynamic limit, i.e., replacing the sum $\Sigma_{\{I_\theta\}}$ into the integral $\Pi_{\theta' \in \zeta} \int \mathrm{d}I_{\theta'}$. We usually do such a replacement in the thermodynamic limit: e.g., in case of the free Fermion, we use the relation

$$\sum_k \log(1+e^{-\beta k^2}) = L \int \frac{\mathrm{d}k}{2\pi} \log(1+e^{-\beta k^2}). \tag{5.5}$$

The relation (5.4) is obviously equivalent to (3.19). But, there remains a problem with this derivation of (5.4) from the string hypothesis. When we use the Poisson formula (2.5), the orientation of the integral path on the right-hand side of (2.5) should have the following property: the value of an integral $\int \Pi \mathrm{d}I$ for any part of the integral path is positive. Recall that we have defined the orientation of the integral path (3.9) by this condition. The integral path in (5.4), however, does not have this property since the Jacobian $|\partial I/\partial x|$ is not necessarily positive definite. The value of the integral is $O(L^M)$ and the difference between the right-hand side of (5.4) and the value of the integral using the truly oriented integral path is $O(L^{M-1.5})$, where M is the number of up-spins. The solution of this problem is one of the followings: (1) The difference $O(L^{M-1.5})$ does not have any effect on the free energy. (2) The sum of the terms we have dropped in (5.4) is $O(L^{M-1.5})$, i.e., we must not neglect the terms. Note that such neglect in (3.9) has been proved to be valid. (3) The string hypothesis is not true, and a formal replacement of Σ into $\int \mathrm{d}x$ in the thermal Bethe ansatz cancels the error of the string hypothesis.

Note that in the previous paper,[9] we do not claim that the derivation of (3.19) using the string hypothesis is complete, but claim that (3.19) is related to the string hypothesis and the free energy is properly derived when we assume the relation (3.19). On the contrary, in this paper, we have derived (3.19) step by step only assuming the Bethe ansatz equations.

VI. CONCLUSION

In this paper, we have explicitly calculated $\mathrm{Tr}\, e^{-\beta H_M}$ for the one-dimensional XXX Heisenberg model, which is the trace of the Boltzmann weight under the restriction that the number of up-spin M is fixed. This method relies only on the Bethe ansatz equations. Using this method and the result in Ref. 9, we have obtained the free energy, whose expression perfectly agrees with TBA. In a sense, we have generalized the direct method or the Bethe ansatz cluster expansion method[11,12,15] into models with bound states. We emphasize that this derivation of the free energy is independent of QTM, TBA and is free from the string hypothesis. We can replace the Boltzmann weight with some other functions in case that the Boltzmann weight and the functions have the same analyticity. Therefore, it may be possible to calculate some other thermodynamic quantities $\langle A \rangle$ in the same way by replacing the Boltzmann weight $e^{-\beta H}$ with $Ae^{-\beta H}$. A further application of the method to other integrable models is also one of the future problems.

(Received 6 February 2003; accepted 12 May 2003)

Using equivariant bifurcation theory, and on the basis of symmetry considerations independent of the model, we classify square and hexagonally periodic patterns that typically arise when a homeotropic or planar isotropic nematic state becomes unstable, perhaps as a consequence of an applied magnetic or electric field. We relate this to a Landau–de Gennes model for the free energy, and derive dispersion relations in sufficient generality to illustrate the role of up/down symmetry in determining which patterns can arise as a stable bifurcation branch from either initial state. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1598620]

I. INTRODUCTION

There is an extensive amount of literature on spatially periodic pattern-formation in physical and biological systems: see for example the surveys by Cross and Hohenberg (1993) and Cladis and Palffy-Muhoray (1995). The mathematical techniques to analyze the creation and interactions of such patterns often involve reduction of the governing partial differential equations to a finite-dimensional system that captures the essential dynamics near a bifurcation point of a fundamental equilibrium state, followed by a bifurcation analysis to classify the branching of multiple solutions.

The crucial role of *symmetry* in organizing pattern-forming bifurcations has been recognized for some time: see Busse (1962); Buzano and Golubitsky (1983); Golubitsky *et al.* (1984), for example. Indeed, on the basis of symmetry considerations alone, and with some natural nondegeneracy assumptions, a classification of branching behavior for systems with symmetry can be given that is independent of the actual mathematical model. This insight, with the associated technical machinery of group theory and group actions, is the inspiration for the texts such as Golubitsky *et al.* (1988); Chossat and Lauterbach (2000); Golubitsky and Stewart (2002). The general theory provides a framework: in order to make specific predictions of physical behavior exerimental numerical values (or sometimes just their signs) need to be determined, unfortunately not necessarily an easy task.

In this paper we generalize methods that have been previously and successfully applied in other fields (Buzano and Golubitsky, 1983; Golubitsky *et al.*, 1984; Golubitsky *et al.*, 1988; Bressloff *et al.*, 2001a; Golubitsky and Stewart, 2002) to the context of pattern formation in planar liquid crystals. A preliminary version of our results appears in Golubitsky and Chillingworth (2003). We consider periodic planar patterns with square or hexagonal symmetry that can bifurcate from a homeotropic or planar isotropic state. We do not claim to predict experimental conditions under which these states can be observed; rather we set out a dictionary of possibilities on the basis of natural mathematical assumptions. Numerous patterns similar to those we describe have indeed been observed in liquid crystal experiments, see, e.g., de Gennes (1974); Huh *et al.* (2000), but under conditions often quite different from ours. The question of how to detect experimentally

[a)]Electronic mail: drjc@maths.soton.ac.uk
[b)]Electronic mail: mg@uh.edu

the variety of director-field patterns predicted here is one that we are not yet in a position to answer. However, we do give some pointers on dealing with this issue by calculating key aspects of branching behavior for an explicit Landau–de Gennes type model.

II. THE GENERAL STRATEGY

In the Landau theory of phase transitions for a liquid crystal the degree of coherence of alignment of molecules is usually represented by a *tensor order parameter*, a field of symmetric 3×3 tensors $Q(\mathbf{x})$, $\mathbf{x}\in\mathbf{R}^3$ with $\mathrm{tr}(Q)=0$ (Sluckin, 2000). We think of Q as the second moment of a probability distribution for the directional alignment of a rod-like molecule. In a spatially uniform system, Q is independent of $\mathbf{x}\in\mathbf{R}^3$. When $Q=0$ the system is *isotropic*, with molecules not aligned in any particular direction. If there is a preferred direction along which the molecules tend to lie (but with no positional constraints) the liquid crystal is in *nematic* phase. There are many other types of phase involving local and global structures, see Sluckin (2000).

In this paper we consider a thin planar layer of nematic liquid crystal where the top and bottom boundary conditions on this layer are identical. In this situation the symmetries of any liquid crystal model will include planar Euclidean symmetries $\mathbf{E}(2)$ as well as up/down reflection symmetry.

A configuration or *state* of a liquid crystal is often described by a director field (a unit length vector field) that assigns to each point $\mathbf{x}$ in the planar layer a unit vector $\mathbf{n}(\mathbf{x})$ in the direction in $\mathbf{R}^3$ along which molecules tend to align. In this description $\mathbf{n}(\mathbf{x})$ and $-\mathbf{n}(\mathbf{x})$ are not distinguished. We approximate a planar layer by a plane—so for us a liquid crystal state consists of a three-dimensional director field $\mathbf{n}$ defined on $\mathbf{R}^2$.

In the Landau theory the direction of $\mathbf{n}(\mathbf{x})$ is just an eigenvector corresponding to the largest eigenvalue of $Q(\mathbf{x})$—the direction in which a molecule has the ''maximum probability'' of aligning. We shall refer to $Q(\mathbf{x})$ also as the *state* of the system. If $Q(\mathbf{x})$ has two (or three) equal maximum eigenvalues then $\mathbf{n}(\mathbf{x})$ is undefined (a dislocation occurs), whereas the tensor field $Q(\mathbf{x})$ is everywhere defined, continuous and in our case analytic.

In our discussion we assume an initial equilibrium state Q_0 that is $\mathbf{E}(2)$-invariant. Because of translation symmetry such states are spatially uniform and because of rotation symmetry they have the form

$$Q_0=\eta\begin{bmatrix}-1 & 0 & 0\\ 0 & -1 & 0\\ 0 & 0 & 2\end{bmatrix}$$

for some nonzero $\eta\in\mathbf{R}$. For $\eta>0$ the state Q_0 represents a *homeotropic* phase (the state has constant alignment in the vertical direction), whereas for $\eta<0$ it represents a planar *isotropic* liquid crystal (a molecule is equally likely to align in any horizontal direction). The state Q_0 is also invariant under up/down reflection, that is conjugacy by the matrix

$$\tau=\begin{bmatrix}1 & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & -1\end{bmatrix}.$$

We consider models for equilibria that are determined internally by a free energy rather than externally by, say, a magnetic field. Thus, the symmetry group for our discussion is

$$\Gamma=\mathbf{E}(2)\times\mathbf{Z}_2(\tau),$$

since these are the symmetries of both the initial state Q_0 and the model.

Our aim in this paper is to study local bifurcation from Q_0 to states that have spatially varying alignment along the plane. Specifically, we consider bifurcation to states exhibiting spatial peri-

odicity with respect to some planar lattice. Following Golubitsky *et al.* (1988) and Golubitsky and Stewart (2002) we use group representation theory to extract information about nonlinear behavior near bifurcation that is independent of the model.

There is a common approach to all lattice bifurcation problems, which we now describe. This discussion, adapted from Bressloff *et al.* (2001a), will be familiar to anyone who has studied pattern formation in Bénard convection models, although there are minor differences due to the change in context. See Golubitsky *et al.* (1988); Golubitsky and Stewart (2002).

Let λ be a bifurcation parameter and assume that the equations have Q_0 as an equilibrium for all λ. Let L denote the equations linearized about Q_0. In the models, λ is the temperature and bifurcation occurs as λ is decreased.

(1) A linear analysis about Q_0 leads to a *dispersion curve*.

Translation symmetry in a given direction implies that (complex) eigenfunctions have a *plane wave factor* $w_{\mathbf{k}}(\mathbf{x})=e^{2\pi i\mathbf{k}\cdot\mathbf{x}}$ where $\mathbf{k}\in\mathbf{R}^2$. Rotation symmetry implies that the linearized equations have infinite-dimensional eigenspaces; instability occurs simultaneously to all functions $w_{\mathbf{k}}(\mathbf{x})$ with constant $k=|\mathbf{k}|$. The number k is called the *wave number*. Points (k,λ) on the dispersion curve are defined by the maximum values of λ for which an instability of the solution Q_0 to an eigenfunction with wave number k occurs.

(2) Often, the dispersion curve has a unique maximum, that is, there is a *critical* wave number k_* at which the first instability of the homogeneous solution occurs as λ is decreased.

Bifurcation analyses near such points are difficult since the kernel of the linearization is infinite-dimensional. This difficulty can be side-stepped by restricting solutions to the class of possible solutions that are doubly periodic with respect to a planar lattice $\mathcal{L}$.

(3) The symmetries of the bifurcation problem restricted to $\mathcal{L}$ change from Euclidean symmetry in two ways.

First, translations act on the restricted problem modulo $\mathcal{L}$; that is, translations act as a torus $\mathbf{T}^2$. Second, only a finite number of rotations and reflections remain as symmetries. Let the *holohedry* $H_{\mathcal{L}}$ be the group of rotations and reflections that preserve the lattice. The symmetry group $\Gamma_{\mathcal{L}}$ of the lattice problem is then generated by $H_{\mathcal{L}}$, $\mathbf{T}^2$, as well as (in our case) $\mathbf{Z}_2(\tau)$.

(4) The restricted bifurcation problem must be further specialized. First, a *lattice type* needs to be chosen (in this paper square or hexagonal). Second, the *size* of the lattice must be chosen so that a plane wave with critical wave number k_* is an eigenfunction in the space $\mathcal{F}_{\mathcal{L}}$ of matrix functions periodic with respect to $\mathcal{L}$.

Those $\mathbf{k}\in\mathbf{R}^2$ for which the scalar plane wave $e^{2\pi i\mathbf{k}\cdot\mathbf{x}}$ is $\mathcal{L}$-periodic are called *dual wave vectors*. The set of dual wave vectors is a lattice, called the *dual lattice*, and is denoted by $\mathcal{L}^*$. In this paper we consider only those lattice sizes where the critical dual wave vectors are vectors of shortest length in $\mathcal{L}^*$. Therefore, generically, we expect $\ker L=\mathbf{R}^n$ where n is 4 and 6 on the square and hexagonal lattices, respectively.

(5) Since $\ker L$ is finite-dimensional, we can use Liapunov–Schmidt or center manifold reduction to obtain a system of reduced bifurcation equations on $\mathbf{R}^n$ whose zeros are in 1:1 correspondence with the steady states of the original equation. Moreover, this reduction can be performed so that the reduced bifurcation equations are $\Gamma_{\mathcal{L}}$-equivariant.

(6) Solving the reduced bifurcation equations is still difficult. A partial solution can be found as follows. A subgroup $\Sigma\subset\Gamma_{\mathcal{L}}$ is *axial* if $\dim \mathrm{Fix}(\Sigma)=1$ where

$$\mathrm{Fix}(\Sigma)=\{x\in\ker L:\sigma x=x \quad \forall\sigma\in\Sigma\}.$$

The Equivariant Branching Lemma (Golubitsky *et al.*, 1988) states that generically there exists a branch of solutions corresponding to each axial subgroup. These solution types are then classified by finding all axial subgroups, up to conjugacy.

On general grounds, when restricting attention to bifurcations corresponding to shortest wavelength vectors, we may assume the representation (action) of $\Gamma_{\mathcal{L}}$ to be irreducible: see Golubitsky *et al.* (1988); Chossat and Lauterbach (2000). In Sec. III we show that there are four distinct types of irreducible representation of $\Gamma_{\mathcal{L}}$ that can occur in bifurcations from Q_0. These representations

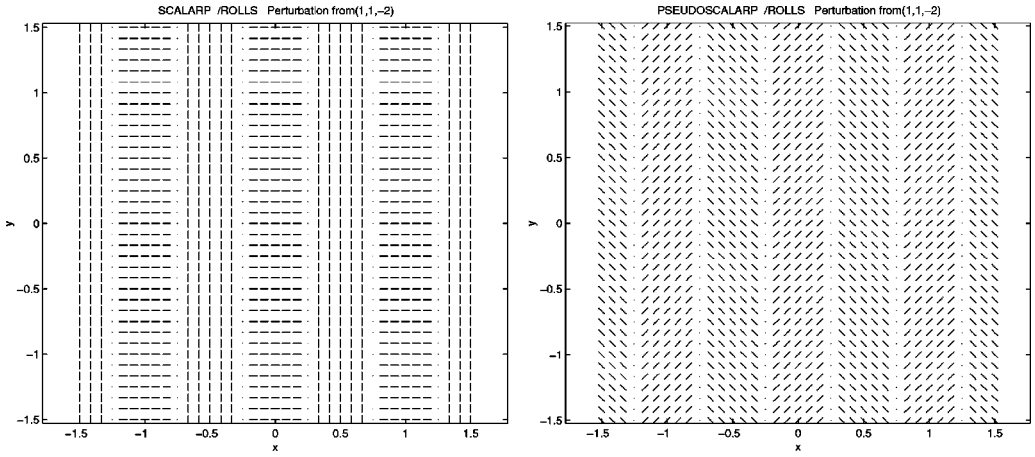

FIG. 1. Stripes from isotropic ($\eta<0$) state with $\tau=+1$ representations: scalar ''martensite'' (left); pseudoscalar ''chevron'' (right). Note that $\cdot$ in the figures indicates points where $Q(\mathbf{x})$ has a double maximum eigenvalue.

are the four combinations of (i) scalar or pseudoscalar (see Bosch Vivancos *et al.*, 1995; Bressloff *et al.*, 2001a; Golubitsky and Stewart, 2002) and (ii) preserve or break τ symmetry. In Sec. III we also compute the axial subgroups for each of these representations and draw pictures of each of the relevant planforms on the square and hexagonal lattices.

Note that line fields near hometropic are almost vertical, whereas line fields near isotropic are almost horizontal. In our figures, where we view the perturbed line fields from above, we see the planar projections of the line field in all cases. We also see the deviation from vertical and, through foreshortening of the line field elements, the deviation from horizontal. However, in this presentation, we cannot distinguish the ''up'' and ''down'' ends of the line field elements. It is an elementary yet curious observation that in Landau models restricted to a planar layer, bifurcations from the homeotropic phase ($\eta>0$) do not lead to clear new patterns unless τ symmetry is broken: the τ symmetry ''freezes'' the director field to the vertical. This point is discussed in more detail in Sec. III. Therefore we present pictures of the four bifurcations from the isotropic case ($\eta<0$) and only the two bifurcations when τ acts as -1 in the homeotropic case ($\eta>0$). The $\tau=+1$ bifurcations in the homeotropic case can lead to patterns in a theory posed on a thickened planar layer. In such a theory, which goes beyond what we present here, the precise form of boundary conditions on the upper and lower boundaries of the layer will determine the pattern types. In the other bifurcations, the contributions to pattern selection of these boundary conditions should be less important.

In fact, the bifurcation theory for each of these four representations of $\Gamma_{\mathcal{L}}$ has been discussed previously in different contexts. It is only the interpretation of eigenfunctions in the context of $Q(\mathbf{x})$ that needs to be computed, along with the pictures of the resulting planforms. More specifically, when τ acts trivially on $\ker \mathsf{L}$ the scalar representation has been used in the study of pattern formation in Rayleigh–Bénard convection by Busse (1962) and Buzano and Golubitsky (1983), and the pseudoscalar representation has been studied by Bosch-Vivancos, Chossat, and Melbourne (1995) and also in the context of geometric visual hallucinations by Bressloff *et al.* (2001b); (2001a). When τ acts nontrivially the two representations have the same matrix generators and although the planforms are different for these two representations the bifurcation theory is identical. Indeed, this theory is just the one studied for Rayleigh–Bénard convection with a midplane reflection by Golubitsky, Swift, and Knobloch (1984).

Perhaps the most interesting patterns that appear from our analysis are the stripes or ''rolls'' (from convection studies) type patterns that bifurcate from the isotropic state when τ symmetry is not broken, that is $\tau=+1$. The scalar pattern is a ''martensite'' pattern whereas the pseudoscalar pattern is a ''chevron'' pattern. See Fig. 1. The fact that such patterns do occur in liquid crystal layers is well known: see, for example, de Gennes (1974), and also Huh *et al.* (2000) from which

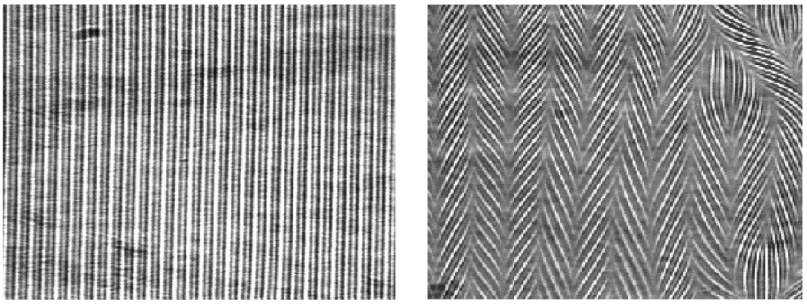

FIG. 2. Rolls (left) and chevrons (right). (Pictures courtesy of J.-H. Huh.)

the pictures in Fig. 2 are taken. However, it is important to emphasize that these patterns were observed under experimental conditions far removed from those to which our theoretical model applies. Moreover, the observed chevrons exhibit additional fine periodic structure (which renders them visible as chevrons and not stripes) that we do not discuss here. We recall that patterns described in this paper are those that can arise close to homeotropic or planar isotropic states.

In Sec. IV we introduce free energies that illustrate that all four representations can be encountered as λ is decreased, although in our model only two of them can be the first bifurcation from homeotropy while only the other two can be the first bifurcation from isotropy. (It is likely that different models will allow other variations.) It then follows from the Equivariant Branching Lemma that each of the axial equilibrium types that we describe in Sec. III is an equilibrium solution to the nonlinear model equations.

III. SPATIALLY PERIODIC EQUILIBRIUM STATES

In this section we list the axial subgroups for each of the four representations of $\Gamma_{\mathcal{L}}$ on the square and hexagonal lattices, and then plot the planforms for the associated bifurcating branches from both the isotropic ($\eta<0$) and homeotropic ($\eta>0$) states. We emphasize that these results depend only on symmetry and can be obtained independently of any particular model. First, we describe the form of the eigenspaces for each of these four representations. Second, we discuss the group actions and the axial subgroups for each of these representations. Finally, we plot the associated direction fields.

A. Linear theory

Let L denote the linearization of the governing system of differential equations at Q_0 [for the free energy model with free energy $\mathcal{F}$ we have $\mathsf{L}=d^2F(Q_0)$]. Bifurcation occurs at parameter values where L has nonzero kernel. We prove that generically, at bifurcation to shortest dual wave vectors, $\ker \mathsf{L}$ has the form given in Theorem 3.1. Let

$$Q^{++}=\begin{bmatrix} a & 0 & 0 \\ 0 & b & 0 \\ 0 & 0 & -a-b \end{bmatrix}, \quad Q^{+-}=\begin{bmatrix} 0 & 0 & i \\ 0 & 0 & 0 \\ i & 0 & 0 \end{bmatrix},$$
$$Q^{-+}=\begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \quad Q^{--}=\begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & i \\ 0 & i & 0 \end{bmatrix}. \tag{1}$$

In the double superscript on Q, the first $\pm$ refers to scalar or pseudoscalar representation and the second $\pm$ refers to the action of τ. In Table I we also fix the generators of the lattice and its dual lattice.

TABLE I. Generators for the planar lattices and their dual lattices.

Lattice	ℓ_1	ℓ_2	$\mathbf{k}_1$	$\mathbf{k}_2$	$\mathbf{k}_3=-(\mathbf{k}_1+\mathbf{k}_2)$
Square	(1,0)	(0,1)	(1,0)	(0,1)	—
Hexagonal	$\left(1,\frac{1}{\sqrt{3}}\right)$	$\left(0,\frac{2}{\sqrt{3}}\right)$	(1,0)	$\frac{1}{2}(-1,\sqrt{3})$	$\frac{1}{2}(-1,-\sqrt{3})$

Theorem 3.1: *On the square lattice, let ξ be rotation counterclockwise by $\pi/2$. Then, in each irreducible representation,* $\ker \mathsf{L}$ *is four-dimensional and its elements have the form*

$$z_1 e^{2\pi i \mathbf{k}_1\cdot\mathbf{x}} Q^{\pm\pm} + z_2\, e^{2\pi i \mathbf{k}_2\cdot\mathbf{x}}\, \xi\cdot Q^{\pm\pm} + \text{c.c.} \tag{2}$$

for $z_1, z_2 \in \mathbf{C}$, where $Q^{\pm\pm}$ is the appropriate matrix specified in (1), $\xi\cdot Q$ denotes $\xi Q \xi^{-1}$, and c.c. *denotes complex conjugate.*

On the hexagonal lattice, let ξ be rotation counterclockwise by $\pi/3$. Then, in each irreducible representation, $\ker \mathsf{L}$ *is six-dimensional and its elements have the form*

$$z_1 e^{2\pi i \mathbf{k}_1\cdot\mathbf{x}} Q^{\pm\pm} + z_2\, e^{2\pi i \mathbf{k}_2\cdot\mathbf{x}}\, \xi^2\cdot Q^{\pm\pm} + z_3\, e^{2\pi i \mathbf{k}_3\cdot\mathbf{x}}\, \xi^4\cdot Q^{\pm\pm} + \text{c.c.} \tag{3}$$

for $z_1, z_2, z_3 \in \mathbf{C}$.

Proof: Let V and $V_{\mathbf{C}}$ denote the space of (respectively) real and complex 3×3 symmetric matrices with zero trace. Planar translation symmetry implies that eigenfunctions (nullvectors) of L are linear combinations of matrices that have the plane wave form

$$e^{2\pi i \mathbf{k}\cdot\mathbf{x}} Q + \text{c.c.}, \tag{4}$$

where $Q \in V_{\mathbf{C}}$ is a constant matrix and $\mathbf{k} \in \mathbf{R}^2$ is a wave vector. For fixed $\mathbf{k}$ let

$$W_{\mathbf{k}} = \{e^{2\pi i \mathbf{k}\cdot\mathbf{x}} Q + \text{c.c.} : Q \in V_{\mathbf{C}}\} \tag{5}$$

be the ten-dimensional L-invariant real linear subspace consisting of such functions.

Rotations and reflections $\gamma \in \mathbf{O}(2)\times\mathbf{Z}_2(\tau) \subset \mathbf{O}(3)$ act on $W_{\mathbf{k}}$ by

$$\gamma(e^{2\pi i \mathbf{k}\cdot\mathbf{x}} Q) = e^{2\pi i (\gamma\mathbf{k})\cdot\mathbf{x}}\, \gamma Q \gamma^{-1}. \tag{6}$$

When looking for nullvectors we can assume, after rotation, that $\mathbf{k} = k(1,0)$. We can also rescale length so that the dual wave vectors of shortest length have length 1; that is, we can assume that $k=1$.

Bosch Vivancos, Chossat, and Melbourne (1995) observed that reflection symmetries can further decompose $W_{\mathbf{k}}$ into two L-invariant subspaces. To see why, consider the reflection

$$\kappa(x,y,z) = (x,-y,z).$$

Note that the action (6) of κ on $W_{\mathbf{k}}$ (dropping the $+$c.c.) is

$$\kappa(e^{2\pi i \mathbf{k}\cdot\mathbf{x}} Q) = e^{2\pi i \kappa(\mathbf{k})\cdot\mathbf{x}}\, \kappa Q \kappa^{-1} = e^{2\pi i \mathbf{k}\cdot\mathbf{x}}\, \kappa Q \kappa^{-1}.$$

Since $\kappa^2 = 1$, the subspace $W_{\mathbf{k}}$ itself decomposes as

$$W_{\mathbf{k}} = W_{\mathbf{k}}^{+} \oplus W_{\mathbf{k}}^{-}, \tag{7}$$

where κ acts trivially on $W_{\mathbf{k}}^+$ and as minus the identity on $W_{\mathbf{k}}^-$, and each of $W_{\mathbf{k}}^+$ and $W_{\mathbf{k}}^-$ are L invariant. We call functions in $W_{\mathbf{k}}^+$ *even* and functions in $W_{\mathbf{k}}^-$ *odd*. Bifurcations based on even eigenfunctions are called *scalar* and bifurcations based on odd eigenfunctions are called *pseudoscalar*.

A further simplification in the form of Q can be made. Consider $\rho \in \mathbf{SO}(2) \subset \mathbf{O}(3)$ given by $(x,y,z) \mapsto (-x,-y,z)$. Since (dropping the $+$c.c.)

$$\rho(e^{2\pi i \mathbf{k}\cdot\mathbf{x}}Q) = e^{2\pi i \rho\mathbf{k}\cdot\mathbf{x}}\rho Q\rho^{-1} = e^{-2\pi i \mathbf{k}\cdot\mathbf{x}}\rho Q\rho^{-1} = e^{2\pi i \mathbf{k}\cdot\mathbf{x}}\overline{\rho Q\rho^{-1}}$$

the associated action of ρ on $V_{\mathbf{C}}$ is related to the conjugacy action by

$$\rho(Q) = \overline{\rho Q \rho^{-1}}. \tag{8}$$

Since L commutes with ρ and $\rho^2 = 1$, the subspaces of the kernel of L where $\rho(Q) = Q$ and $\rho(Q) = -Q$ are L-invariant. Therefore, we can assume that Q is in one of these two subspaces. Note moreover that translation by $\frac{1}{4}\mathbf{k}$ implies that if $e^{2\pi i \mathbf{k}\cdot\mathbf{x}}Q$ is an eigenfunction then $ie^{2\pi i \mathbf{k}\cdot\mathbf{x}}Q$ is a (symmetry related) eigenfunction. It follows from (8) that if ρ acts as minus the identity on Q, then ρ acts as the identity on iQ. Thus we can assume without loss of generality that up to translational symmetry Q is ρ-invariant, that is Q has the form

$$Q = \begin{bmatrix} a & g & ic \\ g & b & ih \\ ic & ih & -a-b \end{bmatrix},$$

where $a,b,c,g,h \in \mathbf{R}$. Therefore we have proved

Lemma 3.2: Up to symmetry eigenfunctions in $W_{\mathbf{k}}$ have the form

$$e^{2\pi i \mathbf{k}\cdot\mathbf{x}}Q + \text{c.c.}$$

where Q is nonzero, ρ-invariant, and either even or odd.

Lemma 3.2 implies that typically eigenfunctions in $W_{\mathbf{k}}$ lie in one of the two-dimensional subspaces $V_{\mathbf{k}}^+, V_{\mathbf{k}}^-$ of $W_{\mathbf{k}}^+, W_{\mathbf{k}}^-$ that have the form

$$V_{\mathbf{k}}^+ = \{ze^{2\pi i \mathbf{k}\cdot\mathbf{x}}Q^+ : z \in \mathbf{C}\},$$

$$V_{\mathbf{k}}^- = \{ze^{2\pi i \mathbf{k}\cdot\mathbf{x}}Q^- : z \in \mathbf{C}\},$$

where

$$Q^+ = \begin{bmatrix} a & 0 & ic \\ 0 & b & 0 \\ ic & 0 & -a-b \end{bmatrix} \quad \text{and} \quad Q^- = \begin{bmatrix} 0 & g & 0 \\ g & 0 & hi \\ 0 & hi & 0 \end{bmatrix} \tag{9}$$

with the specific values $a,b,c,g,h \in \mathbf{R}$ being chosen by L (cf. Golubitsky and Stewart, 2002, Sec. 5.7).

Moreover, since L commutes with τ we can further split

$$V_{\mathbf{k}}^+ = V_{\mathbf{k}}^{++} \oplus V_{\mathbf{k}}^{+-} \quad \text{and} \quad V_{\mathbf{k}}^- = V_{\mathbf{k}}^{-+} \oplus V_{\mathbf{k}}^{--}$$

into subspaces on which τ acts trivially and by minus the identity, and each of these subspaces is L-invariant. Since

TABLE II. (Left) $\mathbf{D}_4 \dotplus \mathbf{T}^2$ action on square lattice; (right) $\mathbf{D}_6 \dotplus \mathbf{T}^2$ action on hexagonal lattice. Here $[\theta_1,\theta_2]=\theta_1\ell_1+\theta_2\ell_2$ as in Table I. For scalar representation $\epsilon=+1$; for pseudoscalar representation $\epsilon=-1$.

$\mathbf{D}_4$	Action	$\mathbf{D}_6$	Action
$\mathbf{1}$	(z_1,z_2)	$\mathbf{1}$	(z_1,z_2,z_3)
ξ	(z_2,z_1)	ξ	(z_2,z_3,z_1)
ξ^2	(z_1,z_2)	ξ^2	(z_3,z_1,z_2)
ξ^3	(z_2,z_1)	ξ^3	(z_1,z_2,z_3)
κ	$\epsilon(z_1,z_2)$	ξ^4	(z_2,z_3,z_1)
$\kappa\xi$	$\epsilon(z_2,z_1)$	ξ^5	(z_3,z_1,z_2)
$\kappa\xi^2$	$\epsilon(z_1,z_2)$	κ	$\epsilon(z_1,z_3,z_2)$
$\kappa\xi^3$	$\epsilon(z_2,z_1)$	$\kappa\xi$	$\epsilon(z_2,z_1,z_3)$
		$\kappa\xi^2$	$\epsilon(z_3,z_2,z_1)$
		$\kappa\xi^3$	$\epsilon(z_1,z_3,z_2)$
		$\kappa\xi^4$	$\epsilon(z_2,z_1,z_3)$
		$\kappa\xi^5$	$\epsilon(z_3,z_2,z_1)$
$[\theta_1,\theta_2]$	$(e^{-2\pi i\theta_1}z_1,e^{-2\pi i\theta_2}z_2)$	$[\theta_1,\theta_2]$	$(e^{-2\pi i\theta_1}z_1,e^{-2\pi i\theta_2}z_2,e^{2\pi i(\theta_1+\theta_2)}z_3)$

$$\tau Q\tau=\begin{bmatrix} a & g & -ic \\ g & b & -ih \\ -ic & -ih & -a-b \end{bmatrix}$$

we see that $V_{\mathbf{k}}^{\pm\pm}=\{ze^{2\pi i\mathbf{k}\cdot\mathbf{x}}Q^{\pm\pm}:z\in\mathbf{C}\}$, where the matrices $Q^{\pm\pm}$ are as given in (1).

Finally, note that $\ker \mathsf{L}$ is invariant under the action of ξ. It follows that on the square lattice

$$\ker \mathsf{L}=V_{\mathbf{k}}^{\pm\pm}\oplus\xi(V_{\mathbf{k}}^{\pm\pm})$$

whereas on the hexagonal lattice

$$\ker \mathsf{L}=V_{\mathbf{k}}^{\pm\pm}\oplus\xi^2(V_{\mathbf{k}}^{\pm\pm})\oplus\xi^4(V_{\mathbf{k}}^{\pm\pm})$$

thus verifying (2), (3) and completing the proof of Theorem (3.1). □

B. Axial subgroups

The scalar and pseudoscalar actions of $\mathbf{E}(2)$ on the eigenfunctions on the square and hexagonal lattices are computed in Bressloff *et al.* (2001a). The results are given in Table II in terms of the coefficients z_j in (2) and (3).

The axial subgroups for each of the four irreducible representations of $\Gamma_{\mathcal{L}}$ are given in Table III, together with generators $(z_1,z_2)\in\mathbf{C}^2$ or $(z_1,z_2,z_3)\in\mathbf{C}^3$ (fixed vectors) of the corresponding one-dimensional fixed-point subspaces (axial eigenspaces) in $\ker \mathsf{L}$, and descriptions of the associated patterns (planforms).

The results in Table III summarize known results for scalar actions with and without the midplane reflection (Buzano and Golubitsky, 1983; Golubitsky *et al.*, 1984) and the less well known results for pseudoscalar actions (Bosch Vivancos *et al.*, 1995; Bressloff *et al.*, 2001a). See also Golubitsky and Stewart (2002). More precisely, on the hexagonal lattice, the scalar$^+$ action is identical to the action studied in Bénard convection (Busse, 1962; Buzano and Golubitsky, 1983) and the scalar$^-$ action is identical to the one studied in Bénard convection with the midplane reflection (Golubitsky *et al.*, 1984). The pseudoscalar$^+$ action is identical to that studied in Bosch Vivancos *et al.* (1995) and Bressloff *et al.* (2001a), whereas the pseudoscalar$^-$ action is again the same as the one in Bénard convection with the midplane reflection—but with different isotropy subgroups, as Figs. 5 and 6 show.

TABLE III. Summary of axial subgroups. On the hexagonal lattice in the scalar case with $\tau=+1$ the points (1,1,1) and $(-1,-1,-1)$ have the same isotropy subgroup $[\mathbf{D}_6(\kappa,\xi)\oplus\mathbf{Z}_2(\tau)]$—but are not conjugate by any element of $\Gamma_{\mathcal{L}}$. Therefore, the associated eigenfunctions generate different planforms.

Lattice	Planform	Axial isotropy subgroup	Fixed vector
		Scalar representation ($\epsilon=+1$); $\tau=+1$	
Square	Squares	$\mathbf{D}_4(\kappa,\xi)\oplus\mathbf{Z}_2(\tau)$	(1,1)
	Stripes	$\mathbf{Z}_2^2(\kappa\xi^2,\tau)\oplus\mathbf{O}(2)[\theta_2,\kappa]$	(1,0)
Hexagonal	Hexagons$^+$	$\mathbf{D}_6(\kappa,\xi)\oplus\mathbf{Z}_2(\tau)$	(1,1,1)
	Hexagons$^-$	$\mathbf{D}_6(\kappa,\xi)\oplus\mathbf{Z}_2(\tau)$	$(-1,-1,-1)$
	Stripes	$\mathbf{Z}_2^2(\kappa\xi^3,\tau)\oplus\mathbf{O}(2)[\theta_2,\kappa]$	(1,0,0)
		Pseudoscalar representation ($\epsilon=-1$); $\tau=+1$	
Square	Squares	$\mathbf{D}_4(\kappa[\frac{1}{2},\frac{1}{2}],\xi)\oplus\mathbf{Z}_2(\tau)$	(1,1)
	Stripes	$\mathbf{Z}_2^2(\kappa\xi^2[\frac{1}{2},0],\tau)\oplus\mathbf{O}(2)[\theta_2,\kappa[\frac{1}{2},0]]$	(1,0)
Hexagonal	Hexagons	$\mathbf{Z}_6(\xi)\oplus\mathbf{Z}_2(\tau)$	(1,1,1)
	Triangles	$\mathbf{D}_3(\kappa\xi,\xi^2)\oplus\mathbf{Z}_2(\tau)$	(i,i,i)
	Rectangles	$\mathbf{Z}_2^3(\kappa,\xi^3,\tau)$	$(0,1,-1)$
	Stripes	$\mathbf{Z}_2^2(\kappa\xi^3[\frac{1}{2},0],\tau)\oplus\mathbf{O}(2)[\theta_2,\kappa[\frac{1}{2},0]]$	(1,0,0)
		Scalar representation ($\epsilon=+1$); $\tau=-1$	
Square	Squares	$\mathbf{D}_4(\kappa,\xi)\oplus\mathbf{Z}_2(\tau[\frac{1}{2},\frac{1}{2}])$	(1,1)
	Stripes	$\mathbf{Z}_2^2(\kappa\xi^2,\tau[\frac{1}{2},0])\oplus\mathbf{O}(2)[\theta_2,\kappa]$	(1,0)

	Stripes	$\mathbf{Z}_2^2(\kappa\xi^3,\tau[\frac{1}{2},0])\oplus\mathbf{O}(2)[\theta_2,\kappa]$	(1,0,0)
		Pseudoscalar representation ($\epsilon=-1$); $\tau=-1$	
Square	Squares	$\mathbf{D}_4(\tau\kappa,\xi)\oplus\mathbf{Z}_2(\tau[\frac{1}{2},\frac{1}{2}])$	(1,1)
	Stripes	$\mathbf{Z}_2^2(\kappa\xi^2[\frac{1}{2},0],\tau[\frac{1}{2},0])\oplus\mathbf{O}(2)[\theta_2,\kappa[\frac{1}{2},0]]$	(1,0)
Hexagonal	Hexagons	$\mathbf{D}_6(\tau\kappa,\xi)$	(1,1,1)
	Triangles	$\mathbf{D}_6(\tau\kappa,\tau\xi)$	(i,i,i)
	Rectangles	$\mathbf{Z}_2^3(\kappa,\xi^3,\tau[0,\frac{1}{2}])$	$(0,1,-1)$
	Stripes	$\mathbf{Z}_2^2(\kappa\xi^3[\frac{1}{2},0],\tau[\frac{1}{2},0])\oplus\mathbf{O}(2)[\theta_2,\kappa[\frac{1}{2},0]]$	(1,0,0)

C. The planforms

We now consider two-dimensional patterns by disregarding the z coordinate in $\mathbf{x}$ (but not in Q) and restricting attention to equilibrium states that are periodic with respect to a square or hexagonal lattice in the xy plane.

To visualize the patterns of bifurcating solutions we assume a layer of liquid crystal material in the xy plane that to first order has the form

$$Q(\mathbf{x})=Q_0+\varepsilon E(\mathbf{x}),$$

where E is an axial eigenfunction, ε is small, and Q_0 is either isotropic ($\eta=-1$) or homeotropic ($\eta=+1$). At each point (x,y) we represent the director field by a standard-length interval in the eigendirection corresponding to the largest eigenvalue of the symmetric 3×3 matrix $Q(\mathbf{x})$ at $\mathbf{x}=(x,y)$ and we plot only the projection of that interval in the xy plane. In this picture, a line element that degenerates to a point corresponds to a vertical eigendirection.

Suppose first that Q_0 is homeotropic. In this case the associated pattern is an array of points. Moreover, in our simulations no pattern will appear in bifurcations for which $Q(\mathbf{x})$ is fixed by the action of τ. For, if $E(\mathbf{x})\in V_{\mathbf{k}}^{++}$ or $V_{\mathbf{k}}^{-+}$ then

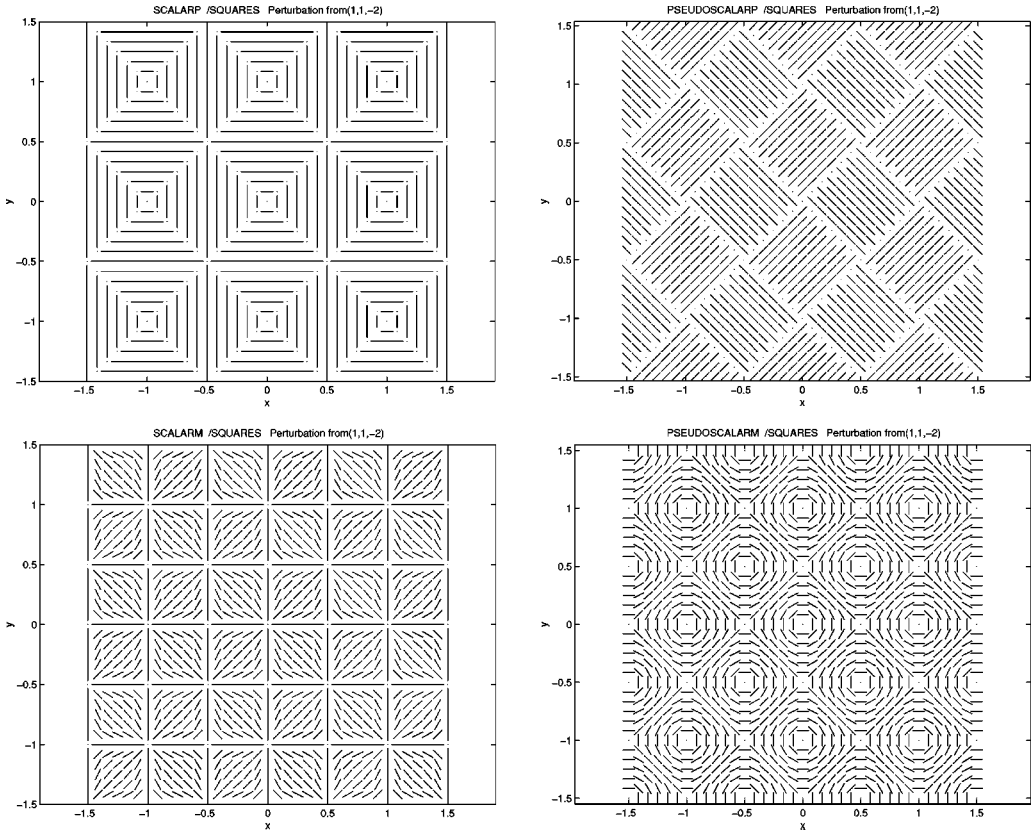

FIG. 3. Square lattice bifurcations from isotropic ($\eta<0$) liquid crystal to square patterns: (upper left) scalar $\tau=+1$; (upper right) pseudoscalar $\tau=+1$; (lower left) scalar $\tau=-1$; (lower right) pseudoscalar $\tau=-1$. Corresponding stripes patterns can be found in Figs. 1 and 7–10.

$$Q(\mathbf{x})=\begin{bmatrix} A & 0 \\ 0 & b \end{bmatrix},$$

where A is a 2×2 block and b is a scalar. Since b is close to 2 (the largest eigenvalue of Q_0) it is also the largest eigenvalue for $Q(\mathbf{x})$ for ε small. Hence, the leading eigendirection (corresponding to the largest eigenvalue) is always vertical and no patterns appear that are determined by changes in eigendirection. Nevertheless, since variation in the vertical eigenvalue of $Q(\mathbf{x})$ represents variation in the propensity of molecules to align vertically it is plausible that indistinct patterns could nevertheless be observed in practice.

Next suppose that Q_0 is planar isotropic. For small ε the director field is nearly horizontal (exactly horizontal if $\tau=+1$) and so our figures represent the pattern fairly accurately. When $\tau=-1$ there are small sinusoidal oscillations in the vertical component of the director field.

Bifurcations from isotropy exhibit lines or points of dislocation (where the director field is undefined) whereas bifurcations from homeotropy do not. In the latter case the director field is near vertical and there are small sinusoidal variations in the horizontal components. In this context the standard ''rolls'' terminology is misleading, as the director field is never horizontal: rather it oscillates about the vertical in a vertical plane and so generates ''stripes.''

In Figs. 3 and 4 we plot solutions corresponding to scalar and pseudoscalar square lattice patterns. In Figs. 5–10 we plot those for a hexagonal lattice. In the planforms obtained by bifurcation from homeotropy $\cdot$ indicates a vertical line element; whereas in the planforms obtained by bifurcation from isotropy $\cdot$ indicates points where $Q(\mathbf{x})$ has a double maximum eigenvalue,

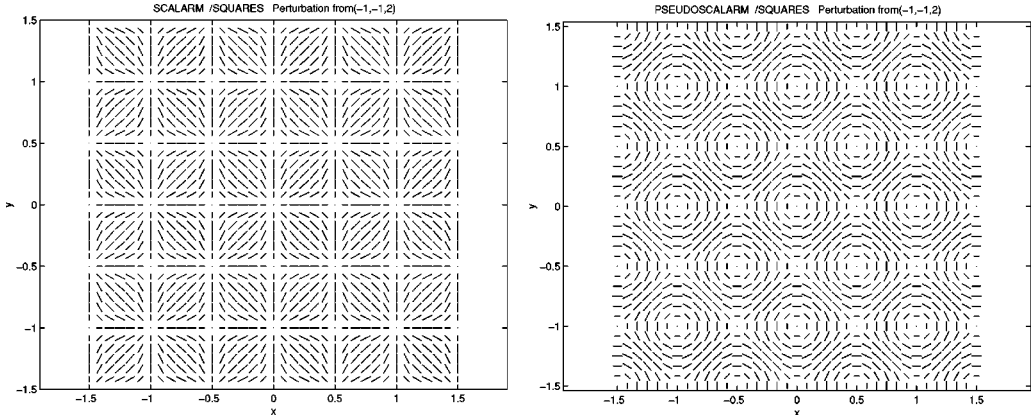

FIG. 4. Square lattice bifurcations from homeotropic ($\eta>0$) to squares with $\tau=-1$: (left) scalar; (right) pseudoscalar. Corresponding stripes patterns can be found in Figs. 5 and 6.

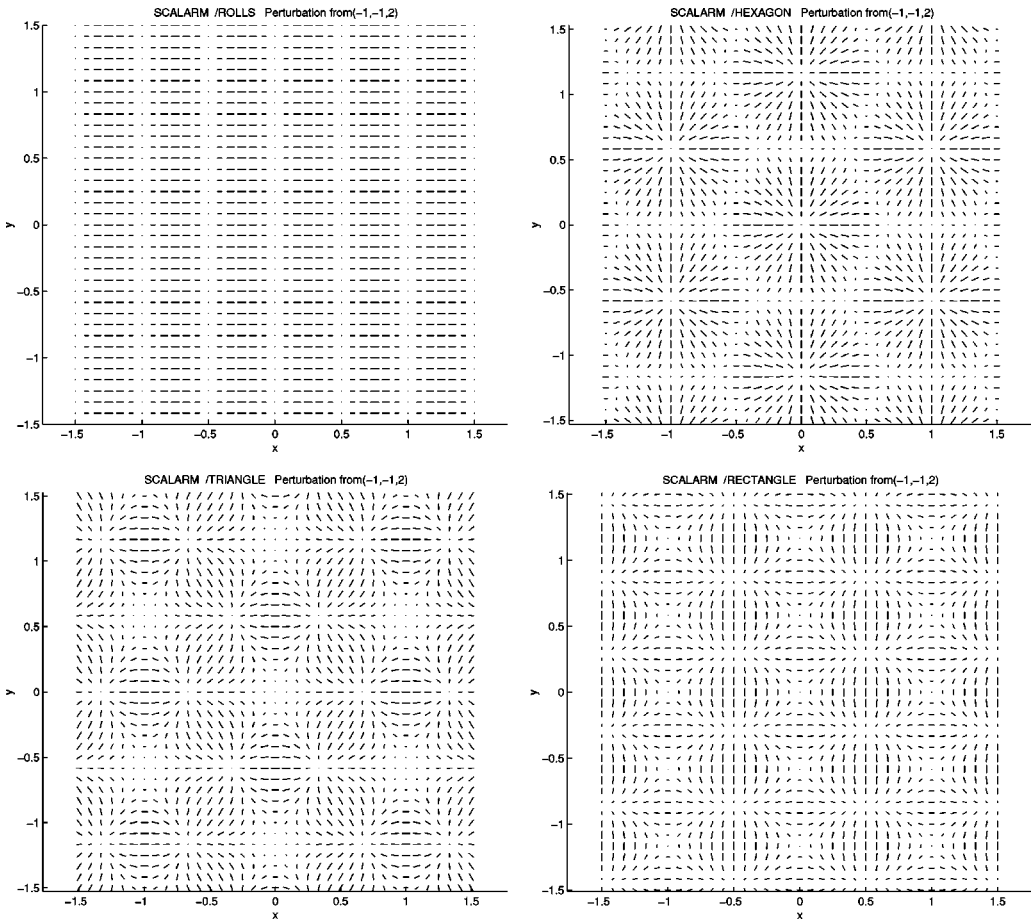

FIG. 5. Hexagonal lattice bifurcations from homeotropic ($\eta>0$) with scalar $\tau=-1$ representation: (upper left) stripes; (upper right) hexagons; (lower left) triangles; (lower right) rectangles.

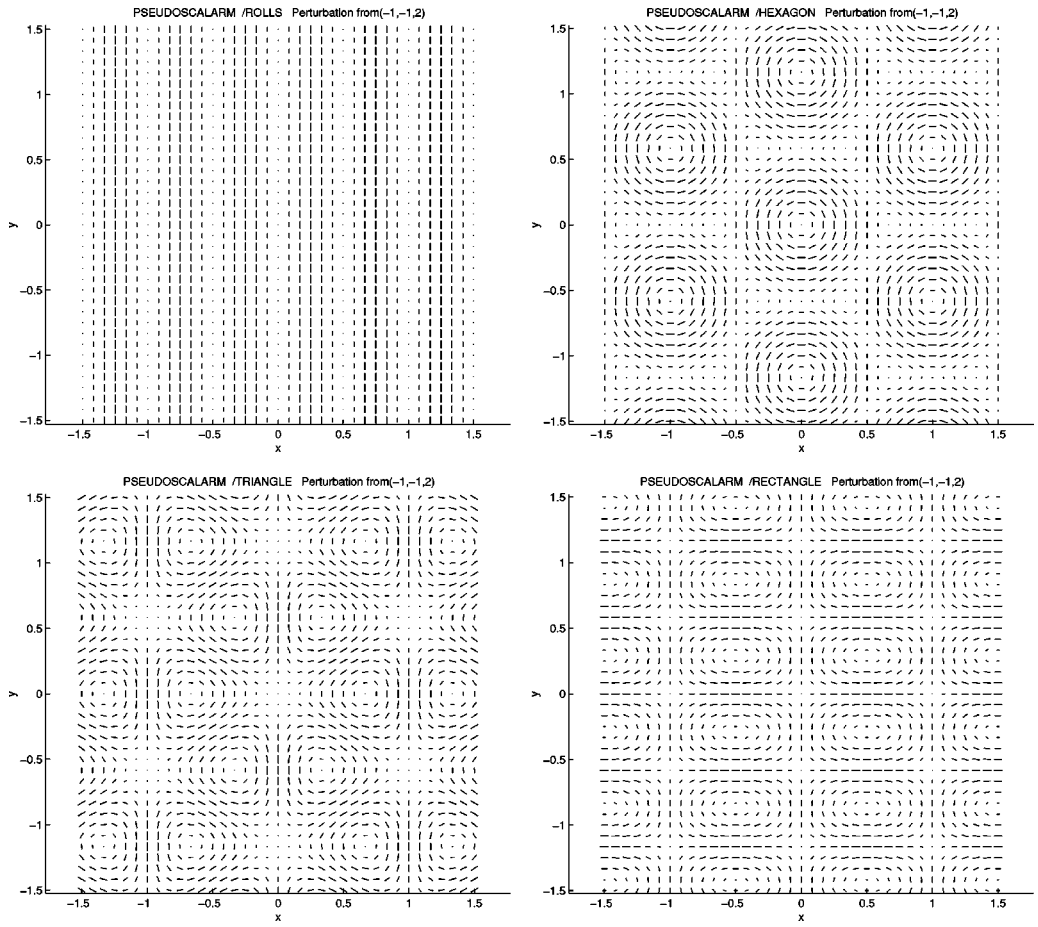

FIG. 6. Hexagonal lattice bifurcations from homeotropic ($\eta>0$) with pseudoscalar $\tau=-1$ representation: (upper left) stripes; (upper right) hexagons; (lower left) triangles; (lower right) rectangles.

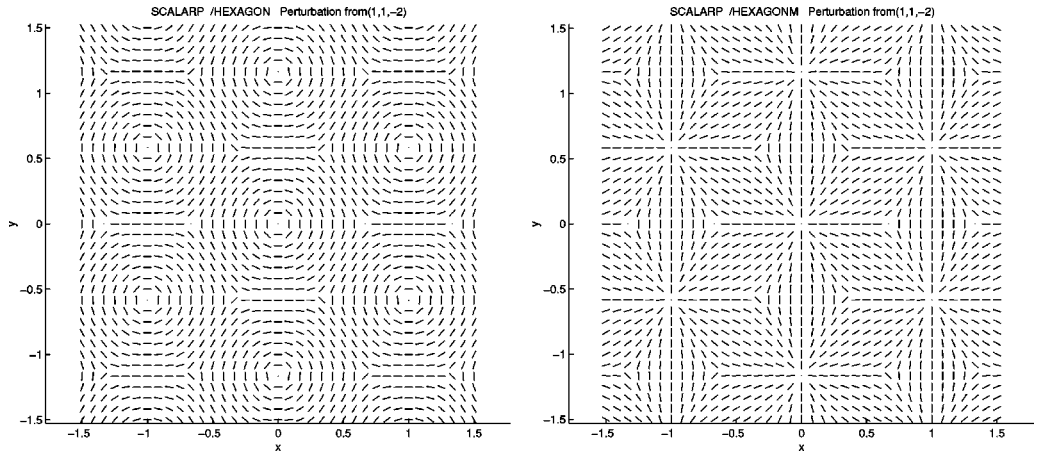

FIG. 7. Hexagonal lattice bifurcations from isotropic ($\eta<0$) with scalar $\tau=+1$ representation: stripes in Fig. 1; (left) hexagons^{+}; (right) hexagons^{-}.

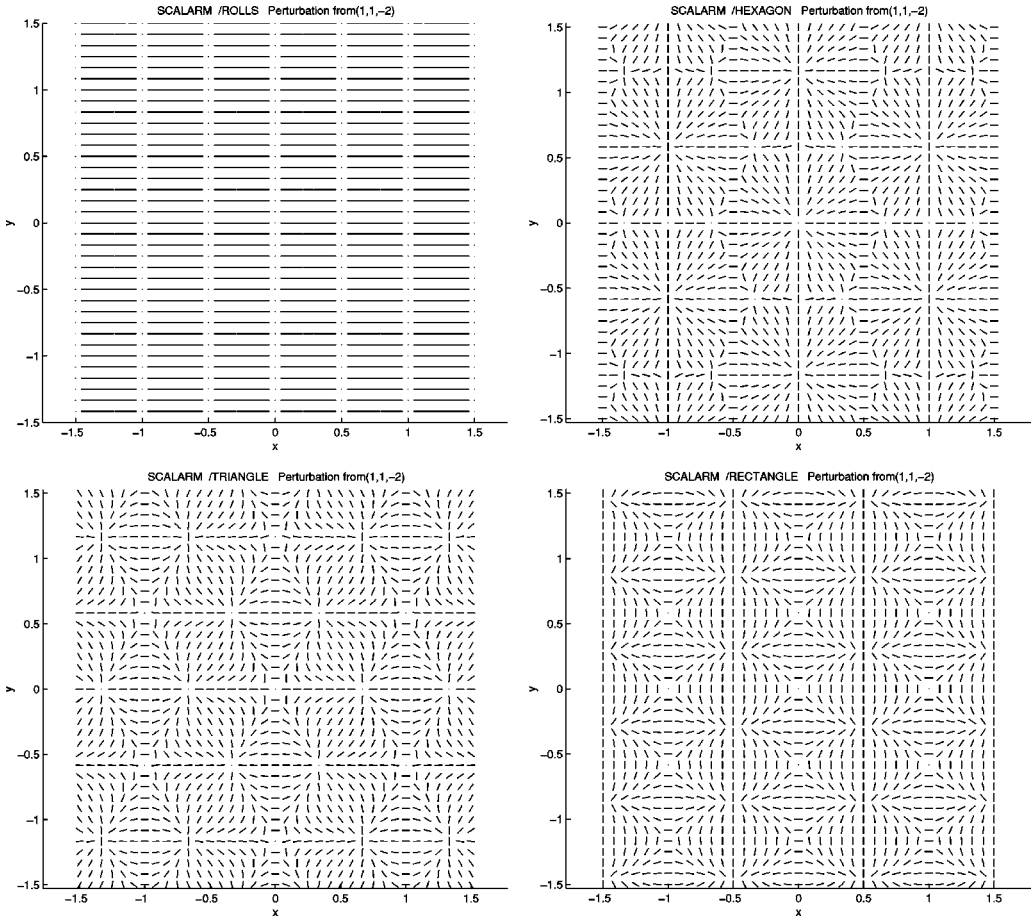

FIG. 8. Hexagonal lattice bifurcations from isotropic ($\eta<0$) with scalar $\tau=-1$ representation: (upper left) stripes; (upper right) hexagons; (lower left) triangles; (lower right) rectangles.

that is, a dislocation. Observe that across lines of dislocation the two competing directions are necessarily orthogonal in $\mathbf{R}^3$.

IV. FREE ENERGY MODELS

These results imply that for a planar liquid crystal there are four types of steady-state bifurcations, scalar, pseudoscalar, and $\tau=\pm 1$ of each type, that can occur from a spatially homogeneous equilibrium to spatially periodic equilibria. Whichever bifurcation occurs, then generically all of the planforms that we listed in the relevant section of Table III will be solutions. We have not discussed the difficult issue of stability of these solutions since these are model dependent results, whereas the classification of equilibria that we have given is independent of the model.

What remains is to complete a linear calculation to determine when a steady-state bifurcation occurs and whether it is scalar or pseudoscalar. The outline of such a calculation goes as follows. We first compute a *dispersion curve* for both scalar and pseudoscalar eigenfunctions. That is, for each wavelength $k=|\mathbf{k}|$ we determine the first value λ_k of the bifurcation parameter λ where L has a nonzero kernel. The curve (k,λ_k) is called the dispersion curve. We then find the minimum value $\lambda_*=\lambda_{k_*}$ on the dispersion curve; the corresponding wavelength k_* is the *critical* wavelength. We expect the first instability of the spatially homogeneous equilibrium to occur at the value λ_* of the bifurcation parameter. A bifurcating branch can consist of stable solutions only if the branch emanates from the first bifurcation (at λ_*).

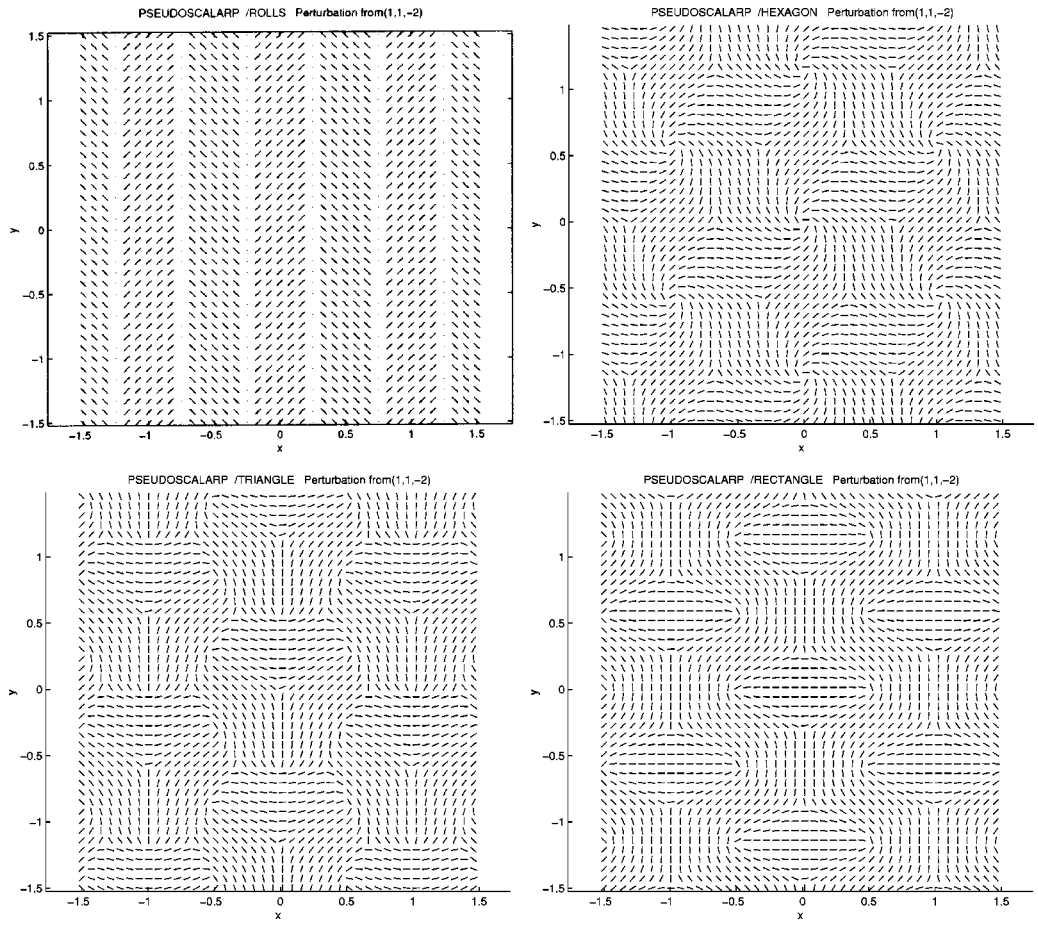

FIG. 9. Hexagonal lattice bifurcations from isotropic ($\eta<0$) with pseudoscalar $\tau=+1$ representation: (upper left) stripes; (upper right) hexagons; (lower left) triangles; (lower right) rectangles.

As an illustration we now carry out these calculations for a Landau–de Gennes type model with appropriate planar symmetry. Related calculations were carried out for bifurcation from the three-dimensional isotropic phase in Grebel *et al.* (1983). In this model we show that there are bifurcations corresponding to each of the four irreducible representations of $\Gamma_{\mathcal{L}}$, and which of them occurs first depends on the action of τ.

A. Dispersion curves for a two-dimensional Landau–de Gennes model

The free energy F is expressed as an integral per unit volume of a *free energy density* $\mathcal{F}$ which has two principal components $\mathcal{F}_0$ and $\mathcal{F}_d$ corresponding to *bulk terms* and *deformation terms*, respectively: we write F accordingly as $F=F_0+F_d$. For a system in three dimensions these typically [see, e.g., Grebel *et al.* (1983)] take the form

$$\mathcal{F}_0(Q)=\tfrac{1}{2}\lambda|Q|^2-\tfrac{1}{3}B\,\mathrm{tr}Q^3+\tfrac{1}{4}C|Q|^4,$$

$$\mathcal{F}_d(Q)=c_1|\nabla Q|^2+c_2|\nabla\cdot Q|^2+c_3|Q\cdot\nabla\wedge Q|,$$

respectively, where $|R|^2$ denotes the sum of the squares of the coefficients of the tensor R. The expression for $\mathcal{F}_0$ represents the simplest $\mathbf{SO}(3)$-invariant function on V exhibiting nontrivial interaction of local minima close to $Q=0$, while $\mathcal{F}_d$ consists of those $\mathbf{SO}(3)$-invariant terms of at most order 2 in spatial first derivatives (the chiral term $|Q\cdot\nabla\wedge Q|$ is not reflection-invariant).

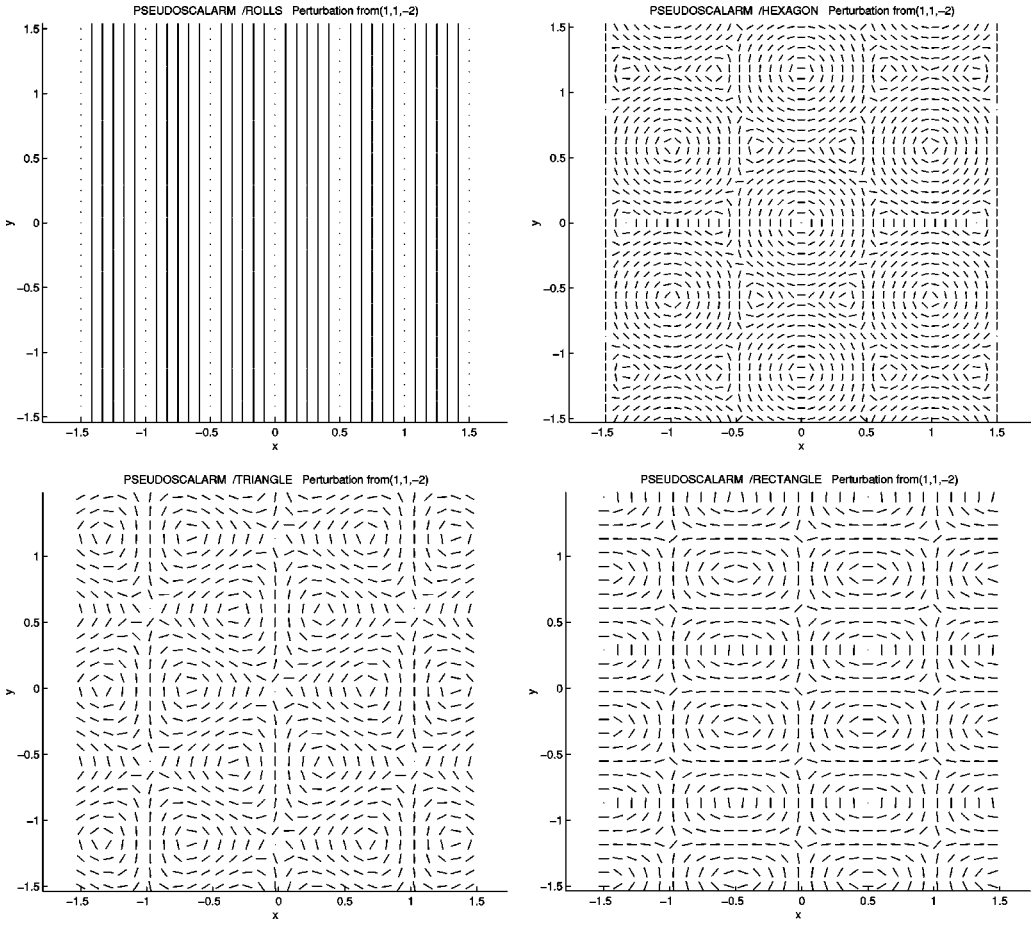

FIG. 10. Hexagonal lattice bifurcations from isotropic ($\eta<0$) with pseudoscalar $\tau=-1$ representation: (upper left) stripes; (upper right) hexagons; (lower left) triangles; (lower right) rectangles.

For a two-dimensional problem this choice of free energy function is not fully appropriate: the relevant symmetry group is now $\Gamma=\mathbf{E}(2)\times\mathbf{Z}_2(\tau)$. Consequently a wider range of terms can appear in $\mathcal{F}_0$, while the $|Q\cdot\nabla\wedge Q|$ term will no longer appear in $\mathcal{F}_d$.

We are interested in planforms that bifurcate from either the bulk homeotropic state or isotropic state, represented by Q_0 with $\eta>0$ or $\eta<0$, respectively. An example of a bulk term with $\mathbf{E}(2)\times\mathbf{Z}_2(\tau)$ invariance is $(Q_0\cdot Q)^2$, and a candidate for a deformation term to replace the chiral term is $|\Delta Q|^2$ representing longer range interactions of molecules. Accordingly we consider a free energy density $\mathcal{F}=\mathcal{F}_0+\mathcal{F}_d$ where now

$$\mathcal{F}_0(Q)=\tfrac{1}{2}\lambda|Q|^2-\tfrac{1}{3}B\mathrm{tr}Q^3+\tfrac{1}{4}C|Q|^4+\tfrac{1}{12}D(Q_0\cdot Q)^2,$$

$$\mathcal{F}_d(Q)=c_1|\nabla Q|^2+c_2|\nabla\cdot Q|^2+c_4|\Delta Q|^2.$$

Equilbrium states are critical points of F, and for $\mathcal{F}_0$ we have

$$d\mathcal{F}_0(Q)R=\lambda Q\cdot R-BQ^2\cdot R+C|Q|^2Q\cdot R+\tfrac{1}{6}D(Q_0\cdot Q)(Q_0\cdot R)$$

for arbitrary 3×3 real symmetric matrices Q,R; thus restricted to Q with trace zero we have $dF_0(Q)=0$ when

$$\lambda Q-B(Q^2-\tfrac{1}{3}|Q|^2I)+C|Q|^2Q+\tfrac{1}{6}D(Q_0\cdot Q)Q_0=0$$

TABLE IV. Computation of $d^2F(Q_0)R^2$.

R	$d^2F_0(Q_0)R^2$	$d^2F_d(Q_0)R^2$
$V_{\mathbf{k}}^{++}$	$\lambda(a^2+b^2-2ab)$ $-B(a^2+b^2+10ab)\eta$ $+6C(7(a^2+b^2)+10ab)\eta^2$	$2k^2(c_2a^2+$ $(a^2+b^2+(a+b)^2)(c_1+c_4k^2))$
$V_{\mathbf{k}}^{+-}$	$4(\lambda-B\eta+6C\eta^2)$ $=-4D\eta^2$ by (10)	$(4c_1+2c_2)k^2+4c_4k^4$
$V_{\mathbf{k}}^{-+}$	$4(\lambda+2B\eta+6C\eta^2)$	$(4c_1+2c_2)k^2+4c_4k^4$
$V_{\mathbf{k}}^{--}$	$4(\lambda-B\eta+6C\eta^2)$ $=-4D\eta^2$	$4c_1k^2+4c_4k^4$

and we easily verify the following:

$$dF_0(Q_0)=0\Leftrightarrow\lambda-B\eta+(6C+D)\eta^2=0. \tag{10}$$

Observe that $dF(Q)R=0$ automatically for any spatially periodic state R with zero mean, as the integral of an expression linear in R or its derivatives remains bounded as the volume tends to infinity. Therefore (10) is the condition for Q_0 to be an equilibrium state in our free energy model.

To study stability of the state Q_0 we evaluate the second derivative of the free energy at Q_0. For $R\in V$ we find

$$d^2F_0(Q_0)R^2=\lambda|R|^2-2BQ_0\cdot R^2+C(2(Q_0\cdot R)^2+|Q_0|^2|R|^2)+\tfrac{1}{6}D(Q_0\cdot R)^2$$

and (integrating over unit area)

$$d^2F_d(Q_0)R^2=c_1\int|\nabla R|^2+c_2\int|\nabla\cdot R|^2+c_4\int|\Delta R|^2$$

since Q_0 is spatially constant and terms linear in R integrate to zero.

We have already seen from Theorem 3.1 that the $\mathbf{E}(2)\times\mathbf{Z}_2(\tau)$ invariance of the free energy implies that generically the eigenfunctions of $d^2F(Q_0)$ on the space of $\mathcal{L}$-periodic matrix functions are linear combinations of functions belonging to one of the four subspaces $V_{\mathbf{k}}^{\pm\pm}$ and their rotations under $\pi/2$ (square lattice) or $\pm2\pi/3$ (hexagonal lattice). We next seek dispersion relations for each of the spaces $V_{\mathbf{k}}^{\pm\pm}$ in turn. When $R=e^{2\pi i\mathbf{k}\cdot\mathbf{x}}Q+\text{c.c.}$ it is easy to check that

$$\frac{1}{4\pi^2}\int|\nabla R|^2=2k^2|Q|^2,\quad\frac{1}{4\pi^2}\int|\nabla\cdot R|^2=2|Q\mathbf{k}|^2,\quad\frac{1}{16\pi^4}\int|\Delta R|^2=2k^4|Q|^2,$$

where $k=|\mathbf{k}|$. Without loss of generality we can take $\mathbf{k}=(k,0,0)$ and then after rescaling k by a factor of 2π the evaluations of $d^2F_0(Q_0)R^2$ and $d^2F_d(Q_0)R^2$ are given in Table IV.

If we normalize by choosing D so that (10) is satisfied by $\eta=1$ (corresponding to homeotropy) then we find the conditions for a zero eigenvalue in each of the last three (one-dimensional) eigenspaces are, respectively,

$$\begin{aligned}\lambda-B+6C+(c_1+\tfrac{1}{2}c_2)k^2+c_4k^4=0,\\ \lambda+2B+6C+(c_1+\tfrac{1}{2}c_2)k^2+c_4k^4=0,\\ \lambda-B+6C+c_1k^2+c_4k^4=0\end{aligned} \tag{11}$$

with the analogous expressions for $\eta=-1$ (bifurcation from two-dimensional isotropy) obtained by merely reversing the sign of B in these equations.

Stationary values of λ as a function of k occur where

$$k^2 = -(c_1 + \tfrac{1}{2}c_2)/2c_4$$

for $V_{\mathbf{k}}^{+-}$ and $V_{\mathbf{k}}^{-+}$, or

$$k^2 = -c_1/2c_4$$

for $V_{\mathbf{k}}^{--}$, giving values

$$\lambda = \begin{cases} B - 6C + (c_1 + \frac{1}{2}c_2)^2/4c_4 & \text{for } V_{\mathbf{k}}^{+-} \\ -2B - 6C + (c_1 + \frac{1}{2}c_2)^2/4c_4 & \text{for } V_{\mathbf{k}}^{-+} \\ B - 6C + c_1^2/4c_4 & \text{for } V_{\mathbf{k}}^{--}. \end{cases} \tag{12}$$

Finally, if $R \in V_{\mathbf{k}}^{++}$ then the matrix for $d^2F_0(Q_0)R^2$ as a quadratic form in a,b is

$$\begin{bmatrix} \lambda - B + 42C & -\lambda - 5B + 30C \\ -\lambda - 5B + 30C & \lambda - B + 42C \end{bmatrix}$$

and for $d^2F_d(Q_0)R^2$ is

$$\begin{bmatrix} 4c_1k^2 + 2c_2k^2 + 4c_4k^4 & 2c_1k^2 + 2c_4k^4 \\ 2c_1k^2 + 2c_4k^4 & 4c_1k^2 + 4c_4k^4 \end{bmatrix}$$

and so $d^2F(Q_0)|V_{\mathbf{k}}^{++}$ has a nontrivial kernel when the determinant of the sum of these two matrices vanishes.

With $c_2 = 0$ (that is, in physical terms, with no energy cost to the molecules for ''splay'') the algebra simplifies to yield the dispersion relation

$$\lambda = -2B - 6C + \frac{c_1^2}{4c_4}. \tag{13}$$

From (11) and (13) we therefore see that with $c_2 = 0$ the values of λ for $V_{\mathbf{k}}^{\pm\pm}$ depend only on the second $\pm$, that is on whether bifurcating solutions have vertical reflection symmetry ($\tau = +1$) or not ($\tau = -1$) and are the same for the scalar and the pseudoscalar representations. Moreover, as λ decreases, the first bifurcation from the homeotropic state ($\eta > 0$) has $\tau = -1$ while the first bifurcation from the isotropic state ($\eta < 0$) has $\tau = +1$. These statements remain true for sufficiently small $|c_2|$.

B. Plausibility and applications

The models that we have described are of course mathematical idealizations of any real physical situation. In particular

(i) full two-dimensional Euclidean lattice symmetry (by its nature infinite) cannot exist in practice, and
(ii) the question of stability of the patterns has not been addressed.

Issue (i) arises in many areas of pattern formation, and it is a common observation that, despite the meaninglessness of full Euclidean lattice symmetry, the types of pattern that such symmetry predicts are indeed seen in physical situations over even fairly small regions. Moreover, attempts to force a planar solution into a sphere or other geometrical surface naturally lead to dislocations in the pattern. For liquid crystals these questions become particularly important in the context of membranes and other structures in biology [Brown and Wolken (1979)] where hexagonal patterns, for example, are not uncommon (although we make no claim to connect them directly

with the hexagonal planforms that we discuss). Our planar idealization may thus form a starting point for understanding two-dimensional pattern formation in more realistic contexts.

The very interesting question of stability of solutions (ii) is a mathematical issue that needs to be addressed on two levels. First, stability restricted to perturbations within the lattice should be considered. The general analysis has been worked out for the scalar representations (Buzano and Golubitsky, 1983; Golubitsky *et al.*, 1984) and discussed for the pseudoscalar $\tau=1$ (Bressloff *et al.*, 2001a), but has not been completed for the pseudoscalar $\tau=-1$ representation (though the analysis should be similar to the pseudoscalar $\tau=1$ case). A full treatment of this stability (based on symmetry and otherwise independent of the equations) will, even for our simplified model, require a long calculation and is beyond the scope of this work. We note that with the extra assumption of a free energy function it might be feasible to address even more general stability issues. However, we again believe that such efforts should be reserved for models more physically realistic than ours.

V. CONCLUSION

We have classified those square and hexagonally periodic patterns that are predicted to arise in the director field of a planar layer of a nematic liquid crystal when a homeotropic or planar isotropic state loses stability via the simplest spatially doubly periodic steady-state bifurcations. The techniques are those of group theory and representation theory, and are valid for any PDE model under various reasonable assumptions. If such patterns are observed experimentally, under conditions consistent with our assumptions, then our analysis provides the explanation: what remains is to evaluate relevant constants (on the basis of physical data) in order to determine *which* of the patterns is to occur. We have investigated some aspects of this for a Landau–de Gennes free energy model. Analogous methods to these have been used for some time in related fields such as Bénard convection, but for liquid crystal models the extra complexity of the matrix order parameter here gives a richer geometric structure.

(Received 18 December 2002; accepted 14 May 2003)

Group lattices (Cayley digraphs) of a discrete group are in natural correspondence with differential calculi on the group. On such a differential calculus geometric structures can be introduced following general recipes of noncommutative differential geometry. Despite the noncommutativity between functions and (generalized) differential forms, for the subclass of ''bicovariant'' group lattices considered in this work it is possible to understand central geometric objects like metric, torsion and curvature as ''tensors'' with (left) covariance properties. This ensures that tensor components (with respect to a basis of the space of 1-forms) transform in the familiar homogeneous way under a change of basis. There is a natural compatibility condition for a metric and a linear connection. The resulting (pseudo-) Riemannian geometry is explored in this work. It is demonstrated that the components of the metric are indeed able to properly describe properties of discrete geometries like lengths and angles. A simple geometric understanding of torsion and curvature in particular is achieved. The formalism has much in common with lattice gauge theory. For example, the Riemannian curvature is determined by parallel transport of vectors around a plaquette (which corresponds to a biangle, a triangle or a quadrangle). © *2003 American Institute of Physics.* [DOI: 10.1063/1.1594820]

I. INTRODUCTION

In a previous paper[1] we started to develop a general formalism of differential geometry of group lattices (Cayley digraphs), based on elementary notions of noncommutative geometry. The present work extends the latter to a formalism of discrete (pseudo-) Riemannian geometry of the subclass of *bicovariant* group lattices, as defined in Ref. 1. A group lattice, which is determined by a *discrete* group G and a *finite* subset S (not containing the unit element e), naturally defines a first-order differential calculus (which extends to higher orders) over the algebra $\mathcal{A}$ of functions on G. If S generates G, bicovariance of the group lattice (G,S) is equivalent to bicovariance of the first-order differential calculus in the sense of Ref. 2.

''Riemannian geometry'' of discrete groups in the context of noncommutative geometry has already been considered in several publications.[3–5] The present approach differs from those in particular by introducing a metric tensor as an element of a left-covariant tensor product of the space of 1-forms with itself. This tensor product is obtained from the *a priori* given tensor product over $\mathcal{A}$ by using the special structure of group lattices and the bicovariance condition. Though this formalism has ideas in common with the approach of Ref. 6, it crucially differs from the latter, where a left-covariant tensor product for arbitrary differential calculi on finite sets was constructed making use of a connection. The present approach is simpler and geometrically more transparent, but restricted to bicovariant group lattices and thus a subclass of *regular*[7] digraphs. One should keep in mind that extensions of geometric structures from ordinary differential geometry to the

a)Electronic mail: dimakis@aegean.gr
b)Author to whom correspondence should be addressed. Electronic mail: fmuelle@gwdg.de

framework of noncommutative geometry may be carried out in various ways and only applications can decide on their usefulness. For our choice, we will demonstrate that it leads to simple and convenient rules of discrete geometry. It is also this last aspect, namely the fact that we establish a geometric interpretation of the *a priori* abstract formalism, which distinguishes the present work from some previous publications on noncommutative geometry of discrete groups.

The reason why we define a metric as a left-covariant tensor is that in this case its components are ''local'' objects (see Sec. II A). More generally, the components of left-covariant tensors obey a homogeneous local transformation law under a change of basis. In this sense they are really counterparts of tensors in ordinary differential geometry. This is quite in the spirit of Wilson's lattice gauge theory: discretization *a priori* moves local fields to nonlocal objects, but via parallel transport around a plaquette local objects are obtained. This is important in order to maintain gauge invariance, which is the main principle behind it. Similarly, we may postulate the preservation of the tensor transformation principle. This also allows us to consider coordinate transformations on group lattices very much in analogy with continuum differential geometry (see Sec. VI). The idea of constructing left- or alternatively right-covariant tensors in a noncommutative differential calculus already appeared in Ref. 8. Viewed as a map between left $\mathcal{A}$-modules, a left-covariant tensor is left $\mathcal{A}$-linear.

Discrete (pseudo-) Riemannian geometry is of relevance for numerical evaluation and also path integral quantization of classical physical models based on continuum Riemannian geometry, like mechanical and general relativistic systems (see Ref. 9, for example). The approach based on concepts of noncommutative geometry is an alternative to Regge calculus.[10] It has the advantage, however, that its formal structure is much closer to continuum differential geometry. Similarities with previous approaches to gravity using concepts of lattice gauge theory exist,[11] but there is little overlap when it comes to the details of the formalism. Of course, discrete geometry is an old subject (see Ref. 12, for example) and relations between the present work and earlier approaches can certainly be established to some extent. This will not be attempted in this work. Rather, we concentrate on what the machinery of algebraic noncommutative geometry applied in a natural way to (bicovariant) group lattices gives us and we reveal the geometric significance of discrete analogs of metric, metric-compatible linear connections, torsion and curvature.

Section II discusses the nonlocality of the tensor product over $\mathcal{A}$ and introduces the left-covariant tensor product for bicovariant group lattices, which induces a left-covariant product in the space of forms Ω. Left-covariant metrics are then introduced and a compatibility condition with a linear connection is formulated. The geometric meaning of the parallel transport determined by a metric-compatible linear connection is explored. Furthermore, we introduce the notion of a ''discrete Killing vector field.'' Section III elaborates the torsion and the curvature of linear connections on bicovariant group lattices and also provides corresponding expressions in terms of basic vector fields (which constitute a subclass of discrete vector fields, see Ref. 1). The Appendix presents expressions of basic formulas with respect to an orthonormal coframe field. Section IV deals with group lattices which carry a metric and a torsion-free compatible linear connection.

A metric-compatible linear connection provides us with a parallel transport which maps part of the group lattice isometrically into the tangent space at some site. Torsion and curvature of the connection are, respectively, corresponding first and second order obstructions. It turns out that torsion plays a much more fundamental role in this discrete framework than in ordinary continuum differential geometry. Linear connections with torsion are needed to describe even simple group lattice geometries in this framework (see Sec. V).

In Sec. VI we introduce the concept of coordinates on group lattices and elaborate in particular the geometry of hypercubic lattices based on the Abelian group $\mathbb{Z}^n$. Some concluding remarks are collected in Sec. VII.

The present work relies on the notation and results of Ref. 1. It is *not* self-contained. We refer to an equation in Ref. 1 in the form $(I.a.b)$ where $(a.b)$ is the equation number in Ref. 1. In the following we restrict our considerations to bicovariant group lattices (G,S), i.e., S is assumed to be closed under the adjoint action of all elements of S and their inverses.

II. TENSOR PRODUCTS, METRICS, AND LINEAR CONNECTIONS

In this section we first briefly discuss the consequences of the nonlocality of the usual tensor product over $\mathcal{A}$. Then we make use of the special structure of bicovariant group lattices in order to construct a new tensor product which is left-covariant so that the corresponding tensor components are ''local'' and able to carry a geometric meaning. The left-covariant tensor product of forms induces a left-covariant (generalized wedge) product in the space of forms. Left-covariant metrics are introduced and a compatibility condition with a linear connection is formulated. The latter involves an extension of the linear connection from the space of 1-forms to a left-covariant tensor product. This is a familiar procedure in the tensor calculus on manifolds, but in general not at all straightforward in noncommutative geometries (see also Ref. 3). Of particular importance for an understanding of the formalism is the observation that a metric-compatible linear connection determines an isometric map of parts of the group lattice into the tangent space at a (fixed) site. In the last subsection we define discrete Killing vector fields and invariant metrics on a (bicovariant) group lattice.

A. Nonlocality of the tensor product over $\mathcal{A}$

For the differential calculus (Ω,d) determined by a group lattice (G,S) there is a distinguished (left and right) $\mathcal{A}$-module basis $\{\theta^h \mid h\in S\}$ of the space of 1-forms Ω^1 which satisfies $\theta^h f = R_h^* f\, \theta^h$ for all elements f of the space of functions $\mathcal{A}$ on G, where R_h is the right action on G by an element $h\in S$. As a consequence,

$$(f\theta^h)\otimes_{\mathcal{A}}(f'\theta^{h'}) = f\,(R_h^* f')\;\theta^h\otimes_{\mathcal{A}}\theta^{h'} \tag{2.1}$$

for all $f,f'\in\mathcal{A}$. For each $g\in G$ there is a function e^g such that $e^g(g')=\delta_{g,g'}$ for all $g'\in G$. For this function we obtain

$$e^g(\,\theta^h\otimes_{\mathcal{A}}\theta^{h'}) = (e^g\theta^h)\otimes_{\mathcal{A}}(e^{gh}\theta^{h'}), \tag{2.2}$$

which shows that the tensor product $\otimes_{\mathcal{A}}$ is nonlocal since the two factors ''sit'' at different (though neighboring) points. Let us consider an object

$$\mathrm{g} = \sum_{h,h'\in S}\gamma_{h,h'}\;\theta^h\otimes_{\mathcal{A}}\theta^{h'} \quad (\gamma_{h,h'}\in\mathcal{A}). \tag{2.3}$$

Under a linear change of basis $\theta^h\mapsto\tilde{\theta}^h := \Sigma_{h'\in S}\,a^h{}_{h'}\;\theta^{h'}$ with coefficients $a^h{}_{h'}\in\mathcal{A}$ we find

$$\mathrm{g} = \sum_{h_1,h_2,h_1',h_2'\in S}\gamma_{h_1',h_2'}\,(a^{-1})^{h_1'}{}_{h_1}\,(R_{h_1}^* a^{-1})^{h_2'}{}_{h_2}\,\tilde{\theta}^{h_1}\otimes_{\mathcal{A}}\tilde{\theta}^{h_2} = \sum_{h_1,h_2\in S}\tilde{\gamma}_{h_1,h_2}\,\tilde{\theta}^{h_1}\otimes_{\mathcal{A}}\tilde{\theta}^{h_2} \tag{2.4}$$

from which we read off the coefficients with respect to the new cobasis:

$$\tilde{\gamma}_{h_1,h_2} = \sum_{h_1',h_2'\in S}\gamma_{h_1',h_2'}\,(a^{-1})^{h_1'}{}_{h_1}\,(R_{h_1}^* a^{-1})^{h_2'}{}_{h_2}. \tag{2.5}$$

Here we see again the nonlocal character of the tensor product $\otimes_{\mathcal{A}}$.

B. Left-covariant tensor product for bicovariant group lattices

By acting on each component, the maps R_h^* and $R_{h^{-1}}^*$ for $h\in S$ extend to tensor products of Ω^1 and to Ω as automorphisms. Then there is another tensor product with a local transformation rule. This ''left-covariant'' tensor product is defined via

$$(\,\theta^{h_1}\otimes_{\mathcal{A}}\cdots\otimes_{\mathcal{A}}\theta^{h_r})\otimes_L T := \theta^{h_1}\otimes_{\mathcal{A}}\cdots\otimes_{\mathcal{A}}\theta^{h_r}\otimes_{\mathcal{A}}R_{h_r^{-1}}^*\cdots R_{h_1^{-1}}^* T, \tag{2.6}$$

where T is an arbitrary element of a tensor product of Ω^1 over $\mathcal{A}$. The inverse relation is

$$(\theta^{h_1}\otimes_{\mathcal{A}}\cdots\otimes_{\mathcal{A}}\theta^{h_r})\otimes_{\mathcal{A}}T=(\theta^{h_1}\otimes_{\mathcal{A}}\cdots\otimes_{\mathcal{A}}\theta^{h_r})\otimes_L R^*_{h_1}\cdots R^*_{h_r}T. \tag{2.7}$$

Using $R^*_h\,\theta^{h'}=\theta^{\mathrm{ad}(h)h'}$ we find in particular

$$\theta^h\otimes_L\theta^{h'}=\theta^h\otimes_{\mathcal{A}}\theta^{\mathrm{ad}(h^{-1})h'},\quad \theta^h\otimes_{\mathcal{A}}\theta^{h'}=\theta^h\otimes_L\theta^{\mathrm{ad}(h)h'}. \tag{2.8}$$

Note also that

$$(\theta^{h_1}\otimes_L\cdots\otimes_L\theta^{h_r})\otimes_L T=(\theta^{h_1}\otimes_L\cdots\otimes_L\theta^{h_r})\otimes_{\mathcal{A}}R^*_{h_1^{-1}}\cdots R^*_{h_r^{-1}}T, \tag{2.9}$$

$$(\theta^{h_1}\otimes_L\cdots\otimes_L\theta^{h_r})\otimes_{\mathcal{A}}T=(\theta^{h_1}\otimes_L\cdots\otimes_L\theta^{h_r})\otimes_L R^*_{h_r}\cdots R^*_{h_1}T. \tag{2.10}$$

A local transformation law is indeed obtained since the new tensor product satisfies

$$(f_1T_1)\otimes_L(f_2T_2)=f_1f_2\,T_1\otimes_L T_2 \tag{2.11}$$

for all $f_1,f_2\in\mathcal{A}$ and elements T_1,T_2 of tensor products of Ω^1.

Lemma 2.1: The left-covariant tensor product $\otimes_L$ is associative:

$$(T_1\otimes_L T_2)\otimes_L T_3=T_1\otimes_L(T_2\otimes_L T_3) \tag{2.12}$$

for all T_i in tensor products of Ω^1.

Proof: In particular, we find

$$\begin{aligned}(\theta^{h_1}\otimes_L\theta^{h_2})\otimes_L T&=(\theta^{h_1}\otimes_{\mathcal{A}}R^*_{h_1^{-1}}\theta^{h_2})\otimes_L T\\&=(\theta^{h_1}\otimes_{\mathcal{A}}\theta^{\mathrm{ad}(h_1^{-1})h_2})\otimes_L T\\&=\theta^{h_1}\otimes_{\mathcal{A}}\theta^{\mathrm{ad}(h_1^{-1})h_2}\otimes_{\mathcal{A}}R^*_{[\mathrm{ad}(h_1^{-1})h_2]^{-1}}R^*_{h_1^{-1}}T\\&=\theta^{h_1}\otimes_{\mathcal{A}}\theta^{\mathrm{ad}(h_1^{-1})h_2}\otimes_{\mathcal{A}}R^*_{h_1^{-1}}R^*_{h_2^{-1}}T\\&=\theta^{h_1}\otimes_{\mathcal{A}}R^*_{h_1^{-1}}(\theta^{h_2}\otimes_{\mathcal{A}}R^*_{h_2^{-1}}T)=\theta^{h_1}\otimes_L(\theta^{h_2}\otimes_L T).\end{aligned}$$

Our more general assertion is proved in the same way. ■

Lemma 2.2: For all T_1,T_2 in tensor products of Ω^1,

$$R^*_h(T_1\otimes_L T_2)=(R^*_hT_1)\otimes_L(R^*_hT_2). \tag{2.13}$$

Proof:

$$\begin{aligned}R^*_h[(f\,\theta^{h_1}\otimes_{\mathcal{A}}\cdots\otimes_{\mathcal{A}}\theta^{h_r})\otimes_L T]&=R^*_h(f\,\theta^{h_1}\otimes_{\mathcal{A}}\cdots\otimes_{\mathcal{A}}\theta^{h_r})\,R^*_hR^*_{h_r^{-1}}\cdots R^*_{h_1^{-1}}R^*_{h^{-1}}R^*_hT\\&=R^*_h(f\,\theta^{h_1}\otimes_{\mathcal{A}}\cdots\otimes_{\mathcal{A}}\theta^{h_r})\,R^*_{[\mathrm{ad}(h)h_r]^{-1}}\cdots R^*_{[\mathrm{ad}(h)h_1]^{-1}}R^*_hT\\&=R^*_h(f\,\theta^{h_1}\otimes_{\mathcal{A}}\cdots\otimes_{\mathcal{A}}\theta^{h_r})\otimes_L R^*_hT\end{aligned}$$

for all $f\in\mathcal{A}$ and all T in a tensor product of Ω^1. Now the assertion follows by linearity. ■

C. A left-covariant product in the space of forms

The nonlocality of the tensor product $\otimes_{\mathcal{A}}$ discussed above is inherited by the product in Ω. For a bicovariant group lattice we can define a left-covariant product in Ω via

$$\omega_1 \cap \omega_2 = \pi(\omega_1 \otimes_L \omega_2), \tag{2.14}$$

where π is the projection $\Omega \otimes_{\mathcal{A}} \Omega \to \Omega$. The new product inherits from $\otimes_L$ left-covariance and associativity. From the definition we obtain

$$(\theta^{h_1} \cdots \theta^{h_r}) \cap \omega = \theta^{h_1} \cdots \theta^{h_r} R^*_{h_r^{-1}} \cdots R^*_{h_1^{-1}} \omega, \tag{2.15}$$

$$\theta^{h_1} \cdots \theta^{h_r} \omega = (\theta^{h_1} \cdots \theta^{h_r}) \cap R^*_{h_1} \cdots R^*_{h_r} \omega, \tag{2.16}$$

and also

$$(\theta^{h_1} \cap \cdots \cap \theta^{h_r}) \cap \omega = (\theta^{h_1} \cap \cdots \cap \theta^{h_r})\, R^*_{h_1^{-1}} \cdots R^*_{h_r^{-1}} \omega, \tag{2.17}$$

$$(\theta^{h_1} \cap \cdots \cap \theta^{h_r})\, \omega = (\theta^{h_1} \cap \cdots \cap \theta^{h_r}) \cap R^*_{h_r} \cdots R^*_{h_1} \omega. \tag{2.18}$$

In particular,

$$\theta^h \cap \theta^{h'} = \theta^h\, \theta^{\mathrm{ad}(h^{-1})h'}, \quad \theta^h\, \theta^{h'} = \theta^h \cap \theta^{\mathrm{ad}(h)h'}. \tag{2.19}$$

The 2-form relations (see Sec. IV of Ref. 1) now read

$$\sum_{h,h' \in S} \delta^g_{h'h}\, \theta^h \cap \theta^{h'} = 0 \quad \forall\, g \in S_{(2)} \tag{2.20}$$

and a 2-form can be decomposed using the projections

$$\begin{aligned} p_{(e)}(\theta^h \cap \theta^{h'}) &= \delta^e_{hh'}\, \theta^h \cap \theta^{h'}, \\ p_{(h)}(\theta^{h'} \cap \theta^{h''}) &= \delta^h_{h''h'}\, \theta^{h'} \cap \theta^{h''}, \quad h \in S_{(1)}, \\ p_{(g)}(\theta^h \cap \theta^{h'}) &= \delta^g_{h'h}\, \theta^h \cap \theta^{h'}, \quad g \in S_{(2)}, \end{aligned} \tag{2.21}$$

where $S_{(1)} = S^2 \cap S$, $S_{(2)} = S^2 \backslash S_e$ and $S_e = S \cup \{e\}$. For a cycle $h_1 h_2 = h_2 h_3 = \cdots = h_r h_1$ we obtain

$$\theta^{h_1} \theta^{h_2} + \theta^{h_2} \theta^{h_3} + \cdots + \theta^{h_r} \theta^{h_1} = \theta^{h_1} \cap \theta^{h_r} + \theta^{h_2} \cap \theta^{h_1} + \cdots + \theta^{h_r} \cap \theta^{h_{r-1}}. \tag{2.22}$$

Hence the structure of 2-form relations is preserved by the $\cap$-product.

Since R^*_h commutes with π, (2.13) leads to

$$R^*_h(\omega_1 \cap \omega_2) = (R^*_h \omega_1) \cap (R^*_h \omega_2). \tag{2.23}$$

In Ref. 1 a map $\Delta : \Omega \to \Omega$ has been introduced which is a graded derivation with respect to the ordinary product in Ω and satisfies

$$\Delta(\theta^h) := \sum_{h',h'' \in S} \delta^h_{h''h'}\, \theta^{h'} \cap \theta^{h''}. \tag{2.24}$$

Lemma 2.3: Δ *is a graded derivation with respect to the* $\cap$*-product in* Ω.

Proof: Using (I.4.11) and (I.4.20) we obtain

$$\begin{aligned}\Delta(\theta^h \cap \omega) &= \Delta(\theta^h R^*_{h^{-1}}\omega)\\ &= \Delta(\theta^h)\, R^*_{h^{-1}}\omega - \theta^h\, \Delta(R^*_{h^{-1}}\omega)\\ &= \Delta(\theta^h)\, R^*_{h^{-1}}\omega - \theta^h\, R^*_{h^{-1}}\Delta(\omega)\\ &= \sum_{h',h''\in S} \delta^h_{h''h'}\, \theta^{h'} \cap \theta^{h''} \cap R^*_{h''h'}\, R^*_{h^{-1}}\omega - \theta^h \cap \Delta(\omega)\\ &= \Delta(\theta^h)\cap\omega - \theta^h \cap \Delta(\omega)\end{aligned}$$

for all $\omega \in \Omega$. This in turn implies the general derivation rule

$$\Delta(\omega' \cap \omega) = \Delta(\omega')\cap\omega + (-1)^r\, \omega' \cap \Delta(\omega),$$

where ω' is an arbitrary r-form. ■

The map d is *not* a derivation with respect to the $\cap$-product. For an r-form ω we obtain from (I.4.12) the formula

$$\mathrm{d}\omega = \sum_{h\in S} \theta^h \cap R^*_h \omega - (-1)^r\, \omega \cap \theta - \Delta(\omega), \tag{2.25}$$

where

$$\theta = \sum_{h\in S} \theta^h. \tag{2.26}$$

This allows us to evaluate d applied to any form in terms of expressions which only involve the $\cap$-product (instead of the original product in Ω). In fact, we could have defined the left-covariant product of forms (and moreover the left-covariant tensor product) by its basic properties (without reference to the tensor product over $\mathcal{A}$) and the action of d directly in terms of (2.25). Reversing some of the arguments would then demonstrate that there is a product in Ω with respect to which d becomes a derivation.

D. Fixing the ambiguity of 2-form components

Given a 2-form

$$\psi = \sum_{h,h'\in S} \psi_{h,h'}\, \theta^h \cap \theta^{h'}, \tag{2.27}$$

the biangle and triangle coefficient functions $\psi_{h,h'}$ are uniquely determined, but there is an ambiguity in the quadrangle coefficients as a consequence of the 2-form relations (2.20). Indeed, writing

$$\psi_{(g)} = p_{(g)}\psi = \sum_{h,h'\in S} \check{\psi}_{(g)\,h,h'}\, \theta^h \cap \theta^{h'} \tag{2.28}$$

for $g \in S_{(2)}$, there is a freedom of gauge transformations $\check{\psi}_{(g)\,h,h'} \mapsto \check{\psi}_{(g)\,h,h'} + \Psi_{(g)}\, \delta^g_{h'h}$ with an arbitrary function $\Psi_{(g)}$ on G.[13] For any two members h,h' and $\hat{h},\hat{h}'$ of the chain $h_1 h_1{}' = \cdots = h_r h_r{}' = g \in S_{(2)}$, the difference

$$\psi_{(g)\,h,h';\hat{h},\hat{h}'} := \check{\psi}_{(g)\,h,h'} - \check{\psi}_{(g)\,\hat{h},\hat{h}'} \tag{2.29}$$

and thus also

$$\psi_{(g)\,h',h} := \sum_{\hat{h},\hat{h}' \in S} \psi_{(g)\,h',h;\hat{h}',\hat{h}} = |g|\,\breve{\psi}_{(g)\,h',h} - \sum_{\hat{h},\hat{h}' \in S} \delta^{g}_{\hat{h}\hat{h}'}\,\breve{\psi}_{(g)\,\hat{h}',\hat{h}} \tag{2.30}$$

is gauge invariant and hence independent of the choice of the coefficient functions $\breve{\psi}_{(g)\,h,h'}$ (from their gauge equivalence class). Here $|g|$ denotes the length of the chain which belongs to g, i.e., $|g| = r$. Furthermore, we obtain $\Sigma_{h,h'} \delta^{g}_{h'h}\,\psi_{(g)\,h,h'} = 0$ and

$$\psi_{(g)} = \frac{1}{|g|} \sum_{h,h' \in S} \delta^{g}_{h'h}\,\psi_{(g)\,h,h'}\,\theta^{h} \cap \theta^{h'}, \tag{2.31}$$

which suggests to *define* the functions (2.30) as the *quadrangle components* of the 2-form ψ (with respect to the $\cap$-product). The equation $\psi_{(g)} = 0$ (for a 2-form ψ) is equivalent to the vanishing of all the differences $\psi_{(g)\,h,h';\hat{h},\hat{h}'}$.

Of course, also in the case of higher than 2-forms there is an ambiguity in the choice of coefficients and a corresponding way of fixing it.

E. Left-covariant metric and compatibility with a linear connection

Let us express g given in (2.3) as

$$\mathrm{g} = \sum_{h,h' \in S} \mathfrak{g}_{h,h'}\,\theta^{h} \otimes_{L} \theta^{h'} \tag{2.32}$$

with $\mathfrak{g}_{h,h'} \in \mathcal{A}$. By comparison with (2.3), we obtain

$$\gamma_{h,h'} = \mathfrak{g}_{h,hh'h^{-1}}. \tag{2.33}$$

We say that g is *symmetric* if $\mathfrak{g}_{h,h'} = \mathfrak{g}_{h',h}$, which corresponds to $\gamma_{h,h^{-1}h'h} = \gamma_{h',h'^{-1}hh'}$. Furthermore, g is said to be *invertible* if the matrix $\mathfrak{g} = (\mathfrak{g}_{h,h'})$ is invertible (at all sites).

An object g as considered above is a candidate for a ''metric tensor.'' Its components should then be expected to determine lengths of vectors and angles between vectors at a site. This interpretation clearly distinguishes the components $\mathfrak{g}_{h,h'}$ and thus the left-covariant tensor product (see also the corresponding remarks in the Introduction). Hence we define a *metric tensor* as an object g of the form (2.32) such that the coefficient matrix $\mathfrak{g}$ is real, symmetric and invertible.

A metric g is called *left-invariant* if $L_h^{*}\mathrm{g} = \mathrm{g}$ for all $h \in S$, where L_h denotes the left action by h on G. This is equivalent to a ''constant metric,'' i.e., $\mathfrak{g}_{h,h'} \in \mathbb{R}$. A left-invariant metric is called *bi-invariant* if it is also *right-invariant*, i.e., $R_h^{*}\mathrm{g} = \mathrm{g}$ for all $h \in S$. This means that the metric is constant and satisfies $\mathfrak{g}_{h_1,h_2} = \mathfrak{g}_{\mathrm{ad}(h)h_1,\mathrm{ad}(h)h_2}$ for all $h, h_1, h_2 \in S$.

Let $\{\ell_h \mid h \in S\}$ be the vector fields dual to $\{\theta^h \mid h \in S\}$, so that $\ell_h f = R_h^{*} f - f$ for $f \in \mathcal{A}$. Let $\mathcal{V}_{\ell_h}$ be the parallel transport along the vector field ℓ_h with respect to a linear connection on Ω^1 (see Ref. 1). We write

$$\mathcal{V}_{\ell_{h'}}\theta^{h} = \sum_{h'' \in S} (R^{*}_{h'^{-1}} V^{h}{}_{h',h''})\,\theta^{h''}, \tag{2.34}$$

where $V_h = (V^{h''}{}_{h,h'})$ are matrices with entries in $\mathcal{A}$. $\mathcal{V}$ extends to $\Omega^1 \otimes_L \Omega^1$ via

$$\mathcal{V}_{\ell_h}(\alpha \otimes_L \beta) = \mathcal{V}_{\ell_h}\alpha \otimes_L \mathcal{V}_{\ell_h}\beta. \tag{2.35}$$

Then $\mathcal{V} := \Sigma_{h \in S} \theta^{h} \otimes_{\mathcal{A}} \mathcal{V}_{\ell_h}$ has the property $\mathcal{V}(f\,\alpha \otimes_L \beta) = f\,\mathcal{V}(\alpha \otimes_L \beta)$ and thus defines a connection according to Lemma 6.1 of Ref. 1.

An element $\mathrm{g} \in \Omega^1 \otimes_L \Omega^1$ is said to be *compatible* with the linear connection ∇ if

$$\nabla \mathrm{g} = 0, \tag{2.36}$$

which in terms of the parallel transport operators takes the form

$$\mathcal{V}_{\ell_h} \mathrm{g} = \mathrm{g} \quad \forall h \in S. \tag{2.37}$$

In components, this reads

$$\sum_{h_1, h_2 \in S} V^{h_1}{}_{h,h'_1} V^{h_2}{}_{h,h'_2} \mathfrak{g}_{h_1,h_2} = R^*_h \mathfrak{g}_{h'_1,h'_2} \tag{2.38}$$

and in matrix form

$$R^*_h \mathfrak{g} = V_h^T \mathfrak{g} V_h. \tag{2.39}$$

If g is a metric, this condition requires that the matrices V_h, $h \in S$, are invertible. For a given metric, there are not always matrices V_h satisfying (2.39).

Lemma 2.4: A linear connection compatible with a metric on a connected component of a bicovariant group lattice exists if and only if the metric has the same signature at all sites.

Proof: This is a direct consequence of the fact that two real symmetric matrices A, B with the same rank are related by $B = V^T A V$ with an invertible matrix V if and only if both have the same signature. ■

A bicovariant group lattice supplied with a metric of constant signature will be called a *Riemannian group lattice* in the following. Since we require a metric to be nondegenerate, a Riemannian group lattice (G, S, g) should be regarded as an $|S|$-dimensional structure.

The metric-compatibility condition determines the transport matrices, and thus the connection, only up to transformations $V_h \mapsto J_h V_h$ with arbitrary isometries J_h, which are matrices of functions on G such that

$$J_h^T \mathfrak{g} J_h = \mathfrak{g}. \tag{2.40}$$

F. Backward parallel transport of vector fields and geometric interpretation of metric-compatible linear connections

Vector fields are elements of the $\mathcal{A}$-bimodule generated by $\{\ell_h \mid h \in S\}$.[1] A linear connection determines a backward parallel transport of vector fields along a vector field:

$$\tilde{\mathcal{V}}_{\ell_h} X := \sum_{h', h'' \in S} (R^*_h X^{h'}) V^{h''}{}_{h,h'} \cdot \ell_{h''}, \quad \tilde{\mathcal{V}}_X := \sum_{h \in S} X^h \tilde{\mathcal{V}}_{\ell_h} \tag{2.41}$$

(see Ref. 1 for details). The vectors

$$V_{h,h'} := \tilde{\mathcal{V}}_{\ell_h} \ell_{h'} = \sum_{h'' \in S} V^{h''}{}_{h,h'} \cdot \ell_{h''} \tag{2.42}$$

are the images in the tangent space at g of the vectors $\ell_{h'}$ at gh. If the transport is metric-compatible, the vectors $V_{h,h'}$ at g carry the metric properties of $\ell_{h'}$ at gh, i.e.,

$$\mathfrak{g}_{h',h''}(gh) = \mathrm{g}(\ell_{h'}, \ell_{h''})(gh) = \mathrm{g}(V_{h,h'}, V_{h,h''})(g). \tag{2.43}$$

Of course, we can also transport tangent vectors from more remote sites to the tangent space at g by iterated application of the operators $\tilde{\mathcal{V}}_{\ell_h}$:

$$V_{h_1,\ldots,h_{r+1}} := \tilde{\mathcal{V}}_{\ell_{h_1}} \cdots \tilde{\mathcal{V}}_{\ell_{h_r}} \ell_{h_{r+1}}. \tag{2.44}$$

The results will, however, be path-dependent in general. But here we see very clearly the geometric significance of a metric-compatible linear connection. It maps part of the group lattice into the tangent space at a site in such a way that the metric relations are preserved, i.e., isometrically. In general, this cannot be done for the whole group lattice. Torsion and curvature are obstructions. We have already shown in Ref. 1 that in the case of vanishing torsion at least the next-neighbor part of the group lattice is mapped isometrically into the tangent space in this way, i.e., the backward parallel transport preserves the group lattice geometry to first order. Curvature is a second order obstruction. Its biangle, triangle and quadrangle parts are given, respectively, by

$$(\tilde{\mathcal{V}}_{\ell_{h_1}}\tilde{\mathcal{V}}_{\ell_{h_2}}-I)\,\ell_h=\sum_{h'\in S}(V_{h_1}R^*_{h_1}V_{h_2}-I)^{h'}{}_h\,\ell_{h'}\quad\text{if } h_1h_2=e,$$

$$(\tilde{\mathcal{V}}_{\ell_{h_1}}\tilde{\mathcal{V}}_{\ell_{h_2}}-\tilde{\mathcal{V}}_{\ell_{h_3}})\,\ell_h=\sum_{h'\in S}(V_{h_1}R^*_{h_1}V_{h_2}-V_{h_3})^{h'}{}_h\,\ell_{h'}\quad\text{if } h_1h_2=h_3\in S_{(1)},$$

$$(\tilde{\mathcal{V}}_{\ell_{h_1}}\tilde{\mathcal{V}}_{\ell_{h_2}}-\tilde{\mathcal{V}}_{\ell_{\hat{h}_1}}\tilde{\mathcal{V}}_{\ell_{\hat{h}_2}})\,\ell_h=\sum_{h'\in S}(V_{h_1}R^*_{h_1}V_{h_2}-V_{\hat{h}_1}R^*_{\hat{h}_1}V_{\hat{h}_2})^{h'}{}_h\,\ell_{h'}\quad\text{if } h_1h_2=\hat{h}_1\hat{h}_2\in S_{(2)}. \tag{2.45}$$

An equivalent curvature definition will be presented in Sec. III. The last formula of (2.45) is a discrete version of a familiar formula of continuum differential geometry: the quadrangle curvature is determined by parallel transport of a vector field around a quadrangle. There are no counterparts of biangle and triangle curvature in continuum differential geometry.

Let us make more precise how an isometric tangent space picture of (part of) a group lattice is obtained if a metric-compatible linear connection is given. If S has n different elements, let $(\,,\,)$ be an inner product in $\mathbb{R}^n$ with the same signature as g. At the origin in $\mathbb{R}^n$ we choose an n-bein $\{\mathbf{u}_h \mid h\in S\}$ such that

$$(\mathbf{u}_h,\mathbf{u}_{h'})=\mathrm{g}(\ell_h,\ell_{h'})(g). \tag{2.46}$$

Then $\iota:\ell_h\mapsto\mathbf{u}_h$ extends to an isomorphism of metric linear spaces. Furthermore, $\mathbf{V}_{h,h'}:=\iota(V_{h,h'})=\Sigma_{h''\in S}V^{h''}{}_{h,h'}\,\mathbf{u}_{h''}$ represents the vector $V_{h,h'}$ in $\mathbb{R}^n$. We attach it at the tip of $\mathbf{u}_h$. More generally, the vector

$$\mathbf{V}_{h_1,\ldots,h_{r+1}}:=\iota(V_{h_1,\ldots,h_{r+1}})=\sum_{h\in S}\mathbf{u}_h\,[V_{h_1}(g)\,V_{h_2}(gh_1)\cdots V_{h_r}(gh_1\cdots h_{r-1})]^h{}_{h_{r+1}} \tag{2.47}$$

has to be attached at the tip of $\mathbf{u}_{h_1}+\mathbf{V}_{h_1,h_2}+\cdots+\mathbf{V}_{h_1,\ldots,h_r}$.

The isometries J_h act on the vectors $\mathbf{V}_{h,h'}$ as follows:

$$J_h(\mathbf{V}_{h,h'}):=\sum_{h_1,h_2}\mathbf{u}_{h_1}J^{h_1}{}_{h,h_2}V^{h_2}{}_{h,h'}. \tag{2.48}$$

The isometry property of the J_h then implies

$$(J_h(\mathbf{V}_{h,h'}),J_h(\mathbf{V}_{h,h''}))=(\mathbf{V}_{h,h'},\mathbf{V}_{h,h''}). \tag{2.49}$$

The backward parallel transport and the isomorphism ι provide us with a convenient way to describe the action of a (metric-compatible) linear connection in $\mathbb{R}^n$ (supplied with a standard inner product). This will be used extensively in Secs. IV and V.

G. Contravariant metric and compatibility with a linear connection

A left-covariant tensor product of vector fields X,Y is defined as follows:

$$X\otimes_L Y:=\sum_{h\in S}X^h\,\ell_h\otimes_{\mathcal{A}}R_{h*}Y\,. \tag{2.50}$$

Given a metric tensor in the sense of Sec. II E, there is also a "contravariant" metric tensor,

$$\mathsf{h}=\sum_{h,h'\in S}\mathfrak{h}^{h,h'}\cdot\ell_h\otimes_L\ell_{h'}=\sum_{h,h'\in S}\mathfrak{h}^{h,\mathrm{ad}(h)h'}\cdot\ell_h\otimes_{\mathcal{A}}\ell_{h'}, \tag{2.51}$$

where $(\mathfrak{h}(g)^{h,h'})$ is the inverse of the matrix $\mathfrak{g}$ at $g\in G$.

If the matrices V_h are invertible for all $h\in S$, the corresponding linear connection on Ω^1 induces a connection on the space $\mathcal{X}$ of vector fields (see Ref. 1). An element $\mathsf{h}\in\mathcal{X}\otimes_L\mathcal{X}$ is *compatible* with the connection ∇ if $\nabla\mathsf{h}=0$, where ∇ has been extended to $\mathcal{X}\otimes_L\mathcal{X}$ following the procedure in Sec. II E. This is

$$R_h^*\mathfrak{h}^{h_1,h_2}=\sum_{h_1',h_2'\in S}(U_h)^{h_1}{}_{h_1'}(U_h)^{h_2}{}_{h_2'}\mathfrak{h}^{h_1',h_2'} \tag{2.52}$$

or $R_h^*\mathfrak{h}=U_h\,\mathfrak{h}\,U_h^T$ in matrix form, where $U_h:=V_h^{-1}$.

H. Discrete Killing vector fields

Let $X=\Sigma_{h\in S}X^h\cdot\ell_h$ be a discrete vector field for which the map $\phi_X:G\to G$, which is determined by $\phi_X^*=I+X$ on functions, is differentiable (see Ref. 1). X will be called a *Killing vector field* of a metric g if $\pounds_X\mathrm{g}=\phi_X^*\mathrm{g}-\mathrm{g}=0$ (with the Lie derivative $\pounds$ introduced in Ref. 1). For $X=\ell_h$ this becomes $R_h^*\mathrm{g}=\mathrm{g}$, i.e.,

$$\mathfrak{g}(gh)_{h_1,h_2}=\mathfrak{g}(g)_{\mathrm{ad}(h)h_1,\mathrm{ad}(h)h_2} \tag{2.53}$$

for all $g\in G$. The right hand side of (2.53) can be expressed in the form $(P_h^T\,\mathfrak{g}(g)\,P_h)_{h_1,h_2}$ where the matrix P_h represents a permutation.

A metric g on a bicovariant group lattice (G,S) is thus right-invariant if it satisfies $\pounds_{\ell_h}\mathrm{g}=0$ for all $h\in S$. A right-invariant metric is completely determined by its values at one site (e.g., at the unit element e).

$V_h:=P_h$ defines a linear connection which is compatible with every right-invariant metric. Each other linear connection compatible with a right-invariant metric is then obtained as $V_h:=J_hP_h$, where J_h is at each lattice site an isometry of the metric.

Example 2.1: Let G be a discrete group and $S\subset G\backslash\{e\}$ finite and *Abelian*. If $\pounds_{\ell_h}\mathrm{g}=0$ for some $h\in S$, the condition (2.53) becomes $\mathfrak{g}(gh)=\mathfrak{g}(g)$, which means that the functions $\mathfrak{g}_{h_1,h_2}$, $h_1,h_2\in S$, are constant on the orbits in G under the right action R_h. Let $G=\mathbb{Z}_n$ or $G=\mathbb{Z}$, and $1\in S$. If ℓ_1 is a Killing vector field, the metric coefficients $\mathfrak{g}_{h_1,h_2}$ are constant on the whole group. The corresponding natural linear connection is then given by $V_h=I$. ■

Example 2.2: Let $G=\mathcal{S}_3$ and $S=\{(12),(13),(23)\}$. We introduce the matrices

$$P_{(12)}=\begin{pmatrix}1&0&0\\0&0&1\\0&1&0\end{pmatrix},\quad P_{(13)}=\begin{pmatrix}0&0&1\\0&1&0\\1&0&0\end{pmatrix},\quad P_{(23)}=\begin{pmatrix}0&1&0\\1&0&0\\0&0&1\end{pmatrix}. \tag{2.54}$$

If $\ell_{(12)}$ is a Killing vector field of a metric g on this group lattice, then $\mathfrak{g}(g\,(12))=P_{(12)}\,\mathfrak{g}(g)\,P_{(12)}$ which determines the metric at the sites $(12),(13),(23)$ in terms of the metric at the sites $e,(132),(123)$, respectively. If $\ell_{(13)}$ and $\ell_{(23)}$ are Killing vector fields of g, then $\mathfrak{g}(g\,(13))=P_{(13)}\,\mathfrak{g}(g)\,P_{(13)}$ and $\mathfrak{g}(g\,(23))=P_{(23)}\,\mathfrak{g}(g)\,P_{(23)}$. The right-invariant metrics on $(\mathcal{S}_3,\{(12),(13),(23)\})$ are then given by

$$\mathfrak{g}(e)=\begin{pmatrix} a & b & c \\ b & d & e \\ c & e & f \end{pmatrix},\quad \mathfrak{g}((12))=\begin{pmatrix} a & c & b \\ c & f & e \\ b & e & d \end{pmatrix},\quad \mathfrak{g}((13))=\begin{pmatrix} f & e & c \\ e & d & b \\ c & b & a \end{pmatrix},$$
$$\mathfrak{g}((23))=\begin{pmatrix} d & b & e \\ b & a & c \\ e & c & f \end{pmatrix},\quad \mathfrak{g}((123))=\begin{pmatrix} d & e & b \\ e & f & c \\ b & c & a \end{pmatrix},\quad \mathfrak{g}((132))=\begin{pmatrix} f & c & e \\ c & a & b \\ e & b & d \end{pmatrix}, \tag{2.55}$$

with constants a,b,c,d,e,f. A linear connection compatible with this family of metrics is obtained by choosing $V_h=P_h$. The family of right-invariant metrics includes

$$\mathfrak{g}(h)=\begin{pmatrix} a & b & b \\ b & a & b \\ b & b & a \end{pmatrix}, \tag{2.56}$$

which is bi-invariant. ■

III. TORSION AND CURVATURE AS LEFT-COVARIANT TENSORS

The torsion 2-forms

$$\Theta^h=\mathrm{d}\theta^h-\pi(\nabla\theta^h)=\mathrm{d}\theta^h-\theta\,\theta^h-\sum_{h',h''\in S} V^h{}_{h',h''}\,\theta^{h'}\theta^{h''} \tag{3.1}$$

can be rewritten in terms of the $\cap$-product and then decomposed into biangle, triangle and quadrangle parts as follows:

$$\begin{aligned}\Theta^h&=\sum_{h_1,h_2\in S} Q^h{}_{h_1,h_2}\,\theta^{h_1}\cap\theta^{h_2}\\ &=\sum_{h_1,h_2\in S}\left(Q^h_{(e)\,h_1,h_2}+\sum_{h_0\in S_{(1)}} Q^h_{(h_0)\,h_1,h_2}+\sum_{g\in S_{(2)}}\check{Q}^h_{(g)\,h_1,h_2}\right)\theta^{h_1}\cap\theta^{h_2}.\end{aligned} \tag{3.2}$$

In this way we find the biangle components

$$Q^h_{(e)\,h_1,h_2}=\delta^e_{h_1h_2}(\delta^h_{h_1}+V^h{}_{h_1,h_2}) \tag{3.3}$$

and the triangle components

$$Q^h_{(h_0)\,h_1,h_2}=\delta^{h_0}_{h_2h_1}(\delta^h_{h_1}-\delta^h_{h_0}+V^h{}_{h_1,h_1^{-1}h_2h_1}). \tag{3.4}$$

In the case of the quadrangle components, one has to take the 2-form relations (2.20) into account. As a consequence of the latter, the functions $Q^h_{(g)\,h_1,h_2}$ are not uniquely determined. Following the discussion in Sec. II D, it is convenient to introduce the differences

$$Q^h_{(g)\,h_1,h_2;\hat{h}_1,\hat{h}_2}:=\check{Q}^h_{(g)\,h_1,h_2}-\check{Q}^h_{(g)\,\hat{h}_1,\hat{h}_2}=\delta^g_{h_2h_1}(\delta^h_{h_1}-\delta^h_{\hat{h}_1}+V^h{}_{h_1,h_1^{-1}h_2h_1}-V^h{}_{\hat{h}_1,\hat{h}_1^{-1}\hat{h}_2\hat{h}_1}) \tag{3.5}$$

[cf. (2.29)] where $\hat{h}_2,\hat{h}_1$ is any pair of elements of S which belongs to the same chain as h_2,h_1 (so that $\hat{h}_2\hat{h}_1=g=h_2h_1$). In particular, the vanishing of the quadrangle part of the torsion 2-form is equivalent to the vanishing of all the quantities (3.5). According to Sec. II D, the quadrangle torsion components should be defined as follows,

$$Q^{h}_{(g)\,h_i',h_i}:=|g|\,\check{Q}^{h}_{(g)\,h_i',h_i}-\sum_{h',h''\in S}\delta^{g}_{h'h''}\,\check{Q}^{h}_{(g)\,h'',h'}=\sum_{\substack{h',h''\in S\\ h'h''=g}}Q^{h}_{(g)\,h_i',h_i;h'',h'},\quad i=1,\dots,|g|, \tag{3.6}$$

if $h_1h_1'=\cdots=h_rh_r'=g$ is the corresponding chain. This does not depend on the choice of the coefficient functions $\check{Q}^{h}_{(g)\,h',h}$ which is ambiguous as a consequence of the 2-form relations.

After some manipulations like

$$\begin{aligned}
&\sum_{h',h''\in S}\theta^{h'}\theta^{h''}\otimes_{\mathcal{A}}\mathcal{V}_{\ell_{h''}}\mathcal{V}_{\ell_{h'}}\theta^{h}\\
&\quad=\sum_{h_1,h''\in S}(\theta^{h_1}\theta^{h''})\otimes_L R^{*}_{h_1}R^{*}_{h''}\mathcal{V}_{\ell_{h''}}\mathcal{V}_{\ell_{h_1}}\theta^{h}\\
&\quad=\sum_{h_1,h''\in S}(\theta^{h_1}\cap\theta^{\mathrm{ad}(h_1)h''})\otimes_L R^{*}_{h_1}R^{*}_{h''}\mathcal{V}_{\ell_{h''}}\mathcal{V}_{\ell_{h_1}}\theta^{h}\\
&\quad=\sum_{h_1,h_2\in S}(\theta^{h_1}\cap\theta^{h_2})\otimes_L R^{*}_{h_2h_1}\mathcal{V}_{\ell_{\mathrm{ad}(h_1^{-1})h_2}}\mathcal{V}_{\ell_{h_1}}\theta^{h}\\
&\quad=\sum_{h_1,h_2\in S}(\theta^{h_1}\cap\theta^{h_2})\otimes_L R^{*}_{h_2h_1}\sum_{h',h''}(R^{*}_{(h_2h_1)^{-1}}V^{h}_{h_1,h''})\\
&\qquad\times(R^{*}_{h_1^{-1}h_2^{-1}h_1}V^{h''}_{h_1^{-1}h_2h_1,h'})\,\theta^{h''}\\
&\quad=\sum_{h_1,h_2,h',h''\in S}(\theta^{h_1}\cap\theta^{h_2})\otimes_L V^{h}_{h_1,h''}(R^{*}_{h_1}V^{h''}_{h_1^{-1}h_2h_1,h'})\,\theta^{\mathrm{ad}(h_2h_1)h''}\\
&\quad=\sum_{h_1,h_2,h',h''\in S}(\theta^{h_1}\cap\theta^{h_2})\otimes_L V^{h}_{h_1,h''}(R^{*}_{h_1}V^{h''}_{\mathrm{ad}(h_1^{-1})h_2,\mathrm{ad}[(h_2h_1)^{-1}]h'})\,\theta^{h'}
\end{aligned}\tag{3.7}$$

the definition of the curvature, see (I.7.4), leads to

$$\begin{aligned}
\mathcal{R}(\theta^{h})=\sum_{h',h_1,h_2\in S}\Bigg(&\sum_{h''\in S}V^{h}{}_{h_1,h''}(R^{*}_{h_1}V^{h''}{}_{h_1^{-1}h_2h_1,\mathrm{ad}[(h_2h_1)^{-1}]h'})-\delta^{h}_{h'}\,\delta^{e}_{h_2h_1}\\
&-\sum_{h''\in S}\delta^{h''}_{h_2h_1}V^{h}{}_{h'',\mathrm{ad}[(h_2h_1)^{-1}]h'}\Bigg)\,\theta^{h_1}\cap\theta^{h_2}\otimes_L\theta^{h'}.
\end{aligned}\tag{3.8}$$

Writing

$$\mathcal{R}(\theta^h) = \sum_{h',h_1,h_2} \mathcal{R}^{h}{}_{h',h_1,h_2}\, \theta^{h_1} \cap \theta^{h_2} \otimes_L \theta^{h'}$$

$$= \sum_{h_1,h_2 \in S} \left(\mathcal{R}^{h}{}_{(e)\,h',h_1,h_2} + \sum_{h_0 \in S_{(1)}} \mathcal{R}^{h}{}_{(h_0)\,h',h_1,h_2} + \sum_{g \in S_{(2)}} \check{\mathcal{R}}^{h}_{(g)\,h',h_1,h_2} \right) \theta^{h_1} \cap \theta^{h_2} \otimes_L \theta^{h'} \tag{3.9}$$

we obtain the biangle components

$$\mathcal{R}^{h}{}_{(e)\,h',h_1,h_2} = \delta^{e}_{h_2 h_1} (V_{h_1} R^{*}_{h_1} V_{h_2} - I)^{h}{}_{h'}, \tag{3.10}$$

the triangle components

$$\mathcal{R}^{h}{}_{(h_0)\,h',h_1,h_2} = \delta^{h_0}_{h_2 h_1} (V_{h_1} R^{*}_{h_1} V_{h_1^{-1} h_2 h_1} - V_{h_0})^{h}{}_{h_0^{-1} h' h_0}, \tag{3.11}$$

and the differences of quadrangle components

$$\mathcal{R}^{h}{}_{(g)\,h',h_1,h_2;\hat{h}_1,\hat{h}_2} := \check{\mathcal{R}}^{h}_{(g)\,h',h_1,h_2} - \check{\mathcal{R}}^{h}_{(g)\,h',\hat{h}_1,\hat{h}_2}$$

$$= \delta^{g}_{h_2 h_1} (V_{h_1} R^{*}_{h_1} V_{h_1^{-1} h_2 h_1} - V_{\hat{h}_1} R^{*}_{\hat{h}_1} V_{\hat{h}_1^{-1} \hat{h}_2 \hat{h}_1})^{h}{}_{g^{-1} h' g}. \tag{3.12}$$

Again, $\hat{h}_2, \hat{h}_1$ is any pair with $\hat{h}_2 \hat{h}_1 = g \in S_{(2)}$.

According to Sec. II D, the quadrangle curvature components should be defined as follows,

$$\mathcal{R}^{h}{}_{(g)\,h',h_i',h_i} := |g|\, \check{\mathcal{R}}^{h}_{(g)\,h',h_i',h_i} - \sum_{h'',h''' \in S} \delta^{g}_{h'' h'''}\, \check{\mathcal{R}}^{h}_{(g)\,h',h''',h''}$$

$$= \sum_{\substack{h'',h''' \in S \\ h'' h''' = g}} \mathcal{R}^{h}{}_{(g)\,h',h_i',h_i;h''',h''},$$

$$i = 1, \ldots, |g|, \tag{3.13}$$

if $h_1 h_1' = \cdots = h_r h_r' = g$ is the corresponding chain. Understanding that the quadrangle part of $\mathcal{R}^{h}{}_{h',h'',h'''}$ is given by the above expression, the components of a *Ricci tensor* can be defined without ambiguity as follows:

$$\mathrm{Ric}_{h,h'} := \sum_{h'' \in S} \mathcal{R}^{h''}{}_{h,h'',h'}. \tag{3.14}$$

With the help of a metric, a *curvature scalar* can be built:

$$R := \sum_{h,h' \in S} (\mathfrak{g}^{-1})^{h,h'} \mathrm{Ric}(\ell_h, \ell_{h'}). \tag{3.15}$$

There is, however, another contraction of the curvature tensor, namely,

$$\widetilde{\mathrm{Ric}}_{h,h'} := \sum_{h'' \in S} \mathcal{R}^{h''}{}_{h,h',h''}, \tag{3.16}$$

which leads in general to a different Ricci tensor and curvature scalar. Moreover, also the contraction $\Sigma_{h'' \in S} \mathcal{R}^{h''}{}_{h'',h,h'}$ is in general different from zero. This complicates finding a suitable analog of the Einstein equation, for example.

A. Bianchi identities

According to Ref. 1, the first Bianchi identity can be expressed as follows:

$$\mathrm{d}\Theta^h+\Theta(\nabla\theta^h)=\pi\circ\mathcal{R}(\theta^h)=\sum_{h',h_1,h_2\in S}\mathcal{R}^h{}_{h',h_1,h_2}\,\theta^{h_1}\cap\theta^{h_2}\cap\theta^{h'}. \tag{3.17}$$

Using $\theta\,\omega=\Sigma_{h\in S}\theta^h\cap R^*_h\omega$ we find

$$\Theta(\nabla\theta^h)=-\theta\,\Theta^h+\sum_{h',h''\in S}V^h{}_{h',h''}\,\theta^{h''}\,\Theta^{h'}=-\sum_{h'\in S}\theta^{h'}\cap R^*_{h'}\Theta^h+\sum_{h',h''\in S}V^h{}_{h',h''}\,\theta^{h''}\cap R^*_{h''}\Theta^{h'}, \tag{3.18}$$

and, thus, with the help of (2.25),

$$\mathrm{d}\Theta^h+\Theta(\nabla\theta^h)=-\Theta^h\cap\theta-\Delta(\Theta^h)+\sum_{h',h''}V^h{}_{h',h''}\theta^{h''}\cap(R^*_{h''}\Theta^{h'}). \tag{3.19}$$

Replacing the left hand side of (3.17) with the last expression, we obtain the first Bianchi identity in terms of the $\cap$-product. In the case of vanishing torsion, it reduces to

$$\sum_{h',h_1,h_2\in S}\mathcal{R}^h{}_{h',h_1,h_2}\,\theta^{h_1}\cap\theta^{h_2}\cap\theta^{h'}=0. \tag{3.20}$$

Using $V^h{}_{h'}:=\Sigma_{h''\in S}V^h{}_{h'',h'}\,\theta^{h''}$ and

$$\mathcal{R}^h{}_{h'}:=\sum_{h_1,h_2\in S}\mathcal{R}^h{}_{\mathrm{ad}(h_2h_1)h',h_1,h_2}\,\theta^{h_1}\cap\theta^{h_2} \tag{3.21}$$

the second Bianchi identity (I.7.15) reads

$$\begin{aligned}\Delta(\mathcal{R}^h{}_{h'})&=\sum_{h''\in S}(V^h{}_{h''}\mathcal{R}^{h''}{}_{h'}-\mathcal{R}^h{}_{h''}V^{h''}{}_{h'})\\&=\sum_{h_1,h_2\in S}V^h{}_{h_1,h_2}\,\theta^{h_1}\cap R^*_{h_1}\mathcal{R}^{h_2}{}_{h'}-\sum_{h_1,h_2,h_3\in S}\mathcal{R}^h{}_{\mathrm{ad}(h_3h_2)h_1,h_2,h_3}\,\theta^{h_2}\cap\theta^{h_3}\cap R^*_{h_3h_2}V^{h_1}{}_{h'}.\end{aligned} \tag{3.22}$$

Evaluating the left hand side with the help of Lemma 2.3, this yields a 3-form expression which only involves the $\cap$-product.

B. Integrability conditions of the metric-compatibility equation

The integrability condition for the metric-compatibility of a linear connection is $\nabla^2\mathrm{g}=0$ and thus involves the curvature. After some manipulations we obtain the conditions

$$V_{h_1}R^*_{h_1}V_{h_2}=B_{h_1,h_2}\quad\text{for a biangle}\quad h_1h_2=e, \tag{3.23}$$

$$V_{h_1}R^*_{h_1}V_{h_2}=T_{h_1,h_2}V_h\quad\text{for a triangle}\quad h_1h_2=h\in S_{(1)}, \tag{3.24}$$

$$V_{h_1}R^*_{h_1}V_{h_2}=K_{h_1,h_2;\hat h_1\hat h_2}V_{\hat h_1}R^*_{\hat h_1}V_{\hat h_2}\quad\text{for a quadrangle}\quad h_1h_2=\hat h_1\hat h_2\in S_{(2)}, \tag{3.25}$$

where for all $g \in G$ the matrices $B_{h_1,h_2}(g)$, $T_{h_1,h_2}(g)$, $K_{h_1,h_2;\hat{h}_1\hat{h}_2}(g)$ are elements of the isometry group of $\mathfrak{g}(g)$. Now we obtain for biangles

$$\mathcal{R}^{h}{}_{(e)\,h',h_1,h_2} = \delta^{e}_{h_2 h_1} (B_{h_1,h_2} - I)^{h}{}_{h'}\,, \tag{3.26}$$

for triangles

$$\mathcal{R}^{h}{}_{(h_0)\,h',h_1,h_2} = \delta^{h_0}_{h_2 h_1} ((T_{h_1,h_2} - I) V_{h_0})^{h}{}_{h_0^{-1} h' h_0}\,, \tag{3.27}$$

and for quadrangles

$$\mathcal{R}^{h}{}_{(g)\,h',h_1,h_2;\hat{h}_1,\hat{h}_2} = \delta^{g}_{h_2 h_1} ((K_{h_1,h_2;\hat{h}_1,\hat{h}_2} - I)\, V_{\hat{h}_1} R^{*}_{\hat{h}_1} V_{\hat{h}_1^{-1}\hat{h}_2\hat{h}_1})^{h}{}_{g^{-1}h'g}\,, \tag{3.28}$$

where $\hat{h}_2\hat{h}_1 = g \in S_{(2)}$. As a consequence, the essential part of the curvature tensor is given by the isometries B, T, K.

C. Torsion and curvature as maps on vector fields

Let (G,S) be a bicovariant group lattice and $Q^{h}{}_{h_1,h_2}$ be the torsion tensor components introduced in (3.2) with the quadrangle part defined in (3.6). For vector fields X, Y we introduce the *torsion tensor*

$$Q(X,Y) := \sum_{h \in S,\ h_1,h_2 \in S_e} X^{h_1} Y^{h_2}\, Q^{h}{}_{h_1,h_2} \cdot \ell_h. \tag{3.29}$$

This expression obviously satisfies $Q(f \cdot X, f' \cdot Y) = f f'\, Q(X,Y)$ and is therefore a (left) tensor. In the following we consider in more detail the case where X, Y are basic. The torsion tensor can then be written as

$$Q(X,Y) = \sum_{h \in S} Q^{h}{}_{s_X, s_Y} \cdot \ell_h\,, \tag{3.30}$$

where the map $s_X : G \to S$ is determined by $X^h(g) = \delta^{h}_{s_X(g)}$ (see also Ref. 1).

Below we will need the following expression for basic vector fields X, Y,

$$\begin{aligned} \tilde{\mathcal{V}}_X R_{X*} Y &= \sum_{h_1,h_2 \in S} X^{h_1}\, Y^{\mathrm{ad}(h_1)h_2}\, \tilde{\mathcal{V}}_{\ell_{h_1}} \ell_{h_2} \\ &= \sum_{h_1,h_2 \in S} \delta^{h_1,s_X}\, \delta^{h_2,\mathrm{ad}(s_X)^{-1} s_Y}\, \tilde{\mathcal{V}}_{\ell_{h_1}} \ell_{h_2} \\ &= \sum_{h \in S} V^{h}{}_{s_X,\mathrm{ad}(s_X)^{-1} s_Y} \cdot \ell_h\,, \end{aligned} \tag{3.31}$$

where we used (I.5.21), (I.7.17), and (I.5.12).

If X, Y form a biangle, so that $s_Y s_X = e$, then

$$Q(X,Y)=\sum_{h\in S} Q^{h}_{(e)s_X,s_Y}\cdot \ell_h$$

$$=\sum_{h\in S} \delta^{e}_{s_Xs_Y}(\delta^{h}_{s_X}+V^{h}_{s_X,s_Y})\cdot \ell_h$$

$$=X+\sum_{h\in S} V^{h}{}_{s_X,s_Y}\cdot \ell_h=X+\tilde{\mathcal{V}}_X R_{X*}Y. \tag{3.32}$$

If X,Y,Z form a triangle, so that $s_Ys_X=s_Z$, we obtain

$$Q(X,Y)=\sum_{h\in S,h_1\in S_{(1)}} Q^{h}_{(h_1)s_X,s_Y}\cdot \ell_h$$

$$=\sum_{h\in S,h_1\in S_{(1)}} \delta^{h_1}_{s_Ys_X}(\delta^{h}_{s_X}-\delta^{h}_{h_1}+V^{h}{}_{s_X,\mathrm{ad}(s_X)^{-1}s_Y})\cdot \ell_h$$

$$=X+\tilde{\mathcal{V}}_X R_{X*}Y-Z. \tag{3.33}$$

Finally, for a quadrangle $X,Y,\hat{X},\hat{Y}$ (which satisfies $s_Ys_X=s_{\hat{Y}}s_{\hat{X}}\notin S_e$) we find

$$Q(X,Y;\hat{X},\hat{Y}):=Q(X,Y)-Q(\hat{X},\hat{Y})$$

$$=\sum_{h\in S,g\in S_{(2)}} Q^{h}_{(g)s_X,s_Y;s_{\hat{X}},s_{\hat{Y}}}\cdot \ell_h$$

$$=\sum_{h\in S,g\in S_{(2)}} \delta^{g}_{s_Ys_X}(\delta^{h}_{s_X}-\delta^{h}_{s_{\hat{X}}}+V^{h}{}_{s_X,\mathrm{ad}(s_X)^{-1}s_Y}-V^{h}{}_{s_{\hat{X}},\mathrm{ad}(s_{\hat{X}})^{-1}s_{\hat{Y}}})\cdot \ell_h$$

$$=X+\tilde{\mathcal{V}}_X R_{X*}Y-\hat{X}-\tilde{\mathcal{V}}_{\hat{X}} R_{\hat{X}*}\hat{Y}\,. \tag{3.34}$$

For arbitrary vector fields X,Y,Z we define the *curvature tensor*

$$\mathcal{R}(X,Y)(Z)=\sum_{h\in S,\ h_1,h_2,h_3\in S_e} X^{h_1}Y^{h_2}Z^{h_3}\,\mathcal{R}^{h}{}_{h_3,h_1,h_2}\cdot \ell_h\,, \tag{3.35}$$

where the ambiguity in the quadrangle components is fixed by (3.13). If X,Y,Z are basic, we obtain

$$\mathcal{R}(X,Y)(Z)=\sum_{h\in S}\mathcal{R}^{h}{}_{s_Z,s_X,s_Y}\cdot \ell_h. \tag{3.36}$$

For further evaluation we need the following expressions,

$$\tilde{\mathcal{V}}_{R_{X*}Y}Z=\sum_{h_1}(R_{X*}Y)^{h_1}\,\tilde{\mathcal{V}}_{\ell_{h_1}}Z$$

$$=\sum_{h_1,h_2}(R_{X*}Y)^{h_1}(R^{*}_{h_1}Z^{h_2})\,\tilde{\mathcal{V}}_{\ell_{h_1}}\ell_{h_2}$$

$$=\sum_{h_1,h_2,h}(R_{X*}Y)^{h_1}(R^{*}_{h_1}Z^{h_2})\,V^{h}{}_{h_1,h_2}\cdot \ell_h \tag{3.37}$$

and

$$\tilde{\mathcal{V}}_X \tilde{\mathcal{V}}_{R_{X*Y}} Z = \sum_{h_1} X^{h_1} \tilde{\mathcal{V}}_{\ell_{h_1}} (\tilde{\mathcal{V}}_{R_{X*Y}} Z) = \sum_{h,h_1,h_2,h_3} X^{h_1} Y^{\mathrm{ad}(h_1)h_2} (R^*_{h_1 h_2} Z^{h_3}) (V_{h_1} R^*_{h_1} V_{h_2})^h{}_{h_3} \cdot \ell_h \tag{3.38}$$

using (I.5.21) and (I.5.12). With the help of these formulas we obtain

$$\mathcal{R}(X,Y)(Z) = \tilde{\mathcal{V}}_X \tilde{\mathcal{V}}_{R_{X*Y}} Z - Z \quad \text{for a biangle } X,Y, \tag{3.39}$$

$$\mathcal{R}(X,Y)(Z) = (\tilde{\mathcal{V}}_X \tilde{\mathcal{V}}_{R_{X*Y}} - \tilde{\mathcal{V}}_W) R_{W*} Z \quad \text{for a triangle } X,Y,W, \tag{3.40}$$

and

$$\begin{aligned} \mathcal{R}(X,Y;\hat{X},\hat{Y})(Z) &:= \mathcal{R}(X,Y)(Z) - \mathcal{R}(\hat{X},\hat{Y})(Z) \\ &= (\tilde{\mathcal{V}}_X \tilde{\mathcal{V}}_{R_{X*Y}} - \tilde{\mathcal{V}}_{\hat{X}} \tilde{\mathcal{V}}_{R_{\hat{X}*\hat{Y}}}) R_{(R_{X*Y})*} R_{X*} Z \\ &\quad \text{for a quadrangle } X,Y,\hat{X},\hat{Y}. \end{aligned} \tag{3.41}$$

The *Ricci tensor* defined in (3.14) can also be expressed as follows:

$$\mathrm{Ric}(X,Y) := \sum_{h \in S} \langle \mathcal{R}(\ell_h, Y)(X), \theta^h \rangle. \tag{3.42}$$

IV. RIEMANNIAN GROUP LATTICES ADMITTING A TORSION-FREE COMPATIBLE LINEAR CONNECTION

Let (G,S) be a bicovariant group lattice and (Ω,d) be the associated differential calculus. The formalism developed in the previous sections enables us to carry familiar constructions of continuum differential geometry over to group lattices. In particular, we may look for an analog of the *Levi-Civita connection* of a metric g. This means we should look for torsion-free linear connections which are compatible with g.

In Sec. II E a (bicovariant) group lattice supplied with a metric tensor g of constant signature has been called a ''Riemannian group lattice.'' In this section we further demand that it admits a *torsion-free* metric-compatible linear connection. Unlike the continuum case, on most group lattices not every metric admits such a connection. As we shall see below, this condition indeed places severe restrictions on the components of a metric. This should not come as a big surprise. In continuum differential geometry the requirement of a smooth metric on a smooth manifold guarantees that the metric components at ''neighboring'' points fit together. On the other hand, given a set of points in a Euclidean space, for example, and prescribing metric components at every point, a corresponding embedded digraph does not exist, in general. This is not the whole story, however. In the case of a maximal group lattice (complete digraph), which corresponds to a maximal set S, vanishing torsion already determines a unique linear connection, so that no freedom is left to satisfy the metric-compatibility conditions for a ''nontrivial'' geometry (see Sec. IV A). Reducing S to smaller sets allows for more freedom in a torsion-free connection and thus for more solutions of the metric-compatibility conditions.

If a metric-compatible linear connection is found for a given metric, it is only determined up to transformations $V_h \mapsto J_h V_h$ of the transport matrices with isometry matrices J_h (see Sec. II E) with coefficients $J^{h'}{}_{h,h''}$. Requiring vanishing torsion restricts this freedom, but in general does not fix it completely. In the following we elaborate this in more detail. More generally, we look separately at the consequences of vanishing biangle, triangle and quadrangle torsion together with the metric-compatibility condition. In the following, the matrices J_h are always constrained by the isometry condition (2.40).

(*a*) *Vanishing biangle torsion.* The biangle torsion vanishes for a biangle $h_1h_2=e$ (at some lattice site) if and only if

$$V^h{}_{h_1,h_2}=-\delta^h_{h_1} \quad \forall\, h\in S, \tag{4.1}$$

which is $V_{h_1,h_2}=-\ell_{h_1}$. Together with the compatibility condition (2.39), this leads to

$$R^*_{h_1}\mathfrak{g}_{h_2,h}=-\sum_{h'\in S}\mathfrak{g}_{h_1,h'}\,V^{h'}{}_{h_1,h} \quad \forall\, h\in S \tag{4.2}$$

and in particular

$$R^*_{h_1}\mathfrak{g}_{h_2,h_2}=\mathfrak{g}_{h_1,h_1} \quad (h_1h_2=e). \tag{4.3}$$

It is natural to assign to $\mathfrak{g}_{h_1,h_1}$ the interpretation of the square of the distance from g to gh_1. Then (4.3) tells us that this distance is equal to the reverse distance, i.e., that from gh_1 to g.

Remark: For making contact with ordinary discrete geometry, this suggests to demand vanishing biangle torsion. It should be noticed, however, that (4.3) does not necessarily require vanishing biangle torsion (see Sec. V B). Furthermore, in a communication network it is natural to allow the possibility of assigning different lengths (routing distances) to a direction and its inverse. ■

As a consequence of (4.1), only transformations of V_{h_1} are allowed with an isometry matrix J_{h_1} subject to

$$J^h{}_{h_1,h_1}=\delta^h_{h_1} \quad \forall\, h\in S. \tag{4.4}$$

This means $J_{h_1}\ell_{h_1}=\ell_{h_1}$, which restricts the freedom to isometries leaving the vector $V_{h_1,h_2}=-\ell_{h_1}$ invariant. These are rotations (including reflections) about V_{h_1,h_2}.

(*b*) *Vanishing triangle torsion.* The vanishing of the triangle torsion for a triangle $h_1h_2=h_0$ (at some lattice site) amounts to

$$V^h{}_{h_1,h_2}=\delta^h_{h_0}-\delta^h_{h_1} \quad \forall\, h\in S, \tag{4.5}$$

which is $V_{h_1,h_2}=\ell_{h_0}-\ell_{h_1}$. Together with (2.39) this implies

$$R^*_{h_1}\mathfrak{g}_{h_2,h}=\sum_{h'\in S}(\mathfrak{g}_{h_0,h'}-\mathfrak{g}_{h_2,h'})\,V^{h'}{}_{h_1,h} \quad \forall\, h\in S \tag{4.6}$$

and in particular

$$R^*_{h_1}\mathfrak{g}_{h_2,h_2}=\mathfrak{g}_{h_1,h_1}+\mathfrak{g}_{h_0,h_0}-2\,\mathfrak{g}_{h_0,h_1} \quad (h_1h_2=h_0). \tag{4.7}$$

Using the standard interpretation of the metric components, this is a well-known law of Euclidean geometry, the cosine law of triangles. Hence, the requirement of a metric-compatible and triangle-torsion-free linear connection restricts the metric in such a way that triangles are always flat. If triangle torsion is admitted, then it is possible to curve a triangle in such a way that the parallel transport is that of a spherical triangle, for example, see Sec. V A.

Equation (4.5) restricts the freedom of isometries in the transport matrices by

$$J^h{}_{h_1,h_0}-J^h{}_{h_1,h_1}=\delta^h_{h_0}-\delta^h_{h_1} \quad \forall\, h\in S, \tag{4.8}$$

which is $J_{h_1}(\ell_{h_0}-\ell_{h_1})=\ell_{h_0}-\ell_{h_1}$. Hence J_{h_1} corresponds to a ''rotation'' which leaves the vector $V_{h_1,h_2}=\ell_{h_0}-\ell_{h_1}$ fixed.

(*c*) *Vanishing quadrangle torsion*. The vanishing of the quadrangle torsion associated with a quadrangle $h_1h_2=\hat{h}_1\hat{h}_2=g\notin S_e$ (at some lattice site) means

$$V^h{}_{h_1,h_2}+\delta^h_{h_1}=V^h{}_{\hat{h}_1,\hat{h}_2}+\delta^h_{\hat{h}_1}\quad\forall\, h\in S \tag{4.9}$$

and thus $V_{h_1,h_2}-V_{\hat{h}_1,\hat{h}_2}=\ell_{\hat{h}_1}-\ell_{h_1}$. Together with the metric-compatibility condition this imposes restrictions on the metric components. In particular, for a positive definite metric the triangle inequalities lead to

$$|\|V_{h_1,h_2}\|-\|V_{\hat{h}_1,\hat{h}_2}\||\leqslant\|\ell_{h_1}-\ell_{\hat{h}_1}\|\leqslant\|V_{h_1,h_2}\|+\|V_{\hat{h}_1,\hat{h}_2}\|, \tag{4.10}$$

where $\|V_{h_1,h_2}\|=\sqrt{g(V_{h_1,h_2},V_{h_1,h_2})}$. Using (2.39), this restricts the metric components by

$$|\sqrt{R^*_{h_1}\mathfrak{g}_{h_2,h_2}}-\sqrt{R^*_{\hat{h}_1}\mathfrak{g}_{\hat{h}_2,\hat{h}_2}}|\leqslant\sqrt{\mathfrak{g}_{h_1,h_1}+\mathfrak{g}_{\hat{h}_1,\hat{h}_1}-2\,\mathfrak{g}_{h_1,\hat{h}_1}}\leqslant\sqrt{R^*_{h_1}\mathfrak{g}_{h_2,h_2}}+\sqrt{R^*_{\hat{h}_1}\mathfrak{g}_{\hat{h}_2,\hat{h}_2}}\,. \tag{4.11}$$

The isometries J_h have to satisfy the equation

$$\sum_{h'\in S}(J^h{}_{h_1,h'}-J^h{}_{\hat{h}_1,h'})\,V^{h'}{}_{h_1,h_2}=J^h{}_{\hat{h}_1,h_1}-\delta^h_{h_1}-J^h{}_{\hat{h}_1,\hat{h}_1}+\delta^h_{\hat{h}_1}\quad\forall\, h\in S, \tag{4.12}$$

which is $J_{h_1}V_{h_1,h_2}-J_{\hat{h}_1}V_{\hat{h}_1,\hat{h}_2}=\ell_{\hat{h}_1}-\ell_{h_1}$. In particular, a rotation which leaves V_{h_1,h_2} fixed, so that $J_{h_1}V_{h_1,h_2}=V_{h_1,h_2}$, together with a rotation which leaves $V_{\hat{h}_1,\hat{h}_2}$ fixed, so that $J_{\hat{h}_1}V_{\hat{h}_1,\hat{h}_2}=V_{\hat{h}_1,\hat{h}_2}$, preserves the quadrangle and thus solves the above constraint. Another possibility is given by combined rotations J_{h_1} and $J_{\hat{h}_1}$ which leave the vector $V_{h_1,h_2}-V_{\hat{h}_1,\hat{h}_2}$ and thus $\ell_{\hat{h}_1}-\ell_{h_1}$ fixed, so that $J_{h_1}(\ell_{h_1}-\ell_{\hat{h}_1})=\ell_{h_1}-\ell_{\hat{h}_1}$ and $J_{\hat{h}_1}(\ell_{h_1}-\ell_{\hat{h}_1})=\ell_{h_1}-\ell_{\hat{h}_1}$.

The following subsections provide examples of Riemannian group lattices which admit torsion-free linear connections. In the discussions we make use of the fact that a linear connection determines a tangent space picture of the group lattice, as described in Sec. II F.

A. Maximal group lattices

A group lattice (G,S) with $S=G\backslash\{e\}$ is called *maximal*. It is bicovariant and carries the universal differential calculus. There are only biangles and triangles, but no quadrangles. The condition of vanishing torsion determines a unique linear connection which is given by

$$V^h{}_{h_1,h_2}=\begin{cases}-\delta^h_{h_1} & \text{if } h_1h_2=e,\\ \delta^h_{h_0}-\delta^h_{h_1} & \text{if } h_0:=h_1h_2\neq e,\end{cases} \tag{4.13}$$

and thus constant. This implies $V_hV_{h^{-1}}=I$ and $V_{h_1}V_{h_2}=V_{h_0}$ if $h_1h_2=h_0$. As a consequence, the curvature of the connection vanishes.[14]

The metric compatibility condition evaluated for this connection becomes

$$R^*_h\mathfrak{g}_{h_1,h_2}=\begin{cases}\mathfrak{g}_{h,h}-\mathfrak{g}_{h,hh_2}-\mathfrak{g}_{hh_1,h}+\mathfrak{g}_{hh_1,hh_2} & \text{if } hh_1\neq e,\ hh_2\neq e,\\ \mathfrak{g}_{h,h}-\mathfrak{g}_{h,hh_2} & \text{if } hh_1=e,\ hh_2\neq e,\\ \mathfrak{g}_{h,h} & \text{if } h_1=h_2,\ hh_1=e.\end{cases} \tag{4.14}$$

Example 4.1: Let G be $\mathbb{Z}_3$, the cyclic group consisting of the three elements 0,1,2 with addition modulo 3 as the group composition. We choose the group lattice determined by S

$=\{1,2\}$ which is the complete digraph with three vertices. There are two biangles, $1+2=0=2+1$ (modulo 3), and two triangles, $1+1=2$ and $2+2=1$ (modulo 3). The unique torsion-free linear connection is determined by the two matrices

$$V_1=\begin{pmatrix} -1 & -1 \\ 1 & 0 \end{pmatrix}, \quad V_2=\begin{pmatrix} 0 & 1 \\ -1 & -1 \end{pmatrix}. \tag{4.15}$$

A metric is given by

$$\mathfrak{g}=\begin{pmatrix} a & b \\ b & c \end{pmatrix} \tag{4.16}$$

with functions a,b,c, and the compatibility condition with the above connection reduces to

$$R_1^*\begin{pmatrix} a & b \\ b & c \end{pmatrix}=\begin{pmatrix} a-2b+c & a-b \\ a-b & a \end{pmatrix}. \tag{4.17}$$

This means that one can specify arbitrary values of the metric functions a,b,c at *one* point. The metric at the other points is then determined by the last equation and the resulting metric on $\mathbb{Z}_3$ is compatible with the above torsion-free connection. Assigning the usual interpretation in terms of Euclidean distances and angles to the metric components, one recovers the rules of Euclidean trigonometry. In particular, in case of a constant metric, the compatibility condition restricts $\mathfrak{g}$ to

$$\mathfrak{g}=a\begin{pmatrix} 1 & \frac{1}{2} \\ \frac{1}{2} & 1 \end{pmatrix} \tag{4.18}$$

with a constant a. This expresses metric properties of a regular Euclidean triangle. The parallel transport determined by the torsion-free connection coincides with that of the Euclidean plane. Indeed, from (2.41) we infer

at $k+1$ mod 3			at k mod 3	at $k+2$ mod 3			at k mod 3
$\tilde{\mathcal{V}}_{\ell_1}$:	ℓ_1	$\mapsto$	$\ell_2-\ell_1$	$\tilde{\mathcal{V}}_{\ell_2}$:	ℓ_1	$\mapsto$	$-\ell_2$
	ℓ_2		$-\ell_1$		ℓ_2		$\ell_1-\ell_2$

which maps the Riemannian group lattice isometrically onto a Euclidean triangle in the tangent space at a site. ■

Example 4.2: Let $G=\mathbb{Z}_4$, $S=\{1,2,3\}$. The torsion-free linear connection is then given by

$$V_1=\begin{pmatrix} -1 & -1 & -1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}, \quad V_2=\begin{pmatrix} 0 & 0 & 1 \\ -1 & -1 & -1 \\ 1 & 0 & 0 \end{pmatrix}, \quad V_3=\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -1 & -1 & -1 \end{pmatrix}. \tag{4.19}$$

Assuming the metric to be constant, the compatibility condition restricts it to the form

$$\mathfrak{g}=\begin{pmatrix} a & b & a-b \\ b & 2b & b \\ a-b & b & a \end{pmatrix}. \tag{4.20}$$

For $b=a/2$ we recover the geometry of a regular tetrahedron in Euclidean $\mathbb{R}^3$. Since we deal with a three-dimensional Riemannian group lattice, we are actually describing the tetrahedron volume. Furthermore, in the limit $b\to a$ the above geometry tends to that of a quadrate in the Euclidean

plane where the vector associated with $2 \in S$ corresponds to the diagonal. Accordingly, in this limit the determinant of $\mathfrak{g}$ vanishes, so that $\mathfrak{g}$ no longer defines a metric according to our definition in Sec. II E. ■

B. Two-dimensional Riemannian group lattices

Let G be a discrete group and $S=\{a,b\}$ be a subset consisting of two different elements of G which generate G such that (G,S) is a bicovariant group lattice. Then either $aba^{-1}=a$, which contradicts $a\neq b$, or $aba^{-1}=b$, which is $ab=ba$. Hence, bicovariance requires that G is Abelian. By a fundamental theorem, every finite Abelian group is isomorphic to a direct product of cyclic groups of prime power order.

The following examples in particular demonstrate that, for a given metric on a group lattice, there may not exist a metric-compatible linear connection with vanishing torsion, i.e., a Levi-Civita connection. Moreover, in contrast to ordinary continuum differential geometry, if such a connection exists, then is not unique in general.

1. $\mathbb{Z}_4$ lattices

(a) Let $G=\mathbb{Z}_4$ and $S=\{1,2\}$. There is one biangle, $2+2=0$ (modulo 4), one triangle, $1+1=2$, and one quadrangle, $1+2=3=2+1$, which implies the 2-form relation $\theta^1\cap\theta^2=-\theta^2\cap\theta^1$. Vanishing torsion restricts the matrices V_i of the linear connection to

$$V_1=\begin{pmatrix} -1 & p \\ 1 & 1+q \end{pmatrix}, \quad V_2=\begin{pmatrix} 1+p & 0 \\ q & -1 \end{pmatrix} \tag{4.21}$$

with arbitrary functions p and q. For a metric of the form (4.16), the metric-compatibility condition $R_1^*\mathfrak{g}=V_1^T\mathfrak{g}V_1$ reads

$$\begin{gathered} R_1^*a=a-2\,b+c\,, \quad R_1^*b=p\,(b-a)+(1+q)(c-b)\,, \\ R_1^*c=p^2\,a+2\,p\,(1+q)\,b+(1+q)^2\,c. \end{gathered} \tag{4.22}$$

With the help of $R_2^*=(R_1^*)^2$, the second condition $R_2^*\mathfrak{g}=V_2^T\mathfrak{g}V_2$ leads to $V_1\,(R_1^*V_1)\,V_2^{-1}=J$, where J is an arbitrary element of the isometry group of the metric (at each site of the group lattice). A lengthy computation, aided by computer algebra, reveals that *every Levi-Civita connection on* $(\mathbb{Z}_4,\{1,2\})$ *is flat, i.e., its curvature vanishes*.[15] The integrability condition (3.27) then enforces $J=I$ so that $V_2=V_1\,R_1^*V_1$. As a consequence, we obtain the following representation of $\mathbb{Z}_4$: $R_1^*p=-p/(1+p+q)$, $R_1^*q=-(2+p+q)/(1+p+q)$. This implies $R_2^*p=-p/(1+p)$ and $R_2^*q=q/(1+p)$ and thus $(R_1^*)^4p=(R_2^*)^2p=p$, $(R_1^*)^4q=(R_2^*)^2q=q$.

Excluding special values of $q(0)$ and $p(0)$, the geometries with a Levi-Civita connection are given by

$$\begin{aligned} &a(1)=a(0)-2\,b(0)+c(0)\,, \quad b(1)=-p(0)\,a(0)+[p(0)-1-q(0)]\,b(0)+[1+q(0)]\,c(0), \\ &c(1)=p(0)^2\,a(0)+2\,p(0)\,[1+q(0)]\,b(0)+[1+q(0)]^2\,c(0), \\ &a(2)=[1+p(0)]^2\,a(0)+2\,q(0)\,[1+p(0)]\,b(0)+q(0)^2\,c(0), \\ &b(2)=-[1+p(0)]\,b(0)-q(0)\,c(0)\,, \quad c(2)=c(0), \\ &a(3)=[1+p(0)]^2\,a(0)+2\,[1+p(0)]\,[1+q(0)]\,b(0)+[1+q(0)]^2\,c(0), \\ &b(3)=p(0)\,[1+p(0)]\,a(0)+[1+2\,p(0)]\,[1+q(0)]\,b(0)+[1+q(0)]^2\,c(0), \\ &c(3)=p(0)^2\,a(0)+2\,p(0)\,[1+q(0)]\,b(0)+[1+q(0)]^2\,c(0), \end{aligned} \tag{4.23}$$

and

$$q(1)=-[2+p(0)+q(0)]/[1+p(0)+q(0)], \quad p(1)=-p(0)/[1+p(0)+q(0)],$$
$$q(2)=q(0)/[1+p(0)], \quad p(2)=-p(0)/[1+p(0)], \tag{4.24}$$
$$q(3)=-[2+p(0)+q(0)]/[1+q(0)], \quad p(3)=p(0)/[1+q(0)].$$

(*b*) Let $G=\mathbb{Z}_4$ again, but now we choose $S=\{1,3\}$. In this case, there are two biangles, $1+3=0=3+1$ (modulo 4), no triangle and a quadrangle corresponding to $1+1=2=3+3$ (modulo 4). The latter leads to the 2-form relation $\theta^1\cap\theta^1+\theta^3\cap\theta^3=0$. The condition of vanishing torsion imposes the following restrictions on a linear connection,

$$V_1=\begin{pmatrix} u & -1 \\ 1+v & 0 \end{pmatrix}, \quad V_3=\begin{pmatrix} 0 & 1+u \\ -1 & v \end{pmatrix}, \tag{4.25}$$

with arbitrary functions u and v. For a metric of the form (4.16) the compatibility condition $R_1^*\mathfrak{g}=V_1^T\mathfrak{g}V_1$ reads

$$R_1^*a=u^2\,a+2u(1+v)\,b+(1+v)^2\,c\,, \quad R_1^*b=-u\,a-(1+v)\,b\,, \quad R_1^*c=a, \tag{4.26}$$

and, with the help of $R_3^*=(R_1^*)^3$, the second metric-compatibility condition $R_3^*\mathfrak{g}=V_3^T\mathfrak{g}V_3$ leads to $V_1\,(R_1^*V_1)[(R_1^*)^2V_1]\,V_3^{-1}=J$ where J is an element of the isometry group of the metric. Further exploration with the help of computer algebra shows that *every Levi-Civita connection on* $(\mathbb{Z}_4,\{1,3\})$ *has vanishing curvature.*

Since the only metric-compatible torsion-free linear connections on the above $\mathbb{Z}_4$ lattices have vanishing curvature, via backward parallel transport they are isometrically mapped to a closed lattice in $\mathbb{R}^2$ which represents the tangent space at a site. In particular, this means that we cannot model something like a tetrahedron surface in this way. To supply the $\mathbb{Z}_4$ group lattices with nonvanishing curvature is only possible if the condition of vanishing torsion is dropped (see Sec. V B).

2. $\mathbb{Z}^2$ lattices

Let us consider the group lattice $(\mathbb{Z}^2,\{\hat{1},\hat{2}\})$ where $\hat{1}:=(1,0)$ and $\hat{2}:=(0,1)$. It has no biangles or triangles, but a quadrangle corresponding to $\hat{1}+\hat{2}=\hat{2}+\hat{1}$. The condition of vanishing torsion restricts the parallel transport matrices $V_i:=V_{\hat{i}}$ to

$$V_1=\begin{pmatrix} p & u \\ q & 1+v \end{pmatrix}, \quad V_2=\begin{pmatrix} 1+u & r \\ v & s \end{pmatrix} \tag{4.27}$$

with arbitrary functions p,q,r,s,u,v. The following example demonstrates that there are torsion-free and metric-compatible parallel transports with *non*vanishing curvature even on a two-dimensional lattice carrying the metric properties of a regular quadratic lattice in Euclidean $\mathbb{R}^2$.

Example 4.3: Let us choose the metric to be

$$\mathfrak{g}=\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \tag{4.28}$$

at all sites. The metric-compatibility condition for the above torsion-free linear connection then leads to the following two classes of solutions. The first class is given by

$$V_1=\begin{pmatrix} \epsilon_1 & 0 \\ 0 & 1 \end{pmatrix}, \quad V_2=\begin{pmatrix} 1 & 0 \\ 0 & \epsilon_2 \end{pmatrix} \tag{4.29}$$

with functions ϵ_i with values in $\{\pm 1\}$. The curvature only vanishes if ϵ_1 and ϵ_2 are constant in the $\hat{1}$ and $\hat{2}$ direction, respectively.

If the curvature vanishes, the (backward) parallel transport does not depend on the path in the lattice, see (2.45). It can thus be used to map the whole group lattice into the tangent space at one point, which is isomorphic to $\mathbb{R}^2$ in the case under consideration. Let us choose the lattice point (0,0). The tangent vectors ℓ_h at this site may then be identified with the vectors $\mathbf{u}_1$ and $\mathbf{u}_2$ pointing from (0,0) to (1,0) and (0,1), respectively, in $\mathbb{R}^2$. Then $\ell_{\hat{1}}$ at the group lattice site (1,0) is mapped to the vector $\mathbf{V}_{1,1}$ which we attach at the tip of $\mathbf{u}_1$ in $\mathbb{R}^2$ according to the prescription of Sec. II F. If $\epsilon_1 = -1$, this vector points into the "wrong direction," i.e., its tip coincides with (0,0). This means that the resulting lattice in $\mathbb{R}^2$ gets *folded*. Similarly, if $\epsilon_2 = -1$, the lattice gets folded in the other direction.

A particular solution is given by $V_h = I$, the unit matrix, at all sites. It corresponds to the ordinary Euclidean parallel transport. This solution certainly has a nice continuum limit. Introducing a lattice spacing parameter, we may write $V_h = I + \kappa \Gamma_h + O(\kappa^2)$. Some of the other solutions V_h given above have negative determinant at some sites and cause folding in the sense described above. They are related to the above solution at those sites by an isometry J_h with determinant -1. As a consequence, they cannot have a continuum limit. The requirement of a continuum limit may thus distinguish a certain connection and eliminate connections with folding.

The second class of solutions is given by

$$V_1 = \begin{pmatrix} 0 & -1 \\ \epsilon_1 & 0 \end{pmatrix}, \quad V_2 = \begin{pmatrix} 0 & \epsilon_2 \\ -1 & 0 \end{pmatrix}. \tag{4.30}$$

The curvature only vanishes if at all sites $R_2^* \epsilon_1 = \epsilon_2$ and $R_1^* \epsilon_2 = \epsilon_1$. An orientation-preserving connection is obtained if $\epsilon_1 = \epsilon_2 = 1$. The corresponding transports in the two directions act with rotations. ■

There are metrics (with constant signature) on $(\mathbb{Z}^2, \{\hat{1}, \hat{2}\})$ which do *not* admit a Levi-Civita connection, although the constraints are by far not as stringent as in our previous examples. Counterexamples are easily constructed. A geometric condition for the existence of a Levi-Civita connection is given by (4.11) in the case of a positive definite metric. Let us recall its origin in the case under consideration. The tangent space at a site a is isomorphic to $\mathbb{R}^2$ with the Euclidean inner product of vectors (see Sec. II F). The tangent vectors $\ell_{\hat{i}}$ are then represented by vectors $\mathbf{u}_i \in \mathbb{R}^2$, $i = 1,2$, such that $\mathbf{u}_i \cdot \mathbf{u}_j = \mathfrak{g}_{ij}(a)$ where $\mathfrak{g}_{ij} := \mathfrak{g}_{\hat{i},\hat{j}}$. The parallel transport $\widetilde{\mathcal{V}}_{\ell_{\hat{i}}}$ maps the tangent space at the site $a + \hat{i}$ into the tangent space at a. Metric-compatibility of the connection means

$$\mathbf{V}_{ij} \cdot \mathbf{V}_{ik} = \mathfrak{g}_{jk}(a + \hat{i}), \tag{4.31}$$

where $\mathbf{V}_{ij}$ represents $\widetilde{\mathcal{V}}_{\ell_{\hat{i}}} \ell_{\hat{j}}$ at the site a. If the connection is (quadrangle) torsion free, then adjacent quadrangles are preserved by the backward parallel transport, so that $\mathbf{u}_i + \mathbf{V}_{ij} = \mathbf{u}_j + \mathbf{V}_{ji}$. The last equation has solutions if and only if $\|\mathbf{V}_{12}| - |\mathbf{V}_{21}\| \leq |\mathbf{u}_2 - \mathbf{u}_1| \leq |\mathbf{V}_{12}| + |\mathbf{V}_{21}|$, where $|\mathbf{V}_{12}|$ denotes the Euclidean norm of $\mathbf{V}_{12}$ in $\mathbb{R}^2$. This is illustrated in Fig. 1. Using (4.31), this condition is expressed as

$$|\sqrt{\mathfrak{g}_{22}(a+\hat{1})} - \sqrt{\mathfrak{g}_{11}(a+\hat{2})}| \leq \sqrt{\mathfrak{g}_{11}(a) + \mathfrak{g}_{22}(a) - 2\,\mathfrak{g}_{12}(a)} \leq \sqrt{\mathfrak{g}_{22}(a+\hat{1})} + \sqrt{\mathfrak{g}_{11}(a+\hat{2})} \tag{4.32}$$

in terms of the metric at the sites a, $a + \hat{1}$ and $a + \hat{2}$ [see also (4.11)]. If this condition is not fulfilled, a Levi-Civita connection does not exist. If the condition is satisfied, a Levi-Civita connection exists, but it is not unique. Even if equality holds in the last part of (4.32), so that the circles in Fig. 1 have exactly one point in common, we still have the freedom to choose $\mathbf{V}_{11}$ and $\mathbf{V}_{22}$ in two possible ways, as illustrated in Fig. 2.

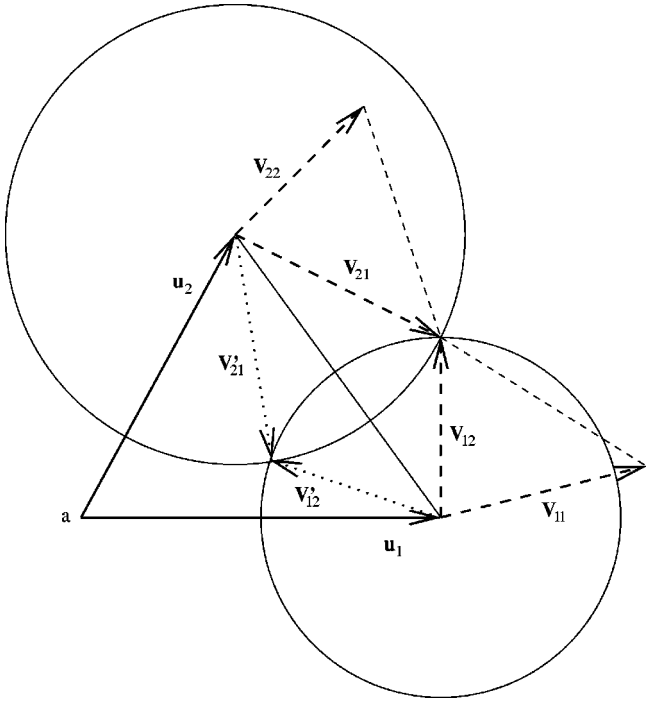

FIG. 1. Levi-Civita connections on a $\mathbb{Z}^2$ lattice exist iff at each lattice site the circle with radius $|\mathbf{V}_{12}|$ around the tip of $\mathbf{u}_1$ intersects the circle with radius $|\mathbf{V}_{21}|$ around the tip of $\mathbf{u}_2$.

The freedom in the parallel transport left by the conditions of metric-compatibility and vanishing torsion is a freedom of reflections about some axes. In Fig. 2 it shows up as reflections about the three axes AC, BC and AB. In Sec. IV C we show that reflections about AB and BC and their composition comprise the whole freedom left for V_1 and V_2 by the conditions of vanishing torsion and metric-compatibility. Such reflections lead to folding of the tangent space lattice obtained by backward parallel transport of the group lattice to the tangent space at a. Moreover, the orientation of some of the frames at a obtained by backward parallel transport of frames of basic tangent vectors at $a+\hat{\imath}$, $i=1,2$, gets changed. This can be excluded by demanding that $\det V_i>0$. But we should also require that the dyad $(\mathbf{V}_{21},\mathbf{V}_{12})$ has positive orientation, which is necessary in order to avoid reflections about the axis AB. This amounts to $V^1{}_{12}+V^2{}_{12}>0$. In higher dimensions, the determination of the ambiguities in the Levi-Civita connections and their reduction appears to be a difficult task (see also Sec. IV C).

Whereas torsion is a first order quantity, curvature is of second order since it expresses features of the geometry determined by the composition of *two* (backward) parallel transports. In the case under consideration, the components of the curvature tensor are given in matrix form by $\mathcal{R}_{ij}:=V_i R_{\hat{i}}^{*} V_j - V_j R_{\hat{j}}^{*} V_i$. In Fig. 3 the vector $\mathbf{z}$ represents $\tilde{\mathcal{V}}_{\ell_1}\tilde{\mathcal{V}}_{\ell_2} Z$ where $Z=\Sigma_i Z^i\cdot \ell_{\hat{\imath}}$. Hence

$$\mathbf{z}=\sum_{i,j}\ \mathbf{u}_i\,[V_1(a)V_2(a+\hat{1})]^i{}_j\,Z^j(a+\hat{1}+\hat{2}). \tag{4.33}$$

The vector $\mathbf{z}'$ represents $\tilde{\mathcal{V}}_{\ell_2}\tilde{\mathcal{V}}_{\ell_1} Z$, so that

$$\mathbf{z}'=\sum_{i,j}\ \mathbf{u}_i\,[V_2(a)V_1(a+\hat{2})]^i{}_j\,Z^j(a+\hat{2}+\hat{1}). \tag{4.34}$$

The difference gives a measure of the curvature at a [see also (2.45)]:

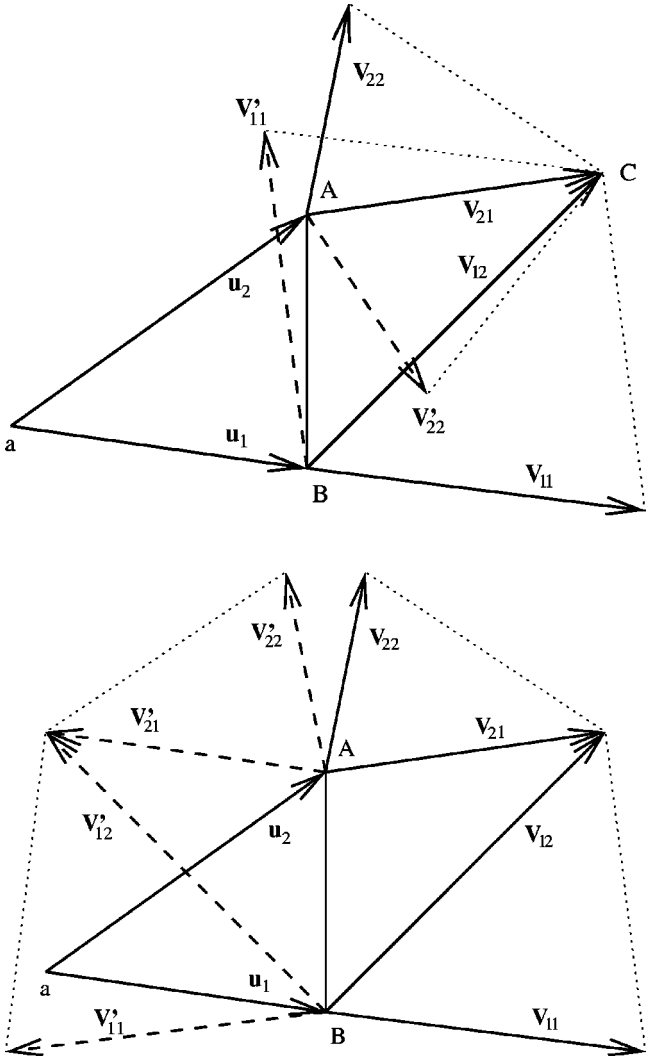

FIG. 2. The vectors $\mathbf{V}_{ij}$ and $\mathbf{V}'_{ij}$ result from torsion-free metric-compatible (backward) parallel transports which differ by a reflection about some axis.

$$\mathbf{z}-\mathbf{z}'=\sum_{i,j}\mathbf{u}_i\,\mathcal{R}^{i}{}_{j12}(a)\,Z^j(a+\hat{1}+\hat{2}). \tag{4.35}$$

If the torsion vanishes at a site a, one can draw an isometric picture of the geometry in the tangent space at a to first order. This represents the site a, its first order neighbors $a+\hat{\imath}$, and the basic tangent vectors at these sites while preserving the metric properties at all these sites and preserving biangles, triangles and quadrangles at a. If, moreover, the curvature vanishes at a, then we can draw an isometric picture to second order.

C. Freedom of Levi-Civita connections on a hypercubic $\mathbb{Z}^n$ lattice

We already learned that, in general, there is no Levi-Civita connection for a given metric on a group lattice. If such a connection exists, it need not be unique. The corresponding freedom will be explored in this section for the case of hypercubic $\mathbb{Z}^n$ lattices given by $G=\mathbb{Z}^n$ and $S=\{\hat{\imath}\mid i=1,\ldots,n\}$, where $\hat{\imath}:=(0,\ldots,1,\ldots,0)$ with the 1 in the ith position. We consider only positive

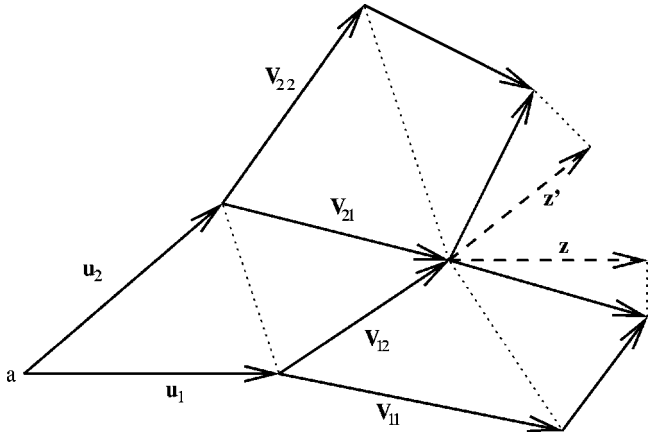

FIG. 3. The familiar effect of curvature: backward parallel transport along different paths results in different vectors in the tangent space at a point.

definite metrics and choose the standard inner product $(\mathbf{u},\mathbf{v})=\mathbf{u}\cdot\mathbf{v}$ for $\mathbf{u},\mathbf{v}\in\mathbb{R}^n$ (cf. Sec. II F). In the case of a hypercubic group lattice the condition of vanishing torsion can be expressed as

$$\mathbf{u}_i+\mathbf{V}_{ij}=\mathbf{u}_j+\mathbf{V}_{ji}\,. \tag{4.36}$$

Together with the metric-compatibility, this determines a Levi-Civita connection up to isometries J_i which preserve the above conditions, i.e.,

$$\mathbf{u}_i+J_i(\mathbf{V}_{ij})=\mathbf{u}_j+\mathbf{J}_j(\mathbf{V}_{ji}) \tag{4.37}$$

[see also (2.48)]. Subtracting (4.36) from (4.37), we find

$$\mathbf{A}_{ij}=\mathbf{A}_{ji}\quad\text{where}\quad\mathbf{A}_{ij}:=J_i(\mathbf{V}_{ij})-\mathbf{V}_{ij}\,. \tag{4.38}$$

Using the isometry condition (2.49) and the last equation, we obtain

$$\mathbf{V}_{ij}\cdot\mathbf{V}_{ij}=J_i(\mathbf{V}_{ij})\cdot J_i(\mathbf{V}_{ij})=\mathbf{V}_{ij}\cdot\mathbf{V}_{ij}+\mathbf{A}_{ij}\cdot(\mathbf{A}_{ij}+2\,\mathbf{V}_{ij}) \tag{4.39}$$

so that

$$\mathbf{A}_{ij}\cdot(\mathbf{A}_{ij}+2\,\mathbf{V}_{ij})=0 \tag{4.40}$$

and because of (4.38) also

$$\mathbf{A}_{ij}\cdot(\mathbf{A}_{ij}+2\,\mathbf{V}_{ji})=0. \tag{4.41}$$

Subtracting the last two equations and using (4.36) leads to

$$\mathbf{A}_{ij}\cdot(\mathbf{u}_j-\mathbf{u}_i)=0. \tag{4.42}$$

For $i\neq j$ and if $\mathbf{A}_{ij}\neq 0$, we set $\mathbf{A}_{ij}=\alpha_{ij}\,\mathbf{a}_{ij}$ with a unit vector $\mathbf{a}_{ij}$ orthogonal to $\mathbf{u}_j-\mathbf{u}_i$. From (4.40) we then obtain $\alpha_{ij}=-2\,\mathbf{a}_{ij}\cdot\mathbf{V}_{ij}=0$, so that

$$\mathbf{A}_{ij}=-2\,(\mathbf{a}_{ij}\cdot\mathbf{V}_{ij})\,\mathbf{a}_{ij} \tag{4.43}$$

and thus

$$J_i(\mathbf{V}_{ij})=\mathbf{V}_{ij}-2\,(\mathbf{a}_{ij}\cdot\mathbf{V}_{ij})\,\mathbf{a}_{ij}\,,\quad J_j(\mathbf{V}_{ji})=\mathbf{V}_{ji}-2\,(\mathbf{a}_{ij}\cdot\mathbf{V}_{ji})\,\mathbf{a}_{ij}. \tag{4.44}$$

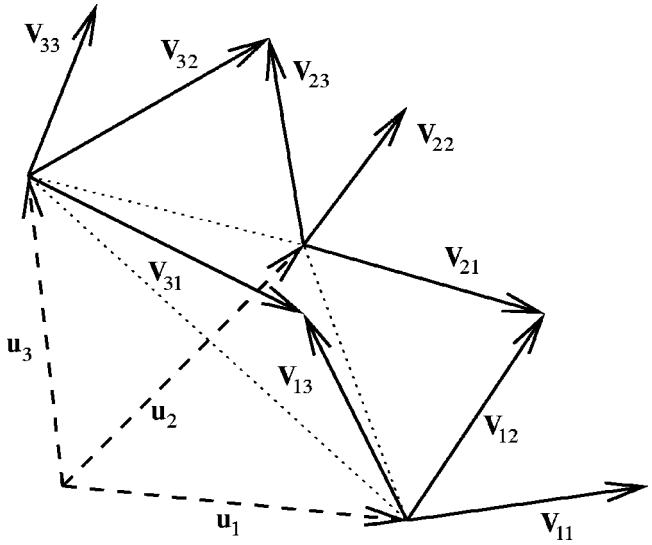

FIG. 4. Tangent space picture of the nearest neighborhood for the cubic $\mathbb{Z}^3$ lattice, as determined by a Levi-Civita connection. The freedom in the choice of such a connection is due to reflections with respect to hyperplanes through $\mathbf{u}_i - \mathbf{u}_j$, $i \neq j$.

As a consequence, the effect of J_i on $\mathbf{V}_{ij}$ is that of a reflection with respect to the hyperplane orthogonal to $\mathbf{a}_{ij}$ (which in turn is orthogonal to $\mathbf{u}_j - \mathbf{u}_i$). If $\mathbf{A}_{ij} \neq 0$ for all $j \neq i$, then J_i for a fixed i reflects all the $n-1$ vectors $\mathbf{V}_{ij}$, $j \neq i$, with respect to the respective hyperplane (orthogonal to $\mathbf{a}_{ij}$). Of course, we still have to respect the remaining conditions which arise from the isometry conditions (2.49), i.e., $J_i(\mathbf{V}_{ik}) \cdot J_i(\mathbf{V}_{il}) = \mathbf{V}_{ik} \cdot \mathbf{V}_{il}$.

Let us look at the two-dimensional case. If $\mathbf{A}_{12} = 0$, we have $J_1(\mathbf{V}_{12}) = \mathbf{V}_{12}$ and $J_2(\mathbf{V}_{21}) = \mathbf{V}_{21}$, so J_1 and J_2 are reduced to reflections about $\mathbf{V}_{12}$ and $\mathbf{V}_{21}$, respectively. If $\mathbf{A}_{12} \neq 0$, then we have $J_1(\mathbf{V}_{12}) = \mathbf{V}_{12} - 2\,(\mathbf{a}_{12} \cdot \mathbf{V}_{12})\,\mathbf{a}_{12}$, $J_2(\mathbf{V}_{21}) = \mathbf{V}_{21} - 2\,(\mathbf{a}_{12} \cdot \mathbf{V}_{21})\,\mathbf{a}_{12}$. The effect of both is a reflection about the axis along $\mathbf{u}_2 - \mathbf{u}_1$. If H_{12} is such a reflection, then $H_{12} J_1(\mathbf{V}_{12}) = \mathbf{V}_{12}$ and $H_{12} J_2(\mathbf{V}_{21}) = \mathbf{V}_{21}$ which reduces the problem to the case $\mathbf{A}_{12} = 0$ for $H_{12} J_i$. In three dimensions (see Fig. 4) a classification of the various possibilities already turns out to be quite involved.

V. GROUP LATTICE GEOMETRIES WITH TORSION

Section IV demonstrated that Riemannian group lattices in general do not possess a Levi-Civita connection. In some cases only *flat* Levi-Civita connections exist so that one has to allow for nonvanishing torsion in order to get nonvanishing curvature and thus enough flexibility to assign a nontrivial geometry to the group lattice. Relaxing the previous requirement of vanishing torsion clearly opens more possibilities for modeling discrete surfaces. In fact, the following examples demonstrate that linear connections with torsion naturally appear as properties of Riemannian group lattice geometries. The first subsection below shows how in the presence of torsion a triangle can be curved so that it fits on the surface of a sphere. The remaining subsection treats a $\mathbb{Z}_4$ lattice example.

A. A $\mathbb{Z}_3$ lattice geometry with torsion

Let $G = \mathbb{Z}_3$ and $S = \{1,2\}$. According to Sec. III the components of the torsion tensor are

$$
\begin{aligned}
&Q^1{}_{1,1} = 1 + V^1{}_{1,1}, \quad Q^1{}_{1,2} = 1 + V^1{}_{1,2}, \quad Q^1{}_{2,1} = V^1{}_{2,1}, \quad Q^1{}_{2,2} = -1 + V^1{}_{2,2}, \\
&Q^2{}_{1,1} = -1 + V^2{}_{1,1}, \quad Q^2{}_{1,2} = V^2{}_{1,2}, \quad Q^2{}_{2,1} = 1 + V^2{}_{2,1}, \quad Q^2{}_{2,2} = 1 + V^2{}_{2,2}.
\end{aligned}
\tag{5.1}
$$

If we do not require the vanishing of the whole torsion, but only of the biangle part, i.e., $Q^h_{(0)\,1,2}=Q^h_{(0)\,2,1}=0$, then we can simulate the geometry of a spherical triangle. Setting

$$\mathfrak{g}=\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}, \tag{5.2}$$

a particular solution of the metric-compatibility conditions is

$$V_1=\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}, \quad V_2=\begin{pmatrix}0 & 1\\ -1 & 0\end{pmatrix}. \tag{5.3}$$

Now (2.41) leads to

	at $k+1$ mod 3		at k mod 3		at $k+2$ mod 3		at k mod 3
$\tilde{\mathcal{V}}_{\ell_1}$:	ℓ_1 ℓ_2	$\mapsto$	ℓ_2 $-\ell_1$	$\tilde{\mathcal{V}}_{\ell_2}$:	ℓ_1 ℓ_2	$\mapsto$	$-\ell_2$ ℓ_1

which matches the parallel transport along a spherical triangle. The curvature tensor has only triangle components. Using the matrix notation $\mathcal{R}_{h_1,h_2}=(\mathcal{R}^h{}_{h',h_1,h_2})$, we obtain

$$\mathcal{R}_{(2)\,1,1}=\begin{pmatrix}-1 & -1\\ 1 & -1\end{pmatrix}, \quad \mathcal{R}_{(1)\,2,2}=\begin{pmatrix}-1 & 1\\ -1 & -1\end{pmatrix}, \tag{5.4}$$

and $\mathcal{R}_{(0)\,1,2}=\mathcal{R}_{(0)\,2,1}=0$ (vanishing biangle curvature). The Ricci tensor $\mathrm{Ric}_{h,h'}=\mathcal{R}^1{}_{h,1,h'}+\mathcal{R}^2{}_{h,2,h'}$ is given by

$$\mathrm{Ric}=-\begin{pmatrix}1 & 1\\ 1 & 1\end{pmatrix} \tag{5.5}$$

in matrix notation, and the curvature scalar is $R=-2$. The torsion 2-form is given by

$$\Theta^1=\theta^1\cap\theta^1, \quad \Theta^2=\theta^2\cap\theta^2. \tag{5.6}$$

This is an example of a geometry which cannot be isometrically embedded in a Euclidean space $\mathbb{R}^n$ for any $n\in\mathbb{N}$, simply due to the fact that with the choice of metric (5.2) the sum of the angles of the triangle is $3\pi/2$ and not π as in Euclidean geometry. This fact is taken care of by the torsion of the connection which causes the backward parallel transport of the group lattice triangle not to close to a triangle in the tangent space at a site. The resulting picture in $\mathbb{R}^2$, which represents the tangent space at the unit element, is drawn in Fig. 5. Here we used $\mathbf{V}_{11}=-\mathbf{V}_{21}=\mathbf{u}_2$, $\mathbf{V}_{12}=-\mathbf{V}_{22}=-\mathbf{u}_1$ which follows from (5.3). The triangle torsion satisfies

$$\sum_i \mathbf{u}_i Q^i{}_{1,1}=\mathbf{u}_1+\mathbf{V}_{11}-\mathbf{u}_2=\mathbf{u}_1, \quad \sum_i \mathbf{u}_i Q^i{}_{2,2}=\mathbf{u}_2+\mathbf{V}_{22}-\mathbf{u}_1=\mathbf{u}_2. \tag{5.7}$$

From (2.47) we obtain $\mathbf{V}_{111}=\mathbf{V}_{221}=-\mathbf{u}_1$, $\mathbf{V}_{112}=\mathbf{V}_{222}=-\mathbf{u}_2$ and, using (2.45) and (3.11), the following curvature expressions:

$$\begin{aligned}&\sum_i \mathbf{u}_i \mathcal{R}^i{}_{(2)\,1,1,1}=-\mathbf{u}_1+\mathbf{u}_2, \quad \sum_i \mathbf{u}_i \mathcal{R}^i{}_{(2)\,2,1,1}=-\mathbf{u}_2-\mathbf{u}_1,\\ &\sum_i \mathbf{u}_i \mathcal{R}^i{}_{(1)\,1,2,2}=-\mathbf{u}_1-\mathbf{u}_2, \quad \sum_i \mathbf{u}_i \mathcal{R}^i{}_{(1)\,2,2,2}=-\mathbf{u}_2+\mathbf{u}_1.\end{aligned} \tag{5.8}$$

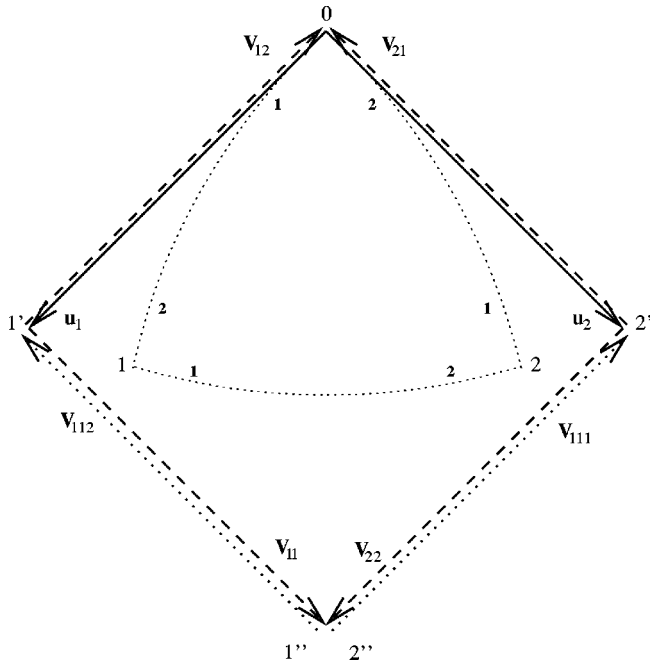

FIG. 5. The result of backward parallel transport of the group lattice $(\mathbb{Z}_3,\{1,2\})$ into the tangent space at 0, using the connection given by (5.3). The points $1'$ and $1''$, and also $2'$ and $2''$, do not coincide because of nonvanishing torsion.

B. The group lattice $(\mathbb{Z}_4,\{1,2\})$

Let $G=\mathbb{Z}_4$ and $S=\{1,2\}$. The torsion of a linear connection has the following components:

$$
\begin{aligned}
&Q^h{}_{2,2}=V^h{}_{2,2}+\delta^h_2 \quad \text{for the biangle } 2+2=0,\\
&Q^h{}_{1,1}=V^h{}_{1,1}-\delta^h_2+\delta^h_1 \quad \text{for the triangle } 1+1=2,\\
&Q^h{}_{2,1}=-Q^h{}_{1,2}=Q^h{}_{1,2;2,1}=V^h{}_{1,2}-V^h{}_{2,1}-\delta^h_2+\delta^h_1 \quad \text{for the quadrangle } 1+2=2+1=3\,.
\end{aligned}
\tag{5.9}
$$

(a) If we require vanishing biangle and triangle torsion, but nonvanishing quadrangle torsion, the coefficient matrices of the parallel transport have the form

$$
V_1=\begin{pmatrix} -1 & p \\ 1 & 1+q \end{pmatrix}, \quad V_2=\begin{pmatrix} 1+r & 0 \\ s & -1 \end{pmatrix} \tag{5.10}
$$

with functions p,q,r,s. As an example, choosing the constant metric

$$
\mathfrak{g}(k)=\begin{pmatrix} 1 & \frac{1}{2} \\ \frac{1}{2} & 1 \end{pmatrix}, \quad k=0,1,2,3 \tag{5.11}
$$

(which is the metric of a regular tetrahedron surface immersed in three-dimensional Euclidean space), and assuming also constant transport matrices, the compatibility conditions with the connection given by (5.10) take the form

$$
q=p\,, \quad p(p+1)=0, \quad s=-1-r/2\,, \quad r(r+2)=0, \tag{5.12}
$$

so that there are four different connections which are compatible with the metric. All solutions have vanishing biangle curvature. The solution with $p=-1,\ r=0$ has nonvanishing triangle and

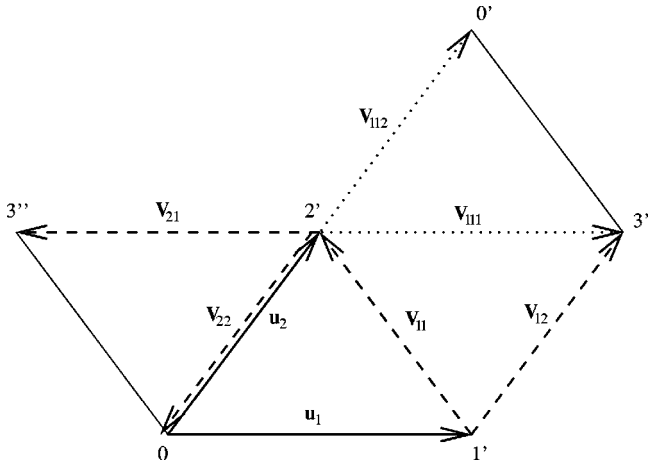

FIG. 6. The result of backward parallel transport of the group lattice $(\mathbb{Z}_4,\{1,2\})$ into the tangent space at 0, using the connection given by (5.13).

quadrangle curvature. The solutions with $(p,r)=(0,0)$, $(p,r)=(-1,-2)$ and $(p,r)=(0,-2)$ possess only nonvanishing triangle curvature. In the latter case $(p=0,r=-2)$ we have

$$V_1=\begin{pmatrix} -1 & 0 \\ 1 & 1 \end{pmatrix}, \quad V_2=\begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}. \tag{5.13}$$

The only nonvanishing part of the curvature 2-form is the triangle part

$$\mathcal{R}_{(2)\,1,1}=V_1V_1-V_2=\begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix}. \tag{5.14}$$

The development of this group lattice in the tangent space at 0 is shown in Fig. 6. Here we used $\mathbf{V}_{11}=\mathbf{u}_2-\mathbf{u}_1$, $\mathbf{V}_{12}=\mathbf{u}_2$, $\mathbf{V}_{21}=-\mathbf{u}_1$ and $\mathbf{V}_{22}=-\mathbf{u}_2$ which follows from (5.13). The resulting surface does not exhibit folding. The quadrangle torsion is given by

$$\sum_i \mathbf{u}_i Q^i{}_{(3)\,1,2}=\mathbf{u}_1+\mathbf{V}_{12}-\mathbf{u}_2-\mathbf{V}_{21}=2\,\mathbf{u}_1. \tag{5.15}$$

Using (2.47) we obtain $\mathbf{V}_{111}=\mathbf{u}_1$, $\mathbf{V}_{112}=\mathbf{u}_2$ and thus the following curvature expressions:

$$\sum_i \mathbf{u}_i \mathcal{R}^i{}_{(2)\,1,1,1}=\mathbf{V}_{111}-\mathbf{V}_{21}=2\,\mathbf{u}_1, \quad \sum_i \mathbf{u}_i \mathcal{R}^i{}_{(2)\,2,1,1}=\mathbf{V}_{112}-\mathbf{V}_{22}=2\,\mathbf{u}_2. \tag{5.16}$$

Remark: In general, the compatibility condition for a constant metric does not enforce a constant connection, i.e., constant transport matrices. Conversely, a constant connection may be compatible with nonconstant metrics. As an example, all metrics of the form

$$\mathfrak{g}(0)=\mathfrak{g}(2)=\begin{pmatrix} a & b \\ b & c \end{pmatrix}, \quad \mathfrak{g}(1)=\mathfrak{g}(3)=\begin{pmatrix} a-2b+c & c-b \\ c-b & c \end{pmatrix} \tag{5.17}$$

are compatible with the connection (5.13). ■

(*b*) If only nonvanishing *biangle torsion* is admitted, the coefficient matrices of the parallel transport take the form

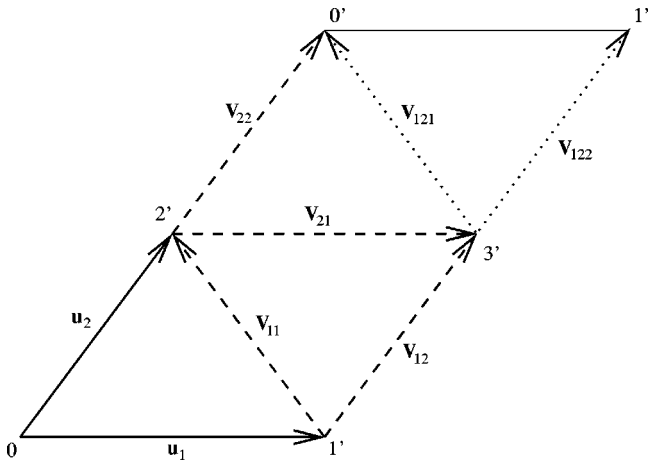

FIG. 7. The group lattice $(\mathbb{Z}_4,\{1,2\})$ mapped to the tangent space at 0 using a connection with nonvanishing biangle torsion, but vanishing triangle and quadrangle torsion.

$$V_1=\begin{pmatrix} -1 & p \\ 1 & 1+q \end{pmatrix}, \quad V_2=\begin{pmatrix} 1+p & u \\ q & v \end{pmatrix} \tag{5.18}$$

with functions p,q,u,v. If these are taken to be constants, the compatibility conditions with the metric (5.11) reduce to

$$\begin{matrix} p=q=0 \\ u=0, v=1 \ \text{ or } \ u=1, v=-1 \end{matrix} \quad \text{or} \quad \begin{matrix} p=q=-1 \\ u=1, v=-1 \ \text{ or } \ u=-1, v=0 \end{matrix}$$

which determines four different connections. The solution with $(p,q,u,v)=(0,0,0,1)$ has the transport matrices

$$V_1=\begin{pmatrix} -1 & 0 \\ 1 & 1 \end{pmatrix}, \quad V_2=\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \tag{5.19}$$

for which the curvature 2-form vanishes. The corresponding tangent space picture obtained by backward parallel transport of the group lattice into the tangent space at 0 is drawn in Fig. 7. Indeed, from the figure we read off $\mathbf{V}_{22}=\mathbf{u}_2$, $\mathbf{u}_1+\mathbf{V}_{11}=\mathbf{u}_2$, $\mathbf{u}_1+\mathbf{V}_{12}=\mathbf{u}_2+\mathbf{V}_{21}$, which determines the above transport matrices. The biangle torsion satisfies $\Sigma_i \mathbf{u}_i\, Q^i{}_{(2)\,1,1}=\mathbf{u}_2+\mathbf{V}_{22}=2\,\mathbf{u}_2$. Furthermore, we have $\mathbf{V}_{121}=\mathbf{V}_{211}=\mathbf{u}_2-\mathbf{u}_1$ and $\mathbf{V}_{122}=\mathbf{V}_{212}=\mathbf{u}_2$.

The solution with $(p,q,u,v)=(-1,-1,1,-1)$ has the properties $V_1V_1=V_2$, $V_2V_2=V_1$ and $[V_1,V_2]=0$, so again the whole curvature 2-form vanishes. The remaining two solutions have vanishing biangle curvature, but nonvanishing triangle and quadrangle curvature.

(c) If only triangle torsion is allowed, there is no connection compatible with the metric (5.11).

VI. GROUP LATTICE GEOMETRY AND COORDINATES

In order to explore discrete structures in close analogy with the continuum it should be of interest to consider analogs of coordinates and coordinate transformations, as well as the associated properties of geometric objects. Moreover, if there is a continuum limit, as in the case of a hypercubic $\mathbb{Z}^n$ lattice, one should recover the corresponding continuum structures.

Let (G,S) be a group lattice with $|S|=n$. Real functions x^μ, $\mu=1,\ldots,n$, are said to be *coordinates* on G if $(x^\mu):G\to\mathbb{R}^n$ is injective and the matrix $(\ell_h x^\mu)$ is invertible at all $g\in G$. If coordinates do not exist globally, they can still be introduced on subsets of G.

The first subsection below presents an example of a coordinate system on a $\mathbb{Z}_4$ lattice. In particular, it demonstrates a relation between discrete structures and noncommutative differential calculi on the algebra of functions on $\mathbb{R}^n$ which has not yet been sufficiently explored. The second subsection then treats in some detail Riemannian geometry of a hypercubic $\mathbb{Z}^n$ lattice in terms of adapted coordinates.

A. Coordinates on $(\mathbb{Z}_4,\{1,2\})$

The two functions

$$x=e^0-e^1+e^2-e^3, \quad y=e^0+e^1-e^2-e^3 \tag{6.1}$$

are coordinates on $\mathbb{Z}_4$ with $S=\{1,2\}$. Since $(x(0),y(0))=(1,1)$, $(x(1),y(1))=(-1,1)$, $(x(2),y(2))=(1,-1)$ and $(x(3),y(3))=(-1,-1)$, the map $(x,y):\mathbb{Z}_4\to\mathbb{R}^2$ is obviously injective. Using $R_1^*x=-x$, $R_2^*x=x$, $R_1^*y=xy$, $R_2^*y=-y$, we obtain the Jacobian

$$(\ell_h x^\mu)=\begin{pmatrix} -2x & 0 \\ (x-1)y & -2y \end{pmatrix}, \tag{6.2}$$

which is indeed invertible at each lattice site. Every function on $\mathbb{Z}_4$ can be expressed as a function of x and y. They satisfy $x^2=y^2=\mathbf{1}$. The coordinates x,y then constitute a representation of $\mathbb{Z}_4$. For the differentials we obtain the expressions

$$\mathrm{d}x=[\theta,x]=-2x\,\theta^1, \quad \mathrm{d}y=[\theta,y]=(x-1)y\,\theta^1-2y\,\theta^2, \tag{6.3}$$

and, thus, using $x^2=\mathbf{1}$,

$$\theta^1=-\frac{1}{2x}\mathrm{d}x, \quad \theta^2=\frac{1}{4}(x-1)\,\mathrm{d}x-\frac{1}{2y}\mathrm{d}y. \tag{6.4}$$

Furthermore, using $\theta^h f=R_h^* f\,\theta^h$ we obtain the following commutation relations between the coordinates x,y and their differentials:

$$[\mathrm{d}x,x]=-2x\,\mathrm{d}x, \quad [\mathrm{d}y,y]=-2y\,\mathrm{d}y, \quad [\mathrm{d}x,y]=[\mathrm{d}y,x]=(x-1)y\,\mathrm{d}x. \tag{6.5}$$

We have thus reached a formulation of the differential calculus on $(\mathbb{Z}_4,\{1,2\})$ as a noncommutative differential calculus on $\mathbb{R}^2$. Indeed, imposing the relations (6.5) on two real functions x,y, the group lattice $(\mathbb{Z}_4,\{1,2\})$ can be essentially recovered. The first two relations imply $\mathrm{d}(x^2)=0=\mathrm{d}(y^2)$. As a consequence, x^2 and y^2 are "constants" for this differential calculus and commute with differentials. Using (6.5) this implies

$$\begin{aligned} 0&=[\mathrm{d}(y^2),x]=[\mathrm{d}x,y^2]=[\mathrm{d}x,y]\,y+y\,[\mathrm{d}x,y]=(x-1)\,y\,(\mathrm{d}x)\,y+(x-1)\,y^2\,\mathrm{d}x \\ &=(x-1)\,y\,xy\,\mathrm{d}x+(x-1)\,y^2\,\mathrm{d}x=(x^2-1)\,y^2\,\mathrm{d}x, \end{aligned} \tag{6.6}$$

and, thus, $x^2=\mathbf{1}$, assuming $y^2\neq 0$ and that Ω^1 is free with basis $\mathrm{d}x,\mathrm{d}y$. The equations (6.5) are homogeneous in y, so that they are not able to fix the value of y^2. But the calculus is obviously consistent with the constraint $y^2=\mathbf{1}$. Passing over to the algebra $\mathcal{A}$ of functions generated by the variables x,y modulo the relations $x^2=y^2=\mathbf{1}$ and setting

$$e^0=\frac{(1+x)(1+y)}{4}, \quad e^1=\frac{(1-x)(1+y)}{4}, \quad e^2=\frac{(1+x)(1-y)}{4}, \quad e^3=\frac{(1-x)(1-y)}{4}, \tag{6.7}$$

we find $e^ie^j=\delta^{i,j}e^i$ and $\Sigma_i e^i=\mathbf{1}$. These are the primitive idempotents of $\mathcal{A}$.

Let us deduce some more consequences from the commutation relations (6.5). They are equivalent to

$$\mathrm{d}x\, x = -x\, \mathrm{d}x\,, \quad \mathrm{d}x\, y = x\, y\, \mathrm{d}x\,, \quad \mathrm{d}y\, y = -y\, \mathrm{d}y\,, \quad \mathrm{d}y\, x = x\, \mathrm{d}y + (x-1)\, y\, \mathrm{d}x, \tag{6.8}$$

so that

$$\mathrm{d}x f(x,y) = f(-x,xy)\, \mathrm{d}x, \tag{6.9}$$

$$\mathrm{d}y f(x,y) = f(x,-y)\, \mathrm{d}y + \frac{f(x,xy)-f(-x,xy)}{2\,x}(x-1)\, y\, \mathrm{d}x\,. \tag{6.10}$$

Introducing (left) partial derivatives of a function f via

$$\mathrm{d}f = \partial_x f \mathrm{d}x + \partial_y f \mathrm{d}y, \tag{6.11}$$

we find

$$\mathrm{d}y f(x,y) - f(x,y)\, \mathrm{d}y = [\mathrm{d}f, y] = (\partial_x f)\, [\mathrm{d}x, y] + (\partial_y f)\, [\mathrm{d}y, y], \tag{6.12}$$

which together with (6.5) and (6.10) leads to

$$\partial_x f = \frac{1}{2x}(f(x,xy) - f(-x,xy))\,, \quad \partial_y f = \frac{1}{2y}(f(x,y) - f(x,-y)). \tag{6.13}$$

A similar calculation starting with $\mathrm{d}x\, f(x,y) - f(x,y)\, \mathrm{d}x = [\mathrm{d}f, x]$ leads to an apparently different expression for $\partial_x f$. It reduces to the above formula with the help of

$$f(x,xy) = \tfrac{1}{2}((x+1)\, f(x,y) - (x-1)\, f(x,-y)), \tag{6.14}$$

which holds as a consequence of $x^2 = \mathbf{1}$. Of course, all geometric structures on $(\mathbb{Z}_4, \{1,2\})$ can now be expressed in terms of the coordinates and their differentials.

B. Hypercubic group lattice geometry in coordinates

Let G be the additive group $\mathbb{Z}^n$ and $S = \{\hat{\mu} \mid \mu = 1,\ldots,n\}$ be the standard basis of $\mathbb{Z}^n$, i.e., $\hat{\mu} = (0,\ldots,0,1,0,\ldots,0)$ with the 1 at the μth position. There are no biangles or triangles, but only quadrangles. The group lattice is the oriented hypercubic lattice and for $a \in \mathbb{Z}^n$ the functions e^a form a basis over $\mathbb{C}$ of $\mathcal{A}$. Then $(\ell_{\hat{\mu}} f)(a) = f(a+\hat{\mu}) - f(a)$ defines a basis $\{\ell_{\hat{\mu}}\}$ of the space $\mathcal{X}$ of vector fields. The dual basis of Ω^1 is given by

$$\theta^{\hat{\mu}} = \sum_{a \in \mathbb{Z}^n} e^a\, \mathrm{d}e^{a+\hat{\mu}}\,. \tag{6.15}$$

The functions $x^\mu = \kappa \sum_{a \in \mathbb{Z}^n} a^\mu e^a$, $\mu = 1,\ldots,n$, with a constant κ, are coordinates on the space. Every function can be written as $f(x)$ with $x = (x^1,\ldots,x^n)$. Furthermore, we find

$$\theta^{\hat{\mu}} = \frac{1}{\kappa}\mathrm{d}x^\mu, \quad \mu = 1, \ldots, n\,. \tag{6.16}$$

Since $\hat{\mu} + \hat{\nu} = \hat{\nu} + \hat{\mu}$, the 2-form relations $\mathrm{d}x^\mu\, \mathrm{d}x^\nu = -\mathrm{d}x^\nu\, \mathrm{d}x^\mu$ hold for all pairs $\mu, \nu = 1,\ldots,n$. As a consequence, every product of the form $\mathrm{d}x^{\mu_1}\cdots\mathrm{d}x^{\mu_r}$ is totally antisymmetric. Since the group is Abelian, $\mathrm{d}x^{\mu_1} \cap \cdots \cap \mathrm{d}x^{\mu_r} = \mathrm{d}x^{\mu_1}\cdots\mathrm{d}x^{\mu_r}$. This implies that $\alpha_1 \cap \cdots \cap \alpha_r$ is totally antisymmetric for arbitrary 1-forms α_i. It should be noticed, however, that $\alpha_1 \cdots \alpha_r$ is not antisymmetric, in general.

Introducing (left) partial derivatives of a function $f(x)$ via

$$\mathrm{d}f=\sum_{\mu=1}^{n}(\partial_{+\mu}f)\,\mathrm{d}x^{\mu}, \tag{6.17}$$

we find

$$\partial_{+\mu}f=\frac{R_{\hat{\mu}}^{*}f-f}{\kappa},\quad (R_{\hat{\mu}}^{*}f)(x)=f(x+\kappa\hat{\mu}). \tag{6.18}$$

The backward parallel transport of a linear connection with transport matrices $V_{\mu}=(V^{\rho}{}_{\mu\sigma})$ acts as follows:

$$\tilde{\mathcal{V}}_{\partial_{+\mu}}\partial_{+\nu}=\frac{1}{\kappa}\sum_{\rho}V^{\rho}{}_{\mu\nu}\cdot\partial_{+\rho}. \tag{6.19}$$

Let us write

$$\nabla\mathrm{d}x^{\mu}=\theta\otimes_{\mathcal{A}}\mathrm{d}x^{\mu}-\sum_{\nu=1}^{n}V^{\mu}{}_{\nu}\otimes_{\mathcal{A}}\mathrm{d}x^{\nu}=-\sum_{\nu=1}^{n}\Gamma^{\mu}{}_{\nu}\otimes_{\mathcal{A}}\mathrm{d}x^{\nu}, \tag{6.20}$$

where

$$V^{\mu}{}_{\nu}=\frac{1}{\kappa}\sum_{\rho=1}^{n}V^{\mu}{}_{\rho\nu}\,\mathrm{d}x^{\rho},\quad \Gamma^{\mu}{}_{\nu}=\sum_{\rho=1}^{n}\Gamma^{\mu}{}_{\rho\nu}\,\mathrm{d}x^{\rho}. \tag{6.21}$$

Using $\theta=\Sigma_{\mu=1}^{n}\theta^{\hat{\mu}}=(1/\kappa)\Sigma_{\mu=1}^{n}\vartheta_{\mu}\,\mathrm{d}x^{\mu}$ with $\vartheta_{\mu}=1$ for $\mu=1,\ldots,n$, we obtain

$$\Gamma^{\mu}{}_{\rho\nu}=\frac{1}{\kappa}[V^{\mu}{}_{\rho\nu}-\vartheta_{\rho}\,\delta^{\mu}_{\nu}]. \tag{6.22}$$

The components of the torsion 2-form $\Theta^{\mu}=\frac{1}{2}\Sigma_{\nu,\rho=1}^{n}Q^{\mu}{}_{\nu\rho}\,\mathrm{d}x^{\nu}\cap\mathrm{d}x^{\rho}$ are

$$Q^{\mu}{}_{\nu\rho}=\frac{1}{\kappa}(V^{\mu}{}_{[\nu\rho]}-\vartheta_{[\nu}\,\delta^{\mu}_{\rho]})=\Gamma^{\mu}{}_{[\nu\rho]} \tag{6.23}$$

and the components of the curvature 2-form $\mathcal{R}(\mathrm{d}x^{\mu})=\frac{1}{2}\Sigma_{\nu,\rho,\sigma=1}^{n}\mathcal{R}^{\mu}{}_{\nu\rho\sigma}\,\mathrm{d}x^{\rho}\cap\mathrm{d}x^{\sigma}\otimes_{L}\mathrm{d}x^{\nu}$ are given by

$$\mathcal{R}^{\mu}{}_{\nu\rho\sigma}=(\mathcal{R}_{\rho\sigma})^{\mu}{}_{\nu}=\frac{1}{\kappa^{2}}(V_{\rho}\,R_{\hat{\rho}}^{*}V_{\sigma}-V_{\sigma}\,R_{\hat{\sigma}}^{*}V_{\rho})^{\mu}{}_{\nu}. \tag{6.24}$$

The two Bianchi identities take the form

$$\sum_{\lambda=1}^{n}V^{\mu}{}_{[\nu|\lambda|}R_{\hat{\nu}}^{*}Q^{\lambda}{}_{\rho\sigma]}-Q^{\mu}{}_{[\nu\rho}R_{\hat{\nu}+\hat{\rho}}^{*}\vartheta_{\sigma]}=\kappa\,\mathcal{R}^{\mu}{}_{[\nu\rho\sigma]},\quad V_{[\nu}R_{\hat{\nu}}^{*}\mathcal{R}_{\rho\sigma]}=\mathcal{R}_{[\nu\rho}R_{\hat{\nu}+\hat{\rho}}^{*}V_{\sigma]}. \tag{6.25}$$

The compatibility condition for the linear connection and a metric tensor

$$\mathrm{g}=\sum_{\mu,\nu=1}^{n}\mathfrak{g}_{\mu\nu}(x)\,\mathrm{d}x^{\mu}\otimes_{L}\mathrm{d}x^{\nu} \tag{6.26}$$

with symmetric components, i.e., $\mathfrak{g}_{\mu\nu}=\mathfrak{g}_{\nu\mu}$, reads

$$R^*_{\hat{\rho}}(\mathfrak{g}_{\mu\nu}) = V^T_\rho(\mathfrak{g}_{\mu\nu})\, V_\rho. \tag{6.27}$$

The integrability condition of this equation (iteration around a plaquette) implies that the matrices $K_{\mu\nu}$, which are defined by

$$V_\mu R^*_{\hat{\mu}} V_\nu = K_{\mu\nu}\, V_\nu R^*_{\hat{\nu}} V_\mu, \tag{6.28}$$

are isometries of $\mathfrak{g}$ at every point of the lattice. The curvature tensor, in matrix form, can now be written as follows:

$$\mathcal{R}_{\mu\nu} = \frac{1}{\kappa^2}(K_{\mu\nu} - I)\, V_\nu R^*_{\hat{\nu}} V_\mu. \tag{6.29}$$

If the torsion vanishes, the first Bianchi identity reduces to $\mathcal{R}^\mu{}_{[\nu\rho\sigma]} = 0$. Then there is (up to the global sign) only one definition of a Ricci tensor:

$$\mathrm{Ric}_{\mu\nu} = \sum_{\rho=1}^{n} \mathcal{R}^\rho{}_{\mu\rho\nu}. \tag{6.30}$$

The curvature scalar is given by

$$\mathcal{R} = \sum_{\mu,\nu=1}^{n} \mathfrak{g}^{\mu\nu}\, \mathrm{Ric}_{\mu\nu} \tag{6.31}$$

involving the components of the inverse metric $\mathrm{g}^{-1} = \Sigma^n_{\mu,\nu=1} \mathfrak{g}^{\mu\nu}\, \partial_{+\mu} \otimes_L \partial_{+\nu}$.

