$$S(t,x,y,z)=-k_xx-k_zz\pm\int\sqrt{\lambda^2-\frac{k_z^2}{c^2}}dy\mp\frac{\sqrt{\lambda^2+k_x^2}}{H}e^{-Ht}, \tag{104}$$

$$\phi_{-\infty}=e^{iS}\to C(x,y,z)\exp\left(\mp i\frac{\sqrt{\lambda^2+k_x^2}}{H}e^{-Ht}\right), \tag{105}$$

and for $t\to\infty$

$$S(t,x,y,z)=-k_xx-k_zz\pm\int\sqrt{\lambda^2-\frac{k_z^2}{c^2}}dy\pm\sqrt{m^2+\frac{e^2E_0^2}{H^2}}t, \tag{106}$$

$$\phi_{\infty}=e^{iS}\to C(x,y,z)\exp\left(\mp i\sqrt{m^2+\frac{e^2E_0^2}{H^2}}t\right). \tag{107}$$

For scalar particles, the Klein–Gordon equation in minimal coupling is written as

$$g^{\alpha\beta}(\nabla_\alpha-ieA_\alpha)(\nabla_\beta-ieA_\beta)\phi-m^2\phi=0. \tag{108}$$

Equation (108) becomes

$$\left(\partial_t^2-\frac{1}{a^2}\left((\partial_x-ieA_1)^2+\partial_y^2+\frac{1}{c^2}\partial_z^2\right)+m^2\right)\psi=0. \tag{109}$$

Since Eq. (109) commutes with the operators $-i\partial_x$ and $-i\partial_z$, we can look at a solution of the form $\psi=e^{ik_xx+ik_zz}\phi$, which reduces Eq. (109) after separation of variables to

$$\left(\partial_t^2-\frac{1}{a^2}\left(ik_x+ie\frac{E_0e^{Ht}}{H}\right)^2+\frac{1}{a^2}\lambda^2+m^2\right)\phi_1=0, \tag{110}$$

$$\left(\partial_y^2-\frac{1}{c^2}k_z^2+\lambda^2\right)\phi_2=0, \tag{111}$$

where λ is a constant of separation and $\phi(t,y)=\phi_1(t)\phi_2(y)$.

For the Kantowiski–Sacks model $c(y)=\sin y$, and we obtain the solution by

$$\phi_2=A\sin^qyF(\tfrac{1}{2}(q+\lambda),\tfrac{1}{2}(q-\lambda),q+\tfrac{1}{2},\sin^2y), \tag{112}$$

where $q=\frac{1}{2}+(k_z^2+\frac{1}{4})^{1/2}$.

For the Bianchi I model $c(y)=y$, we arrive at

$$\phi_2=By^{1/2}Z_\nu(\lambda y), \tag{113}$$

where Z_ν is the general solution of the cylindrical Bessel equation and $\nu=(k_z^2+\frac{1}{4})^{1/2}$.

For the Bianchi III model $c(y)=\sinh y$, the solution takes the form

$$\phi_2=C\sinh^qyF(\tfrac{1}{2}(q+i\lambda),\tfrac{1}{2}(q-i\lambda),q+\tfrac{1}{2},-\sinh^2y), \tag{114}$$

where $q=\frac{1}{2}+(k_z^2+\frac{1}{4})^{1/2}$.

We analyze the inflationary universe case $a(t)=e^{Ht}$, and Eq. (101) can be written as follows,

$$\left(\frac{d^2}{dz^2}+\frac{1}{z}\frac{d}{dz}+\frac{2eE_0k_x}{H^2z}+\frac{e^2E_0^2}{H^2z^2}+\frac{m^2}{H^2z^2}+k_x^2+\lambda^2\right)\phi_1=0, \tag{115}$$

where $z=(1/H)\,e^{-Ht}$. Therefore, we can reduce Eq. (115) to

$$\left(\frac{d^2}{dz^2}+\frac{\frac{1}{4}+e^2E_0^2/H^4+m^2/H^2}{z^2}+\frac{2eE_0k_x}{H^2z}+k_x^2+\lambda^2\right)f=0, \tag{116}$$

with $\phi_1=z^{-1/2}f$. Making a change of variables $u=2i\epsilon(k_x^2+\lambda^2)^{1/2}z$, with $\text{sign}(\epsilon)=\pm1$, we get as a solution for $\text{sign}(\epsilon)=-1$

$$C_1W_{k,\mu}(2i\sqrt{k_x^2+\lambda^2}z)+C_2M_{k,\mu}(2i\sqrt{k_x^2+\lambda^2}z), \tag{117}$$

where

$$\mu=\frac{i}{H^2}\sqrt{m^2H^2+e^2E_0^2}=i|\mu|,\quad k=\frac{ieE_0k_x}{H^2\sqrt{k_x^2+\lambda^2}}. \tag{118}$$

For $z\to\infty$ $(t\to-\infty)$, we get the negative and the positive frequency mode solutions in the form

$$\begin{aligned}\phi_{1,\infty}^{+}&=C_\infty^{+}z^{-1/2}W_{k,\mu}(2i\sqrt{k_x^2+\lambda^2}z),\\ \phi_{1,\infty}^{-}&=C_\infty^{-}z^{-1/2}W_{-k,\mu}(-2i\sqrt{k_x^2+\lambda^2}z),\end{aligned} \tag{119}$$

and for $z\to0$ $(t\to\infty)$ we have

$$\begin{aligned}\phi_{1,0}^{+}&=C_0^{+}z^{-1/2}M_{k,-\mu}(2i\sqrt{k_x^2+\lambda^2}z),\\ \phi_{1,0}^{-}&=C_0^{-}z^{-1/2}M_{k,\mu}(-2i\sqrt{k_x^2+\lambda^2}z),\end{aligned} \tag{120}$$

where C_∞^{+}, C_∞^{-}, C_0^{+} and C_0^{-} are constants of normalization.

Then, using the relation[9]

$$M_{k,\mu}(z)=\Gamma(2\mu+1)e^{i\pi\lambda}\left[\frac{W_{-k,\mu}(e^{i\pi}z)}{\Gamma(\mu-k+\frac{1}{2})}+e^{-i\pi(\mu+1/2)}\frac{W_{k,\mu}(z)}{\Gamma(\mu+k+\frac{1}{2})}\right], \tag{121}$$

with $(-3\pi/2<\arg z<\pi/2;\ 2\mu\neq-1,-2,\ldots)$, and the following relation[9]

$$|\Gamma(\tfrac{1}{2}+iy)|^2=\frac{\pi}{\cosh\pi y}, \tag{122}$$

we arrive at

$$\frac{|\alpha|^2}{|\beta|^2}=\frac{\cosh(\pi|\mu|+\pi eE_0k_x/H^2\sqrt{k_x^2+\lambda^2})}{\cosh(\pi|\mu|-\pi eE_0k_x/H^2\sqrt{k_x^2+\lambda^2})}e^{-2\pi|\mu|}. \tag{123}$$

For $|\mu\pm eE_0k_x/H^2\sqrt{k_x^2+\lambda^2}|\gg1$, Eq. (123) becomes

$$\frac{|\alpha|^2}{|\beta|^2}=\exp\left(-2\pi\left[|\mu|-\frac{eE_0k_x}{H^2\sqrt{k_x^2+\lambda^2}}\right]\right). \tag{124}$$

Considering the normalization condition $|\alpha|^2+|\beta|^2=1$, we obtain the thermal distribution

$$|\beta|^2=\frac{1}{1+\exp(2\pi[|\mu|-eE_0k_x/H^2\sqrt{k_x^2+\lambda^2}])}\approx\exp\left(-\frac{2\pi}{H^2}\left[(m^2H^2+e^2E_0^2)^{1/2}-\frac{eE_0k_x}{H^2\sqrt{k_x^2+\lambda^2}}\right]\right). \tag{125}$$

It points out that the temperature depends on the intensity of the electric field E_0 and on the impulsion k_x of the particle. Moreover, we have that $|\beta|^2$ changes according to the sign of ϵ; the result for $\text{sign}(\epsilon)=+1$ is obtained by replacing e by $-e$ in Eq. (125).

In $(1+1)$ dimension,[2,4] we have $\lambda=0$ and Eq. (125) becomes

$$|\beta|^2\approx\exp\left(-\frac{2\pi}{H^2}[(m^2H^2+e^2E_0^2)^{1/2}-eE_0]\right). \tag{126}$$

In the limit $H\to 0$, we obtain a Minkowski (flat) metric, and the exponent of $|\beta|^2$ in Eq. (126) takes the form

$$\lim_{H\to 0}\left(-\frac{2\pi eE_0}{H^2}\left[\left(\frac{m^2H^2}{e^2E_0^2}+1\right)^{1/2}-1\right]\right)\to-\frac{\pi m^2}{eE_0}, \tag{127}$$

which reduces the flat limit of the density of particles created to

$$|\beta|^2_{\text{flat}}=\lim_{H\to 0}|\beta|^2=e^{-\pi m^2/eE_0}. \tag{128}$$

This result is obtained by Villalba[2] in the study of particle creation by a strong constant electric field in de Sitter space, and it is proportional to the probability, per unit time, per unit volume of pair created by a constant electric field obtained by Schwinger.[10]

VI. CONCLUSION

After solving the relativistic Hamilton–Jacobi, Klein–Gordon and Dirac equations in the gravitational background (2) by separation of variables, we identify the relativistic solutions of negative and positive frequency modes and make comparison with the quasiclassical one obtained by the Hamilton–Jacobi equation to compute the density of scalar and spin-$\frac{1}{2}$ particles.

We also study some special cases of background when a constant electric field is present and calculate the thermal distribution of the density of particles created. We recover the result found in de Sitter space[2,4] in $(1+1)$ dimensions.

Trigonometric osp(1|2) Gaudin model

P. P. Kulish[a] and N. Manojlović[b]
Área Departamental de Matemática, F. C. T., Universidade do Algarve, Campus de Gambelas, 8000-117 Faro, Portugal

(Received 10 July 2002; accepted 22 October 2002)

The problems connected with Gaudin models are reviewed by analyzing model related to the trigonometric osp(1|2) classical r-matrix. The eigenvectors of the trigonometric osp(1|2) Gaudin Hamiltonians are found using explicitly constructed creation operators. The commutation relations between the creation operators and the generators of the trigonometric loop superalgebra are calculated. The coordinate representation of the Bethe states is presented. The relation between the Bethe vectors and solutions to the Knizhnik–Zamolodchikov equation yields the norm of the eigenvectors. The generalized Knizhnik–Zamolodchikov system is discussed both in the rational and in the trigonometric case. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1531250]

I. INTRODUCTION

Classifying integrable systems solvable in the framework of the quantum inverse scattering method[1–3] by underlying dynamical symmetry algebras, one could say that the Gaudin models are the simplest ones being based on loop algebras and classical r-matrices. More sophisticated solvable models correspond to more complicated algebras: Yangians, quantum affine algebras, elliptic quantum groups, dynamical quantum groups, etc.

Gaudin models[4,5] are related to classical r-matrices, and the density of Gaudin Hamiltonians

$$H^{(a)}=\sum_{b\neq a}^{N} r_{ab}(z_a-z_b) \tag{1.1}$$

coincides with the r-matrix. The condition of their commutativity $[H^{(a)},H^{(b)}]=0$ is nothing else but the classical Yang–Baxter equation (YBE)

$$[r_{ab}(z_a-z_b),r_{ac}(z_a-z_c)+r_{bc}(z_b-z_c)]+[r_{ac}(z_a-z_c),r_{bc}(z_b-z_c)]=0, \tag{1.2}$$

where r is antisymmetric and belongs to the tensor product $\mathfrak{g}\otimes\mathfrak{g}$ of a Lie algebra $\mathfrak{g}$, or its representations and the indices fix the corresponding factors in the N-fold tensor product of this algebra (see Sec. II).

The Gaudin models (GMs) related to classical r-matrices of simple Lie algebras were studied intensively (see Refs. 5–14 and references therein). The spectrum and eigenfunctions were found using different methods (coordinate and algebraic Bethe ansatz,[5,6] separated variables,[6] etc.). The correlation functions were evaluated for $\mathfrak{g}=\mathrm{sl}(2)$ by the Gauss factorization approach.[7] A relation to the Knizhnik–Zamolodchikov (KZ) equation of conformal filed theory was established.[11–13]

There exists a variety of classical r-matrices with trigonometric dependence on spectral parameter. Although algebraic construction of integrals of motion is straightforward, the calculation

[a]On leave of absence from Steklov Mathematical Institute, Fontanka 27, 191011, St. Petersburg, Russia. Electronic mail: kulish@pdmi.ras.ru
[b]Electronic mail: nmanoj@ualg.pt

of the spectrum and the corresponding eigenstates, by means of algebraic Bethe ansatz, still depends on the underlining Lie algebra and r-matrix. Moreover, many trigonometric r-matrices are invariant under diagonal action of the Cartan subalgebra only,

$$[h_a+h_b \ , \ r_{ab}(z_a-z_b)]=0\,, \tag{1.3}$$

as opposed to the rational case where the classical r-matrix is invariant under the action of the whole Lie algebra $\mathfrak{g}$. Hence, one can modify the Gaudin Hamiltonian (1.1) by adding a local generator of the Cartan subalgebra

$$H_a \to \tilde{H}^{(a)}=g\,h_a+H^{(a)}\,. \tag{1.4}$$

This modification does not change the creation operators, but the Bethe equations and solutions to the KZ system. However, the dependence on the parameter g (a magnetic field) will be described by a difference equation.[15,16]

The aim of this article is to review problems connected with Gaudin models by analyzing the model related to the trigonometric osp(1|2) classical r-matrix. Results obtained here are in many respects similar to the ones we obtained in the case of osp(1|2)-invariant rational r-matrix.[17] However, connection of Gaudin model with magnetic field and KZ equations requires modification of the latter by adding a dynamical difference equation.[15,16]

There are additional peculiarities of Gaudin models related to classical r-matrices based on Lie superalgebras due to Z_2-grading of representation spaces and operators. The study of the osp(1|2)-invariant Gaudin model corresponding to the simplest nontrivial super-case of the osp(1|2) invariant r-matrix[18] started in Ref. 19. The spectrum of the osp(1|2) invariant Gaudin Hamiltonians $H^{(a)}$ was given, an antisymmetry property of their eigenstates was claimed, and a two site model was connected with some physically interesting one (a Dicke model). Let us also point out that recently rational and trigonometric sl(2) Gaudin models were used to describe different physical phenomena in metallic grains[20] and a condensate fragmentation of confined bosons.[21] Connection with perturbed WZNW models of conformal field theory was found in Ref. 22.

The creation operators used in the sl(2) Gaudin model [and similarly for sl(n) case] coincide with one of the L-matrix entry.[5,6] However, in the osp(1|2) case, as it was shown for rational r-matrix,[17] the creation operators are complicated polynomials of the two generators $X^+(\lambda)$ and $v^+(\mu)$ of the loop superalgebra. We introduce B-operators belonging to the Borel subalgebra of the trigonometric loop superalgebra $\mathcal{L}_t(\mathrm{osp}(1|2))$ by a recurrence relation. Acting on the lowest spin vector (bare vacuum) $B_M(\mu_1,\ldots,\mu_M)\Omega_-$ the B-operators generate exact eigenstates of the Gaudin Hamiltonians $H^{(a)}$, provided Bethe equations are imposed on parameters $\{\mu_j\}$ of the states. For this reason the B-operators are sometimes referred to as the creation operators and the eigenstates as the Bethe vectors, or simply B-vectors. Furthermore, the recurrence relation is solved explicitly and the commutation relations between the B-operators and the generators of the loop superalgebra $\mathcal{L}_t(\mathrm{osp}(1|2))$ as well as the generators of the global superalgebra $\mathrm{osp}(1|2)\subset\mathcal{L}_t(\mathrm{osp}(1|2))$ are calculated. We prove that the constructed states are eigenvectors of the generator of the global Cartan subalgebra h_{gl}, but the B-vectors are not the lowest spin vectors anymore, as it was the case for the invariant model.[23,17] Analogously to the rational case,[17] a striking coincidence between the spectrum of the osp(1|2) invariant Gaudin Hamiltonians of spin s and the spectrum of the Hamiltonians of the sl(2) Gaudin model of the integer spin $2s$ is also confirmed in the trigonometric case.

A connection between the B-states, when the Bethe equations are not imposed on their parameters (''off-shell Bethe states''), of the Gaudin models for simple Lie algebras to the solutions of the Knizhnik–Zamolodchikov equation was established in Refs. 11 and 12. An explanation of this connection based on Wakimoto modules at critical level of the underlying affine algebra was given in Ref. 12. An explicit form of the Bethe vectors in the coordinate representation was given in both Refs. 11 and 12. The coordinate Bethe ansatz for the B-states of the osp(1|2) Gaudin model is obtained in our article as well. Using commutation relations between the B-operators and the

transfer matrix $t(\lambda)$, as well as the Hamiltonians $H^{(a)}$, we give an algebraic proof of the fact that explicitly constructed B-states yield a solution to the Knizhnik–Zamolodchikov equation corresponding to a conformal field theory. This connection permits us to calculate the norm of the eigenstates of the Gaudin Hamiltonians. An analogous connection is expected between quantum osp(1|2) spin system related to the graded Yang–Baxter equation[18,24–26] and quantum Knizhnik–Zamolodchikov equation following the lines of Ref. 27. We point out possible modifications of the Gaudin Hamiltonians and corresponding modifications of the Knizhnik–Zamolodchikov equation, similar to the case of the sl(2) Gaudin model which was interpreted in Refs. 28 and 29 as a quantization of the Schlesinger system for isomonodromy deformation.

The norm and correlation functions of the sl(2) invariant Gaudin model were evaluated in Ref. 7 using Gauss factorization of a group element and the Riemann–Hilbert problem. The study of this problem for the trigonometric Gaudin model based on the osp(1|2) Lie superalgebra is in progress. However, we propose a formula for the scalar products of the Bethe states which is analogous to the sl(2) case.

The article is organized as follows. In Sec. II we review the main data of the quantum trigonometric osp(1|2) spin system: the osp(1|2) solution to the graded Yang–Baxter equation (R-matrix), monodromy matrix $T(\lambda)$, the transfer matrix $t(\lambda)=\mathrm{str}T(\lambda)$, its eigenvalues and the Bethe equations. The eigenvectors of this quantum integrable spin system can be constructed only by a complicated recurrence procedure[30] which is not given here. Nevertheless, it is useful to remind the main data of the quantum integrable spin system because some characteristics of the corresponding Gaudin model can be obtained easily as a quasi-classical limit of these data. The trigonometric osp(1|2) Gaudin model and its creation operators B_M are discussed thoroughly in Sec. III. Some of the most important properties of these operators are formulated and demonstrated pure algebraically: antisymmetry with respect to their arguments, commutation relations with the trigonometric loop superalgebra generators, commutation relations with the generating function $t(\lambda)$ of the Gaudin Hamiltonians, and a differential identity, valid in the case of the Gaudin realization of the loop superalgebra. Using these properties of the B-operators we prove in Sec. IV that, acting on the lowest spin vector Ω_-, these operators generate eigenvectors of the generating function of integrals of motion, provided the Bethe equations are imposed on the arguments of the B-operators. Possible modifications of the Gaudin Hamiltonians are pointed out, also. In particular, one of them yields Ricardson type Hamiltonian. An algebraic proof is given in Sec. V that constructed Bethe vectors are entering into solutions of the Knizhnik–Zamolodchikov equation of conformal field theory. A quasi-classical asymptotic with respect to a parameter of the Knizhnik–Zamolodchikov equation permits us to calculate the norm of the eigenstates of the Gaudin Hamiltonian. We pointed out that modification of Gaudin Hamiltonians by adding a Cartan element requires a more complicated change of KZ system, as opposed to the rational case. Further development on possible evaluation of correlation functions is discussed in Sec. VI. Finally, some definitions of the orthosymplectic Lie superalgebra osp(1|2) are given in the Appendix.

II. QUANTUM osp(1|2) SUPERALGEBRA AND CORRESPONDING SPIN SYSTEM

The quantum superalgebra $\mathcal{U}_q(\mathrm{osp}(1|2))$ as a deformation of the universal enveloping algebra of the Lie superalgebra osp(1|2) (see Appendix) is generated by three elements h, v^+, v^-.[31,32] The q-deformed commutation relations between the generators are

$$[h,v^{\pm}]_-=\pm v^{\pm}, \quad [v^+,v^-]_+=-\frac{q^h-q^{-h}}{q-q^{-1}}:=-[h]_q. \tag{2.1}$$

Its center is spanned by the q-deformed Casimir element

$$c_2(q)=A(q)([h]_q)^2+B(q)-\frac{(q^{1/2}+q^{-1/2})^2}{2}[v^{+2},v^{-2}]_+ +\frac{(q+q^{-1})}{4}(q^h+q^{-h})[v^+,v^-]_- \tag{2.2}$$

with $2A(q)=q+q^{-1}+\frac{1}{2}(q-q^{-1})^2$ and $B(q)=(q^{1/2}+q^{-1/2})^{-2}$. The q-deformed Casimir element can be written also in the form

$$c_2(q)=([h-\tfrac{1}{2}]_q)^2-(q^{1/2}+q^{-1/2})^2 v^+{}^2 v^-{}^2+(q^{h-1}+q^{-h+1})v^+v^-. \tag{2.3}$$

Like in the case of the Lie superalgbra osp(1|2) (see the Appendix), there exists an element

$$c_1(q)=([h-\tfrac{1}{2}]_q+(q^{1/2}+q^{-1/2})v^+v^-), \quad (c_1(q))^2=c_2(q), \tag{2.4}$$

with a grading property $[c_1,h]=0$ and $c_1v^{\pm}=-v^{\pm}c_1$. In the quasi-classical limit $q\to 1$ the relations (2.1)–(2.4) are reduced to the Lie superalgebra osp(1|2) ones.[33] There is a coproduct map $\Delta:\mathcal{U}_q\to\mathcal{U}_q\otimes\mathcal{U}_q$ consistent with the commutation relations (2.1) and a universal R-matrix $\mathcal{R}$ as an element of $\mathcal{U}_q\otimes\mathcal{U}_q$.[31,32] Let us write its matrix form $R(q)=(\rho\otimes\rho)\mathcal{R}$ in the basis $e_1\otimes e_1, e_1\otimes e_2, e_1\otimes e_3,\ldots,e_3\otimes e_3$ of the tensor product of two copies of the fundamental representation $V^{(1)}\otimes V^{(1)}$, $\rho:\mathcal{U}_q\to\mathrm{End}(V^{(1)})$,

$$R(q)=\begin{pmatrix} q & & & & & & & & \\ & 1 & & a & & & & & \\ & & q^{-1} & & b & & c & & \\ & & & 1 & & & & & \\ & & & & 1 & & b & & \\ & & & & & 1 & & a & \\ & & & & & & q^{-1} & & \\ & & & & & & & 1 & \\ & & & & & & & & q \end{pmatrix}, \tag{2.5}$$

here $a=q-q^{-1}$, $b=q^{-3/2}-q^{1/2}$ and $c=(1+q^{-1})(q-q^{-1})$. Multiplying $R(q)$ by the graded permutation $\mathcal{P}$ of $V^{(1)}\otimes V^{(1)}$: $(\mathcal{P})_{ab;cd}=(-1)^{p(a)p(b)}\delta_{ad}\delta_{bc}$, one gets the braid group form of the R-matrix $\check{R}(q)=R(q)\mathcal{P}$ which has a spectral decomposition. Using the projectors on the irreducible representation components in the Clebsch–Gordan decomposition $V^{(1)}\otimes V^{(1)}=V^{(2)}\oplus V^{(1)}\oplus V^{(0)}$, one can represent this R-matrix in the form[31,32]

$$\check{R}(q)=-q^{-2}P_0(q)-q^{-1}P_1(q)+qP_2(q), \tag{2.6}$$

where projectors are

$$P_0(q)=\frac{q^{1/2}+q^{-1/2}}{q^{3/2}+q^{-3/2}}\begin{pmatrix} 0 & & & & & & & & \\ & 0 & & & & & & & \\ & & q^{-1} & & q^{-1/2} & & -1 & & \\ & & & 0 & & & & & \\ & & -q^{-1/2} & & -1 & & q^{1/2} & & \\ & & & & & 0 & & & \\ & & -1 & & -q^{1/2} & & q & & \\ & & & & & & & 0 & \\ & & & & & & & & 0 \end{pmatrix}, \tag{2.7}$$

$$P_1(q)=\frac{1}{q+q^{-1}}\begin{pmatrix} 0 & & & & & & & & \\ & q^{-1} & & -1 & & & & & \\ & & -1 & & -\nu & & 1 & & \\ & -1 & & q & & & & & \\ & & \nu & & \nu^2 & & -\nu & & \\ & & & & & q^{-1} & & -1 & \\ & & 1 & & \nu & & -1 & & \\ & & & & & -1 & & q & \\ & & & & & & & & 0 \end{pmatrix}, \tag{2.8}$$

here $\nu=q^{1/2}+q^{-1/2}$, and $P_2(q)=I-P_0(q)-P_1(q)$. By the Baxterization procedure, or simply changing functions $(\lambda-a)/(\lambda+a)$ to the trigonometric ones $\sinh(\lambda-a)/\sinh(\lambda+a)$ in the osp(1|2)-invariant R-matrix,[18,17] one gets the trigonometric R-matrix related to the quantum affine algebra $\mathcal{U}_q(\widehat{\mathrm{osp}(1|2)})$

$$\check{R}(\lambda,\eta)=P_2-\frac{\sinh(\lambda-2\eta)}{\sinh(\lambda+2\eta)}P_1-\frac{\sinh(\lambda-3\eta)}{\sinh(\lambda+3\eta)}P_0. \tag{2.9}$$

Here $q=e^{2\eta}$ (normalized to $\lambda=0$ $\check{R}=\mathbf{1}$). The L-operator of the quantum spin system on a one-dimensional lattice with N sites coincides with R-matrix acting on a tensor product $V_0\otimes V_a$ of auxiliary space V_0 and the space of states at site $a=1,2,\ldots N$,

$$L_{0a}(\lambda-z_a)=R_{0a}(\lambda-z_a), \tag{2.10}$$

where z_a is a parameter of inhomogeneity (site dependence) and $R_{0a}(\lambda,\eta)=\mathcal{P}\check{R}(\lambda,\eta)$ is the usual R-matrix. Corresponding monodromy matrix T is an ordered product of the L-operators

$$T(\lambda;\{z_a\}_1^N)=L_{0N}(\lambda-z_N)\cdots L_{01}(\lambda-z_1)=\prod_{\substack{a=1\\ \leftarrow}}^{N} L_{0a}(\lambda-z_a). \tag{2.11}$$

The commutation relations of the T-matrix entries follow from the (Z_2-graded) FRT-relation[2]

$$R_{12}(\lambda-\mu)T_1(\lambda)T_2(\mu)=T_2(\mu)T_1(\lambda)R_{12}(\lambda-\mu). \tag{2.12}$$

Multiplying (2.12) by R_{12}^{-1} and taking the super-trace over $V_1\otimes V_2$, one gets commutativity of the transfer matrix

$$t(\lambda)=\mathrm{str}\ \ T(\lambda)=\sum_j (-1)^{j+1}T_{jj}(\lambda;\{z_a\}_1^N)=T_{11}-T_{22}+T_{33} \tag{2.13}$$

for different values of the spectral parameter $t(\lambda)t(\mu)=t(\mu)t(\lambda)$.

The choice of the L-operators (2.10) corresponds to the following space of states of the osp(1|2)-spin system

$$\mathcal{H}=\bigotimes_{a=1}^{N} V_a^{(1)}.$$

The eigenvalues of the transfer matrix $t(\lambda)$ in this space are[18,24,25]

$$\Lambda(\lambda;\{\mu_j\}_1^M)=\alpha_1^{(N)}(\lambda;\{z_a\}_1^N)\prod_{j=1}^{M} S_1(\lambda-\mu_j)-\alpha_2^{(N)}(\lambda;\{z_a\}_1^N)$$
$$\times\prod_{j=1}^{M} S_1(\lambda-\mu_j+\eta)S_{-1}(\lambda-\mu_j+2\eta)$$
$$+\alpha_3^{(N)}(\lambda;\{z_a\}_1^N)\prod_{j=1}^{M} S_{-1}(\lambda-\mu_j+3\eta), \tag{2.14}$$

where $\alpha_j^{(N)}(\lambda;\{z_a\}_1^N)=\Pi_{b=1}^N\alpha_j(\lambda-z_b)$; $j=1,2,3$,

$$\alpha_1(\lambda)=\sinh(\lambda+2\eta)\sinh(\lambda+3\eta),\quad \alpha_2(\lambda)=\sinh(\lambda)\sinh(\lambda+3\eta),$$
$$\alpha_3(\lambda)=\sinh(\lambda)\sinh(\lambda+\eta),\quad S_n(\mu)=\frac{\sinh(\mu-n\eta)}{\sinh(\mu+n\eta)}. \tag{2.15}$$

Although according to (2.14) the eigenvalue has formally two sets of poles at $\lambda=\mu_j-\eta$ and $\lambda=\mu_j-2\eta$, the corresponding residues are zero due to the Bethe equations on the parameters $\{\mu_j\}$ of the eigenstate[18,24,25]

$$\prod_{a=1}^{N}\frac{\sinh(\mu_j-z_a+\eta)}{\sinh(\mu_j-z_a-\eta)}=\prod_{k=1}^{M} S_1(\mu_j-\mu_k)S_{-2}(\mu_j-\mu_k). \tag{2.16}$$

If we take different spins l_a at different sites of the lattice and the following space of states

$$\mathcal{H}=\bigotimes_{a=1}^{N} V_a^{(l_a)},$$

then the factors on the left hand side of (2.16) will be spin dependent, too.

Due to the more complicated structure of the R-matrix (2.9) [see (2.7) and (2.8)], than the $gl(n)$, or $gl(m|n)$ trigonometric R-matrices, the commutation relations of the entries $T_{ij}(\lambda)$ of the T-matrix (2.11) have more terms and construction of the eigenstates of the transfer matrix $t(\lambda)$ by the algebraic Bethe ansatz can be done only using a complicated recurrence relation expressed in terms of $T_{ij}(\mu_k)$.[30] It will be shown below that due to a simplification of this recurrence relation in the quasi-classical limit $\eta\to 0$ one can solve it and find the creation operators for the trigonometric osp(1|2) Gaudin model explicitly. Furthermore, the commutation relations between the creation operators and the generators of the trigonometric loop superalgebra as well as the generating function $t(\lambda)$ of the Gaudin Hamiltonians will be given explicitly, yielding the solution to the eigenvalue problem.

III. osp(1|2) TRIGONOMETRIC GAUDIN MODEL

As in the case of any simple Lie algebra, the trigonometric classical r-matrix of the orthosymplectic Lie superalgebra osp(1|2) can be expressed in a pure algebraic form as an element in the tensor product $\mathrm{osp}(1|2)\otimes\mathrm{osp}(1|2)$

$$\hat{r}(\lambda)=\coth(\lambda)\,h\otimes h+\frac{2}{\sinh(\lambda)}(e^{-\lambda}X^+\otimes X^-+e^{\lambda}X^-\otimes X^+)$$
$$+\frac{1}{\sinh(\lambda)}(e^{-\lambda}v^+\otimes v^-+e^{\lambda}v^-\otimes v^+), \tag{3.1}$$

and it is a solution of the Z_2-graded classical YBE (1.2).[2] This r-matrix can be decomposed naturally into positive and negative parts,[34]

$$\hat{r}(\lambda)=\frac{1}{\sinh\lambda}(e^{\lambda}r^{(-)}+e^{-\lambda}r^{(+)})$$
$$=\frac{e^{\lambda}}{\sinh\lambda}\left(\frac{1}{2}h\otimes h+2X^{-}\otimes X^{+}-v^{-}\otimes v^{+}\right)$$
$$+\frac{e^{-\lambda}}{\sinh\lambda}\left(\frac{1}{2}h\otimes h+2X^{+}\otimes X^{-}+v^{+}\otimes v^{-}\right). \tag{3.2}$$

It can also be represented in another form useful for modifications,

$$\hat{r}(\lambda)=\coth(\lambda)\quad c_2^{\otimes}+2(X^{-}\otimes X^{+}-X^{+}\otimes X^{-})-(v^{-}\otimes v^{+}+v^{+}\otimes v^{-}); \tag{3.3}$$

here

$$c_2^{\otimes}=h\otimes h+2(X^{+}\otimes X^{-}+X^{-}\otimes X^{+})+(v^{+}\otimes v^{-}-v^{-}\otimes v^{+}). \tag{3.4}$$

The matrix form of $\hat{r}$ in the fundamental representation of osp(1|2) follows from (3.1) by substituting appropriate 3×3 matrices instead of the osp(1|2) generators and taking into account the Z_2-graded tensor product of even and odd matrices. One can get it also as the quasi-classical limit $\eta\to0$ from the R-matrix (2.9). Let us write explicitly the matrix form of $\hat{r}$ in the basis of the tensor product of two copies of the fundamental representation $V^{(1)}\otimes V^{(1)}$ (see the Appendix):

$$r(\lambda)=\frac{1}{\sinh(\lambda)}\begin{pmatrix}\cosh(\lambda)&&&&&&&&\\&0&&e^{-\lambda}&&&&&\\&&-\cosh(\lambda)&&-e^{-\lambda}&&2e^{-\lambda}&&\\&e^{\lambda}&&0&&&&&\\&&e^{\lambda}&&0&&-e^{-\lambda}&&\\&&&&&0&&e^{-\lambda}&\\&&2e^{\lambda}&&e^{\lambda}&&-\cosh(\lambda)&&\\&&&&&e^{\lambda}&&0&\\&&&&&&&&\cosh(\lambda)\end{pmatrix} \tag{3.5}$$

with all the other entries of this 9×9 matrix being identically equal to zero.

A quasi-classical limit $\eta\to0$ of the FRT-relations (2.12) $[R(\lambda;\eta)=I+\eta r(\lambda)+\mathcal{O}(\eta^2)$ and $T(\lambda;\eta)=I+\eta L(\lambda)+\mathcal{O}(\eta^2)]$ results in a matrix form of the loop superalgebra relation, the so-called Sklyanin linear bracket,

$$[\underset{1}{L}(\lambda),\underset{2}{L}(\mu)]=-[r_{12}(\lambda-\mu),\underset{1}{L}(\lambda)+\underset{2}{L}(\mu)]. \tag{3.6}$$

Both sides of this relation have the usual commutators of even 9×9 matrices $\underset{1}{L}(\lambda)=L(\lambda)\otimes I_3$, $\underset{2}{L}(\mu)=I_3\otimes L(\mu)$ and $r_{12}(\lambda-\mu)$, where I_3 is 3×3 unit matrix and $L(\lambda)$ has loop superalgebra valued entries:

$$L(\lambda)=\begin{pmatrix}h(\lambda)&-v^{-}(\lambda)&2X^{-}(\lambda)\\v^{+}(\lambda)&0&v^{-}(\lambda)\\2X^{+}(\lambda)&v^{+}(\lambda)&-h(\lambda)\end{pmatrix}. \tag{3.7}$$

From the expression (3.2) of the classical r-matrix it is natural to assume that the L-operator has a triangular decomposition $L_\pm$ as $\lambda \to \pm\infty$,

$$L_+ = h\otimes h_{gl} + 4X^-\otimes X^+_{gl} - 2v^-\otimes v^+_{gl}, \tag{3.8}$$

$$L_- = h\otimes h_{gl} + 4X^+\otimes X^-_{gl} + 2v^+\otimes v^-_{gl}. \tag{3.9}$$

Here the first factors are generators in the fundamental representation $V^{(1)}$ (see the Appendix) and the second factors are generators of a finite dimensional osp(1|2) Lie superagebra.

The relation (3.6) is a compact matrix form of the following commutation relations between the generators $h(\lambda)$, $v^\pm(\mu)$, $X^\pm(\nu)$ of the trigonometric loop superalgebra $\mathcal{L}_t(\mathrm{osp}(1|2))$:

$$\begin{aligned}
&[h(\lambda),\ h(\mu)]_- = 0\,,\\
&[h(\lambda),\ X^\pm(\mu)]_- = \frac{\pm 2}{\sinh(\lambda-\mu)}\left(\cosh(\lambda-\mu)X^\pm(\mu) - e^{\mp(\lambda-\mu)}X^\pm(\lambda)\right),\\
&[X^+(\lambda),\ X^-(\mu)]_- = \frac{-e^{(\lambda-\mu)}}{\sinh(\lambda-\mu)}\left(h(\lambda)-h(\mu)\right),\\
&[h(\lambda),\ v^\pm(\mu)]_- = \frac{\pm 1}{\sinh(\lambda-\mu)}\left(\cosh(\lambda-\mu)v^\pm(\mu) - e^{\mp(\lambda-\mu)}v^\pm(\lambda)\right),\\
&[v^+(\lambda),\ v^-(\mu)]_+ = \frac{e^{(\lambda-\mu)}}{\sinh(\lambda-\mu)}\left(h(\lambda)-h(\mu)\right),\\
&[v^\pm(\lambda),\ v^\pm(\mu)]_+ = \frac{\pm 2}{\sinh(\lambda-\mu)}\left(e^{\pm(\lambda-\mu)}X^\pm(\mu) - e^{\mp(\lambda-\mu)}X^\pm(\lambda)\right),\\
&[X^\pm(\lambda),\ v^\mp(\mu)]_- = \frac{e^{\pm(\lambda-\mu)}}{\sinh(\lambda-\mu)}\left(v^\pm(\mu)-v^\pm(\lambda)\right),\\
&[X^\pm(\lambda),\ v^\pm(\mu)]_- = [X^\pm(\lambda),\ X^\pm(\mu)]_- = 0.
\end{aligned} \tag{3.10}$$

In order to define a dynamical system besides the algebra of observables we need to specify a Hamiltonian. Due to the r-matrix relation (3.6) the elements

$$\begin{aligned}
t(\lambda) &= \tfrac{1}{2}\ \mathrm{str}\ L^2(\lambda) = h^2(\lambda) + 2[X^+(\lambda), X^-(\lambda)]_+ + [v^+(\lambda), v^-(\lambda)]_-\\
&= h^2(\lambda) + h'(\lambda) + 4X^+(\lambda)X^-(\lambda) + 2v^+(\lambda)v^-(\lambda)
\end{aligned} \tag{3.11}$$

commute for different values of the spectral parameter

$$t(\lambda)t(\mu) = t(\mu)t(\lambda)\,. \tag{3.12}$$

Thus, $t(\lambda)$ can be considered as a generating function of integrals of motion. The supertrace in (3.11) for an even matrix $\{A_{ij}\}$ means $\mathrm{str}A = \Sigma_{i=1}^3(-1)^{p(i)}A_{ii}$, and we use the grading $p(1) = p(3) = 0$, $p(2) = 1$ (see the Appendix).

One way to show (3.12) is to notice that the commutation relation between $t(\lambda)$ and $L(\mu)$ can be written in the form

$$[t(\lambda)\,, L(\mu)] = [M(\lambda,\mu)\,, L(\mu)]\,, \tag{3.13}$$

where

$$M(\lambda,\mu)=-\operatorname*{str}_1(r_{12}(\lambda-\mu)L_1(\lambda))-\tfrac{1}{2}\operatorname*{str}_1(r_{12}^2(\lambda-\mu)), \tag{3.14}$$

and the second term is a quantum correction, which is absent if we consider the left hand side of (3.6) and (3.10) as Poisson brackets.[35] Also, in the sl(n) case this term does not contribute since it is proportional to the unit matrix. Using (3.5) and (3.7) it is straightforward to calculate $M(\lambda,\mu)$ explicitly:

$$M(\lambda,\mu)=\frac{-2}{\sinh(\lambda-\mu)}\begin{pmatrix}\cosh(\lambda-\mu)\,h(\mu) & -e^{\lambda-\mu}v^-(\mu) & 2e^{\lambda-\mu}X^-(\mu)\\ e^{-(\lambda-\mu)}v^+(\mu) & 0 & e^{\lambda-\mu}v^-(\mu)\\ 2e^{-(\lambda-\mu)}X^+(\mu) & e^{-(\lambda-\mu)}v^+(\mu) & -\cosh(\lambda-\mu)\,h(\mu)\end{pmatrix}$$
$$-\frac{1}{\sinh^2(\lambda-\mu)}\begin{pmatrix}\cosh^2(\lambda-\mu)+1 & 0 & 0\\ 0 & -2 & 0\\ 0 & 0 & \cosh^2(\lambda-\mu)+1\end{pmatrix}. \tag{3.15}$$

Substituting (3.15) into the equation (3.13) we obtain the commutation relations between $t(\lambda)$ and the generators of the superalgebra $\mathcal{L}_t(\mathrm{osp}(1|2))$. In particular,

$$[t(\lambda),\ X^+(\mu)]_-=4\coth(\lambda-\mu)\,X^+(\mu)h(\lambda)-\frac{4e^{-(\lambda-\mu)}}{\sinh(\lambda-\mu)}X^+(\lambda)h(\mu)+4X^+(\mu)$$
$$-\frac{2e^{-(\lambda-\mu)}}{\sinh(\lambda-\mu)}(v^+(\lambda)v^+(\mu)-v^+(\mu)v^+(\lambda)), \tag{3.16}$$

$$[t(\lambda),\ v^+(\mu)]_-=2\coth(\lambda-\mu)\,v^+(\mu)h(\lambda)-\frac{2e^{-(\lambda-\mu)}}{\sinh(\lambda-\mu)}v^+(\lambda)h(\mu)+v^+(\mu)$$
$$+\frac{4}{\sinh(\lambda-\mu)}(e^{-(\lambda-\mu)}X^+(\lambda)v^-(\mu)-e^{-(\mu-\lambda)}X^+(\mu)v^-(\lambda)). \tag{3.17}$$

Preserving some generality we can consider the representation space $\mathcal{H}$ of the dynamical algebra to be a lowest spin $\rho(\lambda)$ representation of the loop superalgebra with the lowest spin vector Ω_-,

$$h(\lambda)\Omega_-=\rho(\lambda)\Omega_-,\quad v^-(\lambda)\Omega_-=0\,. \tag{3.18}$$

One can study spectrum and eigenstates of $t(\lambda)$ in this general representation $\mathcal{H}$. However, to have a physical interpretation we will use a local realization of the trigonometric superalgebra $\mathcal{L}_t(\mathrm{osp}(1|2))$ with

$$\mathcal{H}=\bigotimes_{a=1}^{N}V_a,$$

as a tensor product of osp(1|2) representations. Then,

$$h(\lambda)=\sum_{a=1}^{N}\coth(\lambda-z_a)\,h_a\,, \tag{3.19}$$

$$v^+(\lambda)=\sum_{a=1}^{N}\frac{e^{\lambda-z_a}}{\sinh(\lambda-z_a)}v_a^+\,,\quad v^-(\lambda)=\sum_{a=1}^{N}\frac{e^{-\lambda+z_a}}{\sinh(\lambda-z_a)}v_a^-\,, \tag{3.20}$$

$$X^+(\lambda)=\sum_{a=1}^{N}\frac{e^{\lambda-z_a}}{\sinh(\lambda-z_a)}X_a^+,\quad X^-(\lambda)=\sum_{a=1}^{N}\frac{e^{-\lambda+z_a}}{\sinh(\lambda-z_a)}X_a^-, \tag{3.21}$$

where h_a, $v_a^{\pm}$, $X_a^{\pm}\in \mathrm{End}\,(V_a)$ are osp(1|2) generators in a representation V_a associated with each site a. If in this realization one considers the limits $\lambda\to\pm\infty$, then one finds the expressions of the generators of the global Lie superalgebra $\mathrm{osp}(1|2)\subset\mathcal{L}_t(\mathrm{osp}(1|2))$ in terms of the local generators

$$Y_{gl}=\sum_{a=1}^{N} Y_a; \tag{3.22}$$

here $Y=(h,X^{\pm},v^{\pm})$.

In particular, a representation of the Gaudin realization can be obtained by considering at each site a an irreducible representations $V_a^{(l_a)}$ of the Lie superalgebra osp(1|2) defined by a spin l_a and a lowest spin vector ω_a such that $v_a^-\omega_a=0$ and $h_a\omega_a=-l_a\omega_a$. Thus,

$$\Omega_-=\bigotimes_{a=1}^{N}\omega_a,\quad \text{and}\quad \rho(\lambda)=\sum_{a=1}^{N}(-l_a)\coth(\lambda-z_a). \tag{3.23}$$

It is a well-known fact in the theory of Gaudin models[5,6] that the Gaudin Hamiltonian is related to the classical r-matrix (1.1) and (3.2),

$$\begin{aligned}H^{(a)}&=\sum_{b\neq a} r_{ab}(z_a-z_b)\\&=\sum_{b\neq a}\frac{1}{\sinh(z_a-z_b)}(e^{(z_a-z_b)}r_{ab}^{(-)}+e^{(z_b-z_a)}r_{ab}^{(+)})\\&=\sum_{b\neq a}\coth(z_a-z_b)h_ah_b+\frac{2}{\sinh(z_a-z_b)}(e^{-(z_a-z_b)}X_a^+X_b^-+e^{(z_a-z_b)}X_a^-X_b^+)\\&\quad+\frac{1}{\sinh(z_a-z_b)}(e^{-(z_a-z_b)}v_a^+v_b^--e^{(z_a-z_b)}v_a^-v_b^+),\end{aligned} \tag{3.24}$$

and can be obtained as the residue of the operator $t(\lambda)$ at the point $\lambda=z_a$ using the expansion

$$t(\lambda)=h_{gl}^2+\sum_{a=1}^{N}\left(\frac{c_2(a)}{\sinh^2(\lambda-z_a)}+2\frac{e^{\lambda-z_a}}{\sinh(\lambda-z_a)}H^{(a)}\right), \tag{3.25}$$

$c_2(a)=h_a^2+2(X_a^+X_a^-+X_a^-X_a^+)+v_a^+v_a^--v_a^-v_a^+$. As opposed to the rational osp(1|2)-invariant case,[17] the generating function (3.25) commutes only with one generator h_{gl} of the global superalgebra osp(1|2):

$$[t(\lambda),h_{gl}]=0. \tag{3.26}$$

To construct the set of eigenstates of the generating function of integrals of motion $t(\lambda)$ we have to define appropriate creation operators. The creation operators used in the sl(2) Gaudin model coincide with one of the L-matrix entry.[5,6] However, in the osp(1|2) case the creation operators are complicated functions of the two generators of the loop superalgebra $X^+(\lambda)$ and $v^+(\mu)$.

Definition 3.1: Let $B_M(\mu_1,\ldots,\mu_M)$ *belong to the Borel subalgebra of the* osp(1|2) *loop super algebra* $\mathcal{L}_t(\mathrm{osp}(1|2))$ *such that*

$$\begin{aligned}B_M(\mu_1,\ldots,\mu_M)&=v^+(\mu_1)B_{M-1}(\mu_2,\ldots,\mu_M)\\&\quad+2X^+(\mu_1)\sum_{j=2}^{M}(-1)^j\frac{e^{-(\mu_1-\mu_j)}}{\sinh(\mu_1-\mu_j)}B_{M-2}^{(j)}(\mu_2,\ldots,\mu_M)\end{aligned} \tag{3.27}$$

with $B_0=1$, $B_1(\mu)=v^+(\mu)$ *and* $B_M=0$ *for* $M<0$. *The notation* $B^{(j)}_{M-2}(\mu_2,\ldots,\mu_M)$ *means that the argument* μ_j *is omitted.*

As we will show below, the B-operators are such that the Bethe vectors are generated by their action on the lowest spin vector Ω_- (3.18). To prove this result we will need some important properties of the B-operators. All the properties of the creation operators $B_M(\mu_1,\ldots,\mu_M)$ listed below can be demonstrated by induction method. Since the proofs are lengthy and quite technical we will present only two of them.

Lemma 3.1: The creation operators $B_M(\mu_1,\ldots,\mu_M)$ *are antisymmetric functions of their arguments*

$$B_M(\mu_1,\ldots,\mu_k,\mu_{k+1},\ldots,\mu_M)=-B_M(\mu_1,\ldots,\mu_{k+1},\mu_k,\ldots,\mu_M), \tag{3.28}$$

here $1\leqslant k<M$ *and* $M\geqslant 2$.

Lemma 3.2: The commutation relations between the creation operator B_M *and the generators* $v^+(\lambda)$, $h(\lambda)$, $v^-(\lambda)$ *of the loop superalgebra are given by*

$$v^+(\lambda)B_M=(-1)^M B_M v^+(\lambda)+2\sum_{j=1}^{M}\frac{(-1)^j}{\sinh(\lambda-\mu_j)}\times(e^{-(\lambda-\mu_j)}X^+(\lambda)-e^{-(\mu_j-\lambda)}X^+(\mu_j))B^{(j)}_{M-1}, \tag{3.29}$$

$$\begin{aligned}h(\lambda)B_M=B_M\Bigg(h(\lambda)+\sum_{i=1}^{M}\coth(\lambda-\mu_i)\Bigg)+\sum_{i=1}^{M}(-1)^i\frac{e^{-(\lambda-\mu_i)}}{\sinh(\lambda-\mu_i)}\\ \times\Bigg(v^+(\lambda)B^{(i)}_{M-1}+2X^+(\lambda)\sum_{j\neq i}^{M}(-1)^{j+\Theta(i-j)}\frac{e^{-(\mu_i-\mu_j)}}{\sinh(\mu_i-\mu_j)}B^{(i,j)}_{M-2}\Bigg),\end{aligned} \tag{3.30}$$

$$\begin{aligned}v^-(\lambda)B_M=(-1)^M B_M v^-(\lambda)+\sum_{j=1}^{M}(-1)^{j-1}B^{(j)}_{M-1}\Bigg(\frac{e^{-(\lambda-\mu_j)}}{\sinh(\lambda-\mu_j)}(h(\lambda)-h(\mu_j))\\ +\sum_{k\neq j}^{M}\frac{e^{-(\lambda-\mu_k)}}{\sinh(\lambda-\mu_k)}\frac{e^{-(\mu_k-\mu_j)}}{\sinh(\mu_k-\mu_j)}\Bigg)+v^+(\lambda)\sum_{i<j}^{M}(-1)^{i-j-1}\\ \times\frac{e^{-(\mu_i-\mu_j)}}{\sinh(\mu_i-\mu_j)}B^{(i,j)}_{M-2}\Bigg(\frac{e^{-(\lambda-\mu_i)}}{\sinh(\lambda-\mu_i)}+\frac{e^{-(\lambda-\mu_j)}}{\sinh(\lambda-\mu_j)}\Bigg).\end{aligned} \tag{3.31}$$

Here the upper index of $B^{(j)}_{M-1}$ *means that the argument* μ_j *is omitted, the upper index of* $B^{(i,j)}_{M-2}$ *means that the parameters* μ_i,μ_j *are omitted and* $\Theta(j)$ *is Heaviside function*

$$\Theta(j)=\begin{cases}1 & \text{if } j>0,\\ 0 & \text{if } j\leqslant 0.\end{cases}$$

It is useful to have explicit formulas for the commutators between the global generators and the B-operators.

Remark 3.1: The commutation relations between the generators of the global osp(1|2) *(3.22) and the* B_M *elements follow from the previous Lemma 3.2. To see this we take the appropriate limit* $\lambda\to\pm\infty$ *in (3.29)–(3.31). In this way we obtain*

$$v^+_{gl}B_M=(-1)^M B_M v^+_{gl}-2\sum_{j=1}^{M}(-1)^j X^+(\mu_j)B^{(j)}_{M-1}, \tag{3.32}$$

$$h_{gl}B_M=B_M(h_{gl}+M), \tag{3.33}$$

$$v_{gl}^{-}B_M=(-1)^M B_M v_{gl}^{-}+\sum_{j=1}^{M}(-1)^j B_{M-1}^{(j)}\left(h_{gl}+h(\mu_j)+\sum_{k\neq j}^{M}\frac{e^{(\mu_j-\mu_k)}}{\sinh(\mu_j-\mu_k)}\right). \tag{3.34}$$

Lemma 3.3: The generating function of integrals of motion $t(\lambda)$ (3.11) has the following commutation relation with the creation operator $B_M(\mu_1,\ldots,\mu_M)$,

$$\begin{aligned}t(\lambda)B_M=&B_M t(\lambda)+B_M\left(2h(\lambda)\sum_{i=1}^{M}\coth(\lambda-\mu_i)+2\sum_{i<j}^{M}\coth(\lambda-\mu_i)\coth(\lambda-\mu_j)+M\right)\\&+2\sum_{i=1}^{M}(-1)^i\frac{e^{-(\lambda-\mu_i)}}{\sinh(\lambda-\mu_i)}\left(v^{+}(\lambda)B_{M-1}^{(i)}+2X^{+}(\lambda)\sum_{j\neq i}^{M}(-1)^{j+\Theta(i-j)}\right.\\&\left.\times\frac{e^{-(\mu_i-\mu_j)}}{\sinh(\mu_i-\mu_j)}B_{M-2}^{(i,j)}\right)\hat{\beta}_M(\mu_i)+4\sum_{i=1}^{M}(-1)^{i+M}\frac{B_{M-1}^{(i)}}{\sinh(\lambda-\mu_i)}(e^{-(\lambda-\mu_i)}X^{+}(\lambda)v^{-}(\mu_i)\\&-e^{-(\mu_i-\lambda)}X^{+}(\mu_i)v^{-}(\lambda)).\end{aligned} \tag{3.35}$$

The notation used here for the operator $\hat{\beta}_M(\mu_i)$ is $\hat{\beta}_M(\mu_i)=h(\mu_i)+\Sigma_{j\neq i}^{M}\coth(\mu_i-\mu_j)$.

In the trigonometric Gaudin realization (3.17)–(3.19) the creation operators $B_M(\mu_1,\ldots,\mu_M)$ have some specific analytical properties.

Lemma 3.4: The B-operators in the Gaudin realization (3.17)–(3.19) satisfy an important differential identity

$$\begin{aligned}\frac{\partial}{\partial z_a}B_M=&\sum_{j=1}^{M}\frac{\partial}{\partial\mu_j}\left((-1)^j\frac{e^{\mu_j-z_a}}{\sinh(\mu_j-z_a)}\right.\\&\left.\times\left(v_a^{+}B_{M-1}^{(j)}+2X_a^{+}\sum_{k\neq j}^{M}(-1)^{k+\Theta(j-k)}\frac{e^{-(\mu_j-\mu_k)}}{\sinh(\mu_j-\mu_k)}B_{M-2}^{(j,k)}\right)\right).\end{aligned} \tag{3.36}$$

This identity will be a fundamental step in establishing a connection between the Bethe vectors and solutions to the KZ equation.

The proofs of the lemmas are based on the induction method. As illustrations, we prove explicitly Lemma 3.1 and the formula (3.29) in Lemma 3.2.

Proof of Lemma 3.1: Consider $M=2$:

$$B_2(\mu_1,\mu_2)=v^{+}(\mu_1)v^{+}(\mu_2)+\frac{2e^{-(\mu_1-\mu_2)}}{\sinh(\mu_1-\mu_2)}X^{+}(\mu_1).$$

Using the commutation relations (3.10) it is straightforward to check that $B_2(\mu_1,\mu_2)$ is antisymmetric:

$$B_2(\mu_1,\mu_2)=-B_2(\mu_2,\mu_1).$$

Assume $B_N(\mu_1,\ldots,\mu_N)$ is antisymmetric for $N\geqslant 2$ and for $N<M$. We have to prove that $B_M(\mu_1,\ldots,\mu_M)$ is antisymmetric also.

Consider $j\geqslant 2$, the antisymmetry of $B_M(\mu_1,\ldots,\mu_M)$ with respect to μ_j and μ_{j+1} follows directly form the recurrence relation (3.27) and our assumption. Namely, the terms $B_{M-2}^{(j)}(\mu_2,\ldots,\mu_M)e^{-(\mu_1-\mu_j)}/\sinh(\mu_1-\mu_j)$ and $B_{M-2}^{(j+1)}(\mu_2,\ldots,\mu_M)e^{-(\mu_1-\mu_{(j+1)})}/\sinh(\mu_1-\mu_{(j+1)})$ enter with the opposite sign.

Therefore we only have to show the antisymmetry of $B_M(\mu_1,\ldots,\mu_M)$ with respect to the interchange of μ_1 and μ_2. To see this we have to iterate the recurrence relation (3.27) twice and combine the appropriate terms

$$B_M(\mu_1,\ldots,\mu_M)=\left(v^+(\mu_1)v^+(\mu_2)+\frac{2e^{-(\mu_1-\mu_2)}}{\sinh(\mu_1-\mu_2)}X^+(\mu_1)\right)B_{M-2}(\mu_3,\ldots,\mu_M)$$
$$+2v^+(\mu_1)X^+(\mu_2)\sum_{j=3}^{M}(-1)^{j+1}\frac{e^{-(\mu_2-\mu_j)}}{\sinh(\mu_2-\mu_j)}\ B^{(j)}_{M-3}(\mu_3,\ldots,\mu_M)$$
$$+2v^+(\mu_2)X^+(\mu_1)\sum_{j=3}^{M}(-1)^{j}\frac{e^{-(\mu_1-\mu_j)}}{\sinh(\mu_1-\mu_j)}\ B^{(j)}_{M-3}(\mu_3,\ldots,\mu_M)$$
$$+4X^+(\mu_1)X^+(\mu_2)\sum_{j=3}^{M}(-1)^{j}\frac{e^{-(\mu_1-\mu_j)}}{\sinh(\mu_1-\mu_j)}\sum_{k=3}^{M}(-1)^{k+\Theta(j-k)}$$
$$\times\frac{e^{-(\mu_2-\mu_k)}}{\sinh(\mu_2-\mu_k)}B^{(j,k)}_{M-4}(\mu_3,\ldots,\mu_M),\tag{3.37}$$

where $B^{(j,k)}_{M-4}(\mu_3,\ldots,\mu_M)$ means that the arguments μ_j and μ_k are omitted. Since $v^+(\mu)$ commutes with $X^+(\nu)$, the antisymmetry of the right hand side of (3.37) with respect to μ_1 and μ_2 follows. Hence we have demonstrated the lemma. □

Proof of Lemma 3.2: Here we prove explicitly only formula (3.29). In particular, when $M=1$, the expression (3.29) is just the anticommutator between $v^+(\lambda)$ and $v^+(\mu)$. Using the recurrence relations (3.27) it is straightforward to check that the formula (3.29) holds for $M=2$:

$$v^+(\lambda)B_2(\mu_1,\mu_2)=B_2(\mu_1,\mu_2)v^+(\lambda)-\frac{2}{\sinh(\lambda-\mu_1)}(e^{-(\lambda-\mu_1)}X^+(\lambda)$$
$$-e^{\lambda-\mu_1}X^+(\mu_1))\ \ v^+(\mu_2)+\frac{2}{\sinh(\lambda-\mu_2)}(e^{-(\lambda-\mu_2)}X^+(\lambda)$$
$$-e^{\lambda-\mu_2}X^+(\mu_2))\ \ v^+(\mu_1).\tag{3.38}$$

Therefore we can proceed to demonstrate Lemma 3.3 by induction. Assume that the relation (3.29) holds for B_N, $M\geqslant N\geqslant 2$. Then we have to show the formula (3.29) is valid for $M+1$. We use the recurrence relations (3.27) to write

$$v^+(\lambda)B_{M+1}=v^+(\lambda)\left(v^+(\mu_1)B_M+2X^+(\mu_1)\sum_{j=2}^{M+1}\frac{e^{-(\mu_1-\mu_j)}}{\sinh(\mu_1-\mu_j)}B^{(j)}_{M-1}\right)$$
$$=-v^+(\mu_1)v^+(\lambda)B_M-\frac{2}{\sinh(\lambda-\mu_1)}(e^{-(\lambda-\mu_1)}X^+(\lambda)-e^{\lambda-\mu_1}X^+(\mu_1))B_M$$
$$+2X^+(\mu_1)\sum_{j=2}^{M+1}(-1)^{j}\frac{e^{-(\mu_1-\mu_j)}}{\sinh(\mu_1-\mu_j)}v^+(\lambda)B^{(j)}_{M-1}.\tag{3.39}$$

Now we can substitute the expressions for $v^+(\lambda)B_M$ and $v^+(\lambda)B^{(j)}_{M-1}$. After rearranging the terms in an appropriate way we have

$$v^+(\lambda)B_{M+1}=(-1)^{M+1}B_{M+1}v^+(\lambda)+2\sum_{j=1}^{M+1}\frac{(-1)^j}{\sinh(\lambda-\mu_j)}$$
$$\times(e^{-(\lambda-\mu_j)}X^+(\lambda)-e^{-(\mu_j-\lambda)}X^+(\mu_j))B^{(j)}_M\ \ .\tag{3.40}$$

This completes the proof of the lemma. □

The proofs of the other lemmas are analogous to the proofs we have illustrated above. They do not contain illuminating insights and are considerably longer than the two we have seen. Thus, we will omit them.

The recurrence relation (3.27) can be solved explicitly. To be able to express the solution in a compact form it is useful to introduce a contraction operator d.

Definition 3.2: Let d be a contraction operator whose action on an ordered product $\prod_{j=1}^{M}\overrightarrow{v^+(\mu_j)}$, $M\geqslant 2$, is given by

$$d(v^+(\mu_1)v^+(\mu_2)\cdots v^+(\mu_M))=2\sum_{j=1}^{M-1}X^+(\mu_j)\sum_{k=j+1}^{M}(-1)^{\sigma(jk)}\frac{e^{-(\mu_j-\mu_k)}}{\sinh(\mu_j-\mu_k)}\prod_{m\neq j,k}^{M}\overrightarrow{v^+(\mu_m)}, \tag{3.41}$$

where $\sigma(jk)$ is the parity of the permutation

$$\sigma:(1,2,\ldots,j,j+1,\ldots,k,\ldots,M)\to(1,2,\ldots,j,k,j+1,\ldots,M).$$

The d operator can be applied on an ordered product $\prod_{j=1}^{M}\overrightarrow{v^+(\mu_j)}$ consecutively several times, up to $[M/2]$, the integer part of $M/2$.

Theorem 3.1: *Explicit solution to the recurrence relation (3.27) is given by*

$$B_M(\mu_1,\ldots,\mu_M)=\prod_{j=1}^{M}\overrightarrow{v^+(\mu_j)}+\sum_{m=1}^{[M/2]}\frac{1}{m!}\,d^m\prod_{j=1}^{M}\overrightarrow{v^+(\mu_j)}=\exp d\prod_{j=1}^{M}\overrightarrow{v^+(\mu_j)}. \tag{3.42}$$

The properties of the creation operators B_M studied in the this section will be fundamental tools in determining characteristics of the trigonometric osp(1|2) Gaudin model. Our primary interest is to obtain the spectrum and the eigenvectors of the generating function of integrals of motion $t(\lambda)$ (3.11).

IV. SPECTRUM AND EIGENSTATES OF TRIGONOMETRIC osp(1|2) GAUDIN MODEL

With the help of the creation operators B_M it is possible to obtain the eigenvectors as well as the corresponding eigenvalues of the Hamiltonians of the trigonometric Gaudin model. This result is a direct consequence of the following theorem.

Theorem 4.1: *The lowest spin vector Ω_- (3.18) is an eigenvector of the generating function of integrals of motion $t(\lambda)$ (3.11) with the corresponding eigenvalue $\Lambda_0(\lambda)$:*

$$t(\lambda)\,\Omega_-=\Lambda_0(\lambda)\,\Omega_-,\quad \Lambda_0(\lambda)=\rho^2(\lambda)+\rho'(\lambda). \tag{4.1}$$

Furthermore, the action of the B-operators (3.27) on the lowest spin vector Ω_- yields the eigenvectors

$$\Psi(\mu_1,\ldots,\mu_M)=B_M(\mu_1,\ldots,\mu_M)\quad\Omega_- \tag{4.2}$$

of the $t(\lambda)$ operator

$$t(\lambda)\Psi(\mu_1,\ldots,\mu_M)=\Lambda(\lambda;\{\mu_j\}_{j=1}^{M})\,\Psi(\mu_1,\ldots,\mu_M), \tag{4.3}$$

with the eigenvalues

$$\Lambda(\lambda;\{\mu_j\}_{j=1}^{M})=y^2+\partial_\lambda y. \tag{4.4}$$

Here

$$y(\lambda;\{\mu_j\}_{j=1}^M)=\rho(\lambda)+\sum_{k=1}^{M}\coth(\lambda-\mu_k), \tag{4.5}$$

provided that the Bethe equations are imposed on the parameters $\{\mu_j\}_{j=1}^M$ *of the state (4.2):*

$$\beta_M(\mu_j)=\rho(\mu_j)+\sum_{k\neq j}^{M}\coth(\mu_j-\mu_k)=0. \tag{4.6}$$

Proof: The equation (4.1) can be checked by a direct substitution of the definitions of the operator $t(\lambda)$ and the lowest spin vector Ω_-, the equations (3.11) and (3.18), respectively.

To show the second part of the theorem, we use the equation (4.2) to express the Bethe vectors $\Psi(\mu_1,\ldots,\mu_M)$,

$$t(\lambda)\Psi(\mu_1,\ldots,\mu_M)=t(\lambda)\ \ B_M(\mu_1,\ldots,\mu_M)\ \ \Omega_-. \tag{4.7}$$

Our next step is to use the third property of the B-operators, the equation (3.3), and the definition of the lowest spin vector Ω_-, the equation (3.18), in order to calculate the action of the operator $t(\lambda)$ on the Bethe vectors when the Bethe equations (4.6) are imposed:

$$\begin{aligned} t(\lambda)B_M\Omega_- &= B_M t(\lambda)\Omega_- \\ &\quad+\left(2\rho(\lambda)\sum_{i=1}^{M}\coth(\lambda-\mu_i)+2\sum_{i<j}^{M}\coth(\lambda-\mu_i)\coth(\lambda-\mu_j)+M\right)B_M\Omega_-. \end{aligned} \tag{4.8}$$

We can express the first term on the right hand side since we know how the operator $t(\lambda)$ acts on the vector Ω_-, the equation (4.1). Thus we have

$$t(\lambda)\ \ B_M\Omega_-=\Lambda(\lambda;\{\mu_j\}_{j=1}^M)\ \ B_M\Omega_-, \tag{4.9}$$

with

$$\Lambda(\lambda;\{\mu_j\}_{j=1}^M)=\Lambda_0(\lambda)+2\rho(\lambda)\sum_{i=1}^{M}\coth(\lambda-\mu_i)+2\sum_{i<j}^{M}\coth(\lambda-\mu_i)\coth(\lambda-\mu_j)+M,$$

and we complete the proof by expressing the eigenvalue as

$$\Lambda(\lambda;\{\mu_j\}_{j=1}^M)=y^2+\partial_\lambda y,\quad \text{with}\quad y(\lambda;\{\mu_j\}_{j=1}^M)=\rho(\lambda)+\sum_{k=1}^{M}\coth(\lambda-\mu_k).$$

□

Corollary 4.1: In the trigonometric Gaudin realization given by the equations (3.19)–(3.21) and (3.23) the Bethe vectors $\Psi(\mu_1,\ldots,\mu_M)$ *(4.2) are the eigenvectors of the Gaudin Hamiltonians (3.24) (see also Ref. 36)*

$$H^{(a)}\Psi(\mu_1,\ldots,\mu_M)=E_M^{(a)}\Psi(\mu_1,\ldots,\mu_M), \tag{4.10}$$

with the eigenvalues

$$E_M^{(a)}=\sum_{\substack{b=1\\ b\neq a}}^{N} l_a\, l_b\coth(z_a-z_b)+\sum_{j=1}^{M} l_a\coth(\mu_j-z_a), \tag{4.11}$$

when the Bethe equations are imposed:

$$\beta_M(\mu_j)=\rho(\mu_j)+\sum_{k\neq j}^{M}\coth(\mu_j-\mu_k)=\sum_{a=1}^{N}(-l_a)\coth(\mu_j-z_a)+\sum_{k\neq j}^{M}\coth(\mu_j-\mu_k)=0. \tag{4.12}$$

Proof: The statement of the corollary follows from residue of the equation (4.3) at the point $\lambda=z_a$. The residue can be determined using (3.25), (4.4) and (4.1). □

Comparing the eigenvalues $E_M^{(a)}$ (4.11) of the Gaudin Hamiltonians and the Bethe equations (4.12) with the corresponding quantities of the sl(2) Gaudin model[5,6] we arrive at an interesting observation.

Remark 4.1: The spectrum of the osp(1|2) *trigonometric Gaudin model with the spins* l_a *coincides with the spectrum of the* sl(2) *trigonometric Gaudin system for the integer spins (see an analogous observation for partition functions of corresponding anisotropic vertex models in Ref. 32).*

Remark 4.2: The Bethe vectors are eigenstates of the global generator h_{gl}

$$h_{gl}\Psi(\mu_1,\ldots,\mu_M)=\left(-\sum_{a=1}^{N}l_a+M\right)\Psi(\mu_1,\ldots,\mu_M). \tag{4.13}$$

As opposed to the osp(1|2)-invariant model,[17] these Bethe vectors are not the lowest spin vectors of the global osp(1|2) since they are not annihilated by the generator v_{gl}^{-},

$$v_{gl}^{-}\Psi(\mu_1,\ldots,\mu_M)\neq 0, \tag{4.14}$$

once the Bethe equations are imposed, (4.12). These conclusions follow from Remark 3.1, in particular the equations (3.33) and (3.34), and the definition of the Bethe vectors (4.2).

As was pointed out already in Ref. 5 for the sl(2) case, there are several modifications of the Hamiltonians (3.24). One of them is the Richardson's pairing-force Hamiltonian.[37,38,5] These modifications can be formulated in the framework of the universal L-operator and r-matrix formalism (3.6).[6]

Due to invariance of the r-matrix (3.5) with respect to the Cartan element

$$[r(\lambda),h\otimes I+I\otimes h]=0,\quad h\in\mathrm{osp}(1|2), \tag{4.15}$$

one can add to the L-operator the element h,

$$L(\lambda)\to\tilde{L}(\lambda)=g\,h+L(\lambda), \tag{4.16}$$

preserving commutation relations (3.6). Then

$$\tilde{t}(\lambda)=\tfrac{1}{2}\,\mathrm{str}\,\tilde{L}^2(\lambda)=t(\lambda)+2g\,h(\lambda)+g^2 \tag{4.17}$$

will have the commutativity property, i.e., $\tilde{t}(\lambda)\tilde{t}(\mu)=\tilde{t}(\mu)\tilde{t}(\lambda)$. Hence we can take $\tilde{t}(\lambda)$ to be the generating function of the (modified) integrals of motion,

$$\tilde{t}(\lambda)=(h_{gl}-g)^2+\sum_{a=1}^{N}\left(\frac{c_2(a)}{\sinh^2(\lambda-z_a)}+2\,\frac{e^{\lambda-z_a}}{\sinh(\lambda-z_a)}\tilde{H}^{(a)}\right), \tag{4.18}$$

$$\tilde{H}^{(a)}=\operatorname*{res}_{\lambda=z_a}\tilde{t}(\lambda)=g\;\;h_a+H^{(a)}. \tag{4.19}$$

In this case the eigenstates Ψ_M are generated by the same B-operators. However, corresponding eigenvalues and Bethe equations are now given by

$$\tilde{\Lambda}(\lambda;\{\mu_j\}_{j=1}^{M})=(y+g)^2+\partial_\lambda y; \tag{4.20}$$

here as before $y(\lambda;\{\mu_j\}_{j=1}^{M})=\Sigma_{a=1}^{N}(-l_a)\coth(\lambda-z_a)+\Sigma_{k=1}^{M}\coth(\lambda-\mu_k)$,

$$\tilde{E}_M^{(a)}=E_M^{(a)}+g\,(-l_a), \tag{4.21}$$

$$\sum_{a=1}^{N}(-l_a)\coth(\mu_j-z_a)+\sum_{k\neq j}^{M}\coth(\mu_j-\mu_k)+g=0. \tag{4.22}$$

The crucial step in the proof of these equations is the observation that the commutation relations between the operator $\tilde{t}(\lambda)$ (4.17) and the creation operators B_M are equal to the commutation relations (3.3) but with modified operator $\hat{\beta}_M(\mu_j)\to\hat{\beta}_M(\mu_j)+g$. To see this notice the similarity between the terms with $v^+(\lambda)B_{M-1}^{(i)}$ operators and with $X^+(\lambda)B_{M-2}^{(i,j)}$ operators in Lemma 3.2, the equation (3.30), and in Lemma 3.3, the equation (3.3).

A Richardson-like Hamiltonian[37,38,5,20,21] can be obtained as a coefficient in the $\lambda\to+\infty$ expansion,[17]

$$\tilde{t}(\lambda)=(h_{gl}+g)^2+4e^{-2\lambda}\Big((h_{gl}-1+g)\Big(\sum_a e^{2z_a}h_a\Big)+4X_{gl}^{+}\Big(\sum_a e^{2z_a}X_a^{-}\Big)+2v_{gl}^{+}\Big(\sum_a e^{2z_a}v_a^{-}\Big)\Big)$$
$$+O(e^{-4\lambda}). \tag{4.23}$$

Let us denote the coefficient next to the factor $4e^{-2\lambda}$ by H_+:

$$H_+=(h_{gl}-1+g)\Big(\sum_i e^{2z_a}h_a\Big)+4X_{gl}^{+}\Big(\sum_a e^{2z_a}X_a^{-}\Big)+2v_{gl}^{+}\Big(\sum_a e^{2z_i}v_a^{-}\Big). \tag{4.24}$$

This Hamiltonian is obviously not symmetric. Similar Hamiltonian can be obtained as a coefficient in the $\lambda\to-\infty$ expansion

$$\tilde{t}(\lambda)=(h_{gl}-g)^2+4e^{2\lambda}\Big(\Big(\sum_a e^{-2z_a}h_a\Big)(h_{gl}-1-g)+4\Big(\sum_a e^{-2z_a}X_a^{+}\Big)X_{gl}^{-}$$
$$+2\Big(\sum_a e^{-2z_a}v_a^{+}\Big)v_{gl}^{-}\Big)+O(e^{4\lambda}). \tag{4.25}$$

Let us denote the coefficient next to the factor $4e^{2\lambda}$ by H_-, which is also not symmetric. Thus, we choose the following symmetric combination for a trigonometric generalization of the Richardson Hamiltonian:

$$H_R=\frac{1}{2}(H_++H_-)=(h_{gl}-1)\Big(\sum_a \cosh(2z_a)\;\;h_a\Big)+g\;\;\Big(\sum_a \sinh(2z_a)\;\;h_a\Big)$$
$$+2\Big(X_{gl}^{+}\Big(\sum_a e^{2z_a}X_a^{-}\Big)+\Big(\sum_a e^{-2z_a}X_a^{+}\Big)X_{gl}^{-}\Big)+v_{gl}^{+}\Big(\sum_i e^{2z_a}v_a^{-}\Big)+\Big(\sum_a e^{-2z_a}v_a^{+}\Big)v_{gl}^{-}. \tag{4.26}$$

The eigenvalues of H_R have different dependence on the quasi-momenta from the rational case,[37,17]

$$H_R\Psi_M(\mu_1,\ldots,\mu_M)=E_R(M)\Psi_M(\mu_1,\ldots,\mu_M), \tag{4.27}$$

with

$$E_R(M)=\left(\sum_{j=1}^{M}\cosh(2\mu_j)-\sum_{a=1}^{N}l_a\cosh(2z_a)\right)\left(M-\sum_{a=1}^{N}l_a-1\right)$$
$$+\left(\sum_{j=1}^{M}\sinh(2\mu_j)-\sum_{a=1}^{N}l_a\sinh(2z_a)\right)g. \tag{4.28}$$

More complicated modifications of Gaudin models can be obtained considering the quasiclassical limit of the quantum spin system with nonperiodic boundary conditions and corresponding reflection equation.[39,40] The L-operator can be expressed in terms of the original one (3.7) as

$$L^{(bGM)}(\lambda;\{z_j\})=L(\lambda;\{z_j\})-L(-\lambda;\{z_j\}), \tag{4.29}$$

in the case of the open chain, and it will satisfy more complicated liner brackets, defining a subalgebra of the loop algebra (3.6) (see also Ref. 41 and references therein).

Most of the trigonometric Gaudin model relations have their counterparts in the rational osp(1|2)-invariant case. To show this one takes a scaling limit $\lambda\to\varepsilon\lambda$, $z_a\to\varepsilon z_a$,

$$\lim_{\varepsilon\to 0}\varepsilon L_{\mathrm{trig}}(\varepsilon\lambda;\{\varepsilon z_a\})=L_{\mathrm{inv}}(\lambda;\{z_a\}), \tag{4.30}$$

and in this way one reproduces known results for the osp(1|2)-invariant model. However, as we shall see in the next section, some relations of the invariant GM have quite complicated analogs in the trigonometric case (a generalization of KZ system to include a ''magnetic field'' parameter g requires a difference dynamical equation[15,16]). Also the modified L-operator (4.16) requires to scale the parameter $g\to g/\varepsilon$.

Another modification can be obtained by performing the similarity transformation on the r-matrix (3.1) by the tensor square of the element $\exp(tX^+)$. Then the scaling limit $\lambda\to\varepsilon\lambda$, $t\to\xi/2\varepsilon$, results in a modified r-matrix:

$$\hat{r}(\lambda)=\frac{c_2^{\otimes}}{\lambda}+\xi(h\otimes X^+-X^+\otimes h-v^+\otimes v^+). \tag{4.31}$$

The loop superalgebra will be modified, as well as corresponding Hamiltonians (1.1). Similarly, the algebraic Bethe ansatz will require changes, although the Bethe equations and the spectrum will be the same as in the osp(1|2)-invariant case [see the sl(2) case in Ref. 42].

The expression of the eigenvectors of a solvable model in terms of local variables parametrized by sites of the chain or by space coordinates, is known as coordinate Bethe ansatz.[5] The coordinate representation of the Bethe vectors gives explicitly analytical dependence on the parameters $\{\mu_i\}_1^M$ and $\{z_a\}_1^N$ useful in a relation to the Knizhnik–Zamolodchikov equation (Sec. V). Using the Gaudin realization (3.19)–(3.21) of the generators

$$v^+(\mu)=\sum_{a=1}^{N}\frac{e^{\mu-z_a}}{\sinh(\mu-z_a)}v_a^+,\quad X^+(\mu)=\sum_{a=1}^{N}\frac{e^{\mu-z_a}}{\sinh(\mu-z_a)}X_a^+,$$

and the definition of the creation operators (3.42), one can get the coordinate representation of the B-operators:

$$B_M(\mu_1,\mu_2,\ldots,\mu_M)=\sum_{\pi}(v_{a_1}^+\cdots v_{a_M}^+)_{\pi}\prod_{a=1}^{N}\varphi(\{\mu_m^{(a)}\}_1^{|\mathcal{K}_a|};z_a), \tag{4.32}$$

where the first sum is taken over ordered partitions π of the set $(1,2,\ldots,M)$ into subsets $\mathcal{K}_a$, $a=1,2,\ldots,N$, including empty subsets with the constraints

$$\bigcup_a \mathcal{K}_a=(1,2,\ldots,M), \quad \mathcal{K}_a\cap\mathcal{K}_b=\varnothing \quad \text{for} \quad a\neq b.$$

The corresponding subset of quasimomenta

$$(\mu_1^{(a)}=\mu_{j_1},\mu_2^{(a)}=\mu_{j_2},\ldots,\mu_{|\mathcal{K}_a|}^{(a)}=\mu_{j_{|\mathcal{K}_a|}};j_m\in\mathcal{K}_a),$$

where $|\mathcal{K}_a|$ is the cardinality of the subset $\mathcal{K}_a$, and $j_k<j_{k+1}$, entering into the coordinate wave function

$$\varphi(\{\nu_m\}_1^{|\mathcal{K}|};z)=\sum_{\sigma\in\mathcal{S}_{|\mathcal{K}|}}(-1)^{p(\sigma)}\frac{e^{\nu_{\sigma(1)}-\nu_{\sigma(2)}}}{\sinh(\nu_{\sigma(1)}-\nu_{\sigma(2)})}\frac{e^{\nu_{\sigma(2)}-\nu_{\sigma(3)}}}{\sinh(\nu_{\sigma(2)}-\nu_{\sigma(3)})}\cdots\frac{e^{\nu_{\sigma(|\mathcal{K}|)}-z}}{\sinh(\nu_{\sigma(|\mathcal{K}|)}-z)}.$$

Due to the alternative sum over permutations $\sigma\in\mathcal{S}_{|\mathcal{K}|}$ this function is antisymmetric with respect to the quasi-momenta. Finally, the first factor in (4.32),

$$(v_{a_1}^+\cdots v_{a_M}^+)_\pi,$$

means that for $j_m\in\mathcal{K}_a$, corresponding indices of $v_{a_{j_m}}^+$ are equal to a so that $v_{a_{j_m}}^+=v_a^+$. One can collect these operators into product $\Pi_{a=1}^N(v_a^+)^{|\mathcal{K}_a|}$; consequently, we have an extra sign factor $(-1)^{p(\pi)}$.

This coordinate representation is similar to the representations obtained in Refs. 11–13 for the Gaudin models related to the simple Lie algebras (see also Ref. 43). The Z_2-grading of superalgebra results in extra signs, while the complicated structure of the B_M-operators [for the sl(2) Gaudin model they are just products of B_1-operators $B_1(\mu_j)=X^+(\mu_j)$] is connected with the fact that $(v_j^+)^2=X_j^+\neq 0$ while for $j\neq k$ v_j^+ and v_k^+ anticommute.

V. SOLUTIONS TO THE KNIZHNIK–ZAMOLODCHIKOV EQUATION

Correlation functions $\psi(z_1,\ldots,z_N)$ of a two dimensional conformal field theory satisfy the Knizhnik–Zamolodchikov equation[44]

$$\kappa\ \partial_{z_a}\ \psi(z_1,\ldots,z_N)=H^{(a)}\psi(z_1,\ldots,z_N), \tag{5.1}$$

where $H^{(a)}(a=1,\ldots,N)$ are the Gaudin Hamiltonians (3.24) and $\psi(z_1,\ldots,z_N)$ is a function of N complex variables with its values in a tensor product $\mathcal{H}=\otimes_{a=1}^N V_a^{(l_a)}$.

A relation between the Bethe vectors of the Gaudin model related to simple Lie algebras and the solutions to the Knizhnik–Zamolodchikov equation is well known for some time.[11,12] Approach used here to obtain solutions to the Knizhnik–Zamolodchikov equation corresponding to conformal field theory and Lie superalgebra osp(1|2) starting from B-vectors (4.2) is based on Ref. 11.

A solution in question is represented as a contour integral over the variables $\mu_1,\ldots,\mu_M$

$$\psi(z_1,\ldots,z_N)=\oint\cdots\oint\ \phi(\vec{\mu}|\vec{z})\Psi(\vec{\mu}|\vec{z})\ \ \mathrm{d}\mu_1\cdots\mathrm{d}\mu_M, \tag{5.2}$$

where an integrating factor $\phi(\vec{\mu}|\vec{z})$ is a scalar function

$$\phi(\vec{\mu}|\vec{z})=\prod_{i<j}^M\sinh(\mu_i-\mu_j)^{1/\kappa}\prod_{a<b}^N\sinh(z_a-z_b)^{l_al_b/\kappa}\left(\prod_{k=1}^M\prod_{c=1}^N\sinh(\mu_k-z_c)^{-l_c/\kappa}\right), \tag{5.3}$$

and $\Psi(\vec{\mu}|\vec{z})$ is a Bethe vector (4.2) where the corresponding Bethe equations are not imposed.

As a first step in the proof that $\psi(z_1,\ldots,z_N)$ given by (5.2) is a solution of (5.1) we differentiate the product $\phi\Psi$ with respect to z_a and obtain

$$\partial_{z_a}(\phi\Psi)=\partial_{z_a}(\phi)\Psi+\phi\partial_{z_a}(\Psi). \tag{5.4}$$

Using (5.3) the first term on the right hand side can be calculated explicitly:

$$\kappa\partial_{z_a}\phi=\left(\sum_{\substack{b=1\\ b\neq a}}^{N} l_a\, l_b\coth(z_a-z_b)-\sum_{j=1}^{M} l_a\coth(z_a-\mu_j)\right)\phi=E_M^{(a)}\phi. \tag{5.5}$$

Furthermore, taking a residue of (3.3) at $\lambda=z_a$ we have

$$H^{(a)}\Psi=E_M^{(a)}\Psi+\sum_{j=1}^{M}(-1)^j\frac{e^{-(z_a-\mu_j)}}{\sinh(z_a-\mu_j)}\beta_M(\mu_j)\tilde{\Psi}^{(j,a)}, \tag{5.6}$$

where

$$\tilde{\Psi}^{(j,a)}=\left(v_a^+ B_{M-1}^{(j)}+2X_a^+\sum_{k\neq j}^{M}(-1)^{k+\Theta(j-k)}\frac{e^{-(\mu_j-\mu_k)}}{\sinh(\mu_j-\mu_k)}B_{M-2}^{(j,k)}\right)\ \Omega_-. \tag{5.7}$$

Hence (5.4) can be written as

$$\kappa\partial_{z_a}(\phi\Psi)=H^{(a)}(\phi\Psi)+\phi\sum_{j=1}^{M}(-1)^j\frac{e^{\mu_j-z_a}}{\sinh(\mu_j-z_a)}\beta_M(\mu_j)\tilde{\Psi}^{(j,a)}+\kappa\phi\partial_{z_a}(\Psi). \tag{5.8}$$

Moreover, from (5.3) we also have

$$\kappa\partial_{\mu_j}\phi=\left(\sum_{a=1}^{N}(-l_a)\coth(\mu_j-z_a)+\sum_{\substack{k=1\\ j\neq k}}^{M}\coth(\mu_j-\mu_k)\right)\phi=\beta_M(\mu_j)\phi, \tag{5.9}$$

and from Lemma 3.4 follows

$$\partial_{z_a}\Psi=\sum_{j=1}^{M}(-1)^j\partial_{\mu_j}\left(\frac{e^{\mu_j-z_a}}{\sinh(\mu_j-z_a)}\tilde{\Psi}^{(j,a)}\right). \tag{5.10}$$

Thus, using (5.9) and (5.10), we can combine the last two terms in (5.8) into a sum of first order derivatives in μ_j:

$$\kappa\partial_{z_a}(\phi\Psi)=H^{(a)}(\phi\Psi)+\kappa\sum_{j=1}^{M}(-1)^j\partial_{\mu_j}\left(\frac{e^{\mu_j-z_a}}{\sinh(\mu_j-z_a)}\phi\,\tilde{\Psi}^{(j,a)}\right). \tag{5.11}$$

A closed contour integration of $\phi\Psi$ with respect to $\mu_1,\ldots,\mu_M$ will cancel the contribution from the terms under the sum in (5.11) and therefore $\psi(z_1,\ldots,z_N)$ given by (5.2) satisfies the Knizhnik–Zamolodchikov equation.

Conjugated Bethe vectors $(B_M\Omega_-)^*$ are entering into the solution $\tilde{\psi}(z_1,\ldots,z_N)$ of the dual Knizhnik–Zamolodchikov equation

$$-\kappa\frac{\partial}{\partial z_a}\tilde{\psi}(z_1,\ldots,z_N)=\tilde{\psi}(z_1,\ldots,z_N)\ \ H^{(a)}. \tag{5.12}$$

The scalar product $(\tilde{\psi}(z_1,\ldots,z_N),\ \psi(z_1,\ldots,z_N))$ does not depend on $\{z_j\}_1^N$ and its quasi-classical limit $\kappa\to 0$ gives the norm of the Bethe vectors due to the fact that the stationary points of the contour integrals for $\kappa\to 0$ are solutions to the Bethe equations[13]

$$\frac{\partial S}{\partial \mu_j}=\sum_{a=1}^{N}(-l_a)\coth(\mu_j-z_a)+\sum_{\substack{k=1\\ j\neq k}}^{M}\coth(\mu_j-\mu_k)=0, \tag{5.13}$$

$$S(\vec{\mu}|\vec{z})=\kappa\ln\phi=\sum_{a<b}^{N}l_a l_b\ln(\sinh(z_a-z_b))+\sum_{i<j}^{M}\ln(\sinh(\mu_i-\mu_j))$$
$$-\sum_{a=1}^{N}\sum_{j=1}^{M}l_a\ln(\sinh(z_a-\mu_j)). \tag{5.14}$$

According to the remark at the end of Sec. IV, analytical properties of the Bethe vectors of the trigonometric osp(1|2) Gaudin model coincide with the analytical properties of the trigonometric sl(2) Gaudin model. Thus, the expression for the norm of the Bethe vectors Ψ (4.2) obtained as the first term in the asymptotic expansion $\kappa\to 0$ coincides also

$$(\Psi,\Psi)=\det\left(\frac{\partial^2 S}{\partial\mu_j\ \partial\mu_k}\right), \tag{5.15}$$

$$\frac{\partial^2 S}{\partial\mu_j^2}=\sum_{a=1}^{N}\frac{l_a}{\sinh^2(\mu_j-z_a)}-\sum_{k\neq j}^{M}\frac{1}{\sinh^2(\mu_j-\mu_k)},\quad \frac{\partial^2 S}{\partial\mu_j\ \partial\mu_k}=\frac{1}{\sinh^2(\mu_j-\mu_k)}, \tag{5.16}$$

for $j\neq k$.

Finally we notice that the modification of the Gaudin Hamiltonians we discussed at the end of the previous section can be easily transfered to the corresponding modification of the Knizhnik–Zamolodchikov equations. The modification (4.16) for the sl(2)-invariant Gaudin model was studied in Ref. 29 as a quantization of the Schlesinger system (see also Ref. 28). This modification is related with extra factor in the integrating scalar function (5.3),

$$\phi_j=\exp\left(\frac{S_j}{\kappa}\right),\quad j=0,1, \tag{5.17}$$

where $S_0=S$ (5.14) and

$$S_1=S_0+g\sum_{j=1}^{M}\mu_j-g\sum_{a=1}^{N}l_a z_a \tag{5.18}$$

correspond to the modification (4.16).

Moreover, following the lines of Ref. 29, one can try to extend the connection between the KZ equation and the Guadin model based on the modified L-operator (4.16) by extending the KZ system to include an equation of the form

$$\left(\kappa\frac{\partial}{\partial g}-H_{\mathrm{Rich}}\right)\psi=0\ . \tag{5.19}$$

However, such a straightforward generalization has failed in the trigonometric case (see below). We can comment on the extension in the rational case[17] as a scaling limit of the trigonometric Gaudin model (4.30). The equations of original KZ system are defined by mutually commuting differential operators [see (3.4)]:

$$\nabla_a=\kappa\frac{\partial}{\partial z_a}-\tilde{H}^{(a)}=\kappa\frac{\partial}{\partial z_a}-gh_a-\sum_{b\neq a}\frac{c_2^{\otimes}(a,b)}{z_a-z_b}. \tag{5.20}$$

The operator

$$\nabla_g = \kappa \frac{\partial}{\partial g} - H_{\mathrm{Rich}} = \kappa \frac{\partial}{\partial g} - \sum_{a=1}^{N} z_a h_a - \frac{1}{2g}(c_2(gl) - h_{gl}(h_{gl}-1)) \tag{5.21}$$

is commuting pairwise with the operators ∇_a. Thus in the rational case the KZ system can be generalized to include the operator ∇_g.

To prove that the solution to the modified KZ system with ϕ_1 given by (5.17) and (5.18) is a solution to the generalized KZ system we have to extend the trigonometric KZ equations (5.1) with modified Hamiltonians $gh_a + H^{(a)}$ along the lines of Refs. 15 and 16. A difference equation must be introduced,

$$K(z_1,\ldots,z_N;g) \quad \psi(z_1,\ldots,z_N;g) = \psi(z_1,\ldots,z_N;g-2\kappa), \tag{5.22}$$

instead of (5.21). The operator K is defined on the space $\mathcal{H}$

$$K(z_1,\ldots,z_N;g) = \exp\left(-2\sum_{a=1}^{N} z_a h_a\right) P(g;h_{gl},v_{gl}^{+},v_{gl}^{-}), \tag{5.23}$$

where the operator P depends on the global generators of the subalgebra $\mathrm{osp}(1|2) \subset \mathcal{L}_t$, and is constructed form the extremal projector $p(h,v^{+},v^{-})$ by a shift of the Cartan generator (see the Appendix). We introduce only one K operator since the rank of osp(1|2) Lie superalgebra is one. In the general case of simple Lie superalgebra of rank r, one has to consider a set of K_k, $k=1,\ldots,r$ (see Refs. 15 and 16).

VI. CONCLUSION

By analyzing the model related to the trigonometric osp(1|2) classical r-matrix the algebraic Bethe ansatz approach to the Gaudin models is reviewed. The results presented in this article are in some sense analogous to the ones we obtained for the osp(1|2)-invariant model.[17] In particular, a striking similarity between some of the most fundamental characteristics of this system and the sl(2) trigonometric Gaudin model was confirmed. Although explicitly constructed creation operators B_M (3.42) of the Bethe vectors are complicated polynomials of the L-operator entries $v^{+}(\lambda)$ and $X^{+}(\lambda)$, the coordinate form of the eigenfunctions differs only in signs from the corresponding states in the case of sl(2) trigonometric model, being antisymmetric functions of the quasimomenta. Moreover, the eigenvalues and the Bethe equations coincide, provided that the sl(2) Gaudin model with integer spins is considered. Analogously, the KZ equations based on both trigonometric models and for the nontrivial magnetic field g require extension of the system of equations by the dynamical difference equation.

Let us point out that by the method presented in this article one can construct explicitly creation operators of the Gaudin models related to trigonometric Izergin-Korepin r-matrix[3,30] corresponding to the twisted affine algebra $A_2^{(2)}$. Similarly to the simple Lie algebra case, solutions to the Knizhnik–Zamolodchikov equation were constructed from the Bethe vectors using algebraic properties of the creation operators B_M and the Gaudin realization of the loop superalgebra $\mathcal{L}_t(\mathrm{osp}(1|2))$. This interplay between the Gaudin model and the Knizhnik–Zamolodchikov equation enabled us to determine the norm of eigenfunctions of the Gaudin Hamiltonians

$$\|\Psi(\mu_1,\ldots,\mu_M;\{z_a\}_1^N)\|^2 = \det\left(\frac{\partial^2 S}{\partial \mu_j \ \partial \mu_k}\right).$$

The difficult problem of correlation function calculation for general Bethe vectors

$$\mathcal{C}(\{\nu_j\}_1^M;\{\mu_i\}_1^M;\{\lambda_k\}_1^K) = \left(\Omega_-, \ B_M^{*}(\nu_1,\ldots,\nu_M)\prod_{k=1}^{K} h(\lambda_k)\, B_M(\mu_1,\ldots,\mu_M)\Omega_-\right)$$

was solved nicely for the sl(2)-invariant Gaudin model in Ref. 7 using the Gauss factorization of the loop algebra group element and the appropriate Riemann-Hilbert problem. Although the corresponding factorization is known even for the quantum superalgebra $\mathcal{U}_q(\mathrm{osp}(1|2))$,[45] the final expression of the correlation functions is difficult to obtain due to the complicated structure of the creation operators $B_M(\mu_1,\ldots,\mu_M)=\mathrm{Poly}(v^+,X^+)$ (3.42). The study of this problem is in progress and the following expression for the scalar product of the Bethe states is conjectured (see Ref. 7):

$$(\Omega_-,\ B_M^*(\nu_1,\ldots,\nu_M)B_M(\mu_1,\ldots,\mu_M)\Omega_-)=\sum_{\sigma\in\mathcal{S}_M}(-1)^{p(\sigma)}\det\mathcal{M}^{\sigma},$$

where the sum is over symmetric group $\mathcal{S}_M$ and $M\times M$ matrix $\mathcal{M}^{\sigma}$ is given by

$$\mathcal{M}^{\sigma}_{jj}=\frac{e^{\mu_j-\nu_{\sigma(j)}}}{\sinh(\mu_j-\nu_{\sigma(j)})}(\rho(\mu_j)-\rho(\nu_{\sigma(j)}))-\sum_{k\neq j}^{M}\frac{e^{\mu_j-\mu_k}e^{-(\nu_{\sigma(j)}-\nu_{\sigma(k)})}}{\sinh(\mu_j-\mu_k)\sinh(\nu_{\sigma(j)}-\nu_{\sigma(k)})},$$

$$\mathcal{M}^{\sigma}_{jk}=\frac{e^{\mu_j-\mu_k}e^{-(\nu_{\sigma(j)}-\nu_{\sigma(k)})}}{\sinh(\mu_j-\mu_k)\sinh(\nu_{\sigma(j)}-\nu_{\sigma(k)})},\quad \text{for } j,k=1,2,\ldots,M.$$

APPENDIX: ORTHOSYMPLECTIC LIE SUPERALGEBRA osp(1|2)

The rank of the orthosymplectic Lie algebra osp(1|2) is one and its dimension is five.[33] The three even generators are h,X^+,X^- and the two odd generators are v^+,v^-. The (graded) commutation relations of the generators are

$$\begin{gathered}[h,X^{\pm}]_-=\pm 2X^{\pm},\quad [X^+,X^-]_-=h,\\ [h,v^{\pm}]_-=\pm v^{\pm},\quad [v^+,v^-]_+=-h,\\ [X^{\mp},v^{\pm}]_-=v^{\mp},\quad [v^{\pm},v^{\pm}]_+=\pm 2X^{\pm},\\ [X^{\pm},v^{\pm}]_-=0.\end{gathered}\tag{A1}$$

The Casimir element is

$$c_2=h^2+2(X^+X^-+X^-X^+)+(v^+v^--v^-v^+)=h^2-h+4X^+X^-+2v^+v^-.\tag{A2}$$

It is interesting to point out the existance of a ''square root'' of this element

$$c_1=h+2v^+v^--\tfrac{1}{2},\quad (c_1)^2=c_2+\tfrac{1}{4},\tag{A3}$$

with a grading property $[c_1,X^{\pm}]=0$, $[c_1,h]=0$ and $c_1v^{\pm}=-v^{\pm}c_1$. The finite dimensional irreducible representations $V^{(l)}$ of the osp(1|2) Lie superalgebra are parametrized by an integer l, so that their dimensions $2l+1$ and the values of the Casimir element (A2) $c_2=l(l+1)$ coincide with the same characteristics of the integer spin l irreducible representations of sl(2).

The fundamental irreducible representation $V^{(1)}$ of osp(1|2) is three dimensional. We choose a grading of the basis vectors e_j, $j=1,2,3$, to be (0,1,0). Explicitly we have

$$h=\begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -1 \end{pmatrix},$$

$$v_-=(v_+)^{st}=\begin{pmatrix} 0 & 0 & 0 \\ -1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix},$$

together with $X^{\pm}=\pm(v^{\pm})^2$. The matrix v^+ in the representation $V^{(l)}$ has $2l$ nonzero elements on the second upper diagonal only, and these elements are

$$\{(v^+)_{jj+1}\}=(\sqrt{l},\sqrt{1},\sqrt{l-1},\sqrt{2},\ldots,\sqrt{1},\sqrt{l}),\quad j=1,2,\ldots,2l. \tag{A4}$$

The extermal projector[46] for osp(1|2) (on the lowest weight vectors) is

$$\begin{aligned} p(h,v^+,v^-)&=\sum_{k=0}^{\infty}\frac{(-1)^k}{k!}\left((v^+)^{2k}(v^-)^{2k}+(v^+)^{2k+1}(v^-)^{2k+1}\frac{1}{h-k-1}\right)\prod_{j=1}^{k}\frac{1}{h-j} \\ &=\left(1+v^+v^-\frac{1}{h-1}\right)\left(\sum_{k=0}^{\infty}(X^+)^k(X^-)^k\prod_{j=1}^{k}\frac{1}{j(h-j-1)}\right) \\ &=p_s(h,v^+,v^-)p_0(h,X^+,X^-); \end{aligned} \tag{A5}$$

here $p_0(h,X^+,X^-)$ is the usual sl(2) extermal projector. There is no such factorization property for the extermal projector of the quantum superalgebra $\mathcal{U}_q(\mathrm{osp}(1|2))$.[31]

(Received 5 December 2000; accepted 29 October 2002)

In this paper we deal with the category of nonlinear evolution equations (NLEEs) associated with the spectral problem and provide an approach for constructing their algebraic structure and *r*-matrix. First we introduce the category of NLEEs, which is composed of various positive order and negative order hierarchies of NLEEs both integrable and nonintegrable. The whole category of NLEEs possesses a generalized Lax representation. Next, we present two different Lie algebraic structures of the Lax operator: one of them is universal in the category, i.e., independent of the hierarchy, while the other one is nonuniversal in the hierarchy, i.e., dependent on the underlying hierarchy. Moreover, we find that two kinds of adjoint maps are *r*-matrices under the algebraic structures. In particular, the Virasoro algebraic structures without a central extension of isospectral and nonisospectral Lax operators can be viewed as reductions of our algebraic structure. Finally, we give several concrete examples to illustrate our methods. Particularly, the Burgers' category is linearized when the generator, which generates the category, is chosen to be independent of the potential function. Furthermore, an isospectral negative order hierarchy in the Burgers' category is solved with its general solution. Additionally, in the KdV category we find an interesting fact: the Harry–Dym hierarchy is contained in this category as well as the well-known Harry–Dym equation is included in a positive order KdV hierarchy.
[DOI: 10.1063/1.1532769]

I. INTRODUCTION

The integrability study of nonlinear evolution equations has been an attractive topic in soliton theory and nonlinear phenomenon. Calogero[1] proposed the *C*-integrable (namely, linearizable by an appropriate change of variables) and *S*-integrable (namely, integrable via some spectral transform technique) terminology for dealing with nonlinear partial diiferetial equations (PDEs). Many nonlinear PDEs were shown *C*-integrable and *S*-integrable.[2] Mikhailov, Shabat and Sokolov[3] discussed some classes of nonlinear *C*-integrable and *S*-integrable PDEs through using the symmetry approach. Flaschka, Newell and Tabor[4] considered in detail the Painleve analysis process for both ODEs and PDEs and investigated its test for integrable equations.

On the other hand, the r-matrix method is also an important part in classical and quantum integrable systems.[5] The classical r-matrix has been first introduced by Sklyanin in Refs. 6 and 7 as the limit of its quantum counterpart. Subsequently, Drinfeld used this to introduce a new geometric notion, that of a Poisson Lie group.[8] Following Drinfeld's ideas[8] Semenov–Tian–Shansky showed that the concept of a classical r-matrix leads to an algebraic construction of integrable systems generalizing the AKS scheme. In terms of the r-matrix[9] an effective view of the multi-Hamiltonian property of such equations can be presented. In addition, it gives a general explanation of the dressing transformations used for obtaining solutions in terms of group factorizations.[10] In Ref. 11 Jimbo constructed explicit solutions of the quantum YB equation for the generalized Toda system and moreover obtained many beautiful results[12–14] by using the r-matrix method.

For the study of an algebraic structure of integrable evolution equations, there has also been a discussion in the literature. For example, the well-known W-algebra was constructed by Orlov and Schulman through using the vertex operator.[15] The KP system was also found to have this kind of W-algebraic structure by Dickey,[16] which includes the Virasoro algebra as its subalgebra. The W-algebra played an important role in the so-called second Poinsson structure.[16] For this, the most important thing is to find the generators of W-algebra. All these facts were only for the case of integrable hierarchies. How about the case for both integrable and nonintegrable hierarchies? In this paper we will deal with this problem through introducing the category of nonlinear evolution equations (NLEEs). The category of NLEEs develops the positive order to the negative order hierarchies for both the integrable and the nonintegrable cases. In particular, the positive and the negative order integrable hierarchies will be generated by the recursion operator, its inverse, and some kernel elements from the pair of Lenard's operators. Mikhailov, Shabat and Sokolov[3] extended the integrable equations by employing the symmetry procedure and discussed the classifications for the integrable hierarchies. All of their results were for C-integrable and S-integrable cases. In this paper, we will discuss the case for both integrable and nonintegrable hierarchies and will not interfere with the existence of symmetries. Here, we point out that throughout this paper: ''integrable'' means the sense of Lax, namely, the PDE admits isospectral (i.e., $\lambda_t=0$) or usual nonisospectral (i.e., $\lambda_t=a\lambda^n$, $n\in\mathbb{Z}$, $a\in\mathbb{R}/\mathbb{C}$) Lax form; otherwise, we say the PDE is nonintegrable in the sense of the Lax form.

Our purpose in the present paper is to give an approach to the category of nonlinear evolution equations directly from a spectral problem and to connect the r-matrix to the category of NLEEs. The whole paper is organized as follows. In the next section we first introduce the notation of the category of NLEEs, which is composed of various positive and negative order hierarchies of both integrable and nonintegrable NLEEs, and then we give the generalized Lax representation (GLR). In Secs. III and IV we, respectively, present two different Lie algebraic structures of the Lax operator. One structure is produced independently of the hierarchy in the category while the other holds only within one hierarchy. Moreover, by using these algebraic structures we find that two kinds of adjoint maps result in r-matrices for the NLEEs. In Sec. V, it is pointed out that the well known Virasoro algebraic structures (without the central extension) of isospectral and nonisospectral Lax operators are obtained as reductions of our algebraic structure. Finally, in Sec. VI the examples of several continuous spectral problems are given to illustrate our methods. Particularly, the Burgers' category is linearized when the generator, which generates the category, is chosen to be independent of the potential function. Furthermore, an isospectral negative order hierarchy in the Burgers' category is solved with its general solution. Additionally, in the KdV category we find an interesting fact: the Harry–Dym hierarchy is contained in this category as well as the well-known Harry-Dym equation is included in a positive order KdV hierarchy.

Before displaying our main results, let us first give some necessary notations:

$$x\in R^l,\ \ t\in R,\ \ u=(u_1,\ldots,u_m)^T\in S^m(R^l,R)=\overbrace{S(R^l,R)\times\cdots\times S(R^l,R)}^{m},$$

$$u_i=u_i(x,t)\in S(R^l,R),\ \ i=1,2,\ldots,m,$$

for arbitrarily fixed t, $S(R^l,R)$ stands for the Schwartz function space on R^l. $\mathcal{B}$ denotes all complex (or real) value functions $P(x,t,u)$ of the class C^∞ with respect to x, t, and of the class C^∞ in Gateaux's sense with respect to u. $\mathcal{B}^N=\{(P_1,\ldots,P_N)^T|P_i\in\mathcal{B}\}$, $\mathcal{V}^N$ stands for all linear operators $\phi=\phi(x,t,u)$: $\mathcal{B}^N\to\mathcal{B}^N$ which are of the class C^∞ with respect to x, t, and of the class C^∞ in Gateaux's sense with respect to u.

The Gateaux derivate of vector function $X\in\mathcal{B}^n$ in the direction $Y\in\mathcal{B}^m$ is defined by

$$X_*(Y)=\frac{d}{d\epsilon}\bigg|_{\epsilon=0} X(u+\epsilon Y). \tag{1.1}$$

For the two arbitrary vector fields X, $Y\in\mathcal{B}^m$, define the following operation:

$$[X,\ Y]=X_*(Y)-Y_*(X). \tag{1.2}$$

Then, $\mathcal{B}^m$ composes a Lie algebra about the above multiplication operation.[17] For the operator $\phi\in\mathcal{V}^N$, its Gateaux derivate operator $\phi_*:\mathcal{B}^m\to\mathcal{V}^N$ in the direction ξ is defined as follows:

$$\phi_*(\xi)=\frac{d}{d\epsilon}\bigg|_{\epsilon=0}\phi(u+\epsilon\xi),\quad \xi\in\mathcal{B}^m. \tag{1.3}$$

If not otherwise stated, the spectral operators $L=L(u)$ [or the spectral operators $L=L(u,\ \lambda)$ with the spectral parameter λ] considered in this paper are denoted by $L\in\mathcal{V}^N$, and we always assume that $L_*:\mathcal{B}^m\to\mathcal{V}^N$ is an injective homomorphism. An operator H acting on a function f is denoted by $H\cdot f$. I stands for the $N\times N$ unit operator.

II. CATEGORY OF NLEEs AND GENERALIZED LAX REPRESENTATION (GLR)

In this section, a procedure for constructing the category of NLEEs and generalized Lax representations are presented, and, moreover, it is shown how to construct the $L-A-B$ triple representation[18] for a given nonlinear quation.

Let us start from a general $N\times N$ spectral problem:

$$L\cdot\psi=\lambda\psi,\quad L\in\mathcal{V}^N, \tag{2.1}$$

where λ is a spectral parameter, $\psi\in\mathcal{B}^N$. Denote the functional gradient of spectral parameter λ with regard to the potential vector u by $\delta\lambda/\delta u=(\delta\lambda/\delta u_1,\cdots,\delta\lambda/\delta u_m)^T$. Tu and Cao, respectively, gave some discussions about the calculations of the functional gradient in Ref. 19 and Ref. 20. Strampp ever studied recursion operators, spectral problems, and Bäcklund transformations by introducing a relation between recursion operators and eigenvalue functions.[21,22] Thus, we define the Lenard operators as follows:

Definition 2.1: If there exists a pair of $m\times m$ operators $K=K(u)$, $J=J(u)$: $S^m(R^l,\ R)\to S^m(R^\cdot R)$ such that

$$K\cdot\frac{\delta\lambda}{\delta u}=\lambda^c J\cdot\frac{\delta\lambda}{\delta u}, \tag{2.2}$$

then K, J are called a pair of Lenard operators of (2.1), and (2.2) is called the Lenard spectral problem of (2.1). Here the constant c is definitely chosen by the concrete form of (2.1).

In many cases, there exist (but not unique) the pair of Lenard's operators satisfying (2.2), and frequently both of them are Hamiltonian operators. For instance, for the KdV–Schrödinger spectral problem $\psi_{xx}+u\psi=\lambda\psi$, $\delta\lambda/\delta u=\psi^2$, only choosing $K=-\frac{1}{4}\partial^3-\frac{1}{2}(u\partial+\partial u)$, $J=\partial=\partial/\partial x$, we have $K\cdot\delta\lambda/\delta u=\lambda J\cdot\delta\lambda/\delta u$. Eq. (2.2) plays an important role in the nonlinearization theory and the construction of completely integrable finite-dimensional systems.[23]

Let $M=(m_{ij})_{N\times N}$, $\tilde{M}=(\tilde{m}_{ij})_{N\times N}$ be the arbitrarily given $1+l$-dimensional [i.e., independent variables $(x,\ t)\in R^l\times R,\ l\geqslant 1$] linear $N\times N$ matrix operators. Then we have the following definitions.

Definition 2.2: $G_0\in S^m(R^l,\ R)$, $G_{-1}\in S^m(R^l,\ R)$ *are, respectively, called the positive order and the negative order generators, if they, respectively, satisfy the operator equations,*

$$L_*(J\cdot G_0)=M, \tag{2.3}$$

$$L_*(K\cdot G_{-1})=\tilde{M}. \tag{2.4}$$

Denote the solution sets of (2.3) and (2.4) by $\mathcal{N}_J(M)$ and $\mathcal{N}_K(\tilde{M})$, respectively. In general, they are not empty.

Definition 2.3: Let $\mathcal{N}_J(M)\neq\varnothing$, $\mathcal{N}_K(\tilde{M})\neq\varnothing$ *and choose* $G_0\in\mathcal{N}_J(M)$, $G_{-1}\in\mathcal{N}_K(\tilde{M})$. *Write the recursion operator* $\mathcal{L}=J^{-1}K$. *The sequence* $\{G_j\}_{j=-\infty}^{\infty}\subseteq S^m(R^l,R)$ *recursively determined by*

$$G_j=\begin{cases}\mathcal{L}^j\cdot G_0, & j\geqslant 0,\\ \mathcal{L}^{j+1}\cdot G_{-1}, & j<0,\end{cases} \tag{2.5}$$

is called the Lenard's sequence of (2.1); the set of the following nonlinear equations:

$$u_t=X_m(u,G_0,G_{-1}),\ \ m\in Z, \tag{2.6}$$

produced by the vector field

$$X_m(u,G_0,G_{-1})\triangleq J\cdot G_m,\ \ m\in Z, \tag{2.7}$$

is called the category of nonlinear evolution equations of (2.1). The subset of the equations (2.6) obtained for $m\geqslant 0$ *is called the positive order category while the subset obtained for* $m<0$ *is called the negative order category.*

Apparently, the positive and the negative order generators G_0, G_{-1} depend on the choice of matrix operators M, $\tilde{M}$, thus the category (2.6) is composed of various hierarchies (both integrable and nonintegrable) of NLEEs which are generated according to the choice of operators M, $\tilde{M}$.

For example, with $M\equiv 0$ (i.e., $G_0\in\mathrm{Ker}\ J$), the hierarchy in the positive order category of (2.6) just reads as the isospectral hierarchy of evolution equations;[24] with $\tilde{M}\equiv 0$ (i.e., $G_{-1}\in\mathrm{Ker}\,K$), the hierarchy in the negative order category of (2.6) is exactly the second isospectral hierarchy of evolution equations studied in Ref. 25. Additionally, the negative order generator G_{-1} can be considered to produce finite-dimensional constrained Hamiltonian systems.[26] Obviously, the negative order category of (2.6) is generated with the help of the inverse recursion operator $\mathcal{L}$. Strampp and Oevel gave the inverse recursion operator in an explicit form for the nonlinear derivative Schrödinger equation.[27] In 1991 we suggested the commutator representations for the negative order hierarchy of isospectral NLEEs.[28] Afterwards, we[29] further found that the same spectral problem can generate two different hierarchies of integrable NLEEs: one is the usual higher order (i.e., positive order) hierarchy of NLEEs, the other is the negative order hierarchy of NLEEs. All these equations have the Lax representations.[29] Here we study the generalized case, i.e., the category of NLEEs.

With $M=I$ or $\tilde{M}=I$, under the basic condition $\mathcal{N}_J(I)\neq\varnothing$ or $\mathcal{N}_K(I)\neq\varnothing$, Eq. (2.6) actually gives the positive and the negative order hierarchies of nonisospectral evolution equations, which can be obtained from the following, Theorem 2.2. Thus, by the arbitrariness of M and $\tilde{M}$, Eq. (2.6) unifies together all possible hierarchies of evolution equations associated with the spectral problem (2.1). Due to this fact, Eq. (2.6) is named ''the category of nonlinear evolution equations.''

Theorem 2.1: *Let* $M=(m_{ij})_{N\times N}$, $\tilde{M}=(\tilde{m}_{ij})_{N\times N}$ *be two arbitrarily given* $N\times N$ *linear matrix operators,* $\mathcal{N}_J(M)\neq\varnothing$, *and* $\mathcal{N}_K(\tilde{M})\neq\varnothing$. *Suppose that for* $G=(G^{[1]},\ldots,G^{[m]})^T\in S^m(R^l, R)$ *and* $\alpha,\beta\in Z$ *the operator equation,*

$$[V,L]=L_*(K\cdot G)L^{\beta}-L_*(J\cdot G)L^{\alpha}, \tag{2.8}$$

possesses a solution $V=V(G)$; *then the vector field* $X_m=X_m(u,G_0,G_{-1})$ *satisfy*

$$L_*(X_m)=[W_m,L]+\bar{M}L^{m\eta},\quad m\in Z,\quad \bar{M}=\begin{cases}M, & m\geqslant 0,\\ \tilde{M}, & m<0,\end{cases} \tag{2.9}$$

where $\eta=\alpha-\beta$ *and the operator* W_m *is given by*

$$W_m=\sum V(G_j)L^{(m-j)\eta-\alpha},\quad \sum=\begin{cases}\sum_{j=0}^{m-1}, & m>0,\\ 0, & m=0,\\ -\sum_{j=m}^{-1}, & m<0.\end{cases} \tag{2.10}$$

Here G_j *are determined by (2.5), and* L^{-1} *is the inverse of* L, *i.e.,* $LL^{-1}=L^{-1}L=I$, *and* $[\cdot,\cdot]$ *denotes the usual commutator.*

Proof: For $m=0$, it is obvious. For $m>0$,

$$\begin{aligned}[W_m,L]&=\sum_{j=0}^{m-1}[V(G_j),L]L^{(m-j)\eta-\alpha}\\ &=\sum_{j=0}^{m-1}\{L_*(K\cdot G_j)L^{(m-j-1)\eta}-L_*(J\cdot G_j)L^{(m-j)\eta}\}\\ &=\sum_{j=0}^{m-1}\{L_*(J\cdot G_{j+1})L^{(m-j-1)\eta}-L_*(J\cdot G_j)L^{(m-j)\eta}\}=L_*(X_m)-L_*(J\cdot G_0)L^{m\eta}\\ &=L_*(X_m)-ML^{m\eta}.\end{aligned}$$

For $m<0$, the proof is similar. ■

Remark 2.1: The structure equation (2.8) of commutator representations is a natural generalization of the structure equation $[V,L]=L_*(K\cdot G)-L_*(J\cdot G)L$ presented by Cao Cewen.[30]

Remark 2.2: The choice of constants $\alpha,\beta\in Z$ is determined by the concrete form of (2.1). In many cases,[29] $V=V(G)$ can be solved for the given L.

Theorem 2.2: *The category (2.6) of NLEEs has the following representation:*

$$L_t=[W_m,L]+\bar{M}L^{m\eta},\quad m\in Z,\quad \bar{M}=\begin{cases}M, & m>0,\\ \tilde{M}, & m<0.\end{cases} \tag{2.11}$$

Proof: For $m\geqslant 0$, because $L_*(u_t)=L_t$ and L_* is injective,

$$L_t=[W_m,L]+ML^{m\eta}\Leftrightarrow L_*(u_t-X_m)=0\Leftrightarrow u_t=X_m,$$

which completes the proof. ■

Definition 2.4: Equation (2.11) and W_m *are called the generalized Lax representations (GLR) and the generalized Lax-operator (GLO), respectively.*

Obviously, with $\overline{M}=0$ (i.e., $G_0 \in \mathrm{Ker}\, J$, $G_{-1} \in \mathrm{Ker}\, K$), Eq. (2.11) reduces the standard (i.e., isospectral case: $\lambda_t=0$) Lax representations, and with $\overline{M}=I$ [of course $\mathcal{N}_J(I)\neq\varnothing$ and $\mathcal{N}_K(I)\neq\varnothing$ are needed], Eq. (2.11) reduces the nonisospectral (i.e., $\lambda_t=\lambda^{m\eta}$, $m\in Z$) Lax representations. For two special cases: the isospectral case (i.e. $M=\tilde{M}=0$) and the nonisospectral case (i.e., $M=\tilde{M}=I$), Ma[31] discussed the Lax operator algebras of the positive order (i.e., $m>0$) hierarchy of NLEEs. But a general framework has not been obtained for all integer $m\in Z$ and all linear matrix operators $M,\tilde{M}$. In the following sections, we shall construct a general frame–generalized algebraic structure and furthermore present the r-matrix for the category of NLEEs.

Remark 2.3: Equation (2.11) admits the structure of $L-A-B$ representations of the category (2.6) in an explicit form. Thus, we give a constructive approach to the Manakov operator pair A, B in the $L-A-B$ triple representation.[18] In Ref. 32, we determined the range of the $L-A-B$ triple representation through defining the Lie quotient algebras.

Remark 2.4: Equation (2.11) contains both the integrable and the nonintegrable hierachies because of the multiple choices of $\overline{M}$. Therefore, our category of NLEEs are not included in the system of multi-component KP and its reduction.

Corollary 2.1: Assume that the potential vector function u is independent of t and the following condition holds:

$$\left[\sum_{i=-r}^{s} c_i W_i, L\right] = -\overline{M}\sum_{i=-r}^{s} c_i L^{i\eta},$$

with constants c_i $(-r\leqslant i\leqslant s)$. Then u will satisfy the stationary system of the category (2.6):

$$\sum_{i=-r}^{s} c_i X_i(u)=0,\ \forall r,s\in Z^+.$$

We shall give several concrete examples in Sec. VI.

III. UNIVERSAL ALGEBRAIC STRUCTURE AND *r*-MATRIX

From (2.9), we have seen that for various linear matrix operators $M,\tilde{M}$, the category (2.6) of NLEEs indeed yields different hierarchies of NLEEs. That means the hierarchy in the category (2.6) changes according to the choice of $M,\tilde{M}$. In this section, we shall construct the algebraic structure and r-matrix which holds for all hierarchies of NLEEs in the category (2.6). Let us start from the following definition.

Definition 3.1: Suppose that for a spectral operator $L\in\mathcal{V}^N$ and an integer $n\in Z$ there exist pairs (A,M) of vector fields $X\in\mathcal{B}^m$ and operators $A,M\in\mathcal{V}^N$ with the property

$$[A,L]=L_*(X)-ML^n. \tag{3.1}$$

Then (A,M) is called a Manakov operator pair of L. The set of all Manakov operator pairs is denoted by $\mathcal{M}_L^n$. X is called the vector field corresponding to (A,M). The set of all vector fields X is denoted by $V(\mathcal{M}_L^n)$. The set of all triples (A,M,X) is denoted by $\mathcal{P}_L^n$.

As long as Eq. (2.8) has an operator solution for a given $L\in\mathcal{V}^N$, then by theorem 2.1 and Eq. (2.9) there exists a triple $(A,M,X)\in\mathcal{P}_L^n$ satisfying (3.1).

It is easy to prove the following proposition.

Proposition 3.1:

(1) The vector field associated with each Manakov operator pair is unique;
(2) both $\mathcal{P}_L^n$ and $\mathcal{M}_L^n$ form linear spaces.

Apparently, if there is $A,\quad M\in\mathcal{V}^N$ for $X\in\mathcal{B}^m$ such that Eq. (3.1) holds, then $u_t=X$ possesses the GLR $L_t=[A,\ L]+ML^n$. It is not difficult to see that $\mathcal{P}_L^n$ and $\mathcal{P}_L^0$, $\mathcal{M}_L^n$ and $\mathcal{M}_L^0$ are equiva-

lent, respectively, under the bijective map $\Phi: \mathcal{P}_L^n \to \mathcal{P}_L^0$, defined by $(A, M, X) \mapsto (A, ML^n, X)$. So, in the following we simply consider $\mathcal{P}_L^0$, $\mathcal{M}_L^0$ and write $\mathcal{M}_L^0 = \mathcal{M}_L$, $\mathcal{P}_L^0 = \mathcal{P}_L$.

Definition 3.2: Let $(A, M, X), (B, N, Y) \in \mathcal{P}_L$. *In* $\mathcal{M}_L$, *define a binary operation as follows:*

$$(A, M) \odot (B, N) = (A \odot B, M \odot N), \tag{3.2}$$

where

$$A \odot B = A_*(Y) - B_*(X) + [A, B], \tag{3.3}$$

$$M \odot N = M_*(Y) - N_*(X) + [M, B] - [N, A]. \tag{3.4}$$

Obviously (3.2) is a skew-symmetric and bilinear operation.

Theorem 3.1: *Let* $(A, M, X), (B, N, Y) \in \mathcal{P}_L$, *then* $(A \odot B, M \odot N, [X, Y]) \in \mathcal{P}_L$, *and* $\mathcal{M}_L$ *form a Lie algebra under the operation (3.2).*

Proof: Since $(\mathcal{V}^N, [\cdot, \cdot])$ builds up a Lie algebra under the usual commutator operation, we have

$$\begin{aligned} [[A, B], L] &= [[L, B], A] - [[L, A], B] \\ &= [L_*(X) - M, B] - [L_*(Y) - N, A] \\ &= [L_*(X), B] - [L_*(Y), A] + [N, A] - [M, B]. \end{aligned}$$

For arbitrary $L \in \mathcal{V}^N$, $X, Y \in \mathcal{B}^m$, we also have

$$(L_*(X))_*(Y) - (L_*(Y))_*(X) = L_*([X, Y]).$$

Thus,

$$\begin{aligned} [A \odot B, L] &= [A_*(Y) - B_*(X) + [A, B], L] \\ &= [A_*(Y), L] - [B_*(X), L] + [L_*(X), B] - [L_*(Y), A] + [N, A] - [M, B] \\ &= ([A, L])_*(Y) - ([B, L])_*(X) + [N, A] - [M, B] \\ &= (L_*(X))_*(Y) - (L_*(Y))_*(X) - M_*(Y) + N_*(X) + [N, A] - [M, B] \\ &= L_*([X, Y]) - M \odot N. \end{aligned}$$

That means $(A \odot B, M \odot N, [X, Y]) \in \mathcal{P}_L$.

Now, we shall prove the Jacobi identity. Choosing any $(A_i, M_i, X_i) \in \mathcal{P}_L$, $i = 1, 2, c3$, then we have

$$\begin{aligned} (A_1 \odot A_2) \odot A_3 + c.p. &= (A_{1*}(X_2) - A_{2*}(X_1) + [A_1, A_2]) \odot A_3 + c.p. \\ &= [[A_1, A_2], A_3] + c.p. \\ &= 0. \end{aligned}$$

Similarly, we can show the following equality:

$$(M_1 \odot M_2) \odot M_3 + c.p. = 0, \tag{$*$}$$

which completes the proof. ■

Corollary 3.1: The set of all vector fields $V(\mathcal{M}_L)$ *forms a Lie subalgebra of* $\mathcal{B}^m$ *with regard to the operation (1.2).*

Denote the vector fields of (A, M) and (B, N) by X and Y, respectively, then $u_t=X$, $u_t=Y$ represent the two *different* hierarchies of NLEEs, respectively, determined by M,N. Theorem 3.1 shows that there is universal algebraic structure for the *different* hierarchies of NLEEs, and if both $u_t=X$, and $u_t=Y$ $(X, Y\in\mathcal{B}^m)$ have GLR, then so does the new hierarchy of equations $u_t=[X, Y]$ produced by X, Y.

For the given spectral operator $L\in\mathcal{V}^N$, we now consider the following adjoint map:

$$\mathrm{ad}_L: A\mapsto M=\mathrm{ad}_L A=[L, A],\ \forall A\in\mathcal{V}^N. \tag{3.5}$$

Then according to the original definition of an r-matrix,[9] we have the following theorem.

Theorem 3.2: *The adjoint map* ad_L *is an r-matrix.*

Proof: For any $A, B\in\mathcal{V}^N$, write $M=\mathrm{ad}_L A$, $N=\mathrm{ad}_L B$. Then we have

$$[A, B]_{\mathrm{ad}_L}\triangleq[\mathrm{ad}_L A, B]+[A, \mathrm{ad}_L B]=[M, B]+[A, N]=M\odot N.$$

The last equality holds because the associated vector fields are obviously zero. And Eq. $(*)$ implies that $[A,B]_{\mathrm{ad}_L}$ satisfies the Jacobi identity. Thus the adjoint map ad_L is an r-matrix. ■

In the last section we shall illustrate that through giving several examples.

IV. NONUNIVERSAL ALGEBRAIC STRUCTURE AND *r*-MATRIX

For a given spectral operator $L\in\mathcal{V}^N$ and integer $n\in Z$, in the above section we discussed the Manakov operator pair (A,M), the universal Lie algebraic structure and the r-matrix available for *different* hierarchies of NLEEs. Now, for a given $N\times N$ matrix operator M and a spectral operator $L\in\mathcal{V}^N$, we study the operator algebra and r-matrix which can be attached only to the *underlying* hierarchy of NLEEs.

Let us first give some conventions in this section: (i) M is invertible; (ii) For a given $L\in\mathcal{V}^N$, $\mathcal{V}_L^N$ stands for all matrix operators $S:\mathcal{B}^N\to\mathcal{B}^N$ possessing the following form $S=\Sigma_{\alpha\in Z}P_\alpha(u)L^\alpha$, $P_\alpha(u)\in\mathcal{B}$, where $\Sigma_{\alpha\in Z}$ is a finite sum. Next, we introduce the following definition.

Definition 4.1: Let $L\in\mathcal{V}^N$ *and* M *be a spectral operator and an* $N\times N$ *matrix operator, respectively. If there exist a vector field* $X\in\mathcal{B}^m$ *and operators* $A,P\in\mathcal{V}_L^N$ *such that*

$$[A, L]+MP=L_*(X), \tag{4.1}$$

then (A, P) *is said to be an* LM *operator pair of* L. *The set of all such pairs is denoted by* $\mathcal{L}_L^M$. X *is called the vector field of* (A, P) *associated with* LM. *The set of all associated vector fields is denoted by* $V(\mathcal{L}_L^M)$. *Furthermore, we denote the set of all triples* (A, P, X) *by* $\mathcal{R}_L^M$.

For a given $L\in\mathcal{V}^N$ and an $N\times N$ matrix operator M or $\tilde{M}$ theorem 2.1 and Eq. (2.8) assure that there exists a triple $(A, P, X)\in\mathcal{R}_L^M$ satisfying (4.1). Definition 4.1 directly leads to the following proposition.

Proposition 4.1:

(1) The vector field associated with each LM *operator pair is unique.*
(2) Both $\mathcal{L}_L^M$ *and* $\mathcal{R}_L^M$ *are linear spaces.*

If for given operators L, M there exist $A, P\in\mathcal{V}_L^N$ such that (4.1) holds, then obviously the evolution equation $u_t=X$ has the following representation [also called generalized Lax representation (GLR)]:

$$L_t=[A, L]+MP. \tag{4.2}$$

Now, we define a binary operation in $\mathcal{L}_L^M$.

Definition 4.2: Let $(A, P),(B, Q)\in\mathcal{L}_L^M, X,Y\in V(\mathcal{L}_L^M)$, *respectively, be the vector fields of* $(A, P),(B, Q)$. *Declare a binary operation,*

$$(A,P)\ominus(B,Q)=(A\ominus B,P\ominus Q), \tag{4.3}$$

through

$$A\ominus B=A_*(Y)-B_*(X)+[A,B], \tag{4.4}$$

$$\begin{aligned}P\ominus Q=&P_*(Y)-Q_*(X)+[A,Q]-[B,P]\\&+M^{-1}(M_*(Y)-[B,M])P-M^{-1}(M_*(X)-[A,M])Q.\end{aligned} \tag{4.5}$$

Proposition 4.2:

(1) Equation (4.3) is a skew-symmetric, bilinear binary operation.
(2) $\mathcal{V}_L^N$ is closed under the operations (4.4) and (4.5).

Proof: The proof follows directly from Definition 4.2. ■

Theorem 4.1: *Let $(A,\ P,\ X),(B,\ Q,\ Y)\in\mathcal{R}_L^M$, then $(A\ominus B,\ P\ominus Q,\ [X,Y])\in\mathcal{R}_L^M$, where $[X,\ Y]$ is defined by (1.2). Thus under the operation (4.3) $\mathcal{L}_L^M$ forms an algebra, and $(V(\mathcal{L}_L^M),\ [\cdot,\cdot])$ composes a Lie subalgebra of $\mathcal{B}^m$.*

Proof: Because $(A,\ P,\ X),(B,\ Q,\ Y)\in\mathcal{R}_L^M$, and

$$[[A,\ B],\ L]=[[L,\ B],\ A]-[[L,\ A],\ B]=[L_*(X),\ B]-[L_*(Y),\ A]+[MQ,\ A]-[MP,\ B],$$

we have

$$\begin{aligned}[A\ominus B,\ L]=&[A_*(Y),\ L]-[B_*(X),\ L]+[[A,\ B],\ L]\\=&(L_*(X))_*(Y)-(L_*(Y))_*(X)-(MP)_*(Y)+(MQ)_*(X)+[MQ,A]-[MP,\ B]\\=&L_*([X,\ Y])-M(P\ominus N),\end{aligned}$$

which completes the proof. ■

For a given spectral operator L and an $N\times N$ matrix operator M, denote the vector fields of $(A,\ P),(B,\ Q)$ by $X,\ Y$, respectively. Then from Sec. II we know $u_t=X,\ u_t=Y$ are the two different NLEEs in the *same* hierarchy. Theorem 4.1 reveals that there exists an algebraic structure available for all equations in the *same* hierarchy. And if $u_t=X,\ u_t=Y$ $(X,\ Y\in\mathcal{B}^m)$ have the GLR (4.2); then the evolution equation $u_t=[X,\ Y]$ is still in the same hierarchy, and possesses the GLR (4.2), too.

Remark 4.1: In general, $\mathcal{L}_L^M$ is not forming a Lie algebra under the operation (4.3), because the Jacobi identity cannot be guaranteed. Nevertheless, the subset $S_L^M\subset\mathcal{L}_L^M$, considered below, is an exception.

Set $S_L^M=\{(A,\ P)\in\mathcal{V}_L^N\times\mathcal{V}_L^N|\ P=M^{-1}\,\mathrm{ad}_L A\}$; then S_L^M is corresponding to the stationary system $X(u)=0$ of evolution equation $u_t=X(u)$.

Theorem 4.2: *For all $(A,\ P)\in S_L^M$, define a map r^M:$A\mapsto P=M^{-1}\,\mathrm{ad}_L A$. The map r^M is an r-matrix under the operation (4.5) iff $M=aI,\ a\neq 0,a\in R$.*

Proof: For any $(A,\ P),(B,\ Q)\in S_L^M$, define

$$[A,\ B]_{r^M}\triangleq[r^M(A),\ B]+[A,\ r^M(B)].$$

Then

$$[A,\ B]_{r^M}=[P,\ B]+[A,\ Q]=P\ominus Q\Leftrightarrow M=aI,\ \ a\neq 0,\ \ a\in R,$$

i.e., the map r^M is an r-matrix $\Leftrightarrow M=aI,\ a\neq 0,\ a\in R$. ■

Since M and $\tilde{M}$ can be fixed arbitrarily we have found two algebraic operator structures, namely a universal one being independent of the hierarchy in the category and a nonuniversal one depending on the underlying hierarchy. In addition, in this procedure we have found two kinds of adjoint maps being r-matrices.

The two algebraic structures are associated with the category of NLEEs (2.11) which includes both the integrable and the nonintegrable cases (see Remark 2.4). Therefore, here our algebraic structures are not contained in any W-algebras which are usually suitable for the integrable hierarchy such as the KP, etc.

In the next section, we shall give two reductions of the algebraic structure and the related r-matrix.

V. TWO REDUCTIONS: VIRASORO ALGEBRA AND r-MATRIX OF ISOSPECTRAL AND NONISOSPECTRAL LAX OPERATOR

If we choose $M=0$ in Definition 4.1, then we have $[A,L]=L_*(X)$. That means A is an isospectral ($\lambda_t=0$) Lax operator. Set $[B,L]=L_*(Y)$; then the operation $A\ominus B$ defined by (4.4) forms an algebraic structure of the isospectral Lax operator, which just coincides with the result described in Ref. 31. In this case, the r-matrix is zero, i.e., $\mathrm{ad}_L A=0$, $\forall A\in\mathcal{V}^N$.

In this section, we always choose $M=\tilde{M}=I$ and assume that the conditions of Theorem 2.1 hold. Then, by Theorem 2.1, we obtain

$$(W_m,\ L^{m\eta},\ \sigma_m)\in\mathcal{R}_L^I,\ m\in Z,$$

where W_m is expressed through (2.10), σ_m stands for the corresponding vector field. Therefore W_m is a sequence of nonisospectral ($\lambda_t=\lambda^{m\eta},m\in Z$) Lax operators and this matches with choosing $A=W_m$, $P=L^{m\eta}$ $(m\in Z)$, $X=\sigma_m$ in (4.1). By Theorem 4.1 $\{(W_m,L^{m\eta}),m\in Z\}$ represents an algebra under the operation (4.3), which is called the nonisospectral Lax operator algebra of the spectral operator L. In the stationary case where $\sigma_i=\sigma_j=0$ the following holds.

Theorem 5.1: *A realization of the operations (4.5) and (4.4) on pairs* $(W_i,L^{i\eta})$, $(W_j,L^{j\eta})\in S_L^I$ *is given by*

$$L^{i\eta}\ominus L^{j\eta}=(|i|-|j|)L^{(i+j-1)\eta},\quad \forall i,j\in Z, \tag{5.1}$$

$$W_i\ominus W_j=(|i|-|j|)W_{i+j-1},\quad \forall i,j\in Z, \tag{5.2}$$

respectively.

Proof: For $(W_i,\ L^{i\eta}),(W_j,\ L^{j\eta})\in S_L^I$, we have

$$[W_i,\ L]=-L^{i\eta},\quad [W_j,\ L]=-L^{j\eta}.$$

Thus, in the case $i,j\geqslant 0$,

$$\begin{aligned}L^{i\eta}\ominus L^{j\eta}&=[L^{i\eta},\ W_j]-[L^{j\eta},\ W_i]\\&=\sum_{k=0}^{i-1}L^{(i-1-k)\eta}IL^{(k+j)\eta}-\sum_{k=0}^{j-1}L^{(j-1-k)\eta}IL^{(k+i)\eta}\\&=iL^{(i+j-1)\eta}-jL^{(i+j-1)\eta}=(i-j)L^{(i+j-1)\eta}.\end{aligned}$$

Similarly, Eq. (5.1) holds for the other three cases $i\geqslant 0$, $j\leqslant 0$; $i\leqslant 0$, $j\leqslant 0$; $i\leqslant 0$, $j\geqslant 0$.

Equation (5.2) can be directly obtained by (5.1) and Theorem 4.1. ■

Corollary 5.1: If $M=\tilde{M}=I$, under the operation (5.1) the map $r^I:W_i\mapsto L^{i\eta}$ is an r-matrix.

Proof: This can be directly derived from Theorem 5.1 and Theorem 4.3. ■

Remark 5.1: Theorem 5.1 and Corollary 5.1 actually describe the Lie algebraic structure of the Lax operator for the stationary equation $\sigma_j=0$ $(j\in Z)$ and the r-matrix of a concrete form of an operation (4.5) and (4.4), respectively.

For the usual nonstationary vector field $\sigma_j\neq 0$ $(j\in Z)$ in the nonisospectral case, (5.1) and (5.2) do not hold. But, we have the following results.

Theorem 5.2: *Let* $(W_j,\ L^{j\eta})\in\mathcal{L}_L^I,\ j\in Z$; *then for any* $i,j\in Z$, L *satisfies the relation*

$$L^{i\eta}\ominus L^{j\eta}=(|i|-|j|)\,\eta L^{(i+j+1)\eta-1},\quad \forall i,\ j\in Z. \tag{5.3}$$

Proof: We give the proof only for the case of $i\geqslant 0$, $j\geqslant 0$. The other cases are shown analogously.

Let $(W_i,\ L^{i\eta},\ \sigma_i)$, $(W_j,\ L^{j\eta},\ \sigma_j)\in\mathcal{R}_L^I$; then we have

$$\begin{aligned}(L^{i\eta})_*(\sigma_j)&=\sum_{k=0}^{i-1}L^{(i-1-k)\eta}L_*^{\eta}(\sigma_j)L^{k\eta}\\&=\sum_{k=0}^{i-1}L^{(i-1-k)\eta}([W_j,\ L^{\eta}]+\eta L^{(j+1)\eta+\eta-1})L^{k\eta}\\&=[W_j,\ L^{i\eta}]+i\,\eta L^{(i+j+1)\eta-1},\end{aligned}$$

and

$$(L^{j\eta})_*(\sigma_i)=[W_i,\ L^{j\eta}]+j\,\eta L^{(i+j+1)\eta-1}.$$

So, by Eq. (4.5) and noticing $M=I$, we obtain

$$L^{i\eta}\ominus L^{j\eta}=(i-j)\,\eta L^{(i+j+1)\eta-1},\quad \forall i,\ j\in Z^+, \tag{5.4}$$

which is the desired result. ■

Equations (5.1), (5.2), and (5.3) are three special Virasoro algebras, namely, without a central extension. Because here we do calculations based on our definitions of binary operations (4.4) and (4.5), they have no central extensions.

Remark 5.2: For the usual nonstationary vector field $\sigma_j\neq 0$ $(j\in Z)$ in the nonisospectral case the operation (5.1) does not always satisfy the Jacobi identity, (see Remark 4.1). Thus Corollary 5.1 does not hold in general.

Remark 5.3: A particular case of Theorem 5.2 is $\eta=1$. Then Eq. (5.3) becomes

$$L^{i}\ominus L^{j}=(|i|-|j|)L^{i+j},\quad \forall i,\ j\in Z, \tag{5.5}$$

which implies the following equations:

$$W_i\ominus W_j=(|i|-|j|)\,W_{i+j},\quad \forall i,\ j\in Z, \tag{5.6}$$

and

$$[\sigma_i,\sigma_j]=(|i|-|j|)\sigma_{i+j},\quad \forall i,\ j\in Z. \tag{5.7}$$

Theorem 5.2 reveals that under Eq. (5.5) for the same nonisospectral hierarchy the following holds: if $u_t=\sigma_m$ and $u_t=\sigma_n$, respectively, possess the nonisospectral Lax operators W_m and W_n, then $u_t=\sigma_{m+n}$ still possesses the nonisospectral Lax operator $1/(|m|-|n|)\,W_m\ominus W_n$, $\forall m,n\in Z$. Thus, the Virasoro operator algebras (without the central extension) for the nonisospectral hierarchy of NLEEs is reflected by Eqs. (5.5)–(5.7).

Remark 5.4: If we choose $M=0$ and $M=I$, respectively, then under the algebraic operation (3.3) we can also have the Virasoro algebra of the Lax operator for the isospectral hierarchy and the nonisospectral hierarchy, which is actually a special case of universal algebraic structure.

VI. SOME EXAMPLES

Through taking several examples, we illustrate our methods. For our convenience, we make the following conventions:

$$f^{(m)}=\begin{cases}\dfrac{\partial^m}{\partial x^m}f=f_{mx}, & m\geqslant 0,\\ \underbrace{\int\cdots\int}_{-m} f\,dx, & m<0,\end{cases}\qquad \sum=\begin{cases}\displaystyle\sum_{j=0}^{m-1}, & m>0,\\ 0, & m=0,\\ \displaystyle-\sum_{j=m}^{-1}, & m<0,\end{cases}$$

$f_t=\partial f/\partial t$, $f_{mxt}=\partial^{m+1}f/\partial t\,\partial x^m\,(m\geqslant 0)$, $\partial=\partial/\partial x$, ∂^{-1} is the inverse of ∂, i.e., $\partial\partial^{-1}=\partial^{-1}\partial=1$, $\partial^m f$ means the operator $\partial^m f$ acts on some function g, i.e., $\partial^m f\cdot g=\partial^m(fg)$, $m\in Z$. C_m^k stands for the combinatorial constants: $C_m^k=m(m-1)\cdots(m-k+1)/k!$, i an imaginary unit satisfying $i^2=-1$, and $I_{2\times 2}$ the 2×2 unit matrix.

In the spectral problems (6.1), (6.32) and (6.74) the function u stands for the potential function, and the potential functions in spectral problems (6.43) and (6.56) are denoted by q, r. In those spectral problems, λ is always assumed to be a spectral parameter. The domain of the spatial variable x is Ω which becomes equal to $(-\infty, +\infty)$ or $(0, T)$, while the domain of the time variable t is the positive time axis $R^+=\{t|t\in R,\ t\geqslant 0\}$. In the case $\Omega=(-\infty, +\infty)$ the decaying condition at infinity and in the case $\Omega=(0, T)$ the periodicity condition for the potential function, is imposed.

6.1: Consider the Burger's spectral problem:[33]

$$L\cdot y=\lambda y,\quad L=L(u)=\partial+u. \tag{6.1}$$

Choosing the recursion operator $\mathcal{L}=\partial+\partial u\partial^{-1}$ leads to

$$\mathcal{L}\cdot y_x=\lambda y_x. \tag{6.2}$$

Obviously, $L_*(\xi)=\xi, \forall\,\xi\in\mathcal{B}$, i.e., L_* is an identity operator. In this case, the Lenard's operators pair is chosen as $J=1$, and $K=\mathcal{L}$.

The Lenard recursive sequence $\{G_j\}_{j=-\infty}^{\infty}$ $(G_j=\mathcal{L}^j\cdot M,\ j\in Z)$ gives the Burgers category of NLEEs:

$$u_t=\mathcal{L}^m\cdot M=(e^{-u^{(-1)}}(e^{u^{(-1)}}M^{(-1)})^{(m)})_x,\quad m\in Z, \tag{6.3}$$

where $M\in\mathcal{B}$ is an arbitrarily given function, and $\mathcal{L}=\partial e^{-u^{(-1)}}\partial e^{u^{(-1)}}\partial^{-1}$, $\mathcal{L}^{-1}=\partial e^{-u^{(-1)}}\partial^{-1}e^{u^{(-1)}}\partial^{-1}$ which implies $\mathcal{L}^j=\partial e^{-u^{(-1)}}\partial^j e^{u^{(-1)}}\partial^{-1}$, $j\in Z$.

For an arbitrary $G\in\mathcal{B}$, the operator equation $[V, L]=L_*(\mathcal{L}\cdot G)-L_*(G)L$, which matches with choosing $\beta=0$, $\alpha=1$ in (2.8), has the following solution:

$$V=V(G)=-G+G^{(-1)}\partial. \tag{6.4}$$

Thus the category (6.3) possesses the generalized Lax representation (GLR),

$$L_t=[W_m, L]+ML^m,\quad m\in Z, \tag{6.5}$$

with $W_m=M^{(-1)}L^m-L^m\cdot M^{(-1)}$, $L^m=e^{-u^{(-1)}}\partial^m e^{u^{(-1)}}$, $m\in Z$.

The transformation $u=(\ln v)_x$ yields a simple form of Eq. (6.3):

$$v_t=(vM^{(-1)})^{(m)},\quad m\in Z, \tag{6.6}$$

which has the GLR $L_t=[W_m, L]+ML^m$ with $L=\partial+(\ln v)_x$, $W_m=v^{-1}(M^{(-1)}\partial^m v - (vM^{(-1)})^{(m)})$.

Apparently, if M is chosen to be independent of v ($v=e^{u^{(-1)}}$), then the category (6.3) is linearized. Thus, (6.3) includes many linearized hierarchies. Now, let us discuss reductions of the category (6.3) or (6.6).

A. Positive case ($m=0, 1, 2,\ldots$)

In this case, the Lax operator W_m can be written as

$$W_m=v^{-1}\sum_{k=1}^{m} C_m^k v^{(m-k)}(M^{(-1)}\partial^k-M^{(k-1)}). \tag{6.7}$$

(i) With $M=0$, $0^{(-1)}=1$, the positive order category of (6.3) reads as the well-known Burgers' hierarchy,

$$u_t=((\partial+u)^m\cdot 1)_x. \tag{6.8}$$

Particularly, with $m=2$ it becomes the Burger's equation $u_t=u_{xx}+2uu_x$ whose Lax operator is $W_2=\partial^2+2u\partial$ in the standard Lax representation $L_t=[W_2,L]$. This corresponds to the isospectral case: $\lambda_t=0$. According to Eq. (6.6), a simple but quite interesting fact is that under the transformation $u=v_x/v$ the whole Burgers' hierarchy (6.8) is linearized as

$$v_t=v_{mx},\ m=0,1,2,\ldots. \tag{6.9}$$

Equation (6.9) can be solved very easily and have the standard Lax pair $W_m=v^{-1}\Sigma_{k=1}^m C_m{}^k v^{(m-k)}\partial^k$ and $L=\partial+v_x/v$. In this way, the solutions of all equations in the Burgers' hierarchy (6.8) can be worked out.

(ii) With $M=a$, $a^{(-1)}=ax+f(t)$, $a\in R$, $f(t)\in C^\infty(R)$, the positive order category of (6.3) becomes the nonisospectral ($\lambda_t=a\lambda^m$) Burgers' hierarchy,

$$u_t=((\partial+u)^m\cdot(ax+f(t)))_x. \tag{6.10}$$

A representative equation ($m=2$) of Eq. (6.10) is

$$u_t=(ax+f(t))(u_{xx}+2uu_x)+3au_x+au^2, \tag{6.11}$$

possessing the GLR $L_t=[W_2,L]+aL^2$ with $W_2=(ax+f(t))(\partial^2+2u\partial)-2au$ and $L=\partial+u$. By virtue of $M=a$ and $u=(\ln v)_x$, Eq. (6.10) is linearized as

$$v_t=(ax+f(t))v_{mx}+mav_{(m-1)x}, \tag{6.12}$$

which can be solved. Equation (6.12) has the generalized Lax operator (GLO) $W_m=(ax+f(t))v^{-1}\Sigma_{k=1}^m C_m^k v^{(m-k)}\partial^k-mav^{-1}v^{(m-1)}$. Particularly, Eq. (6.11) has a linearization equation ($m=2$),

$$v_t=(ax+f(t))v_{xx}+2av, \tag{6.13}$$

possessing the GLO $W_2=(ax+f(t))(\partial^2+2v^{-1}v_x\partial)-2av^{-1}v_x$. In a general case, M can be extended as $M=\Sigma_{j=0}^n c_j(t)x^j$, $c_j(t)\in C^\infty(R)$, which will be considered below.

(iii) With $M=\Sigma_{j=0}^n c_j(t)x^j$, $c_j(t)\in C^\infty(R)$, the positive order category of (6.3) reads as a nonisospectral ($\lambda_t=(\Sigma_{j=0}^n c_j(t)x^j)\lambda^m$) hierarchy,

$$u_t=\left((\partial+u)^m\cdot\left(f(t)+\sum_{j=0}^{n} c_j(t)\frac{x^{j+1}}{j+1}\right)\right)_x, \tag{6.14}$$

where an arbitrary $f(t)\in C^\infty(R)$ is attached by virtue of integration with respect to x. Of course, Eq. (6.14) is easily linearized as

$$v_t=\frac{\partial^m}{\partial x^m}\left(vf(t)+v\sum_{j=0}^{n}\frac{c_j(t)}{j+1}x^{j+1}\right), \tag{6.15}$$

via $u=(\ln v)_x$. Equation (6.15) has the generalized Lax operator,

$$W_m=v^{-1}\sum_{k=1}^{m} C_m^k v^{(m-k)}(M^{(-1)}\partial^k-M^{(k-1)}),$$

with

$$M^{(-1)}=f(t)+\sum_{j=0}^{n}\frac{c_j(t)}{j+1}x^{j+1}.$$

(iv) With $M=(u^{-1})_x$, $M^{(-1)}=u^{-1}$, the positive order category of (6.3) reads as the following hierarchy of NLEEs:

$$u_t=((\partial+u)^m\cdot u^{-1})_x,\quad m=0,1,2\ldots. \tag{6.16}$$

A representative equation of (6.16) is

$$u_t=\left(\frac{1}{u}\right)_{xx}, \tag{6.17}$$

with the GLO $W_0=-(u^{-1})_x+u^{-1}\partial$.

B. Negative case ($m=-1,-2,\ldots$)

(i) With $M=0$, the generator $G_{-1}=\partial e^{-u^{(-1)}}\partial^{-1}e^{u^{(-1)}}\partial^{-1}\cdot 0$ is determined by the following two seed functions:

$$\overline{G}_{-1}=f(t)(e^{-u^{(-1)}})_x \tag{6.18}$$

and

$$\tilde{G}_{-1}=g(t)(e^{-u^{(-1)}}(e^{u^{(-1)}})^{(-1)})_x, \tag{6.19}$$

where $f(t)$, $g(t)\in C^\infty(R)$ are two arbitrarily given functions. Apparently, the seed function (6.18) produces the following isospectral ($\lambda_t=0$) negative order hierarchy of (6.3),

$$u_t=f(t)(e^{-u^{(-1)}}1^{(m)})_x,\quad m<0,\ m\in Z, \tag{6.20}$$

i.e.,

$$u_t=f(t)e^{-u^{(-1)}}\sum_{k=0}^{-m-1} c_k\frac{x^{-m-k-2}(-m-k-1-xu)}{(-m-k-1)!},\quad c_0=1, \tag{6.21}$$

where $c_k=c_k(t)\in C^\infty(R)$ $(-m-1\geqslant k\geqslant 1)$ is arbitrarily given. Thus although Eq. (6.20) is nonlinear, we have its general solution:

$$u(x,t)=\frac{\Sigma_{k=0}^{-m-2}c_k(t)\dfrac{x^{-m-k-2}}{(-m-k-2)!}\partial_t^{-1}f(t)+h'(x)}{\Sigma_{k=0}^{-m-1}c_k(t)\dfrac{x^{-m-k-1}}{(-m-k-1)!}\partial_t^{-1}f(t)+h(x)},\quad \forall h(x),\ c_k(t)\in C^\infty(R), \tag{6.22}$$

where $\partial_t^{-1}f(t)=\int f(t)dt$, $c_0(t)=1$, $h'(x)=(d/dx)\,h(x)$. Of course, Eq. (6.21) has the standard Lax representation $L_t=[W_m,L]$ with $W_m=-f(t)e^{-u^{(-1)}}\Sigma_{k=0}^{-m-1}c_k(t)\ x^{-m-k-1}/(-m-k-1)!$.