Let $y^\mu(x)$ be a set of n real-valued functions which can be inverted to express x^ν in terms of the functions y^μ and for which the Jacobian

$$\mathcal{J}^\mu{}_\nu := \partial_{+\nu} y^\mu \tag{6.32}$$

is invertible. The functions y^μ are then new coordinates and we have

$$\mathrm{d}y^\mu = \sum_{\nu=1}^{n} \mathcal{J}^\mu{}_\nu\, \mathrm{d}x^\mu, \quad \mathrm{d}x^\mu = \sum_{\nu=1}^{n} (\mathcal{J}^{-1})^\mu{}_\nu\, \mathrm{d}y^\nu. \tag{6.33}$$

Note that $\mathrm{d}y^\mu \cap \mathrm{d}y^\nu + \mathrm{d}y^\nu \cap \mathrm{d}y^\mu = 0$, while $\mathrm{d}y^\mu\, \mathrm{d}y^\nu + \mathrm{d}y^\nu\, \mathrm{d}y^\mu \neq 0$, in general. Introducing (left) partial derivatives with respect to the basis $\mathrm{d}y^\mu$ via

$$\mathrm{d}f = \sum_{\nu=1}^{n} \partial^y_{+\nu} f\, \mathrm{d}y^\nu, \tag{6.34}$$

we obtain

$$\partial^y_{+\nu} f = \sum_{\mu=1}^{n} (\mathcal{J}^{-1})^\mu{}_\nu\, \partial_{+\mu} f \tag{6.35}$$

and, in particular,

$$(\mathcal{J}^{-1})^\mu{}_\nu = \partial^y_{+\nu} x^\mu. \tag{6.36}$$

Using the coordinates x^μ, the basic commutation relations of the differential calculus are

$$[\mathrm{d}x^\mu, x^\nu] = \kappa\, \delta^{\mu\nu}\, \mathrm{d}x^\mu. \tag{6.37}$$

In terms of y^μ they read

$$[\mathrm{d}y^\mu, y^\nu] = \kappa \sum_{\rho=1}^{n} C^{\mu\nu}{}_{\rho}\, \mathrm{d}y^\rho, \quad C^{\mu\nu}{}_{\rho} := \sum_{\sigma=1}^{n} \mathcal{J}^\mu{}_\sigma \mathcal{J}^\nu{}_\sigma (\mathcal{J}^{-1})^\sigma{}_\rho. \tag{6.38}$$

In the limit as $\kappa \to 0$ we obtain in both coordinate systems the ordinary continuum differential calculus, as long as the coordinate transformation does not involve κ. If f and y^μ are differentiable functions of x^μ, then in this limit $\mathrm{d}f$ becomes $\Sigma_\mu (\partial f/\partial x^\mu)\mathrm{d}x^\mu$ and also $\Sigma_\mu (\partial f/\partial y^\mu)\mathrm{d}y^\mu$ with the help of the chain rule. Although the lattice differential calculus becomes particularly simple when expressed in terms of the coordinates x^μ, in the continuum limit all coordinate systems are on an equal footing. The discrete calculus also allows κ-dependent coordinate transformations. But exploring the continuum limit we should require that such a transformation remains a coordinate transformation in the limit $\kappa \to 0$.

Since the metric is defined using the left-covariant tensor product, the metric components transform homogeneously with the Jacobi matrix:

$$\mathfrak{g}'_{\mu\nu}(y) = \sum_{\rho,\sigma=1}^{n} (\mathcal{J}^{-1})^\rho{}_\mu (\mathcal{J}^{-1})^\sigma{}_\nu\, \mathfrak{g}_{\rho\sigma}(x), \tag{6.39}$$

where $\mathrm{g} = \Sigma_{\mu,\nu} \mathfrak{g}'_{\mu\nu}(y)\mathrm{d}y^\mu \otimes_L \mathrm{d}y^\nu$. This local tensor transformation property is shared by the components of the torsion and curvature, in particular. A linear connection and the associated transport matrices have a nonlocal character. With the help of (2.41) and (6.19) we find

$$V'_\mu(y) = \sum_{\nu=1}^{n} (\mathcal{J}^{-1})^\nu{}_\mu(x)\, \mathcal{J}(x)\, V_\nu(x)\, \mathcal{J}^{-1}(x + \kappa\hat{\nu}). \tag{6.40}$$

For an appropriate Levi-Civita connection, (6.22) should tend to the Christoffel symbols in the continuum limit. Expressing V_ρ in (6.27) in terms of $\Gamma^\rho{}_{\mu\nu}$, we find

$$\partial_{+\rho} g_{\mu\nu} = g_{\mu\lambda} \Gamma^\lambda{}_{\rho\nu} + g_{\lambda\nu} \Gamma^\lambda{}_{\rho\mu} + \kappa\, g_{\kappa\lambda} \Gamma^\kappa{}_{\rho\mu} \Gamma^\lambda{}_{\rho\nu}. \tag{6.41}$$

If torsion vanishes, so that $\Gamma^\lambda{}_{\mu\nu} = \Gamma^\lambda{}_{\nu\mu}$, this implies

$$2\Gamma_{\rho\mu\nu} = \partial_{+\mu}\mathfrak{g}_{\rho\nu} + \partial_{+\nu}\mathfrak{g}_{\rho\mu} - \partial_{+\rho}\mathfrak{g}_{\mu\nu} + \kappa(\Gamma_{\lambda\rho\mu}\Gamma^\lambda{}_{\rho\nu} - \Gamma_{\lambda\mu\rho}\Gamma^\lambda{}_{\mu\nu} + \Gamma_{\lambda\nu\rho}\Gamma^\lambda{}_{\nu\mu}), \tag{6.42}$$

so that indeed the Christoffel symbols, which express $\Gamma^\rho{}_{\mu\nu}$ in terms of the metric functions, are obtained in the continuum limit. There is no such expression in the discrete framework.

VII. CONCLUSIONS

Starting from basic formulas of noncommutative geometry, we developed a formalism of Riemannian geometry of group lattices. More precisely, we restricted our considerations to the subclass of bicovariant group lattices. Only for this subclass there is a simple conversion between the ordinary tensor product $\otimes_{\mathcal{A}}$ and the left-covariant tensor product $\otimes_L$. The latter played a crucial role in making contact with classical geometry. In particular, it allows us to introduce a discrete analog of a metric tensor with a natural geometric interpretation and, more technically, to formulate a compatibility condition with a linear connection.

In particular in the case of a $\mathbb{Z}^n$ group lattice, the discrete geometry obtained has much in common with lattice gauge theory. It yields a discretization of continuum geometry via plaquettes where the curvature results from parallel transport around a plaquette (see also the various approaches[11] to ''lattice gravity'' in this context). In contrast, in Regge calculus the curvature is concentrated at a hinge (which in two dimensions is a vertex).

Given a metric, the compatibility condition for a linear connection leaves us with the freedom of torsion. This is analogous to continuum differential geometry where the additional requirement

of vanishing torsion uniquely determines a particular linear connection, the Levi-Civita connection (which is expressed via the Christoffel symbols in terms of the metric coefficients). The situation is much more complicated for group lattices, however.

A Levi-Civita connection need not exist for a given Riemannian group lattice. Furthermore, if such a connection exists, then it is not unique in general. We achieved a geometric understanding of this ambiguity through the elaboration of several examples. The deeper origin is the fact that our connections have values in a group algebra rather than a Lie algebra. The latter only feels the part of a (continuous) group which is connected with the identity.

The requirement of a Levi-Civita connection for a Riemannian group lattice strongly restricts the metric, in general. On the other hand, we learned from our examples that metric-compatible linear connections with nonvanishing torsion show up quite naturally. A convenient condition which replaces that of vanishing torsion is not available. A few general statements can nevertheless be made. Vanishing triangle torsion means assigning Euclidean properties to the respective triangle. Of course, a group lattice with Euclidean triangles, but more than three sites, may still be curved. Nonvanishing biangle torsion allows for an anisotropy of the distance relation between the respective two lattice sites, adhering to a simple interpretation of the metric coefficients. The requirement of vanishing biangle torsion would rule out this feature. But it would also eliminate geometries without such an anisotropy as we saw in Sec. V B.

On the other hand, a distance anisotropy may indeed appear in communication networks (with a group lattice structure), a relation which should be elaborated elsewhere.[16] The design of a communication network determines its efficiency. The broadcast time, for example, clearly depends on its geometry.[17] For such problems the geometric formalism developed in this work could be of help.

Our examples demonstrate that torsion quite naturally enters the stage. The more we depart from the continuum, the more we get away from the familiar condition of vanishing torsion of continuum (pseudo-) Riemannian geometry. Hypercubic group lattices, which only consist of quadrangles, are rather close to the continuum in this sense. Biangles and triangles add to the rigidity of a lattice, so that torsion becomes necessary in order to curve it. The conclusion is that, in contrast to ordinary continuum differential geometry, (nonzero) torsion is an essential ingredient of our discrete geometric formalism. Interesting field equations will have to take care of this fact and describe the dynamics of metric *and* torsion.

Is there a distinguished geometry associated with a (bicovariant) group lattice? Indeed, a direct consequence of the definition of a group lattice is the existence of a family of vector fields $\ell_h, h \in S$. Requiring that these are Killing vector fields of the metric, so that their flows preserve the metric, restricts the *a priori* possible metrics to the class of right-invariant metrics which are completely determined by the components at one site. If S is Abelian, these are simply the constant metrics, i.e., the components are the same at all sites (which correspond to the group elements). Associated with the class of right-invariant metrics is a distinguished metric-compatible linear connection. Moreover, we have the notion of bi-invariance of a metric which determines a subclass of right-invariant metrics. Interesting relations between group structure and geometry are expected to emerge from this.

Even in the familiar hypercubic lattice case the (pseudo-) Riemannian geometry derived from the general framework of group lattice geometry appears to be new. In particular in the form presented in Sec. VI B, using coordinates on the lattice, the close analogy with continuum Riemannian geometry becomes transparent. This provides an alternative to the existing discretizations of gravity theories.

Representations of ''intrinsic'' group lattice geometries via immersions in a Euclidean space will be treated in a separate work. For two-dimensional Riemannian group lattices (where S consists of two different elements), the bicovariance condition restricts to Abelian groups, and a relatively simple formalism of immersions can be developed in analogy with that of continuum differential geometry. For immersions of higher than two-dimensional Riemannian group lattices in Euclidean $\mathbb{R}^n$ the formalism is more complex and new features will show up.

APPENDIX: ORTHONORMAL COFRAME FIELDS

Let g be a metric on a group lattice (G,S) which has Euclidean (or Lorentzian) signature at each point. An *orthonormal coframe field* is a set of $|S|$ linearly independent 1-forms E^a (at each point of G) such that

$$\mathrm{g}=\sum_{a,b=1}^{|S|}\eta_{ab}\,E^a\otimes_L E^b, \tag{A1}$$

where $\eta=(\eta_{ab})$ has entries ± 1 on the diagonal and zeros otherwise (according to the signature of g). Writing

$$E^a=\sum_{h\in S}E^a{}_h\,\theta^h, \quad a=1,\ldots,|S|, \tag{A2}$$

it follows that the matrix $(E^a{}_h)$ is invertible at all sites $g\in G$. Let $(\overline{E}^h{}_a)$ denote its inverse. In the following, for (η_{ab}) we may take more generally an arbitrary constant symmetric matrix. Using (I.6.5) and (2.34), we find

$$\mathcal{V}_{\ell_h}E^a=\sum_{b=1}^{|S|}(R^*_{h^{-1}}L^a{}_{h,b})\,E^b \tag{A3}$$

with

$$L^a{}_{h,b}:=\sum_{h',h''\in S}E^a{}_{h'}\,V^{h'}{}_{h,h''}\,R^*_h\overline{E}^{h''}{}_b, \tag{A4}$$

or $L_h=E\,V_h\,R^*_h\overline{E}$ in an obvious matrix notation. As a consequence,

$$\nabla E^a=\theta\otimes_{\mathcal{A}}E^a-\sum_b L^a{}_b\otimes_{\mathcal{A}}E^b, \quad L^a{}_b:=\sum_{h\in S}L^a{}_{h,b}\,\theta^h. \tag{A5}$$

Let us introduce the dual frame field

$$\overline{E}_a:=\sum_{h\in S}\overline{E}^h{}_a\cdot\ell_h \tag{A6}$$

which satisfies $\langle\overline{E}_a,E^b\rangle=\delta^b_a$. As a consequence of (I.7.17) and (2.41), we find

$$\tilde{\mathcal{V}}_{\ell_h}\overline{E}_a=\sum_b L^b{}_{h,a}\cdot\overline{E}_b. \tag{A7}$$

The metric-compatibility condition for the connection takes the form

$$L_h^T\,\eta\,L_h=\eta. \tag{A8}$$

The matrices L_h are thus isometries of η, they have values in the orthogonal group $O(\eta)$ of η. This shows that if an orthonormal coframe field is chosen, *an η-compatible linear connection is equivalent to a map $G\times S\to O(\eta)$*.

The components of the torsion 2-form with respect to the coframe E^a are

$$\Theta^a:=\Theta(E^a)=E^a\,\theta-\Delta(E^a)+\sum_{b=1}^{|S|}L^a{}_b\,E^b. \tag{A9}$$

Here we used (I.7.6), $\Delta(f\,\omega)=f\,\Delta(\omega)$, (I.6.5) and (A3). Writing this as

$$\Theta^a=\sum_{h_1,h_2\in S}\left(E^a{}_{h_1}-\sum_{h\in S}E^a{}_h\,\delta^h_{h_1h_2}+\sum_b L^a{}_{h_1,b}\,R^*_{h_1}E^b{}_{h_2}\right)\theta^{h_1}\,\theta^{h_2} \tag{A10}$$

the condition of vanishing torsion $\Theta^a=0$ yields for biangles ($h_1h_2=e, h_1,h_2\in S_{(0)}$)

$$L_{h_1}R^*_{h_1}E_{h_2}=-E_{h_1}, \tag{A11}$$

where, for example, E_{h_1} denotes the column with entries $E^a{}_{h_1}$. For triangles $[h_1h_2=h\in S_{(1)}]$ it yields

$$L_{h_1}R^*_{h_1}E_{h_2}=E_h-E_{h_1}, \tag{A12}$$

and for quadrangles ($h_1h_2=\hat{h}_1\hat{h}_2=g\in S_{(2)}$)

$$L_{h_1}R^*_{h_1}E_{h_2}-L_{\hat{h}_1}R^*_{\hat{h}_1}E_{\hat{h}_2}=E_{\hat{h}_1}-E_{h_1}\,. \tag{A13}$$

The components of the curvature with respect to the coframe E^a are

$$\mathcal{R}(E^a)=\sum_{b=1}^{|S|}\mathcal{R}^a{}_b\otimes_{\mathcal{A}}E^b, \tag{A14}$$

where

$$(\mathcal{R}^a{}_b)=L^2-\Delta(L)-I\,\Delta^e\,,\quad L:=\sum_{h\in S}L_h\,\theta^h. \tag{A15}$$

With the help of the Leibniz rule and (I.2.15), we obtain the first Bianchi identity (I.7.11) in the following form,

$$\mathrm{d}\Theta(E)+(L-\theta)\,\Theta(E)=\left(\sum_b\mathcal{R}^a{}_bE^b\right)=-\Delta^eE-\Delta(L)\,E+L^2\,E, \tag{A16}$$

where E stands for the column with entries E^a. From

$$0=\nabla(\mathcal{R}(E^a))-\mathcal{R}(\nabla E^a)=\sum_b\left(-\Delta(\mathcal{R}^a{}_b)+\sum_c(L^a{}_c\,\mathcal{R}^c{}_b-\mathcal{R}^a{}_cL^c{}_b)\right)\otimes_{\mathcal{A}}E^b \tag{A17}$$

we obtain the following version of the second Bianchi identity:

$$\Delta(\mathcal{R}^a{}_b)=\sum_c(L^a{}_c\,\mathcal{R}^c{}_b-\mathcal{R}^a{}_cL^c{}_b). \tag{A18}$$

Writing

$$\mathcal{R}(E^a)=\sum_{b=1}^{|S|}\sum_{h_1,h_2\in S}\mathcal{R}^a{}_{b,h_1,h_2}\,\theta^{h_1}\cap\theta^{h_2}\otimes_LE^b, \tag{A19}$$

we find the biangle part of the curvature

$$\mathcal{R}_{(e)\,h_1,h_2}=\delta^e_{h_2h_1}(L_{h_1}R^*_{h_1}L_{h_1^{-1}h_2h_1}-I), \tag{A20}$$

the triangle part ($h\in S_{(1)}$)

$$\mathcal{R}_{(h)\,h_1,h_2} = \delta^h_{h_2 h_1}(L_{h_1} R^*_{h_1} L_{h_1^{-1}h_2 h_1} - L_h)\,\mathcal{E}_{(h)}\,, \tag{A21}$$

and the quadrangle curvature ($g \in S_{(2)}$)

$$\mathcal{R}_{(g)\,h_1,h_2;\hat{h}_1,\hat{h}_2} = \delta^g_{h_2 h_1}(L_{h_1} R^*_{h_1} L_{h_1^{-1}h_2 h_1} - L_{\hat{h}_1} R^*_{\hat{h}_1} L_{\hat{h}_1^{-1}\hat{h}_2 \hat{h}_1})\,\mathcal{E}_{(g)}\,. \tag{A22}$$

Here we have introduced

$$\mathcal{E}^a_{(g)\,b} := \sum_{h' \in S} (R^*_g E^a{}_{h'})\,\overline{E^{g h' g^{-1}}}{}_b. \tag{A23}$$

[7] Regular digraphs have constant valency (degree). There are regular graphs, like the well-known Peterson graph, which are not Cayley graphs. The differential calculus associated with a Cayley digraph has the distinguishing property that there is a (left) $\mathcal{A}$-module basis of the space of 1-forms. Moreover, the group structure organizes the arrows in a certain way which leads to the preferred basis $\{\theta^h \mid h \in S\}$ (see Ref. 1).

[13] The ambiguity in the quadrangle coefficient functions of a 2-form is not special to the $\cap$-product, but already appears in the more general formalism using the original product in Ω (see Sec. 4.2 of Ref. 1). In the latter work, $\check{\psi}_{h,h'}$ denoted the quadrangle coefficients of a 2-form ψ with respect to the *original* product in Ω. Here it refers to the $\cap$-product. Of course, they are different in general.
[14] Here the vanishing of the curvature is a special case of a much more general well-known result. If the torsion of a linear connection with respect to a differential calculus on some associative algebra vanishes, then $\pi \circ \nabla = d \circ \pi$. In the case of the universal differential calculus this reduces to $\nabla = \mathrm{d}$ and the vanishing of the curvature follows from $\mathrm{d}^2 = 0$.

Continuous wavelet transform on a special homogeneous space

M. Fashandi,[a] R. A. Kamyabi Gol, A. Niknam, and M. A. Pourabdollah
School of Mathematical Sciences, Ferdowsi University, Mashad, 91775, Iran

(Received 22 July 2002; accepted 23 April 2003)

We consider a semidirect product of two locally compact groups S and T, with S Abelian, denoted by $S\sigma T$. An action of $S\sigma T$ on S is introduced to make S a homogeneous space of $S\sigma T$. Then we define a unitary representation from $S\sigma T$ into the unitary group of $L^2(S)$ which is our main tool for defining the continuous wavelet transform on $L^2(S)$. Also the main properties of the transform are discussed. We prove the Plancherel and inversion formulas and reproducing kernel's formula for this transform. This is finally specialized to the case of the continuous wavelet transform on $L^2(R^d)$. © *2003 American Institute of Physics.*

I. INTRODUCTION AND NOTATIONS

Let G be a locally compact topological group. We denote by $d\mu_G$ a fixed left Haar measure on G and by Δ_G the modular function. By $C_c(G)$ we mean the space of continuous functions of compact support on G. An action of a locally compact group G on a locally compact Hausdorff space S is a continuous map $(x,s)\mapsto xs$ from $G\times S$ to S such that $s\mapsto xs$ is a homeomorphism of S for each $x\in G$, and $x(ys)=(xy)s$, for all $x,y\in G$ and $s\in S$. S is called a transitive G-space if for every $s,t\in S$ there exists $x\in G$ such that $xs=t$. A homogeneous space is a transitive G-space that is isomorphic to a quotient space G/H for some closed subgroup H of G [for more information see Folland (1995), Chap. 2].

Let G/H be a homogeneous space. A rho-function for the pair (G,H) is a continuous function $\rho:G\mapsto(0,\infty)$ such that

$$\rho(x\xi)=\frac{\Delta_H(\xi)}{\Delta_G(\xi)}\rho(x),\quad x\in G,\xi\in H.$$

For any locally compact group G and any closed subgroup H of G, (G,H) admits a rho-function [see Folland (1995), Proposition 2.54].

Any homogeneous space G/H has a strongly quasi-invariant measure which arises from a rho-function and for any rho-function for the pair (G,H) there is a strongly quasi-invariant measure [see Folland (1995), Chap. 2, or Reiter (1968), Chap. 8]. But here we meet a special case of a homogeneous space which has more familiar measure than strongly quasi-invariant measures.

Let G be of the form $G=G_1H$ where G_1 and H are closed subgroups and $G_1\cap H=\{e\}$, so every $x\in G$ could be written uniquely in the form $x=gh$ with $g\in G_1,h\in H$. Suppose further that the map $x\mapsto(g,h)$ of G onto the product $G_1\times H$ is continuous and hence a homeomorphism. Now, the function

$$\rho(x)=\frac{\Delta_H(h)}{\Delta_G(h)},\quad x=gh,g\in G_1,h\in H \tag{1}$$

[a]Electronic mail: Fashandi@math.um.ac.ir

is a rho-function for the pair (G,H). By Reiter (1968), Chap. 8, Sec. 1.4, there is a relatively invariant positive measure $d_\rho \dot{x}$ on G/H such that for all $f \in C_c(G/H)$:

$$\int_{G/H} f(y^{-1}\dot{x})\, \mathrm{d}_\rho(\dot{x}) = \rho(y) \int_{G/H} f(\dot{x})\, \mathrm{d}_\rho(\dot{x}), \quad y \in G, \tag{2}$$

But G/H is isomorphic to G_1 as a topological space, so by Reiter (1968), Chap. 8, Sec. 1.5, $\mathrm{d}_\rho \dot{x}$ is a left Haar measure on G_1, which will be shown by $\mathrm{d}\mu_{G_1}$, and for all $f \in C_c(G)$ we have

$$\int_{G_1} \int_H f(gh) \mathrm{d}\mu_H(h)\, \mathrm{d}\mu_{G_1}(g) = \int_G f(x)\rho(x)\, \mathrm{d}\mu_G(x), \tag{3}$$

or if we replace f by f/ρ we obtain

$$\int_{G_1} \int_H f(gh) \frac{\Delta_G(h)}{\Delta_H(h)} \mathrm{d}\mu_H(h)\, \mathrm{d}\mu_{G_1}(g) = \int_G f(x)\, \mathrm{d}\mu_G(x). \tag{4}$$

Also we can rewrite (2) as follows, which is valid for all $f \in L^1(G_1)$,

$$\int_{G_1} f(y^{-1}x)\, \mathrm{d}\mu_{G_1}(x) = \rho(y) \int_{G_1} f(x)\, \mathrm{d}\mu_{G_1}(x), \quad y \in G. \tag{5}$$

By Reiter (1968), Chap. 8, Sec. 2.3, formula (3) holds for all $f \in L^1(G)$. Later we approach a homogeneous space which has the above properties.

Let S and T be groups and suppose that there is a homomorphism $t \mapsto \sigma_t$ from T into the group of automorphisms of S. For (s,t), $(\acute{s},\acute{t}) \in S \times T$, define

$$(s,t)(\acute{s},\acute{t}) = (s\sigma_t(\acute{s}), t\acute{t}).$$

Then $S \times T$ is a group, it is called a semidirect product of S and T and is denoted by $S\sigma T$. Its identity is (e_1,e_2), where e_1 and e_2 are the identities of S and T, respectively. The inverse of (s,t) is $(\sigma_{t^{-1}}(s^{-1}), t^{-1})$.

Let $\tilde{S} = \{(s,e_2); s \in S\}$ and $\tilde{T} = \{(e_1,t); t \in T\}$. Then $\tilde{S} \trianglelefteq G$ and $\tilde{T} \leqslant G$, $\tilde{S} \cap \tilde{T} = \{(e_1,e_2)\}$, and $G = \tilde{S}\tilde{T}$. If S and T are locally compact groups and $(s,t) \mapsto \sigma_t(s)$ is continuous then G is a locally compact group and $\tilde{S}$ and $\tilde{T}$ are closed in G.

We denote by $\hat{G}$ the dual group of a locally compact Abelian group G and by $\hat{f}$ Fourier transform of a function f. For more information about the properties of $\hat{G}$, the definition of Fourier transform and related theorems, we refer the reader to Rudin (1960), Chap. 1 or Folland (1995), Chap. 4.

By a (unitary) representation we mean a homomorphism π from a locally compact group G into the group $\mathcal{U}(\mathcal{H})$ of unitary operators on some nonzero Hilbert space $\mathcal{H}$ that is continuous with respect to the strong operator topology. A vector $\phi \in \mathcal{H}$ is said to be admissible if

$$\int_G |\langle \phi, \pi(x)\phi \rangle|^2 \mathrm{d}\mu_G(x) < +\infty.$$

A representation π is called irreducible if $\{0\}$ and $\mathcal{H}$ are the only closed linear subspaces that are invariant under the unitary operators $\pi(x); x \in G$. An irreducible representation which has at least one admissible vector is called a square integrable representation. If there exists a vector $\phi \in \mathcal{H}$ such that the closed linear span of $\{\pi(x)\phi, x \in G\}$ is equal to $\mathcal{H}$, then ϕ is called a cyclic vector and π is called a cyclic representation.

In this paper we study the continuous wavelet transform on $L^2(S)$ using a unitary representation from $S\sigma T$ into the unitary group of $L^2(S)$. In particular we extend the results of Koorn-

winder (1993). The idea of working on semidirect product of groups in the framework of wavelet analysis is not new. In Grossman *et al.* (1985), which is one of the first papers of wavelet analysis, the continuous wavelet transform on $L^2(R)$ was defined by means of a certain square integrable representation of the semidirect product $R\sigma R^+$ on the unitary group of $L^2(R)$. The square integrability of this representation guarantees the existence of an inverse wavelet transform and admissibility condition. However, we prove them without square integrability's assumption, instead we use the fact that S is a homogeneous space of $S\sigma T$. In recent years, this kind of result to other groups has been extended, especially the construction of wavelet transform and discrete frames from semidirect product of R^k and a closed matrix group has been considered [see, e.g., Aniello *et al.* (2001), Aniello *et al.* (1998), Fuehr and Meyer (2002)]. Also some authors have concerned the wavelet transform in the context of square integrable representations of locally compact groups on infinite dimensional separable Hilbert spaces [see Wong (2002)]. These wavelet transforms are based on coherent states parametrized by elements in the group G. The book by Ali *et al.* (2000) presents the more general theory of coherent states associated with homogeneous space and contains an extensive list of references on coherent states parametrized by points in a homogeneous space. Torresani (1995) and Antoine and Vandergheynst (1999) have presented some applications of coherent states on manifolds.

II. MAIN RESULTS

Let G be semidirect product of two locally compact groups S and T, that S is Abelian, and let $\cdot: G\times S\mapsto S$ be as follows:

$$(a,b).s = a\sigma_b(s).$$

It is easy to check that "." is an action of G on S. Since for each s_1, $s_2\in S$, $(s_2 s_1^{-1}, e_2).s_1 = s_2$, S is a transitive G-space. Also S is a homogeneous space of G, since $\Phi: G/\tilde{T}\mapsto S$ defined by $\Phi((s,t)\tilde{T}) = s$ is a homeomorphism. Let

$$\rho(s,t) = \rho(e_1,t) = \frac{\Delta_{\tilde{T}}(e_1,t)}{\Delta_G(e_1,t)}.$$

Clearly, ρ is a rho-function for the pair $(G,\tilde{T})$. From now on, we use $\rho(t)$ instead of $\rho(e_1,t)$. ρ satisfies Eq. (1), so there is a left Haar measure $d\mu_{\tilde{S}}(s,e_2)$ on $\tilde{S}$ such that (4) and (5) hold, hence there is a left Haar measure $d\mu_S$ on S, that (4) and (5) could be rewritten as follows:

$$\int_S\int_T \frac{f(s,t)}{\rho(t)}\mathrm{d}\mu_T(t)\mathrm{d}\mu_S(s) = \int_G f(g)\mathrm{d}\mu_G(g), \quad f\in L^1(G), \tag{6}$$

$$\int_S f((a,b)^{-1}.s)\mathrm{d}\mu_S(s) = \rho(b)\int_S f(s)\mathrm{d}\mu_S(s), \quad f\in L^1(S). \tag{7}$$

Now we define π from G into $\mathcal{U}(L^2(S))$, the unitary group of $L^2(S)$ such that

$$[\pi(a,b)f](s) = \rho(b)^{-1/2} f((a,b)^{-1}.s). \tag{8}$$

It can be easily checked that π is a unitary representation.

Definition 1: We say $\Psi\in L^1\cap L^2(S)$ is a *wavelet* if $\|\Psi\|_{L^2(S)} = 1$ and there is a constant C_Ψ such that $0 < C_\Psi < +\infty$ and for any $\gamma\in\hat{S}$,

$$C_\Psi := \int_T |\hat{\Psi}(\gamma\circ\sigma_t)|^2 \mathrm{d}\mu_T(t).$$

For a wavelet Ψ we put

$$\Psi_{s,t} := \pi(s,t)\Psi, \quad (s,t) \in G.$$

Definition 2: For any $f \in L^2(S)$, the *continuous wavelet transform* of f is defined as follows:

$$Wf(s,t) = \langle f, \Psi_{s,t} \rangle_{L^2(S)}.$$

By Parseval's formula [see Rudin (1960), Sec. 1.6.2] we also have

$$Wf(s,t) = \langle \hat{f}, \hat{\Psi}_{s,t} \rangle_{L^2(\hat{S})}, \quad f \in L^2(S).$$

Using the Schwarz inequality it is easy to see that Wf is a bounded and continuous function on G.

Lemma 3: Let $\Psi \in L^2(S)$, then

$$\hat{\Psi}_{s,t}(\gamma) = \rho(t)^{1/2} \overline{\gamma(s)} \hat{\Psi}(\gamma \circ \sigma_t), \quad \gamma \in \hat{S}. \tag{9}$$

Proof: First we assume $\Psi \in L^1 \cap L^2(S)$. Since $\Psi_{s,t} \in L^1 \cap L^2(S)$ by definition of Fourier transform [Rudin (1960), Sec. 1.2.3] and using (7) and (8) we have

$$\hat{\Psi}_{s,t}(\gamma) = \int_S \Psi_{s,t}(x) \overline{\gamma(x)}\, d\mu_S(x) = \rho(t)^{1/2} \int_S \Psi(x) \overline{\gamma((s,t).x)}\, d\mu_S(x) = \rho(t)^{1/2} \overline{\gamma(s)} \hat{\Psi}(\gamma \circ \sigma_t).$$

Now, if $\Psi \in L^2(S)$, by definition of Fourier transform of functions in $L^2(S)$ [see the proof of Theorem 1.6.1 in Rudin (1960)] formula (9) obtains. □

Theorem 4: Let Ψ be a wavelet and $f, g \in L^2(S)$. Then we have

(i) *(Plancherel formula)* $\|Wf\|^2_{L^2(G)} = C_\Psi \|f\|^2_{L^2(S)}$,

(ii) *(Parseval formula)* $\langle Wf, Wg \rangle_{L^2(G)} = C_\Psi \langle f, g \rangle_{L^2(S)}$.

Proof: Put

$$F_t(\gamma) = \hat{f}(\gamma)\, \overline{\hat{\Psi}}(\gamma \circ \sigma_t), \quad t \in T, \gamma \in \hat{S}.$$

By Holder's inequality $F_t \in L^1(\hat{S})$. Also we can easily check that

$$F_t(\gamma) = \rho(t^{-1}) [f \star (\Psi \circ \sigma_{t^{-1}})^\star]\, \hat{}\, (\gamma),$$

where $\Psi^\star(s) = \Psi(s^{-1})$. Since $f \in L^2(S)$ and $(\Psi \circ \sigma_{t^{-1}})^\star \in L^1 \cap L^2(S)$ by Folland (1995), Proposition 2.39, $f \star (\Psi \circ \sigma_{t^{-1}})^\star \in L^2(S)$, thus its Fourier transform is defined, so $F_t \in L^2(\hat{S})$ and by Pontriagin Duality Theorem [Rudin (1960), Theorem 1.7.2], $\hat{F}_t \in L^2(S)$. Also we put $G_t(\gamma) = \hat{g}(\gamma)\, \overline{\hat{\Psi}}(\gamma \circ \sigma_t)$, so G_t satisfies the above results about F_t. Therefore by (9)

$$Wf(s,t) = \langle \hat{f}, \hat{\Psi}_{s,t} \rangle_{L^2(\hat{S})} = \rho(t)^{1/2} \int_{\hat{S}} F_t(\gamma)\, \gamma(s)\, d\mu_{\hat{S}}(\gamma) = \rho(t)^{1/2}\, \hat{F}_t(s^{-1}).$$

Similarly, $Wg(s,t) = \rho(t)^{1/2}\, \hat{G}_t(s^{-1})$. So we have

$$\begin{aligned} \int_T \int_S Wf(s,t) \overline{Wg(s,t)}\, \rho(t)^{-1}\, d\mu_S(s) d\mu_T(t) &= \int_T \langle \hat{F}_t, \hat{G}_t \rangle_{L^2(S)}\, d\mu_T(t) \\ &= \int_T \int_{\hat{S}} F_t(\gamma) \overline{G_t}(\gamma)\, d\mu_{\hat{S}}(\gamma) d\mu_T(t) \\ &= C_\Psi \langle \hat{f}, \hat{g} \rangle_{L^2(\hat{S})} = C_\Psi \langle f, g \rangle_{L^2(S)}. \end{aligned}$$

So by (6) we obtain

$$\int_G Wf(s,t)\overline{Wg(s,t)}\,d\mu_G(s,t)=C_\Psi\langle f,g\rangle_{L^2(S)}. \tag{10}$$

If $f=g$, then

$$\|Wf\|^2_{L^2(G)}=C_\Psi\|f\|^2_{L^2(S)}.$$

That means $Wf\in L^2(G)$, so we have the Parseval formula by (10). □

Remark 5: For a moment, let us define the continuous wavelet transform as follows:

$$Wf(s,t)=\frac{1}{\sqrt{C_\Psi}}\langle f,\Psi_{s,t}\rangle,\quad f\in L^2(S). \tag{11}$$

By Theorem 4 we can easily conclude that W is an isometry of $L^2(S)$ into its range. Theorem 7 will specify the range of continuous wavelet transform which is a closed subspace of $L^2(G)$. The following lemma will be used for proving Theorem 6, we refer the reader to Koornwinder (1993), Lemma 4.1, for its proof.

Lemma 6: Let $\mathcal{H}_1$ and $\mathcal{H}_2$ be Hilbert spaces and let $\Phi:\mathcal{H}_1\to\mathcal{H}_2$ be an isometry into $\mathcal{H}_2$. Then $\Phi\Phi^\star:\mathcal{H}_2\to\mathcal{H}_2$ is the orthogonal projection of $\mathcal{H}_2$ onto $\Phi(\mathcal{H}_2)$.

Theorem 7: *(Reproducing kernel formula)* Let $h\in L^2(G)$. Then $h=Wf$, for some $f\in L^2(S)$ if and only if

$$h(\acute{s},\acute{t})=1/C_\Psi\int_G h(s,t)\,\langle\Psi_{s,t},\Psi_{\acute{s},\acute{t}}\rangle_{L^2(S)}\,d\mu_G(s,t).$$

Proof: Let us consider W as in (11), so by Lemma 6, $WW^\star$ is an orthogonal projection of $L^2(G)$ onto $W(L^2(S))$. Now, if $h\in L^2(G)$ we have

$$\begin{aligned}(WW^\star h)(\acute{s},\acute{t})&=\frac{1}{\sqrt{C_\Psi}}\langle W^\star h,\Psi_{\acute{s},\acute{t}}\rangle_{L^2(S)}\\&=\frac{1}{\sqrt{C_\Psi}}\langle h,W\Psi_{\acute{s},\acute{t}}\rangle_{L^2(G)}\\&=1/C_\Psi\int_G h(s,t)\,\langle\Psi_{s,t},\Psi_{\acute{s},\acute{t}}\rangle_{L^2(S)}\,d\mu_G(s,t).\end{aligned}$$

□

Lemma 8: Let f and $\Psi\in L^1\cap L^2(S)$. Put $h_t(s)=Wf(s,t)$, for a fixed $t\in T$, then

$$\hat{h}_t(\gamma)=\rho(t)^{1/2}\hat{f}(\gamma)\overline{\hat{\Psi}}(\gamma\circ\sigma_t),\quad \gamma\in\hat{S}. \tag{12}$$

Proof: By (9) we have

$$\begin{aligned}h_t(s)=Wf(s,t)&=\rho(t)^{1/2}\int_{\hat{S}}\hat{f}(\gamma)\overline{\hat{\Psi}}(\gamma\circ\sigma_t)\,\gamma(s)\,d\mu_{\hat{S}}(\gamma)\\&=\rho(t)^{-1/2}\int_{\hat{S}}[f\star(\Psi\circ\sigma_{t^{-1}})^\star]\,\hat{}\,(\gamma)\,\gamma(s)\,d\mu_{\hat{S}}(\gamma)\\&=\rho(t)^{-1/2}[f\star(\Psi\circ\sigma_{t^{-1}})^\star](s).\end{aligned}$$

In the last equality we applied Fourier Inversion formula [see Folland (1995), Theorem 2.40] which is valid here because $[f\star(\Psi\circ\sigma_{t^{-1}})^{\star}]\in L^1\cap L^2(S)\cap C_0(S)$, also $[f\star(\Psi\circ\sigma_{t^{-1}})^{\star}]\hat{}\in L^1(\hat{S})$. Therefore $h_t\in L^1\cap L^2(S)$ and (12) obtains. □

Theorem 9: *(Inversion formula)* Let $f\in L^1\cap L^2(S)$ and $\hat{f}\in L^1(\hat{S})$, then for each $u\in S$,

$$f(u)=1/C_\Psi\int_G Wf(s,t)\,\Psi_{s,t}(u)\,\mathrm{d}\mu_G(s,t).$$

Proof: By Lemma 8 we have

$$\int_S Wf(s,t)\,\gamma(s^{-1})\,\mathrm{d}\mu_S(s)=\rho(t)^{1/2}\hat{f}(\gamma)\overline{\hat{\Psi}}(\gamma\circ\sigma_t).$$

Multiplying both sides of the above equality by $\rho(t)^{-1/2}\hat{\Psi}(\gamma\circ\sigma_t)$ and integrating over T we get

$$\hat{f}(\gamma)=1/C_\Psi\int_T\int_S\rho(t)^{-1/2}\,Wf(s,t)\hat{\Psi}(\gamma\circ\sigma_t)\,\gamma(s^{-1})\,\mathrm{d}\mu_S(s)\mathrm{d}\mu_T(t).$$

Now, by the inverse Fourier transform, Lemma 3 and (6) we have

$$\begin{aligned}f(u)=\int_{\hat{S}}\hat{f}(\gamma)\,\gamma(u)\,d\mu_{\hat{S}}(\gamma)&=\frac{1}{C_\Psi}\int_T\rho(t)^{-1}\int_S Wf(s,t)\int_{\hat{S}}\hat{\Psi}_{s,t}(\gamma)\,\gamma(u)\,d\mu_{\hat{S}}(\gamma)\mathrm{d}\mu_S(s)\mathrm{d}\mu_T(t)\\&=\frac{1}{C_\Psi}\int_T\int_S\rho(t)^{-1}Wf(s,t)(u)\Psi_{s,t}(u)\,\mathrm{d}\mu_S(s)\mathrm{d}\mu_T(t)\\&=\frac{1}{C_\Psi}\int_G Wf(s,t)\Psi_{s,t}(u)\,\mathrm{d}\mu_G(s,t).\end{aligned}$$

□

III. EXAMPLE AND REMARKS

As an example of the continuous wavelet transform discussed in Sec. II we consider semidirect product of the additive group R^d and the multiplicative group $R_+:=(0,\infty)$ under homomorphism $\sigma:R^+\to Aut(R^d)$ defined by

$$\sigma_a(b)=ab,\quad a\in R^+,b\in R^d.$$

In order to compare our result with Koornwinder (1993), we reverse the order of R^d and R^+ and we put $G=R^+\sigma R^d$ with the following multiplication and inversion;

$$(a,b)(\acute{a},\acute{b})=(a\acute{a},b+a\acute{b}),\quad (a,b)^{-1}=(a^{-1},-ba^{-1}).$$

Since $(a,b)\to ab$ is continuous so G is a locally compact group with modular function $\Delta_G(a,b)=a^{-d}$ and with Haar measure $a^{-d-1}\mathrm{d}a\,\mathrm{d}b$, where d$a$ is the Lebesgue measure on R and db is the Lebesgue measure on R^d [for more information about computing the Haar measure for semidirect product of two locally compact groups see Hewitt and Ross (1985), Chap. 5, Sec. 15.29]. G acts on R^d with the following action:

$$G\times R^d\to R^d,\quad (a,b).x=ax+b,$$

that are the affine transformations. With this action R^d is a homogeneous space of G. Now formulas (6) and (7) are valid with the rho-function $\rho(a)=a^d,a\in R^+$ and $\mathrm{d}\mu_{R^d}$ appearing in them is equal to the Lebesgue measure on R^d. The representation π defined by (8) is as follows:

$$[\pi(a,b)f](x)=a^{-d/2}f\left(\frac{x-b}{a}\right),\quad (a,b)\in G,x\in R^d,f\in L^2(R^d).$$

Let Ψ be a wavelet as in Definition 1, so

$$C_\Psi = \int_{R^d} |\hat{\Psi}(a\xi)|^2 \frac{da}{a}, \quad \forall \xi \in R^+,$$

and

$$\Psi_{a,b}(x) = a^{-d/2}\Psi\left(\frac{x-b}{a}\right), \quad (a,b) \in G, x \in R^d.$$

We refer the reader to Theorems 2.2, 2.3, 2.5 and Proposition 4.4 in Koornwinder (1993) to compare them with properties of this transform that we obtained in Sec. II.

Remark 10: Theorem 4 implies that any wavelet Ψ is an admissible and cyclic vector for the representation π defined by (8).

Remark 11: If $G = R\sigma R^\star$ where $R^\star = R - \{0\}$, then the representation π defined by (8) is irreducible [see Koornwinder (1993), Sec. 5]; however, if $G = R\sigma R^+$ then

$$\{f \in L^2(R); \text{support } \hat{f} \subseteq [0,\infty)\}$$

is a proper closed invariant subspace for π, so in this case π is not irreducible. Therefore, it is not possible to say anything about irreducibility of π defined by (8).

Remark 12: Let G be a locally compact group, $\mathcal{H}$ a Hilbert space, and π a square integrable representation of G on $\mathcal{U}(\mathcal{H})$ and g be an admissible vector for it. In Grossman *et al.* (1985), the continuous wavelet transform of any $f \in \mathcal{H}$ is defined by

$$W_g f(x) = \langle f, \pi(x) g \rangle,$$

which satisfies in plancherel formula, inversion formula, and reproducing kernel formula because of irreducibility of π [the latest results in this context could be found in Wong (2002)]. We defined the continuous wavelet transform in the same way, but without irreducibility's assumption.

(Received 15 December 2002; accepted 20 May 2003)

We construct Gelfand–Tzetlin coordinates for the unitary orthosymplectic supergroup UOSp($k_1/2k_2$). This extends a previous construction for the unitary supergroup U(k_1/k_2). We focus on the angular Gelfand–Tzetlin coordinates, i.e., our coordinates stay in the space of the supergroup. We also present a generalized Gelfand pattern for the supergroup UOSp($k_1/2k_2$) and discuss various implications for representation theory. © *2003 American Institute of Physics.*

I. INTRODUCTION

If the symmetries of a physical problem are simple enough, proper coordinates are easy to find. However, already the Schrödinger equation for a particle in a potential with spherical symmetry leads to nontrivial group theory, such as parametrization of the Lie group SO(3) with Euler angles, spherical harmonics, Wigner representation functions and, in the case of the hydrogen atom, additional symmetries and the Lie group SO(4). The coordinates mostly used distinguish, for a good physics reason, certain directions and thus do not treat all coordinates on an equal footing. Group theoretically, such parametrizations are called noncanonical. The Euler angles, for example, describe three subsequent rotations, first, about the z-axis, second, about the new y-axis, and, third, about the new z-axis. Nevertheless, there are many problems, particularly in statistical mechanics, in many-body physics and in matrix models, where one does not want to distinguish certain directions. Rather, all variables parametrizing the group should be treated on an equal footing. Gelfand–Tzetlin coordinates[1–3] are such a coordinate system. Their construction is based on a group chain or coset decomposition. Thus Gelfand–Tzetlin coordinates have a clear recursive structure. From a physics point of view, it is important that matrix elements, measures and other quantities reflect this clear recursive structure and can be given very explicitly. The generality of this group chain construction makes Gelfand–Tzetlin coordinates powerful tools in applications (see, for example, Refs. 4 and 5), but also for conceptual studies (see, for example, Refs. 6–8). A particularly intriguing aspect is the intimate and direct connection between Gelfand–Tzetlin coordinates on the group manifold and representations of this group. Their rich features and their relevance for different types of studies ranging from physics applications to pure mathematics render Gelfand–Tzetlin coordinates important objects in their own right.

In Ref. 5, Gelfand–Tzetlin coordinates were constructed for the unitary supergroup U(k_1/k_2). In the present contribution, we further extend this and construct Gelfand–Tzetlin coordinates for the unitary orthosymplectic supergroup UOSp($k_1/2k_2$). As this supergroup appears in the theory of disordered systems,[9] our construction of Gelfand–Tzetlin coordinates might be of direct use for future physics applications. The unitary orthosymplectic supergroup UOSp($k_1/2k_2$) contains the symplectic group USp($2k_2$) and the orthogonal group SO(k_1) as subgroups. Thus, our construction also includes coordinate systems for these two groups in ordinary space. The construction for

[a)]Electronic mail: thomas.guhr@matfys.lth.se
[b)]Electronic mail: heiner.kohler@uam.es

the orthogonal group was implicitly also done in Ref. 8.

For the sake of clarity, an important remark is in order: We distinguish between *angular* and *radial* Gelfand–Tzetlin coordinates. In the present work, we construct angular ones. By that we mean that they never leave the space of the group and its algebra. In previous contributions,[10–13] we constructed radial Gelfand–Tzetlin coordinates to study certain types of group integrals. These radial Gelfand–Tzetlin coordinates are capable of mapping the integral over a group onto integrals over the radial part of a different symmetric space. Hence, in this sense, these coordinates leave the space of the group and its algebra. Here, we always stay with the angular Gelfand–Tzetlin coordinates.

The appreciated explicit formulas resulting from the Gelfand–Tzetlin construction imply the unavoidable disadvantage that a reader, not familiar with the subject, can quickly lose his orientation. Therefore, we decided to skip several detailed calculations if, in our opinion, it would not be too cumbersome for the reader to recover the missing steps by properly adjusting the corresponding ones in Ref. 5. In any case, we recommend that an interested but unexperienced reader studies first Refs. 4 and 8 and then Ref. 5 before reading the present contribution.

The article is organized as follows: In Sec. II, we construct the angular Gelfand–Tzetlin coordinates. We state the generalized Gelfand pattern in Sec. III and discuss some issues related to representation theory. Summary and conclusions are given in Sec. IV.

II. CONSTRUCTION OF THE COORDINATE SYSTEM

In Sec. II A, we collect some properties of the supergroup $\mathrm{UOSp}(k_1/2k_2)$ needed in the sequel. We set up the proper Gelfand–Tzetlin equations and their recursion to all levels in Secs. II B and II C, respectively. We solve these equations in Sec. II D. We summarize the construction of the Gelfand–Tzetlin coordinates for the ordinary unitary symplectic group in Sec. II E. The invariant measure of the supergroup is worked out in Sec. II F. The matrix elements of the supergroup are obtained in Sec. II G.

A. The supergroup $\mathrm{UOSp}(k_1/2k_2)$

The classification of superalgebras and supergroups can be found in Refs. 14–16. Here, we restrict ourselves to summarizing features of the supergroups $\mathrm{OSp}(k_1/2k_2)$ and $\mathrm{UOSp}(k_1/2k_2)$. We will refer to k_1 and $2k_2$ as the bosonic and fermionic dimensions, respectively. We introduce the notation $(k_1/2k_2)$ for the resulting superdimension. The elements of $\mathrm{OSp}(k_1/2k_2)$ are those elements u of the general linear supergroup $\mathrm{GL}(k_1/2k_2)$ which satisfy $u^{\dagger}Lu=L$. The metric L is given by

$$L=\mathrm{diag}(1_{k_1},1_{k_2}\otimes\tau^{(2)}), \tag{1}$$

where 1_{k_1} and 1_{k_2} are the $k_1\times k_1$ and the $k_2\times k_2$ unit matrices and where $\tau^{(2)}$ is one of the two by two matrices,

$$\begin{aligned}\tau^{(0)} &= \begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix}, \quad \tau^{(1)} = \begin{bmatrix}0 & -i\\ -i & 0\end{bmatrix},\\ \tau^{(2)} &= \begin{bmatrix}0 & 1\\ -1 & 0\end{bmatrix}, \quad \tau^{(3)} = \begin{bmatrix}+i & 0\\ 0 & -i\end{bmatrix}.\end{aligned} \tag{2}$$

The supergroup $\mathrm{UOSp}(k_1/2k_2)$ is the compact subgroup of $\mathrm{OSp}(k_1/2k_2)$. By construction, the direct product $\mathrm{SO}(k_1)\otimes\mathrm{USp}(2k_2)$ of the ordinary orthogonal and the ordinary unitary symplectic group is a subgroup of $\mathrm{UOSp}(k_1/2k_2)$. As is well known, the ordinary orthogonal group $\mathrm{SO}(k_1)$ has slightly different features for even and odd dimension k_1. Thus, these differences are also present in the supergroup $\mathrm{UOSp}(k_1/2k_2)$.

The group elements act on a graded space, which we denote by $\mathcal{L}={}^0\mathcal{L}\oplus{}^1\mathcal{L}$. It decomposes into a sum of an even ${}^0\mathcal{L}$ and an odd ${}^1\mathcal{L}$ subspace according to its transformation properties under the parity automorphism.[17] We define a basis $e_j=e_{j1}, j=1,\ldots,k_1$, for ${}^0\mathcal{L}$, and $e_{k_1+j}=e_{j2}, j=1,\ldots,2k_2$, for ${}^1\mathcal{L}$, respectively.

The supergroup $\mathrm{UOSp}(k_1/2k_2)$ can be obtained by the exponential mapping of the superalgebra $\mathrm{uosp}(k_1/2k_2)$, such that $\sigma\in\mathrm{uosp}(k_1/2k_2)$ leads to $u=\exp(\sigma)\in\mathrm{UOSp}(k_1/2k_2)$. The construction of the angular Gelfand–Tzetlin coordinates uses as the starting point the Cartan subalgebra $\mathrm{uosp}^{(0)}(k_1/2k_2)$ of $\mathrm{uosp}(k_1/2k_2)$. For even bosonic dimension $2k_1$, the elements of $\mathrm{uosp}^{(0)}(2k_1/2k_2)$ are the matrices

$$s=\mathrm{diag}(is_{11}\tau^{(2)},\ldots,is_{k_11}\tau^{(2)},s_{12}\tau^{(3)},\ldots,s_{k_21}\tau^{(3)}), \tag{3}$$

while for odd bosonic dimension $2k_1+1$, the $\mathrm{uosp}^{(0)}(2k_1+1/2k_2)$ consists of the matrices

$$s=\mathrm{diag}(is_{11}\tau^{(2)},\ldots,is_{k_11}\tau^{(2)},0,s_{12}\tau^{(3)},\ldots,s_{k_21}\tau^{(3)}). \tag{4}$$

Naturally, $\mathrm{uosp}^{(0)}(k_1/2k_2)$ is the direct sum of the Cartan subalgebras of $\mathrm{so}(k_1)$ and $\mathrm{usp}(2k_2)$.

B. Derivation of the angular Gelfand–Tzetlin equations

Gelfand–Tzetlin coordinates are based on a group chain or, equivalently, on a coset decomposition. The coset decomposition needed for the supergroup $\mathrm{UOSp}(k_1/2k_2)$ is

$$\mathrm{UOSp}(k_1/2k_2)=\frac{\mathrm{UOSp}(k_1/2k_2)}{\mathrm{UOSp}((k_1-1)/2k_2))}\otimes\frac{\mathrm{UOSp}((k_1-1)/2k_2)}{\mathrm{UOSp}((k_1-2)/2k_2))}\otimes\cdots\otimes\frac{\mathrm{UOSp}(1/2k_2)}{\mathrm{USp}(2k_2)}$$
$$\otimes\frac{\mathrm{USp}(2k_2)}{\mathrm{USp}(2k_2-2)}\otimes\cdots\otimes\frac{\mathrm{USp}(4)}{\mathrm{SU}(2)}\otimes\mathrm{SU}(2). \tag{5}$$

Every coset space describes a unit sphere. The first coset $\mathrm{UOSp}(k_1/2k_2)/\mathrm{UOSp}((k_1-1)/2k_2))$ is a sphere in a superspace with dimension $(k_1/2k_2)$. The dimension of the space in which the sphere lives is lowered by one in every step. The sphere $\mathrm{UOSp}(1/2k_2)/\mathrm{USp}(2k_2)$ is the last one living in a superspace; the following spheres in the second line of Eq. (5) are spheres in ordinary spaces. Coordinate systems will be constructed on all these spheres under the nontrivial requirement that the orthogonality, more precisely the equation $u^\dagger Lu=L$, is always respected. Thus, once the coordinate system on one sphere has been obtained, the orthogonal complement to every fixed vector on this sphere has to be constructed, the next sphere lives in this smaller space. Hence, loosely speaking, the spheres in the coset decomposition are orthogonal to each other. The construction to follow is an extension of the one in Ref. 5 for the unitary supergroup. For simplicity, we consider the case of even k_1 first. The differences occurring for odd k_1 will be dealt with in Sec. II C.

To project onto a smaller subspace, we write $u\in\mathrm{UOSp}(k_1/2k_2)$ as $u=[u_1\,u_2\cdots u_{k_1+2k_2}]$ where the columns u_i are normalized supervectors. We denote by u_{ji} their entries in the basis $e_{j1}, j=1,\ldots,k_1$, and $e_{j2}, j=1,\ldots,2k_2$. The orthogonality condition requires the vectors u_i, $i\leqslant k_1$, to be real:

$$u_{ji}=u_{ji}^*,\quad \text{for}\quad 1\leqslant j\leqslant k_1,\quad \text{and}\quad u_{(k_1+2j)i}=u_{(k_1+2j-1)i}^*,\quad \text{for}\quad 1\leqslant j\leqslant k_2. \tag{6}$$

We consider the first vector. It is parametrized by k_1 real commuting variables u_{j1} and $2k_2$ complex anticommuting variables. For the latter we write

$$u_{(k_1+2j)i}=\alpha_j^*,\quad 1\leqslant j\leqslant k_2. \tag{7}$$

We also define $|\alpha_j|^2=\alpha_j^*\alpha_j$. The supervector u_1 describes the coset space $\mathrm{UOSp}(k_1/2k_2)/\mathrm{UOSp}((k_1-1)/2k_2)$ which is—similar to ordinary spaces—isomorphic to the surface of the $(k_1/2k_2)$ dimensional sphere $S^{(k_1-1)/2k_2}$. We go from Cartesean coordinates to a new set of coordinates for u_1 by projecting a fixed element s of the Cartan subalgebra on a space of superdimension $((k_1-1)/2k_2)$ orthogonal to u_1,

$$s^{(1)}=(1_{k_1+2k_2}-u_1u_1^\dagger)s(1_{k_1+2k_2}-u_1u_1^\dagger). \tag{8}$$

The eigenvalues and eigenvectors of this projected matrix are obtained by solving the supersymmetric Gelfand–Tzetlin equation

$$s_p^{(1)}e_p^{(1)}=(1_{k_1+2k_2}-u_1u_1^\dagger)s(1_{k_1+2k_2}-u_1u_1^\dagger)e_p^{(1)}=(1_{k_1+2k_2}-u_1u_1^\dagger)se_p^{(1)}, \tag{9}$$

which extends the equation in Ref. 5 for the unitary supergroup to $\mathrm{UOSp}(k_1/2k_2)$. It is convenient to rotate the basis in such a way that s becomes diagonal before solving Eq. (9). We introduce the primed basis

$$e'_{(2i-1)1}=\frac{1}{\sqrt{2}}(e_{(2i-1)1}+ie_{(2i)1}),$$

$$e'_{(2i)1}=\frac{1}{\sqrt{2}}(ie_{(2i-1)1}+e_{(2i)1}),\quad i=1...,k_1/2, \tag{10}$$

$$e'_{i2}=e_{i2},\quad i=k_1+1,\ldots,k_1+2k_2.$$

The rotation only affects the bosonic degrees of freedom, not the fermionic ones. Due to this rotation, the bosonic entries of u_1' are now complex variables which we write in the form

$$u'_{(2j)1}=iu'^*_{(2j-1)1}=\frac{i}{\sqrt{2}}|v_j^{(1)}|\exp(-i\vartheta_j^{(1)}),\quad j=1,\ldots,k_1/2. \tag{11}$$

The fermionic entries are, also in the primed basis, given by Eq. (7). To calculate the eigenvalues, we need the characteristic function of the eigenvalue equation (9),

$$z(s_p^{(1)})=\mathrm{detg}\,((1_{k_1+2k_2}-u_1u_1^\dagger)s-s_p^{(1)})=-s_p^{(1)}\mathrm{detg}\,(s-s_p^{(1)})u_1^\dagger\frac{1_{k_1+2k_2}}{s-s_p^{(1)}}u_1. \tag{12}$$

Importantly, the function $z(s_p^{(1)})$ behaves differently for the k_1 bosonic eigenvalues, i.e., for those in the boson–boson block $s_p^{(1)}=s_{p1}^{(1)}$, $p=1,\ldots,k_1$, and for the $2k_2$ fermionic eigenvalues, i.e., for those in the fermion–fermion block $s_{k_1+p}^{(1)}=is_{p2}^{(1)}$, $p=1,\ldots,2k_2$. The equation above has therefore to be discussed in the limits

$$z(s_p^{(1)})\to\begin{cases}0 & \text{for } p=1,\ldots,k_1,\\ \infty & \text{for } p=k_1+1,\ldots,\ k_1+2k_2.\end{cases} \tag{13}$$

Together with the normalization condition $u_1^\dagger u_1=1$ we find the following set of equations:

$$1=\sum_{p=1}^{k_1/2}|v_p^{(1)}|^2+\sum_{p=1}^{k_2}|\alpha_p^{(1)}|^2, \tag{14}$$

$$0=(s_{p1}^{(1)})^2\left(\sum_{q=1}^{k_1/2}\frac{|v_q^{(1)}|^2}{(s_{q1})^2-(s_{p1}^{(1)})^2}+\sum_{q=1}^{k_2}\frac{|\alpha_q^{(1)}|^2}{(is_{q2})^2-(s_{p1}^{(1)})^2}\right),\quad p=1,\ldots,(k_1-1), \tag{15}$$

$$z_p=(is_{p2}^{(1)})^2\frac{\Pi_{q=1}^{k_1/2}((s_{q1})^2-(is_{p2}^{(1)})^2)}{\Pi_{q=1}^{k_2}((is_{q2})^2-(is_{p2}^{(1)})^2)}\left(\sum_{q=1}^{k_1/2}\frac{|v_q^{(1)}|^2}{(s_{q1})^2-(is_{p2}^{(1)})^2}+\sum_{q=1}^{k_2}\frac{|\alpha_q^{(1)}|^2}{(is_{q2})^2-(is_{p2}^{(1)})^2}\right),$$

$$z_p\to\infty,\quad p=1,\ldots,2k_2. \tag{16}$$

This is a system of equations in the variables $(s_{p1}^{(1)})^2$ and $(is_{p2}^{(1)})^2$. The second equation has a twofold degenerate solution at $s_{p1}^{(1)}=0$. If $s_{p1}^{(1)}, is_{p2}^{(1)}$ are solutions of the above equations, $-s_{p1}^{(1)}$ and $-is_{p2}^{(1)}$ are solutions as well. Hence the projected matrix (8) is of the form (4) in the proper basis $e_j^{(1)}$ and belongs itself to the Cartan subalgebra $\mathrm{uosp}^{(0)}((k_1-1)/2k_2)$. This is crucial for the recursion. The system (14)–(16) is overdetermined; out of the k_1+2k_2+1 equations in (14)–(16), only $k_1/2+k_2$ are independent. The system yields the moduli squared of the entries of the vector u_1' expressed in terms of the eigenvalues $s^{(1)}$. We call the latter bosonic eigenvalues if they satisfy Eq. (15), and fermionic eigenvalues if they satisfy Eq. (16). With the substitutions $s_{q1}^{(j)}\to(s_{q1}^{(j)})^2$ and $is_{q2}^{(j)}\to(is_{q2}^{(j)})^2$, $j=1,2$, the set of independent equations is equivalent to the corresponding set of equations for the unitary supergroup. Thus, we can directly read off the solutions from Ref. 5. They will be stated in Sec. II D.

C. Recursion to all levels in superspace

The construction just outlined for the first coset space has to be continued recursively to cover the entire group manifold. For the ordinary groups, this recursion can be found in Refs. 1–3. In the present case, we extend the recursion for the unitary supergroup in Ref. 5. As the Cartan subalgebra $\mathrm{uosp}^{(0)}(k_1/2k_2)$ is slightly different for even and odd bosonic dimension k_1 according to Eqs. (3) and (4), we have to distinguish these two cases for the recursion. For brevity, we refer to a level as even, if (k_1-n+1) is even, and as odd otherwise.

In the nth step the vector u_n' is expanded in a set of $k_1-n+1+2k_2$ basis vectors $e_j'^{(n-1)}$, which span the subspace of $\mathcal{L}$ orthogonal to $u=[u_1\,u_2\cdots u_{n-1}]$. This set splits into two disjoint subsets. The first subset contains k_1-n+1 vectors $e_{j1}'^{(n-1)}$ spanning some subspace of ${}^0\mathcal{L}$. The second one contains $2k_2$ basis vectors $e_{j2}'^{(n-1)}$ spanning ${}^1\mathcal{L}$. The entries of u_n in this basis are complex variables

$$e_{(2p)1}'^{(n-1)\dagger}u_n=i(e_{(2p-1)1}'^{(n-1)\dagger}u_n)^*=\frac{i}{\sqrt{2}}|v_p^{(n)}|\exp(-i\vartheta_p^{(n)}),$$

$$p\leqslant\begin{cases}(k_1-n+1)/2 & \text{for } k_1-n+1 \text{ even},\\ (k_1-n)/2 & \text{for } k_1-n+1 \text{ odd},\end{cases} \tag{17}$$

$$e_{(2p)2}'^{(n-1)\dagger}u_n=(e_{(2p-1)2}'^{(n-1)\dagger}u_n)^*=\alpha_p^{(n)*},\quad p\leqslant k_2.$$

For k_1-n+1 odd, the remaining entry is parametrized by a real variable and an integer $r\in\{0,1\}$ as

$$e_{(k_1-n+1)1}'^{(n-1)\dagger}u_n=(-1)^r v_{(k_1-n)/2+1}^{(n)}. \tag{18}$$

Thus, we can write down the rotated nth eigenvector on the $(n-1)$th level,

$$u_n'^{(n-1)}=\sum_{j=1}^{k_1+2k_2-n+1}e_j'^{(n-1)\dagger}u_n e_j'^{(n-1)}. \tag{19}$$

The projection of s onto this subspace after the nth step is given by

$$s^{(n-1)}=\left(\sum_{i=n}^{k_1+2k_2} u_i u_i^\dagger\right) s \left(\sum_{i=n}^{k_1+2k_2} u_i u_i^\dagger\right) = \left(1_{k_1+2k_2}-\sum_{i=1}^{n-1} u_i u_i^\dagger\right) s \left(1_{k_1+2k_2}-\sum_{i=1}^{n-1} u_i u_i^\dagger\right) \quad (20)$$

and belongs to the Cartan subalgebra of $\mathrm{UOSp}((k_1-n)/2k_2)$. The new coordinates are obtained by projecting $s^{(n-1)}$ on the subspace orthogonal to u_n by

$$s_p^{(n)} e_p^{(n)} = (1_{k_1+2k_2}-u_n u_n^\dagger) s^{(n-1)} (1_{k_1+2k_2}-u_n u_n^\dagger) e_p^{(n)} = (1_{k_1+2k_2}-u_n u_n^\dagger) s^{(n-1)} e_p^{(n)}. \quad (21)$$

For k_1-n+1 even, this leads to a system of equations as in (14)–(16) reduced by $(n-1)/2$ unknown variables. For (k_1-n+1) odd, the equations have a slightly different form,

$$1=\sum_{p=1}^{(k_1-n)/2} |v_p^{(n)}|^2+|v_{(k_1-n)/2+1}^{(n)}|^2+\sum_{p=1}^{k_2} |\alpha_p^{(n)}|^2, \quad (22)$$

$$0=s_{p1}^{(n)}\left(\sum_{q=1}^{(k_1-n)/2} \frac{(s_{p1}^{(n)})^2 |v_q^{(n)}|^2}{(s_{q1}^{(n-1)})^2-(s_{p1}^{(n)})^2}+|v_{(k_1-n)/2+1}^{(n)}|^2+\sum_{q=1}^{k_2} \frac{(s_{p1}^{(n)})^2 |\alpha_q^{(n)}|^2}{(is_{q2}^{(n-1)})^2-(s_{p1}^{(n)})^2}\right),$$
$$p=1,\ldots,(k_1-n), \quad (23)$$

$$z_p=-is_{p2}^{(n)} \frac{\prod_{q=1}^{(k_1-n)/2}((s_{q1}^{(n-1)})^2-(is_{p2}^{(n)})^2)}{\prod_{q=1}^{k_2}((is_{q2}^{(n-1)})^2-(is_{p2}^{(n)})^2)} \left(\sum_{q=1}^{(k_1-n)/2} \frac{(s_{p1}^{(n)})^2 |v_q^{(n)}|^2}{(s_{q1}^{(n-1)})^2-(is_{p2}^{(n)})^2}+|v_{(k_1-n)/2+1}|^2 \right.$$
$$\left.+\sum_{q=1}^{k_2} \frac{(s_{p1}^{(n)})^2 |\alpha_q^{(n)}|^2}{(is_{q2}^{(n-1)})^2-(is_{p2}^{(n)})^2}\right), \quad z_p\to\infty, \quad p=1,\ldots,2k_2. \quad (24)$$

The difference between Eqs. (22)–(24) and the corresponding equations (14)–(16) for the even levels is due to the isolated entry (18), which has to be treated separately. This reflects the difference between the even orthogonal group and the odd orthogonal group in ordinary space.

The new basis vectors $e_j'^{(n)}$ are related to the basis vectors of the foregoing level by a $(k_1-n+2k_2)\times(k_1-n+1+2k_2)$ rectangular supermatrix $\hat{b}'^{(n)}$. The moduli squared of its entries $\hat{b}_{pm}'^{(n)}$ are determined by rewriting Eq. (21) and multiplying it from the left hand side with $e_m'^{(n-1)\dagger}$:

$$e_m'^{(n-1)\dagger} s^{(n-1)} e_p'^{(n)} = s_p^{(n)} e_m'^{(n-1)\dagger} e_p'^{(n)} + e_m'^{(n-1)\dagger} u_n b_p^{(n)}, \quad (25)$$

where we defined $b_p^{(n)}=u_n^\dagger s^{(n-1)} e_p'^{(n)}$. On the other hand, we have

$$e_m'^{(n-1)\dagger} s^{(n-1)} e_p'^{(n)} = s_m^{(n-1)} e_m'^{(n-1)} e_p'^{(n)}, \quad (26)$$

which yields for the matrix elements of $\hat{b}'^{(n)}$ the expression

$$\hat{b}_{pm}'^{(n)}=\frac{1}{s_m^{(n-1)}-s_p^{(n)}} u_{mn}'^{(n-1)} b_p^{(n)}. \quad (27)$$

The modulus squared of $b_p^{(n)}$ is determined by the normalization of the rotated basis vectors $e_m'^{(n)\dagger} e_p'^{(n)}=\delta_{mp}$, i.e., by the condition that the matrix $\hat{b}'^{(n)}\hat{b}'^{(n)\dagger}$ is unity in the k_1-n+2k_2 dimensional subspace orthogonal to $u=[u_1\, u_2\cdots u_n]$. Due to the block structure of the supermatrix $\hat{b}'^{(n)}$, the vector $b^{(n)}$ has commuting and anticommuting elements. For k_1-n+1 even we define $|w_p^{(n)}|^2=|b_{2p}^{(n)}|^2=|b_{2p-1}^{(n)}|^2, p=1,\ldots,(k_1-n+1)/2$, for the commuting elements and $|\beta_p^{(n)}|^2=|b_{k_1-n+1+2p}^{(n)}|^2=|b_{k_1-n+2p}^{(n)}|^2, p=1,\ldots,k_2$, for the anticommuting elements. For k_1-n

$+1$ odd we define $|w_p^{(n)}|^2$ and $|\beta_p^{(n)}|^2$ correspondingly. Again, there is a difference in the determining equations of $|w_p^{(n)}|^2$ and $|\beta_p^{(n)}|^2$ between the even and the odd levels of the recursion. For k_1-n+1 even we have

$$\frac{1}{|w_p^{(n)}|^2}=\sum_{m=1}^{(k_1-n+1)/2}\frac{(s_{m1}^{(n-1)})^2+(s_{p1}^{(n)})^2}{((s_{m1}^{(n-1)})^2-(s_{p1}^{(n)})^2)^2}|v_m^{(n)}|^2+\sum_{m'=1}^{k_2}\frac{(is_{m'2}^{(n-1)})^2+(s_{p1}^{(n)})^2}{((is_{m'2}^{(n-1)})^2-(s_{p1}^{(n)})^2)^2}|\alpha_{m'}^{(n)}|^2,$$
$$p=1,\ldots,(k_1-n-1)/2. \tag{28}$$

For the remaining modulus squared we obtain

$$\frac{1}{|w_{(k_1-n+1)/2}^{(n)}|^2}=\sum_{m=1}^{(k_1-n+1)/2}\frac{1}{(s_{m1}^{(n-1)})^2}|v_m^{(n)}|^2+\sum_{m'=1}^{k_2}\frac{1}{(is_{m'2}^{(n-1)})^2}|\alpha_{m'}^{(n)}|^2. \tag{29}$$

The moduli squared of the anticommuting coordinates of $b^{(n)}$ fulfill a formally similar equation. However, it is mathematically more precise to write it in the inverted form to avoid the appearance of purely nilpotent variables in the denominator,

$$1=|\beta_p^{(n)}|^2\left(\sum_{m=1}^{(k_1-n+1)/2}\frac{(s_{m1}^{(n-1)})^2+(is_{p2}^{(n)})^2}{((s_{m1}^{(n-1)})^2-(is_{p2}^{(n)})^2)^2}|v_m^{(n)}|^2+\sum_{m'=1}^{k_2}\frac{(is_{m'2}^{(n-1)})^2+(s_{p1}^{(n)})^2}{((is_{m'2}^{(n-1)})^2-(s_{p1}^{(n)})^2)^2}|\alpha_{m'}^{(n)}|^2\right),$$
$$p=1,\ldots,k_2. \tag{30}$$

The corresponding equations for the odd levels are obtained from Eqs. (28) and (30) by making the following formal replacements. In Eq. (28), the sum over m runs only to $(k_1-n)/2$ and, in addition, the term $|v_{(k_1-n)/2+1}^{(n)}|^2/(s_{p1}^{(n)})^2$ is subtracted. In Eq. (30), the first sum runs only to $(k_1-n)/2$ and the term $|v_{(k_1-n)/2+1}^{(n)}|^2/(is_{p2}^{(n)})^2$ is subtracted. Moreover, Eq. (29) does not exist for the odd levels.

D. Solution of the angular Gelfand–Tzetlin equations

Up to the k_1th level both sets of equations (14)–(16) and (28)–(30) have to be solved for even and odd levels separately. For the even levels, there is, as already mentioned above, a direct correspondence to the case of the unitary supergroup. Thus, we find employing the results of Ref. 5,

$$|v_p^{(n)}|^2=\frac{\Pi_{q=1}^{(k_1-n-1)/2}((s_{p1}^{(n-1)})^2-(s_{q1}^{(n)})^2)\Pi_{q=1}^{k_2}((s_{p1}^{(n-1)})^2-(is_{q2}^{(n-1)})^2)}{\Pi_{q=1,q\neq p}^{(k_1-n+1)/2}((s_{p1}^{(n-1)})^2-(s_{q1}^{(n-1)})^2)\Pi_{q=1}^{k_2}((s_{p1}^{(n-1)})^2-(is_{q2}^{(n)})^2)},$$
$$p=1,\ldots,(k_1-n+1)/2,\quad k_1-n+1 \text{ even},$$
$$|\alpha_p^{(n)}|^2=((is_{p2}^{(n)})^2-(is_{p2}^{(n-1)})^2)\times\frac{\Pi_{q=1}^{(k_1-n-1)/2}((is_{p2}^{(n-1)})^2-(s_{q1}^{(n)})^2)\Pi_{q=1,q\neq p}^{k_2}((is_{p2}^{(n-1)})^2-(is_{q2}^{(n-1)})^2)}{\Pi_{q=1}^{(k_1-n+1)/2}((is_{p2}^{(n-1)})^2-(s_{q1}^{(n-1)})^2)\Pi_{q=1,q\neq p}^{k_2}((is_{p2}^{(n-1)})^2-(is_{q2}^{(n)})^2)},$$
$$p=1,\ldots,k_2. \tag{31}$$

We have included the first level by setting $s=s^{(0)}$. To find the solution of Eqs. (28)–(30), one cannot directly make use of the results in the unitary case. An explicit calculation is necessary which is given in Appendix A. It yields

$$|w_p^{(n)}|^2=\frac{-\prod_{m=1}^{(k_1-n+1)/2}((s_{m1}^{(n-1)})^2-(s_{p1}^{(n)})^2)\prod_{q=1}^{k_2}((s_{p1}^{(n)})^2-(is_{q2}^{(n)})^2)}{2(s_{p1}^{(n)})^2\prod_{q=1,q\neq p}^{(k_1-n-1)/2}((s_{p1}^{(n)})^2-(s_{q1}^{(n)})^2)\prod_{q=1}^{k_2}((s_{p1}^{(n)})^2-(is_{q2}^{(n-1)})^2)},$$

$$p=1,\ldots,(k_1-n-1)/2\ ,$$

$$|w_{(k_1-n+1)/2}^{(n)}|^2=\frac{\prod_{m=1}^{(k_1-n+1)/2}(s_{m1}^{(n-1)})^2\prod_{q=1}^{k_2}(is_{q2}^{(n)})^2}{\prod_{m=1}^{(k_1-n-1)/2}(s_{m1}^{(n)})^2\prod_{q=1}^{k_2}(is_{q2}^{(n-1)})^2}, \tag{32}$$

$$|\beta_p^{(n)}|^2=((is_{p2}^{(n)})^2-(is_{p2}^{(n-1)})^2)$$

$$\times\frac{\prod_{q=1,q\neq p}^{k_2}((is_{p2}^{(n)})^2-(is_{q2}^{(n)})^2)\prod_{q=1}^{(k_1-n+1)/2}((is_{p2}^{(n)})^2-(s_{q1}^{(n)})^2)}{2(is_{p2}^{(n)})^2\prod_{q=1}^{(k_1-n-1)/2}((is_{p2}^{(n)})^2-(s_{q1}^{(n)})^2)\prod_{q=1,q\neq p}^{k_2}((is_{p2}^{(n)})^2-(is_{q2}^{(n-1)})^2)},$$

$$p=1,...,k_2\,.$$

We observe that the squares of the fermionic eigenvalues of the different levels $(is_{p2}^{(n)})^2$ differ only by a nilpotent variable. Hence, we introduce complex anticommuting variables $\xi_p^{(n)}$ such that

$$|\xi_p^{(n)}|^2=(is_{p2}^{(n)})^2-(is_{p2}^{(n-1)})^2. \tag{33}$$

We emphasize that this feature is highly nontrivial: the difference of the squared fermionic eigenvalues for two neighboring levels can be expressed as the modulus squared of one anticommuting variable.

The solutions of Eqs. (22)–(24) for the odd levels, i.e., for k_1-n+1 odd, cannot directly be obtained by adjusting the results of Ref. 5. However, as the necessary modifications are intuitively clear, we do not derive the solutions for the odd levels in detail. We simply state the results,

$$|v_p^{(n)}|^2=\frac{\prod_{q=1}^{(k_1-n)/2}((s_{p1}^{(n-1)})^2-(s_{q1}^{(n)})^2)\prod_{q=1}^{k_2}((s_{p1}^{(n-1)})^2-(is_{q2}^{(n-1)})^2)}{(s_{p1}^{(n-1)})^2\prod_{q=1,q\neq p}^{(k_1-n)/2}((s_{p1}^{(n-1)})^2-(s_{q1}^{(n-1)})^2)\prod_{q=1}^{k_2}((s_{p1}^{(n-1)})^2-(is_{q2}^{(n)})^2)},$$

$$p=1,\ldots,(k_1-n)/2,$$

$$|v_{(k_1-n)/2+1}^{(n)}|^2=\frac{\prod_{q=1}^{(k_1-n)/2}(s_{q1}^{(n)})^2\prod_{q=1}^{k_2}(is_{q2}^{(n-1)})^2}{\prod_{q=1}^{(k_1-n)/2}(s_{q1}^{(n-1)})^2\prod_{q=1}^{k_2}(is_{q2}^{(n)})^2}, \tag{34}$$

$$|\alpha_p^{(n)}|^2=((is_{p2}^{(n)})^2-(is_{p2}^{(n-1)})^2)$$

$$\times\frac{\prod_{q=1}^{(k_1-n)/2}((is_{p2}^{(n-1)})^2-(s_{q1}^{(n)})^2)\prod_{q=1,q\neq p}^{k_2}((is_{p2}^{(n-1)})^2-(is_{q2}^{(n-1)})^2)}{(is_{p2}^{(n-1)})^2\prod_{q=1}^{(k_1-n)/2}((is_{p2}^{(n-1)})^2-(s_{q1}^{(n-1)})^2)\prod_{q=1,q\neq p}^{k_2}((is_{p2}^{(n-1)})^2-(is_{q2}^{(n)})^2)},$$

$$p=1,\ldots,k_2.$$

The solutions of Eqs. (28)–(30) for the odd levels read

$$|w_p^{(n)}|^2=\frac{1}{2}\,\frac{\prod_{m=1}^{(k_1-n)/2}((s_{m1}^{(n-1)})^2-(s_{p1}^{(n)})^2)\prod_{q=1}^{k_2}((s_{p1}^{(n)})^2-(is_{q2}^{(n)})^2)}{\prod_{q=1,q\neq p}^{(k_1-n)/2}((s_{p1}^{(n)})^2-(s_{q1}^{(n)})^2)\prod_{q=1}^{k_2}((s_{p1}^{(n)})^2-(is_{q2}^{(n-1)})^2)},\quad p=1,\ldots,(k_1-n)/2, \tag{35}$$

$$|\beta_p^{(n)}|^2=\frac{1}{2}((is_{p2}^{(n)})^2-(is_{p2}^{(n-1)})^2)\,\frac{\prod_{q=1,q\neq p}^{k_2}((is_{p2}^{(n)})^2-(is_{q2}^{(n)})^2)\prod_{q=1}^{(k_1-n)/2}((is_{p2}^{(n)})^2-(s_{q1}^{(n-1)})^2)}{\prod_{q=1}^{(k_1-n)/2}((is_{p2}^{(n)})^2-(s_{q1}^{(n)})^2)\prod_{q=1,q\neq p}^{k_2}((is_{p2}^{(n)})^2-(is_{q2}^{(n-1)})^2)},$$

$$p=1,\ldots,k_2.$$

From the solutions stated in Eqs. (31)–(35) one derives the corresponding formulas for the group $SO(k_1)$ in ordinary space by setting all anticommuting variables to zero.

A comparison with the results for the unitary supergroup $U(k_1/2k_2)$ in Ref. 5 reveals an interesting formal connection. The Cartan subalgebras $u^{(0)}(k_1-n+1/2k_2)$ and $u^{(0)}(k_1-n/2k_2)$ of $U(k_1-n+1/2k_2)$ and $U(k_1-n/2k_2)$, respectively, are all diagonal matrices:

$$s^{(n-1)}=\mathrm{diag}(s_{11}^{(n-1)},\ldots,s_{(k_1-n+1)1}^{(n-1)},is_{12}^{(n-1)},\ldots,is_{2k_2 2}^{(n-1)}),$$
$$s^{(n)}=\mathrm{diag}(s_{11}^{(n)},\ldots,s_{(k_1-n)1}^{(n)},is_{12}^{(n)},\ldots,is_{2k_2 2}^{(n)}). \tag{36}$$

If one now formally replaces, in the results for the unitary supergroup, these matrices $s^{(n-1)}$ and $s^{(n)}$ with elements of the Cartan subalgebra of $\mathrm{uosp}^{(0)}(k_1-n+1/2k_2)$ and $\mathrm{uosp}^{(0)}(k_1-n/2k_2)$ according to

$$s^{(n-1)}\leftrightarrow\mathrm{diag}(is_{11}^{(n-1)}\tau^{(3)},\ldots,is_{[(k_1-n+1)/2]1}^{(n-1)}\tau^{(3)},-s_{12}^{(n-1)}\tau^{(3)},\ldots,-s_{k_2 2}^{(n-1)}\tau^{(3)}),$$
$$s^{(n)}\leftrightarrow\mathrm{diag}(is_{11}^{(n)}\tau^{(3)},\ldots,is_{[(k_1-n-1)/2]1}^{(n-1)}\tau^{(3)},0,-s_{12}^{(n)}\tau^{(3)},\ldots,-s_{k_2 2}^{(n)}\tau^{(3)}),\quad k_1-n+1\ \text{even}, \tag{37}$$

the results in Eqs. (31) and (32) and in Eqs. (34) and (35) are recovered. This formal connection between the unitary supergroup and the unitary orthosymplectic one is natural and plausible. Unfortunately, we could not make a sound mathematical reasoning out of the replacement (37) which would go beyond the *a posteriori* observation. However, the formal connection stated above illustrates the deep relationship between the groups which will become even more apparent in the generalized Gelfand pattern given in Sec. IV.

E. Ordinary unitary symplectic group

The k_1th step of the recursion is the last one in a superspace. We now approach the second line of Eq. (5). The following steps do not involve anticommuting variables anymore. We are left with the ordinary unitary symplectic group $USp(2k_2)$ and its coset decomposition. We make use of the isomorphism[18] $USp(2k_2)\cong U(k_2;4)$ where $U(k_2;4)$ is the unitary group in k_2 dimensions parametrized over the quaternions. Since $U(k_2;4)$ can be parametrized analogously to $U(k_2;2)=U(k_2)$, i.e., to the unitary group over the complex numbers, we simply have to adjust the results of Refs. 1 and 4 where Gelfand–Tzetlin coordinates for the ordinary unitary group were constructed. We write $U\in U(k_2;4)$ as $U=[U_1\,U_2\cdots U_{k_2}]$. The normalized vectors U_i have quaternionic entries:

$$U_{mi}=U_{mi0}\tau^{(0)}+U_{mi1}\tau^{(1)}+U_{mi2}\tau^{(2)}+U_{mi3}\tau^{(3)}. \tag{38}$$

The quantities U_{mik}, $k=0,...,3$, are real numbers. As basis vectors in Eq. (38), one can use the 2×2 matrices defined in Eq. (2).[18] Thus, we stay with the notation $\tau^{(i)}, i=0,\ldots,3$. The Cartan subalgebra is of the form $s_2^{(k_1)}=\mathrm{diag}\,(s_{12}^{(k_1)}\tau^{(3)},\ldots,s_{k_2 2}^{(k_1)}\tau^{(3)})$. The Gelfand–Tzetlin eigenvalue equation reads for the first level of the $USp(2k_2)$ recursion, i.e., for the level k_1+1 of the $UOSp(k_1/2k_2)$ recursion,

$$(1_{k_2}-U_1U_1^{\dagger})is_2^{(k_1)}(1_{k_2}-U_1U_1^{\dagger})E_n^{(1)}=is_{n2}^{(k_1+1)}E_n^{(1)}. \tag{39}$$

We introduced the notation $U_1=u_{k_1+1}$ and $E_n^{(1)}=e_n^{(k_1+1)}$ to highlight that the vectors and matrices used here span an ordinary vector space. Equation (39) can be viewed either as an eigenvalue equation for a $k_2\times k_2$ matrix over the quaternion field or for a $2k_2\times 2k_2$ matrix over the field of complex numbers. For a comprehensive account on matrices with quaternionic entries see Ref. 19. The eigenvalues on the right hand side of Eq. (39) are in principle still quaternionic. We now can proceed by multiplying Eq. (39) on both sides with $1_{k_2}\otimes\tau^{(3)}$ from the left. This renders the matrix

on the left hand side of Eq. (39) Hermitian self-dual.[19] Employing the Pauli matrices as quaternion basis a Hermitian self-dual $2k_2\times 2k_2$ matrix B is characterized by entries of the form

$$B_{ij}=\begin{bmatrix} z_{ij} & w_{ij}^* \\ -w_{ij} & z_{ij}^* \end{bmatrix}, \quad i\neq j, \quad i,j=1,\ldots,k_2, \quad \text{and} \quad B_{ii}=\begin{bmatrix} z_{ii} & 0 \\ 0 & z_{ii}^* \end{bmatrix}, \quad i=1,\ldots,k_2. \tag{40}$$

It is easy to see that $\tau^{(3)}((1_{k_2}-U_1U_1^\dagger)is_2^{(k_1)}(1_{k_2}-U_1U_1^\dagger))_{ij}$ has exactly this property. In physics, Hermitian self-dual matrices describe systems with Kramers degeneracy. We now use a standard result for matrices with quaternionic entries: A Hermitian self-dual matrix has k_2 scalar eigenvalues $s_{p2}^{(k_1+1)}\tau^{(0)}$.[19] In order to keep the notation simple, we also denote them by $s_{p2}^{(k_1+1)}$. After this adjustment, we can proceed along the same lines which led to Eq. (12). The equation reduces to the well known Gelfand–Tzetlin equations[1,4] of the unitary group $\mathrm{U}(k_2;2)=\mathrm{U}(k_2)$,

$$\begin{aligned} 1&=\sum_{n=1}^{k_2}|U_{n1}|^2, \\ 0&=\sum_{m=1}^{k_2}\frac{|U_{m1}|^2}{is_{m2}^{(k_1)}-is_{p2}^{(k_1+1)}}, \quad p=1,\ldots,k_2-1. \end{aligned} \tag{41}$$

This establishes a one-to-one correspondence between the (k_2-1) eigenvalues $is_{p2}^{(k_1+1)}$ and the moduli squared of the quaternionic entries

$$|U_{m1}|^2=\sum_{k=0}^{3}U_{m1k}^2. \tag{42}$$

All formulas derived in Refs. 1 and 4 for the unitary group can now be adopted to the unitary symplectic one.

F. Invariant measure

According to the coset decomposition (5), the invariant measure $d\mu(u)$ of $u\in\mathrm{UOSp}(k_1/2k_2)$ is the product of all measures on the cosets, i.e., on the spheres described by them. Of course, these measures are conditioned, because the orthogonality of the vectors u_n in $u=[u_1\,u_2\cdots u_{k_1+2k_2}]$ has to be respected. As we will see, the Gelfand–Tzetlin coordinates take care of this condition in a most convenient way. We evaluate the squared invariant length element $du_n^\dagger du_n$. For (k_1-n+1) even, it reads,

$$\begin{aligned} du_n'^\dagger du_n' &= du_n^\dagger du_n \\ &= \sum_{m=1}^{(k_1-n+1)/2}\frac{1}{4|v_m^{(n)}|^2}(d|v_m^{(n)}|^2)^2+\sum_{m=1}^{(k_1-n+1)/2}|v_m^{(n)}|^2(d\vartheta_m^{(n)})^2+\sum_{m'=1}^{k_2}d(\alpha_{m'}^{(n)})^*d\alpha_{m'}^{(n)}, \end{aligned} \tag{43}$$

where we use the parametrization (11). The first equality is due to the basis independence of the invariant length element. It is a highly welcomed feature of the Gelfand–Tzetlin coordinates for the unitary group in ordinary space[1,4] and in superspace[5] that the metric remains diagonal. This holds also in the present problem. Extending the corresponding calculation of Ref. 5, we find for the even levels, i.e., for k_1-n+1 even,

$$d\mu(u_n)=2^{k_2}\prod_{p=1}^{(k_1-n-1)/2} s_{p1}^{(n)}\frac{B_{[(k_1-n-1)/2]\,k_2}((s^{(n)})^2)}{B_{[(k_1-n+1)/2]\,k_2}((s^{(n-1)})^2)}d[s_1^{(n)}]d[\vartheta^{(n)}]d[\xi^{(n)}],$$

$$n\leqslant k_1,\quad k_1-n+1 \text{ even}, \tag{44}$$

and for the odd levels, i.e., for k_1-n+1 odd, we have

$$d\mu(u_n)=2^{k_2}\frac{\Pi_{p=1}^{k_2} is_{p2}^{(n)}is_{p2}^{(n-1)}}{\Pi_{p=1}^{(k_1-n)/2}s_{p1}^{(n-1)}}\frac{B_{[(k_1-n)/2]\,k_2}((s^{(n)})^2)}{B_{[(k_1-n)/2]\,k_2}((s^{(n-1)})^2)}d[s_1^{(n)}]d[\vartheta^{(n)}]d[\xi^{(n)}],$$

$$n\leqslant k_1,\quad k_1-n+1 \text{ odd}. \tag{45}$$

Here, we introduced the function

$$B_{nm}(s)=\frac{\Pi_{p>q}^{n}(s_{p1}-s_{q1})\Pi_{p>q}^{m}(is_{p2}-is_{q2})}{\Pi_{p,q}(s_{p1}-is_{q2})}=\frac{\Delta_n(s_1)\Delta_m(is_2)}{\Pi_p^n\Pi_q^m(s_{p1}-is_{q2})}. \tag{46}$$

It contains the ordinary Vandermonde determinants $\Delta_n(s_1)$ and $\Delta_m(is_2)$ and can be viewed as the supersymmetric generalization of the Vandermonde determinant.[5,20,21] Furthermore, we defined

$$d[s_1^{(n)}]=\prod_{p=1}^{(k_1-n+1)/2} ds_{p1}^{(n)},\quad d[\vartheta^{(n)}]=\prod_{p=1}^{(k_1-n+1)/2} d\vartheta_p^{(n)},\quad \text{and}\quad d[\xi^{(n)}]=\prod_{p=1}^{k_2} d\xi_p^{(n)*}d\xi_p^{(n)}. \tag{47}$$

Remarkably, Eqs. (44) and (45) imply that the measures on all cosets factorize. Collecting all these measures up to the k_1th step, we obtain the invariant measure of $u\in \mathrm{UOSp}(k_1/2k_2)$ in the form

$$d\mu(u)=2^{k_1k_2}\frac{\Delta_{k_2}((is_2^{(k_1)})^2)}{B_{k_1/2\,k_2}(s^2)}\prod_{i=1}^{k_1}\prod_{p=1}^{k_2} is_{p2}^{(i)}d[s_1^{(i)}]d[\vartheta^{(i)}]d[\xi^{(i)}]d\mu(U), \tag{48}$$

where $d\mu(U)$ is the invariant measure on $U\in \mathrm{USp}(2k_2)$. We mention in passing that the measure of the orthogonal group in ordinary space can be obtained by setting all anticommuting variables to zero in the invariant length (43), and skipping all couplings between the bosonic and fermionic eigenvalues in Eq. (48).

The measure (48) on $\mathrm{UOSp}(k_1/2k_2)$ has an important feature: Most conveniently, it is, apart from $d\mu(U)$, flat. This follows directly from the factorization of the measures (44) and (45) on the coset spaces. This is also true for the Gelfand–Tzetlin coordinates of the unitary group in ordinary[1,4] and in superspace[5] as well as for the ones of the orthogonal group in ordinary space. However, this important feature does not continue beyond the k_1th level. We will see that now in working out the measure $d\mu(U)$ for $U\in \mathrm{USp}(2k_2)$. We write $u=[U_1\,U_2\cdots U_{k_2}]$ and decompose the entry U_{nm} as $U_{nm}=|U_{nm}|\hat{U}_{nm}$, with $\hat{U}_{nm}$ a unimodular quaternion. We introduce a parametrization of the unimodular quaternion,

$$\hat{U}_{nm}=\begin{bmatrix}\cos\psi_n^{(m)}\exp(-i\gamma_{n1}^{(m)}) & -\sin\psi_n^{(m)}\exp(i\gamma_{n2}^{(m)})\\ \sin\psi_n^{(m)}\exp(-i\gamma_{n2}^{(m)}) & \cos\psi_n^{(m)}\exp(i\gamma_{n1}^{(m)})\end{bmatrix}, \tag{49}$$

which allows us to write the invariant length element squared as

$$\mathrm{Tr}\,dU_m^{\dagger}dU_m=\sum_{n=1}^{k_2}\left(\frac{1}{4|U_{nm}|^2}(d|U_{nm}|^2)^2+\sum_{i=1}^{2}|U_{nm}|^2(d\gamma_{ni}^{(m)})^2+|U_{nm}|^2(d\cos\psi_n^{(m)})^2\right),$$

$$m=1,\ldots,k_2. \tag{50}$$

Employing and properly adjusting the results of Refs. 1 and 4, one finds the measure of the coset in the mth level

$$d\mu(U_m)=\frac{\Delta_{k_2-m}(is_2^{(k_1+m)})}{2^{k_2-m}\Delta^3_{k_2-m+1}(is_2^{(k_1+m-1)})}\prod_{p,q}\,(is_{p2}^{(k_1+m-1)} - is_{q2}^{(k_1+m)})d[s_2^{(k_1+m)}]d[\cos\psi^{(m)}]d[\gamma^{(m)}], \tag{51}$$

with the definitions

$$d[s_2^{(k_1+m)}]=\prod_{p=1}^{k_2-m+1} ds_{p2}^{(k_1+m)}, \quad d[\cos\psi^{(m)}]=\prod_{p=1}^{k_2-m+1} d\cos\psi_p^{(m)}, \quad \text{and}$$

$$d[\gamma^{(m)}]=\prod_{p=1}^{k_2-m+1} d\gamma_{p1}^{(m)}d\gamma_{p2}^{(m)}. \tag{52}$$

One clearly sees that the factorization property does not hold for the unitary symplectic group. This is a peculiarity of the Gelfand–Tzetlin parametrization for the unitary symplectic group. Collecting all levels we arrive at the invariant measure on $U\in \mathrm{USp}(2k_2)$,

$$d\mu(U)=\frac{1}{2^{k_2(k_2-1)/2}\Delta^3_{k_2}(is_2^{(k_1)})}\prod_{m=1}^{k_2}\prod_{n=1}^{k_2-m+1}\prod_{n'=1}^{k_2-m}\frac{is_{n2}^{(k_1+m-1)}-is_{n'2}^{(k_1+m)}}{\Delta^2_{k_2-m}(is_2^{(k_1+m)})} \times d[s_2^{k_1+m}]d[\cos\psi^{(m)}]d[\gamma^{(m)}], \tag{53}$$

which combines with Eq. (48) to the full measure on $\mathrm{UOSp}(k_1/2k_2)$.

G. Matrix elements

With the results of the previous sections, we can express an arbitrary column u_p of a matrix $u=[u_1\,u_2\cdots u_{k_1+2k_2}]$ in the unitary orthosymplectic supergroup $\mathrm{UOSp}(k_1/2k_2)$ in terms of our angular Gelfand–Tzetlin coordinates. In the rotated primed basis (10), we have

$$u'_p=\hat{b}'^{(1)^T}\hat{b}'^{(2)^T}\cdots\hat{b}'^{(n-1)^T}u_p'^{(n-1)}, \tag{54}$$

where $\hat{b}^{(n)}$ and the scalar products are defined in Eqs. (17)–(19) and in Eqs. (25) and (27). So far, we have constructed a unitary representation of $\mathrm{UOSp}(k_1/2k_2)$. We also wish to obtain an orthosymplectic representation. To this end, we have to assure that the vectors u_j, $j\leqslant k_1$, become real, when the matrix $u'=[u'_1\,u'_2\cdots u'_{k_1+k_2}]$ is rotated back into the unprimed basis. We only discuss the case k_1-n+1 even; the odd case is treated analogously. We recall that the vector $b^{(n)}$ entering in the projection matrix in Eq. (27) has been determined only up to a phase. There is an ambiguity in choosing the phase of $b^{(n)}$. The Gelfand–Tzetlin coordinates parametrize the vector u_n only up to some phases associated with the action of the Cartan subgroup of $\mathrm{UOSp}((k_1-n+1)/2k_2)$. Thus, the projection matrix $\hat{b}^{(n)}$ is as well invariant under the action of this Cartan subgroup. We may multiply $\hat{b}^{(n)}$ with an arbitrary element of the Cartan subgroup without changing its projection properties. We set $b^{(n)}_{2p}=ib^{(n)}_{2p-1}$, $p\leqslant(k_1-n-1)/2$, and $b^{(n)}_{k_1-n}=i|w_{(k_1-n+1)/2}|$ in the commuting sector and $b^{(n)}_{k_1-n+1+2p}=-b^{(n)*}_{k_1-n+2p}$, $p=1,\ldots,k_2$, in the anticommuting one. The remaining phases may be set to zero. With this choice of phases and after undoing the basis rotation, the columns as well as the rows of $\hat{b}^{(n)T}$ fulfill the reality condition (6). The vectors $u_n^{(n-1)}$ become real, too. An explicit form of the real matrices $\hat{b}^{(n)}$ is given in Appendix B.

III. GENERALIZED GELFAND PATTERN

The unitary Lie group $U(k;\beta)$ over the real ($\beta=1$) and complex ($\beta=2$) numbers and over the quaternions ($\beta=4$) is isomorphic to the orthogonal, unitary and unitary symplectic group, $SO(k)\cong U(k;1)$, $U(k)\cong U(k;2)$, and $USp(2k)\cong U(k;4)$. The Gelfand–Tzetlin representation scheme are obtained from the following procedure.[3] An irreducible representation is defined by an ordered set of integers or half integers called highest weights. This irreducible representation can be decomposed in irreducible representations of $U(k-1;\beta)$. In the decomposition each irreducible representation of $U(k-1;\beta)$ occurs either exactly once or never. Only those irreducible representations appear whose highest weights satisfy certain betweenness conditions depending on the group under consideration. Going through all steps of the group chain or, equivalently, the coset decomposition,

$$U(k;\beta)=\frac{U(k;\beta)}{U(k-1;\beta)}\otimes\frac{U(k-1;\beta)}{U(k-2;\beta)}\otimes\cdots\otimes\frac{U(2;\beta)}{U(1;\beta)}\otimes U(1;\beta), \tag{55}$$

one has labeled all states in the irreducible representation of $U(k;\beta)$ by a set of integers or half integers, arranged in a Gelfand pattern.

The analog for the coordinates is as follows. We consider the adjoint group action $\mathcal{O}_k=U^\dagger xU$ on an element x of the Cartan subalgebra $u^{(0)}(k;\beta)$ with $U\in U(k;\beta)$. Here, in this one instance, we use the symbol x for an element in the algebra, because we want to emphasize that the present discussion so far applies to ordinary groups and because we want to avoid confusion with the discussion to follow on the supergroups. This subset $\mathcal{O}_k=U^\dagger xU$ of the complete algebra is called *orbit*. We can map the $U(k;\beta)$ orbit labeled by an ordered set of eigenvalues $x_i>x_{i+1}$ onto many different $U(k-1;\beta)$ orbits by projecting $\mathcal{O}_k$ onto a $k-1$ dimensional subspace. But only those $U(k-1;\beta)$ orbits $\mathcal{O}_{k-1}$ can be reached, whose eigenvalues interlace two neighboring eigenvalues of $\mathcal{O}_k$. This is the so called minimax principle for self-adjoint operators.[22] The Gelfand–Tzetlin method uses the eigenvalues of the projected matrix as coordinates of the coset $U(k;\beta)/U(k-1;\beta)$. However, x is a fixed point of the action of the Cartan subgroup $\exp(ix_0)$, $x_0\in u^{(0)}(k;\beta)$. Hence, the coset $U(k;\beta)/U(k-1;\beta)$ is parametrized by the eigenvalues of $\mathcal{O}_{k-1}$ only up to equivalence classes with respect to the action of the Cartan subgroup of $U(k;\beta)$, parametrized by x_0. In this way the set of variables describing the coset is split into two parts: One part consists of the eigenvalues of $\mathcal{O}_{k-1}$, the other one of the independent elements of x_0. Guillemin and Sternberg[6] introduced the concept of complete integrability by interpreting the entries of x as action and the elements of x_0 as angle coordinates of a generalized mechanical system. We emphasize that this usage of the term angles is different from the one introduced previously. We distinguish between radial and angular Gelfand–Tzetlin coordinates. However, both Gelfand–Tzetlin coordinates, the radial and the angular ones, allow for a further distinction between action and angle degrees of freedom, although the interpretation is slightly different in the two cases. The Guillemin–Sternberg theory applies only to the groups $U(k;\beta)$ for $\beta=1,2$ but not to the unitary symplectic group. This can be considered as the reason for the relatively complicated expression of the measure for $USp(2k)\cong U(k;4)$.

The generalized Gelfand pattern for $UOSp(k_1/2k_2)$ can be extracted from the positive definiteness of the moduli squared of the bosonic matrix elements $|v_i^{(n)}|^2$. If one restricts oneself to the subgroup, which consists of the direct product $SO(k_1)\otimes USp(2k_2)$, the pattern of the $SO(k_1)$ and $USp(2k_2)$ are rederived which are well known from representation theory.[3] We state them here in a different form which emphasizes the relation to the pattern of the unitary group $U(k)$ which is the famous triangle[23]

$$
\begin{array}{ccccccccc}
\underline{x_1^{(0)}} & & \underline{x_2^{(0)}} & & \cdots & & \underline{x_k^{(0)}} & & \underline{x_{k+1}^{(0)}} \\
& x_1^{(1)} & & x_2^{(1)} & \cdots & x_{k-2}^{(1)} & & x_k^{(1)} & \\
& & & \vdots & & & & & \\
& & x_1^{(k-1)} & & & & x_2^{(k-1)} & & \\
& & & & x_1^{(k)} & & & &
\end{array}
\tag{56}
$$

with the betweenness conditions

$$
x_{i+1}^{(j-1)} \leqslant x_i^{(j)} \leqslant x_i^{(j-1)}. \tag{57}
$$

The first row in the pattern (56) labels the orbit which was used as the starting point for the construction of the parametrization. We underline them to distinguish them from the coordinates of the group. From this pattern the pattern of the orthogonal group can be derived by the substitution rule (37), i.e., by assigning to the Cartan subalgebra $\mathrm{u}^{(0)}(k)$ of the unitary group $\mathrm{U}(k)$ the corresponding one $\mathrm{so}^{(0)}(k)$ of the orthogonal group $\mathrm{SO}(k)$. We restrict ourselves to the case of even k. The pattern (56) acquires the form

$$
\begin{array}{ccccccccccccc}
\underline{+x_1^{(0)}} & & \underline{+x_2^{(0)}} & & \cdots & & \underline{+x_{k+1}^{(0)}} & & \underline{-x_{k+1}^{(0)}} & & \cdots & & \underline{-x_2^{(0)}} & & \underline{-x_1^{(0)}} \\
& x_1^{(1)} & & x_2^{(1)} & \cdots & x_k^{(1)} & & 0 & & \underline{-x_k^{(1)}} & \cdots & \underline{-x_2^{(1)}} & & \underline{-x_1^{(1)}} & \\
& & & & & \vdots & & & & & & & & & \\
& & x_1^{(2k-2)} & & x_2^{(2k-2)} & & \underline{-x_2^{(2k-2)}} & & & & \underline{-x_1^{(2k-2)}} & & & & \\
& & & x_1^{(2k-1)} & & 0 & & & \underline{-x_1^{(2k-1)}} & & & & & & \\
& & & & x_1^{(2k)} & & \underline{-x_1^{(2k)}} & & & & & & & & \\
& & & & & 0 & & & & & & & & &
\end{array}
\tag{58}
$$

with the betweenness conditions

$$
\begin{aligned}
x_{i+1}^{(j-1)} &\leqslant x_i^{(j)} \leqslant x_i^{(j-1)}, \\
\left|x_j^{(2k-2j+2)}\right| &\leqslant x_j^{(2k-2j+1)}.
\end{aligned}
\tag{59}
$$

We notice the symmetry along the middle axis. The variable space of the $\mathrm{SO}(2k+2)$ is already covered by the left half of the triangle. The other half is shown to indicate its relation to the unitary case (56). This symmetry in the pattern is due to the presence of an anti-unitary invariance (see the discussion in Ref. 24). In most physics applications, this is time reversal invariance: A system which is not invariant under time reversal is modeled by Hermitian operators. One can go to a time reversal invariant system by replacing these operators with real symmetric ones. Restricting the pattern (58) to the left half of the triangle, the patterns appear in their traditional form.[2] By construction, the pattern of the unitary symplectic group $\mathrm{USp}(2k)$ coincides with the one of the unitary group $\mathrm{U}(k)$; this is due to the fact that only the action variables are used in the pattern. The unitary group has only one, but the unitary symplectic group has three angle variables coming with every action.

The two patterns of the orthogonal and the unitary symplectic groups together represent the subgroup $\mathrm{SO}(k_1)\otimes\mathrm{USp}(2k_2)$ of $\mathrm{UOSp}(k_1/2k_2)$. What represents the coset $\mathrm{UOSp}(k_1/2k_2)/(\mathrm{SO}(k_1)\otimes\mathrm{USp}(2k_2))$? We observe that the lengths squared $|\xi_p^{(n)}|^2$ of the anticommuting variables $\xi_p^{(n)}$ introduced in Eq. (33) have a distinguished meaning. We may identify these lengths of the anticommuting variables as the analogs of the actions stemming from the commuting degrees of freedom. We can organize the lengths squared $|\xi_p^{(n)}|^2$ in a rectangular pattern. Thus, the generalized Gelfand pattern for the unitary orthosymplectic supergroup $\mathrm{UOSp}(k_1/2k_2)$ are obtained,

$$
\begin{array}{ccccccccccccc}
\underline{+s_{11}^{(0)}} & & \underline{+s_{21}^{(0)}} & & \cdots & & \underline{+s_{k+11}^{(0)}} & & \underline{-s_{k+11}^{(0)}} & & \cdots & & \underline{-s_{21}^{(0)}} \quad \underline{-s_{11}^{(0)}} \\
& s_{11}^{(1)} & & s_{21}^{(1)} & \cdots & s_{k1}^{(1)} & & 0 & & \underline{-s_{k1}^{(1)}} & \cdots & \underline{-s_{21}^{(1)}} \quad \underline{-s_{11}^{(1)}} & \\
& & & & & \vdots & & & & & & & \\
& & s_{11}^{(2k-2)} & & s_{21}^{(2k-2)} & & & \underline{-s_{21}^{(2k-2)}} & & \underline{-s_{11}^{(2k-2)}} & & & \\
& & & s_{11}^{(2k-1)} & & 0 & & \underline{-s_{11}^{(2k-1)}} & & & & & \\
& & & & s_{11}^{(2k)} & & \underline{-s_{11}^{(2k)}} & & & & & & \\
& & & & & & 0 & & & & & & \\
& & & & & |\xi_1^{(1)}|^2 & & |\xi_2^{(1)}|^2 & \cdots & |\xi_{k_2-1}^{(1)}|^2 & & |\xi_{k_2}^{(1)}|^2 & \\
& & & & & |\xi_1^{(2)}|^2 & & |\xi_2^{(2)}|^2 & \cdots & |\xi_{k_2-1}^{(2)}|^2 & & |\xi_{k_2}^{(2)}|^2 & \\
& & & & & & \vdots & & & & & & & \\
& & & & & |\xi_1^{(k_1)}|^2 & & |\xi_2^{(k_1)}|^2 & \cdots & |\xi_{k_2-1}^{(k_1)}|^2 & & |\xi_{k_2}^{(k_1)}|^2 & \\
& & & & s_{12}^{(k_1)} & & s_{22}^{(k_1)} & & \cdots & & s_{(k_2-1)2}^{(k_1)} & & s_{k_2 2}^{(k_1)} \\
& & & s_{12}^{(k_1+1)} & & s_{22}^{(k_1+1)} & & \cdots & & s_{(k_2-2)2}^{(k_1+1)} & & s_{(k_2-1)2}^{(k_1+1)} & \\
& & & & & & \vdots & & & & & & & \\
& & & & s_{12}^{(k_1+k_2-1)} & & & & s_{22}^{(k_1+k_2-1)} & & & & \\
& & & & & & s_1^{(k_1+k_2)} & & & & & &
\end{array}
\tag{60}
$$

with the betweenness conditions

$$
\begin{gathered}
s_{(i+1)1}^{(m-1)} \leqslant s_{i1}^{(m)} \leqslant s_{i1}^{(m-1)}, \\
s_{(i+1)2}^{(k_1+l)} \leqslant s_{i2}^{(k_1+l+1)} \leqslant s_{i2}^{(k_1+l)}, \\
-s_{j1}^{(k_1-2j-1)} \leqslant s_{j1}^{(k_1-2j)} \leqslant s_{j1}^{(k_1-2j-1)},
\end{gathered}
\tag{61}
$$

where $1\leqslant j\leqslant k_1/2-1$, $1\leqslant m\leqslant k_1-2$, and $0\leqslant l\leqslant k_2-1$. It was shown in Ref. 25 that the unitary supergroup U(1/1) can be represented by supersymmetric generalizations of Wigner functions.

This representation of the supergroup U(1/1) is labeled by the length of an anticommuting variable. Therefore, we want to interpret the generalized Gelfand pattern (60) as labeling another kind of representation which involves anticommuting variables as labels. The two triangles label the basis of an irreducible representation of the product $\mathrm{SO}(k_1)\otimes\mathrm{USp}(2k_2)$, whereas the remaining coset $\mathrm{UOSp}(k_1/2k_2)/(\mathrm{SO}(k_1)\otimes\mathrm{USp}(2k_2))$ is represented by the rectangular block of the lengths squared of anticommuting variables. This extends the corresponding considerations for the unitary supergroup in Ref. 5. It is challenging to find a further interpretation of these new representations of supergroups, possibly by generalizing the Guillemin–Sternberg theory.

IV. SUMMARY AND CONCLUSIONS

We constructed Gelfand–Tzetlin coordinates for the unitary orthosymplectic supergroup $\mathrm{UOSp}(k_1/2k_2)$. To this end, we further extended the construction for the unitary supergroup $\mathrm{U}(k_1/k_2)$. We obtained *angular* Gelfand–Tzetlin coordinates, which always live in the space of the unitary orthosymplectic supergroup. They ought to be distinguished from *radial* Gelfand–Tzetlin which map group degrees of freedom onto those of another space. We also calculated the invariant Haar measure on $\mathrm{UOSp}(k_1/2k_2)$ and obtained an expression that is fairly simple due to the recursive structure of the coordinates. As the orthogonal and the unitary symplectic groups are subgroups of the unitary orthosymplectic supergroup, our construction also includes *angular* Gelfand–Tzetlin coordinates on these ordinary groups.

The Gelfand–Tzetlin coordinates can be arranged in a generalized Gelfand pattern. A remarkable feature of this pattern is the appearance of moduli squared of anticommuting variables. We argued that an interpretation of these anticommuting variables as eigenvalues of a set of invariant operators is likely to exist. It is an interesting task to clarify the rôle of these anticommuting variables in the representation theory for supergroups.

So far, Gelfand–Tzetlin coordinates were only constructed for compact groups. But there is no apparent obstacle to construct them also for noncompact groups. It would be interesting to see if such a construction is indeed possible and how the noncompactness of some variables is reflected in the corresponding Gelfand pattern, in ordinary and in superspace.

APPENDIX A: SOLUTION OF EQS. (28)–(30)

We consider Eq. (28) and insert the solutions for $|v_m^{(n)}|^2$ and $|\alpha_m^{(n)}|^2$ given in (31). The right hand side of Eq. (28) can then be expanded in a sum of monomials in the nilpotent Gelfand–Tzetlin variables $|\xi_q^{(n)}|^2$, $q=1,\ldots,k_2$. Since each of the $|\xi_q^{(n)}|^2$ only appears linearly, the rank of the monomials cannot exceed k_2. Thus, we can rewrite Eq. (28) in the form

$$\frac{1}{|w_p^{(n)}|^2}=\sum_{r=0}^{k_2} M^{(r)}\ , \tag{A1}$$

where $M^{(r)}$ is the nilpotent part of $1/|w_p^{(n)}|^2$, consisting of monomials in $|\xi_q^{(n)}|^2$ with rank r. Explicitly we have

$$M^{(r)}=\sum_{j_1\leqslant j_2\leqslant\cdots\leqslant j_r}^{k_2}\sum_{m}^{(k_1-n+1)/2}\frac{\Pi_{q=1,q\neq p}^{(k_1-n-1)/2}((s_{m1}^{(n-1)})^2-(s_{q1}^{(n)})^2)}{\Pi_{q=1,q\neq m}^{(k_1-n+1)/2}((s_{m1}^{(n-1)})^2-(s_{q1}^{(n-1)})^2)}\frac{(s_{m1}^{(n-1)})^2+(s_{p1}^{(n)})^2}{(s_{m1}^{(n-1)})^2-(s_{p1}^{(n)})^2}$$
$$\times\frac{\Pi_{i=1}^{r}|\xi_{j_i}|^2}{\Pi_{i=1}^{r}((s_{m1}^{(n-1)})^2-(is_{j_i2}^{(n-1)})^2)}$$
$$+\sum_{\substack{j_2\leqslant\cdots\leqslant j_r\\ j_1\neq j_i}}^{k_2}\frac{\Pi_{q=1,q\neq p}^{(k_1-n-1)/2}((is_{j_12}^{(n-1)})^2-(s_{q1}^{(n)})^2)}{\Pi_{q=1}^{(k_1-n+1)/2}((is_{j_12}^{(n-1)})^2-(s_{q1}^{(n-1)})^2)}\frac{(is_{j_12}^{(n-1)})^2+(s_{p1}^{(n)})^2}{(is_{j_12}^{(n-1)})^2-(s_{p1}^{(n)})^2}$$
$$\times\frac{\Pi_{i=1}^{r}|\xi_{j_i}|^2}{\Pi_{i=2}^{r}((is_{j_12}^{(n-1)})^2-(is_{j_i2}^{(n-1)})^2)}, \tag{A2}$$

for $r=1,\ldots,k_2$. The sum over m is the Laplace expansion of a determinant. For its evaluation we use the formula

$$\frac{1}{\Pi_{i=1}^{r}((s_{m1}^{(n-1)})^2-(is_{i2}^{(n-1)})^2)}=\sum_{i=1}^{r}\frac{1}{(s_{m1}^{(n-1)})^2-(is_{i2}^{(n-1)})^2}\frac{1}{\Pi_{i'\neq i}^{r}((is_{i2}^{(n-1)})^2-(is_{i'2}^{(n-1)})^2)}, \tag{A3}$$

which is well known from complex analysis. After symmetrizing the second sum in the indices, $j_i, i=1,\ldots,r$, we arrive at the following expression for $M^{(r)}$:

$$M^{(r)}=\sum_{j_1\leqslant j_2\leqslant\cdots\leqslant j_r}^{k_2}\sum_{i=1}^{r}\frac{1}{\Pi_{i'\neq i}^{r}((is_{j_i2}^{(n-1)})^2-(is_{j_{i'}2}^{(n-1)})^2)}$$
$$\times\sum_{m}^{(k_1-n+1)/2}\frac{\Pi_{q=1,q\neq p}^{(k_1-n-1)/2}((s_{m1}^{(n-1)})^2-(s_{q1}^{(n)})^2)}{\Pi_{q=1,q\neq m}^{(k_1-n+1)/2}((s_{m1}^{(n-1)})^2-(s_{q1}^{(n-1)})^2)}\left[\frac{(s_{m1}^{(n-1)})^2+(s_{p1}^{(n)})^2}{((s_{p1}^{(n)})^2-(is_{j_i2}^{(n-1)})^2)((s_{m1}^{(n-1)})^2-(s_{p1}^{(n)})^2)}\right.$$
$$\left.-\frac{(s_{m1}^{(n-1)})^2+(s_{p1}^{(n)})^2}{((s_{p1}^{(n)})^2-(is_{j_i2}^{(n-1)})^2)((s_{m1}^{(n-1)})^2-(is_{j_i2}^{(n-1)})^2)}\right]\prod_{i=1}^{r}|\xi_{j_i}|^2$$
$$+\sum_{j_1\leqslant j_2\leqslant\cdots\leqslant j_r}^{k_2}\sum_{i=1}^{r}\frac{1}{\Pi_{i'\neq i}^{r}((is_{j_i2}^{(n-1)})^2-(is_{j_{i'}2}^{(n-1)})^2)}$$
$$\times\frac{\Pi_{q=1,q\neq p}^{(k_1-n-1)/2}((is_{j_12}^{(n-1)})^2-(s_{q1}^{(n)})^2)}{\Pi_{q=1}^{(k_1-n+1)/2}((is_{j_12}^{(n-1)})^2-(s_{q1}^{(n-1)})^2)}\frac{(is_{j_12}^{(n-1)})^2+(s_{p1}^{(n)})^2}{(is_{j_12}^{(n-1)})^2-(s_{p1}^{(n)})^2}\prod_{i=1}^{r}|\xi_{j_i}|^2. \tag{A4}$$

Now the determinant mentioned above can be evaluated by using the translational invariance of the differences. The second term in the squared bracket cancels completely; we are left with

$$M^{(r)}=\sum_{j_1\leqslant j_2\leqslant\cdots\leqslant j_r}^{k_2}\sum_{i=1}^{r}\frac{1}{\Pi_{i'\neq i}^{r}((is_{j_i2}^{(n-1)})^2-(is_{j_{i'}2}^{(n-1)})^2)}$$
$$\times\frac{2(s_{p1}^{(n)})^2\Pi_{q=1,q\neq p}^{(k_1-n-1)/2}((s_{q1}^{(n)})^2-(s_{p1}^{(n)})^2)}{((s_{p1}^{(n)})^2-(is_{j_i2}^{(n-1)})^2)\Pi_{m=1}^{(k_1-n+1)/2}((s_{m1}^{(n-1)})^2-(s_{p1}^{(n)})^2)}\prod_{i=1}^{r}|\xi_{j_i}|^2. \tag{A5}$$

Using identity (A3) once more and summing over r gives

$$\frac{1}{|w_p^{(n)}|^2}=\frac{-2(s_{p1}^{(n)})^2\Pi_{q=1,q\neq p}^{(k_1-n-1)/2}((s_{p1}^{(n)})^2-(s_{q1}^{(n)})^2)}{\Pi_{m=1}^{(k_1-n+1)/2}((s_{m1}^{(n-1)})^2-(s_{p1}^{(n)})^2)}\left(\sum_{r=0}^{k_2}\sum_{j_1\leqslant j_2\leqslant\cdots t\leqslant j_r}^{k_2}\prod_{i=1}^{r}\frac{|\xi_{j_i}|^2}{(s_{p1}^{(n)})^2-(is_{j_i2}^{(n-1)})^2}\right). \tag{A6}$$

The double sum in Eq. (A6) simply amounts to

$$\prod_{q=1}^{k_2}\left(1+\frac{|\xi_q^{(n)}|^2}{(s_{p1}^{(n)})^2-(is_{q2}^{(n-1)})^2}\right). \tag{A7}$$

Employing the definition (33) of $|\xi_q^{(n)}|^2$, we arrive at the final result for $|w_p^{(n)}|^2$ in Eq. (32). Equation (29) and the corresponding equation for the odd levels are evaluated similarly, yielding the results stated in Sec. II D. Equation (30) has to be treated differently due to the Grassmann singularities, occurring on the left hand side. Inserting the expressions Eq. (31) into Eq. (30) we have

$$\begin{aligned}1=|\beta_p^{(n)}|^2\Bigg(&\sum_{m}^{(k_1-n+1)/2}\frac{(s_{m1}^{(n-1)})^2+(is_{p2}^{(n)})^2}{((s_{m1}^{(n-1)})^2-(is_{p2}^{(n)})^2)^2}|v_m^{(n)}|^2+\sum_{\substack{m'=1\\m'\neq p}}^{k_2}\frac{(is_{m'2}^{(n-1)})^2+(is_{p2}^{(n)})^2}{((is_{m'2}^{(n-1)})^2-(is_{p2}^{(n)})^2)^2}|\alpha_{m'}^{(n)}|^2\\&+\frac{\Pi_{q=1}^{(k_1-n-1)/2}((is_{p2}^{(n-1)})^2-(s_{q1}^{(n)})^2)\Pi_{q=1,q\neq p}^{k_2}((is_{p2}^{(n-1)})^2-(is_{q2}^{(n-1)})^2)}{\Pi_{q=1,q\neq p}^{k_2}((is_{p2}^{(n-1)})^2-(is_{q2}^{(n)})^2)\Pi_{q=1}^{(k_1-n+1)/2}((is_{p2}^{(n-1)})^2-(s_{q1}^{(n-1)})^2)}\\&\times\frac{(is_{p2}^{(n-1)})^2+(is_{p2}^{(n)})^2}{|\xi_p^{(n)}|^2}\Bigg).\end{aligned} \tag{A8}$$

To cancel the singularity, $|\beta_p^{(n)}|^2$ has to be expanded in terms of $c_p^{(n)}|\xi_p^{(n)}|^2$. The expansion coefficient $c_p^{(n)}$ now contains a nonzero part and its inverse is therefore well defined. Dividing both sides by $c_p^{(n)}$ and ordering the right hand side by powers of $|\xi_p^{(n)}|^2$, one finds

$$\begin{aligned}\frac{1}{c_p^{(n)}}=&2(is_{p2}^{(n-1)})^2\frac{\Pi_{q=1}^{(k_1-n-1)/2}((is_{p2}^{(n-1)})^2-(s_{q1}^{(n)})^2)\Pi_{q=1,q\neq p}^{k_2}((is_{p2}^{(n-1)})^2-(is_{q2}^{(n-1)})^2))}{\Pi_{q=1,q\neq p}^{k_2}((is_{p2}^{(n-1)})^2-(is_{q2}^{(n)})^2)\Pi_{q=1}^{(k_1-n+1)/2}((is_{p2}^{(n-1)})^2-(s_{q1}^{(n-1)})^2)}\\&+\Bigg(\sum_{m}^{(k_1-n+1)/2}\frac{(s_{m1}^{(n-1)})^2+(is_{p2}^{(n)})^2}{((s_{m1}^{(n-1)})^2-(is_{p2}^{(n)})^2)^2}|v_m^{(n)}|^2+\sum_{\substack{m'=1\\m'\neq p}}^{k_2}\frac{(is_{m'2}^{(n-1)})^2+(is_{p2}^{(n)})^2}{((is_{m'2}^{(n-1)})^2-(is_{p2}^{(n)})^2)^2}|\alpha_{m'}^{(n)}|^2\\&-\frac{\Pi_{q=1}^{(k_1-n-1)/2}((is_{p2}^{(n-1)})^2-(s_{q1}^{(n)})^2)\Pi_{q=1,q\neq p}^{k_2}((is_{p2}^{(n-1)})^2-(is_{q2}^{(n-1)})^2))}{\Pi_{q=1,q\neq p}^{k_2}((is_{p2}^{(n-1)})^2-(is_{q2}^{(n)})^2)\Pi_{q=1}^{(k_1-n+1)/2}((is_{p2}^{(n-1)})^2-(s_{q1}^{(n-1)})^2)}\Bigg)|\xi_p^{(n)}|^2.\end{aligned} \tag{A9}$$

Since $c_p^{(n)}$ and thus $1/c_p^{(n)}$ are of order zero in $|\xi_p^{(n)}|^2$, the whole term in round brackets can be neglected. It can be shown by straightforward manipulations that this term leads just to a shift of $(is_{p2}^{(n-1)})^2\rightarrow(is_{p2}^{(n)})^2$ in the resulting expression for $c_p^{(n)}$. This does not affect $|\beta_p^{(n)}|^2$. Hence, we immediately arrive at the result for $|\beta_p^{(n)}|^2$ given in Eq. (32). The equations for the odd levels are treated accordingly.

APPENDIX B: REAL FORM OF THE PROJECTION MATRICES $\hat{b}^{(n)}$

We restrict ourselves to the case $n\leqslant k_1$, (k_1-n+1) even. The odd case can be treated accordingly. The rectangular $(k_1-n+1+k_2)\times(k_1-n+k_2)$ matrix $\hat{b}^{(n)T}$ can schematically be written as

$$\hat{b}^{(n)}=\begin{bmatrix} \tilde{b}_{11}^{(n)} & \tilde{b}_{1}^{(n)} & \tilde{b}_{12}^{(n)} \\ \tilde{b}_{21}^{(n)} & \tilde{b}_{2}^{(n)} & \tilde{b}_{22}^{(n)} \end{bmatrix}. \tag{B1}$$

Here, $\tilde{b}_{11}^{(n)}$ is a $(k_1-n+1)/2\times(k_1-n-1)/2$ matrix with entries

$$(\tilde{b}_{11}^{(n)})_{ij}=\sqrt{2}\,\frac{|v_i^{(n)}||w_j^{(n)}|}{(s_{i1}^{(n-1)})^2-(s_{j1}^{(n)})^2}\begin{bmatrix} s_{j1}^{(n)}\cos\vartheta_i^{(n)} & s_{j1}^{(n-1)}\sin\vartheta_i^{(n)} \\ -s_{j1}^{(n)}\sin\vartheta_i^{(n)} & s_{j1}^{(n-1)}\cos\vartheta_i^{(n)} \end{bmatrix}. \tag{B2}$$

The matrix $\tilde{b}_{12}^{(n)}$ has dimension $(k_1-n+1)/2\times k_2$ and entries

$$\begin{aligned}(\tilde{b}_{12}^{(n)})_{ij}=&\frac{|v_i^{(n)}|}{(s_{i1}^{(n-1)})^2-(is_{j2}^{(n)})^2}\\ &\times\begin{bmatrix} \beta_j^{(n)*}(is_{j2}^{(n)}\cos\vartheta_i^{(n)}+s_{j1}^{(n-1)}i\sin\vartheta_i^{(n)}) & -i\beta_j^{(n)*}(s_{i1}^{(n-1)}\cos\vartheta_i^{(n)}+is_{j2}^{(n)}i\sin\vartheta_i^{(n)}) \\ -\beta_j^{(n)}(is_{j2}^{(n)}\cos\vartheta_i^{(n)}-s_{j1}^{(n-1)}i\sin\vartheta_i^{(n)}) & -i\beta_j^{(n)}(s_{i1}^{(n-1)}\cos\vartheta_i^{(n)}-is_{j2}^{(n)}i\sin\vartheta_i^{(n)}) \end{bmatrix}.\end{aligned} \tag{B3}$$

Moreover, $\tilde{b}_{21}^{(n)}$ is a $k_2\times(k_1-n+1)/2$ matrix with entries

$$(\tilde{b}_{21}^{(n)})_{ij}=\frac{|w_j^{(n)}|}{(is_{i2}^{(n-1)})^2-(s_{j1}^{(n)})^2}\begin{bmatrix} \alpha_i^{(n)}s_{j1}^{(n)} & i\alpha_i^{(n)}is_{i2}^{(n-1)} \\ \alpha_i^{(n)*}s_{j1}^{(n)} & -i\alpha_i^{(n)*}is_{i2}^{(n-1)} \end{bmatrix}, \tag{B4}$$

and $\tilde{b}_{22}^{(n)}$ is a $k_2\times(k_1-n+1)/2$ matrix with entries

$$(\tilde{b}_{22}^{(n)})_{ij}=\sqrt{2}\begin{bmatrix} \alpha_i^{(n)}\beta_j^{(n)*}/(is_{i2}^{(n-1)}-is_{j2}^{(n)}) & \alpha_i^{(n)}\beta_j^{(n)}/(is_{i2}^{(n-1)}+is_{j2}^{(n)}) \\ -\alpha_i^{(n)*}\beta_j^{(n)*}/(is_{i2}^{(n-1)}+is_{j2}^{(n)}) & -\alpha_i^{(n)*}\beta_j^{(n)}/(is_{i2}^{(n-1)}-is_{j2}^{(n)}) \end{bmatrix}. \tag{B5}$$

Finally, the entries of $\tilde{b}_1^{(n)}$ and $\tilde{b}_2^{(n)}$ are given by

$$\begin{aligned}(\tilde{b}_1^{(n)})_i&=\sqrt{2}\,\frac{|v_i^{(n)}||w_{(k_1-n+1)/2}^{(n)}|}{s_{i1}^{(n-1)}}\begin{bmatrix}\sin\vartheta_i^{(n)}\\ \cos\vartheta_i^{(n)}\end{bmatrix},\quad i=1,\ldots,\frac{k_1-n+1}{2},\\ (\tilde{b}_2^{(n)})_i&=\frac{1}{\sqrt{2}}\,\frac{|w_{(k_1-n+1)/2}^{(n)}|}{s_{i1}^{(n-1)}}\begin{bmatrix} i\alpha_i^{(n)} \\ -i\alpha_i^{(n)*}\end{bmatrix},\quad i=1,\ldots,k_2.\end{aligned} \tag{B6}$$

We notice that all elements of $\hat{b}^{(n)}$ are real.

On the construction of self-polar and self-polar Hilbertian norms on Minkowski space of dimension 2

Gerald Hofmann
Fritz-Siemon-Str. 7, D-04347 Leipzig, Germany

(Received 12 February 2003; accepted 15 April 2003)

Considering the real Minkowski space $\mathcal{M}^2$ endowed with the indefinite inner product $(\vec{a},\vec{b})=x_a x_b - y_a y_b$, $\vec{a}=(x_a,y_a)$, $\vec{b}=(x_b,y_b)\in\mathcal{M}^2$, we give a general construction for the boundary $\partial U_p=\{\vec{a}\in\mathcal{M}^2; p(\vec{a})=1\}$ of the unit ball U_p of some self-polar norm p on $\mathcal{M}^2$. We show further that every self-polar norm p on $\mathcal{M}^2$ is obtained by our construction. A detailed investigation of the possible choices of the ingredients of our construction (two points P_j, $j=1,2$, and a convex arc connecting P_1 and P_2) yields a complete classification of all self-polar norms on $\mathcal{M}^2$. Our results are finally applied to the special case of Hilbertian self-polar norms. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1597421]

I. INTRODUCTION AND SOME PRELIMINARIES

For a pre-Hilbert (unitary) space $E,[.,.]$ (i.e., the inner product $[.,.]$ is positive definite), a canonical norm

$$p(x)=\sqrt{[x,x]}, \tag{1}$$

$x\in E$, exists on E. Now it is of interest to find the corresponding substitutes when the pre-Hilbert space is replaced by some nondegenerate inner product space $E,(.,.)$, [i.e., E is a real or complex vector space equipped with a bilinear symmetric respective sesquilinear Hermitian form $(.,.)$ which is nondegenerate, see Refs. 4 and 3].

If the inner product $(.,.)$ is indefinite, then (1) does not define a norm, and thus, no canonical norm is available. As explained in Refs. 8 and 9, the role of the canonical norm (1) is now played by Hilbertian self-polar norms q satisfying

$$q(x)=\sup_{0\neq y\in E}\frac{|(x,y)|}{q(y)}, \tag{2}$$

and furthermore, given by

$$q(x)=\sqrt{[x,x]}, \tag{3}$$

$x\in E$, in terms of a positive definite inner product $[.,.]$ on $E\times E$.

In generalization of the positive definite case, where the canonical norm is uniquely defined, the following is possible in the general case of an inner product space:

(i) there is no self-polar norm on $E,(.,.)$, (cf. Ref. 4, Example III.3.2).
(ii) there is exactly one self-polar norm on $E,(.,.)$, (cf. Ref. 10, and references cited there).
(iii) there is a whole family of self-polar norms defining nonequivalent topologies on E, (such a family of self-polar norms was explicitely constructed by Araki in Ref. 1).

If (iii) applies to some inner product space $E,(.,.)$, it is of interest to have a complete classification of all self-polar norms as well as Hilbertian self-polar norms on $E,(.,.)$. Along these lines, the present paper is aimed at such a classification in the easiest instance of an indefinite inner

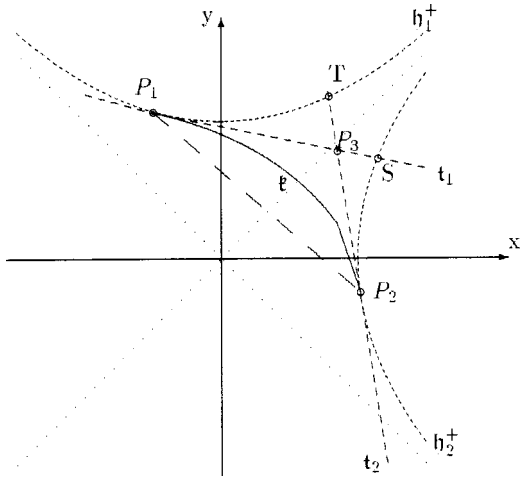

FIG. 1. Steps I and II of the construction.

product space, namely, the real Minkowski space $\mathcal{M}^2$ of dimension 2. Let us mention that a special example of such a self-polar norm on $\mathcal{M}^2$, which is different from the well-known Euclidean norm, is given in Ref. 6, Example 2.9. Furthermore, the self-polar and Hilbertian self-polar norms on $\mathcal{M}^2$ are also of some interest, since they serve as building blocks for the construction of self-polar and Hilbertian self-polar norms, respectively, on inner product spaces of higher dimensions, including the case of infinitely many dimensions, where those norms define nonequivalent locally convex topologies (see Ref. 10, Sec. 6.2).

In order to obtain such a classification, we give a general construction which explicitly yields all self-polar and Hilbertian self-polar norms, respectively, on $\mathcal{M}^2$. It turns out that in contrast to the positive definite case, where exactly one Hilbertian self-polar norm exists, on $\mathcal{M}^2$ there are as well nondenumerably many self-polar as nondenumerably many Hilbertian self-polar norms.

Remembering that on the one hand the unit ball $U_p=\{a\in\mathcal{M}^2;\, p(a)\leqslant 1\}$ of some norm p is a symmetric, convex, compact set containing the origin O as an inner point, and on the other hand, p is the gauge of U_p, we have a one-to-one correspondence between the norms p and the convex curves $\partial U_p=\{a\in\mathcal{M}^2;\, p(a)=1\}$ (see Lemma 4.1 for more details). The idea of our construction is to construct those curves ∂U_p for which the norm p is self-polar and Hilbertian self-polar, respectively.

In all what follows let a connected piece of the boundary of some convex, compact set containing O as an inner point be denoted as *convex arc*. Roughly speaking, we show that every convex arc $\mathfrak{k}$, which connects the two halfs of hyperbolae

$$\mathfrak{h}_1^+=\{\vec{a}=(x_a,y_a)\in\mathcal{M}^2;\;\; x_a^2-y_a^2=-1, y_a>0\}\,,$$

$$\mathfrak{h}_2^+=\{\vec{a}=(x_a,y_a)\in\mathcal{M}^2;\;\; x_a^2-y_a^2=-1, x_a>0\}$$

from some point $P_1\in\mathfrak{h}_1^+$ to a point $P_2\in\mathfrak{h}_2^+$ and lies completely between them (see Fig. 1), extends to a convex curve ∂U_p related to some self-polar norm p (see Theorem 4.11). On the other hand, we show that every convex curve ∂U_q related to a given self-polar norm q on $\mathcal{M}^2$ is obtained by that construction (see Theorem 4.13).

Let us mention that the well-known Aronszajn–Schatten construction of self-polar norms (Ref. 2 and Ref. 4, Chap. IV.4) is completely different from our construction, because our construction completes some convex arc $\mathfrak{k}$ to the boundary of the unit ball of a self-polar norm, while

the Aronszajn–Schatten construction starts with some norm q satisfying $q' \leqslant q$ (q' denotes the polar norm of q) and then constructs a self-polar norm q_∞ by an iteration process.

The pattern of the present paper is as follows. While the three steps I, II, III of the construction of ∂U_p of some self-polar norm p is described in Sec. II, Sec. III is aimed at the determination of this construction. More precisely, the possible choices of $P_j \in \mathfrak{h}_j^+$, $j=1,2$, are characterized in Lemma 3.1, and then all the possible constructions of Sec. II are parametrized in Corollary 3.3. Our main results are contained in Sec. IV. While Theorem 4.11 shows that self-polar norms are obtained by our construction, Theorem 4.13 proves that every self-polar norm on $\mathcal{M}^2$ is given by our construction. Using those results, a complete classification of all self-polar norms on $\mathcal{M}^2$ is contained in Corollary 4.14. In Sec. V, the above results on self-polar norms are applied to the interesting case of Hilbertian self-polar norms. Along these lines all self-polar Hilbertian norms are explicitely given in Proposition 5.2, and those constructions of Sec. II, which yield Hilbertian self-polar norms, are characterized in Corollary 5.6. Let us mention that some ideas of the present paper are taken from Ref. 11.

II. THE CONSTRUCTION

In the present section the construction of the boundary ∂U_p of the unit ball

$$U_p = \{\vec{a} \in \mathcal{M}^2; p(\vec{a}) \leqslant 1\}$$

of some self-polar norm p on the real Minkowski space $\mathcal{M}^2$ is given. Using Cartesian (x,y)-coordinates, remember that the inner product on $\mathcal{M}^2$ is given by

$$(\vec{a},\vec{b}) = x_a x_b - y_a y_b\,,$$

where $\vec{a}=(x_a,y_b), \vec{b}=(x_b,y_b) \in \mathcal{M}^2$, $x_a, y_a, x_b, y_b \in \mathbb{R}$.

Let us consider the following four halfs of hyperbolae:

$$\mathfrak{h}_1^+ = \{\vec{a} \in \mathcal{M}^2; x_a^2 - y_a^2 = -1, y_a > 0\}, \tag{4}$$

$$\mathfrak{h}_1^- = \{\vec{a} \in \mathcal{M}^2; x_a^2 - y_a^2 = -1, y_a < 0\}, \tag{5}$$

$$\mathfrak{h}_2^+ = \{\vec{a} \in \mathcal{M}^2; x_a^2 - y_a^2 = 1, x_a > 0\}, \tag{6}$$

$$\mathfrak{h}_2^- = \{\vec{a} \in \mathcal{M}^2; x_a^2 - y_a^2 = 1, x_a < 0\}. \tag{7}$$

The construction proceeds through the following steps I–III.

Step I:

(1) Choosing an arbitrary $x_1 \in \mathbb{R}$, consider the point
$$P_1 = (x_1, \sqrt{1+x_1^2}) \in \mathfrak{h}_1^+\,.$$

(2) Consider the tangent $\mathfrak{t}_1$ on $\mathfrak{h}_1^+$ at P_1 given by
$$\mathfrak{t}_1: \quad y = \sqrt{1+x_1^2} + \frac{x_1}{\sqrt{1+x_1^2}}(x - x_1)\,. \tag{8}$$

(3) Consider the intersection point $S = \mathfrak{t}_1 \cap \mathfrak{h}_2^+$ with coordinates x_S, y_S, which are explicitly given by
$$\begin{aligned} x_S &= x_1 + \sqrt{2}\,\sqrt{1+x_1^2}\,, \\ y_S &= \sqrt{2}\,x_1 + \sqrt{1+x_1^2}\,. \end{aligned} \tag{9}$$

Step II:

(1) Choose a point $P_2 \in \mathfrak{h}_2^+$ with coordinates $P_2=(x_2,y_2)$ such that

$$\text{(i)}\quad y_2 \leqslant \sqrt{2}\, x_1 + \sqrt{1+x_1^2}\,, \tag{10}$$

$$\text{(ii)}\quad x_1 \leqslant \sqrt{2}\, y_2 + \sqrt{1+y_2^2} \tag{11}$$

are satisfied.

(2) Choose a convex arc $\mathfrak{k}$ with the properties

$$\begin{aligned} &\text{(i)} \quad \mathfrak{k} \text{ connects } P_2 \text{ with } P_1\,, \\ &\text{(ii)} \quad \mathfrak{k} \text{ does not contain any points of } \mathfrak{h}_1^+ \text{ or } \mathfrak{h}_2^+ \text{ other than } P_1 \text{and } P_2\,. \end{aligned} \tag{12}$$

(See Fig. 1.)

Remark 2.1: (a) Using polar coordinates, the above conditions (10), (11) upon P_2 are more transparently described in (30). Especially, it will be shown in Remark 3.2(b) that P_2 satisfying (10), (11) always exists.

(b) The geometric interpretation of (10), (11) is the following. Considering the tangent $\mathfrak{t}_2$ on $\mathfrak{h}_2^+$ at P_2, given by

$$\mathfrak{t}_2\colon\ \frac{x-x_2}{y-y_2} = \frac{y_2}{\sqrt{1+y_2^2}}\ , \tag{13}$$

and the intersection point $P_3=\mathfrak{t}_1 \cap \mathfrak{t}_2$, we get that (10), (11) are equivalent to the property that the triangle $\Delta(P_1P_2P_3)$ is either positively orientated or it collapses to the straight line $\overline{P_1P_2}$.

[*Proof:* Consider the intersection point $T=\mathfrak{t}_2 \cap \mathfrak{h}_1^+$ with coordinates

$$\begin{aligned} x_T &= \sqrt{2}\, y_2 + \sqrt{1+y_2^2}\,, \\ y_T &= \sqrt{2}\, \sqrt{1+y_2^2} + y_2\,. \end{aligned} \tag{14}$$

Notice that the triangle $\Delta(P_1P_2P_3)$ is positively orientated or it collapses to the straight line $\overline{P_1P_2}$ if and only if

$$y_2 \leqslant y_S\,, \tag{15}$$

$$x_1 \leqslant x_T\,, \tag{16}$$

are satisfied. Inserting (9) and (14) in (15) and (16), respectively, the proof is completed.] □

(c) Considering the triangle $\Delta(P_1P_2P_3)$ given above, we get that a convex arc $\mathfrak{k}$ connecting P_2 with P_1 satisfies (12) if and only if $\mathfrak{k}$ is inside or at the boundary of $\Delta(P_1P_2P_3)$. Hence, such an arc $\mathfrak{k}$ always exists by Remark 2.1(b).

Step III: Introducing polar coordinates $r=\sqrt{x^2+y^2}$, $\varphi=\arctan(y/x)$ on $\mathcal{M}^2$, let the convex arc $\mathfrak{k}$ be given by the function

$$\varphi \to r_{\mathfrak{k}}(\varphi) \quad \text{with} \quad \varphi_2 \leqslant \varphi \leqslant \varphi_1\,,$$

where $\varphi_j=\arctan(y_j/x_j)$ denote the polar angles of P_j, $j=1,2$. Then,

$$r(\varphi)=\begin{cases} r_{\mathfrak{k}}(\varphi) \quad \text{for } \varphi_2 \leqslant \varphi \leqslant \varphi_1\,, \\ \left(\sup\limits_{\varphi_2 \leqslant \psi \leqslant \varphi_1} r_{\mathfrak{k}}(\psi)\cos(\psi+\varphi-\pi)\right)^{-1} \quad \text{for } \varphi_1 < \varphi \leqslant \varphi_2+\pi, \\ r_{\mathfrak{k}}(\varphi+\pi) \quad \text{for } \varphi_2+\pi < \varphi \leqslant \varphi_1+\pi, \\ \left(\sup\limits_{\varphi_2 \leqslant \psi \leqslant \varphi_1} r_{\mathfrak{k}}(\psi)\cos(\psi+\varphi)\right)^{-1} \quad \text{for } \varphi_1+\pi < \varphi < \varphi_2+2\pi \end{cases} \tag{17}$$

describes the boundary ∂U_p of the unit ball U_p of some self-polar norm p on $\mathcal{M}^2$.

While the proof that $\varphi \to r(\varphi)$ given in (17) describes the boundary of the unit ball of some norm p [which especially implies that $\varphi \to r(\varphi)$ is continuous at $\varphi_1, \varphi_2, \varphi_1+\pi, \varphi_2+\pi$] will be given in Lemmas 4.1a and 4.2, the self-polarity of p will be shown in Theorem 4.11.

The suprema used in (17) are considered next.

Lemma 2.2: (a) The suprema considered in (17) are positive.

(b) The following relations hold:

$$r(\varphi) = \inf_{\substack{\varphi_2 \leqslant \psi \leqslant \varphi_1, \\ \pi/2 < \psi+\varphi < 3/2\,\pi}} (r_{\mathfrak{k}}(\psi)\cos(\psi+\varphi-\pi))^{-1}$$

$$\text{for} \quad \varphi_1 < \varphi \leqslant \varphi_2 + \pi, \tag{18}$$

$$r(\varphi) = \inf_{\substack{\varphi_2 \leqslant \psi \leqslant \varphi_1, \\ 3/2\,\pi < \psi+\varphi < 5/2\,\pi}} (r_{\mathfrak{k}}(\psi)\cos(\psi+\varphi))^{-1}$$

$$\text{for} \quad \varphi_1 + \pi < \varphi \leqslant \varphi_2 + 2\,\pi. \tag{19}$$

Proof: (a) Let us consider the first sup in (17):

$$\left(\sup_{\varphi_2 \leqslant \psi \leqslant \varphi_1} r_{\mathfrak{k}}(\psi)\cos(\psi+\varphi-\pi) \right)^{-1} \quad \text{for} \quad \varphi_1 < \varphi \leqslant \varphi_2 + \pi\,. \tag{20}$$

For proving that this sup is positive, it is enough to show that for each $\varphi \in (\varphi_1, \varphi_2+\pi]$ there is a $\psi_0 \in [\varphi_2, \varphi_1]$ such that

$$\frac{\pi}{2} < \psi_0 + \varphi < \frac{3}{2}\,\pi \tag{21}$$

are satified, since then $\cos(\psi_0+\varphi-\pi) > 0$ follows. Notice first that

$$-\frac{\pi}{4} < \varphi_2 < \frac{\pi}{4}, \quad \frac{\pi}{4} < \varphi_1 < \frac{3}{4}\,\pi$$

by construction. We consider now two cases. (i) If $\varphi \in (\varphi_1, \varphi_2 + (\pi/2)]$, then choose $\psi_0 = \varphi_1$. (21) now follows from $\psi_0 + \varphi = \varphi_1 + \varphi$ and

$$\frac{\pi}{2} < 2\varphi_1 < \varphi_1 + \varphi \leqslant \varphi_1 + \varphi_2 + \frac{\pi}{2} < \frac{\pi}{4} + \frac{3}{4}\,\pi + \frac{\pi}{2} = \frac{3}{2}\,\pi\,.$$

(ii) If $\varphi \in (\varphi_2 + (\pi/2), \varphi_2 + \pi]$, then choose $\psi_0 = \varphi_2$. (21) then follows from $\psi_0 + \varphi = \varphi_2 + \varphi$ and

$$0 < 2\varphi_2 + \frac{\pi}{2} < \varphi_2 + \varphi < 2\varphi_2 + \pi < \frac{3}{2}\,\pi\,.$$

The proof for the second sup in (17) is analogous.

(b) Equation (18) follows from (a) and the fact that this sup is positive if and only if (21) is satisfied with $\psi_0 = \psi$ modulo 2π. If we take $\varphi' = \varphi + \pi$ in (18) then (19) follows. □

The following is aimed at a geometric intepretation of (17) which yields a construction of the curve $\varphi \to r(\varphi)$. For each $\psi \in [\varphi_2, \varphi_1]$, consider

$$\chi \to g_\psi(\chi) = (r_{\mathfrak{k}}(\psi)\cos(\psi+\chi-\pi))^{-1} \quad \text{for} \quad \frac{\pi}{2} - \psi < \chi < \frac{3}{2}\,\pi - \psi\,, \tag{22}$$

and notice that (22) describes in polar coordinates a straight line $\mathfrak{g}_\psi$ through the point

$$P_\psi \equiv ((r_{\mathfrak{k}}(\psi))^{-1}, \pi - \psi)$$

and with normal direction $\pi-\psi$ in polar coordinates [see also Remark 2.5(b)]. Let G_ψ be the half-plane which is defined by the straight line $\mathfrak{g}_\psi$ and contains O. The equation (18) readily yields the following.

Proposition 2.3: The curve $\varphi \to r(\varphi)$, $\varphi_1 < \varphi \leqslant \varphi_2 + \pi$, *given in (17) coincides with the boundary of the figure* $\cap_{\psi \in [\varphi_2, \varphi_1]} G_\psi$ *in the sector with polar angles* $\varphi_1 < \varphi \leqslant \varphi_2 + \pi$. □

Corollary 2.4: The curve $\varphi \to r(\varphi)$, $\varphi_1 < \varphi \leqslant \varphi_2 + \pi$, *given in (17) is a convex arc in* $\mathcal{M}^2$.

Proof: Due to Proposition 2.3, the curve under consideration arrises as the inner boundary of that part of the sector with polar angles beween φ_1 and $\varphi_2+\pi$ which is enveloped by the lines $\mathfrak{g}_\psi$, $\psi \in [\varphi_2, \varphi_1]$, given in (22). Consequently, the curve under consideration is a convex arc (see Ref. 7, Example 1.2.2). □

Remark 2.5: (a) Since $\varphi \to r(\varphi), \varphi_2 \leqslant \varphi < \varphi_2 + 2\pi$, given in (17) is π-periodic by construction, analogues statements to Proposition 2.3 and Corollary 2.4 apply to $\varphi \to r(\varphi)$ with $\varphi_1 + \pi < \varphi < \varphi_2 + 2\pi$, too.

(b) We confirm for all what follows that the normal direction of a straight line $\mathfrak{g}$ not containing O points into the half plane which is defined by $\mathfrak{g}$ and does not contain O.

III. DETERMINATION OF THE CONSTRUCTION

The aim of the present section is to describe all possible choices of the ingredients of the construction given in Sec. II, and then to parametrize all the constructions in Corollary 3.3.

For later use, let us describe the geometric objects considered in Sec. II in polar coordinates (see Fig. 1).

(1) The hyperbolae,

$$\mathfrak{h}_1^+ : \; r_{\mathfrak{h}_1^+}(\varphi) = (\sqrt{|\cos 2\varphi|})^{-1} \quad \text{for } \frac{\pi}{4} < \varphi < \frac{3\pi}{4}; \tag{23}$$

$$\mathfrak{h}_2^+ : \; r_{\mathfrak{h}_2^+}(\varphi) = (\sqrt{\cos 2\varphi})^{-1} \quad \text{for } -\frac{\pi}{4} < \varphi < \frac{\pi}{4}. \tag{24}$$

(2) The points,

$$P_1 : \; (r_1, \varphi_1) \quad \text{with } \; r_1 = r_{\mathfrak{k}}(\varphi_1) = (\sqrt{|\cos 2\varphi_1|})^{-1}; \tag{25}$$

$$P_2 : \; (r_2, \varphi_2) \quad \text{with } \; r_2 = r_{\mathfrak{k}}(\varphi_2) = (\sqrt{\cos 2\varphi_2})^{-1}. \tag{26}$$

(3) The tangents $\mathfrak{t}_j$ on $\mathfrak{h}_j^+$ at P_j, $j=1,2$,

$$\mathfrak{t}_1 : \; r_{\mathfrak{t},1}(\varphi) = (r_1 \cos(\pi - \varphi_1 - \varphi))^{-1} \quad \text{for } \frac{\pi}{2} - \varphi_1 < \varphi < \frac{3}{2}\pi - \varphi_1, \tag{27}$$

$$\mathfrak{t}_2 : \; r_{\mathfrak{t},2}(\varphi) = (r_2 \cos(\varphi_2 + \varphi))^{-1} \quad \text{for } -\frac{\pi}{2} - \varphi_2 < \varphi < \frac{\pi}{2} - \varphi_2. \tag{28}$$

Let us also consider the half-lines $\mathfrak{s}_j = \{\lambda \vec{OP}_j ; \; \lambda > 0\}$, $j=1,2$, and the intersection points

$$Q_1 = \mathfrak{s}_1 \cap \mathfrak{t}_2 \quad \text{and} \quad Q_2 = \mathfrak{s}_2 \cap \mathfrak{t}_1 . \tag{29}$$

The possible choices of the points P_j, $j=1,2$, considered in Sec. II, steps I, II, are characterized next.

Lemma 3.1: Let the Cartesian and polar coordinates of P_j, $j=1,2$, be given by

$$P_j \equiv (x_j, y_j) \equiv (r_j, \varphi_j),$$

respectively. Then the following are equivalent.

(i) *The Cartesian coordinates of P_j, $j=1,2$, satisfy the inequalities (10) and (11).*

(ii) *The triangle $\Delta(P_1P_2P_3)$ [see Remark 2.1(b)] is either positively orientated or it collapses to the straight line $\overline{P_1P_2}$.*

(iii) *The following two properties hold:*
(α) either the origin O and P_1 are in the same half-plane relative to the tangent $\mathfrak{t}_2$ or $P_1 \in \mathfrak{t}_2$;
(β) either the origin O and P_2 are in the same half-plane relative to the tangent $\mathfrak{t}_1$ or $P_2 \in \mathfrak{t}_1$.

(iv) *The following two properties hold:*
(α) if Q_1 exists, then $|\overline{OP_1}| \leqslant |\overline{OQ_1}|$; (e.g., here $|\overline{OP_1}|$ denotes the Euclidean length of the straight line segment $\overline{OP_1}$);
(β) if Q_2 exists, then $|\overline{OP_2}| \leqslant |\overline{OQ_2}|$;

(v) *The polar angles φ_j of P_j satisfy*

$$\cos^2(\varphi_1+\varphi_2) \leqslant |\cos(2\varphi_1)| \cos(2\varphi_2), \tag{30}$$

where

$$-\frac{\pi}{4} < \varphi_2 < \frac{\pi}{4}, \quad \frac{\pi}{4} < \varphi_1 < \frac{3}{4}\pi.$$

Proof: (i)$\Leftrightarrow$(ii) The proof is given in Remark 2.1(b). (ii)$\Leftrightarrow$(iii) is obvious. (iii)$\Leftrightarrow$(iv), First we prove the following:

$$Q_1 = \mathfrak{s}_1 \cap \mathfrak{t}_2 \quad \text{exists if and only if} \quad \varphi_1+\varphi_2 < \frac{\pi}{2}, \tag{31}$$

$$Q_2 = \mathfrak{s}_2 \cap \mathfrak{t}_1 \quad \text{exists if and only if} \quad \varphi_1+\varphi_2 > \frac{\pi}{2}. \tag{32}$$

Noticing that the normal direction of the tangent $\mathfrak{t}_2$ is $-\varphi_2$ by (28) [see also Remark 2.5(b)], we get that Q_1 exists if and only if $(\pi/2)-\varphi_2 > \varphi_1$, and so (31) applies. The proof of (32) is analogous.

In view of (31) and (32), we consider the following three cases separately.

Case 1: Let $\varphi_1+\varphi_2 < (\pi/2)$. Note first that if Q_1 (respectively, Q_2) does not exist, then (iii)(α) [respectively, (iii)(β)] is satisfied. In the case under consideration we have that Q_1 exists, and Q_2 does not exist. Hence, both (iii)(β) and (iv)(β) hold. Furthermore, (iii)(α) is obviously satisfied if and only if $|\overline{OP_1}| \leqslant |\overline{OQ_1}|$, i.e., (iv)($\alpha$) holds.

Case 2: Let $\varphi_1+\varphi_2 > (\pi/2)$. The proof is analogous to case 1.

Case 3: Let $\varphi_1+\varphi_2 = (\pi/2)$. Now, neither Q_1 nor Q_2 exist by (31), (32). Consequently (iii)(α),(β) and (iv)(α),(β) are satisfied.

(iv)$\Leftrightarrow$(v): The above three cases are again considered.

Case 1: $\varphi_1+\varphi_2 < (\pi/2)$. (28) and (31) now yield

$$|\overline{OQ_1}| = r_{\mathfrak{t},2}(\varphi_1) = \frac{1}{r_2 \cos(\varphi_1+\varphi_2)}.$$

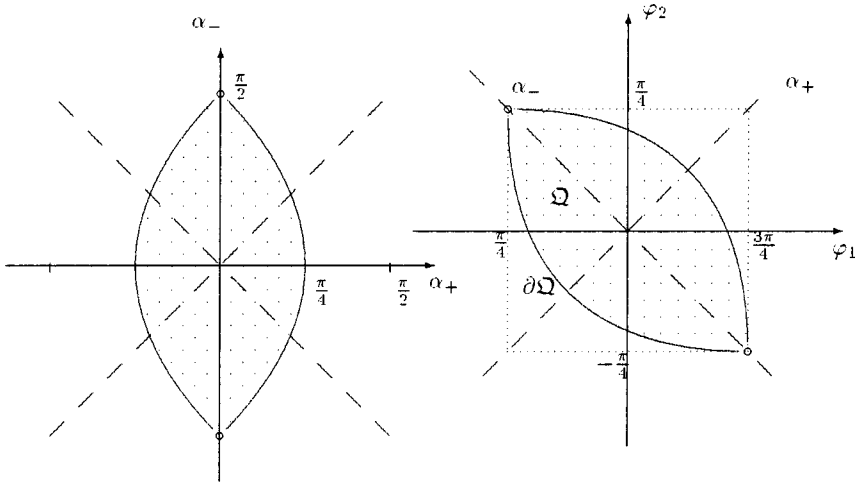

FIG. 2. The admissible values for (α_+,α_-) and (φ_1,φ_2).

Then (iv)(α) is satisfied if and only if

$$r_1 \leqslant \frac{1}{r_2 \cos(\varphi_1+\varphi_2)}. \tag{33}$$

Inserting (25), (26) in (33), we get that (iv) holds if and only if (30) is satisfied.

Case 2: $\varphi_1+\varphi_2>(\pi/2)$. The proof is analogous to case 1.

Case 3: $\varphi_1+\varphi_2=(\pi/2)$. Because (30) as well as (iv) are obviously satisfied, the proof is completed. □

Motivated by (30), let us put

$$\Omega=\left\{(\varphi_1,\varphi_2);\ \frac{\pi}{4}<\varphi_1<\frac{3\pi}{4},-\frac{\pi}{4}<\varphi_2<\frac{\pi}{4},\cos^2(\varphi_1+\varphi_2)<|\cos(2\varphi_1)|\cos(2\varphi_2)\right\}, \tag{34}$$

$$\partial\Omega=\left\{(\varphi_1,\varphi_2);\ \frac{\pi}{4}<\varphi_1<\frac{3\pi}{4},-\frac{\pi}{4}<\varphi_2<\frac{\pi}{4},\cos^2(\varphi_1+\varphi_2)=|\cos(2\varphi_1)|\cos(2\varphi_2)\right\}, \tag{35}$$

see Fig. 2.

Remark 3.2: (a) Introducing new variables

$$\alpha_\pm=\varphi_2\pm\left(\varphi_1-\frac{\pi}{2}\right),$$

we get $\cos^2(\varphi_1+\varphi_2)=\sin^2(\alpha_+)$ and

$$\begin{aligned}|\cos(2\varphi_1)|\cos(2\varphi_2)&=(\cos\alpha_+\cos\alpha_-)^2-(\sin\alpha_+\sin\alpha_-)^2\\&=-1+\cos^2\alpha_++\cos^2\alpha_-\\&=\cos^2\alpha_--\sin^2\alpha_+.\end{aligned}$$

Inserting the above in (30), we obtain

$$\sin^2(\alpha_+)\leqslant\tfrac{1}{2}\cos^2(\alpha_-).$$

Hence the polar angles φ_j of P_j, $j=1,2$, satisfy (30) if and only if (φ_1,φ_2) belongs to the shaded area given in Fig. 2. Especially, it is now obvious that for each $\pi/4<\varphi_1<3\pi/4$, there is some $-\pi/4<\varphi_2<\pi/4$ such that (30) holds.

(b) A slight modification of the above proof yields the following refinement of Lemma 3.1, (ii)$\Leftrightarrow$(v):

(α) the triangle $\Delta(P_1,P_2,P_3)$ is positively orientated if and only if

$$(\varphi_1,\varphi_2)\in\mathfrak{Q};$$

(β) the triangle $\Delta(P_1,P_2,P_3)$ collapses to the straight line $\overline{P_1P_2}$ if and only if $(\varphi_1,\varphi_2)\in\partial\mathfrak{Q}$.

A parametrization of all the constructions of self-polar norms given in Sec. II is given next.

Corollary 3.3: Let $\mathcal{Z}$ denote the set of all convex arcs connecting A_1 with A_2, and lying inside or at the border of the triangle $\Delta(A_1A_2A_3)$, where $A_1=(0,1),A_2=(1,0),A_3=(1,1)$ in Cartesian coordinates, we have a bijection from

$$\mathfrak{P}=(\mathfrak{Q}\times\mathcal{Z})\cup\partial\mathfrak{Q}\quad(\cup\ \textit{denotes disjoint union})$$

onto the set of (self-polar) norms constructed in Sec. II.

Proof: Using Lemma 3.1, (i)$\Leftrightarrow$(v), and (34), (35), the ingredients $\{P_1,P_2,\mathfrak{k}\}$ of our construction given in Sec. II are determined by a pair $(\varphi_1,\varphi_2)\in\mathfrak{Q}\cup\partial\mathfrak{Q}$ and a convex arc $\mathfrak{k}$ satisfying the requirements of step II of our construction. Assume first that $(\varphi_1,\varphi_2)\in\mathfrak{Q}$. For each $(\varphi_1,\varphi_2)\in\mathfrak{Q}$ let us now introduce an affine mapping $\Xi_{(\varphi_1,\varphi_2)}:\mathbb{R}^2\to\mathbb{R}^2$ defined by

$$\Xi_{(\varphi_1,\varphi_2)}(P_j)=A_j,\quad j=1,2,3, \tag{36}$$

and notice that $\Xi_{(\varphi_1,\varphi_2)}$ is regular (i.e., one-to-one) since P_1,P_2,P_3 are affinely independent by Remark 3.2(b), (α). Note then that a convex arc $\mathfrak{k}$ satisfies the requirements of step II [see Remark 2.1(c)] if and only if $\Xi_{(\varphi_1,\varphi_2)}(\mathfrak{k})\in\mathcal{Z}$ due to elementary geometric properties of affine mappings (Ref. 5. Kap. E2). Otherwise, if $(\varphi_1,\varphi_2)\in\partial\mathfrak{Q}$ then the triangle $\Delta(P_1P_2P_3)$ collapses to the straight line P_1P_2 [see Remark 3.2 (b), (β)], and consequently, we get $\mathfrak{k}=P_1P_2$. Finally, because on the one hand a unit ball U_p uniquely defines the ingredients $(P_1,P_2,\mathfrak{k})$ of our constuction by $P_j=\partial U_p\cap\mathfrak{h}_j$, $j=1,2$, and $\mathfrak{k}$ is that part of ∂U_p which connects P_2 with P_1, and on the other hand, equal choices of the ingredients give the same norm by (17), the map from $\mathfrak{P}$ onto the set of norms constructed in (17) is a bijection. □

IV. PROOF OF THE CONSTRUCTION

The aim of the present section is to show that $\varphi\to r(\varphi)$, $\varphi_2\leqslant\varphi<\varphi_2+2\pi$, given in (17) describes the boundary ∂U_p of some self-polar norm p on $\mathcal{M}^2$. The proof is based on the following five Lemmata 4.1, 4.2, 4.5, 4.9, 4.10. While Lemmata 4.1, 4.2 are concerned with general properties of a norm p, its polar norm p' will be considered in Lemmata 4.5, 4.9, 4.10.

Throughout the present section let us use polar coordinates (r,φ) on $\mathcal{M}^2$.

While (a) of the following lemma characterizes those functions $\varphi\to r(\varphi)$ which describe the boundary ∂U_p of some norm p, part (b) gives a relation between a norm p and the function $\varphi\to r_p(\varphi)$ which describes ∂U_p in polar coordinates.

Lemma 4.1: (a) A function $\varphi\to r_p(\varphi)$, $\varphi_0\leqslant\varphi<\varphi_0+2\pi$, with some $\varphi_0\in\mathbb{R}$ describes the boundary $\partial U_p=\{\vec{a}\in\mathcal{M}^2;\ p(\vec{a})=1\}$ of a norm p on $\mathcal{M}^2$ if and only if

(i) $\varphi\to r_p(\varphi)$, $\varphi_0\leqslant\varphi<\varphi_0+2\pi$, with some $\varphi_0\in\mathbb{R}$ describes the outer boundary of a convex figure in $\mathcal{M}^2$, which contains O,

(ii) r_p is π-periodic, i.e.,

$$r_p(\varphi_0+\varphi+\pi)=r_p(\varphi_0+\varphi)\quad\text{for}\ \varphi_0\leqslant\varphi<\varphi_0+\pi.$$

(iii) There are reals c_j *with* $0<c_j<\infty$, $j=1,2$, *such that*

$$c_1 \leqslant r_p(\varphi) \leqslant c_2$$

for $\varphi_0 \leqslant \varphi < \varphi_0 + 2\pi$.

(b) If $\varphi \to r_p(\varphi)$, $0 \leqslant \varphi < 2\pi$, *describes the boundary* ∂U_p *of some norm* p *on* $\mathcal{M}^2$, *then for* $\vec{a}=(x_a, y_a) \in \mathcal{M}^2$, $a_x = \varrho \cos\varphi$, $a_y = \varrho \sin\varphi$, *we have*

$$p(\vec{a}) = \frac{\varrho}{r_p(\varphi)}. \tag{37}$$

Proof: The above assertions are immedeate consequences of the defining properties of a norm which yield that the unit ball $U_p = \{\vec{a} \in \mathcal{M}^2;\ \ p(\vec{a}) \leqslant 1\}$ associated with p is a symmetric, convex, compact set containing the origin O as an inner point, and vice versa, p is the gauge of U_p (e.g., see Ref. 7, C, Sec. 1.2), (Ref. 12, Sec. 14.1). □

Under the situation of Lemma 4.1, let the π-periodic extension of the above r_p also be denoted by the same symbol r_p.

Lemma 4.2: Properties (i), (ii), (iii) of the above Lemma 4.1 are satisfied by $\varphi \to r(\varphi)$, $\varphi_2 \leqslant \varphi < \varphi_2 + 2\pi$, *given in (17).*

Proof: Setting $\varphi_0 = \varphi_2$ in Lemma 4.1(a), property (ii) is obviously satisfied by the construction given in (17).

For verifying (i), let us consider the curve $\mathfrak{l}$ defined by

$$\mathfrak{l}: \quad \varphi \to r_{\mathfrak{l}}(\varphi) = \inf_{\substack{\varphi_2 \leqslant \psi \leqslant \varphi_1 \\ \pi/2 < \psi + \varphi < 3/2\,\pi}} (r_{\mathfrak{k}}(\psi)\cos(\psi + \varphi - \pi))^{-1}, \quad \varphi_1 \leqslant \varphi \leqslant \varphi_2 + \pi. \tag{38}$$

Due to Corollary 2.4, $\mathfrak{l}$ is a convex arc. Noticing now that both curves $\mathfrak{k}$ and $\mathfrak{l}$ are continuous due to their convexity, it is enough to show the following (1) and (2) for verifying that $\mathfrak{k}$ and $\mathfrak{l}$ "glue" together to one convex arc $\mathfrak{k} \cup \mathfrak{l}$:

(1) $\mathfrak{k} \cup \mathfrak{l}$ is continuous at φ_1, i.e.,

$$\inf_{\substack{\varphi_2 \leqslant \psi \leqslant \varphi_1 \\ \pi/2 < \psi + \varphi_1 < 3/2\,\pi}} (r_{\mathfrak{k}}(\psi)\cos(\psi + \varphi_1 - \pi))^{-1} = r_{\mathfrak{k}}(\varphi_1), \tag{39}$$

(2) the tangent $\mathfrak{t}_1$ touches $\mathfrak{k} \cup \mathfrak{l}$ at P_1, and $\mathfrak{t}_1$ does not have any further points of $\mathfrak{k} \cup \mathfrak{l}$ in common, i.e.,

$$\mathfrak{t}_1 \cap (\mathfrak{k} \cup \mathfrak{l}) = P_1. \tag{40}$$

Noticing that $\pi/2 < 2\,\varphi_1 < \frac{3}{2}\pi$, we insert $\varphi = \varphi_1$ in (38) and then use (25):

$$\begin{aligned} r_{\mathfrak{l}}(\varphi_1) &= \inf_{\substack{\varphi_2 \leqslant \psi \leqslant \varphi_1 \\ \pi/2 < \varphi_1 + \psi < 3/2\,\pi}} (r_{\mathfrak{k}}(\psi)\cos(\psi + \varphi_1 - \pi))^{-1} \\ &\leqslant (r_{\mathfrak{k}}(\varphi_1)\cos(2\varphi_1 - \pi))^{-1} \\ &= (r_{\mathfrak{k}}(\varphi_1)\,|\cos(2\varphi_1)|)^{-1} = (r_{\mathfrak{k}}(\varphi_1)\,(r_1)^{-2})^{-1} = r_1. \end{aligned} \tag{41}$$

For showing the converse estimation, remember first that the tangent $\mathfrak{t}_1$ lies above arc $\mathfrak{k}$ by Remark 2.1(c), i.e.,

$$(r_1 \cos(\pi - \varphi_1 - \psi))^{-1} \geqslant r_{\mathfrak{k}}(\psi) \quad \text{for } \psi \in [\varphi_2, \varphi_1] \cap \left(\frac{\pi}{2} - \varphi_1, \frac{3}{2}\pi - \varphi_1\right)$$

by (27). Hence,

$$(r_{\mathfrak{k}}(\psi)\cos(\pi-\varphi_1-\psi))^{-1}\geqslant r_1 \quad \text{for } \psi\in[\varphi_2,\varphi_1]\cap\left(\frac{\pi}{2}-\varphi_1,\frac{3}{2}\pi-\varphi_1\right),$$

and thus

$$r_{\mathfrak{l}}(\varphi_1)=\inf_{\substack{\varphi_2\leqslant\psi\leqslant\varphi_1\\ \pi/2<\varphi+\psi<3/2\,\pi}}(r_{\mathfrak{k}}(\psi)\cos(\psi+\varphi_1-\pi))^{-1}\geqslant r_1. \tag{42}$$

(39) is now a consequence of (41), (42), and (25). Because $\mathfrak{g}_{\varphi_1}=\mathfrak{t}_1$, (40) follows from (38) and Remark 2.1(c). Hence $\mathfrak{k}\cup\mathfrak{l}$ is a convex arc.

Considering now the curve $\mathfrak{m}$ given by

$$\varphi\to r_{\mathfrak{m}}(\varphi)=\inf_{\substack{\varphi_2\leqslant\psi\leqslant\varphi_1,\\ 3/2\,\pi<\psi+\varphi<5/2\,\pi}}(r_{\mathfrak{k}}(\psi)\cos(\psi+\varphi))^{-1}$$
$$\text{for } \varphi_1+\pi<\varphi\leqslant\varphi_2+2\,\pi,$$

and arguing as above, we get that $\mathfrak{k}\cup\mathfrak{m}$ is a convex arc, too. Finally using π-periodicity of $\varphi\to r(\varphi)$, we obtain (ii).

In order to verify (iii), note first that the construction of $\mathfrak{k}$ implies that there are constants $0<d_j<\infty$, $j=1,2$, such that

$$d_1<r_{\mathfrak{k}}(\varphi)<d_2 \quad \text{for } \varphi\in[\varphi_2,\varphi_1]$$

[see Remark 2.1(c)]. Because the convex arc $\mathfrak{l}$ connects the points P_1 and

$$P_4\equiv(r_2,\varphi_2+\pi),$$

it is obvious that the straight line through P_1,P_3 does not contain the origin O, and the triangle $\Delta(P_1,P_3,0)$ is positively orientated. For the distance $0<d_3<\infty$ of O to the straight line through P_1,P_3, the convexity of $\mathfrak{l}$ yields

$$r(\varphi)>d_3 \quad \text{for } \varphi\in[\varphi_1,\varphi_2+\pi].$$

The continuity of $\mathfrak{l}$ then implies that there is a $0<d_4<\infty$ with

$$r(\varphi)<d_4 \quad \text{for } \varphi\in[\varphi_1,\varphi_2+\pi].$$

Again using (i), we finally obtain

$$c_1<r(\varphi)<c_2 \quad \text{for } \varphi\in[\varphi_2,\varphi_2+2\pi],$$

where $0<c_1=\min\{d_1,d_3\}<\infty$, $0<c_2=\max\{d_2,d_4\}<\infty$. □

The polar norm

$$p'(\vec{a})=\sup_{0\neq\vec{b}\in\mathcal{M}^2}\frac{|x_a x_b-y_a y_b|}{p(\vec{b})} \tag{43}$$

of some norm p on $\mathcal{M}^2$ is considered next, where $\vec{a}=(x_a,y_a)$, $\vec{b}=(x_b,y_b)$.

Definition 4.3: Let $\varphi\to r_p(\varphi)$, $0\leqslant\varphi<2\pi$, describe the boundary ∂U_p of the unit ball of some norm p on $\mathcal{M}^2$. Then let us consider $\varphi\to r_p^*(\varphi)$, $0\leqslant\varphi<2\pi$, where

$$r_p^*(\varphi)=\left(\sup_{0\leqslant\vartheta<2\pi}r_p(\vartheta)\cos(\vartheta-\varphi)\right)^{-1}. \tag{44}$$

Remark 4.4: Using π-periodicity of r_p and $\cos(\vartheta-\varphi\pm\pi)=-\cos(\vartheta-\varphi)$, we get

$$r_p^*(\varphi)=\left(\sup_{0\leqslant\vartheta<2\pi} r_p(\vartheta)\,|\cos(\vartheta-\varphi)|\right)^{-1}=\left(\sup_{\vartheta\in} r_p(\vartheta)\,|\cos(\vartheta-\varphi)|\right)^{-1}. \tag{45}$$

Lemma 4.5: For every norm p on $\mathcal{M}^2$, the boundary

$$\partial U_{p'}=\{\vec{a}\in\mathcal{M}^2;\ \ p'(\vec{a})=1\}$$

of the unit ball of its polar norm p' is given by $\varphi\to r_{p'}(\varphi)$, $0\leqslant\varphi<2\pi$, where

$$r_{p'}(\varphi)=r_p^*(-\varphi)\,. \tag{46}$$

Proof: For $\vec{a}=(x_a,y_a)=(\varrho\cos\varphi,\varrho\sin\varphi$, $\vec{b}=(x_b,y_b)=(\sigma\cos\psi,\sigma\sin\psi)$, Eqs. (37), (43), (45) imply

$$\begin{aligned}\frac{\varrho}{r_{p'}(\varphi)}&=p'(\vec{a})\\&=\sup_{\substack{\sigma>0\\0\leqslant\psi<2\pi}}\frac{\varrho\,\sigma|\cos\varphi\cos\psi-\sin\varphi\sin\psi|}{\dfrac{\sigma}{r_p(\psi)}}\\&=\varrho\sup_{0\leqslant\psi<2\pi}\{r_p(\psi)\,|\cos(\varphi+\psi)|\}\\&=\frac{\varrho}{r_p^*(-\varphi)},\end{aligned}$$

and consequently, $r_{p'}(\varphi)=r_p^*(-\varphi)$. □

Remark 4.6: (a) Since p' is a norm on $\mathcal{M}^2$ (e.g., see Ref. 4, Chap. III.4), (46) implies that properties (i), (ii), (iii) of Lemma 4.1(a) are satisfied by $\varphi\to r_p^*(\varphi)$, too.

(b) For a construction of the polar norm in case of Euclidean metric, the reader is referred to Ref. 7, C, Sec. 3.2.

In order to get relations between r_p and r_p^*, we need the following prerequisites. Remembering the following properties of a convex curve $\varphi\to r(\varphi)$, $0\leqslant\varphi<2\pi$:

(i) $\varphi\to r(\varphi)$ is continuous for $\varphi\in[0,2\pi)$, and

$$\lim_{\varphi\to 2\pi-0} r(\varphi)=\lim_{\varphi\to+0} r(\varphi)=r(0)\,.$$

(ii) The left and right derivative,

$$(\partial^{\pm}r)(\varphi_0)=\lim_{h\to\pm 0}\frac{r(\varphi_0+h)-r(\varphi_0)}{h} \tag{47}$$

exits for each $\varphi_0\in[0,2\pi)$.

(iii) $\varphi\to r(\varphi)$ is everywhere differentiable (i.e., $\partial^+=\partial^-$) exept on a countable set of points.

Let us introduce the notion of a support line, its normal direction, extremal support lines, and functions assigning the normal directions of all the support lines and of the extremal support lines, respectively, at a given point.

Definition 4.7: Let ∂U_p: $\varphi\to r_p(\varphi)$, $0\leqslant\varphi<2\pi$, be a convex curve satisfying (i), (ii), (iii) of Lemma 4.1(a).

(a) A straight line $\mathfrak{g}$ is then called support line *on $\mathfrak{g}$ at point $P_0\equiv(r(\varphi_0),\varphi_0)$ if both $P_0\in\mathfrak{g}\cap\partial U_p$ and U_p lies on one side of $\mathfrak{g}$.*

(b) The normal direction *of a support line $\mathfrak{g}$ on ∂U_p is the direction of a vector being orthogonal on $\mathfrak{g}$ and pointing into that half-plane which is defined by $\mathfrak{g}$ and does not contain the origin O.*

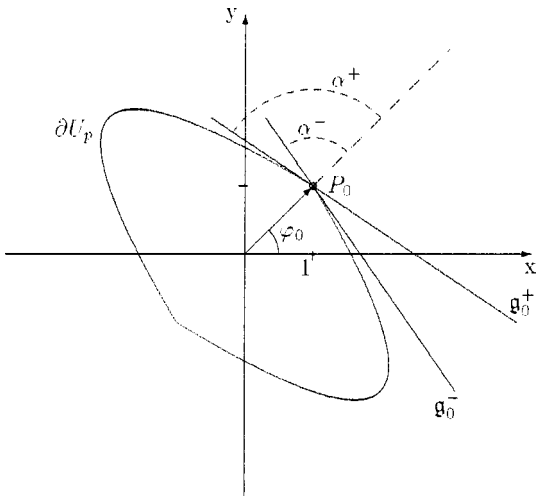

FIG. 3. The extremal support lines on ∂U_p at P_0.

(c) For every point $P_0 \in \partial U_p$, *let us consider the* extremal support lines $\mathfrak{g}_0^{\pm}$ *on* ∂U_p *at* P_0 *defined as the limits of the straight lines* $\mathfrak{s}^{\pm}$ *through the points* P_0 *and*

$$P^{\pm} \equiv (r_p(\varphi_0 \pm h), \varphi_0 \pm h)$$

as $h \to 0$.

(d) Let $\Theta_r : \mathbb{R} \to \{\text{intervals of } S^1\}$ *denote the* 2π*-periodic function which assigns to each* $\varphi_0 \in \mathbb{R}$ *the set of the normal directions of all the support lines on* ∂U_p *at* $P_0 \equiv (r_p(\varphi_0), \varphi_0)$. *(Here* S^1 *denotes the unit sphere in two dimensions.)*

(e) Let $\Phi_r^{\pm} : \mathbb{R} \to \mathbb{R}$ *be the* 2π*-periodic functions which assigns to each* $\varphi_0 \in \mathbb{R}$ *the normal directions of the extremal support lines* $\mathfrak{g}_0^{\pm}$ *[cf. (c)].*

If it is clear from the context, then let us write Θ and $\Phi^{\pm}$ instead of Θ_r and $\Phi_r^{\pm}$, respectively.

Remark 4.8: (a) Obviously, a support line exists at every point $P \equiv (r_p(\varphi), \varphi)$. (b) If $\varphi \to r_p(\varphi)$ is differentiable at $\varphi = \varphi_0$, then the tangent on ∂U_p at P_0 is the unique support line at P_0. (c) Recall that the angles $\alpha^{\pm}$ between the extremal support lines $\mathfrak{g}_0^{\pm}$ and the vector $\overrightarrow{OP}_0$ are given by

$$\tan \alpha^{\pm} = \frac{r_p(\varphi_0)}{(\partial^{\pm} r_p)(\varphi_0)}, \tag{48}$$

where $\alpha^{\pm} = \pi/2$ is confirmed if $\partial^{\pm} r_p = 0$, see Fig. 3. Since $0 \leqslant \alpha^- \leqslant \alpha^+ < \pi$, here and in the following we make the convention $0 \leqslant \arctan \varrho < \pi$, $\varrho \in \mathbb{R}$, i.e.,

$$\arctan \varrho = \begin{cases} \operatorname{Arctan} \varrho & \text{if } \varrho \geqslant 0, \\ \pi + \operatorname{Arctan} \varrho & \text{if } \varrho < 0, \end{cases} \tag{49}$$

where Arctan denotes the principal branch. The normal directions of $\mathfrak{g}_0^{\pm}$ are then given by

$$\Phi^{\pm}(\varphi_0) = \alpha^{\pm} + \varphi_0 - \frac{\pi}{2} = \left(\arctan \frac{r_p(\varphi_0)}{(\partial^{\pm} r_p)(\varphi_0)} \right) + \varphi_0 - \frac{\pi}{2}. \tag{50}$$

(d) We have $\Theta(\varphi_0) = [\Phi^-(\varphi_0), \Phi^+(\varphi_0)]$, since a straight line $\mathfrak{g}_\vartheta$ with normal direction ϑ through P_0 is a support line on ∂U_p at $P_0 \equiv (r_p(\varphi_0), \varphi_0)$ if and only if

$$\Phi^-(\varphi_0) \leqslant \vartheta \leqslant \Phi^+(\varphi_0). \tag{51}$$

The convexity of ∂U_p readily yields the following.

Lemma 4.9: Let $\varphi \to r_p(\varphi)$ describe the boundary ∂U_p of some norm p on $\mathcal{M}^2$, and $0 \leqslant \chi_1 < \chi_2 < \chi_3 < 2\pi$.

(a) For each $\vartheta \in \Theta(\chi_2)$, we have $\Phi^+(\chi_1) \leqslant \vartheta \leqslant \Phi^-(\chi_3)$.

(b) If $\Phi^+(\chi_1) < \Phi^-(\chi_2)$, then $\Theta(\chi_1) \cap \Theta(\chi_2) = \varnothing$.

(c) If $\Phi^+(\chi_1) = \Phi^-(\chi_2)$, then $\Theta(\chi_1) \cap \Theta(\chi_2) = \Phi^+(\chi_1)$.

(d) It holds $\cup_{\chi \in [0,2\pi)} \Theta(\chi) = S^1$, and

$$\bigcup_{\chi \in [\chi_1, \chi_2]} \Theta(\chi) = [\Phi^-(\chi_1), \Phi^+(\chi_2)]\,. \tag{52}$$

Proof: See Ref. 13. Theorem 24.1. □

In the following the π-periodic extensions of r_p and r_p^* are again denoted by r_p and r_p^*, respectively.

Lemma 4.10: Let $\varphi \to r_p(\varphi)$ describe the boundary ∂U_p of some norm p on $\mathcal{M}^2$. Then,

(a) for each $\varphi, \vartheta \in \mathbb{R}$, we have

$$r_p^*(\vartheta)\, r_p(\varphi)\, |\cos(\varphi - \vartheta)| \leqslant 1\,;$$

(b) the following are equivalent:

(i) the function

$$\chi \to g_\vartheta(\chi) = \frac{r_p(\varphi_0)\cos(\varphi_0 - \vartheta)}{\cos(\chi - \vartheta)}, \quad \chi \in \left(\vartheta - \frac{\pi}{2}, \vartheta + \frac{\pi}{2}\right),$$

defines a support line $\mathfrak{g}_\vartheta$ with normal direction ϑ on ∂U_p at $P_0 \equiv (r(\varphi_0), \varphi_0)$,

(ii) $\vartheta \in \Theta_r(\varphi_0)$,

(iii) $r_p^*(\vartheta)\, r_p(\varphi_0) \cos(\varphi_0 - \vartheta) = 1$,

(iv)

$$\arctan\left(\frac{r_p(\varphi_0)}{(\partial^- r_p)(\varphi_0)}\right) \leqslant \vartheta - \varphi_0 + \frac{\pi}{2} \leqslant \arctan\left(\frac{r_p(\varphi_0)}{(\partial^+ r_p)(\varphi_0)}\right);$$

(c) $r_p(\varphi) = r_p^{**}(\varphi), \varphi \in \mathbb{R}$.

Proof. (a) Using (45), we obtain the estimation under consideration from

$$r_p^*(\vartheta) r_p(\varphi)\, |\cos(\varphi - \vartheta)| = \frac{r_p(\varphi)\, |\cos(\varphi - \vartheta)|}{\sup_{\chi \in} r_p(\chi)\, |\cos(\chi - \vartheta)|} \leqslant \frac{r_p(\varphi)\, |\cos(\varphi - \vartheta)|}{r_p(\varphi)\, |\cos(\varphi - \vartheta)|} = 1\,.$$

(b) *(i)⇔(ii)* readily follows from Definition 4.7 (d).

(i)⇔(iii): Notice first that

$$\mathfrak{g}_\vartheta\colon\ \chi \to g_\vartheta = \frac{r_p(\varphi_0)\cos(\varphi_0 - \vartheta)}{\cos(\chi - \vartheta)},\ \ \chi \in \left(\vartheta - \frac{\pi}{2}, \vartheta + \frac{\pi}{2}\right),$$

is a support line on ∂U_p at $P_0 \equiv (r_p(\varphi_0), \varphi_0)$ if and only if

$$r_p(\chi) \leqslant \frac{r_p(\varphi_0)\cos(\varphi_0 - \vartheta)}{\cos(\chi - \vartheta)}, \quad \chi \in \left(\vartheta - \frac{\pi}{2}, \vartheta + \frac{\pi}{2}\right). \tag{53}$$

Using π-periodizity of r_p, (53) is equivalent to

$$r_p(\varphi)\,|\cos(\varphi-\vartheta)|\leqslant r_p(\varphi_0)\cos(\varphi_0-\vartheta)\,,\quad \varphi\in\mathbb{R}\,. \tag{54}$$

Because (54) is equivalent to

$$r_p^*(\vartheta)=(r_p(\varphi_0)\cos(\varphi_0-\vartheta))^{-1}$$

by (45), the euivalence $(i)\Leftrightarrow(iii)$ follows.

(i)⇔(iv): Considering the extemal support lines $\mathbf{t}_0^{\pm}$ on ∂U_p at P_0, and taking (49), (50) into account, we get the equivalence under consideration by (51).

(c) Let $\varphi\in\mathbb{R}$. We get

$$(r_p^{**}(\varphi))^{-1}\,r_p(\varphi)=\sup_{\vartheta\in} r_p^*(\vartheta)\cos(\varphi-\vartheta)\,r_p(\varphi)\leqslant 1 \tag{55}$$

by Definition 4.3 and Lemma 4.10(a). Furthermore, (52) yields that there is a $\vartheta_0\in\Theta(\varphi)$, and then

$$r_p^*(\vartheta_0)\cos(\varphi-\vartheta_0)\,r_p(\varphi)=1 \tag{56}$$

by Lemma 4.10(b). Now, (55) and (56) yield the assertion under consideration. □

We are now prepared to prove the first main result of this section.

Theorem 4.11: *The curve $\varphi\to r(\varphi)$, $\varphi_2\leqslant\varphi<\varphi_2+2\pi$, given in (17) describes the boundary*

$$\partial U_p=\{\vec{a}\in\mathcal{M}^2;\;\; p(\vec{a})=1\} \tag{57}$$

of some self-polar norm p on Minkowski space $\mathcal{M}^2$.

Proof: Due to Lemmas 4.1 and 4.2, there is some norm p on $\mathcal{M}^2$ such that (57) holds. For showing that p is self-polar, it is enough to verify that

$$r(\varphi)=r^*(-\varphi) \tag{58}$$

for $\varphi\in\mathbb{R}$, by Lemma 4.5. Since both r and r^* are π-periodic, it suffices to show (58) for $\varphi\in[\varphi_1-\pi,\,\varphi_2]\cup[\varphi_2,\varphi_1]$.

Case 1: Let $\varphi\in[\varphi_1-\pi,\,\varphi_2]$. Noticing that the normal directions ϑ_j of the tangents $\mathbf{t}_j$, $j=1,2$, introduced in (8) and (13) are given by

$$\vartheta_1=\pi-\varphi_1\quad\text{and}\quad\vartheta_2=-\varphi_2\,, \tag{59}$$

respectively [see (27), (28)], we get

$$-\varphi\in[\,\vartheta_2,\,\vartheta_1]\,. \tag{60}$$

Furthermore, we have $\vartheta_1\in\Theta_r(\varphi_1)$ since both (1) ϑ_1 is the normal direction of $\mathbf{t}_1$ and (2) $\mathbf{t}_1$ is a support line at φ_1 by (40) and the explanation beforehand of (40). An analogous reasoning yields $\vartheta_2\in\Theta_r(\varphi_2)$.

Because of (52) and Lemma 4.9(a), (60) implies that there is some $\psi_0\in[\varphi_2,\,\varphi_1]$ such that

$$-\varphi\in\Theta(\psi_0)\,. \tag{61}$$

Due to Lemma 4.10(b), *(ii)⇔(iii),* relation (61) yields

$$r^*(-\varphi)r(\psi_0)\cos(\varphi+\psi_0)=1. \tag{62}$$

Now,

$$
\begin{aligned}
r(\varphi) &\overset{(*)}{\leqslant} (r(\psi_0)\cos(\varphi+\psi_0))^{-1} \\
&\overset{(**)}{=} r^*(-\varphi) \\
&\overset{(***)}{=} \left(\sup_{0\leqslant\chi<2\pi}\{r(\chi)\cos(\chi+\varphi)\}\right)^{-1} \\
&\leqslant \left(\sup_{\varphi_2\leqslant\psi\leqslant\varphi_1}\{r(\psi)\cos(\psi+\varphi)\}\right)^{-1} \\
&\overset{(*)}{=} r(\varphi)
\end{aligned}
$$

verifies (58) in case 1, where (*) follows from (17), (**) from (62), and (***) from (44).

Case 2: Let $\varphi\in[\varphi_2,\varphi_1]$. (59) then implies

$$-\varphi\in[-\varphi_1,-\varphi_2]=[\vartheta_1-\pi,\vartheta_2]\,. \tag{63}$$

The same reasoning as in case 1 yields the existence of a $\tilde{\psi}_0\in[\varphi_1-\pi,\varphi_2]$ such that

$$-\varphi\in\Theta_r(\tilde{\psi}_0)\,, \tag{64}$$

and

$$r^*(-\varphi)r(\tilde{\psi}_0)\cos(\tilde{\psi}_0+\varphi)=1\,. \tag{65}$$

As for $\chi\to r^*(\chi),\chi\in\mathbb{R}$, the further proof is based on the assertion

$$\varphi\in\Theta_{r^*}(-\tilde{\psi}_0) \tag{66}$$

which will be verified at the end of the proof. Due to Lemma 4.10(b), *(ii)*⇔*(iii)*, applied to $\chi\to r^*(\chi)$, (66) yields

$$r^{**}(\varphi)r^*(-\tilde{\psi}_0)\cos(\tilde{\psi}_0+\varphi)=1\,. \tag{67}$$

Because of relations $r^{**}(\varphi)=r(\varphi)$ due to Lemma 4.10(c), and $r^*(-\tilde{\psi}_0)=r(\tilde{\psi}_0)$ already proved in case 1 above, (67) implies

$$r(\varphi)r(\tilde{\psi}_0)\cos(\tilde{\psi}_0+\varphi)=1\,.$$

The last equation and (65) now imply $r(\varphi)=r^*(-\varphi)$ in case 2.

Proof of (66): If $\tilde{\psi}_0\in(\varphi_1-\pi,\varphi_2)$, then $r(\tilde{\psi}_0)=r^*(-\tilde{\psi}_0)$ by case 1, and

$$(\partial^{\pm}r^*)(-\tilde{\psi}_0)=-(\partial^{\mp}r)(\tilde{\psi}_0) \tag{68}$$

readily follows from (47). Using (49), (50) and Remark 4.8(d), we get

$$\Theta_{r^*}(-\tilde{\psi}_0)=-\Theta_r(\tilde{\psi}_0)$$

from (68). The last equation and (64) now imply (66).

Assume now $\tilde{\psi}_0=\varphi_2$. Due to (63), (64) and $\vartheta_2\in\Theta_r(\varphi_2)$, we get

$$-\varphi\in[\vartheta_1-\pi,\vartheta_2]\cap\Theta_r(\tilde{\psi}_0)=[\vartheta_1-\pi,\vartheta_2]\cap[\Phi_r^-(\varphi_2),\Phi_r^+(\varphi_2)]=[\Phi_r^-(\varphi_2),\vartheta_2]\,.$$

Then,

$$\varphi \in [-\vartheta_2, -\Phi_r^-(\varphi_2)] = [\varphi_2, \Phi_{r*}^+(-\varphi_2)] \tag{69}$$

by (59), and $r^*(-\varphi_2) = r(\varphi_2)$ (which is a consequence of case 1) yields $\Phi_r^-(\varphi_2) = -\Phi_{r*}^+(-\varphi_2)$ by (68) and (50). Noticing that

$$r^{**}(\varphi_2) r^*(-\varphi_2) \cos 2\varphi_2 = r(\varphi_2) r^*(-\varphi_2) \cos 2\varphi_2 = 1$$

by Lemma 4.10(c), $-\varphi_2 = \vartheta_2 \in \Theta(\varphi_2)$ and Lemma 4.10(b), *(ii)⇔(iii),* we get

$$\varphi_2 \in \Theta_{r*}(-\varphi_2) = [\Phi_{r*}^-(-\varphi_2), \Phi_{r*}^+(-\varphi_2)]$$

from Lemma 4.10(b), *(ii)⇔(iii),* too. The assertion to be shown now follows from

$$\varphi \in [\varphi_2, \Phi_{r*}^+(-\varphi_2)] \subset [\Phi_{r*}^-(-\varphi_2), \Phi_{r*}^+(-\varphi_2)] = \Theta_{r*}(-\varphi_2) = \Theta_{r*}(-\tilde{\psi}_0) .$$

The final case $\tilde{\psi}_0 = \varphi_1 - \pi$ is treated analogously. The proof of Theorem IV is completed. □

The following is aimed at showing that every self-polar norm on $\mathcal{M}^2$ is obtained by our construction given in Sec. II.

Lemma 4.12: Let p be any self-polar norm on $\mathcal{M}^2$, *and* $\partial U_p = \{\vec{x} \in \mathcal{M}^2; p(\vec{x}) = 1\}$ *the boundary of the unit ball* U_p *of p. Then* ∂U_p *touches each of the four hyperbolae* $\mathfrak{h}_j^{\pm}$, $j = 1,2$, *[cf. (4)–(7)] in exactly one point. The tangents of the hyperbolae in these points are support lines on* ∂U_p.

Proof: (Uniqueness). Let $\varphi \to r_p(\varphi)$, $0 \leqslant \varphi < 2\pi$, denote the function describing ∂U_p in polar coordinates. Because the assumption $p = p'$ of the lemma under consideration implies $r_p^*(-\varphi) = r_p(\varphi)$, $0 \leqslant \varphi < 2\pi$, by (46), Lemma 4.10(a) yields

$$1 \geqslant r_p^*(-\varphi) r_p(\varphi) |\cos(2\varphi)| = (r_p(\varphi))^2 |\cos(2\varphi)| ,$$

and consequently, $(r_p(\varphi))^2 \leqslant |\cos(2\varphi)|^{-1}$ for $0 \leqslant \varphi < 2\pi$. Remembering the equations of the hyperbolae $\mathfrak{h}_j^{\pm}$, $j = 1,2$, [see (23), (24), and related equations for $\mathfrak{h}_j^-$], we obtain that the curve ∂U_p must lie between the four hyperbolae. On the other hand, ∂U_p has to be convex, and so there cannot be more than one point of intersection with each of the four hyperbolae.

Existence of intersection points: In analogy to Definition 4.7(d) let us introduce a function $\Theta_{\mathfrak{h}_2^+}: (-\pi/4, \pi/4) \to \mathbb{R}$ given by

$$\Theta_{\mathfrak{h}_2^+}(\varphi) = -\varphi , \quad \varphi \in \left(-\frac{\pi}{4}, \frac{\pi}{4} \right) , \tag{70}$$

and notice that $\Theta_{\mathfrak{h}_2^+}(\varphi_0)$ gives the normal direction of the tangent $\mathfrak{t}$ on $\mathfrak{h}_2^+$ at $P_0 \equiv ((\sqrt{\cos 2\varphi_0})^{-1}, \varphi_0)$ (in polar coordinates). Furthermore, $\varphi \to \Theta_{\mathfrak{h}_2^+}(\varphi)$ is a continuous, strictly monotone decreasing function which satisfies

$$\lim_{\varphi \to -\pi/4 + 0} \Theta_{\mathfrak{h}_2^+}(\varphi) = \frac{\pi}{4}, \tag{71}$$

$$\lim_{\varphi \to \pi/4 - 0} \Theta_{\mathfrak{h}_2^+}(\varphi) = -\frac{\pi}{4}. \tag{72}$$

Since on the one hand the unit ball U_p is a convex figure containing O as an inner point and lying between the four hyperbolae $\mathfrak{h}_j^{\pm}$, $j = 1,2$, and on the other hand, the tangents $\mathfrak{t}_\varphi$ on $\mathfrak{h}_2^+$ at $P_\varphi \equiv ((\sqrt{\cos 2\varphi_0})^{-1}, \varphi_0)$ approach the straight line $y = -x$ from above as $\varphi \to -\pi/4 + 0$ there has to be an angle $-\pi/4 < \beta < 0$ such that $\mathfrak{t}_\beta \cap U_p \neq \varnothing$ and the triangle $\Delta(OP_\beta R)$ is positively orientated for some point $R \in \mathfrak{t}_\beta \cap U_p$. Then

$$\Phi^{+}_{r_p}(\beta)\leqslant\Theta_{\mathfrak{h}^{+}_2}(\beta) \tag{73}$$

since $\Phi^{+}_{r_p}(\beta)$ is the normal direction of the extremal support line $\mathfrak{g}^{+}_{\beta}$ [see Definition 4.7(e)] on ∂U_p at β which cannot intersect the inner of the convex figure U_p. Noticing then that the tangents $\mathfrak{t}_{\varphi}$ considered above approach the straight line $y=x$ from below as $\varphi\to(\pi/4)-0$, we get analogously the existence of some angle $0<\tilde{\beta}<\pi/4$ such that

$$\Phi^{-}_{r_p}(\tilde{\beta})\geqslant\Theta_{\mathfrak{h}^{+}_2}(\tilde{\beta})\,. \tag{74}$$

Because of (52) of Lemma 4.9, the continuity of $\Theta_{\mathfrak{h}^{+}_2}$ and (73), (74) yield the existence of some $\psi_0\in[\beta,\tilde{\beta}]\subset(-\pi/4,\pi/4)$ such that

$$\Theta_{\mathfrak{h}^{+}_2}(\psi_0)\in[\Phi^{-}_{r_p}(\psi_0),\Phi^{+}_{r_p}(\psi_0)]\,. \tag{75}$$

Due to Lemma 4.10(b) [*(ii)*⇔*(iii)*], (75) and (70) with $\varphi_0=\psi_0$ imply

$$1=r^{*}_p(-\psi_0)r_p(\psi_0)\cos(2\psi_0)\overset{(*)}{=}(r_p(\psi_0))^2\cos(2\psi_0)\,, \tag{76}$$

where (*) follows from (46) and the assumption $p=p'$ of the lemma under consideration. Now, (76) and the equation of the hyberbola $\mathfrak{h}^{+}_2$ given in (24) imply

$$C\in\partial U_p\cap\mathfrak{h}^{+}_2\,,$$

where the polar coordinates of the intersection point C are given by $(r_p(\psi_0),\psi_0)$. Furthermore, Lemma 4.10(b) [*(i)*⇔*(ii)*] and (75) imply that the tangent $\mathfrak{t}$ on $\mathfrak{h}^{+}_2$ at C is a support line of ∂U_p.

The remaining three hyperbolae can be treated in the same way. □

Theorem 4.13: *For every self-polar norm p on Minkowski space $\mathcal{M}^2$, there exist ingredients $\{P_1,P_2,\mathfrak{k}\}$ of the construction given in Sec. II such that the boundary ∂U_p of the unit ball of p is obtained by (17).*

Proof: Let p denote a self-polar norm on $\mathcal{M}^2$. We consider the π-periodic function

$$\varphi\to r_p(\varphi)\,,\quad \varphi\in\mathbb{R}\,,$$

which describes ∂U_p in polar coordinates. Due to Lemma 4.12, there are four points

$$C^{\pm}_j=\partial U_p\cap\mathfrak{h}^{\pm}_j\,,\quad j=1,2\,,$$

at which ∂U_p touches the hyperbolae $\mathfrak{h}^{\pm}_j$. Set $P_j=C^{+}_j$. Let φ_j denote the polar angles of P_j, $j=1,2$. Because the tangents $\mathfrak{t}_j$ on $\mathfrak{h}^{+}_j$ at P_j, $j=1,2$, are support lines for ∂U_p by Lemma 4.12 and because ∂U_p is the outer boundary of a convex figure containing O as an inner point, $\{P_1,P_2,\mathfrak{k}\}$ satisfy the requirements of steps I, II of our construction, where $\mathfrak{k}$ is given by $\varphi\to r_p(\varphi)$, $\varphi_2\leqslant\varphi\leqslant\varphi_1$. Let now

$$\varphi\to r(\varphi)\,,\quad \varphi_2\leqslant\varphi<\varphi_2+2\pi\,,$$

denote the function given in (17). Obviously, $r_p(\varphi)=r(\varphi)$ for $\varphi_2\leqslant\varphi\leqslant\varphi_1$. Using the π-periodicity of both r and r_p, it remains to verify that $r_p(\varphi)=r(\varphi)$ for $\varphi_1\leqslant\varphi\leqslant\varphi_2+\pi$. So let $\varphi_0\in[\varphi_1,\varphi_2+\pi]$. Analogously to (60) we obtain

$$-\varphi_0\in[\vartheta_2,\vartheta_1]\,,$$

where ϑ_j denote the normal directions of the tangents $\mathfrak{t}_j$ on $\mathfrak{h}^{+}_j$ at P_j, $j=1,2$. Due to (52), there is a

$$\psi_0 \in [\varphi_2, \varphi_1] \tag{77}$$

such that $-\varphi_0 \in \Theta_r(\psi_0)$. Applying Lemma 4.10(b), $(ii) \Leftrightarrow (iii)$, to both r and r_p, we get

$$1 = r_p^*(-\varphi_0) r_p(\psi_0) \cos(\psi_0 + \varphi_0) \overset{(*)}{=} r_p(\varphi_0) r_p(\psi_0) \cos(\psi_0 + \varphi_0), \tag{78}$$

$$1 = r^*(-\varphi_0) r(\psi_0) \cos(\psi_0 + \varphi_0) \overset{(**)}{=} r(\varphi_0) r_p(\psi_0) \cos(\psi_0 + \varphi_0), \tag{79}$$

where (*) follows from $p = p'$, and (**) from the facts that $r(\varphi)$ describes the boundary ∂U of the unit ball of some self-polar norm by Theorem 4.11 and then $r_p(\psi_0) = r(\psi_0)$ by (77). Now, (78) and (79) imply $r_p(\varphi_0) = r(\varphi_0)$. □

Corollary 3.3 and Theorem 4.13 immedeately yield the following parametrization of all self-polar norms on $\mathcal{M}^2$.

Corollary 4.14: The mapping given in Corollary 3.3 is a bijection between $\mathfrak{P} = (\Omega \times \mathcal{Z}) \cup \partial\Omega$ *and the set of all self-polar norms on* $\mathcal{M}^2$. □

V. HILBERTIAN SELF-POLAR NORMS ON $\mathcal{M}^2$

The aim of the present section is to characterize those self-polar norms on $\mathcal{M}^2$ which are Hilbertian in addition. To do so, we apply the following taken from Ref. 9, Theorem 5.4.

Proposition 5.1: Let q *be a norm on an inner product space* $E, (.,.)$ *with complete Hilbertian majorant* $\tau(p)$, $p(.) = \sqrt{[.,.]}$, *and Gram operator* G, $(x,y) = [x, Gy]$, $x, y \in E$. *Then the following are equivalent:*

(i) q *is Hilbertian and self-polar,*

(ii) a symmetry S $(= S^{-1} = S^*)$ *and a bounded linear operator* B *exist on the Hilbert space* $E, [.,.]$ *such that*

(1) B *is positive on* $E, [.,.]$,

(2) $Gx = BSBx$, $x \in E$,

(3) $q(x) = p(Bx)$, $x \in E$.

In the case at hand we have $E = \mathcal{M}^2$, $[\vec{a}, \vec{b}] = x_a x_b + y_a y_b$, $(\vec{a}, \vec{b}) = x_a x_b - y_a y_b$, $p(\vec{a}) = \sqrt{x_a^2 + y_a^2}$, Gram operator $G = \left(\begin{smallmatrix} 1 & 0 \\ 0 & -1 \end{smallmatrix}\right)$, $\vec{a} = (x_a, y_a)$, $\vec{b} = (x_b, y_b)$.

Proposition 5.2: All the Hilbertian self-polar norms on $\mathcal{M}^2$ *are given by*

$$q_\alpha(\vec{a}) = \sqrt{\alpha\, \xi_+^2 + \frac{1}{\alpha} \xi_-^2}, \quad \xi_\pm = \frac{1}{\sqrt{2}} (x_a \pm y_a),$$

where $\alpha > 0$.

Proof: Consider the linear operator $A = B^2$, where B is taken from Proposition 5.1(ii), (2). Let $\vec{a}^{(j)} = (x^{(j)}, y^{(j)})$ and $\lambda^{(j)} > 0$, $j = 1,2$, be eigenvectors and eigenvalues of the positive operator A, respectively. Using $G^2 = I$ (identity operator) and $A = B^2 = BSBB^{-2}BSB = GB^{-2}G = GA^{-1}G$, we get

$$A(G\vec{a}^{(1)}) = GA^{-1}G^2\vec{a}^{(1)} = GA^{-1}\vec{a}^{(1)} = \lambda^{-1}(G\vec{a}^{(1)}).$$

Hence $G\vec{a}^{(1)}$ is an eigenvector of A, too, and so

$$\lambda^{(2)} = \frac{1}{\lambda^{(1)}}.$$

If $\lambda^{(1)} = \lambda^{(2)} = 1$, then $A = B = I$. Otherwise, $\vec{a}^{(2)} = G\vec{a}^{(1)} = (x^{(1)}, -y^{(1)})$ and the orthogonality of the eigenvectors $x^{(1)}x^{(2)} + y^{(1)}y^{(2)} = 0$ imply

$$\vec{a}^{(1)}=\frac{1}{\sqrt{2}}(1,1)\,,\quad \vec{a}^{(2)}=\frac{1}{\sqrt{2}}(1,-1)\,.$$

Hence,

$$A=\frac{1}{2}\begin{pmatrix}1 & 1\\ 1 & -1\end{pmatrix}\begin{pmatrix}\lambda^{(1)} & 0\\ 0 & (\lambda^{(1)})^{-1}\end{pmatrix}\begin{pmatrix}1 & 1\\ 1 & -1\end{pmatrix}$$

follows. The assertion to be shown now follows from Proposition 5.1 (ii), (3), and

$$\begin{aligned}(q_\alpha(\vec{a}))^2&=[B\vec{a},B\vec{a}]\\ &=\left[\frac{1}{\sqrt{2}}\begin{pmatrix}1 & 1\\ 1 & -1\end{pmatrix}\begin{pmatrix}x_a\\ y_a\end{pmatrix},\frac{1}{\sqrt{2}}\begin{pmatrix}\lambda^{(1)} & 0\\ 0 & \dfrac{1}{\lambda^{(1)}}\end{pmatrix}\begin{pmatrix}1 & 1\\ 1 & -1\end{pmatrix}\begin{pmatrix}x_a\\ y_a\end{pmatrix}\right]\\ &=\frac{\lambda^{(1)}}{2}(x_a+y_a)^2+\frac{1}{2\lambda^{(1)}}(x_a-y_a)^2=\lambda^{(1)}\xi_+^2+(\lambda^{(1)})^{-1}\xi_-^2\end{aligned}$$

with $\alpha=\lambda^{(1)}$, and $\xi_\pm=1/\sqrt{2}\,(a_x\pm a_y)$. □

Proposition 5.2 readily yields the following.

Corollary 5.3: The boundary $\partial U_{q,\alpha}=\{\vec{a}\in\mathcal{M}^2;\,q_\alpha(\vec{a})=1\}$ *of the unit ball* $U_{q,\alpha}$ *is given by the ellipse* $\mathfrak{E}_\alpha$*:*

$$\frac{\alpha^2+1}{2\alpha}(x^2+y^2)+\frac{\alpha^2-1}{\alpha}xy=1\,. \tag{80}$$

Remark 5.4: (a) The semiaxis of the ellipse $\mathfrak{E}_\alpha$ considered in (80) are given by

$$\vec{b}^{(1)}=\frac{1}{\sqrt{2\alpha}}(1,1)\,,\quad \vec{b}^{(2)}=\sqrt{\frac{\alpha}{2}}\,(1,-1)\,.$$

(b) The ellipse $\mathfrak{E}_\alpha$ is given in polar coordinates by

$$r(\varphi)=\left(\sqrt{\frac{\alpha^2+1}{2\alpha}+\frac{\alpha^2-1}{2\alpha}\sin 2\varphi}\;\right)^{-1},\quad 0\leqslant\varphi<2\pi\,. \tag{81}$$

The aim of the following is to derive a relation between the general construction given in Sec. II and $\partial U_{q,\alpha}$ described in (80), (81). More precicely, the ingredients of the general construction P_1,P_2 and $\mathfrak{k}$ will be given for the case at hand.

Lemma 5.5: We have $\mathfrak{E}_\alpha\cap\mathfrak{h}_j^\pm=Q_j^\pm$, $j=1,2$, *where the polar coordinates of the points* $Q_j^\pm$ *are given by*

$$Q_j^\pm\equiv\left(\sqrt{\frac{\alpha^2+1}{2\alpha}},\varphi_{\alpha,j}^\pm\right),$$

with $\varphi_{\alpha,2}^+=-\frac{1}{2}\arcsin(\alpha^2-1)/(\alpha^2+1)$, $\varphi_{\alpha,2}^-=\varphi_{\alpha,2}^++\pi$, $\varphi_{\alpha,1}^+=(\pi/2)-\varphi_{\alpha,2}^+$, *and* $\varphi_{\alpha,1}^-=(3\pi/2)-\varphi_{\alpha,2}^+$.

Proof: Equations (24) and (81) imply

$$\frac{\alpha^2+1}{2\alpha}+\frac{\alpha^2-1}{2\alpha}\sin 2\varphi=\cos 2\varphi\,,\quad -\frac{\pi}{4}<\varphi<\frac{\pi}{4}\,,$$

and a simple calculation yields the polar coordinates of Q_2^+:

$$\varphi^+_{\alpha,2} = -\frac{1}{2}\arcsin\frac{\alpha^2-1}{\alpha^2+1}$$

and

$$r_{\mathfrak{h}_2^+}(\varphi^+_{\alpha,2}) = \left(1-\left(\frac{\alpha^2-1}{\alpha^2+1}\right)^2\right)^{-1/4} = \sqrt{\frac{\alpha^2+1}{2\alpha}}.$$

The second half of the lemma under consideration is now obvious by symmetry. □

Since a self-polar norm on $\mathcal{M}^2$ is uniquely determined by the ingredients $\{P_1, P_2, \mathfrak{k}\}$ of our construction (see Corollary 4.14), we get the following characterization of those constructions which yield Hilbertian self-polar norms on $\mathcal{M}^2$.

Corollary 5.6: The general construction given in Sec. II with the ingredients $P_1 = Q_1^+$, $P_2 = Q_2^+$ *and the convex arc* $\mathfrak{k}$ *given in polar coordinates by*

$$\varphi \to \left(\sqrt{\frac{\alpha^2+1}{2\alpha} + \frac{\alpha^2-1}{2\alpha}\sin 2\varphi}\right)^{-1}, \quad \varphi^+_{\alpha,2} \leqslant \varphi < \varphi^+_{\alpha,1}$$

yields the curve $\partial U_{q,\alpha}$ *described in* (80), (81). □

The eigenvalue equation on the Eguchi–Hanson space

Andreas Malmendier[a)]
Department of Mathematics, Massachusetts Institute of Technology, 77 Massachusetts Avenue, Cambridge, Massachusetts 02139

(Received 14 December 2002; accepted 23 February 2003)

We consider the eigenvalue equation for the Laplace–Beltrami operator acting on scalar functions on the noncompact Eguchi–Hanson space. The corresponding differential equation is reducible to a confluent Heun equation with Ince symbol $[0,2,1_2]$. We construct approximations for the eigenfunctions and their asymptotic scattering phases with the help of the Liouville–Green approximation (WKB). Furthermore, for specific discrete eigenvalues obtained by a continued T-fraction we construct the solution by the Frobenius method and determine its scattering phase by a monodromy computation. © *2003 American Institute of Physics.*

I. INTRODUCTION

The Eguchi–Hanson metric (Eguchi and Hanson, 1979) is a self-dual, asymptotically locally Euclidean (ALE) metric on the cotangent bundle of the 2-sphere T^*S^2. Geometrically, this corresponds to a Ricci-flat metric on the smooth resolution space of an A_1-singularity—such a singularity looks like the origin of $\mathbb{C}^2/\mathbb{Z}_2$, where the $\mathbb{Z}_2$-group acts by point reflection at the origin.

Apart from Euclidean quantum gravity this metric has physical applications in string compactification. In fact, it is well known that the only nontrivial two-dimensional Calabi–Yau manifold—this is a K3-surface—can be obtained from the $\mathbb{Z}_2$-orbifold limit $\mathbb{T}^2_{\mathbb{C}}/\mathbb{Z}_2$ by blowing up its 16 A_1-singularities (where $\mathbb{T}^2_{\mathbb{C}}$ is the complex two-dimensional torus). By gluing the Eguchi–Hanson metric together with the flat torus metric one can explicitly construct an almost Ricci-flat metric on a K3-surface (Bozhkov, 1988) which is related to a Ricci-flat metric on K3 by a gauge transformation (Taubes, 1982).

In this paper we shall examine the eigenvalue equation for the Laplace–Beltrami operator on the Eguchi–Hanson space. The problem is interesting from a mathematical point of view since the differential equation is separable and reduces to an ordinary differential equation which due to its singularities can be identified as confluent Heun equation with corresponding Ince symbol $[0,2,1_2]$ (see Decarreau, Maroni, and Robert, 1978 for definitions). The Heun equation is an ordinary differential equation with four regular singularities on the punctured Riemann sphere. By coalescing two of the regular singularities to one irregular singularity one obtains the confluent Heun equation (analogously to the procedure by which one obtains the confluent hypergeometric differential equation from the hypergeometric one).

The problem is also interesting from a physical point of view since the functions that are obtained by gluing the eigenfunctions on the Eguchi–Hanson space together with the well known eigenfunctions on the flat torus describe the quantum mechanical limit of string fields on K3.

The plan of the paper is as follows: In Sec. II we introduce the ordinary differential equation that describes the radial part of the eigenvalue equation of the Laplace operator on the Eguchi–Hauson space. In Sec. III we construct its solutions and their corresponding scattering phases by the Liouville–Green approximation (WKB). This extends and corrects a result in Mignemi (1991). In Mignemi (1991) the author used the ad hoc version of the Liouville–Green approximation. This version did not give approximations for the wave functions which are valid over the whole range. Furthermore, we give error bounds for the constructed solutions and their scattering phases. The

a)Electronic mail: malmendi@mit.edu

explicit calculations can be found in the Appendix (cf. Appendices A and B). In Sec. IV we construct the exact solutions for specific discrete eigenvalues by the Frobenius method. These special values are given by the vanishing condition for a continned fraction. This approach is similar to the treatment of the generalized spheroidal wave equation in Wilson (1928) and Leaver (1986). In addition, we can determine the exact scattering phase by a monodromy computation. Finally, we will show how this information can be used to compute the asymptotic scattering phase for this discrete set of eigenvalues. In Sec. V we present the numerical results obtained by the method of Secs. III and IV and show that they match up to a high accuracy. In Sec. VI we give the conclusions of this article and a brief outlook.

II. THE EIGENVALUE EQUATION

In this section we introduce the eigenvalue equation for the Laplace–Beltrami operator of the Eguchi–Hanson space. Using the SU(2)×U(1) symmetry of the Eguchi–Hanson space this eigenvalue equation will reduce to an ordinary differential equation of second order. A complete derivation of these and similar results can be found in Gibbons and Manton (1986) and Perry (1978).

The Riemannian metric on T^*S^2 that is known as the Eguchi–Hanson metric is Hyperkähler. Moreover, a complex structure which is compatible with the Hyperkähler structure can be introduced by identifying T^*S^2 with the complex manifold $T^*\mathbb{CP}^1$. In particular, the latter can be covered by two coordinate charts $U\cong U'\cong\mathbb{C}^2$ with coordinates (u,ξ), (u',ξ'), respectively. Here, u, u' denote Euclidean coordinates on the base $\mathbb{C}P^1$, and ξ, ξ' parameterize the fiber of the bundle $T^*\mathbb{CP}^1\to\mathbb{CP}^1$. This means that

$$U\cap U'\cong\mathbb{C}^*\times\mathbb{C},\quad (u',\xi')\in U\cap U':(u',\xi')=(u^{-1},u^2\xi). \tag{1}$$

Note that $T^*\mathbb{CP}^1$ describes the minimal resolution $\widetilde{\mathbb{C}^2/\mathbb{Z}_2}$ of $\mathbb{C}^2/\mathbb{Z}_2$, where $\mathbb{Z}_2$ acts on $(z^1,z^2)\in\mathbb{C}^2$ by $(z^1,z^2)\mapsto(-z^1,-z^2)$. To see this, on $U_0:=\{(u,\xi)\in U|\xi\neq 0\}$ use $(u,\xi)=(z^1/z^2,(z^2)^2)$, and analogously for the other chart. Then (1) is given by $z^1\leftrightarrow z^2$, and by the above we identify $\mathbb{C}^2/\mathbb{Z}_2$ with $T^*\mathbb{CP}^1$ with the zero section removed. The exceptional divisor of $\widetilde{\mathbb{C}^2/\mathbb{Z}_2}$ therefore corresponds to the zero section of $T^*\mathbb{CP}^1$. In these coordinates, i.e., outside the exceptional divisor, the Eguchi–Hanson metric takes the form,

$$g^{\mathrm{EH}}_{i\bar{j}}=\frac{\sqrt{c^4+R^4}}{R^2}\left\{\delta_{i\bar{j}}-\frac{c^4 z_i z_{\bar{j}}}{R^2(c^4+R^4)}\right\},$$

where

$$R^2=|z^1|^2+|z^2|^2,$$

and $c>0$ is the parameter of the Eguchi–Hanson metric. Introducing the Euler angles (θ,ϕ,ψ) on S^3 by

$$\begin{pmatrix}z^1\\ z^2\end{pmatrix}=R\begin{pmatrix}\cos\dfrac{\theta}{2}e^{(i/2)(\psi+\phi)}\\ \sin\dfrac{\theta}{2}e^{(i/2)(\psi-\phi)}\end{pmatrix},$$

we can describe coordinates (in the coordinate patch with $z_2\neq 0$) by a radial part $R\in\mathbb{R}_{>0}$ and the angles $\theta\in(0,\pi)$, $\phi\in[0,2\pi)$, $\psi\in[0,4\pi)$. In the following, it will be more convenient to use $r:=\sqrt[4]{R^4+c^4}$ instead of R.