On the other hand, the seed function (6.19) generates the following isospectral ($\lambda_t=0$) negative order hierarchy of (6.3):

$$u_t=g(t)(e^{-u^{(-1)}}(e^{u^{(-1)}})^{(m)})_x,\quad m<0,\ m\in Z, \tag{6.23}$$

which is a hierarchy of integro-differential equations and can be changed to the linear differential equations,

$$v_{-mxt}=g(t)v,\ \ m<0,\ \ m\in Z, \tag{6.24}$$

via the transformation $u=v^{-1}v_x$. The Lax operator W_m of (6.23) or (6.24) is $W_m=-g(t)e^{-u^{(-1)}}(e^{u^{(-1)}})^{(m)}$ or $W_m=-g(t)v^{-1}v^{(m)}$, $m<0$.

(ii) With $M=a$, $a^{(-1)}=ax+f(t)$, $a\in R$, $f(t)\in C^\infty(R)$, the negative order category of (6.3) through setting $u=v^{-1}v_x$ reads as the linear equations,

$$v_{-mxt}=(ax+f(t))v,\ \ m<0,\ \ m\in Z, \tag{6.25}$$

which corresponds to the nonisospectral case: $\lambda_t=a\lambda^m$, and has the GLO $W_m=v^{-1}(ax+f(t))\partial^m v-v^{-1}(v(ax+f(t)))^{(m)}$, $m<0$. For a general case, we have the following.

(iii) Setting $M=\Sigma_{j=0}^n c_j(t)x^j$ $(c_j(t)\in C^\infty(R))$ yields a negative order hierarchy of (6.3),

$$u_t=\left(e^{-u^{(-1)}}\partial^m e^{u^{(-1)}}\cdot\sum_{j=0}^n c_j(t)\frac{x^{j+1}}{j+1}\right)_x,\ \ m<0,\ \ m\in Z, \tag{6.26}$$

which corresponds to the nonisospectral case $\lambda_t=(\Sigma_{j=0}^n c_j(t)x^j)\lambda^m$, and can be linearized as

$$v_{-mxt}=v\sum_{j=0}^n c_j(t)\frac{x^{j+1}}{j+1},\ m<0,\ m\in Z, \tag{6.27}$$

via $u=v^{-1}v_x$. Equation (6.27) has the Lax operator

$$W_m=v^{-1}\sum_{j=0}^n\frac{c_j(t)}{j+1}(x^{j+1}\partial^m v-(vx^{j+1})^{(m)}),\quad m<0.$$

(iv) With $M=(v/v_x)_x$, $\partial^{-1}M=v/v_x$, the associated negative order hierarchy of (6.3) is

$$v_{-mxt}=\frac{v^2}{v_x},\ \ m<0,\ \ m\in Z, \tag{6.28}$$

which has a representative equation $(m=-1)$

$$v_xv_{xt}=v^2, \tag{6.29}$$

with the Lax operator $W_{-1}=(1/v_x)\partial^{-1}v-(1/v)(v^2/v_x)^{(-1)}$.

Through choosing different M, we still have other hierarchies of (6.3). Because of the arbitrariness of M, all results in Secs. III–V are valid for the Burgers' (B) spectral problem (6.1). Particularly, the r-matrix ad_L becomes

$$\mathrm{ad}_L^{\mathcal{B}}: W_m\mapsto ML^m,\ \ m\in Z, \tag{6.30}$$

where $W_m=M^{(-1)}L^m-L^m\cdot M^{(-1)}$, $L^m=e^{-u^{(-1)}}\partial^m e^{u^{(-1)}}$, $M\in\mathcal{B}$ is an arbitrarily given function. And the r-matrix r^M $(M=a\neq 0,\ a\in R)$ reads as

$$r_B^a: W_m\mapsto L^m,\ \ m\in Z, \tag{6.31}$$

where $W_m=(ax+f(t))L^m-L^m\cdot(ax+f(t))$. Equations (6.30) and (6.31) generate the stationary B-categorical systems $(L^m\cdot M^{(-1)})_x=0$ and $(L^m\cdot(ax+f(t)))_x=0$, respectively.

We can also apply the above procedure to other spectral problems. Now, we list some main results as follows.

6.2: KdV case. The KdV–Schrödinger spectral problem,[34]

$$L\cdot y=\lambda y,\ L=L(u)=\partial^2+u, \tag{6.32}$$

has the following Lenard operator pair:

$$K=\tfrac{1}{4}\partial^3+\tfrac{1}{2}(\partial u+u\partial),\quad J=\partial. \tag{6.33}$$

Apparently, $L_*(\xi)=\xi,\forall\,\xi\in\mathcal{B}$. Setting $u=-\phi_{xx}/\phi$ yields the product-form of K and its inverse,

$$\begin{aligned} K&=\tfrac{1}{4}\phi^{-2}\,\partial\phi^2\,\partial\phi^2\,\partial\phi^{-2},\\ K^{-1}&=4\phi^2\,\partial^{-1}\phi^{-2}\,\partial^{-1}\phi^{-2}\,\partial^{-1}\phi^2. \end{aligned} \tag{6.34}$$

Let $M,\ \tilde{M}\in\mathcal{B}$ be two arbitrarily given functions. Then the positive order and negative order generators,

$$G_0=M^{(-1)};\ \ G_{-1}=K^{-1}\cdot\tilde{M}=4\phi^2\,\partial^{-1}\phi^{-2}\,\partial^{-1}\phi^{-2}\,\partial^{-1}\cdot(\phi^2\tilde{M}), \tag{6.35}$$

leads to the KdV category of NLEEs

$$u_t=J\cdot G_m,\ \ m\in Z,\ \ G_m=\begin{cases}\mathcal{L}^m\cdot G_0, & m\geqslant 0,\\ \mathcal{L}^{m+1}\cdot G_{-1}, & m<0,\end{cases} \tag{6.36}$$

where the recursion operator $\mathcal{L}$ is given by

$$\mathcal{L}=J^{-1}K=\tfrac{1}{4}\partial^2+\tfrac{1}{2}(u+\partial^{-1}u\partial)=\tfrac{1}{4}\partial^{-1}\phi^{-2}\,\partial\phi^2\,\partial\phi^2\,\partial\phi^{-2},$$

and its inverse is

$$\mathcal{L}^{-1}=4\phi^2\,\partial^{-1}\phi^{-2}\,\partial^{-1}\phi^{-2}\,\partial^{-1}\phi^2\,\partial.$$

For an arbitrary $G\in\mathcal{B}$, the operator equation $[V,L]=L_*(K\cdot G)-L_*(J\cdot G)L$ has the following operator solution:

$$V=V(G)=-\tfrac{1}{4}G_x+\tfrac{1}{2}G\partial, \tag{6.37}$$

which implies that the KdV category (6.36) possesses the GLR,

$$L_t=[W_m,\,L]+\overline{M}L^m,\ \ m\in Z,\ \overline{M}=\begin{cases}M, & m\geqslant 0,\\ \tilde{M}, & m<0,\end{cases} \tag{6.38}$$

with the GLO

$$W_m=\sum V(G_j)L^{m-j-1}. \tag{6.39}$$

Here $V(G_j)$ is determined by (6.37) with $G=G_j=\mathcal{L}^j\cdot G_0,\ \ j\geqslant 0$ or $G=G_j=\mathcal{L}^{j+1}\cdot G_{-1},\ j<0$, $L=\partial^2+u=\phi^{-1}\,\partial\phi^{-2}\,\partial\phi^{-2}$, and $L^{-1}=\phi^2\,\partial^{-1}\phi^2\,\partial^{-1}\phi$.

In particular, we are concerned with the following reduction.

(i) With $M=4(u^{-1/2})_x$, $G_0=M^{(-1)}=4u^{-1/2}$, the positive order category of (6.36) reads as the well-known Harry–Dym hierarchy,

$$u_t=J\mathcal{L}^m\cdot 4u^{-1/2},\ \ m=0,1,2,\ldots. \tag{6.40}$$

With $m=1$, Eq. (6.40) yields the Harry–Dym equation,

$$u_t=\left(\frac{1}{\sqrt{u}}\right)_{xxx}, \tag{6.41}$$

which has now the GLR $L_t=[W_0,L]+4(u^{-1/2})_xL$ with $W_0=-(u^{-1/2})_x+2u^{-1/2}\partial$, and apparently belongs to the KdV category (6.36); with $m=2$, Eq. (6.40) yields a higher order Harry–Dym equation,

$$u_t=\tfrac{1}{4}\left(\frac{1}{\sqrt{u}}\right)_{4x}+u\left(\frac{1}{\sqrt{u}}\right)_{3x}+\tfrac{1}{2}u_x\left(\frac{1}{\sqrt{u}}\right)_{xx} \tag{6.42}$$

possessing the GLO $W_1=2u^{-1/2}\partial^3-(u^{-1/2})_x\partial^2+\frac{1}{2}((u^{-1/2})_{xx}+4u^{-1/2})\partial-\frac{1}{4}(u^{-1/2})_{xxx}+u^{-1/2}u_x$.

So, we have obtained an interesting fact: *the Harry–Dym equation (6.41) can be included in the KdV category (6.36) with the generalized Lax operator*. Similar to the process of the Burgers' case, we can also have many reduced hierarchies both positive and negative from Eq. (6.36).

6.3: AKNS case. The ZS-AKNS spectral problem,[35,36]

$$L\cdot y=\lambda y,\quad L=L(q,r)=i\begin{pmatrix}\partial & -q\\ r & -\partial\end{pmatrix},\quad y=\begin{pmatrix}y_1\\ y_2\end{pmatrix}, \tag{6.43}$$

has its Lenard's operators pair,

$$K=\begin{pmatrix}q\,\partial^{-1}q & \frac{1}{2}\partial-q\,\partial^{-1}r\\ \frac{1}{2}\partial-r\,\partial^{-1}q & r\,\partial^{-1}r\end{pmatrix},\quad J=i\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}. \tag{6.44}$$

Apparently,

$$L_*(\xi)=\begin{pmatrix}0 & -i\xi_1\\ i\xi_2 & 0\end{pmatrix},\quad \xi=(\xi_1,\xi_2)^T\in\mathcal{B}^2, \tag{6.45}$$

is an injective homomorphism.

Equation (6.44) gives the recursion operator

$$\mathcal{L}=J^{-1}K=\frac{1}{2}i\begin{pmatrix}-\partial+2r\,\partial^{-1}q & -2r\,\partial^{-1}r\\ 2q\,\partial^{-1}q & \partial-2q\,\partial^{-1}r\end{pmatrix}. \tag{6.46}$$

Choosing two functions θ, $\sigma\in C^\infty(R)$ satisfying $\theta_x=\frac{1}{2}\theta^2+r^{-1}r_x\theta-2qr$, $\sigma_x=\frac{1}{2}\sigma^2+q^{-1}q_x\sigma-2qr$, leads to the inverse of $\mathcal{L}$,

$$\mathcal{L}^{-1}=K^{-1}J=-2i\begin{pmatrix}-\mathcal{E}(\partial r^{-1}\,\partial r^{-1}-2qr^{-1}) & -2\mathcal{E}\\ 2\mathcal{F} & \mathcal{F}(\partial q^{-1}\,\partial q^{-1}-2rq^{-1})\end{pmatrix}, \tag{6.47}$$

where $\mathcal{E}$, $\mathcal{F}$ denote the following two operators:

$$\mathcal{E}=e^{-\theta^{(-1)}}\partial^{-1}e^{\theta^{(-1)}}\,r\,\partial^{-1}r\,e^{\theta^{(-1)}}\partial^{-1}e^{-\theta^{(-1)}},\quad \mathcal{F}=e^{-\sigma^{(-1)}}\partial^{-1}e^{\sigma^{(-1)}}\,q\,\partial^{-1}q\,e^{\sigma^{(-1)}}\partial^{-1}e^{-\sigma^{(-1)}}. \tag{6.48}$$

Let $A,B,C,D\in\mathcal{B}$ be four arbitrarily given functions; then iff

$$M=\begin{pmatrix}0 & -B\\ -A & 0\end{pmatrix},\quad \tilde{M}=\begin{pmatrix}0 & -D\\ -C & 0\end{pmatrix}, \tag{6.49}$$

the operator equations $L_*(J\cdot G_0)=M$, $L_*(K\cdot G_{-1})=\tilde{M}$ give the positive order and negative order generators (function vectors),

$$G_0=\begin{pmatrix}A\\B\end{pmatrix},\quad G_{-1}=-2i\begin{pmatrix}-\mathcal{E}\cdot(\partial r^{-1}\cdot(r^{-1}C)_x-2qr^{-1}C+2D)\\ \mathcal{F}\cdot(\partial q^{-1}\cdot(q^{-1}D)_x-2rq^{-1}D+2C)\end{pmatrix}, \tag{6.50}$$

which directly leads to the AKNS category of NLEEs:

$$\begin{pmatrix}q\\r\end{pmatrix}_t=\begin{cases}J\mathcal{L}^m\cdot(A,B)^T, & m=0,1,2,...,\\ J\mathcal{L}^m\cdot(C,D)^T, & m=-1,-2,\ldots,\end{cases} \tag{6.51}$$

where J, $\mathcal{L}$ and $\mathcal{L}^{-1}$ are defined by (6.44), (6.46) and (6.47), respectively.

For an arbitrarily given $G=(G^{[1]},G^{[2]})^T\in\mathcal{B}^2$, the operator equation $[V,L]=L_*(K\cdot G)-L_*(J\cdot G)L$ has the solution

$$V=V(G)=\frac{1}{2}\begin{pmatrix}-(rG^{[2]}-qG^{[1]})^{(-1)} & G^{[2]}\\ G^{[1]} & (rG^{[2]}-qG^{[1]})^{(-1)}\end{pmatrix}, \tag{6.52}$$

which is obviously a function matrix. Thus, the AKNS category (6.51') has the GLR:

$$L_t=[W_m,L]+\bar{M}L^m,\quad m\in Z, \tag{6.53}$$

$$\bar{M}=\begin{cases}\begin{pmatrix}0 & B\\ A & 0\end{pmatrix}, & m\geqslant 0,\\ \begin{pmatrix}0 & D\\ C & 0\end{pmatrix}, & m<0,\end{cases}$$

with the GLO

$$W_m=\sum V(G_j)L^{m-j-1},\quad m\in Z. \tag{6.54}$$

Here $V(G_j)$ is given by (6.52) with $G=G_j=\mathcal{L}^j\cdot(A,B)^T$, $j\geqslant 0$ or $\mathcal{L}^j\cdot(C,D)^T$, $j<0$, L is defined by (6.43), and its inverse L^{-1} is determined by

$$L^{-1}=i\begin{pmatrix}\mathcal{S}\partial q^{-1} & -\mathcal{S}\\ -\mathcal{T} & \mathcal{T}\partial r^{-1}\end{pmatrix}, \tag{6.55}$$

with the operators $\mathcal{S}=e^{-\rho^{(-1)}}\partial^{-1}e^{2\rho^{(-1)}}q\,\partial^{-1}e^{-\rho^{(-1)}}$, $\mathcal{T}=e^{-\mu^{(-1)}}\partial^{-1}e^{2\mu^{(-1)}}r\,\partial^{-1}e^{-\mu^{(-1)}}$, where ρ and μ are two functions satisfying $\rho_x=\rho^2+q^{-1}q_x\rho-qr$, $\mu_x=\mu^2+r^{-1}r_x\mu-qr$.

Here, we omit the reductions and the r-matrix representation of the AKNS category (6.51).

6.4: WKI (Wadati–Konno–Ichikowa) case. The WKI spectral problem,[37]

$$L\cdot y=\lambda y,\ L=L(q,r)=\frac{1}{1-qr}\begin{pmatrix}i & -q\\ -r & -i\end{pmatrix}\partial,\ y=\begin{pmatrix}y_1\\y_2\end{pmatrix}, \tag{6.56}$$

has the following Lenard's operators pair:

$$K=\frac{1}{2i}\begin{pmatrix}-\frac{1}{2}\partial^2\frac{q}{p}\partial^{-1}\frac{q}{p}\partial^2 & \partial^3+\frac{1}{2}\partial^2\frac{q}{p}\partial^{-1}\frac{r}{p}\partial^2\\ \partial^3+\frac{1}{2}\partial^2\frac{r}{p}\partial^{-1}\frac{q}{p}\partial^2 & -\frac{1}{2}\partial^2\frac{r}{p}\partial^{-1}\frac{r}{p}\partial^2\end{pmatrix}, \tag{6.57}$$

$$J=\begin{pmatrix} 0 & -\partial^2 \\ \partial^2 & 0 \end{pmatrix}, \quad p=\sqrt{1-qr}, \tag{6.58}$$

which yields the recursion operator $\mathcal{L}=J^{-1}K$

$$\mathcal{L}=\frac{1}{2i}\begin{pmatrix} \partial+\frac{r}{2p}\partial^{-1}\frac{q}{p}\partial^2 & -\frac{r}{2p}\partial^{-1}\frac{r}{p}\partial^2 \\ \frac{q}{2p}\partial^{-1}\frac{q}{p}\partial^2 & -\partial-\frac{q}{2p}\partial^{-1}\frac{r}{p}\partial^2 \end{pmatrix}. \tag{6.59}$$

Apparently, the Gateaux derivative operator $L_*(\xi)$ of the spectral operator L in the direction $\xi=(\xi_1,\xi_2)^T\in\mathcal{B}^2$ is

$$L_*(\xi)=\frac{1}{1-qr}\begin{pmatrix} q\xi_2 & -i\xi_1 \\ i\xi_2 & r\xi_1 \end{pmatrix}L, \tag{6.60}$$

which is an injective homomorphism.

Through lengthy calculations, one can obtain the invertible operators of L, J, K and $\mathcal{L}$:

$$L^{-1}=\begin{pmatrix} -i\partial^{-1} & \partial^{-1}q \\ \partial^{-1}r & i\partial^{-1} \end{pmatrix}, \tag{6.61}$$

$$J^{-1}=\begin{pmatrix} 0 & \partial^{-2} \\ -\partial^{-2} & 0 \end{pmatrix}, \tag{6.62}$$

$$K^{-1}=2i\begin{pmatrix} \frac{1}{2}\partial^{-1}r\,\partial^{-1}r\,\partial^{-1} & \partial^{-3}-\frac{1}{2}\partial^{-1}r\,\partial^{-1}q\,\partial^{-1} \\ \partial^{-3}-\frac{1}{2}\partial^{-1}q\,\partial^{-1}r\,\partial^{-1} & \frac{1}{2}\partial^{-1}q\,\partial^{-1}q\,\partial^{-1} \end{pmatrix}, \tag{6.63}$$

$$\mathcal{L}^{-1}=2i\begin{pmatrix} \partial^{-1}-\frac{1}{2}\partial^{-1}r\,\partial^{-1}q\,\partial & -\frac{1}{2}\partial^{-1}r\,\partial^{-1}r\,\partial \\ \frac{1}{2}\partial^{-1}q\,\partial^{-1}q\,\partial & -\partial^{-1}+\frac{1}{2}\partial^{-1}q\,\partial^{-1}r\,\partial \end{pmatrix}. \tag{6.64}$$

Let A, B, C, D be four arbitrarily given C^∞-functions; then iff

$$M=\frac{1}{1-qr}\begin{pmatrix} qA & iB \\ iA & -rB \end{pmatrix}L, \quad \tilde{M}=\frac{1}{1-qr}\begin{pmatrix} qC & iD \\ iC & -rD \end{pmatrix}L, \tag{6.65}$$

the operator equations $L_*(J\cdot G_0)=M$, $L_*(K\cdot G_{-1})=\tilde{M}$ have the following solutions:

$$G_0=\begin{pmatrix} A^{(-2)} \\ B^{(-2)} \end{pmatrix}, \tag{6.66}$$

$$G_{-1}=\begin{pmatrix} 2iC^{(-3)}-i\,\partial^{-1}r\,\partial^{-1}\cdot(rD^{(-1)}+qC^{(-1)}) \\ -2iD^{(-3)}+i\,\partial^{-1}q\,\partial^{-1}\cdot(rD^{(-1)}+qC^{(-1)}) \end{pmatrix}, \tag{6.67}$$

which directly yields the WKI category of NLEEs:

$$\begin{pmatrix} q \\ r \end{pmatrix}_t = J \cdot G_m, \quad m \in Z, \tag{6.68}$$

$$G_m = \begin{cases} \mathcal{L}^m \cdot (A^{(-2)}, B^{(-2)})^T, & m = 0,1,2,..., \\ \mathcal{L}^m \cdot (C^{(-2)}, D^{(-2)})^T, & m = -1,-2,\ldots, \end{cases} \tag{6.69}$$

where J, $\mathcal{L}$ and $\mathcal{L}^{-1}$ are defined by (6.58), (6.59) and (6.64), respectively.

For any given $G = (G^{[1]}, G^{[2]})^T \in \mathcal{B}^2$, the equation $[V, L] = L_*(K \cdot G)L^{-1} - L_*(J \cdot G)$ has the following operator solution:

$$V = V(G) = \begin{pmatrix} 0 & \overline{B} \\ \overline{C} & 0 \end{pmatrix} + \overline{A} \begin{pmatrix} -i & q \\ r & i \end{pmatrix} L, \tag{6.70}$$

where $\overline{A}$, $\overline{B}$, $\overline{C}$ are the following three functions given by

$$\overline{A} = \overline{A}(G) = \frac{1}{2p}\left(\frac{q}{p}G_{xx}^{[1]} - \frac{r}{p}G_{xx}^{[2]}\right)^{(-1)}, \quad p = \sqrt{1-qr},$$

$$\overline{B} = \overline{B}(G) = \frac{1}{4i}\left(2G_{xx}^{[2]} - \partial\frac{q}{p} \cdot \left(\frac{q}{p}G_{xx}^{[1]} - \frac{r}{p}G_{xx}^{[2]}\right)^{(-1)}\right),$$

$$\overline{C} = \overline{C}(G) = \frac{1}{4i}\left(2G_{xx}^{[1]} + \partial\frac{r}{p} \cdot \left(\frac{q}{p}G_{xx}^{[1]} - \frac{r}{p}G_{xx}^{[2]}\right)^{(-1)}\right).$$

Thus, the WKI category (6.68) has the GLR:

$$L_t = [W_m, L] + \overline{M}L^{m+1}, \quad m \in Z, \tag{6.71}$$

$$\overline{M} = \begin{cases} \dfrac{1}{1-qr}\begin{pmatrix} qA & iB \\ iA & -rB \end{pmatrix}, & m \geqslant 0, \\ \dfrac{1}{1-qr}\begin{pmatrix} qC & iD \\ iC & -rD \end{pmatrix}, & m < 0, \end{cases} \tag{6.72}$$

with the GLO

$$W_m = \sum V(G_j)L^{m-j}, \quad m \in Z. \tag{6.73}$$

Here L, L^{-1} and $V(G_j)$ are given by (6.56), (6.61) and (6.70) with $G = G_j$ defined by (6.69), respectively.

6.5: The following spectral problem:

$$L \cdot y = \lambda y, \quad L = L(u) = \frac{1}{u}\begin{pmatrix} i & 1-u \\ 1 & -i \end{pmatrix}\partial, \quad y = \begin{pmatrix} y_1 \\ y_2 \end{pmatrix}, \tag{6.74}$$

yields its Lenard operators pair,

$$K = \partial^3, \quad J = -2(\partial u + u\partial).$$

The Gateaux derivative operator $L_*(\xi)$ of the spectral operator L in the direction $\xi \in \mathcal{B}$ is

$$L_*(\xi)=\frac{\xi}{u^2}\begin{pmatrix}-i & -1\\ -1 & i\end{pmatrix}\partial=\frac{\xi}{u}\begin{pmatrix}0 & -i\\ 0 & -1\end{pmatrix}L. \tag{6.75}$$

Apparently, L_* is a homomorphism and $L_*(\xi)=0\Leftrightarrow\xi=0$.

In the category derived from Eq. (6.75), we can obtain the Harry–Dym hierarchy as well as some new integrable equations. For example, the following nonlinear equation:

$$v_{xt_{-2}}=2vv_{xx}+v_x^2 \tag{6.76}$$

is a new integrable equation with many unknown physical properties. In fact, this equation is included in an isospectral ($\lambda_{t_{-2}}=0$) negative order hierarchy of (6.74), and its standard Lax operator is

$$W_{-2}=-V(G_{-2})L^{-1}-V(G_{-1})L^{-3},$$

where $V(G_j)$ $(j=-2,-1)$ is given by

$$V=V(G)=G_{xx}\begin{pmatrix}0 & 1\\ 0 & 0\end{pmatrix}+G_x\begin{pmatrix}1 & -2i\\ 0 & -1\end{pmatrix}L+2G\begin{pmatrix}-i & u-1\\ -1 & i\end{pmatrix}L^2, \tag{6.77}$$

with $G=G_{-2}=-v^{(-1)}$, $G_{-1}=\frac{1}{2}$, respectively, and L^{-1} is the inverse of L, given by

$$L^{-1}=\begin{pmatrix}-i\partial^{-1} & \partial^{-1}v_x-\partial^{-1}\\ -\partial^{-1} & i\partial^{-1}\end{pmatrix}. \tag{6.78}$$

We will give in detail some reductions for the latter four spectral problems in a later paper.

(Received 21 February 2001; accepted 4 November 2002)

Employing the construction method of Dirichlet forms on standard forms of von Neumann algebras developed in *Infinite Dimensional Analysis, Quantum Probability and Related Topics*, 2000, Vol. 3, No. 1, pp. 1–14 (Ref. 1), we construct Dirichlet forms and associated symmetric Markovian semigroups on CCR algebras with respect to quasi-free states. More precisely, let $\mathcal{A}(\mathfrak{h}_0)$ be the CCR algebra over a complex separable pre-Hilbert space $\mathfrak{h}_0$ and let ω be a quasi-free state on $\mathcal{A}(\mathfrak{h}_0)$. For any normalized admissible function f and complete orthonormal system (CONS) $\{g_n\}\subset\mathfrak{h}_0$, we construct a Dirichlet form and corresponding symmetric Markovian semigroup on the natural standard form associated to the GNS representation of $(\mathcal{A}(\mathfrak{h}_0),\omega)$. It turns out that the form is independent of admissible function f and CONS $\{g_n\}$ chosen. By analyzing the spectrum of the generator (Dirichlet operator) of the semigroup, we show that the semigroup is ergodic and tends to the equilibrium exponentially fast. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1532770]

I. INTRODUCTION

Our purpose in this paper is to construct Dirichlet forms and associated symmetric Markovian semigroups on CCR algebras with respect to gauge invariant quasi-free states, and then investigate detailed properties such as ergodicity of the semigroups. Let $\mathcal{A}(\mathfrak{h}_0)$ be the CCR algebra over a complex separable pre-Hilbert space $\mathfrak{h}_0$ and let ω be a gauge invariant quasi-free state on $\mathcal{A}(\mathfrak{h}_0)$.[2] For any normalized admissible function f and complete orthonormal system (CONS) $\{g_n\}\subset\mathfrak{h}_0$, we use the general construction method of Dirichlet forms developed in Ref. 1 to construct a Dirichlet form and corresponding symmetric Markovian semigroup on the natural standard form associated to the GNS representation of the pair $(\mathcal{A}(\mathfrak{h}_0),\omega)$. We show that the Dirichlet form we constructed is independent of the admissible function f and the CONS $\{g_n\}$ chosen. By establishing a (chaos) decomposition of the quasi-free Hilbert space (see Sec. V) and investigating the spectrum of the generator (Dirichlet operator) of the semigroup, we prove that the semigroup is ergodic and tends to the equilibrium exponentially fast.

The study of noncommutative Dirichlet forms was pioneered by Albeverio and Høegh-Krohn,[3] Sauvageot[4–6] and extensively developed by Davies and Lindsay,[7] and Guido, Isola, and Scarlatti.[8] All these authors considered Markovianity of forms and semigroups only with respect to a tracial state ϕ_0. Recently, the abstract theory has been extended to a faithful normal state ϕ_0 by Goldstein and Lindsay[9,10] in the setting of the Haagerup's standard forms and by Cipriani[11] in the context of general standard forms of von Neumann algebras, respectively.

The need to construct Markovian semigroups on von Neumann algebras, which are symmetric with respect to a nontracial state, is clear for various applications to open systems,[12] quantum

[a)]Electronic-mail: bahn@yonsei.ac.kr
[b)]Electronic-mail: kochulki@hotmail.com
[c)]Electronic-mail: ympark@yonsei.ac.kr

statistical mechanics,[2] and quantum probability theory.[13–15] Although on an abstract level we have quite a well-developed theory as mentioned above, the progress in a concrete application is very slow. We would like to mention a few recent works in this direction. The completely positive Hamiltonian semigroup for quantum spin chains in the ground state representation has been considered in Refs. 16–18. In Refs. 19–20, Majewski and Zegarlinski used the generalized conditional expectation to construct generators of spin-flip type dynamics for quantum spin systems. In Ref. 1, one of the authors gave a general construction method of Dirichlet forms on standard forms of von Neumann algebras and applied the method to construct translation invariant Markovian semigroups for quantum spin systems. In Ref. 21, quantum Ornstein–Uhlenbeck semigroups were constructed by means of noncommutative Dirichlet forms. Extending the methods of Ref. 1 and the techniques developed in this paper, we construct symmetric Markovian semigroups on CAR algebras with respect to quasi-free states.[22]

Let us describe the content of this paper briefly. Let $\mathfrak{h}_0$ be a complex separable pre-Hilbert space and $\mathfrak{h}$ the completion of $\mathfrak{h}_0$. Denote by $\mathcal{A}(\mathfrak{h}_0)$ the C^*-algebra over $\mathfrak{h}_0$ generated by the Weyl operators $W(g)$, $g\in\mathfrak{h}_0$. Let A be a self-adjoint operator on $\mathfrak{h}$ satisfying

$$0<A\leqslant\alpha\mathbf{1}<\mathbf{1}, \tag{1.1}$$

for some $\alpha\in(0,1)$. The gauge invariant quasi-free state ω on $\mathcal{A}(\mathfrak{h}_0)$ is given by

$$\omega(W(f))=\exp\{-(f,\tfrac{1}{4}(\mathbf{1}+A)(\mathbf{1}-A)^{-1}f)\},\quad f\in\mathfrak{h}_0.$$

We assume that A^{-1} exists as a (unbounded) self-adjoint operator and that any vector in $\mathfrak{h}_0$ is an analytic vector for $A^{-1/2}$ (Assumption 3.1).

Let $(\mathcal{H}_\omega,\pi_\omega,\Omega_\omega)$ be the GNS representation of the pair $(\mathcal{A}(\mathfrak{h}_0),\omega)$ and $\mathcal{M}=\pi_\omega(\mathcal{A}(\mathfrak{h}_0))''$. We suppress ω and π_ω from the notation, i.e., $\mathcal{H}=\mathcal{H}_\omega$, $W(f)=\pi_\omega(W(f))$, etc. We also write $\xi_0=\Omega_\omega$. Let $\sigma_t:\mathcal{M}\to\mathcal{M}$ be the one parameter group of automorphisms defined by

$$\sigma_t(W(f))=W(A^{it}f),\quad f\in\mathfrak{h}_0,\ t\in\mathbb{R}.$$

Then ω satisfies σ-KMS conditions.[2] We use Δ and J to denote the modular operator and the modular conjugation, respectively. Then σ_t becomes the modular group : $\sigma_t(B)=\Delta^{it}B\Delta^{-it}$, $B\in\mathcal{M}$. Let $\mathcal{M}'$ be the commutant of $\mathcal{M}$. The map $j:\mathcal{M}\to\mathcal{M}'$ is the antilinear $*$-isomorphism defined by $j(B)=JBJ$, $B\in\mathcal{M}$. The natural positive cone $\mathcal{P}$ associated with $(\mathcal{M},\xi_0)$ is the closure of the set $\{Bj(B)\xi_0: B\in\mathcal{M}\}$. The form $(\mathcal{M},\mathcal{H},\mathcal{P},J)$ is the standard form associated with $(\mathcal{M},\xi_0)$.

For any $g\in\mathfrak{h}_0$, let $\Phi(g)$ be the infinitesimal generator of the unitary group $W(tg)$, $t\in\mathbb{R}$, and

$$a(g)=2^{-1/2}(\Phi(g)+i\Phi(ig)),$$

$$a^*(g)=2^{-1/2}(\Phi(g)-i\Phi(ig)).$$

For any $f,g\in\mathfrak{h}_0$, $a(f)$ and $a^*(g)$ are densely defined, closed and $a(f)^*=a^*(f)$, and satisfy the canonical commutation relations (CCRs).[2] Notice that $a^\#(g)$ and $j(a^\#(g))$, $g\in\mathfrak{h}_0$, are affiliated with $\mathcal{M}$ and $\mathcal{M}'$, respectively, where $a^\#(g)$ stands for either $a(g)$ or $a^*(g)$.

For any $B\in\mathcal{M}$ and $n\in\mathbb{N}$, we write

$$B_n=\left(\frac{n}{\pi}\right)^{1/2}\int\sigma_t(B)e^{-nt^2}dt.$$

Let $\mathcal{W}$ be the algebra generated by $W(f)$, $f\in\mathfrak{h}_0$. We set $W_n(f):=W(f)_n$, where $W(f)_n$ is defined in the above with $B=W(f)$. We use $\mathcal{W}_0$ and $\mathcal{M}_0$ to denote the algebras generated by $W_n(f)$, $f\in\mathfrak{h}_0$, $n\in\mathbb{N}$ and by B_n, $B\in\mathcal{M}$, $n\in\mathbb{N}$, respectively. We also use $\mathcal{H}_{\text{fin}}$ to denote the subspace of $\mathcal{H}$ spanned by the vectors of the form $(\Pi_{j=1}^n\Phi(g_j))\xi_0$, $g_j\in\mathfrak{h}_0$, $j=1,2,\ldots,n$. Obviously, $\mathcal{W}\xi_0$, $\mathcal{W}_0\xi_0$, $\mathcal{M}_0\xi_0$ and $\mathcal{H}_{\text{fin}}$ are dense in $\mathcal{H}$.

For any normalized admissible function f (Definition 2.1) and CONS $\{g_n\}\subset\mathfrak{h}_0$ for $\mathfrak{h}$, we define a sesquilinear form $\mathcal{E}:D(\mathcal{E})\times D(\mathcal{E})\to\mathbb{C}$ by

$$\begin{aligned} &D(\mathcal{E})=\mathcal{W}_0\xi_0\ (\text{ or } \mathcal{W}\xi_0,\ \mathcal{M}_0\xi_0),\\ &\mathcal{E}(\eta,\ \xi)=\sum_{n=1}^{\infty}\ \mathcal{E}^{(n)}(\eta,\ \xi),\quad \eta,\ \xi\in D(\mathcal{E}), \end{aligned} \tag{1.2}$$

where for each $n\in\mathbb{N}$, $\eta,\ \xi\in D(\mathcal{E}^{(n)})=\mathcal{W}_0\xi_0$ (or $\mathcal{W}\xi_0,\ \mathcal{M}_0\xi_0$)

$$\begin{aligned} \mathcal{E}^{(n)}(\eta,\ \xi)=&\int\langle(\sigma_{t-i/4}(a(g_n))-j(\sigma_{t-i/4}(a^*(g_n))))\eta,\\ &(\sigma_{t-i/4}(a(g_n))-j(\sigma_{t-i/4}(a^*(g_n))))\xi\rangle f(t)\,dt\\ &+\int\langle(\sigma_{t-i/4}(a^*(g_n))-j(\sigma_{t-i/4}(a(g_n))))\eta,\\ &(\sigma_{t-i/4}(a^*(g_n))-j(\sigma_{t-i/4}(a(g_n))))\xi\rangle f(t)\,dt. \end{aligned} \tag{1.3}$$

See Sec. III for the details.

It turns out that the forms $(\mathcal{E},\ \mathcal{W}\xi_0)$ and $(\mathcal{E},\ \mathcal{W}_0\xi_0)$ are closable and independent of the admissible function f and the CONS $\{g_n\}$ chosen (Proposition 3.1). For each $n\in\mathbb{N}$, the form $(\mathcal{E}^{(n)},\ \mathcal{M}_0\xi_0)$ is closable and its closure $(\overline{\mathcal{E}^{(n)}},\ D(\overline{\mathcal{E}^{(n)}}))$ is a Dirichlet form (Proposition 3.2). Let $\overline{\mathcal{E}}$ be the form defined by

$$\overline{\mathcal{E}}=\sum_{n=1}^{\infty}\ \overline{\mathcal{E}^{(n)}}.$$

Then $(\overline{\mathcal{E}},\ D(\overline{\mathcal{E}}))$ is a densely defined Dirichlet form (Theorem 3.1). As a Corollary of Theorem 3.2, the form $(\overline{\mathcal{E}},\ D(\overline{\mathcal{E}}))$ is also independent of the f and $\{g_n\}$ we have chosen.

Let H be the infinitesimal generator of the Markovian semigroup $\{T_t\}_{t\geqslant 0}$ associated to $(\overline{\mathcal{E}},\ D(\overline{\mathcal{E}}))$. In order to analyze the spectrum $\sigma(H)$ of H, we introduce a (chaos) decomposition of $\mathcal{H}$. Let B be the operator given by

$$B:=A^{-1/2}-A^{1/2}. \tag{1.4}$$

For any $g\in\mathfrak{h}_0$, let $D_1(g)$ and $D_2(g)$ be the operators on $\mathcal{H}$ defined by

$$\begin{aligned} &D_1(g):=\sigma_{-i/4}(a(B^{-1/2}g))-j(\sigma_{-i/4}(a^*(B^{-1/2}g))),\\ &D_2(g):=\sigma_{-i/4}(a^*(B^{-1/2}g))-j(\sigma_{-i/4}(a(B^{-1/2}g))). \end{aligned}$$

Then $D_i(f)\xi_0=0$, $i=1,2$, $f\in\mathfrak{h}_0$ (Lemma 5.1) and the following CCRs hold (Proposition 5.1) : for any $f,\ g\in\mathfrak{h}_0$,

$$\begin{aligned} &[D_1(f),\ D_1(g)^*]=(f,\ g)\mathbf{1},\\ &[D_2(f),\ D_2(g)^*]=(g,\ f)\mathbf{1},\\ &[D_i(f),\ D_i(g)]=0,\quad i=1,2,\\ &[D_1(f)^{\#},D_2(g)^{\#}]=0, \end{aligned}$$

where $D_i(f)^{\#}$ is either $D_i(f)$ or $D_i(f)^*$, $i=1,2$. Thus $D_i(f)$ and $D_i(g)^*$ can be considered as annihilation and creation operators, respectively, and ξ_0 is the vacuum vector. Thus $\mathcal{H}$ has the following decomposition (Theorem 5.1):

$$\mathcal{H}=\bigoplus_{m,n=0}^{\infty}\mathcal{H}^{(m,n)},$$

where for each $m,n\in\mathbb{N}\cup\{0\}$, $\mathcal{H}^{(m,n)}$ is the closure of the subspace spanned by vectors of the form

$$\left(\prod_{j=1}^{m}D_1(g_j)^*\right)\left(\prod_{l=1}^{n}D_2(h_l)^*\right)\xi_0,\quad g_j,h_l\in\mathfrak{h}_0.$$

It follows that $\mathcal{H}_{\text{fin}}\subset D(H)$ and for any CONS $\{g_n\}\subset\mathfrak{h}_0$,

$$H=\sum_{n=1}^{\infty}\{D_1(B^{1/2}g_n)^*D_1(B^{1/2}g_n)+D_2(B^{1/2}g_n)^*D_2(B^{1/2}g_n)\},$$

as a bilinear form on $\mathcal{H}_{\text{fin}}\times\mathcal{H}_{\text{fin}}$ [Lemma 5.4(b)]. Let $\mathcal{F}$ be the symmetric Fock space over $\mathfrak{h}$.[2] Then there is an anti-unitary operator $V:\mathcal{F}\to\mathcal{F}$ and a unitary operator $U:\mathcal{H}\to\mathcal{F}\otimes V\mathcal{F}(=\mathcal{F}\otimes\mathcal{F})$ (Proposition 5.2) such that

$$UHU^{-1}=d\Gamma(B)\otimes\mathbf{1}+\mathbf{1}\otimes d\Gamma(B),$$

where $d\Gamma(B)$ is the second quantization of B.[2] Thus H is essentially self-adjoint on $\mathcal{H}_{\text{fin}}$ and independent of the admissible function f and CONS $\{g_n\}\subset\mathfrak{h}_0$ chosen. Moreover the zero is a simple eigenvalue of H with eigenvector ξ_0 and $(0,\alpha^{-1/2}-\alpha^{1/2})\cap\sigma(H)=\varnothing$ (Theorem 3.2).

We should mention that the main results in this paper can be generalized. For instance, if one replaces g_n by $B^{\lambda}g_n$, $n\in\mathbb{N}$, $\lambda\in[-\frac{1}{2},\infty)$, in the definition of $\mathcal{E}(\eta,\xi)$ in (1.2) and (1.3), the results in Sec. III still hold with an appropriate modification on the spectral gap. See Remark 3.3.

We organize this paper as follows: In Sec. II we first introduce some terminologies in the theory of noncommutative Dirichlet forms[11] and then review the general construction method of Ref. 1. We extend the method of Ref. 1 slightly and produce its proof. In Sec. III, we give an explicit expression of a Dirichlet form for given normalized admissible function f and CONS $\{g_n\}\subset\mathfrak{h}_0$ for $\mathfrak{h}$, and then state main results in this paper. Section IV is devoted to the proofs of Proposition 3.1, Proposition 3.2 and Theorem 3.1. In Sec. V, we introduce a chaos decomposition of $\mathcal{H}$ and then prove the ergodicity of the semigroup and the existence of a spectral gap. In the Appendix, we give the proofs of technical lemmas (Lemma 4.3 and Lemma 5.4).

II. REVIEW ON CONSTRUCTION OF DIRICHLET FORMS ON STANDARD FORMS OF VON NEUMANN ALGEBRAS

In this section, we first introduce necessary terminologies in the theory of noncommutative Dirichlet forms in the sense of Cipriani,[11] and then describe the general construction method of Dirichlet forms on the standard form of von Neumann algebras developed in Ref. 1. We extend the result of Ref. 1 slightly and give its proof.

Let $\mathcal{M}$ be a σ-finite von Neumann algebra acting on a complex Hilbert space $\mathcal{H}$. A self-dual cone $\mathcal{P}$ in $\mathcal{H}$ is a subset satisfying the property

$$\{\xi\in\mathcal{H}:\langle\xi,\eta\rangle\geqslant 0,\quad\forall\,\eta\in\mathcal{P}\}=\mathcal{P}.$$

$\mathcal{P}$ is then a closed convex cone and $\mathcal{H}$ is the complexification of the real subspace $\mathcal{H}^J:=\{\xi\in\mathcal{H}:\langle\xi,\eta\rangle\in\mathbb{R},\ \forall\,\eta\in\mathcal{P}\}$, which elements are called *J-real*: $\mathcal{H}=\mathcal{H}^J+i\mathcal{H}^J$. Such a $\mathcal{P}$ gives rise to a structure of ordered Hilbert space on $\mathcal{H}^J$ (denoted by $\leqslant$) and to an anti-unitary involution J on

$\mathcal{H}$, which preserves $\mathcal{H}^J$: $J(\xi+i\eta):=\xi-i\eta$ for all $\xi,\eta\in\mathcal{H}^J$. Any J-real element $\xi\in\mathcal{H}^J$ can be decomposed uniquely as a difference, $\xi=\xi_+-\xi_-$, of two orthogonal, positive elements, called the positive and the negative part of ξ: ξ_+, $\xi_-\in\mathcal{P}$, $\langle\xi_+,\xi_-\rangle=0$.

A *standard form* $(\mathcal{M},\mathcal{H},\mathcal{P},J)$ of the von Neumann algebra $\mathcal{M}$ acting faithfully on the Hilbert space $\mathcal{H}$ consists of self-dual, closed, convex cone $\mathcal{P}$ in $\mathcal{H}$ and the anti-unitary involution J satisfying the following properties:

(a) $J\mathcal{M}J=\mathcal{M}'$
(b) $JxJ=x^*,\quad \forall x\in\mathcal{M}\cap\mathcal{M}'$
(c) $J\xi=\xi,\quad \forall\xi\in\mathcal{P}$
(d) $xJxJ(\mathcal{P})\subset\mathcal{P},\quad \forall x\in\mathcal{M}$,

where $\mathcal{M}'$ is the commutant of $\mathcal{M}$.

A bounded operator A on $\mathcal{H}$ is called *J-real* if $AJ=JA$ and *positive preserving* if $A\mathcal{P}\subset\mathcal{P}$. The semigroup $\{T_t\}_{t\geqslant 0}$ is said to be *J-real* if T_t is J-real for any $t\geqslant 0$ and it is called *positive preserving* if T_t is positive preserving for any $t\geqslant 0$.

Let us fix a cyclic and separating vector ξ_0 in $\mathcal{P}$. A bounded operator $A:\mathcal{H}\to\mathcal{H}$ is called *sub-Markovian* (with respect to ξ_0) if $0\leqslant\xi\leqslant\xi_0$ implies $0\leqslant A\xi\leqslant\xi_0$. A is called *Markovian* if it is sub-Markovian and also $A\xi_0=\xi_0$. A semigroup $\{T_t\}_{t\geqslant 0}$ is said to be *sub-Markovian* (with respect to ξ_0) if T_t is sub-Markovian for every $t\geqslant 0$. The semigroup $\{T_t\}_{t\geqslant 0}$ is called *Markovian* if T_t is Markovian for every $t\geqslant 0$.

Next, we consider a sesquilinear form on some linear manifold of $\mathcal{H}$: $\mathcal{E}(\cdot,\cdot):D(\mathcal{E})\times D(\mathcal{E})\to\mathbb{C}$. We also consider the associated quadratic form: $\mathcal{E}[\cdot]:D(\mathcal{E})\to\mathbb{C}$, $\mathcal{E}[\xi]:=\mathcal{E}(\xi,\xi)$. A real valued quadratic form $\mathcal{E}[\cdot]$ is said to be *semi-bounded* if $\inf\{\mathcal{E}[\xi]:\xi\in D(\mathcal{E}),\ \|\xi\|=1\}=-b>-\infty$. A quadratic form $(\mathcal{E},D(\mathcal{E}))$ is said to be *J-real* if $JD(\mathcal{E})\subset D(\mathcal{E})$ and $\mathcal{E}[J\xi]=\overline{\mathcal{E}[\xi]}$ for any $\xi\in D(\mathcal{E})$. For a given semi-bounded quadratic form $\mathcal{E}$, one consider the inner product given by $\langle\xi,\eta\rangle_\lambda:=\mathcal{E}(\xi,\eta)+\lambda\langle\xi,\eta\rangle$, for $\lambda>b$. The form $\mathcal{E}$ is *closed* if $D(\mathcal{E})$ is a Hilbert space for some of the above norms. The form $\mathcal{E}$ is called *closable* if it admits a closed extension.

Associated to a semi-bounded closed form $\mathcal{E}$, there are a self-adjoint operator $(H,\ D(H))$ and a strongly continuous, symmetric semigroup $\{T_t\}_{t\geqslant 0}$. Each of the above objects determines uniquely the others according to well known relations (see Section 3.1 of Ref. 2 and Section 1.3 of Ref. 23).

From now on we will consider only J-real, real-valued, semi-bounded, densely defined quadratic forms. It is easy to check that these forms satisfy the relation $\mathcal{E}[\xi+i\eta]=\mathcal{E}[\xi]+\mathcal{E}[\eta]$ for all $\xi+i\eta\in D(\mathcal{E})^J+iD(\mathcal{E})^J=D(\mathcal{E})$ where $D(\mathcal{E})^J:=D(\mathcal{E})\cap H^J$.

Let us denote by $\mathrm{Proj}\,(\xi,\mathcal{Q})$ the projection of the vector $\xi\in\mathcal{H}^J$ onto the closed, convex cone $\mathcal{Q}\subset\mathcal{H}^J$. For $\xi,\eta\in\mathcal{H}^J$, define

$$\xi\vee\eta:=\mathrm{Proj}\,(\xi,\eta+\mathcal{P}),$$

$$\xi\wedge\eta:=\mathrm{Proj}\,(\xi,\eta-\mathcal{P}).$$

A J-real, real-valued, densely defined quadratic form $(\mathcal{E},D(\mathcal{E}))$ is called *Markovian* with respect to $\xi_0\in\mathcal{P}$ if

$$\xi\in D(\mathcal{E})^J \text{ implies } \quad \xi\wedge\xi_0\in D(\mathcal{E}) \text{ and } \mathcal{E}[\xi\wedge\xi_0]\leqslant\mathcal{E}[\xi].$$

A closed Markovian form is called a *Dirichlet form*. Let $\{T_t\}_{t\geqslant 0}$ be the semigroup associated to a semi-bounded closed form $(\mathcal{E},D(\mathcal{E}))$. Then one of the main results in Ref. 11 is that $\{T_t\}_{t\geqslant 0}$ is sub-Markovian if and only if $(\mathcal{E},D(\mathcal{E}))$ is a Dirichlet form (Theorem 4.11 of Ref. 11).

Next, we describe a general construction method of Dirichlet forms on the natural standard forms of von Neumann algebras associated with the Tomita–Takesaki theory.[2,24] The method has been developed in Ref. 1. However we generalize the result of Ref. 1 slightly and produce the proof.

Let $\mathcal{M}$ be a σ-finite von Neumann algebra acting on a Hilbert space $\mathcal{H}$ and let $\xi_0 \in \mathcal{H}$ be a cyclic and separating vector for $\mathcal{M}$. We use Δ and J to denote, respectively, the modular operator and the modular conjugation associated with the pair $(\mathcal{M}, \xi_0)$.[2,25] The associated modular automorphism group is denoted by $\sigma_t : \sigma_t(A) = \Delta^{it} A \Delta^{-it}$, $A \in \mathcal{M}$. Finally, $j : \mathcal{M} \to \mathcal{M}'$ is the antilinear $*$-isomorphism defined by $j(A) = JAJ$, $A \in \mathcal{M}$. The natural positive cone $\mathcal{P}$ associated with $(\mathcal{M}, \xi_0)$ is the closure of the set

$$\{Aj(A)\xi_0 : A \in \mathcal{M}\}.$$

By a general result the cone $\mathcal{P}$ can be obtained by the closure of the set,

$$\{\Delta^{1/4} AA^* \xi_0 : A \in \mathcal{M}\}.$$

The natural cone $\mathcal{P}$ is self-dual.[2,25] For the detailed properties of $\mathcal{P}$, we refer to Section 2.5.4 of Ref. 2. The form $(\mathcal{M}, \mathcal{H}, \mathcal{P}, J)$ is the standard form associated with the pair $(\mathcal{M}, \xi_0)$.

In order to construct Dirichlet forms, let us introduce the notion of admissible functions:

Definition 2.1: An analytic function $f : D \to \mathbb{C}$ on a domain D containing the strip $\mathrm{Im}\, z \in [-1/4, 1/4]$ *is said to be admissible if the following properties hold:*

(a) $f(t) \geqslant 0$ *for* $\forall t \in \mathbb{R}$,
(b) $f(t + i/4) + f(t - i/4) \geqslant 0$, *for* $\forall t \in \mathbb{R}$,
(c) there exist $M > 0$ *and* $p > 1$ *such that the bound*

$$|f(t + is)| \leqslant M(1 + |t|)^{-p}$$

holds uniformly in $s \in [-1/4, 1/4]$.

Let us give an example of an admissible function. Using the residue integration method it is easy to check that

$$\int_{-\infty}^{\infty} (\cosh k)^{-1} e^{ikt}\, dk = 2\pi (e^{\pi/2\, t} + e^{-\pi/2\, t})^{-1}.$$

See also the expression in p. 94 of Ref. 2. Consider the following function:

$$f(t) = \frac{2}{\sqrt{2\pi}} \int_{-\infty}^{\infty} (e^{k/4} + e^{-k/4})^{-1} e^{-1/2\, k^2} e^{-ikt}\, dk. \tag{2.1}$$

Clearly f has an analytic extension to a domain containing the strip. It can be checked that f is an admissible function such that the bound in Definition 2.1 (c) holds with any $p > 1$. See the proof of Lemma 3.1 of Ref. 1.

We are ready to give a construction of Dirichlet forms on the standard form $(\mathcal{M}, \mathcal{H}, \mathcal{P}, J)$ associated with the pair $(\mathcal{M}, \xi_0)$. Denote by $\mathcal{M}_{\mathrm{an}}$ the dense subset of $\mathcal{M}$ consisting of every σ_t-analytic element with a domain containing the strip $I_{1/2} := \{z : |\mathrm{Im}\, z| \leqslant \frac{1}{2}\}$.[2] By Prop. 2.5.21 of Ref. 2, any $A \in \mathcal{M}_{\mathrm{an}}$ is strongly analytic. In the following, the inner product $\langle \cdot, \cdot \rangle$ on $\mathcal{H}$ is conjugate linear in the first and linear in the second variable. For given admissible function f and $x \in \mathcal{M}_{\mathrm{an}}$, define a sesquilinear form $\mathcal{E} : \mathcal{H} \times \mathcal{H} \to \mathbb{C}$ by

$$\begin{aligned}
\mathcal{E}(\eta, \xi) = & \int \langle (\sigma_{t - i/4}(x) - j(\sigma_{t - i/4}(x^*)))\eta, (\sigma_{t - i/4}(x) - j(\sigma_{t - i/4}(x^*)))\xi \rangle f(t)\, dt \\
& + \int \langle (\sigma_{t - i/4}(x^*) - j(\sigma_{t - i/4}(x)))\eta, (\sigma_{t - i/4}(x^*) - j(\sigma_{t - i/4}(x)))\xi \rangle f(t)\, dt \\
\equiv & \mathcal{E}^{(1)}(\eta, \xi) + \mathcal{E}^{(2)}(\eta, \xi).
\end{aligned} \tag{2.2}$$

Then the associated quadratic form is given by

$$\mathcal{E}[\xi]=\int \|[\sigma_{t-i/4}(x)-j(\sigma_{t-i/4}(x^*))]\xi\|^2 f(t)\,dt+\int \|[\sigma_{t-i/4}(x^*)-j(\sigma_{t-i/4}(x))]\xi\|^2 f(t)\,dt$$
$$\equiv \mathcal{E}^{(1)}[\xi]+\mathcal{E}^{(2)}[\xi]. \tag{2.3}$$

In Ref. 1, we have considered the case $x=x^*\in\mathcal{M}_{\mathrm{an}}$. The following is the result corresponding to Theorem 3.1 of Ref. 1.

Theorem 2.1: *For a given admissible function f and $x\in\mathcal{M}_{\mathrm{an}}$, let $(\mathcal{E},\mathcal{H})$ be defined as in (2.2). Let H be the self-adjoint operator associated with $(\mathcal{E},\mathcal{H})$. Assume that there exists a constant $M>0$ such that the bound*

$$\sup_{s\in[-1/4,1/4]} \|\sigma_{t+is}(x)\|\leqslant M$$

holds uniformly in $t\in\mathbb{R}$. Then the following properties hold:

(a) $H\xi_0=0$,
(b) $\mathcal{E}$ *is J-real,*
(c) $\mathcal{E}(\xi_+,\xi_-)\leqslant 0 \quad \forall \xi\in\mathcal{H}^J$.

Furthermore the form $(\mathcal{E},\mathcal{H})$ is a Dirichlet form.

We will produce the proof of Theorem 2.1 at the end of this section. The following is a consequence of Theorem 2.1.

Theorem 2.2: *Let $\{T_t\}_{t\geqslant 0}$ be the semigroup generated by the form $(\mathcal{E},\mathcal{H})$ in Theorem 2.1. Then $\{T_t\}_{t\geqslant 0}$ is a J-real, strongly continuous, symmetric Markovian semigroup.*

Proof: It follows from Theorem 2.1 (a) that $T_t(\xi_0)=\xi_0$ for any $t\geqslant 0$. Thus the theorem follows from Theorem 4.11 of Ref. 11. □

Remark 2.1: Consider the symmetric embedding:

$$i_0:\mathcal{M}\to\mathcal{H},$$

$$i_0(A)=\Delta^{1/4}A\xi_0.$$

Define the maps S_t on $\mathcal{M}$ by

$$S_t:\mathcal{M}\to\mathcal{M},\quad i_0\circ S_t\equiv T_t\circ i_0.$$

It follows from Theorem 2.12 of Ref. 11 that $\{S_t\}_{t\geqslant 0}$ is a weakly continuous, Markovian semigroup on $\mathcal{M}$. The Markoviam semigroup $\{T_t\}$ extends also to a strongly continuous semigroup on its predual space and to a family of strongly continuous Markovian semigroups on their interpolation L^p-space. See Theorem 2.12 and Theorem 2.14 of Ref. 11.

We now produce the proof of Theorem 2.1.

Proof of Theorem 2.1: (a) Notice that $JA\xi_0=\Delta^{1/2}A^*\xi_0$ for any $A\in\mathcal{M}$. Thus we have that

$$(\sigma_{t-i/4}(x)-j(\sigma_{t-i/4}(x^*)))\,\xi_0=\Delta^{1/4}\sigma_t(x)\xi_0-J\Delta^{1/4}\sigma_t(x)^*\Delta^{-1/4}\xi_0$$
$$=\Delta^{1/4}\sigma_t(x)\xi_0-\Delta^{1/4}\sigma_t(x)\xi_0=0.$$

Replacing x by x^* in the above, we get

$$(\sigma_{t-i/4}(x^*)-j(\sigma_{t-i/4}(x)))\,\xi_0=0.$$

Thus (a) follows from (2.2) and the above facts.

(b) A direct estimate shows that

$$\|(\sigma_{t-i/4}(x)-j(\sigma_{t-i/4}(x^*)))J\xi\|^2 = \|-J(\sigma_{t-i/4}(x^*)-j(\sigma_{t-i/4}(x)))\xi\|^2$$
$$= \|(\sigma_{t-i/4}(x^*)-j(\sigma_{t-i/4}(x)))\xi\|^2,$$

which implies $\mathcal{E}^{(1)}[J\xi]=\mathcal{E}^{(2)}[\xi]$. The method used in the above also implies that $\mathcal{E}^{(2)}[J\xi]=\mathcal{E}^{(1)}[\xi]$.

(c) By the expression of $\mathcal{E}(\eta,\xi)$ in (2.2), $\mathcal{E}(\xi_+,\xi_-)$ can be written as

$$\mathcal{E}(\xi_+,\xi_-)=\mathcal{E}^{(1)}(\xi_+,\xi_-)+\mathcal{E}^{(2)}(\xi_+,\xi_-)=(\mathrm{I}^{(1)}+\mathrm{II}^{(1)})+(\mathrm{I}^{(2)}+\mathrm{II}^{(2)}), \tag{2.4}$$

where

$$\mathrm{I}^{(1)}=\int(\langle\sigma_{t-i/4}(x)\xi_+,\sigma_{t-i/4}(x)\xi_-\rangle+\langle\sigma_{t-i/4}(x^*)\xi_-,\sigma_{t-i/4}(x^*)\xi_+\rangle)f(t)\,dt, \tag{2.5}$$

$$\mathrm{II}^{(1)}=-\int(\langle\sigma_{t-i/4}(x)\xi_+,j(\sigma_{t-i/4}(x^*))\xi_-\rangle+\langle j(\sigma_{t-i/4}(x^*))\xi_+,\sigma_{t-i/4}(x)\xi_-\rangle)f(t)\,dt$$

and $\mathrm{I}^{(2)}$ and $\mathrm{II}^{(2)}$ are obtained from $\mathrm{I}^{(1)}$ and $\mathrm{II}^{(1)}$, respectively, replacing x by x^* in the above.

As a consequence of Theorem 4(7) of Ref. 25, $\mathcal{M}\xi_+\perp\mathcal{M}\xi_-$, which implies $\mathrm{I}^{(1)}=0$ and $\mathrm{I}^{(2)}=0$. See also the proof of Proposition 5.3 (ii) of Ref. 11. Next, we first consider $\mathrm{II}^{(1)}$. It can be checked that $\sigma_{t-is}(x)^*=\sigma_{t+is}(x^*)$, for any $x\in\mathcal{M}_{\mathrm{an}}$ and $s\in\mathbb{R}$, and so

$$\langle\sigma_{t-i/4}(x)\xi_+,j(\sigma_{t-i/4}(x^*))\xi_-\rangle=\langle\xi_+,\sigma_{t+i/4}(x^*)j(\sigma_{t+i/4}(x)^*)\xi_-\rangle \tag{2.6}$$

and

$$\langle j(\sigma_{t-i/4}(x^*))\xi_+,\sigma_{t-i/4}(x)\xi_-\rangle=\langle\xi_+,\sigma_{t-i/4}(x)j(\sigma_{t-i/4}(x^*)^*)\xi_-\rangle. \tag{2.7}$$

It follows from (2.5)–(2.7) that

$$\mathrm{II}^{(1)}=-\int\langle\xi_+,\sigma_{t+i/4}(x^*)j(\sigma_{t+i/4}(x)^*)\xi_-\rangle f(t)dt$$
$$-\int\langle\xi_+,\sigma_{t-i/4}(x)j(\sigma_{t-i/4}(x^*)^*)\xi_-\rangle f(t)dt.$$

Notice that the map $A\mapsto j(A^*)$ from $\mathcal{M}$ to $\mathcal{M}'$ is linear. It can be shown that for any $x\in\mathcal{M}_{\mathrm{an}}$ and $\xi\in\mathcal{H}$, the map

$$z\mapsto j(\sigma_z(x)^*)\xi$$

is analytic on a domain containing the strip $I_{1/2}$. In fact, the analyticity follows from the facts that $\langle\eta,j(\sigma_z(x)^*)\xi\rangle=P(\sigma_z(x)^*J\xi,J\eta\rangle=\langle J\xi,\sigma_z(x)J\eta\rangle$ for any $\eta,\xi\in\mathcal{H}$, and that weak analyticity implies strong analyticity (see Theorem VI.4 of Ref. 26).

Using the Cauchy integral theorem, the assumption in the theorem, the property (c) in the Definition 2.1 and $\sigma_t(x)^*=\sigma_t(x^*)$, we obtain that

$$\mathrm{II}^{(1)}=-\int\langle\xi_+,\sigma_t(x)^*j(\sigma_t(x)^*)\xi_-\rangle f(t-i/4)\,dt-\int\langle\xi_+,\sigma_t(x)j(\sigma_t(x))\xi_-\rangle f(t+i/4)\,dt.$$

Replacing x and x^* in the above, we obtain the expression of $\mathrm{II}^{(2)}$. Thus we get

$$\mathrm{II}=-\int\langle\xi_+,[\sigma_t(x)j(\sigma_t(x))+\sigma_t(x)^*j(\sigma_t(x)^*)]\xi_-\rangle\cdot(f(t-i/4)+f(t+i/4))\,dt.$$

Since $\sigma_t(x)j(\sigma_t(x))\xi_- \in \mathcal{P}$, $\langle \xi_+, [\sigma_t(x)j(\sigma_t(x))+\sigma_t(x)^*j(\sigma_t(x)^*)]\xi_- \rangle \geqslant 0$ for $t \in \mathbb{R}$. By the property (b) in the Definition 2.1, we conclude that II$\leqslant 0$. This proved the part (c) of the theorem.

Clearly $\mathcal{E}[\cdot] \geqslant 0$. Note that $\mathcal{E}(\xi_0, \xi)=0$, $\forall \xi \in \mathcal{H}$. By Theorem 2.1 (b)–(c), Proposition 4.5 (b) of Ref. 11 and Proposition 4.10 (ii) of Ref. 11, $(\mathcal{E}, \mathcal{H})$ is a Dirichlet form. □

III. DIRICHLET FORMS ON CCR ALGEBRAS WITH RESPECT TO QUASI-FREE STATES: PRELIMINARIES AND MAIN RESULTS

Let $\mathfrak{h}_0$ be a complex separable pre-Hilbert space. Denote by $\mathfrak{h}$ the completion of $\mathfrak{h}_0$. The inner product $(\cdot,\cdot)$ on $\mathfrak{h}$ is conjugate linear in the first and linear in the second variable. Let $\mathcal{A}(\mathfrak{h}_0)$ be the C^*-algebra generated by the Weyl operators $W(f)$, $f \in \mathfrak{h}_0$, satisfying

$$W(-f)=W(f)^*,$$

$$W(f)W(g)=e^{-(i/2)\,\mathrm{Im}(f,g)}W(f+g), \quad \forall f,g \in \mathfrak{h}_0. \tag{3.1}$$

For the abstract properties of $\mathcal{A}(\mathfrak{h}_0)$, see Theorem 5.2.8 of Ref. 2.

Next, we describe quasi-free states on $\mathcal{A}(\mathfrak{h}_0)$. Let A be a bounded and non-negative operator on $\mathfrak{h}$. Recall that $\varphi \in \mathfrak{h}$ is an analytic vector for an operator B on $\mathfrak{h}$ if $\varphi \in D(B^n)$, $n \in \mathbb{N}$, and if

$$\sum_{n=0}^{\infty} \frac{\|B^n\varphi\|}{n!}t^n < \infty,$$

for some $t>0$. In the rest of this paper, we assume that A satisfies the following properties.

Assumption 3.1: *(a) There exists* $\alpha \in (0,1)$ *such that*

$$0 < A \leqslant \alpha \mathbf{1} < \mathbf{1}.$$

(b) The inverse A^{-1} *of* A *exists as a (unbounded) self-adjoint and positive operator on* $\mathfrak{h}$.

(c) For any $z \in \mathbb{C}$, A^z *leaves* $\mathfrak{h}_0$ *invariant, i.e.,* $A^z\mathfrak{h}_0 \subset \mathfrak{h}_0$. *Moreover,* $z \mapsto A^z\varphi$ *is entire analytic for any* $\varphi \in \mathfrak{h}_0$.

(d) Any $\varphi \in \mathfrak{h}_0$ *is an analytic vector for* $A^{-1/2}$.

We remark that a dense submanifold $\mathfrak{h}_0$ of $\mathfrak{h}$ satisfying the assumption exists by the spectral theorem.

Example 3.1 (ideal Bose gases): Let $\mathfrak{h}$ *be* $L^2(\mathbb{R}^d, dx)$ *and* Δ *the Laplacian operator on* $L^2(\mathbb{R}^d, dx)$. *Let* A *be given by*

$$A=\exp\{-\beta(-\tfrac{1}{2}\Delta+\mu\mathbf{1})\},$$

where $\beta>0$ *and* $\mu>0$. *For* $f \in L^2(\mathbb{R}^d, dx)$, *denote by* $\hat{f}$ *the Fourier transform of* f. *Choose* $\mathfrak{h}_0 = \{f \in L^2(\mathbb{R}^d, dx) : \hat{f} \in C_c(\mathbb{R}^d)\}$. *Clearly Assumption 3.1 satisfied with* $\alpha = \exp(-\beta\mu)$.

For given $A \in \mathcal{L}(\mathfrak{h})$ satisfying Assumption 3.1, the gauge invariant quasi-free state ω on $\mathcal{A}(\mathfrak{h}_0)$ is defined by

$$\omega(W(f))=\exp\{-(f, \tfrac{1}{4}(\mathbf{1}+A)(\mathbf{1}-A)^{-1}f)\}, \quad f \in \mathfrak{h}_0. \tag{3.2}$$

Let $(\mathcal{H}_\omega, \pi_\omega, \Omega_\omega)$ be the *GNS* representation[2] of $(\mathcal{A}(\mathfrak{h}_0), \omega)$, and let $\mathcal{M}=\pi_\omega(\mathcal{A}(\mathfrak{h}_0))''$. Notice that the representation $(\mathcal{H}_\omega, \pi_\omega, \Omega_\omega)$ of the CCR algebra $\mathcal{A}(\mathfrak{h}_0)$ is regular[2] in the sense that the unitary groups $t \in \mathbb{R} \mapsto \pi_\omega(W(tf))$ are strongly continuous for all $f \in \mathfrak{h}_0$. We use the notation $\Phi_\omega(f)$ to denote the infinitesimal generator of the unitary group $\pi_\omega(W(tf))$:

$$\pi_\omega(W(tf))=\exp(it\Phi_\omega(f)). \tag{3.3}$$

Notice that, since ω is an entire analytic state[2] by (3.2) and Assumption 3.1, the cyclic vector Ω_ω is an entire analytic vector for all $\Phi_\omega(f)$, $f\in\mathfrak{h}_0$. The annihilation and creation operators defined for each $f\in\mathfrak{h}_0$ by

$$D(a_\omega(f))=D(\Phi_\omega(f))\cap D(\Phi_\omega(if))=D(a_\omega^*(f))$$

and

$$\begin{aligned} a_\omega(f)&:=2^{-1/2}(\Phi_\omega(f)+i\Phi_\omega(if)),\\ a_\omega^*(f)&:=2^{-1/2}(\Phi_\omega(f)-i\Phi_\omega(if)), \end{aligned} \tag{3.4}$$

are densely defined, closed and $a_\omega(f)^*=a_\omega^*(f)$, and satisfy the canonical commutation relations (CCRs): for $\forall f,\ g\in\mathfrak{h}_0$,

$$\begin{aligned} [a_\omega(f),\ a_\omega(g)]&=0,\\ [a_\omega(f),\ a_\omega^*(g)]&=(f,g)\mathbf{1}. \end{aligned} \tag{3.5}$$

See Sec. 5.2.3 of Ref. 2 for the details.

In the rest of this paper, we suppress ω and π_ω from the notations. Thus $\mathcal{H}=\mathcal{H}_\omega$, $W(f)=\pi_\omega(W(f))$, $\Phi(f)=\Phi_\omega(f)$, $a(f)=a_\omega(f)$ and $a^*(f)=a_\omega^*(f)$ for any $f\in\mathfrak{h}_0$. We also use the notation $\xi_0=\Omega_\omega$. Let $\sigma_t:\mathcal{M}\to\mathcal{M}$ be the group of automorphisms on $\mathcal{M}$ defined by

$$\sigma_t(W(f))=W(A^{it}f),\quad f\in\mathfrak{h}_0.$$

It can be checked that the state ω defined by (3.2) is a σ-KMS state.[2] Thus σ_t, $t\in\mathbb{R}$, is the modular automorphism by Theorem 5.3.10 of Ref. 2. Let Δ and J be the modular operator and modular conjugation, respectively. Then $(\mathcal{M},\ \mathcal{H},\ \mathcal{P},\ J)$ is the natural standard form associated to $(\mathcal{M},\ \xi_0)$.

Next, we introduce several dense manifolds of $\mathcal{H}$. For any $B\in\mathcal{M}$, define

$$B_n=\left(\frac{n}{\pi}\right)^{1/2}\int\sigma_t(B)e^{-nt^2}dt,\quad n\in\mathbb{N}. \tag{3.6}$$

Then B_n is an entire analytic element for σ_t, $\|B_n\|\leqslant\|B\|$ for all $n\in\mathbb{N}$ and $B_n\to B$ strongly. See the proof of Proposition 2.5.22 of Ref. 2. In the rest of this paper, we write that $W_n(f):=W(f)_n$, $f\in\mathfrak{h}_0$, where $W(f)_n$ is defined as in (3.6) with $B=W(f)$. Put

$$\begin{aligned} \mathcal{M}_0&:=\text{the algebra generated by}\quad B_n,\quad B\in\mathcal{M},n\in\mathbb{N};\\ \mathcal{W}_0&:=\text{the algebra generated by}\quad W_n(f),\quad f\in\mathfrak{h}_0,n\in\mathbb{N};\\ \mathcal{W}&:=\text{the algebra generated by}\quad W(f),\quad f\in\mathfrak{h}_0. \end{aligned} \tag{3.7}$$

Denote by $\mathcal{H}_{\text{fin}}$ the subset of finite linear combinations of the vectors of the following type:

$$\psi_n=\left[\prod_{j=1}^{n}\Phi(f_j)\right]\xi_0,\quad \text{for } f_j\in\mathfrak{h}_0,\ j=1,\ldots,n,\ n\in\mathbb{N}.$$

Clearly $\mathcal{M}_0\xi_0$, $\mathcal{W}_0\xi_0$, $\mathcal{W}\xi_0$ and $\mathcal{H}_{\text{fin}}$ are dense in $\mathcal{H}$ (See Lemma 4.1).

We denote by $a^\#(f)$ either $a(f)$ or $a^*(f)$, for any $f\in\mathfrak{h}_0$. Notice that $a^\#(f)$ and $j(a^\#(f))$, $f\in\mathfrak{h}_0$, are affiliated with $\mathcal{M}$ and $\mathcal{M}'$, respectively. For any $f\in\mathfrak{h}_0$ and $z\in\mathbb{C}$, we write

$$\sigma_z(a(f)):=a(A^{i\bar{z}}f), \tag{3.8}$$

$$\sigma_z(a^*(f)) := a^*(A^{iz}f).$$

In fact, one may be able to show that for any $f \in \mathfrak{h}_0$ and $\xi \in \mathcal{M}_0\xi_0$ the function $t \mapsto \sigma_t(a^\#(f))\xi$ has an analytic extension on $\mathbb{C}$, which is denoted by $\sigma_z(a^\#(f))\xi$, and that $\sigma_z(a^\#(f))$ is equal to that on the right hand side of (3.8) on $\mathcal{M}_0\xi_0$. See the proof of Lemma 4.3.

We are ready to describe Dirichlet forms. An admissible function f is said to be *normalized* if $\int f(t)dt = 1$. For given normalized admissible function f and a complete orthonormal system-(CONS) $\{g_n\}_{n=1}^{\infty} \subset \mathfrak{h}_0$ of $\mathfrak{h}$, define a sesquilinear form $\mathcal{E}: D(\mathcal{E}) \times D(\mathcal{E}) \to \mathbb{C}$ as follows:

$$\begin{aligned} &D(\mathcal{E}) = \mathcal{W}_0\xi_0 \ (\text{or } \mathcal{W}\xi_0, \mathcal{M}_0\xi_0), \\ &\mathcal{E}(\eta, \xi) = \sum_{n=1}^{\infty} \mathcal{E}^{(n)}(\eta, \xi), \quad \eta, \xi \in D(\mathcal{E}), \end{aligned} \tag{3.9}$$

where for each $n \in \mathbb{N}$, $\eta, \xi \in D(\mathcal{E}^{(n)}) = \mathcal{W}_0\xi_0$ (or $\mathcal{W}\xi_0, \mathcal{M}_0\xi_0$):

$$\begin{aligned} \mathcal{E}^{(n)}(\eta, \xi) = &\int \langle (\sigma_{t-i/4}(a(g_n)) - j(\sigma_{t-i/4}(a^*(g_n))))\eta, \\ &(\sigma_{t-i/4}(a(g_n)) - j(\sigma_{t-i/4}(a^*(g_n))))\xi \rangle f(t)\, dt \\ &+ \int \langle (\sigma_{t-i/4}(a^*(g_n)) - j(\sigma_{t-i/4}(a(g_n))))\eta, \\ &(\sigma_{t-i/4}(a^*(g_n)) - j(\sigma_{t-i/4}(a(g_n))))\xi \rangle f(t)\, dt. \end{aligned} \tag{3.10}$$

We also define the associated quadratic forms by

$$\mathcal{E}^{(n)}[\xi] = \mathcal{E}^{(n)}(\xi, \xi), \quad \xi \in D(\mathcal{E}^{(n)}), \ n \in \mathbb{N};$$

$$\mathcal{E}[\xi] = \sum_{n=1}^{\infty} \mathcal{E}^{(n)}[\xi], \quad \xi \in D(\mathcal{E}).$$

We remark that the expression $\mathcal{E}^{(n)}(\eta, \xi)$ in (3.10) can be obtained from $\mathcal{E}(\eta, \xi)$ in (2.2) by replacing x by $a(g_n)$.

We state the main results. It turns out that the form defined in (3.9) and (3.10) is independent of the normalized admissible function f and the CONS $\{g_n\} \subset \mathfrak{h}_0$ we have chosen.

Proposition 3.1: Let $D(\mathcal{E})$ be either $\mathcal{W}_0\xi_0$ or else $\mathcal{W}\xi_0$ and let $(\mathcal{E}, D(\mathcal{E}))$ be defined as in (3.9) and (3.10). The form $(\mathcal{E}, D(\mathcal{E}))$ is closable. Moreover, $(\mathcal{E}, D(\mathcal{E}))$ is independent of the normalized admissible function f and the CONS $\{g_n\} \subset \mathfrak{h}_0$ we have chosen.

Proposition 3.2: For each $n \in \mathbb{N}$, $(\mathcal{E}^{(n)}, \mathcal{M}_0\xi_0)$ is closable. The closure $(\overline{\mathcal{E}^{(n)}}, D(\overline{\mathcal{E}^{(n)}}))$ is a Dirichlet form.

Theorem 3.1: *Let us consider the following form:*

$$D(\overline{\mathcal{E}}) = \left\{ \xi \in \bigcap_{n=1}^{\infty} D(\overline{\mathcal{E}^{(n)}}) : \sum_{n=1}^{\infty} \overline{\mathcal{E}^{(n)}}[\xi] < \infty \right\},$$

$$\overline{\mathcal{E}}[\xi] = \sum_{n=1}^{\infty} \overline{\mathcal{E}^{(n)}}[\xi],$$

where for each $n \in \mathbb{N}$, $(\overline{\mathcal{E}^{(n)}}, D(\overline{\mathcal{E}^{(n)}}))$ is the Dirichlet form obtained in Proposition 3.2. Then $(\overline{\mathcal{E}}, D(\overline{\mathcal{E}}))$ is a densely defined Dirichlet form.

Theorem 3.2: *Let $\{T_t\}$ be the symmetric Markovian semigroup associated to the Dirichlet form $(\overline{\mathcal{E}}, D(\overline{\mathcal{E}}))$, and let H be the Dirichlet operator, i.e., $T_t = e^{-tH}$, $t \geq 0$. Then the following results hold:*

(a) H is essentially self-adjoint on $\mathcal{H}_{\text{fin}}$.
(b) H is independent of the normalized admissible function f and the CONS $\{g_n\} \subset \mathfrak{h}_0$ we have chosen.
(c) The zero is a simple eigenvalue of H with eigenvector ξ_0. Moreover $(0, \alpha^{-1/2} - \alpha^{1/2}) \cap \sigma(H) = \varnothing$. Thus $\{T_t\}$ is ergodic in the sense of Cipriani.[27] See Remark 3.2.

By the spectral theorem, Theorem 3.2 (c) implies that for any $\xi \in \mathcal{H}$ and $t \geq 0$,

$$\|T_t \xi - \langle \xi_0, \xi \rangle \xi_0\|_{\mathcal{H}} \leq e^{-mt} \|\xi - \langle \xi_0, \xi \rangle \xi_0\|_{\mathcal{H}}, \tag{3.11}$$

where $m = \alpha^{-1/2} - \alpha^{1/2}$. Thus $\{T_t\}_{t \geq 0}$ converges to the equilibrium exponentially fast. Before closing this section, we would like to make the following remarks.

Remark 3.1: As a consquence of Theorem 2.12 of Ref. 11 and Theorem 3.1 in the above, the Markovian semigroup extends to a weakly continuous Markovian semi-group S_t on $\mathcal{M} = (\pi(\mathcal{A}(\mathfrak{h}_0)))''$. See Remark 2.1.

Remark 3.2: Theorem 3.2 (c) implies that the vector ξ_0 is a simple, strictly positive ground state for the generator H. In view of Ref. 27, T_t satisfies the indecomposability and the ergodicity (for each positive ξ, η, there exists $t > 0$ such that $\langle \xi, T_t \eta \rangle > 0$). See Theorem 4.3 of Ref. 27.

Remark 3.3: The main results in this paper can be generalized in several ways. For instance, let B be the operator on $\mathfrak{h}$ defined in (1.4). If one replaces g_n by $B^{\lambda} g_n$, $n \in \mathbb{N}$, for some $\lambda \in [-\frac{1}{2}, \infty)$ in the definition of $\mathcal{E}(\eta, \xi)$ in (3.9) and (3.10), and modify Assumption 3.1 (d) appropriately, then all of the results in this section still hold with a modified spectral gap in Theorem 3.2 (c), i.e., $(0, (\alpha^{-1/2} - \alpha^{1/2})^{1+2\lambda}) \cap \sigma(H) = \varnothing$.

IV. MARKOVIANITY OF FORMS: PROOFS OF PROPOSITION 3.1–THEOREM 3.1

In this section, we produce the proofs of Proposition 3.1, Proposition 3.2 and Theorem 3.1. The most difficult part is the proof of Proposition 3.2 which states the Dirichlet property of each component $\mathcal{E}^{(n)}$, $n \in \mathbb{N}$, of $\mathcal{E}$ in (3.10). In Theorem 2.1, we established the Dirichlet property for any σ_t-analytic element $x \in \mathcal{M}$. However $a(g_n)$ in the definition of $\mathcal{E}^{(n)}$ in (3.10) is an unbounded operator affiliated with $\mathcal{M}$ for any $g_n \in \mathfrak{h}_0$. Thus we have to employ several limiting processes which make the paper lengthy.

Recall the definitions of $\mathcal{W}$, $\mathcal{W}_0$, and $\mathcal{M}_0$ in (3.7) and $\mathcal{H}_{\text{fin}}$ in the below of (3.7). In the rest of this paper, we denote by $a^{\#}(f)$ either $a(f)$ or $a^*(f)$, $f \in \mathfrak{h}_0$. We first state elementary facts.

Lemma 4.1: (a) $\mathcal{W}\xi_0$, $\mathcal{W}_0\xi_0$, $\mathcal{M}_0\xi_0$ and $\mathcal{H}_{\text{fin}}$ are dense in $\mathcal{H}$.

(b) The inclusions

$$\mathcal{W}\xi_0 \subset D(a^{\#}(f)), \quad \mathcal{W}_0\xi_0 \subset D(a^{\#}(f)) \text{ and } \quad \mathcal{H}_{\text{fin}} \subset D(a^{\#}(f))$$

hold for any $f \in \mathfrak{h}_0$.

(c) The inclusion

$$\mathcal{M}_0\xi_0 \subset D(a^{\#}(f))$$

holds for any $f \in \mathfrak{h}_0$. Moreover the relation

$$a^{\#}(f) B \xi_0 = j(\sigma_{-i/2}(B^*)) a^{\#}(f) \xi_0$$

holds for any $f \in \mathfrak{h}_0$ and $B \in \mathcal{M}_0$.

Proof: (a) Since $\mathcal{W}$ is norm-dense in $\pi_\omega(\mathcal{A}(\mathfrak{h}_0))$, $\mathcal{W}\xi_0$ is dense in $\mathcal{H}$. Let $f \in \mathfrak{h}_0$ be given. Using (3.6) and (3.2) it is easy to show that the sequence $\{W_n(f)\xi_0\}$ converges to $W(f)\xi_0$. This implies that $\mathcal{W}_0\xi_0$ is dense in $\mathcal{H}$. Since $\mathcal{W}_0\xi_0 \subset \mathcal{M}_0\xi_0$, $\mathcal{M}_0\xi_0$ is dense in $\mathcal{H}$. It follows from (3.2)

and Assumption 3.1 that ω is an entire analytic state[2] and so the cyclic vector ξ_0 is an entire analytic vector for $\Phi(f)$, $f\in\mathfrak{h}_0$. Also see Sec. 5.2.3 of Ref. 2. Thus the sequence of the vectors,

$$\sum_{k=0}^{n}\frac{i^k}{k!}\Phi(f)^k\xi_0,$$

converge to $W(f)\xi_0$, which implies that $\mathcal{H}_{\text{fin}}$ is dense in $\mathcal{H}$.

(b) For any $f\in\mathfrak{h}_0$ and $n\in\mathbb{N}$, we write that

$$\Phi(f,n)=-in\left(W\left(\frac{1}{n}f\right)-1\right).$$

For given $g\in\mathfrak{h}_0$, consider the sequence $\{\Phi(f,n)W(g)\xi_0\}$. Using (3.1) and (3.2), it can be checked that the sequence is a Cauchy sequence. Thus $W(g)\xi_0\in D(\Phi(f))$ for any $f,g\in\mathfrak{h}_0$, and so $\mathcal{W}\xi_0\subset D(\Phi(f))$, $f\in\mathfrak{h}_0$. By (3.4), this implies that $\mathcal{W}\xi_0\subset D(a^{\#}(f))$, $f\in\mathfrak{h}_0$. The method similar to that used in the above implies that $\mathcal{W}_0\xi_0\subset D(a^{\#}(f))$, $f\in\mathfrak{h}_0$. Since ξ_0 is an entire analytic vector for $\Phi(f)$, $f\in\mathfrak{h}_0$, $\mathcal{H}_{\text{fin}}\subset D(a^{\#}(f))$, $f\in\mathfrak{h}_0$.

(c) Notice that for any $B\in\mathcal{M}_0$, $j(\sigma_{-i/2}(B^*))\xi_0=B\xi_0$. Thus we have that

$$\Phi(f,n)B\xi_0=\Phi(f,n)j(\sigma_{-i/2}(B^*))\xi_0=j(\sigma_{-i/2}(B^*))\Phi(f,n)\xi_0.$$

Since the sequence $\{\Phi(f,n)\xi_0\}$ converges to $\Phi(f)\xi_0$, it follows that $B\xi_0\in D(\Phi(f))$ and the relation

$$\Phi(f)B\xi_0=j(\sigma_{-i/2}(B^*))\Phi(f)\xi_0,$$

hold for any $f\in\mathfrak{h}_0$ and $B\in\mathcal{M}_0$. By (3.4), this proved the part (c). □

We next state a well-known formula (4.2) on quasi-free expectations which we will use repeatedly in the sequel.

Lemma 4.2: Let ω be the quasi-free state given in (3.2). The equalities

$$\omega(\Phi(f)\Phi(g))=\tfrac{1}{2}((f,(\mathbf{1}-A)^{-1}g)+(g,A(\mathbf{1}-A)^{-1}f)) \tag{4.1}$$

and

$$\begin{aligned}&\omega\left(\Phi(f)\left(\prod_{j=1}^{m}\Phi(g_j)\right)\left(\prod_{l=1}^{n}W(h_l)\right)\right)\\&\quad=\sum_{k=1}^{m}\omega(\Phi(f)\Phi(g_k))\omega\left(\left(\prod_{j=1}^{k-1}\Phi(g_j)\right)\left(\prod_{j=k+1}^{m}\Phi(g_j)\right)\left(\prod_{l=1}^{n}W(h_l)\right)\right)\\&\quad+i\sum_{k=1}^{n}\omega(\Phi(f)\Phi(h_k))\omega\left(\left(\prod_{j=1}^{m}\Phi(g_j)\right)\left(\prod_{l=1}^{n}W(h_l)\right)\right)\end{aligned} \tag{4.2}$$

hold for any $f,g,g_j,h_l\in\mathfrak{h}_0$, $j=1,\ldots,m$, $l=1,\ldots,n$.

Proof: The Weyl relations in (3.1) and the quasi-free expectation in (3.2) yield

$$\omega(W(f)W(g))=\exp\left\{-\frac{i}{2}\text{Im}(f,g)-\tfrac{1}{4}(f+g,D(f+g))\right\},$$

for any $f,g\in\mathfrak{h}_0$, where $D=(\mathbf{1}+A)(\mathbf{1}-A)^{-1}$. Replacing f and g by tf and sg, respectively, in the above, and differentiating both sides with respect to $t\in\mathbb{R}$ and $s\in\mathbb{R}$ at the zero, one obtains (4.1).

Again, replacing f by tf in the above relation and differentiating with respect to $t \in \mathbb{R}$ at the zero, one can deduce that

$$\omega(\Phi(f)W(g)) = i\omega(\Phi(f)\Phi(g))\omega(W(g)).$$

Setting $g = g_1 + \cdots + g_p$ in the above and using the relation in (3.1), one obtains

$$\omega\left(\Phi(f)\left(\prod_{j=1}^{p} W(g_j)\right)\right) = i\left(\sum_{k=1}^{p} \omega(\Phi(f)\Phi(g_k))\right)\omega\left(\prod_{j=1}^{p} W(g_j)\right).$$

Choose $p = m + n$. Replacing g_j by $t_j g_j$, $j = 1,\ldots,m$ and g_{m+l} by h_l, $l = 1,\ldots,n$, in the above, and differentiating with respect to t_j, $j = 1,\ldots,m$, at the zero, we obtain (4.2). □

We remark that $f \mapsto a(f)$ is conjugate linear and $f \mapsto a^*(f)$ is linear. See (3.4), (3.1) and (3.2). Recall the definitions of $\sigma_z(a^{\#}(f))$, $f \in \mathfrak{h}_0$, $z \in \mathbb{C}$ in (3.8), i.e.,

$$\sigma_z(a(f)) := a(A^{i\bar{z}}f),$$

$$\sigma_z(a^*(f)) := a^*(A^{iz}f).$$

We also write that

$$\sigma_z(\Phi(f)) := \frac{1}{\sqrt{2}}\{a(A^{i\bar{z}}f) + a^*(A^{iz}f)\}, \tag{4.3}$$

for any $z \in \mathbb{C}$ and $f \in \mathfrak{h}_0$. Using CCRs in (3.5), one can check that for any $f, g \in \mathfrak{h}_0$ the relations

$$\begin{aligned} [a(f),\ W(g)] &= \frac{i}{\sqrt{2}}(f,\ g)W(g), \\ [a^*(f),\ W(g)] &= -\frac{i}{\sqrt{2}}(g,\ f)W(g), \end{aligned} \tag{4.4}$$

hold on $\mathcal{W}\xi_0$ (also on $\mathcal{W}_0\xi_0$). See also the proof of Proposition 5.2.4.(1) of Ref. 2.

For any $f \in \mathfrak{h}_0$ and $m, n \in \mathbb{N}$, we write that

$$\begin{aligned} \Phi(f,n) &:= -in\left\{\exp\left(\frac{i}{n}\Phi(f)\right) - 1\right\}, \\ \Phi_m(f) &:= \sqrt{\frac{m}{\pi}}\int \sigma_t(\Phi(f))e^{-mt^2}\,dt, \\ \Phi_m(f,n) &:= \sqrt{\frac{m}{\pi}}\int \sigma_t(\Phi(f,n))e^{-mt^2}\,dt. \end{aligned} \tag{4.5}$$

Notice that for any $f \in \mathfrak{h}_0$ and $m,\ n \in \mathbb{N}$, $\Phi_m(f,\ n)$ is an entire analytic element for σ_t and $\sigma_z(\Phi_m(f,n))$ is given by

$$\sigma_z(\Phi_m(f,\ n)) = \sqrt{\frac{m}{\pi}}\int \sigma_t(\Phi(f,\ n))e^{-m(t-z)^2}\,dt, \tag{4.6}$$

for any $z \in \mathbb{C}$. See the proof of Proposition 2.5.22 of Ref. 2.

We establish technical lemmas which will be used later.

Lemma 4.3: (a) For any $f\in\mathfrak{h}_0$, $m,n\in\mathbb{N}$ *and* $z=t+is\in\mathbb{C}$, *there exist constants* $M_1(f,\ s)$ *and* $M_2(f,\ s)$ *depending only on* $f\in\mathfrak{h}_0$ *and* $s=\mathrm{Im}\,z$ *such that the bounds*

$$\|\sigma_z(\Phi_m(f,\ n))\xi_0\|\leqslant M_1(f,\ s),$$

$$\|\sigma_z(\Phi(f))\xi_0\|\leqslant M_2(f,\ s),$$

hold (*uniformly on* $m,\ n\in\mathbb{N}$).

(b) For any $f\in\mathfrak{h}_0$, $n\in\mathbb{N}$ *and* $z\in\mathbb{C}$, *the equality*

$$\sigma_z(\Phi(f))\xi_0=\lim_{n\to\infty}\sigma_z(\Phi_n(f,n))\xi_0$$

holds.

The proof of the above lemma will be given in the Appendix.

We define that for any $f\in\mathfrak{h}_0$ and $m,n\in\mathbb{N}$,

$$a_m(f,\ n):=\frac{1}{\sqrt{2}}\{\Phi_m(f,\ n)+i\Phi_m(if,\ n)\},\tag{4.7}$$

$$a_m^*(f,\ n):=\frac{1}{\sqrt{2}}\{-\Phi_m(-f,\ n)+i\Phi_m(-if,\ n)\}.$$

We denote by $a_m^{\#}(f,\ n)$ either $a_m(f,\ n)$ or $a_m^*(f,\ n)$. The following is a consequence of Lemma 4.3.

Corollary 4.1: (a) For any $f\in\mathfrak{h}_0$, $m,\ n\in\mathbb{N}$ *and* $z=t+is\in\mathbb{C}$, *there exist constants* $M_3(f,\ s)$ *and* $M_4(f,\ s)$ *depending only on* $f\in\mathfrak{h}_0$ *and* $s=\mathrm{Im}\,z$ *such that the bounds*

$$\|\sigma_z(a_m^{\#}(f,\ n))\xi_0\|\leqslant M_3(f,\ s),$$

$$\|\sigma_z(a^{\#}(f))\xi_0\|\leqslant M_4(f,\ s),$$

hold (*uniformly on* $m,n\in\mathbb{N}$).

(b) For any $f\in\mathfrak{h}_0$, $n\in\mathbb{N}$ *and* $z\in\mathbb{C}$, *the equality*

$$\sigma_z(a^{\#}(f))\xi_0=\lim_{n\to\infty}\sigma_z(a_n^{\#}(f,\ n))\xi_0$$

holds.

Proof: The corollary follows from Lemma 4.3 and the definition of $a_m^{\#}(f,\ n)$ in (4.7). □

Lemma 4.4: (a) For any $f\in\mathfrak{h}_0$, $m,n\in\mathbb{N}$, $z=t+is\in\mathbb{C}$ *and* $B\in\mathcal{M}_0$, *there exist constants* $M_5(B,\ f,\ s)$ *and* $M_6(B,\ f,\ s)$ *such that the bounds*

$$\|\sigma_z(a_m^{\#}(f,n))B\xi_0\|\leqslant M_5(B,\ f,\ s),$$

$$\|\sigma_z(a^{\#}(f))B\xi_0\|\leqslant M_6(B,\ f,\ s)$$

hold (*uniformly on* $m,\ n\in\mathbb{N}$).

(b) The equality

$$\sigma_z(a^{\#}(f))B\xi_0=\lim_{n\to\infty}\sigma_z(a_n^{\#}(f,\ n))B\xi_0$$

holds for any $f\in\mathfrak{h}_0$, $z\in\mathbb{C}$ *and* $B\in\mathcal{M}_0$.

Proof: (a) As in the proof of Lemma 4.1 (c), one has that for any m, $n\in\mathbb{N}$, $B\in\mathcal{M}_0$ and $z\in\mathbb{C}$,

$$\sigma_z(a_m^{\#}(f,\,n))B\xi_0=j(\sigma_{-i/2}(B^*))\sigma_z(a_m^{\#}(f,\,n))\xi_0. \tag{4.8}$$

Thus the bounds follow from Corollary 4.1 (a), Lemma 4.1 (c) and the above relations.

(b) This follows from Corollary 4.1 (b), (4.8) and Lemma 4.1 (c). □

In order to show the closability of the form $(\mathcal{E}^{(n)},\,\mathcal{M}_0\xi_0)$, $n\in\mathbb{N}$, in Proposition 3.2, we will use the proposition listed below. The proposition is probably well known to the experts.

Proposition 4.1: Let $(\Omega,\,\mu)$ be a probability space, $\mathcal{H}$ a separable Hilbert space and D a dense subset in $\mathcal{H}$. For any $t\in\Omega$, let $A(t)$ be an operator defined on D satisfying the following properties:

(a) $(A(t),\,D)$ is closable for each $t\in\Omega$,
(b) for any $\xi\in D$, $\Omega\ni t\mapsto\|A(t)\xi\|^2$ is an integrable function on Ω.

Then the quadratic form defined by

$$D(\mathcal{E})=D,$$

$$\mathcal{E}[\xi]=\int_\Omega\|A(t)\xi\|^2d\mu(t),\quad \xi\in D,$$

is closable.

Proof: Let $\{\xi_n\}$ be a sequence in D such that $\xi_n\to0$ as $n\to\infty$ and $\mathcal{E}[\xi_n-\xi_m]\to0$ as $n,\,m\to\infty$. One has to show that $\mathcal{E}[\xi_n]\to0$ as $n\to\infty$. Since $\{\xi_n\}$ is a $\mathcal{E}$-Cauchy sequence, one can choose a subsequence $\{\xi_{n_k}\}$ of $\{\xi_n\}$ such that $\mathcal{E}[\xi_{n_{k+1}}-\xi_{n_k}]<1/2^{2k}$ for any $k\in\mathbb{N}$, which implies that

$$\sum_{k=1}^{\infty}\mathcal{E}[\xi_{n_{k+1}}-\xi_{n_k}]^{1/2}<\infty.$$

It follows from the Schwarz inequality and the above bound that

$$\sum_{k=1}^{\infty}\int_\Omega\|A(t)(\xi_{n_{k+1}}-\xi_{n_k})\|\,d\mu(t)<\infty.$$

The monotone convergence theorem and the above bound imply that

$$\sum_{k=1}^{\infty}\|A(t)(\xi_{n_{k+1}}-\xi_{n_k})\|<\infty,\quad \mu-a.e.$$

This implies that $\{A(t)\xi_{n_k}\}$ is a Cauchy sequence $\mu-a.e.$ Since $A(t)$ is closable on D for any $t\in\Omega$, we conclude that

$$A(t)\xi_{n_k}\to0,\quad \text{as } k\to\infty,\ \mu-a.e.$$

Using Fatou's lemma and the above result, we obtain that

$$\mathcal{E}[\xi_n]=\int\underline{\lim}_{k\to\infty}\|A(t)(\xi_n-\xi_{n_k})\|^2\,d\mu(t)\leqslant\underline{\lim}_{k\to\infty}\mathcal{E}[\xi_n-\xi_{n_k}],$$

which implies that $\mathcal{E}[\xi_n]\to0$ as $n\to\infty$. This proved the proposition. □

We write that

$$\delta(a^{\#}(f)) := a^{\#}(f) - j(\sigma_{-i/2}((a^{\#}(f))^*)), \tag{4.9}$$

for $f \in \mathfrak{h}_0$. By Lemma 4.1, $\delta(a^{\#}(f))$ is well defined on $\mathcal{W}\xi_0$ and also on $\mathcal{M}_0\xi_0$ for any $f \in \mathfrak{h}_0$. Notice that for any $B \in \mathcal{M}_0$, $j(\sigma_{-i/2}(B^*))\xi_0 = B\xi_0$. Thus it follows from Lemma 4.1 (b) and Corollary 4.1 (b) that for any $f, h \in \mathfrak{h}_0$,

$$\delta(a^{\#}(f))W(h)\xi_0 = [a^{\#}(f), W(h)]\xi_0. \tag{4.10}$$

Since $(\sigma_{-i/4}(a^{\#}(f)))^* = \sigma_{i/4}((a^{\#}(f))^*)$ by (3.8), we have that

$$\delta(\sigma_{-i/4}(a^{\#}(f))) = \sigma_{-i/4}(a^{\#}(f)) - j(\sigma_{-i/4}((a^{\#}(f))^*)), \tag{4.11}$$

for any $f \in \mathfrak{h}_0$.

We are ready to prove Proposition 3.1, Proposition 3.2 and Theorem 3.1. We first produce the proof of Proposition 3.1.

Proof of Proposition 3.1: Let us first consider $(\mathcal{E}, \mathcal{W}\xi_0)$. Recall the definition of $\mathcal{E}(\eta, \xi)$ in (3.9)–(3.10). Let f be a normalized admissible function and let $\{g_n\} \subset \mathfrak{h}_0$ be a CONS for $\mathfrak{h}$. We first note that by (4.10) and (4.4),

$$\delta(\sigma_{t-i/4}(a(g_n)))W(h)\xi_0 = \delta(a(A^{it-1/4}g_n))W(h)\xi_0 = \frac{i}{\sqrt{2}}(A^{it-1/4}g_n,\ h)W(h)\xi_0,$$

$$\delta(\sigma_{t-i/4}(a^*(g_n)))W(h)\xi_0 = -\frac{i}{\sqrt{2}}(h,\ A^{it+1/4}g_n)W(h)\xi_0.$$

It follows from (3.9), the above relations, the dominated convergence theorem and the Parserval relations that for $g, h \in \mathfrak{h}_0$,

$$\begin{aligned}
\mathcal{E}(W(g)\xi_0,\ W(h)\xi_0) = &\left\{ \frac{1}{2}\sum_{n=1}^{\infty} \int (A^{-it-1/4}g,\ g_n)(g_n,\ A^{-it-1/4}h) f(t)\, dt \right\} \\
&\times \langle W(g)\xi_0, W(h)\xi_0 \rangle \\
&+ \left\{ \frac{1}{2}\sum_{n=1}^{\infty} \int (A^{-it+1/4}h,\ g_n)(g_n,\ A^{-it+1/4}g) f(t)\, dt \right\} \\
&\times \langle W(g)\xi_0,\ W(h)\xi_0 \rangle \\
= &\frac{1}{2}\{(g,\ A^{-1/2}h) + (h,\ A^{1/2}g)\}\langle W(g)\xi_0, W(h)\xi_0 \rangle.
\end{aligned} \tag{4.12}$$

Here we have used the fact that by the Schwarz inequality and the Bessel inequality,

$$\left| \sum_{n=1}^{m} (A^{-it}h_1,\ g_n)(g_n,\ A^{-it}h_2) \right| \leqslant \|h_1\|\|h_2\|,$$

for any $m \in \mathbb{N}$, $t \in \mathbb{R}$ and $h_1,\ h_2 \in \mathfrak{h}_0$. Thus $\mathcal{E}$ is well defined on $\mathcal{W}\xi_0$ and independent of the normalized admissible function f and the CONS $\{g_n\}$ chosen.

In order to show that the closability of $(\mathcal{E}, \mathcal{W}\xi_0)$, we introduce the operator $(H, \mathcal{W}\xi_0)$ defined by

$$D(H) = \mathcal{W}\xi_0,$$

$$HW(h)\xi_0=\frac{i}{\sqrt{2}}(\delta(a(A^{-1/2}h)))^*W(h)\xi_0-\frac{i}{\sqrt{2}}(\delta(a^*(A^{1/2}h)))^*W(h)\xi_0. \tag{4.13}$$

By (4.9) and Lemma 4.1 (b), H is well-defined on $\mathcal{W}\xi_0$. It follows from (4.10) and (4.4) that for any $g,h\in\mathfrak{h}_0$,

$$\begin{aligned}\langle W(g)\xi_0,HW(h)\xi_0\rangle&=\frac{i}{\sqrt{2}}\langle\delta(a(A^{-1/2}h))W(g)\xi_0,W(h)\xi_0\rangle\\&\quad-\frac{i}{\sqrt{2}}\langle\delta(a^*(A^{1/2}h))W(g)\xi_0,W(h)\xi_0\rangle\\&=\tfrac{1}{2}\{(g,A^{-1/2}h)+(h,A^{1/2}g)\}\langle W(g)\xi_0,W(h)\xi_0\rangle.\end{aligned} \tag{4.14}$$

By the method used in the above, we get that for any $g,h\in\mathfrak{h}_0$, $\langle HW(g)\xi_0,W(h)\xi_0\rangle$ is equal to the right hand side of (4.14). Thus H is symmetric on $\mathcal{W}\xi_0$. It follows from (4.12) and (4.14) that

$$\langle\eta,H\xi\rangle=\mathcal{E}(\eta,\xi),$$

for $\eta,\xi\in\mathcal{W}\xi_0$. Since $(H,\mathcal{W}\xi_0)$ is a positive symmetric operator, the form $(\mathcal{E},\mathcal{W}\xi_0)$ is closable (Theorem X.23 of Ref. 26).

Next, we consider $(\mathcal{E},\mathcal{W}_0\xi_0)$. Employing the method similar to that used to derive (4.12), one can check that $(\mathcal{E},\mathcal{W}_0\xi_0)$ is independent of admissible function f and the CONS $\{g_n\}\subset\mathfrak{h}_0$ chosen. To prove the closability, one may introduce the Dirichlet operator $(H,\mathcal{W}_0\xi_0)$ similar to that in (4.13) and then use the argument in the below of (4.13). We leave the details to the reader. □

Remark 4.1: For any CONS $\{g_n\}\subset\mathfrak{h}_0$, the relation

$$\begin{aligned}\mathcal{E}(\eta,\xi)&=\sum_{n=1}^{\infty}\langle\delta(\sigma_{-i/4}(a(g_n)))\eta,\ \delta(\sigma_{-i/4}(a(g_n)))\xi\rangle\\&\quad+\sum_{n=1}^{\infty}\langle\delta(\sigma_{-i/4}(a^*(g_n)))\eta,\ \delta(\sigma_{-i/4}(a^*(g_n)))\xi\rangle\end{aligned} \tag{4.15}$$

holds for any $\eta,\xi\in\mathcal{W}\xi_0$. In fact, the relation follows from the method used to derive (4.12).

In order to show Proposition 3.2, we introduce the following forms: For given normalized admissible function f and $g\in\mathfrak{h}_0$, let $(\tilde{\mathcal{E}},\mathcal{M}_0\xi_0)$ be a sesquilinear form defined by

$$D(\tilde{\mathcal{E}})=\mathcal{M}_0\xi_0,$$

$$\begin{aligned}\tilde{\mathcal{E}}(\eta,\xi)&=\int\langle\delta(\sigma_{t-i/4}(a(g)))\eta,\ \delta(\sigma_{t-i/4}(a(g)))\xi\rangle f(t)dt\\&\quad+\int\langle\delta(\sigma_{t-i/4}(a^*(g)))\eta,\ \delta(\sigma_{t-i/4}(a^*(g)))\xi\rangle f(t)dt,\end{aligned} \tag{4.16}$$

where for any $h\in\mathfrak{h}_0$, $\delta(a^{\#}(h))$ has been defined in (4.9). For any $n\in\mathbb{N}$, let $(\tilde{\mathcal{E}}_n,\mathcal{H})$ be the form given by

$$\begin{aligned}\tilde{\mathcal{E}}_n(\eta,\xi)&=\int\langle\delta(\sigma_{t-i/4}(a_n(g,n)))\eta,\ \delta(\sigma_{t-i/4}(a_n(g,n)))\xi\rangle f(t)dt\\&\quad+\int\langle\delta(\sigma_{t-i/4}(a_n^*(g,n)))\eta,\ \delta(\sigma_{t-i/4}(a_n^*(g,n)))\xi\rangle f(t)dt,\end{aligned} \tag{4.17}$$

where for $n \in \mathbb{N}$ and $g \in \mathfrak{h}_0$, $a_n^{\#}(g, n)$ has been defined in (4.7). Since $a_n^{\#}(g, n) \in \mathcal{M}_0$, it follows from Theorem 2.1 that $(\tilde{\mathcal{E}}_n, \mathcal{H})$ is a Dirichlet form for each $n \in \mathbb{N}$.

Lemma 4.5: For any $\eta, \xi \in \mathcal{M}_0\xi_0$,

$$\tilde{\mathcal{E}}(\eta, \xi) = \lim_{n\to\infty} \tilde{\mathcal{E}}_n(\eta, \xi).$$

Proof: The lemma follows from Lemma 4.4 and the dominated convergence theorem. □

Proposition 4.2: The form $(\tilde{\mathcal{E}}, \mathcal{M}_0\xi_0)$ *defined in (4.16) is closable. Denote by* $(\tilde{\mathcal{E}}, D(\tilde{\mathcal{E}}))$ *the closure of* $(\tilde{\mathcal{E}}, \mathcal{M}_0\xi_0)$ *and by* $\tilde{H}$ *the positive self-adjoint operator associated to* $(\tilde{\mathcal{E}}, D(\tilde{\mathcal{E}}))$. *Then the following properties hold:*

(a) $\xi_0 \in D(\tilde{H})$ *and* $\tilde{H}\xi_0 = 0$,

(b) $\tilde{\mathcal{E}}$ *is J-real,*

(c) $\tilde{\mathcal{E}}(\xi_+, \xi_-) \leqslant 0$ *for any* $\xi \in D(\tilde{\mathcal{E}})^J$.

Furthermore the form $(\tilde{\mathcal{E}}, D(\tilde{\mathcal{E}}))$ *is a Dirichlet form.*

Proof of Proposition 3.2: By setting $g = g_n$, $n \in \mathbb{N}$, the proposition follows from Proposition 4.2. □

Proof of Proposition 4.2: The closability of $(\tilde{\mathcal{E}}, \mathcal{M}_0\xi_0)$ follows from Lemma 4.1 (c), Lemma 4.4 and Proposition 4.1.

(a) It follows from (4.16) that for $m, n \in \mathbb{N}$ and $h_1, h_2 \in \mathfrak{h}_0$,

$$\tilde{\mathcal{E}}(W_m(h_1)\xi_0, W_n(h_2)\xi_0) = \langle W_m(h_1)\xi_0, \tilde{H}W_n(h_2)\xi_0\rangle,$$

where

$$\tilde{H} = \int (\delta(\sigma_{t-i/4}(a(g))))^* \delta(\sigma_{t-i/4}(a(g)))\, f(t)\, dt + \int (\delta(\sigma_{t-i/4}(a^*(g))))^* \delta(\sigma_{t-i/4}(a^*(g)))\, f(t)\, dt.$$

Using (4.10) and Lemma 4.4 (a), it is not hard to show that $\tilde{H}W_n(h_2)\xi_0$ is defined as a vector in $\mathcal{H}$. Since $\mathcal{W}_0\xi_0 \subset \mathcal{M}_0\xi_0$, we conclude that $\mathcal{W}_0\xi_0 \subset D(\tilde{H})$. By (4.10), we get that

$$\delta(\sigma_{t-i/4}(a^{\#}(g)))\xi_0 = 0,$$

for any $t \in \mathbb{R}$ and $g \in \mathfrak{h}_0$, and so $\tilde{H}\xi_0 = 0$.

(b) This follows from the method in the proof of the property (b) in Theorem 2.1 and the fact that $\mathcal{M}_0\xi_0$ is a form core.

(c) The proof of the property (c) is the hardest part in the proof. We have to employ several limiting processes. We assert that

$$\xi \in \mathcal{M}_0\xi_0 \cap \mathcal{H}^J \Rightarrow \xi_+, \xi_- \in D(\tilde{\mathcal{E}}) \quad \text{and} \quad \tilde{\mathcal{E}}[\xi_\pm] = \lim_{m\to\infty} \tilde{\mathcal{E}}_m[\xi_\pm]. \tag{4.18}$$

Let us prove our assertion. Let s_+ and s_- be the projections onto the closure of $\mathcal{M}'\xi_+$ and $\mathcal{M}'\xi_-$, where $s_+, s_- \in \mathcal{M}$. See Ref. 25. For $\xi = A\xi_0, A \in \mathcal{M}_0$, we write that

$$\xi_{n,\pm} = (s_\pm A)_n \xi_0,$$

where

$$(s_\pm A)_n = \sqrt{\frac{n}{\pi}} \int \sigma_t(s_\pm A) e^{-nt^2}\, dt.$$

Notice that $\|(s_\pm A)_n\| \leq \|A\|$, $n \in \mathbb{N}$, and that for any $\eta \in \mathcal{H}$, $(s_\pm A)_n \eta \to s_\pm A \eta$ as $n \to \infty$. See, i.e., the proof of Proposition 2.5.22 of Ref. 2. Since $\Delta^{it}\mathcal{P} \subset \mathcal{P}$ for $t \in \mathbb{R}$, $\xi_{n,\pm} = (s_\pm A)_n \xi_0 = j((s_\pm A)_n)\xi_0$, and so

$$\sigma_z(a^\#(g))\xi_{n,\pm} = j((s_\pm A)_n)\sigma_z(a^\#(g))\xi_0,$$

for any $z \in \mathbb{C}$. Since $\sigma_z(a^\#(g))$ is a closed operator for any $g \in \mathfrak{h}_0$, $z \in \mathbb{C}$, we take n to infinity to conclude that $\xi_\pm \in D(\sigma_z(a^\#(g)))$, and

$$\sigma_z(a^\#(g))\xi_\pm = j(s_\pm A)\sigma_z(a^\#(g))\xi_0,$$

and so

$$\delta(\sigma_z(a^\#(g)))\xi_\pm = j(s_\pm A)\sigma_z(a^\#(g))\xi_0 - (s_\pm A)j(\sigma_{-i/2}(\sigma_z(a^\#(g)))^*)\xi_0. \tag{4.19}$$

Thus, it follows from Corollary 4.1 (a) and the dominated convergence theorem that $\tilde{\mathcal{E}}[\xi_{m,\pm} - \xi_{n,\pm}] \to 0$ as $m,n \to \infty$. Since $(\tilde{\mathcal{E}}, D(\tilde{\mathcal{E}}))$ is closed, $\xi_\pm \in D(\tilde{\mathcal{E}})$. Next we will prove that $\tilde{\mathcal{E}}_n[\xi_\pm]$ converges to $\tilde{\mathcal{E}}[\xi_\pm]$ as n tends to infinity. Using (4.19), the analogous relation for $\sigma_z(a_n^\#(g,n))$, and Corollary 4.1 (a), we conclude that for $\xi = A\xi_0$, there exists a constant $M > 0$ such that the bounds

$$\|\delta(\sigma_{t-i/4}(a_n^\#(g,n)))\xi_\pm\| + \|\delta(\sigma_{t-i/4}(a^\#(g)))\xi_\pm\| \leq M$$

hold uniformly in $n \in \mathbb{N}$ and $t \in \mathbb{R}$. Using the above bounds, (4.19) and Corollary 4.1, we get that

$$\begin{aligned}|\tilde{\mathcal{E}}_n[\xi_\pm] - \tilde{\mathcal{E}}[\xi_\pm]| &\leq 2M \int \|\{\delta(\sigma_{t-i/4}(a_n^\#(g,\, n))) - \delta(\sigma_{t-i/4}(a^\#(g)))\}\xi_\pm\| f(t)dt \\ &\leq M' \int \|\sigma_{t-i/4}(a_n^\#(g,\, n))\xi_0 - \sigma_{t-i/4}(a^\#(g))\xi_0\| f(t)dt \to 0, \text{ as } n \to \infty.\end{aligned}$$

Here we have used Corollary 4.1 (b) and the dominated convergence theorem to obtain the last conclusion in the above. This completes the proof of our assertion.

We turn to the proof of the property (c). A direct computation shows that

$$\|\xi_\pm - \eta_\pm\| \leq \|\xi - \eta\|, \quad \forall \xi,\, \eta \in \mathcal{H}^J. \tag{4.20}$$

See also the proof of Proposition 1.2 of Ref. 7. Since $|\xi| = \xi_+ + \xi_-$, the assertion (4.18) implies that

$$\xi \in \mathcal{M}_0\xi_0 \cap \mathcal{H}^J \Rightarrow |\xi| \in D(\tilde{\mathcal{E}}) \quad \text{and} \quad \tilde{\mathcal{E}}[|\xi|] = \lim_{n\to\infty} \tilde{\mathcal{E}}_n[|\xi|]. \tag{4.21}$$

Let $\xi \in D(\tilde{\mathcal{E}}) \cap \mathcal{H}^J$ be given. Choose $\{\xi_k\}$ in $\mathcal{M}_0\xi_0 \cap \mathcal{H}^J$ such that $\xi_k \to \xi$ and $\tilde{\mathcal{E}}[\xi_k] \to \tilde{\mathcal{E}}[\xi]$ as $k \to \infty$. By (4.20), $|\xi_k| \to |\xi|$ as $k \to \infty$. Notice that $\tilde{\mathcal{E}}[|\xi|] \leq \tilde{\mathcal{E}}[\xi]$ is equivalent to $\tilde{\mathcal{E}}(\xi_+,\, \xi_-) \leq 0$ and that each $\tilde{\mathcal{E}}_m$, $m \in \mathbb{N}$, satisfies the property (c) by Theorem 2.1. By the lower semi-continuity of $\tilde{\mathcal{E}}$ and (4.21), we obtain that

$$\tilde{\mathcal{E}}[|\xi|] \leq \underline{\lim}_{k\to\infty} \tilde{\mathcal{E}}[|\xi_k|] = \underline{\lim}_{k\to\infty} \left(\lim_{n\to\infty} \tilde{\mathcal{E}}_n[|\xi_k|] \right) \leq \underline{\lim}_{k\to\infty} \left(\lim_{n\to\infty} \tilde{\mathcal{E}}_n[\xi_k] \right) = \underline{\lim}_{k\to\infty} \tilde{\mathcal{E}}[\xi_k] = \tilde{\mathcal{E}}[\xi].$$

Thus $|\xi| \in D(\tilde{\mathcal{E}})$ and $\tilde{\mathcal{E}}[|\xi|] \leq \tilde{\mathcal{E}}[\xi]$. This completes the proof of the property (c).

Since $\tilde{\mathcal{E}}(\xi, \xi_0) = 0$ for any $\xi \in D(\tilde{\mathcal{E}})$, the properties (b) and (c) imply that $\tilde{\mathcal{E}}$ is a Dirichlet form. □

Proof of Theorem 3.1: By Proposition 3.1, $\mathcal{W}_0\xi_0 \subset D(\overline{\mathcal{E}})$. Since each component $\overline{\mathcal{E}_n}$ is a Dirichlet form, it follows from Theorem 5.2 of Ref. 11 that $(\overline{\mathcal{E}}, D(\overline{\mathcal{E}}))$ is a Dirichlet form. □

V. DECOMPOSITION OF QUASI-FREE HILBERT SPACE: ERGODICITY

For given quasi-free state ω, we will decompose the Hilbert space $\mathcal{H}=\mathcal{H}_\omega$ into a direct sum of $\mathcal{H}^{(m,n)}$, $m, n \in \mathbb{N}\cup\{0\}$, where $\mathcal{H}^{(m,n)}$ is the Hilbert space of m quasi-particles and n anti-quasi-particles. We then use the result to show that the symmetric Markovian semigroup is ergodic.

Recall the definition of $\delta(a^{\#}(g))$, $g \in \mathfrak{h}_0$ in (4.9). Denote by B the operator given by

$$B = A^{-1/2} - A^{1/2}. \tag{5.1}$$

It follows from (4.9) that for $g \in \mathfrak{h}_0$,

$$\begin{aligned}\delta(a(B^{-1/2}A^{-1/4}g)) &= a(B^{-1/2}A^{-1/4}g) - j(\sigma_{-i/2}(a^*(B^{-1/2}A^{-1/4}g)))\\ &= a(B^{-1/2}A^{-1/4}g) - j(a^*(B^{-1/2}A^{1/4}g)),\end{aligned} \tag{5.2}$$

$$\begin{aligned}\delta(a^*(B^{-1/2}A^{1/4}g)) &= a^*(B^{-1/2}A^{1/4}g) - j(\sigma_{-i/2}(a(B^{-1/2}A^{1/4}g)))\\ &= a^*(B^{-1/2}A^{1/4}g) - j(a(B^{-1/2}A^{-1/4}g)).\end{aligned}$$

The above operators are well defined on $\mathcal{M}_0\xi_0$ and also on $\mathcal{H}_{\text{fin}}$. Since $(j(a(g)))^* = j(a^*(g))$, etc., a computation shows that

$$\begin{aligned}(\delta(a(B^{-1/2}A^{-1/4}g)))^* &= a^*(B^{-1/2}A^{-1/4}g) - j(a(B^{-1/2}A^{1/4}g))\\ &= a^*(B^{-1/2}A^{-1/4}g) - j(\sigma_{-i/2}(a(B^{-1/2}A^{3/4}g)))\\ &= a^*(B^{1/2}A^{1/4}g) + \delta(a^*(B^{-1/2}A^{3/4}g)).\end{aligned} \tag{5.3}$$

Here we have used the fact that $B^{-\frac{1}{2}}(A^{-\frac{1}{4}} - A^{\frac{3}{4}}) = B^{\frac{1}{2}}A^{\frac{1}{4}}$. Using the method similar to that used in the above, we get that

$$(\delta(a^*(B^{-1/2}A^{1/4}g)))^* = -a(B^{1/2}A^{-1/4}g) + \delta((a(B^{-1/2}A^{-3/4}g)). \tag{5.4}$$

From notational brevity, we write that for $g \in \mathfrak{h}_0$,

$$\begin{aligned}D_1(g) &:= \delta(a(B^{-1/2}A^{-1/4}g)),\\ D_2(g) &:= \delta(a^*(B^{-1/2}A^{1/4}g)).\end{aligned} \tag{5.5}$$

Then it follows from (5.3) and (5.4) that

$$D_1(g)^* = a^*(B^{1/2}A^{1/4}g) + D_2(A^{1/2}g), \tag{5.6}$$

$$D_2(g)^* = -a(B^{1/2}A^{-1/4}g) + D_1(A^{-1/2}g).$$

We first collect some properties of $D_i(g)$ for $g \in \mathfrak{h}_0$ and $i = 1, 2$.

Lemma 5.1: $D_i(g)\xi_0 = 0$ *for any* $g \in \mathfrak{h}_0$ *and* $i = 1, 2$.

Proof: This follows from (5.5) and (4.10). □

Lemma 5.2: As operators defined on $\mathcal{W}\xi_0$ *and* $\mathcal{W}_0\xi_0$, *the following relations hold for any* $g, h \in \mathfrak{h}_0$:

(a) $[D_i(g), {}_j(h)] = 0$, $i = 1, 2$, $j = 1, 2$,
(b) $[D_1(g), a(h)] = 0$,

(c) $[D_2(g),\ a^*(h)]=0$,

(d) $[D_1(g),\ a^*(B^{\frac{1}{2}}A^{\frac{1}{4}}h)]=(g,\ h)\mathbf{1}$,

(e) $[D_2(g),\ a(B^{\frac{1}{2}}A^{-\frac{1}{4}}h)]=-(h,\ g)\mathbf{1}$.

Proof: We first remark that each operator in the commutators in the lemma is defined on $\mathcal{W}\xi_0$ and also $\mathcal{W}_0\xi_0$. (a) This follows from (4.10), (4.4) and the definition of $D_i(g)$, $i=1, 2$, in (5.5). (b) and (c) follow from (5.5) and (4.9). (d) and (e) follow from (5.5), (4.9) and the CCRs in (3.5). □

Proposition 5.1: As operators defined on $\mathcal{W}\xi_0$, $\mathcal{W}\xi_0$ and also on $\mathcal{H}_{\text{fin}}$, the following canonical commutation relations (CCRs) hold for any $g, h\in\mathfrak{h}_0$:

(a) $[D_1(g),\ D_1(h)^*]=(g,\ h)\mathbf{1}$,
$[D_1(g),\ D_1(h)]=0$, $[D_1(g)^*,\ D_1(h)^*]=0$;

(b) $[D_2(g),\ D_2(h)^*]=(h,\ g)\mathbf{1}$,
$[D_2(g),\ D_2(h)]=0$, $[D_2(g)^*,\ D_2(h)^*]=0$;

(c) $[D_1(g),\ D_2(h)]=0$, $[D_1(g),\ D_2(h)^*]=0$,
$[D_1(g)^*,\ D_2(h)]=0$, $[D_1(g)^*,\ D_2(h)^*]=0$.

Proof: The commutation relations on $\mathcal{W}\xi_0$ and $\mathcal{W}_0\xi_0$ in the proposition follow from Lemma 5.2 and (5.6). Thus we need to extend the relations to $\mathcal{H}_{\text{fin}}$. Recall the definition of $\Phi(f,\ n)$, $f\in\mathfrak{h}_0$, $n\in\mathbb{N}$, in (4.5). Using Lemma 4.2 and (3.2), it is not hard to check that for any $g,\ h,\ f_j,\ \in\mathfrak{h}_0,\ n_j\in\mathbb{N},\ j=1,\ldots,m$,

$$\Phi(g)\Phi(h)\left(\prod_{j=1}^{m}\Phi(f_j,n_j)\right)\xi_0\to\Phi(g)\Phi(h)\left(\prod_{j=1}^{m}\Phi(f_j)\right)\xi_0, \tag{5.7}$$

as $n_j\to\infty$, $j=1,\ldots,m$. This implies that the relations in the proposition extend to $\mathcal{H}_{\text{fin}}$. □

We are ready to decompose the Hilbert space $\mathcal{H}=\mathcal{H}_\omega$, called quasi-free Hilbert space. According to Lemma 5.1 and the CCRs in Proposition 5.1, $D_i(g)$ and $D_i(h)^*$, $g,\ h\in\mathfrak{h}_0$, $i=1, 2$, can be thought of as annihilation and creation operators, respectively. We remark that $h\mapsto D_1(h)^*$ is linear, but $g\to D_2(g)^*$ is conjugate linear. With an abuse of terminology, we call $D_1(h)^*$ and $D_2(h)^*$ the creation operators for quasi-particles and anti-quasi-particles, respectively, for $h\in\mathfrak{h}_0$. The following is the decomposition of $\mathcal{H}$.

Theorem 5.1: *The following decomposition holds:*

$$\mathcal{H}=\bigoplus_{m,n=0}^{\infty}\mathcal{H}^{(m,n)},$$

where for each $m,n\in\mathbb{N}\cup\{0\}$, $\mathcal{H}^{(m,n)}$ is the closure of the subspace spanned by the vectors of the form

$$\left(\prod_{j=1}^{m}D_1(g_j)^*\right)\left(\prod_{l=1}^{n}D_2(h_l)^*\right)\xi_0,\ g_j,\ h_l\in\mathfrak{h}_0.$$

In the case in which $m=0$ $(n=0)$, we replace the operator in the first (second) parentheses in the above by the identity.

Proof: It follows from (5.6) that any $\Phi(g), g\in\mathfrak{h}_0$, can be written as the sum of four $D_i(h)^\#$, $h\in\mathfrak{h}_0$, $i=1, 2$. Thus any $(\Pi_{l=1}^{m}\Phi(g_l))\xi_0$, $g_l\in\mathfrak{h}_0$, $l=1,\ldots,m$, can be expressed as a finite linear combination of the vectors of the form

$$\left(\prod_{j=1}^{p}D_1(g_j')^\#\right)\left(\prod_{l=1}^{q}D_2(h_l')^\#\right)\xi_0,\ g_j',\ h_l'\in\mathfrak{h}_0,$$

where $D_i^{\#}(g)$ is either $D_i(g)$ or $D_i^*(g)$, $i=1,2$. As a consequence of Lemma 5.1 and the CCRs in Proposition 5.1, the above vector can be expressed as a finite linear combination of the vector of the form

$$\left(\prod_{j=1}^{m'} D_1(g_j')^*\right)\left(\prod_{l=1}^{n'} D_2(h_l')^*\right)\xi_0,\ g_j',\ h_l' \in \mathfrak{h}_0,\ m',\ n' \in \mathbb{N}\cup\{0\}.$$

Since $\mathcal{H}_{\text{fin}}$ is dense in $\mathcal{H}$, we conclude that the set of finite linear combinations of the vectors of the above form is dense in $\mathcal{H}$. Thus the decomposition follows from Lemma 5.1 and the CCRs in Proposition 5.1. □

Recall that $\mathfrak{h}_0$ is a dense subspace of a complex Hilbert space $\mathfrak{h}$. Let $\mathcal{F}=\mathcal{F}(\mathfrak{h})$ be the symmetric Fock space over $\mathfrak{h}$, and $a(g)$ and $a^*(g)$, $g\in\mathfrak{h}_0$, the annihilation and creation operator, respectively. Denote by Ω the vacuum vector in $\mathcal{F}$. Let $C:\mathfrak{h}\to\mathfrak{h}$ be an anti-unitary operator. If $\mathfrak{h}$ is a L^2-space, one may consider that C is the complex conjugation. Denote by $\Gamma(C)$ the second quantization of C. See Sec. 5.2.1 of Ref. 2. Let $\mathcal{F}_1$, Ω_1, $a_1(g)$ and $a_1^*(g)$, $g\in\mathfrak{h}_0$ be the identical copies of $\mathcal{F}$, Ω, $a(g)$ and $a^*(g)$, $g\in\mathfrak{h}_0$, respectively. Notice that $\Gamma(C)a^{\#}(g)\Gamma(C)^{-1}=a^{\#}(Cg)$. We write that $\mathcal{F}_2=\Gamma(C)\mathcal{F}(=\mathcal{F})$, $\Omega_2=\Omega$, $a_2(g)=a(Cg)$, and $a_2^*(g)=a^*(Cg)$, $g\in\mathfrak{h}_0$. Then the following commutation relations hold: for $g,h\in\mathfrak{h}_0$,

$$\begin{aligned}[a_2(g),\ a_2^*(h)]&=(h,\ g)\mathbf{1},\\ [a_2(g),\ a_2(h)]&=0.\end{aligned}\tag{5.8}$$

One may compare the above relations to those in Proposition 5.1 (b).

Proposition 5.2: Let U be the operator defined by

$$U:\mathcal{H}\to\mathcal{F}_1\otimes\mathcal{F}_2,\left(\prod_{j=1}^{m} D_1(g_j)^*\right)\left(\prod_{l=1}^{n} D_2(h_l)^*\right)\xi_0\mapsto\left(\prod_{j=1}^{m} a_1^*(g_j)\right)\Omega_1\otimes\left(\prod_{l=1}^{n} a_2^*(h_l)\right)\Omega_2,$$

for g_j, $h_l\in\mathfrak{h}_0$, $j=1,\ldots,m$, $l=1,\ldots,n$. Then U is unitary.

Proof: Since $D_1^{\#}(g)$ and $a_1^{\#}(g)$, and $D_2^{\#}(g)$ and $a_2^{\#}(g)$ for $g\in\mathfrak{h}_0$ satisfy the same commutation relations, respectively, by Proposition 5.1 and (5.8), the unitarity of U follows from the fact that $a(g)\Omega=0$ for any $g\in\mathfrak{h}_0$. □

We next turn to the spectral analysis of $\overline{H}$, where $\overline{H}$ is the generator of the symmetric Markovian semigroup $\{T_t\}_{t\geqslant 0}$ associated to the Dirichlet form $(\overline{\mathcal{E}},D(\overline{\mathcal{E}}))$.

Let us first describe the basic idea of the proof Theorem 3.2. Recall the definitions of $D_1(g)$ and $D_2(g)$ in (5.5). Let $\{f_n\}\subset\mathfrak{h}_0$ *be a CONS for* $\mathfrak{h}$. By Remark 4.1 and (5.5), we have that for any $g,h\in\mathfrak{h}_0$,

$$\begin{aligned}\overline{\mathcal{E}}(W(g)\xi_0,W(h)\xi_0)&=\sum_{n=1}^{\infty}\langle D_1(B^{1/2}f_n)W(g)\xi_0,\ D_1(B^{1/2}f_n)W(h)\xi_0\rangle\\ &\quad+\sum_{n=1}^{\infty}\langle D_2(B^{1/2}f_n)W(g)\xi_0,\ D_2(B^{1/2}f_n)W(h)\xi_0\rangle\\ &=\langle W(g)\xi_0,HW(h)\xi_0\rangle,\end{aligned}$$

where

$$H=\sum_{n=1}^{\infty}\{D_1^*(B^{1/2}f_n)D_1(B^{1/2}f_n)+D_2^*(B^{1/2}f_n)D_2(B^{1/2}f_n)\},\tag{5.9}$$

as a bilinear form on $\mathcal{W}\xi_0\times\mathcal{W}\xi_0$. By Proposition 5.2, one can see that H is unitary equivalent to sum of two second quantizations of B. If one can show that $\mathcal{H}_{\text{fin}}\subset D(\overline{H})$, $\overline{H}=H$ on $\mathcal{H}_{\text{fin}}$, and that $\mathcal{H}_{\text{fin}}$ is a core for $\overline{H}$, then one expects that the spectrum of $\overline{H}$ can be analyzed completely.

We first establish technical lemmas. Recall that $\mathcal{W}_0\xi_0\subset D(\overline{\mathcal{E}})$.

Lemma 5.3: $\mathcal{W}\xi_0\subset D(\overline{\mathcal{E}})$

Proof: Since $(\overline{\mathcal{E}},D(\overline{\mathcal{E}}))$ is closed and $\mathcal{W}_0\xi_0\subset D(\mathcal{E})$, it is sufficient to show that for any $g\in\mathfrak{h}_0$,

$$\overline{\mathcal{E}}[W_n(g)\xi_0-W(g)\xi_0]\to 0,\quad \text{as}\quad n\to\infty.$$

Notice that by Remark 4.1,

$$\begin{aligned}\overline{\mathcal{E}}[(W_n(g)-W(g))\xi_0]&=\sum_{m=1}^{\infty}\int\|\delta(\sigma_{\tau-i/4}(a(g_m)))(W_n(g)-W(g))\xi_0\|^2 f(\tau)\,d\tau\\&\quad+\sum_{m=1}^{\infty}\int\|\delta(\sigma_{\tau-i/4}(a^*(g_m)))(W_n(g)-W(g))\xi_0\|^2 f(\tau)\,d\tau\\&\equiv A_n^{(1)}+A_n^{(2)}.\end{aligned}$$

Employing the method similar to that used to derive (4.12), it is easy to show that

$$A_n^{(1)}=\frac{n}{2\pi}\int\int K(t_1,t_2,g)e^{-nt_1^2}e^{-nt_2^2}\,dt_1\,dt_2,$$

where

$$\begin{aligned}K(t_1,t_2,g)&=(A^{it_1}g,\,(A^{it_2}-\mathbf{1})A^{-1/2}g)\langle W(A^{it_1}g)\xi_0,W(A^{it_2}g)\xi_0\rangle\\&\quad+(A^{it_1}g,\,A^{-1/2}g)\langle W(A^{it_1}g)\xi_0,(W(A^{it_2}g)-W(g))\xi_0\rangle\\&\quad+(g,\,A^{-1/2}A^{it_2}g)\langle W(g)\xi_0,(W(g)-W(A^{it_2}g))\xi_0\rangle\\&\quad+(g,\,A^{-1/2}(\mathbf{1}-A^{it_2})g)\langle W(g)\xi_0,W(g)\xi_0\rangle.\end{aligned}$$

Notice that $K(t_1,\,t_2,\,g)$ is bounded uniformly with respect to $(t_1,\,t_2)\in\mathbb{R}^2$. Changing the variables $(t_1'=n^{1/2}t_1,\,t_2'=n^{1/2}t_2)$ and using the dominated convergence theorem, we conclude that

$$A_n^{(1)}\to 0,\quad \text{as}\quad n\to\infty.$$

By the similar calculation, we get that

$$A_n^{(2)}\to 0,\quad \text{as}\quad n\to\infty.$$

This proved the lemma completely. □

Lemma 5.4: (a) $\mathcal{H}_{\text{fin}}\subset D(\overline{\mathcal{E}})$.

(b) Let $\{g_n\}\subset\mathfrak{h}_0$ *be a CONS for* $\mathfrak{h}$. *Then for* $\xi\in\mathcal{H}_{\text{fin}}$ *the equality*

$$\overline{\mathcal{E}}[\xi]=\sum_{n=1}^{\infty}\{\|D_1(B^{1/2}g_n)\xi\|^2+\|D_2(B^{1/2}g_n)\xi\|^2\}\tag{5.10}$$

holds.

The proof of the above lemma will be given in the Appendix.

The following theorem is one of the main results in this section.

Theorem 5.2: *(a) Let* $H:\mathcal{H}_{\text{fin}}\to\mathcal{H}$ *be the operator defined by*

$$H\prod_{p=1}^{m} D_1(g_p)^*\prod_{q=1}^{n} D_2(h_q)^*\xi_0=\sum_{k=1}^{m}\prod_{p=1}^{k-1} D_1(g_p)^*D_1(Bg_k)^*\prod_{p=k+1}^{m} D_1(g_p)^*\prod_{q=1}^{n} D_2(h_q)^*\xi_0$$
$$+\sum_{k=1}^{n}\prod_{p=1}^{m} D_1(g_p)^*\prod_{q=1}^{k-1} D_2(h_q)^*D_2(Bh_k)^*\prod_{q=k+1}^{n} D_2(h_q)^*\xi_0, \tag{5.11}$$

for any $m,\ n\in\mathbb{N}\cup\{0\}$ *and* $g_p,\ h_q\in\mathfrak{h}_0$, $p=1,\ldots,m, q=1,\ldots,n$. *Then the relation*

$$\overline{\mathcal{E}}(\eta,\xi)=\langle\eta,\ H\xi\rangle$$

holds for any $\eta,\ \xi\in\mathcal{H}_{\mathrm{fin}}$.

(b) H is essential self-adjoint and the self-adjoint extension denoted by H again is equal to the Dirichlet operator $\overline{H}$.

Proof: (a) Let $(\mathcal{E}_1,\ \mathcal{H}_{\mathrm{fin}})$ be the form given by

$$\mathcal{E}_1[\xi]=\sum_{k=1}^{\infty}\|D_1(B^{1/2}f_k)\xi\|^2,$$

where $\{f_k\}$, $f_k\in\mathfrak{h}_0$ is a CONS for $\mathfrak{h}$. We write $H=H_1+H_2$, where the image under H_1 (resp., H_2) is defined by the first (resp., second) vector on the right hand side of (5.11). The CCRs in Proposition 5.1 (a) and Lemma 5.1 imply that

$$\mathcal{E}_1\left[\left(\prod_{j=1}^{m} D_1(g_j)^*\right)\xi_0\right]=\sum_{k=1}^{\infty}\sum_{p=1}^{m}\sum_{q=1}^{m}(B^{1/2}g_p,\ f_k)(f_k,\ B^{1/2}g_q)G(g_1,\ldots,\ g_m;\ p,q),$$

where

$$G(g_1,\ldots,\ g_m;\ p,\ q):=\left\langle\prod_{\tau=1}^{p-1} D_1(g_\tau)^*\prod_{\tau=p+1}^{m} D_1(g_\tau)^*\xi_0,\ \prod_{\tau=1}^{q-1} D_1(g_\tau)^*\prod_{\tau=q+1}^{m} D_1(g_\tau)^*\xi_0\right\rangle.$$

Using the Parserval relations and the fact that

$$\sum_{p=1}^{m}(g_p,\ Bg_q)G(g_1,\ldots,\ g_m;\ p,q)$$
$$=\left\langle D_1(Bg_q)\prod_{k=1}^{m} D_1(g_k)^*\xi_0,\ \prod_{k=1}^{q-1} D_1(g_q)^*\prod_{k=q+1}^{m} D_1(g_k)^*\xi_0\right\rangle,$$

we have that

$$\mathcal{E}_1\left[\prod_{j=1}^{m} D_1(g_j)^*\xi_0\right]=\sum_{q=1}^{m}\left\langle\prod_{j=1}^{m} D_1(g_j)^*\xi_0,\prod_{j=1}^{q-1} D_1(g_j)^*D_1(Bg_q)^*\prod_{j=q+1}^{m} D_1(g_j)^*\xi_0\right\rangle$$
$$=\left\langle\prod_{j=1}^{m} D_1(g_j)^*\xi_0,\ H_1\prod_{j=1}^{m} D_1(g_j)^*\xi_0\right\rangle.$$

Notice that $H_2=H-H_1$ commutes with $D_1(g)^*$ for any $g\in\mathfrak{h}_0$ by (5.11). Thus by the polarization identity, we proved that

$$\mathcal{E}_1(\eta,\ \xi)=\langle\eta,\ H_1\xi\rangle,$$

for any $\eta, \xi \in \mathcal{H}_{\text{fin}}$. The method similar to that used in the above implies that

$$\mathcal{E}_2(\eta, \xi) = \langle \eta, H_2 \xi \rangle,$$

for any $\eta, \xi \in \mathcal{H}_{\text{fin}}$. This proved the part (a) of the theorem.

(b) By Proposition 5.2, we have that

$$UHU^{-1} = d\Gamma_1(B) \otimes \mathbf{1} + \mathbf{1} \otimes d\Gamma_2(B), \tag{5.12}$$

where each i, $i=1, 2$, $d\Gamma_i(B)$ is the second quantization of B on $\mathcal{F}_i$. We remark that $d\Gamma_2(B)$ is anti-unitary equivalent to $d\Gamma_1(B)$. By Assumption 3.1, any $g \in \mathfrak{h}_0$ is an analytic vector for B, and so it is easy to check that $(\Pi_{j=1}^m a^*(g_j))\Omega$ is an analytic vector for $d\Gamma(B)$ for any $g_j \in \mathfrak{h}_0$, $j = 1, \ldots, m$. Thus it follows that any $\xi \in \mathcal{H}_{\text{fin}}$ is an analytic vector for H. Since $H\mathcal{H}_{\text{fin}} \subset \mathcal{H}_{\text{fin}}$ by (5.11) and since $H = \overline{H}$ on $\mathcal{H}_{\text{fin}}$ by part (a) of the theorem, it follows from Corollary 2 of Theorem X. 39 in Ref. 26 that H and $\overline{H}$ are essentially self-adjoint on $\mathcal{H}_{\text{fin}}$, and so $H = \overline{H}$. □

Finally we are able to produce the proof of Theorem 3.2.

Proof of Theorem 3.2: (a) and (b) follow from Theorem 5.2.

To show (c), recall $0 < A \leqslant \alpha \mathbf{1}$, $0 < \alpha < 1$. Since $B = A^{-1/2} - A^{1/2}$,

$$\inf \sigma(B) \geqslant \alpha^{-1/2} - \alpha^{1/2}.$$

It follows from the above lower bound and (5.12) that zero is a simple eigenvalue with eigenvector ξ_0 and

$$\inf(\sigma(H) - \{0\}) \geqslant \alpha^{-1/2} - \alpha^{1/2}.$$

Thus the Markovian semigroup $\{T_t\}_{t \geqslant 0}$ is ergodic. This completes the proof of Theorem 3.2. □

APPENDIX: PROOFS OF LEMMA 4.3 AND LEMMA 5.4

Proof of Lemma 4.3: (a) Let us prove the first bound. Recall the definition of $\Phi(f, n)$, $f \in \mathfrak{h}_0$, $n \in \mathbb{N}$, in (4.5). Notice that

$$\Phi(f, n) = \int_0^1 W\left(\frac{s}{n} f\right) \Phi(f) \, ds. \tag{A1}$$

It follows from (4.6) and (A1) that

$$\|\sigma_z(\Phi_m(f, n))\xi_0\|^2 = \left(\frac{m}{\pi}\right) \int \int \left(\int_0^1 \int_0^1 F(t_1, t_2, s_1, s_2; f, n) \, ds_1 \, ds_2 \right) \cdot e^{-m(t_1 - \bar{z})^2} e^{-m(t_2 - z)^2} dt_1 \, dt_2,$$

where

$$F(t_1, t_2, s_1, s_2; f, n) := \omega\left(\sigma_{t_1}(\Phi(f)) \sigma_{t_1}\left(W\left(-\frac{s_1}{n} f \right) \right) \sigma_{t_2}\left(W\left(\frac{s_2}{n} f \right) \right) \sigma_{t_2}(\Phi(f)) \right).$$

We use (4.4) and the fact that $\sigma_t(\Phi(f)) = \Phi(A^{it} f)$, etc., to obtain that

$$F(t_1,\,t_2,\,s_1,\,s_2;\,f,\,n)=\omega\Big(\Phi(A^{it_1}f)\Phi(A^{it_2}f)W\Big(-\frac{s_1}{n}A^{it_1}f\Big)W\Big(\frac{s_2}{n}A^{it_2}f\Big)\Big)$$
$$+\frac{s_1}{n}\mathrm{Im}\,(A^{it_1}f,A^{it_2}f)\,\omega\Big(\Phi(A^{it_1}f)W\Big(-\frac{s_1}{n}A^{it_1}f\Big)W\Big(\frac{s_2}{n}A^{it_2}f\Big)\Big).$$

Iterating (4.2) and then using (4.1), (3.1) and (3.2), the above function can be calculated explicitly. More precisely, let us use (4.2) iteratively in the above to obtain that

$$F(t_1,\,t_2,\,s_1,\,s_2;\,f,\,n)=\sum_{k=1}^{7}F^{(k)}(t_1,\,t_2,\,s_1,\,s_2;\,f,\,n),$$

where

$$F^{(1)}(t_1,\,t_2,\,s_1,\,s_2;\,f,\,n)=\omega(\Phi(A^{it_1}f)\Phi(A^{it_2}f))\omega\Big(W\Big(-\frac{s_1}{n}A^{it_1}f\Big)W\Big(\frac{s_2}{n}A^{it_2}f\Big)\Big),$$

and appropriate expressions for $F^{(k)}(t_1,\,t_2,\,s_1,\,s_2;\,f,\,n)$, $k=2,\ldots,7$. It follows from (4.1), (3.1) and (3.2) that

$$F^{(1)}(t_1,\,t_2,\,s_1,\,s_2;\,f,\,n)=\tfrac{1}{2}((f,\,(\mathbf{1}-A)^{-1}A^{-it_1}A^{it_2}f)+(f,\,A(\mathbf{1}-A)^{-1}A^{it_1}A^{-it_2}f))$$
$$\cdot\exp\Big\{\frac{i}{2}\mathrm{Im}\Big(f,\,\frac{s_1}{n}\frac{s_2}{n}A^{-it_1}A^{it_2}f\Big)\Big\}$$
$$\cdot\exp\Big\{-\frac{1}{4}\Big(\Big(\frac{s_2}{n}A^{it_2}-\frac{s_1}{n}A^{it_1}\Big)f,\,D\Big(\frac{s_2}{n}A^{it_2}-\frac{s_1}{n}A^{it_1}\Big)f\Big)\Big\},$$

where $D=(\mathbf{1}+A)(\mathbf{1}-A)^{-1}$. By Assumption 3.1, $F^{(1)}$ has an analytic extension on $\mathbb{C}\times\mathbb{C}$ in t_1 and t_2 variables. From the above expression, it is easy to see that there exists a constant $C_1(f,\mathrm{Im}\,z)$ independent of n such that

$$\sup_{s_1,s_2\in[0,1]}|F^{(1)}(t_1+\overline{z},\,t_2+z,\,s_1,\,s_2;\,f,\,n)|\leqslant C_1(f,\mathrm{Im}\,z),$$

for any $n\in\mathbb{N}$. Using the Cauchy integral theorem and the above bound, we conclude that the contribution of $F^{(1)}$ in F is bounded by $C_1(f,\mathrm{Im}\,z)$. Now, it is obvious that the function $F(t_1,\,t_2,\,s_1,\,s_2;\,f,\,n)$ has an analytic extension on $\mathbb{C}\times\mathbb{C}$ in t_1 and t_2 variables and there exists a constant $M_1(f,\mathrm{Im}\,z)$ depending only on $f\in\mathfrak{h}_0$ and $\mathrm{Im}\,z$ such that the bound similar to that in the above holds. We use the Cauchy integral theorem to conclude that

$$\|\sigma_z(\Phi_m(f,\,n))\xi_0\|^2=\Big(\frac{m}{\pi}\Big)\int\int\Big(\int_0^1\int_0^1F(t_1+\overline{z},\,t_2+z,\,s_1,\,s_2;\,f,\,n)ds_1\,ds_2\Big)$$
$$\cdot e^{-mt_1^2}e^{-mt_2^2}dt_1\,dt_2\leqslant M_1(f,\,\mathrm{Im}\;z)^2.$$

We leave the details to the reader.

We next consider the second bound. It follows from (4.1) that

$$\omega(a^*(f)a(g))=(g,\,A(\mathbf{1}-A)^{-1}f),\tag{A2}$$
$$\omega(a(g)a^*(f))=(g,\,(\mathbf{1}-A)^{-1}f).$$

A direct computation yields that

$$\|\sigma_z(\Phi(f))\xi_0\|^2 = \tfrac{1}{2}(\omega(a^*(A^{i\overline{z}}f)a(A^{i\overline{z}}f)) + \omega(a(A^{iz}f)a^*(A^{iz}f))).$$

Thus the bound follows from (A2) and the above result.

(b) Notice that

$$\begin{aligned}\|\sigma_z(\Phi_n(f,\,n))\xi_0 - \sigma_z(\Phi(f))\xi_0\| &\leqslant \|\sigma_z(\Phi_n(f,\,n))\xi_0 - \sigma_z(\Phi_n(f))\xi_0\| \\ &\quad + \|\sigma_z(\Phi_n(f))\xi_0 - \sigma_z(\Phi(f))\xi_0\| \\ &\equiv A_n^{(1)} + A_n^{(2)}. \end{aligned} \tag{A3}$$

It follows from (4.5) and (A1) that

$$(A_n^{(1)})^2 = \left(\frac{n}{\pi}\right)\int\int\left(\int_0^1\int_0^1 G(t_1,\,t_2,\,s_1,\,s_2;\,f,\,n)\,ds_1\,ds_2\right)\cdot e^{-n(t_1-\overline{z})^2}e^{-n(t_2-z)^2}\,dt_1\,dt_2,$$

where

$$G(t_1,\,t_2,\,s_1,\,s_2;\,f,\,n) := \omega\left(\Phi(A^{it_1}f)\left(W\left(-\frac{s_1}{n}A^{it_1}f\right)-\mathbf{1}\right)\left(W\left(\frac{s_2}{n}A^{it_2}f\right)-\mathbf{1}\right)\Phi(A^{it_2}f)\right). \tag{A4}$$

Notice that for $s,\,t\in\mathbb{R}$,

$$W\left(\frac{s}{n}A^{it}f\right)-\mathbf{1} = i\frac{s}{n}\Phi(A^{it}f)\int_0^1 W\left(\frac{s\tau}{n}A^{it}f\right)d\tau. \tag{A5}$$

We substitute (A5) into (A4). Iterating (4.2), and then using (4.1) and (3.2), the function given in (A4) can be calculated explicitly. Using Assumption 3.1, it can be proved that $G(t_1,\,t_2,\,s_1,\,s_2;\,f,\,n)$ has an analytic extension on $\mathbb{C}\times\mathbb{C}$ in the t_1 and t_2 variables. By using the method similar to that used in the proof of the part (a) of the lemma, it is not hard to check that there exists constant $C_2(f,\,\mathrm{Im}\,z)$ such that

$$\sup_{s_1,s_2\in[0,1]}|G(t_1+\overline{z},\,t_2+z,\,s_1,\,s_2;\,f,\,n)| \leqslant \frac{1}{n^2}C_2(f,\,\mathrm{Im}\quad z).$$

It follows from the Cauchy integral theorem and the above bound that

$$(A_n^{(1)})^2 \to 0, \quad \text{as } n\to\infty.$$

We leave again the details to the reader.

Next, consider $A_n^{(2)}$ defined in (A3). Notice that

$$(A_n^{(2)})^2 = \left(\frac{n}{\pi}\right)\int\int\widetilde{G}(t_1,\,t_2;\,f)e^{-n(t_1-\overline{z})^2}e^{-n(t_2-z)^2}\,dt_1\,dt_2,$$

where

$$\widetilde{G}(t_1,\,t_2;\,f) = \omega((\Phi(A^{it_1}f)-\sigma_{\overline{z}}(\Phi(f)))(\Phi(A^{it_2}f)-\sigma_z(\Phi(f)))).$$

We use (A2) to obtain that

$$\begin{aligned}\tilde{G}(t_1,t_2;f) &= \tfrac{1}{2}\omega(\{a(A^{it_1}f)-a(A^{iz}f)\}\{a^*(A^{it_2}f)-a^*(A^{iz}f)\})\\ &\quad+\tfrac{1}{2}\omega(\{a^*(A^{it_1}f)-a^*(A^{i\bar{z}}f)\}\{a(A^{it_2}f)-a(A^{i\bar{z}}f)\})\\ &= \tfrac{1}{2}((A^{it_1}-A^{iz})f,\ (\mathbf{1}-A)^{-1}(A^{it_2}-A^{iz})f)\\ &\quad+\tfrac{1}{2}((A^{it_2}-A^{i\bar{z}})f,\ A(\mathbf{1}-A)^{-1}(A^{it_1}-A^{i\bar{z}})f).\end{aligned}$$

Thus $\tilde{G}(t_1,tt_2;\ f)$ has an analytic extension on $\mathbb{C}\times\mathbb{C}$ in the t_1 and t_2 variables and

$$\begin{aligned}\tilde{G}(t_1+\bar{z},\ t_2+z;\ f) &= \tfrac{1}{2}(f,\ (\mathbf{1}-A)^{-1}(A^{-it_1}-\mathbf{1})(A^{it_2}-\mathbf{1})A^{-i\bar{z}}A^{iz}f)\\ &\quad+\tfrac{1}{2}(f,\ A(\mathbf{1}-A)^{-1}(A^{it_1}-\mathbf{1})(A^{-it_2}-\mathbf{1})A^{-iz}A^{i\bar{z}}f).\end{aligned}\tag{A6}$$

We use the Cauchy integral theorem to get

$$(A_n^{(2)})^2=\left(\frac{n}{\pi}\right)\int\int \tilde{G}(t_1+\bar{z},\ t_2+z;\ f)e^{-nt_1^2}e^{-nt_2^2}\,dt_1dt_2.$$

By (A6), $\tilde{G}(t_1+\bar{z},\ t_2+z;\ f)$ is bounded uniformly with respect to $(t_1,\ t_2)\in\mathbb{R}^2$. Changing the variables ($t_1'=n^{1/2}t_1$ and $t_2'=n^{1/2}t_2$) and using the dominated convergence theorem, we conclude that

$$A_n^{(2)}\to 0,\quad \text{as}\ \ n\to\infty.$$

This proved the part (b) of the lemma completely. □

Proof of Lemma 5.4: (a) Recall the definition of $\Phi(f,\ n)$ in (4.5) for any $f\in\mathfrak{h}_0$ and $n\in\mathbb{N}$. For given (fixed) $m\in\mathbb{N}\cup\{0\}$ and $h_l\in\mathfrak{h}_0,\ l=1,\ldots,m$ we will use the following abbreviated notations:

$$\begin{gathered}\Phi_l(n):=\Phi(h_l,\ n),\ l=1,\ldots,m,\\ \Phi_l:=\Phi(h_l),\ l=1,\ldots,m,\\ \xi(n):=\left(\prod_{l=1}^{m}\Phi_l(n)\right)\xi_0,\ \text{and}\ \ \xi:=\left(\prod_{l=1}^{m}\Phi_l\right)\xi_0.\end{gathered}\tag{A7}$$

Notice that $\xi(n)\in\mathcal{W}\xi_0,\ n\in\mathbb{N}$ and $\xi\in\mathcal{H}_{\text{fin}}$. It is not hard to show that $\xi(n)\to\xi$ as $n\to\infty$. See the method used below. We will show that $\overline{\mathcal{E}}[\xi(n)-\xi]\to 0$ as $n\to\infty$. Since $\overline{\mathcal{E}}$ is closed, this implies that $\mathcal{H}_{\text{fin}}\subset D(\overline{\mathcal{E}})$ and

$$\overline{\mathcal{E}}[\xi]=\lim_{n\to\infty}\overline{\mathcal{E}}[\xi(n)].\tag{A8}$$

By Remark 4.1 and (5.5), the relation (5.10) holds for $\xi\in\mathcal{W}\xi_0$. Let ξ and $\xi(n),\ n\in\mathbb{N}$ be defined as in (A7). Notice that

$$\xi(n)-\xi=\sum_{p=1}^{m}\left(\prod_{l=1}^{p-1}\Phi_l(n)\right)(\Phi_p(n)-\Phi_p)\left(\prod_{l=p+1}^{m}\Phi_l\right)\xi_0.$$

We use the Schwarz inequality twice to obtain that

$$\|D_1(B^{1/2}g_k)(\xi(n)-\xi)\|^2 \leq m\sum_{p=1}^{m}\left\|D_1(B^{1/2}g_k)\left(\prod_{l=1}^{p-1}\Phi_l(n)\right)(\Phi_p(n)-\Phi_p)\left(\prod_{l=p+1}^{m}\Phi_l\right)\xi_0\right\|^2. \tag{A9}$$

Recall that $D_1(B^{1/2}g_k)=a(A^{-1/4}g_k)-j(\sigma_{-i/2}(a(A^{-1/4}g_k)))$. It follows from the CCRs and Lemma 5.1 that

$$D_1(B^{1/2}g_k)\left(\prod_{l=1}^{p-1}\Phi_l(n)\right)(\Phi_p(n)-\Phi_p)\left(\prod_{l=p+1}^{m}\Phi_l\right)\xi_0=\frac{1}{\sqrt{2}}\sum_{q=1}^{m}(g_k, A^{-1/4}h_q)\Psi^{(m)}(p, q; n), \tag{A10}$$

where

$$\Psi^{(m)}(p, q; n):=\left(\prod_{l=1}^{q-1}\Phi_l(n)\right)W\left(\frac{1}{n}h_q\right)\left(\prod_{l=q+1}^{p-1}\Phi_l(n)\right)\cdot(\Phi_p(n)-\Phi_p)\left(\prod_{l=p+1}^{m}\Phi_l\right)\xi_0,$$

$$1\leq q\leq p-1,$$

$$\Psi^{(m)}(p, q; n):=\left(\prod_{l=1}^{p-1}\Phi_l(n)\right)\left(W\left(\frac{1}{n}h_p\right)-\mathbf{1}\right)\left(\prod_{l=p+1}^{m}\Phi_l\right)\xi_0, \quad q=p,$$

$$\Psi^{(m)}(p, q; n):=\left(\prod_{l=1}^{p-1}\Phi_l(n)\right)(\Phi_p(n)-\Phi_p)\left(\prod_{l=p+1}^{q-1}\Phi_l(n)\right)\cdot\left(\prod_{l=q+1}^{m}\Phi_l\right)\xi_0, \quad p+1\leq q\leq m.$$

We use the Schwarz inequality twice again to (A10) and substitute the result into (A9) to conclude that

$$\|D_1(B^{1/2}g_k)(\xi(n)-\xi)\|^2\leq\frac{1}{2}m^2\sum_{p=1}^{m}\sum_{q=1}^{m}|(g_k, A^{-1/4}h_q)|^2\|\Psi^{(m)}(p, q; n)\|^2.$$

Using the Parserval relation, we obtain that

$$\sum_{k=1}^{\infty}\|D_1(B^{1/2}g_k)(\xi(n)-\xi)\|^2\leq\frac{1}{2}m^2\sum_{p=1}^{m}\sum_{q=1}^{m}\|A^{-1/4}h_q\|^2\|\Psi^{(m)}(p, q; n)\|^2. \tag{A11}$$

Iterating (4.2), $\|\Psi^{(m)}(p, q; n)\|^2$ can be calculated explicitly for any p, q and n. One notes that each $\Psi^{(m)}(p, q; n)$ contains either $(\Phi_p(n)-\Phi_p)$ or else $(W(1/n\,h_p)-\mathbf{1})$, which implies that

$$\|\Psi^{(m)}(p, q; n)\|^2\to 0, \text{ as } n\to\infty,$$

for any p, q. Thus it follows from (A11) that

$$\sum_{k=1}^{\infty}\|D_1(B^{1/2}g_k)(\xi(n)-\xi)\|^2\to 0, \text{ as } n\to\infty.$$

The method similar to that used in the above implies that

$$\sum_{k=1}^{\infty}\|D_2(B^{1/2}g_k)(\xi(n)-\xi)\|^2\to 0, \quad \text{as } n\to\infty.$$

This proved part (a) of this lemma.

(b) This follows from (5.9) and (A8). □

We classify all finite growth representations of all infinite rank subalgebras of the Lie conformal algebra gc_1 that contain a Virasoro subalgebra. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1534890]

I. INTRODUCTION

In this paper we study representation theory of some infinite rank subalgebras of the Lie conformal algebra gc_1 associated to the Lie algebra $\mathcal{D}$ of differential operators on the circle. Recall that $gc_1=\mathbb{C}[\partial,x]$, with λ-bracket given by (see Refs. 3 and 7)

$$[a(\partial,x)_\lambda b(\partial,x)]=a(-\lambda,\lambda+\partial+x)b(\lambda+\partial,x)-b(\lambda+\partial,-\lambda+x)a(-\lambda,x).$$

Also recall that the *Virasoro conformal algebra* (which is particularly important in physics) is defined as the free $\mathbb{C}[\partial]$-module of rank 1 generated by an element L, with λ-bracket defined by

$$[L_\lambda L]=(2\lambda+\partial)L,$$

and extended to $\mathbb{C}[\partial]L$ using sesquilinearity. Observe that all Virasoro subalgebras of gc_1 are generated by

$$L=x+\alpha\partial, \quad \alpha\in\mathbb{C}.$$

The complete list of infinite rank proper subalgebras of gc_1 that contain a Virasoro subalgebra is (see Ref. 3 and Remark 3.10 in Ref. 5):

$$gc_{1,x}=x\,\mathbb{C}[\partial,x],$$

$$oc_1=\{a(\partial,x)-a(\partial,-\partial-x)\mid a(\partial,x)\in\mathbb{C}[\partial,x]\},$$

$$spc_1=\{x[a(\partial,x)+a(\partial,-\partial-x)]\mid a(\partial,x)\in\mathbb{C}[\partial,x]\},$$

where the Virasoro element is $x+\alpha\partial$, with $\alpha=0,\frac{1}{2},0$, respectively. They are the most important gc_1-subalgebras from the point of view of physics.

In the present paper we classify all finite growth representations of all infinite rank conformal subalgebras of gc_1 that contain a Virasoro subalgebra.

b)Electronic mail: kac@math.mit.edu
c)Electronic mail: liberati@mate.uncor.edu

This problem reduces to the study of finite growth representations on the corresponding extended annihilation algebras, which are certain subalgebras of $\mathcal{D}$ (see Ref. 7). The main tools used here are the recent results (Refs. 1, 4, 9–11) on the classification of quasifinite highest weight modules over the central extension of $\mathcal{D}$ and some of its important subalgebras.

The paper is organized as follows. In Sec. II, we describe the infinite rank Lie algebra $\widehat{g\ell}_{\infty}^{[m]}$ and its classical subalgebras, and discuss their representation theory that will be needed. In Secs. III–VI, we obtain the classification of all finite growth representations of gc_1, $gc_{1,x}$, oc_1, and spc_1 respectively.

II. LIE ALGEBRA $\widehat{g\ell}_{\infty}^{[m]}$ AND ITS CLASSICAL SUBALGEBRAS

A. Lie algebra $\widehat{g\ell}_{\infty}^{[m]}$

Denote by $\mathbb{C}^{+\infty}$ the set of all sequences $\lambda=(\lambda_1,\lambda_2,\ldots)$ for which all but a finite number of λ_i's are zero, and let $d(\lambda)$ denote the number of nonzero λ_i's and $|\lambda|$ denote their sum. Denote by Par^+ the subset of $\mathbb{C}^{+\infty}$ consisting of nonincreasing sequences of (non-negative) integers.

Denote by $g\ell_{+\infty}$ the Lie algebra of all matrices $(a_{ij})_{i,j=1}^{+\infty}$ with a finite number of nonzero entries $a_{ij}\in\mathbb{C}$. Given $\lambda\in\mathbb{C}^{+\infty}$, there exists a unique irreducible $g\ell_{+\infty}$-module $L^+(\lambda)$, also denoted by $L(g\ell_{+\infty};\lambda)$, which admits a nonzero vector v_λ such that

$$E_{ij}v_\lambda=0 \quad \text{for} \quad i<j \quad \text{and} \quad E_{ii}v_\lambda=\lambda_i v_\lambda\,. \tag{2.1}$$

Here and further E_{ij} denotes, as usual, the matrix whose (i,j)-entry is 1 and all other entries are 0. Each $L^+(\lambda)$ has a unique $\mathbb{Z}_+$-gradation. $L^+(\lambda)=\oplus_{j\in\mathbb{Z}_+}L^+(\lambda)_j$, called its *principal gradation*, which satisfies the properties

$$L^+(\lambda)_0=\mathbb{C}v_\lambda\,,\quad E_{ij}L^+(\lambda)_k\subset L^+(\lambda)_{k+i-j}\,.$$

Since $\lambda\in\mathbb{C}^{+\infty}$, it is easy to see that $\dim L^+(\lambda)_j<\infty$, hence we can define the q-character

$$\mathrm{ch}_q L^+(\lambda)=\sum_{j\in\mathbb{Z}_+}(\dim L^+(\lambda)_j)q^j\,.$$

For $\lambda\in\mathrm{Par}^+$, let $d=d(\lambda)$ and $\overline{\lambda}=(\lambda_1,\ldots,\lambda_d)$. Let $g\ell_d$ be the Lie algebra of all $d\times d$ matrices $(a_{ij})_{i,j=1}^d$; it may be viewed as a subalgebra of $g\ell_{+\infty}$ in a natural way. Denote by $\overline{L^+}(\overline{\lambda})$ the (irreducible) $g\ell_d$-submodule of $L^+(\lambda)$ generated by v_λ. It is, of course, isomorphic to the finite-dimensional irreducible $g\ell_d$-module associated to $\overline{\lambda}$, so that its q-character is a (well-known) polynomial in q.

Lemma 2.1: Let $\lambda\in\mathrm{Par}^+, d=d(\lambda)$. *Then*

$$\mathrm{ch}_q L^+(\lambda)=\mathrm{ch}_q\overline{L^+}(\overline{\lambda})\Big/\prod_{j=1}^{d}(1-q^j)_q^{\lambda_{d-j+1}}\,,$$

where $(1-a)_q^m=(1-a)(1-qa)\cdots(1-q^{m-1}a)$.

Proof: Recall the well-known formula (see Ref. 6):

$$\mathrm{ch}_q L^+(\lambda)=\prod_{\alpha>0}(1-q^{\langle\lambda+\rho,\alpha\rangle})/(1-q^{\langle\rho,\alpha\rangle})\,. \tag{2.2}$$

Here the product is taken over the set of all positive coroots of $g\ell_{+\infty}$, which are all elements $E_{ii}-E_{jj}$ with $i<j$, $\langle\lambda,E_{ii}\rangle=\lambda_i$ and $\langle\rho,E_{ii}\rangle=-i$. Of course, a similar formula holds for $\mathrm{ch}_q\overline{L^+}(\overline{\lambda})$; it is a part of the product (2.2) corresponding to $i<j\leqslant d$.

It is also clear that the factors of (2.2) corresponding to $d<i<j$ are equal to 1, and it is easy to see that the product over all pairs i, j with fixed $i\leqslant d$ and all $j>d$ is equal to $1/(1-q^{d-i+1})_q^{\lambda_i}$.

□

Recall that, given a vector space V with an increasing filtration by finite-dimensional subspaces $V_{[j]}$, the *growth* of V is defined by

$$\text{growth}\, V=\overline{\lim_{j\to+\infty}}\,(\log\dim V_{[j]})/\log j\,.$$

We define the growth of $L^+(\lambda)$ using its filtration $L^+(\lambda)_{[j]}=\oplus_{i\leqslant j}L^+(\lambda)_i$ associated to the principal gradation.

Theorem 2.2: (*a*) *If* $\lambda\in\text{Par}^+$, *then*

$$\text{growth}\, L^+(\lambda)=|\lambda|\,.$$

(*b*) *If* $\lambda\in\mathbb{C}^{+\infty}\backslash\text{Par}^+$, *then* growth$L^+(\lambda)=\infty$.

Proof: It follows from Lemma 2.1 that for $\lambda\in\text{Par}^+$, growth$L^+(\lambda)$ is equal to the growth of the polynomial algebra on generators of degree $1,2,\ldots,\lambda_s$; $2,3,\ldots,\lambda_{s-1}+1$; ...; $s,s+1,\ldots,\lambda_1+s-1$. The total number of these generators is $|\lambda|$, and since growth of a polynomial algebra is independent of the degrees of generators, (a) is proved.

Let now $\lambda\in\mathbb{C}^{+\infty}\backslash\text{Par}^+$. Then $\lambda_k-\lambda_{k+1}\notin\mathbb{Z}_+$ for some k. But then $E_{k+1,k}^N v_\lambda\neq 0$ for each $N\in\mathbb{Z}_+$. Looking at the subalgebra of $g\ell_{+\infty}$ spanned by all E_{ij} with $i,j\geqslant k+1$, we conclude from (a) that

$$\text{growth}\, L^+(\lambda)\geqslant N+\sum_{i\geqslant k+1}\lambda_i\,.$$

This proves (b). □

In a similar fashion one may consider the Lie algebra $g\ell_{-\infty}$ of all matrices $(a_{ij})_{i,j=0}^{-\infty}$ with a finite number of nonzero entries and the irreducible $g\ell_{-\infty}$-modules $L^-(\lambda)$, also denoted by $L(g\ell_{-\infty};\lambda)$, parametrized by the set $\mathbb{C}^{-\infty}$ of sequences $\mu=(\ldots,\mu_{-1},\mu_0)$ with finitely many nonzero members. Results similar to Lemma 2.1 and Theorem 2.2 hold for the subset $\text{Par}^-\subset\mathbb{C}^{-\infty}$ consisting of nonincreasing sequences of (nonpositive) integers.

Let $\widetilde{g\ell}_\infty$ denote the Lie algebra of all matrices $(a_{ij})_{i,j\in\mathbb{Z}}$ such that $a_{ij}=0$ if $|i-j|\gg 0$. Denote by $\widetilde{g\ell}_{+\infty}$ (respectively, $\widetilde{g\ell}_{-\infty}$) the subalgebra of $\widetilde{g\ell}_\infty$ consisting of matrices with $a_{ij}=0$ for i or $j\leqslant 0$ (respectively, i or $j>0$). Note that these two subalgebras commute and that $\widetilde{g\ell}_{\pm\infty}$ contains $g\ell_{\pm\infty}$ as a subalgebra. Note also that the $g\ell_{\pm\infty}$-modules $L^\pm(\lambda)$ extend uniquely to $\widetilde{g\ell}_{\pm\infty}$.

The Lie algebra $\widetilde{g\ell}_\infty$ has a well-known central extension $\widehat{g\ell}_\infty=\widetilde{g\ell}+\mathbb{C}C$ by $\mathbb{C}$ defined by the cocycle

$$\alpha(A,B)=\text{tr}[J,A]B\,,\quad\text{where}\quad J=\sum_{i\leqslant 0}E_{ii}\,.\tag{2.3}$$

The restriction of this cocycle to $\widetilde{g\ell}_{+\infty}$ and to $\widetilde{g\ell}_{-\infty}$ is zero.

We will also need briefly the Lie algebra $\widehat{g\ell}_\infty^{[m]}$ defined for each $m\in\mathbb{Z}_+$ by replacing $\mathbb{C}$ by $R_m=\mathbb{C}[u]/(u^{m+1})$. That is, $\widehat{g\ell}_\infty^{[m]}=\widetilde{g\ell}_\infty^{[m]}\oplus R_m$ is the central extension of $\widetilde{g\ell}_\infty^{[m]}$ by the 2-cocycle (2.3) with values in R_m, where $\widetilde{g\ell}_\infty^{[m]}$ is the Lie algebra of infinite matrices with finitely many nonzero diagonals with entries in R_m.

The principal $\mathbb{Z}$-gradation of all the above Lie algebras is defined by letting

$$\deg E_{ij}=i-j\tag{2.4}$$

(in the case of $\widehat{g\ell}_\infty^{[m]}$ we also let $\deg R_m=0$). This gives us a triangular decomposition

$$\widehat{g\ell}_\infty^{[m]}=(\widehat{g\ell}_\infty^{[m]})_+\oplus(\widehat{g\ell}_\infty^{[m]})_0\oplus(\widehat{g\ell}_\infty^{[m]})_-,$$

where

$$(\widehat{g\ell}_\infty^{[m]})_\pm=\oplus_{j\in\mathbb{N}}(\widehat{g\ell}_\infty^{[m]})_{\pm j}.$$

The Lie algebra $\widehat{g\ell}_\infty$ has a family of modules $L(\widehat{g\ell}_\infty;\lambda,c)$, parametrized by $\lambda\in\mathbb{C}^\infty=\{(\lambda_i)_{i\in\mathbb{Z}}|$ all but finitely many of λ_i are $0\}$ and $c\in\mathbb{C}$, defined by (2.1) and $Cv_\lambda=cv_\lambda$. Similarly, $\widehat{g\ell}_\infty^{[m]}$ has a family of modules $L(\widehat{g\ell}_\infty^{[m]};\vec{\lambda},\vec{c})$, where $\vec{\lambda}\in(\mathbb{C}^\infty)^{m+1}$, $\vec{c}\in\mathbb{C}^{m+1}$, defined in a similar fashion. That is, the highest weight $\widehat{g\ell}_\infty^{[m]}$-module $L(\widehat{g\ell}_\infty^{[m]};\Lambda)$, with highest weight $\Lambda\in(\widehat{g\ell}_\infty^{[m]})_0^*$ that is determined by its *labels* $\vec{\lambda}_i^{(j)}=\Lambda(u^jE_{ii})$ and the *central charges* $\vec{c}_j=\Lambda(u^j)$.

The gradation (2.4) is obviously consistent with the principal gradation of $L^\pm(\lambda)$ and of $L(\widehat{g\ell}_\infty;\lambda,c)$.

B. Lie algebras $b_\infty^{[m]}$ and $d_\infty^{[m]}$

The Lie algebra $\widetilde{g\ell}_\infty^{[m]}$ acts on the vector space $R_m[t,t^{-1}]$ via the usual formula

$$E_{ij}v_k=\delta_{j,k}v_i,$$

where $v_i=t^{-i}$, $i\in\mathbb{Z}$ is an R_m basis. Now consider the following $\mathbb{C}$-bilinear forms on this space:

$$B(u^mv_i,u^nv_j)=u^m(-u^n)\delta_{i,-j},$$

$$D(u^mv_i,u^nv_j)=u^m(-u^n)\delta_{i,1-j}.$$

Denote by $\overline{b}_\infty^{[m]}$ (respectively, $\overline{d}_\infty^{[m]}$) the Lie subalgebra of $\tilde{g}\ell_\infty^{[m]}$ which preserves the bilinear form B (respectively, D). We have

$$\overline{b}_\infty^{[m]}=\{(a_{ij}(u))_{i,j\in\mathbb{Z}}\in\widetilde{g\ell}_\infty^{[m]}\,|\,a_{ij}(u)=-a_{-j,-i}(-u)\},$$

$$\overline{d}_\infty^{[m]}=\{(a_{ij}(u))_{i,j\in\mathbb{Z}}\in\widetilde{g\ell}_\infty^{[m]}\,|\,a_{ij}(u)=-a_{1-j,1-i}(u)\}.$$

Denote by $b_\infty^{[m]}=\overline{b}_\infty^{[m]}\oplus R_m$ (respectively, $d_\infty^{[m]}=\overline{d}_\infty^{[m]}\oplus R_m$) the central extension of $\overline{b}_\infty^{[m]}$ (respectively, $\overline{d}_\infty^{[m]}$) given by the 2-cocycle defined in $\widetilde{g\ell}_\infty^{[m]}$. Both subalgebras inherit the form $\widehat{g\ell}_\infty^{[m]}$ the principal $\mathbb{Z}$-gradation and the triangular decomposition, (see Refs. 11 and 6 for notation)

$$b_\infty^{[m]}=\oplus_{j\in\mathbb{Z}}(b_\infty^{[m]})_j,\quad b_\infty^{[m]}=(b_\infty^{[m]})_+\oplus(b_\infty^{[m]})_0\oplus(b_\infty^{[m]})_-,$$

$$d_\infty^{[m]}=\oplus_{j\in\mathbb{Z}}(d_\infty^{[m]})_j,\quad d_\infty^{[m]}=(d_\infty^{[m]})_+\oplus(d_\infty^{[m]})_0\oplus(d_\infty^{[m]})_-.$$

In particular when $m=0$, we have the usual Lie subalgebras of $\widehat{g\ell}_\infty$, denoted by b_∞ (respectively, d_∞).

Denote by $L(b_\infty^{[m]};\lambda)$ [respectively, $L(d_\infty^{[m]};\lambda)$] the highest weight module over $b_\infty^{[m]}$ (respectively, $d_\infty^{[m]}$) with highest weight $\lambda\in(b_\infty^{[m]})_0^*$ [respectively $\lambda\in(d_\infty^{[m]})_0^*$] parametrized by ${}^b\vec{\lambda}\in(\mathbb{C}^\infty)^{m+1}$, $\vec{c}\in\mathbb{C}^{m+1}$, with

$$\vec{c}_i=\lambda(u^i),$$

$${}^b\vec{\lambda}_j^{(i)}=\lambda(u^iE_{j,j}-(-u)^iE_{-j,-j}),$$

[respectively, ${}^d\vec{\lambda}\in(\mathbb{C}^\infty)^{m+1}$, with ${}^d\vec{\lambda}_j^{(i)}=\lambda(u^iE_{j,j}-(-u)^iE_{1-j,1-j})$]. The superscripts b and d here mean B and D type, respectively. The ${}^b\vec{\lambda}_j^{(i)}$ (respectively, ${}^d\vec{\lambda}_j^{(i)}$) are called the labels and $\vec{c}_j$ the central charges of $L(b_\infty^{[m]};\lambda)$ [respectively, $L(d_\infty^{[m]};\lambda)$].

All these modules will appear in Sec. V. Now, we are interested in representation theory of b_∞.

The set of simple coroots of b_∞, can be described as follows [cf. Ref. 11]:

$$\Pi^\vee=\{\alpha_0{}^\vee=2(E_{-1,-1}-E_{1,1})+2C,$$

$$\alpha_i{}^\vee=E_{i,i}-E_{i+1,i+1}-E_{-i,-i}+E_{-1-i,-1-i},\ i\in\mathbb{N}\}.$$

The set of roots is

$$\Delta=\{\pm\varepsilon_0,\ \pm\varepsilon_i,\ \pm\varepsilon_i\pm\varepsilon_j,\ i\neq j,\ i,j\in\mathbb{N}\}.$$

The set of positive coroots is

$$\Delta_+{}^\vee=\{\alpha_i{}^\vee+\alpha_{i+1}{}^\vee+\cdots+\alpha_j{}^\vee,\ 0\leqslant i\leqslant j\}\cup\{\alpha_0{}^\vee+2\alpha_1{}^\vee+\cdots+2\alpha_i{}^\vee+\alpha_{i+1}{}^\vee+\cdots+\alpha_{j-1}{}^\vee,\ 1\leqslant i<j\}.$$

The set of simple roots

$$\Pi=\{\alpha_0=-\varepsilon_1,\ \alpha_i=\varepsilon_i-\varepsilon_{i+1},\ i\in\mathbb{N}\}.$$

Here ε_i are viewed restricted to the restricted dual of the Cartan subalgebra of b_∞, so that $\varepsilon_i=-\varepsilon_{-i}$. Given $\lambda\in(b_\infty)_0^*$, the labels and central charge are simply (in this case, we skip the superscript b)

$$\lambda_i=\lambda(E_{i,i}-E_{-i,-i}),\quad i>0,\quad c=\lambda(C).$$

So that $\lambda(\alpha_0{}^\vee)=2c-2\lambda_1$ and $\lambda(\alpha_i{}^\vee)=\lambda_i-\lambda_{i+1}$ for $i\in\mathbb{N}$. Denote by Λ_i the ith fundamental weight of b_∞, namely $\Lambda_i(\alpha_j{}^\vee)=\delta_{i,j}$.

Let $P_+=\{\lambda\in(b_\infty)_0^*\,|\,\langle\lambda,\alpha_i{}^\vee\rangle\in\mathbb{Z}_+$, for all $i\in\mathbb{Z}_+\}$ denote the set of dominant integral weights of b_∞. Given $\lambda\in P_+$, we have $\lambda=\Lambda_{n_1}+\Lambda_{n_2}+\cdots+\Lambda_{n_k}+h\Lambda_0$, $n_1\geqslant n_2\geqslant\cdots\geqslant n_k\geqslant 1$, $h\in\mathbb{Z}_+$, and the module $L(b_\infty;\lambda)$ has central charge $c=k+h/2$. Observe that the conjugate of the Young diagram corresponding to the partition $(n_1,n_2,\ldots,n_k)$ is $(\lambda_1,\ldots,\lambda_{n_1})$, and $\lambda_i=0$ for $i>n_1$. Note that $n_1=n_1(\lambda)=\max\{i\in\mathbb{N}\,|\,\langle\lambda,\alpha_i\rangle\neq 0\}$. Observe that $\mathfrak{so}(2n_1+1)$ may be viewed as a subalgebra of b_∞ in a natural way, whose set of simple roots is $\{-\varepsilon_1,\varepsilon_1-\varepsilon_2,\ldots,\varepsilon_{n_1-1}-\varepsilon_{n_1}\}$. Denote by $\overline{\lambda}$ the dominant integral weight of $\mathfrak{so}(2n_1+1)$ given by $\overline{\lambda}(2(E_{-1,-1}-E_{1,1}))=2(c-\lambda_1)$ and $\overline{\lambda}(E_{i,i}-E_{i+1,i+1}-E_{-i,-i}+E_{-1-i,-1-i})=\lambda_i-\lambda_{i+1}$ for $1\leqslant i<n_1$. Denote by $\overline{L(\lambda)}$ the (irreducible) $\mathfrak{so}(2n_1+1)$-submodule of $L(b_\infty;\lambda)$ generated by its highest weight vector. It is, of course, isomorphic to the finite-dimensional irreducible $\mathfrak{so}(2n_1+1)$-module associated to $\overline{\lambda}$, so that its q-character is a (well-known) polynomial in q.

Lemma 2.3: Let $\lambda\in P_+$, $n_1=n_1(\lambda)$. *Then*

$$\mathrm{ch}_q L(b_\infty;\lambda)=\mathrm{ch}_q\overline{L(\lambda)}\prod_{j=1}^{n_1}\frac{1}{(1-q^j)_q^{\lambda_{n_1-j+1}}}\prod_{i=1}^{n_1}\frac{1}{(1-q^{n_1+i})_q^{2c-\lambda_i}}\prod_{n_1\leqslant i}\frac{1}{(1-q^{2i+1})_q^{2c}},$$

where $(1-a)_q^m=(1-a)(1-qa)\cdots(1-q^{m-1}a)$.

Proof: The proof is completely similar to the one of Lemma 2.1, using the data introduced above (cf. proof of Proposition 1.1 in Ref. 11).

□

Theorem 2.4: *All nontrivial modules* $L(b_\infty^{[m]};\lambda)$ *have infinite growth.*

Proof: It is enough to consider the case $m=0$. Given $\lambda \in (b_\infty)_0^*$, we look at the subalgebra of b_∞ isomorphic to $g\ell_{+\infty}$ spanned by all $E_{i,j}-E_{-j,-i}$ with $i,j\geqslant 1$, and by Theorem 2.2, we conclude that $L(b_\infty;\lambda)$ has infinite growth if $\lambda_i-\lambda_{i+1}\notin \mathbb{Z}_+$ for some $i\geqslant 1$.

Let us assume $\lambda_i-\lambda_{i+1}\in\mathbb{Z}_+$ for all $i\geqslant 1$. If $2c-2\lambda_1\notin\mathbb{Z}_+$, then $(E_{1,0}-E_{0,-1})^N v_\lambda\neq 0$ for each $N\in\mathbb{Z}_+$. Looking at the subalgebra of b_∞ isomorphic to $g\ell_{+\infty}$ previously defined, we conclude from Theorem 2.2 that

$$\operatorname{growth} L(b_\infty;\lambda)\geqslant N+\sum_{i\geqslant 1}\lambda_i .$$

If $2c-2\lambda_1\in\mathbb{Z}_+$, then by the same argument in the proof of Theorem 2.2, and looking at the last factor in Lemma 2.3, we conclude that $L(b_\infty;\lambda)$ has the same growth as the polynomial algebra in infinitely many generators, finishing the proof.

□

C. Lie algebra $c_\infty^{[m]}$

As before, we consider the vector space $R_m[t,t^{-1}]$, and take the R_m-basis $v_i=t^{-i}$, $i\in\mathbb{Z}$. Denote by $\overline{c}_\infty^{[m]}$ the Lie subalgebra of $\widetilde{g\ell}_\infty^{[m]}$ which preserves the bilinear form

$$C(u^m v_i,u^n v_j)=u^m(-u^n)(-1)^i\,\delta_{i,1-j}. \tag{2.5}$$

We have

$$\overline{c}_\infty^{[m]}=\{(a_{ij}(u))_{i,j\in\mathbb{Z}}\in\widetilde{g\ell}_\infty^{[m]}\mid a_{ij}(u)=(-1)^{i+j+1}a_{1-j,1-i}(-u)\}.$$

Denote by $c_\infty^{[m]}=\overline{c}_\infty^{[m]}\oplus R_m$ the central extension of $\overline{c}_\infty^{[m]}$ given by the 2-cocycle defined in $\widetilde{g\ell}_\infty^{[m]}$. This subalgebra inherits the form $\widehat{g\ell}_\infty^{[m]}$ of the principal $\mathbb{Z}$-gradation and the triangular decomposition (see Refs. 11 and 6 for notation)

$$c_\infty^{[m]}=\oplus_{j\in\mathbb{Z}}(c_\infty^{[m]})_j,\quad c_\infty^{[m]}=(c_\infty^{[m]})_+\oplus(c_\infty^{[m]})_0\oplus(c_\infty^{[m]})_- .$$

In particular when $m=0$, we have the usual Lie subalgebra of $\widehat{g\ell}_\infty$, denoted by c_∞ (see Ref. 6).

Denote by $L(c_\infty^{[m]};\lambda)$ the highest weight module over $c_\infty^{[m]}$ with highest weight $\lambda\in(c_\infty^{[m]})_0^*$ parametrized by its labels ${}^c\vec{\lambda}\in(\mathbb{C}^\infty)^{m+1}$ and central charges $\vec{c}\in\mathbb{C}^{m+1}$, with

$$\vec{c}_i=\lambda(u^i),$$

$${}^c\vec{\lambda}_j^{(i)}=\lambda(u^i E_{j,j}-(-u)^i E_{1-j,1-j}).$$

Now, we are interested in representation theory of c_∞.

The set of simple coroots of c_∞, denoted by $\Pi^\vee$, can be described as follows (cf. Ref. 11):

$$\Pi^\vee=\{\alpha_0{}^\vee=E_{0,0}-E_{1,1}+C,$$

$$\alpha_i{}^\vee=E_{i,i}-E_{i+1,i+1}+E_{-i,-i}-E_{1-i,1-i},\ i\in\mathbb{N}\}.$$

The set of roots is

$$\Delta=\{\pm 2\varepsilon_i,\ \pm\varepsilon_i\pm\varepsilon_j,\ i\neq j,\ i,j\in\mathbb{N}\}.$$

The set of positive coroots is

$$\Delta_+{}^\vee=\{\alpha_i{}^\vee+\alpha_{i+1}{}^\vee+\cdots+\alpha_j{}^\vee,\ 0\leqslant i\leqslant j\}\cup\{2\alpha_0{}^\vee+2\alpha_1{}^\vee+\cdots+2\alpha_i{}^\vee+\alpha_{i+1}{}^\vee+\cdots+\alpha_j{}^\vee,\ 0\leqslant i<j\}.$$

The set of simple roots is

$$\Pi=\{\alpha_0=-2\varepsilon_1,\ \alpha_i=\varepsilon_i-\varepsilon_{i+1},\ i\in\mathbb{N}\}.$$

Here ε_i are viewed restricted to the restricted dual of the Cartan subalgebra of c_∞, so that $\varepsilon_i=-\varepsilon_{1-i}$. Given $\lambda\in(c_\infty)_0^*$, the labels and central charge are simply (in this case, we skip the superscript c):

$$\lambda_j=\lambda(E_{j,j}-E_{1-j,1-j}),\quad j\in\mathbb{N},\quad c=\lambda(C).$$

So that $\lambda(\alpha_0\hat{})=-\lambda_1+c$ and $\lambda(\alpha_i\hat{})=\lambda_i-\lambda_{i+1}$ for $i\in\mathbb{N}$. Denote by Λ_i the ith fundamental weight of b_∞, namely $\Lambda_i(\alpha_j\hat{})=\delta_{i,j}$.

Let $P_+=\{\lambda\in(c_\infty)_0^*\mid\langle\lambda,\alpha_i\hat{}\rangle\in\mathbb{Z}_+,\text{for all } i\in\mathbb{Z}_+\}$ denote the set of dominant integral weights of c_∞. Given $\lambda\in P_+$, we have $\lambda=\Lambda_{n_1}+\Lambda_{n_2}+\cdots+\Lambda_{n_k}+h\Lambda_0$, $n_1\geqslant n_2\geqslant\cdots\geqslant n_k\geqslant 1$, $h\in\mathbb{Z}_+$, and the module $L(c_\infty,\lambda)$ has central charge $c=k+h$. Observe that the conjugate of the Young diagram corresponding to the partition $(n_1,n_2,\ldots,n_k)$ is $(\lambda_1,\ldots,\lambda_{n_1})$, and $\lambda_i=0$ for $i>n_1$. Note that $n_1=n_1(\lambda)=\max\{i\in\mathbb{N}\mid\langle\lambda,\alpha_i\rangle\neq 0\}$. Observe that $\mathfrak{sp}(2n_1)$ may be viewed as a subalgebra of c_∞ in a natural way, whose set of simple roots is $\{-2\varepsilon_1,\varepsilon_1-\varepsilon_2,\ldots,\varepsilon_{n_1-1}-\varepsilon_{n_1}\}$. Denote by $\overline{\lambda}$ the dominant integral weight of $\mathfrak{sp}(2n_1)$ given by $\overline{\lambda}((E_{0,0}-E_{1,1}))=c-\lambda_1$ and $\overline{\lambda}(E_{i,i}-E_{i+1,i+1}+E_{-i,-i}-E_{1-i,1-i})=\lambda_i-\lambda_{i+1}$ for $1\leqslant i<n_1$. Denote by $\overline{L(\lambda)}$ the (irreducible) $\mathfrak{sp}(2n_1)$-submodule of $L(c_\infty,\lambda)$ generated by its highest weight vector. It is, of course, isomorphic to the finite-dimensional irreducible $\mathfrak{sp}(2n_1)$-module associated to $\overline{\lambda}$, so that its q-character is a (well-known) polynomial in q.

Lemma 2.5: Let $\lambda\in P_+$, $n_1=n_1(\lambda)$. *Then*

$$\mathrm{ch}_q L(c_\infty;\lambda)=\mathrm{ch}_q\overline{L(\lambda)}\prod_{i=1}^{n_1}\frac{1}{(1-q^j)_q^{\lambda_{n_1-j+1}}}\cdot\prod_{i=1}^{n_1}\frac{1}{(1-q^{n_1+i+3})_q^{2c-\lambda_{i+1}}}$$
$$\times\frac{1}{(1-q^{n_1+1})_q^{c}}\prod_{n_1\leqslant i}\frac{1}{(1-q^{2i+3})_q^{2c}},$$

where $(1-a)_q^m=(1-a)(1-qa)\cdots(1-q^{m-1}a)$.

Proof: The proof is completely similar to the one of Lemma 2.1, using the data introduced above (cf. proof of Proposition 1.1 in Ref. 11).

□

Theorem 2.6: *All nontrivial modules* $L(c_\infty^{[m]};\lambda)$ *have infinite growth.*

Proof: It is enough to consider the case $m=0$. Given $\lambda\in(c_\infty)_0^*$, we look at the subalgebra of c_∞ isomorphic to $g\ell_{+\infty}$ spanned by all $E_{i,j}-E_{1-j,1-i}$ with $i,j\geqslant 1$, and by Theorem 2.2, we conclude that $L(c_\infty,\lambda)$ has infinite growth if $\lambda_i-\lambda_{i+1}\notin\mathbb{Z}_+$ for some $i\geqslant 1$.

Let us assume $\lambda_i-\lambda_{i+1}\in\mathbb{Z}_+$ for all $i\geqslant 1$. If $c-\lambda_1\notin\mathbb{Z}_+$, then $(E_{1,0})^N v_\lambda\neq 0$ for each $N\in\mathbb{Z}_+$. Looking at the subalgebra of c_∞ isomorphic to $g\ell_{+\infty}$ previously defined, we conclude from Theorem 2.2 that

$$\mathrm{growth}\,L(c_\infty,\lambda)\geqslant N+\sum_{i\geqslant 1}\lambda_i.$$

If $c-\lambda_1\in\mathbb{Z}_+$, then by the same argument in the proof of Theorem 2.2, and looking at the last factor in Lemma 2.3, we conclude that $L(c_\infty,\lambda)$ has the same growth as the polynomial algebra in infinitely many generators, finishing the proof.

□

III. IRREDUCIBLE FINITE GROWTH gc_1-MODULES

We are interested in representation theory of the Lie algebra $\mathcal{D}^-$ of regular differential operators on $\mathbb{C}$. It consists of linear combinations of differential operators of the form $f(t)\times(d/dt)^m$, where f is a polynomial and $m\in\mathbb{Z}_+$. In particular, $D=t(d/dt)\in\mathcal{D}^-$. The principal $\mathbb{Z}$-gradation $\mathcal{D}^-=\oplus_{j\in\mathbb{Z}}\mathcal{D}^-_j$ is defined by letting

$$\deg t=-1 \quad \deg\frac{d}{dt}=1.$$

Given a sequence of complex numbers $\Delta=(\Delta_0,\Delta_1,\ldots)$ we define the highest weight module $L(\Delta;\mathcal{D}^-)$ over $\mathcal{D}^-$ as the (unique) irreducible module that has a nonzero vector v_Δ with the following properties:

$$\mathcal{D}^-_j v_\Delta=0 \quad \text{for } j<0, \quad D^n v_\Delta=\Delta_n v_\Delta \quad \text{for } n\in\mathbb{Z}_+.$$

The principal gradation of $\mathcal{D}^-$ induces the principal gradation $L(\Delta;\mathcal{D}^-)=\oplus_{j\in\mathbb{Z}_+}L_j$ such that $L_0=\mathbb{C}v_\Delta$. The module $L(\Delta;\mathcal{D}^-)$ is called *quasifinite* if $\dim L_j<\infty$ for all $j\in\mathbb{Z}_+$.

Quasifinite modules over $\mathcal{D}^-$ can be constructed as follows. Consider the natural action of $\mathcal{D}^-$ on $\mathbb{C}[t,t^{-1}]$ and choose the basis $v_j=t^{-j}(j\in\mathbb{Z})$ of $\mathbb{C}[t,t^{-1}]$. This gives an embedding of $\mathcal{D}^-$ in $\widetilde{g\ell}_\infty$. Since $\mathbb{C}[t]$ is $\mathcal{D}^-$-invariant, we get $\mathcal{D}^-$-modules $\mathbb{C}[t,t^{-1}]/\mathbb{C}[t]$ and $\mathbb{C}[t]$, which gives us an embedding of $\mathcal{D}^-$ in $\widetilde{g\ell}_{+\infty}$ and $\widetilde{g\ell}_{-\infty}$, respectively, hence an embedding of $\mathcal{D}^-$ in $\widetilde{g\ell}_{+\infty}\oplus\widetilde{g\ell}_{-\infty}$. All these embeddings respect the principal gradations. Now take $\lambda^\pm\in\mathbb{C}^{\pm\infty}$ and consider the $\widetilde{g\ell}_{+\infty}\oplus\widetilde{g\ell}_{-\infty}$-module $L^+(\lambda^+)\otimes L^-(\lambda^-)$. The same argument as in Ref. 10, gives us the following.

Lemma 3.1: When restricted to $\mathcal{D}^-$, the module $L^+(\lambda^+)\otimes L^-(\lambda^-)$ remains irreducible.

It follows immediately that $L^+(\lambda^+)\otimes L^-(\lambda^-)$ is an irreducible highest weight module over $\mathcal{D}^-$, which is obviously quasifinite. It is easy to see that we have

$$\Delta_n=\sum_{j\geqslant 1}(-j)^n\lambda_j^+ +\sum_{j\leqslant 0}(-j)^n\lambda_j^-,$$

so that

$$\Delta(x):=\sum_{n\geqslant 0}\Delta_n x^n/n!=\sum_{j\geqslant 1}\lambda_j^+ e^{-jx}+\sum_{j\leqslant 0}\lambda_j^- e^{-jx}.$$

It is also clear that for $\lambda^\pm\in\mathrm{Par}^\pm$ we have (cf. Theorem 1a):

$$\mathrm{growth}\, L^+(\lambda^+)\otimes L^-(\lambda^-)=|\lambda^+|+|\lambda^-|.$$

We shall prove the following theorem.

Theorem 3.2: *The $\mathcal{D}^-$-modules $L^+(\lambda^+)\otimes L^-(\lambda^-)$, where $\lambda^\pm\in\mathrm{Par}^\pm$, exhaust all quasifinite irreducible highest weight $\mathcal{D}^-$-modules that have finite growth.*

Let $\mathcal{D}$ denote the Lie algebra of all regular differential operators on $\mathbb{C}^*$. The Lie algebra $\mathcal{D}$ is the linear span of differential operators $f(t)(d/dt)^k$, where $f(t)\in\mathbb{C}[t,t^{-1}]$ and $k\in\mathbb{Z}_+$, or, equivalently of operators $t^k f(D)$, where $f(D)\in\mathbb{C}[D]$ and $k\in\mathbb{Z}$. Obviously, $\mathcal{D}^-$ is a subalgebra of $\mathcal{D}$, and the principal gradation extends from $\mathcal{D}^-$ to $\mathcal{D}$ in the obvious way.

The basic idea of the proof of Theorem 3.2 is the same as in Ref. 10: to reduce the problem to the well developed (in Ref. 10) representation theory of the universal central extension $\hat{\mathcal{D}}$ of $\mathcal{D}$. Recall that the central extension $\hat{\mathcal{D}}=\mathcal{D}+\mathbb{C}C$ is defined by the cocycle[10]

$$\Psi\left(f(t)\left(\frac{d}{dt}\right)^m, g(t)\left(\frac{d}{dt}\right)^n\right)=\mathrm{Res}_0\, dt\, f^{(n+1)}(t)g^{(m)}(t). \tag{3.1}$$

The principal gradation of $\mathcal{D}$ lifts to $\hat{\mathcal{D}}$ by letting $\deg C=0$. Note also that the restriction of the cocycle Ψ to $\mathcal{D}^-$ is zero.

For each $s\in\mathbb{C}$ one defines a Lie algebra homomorphism $\varphi_s:\mathcal{D}\to\widetilde{g\ell}_\infty$ (via the action of $\mathcal{D}$ on $t^s\mathbb{C}[t,t^{-1}]$) by

$$\varphi_s(t^k f(D))=\sum_{j\in\mathbb{Z}} f(-j+s)E_{j-k,j}\,. \tag{3.2}$$

This homomorphism lifts to a homomorphism of central extension $\hat{\varphi}_s:\hat{\mathcal{D}}\to\widehat{g\ell}_\infty$ by

$$\begin{aligned}&\hat{\varphi}_s(t^k f(D))=\varphi_s(t^k f(D))\text{if}\quad k\neq 0\,,\\ &\hat{\varphi}_s(e^x D)=\varphi_s(e^{xD})-\frac{e^{sx}-1}{e^x-1},\hat{\varphi}_s(C)=C\,.\end{aligned} \tag{3.3}$$

More generally, for each $m\in\mathbb{Z}_+$ one defines a homomorphism $\varphi_s^{[m]}:\mathcal{D}\to\widetilde{g\ell}_\infty^{[m]}$ by

$$\varphi_s^{[m]}(t^k f(D))=\sum_{j\in\mathbb{Z}} f(-j+s+u)E_{j-k,j}=\sum_{i=0}^{m}\sum_{j\in\mathbb{Z}}\frac{f^{(i)}(-j+s)}{i}u^i E_{j-k,j}\,, \tag{3.4}$$

which lifts to $\hat{\varphi}_s^{[m]}:\hat{\mathcal{D}}\to\widehat{g\ell}_\infty^{[m]}$ in a similar way. One of the main results of Ref. 10 is the following.

Lemma 3.3: For each $i=1,\dots,r$, *pick a collection* $m_i\in\mathbb{Z}_+$, $s_i\in\mathbb{C}$, $\vec{\lambda}_i\in(\mathbb{C}^\infty)^{m_i+1}$, $\vec{c}_i\in\mathbb{C}^{m_i+1}$, *such that* $s_i-s_j\notin\mathbb{Z}$ *for* $i\neq j$. *Then the* $\oplus_{i=1}^r\widehat{g\ell}_\infty^{[m_i]}$*-module* $\otimes_{i=1}^r L^{[m_i]}(\vec{\lambda}_i,\vec{c}_i)$ *remains irreducible when restricted to* $\hat{\mathcal{D}}$ *via the embedding* $\oplus_{i=1}^r\hat{\varphi}_{s_i}^{[m_i]}:\hat{\mathcal{D}}\to\oplus_{i=1}^r\widehat{g\ell}_\infty^{[m_i]}$. *All irreducible quasifinite highest weight* $\hat{\mathcal{D}}$*-modules are obtained in this way.*

Proof of Theorem 3.2: Note that for $j\geqslant 1$ one has

$$\mathcal{D}_j^-=\{t^{-j}f(D)\,|\,f(0)=f(1)=\cdots=f(j-1)=0\}\,. \tag{3.5}$$

Hence $\mathcal{D}_j^-$ has finite codimension in $\mathcal{D}_j$ and therefore the quasifiniteness of a $\mathcal{D}^-$-module $L(\Delta;\mathcal{D}^-)$ implies the quasifiniteness of any of the $\hat{\mathcal{D}}$-modules $L(\Delta,c;\hat{\mathcal{D}})$. Due to Lemma 3.3, $L(\Delta,c;\hat{\mathcal{D}})$ is a tensor product of the $\widehat{g\ell}_\infty^{[m]}$-modules $L^{[m]}(\vec{\lambda},\vec{c})$ on which $\hat{\mathcal{D}}$ acts via the embedding $\hat{\varphi}_s^{[m]}$ defined by (3.2) and (3.3).

It is clear from Theorem 2.2 that all non-trivial modules $L^{[m]}(\vec{\lambda}_i,\vec{c}_i)$ have infinite growth (by choosing an appropriate subalgebra isomorphic to $g\ell_{+\infty}$ in $g\ell_\infty$).

Recall that for any quasifinite $\hat{\mathcal{D}}$-module one can extend the action of $\hat{\mathcal{D}}_j$ for $j\neq 0$ to $\hat{\mathcal{D}}_j^{\mathcal{O}}$, where $\mathcal{O}$ is the algebra of all holomorphic functions on $\mathbb{C}$,[10] in other words, in (3.2) and (3.3) one can take any $f\in\mathcal{O}$ if $j\neq 0$. The same holds for $\mathcal{D}^-$, except that for $j\geqslant 1$, f must obey conditions in (3.5). We apply this to the $\hat{\mathcal{D}}$-module $L(\widehat{g\ell}_\infty^{[m]};\vec{\lambda},\vec{c})$ on which $\hat{\mathcal{D}}$ acts via $\hat{\varphi}_s^{[m]}$.

Choosing $f\in\mathcal{O}$ such that for all $j\in\mathbb{Z}$:

$$f(-j+s)=\delta_{rj},\ f^{(i)}(-j+s)=0\quad\text{if}\quad i=1,\dots,m\,,$$

we see from (3.2) that all operators $E_{r+1,r}$ lie in the image of $\hat{\varphi}_s^{[m]}(\mathcal{D}^{-\mathcal{O}})$, except for $E_{1,0}$ when $s=0$ [here we use (3.5) for $j=1$]. Hence, when restricted to $\mathcal{D}^-$, the module $L^{[m]}(\vec{\lambda},\vec{c})$ remains irreducible, provided that $s\neq 0$. Thus, if $L(\Delta;\mathcal{D}^-)$ has finite growth, then $L(\Delta;\hat{\mathcal{D}})=L^{[m]}(\vec{\lambda},\vec{c})$ on which $\hat{\mathcal{D}}$ acts via the embedding $\hat{\varphi}_0^{[m]}$.

Choosing $f\in\mathcal{O}$ to vanish in all $j\in\mathbb{Z}$ up to mth derivative except for ith derivative ($0<i\leqslant m$) at $j=-r$, we see that all operators $u^i E_{r+1,r}$ with $0<i\leqslant m$ lie in the image of $\hat{\varphi}_s^{[m]}(\mathcal{D}^{-\mathcal{O}})$.

Suppose that the mth coordinate of $\vec{\lambda}_r$ is nonzero, and that $m>0$. Then $v:=(u^m E_{r+1,r})^N v_{\vec{\lambda}} \neq 0$ for all $N>0$. But

$$E_{rr}v=(-N+\lambda_r^0)v,\ E_{r+1,r+1}v=(N+\lambda_{r+1}^0)v.$$

Therefore, restricting to the subalgebra of $g\ell_\infty$ consisting of matrices $(a_{ij})_{i,j\leqslant r}$ or $(a_{ij})_{i,j\geqslant r+1}$ we conclude by Theorem 2.2, that $L(\widehat{g\ell_\infty^{[m]}};\vec{\lambda},\vec{c})$ is either trivial or is of infinite growth.

Thus, the only possibility that remains is $s=m=0$. As has been already shown, the image of $\hat{\varphi}_s(\mathcal{D}^{-\mathcal{O}})$ contains all $E_{r+1,r}$ except for $E_{1,0}$, hence it contains all operators from $g\ell_{-\infty} \oplus g\ell_{+\infty}$. Therefore, by Theorem 2.2, the highest weight of a finite growth $\mathcal{D}^-$-module must be the same as one of the $\mathcal{D}^-$-modules $L^+(\lambda^+)\otimes L^-(\lambda^-)$ with $\lambda^\pm \in \mathrm{Par}^\pm$.

□

Given two partitions $\lambda^\pm \in \mathrm{Par}^\pm$, we denote by $L(\lambda^+,\lambda^-)$ the $\mathcal{D}^-$-module, obtained by restriction via φ_0 from the $\widetilde{g\ell}_{+\infty}\oplus\widetilde{g\ell}_{-\infty}$-module $L^+(\lambda^+)\otimes L^-(\lambda^-)$. Now we shall construct the $\mathcal{D}^-$-modules $L(\lambda^+,\lambda^-)$ explicitly.

Consider the $\mathcal{D}^-$-module $\mathbb{C}[t,t^{-1}]$. Then $\mathbb{C}[t]$ is its maximal submodule (which is irreducible). Hence the $\mathcal{D}^-$-module

$$V:=\mathbb{C}[t,t^{-1}]/\mathbb{C}[t] \tag{3.6}$$

is irreducible. It is clear that this is the highest weight $\mathcal{D}^-$-module of growth 1 with a highest weight vector $t^{-1}+\mathbb{C}[t]$. It is immediate to deduce that V is isomorphic to $L(\omega_1,0)$ where $\omega_1=(1,0,\ldots)\in \mathrm{Par}^+$.

Likewise, the $\mathcal{D}^-$-module $\mathbb{C}[t]^*=\oplus_{j\in\mathbb{Z}_+}(\mathbb{C}t^j)^*$ is an irreducible highest weight module of growth 1 with a highest weight vector 1^*, hence it is isomorphic to $L(0,\omega_{-1})$, where $\omega_{-1}=(\ldots,0,-1)\in \mathrm{Par}^-$. We denote this $\mathcal{D}^-$-module by V'.

As in the Schur–Weyl theory, the $\mathcal{D}^-$-module $T^M(V)\otimes T^N(V')$ has a natural decomposition as $(\mathcal{D}^-,S_M\times S_N)$-modules:

$$T^M(V)\otimes T^N(V')=\bigoplus_{\substack{\lambda^\pm\in \mathrm{Par}^\pm\\ |\lambda^+|=M\\ |\lambda^-|=N}} (V_{\lambda^+}\otimes V'_{\lambda^-})\otimes(U_{\lambda^+}\otimes U_{\lambda^-}),$$

where $U_{\lambda^+ \text{ (respectively, } \lambda^-)}$ denotes the irreducible $S_{M \text{ (respectively, } N)}$-module corresponding to the partition λ^+ (respectively, λ^-).

Lemma 3.4: The $\mathcal{D}^-$-modules $V_{\lambda^+}\otimes V'_{\lambda^-}$ are irreducible.

Proof: As in the proof of Theorem 3.2, we extend the action of $\mathcal{D}^-$ on $V_{\lambda^+}\otimes V'_{\lambda^-}$ to $\mathcal{D}_j^{-\mathcal{O}}$ for each $j\neq 0$, to obtain that any $\mathcal{D}^-$-submodule of $V_{\lambda^+}\otimes V'_{\lambda^-}$ is a submodule over $g\ell_{+\infty}\oplus g\ell_{-\infty}$. But, by Schur–Weyl theory, the $g\ell_{+\infty}\oplus g\ell_{-\infty}$-module $V_{\lambda^+}\otimes V'_{\lambda^-}$ is irreducible, which completes the proof. □

Thus, we have proved the following.

Theorem 3.5: *The $\mathcal{D}^-$-module $L(\lambda^+,\lambda^-)$ is isomorphic to $V_{\lambda^+}\otimes V'_{\lambda^-}$ for any pair $\lambda^\pm \in \mathrm{Par}^\pm$.*

Remark: Considering $\lambda=(\lambda^-,\lambda^+)\in\mathbb{C}^\infty$ we may say that irreducible highest weight $\mathcal{D}^-$-modules of finite growth are parametrized by nonincreasing sequences of integers $(\lambda_j)_{j\in\mathbb{Z}}\in\mathbb{C}^\infty$ with the exception that $\lambda_0\leqslant\lambda_1$. Equivalently, letting $m_i=\lambda_i-\lambda_{i+1}$ we may say that these modules are parametrized by sequences of non-negative integers $(m_i)_{i\in\mathbb{Z}\setminus\{0\}}$, all but finite numbers of which are zero.

Recall that the extended annihilation algebra $\mathrm{Lie}^-(gc_1)$ for gc_1 is isomorphic to the direct sum of the Lie algebra $\mathcal{D}^-$ and the one-dimensional Lie algebra $\mathbb{C}[\partial+(d/dt)]$ and that conformal modules for a Lie conformal algebra coincide with the conformal modules over the associated extended annihilation algebra.[7]

Given a module M over a Lie conformal algebra R and $\alpha\in\mathbb{C}$, we may construct the α-twisted module M_α by replacing ∂ by $\partial+\alpha$ in the formulas for action of R on M. Theorems 3.2 and 3.5 and the above remarks imply the following.

Theorem 3.6: *The gc_1-modules $L(\lambda^+,\lambda^-)_\alpha$, where $\lambda^\pm\in\mathrm{Par}^\pm$, $\alpha\in\mathbb{C}$, exhaust all irreducible conformal gc_1-modules of finite growth.*

Corollary: The gc_1-modules $\mathbb{C}[\partial]_\alpha$ and $\mathbb{C}[\partial]^*_\alpha$, where $\alpha\in\mathbb{C}$, exhaust all finite irreducible gc_1-modules.

Remark: It is straightforward to generalize Theorems 3.2 and 3.5 to the case of $N\times N$ matrix differential operators and hence Theorem 3.6 to the case of gc_N. In particular the gc_N-modules $\mathbb{C}[\partial]^N_\alpha$ and $(\mathbb{C}[\partial]^N*)_\alpha$, where $\alpha\in\mathbb{C}$, exhaust all finite irreducible gc_N-modules. This is a result of Kac, Radul, and Wakimoto. Moreover, these authors completely described all finite gc_N-modules, which amounted to prove a complete reducibility result for finite modules over the annihilation algebra (see Ref. 8). It is an open question whether a similar complete reducibility result holds in the case of finite growth modules.

IV. IRREDUCIBLE FINITE GROWTH $gc_{1,x}$-MODULES

The results of this section are almost the same as the preceding section as well as the proofs. Therefore, we will skip the details.

Let $\mathcal{D}_0$ (respectively, $\mathcal{D}_0^-$) be the Lie subalgebra of $\mathcal{D}$ (respectively, $\mathcal{D}^-$) of all regular differential operators on $\mathbb{C}^*$ (respectively, $\mathbb{C}$) that kill constants. That is, $\mathcal{D}_0$ consists of linear combinations of elements of the form $t^kDf(D)$, where f is a polynomial. Denote by $\hat{\mathcal{D}}_0$ the corresponding central extension. These algebras inherit the $\mathbb{Z}$-gradation from $\hat{\mathcal{D}}$.

In this section, we will need the representation theory of the Lie algebra $\mathcal{D}_0^-$.

Given a sequence of complex numbers $\Delta=(\Delta_1,\Delta_2,\ldots)$ we define the highest weight module $L(\Delta;\mathcal{D}_0^-)$ over $\mathcal{D}_0^-$ as the (unique) irreducible module that has a nonzero vector v_Δ with the following properties:

$$(\mathcal{D}_0^-)_j v_\Delta=0 \quad \text{for } j<0, \quad D^n v_\Delta=\Delta_n v_\Delta \quad \text{for } n\in\mathbb{N}.$$

The principal gradation of $\mathcal{D}_0^-$ induces the principal gradation $L(\Delta;\mathcal{D}_0^-)$.

Quasifinite modules over $\mathcal{D}_0^-$ can be constructed as follows. The $\mathcal{D}_0^-$-modules $\mathbb{C}[t,t^{-1}]/\mathbb{C}[t]$ and $\mathbb{C}[t]/\mathbb{C}$, give us an embedding of $\mathcal{D}_0^-$ in $\widetilde{g\ell}_{+\infty}$ and $\widetilde{g\ell}_{-\infty}$, respectively, hence an embedding of $\mathcal{D}_0^-$ in $\widetilde{g\ell}_{+\infty}\oplus\widetilde{g\ell}_{-\infty}$. All these embeddings respect the principal gradations. Now take $\lambda^\pm\in\mathbb{C}^{\pm\infty}$ and consider the $\widetilde{g\ell}_{+\infty}\oplus\widetilde{g\ell}_{-\infty}$-module $L^+(\lambda^+)\otimes L^-(\lambda^-)$.

The same argument as in Ref. 10, gives us the following.

Lemma 4.1: When restricted to $\mathcal{D}_0^-$, the module $L^+(\lambda^+)\otimes L^-(\lambda^-)$ remains irreducible.

It follows immediately that $L^+(\lambda^+)\otimes L^-(\lambda^-)$ is an irreducible highest weight module over $\mathcal{D}_0^-$, which is obviously quasifinite.

We have the following theorem.

Theorem 4.2: *The $\mathcal{D}_0^-$-modules $L^+(\lambda^+)\otimes L^-(\lambda^-)$, where $\lambda^\pm\in\mathrm{Par}^\pm$, exhaust all quasifinite irreducible highest weight $\mathcal{D}_0^-$-modules that have finite growth.*

The proof of Theorem 4.2 is the same as Theorem 3.2, but in this case we reduce the problem to the representation theory of the universal central extension $\hat{\mathcal{D}}_0$ of $\mathcal{D}_0$ that was developed in Refs. 1 and 9.

Let $s\in\mathbb{Z}$ and denote by $\widehat{g\ell}^{[m]}_{\infty,s}$ the Lie subalgebra of $\widehat{g\ell}^{[m]}_\infty$ generated by C and $\{u^lE_{ij}|0\leqslant l\leqslant m, i\neq s \text{and } j\neq s\}$. Observe that $\widehat{g\ell}^{[m]}_{\infty,s}$ is naturally isomorphic to $\widehat{g\ell}^{[m]}_\infty$. Let $p_s:\widehat{g\ell}^{[m]}_\infty\to\widehat{g\ell}^{[m]}_{\infty,s}\to\widehat{g\ell}^{[m]}_\infty$ be the projection map composed with this isomorphism. If $s\notin\mathbb{Z}$, we also denote by $\hat{\varphi}^{[m]}_s$ the homomorphism (3.4) restricted to $\hat{\mathcal{D}}_0$. If $s\in\mathbb{Z}$, we redefine $\hat{\varphi}^{[m]}_s$ by the homomorphism $p_s\circ\hat{\varphi}^{[m]}_s:\hat{\mathcal{D}}_0\to\widehat{g\ell}^{[m]}_{\infty,s}$.

In this case, we should replace Lemma 3.3 by one of the results of Ref. 9 (see also Ref. 1):

Lemma 4.3: For each $i=1,\ldots,r$, *pick a collection* $m_i\in\mathbb{Z}_+$, $s_i\in\mathbb{C}$, $\vec{\lambda}_i\in(\mathbb{C}^\infty)^{m_i+1}$, $\vec{c}_i\in\mathbb{C}^{m_i+1}$, *such that* $s_i-s_j\notin\mathbb{Z}$ *for* $i\neq j$. *Then the* $\oplus_{i=1}^r\widehat{g\ell}_\infty^{[m_i]}$*-module* $\otimes_{i=1}^r L^{[m_i]}(\vec{\lambda}_i,\vec{c}_i)$ *remains irreducible when restricted to* $\hat{\mathcal{D}}_0$ *via the embedding* $\oplus_{i=1}^r\hat{\varphi}_{s_i}^{[m_i]}:\hat{\mathcal{D}}_0\to\oplus_{i=1}^r\widehat{g\ell}_\infty^{[m_i]}$. *All irreducible quasifinite highest weight* $\hat{\mathcal{D}}_0$*-modules are obtained in this way.*

Proof of Theorem 4.2: The proof is the same as Theorem 3.2 but use Lemma 4.3, and in the case $s=0$ one should use the redefined $\hat{\varphi}_0^{[m]}$.

□

Given two partitions $\lambda^\pm\in\mathrm{Par}^\pm$, the $\mathcal{D}^-$-module $L(\lambda^+,\lambda^-)$ that is obtained by restriction via φ_0 from the $\widetilde{g\ell}_{+\infty}\oplus\widetilde{g\ell}_{-\infty}$-module $L^+(\lambda^+)\otimes L^-(\lambda^-)$, remains irreducible as a $\mathcal{D}_0^-$-module. The construction of the $\mathcal{D}_0^-$-modules $L(\lambda^+,\lambda^-)$ is the same as before, and Lemma 3.4 and Theorem 3.5 holds for $\mathcal{D}_0^-$.

In this case, the extended annihilation algebra $\mathrm{Lie}^-(gc_{1,x})$ for $gc_{1,x}$ is isomorphic to the direct sum of the Lie algebra $\mathcal{D}_0^-$ and the one-dimensional Lie algebra $\mathbb{C}[\partial+(d/dt)]$. Theorems 4.2 and 3.5 and the above remarks imply the following.

Theorem 4.4: *The* $gc_{1,x}$*-modules* $L(\lambda^+,\lambda^-)_\alpha$, *where* $\lambda^\pm\in\mathrm{Par}^\pm$, $\alpha\in\mathbb{C}$, *exhaust all irreducible conformal* $gc_{1,x}$*-modules of finite growth.*

Corollary: The $gc_{1,x}$-modules $\mathbb{C}[\partial]_\alpha$ and $\mathbb{C}[\partial]_\alpha^*$, where $\alpha\in\mathbb{C}$, exhaust all finite irreducible $gc_{1,x}$-modules.

V. IRREDUCIBLE FINITE GROWTH oc_1-MODULES

Now, consider the anti-involution σ on $\mathcal{D}$ defined by (cf. Ref. 11)

$$\sigma(t)=t,\quad \sigma\left(\frac{d}{dt}\right)=-\frac{d}{dt}.$$

Denote by $\mathcal{D}_\sigma$ the fixed subalgebra of $\mathcal{D}$ by $-\sigma$, namely, $\mathcal{D}_\sigma=\{a\in\mathcal{D}\,|\,\sigma(a)=-a\}$. This subalgebra corresponds to the Lie algebra denoted by $\mathcal{D}^+$ in Ref. 11. Let $\hat{\mathcal{D}}_\sigma=\mathcal{D}_\sigma+\mathbb{C}C$ denote the central extension given by the restriction of the cocycle (3.1) on $\mathcal{D}$.

We are interested in representation theory of the Lie subalgebra $\mathcal{D}_\sigma^-=\mathcal{D}^-\cap\hat{\mathcal{D}}_\sigma$ of regular differential operators on $\mathbb{C}$ that are invariant by $-\sigma$. Both subalgebras inherit a $\mathbb{Z}$-gradation from $\mathcal{D}$, since σ preserve the principal $\mathbb{Z}$-gradation of $\mathcal{D}$, and we have $\mathcal{D}_\sigma=\oplus_{j\in\mathbb{Z}}(\mathcal{D}_\sigma)_j$, where

$$(\mathcal{D}_\sigma)_j=\{t^jg(D+(j+1)/2)\,|\,g(w)\in\mathbb{C}[w]\text{is odd}\}. \tag{5.1}$$

In the case of $(\mathcal{D}_\sigma^-)_j$, we need to add condition (3.5) for $j<0$.

Similarly, we have the corresponding subalgebras of $\mathcal{D}^{\mathcal{O}}$, denoted by $\mathcal{D}_\sigma^{\mathcal{O}}$ and $\mathcal{D}_\sigma^{-\mathcal{O}}$.

As in the case of $\mathcal{D}^-$, given a sequence of complex numbers $\Delta=\{\Delta_n\}_{n\in\mathbb{N}_{\mathrm{odd}}}$, we define the highest weight module $L(\Delta;\mathcal{D}_\sigma^-)$ over $\mathcal{D}_\sigma^-$ as the (unique) irreducible module that has a nonzero vector v_Δ with the following properties:

$$(\mathcal{D}_\sigma^-)_jv_\Delta=0\quad\text{for } j<0,\quad (D+1/2)^nv_\Delta=\Delta_nv_\Delta\quad\text{for } n\in\mathbb{N}_{\mathrm{odd}}.$$

The principal gradation of $\mathcal{D}_\sigma^-$ induces the principal gradation $L(\Delta;\mathcal{D}_\sigma^-)=\oplus_{j\in\mathbb{Z}_+}L_j$ such that $L_0=\mathbb{C}v_\Delta$. The module $L(\Delta;\mathcal{D}_\sigma^-)$ is called *quasifinite* if $\dim L_j<\infty$ for all $j\in\mathbb{Z}_+$.

Quasifinite modules over $\mathcal{D}_\sigma^-$ can be constructed as follows. The $\mathcal{D}_\sigma^-$-module $\mathbb{C}[t,t^{-1}]/\mathbb{C}[t]$ gives us an embedding of $\mathcal{D}_\sigma^-$ in $\widetilde{g\ell}_{+\infty}$. This embedding respect the principal gradations. Now take $\lambda^+\in\mathbb{C}^{+\infty}$ and consider the $\widetilde{g\ell}_{+\infty}$-module $L^+(\lambda^+)$ introduced in (2.1). The same argument as in Ref. 10, gives us the following.

Lemma 5.1: When restricted to $\mathcal{D}_\sigma^-$, *the module* $L^+(\lambda^+)$ *remains irreducible.*

Therefore $L^+(\lambda^+)$ is an irreducible quasifinite highest weight module over $\mathcal{D}_\sigma^-$, and it is easy to see that we have

$$\Delta_n=\sum_{j\geqslant 1}(-j+1/2)^n\lambda_j^+\,,\quad n\in\mathbb{N}_{\text{odd}}\,,$$

so that

$$\Delta(x):=\sum_{n\in\mathbb{N}_{\text{odd}}}\Delta_n x^n/n!=\sum_{j\geqslant 1}\lambda_j^+\,2\sinh((-j+1/2)x)\,.$$

We shall prove the following theorem.

Theorem 5.2: *The $\mathcal{D}_\sigma^-$-modules $L^+(\lambda^+)$, where $\lambda^+\in\mathrm{Par}^+$, exhaust all quasifinite irreducible highest weight $\mathcal{D}_\sigma^-$-modules that have finite growth.*

The basic idea of the proof of Theorem 5.2 is the same as in Theorem 3.2: to reduce the problem to the well developed (in Ref. 11) representation theory of the universal central extension $\hat{\mathcal{D}}_\sigma$.

Recall that the homomorphism $\hat{\varphi}_s^{[m]}:\hat{\mathcal{D}}\to\widehat{g\ell}_\infty^{[m]}$ defined in (3.4) lift to a homomorphism $\hat{\varphi}_s^{[m]}:\hat{\mathcal{D}}^{\mathcal{O}}\to\widehat{g\ell}_\infty^{[m]}$. Now, the restriction $\hat{\varphi}_s^{[m]}:\hat{\mathcal{D}}_\sigma^{\mathcal{O}}\to\widehat{g\ell}_\infty^{[m]}$ to $\hat{\mathcal{D}}_\sigma^{\mathcal{O}}$ is surjective iff $s\notin\mathbb{Z}/2$, and in the other cases, using (5.1), we have that (see Ref. 11 for details)

$$\hat{\varphi}_0^{[m]}:\hat{\mathcal{D}}_\sigma^{\mathcal{O}}\to d_\infty^{[m]}\,,\quad \hat{\varphi}_{-1/2}^{[m]}:\hat{\mathcal{D}}_\sigma^{\mathcal{O}}\to b_\infty^{[m]}\tag{5.2}$$

are surjective homomorphisms. Now, let us consider the restriction to $\mathcal{D}_\sigma^{-\mathcal{O}}$. Since the constrains given by (3.5) do not affect the case $s\neq 0$, we still have that $\hat{\varphi}_s^{[m]}:\mathcal{D}_\sigma^{-\mathcal{O}}\to\widehat{g\ell}_\infty^{[m]}$ $(s\notin\mathbb{Z}/2)$ and $\hat{\varphi}_{-1/2}^{[m]}:\mathcal{D}_\sigma^{-\mathcal{O}}\to b_\infty^{[m]}$ are surjective.

One of the main results of Ref. 11 is the following.

Lemma 5.3: For each $i=1,\ldots,r$, pick a collection $m_i\in\mathbb{Z}_+$, $s_i\in\mathbb{C}$, $\vec{\lambda}_i\in(\mathbb{C}^\infty)^{m_i+1}$, $\vec{c}_i\in\mathbb{C}^{m_i+1}$, such that $s_i\in\mathbb{Z}$ implies $s_i=0$, $s_i\in\frac{1}{2}+\mathbb{Z}$ implies $s_i=-\frac{1}{2}$, and $s_i-s_j\notin\mathbb{Z}$ for $i\neq j$. Then the $\oplus_{i=1}^r\mathfrak{g}^{[m_i]}$-module $\otimes_{i=1}^r L(\mathfrak{g}^{[m_i]};\vec{\lambda}_i,\vec{c}_i)$ remains irreducible when restricted to $\hat{\mathcal{D}}_\sigma$ via the embedding $\oplus_{i=1}^r\hat{\varphi}_{s_i}^{[m_i]}:\hat{\mathcal{D}}_\sigma\to\oplus_{i=1}^r\mathfrak{g}^{[m_i]}$, where $\mathfrak{g}^{[m_i]}=\widehat{g\ell}_\infty^{[m_i]}$ (respectively, $b_\infty^{[m_i]}$ or $d_\infty^{[m_i]}$) if $s_i\notin\mathbb{Z}/2$ (respectively, $s_i=-\frac{1}{2}$ or si=0). All irreducible quasifinite highest weight $\hat{\mathcal{D}}_\sigma$-modules are obtained in this way.

Proof of Theorem 5.2: The proof is similar to that of Theorem 3.2. Due to Lemma 5.3, Theorem 2.4 and (5.2), it is easy to see that if $L(\Delta;\mathcal{D}_\sigma^-)$ has finite growth, then $L(\Delta;\hat{\mathcal{D}}_\sigma)=L(d_\infty^{[m]};\vec{\lambda},\vec{c})$ on which $\hat{\mathcal{D}}_\sigma$ acts via the embedding $\hat{\varphi}_0^{[m]}$.

Choosing $f\in\mathcal{O}_{\text{odd}}$ to vanish in all $j\in\mathbb{Z}$ up to mth derivative except for ith derivative $(0<i\leqslant m)$ at $j=-r$, we see that all operators $u^iE_{r+1,r}-(-u)^iE_{-r+1,-r}$ with $0<i\leqslant m$ lie in the image of $\hat{\varphi}_0^{[m]}(\mathcal{D}_\sigma^{-\mathcal{O}})$.

Suppose that the mth coordinate of $\vec{\lambda}_r$ is nonzero, and that $m>0$. Then $v:=(u^mE_{r+1,r}-(-u)^iE_{-r+1,-r})^Nv_{\vec{\lambda}}\neq 0$ for all $N>0$. But

$$E_{r+1,r+1}v=(N+\lambda_{r+1}^0)v\,.$$

As in Theorem 3.2, restricting to the subalgebra of $d_\infty^{[m]}$ isomorphic to $g\ell_{+\infty}$ consisting of matrices $(a_{i,j}-a_{1-j,1-i})_{i,j\geqslant r+1}$ we conclude by Theorem 2.2, that $L(d_\infty^{[m]};\vec{\lambda},\vec{c})$ is either trivial or is of infinite growth.

Thus, the only possibility that remains is $s=m=0$. As has been already shown, the image of $\hat{\varphi}_s(\mathcal{D}_\sigma^{-\mathcal{O}})$ contains all $E_{r+1,r}-E_{1-r,-r}$ for all $r\neq 0$, hence it contains all operators from $d_\infty\cap(g\ell_{-\infty}\oplus g\ell_{+\infty})\simeq g\ell_{+\infty}$. Therefore, by Theorem 2.2, the highest weight of a finite growth $\mathcal{D}_\sigma^-$-module must be the same as one of the $\mathcal{D}_\sigma^-$-modules $L^+(\lambda^+)$ with $\lambda^+\in\mathrm{Par}^+$.

□

Now we shall construct the $\mathcal{D}_\sigma^-$-modules $L^+(\lambda^+)$ explicitly. The $\mathcal{D}^-$-module $V=\mathbb{C}[t,t^{-1}]/\mathbb{C}[t]$ defined in (3.6), viewed as a $\mathcal{D}_\sigma^-$-module, remains irreducible. This is the highest weight $\mathcal{D}_\sigma^-$-module of growth 1 isomorphic to $L^+(\omega_1)$ where $\omega_1=(1,0,\ldots)\in \mathrm{Par}^+$.

Observe that the $\mathcal{D}_\sigma^-$-module $\mathbb{C}[t]^*=\oplus_{j\in\mathbb{Z}_+}(\mathbb{C}t^j)^*$ is isomorphic to $L^+(\omega_1)$.

As in the Schur–Weyl theory, the $\mathcal{D}_\sigma^-$-module $T^M(V)$ has a natural decomposition as $(\mathcal{D}_\sigma^-,S_M)$-modules:

$$T^M(V)=\bigoplus_{\substack{\lambda^+\in \mathrm{Par}^+\\ |\lambda^+|=M}} V_{\lambda^+}\otimes U_{\lambda^+},$$

where U_{λ^+} denotes the irreducible S_M-module corresponding to the partition λ^+.

Lemma 5.4: The $\mathcal{D}_\sigma^-$-modules V_{λ^+} are irreducible.

Proof: As in the proof of Theorem 5.2, we extend the action of $\mathcal{D}_\sigma^-$ on V_{λ^+} to $(\mathcal{D}_\sigma^{-\mathcal{O}})_j$ for each $j\neq 0$, to obtain that any $\mathcal{D}_\sigma^-$-submodule of V_{λ^+} is a submodule over $g\ell_{+\infty}[\simeq d_\infty\cap(g\ell_{+\infty}\oplus g\ell_{-\infty})]$. But, by Schur–Weyl theory, the $g\ell_{+\infty}$-module V_{λ^+} is irreducible, which completes the proof. □

Thus, we have proved the following.

Theorem 5.5: *The $\mathcal{D}_\sigma^-$-module $T^M(V)$ has the following decomposition as $(\mathcal{D}_\sigma^-,S_M)$-modules:*

$$T^M(V)=\bigoplus_{\substack{\lambda^+\in \mathrm{Par}^+\\ |\lambda^+|=M}} L^+(\lambda^+)\otimes U_{\lambda^+},$$

where U_{λ^+} denotes the irreducible S_M-module corresponding to the partition λ^+.

Remark: Considering $\lambda^+\in\mathbb{C}^{+\infty}$ we may say that irreducible highest weight $\mathcal{D}_\sigma^-$-modules of finite growth are parametrized by nonincreasing sequences of integers $(\lambda_j)_{j\in\mathbb{N}}\in\mathbb{C}^{+\infty}$. Equivalently, letting $m_i=\lambda_i-\lambda_{i+1}$ we may say that these modules are parametrized by sequences of non-negative integers $(m_i)_{i\in\mathbb{N}}$, all but finite numbers of which are zero.

Recall that the extended annihilation algebra $\mathrm{Lie}^-(oc_1)$ for oc_1 is isomorphic to the direct sum of the Lie algebra $\mathcal{D}_\sigma^-$ and the one-dimensional Lie algebra $\mathbb{C}[\partial+d/dt]$ and that conformal modules for a Lie conformal algebra coincide with the conformal modules over the associated extended annihilation algebra.[7]

Theorems 5.2 and the above remarks imply the following.

Theorem 5.6: *The oc_1-modules $L^+(\lambda^+)_\alpha$, where $\lambda^+\in\mathrm{Par}^+$, $\alpha\in\mathbb{C}$, exhaust all irreducible conformal oc_1-modules of finite growth.*

Corollary: The gc_1-modules $L^+(\lambda^+)$, where $\lambda^+\in\mathrm{Par}^+$, remain irreducible when restricted to oc_1.

Corollary: The oc_1-modules $\mathbb{C}[\partial]_\alpha$, where $\alpha\in\mathbb{C}$, exhaust all finite irreducible oc_1-modules.

VI. IRREDUCIBLE FINITE GROWTH spc_1-MODULES

Now, consider the anti-involution $\overline{\sigma}$ on $\mathcal{D}_0$ defined by

$$\overline{\sigma}(t^kDf(D))=-t^kDf(-D-k).$$

This antiinvolution was studied by Bloch[2] in connection with the values of ζ-function.

Denote by $\mathcal{D}_{0,\overline{\sigma}}$ the Lie subalgebra of $\mathcal{D}_0$ fixed by $-\overline{\sigma}$. Let $\hat{\mathcal{D}}_{0,\overline{\sigma}}=\mathcal{D}_{0,\overline{\sigma}}+\mathbb{C}C$ denote the central extension given by the restriction of the cocycle on $\mathcal{D}$.

We are interested in representation theory of the Lie subalgebra $\mathcal{D}^-_{0,\overline{\sigma}}=\mathcal{D}^-\cap\hat{\mathcal{D}}_{0,\overline{\sigma}}$ of regular differential operators on $\mathbb{C}$ that kills constants and are invariant by $-\overline{\sigma}$. Both subalgebras inherit a $\mathbb{Z}$-gradation from $\mathcal{D}_0$, since $\overline{\sigma}$ preserve the principal $\mathbb{Z}$-gradation of $\mathcal{D}_0$: $\mathcal{D}_{0,\overline{\sigma}}=\oplus_{j\in\mathbb{Z}}(\mathcal{D}_{0,\overline{\sigma}})_j$, where

$$(\mathcal{D}_{0,\bar{\sigma}})_j=\left\{ t^j D\, g\left(D+\frac{j}{2}\right) \,\middle|\, g(w)\in\mathbb{C}[w]\text{is even} \right\}. \tag{6.1}$$

In the case of $(\mathcal{D}^-_{0,\bar{\sigma}})_j$, we need to add condition (3.5) for $j<0$.

Similarly, we have the corresponding subalgebras of $\mathcal{D}^{\mathcal{O}}$, denoted by $\mathcal{D}^{\mathcal{O}}_{0,\bar{\sigma}}$ and $\mathcal{D}^{-\mathcal{O}}_{0,\bar{\sigma}}$.

As in the case of $\mathcal{D}^-$, given a sequence of complex numbers $\Delta=\{\Delta_n\}_{n\in\mathbb{N}_{\text{odd}}}$, we define the highest weight module $L(\Delta;\mathcal{D}^-_{0,\bar{\sigma}})$ over $\mathcal{D}^-_{0,\bar{\sigma}}$ as the (unique) irreducible module that has a nonzero vector v_Δ with the following properties:

$$(\mathcal{D}^-_{0,\bar{\sigma}})_j v_\Delta=0 \quad \text{for } j<0, \quad D^n v_\Delta=\Delta_n v_\Delta \quad \text{for } n\in\mathbb{N}_{\text{odd}}.$$

The principal gradation of $\mathcal{D}^-_{0,\bar{\sigma}}$ induces the principal gradation $L(\Delta;\mathcal{D}^-_{0,\bar{\sigma}})=\oplus_{j\in\mathbb{Z}_+}L_j$ such that $L_0=\mathbb{C}v_\Delta$. The module $L(\Delta;\mathcal{D}^-_{0,\bar{\sigma}})$ is called *quasifinite* if $\dim L_j<\infty$ for all $j\in\mathbb{Z}_+$.

As in the preceding section, the $\mathcal{D}^-_{0,\bar{\sigma}}$-module $\mathbb{C}[t,t^{-1}]/\mathbb{C}[t]$ gives us an embedding of $\mathcal{D}^-_{0,\bar{\sigma}}$ in $\widetilde{g\ell}_{+\infty}$. This embedding respects the principal gradations. Now take $\lambda^+\in\mathbb{C}^{+\infty}$ and consider the $\widetilde{g\ell}_{+\infty}$-module $L^+(\lambda^+)$ introduced in (2.1). The same argument as in Ref. 10, gives us the following.

Lemma 6.1: When restricted to $\mathcal{D}^-_{0,\bar{\sigma}}$, the quasifinite module $L^+(\lambda^+)$ remains irreducible.

We shall prove the following theorem.

Theorem 6.2: *The $\mathcal{D}^-_{0,\bar{\sigma}}$-modules $L^+(\lambda^+)$, where $\lambda^+\in\text{Par}^+$, exhaust all quasifinite irreducible highest weight $\mathcal{D}^-_{0,\bar{\sigma}}$-modules that have finite growth.*

The basic idea of the proof of Theorem 6.2 is the same as in Theorem 3.2: to reduce the problem to the recently developed (in Ref. 4) representation theory of the universal central extension $\hat{\mathcal{D}}_{0,\bar{\sigma}}$.

Recall that the homomorphism $\hat{\varphi}^{[m]}_s:\hat{\mathcal{D}}\to\widehat{g\ell}^{[m]}_\infty$ defined in (3.4) lift to a homomorphism $\hat{\varphi}^{[m]}_s:\hat{\mathcal{D}}^{\mathcal{O}}\to\widehat{g\ell}^{[m]}_\infty$. Now, the restriction $\hat{\varphi}^{[m]}_s:\hat{\mathcal{D}}^{\mathcal{O}}_{0,\bar{\sigma}}\to\widehat{g\ell}^{[m]}_\infty$ to $\hat{\mathcal{D}}^{\mathcal{O}}_{0,\bar{\sigma}}$ is surjective iff $s\notin\mathbb{Z}/2$, and in the other case, using (6.1), we have that (see Ref. 2 for details)

$$\hat{\varphi}^{[m]}_s:\hat{\mathcal{D}}^{\mathcal{O}}_{0,\bar{\sigma}}\to c^{[m]}_\infty, \qquad s\in\mathbb{Z}/2 \tag{6.2}$$

is a surjective homomorphism. Now, let us consider the restriction to $\mathcal{D}^{-\mathcal{O}}_{0,\bar{\sigma}}$. Since the constrains given by (3.5) do not affect the case $s\neq0$, we still have that $\hat{\varphi}^{[m]}_s:\mathcal{D}^{-\mathcal{O}}_{0,\bar{\sigma}}\to\widehat{g\ell}^{[m]}_\infty$ $(s\notin\mathbb{Z}/2)$ and $\hat{\varphi}^{[m]}_{-1/2}:\mathcal{D}^{-\mathcal{O}}_{0,\bar{\sigma}}\to c^{[m]}_\infty$ are surjective.

One of the main results of Ref. 4 is the following.

Lemma 6.3: For each $i=1,\ldots,r$, pick a collection $m_i\in\mathbb{Z}_+$, $s_i\in\mathbb{C}$, $\vec{\lambda}_i\in(\mathbb{C}^\infty)^{m_i+1}$, $\vec{c}_i\in\mathbb{C}^{m_i+1}$, such that $s_i\in\mathbb{Z}$ implies $s_i=0$, $s_i\in\frac{1}{2}+\mathbb{Z}$ implies $s_i=-\frac{1}{2}$, and $s_i-s_j\notin\mathbb{Z}$ for $i\neq j$. Then the $\oplus^r_{i=1}\mathfrak{g}^{[m_i]}$-module $\otimes^r_{i=1}L(\mathfrak{g}^{[m_i]};\vec{\lambda}_i,\vec{c}_i)$ remains irreducible when restricted to $\hat{\mathcal{D}}_{0,\bar{\sigma}}$ via the embedding $\oplus^r_{i=1}\hat{\varphi}^{[m_i]}_{s_i}:\hat{\mathcal{D}}_{0,\bar{\sigma}}\to\oplus^r_{i=1}\mathfrak{g}^{[m_i]}$, where $\mathfrak{g}^{[m_i]}=\widehat{g\ell}^{[m_i]}_\infty$ (respectively, $c^{[m_i]}_\infty$) if $s_i\notin\mathbb{Z}/2$ (respectively, $s_i=-\frac{1}{2}$ or $s_i=0$). All irreducible quasifinite highest weight $\hat{\mathcal{D}}_{0,\bar{\sigma}}$-modules are obtained in this way.

Proof of Theorem 6.2: The proof is similar to that of Theorem 3.2. Due to Lemma 6.3, Theorem 2.6 and (6.2), it is easy to see that if $L(\Delta;\mathcal{D}^-_{0,\bar{\sigma}})$ has finite growth, then $L(\Delta;\hat{\mathcal{D}}_{0,\bar{\sigma}})=L(c^{[m]}_\infty;\vec{\lambda},\vec{c})$ on which $\hat{\mathcal{D}}_{0,\bar{\sigma}}$ acts via the embedding $\hat{\varphi}^{[m]}_0$.

Choosing $f\in\mathcal{O}_{\text{odd}}$ to vanish in all $j\in\mathbb{Z}$ up to mth derivative except for ith derivative $(0<i\leqslant m)$ at $j=-r$, we see that all operators $u^iE_{r+1,r}+(-u)^iE_{-r+1,-r}$ with $0<i\leqslant m$ lie in the image of $\hat{\varphi}^{[m]}_0(\mathcal{D}^{-\mathcal{O}}_{0,\bar{\sigma}})$.

Suppose that the mth coordinate of $\vec{\lambda}_r$ is nonzero, and that $m>0$. Then $v:=(u^mE_{r+1,r}+(-u)^iE_{-r+1,-r})^Nv_{\vec{\lambda}}\neq0$ for all $N>0$. But

$$E_{r+1,r+1}v=(N+\lambda^0_{r+1})v.$$

As in Theorem 3.2, restricting to the subalgebra of $c_\infty^{[m]}$ isomorphic to $g\ell_{+\infty}$ consisting of matrices $(a_{i,j}-(-1)^{i+j}a_{1-j,1-i})_{i,j\geqslant r+1}$ we conclude by Theorem 2.2, that $L(c_\infty^{[m]};\vec{\lambda},\vec{c})$ is either trivial or is of infinite growth.

Thus, the only possibility that remains is $s=m=0$. As has been already shown, the image of $\hat{\varphi}_s(\mathcal{D}^{-\mathcal{O}}_{0,\bar{\sigma}})$ contains all $E_{r+1,r}+E_{1-r,-r}$ for all $r\neq 0$, hence it contains all operators from $c_\infty\cap(g\ell_{-\infty}\oplus g\ell_{+\infty})\simeq g\ell_{+\infty}$. Therefore, by Theorem 2.2, the highest weight of a finite growth $\mathcal{D}^-_{0,\bar{\sigma}}$-module must be the same as one of the $\mathcal{D}^-_{0,\bar{\sigma}}$-modules $L^+(\lambda^+)$ with $\lambda^+\in \mathrm{Par}^+$.

□

As in the preceding section, we can construct the $\mathcal{D}^-_{0,\bar{\sigma}}$-modules $L^+(\lambda^+)$ explicitly. The $\mathcal{D}^-$-module $V=\mathbb{C}[t,t^{-1}]/\mathbb{C}[t]$ defined in (3.6), viewed as a $\mathcal{D}^-_{0,\bar{\sigma}}$-module, remains irreducible. This is the highest weight $\mathcal{D}^-_{0,\bar{\sigma}}$-module of growth 1 isomorphic to $L^+(\omega_1)$ where $\omega_1=(1,0,\ldots)\in \mathrm{Par}^+$.

Observe that the $\mathcal{D}^-_{0,\bar{\sigma}}$-module $\mathbb{C}[t]^*=\oplus_{j\in\mathbb{Z}_+}(\mathbb{C}t^j)^*$ is isomorphic to $L^+(\omega_1)$.

As in the Schur–Weyl theory, the $\mathcal{D}^-_{0,\bar{\sigma}}$-module $T^M(V)$ has a natural decomposition as $(\mathcal{D}^-_{0,\bar{\sigma}},S_M)$-modules:

$$T^M(V)=\bigoplus_{\substack{\lambda^+\in \mathrm{Par}^+\\ |\lambda^+|=M}} V_{\lambda^+}\otimes U_{\lambda^+},$$

where U_{λ^+} denotes the irreducible S_M-module corresponding to the partition λ^+.

Lemma 6.4: The $\mathcal{D}^-_{0,\bar{\sigma}}$-modules V_{λ^+} are irreducible.

Proof: As in the proof of Theorem 5.2, we extend the action of $\mathcal{D}^-_{0,\bar{\sigma}}$ on V_{λ^+} to $(\mathcal{D}^{-\mathcal{O}}_{0,\bar{\sigma}})_j$ for each $j\neq 0$, to obtain that any $\mathcal{D}^-_{0,\bar{\sigma}}$-submodule of V_{λ^+} is a submodule over $g\ell_{+\infty}[\simeq c_\infty\cap(g\ell_{+\infty}\oplus g\ell_{-\infty})]$. But, by Schur–Weyl theory, the $g\ell_{+\infty}$-module V_{λ^+} is irreducible, which completes the proof. □

Thus, we have proved the following.

Theorem 6.5: *The $\mathcal{D}^-_{0,\bar{\sigma}}$-module $T^M(V)$ has the following decomposition as $(\mathcal{D}^-_{0,\bar{\sigma}},S_M)$-modules:*

$$T^M(V)=\bigoplus_{\substack{\lambda^+\in \mathrm{Par}^+\\ |\lambda^+|=M}} L^+(\lambda^+)\otimes U_{\lambda^+},$$

where U_{λ^+} denotes the irreducible S_M-module corresponding to the partition λ^+.

Recall that the extended annihilation algebra $\mathrm{Lie}^-(spc_1)$ for spc_1 is isomorphic to the direct sum of the Lie algebra $\mathcal{D}^-_{0,\bar{\sigma}}$ and the one-dimensional Lie algebra $\mathbb{C}[\partial+(d/dt)]$ and that conformal modules for a Lie conformal algebra coincide with the conformal modules over the associated extended annihilation algebra.[7]

Theorems 6.2 and the above remarks imply the following.

Theorem 6.6: *The spc_1-modules $L^+(\lambda^+)_\alpha$, where $\lambda^+\in \mathrm{Par}^+$, $\alpha\in\mathbb{C}$, exhaust all irreducible conformal spc_1-modules of finite growth.*

Corollary: The gc_1-modules $L^+(\lambda^+)$, where $\lambda^+\in \mathrm{Par}^+$, remain irreducible when restricted to spc_1.

Corollary: The spc_1-modules $\mathbb{C}[\partial]_\alpha$, where $\alpha\in\mathbb{C}$, exhaust all finite irreducible spc_1-modules.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 2 FEBRUARY 2003

On the invariants of some solvable rigid Lie algebras

Rutwig Campoamor-Stursberg[a)]
Laboratoire de Mathématiques et Applications, Faculté de Sciences et Techniques, Université de Haute Alsace, 4, rue des Frères Lumière, F-68093 Mulhouse Cedex, France

(Received 5 April 2002; accepted 21 October 2002)

We determine fundamental systems of invariants for complex solvable rigid Lie algebras having nonsplit nilradicals of characteristic sequence (3,1,...,1), these algebras being the natural followers of solvable algebras having Heisenberg nilradicals. A special case of this allows us to obtain a criterion to determine the number of functionally independent invariants of rank one subalgebras of (real or complex) solvable Lie algebras. Finally, we give examples of the inverse procedure, obtaining fundamental systems of an algebra starting from rank one subalgebras, and a criterion for the nonexistence of nontrivial invariants. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1532536]

I. INTRODUCTION

An important problem arising in the theory of representations of Lie algebras and various physical applications is the determination of invariant functions for the coadjoint representation. These are useful for labeling irreducible representations or splitting arbitrary representations into irreducible ones. Reductions like the Levi decomposition theorem simplify the question to the classes of semi-simple and solvable Lie algebras. The invariants in the semi-simple case were determined in 1950 by Racah.[18] Here the invariants are polynomials, which correspond to classical Casimir operators (i.e., polynomials in the generators which are in the center of the universal enveloping algebra). Their number coincides with the rank of the algebra. The study of the non-semi-simple case is physically motivated by considerations like internal symmetries of particles or the invariant operators of symmetry groups of physical systems.[9,13] Important groups such as the Galilei and Poincaré groups have been deeply studied,[11–13,19] as well as the subgroups of the latter. These invariants allow us to characterize certain systems by giving their energy spectra, angular momenta, etc. For solvable Lie algebras, much less is known. These algebras have shown their interest in relation with the integrability problem of Hamiltonian systems. Their invariants have been determined up to dimension six.[15,17] The invariants found here need not be polynomials any more, which suggests calling them generalized invariants. The nonexistence of classifications of solvable algebras in dimension $n \geqslant 7$ forces us to restrict to more concrete classes. In this frame, the generalized Casimir invariants of solvable algebras having an Abelian or a Heisenberg Lie algebra as nilradical (i.e., as maximal nilpotent ideal) have recently been computed.[14,20] The choice of these maximal nilpotent ideals is not casual. The Heisenberg Lie algebra is the simplest nontrivial nilpotent Lie algebra, and has the lowest nilpotence index. Their deformations are of much interest in the study of Lie algebras of nilindex 2. However, for a solvable Lie algebra with arbitrary nilradical the invariants will not be inferrable in arbitrary dimension, either because the structure of the algebra depends on too many parameters or because of formidable computational obstructions.[20] However, if we restrict to the class of rigid (also called stable) Lie algebras, i.e., the algebras all of whose deformations lead to an equivalent structure, the number and form of the invariants can always be determined in arbitrary dimension, at least what concerns solvable algebras (the semi-simple being well known). This is a consequence of the structural properties of these algebras, which are determined, in some sense, by the action of semisimple elements on the

a)Electronic mail: r.campoamor@uha.fr

maximal nilpotent ideal. The main advantage of studying rigid algebras lies in the fact that the analysis of the invariants in low dimension will always allow us to determine the number and the form of the invariants in arbitrary dimension.

Starting from this situation, we determine fundamental systems of invariants for all solvable rigid Lie algebras whose nilradical is a nonsplit of characteristic sequence (3,1,...,1). These algebras are the natural followers of those having Heisenberg nilradicals. It is shown that the number of functionally independent invariants is a linear function of their rank. As applications, we deduce a general result on the cardinal of fundamental systems of invariants of rank one subalgebras of a solvable Lie algebra. The converse of this procedure, whenever possible, is also of interest, since it allows us to calculate fundamental systems of an algebra analyzing certain rank one subalgebras. In particular, we can find a criterion to ensure that a solvable Lie algebras has no nontrivial invariants.

We convene that nonwritten brackets are either zero or obtained by antisymmetry. We also use Einstein's convention for sums. Unless otherwise stated, any Lie algebra is nonsplit (i.e., it is not a direct sum of ideals) and complex.

II. GENERALITIES

Let G be a connected Lie group and $\mathfrak{g}$ its Lie algebra. As known, the coadjoint representation is given by

$$\mathrm{ad}^*: \mathrm{G} \to \mathrm{GL}(\mathfrak{g}^*): \quad (\mathrm{ad}_g^* x)(y) = x(\mathrm{ad}_{g^{-1}} y), \quad x, y \in \mathfrak{g}^*, g \in \mathrm{G} \tag{2.1}$$

and a function $F \in C^\infty \mathfrak{g}^*$ is called invariant if $F(x) = F(\mathrm{ad}_g^* x)$. Clearly it suffices to find a maximal set of functionally independent invariants to obtain all of them. Such a family is usually called a fundamental set of invariants for the coadjoint representation. The most extended method in the physical literature to obtain the invariants of a Lie algebra is not the orbit method,[9] but its reduction to the problem of solving a system of linear first order partial differential equations.[1] Low dimensional Lie algebras and subalgebras of the Poincaré algebra have been studied using this procedure.[14–17] Let $\mathfrak{g}$ be an n-dimensional Lie algebra with structure constants $\{C_{ij}^k\}$ over the basis $\{X_1, \ldots, X_n\}$. Let $\{x_1, \ldots, x_n\}$ be the dual basis and consider the differential operators

$$\widehat{X}_i = -C_{ij}^k x_k \frac{\partial}{\partial x_j}, \quad 1 \leqslant i \leqslant n. \tag{2.2}$$

These operators act on differentiable functions $f(x_1, \ldots, x_n) \in C^\infty(\mathfrak{g}^*)$. It is a straightforward verification that these operators satisfy the brackets

$$[\hat{X}_i, \hat{X}_j] = C_{ij}^k \hat{X}_k,$$

and therefore define a representation of $\mathfrak{g}$. Now an invariant is a function $F(x_1, \ldots, x_n)$ such that

$$\hat{X}_i F(x_1, \ldots, x_n) = 0, \quad 1 \leqslant i \leqslant n. \tag{2.3}$$

This reduces the problem to solve the system of partial differential equations (PDEs):

$$-C_{ij}^k x_k \frac{\partial}{\partial x_j} F(x_1, \ldots, x_n) = 0, \ 1 \leqslant i \leqslant n. \tag{2.4}$$

Since the solutions of this system are not necessarily polynomials, it is reasonable to call the solutions generalized Casimir invariants. If F is a polynomial solution of (2.4), then we obtain a Casimir operator by symmetrizing the polynomial with respect to the variables x_i and then substituting them by the corresponding generator X_i of the algebra. The corresponding bracket in the enveloping algebra satisfies

$$[X_i, F(X_1,\ldots,X_n)]=0, \tag{2.5}$$

which is easily seen to be equivalent to requirement (2.4). For rational invariants an analogous procedure is possible, by symmetrizing numerator and denominator and substituting properly.

The number of functionally independent invariants $\mathcal{N}$ of the coadjoint representation ad* of a Lie algebra $\mathfrak{g}$ can be computed by elementary algebraic means, as shown Beltrametti and Blasi.[5] They proved that

$$\mathcal{N}(\mathfrak{g})=\dim(\mathfrak{g})-sup_{x_1,\ldots,x_n}\{\text{rank } (C_{ij}^k x_k)\}, \tag{2.6}$$

where $(C_{ij}^k x_k)$ is the matrix representing the commutator table of $\mathfrak{g}$ for the chosen basis. Since the matrix $(C_{ij}^k x_k)$ is skew-symmetric, its rank is even, which implies that dim $(\mathfrak{g})$ and $\mathcal{N}(\mathfrak{g})$ have the same parity. However, the preceding formula does not distinguish whether the solutions are polynomials or not. Thus we will have $p \leqslant \mathcal{N}(\mathfrak{g})$ Casimir operators (and possibly none, as happens for the algebra of dilatations and translations in the plane, which has one rational solution[1]) for the general case.

The following example illustrates the method and the application of the Beltrametti–Blasi formula: Consider the four dimensional Lie algebra given by the brackets

$$[X_0,X_1]=X_2,$$

$$[X_0,X_2]=X_3,$$

over the basis $\{X_0,X_1,X_2,X_3\}$ (the representations of this algebra are used in the theory of anharmonic oscillators). The matrix associated to the commutator table is

$$\begin{pmatrix} 0 & x_2 & x_3 & 0 \\ -x_2 & 0 & 0 & 0 \\ -x_3 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}. \tag{2.7}$$

The rank of the matrix is two, so that this algebra has a fundamental set of invariants formed by two functions, which are solutions of the following system:

$$\hat{X}_0 F=(-x_2\partial_{x_2}-x_3\partial_{x_2})F=0, \tag{2.8}$$

$$\hat{X}_1 F=(x_2\partial_{x_0})F=0, \tag{2.9}$$

$$\hat{X}_2 F=(x_3\partial_{x_0})F=0, \tag{2.10}$$

$$\hat{X}_3 F=0. \tag{2.11}$$

The equations $\hat{X}_i F=0$ $(i=1,2)$ imply that F does not depend on x_0. From $\hat{X}_3 F=0$ we see that x_3 is a polynomial solution, while the equation $\hat{X}_1 F=0$ gives us the subsidiary equation

$$\frac{dx_1}{x_2}=\frac{dx_2}{x_3}, \tag{2.12}$$

which can be immediately integrated and gives the solution $x_2^2-2x_1x_3$. In this case both solutions are polynomials and correspond to classical Casimir operators.

As told before, invariants of solvable Lie algebras have been determined only in low dimensions, due to the impossibility of obtaining classifications in dimensions $n \geqslant 7$ (even the existing

classification of six dimensional solvable Lie algebras has been proven to contain mistakes). Two types of solvable algebras have been analyzed in some detail in arbitrary dimension: those having Abelian nilradical and those having it isomorphic to the Heisenberg Lie algebra $\mathfrak{h}_k$. An important class of solvable rigid Lie algebras consists of those algebras having a Heisenberg Lie algebra $\mathfrak{h}_k$ as nilradical. Since for rigid Lie algebras the torus determines almost completely the isomorphism class of the nilradical and these algebras decompose in a particular manner, in addition to the existing algorithms that allow (theoretically) a classification of solvable rigid Lie algebras,[4] it is reasonable to focus on this class and their invariants. We therefore recall the most elementary facts about rigidity:

The set $\mathcal{L}^n$ of all n-dimensional Lie algebras is well known to form an algebraic variety, on which the general linear group $\mathrm{GL}(n,\mathbb{C})$ acts as follows:

$$\phi*[X,Y]_{\mathfrak{g}}=\phi[\phi^{-1}X,\phi^{-1}Y]_{\mathfrak{g}},\quad x,y\in\mathfrak{g}, \tag{2.13}$$

where $[\_,\_]_{\mathfrak{g}}$ denotes the Lie bracket of $\mathfrak{g}$. The action is nothing more than the changes of basis, so that it is immediate that the orbit $\mathcal{O}(\mathfrak{g})$ of $\mathfrak{g}$ by this action consists of all Lie algebras isomorphic to $\mathfrak{g}$.

Definition 1: The algebra $\mathfrak{g}$ is called rigid if the orbit $\mathcal{O}(\mathfrak{g})$ is open in $\mathcal{L}^n$.

If an algebra $\mathfrak{g}$ does not admit nontrivial deformations, i.e., if it is rigid in the sense of Gerstenhaber, then its orbit is easily seen to be open. Indeed the classical definition of rigidity and Definition 1 are equivalent over $\mathbb{C}$. Rigidity imposes severe structural restrictions in the solvable case, which simplifies their description. Solvable rigid Lie algebras $\mathfrak{g}$ decompose as a semidirect product:

$$\mathfrak{g}=\mathfrak{n}\vec{\oplus}\mathfrak{t}, \tag{2.14}$$

where $\mathfrak{n}$ is the nilradical of $\mathfrak{g}$ and $\mathfrak{t}$ is an Abelian subalgebra consisting of ad-semisimple endomorphisms. Such an algebra will be called decomposable, and $\mathfrak{t}$ will called a torus of derivations. The similarity of this decomposition with the Cartan decomposition of classical algebras is suggested to consider a linear system of roots for solvable decomposable Lie algebras. These are formal linear systems for which the eigenvalues of the adjoint operators $\mathrm{ad}(X)$ for elements $X\in\mathfrak{t}$ are solutions. The rank of this system provides a useful criterion for the rigidity of a solvable Lie algebra.

Given a solvable rigid Lie algebra $\mathfrak{n}\vec{\oplus}\mathfrak{t}$, we say that $X\neq 0$ is a regular vector if the dimension of the kernel of the adjoint operator is minimal among the elements of $\mathfrak{t}$, i.e.,

$$\dim\ \mathrm{Ker}\,\mathrm{ad}(X)=\min\ \{\dim\ \mathrm{Ker}\,\mathrm{ad}(Y)\ \mid\ Y\in\mathfrak{t}\}. \tag{2.15}$$

If $q=\dim\ \mathrm{Ker}\,\mathrm{ad}(X)$, then we can find a basis formed by eigenvectors of the adjoint operator $(X_1,\ldots,X_n=X)$ such that $(X_1,\ldots,X_{p+q})$ is a basis of the nilradical $\mathfrak{n}$, $(X_{p+1+q},\ldots,X_n)$ is a basis of $\mathfrak{t}$ and $(X_{p+1},\ldots,X_n)$ is a basis of $\mathrm{Ker}\ \mathrm{ad}(X)$.

The linear system of roots associated to $(X_1,\ldots,X_n)$ is the linear system to $n-1$ variables x_i whose equations are

$$x_i+x_j=x_k \tag{2.16}$$

if the X_k-component of the bracket $[X_i,X_j]$ is nonzero. We will note this system by $S(X)$ or simply (S). The following result establishes a necessary condition for a Lie algebra to be rigid.[10]

Theorem 1: *(of the rank[10]) If the solvable, decomposable Lie algebra $\mathfrak{g}=\mathfrak{n}\vec{\oplus}\mathfrak{t}$ is rigid, then for all regular vectors X we have*

$$\mathrm{rank}\ \ S(X)=\dim\mathfrak{n}-1.$$

In particular the rank does not depend on the choice of the basis or the regular vector.

Corollary 1: If $\mathfrak{g}=\mathfrak{n}\vec{\oplus}\mathfrak{t}$ *is rigid, then* $\mathfrak{t}$ *is a maximal torus (for the inclusion relation).*

As an example of how the linear system is applied, let us consider the four dimensional subalgebra $P_{7,4}$ of the Poincaré algebra generated by $\{K_3, L_1-K_2, L_2+K_1, P_0-P_3\}$, where L_i denotes the rotation operators, K_i the boosts and P_j the translations.[1] $P_{7,4}$ is a solvable Lie algebra whose derived algebra $[P_{7,4}, P_{7,4}]$ is isomorphic to the three dimensional Abelian algebra $3A_1$. Therefore the system (S) associated to $P_{7,4}$ is zero (K_3 being a regular vector), and since $\dim(3A_1)-1\neq\operatorname{rank}(S)$, this algebra is not rigid. Indeed the minimal dimensional rigid Lie algebra which contains $P_{7,4}$ as subalgebra is $P_{7,2}$, which is generated by the above generators and $\{P_1, P_2\}$.[17]

For a decomposable algebra, we note the rank by $rg(\mathfrak{g})=\dim\ \mathfrak{t}$. If $\mathfrak{g}$ is rigid we can always find a regular vector such that the operator $\operatorname{ad}(X)$ is diagonalizable and its eigenvalues are integers.[10] The preceding results allow us to search for rigid laws either starting with a sequence of weights for a fixed regular vector X, or considering fixed nilpotent Lie algebras as nilradicals and analyzing their semisimple derivations. Since nilpotent Lie algebras are classified only for dimension $n\leqslant 7$, the latter method is valid in generic dimension only if we introduce a new invariant, called the characteristic sequence.[10] This invariant measures the dimension of successive Jordan blocks of the matrices of adjoint operators $\operatorname{ad}(X)$, and in particular it indicates the nilpotence index of the algebra. Let $\mathfrak{n}$ be a nilpotent Lie algebra and $X\in\mathfrak{n}-[\mathfrak{n},\mathfrak{n}]$ be a nonzero vector. We denote by $c(X)$ the ordered sequence of dimensions of the Jordan blocks for the adjoint operator $\operatorname{ad}(X)$. Considering the lexicographical order in the set of these sequences, i.e.,

$$(c_1,\ldots,c_t)\geqslant(c_1',\ldots,c_s')\Leftrightarrow\exists i \text{ such that } c_j=c_j' \text{ for } i>j \text{ and } c_i>c_i', \tag{2.17}$$

we define the characteristic sequence of $\mathfrak{g}$ as

$$c(\mathfrak{g})=\max_{X\in\mathfrak{g}-[\mathfrak{g},\mathfrak{g}]}\{c(X)\}. \tag{2.18}$$

A vector $X\neq 0$, $X\in\mathfrak{g}-[\mathfrak{g},\mathfrak{g}]$ satisfying $c(\mathfrak{g})=c(X)$ is called characteristic vector.

Example 1: Let $\mathfrak{n}$ *be a nilpotent Lie algebra.*

(i) *If* $c(\mathfrak{n})=(1,1,\ldots,1)$, *then for any element* $X\notin[\mathfrak{n},\mathfrak{n}]$ *the Jordan form of* $\operatorname{ad}(X)$ *is zero. This shows that* $\mathfrak{n}$ *is an Abelian Lie algebra.*

(ii) *If* $c(\mathfrak{n})=(2,1,\ldots,1)$, *then* $\mathfrak{n}$ *is an algebra of nilindex 2, i.e.,* $[X,[Y,Z]]=0$ *for any* $X,Y,Z\in\mathfrak{n}$. *We can find a basis* $\{X_1,\ldots,X_n\}$ *such that* X_1 *is a regular vector,* $[X_1,X_2]=X_3$ *and* $[X_1,X_i]=0$ *for* $i\geqslant 3$. *In particular the rank of the matrix of* $\operatorname{ad}(X_1)$ *is one. If there exists a vector* $Y=\Sigma_{i\geqslant 3}a_iX_i$ *such that* $[X_2,Y]\neq 0$, *then necessarily* $[X_2,Y]=\alpha X_3$, *since otherwise we can consider the vector* $X_1'=X_1+X_2$ *whose matrix of* $\operatorname{ad}(X_1')$ *has rank 2, contradicting the assumption that* X_1 *is regular. Therefore we can reorder the basis such that* $\mathfrak{g}\simeq\mathfrak{h}_k\oplus\mathbb{C}^{n-(2k+1)}$, *where* $\mathfrak{h}_k$ *is the* $(2k+1)$*-dimensional Heisenberg Lie algebra. If, moreover,* $\mathfrak{g}$ *is not a direct sum of ideals, then* $\dim(\mathfrak{g})$ *is odd and* $\mathfrak{g}=\mathfrak{h}_k$ *for some* $k\geqslant 1$.

Thus the characteristic sequence divides the nilpotent Lie algebras of nilindex k into more specific classes. It should be remarked that the classification of seven-dimensional nilpotent Lie algebras can be made by using only this invariant. The natural followers of Heisenberg Lie algebras are those of characteristic sequence $(3,1,\ldots,1)$. These are the simplest nilpotent Lie algebras of nilindex 3. Contrary to the previous case, where the Heisenberg is the only nonsplit algebra obtained, we will obtain two families of algebras having this property:[2]

Theorem 2: *Any solvable rigid law whose nilradical* $\mathfrak{n}$ *is of characteristic sequence* $(3,1,\ldots,1)$ *is isomorphic to one of the following algebras:*

(i) The Lie algebra $\mathfrak{d}_{2m}=\mathfrak{g}_{2m}\vec{\oplus}\mathfrak{t}(m\geqslant 2)$ *with basis* $(X_0,X_1,X_2,X_3,Y_1,\ldots,Y_{2m-4},V_1,\ldots,V_m)$ *and brackets*

$$[X_0,X_i]=X_{i+1},\quad i=1,2,$$

$$[Y_{2i-1},Y_{2i}]=X_3,\ \ 1\leqslant i\leqslant m-2,$$

$$[V_1,X_i]=X_i,\ \ i=0,2,$$

$$[V_1,X_3]=2Y_3,$$

$$[V_1,Y_{2i}]=2Y_{2i},\ \ 1\leqslant i\leqslant m-2,$$

$$[V_2,X_i]=X_i,\ \ i=1,2,3,$$

$$[V_2,Y_{2i}]=Y_{2i},\ \ 1\leqslant i\leqslant m-2,$$

$$[V_{i+2},Y_{2i-1}]=Y_{2i-1},\ \ 1\leqslant i\leqslant m-2,$$

$$[V_{i+2},Y_{2i}]=-Y_{2i},\ \ 1\leqslant i\leqslant m-2.$$

(ii) The Lie algebra $\mathfrak{d}_{2m+1}=\mathfrak{g}_{2m+1}\vec{\oplus}\mathfrak{t}(m\geqslant 2)$ *with basis* $(X_0,\ldots,X_3,Y_1,\ldots,Y_{2m-3},V_1,\ldots,V_m)$ *and brackets*

$$[X_0,X_i]=X_{i+1},\ \ i=1,2,$$

$$[X_1,Y_{2m-3}]=X_3,$$

$$[Y_{2i-1},Y_{2i}]=X_3,\ \ 1\leqslant i\leqslant m-2,$$

$$[V_1,X_i]=X_i,\ \ i=0,2,$$

$$[V_1,X_3]=2X_3,$$

$$[V_1,Y_{2i}]=2Y_{2i},\ \ 1\leqslant i\leqslant m-2,$$

$$[V_1,Y_{2m-3}]=2Y_{2m-3},$$

$$[V_2,X_i]=X_i,\ \ i=1,2,3,$$

$$[V_2,Y_{2i}]=Y_{2i},\ \ 1\leqslant i\leqslant m-2,$$

$$[V_{i+2},Y_{2i-1}]=Y_{2i-1},\ \ 1\leqslant i\leqslant m-2,$$

$$[V_{i+2},Y_{2i}]=-Y_{2i},\ \ 1\leqslant i\leqslant m-3.$$

(iii) The seven dimensional Lie algebra $\mathfrak{d}_5'$ *with basis* $(X_0,\ldots,X_3,Y_1,V_1,V_2)$ *and brackets*

$$[X_0,X_i]=X_{i+1},\ \ i=1,2,$$

$$[X_1,X_2]=Y_1,$$

$$[V_1,X_i]=(i+1)X_i,\ \ i=0,1,2,3,$$

$$[V_1,Y_1]=5Y_1,$$

$$[V_2,X_i]=X_i,\ \ i=1,2,3,$$

$$[V_2,Y_1]=2Y_1.$$

Remark 1: Indeed more is true: any nonsplit nilpotent Lie algebra $\mathfrak{n}$ *of characteristic sequence* (3,1,...,1) *is isomorphic to the nilradical of one of the former solvable algebras.*[2]

III. THE INVARIANTS

In this section we determine the invariants of the preceding solvable Lie algebras. We claim that it suffices to analyze the lowest dimensional algebras to deduce both the number $\mathcal{N}$ and the explicit form of the invariants in arbitrary dimension. Table I presents the invariants of the algebras for the values $m=2,3,4,5$.

We observe that the algebras $\mathfrak{d}_4$, $\mathfrak{d}_6$, $\mathfrak{d}_8$ and $\mathfrak{d}_{10}$ admit the same invariant $I=(v_3x_3+y_1y_2)/x_3$, and that

$$\mathcal{N}(\mathfrak{d}_{10})=\mathcal{N}(\mathfrak{d}_8)+1=\mathcal{N}(\mathfrak{d}_6)+2=\mathcal{N}(\mathfrak{d}_4)+3. \tag{3.1}$$

We can thus expect that for the general case we will have $\mathcal{N}(\mathfrak{d}_{2m})=m-2$, and that a fundamental set of invariants is formed by the rational functions $I=(v_{i+2}x_3+y_{2i-1}y_{2i})/x_3$. For the algebras $\mathfrak{d}_{2m+1}$ the situation is similar: $\mathfrak{d}_{11}$ has four invariants, three invariants $(v_3x_3+y_1y_2)/x_3$, $(v_4x_3+y_3y_4)/x_3$, $(v_5x_3+y_5y_6)/x_3$, from which the first is an invariant of $\mathfrak{d}_7$ and $\mathfrak{d}_9$ and the second an invariant of $\mathfrak{d}_9$, and a function $(x_0x_2x_3+x_2^2y_7-2x_3^2v_2+v_1x_3^2-2x_1x_3y_7)/x_3^2$. This is also an invariant of $\mathfrak{d}_5$, $\mathfrak{d}_7$ and $\mathfrak{d}_9$ if we substitute y_7 by y_1, y_3 and y_5, respectively. We can thus expect that $\mathcal{N}(\mathfrak{d}_{2m+1})=m-1$ and that the invariants are of the preceding form.

Theorem 3: *Let* $\mathfrak{r}$ *be a solvable rigid Lie algebra whose nilradical is nonsplit of characteristic sequence* (3,1,...,1). *Then a fundamental set of invariants is given by*

(i) $\{y_{2k-1}y_{2k}+x_3v_{k+2}/x_3\}_{1\leqslant k\leqslant m-2}$ *if* $\mathfrak{r}\simeq\mathfrak{d}_{2m}$,

(ii) $\{x_0x_2x_3+x_2^2y_{2m-3}-2x_3^2v_2+v_1x_3^2-2x_1x_3y_{2m-3}/-2x_3^2, x_3v_{k+2}+y_{2k-1}y_{2k}/x_3\}_{1\leqslant k\leqslant m-2}$ *if* $\mathfrak{r}\simeq\mathfrak{d}_{2m+1}$,

(iii) $\{(2x_0y_1+x_2^2-2x_1x_3)^3/(x_3y_1)^2\}$ *if* $\mathfrak{r}\simeq\mathfrak{d}_5'$.

Proof:

(i) Let $\mathfrak{r}=\mathfrak{d}_{2m}$. The system (2.4) is in this case

$$\widehat{X_0}F=(-x_2\partial_{x_1}-x_3\partial_{x_2}+x_0\partial_{v_1})=0, \tag{3.2}$$

$$\widehat{X_1}F=(x_2\partial_{x_0}+x_1\partial_{v_2})F=0, \tag{3.3}$$

$$\widehat{X_2}F=(x_3\partial_{x_0}+x_2\partial_{v_1}+x_2\partial_{v_2})F=0, \tag{3.4}$$

$$\widehat{X_3}F=(2x_3\partial_{v_1}+x_3\partial_{v_2})F=0, \tag{3.5}$$

$$\hat{Y}_{2i-1}F=(-x_3\partial_{y_{2i}}+y_{2i-1}\partial_{v_{i+2}})F=0,\quad 1\leqslant i\leqslant m-2, \tag{3.6}$$

$$\widehat{Y_{2i}}F=(x_3\partial_{y_{2i-1}}-y_{2i}\partial_{v_{i+2}}+2y_{2i}\partial_{v_1}+y_{2i-1}\partial_{v_2})F=0,\quad 1\leqslant i\leqslant m-2, \tag{3.7}$$

$$\hat{V}_1F=\left(x_0\partial_{x_0}+x_2\partial_{x_2}+2x_3\partial_{x_3}+2\sum_{i=1}^{m-2}y_{2i}\partial_{y_{2i}}\right)F=0, \tag{3.8}$$

$$\hat{V}_2F=\left(x_1\partial_{x_1}+x_2\partial_{x_2}+x_3\partial_{x_3}+\sum_{i=1}^{m-2}y_{2i}\partial_{y_{2i}}\right)F=0, \tag{3.9}$$

$$\hat{V}_{i+1}F=(y_{2i-1}\partial_{y_{2i-1}}-y_{2i}\partial_{y_{2i}})F=0,\quad 1\leqslant i\leqslant m-2. \tag{3.10}$$

		$[V_2,X_i]=X_i$ $(i=1,2,3)$;	$[V_2,Y_1]=2Y_1$	

Elementary manipulations of the equations $\widehat{X}_iF=0(0\leqslant i\leqslant 3)$ show that $\partial_{v_i}F=0(i=1,2)$ and $\partial_{x_0}F=0$. Moreover, from the equations $\hat{V}_iF=0(i=1,2)$ we easily deduce that $\partial_{x_i}F=0$ for $i=1,2$. This reduces the system to the following:

$$(-x_3\partial_{y_{2i}}+y_{2i-1}\partial_{v_{i+2}})F=0,\quad 1\leqslant i\leqslant m-2, \tag{3.11}$$

$$(x_3\partial_{y_{2i-1}}-y_{2i}\partial_{v_{i+2}})F=0,\quad 1\leqslant i\leqslant m-2, \tag{3.12}$$

$$\left(x_3\partial_{x_3}+\sum_{i=1}^{m-2}y_{2i}\partial_{y_{2i}}\right)F=0, \tag{3.13}$$

$$(y_{2i-1}\partial_{y_{2i-1}}-y_{2i}\partial_{y_{2i}})F=0. \tag{3.14}$$

Equations (3.11), (3.12) and (3.14) show that we can find invariants of the form $f(x_3,y_{2i-1},y_{2i},v_{i+2})$, which are clearly functionally independent for distinct values of i. Integration of Eq. (3.13) taking into account this observaion provides us with the following fundamental set of invariants:

$$\left\{f_i=\frac{y_{2i-1}y_{2i}+x_3v_{i+2}}{x_3}\right\}_{1\leqslant i\leqslant m-2}. \tag{3.15}$$

(ii) Let $\mathfrak{r}=\mathfrak{d}_{2m+1}$. The system of PDEs corresponding to this algebra has the following subsystem:

$$\widehat{X}_i.F=0,\ 0\leqslant i\leqslant 3, \tag{3.16}$$

$$\hat{Y}_{2m-3}.F=0. \tag{3.17}$$

This is the same system which we obtain for $m=2$, whose invariant has already been computed in Table I:

$$f_1=\frac{2x_3^2v_2-x_3^2v_1+2x_1x_3y_{2m-3}-x_0x_2x_3-x_2^2y_{2m-3}}{x_3^2}. \tag{3.18}$$

Therefore this function is an invariant of $\mathfrak{d}_{2m+1}$ for any $m\geqslant 2$. Now observe that, since $\widehat{X_3}.F=x_3(2\partial_{v_1}+\partial_{v_2})=0$, the equation $\widehat{Y_{2i}}.F=0$ can be reduced to

$$\widehat{Y'_{2i}}F=(x_3\partial_{y_{2i-1}}-y_{2i}\partial_{v_{i+2}})F=0. \tag{3.19}$$

As a consequence, the function f_1 is a solution of (3.16) and (3.17) for any $m\geqslant 3$, and the remaining fundamental solutions are obtained from the system

$$\hat{Y}_{2i-1}.F=(-x_3\partial_{y_{2i}}+y_{2i-1}\partial_{v_{i+2}})F=0, \tag{3.20}$$

$$\hat{Y}'_{2i}.F=0,\ 1\leqslant i\leqslant m-2,\quad \hat{V}_1.F=(x_3\partial_{y_{2i-1}}-y_{2i}\partial_{v_{i+2}})F=0, \tag{3.21}$$

$$\hat{V}_{i+2}.F=(y_{2i-1}\partial_{y_{2i-1}}-y_{2i}\partial_{y_{2i}})F=0,\quad i\geqslant 1, \tag{3.22}$$

for $1\leqslant i\leqslant m-2$. This system is equivalent to the one given by Eqs. (3.11)–(3.14), from which we deduce the solutions

$$f_{i+1}=\frac{x_3v_{i+2}+y_{2i-1}y_{2i}}{x_3}. \tag{3.23}$$

Thus a fundamental system of invariants for $\mathfrak{d}_{2m+1}$ is given by $\{f_1,f_{i+1}\}_{1\leqslant i\leqslant m-2}$.

(iii) It is easily verified that any invariant satisfies $\partial_{v_1}F=\partial_{v_2}F=0$. Elementary transformations of the corresponding system show that an invariant function F must be a solution of the following equation:

$$(-x_2^2+y_1x_0+2x_1x_3)\partial_{x_1}F+3y_1x_3\partial_{y_1}F=0. \tag{3.24}$$

This equation admits the rational solution

$$F_1=\frac{(2x_0y_1+x_2^2-2x_1x_3)^3}{x_3^2y_1^2} \tag{3.25}$$

and it can be easily verified that this function satisfies the system. Thus a set of invariants is given by $\{F_1\}$.

■

Since the fundamental sets of invariants of the algebras $\mathfrak{d}_m$ and $\mathfrak{d}'_5$ consist of rational functions, one can ask whether these invariants will confirm the observation that rational functions occur as ratio of two commuting polynomials.[15,17] For the algebras $\mathfrak{d}_{2m}$ we have $[X_3,Y]=0$ for any $Y\notin\mathbb{C}V_1\oplus\mathbb{C}V_2$. Thus, as polynomial operators, the following identity holds for any $k\in\{1,...,m-2\}$:

$$[X_3,Y_{2k-1}Y_{2k}+X_3V_{k+2}]=0, \tag{3.26}$$

which shows that the numerator and denominator of the invariants are commuting polynomials. For the algebras $\mathfrak{d}_{2m+1}$ we also have $[X_3,Y]=0$ whenever $Y\notin\mathbb{C}V_1\oplus\mathbb{C}V_2$. Therefore the invariants $(v_{k+2}x_3+y_{2k-1}y_{2k})/x_3$ are also the ratio of commuting polynomials. The remaining invariant $I=(x_0x_2x_3+x_2^2y_{2m-3}+x_3^2(v_1-2v_2)-2x_1x_3y_{2m-3})/x_3^2$ depends on both V_1 and V_2, but, since $[V_1,X_3]=2X_3$ and $[V_2,X_3]=X_3$, we again obtain that

$$[X_0X_2X_3+X_2^2Y_{2m-3}+X_3^2(V_1-2V_2)-2X_1X_3Y_{2m-3},X_3]=0. \tag{3.27}$$

Finally, for the special case $\mathfrak{d}_5'$ the center is spanned by X_3 and Y_1, and since the invariant does not depend on the variables v_1,v_2 associated to toral elements, the numerator and denominator of the invariant are commuting polynomials.

In terms of representation theory this fact is of importance, since it ensures us the existence of bases for irreducible representations in which the operators are all simultaneously diagonal, giving to the invariants a precise meaning which is useful to characterize the representations of these algebras.

IV. APPLICATIONS TO RANK ONE SUBALGEBRAS

The seven dimensional rigid Lie algebra $\mathfrak{d}_5'$ is a nice example to illustrate how, under certain assumptions, we can deduce the invariants of some subalgebras. Let us consider the rank one solvable (non-nilpotent) subalgebras $\mathfrak{d}_5^{a,b}$ of $\mathfrak{d}_5'$ having the following brackets:

$$[X_0,X_1]=X_2,\quad [X_0,X_2]=X_3,\quad [X_1,X_2]=Y_1,$$

$$[V,X_0]=aX_0,\quad [V,X_1]=bX_1,\quad [V,X_2]=(a+b)X_2,$$

$$[V,X_3]=(2a+b)X_3,\quad [V,Y_1]=(a+2b)Y_1;\quad a,b\in\mathbb{C}.$$

Clearly we have $V=aV_1+bV_2$. The system of PDEs giving the invariants of $\mathfrak{d}_5^{a,b}$ is

$$\widehat{X}_iF=0,\ 0\leqslant i\leqslant 3, \tag{4.1}$$

$$\hat{Y}_1F=0, \tag{4.2}$$

$$\hat{V}F=0, \tag{4.3}$$

where

$$\hat{V}=(ax_0\partial_{x_0}+bx_1\partial_{x_1}+(a+b)x_2\partial_{x_2}+(2a+b)x_3\partial_{x_3}+(a+2b)y_1\partial_{y_1}). \tag{4.4}$$

Now any invariant F satisfies $\partial_vF=0$, and we obtain that any invariant of $\mathfrak{d}_5'$ is also an invariant of $\mathfrak{d}_5^{a,b}$, since the five first equations coincide and the sixth is a linear combination of the toral equations of $\mathfrak{d}_5'$.

Lemma 1: For any $a,b\in\mathbb{C}$ not simultaneously zero we have $\mathcal{N}(\mathfrak{d}_5^{a,b})=2$.

Proof: Since F_1 satisfies the system, $\mathcal{N}\geqslant 1$. Now it can easily be seen that the matrix obtained from the commutation table has rank four, from which the assertion follows. ■

We make a distinction among the subalgebras $\mathfrak{d}_5^{a,b}$: those having trivial center and those not. It is a routine verification that $\mathfrak{d}_5^{a,b}$ has nontrivial center if and only if $a+2b=0$ or $2a+b=0$. Since solvable Lie algebras having nontrivial center admit at least a polynomial invariant, we obtain the following:

Lemma 2: Let $\mathfrak{d}_5^{a,b}$ have nontrivial center. Then a fundamental set of invariants is given by
(i) $\{F_1,x_3\}$ *if* $2a+b=0$,
(ii) $\{F_1,y_1\}$ *if* $a+2b=0$.

For the case of a nontrivial center, it is easy to verify that any invariant of $\mathfrak{d}_5^{a,b}$ is a function of F_1, x_3 and y_1. Specifically, we have the following.

Lemma 3: If $Z(\mathfrak{d}_5^{a,b})\neq 0$, a fundamental set of invariants for $\mathfrak{d}_5^{a,b}$ is given by $\{F_1,y_1^{2a+b}/x_3^{a+2b}\}$.

The interest of this example is that it provides us with a general result: Let $\mathfrak{r}=\mathfrak{n}\vec{\oplus}\mathfrak{t}$ be a solvable non-nilpotent Lie algebra over $\mathbb{K}=\{\mathbb{R},\mathbb{C}\}$ and $\mathfrak{t}$ a torus of derivations. Let $\{X_1,\ldots,X_n,V_1,\ldots,V_p\}$ be a basis such that the nilradical $\mathfrak{n}$ is generated by the X_i and the torus by the V_i. Suppose, moreover, that $\mathfrak{r}$ satisfies the following property:

$$\partial_{v_i}F=0, \quad 1\leqslant i\leqslant p \text{ for any invariant } F, \quad \forall v_i\in\mathfrak{t}. \tag{4.5}$$

Let $\mathfrak{t}'$ be a one dimensional subtorus of $\mathfrak{t}$ and $\mathfrak{r}'=\mathfrak{n}\vec{\oplus}\mathfrak{t}'$ such that $\mathfrak{t}'.Z(\mathfrak{n})\neq 0$, i.e., the action of the subtorus $\mathfrak{t}'$ on the center of the nilradical is nonzero.

Proposition 1: In the preceding conditions, any element F of a fundamental set of invariants for $\mathfrak{r}$ is an invariant of $\mathfrak{r}'$. Moreover, $\mathcal{N}(\mathfrak{r}')\geqslant\mathcal{N}(\mathfrak{r})$.

Proof: Let V generate $\mathfrak{t}'$. We can find coefficients $\alpha_1,\ldots,\alpha_p\in\mathbb{K}$ such that $V=\Sigma_{i=1}^{p}\alpha_iV_i$. Since $\mathfrak{n}$ is nilpotent, its center is nonzero, and by $\mathfrak{t}'.Z(\mathfrak{n})\neq 0$, we deduce that $\partial_vF=0$ for any invariant F of $\mathfrak{r}'$. The system of PDEs giving the invariants is

$$\widehat{X_i}.F=-[X_i,X_j]\partial_{x_j}.F=0, \quad 1\leqslant i\leqslant n, \tag{4.6}$$

$$\hat{V}.F=-[V,X_i]\partial_{x_i}.F=0. \tag{4.7}$$

Now $\hat{V}=\Sigma_{i=1}^{p}\alpha_i\hat{V}_i$. This shows that any invariant G of $\mathfrak{r}$ also satisfies the system (4.6) and (4.7), since the equations concerning the operators $\widehat{X_i}$ coincide, and the last equation is a linear combination of the equations $\{\hat{V}_i.F=0\}$ of $\mathfrak{r}$. Thus any fundamental set of invariants for $\mathfrak{r}$ is a set of functionally independent invariants for $\mathfrak{r}'$. As a consequence $\mathcal{N}(\mathfrak{r}')\geqslant\mathcal{N}(\mathfrak{r})$. ■

Remark 2: If p is even, by the Beltrametti–Blasi formula we deduce $\mathcal{N}(\mathfrak{r}')\geqslant\mathcal{N}(\mathfrak{r})+1$.

The main interest of this result is its application in the other direction (whenever it makes sense), i.e., starting from the invariants of a rank one subalgebra to find a fundamental set of the algebra $\mathfrak{r}$. We illustrate it by an example:

Example 2: Consider the solvable Lie algebra $\mathfrak{g}$ given by the brackets

$$[V_1,Y_i]=iY_i, \quad 1\leqslant i\leqslant 7,$$

$$[V_2,Y_i]=Y_i, \quad 2\leqslant i\leqslant 7,$$

$$[Y_1,Y_i]=Y_{i+1}, \quad 2\leqslant i\leqslant 6.$$

This algebra is of rank two, and a torus is generated by V_1 and V_2. From the corresponding system (2.4) it can be seen that for any invariant F of $\mathfrak{g}$ we have $\partial_{v_i}F=0, i=1,2$, thus we can apply the preceding proposition. Consider the one dimensional subtorus generated by V_2. The semidirect product of this torus and the nilradical is an eight dimensional Lie algebra $\mathfrak{g}'$ satisfying $\mathcal{N}(\mathfrak{g}')=2$. A fundamental set of invariants for this algebra is formed by the following functions:

$$g_1=\frac{6y_4y_6y_7^2-6y_3y_7^3+2y_6^4-8y_5y_6^2y_7+5y_5^2y_7^2}{3y_4y_7^3+y_6^3y_7-3y_5y_6y_7^2},$$

$$g_2=\frac{-5y_2y_7^4+5y_4y_5y_7^3+5y_5y_6^3y_7-5y_5^2y_6y7^2-y_6^5+5y_3y_6y_7^3-5y_4y_6^2y_7^2}{3y_4y_7^4+y_6^3y_7^2-3y_5y_6y_7^3}.$$

As the assumption of the proposition are satisfied, we know that there exists a function $F(g_1,g_2)$ that forms a fundamental system of invariants for the Lie algebra $\mathfrak{g}$. In this case it is not difficult to see that such a function is given by $F=g_2/g_1^2$. Since both g_1 and g_2 are ratios of commuting polynomials, we deduce that F is also a rational invariant of this kind (in the corresponding enveloping algebras).

Of course this inverse procedure is applicable only in quite concrete cases, since the algebra $\mathfrak{r}$ could have no invariants, while a rank one odd dimensional Lie subalgebra necessarily has solutions. Condition (4.5) provides us with another interesting fact: Let $\mathfrak{r}=\mathfrak{n}\vec{\oplus}\mathfrak{t}$ be an even dimensional solvable Lie algebra satisfying (4.5).

Proposition 2: If $\mathcal{N}(\mathfrak{n})=1$, *then* $\mathfrak{r}$ *has no nontrivial invariants.*

Proof: Since $\partial_v F=0$ for any invariant F and any $v\in\mathfrak{t}$, over an arbitrary basis $\{X_1,\ldots,X_{2p+1},V_1,\ldots,V_{2q+1}\}$ such that $\{X_1,\ldots,X_{2p+1}\}$ is a basis of $\mathfrak{n}$ and $\{V_1,\ldots,V_{2q+1}\}$ is a basis of $\mathfrak{t}$, the system of PDEs giving the invariants is

$$\hat{X}_i.F=0,\ 1\leqslant i\leqslant 2p+1, \tag{4.8}$$

$$\hat{V}_i.F=0,\ 1\leqslant i\leqslant 2q+1. \tag{4.9}$$

Since there is only one functionally independent invariant F_0 satisfying the equation (4.8), because it corresponds exactly to the system of $\mathfrak{n}$, we would obtain a fundamental set of invariants of $\mathfrak{r}$ generated by at most one invariant, namely some function of F_0. But this contradicts the fact that $\mathcal{N}(\mathfrak{r})$ has the same parity as dim $\mathfrak{r}$, which is even. Thus $\mathcal{N}(\mathfrak{r})=0$. ■

This property can be of interest for some physical applications. The six dimensional subalgebra $P_{5,2}$ of the Poincaré algebra generated by $\{\cos\alpha L_3+\sin\alpha K_3, L_2+K_1, L_1-K_2, P_0-P_3, P_1, P_2\}$ with $0\leqslant\alpha\leqslant\pi, \alpha\neq\pi/2$ satisfies the preceding conditions. Its nilradical $\mathfrak{n}$ is five dimensional, and the center of $\mathfrak{n}$ is generated by (P_0-P_3). This ensures that $\partial_t F=0$ for any invariant, where $t=\cos\alpha l_3+\sin\alpha k_3$. Since the invariants of $\mathfrak{n}$ are all functions of (p_0-p_3), the algebra $P_{5,2}$ has none invariants.

V. CONCLUDING REMARKS

The preceding results show that rigid Lie algebras are an adequate class for studying the generalized Casimir invariants. Since the torus determines the nilradical, the equations describing the action of the torus are of importance for the structure of the invariants, specifically if those invariants do not depend on the variables corresponding to toral elements. Since solvable rigid Lie algebras can theoretically be classified following the algorithm given in Ref. 4, the analysis of these algebras in relatively low dimension and their subalgebras can provide alternative criteria to attack the general case, as classifications in general are not possible. This in particular applies to the class of two-step solvable Lie algebras (the Heisenberg algebras being the most important examples), for which general constructions exist.[6] Observe further that, like in Proposition 1, the results do not depend on the field, which allows us to derive results for both real and complex Lie algebras. The reason to analyze the complex rigid laws lies in their decomposition: for real rigid Lie algebras no decomposition like (2.14) is known, and it is still an open question whether it can exist.[8]

Finally, the same analysis could be applied to any solvable Lie algebra whose nilradical has characteristic sequence $(p,1,...,1)$ for $p\geqslant 4$. These algebras, which are completely classified up to $p=5$,[3,7] consist of a low dimensional subalgebra $\mathfrak{m}$ generated by a characteristic vector, to which three dimensional Heisenberg Lie algebras having their derived subalgebras in the center of $\mathfrak{m}$ are glued. For the solvable Lie algebras having nilradicals of this type the determination of a fundamental set of invariants should also be possible from the analysis in low dimensions. This structure makes this class worthy of being analyzed to obtain alternative criteria for the generalized Casimir invariants of solvable Lie algebras.

Finally, the absence of invariants of an algebra is a very interesting property, because, whenever the algebra is related to some physical system, other solutions in more general spaces could also provide important information on the system (as happens with the sign of energy for the Poincaré algebra).[17] It is also of interest to find characterizations of these algebras.

(Received 20 June 2002; accepted 15 October 2002)

Modified braid equations satisfied by generalized $\hat{R}$ matrices (for a *given* set of group relations obeyed by the elements of T matrices) are constructed for q-deformed quantum groups $GL_q(N)$, $SO_q(N)$, and $Sp_q(N)$ with arbitrary values of N. The Baxterization of $\hat{R}$ matrices, treated as an aspect complementary to the *modification* of the braid equation, is obtained for all these cases in particularly elegant forms. A new class of braid matrices is discovered for the quantum groups $SO_q(N)$ and $Sp_q(N)$. The $\hat{R}$ matrices of this class, while being distinct from the restrictions of the universal $\hat{\mathcal{R}}$ matrix to the corresponding vector representations, satisfy the *standard* braid equation. The modified braid equation and the Baxterization are obtained for this new class of $\hat{R}$ matrices. Diagonalization of the generalized $\hat{R}$ matrices is studied. The diagonalizers are obtained explicitly for some lower dimensional cases in a convenient way, giving directly the eigenvalues of the corresponding $\hat{R}$ matrices. Applications of such diagonalization are then studied in the context of associated covariantly quantized noncommutative spaces. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1530370]

I. INTRODUCTION

Previously one of us has studied the *modified* braid equation (MBE) in the context of the quantum groups $GL_{p,q}(2)$, $GL_{g,h}(2)$, and $GL_{q,h}(1|1)$ (biparametric unitary, nonstandard Jordanian and hybrid deformations respectively) in Ref. 1; and also the orthogonal quantum group $SO_q(3)$ in Ref. 2. The terminology is adopted from that of Gerstenhaber, Giaquinto, and Schack,[3,4] who have studied a generalized class of deformations leading to MBE, where unlike the standard Yang–Baxter equation there are also inhomogeneous terms linear in tensored $\hat{R}$ matrices. These authors indicate the significance of and the interest in this equation. In Refs. 1 and 2 the most general solutions of the quantum inverse scattering equation

$$\hat{R}\mathsf{T}_1\mathsf{T}_2-\mathsf{T}_1\mathsf{T}_2\hat{R}=0, \quad \mathsf{T}_1=\mathsf{T}\otimes\mathsf{I}, \quad \mathsf{T}_2=\mathsf{I}\otimes\mathsf{T} \tag{1.1}$$

for the relevant quantum groups were considered. Starting from a *given* set of group relations of the elements of the monodromy matrix T, the most general $\hat{R}$ matrix satisfying (1.1) was constructed. It was observed that the standard braid equation was modified for this generalized $\hat{R}$ matrix. In this procedure the *conservation of the group laws postulated for the elements of the* T *matrix was maintained*.

Here we construct, systematically and explicitly, the MBE for the quantized groups $\mathrm{GL}_q(N)$, $\mathrm{SO}_q(N)$, and $\mathrm{Sp}_q(N)$, respectively. As explained in Sec. 1 of Ref. 2, we will methodically use the generalized spectral decomposition of the relevant $\hat{R}$ matrices in the vector representations. For an $\hat{R}$ matrix obeying the characteristic equation

$$(\hat{R}-k_1\mathsf{I})\ (\hat{R}-k_2\mathsf{I})\cdots(\hat{R}-k_p\mathsf{I})=0, \quad (k_i\neq k_j \ \text{ if } \ i\neq j|(i,j)=(1,2,\ldots,p)), \tag{1.2}$$

the projectors in the eigenspaces of this $\hat{R}$ matrix read

$$P_i=\prod_{j\neq i}\frac{(\hat{R}-k_j\mathsf{I})}{(k_i-k_j)}, \tag{1.3}$$

and satisfy the usual property

$$P_iP_j=P_i\delta_{ij}, \quad \sum_i P_i=\mathsf{I}. \tag{1.4}$$

This orthonormalized set then provides the spectral decomposition.

Following Refs. 5–7 we first review the situation for the standard braid equation. In our discussion concerning braiding matrices, projectors and so on, we draw on Refs. 5 and 6. In our study of the Baxterization of the $\hat{R}$ matrices the analysis in Ref. 7 is particularly relevant. A large number of sources are cited in Ref. 7, and we also refer to that list. The standard, i.e., nonmodified in our context, braid equation reads

$$\hat{R}_{12}\hat{R}_{23}\hat{R}_{12}-\hat{R}_{23}\hat{R}_{12}\hat{R}_{23}=0. \tag{1.5}$$

The spectral decomposition of the braid matrix of the quantum group $\mathrm{GL}_q(N)$ with the conventional normalization[7] is given by

$$\hat{\mathsf{R}}=qP_{(+)}-q^{-1}P_{(-)}, \tag{1.6}$$

whereas braid matrices of the quantum groups $\mathrm{SO}_q(N)$ and $\mathrm{Sp}_q(N)$ (where $N=2n$) in the usual normalization[7] may be written in a unified manner

$$\hat{\mathsf{R}}=qP_{(+)}-q^{-1}P_{(-)}+\varepsilon q^{\varepsilon-N}P_{(0)}. \tag{1.7}$$

In (1.7) we have $\varepsilon=1(-1)$ for the quantum group $\mathrm{SO}_q(N)$ $[\mathrm{Sp}_q(N)]$. The explicit expressions of the $\hat{R}$ matrices and the corresponding projectors for the above quantum groups are given in Refs. 5–7.

Now we proceed as follows. Maintaining the *same* projectors as in the standard braid equation, we generalize the $\hat{R}$ matrix of the quantum group $\mathrm{GL}_q(N)$ as

$$\hat{R}(v)=\mathsf{I}+vP_{(-)}=P_{(+)}+(1+v)P_{(-)}. \tag{1.8}$$

A similar parametrization in the context of the quantum group $\mathrm{GL}_q(2)$ was used in Ref. 8. The generalized $\hat{R}$ matrices for the quantum groups $\mathrm{SO}_q(N)$ and $\mathrm{Sp}_q(N)$ read

$$\hat{R}(v,w)=\mathsf{I}+vP_{(-)}+wP_{(0)}=P_{(+)}+(1+v)P_{(-)}+(1+w)P_{(0)}. \tag{1.9}$$

Setting the braid values of the variables

$$v=-(1+q^{\mp 2}), \quad w=-(1-\varepsilon q^{\mp(N+1-\varepsilon)}) \tag{1.10}$$

in (1.8) and (1.9) we may recover the $\hat{R}^{\pm 1}$ matrices satisfying the braid equation (1.5). Here and henceforth we adopt the convention that for the braid matrices satisfying (1.5) we do not explicitly exhibit the corresponding values of the relevant spectral variables. We will throughout implement the normalizations used in (1.8) and (1.9). For the purpose of later use we enlist here the braid matrices and their inverses according to our normalization scheme. The $\hat{R}^{\pm 1}$ matrices of the quantum group $\mathrm{GL}_q(N)$ read

$$\hat{R}^{\pm 1} = \mathsf{I} - (1+q^{\mp 2})P_{(-)}, \tag{1.11}$$

whereas the $\hat{R}^{\pm 1}$ matrices of the quantum groups $\mathrm{SO}_q(N)$ and $\mathrm{Sp}_q(N)$ are given by

$$\hat{R}^{\pm 1} = \mathsf{I} - (1+q^{\mp 2})P_{(-)} - (1-\varepsilon q^{\mp(N+1-\varepsilon)})P_{(0)}. \tag{1.12}$$

We observe that the braid matrices defined in (1.11) and (1.12) following our normalization scheme and the corresponding matrices given, respectively, by (1.6) and (1.7) as per the usual normalization prescriptions, differ by an overall multiplicative factor

$$\hat{\mathsf{R}} = q\hat{R}. \tag{1.13}$$

The $\hat{R}(v)$ and $\hat{R}(v,w)$, defined, respectively, in (1.8) and (1.9), satisfy the following characteristic equations:

$$(\hat{R}(v)-\mathsf{I})(\hat{R}(v)-(1+v)\mathsf{I}) = 0, \tag{1.14}$$

$$(\hat{R}(v,w)-\mathsf{I})(\hat{R}(v,w)-(1+v)\mathsf{I})(\hat{R}(v,w)-(1+w)\mathsf{I}) = 0. \tag{1.15}$$

Using (1.3) the relevant projectors can also be expressed directly as linear and quadratic functions of $\hat{R}(v)$ and $\hat{R}(v,w)$, respectively. We also note that any $\hat{R}$ matrix satisfying (1.1) also necessarily satisfies

$$f(\hat{R})\mathsf{T}_1\mathsf{T}_2 - \mathsf{T}_1\mathsf{T}_2 f(\hat{R}) = 0, \tag{1.16}$$

where $f(x)$ is any well-behaved function. Due to the relations (1.14) and (1.15) the operator $f(\hat{R})$ reduces to a linear and a quadratic expression in the matrix $\hat{R}$ in the respective cases. Thus for arbitrary values of the variables v and (v,w), our constructions in (1.8) and (1.9) provide the *most general solutions* in the relevant examples.

Now comes the crucial question. What modifications in the braid equation (1.5) are enacted as the variables v and (v,w) move away from the braid values given in (1.10)? We are thus lead to our MBE for each case considered. As shown later in Sec. II, the MBE for the quantum group $\mathrm{GL}_q(N)$ reads

$$\hat{R}_{12}(v)\hat{R}_{23}(v)\hat{R}_{12}(v) - \hat{R}_{23}(v)\hat{R}_{12}(v)\hat{R}_{23}(v) = c(\hat{R}_{12}(v) - \hat{R}_{23}(v)), \tag{1.17}$$

whereas in the examples of the quantum groups $\mathrm{SO}_q(N)$ and $\mathrm{Sp}_q(N)$ these equations have the form

$$\begin{aligned}
&\hat{R}_{12}(v,w)\hat{R}_{23}(v,w)\hat{R}_{12}(v,w) - \hat{R}_{23}(v,w)\hat{R}_{12}(v,w)\hat{R}_{23}(v,w) \\
&\quad = c_1(\hat{R}_{12}(v,w) - \hat{R}_{23}(v,w)) + c_2(\hat{R}_{12}^{-1}(v,w) - \hat{R}_{23}^{-1}(v,w)) + c_3(\hat{R}_{12}(v,w)\hat{R}_{23}^{-1}(v,w) \\
&\qquad - \hat{R}_{23}(v,w)\hat{R}_{12}^{-1}(v,w)) - c_3(\hat{R}_{12}^{-1}(v,w)\hat{R}_{23}(v,w) - \hat{R}_{23}^{-1}(v,w)\hat{R}_{12}(v,w)).
\end{aligned} \tag{1.18}$$

The coefficients c and (c_1,c_2,c_3) are given explicitly in Secs. II and III, respectively. Inhomogeneous terms linearly depending on $\hat{R}$ matrix elements on the right hand side of the modified

braid equation, as in (1.17), were first considered[3,4] in the context of the quantum group $GL_q(N)$ with two projectors. There is, however, a sudden leap in complexity as the number of projectors increases by one as in the cases of quantum groups $SO_q(N)$ and $Sp_q(N)$. By restricting the parameters v and w, we also select special cases in Secs. III and IV, where, for instance, $c_3=0$ or $\{c_2=0,c_3=0\}$ holds.