The singularity of $\mathbb{C}^2/\mathbb{Z}_2$ then sits at $r=c$. On the exceptional divisor, the Eguchi–Hanson metric takes the form of the Fubini–Study metric on $\mathbb{CP}^1$, and therefore assigns volume π to the exceptional divisor (Eguchi and Hanson, 1979).

The $\mathbb{Z}_2$-operation mentioned above takes the form

$$\mathbb{Z}_2: \quad \begin{pmatrix} z^1 \\ z^2 \end{pmatrix} \mapsto -\begin{pmatrix} z^1 \\ z^2 \end{pmatrix}$$

$$(\theta, \psi, \phi) \mapsto (\theta, \psi + 2\pi, \phi).$$

In these new coordinates the metric takes the form originally found by Eguchi and Hanson. The Lie group SO(3) acts on itself by multiplication from the left and from the right. Let us call the vector fields that generate the right-multiplication (ξ_1, ξ_2, ξ_3), and the ones that generate the left-multiplication $(\bar{\xi}_1, \bar{\xi}_2, \bar{\xi}_3)$. Since $SO(3) \cong SU(2)/\mathbb{Z}_2 \cong S^3/\mathbb{Z}_2$ we have an action of these vector fields on the Eguchi–Hanson space. In Gibbons and Manton (1986) the authors derive that $\forall i,j: [\xi_i, \bar{\xi}_j] = 0$ and that $(\xi_1, \xi_2, \xi_3, \bar{\xi}_1)$ define Killing vector fields that generate an $su(2)_L \oplus u(1)_R$ symmetry algebra of the Eguchi–Hanson space.

Let Δ denote the Laplace–Beltrami operator on functions that is associated to the Eguchi–Hanson metric. Furthermore, let Ψ denote a smooth function on the Eguchi–Hanson space. We consider the eigenvalue equation for the real positive eigenvalue. (We are considering only the scattering case since we want to glue together the eigenfunctions on the Eguchi–Hanson space and the flat torus. However, eigenfunctions for $E < 0$ would correspond to bounded states.) i.e., $(E + \Delta)\Psi = 0$ for $E > 0$. The operator $E + \Delta$ can be expressed merely in terms of d/dr, $\xi^2 = \Sigma_{i=1}^3 \xi_i^2$, ξ_3^2, i.e.,

$$E + \Delta = E + \left(1 - \frac{c^4}{r^4}\right)\frac{d^2}{dr^2} + \left(\frac{3}{r} + \frac{c^4}{r^5}\right)\frac{d}{dr} + \frac{4\xi^2}{r^2} + \frac{4c^4\xi_3^2}{r^2(r^4 - c^4)}.$$

Due to their commutation relations we can diagonalize the operators ξ_3, $\bar{\xi}_3$, ξ^2 simultaneously and expand the eigenfunctions in terms of Wigner functions $D^j_{qm}(\theta, \psi, \phi)$ [see Abramowitz and Stegun (1955) for definitions], i.e.,

$$\Psi(r, \theta, \psi, \phi) = \sum_{j=0}^{\infty} \sum_{q,m=-j}^{j} \alpha^j_{qm} A(j, q, \beta | z) D^j_{qm}(\theta, \psi, \phi),$$

where $z := r^2/c^2$, $\beta := c^2 E/4$, and α^j_{qm} are complex coefficients, and the $A(j, q, \beta | z)$ are functions that depend only on the coordinate z. The Wigner functions fulfill

$$\bar{\xi}_3 D^j_{qm} = -imD^j_{qm},$$

$$\xi_3 D^j_{qm} = iqD^j_{qm},$$

$$(\xi_1^2 + \xi_2^2 + \xi_3^2) D^j_{qm} = -j(j+1) D^j_{qm},$$

where

$$j \in \mathbb{N}, \quad q, m \in [-j, j]_{\mathbb{N}}.$$

Here, j, q are the quantum numbers that label the SU(2) representation. The eigenvalue equation for Ψ then reduces to an ordinary differential equation for $A(j, q, \beta | .)$,

$$0 = \left[\frac{d^2}{dz^2} + \frac{2z}{z^2 - 1}\frac{d}{dz} + \frac{(\beta z - j(j+1))(z^2 - 1) - q^2}{(z^2 - 1)^2}\right] A(j, q, \beta | z). \tag{2}$$

The differential equation (2) has three singularities which we have summarized in the following table:

z	r	singularity	roots
1	c	regular	$\pm\frac{q}{2}$
-1	ic	regular	$\pm\frac{q}{2}$
∞	∞	irregular	

(for $q=0$ the regular singularities are logarithmic).

One should notice that our differential equation has an irregular singularity at infinity, thus is *not* of Fuchsian-type. More precisely, it is a confluent Heun equation with Ince symbol $[0,2,1_2]$. To construct a continuous solution valid on the whole Eguchi–Hanson sphere we have to choose the regular boundary condition at $z=1$ (then we can extend this solution to $z=1$, i.e., the blown up A_1-singularity). This means that we are looking for the *recessive* solutions that behave like $(z-1)^{q/2}$ for $z\to 1$. This means that all the eigenfunctions obtain a constant value on the entire $\mathbb{CP}^1$ which gives the exceptional divisor of the blow-up. By approaching the singular point of $\mathbb{C}^2/\mathbb{Z}_2$ with different slopes, one reaches different points in the exceptional divisor. But for a well-defined solution of the differential equation, the limit does not depend on the chosen slope.

We remark that the differential equation (2) does not depend on q but only on q^2. Therefore, it suffices to restrict ourselves to $q\geqslant 0$. Then, the function Ψ takes the following form:

$$\Psi(r,\theta,\psi,\phi)=\sum_{j=0}^{\infty}\sum_{q=0}^{j}A(j,q,\beta|z)\sum_{m=-j}^{j}(\alpha^j_{qm}D^j_{qm}(\theta,\psi,\phi)+\alpha^j_{-qm}D^j_{-qm}(\theta,\psi,\phi)).$$

On these functions the differential operator of Eq. (2) is self-adjoint: Since the differential operator in Eq. (2) is already formally self-adjoint the statement follows from the application of the results in [Coddington and Levinson (1955), Sec. 3.9] and a detailed study of the singularity at $z=1$ for $q=0$, where the differential equation is of a *limit-circle* type, and for $q\geqslant 1$, where it is of *limit-point* type; for more details see Coddington and Levinson (1955).

The specific problems that arise in the treatment of the differential Eq. (2) are due to the structure of singularities. In particular, the major issue is to treat *three* singularities—one being an *irregular* singularity—at the same time. The problem is to derive the connection between the different bases which provide expansions of the solutions in the neighborhood of the singular points. Another important question is how given a system of solutions the solutions transform into each other when passing through a cycle around the corresponding singularity.

For the thrice-punctured Riemann sphere with only regular singularities (this is a generalized hypergeometric equation) this can be done in terms of the Meijer transcendental functions—as they were recently applied in Greene and Lazaroiu (2001). Here, the key technique lies in a representation of the solutions in terms of Mellin–Barnes integrals.

For only two singularities—one being regular, one being singular—techniques can be applied which are familiar from the treatment of the Bessel differential equation. This corresponds to the confluent hypergeometric equation, i.e., a hypergeometric equation where two regular singularities are coalescing and forming one irregular singularity. Here, the key technique is a generalized Borel transformation [Gurarii and Matsaev (1994) and Gurarii and Matsaev (1994)] which relates a cycle around the regular singularity at $z=1$ to the irregular one at $z=\infty$.

In the case of two regular and one irregular singularities we cannot apply Mellin–Barnes integrals. Due to the irregular singularity solutions are oscillating at large real values. Thus, the conditions for convergence for the Mellin–Barnes integrals when continuing into the complex plane to close the path of integration to a cycle are not satisfied any more.

On the other hand, due to the third singularity at $z=-1$ a cycle around infinity is also not homologous to a cycle around $z=1$. Thus, an asymptotic expansion of the regular solution cannot be derived by a Borel transformation. However, as we will show in Sec. IV B, in some particular cases one can still use a similar argument.

III. WKB-TYPE SOLUTIONS

In this section we give approximations to the recessive solutions of differential equation (2) that can be obtained by the Liouville–Green approximation (WKB). The explicit derivation of the results can be found in Appendices A.1–A.4.

From now on we suppress the labels β, j, q in $A(\beta,j,q|z)$. Substituting $A(z)=(z^2-1)^{-(1/2)}w(u,z)$ in Eq. (2) we find

$$\frac{d^2}{dz^2}w(u,z)=[-u^2f(z)+g(z)]w(u,z), \tag{3}$$

where $u^2=\beta$, $g(z)=-(z^2-1)^{-2}$, $a=j(j+1)/\beta$, $b=q^2/\beta$, and

$$f(z)=\frac{(z-a)(z^2-1)-b}{(z^2-1)^2}.$$

We remark that due to the possible values for j, q, β we will always have $1\leqslant b+1<a$ and $0\leqslant a$.

Equation (3) is the standard form of a differential equation of second order considered for Liouville–Green approximation (WKB). Following the discussion in Olver (1974), the specific approximation depends on the order of the pole at $z=1$ as well as the number of *simple transition points* (tps), i.e., simple zeros, in the region $z>1$ which is of interest in connection with the geometry discussed in Sec. II. A simple analysis of the function f shows that we have to deal with the four different cases (I–IV) which are summarized in the table below.

case	condition	order of pole at $z=1$	tp for $z>1$
I	$1<b+1<a$	2	yes
II	$b=0$, $1<a$	1	yes
III	$b=0$, $a=1$	0	no
IV	$b=0$, $0\leqslant a<1$	1	no

For the different cases one can then apply the Liouville–Green approximation. First, one performs a Liouville-transformation of the variable z to the new variable ζ. The transformation is given by an integral equation of the form,

$$\forall z\geqslant z_0: G(\zeta)=\int_{z_0}^{z}\sqrt{|f(t)|}dt$$

such that ζ and z are analytic functions of each other, and where the function G and the point z_0 depend on the case (I–IV) we are dealing with. Simultaneously, we replace the function w by a function W according to $w(u,z)=\sqrt{|dz/d\zeta|}W(u,\zeta)$. The choices are as follows:

case	$G(\zeta)$	z_0
I	$\frac{2}{3}(-\zeta)^{2/3}$	>1 such that $f(z_0)=0$
II	$\zeta^{1/2}(\zeta-\alpha)^{1/2}-\frac{\alpha}{2}\ln\left(\frac{2\zeta-\alpha+2\zeta^{1/2}(\zeta-\alpha)^{1/2}}{\alpha}\right)$	a
III	ζ	1
IV	$(-\zeta)^{1/2}$	1

and

$$\alpha := \frac{2}{\pi}\int_1^a dt\sqrt{-f(t)}.$$

The aim of this transformation is to transform the differential equation (3) to a differential equation of the form,

$$\frac{d^2}{d\zeta^2}W(u,\zeta) = (T_1(u,\zeta)+T_2(\zeta))W(u,\zeta),$$

where T_1 and T_2 are real-valued functions such that the approximating differential equation obtained by omitting T_2 has solutions which are functions of a single variable. However, this transformation has been done in a way that the approximate solution will still reflect the right behavior of the solution at the singularity at $z=1$ and for $z\to\infty$. From now on we suppress the dependence of u in w and W.

We have found the following approximations for the solutions of differential equation (2) that are regular at $z=1$:

case	approx. function	form
I	Airy	$w(z)=\sqrt[4]{-\frac{\zeta}{f(z)}}\,\mathrm{Ai}(u^{2/3}\zeta)$
II	Whittaker	$w(z)=\sqrt[4]{\frac{\zeta-\alpha}{2u\zeta f(z)}}\,e^{-i\pi/4}\mathrm{M}_{iu\alpha/2,0}(2iu\zeta)$
III	Bessel	$w(z)=\frac{\zeta^{1/2}}{\sqrt[4]{f(z)}}\,\mathrm{J}_0(u\zeta)$
IV	Bessel	$w(z)=\frac{\lvert\zeta\rvert^{1/2}}{\sqrt[4]{4\lvert\zeta\rvert f(z)}}\,\mathrm{J}_0(u\lvert\zeta\rvert^{1/2})$

Asymptotically, the Eguchi–Hanson metric becomes the flat metric. Therefore, the solutions of the differential equation (2) must have the following behavior:

$$A(z) \overset{z\to\infty}{\sim} \frac{1}{z^{3/4}}\sin(2\sqrt{\beta z}+\Delta_{j,q}), \tag{4}$$

where $\Delta_{j,q}$ is called the scattering phase. Based on the results of Olver *et al.* (see Appendices A.1–A.4 for details), for the scattering phase we obtain the results listed below, where in the last column we give the equation number for the error bounds that are determined in Appendix A,

case	$\Delta_{j,q}(\beta)$	error
I	$\sqrt{\beta}\lim_{z\to\infty}\left(\int_{z_0}^{z}\sqrt{f(t)}dt-2\sqrt{z}\right)+\frac{\pi}{4}$	(22)
II	$-2\sqrt{\beta}\sqrt{1+a}\,\mathrm{E}\left[\sqrt{\frac{2}{1+a}}\right]+\frac{\alpha\sqrt{\beta}}{2}$ $-\frac{\alpha\sqrt{\beta}}{2}\ln\left(\frac{\alpha\sqrt{\beta}}{2}\right)+\arg\Gamma\left(\frac{1}{2}+\frac{i\alpha\sqrt{\beta}}{2}\right)+\frac{\pi}{4}$	(24)
III	$-\sqrt{8\beta}+\frac{\pi}{4}$	(27)
IV	$(1-a)\sqrt{2\beta}\,\mathrm{K}\left[\sqrt{\frac{1+a}{2}}\right]-2\sqrt{2\beta}\,\mathrm{E}\left[\sqrt{\frac{1+a}{2}}\right]+\frac{\pi}{4}.$	(30)

Here, $F(\phi,m)$, $E(\phi,m)$ denote elliptic integrals of the first and second kind, and $K(m)=F(\pi/2,m)$ and $E(m)=E(\pi/2,m)$ are the corresponding complete elliptic integrals [cf. Abramowitz and Stegun (1955), Sec. 17]. This corrects a result in Mignemi (1991).

IV. SOLUTIONS RELATED TO CONTINUED FRACTIONS

In this section we determine for which values of β, j, q the exact solution of the differential equation (2) can be obtained by a formal power series expansion (Frobenius method) around the singularity at $z=1$.

For an expansion around the regular singularity at $z=1$ a transformation according to $\zeta=\frac{1}{2}(z-1)$ is suitable. Substitution of

$$A(z)=(z^2-1)^{q/2}u(\zeta) \tag{5}$$

in Eq. (2) yields

$$0=\zeta(\zeta+1)u''(\zeta)+(q+1)(2\zeta+1)u'(\zeta)+(\beta(2\zeta+1)+\mu)u(\zeta), \tag{6}$$

where $\mu=q(q+1)-j(j+1)$. In a neighborhood of $z=1$ the two linearly independent solutions can be represented by the series,

$$\begin{aligned} u_{\mathrm{reg}}(\zeta)&=\sum_{k=0}^{\infty} a_k(\beta,j,q)\zeta^k,\\ u_{\mathrm{sing}}(\zeta)&=u_{\mathrm{reg}}(\zeta)(\ln\zeta+B_u)+\frac{1}{\zeta^q}\sum_{k=0}^{\infty} b_k(\beta,j,q)\zeta^k, \end{aligned} \tag{7}$$

where B_u is a real number. Since the singular solution is not unique (one can always add a multiple of the regular solution), the parameter B_u is not uniquely determined. However, the parameter can be fixed by fixing the asymptotic scattering phase of the singular solution.

By the Frobenius method [cf. Rabenstein (1972), Chap. 3.6] we obtain the coefficients $(a_k)_{k\geqslant -1}$ as solutions of the following three-term recurrence relation:

$$\begin{aligned} &a_{-1}=0,\\ \forall k\geqslant 0:\quad &a_{k+1}=-\frac{k(k+2q+1)+\mu+\beta}{(k+1)(k+q+1)}a_k-\frac{2\beta}{(k+1)(k+q+1)}a_{k-1}. \end{aligned} \tag{8}$$

Notice that a rescaling of the parameter a_0 results in a general rescaling of all the coefficients $(a_k)_{k\geqslant -1}$ since Eq. (8) is linear. However, the crucial information, i.e., the ratio of a_1 and a_0 is fixed by the recurrence relation (8). By standard methods one can show that there are only two types of solutions for $(a_k)_{k\in\mathbb{N}}$ in (8) depending on the radius of convergence r_c of the series $\Sigma_{k=0}^{\infty}a_k\zeta^k$,

$$\lim_{k\to\infty}\frac{a_{k+1}}{a_k}=\begin{cases}-1 & r_c=1,\\ 0 & r_c=\infty.\end{cases}$$

A solution with $r_c=1$ corresponds to a solution of the recurrence relation for generic values of (β,j,q), whereas the solution with $r_c=\infty$ is the *minimal solution*. [A minimal solution $(g_n)_{n\in\mathbb{N}}$ is defined by the universal property that for any other solution $(h_n)_{n\in\mathbb{N}}$ one obtains $\lim_{n\to\infty} g_n/h_n=0$.] The question for which values of the parameters (β,j,q) this minimal solution exists will be considered in Sec. IV A. One should mention that it is possible to derive an explicit representation of the coefficients $(a_k)_{k\in\mathbb{N}}$ by the use of Babister's inhomogeneous hypergeometric functions (Exton, 1991). However, this approach did not enable us to derive the asymptotic behavior in the

case of a minimal solution. To solve the differential equation (6) by a Laplace transformation as in Exton (1991) for similar differential equations or an Euler transformation as in Kazakov (1998) is not possible due to the structure of the coefficients in Eq. (6).

To gain a better understanding of solutions to (6), let us take a look at the solution u_{reg} which is regular at $z=1$ ($\zeta=0$) in terms of the singularity at $z=-1$ ($\zeta=-1$). Let $v_{\mathrm{reg}}(\zeta)$ be the solution regular at $z=-1$ ($\zeta=-1$). Its continuation to $\zeta\to\infty$ shall have an asymptotic scattering phase of γ, which by (4) and (5) gives an asymptotic expansion,

$$v_{\mathrm{reg}}(\zeta)\overset{\zeta\to\infty}{\sim}\frac{\sin(2\sqrt{2\beta\zeta}+\gamma)}{\zeta^{q+(3/4)}}\left(1+O\left(\frac{1}{\zeta}\right)\right).$$

We fix a solution singular at $z=-1$ ($\zeta=-1$) by the requirement that its asymptotic scattering phase differs from the regular solution by a phase of $\pi/2$, giving an asymptotic expansion,

$$v_{\mathrm{sing}}(\zeta)\overset{\zeta\to\infty}{\sim}\frac{\cos(2\sqrt{2\beta\zeta}+\gamma)}{\zeta^{q+(3/4)}}\left(1+O\left(\frac{1}{\zeta}\right)\right).$$

To resume, looking for the nontrivial solutions of the differential equation (2) we have already found two contributions: for a generic set of parameters (β,j,q) the solution regular at $z=1$ ($\zeta=0$) has a regular singularity at $z=-1$ ($\zeta=-1$). This means that it is a linear combination of v_{reg} and v_{sing}, without loss of generality,

$$u_{\mathrm{reg}}(\zeta)=\cos(\alpha)v_{\mathrm{reg}}(\zeta)+\sin(\alpha)v_{\mathrm{sing}}(\zeta)$$

$$\overset{\zeta\to\infty}{\sim}\frac{1}{\zeta^{q+(3/4)}}\sin(2\sqrt{2\beta\zeta}+\underbrace{\gamma+\alpha}_{=\Delta_{j,q}(\beta)})\left(1+O\left(\frac{1}{\zeta}\right)\right).$$

Because of the singularity at $z=-1$ ($\zeta=-1$) the representation of u_{reg} by a power series expansion must break down for all values $|\zeta|>1$. Therefore, the asymptotic scattering phase of u_{reg} can in general not be obtained from (7).

Only for those values $(\beta_n)_{n\in\mathbb{N}}$ that lead to a minimal solution of the recurrence relation (8) the solution regular at $z=1$ is regular at $z=-1$ as well, and therefore of class $C^\infty(\mathbb{R})$. This means $\sin\alpha=0$ and therefore

$$\Delta_{j,q}(\beta_n)=\gamma \bmod \pi. \tag{9}$$

Since we can always change the sign of the solution by an overall factor the scattering phase is only determined up to an integer multiple of π. In Sec. IV B we will eventually determine γ.

A. Minimal solutions and continued fractions

According to Pincherle's Theorem (see Jones and Thron (1980), Sec. 5.3) a three-term recurrence relation,

$$\forall_{n\geqslant 1}\quad y_{n+1}=-\delta_n y_n+\gamma_n y_{n-1}$$

has a minimal solution if and only if the following continued fraction converges,

$$\sum_{k=1}^{\infty}\frac{\gamma_k|}{|\delta_k}=\frac{\gamma_1}{\delta_1+\dfrac{\gamma_2}{\delta_2+\dfrac{\gamma_3}{\delta_3+\cdots}}}.$$

In particular, if $(a_n)_{n\in\mathbb{N}}$ is the minimal solution it follows that $a_0\neq 0$ and

$$-\frac{a_1}{a_0}+\sum_{k=1}^{\infty}\frac{\gamma_k|}{|\delta_k}=0.$$

For any set of parameters (j,q), where as before $q\geqslant 0$, we now define the function $\tilde{\mathcal{M}}(j,q|x)$ by the continued fraction of *Thron* type (or T-fraction),

$$\tilde{\mathcal{M}}(j,q|x):=\delta_0+\sum_{k=1}^{\infty}\frac{\gamma_k|}{|\delta_k},$$

where

$$\forall_{k\geqslant 0}\quad \delta_k:=\frac{k(k+2q+1)+\mu-x}{(k+1)(k+q+1)},$$

$$\forall_{k\geqslant 1}\quad \gamma_k:=\frac{2x}{(k+1)(k+q+1)}.$$

Using the Umordnungssatz [Perron, 1977, Kap. 6.42, Satz 2] and [Jones and Thron (1980), Sec. 7.3, Th. 7.23], we can conclude that the function $\tilde{\mathcal{M}}(j,q|x)$ is a meromorphic function on $\mathbb{C}$. Moreover, by the above its real zeros determine the values of $x=-\beta$ for which the recurrence relation (8) has a minimal solution, i.e., the radius of convergence of the power series expansion (7) becomes infinite.

The corresponding solution u_{reg} is then of class $C^{\infty}(\mathbb{R})$. Since the relation $A(\beta,j,q|z)=A(-\beta,j,q|-z)$ holds for the differential Eq. (2), it follows that any such smooth solution for β,j,q in z is simultaneously a smooth solution for $-\beta,j,q$ in the variable $-z$. Therefore, $x=\beta$ must be another zero of $\tilde{\mathcal{M}}(j,q|x)$. This is,

$$\tilde{\mathcal{M}}(j,q|\beta)=0\Leftrightarrow\tilde{\mathcal{M}}(j,q|-\beta)=0.$$

Using the Umordnungssatz [Perron (1977), Kap. 6.42, Satz 2], one can see that one can cancel the factor $(k+1)(k+q+1)$ in γ_k, δ_k. Namely, it is equivalent to calculate the zeros of the meromorphic function $\mathcal{M}(j,q|x)$ instead of $\tilde{\mathcal{M}}(j,q|x)$, where $\mathcal{M}(j,q|x)$ is defined by the continued fraction,

$$\mathcal{M}(j,q|x):=d_0+\sum_{k=1}^{\infty}\frac{c_k|}{|d_k},\tag{10}$$

where

$$\forall_{k\geqslant 0}\quad d_k:=k(k+2q+1)+\mu-x,$$

$$\forall_{k\geqslant 1}\quad c_k:=2k(k+q)x.$$

For this continued fraction one can even prove separate convergence [see Thron (1991) for definitions]. To see this, recall that $\mu=(q-j)(j+q+1)$, and rewrite the continued fraction in the following way:

$$\forall_{j-q\geqslant 1}\quad \mathcal{M}(j,q|x)=d_0+\sum_{k=1}^{j-q-1}\frac{c_k|}{|d_k}+\frac{2j(j-q)}{-1+\dfrac{m(j,q|x)}{x}},$$

$$\forall_{j\geqslant 0}\ \ \mathcal{M}(j,j|x)=x\left(-1+\frac{m(j,j|x)}{x}\right).$$

Here,

$$m(j,q|x):=\sum_{k=j-q+1}^{\infty}\frac{c_k|}{|d_k}$$

can be written as a T-fraction using again the Umordnungssatz [Perron (1977), Kap. 6.42, Satz 2], i.e.,

$$m(j,q|x)=\sum_{k=j-q+1}^{\infty}\frac{F_k x|}{|1+G_k x}, \tag{11}$$

where

$$\forall_{k\geqslant j-q+1}\ \ G_k:=-\frac{1}{(k-j+q)(k+j+q+1)},$$

$$\forall_{k\geqslant j-q+2}\ \ F_k:=\frac{2k(k+q)}{(k-j+q-1)(k-j+q)(k+j+q)(k+j+q+1)},$$

$$F_{j-q+1}:=j-q+1.$$

Since we have both $\Sigma_{k=j-q+1}^{\infty}|F_k|<\infty$ and $\Sigma_{k=j-q+1}^{\infty}|G_k|<\infty$ we can apply [Thron (1991), Sec. 3, Th. 3.1] to the T-fraction (11): let $A_k(x)$ and $B_k(x)$ be the numerators and denominators, respectively, of the nth approximant of the T-fraction (11). Then the sequences $(A_k(x))_{k\geqslant j-q+1}$ and $(B_k(x))_{k\geqslant j-q+1}$ converge, uniformly on compact subsets of $\mathbb{C}$, to entire functions $A(x)$ and $B(x)$ of order at most one. Further $B(0)=1$, $A(0)=0$, $A'(0)=F_{j-q+1}$ so that neither function is identically zero, and $(1/x)m(j,q|x)$ is well defined at $x=0$.

B. The determination of the scattering phase and the monodromy

In this section we calculate the scattering phase of the regular solution u_{reg} in the case that it is also regular at $\zeta=-1$.

Let us first look at the asymptotic expansion of the solutions of Eq. (6). For an asymptotic expansion a Fabry transformation (Olver, 1974) is suitable, i.e., a change of the variable according to $x^2=\zeta$. With $u(\zeta)=U(x)$, Eq. (6) becomes

$$(x^2+1)U''(x)+\left(-\frac{x^2+1}{x}+\frac{2(q+1)(2x^2+1)}{x}\right)U'(x)+(4\beta(2x^2+1)+4\mu)U(x)=0.$$

By standard methods, [cf. Coddington and Levinson (1955)] one finds that this equation has two linearly independent solutions H_1, H_2, such that for some $\delta>0$ the following asymptotic expansions hold,

$$\begin{aligned}
&\forall_x\ \ -2\pi+\delta\leqslant\arg x\leqslant\pi-\delta:\ \ H_1(x)\sim\frac{1}{x^{2q+(3/2)}}e^{-2i\sqrt{2\beta}x}\sum_{k=0}^{\infty}\frac{(-1)^k p_k}{(4i\sqrt{2\beta}x)^k},\\
&\forall_x\ \ -\pi+\delta\leqslant\arg x\leqslant 2\pi-\delta:\ \ H_2(x)\sim\frac{1}{x^{2q+(3/2)}}e^{-2i\sqrt{2\beta}x}\sum_{k=0}^{\infty}\frac{p_k}{(4i\sqrt{2\beta}x)^k},
\end{aligned} \tag{12}$$

where the coefficients $(p_k)_{k\in\mathbb{N}}$ fulfill the following four-term recurrence relation:

$$
\begin{aligned}
&p_{-2}=p_{-1}=0,\\
\forall k\geqslant 0:\quad &p_{k+1}=\frac{k(k+1)-4\beta-4j(j+1)-\frac{3}{4}}{k+1}p_k+32\beta\frac{k+q}{k+1}p_{k-1}\\
&-32\beta\frac{k^2+(2q-1)k-q+\frac{1}{4}}{k+1}p_{k-2}.
\end{aligned}
\tag{13}
$$

It follows from this recurrence relation that for $p_0\in\mathbb{R}$ the coefficients $(p_k)_{k\in\mathbb{N}}$ are real. In particular, we have $H_1(x)=\overline{H_2(\bar{x})}$. This property remains true not only asymptotically, but also for the actual solutions: Since all the coefficients in the differential equation are real, the complex conjugate of any solution is again a solution.

The Stokes phenomenon will lead to a nontrivial monodromy of the solutions if we pass through a cycle around infinity (Olde Daalhuis, 1995). However, since the solutions H_1, H_2 are a complete system of solutions the new solutions can be expressed as linear combinations of them. These are the connection formulas. In the case of a second order differential equation they had been explicitly calculated, namely in Olde Daalhuis and Olver (1994). We obtain for $|x|\gg 0$,

$$
\begin{aligned}
&\lim_{\theta\to 1} H_1(xe^{-2\pi i\theta})=-H_1(x)+2\pi iPH_2(x),\\
&\lim_{\theta\to 1} H_2(xe^{2\pi i\theta})=-2\pi iPH_1(x)-H_2(x).
\end{aligned}
\tag{14}
$$

The parameter P can be determined by a generalized Borel transformation of the asymptotic solution as pointed out in Gurarii and Matsaev (1994) and Gurarii and Matsaev (1994). For ordinary differential equations of second order this has been done explicitly by Olde Daalhuis and Olver (1994). Applying these results we can determine the parameter P from the coefficients in the asymptotic expansion (13), i.e.,

$$
P=\lim_{k\to\infty}\frac{1}{(k-1)!}\frac{p_k}{p_0}. \tag{15}
$$

In particular, the parameter P is real. We subsume the solutions H_1, H_2 in the vector $\mathbf{H}:={}^t(H_1,H_2)$. We are interested in the matrix $\mathbf{C}$ which describes the behavior if we go around the singularity at $x=\infty$, i.e.,

$$
\begin{aligned}
&\lim_{\theta\to 1}\mathbf{H}(xe^{2\pi i\theta})=\mathbf{C}\cdot\mathbf{H}(x),\\
&\lim_{\theta\to 1}\mathbf{H}(xe^{-2\pi i\theta})=(\mathbf{C})^{-1}\cdot\mathbf{H}(x).
\end{aligned}
$$

From the connection formulas (14) we obtain

$$
\mathbf{C}=-\begin{pmatrix} 1-4\pi^2P^2 & 2\pi iP\\ 2\pi iP & 1\end{pmatrix}. \tag{16}
$$

Notice that this matrix describes the monodromy by passing through a cycle around infinity (in the x-variable). In the original variable ζ this describes a cycle that winds up twice around infinity.

As a last step we need to calculate the linear combination of the regular solution $u_{\mathrm{reg}}(\zeta)$ in terms of the solutions $\mathbf{H}(x)$ derived earlier. This amounts to determining a complex parameter $\lambda\in U(1)$ such that

$$u_{\mathrm{reg}}(\zeta)=(\lambda\ \ \overline{\lambda})\cdot\mathbf{H}(x).$$

The occurrence of λ and $\overline{\lambda}$ is due to the fact that $u_{\mathrm{reg}}(\zeta)$ is real, i.e., $\overline{u_{\mathrm{reg}}(\zeta)}=u_{\mathrm{reg}}(\zeta)$, and $\overline{H_1(\overline{x})}=H_2(x)$.

Now, the representation of $u_{\mathrm{reg}}(\zeta)$ by the power series (7) is valid for $|\zeta|>1$ iff the coefficients $(a_k)_{k\geqslant 1}$ constitute a minimal solution of the recurrence relation (8). Therefore, $u_{\mathrm{reg}}(\zeta)$ has a trivial monodromy around both of the regular singularities iff the $(a_k)_{k\geqslant 1}$ constitute a minimal solution of Eq. (8). Hence, iff for any set of parameters (β,j,q) the equation $\mathcal{M}(j,q|\beta)=0$ holds, then the following equation must hold:

$$u_{\mathrm{reg}}(\zeta)=\lim_{\theta\to 1}u_{\mathrm{reg}}(\zeta e^{4\pi i\theta})=(\lambda\ \ \overline{\lambda})\cdot\lim_{\theta\to 1}\mathbf{H}(xe^{2\pi i\theta})=(\lambda\ \ \overline{\lambda})\cdot\mathbf{C}\cdot\mathbf{H}(x).$$

Thus, the equation $\mathcal{M}(j,q|\beta)=0$ holds iff

$$(\lambda\ \ \overline{\lambda})=(\lambda\ \ \overline{\lambda})\cdot\mathbf{C},$$

or equivalently (since P is real),

$$P^2=\frac{1}{\pi^2},$$

$$\overline{\lambda}=-i\pi P\lambda.$$

If we set $\lambda=ie^{-i\gamma}$ with $\gamma\in\mathbb{R}$ we obtain

$$\gamma=\begin{cases}\dfrac{\pi}{4} & \text{if } P=\dfrac{1}{\pi}\\[2ex] \dfrac{3\pi}{4} & \text{if } P=-\dfrac{1}{\pi}\end{cases}\quad \mathrm{mod}\ \pi. \tag{17}$$

Thus, λ encodes the crucial information for the asymptotic expansion of the regular solution, i.e.,

$$u_{\mathrm{reg}}(\zeta)=\frac{1}{i}(e^{i\gamma}H_2(x)-e^{-i\gamma}H_1(x))\sim\frac{2p_0}{\zeta^{q+(3/4)}}\left(\sin(2\sqrt{2\beta\zeta}+\gamma)+O\left(\frac{1}{\sqrt{\zeta}}\right)\right).$$

This is the desired formula for the scattering phase in the case that the set of parameters (β,j,q) induces a minimal solution of the recurrence relation (8).

By standard methods one can show that there are only the following two types of asymptotic behavior for solutions $(p_k)_{k\in\mathbb{N}}$ of the recurrence relation (13),

$$\frac{p_{k+1}}{p_k}=\begin{cases}k+O\left(\dfrac{1}{k}\right)\\[2ex] \pm 4\sqrt{2\beta}+O\left(\dfrac{1}{k}\right).\end{cases} \tag{18}$$

Therefore, if $P_k:=1/(k-1)!(p_k/p_0)$ converges to σ/π [cf. Eqs. (15) and (17)] i.e.,

$$P_k=\frac{\sigma}{\pi}+\frac{m}{k^n}+o\left(\frac{1}{k^n}\right),$$

where σ is either -1 or 1 and $m \in \mathbb{R}$, $n \in \mathbb{R}_{>0}$, the ratio of the coefficients p_{k+1} and p_k must behave asymptotically as

$$\frac{p_{k+1}}{p_k} = k - \frac{nm\sigma\pi}{k^n} + o\left(\frac{1}{k^n}\right).$$

A comparison with (18) then gives $n \geqslant 1$, and by expanding the RHS of (13) we finally obtain

$$\frac{p_{k+1}}{p_k} = k - \frac{m\sigma\pi}{k} + O\left(\frac{1}{k^2}\right),$$

$$m\sigma\pi = 4\beta + 4j(j+1) + \tfrac{3}{4}.$$

Therefore, the coefficients $(p_k)_{k\in\mathbb{N}}$ must be a dominant solution of Eq. (13) if P_k converges to σ/π.

C. Computation

The numerical determination of the scattering phase consists of two steps: First, we have to determine the successive zeros of the function $\mathcal{M}(j,q|x)$. However, one should mention that for the necessary evaluation of the continued fraction one has to use a backward algorithm since any forward algorithm must be numerically instable as shown in Gautschi (1967).

We have determined the positive zeros $(\beta_n)_{n\in\mathbb{N}}$ of $\mathcal{M}(j,q|x)$ by a simple bisection algorithm where the evaluation of the continued fraction was accomplished by the Gautschi algorithm. It is essential to use the function $\mathcal{M}(j,q|x)$ instead of the earlier defined $\tilde{\mathcal{M}}(j,q|x)$: Because of the structure of the coefficients in the continued fraction the typical values of $\tilde{\mathcal{M}}(j,q|x)$ become very small, and the determination of its zeros unstable.

Second, for those values of β_n for which the recurrence relation (8) has a minimal solution by (17) the asymptotic scattering phase is either $\pi/4$ or $3\pi/4$ depending on the sign of P. P is determined by a solution of the four-term recurrence relation (13). We have proven in Sec. IV B that for the parameters (β_n, j, q) this must be a dominant solution of the recurrence relation (13). Thus, P can be determined by a simple forward algorithm which will be numerically stable. With the set $(\beta_n, j, q, \operatorname{sign} P)$ we then have the data needed for a numerical interpolation of the scattering phase over the whole range of β.

V. NUMERICAL RESULTS

A. Numerical results for the WKB approximation

The figures below show the scattering phases for different quantum numbers j and q with varying parameter β obtained by the WKB approximation from Sec. III. In Figs. 1–4 we have applied the WKB approximation of case I. Figure 1 shows (from the top to the bottom) the graphs for $\Delta_{j,q}$ for $j=1,...,10$ and $q=1$. Figure 2 shows (from the top to the bottom) the graphs for $\Delta_{j,q}$ for $j=3,...,10$ and $q=3$. Figure 3 shows (from the top to the bottom) the graphs for $\Delta_{j,q}$ for $j=4,...,10$ and $q=4$. Figure 4 shows (from the top to the bottom) the graphs for $\Delta_{j,q}$ for $j=5$ and $q=1,3,5$. In Figs. 5 and 6 we have compared the WKB approximation of case II–IV (left) with the WKB approximation of case I (right) for the values $j=9$, $q=0$. The vertical line in Fig. 5 is indicating the transition from case II–IV. Figure 7 shows (from the top to the bottom) the graphs for $\Delta_{j,0}$ for $j=1,3,5$. Figure 8 shows the graph for $\Delta_{12,0}$.

B. Comparison between WKB and Frobenius method

In this section we compare the numerical results for the asymptotic scattering phase obtained by the WKB approximation (already shown in Sec. V A) with the numerical data obtained by the Frobenius/continued-fraction method as described in Sec. IV C.

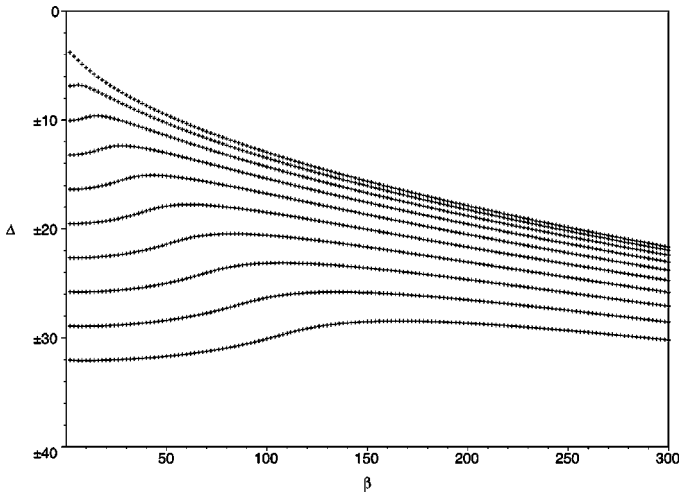

FIG. 1. $\Delta_{j,q}$ for $j=1,...,10;\ q=1$.

The figures below show the scattering phases for different quantum numbers j and q with varying parameter β. Each figure will show the graph $[\beta,\Delta_{j,q}^{\mathrm{WKB}}(\beta)]$ of the corresponding WKB approximation, and crosses will mark the points $[\beta_n,\Delta_{j,q}^{\mathrm{Fr}}(\beta_n)]_{n\geqslant 1}$ obtained by the Frobenius/continued-fraction method where β_n is the nth zero of $\mathcal{M}(j,q|\beta)$ and

$$\Delta_{j,q}^{\mathrm{Fr}}(\beta_n)=-\frac{\pi}{4}(2+\sigma)-l_{j,q}(n)\,\pi-\max(0,j-1)\,\pi \tag{19}$$

with $\sigma=\mathrm{sign}(P)$ (cf. Sec. IV B) and $\forall_{n\geqslant 1}: l_{j,q}(n)\in\mathbb{N}_0$. Notice that the scattering phase is only determined up to a multiple of π since we can always change the sign of a solution by an overall factor. Therefore, Eq. (19) is equivalent to Eq. (17). We will also present an additional and more significant diagram of $(\Delta_{j,q}(\beta)\mathrm{mod}\,\pi)$ and varying parameter β.

Figures 9, 11, 13, 15 show $\Delta_{j,0}(\beta)$ with varying β. For all j and $q=0$ we have found $\sigma=\mathrm{sign}(P)=-1$. For $j\leqslant 6$ it is $l(n):=n$ and all $\beta_n>j(j+1)$, i.e., $1>a\geqslant 0$ and we have to compare it to case IV of the WKB approximation. $j=7$ is the lowest value where for $q=0$ we

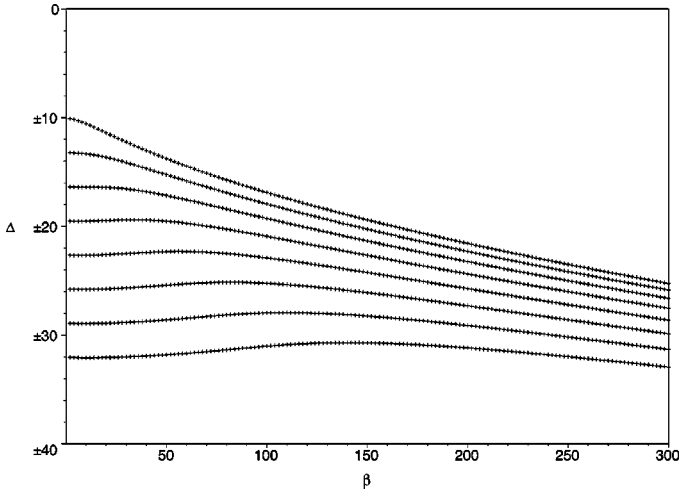

FIG. 2. $\Delta_{j,q}$ for $j=3,...,10;\ q=3$.

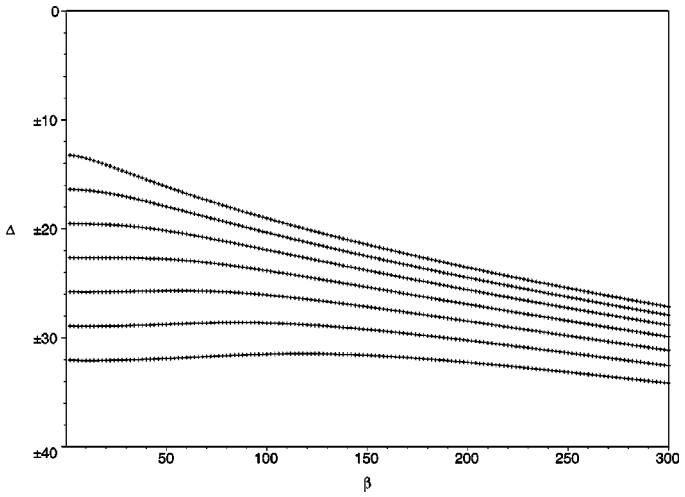

FIG. 3. $\Delta_{j,q}$ for $j=4,\ldots,10$; $q=4$.

have $\beta_1<j(j+1)$, i.e., $1<a$, and we have to compare it to case II of the WKB approximation; we have to relabel the β_n. This can be done by setting $\forall_{j\geqslant 7}: l(n):=|n-\frac{3}{2}|-\frac{1}{2}$.

However, since the phase can be obtained only up to multiples of π the function $l(n)$ is irrelevant for the comparison of $\Delta_{j,q}^{\mathrm{WKB}}(\beta)$ and $\Delta_{j,0}^{\mathrm{Fr}}(\beta_n)$. For this purpose one can look at Figs. 10–16, which are independent of $l(n)$. These figures show an exact match of the data sets obtained by the WKB approximation and the Frobenius/continued-fraction method.

Figures 17–24 show $\Delta_{j,1}(\beta)$ with varying β. For all j and $q=1$ we have found $\sigma=\mathrm{sign}(P)=-1$. For $j\leqslant 8$ it is $l(n):=n$. $j=9$ is the lowest value where for $q=1$ we have $\beta_1<\beta_{\max}$, where $\beta_{\max}$ denotes the local maximum of the WKB approximation: We have to relabel the β_n. This can be done by setting $\forall_{j\geqslant 9}: l(n):=|n-\frac{3}{2}|-\frac{1}{2}$. Figures 17–24 show an exact match of the data sets obtained by the WKB approximation and the Frobenius/continued-fraction method.

Figures 25–32 show $\Delta_{j,2}(\beta)$ with varying β. For all j and $q=2$ we have found $\sigma=\mathrm{sign}(P)=-1$. For $j\leqslant 11$ it is $l(n):=n$. Figures 25–32 show an exact match of the data sets obtained by the WKB approximation and the Frobenius/continued-fraction method.

The accuracy of the WKB approximation can be explained as follows: from the error bound in Eq. (30) we can deduce the following numerical result for the error $\delta_{j,q}(\beta)$ of $\Delta_{j,q}(\beta)$;

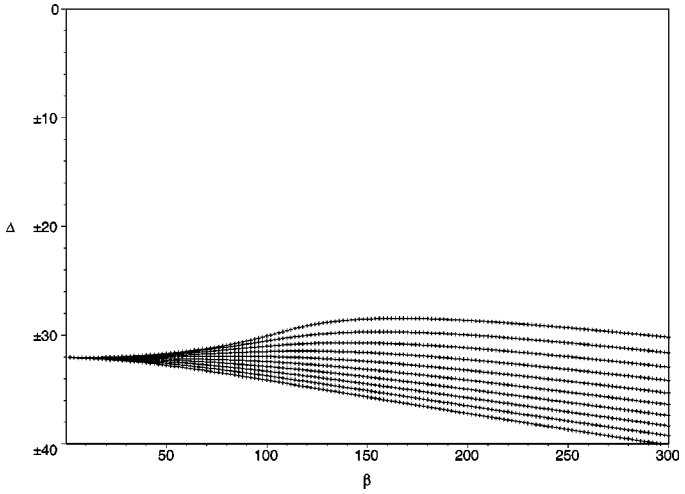

FIG. 4. $\Delta_{j,q}$ for $j=10$, $q=1,\ldots,10$.

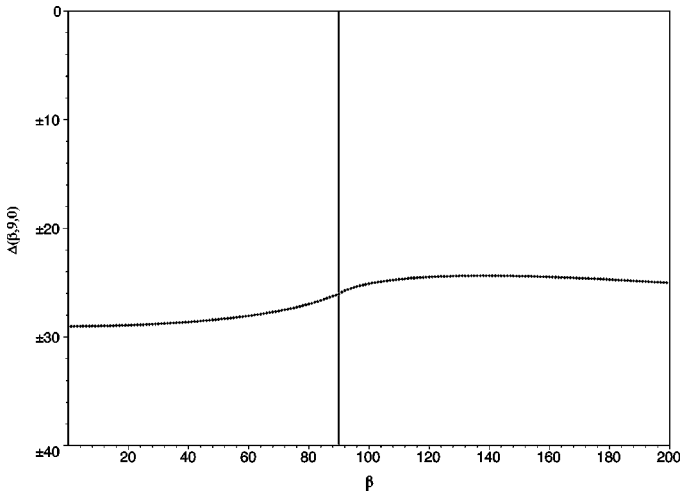

FIG. 5. $\Delta_{9,0}$ for cases II, III, IV.

$$|\delta_{j,q=0}(\beta)| \leqslant \frac{\pi}{2}\min(1,1.1e^{(1.2/\sqrt{\beta})}-1).$$

This means that for $\beta>4$ we already have

$$|\delta_{j,q=0}(\beta)| \leqslant \frac{\pi}{2}(e^{(1.2/\sqrt{\beta})}-1),$$

and for $\beta>100$ we find $|\delta_{j,q=0}(\beta)| \leqslant \pi/10$.

The same computations can be made for $q \geqslant 1$ with similar results since we also have a similar error bound for the general $\delta_{j,q}(\beta)$ in Eq. (22).

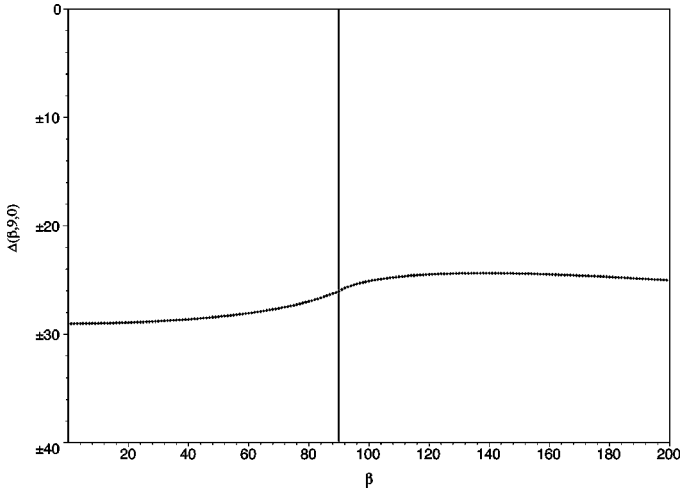

FIG. 6. $\Delta_{9,0}$ for case I.

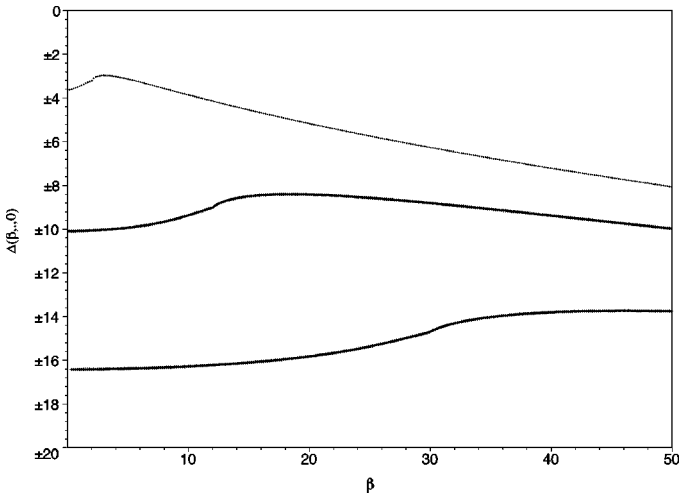

FIG. 7. $\Delta_{j,0}$ for $j=1, 3, 5$.

VI. CONCLUSIONS AND OUTLOOK

The eigenvalue equation for the Laplace–Beltrami operator acting on scalar functions on the noncompact Eguchi–Hanson space reduces to a confluent Heun equation [(2) or after a suitable substitution (6)] with the Ince symbol $[0,2,1_2]$.

With the help of the Liouville–Green approximation (WKB) we have constructed approximations for the eigenfunctions by special functions in Sec. III. Depending on the quantum numbers that label the SU(2)-representation the approximating functions are either Airy, Whittaker, or Bessel functions. Furthermore, we have derived the scattering phases and error bounds in these cases.

Moreover, for specific discrete values of the eigenvalue in Sec. IV we have constructed the exact solutions by the Frobenius methods. These eigenvalues are given by the zeros of a meromorphic function defined by the infinite continuous fraction (10). Together with a monodromy computation this has provided us with the data needed for a numerical interpolation of the scattering phases.

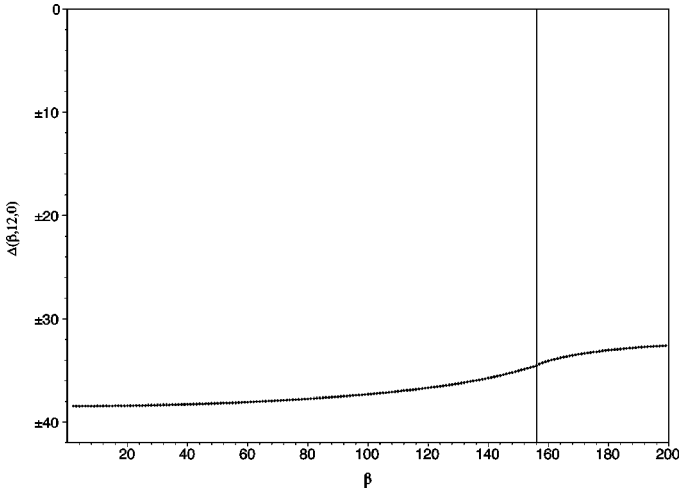

FIG. 8. $\Delta_{12,0}$.

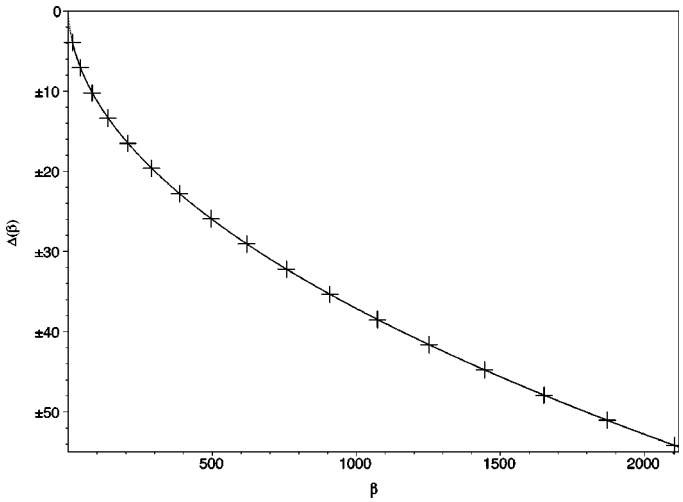

FIG. 9. $\Delta_{0,0}^{\mathrm{WKB}}$ and $\Delta_{0,0}^{\mathrm{Fr}}$.

Finally, in Sec. V we have shown that these two sets of data (obtained by the WKB approximation and the Frobenius/continued-fraction method) agree to a high accuracy. This shows that one can find a discrete set of exact values for the spectral density of the Laplace–Beltrami operator by the method described in Sec. IV C. Conversely, it shows that the expressions for the eigenfunctions and scattering phases which were derived in Sec. III and which have the advantage of being given in terms of explicit functions are very accurate approximations and can be used for all numerical purposes.

It is now interesting to ask whether the meromorphic function defined by the continued fraction (10) can be expressed explicitly as a ratio of special functions. If so we could obtain the discrete eigenvalues—for which we have already calculated the exact scattering phase and which we have also computed numerically by the continued fraction—as zeros of this ratio of special functions. A first step towards an explicit representation of the continued fraction might arise from the method of Pincherle. If we apply Perron (1977) (Kap. 21.84, Satz 8) to the continued fraction (10) we obtain the following result: a representation of the meromorphic function defined by the T-fraction (10) is given by

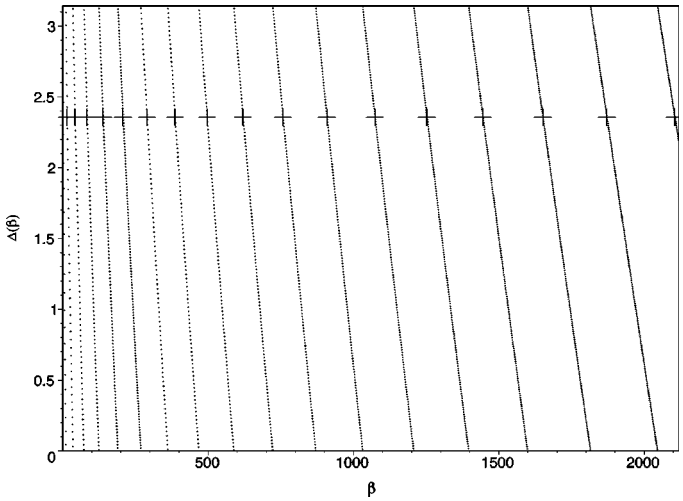

FIG. 10. $\Delta_{0,0}^{\mathrm{WKB}}$ and $\Delta_{0,0}^{\mathrm{Fr}}$ modulo π.

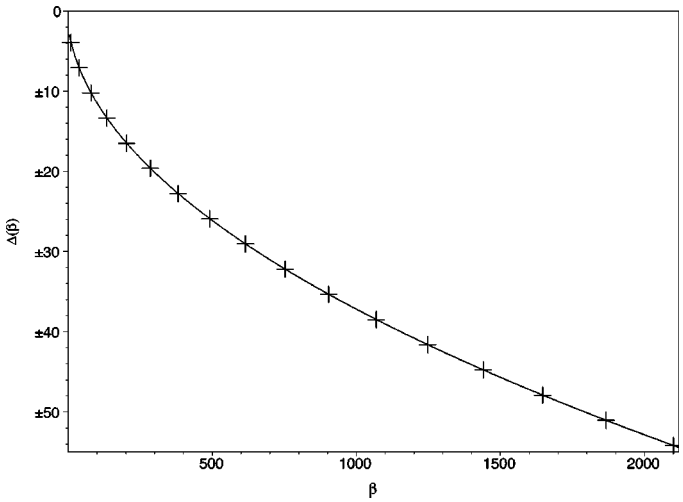

FIG. 11. $\Delta_{1,0}^{\mathrm{WKB}}$ and $\Delta_{1,0}^{\mathrm{Fr}}$.

$$\mathcal{M}(j,q|x)=q(q+1)-j(j+1)+x+\frac{\delta_{q0}16\pi x^3\phi\left(\frac{1}{2x}\right)+\int_{1/2x}^{\infty}dz\,\phi(z)z^{-3}}{\delta_{q0}8\pi x^2\phi\left(\frac{1}{2x}\right)+\int_{1/2x}^{\infty}dz\,\phi(z)z^{-2}}.$$

Here, ϕ is the solution of the differential equation,

$$\left\{z^3\left(z-\frac{1}{2x}\right)\frac{d^2}{dz^2}+z^2\left((q+1)z-\frac{q}{x}\right)\frac{d}{dz}+\left(\frac{x-q(q+1)+j(j+1)}{2x}z-\frac{1}{2x}\right)\right\}\phi(z)=0$$

that behaves as $(z-(1/2x))^q$ at the regular singularity $z=1/2x$. An analysis of the differential equation shows that such a solution always exists. A further analysis of the behavior at the irregular singularity $z=\infty$ then shows that all the appearing integrals also exist.

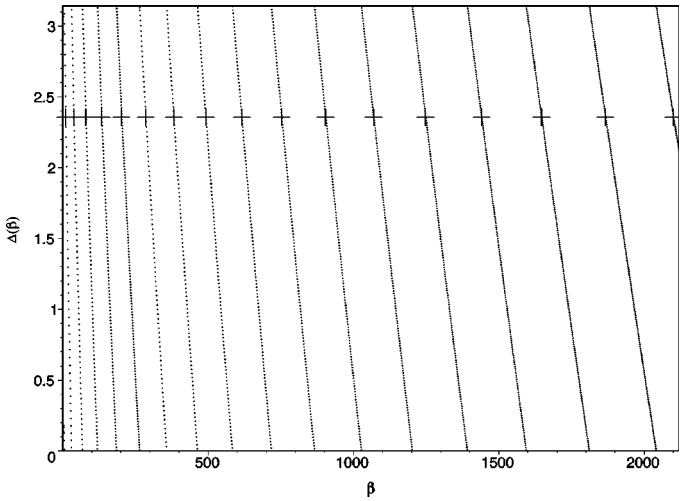

FIG. 12. $\Delta_{1,0}^{\mathrm{WKB}}$ and $\Delta_{1,0}^{\mathrm{Fr}}$ modulo π.

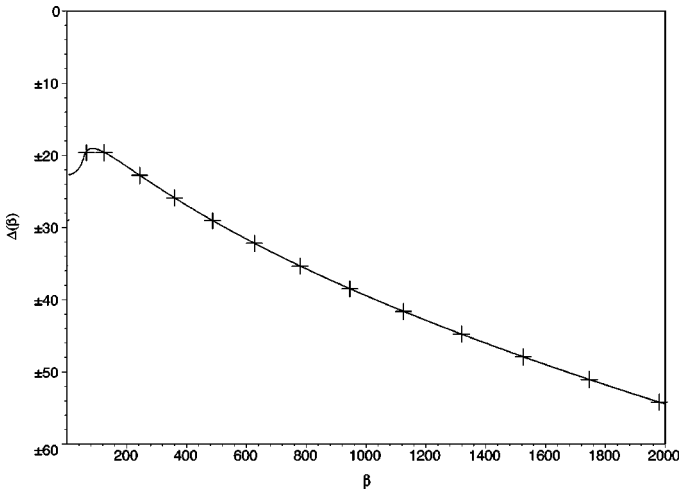

FIG. 13. $\Delta_{7,0}^{\mathrm{WKB}}$ and $\Delta_{7,0}^{\mathrm{Fr}}$.

A closer investigation of the meromorphic function $\mathcal{M}(j,q|x)$ is subject of our ongoing research.

ACKNOWLEDGMENTS

I would like to thank Professor W. Nahm for suggesting the problem and some useful discussions. Moreover, I wish to thank Professor F. W. J. Olver and Professor W. B. Jones for bringing the articles Dunster (1994) and Thron (1991) to my attention. In particular, I would like to thank Katrin Wendland for many helpful discussions and a lot of encouragement. I also wish to thank the Physics Department of the UNC at Chapel Hill for hospitality, and the *Studienstiftung des deutschen Volkes* and the *Deutschen Akademischen Austauschdienst* (DAAD) for financial support.

APPENDIX A: THE DIFFERENT CASES IN THE WKB APPROXIMATION

In this Appendix we show the explicit construction of the approximate solutions of the differential equation (3) by the Liouville–Green approximation (WKB) in cases I–IV (cf. Sec. III).

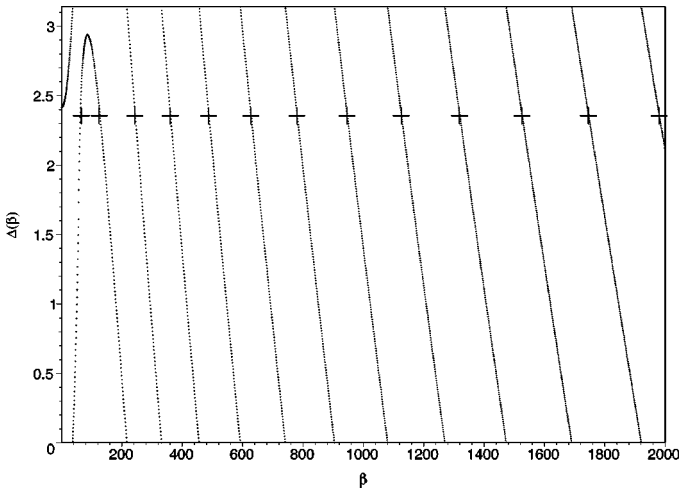

FIG. 14. $\Delta_{7,0}^{\mathrm{WKB}}$ and $\Delta_{7,0}^{\mathrm{Fr}}$ modulo π.

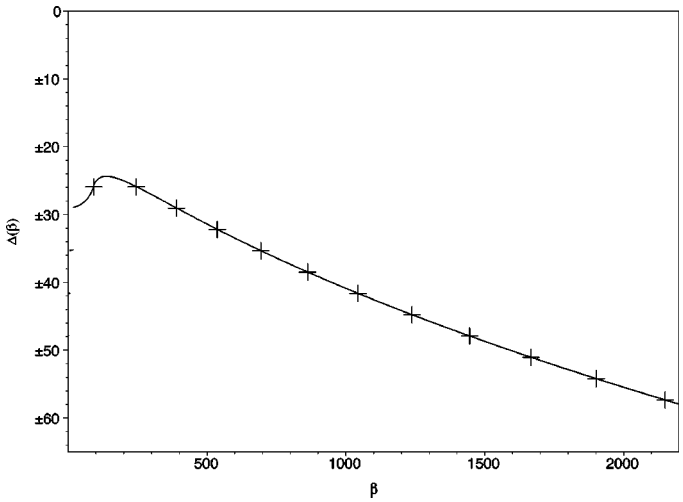

FIG. 15. $\Delta_{9,0}^{\mathrm{WKB}}$ and $\Delta_{9,0}^{\mathrm{Fr}}$.

The construction of an error bound in cases I–III can be found in the references. The construction of the bound in case IV is given in Appendix B and might explain the construction and philosophy behind these error bounds.

To give bounds for the different cases I–IV we need the notion of auxiliary weight, modulus, and phase function E, M, and θ: If X, Y are solutions of the respective differential equation of the first and second kind, then $X=ME^{-1}\sin\theta$ and $Y=EM\cos\theta$.

In particular, in case I we will need E, M, θ for the Airy function [see Olver (1974), Sec. 11.2] for more details),

$$\mathrm{Ai}(x)=\frac{M(x)}{E(x)}\sin\theta(x),\quad \mathrm{Bi}(x)=E(x)M(x)\cos\theta(x).$$

In cases III and IV, we will use the functions E_0, M_0, θ_0 for the Bessel function [see Olver (1974), Secs. 12.1 and 12.3 for more details],

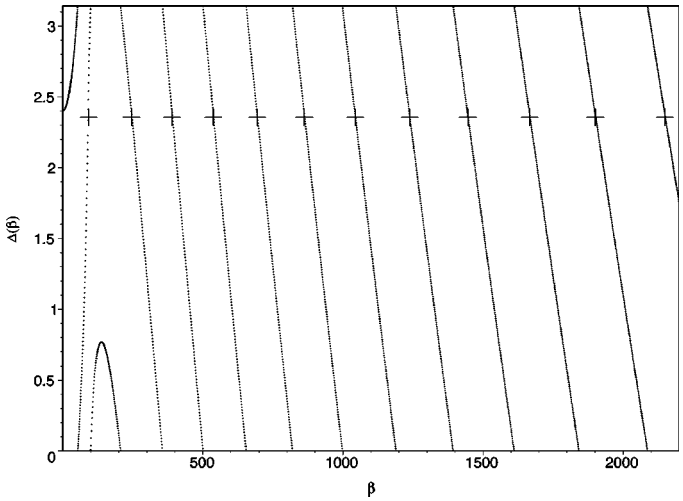

FIG. 16. $\Delta_{9,0}^{\mathrm{WKB}}$ and $\Delta_{9,0}^{\mathrm{Fr}}$ modulo π.

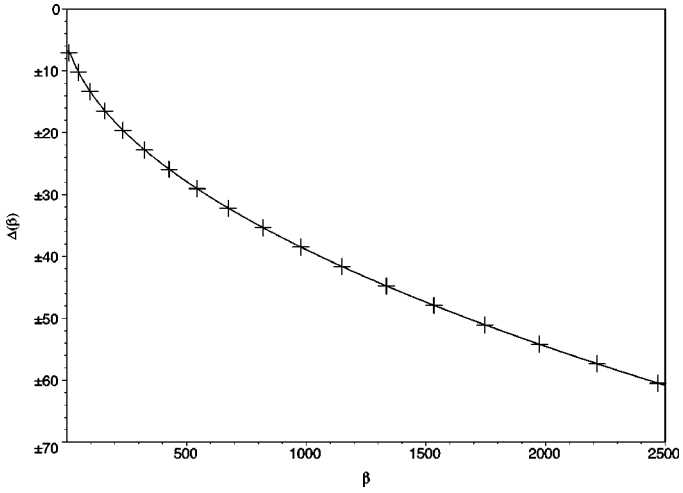

FIG. 17. $\Delta_{2,1}^{\mathrm{WKB}}$ and $\Delta_{2,1}^{\mathrm{Fr}}$.

$$\mathrm{J}_0(x)=\frac{M_0(x)}{E_0(x)}\cos\theta_0(x),\quad \mathrm{Y}_0(x)=E_0(x)M_0(x)\sin\theta_0(x).$$

For case II, the definition of modulus and weight function is the most complicated. Therefore, we refer to [Dunster (1994), Chap. 2, Th. 1] for quite extensive definitions in this case.

1. Case I

In case I it is easy to prove that the function f has a transition point (i.e., simple zero) at $z>1$ which we denote by z_0. The idea is now to perform the transformation of the variable z and the function $w(z)$ to ζ, $W(\zeta)$ according to

$$\begin{cases} \forall\ z\geqslant z_0: & \frac{2}{3}(-\zeta)^{3/2}=\displaystyle\int_{z_0}^{z}\sqrt{f(t)}dt, \\ \forall\ z\leqslant z_0: & \frac{2}{3}\zeta^{3/2}=\displaystyle\int_{z}^{z_0}\sqrt{-f(t)}dt, \end{cases}$$

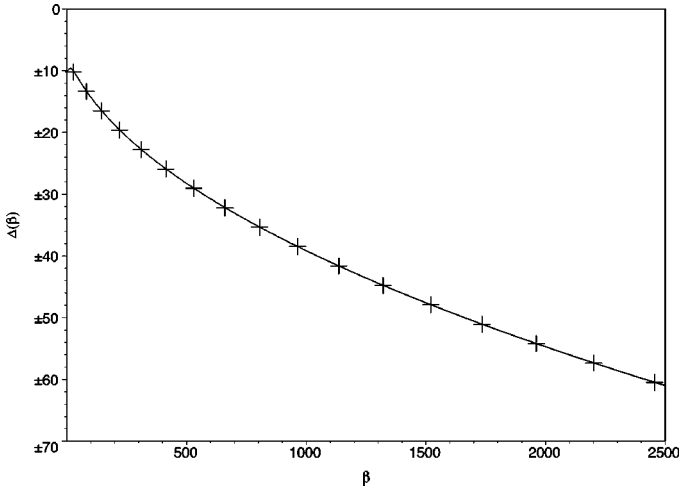

FIG. 18. $\Delta_{3,1}^{\mathrm{WKB}}$ and $\Delta_{3,1}^{\mathrm{Fr}}$.

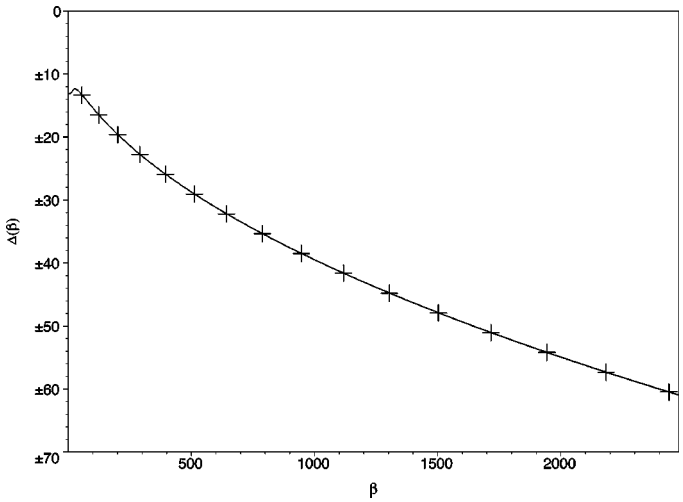

FIG. 19. $\Delta_{4,1}^{\mathrm{WKB}}$ and $\Delta_{4,1}^{\mathrm{Fr}}$.

and $w(z)=\sqrt{-(dz/d\zeta)}W(\zeta)$. Note that $\zeta\to-\infty$ corresponds to $z\to\infty$, $\zeta\to 0-$ to $z\to z_0+$, and $\zeta\to\infty$ to $z\to 1$. Equation (3) becomes

$$\frac{d^2}{d\zeta^2}W(\zeta)=[u^2\zeta+\psi(\zeta)]W(\zeta),$$
$$\psi(\zeta)=\frac{5}{16\zeta^2}-[4f(z)f''(z)-5f'(z)^2]\frac{\zeta}{16f(z)^3}-\frac{\zeta g(z)}{f(z)}. \tag{A1}$$

Approximate solutions of (3), i.e., solutions of (A1) with $\psi=0$, that are regular at $z=1$, are given by Olver (1974) (Sec. 11.3, Th. 3.1),

$$w(z)=\sqrt[4]{-\frac{\zeta}{f(z)}}[\mathrm{Ai}(u^{2/3}\zeta)+\epsilon(u,\zeta)], \tag{A2}$$

with

$$|\epsilon(u,\zeta)|\leqslant\frac{1}{\lambda}\frac{M(u^{2/3}\zeta)}{E(u^{2/3}\zeta)}[e^{(2\lambda/u)\mathcal{V}_{\zeta,\infty}(|\zeta|^{1/2}\mathcal{B}_0(\zeta))}-1].$$

The constant λ and the function $\mathcal{B}_0$ are defined as follows:

$$\lambda:=\sup_x\left\{\pi|x|\frac{1}{2}M^2(x)\right\},$$

$$\mathcal{B}_0(\zeta):=\frac{1}{2\sqrt{|\zeta|}}\int_\zeta^\infty\frac{dv}{|v|^{1/2}}\psi(u,v),$$

and $\mathcal{V}$ is the variational operator, i.e.,

$$\mathcal{V}_{\zeta,\infty}(|\zeta|^{1/2}\mathcal{B}_0(\zeta))=\frac{1}{2}\int_\zeta^\infty\frac{dv}{|v|^{1/2}}|\psi(u,v)|.$$

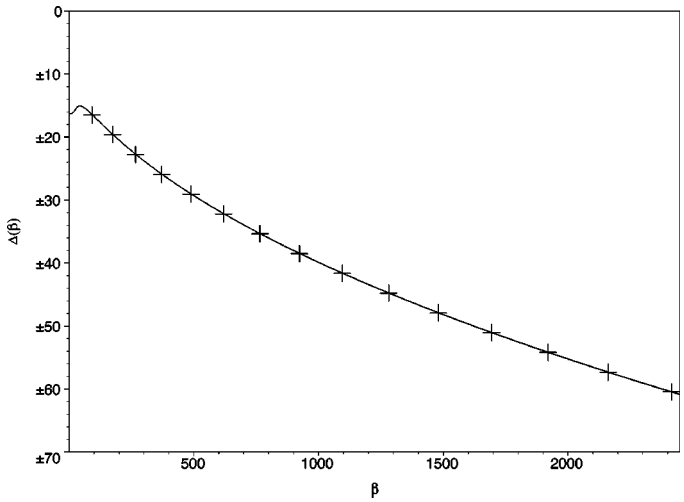

FIG. 20. $\Delta_{5,1}^{\mathrm{WKB}}$ and $\Delta_{5,1}^{\mathrm{Fr}}$.

Following the discussion in Olver (1974) (Sec. 13.7.2) we can determine the behavior for $z\to 1$ and $z\to\infty$,

$$A(z) \xrightarrow{z\to 1} \frac{\sqrt[4]{\beta}}{2\sqrt{\pi q}}(z-1)^{q/2},$$

$$A(z) \overset{z\to\infty}{\sim} \frac{1}{\sqrt{\pi}z^{3/4}}\sin\left(u\int_{z_0}^{z}\sqrt{f(t)}dt+\frac{\pi}{4}+\delta\right),$$

where we have used $\lim_{\zeta\to\infty}\epsilon(u,\zeta)=0$, and the phase δ is determined by $\lim_{\zeta\to\infty}\epsilon(u,\zeta)$. We know that the argument of the sin-function equals $2\sqrt{\beta z}+\Delta_{j,q}$ for large z, i.e.,

$$A(z) \overset{z\to\infty}{\sim} \frac{1}{\sqrt{\pi}z^{3/4}}\sin(2\sqrt{\beta z}+\Delta_{j,q}).$$

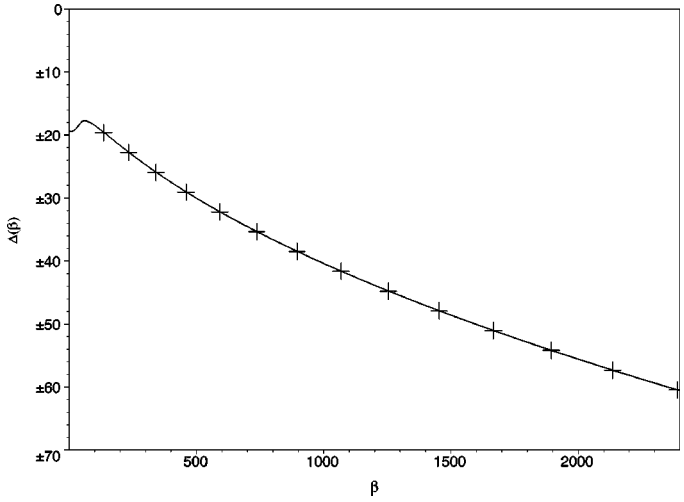

FIG. 21. $\Delta_{6,1}^{\mathrm{WKB}}$ and $\Delta_{6,1}^{\mathrm{Fr}}$.

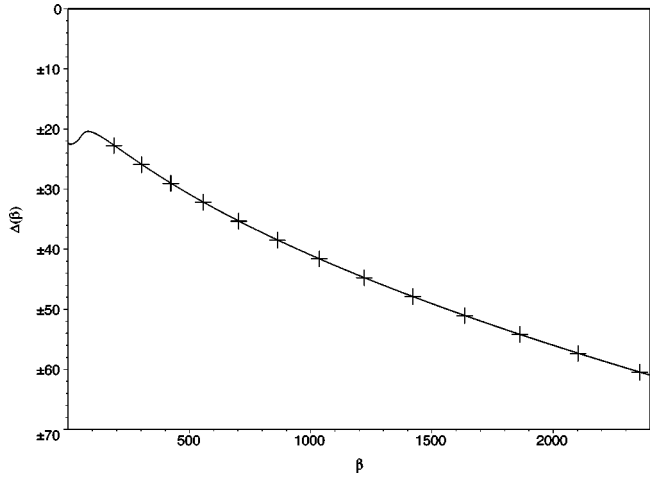

FIG. 22. $\Delta_{7,1}^{\mathrm{WKB}}$ and $\Delta_{7,1}^{\mathrm{Fr}}$.

Therefore, for the scattering phase we obtain

$$\Delta_{j,q} = u \lim_{z\to\infty}\left(\int_{z_0}^{z} \sqrt{f(t)}\,dt - 2\sqrt{z}\right) + \frac{\pi}{4} + \delta,$$

and with the help of Olver (1974) (Sec. 11.2) it follows that

$$\frac{2|\delta|}{\pi} \leqslant \min\left\{ 1, \frac{1}{\lambda}\left[e^{(2\lambda/u)\mathcal{V}_{-\infty,\infty}(|\zeta|^{1/2}\mathcal{B}_0(\zeta))} - 1\right]\right\}. \tag{A3}$$

To resume, the solution (A2) can be considered as relation between the recessive solution and its asymptotic expansion. In this sense, the solution is a *connection formula* and it is known as the *Gans–Jeffreys* formula.

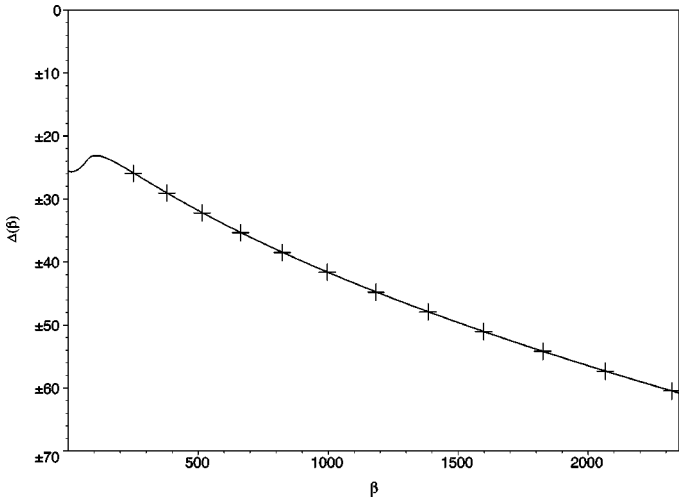

FIG. 23. $\Delta_{8,1}^{\mathrm{WKB}}$ and $\Delta_{8,1}^{\mathrm{Fr}}$.

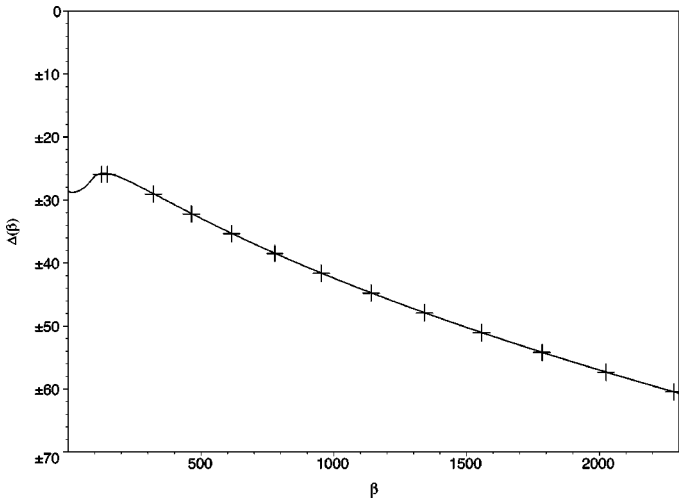

FIG. 24. $\Delta_{9,1}^{\mathrm{WKB}}$ and $\Delta_{9,1}^{\mathrm{Fr}}$.

2. Case II

In case II, $f(z)=(z-a)/(z^2-1)$, we can apply a result of Olver and Nestor that has been generalized in Dunster (1994). The Liouville transformation takes the form,

$$\int_{\alpha}^{\zeta}\left(\frac{\tau-\alpha}{\tau}\right)^{1/2}d\tau=\int_{a}^{z}dt\sqrt{f(t)}$$

with

$$\alpha:=\frac{2}{\pi}\int_{1}^{a}\sqrt{-f(t)}dt.$$

Therefore, we perform the transformation of the variable z and the function $w(z)$ to ζ, $W(\zeta)$ according to

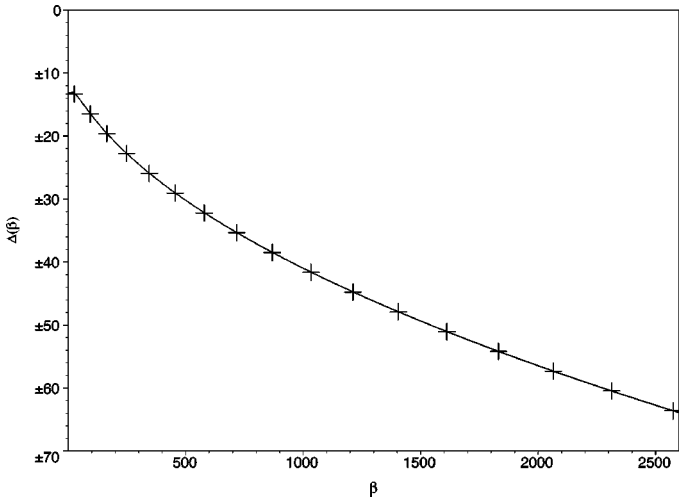

FIG. 25. $\Delta_{4,2}^{\mathrm{WKB}}$ and $\Delta_{4,2}^{\mathrm{Fr}}$.

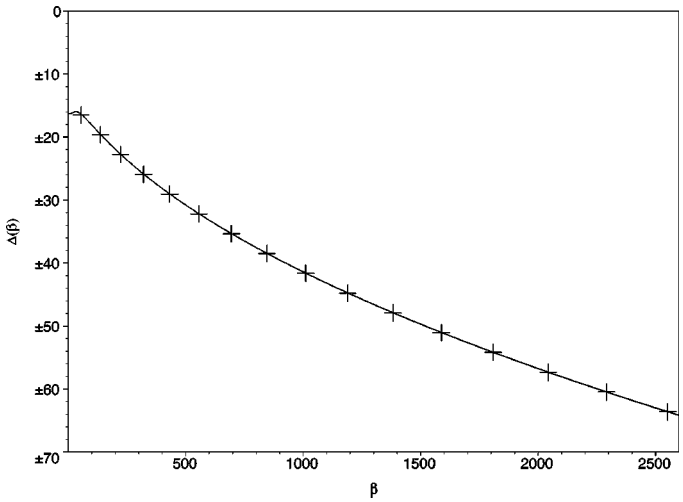

FIG. 26. $\Delta^{\mathrm{WKB}}_{5,2}$ and $\Delta^{\mathrm{Fr}}_{5,2}$.

$$\zeta^{1/2}(\zeta-\alpha)^{1/2}-\frac{\alpha}{2}\ln\left(\frac{2\zeta-\alpha+2\zeta^{1/2}(\zeta-\alpha)^{1/2}}{\alpha}\right)=\int_a^z\sqrt{f(t)}dt$$

and $w(z)=\sqrt{dz/d\zeta}W(\zeta)$. The integral can be expressed through an elliptic integral of the second kind;

$$\int_a^z\sqrt{f(t)}dt=2\sqrt{\frac{(z-a)(z+1)}{z-1}}-2\sqrt{1+a}\,\mathrm{E}\left[\arcsin\left(\sqrt{\frac{z-a}{z-1}}\right),\sqrt{\frac{2}{1+a}}\right].$$

Note that $\zeta\to\alpha$ corresponds to $z\to a$, $\zeta\to 0$ to $z\to 1$, where branches of ζ must be chosen such that it is an analytic function at both values. Moreover, $\zeta\to\infty$ corresponds to $z\to\infty$. Equation (3) becomes

$$\frac{d^2}{d\zeta^2}W(\zeta)=\left[u^2\frac{\alpha-\zeta}{\zeta}-\frac{1}{4\zeta^2}+\frac{\psi(\zeta)}{\zeta}\right]W(\zeta),$$

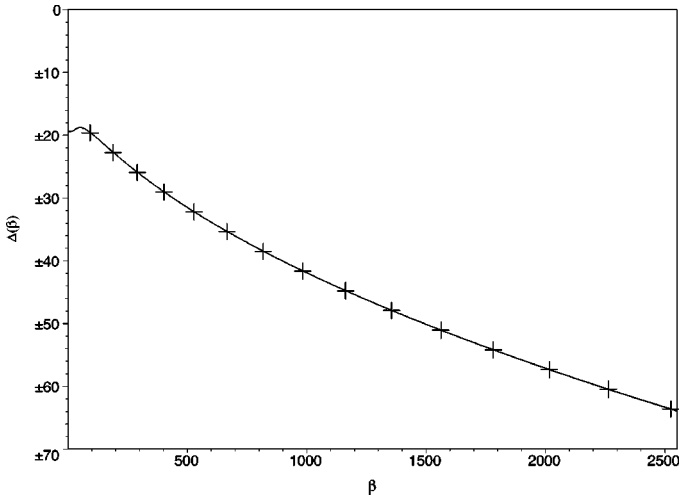

FIG. 27. $\Delta^{\mathrm{WKB}}_{6,2}$ and $\Delta^{\mathrm{Fr}}_{6,2}$.

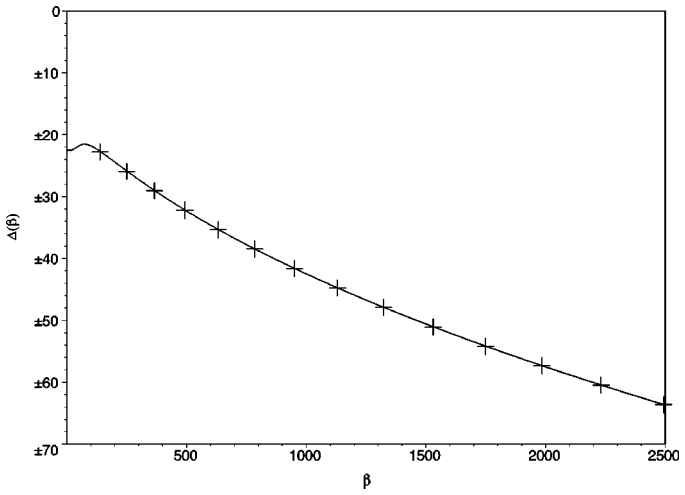

FIG. 28. $\Delta_{7,2}^{\mathrm{WKB}}$ and $\Delta_{7,2}^{\mathrm{Fr}}$.

$$\psi(\zeta)=\frac{4\zeta^2+\alpha^2}{16\zeta(\alpha-\zeta)^2}+[4f(z)f''(z)-5f'(z)^2]\frac{\zeta-\alpha}{16f(z)^3}+\frac{(\zeta-\alpha)g(z)}{f(z)}.$$

Approximate solutions of (3), i.e., solutions of (20) with $\psi=0$, that are regular at $z=1$, are given in Dunster (1994) (Chap. 2, case 1, $m=0$) in terms of the Whittaker function M, i.e.,

$$w(z)=\sqrt[4]{\frac{\zeta-\alpha}{\zeta f(z)}}\left[e^{-(i\pi/4)}\sqrt{\frac{2\pi}{1+e^{\pi u\alpha}}}\,\mathrm{M}_{iu\alpha/2,0}(2iu\zeta)+\epsilon(u,\zeta)\right] \tag{A4}$$

with

$$|\epsilon(u,\zeta)|\leqslant\frac{M^{(1)}_{u\alpha/2,0}(2u\zeta)}{E^{(0)}_{u\alpha/2,0}(2u\zeta)}[e^{\kappa_0(u\alpha/2+1)^{1/3}/2u\mathcal{V}_{\mathcal{P}^{(0)}}(F)}-1].$$

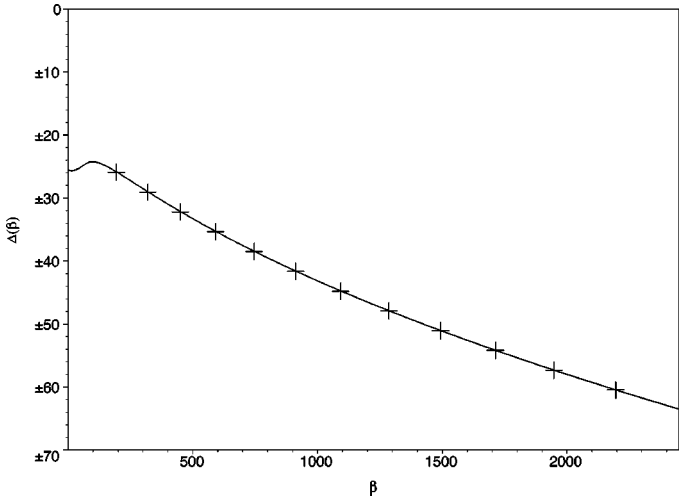

FIG. 29. $\Delta_{8,2}^{\mathrm{WKB}}$ and $\Delta_{8,2}^{\mathrm{Fr}}$.

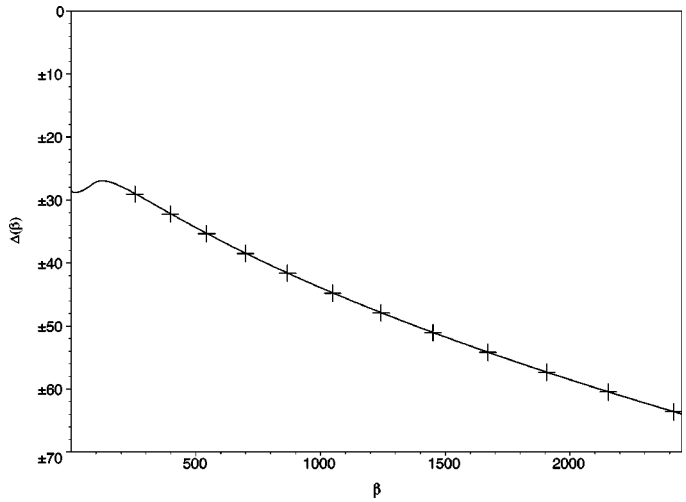

FIG. 30. $\Delta_{9,2}^{\mathrm{WKB}}$ and $\Delta_{9,2}^{\mathrm{Fr}}$.

For the error bound we have adopted the notation of Dunster (1994) (Chap. 2, Th. 1). Using formula (2.19) in Dunster (1994) we determine the behavior of the solution for $z\to 1$,

$$A(z) \xrightarrow{z\to 1} \sqrt{\frac{2\pi}{1+e^{\pi u\alpha}}}\sqrt[4]{\frac{2\alpha u^2}{a-1}}\left(\frac{\zeta}{z-1}\right)^{1/4},$$

where we have used $\lim_{\zeta\to 0}\epsilon(u,\zeta)=0$. A close examination of the Liouville transformation then shows that $\zeta/(z-1)\to(a-1)/(2\alpha)$ for $\zeta\to 0$ and $z\to 1$. Using Dunster (1994) [(2.16)–(2.18)] we obtain for $z\to\infty$,

$$A(z) \overset{z\to\infty}{\sim} \frac{2}{z^{3/4}}\sin\left(u\zeta-\frac{u\alpha}{2}\ln(2u\zeta)+\frac{\pi}{4}+\gamma+\delta\right),$$

where

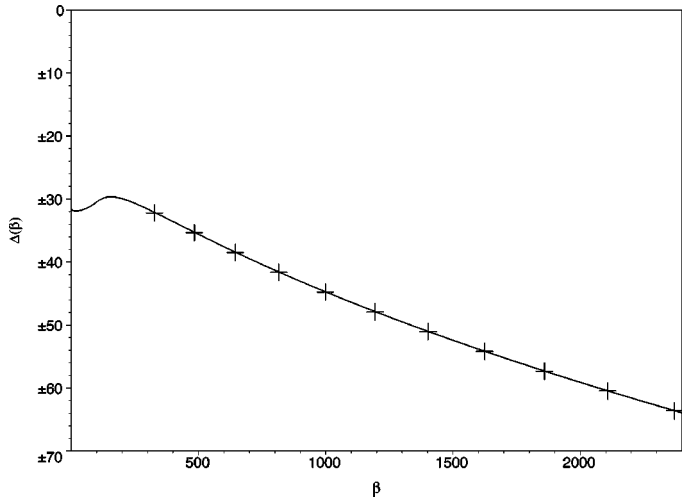

FIG. 31. $\Delta_{10,2}^{\mathrm{WKB}}$ and $\Delta_{10,2}^{\mathrm{Fr}}$.

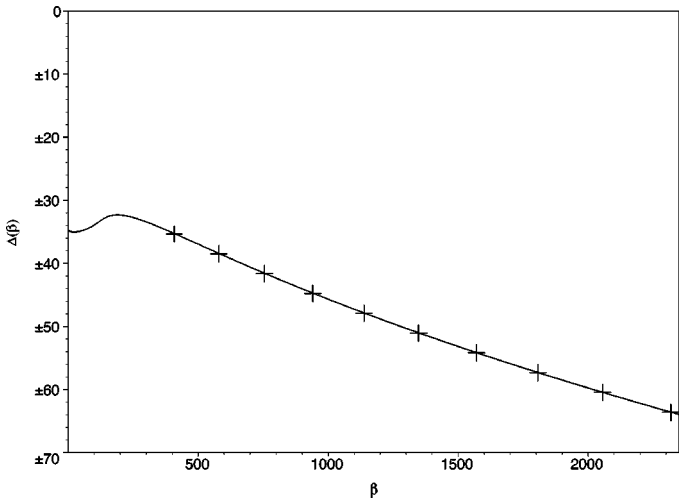

FIG. 32. $\Delta_{11,2}^{\mathrm{WKB}}$ and $\Delta_{11,2}^{\mathrm{Fr}}$.

$$\gamma = \arg\Gamma\left(\frac{1}{2}+\frac{iu\alpha}{2}\right)$$

and the phase δ is determined by $\lim_{\zeta\to\infty}\epsilon(u,\zeta)$. We know that the argument in the sin-function equals $2\sqrt{\beta z}+\Delta_{j,0}$ for large z, i.e.,

$$A(z) \overset{z\to\infty}{\sim} \frac{1}{z^{3/4}}\sin(2\sqrt{\beta z}+\Delta_{j,0}|_{a>1}).$$

A careful examination of the Liouville transformation reveals the following relation between large ζ and z,

$$\zeta-\frac{\alpha}{2}-\frac{\alpha}{2}\ln(\zeta)+\frac{\alpha}{2}\ln\left(\frac{\alpha}{4}\right)+O(\zeta^{-1})=2\sqrt{z}-2\sqrt{1+a}\,\mathrm{E}\left[\sqrt{\frac{2}{1+a}}\right]+O(z^{-(1/2)}).$$

Therefore, for the scattering phase we obtain

$$\begin{aligned}\Delta_{j,0}|_{a>1} &= u\lim_{z\to\infty}\left(\zeta-\frac{\alpha}{2}\ln(2u\zeta)-2\sqrt{z}\right)+\frac{\pi}{4}+\gamma+\delta\\ &= -2u\sqrt{1+a}\,\mathrm{E}\left[\sqrt{\frac{2}{1+a}}\right]+\frac{\alpha u}{2}-\frac{\alpha u}{2}\ln\left(\frac{\alpha u}{2}\right)+\frac{\pi}{4}+\gamma,\end{aligned}$$

$$\gamma = \arg\Gamma\left(\frac{1}{2}+\frac{iu\alpha}{2}\right), \tag{A5}$$

$$\frac{2|\delta|}{\pi} \leqslant \min\{1,[e^{\kappa_0(u\alpha/2+1)^{1/3}/2u\mathcal{V}_{\mathcal{P}^{(0)}}(F)}-1]\}.$$

The phase $\Delta_{j,0}|_{a>1}$ differs from the one obtained in Mignemi (1991).

3. Case III

In case III, the function f has neither a transition point nor a pole for $z \geqslant 1$. This case can be understood as the limit $a \to 1$ of case II, and applying further results of Olver's (1977), in this limit the Whittaker function will become the Bessel function J_0.

The idea is to perform the transformation of the variable z and the function $w(z)$ to ζ, $W(\zeta)$ according to

$$\zeta = \int_1^z \sqrt{f(t)}\,dt = 2\sqrt{z+1} - 2\sqrt{2}$$

and $w(z) = \sqrt{dz/d\zeta}\,W(\zeta)$. Note that $\zeta \to \infty$ corresponds to $z \to \infty$ and $\zeta \to 0$ to $z \to 1$. Equation (3) becomes

$$\begin{aligned} \frac{d^2}{d\zeta^2} W(\zeta) &= \left[-u^2 - \frac{1}{4\zeta^2} + \frac{\psi(\zeta)}{\zeta} \right] W(\zeta), \\ \psi(\zeta) &= \frac{1}{4\zeta} + [4f(z)f''(z) - 5f'(z)^2] \frac{\zeta}{16 f(z)^3} + \frac{\zeta g(z)}{f(z)}. \end{aligned} \tag{A6}$$

Approximate solutions of (3), i.e., solutions of (A6) with $\psi = 0$, that are regular at $z = 1$, are given by Olver (1977) (Chap. 5, Th. 2, case 2, $\nu = 0$, $\mu = 0$), i.e.,

$$w(z) = \frac{1}{\sqrt[4]{f(z)}} [\zeta^{1/2} \mathrm{J}_0(u\zeta) + \epsilon(u,\zeta)], \tag{A7}$$

with

$$|\epsilon(u,\zeta)| \leqslant \frac{l_{0,1}}{l_{0,0}} \frac{M_0(u\zeta)}{E_0(u\zeta)} [e^{l_{0,0} \mathcal{V}_{0,\zeta}(H)} - 1].$$

The constants $l_{0,0}$, $l_{0,1}$, and the function H are defined as follows:

$$l_{0,0} := \sup_x \{\pi \Omega_0(x) M_0^2(x)\},$$

$$l_{0,1} := \sup_x \{\pi \Omega_0(x) |J_0(x)| E_0(x) M_0(x)\},$$

$$H(u,\zeta) := \frac{1}{2} \int \frac{\psi(u,\zeta)}{\Omega_0(\zeta)}\,d\zeta,$$

$$\Omega_0(x) := \frac{1+x}{\ln\left(e + \frac{1}{x}\right)},$$

and $\mathcal{V}$ is the variational operator, i.e.,

$$\mathcal{V}_{0,\zeta}(H) = \frac{1}{2} \int_0^\zeta \frac{dv}{\Omega_0(uv)} |\psi(u,v)|.$$

We determine the behavior of the solutions for $z \to 1$ and $z \to \infty$,

$$A(z) \xrightarrow{z\to 1} \frac{1}{\sqrt{2}} J_0\left(u\,\frac{z-1}{\sqrt{2}}\right) \to \frac{1}{\sqrt{2}},$$

$$A(z) \overset{z\to\infty}{\sim} \frac{\sqrt{2}}{\sqrt{\pi u} z^{3/4}} \sin\left(u \int_1^z \sqrt{f(t)}\,dt + \frac{\pi}{4} + \delta\right),$$

where we have used $\lim_{\zeta\to 0+} \epsilon(u,\zeta)=0$, and the phase δ is determined by $\lim_{\zeta\to\infty} \epsilon(u,\zeta)$. We know that the argument of the sin-function equals $2\sqrt{\beta z}+\Delta_{j,0}|_{a=1}$ for large z, i.e.,

$$A(z) \overset{z\to\infty}{\sim} \frac{\sqrt{2}}{\sqrt{\pi u} z^{3/4}} \sin(2\sqrt{\beta z}+\Delta_{j,0}|_{a=1}).$$

Therefore, for the scattering phase we obtain

$$\Delta_{j,0}|_{a=1} = u \lim_{z\to\infty}\left(\int_1^z \sqrt{f(t)}\,dt - 2\sqrt{z}\right) + \frac{\pi}{4} + \delta = -\sqrt{8\beta} + \frac{\pi}{4} + \delta$$

and with the help of Olver (1977) (Chap. 5) and analogous to Appendix B the bound for ϵ in (A7) gives a bound for the phase δ. It follows that

$$\frac{2|\delta|}{\pi} \leqslant \min\left\{ 1, \frac{l_{0,1}}{l_{0,0}} [e^{l_{0,0}/u \mathcal{V}_{0,\infty}(H)} - 1]\right\}. \tag{A8}$$

The phase $\Delta_{j,0}$ differs from the one obtained in Mignemi (1991) by $\pi/4$.

4. Case IV

In case IV the function f has no transition point for $z \geqslant 1$ and takes the form $f(z)=(z-a)/(z^2-1)$. The idea is now to perform the transformation of the variable z and the function $w(z)$ to ζ, $W(\zeta)$ according to

$$(-\zeta)^{1/2} = \int_1^z \sqrt{f(t)}\,dt$$

and $w(z)=\sqrt{-(dz/d\zeta)}W(\zeta)$. The integral can be expressed through elliptic integrals of the first and second kind,

$$\int_1^z \sqrt{f(t)}\,dt = 2\sqrt{\frac{z^2-1}{z-a}} + (1-a)\sqrt{2}\,\mathrm{F}\left[\arcsin\left(\sqrt{\frac{z-1}{z-a}}\right), \sqrt{\frac{1+a}{2}}\right]$$
$$-2\sqrt{2}\,\mathrm{E}\left[\arcsin\left(\sqrt{\frac{z-1}{z-a}}\right), \sqrt{\frac{1+a}{2}}\right].$$

Note that $\zeta\to-\infty$ corresponds to $z\to\infty$ and $\zeta\to 0-$ to $z\to 1+$. Equation (3) becomes

$$\frac{d^2}{d\zeta^2} W(\zeta) = \left[\frac{u^2}{4\zeta} - \frac{1}{4\zeta^2} + \frac{\psi(\zeta)}{\zeta}\right] W(\zeta),$$
$$\psi(\zeta) = \frac{1}{16\zeta} - \frac{g(z)}{4f(z)} - \frac{4f(z)f''(z) - 5f'(z)^2}{64 f(z)^3}. \tag{A9}$$

Approximate solutions of (3), i.e., solutions of (A9) with $\psi=0$, that are regular at $z=1$, are then given by Olver (1974) (Sec. 12.4, Th. 4.1, $\nu=0$, $n=0$), i.e.,

$$\omega(z)=\frac{1}{\sqrt[4]{4|\zeta|f(z)}}[|\zeta|^{1/2}J_0(u|\zeta|^{1/2})+\epsilon(u,\zeta)] \tag{A10}$$

with

$$|\epsilon(u,\zeta)|\leqslant\frac{\lambda_{0,1}}{\lambda_{0,0}}|\zeta|^{1/2}\frac{M_0(u\zeta)}{E_0(u\zeta)}[e^{\lambda_{0,0}/u\mathcal{V}_{\zeta,0}(|\zeta|^{1/2}\mathcal{B}_0(\zeta))}-1].$$

The bound for the error ϵ is derived in Appendix B. The constants $\lambda_{0,0},\lambda_{0,1}$, as well as the function $\mathcal{B}_0$ are defined as follows:

$$\lambda_{0,0}:=\sup_{x\geqslant 0}\{\pi x M_0^2(x)\},$$

$$\lambda_{0,1}:=\sup_{x\geqslant 0}\{\pi x M_0^2(x),\cos\theta_0(x)\},$$

$$\mathcal{B}_0(\zeta):=\frac{1}{|\zeta|^{1/2}}\int_\zeta^0\frac{dv}{|v|^{1/2}}\psi(v),$$

and $\mathcal{V}$ is the variational operator, i.e.,

$$\mathcal{V}_{\zeta,0}(|\zeta|^{1/2}\mathcal{B}_0(\zeta))=\int_\zeta^0\frac{dv}{|v|^{1/2}}|\psi(v)|,$$

We determine the behavior of the solutions for $z\to 1$ and $z\to\infty$,

$$A(z)\xrightarrow{z\to 1}\frac{1}{\sqrt{2}}J_0(u\sqrt{2(1-a)}\sqrt{z-1})\to\frac{1}{\sqrt{2}},$$

$$A(z)\overset{z\to\infty}{\sim}\frac{1}{\sqrt{\pi u}z^{3/4}}\sin\left(u\int_1^z\sqrt{f(t)}dt+\frac{\pi}{4}+\delta\right),$$

where we have used that $\lim_{\zeta\to 0-}\epsilon(u,\zeta)=0$ and the phase δ is determined by $\lim_{\zeta\to-\infty}\epsilon(u,\zeta)$. We know that the argument of the sin-function equals $2\sqrt{\beta z}+\Delta_{j,0}$ for large z, i.e.,

$$A(z)\sim\frac{1}{\sqrt{\pi u}z^{3/4}}\sin(2\sqrt{\beta z}+\Delta_{j,0}).$$

Therefore, we obtain for the scattering phase,

$$\begin{aligned}\Delta_{j,0}|_{a<1}&=u\lim_{z\to\infty}\left(\int_1^z\sqrt{f(t)}dt-2\sqrt{z}\right)+\frac{\pi}{4}+\delta\\&=(1-a)\sqrt{2\beta}\,\mathrm{K}\left[\sqrt{\frac{1+a}{2}}\right]-2\sqrt{2\beta}\,\mathrm{E}\left[\sqrt{\frac{1+a}{2}}\right]+\frac{\pi}{4}+\delta.\end{aligned}$$

In addition, we will derive in Appendix B,

$$\frac{2|\delta|}{\pi} \leqslant \min\left\{1, \frac{\lambda_{0,1}}{\lambda_{0,0}}\left[e^{(\lambda_{0,0}/u)\mathcal{V}_{-\infty,0}(|\zeta|^{1/2}\mathcal{B}_0(\zeta))} - 1\right]\right\}. \tag{A11}$$

The phase $\Delta_{j,0}|_{a<1}$ differs from the one obtained in Mignemi (1991) by $\pi/4$ and the factor in front of the elliptic integral of the first kind.

APPENDIX B: ERROR BOUNDS

In this Appendix we apply the construction of error bounds presented in Olver (1974) (Sec. 11.3) to case IV [cf. Olver (1974) (Sec. 12.4, Ex. 4.4)]. In case IV the Bessel functions $|\zeta|^{1/2}\mathrm{J}_0(u|\zeta|^{1/2})$ and $|\zeta|^{1/2}\mathrm{Y}_0(u|\zeta|^{1/2})$ of the first and second type, are first approximations for W. They are exact solutions if $\psi \equiv 0$. Substituting $W(\zeta) = |\zeta|^{1/2}\mathrm{J}_0(u|\zeta|^{1/2}) + \epsilon(u,\zeta)$, the differential equation becomes

$$\frac{d^2}{d\zeta^2}\epsilon(u,\zeta) - \left[\frac{u^2}{4\zeta} - \frac{1}{4\zeta^2}\right]\epsilon(u,\zeta) = \frac{\psi(\zeta)}{\zeta}\left[\epsilon(u,\zeta) + |\zeta|^{1/2}\mathrm{J}_0(u|\zeta|^{1/2})\right].$$

If we rewrite it as an integral equation we obtain a Volterra integral equation,

$$\epsilon(u,\zeta) = \int_{\zeta}^{0} \mathrm{K}(\zeta,v)\frac{\psi(v)}{|v|^{1/2}}\left[\epsilon(v) + |v|^{1/2}\mathrm{J}_0(u|v|^{1/2})\right]dv,$$

where

$$\mathrm{K}(\zeta,v) = \pi|v|^{1/2}\left[\mathrm{J}_0(u|\zeta|^{1/2})\mathrm{Y}_0(u|v|^{1/2}) - \mathrm{Y}_0(u|\zeta|^{1/2})\mathrm{J}_0(u|v|^{1/2})\right].$$

Using the fact that E_0 is a nonincreasing function we obtain

$$\forall\, \zeta \leqslant v \leqslant 0: \quad |\mathrm{K}(\zeta,v)| \leqslant \underbrace{\frac{M_0(u|\zeta|^{1/2})}{E_0(u|\zeta|^{1/2})}}_{=:P_0(\zeta)} \underbrace{\pi|v|^{1/2}M_0(u|v|^{1/2})E_0(u|v|^{1/2})}_{=:Q(v)}.$$

We introduce the parameters κ_0, κ by

$$\kappa_0 := \sup_{v\in[\zeta,0]}\{P_0(v)Q(v)\} \leqslant \frac{\lambda_{0,0}}{u},$$

$$\kappa := \sup_{v\in[\zeta,0]}\{Q(v)||v|^{1/2}\mathrm{J}_0(u|v|^{1/2})|\} \leqslant \frac{|\zeta|^{1/2}\lambda_{0,1}}{u}.$$

With the help of Olver (1974) (Sec. 6.10, Th. 10.2) which establishes a bound for the solution of a Volterra integral equation we end up with a bound for ϵ,

$$\frac{|\epsilon(u,\zeta)|}{P_0(\zeta)} \leqslant \frac{\kappa}{\kappa_0}\left[\exp\{\kappa_0\mathcal{V}_{\zeta,0}(|\zeta|^{1/2}\mathcal{B}_0(\zeta))\} - 1\right] \leqslant |\zeta|^{1/2}\frac{\lambda_{0,1}}{\lambda_{0,0}}\left[\exp\left\{\frac{\lambda_{0,0}}{u}\mathcal{V}_{\zeta,0}(|\zeta|^{1/2}\mathcal{B}_0(\zeta))\right\} - 1\right]. \tag{B1}$$

We are interested in an error bound for the phase in the asymptotic expansion of the solution. Assume that the solution W takes the following form for large arguments ζ:

$$W(u,\zeta) \overset{\zeta\to\infty}{\sim} \left(\frac{2|\zeta|^{1/2}}{\pi u}\right)^{1/2}\left((1+\rho)\sin\left(u|\zeta|^{1/2} + \frac{\pi}{4} + \delta\right) + o(1)\right).$$

As in Olver (1974) (Sec. 6.7) we rewrite the difference of the exact and the approximate solution as a trigonometric function,

$$\epsilon(u,\zeta)=W(u,\zeta)-|\zeta|^{1/2}\mathrm{J}_0(u|\zeta|^{1/2})$$

$$\overset{\zeta\to\infty}{\sim}\left(\frac{2|\zeta|^{1/2}}{\pi u}\right)^{1/2}\left\{[1+\rho]\sin\left(u|\zeta|^{1/2}+\frac{\pi}{4}+\delta\right)-\sin\left(u|\zeta|^{1/2}+\frac{\pi}{4}\right)\right\}$$

$$=\left(\frac{2|\zeta|^{1/2}}{\pi u}\right)^{1/2}\sigma\sin\left(u|\zeta|^{1/2}+\frac{\pi}{4}+\eta\right),$$

where the new parameters σ (always considered to be positive) and η are related to ρ and δ by

$$(1+\rho)e^{i\delta}=1+\sigma e^{i\eta}.$$

By elementary geometry it follows that $2|\delta|/\pi\leqslant\sigma$. Then, the bound for ϵ in (B1) gives a bound for σ. Now, we choose a sequence (ζ_n) with $\lim_{n\to\infty}\zeta_n=-\infty$ for which $u|\zeta|^{1/2}+(\pi/4)+\eta$ is an odd integer multiple of $\pi/2$. This shows that

$$\sigma_{\zeta\to-\infty}=\lim_{\zeta\to-\infty}\left(\frac{\pi u}{2|\zeta|^{1/2}}\right)^{1/2}|\epsilon(u,\zeta)|.$$

Finally, since

$$M_0(x)\overset{x\to\infty}{\sim}\left(\frac{2}{\pi x}\right)^{1/2},$$

$$E_0(x)\overset{x\to\infty}{=}1,$$

we obtain a bound for δ,

$$\frac{2|\delta|}{\pi}\leqslant\min\left\{1,\frac{\lambda_{0,1}}{\lambda_{0,0}}[e^{(\lambda_{0,0}/u)\mathcal{V}_{-\infty,0}(|\zeta|^{1/2}\mathcal{B}_0(\zeta))}-1]\right\}.$$

(Received 27 November 2002; accepted 21 April 2003)

We introduce and study, in the framework of a theory of quantum Cartan domains, a q-analog of the Berezin transform on the unit ball. We construct q-analogs of weighted Bergman spaces, Toeplitz operators, and covariant symbol calculus. In studying the analytical properties of the Berezin transform we introduce also the q-analog of the SU(n,1)-invariant Laplace operator (the Laplace–Beltrami operator) and present related results on harmonic analysis on the quantum ball. These are applied to obtain an analog of one result by A. Unterberger and H. Upmeier. An explicit asymptotic formula expressing the q-Berezin transform via the q-Laplace–Beltrami operator is also derived. At the end of the article, we give an application of our results to basic hypergeometric q-orthogonal polynomials.
 [DOI: 10.1063/1.1593226]

I. INTRODUCTION

Since the appearance of quantum groups in the middle of the 1980s there have been different attempts to find an appropriate generalization to the q-case of various classical constructions in the analysis and geometry of Lie groups. Recently, it became clear[1] that there should exist a substantial q-analog of the theory of Cartan domains (the most studied class of such domains constitutes the so-called classical domains[2]). In turn, this observation has opened a way to generalization of other important theories about those domains. One of the most fascinating among them is the Berezin quantization.[3] Though Berezin applied his construction to a wide class of Kähler manifolds, the most complete and precise results have been obtained just in the particular case of Cartan domains.[4,5]

It should be noted that first attempts to find q-analogs of some constructions of the Berezin theory were made before the study of q-Cartan domains was initiated. For example, in Ref. 6 the authors studied a two-parameter deformation $\mathcal{P}_{q,\lambda}$ of the polynomial algebra $\mathbb{C}[z,\bar{z}]$ related to certain SU(1,1)-covariant Poisson brackets on the unit disk. They showed, among other things, that for any λ the algebra $\mathcal{P}_{q,\lambda}$ is acted upon by the quantum universal enveloping algebra $U_q\mathfrak{sl}_2$. Also, for each q the authors defined q-analogs of the weighted Bergman spaces $L^2_a((1-|z|^2)^\lambda d\bar{z}dz)$ ($\lambda \geqslant 0$) on the unit disk and showed that $\mathcal{P}_{q,\lambda}$ could be realized as the algebra of Toeplitz operators (with symbols from $\mathcal{P}_{q,0}$) on the q-weighted Bergman space corresponding to λ. This observation suggests that it is reasonable to regard $\mathcal{P}_{q,0}$ as a genuine function algebra on the *quantum* unit disk and $\mathcal{P}_{q,\lambda}$ as a result of the Toeplitz quantization of $\mathcal{P}_{q,0}$ which, in addition, respects the $U_q\mathfrak{sl}_2$-actions in complete analogy with the classical setting.

This point of view was developed in detail in Ref. 7. There, in addition to the results of Ref. 6, q-analogs of covariant symbols and of the Berezin transform on the quantum unit disk were produced (see Ref. 8 for a concise account). Also, in Ref. 7 an explicit asymptotic formula, expressing the q-Berezin transform via a q-Laplace–Beltrami operator on the quantum disk, was

a)Electronic mail: shklyarov@ilt.kharkov.ua
b)Author to whom correspondence should be addressed. Electronic mail: genkai@math.chalmers.se

derived. This allowed the authors to produce an analog of the Berezin star product and thus to obtain a formal deformation of the algebra $\mathcal{P}_{q,0}$.

The present article continues the study of the q-Berezin transform initiated in Ref. 7. Here we investigate the case of the quantum unit ball, whose one-dimensional version is the aforementioned quantum unit disk, and generalize to this case almost all constructions of Ref. 7. Namely, we produce analogs of the weighted Bergman spaces, Toeplitz operators, covariant symbols, and the Berezin transform on the unit ball. Also, we define a q-analog of the SU(n,1)-invariant Laplace operator (the Laplace–Beltrami operator) and derive an explicit asymptotic formula expressing the q-Berezin transform via the q-Laplace–Beltrami operator.

It is appropriate to mention here that in the case of the quantum unit ball we encounter a new phenomenon imperceptible in the case of the quantum unit disk. Namely, there is not any satisfactory analog of coherent states on the ball which are used to define covariant symbols of operators and regarded as a basic ingredient of the Berezin's theory. An appropriate analog for the quantum unit disk was found in Ref. 7. However, that was possible due to commutativity of the algebra of ''holomorphic functions'' on the quantum disk, but the commutativity fails in the case of the quantum ball. Fortunately, even in the classical setting there is an alternative way to define covariant symbols. Namely, the map

$$\begin{array}{c}\text{operator on a}\\ \text{weighted Bergman space}\end{array} \mapsto \begin{array}{c}\text{covariant symbol,}\\ \text{a function on the ball}\end{array}$$

is, roughly speaking, the adjoint of the map

$$\begin{array}{c}\text{function}\\ \text{on the ball}\end{array} \mapsto \begin{array}{c}\text{Toeplitz operator on a}\\ \text{weighted Bergman space}\end{array}$$

with respect to certain SU(n,1)-invariant inner products in the spaces of functions and operators (see Ref. 5). The significance of the Toeplitz and covariant calculi is of course well known and has been intensively studied. We exploit just this idea to define covariant symbols and thus the Berezin transform in the q-setting.

Let us turn now to description of the contents of the article.

Our results rely heavily on function theory in the quantum unit ball. In Sec. II we recall the basic setup and results from that theory obtained earlier by L. Vaksman and his group[9,10] in the more general setting of quantum *matrix* balls. In brief, we define an involutive algebra of ''polynomials'' on the quantum $\mathbb{C}^n$ which generalize the algebra $\mathcal{P}_{q,0}$ mentioned above. The algebra is endowed with an action of the quantum universal enveloping algebra $U_q\mathfrak{su}_{n,1}$. This is a counterpart of the classical SU(n,1)-action on the unit ball. Using the polynomial algebra, we produce the spaces of ''finite functions'' and ''distributions'' on the quantum ball which inherit the $U_q\mathfrak{su}_{n,1}$-action. The crucial property, which justifies our definition of the space of finite functions on the quantum ball, is the existence of a $U_q\mathfrak{su}_{n,1}$-invariant integral on that space, an analog of the integral with respect to the SU(n,1)-invariant measure on the ball. We present an explicit formula for that integral. We note that the existence of the integral allows one to formulate many problems of harmonic analysis on the quantum ball. Though the present article does not deal with harmonic analysis, we develop some partial results (see description of Sec. IV below) which are needed to put our result in a coherent and rigorous mathematics context.

Section III is devoted to find an appropriate algebraic and analytical setting. There we start developing of the q-Berezin's theory and present all necessary definitions. First, we define analogs of the weighted Bergman spaces in the ball and produce the notion of Toeplitz operators with polynomial or finite symbols. Though the finite symbols are of more importance for our exposition, we devote a separate subsection to the study of the algebra of Toeplitz operators with polynomial symbols. This is motivated by the observation that this algebra is a multivariable generalization of the algebra $\mathcal{P}_{q,\lambda}$ studied in Ref. 6. Results of Ref. 6 suggest that the algebra of Toeplitz operators with polynomial symbols might be interesting from the point of view of the theory of operator algebras. In the last subsection we present definitions of covariant symbols and

of the q-Berezin transform. Thus, in Sec. III we define three important maps: the map that sends a function to the corresponding Toeplitz operator, the map that sends an operator to its covariant symbol (a function on the quantum ball), and, finally, their composition—the q-Berezin transform—which sends a function to the covariant symbol of the corresponding Toeplitz operator. We observe also that the three maps intertwine natural $U_q\mathfrak{su}_{n,1}$-actions on the spaces of functions and operators. This quantum group symmetry of the q-Berezin transform simplifies drastically many computations in subsequent sections.

To investigate the q-Berezin transform further, for instance, to find its asymptotic expansion, we need some results on harmonic analysis, particularly on q-spherical transform in the quantum ball. These are presented in Sec. IV. First of all, we define there an analog of the Laplace–Beltrami operator on the ball. At first sight, our definition seems to be somewhat unusual: the q-Laplace–Beltrami operator appears as the first term in the asymptotic expansion of the q-Berezin transform. However, this agrees with the classical Berezin's theory. Besides, we believe that results of Sec. IV provide a sufficient evidence of rationality of such a definition. In particular, a ''radial part'' of our q-Laplace–Beltrami operator turns out to be a second order difference operator which tends to the radial part of the classical Laplace–Beltrami operator as q approaches 1. Moreover, the difference operator turned out to be quite well studied by experts in the theory of q-special functions (see, for instance, Ref. 11). In particular, the problem of expansion in eigenfunctions of that difference operator had been already solved, and we recall explicit formulas in the text. In view of our approach, those eigenfunctions should be regarded as analogs of the spherical functions on the ball while the expansion is an analog of the spherical transform (see Ref. 12). Moreover, the Plancherel measure, which appears in the inverse transform, involves an analog of the Harish–Chandra c-function for the ball.

After we present the results on the q-spherical transform, we turn back in Sec. V to the study of the q-Berezin transform. In the first subsection of Sec. V we consider its ''radial part.'' We prove that the radial part of the transform is extended to a bounded self-adjoint operator on the space of square-integrable radial function on the quantum ball (we mean square-integrability with respect to the invariant q-integral). Moreover, the resulting operator commutes with the radial part of the q-Laplace–Beltrami operator which is also a bounded self-adjoint operator on the same space. Since the latter operator has simple spectrum (this is stated in Sec. IV), the radial part of the q-Berezin transform appears to be a function of the radial part of the q-Laplace–Beltrami operator. We found the function explicitly. We note that in the classical case the corresponding result was obtained in Ref. 5 for any Cartan domain. This computation has a number of consequences, some of which we use further in Sec. VI. In the last subsection of Sec. V, we present an asymptotic formula expressing the q-Berezin transform via the q-Laplace–Beltrami operator.

Section VI is meant for those readers who are interested in various mathematical applications of the Berezin transform. It is, however, nevertheless related to quantization. In the theory of Wick quantization one associates to each function an operator so that the one-dimensional projections onto the coherent state at a point (in the phase space) are assigned to the delta function. However, if the given Hilbert space has an orthogonal basis, the projections onto the basis vectors are also natural subjects so it is interesting to compute their covariant symbols. Here in our setting we show that the spherical transforms of those covariant symbols are, roughly speaking, hypergeometric orthogonal q-polynomials. We derive orthogonality relations for those orthogonal polynomials, the so-called continuous dual q-Hahn polynomials.[13] The entire family of these polynomials depends on three parameters (not counting q) while we treat a two-parameter subfamily which appears naturally in connection with the q-Berezin transform. The idea we use appeared for the first time in Ref. 14 in the classical setting (see also Ref. 15).

Let us make some comments about the most important agreements and notations used in the article. First of all, the quantum-group parameter q is supposed to be a number from the interval (0,1). Next, we put $h:=\log q^{-2}$, so $h>0$; $t:=q^{2\alpha}$ will be the deformation parameter in the Berezin transform. Finally, we describe some convenient multi-index notations. We denote multi-indices by underlined small letters, the zero multi-index by $\underline{0}$. For $\underline{i}=(i_1,\ldots,i_n)$, $\underline{j}=(j_1,\ldots,j_n)$ we put

$|\underline{i}|=i_1+i_2+\cdots+i_n$ and $\underline{i}\times\underline{j}=(i_1\cdot j_1,\ldots,i_n\cdot j_n)$. For noncommuting variables $z_1,z_2,\ldots,z_n$ and $z_1^*,z_2^*,\ldots,z_n^*$ we set

$$\mathbf{z}^{\underline{i}}:=z_n^{i_n}\cdot z_{n-1}^{i_{n-1}}\cdot\ \cdots\ \cdot z_1^{i_1},\quad \mathbf{z}^{*\underline{i}}:=z_1^{*i_1}\cdot\ \cdots\ \cdot z_{n-1}^{*i_{n-1}}\cdot z_n^{*i_n}.$$

Finally, we denote $P(n)=\{\underline{k}\in\mathbb{Z}^n_{\geqslant 0}\ \mid\ k_1\geqslant k_2\geqslant\cdots\geqslant k_n\}$.

II. BASICS OF FUNCTION THEORY IN THE QUANTUM UNIT BALL

The aim of Sec. II is to introduce some notions of function theory in the quantum ball. We define the involutive algebra of finite functions and the space of distributions on the q-ball. These spaces admit actions of certain quantum universal enveloping algebra. Finally, we produce an explicit formula for the invariant integral on the space of finite functions. The material presented in this section is not new: the quantum ball treated here is a particular case of the quantum *matrix* ball considered in details in Refs. 9 and 10. Most results can be found in those papers, however, we reformulate some of them for our particular purpose.

A. Polynomials on the quantum $\mathbb{C}^n$

An initial object in constructing function theory in the quantum ball is the unital involutive algebra given by its generators $z_1,z_2,\ldots,z_n$ and the relations

$$z_iz_j=qz_jz_i,\quad i<j, \tag{2.1}$$

$$z_i^*z_j=qz_jz_i^*,\quad i\neq j, \tag{2.2}$$

$$z_j^*z_j=q^2z_jz_j^*+(1-q^2)\left(1-\sum_{k=j+1}^{n}z_kz_k^*\right). \tag{2.3}$$

We denote this algebra by $\mathcal{P}(\mathbb{C}^n)_q$ and treat it as the polynomial algebra on the quantum $\mathbb{C}^n$. The algebra $\mathcal{P}(\mathbb{C}^n)_q$ is a particular case of the algebra $\mathrm{Pol}(\mathrm{Mat}_{m,n})_q$ of polynomials on the quantum space of $m\times n$ matrices considered in Refs. 9 and 10. Specifically, $\mathcal{P}(\mathbb{C}^n)_q$ coincides with $\mathrm{Pol}(\mathrm{Mat}_{1,n})_q$. [Moreover, it is not hard to show that $\mathcal{P}(\mathbb{C}^n)_q$ is isomorphic to the known twisted CCR-algebra.[16]]

In the sequel we use the algebra $\mathcal{P}(\mathbb{C}^n)_q$ to produce some ''functional'' spaces and algebras on the quantum ball. Those spaces, as well as the algebra $\mathcal{P}(\mathbb{C}^n)_q$ itself, are endowed with structures of $U_q\mathfrak{su}_{n,1}$-modules where $U_q\mathfrak{su}_{n,1}$ is certain $*$-Hopf algebra called the quantized universal enveloping algebra for $\mathfrak{su}_{n,1}$. Let us turn to precise definitions.

We recall first the definition of $U_q\mathfrak{su}_{n,1}$. It is a ''real form'' of the Drinfeld–Jimbo quantum universal enveloping algebra $U_q\mathfrak{sl}_{n+1}$. The latter algebra is the unital algebra given by the generators $E_i,F_i,K_i^{\pm 1}$, $i=1,2,\ldots,n$, and the following relations:

$$K_iK_j=K_jK_i,\ \ K_iK_i^{-1}=K_i^{-1}K_i=1,\ \ K_iE_j=q^{a_{ij}}E_jK_i,$$

$$K_iF_j=q^{-a_{ij}}F_jK_i,\quad E_iF_j-F_jE_i=\delta_{ij}(K_i-K_i^{-1})/(q-q^{-1}),$$

$$E_i^2E_j-(q+q^{-1})E_iE_jE_i+E_jE_i^2=0,\quad |i-j|=1,$$

$$F_i^2F_j-(q+q^{-1})F_iF_jF_i+F_jF_i^2=0,\quad |i-j|=1,$$

$$[E_i,E_j]=[F_i,F_j]=0,\quad |i-j|\neq 1,$$

with (a_{ij}) being the Cartan matrix of type A_n. Moreover, $U_q\mathfrak{sl}_{n+1}$ is a Hopf algebra. The comultiplication Δ, the antipode S, and the counit ε are determined by

$$\Delta(E_i)=E_i\otimes 1+K_i\otimes E_i,\quad \Delta(F_i)=F_i\otimes K_i^{-1}+1\otimes F_i,\quad \Delta(K_i)=K_i\otimes K_i,$$

$$S(E_i)=-K_i^{-1}E_i,\quad S(F_i)=-F_iK_i,\quad S(K_i)=K_i^{-1},$$

$$\varepsilon(E_i)=\varepsilon(F_i)=0,\quad \varepsilon(K_i)=1.$$

The quantum universal enveloping algebra $U_q\mathfrak{su}_{n,1}$ is defined as the $*$-Hopf algebra $(U_q\mathfrak{sl}_{n+1},*)$ with $*$ being the involution in $U_q\mathfrak{sl}_{n+1}$ given by

$$E_n^*=-K_nF_n,\quad F_n^*=-E_nK_n^{-1},\quad (K_n^{\pm 1})^*=K_n^{\pm 1},$$

$$E_j^*=K_jF_j,\quad F_j^*=E_jK_j^{-1},\quad (K_j^{\pm 1})^*=K_j^{\pm 1},\quad \text{for}\quad j\neq n$$

(see Ref. 17 for basic definitions concerning $*$-Hopf algebras).

We need also the notion of $U_q\mathfrak{su}_{n,1}$-module algebra. Let A be a Hopf algebra. An algebra F is said to be an A-module algebra if F carries a structure of A-module and multiplication in F agrees with the A-action, i.e., the multiplication $F\otimes F\to F$ is a morphism of A-modules. (We recall that for any A-modules V_1, V_2 their tensor product is endowed with an A-module structure via the comultiplication $\Delta:A\to A\otimes A$.) If A or F has some extra structures this definition includes natural additional requirements. For example, in the case of a unital algebra F one adds the requirement of A-invariance of the unit: $\xi(1)=\varepsilon(\xi)\cdot 1$, $\xi\in A$. In the case of an involutive algebra F and a $*$-Hopf algebra A one imposes the requirement of agreement of the involutions:

$$(\xi(f))^*=S(\xi)^*(f^*),\quad \xi\in A, f\in F. \tag{2.4}$$

Some natural examples of module algebras appear in the classical setting. Suppose X is a smooth G-space with G being a Lie group. The G-action induces an action of the universal enveloping algebra $U\mathfrak{g}$ in the space $C^\infty(X)$ via differential operators. The usual Leibnitz rule for the differentiation of product of two functions means that $C^\infty(X)$ is a $U\mathfrak{g}$-module algebra. This example suggests the use of the language of module algebras for description of algebras of functions on *quantum* G-spaces.

The structure of $U_q\mathfrak{su}_{n,1}$-module algebra in $\mathcal{P}(\mathbb{C}^n)_q$ which we are going to present has the following classical counterpart. The unit ball $U_n=\{\mathbf{z}\in\mathbb{C}^n|\|\mathbf{z}\|<1\}$ is a homogeneous space of the group SU$(n,1)$ whose elements act via (biholomorphic) linear-fractional transformations. Elements of the universal enveloping algebra $U\mathfrak{su}_{n,1}$ act on the space $C^\infty(U_n)$ via differential operators with polynomial coefficients and thus keep the subspace of polynomials invariant. This induces a $U\mathfrak{su}_{n,1}$-module algebra structure in the polynomial algebra on $\mathbb{C}^n$. We turn now to the quantum case.

To describe the $U_q\mathfrak{su}_{n,1}$-module algebra structure in $\mathcal{P}(\mathbb{C}^n)_q$ we consider the action of the elements $E_i,F_i,K_i^{\pm 1}$ on the generators z_i,z_i^*. Moreover, by (2.4) it is sufficient to present formulas for the action of $E_i,F_i,K_i^{\pm 1}$ on the "holomorphic" part $z_1,\ldots,z_n$ of generators of $\mathcal{P}(\mathbb{C}^n)_q$. These are given in the following:

Proposition 2.1: There exists a unique structure of $U_q\mathfrak{su}_{n,1}$-module algebra in $\mathcal{P}(\mathbb{C}^n)_q$ such that, for $k\neq n$,

$$K_kz_i=\begin{cases} qz_i, & i=k,\\ q^{-1}z_i, & i=k+1,\\ z_i, & \text{otherwise,}\end{cases} \tag{2.5}$$

$$F_kz_i=q^{1/2}\cdot\begin{cases} z_{i+1}, & i=k,\\ 0, & \text{otherwise,}\end{cases} \tag{2.6}$$

$$E_k z_i = q^{-1/2} \cdot \begin{cases} z_{i-1}, & i = k+1, \\ 0, & \text{otherwise}, \end{cases} \tag{2.7}$$

and

$$K_n z_i = \begin{cases} q^2 z_i, & i = n, \\ q z_i, & \text{otherwise}, \end{cases} \tag{2.8}$$

$$F_n z_i = q^{1/2} \cdot \begin{cases} 1, & i = n, \\ 0, & \text{otherwise}, \end{cases} \tag{2.9}$$

$$E_n z_i = -q^{1/2} \cdot \begin{cases} z_n^2, & i = n, \\ z_n z_i, & \text{otherwise}. \end{cases} \tag{2.10}$$

This statement may be deduced from Proposition 2.1 and Corollary 5.6 in Ref. 9 by easy computations. In the next subsection we will introduce some other important $U_q\mathfrak{su}_{n,1}$-module algebras.

B. Finite functions on the quantum ball

It should be noted that in the classical case the space of polynomials does not suit purposes of harmonic analysis in the ball because the volume of the ball with respect to the SU(n,1)-invariant measure

$$d\nu(\mathbf{z}) = \frac{dm(\mathbf{z})}{(1-\|\mathbf{z}\|^2)^{n+1}} \tag{2.11}$$

[where $dm(\mathbf{z})$ is the normalized Lebesgue measure] is infinite. One observes the same problem in the quantum setting: there is no $U_q\mathfrak{su}_{n,1}$-invariant integral on $\mathcal{P}(\mathbb{C}^n)_q$, i.e., a linear positive functional $\nu:\mathcal{P}(\mathbb{C}^n)_q \to \mathbb{C}$ such that $\nu(\xi(f)) = \varepsilon(\xi)\cdot\nu(f)$ for any $\xi \in U_q\mathfrak{su}_{n,1}$ (ε is the counit of $U_q\mathfrak{su}_{n,1}$). Thus it is reasonable to look for a quantum counterpart of the space of finite functions on the ball (functions with compact supports inside the ball). The following construction for such a counterpart was proposed in Ref. 9, Sec. 7.

Let us add to the algebra $\mathcal{P}(\mathbb{C}^n)_q$ one more generator f_0 which satisfies the relations

$$f_0^* = f_0^2 = f_0, \quad z_i^* f_0 = f_0 z_i = 0, \quad i = 1,2,\ldots,n. \tag{2.12}$$

The resulting involutive algebra will be denoted by $\mathcal{F}(U_n)_q$. It is demonstrated in Ref. 9, Sec. 7, that one may extend the structure of $U_q\mathfrak{su}_{n,1}$-module algebra in $\mathcal{P}(\mathbb{C}^n)_q$ to one in $\mathcal{F}(U_n)_q$ as follows:

$$K_k f_0 = f_0, \quad F_k f_0 = E_k f_0 = 0, \tag{2.13}$$

with $k \neq n$ and

$$K_n f_0 = f_0, \quad F_n f_0 = -\frac{q^{1/2}}{q^{-2}-1} f_0 \cdot z_n^*, \quad E_n f_0 = -\frac{q^{1/2}}{1-q^2} z_n \cdot f_0. \tag{2.14}$$

The involutive algebra $\mathcal{D}(U_n)_q$ of finite functions on the quantum ball is defined as the two-sided ideal $\mathcal{F}(U_n)_q \cdot f_0 \cdot \mathcal{F}(U_n)_q$ in $\mathcal{F}(U_n)_q$. Due to (2.13) and (2.14), $\mathcal{D}(U_n)_q$ is a $U_q\mathfrak{su}_{n,1}$-module subalgebra in $\mathcal{F}(U_n)_q$. In the next subsection we present an explicit formula for a $U_q\mathfrak{su}_{n,1}$-invariant integral on $\mathcal{D}(U_n)_q$.

The above definition of $\mathcal{D}(U_n)_q$ is convenient for many purposes but performing computations. We present therefore an alternative description of $\mathcal{D}(U_n)_q$. For that purpose we let H be the $\mathcal{P}(\mathbb{C}^n)_q$-module given by its unique generator e_0 such that $z_i^* e_0 = 0$, $i = 1,2,\ldots,n$. By the formulas

(2.2) and (2.3), $H=\mathcal{P}(\mathbb{C}^n)_q\cdot e_0=\mathbb{C}[\mathbb{C}^n]_q\cdot e_0$ with $\mathbb{C}[\mathbb{C}^n]_q$ being the unital (noninvolutive) subalgebra in $\mathcal{P}(\mathbb{C}^n)_q$ generated by z_i, $i=1,2,\ldots,n$. Moreover, the elements $\{\mathbf{z}^{\underline{m}}\cdot e_0\}_{\underline{m}\in\mathbb{Z}^n_{\geqslant 0}}$ constitute a basis in H. The following statement may be deduced from known results concerning the twisted CCR-algebra (see, for instance, Ref. 18).

Proposition 2.2: (i) There exists a (unique up to a positive multiplier) scalar product in H such that

$$(f\cdot e_1,e_2)=(e_1,f^*\cdot e_2)$$

for any $f\in\mathcal{P}(\mathbb{C}^n)_q$ *and* $e_1,e_2\in H$.

(ii) The corresponding $*$*-representation T of* $\mathcal{P}(\mathbb{C}^n)_q$ *in the completion* $\overline{H}$ *of the pre-Hilbert space H* (*the so-called Fock representation*) *is a faithful irreducible representation by bounded operators*.

We let $C^*(\mathcal{P}(\mathbb{C}^n)_q)$ be the C^*-algebra generated by $\mathcal{P}(\mathbb{C}^n)_q$ via the representation T. We describe now an embedding of $\mathcal{D}(U_n)_q$ in $C^*(\mathcal{P}(\mathbb{C}^n)_q)$.

The representation T can be extended to a faithful $*$-representation of the algebra $\mathcal{F}(U_n)_q$ by setting

$$T(f_0)=\text{orthogonal projection onto } \mathbb{C}\cdot e_0.$$

It is easy to show that the subalgebra $\{T(f)\mid f\in\mathcal{D}(U_n)_q\}$ of the algebra of bounded operators on $\overline{H}$ coincides with the subalgebra of those operators whose matrices in the basis $\{\mathbf{z}^{\underline{m}}\cdot e_0\}_{\underline{m}\in\mathbb{Z}^n_{\geqslant 0}}$ have only finitely many nonzero entries. Thus the algebra $\mathcal{D}(U_n)_q$ can be realized as a subalgebra of $C^*(\mathcal{P}(\mathbb{C}^n)_q)$. It admits the following transparent description.

Let $y_i=1-z_iz_i^*-\cdots-z_nz_n^*\in\mathcal{P}(\mathbb{C}^n)_q$, $i=1,2,\ldots,n$. Then $(y_1,\ldots,y_n)$ is a tuple of pairwise commuting positive operators on $\overline{H}$. The joint spectrum of the tuple $(y_1,\ldots,y_n)$ in $C^*(\mathcal{P}(\mathbb{C}^n)_q)$ is the closure in $\mathbb{R}^n$ of the "q-simplex"

$$\mathfrak{M}=\{(q^{2k_1},q^{2k_2},\ldots,q^{2k_n})\mid \underline{k}\in P(n)\} \tag{2.15}$$

[$P(n)$ is defined in the Introduction]. This is a consequence of the commutation relations

$$z_iy_j=\begin{cases}q^{-2}y_jz_i, & i\leqslant j,\\ y_jz_i, & \text{otherwise,}\end{cases}\qquad z_i^*y_j=\begin{cases}q^2y_jz_i^*, & i\leqslant j,\\ y_jz_i^*, & \text{otherwise.}\end{cases} \tag{2.16}$$

We will henceforth identify a function $f(y_1,\ldots,y_n)$ with a function f on the set $\mathfrak{M}$ via the spectral calculus.

Using the definition of y_i's and (2.16), one can write an arbitrary element $f\in\mathcal{P}(\mathbb{C}^n)_q$ uniquely in the form

$$f=\sum_{\underline{i}\times\underline{j}=0}\mathbf{z}^{\underline{i}}f_{\underline{i},\underline{j}}(y_1,y_2,\ldots,y_n)\mathbf{z}^{*\underline{j}}. \tag{2.17}$$

The subalgebra $\mathcal{D}(U_n)_q\subset C^*(\mathcal{P}(\mathbb{C}^n)_q)$ may be identified with the algebra of finite sums of the form (2.17) whose coefficients are functions on $\mathfrak{M}$ with finite supports.

We will use both descriptions of $\mathcal{D}(U_n)_q$. It is clear that the "distinguished" finite function f_0 which appears in the definition of $\mathcal{D}(U_n)_q$ may be described, in those terms, as follows: $f_{\underline{i},\underline{j}}\equiv 0$ provided $\underline{i}\neq\underline{0}$ or $\underline{j}\neq\underline{0}$, and

$$f_{\underline{0},\underline{0}}(q^{2k_1},q^{2k_2},\ldots,q^{2k_n})=\begin{cases}1, & \underline{k}=\underline{0},\\ 0, & \text{otherwise.}\end{cases}$$

The following crucial property of f_0 will simplify proofs of many results.

Proposition 2.3: f_0 generates $\mathcal{D}(U_n)_q$ as a $U_q\mathfrak{su}_{n,1}$-module.
A proof can be found in Ref. 9, Sec. 7.

C. Invariant integral

In this subsection we present an explicit formula for the $U_q\mathfrak{su}_{n,1}$-invariant integral on the quantum ball. This formula was found in Ref. 9, Sec. 9.

Keep in mind the notation T for the Fock representation of $\mathcal{P}(\mathbb{C}^n)_q$ and H for a $\mathcal{P}(\mathbb{C}^n)_q$-module, a dense linear subspace in the Hilbert space $\overline{H}$ of the representation T (see the previous subsection). It is easy to observe that $T(f)(H)\subset H$ for any finite function f. Thus H becomes a $\mathcal{D}(U_n)_q$-module. It is convenient to identify the $\mathcal{D}(U_n)_q$-module H with the left ideal $\mathbb{C}[\mathbb{C}^n]_q\cdot f_0$ [this is possible due to (2.12)], with which we may equip H with some extra structures. In particular, the isomorphism of $\mathcal{D}(U_n)_q$-modules

$$H\simeq\mathbb{C}[\mathbb{C}^n]_q\cdot f_0\subset\mathcal{D}(U_n)_q$$

and formulas (2.5), (2.8), (2.13), and (2.14) define H as a $U_q\mathfrak{h}$-module where $U_q\mathfrak{h}$ is the Hopf subalgebra in $U_q\mathfrak{sl}_{n+1}$ generated by $K_i^{\pm 1}$, $i=1,2,\ldots,n$. Denote the corresponding representation of $U_q\mathfrak{h}$ in H by Γ. The following statement was proved in Ref. 9.

Proposition 2.4: The linear functional on $\mathcal{D}(U_n)_q$ given by

$$f\mapsto\nu(f)=\mathrm{tr}\left(T(f)\Gamma\left(\prod_{j=1}^{n}K_j^{-j(n+1-j)}\right)\right)$$

is a $U_q\mathfrak{su}_{n,1}$-invariant integral, i.e., $\nu(f^*f)>0$, $f\neq 0$, and $\nu(\xi(f))=\varepsilon(\xi)\cdot\nu(f)$, $\xi\in U_q\mathfrak{su}_{n,1}$.

We shall use the normalized integral

$$\int_{U_n}f d\nu_q=(q^2;q^2)_n\cdot\nu(f)$$

with $(q^2;q^2)_n=(1-q^2)(1-q^4)\cdots(1-q^{2n})$.

The invariant integral is unique up to a positive scalar. This is an immediate consequence of Proposition 2.3.

We can rewrite now the formula for the invariant integral in a more convenient form. Suppose $f\in\mathcal{D}(U_n)_q$ is written in the form (2.17). Then one checks easily that

$$\int_{U_n}f d\nu_q=(q^2;q^2)_n\cdot\sum_{\underline{k}\in P(n)}f_{\underline{0},\underline{0}}(q^{2k_1},q^{2k_2},\ldots,q^{2k_n})\cdot q^{-2nk_1}\cdot q^{2k_2}\cdot\ldots\cdot q^{2k_n}. \tag{2.18}$$

In the next proposition we explain how the $U_q\mathfrak{su}_{n,1}$-invariant integral makes $\mathcal{D}(U_n)_q$ into a unitary $U_q\mathfrak{su}_{n,1}$-module and thus provides a setup for harmonic analysis in the quantum ball.

Proposition 2.5: The scalar product in $\mathcal{D}(U_n)_q$ given by

$$(\varphi_1,\varphi_2)=\int_{U_n}\varphi_2^*\cdot\varphi_1 d\nu_q$$

is $U_q\mathfrak{su}_{n,1}$-invariant, i.e., $(\xi(\varphi_1),\varphi_2)=(\varphi_1,\xi^*(\varphi_2))$ for any $\varphi_1,\varphi_2\in\mathcal{D}(U_n)_q$ and any $\xi\in U_q\mathfrak{su}_{n,1}$.

Proof: This follows from the condition (2.4) in $\mathcal{D}(U_n)_q$ and the following formula of "integrating by parts:" for any $\varphi_1,\varphi_2\in\mathcal{D}(U_n)_q$ and $\xi\in U_q\mathfrak{su}_{n,1}$ one has

$$\int_{U_n}\xi(\varphi_1)\cdot\varphi_2 d\nu_q=\int_{U_n}\varphi_1\cdot S(\xi)(\varphi_2)d\nu_q \tag{2.19}$$

with S being the antipode of $U_q\mathfrak{su}_{n,1}$. To prove the latter formula, it is sufficient to verify the equality on generators $E_i, F_i, K_i^{\pm 1}$ of $U_q\mathfrak{su}_{n,1}$. In this particular case the equality is equivalent to the $U_q\mathfrak{su}_{n,1}$-invariance of the integral. ■

D. Distributions on the quantum ball

The aim of this subsection is to define the space $\mathcal{D}(U_n)_q'$ of distributions on the quantum ball. We follow ideas in Ref. 19, Sec. 1, where the simplest case $n=1$ is treated.

Equip the vector space $\mathcal{D}(U_n)_q$ with the weakest topology so that all the linear functionals

$$l^{\underline{k}}_{\underline{i},\underline{j}}: f \mapsto f_{\underline{i},\underline{j}}(q^{2k_1}, q^{2k_2}, \ldots, q^{2k_n})$$

are continuous [here $\underline{i},\underline{j} \in \mathbb{Z}^n_{\geqslant 0}$ satisfy $\underline{i} \times \underline{j} = \underline{0}$, $\underline{k} \in P(n)$, and $f_{\underline{i},\underline{j}}$ is the corresponding coefficient in the expansion (2.17) of f].

The following results can be proved by direct, however tedious, computations, which we omit.

Proposition 2.6: For a fixed $f \in \mathcal{D}(U_n)_q$ the operator in $\mathcal{D}(U_n)_q$ of the right multiplication by f is continuous. Also, the $U_q\mathfrak{su}_{n,1}$-action in $\mathcal{D}(U_n)_q$ is continuous.

Let $\mathcal{D}(U_n)_q'$ be the completion of the topological vector space $\mathcal{D}(U_n)_q$. We shall use the concrete realization of $\mathcal{D}(U_n)_q'$ as the space of infinite sums of the form (2.17) whose coefficients $f_{\underline{i},\underline{j}}$ are arbitrary functions on the q-simplex $\mathfrak{M}$ [see (2.15)]. The above proposition, by continuity, implies that $\mathcal{D}(U_n)_q'$ is a right $\mathcal{D}(U_n)_q$-module and a $U_q\mathfrak{su}_{n,1}$-module. Moreover, these structures agree: the multiplication map $\mathcal{D}(U_n)_q' \otimes \mathcal{D}(U_n)_q \to \mathcal{D}(U_n)_q'$ is a morphism of $U_q\mathfrak{su}_{n,1}$-modules. This is a consequence of $U_q\mathfrak{su}_{n,1}$-moduleness of the algebra $\mathcal{D}(U_n)_q$.

Let us construct a nondegenerate pairing $\mathcal{D}(U_n)_q' \times \mathcal{D}(U_n)_q \to \mathbb{C}$ which will justify the term "distribution." Let $\{\psi_\beta\}_\beta$ be a convergent net in $\mathcal{D}(U_n)_q$ and suppose $\lim_\beta \psi_\beta = \psi$, $\psi \in \mathcal{D}(U_n)_q'$. Then for any $\varphi \in \mathcal{D}(U_n)_q$ the limit $\lim_\beta \int_{U_n} \psi_\beta \varphi \, d\nu_q$ exists and depends only on ψ and φ (i.e., independent of a choice of ψ_β). Indeed, let us prove existence of $\lim \int_{U_n} \psi_\beta \varphi \, d\nu_q$. Proposition 2.3 implies that there exists $\xi_\varphi \in U_q\mathfrak{su}_{n,1}$ such that $\varphi = \xi_\varphi(f_0)$. By (2.19)

$$\int_{U_n} \psi_\beta \varphi \, d\nu_q = \int_{U_n} S^{-1}(\xi_\varphi)(\psi_\beta) f_0 \, d\nu_q .$$

Since the $U_q\mathfrak{su}_{n,1}$-action is continuous, it is sufficient now to prove existence of the limit in the particular case $\varphi := f_0$. But in this case existence is equivalent to continuity of the functional $l^{\underline{0}}_{\underline{0}\underline{0}}$ and thus is obvious. Independence of the limit on a particular choice of the net $\{\psi_\beta\}$ can be proved by the same arguments.

Thus we get a well defined pairing

$$\mathcal{D}(U_n)_q' \times \mathcal{D}(U_n)_q \to \mathbb{C}, \quad (\psi, \varphi) \mapsto \int_{U_n} \psi \varphi \, d\nu_q ,$$

and, due to (2.19), it satisfies the property

$$\int_{U_n} \xi(\psi) \cdot \varphi \, d\nu_q = \int_{U_n} \psi \cdot S(\xi)(\varphi) \, d\nu_q \tag{2.20}$$

for any $\psi \in \mathcal{D}(U_n)_q'$, $\varphi \in \mathcal{D}(U_n)_q$, and $\xi \in U_q\mathfrak{su}_{n,1}$. In other words, we have constructed a morphism of $U_q\mathfrak{su}_{n,1}$-modules,

$$\mathcal{D}(U_n)_q' \to \text{dual of } \mathcal{D}(U_n)_q .$$

[For an A-module V the dual space V^* is endowed with an A-module structure via the antipode: $\xi f(\cdot) = f(S(\xi)\cdot)$.] In fact, this is an isomorphism. This can be proved by computation just as it was done in Ref. 19, Sec. 1, in the case $n=1$.

III. q-BEREZIN TRANSFORM

The aim of this section is to construct a q-analog of the Berezin transform in the unit ball. For that purpose we define also q-analogs of the weighted Bergman spaces, Toeplitz operators, and covariant symbols.

A. q-weighted Bergman spaces

In the classical case the weighted Bergman space is defined as the closure of the space of holomorphic polynomials with respect to the norm

$$\|f\|_\alpha=\left(\frac{\Gamma(n+\alpha+1)}{\Gamma(n+1)\Gamma(\alpha+1)}\int_{U_n}|f(\mathbf{z})|^2(1-\|\mathbf{z}\|^2)^\alpha dm(\mathbf{z})\right)^{1/2}. \tag{3.1}$$

Here $\alpha>-1$, dm is the normalized Lebesgue measure, and the multiplier $\Gamma(n+\alpha+1)/\Gamma(n+1)\Gamma(\alpha+1)$ normalizes the measure $dm_\alpha=(1-\|\mathbf{z}\|^2)^\alpha dm(\mathbf{z})$. Let us define a q-analog of dm_α.

Suppose $\alpha\in\mathbb{Z}_{\geqslant 0}$. The formula (3.1), along with (2.11), suggests the following definition of the q-weighted integral,

$$\int_{U_n} f dm_{\alpha,q}=\frac{\Gamma_{q^2}(n+\alpha+1)}{\Gamma_{q^2}(n+1)\Gamma_{q^2}(\alpha+1)}\int_{U_n} f\cdot y_1^{\alpha+n+1} d\nu_q \tag{3.2}$$

with $y_1=1-z_1z_1^*-\cdots-z_nz_n^*\in\mathcal{P}(\mathbb{C}^n)_q$ (see Sec. II B). Here we use the standard notation:[20]

$$\Gamma_q(x)=\frac{(q;q)_\infty}{(q^x;q)_\infty}(1-q)^{1-x}$$

with

$$(a;q)_\infty=(1-a)(1-aq)(1-aq^2)\cdots,\quad (a;q)_\gamma=\frac{(a;q)_\infty}{(aq^\gamma;q)_\infty},\quad \gamma\in\mathbb{C}.$$

Using (2.18) and the definition of Γ_{q^2}, we may rewrite the integral in the following way:

$$\int_{U_n} f dm_{\alpha,q}=(q^{2\alpha+2};q^2)_n\sum_{\underline{k}\in P(n)} f_{\underline{0},\underline{0}}(q^{2k_1},q^{2k_2},\ldots,q^{2k_n})\cdot q^{2k_1(\alpha+1)}\cdot q^{2k_2}\cdot\ldots\cdot q^{2k_n}. \tag{3.3}$$

The latter formula can be used to define the q-weighted integral for arbitrary $\alpha\in\mathbb{R}$.

We define $L^2(dm_{\alpha,q})$ as the completion of $\mathcal{D}(U_n)_q$ with respect to the norm

$$\|f\|_{\alpha,q}=\left(\int_{U_n} f^*\cdot f dm_{\alpha,q}\right)^{1/2}.$$

We shall use the concrete realization of $L^2(dm_{\alpha,q})$ as the subspace in $\mathcal{D}(U_n)_q'$ of those distributions for which the right-hand side is finite.

From now on we suppose α is a positive real number. In this case, we have $\mathcal{P}(\mathbb{C}^n)_q\subset L^2(dm_{\alpha,q})$ [this may be checked by direct computations using formula (3.3)]. By analogy with the classical case, we define the q-weighted Bergman space $L_a^2(dm_{\alpha,q})$ as the closure in $L^2(dm_{\alpha,q})$ of the subspace $\mathbb{C}[\mathbb{C}^n]_q$ of "holomorphic" polynomials.

Proposition 3.1: The monomials $\mathbf{z}^{\underline{m}}$ constitute an orthogonal basis in $L_a^2(dm_{\alpha,q})$ and

$$\|\mathbf{z}^{\underline{m}}\|_{\alpha,q}^2=\frac{\Gamma_{q^2}(n+\alpha+1)\Gamma_{q^2}(m_1+1)\cdots\Gamma_{q^2}(m_n+1)}{\Gamma_{q^2}(m_1+\cdots+m_n+n+\alpha+1)}.$$

Proof: By the above definitions

$$(\mathbf{z}^{\underline{m}},\mathbf{z}^{\underline{l}})_{\alpha,q}=(q^{2\alpha+2};q^2)_n\sum_{\underline{k}\in P(n)} f_{\underline{0},\underline{0}}(q^{2k_1},q^{2k_2},\ldots,q^{2k_n})\cdot q^{2k_1(\alpha+1)}\cdot q^{2k_2}\cdot\ \ldots\ \cdot q^{2k_n},$$

where $f_{\underline{0},\underline{0}}$ is the corresponding term in the expansion (2.17) of the polynomial $\mathbf{z}^{*\underline{l}}\mathbf{z}^{\underline{m}}$. Obviously, the $f_{\underline{0},\underline{0}}$-term vanishes for $\underline{m}\neq\underline{l}$. This implies the pairwise orthogonality of the monomials. Suppose $\underline{m}=\underline{l}$. It is easy to show that

$$\mathbf{z}^{*\underline{m}}\mathbf{z}^{\underline{m}}=y_2^{m_1}y_3^{m_2}\cdots y_n^{m_{n-1}}\left(q^2\frac{y_1}{y_2};q^2\right)_{m_1}\left(q^2\frac{y_2}{y_3};q^2\right)_{m_2}\cdots\left(q^2\frac{y_{n-1}}{y_n};q^2\right)_{m_{n-1}}(q^2y_n;q^2)_{m_n}. \tag{3.4}$$

Denote by $f(y_1,y_2,\ldots,y_n)$ the right-hand side of the latter equality. One has

$$\sum_{\underline{k}\in P(n)} f(q^{2k_1},q^{2k_2},\ldots,q^{2k_n})\cdot q^{2k_1(\alpha+1)+2k_2+\cdots+2k_n}$$
$$=\frac{1}{(1-q^2)^n}\prod_{j=0}^{n-1}\int_0^1 t^{\alpha+m_1+\cdots+m_j+j}(q^2t;q^2)_{m_{j+1}}d_{q^2}t$$

where $\int_0^1 f(t)d_{q^2}t$ is the Jackson integral given by

$$\int_0^1 f(t)d_{q^2}t=(1-q^2)\sum_{l=0}^{\infty} f(q^{2l})q^{2l}. \tag{3.5}$$

What remains is to use the following well known formula:[20]

$$\int_0^1 t^a(q^2t;q^2)_b d_{q^2}t=\frac{\Gamma_{q^2}(a+1)\Gamma_{q^2}(b+1)}{\Gamma_{q^2}(a+b+2)}.$$

■

In the classical case the Hilbert space $L^2(dm_\alpha)$ admits a natural unitary $\widetilde{\mathrm{SU}(n,1)}$-action, where $\widetilde{\mathrm{SU}(n,1)}$ is the universal covering of $\mathrm{SU}(n,1)$. The invariant subspace $L_a^2(dm_\alpha)$ of holomorphic functions is called the representation of the holomorphic discrete series.[21,22] The corresponding infinitesimal $U\mathfrak{su}_{n,1}$-action is obtained by a simple twisting of the natural action. Below, we produce an analog of the twisted $U\mathfrak{su}_{n,1}$-action.

It was proved in Ref. 10, Sec. 6, that there exists a unique representation π_α of $U_q\mathfrak{su}_{n,1}$ in $\mathcal{P}(\mathbb{C}^n)_q$ and $\mathcal{D}(U_n)_q$ such that for all $f\in\mathcal{P}(\mathbb{C}^n)_q$ [or $f\in\mathcal{D}(U_n)_q$]

$$\pi_\alpha(E_j)f=\begin{cases}E_jf, & j\neq n,\\ E_nf-q^{1/2}\dfrac{1-q^{2\alpha+2n+2}}{1-q^2}(K_nf)z_n, & j=n,\end{cases} \tag{3.6}$$

$$\pi_\alpha(F_j)f=\begin{cases}F_jf, & j\neq n,\\ q^{-\alpha-n-1}F_nf, & j=n,\end{cases} \tag{3.7}$$

$$\pi_\alpha(K_j^{\pm1})f=\begin{cases}K_j^{\pm1}f, & j\neq n,\\ q^{\pm(\alpha+n+1)}K_n^{\pm1}f, & j=n,\end{cases} \tag{3.8}$$

where E_jf,F_jf,K_jf are defined in Proposition 2.1 [(2.13) and (2.14) for $f\in\mathcal{D}(U_n)_q$]. In order to not consider the polynomials and finite functions separately, it will be convenient sometimes to regard π_α as a representation of $U_q\mathfrak{su}_{n,1}$ in $\mathcal{F}(U_n)_q$.

The following statement is proved in Ref. 10, Sec. 6.

Proposition 3.2: For any $\varphi_1, \varphi_2 \in \mathcal{F}(U_n)_q$ *and any* $\xi \in U_q\mathfrak{su}_{n,1}$

$$(\pi_\alpha(\xi)\varphi_1, \varphi_2)_{\alpha,q} = (\varphi_1, \pi_\alpha(\xi^*)\varphi_2)_{\alpha,q}$$

with $(\cdot,\cdot)_{\alpha,q}$ *being the scalar product in* $L^2(dm_{\alpha,q})$.

Note that the subspace $\mathbb{C}[\mathbb{C}^n]_q \subset \mathcal{F}(U_n)_q$ is actually a $U_q\mathfrak{su}_{n,1}$-submodule. It should be treated as a module of the holomorphic discrete series for $U_q\mathfrak{su}_{n,1}$.

Before we proceed further, let us fix more notation. The space $\mathbb{C}[\mathbb{C}^n]_q$ [as well as $\mathcal{F}(U_n)_q$] admits two different $U_q\mathfrak{su}_{n,1}$-actions, namely, the original one which was introduced earlier in Proposition 2.1 and the twisted one which appeared in this subsection. In order to emphasize that a space is considered together with the twisted $U_q\mathfrak{su}_{n,1}$-action π_α we shall add the subscript α in the notation, for example, $\mathbb{C}[\mathbb{C}^n]_{q,\alpha}$. The subscript will also indicate the pre-Hilbert space structure given by the scalar product $(\cdot,\cdot)_{\alpha,q}$.

The following important observation relates the usual and the twisted $U_q\mathfrak{su}_{n,1}$-actions: the multiplication map $\mathcal{F}(U_n)_q \otimes \mathcal{F}(U_n)_{q,\alpha} \to \mathcal{F}(U_n)_{q,\alpha}$ is a morphism of $U_q\mathfrak{su}_{n,1}$-modules. This can be proved by direct computations.

B. Toeplitz operators

In this subsection we produce q-analogs of Toeplitz operators with polynomial and finite symbols. As in the previous subsection, it is convenient to consider symbols from the algebra $\mathcal{F}(U_n)_q$ when there is no necessity to consider the cases of polynomial and finite symbols separately.

Let $P_{\alpha,q}$ be the orthogonal projection in $L^2(dm_{\alpha,q})$ onto $L^2_a(dm_{\alpha,q})$. The Toeplitz operator T_f with the symbol $f \in \mathcal{F}(U_n)_q$ is defined as follows:

$$T_f : \mathbb{C}[\mathbb{C}^n]_{q,\alpha} \to \mathbb{C}[\mathbb{C}^n]_{q,\alpha}, \quad T_f(\psi) = P_{\alpha,q}(f \cdot \psi).$$

To formulate the principal result of the present subsection, we recall the following well known construction. Let A be a Hopf algebra and V an A-module. Then the space $\mathrm{End}(V)$ admits the following "canonical" structure of the A-module: for $\xi \in A$, $T \in \mathrm{End}(V)$,

$$\xi(T) = \sum_j \xi'_j \cdot T \cdot S(\xi''_j),$$

where S is the antipode of A, $\Delta(\xi) = \Sigma_j \xi'_j \otimes \xi''_j$ (with Δ being the comultiplication), and the elements on the right-hand side are multiplied within the algebra $\mathrm{End}(V)$. This action of A in $\mathrm{End}(V)$ makes $\mathrm{End}(V)$ into an A-module algebra.

Proposition 3.3: The linear map

$$\mathcal{F}(U_n)_q \to \mathrm{End}(\mathbb{C}[\mathbb{C}^n]_{q,\alpha}), \quad f \mapsto T_f,$$

is a morphism of $U_q\mathfrak{su}_{n,1}$*-modules.*

Proof: In the classical case the projection $P_{\alpha,q}$ intertwines the twisted $\widetilde{\mathrm{SU}(n,1)}$-action in $L^2(dm_\alpha)$ and $L^2_a(dm_\alpha)$. In the quantum case the $U_q\mathfrak{su}_{n,1}$-action π_α is not defined on the entire $L^2(dm_{\alpha,q})$. Nevertheless, the intertwining property may be formulated due to the equality

$$P_{\alpha,q}(\mathcal{F}(U_n)_{q,\alpha}) = \mathbb{C}[\mathbb{C}^n]_{q,\alpha}.$$

To prove the equality, we endow the space $\mathbb{C}[\mathbb{C}^n]_{q,\alpha}$ with the obvious $\mathbb{Z}_{\geqslant 0}$-grading by powers of monomials and observe that each $f \in \mathcal{F}(U_n)_{q,\alpha}$ is orthogonal to all but finitely many homogeneous components of $\mathbb{C}[\mathbb{C}^n]_{q,\alpha}$. Now it is evident that the operator $P_{\alpha,q} : \mathcal{F}(U_n)_{q,\alpha} \to \mathbb{C}[\mathbb{C}^n]_{q,\alpha}$ is a morphism of $U_q\mathfrak{su}_{n,1}$-modules: this follows from $U_q\mathfrak{su}_{n,1}$-invariance of the orthogonal complement of $\mathbb{C}[\mathbb{C}^n]_{q,\alpha}$ in $\mathcal{F}(U_n)_{q,\alpha}$.

Let $f \in \mathcal{F}(U_n)_q$. Denote by $\hat{f} = \hat{f}_\alpha$ the endomorphism of $\mathcal{F}(U_n)_{q,\alpha}$ given by $\hat{f}_\alpha(\varphi) = f \cdot \varphi$. The map

$$\mathcal{F}(U_n)_q \to \mathrm{End}(\mathcal{F}(U_n)_{q,\alpha}), \quad f \mapsto \hat{f}_\alpha,$$

is a morphism $U_q\mathfrak{su}_{n,1}$-modules (see the remark at the end of the previous subsection). It remains to use the equality $T_f = P_{q,\alpha} \cdot \hat{f}_\alpha|_{\mathbb{C}[\mathbb{C}^n]_{q,\alpha}}$. ■

Remark: One can use the above observation to show that the projection $P_{\alpha,q}$ is a q-integral operator with a simple kernel which is a q-analog of the so-called Bergman kernel; see Ref. 10. But this result is not needed in the present article.

C. On the case of polynomial symbols

For purposes of this article we need mostly Toeplitz operators with finite symbols. However, we present some results about the polynomial case which seem to be interesting by themselves.

Let $\hat{z}_i$ stand for the operator in $\mathbb{C}[\mathbb{C}^n]_{q,\alpha}$ of the left multiplication by z_i, $\hat{z}_i^*$ for the adjoint operator. The following observation is straightforward: for a polynomial $f = \Sigma a_{\underline{l},\underline{m}} \mathbf{z}^{*\underline{l}} \mathbf{z}^{\underline{m}}$ one has $T_f = \Sigma a_{\underline{l},\underline{m}} \hat{\mathbf{z}}^{*\underline{l}} \hat{\mathbf{z}}^{\underline{m}}$. Thus all Toeplitz operators with polynomial symbols belong to the unital subalgebra in $\mathrm{End}(\mathbb{C}[\mathbb{C}^n]_{q,\alpha})$ generated by $\hat{z}_i$ and $\hat{z}_i^*$, $i = 1,2,\ldots,n$. Denote this subalgebra by $\mathcal{P}_{n,q,\alpha}$. It is an involutive algebra with the involution given by $*: \hat{z}_i \mapsto \hat{z}_i^*$.

Proposition 3.4: The $U_q\mathfrak{su}_{n,1}$-action in $\mathrm{End}(\mathbb{C}[\mathbb{C}^n]_{q,\alpha})$ *induces a $U_q\mathfrak{su}_{n,1}$-module algebra structure in $\mathcal{P}_{n,q,\alpha}$.*

Proof: First we have to establish $U_q\mathfrak{su}_{n,1}$-invariance of the subspace $\mathcal{P}_{n,q,\alpha}$ in $\mathrm{End}(\mathbb{C}[\mathbb{C}^n]_{q,\alpha})$, that is, to show that $\xi(\hat{z}_i^{*a} \hat{z}_j^b)$ belong to $\mathcal{P}_{n,q,\alpha}$ for any $a,b \in \mathbb{Z}_{\geqslant 0}$, $i,j = 1,2,\ldots,n$, and $\xi \in U_q\mathfrak{su}_{n,1}$. According to Proposition 3.3

$$\xi(\hat{z}_i^{*a} \hat{z}_j^b) = \xi(T_{z_i^{*a} z_j^b}) = T_{\xi(z_i^{*a} z_j^b)}.$$

By the remark preceding the present proposition, $T_{\xi(z_i^{*a} z_j^b)} \in \mathcal{P}_{n,q,\alpha}$. It remains to prove module algebra property (2.4) for $\mathcal{P}_{n,q,\alpha}$. But it may be derived easily from Proposition 3.2. ■

Proposition 3.5: The following commutation relations hold:

$$\hat{z}_i \hat{z}_j = q \hat{z}_j \hat{z}_i, \quad i < j,$$

$$\hat{z}_i^* \hat{z}_j = q \hat{z}_j \hat{z}_i^* + q^{2\alpha+2n} \left(\hat{z}_i^* \hat{z}_j \left(q^2 + (1-q^2) \sum_{k=1}^{n} \hat{z}_k \hat{z}_k^* \right) - q \hat{z}_j \hat{z}_i^* \right), \quad i \neq j,$$

$$\hat{z}_j^* \hat{z}_j = q^2 \hat{z}_j \hat{z}_j^* + (1-q^2) \left(1 - \sum_{k=j+1}^{n} \hat{z}_k \hat{z}_k^* \right)$$
$$+ q^{2\alpha+2n} \left(\hat{z}_j^* \hat{z}_j \left(q^2 + (1-q^2) \sum_{k=1}^{n} \hat{z}_k \hat{z}_k^* \right) - q^2 \hat{z}_j \hat{z}_j^* - (1-q^2) \sum_{k=1}^{j} \hat{z}_k \hat{z}_k^* \right).$$

Proof: The relations may be deduced from the formulas

$$\hat{z}_i(\mathbf{z}^{\underline{m}}) = q^{m_n + m_{n-1} + \cdots + m_{i+1}} \mathbf{z}^{\underline{m}'}$$

[where $\underline{m}' = (m_1, \ldots, m_i + 1, \ldots, m_n)$],

$$\hat{z}_i^*(\mathbf{z}^{\underline{m}}) = 0, \quad m_i = 0,$$

$$\hat{z}_i^*(\mathbf{z}^{\underline{m}}) = \frac{q^{m_n + m_{n-1} + \cdots + m_{i+1}} (1 - q^{2m_i})}{1 - q^{2m_1 + 2m_2 + \cdots + 2m_n + 2n + 2\alpha}} \mathbf{z}^{\underline{m}''}$$

[where $\underline{m}''=(m_1,\ldots,m_i-1,\ldots,m_n)$]. The first equality is obvious, the other follows from Proposition 3.1. ■

Note that for $\alpha=\infty$ the above relations coincide with the defining relations for $\mathcal{P}(\mathbb{C}^n)_q$.

The unital involutive algebra given by the above commutation relations can be viewed as a two-parameter deformation of the polynomial algebra on $\mathbb{C}^n$. It is easy to show that for $n=1$ the algebra is isomorphic to the one considered in details in Ref. 6 (see the Introduction).

D. Covariant symbols and *q*-Berezin transform

In this subsection, we define the notion of covariant symbols of operators on the q-weighted Bergman spaces and use it to define a q-analog of the Berezin transform.

To define covariant symbols we need a certain inner product in the space of operators on a q-weighted Bergman space (see the Introduction). This product is defined via the so-called q-trace. So we recall first its definition.

Let V be a finite-dimensional $U_q\mathfrak{sl}_{n+1}$-module. The q-trace is the linear functional on $\mathrm{End}(V)$ given by

$$\mathrm{tr}_q : T \mapsto \mathrm{tr}\left(T \cdot \prod_{j=1}^{n} K_j^{-j(n+1-j)} \right). \tag{3.9}$$

The following well known observation explains the importance of this functional (see Ref. 17): the q-trace is an invariant linear functional on $\mathrm{End}(V)$, i.e., $\mathrm{tr}_q(\xi(T))=\varepsilon(\xi)\cdot\mathrm{tr}_q(T)$ for any $\xi \in U_q\mathfrak{sl}_{n+1}$ and $T\in\mathrm{End}(V)$.

We will modify the definition slightly for the infinite-dimensional space $V=\mathbb{C}[\mathbb{C}^n]_{q,\alpha}$. Let $\mathrm{End}_0(\mathbb{C}[\mathbb{C}^n]_{q,\alpha})$ be the subspace in $\mathrm{End}(\mathbb{C}[\mathbb{C}^n]_{q,\alpha})$ of those automorphisms whose matrices in the basis $\{\mathbf{z}^{\underline{m}}\}$ have only finitely many nonzero entries. The q-trace (3.9) is a well defined linear functional on $\mathrm{End}_0(\mathbb{C}[\mathbb{C}^n]_{q,\alpha})$. The invariance property still holds in this case.

Proposition 3.6: The q-trace is an invariant linear functional on $\mathrm{End}_0(\mathbb{C}[\mathbb{C}^n]_{q,\alpha})$.

Sketch of a proof: A standard proof in the finite-dimensional case uses the canonical isomorphism of $U_q\mathfrak{sl}_{n+1}$-modules $\mathrm{End}(V)\simeq V\otimes V^*$ with V^* being the dual $U_q\mathfrak{sl}_{n+1}$-module.[17] The statement of Proposition 3.6 can be proved by the same argument since $\mathrm{End}_0(\mathbb{C}[\mathbb{C}^n]_{q,\alpha}) \simeq \mathbb{C}[\mathbb{C}^n]_{q,\alpha}\otimes\mathbb{C}[\mathbb{C}^n]^*_{q,\alpha}$. ■

Remarks: (i) The formula (3.9) is the same as the one which defines the invariant integral on the quantum ball (see Proposition 2.4). But Proposition 2.4 does not follow formally from the above statement since the $\mathcal{D}(U_n)_q$-module H is not a $U_q\mathfrak{sl}_{n+1}$-module.

(ii) Using the equality (3.12) below and the same idea as in the proof of Proposition 2.5 one can show that the scalar product in $\mathrm{End}_0(\mathbb{C}[\mathbb{C}^n]_{q,\alpha})$ given by $(T_1,T_2)=\mathrm{tr}_q(T_2^*\cdot T_1)$ is $U_q\mathfrak{su}_{n,1}$-invariant. The unitary representation of $U_q\mathfrak{su}_{n,1}$ in $\mathrm{End}_0(\mathbb{C}[\mathbb{C}^n]_{q,\alpha})$ should be treated as a q-analog of the canonical representation of $\mathrm{SU}(n,1)$.[23]

For a particular α, we shall use the modified q-trace Tr_q on $\mathrm{End}_0(\mathbb{C}[\mathbb{C}^n]_{q,\alpha})$ which differs from tr_q by a constant:

$$\mathrm{Tr}_q = q^{n(n+\alpha+1)} \frac{(q^2;q^2)_n}{(q^{2+2\alpha};q^2)_n} \mathrm{tr}_q .$$

It is easy to deduce the following explicit formula for Tr_q. Let $A\in\mathrm{End}_0(\mathbb{C}[\mathbb{C}^n]_{q,\alpha})$ be the endomorphism given by $A(\mathbf{z}^{\underline{m}})=\Sigma_{\underline{k}}A^{\underline{m}}_{\underline{k}}\cdot\mathbf{z}^{\underline{k}}$. Then

$$\mathrm{Tr}_q(A)=\frac{(q^2;q^2)_n}{(q^{2+2\alpha};q^2)_n}\cdot\sum_{\underline{m}} A^{\underline{m}}_{\underline{m}}\cdot q^{-2n(m_1+m_2+\cdots+m_n)}\cdot q^{2m_2+\cdots+2m_n}\cdot\ \cdots\ \cdot q^{2m_n}. \tag{3.10}$$

Now we are ready to define the notion of covariant symbols. Let $T\in\mathrm{End}(\mathbb{C}[\mathbb{C}^n]_{q,\alpha})$. A distribution $\sigma(T)\in\mathcal{D}(U_n)'_q$ is said to be the covariant symbol of T if for any $f\in\mathcal{D}(U_n)_q$

$$\int_{U_n} \sigma(T)\cdot f d\nu_q = \mathrm{Tr}_q(T\cdot T_f). \tag{3.11}$$

Note that for $f\in\mathcal{D}(U_n)_q$ one has $T_f\in \mathrm{End}_0(\mathbb{C}[\mathbb{C}^n]_{q,\alpha})$. Thus the right-hand side of (3.11) is well defined. The arguments cited at the end of Sec. II D imply existence and uniqueness of the covariant symbol of an arbitrary endomorphism F. Actually, the map $T\mapsto\sigma(T)$ is conjugated to the map $f\mapsto T_f$.

We have the following elementary property of the q-trace, which can be proved by the same arguments as the formula of integrating by parts (see the proof of Proposition 2.5): for any $T\in\mathrm{End}(\mathbb{C}[\mathbb{C}^n]_{q,\alpha})$, $T_0\in\mathrm{End}_0(\mathbb{C}[\mathbb{C}^n]_{q,\alpha})$, and $\xi\in U_q\mathfrak{su}_{n,1}$,

$$\mathrm{Tr}_q(\xi(T)\cdot T_0)=\mathrm{Tr}_q(T\cdot S(\xi)(T_0)). \tag{3.12}$$

This implies the following.

Proposition 3.7: The map

$$\mathrm{End}(\mathbb{C}[\mathbb{C}^n]_{q,\alpha})\to\mathcal{D}(U_n)'_q,\quad T\mapsto\sigma(T),$$

is a morphism of $U_q\mathfrak{su}_{n,1}$-modules.

Proof: The equality (3.12) gives an identification of the $U_q\mathfrak{su}_{n,1}$-module $\mathrm{End}(\mathbb{C}[\mathbb{C}^n]_{q,\alpha})$ with the dual of $\mathrm{End}_0(\mathbb{C}[\mathbb{C}^n]_{q,\alpha})$ (see the definition of the dual module in Sec. II D). What remains is to use Proposition 3.3 and the observation that the map $\mathrm{End}(\mathbb{C}[\mathbb{C}^n]_{q,\alpha})\to\mathcal{D}(U_n)'_q$, $T\mapsto\sigma(T)$ is conjugated to $\mathcal{D}(U_n)_q\to\mathrm{End}_0(\mathbb{C}[\mathbb{C}^n]_{q,\alpha})$, $f\mapsto T_f$. ■

We are in position to define the q-Berezin transform $B_{q,\alpha}$. It is defined as the linear map from $\mathcal{D}(U_n)_q$ to $\mathcal{D}(U_n)'_q$ which sends a finite function to the covariant symbol of the corresponding Toeplitz operator:

$$B_{q,\alpha}: f\mapsto\sigma(T_f).$$

The following crucial statement is straightforward.

Proposition 3.8: The q-Berezin transform is a morphism of $U_q\mathfrak{su}_{n,1}$-modules.

Due to Proposition 2.3, any morphism of $U_q\mathfrak{su}_{n,1}$-modules $T:\mathcal{D}(U_n)_q\to\mathcal{D}(U_n)'_q$ is completely determined by the element $T(f_0)\in\mathcal{D}(U_n)'_q$. Thus it would be very useful to compute $B_{q,\alpha}(f_0)$.

Proposition 3.9:

$$B_{q,\alpha}(f_0)=(q^{2\alpha+2};q^2)_n\cdot y_1^{\alpha+n+1}.$$

Proof: We have to check that for any $f\in\mathcal{D}(U_n)_q$

$$(q^{2\alpha+2};q^2)_n\int_{U_n} y_1^{\alpha+n+1}\cdot f d\nu_q=\mathrm{Tr}_q(T_{f_0}\cdot T_f). \tag{3.13}$$

Let us denote by $f^{\underline{k}}_{\underline{i},\underline{j}}$ ($\underline{k}\in P(n)$, $\underline{i},\underline{j}\in\mathbb{Z}^n_{\geqslant 0}$, $\underline{i}\times\underline{j}=\underline{0}$) the finite function given by $f^{\underline{k}}_{\underline{i},\underline{j}}=\mathbf{z}^{\underline{i}}f_{\underline{k}}(y_1,y_2,\ldots,y_n)\mathbf{z}^{*\underline{j}}$ with

$$f_{\underline{k}}(q^{2l_1},q^{2l_2},\ldots,q^{2l_n})=\begin{cases}1, & \underline{k}=\underline{l}\\ 0, & \text{otherwise.}\end{cases}$$

For example, $f^{\underline{0}}_{\underline{0},\underline{0}}=f_0$. Evidently, the functions $f^{\underline{k}}_{\underline{i},\underline{j}}$ constitute a basis in $\mathcal{D}(U_n)_q$.

It follows from the definitions that both sides of (3.13) vanish for $f:=f^{\underline{k}}_{\underline{i},\underline{j}}$ provided $\underline{i}\neq\underline{0}$ or $\underline{j}\neq\underline{0}$. Thus we have to verify (3.13) for $f:=f_{\underline{k}}$. It follows from (2.18) that

$$(q^{2\alpha+2};q^2)_n \int_{U_n} y_1^{\alpha+n+1} \cdot f_{\underline{k}} d\nu_q = (q^{2\alpha+2};q^2)_n \cdot (q^2;q^2)_n \cdot q^{2k_1(\alpha+1)} \cdot q^{2k_2} \cdot \ldots \cdot q^{2k_n}.$$

Let us compute the right-hand side of (3.13) with $f := f_{\underline{k}}$. Evidently,

$$f_0 \cdot \mathbf{z}^{\underline{m}} = \begin{cases} f_0, & \underline{m} = \underline{0}, \\ 0, & \text{otherwise.} \end{cases}$$

Besides, $\int_{U_n} f_0 dm_{\alpha,q} = (q^{2\alpha+2};q^2)_n$. These equalities mean that

$$T_{f_0}(\mathbf{z}^{\underline{m}}) = \begin{cases} (q^{2\alpha+2};q^2)_n, & \underline{m} = \underline{0}, \\ 0, & \text{otherwise.} \end{cases}$$

Clearly, the vector $f_{\underline{k}} \cdot \mathbf{z}^{\underline{m}} \in L^2(dm_{\alpha,q})$ is orthogonal to any monomial $\mathbf{z}^{\underline{l}}$ except the case $\underline{l} = \underline{m}$. In particular, the monomials are eigenvectors of $T_{f_{\underline{k}}}$. Thus

$$\begin{aligned} \mathrm{Tr}_q(T_{f_0} \cdot T_{f_{\underline{k}}}) &= (q^2;q^2)_n (T_{f_{\underline{k}}}(1),1)_{\alpha,q} \\ &= (q^2;q^2)_n \int_{U_n} f_{\underline{k}} dm_{\alpha,q} \\ &= (q^{2\alpha+2};q^2)_n \cdot (q^2;q^2)_n \cdot q^{2k_1(\alpha+1)} \cdot q^{2k_2} \cdot \ldots \cdot q^{2k_n}. \end{aligned}$$

■

IV. *q*-LAPLACE–BELTRAMI OPERATOR AND ASSOCIATED *q*-SPHERICAL TRANSFORM

In this section we define a q-analog of the SU(n.1)-invariant Laplace operator (the Laplace–Beltrami operator) on the unit ball and study a q-analog of the spherical transform in the unit ball. Namely, we calculate the ''radial part'' of the q-Laplace-Beltrami operator, find q-spherical functions, and present an inversion formula for the q-spherical transform.

A. *q*-Laplace–Beltrami operator

In this subsection, we consider the asymptotic expansion of the q-Berezin transform $B_{q,\alpha}$ at the limit $t = q^{2\alpha} \to 0$. A q-analog of the Laplace–Beltrami operator on the ball is defined as the coefficient at t in that expansion.

Recall (see the proof of Proposition 3.9) the notation $f^{\underline{k}}_{\underline{i},\underline{j}}$ ($\underline{k} \in P(n)$, $\underline{i},\underline{j} \in \mathbb{Z}^n_{\geqslant 0}$, $\underline{i} \times \underline{j} = \underline{0}$). Suppose T is the linear map from $\mathcal{D}(U_n)_q$ to $\mathcal{D}(U_n)'_q$. The numbers

$$T^{\underline{k},\underline{s}}_{\underline{i},\underline{j};\underline{p},\underline{r}} = \int_{U_n} T(f^{\underline{k}}_{\underline{i},\underline{j}}) \cdot f^{\underline{s}}_{\underline{p},\underline{r}} d\nu_q$$

will be called the matrix entries of T. Due to nondegeneracy of the pairing $\mathcal{D}(U_n)'_q \times \mathcal{D}(U_n)_q \to \mathbb{C}$ (Sec. II D), the matrix entries determine T completely.

Let us denote the matrix entries of the q-Berezin transform $B_{q,\alpha}$ by $B^{\underline{k},\underline{s}}_{\underline{i},\underline{j};\underline{p},\underline{r}}(\alpha)$. Introduce the new variable $t = q^{2\alpha}$. We will regard the matrix entries $B^{\underline{k},\underline{s}}_{\underline{i},\underline{j};\underline{p},\underline{r}}(\alpha)$ as functions of t and use the notation $B^{\underline{k},\underline{s}}_{\underline{i},\underline{j};\underline{p},\underline{r}}(t) := B^{\underline{k},\underline{s}}_{\underline{i},\underline{j};\underline{p},\underline{r}}(\alpha)$, $B_{q,t} := B_{q,\alpha}$.

Proposition 4.1: There exists a sequence $\{B_{q,j}\}_{j \in \mathbb{N}}$ *of linear endomorphisms of* $\mathcal{D}(U_n)_q$ *such that*

(i) $B_{q,j}$ *are independent of t (i.e., their matrix entries are independent of t);*

(ii) each $B_{q,j}$ *is a* $U_q\mathfrak{su}_{n,1}$*-module morphism; and*

(iii) for any $f \in \mathcal{D}(U_n)_q$

$$B_{q,t}(f)=f+\sum_{j=1}^{\infty} B_{q,j}(f)\cdot t^j, \tag{4.1}$$

where the series is convergent in $\mathcal{D}(U_n)_q'$.

Proof: First of all, we will construct a sequence $\{B_{q,j}\}_{j\in\mathbb{Z}_{\geqslant 0}}$ of linear operators from $\mathcal{D}(U_n)_q$ to $\mathcal{D}(U_n)_q'$ such that each $B_{q,j}$ is independent of t and $B_{q,t}(f)=\Sigma_{j=0}^{\infty}B_{q,j}(f)\cdot t^j$ for any $f\in\mathcal{D}(U_n)_q$ (the series is convergent in the sense that all the corresponding series of matrix entries are convergent). For that purpose we need the following.

Lemma 4.2: The matrix entries $B^{\underline{k},\underline{s}}_{\underline{i},\underline{j};\underline{p},\underline{r}}(t)$ *are polynomials in* t.

Proof of the lemma: Due to Proposition 2.3, for any $\underline{k},\underline{i},\underline{j}\in\mathbb{Z}^n_{\geqslant 0}$ ($\underline{i}\times\underline{j}=\underline{0}$) there exists $\xi^{\underline{k}}_{\underline{i},\underline{j}}\in U_q\mathfrak{su}_{n,1}$ such that $f^{\underline{k}}_{\underline{i},\underline{j}}=\xi^{\underline{k}}_{\underline{i},\underline{j}}(f_0)$. Then,

$$B^{\underline{k},\underline{s}}_{\underline{i},\underline{j};\underline{p},\underline{r}}(t)=\int_{U_n}B_{q,t}(f^{\underline{k}}_{\underline{i},\underline{j}})\cdot f^{\underline{s}}_{\underline{p},\underline{r}}d\nu_q=\int_{U_n}B_{q,t}(\xi^{\underline{k}}_{\underline{i},\underline{j}}(f_0))\cdot f^{\underline{s}}_{\underline{p},\underline{r}}d\nu_q=\int_{U_n}B_{q,t}(f_0)\cdot S(\xi^{\underline{k}}_{\underline{i},\underline{j}})(f^{\underline{s}}_{\underline{p},\underline{r}})d\nu_q,$$

where the last equality is due to Proposition 3.8 and the equality (2.20). Thus to prove the lemma it suffices to establish that the entries $B^{\underline{0},\underline{s}}_{\underline{0},\underline{0};\underline{p},\underline{r}}(t)=\int_{U_n}B_{q,t}(f_0)\cdot f^{\underline{s}}_{\underline{p},\underline{r}}d\nu_q$ are polynomials.

Recall (Proposition 3.9) that $B_{q,\alpha}(f_0)=(q^{2\alpha+2};q^2)_n\cdot y_1^{\alpha+n+1}$. Thus

$$\int_{U_n}B_{q,t}(f_0)\cdot f^{\underline{s}}_{\underline{p},\underline{r}}d\nu_q=(q^{2\alpha+2};q^2)_n\int_{U_n}y_1^{\alpha+n+1}\cdot f^{\underline{s}}_{\underline{p},\underline{r}}d\nu_q.$$

The latter integral vanishes with $\underline{p}\neq\underline{0}$ or $\underline{r}\neq\underline{0}$. Consider the integral $(q^{2\alpha+2};q^2)_n\int_{U_n}y_1^{\alpha+n+1}\cdot f_{\underline{k}}d\nu_q$ ($f_{\underline{k}}$ are defined in the proof of Proposition 3.9). Obviously,

$$\begin{aligned}(q^{2\alpha+2};q^2)_n\int_{U_n}y_1^{\alpha+n+1}\cdot f_{\underline{k}}d\nu_q&=(q^{2\alpha+2};q^2)_n(q^2;q^2)_n q^{2k_1(\alpha+1)}q^{2k_2}\cdots q^{2k_n}\\&=(q^2t;q^2)_n(q^2;q^2)_n q^{2k_1}t^{k_1}q^{2k_2}\cdots q^{2k_n}.\end{aligned}$$

■

Now we can define $\{B_{q,m}\}_{m\in\mathbb{Z}_{\geqslant 0}}$ by their matrix coefficients

$$(B_{q,m})^{\underline{k},\underline{s}}_{\underline{i},\underline{j};\underline{p},\underline{r}}=\frac{1}{m!}\left.\frac{d^mB^{\underline{k},\underline{s}}_{\underline{i},\underline{j};\underline{p},\underline{r}}(t)}{dt^m}\right|_{t=0}.$$

This definition implies the $U_q\mathfrak{su}_{n,1}$-invariance of the maps $B_{q,m}$. Indeed, we should prove coincidence of the maps $B_{q,m}\cdot\xi$ and $\xi\cdot B_{q,m}$ for any $\xi\in U_q\mathfrak{su}_{n,1}$, or, equivalently, equality of all matrix entries $(B_{q,m}\cdot\xi)^{\underline{k},\underline{s}}_{\underline{i},\underline{j};\underline{p},\underline{r}}$ and $(\xi\cdot B_{q,m})^{\underline{k},\underline{s}}_{\underline{i},\underline{j};\underline{p},\underline{r}}$. Due to $U_q\mathfrak{su}_{n,1}$-invariance of $B_{q,t}$, one has

$$(B_{q,t}\cdot\xi)^{\underline{k},\underline{s}}_{\underline{i},\underline{j};\underline{p},\underline{r}}=(\xi\cdot B_{q,t})^{\underline{k},\underline{s}}_{\underline{i},\underline{j};\underline{p},\underline{r}}$$

for any $\underline{i},\underline{j},\underline{p},\underline{r},\underline{k},\underline{s}$. What remains is to differentiate the latter equality.

Let us show that the image of the map $B_{q,m}:\mathcal{D}(U_n)_q\to\mathcal{D}(U_n)_q'$ is contained in $\mathcal{D}(U_n)_q$. Since all $B_{q,m}$ are morphisms of $U_q\mathfrak{su}_{n,1}$-modules, we need to verify that $B_{q,m}(f_0)\in\mathcal{D}(U_n)_q$. This can be easily deduced from the following equivalent formulation of Proposition 3.9:

$$B_{q,t}(f_0)=(q^2t;q^2)_n\cdot\sum_{k=0}^{\infty}f_kq^{2k(n+1)}t^k, \tag{4.2}$$

where f_k, $k\in\mathbb{Z}_{\geqslant 0}$, are the finite functions given by

$$f_k = f_k(y_1, y_2, \ldots, y_n) = \begin{cases} 1, & y_1 = q^{2k}, \\ 0, & \text{otherwise}, \end{cases} \tag{4.3}$$

and the series (4.2) is convergent in $\mathcal{D}(U_n)'_q$. Differentiating with respect to t proves $B_{q,m}(f_0) \in \mathcal{D}(U_n)_q$.

The equality (4.2) and continuity of the $U_q\mathfrak{su}_{n,1}$-action in $\mathcal{D}(U_n)'_q$ prove also statement (iii) of Proposition 4.1. ■

Proposition 4.1 implies, in particular, that $B_{q,t} = \mathrm{id} + o(1)$ when $t \to 0$. By analogy with the classical case we call the first term of the asymptotic series (4.1) the q-Laplace–Beltrami operator on the quantum ball:

$$\Delta_{n,q} = \frac{q^{-2n}}{1-q^2} \frac{dB_{q,t}}{dt}\bigg|_{t=0}. \tag{4.4}$$

Clearly, $\Delta_{n,q}: \mathcal{D}(U_n)_q \to \mathcal{D}(U_n)_q$ is a morphism of $U_q\mathfrak{su}_{n,1}$-modules.

There are many evidences that this operator should indeed be treated as a q-analog of the classical Laplace-Beltrami operator in the unit ball. The results of the present section provide an example of such an evidence.

In conclusion, we make also the following remark. The operator $\Delta_{n,q}$ appeared as the first term of asymptotic of the q-Berezin transform. It turns out that other terms can be explicitly expressed via $\Delta_{n,q}$. This will be shown in the next section (Sec. V B).

B. Radial part of the *q*-Laplace–Beltrami operator

In the classical case the Laplace–Beltrami operator in the unit ball keeps invariant the space of smooth radial functions, i.e., functions depending on the radius only. The reason is that the radial functions are precisely the $\mathrm{S}(\mathrm{U}(n)\times\mathrm{U}(1))$-invariant functions with $\mathrm{S}(\mathrm{U}(n)\times\mathrm{U}(1)) \subset \mathrm{SU}(n,1)$ being the isotropy group of the center of the ball. Thus the "right" q-analog of the radial functions are functions on the quantum ball which are $U_q\mathfrak{s}(\mathfrak{u}_n \times \mathfrak{u}_1)$-invariant where $U_q\mathfrak{s}(\mathfrak{u}_n \times \mathfrak{u}_1)$ is the $*$-Hopf subalgebra in $U_q\mathfrak{su}_{n,1}$ generated by E_i, F_i, $i = 1,2,\ldots,n-1$, and all $K_j^{\pm 1}$, s.

It can be proved that any $U_q\mathfrak{s}(\mathfrak{u}_n \times \mathfrak{u}_1)$-invariant element in $\mathcal{P}(\mathbb{C}^n)_q$ is a polynomial in $z_1 z_1^* + z_2 z_2^* + \cdots + z_n z_n^*$. The idea of the proof is as follows. $U_q\mathfrak{s}(\mathfrak{u}_n \times \mathfrak{u}_1)$-invariance of a polynomial, in particular, implies its $U_q\mathfrak{h}$-invariance, i.e., K_j-invariance for any j. Obviously, the latter means that the polynomial depends on $z_1 z_1^*, z_2 z_2^*, \ldots, z_n z_n^*$ only. One can write down without difficulties explicit formulas for the action of the generators E_i, F_i, $i = 1,2,\ldots,n-1$, on an arbitrary element which depends on $z_1 z_1^*, z_2 z_2^*, \ldots, z_n z_n^*$ and find the invariant elements.

In many computations it is convenient to use the element $y_1 = 1 - z_1 z_1^* - \cdots - z_n z_n^*$ instead of $z_1 z_1^* + z_2 z_2^* + \cdots + z_n z_n^*$ since the former quasicommutes with all the generators z_i, z_i^* [see (2.16)]:

$$z_i y_1 = q^{-2} y_1 z_i, \quad z_i^* y_1 = q^2 y_1 z_i^*.$$

In the sequel we omit the subscript 1 in the notation for y_1.

Using precisely the same arguments, one can show that any $U_q\mathfrak{s}(\mathfrak{u}_n \times \mathfrak{u}_1)$-invariant finite function or distribution on the quantum ball depends on $y = y_1$ only.

Recall the notation f_k, $k \in \mathbb{Z}_{\geqslant 0}$, from the previous subsection:

$$f_k(y) = \begin{cases} 1, & y = q^{2k}, \\ 0, & \text{otherwise}. \end{cases}$$

These functions constitute a basis in the space of radial finite functions on the quantum ball. They have the following obvious properties: first, $f_k \cdot f_l = \delta_{kl} f_k$ with δ_{kl} being the Kronecker symbol, and, second, for any distribution $f(y)$,

$$f=\sum_{k=0}^{\infty} f(q^{2k})\cdot f_k,$$

where the series converges in $\mathcal{D}(U_n)'_q$.

Our aim now is to compute the action of the q-Laplace–Beltrami operator $\Delta_{n,q}$ on radial finite functions. We would determine the action completely if we find $\Delta_{n,q}(f_k)$.

Proposition 4.3: The operator $\Delta_{n,q}$ has the following matrix form:

$$\Delta_{n,q}(f_k)=\frac{q^2}{(1-q^2)^2}\cdot((1-q^{2k+2})f_{k+1}-(1+q^{-2n}-2q^{2k})f_k+(q^{-2n}-q^{2k-2})f_{k-1})$$

(we assume $f_k\equiv 0$ for $k<0$).

The proof of the proposition will be given in Sec. IV D.

Proposition 4.3 allows us to apply the q-Laplace–Beltrami operator to any radial function $f=f(y)$. We call the restriction of the operator to the space of radial functions the radial part of the q-Laplace–Beltrami operator and denote it by $\Delta^{(\mathrm{r})}_{n,q}$. Using the explicit formula from Proposition 4.3, one can show that the radial part is given by the following second-order difference operator

$$\Delta^{(\mathrm{r})}_{n,q}=\frac{q^{-n}y^{n+1}}{(yq^2;q^2)_{n-1}}Dy^{-n+1}(yq;q^2)_nD \tag{4.5}$$

with $Df(y)=[f(q^{-1}y)-f(qy)]/(q^{-1}y-qy)$.

C. *q*-spherical transform

In this subsection we describe eigenfunctions of the operator $\Delta^{(\mathrm{r})}_{n,q}$ and present an explicit formula for expansion in these functions. The associated q-spherical transform should be viewed as a q-analog of the spherical transform in the unit ball.[12] The eigenfunctions of $\Delta^{(\mathrm{r})}_{n,q}$ appear to be closely related to certain one-parameter family of the Al-Salam-Chihara polynomials,[13] and this observation simplifies proofs of many statements.

Recall the definition of the basic hypergeometric series ${}_3\phi_2$:[20]

$${}_3\phi_2\left(\begin{matrix}a_1, & a_2, & a_3\\ b_1, & b_2\end{matrix}\,q,\quad z\right)=\sum_{n=0}^{\infty}\frac{(a_1;q)_n\cdot(a_2;q)_n\cdot(a_3;q)_n}{(b_1;q)_n\cdot(b_2;q)_n\cdot(q;q)_n}z^n.$$

Recall also the notation $h=\log q^{-2}$ (see the Introduction). We define the element $\phi_\rho(y)\in\mathcal{D}(U_n)'_q$ as follows:

$$\phi_\rho(y)={}_3\phi_2\left(\begin{matrix}y^{-1}, & q^{n+i\rho}, & q^{n-i\rho}\\ & q^{2n}, & 0\end{matrix}\,q^2,\quad q^2\right),\qquad \rho\in\left[0;\frac{2\pi}{h}\right]. \tag{4.6}$$

Obviously, $\phi_\rho(1)=1$. It is a q-analog of the spherical function in the unit ball as one can see from the following.

Proposition 4.4: The distribution $\phi_\rho(y)$ is an eigenvector of the operator $\Delta^{(\mathrm{r})}_{n,q}$:

$$\Delta^{(\mathrm{r})}_{n,q}(\phi_\rho(y))=\lambda(\rho)\cdot\phi_\rho(y)$$

with $\lambda(\rho)=-q^{2-2n}(1-q^{n+i\rho})(1-q^{n-i\rho})/(1-q^2)^2$, $\rho\in[0;2\pi/h]$.

Proof: Recall the notation $Q_m(x;a,b|q)$ for the Al-Salam-Chihara polynomials (Ref. 13, Sec. 3.8). It is straightforward that

$$\phi_\rho(q^{2m})=\frac{q^{nm}}{(q^{2n};q^2)_m}\cdot Q_m\left(\cos\frac{h\rho}{2};q^n,q^n\middle|q^2\right). \tag{4.7}$$

The statement of Proposition 4.4 is just another formulation of the recurrence relation for the Al-Salam-Chihara polynomials [Ref. 13, (3.8.4)]. ■

Let us compute restriction of the invariant integral in the quantum ball onto the space of radial finite functions:

$$\begin{aligned}\int_{U_n} f(y)\,d\nu_q &= (q^2;q^2)_n\cdot\sum_{\underline{k}\in P(n)} f(q^{2k_1})\cdot q^{-2nk_1}\cdot q^{2k_2}\cdot\ \dots\ \cdot q^{2k_n}\\ &= (q^2;q^2)_n\cdot\sum_{k=0}^{\infty} f(q^{2k})\cdot q^{-2nk}\sum_{0\leqslant k_n\leqslant\dots\leqslant k_2\leqslant k} q^{2k_2}\cdot\ \dots\ \cdot q^{2k_n}.\end{aligned}$$

Using the formula (4.15) and the Jackson integral (3.5), we finally get

$$\int_{U_n} f(y)\,d\nu_q=\frac{1-q^{2n}}{1-q^2}\int_0^1 f(y)y^{-n-1}(yq^2;q^2)_{n-1}d_{q^2}y. \tag{4.8}$$

Let us denote by $\mathcal{L}_{n,q}$ and $\mathcal{L}'_{n,q}$ the spaces of radial finite functions and radial distributions on the quantum ball, respectively. Elements of these spaces can be treated as functions on the geometric progression $q^{2\mathbb{Z}_{\geqslant 0}}$. We also impose the notation $\mathcal{L}^2_{n,q}$ for the Hilbert space of ''square integrable'' radial distributions:

$$\mathcal{L}^2_{n,q}=\left\{ f(y)\in\mathcal{L}'_{n,q}\ \middle|\ \|f\|^2_{\mathcal{L}^2}=\frac{1-q^{2n}}{1-q^2}\int_0^1|f(y)|^2y^{-n-1}(yq^2;q^2)_{n-1}d_{q^2}y<\infty\right\}.$$

We define the q-spherical transform as the map $\mathcal{F}:\mathcal{L}_{n,q}\to C^\infty(0;2\pi/h)$ given by

$$f(y)\mapsto\mathcal{F}f(\rho)=\frac{1-q^{2n}}{1-q^2}\int_0^1 f(y)\phi_\rho(y)y^{-n-1}(yq^2;q^2)_{n-1}d_{q^2}y. \tag{4.9}$$

It is clear (see the proof of Proposition 4.4) that

$$\begin{aligned}\mathcal{F}f_k(\rho)&=(1-q^{2n})\cdot q^{-2kn}\cdot(q^{2k+2};q^2)_{n-1}\cdot\phi_\rho(q^{2k})\\ &=(1-q^{2n})\cdot q^{-kn}\cdot\frac{(q^{2k+2};q^2)_{n-1}}{(q^{2n};q^2)_k}\cdot Q_k\left(\cos\frac{h\rho}{2};q^n,q^n\middle|q^2\right).\end{aligned} \tag{4.10}$$

Hence the image of $\mathcal{F}$ is the space of polynomials in $\cos h\rho/2$.

The following proposition can be derived from the spectral decomposition of the operator $\Delta^{(\mathrm{r})}_{n,q}$, and a special case of a general result of Ref. 11, Sec. 5.

Proposition 4.5: (i) The operator $\Delta^{(\mathrm{r})}_{n,q}$ on $\mathcal{L}_{n,q}$ can be extended to a bounded self-adjoint operator on $\mathcal{L}^2_{n,q}$. It has simple purely continuous spectrum which coincides with the segment $[\lambda(2\pi/h);\lambda(0)]$ (with λ being defined in Proposition 4.4).

(ii) For any finite function $f(y)$

$$f(y)=\frac{1}{4\pi}\cdot\frac{h}{1-q^{2n}}\cdot\int_0^{2\pi/h}\mathcal{F}f(\rho)\phi_\rho(y)\frac{d\rho}{|c(\rho)|^2}, \tag{4.11}$$

where $c(\rho)$ (a q-analog of the Harish–Chandra function) is given by

$$c(\rho)=\frac{\Gamma_{q^2}(n)\Gamma_{q^2}(i\rho)}{\Gamma^2_{q^2}(n/2+i\rho/2)}.$$

(iii) The q-spherical transform $\mathcal{F}:\mathcal{L}_{n,q}\to C^\infty(0;2\pi/h)$ *can be extended to a unitary linear operator* $\mathcal{F}:\mathcal{L}^2_{n,q}\to L^2(d\rho/|c(\rho)|^2)$:

$$\frac{1-q^{2n}}{1-q^2}\int_0^1|f(y)|^2y^{-n-1}(yq^2;q^2)_{n-1}d_{q^2}y=\frac{1}{4\pi}\cdot\frac{h}{1-q^{2n}}\cdot\int_0^{2\pi/h}|\mathcal{F}f(\rho)|^2\frac{d\rho}{|c(\rho)|^2} \quad (4.12)$$

(the Plancherel formula).

Note that, due to (4.10), statement (*iii*) can be rewritten as the orthogonality relations for the Al-Salam-Chihara polynomials (Ref. 13, Sec. 3.8):

$$\frac{1}{4\pi}\int_0^{2\pi/h}Q_k\left(\cos\frac{h\rho}{2};q^n,q^n\middle|q^2\right)Q_m\left(\cos\frac{h\rho}{2};q^n,q^n\middle|q^2\right)\frac{d\rho}{|c(\rho)|^2}=\delta_{km}\cdot\frac{(q^{2n};q^2)^2_k}{h(q^{2k+2};q^2)_{n-1}}. \quad (4.13)$$

D. Proof of Proposition 4.3

It suffices, due to (4.4), to verify that

$$B_{q,t}(f_k)=f_k+t\frac{q^{2n+2}}{(1-q^2)}\cdot((1-q^{2k+2})f_{k+1}-(1+q^{-2n}-2q^{2k})f_k+(q^{-2n}-q^{2k-2})f_{k-1}) \quad (4.14)$$

modulo t^2. For that purpose we compute first T_{f_k}.

Recall the notation $\mathbb{C}[\mathbb{C}^n]_{q,\alpha}$ (Sec. III A). Define a $\mathbb{Z}_{\geqslant 0}$-grading in the space $\mathbb{C}[\mathbb{C}^n]_{q,\alpha}$ as follows:

$$\mathbb{C}[\mathbb{C}^n]^{(m)}_{q,\alpha}=\text{linear span of } \mathbf{z}^{\underline{m}},\ |\underline{m}|=m.$$

We need first the following lemma.

Lemma 4.6:

$$T_{f_k}|_{\mathbb{C}[\mathbb{C}^n]^{(m)}_{q,\alpha}}=q^{2(k-m)(\alpha+1)}\cdot\frac{(q^{2\alpha+2};q^2)_{n+m}\cdot(q^{2k-2m+2};q^2)_{n+m-1}}{(q^2;q^2)_{n+m-1}}.$$

Proof of the lemma: Using the same arguments as in the classical case, it can be proved that $\mathbb{C}[\mathbb{C}^n]^{(m)}_{q,\alpha}$, $m\in\mathbb{Z}_{\geqslant 0}$, are pairwise non-isomorphic irreducible $U_q\mathfrak{s}(\mathfrak{u}_n\times\mathfrak{u}_1)$-modules [we mean restriction of the representation π_α onto $U_q\mathfrak{s}(\mathfrak{u}_n\times\mathfrak{u}_1)$]. Due to the $U_q\mathfrak{s}(\mathfrak{u}_n\times\mathfrak{u}_1)$-invariance of f_k [with respect to the untwisted $U_q\mathfrak{s}(\mathfrak{u}_n\times\mathfrak{u}_1)$-action], Proposition 3.3, and the Schur lemma,

$$T_{f_k}|_{\mathbb{C}[\mathbb{C}^n]^{(m)}_{q,\alpha}}=c_k^m.$$

[Since $\mathbb{C}[\mathbb{C}^n]^{(m)}_{q,\alpha}$ is an irreducible $U_q\mathfrak{s}(\mathfrak{u}_n\times\mathfrak{u}_1)$-module, the algebra homomorphism $U_q\mathfrak{s}(\mathfrak{u}_n\times\mathfrak{u}_1)\to\mathrm{End}(\mathbb{C}[\mathbb{C}^n]^{(m)}_{q,\alpha})$ is surjective, however the only operators commuting with the full matrix algebra are constants.] To compute the constant c_k^m we apply T_{f_k} to a distinguished vector in $\mathbb{C}[\mathbb{C}^n]^{(m)}_{q,\alpha}$, for example, z_n^m:

$$c_k^m=\frac{(T_{f_k}z_n^m,z_n^m)_{\alpha,q}}{(z_n^m,z_n^m)_{\alpha,q}}=\frac{(f_kz_n^m,z_n^m)_{\alpha,q}}{(z_n^m,z_n^m)_{\alpha,q}}.$$

By Proposition 3.1 the denominator is equal to $(q^2;q^2)_m/(q^{2n+2\alpha+2};q^2)_m$. What remains is to compute the numerator:

$$
\begin{aligned}
(T_{f_k} z_n^m, z_n^m)_{\alpha,q} &= \int_{U_n} z_n^{*m} f_k z_n^m dm_{\alpha,q} \\
&= \int_{U_n} f_{k-m}(q^2 y_n; q^2)_m dm_{\alpha,q} \\
&= (q^{2\alpha+2};q^2)_n \sum_{\underline{k}\in P(n)} f_{k-m}(q^{2k_1})(q^{2+2k_n};q^2)_m q^{2k_1(\alpha+1)} q^{2k_2}\cdots q^{2k_n} \\
&= (q^{2\alpha+2};q^2)_n q^{2(k-m)(\alpha+1)} \sum_{0\leqslant k_n\leqslant\cdots\leqslant k_2\leqslant k-m} (q^{2+2k_n};q^2)_m q^{2k_2}\cdots q^{2k_n}.
\end{aligned}
$$

To continue computation we need the following simple formula which can be proved by induction:

$$
\sum_{a\leqslant l_n\cdots\leqslant l_1\leqslant b} q^{2l_1}\cdots q^{2l_n} = q^{2an}\frac{(q^{2b-2a+2};q^2)_n}{(q^2;q^2)_n}. \tag{4.15}
$$

By this formula $(q^{2+2k_n};q^2)_m = (q^2;q^2)_m \Sigma_{0\leqslant l_m\leqslant\cdots\leqslant l_1\leqslant k_n} q^{2l_1}\cdots q^{2l_m}$. Applying (4.15) one more time, we finally get

$$
(T_{f_k} z_n^m, z_n^m)_{\alpha,q} = (q^{2\alpha+2};q^2)_n q^{2(k-m)(\alpha+1)} (q^2;q^2)_m \frac{(q^{2k-2m+2};q^2)_{n+m-1}}{(q^2;q^2)_{n+m-1}}.
$$

■

Let P_m denote the orthogonal projection in $\mathbb{C}[\mathbb{C}^n]_{q,\alpha}$ onto $\mathbb{C}[\mathbb{C}^n]_{q,\alpha}^{(m)}$. The above lemma says that

$$
T_{f_k} = \sum_{m=0}^{k} q^{2(k-m)(\alpha+1)} \cdot \frac{(q^{2\alpha+2};q^2)_{n+m}\cdot(q^{2k-2m+2};q^2)_{n+m-1}}{(q^2;q^2)_{n+m-1}} \cdot P_m. \tag{4.16}
$$

Lemma 4.7: The covariant symbol $\sigma(P_m)$ is given by

$$
\sigma(P_m) = q^{-2m(\alpha+n+1)} \cdot \frac{(q^{2\alpha+2n+2};q^2)_m}{(q^2;q^2)_m} \cdot y^{\alpha+n+1} \cdot (yq^{-2m+2};q^2)_m.
$$

Proof of the lemma: Since $\mathbb{C}[\mathbb{C}^n]_{q,\alpha}^{(m)}$, $m\in\mathbb{Z}_{\geqslant 0}$, are pairwise non-isomorphic irreducible $U_q\mathfrak{s}(\mathfrak{u}_n\times\mathfrak{u}_1)$-modules, the projections P_m are $U_q\mathfrak{s}(\mathfrak{u}_n\times\mathfrak{u}_1)$-module morphisms. Thus by Proposition 3.7 $\sigma(P_m)$ should be a function of y. Denote it by $p_m(y)$. Recall that $p_m(y) = \Sigma_{k=0}^{\infty} p_m(q^{2k}) f_k(y)$. The coefficients $p_m(q^{2k})$ can be derived from the equalities

$$
\int_{U_n} p_m(y)\cdot f_l d\nu_q = \mathrm{Tr}_q(P_m\cdot T_{f_l}), \quad l\in\mathbb{Z}_{\geqslant 0}.
$$

Using the property $f_k\cdot f_l = \delta_{kl} f_k$ and Lemma 4.6, we can rewrite the latter equality as follows:

$$
\begin{aligned}
& p_m(q^{2l})\cdot(q^2;q^2)_n\cdot q^{-2nl}\cdot \sum_{0\leqslant k_n\leqslant\cdots\leqslant k_2\leqslant l} q^{2k_2}\cdots q^{2k_n} \\
&\quad = q^{2(l-m)(\alpha+1)}\cdot \frac{(q^{2\alpha+2};q^2)_{n+m}\cdot(q^{2l-2m+2};q^2)_{n+m-1}}{(q^2;q^2)_{n+m-1}}\cdot \mathrm{Tr}_q(P_m).
\end{aligned}
$$

By (3.10) $\mathrm{Tr}_q(P_m) = [(q^2;q^2)_n/(q^{2\alpha+2};q^2)_n]\cdot q^{-2nm}\cdot\Sigma_{0\leqslant k_n\leqslant\cdots\leqslant k_2\leqslant m} q^{2k_2}\cdots q^{2k_n}$. Using (4.15) we obtain $p_m(q^{2l}) = [(q^{2\alpha+2n+2};q^2)_m\cdot(q^{2l-2m+2};q^2)_m/(q^2;q^2)_m]\cdot q^{2(l-m)(\alpha+n+1)}$. ■

We continue the proof of our proposition. Lemmas 4.6 and 4.7 now imply

$$B_{q,\alpha}(f_k)=q^{2k(\alpha+1)}\cdot y^{\alpha+n+1}\cdot\sum_{m=0}^{k}q^{-4m(\alpha+1)-2mn}\cdot\frac{(q^{2\alpha+2};q^2)_{n+m}(q^{2k-2m+2};q^2)_{n+m-1}(q^{2\alpha+2n+2};q^2)_m}{(q^2;q^2)_{n+m-1}(q^2;q^2)_m}\cdot(yq^{-2m+2};q^2)_m.\tag{4.17}$$

Note that $(yq^{-2m+2};q^2)_m=\Sigma_{l=0}^{\infty}(q^{2l-2m+2};q^2)_m\cdot f_l=\Sigma_{l=m}^{\infty}(q^{2l-2m+2};q^2)_m\cdot f_l$. Consequently,

$$y^{\alpha+n+1}\cdot(yq^{-2m+2};q^2)_m=\sum_{l=m}^{\infty}q^{2l(\alpha+n+1)}\cdot(q^{2l-2m+2};q^2)_m\cdot f_l=\sum_{r=0}^{\infty}q^{2(m+r)(\alpha+n+1)}\cdot(q^{2r+2};q^2)_m\cdot f_{m+r},$$

and

$$B_{q,\alpha}(f_k)=\sum_{m=0}^{k}\sum_{r=0}^{\infty}q^{2\alpha(k-m+r)}\cdot q^{2k-2m+2rn+2r}\cdot\frac{(q^{2\alpha+2};q^2)_{n+m}(q^{2k-2m+2};q^2)_{n+m-1}(q^{2\alpha+2n+2};q^2)_m(q^{2r+2};q^2)_m}{(q^2;q^2)_{n+m-1}(q^2;q^2)_m}\cdot f_{m+r}.$$

The substitution $t=q^{2\alpha}$ gives

$$B_{q,t}(f_k)=\sum_{m=0}^{k}\sum_{r=0}^{\infty}t^{k-m+r}\cdot q^{2k-2m+2rn+2r}\cdot\frac{(tq^2;q^2)_{n+m}(q^{2k-2m+2};q^2)_{n+m-1}(tq^{2n+2};q^2)_m(q^{2r+2};q^2)_m}{(q^2;q^2)_{n+m-1}(q^2;q^2)_m}\cdot f_{m+r}.$$

To finish the proof of (4.14) we have to compute the coefficient at t in the last series. Due to presence of t^{k-m+r} in the sum, the only terms which might give a nonzero contribution to this coefficient correspond to the values $(m,r)=(k,0)$, $(m,r)=(k,1)$, or $(m,r)=(k-1,0)$ which we treat separately.

(1) $(m,r)=(k,0)$: the corresponding term is equal to

$$(tq^2;q^2)_{n+k}(tq^{2n+2};q^2)_k f_k=\left(1-t\frac{q^{2n+2}}{(1-q^2)}(1+q^{-2n}-2q^{2k})\right)f_k+o(t).$$

(2) $(m,r)=(k,1)$: the corresponding term is equal to

$$t\cdot q^{2n+2}\cdot(tq^2;q^2)_{n+k}(tq^{2n+2};q^2)_k\frac{1-q^{2k+2}}{1-q^2}f_{k+1}=t\cdot\frac{q^{2n+2}}{(1-q^2)}\cdot(1-q^{2k+2})f_{k+1}+o(t).$$

(3) $(m,r)=(k-1,0)$: the corresponding term is equal to

$$t\cdot q^2\cdot(tq^2;q^2)_{n+k-1}(tq^{2n+2};q^2)_{k-1}\frac{1-q^{2n+2k-2}}{1-q^2}f_{k-1}=t\cdot\frac{q^{2n+2}}{(1-q^2)}\cdot(q^{-2n}-q^{2k-2})f_{k-1}+o(t).$$

This finishes the proof.