There is another aspect of our analysis. In Refs. 1 and 2 (particularly in Sec. 4 of Ref. 2) it was pointed out that the *modification* of the braid equation and the Baxterization of the $\hat{R}$ matrix are two complimentary facets of the generalized spectral decompositions in (1.8) and (1.9). It is possible to proceed in one of the following two alternate directions.

(i) The variables v and w are held fixed in each factor of the left, as in (1.17) and (1.18), and the inhomogeneous terms on the right are computed. This yields the MBE.

(ii) The inhomogeneous terms on the right-hand side of the braid equation may be constrained to be zero. This fixes the variables v and w in the appropriate $\hat{R}$ matrices in a particular fashion to be shown below. This provides the Baxterization of the $\hat{R}$ matrices.

The final results for the first possibility were presented above. Similarly we enlist below the final results for the other possibility. In Sec. III C we study the additive form of Baxterization of the $\hat{R}$ matrices

$$\hat{R}_{12}(\theta)\hat{R}_{23}(\theta+\theta')\hat{R}_{12}(\theta')-\hat{R}_{23}(\theta')\hat{R}_{12}(\theta+\theta')\hat{R}_{23}(\theta)=0, \tag{1.19}$$

where $q=\exp(h)$. For this form of Baxterization the variable $v(\theta)$ reads

$$v(\theta)=\frac{\sinh(h-\theta)}{\sinh(h+\theta)}-1, \tag{1.20}$$

for all the quantum groups studied here, namely $GL_q(N)$, $SO_q(N)$, and $Sp_q(N)$. The variable $w(\theta)$, appearing for the quantum groups $SO_q(N)$ and $Sp_q(N)$, assumes two alternate forms. For the orthogonal quantum group $SO_q(N)$ it is given by

$$w(\theta)=\frac{\cosh\left(\frac{N}{2}h-\theta\right)}{\cosh\left(\frac{N}{2}h+\theta\right)}-1 \tag{1.21}$$

or

$$w(\theta)=\frac{\sinh\left(\left(\frac{N}{2}-1\right)h-\theta\right)\sinh(h-\theta)}{\sinh\left(\left(\frac{N}{2}-1\right)h+\theta\right)\sinh(h+\theta)}-1. \tag{1.22}$$

For the symplectic quantum group $Sp_q(N)$, where $N=2n$, the variable $w(\theta)$ assumes the form

$$w(\theta)=\frac{\sinh((n+1)h-\theta)}{\sinh((n+1)h+\theta)}-1 \tag{1.23}$$

or

$$w(\theta)=\frac{\cosh(nh-\theta)\sinh(h-\theta)}{\cosh(nh+\theta)\sinh(h+\theta)}-1. \tag{1.24}$$

In each case our parametrization and normalization assure the validity of the constraint

$$\hat{R}(\theta)\hat{R}(-\theta)=\mathrm{I}. \tag{1.25}$$

It has been implicitly assumed above that $v\neq 0, w\neq 0$. But the parametrization (1.9) insistently points at the following question. What happens for the special choices $(v\neq 0, w=0)$ and $(v=0, w\neq 0)$? Certain properties of the projectors $P_{(-)}$ and $P_{(0)}$ being different, there is no reciprocal symmetry concerning the two above choices. For the $w=0$ case there is no nontrivial solution. But for the $v=0$ case we discuss *a hitherto unnoticed new class of solutions* studied in detail in Sec. IV. Even in the limit $q=1$, this class of solutions *remains nontrivial*. For the purpose of comparison with the preceding results, here we just exhibit the Baxterized values of the spectral variables corresponding to these solutions for the quantum groups $\mathrm{SO}_q(N)$ and $\mathrm{Sp}_q(N)$:

$$v=0, \quad w(\theta)=\frac{\sinh(\eta-\theta)}{\sinh(\eta+\theta)}-1, \quad \text{where} \quad \tanh\eta=(1-4(1+\varepsilon[N-\varepsilon])^{-2})^{1/2}. \tag{1.26}$$

In (1.26) we have used the standard notation $[x]=(q^x-q^{-x})/(q-q^{-1})$. The quantity under the radical sign in (1.26) is positive for $N>2$, and hence its square root is real.

In Sec. V we construct matrices diagonalizing the generalized braid operators $\hat{R}(v)$ and $\hat{R}(v,w)$. Explicit results are presented for the quantum groups $\mathrm{GL}_q(2)$, $\mathrm{SO}_q(3)$, and $\mathrm{SO}_q(4)$. The key result valid for the cases studied is that the indefinite parameters in the diagonalizers may be chosen to ensure *the mutual orthogonality of their rows*. This remarkably helpful property allows us to effortlessly obtain the eigenvectors of the generalized braiding matrices $\hat{R}(v)$ and $\hat{R}(v,w)$. These can be of interest in related statistical models.

Also we show, in Sec. VI, how such diagonalizations may be exploited in the description of associated noncommutative spaces. One principal objective in introducing our generalized spectral decompositions has been[1,2] the exploration of the roles of the variables (v,w) in the instances, where the generalized braid matrices $\hat{R}(v)$ and $\hat{R}(v,w)$ are used to construct the relevant noncommutative spaces. The constraints due to Leibnitz rule and the covariance properties—discussed, for instance, in Refs. 9–11 and a large number of sources cited therein—are presented in Sec. VI after incorporating our spectral variables.

But in this paper our study remains essentially limited to showing how the the diagonalization of Sec. V can help in better understanding certain features of such spaces. We hope to develop other aspects elsewhere. Remarks on various features of the results obtained and other perspectives are presented in Sec. VII.

II. MODIFIED BRAID EQUATION AND BAXTERIZATION FOR THE QUANTUM GROUP $\mathrm{GL}_q(N)$

In the vector representation the braid matrix $\hat{R}$ of the quantum group $\mathrm{GL}_q(N)$ has two orthogonal projectors. The spectral decomposition of its generalized $\hat{R}(v)$ matrix has been defined in (1.8). Adopting the definitions

$$X_1=P_{(-)}\otimes\mathrm{I}, \quad X_2=\mathrm{I}\otimes P_{(-)}, \quad S_1=(X_1-X_2), \quad T_1=(X_1X_2X_1-X_2X_1X_2), \tag{2.1}$$

we write

$$\hat{R}_{12}(v)\hat{R}_{23}(v')\hat{R}_{12}(v'')-\hat{R}_{23}(v'')\hat{R}_{12}(v')\hat{R}_{23}(v)=(v+v''+vv''-v')S_1+vv'v''T_1. \tag{2.2}$$

Equating the variables to their braid values $v=v'=v''=-(1+q^{-2})$ the right-hand side of (2.2) vanishes as in this limit the braid matrix $\hat{R}$ in (1.11) satisfying the braid equation (1.5) is obtained. This restricts

$$T_1=\frac{S_1}{[2]^2}. \tag{2.3}$$

Hence the right-hand side of (2.2) reads

$$\left((v+v''+vv''-v')+\frac{vv'v''}{[2]^2}\right)S_1, \tag{2.4}$$

where following (1.8) and the related discussions we obtain

$$S_1=v^{-1}(\hat{R}_{12}(v)-\hat{R}_{23}(v))=-q[2]^{-1}(\hat{R}_{12}-\hat{R}_{23}). \tag{2.5}$$

Setting $v=v'=v''$ we obtain the MBE obeyed by the generalized braid matrix $\hat{R}(v)$ of the quantum group $\mathrm{GL}_q(N)$:

$$\hat{R}_{12}(v)\hat{R}_{23}(v)\hat{R}_{12}(v)-\hat{R}_{23}(v)\hat{R}_{12}(v)\hat{R}_{23}(v)=(1+v+[2]^{-2}v^2)(\hat{R}_{12}(v)-\hat{R}_{23}(v)). \tag{2.6}$$

Comparing the above MBE with (1.17) we obtain

$$c=1+v+[2]^{-2}v^2. \tag{2.7}$$

For the Baxterization of the $\hat{R}(v)$ matrix we set

$$v=v(x), \quad v''=v(y), \quad v'=v(xy) \tag{2.8}$$

and denote $\hat{R}(v)\equiv\hat{R}(x)$. Now for the right-hand side of (2.2) to vanish, we must have

$$v(xy)=\frac{v(x)+v(y)+v(x)v(y)}{1-[2]^{-2}v(x)v(y)}. \tag{2.9}$$

This functional relation is solved in a more general form in Sec. III. Here we present the final result concerning the function $v(x)$ as follows. The solution satisfying the constraint

$$\hat{R}(x)\hat{R}(x^{-1})=1 \tag{2.10}$$

reads

$$v(x)=\frac{qx^{-1}-q^{-1}x}{qx-q^{-1}x^{-1}}-1. \tag{2.11}$$

Setting $x=\exp(\theta)$ and $q=\exp(h)$ in (2.11), we obtain the functional structure in (1.20). For the choice $y=\exp(\theta')$ and the above value of $v(\theta)$ the braid equation takes the form given in (1.19). Combining (1.8), (1.11), and (2.11) we may express $\hat{R}(x)$ as

$$\hat{R}(x)=\frac{qx\hat{R}-q^{-1}x^{-1}\hat{R}^{-1}}{qx-q^{-1}x^{-1}}. \tag{2.12}$$

Suitably changing the normalizations, namely, observing (1.13) and setting

$$\hat{\mathsf{R}}(x)=(qx^{-1}-q^{-1}x)\hat{R}(x^{-1}), \tag{2.13}$$

we obtain

$$\hat{\mathsf{R}}(x)=x^{-1}\hat{\mathsf{R}}-x\hat{\mathsf{R}}^{-1}. \tag{2.14}$$

In this form the Baxterization of the $\hat{R}$ matrix of the quantum group $\mathrm{GL}_q(N)$ is often presented.[7] We have preferred (2.12) to achieve uniform utilization of the same functional equation in Secs. II, III, and IV. This also ensures *one uniform normalization prescription*, whether the $\hat{R}$ matrix is Baxterized or not, by fixing the top left element (row 1, column 1) to be unity. This condition is evidently satisfied by (2.12).

III. MODIFIED BRAID EQUATION AND BAXTERIZATION FOR THE QUANTUM GROUPS $\mathrm{SO}_q(N)$ AND $\mathrm{Sp}_q(N)$

A. Reduction of trilinear terms

For arbitrary parameters (v,w) the generalized $\hat{R}(v,w)$ matrix is given by (1.9). In addition to quantities already introduced in (2.1), here we further define the following objects:

$$Y_1=P_{(0)}\otimes \mathsf{I}, \quad Y_2=\mathsf{I}\otimes P_{(0)}, \quad S_2=(Y_1-Y_2),$$

$$J_1=(X_1Y_2-Y_1X_2), \quad J_2=(Y_2X_1-X_2Y_1),$$

$$K_1=(X_1X_2Y_1-Y_2X_1X_2), \quad K_2=(X_1Y_2X_1-X_2Y_1X_2), \quad K_3=(Y_1X_2X_1-X_2X_1Y_2),$$

$$L_1=(Y_1Y_2X_1-X_2Y_1Y_2), \quad L_2=(Y_1X_2Y_1-Y_2X_1Y_2), \quad L_3=(X_1Y_2Y_1-Y_2Y_1X_2),$$

$$S_3=(K_1+K_2+K_3), \quad S_4=(L_1+L_2+L_3), \quad T_2=(Y_1Y_2Y_1-Y_2Y_1Y_2). \tag{3.1}$$

In terms of these quantities we obtain

$$\begin{aligned}
&\hat{R}_{12}(v,w)\hat{R}_{23}(v',w')\hat{R}_{12}(v'',w'')-\hat{R}_{23}(v'',w'')\hat{R}_{12}(v',w')\hat{R}_{23}(v,w)\\
&\quad=(v+v''+vv''-v')S_1+(w+w''+ww''-w')S_2+(vw'-v'w)J_1+(w'v''-w''v')J_2\\
&\qquad+(vv'w'')K_1+(vw'v'')K_2+(wv'v'')K_3+(ww'v'')L_1+(wv'w'')L_2+(vw'w'')L_3\\
&\qquad+(vv'v'')T_1+(ww'w'')T_2.
\end{aligned} \tag{3.2}$$

We will discuss below how to express the trilinear combinations $(K_1,K_2,K_3,L_1,L_2,L_3,T_1,T_2)$ in terms of the linear (S_1,S_2) and the bilinear (J_1,J_2) constructs. For the braid values of the parameters

$$v=v'=v''=-(1+q^{-2}), \quad w=w'=w''=-(1-\varepsilon q^{-(N+1-\varepsilon)}) \tag{3.3}$$

the right-hand side of (3.2) vanishes. As noted before, when the spectral variables assume their braid values, the generalized braid matrix $\hat{R}(v,w)$, while satisfying (1.5), reduces to the $\hat{R}$ matrix given in (1.12). The characteristic equation (1.2) for the $\hat{R}$ matrix now reads

$$(\hat{R}-\mathsf{I})(\hat{R}+q^{-2}\mathsf{I})(\hat{R}-\varepsilon q^{-(N+1-\varepsilon)}\mathsf{I})=0. \tag{3.4}$$

The projectors may be extracted from (3.4) as quadratic expression in the matrix $\hat{R}$ *à la* (1.3). For the choice

$$v=v'=v''=-(1+q^{2}), \quad w=w'=w''=-(1-\varepsilon q^{N+1-\varepsilon}) \tag{3.5}$$

the inverse of the braiding matrix, namely $\hat{R}^{-1}$ is obtained. The braid matrix and its inverse $\hat{R}^{\pm 1}$ obtained following the choices (3.3) and (3.5) have been listed in (1.12). For these matrices, as mentioned before, we will suppress the particular values of the spectral variables. For future use here we note that the inverse of the generalized braid matrix (1.9) is given by

$$(\hat{R}(v,w))^{-1}=\mathrm{I}-v(1+v)^{-1}P_{(-)}-w(1+w)^{-1}P_{(0)}. \tag{3.6}$$

The braid equation (1.5) may be utilized to yield the well-known constraints

$$f(\hat{R}_{12}^{\pm 1})\hat{R}_{23}^{\pm 1}\hat{R}_{12}^{\pm 1}=\hat{R}_{23}^{\pm 1}\hat{R}_{12}^{\pm 1}f(\hat{R}_{23}^{\pm 1}),\quad \hat{R}_{12}^{\pm 1}\hat{R}_{23}^{\pm 1}\ \ f(\hat{R}_{12}^{\pm 1})=f(\hat{R}_{23}^{\pm 1})\ \ \hat{R}_{12}^{\pm 1}\hat{R}_{23}^{\pm 1}, \tag{3.7}$$

where $f(x)$ is any well-behaved function of x. The projectors $P_{(-)}$ and $P_{(0)}$ are quadratic functions of the matrix $\hat{R}$. Choosing these particular functions in the constraints (3.7), and utilizing the definitions (2.1) and (3.1) we obtain

$$X_1A_{(\pm)}=A_{(\pm)}X_2,\quad Y_1A_{(\pm)}=A_{(\pm)}Y_2,\quad B_{(\pm)}X_1=X_2B_{(\pm)},\quad B_{(\pm)}Y_1=Y_2B_{(\pm)}, \tag{3.8}$$

where the bilinear elements read

$$\begin{aligned}A_{(\pm)}=\hat{R}_{23}^{\pm 1}\hat{R}_{12}^{\pm 1}=&\mathrm{I}-(1+q^{\mp 2})(X_1+X_2)-(1-\varepsilon q^{\mp(N+1-\varepsilon)})(Y_1+Y_2)+(1+q^{\mp 2})^2X_2X_1\\&+(1+q^{\mp 2})(1-\varepsilon q^{\mp(N+1-\varepsilon)})(X_2Y_1+Y_2X_1)+(1-\varepsilon q^{\mp(N+1-\varepsilon)})^2Y_2Y_1,\end{aligned} \tag{3.9}$$

$$\begin{aligned}B_{(\pm)}=\hat{R}_{12}^{\pm 1}\hat{R}_{23}^{\pm 1}=&\mathrm{I}-(1+q^{\mp 2})(X_1+X_2)-(1-\varepsilon q^{\mp(N+1-\varepsilon)})(Y_1+Y_2)+(1+q^{\mp 2})^2X_1X_2\\&+(1+q^{\mp 2})(1-\varepsilon q^{\mp(N+1-\varepsilon)})(X_1Y_2+Y_1X_2)+(1-\varepsilon q^{\mp(N+1-\varepsilon)})^2Y_1Y_2.\end{aligned} \tag{3.10}$$

We also enlist other useful relations,

$$Y_iY_jY_i=(1+\varepsilon[N-\varepsilon])^{-2}Y_i, \tag{3.11}$$

$$Y_iX_jY_i=\frac{\varepsilon[N-\varepsilon]([2]+\varepsilon[N-1-\varepsilon])}{[2](1+\varepsilon[N-\varepsilon])^2}Y_i, \tag{3.12}$$

where $(i,j)=(1,2)$ or (2, 1). Employing the above constraints and defining the following quantities:

$$\begin{aligned}c=&\frac{\varepsilon[N-\varepsilon+1]}{[2](1+\varepsilon[N-\varepsilon])},\quad d=(1+\varepsilon[N-\varepsilon])^{-1},\\k=&(q-q^{-1})\frac{q^{(N+1-\varepsilon)/2}-\varepsilon q^{-(N+1-\varepsilon)/2}}{q^{(N-1-\varepsilon)/2}+\varepsilon q^{-(N-1-\varepsilon)/2}},\end{aligned} \tag{3.13}$$

we obtain the promised reduction

$$\begin{aligned}&K_1=-c(J_2+(1-c)S_2),\quad K_2=(1-c)(J_1+J_2+(1-c)S_2),\quad K_3=-c(J_1+(1-c)S_2),\\&L_1=-d(J_1+(1-c)S_2),\quad L_2=(1-c)(1-d)S_2,\quad L_3=-d(J_2+(1-c)S_2),\\&T_1=[2]^{-2}(S_1+k(J_1+J_2+(1-c)S_2)),\quad T_2=d^2S_2.\end{aligned} \tag{3.14}$$

It is useful to define the ratios of the spectral variables (w/v) for the $\hat{R}^{\pm 1}$ matrices as given in (1.12):

$$f_{\pm}=q^{\pm 1}[2]^{-1}(1-\varepsilon q^{\mp(N+1-\varepsilon)})=-\varepsilon q^{\mp(N+1-\varepsilon)}f_{\mp}. \tag{3.15}$$

Then it may be shown that

$$c=[2]^{-1}\left(\frac{q^{-1}f_+-qf_-}{f_+-f_-}\right),\quad d=\frac{q-q^{-1}}{[2](f_+-f_-)},$$
$$k=-(q^2-q^{-2})\left(\frac{f_+f_-}{f_+-f_-}\right)=-[2]^2df_+f_-. \tag{3.16}$$

For the special case of the quantum group $SO_q(3)$, where $\varepsilon=1$ and $N=3$, we obtain the parametric values

$$c=1-[2]^{-1},\quad d=(1+[2])^{-1},\quad k=-(1+[2])(2-[2]). \tag{3.17}$$

As a valuable consistency check we carried through the reduction starting directly with $\varepsilon=1$, $N=3$. Agreement for this special case was obtained as the reduction scheme (3.14) was reproduced with the appropriate values of the parameters (3.17).

B. Modified braid equation

For the choice of the variables $v=v'=v''$ and $w=w'=w''$, the result (3.2) reduces to

$$\hat{R}_{12}(v,w)\hat{R}_{23}(v,w)\hat{R}_{12}(v,w)-\hat{R}_{23}(v,w)\hat{R}_{12}(v,w)\hat{R}_{23}(v,w)$$
$$=v(1+v)S_1+w(1+w)S_2+v^2wS_3+vw^2S_4+v^3T_1+w^3T_2, \tag{3.18}$$

where, using (3.14) we obtain

$$S_3=K_1+K_2+K_3=(1-c)(1-3c)S_2+(1-2c)(J_1+J_2),$$
$$S_4=L_1+L_2+L_3=(1-c)(1-3d)S_2-d(J_1+J_2). \tag{3.19}$$

Using the reduction (3.14) for the trilinear constructs T_1 and T_2, we finally obtain the right-hand side of (3.18) as

$$a_1S_1+a_2S_2+b(J_1+J_2), \tag{3.20}$$

where the coefficients read

$$a_1=[2]^{-2}v(v+[2]q)(v+[2]q^{-1}),$$
$$a_2=w(1+w)+d^2w^3+(1-c)v^3\left([2]^{-2}k+(1-3c)\left(\frac{w}{v}\right)+(1-3d)\left(\frac{w}{v}\right)^2\right), \tag{3.21}$$
$$b=-dv^3\left(\frac{w}{v}-f_+\right)\left(\frac{w}{v}-f_-\right).$$

The choice of the 'braid values' for the variables $v=-[2]q^{\mp1}$, $w/v=f_\pm$ for the $\hat{R}^{\pm1}$ matrices readily reduces (3.21) to $a_1=0$, $a_2=0$, $b=0$. This is obvious for a_1 and b, whereas the result for a_2 provides a good consistency check.

To obtain the general MBE we now express (3.20) in terms of $(\hat{R}(v,w))^{\pm1}$. The projectors now read

$$P_{(-)}=\frac{1+v}{v(v-w)}((\hat{R}(v,w)-\mathrm{I})+(1+w)(\hat{R}^{-1}(v,w)-\mathrm{I})),$$
$$P_{(0)}=\frac{1+w}{w(w-v)}((\hat{R}(v,w)-\mathrm{I})+(1+v)(\hat{R}^{-1}(v,w)-\mathrm{I})). \tag{3.22}$$

In passing we mention that by implementing the braid values (1.10) of the variables (v,w) the projectors $P_{(+)}$ and $P_{(0)}$ may also be expressed in terms of the braid matrices $\hat{R}^{\pm 1}$. Now we can express the constructs S_1, S_2, J_1 and J_2 defined in (3.1) in terms of the generalized braid matrices $\hat{R}_{12}^{\pm 1}(v,w)$ and $\hat{R}_{23}^{\pm 1}(v,w)$. Substituting these results in (3.20) we obtain the general MBE stated in (1.18), where, with the values of (a_1,a_2,b) given in (3.21), the coefficients read

$$c_1=\frac{(1+v)(1+w)}{vw(v-w)}\left(\frac{w}{1+w}a_1-\frac{v}{1+v}a_2+2b\right),$$
$$c_2=\frac{(1+v)(1+w)}{vw(v-w)}(wa_1-va_2-2b),\quad c_3=-\frac{(1+v)(1+w)}{vw(v-w)}\,b. \tag{3.23}$$

For the braid values (1.10) of the variables v and w the coefficients (c_1,c_2,c_3) vanish.

We now discuss the following special cases depending on values of the parameters v and w.

(i) For an *arbitrary* nonzero value of v, and for the choices $w=f_{\pm}v$, we, *via* (3.21) and (3.23), obtain $c_3=0$. Hence the right hand side of the MBE (1.18) reduces to the first two terms. Using the characteristic equation (1.15) the right-hand side of the MBE may now be expressed in terms of the generalized braiding operators $(\hat{R}_{12}(v,w)-\hat{R}_{23}(v,w))$ and $(\hat{R}_{12}^2(v,w)-\hat{R}_{23}^2(v,w))$.

(ii) For $v=0$ and an arbitrary value of w we have an interesting case deserving a detailed treatment that is provided in Sec. IV. Here we just note that, for these parametric values, the operator $\hat{R}(0,w)$ satisfies a *quadratic* rather than a cubic characteristic equation; and the right-hand side of the MBE (1.18) is now proportional to $(\hat{R}_{12}(0,w)-\hat{R}_{23}(0,w))$.

C. Baxterization

As was noted in Sec. I, the MBE and the Baxterization are two complementary aspects of the generalized braid operator $\hat{R}(v,w)$ with its spectral decomposition given in (1.9). Having formulated the MBE, we now turn to Baxterization of the braid operator.

From (3.2) and (3.14) we obtain

$$\hat{R}_{12}(v,w)\hat{R}_{23}(v',w')\hat{R}_{12}(v'',w'')-\hat{R}_{23}(v'',w'')\hat{R}_{12}(v',w')\hat{R}_{23}(v,w)=\mathsf{a}_1S_1+\mathsf{a}_2S_2+\mathsf{b}_1J_1+\mathsf{b}_2J_2, \tag{3.24}$$

where, with the parameters c, d and k given by (3.13), the coefficients read

$$\begin{aligned}
\mathsf{a}_1&=(v+v''+vv'')-(1-[2]^{-2}vv'')v',\\
\mathsf{a}_2&=(w+w''+ww'')-(1-d^2ww'')w'+(1-c)((1-c)vv''w'-c(vw''+v''w)v')\\
&\quad+(1-c)((1-d)ww''v'-d(vw''+v''w)w')+(1-c)k[2]^{-2}vv''v',\\
\mathsf{b}_1&=(vw'-wv')-cwv''v'+(1-c)vv''w'-dwv''w'+k[2]^{-2}vv''v',\\
\mathsf{b}_2&=(v''w'-w''v')-cvw''v'+(1-c)vv''w'-dvw''w'+k[2]^{-2}vv''v'.
\end{aligned} \tag{3.25}$$

For Baxterization the variables (v,v'',v') and (w,w'',w') are re-expressed as $(v(x),v(y),v(xy))$ and $(w(x),w(y),w(xy))$, respectively; and then the functional equations

$$\mathsf{a}_i(x,y)=0,\quad \mathsf{b}_i(x,y)=0,\quad i=(1,2) \tag{3.26}$$

obtained *via* (3.25) are solved.

We start by noting a crucial constraint on the functional solutions to be implemented systematically. In (3.24) the $\hat{R}(v,w)$ matrix may be replaced with its inverse $\hat{R}^{-1}(v,w)$ given in (3.6). Hence for consistency our functional solutions must be such that

$$-\frac{v(x)}{1+v(x)}=v(x'),\quad -\frac{w(x)}{1+w(x)}=w(x'), \tag{3.27}$$

where x' is some suitable function of x. We have chosen the parametrization

$$x'=x^{-1} \tag{3.28}$$

such that the validity of the constraint

$$\hat{R}(x)\hat{R}(x^{-1})=\mathsf{I} \tag{3.29}$$

is assured. The functions $f(x)$ and $g(x)$ being suitably well-defined, the relations (3.27) and (3.28) now imply

$$v(x)=\frac{f(x)}{f(x^{-1})}-1,\quad w(x)=\frac{g(x)}{g(x^{-1})}-1. \tag{3.30}$$

It will, in fact, thus be necessary to solve only *two* functional equations from the set (3.26):

$$\mathsf{a}_1(x,y)=0,\quad \mathsf{b}_1(x,y)=0. \tag{3.31}$$

As for the function b_2 we note that the following exchange relation holds:

$$\mathsf{b}_2(x,y)=\mathsf{b}_1(y,x). \tag{3.32}$$

Moreover the solutions of the functional equations (3.31), along with (3.30), will be seen to fix the functions $v(x)$ and $w(x)$ *completely with all the parameters determined*. Then the much more complicated functional equation for $\mathsf{a}_2(x,y)$ does not have to be solved at all. The consistency of the scheme may be verified by checking that $\mathsf{a}_2(x,y)$ indeed vanishes by implementing $v(x)$ and $w(x)$ already available. So now we consider the equations in (3.31). The first equation in (3.31) implies (2.9). It will turn out to be quite useful to solve a more general function equation with arbitrary λ given by

$$u(xy)=\frac{u(x)+u(y)+u(x)u(y)}{1-\lambda^2u(x)u(y)}. \tag{3.33}$$

By direct substitution it may be verified that the general solution maintaining the structure (3.30), namely

$$u(x)=\frac{\alpha(x)}{\alpha(x^{-1})}-1 \tag{3.34}$$

is given by

$$\alpha(x)=-(x-x^{-1})\pm\sqrt{1-4\lambda^2}(x+x^{-1}). \tag{3.35}$$

For all cases of interest to us the square root will turn out to be real. The lower sign before the root in the right-hand side of (3.35) corresponds to $u(x^{-1})$ with the upper sign. So it is sufficient to consider only one, say, the upper sign before the root, since, more generally, replacing of x by x^p in (3.30) does not change the essential functional form. Now setting $\lambda=[2]^{-1}$, we obtain the solution of the first equation in (3.30) with the function $f(x)$ given by

$$f(x)=-(x-x^{-1})+(q-q^{-1})[2]^{-1}(x+x^{-1}). \tag{3.36}$$

Apart from the basic structures (3.34) and (3.35), the following form is also of interest:

$$u(x)=\beta\left(\frac{x^2-1}{x^2+\beta+1}\right), \quad \text{where} \quad \beta=-2(1+\sqrt{1-4\lambda^2})^{-1}. \tag{3.37}$$

Substituting $x=\exp(\theta)$, $\tanh\gamma=\sqrt{1-4\lambda^2}$ we obtain the elegant form of additive Baxterization, as seen in the context of (1.19):

$$u(x)\sim u(\theta)=\frac{\sinh(\gamma-\theta)}{\sinh(\gamma+\theta)}-1. \tag{3.38}$$

For the function $v(x)\sim v(\theta)$, we obtain, after setting $q=\exp(h)$, the solution (1.20).

Now to solve the second equation in (3.31) we proceed in successive steps as follows. Expressing the parameters (c,d,k) in terms of the ratios $f_\pm$ as given in (3.16), we define

$$\mathsf{b}_1\equiv-\frac{vv'v''}{[2](f_+-f_-)}F, \tag{3.39}$$

where

$$F=(q-q^{-1})\frac{w}{v}\frac{w'}{v'}+[2]\frac{f_+-f_-}{v''}\left(\frac{w}{v}-\frac{w'}{v'}\right)+(q^{-1}f_+-qf_-)\frac{w}{v}$$
$$-(qf_+-q^{-1}f_-)\frac{w'}{v'}+(q-q^{-1})f_+f_-. \tag{3.40}$$

In (3.40) we have assumed that the spectral function $v\neq 0$. Now defining

$$U=[2]d(wv^{-1}-f_+), \tag{3.41}$$

we obtain after simplification

$$F=(q-q^{-1})\frac{UU'}{([2]d)^2}\left(1+\left(q+\frac{[2]}{v''}\right)\frac{1}{U'}-\left(q^{-1}+\frac{[2]}{v''}\right)\frac{1}{U}\right). \tag{3.42}$$

In the context of (3.41) we note that by translating the ratio (w/v) by f_- the same functional solutions are finally obtained. Substituting for the function v the form corresponding to (3.37), i.e.,

$$v''=v(y)=-[2]q^{-1}(y^2-1)(y^2-q^{-2})^{-1}, \tag{3.43}$$

we find that the requirement for $F=0$ reads

$$U^{-1}(xy)+(q-q^{-1})^{-1}=(U^{-1}(x)+(q-q^{-1})^{-1})y^2. \tag{3.44}$$

Hence, with an as yet arbitrary parameter δ that is to be fixed immediately afterwards, we obtain the solution as

$$U^{-1}(x)+(q-q^{-1})^{-1}=\delta(q-q^{-1})^{-1}x^2. \tag{3.45}$$

Now the spectral function $w(x)$ may be solved in terms of the already known solution $v(x)$:

$$w(x)=(f_+\delta x^2-f_-)(\delta x^2-1)^{-1}v(x). \tag{3.46}$$

Using the crucial constraint (3.30) on $w(x)$ now it may be shown that there are *only two permitted values* of the parameter δ, which, in turn, generate the corresponding solutions of the spectral function $w(x)$:

$$\delta=-\varepsilon q^{(N+1-\varepsilon)}\Rightarrow w(x)=\frac{x+\varepsilon q^{(N+1-\varepsilon)}x^{-1}}{x^{-1}+\varepsilon q^{(N+1-\varepsilon)}x}-1, \tag{3.47}$$

$$\delta=\varepsilon q^{(N-1-\varepsilon)}\Rightarrow w(x)=\frac{(qx-\varepsilon q^{(N-\varepsilon)}x^{-1})(q^{-1}x-qx^{-1})}{(qx^{-1}-\varepsilon q^{(N-\varepsilon)}x)(q^{-1}x^{-1}-qx)}-1. \tag{3.48}$$

At this stage our procedure of Baxterization of the braid operator is complete. In view of the discussion following (3.32) we need not solve the functional equations corresponding to $\mathsf{a}_2(x,y)$ and $\mathsf{b}_2(x,y)$. The function $w(x)$ corresponding to the additive form of Baxterization may be obtained by setting $x=\exp(\theta),q=\exp(h)$ in the solutions (3.47) and (3.48). For the quantum group $\mathrm{SO}_q(N)$, with $\varepsilon=1$, these solutions assume the form (1.21) and (1.22), respectively. Similarly for the quantized symplectic group $\mathrm{Sp}_q(N)$, where $\varepsilon=-1$ and $N=2n$, they are given by (1.23) and (1.24), respectively.

Finally, expressing the projection operators $P_{(-)}$ and $P_{(0)}$ in terms of the braid matrices $\hat{R}^{\pm 1}$, as discussed following equation (3.22), we obtain

$$\hat{R}(x)=l_{(0)}(x)\mathsf{I}+l_{(+)}(x)\hat{R}+l_{(-)}(x)\hat{R}^{-1}. \tag{3.49}$$

Denoting the braid values (1.10) of the spectral variables corresponding to the $\hat{R}$ matrix by (v_0,w_0), respectively, the coefficients in (3.49) may be listed as

$$\begin{aligned}
l_{(0)}(x)&=1-(1+v_0)(2+w_0)v_0^{-1}(v_0-w_0)^{-1}\,v(x)-(2+v_0)(1+w_0)w_0^{-1}(w_0-v_0)^{-1}\,w(x),\\
l_{(+)}(x)&=(1+v_0)v_0^{-1}(v_0-w_0)^{-1}\,v(x)+(1+w_0)w_0^{-1}(w_0-v_0)^{-1}\,w(x),\\
l_{(-)}(x)&=(1+v_0)(1+w_0)(v_0^{-1}(v_0-w_0)^{-1}\,v(x)+w_0^{-1}(w_0-v_0)^{-1}w(x)).
\end{aligned} \tag{3.50}$$

Consistent with our normalization, the relation $l_{(0)}(x)+l_{(+)}(x)+l_{(-)}(x)=1$ is maintained.

IV. A NEW CLASS OF SOLUTIONS OF THE BRAID EQUATION

So far we have been studying the general case $(v\neq 0,w\neq 0)$ of the spectral variables. We note that for the choice $w=0$, there is no solution of the braid equation with nontrivial v as more than one functional constraints on the single spectral parameter, or the function $v(x)$ in the Baxterized case, need to be satisfied.

For the alternate choice $v=0$, it is, however, *possible* to obtain a remarkable class of generalized braid matrices $\hat{R}(w)$ depending on the single variable w. This was already studied in the context of the quantum group $\mathrm{SO}_q(3)$ in Ref. 2. Here we present this class for general quantum groups $\mathrm{SO}_q(N)$ and $\mathrm{Sp}_q(N)$. Denoting the generalized braid matrix $\hat{R}(0,w)$ by $\hat{R}(w)$, we write

$$\hat{R}(w)=\mathsf{I}+wP_{(0)},\quad \hat{R}^{-1}(w)=\mathsf{I}-w(1+w)^{-1}P_{(0)}, \tag{4.1}$$

where the matrix $\hat{R}(w)$ satisfies a quadratic characteristic equation

$$(\hat{R}(w)-\mathsf{I})(\hat{R}(w)-(1+w)\,\mathsf{I})=0. \tag{4.2}$$

Instead of restricting our preceding general formulas to the special case $v=0$ it is much simpler to start again with (3.2) which, in conjunction with the last relation in (3.14), now gives

$$\hat{R}_{12}(w)\hat{R}_{23}(w)\hat{R}_{12}(w)-\hat{R}_{23}(w)\hat{R}_{12}(w)\hat{R}_{23}(w)$$
$$=(w(1+w)+d^2w^3)S_2=(1+w+d^2w^2)(\hat{R}_{12}(w)-\hat{R}_{23}(w)). \tag{4.3}$$

Thus we have already obtained the MBE with a simple linear structure in the generalized braid matrix on the right-hand side. But as the coefficient on the right-hand side of (4.3) may be factorized as

$$d^2w^2+w+1=d^2(w-w_+)(w-w_-), \quad w_\pm=2^{-1}d^{-2}(-1\pm\sqrt{1-4d^2}), \tag{4.4}$$

we obtain two nonmodified *new braid matrices*:

$$\hat{R}_{12}(w_\pm)\hat{R}_{23}(w_\pm)\hat{R}_{12}(w_\pm)-\hat{R}_{23}(w_\pm)\hat{R}_{12}(w_\pm)\hat{R}_{23}(w_\pm)=0. \tag{4.5}$$

But the constraint

$$\hat{R}(w_+)\hat{R}(w_-)=\mathsf{I}, \tag{4.6}$$

observed using (4.1) and (4.4) indicate the presence of only *one* braid matrix and its inverse. Following the expression of d in (3.13) we also note that the quantity under the radical sign in (4.4) satisfies $1>(1-4d^2)>0$ for all values of (N,ε) relevant to us. Hence the square root is real.

The prescription of Baxterization of this class of $\hat{R}(w)$ matrices is immediately obtained from (3.33)–(3.35). Only relevant functional equation $\mathsf{a}_2(x,y)=0$ in the set (3.26) now yields

$$w(xy)=\frac{w(x)+w(y)+w(x)w(y)}{1-d^2w(x)\,w(y)}, \tag{4.7}$$

whereas the other functional equations in the set (3.26) trivially vanishes for the case $v=0$. The solution of the equation (4.7) read

$$w(x)=\frac{-(x-x^{-1})+\sqrt{1-4d^2}(x+x^{-1})}{(x-x^{-1})+\sqrt{1-4d^2}(x+x^{-1})}-1. \tag{4.8}$$

Setting $x=\exp(\theta)$ and $\tanh\eta=\sqrt{1-4d^2}$, we, following (3.38), obtain

$$w(x)\sim w(\theta)=\frac{\sinh(\eta-\theta)}{\sinh(\eta+\theta)}-1. \tag{4.9}$$

For the quantum group $\mathrm{SO}_q(3)$ the generalized braid operator $\hat{R}(w)$ in the present class was explicitly presented before in Ref. 2. Here we present the general prescription regarding the quantum groups $\mathrm{SO}_q(N)$ and $\mathrm{Sp}_q(N)$. To this end we include the standard and well-known construction of the projectors for the sake of completeness. Let $(\rho_1,\rho_2,\ldots,\rho_N)$ denote the N-tuple with the following assignments for the respective quantum groups:

$$\left(n-\tfrac{1}{2},n-\tfrac{3}{2},\ldots,\tfrac{1}{2},0,-\tfrac{1}{2},\ldots,-n+\tfrac{1}{2}\right) \quad \text{for } \mathrm{SO}_q(2n+1),$$
$$(n-1,n-2,\ldots,1,0,0,-1,\ldots,-n+1) \quad \text{for } \mathrm{SO}_q(2n), \tag{4.10}$$
$$(n,n-1,\ldots,1,-1,\ldots,-n) \quad \text{for } \mathrm{Sp}_q(2n).$$

We also fix the values $\{\epsilon_i=1|i=1,\ldots,N\}$ for the quantum group $\mathrm{SO}_q(N)$; and $\{\epsilon_i=1$, if $i\leqslant n$, $\epsilon_i=-1$, if $i>n\}$ for the quantum group $\mathrm{Sp}_q(2n)$. As usual E_{ij} denotes the $N\times N$ matrix where the only nonzero element (i,j) equals unity. With these notations the projectors are given by

$$P_{(0)}=(1+[N-1])^{-1}\sum_{i,j=1}^{N} q^{(\rho_i-\rho_j)}\ E_{i',j}\otimes E_{i,j'} \tag{4.11}$$

and

$$P_{(0)}=(1-[N+1])^{-1}\sum_{i,j=1}^{N} q^{(\rho_i-\rho_j)}\ \epsilon_i\epsilon_j\ E_{i',j}\otimes E_{i,j'} \tag{4.12}$$

for the quantum groups $\mathrm{SO}_q(N)$ and $\mathrm{Sp}_q(N)$, (where $N=2n$), respectively. In the above equations we have used the notation $i'=N+1-i$. We have recapitulated the above standard prescription for the additional purpose of displaying the braid operators in the $q=1$ limit.

We enlist below the lowest dimensional cases as examples. The projector $P_{(0)}$ in the 9×9 vector representation for the quantum group $\mathrm{SO}_q(3)$ is given by

$$\begin{aligned}(1+[2])P_{(0)}=&q^{-1}E_{11}\otimes E_{33}+q^{-1/2}E_{12}\otimes E_{32}+E_{13}\otimes E_{31}+q^{-1/2}E_{21}\otimes E_{23}+E_{22}\otimes E_{22}+q^{1/2}E_{23}\\&\otimes E_{21}+E_{31}\otimes E_{13}+q^{1/2}E_{32}\otimes E_{12}+qE_{33}\otimes E_{11},\end{aligned} \tag{4.13}$$

whereas 16×16 vector representations for the quantum groups $\mathrm{SO}_q(4)$ and $\mathrm{Sp}_q(4)$ read as

$$\begin{aligned}(1+[3])P_{(0)}=&q^{-2}E_{11}\otimes E_{44}+q^{-1}E_{12}\otimes E_{43}+q^{-1}E_{13}\otimes E_{42}+E_{14}\otimes E_{41}+q^{-1}E_{21}\otimes E_{34}+E_{22}\otimes E_{33}\\&+E_{23}\otimes E_{32}+qE_{24}\otimes E_{31}+q^{-1}E_{31}\otimes E_{24}+E_{32}\otimes E_{23}+E_{33}\otimes E_{22}+qE_{34}\otimes E_{21}+E_{41}\\&\otimes E_{14}+qE_{42}\otimes E_{13}+qE_{43}\otimes E_{12}+q^2E_{44}\otimes E_{11}\end{aligned} \tag{4.14}$$

and

$$\begin{aligned}([5]-1)P_{(0)}=&q^{-4}E_{11}\otimes E_{44}+q^{-3}E_{12}\otimes E_{43}-q^{-1}E_{13}\otimes E_{42}-E_{14}\otimes E_{41}+q^{-3}E_{21}\otimes E_{34}+q^{-2}E_{22}\\&\otimes E_{33}-E_{23}\otimes E_{32}-qE_{24}\otimes E_{31}-q^{-1}E_{31}\otimes E_{24}-E_{32}\otimes E_{23}+q^2E_{33}\otimes E_{22}+q^3E_{34}\\&\otimes E_{21}-E_{41}\otimes E_{14}-qE_{42}\otimes E_{13}+q^3E_{43}\otimes E_{12}+q^4E_{44}\otimes E_{11},\end{aligned} \tag{4.15}$$

respectively.

For this class, directly setting $q=1$ we still get nontrivial braid matrices, the MBE satisfied by them, and also the Baxterized forms of these braid matrices. (We note that we are not considering the so-called quasiclassical limit obtained as the coefficients of the terms linear in h, while implementing series expansion in $h\equiv\ln q$. We simply set $q=1$ in the relevant quantities, and thus obtain the terms of zero order in h). The corresponding example for the quantum group $\mathrm{SO}_q(3)$ was discussed in Ref. 2.

In the classical $q=1$ limit, we denote the projectors by $\hat{P}$ to avoid confusion. Using (4.11) we now obtain the projector for the classical group $\mathrm{SO}(N)$ as

$$\hat{P}_{(0)}=N^{-1}\sum_{i,j=1}^{N} E_{i',j}\otimes E_{i,j'}, \tag{4.16}$$

while the projector for the classical symplectic group $\mathrm{Sp}(N)$ reads

$$\hat{P}_{(0)}=-N^{-1}\sum_{i,j=1}^{N} \epsilon_i\epsilon_j E_{i',j}\otimes E_{i,j'}. \tag{4.17}$$

Moreover the parameters, *via* (3.13), (4.4), and (4.9), are obtained in the limit $q=1$ as

$$d|_{(q=1)} \equiv \hat{d} = \varepsilon N^{-1}, \quad \eta|_{(q=1)} \equiv \hat{\eta} = \operatorname{arctanh}(N^{-1}\sqrt{N^2-4}),$$
$$w_{(\pm)}|_{(q=1)} \equiv \hat{w}_{(\pm)} = \frac{N}{2}(-N \pm \sqrt{N^2-4}). \tag{4.18}$$

Using the above value of $\hat{d}$ in (4.3) we may directly obtain the MBE in the $q=1$ case. In the Baxterized function (4.9) we now use the value of $\hat{\eta}$ given in (4.18), and thereby obtain the limiting structure

$$w(\theta)|_{(q=1)} = \hat{w}(\theta) = \frac{\sinh(\hat{\eta}-\theta)}{\sinh(\hat{\eta}+\theta)} - 1. \tag{4.19}$$

We now focus on the $q=1$ limiting case of the braid solution described in (4.5). The braid matrices in this limit has the structure

$$\hat{R}(\hat{w}_{(\pm)}) = \mathrm{I} + \hat{w}_{(\pm)}\hat{P}_{(0)}. \tag{4.20}$$

Even in the said $q=1$ limit, these matrices, on account of the characteristic equation (4.2), satisfy a nontrivial Hecke condition. These braid matrices are not of co-boundary type, which may be obtained by twisting the identity operator. The situation may be profitably contrasted with the $q=1$ limiting behavior of the general case ($v \neq 0$) of braid matrices satisfying (1.5). Setting the limit $q=1$ in the braid values (1.10) of the spectral variables we obtain

$$v|_{(q=1)} \equiv \hat{v} = -2, \quad w|_{(q=1)} \equiv \hat{w} = -(1-\varepsilon). \tag{4.21}$$

Incidentally, identical conditions in the said classical limit $h=0$ may be derived from the Baxterized version of the spectral variables given in (1.20)–(1.24). For the values of the spectral variables given in (4.21) the braid matrix for the quantum group $\mathrm{SO}_q(N)$ assumes the form

$$\hat{R}(\hat{v},\hat{w}) = \mathrm{I} - 2P_{(-)}, \tag{4.22}$$

whereas the the braid matrix for the quantum group $\mathrm{Sp}_q(N)$ reads

$$\hat{R}(\hat{v},\hat{w}) = \mathrm{I} - 2P_{(-)} - 2P_{(0)} = 2P_{(+)} - \mathrm{I}. \tag{4.23}$$

The above two braid matrices satisfy the condition $(\hat{R}(\hat{v},\hat{w}))^2 = \mathrm{I}$, typical of twisted identity matrices. Finally we note that here the result parallel to (2.12) is

$$\hat{R}(w) = \frac{(w-w_-)\hat{R}(w_+) - (w-w_+)\hat{R}(w_-)}{(w_+ - w_-)}, \tag{4.24}$$

where $w_\pm$, *via* (4.4), is given by $w_\pm = -(1+\exp(\mp 2\eta))$.

V. DIAGONALIZATION OF THE MODIFIED BRAID MATRICES AND THEIR CORRESPONDING EIGENVECTORS

We present below explicitly the 4×4, 9×9, and 16×16 matrices which, through similarity transformations, diagonalize respectively the matrices $\hat{R}(v)$ for the quantum group $\mathrm{GL}_q(2)$, and $\hat{R}(v,w)$ for the quantum groups $\mathrm{SO}_q(3)$ and $\mathrm{SO}_q(4)$. Explicit constructions for arbitrary dimensions $N\times N$ is beyond the scope of the present work. But we start by considering, for deeper understanding, certain aspect of the problem for the general quantized orthogonal group $\mathrm{SO}_q(N)$. The case for the general linear quantum group $\mathrm{GL}_q(N)$ is, as usual, much simpler. In the diago-

nalization process, as throughout the present work, the projectors involved in the spectral decomposition of the generalized braid matrices play essential roles. Interest in the results obtained will be discussed at the end.

Traces of the projectors satisfying the completeness property

$$P_{(+)}+P_{(-)}+P_{(0)}=\mathsf{I}_{N^2\times N^2}, \tag{5.1}$$

are given by

$$\mathrm{Tr}\,P_{(+)}=\tfrac{1}{2}N(N+1)-\tfrac{1}{2}(\varepsilon+1),\quad \mathrm{Tr}\,P_{(-)}=\tfrac{1}{2}N(N-1)+\tfrac{1}{2}(\varepsilon-1),\quad \mathrm{Tr}\,P_{(0)}=1. \tag{5.2}$$

The sum of the above three traces, consistent with (5.1), is N^2. We consider below only the examples of quantum orthogonal algebras corresponding to the choice $\varepsilon=1$. Moreover, in view of (5.1), we will only consider the projectors $P_{(-)}$ and $P_{(0)}$, thus continuing the methodology followed in the earlier sections.

A projector when diagonalized can have for each diagonal element *either zero or unity*. The number of unit elements are fixed by trace. The diagonal elements can be permuted by successive similarity transformations. So we can choose a suitable canonical ordering for them as follows. Denoting a diagonalized projector P by $P^{(\mathrm{d})}$, we choose the ordering presented below. For the quantum group $\mathrm{SO}_q(3)$ the diagonalized projectors read

$$\begin{aligned} P^{(\mathrm{d})}_{(0)}&=(1,0,0,0,0,0,0,0,0)_{(\mathrm{diagonal})},\\ P^{(\mathrm{d})}_{(-)}&=(0,1,1,1,0,0,0,0,0)_{(\mathrm{diagonal})}, \end{aligned} \tag{5.3}$$

whereas these diagonalized projectors for the quantum group $\mathrm{SO}_q(4)$ are given by

$$\begin{aligned} P^{(\mathrm{d})}_{(0)}&=(1,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0)_{(\mathrm{diagonal})},\\ P^{(\mathrm{d})}_{(-)}&=(0,1,1,1,1,1,1,0,0,0,0,0,0,0,0,0)_{(\mathrm{diagonal})}. \end{aligned} \tag{5.4}$$

The prescription for general quantized orthogonal group $\mathrm{SO}_q(N)$ is evident.

A transformation that diagonalizes the generalized braid matrix $\hat{R}(v,w)$ must diagonalize each projector *separately*, as these projectors are functions of the matrix $\hat{R}(v,w)$. Using the above form of the diagonalized projectors, we avoid introducing the inverse of the diagonalizing matrix M as follows. Assuming that a diagonalizing matrix of nonzero determinant exists, we have

$$MP_{(0)}=P^{(\mathrm{d})}_{(0)}M,\quad MP_{(-)}=P^{(\mathrm{d})}_{(-)}M, \tag{5.5}$$

where the diagonalized projectors $P^{(\mathrm{d})}$ have explicit forms given by (5.3) and (5.4), and their evident generalizations. The projectors $P_{(0)}$ and $P_{(-)}$ being known from the standard results, we avoid direct introduction of the matrix M^{-1}, which is nonlinear in elements of M.

The diagonalizing relations (5.5) generate a set of *linear* constraints on the elements of M. The coefficients in each equation are fully known. They will in general leave room for many arbitrary parameters in the matrix M, subject to the constraint that it has a nonzero determinant. This arbitrariness can be factored out as follows. Supposing that in the case of the the quantum group $\mathrm{SO}_q(3)$ we have found a convenient solution $\hat{M}$ for the diagonalizing matrix, the relation (5.5) in conjunction with (5.3) yield the structure

$$\hat{M}\hat{R}(v,w)\hat{M}^{-1}=\hat{M}(\mathsf{I}+vP_{(-)}+wP_{(0)})\hat{M}^{-1}=(1+w,1+v,1+v,1+v,1,1,1,1,1)_{(\mathrm{diagonal})}. \tag{5.6}$$

Keeping the above block structure in mind we now use a block diagonal matrix

$$\mathsf{M}=(\mathsf{M}_{(0)},\mathsf{M}_{(-)},\mathsf{M}_{(+)})_{(\text{block diagonal})}, \tag{5.7}$$

where $\mathsf{M}_{(0)}$, $\mathsf{M}_{(-)}$, and $\mathsf{M}_{(+)}$, respectively, are 1×1, 3×3, and 5×5 invertible matrices with nonzero determinant. Using the property (5.6) and the above structure of the matrix M, we obtain

$$(\mathsf{M}\hat{M})\hat{R}(v,w)(\mathsf{M}\hat{M})^{-1}=\hat{M}\hat{R}(v,w)\hat{M}^{-1}. \tag{5.8}$$

Thus the diagonalization is preserved exactly. The above matrix $\mathsf{M}_{(0)}$ is a nonzero constant, whereas the matrices $\mathsf{M}_{(\mp)}$, apart from the single constraint of invertibility have *arbitrary* elements. This is the source of arbitrariness in the diagonalization procedure. For the general case the dimensions of $\mathsf{M}_{(0)}$, $\mathsf{M}_{(-)}$, and $\mathsf{M}_{(+)}$ are given by the respective traces (5.2) of the corresponding projectors.

But how do we select $\hat{M}$? For the quantum groups $\mathrm{SO}_q(3)$ and $\mathrm{SO}_q(4)$ we present below the diagonalizing matrix $\hat{M}$ possessing a remarkably helpful feature: *the rows of $\hat{M}$ are mutually orthogonal*. It is presumably possible to choose the diagonalizing matrix $\hat{M}$ retaining this feature for all orthogonal quantum groups. But here we do not attempt to construct such a general solution for an arbitrary case.

For the quantum group $\mathrm{SO}_q(3)$ we define the parameters $s=-q^{-1/2}(1-q)$, $t=-q^{-3/2}(1+q)$, and obtain the relevant diagonalizing matrix:

$$\hat{M}=\begin{pmatrix} 0 & 0 & 1 & 0 & q^{1/2} & 0 & q & 0 & 0 \\ 0 & 1 & 0 & -q & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & -q & 0 \\ 0 & 0 & 1 & 0 & s & 0 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & q^{-1} & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & t & 0 & q^{-2} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & q^{-1} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}. \tag{5.9}$$

Here we note the existence of the following orthogonal triplets:

$$(1,q^{1/2},q),(1,s,-1),(1,t,q^{-2}), \tag{5.10}$$

which, as will be seen later, play a role in the context of the noncommutative coordinates. For the quantum group $\mathrm{SO}_q(4)$, one possible choice of the ordering of the rows gives the following diagonalizing matrix:

$$\hat{M}=\begin{pmatrix}
0&0&0&1&0&0&q&0&0&q&0&0&q^2&0&0&0\\
0&0&0&1&0&0&q&0&0&-q^{-1}&0&0&-1&0&0&0\\
0&1&0&0&-q&0&0&0&0&0&0&0&0&0&0&0\\
0&0&1&0&0&0&0&0&-q&0&0&0&0&0&0&0\\
0&0&0&0&0&0&0&1&0&0&0&0&0&-q&0&0\\
0&0&0&0&0&0&0&0&0&0&0&1&0&0&-q&0\\
0&0&0&1&0&0&-q^{-1}&0&0&q&0&0&-1&0&0&0\\
1&0&0&0&0&0&0&0&0&0&0&0&0&0&0&0\\
0&1&0&0&q^{-1}&0&0&0&0&0&0&0&0&0&0&0\\
0&0&1&0&0&0&0&0&q^{-1}&0&0&0&0&0&0&0\\
0&0&0&1&0&0&-q^{-1}&0&0&-q^{-1}&0&0&q^{-2}&0&0&0\\
0&0&0&0&0&0&0&1&0&0&0&0&0&q^{-1}&0&0\\
0&0&0&0&0&0&0&0&0&0&0&1&0&0&q^{-1}&0\\
0&0&0&0&0&0&0&0&0&0&1&0&0&0&0&0\\
0&0&0&0&0&1&0&0&0&0&0&0&0&0&0&0\\
0&0&0&0&0&0&0&0&0&0&0&0&0&0&0&1
\end{pmatrix}. \tag{5.11}$$

Here the relevant orthogonal quadruplets read

$$(1,q,q,q^2),(1,q,-q^{-1},-1),(1,-q^{-1},q,-1),(1,-q^{-1},-q^{-1},q^{-2}). \tag{5.12}$$

It may be noted that the orthogonality of the rows delivers the inverse of the diagonalizing matrix $\hat{M}^{-1}$ effortlessly. To this end, we take the transposed matrix $\hat{M}^{\mathsf{T}}$ and normalize each element of its column j by the same factor c_j so that the sum of squares of all elements of this column j multiplied with c_j equates to unity. For the diagonalizing matrix $\hat{M}$ in (5.9), these normalization constants are given by

$$\begin{aligned}q(1+[2])c_1=q[2]c_2=q[2]c_3=[2]c_4=c_5=q^{-1}[2]c_6,\\ =q^{-2}[2](1+[2])c_7=q^{-1}[2]c_8=c_9=1,\end{aligned} \tag{5.13}$$

whereas the corresponding normalization constants for the matrix in (5.11) read

$$\begin{aligned}q^2[2]^2c_1=[2]^2c_2=q[2]c_3=q[2]c_4=q[2]c_5=q[2]c_6=[2]^2c_7=c_8=q^{-1}[2]c_9=q^{-1}[2]c_{10}\\ =q^{-2}[2]^2c_{11}=q^{-1}[2]c_{12}=q^{-1}[2]c_{13}=c_{14}=c_{15}=c_{16}=1.\end{aligned} \tag{5.14}$$

Now we show that the orthogonality of the rows also directly leads to the eigenvectors of the generalized braid matrix $\hat{R}(v,w)$. We again choose the quantum group $\mathrm{SO}_q(3)$ as a typical example. Let $\{|V_k\rangle|(k=1,\ldots,9)\}$ be the eigenvectors of the $\hat{R}(v,w)$ matrix with the eigenvalues a_k:

$$\hat{R}(v,w)|V_k\rangle=a_k|V_k\rangle, \tag{5.15}$$

where no summation over the index k on the right is implied. Multiplying the equation (5.15) with the matrix $\hat{M}$ on both sides and employing diagonalization property (5.6) we obtain

$$(1+w,1+v,1+v,1+v,1,1,1,1,1)_{(\mathrm{diagonal})}|\hat{M}V_k\rangle=a_k|\hat{M}V_k\rangle. \tag{5.16}$$

Hence, apart from overall constant factors, we may choose the transposed vectors as follows:

$$|\hat{M}V_k\rangle^{\mathsf{T}}=\{(1,0,\ldots,0),(0,1,0,\ldots,0),\ldots,(0,\ldots,0,1)\}. \tag{5.17}$$

The eigenvalues are given by the diagonal elements of the matrix $\hat{M}\hat{R}(v,w)\hat{M}^{-1}$ as exhibited in (5.6). Hence the obvious construction $|V_k\rangle=\hat{M}^{-1}|\hat{M}V_k\rangle$, along with (5.17) furnishes the eigenvector $|V_k\rangle$ as the kth column of $\hat{M}^{-1}$. Now, in view of the construction of the inverse matrix $\hat{M}^{-1}$ previously discussed preceding (5.13), the eigenvector $|V_k\rangle$ *is finally given by the* kth *row of the matrix* $\hat{M}$. Replacing here the matrix $\hat{M}$ by its alternatives $\mathsf{M}\hat{M}$ amounts to, as given in (5.8), taking linear combinations of the above eigenvectors with the same eigenvalue. The eigenvectors and particularly the highest eigenvalue, dependent here on the choice of the spectral variables (v,w), of the generalized braid matrix $\hat{R}(v,w)$ are of interest in related models of statistical mechanics. Another, quite different, interest in the above diagonalization of the $\hat{R}(v,w)$ matrix will be pointed out in Sec. VI in the context of noncommutative spaces.

So far we have considered the orthogonal quantum group $\mathrm{SO}_q(N)$. A parallel, but much simpler, formalism may be developed for the linear quantum group $\mathrm{GL}_q(N)$, as only two projectors are present there. Instead of discussing the general case, we, for the purpose of illustration, consider a biparametric (p,q) deformation of the group GL(2) in the remaining part of the present section. In Ref. 1 one of us introduced the generalized braid matrix (for $p\neq 0$)

$$\hat{R}(K;p,q)=\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & (1-K) & Kp^{-1} & 0 \\ 0 & Kq & (1-Kqp^{-1}) & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \tag{5.18}$$

which satisfies the strict braid equation for the two parametric values $K=1,pq^{-1}$. Maintaining a specific parametrization of the spectral variable v, we write in conformity with the notations of the Sec. II:

$$\hat{R}(K;p,q)=\mathsf{I}-K(1+qp^{-1})P_{(-)}, \tag{5.19}$$

where the projector is

$$P_{(-)}=(1+qp^{-1})^{-1}\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 1 & -p^{-1} & 0 \\ 0 & -q & qp^{-1} & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}. \tag{5.20}$$

The projector $P_{(-)}$ may be diagonalized by

$$\hat{M}=\begin{pmatrix} 0 & -1 & p^{-1} & 0 \\ 0 & q & 1 & 0 \\ 1 & 0 & 0 & 1 \\ 1 & 0 & 0 & -1 \end{pmatrix} \tag{5.21}$$

giving $\hat{M}P_{(-)}\hat{M}^{-1}=(1,0,0,0)_{(\mathrm{diagonal})}$. This, following the spectral decomposition (5.19), provides the diagonalized $\hat{R}$ matrix. In this simple case the matrix $\hat{M}^{-1}$ may be easily computed for all values of deformation parameters (p,q). But except for the special case $pq=1$, the first two rows of the present diagonalizer $\hat{M}$ are not orthogonal to each other.

VI. GENERALIZED BRAID MATRICES AND CONSEQUENT NONCOMMUTATIVE SPACES

We first present the general prescription for covariant quantization of spaces implementing the generalized braid matrices $\hat{R}(v)$ and $\hat{R}(v,w)$. Our prescription follow the standard structure except for the presence of the arbitrary values of the spectral variables (v,w). Then we will display how the diagonalizations of the generalized braid matrices presented in Sec. V enable us to extract in a convenient fashion the contents of the above prescription using, as before, the quantum groups $\mathrm{GL}_q(2)$, $\mathrm{SO}_q(3)$, and $\mathrm{SO}_q(4)$ as examples. Generalization to higher dimensional quantum groups can then be easily carried out. Our study will thus be limited. We hope to present elsewhere a fuller exploration of the possible roles of the variables (v,w).

For the quantum group $\mathrm{GL}_q(2)$, we use the projector (5.20) with the restriction $p=q^{-1}$, and set the $\hat{R}(v)$ matrix as in (1.8) satisfying the characteristic equation (1.14). Using the standard notations with coordinates and differentials given, respectively, by $\{x_i,\xi_i\equiv dx_i|i=(1,2)\}$, we obtain

$$P_{(-)}x\otimes x=0 \tag{6.1}$$

and

$$x\otimes\xi=B\xi\otimes x, \tag{6.2}$$

whereas Leibnitz rule and covariance lead to

$$(B+\mathrm{I})\xi\otimes\xi=0. \tag{6.3}$$

The matrix B reads

$$B=-\mathrm{I}+\mu(\hat{R}(v)-(1+v)\mathrm{I}), \tag{6.4}$$

while the parameter μ is arbitrary. We also note that the above structure of B ensures the orthogonality: $(B+\mathrm{I})P_{(-)}=0$. Using the diagonalizer $\hat{M}$ given in (5.21), and adapting it to the parametric choice $p=q^{-1}$, we evaluate

$$\hat{M}x\otimes\xi=\hat{M}\begin{pmatrix}x_1\xi_1\\ x_1\xi_2\\ x_2\xi_1\\ x_2\xi_2\end{pmatrix}=\begin{pmatrix}-x_1\xi_2+qx_2\xi_1\\ qx_1\xi_2+x_2\xi_1\\ x_1\xi_1+x_2\xi_2\\ x_1\xi_1-x_2\xi_2\end{pmatrix}. \tag{6.5}$$

The analogous results for $\hat{M}x\otimes x$, $\hat{M}\xi\otimes\xi$, and $\hat{M}\xi\otimes x$ can be read off (6.5) readily. Using the previous explicit constructions we may now obtain the following diagonalized structures:

$$\begin{aligned}\hat{M}P_{(-)}\hat{M}^{-1}&=(1,0,0,0)_{(\mathrm{diagonal})},\\ \hat{M}\hat{R}(v)\hat{M}^{-1}&=(1+v,1,1,1)_{(\mathrm{diagonal})},\\ \hat{M}(B+\mathrm{I})\hat{M}^{-1}&=\mu(0,-v,-v,-v)_{(\mathrm{diagonal})},\\ \hat{M}B\hat{M}^{-1}&=-(1,1+\mu v,1+\mu v,1+\mu v)_{(\mathrm{diagonal})},\end{aligned} \tag{6.6}$$

which in conjunction with (6.5) allow us to immediately write down the relations

$$x_1x_2=qx_2x_1,\quad \xi_1\xi_2=-q^{-1}\xi_2\xi_1,\quad \xi_1^2=0,\quad \xi_2^2=0 \tag{6.7}$$

and

$$
\begin{aligned}
(-x_1\xi_2+qx_2\xi_1)&=-(-\xi_1x_2+q\xi_2x_1),\\
(qx_1\xi_2+x_2\xi_1)&=-(1+\mu v)(q\xi_1x_2+\xi_2x_1),\\
(x_1\xi_1+x_2\xi_2)&=-(1+\mu v)(\xi_1x_1+\xi_2x_2),\\
(x_1\xi_1-x_2\xi_2)&=-(1+\mu v)(\xi_1x_1-\xi_2x_2).
\end{aligned}
\tag{6.8}
$$

Adapting notations and parametrizations the corresponding results of Ref. 1 may be obtained. But the consequences of the diagonalization is particularly striking in the modular structure evident in (6.8). Linear combinations of $x_i\xi_j$ are picked out that are *proportional to the same combination* of ξ_ix_j on the right. This is, as will be seen, a general feature in all cases. It was shown in Ref. 1 that

$$\Phi^2=(\xi_1x_2-q\xi_2x_1)^2=0. \tag{6.9}$$

Here, using (6.8) it immediately follows that the combination $(x_1\xi_2-qx_2\xi_1)$ is also nilpotent. Our formalism also signals clearly special values of the parameters. It is evident from (6.8) that $\mu=-v^{-1}$ is a very special case. For the quantum group $\mathrm{GL}_q(N)$ for an arbitrary N the prescriptions (6.1) to (6.4) remain the same except that higher dimensional $N^2\times N^2$ matrices need to be considered.

Now we consider the noncommuting spaces associated with the generalized braid matrix $\hat{R}(v,w)$ of the orthogonal quantum group $\mathrm{SO}_q(N)$. This matrix has the structure (1.9) and it satisfies the characteristic equation (1.15). The braiding structure (6.1) of the noncommutative coordinates now may also be expressed as

$$(\hat{R}(v,w)-\mathrm{I})(\hat{R}(v,w)-(1+w)\mathrm{I})x\otimes x=0. \tag{6.10}$$

Leibnitz rule and covariance ensure equations (6.2) and (6.3) with the matrix B given by (6.4). As there are three projectors for the orthogonal quantum groups, the braiding relation (6.3) now reduces to

$$P_{(+)}\xi\otimes\xi=0,\quad P_{(0)}\xi\otimes\xi=0. \tag{6.11}$$

Now we will explicitly demonstrate the above structure for the quantum groups $\mathrm{SO}_q(3)$ and $\mathrm{SO}_q(4)$. For the quantum group $\mathrm{SO}_q(3)$ the diagonalizing matrix $\hat{M}$ is given in (5.9). The diagonalized operators now read

$$
\begin{aligned}
\hat{M}P_{(-)}\hat{M}^{-1}&=(0,1,1,1,0,0,0,0,0)_{(\mathrm{diagonal})},\\
\hat{M}\hat{R}(v,w)\hat{M}^{-1}&=(1+w,1+v,1+v,1+v,1,1,1,1,1)_{(\mathrm{diagonal})},\\
\hat{M}B\hat{M}^{-1}&=-(1+\mu(v-w),1,1,1,1+\mu v,1+\mu v,1+\mu v,1+\mu v,1+\mu v)_{(\mathrm{diagonal})}.
\end{aligned}
\tag{6.12}
$$

Here we choose, as in Ref. 2, the triplets (x_-,x_0,x_+) and (ξ_-,ξ_0,ξ_+) as the basis elements for the noncommuting coordinates and the differentials, respectively. Using the diagonalizing matrix $\hat{M}$ given in (5.9) we now compute

$$\hat{M}x\otimes\xi=\hat{M}\begin{pmatrix} x_-\xi_- \\ x_-\xi_0 \\ x_-\xi_+ \\ x_0\xi_- \\ x_0\xi_0 \\ x_0\xi_+ \\ x_+\xi_- \\ x_+\xi_0 \\ x_+\xi_+ \end{pmatrix}=\begin{pmatrix} x_-\xi_+ + q^{1/2}x_0\xi_0 + qx_+\xi_- \\ x_-\xi_0 - qx_0\xi_- \\ x_0\xi_+ - qx_+\xi_0 \\ x_-\xi_+ + sx_0\xi_0 - x_+\xi_- \\ x_-\xi_- \\ x_-\xi_0 + q^{-1}x_0\xi_- \\ x_-\xi_+ + tx_0\xi_0 + q^{-2}x_+\xi_- \\ x_0\xi_+ + q^{-1}x_+\xi_0 \\ x_+\xi_+ \end{pmatrix}. \tag{6.13}$$

The matrices $\hat{M}x\otimes x$, $\hat{M}\xi\otimes\xi$ and $\hat{M}\xi\otimes x$ have evident analogous forms. The parameters (μ,v,w) do not appear in the braiding structures (6.1) and (6.11). Therefore these braiding relations have the usual form, given, for example, in Eq. (3.48) of Ref. 2. For the sake of completeness we present them here

$$x_-x_0=qx_0x_-,\quad x_0x_+=qx_+x_0,\quad x_+x_- - x_-x_+=(q^{1/2}-q^{-1/2})x_0^2,$$

$$\xi_-^2=0,\quad \xi_+^2=0,\quad \xi_-\xi_+ + \xi_+\xi_-=0, \tag{6.14}$$

$$q\xi_-\xi_0+\xi_0\xi_-=0,\quad q\xi_0\xi_+ + \xi_+\xi_0=0,\quad \xi_0^2=(q^{1/2}-q^{-1/2})\xi_-\xi_+ .$$

The constraints due to (6.2) do involve the parameters (μ,v,w) and have been obtained in Eq. (3.48) of Ref. 2. Here we present them in the form directly given by (6.12) and (6.13). After implementing our diagonalization, we obtain

$$(x_-\xi_+ + q^{1/2}x_0\xi_0 + qx_+\xi_-)=-(1+\mu(v-w))(\xi_-x_+ + q^{1/2}\xi_0x_0 + q\xi_+x_-),$$

$$(x_-\xi_+ + sx_0\xi_0 - x_+\xi_-)=-(\xi_-x_+ + s\xi_0x_0 - \xi_+x_-),$$

$$(x_-\xi_+ + tx_0\xi_0 + q^{-2}x_+\xi_-)=-(1+\mu v)(\xi_-x_+ + t\xi_0x_0 + q^{-2}\xi_+x_-),$$

$$(x_-\xi_0 - qx_0\xi_-)=-(\xi_-x_0 - q\xi_0x_-),$$

$$(x_-\xi_0 + q^{-1}x_0\xi_-)=-(1+\mu v)(\xi_-x_0 + q^{-1}\xi_0x_-), \tag{6.15}$$

$$(x_0\xi_+ - qx_+\xi_0)=-(\xi_0x_+ - q\xi_+x_0),$$

$$(x_0\xi_+ + q^{-1}x_+\xi_0)=-(1+\mu v)(\xi_0x_+ + q^{-1}\xi_+x_0),$$

$$x_-\xi_-=-(1+\mu v)\xi_-x_-,$$

$$x_+\xi_+=-(1+\mu v)\xi_+x_+ .$$

Thus, as signaled before, the diagonalization selects out linear combinations, which are proportional under the operation $x_i\xi_j\rightarrow\xi_ix_j$. We note that the coefficients appearing in the triplets, namely: $(1,q^{1/2},q),(1,-q^{-1/2}(1-q),-1),(1,-q^{-3/2}(1+q),q^{-2})$ are mutually orthogonal. The same property is evident with the doublets: $(1,-q),(1,q^{-1})$. The parametric values $\mu=-v^{-1}$ again generate a special case. Using (6.15) each $x_i\xi_j$ may be written as linear combination of ξ_kx_l terms. This is provided in Ref. 2. Here we want to emphasize the modular structure of (6.15). In the preceding discussion regarding the quantum group $\mathrm{GL}_q(2)$ it was noted that a nilpotent bilinear structure, given in (6.9), arise directly out of the diagonalization process. Presence of such structures in (6.15) should be sought. A detailed study of our generalized spaces, arising as a consequence of generalized braid matrices, will be presented elsewhere.

To investigate our noncommutative spaces associated with the quantum group $SO_q(4)$, we proceed exactly as in the previous example. Now the diagonalizing matrix $\hat{M}$ is given by (5.11). The basis for the coordinates and the corresponding basis for the differentials are denoted by (x_1,x_2,x_3,x_4) and $(\xi_1,\xi_2,\xi_3,\xi_4)$, respectively. The braiding relations for the bilinears $x\otimes x$ and $\xi\otimes\xi$ are independent of the parameters (μ,v,w) introduced here; and, consequently, remain the standard noncommutativity constraints. We exhibit below, for brevity, only the relevant modular structure analogous to (6.15). Now we have the quadruplets, doublets and singlets with typically orthogonalized constraints as before:

$$\begin{gathered}(x_1\xi_4+qx_2\xi_3+qx_3\xi_2+q^2x_4\xi_1)=-(1+\mu(v-w))(\xi_1x_4+q\xi_2x_3+q\xi_3x_2+q^2\xi_4x_1),\\ (x_1\xi_4+qx_2\xi_3-q^{-1}x_3\xi_2-x_4\xi_1)=-(\xi_1x_4+q\xi_2x_3-q^{-1}\xi_3x_2-\xi_4x_1),\\ (x_1\xi_4-q^{-1}x_2\xi_3+qx_3\xi_2-x_4\xi_1)=-(\xi_1x_4-q^{-1}\xi_2x_3+q\xi_3x_2-\xi_4x_1),\\ (x_1\xi_4-q^{-1}x_2\xi_3-q^{-1}x_3\xi_2+q^{-2}x_4\xi_1)=-(1+\mu v)(\xi_1x_4-q^{-1}\xi_2x_3-q^{-1}\xi_3x_2+q^{-2}\xi_4x_1),\end{gathered} \tag{6.16}$$

$$\begin{gathered}(x_i\xi_j-qx_j\xi_i)=-(\xi_ix_j-q\xi_jx_i),\\ (x_i\xi_j+q^{-1}x_j\xi_i)=-(1+\mu v)(\xi_ix_j+q^{-1}\xi_jx_i),\\ x_k\xi_k=-(1+\mu v)\xi_kx_k,\end{gathered}$$

where $(i,j)=\{(1,2),(1,3),(2,4),(3,4)\}$, and $k=\{1,2,3,4\}$. No summation over the index k is meant in the last equation in (6.16). Comments parallel to those following (6.15) are relevant here.

Here we sum up the above procedure for the quantum group $SO_q(N)$ with an arbitrary value of N. The formalism described in equations (6.1)–(6.4), and also in (6.11) holds for an arbitrary value of N. We have emphasized on the modular structure and the parameter dependence of the braiding relations arising from (6.2) and our diagonalization of the generalized braid matrices. Setting the spectral variables (v,w) equal to their braid values (1.10), and also fixing the parameter $\mu=q^2$, we may recover the standard quantization prescriptions. So far we have implicitly assumed that the spectral variables are nonvanishing: $v\neq 0,w\neq 0$. When one of them vanishes, the characteristic equation obeyed by the generalized braid matrix becomes, as discussed for instance in (4.2), quadratic rather than cubic. The corresponding reformulation of the prescription for our noncommutative spaces is straightforward and will not be presented here.

VII. REMARKS

The following braid matrices,

$$\hat{R}=\begin{pmatrix}1&0&0&1\\0&1&-1&0\\0&1&1&0\\-1&0&0&1\end{pmatrix} \tag{7.1}$$

and

$$\hat{R}=\begin{pmatrix}0&0&0&q\\0&1&0&0\\0&0&1&0\\q&0&0&0\end{pmatrix}, \tag{7.2}$$

were studied in detail[12–14] in the context of exotic bialgebras. These authors investigated the spectral decomposition of these braid matrices and the Baxterization thereof. These respective cases were denominated as $S03$ and $S14$ in the classification scheme of 4×4 braid matrices presented in Ref. 15. The analogies and differences of the $\hat{R}$ matrix in (7.1) with the unitary case, and that in (7.2) with the orthogonal case have been discussed[12–14] earlier. Noncommutative spaces associated with these two and other exotic 4×4 $\hat{R}$ matrices have also been studied.[12–14] These 4×4 matrices classified in Ref. 15 are exotic in the sense that they are not obtained by restricting some universal $\hat{\mathcal{R}}$ matrix to this dimension. They represent distinct supplementary possibilities for the dimension 4×4.

How do we construct higher dimensional analogues of these matrices? In Sec. IV we have presented a canonical construction of a class of $N^2\times N^2$ braid matrices complete with the corresponding MBE and the Baxterized forms of these matrices. In fact for each even N we have *two* solutions: exotic orthogonal for the choice $\varepsilon=1$, and exotic symplectic for the parametric value $\varepsilon=-1$. But these class presumably does not exhaust such possibilities for each N. Our general reduction of trilinear terms in Sec. III insistently pointed out the class studied in Sec. IV. How do we investigate other possibilities? Generalization of Hietarinta's approach[15] to higher dimensional cases would be extremely laborious. Still a more thorough search may be worthwhile.

Several interesting aspects of our formalism have not been addressed in the present work. Quasiclassical limits, L operators and Yangians are relevant examples. Applications, particularly of our new class of solutions, to integrable models[16,17] would be worth exploring. Certain specific properties would be lost if the parameters (μ,υ,w) move away from their standard values. We wish to study new interesting features which may emerge for other values of the parameters (μ,υ,w). The present approach via diagonalization may be helpful.

Let us end by taking a closer look at the mutually orthogonal sets of triplets and quadruplets, appearing in (5.10) and (5.12) as a consequence of our diagonalizations. For the quantum group $\mathrm{SO}_q(3)$ the constraint (6.1) contain, corresponding to the set $(1,(q^{1/2}-q^{-1/2}),-1)$ in (5.10), the commutation relation, listed before in the set (6.14) but remodeled here for the purpose of convenience:

$$x_-x_+-x_+x_-+(q^{1/2}-q^{-1/2})x_0^2=0. \tag{7.3}$$

A constraint trivially true in the commutative limit $(q=1)$ is thus consistently maintained. The analogous expressions corresponding to the other two triplets in the set (5.10), selected out by the other two diagonalized projectors $P_{(0)}$ and $P_{(+)}$ are *not* constrained to be zero. Introducing the metric and the star operation (Ex. 4.1.22 in Ref. 10) as

$$(x_\pm)^*=q^{\mp1/2}(x_\mp),\quad x_0^*=x_0, \tag{7.4}$$

the other two triplets mentioned above lead to the surfaces with invariants k_1 and k_2:

$$\begin{aligned} x_-^*x_-+x_+^*x_++x_0^*x_0&=\mathsf{k}_1,\\ q^{-3/2}x_-^*x_-+q^{3/2}x_+^*x_+-(q^{1/2}+q^{-1/})x_0^*x_0&=\mathsf{k}_2, \end{aligned} \tag{7.5}$$

where k_1 is usually denoted as the distance squared, i.e., $\mathsf{k}_1\equiv\mathsf{r}^2\geqslant0$. The above two surfaces denote a q-deformed sphere and a q-deformed hyperboloid, respectively. In the context of our diagonalization scheme these two noncommutative surfaces enter in a parallel fashion.

For the quantum group $\mathrm{SO}_q(4)$ the second and the third quadruplets in the set (5.12) correspond to the constraints originating from (6.1), namely

$$\begin{aligned} x_1x_4+qx_2x_3-q^{-1}x_3x_2-x_4x_1&=0,\\ x_1x_4-q^{-1}x_2x_3+qx_3x_2-x_4x_1&=0. \end{aligned} \tag{7.6}$$

The consistency with the commutative limit is, therefore, maintained. The other two quadruplets in the list (5.12) correspond to the action of the diagonalized projectors $P_{(+)}$ and $P_{(0)}$ on the tensor product space $\hat{M}(x\otimes x)$, and thereby lead to the q-deformation of the surfaces

$$x_1x_4+x_2x_3=\mathsf{k}_1, \quad x_1x_4-x_2x_3=\mathsf{k}_2. \tag{7.7}$$

Changing the basis from (x_1,x_4) and (x_2,x_3) to $(x\pm it)$ and $(y\pm iz)$, respectively, we obtain a 3-sphere in the first case (with $\mathsf{k}_1\geqslant 0$) and a noncompact surface in the second case, as obtained before in the second equation in (7.5). Suitably implementing the q-dependent star operation we may obtain the corresponding noncommutative deformations related to the first and the last quadruplets in (5.12).

APPENDIX A

Here we briefly indicate the derivations of the relations (3.11) and (3.12). We demonstrate this in the case of the quantum group $\mathrm{SO}_q(N)$, where the parameter $\varepsilon=1$. To this end we define the operator

$$K\equiv(1+[N-1])P_{(0)}=\sum_{i,j=1}^{N} q^{(\rho_i-\rho_j)}E_{i',j}\otimes E_{i,j'}, \tag{A1}$$

where $i'=N+1-i$. The relevant notations are explained in Sec. IV. Using the standard tensor structures

$$K_{12}=\sum_{i,j=1}^{N} q^{(\rho_i-\rho_j)}E_{i',j}\otimes E_{i,j'}\otimes \mathsf{I}_{N\times N} \quad K_{23}=\sum_{i,j=1}^{N} q^{(\rho_i-\rho_j)}\mathsf{I}_{N\times N}\otimes E_{i',j}\otimes E_{i,j'}, \tag{A2}$$

and the identity $E_{i,j'}E_{k',l}=\delta_{j,k}E_{i,l}$, we obtain

$$K_{12}K_{23}=\sum_{i,j,k=1}^{N} q^{(\rho_i-\rho_k)}E_{i',j}\otimes E_{i,k}\otimes E_{j,k'} \tag{A3}$$

and the following triple product rules:

$$K_{12}K_{23}K_{12}=\left(\sum_{i,j=1}^{N} q^{(\rho_i-\rho_j)}E_{i',j}\otimes E_{i,j'}\right)\otimes\sum_{k=1}^{N} E_{k,k}=K\otimes \mathsf{I}_{N\times N}\equiv K_{12},$$

$$K_{23}K_{12}K_{23}=\sum_{i=1}^{N} E_{i,i}\otimes\left(\sum_{j,k=1}^{N} q^{(\rho_j-\rho_k)}E_{j',k}\otimes E_{j,k'}\right)\mathsf{I}_{N\times N}\otimes K\equiv K_{23}. \tag{A4}$$

The triple product rules (A4) and the defining property (A1) ensure that the following identities hold:

$$P_{(0)12}P_{(0)23}P_{(0)12}=(1+[N-1])^{-2}P_{(0)12}, \quad P_{(0)23}P_{(0)12}P_{(0)23}=(1+[N-1])^{-2}P_{(0)23}. \tag{A5}$$

Using the definitions (4.10) and (4.12) we may proceed analogously for the quantum group $\mathrm{Sp}_q(N)$, where $N=2n$. The two cases can finally be unified after adopting the following definition:

$$K\equiv(1+\varepsilon[N-\varepsilon])P_{(0)} \tag{A6}$$

and then proceeding as before. The final results may be summarized as

$$P_{(0)12}P_{(0)23}P_{(0)12}=(1+\varepsilon[N-\varepsilon])^{-2}P_{(0)12},$$
$$P_{(0)23}P_{(0)12}P_{(0)23}=(1+\varepsilon[N-\varepsilon])^{-2}P_{(0)23}. \tag{A7}$$

Employing the definitions of (Y_1,Y_2) given in (3.1), we now obtain (3.11).

In order to prove the identity (3.12) we proceed as follows. Using the standard expressions for the braid generators $\hat{R}^{\pm 1}$ for the quantum groups $\mathrm{SO}_q(N)$ and $\mathrm{Sp}_q(N)$, and proceeding exactly analogously as before we obtain

$$P_{(0)12}\hat{R}^{\pm 1}_{23}P_{(0)12}=\frac{\varepsilon q^{\pm(N-1-\varepsilon)}}{1+\varepsilon[N-\varepsilon]}P_{(0)12}, \quad P_{(0)23}\hat{R}^{\pm 1}_{12}P_{(0)23}=\frac{\varepsilon q^{\pm(N-1-\varepsilon)}}{1+\varepsilon[N-\varepsilon]}P_{(0)23}. \tag{A8}$$

Expressing the braid matrices as in (1.12) we now use the relations (A7) and (A8) to obtain

$$P_{(0)12}P_{(-)23}P_{(0)12}=\frac{\varepsilon[N-\varepsilon]([2]+\varepsilon[N-1-\varepsilon])}{[2](1+\varepsilon[N-\varepsilon])^2}P_{(0)12}. \tag{A9}$$

The above result also holds after an exchange of the tensor indices: $(12)\rightleftharpoons(23)$. The equation (A9), in conjunction with the definitions (2.1) and (3.1), now produces the identity (3.12).

APPENDIX B

The correspondence between our result for Baxterization and that of Ref. 7 being quite simple in the context of the quantum group $\mathrm{GL}_q(N)$, we discuss below the results for the quantum groups $\mathrm{SO}_q(N)$ and $\mathrm{Sp}_q(N)$. In Sec. 3.9 of Ref. 7 Isaev starts Baxterization of the braid matrices with the parametrization

$$\hat{\mathsf{R}}(x)=c(x)(\mathsf{I}+a(x)\hat{\mathsf{R}}+b(x)K), \tag{B1}$$

where the matrices $\hat{\mathsf{R}}$ and K are given in (1.7) and (A6), respectively. Substituting these results we may rewrite

$$\hat{\mathsf{R}}=c(x)(1+qa(x))\hat{R}(x), \tag{B2}$$

where

$$\hat{R}(x)=\mathsf{I}-\frac{[2]a(x)}{1+qa(x)}P_{(-)}+\frac{(1+\varepsilon[N-\varepsilon])b(x)-q(1-\varepsilon q^{-(N+1-\varepsilon)})a(x)}{1+qa(x)}P_{(0)}. \tag{B3}$$

Comparing this with our starting point (1.9) we obtain the relations

$$a(x)=-\frac{v(x)}{[2]+qv(x)}, \quad b(x)=\frac{[2](w(x)-f_+v(x))}{([2]+qv(x))(1+\varepsilon[N-\varepsilon])}, \quad c(x)=[2]^{-1}([2]+qv(x)), \tag{B4}$$

where the parameter f_+ has been defined in (3.15). In the present work we have preferred the parametrization in (1.9) as it assigns the key roles to the two projectors $P_{(-)}$ and $P_{(0)}$, leading to the systematic reduction of the trilinear forms presented in (3.14). As emphasized earlier this permitted us to display MBE and Baxterization as complementary facets of the same generalized $\hat{R}(v,w)$ matrix. As for solutions of the braid equation obtained in the present work we note that the special case of the spectral variables $v=0, w\neq 0$ has not been discussed in Ref. 7. We have devoted Sec. IV to study this remarkable new class of solutions.

Our formalism led through (3.27) to the significant parallel structures of the Baxterized functions $v(x)$ and $w(x)$ given in (3.30). This enabled us to obtain the solutions *completely* by solving the two simplest equations, before verifying that the more complex functional equation [corre-

sponding to a_2 in (3.25)] is indeed consistent with them. In Ref. 7 the relatively complicated equation [Eq. (3.9.7) of Ref. 7] had to be used to fix the two possible values of a parameter [Eq. (3.9.15) of Ref. 7]. The attractive forms of additive Baxterization, as evident in (1.20) and (1.21)–(1.24) for the functions $v(\theta)$ and $w(\theta)$, respectively, are also direct consequences of our formalism.

A Weierstrass-type system of equations corresponding to CP^N harmonic maps is presented. It constitutes a generalization of the previously constructed systems for CP^1 and CP^2 fields. From the linear spectral problem for the CP^N model a set of conserved quantities is derived and used for a construction of a generalized Weierstrass representation for conformally parametrized surfaces immersed in multidimensional Euclidean spaces. Based on this representation a possible geometrical interpretation of CP^N harmonic maps is discussed. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1534384]

I. INTRODUCTION

Recently many studies have been performed of various σ models in low dimensions. Of these, σ models in two spatial dimensions have, perhaps, been the most commonly studied as, on one hand, they lead to interesting generalizations of harmonic maps and on the other, they can be treated as analogs, with many properties in common, of four-dimensional non-Abelian gauge theories.

Among two-dimensional σ models perhaps the most interesting ones, from the topological point of view, are the so-called CP^N sigma models. Their classical solutions are examples of topological solitons, i.e., extended structures whose stability is partially guaranteed by topological considerations.

The CP^N models are, in fact, a generalization of the, perhaps the s mplest, sigma model, namely the S^2 model—also called the vector $O(3)$ model. The CP^N models involve maps from R^2, or S^2 if one wants to have a nontrivial topology, to CP^N, i.e.,

$$CP^N: C \supset \Omega \ni \zeta = \zeta_1 + i\zeta_2 \mapsto z = (z^1, \ldots, z^N) \in S^{2N} \cong \mathrm{SU}(N)/\mathrm{SU}(N-1), \tag{1}$$

where the homogeneous coordinates $z = (z^1, \ldots, z^N)$ have the following properties

$$z \sim z' = \lambda z \quad \text{for } \lambda \neq 0.$$

Exploiting projective invariance we can require that

$$z^\dagger \cdot z = 1, \tag{2}$$

holds, where † denotes the Hermitian conjugation, and we are still left with gauge symmetry

$$z \sim z' = z e^{i\phi}, \tag{3}$$

where ϕ is the real-valued function.

[a)]Electronic mail: Grundlan@crm.umontreal.ca
[b)]Electronic mail: W.J.Zakrzewski@durham.ac.uk

It is easiest to define CP^N models in terms of the Lagrangian density[1]

$$L=\tfrac{1}{4}(D_\mu z)^\dagger\cdot D_\mu z,\quad z^\dagger\cdot z=1, \tag{4}$$

where the covariant derivatives D_μ act on $z:S^2\to CP^N$ according to the formula

$$D_\mu z=\partial_\mu z-(z^\dagger\cdot\partial_\mu z)z. \tag{5}$$

Here the index $\mu=1,2$ denotes ζ_1 and ζ_2. Note that the covariant derivatives $D_\mu z$ transform under gauge (3)

$$D_\mu z\to D_\mu z'=(D_\mu z)e^{i\phi}, \tag{6}$$

so that the dependence on phase ϕ drops out of Lagrangian density (4) and hence the model is really based on CP^N. The total Lagrangian is given by

$$\mathcal{L}=\int L\,d\zeta\,d\overline{\zeta} \tag{7}$$

and if the CP^N model is defined over S^2 we require that $\mathcal{L}$ is finite.

For the CP^N sigma model it is convenient to define

$$z=\frac{f}{|f|}, \tag{8}$$

where we have used the following notation $|f|=(f^\dagger\cdot f)^{1/2}$. In terms of f the Lagrangian (7) becomes

$$\mathcal{L}=\int\frac{|\overline{\partial}f|^2+|\partial f|^2}{|f|^4}d\zeta\,d\overline{\zeta}, \tag{9}$$

where $|\partial f|^2=(\partial f)^\dagger\cdot(\partial f)$ and $|\overline{\partial}f|^2=(\overline{\partial}f)^\dagger\cdot\overline{\partial}f$. The Euler Lagrange equations for f take the form

$$\left(1-\frac{f\otimes f^\dagger}{|f|^2}\right)\left[\partial\overline{\partial}f-\partial f\frac{(f^\dagger\cdot\overline{\partial}f)}{|f|^2}-\overline{\partial}f\frac{(f^\dagger\cdot\partial f)}{|f|^2}\right]=0, \tag{10}$$

where we have introduced holomorphic and antiholomorphic derivatives

$$\partial=\frac{\partial}{\partial(\zeta_1+i\zeta_2)}=\frac{\partial}{\partial\zeta},\quad \overline{\partial}=\frac{\partial}{\partial(\zeta_1-i\zeta_2)}=\frac{\partial}{\partial\overline{\zeta}} \tag{11}$$

and a bar denotes the complex conjugation.

As is well known[2] equation (10) can be written as a compatibility condition for a set of two linear spectral equations for a N component auxiliary vector Ψ

$$\begin{aligned}\partial\Psi&=\frac{2}{1+\lambda}[\partial P,P]\Psi,\\ \overline{\partial}\Psi&=\frac{2}{1-\lambda}[\overline{\partial}P,P]\Psi,\end{aligned} \tag{12}$$

where λ is a spectral parameter and the N by N matrix P is the projector given by

$$P=\frac{1}{|f|^2}f\otimes f^\dagger,\quad P^\dagger=P,\quad P^2=P. \tag{13}$$

The compatibility conditions for (12) are,

$$[\partial\overline{\partial}P, P]=0 \tag{14}$$

which, as can be easily checked, are equivalent to equations (10). Note that (14) can be written in the form of a conservation law

$$\partial[\overline{\partial}P, P]+\overline{\partial}[\partial P, P]=0 \tag{15}$$

or, equivalently, using the tracelessness of matrix K

$$\partial K-\overline{\partial}K^{\dagger}=0, \tag{16}$$

where the matrices K and $K^{\dagger}$ are given by

$$K=[\overline{\partial}P, P]=\frac{\overline{\partial}f\otimes f^{\dagger}-f\otimes\overline{\partial}f^{\dagger}}{|f|^2}+\frac{f\otimes f^{\dagger}}{|f|^4}[(\overline{\partial}f^{\dagger}\cdot f)-(f^{\dagger}\cdot\overline{\partial}f)], \quad \operatorname{tr}K=0, \tag{17}$$

and consequently

$$K^{\dagger}=-[\partial P, P]=-\frac{\partial f\otimes f^{\dagger}-f\otimes\partial f^{\dagger}}{|f|^2}+\frac{f\otimes f^{\dagger}}{|f|^4}[(\partial f^{\dagger}\cdot f)-(f^{\dagger}\cdot\partial f)].$$

Note that due to the invariance of the Lagrangian (4) under gauge (3), without loss of generality, we can set one of the components of the vector field f, say f_1, to 1. Then, in the CP^1 case, all quantities are expressible through one variable

$$w=\frac{f_2}{f_1}=f_2 \tag{18}$$

and the Euler Lagrange equations (10) take the form

$$\partial\overline{\partial}w-\frac{2\overline{w}}{(1+|w|^2)}\partial w\overline{\partial}w=0. \tag{19}$$

Recently, a lot of effort has been put into relating CP^1 maps to the solutions of the Weierstrass problem.[3,6] In this case one considers a system of first order equations (of Dirac type) for two complex fields φ and ψ of the form

$$\partial\psi=p\varphi, \quad \overline{\partial}\varphi=-p\psi, \quad p=|\varphi|^2+|\psi|^2. \tag{20}$$

In Ref. 7 it was shown that solutions of the Weierstrass system (20) are in a one to one correspondence with the solutions of the CP^1 sigma eqution (19). If ψ and φ are solutions of the Weierstrass system (20), then the function w, defined by

$$w=\frac{\psi}{\overline{\varphi}}, \tag{21}$$

is a solution of the CP^1 equations (19). The converse is also true.[6] Thus, if w is a solution of (19), then the functions φ and ψ of the Weierstrass system (20) have the form (up to an overall multiplication of φ and ψ by -1)

$$\psi=w\frac{(\overline{\partial}\overline{w})^{1/2}}{1+|w|^2}, \quad \varphi=\frac{(\partial w)^{1/2}}{1+|w|^2}, \quad p=\frac{|\partial w|}{1+|w|^2}. \tag{22}$$

From the Weierstrass system (20) one can construct three conservation laws (15). These, in turn, allow us to determine four real valued quantities $X_i(\zeta,\overline{\zeta})$, three of which are linearly independent (due to the tracelessness of the matrix K). X_i are constructed by taking diagonal and off-diagonal entries of matrix K and are given by[3]

$$X_1=\int_\gamma(\psi_1^2-\psi_2^2)d\zeta'+(\overline{\psi}_1^2-\overline{\psi}_2^2)d\overline{\zeta}',$$

$$X_2=\int_\gamma(\psi_1^2+\psi_2^2)d\zeta'-(\overline{\psi}_1^2+\overline{\psi}_2^2)d\overline{\zeta}', \tag{23}$$

$$X_3=-\int_\gamma\psi_1\psi_2\,d\zeta'+\overline{\psi}_1\overline{\psi}_2\,d\overline{\zeta}',$$

respectively, where γ is any curve from a fixed point to ζ.

The geometrical aspects of surfaces obtained from representation (23), where functions ψ and φ obey the Weierstrass system (20), are described in detail in Ref. 4. In two recent papers[8,9] we have generalized this construction to the case of the CP^2 sigma model.[5] The aim of this paper is to present a generalization to the CP^N case.

The paper is organized as follows. In Sec. II, we derive the explicit form of conservation laws corresponding to the CP^N model. Section III deals with CP^N maps and the corresponding Weierstrass representation for conformally parametrized two-dimensional surfaces immersed in multidimensional Euclidean space. In Sec. IV we discuss some geometric aspects of CP^N maps and present some geometric characteristics of surfaces. The last section presents further remarks, discusses some possible developments and mentions some more ambitious objectives.

II. THE CP^N MODEL

Here we derive explicit conservation laws (15) which are equivalent to the Euler Lagrange equations (10). In order to construct them we look first at the general form of the elements of the matrices K and $K^\dagger$ in terms of f, given by (17). Thus we have

$$K_{ij}=\frac{1}{A^2}[\overline{f}_k f_k\,\overline{\partial}f_i\,\overline{f}_j-\overline{f}_k f_k f_i\,\overline{\partial f_j}+f_i\,\overline{f}_j\,\overline{\partial f_k}\,f_k-f_i\,\overline{f}_j\,\overline{f}_k\,\overline{\partial}f_k], \tag{24}$$

and consequently

$$K^\dagger_{ij}=\frac{-1}{A^2}[\overline{f}_k f_k\,\partial f_i\,\overline{f}_j-\overline{f}_k f_k f_i\,\partial\overline{f}_j+f_i\,\overline{f}_j\,\partial\overline{f}_k\,f_k-f_i\,\overline{f}_j\,\overline{f}_k\,\partial f_k],$$

where $A=f^\dagger\cdot f$ and the summation convention over the repeated indices from now on, is assumed throughout this paper.

Let us define

$$F_{ij}=f_i\,\partial f_j-f_j\partial f_i,$$

and

$$G_{ij}=f_i\,\overline{\partial}f_j-f_j\overline{\partial}f_i. \tag{25}$$

Then, using expressions (25), the matrices K and $K^\dagger$ take, equivalently, a simple form

$$K_{ij}=\overline{f}_j\overline{\Phi}_i^2-f_i\overline{\varphi}_j^2, \tag{26}$$

and

$$K_{ij}^{\dagger}=-\overline{f}_j\varphi_i^2-f_i\Phi_j^2, \tag{27}$$

where we have introduced

$$\varphi_i^2=\frac{1}{A^2}\overline{f}_k F_{ki}, \tag{28}$$

and

$$\Phi_i^2=\frac{1}{A^2}f_k\overline{G_{ki}}. \tag{29}$$

Note that from equations (25), (28), and (29) we have two algebraic constraints, namely

$$\overline{f}_k\,\varphi_k^2=0, \quad f_k\,\Phi_k^2=0, \tag{30}$$

which imply that only $(N-1)$ functions φ_i^2 are linearly independent. So in our further discussion it is convenient to take as indepedent functions $\varphi_2^2,\ldots,\varphi_N^2$. Analogous situation holds for functions Φ_i^2. Making use of the symmetry (3) we can set, without loss of generality, say, $f_1=1$, and so we end up with the expressions [for (28) and (29)]

$$\varphi_i^2=\frac{1}{A^2}[(1+f_k\overline{f}_k)\,\partial f_i-f_i(\overline{f}_k\,\partial f_k)],$$

$$\Phi_i^2=\frac{1}{A^2}[(1+f_k\overline{f}_k)\,\overline{\partial} f_i-f_i(\overline{f}_k\,\overline{\partial} f_k)], \quad i=2,\ldots,N, \tag{31}$$

where

$$A=1+|f_2|^2+|f_3|^2\ldots+|f_N|^2,$$

and all the sums over repeated indices run over $k=2,\ldots,N$. Note that in (31) the terms $k=i$ in the sum cancel leaving just term ∂f_i. For instance if $k=i=2$ then we have

$$\varphi_2^2=\frac{1}{A^2}[(1+f_l\overline{f}_l)\,\partial f_2-f_2(\overline{f}_l\,\partial f_l)],$$

where the sums over the repeated indices run over $l=3,\ldots,N$. This fact allows us to invert expressions (31) and so express all derivatives ∂f_i in terms of φ_i^2's and f_i. This way we find

$$\partial f_i=A\,[\varphi_i^2+f_i\,\overline{f}_k\varphi_k^2]. \tag{32}$$

Thus, in particular, for the CP^1 case, equation (32) becomes

$$\partial f_2=A^2\varphi_2^2, \quad A=1+|f_2|^2,$$

and f_2 is often denoted in Ref. 1 by w, while in the CP^2 case we have

$$\partial f_2=A[(1+|f_2|^2)\varphi_2^2+f_2\overline{f}_3\,\varphi_3^2],$$

$$\partial f_3=A[(1+|f_3|^2)\varphi_3^2+f_3\overline{f}_2\,\varphi_2^2], \tag{33}$$

$$A=1+|f_2|^2+|f_3|^2.$$

Note that in Refs. 8 and 9 the functions f_2 and f_3 are denoted by w_1 and w_2, respectively. Similarly, all this discussion can be repeated for Φ_i^2's in the same way but using $\overline{\partial}$ instead of ∂, $\overline{f}$ instead of f, and $\overline{G}_{ij}$ instead of F_{ij}.

III. THE GENERALIZED WEIERSTRASS REPRESENTATION IN R^M

To introduce a generalized Weierstrass system in multidimensional spaces we need a set of φ_i and ψ_i which generalize the φ and ψ of the CP^1 case and φ_i and ψ_i, $i=1,2$ of the CP^2 case.

Note that the quantities φ_i^2, $i=2,...,N$, defined in (28) provide such a choice as (32) agrees with the definition of the function φ in expression (22). Next we address the question of what should we use for the function ψ_i? Clearly, relation (21) suggests that we put

$$\psi_i = f_i \overline{\varphi}_i \tag{34}$$

with no summation over the indices $i=2,\ldots,N$. Then to complete the generalization of the Weierstrass system in multidimensional spaces we need analogs of relations (20). We need to prescribe the first derivatives $\overline{\partial}\varphi_i$ and $\partial\psi_i$ in terms of φ_i and ψ_i. Note that from (34) we get

$$\partial\psi_i = \partial(f_i \overline{\varphi}_i) = \partial f_i \overline{\varphi}_i + f_i \overline{(\overline{\partial}\varphi_i)}. \tag{35}$$

So we need to specify $\overline{\partial}\varphi_i$ in terms of φ_i, f_i and their derivatives. To do this we note that from (32) we get

$$\varphi_i^2 = \frac{1}{A}\partial f_i - f_i \frac{f^\dagger \cdot \partial f}{A^2}, \quad A = (f^\dagger \cdot f + 1). \tag{36}$$

So we have

$$\overline{\partial}\varphi_i^2 = 2\frac{f_i(\overline{f_l}\,\partial f_l)}{A^3}(\overline{f_k}\,\overline{\partial} f_k + f_k\,\overline{\partial f_k}) + \frac{1}{A^2}[(1+|f|^2)\partial\overline{\partial} f_i - (\overline{f_k}\overline{\partial} f_k)\partial f_i - (f_k\overline{\partial f_k})\partial f_i - \overline{\partial} f_i(\overline{f_k}\partial f_k)$$
$$- f_i(\overline{\partial f_k}\partial f_k) - f_i(\overline{f_k}\,\partial\overline{\partial} f_k)]. \tag{37}$$

However, equation (10) gives us

$$\partial\overline{\partial} f_i = f_i\frac{(\overline{f_k}\,\partial\overline{\partial} f_k)}{A} + \partial f_i\frac{(\overline{f_k}\,\overline{\partial} f_k)}{A} + \overline{\partial} f_i\frac{(\overline{f_k}\,\partial f_k)}{A} - 2\,f_i\frac{(\overline{f_k}\,\partial f_k)(\overline{f_l}\,\overline{\partial} f_l)}{A^2}. \tag{38}$$

Eliminating the second derivatives $\partial\overline{\partial} f_i$ from equations (37) and (38) we note that all the terms involving the first derivatives $\overline{\partial f}$ and $\overline{\partial f}$ in (37) cancel and we end up with a simple expression

$$\overline{\partial}\varphi_i = -\frac{\varphi_i}{2A}(f_k\,\overline{\partial f_k}) - \frac{f_i}{2\varphi_i A^2}(\overline{\partial f_k}\partial f_k) + \frac{f_i}{2\varphi_i A^3}(\overline{\partial f_k} f_k)(\overline{f_l}\partial f_l). \tag{39}$$

Moreover, taking the complex conjugation of (32),

$$\overline{\partial f_k} = A\,[\overline{\varphi}_k^2 + \overline{f_k}\,f_l\overline{\varphi}_l^2] \tag{40}$$

and so by the virtue of (40) we have

$$\overline{\partial}\varphi_i = -\frac{1}{2}\left\{A\varphi_i(\overline{\varphi}\cdot\psi) + \frac{\psi_i}{\varphi_i\overline{\varphi}_i}[(\overline{\varphi}^2\cdot\varphi^2) + (\overline{\varphi}\cdot\psi)(\overline{\psi}\cdot\varphi)]\right\} \tag{41}$$

(no summation over i). The second pair of equations for ψ_i then follows from (35)

$$\partial\psi_i = A\overline{\varphi}_i\varphi_i^2 + \frac{1}{2}A\psi_i(\overline{\psi}\cdot\varphi) - \frac{1}{2}\frac{|\psi_i|^2}{|\varphi_i|^2\overline{\varphi}_i}[(\overline{\varphi}^2\cdot\varphi^2) + (\overline{\varphi}\cdot\psi)(\overline{\psi}\cdot\varphi)] \tag{42}$$

(no summation over i).

To summarize: the modified Weierstrass system in multidimensional space is a set of $(2N-2)$ complex functions φ_i and ψ_i, $i=2,3,\ldots,N$ which obey the following system of equations (no summation over i):

$$\overline{\partial}\varphi_i = -\frac{1}{2}\left\{A\varphi_i(\overline{\varphi}\cdot\psi) + \frac{\psi_i}{\varphi_i\overline{\varphi}_i}[(\overline{\varphi}^2\cdot\varphi^2) + (\overline{\varphi}\cdot\psi)(\overline{\psi}\cdot\varphi)]\right\}$$

and

$$\partial\psi_i = A\overline{\varphi}_i\varphi_i^2 + \frac{1}{2}A\psi_i(\overline{\psi}\cdot\varphi) - \frac{1}{2}\frac{|\psi_i|^2}{|\varphi_i|^2\overline{\varphi}_i}[(\overline{\varphi}^2\cdot\varphi^2) + (\overline{\varphi}\cdot\psi)(\overline{\psi}\cdot\varphi)], \tag{43}$$

where

$$A = 1 + \sum_{k=2}^{N}\frac{|\psi_k|^2}{|\varphi_k|^2}.$$

From our construction it is clear that the above system of equations is equivalent to the equations of the CP^N sigma model (10). Moreover, it is easy to check that the system of equations (43), for $N=1$ reduces to the equations (20), and for $N=2$ to the equations which were studied in Refs. 8 and 9.

Note that under the requirement of finiteness of the action all solutions of the CP^N sigma model (10) are well known[1] and they split into three separate cases: analytic, antianalytic and the mixed ones. Hence based on this result we can construct large classes of solutions of the modified Weierstrass system (43).

IV. GEOMETRICAL ASPECTS

Here we address the question of the existence of real variables Z_i, of ζ and $\overline{\zeta}$, which are constructed out of our ψ_i's and φ_i's determined by the system of equations (43). Here we treat $Z_i(\zeta,\overline{\zeta})$ as a map of C into R^M

$$Z = (Z_1,\ldots,Z_M): D\subset C\to R^M, \tag{44}$$

where D is a region in the complex plane C. For some values of M we can give a geometrical interpretation of two-dimensional surfaces immersed in R^M. This discussion will generalize the result obtained by Konopelchenko and colaborators.[3,4,10] Moreover, we will find that the surface is immersed in $M=(N^2-1)$-dimensional Euclidean space. To construct real valued functions $Z_i(\zeta,\overline{\zeta})$ it is convenient to exploit the conservation laws for the system of equations (43). To derive these conservation laws we look at (16) and we note that we can exploit the matrices K and $K^\dagger$ given by (26) and (27). However, we note that we can drop the terms Φ_j^2 in expressions (26) and (27) and we still have the conservation laws associated with (10). Namely, we can define

$$K'_{ij} = -f_i\,\overline{\varphi}_j^2 \tag{45}$$

and

$$(K'_{ij})^\dagger = \varphi_i^2\,\overline{f}_j, \tag{46}$$

and we still have the conservation laws of the form

$$\partial K' + \overline{\partial}(K')^{\dagger} = 0. \tag{47}$$

It is easy to check the validity of (47) by making use of the equations (40) and (41).

Note that as our conservation laws do not involve terms containing Φ_i then they can be written entirely in terms of Weierstrass variables φ_i and ψ_i. As a result of so obtained conservation laws we can introduce real valued functions

$$Z_{ll} = \int_\gamma \overline{f}_l \varphi_l^2 \, d\zeta + \int_\gamma f_l \, \overline{\varphi}_l^2 \, d\overline{\zeta} = \int_\gamma \overline{\psi}_l \varphi_l \, d\zeta + \int_\gamma \psi_l \, \overline{\varphi}_l \, d\overline{\zeta} \tag{48}$$

(no summation over index $l = 1, \ldots, N$). These quantities have been constructed from the diagonal entries of matrices K' and $(K')^{\dagger}$. From the off-diagonal entries of matrices K' and $(K')^{\dagger}$ we can construct

$$Z_{lk} = X_{lk} + iY_{lk} = \int_\gamma (\alpha \overline{f}_l \varphi_k^2 + \overline{\alpha} \overline{f}_k \varphi_l^2) d\zeta + \int_\gamma (\overline{\alpha} f_l \, \overline{\varphi}_k^2 + \alpha f_k \, \overline{\varphi}_l^2) d\overline{\zeta}, \quad \alpha \in C. \tag{49}$$

The transposition of the indices lk to kl in Eq. (49) corresponds to the interchange α to $\overline{\alpha}$ and vice versa. In our expression we take all $l,k = 1,\ldots,N$ and for $k = 1$ or $l = 1$ we can use our algebraic constraints (30) to rewrite all our expressions in terms of independent functions φ_i and ψ_i, $i = 2,\ldots,N$. For our real variables Z_i we take Z_{ii}, X_{lk} and Y_{lk}.

Note that the conservation laws (47) guarantee that Z_{ll} and Z_{lk} do not depend on the choice of the contour γ but only on its endpoints in C. This fact takes place because all Z's can be written in the form

$$Z = \int_\Gamma F(\zeta, \overline{\zeta}) \, d\zeta + \overline{F}(\zeta, \overline{\zeta}) \, d\overline{\zeta},$$

where F and $\overline{F}$ satisfy the conserved quantity

$$\overline{\partial} F = \partial \overline{F},$$

which shows that the integrands are total derivatives.

Looking at the diagonal terms in (48) we note that

$$\sum_l Z_{ll} = 0. \tag{50}$$

This follows from the tracelessness of matrices K' and $(K')^{\dagger}$.

Note that all our expressions for Z_{ll} and Z_{lk} are quadratic in terms of φ_i and $\overline{\psi_i}$ and their complex conjugates. They formally include φ_1 and ψ_1, with $\psi_1 = f_1 \overline{\varphi_1}$. However, both these quantities (ψ_1 and φ_1) should be eliminated using the algebraic constraint [i.e., the first expression in (30)] and $f_1 = 1$. It is easy to check that this process of elimination, in the CP^1 case leads to

$$Z_{11} = -2 \int_\gamma \overline{\psi}\varphi \, d\zeta' + \psi\overline{\varphi} \, d\overline{\zeta}',$$

$$X_{12} = \int_\gamma (\overline{\psi}_2^2 - \varphi_2^2) \, d\zeta' + (\psi_2^2 - \overline{\varphi}_2^2) \, d\overline{\zeta}', \tag{51}$$

$$Y_{12} = i \int_\gamma (\overline{\psi}_2^2 + \varphi_2^2) \, d\zeta' - (\psi_2^2 + \overline{\varphi}_2^2) \, d\overline{\zeta}',$$

which appeared in Ref. 3.

Next, following Ref. 11 we can calculate some geometric characteristics of a surface immersed in multidimensional space. We treat the functions Z_{ll}, X_{lk}, and Y_{lk}, as the coordinates of a surface. We introduce the components of the induced metric

$$g_{\alpha\beta}=\sum_{lk}\frac{\partial Z_{lk}}{\partial\alpha}\frac{\partial\overline{Z}_{lk}}{\partial\beta}, \tag{52}$$

where α and β are ζ or $\overline{\zeta}$. For conformally parametrized surfaces we have to make a choice for the normalization of the off-diagonal entries of coordinates X_{kl} and Y_{kl}. We make the natural choice $\alpha=(1+i)/2$. We find that

$$g_{\zeta\zeta}=\left(\sum_{i=1}^{N}\overline{f}_i\,\varphi_i^2\right)^2=0 \tag{53}$$

which coincides with the first algebraic contraint (30). Similarly, its respective complex conjugate equation is

$$g_{\overline{\zeta}\overline{\zeta}}=0. \tag{54}$$

The only nonzero term of the induced metric is

$$g_{\zeta\overline{\zeta}}=(1+|f_2|^2+|f_3|^2+\cdots+|f_N|^2)\left[\left|\sum_{k=2}^{N}\overline{f}_k\varphi_k^2\right|^2+|\varphi_2|^4+|\varphi_3|^4+\cdots+|\varphi_N|^4\right]. \tag{55}$$

Of course, we can rewrite this expression to involve Weierstrass data φ_i and ψ_i by using expressions (34) but the expressions become very complicated. Note, however, that writing all quantities in terms of f_i and ∂f_i, through (31), our expressions simplify considerably and we obtain

$$g_{\zeta\overline{\zeta}}=|Dz|^2, \tag{56}$$

where $D=\frac{1}{2}(D_1-iD_2)$ and D_1, D_2 are the covariant derivatives given by (5) involving ∂ (i.e., evaluated with respect to ζ).

In the special case of the CP^1 maps the component of the induced metric $g_{\zeta\overline{\zeta}}$ takes a particularly simple form; it is given by

$$g_{\zeta\overline{\zeta}}=\left(1+\frac{|\psi_2|^2}{|\varphi_2|^2}\right)[|\varphi_2|^4+|\psi_2|^2|\varphi_2|^2]=[|\psi_2|^2+|\varphi_2|^2]^2=\frac{|\partial f_2|^2}{(|f_2|^2+1)^2} \tag{57}$$

which is exactly, of course $|Dz|^2$; while in the CP^2 case we have

$$g_{\zeta\overline{\zeta}}=\frac{|\partial f_2|^2+|\partial f_3|^2+|f_2\partial f_3-f_3\partial f_2|^2}{(1+|f_2|^2+|f_3)^2|} \tag{58}$$

which also is $|Dz|^2$.

Thus we have proved that the conformal immersion of surfaces in R^{N^2-1} are determined by the generalized Weierstrass representation (48) and (49), where the functions φ_l and ψ_l, or equivalently φ_l and f_l, have to obey system (43) of first order equations. Note that formulas (48) and (49) define a surface on SU(N) and then using expressions in Ref. 12 we can calculate, in a closed form, all geometric characteristics of this surface.

V. SUMMARY AND CONCLUDING REMARKS

The main aim of this paper has been to derive a generalization of the Weierstrass system to the CP^N case. Thus we have found a set of $2N$ complex functions ψ_i and φ_i which satisfy a system of first order equations (43) that are equivalent to the full system of equations of the CP^N model (10).

We have also introduced a set of (N^2-1) real quantities Z's, which can be treated as coordinates of a surface immersed in R^{N^2-1} and we have shown that the induced metric of our map is given by

$$ds^2 = 2|Dz|^2\, d\zeta\, d\overline{\zeta}. \tag{59}$$

The study of the generalized Weierstrass representations for surfaces immersed in multidimensional spaces was initiated by Konopelchenko *et al.*[10] Our work here, in which we adopted an alternative approach based on CP^N sigma models, provides a generalization of their results.

A question arises whether our approach can be extended to Weierstrass systems describing surfaces immersed in multidimensional pseudo-Riemannian spaces. Further, can it provide new classes of solutions which will describe types of surfaces more diverse than those found in multidimensional Euclidean spaces.

ACKNOWLEDGMENTS

A Laplace operator and harmonics on the quantum complex vector space

N. Z. Iorgov and A. U. Klimyk[a)]
Institute for Theoretical Physics, Kiev 03143, Ukraine

(Received 26 July 2002; accepted 28 October 2002)

The aim of this article is to study the q-Laplace operator and q-harmonic polynomials on the quantum complex vector space generated by elements z_i, w_i, $i=1,2,\ldots,n$, on which the quantum group $\mathrm{GL}_q(n)$ [or $\mathrm{U}_q(n)$] acts. The q-harmonic polynomials are defined as solutions of the equation $\Delta_q p=0$, where p is a polynomial in z_i, w_i, $i=1,2,\ldots,n$, and the q-Laplace operator Δ_q is determined in terms of q-derivatives. The q-Laplace operator Δ_q commutes with the action of $\mathrm{GL}_q(n)$. The projector $\mathsf{H}_{m,m'}:\mathcal{A}_{m,m'}\to\mathcal{H}_{m,m'}$ is constructed, where $\mathcal{A}_{m,m'}$ and $\mathcal{H}_{m,m'}$ are the spaces of homogeneous (of degree m in z_i and of degree m' in w_i) polynomials and homogeneous q-harmonic polynomials, respectively. By using these projectors, a q-analog of the classical zonal spherical and associated spherical harmonics are constructed. They constitute an orthogonal basis of $\mathcal{H}_{m,m'}$. A q-analog of separation of variables is given. The quantum algebra $\mathrm{U}_q(\mathrm{gl}_n)$, acting on $\mathcal{H}_{m,m'}$, determines an irreducible representation of $\mathrm{U}_q(\mathrm{gl}_n)$. This action is explicitly constructed. The results of the article lead to the dual pair $(\mathrm{U}_q(\mathrm{sl}_2),\mathrm{U}_q(\mathrm{gl}_n))$ of quantum algebras. © *2003 American Institute of Physics.*

I. INTRODUCTION

Laplace operators, harmonic polynomials, and related separations of variables of the classical analysis are of a great importance for mathematical and theoretical physics. They are closely related to the rotation groups $\mathrm{SO}(n)$ (if we deal with Euclidean space) and to the unitary groups $\mathrm{U}(n)$ (if we deal with the complex vector space) (see, for example, Ref. 1, Chaps. 10 and 11). In this article we are interested in a q-analog of Laplace operators, harmonic polynomials, and related separations of variables on complex spaces.

Harmonic polynomials on the n-dimensional complex vector space are defined by the equation $\Delta p=0$, where Δ is the Laplace operator $\sum_{i=1}^{n}\partial^2/\partial z_i\partial\overline{z_i}$ and p belongs to the space $\mathcal{R}$ of polynomials in $z_1,\ldots,z_n,\overline{z_1},\ldots,\overline{z_n}$ on the complex space $\mathbb{C}^n$. The space $\mathcal{H}$ of all harmonic polynomials on $\mathbb{C}^n$ decomposes as a direct sum of the subspaces $\mathcal{H}_{m,m'}$ of homogeneous harmonic polynomials of degree m in $z_1,\ldots,z_n$ and of degree m' in $\overline{z_1},\ldots,\overline{z_n}$: $\mathcal{H}=\oplus_{m,m'=0}^{\infty}\mathcal{H}_{m,m'}$. The Laplace operator Δ on $\mathbb{C}^n$ commutes with the natural action of the unitary group $\mathrm{U}(n)$ on the space $\mathbb{C}^n$. This means that the subspaces $\mathcal{H}_{m,m'}$ are invariant with respect to $\mathrm{U}(n)$. The irreducible representation $T_{m,m'}$ of the group $\mathrm{U}(n)$ with highest weight $(m,0,\ldots,0,-m')$ is realized on $\mathcal{H}_{m,m'}$.

The equation $\Delta p=0$ permits solutions in separated variables on the space $\mathcal{H}_{m,m'}$. In other words, there exist different coordinate systems (spherical, polyspherical, etc.) on $\mathbb{C}^n$ and for each of them it is possible to find the corresponding basis of the space of solutions of the equation $\Delta p=0$ consisting of products of functions depending on separated variables (see Ref. 2 for the general theory of separation of variables). To different coordinate systems there correspond different separations of variables. From the other side, to different coordinate systems there correspond different chains of subgroups of the group $\mathrm{U}(n)$ (see Ref. 1, Chap. 11, for details of this

a)Author to whom correspondence should be addressed. Electronic mail: aklimyk@bitp.kiev.ua

correspondence). The bases of the space $\mathcal{H}_{m,m'}$ in separated variables consist of products of Jacobi polynomials multipled by $r^{m+m'}$ (different sets of Jacobi polynomials for different separations of variables), where r is the radius. These polynomials (considered only on the unit sphere $S_{\mathbb{C}}^{n-1}$ in $\mathbb{C}^n$) are matrix elements of the class 1 [with respect to the subgroup $U(n-1)$] irreducible representations $T_{m,m'}$ of $U(n)$ belonging to zero column (see Ref. 1, Chap. 11).

Many new directions of mathematical physics are related to quantum group and noncommutative geometry. It is natural to generalize the above-described theory to noncommutative spaces. Such generalizations can be of a great importance for further development of some branches of mathematical and theoretical physics related to noncommutative geometry.

The aim of this article is to construct a q-deformation of the above-described classical theory. In the q-deformed case, instead of $\mathbb{C}^n$ we take the quantum complex vector space. It is defined by the associative algebra $\mathcal{A}$ generated by the elements $z_1,\ldots,z_n,w_1,\ldots,w_n$ satisfying a certain natural defining relations. The elements $z_1,\ldots,z_n$ play a role of Cartesian coordinates of $\mathbb{C}^n$ and $w_1,\ldots,w_n$ play a role of $\overline{z_1},\ldots,\overline{z_n}$.

The q-Laplace operator Δ_q on $\mathcal{A}$ is defined in terms of q-derivatives [see formula (17) below]. The quantum group $U_q(n)$ plays a role of the unitary group $U(n)$ in the q-deformed case. It will be convenient for us to use the quantum algebra (that is, the quantized universal enveloping algebra) $U_q(\mathrm{gl}_n)$ instead of the quantum group $U_q(n)$. The q-harmonic polynomials on the quantum complex vector space are defined as elements p of the algebra $\mathcal{A}$ (that is, polynomials in $z_1,\ldots,z_n,w_1,\ldots,w_n$) for which $\Delta_q p=0$. By using the quantum algebra $U_q(\mathrm{gl}_n)$ we construct for q-harmonic polynomials a theory similar to the theory for classical harmonic polynomials. We construct the projector $\mathsf{H}_{m,m'}:\mathcal{A}_{m,m'}\to\mathcal{H}_{m,m'}$, where $\mathcal{A}_{m,m'}$ and $\mathcal{H}_{m,m'}$ are the subspaces of homogeneous (of degree m in $z_1,\ldots,z_n$ and of degree m' in $w_1,\ldots,w_n$) polynomials in $\mathcal{A}$ and in the space $\mathcal{H}$ of all q-harmonic polynomials from $\mathcal{A}$, respectively. Using these projectors we can make different calculations in $\mathcal{H}_{m,m'}$. In this way, zonal spherical and associated spherical polynomials can be calculated. The associated spherical polynomials of $\mathcal{H}_{m,m'}$ constitute an orthogonal basis of this space. Here we obtain a q-analog of the spherical separation of coordinates. We show that the natural action of the algebra $U_q(\mathrm{gl}_n)$ on the quantum complex vector space realizes on the space $\mathcal{H}_{m,m'}$ the irreducible representation of this algebra with highest weight $(m,0,\ldots,0,-m')$. Note that restrictions of zonal spherical and associated spherical polynomials from $\mathcal{H}_{m,m'}$ to the quantum sphere in the quantum complex vector space coincide with matrix elements of irreducible representations $T_{m,m'}$ of the quantum group $U_q(n)$ corresponding to zero column (the latter matrix elements were calculated in Ref. 3; see also Ref. 4). Some our formulas coincide with formulas of Ref. 3. However, no Laplace operator and no q-harmonic polynomials are presented in Ref. 3.

Note that this article is an extension of the results of our previous paper (see Ref. 5) (where we studied q-Laplace operator and q-harmonic polynomials on the quantum real vector space) to the case of quantum complex vector space. It is well known that in the classical case, the theory of Laplace operators and harmonic polynomials on $\mathbb{C}^n$ can be reduced to the corresponding theory for the real space $\mathbb{R}^{2n}$ (see Ref. 1, Chap. 11). It is not the case for the quantum spaces. The reason is that the quantum complex vector space cannot be obtained from the quantum real vector space in the same way as in the classical case.

Everywhere below we suppose that q is not a root of unity. Under considering a scalar product on the spaces $\mathcal{A}$ and $\mathcal{H}$ we assume that q is a positive real number. By $[a]$, $a\in\mathbb{C}$, we denote the so called q-number defined as

$$[a]=\frac{q^a-q^{-a}}{q-q^{-1}}.$$

II. THE QUANTUM ALGEBRA $U_q(\mathrm{gl}_n)$ AND THE QUANTUM VECTOR SPACE

The Drinfeld-Jimbo quantum algebra $U_q(\mathrm{gl}_n)$ is generated by the elements $k_i^{1/2}\equiv q^{h_i/2}$, $k_i^{-1/2}\equiv q^{-h_i/2}$, $i=1,2,\ldots,n$, and e_j, f_j, $j=1,2,\ldots,n-1$, satisfying the relations

$$k_i k_i^{-1}=k_i^{-1}k_i=1,\quad k_i k_j=k_j k_i,\qquad k_i e_j k_i^{-1}=q^{a_{ij}}e_j,\quad k_i f_j k_i^{-1}=q^{-a_{ij}}f_j,$$

$$[e_i,f_j]\equiv e_i f_j-f_j e_i=\delta_{ij}\frac{k_i k_{i+1}^{-1}-k_i^{-1}k_{i+1}}{q-q^{-1}},$$

$$e_i^2 e_{i\pm1}-(q+q^{-1})e_i e_{i\pm1}e_i+e_{i\pm1}e_i^2=0,$$

$$f_i^2 f_{i\pm1}-(q+q^{-1})f_i f_{i\pm1}f_i+f_{i\pm1}f_i^2=0,$$

$$[e_i,e_j]=[f_i,f_j]=0,\qquad |i-j|>1,$$

where $a_{ii}=1$, $a_{i,i-1}=a_{i-1,i}=-1$ and $a_{ij}=0$ otherwise (see, for example, Ref. 6, Chap. 6).

The algebra $\mathrm{U}_q(\mathrm{gl}_n)$ is a Hopf algebra, and the Hopf algebra operations (comultiplication Δ, counit ε and antipode S) are given by the formulas

$$\Delta(k_i^{\pm1})=k_i^{\pm1}\otimes k_i^{\pm1},\qquad \Delta(e_i)=e_i\otimes k_i^{-1/2}k_{i+1}^{1/2}+k_i^{1/2}k_{i+1}^{-1/2}\otimes e_i,$$

$$\Delta(f_i)=f_i\otimes k_i^{-1/2}k_{i+1}^{1/2}+k_i^{1/2}k_{i+1}^{-1/2}\otimes f_i,\qquad \varepsilon(k_i)=1,\qquad \varepsilon(e_i)=\varepsilon(f_i)=0,$$

$$S(k_i)=k_i^{-1},\qquad S(e_i)=-q^{-1}e_i,\qquad S(f_i)=-qf_i.$$

The group $\mathrm{GL}(n,\mathbb{C})$ and its Lie algebra $\mathrm{gl}(n,\mathbb{C})$ act linearly on the n-dimensional complex vector space. Similarly, the quantum group $\mathrm{GL}_q(n,\mathbb{C})$ and the algebra $\mathrm{U}_q(\mathrm{gl}_n)$ acts on the quantum (noncommutative) analog of the complex vector space. This quantum space is determined by the algebra of polynomials $\mathcal{A}\equiv\mathbb{C}_q[z_1,\ldots,z_n,\ w_1,\ldots,w_n]$ (see Ref. 7). This algebra is the associative algebra generated by elements $z_1,\ z_2,\ldots,z_n,\ w_1,\ w_2,\ldots,w_n$ satisfying the defining relations

$$z_i z_j=q z_j z_i,\qquad w_i w_j=q^{-1}w_j w_i,\qquad i<j, \tag{1}$$

$$w_j z_i=q z_i w_j,\qquad i\neq j,\quad i,j=1,2,\ldots,n, \tag{2}$$

$$w_k z_k=z_k w_k+(1-q^2)\sum_{s=1}^{k-1} z_s w_s. \tag{3}$$

The elements $w_1,\ldots,\ w_n$ play a role of $\overline{z_1},\ldots,\ \overline{z_n}$ in the classical analysis.

A $*$-operation can be defined on the algebra $\mathcal{A}$ turning it into a $*$-algebra. This $*$-operation is uniquely determined by the relations $z_i^*=w_i,\ w_i^*=z_i,\ i=1,2,\ldots,\ n$. The compact quantum group $\mathrm{U}_q(n)$ acts on this $*$-algebra. Note that the algebra $\mathcal{A}$ is similar to (and not coinciding with) the algebra considered by Pusz and Woronowicz.[8]

Note that the relations (3) are equivalent to the following ones:

$$z_k w_k=w_k z_k-(1-q^2)\sum_{s=1}^{k-1} q^{2(k-s-1)}w_s z_s. \tag{4}$$

The set of all monomials

$$z_1^{r_1}z_2^{r_2}\cdots z_n^{r_n}w_1^{s_1}w_2^{s_2}\cdots w_n^{s_n},\quad r_j,\ s_j=0,1,2,\ldots, \tag{5}$$

form a basis of the algebra $\mathcal{A}$ (see Ref. 9). The set

$$w_1^{r_1}w_2^{r_2}\cdots w_n^{r_n}z_1^{s_1}z_2^{s_2}\cdots z_n^{s_n},\quad r_j,\ s_j=0,1,2,\ldots, \tag{6}$$

also form a basis of this algebra.

The vector space of the algebra $\mathcal{A}$ can be represented as a direct sum of the vector subspaces $\mathcal{A}_{m,m'}$ consisting of homogeneous polynomials of homogeneity degree m in $z_1, z_2, \ldots, z_n$ and of homogeneity degree m' in $w_1, w_2, \ldots, w_n$, $m, m' = 0, 1, 2, \ldots$:

$$\mathcal{A} = \bigoplus_{m=0}^{\infty} \bigoplus_{m'=0}^{\infty} \mathcal{A}_{m,m'}. \tag{7}$$

We have the linear space isomorphism

$$\mathcal{A} \simeq \mathcal{A}_z \otimes \mathcal{A}_w,$$

where the associative algebra $\mathcal{A}_z$ (the associative algebra $\mathcal{A}_w$) is a subalgebra of $\mathcal{A}$ coinciding with $\oplus_{m=0}^{\infty} \mathcal{A}_{m,0}$ (respectively, with $\oplus_{m'=0}^{\infty} \mathcal{A}_{0,m'}$).

We can define an action of the algebra $\mathrm{U}_q(\mathrm{gl}_n)$ on the vector space $\mathcal{A}$. To determine this action we give the action of $\mathrm{U}_q(\mathrm{gl}_n)$ on z_j and w_j by the formulas[9]

$$k_i \triangleright z_j = q^{\delta_{ij}} z_j, \qquad e_i \triangleright z_j = \delta_{j,i+1} z_{j-1}, \quad f_i \triangleright z_j = \delta_{j,i} z_{j+1}, \tag{8}$$

$$k_i \triangleright w_j = q^{-\delta_{ij}} w_j, \qquad e_i \triangleright w_j = -\delta_{j,i} q^{-1} w_{j+1}, \quad f_i \triangleright w_j = -\delta_{j,i+1} q w_{j-1}, \tag{9}$$

and extend it to $\mathcal{A}$ by using the comultiplication, that is, by means of the relation

$$X \triangleright (p_1 p_2) = \sum (X_{(1)} \triangleright p_1)(X_{(2)} \triangleright p_2),$$

where $\Delta(X) = \Sigma X_{(1)} \otimes X_{(2)}$ (in the Sweedler notation), and linearity.

This action of the algebra $\mathrm{U}_q(\mathrm{gl}_n)$ on the vector space $\mathcal{A}$ determines a representation of $\mathrm{U}_q(\mathrm{gl}_n)$ on this space (we denote it by L). Evidently, the subspaces $\mathcal{A}_{m,m'}$ are invariant with respect to this action. Therefore, L determines representations of $\mathrm{U}_q(\mathrm{gl}_n)$ on these subspaces, which are denoted by $L_{m,m'}$. We have $L = \oplus_{m,m'=0}^{\infty} L_{m,m'}$.

III. OPERATORS ON THE ALGEBRA $\mathcal{A}$

In order to introduce the q-Laplace operator on $\mathcal{A}$ and to study q-harmonic polynomials we need some operators on the linear space of the algebra $\mathcal{A}$. By γ_i and $\overline{\gamma_i}$ we denote the linear operators acting on monomials as

$$\gamma_i(z_1^{r_1} z_2^{r_2} \cdots z_n^{r_n} w_1^{s_1} w_2^{s_2} \cdots w_n^{s_n}) = q^{r_i} z_1^{r_1} z_2^{r_2} \cdots z_n^{r_n} w_1^{s_1} w_2^{s_2} \cdots w_n^{s_n},$$

$$\overline{\gamma_i}(w_1^{r_1} w_2^{r_2} \cdots w_n^{r_n} z_1^{s_1} z_2^{s_2} \cdots z_n^{s_n}) = q^{r_i} w_1^{r_1} w_2^{r_2} \cdots w_n^{r_n} z_1^{s_1} z_2^{s_2} \cdots z_n^{s_n}.$$

Definition of the operators γ_i^{-1} and $\overline{\gamma_i}^{-1}$ is obvious.

By $\hat{z}_i$ and $\check{z}_i$ we denote the linear operators of multiplication by the element z_i:

$$\hat{z}_i(z_1^{r_1} z_2^{r_2} \cdots z_n^{r_n} w_1^{s_1} w_2^{s_2} \cdots w_n^{s_n}) = z_i z_1^{r_1} z_2^{r_2} \cdots z_n^{r_n} w_1^{s_1} w_2^{s_2} \cdots w_n^{s_n},$$

$$\check{z}_i(z_1^{r_1} z_2^{r_2} \cdots z_n^{r_n} w_1^{s_1} w_2^{s_2} \cdots w_n^{s_n}) = z_1^{r_1} z_2^{r_2} \cdots z_n^{r_n} z_i w_1^{s_1} w_2^{s_2} \cdots w_n^{s_n}.$$

The corresponding linear operators $\hat{w}_i$ and $\check{w}_i$ are defined as

$$\hat{w}_i(w_1^{r_1} w_2^{r_2} \cdots w_n^{r_n} z_1^{s_1} z_2^{s_2} \cdots z_n^{s_n}) = w_i w_1^{r_1} w_2^{r_2} \cdots w_n^{r_n} z_1^{s_1} z_2^{s_2} \cdots z_n^{s_n},$$

$$\check{w}_i(w_1^{r_1} w_2^{r_2} \cdots w_n^{r_n} z_1^{s_1} z_2^{s_2} \cdots z_n^{s_n}) = w_1^{r_1} w_2^{r_2} \cdots w_n^{r_n} w_i z_1^{s_1} z_2^{s_2} \cdots z_n^{s_n}.$$

We define on $\mathcal{A}$ the q-differentiations ∂_i and $\overline{\partial_i}$. The linear operators ∂_i act as $\partial_i p=0$ on monomials p of the form (5) not containing z_i and as

$$\partial_i=\check{z}_i^{-1}\frac{\gamma_i-\gamma_i^{-1}}{q-q^{-1}} \tag{10}$$

on monomials containing z_i. The q-differentiations $\overline{\partial_i}$ are linear operators acting as $\overline{\partial_i}p=0$ on monomials p of the form (6) not containing w_i and as

$$\overline{\partial_i}=\check{w}_i^{-1}\frac{\overline{\gamma_i}-\overline{\gamma_i}^{-1}}{q-q^{-1}} \tag{11}$$

on monomials containing w_i. In particular, we have

$$\partial_i(z_1^{r_1}\cdots z_n^{r_n}w_1^{s_1}\cdots w_n^{s_n})=[r_i]q^{r_{i+1}+\cdots+r_n}z_1^{r_1}\cdots z_i^{r_i-1}\cdots z_n^{r_n}w_1^{s_1}\cdots w_n^{s_n},$$

$$\overline{\partial_i}(w_1^{r_1}\cdots w_n^{r_n}z_1^{s_1}\cdots z_n^{s_n})=[r_i]q^{-(r_{i+1}+\cdots+r_n)}w_1^{r_1}\cdots w_i^{r_i-1}\cdots w_n^{r_n}z_1^{s_1}\cdots z_n^{s_n}.$$

The action formulas (8) and (9) mean that the multiplication operators $\hat{z}_j$, $j=1, 2,\ldots, n$, and $\hat{w}_j$, $j=1, 2,\ldots, n$, constitute tensor operators transforming under the vector representation and under the contragredient to the vector representation, respectively.

The actions (8) and (9) of $\mathrm{U}_q(\mathrm{gl}_n)$ on z_j and w_j determines its action on the operators ∂_j and $\overline{\partial_j}$:

$$k_i\triangleright\partial_j=q^{-\delta_{ij}}\partial_j,\qquad e_i\triangleright\partial_j=-\delta_{j,i}q^{-1}\partial_{j+1},\quad f_i\triangleright\partial_j=-\delta_{j,i+1}q\partial_{j-1}, \tag{12}$$

$$k_i\triangleright\overline{\partial_j}=q^{\delta_{ij}}\overline{\partial_j},\qquad e_i\triangleright\overline{\partial_j}=\delta_{j,i+1}q^{-2}\overline{\partial_{j-1}},\quad f_i\triangleright\overline{\partial_j}=\delta_{j,i}q^{2}\overline{\partial_{j+1}}. \tag{13}$$

That is, the set $\overline{\partial_j}$, $j=1, 2,\ldots, n$, (respectively, the set ∂_j, $j=1, 2,\ldots, n$) is a tensor operator transforming under vector (respectively, contragredient to vector) representation.

The operators ∂_i, $\overline{\partial_i}$, $\hat{z}_i$, $\hat{w}_i$ satisfy the relations, which will be presented by means of the quantum R-matrix R for the quantum algebra $\mathrm{U}_q(\mathrm{gl}_n)$ (see, for example, Ref. 6, Sec. 8.1, and Ref. 7 for definition of the R-matrix). Let $\mathbf{R}=PR$, where the matrix P permutes the spaces in the tensor product of two spaces on which R-matrix acts. Then

$$\mathbf{R}_{kl}^{ij}=q^{\delta_{ij}}\delta_{il}\delta_{jk}+(q-q^{-1})\,\delta_{ik}\delta_{jl}\theta(j-i),$$

where $\theta(k)=1$ if $k>0$ and $\theta(k)=0$ if $k\leqslant 0$. Its inverse matrix is

$$(\mathbf{R}^{-1})_{kl}^{ij}=q^{-\delta_{ij}}\delta_{il}\delta_{jk}-(q-q^{-1})\,\delta_{ik}\delta_{jl}\theta(i-j).$$

We also need the matrix $\Phi_{kl}^{ij}=\mathbf{R}_{lk}^{ji}q^{2(i-l)}$, which satisfies the relations

$$\sum_{j,l}\Phi_{pj}^{ul}(\mathbf{R}^{-1})_{lk}^{ji}=\sum_{j,l}(\mathbf{R}^{-1})_{pj}^{ul}\Phi_{lk}^{ji}=\delta_{up}\delta_{ik},$$

$$\sum_{l}\Phi_{lk}^{li}=\delta_{ik}q^{2(n-i)+1},\quad \sum_{k}\Phi_{lk}^{jk}=\delta_{jl}q^{2l-1}.$$

The relations (1)–(3) rewritten for operators $\hat{z}_i$ and $\hat{w}_i$ can be presented as

$$\hat{z}_i\hat{z}_j=q^{-1}\mathbf{R}_{ij}^{kl}\hat{z}_k\hat{z}_l,\quad \hat{w}_i\hat{w}_j=q^{-1}\mathbf{R}_{lk}^{ji}\hat{w}_k\hat{w}_l,\quad \hat{w}_i\hat{z}_j=q(\mathbf{R}^{-1})_{jl}^{ik}\hat{z}_k\hat{w}_l.$$

We also have the relations

$$\partial_i\partial_j = q^{-1}\mathbf{R}^{ji}_{lk}\partial_k\partial_l, \quad \overline{\partial_i\partial_j} = q^{-1}\mathbf{R}^{kl}_{ij}\overline{\partial_k}\,\overline{\partial_l}, \quad \partial_i\overline{\partial_j} = q^{-1}\Phi^{ki}_{lj}\overline{\partial_k}\partial_l,$$

$$\partial_i\hat{w}_j = q(\mathbf{R}^{-1})^{ji}_{lk}\hat{w}_k\partial_l, \quad \overline{\partial_i}\hat{z}_j = q\Phi^{lk}_{ji}\hat{z}_k\overline{\partial_l},$$

$$\partial_i\hat{z}_j = \gamma^{\mp 1}\delta_{ij} + (\mathbf{R}^{\pm 1})^{ik}_{jl}\hat{z}_k\partial_l, \quad \overline{\partial_i}\hat{w}_j = \overline{\gamma^{\mp 1}}\delta_{ij} + (\mathbf{R}^{\pm 1})^{lj}_{ki}\hat{w}_k\overline{\partial_l},$$

which can be represented in the form

$$\partial_i\partial_j = q^{-1}\partial_j\partial_i, \quad \overline{\partial_i\partial_j} = q\overline{\partial_j}\,\overline{\partial_i}, \quad i<j,$$

$$\overline{\partial_i}\partial_j = q\partial_j\overline{\partial_i}, \quad i\neq j, \quad \overline{\partial_i}\partial_i = \partial_i\overline{\partial_i} + (1-q^2)\sum_{k>i}\partial_k\overline{\partial_k},$$

$$\partial_i\overline{\partial_i} = \overline{\partial_i}\partial_i + (1-q^{-2})\sum_{k>i} q^{2(k-i)}\overline{\partial_k}\partial_k.$$

$$\partial_i\hat{w}_i = \hat{w}_i\partial_i, \quad \partial_i\hat{w}_j - q\hat{w}_j\partial_i = (1-q^2)\hat{w}_i\partial_j, \quad \partial_j\hat{w}_i = q\hat{w}_i\partial_j, \quad i<j,$$

$$\overline{\partial_i}\hat{z}_i = \hat{z}_i\overline{\partial_i}, \quad \overline{\partial_i}\hat{z}_j - q^{-1}\hat{z}_j\overline{\partial_i} = (1-q^{-2})q^{2(j-i)}\hat{z}_i\overline{\partial_j}, \quad \overline{\partial_j}\hat{z}_i = q^{-1}\hat{z}_i\overline{\partial_j}, \quad i<j,$$

$$\partial_i\hat{z}_j = \hat{z}_j\partial_i, \quad \overline{\partial_i}\hat{w}_j = \hat{w}_j\overline{\partial_i}, \quad i\neq j,$$

$$\partial_i\hat{z}_i = q\hat{z}_i\partial_i + (q-q^{-1})\sum_{k>i}\hat{z}_k\partial_k + \gamma^{-1} = q^{-1}\hat{z}_i\partial_i - (q-q^{-1})\sum_{k<i}\hat{z}_k\partial_k + \gamma,$$

$$\overline{\partial_i}\hat{w}_i = q\hat{w}_i\overline{\partial_i} + (q-q^{-1})\sum_{k<i}\hat{w}_k\overline{\partial_k} + \overline{\gamma}^{-1} = q^{-1}\hat{w}_i\overline{\partial_i} - (q-q^{-1})\sum_{k>i}\hat{w}_k\overline{\partial_k} + \overline{\gamma},$$

where $\gamma = \gamma_1\gamma_2\cdots\gamma_n$ and $\overline{\gamma} = \overline{\gamma_1}\,\overline{\gamma_2}\cdots\overline{\gamma_n}$. From last two lines, we obtain

$$\sum_{k=1}^{n}\hat{z}_k\partial_k = \{\gamma\} \equiv \frac{\gamma-\gamma^{-1}}{q-q^{-1}}, \quad \sum_{k=1}^{n}\hat{w}_k\overline{\partial_k} = \{\overline{\gamma}\} \equiv \frac{\overline{\gamma}-\overline{\gamma}^{-1}}{q-q^{-1}}.$$

We also have the relations

$$\gamma\hat{z}_i = q\hat{z}_i\gamma, \quad \gamma\hat{w}_i = \hat{w}_i\gamma, \quad \overline{\gamma}\hat{z}_i = \hat{z}_i\overline{\gamma}, \quad \overline{\gamma}\hat{w}_i = q\hat{w}_i\overline{\gamma},$$

$$\gamma\partial_i = q^{-1}\partial_i\gamma, \quad \gamma\overline{\partial_i} = \overline{\partial_i}\gamma, \quad \overline{\gamma}\partial_i = \partial_i\overline{\gamma}, \quad \overline{\gamma}\,\overline{\partial_i} = q^{-1}\overline{\partial_i}\,\overline{\gamma}.$$

Note that

$$\gamma p = q^m p, \quad \overline{\gamma}p = q^{m'}p, \quad p\in\mathcal{A}_{m,m'}. \tag{14}$$

To compare these relations with those known from literature, we introduce the operators $\partial_i' = \gamma\partial_i$, $\overline{\partial_i'} = \overline{\gamma}^{-1}\overline{\partial_i}$. Then the operators $\hat{z}_i$, $\hat{w}_i$, ∂_i', $\overline{\partial_i'}$, $i=1,\ldots,n$, satisfy the relations from Ref. 10 which are known to be covariant with respect to $\mathrm{U}_q(\mathrm{gl}_n)$. Note that the operators $\partial_i' = \gamma\partial_i$ coincide with the q-deformed differential operators of Pusz and Woronowicz[8] and of Wess and Zumino[11] if to restrict their action upon the subalgebra $\mathcal{A}_z$ generated by $z_1, z_2, \ldots, z_n$.

Note that the above elements $\hat{z}_1,\ldots,\hat{z}_n$, $\partial_1',\ldots,\partial_n'$ generate the q-Weyl algebra, that is, they satisfy the relations

$$\hat{z}_i\hat{z}_j = q\hat{z}_j\hat{z}_i, \quad \partial'_i\partial'_j = q^{-1}\partial'_j\partial'_i \quad i<j, \quad \partial'_i\hat{z}_j = q\hat{z}_j\partial'_i, \quad i\neq j,$$

$$\partial'_i\hat{z}_i - q^2\hat{z}_i\partial'_i = 1 + (q^2-1)\sum_{j>i}\hat{z}_j\partial'_j$$

(the definition of the q-Weyl algebra; see, for example, in Ref. 6, Chap. 12). Similarly, the elements $\hat{w}_1,\ldots,\hat{w}_n,\overline{\partial'_1},\ldots,\overline{\partial'_n}$ generate the q^{-1}-Weyl algebra.

The operators $D:=\Sigma_{k=1}^n\hat{z}_k\partial_k$ and $\overline{D}:=\Sigma_{k=1}^n\hat{w}_k\overline{\partial_k}$ are called the *q-Euler operators*. The formula (7) gives the decomposition of $\mathcal{A}$ into a direct sum of eigenspaces of the operators D and $\overline{D}$.

Let us show that the above relations for the operators $\partial_i,\overline{\partial_i},\hat{z}_i,\hat{w}_i$ determine uniquely the formulas (10) and (11) for $\partial_i,\overline{\partial_i}$. We use the action formulas $\partial_i 1=\overline{\partial_i}1=0$, take into account that $\hat{z}_i$, $\hat{w}_i$ act as the operators of left multiplication on the basis elements (5) and (6), respectively, and γ, $\overline{\gamma}$ are gradation operators on $\mathcal{A}$ [see (14)]. By means of commutation relations between ∂_i and $\hat{w}_j$, it is easy to obtain that $\partial_i w_1^{s_1}w_2^{s_2}\cdots w_n^{s_n}=0$. To calculate $\partial_i(z_i^{r_i}w_1^{s_1}w_2^{s_2}\cdots w_n^{s_n})$ with $r_i>0$, we use the relation

$$\partial_i\hat{z}_i = q\hat{z}_i\partial_i + (q-q^{-1})\sum_{k>i}\hat{z}_k\partial_k + \gamma^{-1}.$$

It gives $\partial_i(z_i^{r_i}w_1^{s_1}w_2^{s_2}\cdots w_n^{s_n}) = [r_i]z_i^{r_i-1}w_1^{s_1}w_2^{s_2}\cdots w_n^{s_n}$. Finally, we have the action formula

$$\begin{aligned}\partial_i(z_1^{r_1}\cdots z_i^{r_i}\cdots z_n^{r_n}w_1^{s_1}\cdots w_n^{s_n}) &= q^{r_i(r_{i+1}+\cdots+r_n)}\partial_i(z_1^{r_1}\cdots z_{i-1}^{r_{i-1}}z_{i+1}^{r_{i+1}}\cdots z_n^{r_n}z_i^{r_i}w_1^{s_1}\cdots w_n^{s_n})\\ &= q^{r_i(r_{i+1}+\cdots+r_n)}\hat{z}_1^{r_1}\cdots\hat{z}_{i-1}^{r_{i-1}}\hat{z}_{i+1}^{r_{i+1}}\cdots\hat{z}_n^{r_n}\partial_i(z_i^{r_i}w_1^{s_1}\cdots w_n^{s_n})\\ &= q^{r_{i+1}+\cdots+r_n}[r_i]z_1^{r_1}\cdots z_i^{r_i-1}\cdots z_n^{r_n}w_1^{s_1}\cdots w_n^{s_n},\end{aligned}$$

which exactly coincides with the action (10). The action formula for $\overline{\partial_i}$ is recovered in a similar way.

The action of the algebra $\mathrm{U}_q(\mathrm{gl}_n)$ on $\mathcal{A}\simeq\mathcal{A}_z\otimes\mathcal{A}_w$, defined by formulas (8) and (9), can be determined in terms of the operators ∂_i and $\overline{\partial_j}$. We first note that the action of $\mathrm{U}_q(\mathrm{gl}_n)$ on $\mathcal{A}_z$ is given by the operators

$$L(k_i)=\gamma_i, \qquad L(e_i)=q^{-1/2}(\gamma_i\gamma_{i+1})^{1/2}\check{z}_i\partial_{i+1}, \qquad L(f_i)=q^{1/2}(\gamma_i\gamma_{i+1})^{-1/2}\check{z}_{i+1}\partial_i$$

and on $\mathcal{A}_w$ by the operators

$$L(k_i)=\overline{\gamma}_i^{-1}, \quad L(e_i)=-q^{-3/2}(\overline{\gamma}_i\overline{\gamma}_{i+1})^{1/2}\check{w}_{i+1}\overline{\partial}_i, \quad L(f_i)=-q^{3/2}(\overline{\gamma}_i\overline{\gamma}_{i+1})^{-1/2}\check{w}_i\overline{\partial}_{i+1}.$$

Taking into account the comultiplication on $\mathrm{U}_q(\mathrm{gl}_n)$ the action of $\mathrm{U}_q(\mathrm{gl}_n)$ on the linear space $\mathcal{A}\simeq\mathcal{A}_z\otimes\mathcal{A}_w$ can be written as $L(k_i)=\gamma_i\otimes\overline{\gamma}_i^{-1}$ and

$$L(e_i)=q^{-1/2}(\gamma_i\gamma_{i+1})^{1/2}\check{z}_i\partial_{i+1}\otimes(\overline{\gamma}_i\overline{\gamma}_{i+1}^{-1})^{1/2}-q^{-3/2}(\gamma_i\gamma_{i+1}^{-1})^{1/2}\otimes(\overline{\gamma}_i\overline{\gamma}_{i+1})^{1/2}\check{w}_{i+1}\overline{\partial}_i,$$

$$L(f_i)=q^{1/2}(\gamma_i\gamma_{i+1})^{-1/2}\check{z}_{i+1}\partial_i\otimes(\overline{\gamma}_i\overline{\gamma}_{i+1}^{-1})^{1/2}-q^{3/2}(\gamma_i\gamma_{i+1}^{-1})^{1/2}\otimes(\overline{\gamma}_i\overline{\gamma}_{i+1})^{-1/2}\check{w}_i\overline{\partial}_{i+1}.$$

IV. SQUARED *q*-RADIUS AND *q*-LAPLACE OPERATOR

The element

$$Q=\sum_{i=1}^n z_iw_i=\sum_{i=1}^n q^{2(n-i)}w_iz_i\in\mathcal{A}_{1,1} \tag{15}$$

of the algebra $\mathcal{A}$ is called the *squared q-radius* on the quantum complex vector space. It is an important element in $\mathcal{A}$. One can check by a direct computation that Q *is invariant with respect to the representation* $L_{1,1}$ (and hence with respect to the representation L), that is, $L(k_i^{\pm 1})Q=Q$, $L(e_j)Q=0$ and $L(f_j)Q=0$. Similarly, the element $Q^k \in \mathcal{A}_{k,k}$ is invariant with respect to the representation $L_{k,k}$.

The squared q-radius Q belongs to the center of the algebra $\mathcal{A}$, that is, $Qz_i=z_iQ$, $Qw_i=w_iQ$, $i=1, 2,\ldots, n$. We shall also use the elements

$$Q_j=\sum_{i=1}^{j} z_iw_i=\sum_{i=1}^{j} q^{2(j-i)}w_iz_i,$$

which are squared q-radii for the subalgebras $\mathbb{C}_q[z_1, w_1,\ldots, z_j, w_j]$. They satisfy the relations[9]

$$Q_jQ_i=Q_iQ_j, \qquad z_iw_i=Q_i-Q_{i-1}, \qquad w_iz_i=Q_i-q^2Q_{i-1},$$

$$z_iQ_j=q^{-2}Q_jz_i, \qquad w_iQ_j=q^2Q_jw_i \qquad \text{for} \qquad i>j,$$

$$z_iQ_j=Q_jz_i, \qquad w_iQ_j=Q_jw_i \qquad \text{for} \qquad i\leqslant j.$$

It can be checked[9] by direct computation that

$$z_i^kw_i^k=Q_i^k(Q_{i-1}/Q_i;q^{-2})_k, \quad w_i^kz_i^k=Q_i^k(q^2Q_{i-1}/Q_i;q^2)_k, \tag{16}$$

where

$$(a;q)_s=(1-a)(1-aq)\cdots(1-aq^{s-1}).$$

We consider on $\mathcal{A}$ the operator

$$\Delta_q=\partial_1\overline{\partial_1}+\partial_2\overline{\partial_2}+\cdots+\partial_n\overline{\partial_n}=\sum_{i=1}^{n} q^{2(i-1)}\overline{\partial_i}\partial_i, \tag{17}$$

which is called the *q-Laplace operator* on the quantum complex vector space. Since $\gamma\Delta_q=q^{-1}\Delta_q\gamma$ and $\overline{\gamma}\Delta_q=q^{-1}\Delta_q\overline{\gamma}$, then $\Delta_q:\mathcal{A}_{m,m'}\to\mathcal{A}_{m-1,m'-1}$.

To the element (15) there corresponds the operator $\hat{Q}$ on $\mathcal{A}$ defined as

$$\hat{Q}=\hat{z}_1\hat{w}_1+\hat{z}_2\hat{w}_2+\cdots+\hat{z}_n\hat{w}_n.$$

Proposition 1: The operators Δ_q *and* $\hat{Q}$ *satisfy the relations*

$$\Delta_q\hat{Q}^k-\hat{Q}^k\Delta_q=q^{n-1}\hat{Q}^{k-1}[k]\{q^{k+n-1}\gamma\overline{\gamma}\}, \tag{18}$$

$$\Delta_q(Q^k)=q^{n-1}Q^{k-1}[k][k+n-1], \tag{19}$$

where

$$\{a\}=\frac{a-a^{-1}}{q-q^{-1}}$$

and $[r]\equiv\{q^r\}$ *is a q-number.*

Proof: First we prove the relation $[\Delta_q,\hat{Q}]=q^{n-1}\{q^n\gamma\overline{\gamma}\}$. Using relations of Sec. III we derive

$$\Delta_q\hat{Q}=\sum_{k,l}\partial_k\overline{\partial}_k\hat{z}_l\hat{w}_l$$

$$=\sum_{k,l,i,j}\partial_k(q^{-1}\Phi^{ji}_{lk}\hat{z}_i\overline{\partial}_j)\hat{w}_l$$

$$=\sum_{k,l,i,j}q^{-1}\Phi^{ji}_{lk}\left(\delta_{ik}\gamma^{-1}+\sum_{r,s}\mathbf{R}^{kr}_{is}\hat{z}_r\partial_s\right)\overline{\partial}_j\hat{w}_l$$

$$=\sum_{k,l,j}q^{-1}\Phi^{jk}_{lk}\gamma^{-1}\overline{\partial}_j\hat{w}_l+\sum_{k,l,i,j,r,s}q^{-1}\Phi^{ji}_{lk}\mathbf{R}^{kr}_{is}\hat{z}_r\partial_s\left(\delta_{jl}\overline{\gamma}+\sum_{u,p}(\mathbf{R}^{-1})^{ul}_{pj}\hat{w}_p\overline{\partial}_u\right)$$

$$=\sum_l q^{2l-2}\gamma^{-1}\overline{\partial}_l\hat{w}_l+\sum_{i,r,s}q^{2(n-i)}\mathbf{R}^{ir}_{is}\hat{z}_r\partial_s\overline{\gamma}+\sum_{k,i,r,s}q^{-1}\mathbf{R}^{kr}_{is}\hat{z}_r\partial_s\hat{w}_i\overline{\partial}_k.$$

The third summand is equal to

$$\sum_{k,i,r,s}q^{-1}\mathbf{R}^{kr}_{is}\hat{z}_r\partial_s\hat{w}_i\overline{\partial}_k=\sum_{k,i,r,s}q^{-1}\mathbf{R}^{kr}_{is}\hat{z}_r\left(q\sum_{u,p}(\mathbf{R}^{-1})^{is}_{pu}\hat{w}_u\partial_p\right)\overline{\partial}_k=\hat{Q}\Delta_q.$$

Using explicit expressions for matrix elements of $\mathbf{R}$ and $\mathbf{R}^{-1}$ we have

$$\sum_i q^{2(n-i)}\mathbf{R}^{ir}_{is}=q^{2n-1}\delta_{rs},\qquad \sum_l q^{2l-2}(\mathbf{R}^{-1})^{ul}_{pl}=q^{-1}\delta_{pu},$$

$$\sum_l q^{2l-2}\overline{\partial}_l\hat{w}_l=\sum_l q^{2l-2}\left(\overline{\gamma}+\sum_{u,p}(\mathbf{R}^{-1})^{ul}_{pl}\hat{w}_p\overline{\partial}_u\right)$$

$$=q^{n-1}[n]\overline{\gamma}+q^{-1}\sum_p\hat{w}_p\overline{\partial}_p$$

$$=q^{n-1}[n]\overline{\gamma}+q^{-1}\{\overline{\gamma}\}$$

$$=q^{n-1}\{q^n\overline{\gamma}\}.$$

Thus, $[\Delta_q,\hat{Q}]=q^{n-1}\gamma^{-1}\{q^n\overline{\gamma}\}+q^{2n-1}\{\gamma\}\overline{\gamma}=q^{n-1}\{q^n\gamma\overline{\gamma}\}$. Now, it is easy to obtain (18) by induction if to use the relation $\{q^r\gamma\overline{\gamma}\}\hat{Q}=\hat{Q}\{q^{r+2}\gamma\overline{\gamma}\}$ and the explicit expression for $\{a\}$. Acting by both sides of (18) on 1 we obtain (19).

Proposition 2: The operators Δ_q and $\hat{Q}$ commute with the action of the algebra $\mathrm{U}_q(\mathrm{gl}_n)$ on $\mathcal{A}$, that is, with all operators of the representation L of $\mathrm{U}_q(\mathrm{gl}_n)$.

Proof: It follows from (12) and (13) that $k_i\triangleright\Delta_q=\Delta_q$, $e_j\triangleright\Delta_q=0$ and $f_j\triangleright\Delta_q=0$. Now using the comultiplication for k_i, e_j and f_j, we obtain the proposition for the q-Laplace operator. For $\hat{Q}$ the proposition is proved similarly.

V. *q*-HARMONIC POLYNOMIALS

A polynomial $p\in\mathcal{A}$ is called *q-harmonic* if $\Delta_q p=0$. The linear subspace of $\mathcal{A}$ consisting of all q-harmonic polynomials is denoted by $\mathcal{H}$. Let

$$\mathcal{H}_{m,m'}=\mathcal{A}_{m,m'}\cap\mathcal{H}.$$

Proposition 3: The space $\mathcal{A}_{m,m'}$ can be represented as the direct sum

$$\mathcal{A}_{m,m'}=\mathcal{H}_{m,m'}\oplus Q\mathcal{A}_{m-1,m'-1}. \tag{20}$$

Proof: First we prove that $\mathcal{H}_{m,m'} \cap Q\mathcal{A}_{m-1,m'-1} = \{0\}$. If it is not true, then there exists nonzero element $p \in \mathcal{H}_{m,m'} \cap Q\mathcal{A}_{m-1,m'-1}$. Let k be a maximal integer such that $p = Q^k p'$ with some nonzero polynomial p'. Then it follows from $\Delta_q(p) = 0$ and (18) that

$$0 = \Delta_q(Q^k p') = Q^k \Delta_q(p') + Q^{k-1} q^{n-1} [k][k+n-1+m+m'-2k] p'.$$

Since $q^{n-1}[k][k+n-1+m+m'-2k] \neq 0$, then p' can be divided by Q. This is a contradiction. Thus, $\mathcal{H}_{m,m'} \cap Q\mathcal{A}_{m-1,m'-1} = \{0\}$. Using this fact and the equality $\ker \Delta_q = \mathcal{H}_{m,m'}$, where Δ_q is considered only on $\mathcal{A}_{m,m'}$, we obtain the chain of inequalities

$$\dim\ \mathcal{A}_{m,m'} - \dim\ \ker\ \Delta_q \geqslant \dim\ Q\mathcal{A}_{m-1,m'-1} = \dim\ \mathcal{A}_{m-1,m'-1} \geqslant \dim\ \mathrm{im}\ \Delta_q.$$

The last inequality follows from the fact that $\Delta_q : \mathcal{A}_{m,m'} \to \mathcal{A}_{m-1,m'-1}$. Now we take into account the relation $\dim \ker \Delta_q + \dim \mathrm{im}\, \Delta_q = \dim \mathcal{A}_{m,m'}$. Thus, in fact, the above inequalities are exact equalities, and $\mathcal{A}_{m,m'} = \mathcal{H}_{m,m'} \oplus Q\mathcal{A}_{m-1,m'-1}$. Proposition is proved.

Remark: If $n = 1$, then $\mathcal{A}$ consists of all polynomials in commuting elements z_1 and w_1. In this case, the space $\mathcal{H}$ of q-harmonic polynomials has a basis consisting of the polynomials

$$1, \quad z_1^k, \quad w_1^k, \qquad k = 1, 2, \ldots. \tag{21}$$

The decomposition (20) has also the following consequences:

Corollary 1: If $p \in \mathcal{H}_{m,m'}$, then p cannot be represented as $p = Q^k p'$, $k \neq 0$, with some polynomial p'.

Corollary 2: The space $\mathcal{A}_{m,m'}$ decomposes into the direct sum

$$\mathcal{A}_{m,m'} = \bigoplus_{j=0}^{\min(m,m')} Q^j \mathcal{H}_{m-j,m'-j}. \tag{22}$$

Corollary 3: For dimension of the space of q-harmonic polynomials $\mathcal{H}_{m,m'}$ we have the formula

$$\dim\ \mathcal{H}_{m,m'} = \frac{(m+n-2)!(m'+n-2)!(m+m'+n-1)}{(n-1)!(n-2)!m!m'!}.$$

Corollary 4: The space of q-harmonic polynomials $\mathcal{H}$ can be represented in the form of a direct sum

$$\mathcal{H} = \bigoplus_{m=0}^{\infty} \bigoplus_{m'=0}^{\infty} \mathcal{H}_{m,m'}.$$

Corollary 1 is a direct consequence of formula (20). Corollary 2 easily follows from repeated application of (20). Corollary 3 is proved in the same way as in the classical case (see, for example, Ref. 1, Chap. 10). For this we note that

$$\dim\ \mathcal{A}_{m,m'} = \frac{(n+m-1)!(n+m'-1)!}{(n-1)!^2 m!m'!}.$$

Hence, for $\dim \mathcal{H}_{m,m'} = \dim \mathcal{A}_{m,m'} - \dim \mathcal{A}_{m-1,m'-1}$ we obtain the expression stated in the corollary. In order to prove Corollary 4 we note that

$$\mathcal{A} = \bigoplus_{m \geqslant 0} \bigoplus_{m' \geqslant 0} \bigoplus_{j=0}^{p} Q^j \mathcal{H}_{m-j,m'-j} = \bigoplus_{m \geqslant 0} \bigoplus_{m' \geqslant 0} \left(\mathcal{H}_{m,m'} \oplus \left(\bigoplus_{j=1}^{p} Q^j \mathcal{H}_{m-j,m'-j} \right) \right),$$

where $p = \min(m,m')$. Now Corollary 4 follows from here and Corollary 1.

Theorem 1: *The linear space isomorphism* $\mathcal{A}\simeq\mathbb{C}[Q]\otimes\mathcal{H}$ *is true, where* $\mathbb{C}[Q]$ *is the space of all polynomials in* Q.

This theorem follows from Corollary 2.

The decomposition $\mathcal{A}\simeq\mathbb{C}[Q]\otimes\mathcal{H}$ is a q-analog of the theorem on separation of variables for Lie groups in an abstract form.[12] It follows from this decomposition that

$$\mathcal{A}\simeq\mathbb{C}[Q]\otimes\mathcal{H}\simeq\mathbb{C}[Q]\otimes\bigoplus_{m\geqslant 0}\bigoplus_{m'\geqslant 0}\mathcal{H}_{m,m'}=\bigoplus_{m\geqslant 0}\bigoplus_{m'\geqslant 0}(\mathbb{C}[Q]\otimes\mathcal{H}_{m,m'}). \tag{23}$$

Since the subspaces $\mathcal{A}_{m,m'}$ are invariant with respect to the action of the algebra $\mathrm{U}_q(\mathrm{gl}_n)$, it follows from Proposition 2 for Δ_q that the subspace $\mathcal{H}_{m,m'}$ is invariant with respect to the representation $L_{m,m'}$ of $\mathrm{U}_q(\mathrm{gl}_n)$. We denote the restriction of this representation to $\mathcal{H}_{m,m'}$ by $T_{m,m'}$. It follows from Proposition 2 for Q and from (22) that

$$L_{m,m'}=\bigoplus_{j=0}^{\min(m,m')}T_{m-j,m'-j}. \tag{24}$$

Proposition 4: The representations $T_{m-j,m'-j}$ of $\mathrm{U}_q(\mathrm{gl}_n)$ *in (24) are irreducible with highest weights* $(m-j,0,\ldots,0,-m'+j)$, *respectively.*

Proof: Let us show that the representation $L_{m,0}=T_{m,0}$ in the space of holomorphic polynomials $\mathcal{A}_{m,0}$ is irreducible with highest weight $(m,0,\ldots,0)$. In fact, a direct calculation shows that the monomials $z_1^{m_1}\cdots z_n^{m_n}$, $m_1+\cdots+m_n=m$, are weight vectors of this representation. The highest weight vector coincides with z_1^m. Therefore, the irreducible representation with highest weight $(m,0,\ldots,0)$ is a subrepresentation of $L_{m,0}=T_{m,0}$. Since their dimensions coincide, $L_{m,0}=T_{m,0}$ is an irreducible representation with highest weight $(m,0,\ldots,0)$. It can be proved in the same way that the representation $L_{0,m'}=T_{0,m'}$ in the space of polynomials $\mathcal{A}_{0,m'}$ is irreducible with highest weight $(0,\ldots,0,-m')$.

Now we can prove the proposition by the induction. Assume that the proposition is true for the representations $T_{m-1-j,m'-1-j}$ which are contained in the decomposition

$$L_{m-1,m'-1}=\bigoplus_{j=0}^{\min(m-1,m'-1)}T_{m-1-j,m'-1-j}. \tag{25}$$

Note that since $\mathcal{A}_{m,m'}=\mathcal{H}_{m,m'}\oplus Q\mathcal{A}_{m-1,m'-1}$, then $L_{m-1,m'-1}$ is a subrepresentation in $L_{m,m'}$ and

$$\dim\mathcal{A}_{m-1,m'-1}=\dim L_{m-1,m'-1}=\sum_{j=0}^{\min(m-1,m'-1)}\dim T_{m-1-j,m'-1-j}.$$

The space $\mathcal{A}_{m,m'}$ contains the highest weight vector $z_1^m w_n^{m'}$ which is of the weight $(m,0,\ldots,0,-m')$. Therefore, $L_{m,m'}$ contains an irreducible representation $\hat{T}_{m,m'}$ of $\mathrm{U}_q(\mathrm{gl}_n)$ with highest weight $(m,0,\ldots,0,-m')$. This irreducible representation is absent in the decomposition (25). Hence, $\hat{T}_{m,m'}$ is a subrepresentation in $T_{m,m'}$. By the formula for dimensions of irreducible representations of $\mathrm{U}_q(\mathrm{gl}_n)$ and by Corollary 3 we have $\dim\hat{T}_{m,m'}=\dim\mathcal{H}_{m,m'}$. Therefore, $\hat{T}_{m,m'}$ is equivalent to $T_{m,m'}$. Proposition is proved.

Thus, we proved that the action of the algebra $\mathrm{U}_q(\mathrm{gl}_n)$ on the space $\mathcal{A}$ realizes the irreducible representations $T_{m,m'}$ on the subspaces $\mathcal{H}_{m,m'}$ of homogeneous q-harmonic polynomials, respectively.

We denote by $\mathcal{A}^{U_q(\mathrm{gl}_n)}$ the space of elements of $\mathcal{A}$ consisting of invariant elements with respect to the action of $\mathrm{U}_q(\mathrm{gl}_n)$.

Proposition 5: We have $\mathcal{A}^{U_q(\mathrm{gl}_n)}=\mathbb{C}[Q]$ *and*

$$\mathcal{A}^{U_q(\mathrm{gl}_{n-1})} \simeq \bigoplus_{k,l} \mathbb{C}[Q_{n-1}] z_n^k w_n^l \simeq \bigoplus_{k,l} \mathbb{C}[Q] z_n^k w_n^l .$$

Proof: The formula (23) leads to the decomposition of the representation L on $\mathcal{A}$ into irreducible subrepresentations of $\mathrm{U}_q(\mathrm{gl}_n)$ (the representation multiple to the irreducible representation $T_{m,m'}$ is realized on $\mathbb{C}[Q]\otimes\mathcal{H}_{m,m'}$). Since the trivial representation of $\mathrm{U}_q(\mathrm{gl}_n)$ is realized only on $\mathcal{H}_{0,0}$, then $\mathcal{A}^{U_q(\mathrm{gl}_n)}$ coincides with $\mathbb{C}[Q]\otimes\mathcal{H}_{0,0} \equiv \mathbb{C}[Q]\otimes\mathbb{C} \simeq \mathbb{C}[Q]$.

In order to prove the second equality we note that for $\mathrm{U}_q(\mathrm{gl}_{n-1})$-module $\mathcal{A}$ we have

$$\mathcal{A} = \mathbb{C}_q[z_1, w_1, \ldots, z_n, w_n] = \bigoplus_{k,l} \mathbb{C}_q[z_1, w_1, \ldots, z_{n-1}, w_{n-1}] z_n^k w_n^l .$$

The action of the subalgebra $\mathrm{U}_q(\mathrm{gl}_{n-1})$ on monomials $z_n^k w_n^l$ is trivial. Moreover, $\mathbb{C}[z_1, w_1, \ldots, z_{n-1}, w_{n-1}]^{U_q(\mathrm{gl}_{n-1})} = \mathbb{C}[Q_{n-1}]$, where $Q_{n-1} = z_1 w_1 + \cdots + z_{n-1} w_{n-1}$. Since $Q = Q_{n-1} + z_n w_n$, we have $\mathcal{A}^{U_q(\mathrm{gl}_{n-1})} \simeq \oplus_{k,l} \mathbb{C}[Q_{n-1}] z_n^k w_n^l \simeq \oplus_{k,l} \mathbb{C}[Q] z_n^k w_n^l$. Proposition is proved.

VI. THE DUAL PAIR $(\mathrm{U}_q(\mathrm{sl}_2), \mathrm{U}_q(\mathrm{gl}_n))$

The formulas

$$ke = q^2 ek, \qquad kf = q^{-2} fk, \qquad ef - fe = \frac{k - k^{-1}}{q - q^{-1}} \tag{26}$$

determine the quantum algebra $\mathrm{U}_q(\mathrm{sl}_2)$ generated by the elements k, k^{-1}, e, f. Let $\mathcal{L}(\mathcal{A})$ be the space of linear operators on the algebra $\mathcal{A}$. It is directly verified by means of formula (18) that the operators

$$\omega(k) = q^n \gamma\overline{\gamma}, \qquad \omega(e) = q^{-n+1}\hat{Q}, \qquad \omega(f) = -\Delta_q \tag{27}$$

satisfy relations (26). This means that the algebra homomorphism $\omega: \mathrm{U}_q(\mathrm{sl}_2) \to \mathcal{L}(\mathcal{A})$ uniquely determined by formulas (27) is a representation of $\mathrm{U}_q(\mathrm{sl}_2)$.

Since the operators $\omega(k)$, $\omega(e)$, $\omega(f')$ commute with the operators $L(X)$, $X \in \mathrm{U}_q(\mathrm{gl}_n)$ we can introduce the representation $\omega \times L$ of the algebra $\mathrm{U}_q(\mathrm{sl}_2) \times \mathrm{U}_q(\mathrm{gl}_n)$ on $\mathcal{A}$, where L is the above defined natural action of $\mathrm{U}_q(\mathrm{gl}_n)$ on $\mathcal{A}$. This representation is reducible. Let us decompose it into irreducible constituents.

By (23), we have $\mathcal{A} = \oplus_{m,m' \geqslant 0} (\mathbb{C}[Q]\otimes\mathcal{H}_{m,m'})$. The subspaces $\mathbb{C}[Q]\otimes\mathcal{H}_{m,m'}$ are invariant under $\mathrm{U}_q(\mathrm{sl}_2) \times \mathrm{U}_q(\mathrm{gl}_n)$, since the space $\mathbb{C}[Q]$ is elementwise invariant under $\mathrm{U}_q(\mathrm{gl}_n)$, and for $f \in \mathbb{C}[Q]$ and $h_{m,m'} \in \mathcal{H}_{m,m'}$ we have

$$\hat{Q}(f(Q)\otimes h_{m,m'}) = Qf(Q)\otimes h_{m,m'}, \tag{28}$$

$$\Delta_q(Q^r \otimes h_{m,m'}) = q^{n-1}[r][r+m+m'+n-1] Q^{r-1} \otimes h_{m,m'}, \tag{29}$$

$$\gamma\overline{\gamma}(Q^r \otimes h_{m,m'}) = q^{2r+m+m'}(Q^r \otimes h_{m,m'}). \tag{30}$$

These formulas show that $\mathrm{U}_q(\mathrm{sl}_2)$ acts on $\mathbb{C}[Q]$ and $\mathrm{U}_q(\mathrm{gl}_n)$ acts on $\mathcal{H}_{m,m'}$. However, this action of $\mathrm{U}_q(\mathrm{sl}_2)$ depends on the component $\mathcal{H}_{m,m'}$. Taking the basis

$$|r\rangle := q^{-r(n-1)}[r+m+m'+n-1]!^{-1} Q^r, \quad r = 0, 1, 2, \ldots,$$

in the space $\mathbb{C}[Q]$, we find from (28)–(30) that

$$\omega(k)|r\rangle = q^{2r+m+m'+n}|r\rangle, \qquad \omega(f)|r\rangle = -[r]|r-1\rangle,$$

$$\omega(e)|r\rangle = [r+m+m'+n]|r+1\rangle.$$

Comparing this representation with the known irreducible representations of $U_q(sl_2)$ (see, for example, Ref. 13) we derive that the irreducible representation of $U_q(sl_2)$ of the discrete series with lowest weight $m+m'+n$ is realized on the component $\mathbb{C}[Q]$ of the space $\mathbb{C}[Q]\otimes\mathcal{H}_{m,m'}$. We denote this representation of $U_q(sl_2)$ by $D_{m+m'+n}$.

Thus, we have derived that on the subspace $\mathbb{C}[Q]\otimes\mathcal{H}_{m,m'}\subset\mathcal{A}$ the irreducible representation $D_{m+m'+n}\times T_{m,m'}$ of the algebra $U_q(sl_2)\times U_q(gl_n)$ acts. This means that for the reducible representation $\omega\otimes L$ we have the following decomposition into irreducible components:

$$\omega\times L=\bigoplus_{m,m'=0}^{\infty} D_{m+m'+n}\times T_{m,m'},$$

that is, each irreducible representation of $U_q(gl_n)$ in this decomposition determines uniquely the corresponding irreducible representation of $U_q(sl_2)$ and vise versa. This means that $U_q(sl_2)$ and $U_q(gl_n)$ constitute a *dual pair* under the action on $\mathcal{A}$.

VII. RESTRICTION OF *q*-HARMONIC POLYNOMIALS ONTO THE QUANTUM SPHERE

The associative algebra $\mathcal{F}(S^{\mathbb{C}}_{q,n-1})$ generated by the elements $z_1,\ldots,z_n,\ w_1,\ldots,\ w_n$ satisfying the relations (1)–(3) and the relation

$$z_1w_1+z_1w_1+\cdots+z_nw_n=1$$

is called *the algebra of functions on the quantum sphere* $S^{\mathbb{C}}_{q,n-1}$ (see Ref. 6, Chap. 11, and Ref. 7). It is clear that the following canonical algebra isomorphism has place:

$$\mathcal{F}(S^{\mathbb{C}}_{q,n-1})\simeq\mathcal{A}/\mathcal{I},$$

where $\mathcal{I}$ is the two-sided ideal of $\mathcal{A}$ generated by the element $Q-1\equiv\Sigma_i z_iw_i-1$. We denote by τ the canonical algebra homomorphism

$$\tau:\mathcal{A}\to\mathcal{A}/\mathcal{I}\simeq\mathcal{F}(S^{\mathbb{C}}_{q,n-1}).$$

This homomorphism is called the *restriction* of polynomials of $\mathcal{A}$ onto the quantum sphere $S^{\mathbb{C}}_{q,n-1}$.

Proposition 6: We have $\tau\mathcal{H}\simeq\mathcal{F}(S^{\mathbb{C}}_{q,n-1})$. *This means that* $\tau:\mathcal{H}\to\mathcal{F}(S^{\mathbb{C}}_{q,n-1})$ *is a one-to-one mapping, that is, the restriction of a q-harmonic polynomial to the sphere* $S^{\mathbb{C}}_{q,n-1}$ *determines this polynomial uniquely.*

Proof: By Theorem 1, we have $\mathcal{F}(S^{\mathbb{C}}_{q,n-1})=\tau\mathcal{A}=\tau(\mathbb{C}[Q]\otimes\mathcal{H})=\tau\mathcal{H}$. Since Q is invariant with respect to the action of the algebra $U_q(gl_n)$, then the ideal $\mathcal{I}$ is an invariant subspace under the action of $U_q(gl_n)$ on $\mathcal{A}$. Therefore, an action of $U_q(gl_n)$ on $\mathcal{A}/\mathcal{I}$ is defined. This action coincides with the action in Ref. 9. The homomorphism τ intertwines the action of $U_q(gl_n)$ on $\mathcal{A}$ and on $\mathcal{A}/\mathcal{I}$. Since $\tau\mathcal{H}_{m,m'}\neq\{0\}$, then the action of $U_q(gl_n)$ realizes the same irreducible representation on $\mathcal{H}_{m,m'}$ and on $\tau\mathcal{H}_{m,m'}$. This means that $\dim\mathcal{H}_{m,m'}=\dim\tau\mathcal{H}_{m,m'}$, that is, the mapping τ is one-to-one on $\mathcal{H}_{m,m'}$. Therefore, it is one-to-one on $\mathcal{H}$. Proposition is proved.

Proposition 6 allows us to determine a scalar product on $\mathcal{H}$. For this, we use the invariant functional h on the quantum sphere defined in Ref. 9, Sec. 4.2. This functional h is determined by introducing a linear gradation in $\tau\mathcal{A}$: $\tau\mathcal{A}=\Sigma_{\lambda\in\mathbb{Z}^n}(\tau\mathcal{A})^\lambda$, where $(\tau\mathcal{A})^\lambda=\{p\in\tau\mathcal{A}|p(\mathbf{tz},\mathbf{t}^{-1}\mathbf{w})=\mathbf{t}^\lambda p(\mathbf{z},\mathbf{w})\}$, $\mathbf{t}=(t_1,t_2,\ldots,t_n)$ are n indeterminates, and

$$\mathbf{tz}=(t_1z_1,\ldots,t_nz_n),\qquad \mathbf{t}^{-1}\mathbf{w}=(t_1^{-1}w_1,\ldots,t_n^{-1}w_n),\ [\backslash]n\quad \mathbf{t}^\lambda=t_1^{\lambda_1}\ldots t_n^{\lambda_n}.$$

The subalgebra $(\tau\mathcal{A})^0$ is spanned by the monomials $z_1^{\mu_1}\cdots z_n^{\mu_n}w_n^{\mu_n}\cdots w_1^{\mu_1}$ (or by the monomials $w_1^{\mu_1}\cdots w_n^{\mu_n}z_n^{\mu_n}\cdots z_1^{\mu_1}$), $\mu_i=0,1,2,\ldots$. The functional h is defined as a linear mapping $h:\tau\mathcal{A}\to\mathbb{C}$ such that $h(p)=0$ if $p\in((\tau\mathcal{A})^\lambda,\ \lambda\neq0$, and

$$h(w_1^{\mu_1}\cdots w_n^{\mu_n}z_n^{\mu_n}\cdots z_1^{\mu_1})=\frac{(q^2;\,q^2)_{\mu_1}\cdots(q^2;\,q^2)_{\mu_n}(q^2;\,q^2)_{n-1}}{(q^2;\,q^2)_{\mu_1+\cdots+\mu_n+n-1}}.$$

The following assertions are proved in Ref. 9:

(a) The subalgebra $(\tau\mathcal{A})^0$ is a commutative algebra generated by the elements Q_{n-1}, $Q_{n-2},\ldots,Q_1$.

(b) The algebra $(\tau\mathcal{A})^0$ is isomorphic to the polynomial algebra in $n-1$ commuting indeterminates.

(c) For any polynomial $p(\mathbf{z},\mathbf{w})=f(Q_1,\ldots,\,Q_{n-1})\in(\tau\mathcal{A})^0$ the value $h(p)$ is expressed in term of Jackson integral:

$$h(p)=\frac{(q^2;q^2)_{n-1}}{(1-q^2)^{n-1}}\int_0^1\int_0^{Q_{n-1}}\cdots\int_0^{Q_2}f(Q_1,\ldots,\,Q_{n-1})d_{q^2}Q_1\cdots d_{q^2}Q_{n-1}$$

(the definition of Jackson integral; see, for example, in Ref. 14, Chap. 1).

(d) Now we can introduce a scalar product $\langle\cdot,\cdot\rangle$ on $\mathcal{H}$:

$$\langle p_1,\,p_2\rangle=h((\tau p_1)(\tau p_2)^*),\tag{31}$$

where a^* determines an element conjugate to $a\in\mathcal{A}$ under action of the $*$-operation.

Proposition 7: We have $\mathcal{H}_{m,m'}\perp\mathcal{H}_{r,r'}$ *if* $(m,\,m')\neq(r,\,r')$.

Proof follows from the fact that $(\tau p_1)(\tau p_2)^*\notin(\tau\mathcal{A})^0$ if $p_1\in\mathcal{H}_{m,m'}$, $p_2\in\mathcal{H}_{r,r'}$, and $(m,\,m')\neq(r,\,r')$.

VIII. THE PROJECTION $\mathcal{A}_{m,m'}\to\mathcal{H}_{m,m'}$

Let us go back to the decomposition (20) and construct the projector

$$\mathsf{H}_{m,m'}:\mathcal{A}_{m,m'}=\mathcal{H}_{m,m'}\oplus Q\mathcal{A}_{m-1,m'-1}\to\mathcal{H}_{m,m'}.$$

We present this projector in the form

$$\mathsf{H}_{m,m'}p=\sum_{k=0}^{\min(m,m')}\alpha_k\hat{Q}^k\Delta_q^k p,\quad \alpha_k\in\mathbb{C},\qquad p\in\mathcal{A}_{m,m'}.\tag{32}$$

We have to calculate values of the coefficients α_k. In order to do this, we act by the operator Δ_q upon both parts of (32) and use the relation (18). Under this action, the left hand side vanishes. Equating the right hand side to 0, we derive a recurrence relation

$$q^{n-1}[k][m+m'+n-k-1]\alpha_k+\alpha_{k-1}=0$$

for α_k which gives

$$\alpha_k=(-1)^k q^{-(n-1)k}\frac{[m+m'+n-k-2]!}{[k]![m+m'+n-2]!},\tag{33}$$

where $[s]!=[s][s-1][s-2]\cdots[1]$ for $s\neq0$ and $[0]!=1$.

Note that the coefficients α_k are determined by the recurrence relation uniquely up to a constant. In (33) we have chosen this constant in such a way that $\mathsf{H}_{m,m'}p=p$ for $p\in\mathcal{H}_{m,m'}$. This means that $\mathsf{H}_{m,m'}^2=\mathsf{H}_{m,m'}$.

Proposition 8: The operator $\mathsf{H}_{m,m'}$ *commutes with the action of* $\mathrm{U}_q(\mathrm{gl}_n)$, *that is, with the operators of the representation* $L_{m,m'}$ *of* $\mathrm{U}_q(\mathrm{gl}_n)$.

Proof: This assertion follows from the fact that the operators $L_{m,m'}(X)$, $X\in\mathrm{U}_q(\mathrm{gl}_n)$, commute with $\hat{Q}$ and Δ_q (see Proposition 2). Proposition is proved.

A polynomial φ of the space $\mathcal{H}_{m,m'}$ is called *zonal* if it is invariant with respect to operators $L_{m,m'}(X)$, $X \in \mathrm{U}_q(\mathrm{gl}_{n-1})$. We shall show below that zonal polynomials can be expressed in terms of the basic hypergeometric function ${}_2\varphi_1$ which is defined by the formula

$$ {}_2\varphi_1(a,\ b;\ c;\ q,\ x) = \sum_{k=0}^{\infty} \frac{(a;\ q)_k (b;\ q)_k}{(c;\ q)_k (q;\ q)_k} x^k $$

(see Refs. 14 and 15 for properties of this function).

Proposition 9: (a) The subspace of zonal polynomials in $\mathcal{H}_{m,m'}$ is one-dimensional. (b) Up to a constant, a zonal polynomial of $\mathcal{H}_{m,m'}$ is given by the formula

$$ \varphi'_{m,m'} = z_n^{m-m'} Q^{m'} \sum_{s=0}^{m'} \frac{(q^{-2m'};q^2)_s (q^{2(m+n-1)};q^2)_s}{(q^{2(n-1)};q^2)_s (q^2;q^2)_s} \frac{Q_{n-1}^s}{Q^s} q^{2s} \tag{34} $$

if $m \geqslant m'$, and by the formula

$$ \varphi'_{m,m'} = Q^m \sum_{s=0}^{m} \frac{(q^{-2m};q^2)_s (q^{2(m'+n-1)};q^2)_s}{(q^{2(n-1)};q^2)_s (q^2;q^2)_s} \frac{Q_{n-1}^s}{Q^s} q^{2s} w_n^{m'-m} \tag{35} $$

if $m \leqslant m'$.

Proof: (a) As we have seen, the irreducible representation $T_{m,m'}$ of $\mathrm{U}_q(\mathrm{gl}_n)$ with highest weight $(m, 0, \ldots, 0, -m')$ is realized on $\mathcal{H}_{m,m'}$. It is known that this representation, under restriction to $\mathrm{U}_q(\mathrm{gl}_{n-1})$, contains trivial (one-dimensional) representation of this subalgebra with multiplicity 1. This proves the first assertion.

(b) We construct a zonal polynomial of $\mathcal{H}_{m,m'}$ by using the projection operator $\mathsf{H}_{m,m'}$. In order to do this, we have to take a polynomial $p \in \mathcal{A}_{m,m'}$ invariant with respect to $\mathrm{U}_q(\mathrm{gl}_{n-1})$ and to act upon it by the operator $\mathsf{H}_{m,m'}$. Since the projector $\mathsf{H}_{m,m'}$ commutes with the action of $\mathrm{U}_q(\mathrm{gl}_{n-1})$, a polynomial obtained in this way is a zonal polynomial. Clearly, the polynomial $p = z_n^m w_n^{m'}$ belongs to $\mathcal{A}_{m,m'}$ and is invariant under the action of $\mathrm{U}_q(\mathrm{gl}_{n-1})$. In order to find an expression for $\mathsf{H}_{mm'}(z_n^m w_n^{m'})$ we first assume that $m \geqslant m'$.

Using the second expression for Δ_q in (17) and relation $\overline{\partial}_n \hat{z}_n = \hat{z}_n \overline{\partial}_n$ we have

$$ \varphi_{m,m'} := \mathsf{H}_{m,m'}(z_n^m w_n^{m'}) = \sum_{s=0}^{m'} \alpha_s \hat{Q}^s \Delta_q^s z_n^m w_n^{m'} $$

$$ = z_n^{m-m'} \sum_{s=0}^{m'} \alpha_s q^{2(n-1)s} \hat{Q}^s \frac{[m]!}{[m-s]!} \frac{[m']!}{[m'-s]!} z_n^{m'-s} w_n^{m'-s}. $$

Taking into account the expression for the coefficients α_s and using the formulas

$$ [s]! = \frac{(q^2;q^2)_s (-1)^s}{(q-q^{-1})^s} q^{-s(s+1)/2}, \qquad \frac{[m]!}{[m-s]!} = \frac{(q^{-2m};q^2)_s}{(q-q^{-1})^s} q^{ms-s(s-1)/2}, $$

we obtain

$$ \varphi_{m,m'} = z_n^{m-m'} \sum_{s=0}^{m'} q^{2s} \frac{(q^{-2m};q^2)_s (q^{-2m'};q^2)_s}{(q^2;q^2)_s (q^{-2(m+m'+n-2)};q^2)_s} Q^s z_n^{m'-s} w_n^{m'-s}. \tag{36} $$

Using the first relation in (16) we obtain from (36) that

$$\varphi_{m,m'}=Q^{m'}z_n^{m-m'}\sum_{s=0}^{m'} q^{2s}\frac{(q^{-2m};q^2)_s(q^{-2m'};q^2)_s}{(q^2;q^2)_s(q^{-2(m+m'+n-2)};q^2)_s}(Q_{n-1}/Q;q^{-2})_{m'-s}.$$

Since [see relation (II.4) from Appendix II in Ref. 14]

$$(Q_{n-1}/Q;q^{-2})_{m'-s}=\sum_{\nu=0}^{m'-s} q^{2\nu}\frac{(q^{-2(m'-s)};q^2)_\nu}{(q^2;q^2)_\nu}Q_{n-1}^\nu/Q^\nu,$$

we have

$$\begin{aligned}\varphi_{m,m'}&=Q^{m'}z_n^{m-m'}\sum_{s=0}^{m'}\frac{q^{2s}(q^{-2m};\,q^2)_s(q^{-2m'};\,q^2)_s}{(q^2;\,q^2)_s(q^{-2(m+m'+n-2)};\,q^2)_s}\sum_{\nu=0}^{m'-s} q^{2\nu}\frac{(q^{-2(m'-s)};\,q^2)_\nu}{(q^2;\,q^2)_\nu}\frac{Q_{n-1}^\nu}{Q^\nu}\\&=Q^{m'}z_n^{m-m'}\sum_{\nu=0}^{m'}\frac{Q_{n-1}^\nu}{Q^\nu}q^{2\nu}\sum_{s=0}^{m'-\nu}\frac{(q^{-2(m'-s)};\,q^2)_\nu}{(q^2;\,q^2)_\nu}\frac{q^{2s}(q^{-2m};\,q^2)_s(q^{-2m'};\,q^2)_s}{(q^2;\,q^2)_s(q^{-2(m+m'+n-2)};\,q^2)_s}.\end{aligned}\tag{37}$$

Applying relation (I.7) and then relation (I.13) from Appendix I in Ref. 14 we find

$$(q^{-2(m'-s)};\,q^2)_\nu=(-1)^\nu q^{-2m'\nu}q^{\nu(\nu-1)}\frac{(q^{2m'-2\nu+2};\,q^2)_\nu(q^{-2m'+2\nu};\,q^2)_s}{(q^{-2m'};\,q^2)_s}.$$

Therefore, for the sum over s in (37) (which will be denoted by I_ν) we obtain the expression

$$I_\nu=(-1)^\nu q^{-2m'\nu}q^{\nu(\nu-1)}\frac{(q^{2m'-2\nu+2};\,q^2)_\nu}{(q^2;\,q^2)_\nu}\sum_{s=0}^{m'-\nu}\frac{(q^{-2m'+2\nu};\,q^2)_s(q^{-2m};\,q^2)_s q^{2s}}{(q^2;\,q^2)_s(q^{-2(m+m'+n-2)};\,q^2)_s}.$$

The sum over s here is the basic hypergeometric function

$${}_2\varphi_1(q^{-2m},\ q^{-2m'+2\nu};\ q^{-2(m+m'+n-2)};\,q^2,\ q^2)=\frac{q^{-2mm'+2m\nu}(q^{-2m'-2n+4};\,q^2)_{m'-\nu}}{(q^{-2(m+m'+n-2)};\,q^2)_{m'-\nu}},$$

where we used formula (II.6) from Appendix II in Ref. 14.

Therefore, for the function $\varphi_{m,m'}$ we have the expression

$$\begin{aligned}\varphi_{m,m'}=Q^{m'}z_n^{m-m'}\sum_{\nu=0}^{m'}\frac{Q_{n-1}^\nu}{Q^\nu}q^{2\nu}(-1)^\nu q^{-2m'\nu}q^{\nu(\nu-1)}q^{-2mm'+2m\nu}\\\times\frac{(q^{2m'-2\nu+2};\,q^2)_\nu}{(q^2;\,q^2)_\nu}\frac{(q^{-2m'-2n+4};\,q^2)_{m'-\nu}}{(q^{-2(m+m'+n-2)};\,q^2)_{m'-\nu}}.\end{aligned}$$

By formula (I.8) of Appendix I in Ref. 14 we have

$$(q^{2m'-2\nu+2};\,q^2)_\nu=(q^{-2m'};\,q^2)_\nu(-1)^\nu q^{2m'\nu}q^{-\nu(\nu-1)}$$

and by formula (I.11) from Appendix I in Ref. 14 we obtain

$$\frac{(q^{-2m'-2n+4};\,q^2)_{m'-\nu}}{(q^{-2(m+m'+n-2)};\,q^2)_{m'-\nu}}=q^{-2m\nu}\frac{(q^{-2m'-2n+4};\,q^2)_{m'}}{(q^{-2(m+m'+n-2)};\,q^2)_{m'}}\frac{(q^{2(m+n-1)};\,q^2)_\nu}{(q^{2n-2};\,q^2)_\nu}.$$

For this reason, we have

$$\mathsf{H}_{mm'}(z_n^m w_n^{m'}) = \varphi_{m,m'} = q^{-2mm'} \frac{(q^{-2m'-2n+4};\, q^2)_{m'}}{(q^{-2(m+m'+n-2)};q^2)_{m'}} Q^{m'} z_n^{m-m'}$$
$$\times \sum_{\nu=0}^{m'} \frac{(q^{-2m'};\, q^2)_\nu (q^{2(m+n-1)};\, q^2)_\nu}{(q^2;q^2)_\nu (q^{2(n-1)};q^2)_\nu} \frac{Q_{n-1}^\nu}{Q^\nu} q^{2\nu}$$
$$= \frac{(q^{2(n-1)};\, q^2)_{m'}}{(q^{2(m+n-1)};\, q^2)_{m'}} Q^{m'} z_n^{m-m'}\, {}_2\varphi_1(q^{-2m'},\, q^{2(m+n-1)};$$
$$\times q^{2(n-1)};\, q^2,\, q^2 Q_{n-1}/Q).$$

This proves the second assertion of the proposition for the case $m \geqslant m'$. The case $m < m'$ is proved in the same way. Proposition is proved.

The formula

$$P_k^{(\alpha,\beta)}(x;\ q) = {}_2\varphi_1(q^{-k},\ q^{\alpha+\beta+k+1};\ q^{\alpha+1};\ q,\ qx)$$

defines the so-called little q-Jacobi polynomials. The zonal polynomials from Proposition 9 can be written in term of these polynomials as

$$\varphi'_{m,m'} = Q^{m'} z_n^{m-m'} P_{m'}^{(n-2,m-m')}(Q_{n-1}/Q;\ q^2)$$

if $m \geqslant m'$ and as

$$\varphi'_{m,m'} = Q^m P_m^{(n-2,m'-m)}(Q_{n-1}/Q;\ q^2) w_n^{m'-m}$$

if $m \leqslant m'$. Restricting these polynomials onto the quantum sphere $S^{\mathbb{C}}_{q,n-1}$ we obtain

$$\tau\varphi'_{m,m'} = z_n^{m-m'} P_{m'}^{(n-2,m-m')}(Q_{n-1};q^2)$$

if $m \geqslant m'$ and

$$\tau\varphi'_{m,m'} = P_m^{(n-2,m'-m)}(Q_{n-1};\ q^2) w_n^{m'-m}$$

if $m \leqslant m'$. These polynomials are called *zonal spherical functions* on the quantum sphere $S^{\mathbb{C}}_{q,n-1}$ and were calculated in Ref. 9 (see also Refs. 3 and 4).

IX. q-ANALOG OF ASSOCIATED SPHERICAL HARMONICS WITH RESPECT TO $\mathsf{U}_q(\mathsf{gl}_{n-1})$

It is known (see Ref. 1, Chap. 11) that in the space of classical homogeneous harmonic polynomials on the unitary (complex Euclidean) space $E^{\mathbb{C}}_n$ there exist different orthonormal bases. They correspond to different separations of variables. Each separation of variables corresponds to a certain chain of subgroups of the unitary group $U(n)$. A similar picture has place for the spaces $\mathcal{H}_{m,m'}$ of homogeneous q-harmonic polynomials. We consider in this section a q-analog of separation of variables corresponding to spherical coordinates on the sphere $S^{\mathbb{C}}_{n-1}$ (see Ref. 1, Chap. 11).

In the classical case, the tree method distinguishes different separations of variables. Different separations of variables are in a one-to-one correspondence with different chains of subgroups of $\mathrm{U}(n)$. The same tree method can be used for q-harmonic polynomials, but instead of chains of subgroups of $\mathrm{U}(n)$ we have to take the corresponding chains of subalgebras of the algebra $\mathrm{U}_q(\mathrm{gl}_n)$. A certain orthogonal basis corresponds to such a chain of subalgebras.

The aim of this section is to construct an orthogonal basis of the space $\mathcal{H}_{m,m'}$ of homogeneous q-harmonic polynomials which corresponds to the chain

$$\mathrm{U}_q(\mathrm{gl}_n)\supset \mathrm{U}_q(\mathrm{gl}_{n-1})\supset\cdots\supset \mathrm{U}_q(\mathrm{gl}_3)\supset \mathrm{U}_q(\mathrm{gl}_2)\supset \mathrm{U}_q(\mathrm{gl}_1). \tag{38}$$

This basis is a q-analog of the set of associated spherical harmonics on the complex vector space which are products of certain Jacobi polynomials (see Ref. 1, Chap. 11). The basis elements give solutions of the equation $\Delta_q p=0$ in "separated coordinates." So, we obtain a q-analog of the classical separation of variables.

Lemma 1: Let $f_{k'}(\mathbf{z}')$ and $g_{l'}(\mathbf{w}')$ be homogeneous polynomials of degrees k' in $\mathbf{z}'\equiv(z_1, z_1,\ldots, z_{n-1})$ and of degrees l' in $\mathbf{w}'\equiv(w_1, w_1,\ldots, w_{n-1})$, respectively. Then for any non-negative integers k and l we have

$$\Delta_q(z_n^k w_n^l f_{k'}(\mathbf{z}')g_{l'}(\mathbf{w}'))=q^{l-k}z_n^k w_n^l\Delta_{n-1}(f_{k'}(\mathbf{z}')g_{l'}(\mathbf{w}'))+q^{2(n-1)}q^{l'+k'}[k]\times[l]z_n^{k-1}w_n^{l-1}f_{k'}(\mathbf{z}')g_{l'}(\mathbf{w}'),$$

where $\Delta_{n-1}=\Sigma_{i=1}^{n-1}q^{2i-2}\overline{\partial}_i\partial_i$ is the q-Laplace operator for the elements $\mathbf{z}'\equiv(z_1,\ldots, z_{n-1})$ and $\mathbf{w}'\equiv(w_1,\ldots,w_{n-1})$.

Proof: Using the relations for the operators from Sec. III we derive

$$\begin{aligned}
\overline{\partial}_n\partial_n z_n^k w_n^l f_{k'}(\mathbf{z}')g_{l'}(\mathbf{w}')&=q^{(l-k)k'}\overline{\partial}_n\partial_n f_{k'}(\mathbf{z}')z_n^k w_n^l g_{l'}(\mathbf{w}')\\
&=q^{(l-k)k'}[k]\overline{\partial}_n f_{k'}(\mathbf{z}')z_n^{k-1}w_n^l g_{l'}(\mathbf{w}')\\
&=q^{(l-1)k'}[k]\overline{\partial}_n z_n^{k-1}f_{k'}(\mathbf{z}')w_n^l g_{l'}(\mathbf{w}')\\
&=q^{(l-1)k'}[k]z_n^{k-1}\overline{\partial}_n f_{k'}(\mathbf{z}')w_n^l g_{l'}(\mathbf{w}')\\
&=q^{-2k'+l(k'+l')}[k]z_n^{k-1}f_{k'}(\mathbf{z}')\overline{\partial}_n g_{l'}(\mathbf{w}')w_n^l\\
&=q^{-2k'+lk'+l'}[k][l]z_n^{k-1}f_{k'}(\mathbf{z}')w_n^{l-1}g_{l'}(\mathbf{w}')\\
&=q^{-k'+l'}[k][l]z_n^{k-1}w_n^{l-1}f_{k'}(\mathbf{z}')g_{l'}(\mathbf{w}').
\end{aligned}$$

Since $\partial_i\hat{w}_n=q\hat{w}_n\partial_i+(1-q^2)\hat{w}_i\partial_n$, $i<n$, and $\partial_n(w_n^l f_{k'}(\mathbf{z}')g_{l'}(\mathbf{w}'))=0$, we have

$$\overline{\partial}_i\partial_i z_n^k w_n^l f_{k'}(\mathbf{z}')g_{l'}(\mathbf{w}')=\overline{\partial}_i z_n^k\partial_i w_n^l f_{k'}(\mathbf{z}')g_{l'}(\mathbf{w}')=q^l\overline{\partial}_i z_n^k w_n^l\partial_i f_{k'}(\mathbf{z}')g_{l'}(\mathbf{w}').$$

Using recurrently the relation $\overline{\partial}_i\hat{z}_n=q^{-1}\hat{z}_n\overline{\partial}_i+(1-q^{-2})q^{2(n-i)}\hat{z}_i\overline{\partial}_n$, we obtain

$$\overline{\partial}_i\partial_i z_n^k w_n^l f_{k'}(\mathbf{z}')g_{l'}(\mathbf{w}')=q^{l-k}z_n^k w_n^l\overline{\partial}_i\partial_i f_{k'}(\mathbf{z}')g_{l'}(\mathbf{w}')+q^{2(n-i)}(1-q^{-2})q^{l'+1}[k]\times[l]z_n^{k-1}w_n^{l-1}\hat{z}_i\partial_i f_{k'}(\mathbf{z}')g_{l'}(\mathbf{w}').$$

Thus, one has

$$\Delta_{n-1}(z_n^k w_n^l f_{k'}(\mathbf{z}')g_{l'}(\mathbf{w}'))=q^{l-k}z_n^k w_n^l\Delta_{n-1}f_{k'}(\mathbf{z}')g_{l'}(\mathbf{w}')+q^{2n-3}(q^2-1)q^{l'}[k][l]\times[k']z_n^{k-1}w_n^{l-1}f_{k'}(\mathbf{z}')g_{l'}(\mathbf{w}'),$$

where the relation

$$\sum_{i=1}^{n-1}\hat{z}_i\partial_i f_{k'}(\mathbf{z}')g_{l'}(\mathbf{w}')=\sum_{i=1}^{n}\hat{z}_i\partial_i f_{k'}(\mathbf{z}')g_{l'}(\mathbf{w}')=\{\gamma\}f_{k'}(\mathbf{z}')g_{l'}(\mathbf{w}')=[k']f_{k'}(\mathbf{z}')g_{l'}(\mathbf{w}')$$

has been used. From the above results and from the equality $\Delta_q = q^{2(n-1)}\overline{\partial}_n \partial_n + \Delta_{n-1}$, the lemma follows.

Proposition 10: Let s and s' be integers such that $0 \leqslant s \leqslant m$ and $0 \leqslant s' \leqslant m'$. Let $h_{s,s'}(\mathbf{z}', \mathbf{w}')$ be a homogeneous harmonic polynomial of degree s in $\mathbf{z}' = (z_1, z_2, \ldots, z_{n-1})$ and of degree s' in $\mathbf{w}' = (w_1, w_2, \ldots, w_{n-1})$. Then for $z_n^{m-s} w_n^{m'-s'} h_{s,s'}(\mathbf{z}', \mathbf{w}') \in \mathcal{A}_{m,m'}$ we have

$$\mathsf{H}_{m,m'}(z_n^{m-s} w_n^{m'-s'} h_{s,s'}(\mathbf{z}', \mathbf{w}')) = z_n^{m-s-m'+s'} Q^{m'-s'} d_{ss'}^{mm'} h_{s,s'}(\mathbf{z}', \mathbf{w}'), \tag{39}$$

where $m - s \geqslant m' - s'$,

$$d_{ss'}^{mm'} = q^{-2(m-s)(m'-s')} \frac{(q^{-2m'-2s-2n+4}; q^2)_{m'-s'}}{(q^{-2m-2m'-2n+4}; q^2)_{m'-s'}} \times {}_2\varphi_1(q^{-2(m'-s')}, q^{2(m+s'+n-1)}; q^{2(s+s'+n-1)};\ q^2,\ q^2 Q_{n-1}/Q),$$

and

$$\mathsf{H}_{m,m'}(z_n^{m-s} w_n^{m'-s'} h_{s,s'}(\mathbf{z}', \mathbf{w}')) = Q^{m-s} d_{ss'}^{mm'} w_n^{m'-s'-m+s} h_{s,s'}(\mathbf{z}', \mathbf{w}'), \tag{40}$$

where $m - s \leqslant m' - s'$,

$$d_{ss'}^{mm'} = q^{-2(m-s)(m'-s')} \frac{(q^{-2m-2s'-2n+4}; q^2)_{m-s}}{(q^{-2m-2m'-2n+4}; q^2)_{m-s}} \times {}_2\varphi_1(q^{-2(m-s)}, q^{2(m'+s+n-1)}; q^{2(s+s'+n-1)};\ q^2,\ q^2 Q_{n-1}/Q).$$

Proof: The proof of this proposition is similar to that of Proposition 6 and we shall omit details. Taking into account formula (32) for the projector $\mathsf{H}_{m,m'}$ and Lemma 1, we obtain

$$\begin{aligned}\mathsf{H}_{m,m'}(z_n^{m-s} w_n^{m'-s'} h_{s,s'}(\mathbf{z}', \mathbf{w}')) &= \sum_{k=0}^{\min(m,m')} \alpha_k Q^k \Delta_q^k z_n^{m-s} w_n^{m'-s'} h_{s,s'}(\mathbf{z}', \mathbf{w}') \\ &= \sum_{k=0}^{b} \alpha_k Q^k q^{2(n-1)k} q^{(s+s')k} \frac{[m-s]![m'-s']!}{[m-s-k]![m'-s'-k]!} \\ &\quad \times z_n^{m-s-k} w_n^{m'-s'-k} h_{s,s'}(\mathbf{z}', \mathbf{w}'),\end{aligned}$$

where $b = \min(m-s, m'-s')$. Let $m - s \geqslant m' - s'$, then

$$\mathsf{H}_{m,m'}(z_n^{m-s} w_n^{m'-s'} h_{s,s'}(\mathbf{z}', \mathbf{w}')) = z_n^{m-s-m'+s'} Q^{m'-s'} d_{ss'}^{mm'} h_{s,s'}(\mathbf{z}', \mathbf{w}'),$$

where

$$d_{ss'}^{mm'} = \sum_{k=0}^{m'-s'} q^{2k} \frac{(q^{-2(m-s)};\, q^2)_k (q^{-2(m'-s')};\, q^2)_k}{(q^2;\, q^2)_k (q^{-2(m+m'+n-2)};\, q^2)_k} \sum_{\nu=0}^{d} q^{2\nu} \frac{(q^{-2(m'-s'-k)};\, q^2)_\nu}{(q^2;\, q^2)_\nu} \frac{Q_{n-1}^\nu}{Q^\nu}.$$

Here $d = m' - s' - k$. Changing the order of summations in the last expression we have

$$d_{ss'}^{mm'} = \sum_{\nu=0}^{\sigma'} \frac{(Q_{n-1}/Q)^\nu q^{2\nu}}{(q^2;\, q^2)_\nu} \sum_{k=0}^{\sigma'-\nu} q^{2k} \frac{(q^{-2(m-s)};\, q^2)_k (q^{-2(m'-s'-k)};\, q^2)_\nu (q^{-2(m'-s')};\, q^2)_k}{(q^2;\, q^2)_k (q^{-2(m+m'+n-2)};\, q^2)_k}, \tag{41}$$

where $\sigma'=m'-s'$. Since

$$(q^{-2(m'-s'-k)};\,q^2)_\nu=q^{\nu(\nu-1)}(-q^{-2(m'-s'-k)})^\nu(q^{2m'-2s'-2k}q^{-2\nu+2};\,q^2)_\nu$$
$$=(-1)^\nu q^{\nu(\nu-1)}q^{-2(m'-s')\nu}\frac{(q^{2m'-2s'-2\nu+2};\,q^2)_\nu(q^{-2m'+2s'+2\nu};\,q^2)_k}{(q^{-2m'+2s'};\,q^2)_k},$$

for the sum over k in (41) we have

$$\frac{(-1)^\nu q^{\nu(\nu-1)}(q^{-2\nu}q^{2m'-2s'+2};\,q^2)_\nu}{q^{2(m'-s')\nu}}\sum_{k=0}^{\sigma'-\nu}\frac{(q^{-2m'+2s'+2\nu};\,q^2)_k(q^{-2(m-s)};\,q^2)_k}{(q^2;\,q^2)_k(q^{-2(m+m'+n-2)};q^2)_k}q^{2k}$$
$$=a_\nu(-1)^\nu q^{\nu(\nu-1)}q^{-2(m'-s')\nu}{}_2\varphi_1(q^{-2(m-s)},\,q^{-2(m'-s')+2\nu};\,q^{-2(m+m'+n-2)};\;q^2,\,q^2)$$
$$=a_\nu(-1)^\nu q^{\nu(\nu-1)}q^{-2(m'-s')\nu}\frac{(q^{-2m'-2s-2n+4};\,q^2)_{m'-s'-\nu}}{(q^{-2m-2m'-2n+4};\,q^2)_{m'-s'-\nu}}q^{-2(m-s)(m'-s'-\nu)}$$
$$=a_\nu\frac{(-1)^\nu q^{\nu(\nu-1)}}{q^{2(m'-s')\nu}}\frac{(q^{-2m'-2s-2n+4};\,q^2)_{m'-s'}}{(q^{-2m-2m'-2n+4};\,q^2)_{m'-s'}}\frac{(q^{2m+2s'+2n-2};\,q^2)_\nu}{(q^{2s+2s'+2n-2};\,q^2)_\nu}q^{-2(m-s)(m'-s')},$$

where $a_\nu=(q^{-2\nu}q^{2m'-2s'+2};\,q^2)_\nu$. Since

$$a_\nu\equiv(q^{-2\nu}q^{2m'-2s'+2};\,q^2)_\nu=(-1)^\nu q^{-\nu(\nu-1)}q^{2(m'-s')\nu}(q^{-2m'+2s'};\,q^2)_\nu,$$

for $d_{ss'}^{mm'}$ we have the expression

$$d_{ss'}^{mm'}=c_{ss'}^{mm'}{}_2\varphi_1(q^{-2(m'-s')},\,q^{2(m+s'+n-1)};\,q^{2(s+s'+n-1)};\;q^2,\;q^2Q_{n-1}/Q),$$

where

$$c_{ss'}^{mm'}=q^{-2(m-s)(m'-s')}\frac{(q^{-2m'-2s-2n+4};\,q^2)_{m'-s'}}{(q^{-2m-2m'-2n+4};\,q^2)_{m'-s'}}=\frac{(q^{2(s+n-1)};\,q^2)_{m'-s'}}{(q^{2(m+n-1)};\,q^2)_{m'-s'}}.$$

In the case when $m-s\leqslant m'-s'$, the proof is similar and we omit it. Proposition is proved.

Remark: If $n=2$, then polynomials $h_{s,s'}(z_1,\,w_1)$ in Proposition 10 are multiple to elements from (21), that is, we have $s=0$ or $s'=0$ or $s=s'=0$.

The expressions for $d_{ss'}^{mm'}$ from Proposition 10 can be represented in terms of little q-Jacobi polynomials $P_k^{(\alpha,\beta)}(x;\,q)$ as

$$d_{ss'}^{mm'}=c_{ss'}^{mm'}P_{m'-s'}^{(s+s'+n-2,m-s-m'+s')}(Q_{n-1}/Q),$$

if $m-s\geqslant m'-s'$, and as

$$d_{ss'}^{mm'}=c_{s's}^{m'm}P_{m-s}^{(s+s'+n-2,m'-s'-m+s)}(Q_{n-1}/Q),$$

if $m-s\leqslant m'-s'$.

We denote the expression $z_n^{m-s+m'+s'}Q^{m'-s'}d_{ss'}^{mm'}$ from formula (39) and the expression $Q^{m-s}d_{ss'}^{mm'}w_n^{m'-s'+m+s}$ from (40) by $t_{s,s'}^{n;m,m'}$. Then

$$\mathsf{H}_{m,m'}(z_n^{m-s}w_n^{m'-s'}h_{s,s'}(\mathbf{z}',\mathbf{w}'))=t_{s,s'}^{n;m,m'}h_{s,s'}(\mathbf{z}',\mathbf{w}'). \tag{42}$$

Moreover, the space $\mathcal{H}_{m,m'}$ can be represented as the direct sum

$$\mathcal{H}_{m,m'}=\bigoplus_{s=0}^{m}\bigoplus_{s'=0}^{m'} t_{s,s'}^{n;m,m'}\mathcal{H}_{s,s'}^{(n-1)}, \tag{43}$$

where $\mathcal{H}_{s,s'}^{(n-1)}$ are the corresponding spaces of homogeneous q-harmonic polynomials in z_i, w_i, $i=1, 2,\ldots, n-1$. To prove this, we note that the subspaces $t_{s,s'}^{n;m,m'}\mathcal{H}_{s,s'}^{(n-1)}$ pairwise do not intersect and $\oplus_{s=0}^{m}\oplus_{s'=0}^{m'}t_{s,s'}^{n;m,m'}\mathcal{H}_{s,s'}^{(n-1)}\subset\mathcal{H}_{mm'}$. Now the equality (43) follows from the fact that dimensions of the spaces on the right and on the left coincide.

To have a correspondence with the classical case, below we denote $t_{s,s'}^{2;m,m'}$ (in this case $s=0$ or $s'=0$) by $t_{s}^{2;m,m'}$ if $s'=0$ and by $t_{-s'}^{2;m,m'}$ if $s=0$.

Taking into account the orthogonality relation (7.3.3) in Ref. 14 for little q-Jacobi polynomials we obtain for the scalar product of $t_{s,s'}^{n;m,m'}h_{s,s'}^{(n-1)}$ and $t_{r,r'}^{n;m,m'}h_{r,r'}^{(n-1)}$, $h_{p,p'}^{(n-1)}\in\mathcal{H}_{p,p'}^{(n-1)}$, the expression

$$\langle t_{s,s'}^{n;m,m'}h_{s,s'}^{(n-1)},\ t_{r,r'}^{n;m,m'}h_{r,r'}^{(n-1)}\rangle=\delta_{sr}\delta_{s'r'}(c_{ss'}^{mm'})^{-2}b_{ss'}^{mm'}\langle h_{s,s'}^{(n-1)},\ h_{r,r'}^{(n-1)}\rangle_{(n-1)},$$

where $\langle\cdot,\cdot\rangle_{(n-1)}$ is the scalar product in the space $\mathcal{H}_{ss'}^{(n-1)}$ and

$$b_{ss'}^{mm'}=\frac{(1-q^{2(n+s+s'-1)})q^{2(m'-s')(n+s+s'-1)}(q^2;\,q^2)_{m-s}(q^2;\,q^2)_{m'-s'}}{(1-q^{2(2m+n-1)})(q^{2(n+s+s'-1)};\,q^2)_{m-s}(q^{2(n+s+s'-1)};\,q^2)_{m'-s'}}.$$

Note that a calculation of this scalar product reduces to q-integration (see Refs. 3 and 4 on calculation of q-integrals of this type).

Now we apply the decomposition (43) to the subspaces $\mathcal{H}_{s,s'}^{(n-1)}$ and obtain

$$\mathcal{H}_{m,m'}=\bigoplus_{s=0}^{m}\bigoplus_{s'=0}^{m'}\bigoplus_{r=0}^{s}\bigoplus_{r'=0}^{s'} t_{s,s'}^{n;m,m'}t_{r,r'}^{n-1;s,s'}\mathcal{H}_{r,r'}^{(n-2)},$$

where $\mathcal{H}_{r,r'}^{(n-2)}$ are the subspaces of homogeneous q-harmonic polynomials in z_i, w_i, $i=1, 2,\ldots, n-2$. Continuing such decompositions we obtain the decomposition

$$\mathcal{H}_{m,m'}=\bigoplus_{\mathbf{m},\mathbf{m}',m_1}\mathbb{C}\Xi_{\mathbf{m},\mathbf{m}',m_1}(\mathbf{z},\mathbf{w}),$$

where the polynomials $\Xi_{\mathbf{m},\mathbf{m}',m_1}$ are given by the formula

$$\Xi_{\mathbf{m},\mathbf{m}',m_1}(\mathbf{z},\mathbf{w})=t_{m_{n-1},m'_{n-1}}^{n;m,m'}\,t_{m_{n-2},m'_{n-2}}^{n-1;m_{n-1},m'_{n-1}}\cdots t_{m_2,m'_2}^{3;m_3,m'_3}t_{m_1}^{2;m_2,m'_2}t^{1;m_1}, \tag{44}$$

and the summation is over all sets of $2n-3$ integers $\mathbf{m}=(m_{n-1},\ldots, m_2)$, $\mathbf{m}'=(m'_{n-1},\ldots, m'_2)$, m_1 such that $m_i\geqslant 0$, $m'_i\geqslant 0$, $i=2, 3,\ldots, n-1$, $m_2\geqslant m_1\geqslant -m'_2$,

$$m\geqslant m_{n-1}\geqslant m_{n-2}\geqslant\cdots\geqslant m_2,\quad m'\geqslant m'_{n-1}\geqslant m'_{n-2}\geqslant\cdots\geqslant m'_2.$$

Here $t_{m_{p-1},m'_{p-1}}^{p;m_p,m'_p}$ and $t_{m_1}^{2;m_2,m'_2}$ are determined by formulas given above and

$$t^{1;m_1}=z_1^{m_1}\quad\text{for } m_1>0,\quad t^{1;0}=1,\quad t^{1;m_1}=w_1^{-m_1}\quad\text{for } m_1<0.$$

It is easy to show that the basis (44) is orthogonal with respect to the scalar product introduced above.

At $q=1$, polynomials (44) turn into the basis elements of the spaces of homogeneous harmonic polynomials on $\mathbb{C}^n$ in separated coordinates determined by formulas (2) of Sec. 11.1.4 in Ref. 1. These classical homogeneous harmonic polynomials, restricted to the sphere $S^{\mathbb{C}}_{n-1}$, coincide with associated spherical functions from Sec. 11.3 in Ref. 1. They are matrix elements of zero column of the corresponding irreducible representations of the group $\mathrm{U}(n)$.

The basis elements (44) give solutions of the equation $\Delta p=0$ in $\mathcal{H}_{m,m'}$. A representation of solutions in the form (44) can be considered as a q-analog of the corresponding classical separation of variables.

In order to have an orthonormal basis in $\mathcal{H}_{m,m'}$ we replace each $t^{n-i;m_{n-i},m'_{n-i}}_{m_{n-i-1},m'_{n-i-1}}$ in the expression (44) for $\Xi_{\mathbf{m},\mathbf{m}',m_1}(\mathbf{z},\mathbf{w})$ by

$$\hat{t}^{n-i;m_{n-i},m'_{n-i}}_{m_{n-i-1},m'_{n-i-1}}=c^{m_{n-i},m'_{n-i}}_{m_{n-i-1},m'_{n-i-1}}\,(b^{m_{n-i},m'_{n-i}}_{m_{n-i-1},m'_{n-i-1}})^{-1/2}t^{n-i;m_{n-i},m'_{n-i}}_{m_{n-i-1},m'_{n-i-1}}.$$

We denote the expression (44) with such the replacement by $\hat{\Xi}_{\mathbf{m},\mathbf{m}',m_1}(\mathbf{z},\mathbf{w})$. These polynomials constitute an orthonormal basis of $\mathcal{H}_{m,m'}$.

It was shown above that the irreducible representation $T_{m,m'}$ with highest weight $(m,0,\ldots,0,-m')$ acts on the space $\mathcal{H}_{m,m'}$. The following assertion is true.

Proposition 11: The operators $T_{m,m'}(e_j)$, $T_{m,m'}(f_j)$ and $T_{m,m'}(k_j)$, corresponding to the generating elements e_j,f_j,k_j of the algebra $\mathrm{U}_q(\mathrm{gl_n})$, act upon the basis elements $\hat{\Xi}_{\mathbf{m},\mathbf{m}',m_1}\equiv|\mathbf{m},\mathbf{m}',m_1\rangle$ as

$$T_{m,m'}(e_{j-1})|\mathbf{m},\mathbf{m}',m_1\rangle=A(\mathbf{m},\mathbf{m}')|\mathbf{m}^{+1}_{j-1},\mathbf{m}',m_1\rangle+B(\mathbf{m},\mathbf{m}')|\mathbf{m},\mathbf{m}'^{-1}_{j-1},m_1\rangle,$$

$$T_{m,m'}(f_{j-1})|\mathbf{m},\mathbf{m}',m_1\rangle=A(\mathbf{m}^{-1}_{j-1},\mathbf{m}')|\mathbf{m}^{-1}_{j-1},\mathbf{m}',m_1\rangle+B(\mathbf{m},\mathbf{m}'^{+1}_{j-1})|\mathbf{m},\mathbf{m}'^{+1}_{j-1},m_1\rangle,$$

$$T_{m,m'}(k_{j-1})|\mathbf{m},\mathbf{m}',m_1\rangle=q^{m'_j-m_j+m_{j-1}-m'_{j-1}}|\mathbf{m},\mathbf{m}',m_1\rangle,$$

where

$$A(\mathbf{m},\mathbf{m}')=\left(\frac{[m_j-m_{j-1}][m'_j+m_{j-1}+j-1][m_{j-1}-m_{j-2}+1][m_{j-1}+m'_{j-2}+j-2]}{[m_{j-1}+m'_{j-1}+j-2][m_{j-1}+m'_{j-1}+j-1]}\right)^{1/2},$$

$$B(\mathbf{m},\mathbf{m}')=\left(\frac{[m'_j-m'_{j-1}+1][m_j+m'_{j-1}+j-2][m'_{j-1}-m'_{j-2}][m'_{j-1}+m_{j-2}+j-3]}{[m_{j-1}+m'_{j-1}+j-2][m_{j-1}+m'_{j-1}+j-3]}\right)^{1/2},$$

$m_n\equiv m$, $m'_n\equiv m'$, and $\mathbf{m}^{\pm1}_j$ *denotes the set of the numbers* $\mathbf{m}_{j-1}$ *with* m_{j-1} *replaced by* $m_{j-1}\pm1$, *respectively*.

A proof of this proposition is awkward. Since it is similar to that of Theorem 1 in Ref. 5, we omit it.

X. q-ANALOG OF ASSOCIATED SPHERICAL HARMONICS WITH RESPECT TO $\mathrm{U}_q(\mathrm{gl}_p)\times\mathrm{U}_q(\mathrm{gl}_{n-p})$

In Sec. IX we found an orthogonal basis of the space $\mathcal{H}_{mm'}$ of homogeneous q-harmonic polynomials corresponding to the chain of subalgebras (38). In this section we shall find orthogonal bases of the same space corresponding to the reductions

$$\mathrm{U}_q(\mathrm{gl}_n)\supset\mathrm{U}_q(\mathrm{gl}_p)\times\mathrm{U}_q(\mathrm{gl}_{n-p})\supset\cdots. \tag{45}$$

In the classical case (see Ref. 1, Chap. 11), further reductions can be made taking any chain of subgroups of the groups $U(p)$ and $U(n-p)$. In particular, the usual tree method (see Ref. 1, Sec. 10.2) can be used to describe different chains of these groups corresponding to different orthogonal bases of $\mathcal{H}_{mm'}$. In our case, there are some difficulties with construction of orthogonal bases corresponding to any chain of subalgebras in (45). For this reason, we construct orthogonal bases corresponding to the case, when we take chains of the type (38) for the subalgebras $U_q(gl_p)$ and $U_q(gl_{n-p})$ in (45).

We represent the set $(\mathbf{z},\mathbf{w})=(z_1,\ldots,z_n;w_1,\ldots,w_n)$ as $(\mathbf{y},\mathbf{t})$, where $\mathbf{y}=(z_1,z_2,\ldots,z_p,w_1,w_2,\ldots,w_p)$ and $\mathbf{t}=(z_{p+1},\ldots,z_n,w_{p+1},\ldots,w_n)$. Then the q-Laplace operator Δ_q can be written as

$$\Delta_q=\Delta_{(\mathbf{y})}+\Delta_{(\mathbf{t})}, \tag{46}$$

where

$$\Delta_{(\mathbf{y})}=\partial_1\overline{\partial}_1+\cdots+\partial_p\overline{\partial}_p, \quad \Delta_{(\mathbf{t})}=\partial_{p+1}\overline{\partial}_{p+1}+\cdots+\partial_n\overline{\partial}_n=\sum_{i=1}^{n-p}q^{2(i-1)}\overline{\partial}_{p+i}\partial_{p+i}. \tag{47}$$

The operator Δ_q can be also represented as

$$\Delta_q=\hat{\Delta}_{(\mathbf{y})}+q^{2p}\Delta_{(\mathbf{t})},$$

where

$$\hat{\Delta}_{(\mathbf{y})}=\overline{\partial}_1\partial_1+q^2\overline{\partial}_2\partial_2+\cdots+q^{2(p-1)}\overline{\partial}_p\partial_p. \tag{48}$$

We have

$$\Delta_{(\mathbf{y})}-\hat{\Delta}_{(\mathbf{y})}=(1-q^{2p})\Delta_{(\mathbf{t})}. \tag{49}$$

In order to find bases of $\mathcal{H}_{m,m'}$ corresponding to the reduction (45) we take non-negative numbers r, r', s, s' such that

$$u:=m-r-s=m'-r'-s'\geqslant 0.$$

We wish to find a harmonic projection of the polynomials

$$Q_{\mathbf{y}}^u h_{s,s'}(\mathbf{t})h_{r,r'}(\mathbf{y})\in\mathcal{A}_{mm'}, \quad h_{s,s'}(\mathbf{t})\in\tilde{\mathcal{H}}_{ss'}^{(\mathbf{t})}, \quad h_{r,r'}(\mathbf{y})\in\mathcal{H}_{r,r'}^{(\mathbf{y})}, \tag{50}$$

where $Q_{\mathbf{y}}:=z_1w_1+\cdots+z_pw_p$, $\mathcal{H}_{r,r'}^{(\mathbf{y})}$ is the space of homogeneous q-harmonic polynomials in $\mathbf{y}=(z_1,z_2,\ldots,z_p,w_1,w_2,\ldots,w_p)$, and $\tilde{\mathcal{H}}_{s,s'}^{(\mathbf{t})}$ is the space obtained in the following way. We take the space $\mathcal{H}_{s,s'}^{(n-p)}$ of homogeneous q-harmonic polynomials in $(z_1,\ldots,z_{n-p},w_1,\ldots,w_{n-p})$ and, using the relations between z_i and w_j, represent each of its polynomial in such a form that in each of its summands (monomials) the elements $z_1,\ldots,z_{n-p}$ stand before the elements $w_1,\ldots,w_{n-p}$. Then we replace $z_1,\ldots,z_{n-p},w_1,\ldots,w_{n-p}$ by $z_{p+1},\ldots,z_n,w_{p+1},\ldots,w_n$, respectively, in each of these polynomials. The space of these polynomials in $z_{p+1},\ldots,z_n,w_{p+1},\ldots,w_n$ is denoted by $\tilde{\mathcal{H}}_{ss'}^{(\mathbf{t})}$.

Lemma 2: Polynomials P of $\tilde{\mathcal{H}}_{s,s'}^{(\mathbf{t})}$ satisfy the conditions $\partial_iP=0$, $\overline{\partial}_iP=0$, $i=1,2,\ldots,p$.

Proof: Fulfillment of the conditions $\partial_iP=0$, $i=1,2,\ldots,p$, follow from the construction of polynomials of the space $\tilde{\mathcal{H}}_{s,s'}^{(\mathbf{t})}$. In order to prove the fulfillment of the conditions $\overline{\partial}_iP=0$, $i=1,2,\ldots,p$, we note that according to formulas (8) and (9) the space $\tilde{\mathcal{H}}_{s,s'}^{(\mathbf{t})}$ is elementwise invariant with respect to the subalgebra $U_q(gl_p)$. Moreover, this space is invariant and irreducible with respect to the subalgebra $U_q(gl_{n-p})$ acting on $\mathbf{t}$.

Now we rearrange elements $z_{p+1},\dots,z_n,\ w_{p+1},\dots,w_n$ in each of polynomials of $\widetilde{\mathcal{H}}^{(\mathbf{t})}_{s,s'}$ such that in each summand (monomial) elements $w_{p+1},\dots,w_n$ stand before the elements $z_{p+1},\dots,z_n$. We denote the space $\widetilde{\mathcal{H}}^{(\mathbf{t})}_{s,s'}$ with this rearrangement in polynomials by $\mathcal{L}^{(\mathbf{t})}_{s,s'}$. Because of element-wise invariance with respect to $\mathrm{U}_q(\mathrm{gl}_p)$, the space $\mathcal{L}^{(\mathbf{t})}_{s,s'}$ can be represented as a direct sum

$$\mathcal{L}^{(\mathbf{t})}_{s,s'}=\mathcal{R}_{s,s'}\oplus Q_{\mathbf{y}}\mathcal{R}_{s-1,s'-1}\oplus Q^2_{\mathbf{y}}\mathcal{R}_{s-2,s'-2}\oplus\cdots, \tag{51}$$

where $\mathcal{R}_{s-j,s'-j}$ denote the space of homogeneous polynomials in which $w_{p+1},\dots,w_n$ stand before $z_{p+1},\dots,z_n$. Due to formulas (8) and (9), the spaces $\mathcal{R}_{s-j,s'-j}$ are invariant with respect to $\mathrm{U}_q(\mathrm{gl}_{n-p})$. However, the representation of $\mathrm{U}_q(\mathrm{gl}_{n-p})$ on $\mathcal{L}^{(\mathbf{t})}_{s,s'}$ is irreducible. Therefore, the decomposition (51) contains only one summand and $\mathcal{L}^{(\mathbf{t})}_{s,s'}=\mathcal{R}_{s,s'}$. It is clear that for elements of $\mathcal{R}_{s,s'}$ the conditions $\overline{\partial}_i P=0$, $i=1,2,\dots,p$, are fulfilled. Lemma is proved.

Corollary 1: Elements P of the space $\widetilde{\mathcal{H}}^{(\mathbf{t})}_{s,s'}$, satisfy the relation $\Delta_{(\mathbf{t})}P=0$.

Corollary 2: Elements P of the space $\widetilde{\mathcal{H}}^{(\mathbf{t})}_{s,s'}$, are q-harmonic, that is, $\Delta_q P=0$.

Corollary 1 follows from (47)–(49). Corollary 2 follows from Corollary 1 and formula (46).

Lemma 3: For polynomial $h_{s,s'}(\mathbf{t})\in\widetilde{\mathcal{H}}^{(\mathbf{t})}_{s,s'}$, and arbitrary polynomial $f(\mathbf{y})$ we have

$$\hat{\Delta}_{(\mathbf{y})}h_{s,s'}(\mathbf{t})f(\mathbf{y})=q^{s-s'}h_{s,s'}(\mathbf{t})\hat{\Delta}_{(\mathbf{y})}f(\mathbf{y}).$$

Proof: We first prove the relations $\partial_i h_{s,s'}(\mathbf{t})f(\mathbf{y})=q^{s'}h_{s,s'}(\mathbf{t})\partial_i f(\mathbf{y})$, $i=1,\dots,p$. The polynomial $h_{s,s'}(\mathbf{t})$ can be represented in the form of a linear combination of monomials $z^{k_{p+1}}_{p+1}\cdots z^{k_n}_n w^{l_n}_n\cdots w^{l_{p+1}}_{p+1}$, where $k_{p+1}+\cdots+k_n=s$, $l_{p+1}+\cdots+l_n=s'$. We have

$$\begin{aligned}\partial_i z^{k_{p+1}}_{p+1}\cdots z^{k_n}_n w^{l_n}_n\cdots w^{l_{p+1}}_{p+1}f(\mathbf{y})&=z^{k_{p+1}}_{p+1}\cdots z^{k_n}_n(\partial_i w^{l_n}_n\cdots w^{l_{p+1}}_{p+1}f(\mathbf{y}))\\&=q^{s'}z^{k_{p+1}}_{p+1}\cdots z^{k_n}_n w^{l_n}_n\cdots w^{l_{p+1}}_{p+1}(\partial_i f(\mathbf{y})),\end{aligned}$$

where the relation $\partial_j f(\mathbf{y})=0$ and relations from Sec. III were used. It proves our relations. We analogously prove the relations $\overline{\partial}_i h_{s,s'}(\mathbf{t})f(\mathbf{y})=q^{-s}h_{s,s'}(\mathbf{t})\overline{\partial}_i f(\mathbf{y})$, $i=1,\dots,p$. In this case, it is useful to represent the polynomial $h_{s,s'}(\mathbf{t})$ in the form of a linear combination of monomials $w^{l_{p+1}}_{p+1}\cdots w^{l_n}_n z^{k_n}_n\cdots z^{k_{p+1}}_{p+1}$ (such representation is possible due to Lemma 2). Now the lemma follows from explicit formula for $\hat{\Delta}_{(\mathbf{y})}$. Lemma is proved.

Since $\Delta_{(\mathbf{t})}(Q^u_{\mathbf{y}}h_{s,s'}(\mathbf{t})h_{r,r'}(\mathbf{y}))=0$, then using Lemma 3 and relation (18) with n replaced by p we have

$$\begin{aligned}\Delta_q(Q^u_{\mathbf{y}}h_{s,s'}(\mathbf{t})h_{r,r'}(\mathbf{y}))&=\hat{\Delta}_{(\mathbf{y})}(Q^u_{\mathbf{y}}h_{s,s'}(\mathbf{t})h_{r,r'}(\mathbf{y}))\\&=q^a h_{s,s'}(\mathbf{t})\Delta_{(\mathbf{y})}Q^u_{\mathbf{y}}h_{r,r'}(\mathbf{y})\\&=q^a[u][p+u+r+r'-1](Q^{u-1}_{\mathbf{y}}h_{s,s'}(\mathbf{t})h_{r,r'}(\mathbf{y})),\end{aligned}$$

where $a=2(s-s')u+s'-s$.

Now we may find a harmonic projection of the polynomials (50). Denoting this projection by $h^{(r,r';s,s')}_{m,m'}(\mathbf{z},\mathbf{w})$ we have

$$\begin{aligned}h^{(r,r';s,s')}_{m,m'}(\mathbf{z},\mathbf{w})&=\sum_{k=0}^{\min(m,m')}\alpha_k Q^k\Delta^k_q(Q^u_{\mathbf{y}}h_{s,s'}(\mathbf{t})h_{r,r'}(\mathbf{y}))\\&=\left(\sum_{k=0}^{u}\alpha_k Q^k q^{(s-s'+p-1)k}\frac{[u]![r+r'+p+u-1]!}{[u-k]![r+r'+p+u-k-1]!}Q^{u-k}_{\mathbf{y}}\right)h_{s,s'}(\mathbf{t})h_{r,r'}(\mathbf{y}),\end{aligned}$$

where α_k is determined by formula (33). Denoting the expression in the parentheses by $t^{n,p;m,m'}_{r,r';s,s'}(Q_{\mathbf{y}},Q_{\mathbf{t}})$, we have

$$h^{(r,r';s,s')}_{m,m'}(\mathbf{z},\mathbf{w})=\mathsf{H}_{m,m'}(Q_{\mathbf{y}}^{m-r-s}h_{s,s'}(\mathbf{t})h_{r,r'}(\mathbf{y}))=t^{n,p;m,m'}_{r,r';s,s'}(Q_{\mathbf{y}},Q_{\mathbf{t}})h_{s,s'}(\mathbf{t})h_{r,r'}(\mathbf{y}). \quad (52)$$

After some simple transformations, we obtain for $t^{n,p;m,m'}_{r,r';s,s'}(Q_{\mathbf{y}},\ Q_{\mathbf{t}})$ the expression

$$t^{n,p;m,m'}_{r,r';s,s'}(Q_{\mathbf{y}},\ Q_{\mathbf{t}})=Q_{\mathbf{y}}^{u}\sum_{k=0}^{u}\frac{(q^{-2u};\ q^2)_k(q^{-2(r+r'+p+u-1)};\ q^2)_k}{(q^{-2(m+m'+n-2)};\ q^2)_k(q^2;\ q^2)_k}q^{k\sigma}Q^kQ_{\mathbf{y}}^{-k},$$

where $\sigma=-2n-2s'+2+2p$. Taking into account the definition of the basis hypergeometric function ${}_2\varphi_1$, we derive

$$t^{n,p;m,m'}_{r,r';s,s'}(Q_{\mathbf{y}},\ Q_{\mathbf{t}})=Q_{\mathbf{y}}^{u}\,{}_2\varphi_1(q^{-2u},\ q^{-2(r+r'+p+u-1)};\ q^{-2(m+m'+n-2)};\ q^2,\ QQ_{\mathbf{y}}^{-1}q^{\sigma}).$$

Applying the relation

$${}_2\varphi_1(q^{-n},\ b;\ c;\ q,\ z)=q^{-(n+1)n/2}(-z)^n\frac{(b;\ q)_n}{(c;\ q)_n}\,{}_2\varphi_1(q^{-n},\ q^{1-n}/c;\ q^{1-n}/b;\ q,\ cq^{n+1}/bz)$$

[see, for example, formula (2) of Sec. 14.1.8 in Ref. 16] we reduce this expression to

$$t^{n,p;m,m'}_{r,r';s,s'}(Q_{\mathbf{y}},\ Q_{\mathbf{t}})=(-q^{\sigma})^uq^{-(u+1)u}\frac{(q^{-2(r+r'+p+u-1)};\ q^2)_u}{(q^{-2(m+m'+n-2)};\ q^2)_u}Q^u$$
$$\times\,{}_2\varphi_1(q^{-2u},\ q^{2(m+m'+n-u-1)};\ q^{2(r+r'+p)};\ q^2,\ q^{-2s+2}Q_{\mathbf{y}}/Q).$$

Using the definition of the little q-Jacobi polynomials, we derive from here that

$$t^{n,p;m,m'}_{r,r';s,s'}(Q_{\mathbf{y}},Q_{\mathbf{t}})=(-q^{\sigma})^uq^{-(u+1)u}\frac{(q^{-2(r+r'+p+u-1)};\ q^2)_u}{(q^{-2(m+m'+n-2)};\ q^2)_u}Q^u$$
$$\times P_u^{(r+r'+p-1,s+s'+n-p-1)}(q^{-2s}Q_{\mathbf{y}}/Q;\ q^2). \quad (53)$$

Thus, we proved that *the projection* $\mathsf{H}_{m,m'}(Q_{\mathbf{y}}^{m-r-s}h_{s,s'}(\mathbf{t})h_{r,r'}(\mathbf{y}))$ *is given by formula (52), where* $t^{n,p;m,m'}_{r,r';s,s'}$ *is determined by (53).* The restriction $\tau h^{(r,r';s,s')}_{m,m'}(\mathbf{z},\mathbf{w})$ of this projection onto the quantum sphere $S^{\mathbb{C}}_{q,n-1}$ is given by

$$\tau h^{(r,r';s,s')}_{m,m'}(\mathbf{z},\mathbf{w})=(\tau t^{n,p;m,m'}_{r,r';s,s'})(Q_{\mathbf{y}})h_{s,s'}(\mathbf{t})h_{r,r'}(\mathbf{y}),$$

where $(\tau t^{n,p;m,m'}_{r,r';s,s'})(Q_{\mathbf{y}})=cP_u^{(r+r'+p-1,s+s'+n-p-1)}(q^{-2s}Q_{\mathbf{y}}/Q;q^2)$ [c is the multiplier from the right hand side of (53)].

For the scalar product of polynomials of the form (52) we have

$$\langle h^{(r,r';s,s')}_{m,m'},h^{(r'',r''';s'',s''')}_{m,m'}\rangle=0 \quad \text{if} \quad (r,\ r',s,\ s')\neq(r'',\ r''',\ s'',\ s''')$$

(since the spaces $\mathcal{H}^{(\mathbf{y})}_{r,r'}$ and $\mathcal{H}^{(\mathbf{y})}_{r'',r'''}$ and the spaces $\tilde{\mathcal{H}}^{(\mathbf{t})}_{s,s'}$ and $\tilde{\mathcal{H}}^{(\mathbf{t})}_{s'',s'''}$ are orthogonal). If $(r,\ r',\ s,\ s')=(r'',\ r''',\ s'',\ s''')$, then the norm of the polynomial (52) reduces to the orthogonality relation for q-Jacobi polynomials and to norms of $h_{s,s'}(\mathbf{t})$ and $h_{r,r'}(\mathbf{y})$.

In order to obtain a q-analog of separation of variables in this case we have to take bases of the spaces $\mathcal{H}^{(\mathbf{y})}_{r,r'}$ and $\tilde{\mathcal{H}}^{(\mathbf{t})}_{s,s'}$ in separated coordinates (as it was made in Sec. IX).

A sum rule for associated Legendre polynomials with spherical triangles

Armik V. M. Khachatourian and Anders O. Wistrom[a)]
Department of Chemical and Environmental Engineering, University of California, Riverside, California 92521

(Received 14 September 2001; accepted 27 September 2002)

An explicit solution to the classical electrostatic problem of the electrostatic force between *N* conducting spheres requires the expansion of the electrostatic potential. The boundary conditions for the potentials are given by Gauss which requires an expansion of the inverse of the distance that encompasses six angles. A sum rule for this expansion is presented in terms of associated Legendre polynomials with complex exponentials. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1525048]

The expansion of the inverse of the distance in systems involving more than two objects requires a sum rule for associated Legendre polynomials on the sphere. A solution is presented that expresses the product of the associated Legendre polynomials and the complex exponentials in terms of the relations for oblique spherical triangles.

Consider *N* conducting spheres each held at constant potential. The boundary condition on the surface of the spheres is given by Gauss,[1]

$$V_i = K \sum_{j=1}^{N} \int \frac{dQ_j}{R_{ij}}, \tag{1}$$

where the geometry is shown in Fig. 1. For a system comprised of three conducting spheres. Equation (1) can be written terms of Legendre polynomials. Since V_2, V_3, etc. follow from obvious interchange of symbols we need only to consider the expression for V_1:

$$V_1 = \sum_{\ell=0}^{\infty} \sum_{m=-\ell}^{\ell} \left[P_\ell^m(\cos\beta) \frac{1}{a_1^{\ell+1}} e^{im\phi} A_{\ell,m}^1 + P_\ell^m(\cos\beta) e^{im\phi} \sum_{j=0}^{\infty} \frac{(\ell+j)!}{(\ell+m)!(j-m)!} \frac{a_1^\ell}{h_{12}^{j+\ell+1}} A_{j,m}^2 \right.$$
$$\left. + P_\ell^m(\cos\beta_{13}') e^{im\phi'} \sum_{j=0}^{\infty} \frac{(\ell+j)!}{(\ell+m)!(j-m)!} \frac{a_1^\ell}{h_{13}^{j+\ell+1}} A_{j,m}^3 \right], \tag{2}$$

where $A_{j,m}^n = (-1)^m a_n^{j+2} \int_0^\pi \int_0^{2\pi} \sigma_n(\theta,g) \sin\theta \, d\theta dg \, P_j^{-m}(\cos\theta) e^{img}$, and where $\sigma_n(\theta,g)$ is the electric charge density on the surface of the *n*th sphere and where the first, second, and third terms are the contributions stemming from charges on sphere 1, sphere 2, and sphere 3, respectively. To express the expansion of the inverse of the distance in *N*-body systems thus requires a sum rule for associated Legendre polynomials expressed as the product of the two basis—the associated Legendre polynomials and the complex exponentials, $P_\ell^m(\cos\beta_{13}') e^{im\phi'}$.

The derivation of a sum rule for associated Legendre polynomials proceeds as follows given that the six angles (Fig. 1) satisfy the relationships for oblique spherical triangles:[2]

$$\cos\beta_{13}' = \cos\lambda_{13}\cos\beta + \sin\lambda_{13}\sin\beta\cos(\phi - \phi_{\lambda 13}), \tag{3}$$

a)Author to whom correspondence should be addressed. Electronic mail: wistrom@engr.ucr.edu

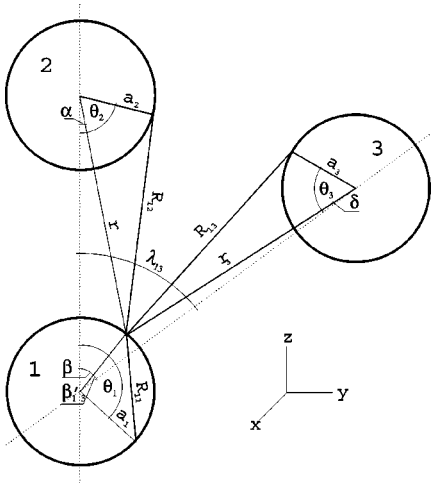

FIG. 1. Schematic representation of three spheres with radii a_1, a_2, and a_3 each having constant potential.

$$\frac{\sin\beta}{\sin(\phi_{\lambda 13}-\phi')}=\frac{\sin\beta'_{13}}{\sin(\phi-\phi_{\lambda 13})}.$$

From Eq. (3) it follows that

$$\cos\beta=\cos\lambda_{13}\cos\beta'_{13}+\sin\lambda_{13}\sin\beta'_{13}\cos(\phi_{\lambda 13}-\phi') \tag{4}$$

and, substitution of $\cos\beta'_{13}$ from Eq. (3) into Eq. (4) gives

$$-\sin\lambda_{13}\cos\beta+\cos\lambda_{13}\sin\beta\cos(\phi-\phi_{\lambda 13})+\sin\beta'_{13}\cos(\phi_{\lambda 13}-\phi')=0. \tag{5}$$

From Eqs. (3)–(5) the following relations [Eqs. (6) and (7)] are obtained when the partial derivatives are performed with β and ϕ constant (we have dropped the subscripts 13 in what follows):

$$\left(\frac{\partial}{\partial\lambda}\pm\frac{i}{\sin\lambda}\frac{\partial}{\partial\phi_\lambda}\right)\cos\beta'=\sin\beta' e^{\pm i(\phi'-\phi_\lambda)}, \tag{6}$$

$$\left(\frac{\partial}{\partial\lambda}\pm\frac{i}{\sin\lambda}\frac{\partial}{\partial\phi_\lambda}\right)\sin\beta' e^{\pm i(\phi'-\phi_\lambda)}=\frac{\cos\lambda}{\sin\lambda}\sin\beta' e^{\pm i(\phi-\phi_\lambda)}. \tag{7}$$

It follows that

$$\frac{1}{\sin\lambda}\left(\frac{\partial}{\partial\lambda}\pm\frac{i}{\sin\lambda}\frac{\partial}{\partial\phi_\lambda}\right)P_\ell(\cos\beta')=\left(\frac{e^{\pm i(\phi'-\phi_\lambda)}}{\sin\lambda}\right)P_\ell^1(\cos\beta'), \tag{8}$$

from which the recursive product to all orders follows:

$$\begin{aligned}\frac{1}{\sin\lambda}\left(\frac{\partial}{\partial\lambda}\pm\frac{i}{\sin\lambda}\frac{\partial}{\partial\phi_\lambda}\right)\frac{1}{\sin\lambda}\left(\frac{\partial}{\partial\lambda}\pm\frac{i}{\sin\lambda}\frac{\partial}{\partial\phi_\lambda}\right)P_\ell(\cos\beta')&=\left(\frac{e^{\pm i(\phi'-\phi_\lambda)}}{\sin\lambda}\right)^2P_\ell^2(\cos\beta')\\ &\vdots\\ \left(\frac{1}{\sin\lambda}\left(\frac{\partial}{\partial\lambda}\pm\frac{i}{\sin\lambda}\frac{\partial}{\partial\phi_\lambda}\right)\right)^mP_\ell(\cos\beta')&=\left(\frac{e^{\pm i(\phi'-\phi_\lambda)}}{\sin\lambda}\right)^mP_\ell^m(\cos\beta'),\end{aligned} \tag{9}$$

which can also be written as

$$e^{im\phi'}P_\ell^m(\cos\beta')=\sin^m\lambda\, e^{im\phi_\lambda}\left[\frac{1}{\sin\lambda}\left(\frac{\partial}{\partial\lambda}+\frac{i}{\sin\lambda}\,\frac{\partial}{\partial\phi_\lambda}\right)\right]^m P_\ell(\cos\beta') \tag{10}$$

where $P_\ell(\cos\beta')=\Sigma_{n=-\ell}^{\ell}(-1)^m P_\ell^{-n}(\cos\beta)P_\ell^n(\cos\lambda)e^{in(g_\lambda-g)}$ and is the sought-after sum rule for the associated Legendre polynomial with complex exponentials. Noticeably, this result was obtained directly from the boundary conditions on the spheres given by Gauss without invoking any approximations or simplifications with respect to vectorial quantities of the electric field. For the sake of completeness we also give the relation:

$$\left[\frac{1}{\sin\lambda}\left(\frac{\partial}{\partial\lambda}+\frac{i}{\sin\lambda}\,\frac{\partial}{\partial\phi_\lambda}\right)\right]^m P_\ell^k(\cos\lambda)e^{-ik\phi_\lambda}$$
$$=e^{-ik\phi_\lambda}\sum_{j=k}^{\ell}(-1)^j\frac{(\ell+1)!(1+\cos\lambda)^{k/2}(1-\cos\lambda)^{j-k/2-m}}{2^j(\ell-j)!(j-k)!(j-m)!},$$

which may be verified directly using the definition[2] for associated Legendre polynomials $P_\ell^k(x)=\Sigma_{j=0}^{\ell}(-1)^j[(\ell+j)!/2^j j!(\ell-j)!(j-k)!](1+x)^{k/2}(1-x)^{j-k/2}$. Using the well-known orthogonality relations of Legendre polynomials and the new sum rule the boundary condition for sphere 1 can now be written as

$$V_1\delta_{k,0}\delta_{\ell',0}=(-1)^k\frac{1}{a_1^{\ell'+1}}A_{\ell',-k}^1+(-1)^k\sum_{j=0}^{\infty}\frac{(\ell'+j)!}{(\ell'-k)!(j+k)!}\,\frac{a_1^{\ell'}}{h_{12}^{j+\ell'+1}}A_{j,-k}^2$$
$$+\sum_{j=0}^{\infty}(\ell'+j)!\,\frac{a_1^{\ell'}}{h_{13}^{j+\ell'+1}}\sum_{m=-\ell'}^{\ell'}\frac{g_{\ell',k}^m(-\cos\lambda_{13})}{(\ell'+m)!(j-m)!}(-1)^{m+\ell+k}e^{i(m+k)\phi_{\lambda_{13}}}A_{j,m}^3$$

for $k\geqslant 0$, and

$$g_{\ell',k}^m(-\cos\lambda)=\sum_{n=0}^{\ell'}\frac{(-1)^n(\ell'+n)!}{2^n(n-m)!(n-k)!(\ell'-n)!}\,(1-\cos\lambda)^{(k+m)/2}(1+\cos\lambda)^{n-(k+m)/2} \tag{11}$$

and, importantly, be generalized to any number of spheres by cyclic permutation.

The sum rule for associated Legendre polynomials is an important result because it allows the expansion of the potential that is proportional to the inverse of the distance for any number of spheres that are finite in size. As a result, many-body interactions between spheres can now be accounted for in a true three-dimensional system by explicitly including the r, θ, and ϕ components of the potentials.

A consequence of the expansion [Eq. (10)] is an explicit definition of an operator, here called a ''rotor,'' to all orders in the from ($J'_{+,1}\equiv J_+$)

$$J'_{+,m}=(\sin\lambda\, e^{i\phi_\lambda})^m\left[\frac{1}{\sin\lambda\, e^{i\phi_\lambda}}J_+\right]^m, \tag{12}$$

where

$$J_+=e^{i\phi}\left(\frac{\partial}{\partial\lambda}+\frac{i}{\sin\lambda}\,\frac{\partial}{\partial\phi_\lambda}\right)=L_++S_+.$$

Examination of its structure exhibits the familiar characteristics of the angular momentum operator $J_+=L_++S_+$ where the complex angular momentum operator for space is

$$L_+ = e^{i\phi_\lambda}\left(\frac{\partial}{\partial\lambda} + i\cot\lambda\,\frac{\partial}{\partial\phi_\lambda}\right) \tag{13}$$

and the second term is identified as the first-order spin operator

$$S_+ = ie^{i\phi_\lambda}\tan\frac{\lambda}{2}\,\frac{\partial}{\partial\phi_\lambda}. \tag{14}$$

In this light,

$$e^{im\phi'}P_\ell^m(\cos\beta') = L_+^m(\beta',\phi')P_\ell(\cos\beta') = J'_{+,m}(\lambda,\phi_\lambda)P_\ell(\cos\beta'), \tag{15}$$

which states that $J'_{+,m}(\lambda,\phi_\lambda)$ is the eigenvalue of the space angular momentum $L_+^m(\beta',\phi')$ noting that no assumptions with respect to vectorial quantities of the electric field have been made.

Probability density distribution of random line segments inside a convex body: Application to random media

Alain Mazzolo[a)]
CEA-Centre d'Etudes de Saclay, DEN/DM2S/SERMA/LEPP, 91191 Gif sur Yvette, France

(Received 26 August 2002; accepted 11 November 2002)

We study the probability density distribution of random line segments entirely contained inside a convex body of $\mathbf{R}^n$. Relations between this distribution function and other distribution functions of importance in geometric probability are shown. The expression for the probability density distribution of random line segments is given for several simple geometric bodies in $\mathbf{R}^2$, $\mathbf{R}^3$, and $\mathbf{R}^n$, application to random media is then presented. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1536254]

I. INTRODUCTION

In his paper on random packing, Dixmier[1] introduces the probability distribution of radii for a convex body K in $\mathbf{R}^n$, where the radius of length r is defined by the distance of a point inside K to the frontier ∂K of K. Dixmier also considers sets of random lines which intersect K, measured with the uniform density M in the sense of the theory of geometric probability.[2–4] Let $P(l)=\Pr\{l(M)\leqslant l: M\cap K\neq\varnothing\}$ be the distribution function of l (the length of the chord) and $G(r)=\Pr\{|P_1P_2|\leqslant r:\ P_1\in K,\ P_2\in\partial K\}$ the distribution function of the radii. Moreover, let $p(l)=dP(l)/dl$ and $g(r)=dG(r)/dr$ be the corresponding density functions. Dixmier shows that since the radii are supported by the chords of length greater than r, the distribution of radii $g(r)$ is related to the distribution of random chords $p(l)$ by

$$g(r)=\frac{1}{\overline{l}}\int_r^{\delta} p(l)\,dl, \tag{1}$$

where $\delta=\max(l)$ and $\overline{l}$ is the mean value of the chord:

$$\overline{l}=\int_0^{\delta} l\,p(l)\,dl. \tag{2}$$

Dixmier found several interesting relations between kth moments of the chords and kth moments of the radii, in particular:

$$\overline{r}=\frac{\overline{l^2}}{2\overline{l}}, \tag{3}$$

Following Dixmier's approach we define the probability distribution function for a line segment of length z of being entirely inside K as $S(z)=\Pr\{S(M)\leqslant z:\ M\cap K\neq\varnothing,\ S\subset K\}$, and let $s(z)=dS(z)/dz$ be the corresponding density function. Considering that a line segment of length z belongs to a chord of length greater than z, the conditional density distribution function follows from the definition:

a)Electronic mail: alain.mazzolo@cea.fr

$$s(z)=\frac{\int_{y\leqslant\delta}\Theta(y-z)(y-z)p(y)dy}{\int_{z\leqslant\delta}dz\int_{y\leqslant\delta}\Theta(y-z)(y-z)p(y)dy}, \tag{4}$$

where $\Theta(x)$ is the Heavyside step function.

The denominator is

$$\int_0^\delta dz\int_0^y(y-z)p(y)dy=\int_0^\delta dyp(y)\int_0^y dz(y-z)=\frac{\overline{l^2}}{2}, \tag{5}$$

where $\overline{l^2}$ is the second moment of the chord distribution:

$$\overline{l^2}=\int_0^\delta l^2\ \ p(l)dl. \tag{6}$$

Thus, the line segment distribution function is related to the chord distribution by

$$s(z)=\frac{2}{\overline{l^2}}\int_z^\delta(y-z)p(y)dy. \tag{7}$$

II. PROPERTIES OF THE PROBABILITY DENSITY OF RANDOM LINE SEGMENTS

Properties of the function $s(z)$ are easily obtained from Eq. (7). $s(z)$ is a concave function since

$$d^2s(z)/dz^2=2p(z)/\overline{l^2}\geqslant 0 \tag{8}$$

moreover $s(0)=2\overline{l}/\overline{l^2}$, and $s(0)'=-2/\overline{l^2}$.

More generally, the kth moment of the random line segment is given by

$$\overline{s^k}=\frac{2}{\overline{l^2}}\int_0^\delta dzz^k\int_0^y(y-z)p(y)dy=\frac{2}{\overline{l^2}}\int_0^\delta dyp(y)\int_0^y dzz^k(y-z)=\frac{2}{(k+1)(k+2)}\frac{\overline{l^{k+2}}}{\overline{l^2}}, \tag{9}$$

where $\overline{l^k}$ denotes the kth moment of the random chord.
In particular, the mean line segment is given by

$$\overline{s}=\frac{1}{3}\frac{\overline{l^3}}{\overline{l^2}}. \tag{10}$$

Except in the one-dimensional case, where $\overline{s^k}=L^k2/(k+1)(k+2)$ where L is the length of K, from Eq. (9), there is no simple relation between $\overline{s^k}$ and the surface and the volume of the body. However, by using (see Ref. 2 for instance)

$$\overline{l^{n+1}}=n(n+1)\frac{V^2}{F}\Gamma\left[\frac{n+1}{2}\right]\pi^{(1-n)/2}$$

where F is the surface area of K, $\overline{s^{n-1}}$ simplifies to

$$\overline{s^{n-1}}=2\frac{V^2}{F}\frac{\Gamma\left[\dfrac{n+1}{2}\right]}{\pi^{(n-1)/2}}\frac{1}{\overline{l^2}}. \tag{11}$$

Another distribution function of interest in geometric probability is the distribution function of the distance $|P_1P_2|$ between two random points P_1 and P_2 in K: $T(z)=\Pr\{|P_1P_2|\leqslant r\colon P_1,P_2 \in K\}$. $t(z)=dT(z)/dz$ is as usual the corresponding probability function. Piefke[5] proves that

$$t(z)=B_n z^{n-1}\int_z^\delta (y-z)p(y)dy \quad \text{with } n\geqslant 2 \tag{12}$$

where

$$B_n=F\pi^{(n-1)/2}\left[V^2\Gamma\left[\frac{n+1}{2}\right]\right]^{-1}.$$

So from Eqs. (7) and (12) the distribution function of line segments and the distribution function of the distance of two random points in K are related by

$$s(z)=\frac{2}{\overline{l^2}B_n}\frac{t(z)}{z^{n-1}}. \tag{13}$$

Normalizing Eq. (13) leads to

$$\overline{l^2}=\frac{2}{B_n}\int_0^\delta \frac{t(z)}{z^{n-1}}dz \tag{14}$$

and Eq. (13) can be rewritten only in terms of $t(z)$,

$$s(z)=\frac{\dfrac{t(z)}{z^{n-1}}}{\displaystyle\int_0^\delta \frac{t(z)}{z^{n-1}}dz}. \tag{15}$$

The last relation will be useful when $\overline{l^2}$ is unknown.

As a consequence of Eq. (13) there are also relations between the moments of the line segments distribution and the moments of the distance distribution. A simple calculation shows that

$$\overline{s^k}=\frac{2}{\overline{l^2}B_n}\overline{t^{k+1-n}} \quad \text{with} \quad k+1-n\geqslant 0 \quad \text{and} \quad n\geqslant 2. \tag{16}$$

By taking $k=n-1$ in Eq. (16) we recover Eq. (11). Equation (16) gives also the remarkable identity:

$$\overline{t}=\frac{\overline{s^n}}{\overline{s^{n-1}}}. \tag{17}$$

In Sec. III we shall derive an analytical expression for $s(z)$ and its moments for various simple geometric objects in two, three, and n dimensions and then extend our analysis to random media.

III. EXAMPLES

A. Sphere

The chord distribution function for a sphere of diameter D in arbitrary dimension has been derived by Dixmier:[1]

$$p(l)=\begin{cases}(n-1)D^{-2}\ \ l\left(1-\dfrac{l^2}{D^2}\right)^{(n-3)/2} & (l\leqslant D)\\ 0 \quad (l>D)\end{cases}. \tag{18}$$

The kth moment of the chord is given by

$$\overline{l^k}=D^k\,\frac{\Gamma\left(\dfrac{k}{2}+1\right)\Gamma\left(\dfrac{n+1}{2}\right)}{\Gamma\left(\dfrac{n+k+1}{2}\right)}. \tag{19}$$

Since the second moment of the chord is $\overline{l^2}=2D^2/(n+1)$, by using Eq. (9) we obtain

$$\overline{s^k}=D^k\,\frac{\Gamma\left(\dfrac{k}{2}+1\right)\Gamma\left(\dfrac{n+3}{2}\right)}{(k+1)\Gamma\left(\dfrac{n+k+3}{2}\right)} \tag{20}$$

and in particular the mean line segment is

$$\overline{s}=\frac{D}{4}\sqrt{\pi}\,\frac{\Gamma\left(\dfrac{n+3}{2}\right)}{\Gamma\left(\dfrac{n+4}{2}\right)}, \quad \overline{s}\underset{n\to\infty}{\sim}\frac{D}{2}\sqrt{\frac{\pi}{2n}}. \tag{21}$$

Using Dixmier's result,[1] namely

$$\overline{l}\underset{n\to\infty}{\sim}D\sqrt{\pi/2n},$$

yields:

$$\lim_{n\to\infty}\frac{\overline{s}}{\overline{l}}=\frac{1}{2}. \tag{22}$$

Analytical expressions for $s(z)$ in the two- and three-dimensional case are given in the following.

1. Two-dimensional case (disk)

The chord density distribution function for the disk is given by Eq. (18) (with $n=2$). A straightforward integration of Eq. (7) gives

$$s(z)=\frac{3}{4D^2}\left[\pi D-2z\sqrt{1-\frac{z^2}{D^2}}-2D\arcsin\left(\frac{z}{D}\right)\right] \tag{23}$$

in agreement with Santalo.[2]

This result can be achieved by a simple geometric argument as follows: Since the disk is invariant under rotations we can fix the direction Ω of the random line segments. Let $D(z,\Omega)$ be the translate of D by a distance z in the direction Ω. Line segments of length z that contribute to $s(z)$ have their right end lying inside $D\cap D(z,\Omega)\equiv A(z)$ (hatched area in Fig. 1). So the line segments distribution function is $A(z)$ averaged over all possible $A(z)$, i.e.,

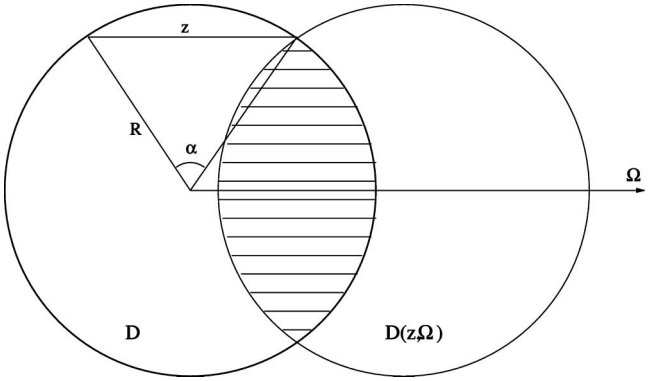

FIG. 1. Geometric interpretation of the distribution function of the random line segment for the disk.

$$s(z)=\frac{A(z)}{\int_0^D A(z)dz}. \tag{24}$$

Figure 1 yields

$$A(z)=\pi\left(\frac{D}{2}\right)^2-2z\frac{D}{2}\cos\left(\frac{\alpha}{2}\right)-\left(\frac{D}{2}\right)^2\frac{(\alpha-\sin\alpha)}{2}=\frac{D}{4}\left[\pi D-2z\sqrt{1-\frac{z^2}{D^2}}-2D\arcsin\left(\frac{z}{D}\right)\right]. \tag{25}$$

Since $\int_0^D A(z)dz=D^3/3$, by using Eq. (24) we recover Eq. (23). These geometric techniques have been recently used by Tu and Fischbach[6] for calculating the random distance between two uniform random points inside an N-dimensional spherical object. Several of their analytical results are similar to ours since the distance distribution is linked to the line segments distribution through Eq. (13). The authors of Ref. 6 also discussed the cases of nonuniform random point distributions (spherically symmetric density distributions and arbitrary density distributions).

2. Three-dimensional case (sphere)

This case is particularly simple since, with $n=3$, Eq. (18) reduces to $p(l)=2l/D^2$. We find:

$$s(z)=\frac{8}{D^4}\left[D^2\left(\frac{D}{3}-\frac{z}{2}\right)+\frac{z^3}{6}\right] \tag{26}$$

and $\overline{s^k}=8D^k/(k+1)(k+2)(k+4)$ in particular $\overline{s}=4D/15$, again in agreement with Santalo's results.[2]

B. Three-dimensional hemisphere

The chord density distribution for the three-dimensional unit hemisphere has been obtained by Dirac and co-workers,[7]

$$p(l)=\begin{cases}\dfrac{2}{3\pi}\left[\sqrt{1-\dfrac{l^2}{D^2}}\left(\dfrac{3}{D}+\dfrac{D}{2l^2}\right)+\dfrac{D^2}{2l^3}\arccos\left(\dfrac{l}{D}\right)-\dfrac{\pi}{4}\left(\dfrac{D^2}{l^3}-16\dfrac{l}{D^2}\right)\right] & \left(l\leqslant\dfrac{1}{2}\right)\\ \dfrac{2}{3\pi}\left[\sqrt{1-\dfrac{l^2}{D^2}}\left(\dfrac{3}{D}+\dfrac{D}{2l^2}\right)+\dfrac{D^2}{2l^3}\arccos\left(\dfrac{l}{D}\right)\right] & \left(l>\dfrac{1}{2}\right)\end{cases}. \tag{27}$$

From Eq. (27), we first calculate $\overline{l^2}=D^2/4$. Using Eq. (7) we thus obtain the probability density function of the random line segment:

$$s(z)=\begin{cases}\dfrac{2}{9\pi z}\left[6\dfrac{z}{D}\left(1+2\left(\dfrac{z}{D}\right)^2\right)\sqrt{1-\left(\dfrac{z}{D}\right)^2}+6\arccos\left(\dfrac{z}{D}\right)\right. & \\ \left.\quad+\pi\left(4\dfrac{z}{D}\left(4-9\dfrac{z}{D}+4\left(\dfrac{z}{D}\right)^3\right)-3\right)+24\left(\dfrac{z}{D}\right)^2\arcsin\left(\dfrac{z}{D}\right)\right] & \left(z\leqslant\dfrac{D}{2}\right) \\ \dfrac{4}{3\pi z}\left[\dfrac{z}{D}\left(1+2\left(\dfrac{z}{D}\right)^2\right)\sqrt{1-\left(\dfrac{z}{D}\right)^2}+\left(1-4\left(\dfrac{z}{D}\right)^2\right)\arccos\left(\dfrac{z}{D}\right)\right] & \left(z>\dfrac{D}{2}\right)\end{cases}. \tag{28}$$

The kth moment of the random line segment in the hemisphere is

$$\overline{s^k}=\frac{2}{(k+1)(k+2)}\left(\frac{D}{2}\right)^k\left[\frac{(k+1)\Gamma(5+k)-4(k+3)\Gamma\left(2+\dfrac{k}{2}\right)\Gamma\left(3+\dfrac{k}{2}\right)}{3k(k+3)\Gamma\left(3+\dfrac{k}{2}\right)^2}\right]. \tag{29}$$

In particular the mean random line segment is

$$\overline{s}=\frac{4(32-3\pi)}{135\pi}D. \tag{30}$$

C. Square

To the author's knowledge the chord length distribution function for the square has not been derived. However, Ghosh[8] found that the cumulative probability for the distance between two points randomly positioned in a unit square is

$$T(z)=\begin{cases}z^2\left(\dfrac{z^2}{2}-\dfrac{8z}{3}+\pi\right) & (0\leqslant z\leqslant 1) \\ \dfrac{4}{3}\sqrt{z^2-1}(2z^2+1)-\left(\dfrac{z^4}{2}+2z^2-\dfrac{1}{3}\right) & \\ \quad+2z^2\left(\arcsin\left(\dfrac{1}{z}\right)-\arccos\left(\dfrac{1}{z}\right)\right) & (1<z\leqslant\sqrt{2})\end{cases}. \tag{31}$$

Thus, the probability distribution of the distance is

$$t(z)=\begin{cases}2\pi z+2z^2(z-4) & (0\leqslant z\leqslant 1) \\ -4z-2z^2+\dfrac{16}{3}z\sqrt{z^2-1}-\dfrac{8}{3}\dfrac{z}{\sqrt{z^2-1}}+\dfrac{8}{3}\dfrac{z^3}{\sqrt{z^2-1}} & \\ \quad+4z\left(\arcsin\left(\dfrac{1}{z}\right)-\arccos\left(\dfrac{1}{z}\right)\right) & (1<z\leqslant\sqrt{2})\end{cases}. \tag{32}$$

Since $\overline{l^2}$ is unknown, we use Eq. (15) to compute $s(z)$; the denominator of Eq. (15) is

$$\int_0^{\sqrt{2}}\frac{t(z)}{z}dz=\frac{4}{3}[1-\sqrt{2}+3\log(1+\sqrt{2})]=C_0, \tag{33}$$

which is the mean value of the inverse of the distance for two random points inside the square. Finaly from Eqs. (15), (32), and (33) we get

$$s(z)=\frac{1}{C_0}\begin{cases} 2\pi z+2z^2(z-4) & (0\leqslant z\leqslant 1)\\ -4-2z+\dfrac{16}{3}\sqrt{z^2-1}-\dfrac{8}{3}\dfrac{1}{\sqrt{z^2-1}} & \\ +\dfrac{8}{3}\dfrac{z^2}{\sqrt{z^2-1}}+4\left(\arcsin\left(\dfrac{1}{z}\right)-\arccos\left(\dfrac{1}{z}\right)\right) & (1<z\leqslant\sqrt{2}) \end{cases}. \tag{34}$$

D. Cube

The chord density distribution for the three-dimensional unit cube has been obtained independently by several authors:[9,10]

$$p(l)=\frac{1}{3\pi}\begin{cases} 8-3l & (0\leqslant l\leqslant 1)\\ \dfrac{6\pi-1}{l^3}+6l-\dfrac{8}{l^3}(2l^2+1)\sqrt{l^2-1} & (1<l\leqslant\sqrt{2})\\ \dfrac{6\pi-5}{l^3}-3l+\dfrac{8}{l^3}(l^2+1)\sqrt{l^2-2} & \\ -\dfrac{24}{l^3}\arctan\sqrt{l^2-2} & (\sqrt{2}<l\leqslant\sqrt{3}) \end{cases}. \tag{35}$$

Unfortunately due to the term $\arctan(\sqrt{l^2-2})/l$, $\overline{l^2}$ cannot be simply evaluated. A numerical integration gives $\overline{l^2}=0.5978$. Using Eq. (13) with $B_3(\text{cube})=6\pi$ and another result due to Piefke[5] who found the density distribution of the distance inside the unit cube (see the Appendix for Piefke's result, where we calculate the interaction energy of two constant charge distributions inside a cube), we obtain

$$s(z)=\frac{1.673}{3\pi}\begin{cases} 4\pi-6\pi z+8z^2-z^3 & (0\leqslant z\leqslant 1)\\ \dfrac{6\pi-1}{z}-8\pi+6z+2z^3-\dfrac{8}{z}(2z^2+1)\sqrt{z^2-1} & \\ +24z\arccos\left(\dfrac{1}{z}\right) & (1<z\leqslant\sqrt{2})\\ \dfrac{6\pi-5}{z}+4\pi-6(1+\pi)z-z^3 & \\ +\dfrac{8}{z}(z^2+1)\sqrt{z^2-2}-\dfrac{24}{z}A(z) & (\sqrt{2}<z\leqslant\sqrt{3}) \end{cases} \tag{36}$$

with

$$A(z)=\arctan\sqrt{z^2-2}+2z\arctan(z^2-1-z\sqrt{z^2-2})-z^2\arctan\frac{1}{\sqrt{z^2-2}}.$$

Density distributions of random line segments inside a disk, a sphere, an hemisphere, a square, and a cube are plotted in Fig. 2.

E. Random media

In the last section we considered a two phase random media made of monosize hard spheres of radius R randomly placed in space. Under such conditions the system is statistically isotropic. Spheres fill the space with a volume fraction (or packing fraction) ϕ_2 and the void has the volume fraction $\phi_1=1-\phi_2$. Following Torquato[11] we define the chords as the line segments between the

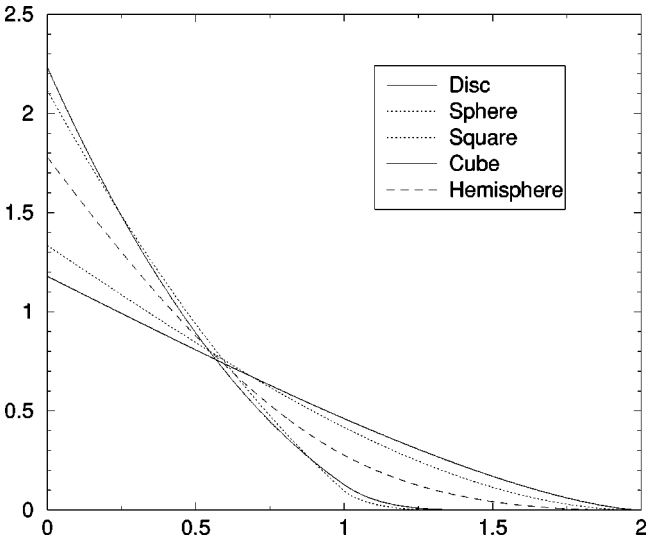

FIG. 2. Random line segment distribution functions for various geometric shapes.

intersections of an infinitely long line with the two-phase interface (these lines are measured as usual with the uniform density). The void is in general a nonconvex domain as shown in Fig. 3.

With these hypotheses, valid in any dimension, Torquato found that the density distribution function for the chords inside the void region is given by

$$p(l)=\frac{\phi_2\omega_{n-1}}{\phi_1\omega_n R}\exp\left[-\frac{\phi_2\omega_{n-1}}{\phi_1\omega_n}\frac{l}{R}\right], \tag{37}$$

where ω_n is the n-dimensional volume of the unit sphere, i.e., $\omega_n=\pi^{n/2}/\Gamma(1+n/2)$. Note that formula (37) is exact only in one dimension, in higher dimension formula (37) is an accurate approximation for isotropic equilibrium hard-sphere system Ref. 12. Since $\overline{l}=(\phi_1\omega_n R)/(\phi_2\omega_{n-1})$, we rewrite Eq. (37) as

$$p(l)=\frac{1}{\overline{l}}e^{-l/\overline{l}}. \tag{38}$$

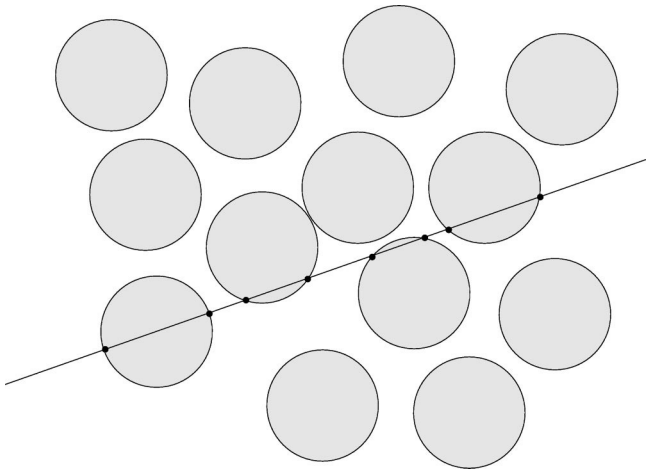

FIG. 3. Examples of chords for randomly placed disks in the plane.

From Eq. (38) we have immediately $\overline{l^2}=2\overline{l}^2$ and from Eq. (7):

$$s(z)=\frac{1}{\overline{l}}e^{-z/\overline{l}}. \tag{39}$$

So $p(l)$ and $s(z)$ have the same distribution function. As a matter of fact, in an infinite medium, if $p(l)$ and $s(z)$ are the same, they must be exponential distributions (38): In Eq. (8), with $s(z)=p(z)$ we have: $d^2s(z)/dz^2=2s(z)/\overline{l^2}$ whose solution with the condition $\int_0^\infty s(z)dz=1$ is:

$$s(z)=\sqrt{\frac{2}{\overline{l^2}}}\exp\left[-\sqrt{\frac{2}{\overline{l^2}}}z\right],$$

which is just Eq. (39).

Moreover, for asymptotically large n we have

$$\overline{s}\underset{n\to\infty}{\sim}\frac{\phi_1}{\phi_2}\sqrt{\frac{n}{2}}R. \tag{40}$$

Thus, as n gets large, the behavior of $\overline{s_{\text{void}}}$ is the inverse of $\overline{s_{\text{sphere}}}$ (see Eq. (21)). More precisely

$$\overline{s_{\text{void}}}\ \overline{s_{\text{sphere}}}=\frac{R^2}{2}\sqrt{\pi}\frac{\phi_1}{\phi_2}, \tag{41}$$

which is independent of n.

Lu and Torquato[13] also introduce a useful statistical measure $L^i(z)$ called the lineal-path-function, which is defined for statistically isotropic media as the probability that a line segment of length z lies wholly in phase i when randomly thrown into the sample.

Note that $L^i(z)$ is a probability and not a probability density. Using a simple probabilist argument these authors[12] show that $L^i(z)$ is related to the usual chord length probability density function in phase i, $p^i(z)$ by

$$L^i(z)=\frac{\phi_i}{\overline{l}}\int_0^\infty \Theta(y-z)(y-z)p(y)dy. \tag{42}$$

So we have immediately from Eqs. (42) and (7) the simple relation between $L^i(z)$ and $s^i(z)$:

$$L^i(z)=\phi_i\frac{\overline{l^2}}{2\overline{l}}s^i(z). \tag{43}$$

IV. CONCLUSION

As already noted by Santalo,[2] the problem of finding the measure of segments of a constant length that are contained in a convex body has no simple solution. The solution depends largely on the shape of the body through the $\overline{l^2}$ term. However this article shows that the links between the segment distribution function and other distribution functions thoroughly covered in the literature, allow us to find an analytical solution for several geometric shapes such as the square, the cube, or the hemisphere. Results can also be applied for certain types of random media where the chord distribution function is well defined. Moreover, in the Appendix, we have shown that geometric probability techniques are a powerful tool for calculating quantities that are extremely difficult to treat otherwise.

ACKNOWLEDGMENTS

APPENDIX: INTERACTION ENERGY OF TWO CONSTANT CHARGE DISTRIBUTIONS IN A CUBE

In this Appendix, we show how Piefke's results regarding the random distribution of distance inside a cube, allow us to calculate the electrostatic energy of two constant charge distributions inside a cube. So far, this quantity, of interest in the theory of ionic crystals as well as in other areas of solid state theory (Ref. 14), has only been evaluated numerically (Ref. 15).

We consider two electrons of charge e in a cubic box of length L and we assume that both electrons have a constant charge density $\rho=e/L^3$ in this box. The Coulomb electrostatic interaction energy of such a charge distribution is:

$$\left[\int_{r_1\in\Omega_L^1}\left(\int_{r_2\in\Omega_L^2}\frac{d\mathbf{V}_2}{|\mathbf{r}_1-\mathbf{r}_2|}\right)d\mathbf{V}_1\right]\left(\frac{e}{L^3}\right)^2\equiv C_c\frac{e^2}{L^6}, \tag{A1}$$

where Ω_L^i $(i=1,2)$ denote the cubic regions over which the integration variables, $r_i=(x_i,y_i,z_i)$ take their values. If we introduce units so that $e=L=1$ these regions are then $\Omega^i=\{(x_i,y_i,z_i);\ 0\leqslant x_i\leqslant 1,\ 0\leqslant y_i\leqslant 1,\ 0\leqslant z_i\leqslant 1\}$ $(i=1,2)$ and the energy can simply be expressed as

$$C_c=\int_{\Omega^1}\int_{\Omega^2}\frac{d\mathbf{V}_1 d\mathbf{V}_2}{|\mathbf{r}_1-\mathbf{r}_2|} \tag{A2}$$

or alternatively in the form of a six-dimensional integral

$$C_c=\int_0^1\int_0^1\int_0^1\int_0^1\int_0^1\int_0^1\frac{dx_1dy_1dz_1dx_2dy_2dz_2}{\sqrt{(x_1-x_2)^2+(y_1-y_2)^2+(z_1-z_2)^2}}. \tag{A3}$$

Essen and Nordmark have performed this integral numerically (five integrations are done analytically and the last integration is done numerically, see Ref. 15 for calculation details), they found:

$$C_c=1.882\ \ 312\ \ 645. \tag{A4}$$

In light of geometric probability, integral (A2) is reinterpreted as the average of the function $1/z$ taken with the probability density function $t(z)$ of finding two points separated by a distance z, randomly chosen in a uniform cube. So, C_c immediately appears as a one-dimensional integral:

$$C_c=\int_0^\delta dz\,\frac{t(z)}{z}. \tag{A5}$$

This approach has been applied with success for general radial potential Ref. 16 and the uniform ellipsoid Ref. 17. We used Piefke's formula Ref. 5 for the density distribution of the distance inside the unit cube

$$t(z)=\begin{cases}4\pi z^2-6\pi z^3+8z^4-z^5\equiv t_1(z) & (0\leqslant z\leqslant 1)\\ (6\pi-1)z-8\pi z^2+6z^3+2z^5-8z(2z^2+1)\sqrt{z^2-1} & \\ \quad+24z\arccos\left(\dfrac{1}{z}\right)\equiv t_2(z) & (1<z\leqslant\sqrt{2})\\ (6\pi-5)z+4\pi z^2-6(1+\pi)z^3-z^5 & \\ \quad+8z(z^2+1)\sqrt{z^2-2}-24zA(z)\equiv t_3(z) & (\sqrt{2}<z\leqslant\sqrt{3})\end{cases} \tag{A6}$$

with:

$$A(z)=\arctan\sqrt{z^2-2}+2z\arctan(z^2-1-z\sqrt{z^2-2})-z^2\arctan\frac{1}{\sqrt{z^2-2}}.$$

So C_c is

$$C_c=\int_0^1\frac{t_1(z)}{z}dz+\int_1^{\sqrt{2}}\frac{t_2(z)}{z}dz+\int_{\sqrt{2}}^{\sqrt{3}}\frac{t_3(z)}{z}dz. \tag{A7}$$

These three integrals can be evaluated analytically and we obtain

$$\int_0^1\frac{t_1(z)}{z}dz=\frac{9}{5},$$

$$\int_1^{\sqrt{2}}\frac{t_2(z)}{z}dz=-\frac{7}{5}-\frac{47\sqrt{2}}{5}+10(\sqrt{2}-1)\pi+2\log(1+\sqrt{2}), \tag{A8}$$

$$\int_{\sqrt{2}}^{\sqrt{3}}\frac{t_3(z)}{z}dz=\frac{49\sqrt{2}}{5}-\frac{4\sqrt{3}}{5}+\left(\frac{28}{3}-10\sqrt{2}\right)\pi-2\log 2+4\log(1+\sqrt{3}),$$

and eventually the constant C_c is

$$C_c=\frac{2}{5}+\frac{2\sqrt{2}}{5}-\frac{4\sqrt{3}}{5}-\frac{2\pi}{3}-2\log 2+2\log(1+\sqrt{2})+4\log(1+\sqrt{3}). \tag{A9}$$

The numerical value is $C_c=1.882\ 312\ 644\ 389$, which is very close to the approximate value of Eq. (A4) given by Essen and Nordmark.

Induced representations of $U_q so(5)$

Preeti Parashar[a)]
Max-Planck Institut für Mathematik, Vivatsgasse 7, 53111 Bonn, Germany

(Received 15 February 2002; accepted 21 October 2002)

We study the reduction of the left regular representation of the quantum algebra $U_q so(5)$. This yields induced representations of $U_q so(5)$ on some quotient space of the matrix quantum group $SO_q(5)$. To facilitate the construction of a suitable basis the Gauss decomposition of $SO_q(5)$ is worked out explicitly. We then investigate the behavior of these representations for a generic q as well as when q is an Nth root of unity leading to some finite dimensional irreducible representations of $U_q so(5)$. Two basic intertwining operators are also constructed via the right action. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1531822]

I. INTRODUCTION

A canonical method for the construction of differential operators intertwining representations of semisimple Lie groups was proposed in Ref. 1. This rather algebraic procedure was generalized to the case of quantum groups also. The left regular representation, its reduction to infinite family of reducible and irreducible representaions and the q-difference intertwining operators were studied on many quantum algebras, namely, the Lorentz quantum algebra,[2] the Euclidean algebra $U_q e(2)$ (Ref. 3) [as a contraction of $U_q sl(2)$] and generalizations to $U_q sl(3)$ (Ref. 4) and $U_q sl(n)$.[5,6] Recently induced representations of the three dimensional quantum orthogonal algebra $U_q so(3)$ have also been obtained.[7]

In this article we investigate the case of $U_q so(5,\mathbb{C})$, a quantization of the five dimensional complex special orthogonal Lie algebra of rank two. For simplicity we shall prefer to call it just $U_q so(5)$ (and similarly for the dual group). Besides being computationally horrendous, it presents some interesting features which would facilitate generalization to the n-dimensional case and also help us to understand better the important relation between representation theory and the geometry of quantum groups. On the other hand, one of the real forms of this algebra obtained by conjugation is the noncompact quantum anti-de Sitter (AdS) algebra $U_q so(3,2)$ which happens to be the symmetry algebra of the noncommutative AdS space. This aroused a lot of interest especially after the AdS–conformal field theory duality conjecture was formulated (see, for example, Ref. 8 and references therein for physical applications). This connection motivates us further to look at $U_q so(5)$ in somewhat more detail but mainly from the point of view of representation theory.

We start out by defining the quantum matrix group $SO_q(5)$ and the quantum algebra $U_q so(5)$ in Sec. II. The duality pairings between these two Hopf algebras are explicitly given. In Secs. III and IV we present the left and right regular representations of $U_q so(5)$ on the matrix elements (generators) of the dual group $SO_q(5)$. Recall that the classical SO(5) group is defined by ten independent generators, whereas here our quantum group $SO_q(5)$ has 25 generators. We must therefore, redefine these generators to get only ten independent ones. The monomials in these would give us a suitable basis to extend the left and right action. This is achieved by Gauss decomposition of the quantum matrix belonging to $SO_q(5)$ and is explicitly worked out in Sec. V.

Next, in Sec. VI we carry out the procedure of reduction of the left regular representation. As in the classical case the left and right actions commute (due to associativity). Therefore, we use the right covariance to reduce the left regular representation, i.e., we select the eigenspaces of the right regular representation of some particular generators of the quantum algebra $U_q so(5)$. This basi-

a)Electronic mail: parashar@iopb.res.in

cally implies imposing the condition that the Cartan generators act as a multiplication by a constant and that some of the aforementioned generators act as a multiplication by zero. In this way we obtain an infinite family of induced representations of $U_q$so(5) realized on the noncommutative coset space of $SO_q(5)$. In Sec. VII we investigate the reducibility of these induced representaions when q is in general a complex number and also when q is an Nth root of unity. This leads to some finite dimensional irreducible representations under some restricted values of the labels which parametrize them. The right action of the remaining generators on the basis is presented in Sec. VIII. These remaining $U_q$so(5) generators yield (via the right action) interesting intertwining operators which we give in Sec. IX. The explicit commutation relations of the quantum group $SO_q(5)$ are contained in the Appendix. We conclude the article with some remarks.

II. $SO_q(5)$ AND THE DUAL $U_q$so(5)

We begin by defining the matrix quantum group $SO_q(5)$ and its corresponding quantum universal enveloping algebra $U_q$so(5) which can be recovered from the general formulas of Ref. 9.

$SO_q(5)$ is generated by I and elements $T=(t_{ij})$, $i,j=1,\ldots,5$, obeying the following commutation relations:

$$RT_1T_2 = T_2T_1R, \tag{2.1}$$

$$TCT^tC^{-1} = CT^tC^{-1}T = I, \tag{2.2}$$

where R is a quantum $5^2\times 5^2$ invertible matrix, $T_1=T\otimes I$, $T_2=I\otimes T$, I is the identity 5×5 matrix, and C is an (antidiagonal) 5×5 matrix. The coalgebra structure is given by the following co-product Δ, co-unit ε, and antipode S:

$$\Delta(t_{ij}) = \sum_{k=1}^{5} t_{ik}\otimes t_{kj}, \tag{2.3a}$$

$$\varepsilon(t_{ij}) = \delta_{ij}, \tag{2.3b}$$

$$S(T) = C\ T^t\ C^{-1}. \tag{2.3c}$$

Using this compact matrix form relations (2.2) can be rewritten in the general form:

$$T\ S(T) = S(T)\ T = I. \tag{2.4}$$

The quantum R-matrix is given by

$$\begin{aligned} R= & \ q\sum_{i\neq i'}^{5} e_{ii}\otimes e_{ii}+e_{3,3}\otimes e_{3,3}+\sum_{i\neq j,j'}^{5} e_{ii}\otimes e_{jj}+q^{-1}\sum_{i\neq i'}^{5} e_{i'i'}\otimes e_{ii} \\ & +\lambda\sum_{i>j}^{5} e_{ij}\otimes e_{ji}-\lambda\sum_{i>j}^{5} q^{\rho_i-\rho_j}e_{ij}\otimes e_{i'j'}, \end{aligned} \tag{2.5}$$

with $\lambda=q-q^{-1}$, $(\rho_1,\ldots,\rho_5)=(\frac{3}{2},\frac{1}{2},0,-\frac{1}{2},-\frac{3}{2})$ and $i'=5+1-i$. For $SO_q(5)$ the quantum R matrix is a lower triangular 25×25 matrix whose non zero elements are explicitly given below $(R_{ij}^{kl}=e_{ik}\otimes e_{jl})$:

$$R_{ii}^{ii}=q,\ i\neq 3, \qquad R_{ii'}^{ii'}=q^{-1},\ i\neq 3, \qquad R_{33}^{33}=1,$$

$$R_{ij}^{ij}=1,\ i\neq j,j', \qquad R_{ij}^{ji}=\lambda, \quad i>j, \quad i\neq j',$$

$$R^{24}_{33}=R^{33}_{42}=-\lambda q^{-1/2}=\alpha, \qquad R^{24}_{42}=-\lambda(q^{-1}-1)=\beta, \tag{2.6}$$

$$R^{15}_{42}=R^{24}_{51}=-\lambda q^{-2}=\gamma, \qquad R^{15}_{51}=-\lambda(q^{-3}-1)=\delta,$$

$$R^{15}_{33}=R^{33}_{51}=-\lambda q^{-3/2}=\eta, \qquad R^{15}_{24}=R^{42}_{51}=-\lambda q^{-1}=\xi.$$

The corresponding antidiagonal C-matrix is

$$C = \begin{pmatrix} 0 & 0 & 0 & 0 & q^{-3/2} \\ 0 & 0 & 0 & q^{-1/2} & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & q^{1/2} & 0 & 0 & 0 \\ q^{3/2} & 0 & 0 & 0 & 0 \end{pmatrix}, \quad C^2 = I. \tag{2.7}$$

In order to derive the explicit commutation relations among the 25 generators t_{ij} of $\mathrm{SO}_q(5)$ we need to substitute the above R and C matrices in the defining relations (2.1) and (2.2).

By doing so we get an overwhelming number of relations ($\approx$400). These have been condensed to less than 40 in such a way that transparency is not lost. They are given in the Appendix as they would be essential for the Gauss decomposition in Sec. V.

The quantum universal enveloping algebra $\mathrm{U}_q\mathrm{so}(5)$ dual to $\mathrm{SO}_q(5)$ is generated by the unit 1 and the functionals l^+_{ij} with $i<j$; l^-_{ij} with $i>j$; l^+_{ii} and l^-_{ii}, where $i,j=1,\ldots,5$. When arranged in upper- and lower-triangular matrices $L^{\pm}$, respectively, they are defined by the duality conditions[9]

$$(L^{\pm},\ T_1 \ldots T_m)=R^{\pm}_1 \cdots R^{\pm}_m \ , \quad \text{for } m=1,2,\ldots, \tag{2.8}$$

where for $1\leqslant \ell \leqslant m$, $T^{\pm}_{\ell}$ act in the ℓth factor; $R^{\pm}_{\ell}$ act in the $(0,\ell)$th factor of $(\mathbb{C}^5)^{\otimes(m+1)}$; $R^+ = PRP$, $R^- = R^{-1}$ and $P \in \mathrm{Mat}(\mathbb{C}^5 \otimes \mathbb{C}^5)$ is the permutation matrix.

The commutation relations are written in a compact form

$$R^+ L^{\pm}_1 L^{\pm}_2 = L^{\pm}_2 L^{\pm}_1 R^+ \ , \quad R^+ L^+_1 L^-_2 = L^-_2 L^+_1 R^+. \tag{2.9}$$

Additional constraints are

$$l^+_{ii} l^-_{ii} = l^-_{ii} l^+_{ii} = 1, \ \ i=1,...,5 \ ; \tag{2.10}$$

$$l^+_{11} \cdots l^+_{55} = l^-_{11} \cdots l^-_{55} = 1 \ ; \tag{2.11}$$

$$L^{\pm} C^t (L^{\pm})^t (C^{-1})^t = C^t (L^{\pm})^t (C^{-1})^t L^{\pm} = I. \tag{2.12}$$

The complete Hopf algebra structure is given by

$$\Delta(l^{\pm}_{ij}) = \sum_{k=1}^{5} l^{\pm}_{ik} \otimes l^{\pm}_{kj}, \tag{2.13}$$

$$\varepsilon(l^{\pm}_{ij}) = \delta_{ij}, \tag{2.14}$$

$$S(L^{\pm}) = C^t (L^{\pm})^t (C^{-1})^t. \tag{2.15}$$

Since we shall be needing the explicit form of the antipode in defining the left action in the next section, we give it below:

$$S(L^+) = \begin{pmatrix} l_{55}^+ & q l_{45}^+ & q^{3/2} l_{35}^+ & q^2 l_{25}^+ & q^3 l_{15}^+ \\ 0 & l_{44}^+ & q^{1/2} l_{34}^+ & q l_{24}^+ & q^2 l_{14}^+ \\ 0 & 0 & l_{33}^+ & q^{1/2} l_{23}^+ & q^{3/2} l_{13}^+ \\ 0 & 0 & 0 & l_{22}^+ & q l_{12}^+ \\ 0 & 0 & 0 & 0 & l_{11}^+ \end{pmatrix}, \tag{2.16}$$

$$S(L^-) = \begin{pmatrix} l_{55}^- & 0 & 0 & 0 & 0 \\ q^{-1} l_{54}^- & l_{44}^- & 0 & 0 & 0 \\ q^{-3/2} l_{53}^- & q^{-1/2} l_{43}^- & l_{33}^- & 0 & 0 \\ q^{-2} l_{52}^- & q^{-1} l_{42}^- & q^{-1/2} l_{32}^- & l_{22}^- & 0 \\ q^{-3} l_{51}^- & q^{-2} l_{41}^- & q^{-3/2} l_{31}^- & q^{-1} l_{21}^- & l_{11}^- \end{pmatrix}. \tag{2.17}$$

The $l_{ij}^{\pm}$ can be expressed in terms of more popular generators $H_i, X_i^{\pm}$, $i=1,2$, via

$$\begin{gathered} q^{H_2} = l_{11}^+ (l_{22}^+)^{-1}, \quad q^{H_1} = (l_{22}^+)^2, \\ X_2^- = \lambda^{-1} q^{1/2} l_{12}^+ (l_{11}^+)^{-1/2} (l_{22}^+)^{-1/2}, \quad X_1^- = \lambda^{-1} \sqrt{[2]_q} q^{1/2} l_{23}^+ (l_{22}^+)^{-1/2}, \\ X_2^+ = -\lambda^{-1} q^{-1/2} l_{21}^- (l_{11}^+)^{1/2} (l_{22}^+)^{1/2}, \quad X_1^+ = -\lambda^{-1} \sqrt{[2]_q} l_{32}^- (l_{22}^+)^{1/2}. \end{gathered} \tag{2.18}$$

They satisfy the following commutation relations:

$$\begin{gathered} [H_i, H_j] = 0, \ [H_i, X_j^{\pm}] = \pm (a_{ij}) X_j^{\pm}, \ i,j = 1,2, \\ [X_i^+, X_j^-] = \delta_{ij} [H_i]_{q_i}, \ q_1 = q, \ q_2 = q^2, \\ (X_1^{\pm})^3 X_2^{\pm} - [3]_{q_1} (X_1^{\pm})^2 X_2^{\pm} X_1^{\pm} + [3]_{q_1} X_1^{\pm} X_2^{\pm} (X_1^{\pm})^2 - X_2^{\pm} (X_1^{\pm})^3 = 0, \\ (X_2^{\pm})^2 X_1^{\pm} - [2]_{q_2} X_2^{\pm} X_1^{\pm} X_2^{\pm} + X_1^{\pm} (X_2^{\pm})^2 = 0, \end{gathered} \tag{2.19}$$

where $[x]_{q_i} = (q_i^{x/2} - q_i^{-x/2})/(q_i^{1/2} - q_i^{-1/2})$ and $a_{ij} = \begin{pmatrix} 2 & -2 \\ -1 & 2 \end{pmatrix}$ is the Cartan matrix for so(5). The duality between $U_q so(5)$ and $SO_q(5)$ is given by the pairing (2.8) between the generators H_i, $X_i^{\pm}$ and the T matrix:

$$\langle H_1, T \rangle = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -2 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}, \quad \langle H_2, T \rangle = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & -1 \end{pmatrix},$$

$$\langle X_1^+, T \rangle = \sqrt{[2]_{q_1}} \begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}, \quad \langle X_1^-, T \rangle = \sqrt{[2]_{q_1}} \begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}, \tag{2.20}$$

$$\langle X_2^+, T\rangle = \begin{pmatrix} 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & -1 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}, \quad \langle X_2^-, T\rangle = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & 0 \end{pmatrix}.$$

To complete the Hopf algebra structure, the other maps are given as ($i=1,2$)

$$\Delta(H_i) = 1\otimes H_i + H_i \otimes 1, \tag{2.21a}$$

$$\Delta(X_i^{\pm}) = q_i^{H_i/4}\otimes X_i^{\pm} + X_i^{\pm}\otimes q_i^{-H_i/4}, \tag{2.21b}$$

$$\varepsilon(H_i) = 0, \qquad \varepsilon(X_i^{\pm}) = 0, \tag{2.21c}$$

$$S(H_i) = -H_i, \qquad S(X_i^{\pm}) = -q_i^{-H_i/4} X_i^{\pm} q_i^{H_i/4}. \tag{2.21d}$$

III. LEFT REGULAR REPRESENTATION

The left regular representation of $U_q so(5)$ is defined in a standard way as

$$\pi_L(X)\ t_{ij} = \sum_{k=1}^{5} \langle S(X),\ t_{ik}\rangle\ t_{kj}, \qquad X \in U_q so(5), \tag{3.1}$$

which when $q=1$ can be seen as the infinitesimal version of

$$\pi_L(T')\ T = T'^{-1}\ T, \qquad T',\ T \in SO(5). \tag{3.2}$$

In the present case it is explicitly given as

$$\pi_L(H_1)T = 2 \begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ -t_{21} & -t_{22} & -t_{23} & -t_{24} & -t_{25} \\ 0 & 0 & 0 & 0 & 0 \\ t_{41} & t_{42} & t_{43} & t_{44} & t_{45} \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$\pi_L(H_2)T = \begin{pmatrix} -t_{11} & -t_{12} & -t_{13} & -t_{14} & -t_{15} \\ t_{21} & t_{22} & t_{23} & t_{24} & t_{25} \\ 0 & 0 & 0 & 0 & 0 \\ -t_{41} & -t_{42} & -t_{43} & -t_{44} & -t_{45} \\ t_{51} & t_{52} & t_{53} & t_{54} & t_{55} \end{pmatrix},$$

$$\pi_L(X_1^+)T = q_1^{-1/2}\sqrt{[2]}_{q_1} \begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ -t_{31} & -t_{32} & -t_{33} & -t_{34} & -t_{35} \\ t_{41} & t_{42} & t_{43} & t_{44} & t_{45} \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}, \tag{3.3}$$

$$\pi_L(X_1^-)T = q_1^{1/2}\sqrt{[2]}_{q_1}\begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ -t_{21} & -t_{22} & -t_{23} & -t_{24} & -t_{25} \\ t_{31} & t_{32} & t_{33} & t_{34} & t_{35} \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$\pi_L(X_2^+)T = q_2^{-1/2}\begin{pmatrix} -t_{21} & -t_{22} & -t_{23} & -t_{24} & -t_{25} \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ t_{51} & t_{52} & t_{53} & t_{54} & t_{55} \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$\pi_L(X_2^-)T = q_2^{1/2}\begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ -t_{11} & -t_{12} & -t_{13} & -t_{14} & -t_{15} \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ t_{41} & t_{42} & t_{43} & t_{44} & t_{45} \end{pmatrix},$$

supplemented by the following action on the unit element of $SO_q(5)$:

$$\pi_L(H_i)I=0, \qquad \pi_L(X_i^{\pm})I=0, \quad i=1,2. \tag{3.4}$$

The action π_L can be extended on arbitrary monomials by making use of the following twisted derivation rule consistent with the coproduct and the representation structure:

$$\pi_L(x)a\ \ b = m(\pi_L(\sigma\circ\Delta(x))(a\otimes b)), \tag{3.5}$$

where m is the multiplication map and σ is the permutation operator. Explicitly we obtain

$$\pi_L(H_i)a\ \ b = a\cdot\pi_L(H_i)\ \ b+\pi_L(H_i)\ \ a\cdot b, \tag{3.6a}$$

$$\pi_L(X_i^{\pm})a\ \ b = \pi_L(X_i^{\pm})\ \ a\cdot\pi_L(q_i^{H_i/4})\ \ b+\pi_L(q_i^{-H_i/4})\ \ a\cdot\pi_L(X_i^{\pm})\ \ b. \tag{3.6b}$$

Further, we have

$$\begin{aligned} \pi_L(xy) &= \pi_L(x)\cdot\pi_L(y), \\ \pi_L(\alpha x+\beta y) &= \alpha\pi_L(x) + \beta\pi_L(y), \quad \alpha,\beta\in\mathbb{C}, x,\ y\in U_q so(5). \end{aligned} \tag{3.7}$$

IV. RIGHT REGULAR REPRESENTATION

Analogous to the previous section we now introduce the right regular representation of $U_q so(5)$ on $SO_q(5)$ as

$$\pi_R(X)\ \ t_{ij} = \sum_{k=1}^{5} t_{ik}\ \langle X,\ t_{kj}\rangle, \qquad X\in U_q so(5), \tag{4.1}$$

which in the classical case is the infinitesimal counterpart of

$$\pi_R(T')T = TT', \quad T,\ T'\ \in SO(5). \tag{4.2}$$

The explicit expressions are given below in matrix form:

$$
\begin{aligned}
\pi_R(H_1)T &= 2\begin{pmatrix} 0 & t_{12} & 0 & -t_{14} & 0 \\ 0 & t_{22} & 0 & -t_{24} & 0 \\ 0 & t_{32} & 0 & -t_{34} & 0 \\ 0 & t_{42} & 0 & -t_{44} & 0 \\ 0 & t_{52} & 0 & -t_{54} & 0 \end{pmatrix}, \\
\pi_R(H_2)T &= \begin{pmatrix} t_{11} & -t_{12} & 0 & t_{14} & -t_{15} \\ t_{21} & -t_{22} & 0 & t_{24} & -t_{25} \\ t_{31} & -t_{32} & 0 & t_{34} & -t_{35} \\ t_{41} & -t_{42} & 0 & t_{44} & -t_{45} \\ t_{51} & -t_{52} & 0 & t_{54} & -t_{55} \end{pmatrix}, \\
\pi_R(X_1^+)T &= \sqrt{[2]}_{q_1}\begin{pmatrix} 0 & 0 & t_{12} & -t_{13} & 0 \\ 0 & 0 & t_{22} & -t_{23} & 0 \\ 0 & 0 & t_{32} & -t_{33} & 0 \\ 0 & 0 & t_{42} & -t_{43} & 0 \\ 0 & 0 & t_{52} & -t_{53} & 0 \end{pmatrix}, \\
\pi_R(X_1^-)T &= \sqrt{[2]}_{q_1}\begin{pmatrix} 0 & t_{13} & -t_{14} & 0 & 0 \\ 0 & t_{23} & -t_{24} & 0 & 0 \\ 0 & t_{33} & -t_{34} & 0 & 0 \\ 0 & t_{43} & -t_{44} & 0 & 0 \\ 0 & t_{53} & -t_{54} & 0 & 0 \end{pmatrix}, \\
\pi_R(X_2^+)T &= \begin{pmatrix} 0 & t_{11} & 0 & 0 & -t_{14} \\ 0 & t_{21} & 0 & 0 & -t_{24} \\ 0 & t_{31} & 0 & 0 & -t_{34} \\ 0 & t_{41} & 0 & 0 & -t_{44} \\ 0 & t_{51} & 0 & 0 & -t_{54} \end{pmatrix}, \\
\pi_R(X_2^-)T &= \begin{pmatrix} t_{12} & 0 & 0 & -t_{15} & 0 \\ t_{22} & 0 & 0 & -t_{25} & 0 \\ t_{32} & 0 & 0 & -t_{35} & 0 \\ t_{42} & 0 & 0 & -t_{45} & 0 \\ t_{52} & 0 & 0 & -t_{55} & 0 \end{pmatrix}.
\end{aligned}
\tag{4.3}
$$

Similar to the left action, the right action of the generators of $U_q so(5)$ on the unit element of $SO_q(5)$ is zero.