V. FURTHER PROPERTIES OF THE *q*-BEREZIN TRANSFORM

In this section we study further the q-Berezin transform. Namely, we consider its restriction $B^{(\mathrm{r})}_{q,\alpha}$ onto the space of radial functions. We prove that $B^{(\mathrm{r})}_{q,\alpha}$ is extended to a bounded self-adjoint operator on $\mathcal{L}^2_{n,q}$ which commutes with the radial part $\Delta^{(\mathrm{r})}_{n,q}$ of the q-Laplace–Beltrami operator. Since the latter has a simple spectrum, $B^{(\mathrm{r})}_{q,\alpha}$ is a function of $\Delta^{(\mathrm{r})}_{n,q}$. We find the function explicitly. In the classical case this is computed in Ref. 24 We also present an asymptotic expansion for the q-Berezin transform at the limit $t=q^{2\alpha}\to 0$ mentioned at the end of Sec. IV A.

A. Boundedness of the *q*-Berezin transform

Let $B^{(\mathrm{r})}_{q,\alpha}:\mathcal{L}_{n,q}\to\mathcal{L}'_{n,q}$ be restriction of the q-Berezin transform onto the space $\mathcal{L}_{n,q}$ of finite radial functions on the quantum ball.

Proposition 5.1: $B^{(\mathrm{r})}_{q,\alpha}$ can be extended to a bounded self-adjoint operator on $\mathcal{L}^2_{n,q}$. It is a function of $\Delta^{(\mathrm{r})}_{n,q}$. The operator $\mathcal{F}\cdot B^{(\mathrm{r})}_{q,\alpha}\cdot\mathcal{F}^{-1}$ on $L^2(d\rho/|c(\rho)|^2)$ is the multiplication by the (bounded) function

$$b_{q,\alpha}(\rho)=\frac{(q^{2+2\alpha};q^2)_\infty\cdot(q^{2n+2+2\alpha};q^2)_\infty}{(q^{n+2+2\alpha+i\rho};q^2)_\infty\cdot(q^{n+2+2\alpha-i\rho};q^2)_\infty}. \tag{5.1}$$

Proof: We divide the proof into three lemmas.

Lemma 5.2: $B^{(\mathrm{r})}_{q,\alpha}(\mathcal{L}_{n,q})\subset\mathcal{L}^2_{n,q}$ and one has the equality

$$\Delta^{(\mathrm{r})}_{n,q}\cdot B^{(\mathrm{r})}_{q,\alpha}=B^{(\mathrm{r})}_{q,\alpha}\cdot\Delta^{(\mathrm{r})}_{n,q} \tag{5.2}$$

of linear maps from $\mathcal{L}_{n,q}$ to $\mathcal{L}^2_{n,q}$.

Sketch of a proof: The inclusion is due to the formula (4.17). Indeed, one has to show that $y^{\alpha+n+1}\cdot(yq^{-2m+2};q^2)_m\in\mathcal{L}^2_{n,q}$ for any m, and this is clear by the definition.

To prove the equality (5.2), we have to show that $\Delta^{(\mathrm{r})}_{n,q}\cdot B^{(\mathrm{r})}_{q,\alpha}(f_k)=B^{(\mathrm{r})}_{q,\alpha}\cdot\Delta^{(\mathrm{r})}_{n,q}(f_k)$ for any k. The left-hand side may be computed by successive application of (4.17) and (4.5) while the right-hand one may be computed via Proposition 4.3 and (4.17). ■

Lemma 5.3: Suppose B is a linear operator from $\mathcal{L}_{n,q}$ to $\mathcal{L}^2_{n,q}$ which satisfies the properties

$$\Delta^{(\mathrm{r})}_{n,q}\cdot B=B\cdot\Delta^{(\mathrm{r})}_{n,q};$$

$$Bf_0=(q^{2\alpha+2};q^2)_n\cdot y^{\alpha+n+1}.$$

Then $B=B^{(\mathrm{r})}_{q,\alpha}$.

Proof: The statement is a simple consequence of the equality

$$\mathcal{L}_{n,q}=\text{linear span of }\{(\Delta^{(\mathrm{r})}_{n,q})^m f_0\}_{m\in\mathbb{Z}_{\geqslant 0}},$$

which in turn may be deduced easily from Proposition 4.3. ■

Lemma 5.4: The bounded self-adjoint operator $\mathcal{F}^{-1}\cdot b_{q,\alpha}(\rho)\cdot\mathcal{F}$ [$b_{q,\alpha}$ is given by (5.1)] on $\mathcal{L}^2_{n,q}$ possesses the properties from the previous lemma.

Proof: The first property holds trivially. Let us prove the second one.

Let $(\cdot,\cdot)_{L^2}$, $(\cdot,\cdot)_{\mathcal{L}^2}$ be the inner products in $L^2(d\rho/|c(\rho)|^2)$ and $\mathcal{L}^2_{n,q}$, respectively. It is sufficient to show that

$$(b_{q,\alpha}(\rho)\cdot\mathcal{F}f_0,\ \mathcal{F}f_k)_{L^2}=(q^{2\alpha+2};q^2)_n\cdot(y^{\alpha+n+1},\ f_k)_{\mathcal{L}^2}$$

for any $k\in\mathbb{Z}_{\geqslant 0}$. Recall (4.10) that $\mathcal{F}f_k(\rho)=(1-q^{2n})\cdot q^{-kn}\cdot[(q^{2k+2};q^2)_{n-1}/(q^{2n};q^2)_k]\cdot Q_k(\rho)$ with $Q_k(\rho):=Q_k(\cos(h\rho/2);q^n,q^n|q^2)$. We rewrite the condition as follows:

$$(b_{q,\alpha}(\rho),\ Q_k(\rho))_{L^2}=q^{k(n+2+2\alpha)}\cdot\frac{(q^{2\alpha+2};q^2)_n}{(q^2;q^2)_n}. \tag{5.3}$$

Keep in mind the following formula for the generating function of the Al-Salam-Chihara polynomials [Ref. 13 formula (3.8.13)]:

$$\sum_{j=0}^{\infty} \frac{z^j}{(q^2;q^2)_j} \cdot Q_j(\rho) = \frac{(q^n z;q^2)_\infty \cdot (q^n z;q^2)_\infty}{(q^{i\rho} z;q^2)_\infty \cdot (q^{-i\rho} z;q^2)_\infty}.$$

Substitution $z := q^{2\alpha+2+n}$ gives $(q^{2\alpha+2};q^2)_n \Sigma_{j=0}^{\infty} [q^{j(2\alpha+n+2)}/(q^2;q^2)_j] \cdot Q_j(\rho) = b_{q,\alpha}(\rho)$. Now validity of (5.3) follows from the latter equality and the orthogonality relations (4.13) for the Al-Salam-Chihara polynomials. ■

Proposition 5.1 follows directly from the last two lemmas.

B. Asymptotic expansion of the *q*-Berezin transform

Proposition 5.5: For any $f \in \mathcal{D}(U_n)_q$

$$B_{q,t}(f) = (q^2 t;q^2)_n \cdot \sum_{j=0}^{\infty} t^j \cdot q^{2j} \cdot \frac{(q^{2j+2};q^2)_{n-1}}{(q^2;q^2)_{n-1}} \cdot p_j(\Delta_{n,q}) f$$

with

$$p_j(\Delta_{n,q}) = \sum_{l=0}^{j} \frac{(q^{-2j};q^2)_l \cdot q^{2l}}{(q^{2n};q^2)_l \cdot (q^2;q^2)_l} \cdot \prod_{m=0}^{l-1} ((1-q^{2m})(1-q^{2m+2n}) - q^{2m+2n-2}(1-q^2)^2 \Delta_{n,q}).$$

Proof: Recall [see (3.9)] that

$$B_{q,\alpha}(f_0) = (q^{2\alpha+2};q^2)_n \cdot y^{\alpha+n+1} = (q^{2\alpha+2};q^2)_n \cdot \sum_{j=0}^{\infty} q^{2j(\alpha+n+1)} \cdot f_j$$

or, in terms of $t = q^{2\alpha}$,

$$B_{q,t}(f_0) = (tq^2;q^2)_n \cdot \sum_{j=0}^{\infty} t^j q^{2j(n+1)} \cdot f_j.$$

Since any morphism of $U_q\mathfrak{su}_{n,1}$-modules is determined uniquely by its value on the vector f_0, it suffices to prove that $p_j(\Delta_{n,q}) f_0 = q^{2jn} \cdot [(q^2;q^2)_{n-1}/(q^{2j+2};q^2)_{n-1}] \cdot f_j$ or, equivalently,

$$p_j(\Delta_{n,q}^{(r)}) f_0 = q^{2jn} \cdot \frac{(q^2;q^2)_{n-1}}{(q^{2j+2};q^2)_{n-1}} \cdot f_j.$$

Let us apply the q-spherical transform $\mathcal{F}$ to both sides of the latter equality. We get

$$p_j(\lambda(\rho)) \mathcal{F} f_0(\rho) = q^{2jn} \cdot \frac{(q^2;q^2)_{n-1}}{(q^{2j+2};q^2)_{n-1}} \cdot \mathcal{F} f_j(\rho). \tag{5.4}$$

Recall [see (4.10)] that $\mathcal{F} f_k(\rho) = (1-q^{2n}) \cdot q^{-2kn} \cdot (q^{2k+2};q^2)_{n-1} \cdot \phi_\rho(q^{2k})$. This formula reduces proving (5.4) to proving the equality

$$p_j(\lambda(\rho)) = \phi_\rho(q^{2j}), \tag{5.5}$$

and the latter is just a straightforward computation. ■

VI. AN APPLICATION: ORTHOGONALITY RELATIONS FOR CONTINUOUS DUAL *q*-HAHN POLYNOMIALS

The aim of this section is to describe one application of our results to the theory of basic orthogonal polynomials. Namely, we use the q-Berezin and the q-spherical transform to obtain orthogonality relations for certain two-parameter family of the so-called continuous dual q-Hahn polynomials (see Ref. 13). Of course, this result is not new. However, we believe that our approach might be interesting.

Throughout this section $\alpha > -1$ is a fixed number.

A. Auxiliary results

The aim of this subsection is to derive some useful consequences of Proposition 5.1.

Proposition 6.1: $B^{(\mathrm{r})}_{q,\alpha}$ is extended to an invertible operator on $\mathcal{L}^{\,2}_{n,q}$.

Proof: It suffices to observe that the "symbol" $b_{q,\alpha}(\rho)$ is invertible:

$$b_{q,\alpha}(\rho) \geqslant \frac{(q^{2+2\alpha};q^2)_\infty \cdot (q^{2n+2+2\alpha};q^2)_\infty}{(-q^{n+2+2\alpha};q^2)_\infty \cdot (-q^{n+2+2\alpha};q^2)_\infty} > 0.$$

■

To go further, we introduce some auxiliary notations. Denote by $\mathcal{L}_{\mathrm{Op}}$ and $\mathcal{L}'_{\mathrm{Op}}$ the subspaces of $U_q\mathfrak{s}(\mathfrak{u}_n \times \mathfrak{u}_1)$-module morphisms in $\mathrm{End}_0(\mathbb{C}[\mathbb{C}^n]_{q,\alpha})$ and $\mathrm{End}(\mathbb{C}[\mathbb{C}^n]_{q,\alpha})$, respectively. Since the subspaces $\mathbb{C}[\mathbb{C}^n]^{(m)}_{q,\alpha}$, $m \in \mathbb{Z}_{\geqslant 0}$, in $\mathbb{C}[\mathbb{C}^n]_{q,\alpha}$ are pairwise non-isomorphic irreducible $U_q\mathfrak{s}(\mathfrak{u}_n \times \mathfrak{u}_1)$-modules (see the proof of Lemma 4.6), the vector space $\mathcal{L}_{\mathrm{Op}}$ is generated by the orthogonal projections P_m onto the subspaces $\mathbb{C}[\mathbb{C}^n]^{(m)}_{q,\alpha}$. $\mathcal{L}'_{\mathrm{Op}}$ is the space of infinite series of the form

$$T = \sum_m a_m P_m, \quad a_m \in \mathbb{C}.$$

Elements of $\mathcal{L}_{\mathrm{Op}}$ and $\mathcal{L}'_{\mathrm{Op}}$ play the role of "radial" elements in $\mathrm{End}_0(\mathbb{C}[\mathbb{C}^n]_{q,\alpha})$ and $\mathrm{End}(\mathbb{C}[\mathbb{C}^n]_{q,\alpha})$.

Let $\mathcal{L}^{\,2}_{\mathrm{Op}}$ be the subspace in $\mathcal{L}'_{\mathrm{Op}}$ of "q-Hilbert–Schmidt" operators:

$$\mathcal{L}^{\,2}_{\mathrm{Op}} = \{T \in \mathcal{L}'_{\mathrm{Op}} \mid \mathrm{Tr}_q(T^* \cdot T) < \infty\}.$$

Note that the triple $(\mathcal{L}_{\mathrm{Op}}, \mathcal{L}'_{\mathrm{Op}}, \mathcal{L}^{\,2}_{\mathrm{Op}})$ is very similar to the triple $(\mathcal{L}_{n,q}, \mathcal{L}'_{n,q}, \mathcal{L}^{\,2}_{n,q})$ introduced in Sec. IV C.

Recall (Sec. III D) the notation σ for the linear map from $\mathrm{End}_0(\mathbb{C}[\mathbb{C}^n]_{q,\alpha})$ to $\mathcal{D}(U_n)'_q$ which sends endomorphisms to their covariant symbols. Due to Proposition 3.7 $\sigma(\mathcal{L}_{\mathrm{Op}}) \subset \mathcal{L}'_{n,q}$. Let us denote restriction of σ onto $\mathcal{L}_{\mathrm{Op}}$ by $\sigma^{(\mathrm{r})}$.

Proposition 6.2: The image of operator $\sigma^{(\mathrm{r})}$ lies in $\mathcal{L}^{\,2}_{n,q}$. Moreover, $\sigma^{(\mathrm{r})}$ can be extended to a bounded invertible operator from $\mathcal{L}^{\,2}_{\mathrm{Op}}$ to $\mathcal{L}^{\,2}_{n,q}$.

Proof: Recall (Sec. III D) that the map σ is defined via the equality

$$\int_{U_n} \sigma(T) \cdot f \, d\nu_q = \mathrm{Tr}_q(T \cdot T_f),$$

which should be fulfilled for any $f \in \mathcal{D}(U_n)_q$. Let $T^{(\mathrm{r})}$ be restriction onto $\mathcal{L}_{n,q}$ of the operator from $\mathcal{D}(U_n)_q$ to $\mathrm{End}_0(\mathbb{C}[\mathbb{C}^n]_{q,\alpha})$ which sends finite functions to the corresponding Toeplitz operators. By Proposition 3.3 $T^{(\mathrm{r})}(\mathcal{L}_{n,q}) \subset \mathcal{L}'_{\mathrm{Op}}$. More precisely, by Lemma 4.6,

$$T^{(\mathrm{r})}(\mathcal{L}_{n,q}) \subset \mathcal{L}_{\mathrm{Op}}. \tag{6.1}$$

In particular, $T^{(r)}$ can be considered as a densely defined operator from $\mathcal{L}^2_{n,q}$ into $\mathcal{L}^2_{\mathrm{Op}}$. The above definition of σ implies the following equivalent definition of $\sigma^{(r)}$: for an element $T\in\mathcal{L}_{\mathrm{Op}}$ one has $\sigma^{(r)}(T)=t(y)$ iff

$$\frac{1-q^{2n}}{1-q^2}\int_0^1 t(y)f(y)y^{-n-1}(yq^2;q^2)_{n-1}d_{q^2}y=\mathrm{Tr}_q(T\cdot T^{(r)}(f(y))) \tag{6.2}$$

for any $f(y)\in\mathcal{L}_{n,q}$. Let us prove that $T^{(r)}$ can be extended up to a bounded operator from $\mathcal{L}^2_{n,q}$ to $\mathcal{L}^2_{\mathrm{Op}}$. Suppose $f(y)\in\mathcal{L}_{n,q}$. Then, by (6.1) and (6.2)

$$\begin{aligned}\mathrm{Tr}_q((T^{(r)}(f(y)))^*\cdot T^{(r)}(f(y)))&=\frac{1-q^{2n}}{1-q^2}\int_0^1\sigma^{(r)}\cdot T^{(r)}(f(y))\overline{f(y)}y^{-n-1}(yq^2;q^2)_{n-1}d_{q^2}y\\&=\frac{1-q^{2n}}{1-q^2}\int_0^1 B^{(r)}_{q,\alpha}(f(y))\overline{f(y)}y^{-n-1}(yq^2;q^2)_{n-1}d_{q^2}y\\&=(B^{(r)}_{q,\alpha}f,f)_{\mathcal{L}^2}\leqslant\|B^{(r)}_{q,\alpha}\|(f,f)_{\mathcal{L}^2}.\end{aligned}$$

To prove boundedness of $\sigma^{(r)}$ it remains to observe that, by (6.2), $\sigma^{(r)}$ coincides on $\mathcal{L}_{\mathrm{Op}}$ with $(T^{(r)})^*$. Invertibility of $\sigma^{(r)}$ may be deduced using similar arguments and Proposition 6.1. ■

B. Orthogonality relations

First we describe an idea of producing the orthogonality relations. It is based on the following statement.

Proposition 6.3: The operator

$$U_\alpha:\mathcal{L}^2_{\mathrm{Op}}\to L^2\left(\frac{d\rho}{|c(\rho)|^2}\right),\quad T\mapsto\frac{1}{\sqrt{b_{q,\alpha}(\rho)}}\cdot\mathcal{F}\sigma^{(r)}(T)$$

is unitary.

Remark: In the classical case the operator U_α (the product of the spherical transform with the unitary part of the covariant symbol map) was studied in Ref. 14.

Proof: By Proposition 5.1

$$\frac{1}{b_{q,\alpha}(\rho)}\cdot\mathcal{F}=\mathcal{F}(B^{(r)}_{q,\alpha})^{-1}.$$

Keep in mind the notation $(\cdot,\cdot)_{L^2}$, $(\cdot,\cdot)_{\mathcal{L}^2}$ for the inner products in $L^2(d\rho/|c(\rho)|^2)$ and $\mathcal{L}_{n,q}$, respectively. Then

$$\begin{aligned}&\left(\frac{1}{\sqrt{b_{q,\alpha}(\rho)}}\cdot\mathcal{F}\sigma^{(r)}(T),\ \frac{1}{\sqrt{b_{q,\alpha}(\rho)}}\cdot\mathcal{F}\sigma^{(r)}(T)\right)_{L^2}\\&\quad=\left(\frac{1}{b_{q,\alpha}(\rho)}\cdot\mathcal{F}\sigma^{(r)}(T),\ \mathcal{F}\sigma^{(r)}(T)\right)_{L^2}\\&\quad=(\mathcal{F}(B^{(r)}_{q,\alpha})^{-1}\sigma^{(r)}(T),\ \mathcal{F}\sigma^{(r)}(T))_{L^2}=((B^{(r)}_{q,\alpha})^{-1}\sigma^{(r)}(T),\ \sigma^{(r)}(T))_{\mathcal{L}^2}.\end{aligned}$$

The result then follows since $(B^{(r)}_{q,\alpha})^{-1}=(\sigma^{(r)*})^{-1}\cdot(\sigma^{(r)})^{-1}$. ■

Recall that the projections P_m, $m\in\mathbb{Z}_{\geqslant 0}$, constitute an orthogonal basis in the Hilbert space $\mathcal{L}^2_{Op}$. Proposition 6.3 implies that $\mathcal{F}\sigma^{(r)}(P_m)$, $m\in\mathbb{Z}_{\geqslant 0}$, constitute an orthogonal basis in

$L^2(d\rho/b_{q,\alpha}(\rho)|c(\rho)|^2)$. Our intention now is to show that $\mathcal{F}\sigma^{(r)}(P_m)$ are very close to certain continuous dual q-Hahn polynomials, and the above observations will give us the orthogonality relations for these polynomials.

Proposition 6.4: Let $P_m(\rho)=\mathcal{F}\sigma^{(r)}(P_m)(\rho)$. *Then*

$$P_m(\rho)=\frac{(q^2;q^2)_n\cdot(q^{2n+2+2\alpha};q^2)_\infty^2}{(q^{n+2+2\alpha+i\rho};q^2)_\infty\cdot(q^{n+2+2\alpha-i\rho};q^2)_\infty}\cdot q^{-2m(n+\alpha)}\cdot\frac{(q^{2n+2+2\alpha};q^2)_m}{(q^2;q^2)_m}$$
$$\cdot{}_3\phi_2\left(\begin{matrix}q^{-2m}, & q^{n+2+2\alpha+i\rho}, & q^{n+2+2\alpha-i\rho},\\ & q^{2n+2+2\alpha}, & q^{2n+2+2\alpha}\end{matrix}\;\begin{matrix}\\ q^2, & q^2\end{matrix}\right).$$

Proof: Keep in mind (Lemma 4.7) that we have already computed $\sigma^{(r)}(P_m)$

$$\sigma^{(r)}(P_m)=q^{-2m(\alpha+n+1)}\cdot\frac{(q^{2\alpha+2n+2};q^2)_m}{(q^2;q^2)_m}\cdot y^{\alpha+n+1}\cdot(yq^{-2m+2};q^2)_m.$$

By the q-binomial formula[20] the equality can be rewritten as follows:

$$\sigma^{(r)}(P_m)=q^{-2m(\alpha+n+1)}\cdot\frac{(q^{2\alpha+2n+2};q^2)_m}{(q^2;q^2)_m}\cdot\sum_{l=0}^{m}\frac{(q^2;q^2)_m}{(q^2;q^2)_l(q^2;q^2)_{m-l}}\cdot(-1)^m$$
$$\cdot q^{l(l-2m+1)}\cdot y^{n+1+l+\alpha}$$
$$=q^{-2m(\alpha+n+1)}\cdot\sum_{l=0}^{m}\frac{(q^{2\alpha+2n+2};q^2)_m}{(q^2;q^2)_l(q^2;q^2)_{m-l}}\cdot(-1)^m\cdot q^{l(l-2m+1)}\cdot y^{n+1+l+\alpha}. \quad (6.3)$$

Hence it remains to compute $\mathcal{F}y^{n+1+l+\alpha}$ for any $l\geqslant 0$. Let us apply the q-spherical transform to both sides of the formula $B_{q,\alpha}(f_0)=(q^{2\alpha+2};q^2)_n\cdot y^{\alpha+n+1}$. Due to Proposition 5.1

$$\frac{(q^{2+2\alpha};q^2)_\infty\cdot(q^{2n+2+2\alpha};q^2)_\infty}{(q^{n+2+2\alpha+i\rho};q^2)_\infty\cdot(q^{n+2+2\alpha-i\rho};q^2)_\infty}\cdot\mathcal{F}f_0=(q^{2+2\alpha};q^2)_n\cdot\mathcal{F}y^{n+1+\alpha},$$

or, equivalently,

$$\mathcal{F}y^{n+1+\alpha}=\frac{(q^2;q^2)_n\cdot(q^{2n+2+2\alpha};q^2)_\infty^2}{(q^{n+2+2\alpha+i\rho};q^2)_\infty\cdot(q^{n+2+2\alpha-i\rho};q^2)_\infty}.$$

Let us make the substitution $N:=n+1+\alpha$ $(N>n+1)$:

$$\mathcal{F}y^{N}=\frac{(q^2;q^2)_n\cdot(q^{2N};q^2)_\infty^2}{(q^{2N-n+i\rho};q^2)_\infty\cdot(q^{2N-n-i\rho};q^2)_\infty}.$$

Thus,

$$\mathcal{F}y^{n+1+l+\alpha}=\frac{(q^2;q^2)_n\cdot(q^{2n+2+2l+2\alpha};q^2)_\infty^2}{(q^{n+2+2l+2\alpha+i\rho};q^2)_\infty\cdot(q^{n+2+2l+2\alpha-i\rho};q^2)_\infty}.$$

The latter equality, together with (6.3) and simple computations, gives our formula. ■

Recall the notation $p_k(x;a,b,c|q)$ for the continuous dual q-Hahn polynomials (Ref. 13, Sec. 3.3). The above proposition implies

$$\mathcal{F}\sigma^{(r)}(P_m)=\frac{q^{-mn}\cdot(q^2;q^2)_n\cdot(q^{2n+2+2\alpha};q^2)_\infty\cdot(q^{2n+2m+2+2\alpha};q^2)_\infty}{(q^{n+2+2\alpha+i\rho};q^2)_\infty\cdot(q^{n+2+2\alpha-i\rho};q^2)_\infty\cdot(q^2;q^2)_m}$$
$$\cdot p_m\left(\cos\frac{h\rho}{2};q^{n+2+2\alpha},q^n,q^n\middle|q^2\right).$$

Let $p_m(\rho):=p_m(\cos(h\rho/2);q^{n+2+2\alpha},q^n,q^n|q^2)$. Applying Proposition 6.3 and the above observations, we get

$$\frac{1}{4\pi}\int_0^{2\pi/h}p_m(\rho)p_l(\rho)\frac{d\rho}{(q^{n+2+2\alpha+i\rho};q^2)_\infty^2\cdot(q^{n+2+2\alpha-i\rho};q^2)_\infty^2\cdot b_{q,\alpha}(\rho)|c(\rho)|^2}$$
$$=\frac{q^{2mn}\cdot(1-q^{2n})\cdot(q^2;q^2)_m^2}{h\cdot(q^2;q^2)_n^2\cdot(q^{2n+2+2\alpha};q^2)_\infty^2\cdot(q^{2n+2m+2+2\alpha};q^2)_\infty^2}\cdot\mathrm{Tr}_q(P_m\cdot P_l),$$

or, using the explicit formula for $b_{q,\alpha}$,

$$\frac{1}{4\pi}\int_0^{2\pi/h}p_m(\rho)p_l(\rho)\frac{d\rho}{(q^{n+2+2\alpha+i\rho};q^2)_\infty(q^{n+2+2\alpha-i\rho};q^2)_\infty|c(\rho)|^2}$$
$$=\delta_{ml}\frac{(q^2;q^2)_m(q^2;q^2)_{m+n-1}}{h(q^2;q^2)_{n-1}(q^{2n+2m+2+2\alpha};q^2)_\infty^2}.$$

Recall (Proposition 4.5) that

$$\frac{1}{|c(\rho)|^2}=\left|\frac{\Gamma_{q^2}^2(n/2+i\rho/2)}{\Gamma_{q^2}(n)\Gamma_{q^2}(i\rho)}\right|^2=(q^{2n};q^2)_\infty^2\cdot\frac{(q^{2i\rho};q^2)_\infty(q^{-2i\rho};q^2)_\infty}{(q^{n+i\rho};q^2)_\infty^2(q^{n-i\rho};q^2)_\infty^2}.$$

Finally we have

$$\frac{1}{4\pi}\int_0^{2\pi/h}p_m(\rho)p_l(\rho)\frac{(q^{2i\rho};q^2)_\infty(q^{-2i\rho};q^2)_\infty}{(q^{n+2+2\alpha+i\rho};q^2)_\infty(q^{n+2+2\alpha-i\rho};q^2)_\infty(q^{n+i\rho};q^2)_\infty^2(q^{n-i\rho};q^2)_\infty^2}d\rho$$
$$=\delta_{ml}\frac{1}{h(q^{2n+2m+2+2\alpha};q^2)_\infty^2(q^{2m+2};q^2)_\infty(q^{2n+2m};q^2)_\infty}.$$

The latter equality is a particular case of the orthogonality relations for the entire family of continuous dual q-Hahn polynomials given in Ref. 13 (3.3.2).

VII. CONCLUSION

As it was mentioned in the Introduction, this research is, above all, a part of the general program of studying q-Cartan domains, which we believe is a promising subject in quantum group theory. To our knowledge the results above on finding a mathematical setting for the Toeplitz and covariant calculi, expressing Berezin transform as a function of the q-Laplacian operator, and on computing the covariant symbol of the projections are all new. Those results, in the classical case, are naturally related to finding an expansion of the associate $*$-product $f*_h g$ of covariant symbols as a power series in the Planck constant h (see, e.g., Ref. 25). Thus, the most natural continuation of the present paper would be understanding the expansion of the $*$-product in this case since certain computation might be easier than in the classical case, and generalization of our results to the case of other, more complicated q-Cartan domains, first of all, q-matrix balls.[9,10] We mention Ref. 10 where q-weighted Bergman spaces on q-matrix balls are constructed and studied. Using these results, it is not so difficult to generalize our definition of the q-Berezin transform. However, to obtain more deep results (for instance, an explicit asymptotic formula for the q-Berezin trans-

form) one needs to develop to some extent harmonic analysis on q-matrix balls. This seems to be a difficult problem itself. By now, harmonic analysis is developed quite well for compact quantum homogeneous spaces only. Nevertheless, we are fully confident that all the results we present in this article admit generalization to other q-Cartan domains.

ACKNOWLEDGMENTS

It is our pleasure to thank Leonid Vaksman for many interesting discussions. (Received 25 November 2002; accepted 30 April 2003)

The curvature of a three-dimensional Riemannian manifold with Lorentzian signature is algebraically classified using the fact that the spinor equivalent of the traceless part of the Ricci tensor is a totally symmetric four-index spinor. Following G. S. Hall and M. S. Capocci [J. Math. Phys. **40**, 1466 (1999)] it is shown that at each point of the manifold there exists four, possibly complex, null vectors which are analogous to the Debever–Penrose vectors and also satisfy the condition $R_{ab}l^a l^b = 0$. It is also shown that a similar conclusion holds for the Cotton–York tensor. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1592611]

I. INTRODUCTION

The usefulness of the two-component spinor formalism in general relativity is well established and an illustrative example of it can be found in the algebraic classification of the conformal curvature (see, e.g., Refs. 1 and 2). At each point of the space-time manifold, the spinor equivalent of the conformal curvature tensor is given by a totally symmetric four-index spinor (the Weyl spinor) and its complex conjugate. The Weyl spinor is the symmetrized product of four one-index spinors which define four null directions whose coincidences determine the algebraic type of the conformal curvature.

In the case of a Riemannian manifold of dimension three, the Riemann curvature tensor is determined by the Ricci tensor alone and therefore the curvature can be classified using the Ricci tensor directly. By considering a three-dimensional space with indefinite (Lorentzian) metric, Hall *et al.*[3,4] obtained four canonical forms for symmetric two-index tensors in terms of triads $\{l_a, n_a, x_a\}$ such that $l^a n_a = 1 = x^a x_a$, with all other products equal to zero, which were then applied to classify the Ricci and the Cotton–York tensors. The Cotton–York tensor is analogous to the conformal curvature tensor of a Riemannian manifold of dimension greater than three in the sense that its vanishing is locally equivalent to the conformal flatness of the manifold.

It is noteworthy that a spinor formalism similar to that employed in the four-dimensional space–time can be applied in the case of space–times of $2+1$ dimensions, that is, three-dimensional Riemannian manifolds with indefinite metric. By contrast with the two-component spinors in four dimensions, for which two types of spinor indices are necessary, in a three-dimensional space only one type of spinor indices is required.[5–7]

The traceless symmetric real two-index tensors in three-dimensional spaces have been classified in Ref. 6 making use of the fact that the spinor equivalent of a tensor of this type can be expressed as the symmetrized product of four one-index spinors. The aim of this paper is to apply this classification to the traceless part of the Ricci tensor and to the Cotton–York tensor of a three-dimensional manifold with Lorentzian signature and to establish some properties of the curvature tensors that follow from those of their spinor equivalents. It should be remarked that

a)Electronic mail: gtorres@fcfm.buap.mx

since the Cotton–York and the Ricci tensor are symmetric two-index tensors, the same classification scheme can be applied to both of them. The classification employed here is also of interest in the case of a four-dimensional manifold with ultra-hyperbolic, or Kleinian, signature $(++--)$, since its conformal curvature corresponds to two independent four-index totally symmetric spinors and the spin group is isomorphic to the product of two copies of $SL(2,\mathbb{R})$ or of $SU(1,1)$.

In Sec. II a brief description of the spinor formalism for three-dimensional spaces with indefinite metric is given and in Sec. III this formalism is applied in the classification of the curvature of a three-dimensional manifold with Lorentzian signature.

II. SPINORS IN THREE-DIMENSIONAL SPACES WITH INDEFINITE METRIC

A two-component spinor formalism analogous to that employed in the study of the spin of the electron in nonrelativistic quantum mechanics can be applied in any three-dimensional real vector space, V, with an indefinite metric tensor. A one-index spinor has two complex components which will be denoted by symbols like ψ_A or ψ^A, where the capital italic indices take two values only, e.g., 1 and 2. The spinor indices will be lowered or raised following the rules

$$\psi_A=\varepsilon_{AB}\psi^B, \quad \psi^A=-\varepsilon^{AB}\psi_B, \tag{1}$$

where

$$(\varepsilon_{AB})=\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}=(\varepsilon^{AB}). \tag{2}$$

Hence, $\psi_A\phi^A=-\psi^A\phi_A$, for any pair of one-index spinors, $\varepsilon^A{}_B=\delta^A_B$, and $\varepsilon_B{}^A=-\delta^A_B$.

If $\{\mathbf{e}_1,\mathbf{e}_2,\mathbf{e}_3\}$ is an orthogonal basis of V with respect to which the components of the metric tensor are given by $(g_{ab})=\mathrm{diag}(1,1,-1)$, $a,b,\ldots=1,2,3$, and $\sigma^a{}_{AB}$ are (possibly complex) scalars such that

$$\sigma^a{}_{AB}=\sigma^a{}_{BA}, \tag{3}$$

$$\sigma^a{}_{AB}\sigma^b{}_{CD}g_{ab}=-(\varepsilon_{AC}\varepsilon_{BD}+\varepsilon_{AD}\varepsilon_{BC}), \tag{4}$$

then with each vector with components v^a we can associate its spinor equivalent with components

$$v_{AB}=\frac{1}{\sqrt{2}}\sigma^a{}_{AB}v_a. \tag{5}$$

(The tensor indices, $a,b,\ldots$, are raised or lowered by means of g^{ab} and g_{ab} in the usual way.)

Equation (4) is equivalent to

$$\sigma_a{}^{AB}\sigma_{bAB}=-2g_{ab}. \tag{6}$$

Hence, from Eq. (5) we have

$$v_a=-\frac{1}{\sqrt{2}}\sigma_a{}^{AB}v_{AB}. \tag{7}$$

In general, if $t_{ab\cdots d}$ are the components of an n-index tensor, the components of its spinor equivalent are defined by

$$t_{ABCD\cdots GH}=\frac{1}{\sqrt{2}}\sigma^a{}_{AB}\frac{1}{\sqrt{2}}\sigma^b{}_{CD}\cdots\frac{1}{\sqrt{2}}\sigma^d{}_{GH}t_{ab\cdots d}. \tag{8}$$

Then

$$t_{ab\cdots d}=\left(-\frac{1}{\sqrt{2}}\sigma_a{}^{AB}\right)\left(-\frac{1}{\sqrt{2}}\sigma_b{}^{CD}\right)\cdots\left(-\frac{1}{\sqrt{2}}\sigma_d{}^{GH}\right)t_{ABCD\cdots GH} \tag{9}$$

and

$$t_{\cdots a\cdots}\ \ s^{\cdots a\cdots}=-t_{\cdots AB\cdots}\ \ s^{\cdots AB\cdots}. \tag{10}$$

Owing to Eq. (3) the components of the spinor equivalent of a tensor are symmetric on each pair of spinor indices corresponding to a tensor index, $t_{ABCD\cdots GH}=t_{(AB)(CD)\cdots(GH)}$, where the parentheses denote symmetrization on the indices enclosed. The components $t_{ABCD\cdots GH}$ may have additional symmetries depending on those of $t_{ab\ldots d}$. For instance, if t_{ab} are the components of a skewsymmetric two-index tensor then $t_{ABCD}=-t_{CDAB}$ and, therefore, the components t_{ABCD} can be expressed in the form

$$t_{ABCD}=\tau_{BD}\varepsilon_{AC}+\tau_{AC}\varepsilon_{BD}, \tag{11}$$

where τ_{AB} is a symmetric object ($\tau_{AB}=\frac{1}{2}t^R{}_{ARB}$).

Similarly, if the t_{ab} are the components of a symmetric two-index tensor then, in addition to the symmetries $t_{ABCD}=t_{(AB)(CD)}$, we have $t_{ABCD}=t_{CDAB}$, but not necessarily t_{ABCD} will coincide with, e.g., t_{ACBD}; the components t_{ABCD} are totally symmetric iff t_{ab} is symmetric and traceless. In general, $t_{ab\cdots d}$ is symmetric and traceless iff its spinor equivalent $t_{ABCD\cdots GH}$ is totally symmetric.

The *connection symbols*, $\sigma^a{}_{AB}$, are not uniquely defined by Eqs. (3) and (4); a convenient choice is given by the real matrices

$$(\sigma^1{}_{AB})\equiv\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix},\quad (\sigma^2{}_{AB})\equiv\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix},\quad (\sigma^3{}_{AB})\equiv\begin{pmatrix}-1 & 0\\ 0 & -1\end{pmatrix}. \tag{12}$$

Alternatively, we can also make use of

$$(\sigma^1{}_{AB})\equiv\begin{pmatrix}i & 0\\ 0 & i\end{pmatrix},\quad (\sigma^2{}_{AB})\equiv\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix},\quad (\sigma^3{}_{AB})\equiv\begin{pmatrix}0 & i\\ i & 0\end{pmatrix}, \tag{13}$$

which satisfy

$$\overline{\sigma^a{}_{AB}}=-\eta_{AC}\eta_{BD}\sigma^{aCD}, \tag{14}$$

where

$$(\eta_{AB})=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}. \tag{15}$$

The spin transformations will be given by SL(2,$\mathbb{R}$) or SU(1,1) matrices ($U^A{}_B$), depending on whether we employ the connection symbols (12) or (13), respectively.[5] Under a spin transformation the components of an m-index spinor $\psi_{AB\ldots F}$ transform as

$$\psi'^{AB\cdots F}=U^A{}_M U^B{}_N\cdots U^F{}_R\psi^{MN\cdots R}. \tag{16}$$

With any m-index spinor $\psi_{AB\cdots F}$ we can associate another m-index spinor, called the mate, conjugate, or adjoint, of $\psi_{AB\cdots F}$ whose components are given by[5,7]

$$\hat{\psi}_{AB\cdots F}=\begin{cases}\overline{\psi_{AB\cdots F}} & \text{if } \sigma_{aAB} \text{ are given by (12),}\\ i^m \eta_{AM}\eta_{BN}\cdots\eta_{FR}\overline{\psi^{MN\cdots R}} & \text{if the } \sigma_{aAB} \text{ are given by (13).}\end{cases} \tag{17}$$

Then the components $\hat{\psi}_{AB\cdots F}$ also transform according to Eq. (16) (as can be shown noticing that the spin transformations are given by matrices that satisfy the condition $\hat{U}^A{}_B=U^A{}_B$), $\hat{\varepsilon}_{AB}=\varepsilon_{AB}$, $\hat{\hat{\psi}}_{AB\cdots F}=\psi_{AB\cdots F}$, and $t_{AB\cdots GH}$ are the components of the spinor equivalent of a real tensor iff $\hat{t}_{AB\cdots GH}=t_{AB\cdots GH}$. Actually, one can define a spinor as real if it is equal to its mate.

From Eq. (10) it follows that for a vector v^a, $v^a v_a=-v^{AB}v_{AB}=-2\det(v_{AB})$; hence, v^a is null (i.e., $v^a v_a=0$) iff there exists a one-index spinor α_A such that

$$v_{AB}=\alpha_A\alpha_B; \tag{18}$$

the null vector v^a is real iff, additionally, $\hat{\alpha}_A\hat{\alpha}_B=\alpha_A\alpha_B$, which is equivalent to the condition $\hat{\alpha}_A=\pm\alpha_A$. The factorization (18) is a special case of the fact that any totally symmetric m-index spinor $\psi_{AB\cdots F}$ can be expressed as the symmetrized product of m (not necessarily different) one-index spinors

$$\psi_{AB\cdots F}=\alpha_{(A}\beta_B\cdots\delta_{F)}. \tag{19}$$

The spinors α_A, $\beta_A,\ldots,\delta_A$, are defined up to a scalar factor and are called principal spinors of $\psi_{AB\cdots F}$. A one-index spinor ξ_A is a principal spinor of $\psi_{AB\cdots F}$ iff $\psi_{AB\cdots F}\xi^A\xi^B\cdots\xi^F=0$. As in the case of the two-component spinor formalism employed in the four-dimensional space–time, the factorization (19) follows from the fundamental theorem of algebra.[1]

III. ALGEBRAIC CLASSIFICATION OF THE CURVATURE

Let M be a three-dimensional Riemannian manifold with indefinite metric. The components of the curvature tensor R_{abcd} of the Levi–Civita connection of M, with respect to an orthogonal basis of the tangent space of M at a point p such that $(g_{ab})=\mathrm{diag}(1,1,-1)$, satisfy the conditions $R_{abcd}=R_{[ab][cd]}$, where the square brackets denote antisymmetrization on the indices enclosed; hence, applying (11) it follows that the spinor equivalent of R_{abcd} can be expressed in the form[5]

$$R_{ABCDEFHI}=\tfrac{1}{2}(\varepsilon_{AC}\varepsilon_{EH}G_{BDFI}+\varepsilon_{AC}\varepsilon_{FI}G_{BDEH}+\varepsilon_{BD}\varepsilon_{EH}G_{ACFI}+\varepsilon_{BD}\varepsilon_{FI}G_{ACEH}) \tag{20}$$

(the factor 1/2 is introduced for convenience), with

$$G_{ABCD}=G_{(AB)(CD)}. \tag{21}$$

Then, the symmetry $R_{abcd}=R_{cdab}$, is equivalent to $G_{ABCD}=G_{CDAB}$ and from Eq. (20) it follows that

$$G_{ABCD}=R_{ABCD}+\tfrac{1}{4}R(\varepsilon_{AC}\varepsilon_{BD}+\varepsilon_{AD}\varepsilon_{BC}), \tag{22}$$

where R_{ABCD} is the spinor equivalent of the Ricci tensor, $R_{ab}\equiv R^c{}_{acb}$, and R is the scalar curvature, $R=R^a{}_a$. Hence, G_{ABCD} is the spinor equivalent of $G_{ab}=R_{ab}-\frac{1}{2}Rg_{ab}$ and if Φ_{ABCD} denotes the spinor equivalent of the traceless part of the Ricci tensor, $\Phi_{ab}=R_{ab}-\frac{1}{3}Rg_{ab}$, we have

$$G_{ABCD}=\Phi_{ABCD}+\tfrac{1}{12}R(\varepsilon_{AC}\varepsilon_{BD}+\varepsilon_{AD}\varepsilon_{BC}). \tag{23}$$

Thus, the curvature tensor is determined by the totally symmetric spinor Φ_{ABCD} and the scalar curvature R; therefore, the curvature can be classified according to the algebraic structure of Φ_{ABCD}.

In the case of a four-dimensional manifold with Lorentzian signature, at each point of the manifold there exist four (not necessarily different) *real null* vectors l_μ (called Debever–Penrose

vectors) such that $l^{\mu}l_{[\nu}C_{\rho]\mu\sigma[\tau}l_{\lambda]}l^{\sigma}=0$, where $C_{\mu\nu\rho\sigma}$ is the conformal curvature tensor (see Refs. 8 and 9; the existence of these null directions was already implicit in Ref. 10). As we shall show, at each point of a three-dimensional manifold with indefinite metric there exist four, possibly complex, null vectors l_a such that

$$l^a l_{[b}R_{c]ad[e}l_{f]}l^d=0 \tag{24}$$

(see also Ref. 4). In effect, making use of the fact that the spinor equivalent of a null vector is of the form $\alpha_A\alpha_B$ and of the expression (11) for the spinor equivalent of a skewsymmetric two-index tensor, one finds that Eq. (24) amounts to

$$\alpha^A\alpha^M\alpha_{(B}\alpha^N R_{C)NAMDP(E}{}^Q\alpha_{F)}\alpha_Q\alpha^D\alpha^P=0,$$

which, by virtue of Eq. (20), reduces to $G_{NMPQ}\alpha^N\alpha^M\alpha^P\alpha^Q=0$ or, equivalently,

$$\Phi_{NMPQ}\alpha^N\alpha^M\alpha^P\alpha^Q=0, \tag{25}$$

i.e., α_A is a principal spinor of Φ_{ABCD}. Even though Φ_{ABCD} is the spinor equivalent of a real tensor, its principal spinors need not be real. If α_A is a principal spinor of Φ_{ABCD} then so is its mate $\hat{\alpha}_A$; hence, as shown in Ref. 6, $\hat{\Phi}_{ABCD}=\Phi_{ABCD}$ iff Φ_{ABCD} is of one of the following forms:

$$\text{Type I}\quad \Phi_{ABCD}=\alpha_{(A}\beta_B\gamma_C\delta_{D)}\quad \text{with}\quad \hat{\alpha}_A=\alpha_A,\ \hat{\beta}_A=\beta_A,\ \hat{\gamma}_A=\gamma_A,\ \hat{\delta}_A=\delta_A,$$

$$\text{Type II}\quad \Phi_{ABCD}=\alpha_{(A}\beta_B\gamma_C\hat{\gamma}_{D)}\quad \text{with}\quad \hat{\alpha}_A=\alpha_A,\ \hat{\beta}_A=\beta_A,$$

$$\text{Type III}\quad \Phi_{ABCD}=\pm\alpha_{(A}\hat{\alpha}_B\beta_C\hat{\beta}_{D)},$$

$$\text{Type IV}\quad \Phi_{ABCD}=\alpha_{(A}\alpha_B\beta_C\gamma_{D)}\quad \text{with}\quad \hat{\alpha}_A=\alpha_A,\ \hat{\beta}_A=\beta_A,\ \hat{\gamma}_A=\gamma_A,$$

$$\text{Type V}\quad \Phi_{ABCD}=\pm\alpha_{(A}\alpha_B\beta_C\hat{\beta}_{D)}\quad \text{with}\quad \hat{\alpha}_A=\alpha_A,$$

$$\text{Type VI}\quad \Phi_{ABCD}=\pm\alpha_{(A}\alpha_B\beta_C\beta_{D)}\quad \text{with}\quad \hat{\alpha}_A=\alpha_A,\ \hat{\beta}_A=\beta_A,$$

$$\text{Type VII}\quad \Phi_{ABCD}=\pm\alpha_{(A}\alpha_B\hat{\alpha}_C\hat{\alpha}_{D)},$$

$$\text{Type VIII}\quad \Phi_{ABCD}=\alpha_{(A}\alpha_B\alpha_C\beta_{D)}\quad \text{with}\quad \hat{\alpha}_A=\alpha_A,\ \hat{\beta}_A=\beta_A,$$

$$\text{Type IX}\quad \Phi_{ABCD}=\pm\alpha_A\alpha_B\alpha_C\alpha_D\quad \text{with}\quad \hat{\alpha}_A=\alpha_A. \tag{26}$$

Thus, α_A is a principal spinor of Φ_{ABCD} iff $\alpha_A\alpha_B$ is the spinor equivalent of a null vector satisfying Eq. (24).

Equation (25) is equivalent to $R_{ABCD}\alpha^A\alpha^B\alpha^C\alpha^D=0$, i.e.,

$$R_{ab}l^a l^b=0 \tag{27}$$

and therefore we conclude that, at each point of M, there are four, possibly complex, null vectors l_a such that $R_{ab}l^a l^b=0$ and that Eq. (24) is equivalent to Eq. (27) if l_a is null (cf. Ref. 4).

On the other hand, the condition $R_{ab}l^a=\lambda l_b$ is equivalent to $\Phi_{ab}l^a=(\lambda-\frac{1}{3}R)l_b$ and, assuming again that l_a is null and possibly complex we have

$$\Phi_{ABCD}\alpha^A\alpha^B=(\tfrac{1}{3}R-\lambda)\alpha_C\alpha_D, \tag{28}$$

where $\alpha_A\alpha_B$ is the spinor equivalent of l_a. If $\frac{1}{3}R-\lambda=0$, Eq. (28) means that α_A is a triple or quadruple principal spinor of Φ_{ABCD} (types VIII and IX), and conversely; then α_A (and hence l_a)

must be real [see Eq. (26)] and its direction is unique [i.e., there is only one linearly independent solution to Eq. (28)]. When $\frac{1}{3}R-\lambda\neq 0$, α_A is a double principal spinor of Φ_{ABCD} (types IV, V, VI, and VII) and, therefore, in this case there are at most two linearly independent solutions of Eq. (28); furthermore, since $\overline{\gamma^A\delta_A}=\hat{\gamma}^A\hat{\delta}_A$ for any pair of one-index spinors, by inspection of the possible cases in (26), one finds that λ must be real. [Actually, there are exactly two real linearly independent solutions of Eq. (28) iff Φ_{ABCD} is of type VI, in which case $\frac{1}{3}R-\lambda>0$ and there are two complex linearly independent solutions of Eq. (28) iff Φ_{ABCD} is of type VII, then $\frac{1}{3}R-\lambda<0$.]

Using Eqs. (20) and (23) one finds that the spinor equivalent of $R_{abcd}l^b l^c$ is

$$R_{ABCDEFHI}\alpha^C\alpha^D\alpha^E\alpha^F=\tfrac{1}{6}R\,\alpha_A\alpha_B\alpha_H\alpha_I-2\,\alpha_{(A}\Phi_{B)DF(H}\alpha_{I)}\alpha^D\alpha^F,$$

which is proportional to $\alpha_A\alpha_B\alpha_H\alpha_I$ iff Eq. (28) holds. Hence, $R_{abcd}l^b l^c$ is proportional to $l_a l_d$ iff $R_{ab}l^a=\lambda l_b$.[4]

It may be noticed that, for instance, the expression $\Phi_{ABCD}=\alpha_{(A}\beta_B\gamma_C\delta_{D)}$ is the spinor equivalent of the traceless part of the symmetrized product of the vector equivalents of $\alpha_{(A}\beta_{B)}$ and $\gamma_{(A}\delta_{B)}$, i.e., of $\Phi_{ab}=v_{(a}w_{b)}-\frac{1}{3}v^c w_c g_{ab}$, where v_a and w_a are the vector equivalents of $\alpha_{(A}\beta_{B)}$ and $\gamma_{(A}\delta_{B)}$, respectively. (However, if the principal spinors of Φ_{ABCD} are not repeated, the vectors v_a and w_a are not defined uniquely by Φ_{ab} since we can combine α_A, β_A, γ_A, and δ_A in three different ways to form a pair of vectors. By contrast, the directions of the principal spinors of Φ_{ABCD} are uniquely defined.)

In a three-dimensional Riemannian manifold M, the Riemann tensor is completely determined by the Ricci tensor and an analog of the conformal curvature tensor is given by the Schouten–Bach–Cotton–York tensor

$$Y_{ab}=\varepsilon_{acd}(\nabla^c R_b{}^d-\tfrac{1}{4}\delta_b^d\partial^c R)=\varepsilon_{acd}(\nabla^c\Phi_b{}^d+\tfrac{1}{12}\delta_b^d\partial^c R), \tag{29}$$

which is symmetric and traceless. M is locally conformally flat iff Y_{ab} vanishes. The spinor equivalent of Y_{ab} is totally symmetric and can be algebraically classified in the same manner as Φ_{ABCD} [see Eq. (26)]. Thus, we conclude that at each point of M there exist four (not necessarily different) complex null vectors l_a such that

$$Y_{ab}l^a l^b=0 \tag{30}$$

(cf. Ref. 4) and the spinor equivalent of a null vector l_a satisfying Eq. (30) is of the form $\alpha_A\alpha_B$, where α_A is a principal spinor of Y_{ABCD}, the spinor equivalent of Y_{ab}. The eigenvalue equation $Y_{ab}l^a=\lambda l_b$, for l_a null, has solution only if Y_{ABCD} has at least one repeated principal spinor.

The principal spinors of Φ_{ABCD} need not coincide with those of Y_{ABCD} and the algebraic types of Φ_{ABCD} and Y_{ABCD} may be different. However, if α_A is a k-fold repeated principal spinor of Φ_{ABCD} with $k\geqslant 3$, then α_A is at least a $(k-2)$-fold repeated principal spinor of Y_{ABCD}, as can be seen using the fact that Eq. (29) amounts to

$$Y_{ABCD}=-\sqrt{2}\,\nabla^R{}_{(A}\Phi_{BCD)R}, \tag{31}$$

where ∇_{AB} denotes the spinor equivalent of the covariant derivative operator ∇_a.

The spinor formalism obtained with the real connection symbols (12) is equivalent to the triad formalism given in Ref. 3. When the complex connection symbols (13) are employed, instead, the number of independent components and equations reduces almost by half, thus obtaining a formalism closer to the Newman–Penrose formalism applied in the case of the four-dimensional space-time.

Pauli approximations to the self-adjoint extensions of the Aharonov–Bohm Hamiltonian

J. L. Borg[a] and J. V. Pulé[b]
Department of Mathematical Physics, University College Dublin (National University of Ireland, Dublin), Belfield, Dublin 4, Ireland

(Received 6 January 2003; accepted 8 April 2003)

It is well known that the formal Aharonov–Bohm Hamiltonian operator, describing the interaction of a charged particle with a magnetic vortex, has a four-parameter family of self-adjoint extensions, which reduces to a two-parameter family if one requires that the Hamiltonian commutes with the angular momentum operator. The question we study here is which of these self-adjoint extensions can considered as limits of regularized Aharonov–Bohm Hamiltonians, that is Pauli Hamiltonians in which the magnetic field corresponds to a flux tube of nonzero diameter. We show that not all the self-adjoint extensions in this two-parameter family can be obtained by these approximations, but only two one-parameter subfamilies. In these two cases we can choose the gyromagnetic ratio in the approximating Pauli Hamiltonian in such a way that we get convergence in the norm resolvent sense to the corresponding self-adjoint extension. © *2003 American Institute of Physics.*

I. INTRODUCTION

The Aharonov–Bohm Hamiltonian operator, describing the interaction of a charged particle with a magnetic vortex, that is, an infinitely extended, infinitely thin, impenetrable magnetic flux tube, is given by

$$H=\frac{1}{2\mathrm{m}}\left(\mathbf{p}-\frac{e}{c}\mathbf{A}\right)^2, \tag{1.1}$$

where the vector potential $\mathbf{A}$ is given by

$$\mathbf{A}=\frac{\phi}{2\pi}\frac{\mathbf{k}\times\mathbf{r}}{r^2}, \tag{1.2}$$

ϕ being the flux of the tube. It is well known[1,2] that this formal operator has a four-parameter family of self-adjoint extensions, which reduces to a two-parameter family if one requires that the Hamiltonian commutes with the angular momentum operator. These self-adjoint extensions can be obtained formally by adding a delta function. The question we study in this paper is which of these self-adjoint extensions can considered as limits of regularized Aharonov–Bohm (AB) Hamiltonians, that is Pauli Hamiltonians in which the magnetic field corresponds to a flux tube of nonzero diameter.

This problem has been studied by Bordag and Voropaev[3] and by Moroz.[4] These authors make the connection between the regularized Hamiltonian and the self-adjoint extensions of the AB Hamiltonian and show that the gyromagnetic ratio has to be chosen in a particular way. They do

[a]On leave of absence from Department of Mathematics, University of Malta, Msida MSD 06, Malta. Electronic mail: james.borg@um.edu.mt

this by matching the bound states as the radius of the vortex tends to zero, but do not prove convergence of the operators. Also they do not take into account the second parameter in the two-parameter family of self-adjoint extensions mentioned above. Here we proceed more systematically to extend the results of Refs. 3 and 4. We consider convergence in the norm resolvent sense. We show that not all the self-adjoint extensions in this two-parameter family can be obtained by these approximations, but only two one-parameter subfamilies. Tamura[5] has done related work but with a different emphasis.

When the AB Hamiltonian is decomposed into the subspaces corresponding to the values of the angular momentum $m \in \mathbb{Z}$, it turns out that if N is the integer part of the dimensionless parameter $\alpha = \phi e/hc$, then the Hamiltonians restricted to $m=N$ and $m=N+1$ are not essentially self-adjoint while the ones with other values of m are essentially self-adjoint. The operators corresponding to $m=N$ and $m=N+1$ each have a one-parameter family of self-adjoint extensions. We denote these parameters in $(-\infty,\infty]$ by ν_N and ν_{N+1}, respectively, $\nu_N=\infty$ and $\nu_{N+1}=\infty$ corresponding to the *regular* self-adjoint extension. We prove that for the subfamilies $\nu_N \in (-\infty,\infty)$, $\nu_{N+1}=\infty$ and $\nu_{N+1}\in(-\infty,\infty)$, $\nu_N=\infty$ we can choose the gyromagnetic ratio, g, in the approximating Pauli Hamiltonian in such a way that we get convergence in the norm resolvent sense to the corresponding self-adjoint extension. The approximating Hamiltonian is

$$H_R = \frac{1}{2\mathrm{m}}\left(\mathbf{p} - \frac{e}{c}\mathbf{A}_R\right)^2 - \frac{ge\hbar}{2\mathrm{m}c}\mathbf{k}\cdot\mathbf{B}_R \tag{1.3}$$

with $\mathbf{B}_R = \operatorname{curl}\mathbf{A}_R$. The vector potential $\mathbf{A}_R$ is 0 inside a tube of radius R away from its boundary and given by (1.2) outside the tube away from the boundary. It was shown in Refs. 3 and 4 that to obtain a nontrivial limit, g must depend on R and must tend to 2 in a certain way. For a discussion of the physical significance of this limit we refer the reader to these papers. The same result holds here for the self-adjoint extensions with $\nu_N \in (-\infty,\infty)$, $\nu_{N+1}=\infty$. However, for the self-adjoint extensions with $\nu_{N+1}\in(-\infty,\infty)$, $\nu_N=\infty$, which were not considered in Refs. 3 and 4, g must behave like $-2+4(N+1)/\alpha$.

Two other approximations have been considered, namely, the case when the magnetic field inside the tube is homogeneous[3,4] and the case when it is proportional to $1/r$.[3] The situation in these cases is similar but more complex. We deal with these briefly at the end of the paper.

The paper is set out as follows. In Sec. II we give the basic properties of the AB Hamiltonian. In Sec. III we carry out the approximation to the AB Hamiltonian with an infinitely thin infinitely extended cylindrical shell of nonzero radius R. In Sec. IV we smooth the flux shell to give it a nonzero thickness. In this section we only sketch the proof. In Sec. V we discuss the other two approximations. In the Appendixes A and B we give the asymptotic behavior of the special functions needed for these approximations.

II. THE AB HAMILTONIAN

In the sequel we set $\hbar^2/\mathrm{m}=2$ and $e/c=1$ so that the AB Hamiltonian is formally the operator

$$H = (i\nabla + \mathbf{A})^2, \tag{2.1}$$

in $L^2(\mathbb{R}^2)$, where the vector potential $\mathbf{A}$ is now given by

$$\mathbf{A} = \alpha\frac{\mathbf{k}\times\mathbf{r}}{r^2}. \tag{2.2}$$

We let $\alpha = N+\delta$, where $N\in\mathbb{Z}$ and $0<\delta<1$. Without loss of generality, we shall assume that $\alpha > 0$.

This Hamiltonian is discussed in great detail in Refs. 1 and 2. The analysis proceeds by decomposing the underlying space and studying the radial Hamiltonians

$$h_m = -\frac{1}{r}\frac{\partial}{\partial r} r \frac{\partial}{\partial r} + \frac{(m-\alpha)^2}{r^2} \tag{2.3}$$

in $L^2((0,\infty), r\,dr)$. Taking as domain $C_0^\infty((0,\infty), r\,dr)$, these operators are essentially self-adjoint, except for the cases $m=N,N+1$ which have deficiency indices (1,1). These two operators therefore have self-adjoint extensions h_{N,ν_N} and $h_{N+1,\nu_{N+1}}$, parametrized by ν_N and ν_{N+1}, where $-\infty < \nu_N,\ \nu_{N+1} \leqslant \infty$. These self-adjoint extensions can be identified with the boundary conditions

$$\nu_m \phi_0 = \phi_1,$$

where

$$\phi_0 = \lim_{r\downarrow 0} r^{|m-\alpha|}\phi(r)$$

and

$$\phi_1 = \lim_{r\downarrow 0} r^{-|m-\alpha|}[\phi(r) - r^{-|m-\alpha|}\phi_0].$$

A four-parameter family of self-adjoint extensions of H can be constructed from these. If we consider only self-adjoint extensions which commute with the angular momentum operator, this reduces to a two-parameter family. For this particular choice, the self-adjoint extension, $H^{\boldsymbol{\nu}}$, with $\boldsymbol{\nu} \in (-\infty,\infty]^2$, is just the direct sum

$$H^{\boldsymbol{\nu}} = h_{N,\nu_N} \oplus h_{N+1,\nu_{N+1}} \oplus \bigoplus_{\substack{m=-\infty \\ m\neq N,N+1}}^{\infty} h_m .$$

We shall write H^∞ for $H^{\boldsymbol{\nu}}$ with $\boldsymbol{\nu}=(\infty,\infty)$. Let $g_{k,\,m} = (h_m - k^2)^{-1}$. Then

$$g_{k,\,m}(r,r') = \frac{i\pi}{2} J_{|m-\alpha|}(kr_<) H^{(1)}_{|m-\alpha|}(kr_>), \tag{2.4}$$

where $r_< = \min\{r,r'\}$ and $r_> = \max\{r,r'\}$. The resolvents $g^{\nu_m}_{k,m} = (h_{m,\nu_m} - k^2)^{-1}$, $m=N,N+1$, are given by

$$g^{\nu_m}_{k,m}(r,r') = g_{k,\,m}(r,r') + c(m,\nu_m,k) H^{(1)}_{|m-\alpha|}(kr) H^{(1)}_{|m-\alpha|}(kr'), \quad m=N,N+1, \tag{2.5}$$

with

$$c(m,\nu,k) = \frac{-\pi^2}{2\Gamma(1+|m-\alpha|)} \left(\frac{k}{2}\right)^{2|m-\alpha|} \left(e^{-i\pi|m-\alpha|} \frac{\Gamma(1-|m-\alpha|)}{|m-\alpha|} \left(\frac{k}{2}\right)^{2|m-\alpha|} + \nu\Gamma(|m-\alpha|)\right)^{-1}, \tag{2.6}$$

$$c(m,\infty,k) = 0. \tag{2.7}$$

Finally, the resolvent of the Hamiltonian $G^{\boldsymbol{\nu}}_k = (H^{\boldsymbol{\nu}} - k^2)^{-1}$ is given by (see Ref. 1):

$$G^{\boldsymbol{\nu}}_k = g^{\nu_N}_{k,N} \oplus g^{\nu_{N+1}}_{k,N+1} \oplus \bigoplus_{\substack{m=-\infty \\ m\neq N,N+1}}^{\infty} g_{k,m} . \tag{2.8}$$

Note that the operators h_{m,ν_m} have no bound state for $\nu_m \geqslant 0$ and one bound state, E_m, for $\nu_m < 0$ given by

$$\left(i \frac{\sqrt{E_m}}{2} \right)^{2|m-\alpha|} = - \frac{\Gamma(1+|m-\alpha|)}{\Gamma(1-|m-\alpha|)} \nu_m, \quad m = N, N+1. \tag{2.9}$$

III. APPROXIMATION BY FINITE FLUX TUBE

The Aharonov–Bohm Hamiltonian consists of an infinitely thin magnetic flux tube. As a first approximation to H^{AB}, consider a flux tube of radius $R>0$, with a δ-function on a cylindrical shell (following Ref. 3 but see also Refs. 6, 4). That is we take the vector potential

$$\mathbf{A}_R = \begin{cases} 0, & r<R, \\ \alpha \dfrac{\mathbf{k}\times\mathbf{r}}{r^2}, & r>R. \end{cases} \tag{3.1}$$

Then $\mathbf{k}\cdot\mathbf{B}_R = (\alpha/R)\,\delta(r-R)$, so that formally, the Hamiltonian is then given by

$$H_R = (i\nabla + \mathbf{A}_R)^2 + \frac{\beta}{R}\delta(r-R), \tag{3.2}$$

where $\beta = -g\alpha/2$. The components in $L^2((0,\infty), r\,\mathrm{d}r)$ corresponding to the angular momentum m of this formal operator are

$$-\frac{1}{r}\frac{\partial}{\partial r} r \frac{\partial}{\partial r} + \frac{(m-\alpha\Theta(r-R))^2}{r^2} + \frac{\beta}{R}\delta(r-R), \tag{3.3}$$

where Θ is the unit step function. The procedure for adding a point interaction at $r=R$ to a radial Hamiltonian is standard (cf. Ref. 7 Sec. I.3.1). The point we make here is that β, the strength of the point interaction, has to depend on R and α in a definite way so that the self-adjoint extensions obtained in this manner converge to the AB self-adjoint extensions as R tends to 0.

Consider the following operator in $L^2((0,\infty), r\,\mathrm{d}r)$:

$$h_{m,R} = -\frac{1}{r}\frac{\partial}{\partial r} r \frac{\partial}{\partial r} + \frac{(m-\alpha\Theta(r-R))^2}{r^2} \tag{3.4}$$

with the closure of $C_0^\infty((0,\infty)\backslash\{R\})$ as its domain (Ref. 7, p. 75), i.e.,

$$\mathcal{D}(h_{m,\,R}) = \{g \in H^{2,2}((0,\infty), r\,\mathrm{d}r) \ \text{ s.t. } \ h_{m,\,R} g \in L^2((0,\infty), r\,\mathrm{d}r) \ \text{ and } \ g(R)=0\}. \tag{3.5}$$

Then its adjoint has domain (Ref. 7, p. 75)

$$\mathcal{D}(h^*_{m,\,R}) = \{g \in H^{2,2}((0,\infty)\backslash\{R\}, r\,\mathrm{d}r) \cap H^{2,1}((0,\infty), r\,\mathrm{d}r) \text{ s.t. } h_{m,\,R} g \in L^2((0,\infty), r\,\mathrm{d}r)\}. \tag{3.6}$$

The equation $h^*_{m,\,R}\phi = k^2\phi$, $\Im(k)>0$, has one solution in $\mathcal{D}(h^*_{m,\,R})$ for all values of $m \in \mathbb{Z}$ (see Note 1, Appendix A), given by

$$\phi_{m,k}(r) = \begin{cases} J_{|m|}(kr), & r<R, \\ B_m(k) H^{(1)}_{|m-\alpha|}(kr), & r>R, \end{cases} \tag{3.7}$$

where $B_m(k)$ is chosen so that the condition $\phi_{m,k}(R+) = \phi_{m,k}(R-)$ is satisfied. Thus the operators $h_{m,\,R}$ have deficiency indices (1,1). Self-adjoint extensions $h^\beta_{m,\,R}$ are obtained by imposing the following boundary condition on the domain of $h_{m,\,R}$:

$$\phi'_{m,k}(R+) - \phi'_{m,k}(R-) = \frac{\beta(\alpha,R)}{R}\phi_{m,k}(R), \tag{3.8}$$

where $\beta(\alpha,R)$ is a constant parameter (Ref. 7, p. 76). Note that we do not want the parameter $\beta(\alpha,R)$ to depend on m since it represents $-g\alpha/2$. We shall henceforth be writing β for this parameter to make the notation less cumbersome.

Next we find the resolvent $g^{\beta}_{k,\,m,\,R}=(h^{\beta}_{m,\,R}-k^2)^{-1}$. Note first that $g^{0}_{k,\,m,\,R}=(h_{m,\,R}-k^2)^{-1}$, $\Im(k)>0$, is given by (Note 2, Appendix A)

$$g^{0}_{k,\,m,\,R}(r,r')=\begin{cases}\dfrac{i\pi}{2}J_{|m|}(kr_<)\left(\dfrac{A^{(2)}_{m,R}(k)}{B^{(2)}_{m,R}(k)}J_{|m|}(kr_>)+H^{(1)}_{|m|}(kr_>)\right), & r,r'<R,\\[2ex] \dfrac{i\pi}{2}\left(J_{|m-\alpha|}(kr_<)+\dfrac{B^{(1)}_{m,R}(k)}{A^{(1)}_{m,R}(k)}H^{(1)}_{|m-\alpha|}(kr_<)\right)H^{(1)}_{|m-\alpha|}(kr_>), & r,r'>R,\\[2ex] \dfrac{i\pi}{2A^{(1)}_{m,R}(k)}J_{|m|}(kr_<)H^{(1)}_{|m-\alpha|}(kr_>), & \text{otherwise,}\end{cases} \tag{3.9}$$

where the constants $A^{(1)}_{m,R}(k),A^{(2)}_{m,R}(k),B^{(1)}_{m,R}(k)$, and $B^{(2)}_{m,R}(k)$ are given by

$$A^{(1)}_{m,R}(k)=\frac{W[J_{|m|},H^{(1)}_{|m-\alpha|}](kR)}{W[J_{|m-\alpha|},H^{(1)}_{|m-\alpha|}](kR)}, \tag{3.10}$$

$$B^{(1)}_{m,R}(k)=\frac{W[J_{|m|},J_{|m-\alpha|}](kR)}{W[H^{(1)}_{|m-\alpha|},J_{|m-\alpha|}](kR)}, \tag{3.11}$$

$$A^{(2)}_{m,R}(k)=\frac{W[H^{(1)}_{|m-\alpha|},H^{(1)}_{|m|}](kR)}{W[J_{|m|},H^{(1)}_{|m|}](kR)}, \tag{3.12}$$

$$B^{(2)}_{m,R}(k)=\frac{W[J_{|m|},H^{(1)}_{|m-\alpha|}](kR)}{W[J_{|m|},H^{(1)}_{|m|}](kR)}. \tag{3.13}$$

Here $W[\,\cdot\,,\,\cdot\,]$ denotes the Wronskian. Then the resolvent of $h^{\beta}_{m,\,R}$ is given by (Note 3, Appendix A):

$$g^{\beta}_{k,\,m,\,R}=g^{0}_{k,\,m,\,R}-\frac{\beta}{1+\beta g^{0}_{k,\,m,\,R}(R,R)}g^{0}_{k,\,m,\,R}(\,\cdot\,,R)\otimes\overline{g^{0}_{k,\,m,\,R}(\,\cdot\,,R)}, \tag{3.14}$$

for $\Im(k)>0$. We are interested in the behavior of $g^{\beta}_{k,\,m,\,R}(r,r')$ for small R. We note first that $\lim_{R\to 0}g^{0}_{k,\,m,\,R}(r,r')=g_{k,\,m}(r,r')$, which is the resolvent of the regular operator. For small R,

$$g^{0}_{k,\,m,\,R}(r,R)g^{0}_{k,\,m,\,R}(R,r')\simeq\tilde{c}^{2}_{m}(k)R^{2|m-\alpha|}H^{(1)}_{|m-\alpha|}(kr)H^{(1)}_{|m-\alpha|}(kr'), \tag{3.15}$$

where

$$\tilde{c}_{m}(k)=\frac{i\pi}{(|m-\alpha|+|m|)\Gamma(|m-\alpha|)}\left(\frac{k}{2}\right)^{|m-\alpha|}. \tag{3.16}$$

If $|m-\alpha|>1$ (i.e., if $m\notin\{N,N+1\}$), then the second term will either go to zero, or to a constant multiple of $H^{(1)}_{|m-\alpha|}(kr)H^{(1)}_{|m-\alpha|}(kr')$. Now $H^{(1)}_{|m-\alpha|}(kr)$ is not in $L^2((0,\infty),r\,dr)$ since it behaves like $r^{-|m-\alpha|}$ for small r (see Note 1, Appendix A). So in the latter case, the limit is not the kernel of a rank-one operator in $L^2((0,\infty),r\,dr)$. In particular, this means that it cannot be the kernel of a resolvent operator. Thus a meaningful nonzero limit for the second term in Eq. (3.14) exists only for the cases $m=N,N+1$. It shall be shown later that for small R, we get

$$g^0_{k,\ m,\ R}(R,R)\simeq\frac{1}{|m-\alpha|+|m|}\left(1-\frac{2e^{-i\pi|m-\alpha|}\Gamma(1-|m-\alpha|)}{(|m-\alpha|+|m|)\Gamma(|m-\alpha|)}\left(\frac{kR}{2}\right)^{2|m-\alpha|}\right). \tag{3.17}$$

For the case $r,r'>R$ (the other cases are straightforward), this results in

$$g^\beta_{k,\ m,\ R}(r,r')\simeq g^0_{k,\ m,\ R}(r,r')-\frac{\beta\tilde{c}^2_m(k)R^{2|m-\alpha|}}{1+\dfrac{\beta(1-\tilde{c}'(k)R^{2|m-\alpha|})}{|m-\alpha|+|m|}}H^{(1)}_{|m-\alpha|}(kr)H^{(1)}_{|m-\alpha|}(kr'), \tag{3.18}$$

where

$$\tilde{c}'(k)=\frac{2e^{-i\pi|m-\alpha|}\Gamma(1-|m-\alpha|)}{(|m-\alpha|+|m|)\Gamma(|m-\alpha|)}\left(\frac{k}{2}\right)^{2|m-\alpha|}. \tag{3.19}$$

The second term in (3.18) converges to a nonzero limit if β has the following R-dependence for small R:

$$\beta\simeq-(|m-\alpha|+|m|)\left(1-\frac{2|m-\alpha|\,\nu_m}{|m-\alpha|+|m|}R^{2|m-\alpha|}\right). \tag{3.20}$$

Then we obtain

$$\lim_{R\to0}g^\beta_{k,\ m,\ R}(r,r')=g_{k,\ m}(r,r')+c(m,\nu_m,k)H^{(1)}_{|m-\alpha|}(kr)H^{(1)}_{|m-\alpha|}(kr'). \tag{3.21}$$

This gives the correct expression in (2.5) for the kernel of the resolvent of some self-adjoint extension of h_m, $m=N,N+1$.

The following are the only cases of interest.

(I) If $\beta\simeq-\alpha[1-(2\delta/\alpha)\,\nu_N R^{2\delta}]$, then the second term in Eq. (3.14) approaches

(1) a nonzero limit for $m=N$, corresponding to the self-adjoint extension h_{N,ν_N};
(2) zero limit for $m=N+1$, corresponding to the regular self-adjoint extension $h_{N+1,\infty}$;
(3) zero limit for $m\neq N,N+1$, corresponding to the self-adjoint operators h_m.

(II) If $\beta\simeq(\alpha-2(N+1))(1-(2(1-\delta)/[2(N+1)-\alpha])\,\nu_{N+1}R^{2(1-\delta)})$, then the second term in Eq. (3.14) approaches
(1) a non-zero limit for $m=N+1$, corresponding to the self-adjoint extension $h_{N+1,\nu_{N+1}}$;
(2) zero limit for $m=N$, corresponding to the regular self-adjoint extension $h_{N,\infty}$;
(3) zero limit for $m\neq N,N+1$, as before.

We can state the above results as a Theorem.

Theorem 1: *Let*

$$H^\beta_R=\bigoplus_{m=-\infty}^{\infty}h^\beta_{m,R}. \tag{3.22}$$

Then $H^{\beta(\alpha,R)}_R$ converges, as $R\to0$, to one of the self-adjoint extensions H^ν of the AB Hamiltonian only if either

(I) $\beta(\alpha,R)+\alpha/R^{2\delta})\to2\delta\nu_N$
or
(II) $\beta(\alpha,R)-\alpha+2(N+1)/R^{2(1-\delta)}\to2(1-\delta)\nu_{N+1}$.

In case (I) $H_R^{\beta(\alpha,R)}$ converges in the norm resolvent sense, as $R\to 0$, to $H^{(\nu_N,\,\infty)}$, and in case (II) to $H^{(\infty,\,\nu_{N+1})}$.

Proof: Let us consider case (I), case (II) is similar. Since

$$\|(H_R^{\beta(\alpha,R)}-k^2)^{-1}-G_k^{(\nu_N,\,\infty)}\|=\max\{\|g_{k,\,N,\,R}^{\beta(\alpha,R)}-g_{k,\,N}^{\nu_N}\|,\|g_{k,\,N+1,\,R}^{\beta(\alpha,R)}-g_{k,\,N+1}\|,\ \sup_{\substack{m\in\mathbb{Z}\\ m\neq N,N+1}}\|g_{k,\,m,\,R}^{\beta(\alpha,R)}-g_{k,\,m}\|\},\tag{3.23}$$

we not only have to prove that the the terms in the right-hand side of the above equations tend to zero, but we have to show that $\|g_{k,\,m,\,R}^{\beta(\alpha,R)}-g_{k,\,m}\|$ tends to zero uniformly in m. To do this we need to obtain detailed upper and lower bounds on the special functions J_ν and $H_\nu^{(1)}$. These are given in the Appendix.

The first term in the expressions for $g_{k,\,m,\,R}^{\beta(\alpha,R)}$ is $g_{k,\,m,\,R}^{0}$ and first term in the expressions for $g_{k,\,m}^{\nu}$ is $g_{k,\,m}$. Therefore we start with the following lemma. Here $\|\cdot\|_2$ denotes the Hilbert–Schmidt norm, and of course $\|\cdot\|\leqslant\|\cdot\|_2$.

Lemma 1: For any m, $\lim_{R\to 0}\|g_{k,\,m,\,R}^{0}-g_{k,\,m}\|_2=0$. Furthermore, there exists $M\in\mathbb{N}$ such that for $|m|>M$, there exists a constant $c(R)$, independent of m, such that $\|g_{k,\,m,\,R}^{0}-g_{k,\,m}\|_2\leqslant c(R)$, and $\lim_{R\to 0}c(R)=0$.

Proof:

$$\|g_{k,\,m,\,R}^{0}-g_{k,\,m}\|_2\leqslant\|\tilde g_1\|_2+\|\tilde g_2\|_2+\|\tilde g_3\|_2+\|\tilde g_4\|_2+\|\tilde g_5-g_{k,\,m}\|_2,\tag{3.24}$$

where

$$\tilde g_1(r,r')=\frac{i\pi}{2}\frac{A_{m,R}^{(2)}(k)}{B_{m,R}^{(2)}(k)}J_{|m|}(kr)J_{|m|}(kr')\mathbf{1}_{(0,\,R)\times(0,\,R)}(r,r'),\tag{3.25}$$

$$\tilde g_2(r,r')=\frac{i\pi}{2}J_{|m|}(kr_<)H_{|m|}^{(1)}(kr_>)\mathbf{1}_{(0,\,R)\times(0,\,R)}(r,r'),\tag{3.26}$$

$$\tilde g_3(r,r')=\frac{i\pi}{2}\frac{B_{m,R}^{(1)}(k)}{A_{m,R}^{(1)}(k)}H_{|m-\alpha|}^{(1)}(kr)H_{|m-\alpha|}^{(1)}(kr')\mathbf{1}_{(R,\,\infty)\times(R,\,\infty)}(r,r'),\tag{3.27}$$

$$\tilde g_4(r,r')=\frac{i\pi}{2A_{m,R}^{(1)}(k)}J_{|m|}(kr_<)H_{|m-\alpha|}^{(1)}(kr_<)\mathbf{1}_{(0,\,R]\times[R,\,\infty)\cup[R,\,\infty)\times(0,\,R]}(r,r'),\tag{3.28}$$

$$\tilde g_5(r,r')=\frac{i\pi}{2}J_{|m-\alpha|}(kr_<)H_{|m-\alpha|}^{(1)}(kr_>)\mathbf{1}_{(R,\,\infty)\times(R,\,\infty)}(r,r').\tag{3.29}$$

Using the bounds (B32), (B41), and (B45) in Appendix B and the relation

$$W[J_\nu(z),H_\nu^{(1)}(z)]=\frac{2i}{\pi z},\tag{3.30}$$

we can see that for any $\varepsilon>0$, there exists $R_0>0$ such that if $R<R_0$, then the following bounds hold:

$$\frac{1}{|A_{m,R}^{(1)}(k)|}\leqslant\frac{2\Gamma(|m|+1)}{||m-\alpha|+|m||\Gamma(|m-\alpha|)}\left|\frac{kR}{2}\right|^{|m-\alpha|-|m|}(1+\varepsilon),\tag{3.31}$$

$$\left|\frac{B^{(1)}_{m,R}(k)}{A^{(1)}_{m,R}(k)}\right| \leqslant \frac{\pi||m-\alpha|-|m||}{(|m-\alpha|+|m|)\Gamma(|m-\alpha|)\Gamma(|m-\alpha|+1)}\left|\frac{kR}{2}\right|^{2|m-\alpha|}(1+\varepsilon), \tag{3.32}$$

$$\left|\frac{A^{(2)}_{m,R}(k)}{B^{(2)}_{m,R}(k)}\right| \leqslant \frac{||m-\alpha|-|m||\Gamma(|m|)\Gamma(|m|+1)}{2\pi(|m-\alpha|+|m|)}\left|\frac{kR}{2}\right|^{-2|m|}(1+\varepsilon). \tag{3.33}$$

Now we can find bounds for the terms in Eq. (3.24) for small R,

$$\|\tilde{g}_1\|_2^2 = \int\int |\tilde{g}_1(r,r')|^2\, r\,\mathrm{d}r\, r'\,\mathrm{d}r' = \frac{\pi^2}{4}\left|\frac{A^{(2)}_{m,R}(k)}{B^{(2)}_{m,R}(k)}\right|^2\left(\int_0^R r\,\mathrm{d}r|J_{|m|}(kr)|^2\right)^2.$$

Using (3.33) and (B1) we get

$$\|\tilde{g}_1\|_2^2 \leqslant \begin{cases} \dfrac{(|m-\alpha|-|m|)^2R^4}{64|m|^2(|m|+1)^2(|m-\alpha|+|m|)^2}(1+\varepsilon), & m\neq 0, \\ \dfrac{R^4}{64}(1+\varepsilon), & m=0. \end{cases} \tag{3.34}$$

Next we have

$$\begin{aligned}\|\tilde{g}_2\|_2^2 &= \int |\tilde{g}_2(r,r')|^2\, r\,\mathrm{d}r\, r'\,\mathrm{d}r' \\ &= \frac{\pi^2}{4}\int_0^R r\,\mathrm{d}r\, r'\,\mathrm{d}r'|J_{|m|}(kr_<)|^2|H^{(1)}_{|m|}(kr'_>)|^2 \\ &= \frac{\pi^2}{2}\int_0^R r\,\mathrm{d}r|J_{|m|}(kr)|^2\int_r^R r'\,\mathrm{d}r'|H^{(1)}_{|m|}(kr')|^2.\end{aligned}$$

From (B1), (B18) and (B25), we get

$$\|\tilde{g}_2\|_2^2 \leqslant \begin{cases} \dfrac{R^4}{16|m|^2(1+|m|)}(1+\varepsilon), & |m|>1, \\ \dfrac{R^4}{32}(1+\varepsilon), & |m|=1, \\ \dfrac{R^4}{32}(8(\ln kR)^2+4\ln kR+1)(1+\varepsilon), & m=0. \end{cases} \tag{3.35}$$

From the relations $\overline{K_\nu(z)}=K_\nu(\overline{z})$ and

$$H^{(1)}_\nu(z) = -\frac{2i}{\pi}e^{-1/2\,i\pi\nu}K_\nu(-iz), \tag{3.36}$$

we obtain

$$\begin{aligned}\int_R^\infty r\,\mathrm{d}r\ \ |H^{(1)}_{|m-\alpha|}(kr)|^2 &= \frac{4}{\pi^2}\int_R^\infty \mathrm{d}r\,\frac{r^{2|m-\alpha|+\xi-1}}{r^{2|m-\alpha|+\xi-2}}K_{|m-\alpha|}(i\overline{kr})K_{|m-\alpha|}(-ikr) \\ &\leqslant \frac{4R^{2-2|m-\alpha|-\xi}}{\pi^2}\int_0^\infty \mathrm{d}r\, r^{2|m-\alpha|+\xi-1}K_{|m-\alpha|}(i\overline{kr})K_{|m-\alpha|}(-ikr).\end{aligned}$$

for $2|m-\alpha|+\xi>2$.

Using the formula 6.576 of Ref. 8, we then get

$$\int_R^\infty r\,\mathrm{d}r\ |H^{(1)}_{|m-\alpha|}(kr)|^2 \leqslant \frac{2}{\pi^2}|k|^{-2|m-\alpha|-\xi}\left|\frac{R}{2}\right|^{2-2|m-\alpha|-\xi}\frac{\Gamma\left(\frac{\xi}{2}\right)\Gamma\left(\frac{1}{2}\right)}{\Gamma\left(\frac{\xi}{4}+\frac{1}{2}\right)} \times\frac{\Gamma\left(|m-\alpha|+\frac{\xi}{2}+\frac{1}{2}\right)\Gamma\left(2|m-\alpha|+\frac{\xi}{2}\right)\left(\Gamma\left(|m-\alpha|+\frac{\xi}{2}\right)\right)^2}{\Gamma\left(|m-\alpha|+\frac{\xi}{4}+\frac{1}{2}\right)\Gamma(2|m-\alpha|+\xi)} \tag{3.37}$$

for $|m-\alpha|\geqslant 1$ and $\xi>0$.

So, if $m\neq N,N+1$,

$$\begin{aligned}\|\tilde{g}_3\|_2^2 &= \int |\tilde{g}_3(r,r')|^2\,r\,\mathrm{d}r\,r'\,\mathrm{d}r' = \frac{\pi^2}{4}\left|\frac{B^{(1)}_{m,R}(k)}{A^{(1)}_{m,R}(k)}\right|^2\int_R^\infty r\,\mathrm{d}r|H^{(1)}_{|m-\alpha|}(kr)|^2\int_r^\infty r'\,\mathrm{d}r'|H^{(1)}_{|m-\alpha|}(kr')|^2\\ &\leqslant \frac{\pi^2}{4}\left|\frac{B^{(1)}_{m,R}(k)}{A^{(1)}_{m,R}(k)}\right|^2\left[\int_R^\infty r\,\mathrm{d}r|H^{(1)}_{|m-\alpha|}(kr)|^2\right]^2\\ &\leqslant \frac{(|m-\alpha|-|m|)^2}{(|m-\alpha|+|m|)^2}\left(\frac{R}{2}\right)^{4-2\xi}|k|^{-2\xi}\left(\frac{\Gamma\left(\frac{\xi}{2}\right)\Gamma\left(\frac{1}{2}\right)}{\Gamma\left(\frac{\xi}{4}+\frac{1}{2}\right)}\right)^2(1+\varepsilon)\\ &\quad\times\left(\frac{\Gamma\left(|m-\alpha|+\frac{\xi}{2}+\frac{1}{2}\right)\Gamma\left(2|m-\alpha|+\frac{\xi}{2}\right)\left(\Gamma\left(|m-\alpha|+\frac{\xi}{2}\right)\right)^2}{\Gamma\left(|m-\alpha|+\frac{\xi}{4}+\frac{1}{2}\right)\Gamma(2|m-\alpha|+\xi)\Gamma(|m-\alpha|)\Gamma(|m-\alpha|+1)}\right)^2.\end{aligned} \tag{3.38}$$

For $m=N,N+1$ the following bound is sufficient:

$$\|\tilde{g}_3\|_2^2 \leqslant \left(\frac{\pi^2||m-\alpha|-|m||}{4(|m-\alpha|+|m|)\Gamma(|m-\alpha|)\Gamma(|m-\alpha|+1)}\right)^2\left|\frac{kR}{2}\right|^{4|m-\alpha|}\times\|H^{(1)}_{|m-\alpha|}(kr)\|^4(1+\varepsilon). \tag{3.39}$$

Thus, for fixed m, $\|\tilde{g}_3\|_2\to 0$ as $R\to 0$ provided we choose $\xi<2$.

To make the bound for $\|\tilde{g}_3\|_2$ in (3.38) independent of m, we use the following limit:

$$\lim_{n\to\infty} n^{b-a}\frac{\Gamma(n+a)}{\Gamma(n+b)}=1, \tag{3.40}$$

to deduce that there exists $M_0\in\mathbb{N}$ such that, if $|m|>M_0$, then

$$\frac{\left(\Gamma\left(|m-\alpha|+\frac{\xi}{2}+\frac{1}{2}\right)\Gamma(2|m-\alpha|+\xi/2)\right)^2(\Gamma(|m-\alpha|+\xi/2))^4}{\left(\Gamma\left(|m-\alpha|+\frac{\xi}{4}+\frac{1}{2}\right)\Gamma(2|m-\alpha|+\xi)\Gamma(|m-\alpha|)\Gamma(|m-\alpha|+1)\right)^2}\leqslant 2^{-\xi}\overline{m}^{3/2\,\xi-2} \tag{3.41}$$

where $\overline{m}=\lfloor|m-\alpha|\rfloor$, and we must choose $\xi<\frac{4}{3}$.

Similarly, for $m \neq N, N+1$,

$$\|\tilde{g}_4\|_2^2 = \int |\tilde{g}_4(r,r')|^2 r \, \mathrm{d}r \, r' \, \mathrm{d}r' \tag{3.42}$$

$$= \frac{\pi^2}{2|A^{(1)}_{m,R}(k)|^2} \int_0^R r \, \mathrm{d}r |J_{|m|}(kr)|^2 \int_R^\infty r' \, \mathrm{d}r' |H^{(1)}_{|m-\alpha|}(kr')|^2 \tag{3.43}$$

$$\leqslant \frac{2^{\xi-1} R^{4-\xi}}{(|m|+1)(|m-\alpha|+|m|)^2} |k|^{-\xi} \frac{\Gamma\left(\frac{\xi}{2}\right)\Gamma\left(\frac{1}{2}\right)}{\Gamma\left(\frac{\xi}{4}+\frac{1}{2}\right)} (1+\varepsilon)$$
$$\times \frac{\Gamma\left(|m-\alpha|+\frac{\xi}{2}+\frac{1}{2}\right)\Gamma\left(2|m-\alpha|+\frac{\xi}{2}\right)\left(\Gamma\left(|m-\alpha|+\frac{\xi}{2}\right)\right)^2}{\Gamma\left(|m-\alpha|+\frac{\xi}{4}+\frac{1}{2}\right)\Gamma(2|m-\alpha|+\xi)(\Gamma(|m-\alpha|))^2}, \tag{3.44}$$

while for $m = N, N+1$,

$$\|\tilde{g}_4\|_2^2 \leqslant \frac{\pi^2 \left|\frac{k}{2}\right|^{2|m-\alpha|} R^{2|m-\alpha|+2}}{(|m|+1)(|m-\alpha|+|m|)^2 (\Gamma(|m-\alpha|))^2} \|H^{(1)}_{|m-\alpha|}(kr)\|^2 (1+\varepsilon). \tag{3.45}$$

As previously, for fixed m, $\|\tilde{g}_4\|_2 \to 0$ as $R \to 0$ if we choose $\xi < 2$.

To obtain a bound independent of m in (3.44), we again use the limit in (3.40) to show that there exists $M_1 \in \mathbb{N}$ such that, if $|m| > M_1$, then

$$\frac{\Gamma\left(|m-\alpha|+\frac{\xi}{2}+\frac{1}{2}\right)\Gamma\left(2|m-\alpha|+\frac{\xi}{2}\right)\left(\Gamma\left(|m-\alpha|+\frac{\xi}{2}\right)\right)^2}{(1+|m|)\Gamma\left(|m-\alpha|+\frac{\xi}{4}+\frac{1}{2}\right)\Gamma(2|m-\alpha|+\xi)(\Gamma(|m-\alpha|))^2} \leqslant 2^{\xi/4} M_1^{3/4\,\xi-1}. \tag{3.46}$$

Finally,

$$\tilde{g}_5(r,r') - g_{k,\ m}(r,r') = -\frac{i\pi}{2} J_{|m-\alpha|}(kr_<) H^{(1)}_{|m-\alpha|}(kr_>) \mathbf{1}_{\mathbb{R}^2 \setminus (R,\infty)\times(R,\infty)} \tag{3.47}$$

so

$$\|\tilde{g}_5 - g_{k,\ m}\|_2^2 = \frac{\pi^2}{2} \int_0^R r \, \mathrm{d}r |J_{|m-\alpha|}(kr)|^2 \int_r^R r' \, \mathrm{d}r' |H^{(1)}_{|m-\alpha|}(kr')|^2$$
$$+ \frac{\pi^2}{2} \int_0^R r \, \mathrm{d}r |J_{|m-\alpha|}(kr)|^2 \int_R^\infty r' \, \mathrm{d}r' |H^{(1)}_{|m-\alpha|}(kr')|^2. \tag{3.48}$$

The first term is bounded by $R^4(1+\varepsilon)/16|m-\alpha|^2(1+|m-\alpha|)$, while for the second term we need to consider the cases $m \neq N, N+1$ separately using Eq. (3.37).

Then we deduce that for $m \neq N, N+1$,

$$\|\tilde{g}_5 - g_{k,\,m}\|_2^2 \leqslant \frac{R^4(1+\varepsilon)}{8|m-\alpha|^2(1+|m-\alpha|)} + \frac{\left(\frac{2}{k}\right)^{\xi}\Gamma\left(\frac{1}{2}\right)R^{4-\xi}}{8(1+|m-\alpha|)}(1+\varepsilon) \times \frac{\Gamma\left(\frac{\xi}{2}\right)\Gamma\left(|m-\alpha|+\frac{\xi}{2}+\frac{1}{2}\right)\Gamma(2|m-\alpha|+\xi/2)(\Gamma(|m-\alpha|+\xi/2))^2}{\Gamma\left(\frac{\xi}{4}+\frac{1}{2}\right)\Gamma\left(|m-\alpha|+\frac{\xi}{4}+\frac{1}{2}\right)\Gamma(2|m-\alpha|+\xi)(\Gamma(|m-\alpha|+1))^2}, \tag{3.49}$$

while for $m=N,N+1$,

$$\|\tilde{g}_5 - g_{k,\,m}\|_2^2 \leqslant \frac{R^4(1+\varepsilon)}{8|m-\alpha|^2(1+|m-\alpha|)} + \frac{\pi^2\left|\frac{k}{2}\right|^{2|m-\alpha|}R^{2|m-\alpha|+2}}{4(1+|m-\alpha|)(\Gamma(1+|m-\alpha|))^2}\|H^{(1)}_{|m-\alpha|}(kr)\|^2(1+\varepsilon). \tag{3.50}$$

A similar argument to that used previously shows that the bound in (3.49) may be taken to be independent of m. This completes the proof of Lemma 1.

□

Next we shall show that the operator $h^{\beta}_{m,\,R}$ converges in the norm resolvent sense to the appropriate limit provided β obeys condition I or II.

Lemma 2: (a) If condition I (condition II) holds, then for $m\neq N$ ($m\neq N+1$), the operator $h^{\beta}_{m,\,R}$ converges to h_m in the norm resolvent sense as $R\to 0$.

Furthermore, there exists $M\in\mathbb{N}$ such that for $|m|>M$, there exists a constant $c(R)$, independent of m, such that $\|g^{\beta}_{k,\,m,\,R}-g_{k,\,m}\|_2\leqslant c(R)$, and $\lim_{R\to 0}c(R)=0$.

(b) If condition I (condition II) holds, then the operator $h^{\beta}_{N,R}$ converges to h_{N,ν_N} ($h^{\beta}_{N+1,R}$ converges to $h_{N+1,\nu_{N+1}}$) in the norm resolvent sense as $R\to 0$.

Proof: We shall prove the Lemma for the case when condition I holds. The corresponding proof for the case when condition II holds is similar.

First we note the limiting behavior of $g^{0}_{k,\,m,\,R}(R,R)$ for small R,

$$g^{0}_{k,\,m,\,R}(R,R)\simeq\begin{cases}\dfrac{1}{|m-\alpha|+|m|}(1-\tilde{c}'(k)R^{2|m-\alpha|}), & m=N,N+1,\\ \dfrac{1}{|m-\alpha|+|m|}(1-d(k)R^2), & m\neq N,N+1.\end{cases} \tag{3.51}$$

where

$$\tilde{c}'(k)=\frac{2e^{-i\pi|m-\alpha|}\Gamma(1-|m-\alpha|)}{(|m-\alpha|+|m|)\Gamma(|m-\alpha|)}\left(\frac{k}{2}\right)^{2|m-\alpha|} \tag{3.52}$$

and

$$d(k)=\frac{1}{1-|m-\alpha|}\left(1+\frac{|m-\alpha|-|m|}{|m-\alpha|(|m-\alpha|+|m|)}\right)\left(\frac{k}{2}\right)^2. \tag{3.53}$$

(a) Let $m\neq N$ and suppose condition I holds. We need to show that

$$\lim_{R\to 0}\|g^{\beta}_{k,\ m,\ R}-g_{k,\ m}\|_2=0. \tag{3.54}$$

Now

$$\|g^{\beta}_{k,\ m,\ R}-g_{k,\ m}\|_2\leqslant\|g^{0}_{k,\ m,\ R}-g_{k,\ m}\|_2+\left|\frac{\beta}{1+\beta g^{0}_{k,\ m,\ R}(R,R)}\right|\|g^{0}_{k,\ m,\ R}(\ \cdot\ ,R)\|^2. \tag{3.55}$$

In Lemma 1, we have shown that $\lim_{R\to 0}\|g^{0}_{k,\ m,\ R}-g_{k,\ m}\|_2=0$.

The following three cases need to be considered separately:

Case 1. $m=0,1,2,\ldots,N-1$;

Case 2. $m=N+1$;

Case 3. $m\leqslant -1$ or $m\geqslant N+2$.

Case 1. If $m=0,1,2,\ldots,N-1$, then $|m-\alpha|+|m|=\alpha$. For small R,

$$\left|\frac{\beta}{1+\beta g^{0}_{k,\ m,\ R}(R,R)}\right|\simeq\frac{\alpha^2}{2\delta|\nu_N|}R^{-2\delta}, \tag{3.56}$$

while

$$\begin{aligned}\|g^{0}_{k,\ m,\ R}(\ \cdot\ ,R)\|^2&=\int_0^{\infty}r\,\mathrm{d}r|g^{0}_{k,\ m,\ R}(r,R)|^2\\&=\frac{\pi^2}{4|A^{(1)}_{m,R}(k)|^2}\left\{|H^{(1)}_{|m-\alpha|}(kR)|^2\int_0^{R}r\,\mathrm{d}r\left|J_{|m|}(kr)\right|^2\right.\\&\quad\left.+|J_{|m|}(kR)|^2\int_R^{\infty}r\,\mathrm{d}r|H^{(1)}_{|m-\alpha|}(kr)|^2\right\}\\&\leqslant(1+\varepsilon)\left[\frac{R^2}{2\alpha^2(1+|m|)}+\frac{R^{2-\xi}}{2\alpha^2}\left(\frac{2}{k}\right)^{\xi}\frac{\Gamma\left(\frac{\xi}{2}\right)\Gamma\left(\frac{1}{2}\right)}{\Gamma\left(\frac{\xi}{4}+\frac{1}{2}\right)}\right.\\&\quad\left.\times\frac{\Gamma\left(|m-\alpha|+\frac{\xi+1}{2}\right)\Gamma(2|m-\alpha|+\xi/2)(\Gamma(|m-\alpha|+\xi/2))^2}{\Gamma\left(|m-\alpha|+\frac{\xi+2}{4}\right)\Gamma(2|m-\alpha|+\xi)(\Gamma(|m-\alpha|))^2}\right],\end{aligned} \tag{3.57}$$

Taking $\xi<2(1-\delta)$ gives the desired limit.

Case 2. If $m=N+1$, then $|m-\alpha|+|m|=N+2-\delta$. Then

$$\lim_{R\to 0}\left|\frac{\beta}{1+\beta g^{0}_{k,N+1,R}(R,R)}\right|=\frac{\alpha(N+2-\delta)}{2(1-\delta)}, \tag{3.58}$$

while

$$\int_0^\infty r\,\mathrm{d}r|g^0_{k,N+1,R}(r,R)|^2$$

$$=\frac{\pi^2}{4|A^{(1)}_{N+1,R}(k)|^2}\left\{|H^{(1)}_{1-\delta}(kR)|^2\int_0^R r\,\mathrm{d}r|J_{N+1}(kr)|^2+|J_{N+1}(kR)|^2\int_R^\infty r\,\mathrm{d}r|H^{(1)}_{1-\delta}(kr)|^2\right\} \tag{3.59}$$

$$\leqslant\frac{R^2}{2(N+2)(N+2-\delta)^2}(1+\varepsilon)+\frac{\pi^2\|H^{(1)}_{1-\delta}(kr)\|^2}{(N+2-\delta)^2(\Gamma(1-\delta))^2}\left|\frac{kR}{2}\right|^{2(1-\delta)}(1+\varepsilon). \tag{3.60}$$

Case 3. If $m\leqslant -1$ or $m\geqslant N+2$, then $|m-\alpha|+|m|=|2m-\alpha|$. The constant term is bounded as follows:

$$\left|\frac{\beta}{1+\beta g^0_{k,\,m,\,R}(R,R)}\right|\leqslant\frac{\alpha|2m-\alpha|}{|2m-\alpha|-\alpha}(1+\varepsilon), \tag{3.61}$$

and

$$\int_0^\infty r\,\mathrm{d}r|g^0_{k,\,m,\,R}(r,R)|^2=\frac{\pi^2}{4|A^{(1)}_{m,R}(k)|^2}\left\{|H^{(1)}_{|m-\alpha|}(kR)|^2\int_0^R r\,\mathrm{d}r|J_{|m|}(kr)|^2\right.$$

$$\left.+|J_{|m|}(kR)|^2\int_R^\infty r\,\mathrm{d}r|H^{(1)}_{|m-\alpha|}(kr)|^2\right\} \tag{3.62}$$

$$\leqslant\left[\frac{R^2}{2|2m-\alpha|^2(1+|m|)}+\frac{R^{2-\xi}}{2|2m-\alpha|^2}\left(\frac{2}{k}\right)^\xi\frac{\Gamma\left(\frac{\xi}{2}\right)\Gamma\left(\frac{1}{2}\right)}{\Gamma\left(\frac{\xi}{4}+\frac{1}{2}\right)}(1+\varepsilon)\right.$$

$$\left.\times\frac{\Gamma\left(|m-\alpha|+\frac{\xi+1}{2}\right)\Gamma(2|m-\alpha|+\xi/2)(\Gamma(|m-\alpha|+\xi/2))^2}{\Gamma\left(|m-\alpha|+\frac{\xi+2}{2}\right)\Gamma(2|m-\alpha|+\xi)(\Gamma(|m-\alpha|))^2}\right], \tag{3.63}$$

An argument similar to that used in (3.46) ensures that the bound is independent of m if $|m|$ is large enough.

(b) Let $m=N$ and suppose condition I holds. Then

$$\|g^\beta_{k,N,R}-g^{\nu_N}_{k,N}\|_2\leqslant\|g^0_{k,N,R}-g_{k,N}\|_2+\|l_{k,N,R}-l_{k,N}\|_2, \tag{3.64}$$

where

$$l_{k,N,R}(r,r')=\frac{\beta}{1+\beta g^0_{k,N,R}(R,R)}g^0_{k,N,R}(r,R)g^0_{k,N,R}(R,r') \tag{3.65}$$

and

$$l_{k,N}=c(N,\nu_N,k)H^{(1)}_\delta(kr)H^{(1)}_\delta(kr'). \tag{3.66}$$

As noted previously, Lemma 1 proves that $\lim_{R\to 0}\|g^0_{k,N,R}-g_{k,N}\|_2=0$.

Now,

$$\|l_{k,N,R}-l_{k,N}\|_2^2=\int r\,dr\,r'\,dr'\left|\frac{\beta}{1+\beta g^0_{k,N,R}(R,R)}g^0_{k,N,R}(r,R)g^0_{k,N,R}(R,r')\right.$$
$$\left.-c(N,\nu_N,k)H^{(1)}_\delta(kr)H^{(1)}_\delta(kr')\right|^2 \tag{3.67}$$

$$=l^{(1)}+l^{(2)}-l^{(3)}-\overline{l^{(3)}}, \tag{3.68}$$

where

$$l^{(1)}=\left|\frac{\beta}{1+\beta g^0_{k,N,R}(R,R)}\right|^2\int r\,dr\,r'\,dr'|g^0_{k,N,R}(r,R)g^0_{k,N,R}(R,r')|^2, \tag{3.69}$$

$$l^{(2)}=|c(N,\nu_N,k)|^2\int r\,dr\,r'\,dr'|H^{(1)}_\delta(kr)H^{(1)}_\delta(kr')|^2, \tag{3.70}$$

and

$$l^{(3)}=\frac{\beta}{1+\beta g^0_{k,N,R}(R,R)}\overline{c(N,\nu_N,k)}\int r\,dr\,r'\,dr'g^0_{k,N,R}(r,R)g^0_{k,N,R}(R,r')\overline{H^{(1)}_\delta(kr)H^{(1)}_\delta(kr')}. \tag{3.71}$$

For small R,

$$\frac{\beta}{1+\beta g^0_{k,N,R}(R,R)}\simeq\frac{-\alpha^2R^{-2\delta}}{2\delta\nu_N+\alpha\tilde{c}'(k)}. \tag{3.72}$$

Then

$$\int r\,dr\,r'\,dr'|g^0_{k,N,R}(r,R)g^0_{k,N,R}(R,r')|^2$$
$$=\frac{\pi^4}{16|A^{(1)}_{N,R}(k)|^4}\left\{|H^{(1)}_\delta(kR)|^4\left[\int_0^R r\,dr|J_N(kr)|^2\right]^2+\left|J_N(kR)|^4\left[\int_R^\infty r\,dr|H^{(1)}_\delta(kR)|^2\right]^2\right\}. \tag{3.73}$$

The first term is bounded by $[R^4/(4\alpha^4(N+1)^2)](1+\varepsilon)$, while for small R,

$$\left|\frac{\beta}{1+\beta g^0_{k,N,R}(R,R)}\right|^2\frac{\pi^4|J_N(kR)|^4}{16|A^{(1)}_{N,R}(k)|^4}\left[\int_R^\infty r\,dr|H^{(1)}_\delta(kR)|^2\right]^2$$
$$\simeq\frac{\pi^4\left(\frac{k}{2}\right)^{4\delta}}{(\Gamma(\delta))^4(2\delta\nu_N+\alpha\tilde{c}'(k))^2}\|H^{(1)}_\delta(kr)\mathbf{1}_{(R,\infty)}\|^4=|c(N,\nu_N,k)|^2\|H^{(1)}_\delta(kr)\mathbf{1}_{(R,\infty)}\|^4. \tag{3.74}$$

Then $l^{(1)}\to l^{(2)}$ as $R\to 0$ by dominated convergence.

For $l^{(3)}$ we have

$$\int r\,dr\,r'\,dr'\,g^0_{k,N,R}(r,R)g^0_{k,N,R}(R,r')\overline{H^{(1)}_\delta(kr)H^{(1)}_\delta(kr')}$$

$$=\left[\frac{i\pi}{2A^{(1)}_{N,R}(k)}\left\{H^{(1)}_\delta(kR)\int_0^R r\,dr\,J_N(kr)\overline{H^{(1)}_\delta(kr)}\ +J_N(kR)\int_R^\infty r\,dr|H^{(1)}_\delta(kr)|^2\right\}\right]^2. \quad (3.75)$$

The first term in the brackets goes to $[i\Gamma(\delta)R^{2-\delta}/(\alpha\pi(N+2-\delta))]\,(\overline{k}/2)^{-\delta}$, while for small R,

$$\frac{i\pi}{2A^{(1)}_{N,R}(k)}J_N(kR)\int_R^\infty r\,dr|H^{(1)}_\delta(kr)|^2\simeq\frac{i\pi}{\alpha\Gamma(\delta)}\left|\frac{kR}{2}\right|^\delta\|H^{(1)}_\delta(kr)\mathbf{1}_{(R,\infty)}\|^2. \quad (3.76)$$

Then $l^{(3)}\to l^{(2)}$ as $R\to 0$ by dominated convergence, which completes the proof.

□

IV. APPROXIMATION BY SMOOTH FLUX TUBE

In Sec. III, $\mathbf{A}_R=\alpha\,(\mathbf{k}\times\mathbf{r}/r^2)\,\Theta(r-R)$ so that $\mathbf{B}_R$ is concentrated on a cylindrical shell. Now we replace the Θ-function by a smooth step function which approximates the Θ-function as $R\to 0$. Let $a:\mathbb{R}\mapsto\mathbb{R}$ be a differentiable function with $a(r)=0$ for $r\leqslant 0$ and $a(r)=1$ for $r\geqslant r_0$, where $r_0>0$. Furthermore, let a be such that the function $b(r)=(1/r)(\mathrm{d}/\mathrm{d}r)\,a(r)$ is bounded in absolute value (i.e., there exists $b_0\in\mathbb{R}$ such that $|b(r)|\leqslant b_0$). Then $b(r)$ has support only in $(0,r_0)$, and $\int_0^\infty b(r)\,r\,dr=1$. We take

$$\hat{\mathbf{A}}_R=\alpha\frac{\mathbf{k}\times\mathbf{r}}{r^2}a\left(\frac{r-R}{R^5}\right) \quad (4.1)$$

so that $\mathbf{k}\cdot\hat{\mathbf{B}}_R=R^{-5}\alpha\ b((r-R)/R^5)$. Let

$$\hat{H}_R=(i\nabla+\hat{\mathbf{A}}_R)^2+\frac{\beta}{\alpha}\mathbf{k}\cdot\hat{\mathbf{B}}_R. \quad (4.2)$$

β here depends on α and R. Motivated by the result of Sec. III we shall consider two cases:

(a) $\beta(\alpha,R)\simeq-\alpha(1-2\delta/\alpha\,\nu_N R^{2\delta})$,
(b) $\beta(\alpha,R)\simeq(\alpha-2(N+1))(1-2(1-\delta)/2(N+1)-\alpha\,\nu_{N+1}R^{2(1-\delta)})$.

The component of the operator $\hat{H}_R$ on the space with angular momentum m are

$$\hat{h}_{m,R}=-\frac{1}{r}\frac{\partial}{\partial r}r\frac{\partial}{\partial r}+\frac{\left(m-\alpha a\left(\frac{r-R}{R^5}\right)\right)^2}{r^2}+\beta R^{-5}b\left(\frac{r-R}{R^5}\right). \quad (4.3)$$

We shall prove convergence in the norm resolvent sense of the operators $\hat{h}_{m,R}$, and hence of $\hat{H}_R$.

We can rewrite the last equation as

$$\hat{h}_{m,R}=-\frac{1}{r}\frac{\partial}{\partial r}r\frac{\partial}{\partial r}+\frac{(m-\alpha\Theta(r-R))^2}{r^2}+\frac{\beta}{R^5 r}V_m\left(\frac{r-R}{R^5}\right) \quad (4.4)$$

where

$$V_m(r)=r\,b(r)+\frac{R^4}{\beta(rR^4+1)}\{-2m\alpha(a(r)-\Theta(r))+\alpha^2(a^2(r)-\Theta(r))\}. \quad (4.5)$$

We note that $V_m(r)$ has support only in $(0,r_0)$, and that

$$|\hat{a}_m(r)| := |-2m\alpha(a(r)-\Theta(r))+\alpha^2(a^2(r)-\Theta(r))| \leqslant mK, \tag{4.6}$$

where K is a constant independent of m and R.

Define the auxiliary operators

$$\tilde{h}_{m,\,R} = -\frac{1}{r}\frac{\partial}{\partial r} r \frac{\partial}{\partial r} + \frac{\left(m-\alpha\Theta\left(r-\frac{1}{R^4}\right)\right)^2}{r^2} + \frac{R^5\beta}{r} V_m\left(r-\frac{1}{R^4}\right). \tag{4.7}$$

V_m is form compact (Note 4, Appendix A) with respect to

$$-\frac{1}{r}\frac{\partial}{\partial r} r \frac{\partial}{\partial r} + \frac{(m-\alpha\Theta(r-R))^2}{r^2},$$

so the form sum (4.7) is well-defined. From Theorem B.1(b) of Ref. 7, the resolvent of $\tilde{h}_{m,\,R}$ for $k^2 \in \rho(\tilde{h}_{m,\,R})$ and $\Im(k)>0$, is given by

$$[\tilde{h}_{m,\,R}-k^2]^{-1} = g^0_{k,\,m,\,R} - R^5\beta g^0_{k,\,m,\,R}\tilde{v}_m[1+\beta\tilde{B}_{m,R}(k)]^{-1}\tilde{u}_m g^0_{k,\,m,\,R}, \tag{4.8}$$

where

$$\tilde{v}_m(r) = \left|\frac{1}{r}V_m\left(r-\frac{1}{R^4}\right)\right|^{1/2}, \quad \tilde{u}_m(r) = \left|\frac{1}{r}V_m\left(r-\frac{1}{R^4}\right)\right|^{1/2} \operatorname{sgn}\left[V_m\left(r-\frac{1}{R^4}\right)\right] \tag{4.9}$$

and

$$\tilde{B}_{m,R}(k) = R^5\tilde{u}_m g^0_{k,\,m,\,R}\tilde{v}_m, \quad \Im(k)>0. \tag{4.10}$$

$\tilde{B}_{m,R}$ extends to a Hilbert–Schmidt operator (Note 4, Appendix A).

Introducing the unitary scaling group $(U_R g)(r) = (1/R^5)\, g(r/R^5)$, we get

$$\hat{h}_{m,R} = \frac{1}{R^{10}} U_R \tilde{h}_{m,\,R} U_R^{-1}. \tag{4.11}$$

Then, noting that

$$R^{10} U_R g^0_{k,\,m,\,R} U_R^{-1} = g^0_{k/R^5,m,R} \tag{4.12}$$

and taking the translation $r \to r + (1/R^4)$, we obtain

$$\begin{aligned}[\hat{h}_{m,R}-k^2]^{-1} &= \left[\frac{1}{R^{10}} U_R \tilde{h}_{m,\,R} U_R^{-1} - k^2\right]^{-1} \\ &= R^{10} U_R [\tilde{h}_{m,\,R} - (R^5k)^2]^{-1} U_R^{-1} \\ &= R^{10} U_R [g^0_{R^5k,\,m,\,R} - R^5\beta g^0_{R^5k,\,m,\,R}\tilde{v}_m[1+\beta\tilde{B}_{m,R}(R^5k)]^{-1}\tilde{u}_m g^0_{R^5k,\,m,\,R}] U_R^{-1}\end{aligned} \tag{4.13}$$

for $k^2 \in \rho(\hat{h})$ and $\Im(k)>0$. For $\Im(k)>0$, define Hilbert–Schmidt operators $A_{m,R}(k)$, $B_{m,R}(k)$, and $C_{m,R}(k)$, with integral kernels

$$A_{m,R}(k,r,r') = g^0_{k,\,m,\,R}(r, R(1+R^4r'))\hat{v}_m(r'), \tag{4.14}$$

$$B_{m,R}(k,r,r') = \hat{u}_m(r) g^0_{k,\,m,\,R}(R(1+R^4r), R(1+R^4r'))\hat{v}_m(r'), \tag{4.15}$$

$$C_{m,R}(k,r,r')=\hat{u}_m(r)g^0_{k,\ m,\ R}(R(1+R^4r),r'), \tag{4.16}$$

where

$$\hat{v}_m(r)=\left|\frac{V_m(r)}{r}\right|^{1/2} \quad \text{and} \quad \hat{u}_m(r)=\left|\frac{V_m(r)}{r}\right|^{1/2}\operatorname{sgn}[V_m(r)]. \tag{4.17}$$

Then (4.13) becomes

$$[\hat{h}_{m,R}-k^2]^{-1}=g^0_{k,\ m,\ R}-\beta A_{m,R}(k)[1+\beta B_{m,R}(k)]^{-1}C_{m,R}(k) \tag{4.18}$$

for $k^2\in\rho(h_{\varepsilon,\ m,\ R})$ and $\Im(k)>0$.

Using this representation we can prove the following result.

Theorem 2: Let

$$\hat{H}_R=\bigoplus_{m=-\infty}^{\infty}\hat{h}_{m,R}. \tag{4.19}$$

Then $\hat{H}_R$ converges, as $R\to 0$, to one of the self-adjoint extensions H^ν of the AB Hamiltonian only if either

(I) $\beta(\alpha,R)+\alpha/R^{2\delta}\to 2\delta\nu_N$
or
(II) $\beta(\alpha,R)-\alpha+2(N+1)/R^{2(1-\delta)}\to 2(1-\delta)\nu_{N+1}$.

In case (I) $\hat{H}_R$ converges in the norm resolvent sense, as $R\to 0$, to $H^{(\nu_N,\ \infty)}$, and in case (II) to $H^{(\infty,\ \nu_{N+1})}$.

The proof of this theorem is fairly standard but by no means trivial. Because again we require uniform convergence in m we need to control the m behavior and this makes the proof very lengthy. We therefore do not give the proof here but only state the two lemmas required in the case when Condition I holds. Once we have these two lemmas, the proof is similar to that of Theorem 1 and the result follows from them.

We have already proved that $g^0_{k,\ m,\ R}\to g_{k,m}$ in norm. Let

$$v(r)=|b(r)|^{1/2}, \quad u(r)=|b(r)|^{1/2}\operatorname{sgn}[b(r)]. \tag{4.20}$$

Lemma 3: If condition I holds, then

(a) for $m<0$ and $m>N$, the operators $A_{m,R}(k),C_{m,R}(k)\to 0$ in norm;
(b) for $m=0,\ldots,N-1$, the operators $R^{-\delta}A_{m,R}(k),R^{-\delta}C_{m,R}(k)\to 0$ in norm;
(c) for $m=N$, $R^{-\delta}A_{m,R}(k)\to A_N(k)$ and $R^{-\delta}C_{m,R}(k)\to C_N(k)$ in norm, where $A_N(k,r,r')=\tilde{c}_N(k)H^{(1)}_\delta(kr)v(r')$ and $C_N(k,r,r')=\tilde{c}_N(k)u(r)H^{(1)}_\delta(kr')$.

Lemma 4: If condition I holds, then

(a) for $m<0$ and $m>N$, $\|\beta(\alpha,R)B_{m,R}(k)\|_2\leq C|\alpha|/(|m-\alpha|+|m|)$, where C is a constant independent of m and R;
(b) for $m=0,\ldots,N$, $R^{2\delta}[1+\beta(\alpha,R)B_{m,R}]^{-1}\to(1/\kappa_m)\langle v,\cdot\rangle u$ in norm as $R\to 0$, where

$$\kappa_m=\begin{cases}-\dfrac{\alpha}{2\delta\nu_N}, & m=0,\ldots,N-1,\\[2ex] \dfrac{\alpha\tilde{c}_N^2(k)}{c(N,\nu_N,k)}, & m=N.\end{cases} \tag{4.21}$$

V. OTHER APPROXIMATIONS

As mentioned in the Introduction, there are two other very natural approximations. These were investigated also in Refs. 3 and 4. Case (1) is when the magnetic field inside the cylinder of radius R is homogeneous, that is,

$$\mathbf{A}_R=\begin{cases}\alpha\dfrac{\mathbf{k}\times\mathbf{r}}{R^2}\ , & r<R\\ \alpha\dfrac{\mathbf{k}\times\mathbf{r}}{r^2}\ , & r>R.\end{cases} \tag{5.1}$$

Here $\mathbf{k}\cdot\mathbf{B}_R=2\alpha/R^2\,\Theta(R-r)$.

Case (2) is when the magnetic field is proportional to $1/r$ inside the cylinder

$$\mathbf{A}_R=\begin{cases}\alpha\dfrac{\mathbf{k}\times\mathbf{r}}{rR}\ , & r<R,\\ \alpha\dfrac{\mathbf{k}\times\mathbf{r}}{r^2}\ , & r>R.\end{cases} \tag{5.2}$$

In this case $\mathbf{k}\cdot\mathbf{B}_R=(\alpha/rR)\,\Theta(R-r)$.

Let

$$\sigma=\begin{cases}\dfrac{1+N}{M(1,2+N,\alpha)}, & \text{in case (1)}\\ \dfrac{1+2N}{M(1,2+2N,2\alpha)}, & \text{in case (2)},\end{cases} \tag{5.3}$$

where $M(a,b,z)$ is Kummer's function. Let η be a solution of the equation

$$\eta=-\frac{(1-\delta)(2+N)M(\eta,2+N,\alpha)}{\alpha M(\eta+1,3+N,\alpha)}, \tag{5.4}$$

in case (1) and of the equation

$$\eta=-\frac{(1-\delta)(3+2N)M(\eta,3+2N,2\alpha)}{\alpha M(\eta+1,4+2N,2\alpha)}, \tag{5.5}$$

in case (2). Note that both these equations have an infinite number of solutions.
Let

$$\phi_{k,\,m,\,R}(r,r')=g^{\beta}_{k,\,m,\,R}(r,r')-g_{k,\,m}(r,r'),$$

where $g^{\beta}_{k,\,m,\,R}(r,r')$ is the resolvent of the approximating Hamiltonian in each case and $g_{k,\,m}(r,r')$ is as in (2.4).

The following are the only cases which give nontrivial results:

(I) if $\beta\simeq-\alpha[1-\sigma(2\delta/\alpha)\,\nu_N R^{2\delta}]$ as $R\to0$, then $\phi_{k,\,m,\,R}(r,r')$ approaches
(1) a nonzero limit for $m=N$, corresponding to the self-adjoint extension h_{N,ν_N},
(2) zero limit for $m=N+1$, corresponding to the regular self-adjoint extension $h_{N+1,\infty}$,
(3) zero limit for $m\neq N,N+1$, corresponding to the self-adjoint operators h_m.

(II) if $\beta\simeq\alpha(2\eta-1)[1-(2\eta/(2\eta-1))\,\nu_{N+1}R^{2(1-\delta)}]$ as $R\to0$, then $\phi_{k,\,m,\,R}(r,r')$ approaches

(1) a nonzero limit for $m=N+1$, corresponding to the self-adjoint extension $h_{N+1,\nu_{N+1}}$,
(2) zero limit for $m=N$, corresponding to the regular self-adjoint extension $h_{N,\infty}$,
(3) zero limit for $m\neq N,N+1$, as before.

ACKNOWLEDGMENT

One of the authors (J.L.B.) would like to thank the University of Malta (Staff Development Fund) for financial support during the course of this work.

APPENDIX A

Note 1

The Bessel functions of the first and third kind have the following limiting and asymptotic properties:[9]

(1) for small z,

$$J_\nu(z)\simeq\frac{1}{\Gamma(\nu+1)}\left(\frac{z}{2}\right)^\nu \quad (\nu\neq -1,-2,-3,\ldots), \tag{A1}$$

$$H_\nu^{(1)}(z)\simeq\frac{-i\Gamma(\nu)}{\pi}\left(\frac{z}{2}\right)^{-\nu} \quad (\mathcal{R}\nu>0); \tag{A2}$$

(2) for large $|z|$,

$$J_\nu(z)=\sqrt{\frac{2}{\pi z}}\left\{\cos\left(z-\frac{\nu\pi}{2}-\frac{\pi}{4}\right)+e^{|\mathcal{I}z|}O(|z|^{-1})\right\}(\,|\arg z|<\pi), \tag{A3}$$

$$H_\nu^{(1)}(z)=\sqrt{\frac{2}{\pi z}}\,e^{i[z-(\nu\pi/2)-(\pi/4)]} \quad (-\pi<\arg z<2\pi). \tag{A4}$$

Two linearly independent solutions of

$$\left(-\frac{1}{r}\frac{\partial}{\partial r}r\frac{\partial}{\partial r}+\frac{\nu^2}{r^2}\right)\phi_k(r)=k^2\phi_k(r) \tag{A5}$$

are $J_\nu(kr)$ and $H_\nu^{(1)}(kr)$.

In the given case, the only solution for $r<R$ which lies in $\mathcal{D}(h^*_{m,R})$ is $J_{|m|}(kr)$, while for $r>R$ the only solution is $H^{(1)}_{|m-\alpha|}(kr)$.

Note 2

To obtain the Green's function, consider two solutions of Eq. (A5), one of which is regular at $r=0$ and irregular at $r=\infty$, while the other is irregular at $r=0$ and regular at $r=\infty$.

Consider

$$\phi_{1,m,k}(r)=\begin{cases}J_{|m|}(kr), & r<R,\\ A_m^{(1)}(k)J_{|m-\alpha|}(kr)+B_m^{(1)}(k)H^{(1)}_{|m-\alpha|}(kr), & r>R,\end{cases} \tag{A6}$$

$$\phi_{2,m,k}(r)=\begin{cases}A^{(2)}_{m,R}(k)J_{|m|}(kr)+B^{(2)}_{m,R}(k)H^{\{1\}}_{|m|}(kr), & r<R,\\ H^{(1)}_{|m-\alpha|}(kr), & r>R,\end{cases} \tag{A7}$$

where the constants $A^{(1)}_{m,R}(k),A^{(2)}_{m,R}(k),B^{(1)}_{m,R}(k)$, and $B^{(2)}_{m,R}(k)$ are chosen so that the boundary conditions $\phi_{m,k}(R+)=\phi_{m,k}(R-)$ and $\phi'_{m,k}(R+)=\phi'_{m,k}(R-)$ are satisfied (note that the second boundary condition is the one imposed to obtain the regular self-adjoint extension, i.e., the one with $\beta=0$).

Then $g^0_{k,\,m,\,R}(r,r')=c\,\phi_{1,m,k}(r_<)\,\phi_{2,m,k}(r_>)$, where $r_<=\min\{r,r'\}$ and $r_>=\max\{r,r'\}$. The constant c is determined by considering the boundary condition at $r=r'$:

$$\Delta\,\frac{\partial g^0_{k,\,m,\,R}}{\partial r}\bigg|_{r=r'}\equiv\lim_{r\downarrow r'}\frac{\partial g^0_{k,\,m,\,R}}{\partial r}(r,r')-\lim_{r\uparrow r'}\frac{\partial g^0_{k,\,m,\,R}}{\partial r}(r,r')=-\frac{1}{r'}. \tag{A8}$$

Then we obtain

$$g^0_{k,\,m,\,R}(r,r')=\begin{cases}\dfrac{i\pi}{2B^{(2)}_{m,R}(k)}\,\phi_{1,m,k}(r_<)\,\phi_{2,m,k}(r_>), & r,r'\leqslant R,\\[2ex] \dfrac{i\pi}{2A^{(1)}_{m,R}(k)}\,\phi_{1,m,k}(r_<)\,\phi_{2,m,k}(r_>), & r,r'\geqslant R.\end{cases} \tag{A9}$$

Note that the boundary conditions imply that

$$\lim_{R\to 0}\,(A^{(1)}_{m,R}(k)-B^{(2)}_{m,R}(k))=0. \tag{A10}$$

Note 3

(Compare Theorem I.3.1.2 of Ref. 7) The general structure of Eq. (3.14) follows from Krein's formula. To verify the constant in the second term, define for $g\in L^2((0,\infty),r\,\mathrm{d}r)$ and $\Im(k)>0$,

$$f_\beta(r)=((h_{m,R}-k^2)^{-1}g)(r)-\frac{\beta}{1+\beta g^0_{k,\,m,\,R}(R,R)}\langle\overline{g^0_{k,\,m,\,R}(\cdot,R)},g\rangle g^0_{k,\,m,\,R}(r,R). \tag{A11}$$

$$=\int_0^\infty \mathrm{d}r'\,r'\,g^0_{k,\,m,\,R}(r,r')g(r')-\frac{\beta}{1+\beta g^0_{k,\,m,\,R}(R,R)}$$

$$\times\int_0^\infty \mathrm{d}r'\,r'\,g^0_{k,\,m,\,R}(r,R)g^0_{k,\,m,\,R}(R,r')g(r'). \tag{A12}$$

Then $f_\beta\in H^{2,2}_{\mathrm{loc}}((0,\infty)\backslash\{R\},r\,\mathrm{d}r)\cap H^{2,1}((0,\infty),r\,\mathrm{d}r)$ and

$$f'_\beta(R+)-f'_\beta(R-)=\frac{\beta/R}{1+\beta g^0_{k,\,m,\,R}(R,R)}\int_0^\infty \mathrm{d}r'\,r'\,g^0_{k,\,m,\,R}(R,r')g(r')=\frac{\beta}{R}f_\beta(R). \tag{A13}$$

This means that $f_\beta\in\mathcal{D}(h^\beta_{m,\,R})$. Furthermore, for $\Im(k)>0$,

$$(h^\beta_{m,\,R}-k^2)f_\beta=g(r),\quad r\in(0,\infty)\backslash\{R\} \tag{A14}$$

which proves Eq. (3.14).

Note 4

To show that $\tilde{B}$ extends to a Hilbert–Schmidt operator, we need to show that (cf. Ref. 7, p. 80)

$$\int_{[0,\infty)\times[0,\infty)}\mathrm{d}r\,\mathrm{d}r'\,|V(r)||g^0_{k,\,m,\,R}(r,r')|^2|V(r')|\;<\;\infty,\quad \Im(k)>0. \tag{A15}$$

This follows by considering the behavior of the Bessel functions for small and large arguments, as discussed in Note 1. From the previous estimate we obtain

$$\left|\frac{V(r)}{r}\right|^{1/2}\left(-\frac{1}{r}\frac{\partial}{\partial r}r\frac{\partial}{\partial r}+\frac{(m-\alpha\Theta(r-R))^2}{r^2}+E\right)^{1/2}\in\mathcal{B}_\infty(L^2((0,\infty),r\,dr)),\quad E>0. \tag{A16}$$

APPENDIX B

In this section we shall derive bounds for expressions involving the Bessel functions $J_\nu(z)$ and $H_\nu^{(1)}(z)$.

First we shall obtain upper bounds for $|J_\nu(z)|$. If $\nu\geqslant-\frac{1}{2}$, then it follows[10] from Poisson's integral that

$$|J_\nu(z)|\leqslant\frac{\left|\frac{z}{2}\right|^\nu}{\Gamma(\nu+1)}e^{|\Im z|}. \tag{B1}$$

For $\nu<-\frac{1}{2}$, the following series expansion,[9] which is valid for all z and ν, is used:

$$J_\nu(z)=\left(\frac{z}{2}\right)^\nu\sum_{k=0}^{\infty}\frac{\left(-\frac{1}{4}z^2\right)^k}{k!\Gamma(\nu+k+1)} \tag{B2}$$

$$=\frac{\left(\frac{z}{2}\right)^\nu}{\Gamma(\nu+1)}\left(1+\sum_{k=1}^{\infty}\frac{\Gamma(\nu+1)\left(-\frac{1}{4}z^2\right)^k}{k!\Gamma(\nu+k+1)}\right). \tag{B3}$$

For $\nu\neq-1,-2,-3,...,$

$$\frac{|\Gamma(\nu+1)|}{|\Gamma(\nu+k+1)|}\leqslant\frac{1}{|\nu_0+1|^k},$$

where $|\nu_0+1|=\min\{|\nu+1|,|\nu+2|,|\nu+3|,...\}$. Thus we obtain

$$|J_\nu(z)|\leqslant\frac{\left|\frac{z}{2}\right|^\nu}{|\Gamma(\nu+1)|}e^{1/4\,|z|^2/|\nu_0+1|},\quad \nu\neq-1,-2,-3,\ldots. \tag{B4}$$

Next we obtain lower bounds for $|J_\nu(z)|$. Using the series expansion (B2), and the same argument used for (B4), we obtain

$$|J_\nu(z)|\geqslant\frac{\left|\frac{z}{2}\right|^\nu}{|\Gamma(\nu+1)|}(2-e^{1/4\,|z|^2/|\nu_0+1|}),\quad \nu\neq-1,-2,-3,\ldots. \tag{B5}$$

The above bounds imply that, given any $\varepsilon>0$, there exists z_0 such that, for any ν, if $|z|<|z_0|$ then

$$|J_\nu(z)|\leqslant\frac{\left|\frac{z}{2}\right|^\nu}{|\Gamma(\nu+1)|}(1+\varepsilon), \tag{B6}$$

$$|J_\nu(z)|\geqslant\frac{\left|\frac{z}{2}\right|^\nu}{|\Gamma(\nu+1)|}(1-\varepsilon). \tag{B7}$$

If ν is a negative integer, upper and lower bounds may be deduced using

$$J_\nu(z)=(-1)^\nu J_{|\nu|}(z). \tag{B8}$$

Upper and lower bounds for expressions involving the derivatives of $J_\nu(z)$ may be deduced from the recurrence relation

$$J'_\nu(z)=-J_{\nu+1}(z)+\frac{\nu}{z}J_\nu(z). \tag{B9}$$

Now we turn to bounds for $|H_\nu^{(1)}(z)|$. These are obtained using the following relation:

$$H_\nu^{(1)}(z)=i\csc(\nu\pi)\{e^{-\nu\pi i}J_\nu(z)-J_{-\nu}(z)\}. \tag{B10}$$

Note that we are only interested in the case $\nu\geqslant 0$. Thus, when $\nu>0$ and $\nu\notin\mathbb{Z}$,

$$|H_\nu^{(1)}(z)|\leqslant\frac{\Gamma(\nu)}{\pi}\left|\frac{z}{2}\right|^{-\nu}e^{1/4|z|^2/|\nu_1+1|}\left(1+\frac{|\Gamma(1-\nu)|}{\Gamma(1+\nu)}\left|\frac{z}{2}\right|^{2\nu}\right), \tag{B11}$$

$$|H_\nu^{(1)}(z)|\geqslant\frac{\Gamma(\nu)}{\pi}\left|\frac{z}{2}\right|^{-\nu}(2-e^{1/4|z|^2/|\nu_1+1|})\left(1-\frac{|\Gamma(1-\nu)|}{\Gamma(1+\nu)}\left|\frac{z}{2}\right|^{2\nu}\right). \tag{B12}$$

Here $|\nu_1+1|=\min\{|\nu+1|,|\nu+2|,|\nu+3|,\ldots,|-\nu+1|,|-\nu+2|,|-\nu+3|,\ldots\}$.

For $\nu\in\mathbb{Z}^+$, we use the relation

$$H_n^{(1)}(z)=J_n(z)+iY_n(z), \tag{B13}$$

where $Y_n(z)$ is the Bessel function of the second kind with series expansion

$$Y_n(z)=-\frac{\left(\frac{z}{2}\right)^{-n}}{\pi}\sum_{k=0}^{n-1}\frac{(n-k-1)!}{k!}\left(\frac{z^2}{4}\right)^k+\frac{2}{\pi}\ln\left(\frac{z}{2}\right)J_n(z)-\frac{\left(\frac{z}{2}\right)^n}{\pi}\sum_{k=0}^{\infty}\frac{\psi(k+1)+\psi(n+k+1)}{k!(n+k)!}$$
$$\times\left(-\frac{z^2}{4}\right)^k,\quad n\geqslant 1 \tag{B14}$$

with the Digamma function $\psi(n)=\Gamma'(n)/\Gamma(n)$ given by

$$\psi(1)=-\gamma,\quad \psi(n)=-\gamma+\sum_{k=1}^{n-1}\frac{1}{k},\quad n\geqslant 2, \tag{B15}$$

where γ is Euler's constant.

Noting that $(n-k-1)!\leqslant\Gamma(n)$ and $[\psi(k+1)+\psi(n+k+1)]/(n+k)!\leqslant 2\Gamma(n)$ for $n\geqslant 1$, we get the following bounds:

$$|Y_n(z)|\leqslant\frac{\Gamma(n)}{\pi}\left|\frac{z}{2}\right|^{-n}e^{1/4|z|^2}\left\{1+\frac{2}{\Gamma(n)}\left|\frac{z}{2}\right|^{2n}\left(1+\frac{1}{\Gamma(n+1)}\left|\ln\frac{z}{2}\right|e^{|\Im(z)|-1/4|z|^2}\right)\right\},\quad n\geqslant 1, \tag{B16}$$

$$|Y_n(z)|\geqslant\frac{\Gamma(n)}{\pi}\left|\frac{z}{2}\right|^{-n}\left\{(2-e^{1/4|z|^2})-\frac{2}{\Gamma(n)}\left|\frac{z}{2}\right|^{2n}e^{1/4|z|^2}-\frac{2}{\Gamma(n)\Gamma(n+1)}\left|\ln\frac{z}{2}\right|\left|\frac{z}{2}\right|^{2n}e^{|\Im(z)|}\right\},$$
$$n\geqslant 1. \tag{B17}$$

The corresponding inequalities for $H_n^{(1)}(z)$ are

$$|H_n^{(1)}(z)| \leqslant \frac{\Gamma(n)}{\pi}\left|\frac{z}{2}\right|^{-n} e^{1/4|z|^2}\left\{1+\frac{2}{\Gamma(n)}\left|\frac{z}{2}\right|^{2n}\left(1+\left(\left|\ln\frac{z}{2}\right|+\frac{\pi}{2}\right)\frac{1}{\Gamma(n+1)}e^{|\Im(z)|-1/4|z|^2}\right)\right\}, \quad n\geqslant 1, \tag{B18}$$

$$|H_n^{(1)}(z)| \geqslant \frac{\Gamma(n)}{\pi}\left|\frac{z}{2}\right|^{-n}\left\{(2-e^{1/4|z|^2})-\frac{2}{\Gamma(n)}\left|\frac{z}{2}\right|^{2n}e^{1/4|z|^2}\right.$$
$$\left.-\left(2\left|\ln\frac{z}{2}\right|+\pi\right)\frac{1}{\Gamma(n)\Gamma(n+1)}\left|\frac{z}{2}\right|^{2n}e^{|\Im(z)|}\right\}, \quad n\geqslant 1. \tag{B19}$$

The above bounds imply that, given any $\varepsilon>0$, there exists z_0 such that, for any $\nu>0$, if $|z|<|z_0|$ then

$$|H_\nu^{(1)}(z)| \leqslant \frac{\Gamma(\nu)}{\pi}\left|\frac{z}{2}\right|^{-\nu}(1+\varepsilon), \tag{B20}$$

$$|H_\nu^{(1)}(z)| \geqslant \frac{\Gamma(\nu)}{\pi}\left|\frac{z}{2}\right|^{-\nu}(1-\varepsilon). \tag{B21}$$

For $n=0$, we use the following series expansion for $Y_0(z)$:

$$Y_0(z)=\frac{2}{\pi}\left\{\ln\left(\frac{z}{2}\right)+\gamma\right\}J_0(z)+\frac{2}{\pi}\left\{\frac{z^2}{4}-\left(1+\frac{1}{2}\right)\frac{\left(\frac{1}{4}z^2\right)^2}{(2!)^2}-\left(1+\frac{1}{2}+\frac{1}{3}\right)\frac{\left(\frac{1}{4}z^2\right)^3}{(3!)^2}-\cdots\right\}. \tag{B22}$$

Noting that $1+\frac{1}{2}+\cdots+(1/n)\leqslant n!$, we find that the term in the second bracket of (B22) is bounded in absolute value by $e^{1/4|z|^2}-1$. Hence we get the following bounds for $Y_0(z)$:

$$|Y_0(z)| \leqslant \frac{2}{\pi}|\ln z|\left\{|J_0(z)|+\frac{|J_0(z)|}{|\ln z|}(\ln 2+\gamma)+\frac{e^{1/4|z|^2}-1}{|\ln z|}\right\}, \tag{B23}$$

$$|Y_0(z)| \geqslant \frac{2}{\pi}|\ln z|\left\{|J_0(z)|-\frac{|J_0(z)|}{|\ln z|}(\ln 2+\gamma)-\frac{e^{1/4|z|^2}-1}{|\ln z|}\right\}. \tag{B24}$$

Then, using (B4) and (B5) for the case $\nu=0$, we obtain the corresponding bounds for $H_0^{(1)}(z)$:

$$|H_0^{(1)}(z)| \leqslant \frac{2}{\pi}|\ln z|e^{1/4|z|^2}\left\{1+\frac{1}{|\ln z|}\left(\ln 2+\gamma+\frac{\pi}{2}\right)+\frac{1-e^{-1/4|z|^2}}{|\ln z|}\right\}, \tag{B25}$$

$$|H_0^{(1)}(z)| \geqslant \frac{2}{\pi}|\ln z|\left\{(2-e^{1/4|z|^2})-\frac{e^{1/4|z|^2}}{|\ln z|}\left(\ln 2+\gamma+\frac{\pi}{2}\right)-\frac{e^{1/4|z|^2}-1}{|\ln z|}\right\}. \tag{B26}$$

Now, for fixed arg(z), we know that $|\ln z|\geqslant\ln|z|$, and that for any $\varepsilon'>0$, $|\ln z|\leqslant\ln|z|(1+\varepsilon')$ if $|z|$ is small enough. This implies that for any $\varepsilon>0$, there exists z_0 such that, if $|z|<|z_0|$, then

$$|H_0^{(1)}(z)| \leqslant \frac{2}{\pi}\ln|z|(1+\varepsilon), \tag{B27}$$

$$|H_0^{(1)}(z)| \geqslant \frac{2}{\pi}\ln|z|(1-\varepsilon). \tag{B28}$$

Next we obtain bounds for the Wronskians that appear in the expressions for the constants $A_{m,R}^{(1)}(k), A_{m,R}^{(2)}(k), B_{m,R}^{(1)}(k)$, and $B_{m,R}^{(2)}(k)$ which are defined in Note 2 of Appendix A.

Using (B9) and (B10), we can write

$$W[H_\nu^{(1)}(z), J_{\nu'}(z)] = H_\nu^{(1)}(z)J'_{\nu'}(z) - H_\nu^{(1)\prime}(z)J_{\nu'}(z)$$

$$= \frac{i}{\sin(\nu\pi)}(\{e^{-\nu\pi i}J_\nu(z) - J_{-\nu}(z)\}J'_{\nu'}(z) - \{e^{-\nu\pi i}J'_\nu(z) - J'_{-\nu}(z)\}J_\nu(z)) \tag{B29}$$

$$= \frac{i}{\sin(\nu\pi)}\left(-\frac{\nu'+\nu}{z}J_{\nu'}(z)J_{-\nu}(z) + J_{\nu'+1}(z)J_{-\nu}(z) - J_{\nu'}(z)J_{-\nu+1}(z) \right.$$
$$\left. + e^{-i\pi\nu}\left\{ \frac{\nu'-\nu}{z}J_{\nu'}(z)J_\nu(z) - J_{\nu'+1}(z)J_\nu(z) + J_{\nu'}(z)J_{\nu+1}(z) \right\} \right). \tag{B30}$$

From the bounds derived above, we obtain

$$|W[H_\nu^{(1)}(z), J_{\nu'}(z)]| \geqslant \frac{(\nu'+\nu)\Gamma(\nu)}{2\pi\Gamma(\nu'+1)}\left|\frac{z}{2}\right|^{\nu'-\nu-1}\left\{ (2-e^{1/4|z|^2/\nu'+1})(2-e^{1/4|z|^2/|\nu_1+1|}) \right.$$
$$- \frac{2e^{|\Im(z)|}}{\nu'+\nu}\left(\frac{e^{1/4|z|^2/|\nu_1+1|}}{\nu'+1}\left|\frac{z}{2}\right|^2 + \frac{e^{1/4|z|^2/|\nu_1+1|}}{|1-\nu|}\left|\frac{z}{2}\right|^2 + \frac{|\nu'+\nu|e^{|\Im(z)|}}{2\Gamma(\nu+1)}\left|\frac{z}{2}\right|^{2\nu} \right.$$
$$\left. \left. + \frac{|\Gamma(1-\nu)|e^{|\Im(z)|}}{\Gamma(\nu+2)}\left|\frac{z}{2}\right|^{2\nu+2} + \frac{|\Gamma(1-\nu)|e^{|\Im(z)|}}{(\nu'+1)\Gamma(\nu+1)}\left|\frac{z}{2}\right|^{2\nu+2} \right) \right\}, \tag{B31}$$

for $\nu, \nu' > 0$, $\nu \notin \mathbb{Z}$.

Since $\Gamma(1-\nu) = \pi/(\sin(\pi\nu)\Gamma(\nu))$, then for any $\varepsilon_0 > 0$ there exist z_0 and $\tilde{\nu}_0$ such that for $|z| < |z_0|$ and $\nu', \nu > \tilde{\nu}_0$,

$$|W[H_\nu^{(1)}(z), J_{\nu'}(z)]| \geqslant \frac{(\nu'+\nu)\Gamma(\nu)}{2\pi\Gamma(\nu'+1)}\left|\frac{z}{2}\right|^{\nu'-\nu-1}(1-\varepsilon_0). \tag{B32}$$

Using a similar argument to that used in (B30), as well as the relation

$$H_\nu^{(1)\prime}(z) = -H_{\nu+1}^{(1)}(z) + \frac{\nu}{z}H_\nu^{(1)}(z), \tag{B33}$$

we can write

$$W[H_\nu^{(1)}(z), H_n^{(1)}(z)] = H_\nu^{(1)}(z)H_n^{(1)\prime}(z) - H_\nu^{(1)\prime}(z)H_n^{(1)}(z) \tag{B34}$$

$$= \frac{i}{\sin(\nu\pi)}\left(J_{-\nu}(z)H_{n+1}^{(1)}(z) - \frac{n+\nu}{z}J_{-\nu}(z)H_n^{(1)}(z) - J_{1-\nu}(z)H_n^{(1)}(z) \right.$$
$$\left. + e^{-i\pi\nu}\left\{ \frac{n-\nu}{z}J_\nu(z)H_n^{(1)}(z) - J_\nu(z)H_{n+1}^{(1)}(z) + J_{\nu+1}(z)H_n^{(1)}(z) \right\} \right). \tag{B35}$$

Let $n \in \mathbb{Z}^+$, $\nu > 0$, and $\nu \notin \mathbb{Z}$. Using the relation

$$H_{n+1}^{(1)}(z)=\frac{2n}{z}H_n^{(1)}(z)-H_{n-1}^{(1)}(z),$$

and the bounds in (B4) and (B11), one can see that for any $\varepsilon_1>0$ there exist z_1 and n_1 such that for $|z|<|z_1|$ and $\nu,n>n_1$,

$$\left|J_{-\nu}(z)\left(H_{n+1}^{(1)}(z)-\frac{n+\nu}{z}H_n^{(1)}(z)\right)\right|\leqslant\frac{\nu-n}{2\pi}\frac{\Gamma(n)}{|\Gamma(1-\nu)|}\left|\frac{z}{2}\right|^{-n-\nu-1}(1+\varepsilon_1),$$

$$|J_{1-\nu}(z)H_n^{(1)}(z)|\leqslant\frac{\Gamma(n)}{\pi|\Gamma(2-\nu)|}\left|\frac{z}{2}\right|^{-n-\nu+1}(1+\varepsilon_1), \tag{B36}$$

$$\left|\frac{n-\nu}{z}J_\nu(z)H_n^{(1)}(z)\right|\leqslant\frac{|n-\nu|\Gamma(n)}{2\pi\Gamma(\nu+1)}\left|\frac{z}{2}\right|^{-n+\nu-1}(1+\varepsilon_1), \tag{B37}$$

$$|J_\nu(z)H_{n+1}^{(1)}(z)|\leqslant\frac{\Gamma(n+1)}{\pi\Gamma(\nu+1)}\left|\frac{z}{2}\right|^{-n+\nu-1}(1+\varepsilon_1), \tag{B38}$$

$$|J_{\nu+1}(z)H_n^{(1)}(z)|\leqslant\frac{\Gamma(n)}{\pi\Gamma(\nu+2)}\left|\frac{z}{2}\right|^{-n+\nu+1}(1+\varepsilon_1). \tag{B39}$$

The above results imply that for $|z|<|z_1|$ and $\nu,n>n_1$,

$$|W[H_\nu^{(1)}(z),H_n^{(1)}(z)]|\leqslant\frac{|\nu-n|}{2\pi^2}\Gamma(n)\Gamma(\nu)\left|\frac{z}{2}\right|^{-n-\nu-1}\left(1+\frac{2}{|\nu-n||1-\nu|}\left|\frac{z}{2}\right|^2+\frac{|\Gamma(1-\nu)|}{\Gamma(\nu+1)}\left|\frac{z}{2}\right|^{2\nu}\right.$$
$$\left.+\frac{2n|\Gamma(1-\nu)|}{|\nu-n|\Gamma(\nu+1)}\left|\frac{z}{2}\right|^{2\nu}+\frac{2|\Gamma(1-\nu)|}{|\nu-n|\Gamma(\nu+2)}\left|\frac{z}{2}\right|^{2\nu+2}\right)(1+\varepsilon_1). \tag{B40}$$

From this we deduce that for any $\varepsilon_2>0$ there exist z_2 and n_2 such that for $|z|<|z_2|$ and $\nu,n>n_2$,

$$|W[H_\nu^{(1)}(z),H_n^{(1)}(z)]|\leqslant\frac{|\nu-n|}{2\pi^2}\Gamma(n)\Gamma(\nu)\left|\frac{z}{2}\right|^{-n-\nu-1}(1+\varepsilon_2). \tag{B41}$$

Using (B9), we obtain

$$W[J_n(z),J_\nu(z)]=J_n(z)J_\nu'(z)-J_n'(z)J_\nu(z) \tag{B42}$$

$$=\frac{\nu-n}{z}J_n(z)J_\nu(z)-J_n(z)J_{\nu+1}(z)+J_{n+1}(z)J_\nu(z). \tag{B43}$$

Then, for $n\in\mathbb{Z}^+$, and $\nu\geqslant-\frac{1}{2}$,

$$|W[J_n(z),J_\nu(z)]|\leqslant\frac{|\nu-n|e^{|\Im(z)|}}{2\Gamma(n+1)\Gamma(\nu+1)}\left|\frac{z}{2}\right|^{n+\nu-1}\left\{1+\left(\frac{2n}{\nu+1}+\frac{2}{n+1}\right)\left|\frac{z}{2}\right|^2\right\}. \tag{B44}$$

Thus, for any $\varepsilon_3>0$ there exist z_3 and n_3 such that for $|z|<|z_3|$ and $\nu,n>n_3$,

$$|W[J_n(z),J_\nu(z)]| \leqslant \frac{|\nu-n|}{2\Gamma(n+1)\Gamma(\nu+1)}\left|\frac{z}{2}\right|^{n+\nu-1}\{1+\varepsilon_3\}. \tag{B45}$$

Stratified reduction of many-body kinetic energy operators

Toshihiro Iwai[a] and Hidetaka Yamaoka
Department of Applied Mathematics and Physics, Kyoto University, Kyoto 606-8501, Japan

(Received 6 March 2003; accepted 26 May 2003)

The center-of-mass system of many bodies admits a natural action of the rotation group SO(3). According to the orbit types for the SO(3) action, the center-of-mass system is stratified into three types of strata. The principal stratum consists of nonsingular configurations for which the isotropy subgroup is trivial, and the other two types of strata consist of singular configurations for which the isotropy subgroup is isomorphic with either SO(2) or SO(3). Depending on whether the isotropy subgroup is isomorphic with SO(2) or SO(3), the stratum in question consists of collinear configurations or of a single configuration of the multiple collision. It is shown that the kinetic energy operator is expressed as the sum of rotational and vibrational energy operators on each stratum except for the stratum of multiple collision. The energy operator for nonsingular configurations has singularity at singular configurations. However, the singularity is not essential in the sense that both of the rotational and vibrational energy integrals have a finite value. This can be proved by using the boundary conditions of wave functions at singular configurations for three-body systems, for simplicity. It is shown, in addition, that the energy operator for collinear configurations has also singularity at the multiple collision, but the singularity is not essential either in the sense that the kinetic energy integral is not divergent at the multiple collision. Reduction procedure is applied to the respective energy operators for the nonsingular and the collinear configurations to obtain respective reduced operators, both of which are expressed in terms of internal coordinates. © *2003 American Institute of Physics.*

I. INTRODUCTION

This article has an aim to study n-body Hamiltonians by means of a transformation group. A key idea is as follows: Consider a quantum system on a manifold on which a compact Lie group acts. The manifold is then stratified into the disjoint union of strata according to the orbit types of the group action. If a Hamiltonian operator defined on the manifold is invariant under the group action, it will be stratified in such a manner that the Hamiltonian operator has a description on each stratum. The restricted Hamiltonian operator on each stratum will be reduced, by using a unitary irreducible representation of the group, to an operator on the orbit space formed from the stratum in question.

The center-of-mass system for n bodies admits the action of the rotation group SO(3) in a natural manner. According to the orbit types for the SO(3) action, the center-of-mass system is stratified into strata. The principal (or maximal) stratum consists of nonsingular configurations for which the isotropy subgroup is trivial, so that it is made into an SO(3) principal fiber bundle.[1] The strata of lower dimension consist of singular configurations for which the isotropy subgroup is not trivial. Practically, singular configurations are collinear ones and simultaneous multiple collision, and nonsingular configurations are planar or spatial ones.

To study quantum systems for nonsingular configurations, one can apply connection theory on the SO(3) bundle, through which the kinetic energy operator is determined to be the sum of

[a]Electronic mail: iwai@amp.i.kyoto-u.ac.jp

rotational and vibrational energy operators.[2–5] However, these operators fail to be defined at singular configurations. In contrast with the case of nonsingular configurations, the stratum of collinear configurations is not made into a principal fiber bundle, but it remains to have a bundle structure. The present article shows that one can set up quantum systems on each stratum on the basis of the bundle structure of each stratum. The quantum systems defined on respective strata will be reduced to quantum systems defined on respective orbit spaces formed from the respective strata.

On each stratum except for the multiple collision stratum, the kinetic energy operator is decomposed into the sum of rotational and vibrational energy operators. The energy operator for nonsingular configurations has singularity at singular configuration, but it is shown that the singularity is not essential in the sense that both of the rotational and vibrational energy integrals have a finite value. This can be proved by using the boundary conditions of wave functions at singular configurations, while the proof is given only for three-body systems for simplicity. Furthermore, the energy operator for collinear configurations, which is also expressed as the sum of rotational and vibrational energy operators, has also singularity at the multiple collision, but the singularity is not essential either in the sense that the kinetic energy integral is not divergent at the multiple collision. The description of the kinetic energy operator as the sum of rotational and vibrational energy operators is effectively used to provide reduced kinetic energy operators in terms of internal (or shape) coordinates.

The organization of this article is as follows: In Sec. II, a brief review is made of the center-of-mass system along with the stratification by means of the SO(3) action. Section III is a review of the Fourier analysis of wave functions,[6,7] which is an application of the Peter–Weyl theorem on unitary irreducible representations of compact Lie groups. Section IV is concerned with a geometric setting for nonsingular configurations. A connection form and a metric are defined and expressed in terms of local coordinates. Transformation law for locally defined connection forms is discussed also. In Sec. V, the kinetic energy operator is defined for nonsingular configurations, which is broken up into the sum of rotational and vibrational energy operators. Operating on equivariant functions with these operators, one obtains reduced rotational and vibrational energy operators in terms of local coordinates for the shape of nonsingular configurations. Transformation law for locally defined reduced operators is studied as well. Section VI is specialized to three-body systems. Though the three-body system was already studied in the same manner,[4] this section deals with it in a different coordinate system to discuss the singularity of the kinetic energy operator. It is shown that the rotational and the vibrational energy operators are not singular in the sense that the rotational and vibrational energy integrals are not divergent at singular configurations. Section VII deals with collinear configurations. A (singular) connection form will be defined on the stratum of collinear configurations. In Sec. VIII, the kinetic energy operator for collinear configurations is studied on the basis of the singular connection treated in Sec. VII. Operating on equivariant wave functions with the kinetic energy operator, one obtains a reduced kinetic energy operator, which is defined on the shape space of collinear configurations.

II. THE CENTER-OF-MASS SYSTEM

Let $\mathbf{x}_i$ and m_i with $i=1,\ldots,N$ be position vectors and masses of point particles in $\mathbf{R}^3$, respectively. Then the configurations of the point particles are denoted by $x=(\mathbf{x}_1,\mathbf{x}_2,\ldots,\mathbf{x}_N)$. The center-of-mass system M is defined to be

$$M=\left\{ x=(\mathbf{x}_1,\mathbf{x}_2,\ldots,\mathbf{x}_N) \,\middle|\, \mathbf{x}_i\in\mathbf{R}^3, \sum_{i=1}^{N} m_i\mathbf{x}_i=0 \right\}. \tag{1}$$

The configuration x is characterized by the linear subspace

$$F_x := \mathrm{span}\{\mathbf{x}_1,\mathbf{x}_2,\ldots,\mathbf{x}_N\}. \tag{2}$$

According as $\dim F_x = 0,1,2,3$, the configurations of the particles are pointlike, collinear, planar, and spatial, respectively. Thus M is broken up into four subsets:

$$M = \bigcup_{k=0}^{3} M_k, \quad M_k := \{x \in M \mid \dim F_x = k\}, \quad k = 0,1,2,3. \tag{3}$$

The center-of-mass system admits a natural SO(3) action:

$$\Phi_g(x) = gx = (g\mathbf{x}_1, g\mathbf{x}_2, \ldots, g\mathbf{x}_N), \quad g \in \mathrm{SO}(3), \quad x \in M. \tag{4}$$

The isotropy subgroup G_x of $G = \mathrm{SO}(3)$ at $x \in M$ is defined, as usual, to be $G_x = \{g \in G \mid gx = x\}$. Now one can show that the isotropy subgroups are trivial, $G_x = \{e\}$, on $M_2 \cup M_3$, that is, SO(3) acts on $M_2 \cup M_3$ freely. However, on M_1 and on M_0, the isotropy subgroups are nontrivial; at $x \in M_1$ and at $x \in M_0$, they are isomorphic with SO(2) and with SO(3), respectively. Configurations in $M_0 \cup M_1$ are called singular, which are pointlike or collinear. Depending on the dimensionality of the isotropy subgroups G_x, orbits $\mathcal{O}_x$ of G through $x \in M$ are classified into three cases:

$$\mathcal{O}_x \cong \begin{cases} \mathrm{SO}(3) \quad \text{for} \quad x \in M_2 \cup M_3, \\ S^2 \cong \mathrm{SO}(3)/\mathrm{SO}(2) \quad \text{for} \quad x \in M_1, \\ \{0\} \quad \text{for} \quad x \in M_0. \end{cases} \tag{5}$$

According to the orbit types, M is stratified into strata:

$$M = \dot{M} \cup M_1 \cup M_0, \quad \dot{M} := M_2 \cup M_3. \tag{6}$$

On restricting M to $\dot{M} = M_2 \cup M_3$, we can make $\dot{M}$ into a principal fiber bundle $\dot{M} \to \dot{Q} := \dot{M}/\mathrm{SO}(3)$,[1] since SO(3) is compact and since SO(3) acts on $\dot{M}$ freely. However, the total space M cannot be made into a principal fiber bundle. The orbit space $Q := M/\mathrm{SO}(3)$ is not a manifold in general. In fact, in the case of the three-body system, the orbit space is homeomorphic with the closed half space of $\mathbf{R}^3$.[4] In the case of the four-body system, the orbit space is shown to be homeomorphic with $\mathbf{R}^6$.[8] Though M itself is not a principal fiber bundle, we may make M into a stratified fiber bundle with respective projections

$$\dot{M} \to \dot{M}/\mathrm{SO}(3), \quad M_1 \to M_1/S^2, \quad M_0 \to M_0/M_0. \tag{7}$$

It is to be noted that $\dot{M}$ and M_1 are viewed as the configuration spaces for ''nonlinear molecules'' and for ''linear molecules,'' respectively. Equation (7) implies that we can discuss nonlinear and linear molecules separately, but on an equal footing from the viewpoint of transformation group theory.

It is of great use to employ Jacobi vectors in working with the center-of-mass system. The Jacobi vectors $\mathbf{r}_j$, $j = 1,\ldots,N-1$, are defined to be

$$\mathbf{r}_j := \left(\frac{1}{\mu_j} + \frac{1}{m_{j+1}}\right)^{-1/2} \left(\mathbf{x}_{j+1} - \frac{1}{\mu_j} \sum_{i=1}^{j} m_i \mathbf{x}_i\right), \quad \mu_j := \sum_{i=1}^{j} m_i. \tag{8}$$

Since the position vectors $\mathbf{x}_i$ in the center-of-mass system are uniquely described in terms of Jacobi vectors, we can identify the center-of-mass system with the set of collections of Jacobi vectors:

$$M \cong \{x = (\mathbf{r}_1, \ldots, \mathbf{r}_{N-1}) \mid \mathbf{r}_j \in \mathbf{R}^3, \quad j = 1,\ldots,N-1\}. \tag{9}$$

Thus, M is viewed as the linear space formed by $x=(\mathbf{r}_1,\ldots,\mathbf{r}_{N-1})$, or as the space of $3\times(N-1)$ matrices. Since $\operatorname{rank} x=\dim F_x$, we can regard $\dot{M}:=M_2\cup M_3$ as the space of $3\times(N-1)$ matrices of rank greater than or equal to two. M_1 and M_0 are the spaces of $3\times(N-1)$ matrices of rank 1 and of rank 0, respectively. The space of singular configurations, M_1 and M_0, forms the boundary of the space of nonsingular configurations, $M_2\cup M_3$. Note that $\dim\dot{M}=3N-3$, $\dim M_1=N+1$, and $\dim M_0=0$. We note, in conclusion, that the SO(3) action is expressed as

$$(\mathbf{r}_1,\ldots,\mathbf{r}_{N-1})\mapsto(g\mathbf{r}_1,\ldots,g\mathbf{r}_{N-1}). \tag{10}$$

III. FOURIER ANALYSIS OF WAVE FUNCTIONS

To treat wave functions irrespectively of the orbit type of the SO(3) action on the center-of-mass system, it is of great use to apply Fourier analysis on the basis of the Peter–Weyl theorem on unitary irreducible representations of compact Lie groups. To describe this method,[6,7] we put the problem in a general setting. Let M be a manifold on which a compact Lie group G acts. Let μ_M be a G-invariant measure on M. We take the space $L^2(M)$ of square integrable functions on M as the Hilbert space of wave functions, in which the G is represented unitarily through $(U(g)f)(x)=f(g^{-1}x)$, $g\in G$, $x\in M$.

Let μ_G and $L^2(G)$ denote the normalized invariant measure on G and the space of square integrable functions on G with respect to μ_G, respectively. Let $(\mathcal{H}^\chi,\rho^\chi)$ be irreducible unitary representations of G, where χ ranges over all the inequivalent representations. We denote by ρ^χ_{ij} the matrix elements of the representation ρ^χ with respect to some orthonormal basis e^χ_i of $\mathcal{H}^\chi$, where $i,j=1,\ldots,d_\chi$, with $d_\chi=\dim\mathcal{H}^\chi$. The Peter–Weyl theorem states that the set of all the matrix elements $\{\sqrt{d_\chi}\rho^\chi_{ij}\}_{\chi,i,j}$ forms a complete orthonormal system in $L^2(G)$. By this theorem, any function φ of $L^2(G)$ is expanded into

$$\varphi(h)=\sum_{\chi,i,j} d_\chi\rho^\chi_{ij}(h)\int_G\overline{\rho^\chi_{ij}(g)}\varphi(g)d\mu_G(g). \tag{11}$$

We turn to wave functions on M. For a function $f\in L^2(M)$, we may view $f(hx)$ as a function on G with x fixed arbitrarily, $f_x(h):=f(hx)$, and apply the above expansion to f_x to obtain

$$f(hx)=\sum_{\chi,i,j} d_\chi\rho^\chi_{ij}(h)\int_G\overline{\rho^\chi_{ij}(g)}f(gx)d\mu_G(g). \tag{12}$$

We here introduce the operators P^χ_{ij} and P^χ_i on $L^2(M)$ by

$$P^\chi_{ij}:=d_\chi\int_G\rho^\chi_{ij}(g)U(g)d\mu_G(g), \tag{13}$$

$$P^\chi_i:=P^\chi_{ii}, \tag{14}$$

respectively. These operators satisfy that

$$(P^\chi_{ij})^\dagger=P^\chi_{ji},\quad P^\chi_{ij}P^{\chi'}_{k\ell}=\delta^{\chi\chi'}\delta_{jk}P^\chi_{i\ell}, \tag{15}$$

and

$$(P^\chi_i)^\dagger=P^\chi_i,\quad P^\chi_iP^{\chi'}_j=\delta^{\chi\chi'}\delta_{ij}P^\chi_i, \tag{16}$$

respectively. Moreover, one verifies that

$$(P^\chi_{ij})^\dagger P^\chi_{ij}=P^\chi_j,\quad P^\chi_{ij}(P^\chi_{ij})^\dagger=P^\chi_i. \tag{17}$$

It then follows that when restricted to $\mathrm{Im}\,P_j^\chi$, the P_{ij}^χ provides the unitary isomorphism

$$P_{ij}^\chi : \mathrm{Im}\,P_j^\chi \xrightarrow{\sim} \mathrm{Im}\,P_i^\chi . \tag{18}$$

Furthermore, we can show that P_{ij}^χ and $U(g)$ are put together to give

$$P_{ij}^\chi U(g) = \sum_k \rho_{kj}^\chi(g^{-1}) P_{ik}^\chi , \tag{19}$$

$$U(g) P_{ij}^\chi = \sum_k \rho_{ik}^\chi(g^{-1}) P_{kj}^\chi . \tag{20}$$

From (20), it turns out that the map $E_j^\chi : L^2(M) \to \mathcal{H}^\chi \otimes L^2(M)$ defined by

$$E_j^\chi := \frac{1}{\sqrt{d_\chi}} \sum_{i=1}^{d_\chi} e_i^\chi \otimes P_{ij}^\chi \tag{21}$$

satisfies $U(g^{-1})E_j^\chi = \rho^\chi(g) E_j^\chi$, or equivalently

$$(E_j^\chi f)(gx) = \rho^\chi(g)(E_j^\chi f)(x), \quad f \in L^2(M), \tag{22}$$

which implies that the $\mathcal{H}^\chi$-valued function $E_j^\chi f$ is a ρ^χ-equivariant function.

We here introduce the space, $L^2(M;\mathcal{H}^\chi)^G$, of square integrable equivariant $\mathcal{H}^\chi$-valued functions by

$$L^2(M;\mathcal{H}^\chi)^G := \left\{ \psi : M \to \mathcal{H}^\chi \,\middle|\, \int_M \|\psi(x)\|^2 d\mu_M(x) < \infty,\ \psi(gx) = \rho^\chi(g)\psi(g) \right\}, \tag{23}$$

where $g \in G$, $x \in M$, and $\|\cdot\|$ denotes the norm in $\mathcal{H}^\chi$. Then we can view the operator E_j^χ as a map $L^2(M) \to L^2(M;\mathcal{H}^\chi)^G$. The adjoint operator $(E_j^\chi)^\dagger : L^2(M;\mathcal{H}^\chi)^G \to L^2(M)$ is defined, of course, through

$$\langle \psi, E_j^\chi f \rangle_{\mathcal{H}^\chi \otimes L^2(M)} = \langle (E_j^\chi)^\dagger \psi, f \rangle_{L^2(M)}, \quad \psi \in L^2(M;\mathcal{H}^\chi)^G, \quad f \in L^2(M), \tag{24}$$

where the subscripts $\mathcal{H}^\chi \otimes L^2(M)$ and $L^2(M)$ attached to $\langle\,,\rangle$ indicate the spaces on which the respective inner products are defined. Then one can observe that

$$(E_j^\chi)^\dagger E_j^\chi = P_j^\chi, \quad E_j^\chi (E_j^\chi)^\dagger = \mathrm{id}_{L^2(M;\mathcal{H}^\chi)^G}. \tag{25}$$

These relations imply that when restricted to $\mathrm{Im}\,P_j^\chi$, the E_j^χ provides a unitary isomorphism

$$E_j^\chi : \ \mathrm{Im}\,P_j^\chi \xrightarrow{\sim} L^2(M;\mathcal{H}^\chi)^G, \quad j = 1,\ldots,d_\chi . \tag{26}$$

We now apply the above-mentioned Fourier analysis to N-body systems. The manifold M we take is the center-of-mass system for N bodies. We introduce the Euler angles (ϕ, θ, ψ) through

$$g = e^{\phi R(\mathbf{e}_3)} e^{\theta R(\mathbf{e}_2)} e^{\psi R(\mathbf{e}_3)}, \quad g \in \mathrm{SO}(3), \tag{27}$$

where $\mathbf{e}_k$, $k = 1,2,3$, are the standard basis of $\mathbf{R}^3$ and $R(\mathbf{e}_k)$ denote the 3×3 antisymmetric matrices defined through $R(\mathbf{e}_k)\mathbf{a} = \mathbf{e}_k \times \mathbf{a}$ for $\mathbf{a} \in \mathbf{R}^3$. Let $D_{nm}^\ell(g)$ denote the matrix elements of unitary irreducible representations of SO(3) with $\ell = 0,1,2,\ldots$, and $|m|, |n| \leqslant \ell$.[9] They are expressed as

$$D^{\ell}_{nm}(g)=e^{-in\phi}d^{\ell}_{nm}(\theta)e^{-im\psi}, \tag{28}$$

where $d^{\ell}_{nm}(\theta)$ are given by

$$\begin{aligned} d^{\ell}_{nm}(\theta) &= (-1)^{n-m}\sqrt{(\ell+n)(\ell-n)(\ell+m)(\ell-m)} \\ &\times\sum_{k=0}^{\ell-m}\frac{(-1)^k}{k!(\ell-n-k)!(\ell+m-k)!(n-m+k)!}\left(\sin\frac{\theta}{2}\right)^{2k+n-m}\left(\cos\frac{\theta}{2}\right)^{2\ell-2k-(n-m)}. \end{aligned} \tag{29}$$

Let $d\mu(g)$ denote the invariant volume element on SO(3), which is expressed, in terms of the Euler angles, as

$$d\mu(g)=\sin\theta\, d\theta d\phi d\psi \quad \text{with} \quad \int_{\mathrm{SO}(3)} d\mu(g)=8\pi^2. \tag{30}$$

According to (12) with $\rho^{\chi}_{ij}=D^{\ell}_{mn}$, $d_{\chi}=2\ell+1$, and $d\mu_G(g)=d\mu(g)/(8\pi^2)$, a wave function $f(hx)$ on M is expanded into a Fourier series

$$f(hx)=\sum_{\ell=0}^{\infty}\sum_{|m|,|n|\leqslant\ell}\frac{2\ell+1}{8\pi^2}D^{\ell}_{mn}(h)\int_{\mathrm{SO}(3)}\overline{D^{\ell}_{mn}}(g)f(gx)d\mu(g), \quad x\in M. \tag{31}$$

The map $E^{\ell}_{m}: L^2(M)\to\mathcal{H}^{\ell}\otimes L^2(M)$ is defined as in (21):

$$E^{\ell}_{m}f=\frac{1}{\sqrt{2\ell+1}}\sum_{|m'|\leqslant\ell}e^{\ell}_{m'}\otimes P^{\ell}_{m'm}f, \tag{32}$$

where $e^{\ell}_{m'}$, denoted usually by $|\ell\, m'\rangle$, is the basis of the representation space $\mathcal{H}^{\ell}$. The ρ^{χ}-equivariance condition (22) now takes the form

$$(E^{\ell}_{m}f)(hx)=D^{\ell}(h)(E^{\ell}_{m}f)(x). \tag{33}$$

IV. NONSINGULAR CONFIGURATIONS

In this section, we make a brief review of the geometric setting-up for the nonsingular configurations.[4] We note first that the center-of-mass system is now identified with the set of collections of the Jacobi vectors [see (9)]. As is already mentioned, SO(3) acts on $\dot{M}$ freely, so that $\dot{M}$ is made into an SO(3) bundle,

$$\pi:\ \dot{M}\to\dot{Q}:=\dot{M}/\mathrm{SO}(3). \tag{34}$$

The inertia tensor, $A_x:\ \mathbf{R}^3\to\mathbf{R}^3$, is defined for $x\in M$ through

$$A_x(\mathbf{v})=\sum_{j=1}^{N-1}\mathbf{r}_j\times(\mathbf{v}\times\mathbf{r}_j), \quad \mathbf{v}\in\mathbf{R}^3, \tag{35}$$

and the connection form ω is defined for $x\in\dot{M}$ to be

$$\omega_x=R\left(A_x^{-1}\left(\sum_{j=1}^{N-1}\mathbf{r}_j\times d\mathbf{r}_j\right)\right), \tag{36}$$

where $R:\mathbf{R}^3\to\mathrm{so}(3)$ is the isomorphism already mentioned in Sec. III. Note that A_x^{-1} exists only for $x\in\dot{M}$. The connection form ω gives rise to a direct sum decomposition of the tangent space to $\dot{M}$ at $x\in\dot{M}$,

$$T_x(\dot{M})=V_x\oplus H_x, \tag{37}$$

where $V_x:=T_x(\mathcal{O}_x)$ is the tangent space to the SO(3)-orbit $\mathcal{O}_x$ through $x\in\dot{M}$ and $H_x:=\ker\omega_x$ with $\omega_x:T_x(\dot{M})\to\mathrm{so}(3)$. Tangent vectors in V_x and in H_x are called rotational (or vertical) and vibrational (or horizontal), respectively. By definition, rotational vectors are put in the form $R(\mathbf{a})x$ with $\mathbf{a}\in\mathbf{R}^3$. In fact, for a one-parameter group of rotations $e^{tR(\mathbf{a})}$ acting on M, its infinitesimal generator is given by

$$\frac{d}{dt}e^{tR(\mathbf{a})}x\bigg|_{t=0}=R(\mathbf{a})x=(R(\mathbf{a})\mathbf{r}_1,\ldots,R(\mathbf{a})\mathbf{r}_{N-1}). \tag{38}$$

In contrast with this, the definition of H_x implies that

$$u=(\mathbf{u}_1,\ldots,\mathbf{u}_{N-1})\in H_x\Leftrightarrow\sum_{j=1}^{N-1}\mathbf{r}_j\times\mathbf{u}_j=0. \tag{39}$$

Further, it is easy to see that V_x and H_x are orthogonal to each other with respect to the metric

$$ds^2=\sum_{j=1}^{N-1}d\mathbf{r}_j\cdot d\mathbf{r}_j. \tag{40}$$

In fact, for $R(\mathbf{a})x\in V_x$ and $u\in H_x$, one has

$$\sum_j R(\mathbf{a})\mathbf{r}_j\cdot\mathbf{u}_j=\mathbf{a}\cdot\sum_j\mathbf{r}_j\times\mathbf{u}_j=0. \tag{41}$$

For a tangent vector $v=(\mathbf{v}_1,\ldots,\mathbf{v}_{N-1})\in T_x(\dot{M})$, its vertical components $P_x(v)=(P_x(v)_1,\ldots,P_x(v)_{N-1})\in V_x$ are given by

$$P_x(v)_j=\left(A_x^{-1}\left(\sum_{k=1}^{N-1}\mathbf{r}_k\times\mathbf{v}_k\right)\right)\times\mathbf{r}_j. \tag{42}$$

In what follows, we describe the connection form ω and the metric ds^2 in terms of local coordinates. Let σ be a local section defined on an open subset U of $\dot{Q}$, $\sigma:U\to\dot{M}$. Then any point $x\in\pi^{-1}(U)$ is expressed as

$$x=g\sigma(q)=(g\boldsymbol{\sigma}_1(q),\ldots,g\boldsymbol{\sigma}_{N-1}(q)),\quad q\in U. \tag{43}$$

Let $g\in\mathrm{SO}(3)$ and $q\in U$ be assigned by the Euler angles (θ,ϕ,ψ) and by local coordinates q^α, $\alpha=1,\ldots,3N-6$, respectively. Then a straightforward calculation along with (36) and (43) provides

$$\omega_{g\sigma(q)}=dgg^{-1}+g\omega_{\sigma(q)}g^{-1}=g(g^{-1}dg+\omega_{\sigma(q)})g^{-1}, \tag{44}$$

where

$$\omega_{\sigma(q)}:=R\left(A_{\sigma(q)}^{-1}\left(\sum_{j=1}^{N-1}\boldsymbol{\sigma}_j(q)\times d\boldsymbol{\sigma}_j(q)\right)\right). \tag{45}$$

We here express $\omega_{\sigma(q)}$ as

$$\omega_{\sigma(q)}=\sum_{a=1}^{3}\sum_{\alpha=1}^{3N-6}\Lambda^a_\alpha(q)dq^\alpha R(\mathbf{e}_a), \tag{46}$$

and introduce a moving frame $\mathbf{u}_a$, $a=1,2,3$, and the left-invariant one-forms Ψ^a, $a=1,2,3$, on SO(3) by

$$\mathbf{u}_a=g\mathbf{e}_a, \tag{47}$$

$$g^{-1}dg=\sum_{a=1}^{3}\Psi^a R(\mathbf{e}_a), \tag{48}$$

respectively. Then the connection form ω given by (44) is put in the form

$$\omega_{g\sigma(q)}=\sum_a \Theta^a R(\mathbf{u}_a), \quad \Theta^a:=\Psi^a+\sum_\alpha \Lambda^a_\alpha(q)dq^\alpha, \tag{49}$$

where we have used the formula $R(g\mathbf{e}_a)=gR(\mathbf{e}_a)g^{-1}$.

The horizontal lift, $(\partial/\partial q^\alpha)^*$, of a local vector field $\partial/\partial q^\alpha$ on U is defined through

$$\omega_{g\sigma(q)}\left(\left(\frac{\partial}{\partial q^\alpha}\right)^*\right)=0, \quad \pi_*\left(\left(\frac{\partial}{\partial q^\alpha}\right)^*\right)=\frac{\partial}{\partial q^\alpha}, \tag{50}$$

and proves to be given by

$$\left(\frac{\partial}{\partial q^\alpha}\right)^*=\frac{\partial}{\partial q^\alpha}-\sum_a \Lambda^a_\alpha(q)K_a, \quad \alpha=1,2,\ldots,3N-6, \tag{51}$$

where K_a are the left-invariant vector fields on SO(3), which are dual to Ψ^a:

$$\Psi^a(K_b)=\delta^a_b, \quad a,b=1,2,3. \tag{52}$$

The dq^α, Θ^a and the $(\partial/\partial q^\alpha)^*$, K_a form local bases of one-forms and of vector fields on $\pi^{-1}(U)\cong U\times \mathrm{SO}(3)$, respectively, in accordance with the decomposition (37). They are dual to each other:

$$dq^\alpha\left(\left(\frac{\partial}{\partial q^\beta}\right)^*\right)=\delta^\alpha_\beta, \quad dq^\alpha(K_a)=0, \tag{53}$$

$$\Theta^a\left(\left(\frac{\partial}{\partial q^\alpha}\right)^*\right)=0, \quad \Theta^a(K_b)=\delta^a_b. \tag{54}$$

In contrast with left-invariant one-forms and vector fields, right-invariant one-forms Φ^a and vector fields J_a are defined through

$$dgg^{-1}=\sum_{a=1}^{3}\Phi^a R(\mathbf{e}_a), \tag{55}$$

$$\Phi^a(J_b)=\delta^a_b, \quad a,b=1,2,3, \tag{56}$$

respectively. Since $g(g^{-1}dg)g^{-1}=dgg^{-1}$, the right- and left-invariant one-forms are related to each other, and so are the right- and left-invariant vector fields,

$$\Phi^a=\sum_{b=1}^{3} g_{ab}\Psi^b,\quad J_a=\sum_{b=1}^{3} g_{ab}K_b\,, \tag{57}$$

where g_{ab} denote the matrix elements of g.

We here associate the vector fields K_a and J_a with the angular momentum operator. The infinitesimal rotation (38) is put in the form of operator,

$$\sum_{k=1}^{N-1} R(\mathbf{a})\mathbf{r}_k\cdot\frac{\partial}{\partial\mathbf{r}_k}=\mathbf{a}\cdot\left(\sum_{k=1}^{N-1}\mathbf{r}_k\times\frac{\partial}{\partial\mathbf{r}_k}\right)=\mathbf{a}\cdot\mathbf{J}, \tag{58}$$

where we have set

$$\mathbf{J}=\sum_{k=1}^{N-1}\mathbf{r}_k\times\frac{\partial}{\partial\mathbf{r}_k}. \tag{59}$$

Since one has, from (58) with $\mathbf{a}=\mathbf{e}_a$,

$$\mathbf{e}_a\cdot\mathbf{J}=\frac{d}{dt}e^{tR(\mathbf{e}_a)}x\bigg|_{t=0}=\frac{d}{dt}e^{tR(\mathbf{e}_a)}g\,\sigma(q)\bigg|_{t=0}, \tag{60}$$

$\mathbf{e}_a\cdot\mathbf{J}$ can be identified with the right-invariant vector fields J_a on SO(3), $J_a=\mathbf{e}_a\cdot\mathbf{J}$. Further, on account of (47) and (57), we obtain

$$\mathbf{J}=\sum_{a=1}^{3}\mathbf{e}_aJ_a=\sum_{a=1}^{3}\mathbf{u}_aK_a\,. \tag{61}$$

The last equality of the above equation also means that

$$K_a=\mathbf{u}_a\cdot\mathbf{J}=\frac{d}{dt}e^{tR(\mathbf{u}_a)}x\bigg|_{t=0}=\frac{d}{dt}g\,e^{tR(\mathbf{e}_a)}\sigma(q)\bigg|_{t=0}. \tag{62}$$

This implies that K_a can be identified with an infinitesimal rotation with respect to the so-called body frame.

In terms of the Euler angles given by $g=e^{\phi R(\mathbf{e}_3)}e^{\theta R(\mathbf{e}_2)}e^{\psi R(\mathbf{e}_3)}$, the K_a and J_a and the Ψ^a and Φ^a are expressed, respectively, as

$$\begin{aligned}
K_1&=-\frac{\cos\psi}{\sin\theta}\frac{\partial}{\partial\phi}+\sin\psi\frac{\partial}{\partial\theta}+\cot\theta\cos\psi\frac{\partial}{\partial\psi},\\
K_2&=\frac{\sin\psi}{\sin\theta}\frac{\partial}{\partial\phi}+\cos\psi\frac{\partial}{\partial\theta}-\cot\theta\sin\psi\frac{\partial}{\partial\psi},\\
K_3&=\frac{\partial}{\partial\psi},
\end{aligned} \tag{63}$$

$$\begin{aligned}
\Psi^1&=\sin\psi\,d\theta-\sin\theta\cos\psi\,d\phi,\\
\Psi^2&=\cos\psi\,d\theta+\sin\theta\sin\psi\,d\phi,\\
\Psi^3&=d\psi+\cos\theta\,d\phi,
\end{aligned} \tag{64}$$

$$J_1 = -\cos\phi\cot\theta\frac{\partial}{\partial\phi} - \sin\phi\frac{\partial}{\partial\theta} + \frac{\cos\phi}{\sin\theta}\frac{\partial}{\partial\psi},$$

$$J_2 = -\sin\phi\cot\theta\frac{\partial}{\partial\phi} + \cos\phi\frac{\partial}{\partial\theta} + \frac{\sin\phi}{\sin\theta}\frac{\partial}{\partial\psi}, \tag{65}$$

$$J_3 = \frac{\partial}{\partial\phi},$$

$$\Phi^1 = -\sin\phi\, d\theta + \sin\theta\cos\phi\, d\psi,$$

$$\Phi^2 = \cos\phi\, d\theta + \sin\theta\sin\phi\, d\psi, \tag{66}$$

$$\Phi^3 = d\phi + \cos\theta\, d\psi.$$

We now wish to express the metric (40) in terms of dq^α, Θ^a. We first note that the basis vector fields $(\partial/\partial q^\alpha)^*$, K_a are expressed also as

$$\left(\frac{\partial}{\partial q^\alpha}\right)^* = \sum_j \left(\frac{\partial}{\partial q^\alpha}\right)^* \mathbf{r}_j \cdot \frac{\partial}{\partial \mathbf{r}_j}, \quad K_a = \sum_j K_a \mathbf{r}_j \cdot \frac{\partial}{\partial \mathbf{r}_j}, \tag{67}$$

respectively. Since vibrational and rotational vectors are orthogonal to each other, one has

$$ds^2\left(\left(\frac{\partial}{\partial q^\alpha}\right)^*, K_a\right) = \sum_j \left(\frac{\partial}{\partial q^\alpha}\right)^* \mathbf{r}_j \cdot K_a \mathbf{r}_j = 0. \tag{68}$$

We further introduce the quantities $a_{\alpha\beta}$ and A_{ab} by

$$a_{\alpha\beta} := ds^2\left(\left(\frac{\partial}{\partial q^\alpha}\right)^*, \left(\frac{\partial}{\partial q^\beta}\right)^*\right) = \sum_j \left(\frac{\partial}{\partial q^\alpha}\right)^* \mathbf{r}_j \cdot \left(\frac{\partial}{\partial q^\beta}\right)^* \mathbf{r}_j, \tag{69}$$

$$A_{ab} := ds^2(K_a, K_b) = \sum_j K_a \mathbf{r}_j \cdot K_b \mathbf{r}_j. \tag{70}$$

Then the metric ds^2 is put in the form

$$ds^2 = \sum_{\alpha,\beta} a_{\alpha\beta} dq^\alpha dq^\beta + \sum_{a,b} A_{ab}\Theta^a\Theta^b. \tag{71}$$

Since $K_a \mathbf{r}_j = \mathbf{u}_a \times \mathbf{r}_j = g(\mathbf{e}_a \times \boldsymbol{\sigma}_j(q))$, one obtains, from (51),

$$\left(\frac{\partial}{\partial q^\alpha}\right)^* \mathbf{r}_j = g\left(\frac{\partial \boldsymbol{\sigma}_j(q)}{\partial q^\alpha} - \sum_a \Lambda^a_\alpha(q)(\mathbf{e}_a \times \boldsymbol{\sigma}_j(q))\right), \tag{72}$$

and then the quantities $a_{\alpha\beta}$ and A_{ab} are put, respectively, in the form

$$a_{\alpha\beta} = \sum_j \left(\frac{\partial \boldsymbol{\sigma}_j}{\partial q^\alpha} - \sum_a \Lambda^a_\alpha(q)(\mathbf{e}_a \times \boldsymbol{\sigma}_j)\right) \cdot \left(\frac{\partial \boldsymbol{\sigma}_j}{\partial q^\beta} - \sum_b \Lambda^b_\beta(q)(\mathbf{e}_b \times \boldsymbol{\sigma}_j)\right), \tag{73}$$

$$A_{ab} = \sum_j (\mathbf{u}_a \times \mathbf{r}_j) \cdot (\mathbf{u}_b \times \mathbf{r}_j) = \mathbf{u}_a \cdot A_x(\mathbf{u}_b) = \mathbf{e}_a \cdot A_{\sigma(q)}(\mathbf{e}_b). \tag{74}$$

In the remainder of this section, we consider the transformation law for local expressions of the connection form. Let $\tau: V \to \dot{M}$ be another local section defined on an open subset V with $V \cap U \neq \varnothing$. Then the local sections τ and σ are related by $\tau(q) = k(q)\sigma(q)$, $q \in V \cap U$ with $k(q) \in \mathrm{SO}(3)$. From (44), it follows that

$$\omega_{\tau(q)} = dk k^{-1} + k \omega_{\sigma(q)} k^{-1}. \tag{75}$$

Like (46), we describe the connection form $\omega_{\tau(q)}$ as

$$\omega_{\tau(q)} = \sum_a \sum_\alpha \tilde{\Lambda}^a_\alpha(q) dq^\alpha R(\mathbf{e}_a). \tag{76}$$

Then the transformation law (75) brings about

$$\sum_\alpha \tilde{\Lambda}^a_\alpha dq^\alpha = \Phi^a(k) + \sum_b k_{ab} \sum_\alpha \Lambda^b_\alpha dq^\alpha, \tag{77}$$

where $\Phi^a(k)$ are defined through $dk k^{-1} = \Sigma_a \Phi^a(k) R(\mathbf{e}_a)$ and k_{ab} denote the components of $k \in \mathrm{SO}(3)$. Furthermore, we note that the inertia tensor is subject to the transformation $A_{hx} = h A_x h^{-1}$ for any $h \in \mathrm{SO}(3)$, so that the components (A_{ab}) transform according to

$$\tilde{A}_{ab} = \sum_{c,d} k_{ad} A_{dc} k_{bc}, \quad k = (k_{ab}), \tag{78}$$

where

$$\tilde{A}_{ab} = \mathbf{e}_a \cdot A_{\tau(q)}(\mathbf{e}_b). \tag{79}$$

We note also that since the metric ds^2 is SO(3)-invariant, $a_{\alpha\beta}$ are defined independently of the choice of sections, so that the $(a_{\alpha\beta})$ defines a metric tensor on $U \subset \dot{Q}$.

V. KINETIC ENERGY OPERATOR FOR NONSINGULAR CONFIGURATIONS

In this section, we study the kinetic energy operator for nonsingular configurations by using the setup stated in Secs. III and IV, and obtain a reduced kinetic energy operator which is defined on $\dot{Q}$. We begin by considering the gradient vector

$$\nabla = \left(\frac{\partial}{\partial \mathbf{r}_1}, \ldots, \frac{\partial}{\partial \mathbf{r}_{N-1}} \right). \tag{80}$$

For a smooth wave function f, we regard ∇f as a tangent vector to $\dot{M}$, and decompose ∇f according to (37):

$$\nabla f = (\nabla f)_{\mathrm{rot}} + (\nabla f)_{\mathrm{vib}}. \tag{81}$$

The rotational vector $(\nabla f)_{\mathrm{rot}}$ is given by $(\nabla f)_{\mathrm{rot}} := P_x(\nabla f)$, so that its components are expressed, on using (42) with $\mathbf{v}_k = \partial f / \partial \mathbf{r}_k$, as

$$\begin{aligned} P_x(\nabla f)_j &= \left(A_x^{-1} \left(\sum_k \mathbf{r}_k \times \frac{\partial f}{\partial \mathbf{r}_k} \right) \right) \times \mathbf{r}_j \\ &= (A_x^{-1}(\mathbf{J} f)) \times \mathbf{r}_j \\ &= \left(A_x^{-1} \left(\sum_a \mathbf{u}_a K_a f \right) \right) \times \mathbf{r}_j \\ &= \sum_a ((A_x^{-1}(\mathbf{u}_a)) \times \mathbf{r}_j) K_a f. \end{aligned} \tag{82}$$

Then $(\nabla f)_{\mathrm{rot}}$ turns out to have the components

$$\left(\frac{\partial f}{\partial \mathbf{r}_j}\right)_{\mathrm{rot}} = \sum_{a=1}^{3} \mathbf{t}_j^a K_a f, \quad \mathbf{t}_j^a := A_x^{-1}(\mathbf{u}_a) \times \mathbf{r}_j, \quad j = 1, \ldots, N-1. \tag{83}$$

In contrast with this, the components of $(\nabla f)_{\mathrm{vib}}$ can be put in the form

$$\left(\frac{\partial f}{\partial \mathbf{r}_j}\right)_{\mathrm{vib}} = \sum_{\alpha=1}^{3N-6} \mathbf{v}_j^\alpha \left(\frac{\partial}{\partial q^\alpha}\right)^* f, \quad j = 1, \ldots, N-1, \tag{84}$$

where the vectors $\mathbf{v}_j^\alpha$ will be determined as follows: From (67) along with the decomposition $\partial/\partial \mathbf{r}_j = (\partial/\partial \mathbf{r}_j)_{\mathrm{rot}} + (\partial/\partial \mathbf{r}_j)_{\mathrm{vib}}$, the basis tangent vectors can be expressed as

$$K_a = \sum_j K_a \mathbf{r}_j \cdot \left(\sum_b \mathbf{t}_j^b K_b + \sum_\alpha \mathbf{v}_j^\alpha \left(\frac{\partial}{\partial q^\alpha}\right)^* \right), \tag{85}$$

$$\left(\frac{\partial}{\partial q^\beta}\right)^* = \sum_j \left(\frac{\partial}{\partial q^\beta}\right)^* \mathbf{r}_j \cdot \left(\sum_b \mathbf{t}_j^b K_b + \sum_\alpha \mathbf{v}_j^\alpha \left(\frac{\partial}{\partial q^\alpha}\right)^* \right). \tag{86}$$

These equations provide

$$\sum_j K_a \mathbf{r}_j \cdot \mathbf{t}_j^b = \delta_a^b, \quad \sum_j \left(\frac{\partial}{\partial q^\alpha}\right)^* \mathbf{r}_j \cdot \mathbf{t}_j^b = 0, \tag{87}$$

$$\sum_j K_a \mathbf{r}_j \cdot \mathbf{v}_j^\alpha = 0, \quad \sum_j \left(\frac{\partial}{\partial q^\beta}\right)^* \mathbf{r}_j \cdot \mathbf{v}_j^\alpha = \delta_\beta^\alpha. \tag{88}$$

Equations (88) are used to determine $\mathbf{v}_j^\alpha$ or the vectors $v^\alpha := \Sigma_j \mathbf{v}_j^\alpha \cdot (\partial/\partial \mathbf{r}_j)$. It then turns out that v^α are expressed as

$$v^\alpha = \sum_\beta a^{\alpha\beta} \left(\frac{\partial}{\partial q^\beta}\right)^*, \tag{89}$$

or

$$\mathbf{v}_j^\alpha = v^\alpha \mathbf{r}_j = \sum_\beta a^{\alpha\beta} \left(\frac{\partial}{\partial q^\beta}\right)^* \mathbf{r}_j, \tag{90}$$

where

$$(a^{\alpha\beta}) := (a_{\alpha\beta})^{-1}. \tag{91}$$

In addition, it is easy to show that

$$\sum_j \mathbf{t}_j^a \cdot \mathbf{t}_j^b = A^{ab}, \tag{92}$$

$$\sum_j \mathbf{t}_j^a \cdot \mathbf{v}_j^\alpha = 0, \tag{93}$$

$$\sum_j \mathbf{v}_j^\alpha \cdot \mathbf{v}_j^\beta = a^{\alpha\beta}, \tag{94}$$

where

$$A^{ab} := \mathbf{u}_a \cdot A_x^{-1}(\mathbf{u}_b) = \mathbf{e}_a \cdot A_{\sigma(q)}^{-1}(\mathbf{e}_b). \tag{95}$$

It is to be noted that A_x^{-1} is defined only for $x \in \dot{M}$.

We are now in a position to study the kinetic energy operator. The kinetic energy integral of our N-body system is given by

$$T = \frac{1}{2} \int_M \sum_j \overline{\frac{\partial f}{\partial \mathbf{r}_j}} \cdot \frac{\partial f}{\partial \mathbf{r}_j} dV, \tag{96}$$

where dV is the standard volume element of M. The energy operator, which is equal to $-\frac{1}{2}$ times the Laplacian Δ, is defined through integration by part as follows:

$$T = \int_M \overline{f} \left(-\frac{1}{2} \sum_j \left(\frac{\partial}{\partial \mathbf{r}_j} \right)^2 f \right) dV = \int_M \overline{f} \left(-\frac{1}{2} \Delta f \right) dV, \tag{97}$$

where f is assumed to be a smooth function with compact support. According to the orthogonal decomposition, $\nabla = \nabla_{\text{rot}} + \nabla_{\text{vib}}$, of the gradient operator, the kinetic energy is also broken up into rotational and vibrational energies,

$$T = T_{\text{rot}} + T_{\text{vib}}, \tag{98}$$

where

$$T_{\text{rot}} = \frac{1}{2} \int_M \sum_j \left(\overline{\frac{\partial f}{\partial \mathbf{r}_j}} \right)_{\text{rot}} \cdot \left(\frac{\partial f}{\partial \mathbf{r}_j} \right)_{\text{rot}} dV, \tag{99}$$

$$T_{\text{vib}} = \frac{1}{2} \int_M \sum_j \left(\overline{\frac{\partial f}{\partial \mathbf{r}_j}} \right)_{\text{vib}} \cdot \left(\frac{\partial f}{\partial \mathbf{r}_j} \right)_{\text{vib}} dV. \tag{100}$$

The rotational and vibrational energy operators will be defined by carrying out the integration by part for the energy integrals T_{rot} and T_{vib}, respectively. Accordingly, the Laplacian Δ is broken up into two,

$$\Delta = \Delta_{\text{rot}} + \Delta_{\text{vib}}. \tag{101}$$

We wish to express Δ_{rot} and Δ_{vib} in terms of local coordinates. From (71) together with (49), the volume element dV proves to be expressed as

$$dV = dQ \wedge d\mu(g), \tag{102}$$

where

$$dQ = \rho(q) dq^1 \wedge \cdots \wedge dq^{3N-6}, \tag{103}$$

$$\rho(q) = \sqrt{\det(A_{ab}) \det(a_{\alpha\beta})}, \tag{104}$$

$$d\mu(g) = \Psi^1 \wedge \Psi^2 \wedge \Psi^3 = \sin\theta \, d\theta \wedge d\phi \wedge d\psi. \tag{105}$$

By using (83) and (92) and performing integration by part, we obtain

$$T_{\text{rot}} = \frac{1}{2} \int_M \sum_j \sum_a \mathbf{t}_j^a \overline{K_a f} \cdot \sum_b \mathbf{t}_j^b K_b f \, dV = -\frac{1}{2} \int_M \overline{f} \sum_{a,b} K_a (A^{ab} K_b f) \, dV, \tag{106}$$

where we have used the fact that K_a are volume-preserving operators on SO(3). In the same manner, it follows from (84) and (94) that

$$T_{\mathrm{vib}}=\frac{1}{2}\int_M \sum_j \sum_\alpha \mathbf{v}_j^\alpha \overline{\left(\frac{\partial}{\partial q^\alpha}\right)^* f}\cdot \sum_\beta \mathbf{v}_j^\beta \left(\frac{\partial}{\partial q^\beta}\right)^* f\, dV$$
$$=-\frac{1}{2}\int_M \overline{f}\frac{1}{\rho(q)}\sum_{\alpha,\beta}\left(\frac{\partial}{\partial q^\alpha}\right)^*\left(a^{\alpha\beta}\rho(q)\left(\frac{\partial}{\partial q^\beta}\right)^* f\right) dV. \tag{107}$$

Thus we have found the respective expressions of Δ_{rot} and Δ_{vib}:

$$\Delta_{\mathrm{rot}}=\sum_{a,b} K_a(A^{ab}K_b), \tag{108}$$

$$\Delta_{\mathrm{vib}}=\frac{1}{\rho(q)}\sum_{\alpha,\beta}\left(\frac{\partial}{\partial q^\alpha}\right)^*\left(a^{\alpha\beta}\rho(q)\left(\frac{\partial}{\partial q^\beta}\right)^*\right). \tag{109}$$

Note that these operators fail to be defined at singular configurations. In fact, for singular configurations, one has $\det(A_{ab})=0$, so that A^{ab} is not defined, and further $\rho(q)=0$.

In the remainder of this section, we show that the rotational and vibrational energy operators, $-\frac{1}{2}\Delta_{\mathrm{rot}}$ and $-\frac{1}{2}\Delta_{\mathrm{vib}}$, will reduce to operators acting on wave functions of internal variables (q^α). To this end, we restrict ourselves to the subspace $\mathrm{Im}\,P_m^\ell$ of $L^2(M)$. Then we obtain, from (26),

$$\langle P_m^\ell f_1, P_m^\ell f_2\rangle_{L^2(M)}=\int_M \langle E_m^\ell f_1, E_m^\ell f_2\rangle_{\mathcal{H}^\ell} dV,\quad f_1, f_2\in L^2(M), \tag{110}$$

where we have used the fact that $E_m^\ell P_m^\ell f=E_m^\ell f$, and $\langle\ ,\ \rangle_{\mathcal{H}^\ell}$ denotes the inner product on the representation space $\mathcal{H}^\ell$ assigned by ℓ. From (33) together with (43), one finds that the $\mathcal{H}^\ell$-valued function $E_m^\ell f$ is locally expressed as

$$(E_m^\ell f)(g\sigma(q))=D^\ell(g)(E_m^\ell f)(\sigma(q)). \tag{111}$$

If f has a compact support in $\pi^{-1}(U)$, Eq. (110) becomes

$$\langle P_m^\ell f_1, P_m^\ell f_2\rangle_{L^2(M)}=8\pi^2\int_{\dot{Q}}\langle (E_m^\ell f_1)(\sigma(q)),(E_m^\ell f_2)(\sigma(q))\rangle_{\mathcal{H}^\ell} dQ, \tag{112}$$

where we have used the fact that $D^\ell(g)$ is a unitary matrix. This equation means that we may view $(E_m^\ell f)(\sigma(q))$ as a (locally defined) $\mathcal{H}^\ell$-valued wave function on the internal space $\dot{Q}$. If f is smooth enough, the projection operator $P_{m'm}^\ell$ and a differential operator such as $(\partial/\partial q^\alpha)^*$ commute, so that we obtain

$$E_m^\ell\left(\frac{\partial}{\partial q^\alpha}\right)^* f=\left(\mathrm{id}_{\mathcal{H}^\ell}\otimes\left(\frac{\partial}{\partial q^\alpha}\right)^*\right)E_m^\ell f, \tag{113}$$

where $\mathrm{id}_{\mathcal{H}^\ell}$ denotes the identity of $\mathcal{H}^\ell$. The right-hand side of this equation means that we may differentiate $E_m^\ell f$ componentwise. We recall here that the operator K_a acts on the D-functions[10] as

$$K_a D^\ell(g)=-iD^\ell(g)[\hat{J}_a^{(\ell)}], \tag{114}$$

where $\hat{J}_a$ are the angular momentum operators defined to be $\hat{J}_a=-iJ_a$, and $[\hat{J}_a^{(\ell)}]$ denote their representation matrices which are, as usual, given by

$$[\hat{J}_1^{(\ell)}]_{m-1\,m}=\frac{1}{2}\sqrt{(\ell+m)(\ell-m+1)},\quad [\hat{J}_1^{(\ell)}]_{m+1\,m}=\frac{1}{2}\sqrt{(\ell-m)(\ell+m+1)},$$

$$[\hat{J}_2^{(\ell)}]_{m-1\,m}=-\frac{1}{2i}\sqrt{(\ell+m)(\ell-m+1)},\quad [\hat{J}_2^{(\ell)}]_{m+1\,m}=\frac{1}{2i}\sqrt{(\ell-m)(\ell+m+1)},\quad (115)$$

$$[\hat{J}_3^{(\ell)}]_{mm}=m,\qquad \text{the others vanishing.}$$

Operating on $D^{\ell}(g)(E_m^{\ell}f)(\sigma(q))$ with $\mathrm{id}_{\mathcal{H}^{\ell}}\otimes(\partial/\partial q^{\alpha})^*$ and using (114), we obtain

$$\left(\mathrm{id}_{\mathcal{H}^{\ell}}\otimes\left(\frac{\partial}{\partial q^{\alpha}}\right)^*\right)D^{\ell}(g)(E_m^{\ell}f)(\sigma(q))=D^{\ell}(g)\nabla_{\alpha}(E_m^{\ell}f)(\sigma(q)),\quad (116)$$

where

$$\nabla_{\alpha}=I_{2\ell+1}\otimes\frac{\partial}{\partial q^{\alpha}}+i\sum_a\ \Lambda_{\alpha}^{a}(q)[\hat{J}_a^{(\ell)}],\quad (117)$$

and $I_{2\ell+1}$ denotes the $(2\ell+1)\times(2\ell+1)$ identity matrix.

We have to point out that the operators ∇_{α} may be defined independently of the choice of local sections. We recall here that the $\dot{M}$ is made into the fiber bundle (34). Take a representation space $\mathcal{H}^{\ell}\cong\mathbf{C}^{2\ell+1}$ of SO(3). Then the associated complex vector bundle is defined to be $\dot{M}\times_{\ell}\mathcal{H}^{\ell}:=(\dot{M}\times\mathcal{H}^{\ell})/\mathrm{SO}(3)$, where the SO(3) action on the product space $\dot{M}\times\mathcal{H}^{\ell}$ is defined by $(gx,D^{\ell}(g)v)$ for $(x,v)\in\dot{M}\times\mathcal{H}^{\ell}$. The space of equivariant functions on $\dot{M}$ is in one-to-one correspondence with the space of sections in $\dot{M}\times_{\ell}\mathcal{H}^{\ell}$; $s(\pi(x))=[(x,F(x))]$, where s and F are a section and an equivariant function, respectively, and $[\,\cdot\,]$ denotes the equivalence class. We denote this correspondence by $s=\gamma F$. For a local section σ in $\dot{M}$ and the equivariant function $E_m^{\ell}f$, one has $[(x,(E_m^{\ell}f)(x))]=[(\sigma(q),(E_m^{\ell}f)(\sigma(q)))]$, which means that $(E_m^{\ell}f)(\sigma(q))$ serves as a local expression of the section $s(\pi(x))=[(x,(E_m^{\ell}f)(x))]$. For a section s in $\dot{M}\times_{\ell}\mathcal{H}^{\ell}$, the covariant derivative of s with respect to a vector field X on $\dot{Q}=\dot{M}/\mathrm{SO}(3)$ is defined by

$$\nabla_X s=\gamma X^*(\gamma^{-1}s),\quad (118)$$

where X^* denotes the horizontal lift of X. Equation (117) is a local expression of the covariant differential operator with respect to $\partial/\partial q^{\alpha}$.

For confirmation, we show that locally defined operators (117) can be pieced together to define an operator independently of the choice of sections. For another local section τ in $\dot{M}$, we have another local expression $(E_m^{\ell}f)(\tau(q))$ of the section $s(\pi(x))=[(x,(E_m^{\ell}f)(x))]$. The locally defined $\mathcal{H}^{\ell}$-valued functions $(E_m^{\ell}f)(\tau(q))$ and $(E_m^{\ell}f)(\sigma(q))$ are related by the gauge transformation

$$(E_m^{\ell}f)(\tau(q))=D^{\ell}(k(q))(E_m^{\ell}f)(\sigma(q)),\quad q\in V\cap U.\quad (119)$$

For $(E_m^{\ell}f)(\tau(q))$, we have the covariant differential operator, instead of (117),

$$\tilde{\nabla}_{\alpha}=I_{2\ell+1}\otimes\frac{\partial}{\partial q^{\alpha}}+i\sum_a\ \tilde{\Lambda}_{\alpha}^{a}(q)[\hat{J}_a^{(\ell)}].\quad (120)$$

We show that the locally defined covariant differential operators, ∇_{α} and $\tilde{\nabla}_{\alpha}$, are subject to the transformation law

$$\tilde{\nabla}_{\alpha}(E_m^{\ell}f)(\tau(q))=D^{\ell}(k(q))\nabla_{\alpha}(E_m^{\ell}f)(\sigma(q)),\quad (121)$$

or, equivalently,

$$\sum_{\alpha} \tilde{\nabla}_{\alpha}(E_m^{\ell} f)(\tau(q))dq^{\alpha} = D^{\ell}(k(q)) \sum_{\alpha} \nabla_{\alpha}(E_m^{\ell} f)(\sigma(q))dq^{\alpha}. \tag{122}$$

The transformation law (121) shows that locally defined covariant differential operators are pieced together to define a covariant differential operator acting on sections in $\dot{M} \times_{\ell} \mathcal{H}^{\ell}$;

$$[(\sigma(q), \nabla_{\alpha}(E_m^{\ell} f)(\sigma(q)))] = [(\tau(q), \tilde{\nabla}_{\alpha}(E_m^{\ell} f)(\tau(q)))]. \tag{123}$$

To prove (122), we need some formulas on D-functions. In contrast with (114), we have the formula[10]

$$J_a D^{\ell}(g) = -i[\hat{J}_a^{(\ell)}] D^{\ell}(g). \tag{124}$$

From (114) and (124) together with (57), we obtain the formula

$$[\hat{J}_a^{(\ell)}] D^{\ell}(g) = \sum_{b} g_{ab} D^{\ell}(g)[\hat{J}_b^{(\ell)}]. \tag{125}$$

Using the transformation law (77) along with the above formulas and the equation

$$dD^{\ell}(k) = \sum_{a} K_a D^{\ell}(k) \Psi^a(k), \tag{126}$$

we can verify (122) in a straightforward manner.

We proceed to the operators Δ_{rot} and Δ_{vib}. Operating on $D^{\ell}(g)(E_m^{\ell} f)(\sigma(q))$ with $\mathrm{id}_{\mathcal{H}^{\ell}} \otimes \Delta_{\mathrm{rot}}$ and $\mathrm{id}_{\mathcal{H}^{\ell}} \otimes \Delta_{\mathrm{vib}}$, we obtain

$$(\mathrm{id}_{\mathcal{H}^{\ell}} \otimes \Delta_{\mathrm{rot}}) D^{\ell}(g)(E_m^{\ell} f)(\sigma(q)) = -D^{\ell}(g) \sum_{a,b} A^{ab}[\hat{J}_a^{(\ell)}][\hat{J}_b^{(\ell)}](E_m^{\ell} f)(\sigma(q)), \tag{127}$$

$$(\mathrm{id}_{\mathcal{H}^{\ell}} \otimes \Delta_{\mathrm{vib}}) D^{\ell}(g)(E_m^{\ell} f)(\sigma(q)) = D^{\ell}(g) \frac{1}{\rho(q)} \sum_{\alpha,\beta} \nabla_{\alpha}(a^{\alpha\beta} \rho(q) \nabla_{\beta}(E_m^{\ell} f)(\sigma(q))), \tag{128}$$

respectively. From these equations, it turns out that the Laplacian $\Delta = \Delta_{\mathrm{vib}} + \Delta_{\mathrm{rot}}$ reduces to the operator acting on vector-valued wave functions $(E_m^{\ell} f)(\sigma(q))$,

$$\Delta^{\mathrm{red}} := \frac{1}{\rho(q)} \sum_{\alpha,\beta} \nabla_{\alpha}(a^{\alpha\beta} \rho(q) \nabla_{\beta}) - \sum_{a,b} A^{ab}[\hat{J}_a^{(\ell)}][\hat{J}_b^{(\ell)}]. \tag{129}$$

We here have to mention the transformation law for the locally defined reduced Laplacians. For $(E_m^{\ell} f)(\tau(q))$, we have the reduced Laplacian expressed as

$$\tilde{\Delta}^{\mathrm{red}} := \frac{1}{\rho(q)} \sum_{\alpha,\beta} \tilde{\nabla}_{\alpha}(a^{\alpha\beta} \rho(q) \tilde{\nabla}_{\beta}) - \sum_{a,b} \tilde{A}^{ab}[\hat{J}_a^{(\ell)}][\hat{J}_b^{(\ell)}]. \tag{130}$$

Using the transformation law (78) and the formula (125) in addition to (121), we can also show that $\tilde{\Delta}^{\mathrm{red}}$ and Δ^{red} are related by

$$\tilde{\Delta}^{\mathrm{red}}(E_m^{\ell} f)(\tau(q)) = D^{\ell}(k(q)) \Delta^{\mathrm{red}}(E_m^{\ell} f)(\sigma(q)). \tag{131}$$

Thus we obtain the following.

Theorem 1: For nonsingular configurations, the Laplacian reduces to an operator acting on the sections in the associated vector bundle $\dot{M}\times_{\ell}\mathcal{H}^{\ell}$, which is expressed locally as Δ^{red} given by (129) or $\tilde{\Delta}^{\mathrm{red}}$ given by (130) according to the choice of local sections in $\dot{M}\to\dot{Q}$. The reduced local operators Δ^{red} and $\tilde{\Delta}^{\mathrm{red}}$ are subject to the transformation law (131).

VI. THREE-BODY SYSTEMS

Our aim in this section is to show that in spite of the singularity of Δ_{rot} and Δ_{vib} at singular configurations, the rotational and vibrational energy integrals are not divergent at singular configurations. To this end, we need to understand the detailed behavior of wave functions at singular configurations. For this reason, we specialize in three-body systems for simplicity. Let us introduce internal coordinates $(\zeta_1,\zeta_2,\zeta_3)$ by

$$\zeta_1=r_1,\quad \zeta_2=r_2\cos\varphi,\quad \zeta_3=r_2\sin\varphi, \tag{132}$$

where

$$r_1=\|\mathbf{r}_1\|,\quad r_2=\|\mathbf{r}_2\|,\quad \mathbf{r}_1\cdot\mathbf{r}_2=r_1r_2\cos\varphi. \tag{133}$$

Using ζ_α, $\alpha=1,2,3$, we define a local section σ by

$$\boldsymbol{\sigma}_1(q)=\zeta_1\mathbf{e}_3,\quad \boldsymbol{\sigma}_2(q)=\zeta_2\mathbf{e}_3+\zeta_3\mathbf{e}_1. \tag{134}$$

We note here that the local section σ is defined originally on an open subset U of $\dot{Q}=\dot{M}/\mathrm{SO}(3)$. If we are strict in using the term "local section," we must pose the restriction that $\zeta_1>0$ and $\zeta_3>0$ to identify the open subset U. However, $(\zeta_1,\zeta_2,\zeta_3)$ can serve as local coordinates beyond U,

$$\{(\zeta_1,\zeta_2,\zeta_3)|\ \zeta_1\geqslant 0,\zeta_3\geqslant 0\}. \tag{135}$$

The coordinates $(\zeta_1,\zeta_2,\zeta_3)$ work well in the orbit space $M/\mathrm{SO}(3)$ for describing singular configurations. In fact, we have collinear configurations if $\zeta_3=0$, and the configurations that two of three particles collide but the remainder is separate, if $\zeta_1=0$. If $\zeta_1=\zeta_2=\zeta_3=0$, we have a triple collision. With this interpretation, we are allowed to make ζ_3 tend to zero, for example.

From the definition (74) along with (134), the inertia tensor and its inverse at $\sigma(q)$ are put, respectively, in the form

$$(A_{ab})=\begin{pmatrix}\zeta_1^2+\zeta_2^2 & 0 & -\zeta_2\zeta_3\\ 0 & \zeta_1^2+\zeta_2^2+\zeta_3^2 & 0\\ -\zeta_2\zeta_3 & 0 & \zeta_3^2\end{pmatrix}, \tag{136}$$

$$(A^{ab})=\begin{pmatrix}\dfrac{1}{\zeta_1^2} & 0 & \dfrac{\zeta_2}{\zeta_1^2\zeta_3}\\ 0 & \dfrac{1}{\zeta_1^2+\zeta_2^2+\zeta_3^2} & 0\\ \dfrac{\zeta_2}{\zeta_1^2\zeta_3} & 0 & \dfrac{\zeta_1^2+\zeta_2^2}{\zeta_1^2\zeta_3^2}\end{pmatrix}. \tag{137}$$

From (45), (134), and (137), the connection form proves to be expressed as

$$\omega_{\sigma(q)}=\frac{\zeta_2d\zeta_3-\zeta_3d\zeta_2}{\zeta_1^2+\zeta_2^2+\zeta_3^2}R(\mathbf{e}_2). \tag{138}$$

From (51) together with (138), the horizontal lifts of $\partial/\partial\zeta_\alpha$ are given by

$$\left(\frac{\partial}{\partial\zeta_1}\right)^* = \frac{\partial}{\partial\zeta_1},$$

$$\left(\frac{\partial}{\partial\zeta_2}\right)^* = \frac{\partial}{\partial\zeta_2} + \frac{\zeta_3}{\zeta_1^2+\zeta_2^2+\zeta_3^2}K_2, \tag{139}$$

$$\left(\frac{\partial}{\partial\zeta_3}\right)^* = \frac{\partial}{\partial\zeta_3} - \frac{\zeta_2}{\zeta_1^2+\zeta_2^2+\zeta_3^2}K_2.$$

From (73) and (139), the metric tensor and its inverse are calculated, respectively, as

$$(a_{\alpha\beta}) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \dfrac{\zeta_1^2+\zeta_2^2}{\zeta_1^2+\zeta_2^2+\zeta_3^2} & \dfrac{\zeta_2\zeta_3}{\zeta_1^2+\zeta_2^2+\zeta_3^2} \\ 0 & \dfrac{\zeta_2\zeta_3}{\zeta_1^2+\zeta_2^2+\zeta_3^2} & \dfrac{\zeta_1^2+\zeta_3^2}{\zeta_1^2+\zeta_2^2+\zeta_3^2} \end{pmatrix}, \tag{140}$$

$$(a^{\alpha\beta}) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \dfrac{\zeta_1^2+\zeta_3^2}{\zeta_1^2} & -\dfrac{\zeta_2\zeta_3}{\zeta_1^2} \\ 0 & -\dfrac{\zeta_2\zeta_3}{\zeta_1^2} & \dfrac{\zeta_1^2+\zeta_2^2}{\zeta_1^2} \end{pmatrix}. \tag{141}$$

Further, the volume density $\rho(q)$ given in (104) is expressed as

$$\rho(q) = \zeta_1^2\zeta_3. \tag{142}$$

Thus we have obtained all the quantities needed for expressing the rotational and the vibrational energy operators given by (108) and (109), respectively. The resultant expression looks singular at the singular configurations, i.e., at the triple collision, $\zeta_1=\zeta_2=\zeta_3=0$, and at the collinear configuration, $\zeta_1=0$ or $\zeta_3=0$.

To investigate how singular the operators are at singular configurations, we treat the rotational and the vibrational energy integrals in detail. The vibrational energy integral for the three-body system is expressed as

$$T_{\text{vib}} = \frac{1}{2}\int_M \left(\left(\left|\frac{\partial f}{\partial\zeta_1}\right|^2 + \frac{\zeta_1^2+\zeta_3^2}{\zeta_1^2}\left|\left(\frac{\partial}{\partial\zeta_2}\right)^* f\right|^2 + \frac{\zeta_1^2+\zeta_2^2}{\zeta_1^2}\left|\left(\frac{\partial}{\partial\zeta_3}\right)^* f\right|^2 - \frac{\zeta_2\zeta_3}{\zeta_1^2}\left(\overline{\left(\frac{\partial}{\partial\zeta_2}\right)^* f}\left(\frac{\partial}{\partial\zeta_3}\right)^* f \right.\right.\right.$$
$$\left.\left.\left. + \overline{\left(\frac{\partial}{\partial\zeta_3}\right)^* f}\left(\frac{\partial}{\partial\zeta_2}\right)^* f\right)\right)\zeta_1^2\zeta_3 d\zeta_1 d\zeta_2 d\zeta_3 d\mu(g). \tag{143}$$

From this along with (139), we can observe that the integral T_{vib} is not divergent at singular configurations. In fact, at a glance, we see that no singularity occurs at $\zeta_1=0$. Turning to the singular configuration given by $\zeta_1=\zeta_2=\zeta_3=0$, we pick up one of the terms in the integrand, say,

$$\frac{\zeta_1^2+\zeta_3^2}{\zeta_1^2}\left|\left(\frac{\partial}{\partial\zeta_2}\right)^* f\right|^2 = \frac{\zeta_1^2+\zeta_3^2}{\zeta_1^2}\left(\left|\frac{\partial f}{\partial\zeta_2}\right|^2 + \frac{\zeta_3}{\zeta_1^2+\zeta_2^2+\zeta_3^2}\left(\overline{\frac{\partial f}{\partial\zeta_2}}K_2 f + \frac{\partial f}{\partial\zeta_2}\overline{K_2 f}\right) + \frac{\zeta_3^2|K_2 f|^2}{(\zeta_1^2+\zeta_2^2+\zeta_3^2)^2}\right). \tag{144}$$

If we take the spherical polar coordinates for $(\zeta_1,\zeta_2,\zeta_3)$ with the radial variable $r=\sqrt{\zeta_1^2+\zeta_2^2+\zeta_3^2}$, the volume element $dQ=\zeta_1^2\zeta_3 d\zeta_1 d\zeta_2 d\zeta_3$ is put in the form $dQ=r^5 dr d\nu$, where $d\nu$ denotes the area element induced on the quarter sphere given by $\zeta_1^2+\zeta_2^2+\zeta_3^2=1$, $\zeta_1\geqslant 0$, and $\zeta_3\geqslant 0$. Now it is easy to see that if f is smooth in a neighborhood of $r=0$, no divergence occurs at $r=0$ in the integral of the above term with respect to $r^5 dr d\nu$. For the other terms of the integrand, the same proof of non-divergence also runs well.