The twisted derivation rule is given by

$$
\pi_R(x)a \quad b = m(\pi_R(\Delta(x))(a\otimes b)), \tag{4.4}
$$

which in the present situation translates into

$$\pi_R(H_i)a\ \ b\ =\ a\cdot\pi_R(H_i)\ \ b+\pi_R(H_i)\ \ a\cdot\ \ b, \tag{4.5a}$$

$$\pi_R(X_i^{\pm})a\ \ b\ =\ \pi_R(X_i^{\pm})\ \ a\cdot\pi_R(q_i^{-H_i/4})\ \ b+\pi_R(q_i^{H_i/4})\ \ a\cdot\pi_R(X_i^{\pm})\ \ b. \tag{4.5b}$$

Note that since π_R is a representation, relations similar to (3.7) hold for the right action also.

V. GAUSS DECOMPOSITION OF $SO_q(5)$

We know that the classical SO(5) group is defined in terms of ten generators and the Poincare–Birkoff–Witt (PBW) basis is defined as monomials in these generators. We have seen in Sec. II that the quantum analog $SO_q(5)$ has 25 generators t_{ij} obeying hundreds of commutation relations among them, which gives us a lot of freedom to introduce the PBW basis. Here we shall adopt the method of Gauss decomposition to achieve it.

The Gauss decomposition for the quantum T matrix of the $SO_q(5)$ group is

$$T=T_LT_DT_U, \tag{5.1}$$

where $T_L=(l_{ij})$ is a strictly lower-triangular matrix with units on the main diagonal ($l_{ii}=1$), $T_D=\mathrm{diag}(A_{ii})$ and $T_U=(u_{ij})$ is a strictly upper-triangular matrix ($u_{ii}=1$). All these are 5×5 matrices, i.e., $i,\ j=1,\ldots,5$.

After very lengthy and cumbersome computations we find that the matrix elements can be described in terms of generators of which only ten are independent. The diagonal generators A_{ii} are assumed to be invertible:

$$A_{11}=t_{11},\qquad A_{22}=t_{22}-t_{21}{t_{11}}^{-1}t_{12}\ =\ t_{22}-l_{21}A_{11}u_{12},$$

$$A_{33}=t_{33}-l_{31}A_{11}u_{13}-l_{32}A_{22}u_{23}\ =1, \tag{5.2}$$

$$A_{44}={A_{22}}^{-1},\qquad A_{55}={A_{11}}^{-1},$$

$$u_{12}={t_{11}}^{-1}t_{12},\quad u_{13}={t_{11}}^{-1}t_{13},\quad u_{14}={t_{11}}^{-1}t_{14},$$

$$u_{15}={t_{11}}^{-1}t_{15}=-u_{12}u_{14}-q[2]^{-1}{u_{13}}^2,$$

$$u_{23}={A_{22}}^{-1}(t_{23}-t_{21}{t_{11}}^{-1}t_{13}),\quad u_{24}=-[2]^{-1}{u_{23}}^2, \tag{5.3}$$

$$u_{25}=-u_{24}u_{12}-q^{-1/2}u_{23}u_{13}-q^{-1}u_{14},\quad u_{34}=-q^{1/2}u_{23},$$

$$u_{35}=q^{1/2}u_{23}u_{12}-q^{-1/2}u_{13},\quad u_{45}=-u_{12},$$

$$l_{21}=t_{21}{t_{11}}^{-1},\quad l_{31}=t_{31}{t_{11}}^{-1},\quad l_{41}=t_{41}{t_{11}}^{-1},$$

$$l_{51}=t_{51}{t_{11}}^{-1}=-l_{21}l_{41}-q[2]^{-1}{l_{31}}^2,$$

$$l_{32}=(t_{32}-t_{31}{t_{11}}^{-1}t_{12}){A_{22}}^{-1},\quad l_{42}=-[2]^{-1}{l_{32}}^2, \tag{5.4}$$

$$l_{52}=-l_{21}l_{42}-q^{1/2}l_{31}l_{32}-ql_{41},\quad l_{43}=-q^{-1/2}l_{32},$$

$$l_{53}=q^{-1/2}l_{21}l_{32}-q^{1/2}l_{31},\quad l_{54}=-l_{21},$$

where $[2]=(q-q^{-1})/(q^{1/2}-q^{-1/2})$.

It turns out that A_{33} commutes with all the other generators, hence we have set it to 1. So the ten independent generators are A_{11}, A_{22}, u_{12}, u_{13}, u_{14}, u_{23}, l_{21}, l_{31}, l_{41} and l_{32}. Below we give the commutation relations among them ($i,j=2,3,4$) by making use of the relations between the t_{ij} from the Appendix:

$$
\begin{aligned}
A_{11}u_{1i} &= q u_{1i} A_{11}, \qquad & A_{11}l_{i1} &= q l_{i1} A_{11}, \\
A_{11}u_{23} &= u_{23} A_{11}, \qquad & A_{11}l_{32} &= l_{32} A_{11}, \\
[u_{ki}, l_{jl}] &= 0, \ k,l=1,2, \quad k<i, \quad j>l, \qquad & A_{11}A_{22} &= A_{22}A_{11}, \\
A_{22}u_{12} &= q^{-1} u_{12} A_{22}, \qquad & A_{22}l_{21} &= q^{-1} l_{21} A_{22}, \\
A_{22}u_{13} &= u_{13} A_{22}, \qquad & A_{22}l_{31} &= l_{31} A_{22}, \\
A_{22}u_{14} &= q u_{14} A_{22}, \qquad & A_{22}l_{41} &= q l_{41} A_{22}, \\
A_{22}u_{23} &= q u_{23} A_{22}, \qquad & A_{22}l_{32} &= q l_{32} A_{22}, \\
u_{12}u_{13} &= q u_{13} u_{12}, \qquad & l_{21}l_{31} &= q l_{31} l_{21}, \\
u_{12}u_{14} &= u_{14}u_{12} - \lambda [2]^{-1} u_{13}u_{13}, \qquad & l_{21}l_{41} &= l_{41}l_{21} - \lambda [2]^{-1} l_{31}l_{31}, \\
u_{12}u_{23} &= q^{-1} u_{23}u_{12} + q^{-1}\lambda u_{13}, \qquad & l_{21}l_{32} &= q^{-1} l_{32}l_{21} + \lambda l_{31}, \\
u_{13}u_{14} &= q u_{14}u_{13}, \quad & l_{31}l_{41} &= q l_{41}l_{31}, \\
u_{13}u_{23} &= u_{23}u_{13} - q^{-1/2}\lambda u_{14}, \qquad & l_{31}l_{32} &= l_{32}l_{31} - q^{1/2}\lambda l_{41}, \\
u_{14}u_{23} &= q u_{23}u_{14}, \qquad & l_{41}l_{32} &= q l_{32}l_{41}.
\end{aligned}
\tag{5.5}
$$

There is an inherent symmetry in the relations for u's and l's. Note that the diagonal generators A_{ii} form an Abelian subgroup while A_{22}, u_{23} and l_{32} generate the subgroup $\mathrm{SO}_q(3)$. The above commutation relations obtained by Gauss decomposition are much simpler in form and easier to handle and would thus result in a convenient basis for $\mathrm{SO}_q(5)$.

VI. INDUCED REPRESENTATIONS

In this section we shall use the right action to reduce the left regular representation (which is highly reducible). But before we do so we need to construct a basis from the above ten independent generators. Let us choose the following ordering. Then the representation space will have elements which are formal power series in the basis:

$$
\phi \ = \ \sum \ {l_{21}}^{n_1} {l_{31}}^{n_2} {l_{41}}^{n_3} {l_{32}}^{n_4} {A_{11}}^{n_5} {A_{22}}^{n_6} {u_{12}}^{n_7} {u_{13}}^{n_8} {u_{14}}^{n_9} {u_{23}}^{n_{10}}. \tag{6.1}
$$

Here the summation is over n_i, $i=1,2,\ldots,10$. They take values in the set of non-negative integers $\mathbb{Z}_+$, except n_5 and n_6 which belong to the set of integers $\mathbb{Z}$.

We shall now impose the condition of (infinitesimal) right covariance on this independent basis of $\mathrm{SO}_q(5)$. This essentially means annihilation by the raising operators X_i^+ and scalar multiplication by exponentials of the Cartan generators H_i (similar to a highest weight module). Therefore, the right covariance conditions for the holomorphic representations with respect to X_1^+, X_2^+, K_1 and K_2 where $K_1 = q_1^{H_1/2}$, $K_2 = q_2^{H_2/2}$ are given by

$$
\pi_R(X_i^+) \ \phi \ = \ 0, \qquad i=1,2, \tag{6.2a}
$$

$$
\pi_R(K_1) \ {l_{21}}^{n_1} \cdots {u_{23}}^{n_{10}} \ = \ q^{n_6+n_7-n_9-n_{10}} \ {l_{21}}^{n_1} \cdots {u_{23}}^{n_{10}}, \tag{6.2b}
$$

$$
\pi_R(K_2) \ {l_{21}}^{n_1} \cdots {u_{23}}^{n_{10}} \ = \ q^{n_5-n_6-2n_7-n_8+n_{10}} \ {l_{21}}^{n_1} \cdots {u_{23}}^{n_{10}}. \tag{6.2c}
$$

All the l's and A's are annihilated by the right action of X_1^+ and X_2^+ whereas we get nontrivial action on the u's. Thus (6.2) implies that the function ϕ does not depend on u's and hence it is reduced to

$$\phi = \sum_{\substack{n_1,\ldots,n_4\in\mathbb{Z}_+ \\ n_5,n_6\in\mathbb{Z}}} {l_{21}}^{n_1}{l_{31}}^{n_2}{l_{41}}^{n_3}{l_{32}}^{n_4}{A_{11}}^{n_5}{A_{22}}^{n_6}. \tag{6.3}$$

For convenience let us denote by Φ the above ordered monomial, i.e.,

$$\Phi =: {l_{21}}^{n_1}{l_{31}}^{n_2}{l_{41}}^{n_3}{l_{32}}^{n_4}{A_{11}}^{n_5}{A_{22}}^{n_6}. \tag{6.4}$$

Then the right covariance conditions on the reduced basis become

$$\pi_R(X_i^+)\ \Phi = 0, \tag{6.5a}$$

$$\pi_R(K_1)\ \Phi = q^{n_6}\ \Phi, \tag{6.5b}$$

$$\pi_R(K_2)\ \Phi = q^{n_5-n_6}\ \Phi. \tag{6.5c}$$

So the monomial Φ forms a basis in the space of common solutions of the equations (6.5). The above algebra with PBW basis Φ may be viewed as the q-deformation of the quotient manifold $\mathrm{SO}(5)/U$, where U is the subgroup of upper diagonal matrices with 1 on the diagonal.

Next, we shall reduce the left regular representation on the eigenspaces of the right regular representation obtained above. For this we need the left action of K_1 and K_2 on the reduced basis Φ. This turns out to be

$$\pi_L(K_1)\ \Phi = q^{-n_1+n_3+n_4-n_6}\ \Phi, \tag{6.6a}$$

$$\pi_L(K_2)\ \Phi = q^{2n_1+n_2-n_4-n_5+n_6}\ \Phi. \tag{6.6b}$$

In order to proceed for the calculation of the left action of X_i^+ and X_i^- on Φ, it would be convenient to first find the action on the powers of the individual generators. This is obtained by iterating the twisted derivation rule (3.6) which yields

$$\pi_L(X_1^+)\ {l_{21}}^{n_1} = -\sqrt{[2]}\ q^{-n_1/2}\ [n_1]_{q^2}\ {l_{21}}^{n_1-1}\ l_{31}, \tag{6.7a}$$

$$\pi_L(X_1^+)\ {l_{31}}^{n_2} = \sqrt{[2]}\ q^{-n_2/2}\ [n_2]_q\ {l_{31}}^{n_2-1}\ l_{41}, \tag{6.7b}$$

$$\pi_L(X_1^+)\ {l_{41}}^{n_3} = 0, \tag{6.7c}$$

$$\pi_L(X_1^+)\ {l_{32}}^{n_4} = \sqrt{[2]}^{-1}\ q^{-1}\ [n_4]_q\ {l_{32}}^{n_4+1}, \tag{6.7d}$$

$$\pi_L(X_1^+)\ {A_{11}}^{n_5} = 0, \tag{6.7e}$$

$$\pi_L(X_1^+)\ {A_{22}}^{n_6} = -\sqrt{[2]}\ q^{(n_6-2)/2}\ [n_6]_{q^2}\ l_{32}\ {A_{22}}^{n_6}, \tag{6.7f}$$

$$\pi_L(X_2^+)\ {l_{21}}^{n_1} = q^{-3/2}\ [n_1]_{q^2}\ {l_{21}}^{n_1+1}, \tag{6.8a}$$

$$\pi_L(X_2^+)\ {l_{31}}^{n_2} = q^{-(n_2+3)/2}\ [n_2]_{q^2}\ l_{21}\ {l_{31}}^{n_2}, \tag{6.8b}$$

$$\pi_L(X_2^+)\ {l_{41}}^{n_3} = -[2]^{-1}\ q^{-(2n_3+1)/2}\ [n_3]_{q^2}\ {l_{31}}^2\ {l_{41}}^{n_3-1}, \tag{6.8c}$$

$$\pi_L(X_2^+)\ l_{32}{}^{n_4} = -q^{(n_4-3)/2}\ [n_4]_{q^2}\ l_{21}\ l_{32}{}^{n_4} + q^{n_4-1}\ [n_4]_q\ l_{31}\ l_{32}{}^{n_4-1} + (q^{n_4}-1)[n_4-1]_q\ l_{41} l_{32}{}^{n_4-2}, \tag{6.8d}$$

$$\pi_L(X_2^+)\ A_{11}{}^{n_5} = -q^{(n_5-3)/2}\ [n_5]_{q^2}\ l_{21}\ A_{11}{}^{n_5}, \tag{6.8e}$$

$$\pi_L(X_2^+)\ A_{22}{}^{n_6} = q^{-(n_6+3)/2}\ [n_6]_{q^2}\ l_{21}\ A_{22}{}^{n_6}, \tag{6.8f}$$

$$\pi_L(X_1^-)\ l_{21}{}^{n_1} = 0, \tag{6.9a}$$

$$\pi_L(X_1^-)\ l_{31}{}^{n_2} = -\sqrt{[2]}\ q^{(2-n_2)/2}\ [n_2]_q\ l_{21}\ l_{31}{}^{n_2-1}, \tag{6.9b}$$

$$\pi_L(X_1^-)\ l_{41}{}^{n_3} = \sqrt{[2]}\ q^{(2-n_3)/2}\ [n_3]_{q^2}\ l_{31}\ l_{41}{}^{n_3-1}, \tag{6.9c}$$

$$\pi_L(X_1^-)\ l_{32}{}^{n_4} = -\sqrt{[2]}\ q\ [n_4]_q\ l_{32}{}^{n_4-1}, \tag{6.9d}$$

$$\pi_L(X_1^-)\ A_{11}{}^{n_5} = 0, \tag{6.9e}$$

$$\pi_L(X_1^-)\ A_{22}{}^{n_6} = 0, \tag{6.9f}$$

$$\pi_L(X_2^-)\ l_{21}{}^{n_1} = -q^{3/2}\ [n_1]_{q^2}\ l_{21}{}^{n_1-1}, \tag{6.10a}$$

$$\pi_L(X_2^-)\ l_{31}{}^{n_2} = 0, \tag{6.10b}$$

$$\pi_L(X_2^-)\ l_{41}{}^{n_3} = 0, \tag{6.10c}$$

$$\pi_L(X_2^-)\ l_{32}{}^{n_4} = 0, \tag{6.10d}$$

$$\pi_L(X_2^-)\ A_{11}{}^{n_5} = 0, \tag{6.10e}$$

$$\pi_L(X_2^-)\ A_{22}{}^{n_6} = 0. \tag{6.10f}$$

Using the above expressions and again using the twisted derivation rules (3.6) we obtain the left action of the generators on the entire monomial Φ:

$$\pi_L(X_1^+)\ \Phi = -q^{(-n_1+n_3+n_4-n_6)/2}\sqrt{[2]}[n_1]_{q^2}\ \Phi(n_1-1,\ n_2+2) + q^{(n_1-n_2+n_3+n_4-n_6)/2}\sqrt{[2]}[n_2]_q\ \Phi(n_2-1,\ n_3+1) + q^{(n_1-n_3+n_6-2)/2}\sqrt{[2]}[n_4/2-n_6]_{q^2}\ \Phi(n_4+1), \tag{6.11}$$

$$\pi_L(X_2^+)\ \Phi = q^{(-n_2+n_4+n_5-n_6-3)/2}[n_1+n_2-n_4-n_5+n_6]_{q^2}\ \Phi(n_1+1) - q^{(-2n_1-n_2-2n_3+3n_4+3n_5-3n_6-1)/2}[2]^{-1}[n_3]_{q^2}\ \Phi(n_2+2,\ n_3-1) + q^{(-2n_1-n_2-2n_3+2n_4+3n_5-3n_6-2)/2}[n_4]_q\ \Phi(n_2+1,\ n_4-1) + (q^{(-2n_1-n_2-n_5+n_6)/2}+q^{(-2n_1-n_2+n_4+n_5-n_6-2)/2}[n_5-n_6]_{q^2}\lambda) \times (q^{n_4}-1)[n_4-1]_q\ \Phi(n_3+1,\ n_4-2), \tag{6.12}$$

$$\pi_L(X_1^-)\ \Phi = q^{(n_1-n_2+n_3+n_4-n_6+2)/2}\sqrt{[2]}[n_2]_q\ \Phi(n_1+1,\ n_2-1) + q^{(n_1-n_3+n_4-n_6+2)/2}\sqrt{[2]}[n_3]_{q^2}\ \Phi(n_2+1,\ n_3-1) - q^{(n_1-n_3-n_6+2)/2}\sqrt{[2]}[n_4]_q\ \Phi(n_4-1), \tag{6.13}$$

$$\pi_L(X_2^-)\ \Phi = -q^{(n_2-n_4-n_5+n_6+3)/2}[n_1]_{q^2}\ \Phi(n_1-1). \tag{6.14}$$

Therefore, we have obtained induced representations of $U_q so(5)$ on the coset space of $SO_q(5)$ which are parametrized by the integers n_5 and n_6. The noncommutative representation space is spanned by functions Φ obeying the covariance conditions (6.5). Notice that the dependence of Φ on n_5 and n_6 remain constant under the above transformations. Hence it is appropriate to label our representaions by these two integers. For the remaining *n's* the left action induces an increase or decrease in some of these powers. For example, $\Phi(n_1-1, n_2+1)$ appearing on the r.h.s. means that the power of the generator l_{21} is lowered by one while that of l_{31} is raised by one, keeping the other powers constant. More explicitly,

$$\Phi(n_1-1,\ n_2+1)=l_{21}{}^{n_1-1}l_{31}{}^{n_2+1}l_{41}{}^{n_3}l_{32}{}^{n_4}A_{11}{}^{n_5}A_{22}{}^{n_6}.$$

VII. REDUCIBILITY FOR *q* GENERIC AND ROOT OF UNITY

The induced representations obtained above are in general irreducible for complex q and n_5, n_6. However, they become reducible for $q\in\mathbb{C}$ and some specific values of n_5 and n_6. The representation space decomposes into two invariant subspaces as we see below.

Setting $\pi_L(X_1^-)\ \Phi=0$ implies that $n_2=n_3=n_4=0$, which gives us the corresponding lowest weight vector, while setting $\pi_L(X_1^+)\ \Phi=0$ yields the highest weight vector under the condition $n_1=n_2=0$ and $n_4=2n_6$. We call this invariant subspace V_1. The parameter n_6 which up to now belonged to the set of integers, is restricted to only non-negative integers, i.e., $n_6\in\mathbb{Z}_+$.

Similarly for the second subspace V_2, by imposing $\pi_L(X_2^{\pm})\ \Phi=0$ we get the lowest weight vector when $n_1=0$ and the highest weight vector when $n_3=n_4=0$ and $n_1+n_2=n_5-n_6$. Since n_1 and n_2 are both non-negative integers, this restricts the values of $n_5-n_6\geqslant 0$. Thus we get finite dimensional irreducible representations of the quantum algebra $U_q so(5)$ obtained as subrepresentations of the elementary representations realized on the quotient group of $SO_q(5)$ and parametrized by n_5 and n_6.

Next, we wish to observe the behavior of our representations when q is a root of unity, i.e., $q^N=1$ for $N=3,4,5,\ldots$. For this we substitute $q=e^{2\pi i/N}$ and find conditions on the labels $n_1,\ldots,n_6$ for which the representations become reducible (i.e., r.h.s. becomes zero as was done above for the general q). One has to be careful here since we would be dealing with two different q-numbers $[n_j]_q$ and $[n_j]_{q^2}$. Hence we obtain

$$\pi_L(X_1^+)\ \Phi\ =\ 0,\quad n_1=k_1N',\quad n_2=k_2N,\qquad n_4/2-n_6=k'N', \tag{7.1}$$

where k_j $(j=1,2,3,4)$ $=0,1,2,3,\ldots$, $k'=0,\pm1,\pm2,\ldots$, $N'=N$ for odd N and $N/2$ for even N. Also $[2]=\sin(2\pi/N)/\sin(\pi/N)\neq 0$ since $N=3,4,\ldots$,

$$\pi_L(X_1^-)\ \Phi\ =\ 0,\quad n_2=k_2N,\quad n_3=k_3N',\quad n_4=k_4N, \tag{7.2}$$

$$\pi_L(X_2^+)\ \Phi\ =\ 0,\quad n_1+n_2-n_4-n_5+n_6=kN',\quad n_3=k_3N',\quad n_4=k_4N, \tag{7.3}$$

where $k=0,\pm1,\pm2,\ldots$,

$$\pi_L(X_2^-)\ \Phi\ =\ 0,\quad n_1=k_1N', \tag{7.4}$$

It is clear that in this case we have an enlarged center as elements of the form $(l_{ij})^N$ would belong to the center of the group. Analogously elements of the form $(X_i^{\pm})^N$ would lie in the center of the quantum algebra $U_q so(5)$.

Let us now analyze the non trivial conditions given above. The third condition in (7.1) can be written as $n_4=2(k'N'+n_6)$. We know that n_4 is a non-negative integer while n_6 is an integer. Hence two possibilities arise:

$$n_6\geqslant 0,\quad k'=0,1,2,\ \ldots\ , \tag{7.5a}$$

$$n_6<0,\quad k'N'\geqslant -n_6. \tag{7.5b}$$

The first condition in (7.3) can be written as $n_1+n_2=N+n_5-n_6+kN'$. Since the l.h.s. is always a non-negative number, there are three main possibilities:

(1) If $n_5-n_6>0$, then $k=0,1,2,\ldots$ (N and N' are positive valued). k can also have negative values provided $N+n_5-n_6\geqslant -KN'$.
(2) If $n_5-n_6=0$, then $k=0,1,2,\ldots$. No negative values are allowed here.
(3) If $n_5-n_6<0$, then $kN'+N\geqslant -(n_5-n_6)$.

There could be further many subcases of each of the three possibilities mentioned above:

(1) $n_5-n_6>0$ is possible when

$$n_5>0, \quad n_6>0, \quad n_5>n_6, \tag{7.6a}$$
$$n_5<0, \quad n_6<0, \quad n_5>n_6, \tag{7.6b}$$
$$n_5>0, \quad n_6<0, \tag{7.6c}$$
$$n_5>0, \quad n_6=0, \tag{7.6d}$$
$$n_5=0, \quad n_6<0. \tag{7.6e}$$

(2) $n_5-n_6=0$ is possible when

$$n_5=0, \quad n_6=0, \tag{7.7a}$$
$$n_5=n_6\neq 0. \tag{7.7b}$$

(3) $n_5-n_6<0$ is possible when

$$n_5>0, \quad n_6>0, \quad n_5<n_6, \tag{7.8a}$$
$$n_5<0, \quad n_6<0, \quad n_5<n_6, \tag{7.8b}$$
$$n_5<0, \quad n_6>0, \tag{7.8c}$$
$$n_5<0, \quad n_6=0, \tag{7.8d}$$
$$n_5=0, \quad n_6>0. \tag{7.8e}$$

In this way we obtain finite dimensional irreps under certain restrictions on the values of the parameters labeling them. As is clear from the above analysis, the representation theory which is quite similar to the classical case for a generic q changes drastically when q is taken to be a root of unity.

VIII. RIGHT "ACTION"

For the sake of completeness we evaluate the right action on the monomial Φ. The covariance condition (6.5a) implies that the right action of the raising generators X_i^+ on the monomial Φ is zero. Thus we need to compute it only for the remaining lowering generators.

Right action of X_1^- :

$$\pi_R(X_1^-)\ {l_{21}}^{n_1} = 0, \tag{8.1a}$$
$$\pi_R(X_1^-)\ {l_{31}}^{n_2} = 0, \tag{8.1b}$$
$$\pi_R(X_1^-)\ {l_{41}}^{n_3} = 0, \tag{8.1c}$$
$$\pi_R(X_1^-)\ {l_{32}}^{n_4} = \sqrt{[2]}\ q^{(2-n_4)/2}\ [n_4]_q\ {l_{32}}^{n_4-1}\ {A_{22}}^{-1}, \tag{8.1d}$$
$$\pi_R(X_1^-)\ {A_{11}}^{n_5} = 0, \tag{8.1e}$$
$$\pi_R(X_1^-)\ {A_{22}}^{n_6} = \sqrt{[2]}\ q^{(1-n_6)/2}\ [n_6]_{q^2} {A_{22}}^{n_6}\ u_{23}. \tag{8.1f}$$

Right action of X_2^- :

$$\pi_R(X_2^-)\ l_{21}{}^{n_1} = q^{(3-2n_1)/2}\ [n_1]_{q^2} l_{21}{}^{n_1-1}\ A_{11}{}^{-1}\ A_{22}, \tag{8.2a}$$

$$\pi_R(X_2^-)\ l_{31}{}^{n_2} = q^{(2-n_2)/2}([n_2]_q\ l_{31}{}^{n_2-1}\ l_{32}+(q-q^{1-n})[n_2-1]_q\ l_{31}{}^{n_2-2}\ l_{41}) \times A_{11}{}^{-1}\ A_{22}, \tag{8.2b}$$

$$\pi_R(X_2^-)\ l_{41}{}^{n_3} = -[2]^{-1}\ q^{(3-2n_3)/2}\ [n_3]_{q^2}\ l_{41}{}^{n_3-1}\ l_{32}{}^2\ A_{11}{}^{-1}\ A_{22}, \tag{8.2c}$$

$$\pi_R(X_2^-)\ l_{32}{}^{n_4} = 0, \tag{8.2d}$$

$$\pi_R(X_2^-)\ A_{11}{}^{n_5} = q^{(1-n_5)/2}\ [n_5]_{q^2}\ A_{11}{}^{n_5}\ u_{12}, \tag{8.2e}$$

$$\pi_R(X_2^-)\ A_{22}{}^{n_6} = -q^{(1+n_6)/2}\ [n_6]_{q^2}\ A_{22}{}^{n_6}\ u_{12}. \tag{8.2f}$$

So the action on the entire monomial becomes

$$\pi_R(X_1^-)\ \Phi = \sqrt{[2]}\ q^{(2-n_4-n_6)/2}\ [n_4]_q\ \Phi(n_4-1,n_6-1) + \sqrt{[2]}\ q^{(1-n_6)/2}\ [n_6]_{q^2}\ \Phi\ u_{23}, \tag{8.3}$$

$$\begin{aligned}\pi_R(X_2^-)\ \Phi = {} & q^{(-2n_1-2n_2+2n_4-n_5+n_6+3)/2}\ [n_1]_{q^2}\ \Phi(n_1-1,n_5-1,n_6+1)\\ & +q^{(-n_2-2n_3+2n_4-n_5+n_6+2)/2}\ [n_2]_q\Phi(n_2-1,n_4+1,n_5-1,n_6+1)\\ & +q^{(2n_4-n_5+n_6)/2}(q-q^{1-n_2})[n_2-1]_q\ \Phi(n_2-2,n_3+1,n_5-1,n_6+1)\\ & -q^{(-2n_3+2n_4-n_5+n_6+3)/2}\ [2]^{-1}\ [n_3]_{q^2}\ \Phi(n_3-1,n_4+2,n_5-1,n_6+1)\\ & +\ q^{(-n_5+n_6+1)/2}\ [n_5-n_6]_{q^2}\ \Phi\ u_{12}.\end{aligned} \tag{8.4}$$

We notice the appearance of terms involving the variables u_{ij}, which is natural since there is no intrinsic right action of X_i^- on the induced representations. Such actions are needed only as input in singular vectors in which all such terms involving the variables u_{ij} will vanish. Thus, it would be fine to neglect them at this stage provided they do not produce any wanted terms (i.e., terms involving l's and A's) when we act repeatedly with $\pi_R(X_i^-)$. For this we should check the action of X_i^- on u_{ij}.

Right action of X_1^- on the u's:

$$\pi_R(X_1^-)\ u_{12} = \sqrt{[2]}\ u_{13}, \tag{8.5a}$$

$$\pi_R(X_1^-)\ u_{13} = -\sqrt{[2]}\ u_{14}, \tag{8.5b}$$

$$\pi_R(X_1^-)\ u_{14} = 0, \tag{8.5c}$$

$$\pi_R(X_1^-)\ u_{23} = -\sqrt{[2]}(1-q^{-1/2}\ [2]^{-1})\ u_{23}{}^2. \tag{8.5d}$$

Right action of X_2^- on the u's:

$$\pi_R(X_2^-)\ u_{12} = -q^{1/2}\ u_{12}{}^2, \tag{8.6a}$$

$$\pi_R(X_2^-)\ u_{13} = -u_{12}\ u_{13}, \tag{8.6b}$$

$$\pi_R(X_2^-)\ u_{14} = q^{1/2}\ [2]^{-1}\ u_{13}^2, \tag{8.6c}$$

$$\pi_R(X_2^-)\ u_{23} = q(u_{12}\ u_{23}-u_{13}). \tag{8.6d}$$

We see that the u_{23} term in (8.3) would not disappear under the action of X_1^-. Similarly, the u_{12} term in (8.4) would still remain under the action of X_2^-.

IX. INTERTWINERS

There are various partial equivalences among the reducible representations. These partial equivalences are realized by intertwining operators for which a canonical derivation was given in Ref. 1. We shall follow this approach without going into details as here we would be interested in obtaining only the simplest intertwiners.

Let us denote our representation space obtained in Sec. VI by $\mathcal{V}_{\overline{n}}$ where $\overline{n}=(n_5,n_6)$ since it is characterized by the integers n_5,n_6. The corresponding representations are similarly denoted by $\pi_L=\pi_{\overline{n}}^-$. Then the intertwiner is a map from the space $\mathcal{V}_{\overline{n}}^-$ to another space $\mathcal{V}_{\overline{n}'}^-$ labeled by n_5' and n_6' such that

$$\mathcal{I}_i \ \pi_{\overline{n}}^-(X_i^-) \quad = \quad \pi_{\overline{n}'}^-(X_i^-) \ \mathcal{I}_i, \tag{9.1}$$

where $\overline{n}'$ is expected to be $-\overline{n}-1$. According to the general prescription,[1] these operators should be given by $(\pi_R(X_i^-))^s$ and the parameter s is expected to be equal to the dimension of the subspace. It is easy to check this directly. Let $s\in\mathbb{N}$ and suppose that $\Phi' = (\pi_R(X_i^-))^s \Phi$ where Φ' belongs to $\mathcal{V}_{\overline{n}'}^-$. Extending the right covariance condition (6.5a) leads to $\pi_R(X_i^+)\ \Phi' = 0$. Below we calculate this explicitly for X_1^-:

$$\begin{aligned}
\pi_R(X_1^+)\ \Phi' &= \pi_R(X_1^+)\ (\pi_R(X_1^-))^s\ \Phi \\
&= [\pi_R(X_1^+),\ (\pi_R(X_1^-))^s]\ \Phi \\
&= \pi_R([X_1^+,\ (X_1^-)^s])\ \Phi \\
&= \pi_R([s]_q (X_1^-)^{s-1}\ (q^{-(s-1)/2}\ K_1 - q^{(s-1)/2}\ K_1^{-1})/(q^{1/2}-q^{-1/2}))\ \Phi \\
&= [s]_q \pi_R(X_1^-)^{s-1}\ ((q^{-(s-1)/2+n_6} - q^{(s-1)/2-n_6})/(q^{1/2}-q^{-1/2}))\ \Phi \\
&= -[s]_q\ [s-1-2n_6]_q\ \pi_R(X_1^-)^{s-1}\ \Phi.
\end{aligned} \tag{9.2}$$

If q is a generic complex number, then, as expected, this quantity becomes zero only for $s=2n_6+1$. Next, employing the other conditions of right covariance we have $\pi_R(K_i)\ \Phi' = q^{n'}\ \Phi'$, i.e.,

$$\begin{aligned}
\pi_R(K_1)\ \Phi' &= \pi_R(K_1)(\pi_R(X_1^-))^s\ \Phi \\
&= \pi_R(q^{-s}\ (X_1^-)^s\ K_1)\ \Phi \\
&= q^{-s}\ \pi_R(X_1^-)^s\ q^{n_6}\ \Phi = q^{n_6-s}\ \Phi'.
\end{aligned} \tag{9.3}$$

So, $n_6'=n_6-s=-n_6-1$. Then the intertwining operator $\mathcal{I}_1$ (up to a multiplicative nonzero constant) is

$$\mathcal{I}_1 \quad = \quad (\pi_R(X_1^-))^{2n_6+1}. \tag{9.4}$$

Similar calculations for the other generator X_2^- yield

$$\pi_R(X_2^+)\ \Phi' = -[s]_{q^2}\ [s-1-n_5+n_6]_{q^2}\ \pi_R(X_2^-)^{s-1}\ \Phi, \tag{9.5}$$

which vanishes when $s=n_5-n_6+1$. On the other hand,

$$\pi_R(K_2)\ \Phi' \ = \ q^{n_5-n_6-2s}\ \Phi'. \tag{9.6}$$

So, $n_5'-n_6'=n_5-n_6-2s=(-n_5-1)+(n_6-1)$ and thus the second intertwining operator $\mathcal{I}_2$ is indeed given by

$$\mathcal{I}_2 \quad = \quad (\pi_R(X_2^-))^{n_5-n_6+1}. \tag{9.7}$$

The finite-dimensional invariant subspaces V_1 and V_2 discussed earlier are the kernels of these intertwining operators.

X. CONCLUDING REMARKS

In this article we have obtained induced representations of the quantum algebra $U_q so(5)$ realized on some (noncommutative) coset space of the dual quantum group $SO_q(5)$. We remark that although we have assumed integer values for the parameters n_5 and n_6 which characterize them, the formulas (of left action) define a representaion of $U_q so(5)$ also for arbitrary complex values. However, only for integer values, they comprise a deformation of representations which are integrable to a representation of the group $SO_q(5)$. We have also investigated the reducibility of these representations under restricted values of n_5, n_6 which lead to finite dimensional irreps for q generic and for root of unity.

Two basic intertwiners corresponding to the two simple roots were shown to be expressible in terms of powers of the right action. It would be interesting to find out other mixed or composite intertwiners corresponding to the nonsimple roots. For that we would need to compute the powers of the right action explicitly, i.e., by iteration of the results presented in Sec. VIII. In this way one can obtain whole new families of intertwiners. By a suitable redefinition of the generators it should be possible to realize them as q-difference operators. This yields a natural q-deformation of several equations in mathematical physics, which can be viewed as intertwiner between some representations of the underlying symmetry algebra. Also it would be interesting to explore the connection with the noncompact quantum anti-de Sitter algebra $U_q so(3,2)$ in the context of induced representations and q-difference intertwiners. We hope to address all these issues in a sequel.

ACKNOWLEDGMENTS

I thank Professor V. K. Dobrev for suggesting this problem and for useful discussions at various stages of this work. Financial support by CSIR (New Delhi) and infrastructure provided by Institute of Physics, Bhubaneswar (India), where part of the work was done, is gratefully acknowledged. I wish to express my deep gratitude to the Max-Planck Institut für Mathematik in Bonn for a visiting faculty position.

APPENDIX: COMMUTATION RELATIONS OF $SO_q(5)$

Here we give the relations which the 25 elements t_{ij} obey and which follow from (2.1) and (2.2) using (2.6) and (2.7). This explicit form is also necessary for the verification of the Gauss decomposition of Sec. III. The relations are

$$t_{ij}\ t_{i\ell}=q t_{i\ell}\ t_{ij}, \qquad i\neq 3, \quad j<\ell, j'\neq\ell, \tag{A1}$$

$$t_{ij}\ t_{kj}=q t_{kj}\ t_{ij}, \qquad j\neq 3, \quad i<k, i'\neq k, \tag{A2}$$

$$t_{ij}\ t_{ij'}=q^2\ (t_{ij'}\ t_{ij}\ +\lambda\ t_{i,j'+1}\ t_{i,j-1}\ ), \quad i\neq 3, \quad j=1,2, \tag{A3}$$

$$t_{ij}\ t_{i'j}=q^2\ (t_{i'j}\ t_{ij}\ +\lambda\ t_{i'+1,j}\ t_{i-1,j}\ ), \quad j\neq 3, \quad i=1,2, \tag{A4}$$

$$t_{3j}\ t_{3\ell}=t_{3\ell}\ t_{3j}\ +\alpha\ t_{2\ell}\ t_{4j}\ +\eta\ t_{1\ell}\ t_{5j}, \quad j<\ell, \ j'\neq\ell, \tag{A5}$$

$$t_{i3}\ t_{k3}=t_{k3}\ t_{i3}+\alpha\ t_{k2}\ t_{i4}+\eta\ t_{k1}\ t_{i5},\quad i<k,\ i'\neq k, \tag{A6}$$

$$t_{3j}^2=-q^{-1}\ [2]t_{2j}\ t_{4j}-q^{-2}\ [2]t_{1j}\ t_{5j},\quad j\neq 3, \tag{A7}$$

$$t_{i3}^2=-q^{-1}\ [2]t_{i2}\ t_{i4}-q^{-2}\ [2]t_{i1}\ t_{i5},\quad i\neq 3, \tag{A8}$$

$$t_{ij}\ t_{k\ell}=t_{k\ell}\ t_{ij}+\lambda\ t_{kj}\ t_{i\ell},\quad i<k,\ i'\neq k,\ j<\ell,\ j'\neq \ell, \tag{A9}$$

$$t_{ij}\ t_{k\ell}=t_{k\ell}\ t_{ij},\qquad i<k,\ i'\neq k,\ j>\ell, j'\neq \ell, \tag{A10}$$

$$t_{ij}\ t_{i'\ell}=q(t_{i'\ell}\ t_{ij}+\lambda\ t_{i'j}\ t_{i\ell})+\lambda\ t_{i-1,j}\ t_{i'+1,\ell},\quad i=1,2,\ j<\ell,\ j'\neq \ell, \tag{A11}$$

$$t_{ij}\ t_{i'\ell}=q(t_{i'\ell}\ t_{ij}+\lambda\ t_{i'+1,\ell}\ t_{i-1,j}),\quad i=1,2,\ j>\ell,\ j'\neq \ell, \tag{A12}$$

$$t_{ij}\ t_{kj'}=q(t_{kj'}\ t_{ij}+\lambda\ t_{ij'}\ t_{kj}),\quad i<k, i'\neq k, j=1,2, \tag{A13}$$

$$t_{ij'}\ t_{kj}=q^{-1}\ (t_{kj}\ t_{ij'}-\lambda\ t_{k,j-1}\ t_{i,j'+1}),\quad i<k,\ i'\neq k,\ j=1,2, \tag{A14}$$

$$t_{i2}\ t_{k4}=q^{-1}t_{k4}\ t_{i2}+\alpha\ t_{k3}\ t_{i3}+\beta\ t_{k2}\ t_{i4}+\gamma\ t_{k1}\ t_{i5},\quad i<k,\ i'\neq k, \tag{A15}$$

$$t_{11}\ t_{55}=t_{55}\ t_{11}+q(\xi t_{54}\ t_{12}+\eta t_{53}\ t_{13}+\gamma t_{52}\ t_{14}+\delta t_{51}\ t_{15}), \tag{A16}$$

$$t_{12}\ t_{54}=t_{54}\ t_{12}+q(\alpha t_{53}\ t_{13}+\beta t_{52}\ t_{14}+\gamma t_{51}\ t_{15}), \tag{A17}$$

$$t_{13}\ t_{53}=q(t_{53}\ t_{13}+\alpha t_{52}\ t_{14}+\eta t_{51}\ t_{15}), \tag{A18}$$

$$t_{14}\ t_{52}=t_{52}\ t_{14}-\lambda t_{51}\ t_{15}, \tag{A19}$$

$$t_{15}\ t_{51}=t_{51}\ t_{15}, \tag{A20}$$

$$t_{21}\ t_{45}=t_{45}\ t_{21}+q(\xi t_{44}\ t_{22}+\eta t_{43}\ t_{23}+\gamma t_{42}\ t_{24}+\delta t_{41}\ t_{25})+\lambda t_{11}\ t_{55}, \tag{A21}$$

$$t_{22}\ t_{44}=t_{44}\ t_{22}+q(\alpha t_{43}\ t_{23}+\beta t_{42}\ t_{24}+\gamma t_{41}\ t_{25})+\lambda t_{12}\ t_{54}, \tag{A22}$$

$$t_{23}\ t_{43}=q(t_{43}\ t_{23}+\alpha t_{42}\ t_{24}+\eta t_{41}\ t_{25})+\lambda t_{13}\ t_{53}, \tag{A23}$$

$$t_{24}\ t_{42}=t_{42}\ t_{24}+\lambda\ (t_{52}\ t_{14}-t_{51}\ t_{15}-t_{41}\ t_{25}), \tag{A24}$$

$$t_{25}\ t_{41}=t_{41}\ t_{25}+\lambda t_{51}\ t_{15}, \tag{A25}$$

$$t_{31}\ t_{35}=q(t_{35}\ t_{31}+\alpha t_{25}\ t_{41}+\eta t_{15}\ t_{51}), \tag{A26}$$

$$t_{32}\ t_{34}=q(t_{34}\ t_{32}+\alpha t_{24}\ t_{42}+\eta t_{14}\ t_{52})+\lambda t_{31}\ t_{35}. \tag{A27}$$

The additional constraints are $(i=1,2,3,4,5)$

$$\alpha t_{23}\ t_{43}+\eta t_{13}\ t_{53}=\alpha t_{32}\ t_{34}+\eta t_{31}\ t_{35}, \tag{A28}$$

$$q^3\ t_{i5}\ t_{51}+q^2\ t_{i4}\ t_{52}+q^{3/2}\ t_{i3}\ t_{53}+q\ t_{i2}\ t_{54}+t_{i1}\ t_{55}=\delta_{i1}, \tag{A29}$$

$$q^2\ t_{i5}\ t_{41}+qt_{i4}\ t_{42}+q^{1/2}\ t_{i3}\ t_{43}+t_{i2}\ t_{44}+q^{-1}\ t_{i1}\ t_{45}=\delta_{i2}, \tag{A30}$$

$$q^{3/2}\ t_{i5}\ t_{31}+q^{1/2}\ t_{i4}\ t_{32}+t_{i3}\ t_{33}+q^{-1/2}\ t_{i2}\ t_{34}+q^{-3/2}\ t_{i1}\ t_{35}=\delta_{i3}, \tag{A31}$$

$$qt_{i5}\ t_{21}+t_{i4}\ t_{22}+q^{-1/2}\ t_{i3}\ t_{23}+q^{-1}\ t_{i2}\ t_{24}+q^{-2}\ t_{i1}\ t_{25}=\delta_{i4}, \tag{A32}$$

$$t_{i5}\ t_{11}+q^{-1}\ t_{i4}\ t_{12}+q^{-3/2}\ t_{i3}\ t_{13}+q^{-2}\ t_{i2}\ t_{14}+q^{-3}\ t_{i1}\ t_{15}=\delta_{i5}, \tag{A33}$$

$$t_{55}\ t_{1i}+q^{-1}\ t_{45}\ t_{2i}+q^{-3/2}\ t_{35}\ t_{3i}+q^{-2}\ t_{25}\ t_{4i}+q^{-3}\ t_{15}\ t_{5i}=\delta_{1i}, \tag{A34}$$

$$qt_{54}\ t_{1i}+t_{44}\ t_{2i}+q^{-1/2}\ t_{34}\ t_{3i}+q^{-1}\ t_{24}\ t_{4i}+q^{-2}\ t_{14}\ t_{5i}=\delta_{2i}, \tag{A35}$$

$$q^{3/2}\ t_{53}\ t_{1i}+q^{1/2}\ t_{43}\ t_{2i}+t_{33}\ t_{3i}+q^{-1/2}\ t_{23}\ t_{4i}+q^{-3/2}\ t_{13}\ t_{5i}=\delta_{3i}, \tag{A36}$$

$$q^{2}\ t_{52}\ t_{1i}+qt_{42}\ t_{2i}+q^{1/2}\ t_{32}\ t_{3i}+t_{22}\ t_{4i}+q^{-1}\ t_{12}\ t_{5i}=\delta_{4i}, \tag{A37}$$

$$q^{3}\ t_{51}\ t_{1i}+q^{2}\ t_{41}\ t_{2i}+q^{3/2}\ t_{31}\ t_{3i}+qt_{21}\ t_{4i}+t_{11}\ t_{5i}=\delta_{5i}. \tag{A38}$$

In fact, we can obtain the set of relations (A.34)–(A.38) from (A.29)–(A.33) by $q\rightarrow q^{-1}$ and $t_{ij}\ t_{kl}\rightarrow t_{lk}\ t_{ji}$.

(Received 14 August 2002; accepted 10 October 2002)

A systematic investigation on the construction of recursion operators for partial differential–difference equations (PDDEs) with two independent variables (one continuous and one discrete) using its generalized symmetries is presented. Also it is explained how to factorize the obtained recursion operators. The applicability of the above procedure have been illustrated for the relativistic toda (RT), Belov–Chaltikian (BC) and Blaszak–Marciniak (BM) lattice equations and shown that the former two lattice equations admit (2×2) matrix recursion operators while the latter one possesses a (3×3) matrix recursion operator. Furthermore, the constructed recursion operators can be written as a factor of 2 distinct invertible matrix operators in each of the lattice equations. It is also proved explicitly that the factorized operators are Hamiltonian and hence RT, BC and BM lattice equations are bi-Hamiltonian systems. © *2003 American Institute of Physics.*

I. INTRODUCTION

Integrable systems governed by nonlinear partial differential equations (PDEs) admitting solitons have a variety of rich mathematical structures such as Lax representation, certain specific singularity structure in the complex manifold of the independent variables, multi-Hamiltonian formulation, etc.[1–6] A notable characteristic of integrable nonlinear PDEs (if conservative) is the existence of a sequence of generalized symmetries (involving dependent variables and its spatial derivatives) and conserved densities. The existence of generalized symmetries quite often helps to derive other integrability properties: recursion operator, hereditary operator, bi-Hamiltonian formulation, etc., of nonlinear PDEs. This fact has been verified for a large number of nonlinear PDEs with $(1+1)$ and $(2+1)$ dimensions possessing solitons by different researchers during the past few decades[4,7–10] (see also Refs. 11–16). Recent investigation reveals that certain integrable nonlinear discrete systems characterized by nonlinear PDDEs including lattice equations have similar mathematical structures like for integrable nonlinear PDEs.[17–29]

In Ref. 21, we have considered the BC lattice equation, which is a two coupled first order lattice equation,[30] and the BM lattice equation, which is a three coupled one,[31] and shown that both the lattice equations admit a sequence of generalized symmetries (involving dependent variables and their shifts) and conserved densities. In this article, a systematic investigation on the construction of recursion operators for PDDEs with two independent variables (one continuous and one discrete) using its generalized symmetries is presented. Also, it is explained how to factorize the obtained recursion operators. We illustrate the above procedure for the RT,[32] BM and BC lattice equations, respectively, governed by

$$v_{nt}=v_n(u_{n-1}-u_n), \quad u_{nt}=u_n(u_{n-1}-u_{n+1}-v_{n+1}+v_n), \tag{1}$$

$$u_{nt}=w_{n+1}-w_{n-1}, \quad v_{nt}=u_{n-1}w_{n-1}-u_nw_n, \quad w_{nt}=w_n(v_n-v_{n+1}), \tag{2}$$

$$u_{nt}=u_n(u_{n+1}-u_{n-1})+v_{n-1}-v_n, \quad v_{nt}=v_n(u_{n+2}-u_{n-1}), \tag{3}$$

where $u_{nt}=\partial u_n/\partial t$, $v_{nt}=\partial v_n/\partial t$, $w_{nt}=\partial w_n/\partial t$, $u_n=u(n,t)$, $v_n=v(n,t)$, $w_n=w(n,t)$, t is a continuous variable and n is a discrete variable and show that the RT and BC lattice equations admit (2×2) matrix recursion operators while the BM lattice equation possesses (3×3) matrix recursion operator. Furthermore, we prove explicitly that the lattice equations (1)–(3) are bi-Hamiltonian systems.

The plan of the article is as follows. In Sec. II, we consider a first order PDDE with two independent variables (one continuous and one discrete) and show how to construct a recursion operator using its generalized symmetries. Also, we explain how to factorize the obtained recursion operator. In Sec. III, we apply the above procedure to RT, BM and BC lattice equations and construct their recursion operators which can be factorized. Section IV deals with the investigation of the nature of the operators, Hamiltonian or not, in each of the lattice equations, and we prove that all the lattice equations (1)–(3) are bi-Hamiltonian systems. Section V contains a brief summary of our results.

II. PDDES: GENERALIZED SYMMETRIES, RECURSION OPERATOR AND FACTORIZATION

A. Generalized symmetries

To be self-contained, we first explain how to derive generalized symmetries involving dependent variables and their shifts for a given PDDE. Consider, for example, a first order PDDE with two independent variables (one continuous and one discrete) of the form

$$\frac{\partial \mathbf{U}_n}{\partial t}=\mathbf{F}(\ldots,\mathbf{U}_{n-1},\mathbf{U}_n,\mathbf{U}_{n+1},\ldots), \tag{4}$$

where $\mathbf{U}_n=\mathbf{U}(n,t)$ and $\mathbf{F}(...)$ are vector quantities with same number of components, say m. The vector function $\mathbf{F}$ is assumed to be a polynomial in the dependent variable and their shifts. There are no restriction on the level of shifts or the degree of nonlinearity. We also assume that Eq. (4) is invariant under the scaling symmetry.

Let us assume that the PDDE (4) is invariant under the infinitesimal transformations:

$$n^*=n,\quad t^*=t,\quad \mathbf{U}_n^*=\mathbf{U}_n+\epsilon\mathbf{G}(n)+O(\epsilon^2), \tag{5}$$

where $\mathbf{G}(n)=\mathbf{G}(\ldots,\mathbf{U}_{n-1},\mathbf{U}_n,\mathbf{U}_{n+1},\ldots)$. Here $\mathbf{G}(n)=(\mathbf{G}_1(n),\mathbf{G}_2(n),\ldots,\mathbf{G}_m(n))$.

Then the transformed equation is

$$\begin{aligned}\frac{\partial \mathbf{U}_n^*}{\partial t^*}&=\mathbf{F}(\ldots,\mathbf{U}_{n-1}^*,\mathbf{U}_n^*,\mathbf{U}_{n+1}^*,\ldots)\\&=\mathbf{F}(\ldots,U_{n-1}+\epsilon\mathbf{G}(n-1),U_n+\epsilon\mathbf{G}(n),U_{n+1}+\epsilon\mathbf{G}(n+1),\ldots)\end{aligned} \tag{6}$$

provided $\mathbf{U}_n$ satisfy Eq. (4). Now the left hand side of Eq. (6) can be written as

$$\frac{\partial \mathbf{U}_n^*}{\partial t^*}=\frac{\partial}{\partial t}(\mathbf{U}_n+\epsilon\mathbf{G}(n)+O(\epsilon^2))\frac{\partial t}{\partial t^*}=\frac{\partial \mathbf{U}_n}{\partial t}+\epsilon[\mathbf{G}(n)]_t+O(\epsilon^2), \tag{7}$$

where $[\mathbf{G}(n)]_t$ is the first extension given by

$$[\mathbf{G}(n)]_t=\cdots+\frac{\partial \mathbf{G}(\mathbf{n})}{\partial \mathbf{U}_{n-1}}\frac{\partial \mathbf{U}_{n-1}}{\partial t}+\frac{\partial \mathbf{G}(\mathbf{n})}{\partial \mathbf{U}_n}\frac{\partial \mathbf{U}_n}{\partial t}+\frac{\partial \mathbf{G}(\mathbf{n})}{\partial \mathbf{U}_{n+1}}\frac{\partial \mathbf{U}_{n+1}}{\partial t}+\cdots.$$

To compute the right hand side of Eq. (6), we use the Frechet derivative of $\mathbf{F}$ defined as

$$\mathbf{F}'(\mathbf{U}_n)[\mathbf{G}(n)] = \frac{\partial}{\partial \epsilon}\mathbf{F}(\mathbf{U}_n + \epsilon \mathbf{G}(n))\big|_{\epsilon=0}$$

$$= \mathbf{F} + \epsilon\left(\cdots + \frac{\partial \mathbf{F}}{\partial \mathbf{U}_{n-1}}E^{-1} + \frac{\partial \mathbf{F}}{\partial \mathbf{U}_n} + \frac{\partial \mathbf{F}}{\partial \mathbf{U}_{n+1}}E + \ldots\right)\mathbf{G}(n) + O(\epsilon^2), \tag{8}$$

Substituting Eqs. (7) and (8) in Eq. (6) and equating both sides $O(\epsilon)$ terms we obtain the following invariant equation,

$$\frac{\partial \mathbf{G}(\mathbf{n})}{\partial \mathbf{U}_{n-1}}\frac{\partial \mathbf{U}_{n-1}}{\partial t} + \frac{\partial \mathbf{G}(\mathbf{n})}{\partial \mathbf{U}_n}\frac{\partial \mathbf{U}_n}{\partial t} + \frac{\partial \mathbf{G}(\mathbf{n})}{\partial \mathbf{U}_{n+1}}\frac{\partial \mathbf{U}_{n+1}}{\partial t} + \ldots$$

$$= \left(\ldots + \frac{\partial \mathbf{F}}{\partial \mathbf{U}_{n-1}}E^{-1} + \frac{\partial \mathbf{F}}{\partial \mathbf{U}_n} + \frac{\partial \mathbf{F}}{\partial \mathbf{U}_{n+1}}E + \ldots\right)\mathbf{G}(n), \tag{9}$$

where E and E^{-1} are shift operators defined by $E\mathbf{U}_n = \mathbf{U}_{n+1}$, $E^{-1}\mathbf{U}_n = \mathbf{U}_{n-1}$. Solving the invariant equation (9) we can determine the generalized symmetry $\mathbf{G}(n)$ explicitly.

B. Recursion operator

We would like to recall the following definitions required for further discussion.

Definition 1: An operator valued function $\mathcal{R}$ is said to be a recursion operator of Eq. (4) if it satisfies

$$\tilde{\mathbf{G}}(n) = \mathcal{R}\mathbf{G}(n), \tag{10}$$

where the vector functions $\mathbf{G}(n) = (\mathbf{G}_1(n), \mathbf{G}_2(n), \ldots, \mathbf{G}_m(n))$ and $\tilde{\mathbf{G}}(n) = (\tilde{\mathbf{G}}_1(n), \tilde{\mathbf{G}}_2(n), \ldots, \tilde{\mathbf{G}}_m(n))$ are generalized symmetries of (4) and $\mathcal{R}$ is a $(m \times m)$ matrix operator.

Note that there exist different methods to construct recursion operator $\mathcal{R}$ for PDDEs (see, for example, Ref. 28). In this article, we construct the recursion operator satisfying the above relation (10).

Definition 2: A local conservation law is defined by

$$\frac{\partial \rho_n}{\partial t} = J_n - J_{n+1}, \tag{11}$$

which is satisfied on all solutions of (4). The function ρ_n is the local conserved density and J_n is the associated flux.

Let us assume that the components of the generalized symmetry $\mathbf{G}(n)$ and $\tilde{\mathbf{G}}(n)$, respectively, are of ranks $(p_1, p_2, \ldots, p_m)$ and $(q_1, q_2, \ldots, q_m)$. Here $(p_1, p_2, \ldots, p_m)$ and $(q_1, q_2, \ldots, q_m)$ may be integers or rational numbers. The construction of the recursion operator essentially consists of two steps: In the first step, we determine the rank of (R_{ij}), $i, j = 1, 2, \ldots, m$, of the matrix operator $\mathcal{R}$ which must be equal to $(q_j - p_i)$ which can be determined from the following relations,

$$\text{rank } \tilde{\mathbf{G}}_1(n) = \text{rank } R_{11} + \text{rank } \mathbf{G}_1(n) = \cdots = \text{rank } R_{1m} + \text{rank } \mathbf{G}_m(n),$$

$$\text{rank } \tilde{\mathbf{G}}_m(n) = \text{rank } R_{21} + \text{rank } \mathbf{G}_1(n) = \cdots = \text{rank } R_{2m} + \text{rank } \mathbf{G}_m(n),$$

$$\vdots$$

$$\text{rank } \tilde{\mathbf{G}}_m(n) = \text{rank } R_{m1} + \text{rank } \mathbf{G}_1(n) = \cdots = \text{rank } R_{mm} + \text{rank } \mathbf{G}_m(n). \tag{12}$$

The second step involves determination of the explicit form of (R_{ij}) which may be expressed in terms of difference and inverse difference operators of the dependent variables and their inverse satisfying the relations (10) and (12).

C. Factorization of recursion operator

Having constructed the recursion operator $\mathcal{R}$ we explain how it can be factorized. For that, we first assume that the constructed $(m\times m)$ matrix recursion operator $\mathcal{R}=(R_{ij})$ of Eq. (4) can be written as a factor of 2 distinct $(m\times m)$ matrix operators $A=(A_{ij})$ and $B=(B_{ij})$. That is,

$$\begin{bmatrix} R_{11} & \dots & R_{1\mathrm{m}} \\ R_{21} & \dots & R_{2\mathrm{m}} \\ \vdots & & \vdots \\ R_{\mathrm{m}1} & \dots & R_{\mathrm{mm}} \end{bmatrix} = \begin{bmatrix} A_{11} & \dots & A_{1\mathrm{m}} \\ A_{21} & \dots & A_{2\mathrm{m}} \\ \vdots & & \vdots \\ A_{\mathrm{m}1} & \dots & A_{\mathrm{mm}} \end{bmatrix} \begin{bmatrix} B_{11} & \dots & B_{1\mathrm{m}} \\ B_{21} & \dots & B_{2\mathrm{m}} \\ \vdots & & \vdots \\ B_{\mathrm{m}1} & \dots & B_{\mathrm{mm}} \end{bmatrix}. \tag{13}$$

Equation (13) suggests that the entries of the matrix AB must be of the same rank as of $\mathcal{R}$. Accordingly, we choose the entries of (A_{ij}) and (B_{ij}) which may be expressed in terms of difference and inverse difference operators of the dependent variables and their inverse. Substituting then the expression for (A_{ij}) and (B_{ij}) in Eq. (13) and solving yields the explicit form of the matrix operators (A_{ij}) and (B_{ij}) with the required ranks.

III. RT, BM AND BC LATTICE EQUATIONS: RECURSION OPERATORS AND THEIR FACTORIZATION

A. RT lattice equation

1. Generalized symmetries

To be self-contained, in this subsection, we present computational details of the derivation of generalized symmetries for the RT lattice equation given by

$$v_{nt}=v_n(u_{n-1}-u_n), \quad u_{nt}=u_n(u_{n-1}-u_{n+1}-v_{n+1}+v_n),$$

which is invariant under the scaling symmetry

$$(t,u_n,v_n)\to(\lambda^{-1}t,\lambda u_n,\lambda v_n), \tag{14}$$

where λ is an arbitrary parameter. Assume that the RT lattice equation (1) or (14) is invariant under the infinitesimal transformations

$$n^*=n, \quad t^*=t, \quad u_n^*=u_n+\epsilon G_i^{(1)}(n)+O(\epsilon^2), \quad v_n^*=v_n+\epsilon G_i^{(2)}(n)+O(\epsilon^2), \quad i=1,2,\dots, \tag{15}$$

where

$$G_i^{(1)}(n)=G_i^{(1)}(\dots,v_{n-1},u_{n-1},u_n,v_n,u_{n+1},v_{n+1},\dots),$$

$$G_i^{(2)}(n)=G_i^{(2)}(\dots,v_{n-1},u_{n-1},u_n,v_n,u_{n+1},v_{n+1},\dots)$$

provided u_n and v_n satisfy Eq. (1). For clarity, we denote $\mathbf{G}_i(n)=(G_i^{(1)}(n),G_i^{(2)}(n))$ and the subscript i represents the ith order generalized symmetry. Consequently, we obtain the following invariant equation,

$$\frac{\partial G_i^{(1)}(n)}{\partial t}=G_i^{(1)}(n)(u_{n-1}-u_{n+1}+v_n-v_{n+1}) + u_n(G_i^{(1)}(n-1)-G_i^{(1)}(n+1)+G_i^{(2)}(n)-G_i^{(2)}(n+1)), \tag{16a}$$

$$\frac{\partial G_i^{(2)}(n)}{\partial t}=G_i^{(2)}(n)(u_{n-1}-u_n)+v_n(G_i^{(2)}(n-1)-G_i^{(2)}(n)). \tag{16b}$$

From Eq. (16) we see that

$$\mathbf{G}_2(n)=(G_2^{(1)}(n),G_2^{(2)}(n))=(v_n(u_{n-1}-u_n),u_n(u_{n-1}-u_{n+1}+v_n-v_{n+1}))$$

is a trivial generalized symmetry with rank (2,2). This suggests that the components $G_3^{(1)}(n)$ and $G_3^{(2)}(n)$ of the next generalized symmetry $\mathbf{G}_3(n)$ must have rank (3,3). With this in mind we first form monomials in u_n and v_n of rank (3,3) that lead to a set: $L=\{u_n,u_n^2,u_n^3,v_n,v_n^2,v_n^3\}$. For compactness, hereafter we use the following notation unless otherwise specified,

$$u_n=u,\quad v_n=v,\quad u_{n-1}=\underline{u},\quad v_{n-1}=\underline{v},\quad u_{n-2}=\underline{\underline{u}},\quad v_{n-2}=\underline{\underline{v}},\quad u_{n-3}=\underline{\underline{\underline{u}}},\quad v_{n-3}=\underline{\underline{\underline{v}}},$$

$$u_{n+1}=\overline{u},\quad v_{n+1}=\overline{v},\quad u_{n+2}=\bar{\bar{u}},\quad v_{n+2}=\bar{\bar{v}},\quad u_{n+3}=\overline{\overline{\overline{u}}},\quad v_{n+3}=\overline{\overline{\overline{v}}},\ \text{etc.}$$

Then the necessary partial derivatives with respect to t in each monomial of $L=\{u,v,u^2,v^2,u^3,v^3\}$ along with Eq. (14) gives the following

$$\frac{\partial^0}{\partial t^0}(u^3)=u^3,\quad \frac{\partial^0}{\partial t^0}(v^3)=v^3;\quad \frac{\partial}{\partial t}(u^2)=2u^2\ (\underline{u}-\overline{u}+v-\overline{v}),\frac{\partial}{\partial t}(v^2)=2v^2\ (\underline{u}-u),$$

$$\frac{\partial^2}{\partial t^2}(u)=u\ (\underline{u}-\overline{u}+v-\overline{v})^2+u\ \underline{u}(\underline{\underline{u}}-u+\underline{v}-v)$$
$$-u\ \overline{u}(u-\bar{\bar{u}}+\overline{v}-\bar{\bar{v}})+v\ u\ (\underline{u}-u)-u\ \overline{v}\ (u-\overline{u}),$$

$$\frac{\partial^2}{\partial t^2}(v)=v\ (\underline{u}-u)^2+v\ \underline{u}\ (\underline{\underline{u}}-u+\underline{v}-v)-u\ v(\underline{u}-\overline{u}+v-\overline{v}),$$

and a set

$$M=\{u^3,v^3,u^2\ \underline{u},u^2\overline{u},u^2\ v,u^2\ \overline{v},v^2\ \underline{u},v^2\ u,u\underline{u}^2,u\ \overline{u}^2,u\ \overline{v}^2,$$
$$u\ \underline{u}\ v,u\ \overline{u}\ v,u\ \overline{u}\ \overline{v},u\ v\ \overline{v},u\underline{u}\ \underline{\underline{u}},u\ \underline{\underline{u}}\underline{v},u\ \overline{u}\ \bar{\bar{u}},u\ \overline{u}\overline{v},v\ \underline{u}^2,\underline{u}\ \underline{\underline{u}}\ v,\underline{u}\ v\ \underline{v}\}. \tag{17}$$

Thus the most general form of the generalized symmetry $\mathbf{G}_3(n)=(G_3^{(1)}(n),G_3^{(2)}(n))$ will be

$$G_3^{(1)}(n)=a_1u^3+(a_2\ \underline{u}+a_3\ \overline{u}+a_4\ v+a_5\ \overline{v})u^2+(a_6u+a_7v)\underline{u}^2+a_8u\ \overline{u}^2$$
$$+(a_9\underline{u}\ v+a_{10}\overline{u}\overline{v}+a_{11}\overline{u}\ \overline{v}+a_{12}v\ \overline{v}+a_{13}\underline{u}\ \underline{\underline{u}}+a_{14}\underline{u}\ \underline{v}+a_{15}\overline{u}\ \bar{\bar{u}}+a_{16}\overline{u}\ \bar{\bar{v}})u$$
$$+a_{17}v^3+(a_{18}\underline{u}+a_{19}u)v^2+a_{20}u\ \overline{v}^2+(a_{21}\underline{u}\ \underline{\underline{u}}+a_{22}\underline{u}\ \underline{v})v, \tag{18a}$$

$$G_3^{(1)}(n)=b_1u^3+(b_2\ \underline{u}+b_3\ \overline{u}+b_4\ v+b_5\ \overline{v})u^2+(b_6u+b_7v)\underline{u}^2+b_8u\ \overline{u}^2$$
$$+(b_9\underline{u}\ v+b_{10}\overline{u}\overline{v}+b_{11}\overline{u}\ \overline{v}+b_{12}v\ \overline{v}+b_{13}\underline{u}\ \underline{\underline{u}}+b_{14}\underline{u}\ \underline{v}+b_{15}\overline{u}\ \bar{\bar{u}}+b_{16}\overline{u}\ \bar{\bar{v}})u$$
$$+b_{17}v^3+(b_{18}\underline{u}+b_{19}u)v^2+b_{20}u\ \overline{v}^2+(b_{21}\underline{u}\underline{\underline{u}}+b_{22}\underline{u}\ \underline{v})v, \tag{18b}$$

where a_j, b_j, $j=1,2,\ldots,22$, are arbitrary constants. We now substitute the components $G_3^{(1)}(n)$ and $G_3^{(2)}(n)$ in the invariant equation (16) with $i=3$ and making use of the RT lattice equation (1) or (14) we find, after a detailed calculation, that the consistency condition holds only for the following parametric restrictions:

$$a_4=-a_{10}=-a_{12}=a_{18}=-a_{19}=a_{21}=a_{22}=a_7=b_2=b_4=-b_5=1,$$

$$-b_3=b_{11}=-b_{20}=-b_{16}=b_{19}=-b_8=b_6=-b_{15}=b_{21}=1, b_9=2, b_{11}=-2,$$

and so the first nontrivial generalized symmetry $\mathbf{G}_3(n)=(G_3^{(1)}(n),G_3^{(2)}(n))$ with rank (3,3) becomes

$$G_3^{(1)}(n)=-vu^2+(-\overline{u}\ v-v\overline{v})u+(\underline{u}-u)v^2+(\underline{u}\ \underline{u}+\underline{u}^2+\underline{u}\ \underline{v})v, \tag{19a}$$

$$G_3^{(2)}(n)=(\underline{u}+v-\overline{v}-\overline{u})u^2+(\underline{u}\ \underline{v}-\overline{v}^2-\overline{u}\ \bar{v}+v^2-\overline{u}^2+\underline{u}^2+2\underline{u}\ v-\overline{u}\ \bar{u}-2\overline{u}\ \overline{v}+\underline{u}\ \underline{u})u. \tag{19b}$$

Next we look for the generalized symmetry $\mathbf{G}_4(n)=(G_4^{(1)}(n),G_4^{(2)}(n))$ with rank (4,4). As usual we form a monomial in u and v of rank 4 which gives $\tilde{L}=\{u,v,u^2,v^2,u^3,v^3,u^4,v^4\}$ and then, taking the necessary partial derivatives with respect to t in each monomial set $\tilde{L}$, we obtain a set like the one given in Eq. (17). Proceeding further along the lines described earlier we find that the invariant equations (16a) and (16b) with $i=4$ satisfy only if

$$\begin{aligned}G_4^{(1)}(n)=&-vu^3+(-2v\ \overline{v}-2v^2-v\underline{u}-2\overline{u}v)u^2+v\ \underline{u}^3\\&+(v\ \underline{v}+2v^2+uv+v\ \underline{u}+v^2+v\ \underline{u})\underline{u}^2-uv\ \underline{u}^2\\&+(-v\ \overline{v}^2-\overline{u}\ v\ \overline{v}+\overline{u}v^2-v^2\overline{v}+\overline{u}-\overline{u}\ v\ \overline{v}-\overline{u}\ \bar{u}\ v-v^3-\overline{u}\ \bar{u}v+\underline{u}v^2)u\\&+(-uv^2+v^2\ \underline{v}+v^2+\underline{u}v+\underline{u}\underline{v}+\underline{u}v+\underline{u}\ \underline{u})\underline{u},\end{aligned} \tag{20a}$$

$$\begin{aligned}G_4^{(2)}(n)=&(v-\underline{v}+\underline{u}+\overline{u})u^3+(2v^2+4v\ \underline{u}-2\overline{v}^2+2\underline{u}^2+\underline{u}\ \underline{v}+\underline{u}\ \underline{u}-2\overline{u}^2\\&-2\overline{u}\ \overline{v}-\overline{u}\ \bar{u}-2\overline{u}\ \overline{v}-\overline{u}\ \bar{v})u^2+(3\underline{u}\ v^2+\underline{u}\ \underline{v}^2+\underline{u}^2\underline{v}-\overline{v}^2\ \overline{u}-\overline{u}\ \bar{v}^2-\overline{u}\ \bar{u}\ \bar{v}\\&-2\overline{u}^2\bar{v}+\underline{u}^2\ \underline{v}+\underline{u}^2\ \underline{v}+\underline{u}^2v+\underline{u}\underline{u}-\overline{u}^2\ \overline{v}-\overline{u}^2\bar{u}-2\overline{v}^2\ \overline{v}-\overline{u}^2\ \bar{u}-2\overline{v}^2\ \overline{u}-2\overline{u}\bar{u}\ \overline{v}\\&-2\overline{u}\ \overline{v}\ \bar{v}-\overline{u}\ \bar{u}\ \overline{\overline{v}}+2\underline{u}^2\ v+2v\ \underline{v}\ \underline{u}+2v^2\ \underline{u}+2v\ \underline{u}\ \underline{u}-\overline{u}\bar{u}-\overline{u}\ \bar{u}\ \overline{\overline{u}}\\&+\underline{u}\ \underline{u}\ \underline{v}-\overline{v}^3-\overline{u}\ \bar{u}\ \bar{v}-\overline{u}^2\ \bar{u}+\underline{u}\ \underline{u}^2+\underline{u}\ \underline{u}\underline{v}+\underline{u}^2\underline{u}+\underline{u}\underline{u}\ \underline{v}+\underline{u}\underline{u}\ \underline{u})u.\end{aligned} \tag{20b}$$

In a similar manner we have proved that the RT lattice equation admits a sequence of generalized symmetries $\mathbf{G}_5(n)=(G_5^{(1)}(n),G_5^{(2)}(n))$, $\mathbf{G}_6(n)=(G_6^{(1)}(n),G_6^{(2)}(n))$ [with ranks (5,5),(6,6), ...] which involve a lengthy expressions.

2. Conserved densities and flux

It is easy to see that the RT lattice equation is scaling invariant,

$$(t,u,v)\to(\lambda t,\lambda^{-1}u,\lambda^{-1}v),$$

where λ is an arbitrary parameter. To derive a conserved density with rank 2, we form monomials of u and v which gives the list $L_1=\{u,u^2,v,v^2\}$. Introducing then the necessary t derivatives in each monomial of L_1 leads to $\{u^2,v^2,\overline{u}u,\underline{u}u,uv,\underline{u}v\}$. Using $u\ \overline{u}\equiv u\ \underline{u}$ we obtain $M_1=\{u^2,v^2,\overline{u}u,uv,\underline{u}v\}$. Thus the most general form of the conserved density of rank 2 will be

$$\rho_n=c_1u^2+c_2v^2+c_3\overline{u}u+c_4uv+c_5\underline{u}v, \tag{21}$$

where c_1, c_2, c_3, c_4 and c_5 are constants and so

$$\frac{\partial \rho_n}{\partial t} - J_n + J_{n+1} = (-2c_1 + c_4)u^2\ \overline{u} + (2c_1 - c_3)u^2 v + (c_5 - 2c_1)u^2\ \overline{v} + (-2c_2 + c_3)u\ v^2 + (c_4 - c_3)u\ \overline{u}\ v + (c_5 - c_3)u\ v\ \overline{u}, \tag{22a}$$

with flux

$$J_n = 2c_1 u^2\ \underline{u} + 2c_2 \underline{u}\ v^2 + 2c_3 u\ \underline{u}\ v + c_4 u \underline{u}\ \overline{u} + c_5 u\ \underline{u}\ \overline{v}. \tag{22b}$$

The definition of conservation law, Eq. (11), demands that each bracket in the right hand side of Eq. (22a) vanishes and so the conserved density ρ_n and the associated flux J_n become

$$\rho_n = \tfrac{1}{2}u^2 + (v + \overline{u} + \overline{v})u + \tfrac{1}{2}v^2, \quad J_n = u^2\ \underline{u} + (2\underline{u}\ v + \overline{u}\underline{u} + \underline{u}\ \overline{v})u + \underline{u}\ v^2.$$

To find the next conserved density ρ_n of rank 3 and the corresponding flux J_n, as usual we first form the monomials in u and v gives $L_2 = \{u, v, u^2, v^2, u^3, v^3\}$ and then the set M_2 which can be obtained by introducing the necessary t derivatives in each monomial of L_2. Proceeding as before we find the following conserved density ρ_n of rank 3 and the associated flux J_n,

$$\rho_n = \tfrac{1}{3}u^3 + (\overline{u} + v + \overline{v})u^2 + (v^2 + \overline{u^2} + \overline{v^2} + \overline{u}\ v + 2\overline{u}\ \overline{v} + v\ \overline{v} + \overline{u}\ \bar{u} + \overline{u}\ \bar{v})u + \tfrac{1}{3}v^3,$$

$$J_n = u^3\ \underline{u} + (2\overline{u}\ \underline{u} + 3\underline{u}\ v + 2\underline{u}\ \overline{v})u^2 + (\underline{u}\ \overline{u^2} + 3\underline{u}v^2 + \underline{u}\ v\ \overline{v} + 2\underline{u}\ \overline{u}\ v + 2\underline{u}\ v\ \overline{v} + 2\underline{u}\ \overline{u}\ \overline{v} + \underline{u}\ \overline{u}\ \bar{u} + \underline{u}\ \overline{u}\ \bar{v})u + \underline{u}\ v^3.$$

In a similar manner we have proved that the RT lattice equation admits a sequence of conserved densities with rank 4,5,... along with the flux which involves lengthy expressions and so the details are omitted here.

3. Recursion operator

The relation (10) for the RT lattice equation can be written as

$$\begin{bmatrix} G_{k+1}^{(1)}(n) \\ G_{k+1}^{(2)}(n) \end{bmatrix} = \mathcal{R} \begin{bmatrix} G_k^{(1)}(n) \\ G_k^{(2)}(n) \end{bmatrix} = \begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} \end{bmatrix} \begin{bmatrix} G_k^{(1)}(n) \\ G_k^{(2)}(n) \end{bmatrix}, \quad k = 1,2,\ldots, \tag{23}$$

where $\mathbf{G}_k(n) = (G_k^{(1)}(n), G_k^{(2)}(n))$, $\mathbf{G}_{k+1}(n) = (G_{k+1}^{(1)}(n), G_{k+1}^{(2)}(n))$ are the generalized symmetries. The construction of the recursion operator $\mathcal{R}$ for the RT lattice equation is as follows: For $k = 3$, Eq. (23) becomes

$$\begin{bmatrix} G_4^{(1)}(n) \\ G_4^{(2)}(n) \end{bmatrix} = \begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} \end{bmatrix} \begin{bmatrix} G_3^{(1)}(n) \\ G_3^{(2)}(n) \end{bmatrix}, \tag{24}$$

where $\mathbf{G}_3(n), \mathbf{G}_4(n)$ are the generalized symmetries of ranks (3,3) and (4,4) given in Eqs. (19) and (20). From Eq. (24) it is clear that the entries R_{11}, R_{12}, R_{21} and R_{22} of the matrix operator $\mathcal{R}$ must be of ranks 1 which can be determined from the following relations,

$$\text{rank}\ G_4^{(1)}(n) = \text{rank}\ R_{11} + \text{rank} G_3^{(1)}(n) = \text{rank}\ R_{12} + \text{rank}\ G_3^{(2)}(n),$$

$$\text{rank}\ G_4^{(2)}(n) = \text{rank}\ R_{21} + \text{rank} G_3^{(1)}(n) = \text{rank}\ R_{22} + \text{rank}\ G_3^{(2)}(n).$$

So we consider the entries R_{11}, R_{12}, R_{21} and R_{22} written in terms of difference and inverse difference operators of the dependent variables and their shifts having the form

$$R_{11} = e_0 v + e_1 u + e_2 u\Delta + e_3 \Delta u + e_4 \Delta v + e_5 v\Delta + e_6 v\Delta^+ u\Delta^{-1}u^{-1}, \tag{25a}$$

$$R_{12}=f_0v+f_1v\Delta^+u\Delta^{-1}u^{-1}+f_2u+f_3\Delta u+f_4u\Delta+f_5\Delta v+f_6u\Delta, \tag{25b}$$

$$R_{21}=g_0u+g_1u\Delta+g_2v\Delta+g_3\Delta u+g_4\Delta v, \tag{25c}$$

$$R_{22}=h_0u+h_1u\Delta+h_2u\Delta v\Delta^{-1}u^{-1}+h_3u\Delta u\Delta^{-1}u^{-1}+h_4u\Delta^+u\Delta^{-1}u^{-1}, \tag{25d}$$

where $e_i, f_i, i=1,2,3,4,5,6$, $h_j, g_j, j=1,2,3,4$, are arbitrary constants to be determined and Δ and Δ^+ are difference operators defined by

$$\Delta u=u_{n+1}-u_n=\overline{u}-u, \quad \Delta^+u=u_{n-1}-u_n=\underline{u}-u,$$

and Δ^{-1}, $(\Delta-\Delta^+)^{-1}$ and $(\Delta^+)^{-1}$ are inverse difference operators defined as

$$\Delta^{-1}u=\frac{1}{2}\left[\sum_{k=-\infty}^{-1}[u_{n+1+2k}+u_{n+2k}]-\sum_{k=1}^{\infty}[u_{n-1+2k}+u_{n-2+2k}]\right],$$

$$(\Delta-\Delta^+)^{-1}u=\frac{1}{2}\left[\sum_{k=-\infty}^{-1}u_{n+1+2k}-\sum_{k=1}^{\infty}u_{n-1+2k}\right],$$

$$(\Delta^+)^{-1}u=-\frac{1}{2}\left[\sum_{k=-\infty}^{-1}[u_{n+2+2k}+u_{n+1+2k}]-\sum_{k=1}^{\infty}[u_{n+2k}+u_{n-1+2k}]\right].$$

Substituting the entries R_{11}, R_{12}, R_{21} and R_{22} in Eq. (24), we have checked that it is satisfied identically only if

$$e_0=1, \quad f_0=-1, \quad -f_1=h_1=g_1=g_2=g_3=-g_4=1, \quad h_0=g_0=2,$$

and so the recursion operator for the RT lattice equation (1) becomes

$$\mathcal{R}=\begin{bmatrix} v & v+v(1-E^{-1})u(E-1)^{-1}\dfrac{1}{u} \\ u(1+E) & u(1+E)+u(E-1)v(E-1)^{-1}\dfrac{1}{u}+u(E-E^{-1})u(E-1)^{-1}\dfrac{1}{u} \end{bmatrix}, \tag{26}$$

where E and E^{-1} are the shift operators defined by $Eu_n=(1+\Delta)u_n$ and $E^{-1}u_n=(1+\Delta^+)u_n$.

4. Factorization of recursion operator

Let us assume that the constructed (2×2) matrix recursion operator $\mathcal{R}$, Eq. (26), can be written as a product of two distinct (2×2) matrix operators $A=(A_{ij})$ and $B=(B_{ij})$, $i,j=1,2$. That is,

$$\begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} \end{bmatrix}=\begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}\begin{bmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{bmatrix}. \tag{27}$$

Equation (27) suggests that the entries of the matrix AB must be of the same rank as of $\mathcal{R}$. Thus we consider the entries of the matrix operator A and B having the form

$$A_{11}=a_{11}u\Delta v+a_{12}uv\Delta+a_{13}uv\Delta^+ +a_{14}v\Delta u+a_{15}u\Delta^+u, \tag{28a}$$

$$A_{12}=b_{11}u\Delta v+b_{12}v\Delta^+u+b_{13}u\Delta u+b_{14}v\Delta u+b_{15}u\Delta^+u, \tag{28b}$$

$$A_{21}=c_{11}u\Delta v+c_{12}uv\Delta+c_{13}uv\Delta^+ +c_{14}v\Delta u+c_{15}u\Delta^+v+c_{16}v\Delta^+u+c_{17}u\Delta u+c_{18}u\Delta^+u, \tag{28c}$$

$$A_{22}=d_{11}u\Delta u+d_{12}u\Delta^{+}u+d_{13}u\Delta v+d_{14}v\Delta u+d_{15}v\Delta v+d_{16}v\Delta^{+}v, \tag{28d}$$

$$B_{11}=\tilde{a}_{11}u^{-1}\Delta^{-1}u^{-1}+\tilde{a}_{12}u^{-1}(\Delta^{+})^{-1}u^{-1}+\tilde{a}_{13}v^{-1}\Delta^{-1}u^{-1}+\tilde{a}_{14}u^{-1}(\Delta^{+})^{-1}v^{-1}, \tag{29a}$$

$$B_{12}=\tilde{b}_{11}\Delta^{-1}u^{-1}+\tilde{b}_{12}v^{-1}(\Delta^{+})^{-1}+\tilde{b}_{13}v^{-1}\Delta^{-1}+\tilde{b}_{14}(\Delta^{+})^{-1}v^{-1}+\tilde{b}_{15}u^{-1}\Delta^{-1}, \tag{29b}$$

$$B_{21}=\tilde{c}_{11}\Delta^{-1}v^{-1}+\tilde{c}_{12}u^{-1}(\Delta^{+})^{-1}+\tilde{c}_{13}v^{-1}\Delta^{-1}+\tilde{c}_{14}(\Delta^{+})^{-1}u^{-1}+\tilde{c}_{15}\Delta^{-1}u^{-1}, \tag{29c}$$

$$B_{22}=\tilde{d}_{11}v^{-1}\Delta^{-1}+\tilde{d}_{12}\Delta^{-1}u^{-1}+\tilde{d}_{13}u^{-1}(\Delta^{+})^{-1}, \tag{29d}$$

where a_{ij}, $\tilde{a}_{ij}$, b_{ij}, $\tilde{b}_{ij}$ c_{ij}, $\tilde{c}_{ij}$ d_{ij} and $\tilde{d}_{ij}$ are unknown constants to be determined. Substituting the above entries (A_{ij}) and (B_{ij}) on the right hand side of Eq. (27) and then equating with the entries on the left hand side we find that the consistency condition holds only for the following parametric restrictions:

$$b_{12}=-c_{11}=d_{11}=-d_{12}=-\tilde{b}_{11}=\tilde{c}_{12}=\tilde{d}_{13}=-\tilde{d}_{12}=1$$

and so the matrix operators A and B become

$$A=\begin{bmatrix} 0 & v\Delta^{+}u \\ -u\Delta v & u(\Delta-\Delta^{+})u \end{bmatrix}, \quad B=\begin{bmatrix} 0 & -\Delta^{-1}u^{-1} \\ u^{-1}(\Delta^{+})^{-1} & u^{-1}(\Delta^{+})^{-1}-\Delta^{-1}u^{-1} \end{bmatrix}. \tag{30}$$

We have also verified that both the matrix operators A and B are invertible. To write the recursion operator $\mathcal{R}$ in the standard form $\mathcal{R}=H_2H_1^{-1}$ we choose

$$H_2=A=\begin{bmatrix} 0 & v\Delta^{+}u \\ -u\Delta v & u(\Delta-\Delta^{+})u \end{bmatrix} \tag{31a}$$

and

$$B=H_1^{-1},$$

and so

$$H_1=\begin{bmatrix} uE-E^{-1}u & (E^{-1}-1)u \\ -u(E-1) & 0 \end{bmatrix}. \tag{31b}$$

B. BM lattice equation

1. Generalized symmetries

The invariant equation (9) takes the following form for the BM lattice equation:

$$\frac{\partial G_i^{(1)}(n)}{\partial t}=G_i^{(3)}(n+1)-G_i^{(3)}(n-1), \tag{32a}$$

$$\frac{\partial G_i^{(2)}(n)}{\partial t}=G_i^{(1)}(n-1)w_{n-1}+G_i^{(3)}(n-1)u_{n-1}-G_i^{(1)}(n)w_n-G_i^{(3)}(n)u_n, \tag{32b}$$

$$\frac{\partial G_i^{(3)}(n)}{\partial t}=G_i^{(3)}(n)(v_n-v_{n+1})+w_n(G_i^{(2)}(n)-G_i^{(2)}(n+1)). \tag{32c}$$

Solving the above invariant equations along the lines described for the RT lattice equation we have derived a sequence of generalized symmetries. The explicit forms of generalized symmetries (also

conserved densities) are given in Ref. 21. The first few generalized symmetries $\mathbf{G}_2(n)=(G_2^{(1)}(n),G_2^{(2)}(n),G_2^{(3)}(n))$, $\mathbf{G}_3(n)=(G_3^{(1)}(n),G_3^{(2)}(n),G_3^{(3)}(n))$, $\mathbf{G}_4=(G_4^{(1)}(n),G_4^{(2)}(n),G_4^{(3)}(n))$, respectively, having ranks $(\frac{3}{2},2,\frac{5}{2})$, $(\frac{5}{2},3,\frac{7}{2})$, $(\frac{7}{2},4,\frac{9}{2})$, are given by

$$G_2^{(1)}(n)=\overline{w}-\underline{w},\quad G_2^{(2)}(n)=\underline{u}\,\underline{w}-u\ \ w,\quad G_2^{(3)}(n)=w(v-\overline{v}), \tag{33}$$

$$\begin{gathered}G_3^{(1)}(n)=\underline{w}(v+\underline{v})-\overline{w}(\overline{v}+\bar{\bar{v}}),\quad G_3^{(2)}(n)=uw(v+\overline{v})-\underline{u}\,\underline{w}(v+\underline{v})+\underline{w}\,\underline{\underline{w}}-w\overline{w},\\ G_3^{(3)}(n)=w(\overline{v}^2-v^2)+w(\overline{wu}-\underline{w}\,\underline{u}),\end{gathered} \tag{34}$$

$$\begin{aligned}G_4^{(1)}(n)=&-\overline{w}\bar{\bar{v}}^2-\overline{w}\ \ \overline{v}^2-\overline{w}\bar{\bar{w}}\bar{\bar{u}}-w\ \ \overline{w}u+\underline{w}v^2+\underline{w}\underline{v}^2+w\underline{w}u+\underline{w}\,\underline{\underline{w}}\ \ \underline{\underline{u}}+v\underline{w}\,\underline{v}\\&+\underline{u}\,\underline{w}^2-\overline{u}\ \ \overline{w}^2-\overline{w}\overline{v}\bar{\bar{v}},\end{aligned}$$

$$G_4^{(2)}(n)=-uw^2v+uw^2\overline{v}-2\underline{u}\,\underline{w}wv-\underline{u}\ \ \underline{w}w\underline{v}+w\underline{w}\,\underline{\underline{w}}-wv^3+2w\overline{wuv}+w\overline{wu}\bar{\bar{v}}-w\overline{w}\bar{\bar{w}}+w\overline{v}^3, \tag{35}$$

$$\begin{aligned}G_4^{(3)}(n)=&\underline{w}\,\underline{\underline{w}}\,\underline{v}+\underline{w}\,\underline{\underline{w}}\,\underline{\underline{v}}-\underline{u}\,\underline{w}v^2-\underline{u}\,\underline{w}\underline{v}^2-\underline{w}\,\underline{\underline{w}}\,\underline{\underline{u}}\,\underline{\underline{u}}+uw\overline{v}^2+uwv^2\\&+uw\overline{uw}-w\overline{wv}-w\overline{w}\bar{\bar{v}}+u^2w^2+uv\,w\ \ \overline{v}-w\overline{w}v+\underline{w}\,\underline{\underline{w}}v-\underline{u}\,\underline{w}v\,\underline{v}-\underline{u}^2\underline{w}^2,\end{aligned}$$

where $w_n=w,w_{n+1}=\overline{w},w_{n-1}=\underline{w},\ w_{n+2}=\bar{\bar{w}},w_{n-2}=\underline{\underline{w}}$.

2. Recursion operator and factorization

Here the generalized symmetry $\mathbf{G}_k(n)=(G_k^{(1)}(n),G_k^{(2)}(n),G_k^{(3)}(n))$ and so the relation (10) takes

$$\begin{bmatrix}G_{k+1}^{(1)}(n)\\G_{k+1}^{(2)}(n)\\G_{k+1}^{(3)}(n)\end{bmatrix}=\mathcal{R}\begin{bmatrix}G_k^{(1)}(n)\\G_k^{(2)}(n)\\G_k^{(3)}(n)\end{bmatrix}=\begin{bmatrix}R_{11}&R_{12}&R_{13}\\R_{21}&R_{22}&R_{23}\\R_{31}&R_{32}&R_{33}\end{bmatrix}\begin{bmatrix}G_k^{(1)}(n)\\G_k^{(2)}(n)\\G_k^{(3)}(n)\end{bmatrix},\quad k=1,2,\ldots. \tag{36}$$

Let $k=3$. Now

$$\text{rank}\ \ G_3^{(1)}=\tfrac{5}{2},\ \text{rank}\ \ G_3^{(2)}=3,\ \text{rank}\ \ G_3^{(3)}=\tfrac{7}{2},$$

$$\text{rank}\ \ G_4^{(1)}=\tfrac{7}{2},\ \text{rank}\ \ G_4^{(2)}=4,\ \text{rank}\ \ G_4^{(3)}=\tfrac{9}{2}.$$

Then the rank of the entries of $\mathcal{R}$ can be determined from the following relations,

$$\text{rank}\ \ G_4^{(1)}(n)=\text{rank}R_{11}+\text{rank}\ \ G_3^{(1)}(n)=\text{rank}\ \ R_{12}+\text{rank}\ \ G_3^{(2)}(n)=\text{rank}\ \ R_{13}+\text{rank}\ \ G_3^{(3)}(n),$$

$$\text{rank}\ \ G_4^{(2)}(n)=\text{rank}\ \ R_{21}+\text{rank}\ \ G_3^{(1)}(n)=\text{rank}\ \ R_{22}+\text{rank}G_3^{(2)}(n)=\text{rank}\ \ R_{23}+\text{rank}\ \ G_3^{(3)}(n),$$

$$\text{rank}\ \ G_4^{(3)}(n)=\text{rank}\ \ R_{31}+\text{rank}\ \ G_3^{(1)}(n)=\text{rank}\ \ R_{32}+\text{rank}G_3^{(2)}(n)=\text{rank}\ \ R_{33}+\text{rank}\ \ G_3^{(3)}(n),$$

and so

$$\text{rank}\ \ \mathrm{R}_{11}=1,\ \text{rank}\ \ \mathrm{R}_{12}=\tfrac{1}{2},\ \text{rank}\ \ \mathrm{R}_{13}=0,$$

$$\text{rank}\ \ \mathrm{R}_{21}=\tfrac{3}{2},\ \text{rank}\ \ \mathrm{R}_{22}=1,\ \text{rank}\ \ \mathrm{R}_{23}=\tfrac{1}{2},$$

$$\text{rank}\ \ \mathrm{R}_{31}=2,\ \text{rank}\ \ \mathrm{R}_{32}=\tfrac{3}{2},\ \text{rank}\ \ \mathrm{R}_{33}=1.$$

We then choose the entries R_{11}, R_{12}, R_{13}, R_{21}, R_{22}, R_{23}, R_{31}, R_{32}, R_{33} written in terms of the difference and inverse difference operators of the dependent variables and their inverses and, proceeding further as explained for the RT lattice equation, we obtain the explicit form of the recursion operator $\mathcal{R}$,

$$\mathcal{R}=\begin{bmatrix} (Ev-vE^{-1}-u(E-1)\tilde{E}^{-1} & u(E-1)\tilde{E}^{-1} & -(EwE-E^{-1}w)\Delta^{-1}\dfrac{1}{w} \\ (E^{-1}-1)u)(\Delta-\Delta^{+})^{-1} & & \\ (wE-E^{-1}wE^{-1})(\Delta-\Delta^{+})^{-1} & v & (E^{-1}uw-uwE)\Delta^{-1}\dfrac{1}{w} \\ w(E-1)\tilde{E}^{-1}(E^{-1}-1) & w(-\tilde{E}^{-1}+(1-E))\tilde{E}^{-1} & w(E-1)v\Delta^{-1}\dfrac{1}{w} \\ u(\Delta-\Delta^{+})^{-1} & & \end{bmatrix},$$

which can be factorized into

$$\mathcal{R}=H_2H_1^{-1},$$

where

$$H_1=\begin{bmatrix} (\Delta-\Delta^{+}) & 0 & 0 \\ 0 & 0 & \Delta^{+}w \\ 0 & -w\Delta & 0 \end{bmatrix}, \tag{37}$$

$$H_2=\begin{bmatrix} Ev-vE^{-1}-u(E-1) & EwE-E^{-1}w & u(E-1) \\ (\tilde{E})^{-1}(E^{-1}-1)u & & (\tilde{E})^{-1}(E^{-1}-1)w \\ wE-E^{-1}wE^{-1} & E^{-1}uw-uwE & v(E^{-1}-1)w \\ w(E-1)(\tilde{E})^{-1} & -w(E-1)v & w(-\tilde{E}-(E-1)(\tilde{E})^{-1} \\ (E^{-1}-1)u & & (E^{-1}-1))w \end{bmatrix}, \tag{38}$$

where $\tilde{E}=\Delta-\Delta^{+}$, $(\Delta-\Delta^{+})^{-1}$ and $(\Delta^{+})^{-1}$ are inverse difference operators defined as

$$(\Delta-\Delta^{+})^{-1}u=\frac{1}{2}\left[\sum_{k=-\infty}^{-1}u_{n+1+2k}-\sum_{k=1}^{\infty}u_{n-1+2k}\right],$$

and

$$(\Delta^{+})^{-1}u=-\frac{1}{2}\left[\sum_{k=-\infty}^{-1}[u_{n+2+2k}+u_{n+1+2k}]-\sum_{k=1}^{\infty}[u_{n+2k}+u_{n-1+2k}]\right].$$

C. BC lattice equation

1. Generalized symmetries

Here the invariant equation (9) takes the following form,

$$\frac{\partial G_i^{(1)}(n)}{\partial t}=G_i^{(1)}(n)(u_{n+1}-u_{n-1})+u_n(G_i^{(1)}(n+1)-G_i^{(1)}(n-1))+G_i^{(2)}(n-1)-G_i^{(2)}(n), \tag{39a}$$

$$\frac{\partial G_i^{(2)}(n)}{\partial t} = G_i^{(2)}(n)(u_{n+2}-u_{n-1}) + v_n(G_i^{(1)}(n+2)-G_i^{(1)}(n-1)). \tag{39b}$$

In Ref. 21, we have solved the above invariant equations and shown that the BC lattice equation admits a sequence of generalized symmetries (also conserved densities). First few generalized symmetries $\mathbf{G}_2(n)=(G_2^{(1)}(n),G_2^{(2)}(n))$, $\mathbf{G}_3(n)=(G_3^{(1)}(n),G_3^{(2)}(n))$, $\mathbf{G}_4(n)=(G_4^{(1)}(n),G_4^{(2)}(n))$ having ranks (2,3), (3,4), (4,5) are

$$G_2^{(1)}(n)=u(\overline{u}-\underline{u})+\underline{v}-v, \quad G_2^{(2)}(n)=v(\bar{u}-\underline{u}), \tag{40}$$

$$G_3^{(1)}(n)=(v-u\overline{u})(u+\overline{u}+\bar{u})+(u\underline{u}-\underline{v})(u+\underline{u}+\underline{\underline{u}})-u(\underline{\underline{v}}-\overline{v}),$$

$$G_3^{(2)}(n)=\underline{u}v(u+\underline{u}+\underline{\underline{u}})-\bar{u}v(\overline{u}+\bar{u}+\overline{\overline{\overline{u}}})+v(\overline{v}+\bar{v}-\underline{v}-\underline{\underline{v}}), \tag{41}$$

$$\begin{aligned}G_4^{(1)}(n)=&-[u^3\overline{u}+2u^2\overline{u}^2+u\overline{u}^3+u^2\overline{u}\bar{u}+2u\overline{u}^2\bar{u}+u\overline{u}\bar{u}^2+u\overline{u}\bar{u}\overline{\overline{\overline{u}}}-u\underline{u}\underline{\underline{u}}\underline{\underline{\underline{u}}}-u\underline{u}\underline{\underline{u}}^2\\&-2u\underline{u}^2\underline{\underline{u}}-u\underline{u}^3-u^2\underline{u}\underline{\underline{u}}-u^3\underline{\underline{u}}-2u^2\underline{\underline{u}}^2]+3u\overline{u}\overline{v}+\overline{u}^2v+2\overline{u}\overline{\bar{u}}v+2u\overline{u}\overline{v}+u\bar{u}\overline{v}+u\overline{\overline{\overline{u}}}\,\overline{v}\\&+u^2v+u\overline{u}\overline{\bar{v}}+u\bar{u}v-u^2\underline{v}-3u\underline{u}\underline{v}-u\underline{\underline{u}}\underline{v}-u^2\underline{\underline{v}}+u^2\overline{v}-\underline{u}^2\underline{v}-2\underline{u}\underline{\underline{u}}\underline{v}-u\underline{\underline{u}}\underline{\underline{v}}\\&-u\underline{\underline{u}}\underline{\underline{v}}-u\underline{u}\underline{\underline{v}}-\underline{\underline{u}}^2\underline{v}-\underline{\underline{u}}\underline{u}\underline{\underline{v}}+\underline{v}\underline{\underline{v}}+\underline{v}\underline{\underline{v}}+\bar{u}^2v-2u\underline{u}\underline{\underline{v}}+\bar{u}\overline{\overline{\overline{u}}}v-v\overline{v}-v\bar{v}-v^2+\underline{\underline{v}}^2,\end{aligned}$$

$$\begin{aligned}G_4^{(2)}(n)=&-\overline{u}v\underline{v}+u\overline{u}\underline{u}v+\bar{u}v\bar{v}+v\bar{v}\overline{\overline{\overline{u}}}+v\bar{v}\overline{\overline{\overline{\overline{u}}}}-2\bar{u}^2\overline{\overline{u}}v-\bar{u}\overline{\overline{\overline{u}}}^2v-\bar{u}\overline{\overline{\overline{\overline{u}}}}\,\overline{\overline{\overline{\overline{u}}}}v-2\overline{u}\overline{\bar{u}}^2v-\overline{u}^2\bar{u}v\\&-u\overline{u}\bar{u}v+\bar{u}v\overline{v}+\overline{u}v\overline{v}+uv\overline{v}+v^2\bar{u}+\bar{u}v\overline{\overline{\overline{v}}}-\bar{u}^3v-\underline{u}v\underline{v}-uv\underline{v}+2u\underline{u}^2v+u^2\underline{u}v+2\underline{u}^2\underline{\underline{u}}v\\&+\underline{u}\underline{\underline{u}}^2v+\underline{u}\underline{\underline{u}}\underline{\underline{\underline{u}}}v-\underline{u}v\underline{\underline{v}}-\underline{\underline{u}}v\underline{v}-\underline{\underline{u}}v\underline{\underline{v}}-\underline{u}v\underline{\underline{v}}-v^2\underline{\underline{u}}+u\underline{u}\underline{\underline{u}}v-v\underline{\underline{v}}u-v\underline{v}\underline{\underline{u}}+v\overline{v}\overline{\overline{\overline{u}}}\,u-\overline{u}\overline{\bar{u}}\;\overline{\overline{\overline{u}}}\,v\\&+v\bar{v}\overline{u}+\underline{u}^3v.\end{aligned} \tag{42}$$

2. Recursion operator and factorization

Here the relation (10) related with the recursion operator $\mathcal{R}$ is

$$\begin{bmatrix}G_{k+1}^{(1)}(n)\\G_{k+1}^{(2)}(n)\end{bmatrix}=\mathcal{R}\begin{bmatrix}G_k^{(1)}(n)\\G_k^{(2)}(n)\end{bmatrix}=\begin{bmatrix}R_{11}&R_{12}\\R_{21}&R_{22}\end{bmatrix}\begin{bmatrix}G_k^{(1)}(n)\\G_k^{(2)}(n)\end{bmatrix}, \quad k=1,2,\ldots. \tag{43}$$

Let $k=3$. Now

$$\text{rank } G_3^{(1)}(n)=3,\ \text{rank}G_3^{(2)}(n)=4,\ \text{rank } G_4^{(1)}(n)=4, \quad \text{rank}G_4^{(2)}(n)=5.$$

The ranks of the entries of $\mathcal{R}$ can be determined from the following relations,

$$\text{rank } G_4^{(1)}(n)=\text{rank } R_{11}+\text{rank } G_3^{(1)}(n)=\text{rank } R_{12}+\text{rank } G_3^{(2)}(n),$$

$$\text{rank } G_4^{(2)}(n)=\text{rank } R_{21}+\text{rank } G_3^{(1)}(n)=\text{rank } R_{22}+\text{rank } G_3^{(2)}(n).$$

Thus

$$\text{rank } R_{11}=1,\ \text{rank } R_{12}=0,\ \text{rank}R_{21}=2,\ \text{rank } R_{22}=1.$$

Proceeding in a similar manner as for the RT and BM lattice equations (1) and (2) we construct the recursion operator $\mathcal{R}$ which can be written as a product of two invertible operators,

$$\mathcal{R}=H_2H_1^{-1},$$

where

$$H_1=\begin{bmatrix} H_{11}^{(1)} & H_{12}^{(1)} \\ H_{21}^{(1)} & H_{22}^{(1)} \end{bmatrix} \text{ and } H_2=\begin{bmatrix} H_{11}^{(2)} & H_{12}^{(2)} \\ H_{21}^{(2)} & H_{22}^{(2)} \end{bmatrix},$$

$$\begin{aligned} H_{11}^{(1)}&=uEu-uE^{-1}u+E^{-1}v-vE,\\ H_{12}^{(1)}&=-uE^{-2}v+uEv,\\ H_{21}^{(1)}&=vE^2u-vE^{-1}u,\\ H_{22}^{(1)}&=vE^2v+vEv-vE^{-2}v-vE^{-1}v. \end{aligned} \tag{44a}$$

$$\begin{aligned} H_{11}^{(2)}&=u(uE+Eu+EuE-uE^{-1}-E^{-1}u-E^{-1}uE^{-1})u+uE^{-1}v\\ &\quad -uEvE+E^{-1}vE^{-1}u-vE^2u-uvE-vEu+E^{-1}uv+uE^{-2}v),\\ H_{12}^{(2)}&=-u(-uE-Eu-EuE+uE^{-2}+E^{-1}uE^{-2}+E^{-1}uE^{-1})v\\ &\quad -v(1+E+E^2)v+E^{-1}v(1+E^{-1}+E^{-2})v-(uE^{-1}u-uEuE^{-1})v,\\ H_{21}^{(2)}&=-v(uE^{-1}+E^{-1}u+E^{-1}uE^{-1}-EuE-E^2u-E^2uE)u\\ &\quad -v[(1+E+E^2)vE-(1+E^{-1}+E^{-2})v]-v[-uE+EuE^{-1}]u,\\ H_{22}^{(2)}&=-v(E^{-1}uE^{-2}+uE^{-2}-uE-E^2uE+E^{-1}u+E^{-1}uE^{-1}\\ &\quad -E^2uE^{-1}-EuE+EuE^{-2}-E^2u)v. \end{aligned} \tag{44b}$$

IV. BI-HAMILTONIAN SYSTEM

We prove, in this section, that the factorized operators H_1 and H_2 for each of the lattice equations (1)–(3) are Hamiltonian.

A. RT lattice equation

Obviously the operators H_1 and H_2 given in Eqs. (31a) and (31b) are skew-symmetric. In order to prove that the operators H_1 and H_2 are Hamiltonian it remains to prove that they satisfy the Jacobi identity. Let us first consider the skew symmetric operator H_1. It is appropriate to mention the following theorem for a system of nonlinear PDEs $\partial\mathbf{u}/\partial t=K(\mathbf{u})$ due to Olver.[6]

Theorem: Let $\mathcal{D}$ be a skew-adjoint $q\times q$ matrix differential operator of the system of PDEs, $\partial\mathbf{u}/\partial t=K(\mathbf{u})$ and $\Theta=\frac{1}{2}\int\{\Theta\wedge\mathcal{D}\Theta\}\mathrm{d}x$, the corresponding functional bi-vector. Then $\mathcal{D}$ is Hamiltonian if and only if

$$PrV_{\mathcal{D}\theta}(\Theta)=0. \tag{45}$$

Here $\theta=\theta(\mathbf{x},\mathbf{u})$. Recent investigations by Sanders and Wang[33] suggest that the above result, Eq. (45), holds good for nonlinear PDDEs as well. Thus it remains to prove that the skew-symmetric operator H_1, Eq. (31a), of the RT lattice equation (1) satisfies Eq. (45). For nonlinear PDDEs, prolongation of the vector field is defined as[33]

$$PrV_{H\theta}=\sum_{\alpha,J}E_J\left(\sum_{\beta}H_{\alpha\beta}\theta^{\beta}\right)\frac{\partial}{\partial u_J^{\alpha}},$$

where E^J is the shift operator and H is a skew-symmetric operator. Let $\theta_1=(\theta,\varsigma)^T$. Then

$$H_1\theta_1=H_1\begin{bmatrix}\theta\\ \varsigma\end{bmatrix}=\begin{bmatrix}(uE-E^{-1}u)\theta+(E^{-1}-1)u\varsigma\\ -u\Delta\theta\end{bmatrix}=\begin{bmatrix}\Phi_1\\ \Phi_2\end{bmatrix}.$$

Define a bi-vector Θ of H_1 by

$$\Theta_{H_1}=\frac{1}{2}\sum\ [\theta\wedge\Phi_1+\varsigma\wedge\Phi_2]$$

$$=\frac{1}{2}\sum\ [u\ \theta\wedge\overline{\theta}-u\ \overline{\theta}\wedge\theta+u\ \overline{\theta}\wedge\varsigma-u\ \theta\wedge\varsigma-u\ \varsigma\wedge\overline{\theta}+u\ \varsigma\wedge\theta].$$

Making use of the wedge product,

$$\theta\wedge\overline{\theta}=-\overline{\theta}\wedge\theta,\overline{\theta}\wedge\varsigma=-\varsigma\wedge\overline{\theta},\theta\wedge\theta=0,$$

we rewrite the bi-vector Θ_{H_1} as

$$\Theta_{H_1}=\sum\ [u\ \theta\wedge\overline{\theta}+u\overline{\theta}\wedge\varsigma+u\ \varsigma\wedge\theta],$$

where $\overline{\varsigma}=\varsigma_{n+1},\overline{\theta}=\theta_{n+1}$. Now

$$PrV_{H_1\theta_1}(\Theta_{H_1})=\sum\ [(-u\ \overline{\theta}+u\theta)\wedge(\theta\wedge\overline{\theta}+\overline{\theta}\wedge\varsigma+\varsigma\wedge\theta)=0.$$

Here Σ is used to denote the equivalence classes after dividing the image of $(1-E)$. These equivalence classes are called functionals. In a similar manner, we checked that for the skew-symmetric operator H_2,

$$PrV_{H_2\theta_1}(\Theta_{H_2})=0.$$

Thus the operators H_1 and H_2 are Hamiltonian. Hence the RT equation (1) can be written in the bi-Hamiltonian form. Using the compatible Hamiltonian operators H_1 and H_2, we have

$$\begin{bmatrix}v_t\\ u_t\end{bmatrix}=H_1\begin{bmatrix}\dfrac{\delta\mathcal{H}_1}{\delta u}\\ \dfrac{\delta\mathcal{H}_1}{\delta v}\end{bmatrix}=H_2\begin{bmatrix}\dfrac{\delta\mathcal{H}_0}{\delta u}\\ \dfrac{\delta\mathcal{H}_0}{\delta v}\end{bmatrix},$$

associated with the Hamiltonian functionals, $\mathcal{H}_0(u,v)=\Sigma_n\log v$ and $\mathcal{H}_1(u,v)=\Sigma_n[\frac{1}{2}(u^2+v^2)+uv+uv+uu]$. Hence the RT lattice equation (1) is a bi-Hamiltonian system. A similar observation is also pointed out by Fuchssteiner *et al.* using a different approach.[32]

B. BM lattice equation

It is straight forward to check that the operators H_1 and H_2, Eqs. (37) and (38), are skew-symmetric. In order to prove that the operators H_1 and H_2 are Hamiltonian it remains to prove that they satisfy the Jacobi identity. First consider the operator H_1. As before, let $\theta_1=(\theta,\chi,\varsigma)^T$ and

$$H_1\theta_1=H_1\begin{bmatrix}\theta\\ \chi\\ \varsigma\end{bmatrix}=\begin{bmatrix}\tilde{E}\theta\\ (E^{-1}-1)w\varsigma\\ -w(E-1)\chi\end{bmatrix}=\begin{bmatrix}\Phi_1\\ \Phi_2\\ \Phi_3\end{bmatrix}.$$

Define a bi vector Θ of H_1 by

$$\Theta_{H_1}=\frac{1}{2}\sum\ [\theta\wedge\Phi_1+\chi\wedge\Phi_2+\varsigma\wedge\Phi_3]$$

$$=\frac{1}{2}\sum\ [\theta\wedge(E-E^{-1})\theta+\chi\wedge(E^{-1}-1)w\varsigma+\varsigma\wedge(-w(E-1)\chi)]$$

$$=\frac{1}{2}\sum\ [\theta\wedge E\theta-\theta\wedge E^{-1}\theta+\chi\wedge E^{-1}w\varsigma-\chi\wedge w\varsigma-\varsigma\wedge wE\chi+\varsigma\wedge w\chi]$$

$$=\frac{1}{2}\sum\ [\theta\wedge\overline{\theta}-\overline{\theta}\wedge\theta+\overline{\chi}\wedge w\varsigma-\chi\wedge w\varsigma-\varsigma\wedge w\overline{\chi}+\varsigma\wedge w\chi]. \quad (46)$$

Making use of the property of wedge product, we simplify Eq. (46) into

$$\Theta_{H_1}=\sum\ [\theta\wedge\overline{\theta}+w\overline{\chi}\wedge\varsigma+w\varsigma\wedge\chi],$$

where $\overline{\theta}=\theta_{n+1},\overline{\chi}=\chi_{n+1}$, etc. Proceeding as before for the RT lattice equation (1), it is easy to see that

$$PrV_{H_1\theta_1}(\Theta_{H_1})=\sum\ [-w(E-1)\chi\wedge\overline{\chi}\wedge\varsigma-w(E-1)\chi\wedge\varsigma\wedge\chi]$$

$$=\sum\ [-w\ (\overline{\chi}\wedge\overline{\chi}\wedge\varsigma-\chi\wedge\overline{\chi}\wedge\varsigma)-w\ (\overline{\chi}\wedge\varsigma\wedge\chi-\chi\wedge\varsigma\wedge\chi)]=0$$

and hence H_1 is a Hamiltonian operator. Similar conclusion can also be arrived at for the operator H_2. Now the BM lattice equation (2) can be written as

$$\begin{bmatrix}u_t\\ v_t\\ w_t\end{bmatrix}=H_1\begin{bmatrix}\frac{\delta\mathcal{H}_1}{\delta u}\\ \frac{\delta\mathcal{H}_1}{\delta v}\\ \frac{\delta\mathcal{H}_1}{\delta w}\end{bmatrix}=H_2\begin{bmatrix}\frac{\delta\mathcal{H}_0}{\delta u}\\ \frac{\delta\mathcal{H}_0}{\delta v}\\ \frac{\delta\mathcal{H}_0}{\delta w}\end{bmatrix},$$

where the Hamiltonian functionals $\mathcal{H}_0(u,v,w)$ and $\mathcal{H}_1(u,v,w)$ take the forms $\mathcal{H}_0(u,v,w)=\Sigma v$ and $\mathcal{H}_1(u,v,w)=\Sigma[\frac{1}{2}v^2+uw]$ and so the BM lattice equation (2) is a bi-Hamiltonian system. The bi-Hamiltonian formulation for the BM lattice equation has also been obtained by Blaszak *et al.* using a different approach.[31]

C. BC lattice equation

It is straight forward to check that the operators H_1 and H_2 given in Eqs. (44a) and (44b) are skew-symmetric. For Hamiltonian operator, it remains to prove the Jacobi identity. First consider the operator H_1. As before, let $\theta_1=(\theta,\varsigma)^T$ and

$$H_1\theta_1=H_1\begin{bmatrix}\theta\\ \varsigma\end{bmatrix}=\begin{bmatrix}H_{11}^{(1)}\theta+H_{12}^{(1)}\varsigma\\ H_{21}^{(1)}\theta+H_{22}^{(1)}\varsigma\end{bmatrix}=\begin{bmatrix}\Phi_1\\ \Phi_2\end{bmatrix},$$

where $H_{11}^{(1)},H_{12}^{(1)},H_{21}^{(1)},\ H_{22}^{(1)},H_{11}^{(2)},H_{12}^{(2)},H_{21}^{(2)}$ and $H_{22}^{(2)}$ are given in Eqs. (44a) and (44b).

Define a bi-vector Θ of H_1 by

$$\Theta_{H_1}=\frac{1}{2}\sum\,[\theta\wedge\Phi_1+\varsigma\wedge\Phi_2]$$

$$=\frac{1}{2}\sum\,[\theta\wedge(uEu-uE^{-1}u+E^{-1}v-vE)\theta+\theta\wedge(-uE^{-2}v+uEv)\varsigma$$
$$+\varsigma\wedge(vE^2u-vE^{-1}u)\theta+\varsigma\wedge(vE^2v+vEv-vE^{-2}v-vE^{-1}v)\varsigma]$$

$$=\frac{1}{2}\sum\,[\theta\wedge(uEu)\theta-\theta\wedge(uE^{-1}u)\theta+\theta\wedge(E^{-1}v)\theta-\theta\wedge(vE\theta)+\theta\wedge(-uE^{-2}v)\varsigma$$
$$+\theta\wedge(uEv)\varsigma+\varsigma\wedge(vE^2u\theta)-\varsigma\wedge(vE^{-1}u)\theta+\varsigma\wedge(vE^2v)\varsigma$$
$$+\varsigma\wedge(vEv\varsigma)-\varsigma\wedge(vE^{-2}v\varsigma)-\varsigma\wedge(vE^{-1}v)\varsigma]$$

$$=\frac{1}{2}\sum\,[\theta\wedge u\bar{u}\,\bar{\theta}-\bar{\theta}\wedge\bar{u}\,u\theta+\bar{\theta}\wedge v\,\theta-\theta\wedge v\,\bar{\theta}-\bar{\theta}\wedge\bar{u}\,v\,\varsigma+\theta\wedge u\bar{v}\,\bar{\varsigma}$$
$$+\varsigma\wedge v\,\bar{u}\,\bar{\theta}-\bar{\varsigma}\wedge\bar{v}u\,\theta+\varsigma\wedge v\bar{v}\,\bar{\varsigma}+\varsigma\wedge v\bar{v}\,\bar{\varsigma}-\bar{\varsigma}\wedge\bar{v}\,v\,\varsigma-\bar{\varsigma}\wedge\bar{v}\,v\,\varsigma], \tag{47}$$

where $\bar{\varsigma}=\varsigma_{n+1}$, $\underline{\varsigma}=\varsigma_{n-1}$, $\bar{\theta}=\theta_{n+1}$, $\underline{\theta}=\theta_{n-1}$, etc. Making use of the property of the wedge product, Eq. (47) can be written as

$$\Theta_{H_1}=\sum\,[u\,\bar{u}\,\theta\wedge\bar{\theta}+v\,\bar{\theta}\wedge\theta+\bar{u}\,v\,\varsigma\wedge\bar{\theta}+v\,\bar{v}\varsigma\wedge\bar{\varsigma}+u\,\bar{v}\,\theta\wedge\bar{\varsigma}+v\,\bar{v}\,\varsigma\wedge\bar{\varsigma}].$$

Proceeding further along the same lines as for the RT and BM lattice equations (1) and (2) we find that

$$PrV_{H_1\theta_1}(\Theta_{H_1})=0 \tag{48}$$

and so the operator H_1 is Hamiltonian. A similar conclusion can also be arrived at for the operator H_2 and therefore the BC lattice equation (3) can be written as

$$\begin{bmatrix}u_t\\ v_t\end{bmatrix}=H_1\begin{bmatrix}\dfrac{\delta\mathcal{H}_1}{\delta u}\\ \dfrac{\delta\mathcal{H}_1}{\delta v}\end{bmatrix}=H_2\begin{bmatrix}\dfrac{\delta\mathcal{H}_0}{\delta u}\\ \dfrac{\delta\mathcal{H}_0}{\delta v}\end{bmatrix},$$

where the Hamiltonian functionals are $\mathcal{H}_0(u,v)=-\Sigma\frac{1}{3}\log v$ and $\mathcal{H}_1(u,v)=\Sigma u$, indicating that it is a bi-Hamiltonian system. The bi-Hamiltonian formulation for the BC lattice equation has also been obtained by Belov *et al.* using a different approach.[30]

V. CONCLUSION

It is shown how to construct recursion operators systematically for PDDEs with two independent variables (one continuous and one discrete) using its generalized symmetries and then explained how to factorize it explicitly. This was illustrated for the relativistic toda (RT), Belov–Chaltikian (BC) and Blaszak–Marciniak (BM) lattice equations and it was shown that the RT and BC lattice equations admit (2×2) factorizable matrix recursion operators while the BM lattice equation possesses (3×3) factorizable matrix recursion operator. Furthermore, it is explicitly proved that the factorized operators are Hamiltonian in all the lattice equations. The existence of the multi-Hamiltonian structure for the above lattice equations is under investigation.

Kolakoski-$(2m,2n)$ are limit-periodic model sets

Bernd Sing[a)]
Universität Greifswald, Institut für Mathematik und Informatik, Jahnstr. 15a, 17487 Greifswald, Germany

(Received 5 August 2002; accepted 29 August 2002)

We consider (generalized) Kolakoski sequences on an alphabet with two even numbers. They can be related to a primitive substitution rule of constant length ℓ. Using this connection, we prove that they have pure point dynamical and pure point diffractive spectrum, where we make use of the strong interplay between these two concepts. Since these sequences can then be described as model sets with ℓ-adic internal space, we add an approach to "visualize" such internal spaces. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1521239]

I. INTRODUCTION

A one-sided infinite sequence ω over the alphabet $\mathcal{A}=\{1,2\}$ is called a (classical) *Kolakoski sequence* (named after W. Kolakoski who introduced it in 1965, see Ref. 12), if it equals the sequence defined by its run lengths, e.g.,

$$\begin{array}{lccccccccccc} \omega= & \underbrace{22} & \underbrace{11} & \underbrace{2} & \underbrace{1} & \underbrace{22} & \underbrace{1} & \underbrace{22} & \underbrace{11} & \underbrace{2} & \underbrace{11} & \cdots \\ & 2 & 2 & 1 & 1 & 2 & 1 & 2 & 2 & 1 & 2 & \cdots=\omega. \end{array} \tag{1}$$

Here, a *run* is a maximal subword consisting of identical letters. The sequence $\omega'=1\omega$ is the only other sequence which has this property.

One way to obtain ω of (1) is by starting with 2 as a seed and iterating the two substitutions

$$\sigma_0:\ \begin{array}{l}1\mapsto 2\\ 2\mapsto 22\end{array} \quad \text{and} \quad \sigma_1:\ \begin{array}{l}1\mapsto 1\\ 2\mapsto 11,\end{array}$$

alternatingly, i.e., σ_0 substitutes letters on even positions and σ_1 letters on odd positions (we begin counting at 0):

$$2 \mapsto 22 \mapsto 2211 \mapsto 221121 \mapsto 221121221 \mapsto \cdots.$$

Clearly, the iterates converge to the Kolakoski sequence ω (in the obvious product topology), and ω is the unique (one-sided) fixed point of this iteration.

One can generalize this by choosing a different alphabet $\mathcal{A}=\{p,q\}$ [we are only looking at alphabets with $\mathrm{card}(\mathcal{A})=2$]. Such a (generalized) Kolakoski sequence, which is also equal to the sequence of its run lengths, can be obtained by iterating the two substitutions

$$\sigma_0:\ \begin{array}{l}q\mapsto p^q\\ p\mapsto p^p\end{array} \quad \text{and} \quad \sigma_1:\ \begin{array}{l}q\mapsto q^q\\ p\mapsto q^p\end{array} \tag{2}$$

alternatingly. Here, the starting letter of the sequence is p. We will call such a sequence a Kolakoski-(p,q) sequence, or Kol(p,q) for short. The classical Kolakoski sequence ω of (1) is therefore denoted by Kol(2,1) [and ω' by Kol(1,2)].

[a)]Electronic mail: sing@uni-greifswald.de, URL: http://schubert.math-inf.uni-greifswald.de

While little is known about the classical Kolakoski sequence (see Ref. 6), and the same holds for all Kol(p,q) with p odd and q even or vice versa (see Ref. 22), the situation is more favorable if p and q are either both even or both odd. If both are odd, one can, in some cases, rewrite the substitution as a substitution of Pisot type (see Refs. 22 and 2), which can be described as (limit-) aperiodic model sets. By this method, Kol(3,1) is studied in Ref. 2 and shown to be a deformed model set. The case where both symbols are even will be studied below.

It is the aim of this article to determine structure and order of the sequences Kol$(2m,2n)$. This will require two steps: First we establish an equivalent substitution of constant length for Kol$(2m,2n)$ and analyze it with methods known from the theory of dynamical systems. Then we conclude diffractive properties from this.

Remark: Every Kol(p,q) can uniquely be extended to a bi-infinite (or two-sided) sequence. The one-sided sequence (to the right) is Kol(p,q) as explained above. The added part to the left is a reversed copy of Kol(q,p), e.g., in the case of the classical Kolakoski sequence of (1), this reads as

$$\ldots 11221221211221|22112122122112\ldots,$$

where "|" denotes the seamline between the one-sided sequences. Note that, if $q=1$ (or $p=1$), the bi-infinite sequence is mirror symmetric around the first position to the left (right) of the seamline. The bi-infinite sequence equals the sequence of its run lengths, if counting is begun at the seamline. Alternatively, one can get such a bi-infinite sequence by starting with $q|p$ and applying the two substitutions to get $\sigma_1(q)|\sigma_0(p)$ in the first step and so forth. This also implies that Kol(p,q) and Kol(q,p) will have the same spectral properties, and it suffices to study one of them.

II. Kol$(2m,2n)$ AS SUBSTITUTION OF CONSTANT LENGTH

If both letters are even numbers, i.e., $p=2m$ and $q=2n$ (with $m\neq n$, where we can concentrate on $m>n$ by the above discussion), one can build blocks of two letters and obtain an (ordinary) substitution. Setting $A=pp$ and $B=qq$, these substitutions and their *substitution matrix* $\mathbf{M}$ (sometimes called *incidence matrix* of the substitution) are given by

$$\sigma:\ \begin{matrix} A\mapsto A^mB^m \\ B\mapsto A^nB^n \end{matrix} \quad \text{and} \quad \mathbf{M}=\begin{pmatrix} m & m \\ n & n \end{pmatrix}, \tag{3}$$

where the entry M_{ij} is the number of occurrences of j in $\sigma(i)$ $(i,j\in\{A,B\}$; sometimes the transposed matrix is used). A bi-infinite fixed point can be obtained as follows:

$$B|A \mapsto A^nB^n|A^mB^m \mapsto \cdots.$$

This corresponds to the unique bi-infinite Kol$(2m,2n)$ according to our above convention.

A substitution ϱ is *primitive* if the corresponding substitution matrix $\mathbf{M}$ is primitive, i.e., $\mathbf{M}^k$ has positive entries only for some $k\in\mathbb{N}$. Equivalently, ϱ is primitive if there exists a positive integer $k\in\mathbb{N}$ such that every $i\in\mathcal{A}$ occurs in $\varrho^k(j)$ for all $j\in\mathcal{A}$. The vector $\boldsymbol{\ell}$ with components $\ell_i=|\varrho(i)|$, for $i\in\mathcal{A}$, is called the *length* of the substitution ϱ. If all ℓ_i are equal, ϱ is a substitution of *constant length*. For the substitution σ of (3), we have

$$\boldsymbol{\ell}=\begin{pmatrix} 2m \\ 2n \end{pmatrix},$$

which is therefore not of constant length (recall that $m\neq n$).

We will also need some notions from the theory of *dynamical systems*, (see Refs. 18 and 8 Chaps. 1, 5, and 7 for details). Let ϱ be a primitive substitution over $\mathcal{A}$ and $u\in\mathcal{A}^{\mathbb{Z}}$ a bi-infinite

fixed point of ϱ [i.e., $u=\varrho^k(u)$ for some $k\in\mathbb{N}$]. Denote by u_k the kth letter of $u(k\in\mathbb{Z})$ and by T the shift map [i.e., $(T(u))_k=u_{k+1}$]. Let $\mathcal{A}$ be equipped with the discrete and $\mathcal{A}^{\mathbb{Z}}$ with the corresponding product topology. If we set

$$X(\varrho)=\overline{\{T^k(u)|k\in\mathbb{Z}\}},$$

then $(X(\varrho),T)$ is a *dynamical system*. Since we require ϱ to be primitive, this dynamical system is *minimal* [i.e., $\{T^k(u)|k\in\mathbb{Z}\}$ is dense in $X(\varrho)$ for all $u\in(X(\varrho),T)$], does not depend on the chosen fixed point u (if more than one exists, which is possible in the two-sided situation) and has a unique probability measure μ associated with it. In other words, it is *strictly ergodic*. On the Hilbert space $\mathcal{L}^2(X(\varrho),\mu)$, we have the unitary operator

$$U:\ \mathcal{L}^2(X(\varrho),\mu)\to\mathcal{L}^2(X(\varrho),\mu),$$

$$f\qquad\mapsto f\circ T.$$

If $Uf=e^{i\lambda}f$ for some $0\neq f\in\mathcal{L}^2(X(\varrho),\mu)$, we call $e^{i\lambda}$ an *eigenvalue* of $(X(\varrho),T)$ and f the corresponding *eigenfunction*. The *spectrum* (of the dynamical system) is said to be a *pure point dynamical spectrum* (or *discrete spectrum*), if the eigenfunctions span $\mathcal{L}^2(X(\varrho),\mu)$. If 1 is the only eigenvalue and the only eigenfunctions are the constants, the spectrum is *continuous*. It is also possible that it has pure point and continuous components. In that case it is called *partially continuous*. Two dynamical systems (X,T) and (Y,S) are *isomorphic* (or *measure-theoretically isomorphic*), if there exists an invertible measurable map $\varphi:X\to Y$, almost everywhere defined, such that φ preserves the measure and the dynamics (i.e., $\varphi\circ T=S\circ\varphi$).

The spectral theory of primitive substitutions of constant length is well understood. By the following criterion, we know that the substitutions σ of (3) are related to substitutions of constant length.

Lemma 1 (Ref. 5, Sec. V, Theorem 1): Let ϱ *be a substitution of nonconstant length* ℓ. *If* ℓ *is a right eigenvector of the corresponding substitution matrix* $\mathbf{M}$, *then* $(X(\varrho),T)$ *is isomorphic to a substitution dynamical system generated by a substitution of constant length.* □

[Note that from (2), one can also construct a primitive substitution by distinguishing odd and even positions, e.g., for Kol(4,2) we would get (we use $\tilde{\cdot}$ as mark for even positions)

$$4\to 4\tilde{4}4\tilde{4},$$
$$\tilde{4}\to 2\tilde{2}2\tilde{2},$$
$$2\to 4\tilde{4},$$
$$\tilde{2}\to 2\tilde{2}.$$

Instead of (3), we would get a substitution with substitution matrix

$$\mathbf{M}=\begin{pmatrix} m & m & 0 & 0\\ 0 & 0 & m & m\\ n & n & 0 & 0\\ 0 & 0 & n & n\end{pmatrix}, \tag{4}$$

which is also primitive ($\mathbf{M}^2$ has positive entries only), but does not fulfill the requirements of Lemma 1. The eigenvalues of this $\mathbf{M}$ are $\{0,0,0,m+n\}$].

Since the substitutions σ of (3) fulfill the requirements of Lemma 1, the next task is now to construct the corresponding substitutions of constant length. This is achieved by numbering the A's and B's in (3), i.e., we make the substitutions $A^mB^m\to A_1\cdots A_mB_1\cdots B_m$, respectively $A^nB^n\to A_{m+1}\cdots A_{m+n}B_{m+1}\cdots B_{m+n}$. Then, the former substitutions (3) induce

$$\begin{aligned} A_1\cdots A_mB_1\cdots B_m &\mapsto (A_1\cdots A_mB_1\cdots B_m)^m(A_{m+1}\cdots A_{m+n}B_{m+1}\cdots B_{m+n})^m,\\ A_{m+1}\cdots A_{m+n}B_{m+1}\cdots B_{m+n} &\mapsto (A_1\cdots A_mB_1\cdots B_m)^n(A_{m+1}\cdots A_{m+n}B_{m+1}\cdots B_{m+n})^n. \end{aligned} \tag{5}$$

From this we get substitutions of constant length $m+n$ [the eigenvalue of the substitution matrix $\mathbf{M}$ in (3)] by parting the right sides in blocks of $m+n$ letters. For example, let $m=2$ and $n=1$. Then

$$A_1A_2B_1B_2 \mapsto A_1A_2B_1 \quad B_2A_1A_2 \quad B_1B_2A_3 \quad B_3A_3B_3,$$

$$A_3B_3 \mapsto A_1A_2B_1 \quad B_2A_3B_3,$$

and one extracts the following substitution of constant length 3:

$$\begin{aligned} A_1 &\mapsto A_1A_2B_1,\\ A_2 &\mapsto B_2A_1A_2,\\ B_1 &\mapsto B_1B_2A_3,\\ B_2 &\mapsto B_3A_3B_3,\\ A_3 &\mapsto A_1A_2B_1,\\ B_3 &\mapsto B_2A_3B_3. \end{aligned} \tag{6}$$

In the same way, we get substitutions of constant length $m+n$ from (5). Note that these substitutions are all primitive since [compare to (5)] in every block of $2m^2+2n$ successive letters (note that we use $m>n$) every letter of $\mathcal{A}=\{A_1,\ldots,A_{m+n},B_1,\ldots,B_{m+n}\}$ occurs, so if $(m+n)^{k_0} \geqslant 2m^2+2n$, then $\mathbf{M}^{k_0}$ has positive entries only (this holds for $k_0\geqslant 3$). Note also that we can reduce the alphabet by one letter by identifying $A_1=A_{m+1}$ [$A_1=A_3$ in the example (6)], because both A's always yield the same substitution.

Let us now determine the positions of A_1 in the sequence u generated by (5). They are given by $\alpha\cdot 2m+\beta\cdot 2n$ for some $\alpha,\beta\in\mathbb{Z}$ (e.g., $0, 2m, 4m,\ldots, 2m^2, 2m^2+2n, 2m^2+4n, \ldots, 2m^2+2nm,\ldots$). Therefore we get $\gcd\{i|u_i=u_0=A_1\}=\gcd(2m,2n)=2\gcd(m,n)$. The *height* $h(\varrho)$ of a primitive substitution ϱ of constant length ℓ which generates a sequence u is defined as

$$h(\varrho)=\max\{k\geqslant 1|\gcd(k,\ell)=1 \text{ and } k \text{ divides } \gcd\{i|u_i=u_0\}\}. \tag{7}$$

Then the following lemma holds.

Lemma 2: Let $(X(\varrho),T)$ be a dynamical system, where ϱ is a primitive substitution of constant length ℓ and height $h(\varrho)$. Then the pure point part of this dynamical system is isomorphic to the dynamical system $(\mathbb{Z}_\ell\times\mathbb{Z}/h(\varrho)\mathbb{Z},\tau)$, where τ is the addition of (1,1) on the Abelian group $\mathbb{Z}_\ell\times\mathbb{Z}/h(\varrho)\mathbb{Z}$, i.e., the direct product of the ℓ-adic integers $\mathbb{Z}_\ell$ and the cyclic group $\mathbb{Z}/h(\varrho)\mathbb{Z}$ of order $h(\varrho)$. Therefore the pure point dynamical spectrum is given by

$$\{e^{2\pi i\, n/\ell^m + 2\pi i k/h(\varrho)} |\, k,n\in\mathbb{Z},m\in\mathbb{N}\}.$$

Note that

$$\mathbb{Z}_\ell\simeq\mathbb{Z}_{p_1}\times\cdots\times\mathbb{Z}_{p_r}, \tag{8}$$

where $p_1,\ldots,p_r$ are the distinct primes dividing ℓ (see Ref. 16, Sec. 3.10).

Proof: The lemma is just a reformulation of Ref. 5, Theorem II.13 (compare with Ref. 18, Sec. VI and Ref. 8, Sec. 7.3). □

Proposition 1: Suppose $(X(\sigma),T)$ *has pure point dynamical spectrum, where* σ *is the substitution of (3). Then*

$$(X(\sigma),T)\simeq\begin{cases}(\mathbb{Z}_{m+n}\times\mathbb{Z}/2\mathbb{Z},\tau) & \text{if } m+n \text{ is odd,}\\ (\mathbb{Z}_{m+n},\tilde{\tau}) & \text{if } m+n \text{ is even,}\end{cases}$$

where τ *is the addition of* (1,1) and $\tilde{\tau}$ *the addition of* 1.

Proof: For the substitution (5) of constant length $\ell=m+n$, we have already seen that $\gcd\{i|u_i=u_0\}=2\gcd(m,n)$. Therefore, using (7), the height of this substitution is 2 if ℓ is odd and 1 if ℓ is even. The dynamical system of the substitution (5) is isomorphic to $(X(\sigma),T)$ by Lemma 1, therefore they have the same spectrum. The remaining statement follows from Lemma 2. □

We want to show that the spectrum of σ is indeed pure point. For this we use slightly different substitutions of constant length that we deduce from σ. We substitute $A^mB^m\to a_1\cdots a_m$ and $A^nB^n\to b_1\cdots b_n$ [so in (5) we build essentially blocks of two, e.g., $a_1=A_1A_2$]. We get

$$\begin{aligned}a_1\cdots a_m &\mapsto (a_1\cdots a_m)^m(b_1\cdots b_n)^m,\\ b_1\cdots b_n &\mapsto (a_1\cdots a_m)^n(b_1\cdots b_n)^n,\end{aligned}\tag{9}$$

which again gives substitutions of constant length $\ell=m+n$. They are all primitive substitutions by the same argument as before (in every block of m^2+n successive letters every letter occurs). In the case $n>1$, we can reduce the alphabet by one letter by identifying $a_1=b_1\mapsto a_1\cdots a_ma_1\cdots a_n$. So we have two cases, $n=1$ with substitutions

$$\tilde{\theta}:\begin{cases}a_1 \mapsto a_1\ a_2\ a_3\ \dots\ a_{m-1}\ a_m\ a_1,\\ a_2 \mapsto a_2\ a_3\ a_4\ \dots\ a_m\ a_1\ a_2,\\ \vdots\quad \dots\\ a_{m-1} \mapsto a_{m-1}\ a_m\ a_1\ \dots\ a_{m-3}\ a_{m-2}\ a_{m-1},\\ a_m \mapsto a_m\ b_1\ b_1\ \dots\ b_1\ b_1\ b_1,\\ b_1 \mapsto a_1\ a_2\ a_3\ \dots\ a_{m-1}\ a_m\ b_1,\end{cases}\tag{10}$$

and $n>1$ with substitutions θ (it is cumbersome to write down such a θ in general form, but we will investigate its structure in the next section). Now the height of θ and $\tilde{\theta}$ is always 1, because if $n>1$ we get $\gcd\{i|u_0=u_i=a_1\}=\gcd(m,n)$, and if $n=1$ we get $\gcd\{i|u_0=u_i=a_1\}=\gcd(m,m+1)=1$.

Let ϱ be a primitive substitution of constant length ℓ and height $h(\varrho)=1$. One says that ϱ admits a *coincidence*, if there exist a $k\in\mathbb{N}$ and $j<\ell^k$ such that $\varrho^k(i)_j$ is the same for all $i\in\mathcal{A}$ [the jth letter of each $\varrho^k(i)$ is the same, i.e., ϱ^k admits a column of identical values].

Lemma 3 (Ref. 5, Sec. III, Theorem 7): Let $(X(\varrho),T)$ *be a substitution dynamical system of constant length and height* $h(\varrho)=1$. *Then* $(X(\varrho),T)$ *has pure point dynamical spectrum if and only if* ϱ *admits a coincidence.* □

If a substitution has height $h>1$, one gets a substitution of height 1 by combining letters into blocks of h letters. If this new substitution has pure point dynamical spectrum, so has the original substitution of height h (see Ref. 5). Obviously, we get the following: if the substitutions θ and $\tilde{\theta}$ [which arise from (9)] admit coincidences, then the dynamical systems defined by σ of (3) have pure point dynamical spectrum.

III. COINCIDENCES AND COINCIDENCE MATRIX

Let us first check $\tilde{\theta}$ of (10) for coincidences. For this we begin by exploring the structure: $\tilde{\theta}(a_1)$ has two a_1's at position 0 and m, $\tilde{\theta}(a_2)$ has an a_1 at position $m-1$, etc. We get an a_1 in $\tilde{\theta}(a_k)$ at position $m+1-k$ for $1\leqslant k\leqslant m-1$. Similar arguments show that there is an a_m in $\tilde{\theta}(a_k)$

at position $m-k$ for $1\leqslant k\leqslant m$ and at $m-1$ in $\tilde{\theta}(b_1)$. Now, $\tilde{\theta}(a_m)$ has b_1's at all positions $1,\ldots,m$. Furthermore, $\tilde{\theta}(b_1)$ has a b_1 at position m and shares the first m letters with $\tilde{\theta}(a_1)$. Schematically, we get the following structure of $\tilde{\theta}$:

$$\begin{array}{lllllllll}
a_1 & \mapsto & * & * & * & \ldots & * & a_m & a_1, \\
a_2 & \mapsto & \cdot & \cdot & \cdot & \ldots & a_m & a_1 & \cdot, \\
\vdots & & & & & / & / & & \\
\vdots & & & & / & / & & & \\
a_{m-1} & \mapsto & \cdot & a_m & a_1 & \ldots & \cdot & \cdot & \cdot, \\
a_m & \mapsto & a_m & b_1 & b_1 & \ldots & b_1 & b_1 & b_1, \\
b_1 & \mapsto & * & * & * & \ldots & * & a_m & b_1.
\end{array} \tag{11}$$

Here we have omitted (.) all letters that are not necessary and by $*$ we denote the part that $\tilde{\theta}(a_1)$ and $\tilde{\theta}(b_1)$ share. We now check for *pairwise coincidences*, i.e., for $i_1,i_2\in\mathcal{A}$ we check whether there is a $k\in\mathbb{N}$ and a $j<\ell^k=(m+1)^k$ such that $\sigma^k(i_1)_j=\sigma^k(i_2)_j$.

So we pick $i_1,i_2\in\mathcal{A}=\{a_1,\ldots,a_m,b_1\}$, $i_1\neq i_2$. Suppose $i_1\neq a_m$ (otherwise we interchange i_1 and i_2). Then i_2 either equals a_m or at least $\tilde{\theta}(i_2)$ has an a_m [every $\tilde{\theta}(i)$, $i\in\mathcal{A}$ has one]. In the first case take $k=1$, otherwise $k=2$. Observe that there are m successive b_1's in $\tilde{\theta}(a_m)$. So, if we look at $\tilde{\theta}^k(i_1)$ and $\tilde{\theta}^k(i_2)$, we get the following: On the one hand, there are m successive b_1's somewhere in $\tilde{\theta}^k(i_2)$, say at positions $j,\ldots,j+m-1$. On the other hand, in $\tilde{\theta}^k(i_1)$, there is at one of these positions $j,\ldots,j+m-1$ either a b_1, and we have a pairwise coincidence, or an a_1. Say there is an a_1 at $\tilde{j}$ with $j\leqslant\tilde{j}\leqslant j+m-1$. Then in $\tilde{\theta}^{k+1}(i_1)$ and $\tilde{\theta}^{k+1}(i_2)$ we have pairwise coincidences at positions $\tilde{j}\cdot\ell,\ldots,\tilde{j}\cdot\ell+m$ [the $*$'s of (11)].

From this pairwise coincidences we get a coincidence inductively: We start with two letters i_1,i_2 and after $k_1\leqslant 3$ substitutions we have a pairwise coincidence, say at j_1. Now a third letter i_3 may have something else at $\tilde{\theta}^{k_1}(i_3)_{j_1}$, but whatever it is, in $\tilde{\theta}^{k_1+k_2}$ ($k_2\leqslant 3$) all three coincide somewhere at a position j_2 with $j_1\cdot\ell^{k_2}\leqslant j_2<(j_1+1)\cdot\ell^{k_2}$. Since there are $\mathrm{card}(\mathcal{A})=m+1$ letters, we get a coincidence after at most $3\cdot m$ substitutions [i.e., there is a $j<\ell^{3m}$ such that all $\tilde{\theta}^{3m}(i)_j$ are the same for all $i\in\mathcal{A}$].

The structure of θ is different. We have $\mathcal{A}=\{a_1,\ldots,a_m,b_2,\ldots b_n\}$ and therefore $\mathrm{card}(\mathcal{A})=m+n-1$. Let us first show an example, with $m=5$ and $n=3$:

$$\begin{array}{lllllllll}
a_1 & \mapsto & a_1 & a_2 & a_3 & a_4 & a_5 & a_1 & a_2 & a_3, \\
a_2 & \mapsto & a_4 & a_5 & a_1 & a_2 & a_3 & a_4 & a_5 & a_1, \\
a_3 & \mapsto & a_2 & a_3 & a_4 & a_5 & a_1 & a_2 & a_3 & a_4, \\
a_4 & \mapsto & a_5 & a_1 & b_2 & b_3 & a_1 & b_2 & b_3 & a_1, \\
a_5 & \mapsto & b_2 & b_3 & a_1 & b_2 & b_3 & a_1 & b_2 & b_3, \\
b_2 & \mapsto & a_4 & a_5 & a_1 & a_2 & a_3 & a_4 & a_5 & a_1, \\
b_3 & \mapsto & b_2 & b_3 & a_1 & b_2 & b_3 & a_1 & b_2 & b_3.
\end{array} \tag{12}$$

Since the positions of two consecutive a_1's in the sequence differ by at most m, there is an a_1 in every $\theta(i)$ with $i\in\mathcal{A}$ (note that θ is a substitution of constant length $\ell=m+n$). Again we look for pairwise coincidences, so choose $i_1,i_2\in\mathcal{A}$. Then there is (at least) one a_1 in $\theta(i_1)$, say at position j_1, and (at least) one in $\theta(i_2)$, say at position j_2. Since there can be more than one a_1 in either, we choose j_1,j_2 such that $|j_1-j_2|$ is minimal. We further choose i_1,i_2 such that $j_1<j_2$ (in the case $j_1=j_2$, e.g., $i_1=a_1$ and $i_2=a_5$ in the above example, we are already done). If we look at $\theta(i_1)$ and $\theta(i_2)$, there are two cases each (and therefore four cases, if we look at the combina-

tions): Either $\theta(i_1)_{j_1+1}=a_2,\ldots,\theta(i_1)_{j_2}=a_{j_2+1-j_1}$ or $\theta(i_1)_{j_1+1}=b_2,\ldots,\theta(i_1)_{j_2}=b_{j_2+1-j_1}$ and either $\theta(i_2)_{j_1}=a_{m+1+j_1-j_2},\ldots,\theta(i_2)_{j_2-1}=a_m$ or $\theta(i_2)_{j_1}=b_{m+1+j_1-j_2},\ldots,\theta(i_2)_{j_2-1}=b_m$. This is all that can occur by the chosen minimality of $j_2-j_1>0$.

Now we examine the case where $\theta(i_1)_{j_1+1}=a_2,\ldots,\theta(i_1)_{j_2}=a_{j_2+1-j_1}$ and $\theta(i_2)_{j_1}=a_{m+1+j_1-j_2},\ldots,\theta(i_2)_{j_2-1}=a_m$. We want to show that $\theta^2(i_1)$ and $\theta^2(i_2)$ have a pairwise coincidence. Let us look at the a_1's in $\theta(a_i)$ only (we use again the above example, but the reasons given apply for arbitrary m, n):

$$
\begin{aligned}
a_1 &\mapsto \overset{1}{\boldsymbol{a}}_1\ a_2\ a_3\ a_4\ a_5\ \overset{2}{\boldsymbol{a}}_1\ a_2\ a_3,\\
a_2 &\mapsto a_4\ a_5\ \overset{3}{\boldsymbol{a}}_1\ a_2\ a_3\ a_4\ a_5\ \overset{4}{\boldsymbol{a}}_1,\\
a_3 &\mapsto a_2\ a_3\ a_4\ a_5\ \overset{5}{\boldsymbol{a}}_1\ a_2\ a_3\ a_4,\\
a_4 &\mapsto a_5\ \overset{6}{\boldsymbol{a}}_1\ b_2\ b_3\ \overset{7}{\boldsymbol{a}}_1\ b_2\ b_3\ \overset{8}{\boldsymbol{a}}_1,\\
a_5 &\mapsto b_2\ b_3\ \overset{9}{\boldsymbol{a}}_1\ b_2\ b_3\ \overset{10}{\boldsymbol{a}}_1\ b_2\ b_3.
\end{aligned}
\tag{13}
$$

First we number the a_1's with 1,...,2m [left to right in $\theta(a_i)$ and top $(i=1)$ to bottom $(i=m)$] and we will speak of the kth a_1 (with $1\leqslant k\leqslant 2m$) according to that number. We observe the following:

(i) Let $k<m$. If the kth a_1 occurs at position $j\geqslant n$ in $\theta(a_i)$, then the $(k+1)$-st a_1 occurs at position $j-n$ in $\theta(a_{i+1})$. If the kth a_1 occurs at position $j<n$, then the $(k+1)$-st a_1 occurs at $j+m$ in the same $\theta(a_i)$.