The rotational energy integral for the three-body system is expressed as

$$T_{\mathrm{rot}}=\frac{1}{2}\int_M\left(\frac{1}{\zeta_1^2}|K_1 f|^2+\frac{1}{\zeta_1^2+\zeta_2^2+\zeta_3^2}|K_2 f|^2+\frac{\zeta_1^2+\zeta_2^2}{\zeta_1^2\zeta_3^2}|K_3 f|^2+\frac{\zeta_2}{\zeta_1^2\zeta_3}(\overline{K_1 f}K_3 f+\overline{K_3 f}K_1 f)\right)$$
$$\times\zeta_1^2\zeta_3 d\zeta_1 d\zeta_2 d\zeta_3 d\mu(g). \tag{145}$$

It is clear that no divergence occurs at $\zeta_1=0$. We are now interested in the singularity at $\zeta_3=0$. Among the terms of the integrand of the right-hand side of (145), $[(\zeta_1^2+\zeta_2^2)/\zeta_1^2\zeta_3^2]|K_3 f|^2$ might cause the divergence of the integral at $\zeta_3=0$:

$$\int_M\frac{\zeta_1^2+\zeta_2^2}{\zeta_3}|K_3 f|^2 d\zeta_1 d\zeta_2 d\zeta_3 d\mu(g). \tag{146}$$

However, we can show that the integral (146) is not divergent on account of the boundary condition for the wave function f at $\zeta_3=0$. To this end, we may restrict M to $\pi^{-1}(U)$ and use the fact that if f is assumed to be analytic at $\zeta_3=0$, f can be expanded into a Fourier series, with respect to D-functions, of the form

$$f(g\sigma(q))=\sum_{\ell=0}^{\infty}\frac{2\ell+1}{4\pi}\sum_{|n|,|m|\leqslant\ell}D_{mn}^{\ell}(g)\zeta_3^{|n|}\sum_{j=0}^{\infty}\zeta_3^{2j}C_{nmj}(\zeta_1,\zeta_2). \tag{147}$$

We notice here that in Ref. 11 Mitchell and Littlejohn proved that the analyticity assumption for an equivariant function gives rise to a power series in ζ_3 with the exponents of the form $|n|+2j$. By the Fubini theorem, the integral (146) restricted on $\pi^{-1}(U)$ can be written as

$$\int_U d\zeta_1 d\zeta_2 d\zeta_3\frac{\zeta_1^2+\zeta_2^2}{\zeta_3}\int_{\mathrm{SO}(3)}|K_3 f|^2 d\mu(g). \tag{148}$$

Carrying out the integration over SO(3) along with (147), we obtain

$$\int_{\mathrm{SO}(3)}|K_3 f|^2 d\mu(g)=\frac{1}{2}\sum_{\ell=0}^{\infty}(2\ell+1)\sum_{|m|,|n|\leqslant\ell}n^2\zeta_3^{2|n|}F_{nm}(\zeta_1,\zeta_2,\zeta_3), \tag{149}$$

where

$$F_{nm}(\zeta_1,\zeta_2,\zeta_3):=\sum_{j,j'=0}^{\infty}\zeta_3^{2j+2j'}\overline{C_{nmj}}(\zeta_1,\zeta_2)C_{nmj'}(\zeta_1,\zeta_2), \tag{150}$$

and we have used the orthogonality of D-functions,

$$\int_{\mathrm{SO}(3)}\overline{D_{mn}^{\ell}(g)}D_{m'n'}^{\ell'}(g)d\mu(g)=\frac{8\pi^2}{2\ell+1}\delta_{\ell\ell'}\delta_{mm'}\delta_{nn'}, \tag{151}$$

and the fact that $K_3 D_{mn}^{\ell}(g)=-inD_{mn}^{\ell}(g)$. Hence, we obtain

$$\int_U d\zeta_1 d\zeta_2 d\zeta_3 \frac{\zeta_1^2+\zeta_2^2}{\zeta_3} \int_{\mathrm{SO}(3)} |K_3 f|^2 d\mu(g)$$

$$= \frac{1}{2} \sum_{\ell=0}^{\infty} (2\ell+1) \sum_{|m|,|n| \leq \ell} \int_U \frac{\zeta_1^2+\zeta_2^2}{\zeta_3} n^2 \zeta_3^{2|n|} F_{nm}(\zeta_1,\zeta_2,\zeta_3) d\zeta_1 d\zeta_2 d\zeta_3 . \tag{152}$$

From this, we observe that the integral (146) is not divergent at $\zeta_3=0$. We may weaken the analyticity assumption on wave functions at $\zeta_3=0$ to smoothness assumption to some extent.

We turn to the singularity at $\zeta_1=\zeta_2=\zeta_3=0$. In this case, we have to consider whether the integral

$$\int_{\pi^{-1}(U)} \left(\frac{\zeta_1^2\zeta_3}{\zeta_1^2+\zeta_2^2+\zeta_3^2} |K_2 f|^2 + \frac{\zeta_1^2+\zeta_2^2}{\zeta_3} |K_3 f|^2 \right) d\zeta_1 d\zeta_2 d\zeta_3 d\mu(g) \tag{153}$$

is divergent at $\zeta_1=\zeta_2=\zeta_3=0$ or not. In the spherical polar coordinates for $(\zeta_1,\zeta_2,\zeta_3)$, the three-form $d\zeta_1 d\zeta_2 d\zeta_3$ is expressed as $r^2 dr d\nu$. Hence the integral (153) is not divergent at $\zeta_1=\zeta_2=\zeta_3=0$, if f is smooth in the neighborhood of $r=0$. Thus we conclude that

Theorem 2: While the rotational and the vibrational energy operators look singular at singular configurations, the singularity is not essential in the sense that the rotational and the vibrational energy integrals are not divergent at singular configurations on account of the boundary behavior of wave functions there. The reduced kinetic energy operator looks singular as well, but the singularity is not essential in the same sense.

VII. COLLINEAR CONFIGURATIONS

In this section, we consider the space M_1 of collinear configurations. Though M_1 is a part of the boundary of $\dot{M}$, and the rotational and the vibrational energy operators defined on $\dot{M}$ have singularity at M_1, we will be able to define restricted rotational and vibrational energy operators for collinear configurations, if we restrict ourselves to M_1. The rotation group SO(3) does not act freely on M_1, but it has the isotropy subgroup which is isomorphic with SO(2), so that the orbit of SO(3) through $x \in M_1$ is identified with S^2; $\mathcal{O}_x \cong \mathrm{SO}(3)/\mathrm{SO}(2) \cong S^2$. We can decompose the tangent space to M_1 at $x \in M_1$ into a direct sum of vertical and horizontal subspaces; the vertical subspace $V_x^{(1)}$ is defined to be the tangent space to the orbit $\mathcal{O}_x$ through $x \in M_1$, and the horizontal subspace $H_x^{(1)}$ to be the orthogonal complement of $V_x^{(1)}$:

$$T_x(M_1) = V_x^{(1)} \oplus H_x^{(1)}, \quad V_x^{(1)} := T_x(\mathcal{O}_x), \quad H_x^{(1)} := (V_x^{(1)})^{\perp}, \tag{154}$$

where the metric with respect to which the orthogonality is referred is induced on M_1 from that on the center-of-mass system M.

We are to express basis vectors in $V_x^{(1)}$ in terms of local coordinates. To this end, we recall here the formula (62) which holds for singular configurations as well. However, in the present case, we must take the $\sigma(q)$ as a local section in M_1: $\sigma_0 : U^{(1)} \subset M_1/S^2 \to M_1$. The formula (62) restricted to $x \in M_1$ implies that K_a are tangent vectors in $V_x^{(1)}$. To find an explicit local expression of K_a, we take the section σ_0 to be

$$\sigma_0(q) = (\xi_1 \mathbf{e}_3, \ldots, \xi_{N-1} \mathbf{e}_3), \quad q \in U^{(1)}, \tag{155}$$

where ξ_j are local coordinates in $U^{(1)}$. Then a generic point $x \in \pi^{-1}(U^{(1)})$ is expressed as

$$x = g\sigma_0(q) = (\xi_1 g\mathbf{e}_3, \ldots, \xi_{N-1} g\mathbf{e}_3), \quad g \in \mathrm{SO}(3). \tag{156}$$

We put g in the form $g = e^{\phi R(\mathbf{e}_3)} e^{\theta R(\mathbf{e}_2)} e^{\psi R(\mathbf{e}_3)}$. Then the point x is assigned by the local coordinates $(\theta, \phi, \xi_1, \ldots, \xi_{N-1})$, ψ being eliminated on account of $e^{\psi R(\mathbf{e}_3)} \mathbf{e}_3 = \mathbf{e}_3$. Hence we may take the matrix g as $e^{\phi R(\mathbf{e}_3)} e^{\theta R(\mathbf{e}_2)}$.

We first deal with K_1. Using the formula (62) restricted to M_1, one has

$$K_1=\frac{d}{dt}ge^{tR(\mathbf{e}_1)}\sigma_0(q)\bigg|_{t=0}=-(\xi_j g\mathbf{e}_2)=-(\xi_j(-\sin\phi\,\mathbf{e}_1+\cos\phi\,\mathbf{e}_2)). \tag{157}$$

On the other hand, the curve $x(t)=ge^{tR(\mathbf{e}_1)}\sigma_0(q)$ is put, in terms of (θ,ϕ,ξ_j), in the form

$$x(t)=(\xi_j(\sin\theta\cos\phi\,\mathbf{e}_1+\sin\theta\sin\phi\,\mathbf{e}_2+\cos\theta\,\mathbf{e}_3)), \tag{158}$$

where θ and ϕ are viewed as functions of t. Differentiating this with respect to t at $t=0$, and setting the resultant tangent vector equal to K_1 given by (157), we find that

$$K_1^{(1)}=\frac{-1}{\sin\theta}\frac{\partial}{\partial\phi}, \tag{159}$$

where the superscript $^{(1)}$ indicates that the vector field $K_1^{(1)}$ is defined on M_1. In the same manner as above, we have

$$K_2^{(1)}=\frac{\partial}{\partial\theta}. \tag{160}$$

For K_3, we can easily find that

$$K_3^{(1)}=\frac{d}{dt}ge^{tR(\mathbf{e}_3)}\sigma_0(q)\bigg|_{t=0}=0. \tag{161}$$

The vector fields $K_1^{(1)}$ and $K_2^{(1)}$ form a local basis of vertical vector fields on M_1. We have observed, in the course of the above calculation, that $K_1^{(1)}$ and $K_2^{(2)}$ can also be expressed as

$$K_1^{(1)}=-\sum_{j=1}^{N-1}\xi_j\mathbf{u}_2\cdot\frac{\partial}{\partial\mathbf{r}_j},\quad K_2^{(1)}=\sum_{j=1}^{N-1}\xi_j\mathbf{u}_1\cdot\frac{\partial}{\partial\mathbf{r}_j}, \tag{162}$$

respectively.

We proceed to find a local basis in $H_x^{(1)}$. The local vector fields $\partial/\partial\xi_j$ can be put in the form

$$\frac{\partial}{\partial\xi_j}=\sum_{i=1}^{N-1}\frac{\partial\mathbf{r}_i}{\partial\xi_j}\cdot\frac{\partial}{\partial\mathbf{r}_i}=\mathbf{u}_3\cdot\frac{\partial}{\partial\mathbf{r}_j}. \tag{163}$$

From (162) and (163), it follows that $\partial/\partial\xi_j$ are orthogonal to $K_1^{(1)}, K_2^{(1)}$;

$$ds^2(K_a^{(1)},\partial/\partial\xi_j)=0,\quad a=1,2,\quad j=1,\ldots,N-1. \tag{164}$$

This implies that $\partial/\partial\xi_j$, $j=1,\ldots,N-1$, form a local basis of horizontal vector fields. The inner product among these basis vector fields are given by

$$ds^2(K_a^{(1)},K_b^{(1)})=\sum_{j=1}^{N-1}\xi_j^2\delta_{ab},\quad a,b=1,2, \tag{165}$$

$$ds^2(\partial/\partial\xi_i,\partial/\partial\xi_j)=\delta_{ij},\quad i,j=1,\ldots,N-1. \tag{166}$$

It is easy to see that the basis of one-forms dual to $K_a^{(1)}$ and $\partial/\partial\xi_j$ are given by

$$-\sin\theta\,d\phi,\quad d\theta,\quad d\xi_1,\ldots,d\xi_{N-1}, \tag{167}$$

of which the first two are vertical and the remainder horizontal. From (165)–(167), the induced metric on M_1 proves to be expressed as

$$ds^{2(1)}=\sum_{j=1}^{N-1}\xi_j^2(d\theta^2+\sin^2\theta\, d\phi^2)+\sum_{j=1}^{N-1}d\xi_j^2. \tag{168}$$

The volume element on M_1 is then given by

$$dV^{(1)}=dQ^{(1)}\wedge dS, \tag{169}$$

where

$$dQ^{(1)}=\rho_1(\xi)d\xi_1\wedge\cdots\wedge d\xi_{N-1},\quad \rho_1(\xi)\coloneqq\sum_{j=1}^{N-1}\xi_j^2, \tag{170}$$

$$dS=\sin\theta\, d\theta\wedge d\phi. \tag{171}$$

As was already mentioned in Sec. IV, the inertia tensor A_x is singular at $x\in M_1$. However, to study collinear configurations, we have to know to what extent the A_x is singular at $x\in M_1$. For $x=(\mathbf{r}_1,\ldots,\mathbf{r}_{N-1})\in M_1$, one has $\operatorname{rank}x=1$. Hence we can express Jacobi vectors as $\mathbf{r}_j=\lambda_j\mathbf{a}$, where $\lambda_j\in\mathbf{R}$ and $\mathbf{a}\neq 0$. Then for $\mathbf{v}$, the inertia tensor takes the value

$$A_x(\mathbf{v})=\sum_{j=1}^{N-1}\lambda_j^2(|\mathbf{a}|^2\mathbf{v}-(\mathbf{a}\cdot\mathbf{v})\mathbf{a}). \tag{172}$$

Suppose now that $\mathbf{v}\in\ker A_x$. Then one has $\mathbf{v}=(\mathbf{a}\cdot\mathbf{v})\mathbf{a}/|\mathbf{a}|^2$, which means that

$$\ker A_x=\operatorname{span}\{\mathbf{a}\},\quad x\in M_1. \tag{173}$$

In contrast with this, for any vector $\mathbf{u}\in\operatorname{span}\{\mathbf{a}\}^{\perp}$, one has

$$A_x(\mathbf{u})=\sum_{j-1}^{N-1}\lambda_j^2|\mathbf{a}|^2\mathbf{u}, \tag{174}$$

which implies that $\operatorname{span}\{\mathbf{a}\}^{\perp}$ is the eigenspace associated with the multiple eigenvalue $\Sigma_{j=1}^{N-1}\lambda_j^2|\mathbf{a}|^2=\Sigma_{j=1}^{N-1}|\mathbf{r}_j|^2$.

If we take $\mathbf{a}=g\mathbf{e}_3=\mathbf{u}_3$ and set $\lambda_j=\xi_j$, and if we restrict the domain of A_x to the subspace $\operatorname{span}\{\mathbf{u}_1,\mathbf{u}_2\}=\operatorname{span}\{\mathbf{u}_3\}^{\perp}$, the restricted A_x becomes invertible:

$$(A_x^{(1)})^{-1}(\mathbf{u}_a)=\left(\sum_{j=1}^{N-1}\xi_j^2\right)^{-1}\mathbf{u}_a,\quad x\in M_1,\quad a=1,2. \tag{175}$$

The connection form (36) fails to be defined for $x\in M_1$, as is easily seen. However, taking (175) into account, we may define a restricted connection form. We recall here that we have obtained the decomposition (154), which allows the interpretation that M_1 admits a "singular" connection, since (154) may be viewed as an analog to the decomposition (37). We now look into the connection form associated with the decomposition (154). By using the local coordinates given in (156), we obtain

$$\mathbf{r}_j\times d\mathbf{r}_j=\xi_j^2(\Psi^{1(1)}\mathbf{u}_1+\Psi^{2(1)}\mathbf{u}_2), \tag{176}$$

where $\Psi^{a(1)}$ are given by

$$\Psi^{1(1)}=-\sin\theta\, d\phi,\quad \Psi^{2(1)}=d\theta. \tag{177}$$

Note that $\Psi^{a(1)}$ are the reduced form of Ψ^a given in (64). Thus the total angular momentum is put in the form

$$\sum_{j=1}^{N-1} \mathbf{r}_j \times d\mathbf{r}_j = \sum_{j=1}^{N-1} \xi_j^2 (\Psi^{1(1)}\mathbf{u}_1 + \Psi^{2(1)}\mathbf{u}_2). \tag{178}$$

Since this vector is in the space span$\{\mathbf{u}_1, \mathbf{u}_2\}$, we can apply the restricted inverse operator $(A_x^{(1)})^{-1}$ to (178) to obtain a one-form,

$$\omega^{(1)} := R\left((A_x^{(1)})^{-1} \left(\sum_{j=1}^{N-1} \mathbf{r}_j \times d\mathbf{r}_j \right) \right) = \Psi^{1(1)} R(\mathbf{u}_1) + \Psi^{2(1)} R(\mathbf{u}_2). \tag{179}$$

For horizontal and vertical vectors on M_1, the form $\omega^{(1)}$ takes values as follows:

$$\omega^{(1)}(\partial/\partial\xi_j) = 0, \quad j = 1,\ldots,N-1, \tag{180}$$

$$\omega^{(1)}(K_a^{(1)}) = R(\mathbf{u}_a), \quad a = 1,2. \tag{181}$$

Since these equations are in keeping with the decomposition (154), we may call the form $\omega^{(1)}$ a (singular) connection form on M_1. Since $\partial/\partial\xi_i$ form a basis of the horizontal subspace $V_x^{(1)}$ and since $[\partial/\partial\xi_j, \partial/\partial\xi_i] = 0$, the curvature of the connection $\omega^{(1)}$ vanishes.

In conclusion of this section, we show that

$$M_1/S^2 \cong \mathbf{R}_+ \times \mathbf{R}P^{N-2}, \tag{182}$$

where $\mathbf{R}_+ = \{r \in \mathbf{R} \mid r > 0\}$ and $\mathbf{R}P^{N-2}$ denotes the real projective space of dimension $N-2$. Since $x \in M_1$ is of rank 1, we can describe x as $x = (\xi_1\mathbf{u}, \ldots \xi_{N-1}\mathbf{u})$ with $|\mathbf{u}| = 1$ and $(\xi_1, \ldots, \xi_{N-1}) \neq 0$. If $(\xi_1\mathbf{u}, \ldots, \xi_{N-1}\mathbf{u})$ and $(\eta_1\mathbf{v}, \ldots, \eta_{N-1}\mathbf{v})$ are equivalent under the SO(3) action, we have $\eta_k\mathbf{v} = \xi_k g\mathbf{u}$, $k = 1,\ldots,N-1$, for some $g \in \mathrm{SO}(3)$. This implies that $|\eta_k| = |\xi_k|$, hence $\eta_k = \pm\xi_k$, and further the choice of sign should be independent of k. Conversely, if $\eta_k = \pm\xi_k$, then there exist $g \in \mathrm{SO}(3)$ such that $(\eta_1\mathbf{v}, \ldots, \eta_{N-1}\mathbf{v}) = g(\xi_1\mathbf{u}, \ldots, \xi_{N-1}\mathbf{u})$. This is because one has $-\mathbf{u} = e^{\pi R(\mathbf{w})}\mathbf{u}$ for a vector $\mathbf{w}$ such that $\mathbf{w} \perp \mathbf{u}$. It then follows that the map

$$\dot{\mathbf{R}}^{N-1} := \mathbf{R}^{N-1} - \{0\} \to M_1/S^2; \quad (\xi_1, \ldots, \xi_{N-1}) \mapsto [(\xi_1\mathbf{u}, \ldots, \xi_{N-1}\mathbf{u})], \tag{183}$$

where $[(\cdots)]$ denotes the equivalence class, is two-to-one, that is, $\pm(\xi_1, \ldots, \xi_{N-1})$ maps to the same point of M_1/S^2. This results in

$$\dot{\mathbf{R}}^{N-1}/\mathbf{Z}_2 \cong M_1/S^2, \tag{184}$$

where $\mathbf{Z}_2$ acts on $\dot{\mathbf{R}}^{N-1}$ by $(\xi_k) \mapsto \pm(\xi_k)$. Since $\dot{\mathbf{R}}^{N-1} \cong \mathbf{R}_+ \times S^{N-2}$, one obtains

$$M_1/S^2 \cong \mathbf{R}_+ \times S^{N-2}/\mathbf{Z}_2 \cong \mathbf{R}_+ \times \mathbf{R}P^{N-2}. \tag{185}$$

In Ref. 12, they showed that the orbit of the shape, $\pi(x)$, of a collinear configuration $x \in M_1$ by the action of the kinetic group $\mathrm{O}(N-1)$ on $M/\mathrm{SO}(3)$ to the right is diffeomorphic with $\mathbf{R}P^{N-2}$.

VIII. KINETIC ENERGY OPERATOR FOR COLLINEAR CONFIGURATIONS

In the same manner as that used to obtain the kinetic energy operator Δ for nonsingular configurations, we can obtain the kinetic energy operator for singular configurations. From (168), it follows that the kinetic energy integral for collinear configurations is given by

$$\frac{1}{2}\int_{M_1}\left(\frac{1}{\rho_1(\xi)}\left(\left|\frac{\partial f}{\partial\theta}\right|^2+\frac{1}{\sin^2\theta}\left|\frac{\partial f}{\partial\phi}\right|^2\right)+\sum_{j=1}^{N-1}\left|\frac{\partial f}{\partial\xi_j}\right|^2\right)dV^{(1)}, \tag{186}$$

where $dV^{(1)}$ is the volume element given in (169). Integrated by part, this integral is expressed as

$$-\frac{1}{2}\int_{M_1}\overline{f}\left(\frac{1}{\rho_1(\xi)}\left(\frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial f}{\partial\theta}\right)+\frac{1}{\sin^2\theta}\frac{\partial^2 f}{\partial\phi^2}\right)+\frac{1}{\rho_1(\xi)}\sum_{j=1}^{N-1}\frac{\partial}{\partial\xi_j}\left(\rho_1(\xi)\frac{\partial f}{\partial\xi_j}\right)\right)dV^{(1)}. \tag{187}$$

Thus we obtain the kinetic energy operator $-\frac{1}{2}\Delta^{(1)}$ with the Laplacian $\Delta^{(1)}$ on M_1,

$$\Delta^{(1)}=\frac{1}{\rho_1(\xi)}\Lambda+\frac{1}{\rho_1(\xi)}\sum_{j=1}^{N-1}\frac{\partial}{\partial\xi_j}\left(\rho_1(\xi)\frac{\partial}{\partial\xi_j}\right), \tag{188}$$

where Λ is the spherical Laplacian on S^2,

$$\Lambda=\frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial}{\partial\theta}\right)+\frac{1}{\sin^2\theta}\frac{\partial^2}{\partial\phi^2}. \tag{189}$$

The first and second terms on the right-hand side of (188) are a rotational and a vibrational operator, respectively.

The operator $\Delta^{(1)}$ has singularity at multiple collision for which $\rho_1(\xi)=0$. However, it is clear that the energy integral (186) is not divergent at the multiple collision $\xi_j=0$. Note also that the spherical Laplacian Λ has no singularity at $\theta=0,\pi$, as is well known.

We proceed to show that the Laplacian $\Delta^{(1)}$ will reduce to an operator acting on the wave functions of variables (ξ_j). For $x=\sigma_0(q)$ and $h=e^{tR(\mathbf{e}_3)}$, the equivariance condition (33) specializes to

$$(E^\ell_m f)(\sigma_0(q))=(E^\ell_m f)(e^{tR(\mathbf{e}_3)}\sigma_0(q))=D^\ell(e^{tR(\mathbf{e}_3)})(E^\ell_m f)(\sigma_0(q)). \tag{190}$$

Since

$$D^\ell(e^{tR(\mathbf{e}_3)})=\mathrm{diag}(e^{-i\ell t},\ldots,e^{-it},0,e^{it},\ldots,e^{i\ell t}), \tag{191}$$

the above condition implies that the $\mathcal{H}^\ell$-valued function $(E^\ell_m f)(\sigma_0(q))$ has only one non-zero component $(P^\ell_{0m}f)(\sigma(q))/\sqrt{2\ell+1}$, and hence the $\mathcal{H}^\ell$-valued function $(E^\ell_m f)(g\sigma_0(q))=D^\ell(g)(E^\ell_m f)(\sigma_0(q))$ has the nth ($|n|\leqslant\ell$) component expressed as

$$\frac{1}{\sqrt{2\ell+1}}D^\ell_{n0}(g)(P^\ell_{0m}f)(\sigma_0(q))=\sqrt{4\pi}\ \overline{Y_{\ell n}(g\mathbf{e}_3)}(P^\ell_{0m}f)(\sigma_0(q)), \tag{192}$$

where $Y_{\ell n}$ are the spherical harmonics and $g\mathbf{e}_3$ denotes a point of the unit sphere S^2, which are designated by the variables (θ,ϕ).

Operating on (192) with the Laplacian $\Delta^{(1)}$, we obtain (up to the factor $\sqrt{4\pi}$)

$$\Delta^{(1)}\overline{Y_{\ell n}(g\mathbf{e}_3)}(P^\ell_{0m}f)(\sigma_0(q))=\overline{Y_{\ell n}(g\mathbf{e}_3)}\left(-\frac{\ell(\ell+1)}{\rho_1(\xi)}+\frac{1}{\rho_1(\xi)}\sum_{j=1}^{N-1}\frac{\partial}{\partial\xi_j}\left(\rho_1(\xi)\frac{\partial}{\partial\xi_j}\right)\right)\times(P^\ell_{0m}f)(\sigma_0(q)). \tag{193}$$

Thus we find an operator acting on functions $(P^\ell_{0m}f)(\sigma_0(q))$,

$$\Delta^{(1)\mathrm{red}} := \frac{1}{\rho_1(\xi)} \sum_{j=1}^{N-1} \frac{\partial}{\partial \xi_j} \left(\rho_1(\xi) \frac{\partial}{\partial \xi_j} \right) - \frac{\ell(\ell+1)}{\rho_1(\xi)}. \tag{194}$$

We have to note here that this reduced operator is globally expressed on the orbit space M_1/S^2 on account of (184). In fact, the operator (194) is expressed in terms of $(\xi_1,\ldots,\xi_{N-1}) \in \dot{\mathbf{R}}^{N-1}$ and invariant under the inversion $(\xi_k) \mapsto -(\xi_k)$. Thus we have the following.

Theorem 3: For collinear configurations, the reduced kinetic energy operator $-\frac{1}{2}\Delta^{(1)\mathrm{red}}$ on M_1/S^2 is given by (194). It looks singular at the multiple collision configuration $(\xi_j=0)$, but the singularity is not essential in the sense that the kinetic energy integral is not divergent at the multiple collision.

We note that the Hamiltonian operator for linear molecules was already discussed in an elementary manner.[13] The method taken in this article to derive the kinetic energy operator is quite different from that in Ref. 13. Ours is clear and natural from the viewpoint of differential geometry.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 10 OCTOBER 2003

Dense Dirac combs in Euclidean space with pure point diffraction

Christoph Richard
Institut für Mathematik, Universität Greifswald, Jahnstr. 15a, 17487 Greifswald, Germany

(Received 7 February 2003; accepted 9 July 2003)

Regular model sets, describing the point positions of ideal quasicrystallographic tilings, are mathematical models of quasicrystals. An important result in mathematical diffraction theory of regular model sets, which are defined on locally compact Abelian groups, is the pure pointedness of the diffraction spectrum. We derive an extension of this result, valid for dense point sets in Euclidean space, which is motivated by the study of quasicrystallographic random tilings. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1609032]

I. INTRODUCTION

An important question in mathematical diffraction theory concerns the problem of which distributions of matter diffract [Bombieri and Taylor (1986)]. By now, there are only partial answers to this question which go beyond the crystallographic case. A mathematical idealization of the set of atomic positions of a piece of matter are Delone sets [Lagarias (2000)]. A subset Λ of $\mathbb{R}^d$ is called a *Delone* set if it is uniformly discrete and relatively dense. This means that there are radii $r,R>0$ such that each ball of radius r (respectively, R) contains at most (respectively, at least) one point of Λ. This class, however, is too general to obtain specific results about spectral properties. It includes, for example, ordered structures such as crystals, as well as structures with disorder, and also amorphous systems.

A special class of Delone sets are model sets [see, for example, Moody (1997)], which arise from a cut-and-project scheme. We will repeat their precise definition below. Model sets have strong regularity properties such as uniform point densities. They are mathematical abstractions of ideal quasicrystals, whose diffraction spectrum is experimentally known to consist of Bragg peaks only. By now, the study of model sets is a rather well developing subject, and their diffraction properties are well understood [Hof (1995), Hof (1998), Schlottmann (1998), Schlottmann (2000)]. The most general description is in terms of measures on locally compact Abelian groups, in generalization of Euclidean space [Schlottmann (1998)]. It is known that regular model sets are pure point diffractive. A first proof of this fact was given by Hof (1998) and, in a more general setup, by Schlottmann (1998), where they used a dynamical systems approach together with an argument due to Dworkin (1993). Recently, an alternative proof has been given by Baake and Moody (2002), who considered Delone sets with certain additional properties, which include model sets. For these sets, they explicitly constructed a cut-and-project scheme and were able to prove the pure pointedness of the diffraction spectrum directly. As they showed, their results have a natural interpretation in terms of the theory of almost periodic measures [Gil de Lamadrid and Argabright (1990)]. An important assumption of the approach is the (uniform) discreteness of the point set Λ, arising from the physical motivation.

In this paper, we will show that the diffraction result for regular model sets remains valid for certain dense point sets in Euclidean space, which appropriately generalize model sets. These point sets are not a mathematical curiosity but admit an interpretation in terms of averaged structures derived from *random tilings* with quasicrystallographic symmetries [Henley (1999), Richard *et al.* (1998), Richard (1999)]: Soon after the discovery of quasicrystals, it became clear that there are two competing models for the description of their unusual diffraction properties, namely the ideal tiling model and the random tiling model. Whereas the ideal tiling model (i.e., a

model set) leads to a diffraction spectrum consisting of Bragg peaks only, in the random tiling model a continuous background in addition to Bragg peaks was expected, as has been argued by Henley (1999). There is at present no rigorous treatment of diffraction properties of quasicrystallographic random tilings in $d>1$, apart from the comparatively simple situation of disorder arising from independent random variables [Baake and Moody (1998)] and the investigation Külske (2001). For rigorous results about diffraction of crystallographic random tilings in $d=2$ and random tilings in $d=1$, see Baake and Höffe (2000), Höffe and Baake (2000). The derivation of Henley's prediction rests on nonrigorous arguments and uses an averaged point distribution, which can be regarded as a generalized model set, being dense in Euclidean space. This distribution was assumed to exist in dimensions $d>2$ [Henley (1999)]. In the following, we give a rigorous exposition of a main part of this approach, which is, on the other hand, a generalization of the cut-and-project scheme for regular model sets to dense point sets [see also Höffe (2001), which introduces the setup used in this paper, and the review article Baake *et al.* (2003), where the diffraction formula of Theorem 10 is cited]. After recollecting the basic terminology and central theorems of diffraction theory of regular model sets in Sec. II, we will define generalized model sets in Sec. III and show that they are pure point diffractive. This leads to a generalization of Poisson's summation formula to certain dense point sets. Section IV will apply the results within Henley's framework for the description of diffraction properties of quasicrystallographic random tilings. A discussion of open questions and possible future work concludes the paper.

II. DIFFRACTION OF WEIGHTED REGULAR MODEL SETS

In this section, we recollect and extend results from diffraction theory of weighted regular model sets, which we shall generalize in the following section to the setup of a dense Dirac comb.

Throughout the paper, we consider the situation of a *cut-and-project scheme* [Moody (1997)] with a Euclidean space $\mathbb{R}^d$ and a Euclidean space $\mathbb{R}^m$, called *direct* space and *internal space*.

Let $\tilde{L}\subset\mathbb{R}^d\times\mathbb{R}^m$ be a lattice and denote the volume of its fundamental domain by $|\det(\tilde{L})|$. If π_1 and π_2 are the natural (orthogonal) projections of $\mathbb{R}^d\times\mathbb{R}^m$ onto $\mathbb{R}^d$ and $\mathbb{R}^m$, respectively, then $\pi_1|_{\tilde{L}}$ is assumed to be one-to-one and $\pi_2(\tilde{L})$ is assumed to be dense. Set $L=\pi_1(\tilde{L})$ and let $(\,)^\star: L\to\pi_2(\tilde{L})$ denote the mapping $\pi_2\circ(\pi_1|_{\tilde{L}})^{-1}$, also called the *star-map*. This is summarized in the following diagram:

$$\begin{array}{ccccc} & \pi_1 & & \pi_2 & \\ \mathbb{R}^d & \leftarrow & \mathbb{R}^d\times\mathbb{R}^m & \rightarrow & \mathbb{R}^m \\ \cup & {\scriptstyle 1-1}\nwarrow & \cup & \nearrow_{\text{dense}} & \\ L & & \tilde{L}=\{(x,x^\star)\,|\,x\in L\} & & \end{array} \tag{1}$$

For an open and relatively compact subset $W\subset\mathbb{R}^m$, also called *window*, define the *model set* $\Lambda(W)$ by

$$\Lambda(W):=\{x\in L\mid x^\star\in W\}. \tag{2}$$

Denote the volume of W by $\mathrm{vol}(W)$. Model sets are Delone sets, i.e., they are both uniformly discrete and relatively dense [Moody (1997), Schlottmann (1998)]. The model set $\Lambda(W)$ is called *regular* if $\varnothing\neq W=\overline{\mathrm{int}(W)}$ is compact and if ∂W has zero Lebesgue measure.

Associated with the lattice $\tilde{L}$ is its dual lattice $(\tilde{L})^*$, defined via

$$(\tilde{L})^*=\{y\in\mathbb{R}^d\times\mathbb{R}^m\mid y\cdot x\in\mathbb{Z}\ \text{ for all }\ x\in L\}. \tag{3}$$

Denote its image in $\mathbb{R}^d$ by $L^*=\pi_1((\tilde{L})^*)$. A remarkable property of cut-and-project schemes is duality [Moody (1997), p. 418]. We can dualize the given cut-and-project scheme to obtain a cut-and-project scheme for the dual lattice. By identifying direct and internal space with their

corresponding duals, we can see that the projection π_1, restricted to the dual lattice $(\widetilde{L})^*$, is one-to-one, and that the dual lattice has dense image $\pi_2((\widetilde{L})^*)$ in $\mathbb{R}^m$. The corresponding star-map is defined on the set L^*. We denote it by $(\,)^\star$ again.

Regular model sets have a well-defined density. Throughout the paper, we will consider infinite volume limits to be taken on sequences of balls. Existence of these limits may however be derived for more general van Hove sequences, see Schlottmann (2000) for the example of the density formula. Let $B_n(a)$ denote the closed ball of radius n centered at $a\in\mathbb{R}^d$. We set $B_n = B_n(0)$.

Theorem 1: [Density formula (Schlottmann, 1998)] *Let $\Lambda(W)$ be a regular model set. Then*

$$\lim_{r\to\infty}\frac{1}{\mathrm{vol}(B_r(0))}\left(\sum_{x\in\Lambda(W+u)\cap B_r(a)} 1\right)=\frac{\mathrm{vol}(W)}{|\det(\widetilde{L})|},$$

uniformly in a and in u. □

This result may be used to consider sums over weighted regular model sets. Consider first the situation where the weight of a point $x\in\Lambda(W)$ only depends on x.

Lemma 1: Let $\Lambda(W)$ be a regular model set, $f:\mathbb{R}^d\to\mathbb{C}$ bounded and $|x|^{d+1+\alpha}|f(x)|\leqslant C$ for some constants $C>0$ and $\alpha>0$. Then, for $a\in\mathbb{R}^d$ and $u\in\mathbb{R}^m$, the sums

$$s(u,a):=\sum_{x\in\Lambda(W+u)+a} f(x)$$

are absolutely convergent. Moreover, they are uniformly bounded in u and in a, the bound being proportional to $\mathrm{vol}(W)$.

Proof: For $R\in\mathbb{N}$, consider the sums

$$s_<(u,a,R):=\sum_{\substack{x\in\Lambda(W+u)+a\\ |x|<R}}|f(x)|,\quad s_\geqslant(u,a,R):=\sum_{\substack{x\in\Lambda(W+u)+a\\ |x|\geqslant R}}|f(x)|.$$

In the density formula, the sequence on the left-hand side is certainly bounded by twice its limit for almost all r. This implies for the number of points within a ball of radius n,

$$|(\Lambda(W+u)+a)\cap B_n(0)|=|\Lambda(W+u)\cap B_n(-a)|\leqslant c\,\mathrm{vol}(W)\,n^d\quad (n>n_0(W)),$$

uniformly in u and in a, where $c=2S_d/|\det(\widetilde{L})|$, and $S_d\subset\mathbb{R}^d$ denotes the volume of the unit ball. The number $n_0(W)$ is increasing with decreasing volume of W. Together with f bounded, the above estimate implies that $s_<(u,a,R)$ is uniformly bounded in u and in a with a number proportional to $\mathrm{vol}(W)$. We derive a uniform bound on $s_\geqslant(u,a,R)$. By assumption, we have $|x|^{d+1+\alpha}|f(x)|\leqslant C$. Define $g_n:=\Sigma_{n\leqslant|x|<n+1}|f(x)|$ and estimate g_n by

$$g_n\leqslant|(\Lambda(W+u)+a)\cap B_{n+1}(0)|\,\frac{C}{n^{d+1+\alpha}}\leqslant c\,\mathrm{vol}(W)(n+1)^d\frac{C}{n^{d+1+\alpha}}\leqslant\frac{2c\,C\,\mathrm{vol}(W)}{n^{1+\alpha}}\qquad(4)$$

for $n>n_1(W)$. Thus for $R>n_1(W)$,

$$|s_\geqslant(u,a,R)|\leqslant\sum_{n\geqslant R}g_n\leqslant 2c\,C\,\mathrm{vol}(W)\sum_{n=R}^{\infty}\frac{1}{n^{1+\alpha}}<\infty,\qquad(5)$$

since by assumption $\alpha>0$. The bound is independent of u and of a. Note that we have $\lim_{R\to\infty}s_\geqslant(u,a,R)=0$.

Remark: The above sums $s(u,a)$ are absolutely convergent and bounded uniformly in u and in a under the milder assumption $|x|^{d+\alpha}|f(x)|\leqslant C$ for some constants $C>0$ and $\alpha>0$. This follows already from the uniform discreteness of $\Lambda(W)$ by a standard estimation. The additional

property that there exists a bound proportional to $\mathrm{vol}(W)$, which we will use extensively below, is a result of the density formula. It would be interesting to consider whether the assumptions on f in the above lemma may be weakened, since the estimation in Eq. (4) seems rather crude.

Consider now the situation where the weight of a point $x \in \Lambda(W)$ depends only on its internal coordinate $x^\star$. This leads to Weyl's theorem on uniform distribution in the context of regular model sets [Kuipers and Niederreiter (1974), Schlottmann (1998)].

Theorem 2: [Weyl's theorem for regular model sets (Baake and Moody, 2000)] *Let $\Lambda(W)$ be a regular model set, with compact, Riemann measurable $W \subset \mathbb{R}^m$. Let $f: \mathbb{R}^m \to \mathbb{C}$ be continuous with* $\mathrm{supp}(f) \subset W$. *Then, for all $a \in \mathbb{R}^d$,*

$$\lim_{r\to\infty} \frac{1}{\mathrm{vol}(B_r(0))} \sum_{x \in \Lambda(W)\cap B_r(a)} f(x^\star) = \frac{1}{|\det(\tilde{L})|} \int_W f(y)\, \mathrm{d}y,$$

uniformly in a. □

The fundamental object in diffraction theory of weighted model sets is the *weighted Dirac comb* ω defined by

$$\omega = \sum_{x \in \Lambda(W)} f(x^\star)\, \delta_x, \tag{6}$$

where $\sup_{x\in\Lambda(W)} |f(x^\star)| < \infty$. This defines a complex regular Borel measure on $\mathbb{R}^d$, which is translation bounded, since $\Lambda(W)$, being a model set, is uniformly discrete. Recall that a measure ω is *translation bounded* iff, for all compact $K \subset \mathbb{R}^d$, $\sup_{y\in\mathbb{R}^d} |\omega|(y+K) \leqslant C_K < \infty$ for some constant C_K which only depends on K. Here, $|\omega|$ denotes the total variation measure and $y+K = \{y + x \mid x \in K\}$. In the following, we assume that the function f satisfies the assumption of Weyl's theorem for regular model sets, i.e., we assume that $f: \mathbb{R}^m \to \mathbb{C}$ is continuous with $\mathrm{supp}(f) \subset W$.

Diffraction properties can be expressed using the *Fourier–Bohr coefficient* $c_W(k)$ of the weighted Dirac comb ω, defined by

$$c_W(k) = \lim_{r\to\infty} \frac{1}{\mathrm{vol}(B_r(0))} \sum_{x \in \Lambda(W)\cap B_r(a)} f(x^\star) e^{-2\pi\imath k\cdot x}, \tag{7}$$

where $k \in \mathbb{R}^d$ and $a \in \mathbb{R}^d$. We have the following theorem.

Theorem 3: [Fourier–Bohr coefficients (Bernuau and Duneau, 2000; Hof, 1995)] *Let $\Lambda(W)$ be a regular model set, with compact, Riemann measurable $W \subset \mathbb{R}^m$. Let $f: \mathbb{R}^m \to \mathbb{C}$ be continuous with* $\mathrm{supp}(f) \subset W$. *Then, for all $k \in \mathbb{R}^d$, the Fourier–Bohr coefficient $c_W(k)$ exists and is independent of $a \in \mathbb{R}^d$. Its value is given as follows. For any $k \in L^*$, one has*

$$c_W(k) = \frac{1}{|\det(\tilde{L})|} \int_W e^{2\pi\imath k^\star\cdot u} f(u)\, \mathrm{d}u = \frac{1}{|\det(\tilde{L})|} \widehat{f|_W}(-k^\star),$$

and $c_W(k) = 0$ if k does not belong to the $\mathbb{Z}$-module L^*. □

Remark: In Bernuau and Duneau (2000), the theorem is proved only for the case where $f(u)$ equals unity. The statement can be generalized to the situation described above by the same methods which lead to Weyl's formula, generalizing the density formula. For $k \in L^*$, the theorem is a direct consequence of Weyl's density formula.

For regular model sets, the *weighted density of points* ρ exists, because Weyl's theorem for regular model sets implies

$$\rho := \lim_{r\to\infty} \frac{1}{\mathrm{vol}(B_r)}\, \omega(B_r) = \frac{1}{|\det(\tilde{L})|} \int_W f(u)\, \mathrm{d}u. \tag{8}$$

This identity may be viewed as a particular normalization of admissible functions f, which we employ in the following.

Diffraction is described by properties of the Fourier transform of the *autocorrelation*, which we now define [see also Hof (1995), Baake, Moody, and Pleasants (2000)]. Set $\tilde{\omega}(f)=\overline{\omega(\tilde{f})}$, where $\tilde{f}(x)=\overline{f(-x)}$. Define truncated Dirac combs $\omega_n=\omega|_{B_n}$ and set $\tilde{\omega}_n=(\omega_n)^{\sim}$. The finite autocorrelation measures

$$\gamma_\omega^{(n)}:=\frac{1}{\mathrm{vol}(B_n)}\,\omega_n*\tilde{\omega}_n \tag{9}$$

are well defined, since ω_n has compact support. Recall that the *convolution* of two measures μ, ν is defined as $\mu*\nu(f)=\int_{\mathbb{R}^d\times\mathbb{R}^d} f(x+y)\,\mathrm{d}\mu(x)\,\mathrm{d}\nu(y)$, being well defined if at least one of them has compact support. The finite autocorrelation measures read explicitly

$$\gamma_\omega^{(n)}=\sum_{z\in\Delta}\eta_n(z)\,\delta_z,\quad \eta_n(z)=\frac{1}{\mathrm{vol}(B_n)}\sum_{\substack{x,y\in\Lambda(W)\cap B_n\\ x-y=z}} f(x^\star)\overline{f(y^\star)}, \tag{10}$$

where $\Delta=\Lambda(W)-\Lambda(W)$ is the set of difference vectors of $\Lambda(W)$. It can be shown that the vague limit $n\to\infty$ leads to a unique autocorrelation γ_ω.

Theorem 4: (Autocorrelation) *Let $\Lambda(W)$ be a regular model set, with compact, Riemann measurable $W\subset\mathbb{R}^m$. Let $f:\mathbb{R}^m\to\mathbb{C}$ be continuous with* $\mathrm{supp}(f)\subset W$. *Then, the vague limit $n\to\infty$ of the finite autocorrelation measures $\gamma_\omega^{(n)}$ leads to a unique measure γ_ω, called natural autocorrelation, being a translation bounded, positive definite pure point measure. It is given explicitly by*

$$\gamma_\omega=\sum_{z\in\Delta}\eta(z)\,\delta_z,\quad \eta(z)=\frac{1}{|\det(\tilde{L})|}\int_{W\cap(W+z^\star)} f(u)\overline{f(u-z^\star)}\,\mathrm{d}u. \tag{11}$$

□

Recall that a measure μ is *positive definite* iff $\mu(g*\tilde{g})\geqslant 0$ for all compactly supported continuous functions g.

The proof of the theorem proceeds as follows [Baake, Moody, and Pleasants (2000)]. All autocorrelation coefficients $\eta(z)=\lim_{n\to\infty}\eta_n(z)$ exist due to Weyl's theorem for regular model sets. They are locally summable, since Δ is closed and discrete. Then, γ_ω defines a distribution over the space of all C^∞ functions of compact support. The translation boundedness is inherited from ω [see Hof (1995), Prop. 2.2]. Finally, γ_ω can be written as a certain volume-normalized convolution, which implies that it is a distribution of positive type.

Due to Bochner's theorem [Reed and Simon (1980), p. 331], the Fourier transform $\widehat{\gamma_\omega}$ of γ_ω is a positive measure and also translation bounded [Baake, Moody, and Pleasants (2000)]. Recall that the *Fourier transform* $\hat{\mu}$ of a tempered distribution μ is defined as $\hat{\mu}(\varphi)=\mu(\hat{\varphi})$ for all Schwartz functions φ, where $\hat{\varphi}(y)=\int e^{-2\pi\imath y\cdot x}\varphi(x)\,\mathrm{d}x$. It can be shown that the Fourier transform of the autocorrelation is a pure point measure [Schlottmann (2000), Baake and Moody (2002)].

Theorem 5: [Diffraction formula (Bernuau and Duneau, 2000] *Let $\Lambda(W)$ be a regular model set, with compact, Riemann measurable $W\subset\mathbb{R}^m$. Let $f:\mathbb{R}^m\to\mathbb{C}$ be continuous with* $\mathrm{supp}(f)\subset W$. *The Fourier transform $\widehat{\gamma_\omega}$ of the autocorrelation measure γ_ω is a translation bounded, positive pure point measure. It is explicitly given by*

$$\widehat{\gamma_\omega}=\sum_{k\in L^*}|c_W(k)|^2\,\delta_k,$$

where L^* is the projection of the dual lattice into direct space, and $c_W(k)$ are the Fourier–Bohr coefficients of Theorem 3. □

Recall that a measure μ is *positive* iff $\mu(g)\geqslant 0$ for all compactly supported continuous functions $g\geqslant 0$.

Remark: The pure pointedness of $\widehat{\gamma_\omega}$ has been shown in Hof (1998), Schlottmann (1998), and Baake and Moody (2002). The explicit formula for the discrete part of $\widehat{\gamma_\omega}$ was proved in Hof (1995), but appeared earlier at different places in the physical literature. In the context of deformed model sets, which include regular model sets as a special case, the theorem appears in Bernuau and Duneau (2000). The diffraction formula is often stated for unweighted Dirac combs, but also holds for weighted Dirac combs, as is seen by an approximation of the weight function f by step functions, analogously to the proof of Weyl's theorem for regular model sets in Baake and Moody (2000) using the density formula.

III. DIFFRACTION OF DENSE DIRAC COMBS

We now extend the above results to the situation of a dense Dirac comb. The corresponding proofs will rely on the above results. In the following, we assume a cut-and-project scheme as in the preceding section with the additional property that the canonical projections π_1 and π_2, restricted to $\tilde{L}$, are both one-to-one, and the images of $\tilde{L}$ are both dense in $\mathbb{R}^d$ and $\mathbb{R}^m$, respectively. The star-map is then a bijection between L and $L^\star$. This additional assumption makes it possible to regard subsets $B\subset\mathbb{R}^d$ as windows, leading to model sets in internal space $\mathbb{R}^m$.

Define the *weighted Dirac comb* ω by

$$\omega=\sum_{x\in L} f(x^\star)\,\delta_x. \tag{12}$$

Since the $\mathbb{Z}$-module L is dense in Euclidean space, the above sum is now well defined only under special assumptions on the weight function f.

Theorem 6: (Weighted Dirac combs with dense support) *Let $f:\mathbb{R}^m\to\mathbb{C}$ be bounded, and $|x|^{m+1+\alpha}|f(x)|\leqslant C$ for some constants $C>0$ and $\alpha>0$. Then, the weighted Dirac comb ω is a translation bounded measure.*

Proof: Let a compact $K\subset\mathbb{R}^d$ be given. Cover K with a finite number of translated unit balls W_i such that $K\subset\cup_{i=1}^n W_i=W$. For $y\in\mathbb{R}^d$, the total variation measure of ω is bounded by

$$|\omega|(K+y)\leqslant\sum_{x\in L\cap(W+y)}|f(x^\star)|=\sum_{x^\star\in(L\cap(W+y))^\star}|f(x^\star)|=:a_K(y).$$

The additional assumptions on the cut-and-project setup, introduced at the beginning of this section, imply that $(L\cap(W+y))^\star$ is a regular model set with window $(W+y)\subset\mathbb{R}^d$. Lemma 1 then yields that $a_K(y)<b_K<\infty$, uniformly in y, for some b_K. This implies that ω is a measure, and that ω is translation bounded. □

We derive a generalization of Weyl's theorem on uniform distribution to dense point sets.

Theorem 7: (Weyl's theorem for dense point sets) *Let $f:\mathbb{R}^m\to\mathbb{C}$ be continuous, and $|x|^{d+1+\alpha}|f(x)|\leqslant C$ for some constants $C>0$ and $\alpha>0$. Then*

$$\lim_{r\to\infty}\frac{1}{\mathrm{vol}(B_r(0))}\sum_{x\in L\cap B_r(a)}f(x^\star)=\frac{1}{|\det(\tilde{L})|}\int_{\mathbb{R}^m}f(u)\,\mathrm{d}u,$$

uniformly in a.

Proof: For $s\in\mathbb{N}$, let $B_s\subset\mathbb{R}^m$ denote the ball of radius s centered at 0. The idea of the proof is to approximate the dense set L by the model sets $\Lambda(B_s)$. Let $\chi_s:\mathbb{R}^m\to[0,1]$ be continuous with $\chi_s(x)=1$ for $|x|<s-1$ and $\chi_s(x)=0$ for $|x|\geqslant s$. Define the numbers

$$w_{r,s}=\frac{1}{\mathrm{vol}(B_r(0))}\sum_{x\in\Lambda(B_s)\cap B_r(a)}(\chi_s\cdot f)(x^\star),\quad w'_s=\frac{1}{|\det(\tilde{L})|}\int_{B_s}(\chi_s\cdot f)(u)\,\mathrm{d}u,$$

$$w_r = \frac{1}{\mathrm{vol}(B_r(0))} \sum_{x \in L \cap B_r(a)} f(x^\star), \quad w = \frac{1}{|\det(\tilde{L})|} \int_{\mathbb{R}^m} f(u)\, \mathrm{d}u.$$

We have $\lim_{r\to\infty} w_{r,s} = w_s' < \infty$ due to Weyl's theorem for regular model sets. We also have $\lim_{s\to\infty} w_s' = w < \infty$. This follows from Lebesgue's dominated convergence theorem, since the functions $|(\chi_s \cdot f)(u)|$ are bounded by $|f(u)|$ uniformly in s, and $f(u)$ is by assumption absolutely integrable (the integral being finite).

We now show that $\lim_{s\to\infty} w_{r,s} = w_r$ uniformly in r and in a. We have the estimate

$$\begin{aligned} |w_r - w_{r,s}| &= \frac{1}{\mathrm{vol}(B_r(0))} \left| \sum_{x \in L \cap B_r(a)} f(x^\star) - \sum_{x \in \Lambda(B_s) \cap B_r(a)} (\chi_s \cdot f)(x^\star) \right| \\ &\leqslant \frac{1}{\mathrm{vol}(B_r(0))} \left(\sum_{x^\star \in (L \cap B_r(a))^\star \setminus B_s} |f(x^\star)| + \sum_{\substack{x^\star \in (L \cap B_r(a))^\star \\ s-1 \leqslant |x^\star| < s}} |f(x^\star)| \right) \\ &= \frac{1}{\mathrm{vol}(B_r(0))} \left(\sum_{x^\star \in (L \cap B_r(a))^\star \setminus B_{s-1}} |f(x^\star)| \right). \end{aligned}$$

We estimate the last term using Eq. (5) in Lemma 1. Since $n_1(B_{r_2}) \leqslant n_1(B_{r_1})$ for $r_2 \geqslant r_1$, we get for $s \geqslant n_1(B_1)$ and $r > 1$,

$$|w_r - w_{r,s}| \leqslant \frac{1}{\mathrm{vol}(B_r)} \left(2c\, C\, \mathrm{vol}(B_r) \sum_{n=s-1}^{\infty} \frac{1}{n^{1+\alpha}} \right).$$

Since the bound is independent of r and a and vanishes as $s \to \infty$, the assertion follows.

We now use a 3ε argument to show that $w_r \to w$. Fix $\varepsilon > 0$. We have $|w - w_s'| < \varepsilon$ for $s > s_0(\varepsilon)$. We also have $|w_{r,s} - w_r| < \varepsilon$ for $s > s_1(\varepsilon)$ uniformly in r. Last, we have $|w_s' - w_{r,s}| < \varepsilon$ for $r > r_0(\varepsilon, s)$. Take $s > \max\{s_0(\varepsilon), s_1(\varepsilon)\}$. For $r > r_0(\varepsilon, s)$, we thus have

$$|w - w_r| \leqslant |w - w_s'| + |w_s' - w_{r,s}| + |w_{r,s} - w_r| \leqslant 3\,\varepsilon.$$

This establishes the convergence result of the theorem. □

For applications to diffraction, we restrict the class of admissible functions f in the remainder of this paper. Let $f: \mathbb{R}^m \to \mathbb{C}$ be continuous, and $|f(x)| \leqslant C/|x|^{m+1+\alpha}$ for some constants $C > 0$ and $\alpha > 0$. We can argue as in the preceding section, using Weyl's theorem for dense point sets, that the weighted density of points exists,

$$\rho := \lim_{r\to\infty} \frac{1}{\mathrm{vol}(B_r)}\, \omega(B_r) = \frac{1}{|\det(\tilde{L})|} \int_{\mathbb{R}^m} f(u)\, \mathrm{d}u. \tag{13}$$

This identity may be viewed as a particular normalization of admissible functions f. Given a weighted Dirac comb ω with dense support, we consider its Fourier–Bohr coefficients. We define the finite volume approximations

$$c_r(k) = \frac{1}{\mathrm{vol}(B_r(0))} \sum_{x \in L \cap B_r(a)} f(x^\star) e^{-2\pi \imath k \cdot x}, \tag{14}$$

where $k \in \mathbb{R}^d$ and $a \in \mathbb{R}^d$. The numbers $c_r(k)$ exist (and may depend on a), as is seen by an argument similar to that used for proving the existence of the Dirac comb ω. In the limit $r \to \infty$, we have the following result.

Theorem 8: (Fourier–Bohr coefficients for dense point sets) *Let* $f:\mathbb{R}^m\to\mathbb{C}$ *be continuous, and* $|x|^{m+1+\alpha}|f(x)|\leq C$ *for some constants* $C>0$ *and* $\alpha>0$. *Then, for all* $k\in\mathbb{R}^d$, *the Fourier–Bohr coefficient* $c(k)=\lim_{r\to\infty}c_r(k)$ *exists and is independent of* a. *Its value is given as follows. For any* $k\in L^*$ *and for any* $a\in\mathbb{R}^d$, *one has*

$$c(k)=\frac{1}{|\det(\tilde{L})|}\int_{\mathbb{R}^m}e^{2\pi\imath k^\star\cdot u}f(u)\,\mathrm{d}u=\frac{1}{|\det(\tilde{L})|}\hat{f}(-k^\star),$$

and $c(k)=0$ *if* k *does not belong to the* $\mathbb{Z}$*-module* L^*.

Proof: The proof is analogous to the proof of Weyl's theorem for dense point sets above. For $s\in\mathbb{N}$, let $B_s\subset\mathbb{R}^m$ denote the ball of radius s, centered at 0, and define the numbers

$$c_{r,s}(k)=\frac{1}{\mathrm{vol}(B_r(0))}\sum_{x\in\Lambda(B_s)\cap B_r(a)}(\chi_s\cdot f)(x^\star)e^{-2\pi\imath k\cdot x},$$

$$c_s'(k)=\begin{cases}\dfrac{1}{|\det(\tilde{L})|}\displaystyle\int_{B_s}(\chi_s\cdot f)(u)e^{2\pi\imath k^\star\cdot u}\,\mathrm{d}u, & k\in L^*,\\ 0, & k\notin L^*,\end{cases}$$

$$c'(k)=\begin{cases}\dfrac{1}{|\det(\tilde{L})|}\displaystyle\int_{\mathbb{R}^m}f(u)e^{2\pi\imath k^\star\cdot u}\,\mathrm{d}u, & k\in L^*,\\ 0, & k\notin L^*.\end{cases}$$

We have $\lim_{r\to\infty}c_{r,s}(k)=c_s'(k)<\infty$ due to Theorem 3. We also have $\lim_{s\to\infty}c_s'(k)=c'(k)<\infty$ by Lebesgue's dominated convergence theorem. We show that $\lim_{s\to\infty}c_{r,s}(k)=c_r(k)$ uniformly in r and in a. As in Theorem 7, we can then use a 3ε argument to show that $c_r(k)$ converges to $c'(k)$ as $r\to\infty$. Thus $c(k)=\lim_{r\to\infty}c_r(k)=c'(k)$, and the assertion of the theorem follows.

For every $k\in\mathbb{R}^d$, we have the estimate

$$|c_r(k)-c_{r,s}(k)|\leq\frac{1}{\mathrm{vol}(B_r(0))}\left(\sum_{x^\star\in(L\cap B_r(a))^\star\setminus B_s}|f(x^\star)|+\sum_{\substack{x^\star\in(L\cap B_r(a))^\star\\ s-1\leq|x^\star|<s}}|f(x^\star)|\right).$$

This is the same expression as in the proof of Theorem 7. We can repeat the previous argument and derive a uniform bound in r and in a, which vanishes as $s\to\infty$. □

The finite autocorrelation measures of the dense Dirac comb ω,

$$\gamma_\omega^{(n)}:=\frac{1}{\mathrm{vol}(B_n)}\,\omega_n*\tilde{\omega}_n\,,\tag{15}$$

are well defined, since ω_n has compact support. They read explicitly

$$\gamma_\omega^{(n)}=\sum_{z\in L}\eta_n(z)\,\delta_z\,,\quad \eta_n(z)=\frac{1}{\mathrm{vol}(B_n)}\sum_{\substack{x,y\in L\cap B_n\\ x-y=z}}f(x^\star)\overline{f(y^\star)}.\tag{16}$$

We show that the limit $n\to\infty$ leads to a unique autocorrelation. As a first step, we show that the pointwise limit exists.

Lemma 2: Let $\eta_n(z)$ *denote the finite autocorrelation coefficients of the weighted Dirac comb* ω. *The numbers* $\eta_n(z)$ *have a well-defined limit* $\eta(z)$, *which is a positive definite function. It is given by*

$$\lim_{n\to\infty} \eta_n(z) = \eta(z) = \frac{1}{|\det(\widetilde{L})|} \int_{\mathbb{R}^m} f(u)\overline{f(u-z^\star)}\,\mathrm{d}u. \tag{17}$$

Proof: This is an application of Weyl's theorem for dense point sets. We have

$$\begin{aligned}\eta_n(z) &= \frac{1}{\mathrm{vol}(B_n)} \sum_{\substack{x\in L\cap B_n \\ x-z\in L\cap B_n}} f(x^\star)\overline{f(x^\star-z^\star)} \\ &= \frac{1}{\mathrm{vol}(B_n)} \sum_{x\in L\cap B_n} f(x^\star)\overline{f(x^\star-z^\star)} - \frac{1}{\mathrm{vol}(B_n)} \sum_{\substack{x\in L\cap B_n \\ x-z\notin L\cap B_n}} f(x^\star)\overline{f(x^\star-z^\star)}.\end{aligned}$$

The first term in the last line converges to $\eta(z)$ by Weyl's theorem for dense point sets, and the second one, which we denote by $r_n(z)$, converges to zero, as we now show. Note that $|x|<n-|z|$ implies $|x-z|<n$. Consider for $n>|z|$ the estimate

$$\begin{aligned}|r_n(z)| &\leqslant \frac{1}{\mathrm{vol}(B_n)} \left(\sum_{x\in L\cap B_n} - \sum_{x\in L\cap B_{n-|z|}} \right) |f(x^\star)|\,|f(x^\star-z^\star)| \\ &= \frac{1}{\mathrm{vol}(B_n)} \sum_{x^\star\in (L\cap (B_n\setminus B_{n-|z|}))^\star} |f(x^\star)|\,|f(x^\star-z^\star)|.\end{aligned}$$

This is a summation over a regular model set with window $B_n\setminus B_{n-|z|}$. Due to Lemma 1, the sum is bounded by the volume of the window, which is a shell of thickness $|z|$ of the ball of radius n. Thus, the last expression vanishes like $1/n$ as $n\to\infty$. The limit $\eta(z)$ is a positive definite function, since it is the limit of the positive definite functions $\eta_n(z)$. □

Theorem 9: (Autocorrelation) *Let $f:\mathbb{R}^m\to\mathbb{C}$ be continuous, and $|x|^{m+1+\alpha}|f(x)|\leqslant C$ for some constants $C>0$ and $\alpha>0$. The weighted dense Dirac comb ω has the unique autocorrelation*

$$\gamma_\omega = \sum_{z\in L} \eta(z)\,\delta_z, \quad \eta(z) = \frac{1}{|\det(\widetilde{L})|} \int_{\mathbb{R}^m} f(u)\overline{f(u-z^\star)}\,\mathrm{d}u,$$

where γ_ω is a translation bounded, positive definite pure point measure.

Proof: Consider the regular model set autocorrelation measures

$$\gamma_{\omega,s} = \sum_{z\in\Delta_s} \eta_s(z)\,\delta_z, \quad \eta_s(z) = \frac{1}{|\det(\widetilde{L})|} \int_{B_s\cap(B_s+z^\star)} (\chi_s\cdot f)(u)\overline{(\chi_s\cdot f)(u-z^\star)}\,\mathrm{d}u,$$

where B_s denotes the ball of radius $s\in\mathbb{N}$, and $\Delta_s=\Lambda(B_s)-\Lambda(B_s)$. Note that $\Delta_s\subset\Delta_{s+1}\subset L$ and set $\eta_s(z)=0$ if $z\notin\Delta_s$. Consider the associated finite autocorrelation measures

$$\gamma_{\omega,s}^{(n)} = \sum_{z\in\Delta_s} \eta_{n,s}(z)\,\delta_z, \quad \eta_{n,s}(z) = \frac{1}{\mathrm{vol}(B_n)} \sum_{\substack{x,y\in\Lambda(B_s)\cap B_n \\ x-y=z}} (\chi_s\cdot f)(x^\star)(\chi_s\cdot f)(y^\star).$$

Since these measures arise from regular model sets, we have $\gamma_{\omega,s}^{(n)}\to\gamma_{\omega,s}$ vaguely. The measures $\gamma_{\omega,s}$ converge to γ_ω vaguely, as follows from Lebesgue's dominated convergence theorem: Note that $\eta_s(z)\to\eta(z)$ and $|\eta_s(z)|<|\eta|(z) := [1/|\det(\widetilde{L})|]\int_{\mathbb{R}^m}|f(u)|\,|f(u-z^\star)|\mathrm{d}u$. Note that $\gamma_{|\omega|} := \Sigma_{z\in L}|\eta|(z)\,\delta_z$ defines a measure: For $\gamma_{|\omega|}$ and compact K, we have the estimate

$$\gamma_{|\omega|}(K) \leqslant \sum_{z\in L\cap W} |\eta|(z) = \sum_{z^\star\in(L\cap W)^\star} \frac{1}{|\det(\tilde{L})|} \int_{\mathbb{R}^m} |f(u)|\,|f(u-z^\star)|\,\mathrm{d}u$$
$$= \frac{1}{|\det(\tilde{L})|} \int_{\mathbb{R}^m} |f(u)| \left(\sum_{z^\star\in(L\cap W)^\star} |f(u-z^\star)| \right) \mathrm{d}u < \infty,$$

where $W=\cup_{i=1}^{n} W_i$ is a covering of K with a finite number of translated unit balls W_i. In the last equation, we exchanged summation and integration, which is justified by Lebesgue's dominated convergence theorem, since the terms in brackets are bounded uniformly in u due to Lemma 1. For g continuous with support on K, we then have

$$\lim_{s\to\infty} \gamma_{\omega,s}(g) = \lim_{s\to\infty} \sum_{z\in L\cap K} \eta_s(z)g(z) = \sum_{z\in L\cap K} \lim_{s\to\infty} \eta_s(z)g(z) = \sum_{z\in L\cap K} \eta(z)g(z) = \gamma_\omega(g).$$

We will show below that $\gamma_{\omega,s}^{(n)} \to \gamma_\omega^{(n)}$ vaguely, uniformly in n. The above results may then be used with a 3ε argument as in Theorem 7 to show that $\gamma_\omega^{(n)} \to \gamma_\omega$. Since ω is translation bounded, we further conclude that all finite volume approximations $\gamma_\omega^{(n)}$ are uniformly translation bounded [Hof (1995), Prop. 2.2], hence the limit is translation bounded. As it coincides with the pointwise limit, it is unique. The measures $\gamma_\omega^{(n)}$ are positive definite by construction. Since the positive definite measures are closed in the vague topology, γ_ω is a positive definite measure. The explicit form of the vague limit shows that γ_ω is pure point.

To show the uniform convergence of $\gamma_{\omega,s}^{(n)}$, consider for a compact set $K\subset\mathbb{R}^d$ the estimate

$$|\gamma_\omega^{(n)}(K) - \gamma_{\omega,s}^{(n)}(K)| = \frac{1}{\mathrm{vol}(B_n)} \Bigg| \sum_{z\in L\cap K} \sum_{\substack{x\in L\cap B_n \\ x-z\in L\cap B_n}} f(x^\star)\overline{f(x^\star-z^\star)}$$
$$- \sum_{z\in L\cap K} \sum_{\substack{x\in \Lambda(B_s)\cap B_n \\ x-z\in \Lambda(B_s)\cap B_n}} (\chi_s\cdot f)(x^\star)\overline{(\chi_s\cdot f)(x^\star-z^\star)} \Bigg|$$
$$\leqslant \frac{1}{\mathrm{vol}(B_n)} \Bigg| \sum_{z\in L\cap K} \Bigg(\sum_{x\in L\cap B_n} f(x^\star)\overline{f(x^\star-z^\star)}$$
$$- \sum_{x\in \Lambda(B_s)\cap B_n} (\chi_s\cdot f)(x^\star)\overline{(\chi_s\cdot f)(x^\star-z^\star)} \Bigg) \Bigg|$$
$$+ \frac{1}{\mathrm{vol}(B_n)} \Bigg| \sum_{z\in L\cap K} \Bigg(\sum_{\substack{x\in L\cap B_n \\ x-z\notin L\cap B_n}} f(x^\star)\overline{f(x^\star-z^\star)}$$
$$- \sum_{\substack{x\in \Lambda(B_s)\cap B_n \\ x-z\notin \Lambda(B_s)\cap B_n}} (\chi_s\cdot f)(x^\star)\overline{(\chi_s\cdot f)(x^\star-z^\star)} \Bigg) \Bigg|.$$

Both terms in the last inequality may be estimated by

$$\frac{1}{\mathrm{vol}(B_n)} \sum_{z\in L\cap K} \left(\sum_{x^\star\in(L\cap B_n)^\star\setminus B_s} |f(x^\star)|\,|f(x^\star-z^\star)| + \sum_{\substack{x^\star\in(L\cap B_n)^\star \\ s-1\leqslant|x^\star|<s}} |f(x^\star)|\,|f(x^\star-z^\star)| \right)$$

by the same argument as in the proof of Theorem 7. We may now interchange the summations and use the fact that the sum over z is bounded uniformly in $x^\star$ due to Lemma 1. The remaining term

is of the same form as that in Theorem 7. We conclude that it approaches zero as $s\to\infty$ uniformly in n. Thus $\gamma_{\omega,s}^{(n)}\to\gamma_{\omega}^{(n)}$ vaguely and uniformly in n, which concludes the proof. □

It now follows from the theorem of Bochner–Schwartz [Reed and Simon (1980), p. 331] that the Fourier transform of the autocorrelation is a positive, translation bounded measure. An explicit expression for the discrete part $(\widehat{\gamma_\omega})_{pp}$ of $\widehat{\gamma_\omega}$, which is given in the following theorem, can be deduced from Hof (1995), Theorem 3.4. The theorem states that the Fourier transform of the autocorrelation measure has no continuous component.

Theorem 10: (Diffraction formula) *Let $f:\mathbb{R}^m\to\mathbb{C}$ be continuous and, for some constants $C>0$ and $\alpha>0$, $|x|^{m+1+\alpha}|f(x)|\leqslant C$. The Fourier transform $\widehat{\gamma_\omega}$ of the autocorrelation γ_ω of the weighted dense Dirac comb ω is a positive, translation bounded pure point measure and explicitly given by*

$$\widehat{\gamma_\omega}=\sum_{k\in L^*}|c(k)|^2\delta_k=\frac{1}{|\det(\tilde{L})|^2}\sum_{k\in L^*}|\hat{f}(-k^\star)|^2\delta_k,$$

where the $\mathbb{Z}$-module L^* is the projection of the dual lattice.

Proof: We showed in the proof of Theorem 9 that the autocorrelation measures $\gamma_{\omega,s}$ converge vaguely to γ_ω. Since the Fourier transform is continuous in the vague topology, the Fourier transforms of the autocorrelation measures $\widehat{\gamma_{\omega,s}}$ converge vaguely to $\widehat{\gamma_\omega}$. We will show that the vague limit leads to the above expression.

Take a compact set $K\subset\mathbb{R}^d$ and a covering $W=\cup_{i=1}^n W_i$ of K with a finite number of translated unit balls W_i. Since $(L^*\cap W)^\star$ is, by duality, a Delone set, we may order the numbers $k\in L^*\cap K$ to obtain a sequence $(k_i)_{i\in\mathbb{N}}$ with $|k_j^\star|\geqslant|k_i^\star|$ for $j>i$. Moreover, since $c_s'(k)\to c(k)$ (in the notation of the proof of Theorem 8), we may choose a subsequence $(s_j)_{j\in\mathbb{N}}$ such that $||c_{s_j}'(k_i)|^2-|c(k_i)|^2|<2^{-i}$ on $L^*\cap K$ for all $j\in\mathbb{N}$. For explicity of notation, we will suppress the index j in the following. Fix $\varepsilon>0$. We have

$$\sum_{i=m+1}^{\infty}|c_s'(k_i)|^2+\sum_{i=m+1}^{\infty}|c(k_i)|^2\leqslant\sum_{i=m+1}^{\infty}2^{-i}+2\sum_{i=m+1}^{\infty}|c(k_i)|^2<\varepsilon$$

for $m>m_0(\varepsilon)$. The last sum can be made arbitrarily small, since it arises from the discrete part of the measure $\widehat{\gamma_\omega}$, see Hof (1995), Theorem 3.4. Moreover, we have $\Sigma_{i=1}^m(|c_s'(k_i)|^2-|c(k_i)|^2)<\varepsilon$ for $s>s_0(\varepsilon,m)$, since $|c_s'(k)|^2\to|c(k)|^2$ uniformly in k. Fix now $m>m_0(\varepsilon)$. For $s>s_0(\varepsilon,m)$, we have

$$\left|\sum_{i=1}^{\infty}|c_s'(k_i)|^2-\sum_{i=1}^{\infty}|c(k_i)|^2\right|\leqslant\sum_{i=m+1}^{\infty}|c_s'(k_i)|^2+\left|\sum_{i=1}^{m}(|c_s'(k_i)|^2-|c(k_i)|^2)\right|+\sum_{i=m+1}^{\infty}|c(k_i)|^2$$
$$\leqslant 2\varepsilon.$$

For g continuous and compactly supported on K, this implies

$$\widehat{\gamma_\omega}(g)=\lim_{s\to\infty}\widehat{\gamma_{\omega,s}}(g)=\lim_{s\to\infty}\sum_{k\in L^*\cap K}|c_s'(k)|^2g(k)=\sum_{k\in L^*\cap K}|c(k)|^2g(k).$$

Since K was an arbitrary compact set, our claim follows. □

The above results lead to a generalized Poisson summation formula. Recall that, for a lattice $L\subset\mathbb{R}^d$, the Poisson summation formula is [Córdoba (1989)]

$$\left(\sum_{x\in L}\delta_x\right)\hat{}=\frac{1}{|\det(L)|}\sum_{k\in L^*}\delta_k,\tag{18}$$

where $|\det(L)|$ is the volume of the fundamental domain of the lattice L, and the sum ranges over all points of the dual lattice L^*. For regular model sets $\Lambda(W)\subset\mathbb{R}^d$, a generalized Poisson formula is given by

$$\left(\sum_{z\in\Delta}\eta(z)\,\delta_z\right)\hat{}=\sum_{k\in L^*}|c_W(k)|^2\,\delta_k, \tag{19}$$

as is readily inferred from Theorem 5. This identity is not symmetric because the first sum ranges over the uniformly discrete set $\Delta=\Lambda(W)-\Lambda(W)$, whereas the second sum ranges over the projection of the dual lattice L^*, which is a dense set. For weighted Dirac combs defined on a dense $\mathbb{Z}$-module $L\subset\mathbb{R}^d$, we obtain from Theorem 10 the formula

$$\left(\sum_{z\in L}\eta(z)\,\delta_z\right)\hat{}=\sum_{k\in L^*}|c(k)|^2\,\delta_k, \tag{20}$$

where the sums on both sides are defined on a dense set. Within this symmetric setup, it may be easier to investigate which constraints on an underlying point set an identity of the above type imposes [Lagarias (2000), Problem 4.1].

IV. APPLICATIONS TO RANDOM TILINGS

In this section, we explain how the above results can be used to infer diffraction properties of random tiling ensembles.

A *tiling* of $\mathbb{R}^d$ is a face-to-face space filling with tiles from a finite set of $\mathbb{R}^d$-polytopes called *prototiles*, without any gaps and overlaps [Richard *et al.* (1998)]. There might be a number of additional packing rules specifying the allowed configurations. Associated with a tiling is the set Λ of all vertex positions of the tiling. Take a ball $B_n\subset\mathbb{R}^d$ of radius n and count the number of different patches of B_n, where we identify patches which are equal up to a translation. If the number of allowed patches increases exponentially with the volume of the ball, we call the set of all tilings a *random tiling* ensemble.

The usual ideal quasiperiodic tilings like the Penrose tiling, the Ammann–Beenker tiling, and others, have the special property that the vertex positions of its tiles form a (regular) model set. Essentially, the set of all tilings is given by the collection of the original model set together with model sets of arbitrarily translated window. For tilings of $\mathbb{R}^d$ whose vertex positions constitute a Delone set and are described by a primitive substitution, it can be shown that the number of allowed patches of radius n grows asymptotically proportional to n^d [Lenz (2002)].

Relaxation of the packing rules for these tilings usually results in a random tiling ensemble with strictly positive entropy [Henley (1999)]. Since entropy is an indication of disorder, one should expect a nonvanishing continuous component in the diffraction spectrum in addition to a discrete part. By construction, the set of vertex positions of each random tiling can be mapped into internal space via the star-map, resulting in a distribution, which may be supported on an unbounded domain in internal space. This is different from the distribution of a model set $\Lambda(W)$, which is the characteristic function 1_W of the window.

A natural object to consider is the *averaged distribution*, where we take the average over all random tilings. Here, we adopt the normalization that $0\in\Lambda$ for all random tilings Λ. The averaged distribution defines a weighted point set of $\mathbb{R}^d$ which is supported on a countable, dense subset of $\mathbb{R}^d$.

Henley (1999) gives nonrigorous arguments that the averaged distribution (for infinite tilings) exists in dimensions $d>2$. In dimensions $d\leqslant 2$, the width of the averaged distribution for finite patches on balls should diverge with the radius n of the ball. In $d=1$, the divergence is with the square root of the system size, in $d=2$, the divergence is logarithmic. He concludes that in dimension $d\leqslant 2$ the diffraction spectrum of a random tiling should have a trivial discrete part.

In $d=1$, his arguments can be made rigorous [Baake *et al.* (2003)]. Consider, for example, the Fibonacci model set. Other tilings may be treated similarly. Let $\mathbb{Z}[\tau]=\mathbb{Z}+\mathbb{Z}\tau\subset\mathbb{R}$, where $\tau=(1+\sqrt{5})/2$ is the golden mean. The ring $\mathbb{Z}[\tau]$ is the ring of integers of the quadratic field $\mathbb{Q}(\tau)=\mathbb{Q}(\sqrt{5})$. Let $(\,)^\star$ denote the automorphism of $\mathbb{Q}(\tau)$ that maps $\sqrt{5}\mapsto-\sqrt{5}$. The set $\tilde{L}=\{(x,x^\star)\,|\,x\in\mathbb{Z}[\tau]\}$ is a lattice in $\mathbb{R}\times\mathbb{R}$. The Fibonacci model set is the set $\Lambda(W)=\{x\in\mathbb{Z}[\tau]\,|\,x^\star\in(-1,\tau-1]\}$. Consecutive points of the model set have distances 1 or τ. If we regard the point positions as left endpoints of half-open intervals u, v of length 1 and τ, we get the *Fibonacci tiling*. A *Fibonacci random tiling* is an arbitrary sequence (a.s.) of intervals u, v such that the frequency of u is a.s. equal to $1/\tau$. The averaged distribution for a patch of size N is, to leading order in N, given by [Höffe (2001), Baake *et al.* (2003)]

$$\rho(x^\star)=\sqrt{\frac{\tau}{2N}}f\left(x^\star\sqrt{\frac{\tau}{2N}}\right),\quad f(z)=2\left(\frac{e^{-z^2}}{\sqrt{\pi}}-|z|\,\mathrm{erfc}(|z|)\right),\tag{21}$$

where $\mathrm{erfc}(x)=(2/\sqrt{\pi})\int_x^\infty e^{-t^2}\,dt$ denotes the complementary error function. The distribution width therefore grows with the system size as $\sqrt{N}$. Together with the above analysis, this may lead to a trivial Bragg peak at the origin as $N\to\infty$. This corresponds to the behavior of the Fibonacci random tiling, whose diffraction spectrum has been computed explicitly [Baake and Höffe (2000)]. It consists of an absolutely continuous component in addition to a trivial Bragg peak at the origin. It would be interesting to compute the continuous component of the averaged structure, which may be given by large N corrections to the asymptotic behavior in Eq. (21).

For $d>1$, there are no rigorous results about the averaged distribution of quasicrystalline random tilings, which is due to more restrictive matching rules for the prototiles. (In $d=1$, the only matching rule is the face-to-face condition, resulting in Bernoulli ensembles, which are easy to analyze.) There are however numerical investigations for a number of quasicrystallographic random tilings in $d=2$ and $d=3$.

In $d=2$, the averaged distribution of the Ammann–Beenker random tiling appears to be of Gaussian type, with a distribution width diverging logarithmically with the system size [Höffe (2001)]. Thus, the situation is similar to the $d=1$ case discussed above. A numerical analysis of the diffraction measure indicates a trivial Bragg peak at the origin, together with a singular continuous component [Höffe (2001)]. This behavior is believed to be generic in $d=2$ [Henley (1999)].

In $d\geqslant 3$, the averaged distribution is predicted to exist [Henley (1999)]. Our result then implies that the averaged structure is pure point diffractive, if the distribution function is well-behaved. However, the diffraction picture of a typical random tiling in $d\geqslant 3$ is expected to display an diffuse background in addition to Bragg peaks [Henley (1999)]. The averaging on the level of the Dirac comb thus has the effect of extinguishing continuous components of the diffraction spectrum.

To conclude, it is necessary to prove Henley's statements about the existence of an averaged distribution with finite width in $d\geqslant 3$. Furthermore, it would be interesting to investigate the relation between diffraction properties of the averaged structure and the random tiling, in particular whether the discrete parts of both structures coincide and whether the continuous parts coincide in $d\leqslant 2$. Concerning the results of this paper, a natural question is how they can be extended beyond the Euclidean case towards the setup of locally compact Abelian groups. (The proofs of the pure pointedness of the diffraction spectrum used the fact that $\mathbb{R}^n$ is isomorphic to its dual.) Another aspect concerns the connection to the theory of almost periodic measures [Gil de Lamadrid and Argabright (1990)], which may also be used for a characterization of diffraction spectra with continuous components.

On the pseudo-Hermitian nondiagonalizable Hamiltonians

G. Scolarici[a] and L. Solombrino[b]

and INFN, Sezione di Lecce, I-73100 Lecce, Italy

(Received 4 December 2002; accepted 23 June 2003)

We consider a class of (possibly nondiagonalizable) pseudo-Hermitian operators with discrete spectrum, and we establish for such a class the equivalence between the pseudo-Hermiticity property and the existence of an antilinear involutory symmetry. Moreover, we prove that this class actually coincides with the one of (possibly nondiagonalizable) weak pseudo-Hermitian operators, and that in no case (unless they are diagonalizable and have a real spectrum) they are Hermitian with respect to a definite inner product. Finally, we show that a typical degeneracy of the real eigenvalues (which reduces to the well-known Kramers degeneracy in the Hermitian case) occurs whenever a fermionic (possibly nondiagonalizable) pseudo-Hermitian Hamiltonian admits an antilinear symmetry like the time-reversal operator T. Some consequences and applications are briefly discussed. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1609031]

I. INTRODUCTION

Non-Hermitian Hamiltonians play by now a relevant role in physics, in that they appear in several completely different problems.[1] Among them, a remarkable subclass is given by the *pseudo-Hermitian operators*,[2] i.e., those operators which satisfy

$$\eta H \eta^{-1} = H^{\dagger} \tag{1}$$

with $\eta = \eta^{\dagger}$ [instead, whenever (1) holds without any constraint on the (linear and invertible) operator η, H is called *weakly pseudo-Hermitian*[3]]. Of course, Hermiticity is a particular case of pseudo-Hermiticity, corresponding to $\eta = \mathbf{1}$. In particular, in the last several years, the concept of pseudo-Hermiticity has given rise to a growing interest, since it allows one to explain the typical features of PT-symmetric quantum mechanics. Pseudo-Hermiticity also represents the mathematical background of a recent proposal on a *complex extension of Quantum Mechanics*.[4,5]

The essential feature of the pseudo-Hermitian operators is the peculiarity of their spectrum, which can be constituted by real as well as complex (but grouped in complex-conjugate pairs) eigenvalues.[3,6] Another characteristic feature of the pseudo-Hermiticity property is its connection with the existence of antilinear symmetries. The idea of such a connection stemmed naturally from the studies on the PT-symmetric quantum mechanics, as we said above, and it has been already proven in the case of diagonalizable operators.[3,7]

The aim of this paper is just to go on a systematic and deep study on nondiagonalizable, pseudo-Hermitian operators. Such Hamiltonians can arise, for instance, for some critical parameter values, whenever a physical system undergoes a perturbation which preserves the pseudo-Hermiticity, but not the diagonalizability, of its Hamiltonian. An example of such a situation, concerning the effective Hamiltonian for a certain closed FRW mini-super-space-quantum cosmological model, is discussed in Ref. 8; another example is shown in Sec. VI. Furthermore, some cases of nondiagonalizable operators also arise in the classification of the real, 4×4 pseudo-Hermitian energy momentum tensor T^{α}_{β}.[1]

[a]Electronic mail: scolarici@le.infn.it
[b]Electronic mail: solombrino@le.infn.it

We recall that the peculiarity of the spectrum of pseudo-Hermitian operators, originally stated with reference to diagonalizable operators with discrete spectrum, has been recently extended to a class of nondiagonalizable Hamiltonians.[8] In particular, in this paper we intend to establish the equivalence of the pseudo-Hermiticity property and the existence of antilinear symmetries for such class of operators.

To this end, we recall (and partly refine) in Sec. II the basic results on this subject, and we show that the (possibly broader) class of weakly pseudo-Hermitian operators with a discrete spectrum actually coincides with the class of pseudo-Hermitian operators. Next, we inquire in Sec. III into the definiteness or the indefiniteness of the metric induced by η, concluding that for any pseudo-Hermitian operator H with discrete spectrum, the metric is always indefinite unless H is diagonalizable with real spectrum. This result disproves a recently stated theorem on the subject.[8]

Successively, in Sec. IV, we take into account the connection between the pseudo-Hermiticity property and the existence of antilinear symmetries, showing that such connection holds also for the nondiagonalizable case. Section V is devoted to a discussion on the time-reversal invariance of fermionic Hamiltonians, extending a result on the (generalized) Kramers degeneracy that we have already proven for diagonalizable operators.[9] Finally, some concluding remarks and possible applications of the previous results are briefly presented in Sec. VI.

II. THE SPECTRUM OF NONDIAGONALIZABLE PSEUDO-HERMITIAN OPERATORS

According to Ref. 8 we consider here only linear operators H acting in a separable Hilbert space $\mathfrak{H}$ and having discrete spectrum. Moreover, throughout this paper we shall assume that all the eigenvalues E_n of H have finite algebraic multiplicity g_n and that there is a basis of $\mathfrak{H}$ in which H is block diagonal with finite-dimensional diagonal blocks. Then, a complete biorthonormal basis $\mathfrak{E}=\{|\psi_n,a,i\rangle,|\phi_n,a,i\rangle\}$ exists such that the operator H can be written in the following form:[8]

$$H=\sum_n \sum_{a=1}^{d_n} \left(E_n \sum_{i=1}^{p_{n,a}} |\psi_n,a,i\rangle\langle\phi_n,a,i| + \sum_{i=1}^{p_{n,a}-1} |\psi_n,a,i\rangle\langle\phi_n,a,i+1| \right), \tag{2}$$

where d_n denotes the geometric multiplicity (i.e., the degree of degeneracy) of E_n, a is a degeneracy label and $p_{n,a}$ represents the dimension of the simple Jordan block $J_a(E_n)$ associated with the labels n and a (hence, $\Sigma_{a=1}^{d_n} p_{n,a}=g_n$). Furthermore, we denote by $k(n,a)$ the total number of identical simple blocks $J_a(E_n)$ occurring in the above decomposition of H.

Hence, $|\psi_n,a,1\rangle$ (respectively, $|\phi_n,a,p_{n,a}\rangle$) is an eigenvector of H (respectively, $H^\dagger$):

$$H|\psi_n,a,1\rangle=E_n|\psi_n,a,1\rangle, \quad H^\dagger|\phi_n,a,p_{n,a}\rangle=E_n^*|\phi_n,a,p_{n,a}\rangle, \tag{3}$$

and the following relations hold:

$$H|\psi_n,a,i\rangle=E_n|\psi_n,a,i\rangle+|\psi_n,a,i-1\rangle, \quad i\neq 1, \tag{4}$$

$$H^\dagger|\phi_n,a,i\rangle=E_n^*|\phi_n,a,i\rangle+|\phi_n,a,i+1\rangle, \quad i\neq p_{n,a}. \tag{5}$$

The elements of the biorthonormal basis obey the usual relations

$$\langle\psi_m,a,i|\phi_n,b,j\rangle=\delta_{mn}\delta_{ab}\delta_{ij}, \tag{6}$$

$$\sum_n \sum_{a=1}^{d_n} \sum_{i=1}^{p_{n,a}} |\psi_n,a,i\rangle\langle\phi_n,a,i| = \sum_n \sum_{a=1}^{d_n} \sum_{i=1}^{p_{n,a}} |\phi_n,a,i\rangle\langle\psi_n,a,i| = \mathbf{1}. \tag{7}$$

The following theorem has been proven in Ref. 8:

Theorem 1: *Let H be a linear operator acting in a Hilbert space $\mathfrak{H}$. Suppose that the spectrum of H is discrete, that its eigenvalues have finite algebraic multiplicity, and that (2) holds. Then, the following conditions are equivalent:*

(i) *the eigenvalues of H are either real or come in complex-conjugate pairs and the geometric multiplicity and the Jordan dimensions of the complex-conjugate eigenvalues coincide;*
(ii) *H is pseudo-Hermitian.*

In order to fix our notation, and for the benefit of the reader, we prefer to provide here a (somewhat different) proof of the implication (i)⇒(ii), which allows us to obtain a useful decomposition of η.

Let us therefore assume that condition (i) holds, and use (whenever it is necessary) the subscript "0" to denote real eigenvalues, and the subscripts "±" to denote the complex eigenvalues with positive or negative imaginary part, respectively. Then, H assumes the following form [see Eq. (2)]:

$$\begin{aligned} H=&\sum_{n_0}\sum_{a=1}^{d_{n_0}}\left(E_{n_0}\sum_{i=1}^{p_{n_0,a}}|\psi_{n_0},a,i\rangle\langle\phi_{n_0},a,i|+\sum_{i=1}^{p_{n_0,a}-1}|\psi_{n_0},a,i\rangle\langle\phi_{n_0},a,i+1|\right)\\ &+\sum_{n_+,n_-}\sum_{a=1}^{d_{n_+}}\left[\sum_{i=1}^{p_{n_+,a}}(E_{n_+}|\psi_{n_+},a,i\rangle\langle\phi_{n+},a,i|+E_{n_-}|\psi_{n_-},a,i\rangle\langle\phi_{n_-},a,i|)\right.\\ &\left.+\sum_{i=1}^{p_{n_+,a}-1}(|\psi_{n_+},a,i\rangle\langle\phi_{n+},a,i+1|+|\psi_{n_-},a,i\rangle\langle\phi_{n_-},a,i+1|)\right]. \end{aligned} \tag{8}$$

Furthermore, given any complete orthonormal basis $\mathfrak{F}=\{|u_n,a,i\rangle\}$ in our space (that we denote by the same n,a,i labels used for the elements of $\mathfrak{E}$), let us pose

$$S=\sum_n\sum_{a=1}^{d_n}\sum_{i=1}^{p_{n,a}}|\phi_n,a,i\rangle\langle u_n,a,i|, \tag{9}$$

and $\tilde{H}=S^\dagger HS^{\dagger-1}$. By a straightforward calculation one obtains

$$\begin{aligned} \tilde{H}=&\sum_{n_0}\sum_{a=1}^{d_{n_0}}\left(E_{n_0}\sum_{i=1}^{p_{n_0,a}}|u_{n_0},a,i\rangle\langle u_{n_0},a,i|+\sum_{i=1}^{p_{n_0,a}-1}|u_{n_0},a,i\rangle\langle u_{n_0},a,i+1|\right)\\ &+\sum_{n_+,n_-}\sum_{a=1}^{d_{n_+}}\left[\sum_{i=1}^{p_{n_+,a}}(E_{n_-}|u_{n_+},a,i\rangle\langle u_{n+},a,i|+E_{n_+}|u_{n_-},a,i\rangle\langle u_{n_-},a,i|)\right.\\ &\left.+\sum_{i=1}^{p_{n_+,a}-1}(|u_{n_+},a,i\rangle\langle u_{n+},a,i+1|+|u_{n_-},a,i\rangle\langle u_{n_-},a,i+1|)\right]. \end{aligned} \tag{10}$$

Then, let us consider the involutory operators U and V defined, respectively, as follows:

$$U|u_{n_\pm},a,i\rangle=|u_{n_\mp},a,i\rangle,\quad U|u_{n_0},a,i\rangle=|u_{n_0},a,i\rangle, \tag{11}$$

and

$$V|u_n,a,i\rangle=|u_n,a,p_{n,a}+1-i\rangle. \tag{12}$$

The explicit forms of U and V are

$$U=U\mathbf{1}=\sum_{n_0,a,i}|u_{n_0},a,i\rangle\langle u_{n_0},a,i|+\sum_{n_+,n_-,a,i}(|u_{n_-},a,i\rangle\langle u_{n_+},a,i|+|u_{n_+},a,i\rangle\langle u_{n_-},a,i|) \tag{13}$$

and

$$V=V\mathbf{1}=\sum_{n_0,a,i}|u_{n_0},a,p_{n_0,a}+1-i\rangle\langle u_{n_0},a,i|$$
$$+\sum_{n_+,n_-,a,i}(|u_{n_+},a,p_{n_+,a}+1-i\rangle\langle u_{n_+},a,i|+|u_{n_-},a,p_{n_-,a}+1-i\rangle\langle u_{n_-},a,i|). \tag{14}$$

Moreover both U and V are clearly Hermitian operators, and (recalling that, by hypothesis, $p_{n_+,a}=p_{n_-,a}$)

$$UV=UV\mathbf{1}=\sum_{n_0}\sum_{a=1}^{d_{n_0}}\sum_{i=1}^{p_{n_0,a}}|u_{n_0},a,p_{n_0,a}+1-i\rangle\langle u_{n_0},a,i|$$
$$+\sum_{n_+,n_-}\sum_{a=1}^{d_{n_+}}\sum_{i=1}^{p_{n_+,a}}(|u_{n_+},a,p_{n_+,a}+1-i\rangle\langle u_{n_-},a,i|+|u_{n_-},a,p_{n_-,a}+1-i\rangle\langle u_{n_+},a,i|)$$
$$=VU.$$

Thus, one can easily verify that $\tilde{H}$ is a pseudo-Hermitian operator:

$$\tilde{\eta}\tilde{H}\tilde{\eta}^{-1}=\tilde{H}^\dagger,$$

where $\tilde{\eta}=UV$. Hence, finally,

$$\eta H\eta^{-1}=H^\dagger,$$

where

$$\eta=S\tilde{\eta}S^\dagger=SUVS^\dagger=\sum_{n_0}\sum_{a=1}^{d_{n_0}}\sum_{i=1}^{p_{n_0,a}}|\phi_{n_0},a,p_{n_0,a}+1-i\rangle\langle\phi_{n_0},a,i|$$
$$+\sum_{n_+,n_-}\sum_{a=1}^{d_{n_+}}\sum_{i=1}^{p_{n_+,a}}(|\phi_{n_+},a,p_{n_+,a}+1-i\rangle\langle\phi_{n_-},a,i|$$
$$+|\phi_{n_-},a,p_{n_-,a}+1-i\rangle\langle\phi_{n_+},a,i|)$$
$$=\eta^\dagger. \tag{15}$$

In conclusion we see that *the spectrum of a pseudo-Hermitian operator is real if and only if* $U\equiv\mathbf{1}$ *[hence, by Eq. (15),* $\eta=SVS^\dagger$*],* and that *a pseudo-Hermitian operator is diagonalizable if and only if* $V\equiv\mathbf{1}$ *[hence, again by Eq. (15),* $\eta=SUS^\dagger$*].*

Remark: We stress here that in order to prove the implication (ii)⇒(i) only the invertibility of η is needed, while the Hermiticity property $\eta=\eta^\dagger$ does not come into play.[8] Hence, by the same arguments one can prove that even the spectrum of a *weakly pseudo-Hermitian* operator[3] [i.e., an operator which satisfies Eq. (1) without any constraint on the (linear and invertible) operator η],

satisfies condition (i). On the other hand, the above proof shows that condition (i) implies that an Hermitian operator η exists which fulfils Eq. (1). Thus, if we just consider operators having a discrete spectrum, the (possibly broader) class of weakly pseudo-Hermitian operators actually coincides with the one of pseudo-Hermitian operators. (This fact was already pointed out for diagonalizable operators.[3,10]) Nevertheless, we recall that the weak pseudo-Hermiticity is a more useful notion, in that, for instance, it simplifies checking Eq. (1).

III. NONDIAGONALIZABILITY AND METRIC INDEFINITENESS

We have seen in the preceding section that an Hermitian operator η always exists such that a nondiagonalizable operator H [whose spectrum obeys condition (i) in Theorem 1] is pseudo-Hermitian; moreover, it is well known that in this case one can define a new inner product,[8]

$$\langle\langle \psi, \phi \rangle\rangle_\eta := \langle \psi | \eta | \phi \rangle, \tag{16}$$

and, correspondingly, a η-pseudonorm $\langle\langle \psi, \psi \rangle\rangle_\eta$. Then, one may of course inquire into the definiteness or the indefiniteness of the metric induced by $\langle\langle ,\rangle\rangle_\eta$.

Equation (15) in the preceding section clearly shows that the metric associated with such an η cannot be a definite (nor a semidefinite) operator; indeed, being $\tilde{\eta}$ involutory and nonidentical (unless H is a diagonalizable operator with real spectrum), some of its eigenvalues (but not all) must be negative, hence the same happens (by the Sylvester's law of inertia[11]) for the eigenvalues of the operator η. This fact can suggest that in all cases of nondiagonalizable (or else, diagonalizable with complex spectrum) pseudo-Hermitian operators, the metric must be indefinite; however, as Eq. (15) does not provide us the more general form of η, we must resort to some other argument in order to confirm this conjecture.

Let us then consider the simplest 2×2 nondiagonalizable operator A:

$$A = \begin{pmatrix} E & 1 \\ 0 & E \end{pmatrix} (E \in \mathbf{R}).$$

A is clearly pseudo-Hermitian and, by a straightforward calculation, one can easily verify that the *most general* operator η which fulfils Eq. (1) is

$$\eta = \begin{pmatrix} 0 & k \\ k & k' \end{pmatrix} \quad (k \neq 0);$$

moreover $\eta = \eta^\dagger$, if and only if, $k, k' \in \mathbf{R}$, and in this case the eigenvalues of η have with certainty opposite signs. Obviously the same happens for the η-pseudonorm of the corresponding eigenvectors; hence some state exists with a negative η-pseudonorm, besides other states with a positive η-pseudonorm.

This simple example disproves a recently stated theorem according to which "(a nondiagonalizable operator) *H is pseudo-Hermitian if and only if it is Hermitian with respect to a positive semidefinite inner product.*" [8]

Actually, the following theorem holds.

Theorem 2: *Let H be an operator with discrete spectrum. Then, there exists a definite operator η such that H is η-pseudo-Hermitian if and only if H is diagonalizable with real spectrum.*

Proof: Let H be a pseudo-Hermitian operator. We preliminarily observe that, being in any case η an invertible operator, all its eigenvalues must be different from zero, so that the metric induced by the inner product (16) either is definite or is indefinite. Now, let us suppose that a positive (respectively, negative) definite operator η exists which fulfils condition (1); then, an R exists such that $\eta = R^\dagger R$ (respectively, $\eta = -R^\dagger R$),[11] and by Eq. (1) we obtain

$$RHR^{-1} = R^{\dagger -1} H^\dagger R^\dagger = (RHR^{-1})^\dagger,$$

i.e., RHR^{-1} is Hermitian, hence it is diagonalizable and it has a real spectrum. Since the similarity transformations preserve the properties of the spectrum, the same occurs for H. Conversely, if H is diagonalizable with real spectrum, then by Eq. (15) in the preceding section a positive definite metric $\eta=SS^{\dagger}$ exists which fulfils condition (1) (since in this case $U=V\equiv\mathbf{1}$). ■

We recall that the equivalence between the definiteness of a suitable η and the reality of the spectrum of H was already proven for diagonalizable operators.[6]

IV. NONDIAGONALIZABLE OPERATORS AND ANTILINEAR SYMMETRIES

A very intriguing feature of the pseudo-Hermiticity property is its connection with the existence of antilinear symmetries. This connection was already acknowledged to hold in the case of diagonalizable operators with discrete spectrum;[3,7] indeed, the pseudo-Hermiticity property is a necessary and sufficient condition for a (diagonalizable) operator H to admit an antilinear (involutory) symmetry.[3] Considering the great physical interest in the study of such symmetries (we recall that the time-reversal symmetry is associated, in complex quantum mechanics, with an antilinear operator), we intend here to inquire the above-mentioned connection in the case of nondiagonalizable pseudo-Hermitian operators. To this end, let us premise a definition.

Definition (Ref. 12): Given the complete orthonormal basis $\mathfrak{F}=\{|u_m,a,i\rangle\}$ *in a Hilbert space, we call* conjugation *associated with it the involutory antilinear operator*

$$\Theta_{\mathfrak{F}}=\sum_{m,a,i}|u_m,a,i\rangle K\langle u_m,a,i|, \tag{17}$$

where the operator K acts transforming each complex number on the right into its complex conjugate.

Analogously, in the case of a complete biorthonormal basis $\mathfrak{E}=\{|\psi_n,a,i\rangle,|\phi_n,a,i\rangle\}$, we call conjugation associated with it the involutory antilinear operator[3]

$$\Theta_{\mathfrak{E}}=\sum_{n,a,i}|\psi_n,a,i\rangle K\langle\phi_n,a,i|. \tag{18}$$

Then, the following theorem holds.

Theorem 3: *Let H be a linear operator. Suppose that the spectrum of H is discrete, that its eigenvalues have finite algebraic multiplicity and that (2) holds. Then the following conditions are equivalent:*

(i) *an antilinear invertible operator* Ω *exists such that* $[H,\Omega]=0$*;*
(ii) *H is (weakly) pseudo-Hermitian;*
(iii) *an antilinear involutory operator* $\hat{\Omega}$ *exists such that* $[H,\hat{\Omega}]=0$*;*
(iv) *a basis exists in which H assumes a real form.*

Proof: (i)⇒(ii) Let Ω exist such that $[H,\Omega]=0$. This implies that $[\tilde{H},\tilde{\Omega}]=0$, where $\tilde{H}=S^{\dagger}HS^{\dagger-1}$ and $\tilde{\Omega}=S^{\dagger}\Omega S^{\dagger-1}$. Then, the linear operator

$$\tilde{\eta}=V\Theta_{\mathfrak{F}}\tilde{\Omega}$$

[where $\mathfrak{F}$ is the orthonormal basis associated with $\tilde{H}$ [see Eq. (10)], while V and $\Theta_{\mathfrak{F}}$ are defined as in Eqs. (12) and (17), respectively] fulfils the condition stated by Eq. (1), hence $\tilde{H}$ is (weakly) pseudo-Hermitian; indeed,

$$
\begin{aligned}
&V\Theta_{\mathfrak{F}}\tilde{\Omega}\tilde{H}\tilde{\Omega}^{-1}\Theta_{\mathfrak{F}}^{-1}V^{-1}\\
&\quad=V\Theta_{\mathfrak{F}}\tilde{H}\Theta_{\mathfrak{F}}V\\
&\quad=\sum_{n_0}\sum_{a=1}^{d_{n_0}}\left(E_{n_0}\sum_{i=1}^{p_{n_0,a}}|u_{n_0},a,i\rangle\langle u_{n_0},a,i|+\sum_{i=1}^{p_{n_0,a}-1}|u_{n_0},a,i+1\rangle\langle u_{n_0},a,i|\right)\\
&\qquad+\sum_{n_+,n_-}\sum_{a=1}^{d_{n_+}}\left[\sum_{i=1}^{p_{n_+,a}}(E_{n_+}^{*}|u_{n_+},a,i\rangle\langle u_{n+},a,i|+E_{n_+}|u_{n_-},a,i\rangle\langle u_{n_-},a,i|)\right.\\
&\qquad\left.+\sum_{i=1}^{p_{n_+,a}-1}(|u_{n_+},a,i+1\rangle\langle u_{n_+},a,i|+|u_{n_-},a,i+1\rangle\langle u_{n_-},a,i|)\right]=\tilde{H}^{\dagger}.
\end{aligned}
$$

Finally, posing $\eta=S\tilde{\eta}S^{\dagger}=SV\Theta_{\mathfrak{F}}S^{\dagger}\Omega$ one obtains

$$\eta H\eta^{-1}=SV\Theta_{\mathfrak{F}}S^{\dagger}\Omega H(SV\Theta_{\mathfrak{F}}S^{\dagger}\Omega)^{-1}=S\tilde{H}^{\dagger}S^{-1}=H^{\dagger}.$$

(ii)⇒(iii). If H is (weakly) pseudo-Hermitian, the eigenvalues of H are either real or come in complex-conjugate pairs and the geometric multiplicity and the Jordan dimensions of the complex-conjugate eigenvalues coincide (see the remark below Theorem 1). Then, one can easily see, recalling the definition of the operator U provided in the proof of Theorem 1 [Eq. (11)] and Eqs. (10) and (17), that

$$\Theta_{\mathfrak{F}}\tilde{H}\Theta_{\mathfrak{F}}=U\tilde{H}U.$$

Hence the antilinear operator

$$
\begin{aligned}
\tilde{\Omega}=\Theta_{\mathfrak{F}}U=U\Theta_{\mathfrak{F}}=&\sum_{n_0}\sum_{a=1}^{d_{n_0}}\sum_{i=1}^{p_{n_0,a}}|u_{n_0},a,i\rangle K\langle u_{n_0},a,i|\\
&+\sum_{n_+,n_-}\sum_{a=1}^{d_{n_+}}\sum_{i=1}^{p_{n_+,a}}(|u_{n_+},a,i\rangle K\langle u_{n_-},a,i|+|u_{n_-},a,i\rangle K\langle u_{n_+},a,i|)
\end{aligned}
$$

commutes with $\tilde{H}$. Moreover, $\tilde{\Omega}$ is involutory, as one can immediately verify by using the explicit expression of $\tilde{\Omega}$ in the previous equation. Then, it follows immediately [recalling Eq. (18) and observing that $\Theta_{\mathfrak{F}}S^{\dagger}=S^{\dagger}\Theta_{\mathfrak{E}}$] that

$$\hat{\Omega}=S^{\dagger-1}\tilde{\Omega}S^{\dagger}=S^{\dagger-1}U\Theta_{\mathfrak{F}}S^{\dagger}=S^{\dagger-1}US^{\dagger}\Theta_{\mathfrak{E}} \tag{19}$$

commutes with H and is involutory.

(iii)⇒(iv). (See Prop. 5 in Ref. 3, where an analogous statement has been proven, referring to diagonalizable operators.)

If we denote by L the linear part of $\hat{\Omega}$, i.e., $\hat{\Omega}=LK$ (where K is the complex conjugation operator), then $\hat{\Omega}^2=\mathbf{1}$ implies $LL^{*}=\mathbf{1}$ and this is possible if and only if an M exists such that $L=MM^{*-1}$.[12] Then $[H,\hat{\Omega}]=0$ implies $HMM^{*-1}=MM^{*-1}H^{*}$, hence

$$M^{-1}HM=(M^{*-1}H^{*}M^{*})=(M^{-1}HM)^{*}.$$

(iv)⇒(i) Trivially, every operator which assumes a real form in some basis $\mathfrak{B}$ commutes with the conjugation associated with $\mathfrak{B}$. ■

Remark: Note that the equivalence (i)⇔(iv) that we prove above clearly restates precisely a similar (seemingly, more general) result in literature, according to which *whenever H commutes with an antiunitary symmetry A such that $A^{2k}=1$ (k odd), it is possible to construct a basis in which the matrix elements of H are real*.[13]

V. THE KRAMERS DEGENERACY

On the basis of the above-stated theorem [in particular, by the implication (i)⇒(ii)] one can conclude that any time-reversal invariant (diagonalizable or not) Hamiltonian H must belong to the class of pseudo-Hermitian Hamiltonians. The converse does not hold in general, since one cannot always interpret the antilinear symmetry Ω of H as the time-reversal operator T; furthermore, it is well known that in case of fermionic systems

$$T^2=-\mathbf{1}$$

and the above theorem, whereas it assures the existence of an involutory antilinear symmetry, does not say anything about the existence of a symmetry like T.

In order to go more deeply into the matter, we can now state the following.

Theorem 4: *Let H be a linear operator with a discrete spectrum. Then, the following conditions are equivalent:*

(i) an antilinear operator $\mathfrak{T}$ exists such that $[H,\mathfrak{T}]=0$, with $\mathfrak{T}^2=-1$;

(ii) H is pseudo-Hermitian and the Jordan blocks associated with any real eigenvalue occur in pair [i.e., for any couple E_{n_0},a, the number $k(n_0,a)$ is even (see Sec. II)].

Proof: Let us assume that condition (i) holds; then, by Theorem 3, H is pseudo-Hermitian, hence its eigenvalues are either real or come in complex-conjugate pairs and the geometric multiplicity and the Jordan dimensions of the complex-conjugate eigenvalues coincide (see Theorem 2).

Let now $|\psi_{n_0},a,1\rangle$ be an eigenvector of H; then, $\mathfrak{T}|\psi_{n_0},a,1\rangle$ too is an eigenvector of H, corresponding to the same eigenvalue E_{n_0}, and linearly independent from $|\psi_{n_0},a,1\rangle$. (Indeed, assume that $\mathfrak{T}\ |\psi_{n_0},a,1\rangle=\alpha|\psi_{n_0},a,1\rangle$ for some $\alpha\in\mathbf{C}$; applying $\mathfrak{T}$ one gets $|\psi_{n_0},a,1\rangle=-|\alpha|^2|\psi_{n_0},a,1\rangle$, which is impossible.)

If $|\psi_{n_0},b,1\rangle$ is another eigenvector of H, linearly independent from $|\psi_{n_0},a,1\rangle$ and $\mathfrak{T}|\psi_{n_0},a,1\rangle$, also $\mathfrak{T}|\psi_{n_0},b,1\rangle$ is linearly independent from all three; otherwise, applying once again $\mathfrak{T}$ to the relation

$$\alpha|\psi_{n_0},a,1\rangle+\beta\mathfrak{T}|\psi_{n_0},a,1\rangle+\gamma|\psi_{n_0},b,1\rangle+\delta\mathfrak{T}|\psi_{n_0},b,1\rangle=0$$

we could eliminate, for instance, $\mathfrak{T}|\psi_{n_0},b,1\rangle$, thus obtaining a linear dependence between $|\psi_{n_0},a,1\rangle$, $\mathfrak{T}|\psi_{n_0},a,1\rangle$, and $|\psi_{n_0},b,1\rangle$, contrary to the previous hypothesis.

We can conclude, iterating this procedure, that the geometric multiplicity d_{n_0} of E_{n_0} must be necessarily even. Moreover, one can always assume that, for a suitable choice of the basis vectors, $\mathfrak{T}|\psi_{n_0},a,1\rangle\equiv|\psi_{n_0},a',1\rangle$ for some a'.

Let us consider now the subset of vectors $\{|\psi_{n_0},a,i\rangle,i=1,\ldots,p_{n_0,a}\}$. They constitute a basis in the subspace associated with the Jordan block $J_a(E_{n_0})$; then by hypothesis one has

$$\sum_{i=1}^{p_{n_0,a}}\alpha_i|\psi_{n_0},a,i\rangle=0\Leftrightarrow\alpha_i=0\ \forall i=1,\ldots,p_{n_0,a}.$$

Applying $\mathfrak{T}$ to the previous equation, one obtains

$$\sum_{i=1}^{p_{n_0,a}} \alpha_i^* \mathfrak{T}|\psi_{n_0},a,i\rangle = 0 \Leftrightarrow \alpha_i = 0 \ \forall i = 1,\ldots,p_{n_0,a},$$

hence, the vectors $\{\mathfrak{T}|\psi_{n_0},a,i\rangle \equiv |\psi_{n_0},a',i\rangle, i=1,\ldots,p_{n_0,a}\}$ too are linearly independent, and $p_{n_0,a} = \dim J_a(E_{n_0}) \leqslant p_{n_0,a'} = \dim J_{a'}(E_{n_0})$. On the other hand, applying $\mathfrak{T}$ to the basis vectors $\{\mathfrak{T}|\psi_{n_0},a,i\rangle\}$ of the subspace associated with $J_{a'}(n_0)$, one obtains that the dimensions of the two blocks must coincide, hence $J_a(n_0)$ and $J_{a'}(n_0)$ are identical.

[Alternatively, the same result can be obtained by applying $\mathfrak{T}$ to both members of Eq. (4).]

Conversely, let condition (ii) hold; then H assumes the form

$$\begin{aligned} H = \sum_{n_0} \sum_{a=1}^{d_{n_0}/2} \Bigg[& E_{n_0} \sum_{i=1}^{p_{n_0,a}} (|\psi_{n_0},a,i\rangle\langle\phi_{n_0},a,i| + |\psi_{n_0},a+d_{n_0,a}/2,i\rangle\langle\phi_{n_0},a+d_{n_0,a}/2,i|) \\ & + \sum_{i=1}^{p_{n_0,a-1}} (|\psi_{n_0},a,i\rangle\langle\phi_{n_0},a,i+1| + |\psi_{n_0},a+d_{n_0,a}/2,i\rangle\langle\phi_{n_0},a+d_{n_0,a}/2,i+1|) \Bigg] \\ & + \sum_{n_+,n_-} \sum_{a=1}^{d_{n+}} \Bigg[\sum_{i=1}^{p_{n_+,a}} (E_{n_+}|\psi_{n_+},a,i\rangle\langle\phi_{n+},a,i| + E_{n_+}^*|\psi_{n_-},a,i\rangle\langle\phi_{n_-},a,i|) \\ & + \sum_{i=1}^{p_{n_+,a-1}} (|\psi_{n_+},a,i\rangle\langle\phi_{n+},a,i+1| + |\psi_{n_-},a,i\rangle\langle\phi_{n_-},a,i+1|) \Bigg]. \end{aligned}$$

Let us denote by $\mathfrak{T}$ the following antilinear operator:

$$\begin{aligned} \mathfrak{T} = \sum_{n_0} \sum_{a=1}^{d_{n_0}/2} \sum_{i=1}^{p_{n_0,a}} & (|\psi_{n_0},a,i\rangle K\langle\phi_{n_0},a+d_{n_0,a}/2,i| - |\psi_{n_0},a+d_{n_0,a}/2,i\rangle K\langle\phi_{n_0},a,i|) \\ & + \sum_{n_+,n_-} \sum_{a=1}^{d_{n+}} \sum_{i=1}^{p_{n_+,a}} (|\psi_{n_-},a,i\rangle K\langle\phi_{n+},a,i| - |\psi_{n_+},a,i\rangle K\langle\phi_{n_-},a,i|), \end{aligned} \tag{20}$$

where the operator K acts transforming each complex number on the right into its complex conjugate. Then, one easily obtains, by inspection, that $[H,\mathfrak{T}]=0$ and $\mathfrak{T}^2 = -\mathbf{1}$. ■

Recalling that the algebraic multiplicity of any E_n is $g_n = \sum_{a=1}^{d_n} p_{n,a}$, from Theorem 4 in particular it follows that whenever *a pseudo-Hermitian operator H admits an antilinear symmetry* $\mathfrak{T}$ *with* $\mathfrak{T}^2 = -1$, *both the geometric and the algebraic multiplicity of any real eigenvalue of H is even*.

The above-mentioned theorem generalizes an analogous theorem stated from the authors (and referring to diagonalizable pseudo-Hermitian operators),[9] which in turn generalizes from various points of view the Kramers theorem on the degeneracy of any fermionic (Hermitian) Hamiltonian. Hence, by an abuse of language, we will continue to denote as "*Kramers degeneracy*" this typical feature of real eigenvalues of pseudo-Hermitian operators admitting a symmetry like $\mathfrak{T}$.

VI. CONCLUDING REMARKS

Basing on Theorem 4, we can quickly test the T-invariance properties of pseudo-Hermitian Hamiltonians. Indeed, let us consider for instance the operator

$$H_{\text{eff}} = \begin{pmatrix} E & ir \\ is & E \end{pmatrix} (E,r,s \in \mathbf{R})$$

which we already discussed elsewhere,[9] and which arises in the modified Mashhoon model,[14] where one introduces a (T-violating) spin-rotation coupling to explain the muon's anomalous g factor.

This Hamiltonian (as long as it is diagonalizable and $rs<0$) is time-reversal violating;[9] however, for some choice of parameter values (for instance, $r\neq s=0$), H_{eff} is no longer diagonalizable. Now, on the basis of Theorem 4 we can conclude that also for such values H_{eff} cannot admit an antilinear symmetry $\mathfrak{T}$ such that $\mathfrak{T}^2=-\mathbf{1}$ (hence, H_{eff} cannot be T-invariant). In fact, being the geometric multiplicity of its eigenvalue E odd, condition (ii) of Theorem 4 does not hold. We recall however that we obtained the same result by a straightforward calculation.[9]

Finally, we note that in a symmetry-adapted basis $\{|\psi_n\rangle,\mathfrak{T}|\psi_n\rangle\}$ the matrix of any pseudo-Hermitian operator H, satisfying condition (ii) of Theorem 4, assumes a symplectic form. This property, in the Hermitian case, is often used in order to simplify some electronic-structure calculations occurring for instance in molecular or solid-state physics.[15]

(Received 14 May 2003; accepted 13 June 2003)

The behavior of the magnetic potential near a point charge (fluxon) located at a curved regular boundary surface is shown to be essentially different from that of a volume point charge. In addition to the usual inverse distance singularity, two singular terms are generally present. The first of them, a logarithmic one, is axially symmetric with respect to the boundary normal at the charge location, and proportional to the sum of the two principal curvatures of the boundary surface at this point, that is, to the local mean curvature. The second term is asymmetric and proportional to the difference of the two principal curvatures in question; it is also bounded at the charge location. Both terms vanish, apparently, if the charge is at a planar point of the boundary, and only in this case. The field in the charge vicinity behaves accordingly, featuring generally two singular terms proportional to the inverse distance, in addition to the main inverse distance squared singularity. This result is significant, in particular, for studying the interaction of magnetic vortices in type II superconductors. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1605497]

Magnetic vortex lines are formed in type II superconductors.[1] When crossing the superconductor boundary, they create strongly localized surface sources of magnetic field (fluxons), which may play an important role in various physical situations. For instance, two space tests of Einstein's General Relativity, Gravity Probe B,[2,3] and STEP (Space Test of the Equivalence Principle),[4] are based on low temperature technology with type II superconductors, and their setup is significantly affected by fluxons.

The size of a surface magnetic spot is about the microscopic London length,[1] i.e., it is typically much smaller than characteristic macroscopic sizes involved. Thus the *point charge* approximation appears naturally and proves to be sufficient for many applications. Within this approximation, the magnetic potential, $\psi=\psi(\mathbf{R})$, satisfies the Neumann boundary value problem

$$\Delta\psi=0, \quad \mathbf{R}\in D, \tag{1}$$

$$\left.\frac{\partial\psi}{\partial n}\right|_S=\sum_{j=1}^{N}\nu_j\Phi_0\delta_S(\mathbf{R}-\mathbf{R}_j), \quad \mathbf{R},\mathbf{R}_j\in S\,. \tag{2}$$

Here the domain D is the empty space, surface S is the superconductor boundary, $\Phi_0=h/2e$ is the

a)Electronic mail: gleit@relgyro.stanford.edu
b)Electronic mail: ilya@caltech.edu
c)Electronic mail: nemenman@kitp.ucsb.edu

magnetic flux quantum in SI units, and the magnetic field is $\mathbf{B}=-\nabla\psi$. Moreover, $\delta_S(\mathbf{R}-\mathbf{R}_j)$ denotes the surface delta-function at the position, $\mathbf{R}_j$, of a vortex, and ν_j is either plus or minus one, depending on whether the field line enters the domain D ($\nu_j=+1$), or exits it ($\nu_j=-1$). We assume that the boundary S is smooth enough (at least C^3) near every charge. Outside the charge vicinities it may have any singularities compatible with the finite local energy condition, meaning $(\nabla\psi)^2$ is locally integrable.

If D is bounded, then each vortex line starts and ends at the boundary, the number of charges is even, and the total charge vanishes, $\Sigma_{j=1}^{N}\nu_j\Phi_0=0$, which condition is the solvability criterion of the problem, Eqs. (1) and (2). If the domain D is infinite, some field lines may end at infinity, and this condition may not hold; in any case, we do not use it in the following analysis, which is entirely local.

An immediate question regarding the above boundary value problem is how does its solution behave near a surface charge? For a curved boundary, an answer based on the similarity with the volume point charge turns out incorrect. This is seen from the simplest example, a spherical domain. A closed-form exact solution to Eqs. (1) and (2) in the exterior of a sphere was obtained in Ref. 5. It shows that a new logarithmic singular term, inversely proportional to the radius of the sphere, is added to the main inverse distance singularity in the expansion of the potential near the charge. So, what happens with the singularity for a generally curved smooth surface?

Our search for the answer to this natural and, in fact, classical question covered books and papers in both mathematical physics and in the field of vortices in superconductors, as well as communications with colleagues in both fields. We also talked with high energy theorists expecting to find perhaps some relevant results in view of the discussions of the magnetic monopole. However, no ready answer was found, which might not be so surprising. Indeed, the Neumann boundary value problem with surface charges is not relevant to the design of electrostatic systems. On the other hand, its magnetostatic implementation became available only with the widespread technical use of superconductors in the recent years. Last but not least, the answer proves to be not that simple.

In this paper we fill the gap by deriving a complete singular part of the expansion of the solution to Eqs. (1) and (2) near a charge at an arbitrary curved smooth boundary. As compared to the case of a sphere, one more singular term, proportional to the difference of the two principal curvatures, appears in the general case.

We are interested in the behavior of the potential near a single surface charge at some $\mathbf{R}_j$. For brevity, we thus drop the charge index in the following calculation. We put the origin of a Cartesian coordinate system at $\mathbf{R}_j$, so that $\mathbf{r}\equiv\mathbf{R}-\mathbf{R}_j$. We point the z axis along the outward normal to the surface S (that is, into the superconducting bulk), choosing the x and y axes in the tangent plane, so that the unit vectors $\{\hat{x},\hat{y},\hat{z}\}$ form a right orthogonal triplet. Along with Cartesian $\{x, y, z\}$, we will use the corresponding spherical, $\{r, \theta, \phi\}$, and cylindrical, $\{\rho, \phi, z\}$, coordinate systems (see Fig. 1).

The shape of the smooth boundary surface in the vicinity of the charge can be described by the equation $z=F(x,y)$. The Taylor expansion of the function $F(x,y)$ around $x=y=0$ apparently has no terms linear in x or y, since z is oriented along the normal. Moreover, by an appropriate rotation of the coordinate axes $\hat{x},\hat{y}$ in the tangent plane, we can ensure that the second cross-derivative of F vanishes at the origin, hence the expansion acquires the form

$$z=F(x,y)=\frac{k^{(x)}}{2}x^2+\frac{k^{(y)}}{2}y^2+O(\rho^3)\equiv f(x,y)+O(\rho^3)\,, \tag{3}$$

where

$$k^{(x)}=\left.\frac{\partial^2 F}{\partial x^2}\right|_{x=y=0}\,,\quad k^{(y)}=\left.\frac{\partial^2 F}{\partial y^2}\right|_{x=y=0} \tag{4}$$

are the two principal curvatures of the boundary surface at the charge location.

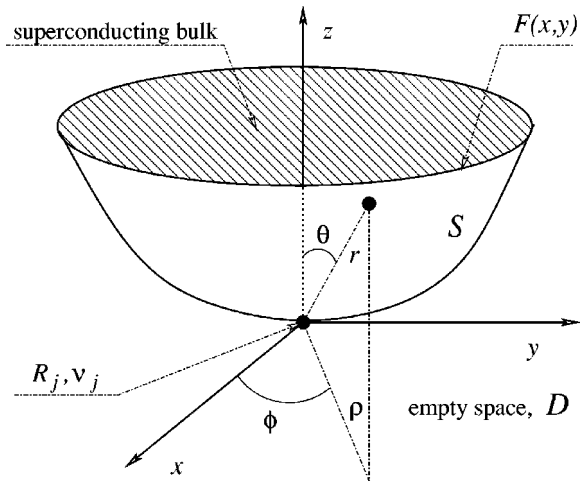

FIG. 1. Definition of coordinate systems near a charge.

Since, near $\mathbf{r}=0$,

$$\delta_S(\mathbf{r})=\delta(x)\,\delta(y)/J,$$

$$\partial/\partial n=\hat{n}\cdot\nabla=(1/J)(\partial/\partial z-F_x\,\partial/\partial x-F_y\,\partial/\partial y),$$

$$J\equiv\sqrt{1+F_x^2+F_y^2},$$

the boundary condition, Eq. (2), in the vicinity of the charge can be written in terms of variables x,y,z as[6]

$$\left.\frac{\partial\psi}{\partial z}\right|_{z=F(x,y)}=\nu\Phi_0\delta(x)\,\delta(y)+\left.\left(F_x\frac{\partial\psi}{\partial x}+F_y\frac{\partial\psi}{\partial y}\right)\right|_{z=F(x,y)}. \tag{5}$$

The partial derivatives of the function $F(x,y)$ near the origin are given, to the order we are interested in, by

$$F_x=k^{(x)}x+O(\rho^2),\quad F_y=k^{(y)}y+O(\rho^2). \tag{6}$$

Once again, we only care about the vicinity of the charge where $z=F(x,y)$ is small, so we can use perturbation of the boundary to move the boundary condition, Eq. (5), to the plane $z=0$. This is done by means of the following Taylor expansion of an arbitrary function $w=w(x,y,z)$:

$$w|_{z=F(x,y)}=w|_{z=0}+F\left.\frac{\partial w}{\partial z}\right|_{z=0}+\frac{F^2}{2}\left.\frac{\partial^2 w}{\partial z^2}\right|_{z=0}+\cdots.$$

Applying this to the derivatives of ψ in Eq. (5) we write it, to the proper order, in the form:

$$\left.\frac{\partial\psi}{\partial z}\right|_{z=0}=\nu\Phi_0\delta(x)\,\delta(y)+\left.\left(F_x\frac{\partial\psi}{\partial x}+F_y\frac{\partial\psi}{\partial y}-F\frac{\partial^2\psi}{\partial z^2}\right)\right|_{z=0}+\cdots. \tag{7}$$

The final step of this derivation is to expand ψ in a series of successively smaller (that is, less singular at the origin) functions $\psi^{(i)}$,

$$\psi=\psi^{(0)}+\psi^{(1)}+\psi^{(2)}+\cdots. \tag{8}$$

Introducing this expansion in the boundary condition Eq. (7) and then matching the terms of the same order, we end up with the following sequence of boundary conditions for $\psi^{(i)}$, $i=0,1,2,\ldots$, at $z=0$:

$$\left.\frac{\partial\psi^{(0)}}{\partial z}\right|_{z=0}=\nu\Phi_0\,\delta(x)\,\delta(y), \tag{9}$$

$$\left.\frac{\partial\psi^{(1)}}{\partial z}\right|_{z=0}=\left[k^{(x)}x\,\frac{\partial\psi^{(0)}}{\partial x}+k^{(y)}y\,\frac{\partial\psi^{(0)}}{\partial y}-f(x,y)\,\frac{\partial^2\psi^{(0)}}{\partial z^2}\right]\Bigg|_{z=0}, \tag{10}$$

and so on. Here we have dropped higher order terms on the right-hand sides by replacing F and F_x, F_y with their main term expressions from Eqs. (3) and (6), respectively. Of course, all functions $\psi^{(i)}$ are subject to the Laplace equation, Eq. (1).

Thus, *locally* we have successfully replaced the boundary value problem of Eqs. (1) and (2) in the domain D by a sequence of problems for functions $\psi^{(i)}$, $i=0,1,2,\ldots$, harmonic in the half-space $z<0$ and satisfying the above boundary conditions, Eqs. (9), (10), etc. We now need to solve these problems for the half-space one by one, until the normal derivative of the solution becomes finite at the boundary.

The zero-order solution $\psi^{(0)}$ obeying the boundary condition of Eq. (9) is, of course,

$$\psi^{(0)}=\frac{\nu\Phi_0}{2\pi}\,\frac{1}{r}. \tag{11}$$

It allows one to immediately calculate the right-hand side of Eq (10). Indeed,

$$f\left.\frac{\partial^2\psi^{(0)}}{\partial z^2}\right|_{z=0}=-\frac{\nu\Phi_0 f}{2\pi}\left(\frac{1}{r^3}-\frac{3z^2}{r^5}\right)\Bigg|_{z=0}=-\frac{\nu\Phi_0}{2\pi}\,\frac{k^{(x)}x^2+k^{(y)}y^2}{2\rho^3},$$

where the second term in the middle expression turns to zero at $z=0$, contributing no δ-like singularities, due to the presence of the factor $f=O(\rho^2)$. Also taking into account that $\partial r^{-1}/\partial x=-x/r^3$, $\partial r^{-1}/\partial y=-y/r^3$, we find the boundary condition for $\psi^{(1)}$ in its final explicit form:

$$\left.\frac{\partial\psi^{(1)}}{\partial z}\right|_{z=0}=-\frac{\nu\Phi_0}{2\pi}\,\frac{k^{(x)}x^2+k^{(y)}y^2}{2\rho^3}=-\frac{\nu\Phi_0}{8\pi}\left[\frac{k^{(x)}+k^{(y)}}{\rho}+\frac{k^{(x)}-k^{(y)}}{\rho}\cos 2\phi\right]. \tag{12}$$

The two terms on the utmost right here have essentially different singularities at the origin. For this reason, we treat them separately by splitting the problem in two in the following way:

$$\psi^{(1)}=\psi_s^{(1)}+\psi_r^{(1)}, \tag{13}$$

$$\left.\frac{\partial\psi_s^{(1)}}{\partial z}\right|_{z=0}=-\frac{\nu\Phi_0}{8\pi}\,\frac{k^{(x)}+k^{(y)}}{\rho}, \tag{14}$$

$$\left.\frac{\partial\psi_r^{(1)}}{\partial z}\right|_{z=0}=-\frac{\nu\Phi_0}{8\pi}\,\frac{k^{(x)}-k^{(y)}}{\rho}\cos 2\phi. \tag{15}$$

The Neumann problem for $\psi_s^{(1)}$ in the half-space does not have solutions bounded at infinity, as one would expect in our investigation (we are actually looking for terms *growing* away from the charge, because a weaker singularity next to the inverse distance is most probably some logarithm tending to infinity at both the charge and the infinite distance from it). For this reason, no solution can be found by means of standard techniques. However, a harmonic and regular in the half-space $z<0$ function

$$\psi_s^{(1)} = K_+ \ln[(r-z)/d] = K_+[\ln(r/d) + \ln(1-\cos\theta)], \tag{16}$$

$$K_\pm \equiv \nu\Phi_0[k^{(x)} \pm k^{(y)}]/8\pi, \tag{17}$$

where $d>0$ is an arbitrary constant of the dimension of length, provides the needed solution. Indeed, it satisfies the boundary condition, Eq. (14), in view of

$$\partial \ln(r-z)/\partial z = (r-z)^{-1}(z/r-1) = -1/r \to -1/\rho, \quad z \to -0.$$

The solution given by Eq. (16) is unique in the class of functions with the logarithmic growth at infinity, namely, those with the asymptotics

$$\psi_s^{(1)} = K_+ \ln(r/d) + K_+ \ln(1-\cos\theta) + o(1), \ \frac{\partial \psi_s^{(1)}}{\partial r} = K_+/r + O(1/r^2), \ r \to \infty.$$

Contrary to the previous one, the Neumann problem for $\psi_r^{(1)}$,

$$\Delta \psi_r^{(1)} = 0, \ z<0, \ \left.\frac{\partial \psi_r^{(1)}}{\partial z}\right|_{z=0} = -\frac{K_-}{\rho}\cos 2\phi, \tag{18}$$

has a unique, up to a constant, solution bounded at infinity [namely, a solution that obeys somewhat unusual conditions $\psi_r^{(1)} = O(1)$, $\partial\psi_r^{(1)}/\partial r = o(1/r^2)$, $r\to\infty$]. The solution is obtained by the standard separation of variables in cylindrical coordinates using the Hankel transform, and it reads:

$$\begin{aligned}\psi_r^{(1)} &= -K_- \cos 2\phi \int_0^\infty J_2(\lambda\rho)\exp(-\lambda|z|)\frac{d\lambda}{\lambda} \\ &= -\frac{K_-\cos 2\phi}{2}\left(\frac{\rho}{r-z}\right)^2 = -\frac{K_-}{2}\frac{x^2-y^2}{(r-z)^2}.\end{aligned} \tag{19}$$

The value of the integral is found in Ref. 7, 4.14.(5), and the constant K_- is defined in Eq. (17). Interestingly, this solution in spherical coordinates does not depend on the radius, being a function of the angles only [singular on the positive semiaxis $z>0$, same as $\psi_s^{(1)}$ in Eq. (16)]:

$$\psi_r^{(1)} = -\frac{K_-}{2}\frac{\sin^2\theta\cos 2\phi}{(1-\cos\theta)^2}, \quad \frac{\partial\psi_r^{(1)}}{\partial r} = 0.$$

It is now straightforward to see that the Neumann boundary data for all higher order corrections to the potential, starting with $\psi^{(2)}$, are finite at the origin (and dropping fast enough at infinity); accordingly, the solutions of the corresponding problems bounded at infinity are unique up to an additive constant. It also means that all the terms in the expansion, Eq. (8), of the potential, whose normal derivative are singular at the location of a surface charge, are given by the solutions already found. Hence, combining the expressions from Eqs. (11), (16), and (19), we find the desired formula for the magnetostatic potential near a surface charge ($r\to 0$):

$$\begin{aligned}\psi &= \psi^{(0)} + \psi_s^{(1)} + \psi_r^{(1)} + \cdots \\ &= \frac{\nu\Phi_0}{2\pi}\left[\frac{1}{r} + \frac{k^{(x)}+k^{(y)}}{4}\ln\frac{r-z}{d} - \frac{k^{(x)}-k^{(y)}}{8}\frac{x^2-y^2}{(r-z)^2}\right] + (\text{nonsingular terms}).\end{aligned} \tag{20}$$

It is easy to rewrite this in our general notations from Eqs. (1) and (2) by replacing $|\mathbf{r}|$ with $|\mathbf{R}-\mathbf{R}_j|$, x with $X-X_j$, etc. Instead, we give the expression of the singular part of the magnetic field near the charge. It can be written in the form:

$$\mathbf{B}=-\nabla\psi=\frac{\nu\Phi_0}{2\pi}\left[\frac{\hat{r}}{r^2}-\frac{k^{(x)}+k^{(y)}}{4r}\left(\hat{r}+\frac{\sin\theta}{1-\cos\theta}\hat{\theta}\right)-\frac{k^{(x)}-k^{(y)}}{4r}\frac{\sin\theta}{(1-\cos\theta)^2}(\cos 2\phi\,\hat{\theta}\right.$$
$$\left.+\sin 2\phi\,\hat{\phi})\right]+(\text{nonsingular terms}). \tag{21}$$

Here are a few concluding remarks regarding the obtained result.

First, notice that the leading order contribution to the potential, Eq. (11), is twice that of the point charge located in a volume away from its boundaries. This is clearly explained by the fact that the field lines and the flux from the surface charge emanate only into the half-space, versus the full space for the volume charge.

The two singular corrections to the usual inverse distance singularity of the potential, Eq. (20), are very different. The first one is logarithmic, axially symmetric about the direction of the normal to the boundary at the charge location, and proportional to the sum of two principal surface curvatures there, i.e., to the mean boundary curvature. Thus, it vanishes if the charge sits at a symmetric saddle point of the boundary. The second additional singularity is asymmetric, proportional to the difference of the principal curvatures, and vanishes thus when the latter are equal, i.e., when the charge is at a spherical point of the boundary. This second term is bounded at the charge location [giving unbounded field components, see Eq. (21)], but is not uniquely defined there, with the limiting values depending on the direction along which the limit is taken. Note that both corrections vanish simultaneously if and only if the charge is at the planar point of the boundary.

In a particular case when the domain D is the exterior of a sphere of the radius a, one has $k^{(x)}=k^{(y)}=1/a$. If there is just one surface charge, $N=j=1$ and $\nu=1$ (so that the incoming vortex line ends at infinity), Eq. (20) becomes

$$\psi=\frac{\Phi_0}{2\pi}\left[\frac{1}{|\mathbf{R}-\mathbf{R}_1|}+\frac{1}{2a}\ln\frac{|\mathbf{R}-\mathbf{R}_1|-\hat{n}\cdot(\mathbf{R}-\mathbf{R}_1)}{d}\right]+(\text{nonconstant nonsingular terms}), \tag{22}$$

in complete agreement with the exact solution obtained in Ref. 5 with $d=2a$.

Finally, the obtained singular expansion of the potential can be used in the derivation of the force acting on a charge in a fashion similar to the one developed in the case of volume point charges,[8] i.e., by means of the geometrical regularization of energy and, henceforth, the force, as the energy gradient in the charge location. However, in a striking contrast with the volume case, the force here is found to depend on the gradient of the curvature at the charge location. Namely, due to the first additional singular term in the potential, Eq. (20), there appears a tangential force on the charge which tries to move it toward the point of the stationary mean curvature of the boundary, and which diverges in the regularization limit. If confirmed, this divergence would mean that either the approximation of the *point* surface charges does not completely describe real microscopic, but finite size fluxons, or, strangely enough, that the fluxons cannot reside at arbitrary points of a curved boundary, or perhaps even something else.

A detailed study of fluxon interactions will be carried out in a separate publication. However, it is clear that it will necessarily use the results of this paper, in view of the relation

$$\psi(\mathbf{r},\mu)=\int_S dS(\boldsymbol{\xi})\,\mu(\boldsymbol{\xi})\,\psi(\mathbf{r}-\boldsymbol{\xi}),$$

where $\psi(\mathbf{r},\mu)$ is the potential created by the surface charge density $\mu(\boldsymbol{\xi})$, $\boldsymbol{\xi}\in S$, and $\psi(\mathbf{r})$ is the potential from Eq. (20). For small, yet finite size fluxons the divergent asymptotics derived above will have an explicit short scale cutoff defined by the spatial extent of the density (presumably, the London length). However, the detailed analysis will require a deeper insight in the real structure of magnetic vortex lines near a boundary. Without such an analysis one cannot, in fact, speculate about the strength and importance of these surface interactions; we will thus limit ourselves to just a few short comments.

First, one compares, naturally, the surface force coming from the logarithmic term in the field potential to the strength of the random pinning force that defines the fluxon's position.[9] The latter depends on the flux tube length and the former does not. So, allowing for a physical regularization of the mathematically divergent surface effects, one will in any case come up with some characteristic length, L, below which the surface force will dominate. The description of the vortex line dynamics that does not account for surface effects at distances from the surface smaller than L is necessarily incomplete.

Second, forces between two vortices in a superconducting bulk are exponentially small if the vortex line separation is larger than the London length (precisely the regime we are discussing). These forces can be neglected. Thus, the surface effects we have found will be the leading interaction terms. Such effects are significant and translate into an experimentally relevant magnetic ''friction'' between superconducting bodies.[10]

(Received 18 March 2003; accepted 15 May 2003)

We generalize the Dirac equation to $D+1$ space–time. The conserved angular momentum operators and their quantum numbers are discussed. The eigenfunctions of the total angular momentums are calculated for both odd D and even D cases. The exact solutions of the $D+1$-dimensional radial equations of the Dirac equation with a Coulomb plus scalar potential are analytically presented by studying the Tricomi equations obtained from a pair of coupled first-order ones. The eigenvalues are also discussed in some detail. © *2003 American Institute of Physics.*

I. INTRODUCTION

The exact solutions of the nonrelativistic and relativistic equations with the Coulomb potential play an important role in quantum mechanics.[1–3] For example, the study of the exact solutions of the Schrödinger equation for a hydrogen atom is an important advance at the beginning of establishment of quantum mechanics. Recently the study of the Dirac equation with the Coulomb plus scalar potential has been investigated. For instance, the bound states of this case have been studied in $3+1$ dimensions.[4,5] Moreover the corresponding S-matrix in the quantum scattering theory has also been carried out by Vaidya and Souza in $3+1$ dimensions.[6] With the interest of the lower-dimensional field theory and condensed matter physics, the lower-dimensional case seems physically relevant since the results obtained in this case exhibit some new features. Therefore, the bound states of the $(2+1)$-dimensional Dirac equation with the Coulomb plus scalar potential have been investigated in our previous work.[7] Similarly with the interest of the higher-dimensional field theory, it is worth studying the exact solutions of this quantum system in $D+1$ dimensional space–time, which is the main purpose of this work.

This article is organized as follows. Section II is devoted to the generalization of the Dirac equation to $D+1$ space–time. In Sec. III, the conserved angular momentum operators and their quantum numbers are discussed. The eigenfunctions of the total angular momentums are calculated for both odd D and even D cases from the view point of the group theory. The radial equations of this quantum system are obtained. In Sec. IV, the exact solutions of the radial equations, which are expressed by the confluent hypergeometric functions, are analytically presented. The energy levels and some special cases are also discussed in great detail. The concluding remarks are given in Sec. V.

II. THE DIRAC EQUATION IN $D+1$ DIMENSIONS

In this section we review some properties of the Dirac equation in $D+1$ dimensional space–time. The Dirac equation in $D+1$ dimensions can be written as[8]

$$i\sum_{\mu=0}^{D} \gamma^{\mu}(\partial_{\mu}+ieA_{\mu})\Psi(\mathbf{x},t)=M\Psi(\mathbf{x},t), \tag{1}$$

where M is the mass of the particle, and $D+1$ matrices γ_{μ} satisfy the anticommutative relations:

$$\gamma^{\mu}\gamma^{\nu}+\gamma^{\nu}\gamma^{\mu}=2\,\eta^{\mu\nu}\mathbf{1}, \tag{2}$$

with

$$\eta^{\mu\nu}=\eta_{\mu\nu}=\begin{cases}\delta_{\mu\nu} & \text{when} \quad \mu=0,\\ -\delta_{\mu\nu} & \text{when} \quad \mu\neq 0.\end{cases} \tag{3}$$

Throughout this article, the natural units $\hbar=c=1$ are employed if not explicitly stated otherwise. Discuss the special case where only A_0 of A_{μ} is nonvanishing and spherically symmetric:

$$eA_0=V(r), \qquad A_a=0, \qquad \text{when} \quad a\neq 0. \tag{4}$$

The Hamiltonian $H(\mathbf{x})$ of the system is expressed as

$$\begin{gathered} i\partial_0\Psi(\mathbf{x},t)=H(\mathbf{x})\Psi(\mathbf{x},t), \qquad H(\mathbf{x})=\sum_{c=1}^{D}\gamma^0\gamma^c p_c+V(r)+\gamma^0 M,\\ p_c=-i\partial_c=-i\frac{\partial}{\partial x^c}, \quad c\in[1,D]. \end{gathered} \tag{5}$$

The orbital angular momentum operators L_{ab}, the spinor operators S_{ab}, and the total angular momentum operators J_{ab} are defined as follows:

$$\begin{gathered} L_{ab}=-L_{ba}=ix_a\partial_b-ix_b\partial_a, \quad S_{ab}=-S_{ba}=i\frac{\gamma_a\gamma_b}{2},\\ J_{ab}=L_{ab}+S_{ab}, \quad 1\leqslant a<b\leqslant D,\\ J^2=\sum_{a<b=2}^{D}J_{ab}^2, \quad L^2=\sum_{a<b=2}^{D}L_{ab}^2, \quad S^2=\sum_{a<b=2}^{D}S_{ab}^2. \end{gathered} \tag{6}$$

The eigenvalue of J^2 (L^2 or S^2) is denoted by the Casimir $C_2(\mathbf{M})$, where $\mathbf{M}$ is the highest weight of the representation to which the total (orbital or spinor) wave function belongs. We will discuss the Casimir in the next section. It is easy to show by the standard method[8] that J_{ab} and κ are commutative with the Hamiltonian $H(\mathbf{x})$,

$$\kappa=\gamma^0\left(\sum_{a<b} i\gamma^a\gamma^b L_{ab}+\frac{D-1}{2}\right)=\gamma^0\left(J^2-L^2-S^2+\frac{D-1}{2}\right). \tag{7}$$

III. THE RADIAL EQUATIONS

Because of the spherically symmetric potential $V(r)$, the symmetry group of the system is SO(D) group. Erdelyi,[9] Louck[10] and Chatterjee[11] have introduced the hyperspherical coordinates in the real D-dimensional space:

$$
\begin{aligned}
x^1 &= r\cos\theta_1 \sin\theta_2 \cdots \sin\theta_{D-1},\\
x^2 &= r\sin\theta_1 \sin\theta_2 \cdots \sin\theta_{D-1},\\
x^b &= r\cos\theta_{b-1} \sin\theta_k \cdots \sin\theta_{D-1}, \quad b\in[3,D-1],\\
x^D &= r\cos\theta_{D-1},\\
\sum_{a=1}^{D} (x^a)^2 &= r^2.
\end{aligned}
\tag{8}
$$

The unit vector along $\mathbf{x}$ is usually denoted by $\hat{\mathbf{x}}=\mathbf{x}/r$. The volume element of the configuration space is

$$
\prod_{a=1}^{D} dx^a = r^{D-1} dr\, d\Omega, \quad d\Omega = \prod_{a=1}^{D-1} (\sin\theta_a)^{a-1} d\theta_a,
\tag{9}
$$

$$
r\in[0,\infty], \qquad \theta_1\in[-\pi,\pi], \quad \theta_c\in[0,\pi], \qquad c\in[2,D-1].
$$

We now sketch some necessary information of the SO(D) group. From the representation theory of Lie groups,[12–14] the Lie algebras of the groups SO($2N+1$) and SO($2N$) are B_N and D_N, respectively. Their Chevalley bases with the subscript μ, $1\leqslant\mu\leqslant N-1$, are the same:

$$
\begin{aligned}
H_\mu(J) &= J_{(2\mu-1)(2\mu)} - J_{(2\mu+1)(2\mu+2)},\\
E_\mu(J) &= \tfrac{1}{2}(J_{(2\mu)(2\mu+1)} - J_{(2\mu-1)(2\mu+2)} - iJ_{(2\mu-1)(2\mu+1)} - iJ_{(2\mu)(2\mu+2)}),\\
F_\mu(J) &= \tfrac{1}{2}(J_{(2\mu)(2\mu+1)} - J_{(2\mu-1)(2\mu+2)} + iJ_{(2\mu-1)(2\mu+1)} + iJ_{(2\mu)(2\mu+2)}).
\end{aligned}
\tag{10a}
$$

However, the bases with the subscript N are different:

$$
\begin{aligned}
H_N(J) &= 2J_{(2N-1)(2N)},\\
E_N(J) &= -iJ_{(2N-1)(2N+1)} + J_{(2N)(2N+1)},\\
F_N(J) &= iJ_{(2N-1)(2N+1)} + J_{(2N)(2N+1)}
\end{aligned}
\tag{10b}
$$

for SO($2N+1$), and

$$
\begin{aligned}
H_N(J) &= J_{(2N-3)(2N-2)} + J_{(2N-1)(2N)},\\
E_N(J) &= \tfrac{1}{2}(J_{(2N-2)(2N-1)} + J_{(2N-3)(2N)} + iJ_{(2N-2)(2N)} - iJ_{(2N-3)(2N-1)}),\\
F_N(J) &= \tfrac{1}{2}(J_{(2N-2)(2N-1)} + J_{(2N-3)(2N)} + iJ_{(2N-3)(2N-1)} - iJ_{(2N-2)(2N)}),
\end{aligned}
\tag{10c}
$$

for SO($2N$). The operator J_{ab} may be replaced by L_{ab} or S_{ab} depending on the studied wave functions. $H_\mu(J)$ span the Cartan subalgebra, and their eigenvalues for an eigenstate $|\mathbf{m}\rangle$ in a given irreducible representation (IR) are the components of a weight vector $\mathbf{m}=(m_1,\ldots,m_n)$:

$$
H_\mu(J)|\mathbf{m}\rangle = m_\mu|\mathbf{m}\rangle, \qquad \mu\in[1,N].
\tag{11}
$$

If the eigenstates $|\mathbf{m}\rangle$ for a given weight $\mathbf{m}$ are degeneracy, this weight is called a multiple weight, otherwise a simple one. E_μ are called the raising operators and F_μ the lowering ones. For an IR there is a highest weight $\mathbf{M}$, which is a simple weight and is used to describe the IR. Generally, the

irreducible representation is also called the highest weight representation and directly denoted by **M**. The Casimir $C_2(\mathbf{M})$ is calculated by the formula [see (1.131) of Ref. 14]

$$C_2(\mathbf{M})=\mathbf{M}\cdot(\mathbf{M}+2\varrho)=\sum_{\mu,\nu=1}^{N} M_\mu d_\mu (A^{-1})_{\mu\nu}(M_\nu+2), \tag{12}$$

where ϱ is the half sum of the positive roots in the Lie algebra, A^{-1} is the inverse of the Carton matrix, and d_μ are the half square lengths of the simple roots.

The orbital wave functions in D-dimensional space are usually expressed by the spherical harmonics $Y^{(l)}_{\mathbf{m}}(\hat{\mathbf{x}})$,[10,11] which belong to the weight **m** of the highest weight representation $(l)\equiv(l,0,\ldots,0)$. For the highest weight state, $\mathbf{m}=(l)$, we have

$$Y^{(l)}_{(l)}(\hat{\mathbf{x}})=N_{D,l}\, r^{-l}(x^1+ix^2)^l, \tag{13a}$$

with the normalization factor

$$N_{D,l}=\begin{cases} 2^{-N-l}\sqrt{\dfrac{(2l+2N-1)!}{\pi^N l!(l+N-1)!}} & \text{when} \quad D=2N+1, \\ \sqrt{\dfrac{(l+N-1)!}{2\pi^N l!}} & \text{when} \quad D=2N. \end{cases} \tag{13b}$$

Its partners $Y^{(l)}_{\mathbf{m}}(\hat{\mathbf{x}})$ is calculated from $Y^{(l)}_{(l)}(\hat{\mathbf{x}})$ by lowering operators $F_\mu(L)$. The Casimir for the spherical harmonic $Y^{(l)}_{\mathbf{m}}(\hat{\mathbf{x}})$ can be calculated by Eq. (12):

$$L^2 Y^{(l)}_{\mathbf{m}}(\hat{\mathbf{x}})=C_2[(l)]Y^{(l)}_{\mathbf{m}}(\hat{\mathbf{x}}), \tag{14}$$

with

$$C_2[(l)]=l(l+D-2).$$

It is known that the spinor wave functions as well as those for the total angular momentum are different for $D=2N+1$ and $D=2N$, as studied in Ref. 15. Nevertheless, for completeness and clearness, it is necessary to review how to calculate these wave functions with the help of the groups SO$(2N+1)$ and SO$(2N)$.

A. The SO$(2N+1)$ case

When $D=2N+1$ we can define

$$\gamma^0=\sigma_3\times\mathbf{1}, \qquad \gamma^a=(i\sigma_2)\times\alpha_a, \qquad a\in[1,2N+1], \tag{15}$$

with the Pauli matrix σ_a, the 2^N-dimensional unit matrix **1** and the $(2N+1)$ matrices α_a satisfying the following anticommutative relations:

$$\alpha_b\alpha_a+\alpha_a\alpha_b=2\delta_{ab}\mathbf{1}, \quad b,\ a=1,\ 2,\ldots,(2N+1). \tag{16}$$

The dimensions of α_a matrices are 2^N. Thus the spinor operator S_{ab} becomes a block matrix

$$S_{ab}=\mathbf{1}\times\overline{S}_{ab}, \quad \overline{S}_{ab}=-i\frac{\alpha_a\alpha_b}{2}. \tag{17}$$

The relation between S_{ab} and $\overline{S}_{ab}$ is very similar to that between the spinor operators for the Dirac spinors and for the Pauli spinors. The operator κ becomes

$$\kappa=\sigma_3\times\overline{\kappa},\quad \overline{\kappa}=-i\sum_{a<b}\ \alpha_a\alpha_b L_{ab}+\frac{D-1}{2}. \tag{18}$$

The spinor $\chi(\mathbf{m})$ belongs to the spinor representation $(s)\equiv(0,\ldots,0,1)$. It is found from Eq. (12) that the Casimir for the representation (s) can be calculated as $C_2[(s)]=(2N^2+N)/4$.

On the other hand, it is well known that the product of $Y^{(l)}_{\mathbf{m}}(\hat{\mathbf{x}})$ and $\chi(\mathbf{m}')$ belongs to the direct product of two representation (l) and (s), which is a reducible representation:

$$(l)\times(s)\simeq(l,0,\ldots,0,1)\oplus(l-1,0,\ldots,0,1). \tag{19}$$

Generally speaking, there are two different ways to construct a wave function belonging to the representation $(j)\equiv(l,0,\ldots,0,1)$, namely, the combination of $Y^{(l)}_{\mathbf{m}}(\hat{\mathbf{x}})\chi(\mathbf{m}')$ and that of $Y^{(l+1)}_{\mathbf{m}}(\hat{\mathbf{x}})\chi(\mathbf{m}')$, which are different in eigenvalues of $\overline{\kappa}$. Considering the spherically symmetric system, we only calculate the highest weight state for the representation (j) from the Clebsch–Gordan coefficients

$$\phi_{|K|,(j)}(\hat{\mathbf{x}})=Y^{(l)}_{(l)}(\hat{\mathbf{x}})\chi[(s)]=N_{D,l}r^{-l}(x^1+ix^2)^l\chi[(s)], \tag{20}$$

with

$$|K|=C_2[(j)]-C_2[(l)]-C_2[(s)]+N=l+N,$$

and

$$\begin{aligned}\phi_{-|K|,(j)}(\hat{\mathbf{x}})&=\sum_{\mathbf{m}}\ Y^{(l+1)}_{\mathbf{m}}(\hat{\mathbf{x}})\chi[(j)-\mathbf{m}]\langle(l+1),\mathbf{m},(s),(j)-\mathbf{m}|(j),(j)\rangle\\&=N_{D,l}r^{-l-1}(x^1+ix^2)^l\{x^{2N+1}\chi[(s)]+(x^{2N-1}+ix^{2N})\chi[(0,\ldots,0,1,\overline{1})]\\&\quad+(x^{2N-3}+ix^{2N-2})\chi[(0,\ldots,0,1,\overline{1},1)]+\cdots+(x^3+ix^4)\chi[(1,\overline{1},0,\ldots,0,1)]\\&\quad+(x^1+ix^2)\chi[(\overline{1},0,\ldots,0,1)]\},\end{aligned} \tag{21}$$

with

$$-|K|=C_2[(j)]-C_2[(l+1)]-C_2[(s)]+N=-l-N.$$

The wave functions $\Psi_{K,(j)}(\mathbf{x})$ of the total angular momentum belonging to the IR (j) can be written as

$$\Psi_{K,(j)}(\mathbf{x},t)=r^{-N}e^{-iEt}\begin{pmatrix}F(r)\phi_{K,(j)}(\hat{\mathbf{x}})\\iG(r)\phi_{-K,(j)}(\hat{\mathbf{x}})\end{pmatrix}, \tag{22a}$$

with the following properties:

$$\begin{aligned}&H_1(J)\Psi_{K,(j)}(\mathbf{x})=l\Psi_{K,(j)}(\mathbf{x}),\\&H_N(J)\Psi_{K,(j)}(\mathbf{x})=\Psi_{K,(j)}(\mathbf{x}),\\&H_\mu(J)\Psi_{K,(j)}(\mathbf{x})=0,\qquad \mu\in[2,N-1],\\&\kappa\Psi_{K,(j)}(\mathbf{x})=K\Psi_{K,(j)}(\mathbf{x}),\quad K=\pm(l+N).\end{aligned} \tag{22b}$$

Their partners can be calculated by the lowering operators F_μ.

The radial equation depends on the explicit forms of α_a matrices, which can be expressed by direct products of N Pauli matrices σ_a:[16]

$$\alpha_{2m-1}=\overbrace{\mathbf{1}\times\ldots\times\mathbf{1}}^{m-1}\times\sigma_1\times\overbrace{\sigma_3\times\ldots\times\sigma_3}^{N-m},$$

$$\alpha_{2m-1}=\overbrace{\mathbf{1}\times\ldots\times\mathbf{1}}^{m-1}\times\sigma_2\times\overbrace{\sigma_3\times\ldots\times\sigma_3}^{N-m}, \tag{23}$$

$$\alpha_{2N+1}=\sigma_3\times\sigma_3\times\ldots\times\sigma_3.$$

From the explicit forms of α_a, one can obtain

$$\begin{aligned}(\vec{\alpha}\cdot\hat{\mathbf{x}})\phi_{K,(j)}(\hat{\mathbf{x}})&=r^{-1}\sum_{b=1}^{2N+1}\alpha_b x^b \quad \phi_{K,(j)}(\hat{\mathbf{x}})=\phi_{-K,(j)}(\hat{\mathbf{x}}),\\ (\vec{\alpha}\cdot\vec{\mathbf{p}})r^{-N}\phi_{K,(j)}(\hat{\mathbf{x}})&=\sum_{b=1}^{2N+1}\alpha_b p_b \quad r^{-N}\phi_{K,(j)}(\hat{\mathbf{x}})=iKr^{-N-1}\phi_{-K,(j)}(\hat{\mathbf{x}}).\end{aligned} \tag{24}$$

Substitution of $\Psi_{K(j)}(\mathbf{x})$ into the Dirac equation (5) leads to the following radial equation,

$$\begin{aligned}G'(r)+\frac{K}{r}G(r)&=[E-V(r)-M]F(r),\\ -F'(r)+\frac{K}{r}F(r)&=[E-V(r)+M]G(r),\end{aligned} \tag{25}$$

where and hereafter the prime denotes the first derivative with respect to the variable $r(\rho)$.

B. The SO(2*N*) case

As we know, the reducible spinor representation of SO($2N$) is reduced to two inequivalent fundamental spinor representations $(+s)\equiv(0,0,\ldots,0,1)$ and $(-s)\equiv(0,0,\ldots,1,0)$. Likewise it is shown from Eq. (12) that the Casimir for both spinor representations can be obtained as $C_2[(\pm s)]=(2n^2-n)/4$. From the α_a matrices given in Eq. (23), we define the γ^μ matrices for $D=2N$:

$$\gamma^0=\alpha_{2N+1},\qquad \gamma^a=\alpha_{2N+1}\alpha_a,\qquad a\in[1,2N]. \tag{26}$$

Here the γ^0 is a diagonal matrix where half of the diagonal elements are equal to $+1$ and the remainder to -1. On considering the spinor operator S_{ab} and the operator κ are commutative with γ^0, each of them becomes a direct sum of two matrices, referring to the rows with the eigenvalues $+1$ and -1 of γ^0, respectively. The spinors $\chi_\pm(\mathbf{m})$ belong to the spinor representations $(+s)$ and $(-s)$, respectively, and satisfy

$$\gamma^0\chi_\pm(\mathbf{m})=\pm\chi_\pm(\mathbf{m}). \tag{27}$$

Thus the product of $Y^{(l)}_{\mathbf{m}}(\hat{\mathbf{x}})$ and $\chi_\pm(\mathbf{m}')$ belongs to the direct product of two representation (l) and $(\pm s)$, which is a reducible representation:

$$\begin{aligned}(l)\times(+s)&\simeq(l,0,\ldots,0,1)\oplus(l-1,0,\ldots,0,1,0),\\ (l)\times(-s)&\simeq(l,0,\ldots,0,1,0)\oplus(l-1,0,\ldots,0,1).\end{aligned} \tag{28}$$

There exist two kinds of representations for the total angular momentum: the representation $(j_1)\equiv(l,0,\ldots,0,1)$ and the representation $(j_2)\equiv(l,0,\ldots,0,1,0)$. Nevertheless, their Casimirs are equal:

$$C_2[(j_1)]=C_2[(j_2)]=l(l+2N-1)+\frac{N(2N-1)}{4}. \tag{29}$$

Similar to the case of $SO(2N+1)$, there exist two different ways to obtain the wave functions belonging to the representation (j_1): the combination of $Y^{(l)}_{\mathbf{m}}(\hat{\mathbf{x}})\chi_+(\mathbf{m}')$ and that of $Y^{(l+1)}_{\mathbf{m}}(\hat{\mathbf{x}})\chi_-(\mathbf{m}')$. Because of the spherical symmetry, one only calculates the highest weight state for the representation (j_1) by the Clebsch–Gordan coefficients:

$$\phi_{K,(j_1)}(\hat{\mathbf{x}})=Y^{(l)}_{(l)}(\hat{\mathbf{x}})\chi_+[(+s)]=N_{D,l}r^{-l}(x^1+ix^2)^l\chi_+[(+s)], \tag{30a}$$

and

$$\begin{aligned}\phi_{-K,(j_1)}(\hat{\mathbf{x}})&=\sum_{\mathbf{m}}\ Y^{(l+1)}_{\mathbf{m}}(\hat{\mathbf{x}})\chi_-[(j_1)-\mathbf{m}]\langle(l+1),\mathbf{m},(+s),(j_1)-\mathbf{m}|(j_1),(j_1)\rangle\\&=N_{D,l}r^{-l-1}(x^1+ix^2)^l\{x^{2N-1}+ix^{2N}\chi_-[(-s)]+(x^{2N-3}+ix^{2N-2})\\&\quad\times\chi_-[(0,\ldots,0,1,\overline{1},0)]+(x^{2N-5}+ix^{2N-4})\chi_-[(0,\ldots,0,1,\overline{1},0,1)]+\cdots\\&\quad+(x^3+ix^4)\chi_-[(1,\overline{1},0,\ldots,0,1)]+(x^1+ix^2)\chi_-[(\overline{1},0,\ldots,0,1)]\},\end{aligned} \tag{30b}$$

with

$$K=C_2[(j_1)]-C_2[(l+1)]-C_2[(+s)]+N-\tfrac{1}{2}=l+N-\tfrac{1}{2}.$$

However, for the representation $(j_2)\equiv(l,0,\ldots,0,1,0)$ we obtain

$$\phi_{-K,(j_2)}(\hat{\mathbf{x}})=Y^{(l)}_{(l)}(\hat{\mathbf{x}})\chi_-[(-s)]=N_{D,l}r^{-l}(x^1+ix^2)^l\chi_-[(-s)], \tag{31a}$$

and

$$\begin{aligned}\phi_{K,(j_2)}(\hat{\mathbf{x}})&=\sum_{\mathbf{m}}\ Y^{(l+1)}_{\mathbf{m}}(\hat{\mathbf{x}})\chi_+[(j_2)-\mathbf{m}]\langle(l+1),\mathbf{m},(-s),(j_2)-\mathbf{m}|(j_2),(j_2)\rangle\\&=N_{D,l}r^{-l-1}(x^1+ix^2)^l\{x^{2N-1}-ix^{2N}\chi[(+s)]+(x^{2N-3}+ix^{2N-2})\chi_+[(0,\ldots,0,1,0,\overline{1})]\\&\quad+(x^{2N-5}+ix^{2N-4})\chi_+[(0,\ldots,0,1,\overline{1},1,0)]+\cdots+(x^3+ix^4)\chi_+[(1,\overline{1},0,\ldots,0,1,0)]\\&\quad+(x^1+ix^2)\chi_+[(\overline{1},0,\ldots,0,1,0)]\},\end{aligned} \tag{31b}$$

with

$$K=C_2[(j_2)]-C_2[(l+1)]-C_2[(+s)]+N-\tfrac{1}{2}=-(l+N-\tfrac{1}{2}).$$

From the explicit forms of α_a one obtains

$$\begin{aligned}(\vec{\alpha}\cdot\hat{\mathbf{x}})\phi_{K,(j_\omega)}(\hat{\mathbf{x}})&=r^{-1}\sum_{a=1}^{2N}\ \alpha_a x^a\phi_{K,(j_\omega)}(\hat{\mathbf{x}})=\phi_{-K,(j_\omega)}(\hat{\mathbf{x}}),\\(\vec{\alpha}\cdot\vec{\mathbf{p}})r^{-N+1/2}\phi_{K,(j_\omega)}(\hat{\mathbf{x}})&=\sum_{a=1}^{2N}\ \alpha_a p_a\ \ r^{-N+1/2}\phi_{K,(j_\omega)}(\hat{\mathbf{x}})=iKr^{-N-1/2}\phi_{-K,(j_\omega)}(\hat{\mathbf{x}}),\end{aligned} \tag{32}$$

with $\omega=1$ or 2.

The wave functions $\Psi_{K,(j_\omega)}(\mathbf{x})$ of the total angular momentum belonging to the IR (j_ω) are expressed as

$$\Psi_{|K|,(j_1)}(\mathbf{x},t)=r^{-N+1/2}e^{-iEt}\{F(r)\phi_{|K|,(j_1)}(\hat{\mathbf{x}})+iG(r)\phi_{-|K|,(j_1)}(\hat{\mathbf{x}})\},$$

$$\Psi_{-|K|,(j_2)}(\mathbf{x},t)=r^{-N+1/2}e^{-iEt}\{F(r)\phi_{-|K|,(j_2)}(\hat{\mathbf{x}})+iG(r)\phi_{|K|,(j_2)}(\hat{\mathbf{x}})\}, \tag{33a}$$

$$\kappa\Psi_{K,(j_\omega)}(\mathbf{x})=K\Psi_{K,(j_\omega)}(\mathbf{x}), \quad |K|=l+N-\tfrac{1}{2}, \quad \omega=1 \text{ or } 2,$$

with the following properties:

$$H_1(J)\Psi_{K,(j_\omega)}(\mathbf{x})=l\Psi_{K,(j_1)}(\mathbf{x}), \qquad H_{N-1}(J)\Psi_{K,(j_1)}(\mathbf{x})=0, \tag{33b}$$

$$H_N(J)\Psi_{K,(j_1)}(\mathbf{x})=\Psi_{K,(j_1)}(\mathbf{x}), \quad H_{N-1}(J)\Psi_{K,(j_2)}(\mathbf{x})=\Psi_{K,(j_2)}(\mathbf{x}), \tag{33c}$$

$$H_N(J)\Psi_{K,(j_2)}(\mathbf{x})=0, \qquad H_\mu(J)\Psi_{K,(j_\omega)}(\mathbf{x})=0, \qquad \mu\in[2,N-2]. \tag{33d}$$

Their partners can be calculated by the lowering operators F_μ.

Substitution of $\Psi_{K(j_\omega)}(\mathbf{x})$ into the Dirac equation (5) allows us to obtain the radial equations, which are in the same forms as those in $D=2N+1$ case:

$$\begin{aligned} G'(r)+\frac{K}{r}G(r)&=[E-V(r)-M]F(r),\\ -F'(r)+\frac{K}{r}F(r)&=[E-V(r)+M]G(r). \end{aligned} \tag{34}$$

IV. THE EXACT SOLUTIONS OF THE RADIAL EQUATION

Although the wavefunctions and the eigenvalues K are different for the $D=2N+1$ case and the $D=2N$ case, the forms of the radial equations are unified

$$\begin{aligned} G'_{KE}(r)+\frac{K}{r}G_{KE}(r)&=[E-V(r)-M]F_{KE}(r),\\ -F'_{KE}(r)+\frac{K}{r}F_{KE}(r)&=[E-V(r)+M]G_{KE}(r), \end{aligned} \tag{35}$$

$$K=\pm(2l+D-1)/2.$$

We now consider the Dirac equation with a mixed potential including a Coulomb potential and a scalar one. The Coulomb potential is derived from the exchange of massless photons between the nucleus and the lepton orbiting around it, namely,

$$V_c=-\frac{A_1}{r}. \tag{36}$$

However, the scalar potential

$$V_s=-\frac{A_2}{r} \tag{37}$$

is added to the mass term of the Dirac equation, which can be interpreted as an effective, position-dependent mass. It is created by the exchange of the massless scalar meson. The A_1 and A_2 are the electrostatic and the scalar coupling constants, respectively.

It is found that the radial components $F_{KE}(r)$ and $G_{KE}(r)$ satisfy the following first-order differential equations

$$\begin{aligned} G'_{KE}(r)+\frac{K}{r}G_{KE}(r)&=\left(E-M+\frac{A_1+A_2}{r}\right)F_{KE}(r),\\ -F'_{KE}(r)+\frac{K}{r}F_{KE}(r)&=\left(E+M+\frac{A_1-A_2}{r}\right)G_{KE}(r). \end{aligned} \tag{38}$$

It is convenient to introduce ρ for the bound states:

$$\rho=2r\sqrt{M^2-E^2}, \qquad |E|<M. \tag{39}$$

We thus have

$$\begin{aligned} G'_{KE}(\rho)+\frac{K}{\rho}G_{KE}(\rho)&=\left(-\frac{1}{2}\sqrt{\frac{M-E}{M+E}}+\frac{A_1+A_2}{\rho}\right)F_{KE}(\rho),\\ F'_{KE}(\rho)-\frac{K}{\rho}F_{KE}(\rho)&=\left(-\frac{1}{2}\sqrt{\frac{M+E}{M-E}}-\frac{A_1-A_2}{\rho}\right)G_{KE}(\rho). \end{aligned} \tag{40}$$

Define the wave functions $\Phi_{\pm}(\rho)$ with the forms

$$\begin{aligned} G_{KE}(\rho)&=\sqrt{M-E}[\Phi_+(\rho)+\Phi_-(\rho)],\\ F_{KE}(\rho)&=\sqrt{M+E}[\Phi_+(\rho)-\Phi_-(\rho)]. \end{aligned} \tag{41}$$

Substitutions of Eq. (41) into Eq. (40) allow us to write down

$$\begin{aligned} \Phi'_+(\rho)+\Phi'_-(\rho)+\frac{K}{\rho}[\Phi_+(\rho)+\Phi_-(\rho)]&=\left[-\frac{1}{2}+\frac{A_1+A_2}{\rho}\sqrt{\frac{M+E}{M-E}}\right][\Phi_+(\rho)-\Phi_-(\rho)],\\ \Phi'_+(\rho)-\Phi'_-(\rho)-\frac{K}{\rho}[\Phi_+(\rho)-\Phi_-(\rho)]&=\left[-\frac{1}{2}-\frac{A_1-A_2}{\rho}\sqrt{\frac{M-E}{M+E}}\right][\Phi_+(\rho)+\Phi_-(\rho)]. \end{aligned} \tag{42}$$

Their addition and subtraction lead to

$$\begin{aligned} \Phi'_+(\rho)-\left(\frac{A_1E+A_2M}{\rho\sqrt{M^2-E^2}}-\frac{1}{2}\right)\Phi_+(\rho)&=-\left(\frac{K}{\rho}+\frac{A_1M+A_2E}{\rho\sqrt{M^2-E^2}}\right)\Phi_-(\rho),\\ \Phi'_-(\rho)+\left(\frac{A_1E+A_2M}{\rho\sqrt{M^2-E^2}}-\frac{1}{2}\right)\Phi_-(\rho)&=-\left(\frac{K}{\rho}-\frac{A_1M+A_2E}{\rho\sqrt{M^2-E^2}}\right)\Phi_+(\rho). \end{aligned} \tag{43}$$

Taking the following conventions,

$$\tau=\frac{A_1E+A_2M}{\sqrt{M^2-E^2}}, \qquad \tau'=\frac{A_1M+A_2E}{\sqrt{M^2-E^2}}, \tag{44}$$

we have

$$\Phi'_+(\rho)-\left(\frac{\tau}{\rho}-\frac{1}{2}\right)\Phi_+(\rho)=-\frac{\tau'+K}{\rho}\Phi_-(\rho),$$
$$\Phi'_-(\rho)+\left(\frac{\tau}{\rho}-\frac{1}{2}\right)\Phi_-(\rho)=\frac{\tau'-K}{\rho}\Phi_+(\rho), \tag{45}$$

from which we can obtain the following important second-order differential equations:

$$\left[\frac{d^2}{d\rho^2}+\frac{1}{\rho}\frac{d}{d\rho}+\left(-\frac{1}{4}+\frac{\tau\pm 1/2}{\rho}-\frac{\eta^2}{\rho^2}\right)\right]\Phi_\pm(\rho)=0,$$
$$\eta^2=K^2-A_1^2+A_2^2. \tag{46}$$

For the weak Coulomb potential, we have

$$\eta=\sqrt{K^2-A_1^2+A_2^2}>0. \tag{47}$$

It is found that Eq. (46) is a special case of the Tricomi equation,[17] which can be expressed as

$$\frac{d^2y}{dx^2}+\left(a+\frac{b}{x}\right)\frac{dy}{dx}+\left(\alpha+\frac{\alpha}{x}+\frac{\xi}{x^2}\right)y=0. \tag{48}$$

From the behaviors of the wave functions at the origin and infinity, we define

$$\Phi_\pm(\rho)=\rho^\eta e^{-\rho/2}R_\pm(\rho). \tag{49}$$

Substitution of this into (47) leads to

$$\frac{d^2}{d\rho^2}R_\pm(\rho)+\left(-1+\frac{1+2\eta}{\rho}\right)\frac{d}{d\rho}R_\pm(\rho)+\frac{\tau-\eta-\frac{1}{2}\pm\frac{1}{2}}{\rho}R_\pm(\rho)=0, \tag{50}$$

whose solutions are the confluent hypergeometric functions

$$R_+(\rho)=a_0\Phi(\eta-\tau,2\eta+1;\rho),$$
$$R_-(\rho)=b_0\Phi(1+\eta-\tau,2\eta+1;\rho), \tag{51}$$

which imply that $G_{KE}(\rho)$ and $F_{KE}(\rho)$ can be directly expressed by the combinations of the confluent hypergeometric functions.

We now study the relation between the coefficients a_0 and b_0. Before proceeding to do so, it is necessary to review the following recursive relations between the confluent hypergeometric functions[17]

$$\gamma\frac{d}{dz}\Phi(\alpha,\gamma;z)=\alpha\,\Phi(\alpha+1,\gamma+1;z),$$
$$z\Phi(\alpha+1,\gamma+1;z)=\gamma\Phi(\alpha+1,\gamma;z)-\gamma\Phi(\alpha,\gamma;z),$$
$$\alpha\Phi(\alpha+1,\gamma+1;z)=(\alpha-\gamma)\Phi(\alpha,\gamma+1;z)+\gamma\Phi(\alpha,\gamma;z), \tag{52}$$
$$\alpha\Phi(\alpha+1,\gamma;z)=(z+2\alpha-\gamma)\Phi(\alpha,\gamma;z)+(\gamma-\alpha)\Phi(\alpha-1,\gamma;z).$$

It is shown from Eqs. (46), (51) and (52) that

$$\left(\frac{\eta-\tau}{\rho}a_0+\frac{\tau'+K}{\rho}b_0\right)\Phi(1+\eta-\tau,2\eta+1;\rho)=0. \tag{53}$$

Since both a_0 and b_0 cannot be vanishing, we obtain

$$b_0=\frac{\tau-\eta}{\tau'+K}a_0. \tag{54}$$

From Eq. (42) we thus have

$$\begin{aligned}
G_{KE}(\rho)&=N_{KE}\sqrt{M-E}\,\rho^{\eta}e^{-\rho/2}\\
&\quad\times[(\tau'+K)\Phi(\eta-\tau,2\eta+1;\rho)+(\tau-\eta)\Phi(1+\eta-\tau,2\eta+1;\rho)],\\
F_{KE}(\rho)&=N_{KE}\sqrt{M+E}\,\rho^{\eta}e^{-\rho/2}\\
&\quad\times[(\tau'+K)\Phi_1(\eta-\tau,2\eta+1;\rho)-(\tau-\eta)\Phi(1+\eta-\tau,2\eta+1;\rho)],
\end{aligned} \tag{55}$$

where the normalization factor $N_{KE}=a_0(\tau'+K)^{-1}(2\sqrt{M^2-E^2})^{-1/2}$ can be determined later.

We now study the eigenvalues of this quantum system. The quantum condition is obtained from the finiteness of the solutions at infinity:

$$\tau-\eta=n'=0,1,2,\ldots, \tag{56}$$

when $n'=0$, $\eta=\tau$, and

$$K^2=\tau^2+A_1^2-A_2^2=(\tau')^2.$$

Therefore K has to be positive in order to avoid the trivial solution.

Introducing the principal quantum number

$$n=|K|-(D-3)/2+n'=|K|-(D-3)/2+\tau-\eta=l+1+n'=1,\ 2,\ldots, \tag{57}$$

we have

$$\frac{EA_1+MA_2}{\sqrt{M^2-E^2}}=n-|K|+\frac{D-3}{2}+\eta=n'+\eta\equiv\kappa. \tag{58}$$

The energy E can be solved from Eq. (58):

$$E(n,K)=M\left\{-\frac{A_1A_2}{A_1^2+\kappa^2}\pm\left[\left(\frac{A_1A_2}{A_1^2+\kappa^2}\right)^2-\frac{A_2^2-\kappa^2}{A_1^2+\kappa^2}\right]^{1/2}\right\}. \tag{59}$$

We now consider a few special cases. First, if $A_1=0$, then $\eta=\sqrt{K^2+A_2^2}$, and

$$E(n,K)=\pm M\left(1-\frac{A_2^2}{\kappa^2}\right)^{1/2}. \tag{60}$$

It implies that there are two branches of solutions symmetric for the positive and negative energies. For a large D, we have

$$E(n,D)\simeq\pm M[1-2A_2^2D^{-2}+4A_2^2(2n-3)D^{-3}-\cdots], \tag{61}$$

which implies that the energy is independent of l for a large D. For a small A_2, we have

$$E(n,l,D)\simeq\pm M\left\{1-\frac{A_2^2}{2[n+(D-3)/2]^2}+\frac{A_2^4}{2[n+(D-3)/2]^4}\left(\frac{2n+D-3}{2l+D-1}-\frac{1}{4}\right)\right\}, \tag{62}$$

where the first term on the right-hand side is the rest energy M ($c^2=1$ in our conventions), the second one is from the solutions of the Schrödinger equation, and the third one is the fine structure energy, which removes the degeneracy between the states with the same n.

Second, if $A_2=0$, then $\eta=\sqrt{K^2-A_1^2}$ and from Eq. (58) E has the same sign as A_1 when $K^2>A_1^2$. For the attractive Coulomb potential ($A_1>0$) we have the positive energy E_{nK}

$$E_{nK}=M\left(1+\frac{A_1^2}{\kappa^2}\right)^{-1/2}. \tag{63}$$

It coincides with the conclusion from the Sturm–Liouville theorem for a weak attractive potential.[18] For a large D similarly we have the same result as Eq. (61).

For a small A_1, we have

$$E(n,l,D)\simeq M\frac{A_1}{|A_1|}\left\{1-\frac{A_1^2}{2[n+(D-3)/2]^2}-\frac{A_1^4}{2[n+(D-3)/2]^4}\left(\frac{2n+D-3}{2l+D-1}-\frac{3}{4}\right)\right\}. \tag{64}$$

Similarly, the physical meanings of three terms are similar to those of Eq. (62) except for the different expansion coefficients.

We are now briefly considering the special case $D=1$ in this case. It is found that there is absence of the bound states since η becomes imaginary regardless of the value of A_1. This can be easily checked from the fact that the eigenvalues and eigenfunctions do not exist at all.

Third, if $A_1=A_2$, we have $\eta=|K|$ and

$$E(n)=M\left[-\frac{A_1^2}{A_1^2+(n+(D-3)/2)^2}\pm\frac{(n+(D-3)/2)^2}{A_1^2+(n+(D-3)/2)^2}\right]. \tag{65}$$

If we choose the negative sign in the result, we have $E=-M$, which is a singular solution of Eq. (58). For the positive sign, we have

$$E(n)=M\left[1-\frac{2A_1^2}{A_1^2+(n+(D-3)/2)^2}\right]. \tag{66}$$

We now determine the normalization factor N_{KE} from the normalization condition

$$\int \Psi_{KE}^{\dagger}\Psi_{KE}dV=1. \tag{67}$$

Noticing $n'=\tau-\eta$ is a non-negative integer, we can express the confluent hypergeometric function by the associated Laguerre polynomial[19]

$$L_n^{\alpha}(\rho)=\frac{\Gamma(\alpha+n+1)}{n!\Gamma(\alpha+1)}{}_1F_1(-n,\alpha+1;\rho), \tag{68}$$

$$\int_0^{\infty}\rho^{\alpha}e^{-\rho}L_n^{\alpha}(\rho)L_m^{\alpha}(\rho)d\rho=\frac{\Gamma(n+\alpha+1)}{n!}\delta_{nm}. \tag{69}$$

Through a direct calculation we obtain

$$N_{KE}=\frac{(M^2-E^2)^{1/4}}{\Gamma(2\eta+1)}\left[\frac{\Gamma(\tau+\eta+1)}{2M\tau'(K+\tau')(\tau-\eta)!}\right]^{1/2}. \tag{70}$$

V. CONCLUDING REMARKS

In this work we have studied the (D+1)-dimensional Dirac equation with a Coulomb plus scalar potential with the interest of higher-dimensional field theory. The eigenfunctions can be analytically obtained by studying the second-order differential equations obtained from the first-order coupled ones. The eigenvalues as well as their special cases are studied. Before ending this article, we give two remarks here. First, in comparison with the 3D case, the angular momentum quantum number K in $D+1$ dimensions plays the role of the good quantum number κ in three dimensions (more strictly, $|K|+\frac{1}{2}\leftrightarrow|\kappa|$). Second, for the special case $D=1$, it is found from Eq. (35) that $K=0$. Therefore, it is shown from Eq. (47) that η becomes imaginary if $|A_2|<|A_1|$, which means that there is absence of the bound states in this case. On the contrary, there exist the bound states if $|A_2|>|A_1|$.

A quantum weak energy inequality for spin-one fields in curved space–time

Christopher J. Fewster[a] and Michael J. Pfenning[b]
Department of Mathematics, University of York, Heslington, York, YO10 5DD, United Kingdom

(Received 4 April 2003; accepted 22 May 2003)

Quantum weak energy inequalities (QWEI) provide state-independent lower bounds on averages of the renormalized energy density of a quantum field. We derive QWEIs for the electromagnetic and massive spin-one fields in globally hyperbolic space–times whose Cauchy surfaces are compact and have trivial first homology group. These inequalities provide lower bounds on weighted averages of the renormalized energy density as ''measured'' along an arbitrary timelike trajectory, and are valid for arbitrary Hadamard states of the spin-one fields. The QWEI bound takes a particularly simple form for averaging along static trajectories in ultrastatic space–times; as specific examples we consider Minkowski space (in which case the topological restrictions may be dispensed with) and the static Einstein universe. A significant part of the paper is devoted to the definition and properties of Hadamard states of spin-one fields in curved space–times, particularly with regard to their microlocal behavior. © *2003 American Institute of Physics.*

I. INTRODUCTION

In common with all observed forms of classical matter, the spin-one fields described by the Maxwell and Proca equations obey the weak energy condition (WEC). That is, the stress-energy tensor T_{ab} obeys $T_{ab}v^a v^b \geqslant 0$ for all timelike vectors v^a. In classical general relativity, energy conditions such as the WEC play a key role in many important results, notably the singularity theorems of Penrose[1] and Hawking.[2] Moreover, since any metric solves the Einstein equations for some choice of stress-energy tensor, it is arguable that general relativity has limited predictive power in the absence of such conditions.

However, all classical energy conditions are violated by quantum fields, as has been known for many years.[3] Typically, the energy density at a given space–time point is unbounded from below as a function of the state. Specific examples of negative energy states are provided by highly squeezed states of light in quantum optics, the Casimir vacuum state for a quantized field between uncharged perfectly conducting parallel planar plates and the Boulware vacuum state outside a black holes. Replacing the classical stress-energy tensor on the right-hand side of Einstein's equation with its quantum expectation value, we must therefore allow for negative energy sources, raising the possibility of exotic phenomena within the realm of semiclassical gravity. For example, negative energy can be used to maintain static traversable wormholes,[4,5] create naked singularities,[6,7] travel faster than light,[8,9] and travel backward through time.[5,10] In negative energy models studied by Parker and Fulling it is even possible to avoid the cosmological singularity,[11] thus threatening to overthrow the classical singularity theorems. One might also expect that negative energy fluxes could lead to macroscopic violations of the second law of thermodynamics.[12]

Of course, macroscopic violations of the second law are not observed in nature. Motivated by these thermodynamic considerations, Ford[12] deduced that the negative fluxes and energy densities

[a]Electronic mail: cjf3@york.ac.uk
[b]Electronic mail: mpj11@york.ac.uk

of quantum fields must be subject to constraints, at least on average. These constraints, known as *quantum inequalities*, or QI, provide state-independent lower bounds on certain weighted averages of the stress-energy tensor. They may therefore be regarded as the remnants of the classical energy conditions after quantization; thus, for example, the analogue of the WEC is sometimes referred to as a *quantum weak energy inequality* or QWEI. Such bounds typically take the form

$$\int \langle :T_{ab}(\gamma(\tau))u^a(\tau)u^b(\tau):\rangle_\omega f(\tau)\mathrm{d}\tau \geqslant -\mathfrak{Q}(\gamma,f)\,, \tag{1}$$

where $f\geqslant 0$ is the weight, or sampling function, γ is a smooth timelike curve, parametrized by proper time τ and with four-velocity $u^a=(\mathrm{d}\gamma/\mathrm{d}\tau)^a$, and $:T_{ab}:$ denotes the stress-energy tensor, normal ordered with respect to some reference state ω_0. The significant point is that the bound $\mathfrak{Q}(\gamma,f)$ is independent of the state ω. The class of states ω for which the bound holds must also be delineated—all bounds in the literature require (at least) that ω and ω_0 be Hadamard states, although this can be weakened slightly. Of course the normal ordered energy density differs from the renormalized energy density by the (renormalized) energy density of the reference state. Accordingly, Eq. (1) may easily be converted into a bound on the renormalized energy density.

As we will shortly describe, various authors have established QWEI's for the scalar and Dirac fields in different circumstances, leading up to general results valid in curved space–times. The main aim of the present paper is to establish similar QWEI's for the Maxwell and Proca fields in general globally hyperbolic space–times. In order to do this, we have also made a detailed study of the field theories concerned, particularly in relation to the class of Hadamard states. Several new results obtained here may therefore be of more general interest.

As already mentioned, the earliest work on quantum inequalities is due to Ford, who established a bound on negative energy fluxes for scalar fields in 1991.[13] The first QWEI was obtained for the massless, minimally coupled scalar field in Minkowski space–time by Ford and Roman,[14] who established the inequality (1) for the case of an inertial worldline γ and with f taking the Lorentzian form $f(\tau)=\tau_0/(\pi(\tau^2+\tau_0^2))$, in which τ_0 sets the characteristic time scale for the averaging. In four dimensions, the resulting bound was

$$\int \langle :T_{ab}(\tau)u^a(\tau)u^b(\tau):\rangle_\omega \frac{\tau_0}{\pi(\tau^2+\tau_0^2)}\,\mathrm{d}\tau \geqslant -\frac{3}{32\pi^2\tau_0^4}\,. \tag{2}$$

These results were then extended by Ford and Roman to the massive scalar field in Minkowski space[14,15] and were further extended by Pfenning and Ford to minimally coupled scalar fields of arbitrary mass in ultrastatic curved space–times.[16–18] In these generalizations, it was found that the dominant term of the QWEI has a form similar to Eq. (2), but with subdominant correction terms due to the curvature and the mass of the field. Pfenning and Ford also showed that one could express the bound on the right-hand side of the QWEI in terms of derivatives of the Euclidean Green's function for the space–time and developed a short sampling time approximation to the QWEI which could be used in space–times where it would be too hard to calculate the exact QWEI bound.

The restriction to the Lorentzian weight $\tau_0/(\pi(\tau^2+\tau_0^2))$ was removed by various authors. By making use of the conformal properties of field theories in two dimensions, Flanagan[19,20] has derived optimal quantum inequalities for the massless scalar field for arbitrary smooth positive sampling functions, and Vollick has done the same for the Dirac field.[21] QWEI's for the minimally coupled scalar field in static curved space–times of any dimension for an arbitrary sampling function were established by Fewster in work with Eveson[22] and Teo.[23]

More recently, techniques drawn from microlocal analysis have been used to considerably generalize previous QWEI's and to put them on a mathematically rigorous footing. Fewster[24] used these techniques to derive a QWEI for minimally coupled scalar fields in general globally hyperbolic space–times (the most general class on which the Klein–Gordon equation is well-posed). In this case, averaging takes place along an arbitrary timelike worldline, using any weight of the form

$f(t)=g(t)^2$ for g smooth, real-valued and compactly supported. Subsequently, Fewster and Verch established similar results for the Dirac and Majorana fields in four-dimensional globally hyperbolic space–times.[25] Averaging over space–time volumes has been considered by Helfer,[26] also in great generality.

Previous work on QWEIs for spin-one fields has focussed on the electromagnetic field, beginning with the work of Ford and Roman,[15] who derived a QWEI for the case of Lorentzian sampling along inertial trajectories in Minkowski space. More recently, Pfenning[27] has derived a QWEI for the electromagnetic field in static curved space–times with arbitrary positive weight sampling functions by using the techniques developed for the scalar field in Refs. 22 and 23. Using similar techniques, Marecki[28] has derived bounds on the fluctuations of the electric field strength, which are of interest in quantum optics.

In this paper we will adapt the methods of Ref. 24 to the Maxwell and Proca fields. This depends crucially on the fact, first discovered by Radzikowski[29] for scalar fields, that the class of Hadamard states may be characterized in terms of a wave-front set condition on the two-point function. Similar reformulations are known for the Dirac field[30–32] but there is as yet no full treatment for the Maxwell and Proca fields in the literature. [See, however, Refs. 33 and 34 for (non microlocal) discussions of Hadamard states for electromagnetism using Faddeev–Popov ghosts.] Our treatment of this issue has been influenced to some extent by the forthcoming work of Junker and Lledó,[35] although it has been conducted largely independently, leading to some technical differences with their approach (Ref. 69).

The paper is structured as follows. The Maxwell and Proca fields are most elegantly described using differential forms; accordingly, we begin in Sec. II with a description of our conventions for differential forms and other geometric objects which will appear in this paper. In particular, we delineate the class of globally hyperbolic space–times to be considered; for technical reasons it is convenient to assume that their Cauchy surfaces are compact and have trivial first homology group. This is followed by a brief introduction to microlocal analysis leading to the definition of the wave-front set for p-form distributions.

In Sec. III we describe the quantization of the Maxwell and Proca fields in globally hyperbolic space–times. We adopt an algebraic approach, giving a direct construction of algebras of observables equivalent to those obtained by Dimock[36] and Furlani.[37] We also define the notion of a Hadamard state for these fields, as a state whose two-point function (Ref. 70) is related in a certain way to a one-form *Klein–Gordon* bisolution of Hadamard form. Such bisolutions and their microlocal properties have been discussed in detail by Sahlmann and Verch;[32] we may therefore read off the microlocal properties of the Maxwell and Proca two-point functions in Hadamard states. This permits us to apply the methods of Ref. 24 to obtain quantum inequalities for these fields in Sec. V. Before this, in Sec. IV, we specialize to the class of ultrastatic space–times in order to gain further insight into the abstract definitions of Sec. III. In particular, we prove the existence of Hadamard states in these space–times and use deformation arguments[38] to deduce from this the existence of Hadamard states in general globally hyperbolic space–times obeying our topological restrictions. We also compare our approach with other quantization schemes, including the Gupta–Bleuler method. As mentioned above, we expect that some of the results obtained here to be of wider interest.

In Sec. VI we investigate our QWEI in Minkowski space, and in general ultrastatic space–times (modulo the usual topological conditions). Simple formulas are obtained for the QWEI bound, which are readily compared with those previously obtained for the scalar field. In Minkowski space, the QWEI bound is weaker by a factor of exactly 2 for the Maxwell field (as already noted in Ref. 27) and by a factor of 3 for the Proca field. This is not very surprising and simply reflects the number of spin degrees of freedom. In curved space–time, however, the spin-one and scalar QWEIs cannot be related in this fashion. To emphasize this, we explicitly determine the QWEI bound in the Einstein static universe, providing a concrete example of our ultrastatic QWEI. Two appendixes contain the proofs of some technical results required in the body of the paper.

II. PRELIMINARIES

Units where $\hbar = c = 1$ are used throughout. The notation $C_0^\infty(\mathbb{R}^n)$ denotes the space of smooth, compactly supported (Ref. 71), complex-valued functions on $\mathbb{R}^n$.

A. Geometry and forms

Spin-one fields on globally hyperbolic space–times are most elegantly formulated in terms of differential forms. We will follow the conventions of Ref. 39, which we now briefly summarize for the benefit of the reader.

Suppose $\mathcal{N}$ is a smooth n-dimensional manifold which is connected, boundaryless, orientable, Hausdorff, paracompact, and equipped with a smooth metric of index s (Ref. 72). We denote the space of smooth, complex-valued p-forms on $\mathcal{N}$ by $\Omega^p(\mathcal{N})$; the subspace of compactly supported p-forms will be written $\Omega_0^p(\mathcal{N})$. Each p-form may be regarded as an antisymmetric covariant p-tensor field and we will occasionally use index notation accordingly. Thus the exterior product $\alpha\wedge\beta \in \Omega^{p+q}(\mathcal{N})$ of $\alpha \in \Omega^p(\mathcal{N})$ and $\beta \in \Omega^q(\mathcal{N})$ is given by

$$(\alpha\wedge\beta)_{a_1\cdots a_{p+q}} = \frac{(p+q)!}{p!q!}\,\alpha_{[a_1\cdots a_p}\beta_{a_{p+1}\cdots a_{p+q}]}, \tag{3}$$

and the exterior derivative $\mathbf{d}:\Omega^p(\mathcal{N})\to\Omega^{p+1}(\mathcal{N})$ is defined by

$$(\mathbf{d}\alpha)_{a_1\cdots a_{p+1}} = (p+1)\nabla_{[a_1}\alpha_{a_2\cdots a_{p+1}]}, \tag{4}$$

where the square brackets denote antisymmetrization and ∇_a is any connection on $\mathcal{N}$ ($\mathbf{d}$ is independent of the choice of connection). The Hodge $*$-operator is defined uniquely as the map $*:\Omega^p(\mathcal{N})\to\Omega^{n-p}(\mathcal{N})$ such that

$$\alpha\wedge *\beta = \frac{1}{p!}\,\alpha_{a_1\ldots a_p}\beta^{a_1\cdots a_p}\mathrm{d}\,\mathrm{vol}_g, \tag{5}$$

where $\mathrm{d}\,\mathrm{vol}_g$ is the positive volume n-form associated with the metric g. In particular, $(*)^2 = (-1)^{p(n-p)+s}$ on p-forms. By combining the Hodge $*$ and exterior derivative, we may define the coderivative $\boldsymbol{\delta}:\Omega^p(\mathcal{N})\to\Omega^{p-1}(\mathcal{N})$ (with the convention that $\boldsymbol{\delta}$ annihilates all zero-forms) by $\boldsymbol{\delta} = (-1)^{n(p-1)+s+1} * \mathbf{d} *$, which reduces to $\boldsymbol{\delta} = *\mathbf{d}*$ in a four-dimensional Lorentzian space–time.

The operations introduced above allow us to define a symmetric pairing $\langle\cdot,\cdot\rangle$ of p-forms under integration: we set

$$\langle\mathcal{U},\mathcal{V}\rangle \equiv \int_{\mathcal{N}} \mathcal{U}\wedge *\mathcal{V} \tag{6}$$

for any $\mathcal{U},\mathcal{V}\in\Omega^p(\mathcal{N})$ for which the integral exists. Since $\mathbf{d}(\mathcal{U}\wedge *\mathcal{V}) = \mathbf{d}\mathcal{U}\wedge *\mathcal{V} - \mathcal{U}\wedge *\boldsymbol{\delta}\mathcal{V}$, Stokes' theorem gives

$$\langle\boldsymbol{\delta}\mathcal{U},\mathcal{V}\rangle = \langle\mathcal{U},\mathbf{d}\mathcal{V}\rangle \tag{7}$$

for smooth $(p+1)$- and p-forms $\mathcal{U}$ and $\mathcal{V}$ whose supports have compact intersection. In this sense the operators $\mathbf{d}$ and $\boldsymbol{\delta}$ are dual.

The Laplace–Beltrami operator is defined as $-(\mathbf{d}\boldsymbol{\delta}+\boldsymbol{\delta}\mathbf{d})$, i.e., it is equal to *minus* the Laplace–de Rahm operator $\mathbf{d}\boldsymbol{\delta}+\boldsymbol{\delta}\mathbf{d}$. Where the manifold $\mathcal{N}$ is a Lorentzian space–time, with signature $+-\cdots-$, the Laplace–Beltrami operator is also known as the D'Alembertian and will be denoted by $\Box$. We wish to point out that Dimock[36] uses $\Box$ to denote the Laplace–de Rahm operator; our usage is determined by the convention that $\Box$ should have principal part $g^{\mu\nu}\partial_\mu\partial_\nu$, in accordance with typical usage in general relativity.

Finally, the spaces $\Omega_0^p(\mathcal{N})$ may be given locally convex topologies (Ref. 73) and the corresponding topological duals $\Omega_0^p(\mathcal{N})'$ will be called the spaces of p-form distributions on $\mathcal{N}$. [The

pairing $\langle \cdot , \cdot \rangle$ provides a natural embedding of $\Omega^p(\mathcal{N})$ in $\Omega_0^p(\mathcal{N})'$.] In the case $p=0$, we will also use $\mathcal{D}(\mathcal{N})$ and $\mathcal{D}'(\mathcal{N})$ for $\Omega_0^0(\mathcal{N})$ and $\Omega_0^0(\mathcal{N})'$, respectively. The exterior derivative and coderivative are defined on these spaces by

$$(\mathbf{d}\mathcal{U})(f)=\mathcal{U}(\boldsymbol{\delta} f) \quad (\mathcal{U}\in\Omega_0^p(\mathcal{N})', \ f\in\Omega_0^{p+1}(\mathcal{N})) \tag{8}$$

and

$$(\boldsymbol{\delta}\mathcal{U})(f)=\mathcal{U}(\mathbf{d} f) \quad (\mathcal{U}\in\Omega_0^p(\mathcal{N})', \ f\in\Omega_0^{p-1}(\mathcal{N})) \tag{9}$$

which extend the definitions given for smooth forms by virtue of the embeddings defined above and the calculation (7). In a similar way, the Hodge $*$-operator may also be extended to a map from p-form distributions to $(n-p)$-form distributions by

$$(*\mathcal{U})(f)=(-1)^{p(n-p)}\mathcal{U}(*f) \quad (\mathcal{U}\in\Omega_0^p(\mathcal{N})', \ f\in\Omega_0^{n-p}(\mathcal{N}))\,; \tag{10}$$

and it is easily checked that the formula $\boldsymbol{\delta}=(-1)^{n(p-1)+s+1}*\mathbf{d}*$ remains true for distributions.

B. Microlocal analysis and the wave-front set

Our proof of the quantum weak energy inequality turns on the detailed singularity properties of various distributions related to the two-point functions of quantum fields in Hadamard states. The information required is encoded in the *wave-front set* of these distributions, which is defined as follows. (See Ref. 40 for a full presentation.)

We will define the Fourier transform $\hat{u}$ of $u\in C_0^\infty(\mathbb{R}^n)$ using the nonstandard convention

$$\hat{u}(k)=\int \mathrm{d}^n y\, u(y) e^{ik\cdot y}, \tag{11}$$

which conforms to the conventions used, e.g., in Ref. 24. The Fourier transform can be extended to scalar distributions of compact support by writing $\hat{u}(k)=u(f_k)$ where $f_k=e^{ik\cdot y}$. Given a cone $V\subset(\mathbb{R}^n\backslash\{0\})$, we will say that $\hat{u}(k)$ is of rapid decrease in V if for each $N\in\mathbb{N}$ there exists a real constant C_N such that

$$|\hat{u}(k)|\leqslant \frac{C_N}{(1+|k|)^N} \quad \forall k\in V, \tag{12}$$

where $|k|$ denotes the Euclidean norm of k.

Smooth compactly supported functions have Fourier transforms which decay faster than any inverse power in the whole of $\mathbb{R}^n$, but the same is not true for arbitrary distributions u of compact support. A well-known example is the Dirac δ-function, whose Fourier transform does not decay at infinity in any direction. We define the set of singular directions $\Sigma(u)$ to be the set of all $k\in\mathbb{R}^n\backslash\{0\}$ having no conical neighborhood V in which $\hat{u}$ is of rapid decrease.

More detailed information about the singularities of u can be gained by localizing the singular directions. In particular, the set of *singular directions* of u at a point x is defined by

$$\Sigma_x(u)=\bigcap_\chi \Sigma(\chi u)\,, \tag{13}$$

where the intersection is taken over all smooth compactly supported test functions $\chi\in C_0^\infty(\mathbb{R}^n)$ with $\chi(x)\neq 0$. The *wave-front set* $\mathrm{WF}(u)$ of u is then defined by

$$\mathrm{WF}(u)=\{(x,k)\in\mathbb{R}^n\times(\mathbb{R}^n\backslash\{0\})\,|\,k\in\Sigma_x(u)\}. \tag{14}$$

The wave-front set can be extended in a natural way to distributions on manifolds. Let $(\mathcal{N},g)$ be a smooth n-dimensional manifold of the type discussed above. Each distribution u in $\mathcal{D}'(\mathcal{N})$ has a representative $u_\kappa \in \mathcal{D}'(\mathbb{R}^n)$ in each coordinate chart (U,κ) [with corresponding coordinates denoted $x^\mu = \kappa(x)^\mu$] defined so that

$$u_\kappa(f\sqrt{-|g|}) = u(f\circ\kappa) \tag{15}$$

holds for every smooth function f compactly supported in $\kappa(U)\subset\mathbb{R}^n$, where $|g|$ is the determinant of $g_{\mu\nu}$. The wave-front set $\mathrm{WF}(u)$ is now a subset of the cotangent bundle $T^*\mathcal{N}$ with the property that $(x,k)\in \mathrm{WF}(u)$ if and only if there is a chart (U,κ) about x so that $(\underline{x},\underline{k}) \in \mathrm{WF}(u_\kappa)$, where $(\underline{x},\underline{k})$ are the coordinates of (x,k) and u_κ is defined as in (15). In fact, it may be shown (see Theorem 8.2.4 and the following discussion in Ref. 40) that the restriction of $\mathrm{WF}(u)$ to U is given by

$$\mathrm{WF}(u)\cap T^*U = \kappa^*\mathrm{WF}(u_\kappa) := \{\kappa^*(\underline{x},\underline{k}) : (\underline{x},\underline{k})\in \mathrm{WF}(u_\kappa)\}\,, \tag{16}$$

where the pull-back κ^* relates $(x,k)\in T^*\mathcal{N}$ to its coordinates by $\kappa^*(\underline{x},\underline{k}) = (x,k)$.

There is a natural extension of the wave-front set to p-form distributions. Let v_i $(i=0,\ldots,n-1)$ be a global orthonormal n-bein on $\mathcal{N}$ (i.e., the vectors v_i obey $g_{ab}v_i^a v_j^b = \eta^{ij}$ and thus $\eta^{ij}v_i^a v_j^b = g^{ab}$, where η^{ij} is diagonal with s entries equal to -1 and the rest equal to $+1$) and let V^i be the dual basis of one-forms: $V_a^i = \eta^{ij}g_{ab}v_j^b$. For each $\mathcal{U}\in\Omega_0^p(\mathcal{N})'$, we may define the component distributions $\mathcal{U}_{i_1\cdots i_p}\in\mathcal{D}'(\mathcal{N})$ by

$$\mathcal{U}_{i_1\cdots i_p}(f) = \eta_{i_1 j_1}\cdots\eta_{i_p j_p}\mathcal{U}(fV^{j_1}\wedge\cdots\wedge V^{j_p}) \tag{17}$$

for $f\in\mathcal{D}(\mathcal{N})$. Then we define the wave-front set of $\mathcal{U}$ to be

$$\mathrm{WF}(\mathcal{U}) = \bigcup_{i_1,\ldots,i_p} \mathrm{WF}(\mathcal{U}_{i_1\ldots i_p})\,, \tag{18}$$

which may be shown to be independent of the particular choice of n-bein v_i.

III. QUANTIZATION OF THE MAXWELL AND PROCA FIELDS

A. Classical theory

We will consider the Maxwell and Proca fields propagating on four-dimensional Lorentzian globally hyperbolic space–times. Each such space–time is a pair $(\mathcal{M},g)$ consisting of a four-dimensional, smooth, real manifold $\mathcal{M}$, with the topological properties listed at the start of Sec. II A, together with a smooth Lorentzian metric g with signature $(+,-,-,-)$. Global hyperbolicity, which will ensure well-posedness of our field equations, requires that $(\mathcal{M},g)$ be time-orientable and that $\mathcal{M}$ contain a Cauchy surface Σ, that is, a smooth spacelike hypersurface intersected precisely once by every inextendible causal curve in $\mathcal{M}$. In fact, one may show[41] that $\mathcal{M}$ is diffeomorphic to $\mathbb{R}\times\Sigma$. We will assume for the most part that Σ (also referred to as the spatial section) is compact and that Σ has trivial first singular homology group with real coefficients, $H_1(\Sigma)$. This is equivalent to the triviality of the compact support de Rahm cohomology group $H_c^3(\mathcal{M})$ (Ref. 74); note that this condition excludes, for example, the 3-torus T^3 as a spatial section. The compactness assumption is made for convenience only; triviality of $H_1(\Sigma)$ is inessential for the Proca field, but appears to be required in order to establish some of our results for the Maxwell field.

The classical uncharged spin-1 field of mass $M>0$ is a real one-form field $\mathcal{A}\in\Omega^1(\mathcal{M})$ obeying the Proca equation

$$(-\boldsymbol{\delta}\mathbf{d}+M^2)\mathcal{A} = 0\,. \tag{19}$$

Applying the coderivative $\boldsymbol{\delta}$ we see that $\boldsymbol{\delta}\mathcal{A}=0$ and so any solution to Eq. (19) also satisfies the one-form Klein–Gordon equation

$$(\Box+M^2)\mathcal{A}=0\,. \tag{20}$$

Conversely, any solution to (20) satisfying the constraint

$$\boldsymbol{\delta}\mathcal{A}=0 \tag{21}$$

solves the Proca equation. The advantage of the system (20) and (21) is that (20) has the hyperbolic principal part $g^{\alpha\beta}\partial_\alpha\partial_\beta$ in local coordinates and therefore admits unique fundamental solutions $E_M^{\pm}:\Omega_0^1(\mathcal{M})\to\Omega^1(\mathcal{M})$, respectively,[37,42] such that

$$(\Box+M^2)E_M^{\pm}=E_M^{\pm}(\Box+M^2)=\mathbb{1} \tag{22}$$

and $\operatorname{supp}(E_M^{\pm}\mathcal{J})\subset J^{\pm}(\operatorname{supp}\mathcal{J})$ for $\mathcal{J}\in\Omega_0^1(\mathcal{M})$. Here, $J^{\pm}(S)$, the causal future $(+)$/past$(-)$ of S, is defined to be the set of points in $(\mathcal{M},g)$ that can be reached from the set $S\subset\mathcal{M}$ by a future $(+)$/past$(-)$ directed causal curve. The operators $E_M^{\pm}$ extend to $\mathcal{J}$ with $\operatorname{supp}\mathcal{J}$ compact to the past/future and for such $\mathcal{J}$, $\mathcal{A}^{\pm}=E_M^{\pm}\mathcal{J}$ is the unique solution of $(\Box+M^2)A^{\pm}=\mathcal{J}$ with $\operatorname{supp}\mathcal{A}$ compact to the past/future. In addition, we introduce the advanced-minus-retarded bisolution[75]

$$E_M=E_M^{-}-E_M^{+}\,, \tag{23}$$

which satisfies the homogenous Klein–Gordon equation

$$(\Box+M^2)E_M=E_M(\Box+M^2)=0\,. \tag{24}$$

We also note that, since $\mathbf{d}$ and $\boldsymbol{\delta}$ commute with the Klein–Gordon operator $\Box+M^2$ (or, more precisely, intertwine its action on zero- and one-forms) these operators also intertwine the action of $E_M^{\pm}$ on zero- and one-forms.

The fundamental solutions for the one-form Klein–Gordon equation allow us to solve the inhomogeneous Proca equation,

$$(-\boldsymbol{\delta}\mathbf{d}+M^2)\mathcal{A}=\mathcal{J}, \tag{25}$$

with advanced $(-)$ or retarded $(+)$ boundary conditions. Assuming the existence of a solution and applying the coderivative, we find $\boldsymbol{\delta}\mathcal{A}=M^{-2}\boldsymbol{\delta}\mathcal{J}$. This allows us to rewrite (25) as

$$(\Box+M^2)\mathcal{A}=(-\boldsymbol{\delta}\mathbf{d}+M^2)\mathcal{A}-\mathbf{d}\boldsymbol{\delta}\mathcal{A}=\mathcal{J}-M^{-2}\,\mathbf{d}\boldsymbol{\delta}\,\mathcal{J}, \tag{26}$$

to which $\mathcal{A}^{\pm}=E_M^{\pm}(\mathcal{J}-M^{-2}\,\mathbf{d}\boldsymbol{\delta}\mathcal{J})$ are the unique solutions with support in $J^{\pm}(\operatorname{supp}\mathcal{J})$. Using the property $\boldsymbol{\delta}E_M^{\pm}=E_M^{\pm}\boldsymbol{\delta}$, these may be shown to be the required solutions to (25). We write

$$\Delta_M^{\pm}=E_M^{\pm}(\mathbb{1}-M^{-2}\,\mathbf{d}\boldsymbol{\delta}) \tag{27}$$

for the corresponding solution operators and define

$$\Delta_M=\Delta_M^{-}-\Delta_M^{+}\,, \tag{28}$$

which will later appear in the commutation relations for the quantized Proca field. We will also use the notation Δ_M and E_M for the bidistributions defined by $\Delta_M(f,g)=\langle f,\Delta_M g\rangle$ and $E_M(f,g)=\langle f,E_M g\rangle$ $(f,g\in\Omega_0^1(\mathcal{M}))$.

Turning to electromagnetism, the theory is described by a one-form potential $\mathcal{A}\in\Omega^1(\mathcal{M})$ obeying

$$\boldsymbol{\delta}\mathbf{d}\mathcal{A}=0\,, \tag{29}$$

which entails that the field strength $\mathcal{F}=\mathbf{d}\mathcal{A}$ obeys Maxwell's equations,

$$\mathbf{d}\mathcal{F}=0 \quad \text{and} \quad \boldsymbol{\delta}\mathcal{F}=0\,. \tag{30}$$

Two potentials $\mathcal{A}$ and $\mathcal{A}'$ are gauge equivalent, denoted by $\mathcal{A}\sim\mathcal{A}'$, if $\mathcal{A}=\mathcal{A}'+\mathbf{d}\chi$ for some $\chi\in\Omega^0(\mathcal{M})$. Since gauge equivalent potentials lead to the same field strength, it is really the gauge equivalence classes $[\mathcal{A}]$ of solutions which are of physical significance rather than the potentials themselves. We can partially fix the gauge freedom by passing to the Lorentz gauge $\boldsymbol{\delta}\mathcal{A}=0$, in which the Maxwell equations are expressed by the $M=0$ case of the system (20), (21). Just as with the Proca equation, the fundamental solutions to (20) permit us to solve the inhomogeneous Maxwell equation

$$-\boldsymbol{\delta}\mathbf{d}\mathcal{A}=\mathcal{J}, \tag{31}$$

where, for consistency, the source $\mathcal{J}\in\Omega_0^1(\mathcal{M})$ is required to obey the current conservation equation $\boldsymbol{\delta}\mathcal{J}=0$. Defining $\mathcal{A}^{\pm}=E_0^{\pm}\mathcal{J}$, we note that $\boldsymbol{\delta}\mathcal{A}^{\pm}=\boldsymbol{\delta}E_0^{\pm}\mathcal{J}=E_0^{\pm}\boldsymbol{\delta}\mathcal{J}=0$ and therefore deduce that $\mathcal{A}^{\pm}$ is the unique Lorentz gauge solution to (31) with support in $J^{\pm}(\mathrm{supp}\,\mathcal{J})$.

B. Quantization: Algebras of observables

The canonical quantization of the Maxwell and Proca fields in globally hyperbolic space–times was accomplished by Dimock[36] and Furlani,[37] respectively (see also Ref. 43). Here, we give a direct construction of suitable algebras of (polynomials in) smeared fields for these theories, isomorphic to those emerging from the constructions of Refs. 36 and 37. We begin with the more straightforward Proca case, for which the algebra of observables will be denoted $\mathfrak{A}_M(\mathcal{M},g)$. This algebra is constructed by first using the set of smooth compactly supported complex valued one-form test functions $\Omega_0^1(\mathcal{M})$ to label a set of abstract objects $\{\mathcal{A}(f)|f\in\Omega_0^1(\mathcal{M})\}$ which generate a free unital $*$-algebra over $\mathbb{C}$. These objects are interpreted as smeared one-form fields

$$\mathcal{A}(f)\ \text{`}=\text{'}\ \langle\mathcal{A},f\rangle\,. \tag{32}$$

The algebra $\mathfrak{A}_M(\mathcal{M},g)$ is defined to be the quotient of $\mathfrak{A}_M$ by the following relations:

(P1) Linearity, $\mathcal{A}(\alpha f_1+\beta f_2)=\alpha\mathcal{A}(f_1)+\beta\mathcal{A}(f_2)$ for all $\alpha,\beta\in\mathbb{C}$ and $f_i\in\Omega_0^1(\mathcal{M})$;
(P2) Hermiticity, $\mathcal{A}(f)^*=\mathcal{A}(\overline{f})$ for all $f\in\Omega_0^1(\mathcal{M})$;
(P3) Field equations, $\mathcal{A}([\boldsymbol{\delta}\mathbf{d}-M^2]f)=0$ for all $f\in\Omega_0^1(\mathcal{M})$;
(P4) CCRs, $[\mathcal{A}(f_1),\mathcal{A}(f_2)]=-i\Delta_M(f_1,f_2)\mathbb{1}$ for all $f_i\in\Omega_0^1(\mathcal{M})$.

Here, Δ_M is the propagator defined in (28).

For electromagnetism, quantization is complicated by gauge freedom. Even in Minkowski space this presents serious problems: as shown by Strocchi[44,45] in the Wightman axiomatic approach, the vector potential cannot exist as an operator-valued distribution if it is to transform correctly under the Lorentz group or even display commutativity at spacelike separations in a weak sense. Dimock[36] circumvented such problems by constructing smeared field operators $[\mathcal{A}]\times(f)$ which may be smeared only with co-closed (divergence-free) test functions, i.e., f must satisfy $\boldsymbol{\delta}f=0$. These objects may be interpreted as smeared gauge-equivalence classes of quantum one-form fields: formally,

$$[\mathcal{A}](f)\ \text{`}=\text{'}\ \langle\mathcal{A},f\rangle\,, \tag{33}$$

where $\mathcal{A}$ is a representative of the equivalence class $[\mathcal{A}]$; since $\boldsymbol{\delta}f=0$, we have $\langle\mathbf{d}\chi,f\rangle=\langle\chi,\boldsymbol{\delta}f\rangle=0$ so this interpretation is indeed gauge independent. Adapting this idea to our present setting, we start with a set of abstract objects $\{[\mathcal{A}](f)\,|f\in\Omega_0^1(\mathcal{M})$ with $\boldsymbol{\delta}f=0\}$ labeled only by co-closed test one-forms. As before, we use this set to generate a free unital $*$-algebra over $\mathbb{C}$ and define the algebra of observables $\mathfrak{A}(\mathcal{M},g)$ to be the quotient of this algebra by the following relations:

(M1) Linearity, $[\mathcal{A}](\alpha f_1+\beta f_2)=\alpha[\mathcal{A}](f_1)+\beta[\mathcal{A}](f_2)$ for all $\alpha,\beta\in\mathbb{C}$ and co-closed $f_i \in\Omega^1_0(\mathcal{M})$;
(M2) Hermiticity, $[\mathcal{A}](f)^*=\mathcal{A}(\overline{f})$ for all co-closed $f\in\Omega^1_0(\mathcal{M})$;
(M3) Field equations, $[\mathcal{A}](\boldsymbol{\delta}\mathbf{d}f)=0$ for all $f\in\Omega^1_0(\mathcal{M})$;
(M4) CCRs, $[[\mathcal{A}](f_1),[\mathcal{A}](f_2)]=-iE_0(f_1,f_2)\mathbb{1}$ for all co-closed $f_i\in\Omega^1_0(\mathcal{M})$.

[Note that the one-forms f appearing in axiom (M3) need not be co-closed.]

To see that these algebras are equivalent to those constructed in Refs. 36 and 37, it suffices to observe that, first, the field operators of Refs. 36 and 37 certainly satisfy the relations above (see Proposition 8 of Ref. 36 and Theorem 3 of Ref. 37; note that there are notational differences) and, second, that the algebras we have constructed admit no nontrivial quotients, as may be seen by applying the theory of Sec. 7.1 in Refs. 46 and 76. Accordingly, our algebras are isomorphic to those of Refs. 36 and 37.

C. Quantization: Hadamard states

A *state* on a $*$-algebra $\mathfrak{A}$ is a linear functional $\omega:\mathfrak{A}\to\mathbb{C}$ which is normalized so that $\omega(\mathbb{1})=1$ and has the positivity property $\omega(\mathcal{B}^*\mathcal{B})\geqslant 0$ for all $\mathcal{B}\in\mathfrak{A}$. However, not all states on $\mathfrak{A}_M(\mathcal{M},g)$ and $\mathfrak{A}(\mathcal{M},g)$ are of physical relevance—many are insufficiently regular to permit the definition of the stress-tensor, for example. We will focus attention on the class of *Hadamard* states, for which the stress-tensor may be defined by point-splitting techniques. The Hadamard condition was first stated rigorously for the scalar field by Kay and Wald;[47] more recently, Sahlmann and Verch[32] have studied the Hadamard form for wave equations with metric principal part. This does not immediately cover either the Maxwell or Proca equations (which are not hyperbolic). Nonetheless, we may exploit the close relationship of these equations to the one-form Klein–Gordon equation to define the notion of Hadamard states for these theories.