(ii) Let $k>m+1$. If the kth a_1 occurs at position $j\geqslant n$, then the $(k-1)$-st a_1 occurs at $j-n$ in the same $\theta(a_i)$. If the kth a_1 occurs at position $j<n$ in $\theta(a_i)$, then the $(k-1)$-st a_1 occurs at position $j+m$ in $\theta(a_{i-1})$. [Notice the contrary behavior of the first two observations in going to a different or staying in the same $\theta(a_i)$ and the position of the corresponding a_1. We call this the "contrary line break property."]

(iii) The second and the $(2m)$-th a_1 occur at the same position m in $\theta(a_1)$, respectively $\theta(a_m)$. With the previous two observations we get the kth and the $(2m+2-k)$-th a_1 occur at the same position for $1<k<m$.

(iv) The first and the $(m+1)$-st a_1 occur in $\theta(a_i)$ where there is at least one more a_1. This is obvious for the first a_i; for the $(m+1)$-st observe that if it occurs at position $j<m$, then there is also one at $j+n$, and if it occurs at position $j\geqslant m$, then there is also one at $j-m$.

These observations are based on the facts that the length of the substitution is $m+n$ and that the position of the a_1's in the sequence are separated by m or n only. Now the fact that the a_i always occur in ascending order (i.e., we have $a_1a_2a_3\cdots$ and not $a_3a_1a_2\cdots$ or something else) together with the first two observations essentially gives us an algorithm, which always yields a pairwise coincidence in $\theta^2(i_1)$ and $\theta^2(i_2)$. Let us explain it in our example (13): Suppose we have $i_1=a_2$ and $i_2=a_3$. Then we have $j_1=2$ and $j_2=4$. The first step is always to reduce j_2 by one, so we have $j_2'=3$. We have $j_2'\neq j_1$, but there is a second a_1 in $\theta(a_m)$ (a_m occurs at position j_2' in i_2!), so we can increment j_1 by 1 and get $j_1'=3$. We have $j_1'=j_2'$, and $\theta(\theta(a_2)_{j_1'})=\theta(a_2)$ and $\theta(\theta(a_3)_{j_2'})=\theta(a_5)$ both have an a_1 at position 2 (the third respectively the ninth a_1). Therefore we get a pairwise coincidence in $\theta^2(a_2)$ and $\theta^2(a_3)$. This algorithm relies on the "contrary line break property."

The other three cases are mutatis mutandis the same [see the positions of the a_1's in (12)]. So, starting with any two i_1, $i_2\in\mathcal{A}$ we get a pairwise coincidence in $\theta^2(i_1)$ and $\theta^2(i_2)$. Inductively

like before, we get a coincidence after at most $2\cdot(m+n-2)$ substitutions. Therefore we have established the following.

Theorem 1: $(X(\sigma),T)$ *with* σ *of* (3) *has pure point dynamical spectrum. Also, the dynamical system of the substitutions of constant length as defined implicitly in* (5) *and* $\theta,\tilde{\theta}$ *of* (9) *and* (10) *have pure point dynamical spectrum.* □

Proposition 1′: We have

$$(X(\sigma),T)\simeq\begin{cases}(\mathbb{Z}_{m+n}\times\mathbb{Z}/2\mathbb{Z},\tau) & \text{if } m+n \text{ is odd,}\\ (\mathbb{Z}_{m+n},\tilde{\tau}) & \text{if } m+n \text{ is even,}\end{cases}\tag{14}$$

where τ *is the addition of* (1,1) *and* $\tilde{\tau}$ *the addition of* 1. □

Remark: Let ϱ be a primitive substitution of constant length ℓ and height 1 over the alphabet $\mathcal{A}=\{1,\ldots,r\}$. Then we can define the coincidence matrix $\mathbf{C}$, which is a quadratic $r\cdot(r+1)/2\times r\cdot(r+1)/2$ matrix. The entries are defined as follows (where $t\leqslant s$ and $v\leqslant u$):

$$C_{(st)(uv)}=\begin{cases}|\{j|\varrho(s)_j=u\ \wedge\ \varrho(t)_j=u\}|, & \text{if } u=v,\\ |\{j|\varrho(s)_j=u\ \wedge\ \varrho(t)_j=v\}|+|\{j|\varrho(s)_j=v\ \wedge\ \varrho(t)_j=u\}|, & \text{if } u\neq v.\end{cases}$$

Note that the substitution matrix $\mathbf{M}$ is a submatrix of $\mathbf{C}$, since $M_{su}=C_{(ss)(uu)}$. Also, $\mathbf{C}$ has row sums ℓ. With this definition, Lemma 3 reads as follows.

Proposition 2 (Ref. 18, Proposition X.1): For $(X(\varrho),T)$ *are equivalent:*

(i) $(X(\varrho),T)$ *has pure point dynamical spectrum.*
(ii) ℓ *is a simple eigenvalue of the corresponding coincidence matrix* $\mathbf{C}$. □

[Note, however, that we use a definition of $\mathbf{C}$ different from Ref. 18. The coincidence matrix there has dimension $r^2\times r^2$ and has the form (with the proper enumeration of the pairs)

$$\begin{pmatrix}M & 0 & 0\\ R & P & Q\\ R & Q & P\end{pmatrix}^t,$$

while the one defined above has the form

$$\begin{pmatrix}M & 0\\ R & P+Q\end{pmatrix}.$$

Here M, P, Q are quadratic matrices and M is the substitution matrix. Proposition 2 is true for both matrices, the proof is analogous.]

Obviously, ℓ is an eigenvalue of $\mathbf{C}$ ($\mathbf{C}/\ell$ is a stochastic matrix with row sum 1). Now the above proof of Theorem 1 translates to the following statements for $\mathbf{C}$:

(a) For $\tilde{\theta}$, the third power of the coincidence matrix, $\mathbf{C}^3$, has a column $(C^3_{(st)(a_1a_1)})$ with nonzero entries only.
(b) For θ, the square of the coincidence matrix, $\mathbf{C}^2$, has a column $(C^2_{(st)(a_1a_1)})$ with nonzero entries only.

Lemma 4 (Ref. 18, Lemma X.3): Let $\mathbf{B}$ *be a quadratic matrix with non-negative integral entries and row sums* ℓ. *If* $B_{ij}\geqslant 1$ *for all* i *and a fixed* j, *then* ℓ *is a simple eigenvalue of* $\mathbf{B}$. □

This establishes the desired result that ℓ is a simple eigenvalue for the coincidence matrix $\mathbf{C}$ of θ ($\tilde{\theta}$), since ℓ^2 (ℓ^3) is a simple eigenvalue of $\mathbf{C}^2$ ($\mathbf{C}^3$).

We end this section with an example. We take $\tilde{\theta}$ for $m=2$, $n=1$ and therefore the substitution

$$\begin{aligned} a_1 &\mapsto a_1\ a_2\ a_1,\\ a_2 &\mapsto a_2\ b_1\ b_1,\\ b_1 &\mapsto a_1\ a_2\ b_1. \end{aligned} \tag{15}$$

We get the coincidence matrix

$$\mathbf{C}=\begin{pmatrix} 2&1&0&0&0&0\\ 0&1&2&0&0&0\\ 1&1&1&0&0&0\\ 0&0&0&1&1&1\\ 1&1&0&0&1&0\\ 0&0&1&1&0&1 \end{pmatrix},\quad \mathbf{C}^2=\begin{pmatrix} 4&3&2&0&0&0\\ 2&3&4&0&0&0\\ 3&3&3&0&0&0\\ 1&1&1&2&2&2\\ 3&3&2&0&1&0\\ 1&1&2&2&1&2 \end{pmatrix}.$$

Here, already $\mathbf{C}^2$ has columns with positive entries only. The eigenvalues of $\mathbf{C}$ are $\{0,0,1,1,2,3\}$.

IV. MODEL SETS AND DIFFRACTION

A *model set* $\Lambda(\Omega)$ *(or cut-and-project set) in physical space* $\mathbb{R}^d$ is defined within the following general cut-and-project scheme (see Refs. 17 and 1)

$$\begin{array}{ccccc} \mathbb{R}^d & \xleftarrow{\ \pi\ } & \mathbb{R}^d\times H & \xrightarrow{\ \pi_{\mathrm{int}}\ } & H\\ & {\scriptstyle 1-1}\nwarrow & \cup & \nearrow{\scriptstyle \mathrm{dense}} & \\ & & \Gamma & & \end{array}$$

where the *internal space* H is a locally compact Abelian group, and $\Gamma\subset\mathbb{R}^d\times H$ is a *lattice*, i.e., a co-compact discrete subgroup of $\mathbb{R}^d\times H$. The projection $\pi_{\mathrm{int}}(\Gamma)$ is assumed to be dense in internal space, and the projection π into physical space has to be one-to-one on Γ. The model set $\Lambda(\Omega)$ is

$$\Lambda(\Omega)=\{\pi(x)\,|\,x\in\Gamma,\ \ \pi_{\mathrm{int}}(x)\in\Omega\}\subset\mathbb{R}^d,$$

where the *window* $\Omega\subset H$ is a relatively compact set with nonempty interior.

Let u be a bi-infinite sequence over $\mathcal{A}=\{1,\ldots,r\}$ and $\nu:\mathcal{A}\to\mathbb{C}$, $i\mapsto c_i$ be a (bounded) function which assigns to every letter a complex number (the *scattering strength*). Then the *autocorrelation coefficients* $\eta(z)$ are given by

$$\eta(z)=\lim_{N\to\infty}\frac{1}{2N+1}\sum_{n=-N}^{N}\overline{\nu(u_n)}\cdot\nu(u_{n+z})$$

provided the limits exist. We write δ_z for the Dirac measure at z, i.e., $\delta_z(f)=f(z)$ for f continuous. Then the *correlation measure* γ of u is given by

$$\gamma=\sum_{z\in\mathbb{Z}}\eta(z)\ \delta_z,$$

and the *diffraction spectrum* is given by the Fourier transform $\hat{\gamma}$ of this measure. [So we think of u as an atomic chain, where there is an atom of type u_n at position n with scattering strength $\nu(u_n)$. We represent this atom as $\nu(u_n)\cdot\delta_n$ and therefore get a (countable) sum of weighted Dirac measures with autocorrelation γ.] If $\hat{\gamma}$ is a sum of Dirac measures only, i.e., $\hat{\gamma}=\Sigma_{k\in S}\ d_k\cdot\delta_k$ with

a countable set S [for any choice of complex numbers $(c_i)_{i\in\mathcal{A}}$], then u is *pure point diffractive*, i.e., the diffraction spectrum consists of *Bragg peaks* only. Also, the d_k's are the square of the absolute value of the corresponding *Fourier–Bohr coefficient* at k and therefore non-negative (real) numbers. If there is no Dirac measure in $\hat{\gamma}$, except one at position 0, δ_0, which is determined by the density of the structure only, then the diffraction spectrum is *continuous*.

For substitutive systems, the diffraction spectrum and the spectrum of the corresponding dynamical system are closely related, see Refs. 7, 19, 21, 13, and 14.

Proposition 3 (Ref. 13, Corollary 1): Let ϱ be a primitive substitution of constant length ℓ with height 1 over $\mathcal{A}=\{1,\ldots,r\}$, where u is a fixed bi-infinite word of ϱ. Define $U_i=\{j\in\mathbb{Z}|u_j=i\}$ for all $i\in\mathcal{A}$. We have $\mathbb{Z}=U_1\dot{\cup}\cdots\dot{\cup}U_r$, where $\dot{\cup}$ denotes disjoint union. Then the following are equivalent:

(i) *ϱ admits a coincidence.*
(ii) *The U_i's are model sets for*

$$\begin{array}{ccccc} \mathbb{R} & \xleftarrow{\ \pi\ } & \mathbb{R}\times\mathbb{Z}_\ell & \xrightarrow{\ \pi_{\mathrm{int}}\ } & \mathbb{Z}_\ell \\ \cup & {\scriptstyle 1-1}\nwarrow & \cup & \nearrow_{\mathrm{dense}} & \cup \\ \mathbb{Z} & \longleftarrow & \Gamma=\{(z,z)|z\in\mathbb{Z}\} & \longrightarrow & \mathbb{Z} \end{array}$$

(iii) *The sequence u and the sets U_i are pure point diffractive.* (By this we mean the special choice of ν, where we set $c_i=1$ and $c_j=0$ for all $j\neq i$.) □

Note that properties ''one-to-one'' and ''dense'' are obvious; the interesting part is that there exist relatively compact windows (with respect to the ℓ-adic topology) with non-empty(!) interior. We will discuss this point in the next section.

With this Proposition, we know that θ and $\tilde{\theta}$ [as defined implicitly in (9)] generate sequences which are pure point diffractive. But we got every letter $i\in\mathcal{A}$ for the appropriate alphabet for θ, $\tilde{\theta}$ by building four-letter blocks in the substitution rule (2), e.g., in (15) we have $a_1=4444$, $a_2=2222$ and $b_1=4422$. Such a deterministic substitution rule [i.e., Kol$(2m,2n)$ is *local derivable* from the sequence generated by θ, respectively $\tilde{\theta}$] does not change the nature of the diffraction spectrum, only the Fourier-Bohr coefficients. The diffraction spectrum of Kol$(2m,2n)$ can be calculated from the one generated by θ, $\tilde{\theta}$ as follows: For Kol$(2m,2n)$ we only have scattering strengths c'_{2m} and c'_{2n}. If we therefore choose c_i ($i\in\mathcal{A}$ with respect to θ, $\tilde{\theta}$) according to its four-letter-composition in $\{2m,2n\}$, then the diffraction spectrum $\hat{\gamma}$ of θ, $\tilde{\theta}$ is also a diffraction spectrum of Kol$(2m,2n)$, where Kol$(2m,2n)$ is realized as an atom chain with atoms not on $\mathbb{Z}$ but $\mathbb{Z}/4$ [we get the diffraction spectrum of Kol$(2m,2n)$ realized on $\mathbb{Z}$ by a simple rescaling with the factor 4]. For the example (15), this means that we choose

$$c_{a_1}=c'_4\cdot(1+e^{-2\pi i/4}+e^{-2\,2\pi i/4}+e^{-3\,2\pi i/4})=0,$$

$$c_{a_2}=c'_2\cdot(1+e^{-2\pi i/4}+e^{-2\,2\pi i/4}+e^{-3\,2\pi i/4})=0,$$

$$c_{b_1}=c'_4\cdot(1+e^{-2\pi i/4})+c'_2\cdot(e^{-2\,2\pi i/4}+e^{-3\,2\pi i/4})=(1-i)(c'_4-c'_2).$$

So in this case, the diffraction spectrum of Kol(4,2) is given by the one of U_{b_1} only. All Kol$(2m,2n)$ are pure point diffractive.

Lemma 5: For a sequence $u=\phi(v)$, where v is a bi-infinite fixed point of a primitive substitution and $\phi:\mathcal{A}_v\to\mathcal{A}_u^*$ is a morphism [where u (v) is a sequence over $\mathcal{A}_u$ ($\mathcal{A}_v$)], the following statements are equivalent:

(i) *The dynamical system of u has pure point dynamical spectrum.*
(ii) *u has pure point diffraction spectrum.*

Proof: This is a (weak) conclusion of Ref. 14, Theorem 3.2. □

We therefore obtain the following.

Theorem 2: *All* Kol$(2m,2n)$ *have pure point diffraction and pure point dynamical spectrum*. □

Remarks: The dynamical system of Kol$(2m,2n)$ is isomorphic to

$$\begin{aligned}&(\mathbb{Z}_{m+n}\times\mathbb{Z}/4\mathbb{Z},\tau) \quad \text{if } m+n\equiv 1,3 \quad (4),\\ &(\mathbb{Z}_{m+n}\times\mathbb{Z}/2\mathbb{Z},\tau) \quad \text{if } m+n\equiv 2 \quad (4),\\ &(\mathbb{Z}_{m+n},\tilde{\tau}) \quad \text{if } m+n\equiv 0 \quad (4),\end{aligned} \tag{16}$$

where τ is the addition of (1,1) and $\tilde{\tau}$ the addition of 1. This can be seen by the fact that we get Kol$(2m,2n)$ from the one generated by σ of (3) by the substitution $A=pp$, $B=qq$, which corresponds just to doubling each letter in the latter one [see the substitution matrices in (3) and (4)].

If we consider how to get from (5), respectively (9), to Kol$(2m,2n)$ and compare this to Proposition 3, we get [compare with (16)] Kol$(2m,2n)$, respectively U_{2m}, U_{2n} are model sets for

$$\begin{array}{ccccc}\mathbb{R} & \xleftarrow{\pi} & \mathbb{R}\times\mathbb{Z}_{m+n}\times F & \xrightarrow{\pi_{\text{int}}} & \mathbb{Z}_{m+n}\times F\\ & {\scriptstyle 1-1}\nwarrow & \cup & \nearrow_{\text{dense}} & \\ & & \Gamma=\{(z,z,z \mod \text{ord}(F))\,|\,z\in\mathbb{Z}\} & & \end{array}$$

where

$$F\simeq\begin{cases}\mathbb{Z}/4\mathbb{Z} & \text{if } m+n\equiv 1,3 \quad (4),\\ \mathbb{Z}/2\mathbb{Z} & \text{if } m+n\equiv 2 \quad (4),\\ \{0\} & \text{if } m+n\equiv 0 \quad (4)\,.\end{cases} \tag{17}$$

(As before, $\mathbb{Z}_{m+n}\simeq\mathbb{Z}_{p_1}\times\cdots\times\mathbb{Z}_{p_r}$, where $p_1,\ldots,p_r$ are the distinct primes dividing $m+n$.) The diffraction spectrum calculated from this cut-and-project scheme is consistent with the previous one, since the Fourier–Bohr coefficients which arise in each $\mathbb{Z}_{m+n}$ separately are weighted by factors 1, $e^{-2\pi i/4}$, $e^{-2\,2\pi i/4}$ or $e^{-3\,2\pi i/4}$ which depend on the element of the cyclic group $\mathbb{Z}/4\mathbb{Z}$ (similar for the case $\mathbb{Z}/2\mathbb{Z}$) (compare with Ref. 3—but this is just how we calculated the c_i's from c'_{2m} and c'_{2n}).

Let us show how one calculates the diffraction spectrum of U_{b_1} of (15) explicitly. This substitution can be written in recursive equations for U_{a_1}, U_{a_2} and U_{b_1} by observing at which position in which substitution a certain letter occurs [e.g., b_1 occurs in $\tilde{\theta}(a_2)$ at positions 1 and 2 and in $\tilde{\theta}(b_1)$ at position 2]:

$$\begin{aligned}U_{a_1}&=(3U_{a_1})\ \cup\ (3U_{a_1}+2)\ \cup\ (3U_{b_1}),\\ U_{a_2}&=(3U_{a_1}+1)\ \cup\ (3U_{a_2})\ \cup\ (3U_{b_1}+1),\\ U_{b_1}&=(3U_{a_2}+1)\ \cup\ (3U_{a_2}+2)\ \cup\ (3U_{b_1}+2),\end{aligned}$$

where $rU_i+s=\{r\cdot z+s\,|\,z\in U_i\}$. {Note that these recursive equations form an *iterated function system* (IFS) in 3-adic space, because multiplication by a factor of 3 is a contraction in the 3-adic topology. The closure of the windows in the 3-adic internal space is therefore given by the unique

compact solution of this IFS by (a generalized version of) Hutchinson's theorem [Ref. 11 Sect. 3.1(3)]. This method is well known for unimodular substitutions of Pisot-type (see Refs. 15 and 2 and the vast literature about Rauzy fractals). Similar results apply for all primitive substitutions of constant length ℓ in ℓ-adic space.} Iterating these equations and using $U_{a_1} \cup U_{a_2} \cup U_{b_1} = \mathbb{Z}$, one gets

$$U_{b_1} = (9\mathbb{Z}+5) \cup (27\mathbb{Z}+17) \cup (27\mathbb{Z}+22) \cup (81\mathbb{Z}+53) \cup (81\mathbb{Z}+58) \cup (81\mathbb{Z}+64) \cup (81\mathbb{Z}+65) \cup \cdots .$$

The Fourier transform of each lattice coset $\omega_{r\mathbb{Z}+s} = \Sigma_{z\in\mathbb{Z}} \delta_{r\cdot z+s}$ is easy to calculate:

$$\widehat{\omega_{r\mathbb{Z}+s}} = \frac{1}{r} e^{-2\pi i k s} \omega_{\mathbb{Z}/r} .$$

Every Fourier–Bohr coefficient of $\widehat{U_{b_1}}$ is then given by the sum of the Fourier–Bohr coefficients of the corresponding $\widehat{\omega_{r\mathbb{Z}+s}}$. The structure of U_{b_1} (similar for all U_i that occur for substitutions of constant length) as a union of a countable but infinite set of (periodic) lattice cosets $r\cdot\mathbb{Z}+s$ gives rise to the name *limit-periodic* (see Ref. 9).

The *support* of the Bragg peaks of Kol$(2m,2n)$ is given by

$$\left\{ \frac{k}{4\cdot(m+n)^s} \middle| k\in\mathbb{Z},\ \ s\in\mathbb{N}_0 \right\} = \left\{ \frac{k}{2^\varepsilon \cdot p_1^{s_1} \cdot \cdots \cdot p_r^{s_r}} \middle| k\in\mathbb{Z},\ \ s_1,\ldots,s_r\in\mathbb{N}_0,\ \ \varepsilon\in\{0,\ldots,\log_2(\mathrm{ord}(F))\} \right\},$$

where $p_1,\ldots,p_r$ are the distinct primes dividing $m+n$ and F is the cyclic group of (17). However, there need not be a Bragg peak on every point of the support, e.g., Kol(8,4) is equivalent to a substitution θ of constant length $\ell = m+n = 6$, but the positions of a letter a_i, b_i are separated by multiples of 2: The support in this case is better described by $\{k/2^s \,|\, k\in\mathbb{Z},\ \ s\in\mathbb{N}_0\}$ than by $\{k/(2^s\cdot 3^r) \,|\, k\in\mathbb{Z},\ \ s,r\in\mathbb{N}_0\}$.

V. EUCLIDEAN MODELS OF ℓ-ADIC INTERNAL SPACES

So far, we have talked in an "abstract" way about the ℓ-adic internal space. Usually the discussion ends at this point, but we want to "visualize" this ℓ-adic space. We hope that by doing this, we also gain some intuition for such spaces and the meaning of p-adic internal spaces for model sets.

Recall that a p-adic integer can be written as a formal series $t = \Sigma_{i\geqslant 0} t_i \cdot p^i$ with integral coefficients t_i satisfying $0 \leqslant t_i \leqslant p-1$ (*Hensel expansion*). For the following, we identify a p-adic integer t with the sequence $(t_i)_{i\geqslant 0}$ of its coefficients. The set of all p-adic integers (a ring) is written as $\mathbb{Z}_p$, while the field of p-adic numbers is written as $\mathbb{Q}_p$ and can be seen as the set of all Laurent series $\Sigma_{i\geqslant N} t_i \cdot p^i$ with $N\in\mathbb{Z}$. There is a p-adic *valuation* $v_p : \mathbb{Q}_p \backslash \{0\} \to \mathbb{Z}$ defined by $v_p(t) = \min\{i\in\mathbb{Z} | t_i \neq 0\}$, which gives rise to the p-adic *metric* with $|t|_p = p^{-v_p(t)}$ and $|0|_p = 0$ (and $\mathbb{Q}_p$ and $\mathbb{Z}_p$ are the completions of $\mathbb{Q}$ and $\mathbb{Z}$ with respect to the p-adic metric). So with respect to the p-adic metric, two numbers in $\mathbb{Z}$ are close if their difference is divisible by a high power of p. Note that this is a *non-Archimedean* absolute value (i.e., $|x+y|_p \leqslant \max\{|x|_p, |y|_p\}$ for all $x,y \in \mathbb{Q}_p$) and we therefore get some "strange" properties: all triangles are isosceles, every point inside a ball $B_r(x) = \{y \,||y-x|_p < r\}$ is the center of this ball, all balls are open and closed, etc., (see Ref. 10).

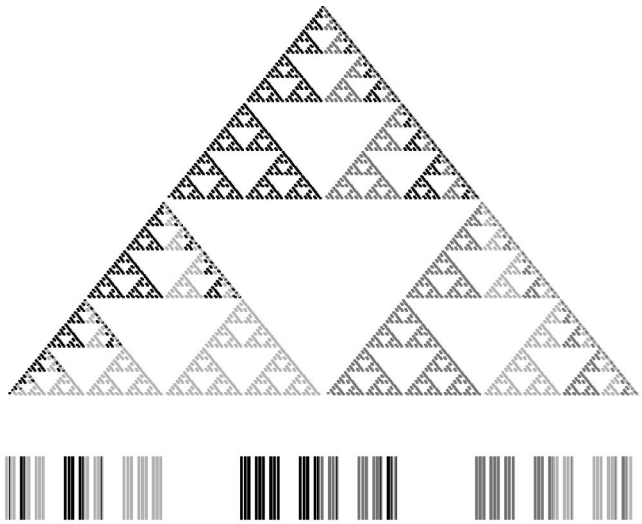

FIG. 1. 3-adic model for the internal space of (14) in $\mathbb{R}^2$ (above) and $\mathbb{R}$ (below, stretched for better representation). The colors correspond to a_1 (black), a_2 (dark gray) and b_1 (light gray).

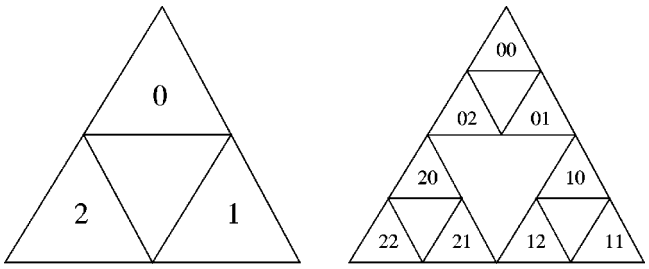
For Euclidean models (see Ref. 20, Sec. 1.2) of $\mathbb{Z}_p$ we only need to know the formal series $t=\Sigma_{i\geqslant 0}t_i\cdot p^i$. We can even show models for $\mathbb{Z}_\ell$, where we do not make use of (8). For this, we use the addressing scheme known for fractals, for example in the Sierpinsky gasket (see Ref. 4, Chap. IV),



Now the interesting thing here is that each point in the Sierpinsky gasket has a unique address (at least if we do not take the usual connected Sierpinsky gasket but the totally disconnected version; this can be obtained by using a contraction factor less than $\frac{1}{3}$ in the IFS for the Sierpinsky gasket). So each point in the Sierpinsky gasket corresponds to a sequence $(t_i)_{i\geqslant 0}$ with elements $0\leqslant t_i \leqslant 2$—this is just the Hensel expansion of the 3-adic integers. Similarly, the Cantor set is such a geometric encoding of the 2-adic integers. ''Reasonable'' geometric representations of $\mathbb{Z}_\ell$ in $\mathbb{R}^d$ are those, where the sets $K_{\{x_0\ldots x_r\}}=\{t\in\mathbb{Z}_\ell | t_0=x_0,\ldots,t_r=x_r\}$ of points starting with the same address are represented by objects of the same size for a fixed $r\in\mathbb{N}$. Therefore we get that in d-dimension, $\mathbb{Z}_\ell$ with $d+1\leqslant\ell\leqslant$(kissing number in $\mathbb{R}^d$)$+1$ can reasonably be represented, if we do not make use of (7). Note that we can represent $\mathbb{Z}_3$ either in $\mathbb{R}^2$ or $\mathbb{R}$.

This geometric representation surely fails for some p-adic (or ℓ-adic) properties (all triangles are isosceles, every point inside a ball is its center, etc.), but some are also ''preserved:'' points which are close in the p-adic topology are also close in this geometric representation and the representation as totally disconnected fractal corresponds to the totally disconnected field $\mathbb{Q}_p$, $\mathbb{Z}_p$ and its geometric models are both compact sets. And balls in the p-adic topology correspond to scaled down copies of the whole fractal.

We like to conclude this section with our example from (15). The 3-adic geometric models are given in Fig. 1. Observe that, in the two-dimensional representation, the parts (according to our above addressing scheme for the Sierpinsky gasket) $K_{\{02\}}$, $K_{\{12\}}$ and $K_{\{21\}}$ are colored by only one

color. This corresponds to the fact that at positions $9\mathbb{Z}+6$ are a_1's, on $9\mathbb{Z}+7$ are a_2's and on $9\mathbb{Z}+5$ are b_1's only in the bi-infinite sequence. So, large patches of the same color in the geometric representations correspond to lattice cosets $\ell^r\mathbb{Z}+s$ with small r. A similar addressing scheme can be used for the one-dimensional representation (and in fact for all ℓ-adic representations).

Geodesic compatibility and integrability of geodesic flows

Peter Topalov[a)]
Universität Zurich, Institut für Mathematik, Winterthurerstrasse, 8057 Zurich, Switzerland

(Received 6 July 2001; accepted 11 October 2002)

We give a natural geometric condition called *geodesic compatibility* that implies the existence of integrals in involution of the geodesic flow of a pseudo-Riemannian metric. We prove that if two metrics satisfy the condition of geodesic compatibility then we can produce a hierarchy of metrics that also satisfy this condition. A lot of metrics studied in Riemannian and Kählerian geometry satisfy such conditions. We apply our results for obtaining an infinite family (hierarchy) of completely integrable flows on the complex projective plane $\mathbf{CP}^n$. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1526939]

I. INTRODUCTION

Our main purpose in the present paper is to prove that if a pair of pseudo-Riemannian metrics g and $\bar{g}$ satisfies a natural geometric condition called *geodesic compatibility* (or PQ^{ϵ}*-projectivity*) then the geodesic flows of the metrics g and $\bar{g}$ admit integrals in involution of a special form. The integrals we find usually have singularities that can be localized out of every arbitrary taken open set D with compact closure (Theorem 1). If the manifold is compact then the integrals can be taken smooth. We prove a Kählerian analog of the results proved in Ref. 1.

In what follows we call pseudo-Riemannian metrics simply *metrics*. Positively definite metrics are called *Riemannian metrics*. All tensor object and manifolds we consider are smooth (C^{∞}). If $E \to M$ is a vector bundle over a manifold M then $\Gamma(E)$ denotes the space of the smooth sections of $E \to M$.

Let us consider some examples of metrics that satisfy the condition of the geodesic compatibility.

(a) *Geodesic equivalence*. A classical example of geodesic compatibility is the so-called *geodesic equivalence*. Recall the main definitions.
Let g and $\bar{g}$ be pseudo-Riemannian metrics given on the manifold M^n, $n = \dim M^n$.
Definition 1: The metrics g and $\bar{g}$ *are called* geodesically equivalent *iff they have the same geodesics (considered as unparametrized curves on* M^n).
We say that the metric g admits *nontrivial geodesic equivalence* iff there exists a metric $\bar{g} \neq \text{const}\, g$ such that g and $\bar{g}$ are geodesically equivalent. The first theorems concerning the existence of integrals of the geodesic flows of the metrics admitting nontrivial geodesic equivalence were proved by Dini, Painlevé, Levi-Civita and Liouville (see Ref. 2). The Liouville integrability of the corresponding geodesic flows in the case when one of the metrics g and $\bar{g}$ is Riemannian is proved in Ref. 3 (see also Refs. 4–9). The pseudo-Riemannian analogs of these theorems are proved in Ref. 11.

(b) *h-projectivity*. Another example of geodesic compatibility appears about a century later in the papers of Otsuki and Tashiro (Refs. 10 and 11).
Let M^{2n} be a $2n$-dimensional real manifold endowed with a complex structure J, $J^2 = -\mathbf{1}$, where $\mathbf{1}$ denotes the identity operator of the tangent bundle TM^{2n}. Recall that, a metric g on M^{2n} is called *Kählerian* iff the next two conditions are satisfied: (1) g is *Hermitian* metric, i.e., $g(J\xi, J\eta) = g(\xi, \eta)$, $\xi, \eta \in T_x M^{2n}$, and (2) the *Kähler form*

a)Permanent address: Department of Differential Equations, Institute of Mathematics, BAS, Sofia 1113, Bulgaria.

$\Omega(\xi,\eta)\overset{\text{def}}{=}g(J\xi,\eta)$ is a symplectic form (i.e., Ω is nondegenerate and closed, $d\Omega=0$).
Denote by ∇ the Levi-Civita connection corresponding to the Kählerian metric g. Following Ref. 10 we give Definition 2.

Definition 2: A smooth curve $(t_1,t_2)\ni t\to\gamma(t)\in M^{2n}$, $t_1<t_2$, *is called* holomorphically planar *(with respect to the Kählerian metric g) iff*

$$\frac{\nabla\dot\gamma}{dt}(t)=a(t)\dot\gamma(t)+b(t)J\dot\gamma(t), \tag{1}$$

where a and b are smooth functions of the parameter t.

Holomorphically planar curves always exist. For example, the geodesic lines of the metric g are holomorphically planar curves. More generally, fixing any smooth functions $a,b\in C^\infty(t_1,t_2)$, a point $x_0\in M^{2n}$ and a tangent vector $\gamma_0\in T_{x_0}M^{2n}$, we can find a small $\epsilon_0>0$ and a unique solution $\gamma:(-\epsilon_0,\epsilon_0)\to M^{2n}$ of Eq. (1) with initial data $\gamma(0)=x_0$, $\dot\gamma(0)=\gamma_0$.

Let g and $\overline{g}$ be Kählerian metrics on M^{2n}.

Definition 3 (see Ref. 11): The Kählerian metrics g and $\overline{g}$ *are called* holomorphically projective *(or h-projective) iff every holomorphically planar with respect to the metric g curve* $\gamma(t)$ *is holomorphically planar with respect to the metric* $\overline{g}$ *as well, and vice versa.*

It is not hard to prove (see, for example, Refs. 11 and 12) that the condition that the Kählerian metrics g and $\overline{g}$ are h-projective is equivalent to a nonlinear partial differential equation on the ''deformation'' tensor of the Levi-Civita connections of the metrics g and $\overline{g}$. In coordinates $\{(x^1,\dots,x^{2n})\}$, the equation is

$$\overline{\Gamma}^i_{jk}-\Gamma^i_{jk}=\delta^i_j\phi_k+\delta^i_k\phi_j-\phi_\alpha J^\alpha_j J^i_k-\phi_\alpha J^\alpha_k J^i_j, \tag{2}$$

where $\phi_l(l=1,\dots,2n)$ are the components of a globally defined on an M^{2n} 1-form, Γ^i_{jk} and $\overline{\Gamma}^i_{jk}$ are the Christoffel symbols of the metrics g and $\overline{g}$, respectively, δ^i_j is the Kronecker delta and J^i_j are the components of the complex structure J. As usual, we use the standard tensor conventions and omit the summation symbols in the formulas. It can be easily seen that $\phi_k=\partial_k\phi$, where ∂_k stands for the partial derivative $\partial/\partial x^k$ and ϕ is a globally defined on an M^{2n} function (see Sec. II A). Remark that Eq. (2) cannot be obtained without using the condition that the metrics g and $\overline{g}$ are Kählerian.

(c) *PQ^ϵ-projectivity.* Here we give the definition of the geodesic compatibility that generalize the both previous notions.

Consider two metrics g and $\overline{g}$ given on the manifold M^m, $m=\dim M^m$. Let $P,Q\in\Gamma(\mathrm{End}(TM^m))$ satisfy the next properties:

(i) P and Q are antisymmetric with respect to the both metrics g and $\overline{g}$;

(ii) $PQ=\epsilon\mathbf{1}$, where ϵ is a fixed real constant such that $\epsilon\neq m+1$ and $\epsilon\neq 1$.

Denote by χ the number $\chi\overset{\text{def}}{=}m+1-\epsilon$. It follows from (ii) that $\chi\neq 0$.

Definition 4: The metrics g and $\overline{g}$ *are called* PQ^ϵ-projective *(or* geodesically compatible*) iff their Christoffel symbols satisfy the equation*

$$\overline{\Gamma}^i_{jk}-\Gamma^i_{jk}=\phi_{(j}\delta^i_{k)}-\phi_\alpha P^\alpha_{(j}Q^i_{k)}, \tag{3}$$

where ϕ_k *are the components of a globally defined on* M^m 1*-form and the operators P* and *Q satisfy relations (i)* and *(ii).*

As usual, Eq. (3) is written in a fixed coordinate chart $\{(x^1,\dots,x^m)\}$ and P^i_j and Q^i_j are the components of the operators P and Q. The brackets $(i\cdots j)$ in formula (3) denote symmetrization with respect to the pointed indices. For example, the tensor field $T_{\alpha(ij)\beta}$ stands for $T_{\alpha ij\beta}+T_{\alpha ji\beta}$. It is not hard to give an invariant definition of PQ^ϵ-projectivity.

Remark 1: If $\epsilon\neq 0$ *then the operators P and Q are nondegenerate on* M^m, $Q=\epsilon P^{-1}$ *and the dimension m of the manifold is even.*

Remark 2: Suppose that g and $\overline{g}$ *are Kählerian metrics given on the complex manifold* M^{2n}

with complex structure J. Taking $P=Q=J$ and $\epsilon=-1$ we see that h-projectivity is a particular case of PQ^{ϵ}-projectivity. Taking $P=Q=0$ and $\epsilon=0$ we obtain the notion of the geodesic equivalence.

Let us give a brief description of the results proved in the paper. Suppose that the metrics g and $\overline{g}$ given on the manifold M^m are PQ^{ϵ}-projective. Define the endomorphism $A \in \Gamma(\mathrm{End}(TM^m))$ of the tangent bundle TM^m by the formula

$$A^i_j(g,\overline{g}) \overset{\text{def}}{=} \left|\frac{\det \overline{g}}{\det g}\right|^{1/\chi} \overline{g}^{i\alpha} g_{\alpha j}. \tag{4}$$

Consider the locally defined one-parameter family of quadratic forms,

$$K_c(g,\overline{g})(\xi) \overset{\text{def}}{=} |\det(A+c\mathbf{1})|^{1/(1-\epsilon)} g((A+c\mathbf{1})^{-1}\xi,\xi), \tag{5}$$

where $\xi \in TM^m$ and c is an appropriately chosen real parameter.

Following Ref. 1 define the *rank of the pair* g and $\overline{g}$. Denote by $r(g,\overline{g})(x)$ the degree of the minimal polynomial of the operator $A(g,\overline{g})|_x$.

Definition 5: The number $r(g,\overline{g})(x)$ is called rank of the pair g and $\overline{g}$ of PQ^{ϵ}-projective metrics at the point $x \in M^m$. *The number $r(g,\overline{g}) \overset{\text{def}}{=} \max_{x\in M^m}(g,\overline{g})(x)$ is called* rank of the pair of PQ^{ϵ}-projective metrics.

Recall that the smooth functions $F_1,\ldots,F_k$ given on a smooth manifold V are called *functionally independent in V* iff the set of the points $x \in V$ where the differentials $d_xF_1,\ldots,d_xF_k$ are linearly independent is dense in V.

Theorem 1: *Suppose that the manifold M^m is connected and let the rank of the pair of PQ^{ϵ}-projective metrics g and $\overline{g}$ be r. Denote by ω_g the symplectic structure on TM^m given by the pull-back $FL_g^*\omega$ where ω is the canonical symplectic structure on T^*M^m (the form "$dp\wedge dq$") and $FL_g: TM^m \to T^*M^m$ denotes the Legendre transformation corresponding to the metric g. Then for every open set $D \subset M^m$ with compact closure in M^m there exist r quadratic in velocities functions $B^D_1(\xi),\ldots,B^D_r(\xi)$, $\xi \in TD$, such that we have the following:*

(a) $B^D_1(\xi),\ldots,B^D_r(\xi)$ are smooth functionally independent pairwise commuting integrals of the geodesic flow of the metric g on D;
(b) if the quadratic form $K_c(g,\overline{g})(\xi)$, $c=\mathrm{const}$, is correctly defined on some open set $U \subset D$ then there exist constants $\alpha_1,\ldots,\alpha_r$ such that $K_c(\xi)=\Sigma_{k=1}^r \alpha_k B^D_k(\xi)$ on D.

The integrals $B^D_1(\xi),\ldots,B^D_r(\xi)$ can be taken in the form $B^D_k(\xi) \overset{\text{def}}{=} K_{c_k}(\xi)$, where the constants $c_1,\ldots,c_r$ are appropriately chosen.

Remark 3: Actually, the constants $c_1,\ldots,c_r$ in Theorem 1 are taken "sufficiently big," i.e., $|c_k| > m_D$, $m_D \overset{\text{def}}{=} \sup_{x\in D} \max_{\lambda\in \mathrm{Spect}(A|_x)} |\lambda|$.

As a simple corollary of this theorem we obtain the next statement.

Corollary 1: The set of the points $x \in M^m$ where $r(g,\overline{g})(x)=r$ is open and dense in M^m.

We prove Theorem 1 in Sec. IV.

A Hermitian version of Theorem 1 is given in Sec. V (see Theorem 4). An important corollary is the next Kählerian analog of that proved in Ref. 1 Theorem 2. Suppose that the Kählerian metrics s and $\tilde{s}$ are h-projective. Denote by r the *Hermitian rank* of the pair s and $\tilde{s}$ (see Definition 9).

Theorem 2: *If two Kählerian metrics s and $\tilde{s}$ are h-projective then their geodesic flows admit r functionally independent integrals in involution.*

The paper is organized as follows.

In Sec. II we prove that the quadratic forms given by formula (5) are integrals of the geodesic flow of the metric g (Proposition 3, Sec. II C). In Sec. II D we prove Proposition 4. As in Ref. 1 the existence of hierarchies is a crucial point proving the commutativity of the integrals given by formula (5). We prove the commutativity of these integrals in Sec. III, Theorem 3. Section IV is devoted to the proof of Theorem 1. The Hermitian analog of this theorem is proved in Sec. V. The last section is devoted to the applications of the results. A simple geometrical construction allows us to find an infinite family (''$\mathbf{CP}^n$-hierarchy'') of completely integrable Hamiltonian systems on the complex projective plane $\mathbf{CP}^n$ (see Theorem 6). The integrals obtained by Thimm in Ref. 13 are not included in this hierarchy as a particular case.

In what follows, if a coordinate chart is fixed, we usually identify the tensor fields we consider with their coordinate (''index'') representations and denote the corresponding objects by the same letters. We use also the common tensor notations and conventions and omit the summation symbols in the formulas. An endomorphism $L \in \Gamma(\mathrm{End}(TM^n))$ is called *invertible* or *nondegenerate* on M^n iff $\det L \neq 0$ on M^n.

II. PROPERTIES OF *PQ*-PROJECTIVITY

In the present section the main properties of the PQ^{ϵ}-projective metrics are established.

A. Existence of an integral

Suppose that the metrics g and $\overline{g}$ are PQ^{ϵ}-projective. Here we prove that the geodesic flow of the metric g admits an integral (Proposition 1).

Contracting the indices i and j in formula (3) and using that trace $Q=0$ we get $\overline{\Gamma}^i_{ik}-\Gamma^i_{ik} = \chi\phi_k$ where $\chi \overset{\text{def}}{=} m+1-\epsilon$. Using that $\Gamma^i_{ik}=\partial_k \ln\sqrt{|\det g|}$ we obtain

$$2\chi\phi_k = \frac{\partial}{\partial x^k}\left(\ln\left|\frac{\det \overline{g}}{\det g}\right|\right). \tag{6}$$

Therefore, $\phi_k=\partial_k\phi$, where ϕ is a smooth function on M^m.

The next technical lemma is needed for the sequel.

Lemma 1: The metrics g and $\overline{g}$ are PQ^{ϵ}-projective if and only if their components satisfy the next equation in covariant derivatives:

$$\nabla_k \overline{g}_{ij} = 2\phi_k \overline{g}_{ij} + \phi_{(i}\overline{g}_{j)k} - \phi_\alpha P^\alpha_{(i}\overline{g}_{j)\beta}Q^\beta_k, \tag{7}$$

where ∇ denotes the Levi-Civita connection of the metric g and the operators P and Q satisfy conditions (i) and (ii).

Proof of Lemma 1: Suppose that the metrics g and $\overline{g}$ are PQ^{ϵ}-projective. In coordinates, we obtain

$$\begin{aligned}
\nabla_k \overline{g}_{ij} &= \partial_k \overline{g}_{ij} - \Gamma^\alpha_{ik}\overline{g}_{\alpha j} - \Gamma^\alpha_{jk}\overline{g}_{i\alpha} \\
&= \overline{\nabla}_k \overline{g}_{ij} + (\phi_{(i}\delta^\alpha_{k)} - \phi_l P^l_{(i}Q^\alpha_{k)})\overline{g}_{\alpha j} + (\phi_{(j}\delta^\alpha_{k)} - \phi_l P^l_{(j}Q^\alpha_{k)})\overline{g}_{i\alpha} \\
&= 2\phi_k\overline{g}_{ij} + \phi_{(i}\overline{g}_{j)k} - \phi_l P^l_{(i}\overline{g}_{j)\alpha}Q^\alpha_k - \phi_l P^l_k Q^\alpha_{(i}\overline{g}_{j)\alpha} \\
&= 2\phi_k\overline{g}_{ij} + \phi_{(i}\overline{g}_{j)k} - \phi_l P^l_{(i}\overline{g}_{j)\alpha}Q^\alpha_k .
\end{aligned}$$

The inverse statement immediately follows from the classical fact that the Levi-Civita connection of some metric is the unique torsion free connection that preserves the considered metric. Lemma 1 is proved.

Equations (7) are equivalent to

$$2\mu\overline{g}_{ij,k} = -2\mu_k\overline{g}_{ij} - \mu_{(i}\overline{g}_{j)k} - \mu_l P^l_{(i}\overline{\Omega}^Q_{j)k}, \tag{8}$$

where $\mu \overset{\text{def}}{=} |\det g/\det \overline{g}|^{1/\chi}$, $\mu_k \overset{\text{def}}{=} \partial\mu/\partial x^k$ $(k=1,\ldots,2n)$, and $\overline{\Omega}^Q_{kj}$ are the components of the 2-form $\overline{\Omega}^Q(\xi,\eta) \overset{\text{def}}{=} \overline{g}(Q\xi,\eta)$, $\xi,\eta \in T_xM^m$. The equivalence of Eqs. (7) and (8) easily follows from the relation $2\phi_k = -\mu_k/\mu$.

Proposition 1: Suppose that the metrics g and $\overline{g}$ are PQ^ϵ-projective. Then the quadratic form,

$$K(\xi) \overset{\text{def}}{=} \left|\frac{\det g}{\det \overline{g}}\right|^{2/\chi} \overline{g}(\xi,\xi), \tag{9}$$

is an integral of the geodesic flow of the metric g.

Proof of Proposition 1: In coordinates, we have $K_{ij} \overset{\text{def}}{=} \mu^2\overline{g}_{ij}$. Following Levi-Civita, a quadratic form $Q(\xi,\xi)=Q_{ij}\xi^i\xi^j$, $Q_{ij}=Q_{ji}$, is an integral of the geodesic flow of the metric g if and only if $Q_{(ijk)} \overset{\text{def}}{=} (Q_{ij,k}+Q_{jk,i}+Q_{ki,j})/3=0$, where $Q_{ij,k} \overset{\text{def}}{=} \nabla_k Q_{ij}$ and ∇ is the Levi-Civita connection of the metric g. Indeed, let $\gamma(s)$ $(\gamma(0)=x_0,\ \dot\gamma(0)=\xi)$ be a geodesic line of the metric g. We have $0=d/ds\,|_{s=0}(Q_{ij}\dot\gamma^i\dot\gamma^j)=Q_{ij,k}(x_0)\xi^k\xi^i\xi^j=Q_{(ijk)}(x_0)\xi^k\xi^i\xi^j$ and therefore $Q_{ij,k}+Q_{jk,i}+Q_{ki,j}=0$. Conversely, if $Q_{ij,k}+Q_{jk,i}+Q_{ki,j}=0$ then Q is an integral of the geodesic flow of the metric g.

We have

$$2K_{ij,k}=4\mu\mu_k\overline{g}_{ij}+2\mu^2\overline{g}_{ij,k},$$

$$2K_{jk,i}=4\mu\mu_i\overline{g}_{jk}+2\mu^2\overline{g}_{jk,i},$$

$$2K_{ki,j}=4\mu\mu_j\overline{g}_{ki}+2\mu^2\overline{g}_{ki,j}.$$

Summing these equations and using (8) we obtain that

$$\begin{aligned}2(K_{ij,k}+K_{jk,i}+K_{ki,j}) = -\mu(&\mu_\alpha P_i^\alpha\overline{\Omega}^Q_{jk}+\mu_\alpha P_j^\alpha\overline{\Omega}^Q_{ik}+\mu_\alpha P_j^\alpha\overline{\Omega}^Q_{ki}+\mu_\alpha P_k^\alpha\overline{\Omega}^Q_{ji}+\mu_\alpha P_k^\alpha\overline{\Omega}^Q_{ij}\\ &+\mu_\alpha P_i^\alpha\overline{\Omega}^Q_{kj})=0.\end{aligned}$$

This completes the proof of Proposition 1.

Remark 4: In the case of geodesically equivalent metrics the integral given by formula (9) coincides with the classical Painlevé integral (see Refs. 1, 2). The existence of the integral (9) in the case of h-projective Kählerian metrics is a new fact.

B. Existence of a family of *PQ*-projective metrics

Suppose that the metrics g and $\overline{g}$ are PQ^ϵ-projective. Consider the endomorphism A of the tangent bundle TM^m defined by formula (4). It is clear that A is self-adjoint with respect to the both metrics g and $\overline{g}$. Condition (i) imposed on the operators P and Q (see p. 5) yields that A commutes with P and Q. The next important technical lemma is needed for the sequel.

Lemma 2: If the metrics g and $\overline{g}$ are PQ^ϵ-projective then the metric $a_{ij} \overset{\text{def}}{=} g_{i\alpha}A_j^\alpha$ satisfies the equation

$$a_{ij,k}=\lambda_{(i}g_{j)k}-\lambda_l P^l_{(i}g_{j)q}Q^q_k, \tag{10}$$

where $\lambda_i \overset{\text{def}}{=} -\phi_l A_i^l$. The operators P and Q are antisymmetric with respect to the metric a. Inversely, consider a metric g and two antisymmetric with respect to g operators P and Q such that $PQ=\epsilon\mathbf{1}$. Suppose that P and Q are antisymmetric with respect to a nondegenerate symmet-

ric form a_{ij} and let a_{ij} satisfy Eq. (10) for some globally defined on M^{2n} 1-form λ_k. Then the metrics g and $\overline{g}\overset{\text{def}}{=}|\det \breve{g}/\det g|^{1/(1-\epsilon)}\breve{g}$, are PQ^{ϵ}-projective, where $\breve{g}_{ij}\overset{\text{def}}{=}g_{i\alpha}a^{\alpha\beta}g_{\beta j}$, $a_{i\alpha}a^{\alpha j}=\delta_i^j$.

Proof of Lemma 2: Suppose that g and $\overline{g}$ are PQ^{ϵ}-projective. Denote $\breve{g}_{ij}\overset{\text{def}}{=}\exp(-2\phi)\overline{g}_{ij}$. Using formula (7) we obtain

$$\breve{g}_{ij,k}=-2\phi_k\breve{g}_{ij}+\exp(-2\phi)\overline{g}_{ij,k}=\phi_{(i}\breve{g}_{j)k}-\phi_l P^l_{(i}\breve{g}_{j)\alpha}Q^{\alpha}_k.$$

For the inverse tensor $\breve{g}^{ij}$ ($\breve{g}_{i\alpha}\breve{g}^{\alpha j}=\delta_i^j$) we have

$$\breve{g}^{ij}_{,k}=-\breve{g}^{i\alpha}\breve{g}_{\alpha\beta,k}\breve{g}^{\beta j}=-\phi_l\breve{g}^{l(i}\delta^{j)}_k+\phi_l P^l_s\breve{g}^{s(i}Q^{j)}_k.$$

Finally, taking $a_{\alpha\beta}\overset{\text{def}}{=}g_{\alpha i}\breve{g}^{ij}g_{j\beta}$ we obtain

$$a_{\alpha\beta,k}=-\phi_l\breve{g}^{li}g_{i(\alpha}g_{\beta)k}+\phi_l P^l_r A^r_{(\alpha}g_{\beta)j}Q^j_k=\lambda_{(\alpha}g_{\beta)k}-\lambda_l P^l_{(\alpha}g_{\beta)q}Q^q_k,$$

where $\lambda_{\alpha}\overset{\text{def}}{=}-\phi_l A^l_{\alpha}$.

Let us prove the inverse part of the proposition. Suppose that the nondegenerate symmetric tensor a_{ij} satisfies Eq. (10) where P and Q are antisymmetric with respect to g and a, $PQ=\epsilon\mathbf{1}$, and λ_k are the components of a globally defined on M^m 1-form. Consider the tensor $\breve{g}^{ij}\overset{\text{def}}{=}g^{i\alpha}a_{\alpha\beta}g^{\beta j}$. For the inverse tensor $\breve{g}_{pq}$ ($\breve{g}_{p\alpha}\breve{g}^{\alpha q}=\delta^q_p$) we have

$$\breve{g}_{pq,k}=-\breve{g}_{pi}\breve{g}^{ij}_{,k}\breve{g}_{jq}=-\lambda_{\alpha}g^{\alpha i}\breve{g}_{i(p}\breve{g}_{q)k}+\lambda_l P^l_{\alpha}g^{\alpha i}\breve{g}_{i(p}\breve{g}_{q)j}Q^j_k.$$

Denoting $\phi_p\overset{\text{def}}{=}-\lambda_{\alpha}g^{\alpha i}\breve{g}_{ip}$ we obtain

$$\breve{g}_{pq,k}=\phi_{(p}\breve{g}_{q)k}-\phi_l P^l_{(p}\breve{g}_{q)j}Q^j_k. \tag{11}$$

Lemma 3: $2\phi_k=\partial_k\ln|\det\breve{g}/\det g|^{1/(1-\epsilon)}$.

Proof of Lemma 3: Denote by $\breve{\Gamma}^i_{jk}$ the Christoffel symbols of the metric $\breve{g}$. Using formula (11) we obtain

$$\begin{aligned}\breve{\Gamma}^{\alpha}_{\alpha k}&=\frac{1}{2}\breve{g}^{\alpha\beta}\frac{\partial\breve{g}_{\alpha\beta}}{\partial x^k}\\&=\frac{1}{2}\breve{g}^{\alpha\beta}(\breve{g}_{\alpha\beta,k}+\breve{g}_{l(\alpha}\Gamma^l_{\beta)k})\\&=\frac{1}{2}\breve{g}^{\alpha\beta}((\phi_{(\alpha}\breve{g}_{\beta)k}-\phi_l P^l_{(\alpha}\breve{g}_{\beta)j}Q^j_k)+\breve{g}_{l(\alpha}\Gamma^l_{\beta)k})\\&=(1-\epsilon)\phi_k+\Gamma^{\alpha}_{\alpha k}.\end{aligned}$$

Therefore, $(1-\epsilon)\phi_k=\breve{\Gamma}^{\alpha}_{\alpha k}-\Gamma^{\alpha}_{\alpha k}=\partial_k\ln|\det\breve{g}/\det g|^{1/2}$. Lemma 3 is proved.

Finally, taking $\overline{g}_{ij}\overset{\text{def}}{=}\exp(2\phi)\breve{g}_{ij}$ we obtain that $g_{ij,k}=2\phi_k\overline{g}_{ij}+\phi_{(i}\overline{g}_{j)k}-\phi_l P^l_{(i}\overline{g}_{j)\alpha}Q^{\alpha}_k$. Using Lemma 1 we complete the proof of Lemma 2.

Proposition 2: Suppose that the metrics g and $\overline{g}$ are PQ^{ϵ}-projective and let c be a real constant such that the operator $A+c\mathbf{1}$ is invertible. Then the metrics g and

$$\overline{g}_c(g,\overline{g})\overset{\text{def}}{=}|\det(A+c\mathbf{1})|^{-1/(1-\epsilon)}g(A+c\mathbf{1})^{-1}, \tag{12}$$

where $A=A(g,\overline{g})$ is given by formula (4), are PQ^{ϵ}-projective.

Proof of Proposition 2: Suppose that the metrics g and $\overline{g}$ are PQ^{ϵ}-projective and let c be the constant given in the statement of the corollary. It follows from Lemma 2 that the metric $a \overset{\text{def}}{=} gA$ satisfies Eq. (10). Hence, the metric $a+cg=g(A+c)$ also satisfies Eq. (10). Using the inverse part of Lemma 2 we obtain that the metrics g and $\overline{g_c} \overset{\text{def}}{=} |\det \breve{g}_c/\det g|^{1/(1-\epsilon)}\breve{g}_c$, $\breve{g}_c \overset{\text{def}}{=} g(a+cg)^{-1}g=g(A+c\mathbf{1})^{-1}$. This completes the proof of Proposition 2.

C. Existence of a family of integrals

Here we prove that the geodesic flows of a pair of PQ^{ϵ}-projective metric locally admit a family of integrals.

Proposition 3: Suppose that the metrics g and $\overline{g}$ are PQ^{ϵ}-projective and let c be a real constant such that the operator $A+c\mathbf{1}$ is nondegenerate on M^m. Then the quadratic form,

$$K_c(g,\overline{g}) \overset{\text{def}}{=} |\det(A+c\mathbf{1})|^{1/(1-\epsilon)}g(A+c\mathbf{1})^{-1}, \tag{13}$$

is an integral of the geodesic flow of the metric g.

Remark 5: Let $D \subset M^m$ be an open set with compact closure in M^m. Taking $|c| \geqslant m_D$, $m_D \overset{\text{def}}{=} \sup_{x \in D} \max_{\lambda \in \mathrm{Spect}A|_x} |\lambda|$, we obtain a one-parameter family of integrals of the geodesic flow of the metric g.

Proof of Proposition 3: Suppose that the metrics g and $\overline{g}$ are PQ^{ϵ}-projective. It follows from Proposition 2 that g and $\overline{g_c}$ [given by formula (12)] are PQ^{ϵ}-projective. Applying Proposition 1 to these metrics we obtain that the quadratic form

$$K_c \overset{\text{def}}{=} \left|\frac{\det g}{\det \overline{g}_c}\right|^{2/\chi} \overline{g_c} = |\det(A+c\mathbf{1})|^{1/(1-\epsilon)}g(A+c\mathbf{1})^{-1}$$

is an integral of the geodesic flow of the metric g. Proposition 3 is proved.

D. Existence of hierarchies

In the present section we prove the next proposition.

Proposition 4: If the metrics g and $\overline{g}$ are PQ^{ϵ}-projective then the metrics $a \overset{\text{def}}{=} gA$ and $\overline{a} \overset{\text{def}}{=} \overline{g}A$ are $P_1Q_1^{\epsilon}$-projective, where $P_1 \overset{\text{def}}{=} PA$, $Q_1 \overset{\text{def}}{=} A^{-1}Q$, and $A=A(g,\overline{g})$ is given by formula (4).

Proof of Proposition 4: It follows from Lemma 2 that $a_{\alpha\beta,k}=\lambda_{(\alpha}g_{\beta)m}-\lambda_l P^l_{(\alpha}g_{\beta)q}Q^q_k$, where $\lambda_\alpha \overset{\text{def}}{=} -\phi_l A^l_\alpha$. We have

$$-\frac{\partial a_{\alpha\beta}}{\partial x^k}+\Gamma^l_{k(\alpha}a_{\beta)l}=-\lambda_{(\alpha}g_{\beta)k}+\lambda_l P^l_{(\alpha}g_{\beta)q}Q^q_k,$$

$$\frac{\partial a_{\alpha k}}{\partial x^\beta}-\Gamma^l_{\beta(\alpha}a_{k)l}=\lambda_{(\alpha}g_{k)\beta}-\lambda_l P^l_{(\alpha}g_{k)q}Q^q_\beta,$$

$$\frac{\partial a_{\beta k}}{\partial x^\alpha}-\Gamma^l_{\alpha(\beta}a_{k)l}=\lambda_{(\beta}g_{k)\alpha}-\lambda_l P^l_{(\beta}g_{k)q}Q^q_\alpha.$$

Summing these equations, and using the relations $\lambda_l \overset{\text{def}}{=} -\phi_\alpha A^\alpha_l$, $PA=AP$, $g(Q\xi,\eta)=-g(\xi,Q\eta)$, we obtain the next formula for the Christoffel symbols A^i_{jk} of the metric a_{ij},

$$A^k_{\alpha\beta}=\Gamma^k_{\alpha\beta}+\lambda_l a^{lk}g_{\alpha\beta}+\lambda_l P^l_{(\alpha}g_{\beta)q}Q^q_r a^{rk}=\Gamma^k_{\alpha\beta}-\phi_l g^{lk}g_{\alpha\beta}+\phi_s P^s_l A^l_{(\alpha}Q^q_{\beta)}\tilde{A}^k_q, \tag{14}$$

where $\tilde{A}^k_q$ are the components of the inverse operator A^{-1}.

By definition, $\overline{a}_{ij} \overset{\text{def}}{=} \overline{g}_{ik} A^k_j = \exp(2\phi) g_{ij}$. Using this relation we immediately obtain the next relation between the Christoffel symbols of the metrics $\overline{a}$ and g,

$$\overline{A}^k_{ij} = \Gamma^k_{ij} + \phi_{(i}\delta^k_{j)} - \phi_l g^{lk} g_{ij}. \tag{15}$$

Finally, (14) and (15) yield

$$\overline{A}^k_{ij} - A^k_{ij} = \phi_{(i}\delta^k_{j)} - \phi_s P^s_l A^l_{(i} Q^q_{j)} \tilde{A}^k_q. \tag{16}$$

This completes the proof of Proposition 4.

Suppose that a pair of PQ^ϵ-projective metrics g and $\overline{g}$ is given. It follows from Proposition 4 that *for every integer k the metrics $g^{(k)} \overset{\text{def}}{=} gA^k$ and $\overline{g}^{(k)} \overset{\text{def}}{=} gA^k$ are P_kQ_k-projective, where $P_k \overset{\text{def}}{=} PA^k$ and $Q_k \overset{\text{def}}{=} A^{-k}Q$*. Indeed, suppose that $g^{(l)}$ and $\overline{g}^{(l)}$ are P_lQ_l-projective. It follows from formula (4) that $A(g^{(l)}, \overline{g}^{(l)}) = A$ and $A(\overline{g}^{(l)}, g^{(l)}) = A^{-1}$. Applying Proposition 4 to the pair $g^{(l)}$ and $\overline{g}^{(l)}$ we obtain that $g^{(l+1)}$ and $\overline{g}^{(l+1)}$ are $P_{l+1}Q_{l+1}$-projective. Similarly, applying Proposition 4 to the pair $\overline{g}^{(l)}$ and $g^{(l)}$ we obtain that $g^{(l-1)}$ and $\overline{g}^{(l-1)}$ are $P_{l-1}Q_{l-1}$-projective.

*Definition 6: The sequence of pairs $g^{(k)}$ and $\overline{g}^{(k)}$ ($k = 0, \pm 1, \dots$) are called the PQ^ϵ-*hierarchy *corresponding to the pair g and $\overline{g}$ of PQ^ϵ-projective metrics*.

The PQ^ϵ-hierarchy is an analog of the *geodesic hierarchy* considered in Ref. 1. Proposition 4 is an analog of the Sinyukov transformation in the theory of geodesically equivalent metrics (see Refs. 14, 15). We will describe the PQ^ϵ-hierarchy by the next formal scheme,

$$\begin{array}{ccc}
\downarrow & & \downarrow \\
g^{(-1)} & \leftrightarrow & \overline{g}^{(-1)} \\
\downarrow & & \downarrow \\
g & \leftrightarrow & \overline{g} \\
\downarrow & & \downarrow \\
g^{(1)} & \leftrightarrow & \overline{g}^{(1)} \\
\downarrow & & \downarrow
\end{array}$$

where the horizontal arrows mean that the metrics $g^{(k)}$ and $\overline{g}^{(k)}$ are P_kQ_k-projective.

III. INVOLUTIVITY OF THE FAMILY OF THE INTEGRALS

In the present section we prove that the integrals given by Proposition 3 are in involution.

Theorem 3: *Suppose that the metrics g and $\overline{g}$ are PQ^ϵ-projective. Suppose in addition that the operators $A + c_1\mathbf{1}$ and $A + c_2\mathbf{1}$ are nondegenerate on M^m where c_1 and c_2 are some fixed real numbers. Then the quadratic forms $K_{c_1}(g, \overline{g})$ and $K_{c_2}(g, \overline{g})$, given by formula* (5)*, are in involution with respect to the symplectic structure $\omega_g \overset{\text{def}}{=} \mathrm{FL}_g^* \omega$, where ω denotes the canonical symplectic structure on the cotangent bundle T^*M^m and $FL_g : TM^m \to T^*M^m$ is the Legendre transformation corresponding to the metric g.*

Proof of Theorem 3: Suppose that the metrics g and $\overline{g}$ are PQ^ϵ-projective. Proposition 2 shows that the metrics g and $\overline{g}_{c_1} \overset{\text{def}}{=} |\det(A + c_1\mathbf{1})|^{-1/(1-\epsilon)} g(A + c_1\mathbf{1})^{-1}$ are PQ^ϵ-projective as well. Consider the corresponding PQ^ϵ-hierarchy,

$$\begin{array}{ccc} \downarrow & & \downarrow \\ g & \leftrightarrow & \overline{g}_{c_1} \\ \downarrow & & \downarrow \\ g^{(1)}_{c_1} & \leftrightarrow & \overline{g}^{(1)}_{c_1} \\ \downarrow & & \downarrow \\ g^{(2)}_{c_1} & \leftrightarrow & \overline{g}^{(2)}_{c_1} \\ \downarrow & & \downarrow \end{array}$$

A simple calculation shows that $A(g,\overline{g}_{c_1})=A+c_1\mathbf{1}$, and $A(\overline{g}_{c_1},g)=(A+c_1\mathbf{1})^{-1}$. Hence, $\overline{g}^{(2)}_{c_1} \overset{\text{def}}{=} \overline{g}_{c_1}A(g,\overline{g}_{c_1})^2=|\det(A+c_1\mathbf{1})|^{-1/(1-\epsilon)}g(A+c_1\mathbf{1})$. It is clear that $A(\overline{g}^{(2)}_{c_1},g^{(2)}_{c_1})=(A+c_1\mathbf{1})^{-1}$. Suppose that the nonzero real number $(-\alpha)$ is not an eigenvalue of the operator $(A+c_1\mathbf{1})^{-1}$. It follows from Proposition 3 that the quadratic form $K_\alpha(\overline{g}^{(2)}_{c_1},g^{(2)}_{c_1})$ is an integral of the geodesic flow of the metric $\overline{g}^{(2)}_{c_1}$. Applying the inverse to the Legendre transformation corresponding to the metric $\overline{g}^{(2)}_{c_1}$, we obtain that the forms

$$(\overline{g}^{(2)}_{c_1})^{-1}=|\det(A+c_1\mathbf{1})|^{1/(1-\epsilon)}(A+c_1\mathbf{1})^{-1}g^{-1} \tag{17}$$

and

$$\begin{aligned}(FL^{-1}_{\overline{g}^{(2)}_{c_1}})^*(K_\alpha) &\overset{\text{def}}{=} |\det((A+c_1)^{-1}+\alpha)|^{1/(1-\epsilon)}((A+c_1)^{-1}+\alpha)^{-1}(\overline{g}^{(2)}_{c_1})^{-1} \\ &= c(\alpha)|\det(A+(c_1+1/\alpha))|^{1/(1-\epsilon)}(A+(c_1+1/\alpha))^{-1}g^{-1},\end{aligned}$$

considered as functions on the cotangent bundle T^*M^m, are in involution with respect to the canonical symplectic structure ω on T^*M^m. Finally, applying the Legendre transformation corresponding to the metric g, we obtain that the forms $K_{c_1}(g,\overline{g})$ and $K_{c_1+\frac{1}{\alpha}}(g,\overline{g})$ are in involution with respect to ω_g. Theorem 3 is proved.

IV. FUNCTIONAL INDEPENDENCE OF THE INTEGRALS

Here we prove Theorem 1 formulated in the Introduction.

Proof of Theorem 1: We follow the idea of the proof of Theorem 2 in Ref. 1.

In what follows we use the next convention. If V is a complex vector space we assume that all linear maps and subspaces are complex linear, all tensor products are over $\mathbf{C}$, and the word ''dimension'' means the complex dimension.

Let V be a real (or complex) vector space of dimension m. Consider a nondegenerate symmetric bilinear form $s\in\mathrm{Symm}(V^*\otimes V^*)$ and a linear self-adjoint with respect to s operator $L\in\mathrm{End}(V)$. Denote by $r(L)$ *the degree of the minimal polynomial of the operator* L. Let δ be a fixed real number. Consider the curves

$$\gamma: t\to|\det(L-t\mathbf{1})|^{\delta}s(L-t\mathbf{1})^{-1}\in\mathrm{Symm}(V^*\otimes V^*)$$

and

$$\gamma_\xi: t\to|\det(L-t\mathbf{1})|^{\delta}s((L-t\mathbf{1})^{-1}\xi,\cdot)\in V^*,$$

where $\xi\in V$ is a fixed vector in V, $\mathbf{1}$ is the identity operator, and the parameter t is defined in an open set U in $\mathbf{R}$ (or $\mathbf{C}$), $U\cap\mathrm{Spect}(L)=\emptyset$. Remark that we admit three possibilities: V is real and t is real, V is complex and t is complex or real. Given a curve $l: D\to W$, where W is a vector space and D is an open domain in $\mathbf{R}$ or $\mathbf{C}$, denote by $\dim_D l$ the dimension of the linear subspace spanned

on the vectors $\{l(t)|t\in D\}$. Following our convention, if W is a complex vector space, $\dim_D l$ denotes the complex dimension of the complex linear subspace spanned on $\{l(t)|t\in D\}$.

Lemma 4:

(a) $\dim_U \gamma = r(L)$;
(b) $\dim_U \gamma_\xi \leqslant r(L)$ *and there exists an open and dense subset* $\Sigma\subset V$ *such that for every* $\xi\in\Sigma$, $\dim_U \gamma_\xi = r(L)$;
(c) *if* $t_1,\dots,t_{r(L)}\in U$, $t_i\neq t_j$ $(i\neq j)$, *then* $\gamma(t_1),\dots,\gamma(t_{r(L)})$ *are linearly independent.*

Proof of Lemma 4: Consider the case when V is a real vector space and the parameter t is real, $t\in U\subset\mathbf{R}$, $U\cap\mathrm{Spect}(L)\neq\emptyset$. The case of complex vector space is considered similarly. It follows from the nondegeneracy of the metric s that $\dim_U\gamma=\dim_U\tilde\gamma$ and $\dim_U\gamma_\xi=\dim_U\tilde\gamma_\xi$, where $\tilde\gamma(t)\overset{\text{def}}{=}\det(L-t\mathbf{1})(L-t\mathbf{1})^{-1}$ and $\tilde\gamma_\xi(t)\overset{\text{def}}{=}\det(L-t\mathbf{1})(L-t\mathbf{1})^{-1}\xi$. It is clear that $\tilde\gamma(t)=L_{m-1}t^{m-1}+\cdots+L_0$, $L_k\in\mathrm{End}(V)$, $L_{m-1}=(-1)^{m-1}\mathbf{1}$. Using the nondegeneracy of the Vandermonde determinant we obtain that $\dim_U\tilde\gamma=\mathrm{rk}\{L_{m-1},\dots,L_0\}$ and $\dim_U\tilde\gamma_\xi=\mathrm{rk}\{L_{m-1}\xi,\dots,L_0\xi\}$. Denote by $V^{\mathbf{C}}$ the complexification of V. Let $L^{\mathbf{C}},L_k^{\mathbf{C}}\in\mathrm{End}(V^{\mathbf{C}})$ be the complexifications of the real operators L and L_k $(k=0,\dots,m-1)$. Denote by r_0 the number $r_0\overset{\text{def}}{=}\max\limits_{\xi\in V}\mathrm{rk}\{L_{m-1}\xi,\dots,L_0\xi\}$.

Lemma 5:

(i) $\mathrm{rk}\{L_{m-1},\dots,L_0\}=\mathrm{rk}_{\mathbf{C}}\{L_{m-1}^{\mathbf{C}},\dots,L_0^{\mathbf{C}}\}$;
(ii) $r_0=\max_{\xi\in V^{\mathbf{C}}}\mathrm{rk}_{\mathbf{C}}\{L_{m-1}^{\mathbf{C}}\xi,\dots,L_0^{\mathbf{C}}\xi\}$;
(iii) *there exists an open dense subset* $\Sigma\subset V$ *such that for every* $\xi\in\Sigma$, $r_0=\mathrm{rk}\{L_{m-1}\xi,\dots,L_0\xi\}$.

Proof of Lemma 5: Item (i) of the lemma is obvious. Let us prove (iii). Taking a basis in V, denote by $(\xi_1,\dots,\xi_m)$ the coordinates of the vectors of V. Consider the $m\times m$ matrix T formed of the coordinates of the vectors $L_{m-1}\xi,\dots,L_0\xi$. The elements of this matrix are linear polynomials of the variables $\xi_1,\dots,\xi_m$. It is clear that there exists a nonzero minor $T_{r_0}\in\mathbf{R}^{r_0}[\xi_1,\dots,\xi_m]$ of the matrix T. The set $\Sigma\overset{\text{def}}{=}\{\xi\in V|T_{r_0}(\xi)\neq 0\}$ satisfies the statement of item (iii). The assumption that the variables $\xi_1,\dots,\xi_m$ take complex values does not change the rank of the matrix T. This proves item (ii). Lemma 5 is proved.

Consider the curves $\tilde\gamma^{\mathbf{C}}(\lambda)\overset{\text{def}}{=}(L^{\mathbf{C}}-\lambda\mathbf{1})^{-1}$ and $\tilde\gamma^{\mathbf{C}}_\xi(\lambda)\overset{\text{def}}{=}\det(L^{\mathbf{C}}-\lambda\mathbf{1})^{-1}\xi$, where $\lambda\in\mathbf{C}\backslash\mathrm{Spect}(L)$, $\xi\in V^{\mathbf{C}}$, and $\mathbf{1}$ denotes the identity operator in $V^{\mathbf{C}}$. As above, using the nondegeneracy of the Vandermonde determinant, we obtain that $\dim_{\mathbf{C}\backslash\mathrm{Spect}(L)}\tilde\gamma^{\mathbf{C}}=\mathrm{rk}_{\mathbf{C}}\{L_{m-1}^{\mathbf{C}},\dots,L_0^{\mathbf{C}}\}$ and $\dim_{\mathbf{C}\backslash\mathrm{Spect}(L)}\tilde\gamma^{\mathbf{C}}_\xi=\mathrm{rk}_{\mathbf{C}}\{L_{m-1}^{\mathbf{C}}\xi,\dots,L_0^{\mathbf{C}}\xi\}$. Lemma 5 shows that $\dim_U\gamma=\dim_{\mathbf{C}\backslash\mathrm{Spect}(L)}\tilde\gamma^{\mathbf{C}}$ and $r_0=\max_{\xi\in V^{\mathbf{C}}}\dim_{\mathbf{C}\backslash\mathrm{Spect}(L)}\tilde\gamma^{\mathbf{C}}_\xi$. Without loss of generality we can suppose that the operator $L^{\mathbf{C}}$ is given in a Jordan's basis. Using the explicit form of $L^{\mathbf{C}}$, it is not hard to see that

$$\dim_{\mathbf{C}\backslash\mathrm{Spect}(L)}\tilde\gamma^{\mathbf{C}}=r(L)$$

and

$$\max_{\xi\in V^{\mathbf{C}}}\dim_{\mathbf{C}\backslash\mathrm{Spect}(L)}\tilde\gamma^{\mathbf{C}}_\xi=r(L).$$

The first equality proves item (a). The second one shows that $r_0=r(L)$. Applying Lemma 5(iii) we prove (b). To prove item (c) remark that instead of the curves $\gamma(t_1),\dots,\gamma(t_{r(L)})$ it is sufficient to prove the linear independence over $\mathbf{C}$ of the curves $\tilde\gamma^{\mathbf{C}}(t_1),\dots,\tilde\gamma^{\mathbf{C}}(t_{r(L)})$, where the operator $L^{\mathbf{C}}$ is given in a Jordan's basis. Using the simple form of these curves we prove item (c). Lemma 4 is proved.

Let us return to the proof of Theorem 1. Suppose that g and $\overline{g}$ are PQ^{ϵ}-projective metrics given on the connected manifold M^m. Denote by r the rank of the pair g and $\overline{g}$, and let $D\subset M^m$ be an open set with compact closure in M^m. Without loss of generality we can suppose that D is connected. Taking r different real numbers $c_1,\dots,c_r$ such that $|c_k|>m_D$, $m_D \overset{\text{def}}{=} \sup_{x\in D}\max_{\lambda\in \mathrm{Spect}(A|_x)}|\lambda|$, consider the quadratic forms $B_i^D \overset{\text{def}}{=} K_{c_i}(g,\overline{g})$ $(i=1,\dots,r)$. The forms B_i^D are well-defined on D. Considered as functions of the tangent bundle TD, B_i^D $(i=1,\dots,r)$ are pairwise commuting integrals of the geodesic flow of the metric g (Theorem 3).

Definition 7: A point $x_0\in M^m$ is called stable *iff the rank $r(g,\overline{g})(x)$ of the pair of PQ^{ϵ}-projective metrics g and $\overline{g}$ is equal to some constant q in an open neighborhood of the point x_0. We say that x_0 is a stable point of rank q.*

Definition 8: A point $x_0\in M^m$ is called singular *iff it is not stable.*

Denote the set of stable points by $\mathcal{M}(g,\overline{g})$ and the set of singular points by $\mathcal{S}(g,\overline{g})$.

Lemma 6: The set of stable points $\mathcal{M}(g,\overline{g})$ is open and dense in M^m.

Proof of Lemma 6: The set $\mathcal{M}(g,\overline{g})$ is open by its definition. It follows from Lemma 4 that *for every $x\in M^m$ there exists an open neighborhood $U(x)$ such that if $y\in U(x)$ then $r(g,\overline{g})(y)\geqslant r(g,\overline{g})(x)$.* Indeed, taking $p=r(g,\overline{g})(x)$ different real numbers $t_1,\dots,t_p$, $(-t_i)\notin \mathrm{Spect}(A|_x)$, we see [item (c), Lemma 4] that the forms $K_{t_1}|_x,\dots,K_{t_p}|_x \in \mathrm{Symm}(T_x^*M^m\otimes T_x^*M^m)$ are linearly independent. There exists an open neighborhood $U(x)$ such that if $y\in U(x)$ then $K_{t_1}|_y,\dots,K_{t_p}|_y$ are linearly independent. Finally, applying item (a) of Lemma 4 we obtain that $r(g,\overline{g})(y)\geqslant r(g,\overline{g})(x)$.

Therefore, *if x_0 is a singular point, then every open neighborhood of x_0 contains a point y such that $r(g,\overline{g})(y)>r(g,\overline{g})(x_0)$.*

Let us prove that the set of stable points $\mathcal{M}(g,\overline{g})$ is dense in M^m. Suppose that there exists an open set $Y\subset M^m$ that consists of singular points. Take a point $y_1\in Y$, $r(g,\overline{g})(y_1)=r_1$. The point y_1 is singular, and therefore there exists a point $y_2\in Y$ such that $r(g,\overline{g})(y_2)=r_2>r_1$. Applying this argument several times we find a (singular!) point $y_l\in Y$ of maximal rank m. From another side, the points of maximal rank m are stable. This contradiction proves Lemma 6.

Lemma 7: Let x_0 be a stable point of rank $q\leqslant r$, $x_0\in D$. Then there exists an open neighborhood $U(x_0)\subset D$ such that we see the following:

(a) the quadratic in velocities functions $B_1^D(\xi),\dots,B_q^D(\xi)$ are functionally independent on $TU(x_0)$. For every fixed $x\in U(x_0)$ the set of the points $\xi\in T_xM^m$ where the differentials $d_\xi B_1^D,\dots,d_\xi B_q^D$ are linearly independent is open and dense in T_xM^m;

(b) if c is a real constant such that $(A+c\mathbf{1})$ is nondegenerate on $U(x_0)$, then there exist constants $\alpha_1,\dots,\alpha_q$ such that

$$K_c(g,\overline{g})(\xi)=\sum_{k=1}^{q}\alpha_k B_k^D(\xi),\quad \xi\in TU(x_0).$$

Proof of Lemma 7: (c) of Lemma 4 shows that the forms $B_1^D|_{x_0},\dots,B_q^D|_{x_0}$, considered as elements of $\mathrm{Symm}(T_{x_0}^*M^m\otimes T_{x_0}^*M^m)$, are linearly independent. There exists an open neighborhood $U(x_0)$ of the point x_0 such that for every $y\in U(x_0)$ the forms $B_1^D|_y,\dots,B_q^D|_y$ are linearly independent and $r(g,\overline{g})(y)=q$. Hence, there exist smooth functions $\alpha_1,\dots,\alpha_q\in C^\infty(U(x_0))$ such that

$$K_c(g,\overline{g})(\xi)=\sum_{k=1}^{q}\alpha_k(y)B_k^D(\xi),$$

where $\xi\in U(x_0)$, $y=\pi(\xi)$, and $\pi:TM^m\to M^m$ is the projection on the base M^m. Denote by E_g the "energy" integral $E_g(\xi)\overset{\text{def}}{=}\frac{1}{2}g(\xi,\xi)$ and let $\{\cdot,\cdot\}_g$ be the Poisson bracket corresponding to the symplectic structure ω_g. Using that $B_1^D(\xi),\dots,B_q^D(\xi)$ and $K_c(\xi)$ are integrals of the geodesic flow of the metric g, we obtain $0=\{E_g,K_c\}_g=\Sigma_{k=1}^q\{E_g,\alpha_k\}_g B_k^D(\xi)$ for every $\xi\in TU(x_0)$. The

linear independence of the forms $B_1^D|_y,\dots,B_q^D|_y$ for every fixed $y\in U(x_0)$ shows that $\{E_g,\alpha_k\}\equiv 0$ on $TU(x_0)$, and therefore α_k are constants. Item (b) of Lemma 7 is proved.

Denote by $B_k^D|_{T_xM^m}$ the restriction of the function $B_k^D(\xi)$ on the fiber $T_xM^m\hookrightarrow TM^m$. Taking a point $\xi\in T_xM^m$, we obtain $d_\xi(B_k^D|_{T_xM^m})(\eta)=2B_k^D|_x(\xi,\eta)$, where $\eta\in T_xM^m\cong T_\xi(T_xM^m)$. It follows from Lemma 4 (b) that for every point $x\in U(x_0)$ there exists an open and dense in T_xM^m subset $\Sigma_x\subset T_xM^m$ such that if $\xi\in\Sigma_x$ then $B_1^D|_x(\xi,.),\dots,B_q^D|_x(\xi,\cdot)\in T_x^*M^m$ are linearly independent. Therefore, the functions $B_1^D(\xi),\dots,B_q^D(\xi)$ are functionally independent in $TU(x_0)$. Lemma 7 is proved.

Let us prove that the functions $B_1^D(\xi),\dots,B_r^D(\xi)$ are functionally independent in TD. According to Lemma 6 and Lemma 7, it is sufficient to prove that the stable points in D have rank r. Assume that there exists a stable point $y_0\in D$ having rank $r_0<r$. Without loss of generality we can suppose that the open set D contains a stable point $x_0\in D$ of rank r. Assume for simplicity that the points x_0 and y_0 can be connected by a geodesic line $t\to\gamma(t)\in D$, $\gamma(0)=x_0$, $\gamma(1)=y_0$. Let us take neighborhoods $U(x_0)$ and $V(y_0)$ of the points x_0 and y_0, respectively, such that the conditions of Lemma 7 are satisfied. We can suppose that the differentials $d_wB_1^D,\dots,d_wB_r^D$ are linearly independent at the point $w\overset{\text{def}}{=}\dot\gamma(0)$ (If not, we take $w'\in T_{x_0}M^m$ such that $d_{w'}B_1^D,\dots,d_{w'}B_r^D$ are linearly independent and $\exp w'\in V(y_0)$ [see Lemma 7 (a)]). Denote by $\zeta_t(\xi)$, $\xi\in TM^m$, the one-parameter family of local diffeomorphisms of TM^m corresponding to the geodesic flow of the metric g. Using the fact that the functions $B_1^D(\xi),\dots,B_r^D(\xi)$ are integrals of the geodesic flow of g, we obtain that the differentials $d_vB_1^D,\dots,d_vB_r^D$, $v\overset{\text{def}}{=}\zeta_1(w)$, are linearly independent. From another side, Lemma 7 (b) shows that $B_{r_0+1}^D(\xi)=\Sigma_{k=1}^{r_0}\alpha_kB_k^D(\xi)$ where ξ lies in $TV(y_0)$ and α_k are some constants. Hence, for every $\xi\in TV(y_0)$, $d_\xi B_{r_0+1}^D=\Sigma_{k=1}^{r_0}\alpha_kd_\xi B_k^D$. This contradiction proves that *the stable points $x\in D$, that can be connected by a geodesic line $\gamma(t)$ lying in D with another stable point $y\in D$ of rank r, are also of rank r*. By assumption, D is connected. Therefore, the stable points in D have rank r. Item (a) of Theorem 1 is proved. Item (b) easily follows from Lemma 7 (b). Theorem 1 is proved.

V. $PQ^{(-1)}$-PROJECTIVE HERMITIAN METRIC

Let M^n be a complex manifold of complex dimension n. Denote by J the complex structure of M^n, $(M^{2n},J)\cong M^n$. Consider a pair of $PQ^{(-1)}$-projective Hermitian metrics s and $\tilde s$ ($\epsilon=-1$ and $PQ=-\mathbf{1}$). Denote by $K_c(s,\tilde s)$ the local family of pairwise commuting integrals of the geodesic flow of the metric s (Theorem 3). In our case $\epsilon=-1$ and we obtain that $K_c(s,\tilde s)\overset{\text{def}}{=}|\det(A+c\mathbf{1})|^{1/2}s(A+c\mathbf{1})^{-1}$, where $A=A(s,\tilde s)$.

Fixing a complex chart $\{(z^1,\dots,z^n)\}$ consider the Hermitian matrices $S\overset{\text{def}}{=}(s_{\alpha\bar\beta})$ and $\tilde S\overset{\text{def}}{=}(\tilde s_{\alpha\bar\beta})$ related to the metrics $ds^2=2s_{\alpha\bar\beta}dz^\alpha d\bar z^\beta$ and $d\tilde s^2=2\tilde s_{\alpha\bar\beta}dz^\alpha d\bar z^\beta$, respectively. As usual, we omit the summation symbols in the formulas. Define the operator $\mathcal{A}\overset{\text{def}}{=}\mathcal{A}_\beta^\alpha(\partial/\partial z^\alpha)\otimes dz^\beta$, where

$$\mathcal{A}_\beta^\alpha\overset{\text{def}}{=}\left|\frac{\det\tilde S}{\det S}\right|^{1/(n+1)}\tilde s^{\alpha\bar\nu}s_{\bar\nu\beta},\tag{18}$$

and $\tilde s^{\alpha\bar\nu}\tilde s_{\bar\nu\beta}=\delta_\beta^\alpha$. By definition, $\mathcal{A}$ is a smooth section of the vector bundle $\mathrm{End}_{\mathbf{C}}(T^{(1,0)}M^n)$, where $T^{(1,0)}M^n$ denotes the bundle of the *holomorphic* tangent vectors to M^n. Fixing a point $x\in M^n$, denote by $\rho(s,\tilde s)(x)$ the minimal polynomial of the operator $\mathcal{A}|_x$.

Definition 9: The number $\rho(s,\tilde s)\overset{\text{def}}{=}\max_{x\in M^n}\rho(s,\tilde s)(x)$ *is called* the Hermitian rank of the pair of $PQ^{(-1)}$-projective Hermitian metrics.

Theorem 4: *Suppose that the complex manifold M^n is connected and let the Hermitian rank of the pair of $PQ^{(-1)}$-projective Hermitian metrics s and $\widetilde{s}$ be r. Then there exist r Hermitian forms $B_1,\dots,B_r$ such that we have the following:*

(a) considered as functions of the tangent bundle TM^n, the quadratic forms $B_1(\xi),\dots,B_r(\xi)$ are functionally independent pairwise commuting integrals of the geodesic flow of the metric s;

(b) for every fixed real constant c, the integral $K_c(s,\widetilde{s})(\xi)$ is well-defined and

$$K_c(s,\widetilde{s})(\xi)=\sum_{k=1}^{r}\alpha_k B_k(\xi),$$

where α_k are some constants.

The functions $B_1(\xi),\dots,B_r(\xi)$ can be taken in the form $B_k=K_{c_k}(s,\widetilde{s})$, where c_k are appropriately chosen constants.

Proof of Theorem 4: Fixing a complex chart $\{(z^1,\dots,z^n)\}$ we have $s=s_{\alpha\overline{\beta}}(dz^\alpha\otimes d\overline{z}^\beta+d\overline{z}^\beta\otimes dz^\alpha)$ and $\widetilde{s}=\widetilde{s}_{\alpha\overline{\beta}}(dz^\alpha\otimes d\overline{z}^\beta+d\overline{z}^\beta\otimes dz^\alpha)$, where $S\overset{\text{def}}{=}(s_{\alpha\overline{\beta}})$ and $\widetilde{S}\overset{\text{def}}{=}(\widetilde{s}_{\alpha\overline{\beta}})$ are Hermitian matrices. Denote by $[s]$ and $[\widetilde{s}]$ the Gramians of the metrics s and $\widetilde{s}$, respectively, i.e.,

$$[s]=\begin{bmatrix}0 & S\\ \overline{S} & 0\end{bmatrix}$$

and

$$[\widetilde{s}]=\begin{bmatrix}0 & \widetilde{S}\\ \overline{\widetilde{S}} & 0\end{bmatrix}.$$

It follows from the definition of the operator $A(s,\widetilde{s})$ [formula (4)] that in the fixed complex chart we have

$$A(s,\widetilde{s})\overset{\text{def}}{=}\left|\frac{\det[\widetilde{s}]}{\det[s]}\right|^{1/2(n+1)}[\widetilde{s}]^{-1}[s]=\left|\frac{\det\widetilde{S}}{\det S}\right|^{1/(n+1)}[\widetilde{s}]^{-1}[s].$$

Hence, $A(s,\widetilde{s})=\mathcal{A}_\beta^\alpha(\partial/\partial z^\alpha)\otimes dz^\beta+\mathcal{A}_\beta^{\overline{\alpha}}(\partial/\partial\overline{z}^\alpha)\otimes d\overline{z}^\beta$, where $\mathcal{A}_\beta^\alpha$ is given by formula (18) and $\mathcal{A}_\beta^{\overline{\alpha}}$ coincides with the complex conjugation of $\mathcal{A}_\beta^\alpha$ (i.e., $\mathcal{A}_\beta^{\overline{\alpha}}=\overline{\mathcal{A}}_\beta^\alpha$). As usual, we identify the operator $\mathcal{A}$ with the square matrix $(\mathcal{A}_\beta^\alpha)$.

Lemma 8: The degree of the minimal polynomial of the operator $\mathcal{A}(s,\widetilde{s})$ coincides with the degree of the minimal polynomial of the operator $A(s,\widetilde{s})$.

Proof of Lemma 8: A simple calculation shows that

$$\mathcal{A}-\overline{\lambda}\mathbf{1}=\widetilde{S}^{-1}(\mathcal{A}-\lambda)^*\widetilde{S},$$

where $(\cdot)^*$ denotes the Hermitian conjugation of a matrix. Hence, for every integer k we have $(\mathcal{A}-\overline{\lambda}\mathbf{1})^k=\widetilde{S}^{-1}[(\mathcal{A}-\lambda)^k]^*\widetilde{S}$. Consider the Jordan's normal form of the operator $\mathcal{A}$. The last equalities show that the Jordan's decompositions corresponding to the eigenvalues λ and $\overline{\lambda}$ coincide. Finally, we conclude the statement of the lemma from the formula $A(s,\widetilde{s})=\mathcal{A}_\beta^\alpha(\partial/\partial z^\alpha)\otimes dz^\beta+\overline{\mathcal{A}}_\beta^\alpha(\partial/\partial\overline{z}^\alpha)\otimes d\overline{z}^\beta$. Lemma 8 is proved.

It follows from Lemma 8 that the rank $r(s,\widetilde{s})$ of the pair s and $\widetilde{s}$ coincides with their Hermitian rank, i.e., $r=r(s,\widetilde{s})=\rho(s,\widetilde{s})$.

Let us fix an arbitrary real constant c. Denote by $\mathcal{K}_c(s,\widetilde{s})$ the Hermitian matrix of the form $K_c(s,\widetilde{s})$. A simple calculation shows that

$$\mathcal{K}_c(s,\tilde{s})=\det(\overline{\mathcal{A}}+c\mathbf{1})S(\overline{\mathcal{A}}+c\mathbf{1})^{-1}=\mathcal{I}_{n-1}(s,\tilde{s})c^{n-1}\cdot\cdots+\mathcal{I}_0(s,\tilde{s}).$$

The last formula is valid in every fixed complex chart. Therefore, there exist well-defined on the whole M^n Hermitian forms $I_{n-1},\ldots,I_0$ such that $K_c=I_{n-1}c^{n-1}+\cdots+I_0$. Denote by $I_{n-1}(\xi),\ldots,I_0(\xi)$ the corresponding smooth functions of the tangent bundle TM^n. We obviously have

$$K_c(\xi)=I_{n-1}(\xi)c^{n-1}+\cdots+I_0(\xi), \tag{19}$$

where $I_j\in C^\infty(TM^n)$. Denote by $\mathcal{I}(s,\tilde{s})$ the vector space spanned on the functions $I_j\in C^\infty(TM^n)$ $(j=0,\ldots,n-1)$. Take a basis $B_1(\xi),\ldots,B_{r'}(\xi)$ of the linear space $\mathcal{I}(s,\tilde{s})$. Let us fix an open set $D\subset M^n$ with compact closure in M^n and consider the quadratic forms $B_1^D(\xi),\ldots,B_r^D(\xi)$ given by Theorem 1. Item (b) of Theorem 1 and formula (19) show that $B_k|_{TD}\in\mathrm{Span}(B_1^D|_{TD},\ldots,B_r^D|_{TD})$ $(k=1,\ldots,r')$ where $\mathrm{Span}(B_1^D|_{TD},\ldots,B_r^D|_{TD})$ denotes the vector space spanned on the restrictions of the functions $B_k^D(\xi)$ on TD. From another side, $B_k^D(\xi)\overset{\text{def}}{=}K_{c_k}(s,\tilde{s})(\xi)$. Using formula (19) again we obtain that $B_k^D|_{TD}\in\mathrm{Span}(B_1|_{TD},\ldots,B_r|_{TD})$ $(k=1,\ldots,r)$. Therefore, $r=r'$. The functions $B_1^D(\xi),\ldots,B_r^D(\xi)$ are functionally independent on TD. Hence, the functions $B_1(\xi),\ldots,B_r(\xi)$ are functionally independent as well. Finally, recall that the set D was taken arbitrary. Theorem 4 is proved.

Remark 6: In the present section we do not use essentially the integrability of the complex structure J. Therefore, Theorem 4 still holds if (M^{2n},J) be an almost complex manifold of real dimension $2n$.

VI. EXAMPLES. INTEGRABLE SYSTEMS ON $\mathbf{CP}^n$

Our aim in the present section is to find a family of completely integrable systems on the complex projective space $\mathbf{CP}^n$. Denote by $\{(z_0:\cdots:z_n)\}$ the homogeneous coordinates of $\mathbf{CP}^n$ and consider the affine chart $\mathbf{C}^n\ni(z_1,\ldots,z_n)\mapsto(1:z_1:\cdots:z_n)\in\mathbf{CP}^n$. In coordinates $\{(z_1,\ldots,z_n)\}$, the Fubini metrics are given by the formula

$$dg^2\overset{\text{def}}{=}2\frac{\Sigma_{\alpha=1}^n\epsilon_\alpha|dz_\alpha|^2+\frac{K}{2}((\Sigma_{\alpha=1}^n\epsilon_\alpha|z_\alpha|^2)(\Sigma_{\alpha=1}^n\epsilon_\alpha|dz_\alpha|^2)-|\Sigma_{\alpha=1}^n\epsilon_\alpha\overline{z}_\alpha dz_\alpha|^2)}{\left(1+\frac{K}{2}\Sigma_{\alpha=1}^n\epsilon_\alpha|z_\alpha|^2\right)^2}, \tag{20}$$

where $K\neq0$ and the "signs" $\epsilon_\alpha=\pm1$ $(\alpha=1,\ldots,n)$ are fixed. Consider the hermitian form $Q(\xi,\overline{\eta})\overset{\text{def}}{=}\xi_0\overline{\eta}_0+K/2\,\Sigma_{\alpha=1}^n\epsilon_\alpha\xi_\alpha\overline{\eta}_\alpha$, $\xi,\eta\in\mathbf{C}^{n+1}$. The hypersurface $Abs\hookrightarrow\mathbf{CP}^n$ given in homogeneous coordinates by $Abs\overset{\text{def}}{=}\{Q(z)=Q(z,\overline{z})=0\}$ is called *absolute* of the corresponding Fubini metric. The Fubini metrics are smoothly defined on $\mathbf{CP}^n\backslash Abs$. If $K>0$ and $\epsilon_\alpha=1$ then $Abs=\emptyset$, and the corresponding Fubini metric is a smooth Riemannian metric on $\mathbf{CP}^n$. The Fubini metrics are usually considered only on the subset $F\overset{\text{def}}{=}\{Q(z)>0\}\subset\mathbf{CP}^n$. Nevertheless, it will be more convenient for us to think of the Fubini metrics as metrics defined on the whole $\mathbf{CP}^n$ and having "singularities" in Abs. The Fubini metrics are Hermitian and the corresponding Hermitian matrices are $g_{\alpha\overline{\beta}}=\epsilon_\alpha\delta_{\alpha\beta}/Q(z)-(K/2)[(\epsilon_\alpha\overline{z}_\alpha)(\epsilon_\beta z_\beta)/Q(z)^2]$. It is well-known that the Fubini metrics are Kählerian metrics.

Denote by ∇ the Levi-Civita connection corresponding to the Fubini metric g. The connection ∇ can be extended in a natural way to a connection on the complexification of the tangent bundle. It can be easily seen that the corresponding Christoffel symbols are given by the formula $\Gamma_{pq}^\alpha=-[K/2Q(z)](\delta_p^\alpha\epsilon_q\overline{z}_q+\delta_q^\alpha\epsilon_p\overline{z}_p)$, $\Gamma_{\overline{pq}}^{\overline{\alpha}}=\overline{\Gamma}_{pq}^\alpha$, and the other components of the Christoffel symbols vanish (see Ref. 10, Sec. 5, for the case $\epsilon_\alpha=1$).

Let $\mu_L:\mathbf{CP}^n\to\mathbf{CP}^n$ be a projective transformation induced by some (complex) linear transformation $L:\mathbf{C}^{n+1}\to\mathbf{C}^{n+1}$ given in matrix form by the nondegenerate complex matrix $L\in GL_{n+1}(\mathbf{C})$. Denote by $\tilde{g}$ the pull-back $\mu_L^* g$.

Proposition 5: The metrics g and $\tilde{g}$ are h-projective Kählerian metrics.

Proof of Proposition 5: Let L_2 be a complex 2-plane in $\mathbf{C}^{n+1}$. The set of complex lines lying in L_2 gives a natural embedding of the complex projective line $\mathbf{CP}^1$ in $\mathbf{CP}^n$. We call such embeddings *projective lines*. Proposition 5 easily follows from the next simple lemma.

Lemma 9: A smooth curve $\gamma(t)\in\mathbf{CP}^n\backslash Abs$ is holomorphically planar with respect to a fixed Fubini metric iff $\gamma(t)$ lies in a projective line.

Proof of Lemma 9: Consider the affine chart $\{(z_1,\dots,z_n)\}$ and suppose that $\gamma(t)=(\gamma^1(t),\dots,\gamma^n(t))$. The condition that $\gamma(t)$ is holomorphically planar with respect to a fixed Fubini metric g is equivalent to the equation

$$\frac{\nabla\dot{\gamma}^\alpha}{dt}(t)=\rho(t)\,\dot{\gamma}^\alpha(t),\quad \alpha=1,\dots,n,$$

where $\rho(t)$ is a smooth complex-valued function of the real parameter t and $\nabla\dot{\gamma}^\alpha/dt$ are the components of the "holomorphic" part of the real vector $\nabla\dot{\gamma}/dt$. Using the explicit form of the Christoffel symbols of the Fubini metric g we obtain

$$\frac{\nabla\dot{\gamma}^\alpha}{dt}(t)=\frac{d^2\gamma^\alpha}{dt^2}+\Gamma^\alpha_{pq}\dot{\gamma}^p\dot{\gamma}^q=\frac{d^2\gamma^\alpha}{dt^2}-\frac{K}{Q}(\epsilon_p\overline{z}_p\dot{\gamma}^p)\dot{\gamma}^\alpha.$$

Therefore, the curve $\gamma(t)$ is holomorphically planar if and only if $d^2\gamma^\alpha/dt^2=\rho_1(t)\,(d\gamma^\alpha/dt)$, where $\rho_1(t)$ is a smooth complex-valued function of t. This completes the proof of Lemma 9.

Finally, Proposition 5 follows from the fact that $\mu_L:\mathbf{CP}^n\to\mathbf{CP}^n$ maps projective lines to projective lines. Proposition 5 is proved.

An analog of Lemma 9 in the case of positive definite Fubini metrics is proved in Ref. 15, Sec. 6.

Let us take $L=\mathrm{diag}(1,\lambda_1,\dots,\lambda_n)$ where λ_α are fixed constants. In the chart $\{(z_1,\dots,z_n)\}$, the induced projective transformation $\mu_L:\mathbf{CP}^n\to\mathbf{CP}^n$ is given by the formula $(z_1,\dots,z_n)\mapsto(\lambda_1 z_1,\dots,\lambda_n z_n)$. We have

$$d\tilde{g}^2=2\,\frac{\tilde{Q}(z)(\Sigma_{\alpha=1}^n\epsilon_\alpha\rho_\alpha|dz_\alpha|^2)-\dfrac{K}{2}|\Sigma_{\alpha=1}^n\epsilon_\alpha\rho_\alpha\overline{z}_\alpha\,dz_\alpha|^2}{\tilde{Q}(z)^2},\tag{21}$$

where $\rho_\alpha\overset{\text{def}}{=}|\lambda_\alpha|^2$ and $\tilde{Q}(z)\overset{\text{def}}{=}1+K/2\,\Sigma_{\alpha=1}^n\epsilon_\alpha\rho_\alpha|z_\alpha|^2$. The components of the corresponding Hermitian matrix are $\tilde{g}_{\alpha\overline{\beta}}=\epsilon_\alpha\rho_\alpha\delta_{\alpha\beta}/\tilde{Q}(z)-(K/2)[(\epsilon_\alpha\rho_\alpha\overline{z}_\alpha)(\epsilon_\beta\rho_\beta z_\beta)/\tilde{Q}^2(z)]$. Let us remark that the metric $\tilde{g}$ is smoothly defined on $\mathbf{CP}^n\backslash\widetilde{Abs}$, where $\widetilde{Abs}\overset{\text{def}}{=}\{\tilde{Q}(z)=0\}$.

Lemma 10: Let B be a non-degenerate symmetric $n\times n$-matrix and $a,b\in\mathbf{C}^n$ are complex vectors considered as $n\times 1$-matrices. Denote by $(\cdot)'$ the transposition of a matrix and $\langle x,y\rangle\overset{\text{def}}{=}\Sigma_{\alpha=1}^n x_\alpha y_\alpha$. Then

(i) $(B+ab')^{-1}=B^{-1}-(B^{-1}a)(B^{-1}b)'/1+\langle B^{-1}a,b\rangle$;
(ii) $\det(B+ab')=(1+\langle B^{-1}a,b\rangle)\det B$.

The proof of Lemma 10 is straightforward.

Using Lemma 10 we obtain $\tilde{g}^{\alpha\overline{\beta}}=\tilde{Q}(\epsilon_\alpha\rho_\alpha^{-1}\delta_{\alpha\beta}+(K/2)\,z_\alpha\overline{z}_\beta)$. Hence, the operator $A(g,\tilde{g})$ is given by the formula $A(g,\tilde{g})=\mathcal{A}^\alpha_\beta(\partial/\partial z_\alpha)\otimes dz_\beta+\mathcal{A}^{\overline{\alpha}}_{\overline{\beta}}(\partial/\partial\overline{z}_\alpha)\otimes d\overline{z}_\beta$, where $\mathcal{A}^{\overline{\alpha}}_{\overline{\beta}}=\overline{\mathcal{A}^\alpha_\beta}$ and $\mathcal{A}^\alpha_\beta=|\det\tilde{G}/\det G|^{1/(n+1)}\tilde{g}^{\alpha\overline{\nu}}g_{\overline{\nu}\beta}$, $\tilde{G}\overset{\text{def}}{=}(\tilde{g}_{\alpha\overline{\beta}})$, $G\overset{\text{def}}{=}(g_{\alpha\overline{\beta}})$ (see Sec. 5). Applying Lemma 10 we obtain

$$\mathcal{A}_{\beta}^{\alpha}=\rho_{\beta}^{-1}\delta_{\beta}^{\alpha}-\frac{K}{2Q}((1-\rho_{\alpha})z_{\alpha}/\rho_{\alpha})(\epsilon_{\beta}\overline{z_{\beta}}). \tag{22}$$

Denote by $\mathcal{A}$ the matrix with elements $\mathcal{A}_{\beta}^{\alpha}$. Consider the sequences of Hermitian matrices $\{G^{(l)}\}_{l\in\mathbf{Z}}$ and $\{\tilde{G}^{(l)}\}_{l\in\mathbf{Z}}$ defined by the formulas $G^{(l)}\overset{\text{def}}{=}G\overline{\mathcal{A}^{l}}$ and $\tilde{G}^{(l)}\overset{\text{def}}{=}\tilde{G}\overline{\mathcal{A}^{l}}$. Denote by $g^{(l)}$ and $\tilde{g}^{(l)}$ the Hermitian metrics,

$$dg^{(l)^2}\overset{\text{def}}{=}2g_{\alpha\overline{\beta}}^{(l)}dz_{\alpha}d\overline{z}_{\beta} \tag{23}$$

and

$$d\tilde{g}^{(l)^2}\overset{\text{def}}{=}2\tilde{g}_{\alpha\overline{\beta}}^{(l)}dz_{\alpha}d\overline{z}_{\beta}, \tag{24}$$

where $g_{\alpha\overline{\beta}}^{(l)}$ and $\tilde{g}_{\alpha\overline{\beta}}^{(l)}$ are the elements of the Hermitian matrices $G^{(l)}$ and $\tilde{G}^{(l)}$, respectively.

Consider the operators $\mathcal{P}_l,\mathcal{Q}_l\in\Gamma(\mathrm{End}_{\mathbf{C}}(T^{(1,0)}(\mathbf{CP}^n\backslash Abs)))$ given in coordinates by the matrices $i\mathcal{A}^{l}$ and $i\mathcal{A}^{-l}$, respectively, and define the "real" operators $P_l\overset{\text{def}}{=}\mathcal{P}_l+\overline{\mathcal{P}_l}$ and $Q_l\overset{\text{def}}{=}\mathcal{Q}_l+\overline{\mathcal{Q}_l}$. The next theorem follows from the results proved in Sec. II D.

Theorem 5: *For every fixed integer $l\in\mathbf{Z}$ the Hermitian metrics $g^{(l)}$ and $\tilde{g}^{(l)}$ given by formulas (23) and (24) are $P_lQ_l^{(-1)}$-projective Hermitian metrics.*

The sequence of metrics $g^{(l)}$ and $\tilde{g}^{(l)}$ ($l\in\mathbf{Z}$) given by Theorem 5 is called a $\mathbf{CP}^n$*-hierarchy*.

Let us consider the one-parameter groups of transformations of $\mathbf{CP}^n$ given in coordinates by the formulas

$$T_k(\phi):(z_1,\ldots,z_k,\ldots,z_n)\mapsto(z_1,\ldots,\exp(i\phi)z_k,\ldots,z_n).$$

It follows from (20) and (21) that $T_k(\phi)$ preserve the metrics g and $\tilde{g}$, and therefore they preserve the whole $\mathbf{CP}^n$-hierarchy. Denote by T_k the corresponding Killing symmetries,

$$T_k\overset{\text{def}}{=}i\left(z_k\frac{\partial}{\partial z_k}-\overline{z_k}\frac{\partial}{\partial\overline{z_k}}\right). \tag{25}$$

Consider the "complex" impulses $p_k\overset{\text{def}}{=}\frac{1}{2}(p_{x_k}-ip_{y_k})$ and $\overline{p_k}\overset{\text{def}}{=}\frac{1}{2}(p_{x_k}+ip_{y_k})$ $(k=1,\ldots,n)$, where p_{x_k} and p_{y_k} are the impulses corresponding to the chart $\{(x_1,y_1,\ldots,x_n,y_n)\}$, $z_k\overset{\text{def}}{=}x_k+iy_k$. The chart $\{(p_1,\ldots,p_n;z_1,\ldots,z_n)\}$ is a complex chart of $T^*\mathbf{CP}^n$. The canonical symplectic structure ω on $T^*\mathbf{CP}^n$ is given by the formula $\omega=\Sigma_{k=1}^{n}dp_k\wedge dz_k+\Sigma_{k=1}^{n}d\overline{p_k}\wedge d\overline{z_k}$.

Theorem 6: *For every fixed integer $l\in\mathbf{Z}$ the functions $\mathcal{I}_{n-1}^{(l)}(p),\ldots,\mathcal{I}_0^{(l)}(p)$ given by the expansion*

$$\mathcal{K}_c^{(l)}(p)\overset{\text{def}}{=}\det(\mathcal{A}+c\mathbf{1})\langle(\mathcal{A}+c\mathbf{1})^{-1}\mathcal{A}^{l}\overline{G}^{-1}\overline{p},p\rangle=\mathcal{I}_{n-1}^{(l)}(p)c^{n-1}+\cdots+\mathcal{I}_0^{(l)}(p), \tag{26}$$

where $p\overset{\text{def}}{=}(p_1,\ldots,p_n)$, $\overline{p}\overset{\text{def}}{=}(\overline{p_1},\ldots,\overline{p_n})$ and $\langle X,Y\rangle\overset{\text{def}}{=}\Sigma_{k=1}^{n}X_kY_k$, are in involution with respect to the canonical symplectic structure ω on the cotangent bundle $T^*\mathbf{CP}^n$. If $\rho_{\alpha}\neq\rho_{\beta}$ $(\alpha\neq\beta)$ then the functions $\mathcal{I}_{n-1}^{(l)}(p),\ldots,\mathcal{I}_0^{(l)}(p)$ are functionally independent on $T^*(\mathbf{CP}^n\backslash Abs)$. Adding to the functions $\mathcal{I}_{n-1}^{(l)}(p),\ldots,\mathcal{I}_0^{(l)}(p)$ the Noether integrals $T_k(p)\overset{\text{def}}{=}i(z_kp_k-\overline{z_k}\overline{p_k})$ $(k=1,\ldots,n)$ corresponding to the Killing symmetries (25), we obtain a complete system of functionally independent functions in involutions on $T^*(\mathbf{CP}^n\backslash Abs)$.

Proof of Theorem 6: It follows from formula (22) that $\mathcal{A}_{\beta}^{\alpha}(0)=\rho_{\beta}^{-1}\delta_{\beta}^{\alpha}$. Hence, if $\rho_{\alpha}\neq\rho_{\beta}$ $(\alpha\neq\beta)$ then the Hermitian rank of the pair $g^{(l)}$ and $\tilde{g}^{(l)}$ is n. Finally, the statement of the theorem follows from Theorem 4, Sec. V, applied to the pair $g^{(-l)}$ and $\tilde{g}^{(-l)}$ from the **CP**-hierarchy. Theorem 6 is proved.

Corollary 2: Provided $\rho_\alpha \neq \rho_\beta$ $(\alpha \neq \beta)$, *the geodesic flows of the metrics* $g^{(l)}$ *and* $\tilde{g}^{(l)}$ *from the* $\mathbf{CP}^n$*-hierarchy are completely integrable.*

Remark 7: Taking $l=0$ *and* $\epsilon_\alpha = 1$, *we obtain a complete family of pairwise commuting integrals of the geodesic flow of the standard Fubini metric on* $\mathbf{CP}^n$ (see Refs. 13 and 16). *Our theorem gives an infinite family of metrics on* $\mathbf{CP}^n$ *with completely integrable geodesic flows.*

Representation of semigroups in rigged Hilbert spaces: Subsemigroups of the Weyl–Heisenberg group

S. Wickramasekara[a] and A. Bohm
Department of Physics, University of Texas at Austin, Austin, Texas 78712

(Received 12 August 2002; accepted 1 November 2002)

In this paper we study how differentiable representations of certain subsemigroups of the Weyl–Heisenberg group may be obtained in suitably constructed rigged Hilbert spaces. These semigroup representations are induced from a continuous unitary representation of the Weyl–Heisenberg group in a Hilbert space. Aspects of the rigged Hilbert space formulation of time asymmetric quantum mechanics are also investigated within the context of the results developed here. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1533835]

I. INTRODUCTION

Rigged Hilbert spaces have been used in quantum physics since the mid-1960's. Although the motivation of the first contributions[1–3] was to provide a rigorous mathematical context for Dirac's (already well-established) bra-and-ket formulation of quantum mechanics, subsequent investigations[4–7] have led to some interesting new physical results. Among these are a formulation of scattering theory which accommodates an asymmetric time evolution given by a *semigroup* of operators, and a related vector description for an (isolated) resonance state. The more recent of these works[7] extend the earlier results to relativistic resonances where it is shown that they can be characterized by irreducible representations of the causal Poincaré semigroup.

Many of the results of these theories can be subsumed under a general study of the representations of Lie groups and their subsemigroups in rigged Hilbert spaces. We call a subset S of a Lie group G a subsemigroup of the group if S contains the identity element and remains invariant under the group multiplication of G. Notice that S need not be closed under the inverse operation $x \to x^{-1}$. If S is such a subsemigroup of a Lie group G, the problem in its broadest generality can be stated as follows: If U is a continuous (often unitary) representation of G in a Hilbert space $\mathcal{H}$, does there exist a rigged Hilbert space $\Phi \subset \mathcal{H} \subset \Phi^\times$ such that Φ reduces U to a continuous representation of S?

It is clear that if $U|_\Phi$ is such a representation of S, then there also exists a dual representation $U|_\Phi^\times$ of S in $\Phi^\times$. The semigroup time evolution of Gamow vectors,[4–7] which describe the (isolated) resonance states, is given by such a representation in $\Phi^\times$ dual to a semigroup representation in Φ. In particular, in the nonrelativistic scattering theory developed in Refs. 4–6, time, i.e., the Lie group of real numbers under addition, is unitarily represented, by way of the mapping $(U(t)f)(E) = e^{iEt} f(E)$, in the Hilbert space of square integrable functions defined on the spectrum of the Hamiltonian H. The rigged Hilbert spaces $\Phi_- \subset \mathcal{H} \subset \Phi_-^\times$ and $\Phi_+ \subset \mathcal{H} \subset \Phi_+^\times$ of Hardy class functions, introduced to represent the in- and out-states, have the property that Φ_+ and Φ_- reduce the unitary group representation $U(t)$ in $\mathcal{H}$ to representations of the semigroups (under addition) of negative and positive real numbers, respectively. In the relativistic theory developed in Ref. 7, there exist two rigged Hilbert spaces which reduce a unitary representation of the Poincaré group in $\mathcal{H}$ to continuous representations of the forward and backward causal Poincaré semigroups.

These cases provide examples to the general question posed above. At present, the complete answer to this question is not known to us. It is perhaps the case that the problem is unanswerable,

[a]Electronic mail: sujeewa@physics.utexas.edu

at least in the affirmative, as stated above; it may be that such rigged Hilbert spaces are possible for only certain classes of subsemigroups of G, and this then means that it is necessary to develop a classification criterion for the subsemigroups S of a Lie group G. (Recall that even in the Lie group theory, all subgroups are not considered to be of much interest. It is Lie subgroups that are generally investigated.) In this paper, we shall mainly restrict ourselves to semigroups which are the unions of the products of continuous one parameter subsemigroups.

Our purpose in this paper is to study the representations of some subsemigroups of the Weyl–Heisenberg group as illustrative of the above general question. Our treatment will also reveal the general group theoretical content underlying the rigged Hilbert space formulation of the time asymmetric quantum mechanics developed in Refs. 4–6.

It is convenient to introduce here some preliminary concepts which we shall make use of in the following sections.

Definition 1.1: A rigged Hilbert space consists of a triad of vector spaces,

$$\Phi \subset \mathcal{H} \subset \Phi^{\times}, \tag{1.1}$$

where

(1) $\mathcal{H}$ *is a Hilbert space*
(2) Φ *is a dense subspace of* $\mathcal{H}$ *and it is endowed with a complete, locally convex, nuclear topology* τ_{Φ} *that is stronger than the* $\mathcal{H}$*-topology*
(3) $\Phi^{\times}$ *is the space of continuous antilinear functionals on* Φ*. It is complete in its weak* topology* $\tau^{\times}$ *and it contains* $\mathcal{H}$ *as a dense subspace.*

Definition 1.2: A continuous representation of a Lie group G *on a topological vector space* Ψ *is a continuous mapping* $\mathcal{T}$: $G \times \Psi \to \Psi$ *such that*

(1) *for every* $g \in G$, $\mathcal{T}(g)$ *is a linear operator in* Ψ
(2) *for every* $\psi \in \Psi$ *and* $g_1, g_2 \in G$, $\mathcal{T}(g_1 g_2)\psi = \mathcal{T}(g_1)\mathcal{T}(g_2)\psi$
(3) $T(e) = I$, *the identity operator in* Ψ

Definition 1.3: A differentiable representation of a Lie group G *on a complete topological vector space* Ψ *is a mapping* $\mathcal{T}$: $G \times \Psi \to \Psi$ *which fulfills all the requirements of Definition 1.2 and has the additional property that for every one parameter subgroup* $\{g(t)\}$ *of* G, $\lim_{t \to 0} \{[\mathcal{T}(g(t))\phi - \phi]/t\}$ *exists for all* $\phi \in \Psi$ *(and, a fortiori, defines a continuous linear operator on* Ψ*).*

The semigroup analogs of these definitions are obvious. For instance, in Definition 1.3, we simply replace the one parameter subgroups $g(t)$ of G by one parameter subsemigroups $g(t)$ of S.

II. WEYL–HEISENBERG GROUP AND ITS SUBSEMIGROUPS

The three dimensional Euclidean space $\mathbb{R}^3$ is a Lie group under the associative multiplication rule, defined by

$$(a,b,c)(\alpha,\beta,\gamma) = (a+\alpha, b+\beta, c+\gamma+a\beta). \tag{2.1}$$

It is easily verified that the origin (0,0,0) of $\mathbb{R}^3$ is the identity element and that each element (a,b,c) has an inverse given by $(a,b,c)^{-1} = (-a,-b,-c+ab)$. Thus, under (2.1) $\mathbb{R}^3$ is a group, the well known Weyl–Heisenberg group. Throughout the rest of this paper we shall refer to this group by G. We shall denote an element of G by (a,b,c), or by $\boldsymbol{\xi}$, where $\boldsymbol{\xi} = (\xi_1, \xi_2, \xi_3)$.

The Lie algebra $\mathcal{G}$ of the group G is also isomorphic to $\mathbb{R}^3$, and the elements $\chi_1 = (1,0,0)$, $\chi_2 = (0,1,0)$ and $\chi_3 = (0,0,1)$ can be chosen as a basis for $\mathcal{G}$. In fact, $\mathcal{G}$ can be made into an associative algebra (of operators acting on $\mathbb{R}^3$ itself) by way of the multiplication rule $\mathcal{G} \otimes \mathcal{G} \to \mathcal{G}$ defined by

$$(a,b,c)(\alpha,\beta,\gamma) = (0,0,a\beta). \tag{2.2}$$

Under (2.2), the basis elements χ_i fulfill the relations $\chi_i\chi_j=\delta_{1i}\delta_{2j}\chi_3$, and thereupon we have the very well-known Heisenberg commutation relations: $[\chi_1,\chi_2]=\chi_3,[\chi_1,\chi_3]=[\chi_2,\chi_3]=0$.

Among the subsemigroups of G are the following:

$$\begin{aligned} S_1(0)&=\{\boldsymbol{\xi}:\ \xi_1\geqslant 0,\ \xi_2=0,\ \xi_3\in\mathbb{R}\},\\ S_1&=\{\boldsymbol{\xi}:\ \xi_1\geqslant 0,\ \xi_2,\xi_3\in\mathbb{R}\},\\ S_2(0)&=\{\boldsymbol{\xi}:\ \xi_1=0,\ \xi_2\geqslant 0,\ \xi_3\in\mathbb{R}\},\\ S_2&=\{\boldsymbol{\xi}:\ \xi_2\geqslant 0,\ \xi_1,\xi_3\in\mathbb{R}\},\\ S_3&=\{\boldsymbol{\xi}:\ \xi_1,\xi_2\geqslant 0,\ \xi_3\in\mathbb{R}\},\\ S_4&=\{\boldsymbol{\xi}:\ \xi_1,\xi_2\geqslant 0,\ \xi_1\xi_2\geqslant\xi_3\geqslant 0\}. \end{aligned} \tag{2.3}$$

It is readily seen that each set in (2.3) is a topological semigroup. More specifically, (2.1) reduces to a continuous, associative multiplication on every S_i, and none is closed under the inverse operation $\boldsymbol{\xi}\to\boldsymbol{\xi}^{-1}$. Thus each S_i is truly a topological subsemigroup of G. Furthermore, it is straightforward to verify that the set consisting of the inverses of the elements in each S_i of (2.3) is also a subsemigroup of G. We shall denote this complementary semigroup to S_i by S_i^{-1}.

Next, let L^2 be the Hilbert space of square integrable (with respect to Lebesgue measure) functions on the real line $\mathbb{R}$. The mapping U: $G\otimes L^2\to L^2$, defined by

$$(U(\boldsymbol{\xi})f)(x)=e^{i\xi_3}e^{ix\xi_2}f(x+\xi_1), \tag{2.4}$$

furnishes a continuous unitary representation of G in L^2. The differential of U at the identity $\mathbf{0}$, $dU|_{\mathbf{0}}$, yields a representation of the Lie algebra $\mathcal{G}$, a well known result from the classical representation theory. In particular, the basis elements χ_i acquire representation as the linear operators,

$$\begin{aligned} (dU|_{\mathbf{0}}(\chi_1)f)(x)&\equiv(Mf)(x)=ixf(x),\\ (dU|_{\mathbf{0}}(\chi_2)f)(x)&\equiv(Df)(x)=\left(\frac{df}{dx}\right)(x),\\ (dU|_{\mathbf{0}}(\chi_3)f)(x)&=if(x). \end{aligned} \tag{2.5}$$

It is clear that the first two equalities may be defined not on the whole of L^2 but on a dense subspace thereof.

In the remainder of this paper we shall discuss how a rigged Hilbert space may be constructed so that the restriction $U|_\Phi$ of U to Φ yields therein a nontrivial (i.e., one that does not extend to a representation of a subgroup of G) differentiable representation of two of the subsemigroups in (2.3). We shall also remark on how rigged Hilbert spaces may be constructed for the other subsemigroups in (2.3).

III. A DIFFERENTIABLE REPRESENTATION OF $S_1(0)$ IN A RIGGED HILBERT SPACE

In this section we shall construct a rigged Hilbert space $\Psi\subset L^2\subset\Psi^\times$ such that the restriction of U to Ψ yields a representation of the subsemigroup $S_1(0)$ of G defined in (2.3). The main technical result is the construction of the rigged Hilbert space.

A. Construction of the rigged Hilbert space

Definitions: Let L^2_+ and L^2_- be the Hilbert spaces of square integrable (with respect to Lebesgue measure) functions supported in $(0,\infty)$ and $(-\infty,0)$, respectively. Let us denote the norms

in these spaces by $\|\cdot\|_+$ and $\|\cdot\|_-$. The restriction of L^2-functions to $(0,\infty)$ and $(-\infty,0)$ define, respectively, two projection operators Q_+ and Q_- onto L^2_+ and L^2_-. Thus, $L^2_+ = Q_+L^2$, $L^2_- = Q_-L^2$, and $L^2 = L^2_- \oplus L^2_+$.

The mapping $\mathbb{H}: L^2 \to L^2$ defined by

$$(\mathbb{H}f)(t) = \frac{1}{\pi}\int_{-\infty}^{\infty} dx \frac{f(x)}{x-t},$$

where the integral is defined as the Cauchy principal value, is called the Hilbert transform. It is well known that the operators $P_+ = \frac{1}{2}(I + i\mathbb{H})$ and $P_- = \frac{1}{2}(I - i\mathbb{H})$ are projections from L^2 onto $\mathcal{H}^2_+$ and $\mathcal{H}^2_-$, the Hilbert spaces of Hardy class functions from above and below, respectively.[8] Thus, $\mathcal{H}^2_+ = P_+L^2$, $\mathcal{H}^2_- = P_-L^2$, and $L^2 = \mathcal{H}^2_- \oplus \mathcal{H}^2_+$.

For any $f \in L^1(\mathbb{R})$, the function $\hat{f}$ defined by the integral

$$\hat{f}(t) = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} f(x)e^{-ixt}\,dx, \tag{3.1}$$

is said to be the Fourier transform of f. It is well known that the mapping $\mathcal{F}: f \to \hat{f}$ defined by (3.1) extends to a unitary transformation on L^2.

Fourier transform $\mathcal{F}$ provides a unitary equivalence between the two sets of projection operators introduced above: A Paley–Wiener theorem asserts that $\mathcal{F}(Q_\pm(L^2)) = P_\mp(L^2)$, $Q_\pm(L^2) = \mathcal{F}^{-1}(P_\mp(L^2))$, $\mathcal{F}^{-1}(Q_\pm(L^2)) = P_\pm(L^2)$, and $Q_\pm(L^2) = \mathcal{F}(P_\pm(L^2))$.

A remarkable theorem of van Winter[9] states that a function in $\mathcal{H}^2_\pm$ is completely determined by its values on $(0,\infty)$ [or on $(-\infty,0)$]. Further, the restriction of $\mathcal{H}^2_\pm$-functions to $(0,\infty)$ form a dense subspace of L^2_+. Similarly, their restrictions to $(-\infty,0)$ are dense in L^2_-. Transcribed to our notation, the theorem states that the L^2-inclusions $Q_+P_\pm(L^2) \subset Q_+(L^2)$ and $Q_-P_\pm(L^2) \subset Q_-(L^2)$ are dense.

Proposition 3.1: The functions $-iP_+(L^2_-)$ form a dense subspace of $\mathcal{H}^2_+$. Similarly, the functions $iP_-(L^2_-)$ are dense in $\mathcal{H}^2_-$.

Proof: Suppose $f_0 \in \mathcal{H}^2_+$, and ϵ, any positive number. For any $h \in \mathcal{H}^2_-$, we have $P_+(f_0 + h) = P_+f_0 = f_0$. Now, by the above mentioned theorem of van Winter, we can choose $h \in \mathcal{H}^2_-$ such that

$$\|-if_0 + h\|_+ < \frac{\epsilon}{2}.$$

For such an h, let $\tilde{g} = Q_-(if_0 - h)$. Then,

$$\begin{aligned}\|-iP_+\tilde{g} - f_0\| &= \|P_+(\tilde{g} - if_0)\| = \|P_+(\tilde{g} - if_0 + h)\| \leqslant \|\tilde{g} - if_0 + h\| \\ &= (\|\tilde{g} - if_0 + h\|^2_- + \|-if_0 + h\|^2_+)^{1/2} = \|-if_0 + h\|_+ < \frac{\epsilon}{2}.\end{aligned} \tag{3.2}$$

Thus, $-iP_+(L^2_-)$ is dense in $\mathcal{H}^2_+$. The same argument shows that $iP_-(L^2_-)$ is dense in $\mathcal{H}^2_-$. □

This proposition shows that the denseness of the inclusions $Q_+P_\pm(L^2) \subset Q_+(L^2)$ and $Q_-P_\pm(L^2) \subset Q_-(L^2)$, i.e., van Winter's theorem, implies the denseness of the complementary inclusions $P_+Q_\pm(L^2) \subset P_+(L^2)$ and $P_-Q_\pm(L^2) \subset P_-(L^2)$.

Definitions: Let $\mathcal{S}$ be the space of Schwartz functions on $\mathbb{R}$. That is, if $f \in \mathcal{S}$, then we have $f \in C^\infty(\mathbb{R})$ and $\lim_{x\to\pm\infty} x^n f(x) = 0$ for $n = 0,1,2,\ldots$. It is well known that $\mathcal{S}$ is dense L^2. There exists a locally convex topology under which $\mathcal{S}$ becomes a Fréchet space, and the Fourier transform $\mathcal{F}$ defined by (3.1) is a homeomorphism on this Fréchet space. [This topology is defined by the countable family of norms $\|f\|_{mn} = \sup_{x\in\mathbb{R}}|x^m(d^n/dx^n)f(x)|$, where m and n are positive integers. Equivalently, the norms $\|f\|_n = \|(M^2 + D^2 + I)^n f\|$ can be used. See also (3.5).] Further,

$\mathcal{S}_\pm$, the space of $\mathcal{S}$-functions with the support in $(0,\pm\infty)$ is dense in $L^2_\pm$. The above mentioned Paley–Wiener theorem implies that $\mathcal{F}(\mathcal{S}_\mp)=\mathcal{S}\cap\mathcal{H}^2_\pm$ and that $\mathcal{S}\cap\mathcal{H}^2_\pm$ is dense in $\mathcal{H}^2_\pm$.

Let $\mathcal{N}$ be the subspace of Schwartz functions with vanishing moments of all orders. That is, if $f\in\mathcal{N}$, then $f\in\mathcal{S}$ and $\int_{-\infty}^{\infty}x^n f(x)dx=0$ for $n=0,1,2,\ldots$. Let $\mathcal{N}_\pm$ be the space of $\mathcal{N}$-functions supported in $(0,\pm\infty)$. It is shown in the Appendix that $\mathcal{N}_\pm$ is dense in $L^2_\pm$. Since $\mathcal{N}_-\oplus\mathcal{N}_+\subset\mathcal{N}$, it then follows that $\mathcal{N}$ is dense in L^2.

The unitarity of the Fourier transform $\mathcal{F}$ implies that the image of $\mathcal{N}$ under $\mathcal{F}$ is dense in L^2. Let this space be denoted by $\mathcal{M}$. A function f in $\mathcal{M}$, being the Fourier transform of a function in $\mathcal{N}$, is smooth, rapidly decaying and has vanishing derivatives of all orders at the origin. Further, from the Appendix, it is clear that $\mathcal{N}_-\oplus\mathcal{N}_+\subset\mathcal{N}\cap\mathcal{M}$, and so, the space $\mathcal{N}\cap\mathcal{M}$ is dense in L^2. It is also straightforward to verify that $\mathcal{N}\cap\mathcal{M}$ is a closed subspace of $\mathcal{S}$. Its invariance under the Fourier transform is an interesting property.

Proposition 3.2: $\mp iP_\pm(\mathcal{N}_-)$ *is dense in* $\mathcal{S}\cap\mathcal{H}^2_\pm$.

Proof: Let f_0, $\tilde{g}$ and ϵ be as in the proof of Proposition 3.1. The denseness of $\mathcal{N}_-$ in L^2_- (see the Appendix) allows us to choose $g\in\mathcal{N}_-$ such that

$$\|g-\tilde{g}\|<\frac{\epsilon}{2}.$$

Thus,

$$\|-iP_+g-f_0\|\leqslant\|-iP_+(g-\tilde{g})\|+\|-iP_+\tilde{g}-f_0\|<\frac{\epsilon}{2}+\frac{\epsilon}{2}=\epsilon.$$

It only remains to show that $-iP_+g\in\mathcal{S}$. To that end, recall that the Fourier transform of the Hilbert transform of a function satisfies the equality $(\mathbb{H}f)\,(y)=-i\,(y/|y|)\hat{f}(y)$. Therefore,

$$(-iP_+g)\,(y)=\left(\frac{1}{2}(\mathbb{H}-iI)g\right)(y)=-\frac{i}{2}\frac{y}{|y|}\hat{g}(y)-\frac{i}{2}\hat{g}(y). \tag{3.3}$$

Since $g\in\mathcal{N}$, $\hat{g}$ has vanishing derivatives of all orders at $y=0$. Thus, $(-iP_+g)$, and therewith also $(-iP_+g)$, belongs to $\mathcal{S}$.

The same argument proves the denseness of $iP_-(\mathcal{N}_-)$ in $\mathcal{S}\cap\mathcal{H}^2_-$. □

The proof of Proposition 3.2 also implies that $\mp iP_\pm(\mathcal{N}_+)$ is dense in $\mathcal{S}\cap\mathcal{H}^2_\pm$.

Remark: Notice that $(-iP_+g)$ is in fact an element of $\mathcal{M}$. This means that $(-iP_+g)\in\mathcal{N}\cap\mathcal{H}^2_+$ whenever $g\in\mathcal{N}$. That is, $\mathcal{N}$ has the interesting property that it is invariant under the Hilbert transform $\mathbb{H}$. Furthermore, it follows that $\mathcal{N}\cap\mathcal{H}^2_+$ is dense in $\mathcal{H}^2_+$, and therefore also in $\mathcal{S}\cap\mathcal{H}^2_+$.

Definitions: From Proposition 3.2 it follows that $-iP_+(\mathcal{N}_-)\oplus iP_-(\mathcal{N}_-)$ is a dense subspace of L^2. If f is an element of this subspace, then for unique functions $g,h\in\mathcal{N}_-$,

$$f=-iP_+g+iP_-h. \tag{3.4}$$

We may introduce a locally convex topology on $-iP_+(\mathcal{N}_-)\oplus iP_-(\mathcal{N}_-)$ by defining a family of norms $\|f\|_n$ for f:

$$\|f\|^2_n=\|-iP_+g\|^2_n+\|iP_-h\|^2_n+\|iP_-g\|^2_n+\|-iP_+h\|^2_n. \tag{3.5}$$

The norms on the right hand side of (3.5) refer to the topology that $-iP_+(\mathcal{N}_-)\oplus iP_-(\mathcal{N}_-)$ inherits as a subspace of $\mathcal{S}$. For instance, $\|-iP_+g\|_n$ can be iteratively defined by

$$\|-iP_+g\|^2_{n+1}=\|M(-iP_+g)\|^2_n+\|D(-iP_+g)\|^2_n+\|-iP_+g\|^2_n,\quad n=0,1,2,\ldots, \tag{3.6}$$

where M and D are the multiplication and differentiation operators defined in (2.5) and $\|\cdot\|_0$ is the L^2-norm. The topology induced on $\mathcal{S}$ by the norms of (3.6) is equivalent to the one given by the more customary norms $\|f\|_{mn}=\sup_{x\in\mathbb{R}}|x^m(d^n/dx^n)f(x)|$.

Let Ψ be the direct sum space $-iP_+(\mathcal{N}_-)\oplus iP_-(\mathcal{N}_-)$ endowed with the topology given by the norms (3.5).

Proposition 3.3: Ψ is a nuclear Fréchet space.

Proof: Local convexity and metrizability of Ψ are obvious from (3.5). To see that Ψ is complete, suppose that $\{f_i\}$ is a Cauchy sequence Ψ. Since each f_i has the decomposition

$$f_i=-iP_+g_i+iP_-h_i, \tag{3.7}$$

for some $g_i,h_i\in\mathcal{N}_-$, we obtain four Cauchy sequences: $\{-iP_+g_i\}$ and $\{-iP_+h_i\}$ in $\mathcal{S}\cap\mathcal{H}_+^2$; $\{iP_-g_i\}$ and $\{iP_-h_i\}$ in $\mathcal{S}\cap\mathcal{H}_-^2$. Since these two spaces are complete, we conclude that there exist functions $g,h\in\mathcal{S}\cap\mathcal{H}_+^2$ and $\tilde{g},\tilde{h}\in\mathcal{S}\cap\mathcal{H}_-^2$ such that

$$\begin{aligned} -iP_+g_i&\to g, \qquad -iP_+h_i\to h,\\ iP_-g_i&\to\tilde{g}, \qquad iP_-h_i\to\tilde{h}. \end{aligned} \tag{3.8}$$

The convergences in (3.8) are of course with respect the $\mathcal{S}$-topology (3.6). Therefore, the functions $(-iP_+g_i)$ converge to g point-wise (and similarly for the other three sequences). Next, notice that the two functions $-iP_+f$ and iP_-f obtained from any $f\in\mathcal{N}_-$ coincide on $(0,\infty)$: $(-iP_+f)(x)=(\mathbb{H}f)(x)=(iP_-f)(x)$ for $x\in(0,\infty)$. Thus, $g(x)=\tilde{g}(x)$ and $h(x)=\tilde{h}(x)$ for $x\in(0,\infty)$. Now let $g_0=i(g-\tilde{g})$, $h_0=i(h-\tilde{h})$, and

$$f_0=-iP_+g_0+iP_-h_0. \tag{3.9}$$

The function f_0 is an element of Ψ. The convergences (3.8) imply that $f_i\to f_0$. Hence, Ψ is a Fréchet space.

It is well-known that $\mathcal{S}$ is a nuclear space. Since every subspace of a nuclear space is nuclear, $-iP_+(\mathcal{N}_-)\oplus iP_-(\mathcal{N}_-)$ is nuclear. It then follows that Ψ is a nuclear space as its topology (3.5) is derived from the nuclear topology (3.6) of $\mathcal{S}$. □

Let $\Psi^\times$ be the space of continuous antilinear functionals on Ψ, endowed with the weak*-topology. Then, the triplet of spaces,

$$\Psi\subset L^2\subset\Psi^\times, \tag{3.10}$$

constitutes a rigged Hilbert space.

Remark: From the proof of Proposition 3.3, in particular from the coincidence of the functions $-iP_+f$ and iP_-f on $(0,\infty)$ for any $f\in\mathcal{N}_-$, it follows that the elements of Ψ do not vanish on any subset of $(0,\infty)$ with nonzero (finite) measure. In fact, this property could have been used to define the space Ψ. Furthermore, if f_+ is the L^2_+-function obtained from some $f\in\Psi$ by $f_+=Q_+f$, then it follows that f_+ extends to both a unique function in $\mathcal{N}\cap\mathcal{H}_+^2\subset\mathcal{S}\cap\mathcal{H}_+^2$ and a unique function in $\mathcal{N}\cap\mathcal{H}_-^2\subset\mathcal{S}\cap\mathcal{H}_-^2$. That is, $Q_+(\Psi)\subset\Phi_+\cap\Phi_-$, where $\Phi_+=Q_+(\mathcal{S}\cap\mathcal{H}_+^2)$ and $\Phi_-=Q_+(\mathcal{S}\cap\mathcal{H}_-^2)$, the spaces defined in Refs. 4 and 5 in their study of scattering and time asymmetric quantum mechanics. The denseness of Ψ in L^2 shows that [$Q_+(\Psi)$ and thus also] the intersection $\Phi_+\cap\Phi_-$ is dense in L^2_+, extending the result in Ref. 5 that it is nontrivial.

B. Representation of $S_1(0)$ in Ψ

Proposition 3.4: The restriction of U to $\mathcal{S}$, where U is the continuous unitary representation of G given in (2.4)*, yields a differentiable representation of G in $\mathcal{S}$.*

Proof: From the definition (2.4), it follows directly that $\mathcal{S}$ remains invariant under all $U(\xi)$, $\xi\in G$. Then, direct computations show,[10] for all $f\in\mathcal{S}$ and $n=0,1,2,\ldots$,

$$\|U(\boldsymbol{\xi})f\|_n \leqslant (1+\xi_1^2+\xi_2^2)^{n/2}\|f\|_n \tag{3.11}$$

and

$$\begin{aligned}
&\lim_{\xi_1\to 0}\left\|\left(\frac{U((\xi_1,0,0))-I}{\xi_1}-D\right)f\right\|_n=0,\\
&\lim_{\xi_2\to 0}\left\|\left(\frac{U((0,\xi_2,0))-I}{\xi_2}-M\right)f\right\|_n=0,\\
&\lim_{\xi_3\to 0}\left\|\left(\frac{U((0,0,\xi_3))-I}{\xi_3}-iI\right)f\right\|_n=0,
\end{aligned} \tag{3.12}$$

where the norms $\|\cdot\|_n$ are those defined in (3.6). This proves that $U|_{\mathcal{S}}$ is a differentiable representation of G. □

Remark: Equations (3.12) show that the $\mathcal{S}$-generators of the representation $U|_{\mathcal{S}}$ coincide on $\mathcal{S}$ with the L^2-generators of U. This has an interesting implication for the rigged Hilbert formulation of quantum physics in that, just as in the conventional Hilbert space theory, the concept of an observable has an interpretation as the infinitesimal form of a symmetry (or asymmetry/semigroup) transformation.

Let us next consider the action of U on the elements of Ψ.

Proposition 3.5: The restriction of U to Ψ yields a nontrivial differentiable representation of $S_1(0)$ in Ψ.

Proof: If Ψ is invariant under $U(\boldsymbol{\xi})$, $\boldsymbol{\xi}\in S_1(0)$, then it follows from the topology (3.5) and Proposition 3.4 that $U|_{\Psi}$ furnishes a differentiable representation of $S_1(0)$. Therefore, we must simply show that $U(\boldsymbol{\xi})$, $\boldsymbol{\xi}\in S_1(0)$, leaves Ψ invariant and that the resulting semigroup representation does not extend in Ψ to a representation of G or a subgroup thereof. To that end, let $f\in\Psi$. Then, there exist unique functions g and h in $\mathcal{N}_-$ such that $f=-iP_+g+iP_-h$, and

$$\begin{aligned}
U((\xi_1,0,\xi_3))f &= U((\xi_1,0,\xi_3))(-iP_+g)+U((\xi_1,0,\xi_3))iP_-h\\
&= -iP_+U((\xi_1,0,\xi_3))g+iP_-U((\xi_1,0,\xi_3))h,
\end{aligned} \tag{3.13}$$

where the second equality follows from the commutativity of translations with the Hilbert transform: $U((\xi_1,0,\xi_3))\mathbb{H}=\mathbb{H}U((\xi_1,0,\xi_3))$.

From the construction of $\mathcal{N}_-$ (the Appendix), it is clear that $U((\xi_1,0,\xi_3))g\in\mathcal{N}_-$ and $U((\xi_1,0,\xi_3))h\in\mathcal{N}_-$ if $\xi_1\geqslant 0$, or, equivalently, if $(\xi_1,0,\xi_3)\in S_1(0)$. That is, Ψ is invariant under the operator semigroup $U((\xi_1,0,\xi_3))$, $\xi_1\geqslant 0$. Furthermore, from the Appendix it is also clear that for any $\xi_1<0$, there exist functions f in $\mathcal{N}_-$ such that $U((\xi_1,0,\xi_3))f\notin\mathcal{N}_-$. Thus, the semigroup representation $U(\boldsymbol{\xi})$, $\boldsymbol{\xi}\in S_1(0)$ in Ψ does not extend to a representation of the whole of G or even the subgroup $\{(\xi_1,0,\xi_3):\ \xi_1,\xi_3\in\mathbb{R}\}$. □

IV. A DIFFERENTIABLE REPRESENTATION OF $S_2(0)$

As a corollary to the construction carried out in Sec. III, we can obtain a rigged Hilbert space $\tilde{\Psi}\subset L^2\subset\tilde{\Psi}^\times$ such that $\tilde{\Psi}$ reduces the continuous unitary representation of G given by (2.4) to a differentiable representation of subsemigroup $S_2(0)$ defined in (2.3). This can be easily achieved by letting $\tilde{\Psi}$ be the Fourier transform $\mathcal{F}(\Psi)$ of the nuclear Fréchet space Ψ constructed in the above section. Since $\mathcal{F}$ is a unitary mapping on L^2, it follows that the triad,

$$\tilde{\Psi}\subset L^2\subset\tilde{\Psi}^\times, \tag{4.1}$$

is a rigged Hilbert space. The topology on $\tilde{\Psi}$ can be induced from the topology of Ψ via the Fourier transform. That is, if $\varphi \in \tilde{\Psi}$, then $\varphi = \hat{f}$ for a unique $f \in \Psi$, and a locally convex nuclear topology can be defined on $\tilde{\Psi}$ by way of the norms

$$\|\varphi\|_n = \|f\|_n, \tag{4.2}$$

where $\|f\|_n$ are the norms in Ψ defined by (3.5).

It is well known that $\mathcal{F}$ (and $\mathcal{F}^{-1}$) establishes a unitary equivalence between the operators $U((\xi_1,0,\xi_3))$ and $U((0,\xi_1,\xi_3))$, i.e., $\mathcal{F}\circ U((\xi_1,0,\xi_3)) = U((0,\xi_1,\xi_3))$ and $U((\xi_1,0,\xi_3)) = \mathcal{F}^{-1} \circ U((0,\xi_1,\xi_3))$. It thus follows that $\tilde{\Psi}$ reduces the unitary representation U of G in L^2 given by (2.4) to a nontrivial differentiable [with respect to the topology given by (4.2)] representation of $S_2(0)$.

It is perhaps worthwhile to take a closer look at the properties of the functions in $\tilde{\Psi}$. Each such function φ is the Fourier transform of a function in Ψ, i.e.,

$$\varphi = (-iP_+ g) + (iP_- h), \tag{4.3}$$

for unique functions g and h in $\mathcal{N}_-$. From (3.3), we then have

$$\varphi(x) = -\frac{i}{2}\left(1 + \frac{x}{|x|}\right)\hat{g}(x) + \frac{i}{2}\left(1 - \frac{x}{|x|}\right)\hat{h}(x). \tag{4.4}$$

This means that the space $\tilde{\Psi}$ is the direct sum of the restrictions of $\mathcal{F}(\mathcal{N}_-)$ to $(0,\infty)$ and to $(-\infty,0)$. Since $\mathcal{F}(\mathcal{N}_-) = \mathcal{M} \cap \mathcal{H}_+^2$, we have

$$\tilde{\Psi} = Q_+(\mathcal{M} \cap \mathcal{H}_+^2) \oplus Q_-(\mathcal{M} \cap \mathcal{H}_+^2). \tag{4.5}$$

The topology of $\tilde{\Psi}$ can also be defined by way of the norms

$$\|\varphi\|_n^2 = \|\hat{g}\|_n^2 + \|\hat{h}\|_n^2, \tag{4.6}$$

where $\hat{g}$ and $\hat{h}$ are as in (4.4) and the norms on the right hand side of (4.6) are as in (3.6). This topology is clearly equivalent to one given by the norms (4.2). In this light, the differentiable representation of $S_2(0)$ in $\tilde{\Psi}$ is just that which is induced from its differentiable representation in $\mathcal{M} \cap \mathcal{H}_+^2$.

V. SUBSEMIGROUPS S_1, S_2 AND S_3

Notice that the centrally significant feature of the preceding constructions of two rigged Hilbert spaces is the existence of dense subspaces of the Hilbert space which remain invariant under the differential $dU|_{\mathbf{0}}$ but not the representation U. Once a subspace invariant under $dU|_{\mathbf{0}}$ and $U(\boldsymbol{\xi})$, $\boldsymbol{\xi} \in S_1(0)$, or $dU|_{\mathbf{0}}$ and $U(\boldsymbol{\xi})$, $\boldsymbol{\xi} \in S_2(0)$, was identified, it was possible to construct the rigged Hilbert space (3.10) or (4.1).

Such dense subspaces can be constructed also for the operator semigroups $\{U(\boldsymbol{\xi}): \boldsymbol{\xi} \in S_1\}$, $\{U(\boldsymbol{\xi}): \boldsymbol{\xi} \in S_2\}$ and $\{U(\boldsymbol{\xi}): \boldsymbol{\xi} \in S_3\}$. It is interesting to notice, however, that any subspace which remains invariant under the operator semigroup $\{U(\boldsymbol{\xi}): \boldsymbol{\xi} \in S_4\}$ will be invariant also under $\{U(\boldsymbol{\xi}): \boldsymbol{\xi} \in S_3\}$. This means that the general method implied by the preceding two constructions (by way of dense subspaces invariant under the relevant operator semigroup) does not lead to a rigged Hilbert space for a nontrivial differentiable representation of the subsemigroup S_4, i.e., such a representation naturally extends to a representation of S_3.

A dense subspace of L^2 which is invariant under the operator Lie algebra $dU|_{\mathbf{0}}$ and the semigroup $U(S_1)$ can be easily obtained from the Ψ of Sec. III. It was shown that Ψ remains

invariant under the operator semigroup $\{U(\boldsymbol{\xi}):\ \boldsymbol{\xi}\in S_1(0)\}$. However, Ψ is not invariant under any operator such as $U(\boldsymbol{\xi})$ where $\boldsymbol{\xi}=(0,\xi_2,\xi_3)$. This is easily seen when either the Hardy class property or the vanishing moment (in $\mathcal{N}$) property of the functions in Ψ is considered. For instance, for an arbitrary element $f\in\Psi$, the integrals $\int_{-\infty}^{\infty}x^n f(x)dx=0$ for $n=0,1,2,\ldots$, but the integrals of the transformed element $U(\boldsymbol{\xi})f$, $\int_{-\infty}^{\infty}x^n(U((0,\xi_2,\xi_3))f)(x)dx = e^{i\xi_3}\int_{-\infty}^{\infty}x^n e^{i\xi_2 x}f(x)dx$ do not vanish for $n=0,1,2,\ldots$, when $\xi_2\neq 0$, i.e., $U((0,\xi_2,\xi_3))f\notin\Psi$. Therefore, let $\Psi_{\boldsymbol{\xi}}=U((0,\xi_2,\xi_3))(\Psi)$. Unitarity of the operators $U((0,\xi_2,\xi_3))$ implies that $\Psi_{\boldsymbol{\xi}}$ is dense in L^2. Thus, a dense subspace of L^2 which remains invariant under the operator semigroup $U(S_1)$ can be obtained by setting

$$\Psi_1=\cup_{\boldsymbol{\xi}\in S_1}\Psi_{\boldsymbol{\xi}}, \tag{5.1}$$

and, starting from the dense subspace (5.1), a rigged Hilbert space may be built as in Sec. III for a differentiable representation of the semigroup S_1.

In complete analogy to (5.1), we can construct a dense subspace invariant under the operator semigroup $\{U(\boldsymbol{\xi}):\ \boldsymbol{\xi}\in S_2\}$, starting from the space $\tilde{\Psi}$ of Sec. IV.

As is evident from the vector space $\mathcal{N}\cap\mathcal{M}$ introduced in Sec. III, there also exist dense subspaces of L^2 which are invariant under the operator Lie algebra $dU|_{\mathbf{0}}$ but not under any nontrivial $U(\boldsymbol{\xi})$, i.e., under any $U(\boldsymbol{\xi})$ where $\boldsymbol{\xi}$ is a noncentral element of G. Now consider the vector space,

$$\Psi_3=\cup_{\boldsymbol{\xi}\in S_3}U(\boldsymbol{\xi})(\mathcal{N}\cap\mathcal{M}). \tag{5.2}$$

The unitarity of $U(\boldsymbol{\xi})$ and the denseness of $\mathcal{N}\cap\mathcal{M}$ imply that Ψ_3 is dense in L^2. By construction, Ψ_3 is invariant under both $dU|_{\mathbf{0}}$ and the operator semigroup $\{U(\boldsymbol{\xi}):\boldsymbol{\xi}\in S_3\}$, but not under any $U(\boldsymbol{\xi})$ with $\boldsymbol{\xi}\notin S_3$. Thus, a rigged Hilbert space furnishing a nontrivial differentiable representation of S_3 may be built from the dense subspace Ψ_3.