To be more specific, a distribution $W\in(\Omega^1_0(\mathcal{M})\times\Omega^1_0(\mathcal{M}))'$ is said to be of Hadamard form if its singular part takes a prescribed form in a causal normal neighborhood $\mathcal{N}$ of some Cauchy surface in $\mathcal{M}$. This requirement is implemented by requiring that $W-H_k$ should be C^k for each $k\in\mathbb{N}$, where H_k is a prescribed sequence of distributions on $\mathcal{N}\times\mathcal{N}$. Furthermore—as in the scalar case[47,48]—if W is a bisolution to $\Box+M^2$ (or even a bisolution modulo C^∞) then the Hadamard form propagates in the sense that W will satisfy the above criterion in any causal normal neighborhood of any Cauchy surface in $\mathcal{M}$ (see Theorem 5.5 in Ref. 32). It follows that the difference $W-W'$ between Hadamard form $(\Box+M^2)$-bisolutions W and W' is everywhere smooth on $\mathcal{M}\times\mathcal{M}$. For our purposes, the second crucial property of a Hadamard bisolution W (first noted in the scalar case by Radzikowski[29]) is that its wave-front set is given explicitly by

$$\mathrm{WF}(W)=\mathcal{R}:=\{(x,k;x',-k')\in\dot{T}^*(\mathcal{M}\times\mathcal{M}) : (x,k)\sim(x',k') \text{ and } k\in\overline{V}^+_x\}. \tag{34}$$

Here, $\dot{T}^*(\mathcal{M}\times\mathcal{M})$ denotes the cotangent bundle of $\mathcal{M}\times\mathcal{M}$ with its zero section excised, and $(x,k)\sim(x',k')$ if and only if k' is the parallel transport of k along a null geodesic connecting x and x', to which k is a cotangent vector at x (if $x=x'$ this degenerates to the requirement that $k=k'$ is null). We have also used $\overline{V}^+_x$ to denote the closed cone of future pointing covectors at x. It is also worth noting that the wave-front set condition essentially characterizes the Hadamard form [see Remark 5.9(i) in (Ref. 32)]: if W is a $(\Box+M^2)$-bisolution $(\mathrm{mod}\,C^\infty)$ which obeys Eq. (34) and has $W(f_1,f_2)-W(f_2,f_1)=-iE_M(f_1,f_2)$ $(\mathrm{mod}\,C^\infty)$ then W is of Hadamard form.

We are now in a position to define the notion of a Hadamard state for the Maxwell and Proca fields. Our definitions are similar to those employed by Junker and Lledó[35] and (particularly in the Maxwell case) were influenced by early versions of their work.[49]

Proca: A state ω on $\mathfrak{A}_M(\mathcal{M},g)$ is Hadamard if there exists a Hadamard form $(\Box+M^2)$-bisolution W_M such that

$$\omega(\mathcal{A}(f_1)\mathcal{A}(f_2))=W_M(f_1,(\mathbb{1}-M^{-2}\,\mathbf{d}\boldsymbol{\delta})f_2) \tag{35}$$

for all $f_i \in \Omega_0^1(\mathcal{M})$.

Maxwell: A state ω on $\mathfrak{A}(\mathcal{M},g)$ is Hadamard if there exists a Hadamard form $\Box$-bisolution W such that

$$\omega([\mathcal{A}](f_1)[\mathcal{A}](f_2)) = W(f_1,f_2) \tag{36}$$

for all $f_i \in \Omega_0^1(\mathcal{M})$ with $\boldsymbol{\delta} f_i = 0$.

Remarks: (a) In neither case is the Hadamard form bisolution uniquely determined by the state.

(b) As stated, these conditions appear global in nature and it is not clear, *a priori*, that any states satisfying these definitions exist in general space–times. These concerns will be allayed in Sec. IV E, where we show that Hadamard states exist on general globally hyperbolic space–times (subject to our usual topological restrictions on Σ). A key part of this argument is the proof (in Appendix A) that it suffices for Eqs. (35) and (36) to hold for f_i supported in a causal normal neighborhood of a Cauchy surface for them to hold for all f_i. In combination with an explicit construction of a Hadamard state in ultrastatic space–times (in Secs. IV B and IV C) this permits us to apply standard deformation arguments[38] to deduce the existence of Hadamard states in general.

(c) Since the two-point function $\omega^{(2)}(f,f') := \omega(\mathcal{A}(f_1)\mathcal{A}(f_2))$ for a Hadamard state ω of the Proca field is given by acting on a Hadamard $(\Box + M^2)$-bisolution with a partial differential operator, we may use Eq. (34) and the nonexpansion of the wave-front set under such operators to obtain

$$\mathrm{WF}(\omega^{(2)}) \subseteq \mathcal{R}. \tag{37}$$

In the Maxwell case, the two-point function $\omega^{(2)}(f,f') := \omega([\mathcal{A}](f_1)[\mathcal{A}](f_2))$ is not a distribution (because it is only defined on co-closed test one-forms f_i). However, the two-point function of the field strength $\mathcal{F}(f) := [\mathcal{A}](\boldsymbol{\delta} f)$ is a bidistribution on two-forms satisfying

$$\omega(\mathcal{F}(f_1)\mathcal{F}(f_2)) = W(\boldsymbol{\delta} f_1, \boldsymbol{\delta} f_2) \tag{38}$$

and therefore has wave-front set contained in $\mathcal{R}$.

(d) The Hadamard condition for electromagnetism was discussed in Refs. 33 and 34 in the context of a Faddeev–Popov method. Here, the action is modified by the addition of a gauge breaking term and the ghost action, describing the dynamics of a complex, anticommuting scalar field. In that context, the electromagnetic potential may be smeared with arbitrary one-form test fields and so the corresponding two-point function is a distributional bisolution to the massless Klein–Gordon equation (at least in the Feynman gauge). In a Hadamard state (on the algebra generated by the vector potential and the ghost fields), this two-point function is required to be of Hadamard form [thus generalizing (36) to non-co-closed f_i]; in addition, a Ward identity is required to connect this two-point function to that of the ghost field. This ensures that the contributions to the stress-energy tensor arising from the gauge-breaking and ghost actions precisely cancel in Hadamard states.

IV. HADAMARD STATES IN ULTRASTATIC SPACE–TIMES

To provide a concrete example of the foregoing definitions, we now specialize to the class of ultrastatic space–times. Although one may quantize the Maxwell and Proca fields directly in such space–times (see, e.g., Refs. 50 and 51) it appears that no attention has been given to whether the resulting Fock vacua are Hadamard. Our approach is rather to construct a distinguished Hadamard state and then to observe that the corresponding representations coincide with those obtained directly. Our analysis of the ultrastatic case will also lead to a proof of the existence of Hadamard states for the Proca and Maxwell fields in general globally hyperbolic space–times as well as providing explicit two-point functions for particular Hadamard states which will be used in Sec. VI. We recall that a space–time $(\mathcal{M},g)$ is said to be ultrastatic if $\mathcal{M} = \mathbb{R} \times \Sigma$ and $g = 1 \oplus -h$,

where (Σ,h) is a smooth Riemannian manifold. As usual, we will also assume that Σ is compact and the homology group $H_1(\Sigma)$ is trivial. We will often denote a point in $\mathcal{M}$ by the pair $(t,\underline{x})$, with $t\in\mathbb{R}$, $\underline{x}\in\Sigma$.

Our discussion in this section will proceed as follows. We begin with the construction of a one-form Hadamard $(\Box+M^2)$-bisolution W_M on $(\mathcal{M},g)$. Next, we construct Fock representations of the Proca and Maxwell fields on $(\mathcal{M},g)$ with the property that the Fock vacuum in each case is Hadamard according to the definitions of the preceding section. In each case, the W_M plays the role of the required Hadamard $(\Box+M^2)$-bisolution. We also discuss the relationship of our procedure to the Gupta–Bleuler approach and the method of quantization in a fixed gauge. Finally, we explain how these results imply the existence of Hadamard states in general space–times. Some parts of the analysis are relegated to Appendix B.

A. Construction of a Hadamard $(\Box+M^2)$-bisolution

As is well-known, the Klein–Gordon equation in an ultrastatic space–time is readily reduced to the analysis of an elliptic eigenvalue problem. Namely, if $\xi\in\Omega^1(\mathcal{M})$ is a static one-form (i.e., independent of the ultrastatic time parameter t) then $\mathcal{A}(t,\underline{x})=e^{-i\omega t}\xi(\underline{x})$ solves the one-form Klein–Gordon equation if and only if

$$K\xi=\omega^2\xi, \tag{39}$$

where the operator K acts on $\xi(\underline{x})=\xi_0(\underline{x})\mathbf{d}t+\xi_\Sigma(\underline{x})$ $(\xi_0\in\Omega^0(\Sigma),\ \xi_\Sigma\in\Omega^1(\Sigma))$ by

$$K\xi=((-\Delta_\Sigma^s+M^2)\xi_0)\mathbf{d}t+(-\Delta_\Sigma+M^2)\xi_\Sigma\,, \tag{40}$$

with Δ_Σ^s and Δ_Σ denoting the scalar and one-form Laplace–Beltrami operators on (Σ,h).

To analyze K further, it is helpful to have various inner product spaces in mind. For each p, the space $\Omega^p(\Sigma)$ may be endowed with a positive definite inner product

$$(u,v)_{\Lambda^p(\Sigma)}=\int_\Sigma \overline{u}\wedge *_\Sigma v\,, \tag{41}$$

where $*_\Sigma$ is the Hodge operator on (Σ,h). By completing $\Omega^p(\Sigma)$ with respect to the corresponding norm we obtain the Hilbert space $\Lambda^p(\Sigma)$ of square integrable p-forms on Σ. The direct sum $\mathsf{H}=\Lambda^0(\Sigma)\oplus\Lambda^1(\Sigma)$ therefore corresponds to a Hilbert space of static one-forms, on which the K may be defined as a positive self-adjoint operator [by using Eq. (40) to define K on $\Omega^0(\Sigma)\oplus\Omega^1(\Sigma)$ and then forming the Friedrichs extension]. Because Σ is compact, K has a purely discrete spectrum.

From a geometrical viewpoint, however, the Hilbert space inner product is not completely natural. It is therefore convenient to introduce an indefinite inner product on H by

$$\langle\!\langle\xi|\,\eta\rangle\!\rangle=\int_\Sigma \overline{\xi_\mu(\underline{x})}\;\eta^\mu(\underline{x})\,\mathrm{d}\,\mathrm{vol}_h(\underline{x})=(\xi_0,\eta_0)_{\Lambda^0(\Sigma)}-(\xi_\Sigma,\eta_\Sigma)_{\Lambda^1(\Sigma)}\,. \tag{42}$$

We will denote the resulting indefinite inner product space (also known as a *Krein space*) by K. In addition, we will say that a set $\{\xi_j:j\in J\}$ of vectors (labeled by the elements of some set J) in K is *pseudo-orthonormal* if $\langle\!\langle\xi_j|\xi_j\rangle\!\rangle=\pm1$ for each j and $\langle\!\langle\xi_j|\xi_{j'}\rangle\!\rangle=0$ for all $j\neq j'$; the set is said to be complete if

$$\eta=\sum_{j\in J}\langle\!\langle\xi_j|\xi_j\rangle\!\rangle\langle\!\langle\xi_j|\,\eta\rangle\!\rangle\,\xi_j \tag{43}$$

holds for all $\eta\in\mathsf{K}$, with the sum converging in the topology induced by the norm of H. We will refer to $\xi\in\mathsf{K}$ as timelike, spacelike or null depending on whether $\langle\!\langle\xi|\xi\rangle\!\rangle$ is positive, negative or zero, respectively.

The following result is proved in Appendix B.

Theorem IV.1: *Let* ξ_j $(j \in J)$ *be a complete, pseudo-orthonormal basis for* K *such that* $K\xi_j = \omega_j^2 \xi_j$ $(\omega_j \geqslant 0)$ *and set* $\mathcal{A}_j(t,\underline{x}) = e^{-i\omega_j t}\xi_j(\underline{x})$. *Then*

$$W_M(f_1,f_2) = -\sum_{j\in J:\omega_j>0} \frac{1}{2\omega_j} \langle\!\langle \xi_j | \xi_j \rangle\!\rangle \langle \mathcal{A}_j, f_1\rangle \langle \overline{\mathcal{A}_j}, f_2\rangle \quad (f_i \in \Omega^1(\Sigma)) \tag{44}$$

defines a one-form Hadamard $(\Box + M^2)$*-bisolution* W_M *on* $(\mathcal{M},g)$ *which is independent of the particular basis chosen. For* $M>0$, *we have*

$$W_M(f_1,f_2) - W_M(f_2,f_1) = -iE_M(f_1,f_2) \tag{45}$$

for all $f_i \in \Omega_0^1(\mathcal{M})$; *in the case* $M=0$, *this holds provided the* f_i *are both co-closed.*

Our task is now to analyze the eigenproblem (39). We may identify various families of eigenfunctions which are more or less convenient for different purposes and which may be combined to form complete pseudo-orthonormal bases (again, different bases are useful in different contexts). A typical eigenfunction will be denoted $\xi(\lambda,j)$, where λ labels the family to which it belongs and j (which labels eigenfunctions within families) takes values in a labeling set $J(\lambda)$. Because K is manifestly positive, the eigenvalues may be expressed as the squares of non-negative quantities $\omega(\lambda,j)$: thus $K\xi(\lambda,j) = \omega(\lambda,j)^2\xi(\lambda,j)$. The corresponding Klein–Gordon solution is

$$\mathcal{A}(\lambda,j)(t,\underline{x}) = e^{-i\omega(\lambda,j)t}\xi(\lambda,j)(\underline{x})\,. \tag{46}$$

We begin by identifying three eigenfunction families which together form a simultaneously K-pseudo-orthonormal and H-orthonormal basis. The analysis of Eq. (39) is considerably simplified by the fact that it decouples into the two equations

$$(-\Delta_\Sigma^s + M^2)\xi_0 = \omega^2\xi_0\,, \tag{47}$$

$$(-\Delta_\Sigma + M^2)\xi_\Sigma = \omega^2\xi_\Sigma\,. \tag{48}$$

Accordingly, choosing φ_j $(j \in J(S))$ to label a complete orthonormal basis of $(-\Delta_\Sigma^s + M^2)$-eigenfunctions for $\Lambda^0(\Sigma)$ with corresponding eigenvalues $\omega(S,j)^2$, we may identify a family of "scalar" K-eigenfunctions given by

$$\xi(S,j) = \varphi_j\,\mathbf{d}t \quad (j \in J(S))\,. \tag{49}$$

(By elliptic regularity, each φ_j is in fact smooth.) Clearly the $\xi(S,j)$ are pseudo-orthonormal and timelike in K, as well as being H orthonormal. For future reference, we note that there is a unique spatially constant eigenfunction $\mathrm{vol}_h(\Sigma)^{-1/2}\,\mathbf{d}t$ with eigenvalue M^2. Writing $\Phi_j(t,\underline{x}) = e^{-i\omega(S,j)t}\varphi_j(\underline{x})$, the corresponding one-form positive frequency modes are

$$\mathcal{A}(S,j) = \Phi_j\,\mathbf{d}t\,. \tag{50}$$

The remaining pseudo-orthogonal modes must have vanishing $\mathbf{d}t$ component; that is, they must lie in the spacelike subspace $\Lambda^1(\Sigma)$ of H. On this subspace, the inner products of H and K differ by an overall sign only, so K-pseudo-orthonormality and H-orthonormality are again identical. Since $H_1(\Sigma)$ is trivial, the Hodge decomposition (see, e.g., Prop. 11.7 in Ref. 52) gives $\Lambda^1(\Sigma) = \overline{\mathbf{d}_\Sigma\Omega^0(\Sigma)} \oplus \overline{\boldsymbol{\delta}_\Sigma\Omega^2(\Sigma)}$, where the decomposition is orthogonal with respect to $(\cdot,\cdot)_{\Lambda^1}$ and hence $\langle\!\langle\cdot|\cdot\rangle\!\rangle$, and the bars denote closure. As is easily verified, the Laplacian Δ_Σ is block diagonal with respect to this decomposition, thus enabling us to seek eigenfunctions within each subspace in turn. If the restriction on $H_1(\Sigma)$ were removed, there would be a third subspace, consisting of harmonic forms (i.e., the kernel of Δ_Σ). In the Proca case, the resulting modes lead to additional terms in various expansions given below and in the quantum inequality, but do not

significantly alter the formalism. By contrast, the incorporation of the harmonic modes in the Maxwell case raises nontrivial issues, to which we hope to return elsewhere.

Now, the ''longitudinal'' subspace $\overline{\mathbf{d}_\Sigma \Omega^0(\Sigma)}$ is clearly spanned by the set of nonvanishing vectors of the form $\mathbf{d}\xi(S,j)$ $(j \in J(S))$; owing to the relation $\Delta_\Sigma \mathbf{d}_\Sigma = \mathbf{d}_\Sigma \Delta_\Sigma^S$, these must also be eigenvectors for $-\Delta_\Sigma + M^2$ with eigenvalue $\omega(L,j)^2 = \omega(S,j)^2$. As the only vanishing vector of this form is obtained from the spatially constant mode, the appropriate labeling set is $J(L) = \{j \in J(S) : \omega(S,j) > M\}$. Furthermore, the calculation

$$\langle\langle \mathbf{d}_\Sigma \varphi_j | \mathbf{d}_\Sigma \varphi_{j'} \rangle\rangle = -(\mathbf{d}_\Sigma \varphi_j, \mathbf{d}_\Sigma \varphi_{j'})_{\Lambda^1(\Sigma)} = -(\varphi_j, \boldsymbol{\delta}_\Sigma \mathbf{d}_\Sigma \varphi_{j'})_{\Lambda^1(\Sigma)} = -(\omega(S,j)^2 - M^2)\delta_{jj'} \quad (51)$$

shows that the appropriately normalized longitudinal eigenfunctions are

$$\xi(L,j) = (\omega(S,j)^2 - M^2)^{-1/2} \mathbf{d}_\Sigma \varphi_j \quad (j \in J(L)). \quad (52)$$

The corresponding Klein–Gordon modes may also be expressed in the form

$$\mathcal{A}(L,j) = \frac{\mathbf{d}\Phi_j + i\omega(L,j)\Phi_j \mathbf{d}t}{\sqrt{\omega(L,j)^2 - M^2}}. \quad (53)$$

All remaining pseudo-orthonormal modes must lie in the coexact subspace $\boldsymbol{\delta}_\Sigma \Omega^2(\Sigma)$. We will refer to these as the transverse modes $\xi(T,j)$ with labeling set $J(T)$ and eigenfrequencies $\omega(T,j)$; they are necessarily spacelike. In general, the $\omega(T,j)$'s will be distinct from the $\omega(S,j)$'s (even in situations of high symmetry such as the Einstein space–time—see Sec. VI C).

Applying Theorem IV A, we obtain a Hadamard bisolution

$$W_M(f_1,f_2) = -\sum_{\lambda \in \{S,L,T\}} \sum_{j \in J(\lambda)} \frac{s(\lambda)}{2\omega(\lambda,j)} \langle \mathcal{A}(\lambda,j), f_1 \rangle \langle \overline{\mathcal{A}(\lambda,j)}, f_2 \rangle, \quad (54)$$

where $s(S) = 1$, $s(L) = s(T) = -1$.

B. The Proca field

We now construct a state on $\mathfrak{A}_M(\mathcal{M},g)$ whose two-point function is related to W_M by Eq. (35) and is therefore Hadamard. We begin by finding an expression for $W_M(f_1, (\mathbb{1} - M^{-2}\mathbf{d}\boldsymbol{\delta}) f_2)$. To this end, we first note that the transverse modes $\xi(T,j)$, being coexact, are necessarily co-closed: $\boldsymbol{\delta}_\Sigma \xi(T,j) = 0$. It follows that $\boldsymbol{\delta}\mathcal{A}(T,j) = 0$, so transverse modes therefore solve the Proca equation. The same cannot be said of the scalar and longitudinal modes, for which

$$\boldsymbol{\delta}\mathcal{A}(S,j) = i\omega(S,j)\Phi_j \quad (55)$$

for all $j \in J(S)$, and

$$\boldsymbol{\delta}\mathcal{A}(L,j) = -\sqrt{\omega(S,j)^2 - M^2}\Phi_j \quad (56)$$

for all $j \in J(L)$. It is convenient to change basis, introducing

$$\xi(P,j) = \frac{1}{M}[\omega(S,j)\xi(L,j) - i\sqrt{\omega(S,j)^2 - M^2}\xi(S,j)], \quad (57)$$

$$\xi(G,j) = \frac{1}{M}[\sqrt{\omega(S,j)^2 - M^2}\xi(L,j) - i\omega(S,j)\xi(S,j)] \quad (58)$$

with labeling sets $J(P)=J(G)=J(L)$. The two sets are pseudo-orthonormal, with $\xi(P,j)$ and $\xi(G,j)$ being spacelike and timelike, respectively. By construction, the "scalar Proca" modes $\mathcal{A}(P,j)(t,\underline{x})=e^{-i\omega(P,j)t}\xi(P,j)(\underline{x})$ are co-closed and therefore obey the Proca equation. We also note the expressions

$$\mathcal{A}(P,j)=\frac{1}{M}[\,\omega(S,j)\mathcal{A}(L,j)-i\sqrt{\omega(S,j)^2-M^2}\mathcal{A}(S,j)\,]$$

$$=\frac{iM}{\sqrt{\omega(S,j)^2-M^2}}\left[\,\Phi_j\,\mathbf{d}t-i\,\frac{\omega(S,j)}{M^2}\,\mathbf{d}\Phi_j\right]. \tag{59}$$

On the other hand, the corresponding "gradient" modes $\mathcal{A}(G,j)$ have

$$\mathcal{A}(G,j)=M^{-1}\,\mathbf{d}\Phi_j \tag{60}$$

and therefore have nonvanishing coderivative

$$\boldsymbol{\delta}\mathcal{A}(G,j)=M\Phi_j\,. \tag{61}$$

From Theorem IV A, we know that W_M is basis independent and may therefore be expressed in terms of the $\mathcal{A}(P,j)$, $\mathcal{A}(G,j)$, $\mathcal{A}(T,j)$ and the unique spatially constant mode. Of these, the scalar Proca and transverse modes are left invariant by the operator $(\mathbb{1}-M^{-2}\,\mathbf{d}\boldsymbol{\delta})$, while the spatially constant mode and the gradient modes are annihilated. Accordingly, with W_M expressed in the new basis, we find

$$W_M((\mathbb{1}-M^{-2}\,\mathbf{d}\boldsymbol{\delta})f_1,f_2)=W_M(f_1,(\mathbb{1}-M^{-2}\,\mathbf{d}\boldsymbol{\delta})f_2)$$

$$=\sum_{\lambda\in\{T,P\}}\sum_{j\in J(\lambda)}\frac{1}{2\omega(\lambda,j)}\langle\mathcal{A}(\lambda,j),f_1\rangle\,\langle\overline{\mathcal{A}(\lambda,j)},f_2\rangle\,. \tag{62}$$

As a consequence of the first equality and Eq. (45) we see that

$$W_M(f_1,(\mathbb{1}-M^{-2}\,\mathbf{d}\boldsymbol{\delta})f_2)-W_M(f_2,(\mathbb{1}-M^{-2}\,\mathbf{d}\boldsymbol{\delta})f_1)=-iE_M(f_1,(\mathbb{1}-M^{-2}\,\mathbf{d}\boldsymbol{\delta})f_2)$$

$$=-i\Delta_M(f_1,f_2), \tag{63}$$

which in turn leads to the expansion

$$\Delta_M(f_1,f_2)=\sum_{\lambda\in\{T,P\}}\sum_{j\in J(\lambda)}\frac{1}{2\omega(\lambda,j)}(\langle\mathcal{A}(\lambda,j),f_1\rangle\,\langle\overline{\mathcal{A}(\lambda,j)},f_2\rangle-\langle\mathcal{A}(\lambda,j),f_2\rangle\,\langle\overline{\mathcal{A}(\lambda,j)},f_1\rangle)\,. \tag{64}$$

To complete the analysis, we define smeared fields

$$\mathcal{A}(f)=\sum_{\lambda\in\{T,P\}}\sum_{j\in J(\lambda)}\frac{1}{\sqrt{2\omega(\lambda,j)}}(\langle\mathcal{A}(\lambda,j),f\rangle\,a(\lambda,j)+\langle\overline{\mathcal{A}(\lambda,j)},f\rangle\,a(\lambda,j)^*) \tag{65}$$

on the Fock space F_M generated by operators $a(\lambda,j)$ obeying $[a(\lambda,j),a(\lambda',j')^*]=\delta_{\lambda\lambda'}\delta_{jj'}\mathbb{1}$. It is now easily verified that the $\mathcal{A}(f)$ provide a representation of axioms (P1)–(P4) on (a dense domain) F_M. Thus the Fock vacuum $|0\rangle$ defines a state on $\mathfrak{A}_M(\mathcal{M},g)$ with two-point function

$$\langle 0|\mathcal{A}(f_1)\mathcal{A}(f_2)|0\rangle=W_M(f_1,(\mathbb{1}-M^{-2}\,\mathbf{d}\boldsymbol{\delta})f_2)\,. \tag{66}$$

Accordingly, this state is Hadamard. Acting on the vacuum with smeared fields, we obtain a dense set of Hadamard states in F_M.

C. The Maxwell field

We now repeat the above analysis for the Maxwell field. In this instance, we begin by finding an expression for $W_0(f_1,f_2)$ for co-closed f_i. Since the $\mathcal{A}(P,j)$ and $\mathcal{A}(G,j)$ diverge as $M\to 0$, we revert to the scalar, longitudinal, and transverse modes of Sec. IV A. Now, from Eqs. (50) and (53), it is simple to show $\langle \mathcal{A}(L,j),F\rangle = i\langle \mathcal{A}(S,j),F\rangle$ for all co-closed F. This has the effect that the contributions to $W_0(f_1,f_2)$ from the scalar and longitudinal modes cancel and so only has contributions from the transverse modes:

$$W_0(f_1,f_2)=\sum_{j\in J(T)}\frac{1}{2\omega(T,j)}\langle \mathcal{A}(T,j),f_1\rangle\,\langle\overline{\mathcal{A}(T,j)},f_2\rangle\,, \tag{67}$$

for any co-closed f_i. Defining

$$[\mathcal{A}](f)=\sum_{j\in J(T)}\frac{1}{\sqrt{2\omega(T,j)}}(\langle \mathcal{A}(T,j),f\rangle\, a(T,j)+\langle\overline{\mathcal{A}(T,j)},f\rangle\, a(T,j)^*) \tag{68}$$

on the Fock space F_0 generated by operators $a(T,j)$ obeying $[a(T,j),a(T,j')^*]=\delta_{jj'}\mathbb{1}$, we may again verify that the $[\mathcal{A}](f)$ provide a representation of axioms (M1)–(M4) on (a dense domain in) F_0. Thus the Fock vacuum $|0\rangle$ defines a state on $\mathfrak{A}(\mathcal{M},g)$ with two-point function

$$\langle 0|[\mathcal{A}](f_1)[\mathcal{A}](f_2)|0\rangle = W_0(f_1,f_2) \tag{69}$$

for all co-closed f_i and is therefore Hadamard, as are states obtained from it by acting with polynomials in smeared fields.

D. Comparison with other quantization methods

It is instructive to compare our approach to two more familiar methods of quantization, in particular, the Gupta–Bleuler formalism[50,53,54] and (for electromagnetism) quantization in a fixed gauge. A detailed presentation of these methods for electromagnetic fields in static space–times can be found in Ref. 27. We will confine our remarks to the Maxwell case, but analogous comments apply to the Proca field.

As is well-known, the Gupta–Bleuler procedure starts by adding a gauge breaking term to the Maxwell Lagrangian. By choosing the coefficient of this term appropriately, the field equations become precisely those of the massless Klein–Gordon equation. (This is sometimes known as the Feynman gauge.) This equation is then quantized using an indefinite inner product space [effectively the symmetric Fock space $\mathsf{F}(\mathsf{K})$ over our Krein space K]. The physical Hilbert space is then selected by the requirement that they be annihilated by the positive frequency part of the divergence of the resulting field operators.

In our approach the various ingredients of the Gupta–Bleuler formalism appear in a different way. We start from the Hadamard bisolution W_0, which is in fact the two-point function of the static vacuum of the Gupta–Bleuler theory in the indefinite space $\mathsf{F}(\mathsf{K})$. In our approach, however, the restriction to the physical state space occurs at the one-particle level: the Hadamard condition and the restriction to co-closed test one-forms pick out a preferred Hilbert subspace of K, namely, the subspace H_{phys} spanned by the transverse modes $\xi(T,j)$. The quantum fields are then given immediately as operators on the symmetric Fock space $\mathsf{F}_0=\mathsf{F}(\mathsf{H}_{\text{phys}})$ over this Hilbert space. The key advantage of our approach over the Gupta–Bleuler method is, of course, that it is not tied to a particular notion of positive frequency and is applicable in general globally hyperbolic space–times.

An alternative to the Gupta–Bleuler approach is to fix a gauge from the outset. Employing the Coulomb gauge,[27] we would seek modes $\mathcal{A}_j$ obeying $\boldsymbol{\delta}\mathcal{A}_j=0$ with vanishing $\mathbf{d}t$ component. These modes are easily seen to constitute the transverse family $\mathcal{A}(T,j)$ and we essentially recover the

field operators of Eq. (68), but without the restriction to co-closed f_i. By contrast, no gauge is ever chosen in our approach and the transverse modes emerge naturally from the Hadamard condition in combination with the restriction to co-closed f_i.

E. Existence of Hadamard states in globally hyperbolic space–times

Once the existence of Hadamard states has been established in ultrastatic space–time, arguments due to Fulling, Narcowich, and Wald[38] may be used to deduce their existence in general globally hyperbolic space–times obeying our usual topological restrictions. We illustrate this for the Proca field, indicating the slight differences required in the Maxwell case.

Let $(\mathcal{M},g)$ and $(\mathcal{M}',g')$ be globally hyperbolic space–times and suppose that there is an isometry $\psi:\mathcal{N}\to\mathcal{N}'$ between causal normal neighborhoods $\mathcal{N}$ and $\mathcal{N}'$ of Cauchy surfaces in $\mathcal{M}$ and $\mathcal{M}'$, respectively. Then any state ω on $\mathfrak{A}_M(\mathcal{M},g)$ determines a state ω' on $\mathfrak{A}_M(\mathcal{M}',g')$ as follows: given any $f_1,\ldots,f_n\in\Omega^1_0(\mathcal{M}')$ choose $\tilde{f}_1,\ldots,\tilde{f}_n\in\Omega^1_0(\mathcal{N}')$ such that $\tilde{f}_k-f_k\in(-\boldsymbol{\delta}\mathbf{d}+M^2)\Omega^1_0(\mathcal{M}')$. [The existence of such $\tilde{f}_k$ follows from Proposition A 3(a).] Now define

$$\omega'(\mathcal{A}'(f_1)\cdots\mathcal{A}'(f_n))=\omega(\mathcal{A}(\psi^*\tilde{f}_1)\cdots\mathcal{A}(\psi^*\tilde{f}_n)), \tag{70}$$

where ψ^* denotes the pull-back, $\psi^*f=f\circ\psi$ and we have used $\mathcal{A}'(f)$ to denote field operators in $\mathfrak{A}_M(\mathcal{M}',g')$. It is easily verified that ω' is a state on $\mathfrak{A}_M(\mathcal{M}',g')$. Moreover, if ω is Hadamard then the isometry ensures that $\omega'(\mathcal{A}(f_1)\mathcal{A}(f_2))=W(f_1,(\mathbb{1}-M^{-1}\mathbf{d}\boldsymbol{\delta})f_2)$ for all $f_i\in\Omega^1_0(\mathcal{N}')$, where W is a $(\Box+M^2)$-bisolution Hadamard bisolution on $\mathcal{N}\times\mathcal{N}$. It then follows from Theorem A.1 that ω' is Hadamard.

Given a globally hyperbolic space–time $(\mathcal{M},g)$, we may now employ a construction described in Ref. 38 to obtain a globally hyperbolic space–times $(\mathcal{M}',g')$ and (M'',g'') so that (i) $(\mathcal{M}'',g'')$ is ultrastatic; (ii) $\mathcal{M}'$ contains Cauchy surfaces Σ'_1 and Σ'_2 with causal normal neighborhoods $\mathcal{N}'_1$ and $\mathcal{N}'_2$ so that $\mathcal{N}'_1$ (respectively, $\mathcal{N}'_2$) is isometric to a causal normal neighborhood of a Cauchy surface in $(\mathcal{M},g)$ [respectively, $(\mathcal{M}'',g'')$]. As all the Cauchy surfaces involved are therefore homeomorphic, $(\mathcal{M}',g')$ and $(\mathcal{M}'',g'')$ will obey our topological restrictions if $(\mathcal{M},g)$ does. Starting with a Hadamard state on the ultrastatic space–time $(\mathcal{M}'',g'')$ we may induce Hadamard states on $(\mathcal{M}',g')$ and hence on $(\mathcal{M},g)$. Thus $\mathfrak{A}_M(\mathcal{M},g)$ admits Hadamard states.

An analogous argument applies in the Maxwell case. The only differences are that all test functions must now be co-closed, we use part (b) of Proposition A instead of part (a), and use the appropriate form of the Hadamard condition.

V. A QUANTUM WEAK ENERGY INEQUALITY

We now proceed to prove our quantum inequality. Let $\tau\mapsto\gamma(\tau)$ be a smooth timelike curve in $\mathcal{M}$ parametrized by its proper time $\tau\in\mathbb{R}$, and let Γ be a tubular neighborhood of γ. Inside Γ let $\{v^\rho_i|i=0,1,2,3\}$ be an orthonormal frame obeying $g^{\rho\sigma}=\eta^{ij}v^\rho_i v^\sigma_j$ and with the property that the restriction of v_0 to γ is the four-velocity $u^\sigma(\tau)=(\mathrm{d}\gamma(\tau)/\mathrm{d}\tau)^\sigma$ of the curve: $v^\sigma_0(\gamma(\tau))=u^\sigma(\tau)$. (See Ref. 25 for an explicit construction of such a frame.)

The first step is to construct the quantized energy density measured along the curve. The starting point is the classical stress-energy tensor, which for the Proca and Maxwell fields, takes the form

$$T_{\mu\nu}=\tfrac{1}{4}g_{\mu\nu}\mathcal{F}_{\rho\sigma}\mathcal{F}^{\rho\sigma}-\mathcal{F}_{\mu\rho}\mathcal{F}^\rho_\nu+M^2(\mathcal{A}_\mu\mathcal{A}_\nu-\tfrac{1}{2}g_{\mu\nu}\mathcal{A}_\rho\mathcal{A}^\rho), \tag{71}$$

with $M=0$ in the Maxwell case. The energy density along the curve is given by $T_{\mu\nu}(\gamma(\tau))u^\mu(\tau)u^\nu(\tau)$; we may extend this quantity off the curve by defining $\mathcal{T}(x)=T_{\mu\nu}(x)v^\mu_0(x)v^\nu_0(x)$. A little manipulation shows that

$$\mathcal{T}(x)=\frac{1}{4}\sum_{i=0}^{3}\sum_{j=0}^{3}(v^\rho_i v^\sigma_j\mathcal{F}_{\rho\sigma})^2+\frac{1}{2}M^2\sum_{i=0}^{3}(v^\rho_i\mathcal{A}_\rho)^2. \tag{72}$$

We may rewrite $\mathcal{T}$ in terms of forms with the aid of the one-form basis $\{V^i : i=0,1,2,3\}$ dual to the v_i, given by $V^i_\mu = \eta^{ij} g_{\mu\nu} v_j^\nu$. Writing $W^{ij} = V^i \wedge V^j$, we find

$$\mathcal{T}(x) = \frac{1}{4}\sum_{i=0}^{3}\sum_{j=0}^{3} [*(\mathcal{F}\wedge *W^{ij})]^2 + \frac{1}{2}M^2 \sum_{i=0}^{3} [*(\mathcal{A}\wedge *V^i)]^2 , \tag{73}$$

which is clearly the restriction to the diagonal $x' = x$ of

$$\begin{aligned} T(x,x') = \frac{1}{4}\sum_{i=0}^{3}\sum_{j=0}^{3} [*(\mathcal{F}\wedge *W^{ij})]|_x [*(\mathcal{F}\wedge *W^{ij})]|_{x'} \\ + \frac{1}{2}M^2 \sum_{i=0}^{3} [*(\mathcal{A}\wedge *V^i)]|_x [*(\mathcal{A}\wedge *V^i)]|_{x'} . \end{aligned} \tag{74}$$

The function $T(x,x')$ provides a point-split classical energy density, related to the true energy density on the curve γ by $\mathcal{T}(\gamma(\tau)) = T(\gamma(\tau),\gamma(\tau))$. Moreover, for $f, f' \in \mathcal{D}(\mathcal{M})$ we see that

$$\begin{aligned} &\int_{\mathcal{M}\times\mathcal{M}} T(x,x') f(x) f'(x') \mathrm{d}\,\mathrm{vol}_g(x) \mathrm{d}\,\mathrm{vol}_g(x') \\ &\quad = \frac{1}{4}\sum_{i=0}^{3}\sum_{j=0}^{3} \langle \mathcal{F}, W^{ij} f\rangle \langle \mathcal{F}, W^{ij} f'\rangle + \frac{1}{2}M^2 \sum_{i=0}^{3} \langle \mathcal{A}, V^i f\rangle \langle \mathcal{A}, V^i f'\rangle \\ &\quad = \frac{1}{4}\sum_{i=0}^{3}\sum_{j=0}^{3} \langle \mathcal{A}, \boldsymbol{\delta}(W^{ij} f)\rangle \langle \mathcal{A}, \boldsymbol{\delta}(W^{ij} f')\rangle + \frac{1}{2}M^2 \sum_{i=0}^{3} \langle \mathcal{A}, V^i f\rangle \langle \mathcal{A}, V^i f'\rangle . \end{aligned} \tag{75}$$

The advantage of this reformulation is that it is easily quantized: given a Hadamard state ω on $\mathfrak{A}_M(\mathcal{M},g)$ for the Proca field, or $\mathfrak{A}(\mathcal{M},g)$ for the Maxwell field we simply replace occurrences of $\langle \mathcal{A},F\rangle\langle \mathcal{A},F'\rangle$ with the two-point function $\omega^{(2)}(F,F')$ thus obtaining a scalar bidistribution $\langle T\rangle_\omega \in \mathcal{D}'(\mathcal{M}\times\mathcal{M})$ given by

$$\langle T\rangle_\omega(f,f') = \frac{1}{4}\sum_{i=0}^{3}\sum_{j=0}^{3} \omega^{(2)}(\boldsymbol{\delta}(W^{ij} f), \boldsymbol{\delta}(W^{ij} f')) + \frac{1}{2}M^2 \sum_{i=0}^{3} \omega^{(2)}(V^i f, V^i f') . \tag{76}$$

(Note that in the Maxwell case, the above expression reduces to its first term, in which the arguments of the two-point function are co-closed.)

Now suppose that a reference Hadamard state ω_0 is specified. Since the difference between Hadamard form $(\Box + M^2)$-bisolutions is smooth,

$$\langle :T: \rangle_\omega = \langle T\rangle_\omega - \langle T\rangle_{\omega_0} \tag{77}$$

is easily seen to be a smooth function on $\mathcal{M}\times\mathcal{M}$. Thus we may unsplit points to define the normal ordered energy density along γ by

$$\langle :\rho: \rangle_\omega(\tau) = \langle :T: \rangle_\omega(\gamma(\tau),\gamma(\tau)) . \tag{78}$$

We will need three further observations. First, $\langle :T: \rangle_\omega$ is symmetric as a consequence of the commutator axiom (P4)/(M4). Second, $\langle T\rangle_\omega$ is a distribution of *positive type*, i.e., $\langle T\rangle_\omega(\overline{f},f) \geqslant 0$ for all $f \in \mathcal{D}(\mathcal{M})$. This is ultimately a consequence of the positivity property $\omega(\mathcal{B}^*\mathcal{B}) \geqslant 0$ and the hermiticity axiom (P2)/(M2). Third, the wave-front set of $\langle T\rangle_\omega$ obeys

$$\mathrm{WF}(\langle T\rangle_\omega) \subseteq \mathcal{R} . \tag{79}$$

In the Proca case, this is a straightforward consequence of the nonexpansion of the wave-front set under partial differential operators. In the electromagnetic case, the key point is that $(F,G)\mapsto\omega^{(2)}(\delta F,\delta G)$ is a distribution (the two-point function of the field strength) whose wave-front set is known to be contained in $\mathcal{R}$.

Now consider the pull-back $\varphi^*\langle T\rangle_\omega$ of the bidistribution $\langle T\rangle_\omega$ induced by the smooth map $\varphi(\tau,\tau')=(\gamma(\tau),\gamma(\tau'))$. This quantity is formally the unrenormalized energy density, with points split along γ. We now claim that $\varphi^*\langle T\rangle_\omega$ is a well-defined distribution of positive type. To verify this, we first note that ${}^t\varphi'(\tau,\tau'):T^*_{(\gamma(\tau),\gamma(\tau'))}(\mathcal{M}\times\mathcal{M})\to\mathbb{R}$ is the linear map

$$ {}^t\varphi'(\tau,\tau'):(k,k')\mapsto(u^\rho(\tau)k_\rho,u^{\sigma'}(\tau')k'_{\sigma'}) \tag{80}$$

from which it follows that φ has the following set of normals:

$$ N_\varphi=\{(\gamma(\tau),k;\gamma(\tau'),k')\in T^*(\mathcal{M}\times\mathcal{M}):u^\rho(\tau)k_\rho=u^{\sigma'}(\tau')k'_{\sigma'}=0\}\,. \tag{81}$$

Second, we note that all the covectors appearing in $\mathrm{WF}(\langle T\rangle_\omega)$ are null, and therefore cannot annihilate any nonzero timelike vector. Accordingly, the intersection $\mathrm{WF}(\langle T\rangle_\omega)\cap N_\varphi$ is empty and the pull-back $\varphi^*\langle T\rangle_\omega$ exists by Theorem 2.5.11′ in Ref. 55 (in which the set of normals is also defined). Theorem 2.2 of Ref. 24 guarantees that it inherits the positive type property.

Theorem 2.5.11′ in Ref. 55 also asserts that the wave-front set of $\varphi^*\langle T\rangle_\omega$ obeys $\mathrm{WF}(\varphi^*\langle T\rangle_\omega)\subset\varphi^*\mathrm{WF}(\langle T\rangle_\omega)$. Thus, we have $(\tau,\zeta;\tau',-\zeta')\in\varphi^*\mathrm{WF}(\langle T\rangle_\omega)$ only if

$$ (\zeta,-\zeta')=({}^t\varphi'(\tau,\tau'))(k,-k')=(u^\rho(\tau)k_\rho,-u^{\sigma'}(\tau')k'_{\sigma'})\,. \tag{82}$$

Since the vectors $u^\sigma(\tau)$, $u^{\sigma'}(\tau')$ and the covectors k_σ, $k'_{\sigma'}$ are all future pointing their contractions will always be positive. It will therefore be the case that $\zeta,\zeta'>0$.

Summarizing, $\varphi^*\langle T\rangle_\omega$ is a well-defined distribution in $\mathcal{D}'(\mathbb{R}^2)$, which is of positive type and has a wave-front set obeying

$$ \mathrm{WF}(\varphi^*\langle T\rangle_\omega)\subset\{(\tau,\zeta;\tau',-\zeta')\,|\,\zeta,\zeta'>0\}\,. \tag{83}$$

We are now in a position to state and prove our quantum weak energy inequality. The proof is in fact essentially identical to that given for the scalar field in Ref. 24; it is given here for completeness.

Theorem V.1: *Let ω and ω_0 be Hadamard states on $\mathfrak{A}_M(\mathcal{M},g)$ for the Proca field, or $\mathfrak{A}(\mathcal{M},g)$ for the electromagnetic field. Define the point-split normal ordered energy density $\langle:T:\rangle_\omega$ relative to ω_0 by Eq. (77) and the normal ordered energy density $\langle:\rho:\rangle_\omega(\tau)$ by Eq. (78). Then the quantum inequality*

$$ \int\mathrm{d}\tau(g(\tau))^2\langle:\rho:\rangle_\omega(\tau)\geqslant-\int_0^\infty\frac{\mathrm{d}\alpha}{\pi}[(g\otimes g)\varphi^*\langle T\rangle_{\omega_0}]\hat{}(-\alpha,\alpha) \tag{84}$$

holds and the right-hand side is finite for all real-valued $g\in C_0^\infty(\mathbb{R})$.

Proof: Letting $g\in C_0^\infty(\mathbb{R})$ be a real valued function of proper time τ, we have

$$\int \mathrm{d}\tau (g(\tau))^2 \langle :\rho: \rangle_\omega(\tau) = \int \mathrm{d}\tau\, (g(\tau))^2 \varphi^* \langle :T: \rangle_\omega(\tau,\tau)$$

$$= \int \mathrm{d}\tau \int \mathrm{d}\tau'\, g(\tau) g(\tau') \delta(\tau-\tau') \varphi^* \langle :T: \rangle_\omega(\tau,\tau')$$

$$= \int_{-\infty}^{\infty} \frac{\mathrm{d}\alpha}{2\pi} \int \mathrm{d}\tau \int \mathrm{d}\tau'\, g_{-\alpha}(\tau) g_\alpha(\tau') \varphi^* \langle :T: \rangle_\omega(\tau,\tau')$$

$$= \int_{-\infty}^{\infty} \frac{\mathrm{d}\alpha}{2\pi} \varphi^* \langle :T: \rangle_\omega (g_{-\alpha} \otimes g_\alpha) = \int_0^{\infty} \frac{\mathrm{d}\alpha}{\pi} \varphi^* \langle :T: \rangle_\omega (\overline{g_\alpha} \otimes g_\alpha), \quad (85)$$

where $g_\alpha(\tau) = g(\tau) e^{i\alpha\tau}$ and we used the symmetry property $\varphi^* \langle :T: \rangle_\omega (\overline{g_\alpha} \otimes g_\alpha) = \varphi^* \langle :T: \rangle_\omega (g_\alpha \otimes \overline{g_\alpha})$ in the last step. Using the definition of $\langle :T: \rangle_\omega$ and the fact that $\varphi^* \langle T \rangle_\omega$ is of positive type we have

$$\int \mathrm{d}\tau (g(\tau))^2 \varphi^* \langle :T: \rangle_\omega(\tau,\tau) \geqslant - \int_0^{\infty} \frac{\mathrm{d}\alpha}{\pi} \varphi^* \langle T \rangle_{\omega_0} (\overline{g_\alpha} \otimes g_\alpha). \quad (86)$$

Setting $e_{(\alpha,\alpha')}(\tau,\tau') = e^{i(\alpha\tau + \alpha'\tau')}$, we note that the integrand in the above expression may be rewritten as

$$\varphi^* \langle T \rangle_{\omega_0} (\overline{g_\alpha} \otimes g_\alpha) = \varphi^* \langle T \rangle_{\omega_0} ((g \otimes g) e_{(-\alpha,\alpha)})$$

$$= [(g \otimes g) \varphi^* \langle T \rangle_{\omega_0}] (e_{(-\alpha,\alpha)})$$

$$= [(g \otimes g) \varphi^* \langle T \rangle_{\omega_0}]\hat{}(-\alpha,\alpha) \quad (87)$$

by our definition for the Fourier transform. Thus we obtain Eq. (84).

The fact that the right-hand side of Eq. (84) is convergent follows from an analysis of the wave-front set. From the definition of the wave-front set, it is obvious that

$$\mathrm{WF}((f_1 \otimes f_2) \varphi^* \langle T \rangle_{\omega_0}) \subseteq \mathrm{WF}(\varphi^* \langle T \rangle_{\omega_0}) \quad (88)$$

for any $f_i \in C_0^\infty(\mathbb{R})$. Thus the singular directions for $(f_1 \otimes f_2) \varphi^* \langle T \rangle_{\omega_0}$ are contained in $\{(\zeta, -\zeta') | \zeta, \zeta' > 0\}$. In consequence, the Fourier transform $[(g \otimes g) \varphi^* \langle T \rangle_{\omega_0}]\hat{}(-\alpha,\alpha)$ decays rapidly as $\alpha \to +\infty$. The integral on the right-hand side of Eq. (84) therefore converges thereby providing a finite bound for all $g \in C_0^\infty(\mathbb{R})$. □

VI. EXAMPLES

A. Minkowski space–time

Although Minkowski space lies outside the discussion of Sec. III because its Cauchy surfaces are noncompact, the arguments presented in Sec. V apply equally well to the two-point functions arising from standard Minkowski quantizations of the Maxwell and Proca fields based on the Poincaré invariant vacua. As we will see, these vacua are Hadamard; furthermore the topology of the Cauchy surface played no role in the proof of our QWEIs. We refer the reader to Ref. 56 (and references therein) for a careful discussion of the quantization of constrained systems in the context of algebraic field theory in Minkowski space.

We illustrate our QWEIs for the case of an inertial worldline γ, using the usual Poincaré invariant vacua as reference states. Boosting to the rest frame of γ, we adopt coordinates in which $\gamma(\tau) = (\tau, x_0, y_0, z_0)$ for some fixed $(x_0, y_0, z_0) \in \mathbb{R}^3$. We also adopt the orthonormal frame $v_i^\mu = (\partial/\partial x^i)^\mu$ for $i = 0, \ldots, 3$.

Let us begin by recalling that the vacuum two-point function for the *scalar* Klein–Gordon equation is given by

$$W_M^{(s)}(x,x') = \int_{\mathbb{R}^3} \frac{\mathrm{d}^3\mathbf{k}}{(2\pi)^3} \frac{1}{2\omega} e^{-ik_l(x-x')^l}, \tag{89}$$

where $k^j=(\omega,\mathbf{k})$ and $\omega=(|\mathbf{k}|^2+M^2)^{1/2}$. This is of course a Hadamard $(\Box+M^2)$-bisolution, and it may be used to define a one-form Hadamard $(\Box+M^2)$-bisolution by

$$W_M(f,f') = -\eta^{ij} W_M^{(s)}(f_i,f_j)\,. \tag{90}$$

[The overall sign is determined by the requirement that—anticipating the commutation relations (P4)/(M4)—the antisymmetric part $W_M(f,f')-W_M(f',f)$ should be equal to $-iE_M(f,f')$ $=-i\eta^{ij}E_M^{(s)}(f_i,f_j)$.]

Turning to the Proca field, the Poincaré invariant vacuum two-point function[57]

$$\omega_0^{(2)}(f,f') = -\int_{\mathbb{R}^3} \frac{\mathrm{d}^3\mathbf{k}}{(2\pi)^3} \frac{1}{2\omega} \left(\eta^{ij} - \frac{k^i k^j}{M^2} \right) \hat{f}_i(-k) \hat{f}_j(k) \tag{91}$$

is easily seen to be of the form

$$\omega_0^{(2)}(f,f') = W_M(f,(\mathbb{1}-M^{-2}\,\mathbf{d}\boldsymbol{\delta})f') \tag{92}$$

and is therefore Hadamard. We may also write the vacuum two-point function in terms of its kernel

$$\omega_0^{(2)ij}(x,x') = -\int_{\mathbb{R}^3} \frac{\mathrm{d}^3\mathbf{k}}{(2\pi)^3} \frac{1}{2\omega} \left(\eta^{ij} - \frac{k^i k^j}{M^2} \right) e^{-ik_l(x-x')^l}. \tag{93}$$

It is not a difficult calculation to show that the point-split vacuum energy density along the worldline γ is

$$\varphi^* \langle T \rangle_{\omega_0}(\tau,\tau') = \frac{3}{2} \int_{\mathbb{R}^3} \frac{\mathrm{d}^3\mathbf{k}}{(2\pi)^3} \omega e^{-i\omega(\tau-\tau')} = \frac{6\pi}{(2\pi)^3} \int_0^\infty \mathrm{d}\kappa\, \kappa^2 \omega(\kappa) e^{-i\omega(\kappa)(\tau-\tau')}\,, \tag{94}$$

where in the last step, we have changed to spherical polar coordinates in the momentum integration, performed the angular integrals, and written $\omega(\kappa)=\sqrt{\kappa^2+M^2}$. This expression can be used to evaluate the right-hand side of Eq. (84), giving

$$\begin{aligned} \int \mathrm{d}\tau \langle :\rho: \rangle_\omega(\tau) g(\tau)^2 &\geqslant -\int_0^\infty \frac{\mathrm{d}\alpha}{\pi} [(g\otimes g)\varphi^* \langle T \rangle_{\omega_0}]\hat{}\,(-\alpha,\alpha) \\ &= -\frac{6}{(2\pi)^3} \int_0^\infty \mathrm{d}\alpha \int_0^\infty \mathrm{d}\kappa\, \kappa^2 \omega(\kappa) |\hat{g}(\alpha+\omega(\kappa))|^2\,. \end{aligned}$$

Before commenting on the above expression, we wish to perform a similar analysis for the electromagnetic field. The vacuum two-point function for electromagnetism in the Coulomb gauge is given by

$$\omega_0^{(2)ij}(x,x') = -\int_{\mathbb{R}^3} \frac{\mathrm{d}^3\mathbf{k}}{(2\pi)^3} \frac{1}{2\omega} h^{ij} e^{-ik_l(x-x')^l}, \tag{95}$$

where $\omega=|\mathbf{k}|$ and

$$h^{ij}=\begin{cases}\eta^{ij}+k^ik^j/\omega^2 & \text{for } i\neq 0\neq j,\\ 0 & \text{otherwise.}\end{cases} \tag{96}$$

It is straightforward to check that, for co-closed test one-forms f,f' [i.e., $k^i\hat{f}_i(k)=0$] we have $\omega_0^{(2)}(f,f')=W_0(f,f')$ and that ω_0 is therefore Hadamard. An identical computation to the above now reveals that

$$\varphi^*\langle T\rangle_{\omega_0}(\tau,\tau')=\int_{\mathbb{R}^3}\frac{\mathrm{d}^3\mathbf{k}}{(2\pi)^3}\,\omega e^{-i\omega(\tau-\tau')}=\frac{4\pi}{(2\pi)^3}\int_0^\infty \mathrm{d}\kappa\,\kappa^2\omega(\kappa)e^{-i\omega(\kappa)(\tau-\tau')}\,, \tag{97}$$

and hence

$$\int \mathrm{d}\tau\langle{:}\rho{:}\rangle_\omega(\tau)g(\tau)^2\geqslant-\frac{4}{(2\pi)^3}\int_0^\infty\mathrm{d}\alpha\int_0^\infty\mathrm{d}\kappa\,\kappa^2\omega(\kappa)|\hat{g}(\alpha+\omega(\kappa))|^2\,. \tag{98}$$

From this point on, the Proca and electromagnetic fields can be treated simultaneously as the two bounds take the common form (setting $M=0$ for electromagnetism)

$$\int \mathrm{d}\tau\langle{:}\rho{:}\rangle_\omega(\tau)g(\tau)^2\geqslant-sI_M(g)\,, \tag{99}$$

where s is the number of spin degrees of freedom for the field, i.e., $s=2$ for Maxwell and $s=3$ for Proca, and

$$I_M(g)=\frac{2}{(2\pi)^3}\int_0^\infty\mathrm{d}\alpha\int_0^\infty\mathrm{d}\kappa\,\kappa^2\omega(\kappa)|\hat{g}(\alpha+\omega(\kappa))|^2\,. \tag{100}$$

This integral can be further simplified by making an additional change of variables,

$$\begin{aligned}u&=\alpha+\omega(\kappa),\\ v&=\omega(\kappa)\,,\end{aligned} \tag{101}$$

whereupon the above integral can be rewritten as

$$I_M(g)=\frac{2}{(2\pi)^3}\int_M^\infty\mathrm{d}u|\hat{g}(u)|^2\int_M^u\mathrm{d}v\,v^2\sqrt{v^2-M^2}. \tag{102}$$

In fact, the scalar field also satisfies Eq. (99) with $s=1$.[22] Thus, in Minkowski space, the QWEI bounds for scalar, Proca and Maxwell fields differ only by a factor equal to the number of spin states (as already noted for the electromagnetic field in Ref. 27). However, in more general curved space–times the scalar and one-form fields can have different eigenfrequency spectra leading to very different quantum weak energy inequalities for each field.

B. Ultrastatic space–times

We now turn to the class of examples in which the space–time is ultrastatic (with compact Cauchy surface obeying our usual requirements) and the energy density is sampled along a static worldline, using the ultrastatic vacua of Sec. IV as reference states. In this case, the quantum inequality Eq. (84) takes a remarkably simple form. Recall that, for both the Proca and the Maxwell fields, the two-point function of the vacuum state can be written compactly as

$$\omega^{(2)}(F,F')=\sum_{\lambda}\sum_{\text{physical}\ j\in J(\lambda)}\frac{1}{2\omega(\lambda,j)}\langle\mathcal{A}(\lambda,j),F\rangle\,\langle\overline{\mathcal{A}(\lambda,j)},F'\rangle, \tag{103}$$

where λ ranges only over the physical families of modes, i.e., $\lambda \in \{T,P\}$ for Proca, but $\lambda = T$ only for Maxwell. In the Maxwell case, we restrict attention to co-closed test one-forms F and F'. Using the mode expansion (103) for the two point function, and recalling that $\mathcal{F} = \mathbf{d}\mathcal{A}$, it is not difficult to show that[77]

$$[(g\otimes g)\varphi^*\langle T\rangle_\omega]\hat{}(-\alpha,\alpha) = \int \mathrm{d}\tau \int \mathrm{d}\tau'\, g(\tau)\, g(\tau')\, e^{-i\alpha(\tau-\tau')} \times \sum_{\lambda}\ \sum_{\text{physical}}\ \sum_{j\in J(\lambda)} N(\lambda,j)(\gamma(\tau),\gamma(\tau'))\,, \tag{104}$$

where

$$N(\lambda,j)(x,x') = \frac{1}{2\omega(\lambda,j)}\left\{ \frac{1}{4}\sum_{p=0}^{3}\sum_{q=0}^{3} [\mathcal{F}_{\mu\nu}(\lambda,j)v_p^\mu v_q^\nu](x)\,[\overline{\mathcal{F}_{\rho\sigma}(\lambda,j)}v_p^\rho v_q^\sigma](x') + \frac{1}{2}M^2\sum_{p=0}^{3}[\mathcal{A}_\mu(\lambda,j)v_p^\mu](x)\,[\overline{\mathcal{A}_\rho(\lambda,j)}v_p^\rho](x')\right\}. \tag{105}$$

Now if we choose a static worldline $\gamma(\tau) = (\tau,\mathbf{x}_0)$, then

$$N(\lambda,j)(\gamma(\tau),\gamma(\tau')) = e^{-i\omega(\lambda,j)(\tau-\tau')}\,\mathfrak{T}(\lambda,j)\,, \tag{106}$$

where

$$\mathfrak{T}(\lambda,j) = \frac{1}{2\omega(\lambda,j)}\left\{\frac{1}{4}\sum_{p=0}^{3}\sum_{q=0}^{3}|[\mathcal{F}_{\mu\nu}(\lambda,j)v_p^\mu v_q^\nu](\gamma(\tau_0))|^2 + \frac{1}{2}M^2\sum_{p=0}^{3}|[\mathcal{A}_\mu(\lambda,j)v_p^\mu](\gamma(\tau_0))|^2\right\} \tag{107}$$

is the classical energy density per mode at the spatial position of the observer's worldline. [Note that the leading factor of $(2\omega(\lambda,j))^{-1}$ appears because our modes were normalized using the L^2-inner product on Σ, rather than the symplectic inner product.] The most notable point to be made here is that $\mathfrak{T}(\lambda,j)$ is τ independent because the $e^{-i\omega_\lambda\tau}$ dependence in the modes is removed by taking the magnitude of the complex functions. Thus Eq. (104) becomes

$$[(g\otimes g)\varphi^*\langle T\rangle_\omega]\hat{}(-\alpha,\alpha) = \sum_{\lambda}\ \sum_{\text{physical}}\ \sum_{j\in J(\lambda)} |\hat{g}(\alpha+\omega(\lambda,j))|^2\mathfrak{T}(\lambda,j)\,, \tag{108}$$

and the quantum weak energy inequality for static observers in ultrastatic space–times becomes

$$\int \mathrm{d}\tau (g(\tau))^2\langle{:}\rho{:}\rangle_\omega(\tau) \geqslant -\int_0^\infty \frac{\mathrm{d}\alpha}{\pi}\sum_{\lambda}\ \sum_{\text{physical}}\ \sum_{j\in J(\lambda)} |\hat{g}(\alpha+\omega(\lambda,j))|^2\mathfrak{T}(\lambda,j). \tag{109}$$

As we will see, the above form turns out to be calculationally convenient in some settings. However, we also note that the quantum weak energy inequality may be written

$$\int \mathrm{d}\tau (g(\tau))^2\langle{:}\rho{:}\rangle_\omega(\tau) \geqslant -\int_0^\infty \mathrm{d}u\, |\hat{g}(u)|^2 Q(u), \tag{110}$$

where

$$Q(u) = \frac{1}{\pi}\sum_{\lambda}\ \sum_{\text{physical}}\ \sum_{\substack{j\in J(\lambda)\\ \text{s.t. } \omega(\lambda,j)\leqslant u}} \mathfrak{T}(\lambda,j) \tag{111}$$

measures the maximum energy density available if no mode with frequency greater than u is excited. The analysis carried out in Sec. 5 of Ref. 24 for the scalar field may be adapted to show that $Q(u)$ is positive and polynomially bounded as $u\to\infty$. Several other systems obey quantum inequalities of this form, which motivated the study of related conditions for general quantum dynamical systems in Ref. 58. In the terminology of that paper, the ultrastatic vacuum states constructed here fulfill a *limiting static QWEI*. We expect that the analysis of Ref. 58 would apply equally well to the Proca and Maxwell fields, thereby establishing links between quantum inequalities and the thermodynamic properties of these fields.

C. Static Einstein universe

A nice example of the ultrastatic quantum inequality is provided by the static Einstein universe $\mathbb{R}\times S^3$ with line element

$$\mathrm{d}s^2=\mathrm{d}t^2-a^2[\mathrm{d}\chi^2+\sin^2\chi(\mathrm{d}\theta^2+\sin^2\theta\mathrm{d}\varphi^2)]. \tag{112}$$

Here a is the radius of the universe and (χ,θ,φ) are spherical polar coordinates on the unit three-sphere. Various authors have studied the electromagnetic mode functions in the Einstein universe[59–61] and it turns out that essentially the same ansatz can be used to obtain the modes of the Proca field.

We know from Sec. IV that the scalar Proca modes are completely specified by finding mode solutions to the massive, minimally coupled scalar wave equation $(\Box^s+M^2)\Phi=0$. A complete set of suitably normalized positive frequency mode solutions in the Einstein universe is given by[62,63]

$$\Phi_{nlm}(x)=a^{-3/2}\Pi_{nl}(\chi)\,Y_{lm}(\theta,\varphi)\,e^{-i\sigma_n t}, \tag{113}$$

where $Y_{lm}(\theta,\varphi)$ are the standard spherical harmonics on a two-sphere,[64] $\Pi_{nl}(\chi)$ can be written in terms of Gegenbauer polynomials $C_\eta^\lambda(x)$[65] as

$$\Pi_{nl}(\chi)=\frac{l!\,2^{l+1/2}\sqrt{(n-l)!(n+1)}}{\sqrt{\pi(n+l+1)!}}\sin^l\chi\,C_{n-l}^{l+1}(\cos\chi), \tag{114}$$

and the frequency of the modes is

$$\sigma_n=\sqrt{\frac{n(n+2)}{a^2}+M^2}. \tag{115}$$

Here, the primary quantum number n ranges over the non-negative integers $n=0,1,2,\ldots$. For a given n there are $(n+1)^2$ harmonic states with the same frequency labeled by the quantum numbers, $l=0,1,\ldots,n$ and $m=-l,-l+1,\ldots,0,\ldots,l-1,l$. However, the case $n=l=m=0$ corresponds to the spatially constant mode; thus the labelling set for the scalar Proca modes given by Eq. (59) is $n=1,2,\ldots$, with l and m as before.

On the other hand, the family of transverse modes breaks up into two subfamilies:[61] the magnetic J-pole modes taking the form

$$\mathcal{A}(M,n,l,m)=*\mathbf{d}(\Psi_{nlm}\,\mathbf{d}t\wedge\mathbf{d}\chi), \tag{116}$$

and the electric J-pole modes,

$$\mathcal{A}(E,n,l,m)=*\mathbf{d}\left(\frac{a}{n}\mathcal{A}(M,n,l,m)\wedge\mathbf{d}t\right), \tag{117}$$

where the scalar functions Ψ_{nlm} obey

$$\left(\Box^s + \frac{2\cos\chi}{a^2\sin\chi}\partial_\chi + M^2\right)\Psi_{nlm} = 0. \tag{118}$$

The positive frequency mode solutions to this partial differential equation are

$$\Psi_{nlm}(x) = \sqrt{2an}\, V_{nl}(\chi)\, Y_{lm}(\theta,\varphi)\, e^{-i\omega_n t}, \tag{119}$$

where

$$V_{nl}(\chi) = \frac{l!\, 2^l\sqrt{(n-l-1)!}}{\sqrt{\pi l(l+1)(n+l)!}}\sin^{l+1}\chi\, C^{l+1}_{n-l-1}(\cos\chi) \tag{120}$$

and the frequency of the modes is given by

$$\omega_n = \sqrt{\frac{n^2}{a^2} + M^2}. \tag{121}$$

Here the quantum numbers range over a different set of allowed values. The primary quantum number n ranges over the integers $n = 2,3,\ldots$. For a given n there are n^2-1 harmonic states with the same frequency labeled by the quantum numbers, $l = 1,2,\ldots,n-1$ and $m = -l,-1+1,\ldots,0,\ldots,l-1,l$. We stress that both transverse subfamilies have an energy spectrum given by Eq. (121), which differs from that of the scalar Proca modes. There is actually a more convenient basis of transverse mode solutions given by

$$\mathcal{A}(\pm,n,l,m) = \frac{1}{\sqrt{2}}[\mathcal{A}(M,n,l,m) \pm \mathcal{A}(E,n,l,m)], \tag{122}$$

which are simultaneous eigenfunctions of $\boldsymbol{\delta}_\Sigma * _\Sigma$ and $-\Delta_\Sigma + M^2$ (which commute). The $\lambda = M$ or E families of modes are, roughly speaking, the linearly polarized solutions of the field while the $\lambda = +$ or $-$ modes are the circularly polarized solutions.

For the interested reader, we also state the component form of the three families of physical modes. The two transverse polarizations of the field are

$$\mathcal{A}_\mu(M,n,l,m) = \frac{1}{a}\left(0, 0, -\frac{1}{\sin\theta}\partial_\varphi, \sin\theta\partial_\theta\right)\Psi_{nlm} \tag{123}$$

and

$$\mathcal{A}_\mu(E,n,l,m) = \frac{1}{an}\left(0, \frac{l(l+1)}{\sin^2\chi}, \partial_\chi\partial_\theta, \partial_\chi\partial_\varphi\right)\Psi_{nlm}, \tag{124}$$

while the scalar Proca modes are

$$\mathcal{A}_\mu(P,n,l,m) = \frac{a\sigma_n^2}{M\sqrt{n(n+2)}}\left(\frac{n(n+2)}{i\sigma_n a^2}, \partial_\chi, \partial_\theta, \partial_\varphi\right)\Phi_{nlm}. \tag{125}$$

One may readily verify that the two transverse modes and the scalar Proca mode all have the property $\boldsymbol{\delta}\mathcal{A}(\lambda,n,l,m) = 0$, for $\lambda = M,E,P$ and therefore solve the Proca equation (19). Moreover, these modes obey the (pseudo)-orthonormality conditions of Sec. IV A.

Since the Einstein space–time is ultrastatic, we can find the quantum weak energy inequality from Eq. (109). To begin, let the worldline for a stationary observer be given by $\gamma(\tau) = (\tau,\chi,\theta,\varphi)$ where (χ,θ,φ) are the coordinates of a fixed point in space. An orthonormal basis in

the neighborhood around γ is given by $v_i^\mu = \sqrt{|g^{\mu\mu}|}(\partial/\partial x^i)^\mu$ (no sum on μ). All of the work is in the evaluation of the classical energy density per mode, $\mathfrak{T}(\lambda,n,l,m)$, defined by Eq. (107), which, in the Einstein space–time takes the form

$$\mathfrak{T}(\lambda,j) = \frac{1}{4\omega(\lambda,j)}\left[\frac{|\mathcal{F}_{01}|^2}{a^2} + \frac{|\mathcal{F}_{02}|^2}{a^2\sin^2\chi} + \frac{|\mathcal{F}_{03}|^2}{a^2\sin^2\chi\sin^2\theta} + \frac{|\mathcal{F}_{12}|^2}{a^4\sin^2\chi} + \frac{|\mathcal{F}_{13}|^2}{a^4\sin^2\chi\sin^2\theta} + \frac{|\mathcal{F}_{23}|^2}{a^4\sin^4\chi\sin^2\theta} + M^2\left(|\mathcal{A}_0|^2 + \frac{|\mathcal{A}_1|^2}{a^2} + \frac{|\mathcal{A}_2|^2}{a^2\sin^2\chi} + \frac{|\mathcal{A}_3|^2}{a^2\sin^2\chi\sin^2\theta}\right)\right]. \tag{126}$$

Beginning with the $\pm$ modes, it is straightforward to calculate the field strength $\mathcal{F}(\pm,n,l,m) = \mathbf{d}\mathcal{A}(\pm,n,l,m)$. Inserting the field strength into the above expression, and using $\partial_\chi \Psi_{nlm} = \partial_\chi \overline{\Psi_{nlm}}$, we arrive at

$$\mathfrak{T}(\pm,n,l,m) = \frac{\omega_n}{4a^4n^2}\left[\left(\frac{l(l+1)}{\sin^2\chi}\right)^2|\Psi_{nlm}|^2 + \frac{1}{\sin^2\chi}\left(|\partial_\chi\partial_\theta\Psi_{nlm}|^2 + \frac{1}{\sin^2\theta}|\partial_\chi\partial_\varphi\Psi_{nlm}|^2\right) + \frac{n^2}{\sin^2\chi}\left(|\partial_\theta\Psi_{nlm}|^2 + \frac{1}{\sin^2\theta}|\partial_\varphi\Psi_{nlm}|^2\right)\right]. \tag{127}$$

Note that the $+$ and $-$ modes have equal energy densities. Next, we use the definition Eq. (119) of the scalar functions Ψ_{nlm} and two identities. The first identity,

$$|\partial_\theta Y_{lm}|^2 + \frac{1}{\sin^2\theta}|\partial_\varphi Y_{lm}|^2 = \frac{1}{2}\Delta_{S^2}|Y_{lm}|^2 + l(l+1)|Y_{lm}|^2 \tag{128}$$

is for the spherical harmonics where

$$\Delta_{S^2} = \frac{1}{\sin\theta}\partial_\theta\sin\theta\partial_\theta + \frac{1}{\sin^2\theta}\partial_\phi^2 \tag{129}$$

is the two-sphere Laplacian. The second identity is

$$\frac{l(l+1)}{\sin^2\chi}V_{nl}^2 + (\partial_\chi V_{nl})^2 = \left(n^2 + \frac{1}{2}\partial_\chi^2\right)V_{nl}^2, \tag{130}$$

which follows from the ordinary differential equation satisfied by $V_{nl}(\chi)$. Using both of these we arrive at

$$\mathfrak{T}(\pm,n,l,m) = \frac{\omega_n}{2a^3n}\left\{\frac{l(l+1)}{\sin^2\chi}\left(2n^2 + \frac{1}{2}\partial_\chi^2\right)V_{nl}^2|Y_{lm}|^2 + \frac{1}{2\sin^2\chi}[(\partial_\chi V_{nl})^2 + n^2V_{nl}^2]\Delta_{S^2}|Y_{lm}|^2\right\}. \tag{131}$$

Because the frequency ω_n is independent of l and m, we can sum over these labels, obtaining considerable simplification from the summation theorems for the spherical harmonics and Gegenbauer polynomials. In the case of the spherical harmonics it is well-known that[64]

$$\sum_{m=-l}^{l}|Y_{lm}(\theta,\varphi)|^2 = \frac{2l+1}{4\pi}, \tag{132}$$

which reduces the sum over all l and m of $\mathfrak{T}(\pm,n,l,m)$ to

$$\sum_{l=1}^{n-1}\sum_{m=-l}^{+l}\mathcal{T}(\pm,n,l,m)=\frac{\omega_n}{8\pi a^3 n}\sum_{l=1}^{n-1}\frac{(2l+1)l(l+1)}{\sin^2\chi}\left(2n^2+\frac{1}{2}\partial_\chi^2\right)V_{nl}^2$$

$$=\frac{\omega}{8\pi a^3 n}\frac{1}{\sin^2\chi}\left(2n^2+\frac{1}{2}\partial_\chi^2\right)\sin^2\chi\sum_{l=1}^{n-1}\frac{(2l+1)l(l+1)}{\sin^2\chi}V_{nl}^2. \quad (133)$$

Using the summation theorem for the Gegenbauer polynomials,

$$\sum_{l=1}^{n-1}\frac{(2l+1)l(l+1)}{\sin^2\chi}V_{nl}^2(\chi)=\frac{1}{\pi}\left[n-\frac{1}{n}\left(\frac{\sin n\chi}{\sin\chi}\right)^2\right], \quad (134)$$

[(Eq. 8.934.3) of Ref. 65] we finally obtain

$$\sum_{l=1}^{n-1}\sum_{m=-l}^{+l}\mathfrak{T}(\pm,n,l,m)=\frac{(n^2-1)\omega_n}{4\pi^2a^3}. \quad (135)$$

It is noteworthy that this expression is exactly the total zero-point energy of n^2-1 harmonic oscillators at frequency ω_n, divided by the spatial volume $2\pi^2a^3$ of the Einstein universe.

The contribution from the scalar Proca modes is calculated in much the same manner. The only difference is that we make use of the following two identities:

$$(\partial_\chi\Pi_{nl})^2+\frac{l(l+1)}{\sin^2\chi}\Pi_{nl}^2=n(n+2)\Pi_{nl}^2+\frac{1}{2\sin^2\chi}\partial_\chi\sin^2\chi\partial_\chi\Pi_{nl}^2, \quad (136)$$

which follows from the ordinary differential equation satisfied by Π_{nl} and

$$\sum_{l=0}^{n}(2l+1)\Pi_{nl}^2(\chi)=\frac{2(n+1)^2}{\pi}, \quad (137)$$

which again follows from the summation theorem for the Gegenbauer polynomials. For the Proca mode we find

$$\sum_{l=0}^{n}\sum_{m=-l}^{+l}\mathfrak{T}(P,n,l,m)=\frac{(n+1)^2\sigma_n}{4\pi^2a^3}. \quad (138)$$

Again we have found the zero-point energy times the multiplicity divided by the spatial volume.

Finally, let s be the total number of spin degrees of freedom for the field, i.e., $s=2$ for Maxwell and $s=3$ for Proca. Substituting Eqs. (135) and (138) into Eq. (109), we can write the quantum weak energy inequality in the Einstein space–time for an arbitrary real-valued test function $g(\tau)\in C_0^\infty(\mathbb{R})$ as

$$\int \mathrm{d}\tau\langle:\rho:\rangle_\omega(\tau)g(\tau)^2\geqslant-\frac{2}{4\pi^2a^3}\sum_{n=2}^{\infty}(n^2-1)\omega_n\int_0^\infty\frac{\mathrm{d}\alpha}{\pi}|\hat{g}(\alpha+\omega_n)|^2$$

$$-\frac{(s-2)}{4\pi^2a^3}\sum_{n=1}^{\infty}(n+1)^2\sigma_n\int_0^\infty\frac{\mathrm{d}\alpha}{\pi}|\hat{g}(\alpha+\sigma_n)|^2, \quad (139)$$

which holds for all Hadamard states ω.

By suitably restricting the class of allowed states (if necessary) this bound may be extended to noncompactly supported g whose Fourier transforms have sufficiently rapid decay.[78] For electromagnetism, the above bound was evaluated for a Lorentzian test function in Ref. 27; here we will treat the example of a Gaussian test function in both the electromagnetic and Proca cases. Setting

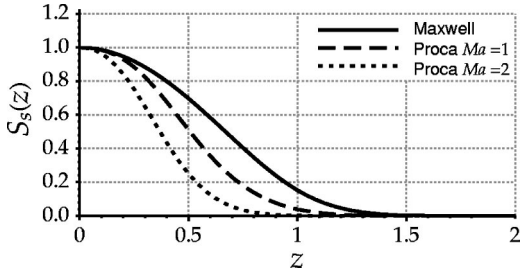

FIG. 1. Plot of the scale function $\mathcal{S}_s(z)$ for the Gaussian sampling function in the Einstein universe. Three different cases are of Eq. (144) are displayed: Electromagnetism (solid line) and two cases of the Proca field for different values of the mass times the radius of universe, Ma$=1$ (dashed line) and Ma$=2$ (dotted line). The plots were produced by evaluating the first 3000 terms in the summation of Eq. (144).

$$g(\tau)=\pi^{-1/4}\tau_0^{-1/2}\exp\left(-\frac{1}{2}\frac{\tau^2}{\tau_0^2}\right), \tag{140}$$

the weight function $g(\tau)^2$ is a normalized Gaussian. Using the Fourier transform of g,

$$\hat{g}(\alpha)=\pi^{1/4}(2\tau_0)^{1/2}\exp\left(-\frac{\alpha^2\tau_0^2}{2}\right), \tag{141}$$

it is now possible to calculate

$$\int_0^\infty \mathrm{d}\alpha|\hat{g}(\alpha+\omega)|^2=\pi\,\mathrm{erfc}(\omega\tau_0), \tag{142}$$

where erfc(x) is the complementary error function. Accordingly, the quantum weak energy inequality for this test function is

$$\int \mathrm{d}\tau\langle:\rho:\rangle_\omega(\tau)g(\tau)^2\geqslant-\frac{3s}{64\pi^2\tau_0^4}\mathcal{S}_s(\tau_0/a), \tag{143}$$

where the scale function

$$\mathcal{S}_s(z)=\frac{16}{3}z^4\left[\frac{2}{s}\sum_{n=2}^{\infty}(n^2-1)\sqrt{n^2+M^2a^2}\,\mathrm{erfc}(\sqrt{n^2+M^2a^2}z)\right.$$
$$\left.+\frac{s-2}{s}\sum_{n=1}^{\infty}(n+1)^2\sqrt{n(n+2)+M^2a^2}\,\mathrm{erfc}(\sqrt{n(n+2)+M^2a^2}z)\right] \tag{144}$$

is plotted in Fig. 1. For very short sampling times the scale function is close to unity and the QWEI bound is the same as that for Minkowski space–time.[27] This is expected because the space–time appears to be flat over time scales which are short relative to the radius of the universe, and we should expect to recover the Minkowski space result. As the sampling time becomes progressively longer, the field has more time to ''sample'' the curvature of the universe, and thus it becomes increasingly difficult to generate negative energy densities. Also, as the mass of the field increases it becomes increasingly difficult to generate negative energy densities. This is seen by the faster decay in the scale functions for larger value of the field mass as seen in previous evaluations of the scale function for scalar fields in other space–times.[15,17,18] As mentioned above, the quantum inequality bound has also been evaluated for electromagnetism with a Lorentzian sampling function[27] and the behavior is very much the same.

APPENDIX A: CONSISTENCY OF THE HADAMARD CONDITION WITH THE CONSTRAINTS

In this appendix we prove the following local-to-global result.

Theorem A.1: *Let ω be a state on either $\mathfrak{A}_M(\mathcal{M},g)$ or $\mathfrak{A}(\mathcal{M},g)$ and suppose that there exists a causal normal neighborhood $\mathcal{N}$ of a Cauchy surface Σ in $\mathcal{M}$, and a Hadamard bisolution W_M (respectively, W) to $\Box+M^2$ (respectively, $\Box$) on $\mathcal{N}\times\mathcal{N}$ such that*

$$\omega(\mathcal{A}(f_1)\mathcal{A}(f_2))=W_M(f_1,(\mathbb{1}-M^{-2}\,\mathbf{d}\boldsymbol{\delta})f_2) \tag{A1}$$

for all $f_i\in\Omega_0^1(\mathcal{N})$ (in the Proca case) or

$$\omega([\mathcal{A}](f_1)[\mathcal{A}](f_2))=W(f_1,f_2) \tag{A2}$$

for all $f_i\in\Omega_0^1(\mathcal{N})$ with $\boldsymbol{\delta}f_i=0$ (in the Maxwell case). Then ω is Hadamard.

Thus the Hadamard conditions introduced in Sec. III C respect the Cauchy evolution of the field equations: if they are satisfied near one Cauchy surface, they hold near all others and hence hold globally. As the Hadamard form for Klein–Gordon bisolutions also propagates in this sense (Theorem 5.5 in Ref. 32), our discussion may be regarded as checking the consistency of the definitions of Sec. III C with the Proca and Maxwell constraints. The propagation property is one of the key ingredients used in Sec. IV E, where we established the existence of Hadamard states on general globally hyperbolic space–times obeying our usual topological conditions. Although we will use the fact that Σ is compact for both the Maxwell and Proca fields this condition can probably be dropped; however in the Maxwell case it appears to be necessary [in Lemma A.4(b)] to assume that $H_1(\Sigma)$ is trivial and that the compact support cohomology group $H_c^3(\mathcal{M})$ of the space–time is therefore also trivial.

The proof of Theorem A relies on a number of results concerning the classical Proca, Maxwell, and Klein–Gordon fields. One fact which will be used repeatedly is that, for $f\in\Omega_0^1(\mathcal{M})$, $E_Mf=0$ if and only if $f\in(\Box+M^2)\Omega_0^1(\mathcal{M})$. Indeed, $f=(\Box+M^2)E_M^+f$ and since, by hypothesis, $E_M^+f=E_M^-f$, the support of E_M^+f is contained in the compact set $J^+(\mathrm{supp}\,f)\cap J^-(\mathrm{supp}\,f)$. Our first observation generalizes this fact to the Proca field.

Lemma A.2: Let $M>0$. For $f\in\Omega_0^1(\mathcal{M})$, $\Delta_Mf=0$ if and only if $f\in(-\boldsymbol{\delta}\mathbf{d}+M^2)\Omega_0^1(\mathcal{M})$.

Proof: Since $(\mathbb{1}-M^{-2}\,\mathbf{d}\boldsymbol{\delta})(-\boldsymbol{\delta}\mathbf{d}+M^2)=\Box+M^2$, sufficiency holds because E_M is a Klein–Gordon bisolution. Conversely, $\Delta_Mf=0$ is equivalent to $E_M(\mathbb{1}-M^{-2}\,\mathbf{d}\boldsymbol{\delta})f=0$; hence, we have

$$(-\mathbf{d}\boldsymbol{\delta}+M^2)f=M^2(\Box+M^2)g \tag{A3}$$

for some $g\in\Omega_0^1(\mathcal{M})$. By applying $\boldsymbol{\delta}\mathbf{d}$ to both sides, we obtain $\boldsymbol{\delta}\mathbf{d}f=(\Box+M^2)\,\boldsymbol{\delta}\mathbf{d}g$, which may be subtracted from the previous expression to yield

$$(\Box+M^2)f=(\Box+M^2)(-\boldsymbol{\delta}\mathbf{d}+M^2)g\,. \tag{A4}$$

Since both f and g are compactly supported, we conclude that $f=(-\boldsymbol{\delta}\mathbf{d}+M^2)g$. □

Proposition A.3: (a) Given any $f\in\Omega_0^1(\mathcal{M})$ there exists $g\in\Omega_0^1(\mathcal{M})$ such that $\tilde{f}=f+(-\boldsymbol{\delta}\mathbf{d}+M^2)g$ is an element of $\Omega_0^1(\mathcal{N})$.

(b) Given any co-closed $f\in\Omega_0^1(\mathcal{M})$ there exists $g\in\Omega_0^1(\mathcal{M})$ such that $\tilde{f}=f-\boldsymbol{\delta}\mathbf{d}g$ is a co-closed element of $\Omega_0^1(\mathcal{N})$.

Proof: (a) Choose smooth functions $\chi^{\pm}$ on $\mathcal{M}$ with $\chi^++\chi^-=1$ and χ^+ equal to unity to the future of $\mathcal{N}$ and vanishing to the past of $\mathcal{N}$. Then

$$\tilde{f}=(-\boldsymbol{\delta}\mathbf{d}+M^2)\chi^+\Delta_Mf \tag{A5}$$

belongs to $\Omega_0^1(\mathcal{N})$ and satisfies $\Delta_M\tilde{f}=\Delta_Mf$. Applying Lemma A.2 to $\tilde{f}-f$, it follows that $\tilde{f}=f+(-\boldsymbol{\delta}\mathbf{d}+M^2)g$ as required.

(b) With $\chi^{\pm}$ as above, set $\tilde{f}=-\boldsymbol{\delta}\mathbf{d}\chi^{+}E_0 f$. Then $\tilde{f}$ belongs to $\Omega^1_0(\mathcal{N})$ and is co-closed; moreover $E_0\tilde{f}$ and $E_0 f$ are gauge equivalent by the proof of Prop. 4(c) in Ref. 36. Accordingly, there exists $\eta\in\Omega^0(\mathcal{M})$ such that $E_0(\tilde{f}-f)=\mathbf{d}\eta$. Taking coderivatives, using $\boldsymbol{\delta}E_0=E_0\boldsymbol{\delta}$ and co-closure of $\tilde{f}$ and f, we have $\boldsymbol{\delta}\mathbf{d}\eta=0$ and hence $\eta=E_0\zeta$ for some $\zeta\in\Omega^0_0(\mathcal{M})$. Substituting back, we see that $E_0(\tilde{f}-f-\mathbf{d}\zeta)=0$, so

$$\tilde{f}-f-\mathbf{d}\zeta=\Box g \tag{A6}$$

for some $g\in\Omega^1_0(\mathcal{M})$. Taking coderivatives again, $\Box(\zeta-\boldsymbol{\delta}g)=0$ and hence (because both ζ and g are compactly supported) $\zeta=\boldsymbol{\delta}g$. Substituting back in Eq. (A6), we have $\tilde{f}=f+\mathbf{d}\boldsymbol{\delta}g+\Box g=f-\boldsymbol{\delta}\mathbf{d}g$ as required. □

Lemma A.4: (a) If $\mathcal{A}$ is a weak one-form $(\Box+M^2)$-solution obeying

$$\mathcal{A}((-\boldsymbol{\delta}\mathbf{d}+M^2)f)=0 \tag{A7}$$

for all $f\in\Omega^1_0(\mathcal{N})$, then Eq. (A7) holds for all $f\in\Omega^1_0(\mathcal{M})$.

(b) If $\mathcal{A}$ is a weak one-form $\Box$-solution vanishing on co-closed $f\in\Omega^1_0(\mathcal{N})$, then $\mathcal{A}$ vanishes on all co-closed $f\in\Omega^1_0(\mathcal{M})$.

Proof: (a) Since, for $f\in\Omega^1_0(\mathcal{N})$, $\mathcal{A}((\Box+M^2)f)=0$, we have by Eq. (A7) that

$$\mathcal{A}(\mathbf{d}\boldsymbol{\delta}f)=0 \tag{A8}$$

for all $f\in\Omega^1_0(\mathcal{N})$. Thus, $\mathcal{A}(\mathbf{d}\cdot)$ is a global weak scalar $(\Box+M^2)$-solution vanishing on $\boldsymbol{\delta}\Omega^1_0(\mathcal{N})$. Now we may fix $f_0\in\Omega^0_0(\mathcal{N})$ such that any $f\in\Omega^0_0(\mathcal{N})$ may be written

$$f=f_0\int f\,\mathrm{d}\,\mathrm{vol}_g+\boldsymbol{\delta}h \tag{A9}$$

for some $h\in\Omega^1_0(\mathcal{N})$. (Since $\mathcal{N}$ is connected, boundaryless and orientable, this follows by de Rahm's theorem: see the remarks following Theorem 7.5.19 in Ref. 39.) Combining Eqs. (A8) and (A9), we have $\mathcal{A}(\mathbf{d}f)=\mathcal{A}(\mathbf{d}f_0)\int f\,\mathrm{d}\,\mathrm{vol}_g$ for all $f\in\Omega^0_0(\mathcal{N})$. Accordingly, $\mathcal{A}(\mathbf{d}\cdot)$ is constant on $\mathcal{N}$ and hence [since it is a $(\Box+M^2)$-solution] on $\mathcal{M}$. It follows that $\mathcal{A}(\mathbf{d}\boldsymbol{\delta}f)=\mathcal{A}(\mathbf{d}f_0)\int\boldsymbol{\delta}f\,\mathrm{d}\,\mathrm{vol}_g=0$ for all $f\in\Omega^1_0(\mathcal{M})$. Since $\mathcal{A}((\Box+M^2)f)=0$, we deduce that Eq. (A7) holds for all $f\in\Omega^1_0(\mathcal{M})$ as required.

(b) $\mathcal{A}(\boldsymbol{\delta}\cdot)$ is a two-form weak $\Box$-solution vanishing on all $h\in\Omega^2_0(\mathcal{N})$ and hence on all $h\in\Omega^2_0(\mathcal{M})$. But since $H^3_c(\mathcal{M})$ is trivial, any $f\in\Omega^1_0(\mathcal{M})$ such that $\boldsymbol{\delta}f=0$ can be written as $f=\boldsymbol{\delta}h$ for some $h\in\Omega^2_0(\mathcal{M})$ and we conclude that $\mathcal{A}(f)=\mathcal{A}(\boldsymbol{\delta}h)=0$. □

After these preliminaries, we may now prove the main result of this section.

Proof of Theorem A.1: The arguments for the two theories run along parallel lines. First one extends the W_M (respectively, W) to be a global bisolution to the appropriate one-form Klein–Gordon equation. Crucially, Theorem 5.5 of Ref. 32 assures us that the Hadamard form propagates and that the resulting bisolution is therefore of Hadamard from on the whole of $\mathcal{M}\times\mathcal{M}$. Thus it suffices to show that Eq. (A1) holds for all $f_i\in\Omega^1_0(\mathcal{M})$ [respectively, that Eq. (A2) holds for all co-closed $f_i\in\Omega^1_0(\mathcal{M})$]. In the Proca case, we apply Proposition A.3(a) together with the field equation axiom (P3) and Eq. (A1) to show that

$$\omega(\mathcal{A}(f_1)\mathcal{A}(f_2))=\omega(\mathcal{A}(\tilde{f}_1)\mathcal{A}(\tilde{f}_2))=W_M(\tilde{f}_1,(\mathbb{1}-M^{-2}\,\mathbf{d}\boldsymbol{\delta})\tilde{f}_2) \tag{A10}$$

for general $f_i\in\Omega^1_0(\mathcal{M})$. In the Maxwell case, we apply Proposition A.3(b), axiom (M3) and Eq. (A2) to obtain

$$\omega([\mathcal{A}](f_1)[\mathcal{A}](f_2))=\omega([\mathcal{A}](\tilde{f}_1)[\mathcal{A}](\tilde{f}_2))=W(\tilde{f}_1,\tilde{f}_2) \tag{A11}$$

for co-closed $f_i\in\Omega^1_0(\mathcal{M})$. The following claim will be proved below.

Proposition A.5: In the Proca case,

$$W_M((-\boldsymbol{\delta}\mathbf{d}+M^2)f,f')=W_M(f',(-\boldsymbol{\delta}\mathbf{d}+M^2)f)=0 \tag{A12}$$

for all $f,f'\in\Omega_0^1(\mathcal{M})$, *while in the Maxwell case, we have*

$$W(\boldsymbol{\delta}\mathbf{d}f,f')=W(f',\boldsymbol{\delta}\mathbf{d}f)=0 \tag{A13}$$

for all $f,f'\in\Omega_0^1(\mathcal{M})$ *with* f' *co-closed.*

In combination with the explicit form of $\tilde{f}_i-f_i$ [and, in the Proca case, the fact that $(\mathbb{1}-M^{-2}\,\mathbf{d}\boldsymbol{\delta})$ and $-\boldsymbol{\delta}\mathbf{d}+M^2$ commute], Proposition A.5 allows us to show that

$$W_M(\tilde{f}_1,(\mathbb{1}-M^{-2}\,\mathbf{d}\boldsymbol{\delta})\tilde{f}_2)=W_M(f_1,(\mathbb{1}-M^{-2}\,\mathbf{d}\boldsymbol{\delta})f_2) \tag{A14}$$

in the Proca case, and that $W(\tilde{f}_1,\tilde{f}_2)=W(f_1,f_2)$ holds for the Maxwell field. Taken together with Eqs. (A10) and (A11), respectively, these relations then establish Eqs. (A1) and (A2). □

The claim made above is proved as follows.

Proof of Proposition A.5: Fix an arbitrary $f'\in\Omega_0^1(\mathcal{N})$ (with the additional requirement that $\boldsymbol{\delta}f'=0$ in the Maxwell case). Then $W_M(\cdot,f')$ and $W_M(f',\cdot)$ [or $W(\cdot,f')$ and $W(f',\cdot)$ in the Maxwell case] obey the hypotheses of Lemma A.4(a) owing to Eq. (A1) and axiom (P3) [respectively, Eq. (A2) and axiom (M3)]. Accordingly, Eq. (A12) [respectively, Eq. (A13)] holds for all $f\in\Omega_0^1(\mathcal{M})$ and the fixed $f'\in\Omega_0^1(\mathcal{N})$. Now fix $f\in\Omega_0^1(\mathcal{M})$ arbitrarily. In the Proca case, $W_M((-\boldsymbol{\delta}\mathbf{d}+M^2)f,\cdot)$ and $W_M(\cdot,(-\boldsymbol{\delta}\mathbf{d}+M^2)f)$ are weak $(\Box+M^2)$-solutions vanishing on $\mathcal{N}$ and hence globally, as required. In the Maxwell case, $W(\boldsymbol{\delta}\mathbf{d}f,\cdot)$ and $W(\cdot,\boldsymbol{\delta}\mathbf{d}f)$ are weak $\Box$-solutions vanishing on co-closed elements of $\Omega_0^1(\mathcal{N})$. Lemma A.4(b) entails that they therefore vanish on all co-closed $f'\in\Omega_0^1(\mathcal{M})$, thereby completing the proof. □

APPENDIX B: CONSTRUCTION OF A HADAMARD $(\Box+M^2)$-BISOLUTION IN ULTRASTATIC SPACE–TIMES

In this appendix we prove Theorem IV.1 by explicitly constructing a Hadamard $(\Box+M^2)$-bisolution W_M on any ultrastatic space–time $(\mathcal{M},g)$ obeying the assumptions stated at the beginning of Sec. IV. For $M>0$, the argument proceeds as follows. First, we use functional calculus on the Hilbert space H to define W_M as a bilinear map from $\Omega_0^1(\mathcal{M})\times\Omega_0^1(\mathcal{M})$ to $\mathbb{C}$. We show that W_M is in fact a one-form bidistributional weak $(\Box+M^2)$-bisolution, with antisymmetric part $-iE_M$, and determine a crude bound on its wave-front set. Next, we appeal to the existence of a *Hadamard* $(\Box+M^2)$-bisolution $\widetilde{W}_M$, also with antisymmetric part $-iE_M$, established in Lemma 5.4(a) of Ref. 32. A simple microlocal argument is used to show that $W_M-\widetilde{W}_M$ is smooth, from which it follows that W_M is itself Hadamard. Finally, we show that W_M may be expanded in terms of any K-pseudo-orthonormal complete set of eigenvectors for the operator K as claimed in Theorem IV.1. The argument is only slightly different in the case $M=0$.

It will be convenient to regard each $\mathcal{A}\in\Omega^1(\mathcal{M})$ as a smooth one-parameter family $t\mapsto\mathcal{A}(t)$ of elements in $\mathsf{H}=\Lambda^0(\Sigma)\oplus\Lambda^1(\Sigma)$, where $\mathcal{A}(t)$ is the restriction of $\mathcal{A}$ to the constant time surface $\{t\}\times\Sigma$. The pairing $\langle\cdot,\cdot\rangle$ of one-forms on $\mathcal{M}$ is related to the inner products of H and K by

$$\langle\mathcal{A},\mathcal{B}\rangle=\int \mathrm{d}t\,\langle\!\langle\overline{\mathcal{A}(t)}|\mathcal{B}(t)\rangle\!\rangle=\int \mathrm{d}t\,(\overline{\mathcal{A}(t)},J\mathcal{B}(t))_{\mathsf{H}}, \tag{B1}$$

where $J=\mathbb{1}_{\Lambda^0(\Sigma)}\oplus-\mathbb{1}_{\Lambda^1(\Sigma)}$. We note that J and $K=(-\Delta_\Sigma^S+M^2)\oplus(-\Delta_\Sigma+M^2)$ commute.

With these conventions, the Klein–Gordon equation $(\Box+M^2)\mathcal{A}=0$ may be written as the Hilbert space ordinary differential equation,

$$-\partial_t^2\mathcal{A}(t)=K\mathcal{A}(t)\,. \tag{B2}$$

Suppose that $M>0$. Because Σ is compact, K has discrete spectrum bounded below by $M^2>0$. Accordingly, the operator $K^{-1/2}$ is well-defined and bounded, and the advanced-minus-retarded solution operator $E_M:\Omega_0^1(\mathcal{M})\to\Omega^1(\mathcal{M})$ may be written

$$(E_M\mathcal{J})(t)=\int \mathrm{d}t'\, K^{-1/2}\sin[K^{1/2}(t'-t)]\mathcal{J}(t')\,, \tag{B3}$$

thus obtaining

$$E_M(\mathcal{J},\mathcal{J}')=\langle\mathcal{J},E_M\mathcal{J}'\rangle=\int \mathrm{d}t\,\mathrm{d}t'\,(\overline{\mathcal{J}(t)},JK^{-1/2}\sin[K^{1/2}(t'-t)]\mathcal{J}'(t'))_{\mathsf{H}}\,. \tag{B4}$$

We define our candidate Hadamard $(\Box+M^2)$-bisolution W_M by taking the positive frequency part of $-iE_M$, i.e., by replacing the sine function by an exponential. To be precise, for $f,f'\in\mathcal{D}(\mathbb{R})$ and $g,g'\in\Omega^0(\Sigma)\oplus\Omega^1(\Sigma)$, we define

$$W_M(f\otimes g,f'\otimes g')=-\tfrac{1}{2}(\hat{\bar{f}}(K^{1/2})\overline{g},K^{-1/2}\hat{f}'(K^{1/2})Jg')_{\mathsf{H}}\,, \tag{B5}$$

in which operators such as $\hat{f}'(K^{1/2})$ are defined by functional calculus. Using the Cauchy–Schwarz inequality and elementary operator norm estimates, we find

$$|W_M(f\otimes g,f'\otimes g')|\leqslant\tfrac{1}{2}\|K^{-1/2}\|\,\|g\|\,\|g'\|\sup_{\omega\in\sigma(K^{1/2})}|\hat{f}(-\omega)|\sup_{\omega\in\sigma(K^{1/2})}|\hat{f}'(\omega)|\,, \tag{B6}$$

from which it follows that W_M extends to a distribution in $(\Omega_0^1(\mathcal{M})\times\Omega_0^1(\mathcal{M}))'$. It is straightforward to check that W_M is a weak $(\Box+M^2)$-bisolution, with antisymmetric part $-iE_M$.

The wave-front set of W_M may be estimated in two ways. First, because it is a $(\Box+M^2)$-bisolution, we have

$$\mathrm{WF}\,(W_M)\subseteq\mathcal{N}\times\mathcal{N}, \tag{B7}$$

where $\mathcal{N}=\{(x,k)\in T^*\mathcal{M}:g^{ab}(x)k_ak_b=0\}$ is the null bundle of $(\mathcal{M},g)$. Second, the explicit bound (B6), coupled with the observation that $\sup_{\omega\in\sigma(K^{1/2})}|\hat{f}(\lambda-\omega)|$ is bounded as $\lambda\to+\infty$, but rapidly decaying for $\lambda\to-\infty$ (and vice versa for $\sup_{\omega\in\sigma(K^{1/2})}|\hat{f}(\lambda+\omega)|$) entails that

$$\mathrm{WF}\,(W_M)\subseteq(\mathcal{T}^+\cup\mathcal{Z})\times(\mathcal{T}^-\cup\mathcal{Z}), \tag{B8}$$

where $\mathcal{T}^\pm=\{(x,k)\in T^*\mathcal{M}:\pm k_0>0\}$ and $\mathcal{Z}=\{(x,k)\in T^*\mathcal{M}:k=0\}$ is the zero section of $T^*\mathcal{M}$. Comparing these two estimates,

$$\mathrm{WF}\,(W_M)\subseteq(\mathcal{N}^+\cup\mathcal{Z})\times(\mathcal{N}^-\cup\mathcal{Z}), \tag{B9}$$

where $\mathcal{N}^\pm=\mathcal{N}\cap\mathcal{T}^\pm$ are the future $(+)$ and past $(-)$ null bundles.

We now appeal to the existence of a Hadamard form $(\Box+M^2)$-bisolution $\tilde{W}_M$ on $(\mathcal{M},g)$ with antisymmetric part $-iE_M$ [Lemma 5.4(a) of Ref. 32]. Since the wave-front set of $\tilde{W}_M$ also obeys (B9), we have

$$\mathrm{WF}\,(W_M-\tilde{W}_M)\subseteq(\mathcal{N}^+\cup\mathcal{Z})\times(\mathcal{N}^-\cup\mathcal{Z})\,. \tag{B10}$$

But $W_M-\tilde{W}_M$ is symmetric, so we also have

$$\mathrm{WF}\,(W_M-\tilde{W}_M)\subseteq(\mathcal{N}^-\cup\mathcal{Z})\times(\mathcal{N}^+\cup\mathcal{Z})\,. \tag{B11}$$

Comparing these two bounds, we see that $\mathrm{WF}(W_M-\widetilde{W}_M)\subseteq\mathcal{Z}\times\mathcal{Z}$ and, since the wave-front set excludes the zero section, we conclude that this wave-front set is in fact empty. Accordingly, $W_M=\widetilde{W}_M \pmod{C^\infty}$ so W_M is of Hadamard form.

The analysis of the massless case is complicated by the existence of a zero eigenvalue mode $\varphi_0=(1,0)$ for K. [Triviality of $H_1(\Sigma)$ precludes the existence of any harmonic one-forms on Σ, so φ_0 is the unique zero mode.] However, the spectrum of K is otherwise bounded away from zero, so $K^{-1/2}$ is well-defined and bounded on $P\mathsf{H}$, where P is the orthogonal projector onto the orthogonal complement of φ_0. In this case, we define

$$W(f\otimes g,f'\otimes g')=-\tfrac{1}{2}(\hat{\bar{f}}(K^{1/2})P\bar{g},K^{-1/2}\hat{f}'(K^{1/2})PJg')_{\mathsf{H}}. \tag{B12}$$

It is easy to check that W is a bi-distributional $\Box$-bisolution, whose antisymmetric part is

$$W(\mathcal{J},\mathcal{J}')-W(\mathcal{J}',\mathcal{J})=-iE_0(\mathcal{J},\mathcal{J}')+i\int \mathrm{d}t\,\mathrm{d}t'\,(t'-t)\,(\overline{\mathcal{J}(t)},\varphi_0)_{\mathsf{H}}(\varphi_0,J\mathcal{J}'(t'))_{\mathsf{H}} \tag{B13}$$

and is therefore equal $(\mathrm{mod}\,C^\infty)$ to $-iE_0$. Appealing as before to the existence of a Hadamard $\Box$-bisolution $\widetilde{W}$ with antisymmetric part $-iE_0$, the argument used above shows that $W=\widetilde{W}$ $(\mathrm{mod}\,C^\infty)$ because $W-\widetilde{W}$ is symmetric $(\mathrm{mod}\,C^\infty)$. It remains to show that the last term in Eq. (B13) vanishes if $\mathcal{J}$ and $\mathcal{J}'$ are both co-closed, as required for consistency with the commutator axiom (M4). Using Eq. (B1) and the fact that $J\varphi_0=\varphi_0$, one may show that the term in question is proportional to $\langle\overline{\mathcal{J}},\mathbf{d}t\rangle\langle t\mathbf{d}t,\mathcal{J}'\rangle-\langle\overline{\mathcal{J}},t\mathbf{d}t\rangle\langle\mathbf{d}t,\mathcal{J}'\rangle$, which vanishes because $\langle\overline{\mathcal{J}},\mathbf{d}t\rangle=\langle\overline{\boldsymbol{\delta}\mathcal{J}},t\rangle=0$ and similarly $\langle\mathbf{d}t,\mathcal{J}'\rangle=0$.

Finally, let ξ_j be a complete set of K-pseudo-orthonormal K-eigenfunctions, with corresponding eigenvalues ω_λ^2 $(\omega_\lambda\geqslant 0)$. Using the completeness relation Eq. (43), we see that

$$\hat{f}'(K^{1/2})^*K^{-1/2}\hat{\bar{f}}(K^{1/2})P\bar{g}=\sum_{j:\omega_j\neq 0}\xi_j\omega_j^{-1}\overline{\hat{f}'(\omega_j)}\hat{\bar{f}}(\omega_j)\langle\!\langle\xi_j|\xi_j\rangle\!\rangle\langle\!\langle\xi_j|\bar{g}\rangle\!\rangle \tag{B14}$$

and hence

$$\begin{aligned}W(\mathcal{J},\mathcal{J}')&=-\sum_{j:\omega_j\neq 0}\frac{1}{2\omega_j}\langle\!\langle\xi_j|\xi_j\rangle\!\rangle\langle\!\langle\hat{\bar{f}}(\omega_j)\bar{g}|\xi_j\rangle\!\rangle\langle\!\langle\xi_j|\hat{f}'(\omega_j)g'\rangle\!\rangle\\&=-\sum_{j:\omega_j\neq 0}\frac{1}{2\omega_j}\langle\!\langle\xi_j|\xi_j\rangle\!\rangle\langle\mathcal{A}_j,\mathcal{J}\rangle\langle\overline{\mathcal{A}_j},\mathcal{J}'\rangle,\end{aligned} \tag{B15}$$

where we have defined the modes $\mathcal{A}_j$ by $\mathcal{A}_j(t)=e^{-i\omega_j t}\xi_\lambda$ and used

$$\langle\!\langle\xi_j|\hat{f}'(\omega_j)g'\rangle\!\rangle=\int \mathrm{d}t\,e^{i\omega_j t}\langle\!\langle\xi_j|f'(t)g'\rangle\!\rangle=\int \mathrm{d}t\,\langle\!\langle\mathcal{A}_j(t)|\mathcal{J}'(t)\rangle\!\rangle=\langle\overline{\mathcal{A}_j},\mathcal{J}'\rangle \tag{B16}$$

and $\langle\!\langle\hat{\bar{f}}(\omega_j)\bar{g}|\xi_j\rangle\!\rangle=\langle\mathcal{J},\mathcal{A}_j\rangle=\langle\mathcal{A}_j,\mathcal{J}\rangle$.

In the case $M>0$, exactly analogous arguments show that the $W_M(\mathcal{J},\mathcal{J}')$ may also be written in the form of the right-hand side of Eq. (B15) (the restriction to $\omega_j>0$ is inessential as all modes obey this condition). This completes the proof of Theorem IV. 1.

ACKNOWLEDGMENTS

Part of this work was conducted at the Erwin Schrödinger Institute for Mathematical Physics, Vienna, during the program on Quantum Field Theory in Curved Space–time. We are grateful to the organisers of this program and to the Institute for its hospitality and financial support. We also thank Atsushi Higuchi, Wolfgang Junker, Fernando Lledó, Ian McIntosh, and Rainer Verch for many illuminating discussions. This work was partially supported by EPSRC Grant No. GR/

R25019/01 to the University of York. M.J.P. also thanks the University of York for a grant awarded under its ''Research Funding for Staff on Fixed Term Contracts'' scheme.

[68] R. Adams, *Sobolev Spaces* (Academic, New York, 1975).
[69] We also observe that their work is directed towards a construction of Hadamard states in general globally hyperbolic space–times which avoids the use of deformation arguments.
[70] Some care is needed over the definition of the two-point function in the Maxwell case (see Sec. III). In particular, it is not a distribution.
[71] The *support* of a function is the closure of the set of points on which it is nonzero.
[72] The index is the number of spacelike (i.e., negative norm-squared) basis vectors in any g-orthonormal frame.
[73] The topology is defined so that a sequence $\mathcal{U}_n \to 0$ in $\Omega_0^p(\mathcal{N})$ if and only if $*(\mathcal{V}LU*\mathcal{U}_n) \to 0$ in $\mathcal{D}(\mathcal{N})$ for every $\mathcal{V} \in \Omega^p(\mathcal{N})$.
[74] Since Σ is compact, it admits a finite good cover (Theorem 5.1 in Ref. 66) which determines a finite good cover of $\mathcal{M}=\mathbb{R}\times\Sigma$. Accordingly, we may use Poincaré duality (Theorem 5.4 in Ref. 66) to prove that $H_c^3(\mathcal{M})$ is isomorphic to $H^1(\mathcal{M})$ and hence to $H^1(\Sigma)$ (see the remarks following Corollary 5.1.1 in Ref. 66). This is isomorphic to $H_1(\Sigma)$ by de Rahm's theorem (Ref. 67).
[75] Note that Dimock (Ref. 36) uses E for the retarded-minus-advanced bisolution.
[76] For example, $\mathfrak{A}_M(\mathcal{M},g)$ is the infinitesimal Weyl algebra over the real symplectic space $\Omega_0^1(\mathcal{M};\mathbb{R})/\ker \Delta_M$ (with the quotient topology) with the addition of the $*$-operation. This has no nontrivial two-sided $*$-ideals (see Sec. 7.1 in Ref. 46).
[77] Effectively, one is substituting the test function $f(x)=\int \mathrm{d}\tau |h(x)|^{-1/2}\delta^4(x-\gamma(\tau))\overline{g_\alpha(\tau)}$ in Eq. (76). This results in the required expression.
[78] The right-hand side of the bound may be written in the form $-\int_0^\infty \mathrm{d}u\, Q(u)|\hat{g}(u)|^2$, where $Q(u)$ is a polynomially bounded function. Accordingly, the integral will converge provided that the Fourier transform $\hat{g}(u)$ decays sufficiently rapidly as $u\to+\infty$; equivalently, provided that g belongs to a Sobolev space $W^{k,2}(\mathbb{R})$ (see e.g., Ref. 68) of sufficiently high regularity (k sufficiently large). If we restrict the class of states so that $\langle :\rho: \rangle_\omega(\tau)$ belongs to the dual Sobolev space $W^{-k,2}(\mathbb{R})$ then Eq. (139) will continue to hold. To see this, we approximate g in the $W^{k,2}(\mathbb{R})$ norm by a sequence of compactly supported smooth functions [using density of $C_0^\infty(\mathbb{R})$ in $W^{k,2}(\mathbb{R})$] and apply Eq. (139). It is not presently known whether this requires a nontrivial restriction on the class of allowed states.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 10 OCTOBER 2003

A direct derivation of polynomial invariants from perturbative Chern–Simons gauge theory

Tomoshiro Ochiai[a)]
Graduate School of Mathematical Sciences, The University of Tokyo, Tokyo 153-8914, Japan

(Received 22 April 2003; accepted 1 June 2003)

There have been several methods to show that the expectation values of Wilson loop operators in the SU(N) Chern–Simons gauge theory satisfy the HOMFLY skein relation. We shall give another method from the perturbative method of the SU(N) Chern–Simons gauge theory in the light-cone gauge, which is more direct than already known methods. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1606525]

I. INTRODUCTION

The connection between the three-dimensional Chern–Simons gauge theory and knot theory was established by E. Witten, who showed that the expectation value of Wilson loop operators in the Chern–Simons gauge theory satisfies the HOMFLY skein relation,[10] using certain conformal field theories [see Fig. 1(a)]. Since then the Chern–Simons gauge theory has been studied from a variety of points of view. J. Frohlich and C. King[3] derived the Knizhnik–Zamolodchikov equations from the Chern-Simons gauge theory in the light-cone gauge [Fig. 1, (b_1)]. The solution of this differential equation was shown to be simply related to the HOMFLY skein relation for links [Fig. 1, (b_2)]. On the other hand, J. M. F. Labastida and E. Perez[6] derived the Kontsevich integral from the perturbative analysis of the Chern–Simons gauge theory in the light-cone gauge [Fig. 1(c)]. It is known that the combination of the Kontsevich integral and the weight system of $\mathfrak{su}(N)$ satisfies the HOMFLY skein relation[7,9] [Fig. 1(d)]. We remark that the Kontsevich integral is derived from the Knizhnik–Zamolodchikov equations, using an iterated integral[5] [Fig. 1(e)]. These relations among the three-dimensional Chern–Simons gauge theory, the HOMFLY skein relation, the Knizhnik–Zamolodchikov equations and the Kontsevich integral imply the deep structure of the Chern–Simons gauge theory.

But these already known methods need rather complicated concepts. Therefore, we would like to give a more straightforward and simpler approach. In this article, inspired by the two methods[6,9] [Figs. 1(c) and 1(d)], we give another such method to derive the HOMFLY skein relation from the Chern–Simons gauge theory [Fig. 1(f)] without using any other theory.

We remark that in Refs. 2 and 4 the skein relation was derived at first order in the coupling constant, using a variational method based on the properties of the path integral.

II. THE FORMULATION OF THE CHERN–SIMONS GAUGE THEORY

In this section, we review the Chern–Simons gauge theory as in Refs. 2, 3, 6, and 8.

The Chern–Simons gauge theory is a three dimensional model based on the Lagrangian L which is a differential three-form defined on $\mathbf{R}^3$ parametrized by (x^0,x^1,x^2):

$$L(A)=tr(A\wedge dA+i\ \tfrac{2}{3}A\wedge A\wedge A),$$

where a connection A is $\mathfrak{su}(N)$-valued one form on $\mathbf{R}^3$, and "tr" means the trace.

The generators of $\mathfrak{su}(N)$ are normalized as follows:

a)Electronic mail: ochiaito@ms.u-tokyo.ac.jp

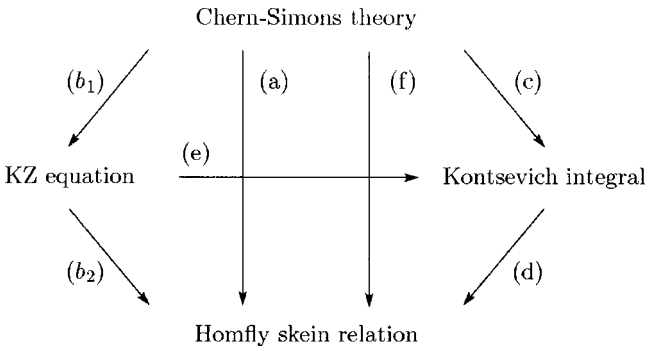

FIG. 1. Illustration of introduction.

$$tr(T_aT_b)=\tfrac{1}{2}\delta_{ab},\ [T_a,T_b]=if^c_{ab}T_c,$$

with the structure constants f^c_{ab}. The action of the Chern–Simons gauge theory is given by

$$S_k(A)=\frac{k}{4\pi}\int_{\mathbf{R}^3}L(A)=\frac{k}{4\pi}\int_{\mathbf{R}^3}dx^0\wedge dx^1\wedge dx^2\epsilon^{\mu\nu\rho}tr\left(A_\mu\partial_\nu A_\rho+i\frac{2}{3}A_\mu A_\nu A_\rho\right)$$
$$=\frac{k}{8\pi}\int_{\mathbf{R}^3}dx^3\epsilon^{\mu\nu\rho}\left(A^a_\mu\partial_\nu A^a_\rho-\frac{1}{3}A^a_\mu A^b_\nu A^c_\rho f^c_{ab}\right),\tag{2.1}$$

where k is a real parameter and

$$A=A_\mu dx^\mu=A^a_\mu T_a dx^\mu.$$

Let us introduce so-called ''Wilson loop operators.'' Let C be a curve parametrized by $\vec{x}(t)$. Define the holonomy of A along a curve C by

$$H_C(A)=P\exp i\oint_C A,\tag{2.2}$$

where the right-hand side of (2.2) means

$$1+\sum_{m=1}^{\infty}i^m\int_{t_{\min}<t_1<\cdots<t_m<t_{\max}}dt_1\cdots dt_m\ \dot{x}^{\mu_m}(t_m)A_{\mu_m}(x(t_m))\cdots\dot{x}^{\mu_1}(t_1)A_{\mu_1}(x(t_1)).$$

The holonomy $H_C(A)$ has the important property as follows. If a curve $C=\{\vec{x}(t)|t_{\min}\leqslant t\leqslant t_{\max}\}$ is divided into n-curves $C_k=\{\vec{x}(s)\ |s_{k-1}\leqslant s\leqslant s_k\}$ $(t_{\min}=s_0<s_1<\cdots<s_n=t_{\max})$, then the holonomy $H_C(A)$ is decomposed as follows:

$$H_C(A)=H_{C_n}(A)\ \cdots\ H_{C_1}(A).\tag{2.3}$$

Let K be a knot (i.e., a closed curve) in $\mathbf{R}^3$. The Wilson loop operator $W_K(A)$ is a special type of functional of connection A defined by

$$W_K(A)=tr(H_K(A)).$$

We extend the above definition to a link. Let $L=\{K_1,\ldots,K_m\}$ be an m-component link which is a union of m knots $K_i(i=1,\ldots,m)$. Then, the definition of the Wilson loop operator can be extended to a link L as follows:

$$W_L(A)=W_{K_1}(A)\cdots W_{K_m}(A). \tag{2.4}$$

We will define the expectation value of the Chern–Simons gauge theory as follows. The expectation value of $W_L(A)$ is defined by

$$\langle W_L\rangle=\frac{1}{Z}\int [DA]e^{iS_k(A)}\ \ W_L(A), \tag{2.5}$$

where

$$Z=\int [DA]e^{iS_k(A)} \tag{2.6}$$

and the symbol $[DA]$ denotes the path integral over all equivalence classes of connections modulo gauge transformations.

It is convenient to introduce new coordinates,

$$z=x^1+ix^2,\ \ \overline{z}=x^1-ix^2,\ \ t=x^0, \tag{2.7}$$

and define also

$$\partial=\frac{1}{2}\left(\frac{\partial}{\partial x_1}-i\frac{\partial}{\partial x_2}\right),\ \ \overline{\partial}=\frac{1}{2}\left(\frac{\partial}{\partial x_1}+i\frac{\partial}{\partial x_2}\right). \tag{2.8}$$

For a connection $A=A_\mu\, dx^\mu$, set

$$A_z=\tfrac{1}{2}(A_1+A_2),\ \ A_{\overline{z}}=\tfrac{1}{2}(A_1-A_2). \tag{2.9}$$

In order to evaluate expectation value (2.5), it is necessary to fix a gauge condition. We introduce the light-cone gauge condition as in Refs. 3 and 6. The light-cone gauge condition is defined by

$$A_{\overline{z}}=\tfrac{1}{2}(A_1-A_2)=0. \tag{2.10}$$

This gauge condition is preferable, since it kills the second term on the right-hand side of (2.1) and greatly simplifies the theory.

Using these new coordinates (2.7)–(2.9) and the light-cone gauge condition (2.10), the action of the Chern–Simons gauge theory (2.1) is transformed into

$$S_k(A)=\frac{k}{4\pi}\int dtd\overline{z}dz\,\frac{1}{2}(A_0^a\overline{\partial}A_z^a-A_z^a\overline{\partial}A_0^a). \tag{2.11}$$

We remark that the above equation is a quadratic form.

Under these conditions, the two-point correlation functions are computed in Refs. 3 and 6. For fixed $\mathbf{x}=(t,z,\overline{z})$, $\mathbf{x}'=(t',z',\overline{z}')$, we can consider $A_0^a(\mathbf{x})A_z^b(\mathbf{x}')$, $A_0^a(\mathbf{x})A_0^b(\mathbf{x}')$ and $A_z^a(\mathbf{x})A_z^b(\mathbf{x}')$ as functionals of A. From the Appendix, their expectation values are given by

$$\langle A_0^a(\mathbf{x})A_z^b(\mathbf{x}')\rangle=-\delta^{ab}\frac{2}{k}\frac{\delta(t-t')}{z-z'}, \tag{2.12}$$

$$\langle A_0^a(\mathbf{x})A_0^b(\mathbf{x}')\rangle=0, \tag{2.13}$$

$$\langle A_z^a(\mathbf{x})A_z^b(\mathbf{x}')\rangle=0. \tag{2.14}$$

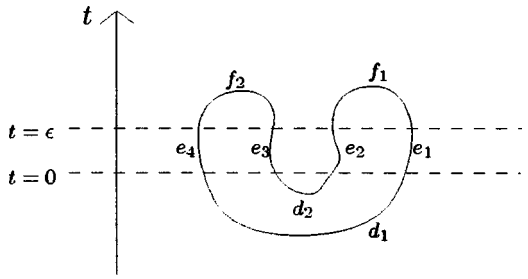

FIG. 2. Division of a knot K.

Under these preparations, we will show that the expectation value of the Wilson loop operator satisfies the HOMFLY skein relation by a direct computation. The main idea of the computation is as follows. First, we decompose $\mathbf{R}^3$ into the three domains $\{t\leqslant 0\}$, $\{0\leqslant t\leqslant \epsilon\}$, $\{\epsilon\leqslant t\}$ called the lower domain, the middle domain and the upper domain, respectively. We will show that the expectation value of the Wilson loop operator is essentially the product of three expectation values corresponding to these three domains. By applying the perturbative method to the expectation value corresponding to the middle domain, we can derive the HOMFLY polynomial.

III. DIVISION OF THE EXPECTATION VALUE OF THE WILSON LOOP OPERATOR

In this section, we divide the expectation value of the Wilson loop operator into three parts. We assume that a knot K is in a special position as follows. We divide a knot K into $4n$ curves

$$C_\alpha=\{\vec{x}(s)\,|\,s_{\alpha-1}\leqslant s\leqslant s_\alpha\},\quad 0=s_0<s_1<\cdots<s_{4n}=1,$$

and set

$$\begin{aligned} d_\alpha &= C_{4\alpha-3}\quad(\alpha=1,2,3,\ldots,n),\\ e_\beta &= C_{2\beta}\quad(\beta=1,2,3,\ldots,2n),\\ f_\alpha &= C_{4\alpha-1}\quad(\alpha=1,2,3,\ldots,n). \end{aligned} \tag{3.1}$$

Moreover, it is assumed that the curves d_α, e_β and f_α are in the region $t\leqslant 0$, $0\leqslant t\leqslant\epsilon$, $\epsilon\leqslant t$, respectively. (See Fig. 2)

Define holonomies $D_K^\alpha(A)$, $E_K^\beta(A)$ and $F_K^\alpha(A)$ for the curves d_α, e_β and f_α by

$$\begin{aligned} D_K^\alpha(A) &= P\exp i\int_{d_\alpha} A,\\ E_K^\beta(A) &= P\exp i\int_{e_\beta} A,\\ F_K^\alpha(A) &= P\exp i\int_{f_\alpha} A. \end{aligned} \tag{3.2}$$

From (2.3), the Wilson loop operator $W_K(A)$ can be expressed as the trace over the product of the matrices D_K^α, E_K^β, and F_K^α $(1\leqslant\alpha\leqslant n,\ 1\leqslant\beta\leqslant 2n)$ as follows:

$$W_K = tr\left(\prod_{\alpha=1}^{4n} H_{C_\alpha}\right) = tr\left(\prod_{\alpha=1}^{n} E_K^{2\alpha} F_K^{\alpha} E_K^{2\alpha-1} D_K^{\alpha}\right)$$

$$= \sum_{i_1\cdots i_{2n}} \sum_{j_1\cdots j_{2n}} \prod_{\alpha=1}^{n} (E_K^{2\alpha})_{j_{2\alpha}}^{i_{2\alpha}} (F_K^{\alpha})_{j_{2\alpha-1}}^{j_{2\alpha}} (E_K^{2\alpha-1})_{i_{2\alpha-1}}^{j_{2\alpha-1}} (D_K^{\alpha})_{i_{2\alpha-2}}^{i_{2\alpha-1}}$$

$$= \sum_{i_1\cdots i_{2n}} \sum_{j_1\cdots j_{2n}} (F_K)_{j_{2n},\cdots,j_1} (E_K)_{i_{2n}\cdots i_1}^{j_{2n}\cdots j_1} (D_K)^{i_{2n}\cdots i_1},$$

where we set $i_{2n}=i_0$ and D_K, E_K and F_K in the last line are defined by

$$(D_K)^{i_{2n}\cdots i_1} = \prod_{\alpha=1}^{n} (D_K^{\alpha})_{i_{2\alpha-2}}^{i_{2\alpha-1}},$$

$$(E_K)_{i_{2n}\cdots i_1}^{j_{2n}\cdots j_1} = \prod_{\alpha=1}^{n} (E_K^{2\alpha})_{j_{2\alpha}}^{i_{2\alpha}} (E_K^{2\alpha-1})_{i_{2\alpha-1}}^{j_{2\alpha-1}},$$

$$(F_K)_{j_{2n},\cdots,j_1} = \prod_{\alpha=1}^{n} (F_K^{\alpha})_{j_{2\alpha-1}}^{j_{2\alpha}}.$$

As a result, we obtain the following lemma.

Lemma 3.1: The Wilson loop operator $W_K(A)$ is decomposed as follows:

$$W_K = F_K \;\; E_K \;\; D_K, \tag{3.3}$$

where the right-hand side of (3.3) means

$$F_K \;\; E_K \;\; D_K = \sum_{i_1\cdots i_{2n}} \sum_{j_1\cdots j_{2n}} (F_K)_{j_{2n},\cdots,j_1} (E_K)_{i_{2n}\cdots i_1}^{j_{2n}\cdots j_1} (D_K)^{i_{2n}\cdots i_1}.$$

Remark: Note that the curves in D_K, E_K, and F_K are in the region $t\leqslant 0$, $0\leqslant t\leqslant \epsilon$, $\epsilon\leqslant t$, respectively.

For a link, we extend the above lemma as follows.

Lemma 3.2: Let $L=\{K_1,\ldots,K_m\}$ be an m-component link. The Wilson loop operator for L is decomposed as follows:

$$W_L = F_L \;\; E_L \;\; D_L, \tag{3.4}$$

where D_L, E_L, and F_L on the right-hand side are defined by

$$D_L = D_{K_1}\cdots D_{K_m},$$

$$E_L = E_{K_1}\cdots E_{K_m},$$

$$F_L = F_{K_1}\cdots F_{K_m}.$$

Proof: From Lemma 3.1, we decompose each Wilson loop operator W_{K_α} $(\alpha=1,2,\ldots,m)$ as follows:

$$W_{K_j} = F_{K_j} \;\; E_{K_j} \;\; D_{K_j} \;\; (j=1,2,\ldots,m).$$

Inserting this into (2.4), we obtain

$$W_L = F_{K_1} \cdots F_{K_m} E_{K_1} \cdots E_{K_m} D_{K_1} \cdots D_{K_m}.$$

This shows (3.4). □

We divide the expectation value of the Wilson loop operator into three parts in the same manner as the Wilson loop operator.

Lemma 3.3: The expectation value of Wilson loop operator for a knot is decomposed as follows:

$$\langle W_K \rangle = \langle F_K \rangle_F \langle E_K \rangle_E \langle D_K \rangle_D, \tag{3.5}$$

where the right-hand side of (3.5) means

$$\langle F_K \rangle_F \langle E_K \rangle_E \langle D_K \rangle_D = \sum_{i_1 \cdots i_{2n}} \sum_{j_1 \cdots j_{2n}} \langle (F_K)_{j_{2n}, \cdots, j_1} \rangle_F \langle (E_K)^{j_{2n} \cdots j_1}_{i_{2n} \cdots i_1} \rangle_E \langle (D_K)^{i_{2n} \cdots i_1} \rangle_D$$

and

$$\langle (D_K)^{i_{2n} \cdots i_1} \rangle_D = \frac{1}{Z_D} \int [DA]_D \exp\left(\frac{ik}{4\pi} \int_{\{-\infty \leqslant t \leqslant 0\}} \right\} L(A) \ \ (D_K(A))^{i_{2n} \cdots i_1},$$

$$\langle (E_K)^{j_{2n} \cdots j_1}_{i_{2n} \cdots i_1} \rangle_E = \frac{1}{Z_E} \int [DA]_E \exp\left(\frac{ik}{4\pi} \int_{\{0 \leqslant t \leqslant \epsilon\}} L(A) \right) (E_K(A))^{j_{2n} \cdots j_1}_{i_{2n} \cdots i_1},$$

$$\langle (F_K)_{j_{2n}, \cdots, j_1} \rangle_F = \frac{1}{Z_F} \int [DA]_F \exp\left(\frac{ik}{4\pi} \int_{\{\epsilon \leqslant t \leqslant \infty\}} L(A) \right) \ \ (F_K(A))_{j_{2n}, \cdots, j_1},$$

where $[DA]_D$, $[DA]_E$ and $[DA]_F$ mean the measure restricted to the region $t \leqslant 0$, $0 \leqslant t \leqslant \epsilon$ and $\epsilon \leqslant t$, respectively. Here, Z_D, Z_E and Z_F are defined as in (2.6), but the regions of the measure and the action are restricted to $t \leqslant 0$, $0 \leqslant t \leqslant \epsilon$ and $\epsilon \leqslant t$, respectively.

Proof: We divide the domain of integration of action (2.1) into three parts:

$$S_k(A) = \frac{k}{4\pi} \int_{\{\infty \leqslant t \leqslant 0\}} L(A) + \frac{k}{4\pi} \int_{\{0 \leqslant t \leqslant \epsilon\}} L(A) + \frac{k}{4\pi} \int_{\{\epsilon \leqslant t \leqslant \infty\}} L(A). \tag{3.6}$$

Next, since the measure of the path integral has the property

$$[DA] = [DA]_F [DA]_E [DA]_D, \tag{3.7}$$

inserting (3.6), (3.7) and (3.4) into (2.5) yields (3.5). □

More generally, Lemma 3.3 can be easily extended for a link L as follows:

Lemma 3.4: $\langle W_L \rangle = \langle F_L \rangle_F \ \langle E_L \rangle_E \ \langle D_L \rangle_D$.

IV. THE MAIN PART OF COMPUTATION

Let L_+, L_- and L_0 be general multi-component links as shown in Fig. 3 which are identical with each other outside the region $0 \leqslant t \leqslant \epsilon$. Especially, we write K_+, K_- and K_0 instead of L_+, L_- and L_0, if L_+, L_- and L_0 are a one-component knot, a one-component knot, and a two-component link, respectively.

From Lemma 3.4, we decompose the expectation value of Wilson loop operators as follows:

$$\langle W_{L_+} \rangle = \langle F_{L_+} \rangle_F \langle E_{L_+} \rangle_E \langle D_{L_+} \rangle_D, \tag{4.1}$$

$$\langle W_{L_-} \rangle = \langle F_{L_-} \rangle_F \langle E_{L_-} \rangle_E \langle D_{L_-} \rangle_D, \tag{4.2}$$

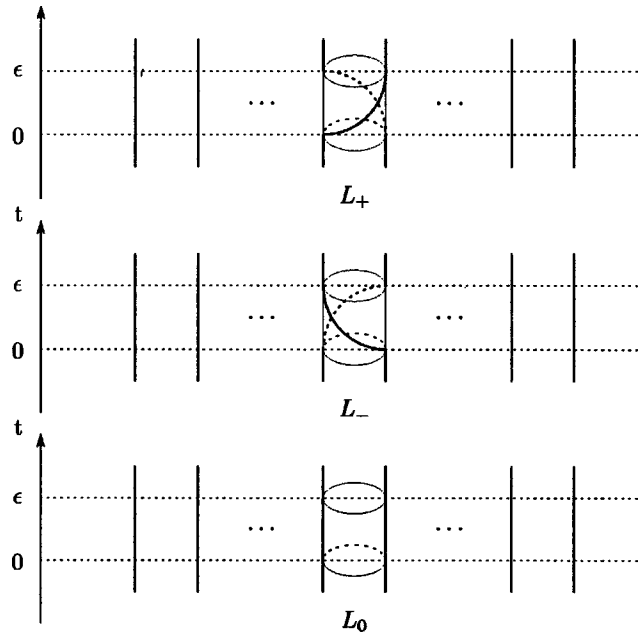

FIG. 3. L_+, L_-, L_0.

$$\langle W_{L_0}\rangle = \langle F_{L_0}\rangle_F \langle E_{L_0}\rangle_E \langle D_{L_0}\rangle_D . \tag{4.3}$$

We will concentrate our attention on the computation of $\langle E_{L_\rho}\rangle_L$ $(\rho = 0, \pm)$, since $\langle D_{L_\rho}\rangle_D$ and $\langle F_{L_\rho}\rangle_F$ take the same value for $\rho = 0, \pm$. But, avoiding unnecessary complexity, we will limit our situation to the case $L_\rho = K_\rho$ $(\rho = 0, \pm)$. Then, decompositions (4.1)–(4.3) become

$$\langle W_{K_+}\rangle = \langle F_{K_+}\rangle_F \langle E_{K_+}\rangle_E \langle D_{K_+}\rangle_D ,$$

$$\langle W_{K_-}\rangle = \langle F_{K_-}\rangle_F \langle E_{K_-}\rangle_E \langle D_{K_-}\rangle_D ,$$

$$\langle W_{K_0}\rangle = \langle F_{K_0}\rangle_F \langle E_{K_0}\rangle_E \langle D_{K_0}\rangle_D .$$

In what follows, we will be mainly concerned with the computation of $\langle E_{K_+}\rangle_E$. Without loss of generality, we may assume that the curves $e_1, e_2, \ldots, e_{2n}$ in K_+ are given as follows. Two curves $e_1(t)$ and $e_3(t)$ are given by

$$e_\alpha(t) = (t, z_\alpha(t)), \qquad \alpha = 1,3 \qquad 0 \leqslant t \leqslant \epsilon,$$

where

$$z_1(t) = -a \exp\left(\frac{i\pi t}{\epsilon}\right), \qquad z_3(t) = a \exp\left(\frac{i\pi t}{\epsilon}\right). \tag{4.4}$$

Here we remark that we have chosen $e_1(t)$ and $e_3(t)$ instead of $e_1(t)$ and $e_2(t)$, since $e_1(t)$ and $e_3(t)$ are upward while $e_2(t)$ is downward [see (3.1)].

The other curves $e_2, e_4, \ldots, e_{2n}$ are straight lines parallel to t-axis

$$e_\alpha(t) = (t, z_\alpha), \qquad \alpha = 2,4,\ldots,2n,$$

where z_α $(\alpha = 2,4,\ldots,2n)$ are fixed points and distinct from each other.

Under these assumptions, we will compute $\langle E_{K_+}\rangle_E$ using the perturbative method.
In new coordinates (2.7) and (2.9), holonomy (3.2) takes the form

$$E^{\alpha}_{K_+}(A)=P\exp i\int_{e_\alpha}A=1+\sum_{m=1}^{\infty}i^m\int_{0<t_1<\cdots<t_m<\epsilon}dt_1\cdots dt_m\quad\prod_{k=1}^{m}(A_0^{a_k}(t_k,z_\alpha(t_k))$$
$$+\dot z_\alpha(t_k)A_z^{a_k}(t_k,z_\alpha(t_k)))\times T^{a_1}\cdots T^{a_m}. \tag{4.5}$$

Let us consider the integrands of (4.5) in the next lemma.
Lemma 4.1:

$$\langle(A_0^a(t,z_\alpha(t))+\dot z_\alpha(t)A_z^a(t,z_\alpha(t)))(A_0^b(s,z_\beta(s))+\dot z_\beta(s)A_z^b(s,z_\beta(s)))\rangle_E$$
$$=\delta^{ab}\quad\delta(t-s)\frac{2}{k}\frac{d}{dt}\log(z_\alpha(t)-z_\beta(t)). \tag{4.6}$$

Proof: The left-hand side of (4.6) is equal to

$$-(\dot z_\alpha(t)-\dot z_\beta(s))\langle A_0^a(t,z_\alpha(t))A_z^b(s,z_\beta(s))\rangle_E\,.$$

Inserting (2.12) into this, we have the right-hand side of (4.6). Here we remark that (2.12) is still valid for $\langle\cdot\rangle_E$, since the argument for deriving (2.12) is independent of the domain of t. See the Appendix. □

Lemma 4.2: For sufficiently small a, $\langle E_{K_+}\rangle_E$ is transformed into the following simple form:

$$\langle(E_{K_+})^{j_{2n}\cdots j_1}_{i_{2n}\cdots i_1}\rangle_E=\delta^{j_{2n}}_{i_{2n}}\cdots\delta^{j_4}_{i_4}\delta^{j_2}_{i_2}\langle(E^3_{K_+}\otimes E^1_{K_+})^{j_3j_1}_{i_3i_1}\rangle_E, \tag{4.7}$$

where

$$(E^3_{K_+}\otimes E^1_{K_+})^{j_3j_1}_{i_3i_1}=(E^3_{K_+})^{j_3}_{i_3}(E^1_{K_+})^{j_1}_{i_1}.$$

Proof: Using (A6) in the Appendix, we can express the left-hand side of (4.7) as the sum of the products of the elements

$$\langle(A_0^a(t,z_\alpha(t))+\dot z_\alpha(t)A_z^a(t,z_\alpha(t)))(A_0^b(s,z_\beta(s))+\dot z_\beta(s)A_z^b(s,z_\beta(s)))\rangle_E\,. \tag{4.8}$$

If a is sufficiently small, for all the combination $(\alpha,\beta)\neq(1,3),(3,1)$, we may consider $z_\alpha(t)$ and $z_\beta(s)$ to be constant. Then, from Lemma 4.1, we find that these elements (4.8) vanish. Hence it is enough to consider the combination $(\alpha,\beta)=(1,3),(3,1)$ only. We can see that this combination directly gives the nontrivial factor $\langle(E^3_{K_+}\otimes E^1_{K_+})^{j_3j_1}_{i_3i_1}\rangle_E$ in (4.7). This completes the proof. □

Next, let us evaluate the nontrivial element $\langle(E^3_{K_+}\otimes E^1_{K_+})^{j_3j_1}_{i_3i_1}\rangle_E$ on the right-hand side of (4.7).

Lemma 4.3: The nontrivial element on the right-hand side of (4.7) is computed as follows:

$$\langle(E^3_{K_+}\otimes E^1_{K_+})^{j_3j_1}_{i_3i_1}\rangle_E=(\exp(\sigma\quad T^a\otimes T^a))^{j_3j_1}_{i_3i_1}, \tag{4.9}$$

where $(\sigma=-2\pi i/k)$.

Proof: Inserting (4.5) into the left-hand side of (4.9) and using Lemma 4.1, we obtain

$$\langle E^3_{K_+}\otimes E^1_{K_+}\rangle_E=1+\sum_{m=1}^{\infty}\left(-\frac{2}{k}T^a\otimes T^a\right)^m\int_{0<t_1<\cdots<t_m<1}\prod_{k=1}^{m}(d\log(z_3(t_k)-z_1(t_k))). \tag{4.10}$$

Here we have used the fact that (4.6) vanishes if $t\neq s$.

Inserting (4.4) into the second term on the right-hand side of (4.10), we have

$$\int_{0<t_1<\cdots<t_m<1}\prod_{k=1}^{m}(d\log(z_3(t_k)-z_1(t_k)))=\frac{1}{m!}(i\pi)^m.$$

Inserting this into the right-hand of (4.10) and summarizing it as an exponential function, we obtain

$$\langle E^3_{K_+}\otimes E^1_{K_+}\rangle_E=\exp(\sigma\ \ T^a\otimes T^a).$$

□

Let $V=\mathbf{R}^n$ be the N-dimensional vector space. Define $P:V\otimes V\to V\otimes V$ by

$$P(v\otimes w)=w\otimes v,$$

where v and w are N-dimensional vectors.

Lemma 4.4:

$$\exp\left(\frac{\sigma}{2N}\right)\langle E^3_{K_+}\otimes E^1_{K_+}\rangle_E-\exp\left(-\frac{\sigma}{2N}\right)\langle E^3_{K_-}\otimes E^1_{K_-}\rangle_E=\left(\exp\left(\frac{\sigma}{2}\right)-\exp\left(-\frac{\sigma}{2}\right)\right)P. \quad (4.11)$$

Proof: Inserting the so-called Fierz identity

$$T^a\otimes T^a=-\frac{1}{2N}1\otimes 1+\frac{1}{2}P$$

into the right-hand side of (4.9), we obtain

$$\langle(E^3_{K_+}\otimes E^1_{K_+})\rangle_E=\exp\left(-\frac{\sigma}{2N}\right)\exp\left(\frac{\sigma}{2}P\right). \quad (4.12)$$

Similarly, we compute the expectation value for K_- in the same manner as K_+ and obtain

$$\langle(E^3_{K_-}\otimes E^1_{K_-})\rangle_E=\exp\left(\frac{\sigma}{2N}\right)\exp\left(-\frac{\sigma}{2}P\right). \quad (4.13)$$

Inserting (4.12) and (4.13) into the left-hand side (4.11) and using

$$\left(\exp\left(\frac{\sigma}{2}P\right)-\exp\left(-\frac{\sigma}{2}P\right)\right)=\left(\exp\left(\frac{\sigma}{2}\right)-\exp\left(-\frac{\sigma}{2}\right)\right)P$$

yields the right-hand side of (4.11). □

Theorem 4.5: The expectation values for L_+, L_- and L_0 satisfy the relation

$$\exp\left(\frac{\sigma}{2N}\right)\langle W_{L_+}\rangle-\exp\left(-\frac{\sigma}{2N}\right)\langle W_{L_-}\rangle=(e^{(1/2)\sigma}-e^{-(1/2)\sigma})\ \langle W_{L_0}\rangle. \quad (4.14)$$

Proof: First, we prove relation (4.14) for K_ρ $(\rho=0,\pm)$, i.e.,

$$\exp\left(\frac{\sigma}{2N}\right)\langle W_{K_+}\rangle-\exp\left(-\frac{\sigma}{2N}\right)\langle W_{K_-}\rangle=(e^{(1/2)\sigma}-e^{-(1/2)\sigma})\langle W_{K_0}\rangle. \quad (4.15)$$

Multiplying both sides of (4.11) by $\delta^{j_{2n}}_{i_{2n}}\cdots\delta^{j_4}_{i_4}\delta^{j_2}_{i_2}$, we have

$$\exp\left(\frac{\sigma}{2N}\right)\langle (E_{K_+})^{j_{2n}\cdots j_1}_{i_{2n}\cdots i_1}\rangle_E - \exp\left(-\frac{\sigma}{2N}\right)\langle (E_{K_-})^{j_{2n}\cdots j_1}_{i_{2n}\cdots i_1}\rangle_E = (e^{\sigma/2}-e^{-\sigma/2})\ \ \delta^{j_{2n}}_{i_{2n}}\cdots\delta^{j_4}_{i_4}\delta^{j_2}_{i_2}P^{j_3 j_1}_{i_3 i_1}.$$

Multiplying this by $\langle (D_{K_\rho})^{i_{2n}\cdots i_1}\rangle_D$ and $\langle (F_{K_\rho})_{j_{2n},\cdots,j_1}\rangle_F$ $(\rho=0,\pm)$, we obtain (4.15).

Next, relation (4.15) can be extended for L_ρ $(\rho=0,\pm)$ in the same way, since the proof of relation (4.15) is focused on two curves $e_1(t)$ and $e_3(t)$ and independent of the other parts. This completes the proof. □

Let $L=\{K_1,\ldots,K_m\}$ be an m-component link which is a union of n knots K_i $(i=1,\ldots,m)$. Define $lk(K_i,K_j)$ to be the linking number between K_i and K_j, and $\psi_f(K_i)$ the framing number, i.e., the linking number between the knot K_i and its framing. For a link L, set

$$w(L)=2\sum_{i<j} lk(K_i,K_j)+\sum_{i=1}^{m}\psi_f(K_i).$$

Next, define $P_L(x,N)$ by

$$P_L(\sigma,N)=\exp\left\{-\sigma\frac{N^2-1}{2N}w(L)\right\}\langle W_L\rangle. \tag{4.16}$$

Then, we easily obtain the following corollary, using standard argument.[2]

Corollary 4.6:

$$\exp\left(\frac{N\sigma}{2}\right)P_{L_+}(\sigma,N)-\exp\left(-\frac{N\sigma}{2}\right)P_{L_-}(\sigma,N)=(e^{(1/2)\sigma}-e^{-(1/2)\sigma})P_{L_0}(\sigma,N). \tag{4.17}$$

Proof: Inserting (4.16) into (4.14) and using

$$w(L_+)-w(L_0)=w(L_0)-w(L_-)=1$$

yield (4.17). □

Remark: Equation (4.17) is called the HOMFLY skein relation.

APPENDIX: THE PERTURBATIVE METHOD

In this section, we review the perturbative method for the Chern–Simons gauge theory for the matter of convenience. See quantum field theory textbooks for more details.

Let $W(A)$ be an arbitrary complex-valued functional of connection A. The expectation value of $W(A)$ is defined by

$$\langle W\rangle=\frac{1}{Z}\int [DA]e^{iS_k(A)}\ \ W(A), \tag{A1}$$

where the symbol $[DA]$ denotes the path integral.

The action of the Chern–Simons gauge theory in light-cone gauge (2.11) is transformed into the matrix form:

$$S_k(A)=\frac{k}{4\pi}\int dtd\bar{z}dz\ \ \frac{1}{2}(A^a_0\overline{\partial}A^a_z-A^a_z\overline{\partial}A^a_0)=-\frac{1}{2}\int dtd\bar{z}dz(A^a_0,A^a_z)\frac{k}{4\pi}\begin{pmatrix}0 & -\overline{\partial}\\ \overline{\partial} & 0\end{pmatrix}\begin{pmatrix}A^a_0\\ A^a_z\end{pmatrix}.$$

We remark that the above equation is a quadratic form. Therefore, for the above equation, we write

$$S_k(A)=-\frac{1}{2}\int d\mathbf{x}\ \ d\mathbf{x}'\ \ {}^t\hat{A}(\mathbf{x})D(\mathbf{x},\mathbf{x}')\hat{A}(\mathbf{x}'),$$

where $\mathbf{x}=(t,z,\overline{z})$, $\mathbf{x}'=(t',z',\overline{z}')$, $\hat{A}={}^t(A_0^a,A_z^a)$,

$$D(\mathbf{x},\mathbf{x}')=\frac{k}{4\pi}\begin{pmatrix}0 & -\overline{\partial}\\ \overline{\partial} & 0\end{pmatrix}\delta(\mathbf{x}-\mathbf{x}')$$

and $\overline{\partial}$ means the derivative with respect to $\overline{z}$.

Then expectation value (A1) is transformed into the following form:

$$\langle W\rangle=\frac{1}{Z}\int [DA_0][DA_z]e^{-(i/2)\int d\mathbf{x}\ d\mathbf{x}'\ {}^t\hat{A}(\mathbf{x})D(\mathbf{x},\mathbf{x}')\hat{A}(\mathbf{x}')}\ W(A). \tag{A2}$$

Unfortunately, A_0 and A_z are infinite dimensional spaces and there is no rigorous method to define the path integral. Instead we know the perturbative analysis, which will be explained as follows.

In order to explain the perturbative method, we start with a finite dimensional situation as in Ref. 1. Let V be an arbitrary complex-valued function on $\mathbf{R}^n$. Let us evaluate

$$\langle V\rangle=\frac{1}{U}\int_{\mathbf{R}^n}d\vec{x}\exp\left(-\frac{i}{2}\sum_{\alpha\beta}\lambda_{\alpha\beta}x^\alpha x^\beta\right)\ V(\vec{x}), \tag{A3}$$

where

$$U=\int_{\mathbf{R}^n}d\vec{x}\ \ e^{-(i/2)\Sigma_{\alpha\beta}\lambda_{\alpha\beta}x^\alpha x^\beta}.$$

This is a finite dimensional analog for infinite dimensional situation (A2). Introducing new variables $J=(J_\alpha)$, we have

$$\begin{aligned}\langle V\rangle&=\frac{1}{U}\int_{\mathbf{R}^n}d\vec{x}\ \ e^{-(i/2)\Sigma_{\alpha\beta}\lambda_{\alpha\beta}x^\alpha x^\beta}V(\vec{x})e^{iJ_\alpha x^\alpha}\big|_{\vec{J}=0},\\ &=V\left(\frac{\partial}{\partial(iJ_\alpha)}\right)\frac{1}{U}\int_{\mathbf{R}^n}d\vec{x}\ \ e^{-(i/2)\Sigma_{\alpha\beta}\lambda_{\alpha\beta}x^\alpha x^\beta}e^{iJ_\alpha x^\alpha}\big|_{\vec{J}=0},\end{aligned}$$

where we set

$$V\left(\frac{\partial}{\partial(iJ_\alpha)}\right)=\sum_{\nu_1\cdots\nu_n}\frac{1}{\nu_1!\cdots\nu_n!}\frac{\partial^{\nu_1+\cdots+\nu_n}V}{(\partial x^1)^{\nu_1}\cdots(\partial x^n)^{\nu_n}}(0)\left(\frac{\partial}{i\partial J_1}\right)^{\nu_1}\cdots\left(\frac{\partial}{i\partial J_n}\right)^{\nu_n}.$$

This integral is Gaussian and easily calculated as follows:

$$\langle V\rangle=V\left(\frac{\partial}{\partial(iJ_\alpha)}\right)e^{-(i/2)\Sigma_{\alpha\beta}\lambda^{\alpha\beta}(iJ_\alpha)(iJ_\beta)}\big|_{\vec{J}=0}, \tag{A4}$$

where $\lambda^{\alpha\beta}$ is the inverse matrix of $\lambda_{\alpha\beta}$. We have the identity

$$F\left(\frac{\partial}{\partial(iJ_\alpha)}\right)G(i\vec{J})\Big|_{\vec{J}=0}=G\left(\frac{\partial}{\partial x^\alpha}\right)F(\vec{x})\Big|_{\vec{x}=0},$$

where F and G are arbitrary functions on $\mathbf{R}^n$. Using this identity, (A4) is transformed into

$$\langle V\rangle=\exp\left(-\frac{i}{2}\sum_{\alpha\beta}\lambda^{\alpha\beta}\frac{\partial}{\partial x^\alpha}\frac{\partial}{\partial x^\beta}\right)V(\vec{x})\big|_{\vec{x}=0}. \tag{A5}$$

This is a final result for the finite dimensional situation.

Now, let us turn our attention to infinite dimensional situation (A2). Let us introduce ''the inverse matrix analog'' of $D(\mathbf{x},\mathbf{x}')$ as follows. Set

$$G(\mathbf{x}-\mathbf{x}')=\begin{pmatrix} 0 & -\frac{2}{k}\frac{\delta(t-t')}{z-z'} \\ \frac{2}{k}\frac{\delta(t-t')}{z-z'} & 0 \end{pmatrix}.$$

Then we have

$$\int d\mathbf{x}' D(\mathbf{x},\mathbf{x}')G(\mathbf{x}'-\mathbf{x}'')=id\ \ \delta(\mathbf{x}-\mathbf{x}''),$$

where ''id'' denotes the identity matrix. Therefore $G(\mathbf{x}-\mathbf{x}')$ is thought to be ''the inverse matrix analog'' of $D(\mathbf{x},\mathbf{x}')$.

Now we can compare infinite dimensional situation (A2) with the finite dimensional one (A3) by the following correspondence:

$$\alpha,\beta\leftrightarrow\mathbf{x}=(t,z,\overline{z}),\mathbf{x}'=(t',z',\overline{z}'),$$

$$\sum_{\alpha\beta}\leftrightarrow\int d\mathbf{x}\ \ d\mathbf{x}',$$

$$x^{\alpha}\leftrightarrow\hat{A}(\mathbf{x})={}^{t}(A_0^a(\mathbf{x}),A_z^a(\mathbf{x})),$$

$$\lambda_{\alpha\beta}\leftrightarrow D(\mathbf{x},\mathbf{x}'),$$

$$\lambda^{\alpha\beta}\leftrightarrow iG(\mathbf{x}-\mathbf{x}').$$

Therefore, comparing (A5), we can evaluate path integral (A2) as follows:

$$\langle W\rangle=\exp\left\{\int dtdzd\overline{z}\int dt'dz'd\overline{z}'\frac{\delta}{\delta A_0^a(\mathbf{x})}\Delta_{0z}^{ab}(\mathbf{x}-\mathbf{x}')\frac{\delta}{\delta A_z^b(\mathbf{x}')}\right\}W(A)|_{A=0},\tag{A6}$$

where $\mathbf{x}=(t,z,\overline{z})$, $\mathbf{x}'=(t',z',\overline{z}')$ and

$$\Delta_{0z}^{ab}(\mathbf{x}-\mathbf{x}')=-\delta^{ab}\frac{2}{k}\frac{\delta(t-t')}{z-z'}.$$

Here we remark that (A6) is still valid for $\langle W\rangle_E$, since the argument for deriving (A6) is independent of the domain of t.

From (A6), we can compute the two-point correlation functions (2.12)–(2.14) as follows:

$$\langle A_0^a(\mathbf{x})A_z^b(\mathbf{x}')\rangle=\Delta_{0z}^{ab}(\mathbf{x}-\mathbf{x}')=-\delta^{ab}\frac{2}{k}\frac{\delta(t-t')}{z-z'},$$

$$\langle A_0^a(\mathbf{x})A_0^b(\mathbf{x}')\rangle=0,$$

$$\langle A_z^a(\mathbf{x})A_z^b(\mathbf{x}')\rangle=0.$$

It is well known that, due to vanishing theorems, there are no nontrivial finite action solutions to the Abelian Seiberg–Witten (SW) monopole equations on Euclidean four-dimensional space $\mathbb{R}^4$. We show that this is no longer true for the noncommutative version of these equations, i.e., on a noncommutative deformation $\mathbb{R}^4_\theta$ of $\mathbb{R}^4$ there exist smooth solutions to the SW equations having nonzero topological charge. We introduce action functionals for the noncommutative SW equations and construct explicit regular solutions. All our solutions have finite energy. We also suggest a possible interpretation of the obtained solutions as codimension four vortex-like solitons representing $D(p-4)$- and $\overline{D(p-4)}$-branes in a Dp-$\overline{Dp}$ brane system in type II superstring theory. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1604454]

I. INTRODUCTION

The Seiberg–Witten (SW) monopole equations[1] have been derived in the context of twisted $\mathcal{N}=2$ supersymmetric Yang-Mills (SYM) theory[2,3] in some limit of the coupling constant. Another limit of this theory yields the anti-self-dual Yang–Mills (ASDYM) equations. Namely, the ASDYM equations correspond to the weak coupling limit while the SW equations are related to the strong coupling regime obtained by the S-dualization (see, e.g., Refs. 1, 4–6 and references therein). Note that the SW equations are associated with the Abelian group $U(1)$ and have a compact moduli space while the ASDYM equations, considered in Donaldson–Witten (DW) theory,[7,2] possess the non-Abelian gauge group $SU(2)$ and a noncompact moduli space. That is why SW theory is much easier to handle compared to DW theory. A bridge between these theories is provided by the non-Abelian SW equations (see, e.g., Refs. 8–11, 6 and references therein) whose moduli space contains both DW and SW moduli spaces as singular submanifolds.

It is well known that, due to a vanishing theorem of the Lichnerowicz–Weitzenböck type, there are no nontrivial finite action solutions to the Abelian SW equations on Riemannian four-manifolds with non-negative scalar curvature and, in particular, on $\mathbb{R}^4$ (cf. Ref. 1). This assertion is also true for lower-dimensional reductions of the SW equations, i.e., these reductions also do not exhibit regular solutions on $\mathbb{R}^{n\leqslant 3}$ with a nonzero topological charge. Nevertheless, one may construct nontrivial non-L^2 solutions, as it has been done, e.g., in Refs. 12–15.

Note that for the vanishing spinor field the SW equations specialize to the Abelian ASDYM equations which have no nontrivial regular solutions (instantons) on $\mathbb{R}^4$ either. However, Nekrasov and Schwarz have demonstrated in Ref. 16 that smooth Abelian instanton solutions do exist on $\mathbb{R}^4_\theta$, which is a noncommutative deformation of $\mathbb{R}^4$ with constant deformation parameters $\theta=(\theta^{\mu\nu})$. Moreover, they have proven that noncommutativity resolves the singularities of the instanton moduli space. In the present paper we observe a similar phenomenon for the SW equations on $\mathbb{R}^4_\theta$ by constructing nontrivial regular solutions to the noncommutative SW equations.

It is well known that the SW equations on Kähler surfaces are similar to the vortex equations in two dimensions. Motivated by this relation, we interpret regular (vortex-like) solutions to the SW equations on $\mathbb{R}^4_\theta$ as $D(p-4)$- and $\overline{D(p-4)}$-branes in a Dp-$\overline{Dp}$ brane–antibrane system in type II superstring theory. This interpretation can also be extended to the commutative case of the SW equations on Kähler surfaces.

The paper is organized as follows. In the next section we formulate the SW equations on $\mathbb{R}^4$ and fix our notation. In Sec. III we introduce the noncommutatively deformed non-Abelian SW equations. We derive them from properly deformed $U(2)$ self-duality type equations in eight dimensions[17] by a dimensional reduction to four dimensions (cf. Ref. 18). The resulting $U_+(1)\times U_-(1)$, $U_+(1)$ and $U_-(1)$ noncommutative SW equations can also be produced from appropriate action functionals by using a Bogomolny type transformation. We point out that the $U_+(1)\times U_-(1)$, $U_+(1)$ and $U_-(1)$ noncommutative SW equations share the same commutative limit. In Sec. IV we present a number of regular solutions to the noncommutative SW equations and discuss their D-brane interpretation in a string theoretic context. In Sec. V we conclude with a brief summary and open problems. Finally, in an Appendix we perform the Bogomolny type transformation for the noncommutative $U_+(1)\times U_-(1)$ SW action functional.

II. SW MONOPOLE EQUATIONS ON $\mathbb{R}^4$

A. SW action functional

In this paper we consider the SW equations on the Euclidean space $\mathbb{R}^4$, provided with the standard metric $g=(\delta_{\mu\nu})$, where $\mu,\nu,\ldots=1,\ldots,4$. The (energy) functional $E=E(A,\Phi)$ for these equations has the form (cf., e.g., Refs. 19–21)

$$E(A,\Phi)=\int_{\mathbb{R}^4}\mathrm{d}^4x\{|F_A|^2+|D_A\Phi|^2+\tfrac{1}{4}|\Phi|^4\}. \tag{2.1}$$

Here $A\in\Omega^1(\mathbb{R}^4,\mathfrak{u}(1))$ is a connection one-form on $\mathbb{R}^4$ with pure imaginary smooth coefficients and $\Phi\in C^\infty(\mathbb{R}^4,\mathbb{C}^2)$ is a Weyl spinor given by a smooth complex-valued vector function on $\mathbb{R}^4$. We denote by $F_A^+\in\Omega^2_+(\mathbb{R}^4,\mathfrak{u}(1))$ the self-dual part of the curvature F_A of A and by D_A the covariant derivative associated with A. Moreover, we use the abbreviation $|D_A\Phi|^2=D_\mu\phi_i(D_\mu\phi_i)^\dagger$ and set $|F_A|^2=\frac{1}{2}F_{\mu\nu}F^\dagger_{\mu\nu}$.

By exploiting a Bogomolny type formula, the energy functional can be rewritten in the form

$$E(A,\Phi)=\mathrm{SW}(A,\Phi)-8\pi^2Q, \tag{2.2}$$

where

$$\mathrm{SW}(A,\Phi)=\int_{\mathbb{R}^4}\mathrm{d}^4x\{|\mathcal{D}_A\Phi|^2+2|F_A^+-\sigma^+(\Phi\otimes\Phi^\dagger)_0|^2\} \tag{2.3}$$

is the SW action functional and

$$Q=-\frac{1}{8\pi^2}\int_{\mathbb{R}^4}F_A\wedge F_A \tag{2.4}$$

is the topological charge. In the above formula (2.3) we denote by $\mathcal{D}_A$ the Dirac operator associated with A. We also use the notation

$$\sigma^+(\Phi\otimes\Phi^\dagger)_0 := \sigma^+(\Phi\otimes\Phi^\dagger - \tfrac{1}{2}|\Phi|^2\mathrm{id}), \tag{2.5}$$

where

$$\sigma^+ : \mathrm{Herm}_0(\mathbb{C}^2) \to \Omega^2_+(\mathbb{R}^4, \mathfrak{u}(1))$$

is a map identifying the space $\mathrm{Herm}_0(\mathbb{C}^2)$ of traceless Hermitian endomorphisms of $\mathbb{C}^2$ with the space $\Omega^2_+(\mathbb{R}^4,\mathfrak{u}(1))$ of imaginary-valued self-dual two-forms on $\mathbb{R}^4$. The inverse of this map is given by the Clifford multiplication by two-forms (see, e.g., Refs. 19–21).

It is easy to see that the functionals (2.1) and (2.3) are invariant under gauge transformations of the form

$$A \mapsto A + g^\dagger \mathrm{d}g \quad \text{and} \quad \Phi \mapsto g^\dagger \Phi, \tag{2.6}$$

where $g \in C^\infty(\mathbb{R}^4, U(1))$.

B. SW monopole equations

Since the functional $\mathrm{SW}(A,\Phi)$ is positive semi-definite and Q is a topological term, the Bogomolny formula (2.2) implies that the lower bound of the energy $E(A,\Phi)$ is attained on solutions to the equations

$$F_A^+ = \sigma^+(\Phi\otimes\Phi^\dagger)_0, \tag{2.7a}$$

$$\mathcal{D}_A\Phi = 0, \tag{2.7b}$$

which are known as the SW monopole equations. They are differential equations of first order and their solutions, which minimize the energy functional $E(A,\Phi)$, automatically satisfy the (second order) Euler–Lagrange equations for the functionals $E(A,\Phi)$ and $\mathrm{SW}(A,\Phi)$.

Writing ${}^t\Phi = (\phi_1,\phi_2)$, one can see that Eqs. (2.7) are equivalent to (cf. Ref. 19)

$$\begin{aligned} F_{12}+F_{34} &= \frac{i}{2}(\phi_1\overline{\phi}_1 - \phi_2\overline{\phi}_2), \\ F_{13}+F_{42} &= -\tfrac{1}{2}(\phi_2\overline{\phi}_1 - \phi_1\overline{\phi}_2), \\ F_{14}+F_{23} &= \frac{i}{2}(\phi_2\overline{\phi}_1 + \phi_1\overline{\phi}_2) \end{aligned} \tag{2.8a}$$

and

$$\begin{pmatrix} -D_4+iD_3 & D_2+iD_1 \\ -D_2+iD_1 & -D_4-iD_3 \end{pmatrix}\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix} = 0. \tag{2.8b}$$

It is easy to prove that these equations have no nontrivial solutions with finite action. Namely, we have the following theorem (see, e.g., Refs. 1, 19–21):

Theorem: *Suppose* $A \in \Omega^1(\mathbb{R}^4,\mathfrak{u}(1))$ *and* $\Phi \in C^\infty(\mathbb{R}^4,\mathbb{C}^2)$ *satisfy the equations (2.8). Moreover, we assume that* $\Phi \in L^2(\mathbb{R}^4)$ *and* $E(A,\Phi) < \infty$. *Then the only solution to (2.8) is the trivial solution* $(A,\Phi) = (0,0)$ *modulo the gauge transformations (2.6).*

This theorem is also true for lower dimensional reductions of the SW equations (defined on $\mathbb{R}^{n\leqslant 3}$), i.e., these reductions do not exhibit regular nontrivial solutions either. However, as we have already mentioned in the Introduction, one can construct nontrivial non-L^2 solutions.[12–15]

C. Perturbed SW action functional and monopole equations

The gauge group action (2.6) on the space of pairs (A,Φ) is free, unless $\Phi\equiv 0$. In order to avoid solutions of the form $(A,0)$, which may cause singularities in the moduli space of solutions, we perturb the monopole equations by adding an extra term to the first SW equation,

$$F_A^+ + \chi^+ = \sigma^+(\Phi\otimes\Phi^\dagger)_0, \tag{2.9a}$$

$$\mathcal{D}_A\Phi = 0, \tag{2.9b}$$

where χ^+ is the self-dual part of a two-form $\chi\in\Omega^2(\mathbb{R}^4,\mathfrak{u}(1))$ (perturbation). Solutions to these equations minimize the functional

$$\mathrm{SW}_\chi(A,\Phi)=\int_{\mathbb{R}^4}\mathrm{d}^4x\{|\mathcal{D}_A\Phi|^2+2|F_A^+ +\chi^+-\sigma^+(\Phi\otimes\Phi^\dagger)_0|^2\}. \tag{2.10}$$

In components Eq. (2.9a) reads as

$$\begin{aligned} F_{12}+F_{34}+\chi_{12}+\chi_{34}&=\frac{i}{2}(\phi_1\overline{\phi_1}-\phi_2\overline{\phi_2}),\\ F_{13}+F_{42}+\chi_{13}+\chi_{42}&=-\tfrac{1}{2}(\phi_2\overline{\phi_1}-\phi_1\overline{\phi_2}),\\ F_{14}+F_{23}+\chi_{14}+\chi_{23}&=\frac{i}{2}(\phi_2\overline{\phi_1}+\phi_1\overline{\phi_2}). \end{aligned} \tag{2.11}$$

The SW action functional, as in the unperturbed case, is related to an energy functional,

$$E_\chi(A,\Phi)=\int_{\mathbb{R}^4}\mathrm{d}^4x\{|F_A|^2+|D_A\Phi|^2+2|\chi^+-\sigma^+(\Phi\otimes\Phi^\dagger)_0|^2\}, \tag{2.12}$$

via a Bogomolny type formula,

$$\mathrm{SW}_\chi(A,\Phi)=E_\chi(A,\Phi)+16\pi^2K_\chi+8\pi^2Q. \tag{2.13}$$

The topological charge Q is given, as before, by formula (2.4) and the Chern–Simons type term K_χ is defined as

$$K_\chi=-\frac{1}{4\pi^2}\int_{\mathbb{R}^4}F_A^+\wedge\chi^+. \tag{2.14}$$

III. SW MONOPOLE EQUATIONS ON $\mathbb{R}^4_\theta$

A. Non-Abelian SW monopole equations

1. Noncommutative Euclidean space $\mathbb{R}^{2n}_\theta$

Let $\mathcal{A}(\mathbb{R}^{2n})$ be the algebra of polynomial functions on $\mathbb{R}^{2n}$ (which is endowed with the canonical metric $\delta_{\alpha\beta}$) and $\theta=(\theta^{\alpha\beta})$ be a real invertible skew-symmetric $2n\times 2n$ matrix with the inverse matrix $\theta^{-1}=(\theta_{\alpha\beta})$ defined by $\theta_{\alpha\gamma}\theta^{\gamma\beta}=\delta_\alpha^\beta$ for $\alpha,\beta,\ldots=1,\ldots,2n$. Then the deformed algebra $\mathcal{A}_\theta(\mathbb{R}^{2n})$ is defined as

$$\mathcal{A}_\theta(\mathbb{R}^{2n}):=T(\mathbb{R}^{2n})/\langle[x^\alpha,x^\beta]-i\theta^{\alpha\beta}\rangle_{1\leqslant\alpha,\beta\leqslant 2n}, \tag{3.1}$$

where $T(\mathbb{R}^{2n})$ is the tensor algebra of $\mathbb{R}^{2n}$ and $\langle[x^\alpha,x^\beta]-i\theta^{\alpha\beta}\rangle_{1\leqslant\alpha,\beta\leqslant 2n}$ denotes the two-sided ideal generated by $[x^\alpha,x^\beta]-i\theta^{\alpha\beta}\subset T(\mathbb{R}^{2n})$. For brevity we shall denote $\mathcal{A}_\theta(\mathbb{R}^{2n})$ simply by $\mathbb{R}^{2n}_\theta$ and call it the noncommutative Euclidean $2n$-dimensional space.

One way to realize the noncommutative extension (3.1) of the algebra $\mathcal{A}(\mathbb{R}^{2n})$ is by deformation of the pointwise product between functions via the so-called star (Moyal) product,

$$(f\star g)(x) := f(x)\exp\left\{\frac{i}{2}\overleftarrow{\partial}_\alpha\theta^{\alpha\beta}\overrightarrow{\partial}_\beta\right\}g(x), \tag{3.2}$$

where $f,g\in C^\infty(\mathbb{R}^{2n},\mathbb{C})$. In particular, it follows from (3.2) that

$$[x^\alpha,x^\beta]_\star := x^\alpha\star x^\beta - x^\beta\star x^\alpha = i\theta^{\alpha\beta}. \tag{3.3}$$

For later convenience we introduce complex coordinates on $\mathbb{R}^{2n}\cong\mathbb{C}^n$,

$$z^a = x^{2a-1}+ix^{2a} \quad \text{and} \quad \overline{z^a} = x^{2a-1}-ix^{2a}, \quad \text{for} \quad a=1,\ldots,n, \tag{3.4}$$

and derivatives

$$\partial_{z^a} = \tfrac{1}{2}(\partial_{2a-1}-i\partial_{2a}) \quad \text{and} \quad \partial_{\overline{z^a}} = \tfrac{1}{2}(\partial_{2a-1}+i\partial_{2a}). \tag{3.5}$$

Note that by an orthogonal change of coordinates one can always transform $\theta^{\alpha\beta}$ to its canonical (Darboux) form whose only nonzero components are $\theta^{2a-1,2a}$ with $a=1,\ldots,n$. Then the commutation relations (3.3) translate to

$$[z^a,\overline{z^a}]_\star = \theta^{a\overline{a}}, \quad \text{with} \quad \theta^{a\overline{a}} = 2\theta^{2a-1,2a}, \tag{3.6}$$

and all other commutators are equal to zero.

2. Self-duality type equations in eight dimensions

A standard way to obtain a noncommutative generalization of a theory is to replace naively the ordinary commutative product between field variables with the noncommutative star product. However, it is well known that this method of translating a commutative theory into a noncommutative one is not uniquely defined when the matter fields are involved. For instance, the scalar fields in noncommutative $U(1)$ gauge theory on $\mathbb{R}^{2n}$ can be regarded in three different ways, namely as elements of a left module [over the algebra $\mathcal{A}_\theta(\mathbb{R}^{2n})$], or as elements of a right module, or they can transform in the adjoint representation. For this reason we propose deriving the noncommutative SW equations from noncommutative self-duality type Yang–Mills (YM) equations in eight dimensions, which are uniquely defined. Eventually, we will discover the equations corresponding to the above mentioned naive substitution rule by a formal reduction of more general equations. In the commutative case a similar idea has been worked out by the authors of Ref. 18.

Let us consider pure $U(2)$ YM theory on $\mathbb{R}^8_\theta$. In star-product formulation the components $F_{\alpha\beta}$ of the YM curvature F_A read as

$$F_{\alpha\beta} = \partial_\alpha A_\beta - \partial_\beta A_\alpha + [A_\alpha,A_\beta]_\star \tag{3.7}$$

and take values in $\mathfrak{u}(2)$. Here α, β,..., run from 1 to 8. Consider the generalized self-duality equations for YM fields in eight dimensions,

$$F_{\alpha\beta} = \tfrac{1}{2}T_{\alpha\beta\gamma\delta}F_{\gamma\delta}, \tag{3.8}$$

where the totally antisymmetric tensor $T_{\alpha\beta\gamma\delta}$ is determined by the octonionic structure constants f_{ijk} as

$$T_{ijkl} = \tfrac{1}{6}\epsilon_{ijklmnq}f_{mnq} \quad \text{and} \quad T_{8ijk} = f_{ijk}, \quad \text{for} \quad i,j,k,\ldots = 1,\ldots,7. \tag{3.9}$$

(In the commutative case these equations were introduced in Ref. 17 and discussed, e.g., in Refs. 22, 23. We use $f_{127}=f_{347}=f_{567}=f_{163}=f_{246}=f_{253}=f_{154}=1$.) Note that the tensor $T_{\alpha\beta\gamma\delta}$ and there-

fore the equations (3.8) are invariant with respect to the group $Spin(7)$ rather than $SO(8)$. In fact, it is impossible to construct a totally antisymmetric tensor of rank four in eight dimensions which is invariant under $SO(8)$ rotations.

Using the definition (3.9), we can write down the generalized self-duality (3.8) in components as follows:

$$\begin{aligned}
&F_{12}+F_{34}+F_{56}+F_{78}=0,\\
&F_{13}+F_{42}+F_{57}+F_{86}=0,\\
&F_{14}+F_{23}+F_{76}+F_{85}=0,\\
&F_{15}+F_{62}+F_{73}+F_{48}=0,\\
&F_{16}+F_{25}+F_{38}+F_{47}=0,\\
&F_{17}+F_{82}+F_{35}+F_{64}=0,\\
&F_{18}+F_{27}+F_{63}+F_{54}=0.
\end{aligned} \tag{3.10}$$

With the help of (3.4) and the definitions

$$A_{z^a}=\tfrac{1}{2}(A_{2a-1}-iA_{2a}) \quad \text{and} \quad A_{\bar{z}^a}=\tfrac{1}{2}(A_{2a-1}+iA_{2a}), \quad \text{for} \quad a=1,\ldots,4, \tag{3.11}$$

we rewrite (3.10) as

$$F_{z^1\bar{z}^1}+F_{z^2\bar{z}^2}+F_{z^3\bar{z}^3}+F_{z^4\bar{z}^4}=0, \tag{3.12a}$$

$$F_{z^1z^2}+F_{\bar{z}^3\bar{z}^4}=0, \tag{3.12b}$$

$$F_{z^2z^4}-F_{\bar{z}^1\bar{z}^3}=0, \tag{3.12c}$$

$$F_{z^1z^4}+F_{\bar{z}^2\bar{z}^3}=0. \tag{3.12d}$$

Note that $A_{\bar{z}^a}=-A^{\dagger}_{z^a}$, since the components A_α are skew-Hermitian.

3. Reduction to four dimensions

Following Baulieu *et al.*,[18] we assume that the gauge potential components A_{z^a} for $a=1,\ldots,4$ do not depend on the coordinates $z^3,z^4,\bar{z}^3,\bar{z}^4$ and define ${}^t\Psi:=(\Psi_1,\Psi_2)$ with $\Psi_1:=A_{\bar{z}^3}$ and $\Psi_2:=A_{z^4}$. Then the equations (3.12) dimensionally reduce to

$$F_{z^1\bar{z}^1}+F_{z^2\bar{z}^2}=-([\Psi_1,\Psi_1^{\dagger}]_\star-[\Psi_2,\Psi_2^{\dagger}]_\star), \tag{3.13a}$$

$$F_{z^1z^2}=[\Psi_1,\Psi_2^{\dagger}]_\star, \tag{3.13b}$$

$$D_{\bar{z}^1}\Psi_1-D_{z^2}\Psi_2=0, \tag{3.13c}$$

$$D_{\bar{z}^2}\Psi_1+D_{z^1}\Psi_2=0, \tag{3.13d}$$

where the covariant derivative D_{z^a} is defined by $D_{z^a}\Psi=\partial_{z^a}\Psi+[A_{z^a},\Psi]_\star$. In the commutative limit these equations coincide with a non-Abelian generalization of the SW equations, considered in Ref. 18. Note that the special case of these equations corresponding to $\Psi_2\equiv 0$ was discussed in Refs. 24, 25.

Along with the unperturbed equations (3.13) we shall also consider the perturbed equations (cf. Refs. 8–10). For that we introduce a $\mathfrak{u}(2)$-valued two-form χ and add its self-dual part χ^+ to F_A^+,

$$F_{z^1\bar{z}^1}+F_{z^2\bar{z}^2}+\chi_{z^1\bar{z}^1}+\chi_{z^2\bar{z}^2}=-([\Psi_1,\Psi_1^\dagger]_\star-[\Psi_2,\Psi_2^\dagger]_\star), \tag{3.14a}$$

$$F_{z^1z^2}+\chi_{z^1z^2}=[\Psi_1,\Psi_2^\dagger]_\star, \tag{3.14b}$$

$$D_{\bar{z}^1}\Psi_1-D_{z^2}\Psi_2=0, \tag{3.14c}$$

$$D_{\bar{z}^2}\Psi_1+D_{z^1}\Psi_2=0. \tag{3.14d}$$

B. Abelian SW monopole equations

In order to get Abelian SW equations from the non-Abelian ones, we shall consider solutions of a particular type given by a suitable ansatz. This will reduce the gauge group $U(2)$ to $U(1)\times U(1)$ and then, further down to $U(1)$.

1. Noncommutative $U_+(1)\times U_-(1)$ SW monopole equations

Let us consider the $U(1)\times U(1)$ subgroup of $U(2)$ with the generators

$$\begin{pmatrix} i & 0 \\ 0 & i \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}, \tag{3.15}$$

and assume that the components of the gauge potential A_{z^a} for $a=1,2$ take the form

$$A_{z^a}:=\begin{pmatrix} A_{+z^a} & 0 \\ 0 & A_{-z^a} \end{pmatrix}, \quad \text{with} \quad A_{\pm z^a}=\tfrac{1}{2}(\mathcal{B}_{z^a}\pm\mathcal{A}_{z^a}), \tag{3.16}$$

and $\mathcal{A}_{z^a},\mathcal{B}_{z^a}\in C^\infty(\mathbb{R}^4,i\mathbb{R}\otimes\mathbb{C})$. (If not stated differently, $a,b,\ldots$, run always from 1 to 2 in the sequel.) Furthermore, we restrict Ψ_1 and Ψ_2 to the form

$$\Psi_{1,2}:=\begin{pmatrix} 0 & \dfrac{1}{\sqrt{8}}\phi_{1,2} \\ 0 & 0 \end{pmatrix}, \tag{3.17}$$

where $\phi_{1,2}\in C^\infty(\mathbb{R}^4,\mathbb{C})$.

Substituting (3.16) and (3.17) into the equations (3.13), after a straightforward calculation we obtain the equations

$$F_{+z^1\bar{z}^1}+F_{+z^2\bar{z}^2}=-\tfrac{1}{8}(\phi_1\star\phi_1^\dagger-\phi_2\star\phi_2^\dagger) \quad \text{and} \quad F_{+z^1z^2}=\tfrac{1}{8}\phi_1\star\phi_2^\dagger, \tag{3.18a}$$

$$F_{-z^1\bar{z}^1}+F_{-z^2\bar{z}^2}=\tfrac{1}{8}(\phi_1^\dagger\star\phi_1-\phi_2^\dagger\star\phi_2) \quad \text{and} \quad F_{-z^1z^2}=-\tfrac{1}{8}\phi_2^\dagger\star\phi_1, \tag{3.18b}$$

as well as

$$D_{\bar{z}^1}\phi_1-D_{z^2}\phi_2=0 \quad \text{and} \quad D_{\bar{z}^2}\phi_1+D_{z^1}\phi_2=0, \tag{3.19}$$

where we have used the definition

$$D_{z^a}\phi:=\partial_{z^a}\phi+A_{+z^a}\star\phi-\phi\star A_{-z^a}. \tag{3.20}$$

Here $F_{\pm z^a\bar{z}^a}$ are the components of the curvature associated with $A_{\pm z^a}$, i.e.,

$$F_{\pm z^a\bar{z}^a}=\partial_{z^a}A_{\pm\bar{z}^a}-\partial_{\bar{z}^a}A_{\pm z^a}+[A_{\pm z^a},A_{\pm\bar{z}^a}]_\star. \tag{3.21}$$

Analogously, by assuming that $\chi=\mathrm{diag}(\chi_+,\chi_-)$ with $\chi_\pm\in\Omega^2(\mathbb{R}^4,\mathrm{i}\mathbb{R})$ in (3.14), we obtain the perturbed equations

$$F_{+z^1\bar{z}^1}+F_{+z^2\bar{z}^2}+\chi_{+z^1\bar{z}^1}+\chi_{+z^2\bar{z}^2}=-\tfrac{1}{8}(\phi_1\star\phi_1^\dagger-\phi_2\star\phi_2^\dagger), \tag{3.22a}$$

$$F_{+z^1z^2}+\chi_{+z^1z^2}=\tfrac{1}{8}\phi_1\star\phi_2^\dagger, \tag{3.22b}$$

$$F_{-z^1\bar{z}^2}+F_{-z^2\bar{z}^2}+\chi_{-z^1\bar{z}^1}+\chi_{-z^2\bar{z}^2}=\tfrac{1}{8}(\phi_1^\dagger\star\phi_1-\phi_2^\dagger\star\phi_2), \tag{3.22c}$$

$$F_{-z^1z^2}+\chi_{-z^1z^2}=-\tfrac{1}{8}\phi_2^\dagger\star\phi_1. \tag{3.22d}$$

We consider the equations (3.18), (3.19) and (3.22), (3.19) as a noncommutative extension of the unperturbed and perturbed Abelian SW equations, respectively. Since there are two gauge potentials in the equations, we call them the noncommutative unperturbed and perturbed $U_+(1)\times U_-(1)$ SW equations.

It remains to find out what kind of gauge transformations leave the $U_+(1)\times U_-(1)$ SW equations invariant. It is obvious from the explicit form of these equations that ϕ_1 and ϕ_2 are in the bi-fundamental representation of $U_+(1)\times U_-(1)$. Hence, Eqs. (3.18), (3.19) and (3.22) are invariant under gauge transformations of the form

$$A_\pm\mapsto g_\pm^\dagger\star A_\pm\star g_\pm+g_\pm^\dagger\star\mathrm{d}g_\pm,\quad \chi_\pm\mapsto g_\pm^\dagger\star\chi_\pm\star g_\pm\quad\text{and}\quad \Phi\mapsto g_+^\dagger\star\Phi\star g_-, \tag{3.23}$$

where $g_\pm\in C^\infty(\mathbb{R}^4,U_\pm(1))$ and ${}^t\Phi=(\phi_1,\phi_2)$.

In the commutative limit the covariant derivative (3.20) turns into

$$D_{z^a}\phi=\partial_{z^a}\phi+(A_{+z^a}-A_{-z^a})\phi=\partial_{z^a}\phi+\mathcal{A}_{z^a}\phi, \tag{3.24}$$

i.e., the gauge potential $\mathcal{B}$ disappears from the equations (3.19). In other words, one copy of $U(1)$ decouples from $U(2)$ and the matter field Φ interacts only with the $SU(2)$ part. Hence, in the commutative case Φ is charged with respect to the diagonal $U(1)$ subgroup of $U_+(1)\times U_-(1)$ corresponding to the gauge potential $\mathcal{A}=A_+-A_-$. Furthermore, the commutator in the expression for the (Abelian) curvature vanishes and hence as a corollary we have $F_{\pm z^a\bar{z}^a}=\frac{1}{2}(F_{\mathcal{B}z^a\bar{z}^a}\pm F_{\mathcal{A}z^a\bar{z}^a})$. In the commutative limit one may choose the perturbations $\chi_\pm$ so that

$$\chi_{\pm z^a\bar{z}^a}=-\tfrac{1}{2}F_{\mathcal{B}z^a\bar{z}^a}\pm\tfrac{1}{2}\chi_{z^a\bar{z}^a}\quad\text{and}\quad \chi_{\pm z^1z^2}=-\tfrac{1}{2}F_{\mathcal{B}z^1z^2}\pm\tfrac{1}{2}\chi_{z^1z^2}, \tag{3.25}$$

where $\chi\in\Omega^2(\mathbb{R}^4,\mathfrak{u}(1))$ is some other perturbation. Then from Eqs. (3.22) we obtain

$$F_{\mathcal{A}z^1\bar{z}^1}+F_{\mathcal{A}z^2\bar{z}^2}+\chi_{z^1\bar{z}^1}+\chi_{z^2\bar{z}^2}=-\tfrac{1}{4}(\phi_1\bar{\phi}_1-\phi_2\bar{\phi}_2)\quad\text{and}\quad F_{\mathcal{A}z^1z^2}+\chi_{z^1z^2}=\tfrac{1}{4}\phi_1\bar{\phi}_2. \tag{3.26}$$

(Note that in the case of complex valued-functions "$\dagger$" goes to "$-$" in the commutative limit.) Thus, we recover the perturbed SW equations (2.8b) and (2.11) (written in complex coordinates). Of course, the choice $\chi\equiv 0$ corresponds to the unperturbed equations.

Remark: Consider the unperturbed equations (3.18) and (3.19). In the commutative limit we arrive at the standard unperturbed SW equations for configurations $(\mathcal{A},\Phi)$ plus the Abelian ASDYM equations for $\mathcal{B}$, i.e.,

$$F_{\mathcal{B}z^1\bar{z}^1}+F_{\mathcal{B}z^2\bar{z}^2}=0\quad\text{and}\quad F_{\mathcal{B}z^1z^2}=0. \tag{3.27}$$

Taking the trivial solution $\mathcal{B}=0$ (recall that there are no Abelian instantons on $\mathbb{R}^4$) we remain with the standard unperturbed SW equations. More generally, any pure gauge configuration for $\mathcal{B}$ will do the same. The noncommutative version of the latter statement is, however, nontrivial. If we choose $\mathcal{B}_{z^a}$ in (3.16) of the form

$$\mathcal{B}_{z^a}=\tfrac{1}{2}(b^\dagger\star\partial_{z^a}b-b\star\partial_{z^a}b^\dagger), \tag{3.28}$$

with $b\in C^\infty(\mathbb{R}^4,U(1))$, then it will correspond in the commutative limit to a pure gauge configuration but, of course, it is not pure gauge in the noncommutative case. Only in the commutative limit the curvature $F_{\mathcal{B}}$ disappears and we arrive at the unperturbed SW equations (2.8).

2. Noncommutative $U_\pm(1)$ SW monopole equations

In Eqs. (3.18)–(3.23) the field Φ is regarded as an element of a $\mathbb{R}^4_\theta$-bimodule transforming in the bi-fundamental representation of the gauge group $U_+(1)\times U_-(1)$. However, in the noncommutative setup the matter field Φ can also be thought of either as an element of a right $\mathbb{R}^4_\theta$-module [the $U_+(1)$ case] or as an element of a left $\mathbb{R}^4_\theta$-module [the $U_-(1)$ case]. These two cases can easily be read off Eqs. (3.22a), (3.22b) and (3.22c), (3.22d), respectively. Namely, consider the equations

$$F_{z^1\bar{z}^1}+F_{z^2\bar{z}^2}+\chi_{z^1\bar{z}^1}+\chi_{z^2\bar{z}^2}=-\tfrac{1}{4}(\phi_1\star\phi_1^\dagger-\phi_2\star\phi_2^\dagger)\quad\text{and}\quad F_{z^1z^2}+\chi_{z^1z^2}=\tfrac{1}{4}\phi_1\star\phi_2^\dagger, \tag{3.29a}$$

as well as

$$D_{\bar{z}^1}\phi_1-D_{z^2}\phi_2=0\quad\text{and}\quad D_{\bar{z}^2}\phi_1+D_{z^1}\phi_2=0, \tag{3.29b}$$

where $\chi\in\Omega^2(\mathbb{R}^4,\mathrm{i}\mathbb{R})$ and the (right) covariant derivative reads as

$$D_{z^a}\phi=\partial_{z^a}\phi+\mathcal{A}_{z^a}\star\phi. \tag{3.29c}$$

[Formally, these equations can be obtained from (3.19)–(3.22) by choosing $\mathcal{B}_{z^a}=\mathcal{A}_{z^a}$ (i.e., $A_{-z^a}=0$), taking $\chi_\pm$ such that $\chi_{+z^a\bar{z}^a}=\chi_{z^a\bar{z}^a}$, $\chi_{+z^1z^2}=\chi_{z^1z^2}$, $\chi_{-z^1\bar{z}^1}+\chi_{-z^2\bar{z}^2}=\frac{1}{8}(\phi_1^\dagger\star\phi_1-\phi_2^\dagger\star\phi_2)$ and $\chi_{-z^1z^2}=-\frac{1}{8}\phi_2^\dagger\star\phi_1$, where $\chi\in\Omega^2(\mathbb{R}^4,\mathrm{i}\mathbb{R})$, and rescaling $\Phi\mapsto\sqrt{2}\Phi$.] Note that the curvature $F_{\mathcal{A}}$ is now computed from $\mathcal{A}$, i.e. $F_{\mu\nu}=\partial_\mu\mathcal{A}_\nu-\partial_\nu\mathcal{A}_\mu+[\mathcal{A}_\mu,\mathcal{A}_\nu]_\star$.

Similarly, we may introduce the equations

$$F_{z^1\bar{z}^1}+F_{z^2\bar{z}^2}+\chi_{z^1\bar{z}^1}+\chi_{z^2\bar{z}^2}=\tfrac{1}{4}(\phi_1^\dagger\star\phi_1-\phi_2^\dagger\star\phi_2)\quad\text{and}\quad F_{z^1z^2}+\chi_{z^1z^2}=-\tfrac{1}{4}\phi_2^\dagger\star\phi_1 \tag{3.30a}$$

and

$$D_{\bar{z}^1}\phi_1-D_{z^2}\phi_2=0\quad\text{and}\quad D_{\bar{z}^2}\phi_1+D_{z^1}\phi_2=0, \tag{3.30b}$$

where $\chi\in\Omega^2(\mathbb{R}^4,\mathrm{i}\mathbb{R})$ and

$$D_{z^a}\phi=\partial_{z^a}\phi-\phi\star\mathcal{B}_{z^a} \tag{3.30c}$$

is the (left) derivative. [These equations can formally be obtained from (3.19)–(3.22) by choosing $\mathcal{B}_{z^a}=-\mathcal{A}_{z^a}$ (i.e., $A_{+z^a}=0$) and putting $\chi_{+z^1\bar{z}^1}+\chi_{+z^2\bar{z}^2}=-\frac{1}{8}(\phi_1\star\phi_1^\dagger-\phi_2\star\phi_2^\dagger)$, $\chi_{+z^1z^2}=\frac{1}{8}\phi_1\star\phi_2^\dagger$, $\chi_{-z^a\bar{z}^a}=\chi_{z^a\bar{z}^a}$ and $\chi_{-z^1z^2}=\chi_{z^1z^2}$, where $\chi\in\Omega^2(\mathbb{R}^4,\mathrm{i}\mathbb{R})$. Again we should rescale $\Phi\mapsto\sqrt{2}\Phi$.] Now the curvature $F_{\mathcal{B}}$ is associated with the gauge potential $\mathcal{B}$, i.e., $F_{\mu\nu}=\partial_\mu\mathcal{B}_\nu-\partial_\nu\mathcal{B}_\mu+[\mathcal{B}_\mu,\mathcal{B}_\nu]_\star$.

We shall call (3.29) and (3.30) the perturbed noncommutative $U_+(1)$ and $U_-(1)$ SW equations. Obviously, the unperturbed equations appear for $\chi\equiv0$. Note that the systems (3.29) and (3.30) are totally equivalent and the only difference between them is an artifact of noncommutativity. The commutative limits of both cases are, of course, identical and produce (2.9). Moreover, in the commutative case the gauge transformations (3.23) reduce to the standard ones, i.e., one may choose the identity either for g_- or for g_+.

C. Operator form of the Abelian SW monopole equations

1. Weyl transform

Due to the nonlocal nature of the star product, explicit calculations might be quite tedious. It is therefore convenient to pass over to the operator formalism via the Weyl ordering $\mathcal{W}$ given by

$$\mathcal{W}: \tilde{f}(k) \mapsto \hat{f}(\hat{x}) = \frac{1}{(2\pi)^{2n}} \int_{\mathbb{R}^{2n}} \mathrm{d}^{2n}k \, \tilde{f}(k) \, e^{ik\hat{x}}, \tag{3.31a}$$

$$\mathcal{W}^{-1}: \hat{f}(\hat{x}) \mapsto \tilde{f}(k) = |\mathrm{Pf}(2\pi\theta)| \mathrm{Tr}\{e^{-ik\hat{x}} \hat{f}(\hat{x})\}, \tag{3.31b}$$

where $\tilde{f}(k)$ stands for the Fourier transform of $f(x) \in \mathcal{S}(\mathbb{R}^{2n})$,

$$f(x) \mapsto \tilde{f}(k) = \int_{\mathbb{R}^{2n}} \mathrm{d}^{2n}x \, f(x) e^{-ikx}. \tag{3.32}$$

Here $\mathcal{S}(\mathbb{R}^{2n})$ is the Schwartz space of fast decreasing functions on $\mathbb{R}^{2n}$, "Tr" denotes the trace in the operator representation of the noncommutative algebra and "Pf$(2\pi\theta)$" is the Pfaffian of $(2\pi\theta^{\alpha\beta})$. (However, in later considerations we shall make suitable choices for f which are weaker.) Also, in these equations kx is a shorthand notation for $k_\alpha x^\alpha$. One can verify (see, e.g., Ref. 26) that the following relations are true:

$$\mathcal{W}: f \star g \mapsto \hat{f}\hat{g} \quad \text{and} \quad \int_{\mathbb{R}^{2n}} \mathrm{d}^{2n}x \, f = |\mathrm{Pf}(2\pi\theta)| \mathrm{Tr}\hat{f}. \tag{3.33}$$

We may regard the coordinates $\hat{x}^\alpha$ as operators which act on some Fock space $\mathcal{H}$, specified in Sec. IV, and satisfy the commutation relations $[\hat{x}^\alpha, \hat{x}^\beta] = i\theta^{\alpha\beta}$. With a proper choice of coordinates the parameters $\theta^{\alpha\beta}$ will have the canonical form (3.6). For the complex coordinates $\hat{z}^a$, also considered as operators in $\mathcal{H}$, we then get

$$[\hat{z}^a, \hat{z}^b] = 0 \quad \text{and} \quad [\hat{z}^a, \hat{\bar{z}}^{\bar{a}}] = \theta^{a\bar{a}}, \quad \text{for} \quad a, b = 1, \ldots, n. \tag{3.34}$$

A straightforward calculation shows that coordinate derivatives are now inner derivations of this algebra, i.e.,

$$\hat{\partial}_{z^a} \hat{f} = \theta_{a\bar{a}} [\hat{\bar{z}}^{\bar{a}}, \hat{f}] \quad \text{and} \quad \hat{\partial}_{\bar{z}^{\bar{a}}} \hat{f} = \theta_{\bar{a}a} [\hat{z}^a, \hat{f}]. \tag{3.35}$$

In the operator formulation, the perturbed noncommutative $U_+(1) \times U_-(1)$ SW equations (3.19) and (3.22) retain their form,

$$\hat{F}_{+z^1\bar{z}^1} + \hat{F}_{+z^2\bar{z}^2} + \hat{\chi}_{+z^1\bar{z}^1} + \hat{\chi}_{+z^2\bar{z}^2} = -\tfrac{1}{8}(\hat{\phi}_1 \hat{\phi}_1^\dagger - \hat{\phi}_2 \hat{\phi}_2^\dagger), \tag{3.36a}$$

$$\hat{F}_{+z^1z^2} + \hat{\chi}_{+z^1z^2} = \tfrac{1}{8} \hat{\phi}_1 \hat{\phi}_2^\dagger, \tag{3.36b}$$

$$\hat{F}_{-z^1\bar{z}^1} + \hat{F}_{-z^2\bar{z}^2} + \hat{\chi}_{-z^1\bar{z}^1} + \hat{\chi}_{-z^2\bar{z}^2} = \tfrac{1}{8}(\hat{\phi}_1^\dagger \hat{\phi}_1 - \hat{\phi}_2^\dagger \hat{\phi}_2), \tag{3.36c}$$

$$\hat{F}_{-z^1z^2} + \hat{\chi}_{-z^1z^2} = -\tfrac{1}{8} \hat{\phi}_2^\dagger \hat{\phi}_1, \tag{3.36d}$$

and

$$\hat{D}_{\bar{z}^1} \hat{\phi}_1 - \hat{D}_{z^2} \hat{\phi}_2 = 0 \quad \text{and} \quad \hat{D}_{\bar{z}^2} \hat{\phi}_1 + \hat{D}_{z^1} \hat{\phi}_2 = 0, \tag{3.36e}$$

where

$$\hat{D}_{z^a}\phi=\hat{\partial}_{z^a}\hat{\phi}+\hat{A}_{+z^a}\hat{\phi}-\hat{\phi}\hat{A}_{-z^a}. \tag{3.37}$$

In order to simplify our notation, from now on we omit the hats over the operators.

2. $U_+(1)\times U_-(1)$ SW action functional

Having introduced the $U_+(1)\times U_-(1)$ noncommutative extension of the SW equations (3.36), we shall define an appropriate action functional. For this purpose we switch back to real coordinates.

Let ${}^t\Phi=(\phi_1,\phi_2)$ and ${}^t\Phi^*:=(\phi_2^\dagger,-\phi_1^\dagger)$. (Note that "$*$" is nothing but a spinor conjugation.) Then the noncommutative deformation of the action functional (2.10) will have the form

$$\begin{aligned}\mathrm{SW}_\chi(A_+,A_-,\Phi;\theta)=\tfrac{1}{2}|\mathrm{Pf}(2\pi\theta)|\mathrm{Tr}\{&|\mathcal{D}_{A_+,A_-}\Phi|^2+|(\mathcal{D}_{A_+,A_-}\Phi)^\dagger|^2+\ 8|F^+_{A_+}\\&+\chi^+_+-\sigma^+(\Phi\otimes\Phi^\dagger)_0|^2+8|F^+_{A_-}+\chi^+_--\sigma^+(\Phi^*\otimes(\Phi^*)^\dagger)_0|^2\},\end{aligned} \tag{3.38}$$

where

$$|\psi|^2:=\psi_1\psi_1^\dagger+\psi_2\psi_2^\dagger \quad\text{and}\quad |\psi^\dagger|^2:=\psi_1^\dagger\psi_1+\psi_2^\dagger\psi_2, \tag{3.39}$$

for any ${}^t\psi=(\psi_1,\psi_2)$. Here, $\mathcal{D}_{A_+,A_-}$ denotes the Dirac operator depending on the two gauge potentials A_+ and A_-, i.e.,

$$\mathcal{D}_{A_+,A_-}\Phi=\begin{pmatrix}-D_4+iD_3 & D_2+iD_1\\ -D_2+iD_1 & -D_4-iD_3\end{pmatrix}\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix}, \tag{3.40}$$

where the covariant derivatives D_μ are given by (3.37). Note that the prefactors in (3.38) are adjusted in such a way that we recover (2.10) in the commutative limit. It is not difficult to see that the (perturbed) $U_+(1)\times U_-(1)$ SW equations following from (3.38) are given by the equations

$$\mathcal{D}_{A_+,A_-}\Phi=0,\quad F^+_{A_+}+\chi^+_+=\sigma^+(\Phi\otimes\Phi^\dagger)_0 \quad\text{and}\quad F^+_{A_-}+\chi^+_-=\sigma^+(\Phi^*\otimes(\Phi^*)^\dagger)_0, \tag{3.41}$$

whose solutions minimize the action functional (3.38). In components these equations coincide with (3.36).

Assuming that $\phi_{1,2}$ and $F_{\pm\mu\nu}$ are of proper trace-class, e.g., $|\mathrm{Tr}\phi_{1,2}|<\infty$ and $|\mathrm{Tr}F_{\pm\mu\nu}|<\infty$, we can show that

$$\mathrm{SW}_\chi(A_+,A_-,\Phi;\theta)=E_\chi(A_+,A_-,\Phi;\theta)+16\pi^2K_\chi-|\mathrm{Pf}(2\pi\theta)|\mathrm{Tr}\mathcal{T}, \tag{3.42}$$

where the functionals E_χ and K_χ are given by

$$\begin{aligned}E_\chi(A_+,A_-,\Phi;\theta)=|\mathrm{Pf}(2\pi\theta)|\mathrm{Tr}\{&2|F_{A_+}|^2+2|F_{A_-}|^2+\tfrac{1}{2}|D_{A_+,A_-}\Phi|^2+\tfrac{1}{2}|(D_{A_+,A_-}\Phi)^\dagger|^2\\&+\ 4|\chi^+_+-\sigma^+(\Phi\otimes\Phi^\dagger)_0|^2+4|\chi^+_--\sigma^+(\Phi^*\otimes(\Phi^*)^\dagger)_0|^2\}\end{aligned} \tag{3.43}$$

and

$$K_\chi=-\frac{1}{8\pi^2}|\mathrm{Pf}(2\pi\theta)|\mathrm{Tr}\sum_{i=\pm}\{F^+_{i\mu\nu},\chi^+_{i\mu\nu}\}. \tag{3.44}$$

The topological term $\mathcal{T}$ reads as

$$\mathcal{T}=\sum_{i=\pm}(F_{i\mu\nu}*F_{i\mu\nu}+\nabla_{i\mu}\mathcal{J}_{i\mu}). \tag{3.45a}$$

Here

$$\nabla_{\pm\mu}\cdot := \partial_\mu \cdot + [A_{\pm\mu}, \cdot\ ], \tag{3.45b}$$

"$*$" denotes the Hodge operator and $\{A,B\} := AB + BA$. The currents $\mathcal{J}_{\pm\mu}$ depend in a particular fashion on the fields ϕ_1 and ϕ_2, their derivatives and on the gauge potentials $A_{\pm\mu}$. The explicit derivation of (3.42) and the expressions for the currents $\mathcal{J}_{\pm\mu}$ are given in Appendix A. Note that similarly to the commutative case the functionals $E_\chi + 16\pi^2 K_\chi$ and SW_χ yield the same equations of motion. The integration of (3.45a) yields the topological charge

$$Q = -\frac{1}{8\pi^2}|\mathrm{Pf}(2\pi\theta)|\mathrm{Tr}\mathcal{T}, \tag{3.46}$$

for the considered field configuration (A_+, A_-, Φ) on $\mathbb{R}^4_\theta$.

3. Generalized coupled vortex equations

Let us put one component of Φ to zero, e.g., consider the case ${}^t\Phi = (\phi_1, \phi_2) =: (\phi, 0)$. [Note that in the case of Kähler manifolds ($\mathbb{R}^4$ is trivially Kähler) the field ϕ can be regarded as a scalar.[20,21]] Moreover, we choose

$$\chi_{\pm z^1 z^2} = 0 \quad \text{and} \quad \chi_{\pm z^1 \bar{z}^1} + \chi_{\pm z^2 \bar{z}^2} = \mp \tfrac{1}{8} v_\pm, \tag{3.47}$$

where $v_\pm$ are some Hermitian operators acting on $\mathcal{H}$. Then the energy functional (3.43) turns into

$$\begin{aligned} E_\chi(A_+, A_-, \Phi; \theta) = |\mathrm{Pf}(2\pi\theta)|\mathrm{Tr}\{&F_{+\mu\nu}F^\dagger_{+\mu\nu} + F_{-\mu\nu}F^\dagger_{-\mu\nu} + \tfrac{1}{2}D_\mu\phi(D_\mu\phi)^\dagger + \tfrac{1}{2}(D_\mu\phi)^\dagger D_\mu\phi \\ &+ \tfrac{1}{8}(v_+ - \phi\phi^\dagger)^2 + \tfrac{1}{8}(v_- - \phi^\dagger\phi)^2\}, \end{aligned} \tag{3.48a}$$

and K_χ is given by

$$K_\chi = -\frac{i}{32\pi^2}|\mathrm{Pf}(2\pi\theta)|\mathrm{Tr}\{\{F_{+12} + F_{+34}, v_+\} - \{F_{-12} + F_{-34}, v_-\}\}. \tag{3.48b}$$

Also the currents $\mathcal{J}_{\pm\mu}$ have a fairly simple form,

$$\mathcal{J}_{+\mu} = \frac{i}{4}(\epsilon_{\mu\nu 12} + \epsilon_{\mu\nu 34})(\phi(D_\nu\phi)^\dagger - (D_\nu\phi)\phi^\dagger), \tag{3.49a}$$

$$\mathcal{J}_{-\mu} = -\frac{i}{4}(\epsilon_{\mu\nu 12} + \epsilon_{\mu\nu 34})(\phi^\dagger(D_\nu\phi) - (D_\nu\phi)^\dagger\phi), \tag{3.49b}$$

where $\epsilon_{\mu\nu\lambda\sigma}$ is the Levi-Civita symbol with $\epsilon_{1234} = 1$ (see the Appendix).

For our choices of Φ and $\chi_\pm$ the perturbed $U_+(1)\times U_-(1)$ SW equations in complex coordinates read as

$$F_{+z^1\bar{z}^1} + F_{+z^2\bar{z}^2} = \tfrac{1}{8}(v_+ - \phi\phi^\dagger) \quad \text{and} \quad F_{+z^1 z^2} = 0, \tag{3.50a}$$

$$F_{-z^1\bar{z}^1} + F_{-z^2\bar{z}^2} = -\tfrac{1}{8}(v_- - \phi^\dagger\phi) \quad \text{and} \quad F_{-z^1 z^2} = 0, \tag{3.50b}$$

$$D_{\bar{z}^1}\phi = 0 \quad \text{and} \quad D_{\bar{z}^2}\phi = 0. \tag{3.50c}$$

In the commutative case these equations were considered, e.g., in Ref. 9.

4. $U_{\pm}(1)$ SW action functionals

Having introduced the $U_+(1)\times U_-(1)$ SW functionals, we are now interested in proper functionals for the $U_{\pm}(1)$ cases (3.29) and (3.30). Let us first discuss the perturbed $U_+(1)$ SW equations. In this case the SW action functional takes the following form:

$$\mathrm{SW}_\chi(\mathcal{A},\Phi;\theta)=|\mathrm{Pf}(2\pi\theta)|\mathrm{Tr}\{|\mathcal{D}_{\mathcal{A}}\Phi|^2+2|F^+_{\mathcal{A}}+\chi^+-\sigma^+(\Phi\otimes\Phi^\dagger)_0|^2\}. \tag{3.51}$$

Note that now the Dirac operator depends only on $\mathcal{A}$ and the covariant derivatives are given by (3.29c). Also here the prefactors have been chosen such that the correct commutative limit will be obtained. As before, the functional SW_χ may be rewritten as

$$\mathrm{SW}_\chi(\mathcal{A},\Phi;\theta)=E_\chi(\mathcal{A},\Phi;\theta)+16\pi^2K_\chi-|\mathrm{Pf}(2\pi\theta)|\mathrm{Tr}\mathcal{T}, \tag{3.52}$$

where E_χ turns out to be

$$E_\chi(\mathcal{A},\Phi;\theta)=|\mathrm{Pf}(2\pi\theta)|\mathrm{Tr}\{|F_{\mathcal{A}}|^2+|D_{\mathcal{A}}\Phi|^2+2|\chi^+-\sigma^+(\Phi\otimes\Phi^\dagger)_0|^2\}. \tag{3.53}$$

The Chern–Simons term K_χ reads as

$$K_\chi=-\frac{1}{16\pi^2}|\mathrm{Pf}(2\pi\theta)|\mathrm{Tr}\{F^+_{\mu\nu},\chi^+_{\mu\nu}\}, \tag{3.54}$$

and the topological term $\mathcal{T}$ is given by

$$\mathcal{T}=\tfrac{1}{4}\{F_{\mu\nu},{*F}_{\mu\nu}\}+\nabla_\mu\mathcal{J}_\mu,\quad \text{with}\quad \nabla_\mu\mathcal{J}_\mu=\partial_\mu\mathcal{J}_\mu+[\mathcal{A}_\mu,\mathcal{J}_\mu], \tag{3.55}$$

implying the charge

$$Q=-\frac{1}{8\pi^2}|\mathrm{Pf}(2\pi\theta)|\mathrm{Tr}\mathcal{T}. \tag{3.56}$$

Again all equations simplify essentially if one chooses ${}^t\Phi=(\phi_1,\phi_2)=(\phi,0)$, $\chi_{z^1z^2}=0$ and $\chi_{z^1\bar{z}^1}+\chi_{z^2\bar{z}^2}=-\frac{1}{4}v$, where v is some Hermitian operator. Then E_χ and K_χ are given by

$$E_\chi(\mathcal{A},\Phi;\theta)=|\mathrm{Pf}(2\pi\theta)|\mathrm{Tr}\{\tfrac{1}{2}F_{\mu\nu}F^\dagger_{\mu\nu}+D_\mu\phi(D_\mu\phi)^\dagger+\tfrac{1}{4}(v-\phi\phi^\dagger)^2\} \tag{3.57a}$$

and

$$K_\chi=-\frac{i}{32\pi^2}|\mathrm{Pf}(2\pi\theta)|\mathrm{Tr}\{F_{12}+F_{34},v\}. \tag{3.57b}$$

The current $\mathcal{J}_\mu$ reduces in this case to

$$\mathcal{J}_\mu=\frac{i}{2}(\epsilon_{\mu\nu12}+\epsilon_{\mu\nu34})(\phi(D_\nu\phi)^\dagger-(D_\nu\phi)\phi^\dagger). \tag{3.58}$$

Finally, the perturbed $U_+(1)$ SW equations read as

$$F_{z^1\bar{z}^1}+F_{z^2\bar{z}^2}=\tfrac{1}{4}(v-\phi\phi^\dagger)\quad\text{and}\quad F_{z^1z^2}=0, \tag{3.59a}$$

$$D_{\bar{z}^1}\phi=0\quad\text{and}\quad D_{\bar{z}^2}\phi=0. \tag{3.59b}$$

In the commutative case these v-vortex equations in four dimensions were considered, e.g., in Ref. 9. Note that in a similar manner one can write down the functionals corresponding to the $U_-(1)$ case (3.30). Since they look essentially the same as the above-introduced $U_+(1)$ functionals we refrain from writing down their explicit form.

IV. PARTICULAR SOLUTIONS

A. Operator realization

The form of the Heisenberg algebra type commutation relations (3.34) suggests that the algebra $\mathbb{R}^4_\theta$ may be represented by a pair of harmonic oscillators in the two-oscillator Fock space $\mathcal{H}\cong\mathcal{H}_1\otimes\mathcal{H}_2\cong\oplus_{n_1,n_2}\mathbb{C}|n_1,n_2\rangle$. We introduce, as usual, annihilation and creation operators $\{c_a,c_a^\dagger\}_{a=1,2}$, satisfying $[c_a,c_a^\dagger]=1$. They act on $\mathcal{H}$ and are defined by the relations

$$c_1|n_1,n_2\rangle=\sqrt{n_1}\,|n_1-1,n_2\rangle \quad \text{and} \quad c_1^\dagger|n_1,n_2\rangle=\sqrt{n_1+1}\,|n_1+1,n_2\rangle, \tag{4.1a}$$

$$c_2|n_1,n_2\rangle=\sqrt{n_2}\,|n_1,n_2-1\rangle \quad \text{and} \quad c_2^\dagger|n_1,n_2\rangle=\sqrt{n_2+1}\,|n_1,n_2+1\rangle, \tag{4.1b}$$

where $\{|n_1,n_2\rangle \mid n_1,n_2\in\mathbb{N}_0\}$ form an orthonormal basis in $\mathcal{H}$. The commutation relations (3.34) imply that the operators $\{c_a,c_a^\dagger\}_{a=1,2}$ have the form

$$c_1:=\frac{\hat z^1}{\sqrt{\theta^{\bar 1\bar 1}}}\frac{1+\mathrm{sgn}(\theta^{\bar 1\bar 1})}{2}+\frac{\hat{\bar z}^{\bar 1}}{\sqrt{\theta^{\bar 1\bar 1}}}\frac{1-\mathrm{sgn}(\theta^{\bar 1\bar 1})}{2} \quad \text{and}$$

$$c_1^\dagger:=\frac{\hat{\bar z}^{\bar 1}}{\sqrt{\theta^{\bar 1\bar 1}}}\frac{1+\mathrm{sgn}(\theta^{\bar 1\bar 1})}{2}+\frac{\hat z^1}{\sqrt{\theta^{\bar 1\bar 1}}}\frac{1-\mathrm{sgn}(\theta^{\bar 1\bar 1})}{2}, \tag{4.2a}$$

$$c_2:=\frac{\hat z^2}{\sqrt{\theta^{\bar 2\bar 2}}}\frac{1+\mathrm{sgn}(\theta^{\bar 2\bar 2})}{2}+\frac{\hat{\bar z}^{\bar 2}}{\sqrt{\theta^{\bar 2\bar 2}}}\frac{1-\mathrm{sgn}(\theta^{\bar 2\bar 2})}{2} \quad \text{and}$$

$$c_2^\dagger:=\frac{\hat{\bar z}^{\bar 2}}{\sqrt{\theta^{\bar 2\bar 2}}}\frac{1+\mathrm{sgn}(\theta^{\bar 2\bar 2})}{2}+\frac{\hat z^2}{\sqrt{\theta^{\bar 2\bar 2}}}\frac{1-\mathrm{sgn}(\theta^{\bar 2\bar 2})}{2}. \tag{4.2b}$$

We introduce so-called shift operators $S^{(a)}$ acting on the Fock spaces $\mathcal{H}_a$. They are partially isometric operators sending the Fock space $\mathcal{H}_a$ to its subspace $(\mathbb{1}^{(a)}-P_0^{(a)})\mathcal{H}_a$, where we denote by $P_0^{(a)}=|0\rangle_a\langle 0|_a$ the orthogonal projector onto the ground state of $\mathcal{H}_a$ and $\mathbb{1}^{(a)}-P_0^{(a)}$ is the complement projector. Then

$$S^{(a)}:\mathcal{H}_a\to(\mathbb{1}^{(a)}-P_0^{(a)})\mathcal{H}_a, \quad \text{with} \quad S^{(a)\dagger}S^{(a)}=\mathbb{1}^{(a)} \quad \text{and} \quad S^{(a)}S^{(a)\dagger}=\mathbb{1}^{(a)}-P_0^{(a)}. \tag{4.3}$$

The operator $S^{(a)}$ may be given by the explicit formula

$$S^{(a)}=\sum_{n\geqslant 0}|n+1\rangle_a\langle n|_a. \tag{4.4}$$

We will sometimes drop the index "a" on the state $|n\rangle_a$ in the following if the meaning is clear from the context.

The next step is to construct a shift operator S on $\mathcal{H}\cong\mathcal{H}_1\otimes\mathcal{H}_2$ such that

$$S:\mathcal{H}\to(\mathbb{1}-P_0)\mathcal{H}, \quad \text{with} \quad P_0=|0,0\rangle\langle 0,0|, \tag{4.5}$$

and $S^\dagger S=\mathbb{1}$ and $SS^\dagger=\mathbb{1}-P_0$. A naive idea to take simply the tensor product $S^{(1)}\otimes S^{(2)}$ does not work. One possible realization of the required operator S is given by the formula[27]

$$S=\mathbb{1}+\sum_{n\geqslant 0}\,(|n+1\rangle\langle n|-|n\rangle\langle n|)\otimes P_0^{(2)}=\mathbb{1}+(S^{(1)}-\mathbb{1}^{(1)})\otimes P_0^{(2)}, \tag{4.6}$$

but there are also other realizations (see, e.g., Ref. 28).

For later convenience we introduce the operators

$$X_{\pm z^a} := A_{\pm z^a} + \theta_{a\bar{a}}\bar{z^a} \quad \text{and} \quad X_{\pm \bar{z}^{\bar{a}}} := A_{\pm \bar{z}^{\bar{a}}} + \theta_{\bar{a}a} z^a, \quad \text{for} \quad a = 1,2. \tag{4.7}$$

Then a short calculation of the YM curvature yields

$$F_{\pm z^1 z^2} = [X_{\pm z^1}, X_{\pm z^2}], \quad F_{\pm z^1 \bar{z}^{\bar{2}}} = [X_{\pm z^1}, X_{\pm \bar{z}^{\bar{2}}}], \quad F_{\pm z^2 \bar{z}^{\bar{1}}} = [X_{\pm z^2}, X_{\pm \bar{z}^{\bar{1}}}], \tag{4.8a}$$

$$F_{\pm z^1 \bar{z}^{\bar{1}}} = [X_{\pm z^1}, X_{\pm \bar{z}^{\bar{1}}}] + \theta_{1\bar{1}}, \quad F_{\pm z^2 \bar{z}^{\bar{2}}} = [X_{\pm z^2}, X_{\pm \bar{z}^{\bar{2}}}] + \theta_{2\bar{2}}, \tag{4.8b}$$

and the covariant derivatives become

$$D_{z^a}\phi = X_{+z^a}\phi - \phi X_{-z^a} \quad \text{and} \quad D_{\bar{z}^{\bar{a}}}\phi = X_{+\bar{z}^{\bar{a}}}\phi - \phi X_{-\bar{z}^{\bar{a}}}. \tag{4.9}$$

B. Solutions to the perturbed SW equations

1. $U_+(1)\times U_-(1)$ SW monopole equations

Let us consider Eqs. (3.50) rewritten in operator form. For the operators (4.7) we take (cf., e.g., Refs. 29, 30)

$$X_{\pm z^a} = \theta_{a\bar{a}} S^N \bar{z^a} (S^\dagger)^N + \sum_{n=0}^{N-1} \lambda_{a,n} |n\rangle\langle n| \otimes P_0^{(2)}, \tag{4.10}$$

where the shift operator S is given by (4.6), $\lambda_{a,n} \in \mathbb{C}$ and $N \in \mathbb{N}$. Then the commutator $[X_{\pm z^a}, X_{\pm \bar{z}^{\bar{a}}}]$ is readily computed to be

$$[X_{\pm z^a}, X_{\pm \bar{z}^{\bar{a}}}] = -\theta_{a\bar{a}}(\mathbb{1} - \mathcal{P}_N), \tag{4.11}$$

where $\mathcal{P}_N$ is given by

$$\mathcal{P}_N := \sum_{n=0}^{N-1} |n\rangle\langle n| \otimes P_0^{(2)}. \tag{4.12}$$

It easy to see that the second equations of (3.50a) and (3.50b) are trivially satisfied. Choosing $v_- \equiv 0$ and

$$\phi = \sqrt{8(\theta_{1\bar{1}} + \theta_{2\bar{2}})}\, \mathcal{P}_N, \tag{4.13}$$

we can solve (3.50c) and the first equation of (3.50b) consistently, while the first equation of (3.50a) implies that

$$v_+ = 16(\theta_{1\bar{1}} + \theta_{2\bar{2}})\mathcal{P}_N. \tag{4.14}$$

Note that the moduli $\lambda_{a,n}$ in (4.10) can be interpreted as position parameters (see, e.g., Refs. 29, 31, 32).

Obviously, the components (4.8) of the curvature and the field ϕ are of proper trace-class. Moreover, it can be easily checked that ϕ is covariantly constant, i.e., along with $D_{\bar{z}^{\bar{a}}}\phi = 0$, required by the SW equations, we also have $D_{z^a}\phi = 0$. This means that the currents $\mathcal{J}_{\pm\mu}$ (3.49) vanish identically. Thus, it is straightforward to evaluate the topological charge (3.46) for this configuration. What we find for the topological term (3.45a) is

$$\mathcal{I} = -8\,\frac{1}{\theta^{12}\theta^{\bar{3}\bar{4}}}\,\mathcal{P}_N. \tag{4.15}$$

Using $|\mathrm{Pf}(2\pi\theta)| = 4\pi^2 |\theta^{12}\theta^{\bar{3}\bar{4}}|$, we get immediately a charge,

$$Q=4\epsilon_1\epsilon_2 N, \quad \text{with} \quad \epsilon_1:=\frac{|\theta^{12}|}{\theta^{12}} \quad \text{and} \quad \epsilon_2:=\frac{|\theta^{34}|}{\theta^{34}}. \tag{4.16}$$

[Note that the definition of the charge (3.46) differs by a factor of 2 in comparison with the standard one.] Note that K_χ given by (3.48b) is also finite. Therefore, the considered field configuration has finite energy

$$E_\chi=32\pi^2 f(\theta)N \quad \text{with} \quad f(\theta):=|\theta^{12}\theta^{34}|\left[\left(\frac{1}{\theta^{12}}\right)^2+\frac{1}{\theta^{12}\theta^{34}}+\left(\frac{1}{\theta^{34}}\right)^2\right]. \tag{4.17}$$

Let us now consider a slight generalization of the ansatz (4.10). We take first

$$X_{\pm z^a}=\theta_{a\bar{a}}S^{N_\pm}\overline{z^a}(S^\dagger)^{N_\pm}+\sum_{n=0}^{N_\pm-1}\lambda^\pm_{a,n}|n\rangle\langle n|\otimes P_0^{(2)}, \tag{4.18a}$$

and find that $[X_{\pm z^a},X_{\pm\bar{z}^{\bar{a}}}]=-\theta_{a\bar{a}}(\mathbb{1}-\mathcal{P}_{N_\pm})$. Second, choosing

$$\phi=\sqrt{8(\theta_{1\bar{1}}+\theta_{2\bar{2}})}\,S^{N_+}(S^\dagger)^{N_-} \tag{4.18b}$$

and the perturbations $v_\pm$ such that

$$v_+=8(\theta_{1\bar{1}}+\theta_{2\bar{2}}) \quad \text{and} \quad v_-=8(\theta_{1\bar{1}}+\theta_{2\bar{2}})(1-2\mathcal{P}_{N_-}), \tag{4.19}$$

one can easily show that our equations are solved consistently. Again, all our operators are of proper trace-class for $N_+\neq N_-$. In the case of $N_+=N_-$ one encounters a slight subtlety since the field ϕ is not of trace-class contrary to our assumption. However, potentially dangerous terms, like $\phi F_{-12}\phi^\dagger$ for instance (see the Appendix), which occurred in (3.43), are obviously zero when $N_+=N_-$. Moreover, the field ϕ is covariantly constant, as one can readily check. Therefore, the currents $\mathcal{J}_{\pm\mu}$ (3.49) are identically zero. The topological term (3.45a) for this configuration thus reads as

$$\mathcal{T}=-4\,\frac{1}{\theta^{12}\theta^{34}}(\mathcal{P}_{N_+}+\mathcal{P}_{N_-}), \tag{4.20}$$

which produces a topological charge $Q=2\epsilon_1\epsilon_2(N_++N_-)$. [Note that the definition of the charge (3.46) differs by a factor of 2 in comparison with the standard one.] The functional E_χ for these solutions computes to

$$E_\chi=16\pi^2 f(\theta)(N_++N_-), \tag{4.21}$$

where $f(\theta)$ is given by (4.17).

2. $U_+(1)$ SW monopole equations

Consider now Eqs. (3.59) and choose the ansatz

$$X_{z^a}=\theta_{a\bar{a}}S^N\overline{z^a}(S^\dagger)^N+\sum_{n=0}^{N-1}\lambda_{a,n}|n\rangle\langle n|\otimes P_0^{(2)} \quad \text{and} \quad \phi=\gamma S^N, \tag{4.22}$$

with $\lambda_{a,n}\in\mathbb{C}$ and $\gamma\in\mathbb{R}$. Then the first equation of (3.59a) can be solved by $\theta_{1\bar{1}}+\theta_{2\bar{2}}=\frac{1}{4}\gamma^2=\frac{1}{4}v$, while the other two equations are trivially satisfied. The only nonvanishing components of the curvature are $F_{z^a\bar{z}^{\bar{a}}}=\theta_{a\bar{a}}\mathcal{P}_N$. Note that the expression for ϕ is covariantly constant which implies the vanishing of the current (3.58). The charge (3.56) is equal to $Q=\epsilon_1\epsilon_2 N$ and the energy E_χ is $8\pi^2 f(\theta)N$, where $f(\theta)$ is given by (4.17).

Consider again Eqs. (3.59). Besides the shift type solution for ϕ we can also find a projector type solution. Namely, we choose $\phi=\gamma P_0$ with $\gamma\in\mathbb{R}$,

$$v=(4(\theta_{1\bar{1}}+\theta_{2\bar{2}})+\gamma^2)P_0, \tag{4.23}$$

and the X_{z^a}'s as previously. With this choice the first two equations of (3.59a) are trivially satisfied, while (3.59b) yields the condition $P_0 z^a=0$. Hence, we have to set $\theta^{a\bar{a}}<0$. Again, the only nonvanishing components of the curvature are $F_{z^a\bar{z}^a}=\theta_{a\bar{a}}P_0$. Moreover, we have

$$D_1\phi=-iD_2\phi=-\sqrt{\theta_{1\bar{1}}}\gamma|0,0\rangle\langle 1,0| \quad \text{and} \quad D_3\phi=-iD_4\phi=-\sqrt{\theta_{2\bar{2}}}\gamma|0,0\rangle\langle 0,1|, \tag{4.24}$$

which imply the vanishing of the current $\mathcal{J}_\mu$ (3.58). The topological charge for this configuration is $Q=\epsilon_1\epsilon_2$.

C. Solutions to the unperturbed SW equations

In this section we shall consider solutions to the unperturbed SW equations. We concentrate on the case of the unperturbed $U_+(1)$ equations, i.e., (3.59) with $v\equiv 0$, as an illustrative example.

1. $U_+(1)$ SW monopole equations with $\Phi\equiv 0$

In this case we obtain the noncommutative Abelian ASDYM equations. Solutions to these equations, i.e., noncommutative Abelian instantons, have been known for quite some time.[16] However, for the sake of completeness we briefly review their construction. Note that in the case $\Phi\equiv 0$ the current $\mathcal{J}_\mu$ is identically zero.

In terms of the operators (4.7) the Abelian ASDYM equations read as

$$[X_{z^1},X_{\bar{z}^1}]+[X_{z^2},X_{\bar{z}^2}]+\theta_{1\bar{1}}+\theta_{2\bar{2}}=0 \quad \text{and} \quad [X_{z^1},X_{z^2}]=0. \tag{4.25}$$

Again we consider an ansatz for X_{z^a} of the form (4.22). This ansatz yields solutions to the equations (4.25) if the deformation tensor $\theta^{\mu\nu}$ is anti-self-dual which trivially follows from (4.22). The only nonvanishing components of the curvature are $F_{z^a\bar{z}^a}=\theta_{a\bar{a}}\mathcal{P}_N$ implying that the charge (3.56) is equal to $Q=-N$. The moduli $\lambda_{a,n}$ entering the solution are position parameters showing the location of the noncommutative instantons[33] (see also Ref. 32 for a recent review).

It is also possible to consider the case of ASDYM equations on a self-dual background for which $\theta^{1\bar{1}}=\theta^{2\bar{2}}=:\theta$. Let us assume that $\theta>0$, which leads to the definitions $c_1=z^1/\sqrt{\theta}$ and $c_2=z^2/\sqrt{\theta}$. We choose the ansatz[34,35]

$$X_{z^1}=-\frac{1}{\theta}S^\dagger\bar{z}^{\bar{1}}f(N)S=-\frac{1}{\sqrt{\theta}}S^\dagger c_1^\dagger f(N)S \quad \text{and} \quad X_{z^2}=-\frac{1}{\theta}S^\dagger\bar{z}^{\bar{2}}f(N)S=-\frac{1}{\sqrt{\theta}}S^\dagger c_2^\dagger f(N)S, \tag{4.26}$$

and assume that $f(N)|0\rangle=f(0)|0\rangle=0$, where $N:=N_1+N_2:=c_1^\dagger c_1+c_2^\dagger c_2$. Then the equation $[X_{z^1},X_{z^2}]=0$ is trivially satisfied. A short calculation yields for $f(N)$ the result[34,35]

$$f^2(N)=\frac{N(N+3)}{(N+1)(N+2)}. \tag{4.27}$$

The nonvanishing components of the curvature in this case are

$$F_{z^a\bar{z}^b}=\frac{1}{\theta}S^\dagger c_a^\dagger(f^2(N+1)-f^2(N))c_b S, \tag{4.28a}$$

$$F_{z^a\bar{z}^a}=\frac{1}{\theta}S^\dagger[(N_a+1)f^2(N)-N_a f^2(N-1)-1]S. \tag{4.28b}$$

Using these expressions, we compute the topological charge (3.56) to be -1. A straightforward extension of the above ansatz allows one to construct multi-instanton configurations, as well.[34,35]

2. Fock spaces with indefinite norm

Let us now discuss the case when Φ does not vanish identically. For that we relax the condition of positivity of the norm of the Fock spaces $\mathcal{H}_{1,2}$ and assume instead that at least one of them has an indefinite norm (cf. Ref. 36). For instance, we can introduce a collection of the creation and annihilation operators $\{c_a, c_a^\dagger\}_{a=1,2}$, satisfying $[c_1, c_1^\dagger]=1$, $[c_2, c_2^\dagger]=-1$, and defined by the relations

$$c_1|n_1,n_2\rangle=\sqrt{n_1}\,|n_1-1,n_2\rangle \quad \text{and} \quad c_1^\dagger|n_1,n_2\rangle=\sqrt{n_1+1}\,|n_1+1,n_2\rangle, \tag{4.29a}$$

$$c_2|n_1,n_2\rangle=-\sqrt{n_2}\,|n_1,n_2-1\rangle \quad \text{and} \quad c_2^\dagger|n_1,n_2\rangle=\sqrt{n_2+1}\,|n_1,n_2+1\rangle, \tag{4.29b}$$

substituting (4.1). The normalization condition is modified to $\langle n_1,n_2|m_1,m_2\rangle = (-1)^{n_2}\delta_{n_1m_1}\delta_{n_2m_2}$. The identity operator is given by

$$\mathbb{1}=\sum_{n_1,n_2}(-1)^{n_2}|n_1,n_2\rangle\langle n_1,n_2|. \tag{4.30}$$

Moreover, we have to redefine the relations between $\{c_a, c_a^\dagger\}_{a=1,2}$ and $\{z^a, \bar{z}^{\bar{a}}\}_{a=1,2}$ so that

$$c_1 := \frac{\hat{z}^1}{\sqrt{\theta^{\bar{1}\bar{1}}}}\frac{1+\mathrm{sgn}(\theta^{\bar{1}\bar{1}})}{2}+\frac{\hat{\bar{z}}^{\bar{1}}}{\sqrt{\theta^{\bar{1}\bar{1}}}}\frac{1-\mathrm{sgn}(\theta^{\bar{1}\bar{1}})}{2} \quad \text{and}$$

$$c_1^\dagger := \frac{\hat{\bar{z}}^{\bar{1}}}{\sqrt{\theta^{\bar{1}\bar{1}}}}\frac{1+\mathrm{sgn}(\theta^{\bar{1}\bar{1}})}{2}+\frac{\hat{z}^1}{\sqrt{\theta^{\bar{1}\bar{1}}}}\frac{1-\mathrm{sgn}(\theta^{\bar{1}\bar{1}})}{2}, \tag{4.31a}$$

$$c_2 := \frac{\hat{\bar{z}}^{\bar{2}}}{\sqrt{\theta^{\bar{2}\bar{2}}}}\frac{1+\mathrm{sgn}(\theta^{\bar{2}\bar{2}})}{2}+\frac{\hat{z}^2}{\sqrt{\theta^{\bar{2}\bar{2}}}}\frac{1-\mathrm{sgn}(\theta^{\bar{2}\bar{2}})}{2} \quad \text{and}$$

$$c_2^\dagger := \frac{\hat{z}^2}{\sqrt{\theta^{\bar{2}\bar{2}}}}\frac{1+\mathrm{sgn}(\theta^{\bar{2}\bar{2}})}{2}+\frac{\hat{\bar{z}}^{\bar{2}}}{\sqrt{\theta^{\bar{2}\bar{2}}}}\frac{1-\mathrm{sgn}(\theta^{\bar{2}\bar{2}})}{2}. \tag{4.31b}$$

The definition of the shift operator $S^{(1)}$ remains the same, while for $S^{(2)}$ we obtain

$$S^{(2)}:\mathcal{H}_2\to(\mathbb{1}^{(2)}-P_0^{(2)})\mathcal{H}_2 \quad \text{with} \quad S^{(2)\dagger}S^{(2)}=-\mathbb{1}^{(2)} \quad \text{and} \quad S^{(2)}S^{(2)\dagger}=-(\mathbb{1}^{(2)}-P_0^{(2)}), \tag{4.32}$$

with the representation

$$S^{(2)}=\sum_{n\geqslant 0}(-1)^n|n+1\rangle_2\langle n|_2. \tag{4.33}$$

For an operator $S:\mathcal{H}\to(\mathbb{1}-P_0)\mathcal{H}$ on $\mathcal{H}$ with the properties $SS^\dagger=\mathbb{1}-P_0$ and $S^\dagger S=\mathbb{1}$, we can use the old expression (4.6), since the indefiniteness of the norm does not affect the verification of these properties. Indeed, S contains only the identity $\mathbb{1}$, given by (4.30), and the projector $P_0^{(2)}$ on $\mathcal{H}_2$.

3. $U_+(1)$ SW monopole equations with ${}^t\Phi=(\phi,0)$

We start from (3.59) with $v\equiv 0$. In this case the SW equations read as

$$F_{z^1\bar{z}^1}+F_{z^2\bar{z}^2}=-\tfrac{1}{4}\phi\phi^\dagger, \quad F_{z^1z^2}=0 \quad \text{and} \quad D_{\bar{z}^a}\phi=0, \tag{4.34}$$

where the covariant derivative D_{z^a} acts as $D_{z^a}\phi=-\theta_{a\bar{a}}\phi\bar{z}^{\bar{a}}+X_{z^a}\phi$. Suppose that $\mathcal{H}_1$ is positive normed while $\mathcal{H}_2$ is endowed with an indefinite norm. Using the definition (4.6) and the ansatz $X_{z^a}=\theta_{a\bar{a}}S\bar{z}^{\bar{a}}S^\dagger$, we find again (4.11). Assuming that $\phi=\gamma P_0$ with $\gamma\in\mathbb{R}$, we can solve the last equation of (4.34) if $P_0z^a=0$, i.e., $z^a\sim c_a^\dagger$. For $a=2$ this is satisfied because of our choice $\theta^{2\bar{2}}>0$ and for $a=1$ it implies $\theta^{1\bar{1}}<0$. The second equation of (4.34) is again identically satisfied, while the first one yields the condition $\theta_{1\bar{1}}+\theta_{2\bar{2}}=-\frac{1}{4}\gamma^2$, which makes sense due to the different signs of $\theta_{1\bar{1}}$ and $\theta_{2\bar{2}}$. The nonvanishing components of the curvature are $F_{z^a\bar{z}^a}=\theta_{a\bar{a}}P_0$ and one can readily verify that the current $\mathcal{J}_\mu$ from (3.58) has no contributions to the topological charge (3.56). Moreover, the computation of the topological charge gives -1. Note that the introduction of an indefinite norm on $\mathcal{H}_2$ was needed for having solutions to the equation $\theta_{1\bar{1}}+\theta_{2\bar{2}}=-\frac{1}{4}\gamma^2$ on the components of $\theta_{\mu\nu}$.

4. $U_+(1)$ SW monopole equations and vortices

Finally we discuss a case which is slightly different from the cases described above, in the sense that we fix the explicit form of the solutions on a two-dimensional subspace of $\mathbb{R}^4_\theta$ from the very beginning. This eventually results in the $U_+(1)$ vortex equations on the complementary two-dimensional subspace.

Again, let $\mathcal{H}_1$ be positive normed and $\mathcal{H}_2$ endowed with an indefinite norm, such that $[z^2,\bar{z}^2]=\theta^{2\bar{2}}>0$ and $[c_2,c_2^\dagger]=-1$. Furthermore, we choose an ansatz for X_{z^2} of the form $X_{z^2}=\theta_{2\bar{2}}\mathbb{1}^{(1)}\otimes S^{(2)}\bar{z}^{\bar{2}}S^{(2)\dagger}$. A short calculation yields the result $F_{z^2\bar{z}^2}=\theta_{2\bar{2}}\mathbb{1}^{(1)}\otimes P_0^{(2)}$. Assuming that $\mathcal{A}_{z^1}=\mathfrak{A}_{z^1}\otimes P_0^{(2)}$, we obtain $F_{z^1\bar{z}^1}=\mathfrak{F}_{z^1\bar{z}^1}\otimes P_0^{(2)}$. Similarly, we take $\phi=\psi\otimes P_0^{(2)}$. Then the equation $D_{\bar{z}^2}\phi=0$ implies the condition $P_0^{(2)}z^2=0$, which is identically satisfied due to the relation $z^2\sim c_2^\dagger$. Moreover, the equation $F_{z^1z^2}=0$ is trivially satisfied. Using $\theta_{2\bar{2}}=-1/\theta^{2\bar{2}}$, we finally arrive at the equations

$$\left\{\mathfrak{F}_{z^1\bar{z}^1}-\left(\frac{1}{\theta^{2\bar{2}}}-\frac{1}{4}\psi\psi^\dagger\right)\right\}\otimes P_0^{(2)}=0, \tag{4.35a}$$

$$(\partial_{\bar{z}^1}+\mathfrak{A}_{\bar{z}^1})\psi\otimes P_0^{(2)}=0. \tag{4.35b}$$

(Note that these equations can also be obtained in the context of the perturbed SW equations if one chooses the perturbation proportional to $P_0^{(2)}$. Then there is no necessity to introduce an indefinite normed space.) Rescaling $\psi\mapsto 2\,\tilde{\psi}/\sqrt{\theta^{2\bar{2}}}$ and introducing $\beta:=4/\theta^{2\bar{2}}$, we obtain the equations

$$\mathfrak{F}_{z^1\bar{z}^1}=\frac{\beta}{4}(1-\tilde{\psi}\tilde{\psi}^\dagger) \quad \text{and} \quad (\partial_{\bar{z}^1}+\mathfrak{A}_{\bar{z}^1})\tilde{\psi}=0, \tag{4.36}$$

on $\mathbb{R}^2_\theta\subset\mathbb{R}^4_\theta$. For $\beta=1$ they coincide with the standard $U_+(1)$ vortex equations. The equations (4.36) with $\theta^{1\bar{1}}=2\,\theta^{12}\neq 0$ and their explicit solutions were extensively discussed in the literature (see, e.g., Refs. 37, 38, 30). Note that the choice of the projector $P_0^{(2)}$ on $\mathcal{H}_2$ ensures a finite charge for this solution. To exemplify this case let us rewrite $\mathfrak{A}_{z^1}$ via $\mathfrak{X}_{z^1}=\mathfrak{A}_{z^1}+\theta_{1\bar{1}}\bar{z}^{\bar{a}}$ with $\mathfrak{X}_{z^1}=\theta_{1\bar{1}}(S^{(1)})^N\bar{z}^{\bar{1}}(S^{(1)\dagger})^N$. Moreover, suppose that $\tilde{\psi}=(S^{(1)})^N$. Then one readily verifies that $\theta_{1\bar{1}}=\beta/4=1/\theta^{2\bar{2}}$. Therefore, we end up with $F_{z^1\bar{z}^1}=\theta_{1\bar{1}}\mathcal{P}_N$ and $\phi=(2/\sqrt{\theta^{2\bar{2}}})\,(S^{(1)})^N\otimes P_0^{(2)}$. Note that $\theta^{1\bar{1}}<0$. The topological charge (3.46) for this configuration is $Q=-N$.

To summarize, we have described solutions on $\mathbb{R}^2_{\theta^{12}}\times\mathbb{R}^2_{\theta^{34}}$. It is also allowed to put θ^{12} to zero in order to have solutions on $\mathbb{R}^2\times\mathbb{R}^2_{\theta^{34}}$. Then the second equation of (4.36) reduces to $\mathfrak{A}_{\bar{z}^1}=-\partial_{\bar{z}^1}\log\tilde{\psi}$. Assuming that $\tilde{\psi}=e^{(u+iv)/2}$ has zeros at points z^1_n in the complex plane, we obtain from the first equation of (4.36) with $\beta=1$ (see, e.g., Refs. 39, 21),

$$\Delta u=e^u-1+4\pi\sum_{n=1}^{N}\delta^{(2)}(z^1-z^1_n,\bar{z}^{\dot{1}}-\bar{z}^{\dot{1}}_n), \tag{4.37}$$

i.e., the standard Liouville type equation on $\mathbb{R}^2\cong\mathbb{C}$. The moduli z^1_n are position parameters of the N-vortex solution on the z^1-plane. It is well known that this equation exhibits regular N-vortex solutions.[39]

D. Noncommutative solitons and *D*-branes

Without refering to string theory the $U_+(1)\times U_-(1)$ and $U_\pm(1)$ SW monopole equations are simply understood as noncommutative generalizations of the Abelian SW equations. In this section we shall discuss how one can interpret solutions to the noncommutative SW equations as D-brane configurations in a stringy context.

1. Brane–antibrane effective action

In the simplest case of type II superstrings living in the target space $\mathbb{R}^{9,1}$ a Dp-brane with a world volume $\mathbb{R}^{p,1}\hookrightarrow\mathbb{R}^{9,1}$ may be defined via a relative map,

$$\varphi:(\Sigma_2,\partial\Sigma_2)\to(\mathbb{R}^{9,1},\mathbb{R}^{p,1}), \tag{4.38}$$

where Σ_2 is a string world sheet with boundary $\partial\Sigma_2$. One may also consider $\overline{Dp}$-branes (=anti-Dp-branes) which are Dp-branes with opposite orientation and Ramond–Ramond (RR) charge.

It is well known that there are stable BPS Dp-branes in type IIA (even p) and type IIB (odd p) superstring theory. Besides that, it is also well known that a system consisting of coincident Dp-brane and $\overline{Dp}$-brane is unstable since open strings ending on these branes have a tachyonic mode ($M^2<0$) in the spectrum (see, e.g., Refs. 40–44 and references therein). This instability can be seen in the low energy effective action for the brane–antibrane pair. Namely, the effective field theory describing light excitations of this system contains two Abelian gauge potentials $A_\pm$ and a complex scalar ϕ (tachyon). The latter one is associated with modes of the open string stretched between brane and antibrane, and is believed to be subject to a ''Mexican hat'' potential. The tachyon carries charge one under the diagonal $U(1)$ subgroup of the group $U_+(1)\times U_-(1)$ with the generator diag$(i,-i)$ corresponding to the gauge potential A_+-A_-. After turning on a constant B-field (generating a noncommutativity tensor θ on $\mathbb{R}^{p,1}$ [45]) the theory becomes noncommutative and the tachyon field transforms in the bi-fundamental representation of $U_+(1)\times U_-(1)$.[46]

In perturbative string theory the first computations of the brane-antibrane effective action were performed in Ref. 47. The resulting effective Lagrangian reads as

$$\mathcal{L}^{(2)}=F_{+\hat{\alpha}\hat{\beta}}\overline{F_+^{\hat{\alpha}\hat{\beta}}}+F_{-\hat{\alpha}\hat{\beta}}\overline{F_-^{\hat{\alpha}\hat{\beta}}}+(D^{\hat{\alpha}}\phi)\overline{D_{\hat{\alpha}}\phi}+\frac{1}{4}(\tau^2-\phi\bar{\phi})^2, \tag{4.39}$$

where the covariant derivative is given by $D_{\hat{\alpha}}\phi=\partial_{\hat{\alpha}}\phi+(A_{+\hat{\alpha}}-A_{-\hat{\alpha}})\phi$, the overbar denotes complex conjugation, τ^2 is a constant and $\hat{\alpha},\hat{\beta},\ldots=0,1,\ldots,p$. This is not the full effective Lagrangian since the coupling between closed string RR fields and open strings gives an additional term $\mathcal{L}_{\mathrm{CS}}$ called the Chern–Simons term.[48] For constant components of the RR fields, which we now consider, this term does not contribute to the equations of motion, and therefore we will not discuss it here. Note that the terms given by (2.14) and (3.44) are of such a kind.

The tachyon potential given by (4.39) has the quartic form

$$V(\phi,\overline{\phi})=\tfrac{1}{4}(\tau^2-\phi\overline{\phi})^2. \tag{4.40}$$

Computations in level truncated superstring field theory yield the same result.[49] Any minimum $\phi\overline{\phi}=\tau^2$ of the tachyon potential describes the closed string vacuum (tachyon condensate). The perturbative spectrum around this vacuum is conjectured not to contain any open string excitations. As it was discussed in Refs. 46, 30, 50, in the presence of a B-field background a noncommutative generalization of the effective theory (4.39) might be of the form

$$\mathcal{L}^{(2)}_{\rm nc}=F_{+\hat{\alpha}\hat{\beta}}F_{+}^{\dagger\hat{\alpha}\hat{\beta}}+F_{-\hat{\alpha}\hat{\beta}}F_{-}^{\dagger\hat{\alpha}\hat{\beta}}+\tfrac{1}{2}\{D^{\hat{\alpha}}\phi,(D_{\hat{\alpha}}\phi)^{\dagger}\}+\tfrac{1}{8}(\tau^2-\phi\phi^{\dagger})^2+\tfrac{1}{8}(\tau^2-\phi^{\dagger}\phi)^2, \tag{4.41}$$

where $D_{\hat{\alpha}}\phi=\partial_{\hat{\alpha}}\phi+A_{+\hat{\alpha}}\phi-\phi A_{-\hat{\alpha}}$. Higher order corrections to the quartic tachyon potential are known (see, e.g., Refs. 51, 43). The result is qualitatively similar (''Mexican hat'' form with minima at $\phi\overline{\phi}<\infty$), and (4.40) is the leading order term. Note that a quartic form of the potential was also obtained in Refs. 45, 52–54 for bound states in $D(p-2)$-Dp and $D(p-4)$-Dp systems by using scattering calculations in string theory, level truncated superstring field theory and by analyzing the fluctuation spectrum around (noncommutative) vortex and instanton solutions.

Quite different results have been obtained in boundary string field theory (BSFT) (see, e.g., Refs. 55, 56 and references therein). There (as in Ref. 57) the Lagrangian density is proportional to the tachyon potential itself, and the potential has the form $V\sim\exp(-\phi\overline{\phi})$ with a ring of minima at $\phi\overline{\phi}\to\infty$. It is believed that the level truncation scheme and the BSFT approach can be related by a field redefinition involving all components of the string field.[55] Various ''improved versions'' of the effective action of the brane–antibrane system have been introduced (see, e.g., Refs. 58, 59), and in the literature there is no final agreement on its form. Thus, the action based on the Lagrangian (4.39) [or (4.41) in the presence of a B-field] might be considered as an approximation of the low energy effective action of the brane–antibrane system. In any case the discussed Yang–Mills–Higgs theory provides a simple field theoretic model of the more complicated string field theory description of brane–antibrane systems.

2. Noncommutative vortices and ABS solitons

Recall that branes and antibranes have opposite RR charge and therefore they can annihilate into the closed string vacuum state with $A_{\pm}=0$ and $\phi\phi^{\dagger}=\phi^{\dagger}\phi=\tau^2$. However, instead of taking the vacuum solution, one can choose as the ground state a (tachyon) soliton solution to the equations of motion for the Lagrangian (4.41). Such kinds of solutions are interpreted as bound states of Dp-branes and $\overline{Dp}$-branes, equivalent to D-branes of lower dimensionality. Here we discuss the main example of such solutions obtained via the Atiyah–Bott–Shapiro (ABS) construction.[40,60–62] These ABS (noncommutative) solitons live in $2n\leqslant p$ dimensions, and for $n=1$ they coincide with noncommutative vortices on $\mathbb{R}^2_{\theta}$. For $n=2$ the ABS solitons are non-Abelian and therefore differ from those (Abelian) SW solutions which also solve the field equations following from (4.41).

To describe the ABS solitons on $\mathbb{R}^{2n}_{\theta}$ we consider a non-Abelian generalization of the Lagrangian (4.41) with a $U_{+}(q)\times U_{-}(q)$ gauge group for $q=2^{n-1}$ and the tachyon field ϕ in the bi-fundamental representation $(q,\overline{q})$ of this group. This model describes two Hermitian rank q vector bundles $E_{\pm}\to\mathbb{R}^{p,1}$ with connection one-forms $A_{\pm}$ and $\phi\in\mathrm{Hom}(E_{-},E_{+})$ and is associated with a system of q Dp-branes and q $\overline{Dp}$-branes with common world volume $\mathbb{R}^{p,1}$. We assume that $2n\leqslant p$ and introduce an ansatz for ABS solitons related to Clifford algebras.

Consider the Clifford algebra of the Euclidean space $(\mathbb{R}^{2n},\delta_{\alpha\beta})$, generated by unity and elements Γ_{α} such that

$$\Gamma_{\alpha}\Gamma_{\beta}+\Gamma_{\beta}\Gamma_{\alpha}=-2\,\delta_{\alpha\beta}, \tag{4.42}$$

with $\alpha,\beta,\ldots=1,\ldots,2n$. In the $2^n\times 2^n$ matrix representation of this algebra the generators Γ_α can be chosen of the form

$$\Gamma_\alpha=\begin{pmatrix} 0 & \gamma_\alpha^\dagger \\ -\gamma_\alpha & 0 \end{pmatrix}, \tag{4.43}$$

where the γ_α's are $q\times q$ gamma matrices with $q=2^{n-1}$. In this representation the spinor space $W\cong\mathbb{C}^{2q}$ can be decomposed into a direct sum $W\cong W^+\oplus W^-$ of semi-spinor spaces $W^\pm$ (the spaces of Weyl spinors). Note that for $n=1$ we have $\gamma_1=1$ and $\gamma_2=i$.

Considering the noncommutative deformation $\mathbb{R}^{2n}_\theta$ of $\mathbb{R}^{2n}$ discussed in Secs. III A and III C, we introduce the operators

$$T=\gamma_\alpha^\dagger x^\alpha\frac{1}{\sqrt{(\gamma x)(\gamma x)^\dagger}} \quad \text{and} \quad T^\dagger=\frac{1}{\sqrt{(\gamma x)(\gamma x)^\dagger}}\gamma_\alpha x^\alpha, \tag{4.44}$$

where γx is a short hand notation for $\gamma_\alpha x^\alpha$. The operator T defines a map,

$$\hat{T}:\mathcal{H}\otimes W^-\to\mathcal{H}\otimes W^+. \tag{4.45}$$

Here $\mathcal{H}$ is the Hilbert space realized as a representation space of n oscillators defined by formulas similiar to (4.1) and (4.2), and $W^\pm$ are the semi-spinor spaces introduced above. In matrix realization $\hat{T}$ looks as

$$\hat{T}=\begin{pmatrix} 0 & T \\ 0 & 0 \end{pmatrix}, \tag{4.46}$$

and hence, following the authors of Refs. 40, 63, 62, 50, we will not distinguish T and $\hat{T}$ in the sequel.

It is not difficult to see that

$$T^\dagger T=\mathbb{1}_q \quad \text{and} \quad TT^\dagger=\mathbb{1}_q-\mathcal{P}_0, \tag{4.47}$$

where $\mathcal{P}_0$ is the projector onto the kernel of $T^\dagger$. This state is the tensor product of the oscillator ground state with itself and the lowest weight spinor of $SO(2n)$ (the fermion ground state). Also, by introducing $T_N:=T^N$ with $T_1\equiv T$, we have

$$T_N^\dagger T_N=\mathbb{1}_q \quad \text{and} \quad T_N T_N^\dagger=\mathbb{1}_q-\mathcal{P}_{N-1}, \tag{4.48}$$

where $\mathcal{P}_{N-1}$ is the projector onto the kernel of $T_N^\dagger$, an N-dimensional subspace in $\mathcal{H}\otimes W$. One can show that

$$\dim\ \ker T_N=0 \quad \text{and} \quad \dim\ \operatorname{coker} T_N:=\dim\ \ker T_N^\dagger=N, \tag{4.49}$$

and therefore the index of T_N is given by

$$\operatorname{ind} T_N:=\dim\ \ker T_N-\dim\ \operatorname{coker} T_N=-N. \tag{4.50}$$

The operators T_N and $T_N^\dagger$ are Toeplitz operators.

Now we reduce the equations of motion for the Lagrangian (4.41) to the space $\mathbb{R}^{2n}_\theta\hookrightarrow\mathbb{R}^{p+1}_\theta$ by assuming that all fields depend only on x^α and by taking $A_{\pm\alpha}$ as the only nonvanishing components of the gauge potentials $A_\pm$. To solve the reduced field equations we consider T_N as $q\times q$ matrices with operator entries and introduce the ansatz,

$$A_{+z^a}=-(A_{+\bar{z}^{\bar{a}}})^\dagger=\tau\theta_{a\bar{a}}(T_{N_+}\bar{z}^{\bar{a}}T_{N_+}^\dagger-\bar{z}^{\bar{a}}),\quad A_{-z^a}=0=A_{-\bar{z}^{\bar{a}}}\quad\text{and}\quad\phi=\tau T_{N_+},\tag{4.51}$$

which solves the equation of motion for (4.41).[30,50] More general solutions can also be constructed. For $n=1$ the solution (4.51) describes N_+ vortices on $\mathbb{R}^2_\theta$. In the case $n=2$ it gives a solution for the $U_+(2)\times U_-(2)$ Yang–Mills–Higgs model on $\mathbb{R}^4_\theta$. Some noncommutative SW solutions [e.g., (4.18a), (4.18b) with $N_-=0$] solve the above equations as well but for the gauge group $U_+(1)\times U_-(1)$. These solutions can therefore be regarded as a new kind of tachyon solitons.

3. Noncommutative SW solitons

Note that the SW equations (3.50) with $v_+=v_-=\tau^2=$const coincide with the first order BPS equations for the Lagrangian (4.41), and therefore their solutions also satisfy the equations of motion for (4.41). In particular, the solution given by (4.18) with $N_+\geqslant 1$ and $N_-=0$ is such a solution. Following the general logic of Sen's proposal, it is natural to interpret this solution as a configuration of N_+ stable $D(p-4)$-branes, corresponding to the topologically stable codimension four SW soliton on a $Dp-\overline{Dp}$ brane pair.

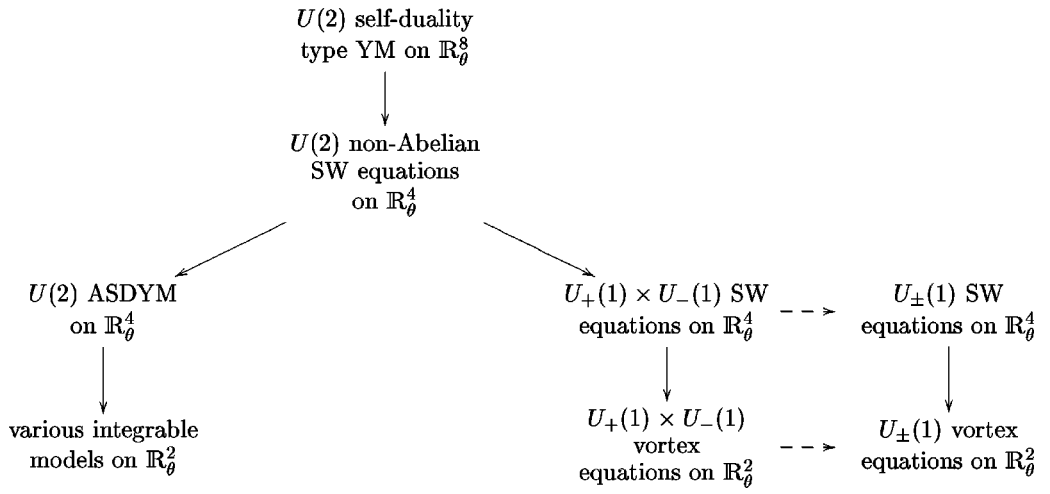
The more general configuration described by (4.18) with $N_\pm\geqslant 1$ can be interpreted in two different ways. First, we may again choose $v_+=v_-=\tau^2=$const. Then one can show that this configuration satisfies the second order equations of motion for the Lagrangian (4.41) but does not satisfy the first order equations (3.50) with constant $v_\pm$. This is natural since this solution corresponds to a system of N_+ $D(p-4)$-branes and N_- $\overline{D(p-4)}$-branes which is not a BPS configuration from the point of view of the Lagrangian (4.41). Second, one may consider the situation where v_+ depends on $\phi\phi^\dagger$ and v_- on $\phi^\dagger\phi$ and take as the low energy effective action the sum of the functional (3.48a) and the Chern–Simons term (3.48b), where the latter contributes to the equations of motion for nonconstant $v_\pm$. Then for proper choices of $v_\pm$ one can obtain configurations which satisfy the noncommutative SW equations. For instance, the choice

$$v_+=\tau^2\quad\text{and}\quad v_-=-\tau^2+2\phi^\dagger\phi\tag{4.52}$$

corresponds to the same tachyon potential $V\sim(\tau^2-\phi\phi^\dagger)^2+(\tau^2-\phi^\dagger\phi)^2$ as in (4.41). However, for the above choice of $v_\pm$ the Chern–Simons term (3.48b) becomes nontrivial and contributes to the equations (3.50) which are the BPS equations for the action $E_\chi+16\pi^2K_\chi$ with E_χ and K_χ determined by (3.48). Therefore, for $v_\pm$ given by (4.52) the configuration (4.18) with $N_\pm\geqslant 1$ is a solution to the SW equations (3.50). So, in both cases the configuration (4.18) may be interpreted as N_+ $D(p-4)$-branes and N_- $\overline{D(p-4)}$-branes. Other solutions to the noncommutative SW equations can be analyzed similarly.

V. CONCLUDING REMARKS

In this paper we have discussed different noncommutative deformations of the (perturbed) SW monopole equations on Euclidean four-dimensional space. Namely, starting from properly deformed $U(2)$ self-duality type YM equations in eight dimensions, we performed a reduction to $U(2)$ noncommutative SW equations on $\mathbb{R}^4_\theta$ with the matter field in the adjoint representation of the gauge group. We then concentrated on the $U_+(1)\times U_-(1)\subset U(2)$ noncommutative SW equations with the matter in the bi-fundamental representation of $U_+(1)\times U_-(1)$. Perturbed versions of these equations have also been discussed. Then, by considering the matter field Φ as an element of a right or left $\mathbb{R}^4_\theta$-module, we have introduced the (perturbed) $U_+(1)$ and $U_-(1)$ SW equations. The commutative limits of all these three Abelian cases are identical to the standard (perturbed) Abelian SW equations on $\mathbb{R}^4$. In summary we may write down the following diagram:



This picture shows the connection between the theories discussed in this paper. Note that the noncommutative vortex equations in two dimensions can easily be obtained via dimensional reduction from the noncommutative SW equations with properly chosen perturbations.

It has been shown that $\mathbb{R}^4_\theta$ supports regular finite-action solutions to the SW equations even if there are no such solutions in the commutative case. This is a well known phenomenon related to the fact that, due to the noncommutativity tensor θ, an additional length scale enters the theory. We have constructed explicit solutions to the $U_+(1)\times U_-(1)$ and $U_\pm(1)$ noncommutative SW equations and interpreted them as D-brane configurations in type II superstring theory. It would be illuminating to generalize the present results to non-Abelian noncommutative SW theory and discuss the latter's relation to superstring theory.

APPENDIX: NONCOMMUTATIVE BOGOMOLNY TRANSFORMATION

In order to derive (3.42) we need the trivial identities

$$(D_\mu\phi)\psi^\dagger=-\phi(D_\mu\psi)^\dagger+\nabla_{+\mu}(\phi\psi^\dagger)\quad\text{and}\quad(D_\mu\phi)^\dagger\psi=-\phi^\dagger(D_\mu\psi)+\nabla_{-\mu}(\phi^\dagger\psi),\tag{A1}$$

where the covariant derivatives $\nabla_{\pm\mu}$ are given by (3.45b). Furthermore, we have

$$[D_\mu,D_\nu]\phi=F_{+\mu\nu}\phi-\phi F_{-\mu\nu}.\tag{A2}$$

Let us consider

$$\begin{aligned}4|F^+_{A_+}+\chi^+_+-\sigma^+(\Phi\otimes\Phi^\dagger)_0|^2&=-2(F^+_{+\mu\nu}+\chi^+_{+\mu\nu}-\sigma^+_{\mu\nu}(\Phi\otimes\Phi^\dagger)_0)^2\\&=-2(F^+_{+\mu\nu})^2-2\{F^+_{+\mu\nu},\chi^+_{+\mu\nu}\}+2\{F^+_{+\mu\nu},\sigma^+_{\mu\nu}(\Phi\otimes\Phi^\dagger)_0\}\\&\quad-2(\chi^+_{+\mu\nu}-\sigma^+_{\mu\nu}(\Phi\otimes\Phi^\dagger)_0)^2.\end{aligned}\tag{A3}$$

This expression contains

$$(F^+_{+\mu\nu})^2=\tfrac{1}{4}(F_{+\mu\nu}+*F_{+\mu\nu})^2=\tfrac{1}{2}(F_{+\mu\nu})^2+\tfrac{1}{4}\{F_{+\mu\nu},*F_{+\mu\nu}\},\tag{A4a}$$

$$\{F^+_{+\mu\nu},\sigma^+_{\mu\nu}(\Phi\otimes\Phi^\dagger)_0\}=\frac{i}{2}\{F^+_{+12},\phi_1\phi_1^\dagger-\phi_2\phi_2^\dagger\}-\tfrac{1}{2}\{F^+_{+13},\phi_2\phi_1^\dagger-\phi_1\phi_2^\dagger\}$$

$$+\frac{i}{2}\{F^+_{+14},\phi_2\phi_1^\dagger+\phi_1\phi_2^\dagger\}, \tag{A4b}$$

$$-(\chi^+_{+\mu\nu}-\sigma^+_{\mu\nu}(\Phi\otimes\Phi^\dagger)_0)^2=2|\chi^+_+-\sigma^+(\Phi\otimes\Phi^\dagger)_0|^2. \tag{A4c}$$

Similarly,

$$\begin{aligned}4|F^+_{A_-}+\chi^+_--\sigma^+(\Phi^*\otimes(\Phi^*)^\dagger)_0|^2&=-2(F^+_{-\mu\nu}+\chi^+_{-\mu\nu}-\sigma^+_{\mu\nu}(\Phi^*\otimes(\Phi^*)^\dagger)_0)^2\\&=-2(F^+_{-\mu\nu})^2-2\{F^+_{-\mu\nu},\chi^+_{-\mu\nu}\}\\&\quad+2\{F^+_{-\mu\nu},\sigma^+_{\mu\nu}(\Phi^*\otimes(\Phi^*)^\dagger)_0\}\\&\quad-2(\chi^+_{-\mu\nu}-\sigma^+_{\mu\nu}(\Phi^*\otimes(\Phi^*)^\dagger)_0)^2\end{aligned} \tag{A5}$$

with

$$(F^+_{-\mu\nu})^2=\tfrac{1}{2}(F_{-\mu\nu})^2+\tfrac{1}{4}\{F_{-\mu\nu},{}^*F_{-\mu\nu}\}, \tag{A6a}$$

$$\{F^+_{-\mu\nu},\sigma^+_{\mu\nu}(\Phi^*\otimes(\Phi^*)^\dagger)_0\}=-\frac{i}{2}\{F^+_{-12},\phi_1^\dagger\phi_1-\phi_2^\dagger\phi_2\}$$

$$+\tfrac{1}{2}\{F^+_{-13},\phi_1^\dagger\phi_2-\phi_2^\dagger\phi_1\}-\frac{i}{2}\{F^+_{-14},\phi_1^\dagger\phi_2+\phi_2^\dagger\phi_1\}, \tag{A6b}$$

$$-(\chi^+_{-\mu\nu}-\sigma^+_{\mu\nu}(\Phi^*\otimes(\Phi^*)^\dagger)_0)^2=2|\chi^+_--\sigma^+(\Phi^*\otimes(\Phi^*)^\dagger)_0|^2. \tag{A6c}$$

A lengthy but straightforward calculation exploiting (A1) and (A2) yields for $\frac{1}{2}|\mathcal{D}_{A_+,A_-}\Phi|^2$ the expression

$$\begin{aligned}\tfrac{1}{2}|\mathcal{D}_{A_+,A_-}\Phi|^2&=\tfrac{1}{2}|iD_3\phi_1-D_4\phi_1+iD_1\phi_2+D_2\phi_2|^2+\tfrac{1}{2}|iD_1\phi_1-D_2\phi_1-iD_3\phi_2-D_4\phi_2|^2\\&=-\frac{i}{2}\{F^+_{+12},\phi_1\phi_1^\dagger-\phi_2\phi_2^\dagger\}+\tfrac{1}{2}\{F^+_{+13},\phi_2\phi_1^\dagger-\phi_1\phi_2^\dagger\}\\&\quad-\frac{i}{2}\{F^+_{+14},\phi_2\phi_1^\dagger+\phi_1\phi_2^\dagger\}+\tfrac{1}{2}|D_{A_+,A_-}\Phi|^2-\nabla_{+\mu}\mathcal{J}_{+\mu}+C_+,\end{aligned} \tag{A7}$$

where

$$\mathcal{J}_{+\mu}=\frac{i}{4}(\epsilon_{\mu\nu12}+\epsilon_{\mu\nu34})\mathcal{J}^{(1)}_{+\nu}+\tfrac{1}{4}(\epsilon_{\mu\nu31}+\epsilon_{\mu\nu24})\mathcal{J}^{(2)}_{+\nu}+\frac{i}{4}(\epsilon_{\mu\nu23}+\epsilon_{\mu\nu14})\mathcal{J}^{(3)}_{+\nu} \tag{A8a}$$

and

$$\mathcal{J}^{(1)}_{+\nu}=\phi_1(D_\nu\phi_1)^\dagger-(D_\nu\phi_1)\phi_1^\dagger-\phi_2(D_\nu\phi_2)^\dagger+(D_\nu\phi_2)\phi_2^\dagger, \tag{A8b}$$

$$\mathcal{J}^{(2)}_{+\nu}=-\phi_1(D_\nu\phi_2)^\dagger+(D_\nu\phi_1)\phi_2^\dagger+\phi_2(D_\nu\phi_1)^\dagger-(D_\nu\phi_2)\phi_1^\dagger, \tag{A8c}$$

$$\mathcal{J}^{(3)}_{+\nu}=\phi_2(D_\nu\phi_1)^\dagger-(D_\nu\phi_2)\phi_1^\dagger+\phi_1(D_\nu\phi_2)^\dagger-(D_\nu\phi_1)\phi_2^\dagger. \tag{A8d}$$

The term C_+ is given by

$$C_+ = -i\phi_2 F^+_{-12}\phi_2^\dagger + i\phi_1 F^+_{-12}\phi_1^\dagger - \phi_2 F^+_{-13}\phi_1^\dagger + i\phi_2 F^+_{-14}\phi_1^\dagger + i\phi_1 F^+_{-14}\phi_2^\dagger + \phi_1 F^+_{-13}\phi_2^\dagger . \tag{A9}$$

In a similar manner, we also have

$$\begin{aligned}\tfrac{1}{2}|(\mathcal{D}_{A_+,A_-}\Phi)^\dagger|^2 = {}& \frac{i}{2}\{F^+_{-12}, \phi_1^\dagger\phi_1 - \phi_2^\dagger\phi_2\} - \tfrac{1}{2}\{F^+_{-13}, \phi_1^\dagger\phi_2 - \phi_2^\dagger\phi_1\} \\ & + \frac{i}{2}\{F^+_{-14}, \phi_1^\dagger\phi_2 + \phi_2^\dagger\phi_1\} + \tfrac{1}{2}|(D_{A_+,A_-}\Phi)^\dagger|^2 - \nabla_{-\mu}\mathcal{J}_{-\mu} + C_- ,\end{aligned} \tag{A10}$$

where

$$\mathcal{J}_{-\mu} = -\frac{i}{4}(\epsilon_{\mu\nu 12} + \epsilon_{\mu\nu 34})\mathcal{J}^{(1)}_{-\nu} - \tfrac{1}{4}(\epsilon_{\mu\nu 31} + \epsilon_{\mu\nu 24})\mathcal{J}^{(2)}_{-\nu} - \frac{i}{4}(\epsilon_{\mu\nu 23} + \epsilon_{\mu\nu 14})\mathcal{J}^{(3)}_{-\nu} \tag{A11a}$$

and

$$\mathcal{J}^{(1)}_{-\nu} = \phi_1^\dagger(D_\mu\phi_1) - (D_\mu\phi_1)^\dagger\phi_1 - \phi_2^\dagger(D_\mu\phi_2) + (D_\mu\phi_2)^\dagger\phi_2 , \tag{A11b}$$

$$\mathcal{J}^{(2)}_{-\nu} = -\phi_2^\dagger(D_\mu\phi_1) + (D_\mu\phi_2)^\dagger\phi_1 + \phi_1^\dagger(D_\mu\phi_2) - (D_\mu\phi_1)^\dagger\phi_2 , \tag{A11c}$$

$$\mathcal{J}^{(3)}_{-\nu} = \phi_1^\dagger(D_\mu\phi_2) - (D_\mu\phi_1)^\dagger\phi_2 + \phi_2^\dagger(D_\mu\phi_1) - (D_\mu\phi_2)^\dagger\phi_1 . \tag{A11d}$$

The term C_- is

$$C_- = i\phi_2^\dagger F^+_{+12}\phi_2 - i\phi_1^\dagger F^+_{+12}\phi_1 - \phi_2^\dagger F^+_{+13}\phi_1 - i\phi_2^\dagger F^+_{+14}\phi_1 - i\phi_1^\dagger F_{+14}\phi_2 + \phi_1^\dagger F_{+13}\phi_2 . \tag{A12}$$

Therefore, we discover that

$$\begin{aligned}&\tfrac{1}{2}|\mathcal{D}_{A_+,A_-}\Phi|^2 + \tfrac{1}{2}|(\mathcal{D}_{A_+,A_-}\Phi)^\dagger|^2 + 4|F^+_{A_+} + \chi^+_+ - \sigma^+(\Phi\otimes\Phi^\dagger)_0|^2 \\ &\quad + 4|F^+_{A_-} + \chi^+_- - \sigma^+(\Phi^*\otimes(\Phi^*)^\dagger)_0|^2 \\ &\quad = \tfrac{1}{2}|D_{A_+,A_-}\Phi|^2 + \tfrac{1}{2}|(D_{A_+,A_-}\Phi)^\dagger|^2 + 2|F_{A_+}|^2 + 2|F_{A_-}|^2 + 4|\chi^+_+ - \sigma^+(\Phi\otimes\Phi^\dagger)_0|^2 \\ &\quad + 4|\chi^+_- - \sigma^+(\Phi^*\otimes(\Phi^*)^\dagger)_0|^2 - \tfrac{1}{2}\{F_{+\mu\nu}, {*F_{+\mu\nu}}\} - 2\{F^+_{+\mu\nu}, \chi^+_{+\mu\nu}\} - \nabla_{+\mu}\mathcal{J}_{+\mu} \\ &\quad - \tfrac{1}{2}\{F_{-\mu\nu}, {*F_{-\mu\nu}}\} - 2\{F^+_{-\mu\nu}, \chi^+_{-\mu\nu}\} - \nabla_{-\mu}\mathcal{J}_{-\mu} + \frac{i}{2}\{F^+_{+12}, \phi_1\phi_1^\dagger - \phi_2\phi_2^\dagger\} \\ &\quad - \tfrac{1}{2}\{F^+_{+13}, \phi_2\phi_1^\dagger - \phi_1\phi_2^\dagger\} + \frac{i}{2}\{F^+_{+14}, \phi_2\phi_1^\dagger + \phi_1\phi_2^\dagger\} + C_+ - \frac{i}{2}\{F^+_{-12}, \phi_1^\dagger\phi_1 - \phi_2^\dagger\phi_2\} \\ &\quad + \tfrac{1}{2}\{F^+_{-13}, \phi_1^\dagger\phi_2 - \phi_2^\dagger\phi_1\} - \frac{i}{2}\{F^+_{-14}, \phi_1^\dagger\phi_2 + \phi_2^\dagger\phi_1\} + C_- .\end{aligned}$$

Now suppose that all operators entering this formula are of proper trace-class, e.g., $|\mathrm{Tr}\phi_{1,2}| < \infty$ and $|\mathrm{Tr}F_{\pm\mu\nu}| < \infty$. Then

$$\mathrm{Tr}\Big\{ \frac{i}{2}\{F^+_{+12},\phi_1\phi_1^\dagger-\phi_2\phi_2^\dagger\}-\tfrac{1}{2}\{F^+_{+13},\phi_2\phi_1^\dagger-\phi_1\phi_2^\dagger\}+\frac{i}{2}\{F^+_{+14},\phi_2\phi_1^\dagger+\phi_1\phi_2^\dagger\}+C_+$$
$$-\frac{i}{2}\{F^+_{-12},\phi_1^\dagger\phi_1-\phi_2^\dagger\phi_2\}+\tfrac{1}{2}\{F^+_{-13},\phi_1^\dagger\phi_2-\phi_2^\dagger\phi_1\}-\frac{i}{2}\{F^+_{-14},\phi_1^\dagger\phi_2+\phi_2^\dagger\phi_1\}+C_-\Big\}=0, \tag{A13}$$

since we can use the invariance of the trace under cyclic permutations. In fact, one can easily check that for each term in (A13) there exists a corresponding term having the opposite sign so that the trace is indeed zero.

Finally we obtain

$$\begin{aligned}
&\mathrm{Tr}\{\tfrac{1}{2}|\mathcal{D}_{A_+,A_-}\Phi|^2+\tfrac{1}{2}|(\mathcal{D}_{A_+,A_-}\Phi)^\dagger|^2+4|F^+_{A_+}+\chi^+_+-\sigma^+(\Phi\otimes\Phi^\dagger)_0|^2\\
&\quad+\ 4|F^+_{A_-}+\chi^+_--\sigma^+(\Phi^*\otimes(\Phi^*)^\dagger)_0|^2\}\\
&\quad=\mathrm{Tr}\{\tfrac{1}{2}|D_{A_+,A_-}\Phi|^2+\tfrac{1}{2}|(D_{A_+,A_-}\Phi)^\dagger|^2+2|F_{A_+}|^2+2|F_{A_-}|^2+4|\chi^+_+-\sigma^+(\Phi\otimes\Phi^\dagger)_0|^2\\
&\qquad+\ 4|\chi^+_--\sigma^+(\Phi^*\otimes(\Phi^*)^\dagger)_0|^2\}-\mathrm{Tr}\mathcal{T}+\frac{16\pi^2}{|\mathrm{Pf}(2\pi\theta)|}K_\chi,
\end{aligned} \tag{A14}$$

which is the desired result. Note that the choice $\phi_1=\phi$ and $\phi_2=0$ yields the expressions (3.49a) and (3.49b) for the currents $\mathcal{J}_{\pm\mu}$.

Semiclassical asymptotics for the Maxwell–Dirac system

C. Sparber[a] and P. Markowich[b]

(Received 5 May 2003; accepted 22 May 2003)

We study the coupled system of Maxwell and Dirac equations from a semiclassical point of view. A rigorous nonlinear WKB-analysis, locally in time, for solutions of (critical) order $O(\sqrt{\varepsilon})$ is performed, where the small semiclassical parameter $\varepsilon \ll 1$ denotes the microscopic/macroscopic scale ratio. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1604455]

I. INTRODUCTION AND SCALING

The *Maxwell–Dirac system* (MD) is fundamental in the relativistic description of spin 1/2 particles. It represents the time-evolution of fast (relativistic) electrons and positrons within external and *self-consistent* generated electromagnetic fields:

$$i\hbar\,\partial_s\Psi=\sum_{k=1}^{3}\alpha^k(-i\hbar c\,\partial_k-e(A_k+A_k^{\mathrm{ext}}))\Psi+e(V+V^{\mathrm{ext}})\Psi+mc^2\beta\Psi,$$
$$\left(\frac{1}{c^2}\partial_s^2-\Delta\right)V=\frac{1}{4\pi\epsilon_0}\rho,\quad \left(\frac{1}{c^2}\partial_s^2-\Delta\right)A=\frac{1}{4\pi c\,\epsilon_0}j, \tag{1.1}$$

where the *particle-* and *current-densities* are defined by

$$\rho:=e|\Psi|^2,\quad j_k:=e\langle\Psi,\alpha^k\Psi\rangle,\quad k=1,2,3. \tag{1.2}$$

Here, $\Psi=\Psi(s,y)\in\mathbb{C}^4$ is the 4-vector of the *spinor field*, normalized s.t.,

$$\int_{\mathbb{R}^3}|\Psi(s,y)|^2\,dy=1, \tag{1.3}$$

with s, $y\equiv(y_1,y_2,y_3)$, denoting the time—resp. spatial coordinates in *Minkowski space*. Further, $V^{(\mathrm{ext})}=V^{(\mathrm{ext})}(s,y)\in\mathbb{R}$ is the *self-consistent* resp. *external electric potential* and $A_k^{(\mathrm{ext})}=A_k^{(\mathrm{ext})}(t,x)\in\mathbb{R}$, the corresponding *magnetic potential*, with $A=(A_1,A_2,A_3)$. In the following, the usual scalar-product for vectors $X,Y\in\mathbb{C}^4$ will be denoted by $\langle X,Y\rangle$ and we shall also write $|X|^2:=\langle X,X\rangle$. The so-called *Dirac matrices* β,α^k, $k=1,2,3$, are explicitly given by

$$\beta:=\begin{pmatrix}\mathbf{1}_2 & 0\\ 0 & -\mathbf{1}_2\end{pmatrix},\quad \alpha^k:=\begin{pmatrix}0 & \sigma^k\\ \sigma^k & 0\end{pmatrix}, \tag{1.4}$$

with $\mathbf{1}_2$, the 2×2 identity matrix and σ^k the 2×2 *Pauli matrices*, i.e.,

$$\sigma^1:=\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix},\quad \sigma^2:=\begin{pmatrix}0 & -i\\ i & 0\end{pmatrix},\quad \sigma^3:=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}. \tag{1.5}$$

[a]Electronic mail: christof.sparber@univie.ac.at
[b]Electronic mail: peter.markowich@univie.ac.at

Hence, α^k, β are *Hermitian* and moreover one easily checks that the following identities hold for $k,l=1,2,3$:

$$\alpha^k\alpha^l+\alpha^l\alpha^k=2\delta_{kl},$$
$$\alpha^k\beta+\beta\alpha^k=0. \tag{1.6}$$

Finally, the appearing physical constants are the normalized Planck constant $\hbar$, the speed of light c, the permittivity of the vacuum ϵ_0, the particle mass m and the charge e.

Additionally to (1.1), we impose the *Lorentz gauge condition*,

$$\frac{1}{c}\partial_s V(s,y)+\operatorname{div} A(s,y)=0, \tag{1.7}$$

for the initial potentials $V(0,y)$ and $A(0,y)$. The gauge is henceforth conserved during the time-evolution. It ensures that the corresponding *electromagnetic fields* E, B are uniquely determined by

$$E(s,y):=-\frac{1}{c}\partial_s A(s,y)-\nabla V(s,y), \quad B(s,y):=\operatorname{curl} A(s,y). \tag{1.8}$$

The MD equations are the underlying field equations of relativistic *quantum electro-dynamics*, cf. Schwabl (1999), where one considers the system within the formalism of *second quantization*. Nevertheless, in order to obtain a deeper understanding for the interaction of matter and radiation, there is a growing interest in the MD system also for classical fields, since one can expect at least qualitative results; cf. Esteban and Sere (2002). From the mathematical point of view, the strongly nonlinear MD system poses a hard problem in the study of PDE's arising from quantum physics. Well posedness and the existence of solutions on all of $\mathbb{R}^3_y$ but only locally in time, has been proved almost forty years ago in Gross (1996). On the other hand, only partial results (i.e., for small initial data) have been obtained in the quest of global-in-time solutions [Chadam (1973), Georgiev (1991), Flato, Simon, and Tafflin (year)] let alone the study of other qualitative features of this system; cf. [Booth and Radford (1997), Esteban, Georgiev, and Sere (1996), Esteban and Sere (2002), Chadam and Glassey (1976)]. However, there are some recent and quite complete results concerning the *nonrelativistic limit* of the MD equations; cf. Bechouche, Mauser, and Selberg (year) also Masmoudi and Mauser (2001).

In this paper, we shall analyze the MD system in a *semiclassical* regime. To do so, we first rewrite the equations such that there remains only one (positive) *dimensionless* parameter,

$$\delta=\frac{4\pi\hbar c\varepsilon_0}{e^2}, \tag{1.9}$$

which is obtained by replacing $y\to y/\overline{y}$, $s\to s/\overline{s}$ and $\Psi(s,y)\to\overline{y}^{-3/2}\Psi(s/\overline{s},y/\overline{y})$, in order to maintain the normalization condition (1.3), with

$$c\overline{s}=\overline{y} \text{ and } \overline{y}=\frac{e^2}{mc^2\varepsilon_0}. \tag{1.10}$$

Here, we also replaced both, the external and the self-consistent potentials, by $A^{(\mathrm{ext})}(s,y)\to\lambda A^{(\mathrm{ext})}(s/\overline{s},y/\overline{y})$ and $V^{(\mathrm{ext})}(s,y)\to\kappa V^{(\mathrm{ext})}(s/\overline{s},y/\overline{y})$, with $\kappa=c\lambda$ and $\lambda=mc/e$. We assume for the following that $A^{\mathrm{ext}}, V^{\mathrm{ext}}$ are of $O(1)$ in these units. In summary, we obtain the MD system in dimensionless form:

$$i\delta\partial_s\Psi=\sum_{k=1}^{3}\alpha^k(-i\delta\partial_k-(A_k+A_k^{\mathrm{ext}}))\Psi+(V+V^{\mathrm{ext}})\Psi+\beta\Psi,$$
$$\Box V=\rho,\quad \Box A=j, \tag{1.11}$$

where from now on $\Box:=\partial_s^2-\Delta$. In (1.11), s,y represent the *microscopic* time and length scales. Note that in general, δ can*not* be considered as a *small* parameter. For example, in the case of electrons δ is indeed the inverse of the *fine structure constant*, i.e., $\delta\approx 137$. Hence, semiclassical asymptotics in δ, i.e., on (1.11) directly, only make sense for highly charged and consequently heavy particles.

Therefore, we need to rescale the system (1.11) such that the time-evolution can be considered semiclassical, independent of the precise physical properties of the particles. We can suppose that the given external electromagnetic potentials are slowly varying w.r.t. to the microscopic scales, i.e. $V^{\mathrm{ext}}=V^{\mathrm{ext}}(s\varepsilon/\delta,y\varepsilon/\delta)$ and likewise $A^{\mathrm{ext}}=A^{\mathrm{ext}}(s\varepsilon/\delta,y\varepsilon/\delta)$, where from now on ε denotes the small *semiclassical parameter*. Here, the δ is included in the scaling in order to eliminate it from the resulting equation. Hence, observing the evolution on macroscopic scales we are led to

$$y=\frac{\delta}{\varepsilon}x,\quad s=\frac{\delta}{\varepsilon}t. \tag{1.12}$$

Moreover, we want the coefficients of all nonlinearities to be $O(1)$, i.e., they should *not* carry a positive power of ε. It turns out that there exists solutions ψ^ε, which obey this requirement. If we set

$$\frac{\delta}{\varepsilon}\Psi(s,y)=\psi^\varepsilon(t,x), \tag{1.13}$$

then the normalization condition for (1.3) gives

$$\int_{\mathbb{R}^3}|\psi^\varepsilon(t,x)|^2\,dy=\frac{\varepsilon}{\delta}\int_{\mathbb{R}^3}|\Psi(s,y)|^2\,dx=\frac{\varepsilon}{\delta}. \tag{1.14}$$

This implies that we need to look for solutions ψ^ε s.t.,

$$\psi^\varepsilon\sim O(\sqrt{\varepsilon}), \tag{1.15}$$

assuming, as mentioned above, that $\delta\sim O(1)$. We therefore end up with the following *semiclassical scaled* MD system:

$$i\varepsilon\partial_t\psi^\varepsilon=\sum_{k=1}^{3}\alpha^k(-i\varepsilon\partial_k-(A_k^\varepsilon+A^{\mathrm{ext}}))\psi^\varepsilon+\beta\psi^\varepsilon+(V^\varepsilon+V^{\mathrm{ext}})\psi^\varepsilon, \tag{1.16}$$

$$\Box V^\varepsilon=|\psi^\varepsilon|^2, \tag{1.17}$$

$$\Box A_k^\varepsilon=\langle\psi^\varepsilon,\alpha^k\psi^\varepsilon\rangle,\quad k=1,2,3, \tag{1.18}$$

subject to *Cauchy initial data*:

$$\psi^\varepsilon|_{t=0}=\psi_I^\varepsilon(x)\sim O(\sqrt{\varepsilon}),$$
$$V^\varepsilon|_{t=0}=V_I^\varepsilon(x),\quad \partial_tV^\varepsilon|_{t=0}=\tilde{V}_I^\varepsilon(x), \tag{1.19}$$
$$A^\varepsilon|_{t=0}=A_I^\varepsilon(x),\quad \partial_tA^\varepsilon|_{t=0}=\tilde{A}_I^\varepsilon(x).$$

For this nonlinear system, we want to find an asymptotic description of $\psi^\varepsilon \sim O(\sqrt{\varepsilon})$ as $\varepsilon \to 0$, i.e., a semiclassical description. Note that, *equivalently*, one could consider asymptotic solutions of the form

$$\Phi^\varepsilon(t,x) := \frac{1}{\sqrt{\varepsilon}} \psi^\varepsilon(t,x) \sim O(1), \tag{1.20}$$

which do not vanish in the limit $\varepsilon \to 0$ and which again satisfy the semiclassical scaled DM system, modified by the fact that the right hand sides of (1.17), (1.18) are multiplied by an additional factor ε. This illustrates the fact that we are dealing with a *small coupling limit*. We further stress that in our scaling the mass is $O(1)$ and *fixed* as $\varepsilon \to 0$, which is different from the otherwise similar scaling used in Kunze and Spohn, where a classical mechanics analogue of the MD system has been studied. The (rigorous) analysis of semiclassical asymptotics has a long tradition in quantum mechanics, the most common technique being the so called *WKB-method*. Quite recently, a semiclassical approach to the *linear* Dirac equation was taken in Bolte and Keppeler (1999) and also, using *Wigner measures*, in Gérard, Markowich, Mauser, Poupaud (1997) and Spohn (2000). For a broader introduction on linear techniques and results, we refer to Maslov and Feydoriuk (1981), Robert (1998), Sparber, Markowich, and Mauser (2003) and the references given therein. Nonlinear extensions of the WKB-method can be found, for example, in Georgiev (1991) and Grenier (1998), where *scalar-valued* semilinear Schrödinger equations are analyzed. We remark that the case of the nonlinear Dirac 4-system introduces significant new difficulties in the WKB-analysis; some of them are already present in the linear setting.

Mathematically, our approach is inspired by techniques developed in Donat and Rauch (1997), which sometimes go under the name *weakly nonlinear geometrical optics*. Due to the appearance of the small parameter ε in front of each derivative in (1.16) we are in the regime of so-called *dispersive* weakly nonlinear geometrical optics, which differs in several aspects from the nondispersive one. We remark that the latter case is much better studied in the so far existing literature and we refer to Joly, Metivier, and Rauch (1999), for a recent review.

To be more precise, we shall seek a local-in-time solution of (1.16), which asymptotically takes the following form:

$$\begin{aligned} \psi^\varepsilon(t,x) &= \sqrt{\varepsilon}\, u^\varepsilon(t,x,\phi(t,x)/\varepsilon), \\ u^\varepsilon(t,x,\theta) &\sim \sum_{j=0}^{\infty} \varepsilon^{j/2} u_j(t,x,\theta). \end{aligned} \tag{1.21}$$

Here, all the $u_j(t,x,\theta) \in \mathbb{C}^4$ being 2π-periodic w.r.t. $\theta \in \mathbb{R}$. Due to the factor $\varepsilon^{1/2}$, we call them *small semiclassical approximate solutions*, or *small WKB-solutions*. As expected, there are two modes of the phase function $\phi_\pm$, which satisfy the (free) relativistic Hamilton–Jacobi equation, corresponding to positive, resp., negative energies and, of course, convergence of the expansion (1.21) can only hold on a time interval, which corresponds to the existence of smooth solutions $\phi_\pm$. In weakly nonlinear geometrical optics, the homogeneity of the nonlinearity determines the required order of smallness of the asymptotic solution and, as we shall see, the factor $\sqrt{\varepsilon}$ precisely fits with the cubic nonlinearities in (1.16). We will show that for this particular scale we obtain, on the one hand, *independent* propagation of the electronic, resp., positronic phase function $\phi_\pm$ and, the other hand, *nonlinear interaction* of the corresponding principal amplitudes $u_{0,\pm}$.

In other words, we study solutions on the threshold of *adiabatic decoupling*, a phenomena which is already well known in the linear case; cf. Panati, Sohn, and Teufel (19XX). In particular, the importance of the $O(\sqrt{\varepsilon})$-scale for the (linear) Dirac equation is stressed in Fermanian-Kammerer (2003), where one can also find a detailed description of the energy-transfer between electrons and positrons in terms of *two-scale* Wigner measures. These results, together with ours, suggest that if one wants to obtain a semiclassical $O(1)$-approximation in the strongly coupled regime, one needs to take into account simultaneous scales of order ε and $O(\sqrt{\varepsilon})$. These

asymptotic solutions are then appropriate for heavily charged particles. We finally remark, that in the very recent paper [Jeanne (2002)], coupled Gauge-fields are studied from a similar point of view as in our work.

This paper is organized as follows: We collect some preliminaries in Sec. II, then we shall determine the critical exponent and the corresponding eikonal equation of the approximate WKB-type solution in Sec. III. The corresponding ε-oscillations introduced by the nonlinearity are determined in Sec. IV and the nonlinear transport of the approximation along the rays of geometrical optics is obtained in Sec. V. Finally, in Sec. VI we shall prove that there exists a (local-in-time) solution of the MD system which stays close to the approximation and we also collect some further qualitative results.

II. PRELIMINARIES

In the following, we will assume that no external electromagnetic fields are present:

$$V^{\mathrm{ext}}(t,x)\equiv 0, \quad A^{\mathrm{ext}}(t,x)\equiv 0. \tag{2.1}$$

Moreover, we assume that at $t=0$ we have

$$V_I^\varepsilon(x)=\tilde{V}_I^\varepsilon(x)\equiv 0, \quad A_I^\varepsilon(x)=\tilde{A}_I^\varepsilon(x)\equiv 0. \tag{2.2}$$

Neither of these assumptions changes the following analysis significantly. They are only imposed for the sake of simplicity. Further note that the DM system is time-reversible, but w.r.o.g. we shall consider positive times only in the sequel.

Using the fundamental solution of the wave equation in dimension $d=3$ and for times $t>0$, we find the following expression for V, called *the retarded potential*:

$$V^\varepsilon[\psi^\varepsilon](t,x)=\frac{1}{4\pi}\int_{|x-y|\leqslant t}\frac{|\psi^\varepsilon(t-|x-y|,y)|^2}{|x-y|}\,dy=:\ \mathcal{G}_r(t,x)*|\psi^\varepsilon(t,x)|^2, \tag{2.3}$$

where $*$ denotes the convolution w.r.t. (t,x) and

$$\mathcal{G}_r(t,x):=\frac{\Theta(t)}{4\pi|x|}\,\delta(t-|x|). \tag{2.4}$$

Likewise, A^ε can be written as

$$A^\varepsilon[\psi^\varepsilon](t,x)=\mathcal{G}_r(t,x)*\langle\psi^\varepsilon(t,x),\alpha^k\psi^\varepsilon(t,x)\rangle. \tag{2.5}$$

If assumption (2.2) is dropped, we would have to additionally include the homogeneous solution of the wave equation in (2.3), (2.5).

Using these representations, we shall rewrite (1.16)–(1.18) in the form of a *semilinear Dirac equation*:

$$\begin{aligned} i\varepsilon\partial_t\psi^\varepsilon-\mathcal{D}_A^\varepsilon(t,x,\varepsilon D_x)\psi^\varepsilon&=\ 0, x\in\mathbb{R}^3,\ \ t>0,\\ \psi^\varepsilon|_{t=0}&=\ \psi_I^\varepsilon(x), \end{aligned} \tag{2.6}$$

where $\mathcal{D}_A^\varepsilon$ is a *matrix-valued* differential operator ($D_x:=-i\nabla$). The corresponding ε-*dependent* symbol is given by

$$\mathcal{D}_A^\varepsilon(t,x,\xi)=\alpha\cdot(\xi-A^\varepsilon[\psi^\varepsilon](t,x))+\beta+V^\varepsilon[\psi^\varepsilon](t,x), \tag{2.7}$$

where $x,\xi,\in\mathbb{R}^3, t\in\mathbb{R}$. Here and in the following we use the notation

$$\alpha\cdot\xi := \sum_{k=1}^{3} \alpha^k \xi_k . \tag{2.8}$$

Note that in the nonlinear equation (2.6), the potentials $A^\varepsilon[\psi^\varepsilon]$, $V^\varepsilon[\psi^\varepsilon]$ depend *non-locally* on ψ^ε, as indicated by the bracket-notation.

Multiplying (2.6) with ψ^ε and taking imaginary parts, we obtain the usual conservation law for $\|\psi^\varepsilon(t,x)\|_2$, hence the *conservation of charge*:

$$\int_{\mathbb{R}^3} \langle \psi^\varepsilon(t,x), \psi^\varepsilon(t,x)\rangle \, dx = \|\psi^\varepsilon(t,x)\|_2^2 = \text{const.} \tag{2.9}$$

The *free Dirac operator* will be denoted by

$$\mathcal{D}(\varepsilon D_x)\psi^\varepsilon := -i\varepsilon(\alpha\cdot\nabla)\psi^\varepsilon + \beta\psi^\varepsilon, \tag{2.10}$$

with the symbol

$$\mathcal{D}(\xi) = \alpha\cdot\xi + \beta. \tag{2.11}$$

This 4×4 matrix has two different eigenvalues $h_\pm(\xi)$ of multiplicity 2 each:

$$h_\pm(\xi) := \pm\lambda(\xi), \quad \xi\in\mathbb{R}^3, \tag{2.12}$$

where

$$\lambda(\xi) := \sqrt{|\xi|^2+1}, \quad \xi\in\mathbb{R}^3. \tag{2.13}$$

As expected, the eigenvalues $h_\pm(\xi)$ are nothing but the *free Hamiltonian* for a *relativistic* particle. The positive, resp., negative sign in (2.13) corresponds to *electrons*, resp., *positrons*. By straightforward calculations we obtain the following lemma.

Lemma 2.1: The spectral projectors $\Pi_\pm(\xi):\mathbb{C}^4\to\mathbb{C}^4$, *associated to* $h_\pm(\xi)$ *are given by*

$$\Pi_\pm(\xi) := \frac{1}{2}\left(\mathrm{id}_4 \pm \frac{1}{\lambda(\xi)}\mathcal{D}(\xi)\right), \quad \Pi_\pm\Pi_\mp \equiv 0. \tag{2.14}$$

The matrix-valued symbol $\mathcal{D}(\xi)$ can therefore be decomposed into its positive and negative energy part in the following way:

$$\mathcal{D}(\xi) = h_+(\xi)\Pi_+(\xi) + h_-(\xi)\Pi_-(\xi). \tag{2.15}$$

We notice that

$$h_\pm(-\xi) = h_\pm(\xi), \quad \text{whereas} \quad \Pi_\pm(-\xi) = \Pi_\mp(\xi). \tag{2.16}$$

For later purposes, we also define the following definition.

Definition 2.2: The *partial inverse* $\Lambda_\pm(\xi):\mathbb{C}^4\to\mathbb{C}^4$, associated to $\Pi_\pm(\xi)$, is given by

$$\Lambda_\pm(\xi)\Pi_\pm(\xi) = 0, \quad \Lambda_\pm(\xi)\mathcal{D}(\xi)X = (\mathrm{id}_4 - \Pi_\pm(\xi))X, \quad \forall X\in\mathbb{C}^4. \tag{2.17}$$

Finally, we recall the definition of *asymptotic equivalences*.

Definition 2.3: Let $\mathcal{O}\subseteq\mathbb{R}^n$, $n\geqslant 1$, be an open set, $a_j(y)\in C^\infty(\mathbb{R}^n;\mathbb{C}^n)$ and $a^\varepsilon\in C^\infty(]0,\varepsilon_0[\times\mathbb{R}^n;\mathbb{C}^n)$. Then we say that a^ε is asymptotically equivalent to the formal sum $\Sigma_{j=0}^\infty \varepsilon^j a_j$ and write

$$a^\varepsilon(y) \sim \sum_{j=0}^{\infty} \varepsilon^j a_j(y), \tag{2.18}$$

if for every $m>0$, every multiindex σ and every compact subset $\mathcal{K}\subset\mathcal{O}$, there exists a $C_{m,\sigma}>0$, such that

$$\sup_{\mathcal{K}}\left|\partial_y^\sigma\left(a^\varepsilon(y)-\sum_{j=0}^{m}\varepsilon^j a_j(y)\right)\right|\leqslant C_{m,\sigma}\varepsilon^m. \tag{2.19}$$

III. GENERALIZED WKB–ANSATZ AND THE EIKONAL EQUATION

At first we will show that the desired $O(\sqrt{\varepsilon})$-asymptotics for the spinor field fits into the framework of weakly nonlinear (dispersive) geometrical optics, as introduced in Donat and Rauch (1997), for nonlinear hyperbolic systems.

We plug the following *generalized WKB–Ansatz* into Eq. (2.6):

$$\psi^\varepsilon(t,x)=\varepsilon^p\,u^\varepsilon(t,x,\phi(t,x)/\varepsilon),$$

$$u^\varepsilon(t,x,\theta)\sim\sum_{j=0}^{\infty}\varepsilon^{jp}u_j(t,x,\theta), \tag{3.1}$$

where the functions $u_j(t,x,\theta)\in\mathbb{C}^4$ are assumed to be sufficiently smooth and 2π-periodic w.r.t. $\theta\in\mathbb{R}$. This gives

$$\begin{aligned}0=&\ i\varepsilon^{p+1}\partial_t u^\varepsilon-\varepsilon^p\,\mathcal{D}_A^\varepsilon(t,x,\varepsilon D_x)u^\varepsilon\\ =&\ i\varepsilon^{p+1}(\partial_t u^\varepsilon+(\alpha\cdot\nabla)u^\varepsilon)-\varepsilon^p\beta u^\varepsilon+i\varepsilon^p\,(\partial_t\phi+(\alpha\cdot\nabla\phi))\partial_\theta u^\varepsilon+\varepsilon^{3p}\mathcal{N}^\varepsilon[u^\varepsilon],\end{aligned} \tag{3.2}$$

with a *nonlinearity*, $\mathcal{N}^\varepsilon:\mathbb{C}^4\to\mathbb{C}^4$, defined by

$$\mathcal{N}^\varepsilon[u^\varepsilon]:=((\alpha\cdot A^\varepsilon[u^\varepsilon])-V^\varepsilon[u^\varepsilon])u^\varepsilon. \tag{3.3}$$

The strategy is now to expand the right-hand side of (3.2) as

$$\varepsilon^p\sum_{j=0}^{\infty}\varepsilon^{jp}R_j(t,x) \tag{3.4}$$

and choose the coefficients u_j of (3.1) in such a way, that $R_j(t,x)\equiv 0$, $\forall j\in\mathbb{N}$.

It is important to note that the first term on the right hand side of (3.2) is of order ε^{p+1}, whereas the second and the third are $\sim O(\varepsilon^p)$. Since $A^\varepsilon[u^\varepsilon]$, $V^\varepsilon[u^\varepsilon]$ are of order ε^{2p}, by Eqs. (2.3), (2.5), the function $\mathcal{N}^\varepsilon[u^\varepsilon]$ is of order ε^{3p}. This nonlinear term is supposed to be *small*, more precisely, it should not enter into the equation for R_0, describing terms of order $O(\varepsilon^p)$, but rather into expressions of $O(\varepsilon^{p+1})$. Thus we are led to the following *normalization condition:*

$$3p=p+1, \tag{3.5}$$

implying $p=1/2$. With this normalization we have $u^\varepsilon\sim O(\varepsilon^{1/2})$ (just as required by the scaling presented in the introduction), whereas the nonlinear term satisfies $\mathcal{N}^\varepsilon[u^\varepsilon]\sim O(\varepsilon^{3/2})$.

Remark 3.1: The choice $p=1/2$ gives the critical exponent in the sense that for amplitudes $O(\varepsilon^{1/2})$ one can prove simultaneously the existence of the approximate smooth solution for times $t=O(1)$, i.e., on a time-scale *independent* of ε, and nontrivial nonlinear behavior in the principal term of the approximation; cf. Donat and Rauch (1997); and Joly, Metivier, and Rauch (1999).

Setting $R_0(t,x)=0$ yields

$$i(\partial_t\phi+(\alpha\cdot\nabla\phi))\partial_\theta u_0-\beta u_0=0. \tag{3.6}$$

Since $u_j\in C^\infty(\mathbb{R}^4\times\mathbb{S}^1;\mathbb{C}^4)$ it can be *Fourier-expanded* w.r.t. θ,

$$u_0(t,x,\theta)=\sum_{m\in\mathbb{Z}} u_{0,m}(t,x)e^{im\theta}. \tag{3.7}$$

By this procedure, we find the following equation for the coefficients $u_{0,m}$:

$$L(m\,d\phi(t,x))u_{0,m}:=(m\,\partial_t\phi+\mathcal{D}(m\nabla\phi))u_{0,m}=0, \tag{3.8}$$

where $\mathcal{D}(\nabla(m\phi))$ is the 4×4 symbol matrix of the free Dirac operator evaluated at $\xi=(m\phi(t,x))$. In order to have a nontrivial solution $u_{0,m}\neq0$ we impose the condition that there exists an open set $\Omega\subseteq\mathbb{R}^{1+3}$, having a nontrivial intersection with $\{t=0\}$, s.t.,

$$\det L(m\,d\phi(t,x))=0,\quad \forall(t,x)\in\Omega\subseteq\mathbb{R}^{1+3}. \tag{3.9}$$

Using Eqs. (2.12), (2.15), this is equivalent to

$$(m\,\partial_t\phi)^2-|m\nabla\phi|^2=1,\quad \forall(t,x)\in\Omega\subseteq\mathbb{R}^{1+3}. \tag{3.10}$$

Thus, for $m=\pm1$, the phase function ϕ satisfies (in Ω) the *eikonal equation* for the *Klein–Gordon operator,* i.e.,

$$(\partial_t\phi)^2-|\nabla\phi|^2=1,\quad \forall(t,x)\in\Omega\subseteq\mathbb{R}^{1+3}. \tag{3.11}$$

Indeed, it is easy to see that the choices $m=\pm1$ are the only possibilities, since Eq. (3.11) gives

$$(m\partial_t\phi)^2-|m\nabla\phi|^2-1=(m^2-1)((\partial_t\phi)^2-|\nabla\phi|^2)=m^2-1, \tag{3.12}$$

which is different from zero for all $m\neq\pm1$. Hence, in the Fourier-series (3.7), there appear only two nontrivial *harmonics,* which are associated to the eikonal equation (3.11): namely $\exp(i\phi(t,x)/\varepsilon)$, for $m=1$ and $\exp(-i\phi(t,x)/\varepsilon)$, for $m=-1$.

For $m=\pm1$ the equation (3.11) is fulfilled by two possible ϕ's, obtained from

$$\partial_t\phi_\pm(t,x)=h_\pm(\nabla\phi_\pm(t,x))\equiv\pm\sqrt{|\nabla\phi_\pm(t,x)|^2+1}=0. \tag{3.13}$$

This is the *Hamilton–Jacobi equation* for free relativistic particles. The following lemma guarantees the existence and uniqueness of smooth solutions, where from now on, we shall denote by $D^2f(x)$, the Hessian of a given function $f:\mathbb{R}^3\to\mathbb{R}$.

Lemma 3.2: Given $\phi_I\in C^\infty(\mathbb{R}^3;\mathbb{R})$, s.t. $\|D^2\phi_I(x)\|\leqslant C$, there exist $T_\pm>0$ and uniquely determined functions $\phi_\pm\in C^\infty(\Omega_\pm;\mathbb{R})$, where $\Omega_\pm:=[0,T_\pm)\times\mathbb{R}^3$, s.t.

$$\begin{aligned}\partial_t\phi_\pm(t,x)&=h_\pm(\nabla\phi_\pm(t,x)),\quad \forall(t,x)\in\Omega_\pm,\\ \phi|_{t=0}&=\phi_I(x).\end{aligned} \tag{3.14}$$

Proof: We only proof the assertion for ϕ_+, since the other case is completely analogous. The initial value problem is *noncharacteristic* everywhere, since

$$\partial_t\phi_+(0,x)=\sqrt{|\nabla\phi_+(0,x)|^2+1}\ \neq0,\ \forall x\in\mathbb{R}^3. \tag{3.15}$$

Thus, $\partial_t\phi_+(0,x)$ can be obtained from the initial data $\phi_+(0,x)=\phi_I(x)\in C_b^\infty(\mathbb{R}^3)$ at each point $x\in\mathbb{R}^3$. Standard PDE theory then guarantees the existence of a unique smooth solution $\phi_+\in C^\infty(\Omega_+;\mathbb{R})$, as long as

$$1-t\,\|D^2h_+(\nabla\phi_I)\|\,\|D^2\phi_I\|\neq0. \tag{3.16}$$

Since $D^2H(\xi)$ is uniformly bounded, this condition holds by assumption and the assertion is proved. □

Remark 3.3: The assumption in Lemma 3.2 can be relaxed to $\phi_I \in C^\infty(\mathbb{R}^3;\mathbb{R})$. In this case, however, one cannot guarantee the existence of a smooth solution ϕ in a space–time slab, but only in some open set $\mathcal{O}\subset\mathbb{R}^{1+3}$. In the following, this would lead to some technical difficulties, which we want to avoid, though, the whole procedure can be generalized to that case.

By Eq. (3.13), we have

$$-\phi_\pm(t,x)=\phi_\mp(t,x), \tag{3.17}$$

assuming that it holds initially at $\{t=0\}\subset\Omega$. In the following, we therefore consider only the solution to (3.13) with a positive sign in front of the square root and write for it $\phi(t,x)\equiv\phi_+(t,x)$. Also, we henceforth denote by $\Omega:=[0,T_+)\times\mathbb{R}^3$ the slab, in which the existence of a smooth function ϕ is guaranteed. This we can do w.r.o.g., as will become clear in a moment:

Since for $\phi\equiv\phi_+$ it holds that $\partial_t\phi-h_+(\nabla\phi)=0$, Eq. (3.8) implies the following *polarization conditions*, locally for all $(t,x)\in\Omega$:

$$(\Pi_-(\nabla\phi)u_{0,+1})(t,x)=0 \Leftrightarrow (\Pi_+(\nabla\phi)u_{0,+1})(t,x)=u_{0,+1}(t,x). \tag{3.18}$$

Likewise, we get

$$(\Pi_+(\nabla\phi)u_{0,-1})(t,x)=0 \Leftrightarrow (\Pi_-(\nabla\phi)u_{0,-1})(t,x)=u_{0,-1}(t,x). \tag{3.19}$$

One easily checks, using (2.16) and (3.17), that the conditions obtained with the choice $\phi=\phi_-$, are *equivalent* to (3.18), (3.19). Thus, Eq. (3.8) indeed carries two degrees of freedom for the phase, given by $\pm\phi$ (or equivalently ϕ_+, ϕ_-). The amplitudes are then rigidly linked, by (3.18), (3.19).

In summary, we find that the *principal term* $u_0(t,x,\theta)$ in our asymptotic description is given by

$$u_0(t,x,\phi(t,x)/\varepsilon):=u_{0,+1}(t,x)e^{i\phi(t,x)/\varepsilon}+u_{0,-1}(t,x)e^{-i\phi(t,x)/\varepsilon}, \tag{3.20}$$

where the amplitudes are polarized according to (3.18), (3.19). From now on we shall use the simplified notation $u_{0,\pm1}=u_{0,\pm}$.

IV. OSCILLATIONS OF THE NONLINEARITY

Let us determine the response of the wave equations (1.17), (1.18) to r.h.s. source terms induced by functions of the form (3.20):

To this end, we calculate:

$$|u_0(t,x,\phi(t,x)/\varepsilon)|^2=|u_{0,+}(t,x)|^2+|u_{0,-}(t,x)|^2. \tag{4.1}$$

The terms, that mix the electronic and positronic components cancel, since $\Pi_\pm$ is Hermitian and $\Pi_\pm\Pi_\mp\equiv0$. Hence, we get from (2.3) (at least formally), that the scalar potential V generated by the principal term u_0, is simply given by

$$V[u_0]=\mathcal{G}_r(t,x)*(|u_{0,+}(t,x)|^2+|u_{0,-}(t,x)|^2). \tag{4.2}$$

In order to calculate the magnetic potential corresponding to u_0, we first note that, by definition, we have the following identity:

$$\Pi_\pm(\xi)(\alpha\cdot\xi+\beta)=h_\pm(\xi)\ \Pi_\pm(\xi). \tag{4.3}$$

Differentiating w.r.t. ξ_k and multiplying (from the right) with $\Pi_\pm(\xi)$ gives

$$\Pi_\pm(\xi)\alpha^k\Pi_\pm(\xi)=\Pi_\pm(\xi)(\partial_{\xi_k}h_\pm(\xi))\Pi_\pm(\xi)=\pm\frac{\xi_k}{\sqrt{|\xi|^2+1}}\ \Pi_\pm(\xi), \tag{4.4}$$

since $\Pi_{\pm}^2(\xi)=\Pi_{\pm}(\xi)$. The expression

$$\omega_{\pm}(\xi):=\nabla_{\xi}h_{\pm}(\xi)=\pm\frac{\xi}{\lambda(\xi)}, \tag{4.5}$$

is called the electronic, resp., positronic *group velocity*, $\omega_{\pm}\in C^{\infty}(\mathbb{R}^3;\mathbb{R}^3)$. Using this definition, we obtain for $k=1,2,3$:

$$\begin{aligned}\langle u_0(t,x,\phi(t,x)/\varepsilon),\alpha^k u_0(t,x,\phi(t,x)/\varepsilon)\rangle&\\ =\omega_{+,k}(\nabla\phi(t,x))|u_{0,+}(t,x)|^2+\omega_{-,k}(\nabla\phi(t,x))|u_{0,-}(t,x)|^2&\\ +\langle u_{0,+}(t,x),\alpha^k u_{0,-}(t,x)\rangle e^{-i2\phi(t,x)/\varepsilon}+\langle u_{0,-}(t,x),\alpha^k u_{0,+}(t,x)\rangle e^{i2\phi(t,x)/\varepsilon}.&\end{aligned} \tag{4.6}$$

The oscillating terms are usually called the *Zitterbewegung* of the Dirac-current, cf. Schwabl (1999), p. 195. The fact that the current-density corresponding to u_0 carries ε-oscillations is in sharp contrast to the WKB-approach for Schrödinger-type problems; see, e.g., Gérard (1992) and Grenier (1998).

The Zitterbewgung may cause severe problems since *a priori* one cannot exclude the possibility of *resonant interactions* between the principal term u_0 and the magnetic potential $A^{\varepsilon}[u_0]$ obtained from (1.18) with the r.h.s. given by (4.6). If this happens to be the case, our one-phase ansatz (3.1) breaks down and instead one would need to establish a so-called *resonant asymptotic expansion* in the spirit of Joly, Metivier, and Rauch (1993). [We remark that so far, only the case of resonances in one spatial dimension can be treated rigorously; cf. Joly, Metivier, and Rauch (1999).]

We will show that these problems do not appear in our situation. To this end, we need to describe precisely what kind of ε-oscillations are present in $A^{\varepsilon}[u_0]$.

First we note that, by the superposition principle, every term appearing on the r.h.s. of (4.6) generates its own potential field. The nonoscillating terms of (4.6) lead to a standard hyperbolic problem; hence (2.5) gives

$$A_0[u_0](t,x):=\mathcal{G}_r(t,x)*(\omega_+(\nabla\phi)|u_{0,+}|^2+\omega_{-,k}(\nabla\phi)|u_{0,-}|^2)(t,x). \tag{4.7}$$

In order to treat the Zitterbewegung, let us define $Z:=(Z_1,Z_2,Z_3)$ by

$$\begin{aligned}Z_k(t,x,\phi(t,x)/\varepsilon):=\langle u_{0,+}(t,x),\alpha^k u_{0,-}(t,x)\rangle e^{-i2\phi(t,x)/\varepsilon}+\langle u_{0,-}(t,x),\alpha^k u_{0,+}(t,x)\rangle e^{i2\phi(t,x)/\varepsilon},&\\ k=1,2,3.&\end{aligned} \tag{4.8}$$

Using this definition, we can now prove the following lemma.

Lemma 4.1: Let $\Omega\subseteq\mathbb{R}^{1+3}$ be the slab in which existence of a smooth phase $\phi\in C^{\infty}(\Omega;\mathbb{R})$, satisfying (3.14), is guaranteed. Then, given $Z\in C^{\infty}(\Omega\times\mathbb{S}^1;\mathbb{C}^3)$, as in (4.8), there exists a uniquely determined smooth $A^{\varepsilon}\in C^{\infty}(\Omega\times\mathbb{S}^1;\mathbb{C}^3)$, with

$$A^{\varepsilon}(t,x,\theta)\sim\sum_{l=1}^{\infty}\varepsilon^l A_l(t,x,\theta), \tag{4.9}$$

s.t. $A^{\varepsilon}(t,x,\phi(t,x)/\varepsilon)$ satisfies

$$\begin{aligned}&\Box A^{\varepsilon}(t,x)-Z(t,x)\sim 0,\quad \text{in } C^{\infty}(\Omega;\mathbb{C}^3),\\ &A^{\varepsilon}|_{t=0}=\partial_t A^{\varepsilon}|_{t=0}=0.\end{aligned} \tag{4.10}$$

More precisely, $A_l(t,x,\phi(t,x)/\varepsilon)$ can be written in the following form:

$$A_l(t,x,\phi(t,x)/\varepsilon)=A_l^+(t,x)e^{i2\phi(t,x)/\varepsilon}+A_l^-(t,x)e^{-i2\phi(t,x)/\varepsilon}, \tag{4.11}$$

with principal amplitudes $A_1^{\pm} \in C^{\infty}(\Omega;\mathbb{C}^3)$, *given by*

$$A_{1,k}^{\pm}(t,x) = \pm \langle u_0(t,x), \alpha^k u_0(t,x)\rangle. \tag{4.12}$$

Proof: The proof can be done separately for each spatial component of $A^{\varepsilon}(t,x,\theta)$ and for both types of oscillations, corresponding to $\pm 2\phi$. Hence, we are led to the following type of problem:

$$\Box a^{\varepsilon}(t,x) = b(t,x) e^{\pm i2\phi(t,x)/\varepsilon}, \quad (t,x) \in \Omega,$$

$$a^{\varepsilon}|_{t=0} = \partial_t a^{\varepsilon}|_{t=0} = 0, \tag{4.13}$$

for some given $b \in C^{\infty}(\Omega;\mathbb{C})$. Let us define a new variable $f^{\varepsilon}(t,x) \in \mathbb{C}^5$ by

$$f^{\varepsilon}(t,x) := (\partial_1 a^{\varepsilon}, \partial_2 a^{\varepsilon}, \partial_3 a^{\varepsilon}, \partial_t a^{\varepsilon}, a^{\varepsilon})^{\top}(t,x).$$

Further, denoting by

$$\hat{b}(t,x) := (0,0,0,b(t,x),0)^{\top},$$

we can rewrite (4.13) in the form of a symmetric hyperbolic system,

$$(\partial_t + (\lambda \cdot \nabla) + \kappa) f^{\varepsilon}(t,x) = \hat{b}(t,x) e^{\pm i2\phi(t,x)/\varepsilon}, \tag{4.14}$$

with λ^k, κ, denoting realvalued (symmetric) 5×5 matrices. In our case, these matrices are simply given by [see, e.g., Racke (1992), p. 21, for more details]:

$$\lambda^k := -(\delta_{mk}\delta_{n4} + \delta_{m4}\delta_{nk})_{m,n}, \quad \kappa := -(\delta_{5m}\delta_{4n})_{m,n}, \quad m,n = 1,\ldots,5, \tag{4.15}$$

where δ_{ab} denotes the Kronecker symbol and $k = 1,2,3$.

It is now possible to use the existing results on linear geometrical optics, provided the phase $\pm 2\phi$ is *not* characteristic for the system (4.14), i.e.,

$$\det(\pm 2\partial_t\phi(t,x) \pm 2\lambda \cdot \nabla\phi(t,x) + \kappa) \neq 0, \quad \forall (t,x) \in \Omega. \tag{4.16}$$

Computing this determinant, we obtain the condition

$$\pm 32\,(\partial_t\phi)^3((\partial_t\phi)^2 - |\nabla\phi|^2) \neq 0, \quad \forall (t,x) \in \Omega. \tag{4.17}$$

Since, by assumption, ϕ solves the Klein–Gordon eikonal equation (3.11) the second factor on the l.h.s. of (4.17) is equal to one and thus, different from zero in all of Ω. On the other hand we get from (3.11): $(\partial_t\phi)^3 = (|\nabla\phi|^2 + 1)^{3/2} \neq 0$, $\forall (t,x) \in \Omega$. Hence, condition (4.16) is fulfilled and the assertion follows from Theorem 4.4 in Rauch (1992). In particular we get

$$A_{1,k}^{\pm}(t,x) = \frac{\mp 1}{-(\partial_t\phi)^2 + |\nabla\phi|^2} \langle u_0(t,x), \alpha^k u_0(t,x)\rangle = \pm\langle u_0(t,x), \alpha^k u_0(t,x)\rangle, \tag{4.18}$$

which concludes the proof. □

Lemma 4.1 shows that the Zitterbewegung in (4.6) generates a magnetic potential which is small, i.e., at least of order $O(\varepsilon)$. Moreover the ε-oscillations, appearing in A^{ε}, are exactly the *same* as in the (4.6) and hence we can consistently proceed with our one-phase expansion for ψ^{ε}.

Remark 4.2: Although the MD system is hyperbolic, Lemma 4.1 can be considered as an analogu of so-called *elliptic* high frequency asymptotics, the main feature of which is the fact that asymptotic solutions can be obtained by *local* (in t,x) algebraic relations. In other words, the Maxwell system can be considered *transparent* w.r.t. to the oscillations generated by the Dirac equation.

The result of Lemma 4.1 implies that the nonlinearity $\mathcal{N}^\varepsilon[u_0]$, defined in (3.3), admits an asymptotic expansion of the form

$$\mathcal{N}^\varepsilon[u_0](t,x,\theta) \sim \mathcal{N}_0[u_0](t,x,\theta) + \sum_{l=1}^{\infty} \varepsilon^l \mathcal{N}_l(t,x,\theta), \tag{4.19}$$

where, using the expressions (4.2), (4.7), we have

$$\mathcal{N}_0(t,x,\theta) = \left((\alpha \cdot A_0[u_0](t,x)) - V[u_0](t,x)\right) u_0(t,x,\theta), \tag{4.20}$$

and for all $l \geqslant 1$:

$$\mathcal{N}_l(t,x,\theta) := (\alpha \cdot A_l(t,x,\theta))\, u_0(t,x,\theta), \tag{4.21}$$

with A_l given by (4.11).

Note that the expression (4.19) represents two kinds of ε-oscillations: Those described by phase-functions $\pm\phi$ are present in all terms $\mathcal{N}_l$ with $l \geqslant 0$, whereas ε-oscillations with phases $\pm 3\phi$ appear in $\mathcal{N}_l$ with $l > 0$. Also, note that u_0 enters in a *nonlocal* way only in the lowest order term (4.20).

V. NONLINEAR TRANSPORT ALONG RAYS

We need to find an evolution equation, which determines u_0 from the initial data. To this end, let us define an operator $\mathbb{P}$, which projects on the set of harmonics corresponding to solutions of the eikonal equation (3.11).

Definition 5.1: Given some $v \in C^\infty(\mathbb{R}^4 \times \mathbb{S}^1; \mathbb{C}^4)$, which can be represented by

$$v(t,x,\theta) = \sum_{m \in \mathbb{Z}} v_m(t,x) e^{im\theta}, \tag{5.1}$$

we define the action of $\mathbb{P}$ on v, by

$$(\mathbb{P}v)(t,x,\theta) := (\Pi_+(\nabla\phi)v_{+1})(t,x)e^{i\theta} + (\Pi_-(\nabla\phi)v_{-1})(t,x)e^{-i\theta}. \tag{5.2}$$

In words: $\mathbb{P}$ picks modes corresponding to $m = \pm 1$ and multiplies them with the matrices $\Pi_\pm(\nabla\phi)$. Note that, at least in Ω, it holds true that

$$(\mathbb{P}u_0)(t,x,\theta) = u_0(t,x,\theta), \tag{5.3}$$

in view of (3.8) and (3.18), (3.19).

From (3.2), we have that the evolution of u_0 is determined by terms of order $O(\varepsilon^{p+1}) = O(\varepsilon^{3/2})$. Setting the corresponding coefficient in (3.4) equal to zero, i.e., $R_2(t,x) = 0$, yields

$$i(\partial_t\phi + (\alpha\cdot\nabla\phi))\partial_\theta u_2 - \beta u_2 + i(\partial_t u_0 + (\alpha\cdot\nabla)u_0) + \mathcal{N}_0[u_0] = 0, \tag{5.4}$$

with $\mathcal{N}_0[u_0]$ as in (4.20). Equation (5.4) implies

$$i(\partial_t + (\alpha\cdot\nabla))u_0 + \mathcal{N}_0[u_0] \in \mathrm{ran}(i(\partial_t\phi + (\alpha\cdot\nabla\phi))\partial_\theta - \beta). \tag{5.5}$$

Applying $\mathbb{P}$ to (5.4) eliminates the term including u_2, since $\mathbb{P}$ projects on the kernel of $i(\partial_t\phi + (\alpha\cdot\nabla\phi))\partial_\theta - \beta$ and we obtain

$$i\mathbb{P}\partial_t u_0 + i\mathbb{P}(\alpha\cdot\nabla)u_0 + \mathbb{P}\mathcal{N}_0[u_0] = 0. \tag{5.6}$$

Using the fact that $\mathbb{P}u_0 = u_0$, by (5.3), this gives

$$\mathbb{P}\partial_t(\mathbb{P}u_0) + \mathbb{P}(\alpha\cdot\nabla)(\mathbb{P}u_0) = i\mathbb{P}\mathcal{N}_0[\mathbb{P}u_0]. \tag{5.7}$$

This equation is similar to the one appearing in Donat and Rauch (1997), however, in contrast to the quoted work, our nonlinearity constitutes only the first term of an asymptotic expansion of the full $\mathcal{N}^\varepsilon[u_0]$.

We proceed by stating a useful identity:

$$\alpha^k \Pi_\pm(\xi) = \Pi_\mp(\xi)\alpha^k + \omega_{\pm,k}(\xi)\mathbb{I}_4, \tag{5.8}$$

obtained from straightforward calculations. After more lengthy but straightforward calculations, in which we apply the relations (4.3), (4.4), and (5.8), we can express the l.h.s. of (5.7) in the form of a transport operator:

$$\Pi_\pm \partial_t(\Pi_\pm u_0) + \Pi_\pm \alpha\cdot\nabla(\Pi_\pm u_0) = \partial_t u_{0,\pm} + (\omega_\pm(\nabla\phi)\cdot\nabla)u_{0,\pm} + \tfrac{1}{2}\operatorname{div}(\omega_\pm(\nabla\phi))u_{0,\pm}. \tag{5.9}$$

On the other hand, computing the action of the projector $\mathbb{P}$ on the nonlinear term $\mathcal{N}_0[u_0]$, we get

$$\begin{aligned}\mathbb{P}\mathcal{N}_0[\mathbb{P}u_0] = {} & e^{i\phi/\varepsilon}((A_0[u_0]\cdot\omega_+(\nabla\phi)) - V[u_0])\, u_{0,+} \\ & + e^{-i\phi/\varepsilon}((A_0[u_0]\cdot\omega_-(\nabla\phi)) - V[u_0])\, u_{0,-}.\end{aligned} \tag{5.10}$$

Here we have again used (4.4). Thus, we finally conclude, that the time-evolution of the *principal amplitudes* $u_{0,\pm}$ is governed by the following semilinear first-order system:

$$\begin{aligned}(\partial_t + (\omega_+(\nabla\phi)\cdot\nabla))u_{0,+}(t,x) &= \Gamma_+[u_0](t,x)\, u_{0,+}(t,x), \\ (\partial_t + (\omega_-(\nabla\phi)\cdot\nabla))u_{0,-}(t,x) &= \Gamma_-[u_0](t,x)\, u_{0,-}(t,x),\end{aligned} \tag{5.11}$$

where

$$\Gamma_\pm[u_0](t,x) := iA_0[u_0]\cdot\omega_\pm(\nabla\phi) - iV[u_0] - \tfrac{1}{2}\operatorname{div}(\omega_\pm(\nabla\phi)). \tag{5.12}$$

By construction, the polarization of $u_{0,\pm}$ is conserved during the evolution. The system (5.11) determines $(\mathbb{P}u_0)(t,x,\theta)$, from its initial data $(\mathbb{P}u_0)(0,x,\theta)$ and since $(\mathbb{P}u_0) = u_0$, we have completely constructed u_0.

Multiplying (5.11) by $\overline{u_{0,+}}$, resp., $\overline{u_{0,-}}$ and integrating by parts, we obtain the important property of charge-conservation:

$$\int_{\mathbb{R}^3} |u_{0,+}(t,x)|^2 + |u_{0,-}(t,x)|^2 \; dx = \|u_0(t,x)\|_2^2 = \text{const.} \tag{5.13}$$

Given u_0, determined by (5.11), it remains to construct the higher order terms $u_j(t,x,\theta)$, $j \geqslant 1$ of our approximate solution. This can be done by a similar construction as given in Donat and Rauch (1997).

We expand the cubic nonlinearity $\mathcal{N}^\varepsilon[u^\varepsilon]$ in powers of ε:

$$\mathcal{N}^\varepsilon[u_0 + \varepsilon u_1 + \cdots] \sim \mathcal{N}^\varepsilon[u_0] + \varepsilon\mathcal{M}^\varepsilon[u_0,u_1] + \cdots, \tag{5.14}$$

where, using the definitions (4.2), (4.8), we easily compute

$$\begin{aligned}\mathcal{M}^\varepsilon[u_0,u_1] = {} & 2\,(\mathcal{G}_r * \langle u_0,u_1\rangle)u_0 + V[u_0]u_1 + \alpha\cdot(\mathcal{G}_r * Z)\, u_1 \\ & + \left(\sum_{k=1}^3 \alpha^k(\mathcal{G}_r * \langle u_0, \alpha^k u_1\rangle + \mathcal{G}_r * \langle u_1, \alpha^k u_0\rangle)\right) u_0.\end{aligned} \tag{5.15}$$

We need to apply Lemma 4.1 to all terms appearing on the r.h.s of (5.14), which results in a similar expansion as given in (4.19). Hence, after rearranging terms in powers of ε, we can write

$$\mathcal{N}^{\varepsilon}[u_0+\varepsilon u_1+\cdots]\sim\mathcal{N}_0[u_0]+\varepsilon\mathcal{N}_1+\varepsilon\mathcal{M}_0[u_0,u_1]+\cdots. \tag{5.16}$$

Consequently, for $j\geqslant 1$, the $O(\varepsilon^{j/2+1/2})$-coefficient is given by

$$\begin{aligned} R_j(t,x)=&\,i(\partial_t\phi+(\alpha\cdot\nabla\phi))\partial_\theta u_j-\beta u_j+i(\partial_t+(\alpha\cdot\nabla))u_{j-2}\\ &+\mathcal{M}_0[u_0,u_{j-2}]+S(u_0,\ldots,u_{n<j-2}), \end{aligned} \tag{5.17}$$

where, as usual, we impose: $u_n(t,x,\theta)=0$, for all $n<0$. The source term S, only depends on lower order coefficients $u_0,\ldots,u_{n<j-2}$. It is obtained by applying Lemma 4.1 to higher order terms in the expansion (5.14), leading to contributions $\mathcal{N}_l$ and $\mathcal{M}_l$ with: $l+1=j/2$.

We can now decompose

$$u_j(t,x,\theta)=(\mathbb{P}u_j)(t,x,\theta)+(\mathrm{id}_4-\mathbb{P})u_j(t,x,\theta). \tag{5.18}$$

Note that in contrast to u_0, where, in view of (5.3), it holds that

$$(\mathrm{id}_4-\mathbb{P})u_0(t,x,\theta)=0, \tag{5.19}$$

we cannot expect all higher order coefficients u_j to be polarized too. Hence, we need to determine separately $\mathbb{P}u_j$ and $(\mathrm{id}_4-\mathbb{P})u_j$. To this end, we introduce the following definition.

Definition 5.2: Again, let $v(t,x,\theta)$ be given as in Definition 5.1, then we define a partial inverse $\mathbb{Q}$, associated to $\mathbb{P}$, by

$$(\mathbb{Q}v)(t,x,\theta):=(\Lambda_+(\nabla\phi)v_{+1})(t,x)e^{i\theta}+(\Lambda_-(\nabla\phi)v_{-1})(t,x)e^{-i\theta}, \tag{5.20}$$

where $\Lambda_\pm$ is the partial inverse to $\Pi_\pm$, defined by (2.17).

Assume now that we already know u_n, for $n<j$, then $(\mathrm{id}_4-\mathbb{P})u_j$ is determined by setting $(\mathbb{Q}R_j)(t,x,\theta)=0$. This gives

$$(\mathrm{id}_4-\mathbb{P})u_j=-\mathbb{Q}(i(\partial_t+(\alpha\cdot\nabla))u_{j-2}+\mathcal{M}_0[u_0,u_{j-2}]+S(u_0,\ldots,u_{n<j-2})). \tag{5.21}$$

On the other hand, setting $(\mathbb{P}R_{j+2})(t,x,\theta)=0$, we obtain an evolution equation for $\mathbb{P}u_j$:

$$i\mathbb{P}\partial_t(\mathbb{P}u_j)+i\mathbb{P}(\alpha\cdot\nabla\mathbb{P}u_j)=-\mathbb{P}\mathcal{M}_0[u_0,u_j]+r(u_0,\ldots,u_j), \tag{5.22}$$

where

$$r(u_0,\ldots,u_j):=-\mathbb{P}S(u_0,\ldots,u_{n<j})-\mathbb{P}(i\partial_t+i(\alpha\cdot\nabla)-\beta)(\mathrm{id}_4-\mathbb{P})u_j. \tag{5.23}$$

Here, the first term on the r.h.s is already known by the inductive hypothesis and the second one is given by Eq. (5.21). Hence, by induction, one can construct all higher order coefficients $u_j(t,x,\theta)$, $j\geqslant 1$ in this way.

Note, that the left hand side of (5.22) is essentially a transport operator, which can be expressed as shown above. Thus (5.22) constitutes a *linear* first order system, which determines the so-called *propagating part* $\mathbb{P}u_j$ from its initial data.

Remark 5.3: The above construction can be generalized to the case, where, additionally *given* external potentials V^{ext}, A^{ext} are included, and/or nonzero Cauchy initial data for the Maxwell equations (1.17), (1.18) are assumed. In the presence of external fields one checks that, instead of (3.13), the following Hamilton–Jacobi equation, corresponding to $m=1$, holds:

$$\partial_t\phi_\pm\pm\sqrt{|\nabla\phi_\pm-A^{\mathrm{ext}}(t,x)|^2+1}+V^{\mathrm{ext}}(t,x)=0. \tag{5.24}$$

Since no other harmonics with $m\neq 1$ exist, one again ends up with two phases $\phi_\pm(t,x)$, corresponding to the electronic, resp., positronic degrees of freedom. In this case, however, $-\phi_+(t,x)\neq\phi_-(t,x)$, in contrast to (3.17). Also, one obtains an additional matrix-valued *spin-*

transport term, appearing on the left-hand side of (5.11) and which can be found in, for example, Bolte and Keppeler (1999); Fermanian-Kammerer (2003); Panati, Sohn, and Teufel (19XX)

We are now in the position of formulating our first theorem (in which we do not aim to impose the weakest possible assumptions). In the following, $C^\infty_{(0)}$ denotes the space of smooth function, compactly supported in $x \in \mathbb{R}^3$.

Theorem 5.4: *Assume that the initial data $\psi^\varepsilon_I(x)$ admits an asymptotic expansion of the form:*

$$\begin{aligned} \psi^\varepsilon_I(x) &= \sqrt{\varepsilon}\, u^\varepsilon(x, \phi_I(x)/\varepsilon), \\ u^\varepsilon(x,\theta) &\sim \sum_{j=0}^{\infty} \varepsilon^{j/2} \chi_j(x,\theta), \end{aligned} \tag{5.25}$$

where $\phi_I \in C^\infty(\mathbb{R}^3;\mathbb{R})$ satisfies $\|D^2\phi_I\| \leqslant C$. Further, let $\chi_j \in C^\infty_{(0)}(\mathbb{R}^3 \times \mathbb{S}^1;\mathbb{C}^4)$ be s.t.,

$$(\mathbb{P}\chi_j)(x,\theta) = \chi_j(x,\theta), \quad \forall j \in \mathbb{N}. \tag{5.26}$$

Then, there exists a $0 < T^* \leqslant T$, a corresponding domain $\Omega^* := [0,T^*) \cap \Omega$ and a uniquely determined $u^\varepsilon \in C^\infty_{(0)}(\Omega^* \times \mathbb{S}^1;\mathbb{C}^4)$, with

$$u^\varepsilon(t,x,\theta) \sim \sqrt{\varepsilon} \sum_{j=0}^{\infty} \varepsilon^{j/2} u_j(t,x,\theta), \tag{5.27}$$

s.t. $u^\varepsilon(t,x,\phi(t,x)/\varepsilon)$ satisfies:

$$\begin{aligned} i\varepsilon \partial_t u^\varepsilon - \mathcal{D}^\varepsilon_A(t,x,\varepsilon D) u^\varepsilon &\sim 0, \quad \forall (t,x) \in \Omega, \\ u^\varepsilon|_{t=0} &= \psi^\varepsilon_I(x). \end{aligned} \tag{5.28}$$

More precisely we have the following. The principal term u_0 is given by (3.20), satisfies $(\mathbb{P}u_0)(t,x,\theta) = u_0(t,x,\theta)$ and solves (5.7) with initial data $(\mathbb{P}u_0)(0,x,\theta) = \chi_0(x,\theta)$.

For all $j \geqslant 1$, the infinite sequence of equations (5.21), (5.22), uniquely determines $u_j(t,x,\theta)$, with initial data $(\mathbb{P}u_j)(0,x,\theta) = \chi_j(x,\theta)$.

Proof: The existence of a smooth phase $\phi \in C^\infty(\Omega;\mathbb{R})$, on the slab $\Omega \subseteq \mathbb{R}^{1+3}$, is already guaranteed by Lemma 3.2.

Next, consider the case $j=0$: Since $\omega_\pm(\nabla\phi) \in \mathbb{R}^3$, defined by (4.5), satisfies for all multi-indices σ, ν,

$$\sup_{(t,x)\in\Omega} \left| \partial_t^\sigma \partial_x^\nu \omega_{\pm,k}(\nabla\phi(t,x)) \right| < \infty, \quad k = 1,2,3, \tag{5.29}$$

we find that the l.h.s. of (5.11) constitutes a linear symmetric hyperbolic system. From L^2-conservation property (5.13) the usual commutator estimates lead to H^s-regularity, i.e., $u_0 \in C^1(\mathbb{R}^3;H^s)$ for all $s \geqslant 0$. Now, it is a standard result for the linear wave equations in $d=3$ spatial dimensions, that source terms in $H^s(\mathbb{R}^3)$ generate solutions (at least) in $H^s(\mathbb{R}^3)$; cf. Hörmander (1985), Chapter XXIII. This fact and Schauder's lemma imply that the map,

$$u_0(t,\cdot) \mapsto \Gamma_\pm[u_0(t,\cdot)], \tag{5.30}$$

are locally Lipschitz from $H^s((0,t) \times \mathbb{R}^3 \times \mathbb{S}^1)$ to itself, for all $s > 2$, uniformly for $0 \leqslant t < T$. By a standard Picard iteration we therefore obtain a local-in-time existence and uniqueness result in $H^s(\Omega^* \times \mathbb{S}^1)$, for every $s > 2$ and a Sobolev imbedding gives $u_0 \in C^1(\Omega^* \times \mathbb{S}^1;\mathbb{C}^4)$. The proof of the asserted regularity for the t-derivatives follows by using the differential equation to express them in terms of x-derivatives and the finite speed of propagation for the solution of (5.11) implies that u_0 is compactly supported in $\mathbb{R}^3_x$ since χ_0 is also.

Finally, for $j>0$, we have that the amplitudes $u_{j,\pm}$ are determined by the linear symmetric hyperbolic system (5.22), (5.21) and the assertion is proved. □

Once again, we stress the fact that we analyze the MD system in a *weakly coupled regime*. Indeed, the above result implies the following.

Corollary 5.5: Let $u^\varepsilon(t,x,\phi(t,x)/\varepsilon)$ be as in Theorem 5.4; then

$$\begin{aligned} V^\varepsilon[u^\varepsilon](t,x) &\sim \varepsilon V[u_0](t,x)+O(\varepsilon^2),\\ A^\varepsilon[u^\varepsilon](t,x) &\sim \varepsilon A_0[u_0](t,x)+O(\varepsilon^2), \end{aligned} \tag{5.31}$$

where $V[u_0]$, $A_0[u_0]$ are nonoscillating and explicitly given by (4.2), (4.7).

VI. STABILITY AND FURTHER RESULTS

In Theorem 5.4 we obtained a function u^ε, which solves the MD equation up to a residual $R^\varepsilon\sim 0$, compactly supported in $[0,T^*]\times\mathbb{R}^3$. We want to compare u^ε to a true solution ψ^ε and prove that $u^\varepsilon-\psi^\varepsilon\sim 0$ on $\Omega^*=[0,T^*]\times\mathbb{R}^3$.

Theorem 6.1: *Under the assumptions of theorem 5.4, there is an $\varepsilon^*\in(0,1)$, s.t. for $\varepsilon<\varepsilon^*$, there exists a unique smooth $\psi^\varepsilon\in C^\infty_{(0)}(\Omega^*;\mathbb{C}^4)$, satisfying*

$$\begin{aligned} i\varepsilon\partial_t\psi^\varepsilon-\mathcal{D}^\varepsilon_A(t,x,\varepsilon D)\psi^\varepsilon&=0,\quad \forall(t,x)\in\Omega^*,\\ \psi^\varepsilon|_{t=0}&=\psi^\varepsilon_I(x), \end{aligned} \tag{6.1}$$

which is asymptotically equivalent to u^ε, i.e.,

$$\psi^\varepsilon(t,x)\sim u^\varepsilon(t,x,\phi(t,x)/\varepsilon),\quad \text{in } C^\infty_{(0)}(\Omega^*;\mathbb{C}^4). \tag{6.2}$$

Proof: Defining $v^\varepsilon:=u^\varepsilon-\psi^\varepsilon$, we obtain for the following IVP:

$$\begin{aligned} i(\varepsilon\partial_t+\varepsilon(\alpha\cdot\nabla))v^\varepsilon-\beta v^\varepsilon+\mathcal{N}^\varepsilon[u^\varepsilon+v^\varepsilon]-\mathcal{N}^\varepsilon[u^\varepsilon]&=-R^\varepsilon,\quad \text{in } \Omega^*,\\ v^\varepsilon|_{t=0}&=0. \end{aligned} \tag{6.3}$$

The nonlinearity can be handled analogous to the proof of Lemma 6.2, in Donat and Rauch (1997), since for smooth sources the wave equation has smooth solutions, which moreover travel with finite speed. Having this in mind, the rest of the proof is a simple modification of the one of Theorem 6.1 in Donat and Rauch (1997). □

As far as the generation of positronic-modes is concerned, the local-in-time solution $\psi^\varepsilon\sim O(\sqrt{\varepsilon})$ shows the following qualitative behavior:

Corollary 6.2: Let ψ^ε_I be as in Theorem 5.4. If initially $(\Pi_-\psi^\varepsilon_I)(x)=0$, then, for $0\leqslant t<T^*$, it holds: $(\Pi_-\psi^\varepsilon)(t,x)\sim O(\varepsilon^{3/2})$, i.e., no positronic-modes are generated, up to $O(\varepsilon^{3/2})$ and the analogous statement for electrons is valid, too.

Proof: The assertion holds true, since a careful examination of the asymptotic expansion shows that both, u_0 *and* u_1, satisfy $(\mathbb{P}u_j)(t,x,\theta)=u_j(t,x,\theta)$, in Ω^*. □

For completeness, we shall also consider the *matrix-valued Wigner transform* corresponding to ψ^ε, i.e.,

$$w^\varepsilon[\psi^\varepsilon](t,x,\xi):=\frac{1}{(2\pi)^3}\int_{\mathbb{R}^3}\psi^\varepsilon\left(t,x+\frac{\varepsilon}{2}y\right)\otimes\overline{\psi^\varepsilon}\left(t,x-\frac{\varepsilon}{2}y\right)e^{i\xi\cdot y}\,dy, \tag{6.4}$$

where $\otimes$ denotes the tensor product of vectors. The real-valued 4×4-matrix $w^\varepsilon[\psi^\varepsilon]$ is a *phase-space description* of the quantum state ψ^ε.

Corollary 6.3: Let $\psi^\varepsilon \sim O(\sqrt{\varepsilon})$ be the unique smooth local-time-solution of the MD system, as guaranteed by Theorem (6.1) and let $w^\varepsilon[\psi^\varepsilon] \sim O(\varepsilon)$ be its Wigner transform. Then, up to extraction of subsequences, we have

$$\lim_{\varepsilon\to 0}\frac{1}{\varepsilon}w^\varepsilon[\psi^\varepsilon]=\mu, \quad in \;\; \mathcal{S}'([0,T^*)\times\mathbb{R}^3_x\times\mathbb{R}^3_\xi) weak-\star, \tag{6.5}$$

where the matrix-valued Wigner measure μ is given by $\mu=\mu_+ + \mu_-$, with

$$\mu_\pm(t,x,\xi)=u_{0,\pm}(t,x)\otimes\overline{u}_{0,\pm}(t,x)\;\delta(\xi\mp\nabla\phi(t,x)). \tag{6.6}$$

Proof: Since ϕ has no stationary points within Ω^*, a nonstationary phase argument implies that all Wigner matrix elements, which mix the electronic and positronic components are of order $O(\varepsilon^\infty)$. The assertion then follows from the well known results on Wigner measures; *cf.* Gérard, Markowich, Mauser, and Poupaud (1997) □

We finally remark on the case of the Dirac–Maxwell system where the Dirac particles have vanishing mass. Instead of (3.13) we obtain

$$\partial_t\phi=\pm|\nabla\phi|, \tag{6.7}$$

which is equivalent to the eikonal equation of the wave equation. It follows that in this case Lemma 4.1 cannot hold, since the phases $\pm\phi$ are characteristic for the wave equation. More precisely, they are indeed *everywhere* characteristic, i.e., in all of Ω, which again allows for an asymptotic description of the A^ε, similar to (4.9), (4.11); *cf.* Lax (1957) or Rauch (1999), Chap. 5. In this case, the ε-oscillations are also given by $\exp(\pm 2i\phi/\varepsilon)$, but the corresponding amplitudes $A_l^\pm$ are of course different. The main difference, however, is the fact that in this case the summation index runs from $l=0$ to infinity, i.e., ε-oscillations are present already in the lowest order term. This leads to a more complicated structure of the transport equations for the amplitudes u_j, but apart from that all results remain valid.

(Received 26 November 2002; accepted 7 July 2003)

Resorting to the finite-order expansion of the Lax matrix, the elliptic coordinates are introduced, from which the discrete Ablowitz–Ladik equations and the $(2+1)$-dimensional Toda lattice are decomposed into solvable ordinary differential equations. The straightening out of the continuous flow and the discrete flow is exactly given through the Abel–Jacobi coordinates. As an application, explicit quasiperiodic solutions for the $(2+1)$-dimensional Toda lattice are obtained. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1605820]

I. INTRODUCTION

Since Ablowitz and Ladik introduced the discrete AKNS equations (called also discrete Ablowitz–Ladik equations),[1,2] numbers of researches were conducted in a series of papers.[1–8] For example, there is research conducted for soliton solutions, Bäcklund transformation, Darboux transformation, Hamiltonian structures, conserved quantities, and other properties. The authors of Refs. 9–12 discuss quasiperiodic solutions for the discrete Ablowitz–Ladik equations, which include the discrete nonlinear Schrödinger equation and the discrete mKdV equation. In Ref. 13, the algebraic–geometrical approach was used to study the discrete Ablowitz–Ladik equations, from which the Baker–Akhiezer function and quasiperiodic solutions corresponding to finite-genus Riemann surfaces were obtained.

In this paper, our main aim is to study straightening out of the discrete Ablowitz–Ladik flows, including the continuous flow and discrete flow, based on the ideas in Refs. 14–16. As an application, we obtain quasiperiodic solutions of the $(2+1)$-dimensional Toda lattice. The outline of the present paper is as follows. In Sec. II the discrete Ablowitz–Ladik hierarchy is constructed with the aid of the Lenard gradient sequences. The relation between the $(2+1)$-dimensional Toda lattice and discrete Ablowitz–Ladik equations is discussed. In Sec. III we introduce a Lax matrix, from which a direct relation between the elliptic coordinates and solutions of the discrete Ablowitz–Ladik equations is established. The $(2+1)$-dimensional Toda lattice is separated into solvable ordinary differential equations. In Sec. IV the Abel–Jacobi coordinates are introduced, by which the straightening out of the continuous flow and the discrete flow are studied in detail. In Sec. V the Riemann–Jacobi inversion is discussed, from which the quasiperiodic solutions for the $(2+1)$-dimensional Toda lattice are obtained by using the Riemann theta functions.

II. THE DISCRETE ABLOWITZ–LADIK HIERARCHY

In this section, we shall derive the Ablowitz–Ladik hierarchy. To this end we first introduce the Lenard gradient sequences

$$K_nS_{j-1}(n)=J_nS_j(n),\quad J_nS_{-1}(n)=0,\quad j\geqslant 0, \tag{2.1}$$

$$K_n\hat{S}_{j-1}(n)=J_n\hat{S}_j(n),\quad K_n\hat{S}_0(n)=0,\quad j\leqslant 0, \tag{2.2}$$

and take

$$S_{-1}(n)=\begin{pmatrix}0\\0\\1\end{pmatrix},\quad \hat{S}_0(n)=\begin{pmatrix}-2u_{n-1}\\-2v_n\\1\end{pmatrix} \tag{2.3}$$

as a starting point of Eq. (2.1) or Eq. (2.2), respectively, with two matrix operators

$$K_n=\begin{pmatrix}E & 0 & u_n(E+1)\\ 0 & 1 & v_n(E+1)\\ v_nE & -u_n & \Delta\end{pmatrix},\quad J_n=\begin{pmatrix}1 & 0 & 0\\ 0 & E & 0\\ v_nE & -u_n & \Delta\end{pmatrix}.$$

Here the shift operator E and the difference operator Δ are defined as $Ef(n)=f(n+1)$, $\Delta f(n)=f(n+1)-f(n)$. It is easy to see that

$$\ker K_n=\{c\hat{S}_0(n)|\forall c\},\quad \ker J_n=\{cS_{-1}(n)|\forall c\}. \tag{2.4}$$

Then $S_j(n)$ and $\hat{S}_{-j}(n)$ $(j\geqslant 0)$ are uniquely determined by the recursion relation Eq. (2.1) or Eq. (2.2) up to a term $c_1S_{-1}(n)$ or $c_2\hat{S}_0(n)$, which are always assumed to be zero. The first few members are

$$S_0(n)=2\begin{pmatrix}u_n\\ v_{n-1}\\ -u_nv_{n-1}\end{pmatrix},\quad \hat{S}_{-1}(n)=2\begin{pmatrix}-u_{n-2}+u_{n-1}(u_{n-1}v_n+u_{n-2}v_{n-1})\\ -v_{n+1}+v_n(u_nv_{n+1}+u_{n-1}v_n)\\ -u_{n-1}v_n\end{pmatrix},$$

$$S_1(n)=2\begin{pmatrix}u_{n+1}-u_n(u_{n+1}v_n+u_nv_{n-1})\\ v_{n-2}-v_{n-1}(u_nv_{n-1}+u_{n-1}v_{n-2})\\ -u_{n+1}v_{n-1}-u_nv_{n-2}+u_nv_{n-1}(u_{n+1}v_n+u_nv_{n-1}+u_{n-1}v_{n-2})\end{pmatrix}.$$

Consider the discrete spectral problem[2,17]

$$\chi(n+1)=U_n\chi(n),\quad U_n=\frac{1}{\gamma_n}\begin{pmatrix}\lambda & u_n\\ v_n & \lambda^{-1}\end{pmatrix},\quad \chi(n)=\begin{pmatrix}\chi^{(1)}(n)\\ \chi^{(2)}(n)\end{pmatrix}, \tag{2.5}$$

where u_n and v_n are two potentials, λ is a constant spectral parameter,

$$\gamma_n=\sqrt{1-u_nv_n}.$$

In order to derive the Ablowitz–Ladik hierarchy, we assume that the time dependence of $\chi(n)$ for the spectral problem (2.5) obeys the differential equation

$$\chi(n)_{t_m}=V_n^{(m)}\chi(n),\quad V_n^{(m)}=\begin{pmatrix}A^{(m)}(n) & B^{(m)}(n)\\ C^{(m)}(n) & -A^{(m)}(n)\end{pmatrix}, \tag{2.6}$$

where

$$A^{(m)}(n)=\alpha\sum_{j=0}^{m-1}S_{j-1}^{(3)}(n)\lambda^{2m-2j}+\beta\sum_{j=0}^{-(m-1)}\hat{S}_j^{(3)}(n)\lambda^{-2m-2j}+\frac{1}{2}\alpha S_{m-1}^{(3)}(n)+\frac{1}{2}\beta\hat{S}_{-m}^{(3)}(n),$$

$$B^{(m)}(n)=\alpha\sum_{j=1}^{m} S_{j-1}^{(1)}(n)\lambda^{2m-2j+1}+\beta\sum_{j=-1}^{-m} \hat{S}_{j+1}^{(1)}(n)\lambda^{-2m-2j-1}, \tag{2.7}$$

$$C^{(m)}(n)=\alpha\sum_{j=1}^{m} S_{j-1}^{(2)}(n)\lambda^{2m-2j+1}+\beta\sum_{j=-1}^{-m} \hat{S}_{j+1}^{(2)}(n)\lambda^{-2m-2j-1}.$$

Then the compatibility condition between Eqs. (2.5) and (2.6) yields the zero-curvature equation $U_{nt_m}+U_nV_n^{(m)}-V_{n+1}^{(m)}U_n=0$, which is equivalent to the evolution equation

$$\begin{aligned}
&\gamma_n(\gamma_n^{-1})_{t_m}=\Delta A^{(m)}(n)+\lambda^{-1}v_nEB^{(m)}(n)-\lambda^{-1}u_nC^{(m)}(n),\\
&u_{nt_m}+u_n\gamma_n(\gamma_n^{-1})_{t_m}=\lambda^{-1}EB^{(m)}(n)-\lambda B^{(m)}(n)+u_n(E+1)A^{(m)}(n),\\
&v_{nt_m}+v_n\gamma_n(\gamma_n^{-1})_{t_m}=\lambda EC^{(m)}(n)-\lambda^{-1}C^{(m)}(n)-v_n(E+1)A^{(m)}(n),\\
&\gamma_n(\gamma_n^{-1})_{t_m}=-\Delta A^{(m)}(n)+\lambda u_nEC^{(m)}(n)-\lambda v_nB^{(m)}(n).
\end{aligned} \tag{2.8}$$

From Eqs. (2.1) and (2.2), it is easy to calculate that

$$\begin{aligned}
&\Delta S_{j-1}^{(3)}(n)+v_nES_{j-1}^{(1)}(n)-u_nS_{j-1}^{(2)}(n)=0,\\
&ES_{j-1}^{(1)}(n)-S_j^{(1)}(n)+u_n(E+1)S_{j-1}^{(3)}(n)=0,\\
&S_{j-1}^{(2)}(n)+v_n(E+1)S_{j-1}^{(3)}(n)-ES_j^{(2)}(n)=0,\\
&-\Delta S_{j-1}^{(3)}(n)+u_nES_j^{(2)}(n)-v_nS_j^{(1)}(n)=0,\quad j\geqslant 0,
\end{aligned} \tag{2.9}$$

$$\begin{aligned}
&\Delta \hat{S}_{j-1}^{(3)}(n)+v_nE\hat{S}_{j-1}^{(1)}(n)-u_n\hat{S}_{j-1}^{(2)}(n)=0,\\
&E\hat{S}_{j-1}^{(1)}(n)-\hat{S}_j^{(1)}(n)+u_n(E+1)\hat{S}_{j-1}^{(3)}(n)=0,\\
&\hat{S}_{j-1}^{(2)}(n)+v_n(E+1)\hat{S}_{j-1}^{(3)}(n)-E\hat{S}_j^{(2)}(n)=0,\\
&-\Delta \hat{S}_{j-1}^{(3)}(n)+u_nE\hat{S}_j^{(2)}(n)-v_n\hat{S}_j^{(1)}(n)=0,\quad j\leqslant 0.
\end{aligned} \tag{2.10}$$

Substituting Eq. (2.7) into Eq. (2.8) and using Eqs. (2.9) and (2.10), we obtain

$$\begin{aligned}
&\gamma_n(\gamma_n^{-1})_{t_m}=\tfrac{1}{2}\Delta(\alpha S_{m-1}^{(3)}(n)+\beta\hat{S}_{-m}^{(3)}(n))+\alpha v_nES_{m-1}^{(1)}(n)-\alpha u_nS_{m-1}^{(2)}(n),\\
&u_{nt_m}+u_n\gamma_n(\gamma_n^{-1})_{t_m}=\alpha ES_{m-1}^{(1)}(n)-\beta\hat{S}_{-m+1}^{(1)}(n)+\tfrac{1}{2}u_n(E+1)(\alpha S_{m-1}^{(3)}(n)+\beta\hat{S}_{-m}^{(3)}(n)),\\
&v_{nt_m}+v_n\gamma_n(\gamma_n^{-1})_{t_m}=\beta E\hat{S}_{-m+1}^{(2)}(n)-\alpha S_{m-1}^{(2)}(n)-\tfrac{1}{2}v_n(E+1)(\alpha S_{m-1}^{(3)}(n)+\beta\hat{S}_{-m}^{(3)}(n)),\\
&\gamma_n(\gamma_n^{-1})_{t_m}=-\tfrac{1}{2}\Delta(\alpha S_{m-1}^{(3)}(n)+\beta\hat{S}_{-m}^{(3)}(n))+\beta u_nE\hat{S}_{-m+1}^{(2)}(n)-\beta v_n\hat{S}_{-m+1}^{(1)}(n),
\end{aligned} \tag{2.11}$$

Resorting to the first expression of Eq. (2.9) and the fourth expression of Eq. (2.10), the first and the fourth expressions of Eq. (2.11) can be written as

$$\gamma_n(\gamma_n^{-1})_{t_m}=\tfrac{1}{2}\Delta(\beta\hat{S}_{-m}^{(3)}(n)-\alpha S_{m-1}^{(3)}(n)). \tag{2.12}$$

Substituting Eq. (2.12) into the second and third expressions of Eq. (2.11) and using Eq. (2.10), we obtain the Ablowitz–Ladik hierarchy

$$\begin{aligned} u_{nt_m} &= \alpha E S^{(1)}_{m-1}(n) + \alpha u_n E S^{(3)}_{m-1}(n) - \beta E \hat{S}^{(1)}_{-m}(n) - \beta u_n E \hat{S}^{(3)}_{-m}(n), \\ v_{nt_m} &= -\alpha S^{(2)}_{m-1}(n) - \alpha v_n S^{(3)}_{m-1}(n) + \beta \hat{S}^{(2)}_{-m}(n) + \beta v_n E \hat{S}^{(3)}_{-m}(n), \quad m \geqslant 0. \end{aligned} \tag{2.13}$$

The first two members are

$$u_{t_0} = (\alpha+\beta)u_n, \quad v_{t_0} = -(\alpha+\beta)v_n, \tag{2.14}$$

$$\begin{aligned} u_{nt_1} &= 2(1-u_n v_n)(\alpha u_{n+1} + \beta u_{n-1}), \\ v_{nt_1} &= -2(1-u_n v_n)(\alpha v_{n-1} + \beta v_{n+1}). \end{aligned} \tag{2.15}$$

Equations (2.15) is, respectively, reduced to the coupled discrete nonlinear Schrödinger equation

$$\begin{aligned} u_{nx} &= (1-u_n v_n)(u_{n+1} + u_{n-1}), \\ v_{nx} &= -(1-u_n v_n)(v_{n-1} + v_{n+1}) \end{aligned} \tag{2.16}$$

for $\alpha = \beta = \frac{1}{2}$, $x = t_1$, and the coupled discrete mKdV equation

$$\begin{aligned} u_{nt} &= (1-u_n v_n)(u_{n+1} - u_{n-1}), \\ v_{nt} &= (1-u_n v_n)(v_{n-1} - v_{n+1}) \end{aligned} \tag{2.17}$$

for $\alpha = -\beta = \frac{1}{2}$, $t = t_1$. Since Eqs. (2.16) and (2.17) are compatible, we assume that (u_n, v_n) is a compatible solution of Eqs. (2.16) and (2.17), and introduce a function w_n by

$$w_n = 1 - u_n v_n. \tag{2.18}$$

Then the function w_n satisfies the $(2+1)$-dimensional Toda lattice equation[18,19]

$$\frac{1}{4}\left(\frac{\partial^2}{\partial x^2} - \frac{\partial^2}{\partial t^2}\right) \ln w_n = 2w_n - w_{n+1} - w_{n-1}, \tag{2.19}$$

which can be verified through a direct calculation.

III. THE ELLIPTIC COORDINATES

Assume that Eqs. (2.5) and (2.6) have two basic solutions $\psi(n) = (\psi^{(1)}(n), \psi^{(2)}(n))^T$ and $\phi(n) = (\phi^{(1)}(n), \phi^{(2)}(n))^T$. We define a Lax matrix W_n of three functions $f(n), g(n), h(n)$ by

$$W_n = \frac{1}{2}(\phi(n)\psi(n)^T + \psi(n)\phi(n)^T)\sigma = \begin{pmatrix} f(n) & g(n) \\ h(n) & -f(n) \end{pmatrix}, \quad \sigma = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}. \tag{3.1}$$

It is easy to verify by (2.5) and (2.6) that

$$W_{n+1}U_n - U_n W_n = 0, \quad W_{nt_m} = [V^{(m)}_n, W_n], \tag{3.2}$$

which imply that the function $\det W_n$ is a constant independent of n and t_m. In fact, we obtain by the first expression of Eq. (3.2) that $W_{n+1} = U_n W_n U_n^{-1}$. Then $\det W_{n+1} = \det W_n$, which means that $\det W_n$ is independent of n. In a way similar to the continuous case, a direct calculation shows that $(\det W_n)_{t_m} = 0$. Equations (3.2) can be written as

$$\begin{aligned}
&\lambda\Delta f(n)+v_nEg(n)-u_nh(n)=0,\\
&\lambda^{-1}Eg(n)-\lambda g(n)+u_n(E+1)f(n)=0,\\
&\lambda Eh(n)-\lambda^{-1}h(n)-v_n(E+1)f(n)=0,\\
&\lambda^{-1}\Delta f(n)-u_nEh(n)+v_ng(n)=0,
\end{aligned}\tag{3.3}$$

and

$$\begin{aligned}
&f(n)_{t_m}=B^{(m)}(n)h(n)-C^{(m)}(n)g(n),\\
&g(n)_{t_m}=2A^{(m)}(n)g(n)-2B^{(m)}(n)f(n),\\
&h(n)_{t_m}=2C^{(m)}(n)f(n)-2A^{(m)}(n)h(n).
\end{aligned}\tag{3.4}$$

Suppose that the functions $f(n)$,$g(n)$, and $h(n)$ are finite-order polynomials in λ,

$$\begin{aligned}
&f(n)=\sum_{j=0}^{N+1}f_{j-1}(n)\lambda^{2(N+1)-2j},\quad g(n)=\sum_{j=1}^{N+1}g_{j-1}(n)\lambda^{2(N+1)-2j+1},\\
&h(n)=\sum_{j=1}^{N+1}h_{j-1}(n)\lambda^{2(N+1)-2j+1}.
\end{aligned}\tag{3.5}$$

Substituting Eq. (3.5) into Eq. (3.3) and comparing the coefficients of the same power of λ yields

$$\begin{aligned}
&K_nG_{j-1}(n)=J_nG_j(n),\quad J_nG_{-1}(n)=0,\\
&K_nG_N(n)=0,
\end{aligned}\tag{3.6}$$

with $G_j(n)=(g_j(n),h_j(n),f_j(n))^T$, $g_{-1}(n)=0$,$h_{-1}(n)=0$. It is easy to see that the equations $J_nG_{-1}(n)=0$ and $K_nG_N(n)=0$ have the general solutions

$$G_{-1}(n)=\alpha_0S_{-1}(n),\tag{3.7}$$

$$G_N(n)=\beta_0\hat{S}_0(n),\tag{3.8}$$

where α_0 and β_0 are constants. Acting with $J_n^{-1}K_n$ and $K_n^{-1}J_n$, respectively, upon Eqs. (3.7) and (3.8) yield

$$\begin{aligned}
&G_0(n)=\alpha_0S_0(n)+\alpha_1S_{-1}(n),\\
&G_{N-1}(n)=\beta_0\hat{S}_{-1}(n)+\beta_1\hat{S}_0(n),
\end{aligned}\tag{3.9}$$

in view of Eqs. (2.1) and (2.2), where α_1 and β_1 are constants. For the sake of convenience, we set $\alpha_0=1$. From Eqs. (3.7)–(3.9), we have

$$\begin{aligned}
&f_{-1}(n)=1,\quad f_0(n)=-2u_nv_{n-1}+\alpha_1,\quad g_0(n)=2u_n,\\
&h_0(n)=2v_{n-1},\quad f_N(n)=\beta_0,\quad g_N(n)=-2\beta_0u_{n-1},\\
&h_N(n)=-2\beta_0v_n,\quad f_{N-1}(n)=-2\beta_0u_{n-1}v_n+\beta_1.
\end{aligned}\tag{3.10}$$

We use $g(n)$ and $h(n)$ as polynomials of λ to define the elliptic coordinates $\{\mu_i(n)\}$ and $\{\nu_i(n)\}$:

$$g(n)=2\lambda u_n\prod_{i=1}^{N}(\zeta-\mu_i(n)),\quad h(n)=2\lambda v_{n-1}\prod_{i=1}^{N}(\zeta-\nu_i(n)) \tag{3.11}$$

with $\zeta=\lambda^2$. By comparing coefficients of the same power for ζ, we get

$$g_1(n)=-g_0(n)\sum_{j=1}^{N}\mu_j(n),\quad h_1(n)=-h_0(n)\sum_{j=1}^{N}\nu_j(n), \tag{3.12}$$

$$\frac{u_{n-1}}{u_n}=(-1)^{N+1}\frac{1}{\beta_0}\prod_{i=1}^{N}\mu_i(n),\quad \frac{v_n}{v_{n-1}}=(-1)^{N+1}\frac{1}{\beta_0}\prod_{i=1}^{N}\nu_i(n). \tag{3.13}$$

As $m=1$ we equating coefficients of λ^{2N+1} from both sides of the second equation of Eq. (3.4),

$$g_0(n)_{t_1}=(\alpha S_0^{(3)}(n)+\beta\hat{S}_{-1}^{(3)}(n))+2\alpha S_{-1}^{(3)}(n)g_1(n)-2\beta f_{-1}(n)\hat{S}_0^{(1)}(n)-2\alpha S_0^{(1)}(n)f_0(n), \tag{3.14}$$

which, together with Eqs. (3.12) and (3.13), implies

$$\begin{aligned}\frac{1}{2}\partial_{t_1}\ln u_n=u_nv_n(-1)^{N+1}&\left[\frac{\alpha\beta_0}{\Pi_{j=1}^{N}\nu_j(n)}-\frac{\beta}{\beta_0}\prod_{j=1}^{N}\mu_j(n)\right]\\&-\alpha\sum_{j=1}^{N}\mu_j(n)+\frac{\beta}{\beta_0}(-1)^{N+1}\prod_{j=1}^{N}\mu_j(n)-\alpha_1\alpha.\end{aligned} \tag{3.15}$$

We now use the original equations (2.15) and (3.13)

$$\frac{1}{2}\partial_{t_1}\ln u_n=(1-u_nv_n)(-1)^{N+1}\left[\frac{\alpha\beta_0}{\Pi_{j=1}^{N}\mu_j(n+1)}+\frac{\beta}{\beta_0}\prod_{j=1}^{N}\mu_j(n)\right]. \tag{3.16}$$

By equating the two expressions of $\frac{1}{2}\partial_{t_1}\ln u_n$, we arrive at

$$w_n=1-u_nv_n=\frac{[\beta_0+(-1)^N\Sigma_{j=1}^{N}\mu_j(n)\Pi_{j=1}^{N}\nu_j(n)+\alpha_1(-1)^N\Pi_{j=1}^{N}\nu_j(n)]\Pi_{j=1}^{N}\mu_j(n+1)}{\beta_0[\Pi_{j=1}^{N}\mu_j(n+1)+\Pi_{j=1}^{N}\nu_j(n)]}. \tag{3.17}$$

Let us consider the function $\det W_n$, which is a $(2N+2)$th-order polynomial in ζ ($\zeta_j=\lambda_j^2$) with constant coefficients of the n flow and t_m flow,

$$-\det W_n=f^2(n)+g(n)h(n)=\prod_{j=1}^{2N+2}(\zeta-\zeta_j)=R(\zeta). \tag{3.18}$$

Substituting Eq. (3.5) into Eq. (3.14) and comparing the coefficients of ζ^{2N+1} and ζ^0 yield

$$\alpha_1=-\frac{1}{2}\sum_{j=1}^{2N+2}\zeta_j,\quad \beta_0=\prod_{j=1}^{2N+2}\lambda_j,\quad 2\beta_0\beta_1=-\sum_{j_1<\cdots<j_{2N+1}}\zeta_{j_1}\cdots\zeta_{j_{2N+1}}. \tag{3.19}$$

Using Eqs. (3.11) and (3.4), we have

$$f(n)|_{\zeta=\mu_k(n)}=\sqrt{R(\mu_k(n))},\quad f(n)|_{\zeta=\nu_k(n)}=\sqrt{R(\nu_k(n))}, \tag{3.20}$$

$$\begin{aligned}
&\frac{\mu_k(n)_{t_1}}{\sqrt{R(\mu_k(n))}}=\frac{u_n^{-1}[\lambda^{-1}B^{(1)}(n)]|_{\zeta=\mu_k(n)}}{\Pi_{i=1,i\neq k}^{N}(\mu_k(n)-\mu_i(n))},\\
&\frac{\nu_k(n)_{t_1}}{\sqrt{R(\nu_k(n))}}=\frac{-v_{n-1}^{-1}[\lambda^{-1}C^{(1)}(n)]|_{\zeta=\nu_k(n)}}{\Pi_{i=1,i\neq k}^{N}(\nu_k(n)-\nu_i(n))},
\end{aligned}\qquad 1\leqslant k\leqslant N, \tag{3.21}$$

with

$$u_n^{-1}[\lambda^{-1}B^{(1)}(n)]|_{\zeta=\mu_k(n)}=2\alpha+\frac{2\beta(-1)^N}{\beta_0\mu_k(n)}\prod_{i=1}^{N}\mu_i(n),$$

$$v_{n-1}^{-1}[\lambda^{-1}C^{(1)}(n)]|_{\zeta=\nu_k(n)}=2\alpha+\frac{2\beta(-1)^N}{\beta_0\nu_k(n)}\prod_{i=1}^{N}\nu_i(n).$$

Then we have

$$\begin{aligned}
&\frac{\mu_k(n)_x}{\sqrt{R(\mu_k(n))}}=\frac{1-\frac{(-1)^N}{\beta_0\mu_k(n)}\Pi_{i=1}^{N}\mu_i(n)}{\Pi_{i=1,i\neq k}^{N}(\mu_k(n)-\mu_i(n))},\\
&\frac{\nu_k(n)_x}{\sqrt{R(\nu_k(n))}}=\frac{-1+\frac{(-1)^N}{\beta_0\nu_k(n)}\Pi_{i=1}^{N}\nu_i(n)}{\Pi_{i=1,i\neq k}^{N}(\nu_k(n)-\nu_i(n))},
\end{aligned}\qquad 1\leqslant k\leqslant N, \tag{3.22}$$

$$\begin{aligned}
&\frac{\mu_k(n)_t}{\sqrt{R(\mu_k(n))}}=\frac{1+\frac{(-1)^N}{\beta_0\mu_k(n)}\Pi_{i=1}^{N}\mu_i(n)}{\Pi_{i=1,i\neq k}^{N}(\mu_k(n)-\mu_i(n))},\\
&\frac{\nu_k(n)_t}{\sqrt{R(\nu_k(n))}}=\frac{-1-\frac{(-1)^N}{\beta_0\nu_k(n)}\Pi_{i=1}^{N}\nu_i(n)}{\Pi_{i=1,i\neq k}^{N}(\nu_k(n)-\nu_i(n))},
\end{aligned}\qquad 1\leqslant k\leqslant N. \tag{3.23}$$

Therefore, if the $(2N+2)$ distinct parameters $\lambda_1,\ldots,\lambda_{2N+2}$ $(|\lambda_k|\neq|\lambda_j|,k\neq j)$ are given, and let $\mu_k(n)$ and $\nu_k(n)$ be solutions of ordinary differential equations (3.22) and (3.23), then (u_n,v_n) determined by Eq. (3.13) solves the coupled discrete nonlinear Schrödinger equation (2.16) and the coupled discrete mKdV equation (2.17). This means that the function w_n by Eq. (2.18) or Eq. (3.17) is a solution of the $(2+1)$-dimensional Toda equation (2.19).

IV. STRAIGHTENING OUT OF THE CONTINUOUS FLOW

In this section, we shall discuss straightening out of the corresponding continuous flow. We first introduce the Riemann surface Γ of the hyperelliptic curve $\xi^2=R(\zeta),R(\zeta)=\Pi_{j=1}^{2N+2}(\zeta-\zeta_j)$, of genus N. On Γ there are two infinite points ∞_1 and ∞_2, which are not branch points of Γ. Equip Γ with the canonical basis of cycles: $a_1,\ldots,a_N$; $b_1,\ldots,b_N$, and the holomorphic differentials

$$\tilde{\omega}_l=\frac{\zeta^{l-1}\,d\zeta}{\sqrt{R(\zeta)}},\quad 1\leqslant l\leqslant N.$$

Then the period matrices A and B defined by

$$A_{ij}=\int_{a_j}\tilde{\omega}_i, \quad B_{ij}=\int_{b_j}\tilde{\omega}_i,$$

are invertible.[20,21] Let $C=A^{-1}$, $\tau=A^{-1}B$. If we normalize $\tilde{\omega}_l$ into the new basis ω_j

$$\omega_j=\sum_{l=1}^{N} C_{jl}\tilde{\omega}_l, \quad 1\leqslant j\leqslant N, \tag{4.1}$$

then we have

$$\int_{a_i}\omega_j=\delta_{ji}, \quad \int_{b_i}\omega_j=\tau_{ji}. \tag{4.2}$$

Now we introduce the Abel map $\mathcal{A}(P)$

$$\mathcal{A}(P)=\int_{P_0}^{P}\omega,$$

which can be extended linearly to the whole divisor group of Γ, $\mathcal{A}$: $\mathrm{Div}(\Gamma)\to\mathcal{J}(\Gamma)=\mathbb{C}^N/\mathcal{T}$, where the lattice $\mathcal{T}$ is spanned by the periodic vectors $\{\delta_k,\tau_k\}$ with components given by Eq. (4.2). The Abel–Jacobi coordinates are defined as

$$\rho^{(1)}(n)=\mathcal{A}\left(\sum_{k=1}^{N} P(\mu_k(n))\right)=\sum_{k=1}^{N}\int_{P_0}^{P(\mu_k(n))}\omega, \tag{4.3}$$

$$\rho^{(2)}(n)=\mathcal{A}\left(\sum_{k=1}^{N} P(\nu_k(n))\right)=\sum_{k=1}^{N}\int_{P_0}^{P(\nu_k(n))}\omega, \tag{4.4}$$

where $P(\mu_k(n))=(\zeta=\mu_k(n),\xi=\sqrt{R(\mu_k(n))})$, $P(\nu_k(n))=(\zeta=\nu_k(n),\xi=\sqrt{R(\nu_k(n))})\in\Gamma$, and P_0 is chosen a base point on Γ. The components of the Abel–Jacobi coordinates in Eqs. (4.3) and (4.4) read

$$\rho_j^{(1)}(n,x,t)=\sum_{k=1}^{N}\int_{P_0}^{P(\mu_k(n,x,t))}\omega_j=\sum_{k=1}^{N}\sum_{l=1}^{N}C_{jl}\int_{\zeta(P_0)}^{\mu_k(n)}\frac{\zeta^{l-1}\,d\zeta}{\sqrt{R(\zeta)}}, \quad 1\leqslant j\leqslant N, \tag{4.5}$$

$$\rho_j^{(2)}(n,x,t)=\sum_{k=1}^{N}\int_{P_0}^{P(\nu_k(n,x,t))}\omega_j=\sum_{k=1}^{N}\sum_{l=1}^{N}C_{jl}\int_{\zeta(P_0)}^{\nu_k(n)}\frac{\zeta^{l-1}\,d\zeta}{\sqrt{R(\zeta)}}, \quad 1\leqslant j\leqslant N, \tag{4.6}$$

where $\lambda(P_0)$ is the local coordinates of P_0. By using Eqs. (4.5) and (3.22), we have

$$\begin{aligned}\partial_x\rho_j^{(1)}(n)&=\sum_{l=1}^{N}\sum_{k=1}^{N}C_{jl}\frac{\mu_k^{l-1}(n)\mu_k(n)_x}{\sqrt{R(\mu_k(n))}}\\&=\sum_{l=1}^{N}\sum_{k=1}^{N}\left[1-\frac{(-1)^N}{\beta_0\mu_k(n)}\prod_{i=1}^{N}\mu_i(n)\right]\frac{\mu_k^{l-1}(n)C_{jl}}{\Pi_{i\neq k}^{N}(\mu_k(n)-\mu_i(n))},\end{aligned}$$

which implies

$$\partial_x\rho_j^{(1)}(n)=C_{jN}+\frac{1}{\beta_0}C_{j1}=\Omega_j^{(1)}, \quad 1\leqslant j\leqslant N \tag{4.7}$$

in view of the equalities

$$\sum_{k=1}^{N}\frac{1}{\mu_k(n)\Pi_{i\neq k}^{N}(\mu_k(n)-\mu_i(n))}=\frac{(-1)^{N+1}}{\Pi_{i=1}^{N}\mu_i(n)},$$
$$\sum_{k=1}^{N}\frac{\mu_k^{l-1}(n)}{\Pi_{i\neq k}^{N}(\mu_k(n)-\mu_i(n))}=\delta_{lN},\quad 1\leqslant l\leqslant N. \tag{4.8}$$

In a similar way, we obtain from Eqs. (4.5), (4.6), (3.22), and (3.23) that

$$\partial_t\rho_j^{(1)}(n)=C_{jN}-\frac{1}{\beta_0}C_{j1}=\Omega_j^{(2)}, \tag{4.9}$$

$$\partial_x\rho_j^{(2)}(n)=-\Omega_j^{(1)},\quad \partial_t\rho_j^{(2)}(n)=-\Omega_j^{(2)},\quad 1\leqslant j\leqslant N. \tag{4.10}$$

V. STRAIGHTENING OUT OF THE DISCRETE FLOW

Let us denote the fundamental solution matrix of Eq. (2.5) by

$$M_n=(\chi_1(n),\chi_2(n))=\begin{pmatrix}p^{(1)}(n) & p^{(2)}(n)\\ q^{(1)}(n) & q^{(2)}(n)\end{pmatrix},\quad M_0=\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}$$

which can be expressed explicitly as

$$M_{n+1}=U_nU_{n-1}\cdots U_0. \tag{5.1}$$

By mathematical induction, it is easy to prove that

$$M_1=\frac{1}{\gamma_0}\begin{pmatrix}\lambda & u_0\\ v_0 & \lambda^{-1}\end{pmatrix},$$

$$M_2=\frac{1}{\gamma_0\gamma_1}\begin{pmatrix}\lambda^2+u_1v_0 & \lambda u_0+\lambda^{-1}u_1\\ \lambda v_1+\lambda^{-1}v_0 & u_0v_1+\lambda^{-2}\end{pmatrix},$$

$$M_3=\frac{1}{\gamma_0\gamma_1\gamma_2}\begin{pmatrix}\lambda^3+\lambda(u_1v_0+u_2v_1)+\lambda^{-1}u_2v_0 & \lambda^2u_0+u_0u_2v_1+\lambda^{-2}u_2\\ \lambda^2v_2+u_1v_0v_2+v_1+\lambda^{-2}v_0 & \lambda u_0v_2+\lambda^{-1}(u_0v_1+u_1v_2)+\lambda^{-3}\end{pmatrix}, \tag{5.2}$$

$$p^{(1)}(n)=\frac{1}{\gamma_0\gamma_1\cdots\gamma_{n-1}}\left\{\lambda^n+\lambda^{n-2}\sum_{j=1}^{n-1}u_jv_{j-1}+\cdots+\lambda^{-n+2}u_{n-1}v_0\right\},$$

$$p^{(2)}(n)=\frac{1}{\gamma_0\gamma_1\cdots\gamma_{n-1}}\left\{\lambda^{n-1}u_0+\lambda^{n-3}u_0\sum_{j=1}^{n-2}u_{j+1}v_j+\cdots+\lambda^{-n+1}u_{n-1}\right\},$$

$$q^{(1)}(n)=\frac{1}{\gamma_0\gamma_1\cdots\gamma_{n-1}}\left\{\lambda^{n-1}v_{n-1}+\lambda^{n-3}\left(v_{n-2}+v_{n-1}\sum_{j=1}^{n-2}u_jv_{j-1}\right)+\cdots+\lambda^{-n+1}v_0\right\},$$

$$q^{(2)}(n)=\frac{1}{\gamma_0\gamma_1\cdots\gamma_{n-1}}\times\left\{\lambda^{n-2}u_0v_{n-1}+\lambda^{n-4}\left(u_1v_{n-1}+u_0v_{n-2}+u_0v_{n-1}\sum_{j=1}^{n-3}u_{j+1}v_j\right)+\cdots+\lambda^{-n}\right\}. \tag{5.3}$$

The Lax matrix W_n satisfies the discrete Lax equation (3.2), $W_{n+1}U_n - U_nW_n = 0$, which implies that the solution space of the linear equation $\chi(n+1) = U_n\chi(n)$ is invariant under the action of W_n. Let ϱ be the eigenvalue of W_n in the solution space, and $\chi(n)$ be the associated eigenfunction, which is called the Baker function (after some normalization):

$$\chi(n+1) = U_n\chi(n), \quad W_n\chi(n) = \varrho\chi(n). \tag{5.4}$$

It is easy to see that $\det|\varrho - W_n| = \varrho^2 - f^2(n) - g(n)h(n) = 0$, which yields the algebraic curve Γ. Thus there are two eigenvalues $\varrho^{\pm} = \pm\varrho$, whereby (3.18):

$$\varrho = \sqrt{f^2(n) + g(n)h(n)} = \sqrt{R(\zeta)}. \tag{5.5}$$

An elementary discussion shows that the corresponding Baker functions can be taken as

$$\chi^{\pm}(n) = \chi_1(n) + b^{\pm}\chi_2(n), \tag{5.6}$$

$$\hat{\chi}^{\pm}(n) = c^{\pm}\chi_1(n) + \chi_2(n) \tag{5.7}$$

with

$$b^{\pm} = \frac{\pm\varrho - f(0)}{g(0)}, \quad c^{\pm} = \frac{f(0) \pm \varrho}{h(0)}. \tag{5.8}$$

Theorem 5.1: (Formulas of Dubrovin–Novikov's type): Let $p^{\pm}(n,\lambda)$ and $q^{\pm}(n,\lambda)$ be the first component and the second one, respectively, of the Baker functions $\chi^{\pm}(n,\lambda)$ and $\hat{\chi}^{\pm}(n,\lambda)$. Then

$$p^+(n,\lambda)p^-(n,\lambda) = \frac{g(n)}{g(0)} = \frac{u_n}{u_0}\prod_{j=1}^{N}\frac{\zeta - \mu_j(n)}{\zeta - \mu_j(0)}, \tag{5.9}$$

$$q^+(n,\lambda)q^-(n,\lambda) = \frac{h(n)}{h(0)} = \frac{v_{n-1}}{v_{-1}}\prod_{j=1}^{N}\frac{\zeta - \nu_j(n)}{\zeta - \nu_j(0)}. \tag{5.10}$$

Proof: Resorting to Eq. (5.1) and the first expression of Eq. (3.2), we have

$$W_nM_n = M_nW_0, \tag{5.11}$$

from which a direct calculation derives Eqs. (5.9) and (5.10).

Proposition 5.2: For $\lambda \to \infty$, we have

$$\begin{aligned} p^+(n,\lambda) &= \frac{\lambda^n}{\gamma_0\cdots\gamma_{n-1}}\{1 + O(\lambda^{-2})\}, \\ p^-(n,\lambda) &= \gamma_0\cdots\gamma_{n-1}\frac{u_n\lambda^{-n}}{u_0}\{1 + O(\lambda^{-2})\}, \end{aligned} \tag{5.12}$$

$$\begin{aligned} q^+(n,\lambda) &= \frac{v_{n-1}\lambda^n}{\gamma_0\cdots\gamma_{n-1}v_{-1}}\{1 + O(\lambda^{-2})\}, \\ q^-(n,\lambda) &= \gamma_0\cdots\gamma_{n-1}\lambda^{-n}\{1 + O(\lambda^{-2})\}. \end{aligned} \tag{5.13}$$

Proof: By using Eqs. (5.5) and (3.5), we obtain

$$\varrho = \lambda^{2(N+1)}\{1 + \alpha_1\lambda^{-2} + O(\lambda^{-4})\}, \tag{5.14}$$

which implies

$$b^+=v_{-1}\lambda^{-1}\{1+O(\lambda^{-2})\},\quad b^-=-\frac{\lambda}{u_0}\{1+O(\lambda^{-2})\},$$
$$c^+=\frac{\lambda}{v_{-1}}\{1+O(\lambda^{-2})\},\quad c^-=-u_0\lambda^{-1}\{1+O(\lambda^{-2})\}. \tag{5.15}$$

Set Eq. (5.3) and the first expression of Eq. (5.15) into $p^+(n,\lambda)=p^{(1)}(n,\lambda)+b^+p^{(2)}(n,\lambda)$, we have the first expression of Eq. (5.12). The estimation of the second expression of Eq. (5.12) for $p^-(n,\lambda)$ is obtained from the first one and

$$p^+(n,\lambda)p^-(n,\lambda)=\frac{u_n}{u_0}\{1+O(\lambda^{-2})\}.$$

Similarly, we can prove Eq. (5.13).

According to Eq. (5.8), it is easy to see that λb^+ and λb^-, λc^+ and λc^- are functions of ζ, which can be regarded as the values of the single-valued functions $[\lambda b](P)$ and $[\lambda c](P)$ on the upper and lower sheets of Γ, respectively. Moreover, it is obvious that the following functions are polynomials of $\zeta=\lambda^2$ with degrees as tabled:

$\lambda^{2k-2}p^{(1)}(2k)$	$2k-1$	$\lambda^{2k-1}p^{(1)}(2k+1)$	$2k$
$\lambda^{2k-1}p^{(2)}(2k)$	$2k-1$	$\lambda^{2k}p^{(2)}(2k+1)$	$2k$
$\lambda^{2k-1}q^{(1)}(2k)$	$2k-1$	$\lambda^{2k}q^{(1)}(2k+1)$	$2k$
$\lambda^{2k}q^{(2)}(2k)$	$2k-1$	$\lambda^{2k+1}q^{(2)}(2k+1)$	$2k$

Therefore, the following expressions

$$p^\pm(2k,\lambda)=p^{(1)}(2k,\lambda)+(\lambda b^\pm)\left\{\frac{1}{\lambda}p^{(2)}(2k,\lambda)\right\},$$
$$\lambda p^\pm(2k+1,\lambda)=\lambda p^{(1)}(2k+1,\lambda)+(\lambda b^\pm)p^{(2)}(2k+1,\lambda), \tag{5.16}$$

$$q^\pm(2k,\lambda)=(\lambda c^\pm)\left\{\frac{1}{\lambda}q^{(1)}(2k,\lambda)\right\}+q^{(2)}(2k,\lambda),$$
$$\lambda q^\pm(2k+1,\lambda)=(\lambda c^\pm)q^{(1)}(2k+1,\lambda)+\lambda q^{(2)}(2k+1,\lambda), \tag{5.17}$$

determine four meromorphic functions of ζ on Γ: $p(2k,P)$ and $[\lambda p](2k+1,P)$, $q(2k,P)$ and $[\lambda q](2k+1,P)$.

In the local coordinates $z=\zeta^{-1}$, $\hat{\xi}=\zeta^{-N-1}\xi$, the equation of Γ near infinity is written as

$$\hat{\xi}^2-R_*(z)=0,\quad R_*(z)=\prod_{j=1}^{2N+2}(1-\zeta_j z). \tag{5.18}$$

On Γ there are two infinities and two zeros

$$\infty_s=(z=0,\hat{\xi}=(-1)^s),\quad 0_s=(\zeta=0,\xi=(-1)^s\beta_0),\quad s=1,2,$$

which are located on the upper ($s=2$) and lower ($s=1$) sheets, respectively. By Proposition 5.2, the principal asymptotic terms of the four meromorphic functions near ∞_2 are

$$p^+(2k,P)\sim\frac{\zeta^k}{\gamma_0\cdots\gamma_{2k-1}},\quad \lambda p^+(2k+1,P)\sim\frac{\zeta^{k+1}}{\gamma_0\cdots\gamma_{2k}},$$
$$q^+(2k,P)\sim\frac{v_{2k-1}\zeta^k}{v_{-1}\gamma_0\cdots\gamma_{2k-1}},\quad \lambda q^+(2k+1,P)\sim\frac{v_{2k}\zeta^{k+1}}{v_{-1}\gamma_0\cdots\gamma_{2k}},\tag{5.19}$$

and their principal asymptotic terms near ∞_1 are

$$p^-(2k,P)\sim\frac{u_{2k}}{u_0}\gamma_0\cdots\gamma_{2k-1}\zeta^{-k},\quad \lambda p^-(2k+1,P)\sim\frac{u_{2k+1}}{u_0}\gamma_0\cdots\gamma_{2k}\zeta^{-k},$$
$$q^-(2k,P)\sim\gamma_0\cdots\gamma_{2k-1}\zeta^{-k},\quad \lambda q^-(2k+1,P)\sim\gamma_0\cdots\gamma_{2k}\zeta^{-k}.\tag{5.20}$$

Proposition 5.3: For $\lambda\to 0$, we have

$$p^-(n,\lambda)=\frac{u_{n-1}\lambda^{-n}}{\gamma_0\cdots\gamma_{n-1}u_{-1}}\{1+O(\lambda^2)\},$$
$$p^+(n,\lambda)=\gamma_0\cdots\gamma_{n-1}\lambda^n\{1+O(\lambda^2)\},\tag{5.21}$$

$$q^-(n,\lambda)=\frac{\lambda^{-n}}{\gamma_0\cdots\gamma_{n-1}}\{1+O(\lambda^2)\},$$
$$q^+(n,\lambda)=\frac{v_n}{v_{-1}}\gamma_0\cdots\gamma_{n-1}\lambda^n\{1+O(\lambda^2)\}.\tag{5.22}$$

Proof: It is easy to see that

$$\varrho=\beta_0+\beta_1\lambda^2+O(\lambda^4),$$
$$b^+=-v_0\lambda\{1+O(\lambda^2)\},\quad b^-=\frac{1}{u_{-1}\lambda}\{1+O(\lambda^2)\},\tag{5.23}$$
$$c^+=-\frac{1}{v_0\lambda}\{1+O(\lambda^2)\},\quad c^-=u_{-1}\lambda\{1+O(\lambda^2)\}.$$

Substituting Eq. (5.3) and the third expression of Eq. (5.23) into $p^-(n,\lambda)=p^{(1)}(n,\lambda)+b^-p^{(2)}(n,\lambda)$, we obtain the first expression of Eq. (5.21). The second expression of Eq. (5.21) is given from the first one and

$$p^+(n,\lambda)p^-(n,\lambda)=\frac{u_n}{u_0}\prod_{j=1}^{N}\frac{\mu_j(n)}{\mu_j(0)}\{1+O(\lambda^2)\}=\frac{u_{n-1}}{u_{-1}}\{1+O(\lambda^2)\}.$$

In a similar way, Eq. (5.22) can be proved.

Resorting to Proposition 5.3, the principal asymptotic terms of the four meromorphic functions near 0_2 are

$$p^+(2k,P)\sim\gamma_0\cdots\gamma_{2k-1}\zeta^k,\quad \lambda p^+(2k+1,P)\sim\gamma_0\cdots\gamma_{2k}\zeta^{k+1},$$
$$q^+(2k,P)\sim\frac{v_{2k}}{v_{-1}}\gamma_0\cdots\gamma_{2k-1}\zeta^k,\quad \lambda q^+(2k+1,P)\sim\frac{v_{2k+1}\zeta^{k+1}}{v_{-1}\gamma_0\cdots\gamma_{2k}},\tag{5.24}$$

and their principal asymptotic terms near 0_1 are

$$p^-(2k,P)\sim\frac{u_{2k-1}\zeta^{-k}}{u_{-1}\gamma_0\cdots\gamma_{2k-1}},\quad \lambda p^-(2k+1,P)\sim\frac{u_{2k}\zeta^{-k}}{u_{-1}\gamma_0\cdots\gamma_{2k}},$$
$$q^-(2k,P)\sim\frac{\zeta^{-k}}{\gamma_0\cdots\gamma_{2k-1}},\quad \lambda q^-(2k+1,P)\sim\frac{\zeta^{-k}}{\gamma_0\cdots\gamma_{2k}}. \tag{5.25}$$

Based on the Dubrovin–Novikov's formulas Eqs. (5.9), (5.10) and through an elementary analysis, it is easy to see the following assertions.

Proposition 5.4: The Baker function $p(2k,P)$ is of the properties:

(i) N simple poles at $\mu_1(0),\ldots,\mu_N(0)$ and two poles of kth order at ∞_2 and 0_1;
(ii) N simple zeros at $\mu_1(2k),\ldots,\mu_N(2k)$ and two zeros of kth order at ∞_1 and 0_2.

The Baker function $[\lambda p](2k+1,P)$ has

(i) N simple poles at $\mu_1(0),\ldots,\mu_N(0)$, a pole of $(k+1)$th order at ∞_2 and a pole of kth order at 0_1;
(ii) N simple zeros at $\mu_1(2k+1),\ldots,\mu_N(2k+1)$, a zero of kth order at ∞_1 and a zero of $(k+1)$th order at 0_2.

Proposition 5.5: The Baker function $q(2k,P)$ is of the properties:

(i) N simple poles at $\nu_1(0),\ldots,\nu_N(0)$ and two poles of kth order at ∞_2 and 0_1;
(ii) N simple zeros at $\nu_1(2k),\ldots,\nu_N(2k)$ and two zeros of kth order at ∞_1 and 0_2.

The Baker function $[\lambda q](2k+1,P)$ has

(i) N simple poles at $\nu_1(0),\ldots,\nu_N(0)$, a pole of $(k+1)$th order at ∞_2 and a zero of $(k+1)$th order at 0_2;
(ii) N simple zeros at $\nu_1(2k+1),\ldots,\nu_N(2k+1)$, a zero of kth order at ∞_1 and a pole of kth order at 0_1.

Theorem 5.6: (Straightening out of the discrete flow)

$$\rho^{(s)}(2k)-\rho^{(s)}(0)=2\Omega^{(0)}k\pmod{\mathcal{T}}, \tag{5.26}$$

$$\rho^{(s)}(2k+1)-\rho^{(s)}(0)=2\Omega^{(0)}k+\eta_2\pmod{\mathcal{T}} \tag{5.27}$$

or

$$\rho^{(s)}(n)-\rho^{(s)}(0)=\Omega^{(0)}n+[1-(-1)^n]\eta_0\pmod{\mathcal{T}}, \tag{5.28}$$

where $\mathcal{T}$ is the lattice spanned by the periodic vectors, and

$$\Omega^{(0)}=\tfrac{1}{2}(\eta_2-\eta_1),\quad \eta_0=\tfrac{1}{4}(\eta_1+\eta_2),\quad \eta_s=\int_{0_s}^{\infty_s}\omega,\quad s=1,2.$$

Proof: For $n=2k$, we introduce the meromorphic differential on Γ:

$$\omega(2k)=\left\{\frac{d}{d\zeta}\ln p(2k,P)\right\}d\zeta \tag{5.29}$$

which has poles at $\mu_j(0)$ and $\mu_j(2k)$ with the residues $-1,1$, respectively, and poles at ∞_1, ∞_2, 0_1, 0_2 with the residues k, $-k$, $-k,k$, respectively. Let Ω be the Abel differential of the second kind, and $\omega(P,Q)$ be the normal Abel differential of the third kind with the residue $1,-1$ at P,Q, respectively, and the properties

$$\int_{a_j}\omega(P,Q)=0,\quad \int_{b_j}\omega(P,Q)=2\pi\sqrt{-1}\int_Q^P\omega_j.$$

Here ω_j is the normalized Abel differential of the first kind given by (4.1). Then the differential (2.25) can be expressed as a linear combination of Ω, $\omega(P,Q)$ and ω_j in view of the poles, that is

$$\omega(2k)=\Omega+k\omega[\infty_1,\infty_2]+k\omega[0_2,0_1]+\sum_{j=1}^N\omega[\mu_j(2k),\mu_j(0)]+\sum_{j=1}^N e_j\omega_j, \tag{5.30}$$

where e_j's are some complex numbers. Integrating Eq. (5.30) along a_l and b_l, we obtain that $e_l=2\pi n_l\sqrt{-1}$ and

$$\sum_{j=1}^N\int_{\mu_j(0)}^{\mu_j(2k)}\omega_l=k\left(\int_{0_2}^{\infty_2}-\int_{0_1}^{\infty_1}\right)\omega_l+m_l-\sum_{j=1}^N n_j\tau_{jl}, \tag{5.31}$$

where n_l and m_l are certain integers. This completes the proof of Eq. (5.26) for $s=1$.

For $n=2k+1$, consider the meromorphic differential

$$\begin{aligned}\omega(2k+1)&=\left\{\frac{d}{d\zeta}\ln[\lambda p](2k+1,P)\right\}d\zeta\\&=\Omega+k\omega[\infty_1,\infty_2]+k\omega[0_2,0_1]+\omega[0_2,\infty_2]\\&\quad+\sum_{j=1}^N\omega[\mu_j(2k+1),\mu_j(0)]+\sum_{j=1}^N\hat{e}_j\omega_j,\end{aligned} \tag{5.32}$$

which implies Eq. (5.27) for $s=1$. Similarly, we can prove Eqs. (5.26) and (5.27) for $s=2$.

Note: Now we have a clear evolution picture of the continuous flows and discrete flow through the Abel–Jacobi coordinates: (i) they are straightened out; (ii) they commute each other. Therefore, the compatible solution of various flows are obtained simply by a linear superposition. Specifically, we have

$$\begin{aligned}\rho^{(1)}(n,x)&=\Omega^{(0)}n+\Omega^{(1)}x+[1-(-1)^n]\eta_0+\rho_0^{(1)},\\\rho^{(2)}(n,x)&=\Omega^{(0)}n-\Omega^{(1)}x+[1-(-1)^n]\eta_0+\rho_0^{(2)},\end{aligned} \tag{5.33}$$

for the coupled discrete nonlinear Schrödinger equation (2.16) and

$$\begin{aligned}\rho^{(1)}(n,t)&=\Omega^{(0)}n+\Omega^{(2)}t+[1-(-1)^n]\eta_0+\rho_0^{(1)},\\\rho^{(2)}(n,t)&=\Omega^{(0)}n-\Omega^{(2)}t+[1-(-1)^n]\eta_0+\rho_0^{(2)},\end{aligned} \tag{5.34}$$

for the coupled discrete mKdV equation (2.17), where

$$\Omega^{(1)}=(\Omega_1^{(1)},\ldots,\Omega_N^{(1)})^T,\quad \Omega^{(2)}=(\Omega_1^{(2)},\ldots,\Omega_N^{(2)})^T,$$

$$\rho_0^{(1)}=\sum_{k=1}^N\int_{P_0}^{P(\mu_k(0))}\omega,\quad \rho_0^{(2)}=\sum_{k=1}^N\int_{P_0}^{P(\nu_k(0))}\omega.$$

Further, for the $(2+1)$-dimensional Toda lattice (2.19) we have

$$\begin{aligned}\rho^{(1)}(n,x,t)&=\Omega^{(0)}n+\Omega^{(1)}x+\Omega^{(2)}t+[1-(-1)^n]\eta_0+\rho_0^{(1)},\\ \rho^{(2)}(n,x,t)&=\Omega^{(0)}n-\Omega^{(1)}x-\Omega^{(2)}t+[1-(-1)^n]\eta_0+\rho_0^{(2)}.\end{aligned}\tag{5.35}$$

VI. EXPLICIT SOLUTIONS

The expression (5.30) gives the explicit solution of the $(2+1)$-dimensional Toda lattice equation (2.19) in the Abel–Jacobi coordinates $(\rho^{(1)}(n),\rho^{(2)}(n))$. In order to get the solution in the original coordinate w_n, the following steps should be completed:

$$(\rho^{(1)}(n),\rho^{(2)}(n))\to(\mu_j(n),\nu_j(n))\to(u_n,v_n)\to w_n.$$

To this end, we consider the Riemann theorem,[20,21] which asserts that there exist constant vectors $M^{(1)}$ and $M^{(2)}$ (the Riemann constants) such that $\theta(\mathcal{A}(P(\zeta))-\rho^{(l)}(n)-M^{(l)})$ has exactly N zeros at $\mu_1(n),\cdots,\mu_N(n)$ for $l=1$ or $\nu_1(n),\cdots,\nu_N(n)$ for $l=2$. Through a standard treatment,[22–24] we obtain

$$\ln\prod_{j=1}^{N}\mu_j(n)=\ln\frac{\theta(\mathcal{A}(0_1)-\rho^{(1)}(n)-M^{(1)})\,\theta(\mathcal{A}(0_2)-\rho^{(1)}(n)-M^{(1)})}{\theta(\mathcal{A}(\infty_1)-\rho^{(1)}(n)-M^{(1)})\,\theta(\mathcal{A}(\infty_2)-\rho^{(1)}(n)-M^{(1)})}+\sum_{j=1}^{N}\int_{a_j}\ln\lambda\,\omega_j,\tag{6.1}$$

$$\ln\prod_{j=1}^{N}\nu_j(n)=\ln\frac{\theta(\mathcal{A}(0_1)-\rho^{(2)}(n)-M^{(2)})\,\theta(\mathcal{A}(0_2)-\rho^{(2)}(n)-M^{(2)})}{\theta(\mathcal{A}(\infty_1)-\rho^{(2)}(n)-M^{(2)})\,\theta(\mathcal{A}(\infty_2)-\rho^{(2)}(n)-M^{(2)})}+\sum_{j=1}^{N}\int_{a_j}\ln\lambda\,\omega_j,\tag{6.2}$$

$$\sum_{j=1}^{N}\mu_j(n)=\frac{1}{2}(\partial_x+\partial_t)\ln\frac{\theta(\rho^{(1)}(n)+M^{(1)}-\mathcal{A}(\infty_1))}{\theta(\rho^{(1)}(n)+M^{(1)}-\mathcal{A}(\infty_2))}+\sum_{j=1}^{N}\int_{a_j}\lambda\,\omega_j,\tag{6.3}$$

$$\sum_{j=1}^{N}\nu_j(n)=\frac{1}{2}(\partial_x+\partial_t)\ln\frac{\theta(\rho^{(2)}(n)+M^{(2)}-\mathcal{A}(\infty_2))}{\theta(\rho^{(2)}(n)+M^{(2)}-\mathcal{A}(\infty_1))}+\sum_{j=1}^{N}\int_{a_j}\lambda\,\omega_j.\tag{6.4}$$

According to Eqs. (5.35), (6.1)–(6.4) can be written as

$$\begin{aligned}\ln\prod_{j=1}^{N}\mu_j(n)=&\ln\frac{\theta(\Omega^{(0)}n+\Omega^{(1)}x+\Omega^{(2)}t+[1-(-1)^n]\eta_0+\kappa_1)}{\theta(\Omega^{(0)}n+\Omega^{(1)}x+\Omega^{(2)}t+[1-(-1)^n]\eta_0+\kappa_2)}\\&+\ln\frac{\theta(\Omega^{(0)}n+\Omega^{(1)}x+\Omega^{(2)}t+[1-(-1)^n]\eta_0+\hat\kappa_1)}{\theta(\Omega^{(0)}n+\Omega^{(1)}x+\Omega^{(2)}t+[1-(-1)^n]\eta_0+\hat\kappa_2)}+\varrho_0,\end{aligned}\tag{6.5}$$

$$\begin{aligned}\ln\prod_{j=1}^{N}\nu_j(n)=&\ln\frac{\theta(\Omega^{(0)}n-\Omega^{(1)}x-\Omega^{(2)}t+[1-(-1)^n]\eta_0+\kappa_3)}{\theta(\Omega^{(0)}n-\Omega^{(1)}x-\Omega^{(2)}t+[1-(-1)^n]\eta_0+\kappa_4)}\\&+\ln\frac{\theta(\Omega^{(0)}n-\Omega^{(1)}x-\Omega^{(2)}t+[1-(-1)^n]\eta_0+\hat\kappa_3)}{\theta(\Omega^{(0)}n-\Omega^{(1)}x-\Omega^{(2)}t+[1-(-1)^n]\eta_0+\hat\kappa_4)}+\varrho_0,\end{aligned}\tag{6.6}$$

$$\sum_{j=1}^{N}\mu_j(n)=\frac{1}{2}(\partial_x+\partial_t)\ln\frac{\theta(\Omega^{(0)}n+\Omega^{(1)}x+\Omega^{(2)}t+[1-(-1)^n]\eta_0+\kappa_2)}{\theta(\Omega^{(0)}n+\Omega^{(1)}x+\Omega^{(2)}t+[1-(-1)^n]\eta_0+\hat\kappa_2)}+\varrho_1,\tag{6.7}$$

$$\sum_{j=1}^{N}\nu_j(n)=\frac{1}{2}(\partial_x+\partial_t)\ln\frac{\theta(\Omega^{(0)}n-\Omega^{(1)}x-\Omega^{(2)}t+[1-(-1)^n]\eta_0+\hat\kappa_4)}{\theta(\Omega^{(0)}n-\Omega^{(1)}x-\Omega^{(2)}t+[1-(-1)^n]\eta_0+\kappa_4)}+\varrho_1,\tag{6.8}$$

where

$$\kappa_1=\rho_0^{(1)}+M^{(1)}-\mathcal{A}(0_1),\quad \hat{\kappa}_1=\rho_0^{(1)}+M^{(1)}-\mathcal{A}(0_2),$$

$$\kappa_2=\rho_0^{(1)}+M^{(1)}-\mathcal{A}(\infty_1),\quad \hat{\kappa}_2=\rho_0^{(1)}+M^{(1)}-\mathcal{A}(\infty_2),$$

$$\kappa_3=\rho_0^{(2)}+M^{(2)}-\mathcal{A}(0_1),\quad \hat{\kappa}_3=\rho_0^{(2)}+M^{(2)}-\mathcal{A}(0_2),$$

$$\kappa_4=\rho_0^{(2)}+M^{(2)}-\mathcal{A}(\infty_1),\quad \hat{\kappa}_4=\rho_0^{(2)}+M^{(2)}-\mathcal{A}(\infty_2),$$

$$\varrho_0=\sum_{j=1}^{N}\int_{a_j}\ln\lambda\,\omega_j,\quad \varrho_1=\sum_{j=1}^{N}\int_{a_j}\lambda\,\omega_j.$$

Substituting Eqs. (6.5)–(6.8) into Eqs. (3.17) yields quasiperiodic solutions of the $(2+1)$-dimensional Toda equation (2.19).

Unifying scheme for generating discrete integrable systems including inhomogeneous and hybrid models

Anjan Kundu[a)]

(Received 19 May 2003; accepted 20 May 2003)

A unifying scheme based on an ancestor model is proposed for generating a wide range of integrable discrete and continuum as well as inhomogeneous and hybrid models. They include in particular discrete versions of sine-Gordon, Landau–Lifshitz, nonlinear Schrödinger (NLS), derivative NLS equations, Liouville model, (non-)relativistic Toda chain, Ablowitz–Ladik model, etc. Our scheme introduces the possibility of building a novel class of integrable hybrid systems including multicomponent models like massive Thirring, discrete self-trapping, two-mode derivative NLS by combining different descendant models. We also construct inhomogeneous systems like Gaudin model including new ones like variable mass sine-Gordon, variable coefficient NLS, Ablowitz–Ladik, Toda chains, etc. keeping their flows isospectral, as opposed to the standard approach. All our models are generated from the same ancestor Lax operator (or its $q \to 1$ limit) and satisfy the classical Yang–Baxter equation sharing the same r-matrix. This reveals an inherent universality in these diverse systems, which become explicit at their action-angle level. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1604456]

I. INTRODUCTION

Though integrable models represent only a special class of nonlinear systems, their numbers and varieties discovered until today have become amazingly large. Therefore it is particularly important now to have well defined schemes, which will be able to generate them in a systematic way, find out their interrelations, detect the fundamental ones and identify their universal properties. Reduction of Lax operators in AKNS spectral problem,[1] classification of soliton bearing equations through self-dual Yang–Mills equation,[2] gauge unification of nonlinear Schrödinger (NLS)-type models[3] are few of such successful approaches. However most of these schemes are designed to deal with the continuous models only, whereas the importance and significance of discrete integrable systems have been well emphasized in recent years.[4] Moreover, the algebraic approach in classical integrable models, though it has a rich and sophisticated formulation through the classical Yang–Baxter equation and the classical r-matrix,[5] as it appears, has not been exploited fully.

Our aim here is therefore to propose an unified algebraic scheme for systematic generation of a large class of integrable discrete models, based on their underlying Poisson bracket (PB) structure. The specialty of this class of models is that they can be easily quantized to yield the corresponding quantum integrable systems and their classification may be done through the associated classical r-matrix with its known trigonometric and rational solutions. We present an integrable discrete ancestor model linked with the trigonometric r-matrix (and its $q \to 1$ form related naturally to the rational solution of r) and containing a set of arbitrary parameters. Various choices of these external parameters define in turn different underlying algebraic structures and the associated Lax operators. This generates through suitable realizations a wide range of diverse integrable systems sharing the same r-matrix with their ancestor model. They are by construction

a)Electronic mail: anjan@theory.saha.ernet.in

integrable discrete models with few of them having also well defined field limits.

Our scheme, the basic idea of which is borrowed from the quantum domain,[6,7] appears to be effective not only in classifying an important class of discrete models as well as their field limits, but also their inhomogeneous extensions. Along with the exactly integrable discrete versions of the well known models like sine-Gordon, Landau–Lifshitz equation, NLS, derivative NLS (DNLS), Liouville model, relativistic and nonrelativistic Toda chain, Ablowitz–Ladik model, we also obtain new inhomogeneous models like variable mass sine-Gordon and more general variable coefficient NLSs, as well as Gaudin model, inhomogeneous Ablowitz–Ladik model and Toda chains. As an important application of our scheme we may construct novel families of integrable hybrid models, by combining different descendant models in different domains of the lattice space (very recently such field models attracted attention[8]), or by fusing copies of a single component model to get its multicomponent generalization. Moreover, the present method of generating integrable inhomogeneous discrete and continuum models reveals the intriguing fact that the conventional approach by considering space–time dependent spectral parameter $\lambda(x,t)$[9–14] is rather restricted and even appears to be misleading, since it would lead in general to a dynamical r-matrix spoiling the underlying algebraic structure and forbidding therefore the possible quantization of the models and their usual action-angle formulation. Moreover, for more general inhomogeneous sine-Gordon and NLS models, as we find here, the conventional treatment of nonisospectral flow would be likely to fail. In our approach on the other hand the necessary isospectrality is kept intact by taking constant λ as in the original homogeneous case and the inhomogeneity is introduced through arbitrary parameters, which act like Casimir operators in the associated Poisson algebra.

Since all these models, in spite of their manifestly diverse forms and nature, are generated from the same ancestor model sharing the same r-matrix (or its $q\to 1$ form), it reveals an intriguing universality among them which is reflected prominently in their description of complete integrability through action-angle variables.

The paper is arranged as follows. In Sec. II we review the theory of integrable systems satisfying classical Yang–Baxter equation associated with classical $r(\lambda-\mu)$ matrix. Section III presents the explicit form of the ancestor model and its $q\to 1$ limit together with the underlying PB algebras. We introduce our generating scheme in Sec. IV and construct concrete models. Section V accounts for the generation of integrable inhomogeneous as well as hybrid models. Section VI focuses on the universal property of all descendant models by explicit construction of their action-angle variables. Section VII is the concluding section.

II. CLASSICAL YANG–BAXTER EQUATION AND INTEGRABLE SYSTEMS

By integrability of a nonlinear discrete system defined on a lattice with sites $j=1,2,\ldots,N$, we mean it in the Liouville sense by requiring the existence of its N number of independent conserved quantities $C_n, n=1,2,\ldots,N$ including the Hamiltonian H of the system with the criteria $\{C_n, C_m\}=0$. Such conserved quantities can be considered as the action variables generated from a spectral parameter λ-dependent transfer matrix as: $\tau(\lambda)=\Sigma_{n=1}^{N} C_n \lambda^n$ and consequently the integrability criteria may be replaced by the single condition

$$\{\tau(\lambda),\tau(\mu)\}=0. \tag{1}$$

For deriving this condition therefore along with the conventional linear spectral problem: $T_{k+1}(\lambda)=L_k(\lambda)T_k(\lambda)$ we define also the PB algebra for its Lax operator $L_k(\lambda)$ in a specific form, which is known as the classical Yang–Baxter equation (CYBE)[5]

$$\{L_k(\lambda)\otimes, L_l(\mu)\}=\delta_{kl}[r(\lambda-\mu), L_k(\lambda)\otimes L_k(\mu)] \tag{2}$$

associated with the classical $r(\lambda-\mu)$-matrix playing the role of structure constants. For the associativity of algebra (2) ensuring its Jacobi identity, the r-matrix in turn must satisfy another form of CYBE,

$$[r_{12}(\lambda-\mu), r_{13}(\lambda-\delta)]+[r_{12}(\lambda-\mu), r_{23}(\mu-\delta)]+[r_{13}(\lambda-\delta), r_{23}(\mu-\delta)]=0. \tag{3}$$

It is crucial to observe that, though there is a variety of Lax operator solutions to (2) with different basic operators and spectral parameter dependence, representing a wide range of integrable systems (for a list see Sec. IV), the associated r-matrix solutions satisfying (3) are only of three types: elliptic, trigonometric, and rational. Moreover most of the known models are linked to the last two cases only, i.e., to the trigonometric r-matrix,

$$r_t(\lambda-\mu)=\frac{1}{i\sin(\lambda-\mu)}\left(\frac{1}{2}\cos(\lambda-\mu)\sigma_3\otimes\sigma_3+\sigma_+\otimes\sigma_-+\sigma_-\otimes\sigma_+\right) \tag{4}$$

or to its $q\to 1$, $\lambda,\ \mu\to 0$ limit given by the rational solution

$$r_r(\lambda-\mu)=\frac{1}{i(\lambda-\mu)}P, \quad \text{where } P=\tfrac{1}{2}(I+\vec{\sigma}\cdot\vec{\sigma}), \tag{5}$$

P being the permutation operator. The above remarkable observation has motivated us to conjecture that all integrable models satisfying the CYBE (2) must be derivable from an ancestor model with their Lax operators obtained as various reductions of this single ancestor Lax operator and this should make the r-matrix, inherited from their ancestor, to be naturally the same for all these descendant models. In the next section we present such an ancestor model in the explicit form associated with the trigonometric r-matrix (4), from which we will be able to generate a rich collection of integrable discrete and continuum models including inhomogeneous as well as hybrid systems, all satisfying the CYBE and sharing the same r-matrix (4) [or its rational limit (5)]. Note that from the CYBE (2) one can go to its global description

$$\{T_N(\lambda)\otimes, T_N(\mu)\}=[r(\lambda-\mu), T_N(\lambda)\otimes T_N(\mu)] \tag{6}$$

for the monodromy matrix

$$T_N(\lambda)=L_N(\lambda)\cdots L_1(\lambda)=\begin{pmatrix} a_N(\lambda) & b_N(\lambda)\\ c_N(\lambda) & d_N(\lambda)\end{pmatrix}. \tag{7}$$

It is important to notice that (6) exhibits exactly the same form as its local relation (2), which reflects a deep underlying Hopf algebra structure, an important characteristic of all such integrable systems.[15] Defining now the transfer matrix as $\tau(\lambda)=\mathrm{tr}T_N(\lambda)=a_N(\lambda)+d_N(\lambda)$ and taking the trace of (6) one can easily derive (since the rhs being the trace of a commutator is zero) the integrability condition (1) for the system. Therefore going backwards in the logical chain we can conclude that the nonlinear systems with its representative Lax operator and the r-matrix satisfying the CYBE (2) must be an integrable system. We shall see below that the relation (6) also carries important information for deriving action-angle variables and reflects an universal property for all integrable systems sharing the same r-matrix and hence belonging to the same class.

Note that in this algebraic approach we are not concerned about the usual Lax pair L,M and do not obtain the dynamical equation from the flatness condition involving them. We on the other hand take the Lax operator $L_k(\lambda)$ satisfying the CYBE as the representative of the integrable model and using it construct the monodromy matrix: $T(\lambda)=\Pi_k L_k(\lambda)$ and then the transfer matrix from its trace $\tau(\lambda)=\mathrm{tr}T(\lambda)$. Expanding further the transfer matrix $\tau(\lambda)$ in spectral parameter λ as described above, we derive the conserved quantities including the Hamiltonian H in the explicit form. The dynamical equation can now be obtained as the Hamilton equation $\psi_t=\{\psi,H\}$, using the fundamental PB relations.

At the lattice constant $\Delta\to 0$ one may recover in some cases the corresponding field model: $L_k(\lambda)\to I+\Delta\mathcal{L}(x,\lambda)+O(\Delta^2)$ with $\mathcal{L}(x,\lambda)$ as the field Lax operator. Though the associated r-matrix remains the same, the CYBE gets deformed and the corresponding monodromy matrix $T(\lambda)$ at the infinite interval limit $l=N\Delta\to\infty$ satisfies also a bit different global CYBE.[5] For continuum models one can extract the conserved quantities more conveniently from the Lax operator using the Ricatti equation derived from the linear spectral problem.

III. ANCESTOR MODELS ASSOCIATED WITH TRIGONOMETRIC AND RATIONAL *r*-MATRIX

As mentioned, our generating scheme for integrable models is based on various reductions of a discrete ancestor Lax operator, which we propose to take in the following form:[7]

$$L_k^{\mathrm{trig(anc)}}(\xi)=\begin{pmatrix} \xi c_1^+ e^{i\alpha S_k^3}+\xi^{-1}c_1^- e^{-i\alpha S_k^3} & 2\sin\alpha S_k^- \\ 2\sin\alpha S_k^+ & \xi c_2^+ e^{-i\alpha S_k^3}+\xi^{-1}c_2^- e^{i\alpha S_k^3} \end{pmatrix}, \quad \xi=e^{i\lambda}, \tag{8}$$

and demand it to satisfy the CYBE (2) with the trigonometric r-matrix (4). $\vec{S}_k$ appearing in (8) are the basic dynamical fields PB algebra of which as specified below is dictated by its integrability and $c_a^{\pm}, a=1,2$ are a set of arbitrary parameters. The structure of the Lax operator (8) becomes clearer if we notice its possible decomposition, after an allowed gauge transformation by $h=e^{i\lambda\sigma_3}$, $L^{t(\mathrm{anc})}(\xi)\to hL^{t(\mathrm{anc})}(\xi)h^{-1}=\xi L_+ +\xi^{-1}L_-$, where $L_\pm$ are spectral parameter ξ-free upper/lower triangular matrices. Note that the r-matrix (4) allows also a similar decomposition (after a similar gauge transformation):

$$r_t\left(\frac{\xi}{\eta}\right)\to\frac{\xi}{\eta}r_+ +\left(\frac{\xi}{\eta}\right)^{-1}r_-, \quad \xi=e^{i\lambda}, \quad \eta=e^{i\mu}$$

with $r_\pm$ being spectral-free upper/lower triangular matrices, which together with $L_\pm$ satisfy the FRT-type[16] PB algebra derivable from the CYBE.[17] The demand of integrability on (8) through the CYBE can be shown to be equivalent to the underlying general algebra

$$\{S_k^3,S_l^\pm\}=\pm i\delta_{kl}S_k^\pm, \quad \{S_k^+,S_l^-\}=i\frac{\delta_{kl}}{\sin\alpha}f(2\alpha S_k^3), \quad \text{with } f(x)=(M^+\sin(x)+M^-\cos(x)), \tag{9}$$

where $M^\pm=\pm\frac{1}{2}\sqrt{\pm 1}(c_1^+c_2^-\pm c_1^-c_2^+)$ are arbitrary parameters acting as central elements with trivial brackets with all others: $\{M^\pm,\cdot\}=0$ and in general may also be site and time dependent. It is important to note that the underlying PB structure (9) is linked with a generalization of the well known quantum group algebra. For generating integrable systems from this ancestor model, we find first a realization of (9) in canonical variables $\{u_k,p_l\}=\delta_{kl}$, in the form

$$S_k^3=u_k, \quad S_k^+=e^{-ip_k}g(u_k), \quad S_k^-=g(u_k)e^{ip_k}, \tag{10}$$

where

$$g(u_k)=[\kappa+\sin\alpha(s-u_k)\{f(\alpha(u_k+s+1))\}]^{1/2}\frac{1}{\sin\alpha}, \tag{11}$$

containing free parameters κ, s and function $f(x)$ as defined in (9). It should be remarked here that realization (10) usually assumes the complex conjugacy $S_k^-=(S_k^+)^*$, which however is not imposed by the integrability condition (9). Note that we have now lots of freedom for generating descendant models from the ancestor Lax operator (8) by using various reductions of (11) under different choices of the arbitrary parameters c's as well as κ and s or its further realization in *bosonic* variables: $\{\psi_k,\psi_l^*\}=i\delta_{kl}$ in (10). Moreover we can multiply these Lax operators from left or right by $\sigma_a, a=1,2,3$, since such transformations are allowed by the CYBE due to a symmetry of (4) and (5) as $[r,\sigma_a\otimes\sigma_a]=0$.

We will demonstrate in the next section that a class of discrete integrable systems with nontrivial deformation parameter q, which may be interpreted as the *relativistic* parameter can be generated in a systematic way from the ancestor Lax operator (8). The nonrelativistic models on the other hand may be constructed in a similar way from the $q\to 1$ limit of (8) given as

$$L_k^{\text{rat.(anc)}}(\lambda)=\begin{pmatrix} c_1^0(\lambda+s_k^3)+c_1^1 & s_k^- \\ s_k^+ & c_2^0(\lambda-s_k^3)-c_2^1 \end{pmatrix}, \tag{12}$$

with $c_a^{0,1}, a=0,1$ being arbitrary parameters. Here due to the corresponding limits of $\vec{S}\to\vec{s}$, $\{c_a^{\pm}\}\to\{c_a^{0,1}\}$, $M^+\to -m^+$, $M^-\to -\alpha m^-$, $\xi\to 1+i\lambda$, the PB algebra (9) reduces to

$$\{s_k^+, s_k^-\}=i\delta_{kl}(2m^+ s_k^3+m^-), \quad \{s_k^3, s_l^{\pm}\}=\pm i\delta_{kl}s_k^{\pm}, \tag{13}$$

where $m^+=c_1^0c_2^0$, $m^-=c_1^1c_2^0+c_1^0c_2^1$ with $\{m^{\pm},\cdot\}=0$. Note that a Casimir operator commuting with all other generators of (13) may be constructed as

$$S^2=s_k^3(m^+s_k^3+m^-)+s_k^+s_k^- \tag{14}$$

and a realization of it (13) given by the generalized *Holstein–Primakov* transformation (HPT)

$$\begin{gathered} s_k^3=s-N_k, \quad s_k^+=g_0(N_k)\psi_k, \quad s_k^-=\psi_k^* g_0(N_k), \\ g_0(N_k)=(m^-+m^+(2s-N_k))^{1/2}, \quad N_k\equiv\psi_k^*\psi_k \end{gathered} \tag{15}$$

in bosonic variables ψ_k, which in fact is the $\alpha\to 0$ limit of (10) and (11). We stress again that since the conjugacy of $s_k^{\pm}$ is not necessarily imposed by the integrability, ψ,ψ^* in (15) in general may not be complex conjugates. Note that the ancestor model (12) represents the undeformed rational class and satisfies the CYBE with the rational r-matrix (5). Equations (8) and (12) serving as the ancestor Lax operators for the discrete integrable models may also yield for some systems the corresponding field models with the Lax operator $\mathcal{L}(x,\lambda)$. The associated r-matrix however would remain the same at the continuum limit, since it is a global nondynamical object independent of site indices. We shall see in Sec. V that parameters c's in general can be space–time dependent and hence could induce inhomogeneity in the model preserving the constancy of the spectral parameter.

IV. UNIFIED GENERATION OF DISCRETE INTEGRABLE MODELS

From the ancestor models proposed we generate here integrable discrete models belonging to both trigonometric and rational class.

A. Relativistic models belonging to trigonometric class

For constructing this class of models we start from the ancestor Lax operator (8) and look into its different realizations by choosing first the arbitrary parameters c's as constants.

(1) *Discrete sine-Gordon model:* Parameter choice $c_1^{\pm}=-c_2^{\pm}=m\Delta$, with m as the constant mass. This gives $M^-=0$, $M^+=-(m\Delta)^2$, and reduces realization (10) correspondingly to yield from (8) (after multiplying it from right by $-i\sigma_1$) the Lax operator

$$L_k(\lambda)=\begin{pmatrix} g(u_k)e^{ip_k\Delta} & m\Delta\sin(\lambda+\alpha u_k) \\ m\Delta\sin(\lambda-\alpha u_k) & e^{-ip_k\Delta}g(u_k) \end{pmatrix}, \quad g^2(u_k)=1-(m\Delta)^2\cos\alpha(2u_k+1). \tag{16}$$

It is important to note that (16) yields exactly the Lax operator of the integrable discrete sine-Gordon model[18] and at the continuum limit $\Delta\to 0$, when $e^{\pm ip_k\Delta}\to 1\pm\Delta ip_k$ and $(u_k,p_k)\to(u(x),p(x))$, recovers clearly the field Lax operator

$$\begin{gathered} L_k(\lambda)=1+\Delta\mathcal{L}(x,\lambda), \quad \mathcal{L}(x,\lambda)=ip(x)\sigma_3+m\sin(\lambda+\alpha u(x))\sigma_+ +m\sin(\lambda-\alpha u(x))\sigma_-, \\ p(x)=\dot{u}(x) \end{gathered} \tag{17}$$

of the well-known sine-Gordon model $u_{tt}-u_{xx}+\sin \alpha u=0$. Remarkably the PB algebra (9) in this case reduces to the classical limit of the celebrated *quantum group*[15] with its familiar relation $\{S^+,S^-\}=-i[2S^3]_q$. We will see in the next section that a more general choice for the parameters would lead to an inhomogeneous extension of this sine-Gordon model.

(2) *Discrete Liouville model:* Parameter choice $c_1^+=c_2^-=\Delta$, $c_1^-=c_2^+=0$. This gives $M^{\pm}=\pm\frac{1}{2}\sqrt{\pm 1}\Delta^2$ and correspondingly reduces (10) to derive from the same ancestor (8) (after multiplying it from right by σ_1) the Lax operator

$$L_k(\xi)=\begin{pmatrix} e^{p_k\Delta}g(u_k) & \Delta\xi e^{\alpha u_k} \\ \dfrac{\Delta}{\xi}e^{\alpha u_k} & g(u_k)e^{-p_k\Delta}\end{pmatrix}, \quad g^2(u_k)=1+\Delta^2 e^{\alpha(2u_k+i)}, \tag{18}$$

which represent the discrete Liouville model[19] and at its field limit ($\Delta\to 0$) the Lax operator $\mathcal{L}=p\sigma_3+e^{\alpha u}[\xi\sigma_+ +(1/\xi)\,\sigma_-]$ of the well known Liouville equation: $u_{tt}-u_{xx}=e^{\alpha u}$. Note that in this case (9) gives a novel PB algebra with exponentially deformed relation like $\{S^+,S^-\}=(1/2\sin\alpha)e^{2i\alpha S^3}$.

It is intriguing to observe here that though the underlying PB structure and hence its realization giving the model are fixed by the choice of $M^{\pm}$, the Lax operator (8) which depends directly on the parameters c's may take different forms for the same model. For example, in the present case with additional choice $c_1^-\neq 0$ would record the same values for $M^{\pm}$, but a different Liouville Lax operator.[20] This opens up therefore a promising possibility for systematically obtaining different useful Lax operators for the same integrable model.

(3) *Relativistic Toda chain:* Different sets of constant choices (i) $c_a^+=1$, $a=1,2$, or (ii) $c_a^-=1$, $a=1,2$, or (iii) $c_1^{\mp}=\pm 1$, or (iv) $c_1^+=1$, with the rest of c's being zero, lead to $M^{\pm}=0$, reducing therefore (9) to the simple PB algebra

$$\{S_k^+,S_l^-\}=0, \quad \{S_k^3,S_l^{\pm}]=\pm i\delta_{kl}S_k^{\pm}, \tag{19}$$

and the realization (10) (after a canonical interchange of variables: $u\to -ip$, $p\to -iu$,) to the form

$$S_k^3=-ip_k, \quad S_k^{\pm}=\alpha e^{\mp u_k}. \tag{20}$$

This generates interestingly from the same ancestor Lax operator (8) different forms of the discrete-time or relativistic Toda chain (RTC). For example, case (iii) yields

$$L_k(\xi)=\begin{pmatrix} \dfrac{1}{\xi}e^{\alpha p_k}-\xi e^{-\alpha p_k} & \alpha e^{u_k} \\ -\alpha e^{-u_k} & 0\end{pmatrix}, \tag{21}$$

recovering the Lax operator found in Ref. 21, while (iv) generates a different Lax operator[22] for the same model. More famous RTC model of Suris[23] however is obtained in this approach after performing a *twisting* transformation with twisting parameter taken as $\pm\alpha$ (of these equivalent cases we consider here only $-\alpha$, for definiteness), which deforms the r_t-matrix (4) by adding a constant matrix Ω to it,[21]

$$r_t\to r_\Omega=r_t-\Omega, \quad \text{where } \Omega=i(\sigma_3\otimes I-I\otimes\sigma_3). \tag{22}$$

As a result the form of the ancestor Lax operator (8) also gets changed with its elements transforming as

$$c_a^{\pm}\to c_a^{\pm}e^{i\alpha S_k^3}, \quad S_k^{\pm}\to\widetilde{S}_k^{\pm}=e^{i1/2\,\alpha S_k^3}S_k^{\pm}e^{i1/2\,\alpha S_k^3}. \tag{23}$$

Implementing the corresponding changes in (21) and using the same realization (20) for the variables (23) we obtain now the explicit form of the Lax operator

$$L_k(\xi)=\begin{pmatrix} \frac{1}{\xi}e^{2\alpha p_k}-\xi & \alpha e^{u_k} \\ -\alpha e^{2\alpha p_k-u_k} & 0 \end{pmatrix}, \tag{24}$$

generating that of the Suris RTC.[23]

(4) *Discrete derivative NLS:* Parameter choice as constants,

$$c_1^+=c_2^+=1, \quad c_1^-=-iq\Delta, \quad c_2^-=\frac{i\Delta}{q}, \text{ giving } M^+=2\Delta\sin\alpha, \quad M^-=2i\Delta\cos\alpha \tag{25}$$

gives (10) a q-bosonic realization as $S_k^+=-Q_k$, $S_k^-=Q_k^*$, $S_k^3=-N_k$, with a PB algebra induced from (9) as

$$\{Q_k,N_l\}=i\delta_{kl}Q, \quad \{Q_k,Q_l^*\}=i\delta_{kl}\frac{\cos(\alpha(2N+1))}{\cos\alpha}, \tag{26}$$

which clearly reduces to the standard bosons ψ_k,ψ_k^* at $\alpha\to 0$. It is worth noting that this new q-bosonic model as realized from the ancestor Lax operator (8) (after introducing Δ) would give

$$L_k(\xi)=\begin{pmatrix} \frac{1}{\xi}q^{-N_k}-i\xi\Delta q^{N_k+1} & Q_k^* \\ Q_k & \frac{1}{\xi}q^{N_k}+i\xi\Delta q^{-(N_k+1)} \end{pmatrix}, \tag{27}$$

which represents an exact lattice version of the DNLS equation.[24] When expressed through bosonic field: $Q=\psi[\Delta([2N]_q/2N\cos\alpha)]^{1/2}$, $N=\Delta|\psi|^2$, Eq. (27) yields at the continuum limit $\Delta\to 0$ the field Lax operator

$$\mathcal{L}(\psi)=-(\tfrac{1}{4}\xi^2-|\psi|^2)\sigma_3+\xi(\psi^*\sigma^+ +\psi\sigma^-) \tag{28}$$

of the well-known Chen–Lee–Liu DNLS equation:[25] $i\psi_t=\psi_{xx}-4i|\psi|^2\psi_x$.

(5) *Ablowitz–Ladik model:* This model involving also another form of q-boson is possible to generate in our scheme, though it needs twisting transformation as in the Suris RTC mentioned above and is associated with the same twisted r_Ω-matrix (22) and the twisted ancestor Lax operator with the change (23). Now the the parameter choice $c_1^+=c_2^-=0$ with $c_1^-=c_2^+=1$ giving $M^\pm=\frac{1}{2}\sqrt{\pm 1}$ (compare with the Liouville case) together with the twisting removes dynamical variables from the diagonal elements of the twisted Lax operator as well as modifies the Poisson algebra of the transformed variables $\tilde{S}_k^\pm$ as derivable from (9). Therefore naming $b_k=2\sin\alpha\tilde{S}_k^+$ we get this modified PB relation as $\{b_k,b_l^*\}=i\delta_{kl}(1-b_k^*b_k)$, confirming the basic variables of the Ablowitz–Ladik model as a type of q-boson with its Lax operator as

$$L_k(\xi)=\begin{pmatrix} \frac{1}{\xi} & b_k^* \\ b_k & \xi \end{pmatrix} \tag{29}$$

related to (22). We will see later how space-time dependent parameters c's give inhomogeneous extensions of this model. Note that another intriguing possibility of generalizing this model arises if we simply consider $c_1^+\neq 0$ in the above construction. It is not dificult to see that, realizing S_k^3

$=-\ln(1-b_k^* b_k)$ this would generate an extra term $\xi c_1^+ (1-b_k^* b_k)^{-2i\alpha}$ in the upper diagonal element of the Ablowitz–Ladik Lax operator (29). Its consequence in the dynamical equation would be an interesting problem to study.

B. Nonrelativistic models belonging to rational class

Deformation parameter $q=e^{i\alpha}$, as we have seen in the above models, serves as the relativistic or the deformed bosonic parameter. We consider now the undeformed limit $q\to 1$ or $\alpha\to 0$, when as explained already, the r-matrix reduces to its rational form (5) and the ancestor Lax operator is converted to (12) with the underlying PB algebra (13).

We find that the integrable models belonging to this rational class are mostly nonrelativistic models, which can be generated in a similar way from the rational ancestor model (12) with different constant choices for parameters $c_a^{0,1}$, $a=1,2$ involved in it.

(6) *Landau–Lifshitz equation (LLE):* Parameter choice $c_a^0=1$, $c_1^1=-c_2^1=-l$ compatible with $m^+=1$, $m^-=0$, reduces (13) to the classical sl_2 spin algebra $\{s_k^\alpha, s_l^\beta\}=i\delta_{kl}\epsilon^{\alpha\beta\gamma}s_l^\gamma$ with spin: $s^2=(s_k^3)^2+s_k^+ s_k^-\equiv \vec{s}_k^2$ as the Casimir operator reduced from (14). The ancestor Lax operator (12) simplifies (ignoring an irrelevant multiplicative factor) to

$$L_k(\lambda)=I+\frac{1}{\lambda-l}\vec{s}_k\cdot\vec{\sigma} \tag{30}$$

representing a discrete version of the LLE. At the continuum limit $\Delta\to 0$ putting $\vec{s}_k\to\Delta\vec{s}(x)$ one gets from the Casimir: $\vec{s}^2(x)=1$ and from the Lax operator $L_k(\lambda)\to I+\Delta\mathcal{L}(\lambda), \mathcal{L}(\lambda)=[1/(\lambda-l)]\vec{s}(x)\cdot\vec{\sigma}$, that for the well known LLE.[26]

(7) *Discrete NLS model:* For the same sl_2 spin algebra transformation (15) yields the standard HPT with $g_0(|\psi_k|)=(2s-\Delta|\psi_k|^2)^{1/2}$ (considering ψ_k,ψ_k^* to be complex conjugates and scaling them by $\sqrt{\Delta}$). This realization by considering parameter $l=0$ leads (12) to the Lax operator of exactly integrable discrete NLS model[18] given by

$$L_k(\lambda)=\begin{pmatrix} \lambda+s-\Delta|\psi_k|^2 & \sqrt{\Delta}\psi^* g_0(|\psi_k|) \\ \sqrt{\Delta}\psi g_0(|\psi_k|) & \lambda-s+\Delta|\psi_k|^2 \end{pmatrix}. \tag{31}$$

At the field limit: $\Delta\to 0$, Eq. (31) yields (after multiplying it from left by $\sigma_3\Delta$ and considering $s=1/\Delta$) the familiar form of the Lax operator

$$\mathcal{L}(\lambda)=\lambda\sigma^3+\sqrt{2}(\psi^*\sigma^+-\psi\sigma^-) \tag{32}$$

for the NLS field equation $i\psi_t=\psi_{xx}+2|\psi|^2\psi$.

(8) *Simple lattice NLS:* On the other hand, a complementary choice $m^+=0$, $m^-=1$, giving $g_0(N_k)=1$ converts (15) directly to the realization $s_k^+=\psi_k$, $s_k^-=\psi_k^*$, $s_k^3=s-\psi_k^*\psi_k$ in bosonic field: $\{\psi_k,\psi_l^*\}=i\delta_{kl}$. Now a compatible choice of parameters: $c_1^0=c_2^1=1$, $c_2^0=c_1^1=0$ together with this bosonic realization generates from the ancestor (12) the Lax operator

$$L_k(\lambda)=\begin{pmatrix} \lambda+s-N_k & \psi_k^* \\ \psi_k & -1 \end{pmatrix}, \quad N_k=\psi_k^*\psi_k, \tag{33}$$

which may be associated with another simple lattice NLS model proposed in Ref. 27 and as noted there ψ,ψ^* may not be complex conjugates at the discrete level. At the continuum limit we recover again the same field Lax operator (32) for the NLS equation and regain also the complex-conjugacy of the fields (see Ref. 27 for details).

(9) *Nonrelativistic Toda chain:* Note that the trivial choice $m^\pm=0$ yields from (13) again the same algebra (19) and therefore we may take the same realization of it as found before. However, the rational form of ancestor model (12) generates now simpler Lax operator

$$L_k(\lambda)=\begin{pmatrix} p_k-\lambda & e^{u_k} \\ -e^{-u_k} & 0 \end{pmatrix} \tag{34}$$

of the nonrelativistic Toda chain associated with the rational r-matrix and described by the Hamiltonian: $H=\Sigma_k \frac{1}{2}p_k^2+e^{(u_k-u_{k+1})}$.

Thus we have demonstrated that discrete and continuum integrable models can be obtained in a unified way from the ancestor Lax operator (8) [or its rational limit (12)] by choosing different sets of constant values for the parameters c's involved in the ancestor model and by using different realizations of the underlying PB algebra. In the next section we find how a more general choice of c's can generate further the inhomogeneous extensions of these integrable models.

We find also a convincing answer to an important question raised above asking why different integrable systems with varied Lax operator solutions should have the same r-matrix, by discovering that all these models are basically obtainable from the same ancestor model (8) associated with the trigonometric r-matrix (4). These descendant models, whose explicit Lax operators we derive here satisfy the CYBE (2) inheriting and sharing the same r-matrix (4). We will see in Sec. VI that this significant fact induces a universality among these seemingly diverse systems by defining their action-angle variables in the same way.

V. INTEGRABLE INHOMOGENEOUS AND HYBRID MODELS WITH ISOSPECTRAL FLOW

We have seen how by fixing the values of certain parameters we could generate a wide spectrum of integrable models belonging to the trigonometric and rational class. We focus here on some promising possibilities to generalize this procedure for constructing novel integrable families of inhomogeneous and hybrid models.

A. Inhomogeneous models

Returning again to the ancestor model (8) we may notice that the parameters $c_a^{\pm}$, $a=1,2$ entering in it [similarly, $c_a^{0,1}$, $a=1,2$ in its rational limit (12)] act like external parameters having trivial PB with all basic variables in their local algebra and therefore, apart from constants as earlier they may be considered in general as site (time) dependent arbitrary functions. As a result $M^{\pm}$ in (10), (11) in turn also become functions $M_k^{\pm}(t), k=1,2,\ldots,N$ [and similarly $m_k^{\pm}(t)$ in (15)] and lead to new integrable descendant models, which are inhomogeneous extensions of the discrete and continuum models constructed above. However this integrable family of inhomogeneous models is obtained in our scheme by keeping the usual isospectral flow. Moreover, such constancy of spectral parameters (except some trivial transformations like shifting, etc.) is essential in this algebraic formalism for satisfying the CYBE (6) with spectral dependent global and nondynamical $r(\lambda-\mu)$-matrix. It is important also to notice that the inhomogeneity is introduced here through a set of different independent parameters: $c_{ak}^{\pm}$ (or $c_{ak}^{0,1}$) with $a=1,2$ and therefore it may not be always possible to absorb them in the single spectral parameter, even by declaring it to be nonisospectral. Therefore we see that, contrary to the standard approach the inhomogeneous models cannot be described in general as nonisospectral flow, at least those that belong to the present family. Moreover isospectrality is a necessary criterion for the CYBE solution, as explained already.

(10) *Variable mass sine-Gordon model:* The construction is parallel to that of the constant mass sine-Gordon model obtained above, where in place of constants we choose now the parameters as four different variable mass: $c_1^{\pm}=m_{1k}^{\pm}(t)\Delta$, $c_2^{\pm}=m_{2k}^{\pm}(t)\Delta$. This would generate from the ancestor Lax operator (8) and realization (10) a general form of a new inhomogeneous sine-Gordon model, which is integrable and satisfies the CYBE associated to the trigonometric r-matrix (4). Particular choices of the inhomogeneities would yield naturally different forms of the variable mass sine-Gordon model, discrete as well as continuum, which seem to have been never considered before.

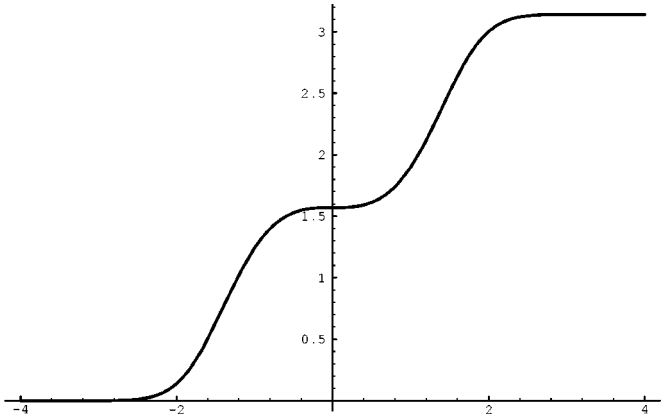

FIG. 1. How the kink solution [for $m_1(x)=1$] deforms in variable mass sine-Gordon model depending on the mass parameter $m_1(x)=x$ and $m_1(x)=x^2$, respectively.

For a demonstration we take up the simplest case when all mass parameters coincide: $m_{ak}^{\pm}(t)=m_k(t)$. This variable mass discrete sine-Gordon model can be described again by the same form (16) by replacing constant m by a variable $m_k(t)$. At the continuum limit this would correspond to a sine-Gordon field model with variable mass $m(x,t)$. If the mass parameter is assumed to be factorized: $m(x,t)\equiv m_0(t)m_1(x)$, by introducing a new coordinate system through nonlinear transformation $(t,x)\rightarrow(T,X)$, $T=\int^t m_0(t')dt'$, $X=\int^x m_1(x)dx'$, the Hamiltonian of the model can be written formally again as the standard sine-Gordon model with unit mass. Nevertheless we notice that even in a further simplified case with $m_0(t)=1$, the soliton solutions in the original system might have quite interesting character depending on the form of the variable mass $m_1(x)$ (see Fig. 1).

(11) *Inhomogeneous NLS model:* Since this model belongs to the rational class, in accordance with our strategy we start with the ancestor Lax operator (12) and consider the parameters involved in it and in realization (15) to be site and time dependent functions: $c_{ak}^{0,1}(t)$, $a=1,2$. With all of them different we naturally get the general inhomogeneous discrete NLS model, which retains its integrability and contrary to the standard approach also its isospectrality, as explained already. For constructing the corresponding field model we take the parameters in the form $c_{1k}^0=g_{1k}$, $c_{2k}^0=-g_{2k}$, $c_{1k}^1=(1/\Delta)+f_{1k}$, $c_{2k}^1=-(1/\Delta)+f_{2k}$, $s=\Delta$ and at the limit $\Delta\rightarrow 0$ obtain the Lax operator

$$\mathcal{L}(\lambda)=\begin{pmatrix}\Lambda_1(x,t) & Q^* \\ -Q & -\Lambda_2(x,t)\end{pmatrix}, \quad \text{where } \Lambda_a(x,t)=\lambda g_a(x,t)+f_a(x,t), \quad a=1,2 \tag{35}$$

and $Q=\psi g_0(x,t)$ with $g_0(x,t)=(g_1(x,t)+g_2(x,t))^{1/2}$, representing an inhomogeneous NLS field model with inhomogeneities introduced by the independent functions $g_a(x,t)$, $f_a(x,t)$, $a=1,2$. It may be stressed again that here the spectral parameter λ is strictly constant and when $\Lambda_1\neq\Lambda_2$, all inhomogeneous parameters apparently cannot be absorbed in this single parameter. It is challenging to derive the explicit form of this integrable variable coefficient general NLS equation, associated with the rational r-matrix (5). For showing that the Lax operator of many known inhomogeneous NLS equations can actually be derived from (35), we consider the particular situation $g_1=g_2\equiv g(x,t)$, $f_1=f_2\equiv f(x,t)$ and rewrite (35) as

$$\mathcal{L}(\lambda)=\Lambda(x,t)\sigma_3+Q^*\sigma_+-Q\sigma_-, \quad \Lambda(x,t)=\lambda g(x,t)+f(x,t). \tag{36}$$

It is remarkable that from this single operator we recover at $g=1$, $f=\alpha t$ the Lax operator of Ref. 9, at $g=1/t$, $f=4x/t$ that of Ref. 10 and similarly at $g=T(t)$, $f=(\alpha/2)xT(t)$ that of Ref. 11. Note however that the actual form of the equations depend also on the time evolution operator M, which is likely to be different in our approach from the known ones, since in our construction the

fundamental canonical PB structure is always preserved. Therefore it would be a challenging problem to derive these new integrable inhomogeneous NLS equations explicitly from their Hamiltonian using the canonical PB.

(12) *Gaudin model:* It is intriguing that just by considering the parameter l in the Lax operator (30) for the discrete LLE to be site dependent: $l \to l_k$, one recovers the Lax operator $L_k(\lambda) = I + [1/(\lambda - l_k)]\vec{s}_k \cdot \vec{\sigma}$ for the celebrated Gaudin model, given by the integrable Hamiltonians $H_k = \sum_{l \neq k}^{N} [1/(l_k - l_l)](\vec{s}_k \cdot \vec{s}_l)$, $k = 1,2,\ldots,N$.[28] This model is associated also with the rational r_r matrix (5).

(13) *Inhomogeneous relativistic and nonrelativistic Toda chains:* It is not difficult to see that by repeating the construction of the Toda chains but taking the parameters to be nonconstants we get integrable inhomogeneous extensions of such models. For example, considering in ancestor Lax operator (12) the parameters to be $c_1^{\pm} = f_k^{\pm}(t)$, $c_2^{\pm} = 0$, but using the same realization as for the original relativistic Toda chain, we get an extension of its Lax operator (21) to include inhomogeneity through arbitrary functions $f_k^{\pm}(t)$:

$$L_k(\xi) = \frac{1}{2}\left(\frac{f_k^-}{\xi} e^{\alpha p_k} - f_k^+ \xi e^{-\alpha p_k} \right)(I + \sigma_3) + \alpha(e^{u_k}\sigma_+ - e^{-u_k}\sigma_-),$$

which therefore would represent a new integrable family of inhomogeneous relativistic Toda chain. We will not present here its explicit form.

At $\alpha \to 0$ this family of relativistic models would go to its nonrelativistic limit represented by the Lax operator

$$L_k(\lambda) = \begin{pmatrix} (p_k - \lambda) + g_{2k} & (c_{1k}^0)^{-1} e^{u_k} \\ -(c_{1k}^0)^{-1} e^{-u_k} & 0 \end{pmatrix}, \tag{37}$$

which is an obvious extension of (34) (by introducing the inhomogeneous parameter $g_{2k} \equiv c_{1k}^1 / c_{1k}^0$ and normalizing it by c_{1k}^0). Without defining any time evolution operator M, we can directly construct from (37) the explicit form of the Hamiltonian through the conserved quantity as $H = C_{N-1}$ and derive the Hamilton equations using the canonical PB between u_k, p_l, yielding $\dot{u}_k = p_k + g_{2k}$ and hence the inhomogeneous Toda chain equation as

$$\frac{\mathrm{d}^2}{\mathrm{dt}^2} u_k = g_1(k) e^{u(k-1) - u(k)} - g_1(k+1) e^{u(k) - u(k+1)} + \dot{g}_2(t) + \text{boundary terms} \tag{38}$$

with arbitrary parameters $g_1(k) = (c_{1k}^0 c_{1k+1}^0)^{-1}$ and $g_2(k)$. Different choices of these parameters would generate from (38) different inhomogeneous Toda chains. For example the particular choices: $g_1(k) = k$, $g_2(k) = \alpha_0 t$ and $g_1(k) = 4k^2 + 1$, $g_2(k) = kt$ derives the Toda chains found in Ref. 12, though in contrast we recover this result in a completely isospectral way.

(14) *Inhomogeneous Ablowitz–Ladik model:* It is easy to notice again that if instead of constants as in the original model, we choose the parameters through arbitrary function $\Gamma(t)$ as $c_1^- = (c_2^+)^{-1} = e^{\Gamma(t)}$, keeping the same trivial choice for $c_1^+ = c_2^- = 0$, we generate from (8) the Lax operator

$$L_k(\xi) = \begin{pmatrix} \dfrac{1}{\xi} e^{\Gamma(t)}, & b_k^* \\ b_k, & \xi e^{-\Gamma(t)} \end{pmatrix}. \tag{39}$$

Remarkably, in spite of our isospectral approach, Eq. (39) recovers exactly the Lax operator of Ref. 13 for arbitrary $\Gamma(t)$ and that of Ref. 14 for $\Gamma(t) = \alpha t$, representing known inhomogeneous Ablowitz–Ladik models.

In a similar way by generalizing the constant parameters to inhomogeneous functions one can generate systematically inhomogeneous extensions of other integrable models constructed here. Note again that all such extensions retain the integrability of the system as well as the isospectrality and the same r-matrix solution.

B. Integrable hybrid models

Our scheme for generating different integrable models from an ancestor model sharing the same r-matrix opens up a possibility of constructing new families of integrable models by *hybridizing* these descended models.

Such constructions can be of two types. The first type of hybrid models may be constructed by using different descendant Lax operators obtained directly from (8) [or alternatively from (12)] as its different but consistent reductions and realizations at different lattice sites. Since all representative Lax operators of these constituent models: $L_k^{d(k)}(\lambda)$, with $d(k)$ denoting different members of the same descendant class inserted at sites k, should share the same r-matrix, the monodromy matrix of this hybrid model: $T^{\{d\}}(\lambda)=\Pi_{d(k),k}L_k^{d(k)}(\lambda)$ must satisfy the global CYBE (6) and represent therefore an integrable system with the set of conserved quantities including the Hamiltonian obtainable as usual through expansion of $\tau^{\rm hyb}(\lambda)=\mathrm{tr}(T^{\{d\}}(\lambda))$ in the spectral parameter. One can generate in this way some exotic hybrid models by combining for example, sine-Gordon and Liouville models, different types of relativistic Toda chain or discrete NLS model, etc., constructed above. These hybrid models presumably would show different dynamics at different domains in the coordinate space. It is encouraging to note that very recently such models have received well deserved attention, though only at the continuum level.[8] We hope that the present idea, based on discrete approach and r-matrix formalism would prove to be promising and fruitful for analyzing such hybrid integrable models.

A second type of hybrid model may be constructed by considering different representation of the Lax operator for different components of the field and inserting their direct product at the same lattice site. As a result one can build new multi-component generalization of a scalar model through the *fused* Lax operator: $L_k^{\{m\}}=\Pi_m L_k^{(m)}$, where each entry in the product would represent individual components. Note that unlike the vector generalization, which needs also enlarged matrix realization for the Lax operator, our multicomponent hybrid models would yield only 2×2 matrix Lax operators. For elaborating this idea we present the detail construction of an integrable hierarchy of two-component DNLS model.

(15) *Integrable hierarchy of two-component DNLS:* Note that in constructing the discrete DNLS model in Sec. IV, the values of $M^{\pm}$ fixed by (25) actually determined the underlying algebra as well as the required realization. It is however crucial to notice now that interchanging the parameters $c_1^{\pm}\leftrightarrow c_2^{\mp}$ would not change the values of $M^{\pm}$ and therefore would lead to the same algebra and its realization, but result to a complementary form for the Lax operator, though representing the same DNLS model. In our construction of the two-component model with fields $\psi_k^{(\beta)}$, $\beta=1,2$ having PB relations $\{\psi_k^{(\beta)},\psi_l^{*(\gamma)}\}=i\delta_{\beta\gamma}\delta_{kl}$, we take $c_a^{\pm}$, $a=1,2$ as in (25) for building the Lax operator $L_k^{(1)}(\psi^{(1)})$ as (27) for the first component. However, for the corresponding construction of $\tilde{L}_k^{(2)}(\psi^{(2)})$ related to the second component we take the complementary choice by considering $c_1^{\pm}\leftrightarrow c_2^{\mp}$. The fused Lax operator taking the form $L_k^{(1,2)}(\psi^{(\beta)})=L_k^{(1)}(\psi^{(1)})\tilde{L}_k^{(2)}(\psi^{(2)})$ represents now a new discrete multicomponent DNLS satisfying the CYBE (2) with the same r-matrix (4). At the continuum limit $\Delta\to 0$, repeating the construction for the scalar DNLS model (28), it is easy to see that the field Lax operator of this two-component model is given simply as a linear superposition $\mathcal{L}(\psi^{(1)},\psi^{(2)})=\mathcal{L}(\psi^{(1)})+\tilde{\mathcal{L}}(\psi^{(2)})$ with the explicit form

$$\mathcal{L}(\psi^{(1)},\psi^{(2)})=\left(\frac{1}{4}\left(\frac{1}{\xi^2}-\xi^2\right)+|\psi|_1^2-|\psi|_2^2\right)\sigma_3+\left(\xi\psi_1^*+\frac{1}{\xi}\psi_2^*\right)\sigma^+ +\left(\xi\psi_1+\frac{1}{\xi}\psi_2\right)\sigma^-,\quad \xi=e^{i\lambda}. \tag{40}$$

It is interesting to show by direct construction that this Lax operator generates an integrable hierarchy of multicomponent DNLS model through the expansion $\ln \tau(\lambda)=\Sigma_{n=0}^{\infty} C_{\pm n}\lambda^{\mp 2n}$ with $H_2=C_2+C_{-2}$ introducing a new two-component generalization of the Chen–Lee–Liu DNLS equation. We are not giving here its explicit form, which can be worked out with little patience. The higher conserved quantities will yield higher order equations. Some similar class of discrete matrix and multicomponent DNLS models was proposed recently.[29]

(16) *Massive Thirring model:* It is remarkable that (40) constructed through a novel hybridization from our ancestor model coincides also with the Lax operator of the bosonic massive Thirring model.[30] Hamiltonian of this relativistic model may be given through the same conserved quantities constructed for the above model in the form $H_1=C_1+C_{-1}$.

(17) *Integrable discrete self-trapping model:* A discrete self-trapping model with two-bosonic modes $\psi^{(a)},\psi^{*(a)},a=1,2$ given by the Hamiltonian

$$H=-\left[\frac{1}{2}\sum_{a}^{2}\ (s_a-N^{(a)})^2+(\psi^{*(1)}\psi^{(2)}+\psi^{*(2)}\psi^{(1)})\right]$$

was studied in Ref. 31. This integrable model is associated with a Lax operator, which may be constructed by fusing two operators as $L(\lambda)=L^{(1)}(\lambda)L^{(2)}(\lambda)$, where $L^{(a)}(\lambda)$ are given by the same Lax operator (33) for each of the modes $a=1,2$.

An interesting line of investigation would be to apply this hybridization method for constructing possible multicomponent extensions of other models like relativistic Toda chain, Ablowitz–Ladik, Liouville model, LLE, Gaudin model, etc. The linear superposition of Lax operators for building new nonlinear integrable systems, as revealed here, seems to be a promising idea worth pursuing.

VI. UNIVERSAL PROPERTIES OF INTEGRABLE DESCENDANT MODELS

We have seen that diverse forms of integrable models: discrete and continuum, homogeneous and inhomogeneous, multicomponent and hybrid models can be generated in a systematic way in our ancestor model scheme. Among this diversity however we find also an unexpected universality. Indeed, as we have found, a wide range of models, namely sine-Gordon, Liouville, DNLS, relativistic Toda chain, etc., including their discrete, inhomogeneous and hybrid variants belong to the trigonometric class, while models like NLS, Toda chain, etc., and their related discrete and inhomogeneous extensions are in the same rational class, which being in fact the undeformed $q\rightarrow 1$ or the nonrelativistic limit of the former class.

The crucial observation is that the diversity of all descendant models belonging to the same class seems to disappear at the global level allowing their description through a universal action-angle variable. The reason for this is very simple. Though these models differ widely at their local level having different forms of the Lax operator, their monodromy matrix $T_N(\lambda)$ (7) satisfies the same global relation (6) with the same r-matrix, which is inherited from their ancestor model and shared by all of them.

As a result, for all models belonging, for example, to the trigonometric class, the PB relations should be given by the same structure constants expressed through the elements of the r_t-matrix (4). For the twisted models, e.g., Suris RTC and Ablowitz–Ladik model the structure constants should similarly be given by the twisted r_Ω-matrix (22). In the same way all models from the rational class should have analogous property expressed through the elements of rational r_r-matrix (5). However, while the action variables are constants in time, the time evolution of angle variables depends on the definition of the Hamiltonians through conserved quantities, which usually differs for different models.

Such differences also bear some additional imprint at the continuum limit, when the monodromy matrix is defined as $T(\lambda)=\lim_{N\rightarrow\infty} L_{\infty}^{-N}(\lambda)T_N(\lambda)L_{\infty}^{-N}(\lambda)$ and the corresponding CYBE is modified as[5] $\{T(\lambda)\otimes,T(\mu)\}=r_+(\lambda-\mu)T(\lambda)\otimes T(\mu)-T(\lambda)\otimes T(\mu)r_-(\lambda-\mu)$, where $r_{\pm}(\lambda-\mu)=\lim_{N\rightarrow\infty} L_{\infty}^{\mp N}(\lambda)\otimes L_{\infty}^{\mp N}(\mu)r(\lambda-\mu)L_{\infty}^{\pm N}(\lambda)\otimes L_{\infty}^{\pm N}(\mu)$. Therefore though the action-angle

description for such models of the same class are again basically the same, the influence of the individual models also enters now due to the appearance of $r_{\pm}$ modified by the asymptotic forms $L_{\infty}(\lambda)$ of the individual Lax operators. Nevertheless it is startling to check that the canonical action-angle variables for widely different field models like DNLS[24] and the sine-Gordon[1] are defined exactly in the same way: $p(\xi)=(1/2\pi c\xi)\ln|a(\xi)|$, $q(\xi)=\arg b(\xi)$ for the continuum modes with PB $\{q(\xi),p(\eta)\}=\delta(\xi-\eta)$, $\xi>0$ and $p_k=(1/2c)\ln\xi_k$, $q_k=\ln b_k$ for the discrete set with $\{q_k,p_l\}=\delta_{kl}$ and similarly for their conjugates $\overline{q_k},\overline{p_l}$.

Therefore we may conclude that all integrable models presented here may be described universally through the ancestor Lax operator (8) and the r_t-matrix (4) (or twisted r_{Ω}) or similarly by the $q\to 1$ limit as the ancestor model (12) and the r_r-matrix (5), where the global relations like action-angle variables are determined by the r-matrix elements alone. The individuality of the models may be reflected only in the definition of their Hamiltonians through conserved quantities and for continuum models, additionally in the limiting forms of their Lax operators.

VII. CONCLUDING REMARKS

We have presented here a unifying scheme based on PB algebra for systematically generating a large class of integrable discrete and continuum models from a single ancestor model. Such models include well known and new integrable systems as well as inhomogeneous models. Based on our construction we conclude that more general and logical approach for inhomogeneous integrable models, at least for models with nondynamical r-matrix, would be to describe them as isospectral flow in inhomogeneous external fields. As another fruitful application of the present scheme we have proposed a simple method for constructing new families of integrable hybrid models by *fusing* different types of descendant models. In spite of the vastly diverse form of these models their common ancestor and common r-matrix reveal an inherent universality in their description through action-angle variables.

We strongly hope that the algebraic approach linked with the quantum group structure formulated here for generating classical integrable discrete as well as field models, though a bit uncommon in the community working in classical integrability, would prove to be much powerful due to its systematic and algorithmic nature. Similarly the novel ideas of construction introduced here, like generating integrable hybrid and multicomponent models and creating integrable inhomogeneity in isospectral flow, are expected to be equally promising.

General soliton matrices in the Riemann–Hilbert problem for integrable nonlinear equations

Valery S. Shchesnovich[a] and Jianke Yang[b]
Department of Mathematics and Statistics, University of Vermont, Burlington, Vermont 05401

(Received 25 May 2003; accepted 5 June 2003)

We derive the soliton matrices corresponding to an arbitrary number of higher-order normal zeros for the matrix Riemann–Hilbert problem of arbitrary matrix dimension, thus giving the complete solution to the problem of higher-order solitons. Our soliton matrices explicitly give all higher-order multisoliton solutions to the nonlinear partial differential equations integrable through the matrix Riemann–Hilbert problem. We have applied these general results to the three-wave interaction system, and derived new classes of higher-order soliton and two-soliton solutions, in complement to those from our previous publication [Stud. Appl. Math. **110**, 297 (2003)], where only the elementary higher-order zeros were considered. The higher-order solitons corresponding to nonelementary zeros generically describe the simultaneous breakup of a pumping wave (u_3) into the other two components (u_1 and u_2) and merger of u_1 and u_2 waves into the pumping u_3 wave. The two-soliton solutions corresponding to two simple zeros generically describe the breakup of the pumping u_3 wave into the u_1 and u_2 components, and the reverse process. In the nongeneric cases, these two-soliton solutions could describe the elastic interaction of the u_1 and u_2 waves, thus reproducing previous results obtained by Zakharov and Manakov [Zh. Éksp. Teor. Fiz. **69**, 1654 (1975)] and Kaup [Stud. Appl. Math. **55**, 9 (1976)].

I. INTRODUCTION

The importance of integrable nonlinear partial differential equations (PDEs) in $1+1$ dimensions in applications to nonlinear physics can hardly be overestimated. Their importance partially stems from the fact that it is always possible to obtain certain explicit solutions, called solitons, by some algebraic procedure. At present, there is a wide range of literature concerning integrable nonlinear PDEs and their soliton solutions (see, for instance, Refs. 1–4 and the references therein). The reader familiar with the inverse scattering transform method knows that it is zeros of the Riemann–Hilbert problem (or poles of the reflection coefficients in the previous nomenclature) that give rise to the soliton solutions. These solutions are usually derived by using one of the several well-known techniques, such as the dressing method,[1,5,6] the Riemann–Hilbert problem approach,[2,3] and the Hirota method (see Ref. 1). In the first two methods, the pure soliton solution is obtained by considering the asymptotic form of a rational matrix function of the spectral parameter, called the soliton matrix in the following. It is known that the generic case of zeros of the matrix Riemann–Hilbert problem is the case of simple zeros[7–12] (see also Ref. 13). A single simple zero produces a one-soliton solution. Several distinct zeros will produce multisoliton solutions, which describe the interaction (scattering) of individual solitons. As far as the generic case is concerned, there is no problem in the derivation of the corresponding soliton solutions.

However, in the nongeneric cases, when at least one higher-order (i.e., multiple) zero is

[a]Also at: Instituto de Fisica Teórica, Universidade Estadual Paulista, Rua Pamplona 145, 01405-900 São Paulo, Brazil; electronic mail: valery@ift.unesp.br
[b]Electronic mail: jyang@emba.uvm.edu

present in the Riemann–Hilbert problem, the situation is not so definite. Higher-order zeros must be considered separately, as, in general, the soliton solutions which correspond to such zeros cannot be derived from the known generic multisoliton solutions by coalescing some of the distinct simple zeros. This is clear from the fact that a higher-order zero generally corresponds to a higher-order pole in the soliton matrix (or its inverse), which cannot be obtained in a regular way by coalescing simple poles in the generic multisoliton matrix. The procedure of coalescing several distinct simple zeros produces only higher-order zeros with equal algebraic and geometric multiplicities (the geometric multiplicity is defined as the dimension of the kernel of the soliton matrix evaluated at the zero), which is just the trivial case of higher-order zeros. For instance, if the algebraic multiplicity is equal to or greater than the matrix dimension, then such coalescing will produce a higher-order zero with the geometric multiplicity no less than the matrix dimension, which could only correspond to the zero solution instead of solitons. Thus the soliton matrices corresponding to higher-order zeros of the Riemann–Hilbert problem require a separate consideration.

Soliton solutions corresponding to higher-order zeros have been investigated in the literature before, mainly for the 2×2-dimensional spectral problem. A soliton solution to the nonlinear Schrödinger (NLS) equation corresponding to a double zero was first given in Ref. 14 but without much analysis. The double- and triple-zero soliton solutions to the KdV equation were examined in Ref. 15 and the general multiple-zero soliton solution to the sine-Gordon equation was extensively studied in Ref. 16 using the associated Gelfand–Levitan–Marchenko equation. In Refs. 17 and 18, higher-order soliton solutions to the NLS equation were studied by employing the dressing method. In Refs. 19–21, higher order solitons in the Kadomtsev–Petviashvili I equation were derived by the direct method and the inverse scattering method. Finally, in our previous publication[22] we have derived soliton matrices corresponding to a single *elementary* higher-order zero—a zero which has the geometric multiplicity equal to 1. Our studies give the general higher-order soliton solutions for the integrable PDEs associated with the 2×2 matrix Riemann–Hilbert problem with a single higher-order zero. Indeed, any zero of the 2×2-dimensional Riemann–Hilbert problem is elementary since a nonzero 2×2 matrix can have only one vector in its kernel.

However, the previous investigations left some of the key questions unanswered. For instance, the general soliton matrix corresponding to a single nonelementary zero remained unknown. Such zeros arise when the matrix dimension of the Riemann–Hilbert problem is greater than 2. Naturally then, the ultimate question—the most general soliton matrices corresponding to an arbitrary number of higher-order zeros in the general $N\times N$ Riemann–Hilbert problem, was not addressed. Because of these unresolved issues, the most general soliton and multisoliton solutions to PDEs integrable through the $N\times N$ Riemann–Hilbert problem (such as the NLS equation,[23] the three-wave interaction system,[2,24–27] and the Manakov equations[28]) have not been derived yet.

In this paper we derive the complete solution to the problem of soliton matrices corresponding to an arbitrary number of higher-order normal zeros for the general $N\times N$ matrix Riemann–Hilbert problem. These normal zeros are defined in Definition 1, and are nonelementary in general. They include almost all physically important integrable PDEs where the involution property [see Eq. (4)] holds. The corresponding soliton solutions can be termed as the higher-order multisolitons, to reflect the fact that these solutions do not belong to the class of the previous generic multisoliton solutions. Our results give a complete classification of all possible soliton solutions in the integrable PDEs associated with the $N\times N$ Riemann–Hilbert problem. In other words, our soliton matrices contain the most general forms of reflection-less (soliton) potentials in the N-dimensional Zakharov–Shabat spectral operator. For these general soliton potentials, the corresponding discrete and continuous eigenfunctions of the N-dimensional Zakharov–Shabat operator naturally follow from our soliton matrices. As an example, we consider the three-wave interaction system, and derive single-soliton solutions corresponding to a nonelementary zero, and higher-order two-soliton solutions. These solutions generate many new processes such as the simultaneous breakup of a pumping wave (u_3) into the other two components (u_1 and u_2) and merger of u_1 and u_2 waves into the pumping u_3 wave, i.e., $u_1+u_2+u_3\leftrightarrow u_1+u_2+u_3$. They also reproduce previous solitons in Refs. 2, 22, 26, 27 as special cases.

The paper is organized as follows. A summary on the Riemann–Hilbert problem is placed in Sec. II. Section III is the central section of the paper. There we present the theory of soliton matrices corresponding to several higher-order zeros under the assumption that these zeros are *normal* (see Definition 1), which include the physically important cases with the involution property [see Eq. (4)]. Applications of these general results to the three-wave interaction system are contained in Sec. IV. Finally, in the Appendix we briefly treat the more general case where the zeros are abnormal.

II. THE RIEMANN–HILBERT PROBLEM APPROACH

The integrable nonlinear PDEs in $1+1$ dimensions are associated with the matrix Riemann–Hilbert problem (consult, for instance, Refs. 1–12, 29–32). The matrix Riemann–Hilbert problem (below we work in the space of $N\times N$ matrices) is the problem of finding the holomorphic factorization, denoted below by $\Phi_+(k)$ and $\Phi_-^{-1}(k)$, in the complex plane of a nondegenerate matrix function $G(k)$ given on an oriented curve γ:

$$\Phi_-^{-1}(k,x,t)\Phi_+(k,x,t)=G(k,x,t)\equiv E(k,x,t)G(k,0,0)E^{-1}(k,x,t), \quad k\in\gamma, \tag{1}$$

where

$$E(k,x,t)\equiv\exp[-\Lambda(k)x-\Omega(k)t].$$

Here the matrix functions $\Phi_+(k)$ and $\Phi_-^{-1}(k)$ are holomorphic in the two complementary domains of the complex k-plane: C_+ to the left and C_- to the right from the curve γ, respectively. The matrices $\Lambda(k)$ and $\Omega(k)$ are called the dispersion laws. Usually the dispersion laws commute with each other, e.g., given by diagonal matrices. We will consider this case [precisely in this case $E(k,x,t)$ is given by the above formula]. The Riemann–Hilbert problem requires an appropriate normalization condition. Usually the curve γ contains the infinite point $k=\infty$ of the complex plane and the normalization condition is formulated as

$$\Phi_\pm(k,x,t)\to I \quad \text{as} \quad k\to\infty. \tag{2}$$

This normalization condition is called the canonical normalization. Setting the normalization condition to an arbitrary nondegenerate matrix function $S(x,t)$ leads to the gauge equivalent integrable nonlinear PDE, e.g., the Landau–Lifshitz equation in the case of the NLS equation.[3] Obviously, the new solution $\hat{\Phi}_\pm(k,x,t)$ to the Riemann–Hilbert problem, normalized to $S(x,t)$, is related to the canonical solution by the following transformation

$$\hat{\Phi}_\pm(k,x,t)=S(x,t)\Phi(k,x,t). \tag{3}$$

Thus, without any loss of generality, we confine ourselves to the Riemann–Hilbert problem under the canonical normalization.

For physically applicable nonlinear PDEs the Riemann–Hilbert problem possesses the involution properties, which reduce the number of the dependent variables (complex fields). The following involution property of the Riemann–Hilbert problem is the most common in applications

$$\Phi_+^\dagger(k)=\Phi_-^{-1}(\overline{k}), \quad \overline{k}=k^*. \tag{4}$$

Here the superscript "†" represents the Hermitian conjugate, and "*" the complex conjugate. Examples include the NLS equation, the Manakov equations, and the N-wave system. The analysis in this article includes this involution (4) as a special case. In this case, the overline of a quantity represents its Hermitian conjugation in the case of vectors and matrices and the complex conjugation in the case of scalar quantities. In other cases, the original and overlined quantities may not be related.

To solve the Cauchy problem for the integrable nonlinear PDE posed on the whole axis x, one usually constructs the associated Riemann–Hilbert problem starting with the linear spectral equation

$$\partial_x \Phi(k,x,t) = \Phi(k,x,t)\Lambda(k) + U(k,x,t)\Phi(k,x,t), \tag{5}$$

whereas the t-dependence is given by a similar equation

$$\partial_t \Phi(k,x,t) = \Phi(k,x,t)\Omega(k) + V(k,x,t)\Phi(k,x,t). \tag{6}$$

The nonlinear integrable PDE corresponds to the compatibility condition of the system (5) and (6):

$$\partial_t U - \partial_x V + [U,V] = 0. \tag{7}$$

The essence of the approach based on the Riemann–Hilbert problem lies in the fact that the evolution governed by the complicated nonlinear PDE (7) is mapped to the evolution of the spectral data given by simpler equations such as (1) and (20a)–(20b). When the spectral data is known, the matrices $U(k,x,t)$ and $V(k,x,t)$ describing the evolution of $\Phi_{\pm}$ can then be retrieved from the Riemann–Hilbert problem. In our case, the potentials $U(k,x,t)$ and $V(k,x,t)$ are completely determined by the (diagonal) dispersion laws $\Lambda(k)$ and $\Omega(k)$ and the Riemann–Hilbert solution $\Phi \equiv \Phi_{\pm}(k,x,t)$. Indeed, let us assume that the dispersion laws are polynomial functions, i.e.,

$$\Lambda(k) = \sum_{j=0}^{J_1} A_j k^j, \quad \Omega(k) = \sum_{j=0}^{J_2} B_j k^j. \tag{8}$$

Then using similar arguments as in Ref. 32 we get

$$U = -\mathcal{P}\{\Phi \Lambda \Phi^{-1}\}, \quad V = -\mathcal{P}\{\Phi \Omega \Phi^{-1}\}. \tag{9}$$

Here the matrix function $\Phi(k)$ is expanded into the asymptotic series,

$$\Phi(k) = I + k^{-1}\Phi^{(1)} + k^{-2}\Phi^{(2)} + \cdots, \quad k \to \infty,$$

and the operator $\mathcal{P}$ cuts out the polynomial asymptotics of its argument as $k \to \infty$. An important property of matrices U and V is that

$$\begin{aligned} \operatorname{Tr} U(k,x,t) &= -\operatorname{Tr} \Lambda(k), \\ \operatorname{Tr} V(k,x,t) &= -\operatorname{Tr} \Omega(k), \end{aligned} \tag{10}$$

which evidently follows from Eq. (9). This property guarantees that the Riemann–Hilbert zeros are (x,t) independent.

Let us consider as an example the physically relevant three-wave interaction system.[2,24,25,27] Set $N=3$,

$$\Lambda(k) = ikA, \quad A = \begin{pmatrix} a_1 & 0 & 0 \\ 0 & a_2 & 0 \\ 0 & 0 & a_3 \end{pmatrix}, \quad \Omega(k) = ikB, \quad B = \begin{pmatrix} b_1 & 0 & 0 \\ 0 & b_2 & 0 \\ 0 & 0 & b_3 \end{pmatrix}, \tag{11}$$

where a_j and b_j are real with the elements of A being ordered: $a_1 > a_2 > a_3$. From Eq. (9) we get

$$U = -\Lambda(k) + i[A, \Phi^{(1)}], \quad V = -\Omega(k) + i[B, \Phi^{(1)}]. \tag{12}$$

Setting

$$u_1=\sqrt{a_1-a_2}\Phi_{12}^{(1)},\quad u_2=\sqrt{a_2-a_3}\Phi_{23}^{(1)},\quad u_3=\sqrt{a_1-a_3}\Phi_{13}^{(1)}, \tag{13}$$

assuming the involution (4), and using Eq. (12) in (7) we get the three-wave system:

$$\partial_t u_1+v_1\partial_x u_1+i\varepsilon\overline{u}_2 u_3=0, \tag{14a}$$

$$\partial_t u_2+v_2\partial_x u_2+i\varepsilon\overline{u}_1 u_3=0, \tag{14b}$$

$$\partial_t u_3+v_3\partial_x u_3+i\varepsilon u_1 u_2=0. \tag{14c}$$

Here

$$v_1=\frac{b_2-b_1}{a_1-a_2},\quad v_2=\frac{b_3-b_2}{a_2-a_3},\quad v_3=\frac{b_3-b_1}{a_1-a_3}, \tag{15}$$

$$\varepsilon=\frac{a_1b_2-a_2b_1+a_2b_3-a_3b_2+a_3b_1-a_1b_3}{[(a_1-a_2)(a_2-a_3)(a_1-a_3)]^{1/2}}. \tag{16}$$

The group velocities satisfy the following condition:

$$\frac{v_2-v_3}{v_1-v_3}=-\frac{a_1-a_2}{a_2-a_3}<0. \tag{17}$$

The three-wave system (14) can be interpreted physically. It describes the interaction of three wave packets with complex envelopes u_1, u_2, and u_3 in a medium with quadratic nonlinearity.

In general, the Riemann–Hilbert problem (1)–(2) has multiple solutions. Different solutions are related to each other by the rational matrix functions $\Gamma(k)$ (which also depend on the variables x and t):[2–6,13]

$$\tilde{\Phi}_{\pm}(k,x,t)=\Phi_{\pm}(k,x,t)\Gamma(k,x,t). \tag{18}$$

The rational matrix $\Gamma(k)$ must satisfy the canonical normalization condition: $\Gamma(k)\to I$ for $k\to\infty$ and must have poles only in C_- [the inverse function $\Gamma^{-1}(k)$ then has poles in C_+ only]. Such a rational matrix $\Gamma(k)$ will be called the soliton matrix below, since it gives the soliton part of the solution to the integrable nonlinear PDE.

To specify a unique solution to the Riemann–Hilbert problem the set of the Riemann–Hilbert data must be given. These data are also called the spectral data. The full set of the spectral data comprises the matrix $G(k,x,t)$ on the right-hand side of Eq. (1) and the appropriate discrete data related to the zeros of $\det\Phi_+(k)$ and $\det\Phi_-^{-1}(k)$. In the case of involution (4), the zeros of $\det\Phi_+(k)$ and $\det\Phi_-^{-1}(k)$ appear in complex conjugate pairs, $\overline{k_j}=k_j^*$. It is known[7–12] (see also Ref. 13) that in the generic case the spectral data include simple (distinct) zeros $k_1,\ldots,k_n$ of $\det\Phi_+(k)$ and $\overline{k_1},\ldots,\overline{k_n}$ of $\det\Phi_-^{-1}(k)$, in their holomorphicity domains, and the null vectors $|v_1\rangle,\ldots,|v_n\rangle$ and $\langle\overline{v_1}|,\ldots,\langle\overline{v_n}|$ from the respective kernels:

$$\Phi_+(k_j)|v_j\rangle=0,\quad \langle\overline{v_j}|\Phi_-^{-1}(\overline{k_j})=0. \tag{19}$$

Using the property (10) one can verify that the zeros do not depend on the variables x and t. The (x,t) dependence of the null vectors can be easily derived by differentiation of (19) and use of the linear spectral equations (5) and (6). This dependence reads

$$|v_j\rangle = \exp\{-\Lambda(k_j)x - \Omega(k_j)t\}|v_{0j}\rangle, \tag{20a}$$

$$\langle\overline{v_j}| = \langle\overline{v}_{0j}|\exp\{\Lambda(\overline{k_j})x + \Omega(\overline{k_j})t\}, \tag{20b}$$

where $|v_{0j}\rangle$ and $\langle\overline{v}_{0j}|$ are constant vectors.

The vectors in Eqs. (20a) and (20b) together with the zeros constitute the full set of the generic discrete data necessary to specify the soliton matrix $\Gamma(k,x,t)$ and, hence, unique solution to the Riemann–Hilbert problem (1)–(2). Indeed, by constructing the soliton matrix $\Gamma(k)$ such that the following matrix functions:

$$\phi_+(k) = \Phi_+(k)\Gamma^{-1}(k), \quad \phi_-^{-1}(k) = \Gamma(k)\Phi_-^{-1}(k) \tag{21}$$

are nondegenerate and holomorphic in the domains C_+ and C_-, respectively, we reduce the Riemann–Hilbert problem with zeros to another one without zeros and hence uniquely solvable (for details see, for instance, Refs. 2–4, 13). Below by matrix $\Gamma(k)$ we will imply the matrix from equation (21) which reduces the Riemann–Hilbert problem (1)–(2) to the one without zeros. The corresponding solution to the integrable PDE (7) is obtained by using the asymptotic expansion of the matrix $\Phi(k)$ as $k\to\infty$ in the linear equation (5). In the N-wave interaction model it is given by formula (12). The pure soliton solutions are obtained by using the rational matrix $\Phi = \Gamma(k)$.

The above set of discrete spectral data (19) holds only for the generic case where zeros of $\det\Phi_+(k)$ and $\det\Phi_-^{-1}(k)$ are simple. If these zeros are higher-order rather than simple, what the discrete spectral data should be and how they evolve with x and t is unknown *a priori*. Moreover, we have stressed in Sec. I that the case of higher-order zeros cannot be treated by coalescing simple zeros, thus is highly nontrivial. In the next sections, we give the complete solution to this problem.

III. SOLITON MATRICES FOR GENERAL HIGHER-ORDER ZEROS

In this section we derive the soliton matrices for an arbitrary matrix dimension N and an arbitrary number of higher-order zeros under the assumption that these zeros are normal (see Definition 1). Normal higher-order zeros are most common in practice. In general, they are non-elementary. Our approach is based on a generalization of the idea in our previous paper.[22]

A. Product representation of soliton matrices

Our starting point to tackle this problem is to derive a product representation for soliton matrices. This product representation is not convenient for obtaining soliton solutions, but it will lead to the summation representation of soliton matrices, which is very useful.

In treating the soliton matrix as a product of constituent matrices [called elementary matrices in Ref. 2, see formulas (24) and (27) below] one can consider each zero of the Riemann–Hilbert problem separately. For instance, consider a pair of zeros k_1 and $\overline{k_1}$, respectively, of $\Phi_+(k)$ and $\Phi_-^{-1}(k)$ from Eq. (1), each having order m:

$$\det\Phi_+(k) = (k-k_1)^m\varphi(k), \quad \det\Phi_-^{-1}(k) = (k-\overline{k_1})^m\overline{\varphi}(k), \tag{22}$$

where $\varphi(k_1)\neq 0$ and $\overline{\varphi}(\overline{k_1})\neq 0$. The geometric multiplicity of k_1 $(\overline{k_1})$ is defined as the number of independent vectors in the kernel of $\Phi_+(k_1)$ $(\Phi_-^{-1}(\overline{k_1}))$, see (19). In other words, the geometric multiplicity of k_1 $(\overline{k_1})$ is the dimension of the kernel space of $\Phi_+(k_1)$ $(\Phi_-^{-1}(\overline{k_1}))$. It can be easily shown that the order of a zero is always greater or equal to its geometric multiplicity. It is also obvious that the geometric multiplicity of a zero is less than the matrix dimension. Let us recall how the soliton matrices are usually constructed (see, for instance, Refs. 2 and 13). Starting from the solution $\Phi_\pm(k)$ to the Riemann–Hilbert problem (1)–(2), one looks for the independent vectors in the kernels of the matrices $\Phi_+(k_1)$ and $\Phi_-^{-1}(\overline{k_1})$. Assuming that the geometric multiplicities of k_1 and $\overline{k_1}$ are the same and equal to r_1, then we have

$$\Phi_+(k_1)|v_{i1}\rangle=0, \quad \langle\overline{v}_{i1}|\Phi_-^{-1}(\overline{k}_1)=0, \quad i=1,\ldots,r_1. \tag{23}$$

Next, one constructs the constituent matrix

$$\chi_1(k)=I-\frac{k_1-\overline{k}_1}{k-\overline{k}_1}P_1, \tag{24}$$

where

$$P_1=\sum_{i,j}^{r_1}|v_{i1}\rangle(K^{-1})_{ij}\langle\overline{v}_{j1}|, \quad K_{ij}=\langle\overline{v}_{i1}|v_{j1}\rangle. \tag{25}$$

Here P_1 is a projector matrix, i.e., $P_1^2=P_1$. It can be shown that $\det\chi_1=(k-k_1)^{r_1}/(k-\overline{k}_1)^{r_1}$ (note that the geometric multiplicity r_1 is equal to $\operatorname{rank}P_1$). If $r_1<m$ then one considers the new matrix functions

$$\tilde{\Phi}_+(k)=\Phi_+(k)\chi_1^{-1}(k), \quad \tilde{\Phi}_-^{-1}(k)=\chi_1(k)\Phi_-^{-1}(k).$$

By virtue of Eqs. (23), the matrices $\tilde{\Phi}_+(k)$ and $\tilde{\Phi}_-^{-1}(k)$ are also holomorphic in the respective half planes of the complex plane (see Lemma 1 in Ref. 22). In addition, k_1 and $\overline{k}_1$ are still zeros of $\det\tilde{\Phi}_+(k)$ and $\det\tilde{\Phi}_-^{-1}(k)$. Assuming that the geometric multiplicities of zeros k_1 and $\overline{k}_1$ in new matrices $\tilde{\Phi}_+(k)$ and $\tilde{\Phi}_-^{-1}(k)$ are still the same and equal to r_2, then the above steps can be repeated, and we can define matrix $\chi_2(k)$ analogous to Eq. (24). In general, if the geometric multiplicities of zeros k_1 and $\overline{k}_1$ in matrices

$$\tilde{\Phi}_+(k)=\Phi_+(k)\chi_1^{-1}(k)\cdots\chi_{l-1}^{-1}(k), \quad \tilde{\Phi}_-^{-1}(k)=\chi_{l-1}(k)\cdots\chi_1(k)\Phi_-^{-1}(k) \tag{26}$$

are the same and given by r_l $(l=1,2,\ldots)$, then we can define a matrix χ_l similar to Eqs. (24) and (25) but the independent vectors $|v_{il}\rangle$ and $\langle\overline{v}_{il}|$ $(i=1,\ldots,r_l)$ are from the kernels of $\tilde{\Phi}_+(k_1)$ and $\tilde{\Phi}_-^{-1}(\overline{k}_1)$ in Eq. (26). When this process is finished, one would get the constituent matrices $\chi_1(k),\ldots,\chi_r(k)$ such that $r_1+r_2+\cdots+r_n=m$, and the product representation of the soliton matrix $\Gamma(k)$,

$$\Gamma(k)=\chi_n(k)\cdots\chi_2(k)\chi_1(k). \tag{27}$$

This product representation (27) is our starting point of this paper. In arriving at this representation, our assumptions are that the zeros k_1 and $\overline{k}_1$ have the same algebraic multiplicity [see Eq. (22)], and their geometric multiplicities in matrices $\tilde{\Phi}_+(k)$ and $\tilde{\Phi}_-^{-1}(k)$ of Eq. (26) are also the same for all l's. For convenience, we introduce the following definition.

Definition 1: A pair of zeros k_1 and $\overline{k}_1$ in the matrix Riemann–Hilbert problem is called normal if the zeros have the same algebraic multiplicity, and their geometric multiplicities in matrices $\tilde{\Phi}_+(k)$ and $\tilde{\Phi}_-^{-1}(k)$ of Eq. (26) are also the same for all l's.

In the text of this paper, we only consider normal zeros of the matrix Riemann–Hilbert problem. The case of abnormal zeros will be briefly discussed in the Appendix.

Remark 1: Under the involution property (4), all zeros are normal. Thus, our results for normal zeros cover almost all the physically important integrable PDEs.

Remark 2: Normal zeros include the elementary zeros of Ref. 22 as special cases, but they are nonelementary in general.

It is an important fact (see Ref. 22, Lemma 2) that the sequence of ranks of the projectors P_l in the matrix $\Gamma(k)$ given by Eq. (27), i.e., built in the described way, is nonincreasing:

$$\text{rank}\, P_n \leqslant \text{rank}\, P_{r-1} \leqslant \cdots \leqslant \text{rank}\, P_1, \tag{28}$$

i.e., $r_n \leqslant r_{n-1} \leqslant \cdots \leqslant r_1$. This result allows one to classify all possible occurrences of a higher-order zero of the Riemann–Hilbert problem for an arbitrary matrix dimension N. In general, for zeros of the same order, different sequences of ranks in Eq. (28) give different classes of higher-order soliton solutions. In Ref. 22 we constructed the soliton matrices for the simplest sequence of ranks, i.e., $1,\ldots,1$. Such zeros are called "elementary." If the matrix dimension $N=2$ (as for the nonlinear Schrödinger equation), then all higher-order zeros are elementary since $\text{rank}\, P_1$ is always equal to 1.

To obtain the product representation for soliton matrices corresponding to several higher-order normal zeros one can multiply the matrices of the type (27) for each zero, i.e., $\Gamma(k) = \Gamma_1(k)\Gamma_2(k)\cdots\Gamma_{N_Z}(k)$, where N_Z is the number of distinct zeros and each $\Gamma_j(k)$ has the form given by formula (27) with n substituted by some n_j.

The product representation (27) of the soliton matrices is difficult to use for actual calculations of the soliton solutions. Indeed, though the representation (27) seems to be simple, derivation of the (x,t) dependence of the involved vectors (except for the vectors in the first projector P_1) requires solving matrix equations with (x,t)-dependent coefficients. One would like to have a more convenient representation, where all the involved vectors have explicit (x,t) dependence. Below we derive such a representation for soliton matrices corresponding to an arbitrary number of higher-order normal zeros.

For the sake of clarity, we consider first the case of a single pair of higher-order zeros, followed by the most general case of several distinct pairs of higher-order zeros.

B. Soliton matrices for a single pair of zeros

Definition 2: For soliton matrices having a single pair of higher-order normal zeros $(k_1,\overline{k_1})$, *suppose* $\Gamma(k)$ *is constructed judiciously as in Eq. (27), with ranks* r_j *of matrices* $P_j(1\leqslant j\leqslant n)$ *satisfying inequality (28), i.e.,*

$$r_n \leqslant r_{n-1} \leqslant \cdots \leqslant r_1.$$

Then a new sequence of positive integers

$$s_1 \geqslant s_2 \geqslant \cdots \geqslant s_{r_1}$$

is defined as follows:

$s_\nu \equiv$ *the index of the last positive integer in the array* $[r_1+1-\nu, r_2+1-\nu, \ldots, r_n+1-\nu]$. *The sequence of integers* $\{r_n, r_{n-1}, \ldots, r_1\}$ *is then the rank sequence associated with the pair of zeros* $(k_1,\overline{k_1})$ *and the new sequence* $\{s_1, s_2, \ldots, s_{r_1}\}$ *is called the block sequence associated with this pair of zeros.*

Remark: It is easy to see that the sum of the block sequence is equal to the sum of all ranks,

$$\sum_{\nu=1}^{r_1} s_\nu = \sum_{l=1}^{n} r_l,$$

with the sum being equal to the algebraic order of the Riemann–Hilbert zeros $(k_1,\overline{k_1})$.

For example, if the rank sequence is {3} [only one constituent matrix in (27)—trivial higher-order zero], then the block sequence is {1,1,1}; if the rank sequence is {1,1,1,1} (an elementary zero), then the block sequence is {4}; if the rank sequence is {2,3,5,7}, then the block sequence is {4,4,3,2,2,1,1}.

With these definitions the most general soliton matrices $\Gamma(k)$ and $\Gamma^{-1}(k)$ for a single pair of higher-order normal zeros $(k_1,\overline{k_1})$ are given as follows. This result is a generalization of our previous result[22] to nonelementary higher-order zeros.

Lemma 1: Consider a single pair of higher-order normal zeros $(k_1,\overline{k_1})$ *in the Riemann–Hilbert problem. Suppose their geometric multiplicity is* r_1, *and their block sequence is* $\{s_1,s_2,\ldots,s_{r_1}\}$. *Then the soliton matrices* $\Gamma(k)$ *and* $\Gamma^{-1}(k)$ *can be written in the following summation forms:*

$$\Gamma(k)=I+\sum_{\nu=1}^{r_1}\overline{\mathcal{S}}_\nu,\quad \Gamma^{-1}(k)=I+\sum_{\nu=1}^{r_1}\mathcal{S}_\nu. \tag{29}$$

Here $\mathcal{S}_\nu$ *and* $\overline{\mathcal{S}}_\nu$ *are the following block matrices,*

$$\overline{\mathcal{S}}_\nu=\sum_{l=1}^{s_\nu}\sum_{j=1}^{l}\frac{|\overline{q}_j^{(\nu)}\rangle\langle\overline{p}_{l+1-j}^{(\nu)}|}{(k-\overline{k}_1)^{s_\nu+1-l}}=(|\overline{q}_{s_\nu}^{(\nu)}\rangle,\ldots,|\overline{q}_1^{(\nu)}\rangle\overline{D}_\nu(k)\begin{pmatrix}\langle\overline{p}_1^{(\nu)}|\\ \vdots\\ \langle\overline{p}_{s_\nu}^{(\nu)}|\end{pmatrix}, \tag{30a}$$

$$\mathcal{S}_\nu=\sum_{l=1}^{s_\nu}\sum_{j=1}^{l}\frac{|p_{l+1-j}^{(\nu)}\rangle\langle q_j^{(\nu)}|}{(k-k_1)^{s_\nu+1-l}}=(|p_1^{(\nu)}\rangle,\ldots,|p_{s_\nu}^{(\nu)}\rangle D_\nu(k)\begin{pmatrix}\langle q_{s_\nu}^{(\nu)}|\\ \vdots\\ \langle q_1^{(\nu)}|\end{pmatrix}, \tag{30b}$$

where $D_\nu(k)$ *and* $\overline{D}_\nu(k)$ *are triangular Toeplitz matrices of the size* $s_\nu\times s_\nu$:

$$\overline{D}_\nu(k)=\begin{pmatrix}\frac{1}{(k-\overline{k}_1)} & 0 & \cdots & 0\\ \frac{1}{(k-\overline{k}_1)^2} & \frac{1}{(k-\overline{k}_1)} & \ddots & \vdots\\ \vdots & \ddots & \ddots & 0\\ \frac{1}{(k-\overline{k}_1)^{s_\nu}} & \cdots & \frac{1}{(k-\overline{k}_1)^2} & \frac{1}{(k-\overline{k}_1)}\end{pmatrix},$$

$$D_\nu(k)=\begin{pmatrix}\frac{1}{(k-k_1)} & \frac{1}{(k-k_1)^2} & \cdots & \frac{1}{(k-k_1)^{s_\nu}}\\ 0 & \ddots & \ddots & \vdots\\ \vdots & \ddots & \frac{1}{(k-k_1)} & \frac{1}{(k-k_1)^2}\\ 0 & \cdots & 0 & \frac{1}{(k-k_1)}\end{pmatrix}. \tag{31}$$

The vectors $|p_i^{(\nu)}\rangle,\langle\overline{p}_i^{(\nu)}|,\langle q_i^{(\nu)}|,|\overline{q}_i^{(\nu)}\rangle$ $(i=1,\ldots,s_\nu)$ *are independent of* k, *and in the two sets* $\{|p_1^{(1)}\rangle,\ldots,|p_1^{(r_1)}\rangle\}$ *and* $\{\langle\overline{p}_1^{(1)}|,\ldots,\langle\overline{p}_1^{(r_1)}|\}$ *the vectors are linearly independent.*

Remark 1: If $r_1=1$, the zeros k_1 and $\overline{k_1}$ are elementary.[22] In this case, the above soliton matrices reduce to those in Ref. 22.

Remark 2: The total number of all $|p\rangle$ vectors or $\langle\overline{p}|$ vectors from all ν blocks are equal to the algebraic order of the zeros k_1 and $\overline{k_1}$.

Proof: The representation (29) can be proved by induction. Consider, for instance, the formula for $\Gamma(k)$. Obviously, this formula is valid for $n=1$ in Eq. (27), where $\Gamma(k)$ contains only a single

matrix $\chi_1(k)$. Now, suppose that this formula is valid for $n>1$. We need to show that it is valid for $n+1$ as well. Indeed, denote the soliton matrices for n and $n+1$ by $\Gamma(k)$, and $\tilde{\Gamma}(k)$, respectively, the rightmost multiplier in $\tilde{\Gamma}(k)$ being $\tilde{\chi}(k)$. Then we have

$$\tilde{\Gamma}(k)=\Gamma(k)\tilde{\chi}(k)=\left(I+\frac{A_1}{k-\overline{k_1}}+\frac{A_2}{(k-\overline{k_1})^2}+\cdots+\frac{A_n}{(k-\overline{k_1})^n}\right)\left(I+\frac{R}{k-\overline{k_1}}\right)$$

$$=I+\frac{\tilde{A}_1}{k-\overline{k_1}}+\frac{\tilde{A}_2}{(k-\overline{k_1})^2}+\cdots+\frac{\tilde{A}_{n+1}}{(k-\overline{k_1})^{n+1}}, \tag{32}$$

where

$$R\equiv(\overline{k_1}-k_1)\tilde{P}=\sum_{l=1}^{\tilde{r}}|u_l\rangle\langle\overline{u_l}|. \tag{33}$$

Here we have normalized the vectors $|u_l\rangle$ and $\langle\overline{u_l}|$ such that

$$\langle\overline{u_l}|u_i\rangle=(\overline{k_1}-k_1)\,\delta_{l,i}\,, \tag{34}$$

and $\tilde{r}=\operatorname{rank}R$. In view of Eq. (28), we know that $\tilde{r}\geqslant r_1$, where r_1 is the geometric multiplicity of k_1 and $\overline{k_1}$ in the soliton matrices $\Gamma(k)$ and $\Gamma^{-1}(k)$. The coefficients at the poles in $\tilde{\Gamma}(k)$ are given by

$$\tilde{A}_1=A_1+R,\quad \tilde{A}_j=A_j+A_{j-1}R,\quad j=2,\ldots,n,\quad \tilde{A}_{n+1}=A_nR. \tag{35}$$

Consider first the coefficients $\tilde{A}_2$ to $\tilde{A}_{n+1}$. The explicit form of the coefficients A_j can be obtained from Eqs. (29), (30), and (32) as

$$A_j\equiv\sum_{\nu=1}^{r_1}A_j^{(\nu)}=\sum_{\nu=1}^{r_1}\sum_{l=1}^{s_\nu+1-j}|\overline{q}_l^{(\nu)}\rangle\langle\overline{p}_{s_\nu+2-j-l}^{(\nu)}|, \tag{36}$$

where the inner sum is zero if $s_\nu+1-j\leqslant 0$. Substituting this expression into (35) and defining the following new vectors in each block:

$$\langle\tilde{\overline{p}}_1^{(\nu)}|=\langle\overline{p}_1^{(\nu)}|R,\quad \langle\tilde{\overline{p}}_j^{(\nu)}|=\langle\overline{p}_j^{(\nu)}|R+\langle\overline{p}_{j-1}^{(\nu)}|,\quad j=2,\ldots,s_\nu, \tag{37}$$

[for blocks of size 1, $s_\nu=1$, the second formula in (37) is dropped], we then put the coefficients $\tilde{A}_2,\ldots,\tilde{A}_{n+1}$ into the required form

$$\tilde{A}_j=\sum_{\nu=1}^{r_1}\sum_{l=1}^{\tilde{s}_\nu+1-j}|\tilde{\overline{q}}_l^{(\nu)}\rangle\langle\tilde{\overline{p}}_{\tilde{s}_\nu+2-j-l}^{(\nu)}|,\quad j=2,\ldots,n+1,$$

where

$$|\tilde{\overline{q}}_l^{(\nu)}\rangle\equiv|\overline{q}_l^{(\nu)}\rangle,\quad l=1,\ldots,\tilde{s}_\nu-1,$$

and $\tilde{s}_\nu=s_\nu+1$, i.e., the size of each ν-block grows by one as we multiply by $\tilde{\chi}(k)$ in formula (32).

Next, we consider the coefficient $\tilde{A}_1$. Defining the vector $\langle\tilde{\overline{p}}_{\tilde{s}_\nu}^{(\nu)}|\equiv\langle\overline{p}_{s_\nu}^{(\nu)}|$ and utilizing the definition (37), we can rewrite $A_1^{(\nu)}$ as

$$A_1^{(\nu)}=\sum_{l=1}^{\tilde{s}_\nu-1}|\overline{q}_l^{(\nu)}\rangle\langle\tilde{\bar{p}}^{(\nu)}_{\tilde{s}_\nu+1-l}|-\sum_{l=2}^{s_\nu}|\overline{q}_l^{(\nu)}\rangle\langle\overline{p}^{(\nu)}_{s_\nu+2-l}|R. \tag{38}$$

To set $\tilde{A}_1=A_1+R$ into the required form

$$\tilde{A}_1=\sum_{\mu=r_1+1}^{\tilde{r}}|\tilde{\bar{q}}_1^{(\mu)}\rangle\langle\tilde{\bar{p}}_1^{(\mu)}|+\sum_{\nu=1}^{r_1}\sum_{l=1}^{\tilde{s}_\nu}|\tilde{\bar{q}}_l^{(\nu)}\rangle\langle\tilde{\bar{p}}^{(\nu)}_{\tilde{s}_\nu+1-l}|, \tag{39}$$

we must define exactly one new vector $|\tilde{\bar{q}}^{(\nu)}_{\tilde{s}_\nu}\rangle$ for each ν-block [in the second term of Eq. (39)] and $\tilde{r}-r_1$ new blocks of size 1 containing $2(\tilde{r}-r_1)$ new vectors $|\overline{q}_1^{(\mu)}\rangle$ and $\langle\tilde{\bar{p}}_1^{(\mu)}|$. Due to formulas (35) and (38), the new vectors to be defined must satisfy the following equation:

$$\sum_{\mu=r_1+1}^{\tilde{r}}|\tilde{\bar{q}}_1^{(\mu)}\rangle\langle\tilde{\bar{p}}_1^{(\mu)}|+\sum_{\nu=1}^{r_1}|\tilde{\bar{q}}^{(\nu)}_{\tilde{s}_\nu}\rangle\langle\overline{p}_1^{(\nu)}|R=R-\sum_{\nu=1}^{r_1}\sum_{l=2}^{s_\nu}|\overline{q}_l^{(\nu)}\rangle\langle\overline{p}^{(\nu)}_{s_\nu+2-l}|R, \tag{40}$$

where the definition of $\langle\tilde{\bar{p}}_1^{(\nu)}|$ in Eq. (37) has been utilized. Substituting the expression (33) for R into the above equation, we get

$$\sum_{\mu=r_1+1}^{\tilde{r}}|\tilde{\bar{q}}_1^{(\mu)}\rangle\langle\tilde{\bar{p}}_1^{(\mu)}|=\sum_{l=1}^{\tilde{r}}|\xi_l\rangle\langle\overline{u_l}|, \tag{41}$$

where

$$|\xi_l\rangle\equiv\left(I-\sum_{\nu=1}^{r_1}\sum_{l=2}^{s_\nu}|\overline{q}_l^{(\nu)}\rangle\langle\overline{p}^{(\nu)}_{s_\nu+2-l}|\right)|u_l\rangle-\sum_{\nu=1}^{r_1}|\tilde{\bar{q}}^{(\nu)}_{\tilde{s}_\nu}\rangle\langle\overline{p}_1^{(\nu)}|u_l\rangle,\quad l=1,\ldots,\tilde{r}.$$

To show that Eq. (41) is solvable, we need to use an important fact that the matrix

$$\mathcal{M}=(\mathcal{M}_{\nu,l}),\quad \mathcal{M}_{\nu,l}=\langle\overline{p}_1^{(\nu)}|u_l\rangle,\quad \nu=1,\ldots,r_1,\quad l=1,\ldots,\tilde{r}_1,$$

has rank r_1. This fact can be proved by contradiction as follows.

Suppose the matrix $\mathcal{M}$ has rank less than r_1. Then its r_1 rows are linearly dependent. Thus, there are such scalars $C_1,C_2,\ldots,C_{r_1}$, not equal to zero simultaneously, that the vector

$$\langle\eta|\equiv\sum_{\nu=1}^{r_1}C_\nu\langle\overline{p}_1^{(\nu)}|$$

is orthogonal to all $|u_l\rangle$'s, i.e.,

$$\langle\eta|u_l\rangle=0,\quad 1\leqslant l\leqslant\tilde{r}. \tag{42}$$

According to our induction assumption that soliton matrices involving n multipliers in formula (27) have the form (29), we can easily show, by equating the coefficient at the highest pole at $k=\overline{k_1}$ in the left-hand side (lhs) of the identity $\Gamma(k)\Gamma^{-1}(k)=I$ to zero, that $\langle\overline{p}_1^{(\nu)}|\Gamma^{-1}(\overline{k_1})=0$ for all $1\leqslant\nu\leqslant r_1$ (see also Ref. 22). Thus $\langle\eta|\Gamma^{-1}(\overline{k_1})=0$ as well. According to Lemma 1 in Ref. 22, if $\langle\eta|$ is in the kernel of $\Gamma^{-1}(\overline{k_1})$ and is orthogonal to all $|u_l\rangle$'s, then $\langle\eta|$ is in the kernel of $\tilde{\Gamma}^{-1}(\overline{k_1})$ as well, i.e., $\langle\eta|\tilde{\Gamma}^{-1}(\overline{k_1})=0$. But according to our construction of soliton matrices [see Eq. (27)], the vectors $\langle\overline{u_l}|$ $(l=1,\ldots,\tilde{r})$ are all the linearly independent vectors in the kernel of $\tilde{\Gamma}^{-1}(\overline{k_1})$. Thus $\langle\eta|$ must be a linear combination of $\langle\overline{u_l}|$'s. Then in view of Eqs. (34) and (42), we find that $\langle\eta|=0$, which leads to a contradiction.

Now that the matrix $\mathcal{M}$ has rank r_1, then we are able to select vectors $|\tilde{\bar{q}}_{\tilde{s}_\nu}^{(\nu)}\rangle$ ($\nu=1,\ldots,r_1$) such that r_1 of the $\tilde{r}$ vectors $\langle\xi_l|$ are zero. With this choice of $|\tilde{\bar{q}}_{\tilde{s}_\nu}^{(\nu)}\rangle$'s, the rhs of Eq. (41) becomes $\tilde{r}-r_1$ blocks of size 1. Assigning these blocks to the lhs of (41), then Eq. (41) can be solved. Hence we can put the coefficient $\tilde{A}_1$ in the required form (39).

Next we prove that all vectors $\langle\tilde{\bar{p}}_1^{(\nu)}|$ ($1\leqslant\nu\leqslant\tilde{r}$) in the matrix $\tilde{\Gamma}(k)$ are linearly independent. These vectors were defined in the above proof as

$$\langle\tilde{\bar{p}}_1^{(\nu)}|=\langle\overline{p}_1^{(\nu)}|R=\sum_{l=1}^{\tilde{r}}\langle\overline{p}_1^{(\nu)}|u_l\rangle\langle\overline{u_l}|,\quad 1\leqslant\nu\leqslant r_1, \tag{43}$$

and $\langle\tilde{\bar{p}}_1^{(\nu)}|$ for $r_1+1\leqslant\nu\leqslant\tilde{r}$ are simply equal to $\tilde{r}-r_1$ of the vectors $\overline{u_l}$ depending on what $r_1\times r_1$ submatrix of $\mathcal{M}$ has rank r_1. To be definite, let us suppose the first r_1 columns of the matrix $\mathcal{M}$ have rank r_1 (i.e., linearly independent). Then according to the above proof, we can uniquely select vectors $|\tilde{\bar{q}}_{\tilde{s}_\nu}^{(\nu)}\rangle$ ($\nu=1,\ldots,r_1$) such that $|\xi_l\rangle=0$ for $1\leqslant l\leqslant r_1$. Thus,

$$\langle\tilde{\bar{p}}_1^{(\nu)}|=\langle\overline{u_\nu}|,\quad r_1+1\leqslant\nu\leqslant\tilde{r}. \tag{44}$$

Recalling that vectors $\langle\overline{u_\nu}|$ ($1\leqslant\nu\leqslant\tilde{r}$) in the projector R (33) are linearly independent, and the first r_1 columns of matrix $\mathcal{M}$ have rank r_1, we easily see that vectors $\langle\tilde{\bar{p}}_1^{(\nu)}|$ ($1\leqslant\nu\leqslant\tilde{r}$) as defined in Eqs. (43) and (44) are linearly independent.

Last, we prove that the sizes of blocks in representations (29) are given by the block sequence defined in Definition 2. An equivalent statement is that the numbers of matrix blocks with sizes $[1,2,3,\ldots,n]$ are given by the pairwise differences in the sequence of ranks: $[r_1-r_2,r_2-r_3,\ldots,r_{n-1}-r_n,r_n]$, where the last number in the sequence defines the number of blocks of size n. This can be easily proven by the induction argument using the fact that the number of new blocks of size 1 in $\tilde{A}_1$ (35) is given by $\tilde{r}-r_1$, while the sizes of old blocks grow by 1 in each multiplication as in formula (32).

Using similar arguments, we can prove that the representation (29) for $\Gamma^{-1}(k)$ is valid, and vectors $|p_1^{(1)}\rangle,\ldots,|p_1^{(r_1)}\rangle$ are linearly independent. This concludes the proof of Lemma 1. Q.E.D.

C. Soliton matrices for several pairs of zeros

Next, we extend the above results to the most general case of several pairs of higher-order normal zeros $\{(k_1,\overline{k_1}),\ldots,(k_{N_Z},\overline{k_{N_Z}})\}$. In this general case, the soliton matrix $\Gamma(k)$ can be constructed as a product of soliton matrices (27) for each zero, which are given by the procedure outlined in the beginning of this section [see Eqs. (22) to (27)]. Thus, $\Gamma(k)$ can be represented as

$$\Gamma(k)=\Gamma_1(k)\cdot\Gamma_2(k)\cdots\Gamma_{N_Z}(k). \tag{45}$$

For each pair of zeros $(k_j,\overline{k_j})$, we can define its rank sequence and block sequence by Definition 2 either from $\Gamma(k)$ directly or from the individual matrix $\Gamma_j(k)$ associated with this zero. It is easy to see that using either of $\Gamma(k)$ or $\Gamma_j(k)$ gives the same results. The inverse matrix $\Gamma^{-1}(k)$ can be represented in a similar way.

The product representation (45) for $\Gamma(k)$ and its counterpart for $\Gamma^{-1}(k)$ are not convenient for deriving soliton solutions. Their summation representations such as Eq. (29) are needed. It turns out that $\Gamma(k)$ and $\Gamma^{-1}(k)$ in the general case are given simply by sums of all the blocks from all pairs of zeros plus the unit matrix. Let us formulate this result in the next lemma.

Lemma 2: Consider several pairs of higher-order normal zeros $\{(k_1,\overline{k_1}),\ldots,(k_{N_Z},\overline{k_{N_Z}})\}$ *in the Riemann–Hilbert problem. Denote the geometric multiplicity of zeros* $(k_n,\overline{k_n})$ *as* $r_1^{(n)}$ *and their block sequence as* $\{s_1^{(n)},s_2^{(n)},\ldots,s_{r_1^{(n)}}^{(n)}\}$ ($1\leqslant n\leqslant N_Z$). *Then the soliton matrices* $\Gamma(k)$ *and* $\Gamma^{-1}(k)$ *can be written in the following summation forms:*

$$\Gamma(k)=I+\sum_{n=1}^{N_Z}\sum_{\nu=1}^{r_1^{(n)}}\overline{\mathcal{S}}_\nu^{(n)},\quad \Gamma^{-1}(k)=I+\sum_{n=1}^{N_Z}\sum_{\nu=1}^{r_1^{(n)}}\mathcal{S}_\nu^{(n)}. \tag{46}$$

Here $\mathcal{S}_\nu^{(n)}$ and $\overline{\mathcal{S}}_\nu^{(n)}$ are the following block matrices:

$$\overline{\mathcal{S}}_\nu^{(n)}=(|\overline{q}_{s_\nu^{(n)}}^{(\nu,n)}\rangle,\ldots,|\overline{q}_1^{(\nu,n)}\rangle)\overline{D}_\nu^{(n)}(k)\begin{pmatrix}\langle\overline{p}_1^{(\nu,n)}|\\ \vdots\\ \langle\overline{p}_{s_\nu^{(n)}}^{(\nu,n)}|\end{pmatrix}, \tag{47a}$$

$$\mathcal{S}_\nu^{(n)}=(|p_1^{(\nu,n)}\rangle,\ldots,|p_{s_\nu^{(n)}}^{(\nu,n)}\rangle)D_\nu^{(n)}(k)\begin{pmatrix}\langle q_{s_\nu^{(n)}}^{(\nu,n)}|\\ \vdots\\ \langle q_1^{(\nu,n)}|\end{pmatrix}, \tag{47b}$$

where $D_\nu^{(n)}(k)$ and $\overline{D}_\nu^{(n)}(k)$ are triangular Toeplitz matrices of the size $s_\nu^{(n)}\times s_\nu^{(n)}$:

$$\overline{D}_\nu^{(n)}(k)=\begin{pmatrix}\frac{1}{(k-\overline{k}_n)} & 0 & \cdots & 0\\ \frac{1}{(k-\overline{k}_n)^2} & \frac{1}{(k-\overline{k}_n)} & \ddots & \vdots\\ \vdots & \ddots & \ddots & 0\\ \frac{1}{(k-\overline{k}_n)^{s_\nu^{(n)}}} & \cdots & \frac{1}{(k-\overline{k}_n)^2} & \frac{1}{(k-\overline{k}_n)}\end{pmatrix},$$

$$D_\nu^{(n)}(k)=\begin{pmatrix}\frac{1}{(k-k_n)} & \frac{1}{(k-k_n)^2} & \cdots & \frac{1}{(k-k_n)^{s_\nu^{(n)}}}\\ 0 & \ddots & \ddots & \vdots\\ \vdots & \ddots & \frac{1}{(k-k_n)} & \frac{1}{(k-k_n)^2}\\ 0 & \cdots & 0 & \frac{1}{(k-k_n)}\end{pmatrix}. \tag{48}$$

Vectors $|p_i^{(\nu,n)}\rangle,\langle\overline{p}_i^{(\nu,n)}|,\langle q_i^{(\nu,n)}|,|\overline{q}_i^{(\nu,n)}\rangle$ $(i=1,\ldots,s_\nu^{(n)})$ are independent of k. In addition, for each n, vectors $\{|p_1^{(1,n)}\rangle,\ldots,|p_1^{(r_1^{(n)},n)}\rangle\}$ and $\{\langle\overline{p}_1^{(1,n)}|,\ldots,\langle\overline{p}_1^{(r_1^{(n)},n)}|\}$ are linearly independent, respectively.

Proof: Again we will rely on the induction argument. As it was already mentioned, the general soliton matrix $\Gamma(k)$ corresponding to several distinct zeros can be represented as a product (45) of individual soliton matrices (27) for each zero. For clarity reason and simplicity of the presentation we will give detailed calculations for the simplest case of just one product in (45). Then we will show how to generalize the calculations. Consider soliton matrix $\Gamma(k)$ for two pairs of distinct higher-order zeros $(k_1,\overline{k}_1)$ and $(k_2,\overline{k}_2)$. We have $\Gamma(k)=\Gamma_1(k)\Gamma_2(k)$ and

$$\Gamma(k)=\left(I+\frac{A_1}{k-\overline{k}_1}+\cdots+\frac{A_{n_1}}{(k-\overline{k}_1)^{n_1}}\right)\left(I+\frac{B_1}{k-\overline{k}_2}+\cdots+\frac{B_{n_2}}{(k-\overline{k}_2)^{n_2}}\right). \tag{49}$$

Here n_j $(j=1,2)$ is the number of simple matrices in the product representation (27) for Γ_j. Due to Lemma 1, the coefficients A_j and B_j are given by formulas similar to (36):

$$A_j=\sum_{\nu=1}^{r_1^{(1)}}\sum_{l=1}^{s_\nu^{(1)}+1-j}|\overline{q}_l^{(\nu,1)}\rangle\langle\overline{p}_{s_\nu^{(1)}+2-j-l}^{(\nu,1)}|, \tag{50}$$

$$B_j=\sum_{\nu=1}^{r_1^{(2)}}\sum_{l=1}^{s_\nu^{(2)}+1-j}|\overline{q}_l^{(\nu,2)}\rangle\langle\overline{p}_{s_\nu^{(2)}+2-j-l}^{(\nu,2)}|. \tag{51}$$

On the other hand, by expanding formula (49) into the partial fractions we get

$$\Gamma(k)=I+\frac{\tilde{A}_1}{k-\overline{k}_1}+\cdots+\frac{\tilde{A}_{n_1}}{(k-\overline{k}_1)^{n_1}}+\frac{\tilde{B}_1}{k-\overline{k}_2}+\cdots+\frac{\tilde{B}_n}{(k-\overline{k}_2)^{n_2}}. \tag{52}$$

Consider first the coefficients $\tilde{A}_j$. Multiplication by $(k-\overline{k}_1)^{n_1}$ of both formulas (49) and (52) and taking derivatives at $k=\overline{k}_1$ using the Leibniz rule gives

$$\tilde{A}_{n_1-l}=\frac{1}{l!}\left\{\frac{\mathrm{d}^l}{\mathrm{d}k^l}(k-\overline{k}_1)^{n_1}\Gamma(k)\right\}_{k=\overline{k}_1}=\sum_{j=0}^{l}\frac{A_{n_1-j}}{(l-j)!}\frac{\mathrm{d}^{(l-j)}\Gamma_2}{\mathrm{d}k^{(l-j)}}(\overline{k}_1). \tag{53}$$

In a similar way we get

$$\tilde{B}_{n_2-l}=\sum_{j=0}^{l}\frac{\mathrm{d}^{(l-j)}\Gamma_1}{\mathrm{d}k^{(l-j)}}(\overline{k}_2)\frac{B_{n_2-j}}{(l-j)!}. \tag{54}$$

Now substituting Eqs. (50) and (51) into (53) and (54) and defining new vectors

$$\langle\tilde{\overline{p}}_m^{(\nu,1)}|=\sum_{j=0}^{m-1}\langle\overline{p}_{m-j}^{(\nu,1)}|\frac{1}{j!}\frac{\mathrm{d}^j\Gamma_2}{\mathrm{d}k^j}(\overline{k}_1),\quad m=1,\ldots,s_\nu^{(1)}, \tag{55}$$

and

$$|\tilde{\overline{q}}_m^{(\nu,2)}\rangle=\sum_{j=0}^{m-1}\frac{1}{j!}\frac{\mathrm{d}^j\Gamma_1}{\mathrm{d}k^j}(\overline{k}_2)|\overline{q}_{m-j}^{(\nu,2)}\rangle,\quad m=1,\ldots,s_\nu^{(2)}, \tag{56}$$

we find that

$$\tilde{A}_j=\sum_{\nu=1}^{r_1^{(1)}}\sum_{l=1}^{s_\nu^{(1)}+1-j}|\overline{q}_l^{(\nu,1)}\rangle\langle\tilde{\overline{p}}_{s_\nu^{(1)}+2-j-l}^{(\nu,1)}|, \tag{57}$$

$$\tilde{B}_j=\sum_{\nu=1}^{r_1^{(2)}}\sum_{l=1}^{s_\nu^{(2)}+1-j}|\tilde{\overline{q}}_l^{(\nu,2)}\rangle\langle\overline{p}_{s_\nu^{(2)}+2-j-l}^{(\nu,2)}|, \tag{58}$$

which give precisely the needed representation (46). Note from definitions (55) and (56) that

$$[\langle\tilde{\bar{p}}_1^{(\nu,1)}|,\ldots,\langle\tilde{\bar{p}}_{r_1^{(1)}}^{(\nu,1)}|]=[\langle\bar{p}_1^{(\nu,1)}|,\ldots,\langle\bar{p}_{r_1^{(1)}}^{(\nu,1)}|]\Gamma_2(\bar{k}_1)$$

and

$$[|\tilde{q}_1^{(\nu,2)}\rangle,\ldots,|\tilde{q}_{r_1^{(2)}}^{(\nu,2)}\rangle]=\Gamma_1(\bar{k}_2)[|\bar{q}_1^{(\nu,2)}\rangle,\ldots,|\bar{q}_{r_1^{(2)}}^{(\nu,2)}\rangle].$$

Due to Lemma 1, vectors $\{\langle\bar{p}_1^{(\nu,1)}|,\ldots,\langle\bar{p}_{r_1^{(1)}}^{(\nu,1)}|\}$ and $\{|\bar{q}_1^{(\nu,2)}\rangle,\ldots,|\bar{q}_{r_1^{(2)}}^{(\nu,2)}\rangle\}$ are linearly independent respectively. In addition, matrices $\Gamma_1(\bar{k}_2)$ and $\Gamma_2(\bar{k}_1)$ are nondegenerate. Thus new vectors $\{\langle\tilde{\bar{p}}_1^{(\nu,1)}|,\ldots,\langle\tilde{\bar{p}}_{r_1^{(1)}}^{(\nu,1)}|\}$ and $\{|\tilde{\bar{q}}_1^{(\nu,2)}\rangle,\ldots,|\tilde{\bar{q}}_{r_1^{(2)}}^{(\nu,2)}\rangle\}$ are linearly independent respectively as well. This completes the proof of Lemma 2 for two pairs of higher-order zeros.

It is easy to see that the above procedure of redefining the vectors in the blocks corresponding to different zeros will also work in the general case, when $\Gamma_1(k)$ is replaced by the product $\Gamma_1(k)\cdots\Gamma_n(k)$, and $\Gamma_2(k)$ replaced by $\Gamma_{n+1}(k)$. In this case, the sum over all distinct poles will be present in the left parentheses in formula (49), and consequently there will be more terms in formula (52). Formula (53) will be valid for coefficients $\tilde{A}$ of each zero, and formula (54) remains valid as well. Thus by defining vectors $\langle\tilde{\bar{p}}_m^{(\nu,j)}|$ by formula (55) for each zero k_j $(1\leqslant j\leqslant n)$, and defining vectors $|\tilde{\bar{q}}_m^{(\nu,n+1)}\rangle$ by formula (56) for zero k_{n+1}, we can show that the matrix $\Gamma(k)$ consisting of $n+1$ products of $\Gamma_j(k)$ can be put in the required form (46). This induction argument then completes the proof of Lemma 2. Q.E.D.

The notations in the representation (46) for soliton matrices with several zeros are getting complicated. To facilitate the presentations of results in the remainder of this paper, let us reformulate the representation (46). For this purpose, we define $r_1=r_1^{(1)}+\cdots+r_1^{(N_Z)}$, where $r_1^{(n)}$'s are as given in Lemma 2. Then we replace the double summations in Eq. (46) with single ones,

$$\Gamma(k)=I+\sum_{\nu=1}^{r_1}\bar{\mathcal{S}}_\nu,\quad \Gamma^{-1}(k)=I+\sum_{\nu=1}^{r_1}\mathcal{S}_\nu. \tag{59}$$

Inside these single summations, the first $r_1^{(1)}$ terms are blocks of type (47) for the first pair of zeros $(k_1,\bar{k}_1)$, the next $r_1^{(2)}$ terms are blocks of type (47) for the second pair of zeros $(k_2,\bar{k}_2)$, and so on. Block matrices $\mathcal{S}_\nu$ and $\bar{\mathcal{S}}_\nu$ can be written as

$$\bar{\mathcal{S}}_\nu=\sum_{l=1}^{s_\nu}\sum_{j=1}^{l}\frac{|\bar{q}_j^{(\nu)}\rangle\langle\bar{p}_{l+1-j}^{(\nu)}|}{(k-\bar{\kappa}_\nu)^{s_\nu+1-l}}=(|\bar{q}_{s_\nu}^{(\nu)}\rangle,\ldots,|\bar{q}_1^{(\nu)}\rangle)\bar{D}_\nu(k)\begin{pmatrix}\langle\bar{p}_1^{(\nu)}|\\ \vdots\\ \langle\bar{p}_{s_\nu}^{(\nu)}|\end{pmatrix}, \tag{60a}$$

$$\mathcal{S}_\nu=\sum_{l=1}^{s_\nu}\sum_{j=1}^{l}\frac{|p_{l+1-j}^{(\nu)}\rangle\langle q_j^{(\nu)}|}{(k-\kappa_\nu)^{s_\nu+1-l}}=(|p_1^{(\nu)}\rangle,\ldots,|p_{s_\nu}^{(\nu)}\rangle)D_\nu(k)\begin{pmatrix}\langle q_{s_\nu}^{(\nu)}|\\ \vdots\\ \langle q_1^{(\nu)}|\end{pmatrix}, \tag{60b}$$

where matrices $D_\nu(k)$ and $\bar{D}_\nu(k)$ are triangular Toeplitz matrices of the size $s_\nu\times s_\nu$:

$$\bar{D}_\nu(k)=\begin{pmatrix}\frac{1}{(k-\bar{\kappa}_\nu)} & 0 & \cdots & 0\\ \frac{1}{(k-\bar{\kappa}_\nu)^2} & \frac{1}{(k-\bar{\kappa}_\nu)} & \ddots & \vdots\\ \vdots & \ddots & \ddots & 0\\ \frac{1}{(k-\bar{\kappa}_\nu)^{s_\nu}} & \cdots & \frac{1}{(k-\bar{\kappa}_\nu)^2} & \frac{1}{(k-\bar{\kappa}_\nu)}\end{pmatrix},$$

$$D_\nu(k)=\begin{pmatrix} \frac{1}{(k-\kappa_\nu)} & \frac{1}{(k-\kappa_\nu)^2} & \cdots & \frac{1}{(k-\kappa_\nu)^{s_\nu}} \\ 0 & \ddots & \ddots & \vdots \\ \vdots & \ddots & \frac{1}{(k-\kappa_\nu)} & \frac{1}{(k-\kappa_\nu)^2} \\ 0 & \cdots & 0 & \frac{1}{(k-\kappa_\nu)} \end{pmatrix}. \tag{61}$$

Here

$$\kappa_\nu=k_j, \quad \text{if} \quad 1+\sum_{l=1}^{j-1} r_1^{(l)}\leqslant\nu\leqslant\sum_{l=1}^{j} r_1^{(l)} \quad (1\leqslant j\leqslant N_Z). \tag{62}$$

In other words, $\kappa_\nu=k_1$ for $1\leqslant\nu\leqslant r_1^{(1)}$, $\kappa_\nu=k_2$ for $r_1^{(1)}+1\leqslant\nu\leqslant r_1^{(1)}+r_1^{(2)}$, etc. In addition, $\{s_\nu, 1+\Sigma_{l=1}^{j-1}r_1^{(l)}\leqslant\nu\leqslant\Sigma_{l=1}^{j}r_1^{(l)}\}$ is the block sequence of the jth pair of zeros $(k_j,\overline{k_j})$. This new representation (59) is equivalent to (46), but it proves to be helpful in the calculations below.

We note that the simplified way of block numeration used in the representation (59) reflects the important property of the solitons matrices: the soliton matrices preserve their form if some of the zeros coalesce (or, vice versa, a zero splits itself into two or more zeros). The only thing that does change is the association of a particular ν-block to the pair of zeros.

The representation (59) [or (46)] is but the first step towards the necessary formulas for the soliton matrices. Indeed, there are twice as many vectors in the expressions (59) for $\Gamma(k)$ and $\Gamma^{-1}(k)$ as compared to the total number of vectors in the constituent matrices in the product of representations of the type (27) for each pair of zeros. As the result, only half of the vector parameters, say $|p_i^{(\nu)}\rangle$ and $\langle\overline{p}_i^{(\nu)}|$, are free. To derive the formulas for the rest of the vector parameters in (59) we can use the identity $\Gamma(k)\Gamma^{-1}(k)=\Gamma^{-1}(k)\Gamma(k)=I$. First of all, let us give the equations for the free vectors themselves.

Lemma 3: The vectors $|p_1^{(\nu)}\rangle,\ldots,|p_{s_\nu}^{(\nu)}\rangle$ *and* $\langle\overline{p}_1^{(\nu)}|,\ldots,\langle\overline{p}_{s_\nu}^{(\nu)}|$ *from each* ν*th block in the representation (59)–(60) satisfy the following linear systems of equations:*

$$\mathbf{\Gamma}_\nu(\kappa_\nu)\begin{pmatrix} |p_1^{(\nu)}\rangle \\ \vdots \\ |p_{s_\nu}^{(\nu)}\rangle \end{pmatrix}=0, \quad \mathbf{\Gamma}_\nu(k)\equiv\begin{pmatrix} \Gamma & 0 & \cdots & 0 \\ \frac{1}{1!}\frac{\mathrm{d}}{\mathrm{d}k}\Gamma & \Gamma & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ \frac{1}{(s_\nu-1)!}\frac{\mathrm{d}^{s_\nu-1}}{\mathrm{d}k^{s_\nu-1}}\Gamma & \cdots & \frac{1}{1!}\frac{\mathrm{d}}{\mathrm{d}k}\Gamma & \Gamma \end{pmatrix}, \tag{63}$$

$$(\langle\overline{p}_1^{(\nu)}|,\ldots,\langle\overline{p}_{s_\nu}^{(\nu)}|)\overline{\mathbf{\Gamma}}_\nu(\overline{\kappa}_\nu)=0, \quad \overline{\mathbf{\Gamma}}_\nu(k)\equiv\begin{pmatrix} \Gamma^{-1} & \frac{1}{1!}\frac{\mathrm{d}}{\mathrm{d}k}\Gamma^{-1} & \cdots & \frac{1}{(s_\nu-1)!}\frac{\mathrm{d}^{s_\nu-1}}{\mathrm{d}k^{s_\nu-1}}\Gamma^{-1} \\ 0 & \Gamma^{-1} & \ddots & \vdots \\ \vdots & \ddots & \ddots & \frac{1}{1!}\frac{\mathrm{d}}{\mathrm{d}k}\Gamma^{-1} \\ 0 & \cdots & 0 & \Gamma^{-1} \end{pmatrix}. \tag{64}$$

Remark: Note that the matrices $\mathbf{\Gamma}_\nu(k)$ and $\mathbf{\Gamma}_\nu^{-1}(k)$ have block-triangular Toeplitz forms, i.e., they have the same (matrix) element along each diagonal.

Proof: The derivation of the systems (63)–(64) exactly reproduces the analogous derivation in Ref. 22 for the case of elementary zeros (as the equations for the νth block resemble analogous

equations for a single block corresponding to a pair of elementary zeros). For instance, the system (63) is derived by considering the poles of $\Gamma(k)\Gamma^{-1}(k)$ at $k=\kappa_\nu$, starting from the highest pole and using the representation (59)–(60) for $\Gamma^{-1}(k)$. The details are trivial and will not be reproduced here. Note that there may be several sets of vectors (from different ν-blocks of the same pair of zeros) which satisfy similar equations if the geometric multiplicity of this pair of zeros is higher than 1. Q.E.D.

Now let us express the $|\overline{q}\rangle$ and $\langle q|$ vectors in the expressions (59)–(60) for $\Gamma(k)$ and $\Gamma^{-1}(k)$ through the $|p\rangle$ and $\langle\overline{p}|$ vectors. This will lead to the needed representation of the soliton matrices given through the $|p\rangle$ and $\langle\overline{p}|$ vectors only. It is convenient to formulate the result in the following lemma.

Lemma 4: The general soliton matrices for several pairs of normal zeros $\{(k_1,\overline{k_1}),\ldots,(k_{N_Z},\overline{k_{N_Z}})\}$ *are given by the following formulas:*

$$\Gamma(k)=I-(|p_1^{(1)}\rangle,\ldots,|p_{s_1}^{(1)}\rangle,\ldots,|p_1^{(r_1)}\rangle,\ldots,|p_{s_{r_1}}^{(r_1)}\rangle)\overline{\mathcal{K}}^{-1}\overline{\mathcal{D}}(k)\begin{pmatrix}\langle\overline{p}_1^{(1)}|\\ \vdots\\ \langle\overline{p}_{s_1}^{(1)}|\\ \vdots\\ \langle\overline{p}_1^{(r_1)}|\\ \vdots\\ \langle\overline{p}_{s_{r_1}}^{(r_1)}|\end{pmatrix}, \tag{65a}$$

$$\Gamma^{-1}(k)=I-(|p_1^{(1)}\rangle,\ldots,|p_{s_1}^{(1)}\rangle,\ldots,|p_1^{(r_1)}\rangle,\ldots,|p_{s_{r_1}}^{(r_1)}\rangle)\mathcal{D}(k)\mathcal{K}^{-1}\begin{pmatrix}\langle\overline{p}_1^{(1)}|\\ \vdots\\ \langle\overline{p}_{s_1}^{(1)}|\\ \vdots\\ \langle\overline{p}_1^{(r_1)}|\\ \vdots\\ \langle\overline{p}_{s_{r_1}}^{(r_1)}|\end{pmatrix}, \tag{65b}$$

where s_ν *and* r_1 *are the same as in Lemma 2. The matrices* $\overline{\mathcal{D}}(k)$ *and* $\mathcal{D}(k)$ *are block-diagonal:*

$$\overline{\mathcal{D}}(k)\equiv\begin{pmatrix}\overline{D}_1(k) & & 0\\ & \ddots & \\ 0 & & \overline{D}_{r_1}(k)\end{pmatrix},\quad \mathcal{D}(k)\equiv\begin{pmatrix}D_1(k) & & 0\\ & \ddots & \\ 0 & & D_{r_1}(k)\end{pmatrix}, \tag{66}$$

where the triangular Toeplitz matrices $\overline{D}_\nu(k)$ *and* $D_\nu(k)$ *are defined in formulas (61). The matrices* $\overline{K}$ *and* K *have the following block matrix representation:*

$$\overline{\mathcal{K}}\equiv\begin{pmatrix}\overline{K}^{(1,1)} & \ldots & \overline{K}^{(1,r_1)}\\ \vdots & & \vdots\\ \overline{K}^{(r_1,1)} & \ldots & \overline{K}^{(r_1,r_1)}\end{pmatrix},\quad \mathcal{K}\equiv\begin{pmatrix}K^{(1,1)} & \ldots & K^{(1,r_1)}\\ \vdots & & \vdots\\ K^{(r_1,1)} & \ldots & K^{(r_1,r_1)}\end{pmatrix}, \tag{67}$$

with the matrices $\overline{K}^{(\nu,\mu)}$ *and* $K^{(\nu,\mu)}$ *being given as*

$$\overline{K}^{(\nu,\mu)}=\sum_{j=0}^{s_\nu-1}\sum_{l=0}^{s_\mu-1}\frac{(-1)^l(j+l)!}{j!l!}\frac{H_{-j}^{(\nu)}\overline{Q}_l^{(\nu,\mu)}}{(\kappa_\mu-\overline{\kappa}_\nu)^{j+l+1}},$$

$$K^{(\nu,\mu)}=\sum_{l=0}^{s_\nu-1}\sum_{j=0}^{s_\mu-1}\frac{(-1)^l(l+j)!}{l!j!}\frac{Q_l^{(\nu,\mu)}H_j^{(\mu)}}{(\overline{\kappa}_\nu-\kappa_\mu)^{l+j+1}}. \tag{68}$$

Here $\{H^{(\nu)}_{-s_\nu+1},\ldots,H^{(\nu)}_{s_\nu-1}\}$ *is the basis for the space of* $s_\nu\times s_\nu$*-dimensional Toeplitz matrices, defined as* $(H_j^{(\nu)})_{\alpha,\beta}\equiv\delta_{\alpha,\beta-j}$. *The nonzero elements of matrices* $\overline{Q}_l^{(\nu,\mu)}$ *and* $Q_l^{(\nu,\mu)}$ *are defined as the inner products between the p-vectors from the blocks with indices* ν *and* μ:

$$\overline{Q}_l^{(\nu,\mu)}\equiv\begin{pmatrix}\langle\overline{p}_1^{(\nu)}|\\ \vdots\\ \langle\overline{p}_{s_\nu}^{(\nu)}|\end{pmatrix}(0,\ldots,0,|p_1^{(\mu)}\rangle,\ldots,|p_{s_\mu-l}^{(\mu)}\rangle,\quad Q_l^{(\nu,\mu)}\equiv\begin{pmatrix}0\\ \vdots\\ 0\\ \langle\overline{p}_1^{(\nu)}|\\ \vdots\\ \langle\overline{p}_{s_\nu-l}^{(\nu)}|\end{pmatrix}(|p_1^{(\mu)}\rangle,\ldots,|p_{s_\mu}^{(\mu)}\rangle. \tag{69}$$

Remark 1: In the case of a single pair of zeros $(k_1,\overline{k_1})$ simply replace κ_μ $(\overline{\kappa}_\mu)$ and κ_ν $(\overline{\kappa}_\nu)$ in formula (67) by k_1 $(\overline{k_1})$.

Remark 2: In the case of the involution (4) property, the obvious relations hold:

$$\overline{\kappa}_\nu=\kappa_\nu^*,\quad \langle\overline{p}_j^{(\nu)}|=|p_j^{(\nu)}\rangle^\dagger,\quad \overline{D}_\nu(k)=D_\nu^\dagger(k^*),\quad \overline{K}^{(\nu,\mu)}=(K^{(\mu,\nu)})^\dagger.$$

Proof: We only need to prove that the $|\overline{q}\rangle$ and $\langle q|$ vectors in soliton matrices (59) and (60) are related to the $|p\rangle$ and $\langle\overline{p}|$ vectors by

$$(|\overline{q}_{s_1}^{(1)}\rangle,\ldots,|\overline{q}_1^{(1)}\rangle,\ldots,|\overline{q}_{s_{r_1}}^{(r_1)}\rangle,\ldots,|\overline{q}_1^{(r_1)}\rangle)\overline{\mathcal{K}}=-(|p_1^{(1)}\rangle,\ldots,|p_{s_1}^{(1)}\rangle,\ldots,|p_1^{(r_1)}\rangle,\ldots,|p_{s_{r_1}}^{(r_1)}\rangle), \tag{70}$$

and

$$\mathcal{K}\begin{pmatrix}\langle q_{s_1}^{(1)}|\\ \vdots\\ \langle q_1^{(1)}|\\ \vdots\\ \langle q_{s_{r_1}}^{(r_1)}|\\ \vdots\\ \langle q_1^{(r_1)}|\end{pmatrix}=-\begin{pmatrix}\langle\overline{p}_1^{(1)}|\\ \vdots\\ \langle\overline{p}_{s_1}^{(1)}|\\ \vdots\\ \langle\overline{p}_1^{(r_1)}|\\ \vdots\\ \overline{p}_{s_{r_1}}^{(r_1)}|\end{pmatrix}, \tag{71}$$

where matrices $\mathcal{K}$ and $\overline{\mathcal{K}}$ are as given in Eq. (67). We will give the proof only for Eq. (70), as the proof for (71) is similar. Note that in the case of involution (4), Eq. (71) follows from (70) by taking the Hermitian conjugate.

To prove Eq. (70), we consider the corresponding expressions (59) and (60) for $\Gamma(k)$,

$$\Gamma(k)=I+\sum_{\nu=1}^{r_1}(|\overline{q}_{s_\nu}^{(\nu)}\rangle,\ldots,|\overline{q}_1^{(\nu)}\rangle)\overline{D}_\nu(k)\begin{pmatrix}\langle\overline{p}_1^{(\nu)}|\\ \vdots\\ \langle\overline{p}_{s_\nu}^{(\nu)}|\end{pmatrix}. \tag{72}$$

We need to determine the $|\overline{q}\rangle$-vectors using Eq. (63). Note that the lth row in the μ-system (63) can be written as

$$\left[\Gamma(\kappa_\mu),\frac{1}{1!}\frac{\mathrm{d}\Gamma}{\mathrm{d}k}(\kappa_\mu),\ldots,\frac{1}{(l-1)!}\frac{\mathrm{d}^{l-1}\Gamma}{\mathrm{d}k^{l-1}}(\kappa_\mu)\right]\begin{pmatrix}|p_l^{(\mu)}\rangle\\ \vdots\\ |p_1^{(\mu)}\rangle\end{pmatrix}=0 \tag{73}$$

for each $1\leqslant\mu\leqslant r_1$. When the expression (72) for $\Gamma(k)$ is substituted into the above equation, we get

$$\sum_{\nu=1}^{r_1}(|\overline{q}_{s_\nu}^{(\nu)}\rangle,\ldots,|\overline{q}_1^{(\nu)}\rangle)\left\{\overline{D}_\nu(\kappa_\mu)\begin{pmatrix}\langle\overline{p}_1^{(\nu)}|\\ \vdots\\ \langle\overline{p}_{s_\nu}^{(\nu)}|\end{pmatrix}|p_l^{(\mu)}\rangle+\frac{1}{1!}\frac{\mathrm{d}\overline{D}_\nu}{\mathrm{d}k}(\kappa_\mu)\begin{pmatrix}\langle\overline{p}_1^{(\nu)}|\\ \vdots\\ \langle\overline{p}_{s_\nu}^{(\nu)}|\end{pmatrix}|p_{l-1}^{(\mu)}\rangle+\cdots\right.$$
$$\left.+\frac{1}{(l-1)!}\frac{\mathrm{d}^{l-1}\overline{D}_\nu}{\mathrm{d}k^{l-1}}(\kappa_\mu)\begin{pmatrix}\langle\overline{p}_1^{(\nu)}|\\ \vdots\\ \langle\overline{p}_{s_\nu}^{(\nu)}|\end{pmatrix}|p_1^{(\mu)}\rangle\right\}=-|p_l^{(\mu)}\rangle. \tag{74}$$

The derivatives of $\overline{D}_\nu(\kappa_\mu)$ can be easily computed as

$$\frac{\mathrm{d}^l\overline{D}_\nu}{\mathrm{d}k^l}(\kappa_\mu)=\sum_{j=0}^{s_\nu-1}\frac{(-1)^l(j+l)!}{j!}\frac{H_{-j}^{(\nu)}}{(\kappa_\mu-\overline{\kappa}_\nu)^{j+l+1}}. \tag{75}$$

Now it is straightforward to verify that all equations of the type (74) can be united in a single matrix equation (70) by padding some columns in the summations of (74) by zeros, precisely as it is done in the definition (69) of $\overline{Q}^{(\nu,\mu)}$. As a result we arrive at the relation (70) between $|\overline{q}\rangle$ and $|p\rangle$ vectors, where the matrix $\overline{\mathcal{K}}$ is precisely as defined in Lemma 4. Q.E.D.

D. Two special cases

Our soliton matrices derived above reproduce all previous results as special cases. The soliton matrices were previously obtained in two special cases: several pairs of Riemann–Hilbert zeros with equal geometric and algebraic multiplicities,[13] and a single pair of elementary higher-order zeros.[22] In the first case, suppose that the geometric and algebraic multiplicities of n pairs of Riemann-Hilbert zeros $\{(k_j,\overline{k}_j),1\leqslant j\leqslant n\}$ are $\{r^{(j)},1\leqslant j\leqslant n\}$, respectively. Then the soliton matrices have been given before[13] (see also Appendix B in Ref. 33) as

$$\Gamma=I-\sum_{i,j=1}^{n}\sum_{m=1}^{r^{(i)}}\sum_{l=1}^{r^{(j)}}\frac{|v_i^{(m)}\rangle(F^{-1})_{im,jl}\langle\overline{v}_j^{(l)}|}{k-\overline{k}_j},\quad \Gamma^{-1}=I+\sum_{i,j=1}^{n}\sum_{m=1}^{r^{(i)}}\sum_{l=1}^{r^{(j)}}\frac{|v_j^{(l)}(F^{-1})_{jl,im}\langle\overline{v}_i^{(m)}|}{k-k_j}, \tag{76}$$

where $r^{(j)}$ vectors $\{|v_j^{(l)}\rangle,1\leqslant l\leqslant r^{(j)}\}$ and $\{\langle\overline{v}_j^{(l)}|,1\leqslant l\leqslant r^{(j)}\}$ are in the kernels of $\Gamma(k_j)$ and $\Gamma^{-1}(\overline{k}_j)$, respectively,

$$\Gamma(k_j)|v_j^{(l)}\rangle=0,\quad \langle\overline{v}_j^{(l)}|\Gamma^{-1}(\overline{k}_j)=0,\quad l=1,\ldots,r^{(j)}, \tag{77}$$

and

$$F_{im,jl}=\frac{\langle\overline{v}_i^{(m)}|v_j^{(l)}\rangle}{k_j-\overline{k}_i}. \tag{78}$$

Moreover,

$$\det \Gamma = \prod_{j=1}^{n} \left(\frac{k-k_j}{k-\overline{k}_j} \right)^{r^{(j)}}.$$

The above special soliton matrices can be easily retrieved from the general soliton matrices (65)–(69) of Lemma 4. Indeed, in this special case, the block sequence of a pair of zeros $(k_j, \overline{k}_j)$ is a row of 1's of length $r^{(j)}$. Thus $s_\nu = 1$ for all ν's. Consequently, matrices D_ν and $\overline{D}_\nu$ in Eq. (66) have dimension 1. In addition, matrices $K^{(\nu,\mu)}$ and $\overline{K}^{(\nu,\mu)}$ in Eq. (68) also have dimension 1, and the summations in their definitions can be dropped since $l=0$ and $j=0$ there. Hence, we get

$$\overline{K}^{(\nu,\mu)} = (K^{(\mu,\nu)})^\dagger = \frac{\langle \overline{p}_1^{(\nu)} | p_1^{(\mu)} \rangle}{\kappa_\mu - \overline{\kappa}_\nu},$$

see (69). Relating $|p\rangle$ vectors $\{|p_1^{(\nu)}\rangle, 1+\Sigma_{l=1}^{j-1} r^{(l)} \leqslant \nu \leqslant \Sigma_{l=1}^{j} r^{(l)}\}$ to $\{|v_j^{(l)}\rangle, 1 \leqslant l \leqslant r^{(j)}\}$ and $\{\langle p_1^{(\nu)}|, 1+\Sigma_{l=1}^{j-1} r^{(l)} \leqslant \nu \leqslant \Sigma_{l=1}^{j} r^{(l)}\}$ to $\{\langle v_j^{(l)}|, 1 \leqslant l \leqslant r^{(j)}\}$ for each $j=1,\ldots,n$, and recalling the definition (62) of κ's, we readily find that our general representation (65) reduces to (76). We note by passing that the soliton matrices (76)–(78) cover the case of simple zeros, where there is just one vector in each kernel in (77).

Our second example is a single pair of elementary higher-order zeros. A higher-order zero is called elementary if its geometric multiplicity is 1.[22] This case has been extensively studied in the literature before (see Refs. 15, 17, 18, 22) for different integrable PDEs. The soliton matrices having similar representation as (65)–(69) for this case were derived in our previous publication.[22] The only difference between that paper's representation and the present one (65)–(69) is the definition of the matrices $\mathcal{K}$ and $\overline{\mathcal{K}}$. However, in this special case, these matrices have just one block each, i.e., $K^{(1,1)}$ and $\overline{K}^{(1,1)}$, since there is just one ν block in the soliton matrices. By comparison of both definitions one can easily establish their equivalence.

E. Invariance properties of soliton matrices

In this section, we discuss the invariance properties of soliton matrices. When the soliton matrix is in the product representation (27) for a single pair of zeros, the invariance property means that one can choose any r_1 linearly independent vectors in the kernels of $\Gamma(k_1)$ and $\Gamma^{-1}(\overline{k}_1)$, or more generally, one can choose any r_l $(1 \leqslant l \leqslant n)$ linearly independent vectors in the kernels of $(\Gamma \chi_1^{-1} \cdots \chi_{l-1}^{-1})(k_1)$ and $(\chi_{l-1} \cdots \chi_1 \Gamma^{-1})(\overline{k}_1)$, and the soliton matrix remains invariant. In other words, given the soliton matrix $\Gamma(k)$, for a fixed set of r_l linearly independent vectors $|v_{il}\rangle$ $(1 \leqslant i \leqslant r_l)$ in the kernels of $(\Gamma \chi_1^{-1} \cdots \chi_{l-1}^{-1})(k_1)$ and another fixed set of r_l linearly independent vectors $\langle \overline{v}_{il}|$ $(1 \leqslant i \leqslant r_l)$ in the kernels of $(\chi_{l-1} \cdots \chi_1 \Gamma^{-1})(\overline{k}_1)$, new sets of vectors

$$[|\tilde{v}_{1l}\rangle, |\tilde{v}_{2l}\rangle, \ldots, |\tilde{v}_{r_l,l}\rangle] = [|v_{1l}\rangle, |v_{2l}\rangle, \ldots, |v_{r_l,l}\rangle] B \tag{79}$$

and

$$\begin{bmatrix} \langle \tilde{\overline{v}}_{1l}| \\ \langle \tilde{\overline{v}}_{2l}| \\ \vdots \\ \langle \tilde{\overline{v}}_{r_l,l}| \end{bmatrix} = \overline{B} \begin{bmatrix} \langle \overline{v}_{1l}| \\ \langle \overline{v}_{2l}| \\ \vdots \\ \langle \overline{v}_{r_l,l}| \end{bmatrix}, \tag{80}$$

where B and $\overline{B}$ are arbitrary k-independent nondegenerate $r_l \times r_l$ matrices, give the same soliton matrix $\Gamma(k)$. This invariance property is obvious from definitions (25) for projector matrices. Note that the invariance transformations (79) and (80) are the most general automorphisms of the respective kernels (i.e., null spaces) of $(\Gamma \chi_1^{-1} \cdots \chi_{l-1}^{-1})(k_1)$ and $(\chi_{l-1} \cdots \chi_1 \Gamma^{-1})(\overline{k}_1)$.

Now let us determine the total number $\mathcal{N}_{\text{free}}$ of free complex parameters characterizing the higher-order soliton solution. For a single pair of the higher-order zeros $(k_1, \overline{k}_1)$ in the case with

no involution, it is given by the total number $\mathcal{N}_{\rm tot}$ $(=2N\Sigma_{l=1}^{n}r_l+2)$ of all complex constants in all the linearly independent vectors in the above null spaces and the pair of zeros $(k_1,\overline{k_1})$, minus the total number $\mathcal{N}_{\rm inv}$ $(=2\Sigma_{l=1}^{n}r_l^2)$ of the free parameters in the invariance matrices (79) and (80). Thus, in the case with no involution, we have

$$\mathcal{N}_{\rm free}\equiv\mathcal{N}_{\rm tot}-\mathcal{N}_{\rm inv}=2N\sum_{l=1}^{n}r_l+2-2\sum_{l=1}^{n}r_l^2. \tag{81}$$

Note that the total number of $|v\rangle$ or $\langle\overline{v}|$ vectors in the product representation (27), given by the sum $\Sigma_{l=1}^{n}r_l$, is equal to the algebraic order of the pair of zeros $(k_1,\overline{k_1})$. In the case of the involution (4), the number $\mathcal{N}_{\rm free}$ is reduced by half. When the soliton matrices have several pairs of zeros as in the product representation (45), the invariance property is similar, and the total number of free soliton parameters is given by the sum of the right-hand side (rhs) of formula (81) for all distinct pairs of zeros.

By analogy, the invariance properties for the summation representation (65) of the soliton matrices are defined as preserving the form of the soliton matrices as well as the equations defining the $|p\rangle$ and $\langle\overline{p}|$ vectors (63) and (64). The equations defining the transformations between different sets of p vectors of the same invariance class must be linear, since all the sets of p vectors in the invariance class satisfy equations (63) and (64) for a *fixed* soliton matrix—i.e., the invariance transformations are a subset of transformations between solutions to a set of *linear* equations. Thus the most general form of the invariance is given by two linear transformations—one for $|p\rangle$ vectors and one for $\langle\overline{p}|$ vectors:

$$(|\tilde{p}_1^{(1)}\rangle,\ldots,|\tilde{p}_{s_1}^{(1)}\rangle,\ldots,|\tilde{p}_1^{(r_1)}\rangle,\ldots,|\tilde{p}_{s_{r_1}}^{(r_1)}\rangle)=(|p_1^{(1)}\rangle,\ldots,|p_{s_1}^{(1)}\rangle,\ldots,|p_1^{(r_1)}\rangle,\ldots,|p_{s_{r_1}}^{(r_1)}\rangle)B \tag{82}$$

and

$$\begin{pmatrix}\langle\tilde{\bar{p}}_1^{(1)}|\\ \vdots\\ \langle\tilde{\bar{p}}_{s_1}^{(1)}|\\ \vdots\\ \langle\tilde{\bar{p}}_1^{(r_1)}|\\ \vdots\\ \langle\tilde{\bar{p}}_{s_{r_1}}^{(r_1)}|\end{pmatrix}=\overline{B}\begin{pmatrix}\langle\bar{p}_1^{(1)}|\\ \vdots\\ \langle\bar{p}_{s_1}^{(1)}|\\ \vdots\\ \langle\bar{p}_1^{(r_1)}|\\ \vdots\\ \langle\bar{p}_{s_{r_1}}^{(r_1)}|\end{pmatrix}. \tag{83}$$

Different from the product representation of the soliton matrices, the transformation matrices B and $\overline{B}$ in Eqs. (82) and (83) cannot be arbitrary in order to keep the soliton matrices (65) and Eqs. (63) and (64) invariant. Let us call such matrices B and $\overline{B}$ which keep the soliton matrices (65) invariant as the invariance matrices. The form of invariance matrices can be determined most easily by considering the invariance of Eqs. (63) and (64).

Recall from Lemma 3 that all $|p\rangle$ vectors in the soliton matrix (65) satisfy the equation

$$\mathbf{\Gamma_B}\begin{pmatrix}|p_1^{(1)}\rangle\\ \vdots\\ |p_{s_1}^{(1)}\rangle\\ \vdots\\ |p_1^{(r_1)}\rangle\\ \vdots\\ |p_{s_{r_1}}^{(r_1)}\rangle\end{pmatrix}=0,\quad \mathbf{\Gamma_B}\equiv\begin{pmatrix}\mathbf{\Gamma}_1(\kappa_1) & & 0\\ & \ddots & \\ 0 & & \mathbf{\Gamma}_{r_1}(\kappa_{r_1})\end{pmatrix}, \tag{84}$$

where $\mathbf{\Gamma}_\nu(\kappa_\nu)$ is the lower-triangular Toeplitz matrix defined in Eq. (63). The matrix B is an invariance matrix if and only if the above equation is still satisfied when the $|p\rangle$ vectors in Eq. (84) are replaced by the transformed vectors $|\tilde{p}\rangle$ in Eq. (82), and the resulting matrices $\mathcal{K}$ and $\overline{\mathcal{K}}$ are nondegenerate [see Eq. (65)]. Note that the transformation (82) can be rewritten in the following form:

$$\begin{pmatrix} |\tilde{p}_1^{(1)}\rangle \\ \vdots \\ |\tilde{p}_{s_1}^{(1)}\rangle \\ \vdots \\ |\tilde{p}_1^{(r_1)}\rangle \\ \vdots \\ |\tilde{p}_{s_{r_1}}^{(r_1)}\rangle \end{pmatrix} = B^T \begin{pmatrix} |p_1^{(1)}\rangle \\ \vdots \\ |p_{s_1}^{(1)}\rangle \\ \vdots \\ |p_1^{(r_1)}\rangle \\ \vdots \\ |p_{s_{r_1}}^{(r_1)}\rangle \end{pmatrix}, \tag{85}$$

where the superscript "T" stands for the matrix transposition. Since the original $|p\rangle$ vectors can be chosen arbitrarily (the matrix $\mathbf{\Gamma_B}$ is determined subsequently from these $|p\rangle$ vectors as well as the $\langle\overline{p}|$ vectors), in order for the above $|\tilde{p}\rangle$ vectors (85) to satisfy Eq. (84) as well, the necessary and sufficient condition is that $\mathbf{\Gamma_B}$ and B^T commute, i.e.,

$$\mathbf{\Gamma_B}\cdot B^T = B^T\cdot\mathbf{\Gamma_B}, \tag{86}$$

and B is nondegenerate. The requirement for the nondegeneracy of B is needed in order for the resulting matrices $\tilde{\mathcal{K}}$ and $\tilde{\bar{\mathcal{K}}}$ to be nondegenerate [see Eq. (96)]. Similarly, we can show that the matrix $\overline{B}$ in Eq. (83) is an invariance matrix if and only if $\overline{\mathbf{\Gamma}}_\mathbf{B}$ and $\overline{B}^T$ commute,

$$\overline{\mathbf{\Gamma}}_\mathbf{B}\cdot\overline{B}^T = \overline{B}^T\cdot\overline{\mathbf{\Gamma}}_\mathbf{B}, \tag{87}$$

and $\overline{B}$ is nondegenerate. Here the block-diagonal matrix $\overline{\mathbf{\Gamma}}_\mathbf{B}$ is

$$\overline{\mathbf{\Gamma}}_\mathbf{B} \equiv \begin{pmatrix} \overline{\mathbf{\Gamma}}_1(\kappa_1) & & 0 \\ & \ddots & \\ 0 & & \overline{\mathbf{\Gamma}}_{r_1}(\kappa_{r_1}) \end{pmatrix}, \tag{88}$$

and upper-triangular Toeplitz matrices $\overline{\mathbf{\Gamma}}_\nu(\kappa_\nu)$ have been defined in Eq. (64). Note that matrices $\mathbf{\Gamma_B}$ and $\overline{\mathbf{\Gamma}}_\mathbf{B}$ have exactly the same forms as $\overline{\mathcal{D}}(k)$ and $\mathcal{D}(k)$, respectively. Thus invariance matrices B^T and $\overline{B}^T$ commute with $\overline{\mathcal{D}}(k)$ and $\mathcal{D}(k)$ as well:

$$\overline{\mathcal{D}}(k)\cdot B^T = B^T\cdot\overline{\mathcal{D}}(k), \quad \mathcal{D}(k)\cdot\overline{B}^T = \overline{B}^T\cdot\mathcal{D}(k). \tag{89}$$

In addition, since $\mathcal{D}^T$ has the same form as $\overline{\mathcal{D}}$, invariance matrices B and $\overline{B}$ also commute with $\mathcal{D}$ and $\overline{\mathcal{D}}$:

$$B\cdot\mathcal{D}(k) = \mathcal{D}(k)\cdot B, \quad \overline{B}\cdot\overline{\mathcal{D}}(k) = \overline{\mathcal{D}}(k)\cdot\overline{B}. \tag{90}$$

The form of these invariance matrices are easy to determine. First of all, the commutability relations (90) demand that the invariance matrix B has a block-diagonal form with each block corresponding to a pair of zeros:

$$B=\begin{pmatrix} B_1 & & & \\ & B_2 & & \\ & & \ddots & \\ & & & B_{N_Z} \end{pmatrix}. \tag{91}$$

Here B_n is a square matrix associated with the nth pair of zeros $(k_n,\overline{k_n})$. The form of each matrix B_n is readily found to be

$$B_n=\begin{pmatrix} B_n^{(1,1)} & \cdots & B_n^{(1,r_1^{(n)})} \\ \vdots & & \vdots \\ B_n^{(r_1^{(n)},1)} & \cdots & B_n^{(r_1^{(n)},r_1^{(n)})} \end{pmatrix}, \tag{92}$$

where $B_n^{(\nu,\mu)}$ is a $s_\nu^{(n)}\times s_\mu^{(n)}$ matrix of the following type:

$$B_n^{(\nu,\mu)}=\begin{pmatrix} 0 & \cdots & 0 & b_1 & b_2 & \cdots & b_{s_\nu^{(n)}-1} & b_{s_\nu^{(n)}} \\ 0 & \ddots & \ddots & 0 & b_1 & b_2 & \ddots & b_{s_\nu^{(n)}-1} \\ \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \vdots \\ 0 & \ddots & \ddots & \ddots & \ddots & 0 & b_1 & b_2 \\ 0 & \cdots & \cdots & \cdots & \cdots & \cdots & 0 & b_1 \end{pmatrix}, \quad \nu\geqslant\mu, \tag{93a}$$

$$B_n^{(\nu,\mu)}=\begin{pmatrix} c_1 & c_2 & \cdots & c_{s_\mu^{(n)}-1} & c_{s_\mu^{(n)}} \\ 0 & c_1 & c_2 & \ddots & c_{s_\mu^{(n)}-1} \\ \vdots & 0 & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & \ddots & c_2 \\ \vdots & \ddots & \ddots & 0 & c_1 \\ \vdots & \ddots & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ 0 & \cdots & \cdots & \cdots & 0 \end{pmatrix}, \quad \nu\leqslant\mu, \tag{93b}$$

$s_1^{(n)}\geqslant s_2^{(n)}\geqslant\ldots\geqslant s_{r_1^{(n)}}^{(n)}$ is the block sequence of zeros $(k_n,\overline{k_n})$ as in Lemma 2 (see Definition 2), and b_j,c_j are arbitrary complex constants which are generally different in different submatrices $B_n^{(\nu,\mu)}$. The invariance matrix $\overline{B}$ has the form of B^T (in general, with arbitrary elements unrelated to those of B).

The above forms (92) and (93) of the invariance matrices B_n and $\overline{B_n}$ follow immediately from the following argument. Consider, for instance, the matrix B_n. The commutability relation with the part of the matrix $\mathcal{D}(k)$ corresponding to the nth pair of zeros, i.e., $\mathcal{D}^{(n)}(k)=\mathrm{diag}[D_1^{(n)}(k),\ldots,D_{r_1^{(n)}}^{(n)}(k)]$ where matrices $D_\nu^{(n)}(k)$ are given by Eq. (48), produces the following set of independent matrix equations:

$$D_\nu^{(n)}(k)B_n^{(\nu,\mu)}=B_n^{(\nu,\mu)}D_\mu^{(n)}(k), \quad \nu,\mu=1,\ldots,r_1^{(n)}. \tag{94}$$

For $\nu=\mu$, the above equations are equivalent to the commutability conditions for the single elementary higher-order zero considered in Ref. 22, thus the form (93) for the diagonal blocks $B_n^{(\nu,\nu)}$ follows accordingly. Consider now the case when $\nu>\mu$ (the other case can be considered similarly). We have then $s_\nu^{(n)}\leqslant s_\mu^{(n)}$, thus the square matrix $D_\mu^{(n)}(k)$ contains the matrix $D_\nu^{(n)}(k)$ in

its lower right corner [consult the definition (48)]. It is easy to conclude, first of all, that the first $\mu-\nu$ columns of the matrix $B_n^{(\nu,\mu)}$ are identically zero, otherwise on the rhs of Eq. (94) we would have higher powers of $(k-k_n)^{-1}$ than the highest power of this quantity on the left-hand side (lhs). Then if we denote the nonzero part of $B_n^{(\nu,\mu)}$ as $\hat{B}_n^{(\nu)}$, the condition (94) becomes

$$D_\nu^{(n)}(k)\hat{B}_n^{(\nu)}=\hat{B}_n^{(\nu)}D_\nu^{(n)}(k),$$

which is equivalent to the one considered above in the case of $\mu=\nu$. Thus the form (93a) for the off-diagonal blocks of the invariance matrix $B_n^{(\nu,\mu)}$ follows as well. Q.E.D.

From the above explicit expressions (91)–(93) for invariance matrices in the summation representation (65), it is easy to see that the total number $\mathcal{N}_{\text{inv}}$ of free complex constants in these invariance matrices coincides with that in the product representation (27) and (45) [see Eq. (81)]. Indeed consider for simplicity just a single pair of zeros. In the case with no involution (4), the total number $\mathcal{N}_{\text{inv}}$ of free complex constants in the invariance matrices (91)–(93) is

$$\begin{aligned}\mathcal{N}_{\text{inv}}&=2\sum_{\nu=1}^{r_1}(2r_1-2\nu+1)s_{r_1-\nu+1}\\&=2\sum_{\mu=1}^{r_1}(2\mu-1)s_\mu\\&=2\left(n\sum_{\mu=1}^{r_n}(2\mu-1)+(n-1)\sum_{\mu=r_n+1}^{r_{n-1}}(2\mu-1)+\cdots+\sum_{\mu=r_2+1}^{r_1}(2\mu-1)\right)=2\sum_{l=1}^{n}r_l^2,\end{aligned}\tag{95}$$

which is exactly the same as that in Eq. (81) for $\mathcal{N}_{\text{inv}}$. Here we have used the fact that the numbers of blocks with sizes $[1,2,3,\ldots,n]$ are given by the differences of the ranks $[r_1-r_2,r_2-r_3,\ldots,r_{n-1}-r_n,r_n]$ (see the end of the proof of Lemma 1 in Sec. III B).

This result is not surprising since the invariance properties of the soliton matrices in the summation representation originate from the invariance properties in the product representation, that is why the respective invariance matrices have the same total number of free parameters. Consequently, the total number of free complex parameters in the summation representation (65) is the same as in the product representation, as expected. In the case with no involution for a single pair of zeros it is given by the same Eq. (81).

Invariance matrices have many important properties. These include (i) the identity matrix I is an invariance matrix; (ii) if B is an invariance matrix, so is cB, where c is any nonzero complex constant; (iii) if B is an invariance matrix, so is B^{-1}; (iv) if B_1 and B_2 are two invariance matrices, so are $B_1\pm B_2$ and $B_1\cdot B_2$. In the former case, $B_1\pm B_2$ should be nondegenerate.

Last, we note that if matrices B and $\overline{B}$ satisfy the commutability relations (90), the transformations (82) and (83) indeed keep the soliton matrices (65) invariant. The proof uses the fact that under the transformation (82) where B is an invariance matrix (the $\langle\overline{p}|$ vectors are held fixed), matrices $\mathcal{K}$ and $\overline{\mathcal{K}}$ are transformed to

$$\tilde{\mathcal{K}}=\mathcal{K}B,\quad \tilde{\overline{\mathcal{K}}}=\overline{\mathcal{K}}B\tag{96}$$

respectively. Similarly, under the transformation (83) while keeping the $|p\rangle$ vectors fixed, matrices $\mathcal{K}$ and $\overline{\mathcal{K}}$ are transformed to

$$\tilde{\mathcal{K}}=\overline{B}\mathcal{K},\quad \tilde{\overline{\mathcal{K}}}=\overline{B}\,\overline{\mathcal{K}}.\tag{97}$$

For a single pair of elementary higher-order zeros these facts have been proved in Ref. 22. The proof for the present general case is given below. Since the proofs for Eqs. (96) and (97) are similar, we only consider Eq. (96).

To prove the transformation (96), we need to recall how matrices $\mathcal{K}$ and $\overline{\mathcal{K}}$ are obtained. The matrix $\overline{\mathcal{K}}$ is derived from Eq. (84). Comparing this equation with (70), we find that

$$(\mathbf{\Gamma_B}-I)\begin{pmatrix} |p_1^{(1)}\rangle \\ \vdots \\ |p_{s_1}^{(1)}\rangle \\ \vdots \\ |p_1^{(r_1)}\rangle \\ \vdots \\ |p_{s_{r_1}}^{(r_1)}\rangle \end{pmatrix} = \overline{\mathcal{K}}^T \begin{pmatrix} |\overline{q}_{s_1}^{(1)}\rangle \\ \vdots \\ |\overline{q}_1^{(1)}\rangle \\ \vdots \\ |\overline{q}_{s_{r_1}}^{(r_1)}\rangle \\ \vdots \\ |\overline{q}_1^{(r_1)}\rangle \end{pmatrix}.$$

Now using the form (85) of the transformation (82) and recalling that B^T and $\mathbf{\Gamma_B}-I$ commute, we readily find that $(\tilde{\overline{\mathcal{K}}})^T = B^T\overline{\mathcal{K}}^T$, thus $\tilde{\overline{\mathcal{K}}} = \overline{\mathcal{K}}B$. As about the matrix $\mathcal{K}$, it is derived from the equation

$$(\langle \overline{p}_1^{(1)}|, \ldots, \langle \overline{p}_{s_1}^{(1)}|, \ldots, \langle \overline{p}_1^{(r_1)}|, \ldots, \langle \overline{p}_{s_{r_1}}^{(r_1)}|)\overline{\mathbf{\Gamma}}_\mathbf{B} = 0,$$

where $\overline{\mathbf{\Gamma}}_\mathbf{B}$ is given by Eqs. (63) and (88). Recall that $\Gamma^{-1}(k)$ is given by Eq. (59), i.e.,

$$\Gamma^{-1}(k) = I + (|p_1^{(1)}\rangle, \ldots, |p_{s_1}^{(1)}\rangle, \ldots, |p_1^{(r_1)}\rangle, \ldots, |p_{s_{r_1}}^{(r_1)}\rangle)\mathcal{D}(k)\begin{pmatrix} \langle q_{s_1}^{(1)}| \\ \vdots \\ \langle q_1^{(1)}| \\ \vdots \\ \langle q_{s_{r_1}}^{(r_1)}| \\ \vdots \\ \langle q_1^{(r_1)}| \end{pmatrix}.$$

Thus, using the transformation (82) and noting that B and $\mathcal{D}$ commute [see Eq. (90)], we readily find that $\tilde{\mathcal{K}} = \mathcal{K}B$, i.e., the equation (96) holds.

Because of Eq. (96) and the commutability relation (90), we see that soliton matrices $\Gamma(k)$ and $\Gamma^{-1}(k)$ in Eq. (65) indeed remain invariant under the transformation (82). Analogously, these soliton matrices are also invariant under the transformation (83) if matrix $\overline{B}$ is an invariance matrix. In the case of involution (4), transformations (82) and (83) need to be performed simultaneously since $|p\rangle$ and $\langle\overline{p}|$ vectors are related by the Hermitian operation. Under these combined transformations, matrix $\mathcal{K}$ transforms to $\tilde{\mathcal{K}} = \overline{B}\mathcal{K}B$, thus soliton matrices (65) remain invariant as well.

The invariance matrices can be used to reduce the number of the free parameters in the soliton solution to the minimum, which is given by the formula (81). They are also used to reduce the (x,t) dependence of the soliton matrices to the simplest possible form (see the next section).

F. Spatial and temporal evolutions of soliton matrices

Finally, we derive the (x,t) dependence of the free vector parameters which enter the soliton matrix (65). The idea is similar to the one used in the derivation of Eqs. (20) in Sec. II. Our starting point is the fact that the soliton matrix $\Gamma(k,x,t)$ satisfies Eqs. (5) and (6) with potentials $U(k,x,t)$ and $V(k,x,t)$:

$$\partial_x \Gamma(k,x,t) = \Gamma(k,x,t)\Lambda(k) + U(k,x,t)\Gamma(k,x,t), \tag{98a}$$

$$\partial_t \Gamma(k,x,t) = \Gamma(k,x,t)\Omega(k) + V(k,x,t)\Gamma(k,x,t). \tag{98b}$$

First we need to find the equations for the triangular block–Toeplitz matrices $\mathbf{\Gamma}_\nu$ and $\overline{\mathbf{\Gamma}}_\nu$. To this goal one needs to differentiate Eqs. (98) with respect to k up to the $(s_\nu - 1)$th order. It is easy to check that the equations for $\mathbf{\Gamma}_\nu$ have the same form as Eqs. (98),

$$\partial_x \mathbf{\Gamma}_\nu(k,x,t) = \mathbf{\Gamma}_\nu(k,x,t)\mathbf{\Lambda}_\nu(k) + \mathbf{U}_\nu(k,x,t)\mathbf{\Gamma}_\nu(k,x,t), \tag{99a}$$

$$\partial_t \mathbf{\Gamma}_\nu(k,x,t) = \mathbf{\Gamma}_\nu(k,x,t)\mathbf{\Omega}_\nu(k) + \mathbf{V}_\nu(k,x,t)\mathbf{\Gamma}_\nu(k,x,t). \tag{99b}$$

Here $\mathbf{\Lambda}_\nu$, $\mathbf{\Omega}_\nu$, $\mathbf{U}_\nu$, and $\mathbf{V}_\nu$ are lower-triangular block–Toeplitz matrices,

$$\mathbf{\Lambda}_\nu \equiv \begin{pmatrix} \Lambda & 0 & \dots & 0 \\ \frac{1}{1!}\frac{\mathrm{d}}{\mathrm{d}k}\Lambda & \ddots & \ddots & \vdots \\ \vdots & \ddots & \Lambda & 0 \\ \frac{1}{(s_\nu-1)!}\frac{\mathrm{d}^{s_\nu-1}}{\mathrm{d}k^{s_\nu-1}}\Lambda & \dots & \frac{1}{1!}\frac{\mathrm{d}}{\mathrm{d}k}\Lambda & \Lambda \end{pmatrix},$$

$$\mathbf{\Omega}_\nu \equiv \begin{pmatrix} \Omega & 0 & \dots & 0 \\ \frac{1}{1!}\frac{\mathrm{d}}{\mathrm{d}k}\Omega & \ddots & \ddots & \vdots \\ \vdots & \ddots & \Omega & 0 \\ \frac{1}{(s_\nu-1)!}\frac{\mathrm{d}^{s_\nu-1}}{\mathrm{d}k^{s_\nu-1}}\Omega & \dots & \frac{1}{1!}\frac{\mathrm{d}}{\mathrm{d}k}\Omega & \Omega \end{pmatrix}, \tag{100}$$

$$\mathbf{U}_\nu \equiv \begin{pmatrix} U & 0 & \dots & 0 \\ \frac{1}{1!}\frac{\mathrm{d}}{\mathrm{d}k}U & \ddots & \ddots & \vdots \\ \vdots & \ddots & U & 0 \\ \frac{1}{(s_\nu-1)!}\frac{\mathrm{d}^{s_\nu-1}}{\mathrm{d}k^{s_\nu-1}}U & \dots & \frac{1}{1!}\frac{\mathrm{d}}{\mathrm{d}k}U & U \end{pmatrix},$$

$$\mathbf{V}_\nu \equiv \begin{pmatrix} V & 0 & \dots & 0 \\ \frac{1}{1!}\frac{\mathrm{d}}{\mathrm{d}k}V & \ddots & \ddots & \vdots \\ \vdots & \ddots & V & 0 \\ \frac{1}{(s_\nu-1)!}\frac{\mathrm{d}^{s_\nu-1}}{\mathrm{d}k^{s_\nu-1}}V & \dots & \frac{1}{1!}\frac{\mathrm{d}}{\mathrm{d}k}V & V \end{pmatrix}. \tag{101}$$

Indeed, this is due to the fact that the matrix multiplication in (99) exactly reproduces the Leibniz rule for higher-order derivatives of a product. Similarly, using the equations for Γ^{-1},

$$\partial_x \Gamma^{-1}(k,x,t) = -\Lambda(k)\Gamma^{-1}(k,x,t) - \Gamma^{-1}(k,x,t)U(k,x,t), \tag{102a}$$

$$\partial_t \Gamma^{-1}(k,x,t) = -\Omega(k)\Gamma^{-1}(k,x,t) - \Gamma^{-1}(k,x,t)V(k,x,t), \tag{102b}$$

one finds that

$$\partial_x \overline{\mathbf{\Gamma}}_\nu(k,x,t) = -\overline{\mathbf{\Lambda}}_\nu(k)\overline{\mathbf{\Gamma}}_\nu(k,x,t) - \overline{\mathbf{\Gamma}}_\nu(k,x,t)\overline{\mathbf{U}}_\nu(k,x,t), \tag{103a}$$

$$\partial_t \overline{\mathbf{\Gamma}}_\nu(k,x,t) = -\overline{\mathbf{\Omega}}_\nu(k)\overline{\mathbf{\Gamma}}_\nu(k,x,t) - \overline{\mathbf{\Gamma}}_\nu(k,x,t)\overline{\mathbf{V}}_\nu(k,x,t), \tag{103b}$$

where $\overline{\mathbf{\Lambda}}_\nu$, $\overline{\mathbf{\Omega}}_\nu$, $\overline{\mathbf{U}}_\nu$, and $\overline{\mathbf{V}}_\nu$ are upper-triangular block–Toeplitz matrices:

$$\overline{\mathbf{\Lambda}}_\nu = \begin{pmatrix} \Lambda & \frac{1}{1!}\frac{\mathrm{d}}{\mathrm{d}k}\Lambda & \cdots & \frac{1}{(s_\nu-1)!}\frac{\mathrm{d}^{s_\nu-1}}{\mathrm{d}k^{s_\nu-1}}\Lambda \\ 0 & \Lambda & \ddots & \vdots \\ \vdots & \ddots & \ddots & \frac{1}{1!}\frac{\mathrm{d}}{\mathrm{d}k}\Lambda \\ 0 & \cdots & 0 & \Lambda \end{pmatrix},$$

$$\overline{\mathbf{\Omega}}_\nu = \begin{pmatrix} \Omega & \frac{1}{1!}\frac{\mathrm{d}}{\mathrm{d}k}\Omega & \cdots & \frac{1}{(s_\nu-1)!}\frac{\mathrm{d}^{s_\nu-1}}{\mathrm{d}k^{s_\nu-1}}\Omega \\ 0 & \Omega & \ddots & \vdots \\ \vdots & \ddots & \ddots & \frac{1}{1!}\frac{\mathrm{d}}{\mathrm{d}k}\Omega \\ 0 & \cdots & 0 & \Omega \end{pmatrix}, \tag{104}$$

$$\overline{\mathbf{U}}_\nu = \begin{pmatrix} U & \frac{1}{1!}\frac{\mathrm{d}}{\mathrm{d}k}U & \cdots & \frac{1}{(s_\nu-1)!}\frac{\mathrm{d}^{s_\nu-1}}{\mathrm{d}k^{s_\nu-1}}U \\ 0 & U & \ddots & \vdots \\ \vdots & \ddots & \ddots & \frac{1}{1!}\frac{\mathrm{d}}{\mathrm{d}k}U \\ 0 & \cdots & 0 & U \end{pmatrix},$$

$$\overline{\mathbf{V}}_\nu = \begin{pmatrix} V & \frac{1}{1!}\frac{\mathrm{d}}{\mathrm{d}k}V & \cdots & \frac{1}{(s_\nu-1)!}\frac{\mathrm{d}^{s_\nu-1}}{\mathrm{d}k^{s_\nu-1}}V \\ 0 & V & \ddots & \vdots \\ \vdots & \ddots & \ddots & \frac{1}{1!}\frac{\mathrm{d}}{\mathrm{d}k}V \\ 0 & \cdots & 0 & V \end{pmatrix}. \tag{105}$$

To obtain the (x,t) dependence of the p vectors, let us differentiate Eqs. (63) and (64). Utilizing Eqs. (100) and (103), we find that

$$\mathbf{\Gamma}_\nu(\kappa_\nu)\left\{ [\partial_x + \mathbf{\Lambda}_\nu(\kappa_\nu)] \begin{pmatrix} |p_1^{(\nu)}\rangle \\ \vdots \\ |p_{s_\nu}^{(\nu)}\rangle \end{pmatrix} \right\} = 0 \tag{106}$$

and

$$\mathbf{\Gamma}_\nu(\kappa_\nu)\left\{[\partial_t+\mathbf{\Omega}_\nu(\kappa_\nu)]\begin{pmatrix}|p_1^{(\nu)}\rangle\\ \vdots\\ |p_{s_\nu}^{(\nu)}\rangle\end{pmatrix}\right\}=0. \tag{107}$$

Due to the invariance properties (the explanation will follow below), we can set the quantities inside the curly brackets of Eqs. (106) and (107) to be zero without any loss of generality:

$$[\partial_x+\mathbf{\Lambda}_\nu(\kappa_\nu)]\begin{pmatrix}|p_1^{(\nu)}\rangle\\ \vdots\\ |p_{s_\nu}^{(\nu)}\rangle\end{pmatrix}=0,\qquad [\partial_t+\mathbf{\Omega}_\nu(\kappa_\nu)]\begin{pmatrix}|p_1^{(\nu)}\rangle\\ \vdots\\ |p_{s_\nu}^{(\nu)}\rangle\end{pmatrix}=0. \tag{108}$$

The reason for it is the uniqueness of solution to the Riemann–Hilbert problem for a given set of the spectral data. Thus, the (x,t) dependence of the $|p\rangle$ vectors is

$$\begin{pmatrix}|p_1^{(\nu)}\rangle\\ \vdots\\ |p_{s_\nu}^{(\nu)}\rangle\end{pmatrix}=\exp\{-\mathbf{\Lambda}_\nu(\kappa_\nu)x-\mathbf{\Omega}_\nu(\kappa_\nu)t\}\begin{pmatrix}|p_{01}^{(\nu)}\rangle\\ \vdots\\ |p_{0s_\nu}^{(\nu)}\rangle\end{pmatrix}. \tag{109}$$

By similar arguments, the (x,t) dependence of the $\langle\overline{p}|$ vectors is given as

$$(\langle\overline{p}_1^{(\nu)}|,\ldots,\langle\overline{p}_{s_\nu}^{(\nu)}|)=(\langle\overline{p}_{01}^{(\nu)}|,\ldots,\langle\overline{p}_{0s_\nu}^{(\nu)}|)\exp\{\overline{\mathbf{\Lambda}}_\nu(\overline{\kappa}_\nu)x+\overline{\mathbf{\Omega}}_\nu(\overline{\kappa}_\nu)t\}. \tag{110}$$

Here the subscript "0" is used to denote constant vectors. The exponential functions in the above two equations can be readily determined. Indeed, by using the property that the operation of raising a diagonal matrix [such as $\Lambda(k)x+\Omega(k)t$ here] to the exponent commutes with the construction of the related triangular block–Toeplitz matrix (see appendix in Ref. 22), we find that

$$\exp\{-\mathbf{\Lambda}_\nu(\kappa_\nu)x-\mathbf{\Omega}_\nu(\kappa_\nu)t\}=\begin{pmatrix}E(k_1) & 0 & \cdots & 0\\ \frac{1}{1!}\frac{\mathrm{d}}{\mathrm{d}k}E(k_1) & \ddots & \ddots & \vdots\\ \vdots & \ddots & E(k_1) & 0\\ \frac{1}{(s_\nu-1)!}\frac{\mathrm{d}^{s_\nu-1}}{\mathrm{d}k^{s_\nu-1}}E(k_1) & \cdots & \frac{1}{1!}\frac{\mathrm{d}}{\mathrm{d}k}E(k_1) & E(k_1)\end{pmatrix} \tag{111a}$$

and

$$\exp\{\overline{\mathbf{\Lambda}}_\nu(\overline{\kappa}_\nu)x+\overline{\mathbf{\Omega}}_\nu(\overline{\kappa}_\nu)t\}=\begin{pmatrix}E^{-1}(\overline{k}_1) & \frac{1}{1!}\frac{\mathrm{d}}{\mathrm{d}k}E^{-1}(\overline{k}_1) & \cdots & \frac{1}{(s_\nu-1)!}\frac{\mathrm{d}^{s_\nu-1}}{\mathrm{d}k^{s_\nu-1}}E^{-1}(\overline{k}_1)\\ 0 & E^{-1}(\overline{k}_1) & \ddots & \vdots\\ \vdots & \ddots & \ddots & \frac{1}{1!}\frac{\mathrm{d}}{\mathrm{d}k}E^{-1}(\overline{k}_1)\\ 0 & \cdots & 0 & E^{-1}(\overline{k}_1)\end{pmatrix}, \tag{111b}$$

where $E(k)\equiv\exp\{-\Lambda(k)x-\Omega(k)t\}$.

Given the spatial and temporal evolutions of vectors $|p\rangle$ and $\langle\overline{p}|$, as in Eqs. (109)–(111), the associated soliton matrices (65) can be constructed. Eventually, the soliton solutions are derived from Eq. (5) by taking the limit $k\to\infty$. The soliton solutions for the three-wave interaction model are given by Eqs. (12) and (13). The corresponding eigenfunctions of the N-dimensional

Zakharov–Shabat spectral problem with these soliton (reflectionless) potentials are then simply the column vectors of the soliton matrices $\Gamma(k)$ and $\Gamma^{-1}(k)$ given by (65) with k either equal to one of the zeros $(k_j, \overline{k_j})$ (the eigenfunctions of the discrete spectrum) or taking values on the real axis (the eigenfunctions of the continuous spectrum).

Last, let us show that other solutions to Eqs. (106) and (107), different from those given by Eq. (108), will give the same soliton matrices. Notice that Eqs. (106) for all ν blocks can be written in the following compact form:

$$\mathbf{\Gamma_B}(\partial_x+\mathbf{\Omega_B})\begin{pmatrix} |p_1^{(1)}\rangle \\ \vdots \\ |p_{s_1}^{(1)}\rangle \\ \vdots \\ |p_1^{(r_1)}\rangle \\ \vdots \\ |p_{s_{r_1}}^{(r_1)}\rangle \end{pmatrix}=0, \qquad \mathbf{\Omega_B}\equiv\begin{pmatrix} \mathbf{\Omega}_1(\kappa_1) & & 0 \\ & \ddots & \\ 0 & & \mathbf{\Omega}_{r_1}(\kappa_{r_1}) \end{pmatrix}. \tag{112}$$

According to the invariance properties discussed in the Sec. III E, any two vectors in the kernel of matrix $\mathbf{\Gamma_B}$ are linearly dependent. Thus the most general $|p\rangle$ solutions to Eq. (106) are such that

$$(\partial_x+\mathbf{\Omega_B})\begin{pmatrix} |\tilde{p}_1^{(1)}\rangle \\ \vdots \\ |\tilde{p}_{s_1}^{(1)}\rangle \\ \vdots \\ |\tilde{p}_1^{(r_1)}\rangle \\ \vdots \\ |\tilde{p}_{s_{r_1}}^{(r_1)}\rangle \end{pmatrix}=B^T(x,t)\begin{pmatrix} |\tilde{p}_1^{(1)}\rangle \\ \vdots \\ |\tilde{p}_{s_1}^{(1)}\rangle \\ \vdots \\ |\tilde{p}_1^{(r_1)}\rangle \\ \vdots \\ |\tilde{p}_{s_{r_1}}^{(r_1)}\rangle \end{pmatrix}, \tag{113}$$

where B is an invariance matrix which depends on x and t in general [see Eq. (85)]. To show that these $|\tilde{p}\rangle$ vectors give the same soliton matrices (65) as the $|p\rangle$ vectors from Eq. (108), we define a matrix function $G(x,t)$ which satisfies the following differential equation and initial condition:

$$\partial_x G(x,t)=B^T(x,t)G(x,t), \qquad G|_{x=0}=I.$$

Because the matrix B here is an invariance matrix and $G(x=0)=I$, obviously the function $G(x,t)$ is an invariance matrix as well (note that G is always nondegenerate by construction). In addition, G^{-1} is also an invariance matrix. Now for any solution $|\tilde{p}\rangle$ of Eq. (112), we define new vectors $|p\rangle$ as

$$\begin{pmatrix} |p_1^{(1)}\rangle \\ \vdots \\ |p_{s_1}^{(1)}\rangle \\ \vdots \\ |p_1^{(r_1)}\rangle \\ \vdots \\ |p_{s_{r_1}}^{(r_1)}\rangle \end{pmatrix}=G^{-1}\begin{pmatrix} |\tilde{p}_1^{(1)}\rangle \\ \vdots \\ |\tilde{p}_{s_1}^{(1)}\rangle \\ \vdots \\ |\tilde{p}_1^{(r_1)}\rangle \\ \vdots \\ |\tilde{p}_{s_{r_1}}^{(r_1)}\rangle \end{pmatrix}.$$

Then these $|p\rangle$ vectors satisfy the first equation in (108). This can be checked directly by substituting the above equation into (108) and noting that matrices G and $\mathbf{\Omega_B}$ commute by virtue of Eq. (86) and the fact that matrices $\mathbf{\Omega_B}$ and $\mathbf{\Gamma_B}$ have identical form. Since G^{-1} is an invariance matrix,

the $|p\rangle$ and $|\tilde{p}\rangle$ vectors, related as above, naturally give the same soliton matrices (65). Thus there is no loss of generality in picking the particular solutions of Eq. (106) given by Eqs. (108).

IV. APPLICATIONS TO THE THREE-WAVE INTERACTION SYSTEM

To illustrate the above general results, we apply them to the three-wave interaction model (14) and display various higher-order soliton solutions. In this case, the involution property (4) holds, thus all zeros are normal and appear in complex conjugate pairs. The soliton matrix $\Gamma(k)$ is given by Eq. (65a), where $\langle\overline{p}|=|p\rangle^{\dagger}$, and the (x,t) evolution of $|p\rangle$ vectors is given by Eqs. (109) and (111a). The general higher-order soliton solutions of the three-wave system are then given by Eq. (13), where

$$\Phi^{(1)}=\Gamma^{(1)}=-(|p_1^{(1)}\rangle,\ldots,|p_{s_1}^{(1)}\rangle,\ldots,|p_1^{(r_1)}\rangle,\ldots,|p_{s_{r_1}}^{(r_1)}\rangle)\overline{\mathcal{K}}^{-1}\begin{pmatrix}\langle\overline{p}_1^{(1)}|\\ \vdots\\ \langle\overline{p}_{s_1}^{(1)}|\\ \vdots\\ \langle\overline{p}_1^{(r_1)}|\\ \vdots\\ \langle\overline{p}_{s_{r_1}}^{(r_1)}|\end{pmatrix}, \tag{114}$$

and matrix $\overline{\mathcal{K}}$ is given in Eq. (67). In all our solutions, we fix the parameters in the dispersion laws (11) as $(a_1,a_2,a_3)=(1,0.5,-0.5)$ and $(b_1,b_2,b_3)=(1,1.5,0.5)$.

A. Soliton solutions for a single pair of nonelementary zeros

First, we derive soliton solutions corresponding to a single pair of nonelementary zeros. In particular, we consider the rank sequence {1, 2} of a pair of zeros $(k_1,\overline{k_1})$. In this case, $r_1=2$ and $r_2=1$. Using formula (81) (for the case of involution) we get the number of free complex parameters in the soliton solution:

$$\mathcal{N}_{\text{free}}=3(2+1)+1-(4+1)=10-5=5.$$

There are three $|p\rangle$ vectors, $|p_1^{(1)}\rangle$, $|p_2^{(1)}\rangle$, and $|p_1^{(2)}\rangle$ in Eq. (114). When k_1 and the initial values $[|p_{01}^{(1)}\rangle,|p_{02}^{(1)}\rangle,|p_{01}^{(2)}\rangle]$ of these vectors are provided, the soliton solutions (13) will then be completely determined.

In the present case, the block sequence reads $\{s_1,s_2\}=\{2,1\}$, the corresponding invariance matrix B can be readily obtained from the general formula (91) as

$$B=\begin{pmatrix}b_{11} & b_{12} & b_{13}\\ 0 & b_{11} & 0\\ 0 & b_{32} & b_{33}\end{pmatrix},$$

which indeed has five free complex parameters [see Eq. (95)]. The invariance matrix $\overline{B}$ is just the Hermitian conjugate of the B matrix.

To display these soliton solutions, we choose $k_1=1+i$, $|p_{02}^{(1)}\rangle=[-1,i,1-i]^T$, $|p_{01}^{(2)}\rangle=[1,0.5,-1]^T$. When $|p_{01}^{(1)}\rangle=[1,1+i,0.5]^T$ (the generic case), the solutions are plotted in the top row of Fig. 1. In the two nongeneric cases (where some elements of the $|p\rangle$ vectors vanish), $|p_{01}^{(1)}\rangle=[0,1+i,0.5]^T$ and $|p_{01}^{(1)}\rangle=[1,0,0.5]^T$, the solutions are plotted in the second and third rows of Fig. 1, respectively. We see that in the generic case, three sech waves in the three components interact and then separate into the same sech waves with their positions shifted. In other words, this is a $u_1(\text{sech})+u_2(\text{sech})+u_3(\text{sech})\rightarrow u_1(\text{sech})+u_2(\text{sech})+u_3(\text{sech})$ process. What happens is that the initial pumping (u_3) wave breaks up into two sech waves in the other two components (u_1 and u_2), while simultaneously the two initial u_1 and u_2 waves combine into a pumping sech wave.

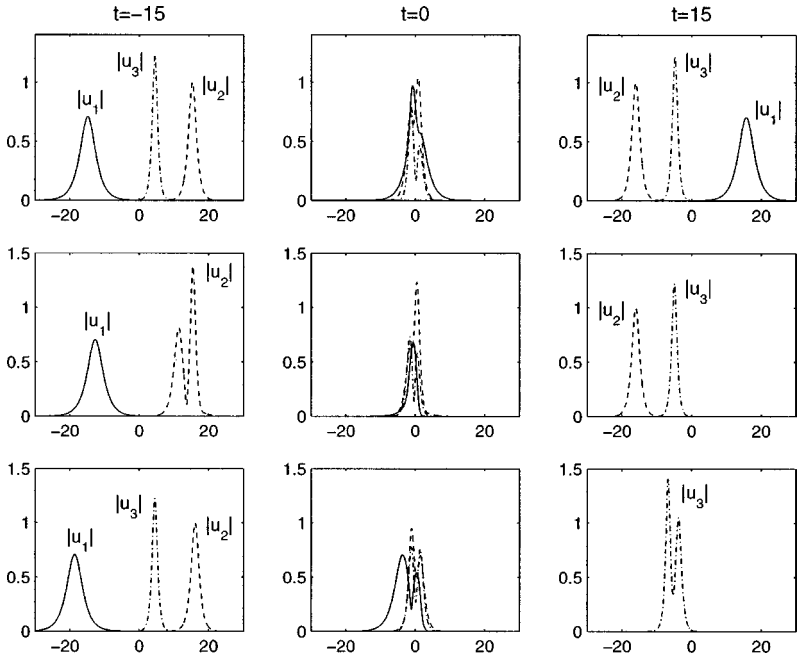

FIG. 1. Soliton solutions in the three-wave system (14) corresponding to a single pair of zeros with rank sequence {1, 2} at time $t=-15$, 0, and 15. Here, $k_1=1+i$, $|p_{02}^{(1)}\rangle=[-1,i,1-i]^T$, $|p_{01}^{(2)}\rangle=[1,0.5,-1]^T$. First row, $|p_{01}^{(1)}\rangle=[1,1+i,0.5]^T$; second row, $|p_{01}^{(1)}\rangle=[0,1+i,0.5]^T$; third row, $|p_{01}^{(1)}\rangle=[1,0,0.5]^T$.

Thus this process is a combination of two subprocesses: $u_3\to u_1+u_2$ and $u_1+u_2\to u_3$. This phenomenon seems related to the rank sequence {1, 2} of the present solitons and the fact that, the rank sequence {1} itself describes the breakup of a pumping sech wave into two nonpumping sech waves, while the rank sequence {2} itself describes the reserve process. In the nongeneric cases, these solutions can describe the $u_1(\text{sech})+u_2(\text{second order})\to u_2(\text{sech})+u_3(\text{sech})$ process, the $u_1(\text{sech})+u_2(\text{sech})+u_3(\text{sech})\to u_3(\text{second order})$ process (see Fig. 1, second and third rows), and many others. In the solutions of Fig. 1, the a_j and b_j parameters are such that $u_2<u_3<u_1$. If $u_1<u_3<u_2$, the processes will be exactly the opposite (see Ref. 22). Thus our solutions can describe the processes reverse to those of Fig. 1 as well.

B. Soliton solutions for two pairs of simple zeros

Here we derive the soliton solutions corresponding to two pairs of simple zeros in the three-wave system (14). Some solutions belonging to this category have been presented in Refs. 26 and 27. But we will show that those solutions are only special (nongeneric) solutions for two pairs of simple zeros. Below, the more general solutions for this case will be presented.

In this case, $r_1^{(1)}=r_1^{(2)}=1$. By using formula (81), for the case of involution (4), for two pairs of zeros, we readily obtain that the number of free complex parameters in the solution is six:

$$\mathcal{N}_{\text{free}}=2(3\times 1+1-1)=6.$$

Indeed, there are two $|p\rangle$ vectors in Eq. (114). Together with the two zeros k_1 and k_2, there are eight complex parameters in the soliton solutions. However, the 2×2 invariance matrix B in this case is diagonal and has two free (diagonal) complex parameters.

Three solutions, with $k_1=1+i$, $k_2=-1+0.5i$ and three different sets of $|p_{01}^{(1)}\rangle$ and $|p_{01}^{(2)}\rangle$ vectors, are displayed in Fig. 2. In the generic case where $|p_{01}^{(1)}\rangle=[1,1+i,0.5]^T$ and $|p_{01}^{(2)}\rangle=[1,0.5,-1]^T$ (see top row of Fig. 2), the solution describes the breakup of a higher-order pumping (u_3) wave into two higher-order u_1 and u_2 waves. This is analogous to solutions for a single pair of elementary zeros with algebraic multiplicity 2 (see Ref. 22). In the nongeneric case

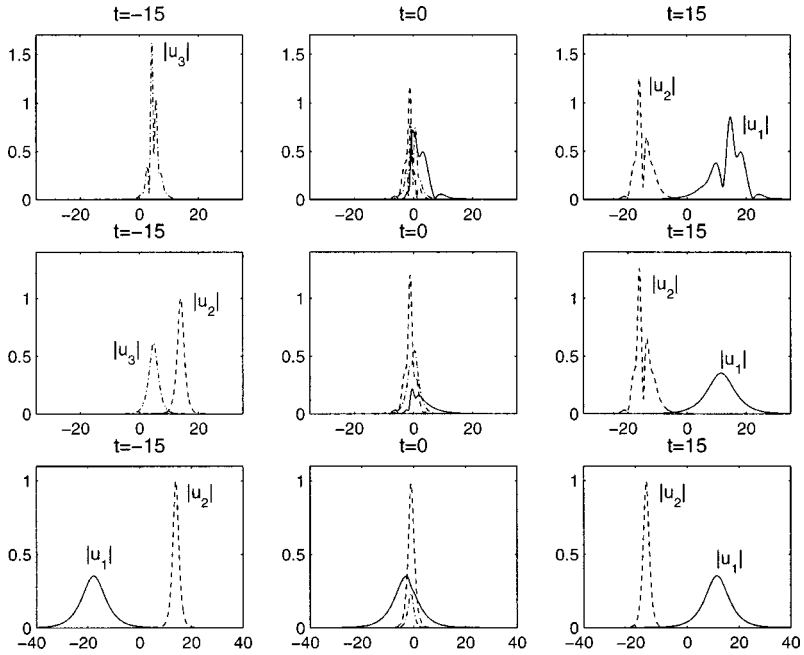

FIG. 2. Soliton solutions in the three-wave system (14) corresponding to two pairs of simple zeros at time $t=-15$, 0, and 15. Here, $k_1=1+i$, $k_2=-1+0.5i$. First row, $|p_{01}^{(1)}\rangle=[1,1+i,0.5]^T$, $|p_{01}^{(2)}\rangle=[1,0.5,-1]^T$; second row, $|p_{01}^{(1)}\rangle=[0,1+i,0.5]^T$, $|p_{01}^{(2)}\rangle=[1,0.5,-1]^T$; third row, $|p_{01}^{(1)}\rangle=[0,1+i,0.5]^T$, $|p_{01}^{(2)}\rangle=[1,0.5,0]^T$.

where $|p_{01}^{(1)}\rangle=[0,1+i,0.5]^T$ and $|p_{01}^{(2)}\rangle=[1,0.5,-1]^T$ (second row in Fig. 2), the present solutions can describe the $u_2(\text{sech})+u_3(\text{sech})\rightarrow u_1(\text{sech})+u_2(\text{second order})$ process. This process has been seen in Ref. 22 for elementary zeros as well. More interestingly, in the nongeneric case when $p_{01}^{(1)}[1]=p_{01}^{(2)}[3]=0$, these solutions describe the elastic interaction of a sech u_1 wave with a sech u_2 wave (see bottom row of Fig. 2). These are precisely the soliton solutions presented in Refs. 26 and 27. We see that these solutions are simply nongeneric solutions for two pairs of simple zeros.

C. Soliton solutions for two pairs of higher-order zeros

Last, we consider two pairs of distinct zeros, one simple and the other one elementary with the algebraic multiplicity 2. Let us say k_1 is the elementary zero, and k_2 is the simple zero. Then the rank sequence for k_1 is $\{1, 1\}$, and the rank sequence for k_2 is $\{1\}$. Thus, $r_1^{(1)}=1$, $r_2^{(1)}=1$, and $r_1^{(2)}=1$. By formula (81), we have

$$\mathcal{N}_{\text{free}}=3(1+1)+1-(1+1)+3\times 1+1-1=8.$$

Indeed, in this case $s_1^{(1)}=2$ and $s_1^{(2)}=1$, hence there are 11 complex parameters in the soliton solutions (nine in the three $|p\rangle$ vectors, plus the two zeros k_1 and k_2). The invariance matrix B can be found from the general formula (91) as

$$B=\begin{pmatrix} b_{11} & b_{12} & 0 \\ 0 & b_{11} & 0 \\ 0 & 0 & b_{33} \end{pmatrix},$$

which has three free complex parameters. Thus $\mathcal{N}_{\text{free}}=11-3=8$ as calculated above.

Three solutions, with $k_1=1+i$, $k_2=-1+0.5i$, $|p_{02}^{(1)}\rangle=[-1,i,1-i]^T$, and three different sets of $|p_{01}^{(1)}\rangle$ and $|p_{01}^{(2)}\rangle$ vectors, are displayed in Fig. 3. In the generic case (first row in Fig. 3),

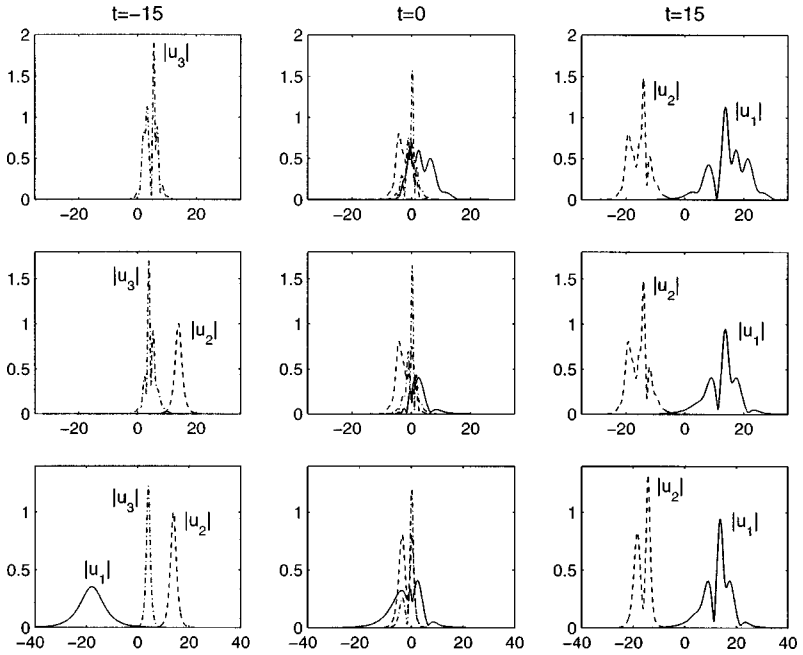

FIG. 3. Soliton solutions in the three-wave system (14) corresponding to two pairs of zeros—one elementary with algebraic multiplicity 2, and the other one simple. Here, $k_1=1+i$ (elementary zero), $k_2=-1+0.5i$ (simple zero), and $|p_{02}^{(1)}\rangle=[-1,i,1-i]^T$. First row, $|p_{01}^{(1)}\rangle=[1,1+i,0.5]^T$, $|p_{01}^{(2)}\rangle=[1,0.5,-1]^T$; second row, $|p_{01}^{(1)}\rangle=[0,1+i,0.5]^T$, $|p_{01}^{(2)}\rangle=[1,0.5,-1]^T$; third row, $|p_{01}^{(1)}\rangle=[0,1+i,0.5]^T$, $|p_{01}^{(2)}\rangle=[1,0.5,0]^T$.

this solution describes the breakup of a higher-order pumping wave (u_3) into the other u_1 and u_2 components (both higher order). In nongeneric cases, it can describe processes such as u_2(sech) $+u_3$(higher order)$\rightarrow u_1$(higher order)$+u_2$(higher order) (second row of Fig. 3), u_1(sech) $+u_2$(sech)$+u_3$(sech)$\rightarrow u_1$(higher order)$+u_2$(higher order) (last row of Fig. 3), and many others. The reverse processes of Fig. 3 can also be described by choosing a_j and b_j values such that $u_1<u_3<u_2$ instead of $u_2<u_3<u_1$ in Fig. 3.

V. CONCLUSION AND DISCUSSION

We have proposed a unified and systematic approach to study the higher-order soliton solutions of nonlinear PDEs integrable by the $N\times N$-dimensional Riemann–Hilbert problem. We have derived the complete solution to the Riemann–Hilbert problem with an arbitrary number of higher-order zeros, and characterized the discrete spectral data. Therefore, we have obtained the most general form of the higher-order multisoliton solutions to nonlinear PDEs integrable through the $N\times N$-dimensional Riemann–Hilbert problem. In other words, the most general reflectionless (soliton) potentials in the N-dimensional Zakharov–Shabat operators have been derived. The eigenfunctions associated with these reflectionless potentials are readily available from our soliton matrices. We have applied these general results to the three-wave interaction system, and new higher-order soliton and two-soliton solutions have been presented. These solutions reveal new processes such as $u_1+u_2+u_3\leftrightarrow u_1+u_2+u_3$. They also reproduce previously known solitons from Refs. 2, 22, 26, and 27 as special cases. Our results can be applied to derive higher-order multisolitons in the NLS equation and the Manakov equations as well, but this is not pursued in this paper.

The results obtained in this paper are significant from both physical and mathematical points of view. Physically, our results completely characterized higher-order solitons and multisolitons in important physical systems such as the three-wave interaction equation, the NLS equation and the Manakov equations. These higher-order solitons can describe new physical processes such as

those displayed in Figs. 1–3. If these integrable equations are perturbed (which is inevitable in a real-world problem), our higher-order solitons then become the starting point for the development of a soliton-perturbation theory which could determine what happens to these higher-order solitons under external or internal perturbations.[34,35] From the mathematical point of view, our results completely characterized the discrete spectral data of higher-order zeros in a general N-dimensional Riemann–Hilbert problem. These results will be useful for many purposes such as proving the completeness of eigenfunctions in a N-dimensional Zakharov–Shabat spectral problem with arbitrary localized potentials. The difficulty of such a proof is caused by higher-order zeros. Hopefully, with our results at hand, this difficulty can be removed.

From a broader perspective, our results are closely related to many other physical and mathematical problems. For instance, the lump solutions in the Kadomtsev–Petviashvili equation are given by the higher-order poles of the time-dependent Schrödinger equation. In Refs. 20 and 21, lump solutions corresponding to certain special higher-order poles were derived, but the most general lump solutions still remain an open question. Note that the time-dependent Schrödinger equation is an infinite-dimensional system compared to our present N-dimensional Riemann–Hilbert system. But the ideas used in this paper might be generalizable to the time-dependent Schrödinger equation as well. This remains to be seen.

APPENDIX: GENERAL RIEMANN–HILBERT PROBLEM WITH ABNORMAL ZEROS

Here we show that our soliton matrices of Sec. III can be generalized to the case of Riemann–Hilbert problem with abnormal zeros. However, due to the lack of important applications, we will show only a simple example, which corresponds to a pair of zeros with different geometric multiplicities but the same algebraic multiplicity. Then we comment on the general case of several nonpaired zeros.

Let us use the simplest example to show the idea behind generalization of our results to the general Riemann–Hilbert problem with abnormal zeros. Consider one pair of zeros $(k_1,\overline{k_1})$ which have the same algebraic multiplicity 2 but different geometric multiplicities, which here will be 1 and 2, respectively. The corresponding soliton matrices are given as follows:

$$\Gamma(k)=I+\frac{(\overline{k_1}-k_1)(|v_1\rangle\langle\overline{v_1}|+|v_2\rangle\langle\overline{v_2}|)}{k-\overline{k_1}}, \tag{A1}$$

$$\Gamma^{-1}(k)=\left(I+\frac{(k_1-\overline{k_1})|v_1\rangle\langle\overline{v_1}|}{k-k_1}\right)\left(I+\frac{(k_1-\overline{k_1})|v_2\rangle\langle\overline{v_2}|}{k-k_1}\right), \tag{A2}$$

with the conditions that $\langle\overline{v_j}|v_j\rangle=1$, $\langle\overline{v_2}|v_1\rangle=0$, and $\langle\overline{v_1}|v_2\rangle\neq 0$. To verify that the above matrices are indeed inverse to each other it is enough to rewrite the matrix $\Gamma(k)$ in the form

$$\Gamma(k)=\left(I+\frac{(\overline{k_1}-k_1)|v_2\rangle\langle\overline{v_2}|}{k-\overline{k_1}}\right)\left(I+\frac{(\overline{k_1}-k_1)|v_1\rangle\langle\overline{v_1}|}{k-\overline{k_1}}\right) \tag{A3}$$

and take into account that $P_j \equiv |v_j\rangle\langle\overline{v_j}|$ is a projector. Equations (A2) and (A3) are in fact the product representations of the form (27). Now let us show that there are exactly two solutions to $\langle\overline{p}|\Gamma^{-1}(\overline{k_1})=0$. Indeed, the corresponding null vectors are as follows:

$$\langle\overline{p_1}|=\langle\overline{v_1}|, \quad \langle\overline{p_2}|=\langle\overline{v_2}|. \tag{A4}$$

This is due to the fact that $\Gamma^{-1}(\overline{k_1})=(I-P_1)(I-P_2)$. But, on the other hand, there is just one solution to $\Gamma(k_1)|p\rangle=0$: $|p_1\rangle=|v_1\rangle$. Suppose that there is another solution $|p_2\rangle$ to $\Gamma(k_1)|p\rangle=0$ linearly independent from $|p_1\rangle$. We have then using formula (A1) for $\Gamma(k_1)$,

$$|p_2\rangle=|v_1\rangle\langle\overline{v_1}|p_2\rangle+|v_2\rangle\langle\overline{v_2}|p_2\rangle. \tag{A5}$$

Thus $|p_2\rangle=a|v_1\rangle+b|v_2\rangle$. Using this in formula (A5) we get, due to $\langle\overline{v_2}|v_1\rangle=0$ and $\langle\overline{v_1}|v_2\rangle\neq 0$,

$$a|v_1\rangle\langle\overline{v_1}|v_2\rangle=0,$$

which is a contradiction, since $a\neq 0$.

The soliton matrices given by formulas (A1)–(A2) have the following form in the standard notations of Lemma 1 of Sec. III:

$$\Gamma(k)=I+\frac{|\overline{q_1}\rangle\langle\overline{p_2}|+|\overline{q_2}\rangle\langle\overline{p_1}|}{k-\overline{k_1}}, \tag{A6}$$

$$\Gamma^{-1}(k)=I+\frac{|p_1\rangle\langle q_2|+|p_2\rangle\langle q_1|}{k-k_1}+\frac{|p_1\langle q_1|}{(k-k_1)^2}, \tag{A7}$$

where

$$|\overline{q_1}\rangle=(\overline{k_1}-k_1)|v_2\rangle, \quad |\overline{q_2}\rangle=(\overline{k_1}-k_1)|v_1\rangle, \quad \langle q_1|=(k_1-\overline{k_1})^2\langle\overline{v_1}|v_2\rangle\langle\overline{v_2}|,$$

$$\langle q_2|=(k_1-\overline{k_1})\langle\overline{v_1}|, \quad |p_2\rangle=\frac{|v_2\rangle}{(k_1-\overline{k_1})\langle\overline{v_1}|v_2\rangle}.$$

Notice that $\Gamma(k)$ has two blocks of size 1, while $\Gamma^{-1}(k)$ has one block of size 2.

In general, for one pair of zeros with different geometric multiplicities, the soliton matrices have the structure of Lemma 1 but with different numbers of blocks in $\Gamma(k)$ and $\Gamma^{-1}(k)$, while the total number of the $|p\rangle$ and $\langle\overline{p}|$ vectors appearing in these matrices is the same and equals to the order of the pair of zeros. One can proceed to derive the representations similar to those in Lemma 4 for this case. Evidently, due to the way of the derivation, the formulas will be similar with the only difference in the number of blocks and block sizes in $\Gamma(k)$ and $\Gamma^{-1}(k)$.

In the more general case of the Riemann–Hilbert problem with abnormal zeros, the zeros can be nonpaired (for instance, zero of order 2 in C_+ and two simple zeros in C_-). Formally, this case can be obtained by ''splitting'' some of the paired zeros into several distinct zeros in the soliton matrices $\Gamma(k)$ and $\Gamma^{-1}(k)$ discussed above, since this limit is obviously regular [the geometric multiplicity of the zero to be split should be at least equal to the number of the new zeros generated in this way, thus providing for the needed number of blocks; formula (A6), for instance, allows splitting of the zero $k=\overline{k_1}$ of $\Gamma^{-1}(k)$ into two simple zeros]. Thus, the most general case can be handled starting from the case of just one pair of zeros, i.e., the case discussed above. The explicit expressions for the soliton matrices $\Gamma(k)$ and $\Gamma^{-1}(k)$ will involve similar relations between the numbers of zeros, their geometric multiplicities and the numbers and sizes of the ν blocks of vectors as those in Lemma 1, though, obviously, with different particular numbers for each of the two matrices.

Isomonodromy deformations for the ZS-AKNS system with quadratic spectral variables

Derchyi Wu[a)]
Institute of Mathematics, Academia Sinica, Taipei, Taiwan

(Received 23 April 2003; accepted 13 May 2003)

We solve the monodromy problem and prove the Painleve property for self-similar ZS-AKNS flows with a quadratic spectral variable in this report. In particular, we obtain meromorphic solutions for the Cauchy problem of the self-similar derivative nonlinear Schrödinger equation. © *2003 American Institute of Physics.*

I. INTRODUCTION

The six Painleve transcendents PI-PVI, were introduced by Painleve [Clarkson (1990)] and Gambier (1910) at the beginning of the 20th century from strictly mathematical consideration. They found second order ordinary differential equations of certain general type can either be integrated in terms of known functions or can be reduced to one of the six Painleve equations. Now Painleve transcendents have appeared in a wide range of physical applications [Fokas *et al.* (1988); Ablowitz and Clarkson (1991)].

One of the most important developments in Painleve theory is the discovery that Painleve equations are the compatibility conditions (or isomonodromy conditions) of suitable overdetermined linear systems with regular or irregular singular points [Fuchs (1907), Garnier (1912), Schlesinger (1912), Flaschka and Newell (1980), Jimbo *et al.* (1981a), Jimbo and Miwa (1981, 1982)]. Therefore the Cauchy problem of a given Painleve equation can be formulated as solving the inverse monodromy problem of the associated overdetermined system. Besides, a close connection between Painleve equations and integrable systems was discovered by Ablowitz (1977), Ablowitz *et al.* (1980), Fokas *et al.* (1982,1988,1992), Olver, etc. They found similarity reductions of integrable systems give rise to Painleve transcendents.

In particular, Beals and Sattinger (1993) derived the overdetermined linear systems for the self-similar solutions of the ZS-AKNS (*with linear spectral variables*) and Gelfand–Dikii flows and studied the associated inverse monodromy problems. More precisely, the corresponding overdetermined linear systems concerned are

$$\begin{aligned} \frac{\partial \Psi}{\partial x} &= [zJ + q_1(x)]\Psi, \\ z\frac{\partial \Psi}{\partial z} &= \sum_{j=0}^{n} z^j A_j'(x)\Psi, \end{aligned} \tag{1.1}$$

and

$$\begin{aligned} \frac{\partial \Psi}{\partial x} &= [J_z + q_2(x)]\Psi, \\ z\frac{\partial \Psi}{\partial z} &= A'(x,z)\Psi, \end{aligned} \tag{1.2}$$

a)Electronic mail: mawudc@math.sinica.edu.tw

where $x \in \mathbf{R}$, $z \in \mathbf{C}$, J_z and $A(x,z)$ are a matrix and certain polynomial in z^n. (There are recursive formulas between q_1 and A_j', q_2 and A'. See Beals and Sattinger (1993).) They gave a more transparent and simpler treatment for the monodromy problem of some general isomonodromy equations, including Painleve Π, self-similar solutions of Korteweg-de Vries (KdV), modified KdV, nonlinear Schrödinger, and Boussinesq equations.

Under the framework of their results, we solve the monodromy problem for *self-similar ZS-AKNS flows with quadratic spectral variables* in this report. That is, instead of (1.1), we consider the linear system

$$\begin{aligned} \frac{\partial \Psi}{\partial x} &= [z^2 J + z q(x) + p(x)]\Psi, \\ z\frac{\partial \Psi}{\partial z} &= \sum_{j=0}^{2n} z^j A_j(x)\Psi, \end{aligned} \tag{1.3}$$

with $x \in \mathbf{R}$, $z \in \mathbf{C}$. [The constraints satisfied by p, q, and A_j will be explained in (2.1), (2.2) and Theorem 1 of Sec. II.] In particular, meromorphic solutions for the Cauchy problem of the self-similar derivative nonlinear Schrödinger equation (DNLS) are obtained. We also characterize rational solutions of the isomonodromy deformation in our case. More precisely, we prove that generically all rational solutions of (1.3) can be reduced to those of (1.1).

The paper is organized as follows. In Sec. II we introduce the ZS-AKNS flows and self-similar ZS-AKNS flows. Then we derive the overdetermined system for self-similar ZS-AKNS flows. In Sec. III we study the associated direct monodromy problem. We will construct appropriate holomorphic eigenfunctions and study their relations. Our monodromic data are constructed from these relations. We also characterize the monodromic data and justify that self-similar ZS-AKNS flows are isomonodromy deformations. In Sec. IV we study the inverse monodromy problem by solving a Riemann–Hilbert problem and use the analytic and algebraic arguments of the inverse scattering theory in Beals and Caifman (1984) to solve the Cauchy problem of the self-similar ZS-AKNS flow equation. Section V is devoted to the characterization of the rational solutions of the self-similar ZS-AKNS flow equations.

II. ZS-AKNS AND SELF-SIMILAR ZS-AKNS FLOWS

We define the ZS-AKNS-flows according to the work of Lee (1989). First of all, let J be a constant diagonal, traceless matrix with diagonal entries $\lambda_1, \lambda_2, \ldots, \lambda_d$. Let $Q(x,t)$ be off-diagonal, the diagonal part of $P(x,t)$ equal to that of $Q(\mathrm{ad}\, J)^{-1}Q$, and Q, P be smooth. Then a formal eigenfunction $\Phi(x,z) = M(x,z)e^{xz^2J} \overset{\text{def}}{=} \sum_{j=0}^{\infty} f_j(x) z^{-j}\, e^{xz^2J}$ of the first formula in (1.3) exists. That is $f_0 = 1$, $(\partial/\partial x - z^2\, \mathrm{ad}\, J - zQ - P)\sum_{j=0}^{k} f_j z^{-j} = \mathcal{O}(z^{-k+1})$, $k = 1,2,\ldots$. Moreover, let μ be any constant diagonal traceless matrix with diagonal entries $\mu_1, \mu_2, \ldots, \mu_d$, then

$$M\mu M^{-1} \sim \mu + \frac{\mathcal{F}_1}{z} + \frac{\mathcal{F}_2}{z^2} + \cdots. \tag{2.1}$$

It can be shown that the coefficients $\mathcal{F}_j = \mathcal{F}_{j,J,\mu}(x,t)$ are independent of the choice of formal solution M and satisfy

$$\begin{aligned} &\mathcal{F}_0 = \mu, \\ &[J, \mathcal{F}_1] + [Q, \mu] = 0, \\ &\left[\frac{\partial}{\partial x} - P, \mathcal{F}_k\right] - [J, \mathcal{F}_{k+2}] - [Q, \mathcal{F}_{k+1}] = 0, \quad k = 0,1,2,\ldots, \end{aligned} \tag{2.1'}$$

$\mu+\frac{\mathcal{F}_1}{z}+\frac{\mathcal{F}_2}{z^2}+\cdots$ has the same characteristic or minimal polynomial as μ.

Therefore $\mathcal{F}_{2j+1}$ and $\mathcal{F}_{2j+2}$ are traceless polynomials in $\partial^r Q/\partial x^r$, $\partial^s P/\partial x^s$, for $r, s \in \{0,1,...,j\}$.

Definition 1: For $t \in \mathbf{R}$, $x \in \mathbf{R}$, the ZS-AKNS flow is defined by the system of nth order partial differential equations

$$\frac{\partial Q}{\partial t}=[J,\mathcal{F}_{2n+1}],$$

$$\frac{\partial P}{\partial t}=[J,\mathcal{F}_{2n+2}]+[Q,\mathcal{F}_{2n+1}],$$

with $\mathcal{F}_j$ defined by (2.1).

As is well known, the ZS-AKNS flow has the Lax pair:

$$\begin{aligned}\frac{\partial \Phi}{\partial x}(x,z,t)&=[z^2J+zQ+P]\Phi(x,z,t),\\ \frac{\partial \Phi}{\partial t}(x,z,t)&=[\mu z^{2n}+\mathcal{F}_1 z^{2n-1}+\cdots+\mathcal{F}_{2n}]\Phi(x,z,t),\end{aligned} \tag{2.2}$$

where $\mathcal{F}_j$ are defined by (2.1).

Definition 2: The ZS-AKNS flow is self-similar if one of the following equivalent conditions is fulfilled:

(1) There exist constants α, β, such that the eigenfunction Φ of the Lax pair (2.2) *is invariant under $T_{\lambda,\alpha,\beta}$ for $\forall \lambda \in \mathbf{C}$;*

(2) There exist constants α, β, γ such that for $\forall \lambda \in \mathbf{C}$,

$$\lambda^{\gamma} Q(\lambda^{\alpha}x,\lambda^{\beta}t)=Q(x,t),$$

$$\lambda^{2\gamma} P(\lambda^{\alpha}x,\lambda^{\beta}t)=P(x,t),$$

where $T_{\lambda,\alpha,\beta}$ is the scaling operator: $T_{\lambda,\alpha,\beta}f(x,z,t)=f(\lambda^{\alpha}x,\lambda z,\lambda^{\beta}t)$.

Lemma 1: For the scaling operator of self-similar ZS-AKNS flows, the indices $(\alpha,\beta,\gamma)=(-2,-2n,-1)$.

Proof:

$$\frac{\partial}{\partial x}(T_{\lambda,\alpha,\beta}\Phi)=\lambda^{\alpha}T_{\lambda,\alpha,\beta}([z^2J+zQ(x,t)+P(x,t)]\Phi)=\lambda^{\alpha}[\lambda^2 z^2 J+\lambda z Q(\lambda^{\alpha}x,\lambda^{\beta}t)$$

$$+P(\lambda^{\alpha}x,\lambda^{\beta}t)]T_{\lambda,\alpha,\beta}\Phi=[z^2J+zQ(x,t)+P(x,t)]\Phi.$$

Thus $\alpha=-2$ and $\gamma=-1$. Similarly we obtain $\beta=-2n$ by equating

$$\frac{\partial}{\partial t}(T_{\lambda,\alpha,\beta}\Phi)=\lambda^{\beta}T_{\lambda,\alpha,\beta}\frac{\partial \Phi}{\partial t}=\lambda^{\beta}[(\lambda z)^{2n}\mu+(\lambda z)^{2n-1}\mathcal{F}_1(\lambda^{\alpha}x,\lambda^{\beta}t)+\cdots$$

$$+\mathcal{F}_{2n}(\lambda^{\alpha}x,\lambda^{\beta}t)]T_{\lambda,\alpha,\beta}\Phi=[z^{2n}\mu+z^{2n-1}\mathcal{F}_1+\cdots+\mathcal{F}_{2n}]\Phi. \qquad \square$$

Using the scaling operator, we derive the overdetermined system for the self-similar ZS-AKNS flow.

Theorem 1: *The ZS-AKNS flow (2.2) is self-similar if and only if*

$$\frac{\partial \Psi}{\partial x}(x,z)=[z^2J+zq(x)+p(x)]\Psi(x,z), \tag{2.3.1}$$

$$z\frac{\partial \Psi}{\partial z}(x,z)=[2n(z^{2n}\mu+z^{2n-1}F_1(x)+\cdots+F_{2n}(x))+2x(z^2J+zq(x)+p(x))]\Psi(x,z)$$

$$\overset{\text{def}}{=}\sum_{j=0}^{2n}A_j(z)z^j\Psi(x,z)\overset{\text{def}}{=}A(x,z)\Psi(x,z), \tag{2.3.2}$$

with

$$m\mu m^{-1}=\mu+\frac{F_1}{z}+\frac{F_2}{z^2}+\cdots,$$

and me^{xz^2J} *is a formal solution of (2.3.1). Moreover*

$$Q(x,1)=q(x),\quad P(x,1)=p(x),\quad \mathcal{F}_j(x,1)=F_j(x),\quad \Phi(x,z,1)=\Psi(x,z).$$

Proof: Suppose (Q,P) is a self-similar ZS-AKNS flow. Then Definition 2 and Lemma 1 imply that

$$\Phi(x,z,t)=\Phi(\lambda^{-2}x,\lambda z,\lambda^{-2n}t). \tag{2.4}$$

So Φ is a function of x, z only. Set $\lambda^{-2n}t=1$. Let

$$\Phi(x,z,t)=\Phi(t^{-1/n}x,t^{1/2n}z,1)\equiv\Psi(t^{-1/n}x,t^{1/2n}z).$$

Differentiating (2.4) with respect to λ at $\lambda=1$, we get

$$-2x\frac{\partial \Phi}{\partial x}+z\frac{\partial \Phi}{\partial z}-2nt\frac{\partial \Phi}{\partial t}=0. \tag{2.5}$$

Evaluating at $t=1$ and using the Lax pair (2.2), we obtain (2.3.1) and (2.3.2). So the if part is proved. To show the other direction, suppose $\Psi(x,z)$ satisfies (2.3.1) and (2.3.2). Let $\Phi(x,z,t)=\Psi(t^{-1/n}x,t^{1/2n}z)$. Thus $\Phi(x,z,t)=\Phi(\lambda^{-2}x,\lambda z,\lambda^{-2n}t)=\Phi(t^{-1/n}x,t^{1/2n}z,1)$. Therefore we obtain the Euler equation (2.4). Combined with (2.3.1) and (2.3.2) this induces

$$\frac{\partial \Phi}{\partial x}(x,z,t)=[z^2J+zt^{-1/2n}q(t^{-1/n}x)+t^{-1/n}p(t^{-1/n}x)]\Phi(x,z,t)$$

$$\overset{\text{def}}{=}[z^2J+zQ(x,t)+P(x,t)]\Phi(x,z,t),$$

$$\frac{\partial \Phi}{\partial t}(x,z,t)=[z^{2n}\mu+z^{2n-1}t^{-1/2n}F_1(t^{-1/n}x)+\cdots+t^{-1}F_{2n}(t^{-1/n}x)]\Phi(x,z,t)$$

$$\overset{\text{def}}{=}[z^{2n}\mu+z^{2n-1}\mathcal{F}_1(x,t)+\cdots+\mathcal{F}_{2n}(x,t)]\Phi(x,z,t).$$

Note that both $M\mu M^{-1}$ and $\mu+\mathcal{F}_1/z+\mathcal{F}_2/z^2+\cdots$ are invariant under $T_{-2,-2n,-1}$. Here $\Phi(x,z,t)=M(x,z,t)e^{xz^2J}=m(t^{-1/n}x,t^{1/2n}z)e^{xz^2J}$ is a formal solution of $\partial\Phi/\partial x=[z^2J+zQ+P]\Phi$. In addition, $(M\mu M^{-1})(x,1)=m\mu m^{-1}=\mu+F_1/z+F_2/z^2+\cdots=\mu+[\mathcal{F}_1(x,1)]/z$

$+[\mathcal{F}_2(x,1)]/z^2+\cdots$. So $M\mu M^{-1}=\mu+\mathcal{F}_1/z+\mathcal{F}_2/z^2+\cdots$. Therefore (Q,P) is a self-similar ZS-AKNS flow. □

Theorem 2: *The self-similar ZS-AKNS flow satisfies the nonlinear ordinary differential system*

$$\begin{aligned} 2n[J,F_{2n+1}]+(2xq)_x-q=0,\\ 2n[J,F_{2n+2}]+2n[q,F_{2n+1}]+(2xp)_x=0, \end{aligned} \tag{2.6}$$

where F_j are defined as in Theorem 1.

Proof: The theorem can be proved by equating the compatibility condition of (2.3.1) and (2.3.2) and using the recursive formula (2.1′) and $F_j(x)=\mathcal{F}_j(x,1)$. □

Example 1: The derivative nonlinear Schrödinger equation (DNLS),

$$u_t=iu_{xx}\pm(|u|^2u)_x,$$

was first derived by plasma physicists [Mio *et al.* (1976), Mjothus (1976)]. Kaup and Newell obtained the soliton solutions of DNLS in Kaup and Newell (1978), Lee (1989) solved the Cauchy problem of DNLS by studying the associated scattering problem of

$$v_t=\frac{i}{2}v_{xx}\mp\frac{1}{2}v^2\bar{v}_x+\frac{i}{4}v|v|^4. \tag{2.7}$$

Note that (2.7) possesses the Lax Pair

$$\begin{aligned} \frac{\partial\Phi}{\partial x}&=[z^2J+zQ+P]\Phi,\\ \frac{\partial\Phi}{\partial t}&=[z^4\mu+z^3\mathcal{F}_1+\cdots+\mathcal{F}_4]\Phi. \end{aligned} \tag{2.8}$$

with $Q=\left(\begin{smallmatrix}0 & v\\ \pm\bar{v} & 0\end{smallmatrix}\right)$, $P=Q(\mathrm{ad}\,J)^{-1}Q=\pm|v|^2/2i\left(\begin{smallmatrix}1 & 0\\ 0 & -1\end{smallmatrix}\right)$, $J=\mu=\left(\begin{smallmatrix}-i & 0\\ 0 & i\end{smallmatrix}\right)$, $\mathcal{F}_0=\mu$, $\mathcal{F}_1=Q$, $\mathcal{F}_2=P$, $\mathcal{F}_3=1/2i\left(\begin{smallmatrix}0 & v\\ \pm\bar{v}_x & 0\end{smallmatrix}\right)$, and $\mathcal{F}_4=(1/(2i)^3|v|^4\pm1/(2i)^2(v\bar{v}_x-v_x\bar{v}))\left(\begin{smallmatrix}1 & 0\\ 0 & -1\end{smallmatrix}\right)$. Applying Theorems 1 and 2, we then obtain the overdetermined system

$$\begin{aligned} \frac{\partial\Psi}{\partial x}&=[z^2J+zq+p]\Psi,\\ z\frac{\partial\Psi}{\partial z}&=\left[4Jz^4+4qz^3+(4p+2xJ)z^2+\left(2xq-2i\begin{pmatrix}0 & -v_x\\ \pm\bar{v}_x & 0\end{pmatrix}\right)z+2xp\right.\\ &\quad\left.+\left(-\frac{1}{2i}|v|^4\mp(v\bar{v}_x-v_x\bar{v})\right)\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}\right]\Psi. \end{aligned}$$

and nonlinear evolution equation of the self-similar DNLS

$$(2xv)_x-v+2iv_{xx}\mp2v^2\bar{v}_x+iv|v|^4=0. \tag{2.9}$$

III. THE FORWARD MONODROMY PROBLEM

Given an initial value of the self-similar ZS-AKNS flow, we will construct special eigenfunction of the system (2.3.1) and (2.3.2) and extract monodromy data from the relations between these eigenfunctions. We first define the characteristic lines and sectors with respect to (2.3.1) and (2.3.2).

Definition 3: The characteristic lines and sectors are

$$\Sigma(j,k)=\{z\in\mathbf{C}:\quad \mathrm{Re}\, z^{2n}(\mu_j-\mu_k)=0\},$$

$$\Sigma=\cup_{j<k}\Sigma(j,k),$$

$\tilde{\Omega}_\nu$ = *a region bounded by two rays from* Σ, *and its interior contains exactly one ray from each* $\Sigma(j,k)$.

Lemma 2: Suppose that (q,p) *is a self-similar ZS-AKNS flow, i.e., satisfies (2.6). Then for* $\forall x\in\mathbf{R}$, $\forall\tilde{\Omega}_\nu$, *there exists a unique holomorphic solution* Ψ_ν *of (2.3.1) and (2.3.2). Moreover,*

$$\Psi_{\nu+1}(x,z)=\Psi_\nu(x,z)S_\nu,\quad z\in\tilde{\Omega}_\nu\cap\tilde{\Omega}_{\nu+1},$$

$$\Psi_\nu=m_\nu e^{z^2xJ+z^{2n}\mu},\quad m_\nu\sim\sum_{j=0}^{\infty}z^{-j}f_j(x),\quad f_0=1.$$

Here S_ν, *certain constant matrices, are called the Stokes matrices.*

Proof: Our proof follows from a close adaptation of the argument in Beals and Sattinger (1993). First of all, let $f(x,z)=\Sigma_{j=0}^{2n}z^{-j}f_j(x)$, with $f_0=1$, $(\partial/\partial x-z^2\mathrm{ad}\,J-zq-p)\Sigma_{j=0}^{N}z^{-j}f_j(x)=\mathcal{O}(z^{-N+1})$, $N=1,...,2n$. Now we look for a solution of (2.3.2) in the form of $\Psi=f\hat{\Psi}$. Then

$$\frac{\partial\hat{\Psi}}{\partial z}=(2n\mu z^{2n-1}+2xzJ)\hat{\Psi}+r(x,z)\hat{\Psi},\quad r(x,z)=\mathcal{O}\left(\frac{1}{|z|^2}\right).$$

Set $\hat{\Psi}=\hat{m}e^{\Phi}$, $\Phi=z^{2n}\mu+xz^2J$. Then the above differential system is converted into

$$\hat{m}(x,z)=1-\int_{\gamma_z}e^{\Phi(z)-\Phi(\xi)}r(\xi)\hat{m}(x,\xi)e^{-\Phi(z)+\Phi(\xi)}\mathrm{d}\xi. \tag{3.1}$$

Note a proper contour γ_x in

$$\Sigma_{x,z}(j,k)=\{\xi\in\mathbf{C}:\mathrm{Re}\{(z^{2n}-\xi^{2n})(\mu_j-\mu_k)+(z^2-\xi^2)(x\lambda_j-x\lambda_k)\}=0\}$$

can be chosen to show the convergence of the integral representation (3.1). So Ψ_ν exists, is holomorphic in $\tilde{\Omega}_\nu$, and satisfies (2.3.2). The uniqueness of Ψ_ν follows from the asymptotic behavior of m_ν and the property that interior of $\tilde{\Omega}_\nu$ contains exactly one ray from each $\Sigma(j,k)$.

Now we need to justify that Ψ_ν satisfies (2.3.1). Let $\tilde{\Psi}=[\partial/\partial x-(z^2J+zq+p)]\Psi_\nu$. By (2.6), we obtain $\tilde{\Psi}_\nu=\Psi_\nu T(x)$. Hence

$$m_\nu^{-1}\left[\frac{\partial}{\partial x}-(z^2J+zq+p)\right]m_\nu=e^{\Phi}T(x)e^{-\Phi}.$$

Comparing the off-diagonal entries of both sides of the above identity and observing that left-hand side grows polynomially, the right-hand side grows exponentially. So $T(x)$ must be a diagonal matrix. Moreover, the leading term of the left-hand side must be off-diagonal by the properties of J, q, and p. So $T(x)\equiv 0$. □

To analyze the monodromy data at the origin, we first define a generic condition for the potential (q,p).

Definition 4: The potential (q,p) *is proper if (2.3.2) admits a fundamental solution of the form*

$$\Psi(x_0,z)=\omega(x_0,z)z^{A_0(x_0)},\quad \omega(x_0,\cdot)\ \textit{entire},\ \ \omega(x_0,0)=1,$$

where $x_0 \in \mathbf{R}$, *and* $A_0(x_0)=2x_0p(x_0)+2nF_{2n}(x_0)$ *is the leading coefficient of the right-hand side of (2.3.2).*

By (2.6) and the proper condition, we can construct an eigenfunction at the origin.

Lemma 3: Suppose that (q,p) *is a proper self-similar ZS-AKNS flow. Then there is a fundamental solution* $\Psi_0(x,z)$ *of (2.3.1) and (2.3.2) which has the form*

$$\Psi_0(x,z)=f(x,z)z^{A_0(x_0)}, \quad z\in \mathbf{C}\backslash 0,$$

with $f(x,\cdot)$ *entire,* $f(x_0,0)=1$.

So the eigenfunction Ψ_0 has monodromy data $A_0(x_0)$ at the origin. Comparing the eigenfunctions Ψ_ν and Ψ_0 obtained by Lemmas 2 and 3, we obtain the following lemma which describes the relation between the monodromy data at the origin and the Stokes matrices (monodromy data at the infinity).

Lemma 4: Suppose that (q,p) *is a proper self-similar ZS-AKNS flow. Then uniquely there exist constant connection matrices* C_ν *such that* $\Psi_\nu C_\nu^{-1}z^{-A_0(x_0)}$ *is regular and*

$$C_\nu^{-1}e^{-2\pi iA_0(x_0)}C_\nu=S_\nu S_{\nu+1}\cdots S_{\nu-1}.$$

Proof: First we note that from Lemmas 2 and 3, we have that Ψ_ν and Ψ_0 satisfy (2.3.1) and (2.3.2). So there exist connection matrices C_ν, constant matrices, such that

$$\Psi_\nu=\Psi_0C_\nu. \tag{3.2}$$

Hence $\Psi_\nu C_\nu^{-1}z^{-A_0(x_0)}$ is regular. Now by (3.2) and Lemma 3, we have

$$\Psi_\nu(ze^{2\pi i})=\Psi_0(z)e^{2\pi iA_0}C_\nu,$$

and thus

$$\Psi_\nu(ze^{2\pi i})\{S_\nu S_{\nu+1}\cdots S_{\nu-2}S_{\nu-1}\}^{-1}=\Psi_\nu(z)C_\nu^{-1}e^{2\pi iA_0}C_\nu.$$

□

Definition 5: The monodromy transform for a proper self-similar ZS-AKNS flow (q,p) *is defined by:*

$$M(q,p)=\{A_0(x_0),C_\nu,S_\nu,J,\mu\}.$$

Note that through the proofs of Lemmas 2–4 and Coddington and Levinson (1955), this definition depends only on the n-jet of q and p at x_0.

So the nonlinear ordinary differential system (2.6) is an isomonodromy deformation. Note that the monodromic data has the following constraints by Lemmas 2–4.

Theorem 3: *For a proper self-similar ZS-AKNS flow, the monodromic data* $M(q,p)=\{A_0,C_\nu,S_\nu,J,\mu\}$ *satisfies the necessary conditions*

$$\begin{gathered}
(1)\ \ tr\ \ A_0=0,\\
(2)\ \ \det C_\nu=1,\\
(3)\ \ e^{-\Phi}S_\nu e^{\Phi}\ \ \text{is bounded as}\ \ z\to\infty\ \ in\ \ \tilde{\Omega}_\nu\cap\tilde{\Omega}_{\nu+1}, S_{jj}=1,\ \ \Phi=z^{2n}\mu+xz^2J,\\
(4)\ \ C_\nu^{-1}e^{-2\pi iA_0}C_\nu=S_\nu S_{\nu+1}\ldots S_{\nu-1}.
\end{gathered} \tag{3.3}$$

IV. THE INVERSE MONODROMY PROBLEM

We state the main theorem

Theorem 4: *The Cauchy problem of the isomonodromy equation (2.6) can be solved uniquely. Moreover, the solution can be extended meromorphically to* $x \in \mathbf{C}$. *So the self-similar ZS-AKNS flow (2.6) is a Painleve transcendent.*

Proof: Given an initial data $\{q(x_0),(\mathrm{d}/\mathrm{d}x)q(x_0),(\mathrm{d}/\mathrm{d}x)p(x_0),\ldots,(\mathrm{d}^j/\mathrm{d}x^j)q(x_0),(\mathrm{d}^j/\mathrm{d}x^j)p(x_0),\ldots,(\mathrm{d}^{n-1}/\mathrm{d}x^{n-1})q(x_0),(\mathrm{d}^{n-1}/\mathrm{d}x^{n-1})p(x_0)\}$, we get $(\mathrm{d}^n/\mathrm{d}x^n)q(x_0)$, and $(\mathrm{d}^n/\mathrm{d}x^n)p(x_0)$ by solving the isomonodromic equation (2.6) at x_0. Then we can apply Lemmas 2–4 to construct eigenfunction $\Psi(x_0,z)$, $\Psi_0(x_0,z)$ and obtain the monodromic data $\{A_0(x_0),C_\nu,S_\nu,J,\mu\}$ such that the monodromy data satisfy the necessary condition (3.3). [Note that even if (q,p) is not proper, we still can obtain modified versions of Lemmas 3 and 4—Beals and Sattinger (1993).]

Now we formulate the Riemann–Hilbert problem: solving a piecewise holomorphic function $M=\{M_0,M_\nu\}$, such that

$$M_0 \text{ defined in } \{z:|z|\leqslant 1\},$$

$$M_\nu \text{ defined in the region bounded by } S^1,\Gamma_{\nu+1}\cap\{z:|z|\geqslant 1\}, \quad \text{and } \Gamma_\nu\cap\{z:|z|\geqslant 1\},$$

$$M_{\nu+1}=M_\nu e^{\Phi}S_\nu e^{-\Phi}, \text{ on } \Gamma_\nu\cap\{z:|z|>1\}, \quad \Phi=z^{2n}\mu+xz^2J, \tag{4.1}$$

$$M_0=M_\nu C_\nu^{-1}z^{-A_0(x_0)}, \text{ on } S^1$$

$$M(x,\cdot)\text{tends to } 1, \text{ as } |z|\to\infty,$$

where Γ_ν is a ray in the intersection $\tilde{\Omega}_\nu\cap\tilde{\Omega}_{\nu+1}$.

One can justify the cyclic product condition around each intersection point of the contour is fulfilled, since it is as $x=x_0$. Then the Riemann–Hilbert problem can be solved by applying the theory of Beals and Coifman (1984), actually, we first find a piecewise rational function u (rational except on $\Gamma_\nu\cap\{z:|z|>1\}\cup S^1$) such that the jumps of u are close enough to those of (4.1) [Lemma 10.2, Beals and Coifman (1984)]. Then (4.1) is reduced to a solution of a small norm Riemann–Hilbert problem [Lemma 10.18, Beals and Coifman (1984)]. Since the kernel of the integral equation and the jumps of u depend on x holomorphically, so M depends on x meromorphically.

Now let us set $\Psi_\nu(x,z)=M_\nu e^{\Phi}$, for $z\in\Omega_\nu\cap\{z\in\mathbf{C}:|z|\geqslant 1\}$ and extend Ψ_ν to $z\in\Omega_\nu\cap\{z\in\mathbf{C}:|z|\leqslant 1\}$ by setting $\Psi_\nu(x,z)=M_0z^{A_0(x_0)}C_\nu$. Here $\{\Omega_\nu\}$ are the components of $\mathbf{C}\backslash(\cup\Gamma_\nu)$. To prove the solvability, we need to show that $\Psi(x,z)$ satisfies (2.3.1) and (2.3.2).

Define $m_\nu=\Psi_\nu(x,z)e^{-\Phi}$. Therefore $\det m$ is continuous, entire, and tending to 1 at ∞. So m is invertible. Now we can justify that

$$\left\{\left(\frac{\partial}{\partial x}-z^2\mathrm{ad}\,J\right)m\right\}m^{-1}$$

is continuous, piecewise holomorphic, and of order $\mathcal{O}(|z|)$, as $|z|\to\infty$. Similarly

$$\left\{\left(z\frac{\partial}{\partial z}-2nz^{2n}\mathrm{ad}\mu-2xz^2\mathrm{ad}\,J\right)m\right\}m^{-1}$$

is continuous, piecewise holomorphic, and of order $\mathcal{O}(|z^{2n-1}|)$, as $|z|\to\infty$. Therefore we have

$$\frac{\partial\Psi}{\partial x}=[z^2J+zq+p]\Psi,$$

$$z\frac{\partial\Psi}{\partial z}=\sum_{j=0}^{2n}A_j(x)z^j\Psi. \tag{4.2}$$

Finally, note

$$\sum_{j=0}^{2n} A_j(x)z^j = m(x,z)(2nz^{2n}\mu + 2xz^2 J)m(x,z)^{-1} + \mathcal{O}(z^{-1})$$

$$= 2nz^{2n} m(x,z)\mu m(x,z)^{-1} + 2xz^2 J$$

$$+ 2xz(f_1 J - J f_1) + 2x(f_2 J - f_1 J f_1 + J f_1^2 - J f_2) + \mathcal{O}(z^{-1})$$

$$= 2nz^{2n} m(x,z)\mu m(x,z)^{-1} + 2xz^2 J + 2xzq + 2xp + \mathcal{O}(z^{-1}).$$

Here we use the formula $m(\dot{x},z) = 1 + f_1/z + f_2/z^2 + \cdots$,

$$q = -[J,f_1], \quad p = -[J,f_2] - [J,f_1]f_1. \tag{4.3}$$

So Theorems 1 and 2 and (4.2) imply that (q,p) satisfy (2.6) with prescribed initial data.

By (4.3) and the meromorphic property of $M(\cdot,z)$, we prove (q,p) can be extended meromorphically to $x \in \mathbf{C}$. Unique solvability and Painleve property follow from the unique solvability of the Riemann-Hilbert problem (4.1) and the meromorphic property of the extended solution (q,p) constructed above. □

Corollary 5: We can obtain meromorphic solution of the Cauchy problem of the self-similar derivative nonlinear Schrödinger equation.

Proof: This follows from the discussion of Example 1 and Theorem 4. □

V. CHARACTERIZATION OF RATIONALITY

One of the main tools in the inverse scattering methods to construct soliton or rational solutions is setting the continuous data to be trivial and then solving the reduced linear algebraic equations to get them. In this section, we prove that all such proper rational self-similar ZS-AKNS flows satisfying (2.3) are actually self-similar ZS-AKNS flows satisfying (1.1). That is, all such proper rational self-similar ZS-AKNS flows with quadratic spectral variables can actually be reduced to self-similar ZS-AKNS flows with linear spectral variables.

Lemma 6: If (q,p) is a proper self-similar ZS-AKNS flow with monodromy data $S_\nu \equiv 1$, then m, p, and q are rational in x. Here $\Psi = me^{z^{2n}\mu + xz^2 J}$ is the eigenfunction obtained in Lemma 2.

Proof: Since $S_\nu \equiv 1$ and Lemmas 3 and 4 we obtain $m_\nu = m$, and $me^{\Phi} = m_\nu e^{\Phi} = m_\nu e^{xz^2 J + z^{2n}\mu} = \Psi_0 C_\nu = f(x,z)z^A C_\nu$. Thus $C_\nu = C_{\nu'}$ and $e^{2\pi i A} = 1$. This implies that A is diagonizable and has integer-valued eigenvalues. So m is rational in z with a unique pole at the origin. Write m as

$$m = 1 + \frac{f_1}{z} + \cdots + \frac{f_r}{z^r}. \tag{5.1}$$

By (4.3), to prove our lemma, it is sufficient to show $f_1, \ldots, f_r$ are rational in x. By (5.1) and the property that $me^{\Phi} C_\nu^{-1} z^{-A}$ is regular at the origin, we obtain the following linear system for f_j [Beals and Sattinger (1993)]:

$$f_r V_{1-r} = 0,$$

$$(f_r C_1 + f_{r-1})V_{2-r} = 0,$$

$$\vdots$$

$$(f_r C_{r-1} + \cdots + f_1)V_0 = 0,$$

$$(f_r C_r + \cdots + f_1 C_1)V_1 = -V_1, \tag{5.2}$$

$$(f_rC_{r+1}+f_{r-1}C_r+\cdots+f_1C_2)V_2=-C_1V_2,$$

$$\vdots$$

$$(f_rC_{r+s-2}+\cdots+f_1C_{s-1})V_{s-1}=-C_{s-2}V_{s-1},$$

$$(f_rC_{r+s-1}+\cdots+f_1C_s)V_s=-C_{s-1}V_s,$$

where $e^{\Phi}=\Sigma_{j=0}^{\infty}z^jC_j(x)$, and $s=s_1\geqslant s_2\geqslant\cdots\geqslant s_d=-r$ are eigenvalues of $C^{-1}AC$ with corresponding eigenvectors $v_1, v_2,\ldots, v_d$. Finally $V_k=(v_j,v_{j-1},\ldots,v_1)$, the set of eigenvectors with eigenvalues$\geqslant k$. Note that the proper condition implies that $A=A_0=2x_0p(x_0)+2nF_{2n}(x_0)$. So $\operatorname{tr}A=0$. Hence (5.2) is a nonempty system.

Now denote d_j the dimension of the eigenspace corresponding to eigenvalue s_j. We compute the number of linear equations represented by (5.2):

$$\begin{aligned}
&d[(d_{1-r}+d_{2-r}+\cdots)+(d_{2-r}+d_{3-r}+\cdots)+(d_{3-r}+\cdots)+\cdots]\\
&\quad=d[d_{1-r}+2d_{2-r}+3d_{3-r}+\cdots]\\
&\quad=d[(1-r)d_{1-r}+(2-r)d_{2-r}+\cdots]+dr[d_{1-r}+d_{2-r}+\cdots]\\
&\quad=d[\operatorname{tr}\ A+rd_{-r}]+dr[d-d_{-r}]=rd^2. \qquad (5.3)
\end{aligned}$$

Note here we use the proper condition to obtain $\operatorname{tr}A=\operatorname{tr}A_0=0$. So (5.2) is a set of rd^2 equations for rd^2 entries of the f_j. Lemma 6 will be proved by noting that C_j are polynomials in x, and applying Fredholm theorem and the following lemma. □

Lemma 7: There is at most one solution of (5.2).

Proof: Suppose that there are two solution $f=(f_1,f_2,\ldots,f_r)$ and $\tilde{f}=(\tilde{f}_1,\tilde{f}_2,\ldots,\tilde{f}_r)$ of (5.2). Denote

$$m=1+\frac{f_1}{z}+\cdots+\frac{f_r}{z^r},$$

$$\tilde{m}=1+\frac{\tilde{f}_1}{z}+\cdots+\frac{\tilde{f}_r}{z^r}.$$

Hence (5.2) is equivalent to $me^{\Phi}z^{-\hat{A}_0}$ and $\tilde{m}e^{\Phi}z^{-\hat{A}_0}$ are regular at the origin, with $\hat{A}_0=C_\nu^{-1}A_0C_\nu$. Besides, note that $\lim_{z\to\infty}\det(me^{\Phi}z^{-\hat{A}_0})=\lim_{z\to\infty}\det(\tilde{m}e^{\Phi}z^{-\hat{A}_0})=1$. So we derive $\det(me^{\Phi}z^{-\hat{A}_0})=\det(\tilde{m}e^{\Phi}z^{-\hat{A}_0})\equiv 1$. So m and $\tilde{m}$ are invertible. This implies $\tilde{m}m^{-1}$ are entire. Combining the condition that $\lim_{z\to\infty}m=\lim_{z\to\infty}\tilde{m}=1$, we prove $m=\tilde{m}$. □

Lemma 8: Suppose that (q,p) is a proper rational solution of (2.5) with trivial Stokes matrices. Let r be the degree of the pole of m obtained by Lemma 2. Then r is even.

Proof: Since $\Phi=z^2xJ+z^{2n}\mu$, $C_i=0$ for odd i. Hence the system (5.2) can be divided into two independent groups if r is odd. One is a system of

$$\sharp_{\text{odd}}=d(d_{1-r}+2d_{3-r}+3d_{5-r}+4d_{7-r}+\cdots)+d(d_{2-r}+2d_{4-r}+3d_{6-r}+4d_{8-r}+\cdots)$$

number of linear equations for $(r+1)d^2/2$ entries of $f_1, f_3,\ldots, f_r$. The other is a system of

$$\sharp_{\text{even}}=d(d_{3-r}+2d_{5-r}+3d_{7-r}+\cdots)+d(d_{2-r}+2d_{4-r}+3d_{6-r}+4d_{8-r}+\cdots)$$

number of linear equations for $(r-1)d^2/2$ entries of $f_2, f_4,\ldots, f_{r-1}$. Hence by (5.3) and the uniqueness property from Lemma 7, we must have $\sharp_{\text{odd}}-\sharp_{\text{even}}=d(d_{1-r}+d_{3-r}+d_{5-r}+d_{7-r}+\cdots)=(r+1)d^2/2-(r-1)d^2/2=d^2$. That is $d_{1-r}+d_{3-r}+d_{5-r}+d_{7-r}+\cdots=d$. So $d_j=0$ for $\forall_j$ odd. But $d_r\neq 0$ by r is odd. So we get a contradiction. □

Lemma 9: Suppose that (q,p) *is a proper rational solution of (2.6) with trivial Stokes matrices. Then* $q=0$.

Proof: By (4.3), we prove this lemma by showing that $f_1=0$ in (5.1). Again the system (5.2) is divided into two groups by noting that $C_i=0$, for odd i. The group for $f_1, f_3,\ldots, f_{r-1}$ is

$$f_{r-1}V_{2-r}=0,$$

$$(f_{r-1}C_2+f_{r-3})V_{4-r}=0,$$

$$\vdots$$

$$(f_{r-1}C_{r-2}+f_{r-3}C_{r-4}+\cdots+f_1)V_0=0,$$

$$(f_{r-1}C_r+f_{r-3}C_{r-2}+\cdots+f_1C_2)V_2=0,$$

$$\vdots$$

$$(f_{r-1}C_{r+s-2}+\cdots+f_1C_s)V_s=0, \text{ if } s \text{ is even},$$

$$\{\text{or}(f_{r-1}C_{r+s-3}+\cdots+f_1C_{s-1})V_{s-1}=0, \text{ if } s \text{ is odd.}\}$$

Since the constant term in the above system is absent. Lemma 7 implies that all of the odd terms $f_1, f_3,\ldots, f_{r-1}$ vanish. □

Theorem 5: *Proper rational self-similar ZS-AKNS flows satisfying (2.3) with trivial Stokes matrices are self-similar ZS-AKNS flows satisfying (1.1).*

Proof: Suppose (q,p) is a proper rational self-similar ZS-AKNS flow satisfying (2.3), or equivalently, (2.6). By Lemma 9, we get $q=0$. Applying Theorem 1, Lemma 1 and Definition 2, we obtain

$$\frac{\partial\Phi}{\partial x}=[z^2J+P(x,t)]\Phi, \tag{5.4.1}$$

$$\frac{\partial\Phi}{\partial t}=[\mu z^{2n}+\mathcal{F}_1z^{2n-1}+\cdots+\mathcal{F}_{2n}]\Phi, \tag{5.4.2}$$

with

$$P(x,1)=p(x),\ \ \lambda^{-2}P(\lambda^{-2}x,\lambda^{-2n}t)=P(x,t), \tag{5.5}$$

$$M\mu M^{-1}\sim\mu+\frac{\mathcal{F}_1}{z}+\frac{\mathcal{F}_2}{z^2}+\cdots,\ \ M(x,1)=m(x), \tag{5.6}$$

and m is defined by (5.1). The proof of Lemma 9 implies $f_1, f_3,\ldots$ vanish. Hence $\mathcal{F}_{2j-1}\equiv 0$ and (5.4) is reduced to

$$\begin{aligned}\frac{\partial\Upsilon}{\partial x}(x,\zeta,t)&=[\zeta J+P(x,t)]\Upsilon(x,\zeta,t),\\ \frac{\partial\Upsilon}{\partial t}(x,\zeta,t)&=[\zeta^n\mu+\zeta^{n-1}\tilde{\mathcal{F}}_1+\cdots+\tilde{\mathcal{F}}_n]\Upsilon(x,\zeta,t),\end{aligned} \tag{5.7}$$

with $\tilde{M}(x,\zeta,t)e^{x\zeta J}=M(x,z^2,t)e^{xz^2J}$, a formal solution to (5.7), $\tilde{M}\mu\tilde{M}^{-1}(x,\zeta,t)\sim\mu+\tilde{\mathcal{F}}_1/\zeta+\tilde{\mathcal{F}}_2/\zeta^2+\ldots$, and $\mathcal{F}_{2j}(x,t)=\tilde{\mathcal{F}}_j(x,t)$. We then finish the proof by (5.5) and [(8.4),BS]. □

(Received 21 June 2002; accepted 23 June 2003)

We present an approach to the construction of action principles (the inverse problem of the calculus of variations), for first order (in time derivatives) differential equations, and generalize it to field theory in order to construct systematically, for integrable equations which are based on the existence of a Nijenhuis (or hereditary) operator, a (multi-Lagrangian) ladder of action principles which is complementary to the well-known multi-Hamiltonian formulation. We work out results for the Korteweg–de Vries (KdV) equation, which is a member of the positive hierarchy related to a hereditary operator. Three negative hierarchies of (negative) evolution equations are defined naturally from the hereditary operator as well, in a concise way, suitable for field theory. The Euler–Lagrange equations arising from the action principles are equivalent to deformations of the original evolution equation, and the deformations are obtained explicitly in terms of the positive and negative evolution vectors. We recognize, after appropriate coordinate transformations, the Liouville, Sinh–Gordon, Hunter–Zheng, and Camassa–Holm equations as negative evolution equations. The multi-Lagrangian ladder for KdV is directly mappable to a ladder for any of these negative equations and other positive evolution equations (e.g., the Harry–Dym and a special case of the Krichever–Novikov equations). For example, several nonequivalent, nonlocal time-reparametrization invariant action principles for KdV are constructed, and a new nonlocal action principle for the deformed system Sinh–Gordon+spatial translation vector is presented. Local and nonlocal Hamiltonian operators are obtained in factorized form as the inverses of all the nonequivalent symplectic two-forms in the ladder. Alternative Lax pairs for all negative evolution vectors are constructed, using the negative vectors and the hereditary operator as only input. This result leads us to conclude that, basically, all positive and negative evolution equations in the hierarchies share the same infinite-dimensional sets of local and nonlocal constants of the motion for KdV, which are explicitly obtained using symmetries and the local and nonlocal action principles for KdV. © *2003 American Institute of Physics.*

I. INTRODUCTION

Hereditary or Nijenhuis operators[1–3] play an important role in the description of integrable systems: in terms of these operators, the very definition of the positive and negative hierarchies of

integrable evolution equations may be given,[4] and they are used to construct, for these equations, symmetries,[4,5] constants of the motion,[5] alternative Lax pairs (Ref. 16), multi-Hamiltonian structures[6] and weakly nonlocal multisymplectic and multi-Hamiltonian structures.[7–9]

The problem of constructing multi-Lagrangian structures (i.e., an infinite ladder of action principles) for the Korteweg–de Vries (KdV) equation has been tackled recently[10,11] in the context of localizable multi-Lagrangian structures, using the bi–Hamiltonian formulation. However, the explicit expression of the action principles associated to each symplectic two-form requires the integration of the respective two-forms, a task which is increasingly difficult as we move to the positive end of the ladder, because of the increasing complexity of the differential terms of the (weakly-nonlocal[9]) two-forms. On the other hand, the symplectic two-forms are increasingly nonlocal as we move to the negative end of the ladder. The known way[11,12] to get rid of the nonlocality problem is to write the action principles in a ''local'' coordinate system (Darboux coordinates) depending on the specific symplectic two-form in the ladder, a process that gets recurrently harder as we move to the negative end. Then, again, the two-form must be integrated by hand in order to get the action principle.

In this work, we make use of the Galilean symmetry[13] and the factorized form of the hereditary operator[14] for the KdV equation, to construct explicitly the action principles for KdV in the positive and negative parts of the ladder. No integration of any two-form is needed, nor is the search for a special coordinate system. The factorized form of the symplectic two-forms allows for the interpretation of the resulting Euler–Lagrange equations (arising from each action principle) as deformed equations, with flows given by KdV+vectors in the positive and negative hierarchies, which are computed explicitly.

Explicit expressions for local and nonlocal constants of the motion for KdV are obtained using symmetries along with the local and nonlocal action principles.

From the action principles obtained for the KdV equation we construct action principles for flows defined by other positive and negative vectors. In particular, a new nonlocal action principle for the Sinh–Gordon (ShG) equation[15] (a negative equation) are constructed.

It is a known result[16] that alternative Lax pairs for the KdV equation and for positive KdV flows may be constructed from the hereditary operator. Here we do the same construction for all the negative KdV flows, and we conclude that the local and nonlocal constants of the motion for KdV, define conserved currents and constants of the motion for all the negative flows as well.

The results here may be mapped to the following equations: a special case of Krichever–Novikov,[17,8] Harry–Dym,[18] Camassa–Holm,[19] Hunter–Zheng,[20] ShG[15] and Liouville, all of which are essentially flows belonging to the KdV positive or negative hierarchies. We stress that the results are quite general and may be extended to other systems related to hereditary operators (e.g., nonlinear Schrödinger equation).

This paper is organized as follows: Section II presents a preview and notation for the method of construction of action principles for given differential evolution equations, and a brief survey of symmetries and constants of the motion in this context. Next, we show the relationship of these principles with Hamiltonian theories, and finally we introduce the hereditary property with the consequent construction of the positive and negative hierarchies of integrable evolution equations. In Sec. III we present and prove theorems on the explicit construction of ladders of action principles and constants of the motion, based on the hereditary operator and the Galilean symmetry (whose definition is quite general and not restricted to KdV), and we show how these action principles give rise to Euler–Lagrange equations which are deformations of the original equations, due to the fact that the symplectic operators have a nonzero kernel.

Section IV is devoted to examples of the above constructions for the KdV equation. We obtain concise expressions for the negative vectors, for the action principles, and for the deformed Euler–Lagrange equations. Symplectic operators are presented in factorized form (this allows for factorized expressions for the Hamiltonian operators). Some known integrable evolution equations are identified within the negative hierarchies. Nonlocal constants of the motion for KdV are concisely obtained using the internal symmetries and the negative action principles. In Sec. V we work out examples of new nonlocal action principles for the ShG equation, which in this context