VI. CONCLUDING REMARKS—JUXTAPOSITION WITH TIME ASYMMETRIC QUANTUM THEORY

In this paper we have investigated how differentiable representations of certain subsemigroups of the Weyl–Heisenberg group may be obtained in rigged Hilbert spaces. These representations were induced from a given continuous unitary representation of the Weyl–Heisenberg group G in the Hilbert space of L^2-functions on $\mathbb{R}$. As stated earlier, the construction of the particular rigged Hilbert space, which we denote here as in Definition 1.1 generically by $\Phi\subset\mathcal{H}\subset\Phi^{\times}$, begins with the identification of a dense subspace of L^2 which stays invariant under the action of the L^2-differential $dU|_{\mathbf{0}}$ and the relevant operator subsemigroup $\{U(\boldsymbol{\xi}):\ \boldsymbol{\xi}\in S_i\}$. In order to make certain that the ensuing differentiable representation is nontrivial, i.e., that it does not extend to a representation of the group G or a subgroup thereof, it was necessary to verify that the dense subspace invariant for the subsemigroup $\{U(\boldsymbol{\xi}):\ \boldsymbol{\xi}\in S_i\}$ does not remain invariant under certain $U(\boldsymbol{\xi})$ with $\boldsymbol{\xi}\notin S_i$. Once such a dense subspace was identified, it was possible to introduce a topology on it, by means of the enveloping operator algebra of $dU|_{\mathbf{0}}$, so as to obtain a differentiable representation of S_i in the inner space Φ of the rigged Hilbert space. With respect to this topology, elements of the enveloping algebra of $dU|_{\mathbf{0}}$ become continuous as operators in Φ. Moreover, as seen from (3.12), the elements of the Φ-differential of the semigroup representation $U(S_i)$ in Φ coincide with the corresponding elements of the $\mathcal{H}$-differential $dU|_{\mathbf{0}}$ of the group representation $U(G)$ in the Hilbert space $\mathcal{H}$.

In a definite technical sense, the semigroup time evolution of the rigged Hilbert space formulation of quantum mechanics developed in Refs. 4–6 has at its heart the Weyl–Heisenberg subsemigroups S_1 and S_2 of (2.3). Recall first that the rigged Hilbert spaces of Hardy class functions constructed in Refs. 4–6 are

$$\mathcal{S}\cap\mathcal{H}^2_+|_+\subset L^2_+\subset(\mathcal{S}\cap\mathcal{H}^2_+|_+)^\times,\quad \mathcal{S}\cap\mathcal{H}^2_-|_+\subset L^2_+\subset(\mathcal{S}\cap\mathcal{H}^2_-|_+)^\times, \tag{6.1}$$

where $|_+$ indicates the restrictions of the $\mathcal{S}\cap\mathcal{H}^2_\pm$-functions to the half line $(0,\infty)$. From the above mentioned van Winter's theorem,[9] a function $f_\pm$ in $\mathcal{S}\cap\mathcal{H}^2_\pm|_+$ extends to a unique function $f^\pm$ in $\mathcal{S}\cap\mathcal{H}^2_\pm$. This property is used in Refs. 4, 5 to define a nuclear Fréchet topology on $\mathcal{S}\cap\mathcal{H}^2_\pm|_+$:

$$\|f_\pm\|_n=\|f^\pm\|_n, \tag{6.2}$$

where the norms on the right hand side refer to the Schwartz space topology (3.5) the space $\mathcal{S}\cap\mathcal{H}^2_\pm$ inherits from $\mathcal{S}^2$. [The countable family of norms used to characterize $\mathcal{S}$ in Refs. 4, 5 is not that of (3.5) but the more customary $\|f\|_n=\|(M^2+D^2+I)^n f\|_0$.] The continuous unitary representation of $\mathbb{R}$ given in L^2_+ by $(U(t)f)(E)=e^{iEt}f(E)$ reduces to a differentiable representation of $(0,\pm\infty)$ in $\mathcal{S}\cap\mathcal{H}^2_\pm|_+$. These semigroup representations can be related to the representations of S_1^{-1} and S_2 of (2.3) in the following way.

Observe that the mapping (2.4) yields a continuous representation of S_1^{-1} in L^2_+ by contractions:

$$(U(\boldsymbol{\xi})f)(x)=e^{i\xi_3}e^{ix\xi_2}f(x+\xi_1),\quad \boldsymbol{\xi}\in S_1^{-1},\ f\in L^2_+, \tag{6.3}$$

and $\|U(\boldsymbol{\xi})f\|_+\leqslant\|f\|_+$.

Further, the multiplication subgroup $\{(0,\xi_2,\xi_3):\xi_2,\xi_3\in\mathbb{R}\}$ of S_1^{-1} is unitarily represented by U in L^2_+:

$$(U((0,\xi_2,\xi_3))f)(x)=e^{i\xi_3}e^{ix\xi_2}f(x). \tag{6.4}$$

The dense subspace $\mathcal{S}_+$ remains invariant under both the operator semigroup $\{U(\boldsymbol{\xi}):\boldsymbol{\xi}\in S_1^{-1}\}$ and the basis elements M, D, I of the differential $dU|_{\mathbf{0}}$. Moreover, $\mathcal{S}_+$, a closed subspace of $\mathcal{S}$, is a nuclear Fréchet space, and therewith the triplet

$$\mathcal{S}_+\subset L^2_+\subset\mathcal{S}_+^\times \tag{6.5}$$

constitutes a rigged Hilbert space. The continuous representation (6.3) of S_1^{-1} in L^2_+ yields a differentiable representation of the semigroup in $\mathcal{S}_+$.

The Fourier transform (3.1) establishes a unitary equivalence between (6.5) and the rigged Hilbert space,

$$\mathcal{S}\cap\mathcal{H}^2_-\subset\mathcal{H}^2_-\subset(\mathcal{S}\cap\mathcal{H}^2_-)^\times, \tag{6.6}$$

while its inverse $\mathcal{F}^{-1}$ maps (6.5) unitarily onto

$$\mathcal{S}\cap\mathcal{H}^2_+\subset\mathcal{H}^2_+\subset(\mathcal{S}\cap\mathcal{H}^2_+)^\times. \tag{6.7}$$

Since $\mathcal{F}$ is a homeomorphism on $\mathcal{S}$, $\mathcal{S}\cap\mathcal{H}^2_\pm$ are closed subspaces of $\mathcal{S}$. They are thus nuclear Fréchet spaces with respect to the Schwartz space topology (3.5).

The mappings from (6.5) onto (6.6) and (6.7) given by $\mathcal{F}$ and $\mathcal{F}^{-1}$ also transform the representation of S_1^{-1} in (6.5) to a representation of S_2^{-1} and S_2 in (6.6) and (6.7), respectively. In particular,

$$\begin{aligned}\mathcal{F}U(\boldsymbol{\xi})\mathcal{F}^{-1}&=U((-\xi_2,\xi_1,\xi_3-\xi_1\xi_2)),\\ \mathcal{F}^{-1}U(\boldsymbol{\xi})\mathcal{F}&=U((\xi_2,-\xi_1,\xi_3-\xi_1\xi_2)),\end{aligned} \tag{6.8}$$

and when $\boldsymbol{\xi}\in S_1^{-1}$, the contractions $U((-\xi_2,\xi_1,\xi_3-\xi_1\xi_2))$ and $U((\xi_2,-\xi_1,\xi_3-\xi_1\xi_2))$ provide continuous representations of S_2^{-1} and S_2 in $\mathcal{H}^2_-$ and $\mathcal{H}^2_+$, respectively. Further, in the nuclear Fréchet spaces $\mathcal{S}\cap\mathcal{H}^2_-$ and $\mathcal{S}\cap\mathcal{H}^2_+$ the mappings (6.8) furnish differentiable representations of the

semigroups S_2 and S_2^{-1}, respectively. In particular, the differentiation operator D generates the one parameter group of translations in both $\mathcal{S}\cap\mathcal{H}_-^2$ and $\mathcal{S}\cap\mathcal{H}_+^2$, whereas the multiplication operator M generates only a one parameter semigroup, one in $\mathcal{S}\cap\mathcal{H}_-^2$ for negative ξ_1 and another in $\mathcal{S}\cap\mathcal{H}_+^2$ for positive ξ_1.

Consider the subsemigroup $S_2(0)$ of S_2. As just seen, it is represented differentiably by the mapping (2.4), $\boldsymbol{\xi}\to U(\boldsymbol{\xi})$, in $\mathcal{S}\cap\mathcal{H}_+^2$:

$$(U(\boldsymbol{\xi})f)(x)=e^{i\xi_3}e^{ix\xi_2}f(x),\quad \boldsymbol{\xi}\in S_2(0),\ f\in\mathcal{S}\cap\mathcal{H}_+^2. \tag{6.9}$$

The relation (6.8) and the description following it shows that this representation of $\mathcal{S}_2(0)$ in $\mathcal{S}\cap\mathcal{H}_+^2$ is nontrivial. Now, since the mapping $\mathcal{S}\cap\mathcal{H}_+^2\to\mathcal{S}\cap\mathcal{H}_+^2|_+$ is one-to-one and onto Refs. 5, 9, it follows that (6.9) induces a non-trivial differentiable representation of $S_2(0)$ in $\mathcal{S}\cap\mathcal{H}_+^2|_+$.

Observe next that the differentiable representation (6.9) of the subsemigroup $S_2(0)$ in $\mathcal{S}\cap\mathcal{H}_+^2|_+$ can be *identified* with the unitary representation (6.4) of the subgroup $\{\boldsymbol{\xi}=(0,\xi_2,\xi_3):\ \xi_2,\xi_3\in\mathbb{R}\}$ in L_+^2. Once this identification is made, we conclude that the continuous unitary representation of $\mathbb{R}$ given by (6.4),

$$(U((0,\xi_2,0))f)(x)=e^{ix\xi_2}f(x), \tag{6.10}$$

in L_+^2 is reduced by the subspace $\mathcal{S}\cap\mathcal{H}_+^2|_+$ to a representation of the half line $(0,\infty)$. This is the semigroup that is interpreted in Refs. 4–6 as governing the asymmetric time evolution of outstates and the decaying Gamow vectors. We see here that it is induced from a continuous representation of the Weyl–Heisenberg semigroup S_2 in $\mathcal{H}_+^2$. The latter representation, in turn, is equivalent to the continuous representation of the semigroup S_1^{-1} in L_+^2, given by (6.3). In this sense, it can be said that the semigroup time evolution of the quantum theory developed in Refs. 4–6, where the Hilbert space L_+^2 consists of the square integrable functions defined on the energy spectrum $(0,\infty)$ and ξ_2 is interpreted as time, t, is obtained from the semigroup of translations in L_+^2 given by (6.3), $(U(\xi)f)(E)=f(E-\xi),\ \xi\in(0,\infty)$.

APPENDIX: DENSENESS OF $\mathcal{N}_+$ IN L_+^2

Proposition A.1: $\mathcal{N}_+$ is dense in L_+^2.

Proof (Ref. 11): We prove this assertion by showing that any compactly supported C^∞-function in L_+^2 can be approximated by functions in $\mathcal{N}_+$. Since the class of C^∞-functions with compact support is dense in L_+^2, the proposition follows.

Let g be a compactly supported smooth function in L_+^2 and ϵ, any positive number. Without loss of generality, let us assume that $\int_0^\infty g(x)dx\neq 0$, for otherwise we may choose a compactly supported smooth function arbitrarily close to g in the L^2-metric with this property. Now, suppose that there exists a family of compactly supported smooth functions f_k, with supports contained in, say (a_k,a_{k+1}), such that we have the following.

(1) The support of f_k is to the right of the support of f_{k-1} and disjoint from it; the support of f_0 is to the right of that of g.

(2) $\int_0^\infty x^i f_k(x)dx=0$, for $i=0,1,2,\ldots,k-1$.

(3) $\int_0^\infty x^k f_k(x)dx=-\int_0^\infty x^k(g+f_0+f_1+\cdots+f_{k-1})(x)dx$.

(4) $\|f_k\|<\epsilon/2^{k+1}a_{k+1}^k$.

If such a family $\{f_k\}$ can be found, then set

$$f=\sum_{k=0}^{\infty} f_k+g. \tag{A1}$$

The f is well defined since for each $0<x<\infty$ all but one f_k are zero.

Since the f_k have disjoint supports,

$$\int_{a_n}^{a_{n+1}} x^m \sum_{k=0}^{\infty} f_k(x)dx = \int_{a_n}^{a_{n+1}} \sum_{k=0}^{\infty} x^m f_k(x)dx = \int_{a_n}^{a_{n+1}} x^m f_n(x)dx = 0, \text{ for all } n>m, \quad \text{(A2)}$$

and so

$$\sum_{n=0}^{\infty} \left(\int_{a_n}^{a_{n+1}} \sum_{k=0}^{\infty} x^m f_k(x)dx \right) = \sum_{n=0}^{m} \left(\int_{a_n}^{a_{n+1}} \sum_{k=0}^{\infty} x^m f_k(x)dx \right) = \sum_{n=0}^{m} \int_{a_n}^{a_{n+1}} x^m f_n(x)dx. \quad \text{(A3)}$$

Therefore,

$$\int_0^{\infty} x^m f(x)dx = \int_0^{\infty} \left(\sum_{k=0}^{\infty} x^m f_k(x) + x^m g(x) \right) dx = \sum_{k=0}^{m} \int_0^{\infty} x^m f_k(x)dx + \int_0^{\infty} x^m g(x)dx = 0,$$
$$\text{for } m = 0,1,2,\ldots, \quad \text{(A4)}$$

where the above property (2) of the f_k is used in the last equality of (A2) and the property (3), in the last equality of (A4). Further, from the inequality (4), it is clear that $x^n f \in L^1((0,\infty))$. Since the functions f_k have increasing supports, it then follows that $f \in \mathcal{N}_+$.

Furthermore, from the disjointness of the supports and the property (4) above of the f_k, it follows readily that

$$\|g-f\| = \left\| \sum_{k=0}^{\infty} f_k \right\| = \left(\sum_{k=0}^{\infty} \|f_k\|^2 \right)^{1/2} \leqslant \left(\sum_{k=0}^{\infty} \frac{\epsilon^2}{2^{2k+2} a_{k+1}^{2k}} \right)^{1/2} < \epsilon, \quad \text{(A5)}$$

i.e., $\mathcal{N}_+$ is dense in L_+^2.

It remains to show that the C^∞ functions f_k can be chosen subject to the conditions (1)–(4) above. This can be done by induction. To that end, suppose the smooth functions $f_0,\ldots,f_{k-1}$ with their supports in $(a_0, a_1),\ldots,(a_{k-1}, a_k)$, respectively, have been aptly chosen. Assume further that the given smooth function is supported in $(0, a_0)$ with $a_0>1$. Define now a function f_k by setting

$$f_k(x) = \gamma_k \frac{d^k g}{dx^k} \left(\frac{a_0(x-a_k)}{a_{k+1}-a_k} \right). \quad \text{(A6)}$$

The function f_k is supported in (a_k, a_{k+1}), where a_{k+1} and the constant γ_k are to be chosen subject to the conditions (A10) and (A12) below.

From the definition (A6) it is clear that

$$\int_0^{\infty} x^i f_k(x)dx = 0, \quad \text{for } n = 0,1,2,\ldots,k-1 \quad \text{(A7)}$$

and

$$\int_0^{\infty} x^k f_k(x)dx = (-1)^k k! I \gamma_k \left(\frac{a_{k+1}-a_k}{a_0} \right)^{k+1}, \quad \text{(A8)}$$

where $I = \int_0^{\infty} g(x)dx$. Next, in accordance with condition (3) above, we require

$$\int_0^{\infty} x^k f_k(x)dx = \lambda, \quad \text{(A9)}$$

where $\lambda = -\int_0^\infty x^k(g(x)+f_0(x)+\cdots+f_{k-1}(x))dx$. Equalities (A8) and (A9) yield

$$\gamma_k = \frac{(-1)^k \lambda}{k! I}\left(\frac{a_0}{a_{k+1}-a_k}\right)^{k+1}. \tag{A10}$$

It remains only to choose a_{k+1}. By the definition (A6) of f_k and the inequality (4) on its L^2 norm, we have

$$\|f_k\| = |\gamma_k|\left(\frac{a_0}{a_{k+1}-a_k}\right)^{1/2}\left\|\frac{d^k g}{dx^k}\right\| < \frac{\epsilon}{2^{k+1}a_{k+1}^k}. \tag{A11}$$

Along with the relation (A10) above, we then observe that a_{k+1} is to be chosen subject to the inequality

$$\frac{(a_{k+1}-a_k)^{k+3/2}}{a_{k+1}^k} > \frac{|\lambda| 2^{k+1}}{\epsilon |I| k!} a_0^{k+3/2}\left\|\frac{d^k g}{dx^k}\right\|. \tag{A12}$$

By construction, $a_k > a_0 > 1$, and so it is clear that this inequality can be fulfilled by choosing a_{k+1} large enough. Once the a_{k+1} is picked out, the equation (A10) determines γ_k, and therewith the expression (A6) completely determines the function f_k. Thus, the functions f_k are simply the derivatives of the given smooth function g with their supports appropriately dilated and translated on the real axis, followed by a suitable overall scaling. □

Erratum: Pseudo-Hermiticity for a class of nondiagonalizable Hamiltonians [J. Math. Phys. 43, 6343 (2002)]

Ali Mostafazadeh[a)]
Department of Mathematics, Koç University, Rumelifeneri Yolu, 34450 Sariyer, Istanbul, Turkey

[DOI: 10.1063/1.1540714]

Recently, the authors of Ref. 1 used the framework provided in Ref. 2 to re-examine the consequences of pseudo-Hermiticity for the class of block-diagonalizable Hamiltonians introduced in Ref. 2. In doing so, they discovered that Theorem 2 of Ref. 2 did not hold, as they could find a counter-example. This theorem must be replaced with the following.

Theorem 2: Let H be as in Theorem 1 of Ref. 2. Then H is pseudo-Hermitian if and only if it is Hermitian with respect to an inner product $\langle\langle ,\rangle\rangle$ that supports a positive-semidefinite basis[3] including the eigenvectors of H. In particular, for every eigenvector ψ of H, $\langle\langle\psi|\psi\rangle\rangle\geqslant 0$; if the corresponding eigenvalue is real and nondefective (algebraic and geometric multiplicities are equal), $\langle\langle\psi|\psi\rangle\rangle>0$; otherwise $\langle\langle\psi|\psi\rangle\rangle=0$.

Proof: As shown in Ref. 2, pseudo-Hermiticity of H implies that H is Hermitian with respect to the inner product $\langle\langle ,\rangle\rangle_\eta$ with η given by Eq. (15) of Ref. 2 and $\sigma_{\nu_0,a}=1$. It is not difficult to check that indeed the basis vectors $|\psi_n,a,i\rangle$, constructed in Ref. 2, have the property that $\langle\langle\psi_n,a,i|\psi_n,a,i\rangle\rangle\geqslant 0$, and that $\langle\langle\psi_n,a,i|\psi_n,a,i\rangle\rangle>0$ only for the cases that $p_{n,a}=1$ and $E_n\in\mathbb{R}$, i.e., $|\psi_n,a,i=1\rangle$ is an eigenvector of H with a real eigenvalue. Furthermore, by construction, this basis includes all the eigenvectors of H. The proof of the converse is the same as the one given in Ref. 2.

It is important to note that having a positive-semidefinite basis does not imply that the inner product $\langle\langle ,\rangle\rangle_\eta$ is positive-semidefinite (unless the Hamiltonian is diagonalizable and has a real spectrum in which case both the basis and the inner product $\langle\langle ,\rangle\rangle_\eta$ are positive definite.[4]) If the Hamiltonian has defective or complex(-conjugate pair(s) of) eigenvalues, there will always be at least two null vectors with negative[3] linear combinations. Unlike positive vectors, linear combinations of nonnegative vectors need not be nonnegative.

[3] A vector ϕ is respectively said to be positive, null (zero), negative, if $\langle\langle\phi|\phi\rangle\rangle>0$, $\langle\langle\phi|\phi\rangle\rangle=0$, $\langle\langle\phi|\phi\rangle\rangle<0$. It is said to be nonnegative if $\langle\langle\phi|\phi\rangle\rangle\geqslant 0$. A basis is called positive-semidefinite if it consists of nonnegative vectors. See, for example, J. Bognar, *Indefinite Inner Product Spaces* (Springer, Berlin, 1974).

(Received 6 November 2002; accepted 15 November 2002)

We investigate the occurrence of critical energies—where the Lyapunov exponent vanishes—in random Schrödinger operators when the potentials have some local order, which we call *random palindrome models*. We give necessary and sufficient conditions for the presence of such critical energies: the commutativity of finite word elliptic transfer matrices. Finally, we perform some numerical calculations of the Lyapunov exponents showing their behavior near the critical energies and the respective time evolution of an initially localized wave packet, obtaining the exponent ruling the algebraic growth of the second momentum. We also consider special random palindrome models with one-letter bounded gap property; the transport effects of such long range order are showed numerically. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1537462]

I. INTRODUCTION

This article is concerned with the random tight-binding Hamiltonian H_v on $l^2(\mathbb{Z})$,

$$(H_v\psi)_n = v_n\psi_n + \psi_{n+1} + \psi_{n-1}, \tag{1}$$

where $v=(v_n)$ is a finitely valued sequence with some local correlation. We address the problem of occurrence of *critical energies* in the spectrum, which are those where the *Lyapunov exponent* $\gamma(E)$ vanishes. For Schrödinger operators in the one-dimensional lattice, $\gamma(E)$ is defined when the limit

$$\lim_{n\to\infty} \frac{1}{n} \log\|T_n(E)\cdots T_1(E)\| \tag{2}$$

exists, where $T_i(E)$ is a sequence of unimodular matrices of the form

$$T_i(E) = \begin{pmatrix} E-v_i & -1 \\ 1 & 0 \end{pmatrix}.$$

This question has come to surface after Dunlap, Wu and Phillips' work on the random dimer,[9] and has been addressed rigorously by some authors.[5,8,11] Although the spectrum is pure point,[8] the behavior of the Lyapunov exponent near the critical energies is responsible for dynamical delocalization, characterized by the positivity of the asymptotic growth exponent, α, of the moment

$$m_\beta(t) = \sum_{n\in\mathbb{Z}} |n|^\beta |\psi_n(t)|^2 \sim t^{\beta\alpha} \tag{3}$$

for a packet initially localized at the origin: $\psi_n(0)=\delta_{n,0}$. This is proven by Jitomirskaya, Schulz-Baldes and Stolz[11] about the time average of the above moment. In the vicinity of a critical energy, the same authors show that the Lyapunov exponent vanishes quadratically, a fact already analyzed by Bovier[5] for the dimer model with some assumptions on the density of the invariant measure

a)Electronic mail: tcarvalho@uel.br

$\lambda(E)$ of the one-dimensional dynamical system obtained from the eigenvalue equation $H_v\psi = E\psi$.

We take as our motivation this striking effect of local order on dynamical delocalization. Our contribution is on the conditions for the appearance of critical energies in random palindrome models: these are obtained as random concatenations of palindrome words (of length greater than 2). Recall that a *palindrome* is a word that reads the same from left to right or from right to left. Since the potential assumes a finite number of values, it is useful to think of a bijective nonconstant real function φ, such that $\varphi^{-1}:\varphi(B)\subset[-\Delta/2,\Delta/2]\to\mathcal{B}$, where $\mathcal{B}$ is some finite alphabet, and identify clusters with words in $\mathcal{B}$.

We are able to tackle the problem of local order fairly generally with what we call *cluster maps*. These are injective maps $\mathfrak{C}:\mathcal{A}\to\mathcal{B}^*$, taking each letter a of an alphabet $\mathcal{A}$ to a cluster $\mathfrak{C}(a)\in\mathcal{B}^*$, where $\mathcal{B}^*$ is the set of finite words in the alphabet $\mathcal{B}$ and $\mathcal{B}\supset\mathcal{A}$. Thus we think of random palindrome models as images of random sequences under a cluster map for which $\mathfrak{C}(a)$ are palindromes for all $a\in\mathcal{A}$. We make some additional assumptions on these maps in Sec. II in order to control the extent of the correlations introduced on $\mathfrak{C}(v)$ for a random v. We stress that the palindromes have appeared quite naturally, as indicated in the discussion in Sec. III D.

The critical energies in random palindrome models occur when the transfer matrices associated with each palindrome in the potential commute and are elliptic. We get a recipe for obtaining a prescribed minimum number of critical energies, in contrast with just two in the random dimer. This result is interesting in its failure to produce an interval of critical energies, which would be an absolutely continuous component of the spectrum. An absolutely continuous spectral component is (already) prohibited by Kotani's theory[12] for almost every H_v in some ergodic structure, but the reasoning which leads us to this provides further understanding of potentials assuming a finite number of values. Our second result will tell us that, apart from a set of codimension 1 in the potential intensities, $\gamma(E)>0$ for almost every E different from the above constructed critical energies, cf. Ref. 8.

The analysis of the invariant measure $\lambda(E)$,[5,13] which could yield the Taylor series of $\gamma(E)$ near these critical energies, is not possible to carry over, because the palindromes need not have the same length. To check the behavior of the Lyapunov exponent near the critical energies, we perform numerical calculations of $\gamma(E)$ using the Thouless formula, or rather its approximation in finite dimension. We also provide some numerics on the mean square displacement, for which $\beta=2$ in Eq. (3), and obtain, due to the larger number of critical energies, a superdiffusive behavior with an exponent α larger than $\frac{3}{4}$ for small disorder, as in the random dimer.[9] For sufficiently large disorder, m_2 is bounded and dynamical localization sets in.

Iterating cluster maps $\mathfrak{C}:\mathcal{A}\to\mathcal{A}^*$ such that for any $a\in\mathcal{A}$, $\mathfrak{C}^k(a)$ contains all letters of $\mathcal{A}$, i.e., *primitive* cluster maps, provides a sequence of potentials $u^{(n)}=\mathfrak{C}^{nk}(v)$, for any $v\in\mathcal{A}^{\mathbb{Z}}$ which, under some additional hypotheses, will converge to a substitution sequence. Here we do not specialize the clusters to palindromes. This is stated and proven in Sec. III F. For primitive cluster maps, for any given potential v, any letter in $\mathcal{A}$ occurs in $\mathfrak{C}(v)$ with bounded gaps. This long range order is not generally present in a random palindrome model and one applied reason for its proposal is that it yields an interesting boost in transport, measured by the second moment m_2.

The article is organized as follows: in Sec. II we give the definition of a cluster map, specialize it to give random palindrome models and state most of our analytic results. We prove them in Sec. III, where we also discuss the ergodic structure of the models and a simple particular example. In Sec. III F we discuss some random models generated by primitive cluster maps. In Sec. IV we illustrate the numerical results with plots of $\gamma(E)$ and $m_2(t)$.

II. THE MODEL AND STATEMENT OF RESULTS

We are given a random sequence in $t=(t_j)\in\mathcal{A}^{\mathbb{Z}}$ and a *cluster map*

$$\mathfrak{C}:\ \mathcal{A}\to\mathcal{B}^*,$$

$$a\mapsto\mathfrak{C}(a),$$

where $\mathcal{B}^*$ is the set of finite words in an alphabet $\mathcal{B}\supset\mathcal{A}$. We consider only cluster maps for which the whole word $\mathfrak{C}(a)$ does not occur in $\mathfrak{C}(b)$, for all $a\neq b\in\mathcal{A}$. This prevents the introduction of spurious long range correlations in $\mathfrak{C}(t)$ even if $t\in\mathcal{A}^{\mathbb{Z}}$ is random (see, however, Sec. III F).

To extend $\mathfrak{C}$ to $t\in\mathcal{A}^{\mathbb{Z}}$ by concatenation, we declare the position of the first letter of $\mathfrak{C}(t_0)$ to be -1 (this will be convenient in Sec. III F):

$$r\overset{\text{def}}{=}\mathfrak{C}(t),\quad r_{-1}r_0\cdots r_{|\mathfrak{C}(t_0)|-2}=\mathfrak{C}(t_0).$$

When $\mathcal{B}=\mathcal{A}$, $\mathfrak{C}$ is also a *substitution*.

The range of the function φ defined in the Introduction defines the *disorder* parameter Δ. Denoting the potential sequences by $v=\varphi(t)$ and $w=\varphi(\mathfrak{C}(t))$, we are interested in finding conditions for the vanishing of the Lyapunov exponent γ for some E in the spectrum of H_w, albeit γ in the spectrum of H_v is positive for almost every $v\in\mathcal{A}^{\mathbb{Z}}$.[6] With the exception of Sec. III F, we restrict our attention to cluster maps for which $\mathfrak{C}(a)$ is a palindrome, for each $a\in\mathcal{A}$. The potential $w=\mathfrak{C}(v)$ for $v\in\mathcal{A}^{\mathbb{Z}}$ is then called a *random palindrome model*. In this setting, we can get a rather complete answer to the problem of making $\gamma(E)$ vanish in the spectrum of H_w.

Consider first the case $\mathcal{A}=\{a,b\}$. Let C_a and C_b be general palindromes with sizes $|C_a|=n$ and $|C_b|=k$; and let $A=\Phi(C_a)$ and $B=\Phi(C_b)$ be their associated transfer matrices. The set of values of the potentials $\{v_i:1\leqslant i\leqslant n+k\}$ in both clusters defines an ordered s-tuple $\mathbf{v}$ taken from some open set $\mathcal{V}\subset\mathbb{R}^s$, where $s=\lceil n/2\rceil+\lceil k/2\rceil$.

Proposition 1: Let $T_i\in\{A,B\}, i\in\mathbb{Z}$, be a Bernoulli trial with A, B transfer matrices of palindromes. Then, if $[A,B]\neq 0$,

$$\Gamma=\lim_{n\to\infty}\frac{1}{n}\|T_n\cdots T_1\| \tag{4}$$

exists and is positive for almost every trial, and except for a set of codimension greater than 1 in $\mathcal{V}$.

In this excluded set of potential intensities, critical energies do occur and have appeared before in Sec. 3 of Ref. 8. There is a simple proportional relation between Γ, Eq. (4), and γ, Eq. (2), when both exist; see Corollary 2.

In proving Proposition 1, we will use the Furstenberg and Kesten theorem, thus the statement is restricted to a set of full measure μ, with μ being the product or Bernoulli measure in $\mathcal{A}^{\mathbb{Z}}$.

Define the left-shift by $(\tau(u))_n=u_{n+1}$. The left-shift translations of $\mathfrak{C}(u)$, $u\in\mathcal{A}^{\mathbb{Z}}$, generate an ergodic system $\Lambda\subset\mathcal{B}^{\mathbb{Z}}$ with a Markov measure ν. We will discuss this point in detail in Sec. III A.

Given a random sequence $u=(u_n)_{n\in\mathbb{Z}}$ in a finite alphabet $\mathcal{A}$, we assume that each letter occurring in u does so with positive probability.

Definition 1: Let $\mathfrak{C}$ be a cluster map defined on the alphabet $\mathcal{A}$, carrying each letter a_i to a palindrome $p_i=\mathfrak{C}(a_i)$. Then we say the sequence $v=\mathfrak{C}(u)$ is tessellated by palindromes.

A transversality argument together with Proposition 1 leads to the following

Theorem 1: *There is a set $Y\subset\Lambda$ of aperiodic sequences tessellated by palindromes, with $\nu(Y)=1$ such that for all $v\in Y$ the critical energies in $\sigma(H_v)$ are at most countable.*

Theorem 1 is a special case of Kotani's results[12] which rule out the absolutely continuous spectrum from potentials assuming finitely many values. However, the sets of realizations to which one and the other refer are not directly related. In order to properly make a comparison, the above mentioned ergodic structure (Λ,τ,ν) is needed. We settle this question in Sec. III A. Finally, we do not have reasons to exclude the possibility of a singular continuous spectrum in random palindrome (cluster) models, particularly with long range order.

We analyze a simple generalization of the random dimer, where $\mathcal{A}=\{a,b\}$. If we restrict C_b to a constant word of length two, $C_b=bb$, we get an open condition on the word C_a, if C_a is a palindrome of odd length, $C_a=t_0t_1\cdots t_k\cdots t_1t_0$, for small disorder. We set $v_i=\varphi(t_i)$, $v_a=\varphi(a)$, $v_b=\varphi(b)$ and

$$\Delta=\max\{|v_i-v_b|,0\leqslant i\leqslant k\}.$$

Theorem 2: *Let $C_b=bb$ and C_a be a palindrome of length $2k+1$, $k\geqslant 1$, with potentials v_i such that $|v_i-v_a|<\epsilon<\Delta$, $0\leqslant i\leqslant k$. Then*

(i) *For small enough disorder $\Delta>0$, any realization of such random palindrome model has at least $2k+1$ critical energies.*
(ii) *For $0<\Delta\leqslant 2$, the random palindrome model has at least k critical energies.*
(iii) *For $2<\Delta<4$, if k is sufficiently large, the random palindrome model has at least one critical energy.*

We build on the proof by De Bièvre and Germinet[8] on the existence of critical energies at $E=\pm v$ if $v\leqslant 1$ for the random dimer. The steps are elementary and the conclusion is based on Taylor series expansions. Bovier mentioned some plans along these lines in his paper on the random dimer.[5] Some generalizations of the random dimer were studied earlier.[13]

Applying Furstenberg and Kesten's theorem we have the following.

Corollary 1: For C_a and C_b as in Theorem 2 and sufficiently small ϵ, there exists $0<z_{\max}<2$ such that, for disorder $\Delta>2+z_{\max}$, the Lyapunov exponent $\gamma(E)$ is positive, whenever it exists.

We will say more about $z_{\max}$ for $\epsilon=0$ from the details of the proof of Theorem 2.

III. PROOFS

A. Ergodic structure

We are given two finite alphabets $\mathcal{A}$ and $\mathcal{B}$, with $\mathcal{B}\supset\mathcal{A}$, $\mathcal{A}$ having more than one element and a cluster map $\mathfrak{C}:\mathcal{A}\to\mathcal{B}^*$. We construct the Kakutani tower[15] from $\mathcal{A}^{\mathbb{Z}}$ as follows: $S_a=\{x\in\mathcal{A}^{\mathbb{Z}}:x_0=a\}\times\{1,\ldots,n_a\}$, where $n_a\overset{\text{def}}{=}|\mathfrak{C}(a)|$, for each $a\in\mathcal{A}$. Write the disjoint union $\Omega=\dot{\cup}_{a\in\mathcal{A}}S_a$ endowed with the metric

$$\rho((x,i),(y,j))=\sum_{n\in\mathbb{Z}}\frac{d(x_n,y_n)}{2^{|n|}}+d(i,j), \tag{5}$$

where d is the discrete metric. Then Ω is compact. On Ω, we have the shift transformation

$$\hat{\tau}(x,i)=\begin{cases}(x,i+1) & \text{if } i<n_a,\\ (\tau(x),1) & \text{if } i=n_a,\end{cases}$$

where τ is the shift on $\mathcal{A}^{\mathbb{Z}}$. We extend $\mathfrak{C}$ to Ω, defining $\hat{\mathfrak{C}}$ so that the diagram below commutes

$$\begin{array}{ccc}\Omega & \overset{\hat{\mathfrak{C}}}{\to} & \mathcal{B}^{\mathbb{Z}}\\ \hat{\tau}\downarrow & & \downarrow\tau\\ \Omega & \overset{\hat{\mathfrak{C}}}{\to} & \mathcal{B}^{\mathbb{Z}}\end{array}$$

and $\hat{\mathfrak{C}}(x,1)=\mathfrak{C}(x)$.

A simple averaging over the components of Ω gives an ergodic measure[11] which, however, does not account for the systematic local repetitions of letters in $\hat{\mathfrak{C}}(\Omega)$. Therefore the push-forward of this ergodic measure does not give a suitable ergodic structure. We have instead the following.

Proposition 2: Let Ω be as above and $\Lambda=\hat{\mathfrak{C}}(\Omega)\subset\mathcal{B}^{\mathbb{Z}}$ be its image under the cluster map. Then Λ is a subshift of finite type.

Let us introduce some terminology. If v is a finite word in $\mathcal{B}^*$, define

$$Y_v=\{x\in\mathcal{B}^{\mathbb{Z}}: v \text{ does not occur in } x\}.$$

We are to prove that Λ is the intersection of finitely many Y_v's. We say that a (finite) word is *acceptable* (in Λ) if it occurs in some $x\in\Lambda$; otherwise we call it *unacceptable*. We shall use *block*, cluster and word interchangeably. If the word u is contained in w, then $Y_u\subset Y_w$.

In our context, note that a word w is acceptable, i.e., $w\in\hat{\mathfrak{C}}(\Omega)$, if, and only if, w is contained in some concatenation of clusters. If an acceptable word v ends with a block and u is an acceptable word beginning with a block, then the concatenation vu is acceptable in $\hat{\mathfrak{C}}(\Omega)$.

Proof of Proposition 2: $\hat{\mathfrak{C}}$ is clearly continuous, therefore Λ is compact, and shift invariant by $\hat{\mathfrak{C}}$'s definition. Then Λ is a subshift.[14]

Note that $\mathcal{B}^*$ is partially ordered with word inclusion and the corresponding length. Fix $w=w_0\cdots w_k$ an arbitrary unacceptable word and let v be a word contained in w formed by blocks $\mathfrak{C}(a)$ which cannot be enlarged with the concatenation of another such block and still be contained in w. Finally let $\overline{v}=w_i\cdots w_j$ be an acceptable word satisfying $v\subset\overline{v}\subset w$ and which cannot be enlarged with the concatenation of any other letter of w. Put $n=\max_{a\in\mathcal{A}}|\mathfrak{C}(a)|$.

We prove that there is some unacceptable u occurring in w, with uniformly bounded length.

Case (i) v is empty. Then $|\overline{v}|\leqslant n-1$. And any word u of length n occurring in w is unacceptable.

Case (ii) v is a single cluster. Then $|\overline{v}|\leqslant n+2(n-1)$ and hence a word $u\supset\overline{v}$, whose maximum length is $3n-1$, occurring in w is unacceptable.

Case (iii) v is the concatenation of various clusters.

Suppose, without loss, that $j<k$ and let $p+1$ be such that w_{p+1} is the first letter of the rightmost cluster in v. Let $s=w_{p+1}\cdots w_{j+1}$ and $r=w_i\cdots w_p$. So, s cannot be acceptable, since otherwise we could append r to its left producing an acceptable word larger than $\overline{v}$. Note that $|s|\leqslant 2n$. □

On Λ, τ is a Markov shift[14] and we have the Markovian measure ν. Consider the projection $\pi:\Omega\to\mathcal{A}^{\mathbb{Z}}$. It is clear that to each set $Y\subset\mathcal{A}^{\mathbb{Z}}$ invariant under the shift, there corresponds an invariant set $\hat{\mathfrak{C}}(\pi^{-1}(Y))\subset\Lambda$.

Kotani's theorem[12] says there is a set $W\subset\Lambda$ with $\nu(W)=1$ such that $\sigma_{ac}(H_v)=\varnothing$ for all $v\in W$. Proposition 1 tells that there is some $Y\subset\mathcal{A}^{\mathbb{Z}}$ with $\mu(Y)=1$, μ the product measure, such that for $u\in Y$, then $\sigma_{ac}(H_{\mathfrak{C}(u)})=\varnothing$. Since $v=\hat{\mathfrak{C}}(t)$ for some t, there is a j such that $\tau^j\hat{\mathfrak{C}}(t)=\mathfrak{C}(u)$, $u\in\mathcal{A}^{\mathbb{Z}}$. The spectrum is the same for points in the same orbit, hence $W\subset\hat{\mathfrak{C}}(\pi^{-1}(Y))$. Therefore $\nu(\hat{\mathfrak{C}}(\pi^{-1}(Y)))=1$. We also have immediately the two useful corollaries:

Corollary 2: Let $Y=\{u\in\mathcal{A}^{\mathbb{Z}}:\Gamma \text{ exists}\}$ and $W=\{v\in\Lambda:\gamma(E) \text{ exists}\}$. Then $W=\hat{\mathfrak{C}}(\pi^{-1}(Y))$.

Proof: Denote by p_a the probability of the letter a appearing in a Bernoulli trial on $\mathcal{A}=\{a,b\}$ referred to in Proposition 1. p_a is the probability of $T_i=A$ in Eq. (4). Then, if γ exists, by the law of large numbers,

$$\Gamma=\lim_{n\to\infty}\frac{1}{n}\|T_n\cdots T_1\|=(p_a|\mathfrak{C}(a)|+(1-p_a)|\mathfrak{C}(b)|)\,\gamma.$$

The reciprocal is analogous. Note also that this can be extended to the case when $\mathcal{A}$ has more than two letters. □

Corollary 3: Let $Y_1 \subset \mathcal{A}^{\mathbb{Z}}$ *be an invariant set such that* $\mu(Y_1)=1$. *Then* $\nu(\hat{\mathfrak{C}}(\pi^{-1}(Y_1)))=1$.

Proof: Let Y and W be the sets of Corollary 2. Consider $Y_2=Y_1\cap Y$. Y_2 is invariant and nonempty, since $\mu(Y_1)=1$. Now $\hat{\mathfrak{C}}(\pi^{-1}(Y_2))\cap W$ is invariant and clearly nonempty, therefore $\nu(\hat{\mathfrak{C}}(\pi^{-1}(Y_2)))=1$. □

B. Some preliminaries

In this subsection, we establish conditions for the existence of critical energies on such locally correlated disordered Hamiltonians. They are preliminaries for the proofs of the main results.

Let $\rho(T)$ denote the spectral radius of the square matrix T. We begin with the following observations.

Lemma 1: Suppose that the matrices A and B commute, $[A,B]=0$, *and* $\rho(A)=\rho(B)=1$. *If* $T_i\in\{A,B\},\forall i$, *then the Lyapunov exponent* γ *vanishes.*

Proof: If n_a is the frequency of A in $T_n\cdots T_1$, then by the law of large numbers $n_a\to p_a$, and similarly $n_b\to(1-p_a)$. Hence, using the definition of the Lyapunov exponent Eq. (2), $\gamma=\log(\rho(A)^{p_a}\rho(B)^{1-p_a})=0$. □

Lemma 2: Let A,B *be* 2×2 *real matrices, and* A *not a multiple of the identity matrix* I.

(i) If $[A,B]=0$, *then there exist* $\theta,\lambda\in\mathbb{R}$ *such that* $B=\theta I+\lambda A$.

(ii) If, moreover, $\det A=\det B=1$, *then*

$$\theta^2+\lambda^2+\lambda\,\theta\,\mathrm{tr}\,A=1.$$

In this case, we denote by $B(\lambda)$ *the pencil of matrices commuting with* A. *If furthermore* $\rho(A)=1$, *then* $\rho(B(\lambda))=1$.

Proof: (*i*) and the first part of (*ii*) follow by direct calculation. To show (*ii*), note first that when $|\mathrm{tr}\,A|<2$, the pair (λ,θ) lies in an ellipse. The extrema of $\mathrm{tr}\,B=2\theta+\lambda\,\mathrm{tr}\,A$ along this ellipse occur at $\lambda=0$. □

Let A denote the transfer matrix corresponding to the cluster C_a and B the transfer matrix of the cluster C_b. For a letter t_i with corresponding potential $v_i=\varphi(t_i)$, recall that

$$T_{v_i}=\begin{pmatrix} E-v_i & -1 \\ 1 & 0 \end{pmatrix}$$

and for the word $C_a=t_0t_1\cdots t_n$, $A=T_{v_n}\cdots T_{v_1}T_{v_0}$ and correspondingly for B. Suppose we can find v_i such that, for some E, they commute. We can then write $(a_{ij})=A(E)$ and $(b_{ij}(\lambda))=B(E,\lambda)$, $\lambda\in\mathbb{R}$, with

$$\begin{aligned} b_{12}&=\lambda a_{12},\\ b_{21}&=\lambda a_{21},\\ b_{11}-b_{22}&=\lambda(a_{11}-a_{22}). \end{aligned} \tag{6}$$

Note that this system is equivalent to $[A,B]=0$, in case A is not a multiple of the identity matrix.

Let us write $\Phi(w)$ for the transfer matrix associated with the finite word w. So the notation for the basic transfer matrices of our lattice is

$$A=\Phi(C_a)\ \text{and}\ B=\Phi(C_b).$$

If t_i is the letter at position i, we have that $\Phi(t_i)$ is a function of $x_i=E-\varphi(t_i)$. The following is well known and can be checked by induction:

Lemma 3: For any word $w=t_0\cdots t_n$, *the transfer matrix* $\Phi(w)$ *has the following form,*

$$\Phi(w)=\begin{pmatrix} P_{n+1}(x_0,\ldots,x_n) & -P_n(x_1,\ldots,x_n) \\ P_n(x_0,\ldots,x_{n-1}) & -P_{n-1}(x_1,\ldots,x_{n-1}) \end{pmatrix},$$

where $P_{n+1}(x_0,\ldots,x_n)=P_n(x_0,\ldots,x_{n-1})x_n-P_{n-1}(x_0,\ldots,x_{n-2})$, $n\geqslant 0$, *with the understanding that* $P_{-1}=0$ *and* $P_0=1$ *(*P_n *is a polynomial of* E *of degree* n*).*

Note that $\Phi(bb)$ has off-diagonal elements with the property $b_{21}=-b_{12}$. An inductive argument shows that A also has this property if C_a is a palindrome:

Lemma 4: If C_a *is a palindrome, the* $A=\Phi(C_a)$ *has off-diagonal elements with the property* $a_{12}=-a_{21}$.

Proof: If C_a is a dimer, we already know A satisfies $a_{12}=-a_{21}$. If it has length $n\geqslant 3$, then $C_a=t_0Pt_0$, where P is a palindrome of length $n-2$, and we can write

$$A=\begin{pmatrix} x_0 & -1 \\ 1 & 0 \end{pmatrix} M \begin{pmatrix} x_0 & -1 \\ 1 & 0 \end{pmatrix}$$

with $M=\left(\begin{smallmatrix} a'_{11} & a'_{12} \\ -a'_{12} & a'_{22} \end{smallmatrix}\right)$, by the induction hypothesis; from this we get $a_{21}=-a_{12}$. □

Lemma 5: If C_a *and* C_b *are palindromes with* $|C_a|>|C_b|\geqslant 2$ *and* C_b *does not occur in* C_a*, then the system (6) has a finite number of solutions.*

Proof: Put $C_a=a_0\cdots a_n$ and $C_b=b_0\cdots b_k$, with $1<k<n$. We will make an induction on the size of the palindromes $|C_a|=n+1$ and $|C_b|=k+1$. Rewriting system (6) using Lemmas 3 and 4, we get

$$P_k(y_1,\ldots,y_k)=\lambda P_n(x_1,\ldots,x_n),$$

$$P_{k+1}(y_0,\ldots,y_k)+P_{k-1}(y_1,\ldots,y_{k-1})=\lambda(P_{n+1}(x_0,\ldots,x_n)+P_{n-1}(x_1,\ldots,x_{n-1})),$$

where $y_i=E-\varphi(b_i)$ and $x_i=E-\varphi(a_i)$. Eliminating λ in the system above, we get the following equation:

$$\begin{aligned} &P_k(y_1,\ldots,y_k)(P_{n+1}(x_0,\ldots,x_n)+P_{n-1}(x_1,\ldots,x_{n-1}))-P_n(x_1,\ldots,x_n)(P_{k+1}(y_0,\ldots,y_k) \\ &\quad +P_{k-1}(y_1,\ldots,y_{k-1}))=0. \end{aligned} \tag{7}$$

If there is an infinite number of energies E_i such that Eq. (7) holds, then it is a *polynomial equality*, meaning that on the left each polynomial coefficient is zero.

For $k=1$ and $k=2$, from this polynomial equation and the recursion relation given in Lemma 3, we can prove directly that C_b occurs in C_a, contrary to our hypothesis. We reduce the problem to the following.

Lemma 6: Let $|C_a|=n+1$ *and* $|C_b|=k+1$, $n>k\geqslant 3$, C_a *and* C_b *palindromes. Let* $Q(j)$ *denote the property described in items (a) and (b) below:*

(a) $$\begin{aligned} &P_{k-j}(y_1,\ldots,y_{k-j})P_{n-j-1}(x_1,\ldots,x_{n-j-1})-P_{k-j}(y_{j+1},\ldots,y_k)P_{n-j-1}(x_{j+2},\ldots,x_n) \\ &\quad \equiv P_{n-j}(x_1,\ldots,x_{n-j})P_{k-j-1}(y_1,\ldots,y_{k-j-1})-P_{n-j}(x_{j+1},\ldots,x_n)P_{k-j-1}(y_{j+2},\ldots,y_k), \end{aligned}$$

(b) $$x_0=y_0=x_n=y_k,\quad \ldots,\quad x_j=y_j=x_{n-j}=y_{k-j},$$

for some $0\leqslant j\leqslant k-2$; *then* $Q(j+2)$ *holds. In particular* $x_{j+1}=y_{j+1}=x_{n-j-1}=y_{k-j-1}$ *and* $x_{j+2}=y_{j+2}=x_{n-j-2}=y_{k-j-2}$.

Proof of Lemma 6: We use the recursion relation of Lemma 3 and

$$P_{n+1}(x_0,\ldots,x_n)=x_0P_n(x_1,\ldots,x_n)-P_{n-1}(x_2,\ldots,x_n).$$

Properties $Q(0)$ and $Q(1)$ are immediate from Eq. (7) and the recursion relations.

From point (a) of $Q(j)$, expanding the occurrences of P_{k-j} and P_{n-j},

$$\begin{aligned}
&y_{k-j}P_{k-j-1}(y_1,\ldots,y_{k-j-1})P_{n-j-1}(x_1,\ldots,x_{n-j-1})\\
&\quad -P_{k-j-2}(y_1,\ldots,y_{k-j-2})P_{n-j-1}(x_1,\ldots,x_{n-j-1})\\
&\quad -y_{j+1}P_{k-j-1}(y_{j+2},\ldots,y_k)P_{n-j-1}(x_{j+2},\ldots,x_n)\\
&\quad +P_{k-j-2}(y_{j+3},\ldots,y_k)P_{n-j-1}(x_{j+2},\ldots,x_n)\\
&\quad =x_{n-j}P_{n-j-1}(x_1,\ldots,x_{n-j-1})P_{k-j-1}(y_1,\ldots,y_{k-j-1})\\
&\qquad -P_{n-j-2}(x_1,\ldots,x_{n-j-2})P_{k-j-1}(y_1,\ldots,y_{k-j-1})\\
&\qquad -x_{j+1}P_{n-j-1}(x_{j+2},\ldots,x_n)P_{k-j-1}(y_{j+2},\ldots,y_k)\\
&\qquad +P_{n-j-2}(x_{j+3},\ldots,x_n)P_{k-j-1}(y_{j+2},\ldots,y_k).
\end{aligned}$$

Since we know that $x_{n-j}=y_{n-j}$ already, the first term and the first term after the equality sign cancel out. The terms containing the highest power in E are the third before and after the equality sign. The other terms do not affect the leading coefficient. Therefore, we have $x_{j+1}=y_{j+1}$, which are also equal to x_{n-j-1} and y_{n-j-1} by palindromicity.

We now expand $P_{k-j-1}(y_{j+2},\ldots,y_k)$ and $P_{n-j-1}(x_{j+2},\ldots,x_n)$ to conclude that $x_{j+2}=y_{j+2}$. The polynomials remaining give the equality (a) of $Q(j+2)$. □

$Q(k)$ contradicts the hypothesis that C_b does not occur in C_a. □

C. Proofs of proposition 1 and theorem 1

Proof of Proposition 1: We follow de Bièvre and Germinet[8] closely. We first note that the group generated by A and B is not compact and, resorting to Theorem II.4.4 of Ref. 3, we will prove that the orbit of any direction $x\in\mathbb{P}(\mathbb{R}^2)$ under this group contains at least three elements. It is sufficient to consider the three cases: (a) A and B elliptic, (b) A parabolic and (c) A hyperbolic, as the other cases will follow by interchanging the roles of A and B.

The noncompactness of the group is clear in cases (b) and (c). Since A and B are palindromic transfer matrices, they have the form (using Lemma 4)

$$A=\begin{pmatrix} a_1+t_A & -a_2\\ a_2 & -a_1\end{pmatrix},\quad B=\begin{pmatrix} b_1+t_B & -b_2\\ b_2 & -b_1\end{pmatrix},$$

where $t_A=\mathrm{tr}\,A$ and $t_B=\mathrm{tr}\,B$. For A and B palindromes, $[A,B]\neq 0\Leftrightarrow[A,B]$ is invertible. Hence using Theorem 7.39.2 of Ref. 2 for A and B elliptic, the noncommutativity implies $\mathrm{tr}\,(ABA^{-1}B^{-1})>2$. This shows that also in this case the group generated by A and B is not compact.

(a) If both $|t_A|<2$ and $|t_B|<2$, then from $A^2=t_AA-I$, one sees that A^2 or B^2 are elliptic, unless both $t_A=t_B=0$. In the first case, the set $\{x,Ax,A^2x,Bx,B^2x\}$ contains at least three different directions. The latter case, viewed as a geometric condition, is the intersection set of zeroes of two transverse polynomials t_A and t_B (by the same analysis of leading order coefficients given in Lemma 5). This intersection is empty unless $\gcd(t_A(E),t_B(E))\neq 1$, that is, if these polynomials have a common divisor.

Now, if for a given s-tuple $\mathbf{v}\in\mathcal{V}$, $\gcd(t_A,t_B)\neq 1$, since t_A and t_B are also polynomials in $\mathbf{v}$, it is clear that to preserve this condition $\mathbf{v}$ has to stay in an algebraic variety in parameter space $\mathcal{V}$.

(b) If $|t_A|=2$, then A has a single fixed point in $\mathbb{P}(\mathbb{R}^2)$, but it cannot be a fixed point of B since

$$[A,B]=((2a_1+t_A)a_2-(2b_1+t_B)b_2)\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix}$$

is invertible. Now it is clear that the set $\{x, Bx, Ax, ABx, A^2x\}$ has at least three different directions.

(c) Again it suffices to consider the orbit of the two eigenvectors of A. If $|t_B| \geqslant 2$, we are done, again because A and B do not have eigenvectors in common. But it could be the case that B, being elliptic, exchanged the eigendirections of A. These are $e_1=(a_1+\lambda,a_2)$ and $e_2=(a_1+\overline{\lambda},a_2)$, where $\lambda=(t_A+\sqrt{t_A^2-4})/2$ and $\overline{\lambda}=1/\lambda$.

From $Be_1=ke_2$ and $Be_2=-k^{-1}e_1$, it follows that $t_B=0$. Moreover, from the system of equations

$$b_1(a_1+\lambda)-b_2a_2=k(a_1+\overline{\lambda}),$$

$$b_2(a_1+\lambda)-b_1a_2=ka_2$$

one obtains the equation $2b_2a_2=(2a_1+t_A)b_1$. Now we have again two polynomials, whose sets of zeros have, by transversality, empty intersection. □

By Corollary 2, there is a set $W\subset\Lambda$ of measure $\nu(W)=1$ which corresponds to the subset of $\mathcal{A}^{\mathbb{Z}}$ given in the proposition above. The closure of the orbit of each periodic sequence is a set of measure zero. The closure of the orbit of a sequence which is periodic except in a finite number of indices (that is, in the complement of a cylinder set[15]) is also a set of measure zero. Subtracting these sets from W we get a measurable set Y of full measure. For every $v\in Y$, $\gamma(E)>0$ except possibly when $[A,B]=0$.

Proof of Theorem 1: Fix A and B transfer matrices of palindromes C_a and C_b. As noted in the proof of Proposition 1, Eq. (6) is a system of two independent polynomials and two variables (λ,E), with a finite number of (real) roots.

A random palindrome model may have long range order; then we have to consider all possibilities of palindromes which tessellate the lattice potential. But since A, B are transfer matrices on factors in a finite alphabet, they belong to a denumerable set of unimodular matrices. Therefore the set of critical energies is at most countable. □

Lemmas 1 and 2 tell us that to find critical energies for the tight binding Hamiltonian, we have to search for commuting transfer matrices with one of them with spectral radius equals to 1. From Lemma 2, the pencil of matrices commuting with a given one is compact in $\mathrm{SL}(2,\mathbb{R})$. Hence, for each A, a choice of B from the intersection of a countable set and a compact set has generically a finite number of possibilities. This reasoning leads us to question whether the critical energies given by system (6) are real.

From Proposition 1, we also have the following.

Corollary 4: Consider Λ the set of all random palindrome models whose potentials are tessellated by palindromes $p_1,\ldots,p_n$ with p_i not contained in p_j, $i\neq j$. Let ν be the Markov measure invariant under the shift. For ν-almost every v, $\gamma(E)=0$ implies that the transfer matrices $A_i=\Phi(p_i)$ are elliptic and pairwise commuting.

D. A particular case

Now we illustrate the construction leading to critical energies in a simple situation: taking $C_a=t_0t_1t_2$ and $C_b=t_3t_4$, we shall determine transfer matrices for which the above setting applies. The potentials $v_i=\varphi(t_i)$ are allowed to take on more than two values. Note that, being the transfer matrices unimodular, the condition on the determinant is automatically fulfilled. As above, denote by A the transfer matrix of the cluster C_a and by B the transfer matrix of C_b:

$$A(E)=T_{v_2}T_{v_1}T_{v_0} \text{ and } B(E)=T_{v_4}T_{v_3}.$$

We shall use the abbreviation $x_i=E-v_i$ and drop the reference to E at our convenience in what follows. From the system of equations (6) we have the following,

$$x_3=\lambda(x_0x_1-1),$$

$$x_4=\lambda(x_1x_2-1),$$

$$x_3x_4=\lambda(x_0x_1x_2-x_0-x_2+x_1),$$

and the condition $\rho(A)=1 \Leftrightarrow |\mathrm{tr}\, A|\leqslant 2$ reads

$$|x_0x_1x_2-x_0-x_1-x_2|\leqslant 2.$$

Since the v_i are fixed values of the potential, we have three equations in two variables. We make the first two of these (algebraic) curves in the (E,λ) plane coincide by setting $v_4=v_3$, and $v_2=v_0$, but with v_0, v_1 and v_3 all different from each other. Notice that this makes C_a and C_b palindromes; that was the initial motivation for Theorem 2.

An obvious solution is $x_3=0$, that is, $E=v_3$, and $\lambda=0$. We call this the *dimer* energy, because for it $B=-I$ and the above lemmas are satisfied trivially, except for the condition $\rho(A)=1$, which remains to be verified for this energy to be critical. If $\lambda\neq 0$, we get the equation

$$x_3(x_0x_1-1)=x_0^2x_1-x_0+(v_0-v_1),$$

with the two solutions (note that $x_i-x_j=v_j-v_i$ is a constant)

$$x_{0\pm}=-\frac{v_{01}\pm\sqrt{v_{01}^2+4+4v_{01}/v_{03}}}{2},$$

where $v_{ij}=v_i-v_j$.

The three energies $E=\{v_3,v_0+x_{0+},v_0+x_{0-}\}$ will be critical energies if the following condition holds:

$$|\mathrm{tr}\, A|\leqslant 2 \;\Leftrightarrow\; |x_0^3+v_{01}x_0^2-3x_0-v_{01}|\leqslant 2.$$

One possible way to achieve this is by setting $v_{01}=2v_{03}$ and $|v_{03}|\leqslant 1$, which is enough for the purpose of showing the existence of three energies where the Lyapunov exponent vanishes.

Remark 1: (i) It may happen that $A=\pm I$ for transfer matrices, and obviously $[B,A]=0$ for any B, but the equations (6) above would have the "strange" solution $\lambda=\infty$. In this case $\rho(B)=1$ alone implies $\gamma=0$.

(ii) From the above remark, or interchanging the roles of A and B in system (6), we see that the natural domain for λ is the projective line $(-\infty,\infty]$.

(iii) We fix $C_b=bb$ from now on and will call the word C_b a dimer. *For those E^* where $A(E^*)=\pm I$, we have $\gamma(E^*)=0$ if $\rho(B)=1$, that is, if $|E^*-v_b|\leqslant 2$.*

To proceed with the generation of critical energies, we choose to enlarge the cluster C_a. For $C_b=bb$, the system of equations (6) always keeps the trivial solution coming from the dimer: $E=v_b$ and $\lambda=0$. Eliminating this solution, we get a polynomial of degree n in the variable E, which has $|C_a|-1$ roots. However, it is harder to anticipate if for these energies $|\mathrm{tr}\, A|\leqslant 2$. Providing this, Lemmas 1 and 2 will yield $\gamma(E)=0$, and since $\gamma(E)>0$ outside the spectrum, $E\in\sigma(H_v)$.

E. Proof of Theorem 2

Let us begin with the idea of the proof. The strategy is first to analyze the simple case where $C_a=a^{2k+1}$ and then make use of perturbative arguments. Without loss of generality, we suppose $v_b>v_a$, so that the disorder strength is $\Delta=v_b-v_a$. We can show that there are $2k$ energies where $A=\pm I$ (actually this is an old known fact[4]), and v_b can be chosen as in Remark 1 (iii). *This imposes the bound on the disorder $\Delta<4$, see below*. These energies are roots of a Chebyshev polynomial of degree $2k$, so they are simple. Then we consider the palindrome $C_a=a^kt'a^k$, meaning that only the central position has a different potential $\varphi(t')=v_a+\epsilon$. If $\epsilon>0$ is small, we can prove that there are $2k$ perturbed energies satisfying $|\mathrm{tr}\, A|<2$. Since this is now an open

condition on C_a, we will conclude the proof of the first part of the theorem. The second and third parts will be proven by an analysis of the sign of the second derivative of tr A in case $\Delta<4$ is arbitrary.

First, for $C_a=a^n$, we have

$$A=\begin{pmatrix} P_n(x_a) & -P_{n-1}(x_a) \\ P_{n-1}(x_a) & -P_{n-2}(x_a) \end{pmatrix},$$

where $x_a=E-v_a$. The recursion relation $P_n(x)=xP_{n-1}(x)-P_{n-2}(x)$ gives that $P_n(x)=U_n(x/2)$, where U_n are the Chebyshev polynomials of the second type, following the notation of Gradshteyn–Ryzhik.[11] The equations for commutativity of A and B read

$$x_b=\lambda P_{n-1}(x_a) \quad \text{and} \quad x_b^2=\lambda(P_n(x_a)+P_{n-2}(x_a)),$$

with $\lambda\in(-\infty,\infty]$ as noted in Remark 1 (iii). Since $x_a\neq x_b$, we have only two possibilities: $x_b=0$ or $P_{n-1}(x_a)=0$. In the latter case, tr $A=-2P_{n-2}(x_a)$. A calculation using the expression $U_n(\theta)=[\sin(n+1)\theta]/\sin\theta$, $\theta=\arccos(x/2)$ shows that at the (simple) roots of P_{n-1}, tr $A=\pm 2$.

So we have the partial conclusion that if we combine constant words of length n and dimers we get at least n critical energies for Δ small enough, namely, less than $2+\min\{z\}$, where z are the roots of $P_{n-1}(x)=0$, again using Remark 1 (iii). In general, these roots z are critical energies if, and only if, $|\Delta-z|\leqslant 2$, for $\epsilon=0$.

However, if $\Delta\geqslant 4$, since every root of $P_{n-1}(x)$ satisfies $|z|<2$, one cannot have simultaneously $\rho(B)=1$, so these critical energies cease to be so. Also, for the dimer energy $E=v_b$, a necessary condition for $|\text{tr } A|\leqslant 2$ is $\Delta\leqslant 2$. In other words, the dimer energy ceases to be critical when the disorder strength $\Delta>2$. Note that this is the same bound for the original *random dimer model*,[9] in particular, for $\Delta=2$,

$$|\text{tr } A|=|U_n(-1)-U_{n-2}(-1)|=2.$$

Now consider the case where $n=2k+1$ and $x_i=x_a$ except for $i=k$ where $x_k=x_a-\epsilon$. Let us make the abbreviation $x=x_a$ and replace $x_b=x-\Delta$. Now A reads

$$A=\begin{pmatrix} (x-\epsilon)P_k^2-2P_kP_{k-1} & -(x-\epsilon)P_kP_{k-1}+P_{k-1}^2+P_kP_{k-2} \\ (x-\epsilon)P_kP_{k-1}-P_{k-1}^2-P_kP_{k-2} & -(x-\epsilon)P_{k-1}^2+2P_{k-1}P_{k-2} \end{pmatrix}.$$

Then for $\lambda\neq 0$,

$$\begin{aligned} \text{tr } A&=(P_k^2-P_{k-1}^2)(x-\epsilon)+2P_{k-1}(xP_{k-1}-2P_k), \\ \Delta(P_k^2-P_{k-1}^2)&=\epsilon(P_k^2+P_{k-1}^2-(x-\Delta)P_kP_{k-1}). \end{aligned} \tag{8}$$

We make Taylor expansions on Eqs. (8) around the critical energies for $\epsilon=0$, namely, around the zeroes of $P_{2k}=P_k^2-P_{k-1}^2$. Let $\{z_i=2\cos[\pi i/(2k+1)];1\leqslant i\leqslant 2k\}$ be the set of roots of $P_k^2(x)=P_{k-1}^2(x)$. For $\epsilon=0$, the fact that tr $A=\pm 2$ at these $2k$ roots yields the useful relation

$$P_k(z_i)(2P_k(z_i)-z_iP_{k-1}(z_i))=1. \tag{9}$$

For small ϵ, the roots of the second equation in (8) will be $\delta(z_i,\epsilon)$ away from z_i, for each $1\leqslant i\leqslant 2k$. We fix i and write $\delta=\delta(z_i,\epsilon)$. Expanding the second equation in (8) one obtains

$$2\Delta\delta\left(\frac{2k+1}{4-z_i^2}\frac{P_{k-1}}{P_k}\right)=\epsilon(1+\Delta P_kP_{k-1})+O_2(\epsilon,\delta),$$

where $O_2(\epsilon,\delta)$ is a remainder of order 2 in ϵ and δ.

Now we compute the first terms in the power series of tr A starting from Eq. (8.949.6) in Ref. 10. To first order in δ and ϵ, $|\text{tr } A|=2$. We omit the details of the calculation of second order terms, which yields

$$\text{tr } A=\tau_0\left(1-\frac{\delta^2}{2}p(z_i,k)\right)+O(\delta^3)$$

where

$$p(x,k)=\frac{4x^2(2k+1)}{(4-x^2)^2}+f(\Delta)\frac{(2k+1)^2}{(4-x^2)^2}+\frac{(2k+1)^2}{4-x^2},$$

$$f(\Delta)=\frac{2\tau_0\Delta}{1-\tau_0\Delta P_k^2(z_i)/2},$$

$$\tau_0=-\frac{2P_{k-1}(z_i)}{P_k(z_i)}.$$

The problem is reduced to evaluating the sign of $p(z_i,k)$. We remark that δ is independent of the disorder strength Δ and therefore can be made as small as one likes by diminishing ϵ. Hence

$$p(z_i,k)>0\Leftrightarrow\ -f(\Delta)<\frac{4z_i^2}{2k+1}+4-z_i^2 \tag{10}$$

and it is clear that, for small Δ, in particular $\Delta\leqslant\sin^2[\pi/(2k+1)]$, the above holds for all $1\leqslant i\leqslant 2k$. Part (i) is proved.

We have $z_i=2\cos(\pi i/(2k+1))$, $1\leqslant i\leqslant 2k$, and for even i, $P_k(z_i)=-P_{k-1}(z_i)$ and consequently $\tau_0=2$, while for odd i, $\tau_0=-2$. If $\tau_0=2$ and $i=2j$, we note that $-f(\Delta)<0$ for small Δ. Therefore, the above inequality (10) remains true for all z_i such that

$$1-\Delta P_k^2(z_i)<0\Leftrightarrow\Delta<\frac{\sin^2[\pi i/(2k+1)]}{\sin^2[\pi ki/(2k+1)]}=4\cos^2\left(\frac{\pi i}{2(2k+1)}\right).$$

For $\tau_0=-2$ and $i=2j+1$, we have

$$\frac{4\Delta}{1+\Delta P_k^2(z_i)}\leqslant 4\sin^2\frac{\pi i}{2k+1}\Leftrightarrow\Delta\leqslant\frac{\sin^2[\pi i/(2k+1)]}{\cos^2[\pi ki/(2k+1)]}=4\cos^2\left(\frac{\pi i}{2(2k+1)}\right).$$

Note that the bound for Δ is a decreasing function of i for $1\leqslant i\leqslant 2k$. To finish, note that for $\Delta<2$, every z_i for $i\leqslant k$ satisfies the above inequality. For $\Delta<4$, the critical energy z_1 remains so for large enough k. □

Remark 2: From the condition that, for $\epsilon=0$, $|\Delta-z_i|\leqslant 2$ if, and only if, $E=v_a+z_i$ is a critical energy, we obtain $z_{\max}=2\cos[\pi/(2k+1)]$. This relates to the critical energy referred to in Theorem 2(iii). This also proves Corollary 1.

F. Primitive cluster maps

In this subsection, we comment upon cluster maps of the form $\mathfrak{C}:\mathcal{A}\to\mathcal{A}^*$, i.e., *substitutions*.[16] Fixing one such cluster map, it can be iterated on random sequences and, providing conditions so that it is a contraction, its fixed point is a substitution sequence. Thus we have a sequence of random locally correlated potentials converging to a potential with long range order (compare Ref. 1).

One extra requirement is that $\mathfrak{C}$ be *primitive:* there exists $k\geqslant 1$ such that for any $a\in\mathcal{A}$, $\mathfrak{C}^k(a)$ contains all letters of $\mathcal{A}$. Without loss of generality we assume $k=1$. We call the extension of such

$\mathfrak{C}$ to $\mathcal{A}^{\mathbb{Z}}$ a *primitive cluster map*. Note that $\mathfrak{C}(v)$, for any $v \in \mathcal{A}^{\mathbb{Z}}$, has also a long range order for primitive $\mathfrak{C}$: this is the bounded gap property for one letter. Further iterations will give rise to larger words occurring in bounded gaps in $\mathfrak{C}^n(v)$.

Theorem 3: *Let $\mathfrak{C}:\mathcal{A}^{\mathbb{Z}} \to \mathcal{A}^{\mathbb{Z}}$ be a primitive cluster map. If the second letter of $\mathfrak{C}(a)$ is the same for every $a \in \mathcal{A}$, then $\mathfrak{C}$ is a contraction.*

In this sense, given $u \in \mathcal{A}^{\mathbb{Z}}$, $\mathfrak{C}^n(u)$ provides a sequence of random cluster potentials converging to an almost periodic one.

Remarks: (i) The assumption on the second letter is due to the definition of $\mathfrak{C}(u)$, $u=(u_n)$, so that the second letter of $\mathfrak{C}(u_0)$ sits at the zeroth position of $\mathfrak{C}(u)$. This assumption in turn is necessary for

$$\lim_{n\to\infty} \mathfrak{C}^n(a)$$

to pertain to $\mathcal{A}^{\mathbb{Z}}$, for each $a \in \mathcal{A}$. In fact, here we also need $|\mathfrak{C}(a)| \geqslant 3$, but this can be accomplished by redefining the substitution $\mathfrak{C}$ on $\mathcal{A}$ as some power of itself.

(ii) It is known that, for primitive substitutions, the finite alphabet $\mathcal{A}$ splits into disjoint classes $\mathcal{A}_j$, $j=1,\ldots,r$, such that, for some $k \geqslant 1$, for each $a \in \mathcal{A}_j$, $\mathfrak{C}^k(a)$ begins with a fixed $a' \in \mathcal{A}_j$. We can relax the assumption above to

for each $a \in \mathcal{A}_j$, *the second letter in $\mathfrak{C}^k(a)$ also belongs to $\mathcal{A}_j$.*

Thus we get r fixed points. The Rudin–Shapiro substitution is an example of this more general setting.

(iii) The hull of an almost periodic sequence u, $\Omega(u)$, is the set of $v \in \mathcal{A}^{\mathbb{Z}}$ such that any finite word occurring in v occurs in u. With this definition it is clear that the limit above yields a sequence in its hull.

(iv) The above assumption can be adjusted to a given substitution: for instance, for the Thue–Morse substitution, $\mathfrak{C}(a)=abbabaab$, $\mathfrak{C}(b)=baababba$, we may use the fourth letter in place of the second.

(v) If $\mathfrak{C}$ is primitive and palindromic, critical energies appearing in $\mathfrak{C}(u)$ for a random u will be given by Theorem 1. In $\mathfrak{C}^2(u)$, these critical energies are preserved, but others may appear as other tessellations by palindromes are generated.

IV. NUMERICAL EXPERIMENTS

In these numerical experiments, we first analyze the behavior of the Lyapunov exponent $\gamma(E)$ near a critical energy E^*. Fixing $\epsilon > 0$ we perform an average of $\gamma(E)$ over a number of realizations of the Schrödinger operator for a finite size lattice. From a fitting procedure, we extract the value of the exponent ν in the expression

$$\gamma(E) \sim C|E-E^*|^{\nu} \quad \text{for small} \quad |E-E^*|.$$

We use the finite basis approximation in the Thouless formula to calculate $\gamma(E)$, $E \in [-2+v_a, 2+v_b]$ (recall that $v_b > v_a$). Fluctuations in $\gamma(E)$, when it is small, spoil the calculation of the exponent ν, and this is why we perform an average over the hull. Since we do not have actual bounds on $|E-E^*|$, a numerical calculated ν is expected to be a rough approximation. Figure 1 illustrates the procedure to estimate the exponent ν.

For the random dimer potential, Bovier[5] has found that $\nu=2$. A look at the calculations showing how the linear term vanishes in the expansion of $\gamma(E)$ and the expression of the leading (second) order term permits us to guess that ν does not increase for the random cluster model (compare Ref. 11). For comparison, we present the numerical values of ν for the dimer case as well, calculated using the same procedure. However, Bovier's hypothesis that the invariant measure (its density, in fact) has a Taylor expansion in the vicinity of the critical energy is not necessarily true in these general models.

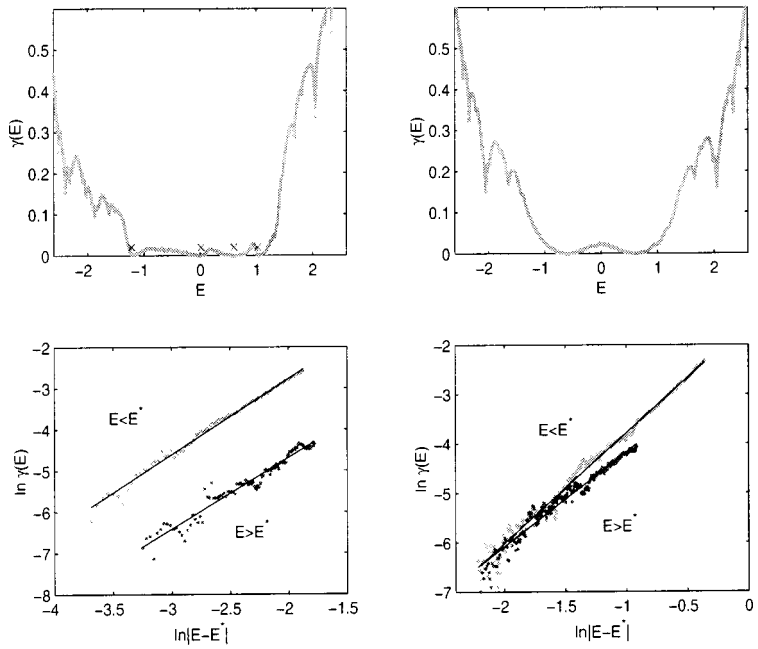

FIG. 1. On top, the graphs of the Lyapunov exponent with disorder $\Delta=1.2$, the *random palindrome model* on the left and the *random dimer* on the right. The bottom figures show examples of dilog fitting of the Lyapunov exponent: On the left, for the *random palindrome model*, near the critical energy $E^*=-1.197$, coming from the first minimum for $\epsilon=0$ (the minima for $\epsilon=0$ occur at $2\cos \pi i/5-0.6$, $i=1,2,3$, and at 0.6, positions marked with $\times$). As seen, the right branch $E<E^*$ approaches zero faster than the left branch $E>E^*$: the slopes of the fitting lines are 1.8 and 1.7, respectively. On the right, for the *random dimer* near $E^*=-0.6$, we get the slopes 2.2 for the left branch and 1.9 for the right branch.

We then perform the time evolution of a packet initially located at the central position of a finite lattice. We integrate the time-dependent Schrödinger equation using a sympletic integrator, the details of which have been explained elsewhere.[7]

We address the question whether propagation over the lattice is enhanced as an effect of the local order compared with the random dimer. We do this by computing the exponent α in the asymptotic regime of

$$[m_2(t)]^2=\sum_{n\in\mathbb{L}} n^2|\psi_n(t)|^2\sim Ct^{2\alpha},$$

where $\mathbb{L}=[-L+1,L]\cap\mathbb{Z}$ is the finite lattice [we used basis sizes up to 2 (Ref. 14)]. For the dimer, $\alpha=\frac{3}{4}$,[9] and we obtain, for the palindrome C_a of size 5, that α is higher at the beginning, but settles down to around $\frac{3}{4}$ at later times.

Table I summarizes the results on transport. For the extreme disorders considered, there is a clear transient behavior. On the one hand, for small Δ it appears that the potential is more transparent, but around $t=1000$, there is a change in slope in a curve $\log m_2$ vs $\log t$. This is why we consider the time span only for $\log t>7$ until the packet reaches the border of the lattice, with probability greater than 10^{-8}. On the other hand, for large Δ, the lattice conducts poorly at the beginning, but after $\log t>7$, m_2 also shows a power law behavior. When Δ is increased α decreases. Furthermore, the disorder can be larger than 2 maintaining superdiffusive behavior: from this we can say that conduction is enhanced in the random palindrome model as compared to the random dimer.

The reason for the higher α for short times and small disorder Δ stems from the extra critical energies, which forces $\gamma(E)$ to be small in a larger portion of the spectrum. This also explains why the ν column in Table I is not a decreasing function of the disorder. The leftmost critical energy for

TABLE I. The growth exponent α and the behavior of $\gamma(E)$ near the critical energy E^* for increasing disorder in the random palindrome model with cords $C_a=aaa'aa$ and $C_b=bb$.

Δ	ν (left branch)	E^*	α	Time span t $\ln T_1-\ln T_2$ $T_1<t<T_2$
0.2	2.2	−1.720	0.78	7–9
0.6	0.8	−0.913	0.73	7–9
1.2	1.8	−1.197	0.75	0–9
2	1.1	−0.3855	0.68	0–9.5
3	1.1	0.1826	0.67	7–10

small Δ ceases to be so around $\Delta=0.38$ for $k=5$. For $\Delta=0.6$, γ is still not growing sufficiently fast off the critical energy -0.913: it is as small as 0.036 at $E=-1.75$, just ten times its minimum value attained at 0.913. For long enough times, the exponential decay eventually sets in so only those states with localization lengths of the order of the lattice size or larger contribute to transport up until the packet reaches the border. Briefly, we have numerically found that α, the exponent measuring transport, does not increase if we have a finite number of contributing critical energies, all of them with the same exponent $\nu\leqslant 2$.

We can make the dimer critical energy and one of the critical energies due to the palindrome C_a for $\epsilon=0$ coalesce, by taking $\Delta=2\cos 2\pi/5$. It is reasonable to expect that $\gamma(E)$ will have a higher tangency at the corresponding critical energy, $E^*=\cos 2\pi/5$, or, more precisely, that $\nu(E^*)$ will be greater than 2. Even though this is apparently true (as we saw numerically), we did not observe an increase in α, which continued around 0.75.

We also investigated the following interesting example: C_a a palindrome whose potential looks like a staircase:

$$-\frac{\varphi(C_a)}{\Delta/2}=\{0.4,0.6,0.8,1,0.8,0.6,0.4\}$$

and $C_b=bb$. We obtain qualitatively the same behavior, as displayed in Figure 2, fixing $\Delta>0$, and computing $\gamma(E)$ and $m_2(t)$. We also get apparent critical energies even for $\Delta>4$, where $\gamma(E)\approx 0$ [however, this could be credited to the disorder definition, which is $\max\{\varphi(u)-v_b, u\in C_a\}$].

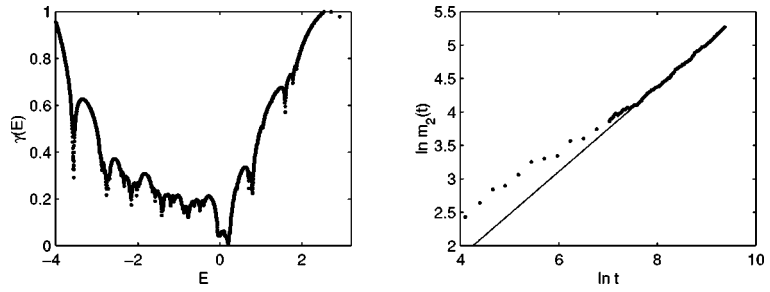

FIG. 2. The Lyapunov exponent for disorder $\Delta=4.2$ and palindrome $C_a=u_1u_2u_3u_4u_3u_2u_1$ of length 7, such that the values of the potential are $\varphi(u_i)=(\Delta/2)(1-0.2|i-4|)$. The approach to zero at $E\approx 0.2$ has $\nu=0.5$ from the left and $\nu=0.8$ from the right. On the right plot, the mean square displacement together with the linear fitting using data for $t>e^{7.5}$, from which we get the slope $\alpha=0.64$.

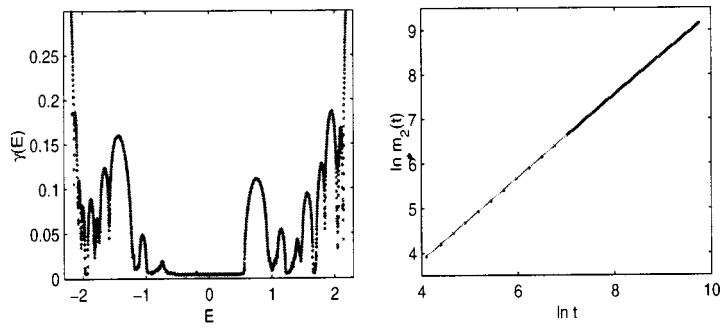

FIG. 3. The Lyapunov exponent for the sequence $\mathfrak{C}^2(u)$, u a random sequence, and disorder $\Delta=0.8$. Note the flat behavior on an interval containing the critical energies -0.4 and 0.4: there $\gamma(E)\leqslant 5\times 10^{-3}$. On the right, the mean square displacement data are shown in dots and the line obtained by a fitting has angular coefficient $\alpha=0.92$.

Finally, we consider a random palindrome model with a primitive cluster map (see Sec. III F). The map $\mathfrak{C}(a)=abbba$ and $\mathfrak{C}(b)=aba$ for $\mathcal{A}=\{a,b\}$ has the one-letter bounded gap property on the image sequence. Since the second letter of $\mathfrak{C}(a)$ and $\mathfrak{C}(b)$ is the same, then independently of the initial sequence v in $\mathcal{A}^{\mathbb{Z}}$, $\mathfrak{C}^n(v)$ tends, for $n\to\infty$, to

$$\cdots abbbaa\cdot baabbba\cdots,$$

which is the limit sequence of $\mathfrak{C}^n(b)$ (recall that the central dot marks, to its right, the zeroth position). Critical energies can be determined from the commutation of the transfer matrices $\Phi(\mathfrak{C}(a))$ and $\Phi(\mathfrak{C}(b))$.

For $\Delta\leqslant 1$ we have two critical energies, when $E=v_a$ and $E=v_b$, and only $E=v_a$ for $1<\Delta\leqslant 2$. The commutation of the transfer matrices corresponding to each cluster is the sole responsible for the critical energies upon the first iteration of $\mathfrak{C}(u)$, for a random $u\in\mathcal{A}^{\mathbb{Z}}$, cf. Proposition 1. We considered, however, the random cluster $w=\mathfrak{C}^2(u)$, with u a random sequence in $\mathcal{A}^{\mathbb{Z}}$. The sequence w has the bounded gap property for the words $\mathfrak{C}(a)$ and $\mathfrak{C}(b)$, whose corresponding transfer matrices commute at the critical energies $E=0.4$ and $E=-0.4$. There appears a new numerical behavior in both $m_2(t)$ and $\gamma(E)$, with an apparent boost in transport $\alpha\approx 0.92$, as seen in Fig. 3.

(Received 7 October 2002; accepted 4 December 2002)

The perturbation series for the ground state energy of the hydrogen atom in the external magnetic field is summed via the sequence transformations. The formula for the large-order behavior of the partial sums of the series is derived. From this formula a new general sequence transformation is suggested. This transformation contains free parameters that can be further optimized. It is shown that if the renormalization approach is used, the optimal choice of these parameters leads to the previously suggested Weniger transformation. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1541119]

I. INTRODUCTION

The hydrogen atom in a constant magnetic field is an elementary but tricky problem, and great deal of effort has been devoted to the solution of this problem (see, e.g., Refs. 1–20 and references therein). It is of special interest from the point of view of the summation of the divergent perturbation series. Searching for the solution of the Schrödinger equation,

$$\left[-\frac{\nabla^2}{2}-\frac{1}{r}+\frac{B^2}{8}(x^2+y^2)\right]\psi=E\psi, \tag{1}$$

in the form of the Rayleigh–Schrödinger perturbation series in the powers of the intensity of the constant magnetic field B

$$E=-\frac{1}{2}+\sum_{n=1}^{\infty}E_n\left(\frac{B^2}{8}\right)^n, \tag{2}$$

it appears that the perturbation coefficients E_n behave for large n as[1–4]

$$E_n=(-1)^{n+1}\left(\frac{4}{\pi}\right)^{5/2}\left(\frac{8}{\pi^2}\right)^n\left(2n+\frac{1}{2}\right)!\,(1+O(1/n)). \tag{3}$$

It means that the series (2) diverges for every $|B|>0$. Moreover, because of the peculiar logarithmic behavior of the energy for high magnetic fields,[5] the series is known to be one of the most difficult summable divergent series encountered in physics. Particularly, it is known[2] that the series is not efficiently summed by the Padé approximants, the most widely used summation technique (see, e.g., Refs. 21–23). Some time ago a new method for the summation of the divergent series, the so-called Weniger summation, was introduced.[24,25] This method was combined with the renormalization approach[26] and succesfully applied to the one-dimensional anharmonic oscillators.[24] Since there have been only a few attempts to sum the series for the hydrogen atom in the magnetic field,[2,6,7] we apply the Weniger summation technique to this problem to better understand its advantages and drawbacks.

The article is organized as follows. In Sec. II, the large-order behavior of the partial sums of the series (2) is derived. On the basis of this behavior a new general sequence transformation is suggested. This transformation contains free parameters that can be further optimized. In special

cases, both previously suggested Levin[23,27,28] and Weniger,[24,25] sequence transformations are obtained. In Sec. III, the renormalization of the energy and the coupling constant is made. In the final section, Sec. IV, discussion of the results and a few general remarks on the sequence transformations are made.

II. SEQUENCE TRANSFORMATIONS

On the basis of some heuristic arguments we suggest in this section a new sequence transformation. We shall proceed in an intuitive way and arguments given here should serve only as a basis for more rigorous treatment.

For the sake of simplicity, we replace the coefficients E_n of the series (2) by their large-order behavior (3) and consider the partial sums of such a series

$$s_m=\sum_{n=0}^{m} a_n, \tag{4}$$

where

$$a_n=C(-1)^{n+1}\left(\frac{B^2}{\pi^2}\right)^n\left(2n+\frac{1}{2}\right)! \tag{5}$$

and $C=(4/\pi)^{5/2}$.

Obviously, the partial sums (4) have no limit in ordinary sense and, consequently, the sum of the series Σa_n does not exist in ordinary sense. Nevertheless, we can try to give some meaning to the sum of such a series. Namely, we can try to fit the partial sums (4) to a finite number of terms. The most natural way of doing it is to write the system of l equations

$$s_m=c_0a_m+c_1a_{m-1}+\cdots+c_{l-2}a_{m-l+2}+s, \quad m=n-l+1,\ldots,n, \tag{6}$$

for l unknown coefficients $c_0,c_1,\ldots,c_{l-2}$ and s. As discussed below, the coefficient s has the meaning of the generalized sum of the series. Since the index of the coefficient a_{m-l+2} has to be greater or equal to zero, and since the smallest value of m is $n-l+1$, we take l as the integer part of $(n+3)/2$.

Now, we extend the meaning of the limit to the sequence $(-1)^{n+1}(2n+\frac{1}{2})!$. Particularly, if we say that such a sequence exhibits ''regular oscillations'' and its generalized limit is zero, then the divergent regular oscillations c_ia_i are singled out by the transformation (6) and the remaining constant term s approaches with increasing n the generalized sum of the series $\Sigma_{n=0}^{\infty}a_n$.

This transformation yields nothing but Padé approximants $[n,n]$ and $[n-1,n]$ for n even and odd, respectively. This is most easily seen by transforming the system of Equations (6) to the system of equations for computing the Padé approximants, [see, e.g., Eq. (3.10) in Ref. 24].

However, the Padé summation (6) does not work efficiently enough for the series with the coefficients growing like $(-1)^n(2n)!$ (see, e.g., Ref. 2), which is also our case. The transformation (6) for such a series is not able to single out all of the regular oscillations and a more efficient method has to be found.

Let us insert the explicit form of the coefficients a_n, Eq. (5), into the system of the equations for the partial sums (6). Then, this system can be rewritten into the form

$$s_m=C(-1)^{m+1}(2m+1/2)!(B/\pi)^{2m}\left(c_0+c_1\frac{\pi^2}{B^2(2m-\frac{1}{2})(2m-\frac{3}{2})}\right.$$
$$\left.+c_2\frac{\pi^4}{B^4(2m-\frac{1}{2})(2m-\frac{3}{2})(2m-\frac{5}{2})(2m-\frac{7}{2})}+\ldots\right)+s. \tag{7}$$

For large m, the partial sums s_m behave as

$$s_m = C(-1)^{m+1}\left(2m+\frac{1}{2}\right)!\left(\frac{B}{\pi}\right)^{2m}\left(d_0+\frac{d_1}{m+1}+\frac{d_2}{(m+1)^2}+\ldots\right)+s, \tag{8}$$

where the coefficients d_i can be obtained from the coefficients c_i by expanding Eq. (7) into the asymptotic series in the powers of $1/(m+1)$. If we fitted the partial sums s_m to the infinite number of the coefficients c_i or d_i, there would be no difference between the sequences (7) and (8). However, if we fit the partial sums s_m to a *finite* number of the coefficients c_i or d_i, the sequence transformation (8) accounts better for the large-order behavior of the partial sums s_m than the transformation (7).

On the basis of these considerations we suggest a new generalized sequence transformation

$$s_m = a_m\left(d_0+\frac{d_1}{(m+q_1)}+\frac{d_2}{(m+q_1)(m+q_2)}+\ldots+\frac{d_{l-2}}{(m+q_1)(m+q_2)\ldots(m+q_{l-2})}\right)+s, \qquad m=n,\ldots,n+l-1, \tag{9}$$

where q_i, $i=1,2,\ldots,l-2$, are arbitrary coefficients that have to be determined from some additional requirement and n denotes the index of the first partial sum taken into account. In principle, it can be arbitrary; however, for fast convergence of the method it is convenient to take it close, but not necessarily equal, to zero (see below).

Equations (9) represent a system of l equations for l unknowns $d_0, d_1, \ldots, d_{l-2}$ and s. It is remarkable that, regardless of the particular form of the coefficients q_i, the system of equations (9) can be solved in the closed form, namely

$$s = s_n + \frac{\Sigma_{j=0}^{l-1}(-1)^j[(l-1)!/(l-1-j)!j!]\,\Pi_{i=1}^{l-2}(j+n+q_i)(s_{j+n}-s_n)/a_{j+n}}{\Sigma_{j=0}^{l-1}(-1)^j[(l-1)!/(l-1-j)!j!]\,\Pi_{i=1}^{l-2}(j+n+q_i)1/a_{j+n}}. \tag{10}$$

This can be interpreted that the sum of the series is the nth partial sum plus a correction involving partial sums of higher order. This result, which is the main result of this article, was derived by generalizing the procedure for derivation of the Levin[23] and Weniger[24] transformations. In special cases $q_i=1$ and $q_i=i$, the Levin and Weniger transformations are obtained, respectively.

III. RENORMALIZATION

In this section, the renormalization of the energy and the coupling constant is discussed.

Proceeding similarly as in Ref. 26, we make the scaling transformation $x\to(1-\kappa)x$, $y\to(1-\kappa)y$ and $z\to(1-\kappa)z$. Equation (1) then becomes

$$(1-\kappa)^{-2}\left[-\frac{\nabla^2}{2}-\frac{1-\kappa}{r}+\frac{B^2}{8}(1-\kappa)^4(x^2+y^2)\right]\psi = E\psi. \tag{11}$$

Introducing the renormalized coupling constant κ related to the coupling constant B via the equation

$$\frac{B^2}{8}=\frac{\kappa}{4(1-\kappa)^4} \tag{12}$$

and the renormalized energy E_R

$$E_R(\kappa)=(1-\kappa)^2E(B) \tag{13}$$

we get from Eq. (11)

TABLE I. The energies E obtained by the summation of the ordinary series for the hydrogen atom in the magnetic field. The sequence transformation (10) for Weniger ($q_i=i$) and quadratic ($q_i=i^2$) choices of the coefficients q_i and the Padé approximants are compared. Only the numbers stabilized for l from 70 to 79 in Eq. (10) are displayed. The constant n in Eq. (10) was set to zero. "-" means that no stabilization was achieved.

B	Weniger	Quadratic	Padé [39,40]	Padé [39,39]
0.6	−0.4274622877	−0.427462287	−0.4274619	−0.4274626
1.0	−0.33116	−0.331168	−0.33105	−0.33128
2.0	-	−0.0221	−0.00648	−0.03868

$$\left[-\frac{\nabla^2}{2}-\frac{1}{r}+\kappa\left(\frac{x^2+y^2}{4}+\frac{1}{r}\right)\right]\psi=E_R\psi. \tag{14}$$

The advantages of the renormalization approach were discussed in detail in Refs. 24, 26, and 29–32 and can be summarized as follows. First, the originally unbounded interval of the magnetic fields $B\in(0,\infty)$ is shrunk to the interval $\kappa\in(0,1)$. Second, in contrast to the ordinary energy E, the renormalized energy E_R remains finite at the point $\kappa=1$ corresponding to $B\to\infty$. The constant 4 in the denominator of Eq. (12) is the result of the optimization procedure suggested in Ref. 26.

The renormalized energy $E_R(\kappa)$ can be expanded into the power series in the coupling constant κ,

$$E_R=-\frac{1}{2}+\sum_{n=1}^{\infty} b_n\kappa^n. \tag{15}$$

Proceeding analogously to Refs. 32 and 33 we find that the coefficients b_n behave for large n as

$$\lim_{n\to\infty}\frac{b_n}{E_n}=\frac{1}{4^n}. \tag{16}$$

Therefore, the rate of the divergence of the coefficients b_n, although somewhat milder, is essentially the same as that of the coefficients E_n.

IV. RESULTS AND DISCUSSION

In this section, we discuss the application of the sequence transformation (10) to the series (2) and (15).

The perturbation coefficients E_n and b_n can be calculated either by using the so(4,2) algebraic formulation of the perturbation theory[2,10] or the Bender–Wu difference equation method described in Appendix D of Ref. 2. We calculated 80 coefficients E_n and b_n in the rational form using MAPLE. The coefficients a_j in Eq. (10) were set to $a_j=E_{j+1}B^{j+1}$ or $a_j=b_{j+1}\kappa^{j+1}$ for $j=0,1,2...$ and the partial sums s_j were calculated via Eq. (4). The zeroth-order coefficient $-\frac{1}{2}$ was added to the sum s at the very end of calculations in both the ordinary and renormalized cases.

The results obtained with the sequence transformation (10) for different choices of the coefficients q_i are compared to those obtained via the Padé approximants in Tables I and II. We found, in agreement with the earlier observation made in the case of the sextic anharmonic oscillator,[24] that except for the fields smaller than $B\approx0.2$ the Levin transformation ($q_i=1$) fails to sum the series (2). The same is true also in the renormalized case. To find the reason for this failure we replaced the actual values of the E_n coefficients by the values given by the large-order formula (3). In this case the Levin choice of the coefficients q_i yields the best results. Therefore, we believe that the reason for failure of the Levin transformation to sum the series (2) is that the large-order formula (3), and consequently also the large-order formula (8), is only asymptotic, i.e., holds only for a sufficiently large m. To remain valid for small values of m, the series (8) has to be truncated after few terms. The smaller m, the sooner the series (8) has to be truncated. Therefore, it is

TABLE II. The energies E obtained by the summation of the renormalized series for the hydrogen atom in the magnetic field. The sequence transformation (10) for different choices of the coefficients q_i and n is compared with the Padé approximants and the results obtained in Ref. 12 with completely different nonperturbative method. The displayed numbers are stabilized for l from 70 to 79 and for l from 65 to 74 for $n=0$ and $n=5$ respectively.

important for efficiency of the sequence transformation (9) that the contribution of the individual terms $d_i/[(m+q_1)(m+q_2)\cdots(m+q_i)]$ in Eq. (9) decreases for small m with increasing i. This is better accomplished by the Weniger choice $q_i=i$ than by the Levin choice $q_i=1$. The decrease has to be moderate; if the growth of the coefficients q_i is too large (e.g., quadratic), the contribution of the terms $d_i/[(m+q_1)(m+q_2)\cdots(m+q_i)]$ in Eq. (9) is suppressed with increasing i not only for small m, but also for large m. Then we fit the partial sums s_m only to few constants d_i and the transformation (9) becomes inefficient again. This is well illustrated in Tables I and II. We see that if the coupling constant B or κ is sufficiently small, i.e., either the external magnetic field is small or the renormalization is made, the Weniger choice $q_i=i$ provides the best results. However, if the coupling constant is too large, the Weniger transformation becomes also unstable and the best result yields the quadratic choice $q_i=i^2$.

Further, we note that the efficiency of the Weniger sequence transformation with respect to the Padé approximants decreases with the increasing value of the coupling constant. Indeed, in the case of the ordinary series the Weniger transformation for the field $B=0.2$ gives the result $-0.490\,381\,565\,034\,762\,584\,774\,394\,74$ which is by ten orders more accurate than the result produced by the Padé approximants. However, for $B=1.0$, the Weniger transformation is only by two orders better than the Padé approximants (see Table I).

The results displayed in Table II show that the results of the summation depend slightly on the choice of n in Eq. (10). Particulary, it is seen that better results for the series (15) are achieved for $n=5$ than for $n=0$. The reason for it is the following. Due to the term $1/r$ in the interaction part of Eq. (14), the first few b_n coefficients in Eq. (15), and consequently also the first few partial sums s_n, behave irregularly (for detailed discussion see Ref. 32). Therefore, it is better to start with n around 5 when these irregularities do not play significant role.

As it is seen from Table II, the results obtained by the sequence transformation (10) agree with the results given in Ref. 12 obtained by a completely different nonperturbative method based on the rigorous Kato inequalities for the operators in the Hilbert space. The only disagreement is for the field $B=0.6$. Since otherwise our results agree with these results, the result given in Ref. 12 for $B=0.6$ contains probably a typographical error.

We also compared our method with the Borel summation and order dependent mapping (ODM) performed in Ref. 7. For this purpose we considered only the first 62 perturbation coefficients as in Ref. 7. The comparison shows that the Weniger method yields results of similar accuracy as the Borel summation up to the field strength $B=20.0$. It is of the same accuracy as ODM up to the field strength $B=1.0$. For larger fields, it yields worse results than ODM. However, it is due to the fact that we did not incorporate into our method behavior of the energy for very large magnetic fields.[5] Moreover, the method given in this paper is both conceptually and technically simpler than those given in Ref. 7.

It is worth remarking the question whether the series (2) does uniquely define the energy $E=E(B^2)$. If the series (2) is the Stieltjes series, then it does (see, e.g., Refs. 21 and 22). In such a case, $[n-1,n]$ and $[n,n]$ Padé approximants provide monotonically decreasing upper bounds and monotonically increasing lower bounds to the exact eigenvalue. Moreover, if the coefficients of

the series do not grow more rapidly than $(-1)^n(2n)!$ (which is also our case), then the sequences $[n-1,n]$ and $[n,n]$ converge to the same value. We do not know the rigorous proof that the series (2) is a Stieltjes one. However, the numerical results indicate strongly that this is really the case. Particularly, if the zeroth term of the series is excluded, then $[n,n]$ and $[n-1,n]$ Padé approximants provide lower and upper bounds to the energy $E(B^2)$ (see Table I and Ref. 2). The renormalized series (15) is not the Stieltjes series. However, it was shown in Ref. 32 on an analogous problem of the one-dimensional anharmonic oscillator that the series (15) consists of a divergent Stieltjes part and a rapidly convergent part (the rate of the convergence is geometric).

Summarizing, we found in this article the large-order behavior of the partial sums of the strongly divergent perturbation series. On the basis of this behavior a new general sequence transformation containing free parameters that can be subject of further optimalization was suggested. This sequence transformation was applied to the problem of the hydrogen atom in the constant magnetic field. Numerical analysis shows that for small values of the coupling constant, the best choice of the parameters leads to the previously suggested Weniger transformation. Such small values of the coupling constant can be achieved even for large fields, by utilizing the idea of the renormalization. Although most of our discussion was restricted to the summation of the series for the ground state energy of the hydrogen atom in magnetic field, we believe that suggestions made in this article are of much broader importance. Particulary, they show that even violently diverging series behaving as $(-1)^n(2n)!$ can be summed to accurate and realiable results.

In this article after defining the abstract concept of compatibility-like functions on quantum states, we prove that every bijective transformation on the set of all states which preserves such a function is implemented by an either unitary or antiunitary operator. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1545164]

In the last couple of years several communications have appeared in connection with the following problem raised by R. Peierls:[8] when different density matrices can characterize the knowledge available to different people about one and the same physical system. The first answer given by Peierls in Refs. 8 and 9 was that the density matrices under consideration must commute and their product must be nonzero. However, C. Fuchs[4] (also see Ref. 5) gave an example which made Peierls' first condition questionable. After that several attempts have been made to find the proper solution of the problem (e.g., Refs. 1 and 5). All those attempts operate with the concept of compatibility of density matrices. According to them, we say that a collection of density matrices is compatible if the supports of the matrices under consideration (i.e., the orthogonal complements of their null spaces) have nontrivial intersection. So, it is just an easy task to determine whether a pair of density matrices is compatible or not. Having this in mind, it is now a natural problem to give sense to the following question: if a pair of density matrices is compatible, then ''how much'' compatible they are. In other words, we arrive at the problem of measuring the compatibility. One possibility to define such a measure was described in Ref. 10. Namely, in some analogy with the fidelity, C. Poulin and R. Blume-Kohout defined a compatibility function (Ref. 10, Definition 1) which fulfills certain natural physical requirements and they proved some important properties.

In our recent paper[7] we have determined the structure of the bijective transformations on the set of all density operators which preserve the fidelity. This result is in close relation with Wigner's theorem on symmetry transformations. In fact, it can be considered as a Wigner-type result for the set of all mixed states (recall that Wigner's original result concerns the pure states). In Ref. 7 we proved that the transformations in question are all implemented by unitary or antiunitary operators on the underlying Hilbert space. In view of this result and the analogy between the fidelity and the measure of compatibility defined by Poulin and Blume-Kohout, it is a natural problem to determine the structure of the bijective transformations of the set of all density matrices which preserve the compatibility function. We shall see below that the solution of this problem is the same as the one concerning fidelity. This is the content of the present article.

Let us begin with the notation. Let H be a (complex, not necessarily finite dimensional) Hilbert space. If not stated otherwise, all operators on H are meant to be bounded and linear. The expression rng A denotes the range of the operator A. If A is positive, $A^{1/2}$ stands for its unique positive square root.

Denote by $S(H)$ the set of all states (or, in another terminology, density operators) on H, i.e., the positive trace-class operators on H with trace 1. The set $S(H)$ is a convex subset of the space

a)Electronic mail: molnarl@math.klte.hu
b)Electronic mail: timmerma@math.tu-dresden.de

of all self-adjoint operators on H and its extreme points (which are exactly the rank-one projections) are called pure states.

Now, instead of using the concept due to Poulin and Blume-Kohout, we define the abstract concept of compatibility-like functions which extends Ref. 10, Definition 1, to obtain a result of higher generality.

Definition 1: Let $C: S(H)\times S(H)\to[0,1]$ be a function such that for any pair $A,\ B\in S(H)$ of states we have

(i) $C(A,B)=0$ if and only if $\mathrm{rng}\ A^{1/2}\cap \mathrm{rng}\ B^{1/2}=\{0\}$,

(ii) $C(A,B)=C(B,A)$, and

(iii) if P is a pure state, then

$$C(A,P)^2=\sup\{\lambda\in[0,1]:\lambda P\leqslant A\}.$$

We say that C is a compatibility-like function on the set of all states on the Hilbert space H.

Several remarks should be made concerning the above definition. First, we emphasize that our definition is formulated for both finite and infinite dimensional Hilbert spaces (in Ref. 10, Definition 1, only finite dimensional spaces were considered). Concerning the correctness of the definition we note the following. The quantity on the right hand side of the equality in (iii) also appears in relation with effects. A self-adjoint operator T on H with the property $0\leqslant T\leqslant I$ (I is the identity operator) is called an effect. The effects are well-known to play important roles in the quantum theory of measurement (e.g., Ref. 3). Now, it is clear that every state on H as a linear operator can also be viewed as an effect. If T is an effect, φ is a unit vector in H, and P_φ denotes the rank-one projection onto the subspace generated by φ, then the quantity

$$\lambda(T,P_\varphi)=\sup\{\lambda\in[0,1]:\lambda P_\varphi\leqslant T\}$$

is called the strength of T along the ray represented by φ. This concept was introduced by Busch and Gudder in Ref. 2. It was proved in Ref. 2, Theorem 3, that $\lambda(T,P_\varphi)=0$ if and only if $\varphi\notin \mathrm{rng}\ T^{1/2}$, which is equivalent to $\mathrm{rng}\ T^{1/2}\cap \mathrm{rng}\ P_\varphi^{1/2}=\{0\}$. This means that there is no contradiction between the conditions (i) and (iii).

Observe that if H is finite dimensional, then the ranges of a positive operator and its square root are the same and they are automatically closed. Therefore, in the finite dimensional case we have

$$\mathrm{rng}\ A^{1/2}=\mathrm{rng}\ A=\overline{\mathrm{rng}\ A}=(\ker A)^\perp,$$

and hence (i) says that $C(A,B)>0$ if and only if $A,\ B$ are compatible in the sense mentioned in the Introduction. The meaning of (ii) is clear. Now, what about (iii)? One might think that this condition is quite restrictive and probably has no physical meaning for states. But it can be shown that the compatibility function defined by Poulin and Blume-Kohout satisfies (iii) (see either Ref. 10, Definition 1 itself or Ref. 10, Theorem 3) as well as (i) and (ii). So, to sum up, our definition is a generalization of the one given by Poulin and Blume-Kohout and hence it certainly has sense at least from the mathematical point of view.

The reason why we assume (iii) is that there is a nice formula to compute $C(A,P)$. Namely, by Ref. 2, Theorem 4, for every unit vector $\varphi\in H$ we have

$$C(A,P_\varphi)^2=\lambda(A,P_\varphi)=\begin{cases}\|A^{-1/2}\varphi\|^{-2}, & \text{if } \varphi\in\mathrm{rng}(A^{1/2});\\ 0, & \text{otherwise.}\end{cases}\tag{1}$$

(Here $A^{-1/2}$ denotes the inverse of $A^{1/2}$ on $\mathrm{rng}\ A^{1/2}$.) The proof of our result is based on this correspondence.

We further note that it would be another natural assumption to suppose that C is invariant under unitary-antiunitary transformations. But, as we do not need it in our proof, we do not assume it.

To conclude our remarks, we show a natural example for a compatibility-like function which might also justify our definition. So, for any pair $A, B \in S(H)$ define

$$C(A,B) = \sup\Bigg\{ \sum_n \sqrt{\lambda_n \mu_n} : \lambda_n, \mu_n \in [0,1], \sum_n \lambda_n = \sum_n \mu_n = 1 \text{ and}$$

$$\exists \text{ pure states } Q_n \text{ with } \sum_n \lambda_n Q_n = A, \sum_n \mu_n B_n = B \Bigg\}.$$

It is easy to verify that this function has the properties (i)–(iii). In fact, in accordance with the discussions in Refs. 1 and 5, we believe that this compatibility-like function represents the most natural way of defining a measure of compatibility between quantum states.

Now, our result reads as follows.

Theorem 2: *Let H be a Hilbert space and let C be a compatibility-like function on $S(H)$. Let $\phi: S(H) \to S(H)$ be a bijective function which preserves C, that is, assume that*

$$C(\phi(A), \phi(B)) = C(A,B) \quad (A,B \in S(H)).$$

Then there exists an either unitary or antiunitary operator U on H such that ϕ is of the form

$$\phi(A) = UAU^* \quad (A \in S(H)).$$

Proof: Clearly, we can assume that $\dim H \geqslant 2$. For temporary use, we say that the states D, A are compatible (resp. incompatible) if $C(D,A) > 0$ [resp. $C(D,A) = 0$]. It is useful to introduce the following notation. If $\mathcal{M}$ is a subset of $S(H)$, then denote

$$\mathcal{M}^{ic} = \{D \in S(H) : C(D,A) = 0 \text{ for all } A \in \mathcal{M}\}.$$

By condition (i) in Definition 1, $C(D,A) = 0$ means that the subspaces rng $D^{1/2}$, rng $A^{1/2}$ of H have trivial intersection. It can be easily verified that the operator $A \in S(H)$ has rank one (which means that A is a pure state) if and only if

$$(\{A\}^{ic})^{ic} = \{A\}.$$

Since ϕ preserves the compatibility in both directions, it follows from this characterization that ϕ preserves the pure states in both directions. This means that $A \in S(H)$ is a pure state if and only if so is $\phi(A)$.

Next we assert that ϕ maps independent pure states to independent ones. Here, a set of n pure states (rank-one projections) is called independent if their ranges generate an n-dimensional subspace of H. To prove the assertion we use induction. The statement is obvious if the set has only one element. Let $\{P_1, \ldots, P_n, P_{n+1}\}$ be a set of $n+1$ pure states such that the subset $\{P_1, \ldots, P_n\}$ is independent. It is easy to see that $\{P_1, \ldots, P_n, P_{n+1}\}$ is dependent if and only if for any $A \in S(H)$ with $C(A,P_1) > 0, \ldots, C(A,P_n) > 0$ we have that $C(A,P_{n+1}) > 0$ holds too. Indeed, this follows from the fact that for any pure state P we have $C(A,P) > 0$ if and only if the range of P is included in the range of $A^{1/2}$ (see the remarks after Definition 1). Using the above description of dependence, it is now clear that assuming ϕ maps independent sets of n pure states to sets of the same kind, we have the same property of ϕ for $n+1$ in the place of n. Since ϕ^{-1} has the same properties as ϕ, we deduce that ϕ preserves the independence of the sets of pure states in both directions.

It is easy to see that an operator $A \in S(H)$ has rank n if and only if there exists an independent set of n pure states such that $C(A,P) > 0$ for every element of that set, but there does not exist a set of $n+1$ elements having the same property. This gives us that ϕ preserves the rank.

Now we prove that ϕ preserves the transition probability between pure states. Recall that for any pair P, Q of pure states, the transition probability between them is $\mathrm{tr}PQ$, where tr is the usual trace-functional. To verify the mentioned preserver property of ϕ, first let P, Q be rank-one projections with orthogonal ranges. Define

$$A=\lambda P+\mu Q,$$

where λ, μ are fixed and satisfy $0<\lambda<\mu<1, \lambda+\mu=1$. Clearly, A acts on the two-dimensional subspace H_A of H generated by the ranges of P, Q. [Here, the phrase that A acts on H_A means that $(\ker A)^{\perp}=\mathrm{rng}\,\overline{A}=\mathrm{rng}\,A=H_A$.] We assert that $\phi(A)$ acts on the subspace generated by the ranges of the independent pure states $\phi(P)$, $\phi(Q)$. Indeed, $\phi(A)$ has rank 2 and taking into account that

$$C(\phi(A),\phi(P))=C(A,P)>0, \quad C(\phi(A),\phi(Q))=C(A,Q)>0,$$

we see that the ranges of $\phi(P)$, $\phi(Q)$ are included in $\mathrm{rng}\,\phi(A)^{1/2}=\mathrm{rng}\,\phi(A)$. This clearly implies our assertion. In what follows we restrict the considerations onto those two-dimensional subspaces, that is, to the ranges of A and $\phi(A)$, respectively. By property (iii) in the definition of compatibility-like functions, we see that

$$\lambda\leqslant C(A,R)^2\leqslant\mu$$

holds for every rank one projection R on the range of A. As ϕ preserves C, we have

$$\lambda\leqslant C(\phi(A),\phi(R))^2\leqslant\mu$$

for every rank-one projection $\phi(R)$ on the range of $\phi(A)$. Moreover, we have

$$C(\phi(A),\phi(P))^2=C(A,P)^2=\lambda, \quad C(\phi(A),\phi(Q))^2=C(A,Q)^2=\mu.$$

Now we refer to a result in Ref. 6. Namely, Lemma 3 given there states that if T is an effect and $0<\epsilon<\delta\leqslant 1$ are scalars such that $\epsilon I\leqslant T\leqslant\delta I$ and we have unit vectors φ, $\psi\in H$ such that $\lambda(T,P_{\varphi})=\epsilon$ and $\lambda(T,P_{\psi})=\delta$, then φ, ψ are eigenvectors of T and the corresponding eigenvalues are ϵ, δ, respectively. Using this result and the correspondence between compatibility-like functions and the strength, we obtain that the range of $\phi(P)$ is the eigensubspace of $\phi(A)$ corresponding to the eigenvalue λ and the range of $\phi(Q)$ is the eigensubspace of $\phi(A)$ corresponding to the eigenvalue μ. Therefore, we have

$$\phi(A)=\lambda\phi(P)+\mu\phi(Q). \tag{2}$$

Now let P, R be arbitrary rank-one projections. Pick a rank-one projection Q which is orthogonal to P such that the subspace generated by the ranges of P and Q includes the range of R. Let λ, μ and A be as above. It is easy to check that by the formula (1) we have

$$C^2(A,R)=\frac{1}{(1/\lambda)\mathrm{tr}PR+(1/\mu)\mathrm{tr}QR}=\frac{\lambda\mu}{\mu\mathrm{tr}PR+\lambda\mathrm{tr}QR}=\frac{\lambda\mu}{\mu\mathrm{tr}PR+\lambda(1-\mathrm{tr}PR)}$$
$$=\frac{\lambda\mu}{(\mu-\lambda)\mathrm{tr}PR+\lambda}. \tag{3}$$

As the spectral resolution of $\phi(A)$ is (2), we similarly have

$$C^2(\phi(A),\phi(R))=\frac{\lambda\mu}{(\mu-\lambda)\mathrm{tr}\phi(P)\phi(R)+\lambda}. \tag{4}$$

Since ϕ preserves C, it follows from (3) and (4) that

$$\mathrm{tr}\phi(P)\phi(R)=\mathrm{tr}PR,$$

which means that ϕ preserves the transition probability between pure states. It follows from Wigner's theorem that ϕ, when restricted onto the set of all pure states, is of the form

$$\phi(P)=UPU^*$$

for some unitary or antiunitary operator U on H.

It remains to show that the above formula holds for every state as well. The proof goes as follows. Let $A\in S(H)$. For every rank-one projection P we compute

$$\lambda(UAU^*,P)=\lambda(A,U^*PU)=C(A,U^*PU)^2=C(\phi(A),\phi(U^*PU))^2=C(\phi(A),P)^2$$
$$=\lambda(\phi(A),P).$$

Now we refer to Ref. 2, Corollary 1, which states that if the strengths of two effects are the same along every ray, then the effects in question are equal. This gives us that

$$\phi(A)=UAU^* \quad (A\in S(H))$$

and the proof is complete. □

Pseudo-Hermiticity and generalized *PT*- and *CPT*-symmetries

Ali Mostafazadeh[a)]
Department of Mathematics, Koç University, Rumelifeneri Yolu, 34450 Sariyer, Istanbul, Turkey

(Received 13 September 2002; accepted 15 November 2002)

We study certain linear and antilinear symmetry generators and involution operators associated with pseudo-Hermitian Hamiltonians and show that the theory of pseudo-Hermitian operators provides a simple explanation for the recent results of Bender, Brody and Jones (quant-ph/0208076) on the CPT-symmetry of a class of PT-symmetric non-Hermitian Hamiltonians. We present a natural extension of these results to the class of diagonalizable pseudo-Hermitian Hamiltonians H with a discrete spectrum. In particular, we introduce generalized parity ($\mathcal{P}$), time-reversal ($\mathcal{T}$), and charge-conjugation ($\mathcal{C}$) operators and establish the $\mathcal{PT}$- and $\mathcal{CPT}$-invariance of H. © *2003 American Institute of Physics.*

I. INTRODUCTION

Bender, Brody and Jones[1] have recently shown that for the class of PT-symmetric Hamiltonians

$$H_\nu = p^2 + x^2(ix)^\nu, \quad \nu \in [0,\infty), \tag{1}$$

one can use a complete set of eigenfunctions ψ_n to construct a linear operator C with the following properties.

(1) C is an involution generating a symmetry of the system, i.e.,

$$C^2 = 1, \quad [C,H_\nu] = 0. \tag{2}$$

In particular, H_ν is CPT-invariant.

(2) In the position representation, C has the form

$$C(x,y) = \sum_n \psi_n(x)\psi_n(y), \quad \forall x,y \in \mathbb{R}. \tag{3}$$

(3) The inner product

$$\langle \phi|\psi\rangle_{CPT} := \int_\gamma dx\,[CPT\phi(x)]\psi(x) \tag{4}$$

is positive-definite, and the eigenfunctions ψ_n are orthonormal with respect to this inner product, i.e.,

$$\langle \psi_m|\psi_n\rangle_{CPT} = \delta_{mn}. \tag{5}$$

(4) For $\nu = 0$, where the Hamiltonian H_0 is Hermitian, $C = P$.

a)Electronic mail: amostafazadeh@ku.edu.tr

In Eq. (4), γ is the contour in the complex plane used to impose the vanishing boundary conditions for the eigenvalue problem of (1).[2] For $\nu\in[0,2)$, γ may be taken as the real line $\mathbb{R}$.

The purpose of this article is twofold. First, we show that the results of Ref. 1, in particular the items 1–4 of the above list, may be explained as a straightforward application of the theory of pseudo-Hermitian operators.[3–7] Second, we outline an extension of these results to the class of quasi-Hermitian Hamiltonians, i.e., diagonalizable Hamiltonians with a real spectrum, and more generally diagonalizable pseudo-Hermitian Hamiltonians. (By definition, a quasi-Hermitian operator is an operator obtained from a Hermitian operator by a similarity transformation.[8] Therefore it is diagonalizable and has a real spectrum. The converse of this statement is also true; as shown in Ref. 4, a diagonalizable operator with a real discrete spectrum is related to a Hermitian operator through a similarity transformation.) In order to achieve this purpose, we explore certain symmetry properties and involution operators associated with pseudo-Hermitian Hamiltonians.

The organization of the article is as follows. In Sec. II, we offer a discussion of pseudo-Hermitian operators and their symmetries. In Sec. III, we consider the problem of the existence and characterization of certain involution operators associated with a pseudo-Hermitian Hamiltonian. In Sec. IV, we explain the mathematical structure underlying the results of Ref. 1 for the Hamiltonians (1) with $\nu\in[0,2)$ and $\gamma=\mathbb{R}$. In Sec. V, we introduce generalized parity ($\mathcal{P}$), time-reversal ($\mathcal{T}$), and charge-conjugation ($\mathcal{C}$) operators for an arbitrary quasi-Hermitian Hamiltonian H with a discrete spectrum and establish the $\mathcal{PT}$- and $\mathcal{CPT}$-invariance of H. In Sec. VI, we extend the results of Sec. V to the more general class of diagonalizable pseudo-Hermitian operators with a discrete spectrum. Finally, in Sec. VII, we conclude the article with a summary of our main results.

II. PSEUDO-HERMITIAN OPERATORS AND THEIR SYMMETRIES

A linear operator H acting in a Hilbert space $\mathcal{H}$ is said to be pseudo-Hermitian[3] if there is a linear, invertible, Hermitian operator $\eta:\mathcal{H}\to\mathcal{H}$ such that

$$H^\dagger=\eta H\eta^{-1}. \tag{6}$$

For a given pseudo-Hermitian operator H, η is not unique.[6,9] If one fixes a particular η, one says that H is η-pseudo-Hermitian. In this case, H is Hermitian with respect to the pseudo-inner product

$$\langle\langle\phi|\psi\rangle\rangle_\eta:=\langle\phi|\eta\psi\rangle, \tag{7}$$

where $\langle\,|\,\rangle$ is the inner product of $\mathcal{H}$. [We use the term pseudo-inner product for a possibly (but not necessarily) indefinite inner product.]

For diagonalizable Hamiltonians with a discrete spectrum pseudo-Hermiticity is equivalent to the condition that the complex eigenvalues come in complex-conjugate pairs.[3] Here the discreteness of the spectrum is not essential, and as shown in Ref. 7 the diagonalizability condition may be replaced by a weaker block-diagonalizability condition. Furthermore, for the class of diagonalizable Hamiltonians with a discrete spectrum, pseudo-Hermiticity is also equivalent to the condition that the Hamiltonian admits an antilinear symmetry.[5]

Pseudo-Hermiticity also provides a characterization of the reality of the spectrum for diagonalizable Hamiltonians with a discrete spectrum. Specifically it may be used to establish the equivalence of the following statements.[4]

(1) The spectrum is real.
(2) The Hamiltonian is quasi-Hermitian.
(3) Among the operators η satisfying (6) there is a positive operator η_+, i.e., the Hamiltonian is η_+-pseudo-Hermitian for a positive operator η_+.
(4) The Hamiltonian is Hermitian with respect to a positive-definite inner product, namely $\langle\langle\,|\,\rangle\rangle_{\eta_+}$.[5,6]

One can actually construct η_+. Given a quasi-Hermitian Hamiltonian H and an associated complete biorthonormal system $\{|\psi_n,a\rangle,|\phi_n,a\rangle\}$, which by definition satisfies $H|\psi_n,a\rangle=E_n|\psi_n,a\rangle$, $H^\dagger|\phi_n,a\rangle=E_n^*|\phi_n,a\rangle$, and

$$\langle\phi_n,a|\psi_m,b\rangle=\delta_{nm}\delta_{ab}, \tag{8}$$

$$\sum_n\sum_{a=1}^{d_n}|\psi_n,a\rangle\langle\phi_n,a|=1, \tag{9}$$

$$H=\sum_n\sum_{a=1}^{d_n}E_n|\psi_n,a\rangle\langle\phi_n,a|, \tag{10}$$

one can express η_+ according to

$$\eta_+=\sum_n\sum_{a=1}^{d_n}|\phi_n,a\rangle\langle\phi_n,a|. \tag{11}$$

In Eqs. (8)–(11) and throughout this article n and m are spectral labels taking non-negative integer values, d_n stands for the multiplicity or degree of degeneracy of E_n, and a and b are degeneracy labels.

It turns out that η_+ is unique up to the choice of the biorthonormal system $\{|\psi_n,a\rangle,|\phi_n,a\rangle\}$.[6] However, besides η_+, there are nonpositive invertible Hermitian operators η that are also associated with the same biorthonormal system and satisfy (6). These are determined by a sequence $\sigma:=\{\sigma_n^a\}$ of signs $\sigma_n^a=\pm$ and have the general form

$$\eta_\sigma:=\sum_n\sum_{a=1}^{d_n}\sigma_n^a|\phi_n,a\rangle\langle\phi_n,a|. \tag{12}$$

Obviously, the choice of the biorthonormal system is arbitrary. This means that given a complete biorthonormal system $\{|\psi_n,a\rangle,|\phi_n,a\rangle\}$, we can express the most general η satisfying (6) according to (12) with $|\phi_n,a\rangle$ replaced with possibly different eigenvectors of $H^\dagger$ with the same eigenvalue as $|\phi_n,a\rangle$. Labeling these by $|\tilde\phi_n,a\rangle$ and noting that both $|\phi_n,a\rangle$ and $|\tilde\phi_n,a\rangle$ form bases of $\mathcal{H}$, we have $|\tilde\phi_n,a\rangle=A^\dagger|\phi_n,a\rangle$ for some invertible linear operator $A:\mathcal{H}\to\mathcal{H}$. Clearly, the vectors $|\tilde\phi_n,a\rangle$ and $|\tilde\psi_n,a\rangle:=A^{-1}|\psi_n,a\rangle$ form a complete biorthonormal system. Furthermore, the operator A commutes with the Hamiltonian, and

$$\eta=A^\dagger\eta_\sigma A. \tag{13}$$

This proves the following proposition. Here we include a direct proof for completeness.

Proposition 1: For a given quasi-Hermitian Hamiltonian H with a complete biorthonormal system $\{|\psi_n,a\rangle,|\phi_n,a\rangle\}$, the most general Hermitian invertible linear operator η satisfying (6) is given by (13) where A is an invertible linear operator commuting with the Hamiltonian (a symmetry generator) and $\sigma=\{\sigma_n^a\}$ is a sequence of signs $\sigma_n^a=\pm$.

Proof: Let η be an arbitrary Hermitian invertible linear operator satisfying (6). Then one can easily check that $X:=\eta_+^{-1}\eta$ commutes with H.[3] Therefore, X is an invertible linear operator generating a symmetry of H. This implies that X and H have simultaneous eigenvectors. In particular, X has the form

$$X=\sum_n\sum_{a,b=1}^{d_n}x_{ab}^n|\psi_n,a\rangle\langle\phi_n,b|, \tag{14}$$

where x^n_{ab} are complex coefficients. Expressing η in terms of η_+ and X and using Eqs. (14), (11) and (8), we find

$$\eta=\eta_+X=\sum_n\sum_{a,b=1}^{d_n}x^n_{ab}|\phi_n,a\rangle\langle\phi_n,b|. \tag{15}$$

Taking the adjoint of both sides of this equation and making use of the Hermiticity of η, we have $x^{n*}_{ab}=x^n_{ba}$. Hence the matrices x^n with entries x^n_{ab} are Hermitian; they may be diagonalized:

$$x^n=u^n\ \ x^n_{\rm diag}\ \ u^{n\dagger}, \tag{16}$$

where u^n are $d_n\times d_n$ unitary matrices and $x^n_{\rm diag}$ are $d_n\times d_n$ diagonal real matrices. Next, we introduce

$$\begin{aligned}U&:=\sum_n\sum_{a,b=1}^{d_n}u^n_{ab}|\psi_n,a\rangle\langle\phi_n,b|,\\ D&:=\sum_n\sum_{a=1}^{d_n}\sqrt{|x^n_a|}\ \ |\psi_n,a\rangle\langle\phi_n,a|,\\ A&:=DU=\sum_n\sum_{a,b=1}^{d_n}\sqrt{|x^n_a|}\ \ u^n_{ab}|\psi_n,a\rangle\langle\phi_n,b|,\end{aligned} \tag{17}$$

where u^n_{ab} and x^n_a denote the entries of u^n and the diagonal entries of $x^n_{\rm diag}$, respectively. Note that because u^n are unitary matrices U is invertible. In fact, one can check by direct computation that

$$U^{-1}:=\sum_n\sum_{a,b=1}^{d_n}u^{*n}_{ba}|\psi_n,a\rangle\langle\phi_n,b|$$

satisfies $U^{-1}U=UU^{-1}=1$. Furthermore, because $X=\eta_+^{-1}\eta$, it is invertible, its eigenvalues x^n_a are nonzero, and D is also invertible. This in turn implies that A is invertible. Finally, using Eqs. (15)–(17), (12), (11), (8) and setting $\sigma^a_n:=x^n_a/|x^n_a|$, we can compute

$$A^\dagger\eta_\sigma A=\sum_n\sum_{abc}u^n_{ac}x^n_cu^{n*}_{bc}|\phi_n,a\rangle\langle\phi_n,b|=\eta.$$

□

Another interesting property of quasi-Hermitian Hamiltonians with a discrete spectrum is that they admit an exact antilinear symmetry. This follows from the observation that every diagonalizable pseudo-Hermitian Hamiltonian with a discrete spectrum is anti-pseudo-Hermitian with respect to the antilinear operator[5]

$$\tau_+:=\sum_n\sum_{a=1}^{d_n}|\phi_n,a\rangle\star\langle\phi_n,a|, \tag{18}$$

where $\star$ is the operation of the complex conjugation of numbers. In particular, for all $|\phi\rangle,|\psi\rangle\in\mathcal{H}$,

$$\star\,\langle\phi|\psi\rangle:=\langle\phi|\psi\rangle^*=\langle\psi|\phi\rangle.$$

Anti-pseudo-Hermiticity of H with respect to τ_+ means

$$H^\dagger=\tau_+H\tau_+^{-1}. \tag{19}$$

Again, up to the choice of a complete biorthonormal system, (18) is the unique antilinear, Hermitian, invertible operator satisfying (19). This in turn leads to the following theorem. Again here we include an explicit proof for completeness.

Proposition 2: For a given diagonalizable pseudo-Hermitian Hamiltonian H with a complete biorthonormal system $\{|\psi_n,a\rangle,|\phi_n,a\rangle\}$, the most general antilinear, Hermitian, invertible operator satisfying (19) has the form

$$\tau=A^\dagger\tau_+A, \tag{20}$$

where A is an invertible linear operator commuting with H.

Proof: Let τ be an arbitrary antilinear, Hermitian, invertible operator satisfying (19). Then one can easily check that $X:=\tau_+^{-1}\tau$ commutes with H.[3] Therefore, X is an invertible linear operator generating a symmetry of H and having the form (14). Solving for τ in $X:=\tau_+^{-1}\tau$ and using (18), (14), and (8), we have

$$\tau=\sum_n\sum_{a,b=1}^{d_n}x^{n*}_{ab}|\phi_n,a\rangle\star\langle\phi_n,b|. \tag{21}$$

Now, we recall that τ is a Hermitian antilinear operator. Therefore $\langle\psi_n,a|\tau|\psi_n,b\rangle=\langle\psi_n,b|\tau|\psi_n,a\rangle$. Substituting (21) in this equation we find $x^n_{ab}=x^n_{ba}$, i.e., the matrices x^n formed out of x^n_{ab} are in general complex symmetric matrices. As shown in Ref. 10, the latter admit a factorization of the form

$$x^n=a^{nT}a^n, \tag{22}$$

where a^n are $n\times n$ matrices and the superscript ^{T} denotes the transpose. Next, we introduce

$$A:=\sum_n\sum_{a,b=1}^{d_n}a^n_{ab}|\psi_n,a\rangle\langle\phi_n,b|, \tag{23}$$

where a^n_{ab} are entries of a^n. Clearly, A commutes with H. Moreover, using Eqs. (18), (21)–(23), and (8), we have

$$A^\dagger\tau_+A=\sum_n\sum_{a,b=1}^{d_n}a^{n*}_{ca}a^{n*}_{cb}|\phi_n,a\rangle\star\langle\phi_n,b|=\tau.$$

For a quasi-Hermitian Hamiltonian with a discrete spectrum, we can use Eq. (20) to define antilinear analogs of the operators η_σ, namely

$$\tau_\sigma:=\sum_n\sum_{a=1}^{d_n}\sigma^a_n|\phi_n,a\rangle\star\langle\phi_n,a|, \tag{24}$$

where again $\sigma=\{\sigma^a_n\}$ is a sequence of signs $\sigma^a_n=\pm$. This is simply done by setting $a^n_{ab}=(\sqrt{\sigma^a_n})^*\delta_{ab}$ in (20).

Combining Eqs. (6) and (19), we see that H commutes with

$$\mathcal{X}:=\eta^{-1}\tau, \tag{25}$$

where η and τ are linear and antilinear Hermitian, invertible, operators such that H is η-pseudo-Hermitian and τ-anti-pseudo-Hermitian; they have the general form (13) and (20), respectively. In particular if we set $\eta=\eta_\sigma$ and $\tau=\tau_+$ in (25), we find a set of *canonical antilinear symmetry generators:*

$$\mathcal{X}_\sigma:=\eta_\sigma^{-1}\tau_+=\eta_+^{-1}\tau_\sigma. \tag{26}$$

In view of Eqs. (8) and (24) and the identity[3]

$$\eta_\sigma^{-1}=\sum_n \sum_{a=1}^{d_n} \sigma_n^a|\psi_n,a\rangle\langle\psi_n,a|, \tag{27}$$

we can easily calculate

$$\mathcal{X}_\sigma=\sum_n \sum_{a=1}^{d_n} \sigma_n^a|\psi_n,a\rangle\star\langle\phi_n,a|. \tag{28}$$

It is not difficult to show that in view of (10), (8), and (28),

$$[\mathcal{X}_\sigma,H]=0, \tag{29}$$

$$\mathcal{X}_\sigma|\psi_n,a\rangle=\sigma_n^a|\psi_n,a\rangle. \tag{30}$$

In particular,

$$\mathcal{X}_+ := \eta_+^{-1}\tau_+ = \eta_\sigma^{-1}\tau_\sigma \tag{31}$$

satisfies

$$[\mathcal{X}_+,H]=0, \tag{32}$$

$$\mathcal{X}_+|\psi_n,a\rangle=|\psi_n,a\rangle. \tag{33}$$

Hence the antilinear symmetry generated by $\mathcal{X}_\sigma$ is an exact symmetry. The converse of this statement is also valid. That is, if a diagonalizable Hamiltonian with a discrete spectrum admits an exact symmetry generated by an invertible antilinear operator, then its spectrum is real;[4] it is quasi-Hermitian. A direct consequence of this statement is that if a diagonalizable pseudo-Hermitian Hamiltonian with a discrete spectrum has nonreal eigenvalues, then it cannot support exact antilinear symmetries. Such a Hamiltonian always admits antilinear symmetries,[5] but these symmetries are necessarily broken.

We can repeat the above analysis of quasi-Hermitian Hamiltonians for the more general diagonalizable pseudo-Hermitian Hamiltonians with a discrete spectrum.[3,5] For the latter Hamiltonians nonreal eigenvalues come in complex-conjugate pairs with identical multiplicity, so we identify the spectral label n with ν_0, ν_+, or ν_- depending on whether the imaginary part of E_n is zero, positive, or negative, respectively. In this case, Eqs. (8)–(10), with $n=\nu_0,\nu_\pm$ and $m=\mu_0,\mu_\pm$, are still valid, $d_{\nu_+}=d_{\nu_-}$, and the analog of the positive operator (11) is the operator

$$\eta_+=\sum_{\nu_0} \sum_{a=1}^{d_{\nu_0}} |\phi_{\nu_0},a\rangle\langle\phi_{\nu_0},a|+\sum_\nu \sum_{a=1}^{d_\nu} (|\phi_{\nu_+},a\rangle\langle\phi_{\nu_-},a|+|\phi_{\nu_-},a\rangle\langle\phi_{\nu_+},a|). \tag{34}$$

Here we use ν to denote the common value of $\nu_\pm$.

It is not difficult to see that the proof of Proposition 1 extends to the class of diagonalizable pseudo-Hermitian Hamiltonians with a discrete spectrum; it yields the following generalization of Proposition 1, see also Ref. 5.

Proposition 3: For a given diagonalizable pseudo-Hermitian Hamiltonian H with a complete biorthonormal system $\{|\psi_n,a\rangle,|\phi_n,a\rangle\}$, the most general Hermitian invertible linear operator η satisfying (6) is given by (13) where A is an invertible linear operator commuting with the Hamiltonian,

$$\eta_\sigma := \sum_{\nu_0} \sum_{a=1}^{d_{\nu_0}} \sigma^a_{\nu_0} |\phi_{\nu_0},a\rangle\langle\phi_{\nu_0},a| + \sum_{\nu} \sum_{a=1}^{d_\nu} (|\phi_{\nu_+},a\rangle\langle\phi_{\nu_-},a| + |\phi_{\nu_-},a\rangle\langle\phi_{\nu_+},a|), \tag{35}$$

and $\sigma=\{\sigma^a_{\nu_0}\}$ is a sequence of signs $\sigma^a_{\nu_0}=\pm$.

Similarly, one can show that every diagonalizable pseudo-Hermitian Hamiltonian H with a discrete spectrum admits antilinear symmetries generated by (25). For instance, we have the canonical antilinear symmetry generators (26) where now η_+ is given by (34) and

$$\tau_\sigma := \sum_{\nu_0} \sum_{a=1}^{d_{\nu_0}} \sigma^a_{\nu_0} |\phi_{\nu_0},a\rangle\star\langle\phi_{\nu_0},a| + \sum_{\nu} \sum_{a=1}^{d_\nu} (|\phi_{\nu_+},a\rangle\star\langle\phi_{\nu_+},a| + |\phi_{\nu_-},a\rangle\star\langle\phi_{\nu_-},a|). \tag{36}$$

We can express these symmetry generators according to

$$\mathcal{X}_\sigma = \sum_{\nu_0} \sum_{a=1}^{d_{\nu_0}} \sigma^a_{\nu_0} |\psi_{\nu_0},a\rangle\star\langle\phi_{\nu_0},a| + \sum_{\nu} \sum_{a=1}^{d_\nu} (|\psi_{\nu_+},a\rangle\star\langle\phi_{\nu_-},a| + |\psi_{\nu_-},a\rangle\star\langle\phi_{\nu_+},a|), \tag{37}$$

where we have used Eqs. (26), (34), (36), and (8) and the identity[3]

$$\eta_\sigma^{-1} = \sum_{\nu_0} \sum_{a=1}^{d_{\nu_0}} \sigma^a_{\nu_0} |\psi_{\nu_0},a\rangle\langle\psi_{\nu_0},a| + \sum_{\nu} \sum_{a=1}^{d_\nu} (|\psi_{\nu_+},a\rangle\langle\psi_{\nu_-},a| + |\psi_{\nu_-},a\rangle\langle\psi_{\nu_+},a|). \tag{38}$$

Next, we observe that in light of Eqs. (10), (8), and (37),

$$[\mathcal{X}_\sigma, H] = 0, \tag{39}$$

$$\mathcal{X}_\sigma |\psi_n,a\rangle = \begin{cases} \sigma^a_{\nu_0} |\psi_{\nu_0},\ a\rangle & \text{if } n=\nu_0, \\ |\psi_{\nu_\mp},\ a\rangle & \text{if } n=\nu_\pm. \end{cases} \tag{40}$$

In particular, the operator (31) satisfies

$$[\mathcal{X}_+, H] = 0, \tag{41}$$

$$\mathcal{X}_+ |\psi_n,a\rangle = \begin{cases} |\psi_{\nu_0},\ a\rangle, & \text{if } n=\nu_0, \\ |\psi_{\nu_\mp},\ a\rangle, & \text{if } n=\nu_\pm. \end{cases} \tag{42}$$

Therefore, $\mathcal{X}_\sigma$ generate symmetries of H which are, however, broken.

III. INVOLUTION OPERATORS ASSOCIATED WITH A PSEUDO-HERMITIAN HAMILTONIAN

Among the basic properties of the P, T, and PT operators (within the scalar/bosonic quantum mechanics) is that they are involutions of the Hilbert space, i.e., their square is the identity operator. In this section we study the problem of the existence and characterization of certain involutions of the Hilbert space which are associated with a given pseudo-Hermitian Hamiltonian.

Proposition 4: The operators $S_\sigma := \eta_+^{-1}\eta_\sigma$ and $\mathcal{X}_\sigma := \eta_+^{-1}\tau_\sigma$ are involutions.

Proof: according to Eqs. (11), (12), and (8), we have

$$S_\sigma = \sum_{\nu_0} \sum_{a=1}^{d_{\nu_0}} \sigma^a_{\nu_0} |\psi_{\nu_0},a\rangle\langle\phi_{\nu_0},a| + \sum_{\nu} \sum_{a=1}^{d_\nu} (|\psi_{\nu_+},a\rangle\langle\phi_{\nu_-},a| + |\psi_{\nu_-},a\rangle\langle\phi_{\nu_+},a|). \tag{43}$$

Squaring this expression and using (8), we find $S_\sigma^2=1$. Similarly, we have $\mathcal{X}_\sigma^2=1$. □

Corollary 1: Every diagonalizable pseudo-Hermitian Hamiltonian H with a discrete spectrum admits a symmetry generated by a linear involution S and a symmetry generated by an antilinear involution Σ, i.e., $[H,S]=[H,\Sigma]=0$ and $S^2=\Sigma^2=1$.

Proof: Again we recall that because η_+ and η_σ satisfy (6), the linear operator $S=S_\sigma := \eta_+^{-1}\eta_\sigma$ commutes with the Hamiltonian.[3] Therefore, in view of Proposition 4, S and $\Sigma=\mathcal{X}_\sigma$ are involutions generating symmetries of H. Clearly, S is linear whereas Σ is antilinear. □

Corollary 2: Let H be a diagonalizable Hamiltonian with a discrete spectrum. Then H is pseudo-Hermitian if and only if it admits an antilinear symmetry generated by an involution.

Proof: If H is pseudo-Hermitian, then according to Proposition 4 it admits such a symmetry. Conversely, suppose that H admits such a symmetry. Then because this is an antilinear symmetry, H must be pseudo-Hermitian.[5] □

Proposition 5: A diagonalizable Hamiltonian H with a discrete spectrum is anti-pseudo-Hermitian with respect to a Hermitian antilinear involution if and only if there is a complete biorthonormal system $\{|\psi_n,a\rangle,|\phi_n,a\rangle\}$ satisfying

$$\langle\phi_n,a|\phi_m,b\rangle=\langle\psi_m,b|\psi_n,a\rangle. \tag{44}$$

Proof: Suppose H is anti-pseudo-Hermitian with respect to a Hermitian antilinear involution τ. Then there is a complete biorthonormal system $\{|\psi_n,a\rangle,|\phi_n,a\rangle\}$ for which $\tau=\tau_+$. Now, imposing the condition that $\tau^2=1$ and using Eq. (8), one finds (44). Conversely, one can check that if a complete biorthonormal system $\{|\psi_n,a\rangle,|\phi_n,a\rangle\}$ satisfies this equation, the Hermitian antilinear operator τ_+ given by (18) is an involution. As we mentioned above and shown in Ref. 5, H is anti-pseudo-Hermitian with respect to this operator. □

Corollary 3: A pseudo-Hermitian Hamiltonian H is anti-pseudo-Hermitian with respect to a Hermitian antilinear involution if and only if for every complete biorthonormal system $\{|\psi_n,a\rangle,|\phi_n,a\rangle\}$ there is an invertible linear symmetry generator A satisfying

$$\sum_n\sum_{a=1}^{d_n}\langle\psi_k,c|(AA^\dagger)^{-1}|\psi_n,a\rangle\langle\psi_m,b|(AA^\dagger)^{-1}|\psi_n,a\rangle=\delta_{km}\delta_{bc}. \tag{45}$$

Proof: According to Proposition 5, anti-pseudo-Hermiticity of H with respect to a Hermitian antilinear involution is equivalent to the existence of a complete biorthonormal system $\{|\tilde\psi_n,a\rangle,|\tilde\phi_n,a\rangle\}$ satisfying

$$\langle\tilde\phi_n,a|\tilde\phi_m,b\rangle=\langle\tilde\psi_m,b|\tilde\psi_n,a\rangle. \tag{46}$$

Now, let $\{|\psi_n,a\rangle,|\phi_n,a\rangle\}$ be an arbitrary complete biorthonormal system. Then there is a linear invertible symmetry generator A satisfying $|\tilde\psi_n,a\rangle=A^{-1}|\psi_n,a\rangle$ and $|\tilde\phi_n,a\rangle=A^\dagger|\phi_n,a\rangle$. Substituting these relations in (46), we find

$$\langle\phi_n,a|AA^\dagger|\phi_m,b\rangle=\langle\psi_m,b|(AA^\dagger)^{-1}|\psi_n,a\rangle. \tag{47}$$

Next, we multiply $\langle\psi_k,c|(AA^\dagger)^{-1}|\psi_n,a\rangle$ by both sides of (47) and sum over n and a. This yields (45). Conversely, assuming the existence of an invertible symmetry generator A satisfying (45), one can easily check that the complete biorthonormal system defined by $|\tilde\psi_n,a\rangle := A^{-1}|\psi_n,a\rangle$ and $|\tilde\phi_n,a\rangle := A^\dagger|\psi_n,a\rangle$ satisfies (46). □

Equation (47) is particularly useful as it gives the necessary and sufficient conditions for a given invertible Hermitian antilinear operator τ satisfying (19) to be an involution. For example, in order to find the necessary and sufficient conditions under which τ_σ of Eq. (36) is an involution, we write $\tau_\sigma=A^\dagger\tau_+A$, where

$$A=\sum_{\nu_0}\sum_{a=1}^{d_{\nu_0}}(\sqrt{\sigma^a_{\nu_0}})^*\ |\psi_{\nu_0},a\rangle\langle\phi_{\nu_0},a|+\sum_\nu\sum_{a=1}^{d_\nu}(|\psi_{\nu_+},a\rangle\langle\phi_{\nu_+},a|+|\psi_{\nu_-},a\rangle\langle\phi_{\nu_-},a|),$$

and substitute this equation in (47). This yields the following conditions:

$$\langle \phi_{\nu_0},a|\phi_{\mu_0},b\rangle=\sigma^a_{\nu_0}\sigma^b_{\mu_0}\langle \psi_{\mu_0},b|\psi_{\nu_0},a\rangle, \tag{48}$$

$$\langle \phi_{\nu_0},a|\phi_{\mu_\pm},b\rangle=\sigma^a_{\nu_0}\langle \psi_{\mu_\pm},b|\psi_{\nu_0},a\rangle, \tag{49}$$

$$\langle \phi_{\nu_\pm},a|\phi_{\mu_\pm},b\rangle=\langle \psi_{\mu_\pm},b|\psi_{\nu_\pm},a\rangle. \tag{50}$$

Proposition 6: A diagonalizable Hamiltonian H with a discrete spectrum is pseudo-Hermitian with respect to a Hermitian linear involution η if and only if there is a complete biorthonormal system $\{|\psi_n,a\rangle,|\phi_n,a\rangle\}$, with $n=\nu_0,\nu_\pm$ as above, and a sequence of signs $\sigma=\{\sigma^a_{\nu_0}\}$ such that

$$\langle \phi_{\nu_0},a|\phi_{\mu_0},b\rangle=\sigma^a_{\nu_0}\sigma^b_{\mu_0}\langle \psi_{\nu_0},a|\psi_{\mu_0},b\rangle, \tag{51}$$

$$\langle \phi_{\nu_0},a|\phi_{\mu_\pm},b\rangle=\sigma^a_{\nu_0}\langle \psi_{\nu_0},a|\psi_{\mu_\mp},b\rangle, \tag{52}$$

$$\langle \phi_{\nu_\pm},a|\phi_{\mu_\pm},b\rangle=\langle \psi_{\nu_\mp},a|\psi_{\mu_\mp},b\rangle. \tag{53}$$

Proof: This follows from a similar argument as the one used in the proof of Proposition 5. It is based on the observation that η takes the canonical form (35) in some complete biorthonormal system $\{|\psi_n,a\rangle,|\phi_n,a\rangle\}$ and that in this system the condition $\eta^2=1$ is equivalent to Eqs. (51)–(53). □

Corollary 4: Let H be a diagonalizable pseudo-Hermitian Hamiltonian H with a discrete spectrum and a complete biorthonormal system $\{|\psi_n,a\rangle,|\phi_n,a\rangle\}$. Then the operators τ_σ of (36) and η_σ of (35) are involutions if and only if Eqs. (48)–(50) and (51)–(53) are satisfied. Furthermore, in this case

$$[\tau_\sigma,\eta_\sigma]=0. \tag{54}$$

Proof: The equivalence of Eqs. (48)–(50) and (51)–(53) with the condition that τ_σ and η_σ are involutions follows from Corollary 4 and Proposition 6. Finally, in view of the identities: $\tau_\sigma=\tau_\sigma^{-1}$, $\eta_\sigma=\eta_\sigma^{-1}$,

$$\tau_+^{-1}=\sum_n\sum_{a=1}^{d_n}|\psi_n,a\rangle\star\langle\psi_n,a|, \tag{55}$$

and Eqs. (36), (35), (38), and (8), we have

$$\tau_\sigma\eta_\sigma=\tau_\sigma\eta_\sigma^{-1}=\tau_+\eta_+^{-1}=\eta_+\tau_+^{-1}=\eta_\sigma\tau_\sigma.$$

□

IV. APPLICATION TO HAMILTONIANS (1) WITH $\gamma=\mathbb{R}$

Consider the class of PT-symmetric Hamiltonians H_ν of Eq. (1) with $\nu\in[0,2)$, $\gamma=\mathbb{R}$, and $\mathcal{H}=L^2(\mathbb{R})$. Then, following Ref. 1, we may choose a set of eigenvectors $|\psi_n\rangle$ of H_ν satisfying

$$PT|\psi_n\rangle=|\psi_n\rangle. \tag{56}$$

Because the eigenvalues of H_ν are nondegenerate, we have dropped the degeneracy label $a=1$. (Note that what we denote by $|\phi_n\rangle$ are eigenvectors of $H^\dagger$. This is the notation used in Refs. 3–7 which differs from that of Ref. 1.) Also as usual the PT operator is defined by $PT\psi(x):=[\psi(-x)]^*$ where $|\psi\rangle$ is an arbitrary state vector represented by the wave function $\psi(x)$. Moreover, relying on the numerical evidence[2] that is also used in Ref. 1, we assume the validity of the completeness relation

$$\sum_n (-1)^n \psi_n(x)\psi_n(y) = \delta(x-y), \tag{57}$$

and the orthogonality condition

$$(\psi_m, \psi_n) = (-1)^n \delta_{mn}, \tag{58}$$

where the indefinite inner product $(\ ,\ )$ is defined by

$$(\phi, \psi) := \int_{\mathbb{R}} dx [PT\phi(x)]\psi(x). \tag{59}$$

Introducing the functions

$$\phi_n(x) := (-1)^n \psi_n(x)^*, \tag{60}$$

which also belong to $\mathcal{H}=L^2(\mathbb{R})$, and using Eqs. (58) and (59) we can show that

$$\langle \phi_m | \psi_n \rangle := \int_{\mathbb{R}} dx \phi_m(x)^* \psi_n(x) = (-1)^m (\psi_m, \psi_n) = \delta_{mn}.$$

This coincides with the biorthonormality relation (8). Furthermore, we write Eq. (57) in the form

$$\delta(x-y) = \sum_n \phi_n(x)\psi_n(y)^* = \sum_n \langle x|\phi_n\rangle\langle \psi_n|y\rangle,$$

which is equivalent to the completeness relation (9). Therefore, $\{|\psi_n\rangle, |\phi_n\rangle\}$ forms a complete biorthonormal system, and the PT-symmetric Hamiltonians (1) are diagonalizable.[5] Moreover, because their spectrum is real and discrete, these Hamiltonians are examples of quasi-Hermitian Hamiltonians having a discrete spectrum.

Next, we calculate

$$\begin{aligned}(\phi, \psi) &= \int_{\mathbb{R}} dx \quad \phi(-x)^* \psi(x) \\ &= \int_{\mathbb{R}} dx \quad \phi(x)^* \psi(-x) \\ &= \int_{\mathbb{R}} dx \quad \phi(x)^* P\psi(x) = \langle \phi | P | \psi \rangle = \langle\langle \phi | \psi \rangle\rangle_P,\end{aligned} \tag{61}$$

where

$$\langle \phi | \psi \rangle := \int_{\mathbb{R}} dx \quad \phi(x)^* \psi(x). \tag{62}$$

According to Eq. (61), the inner product (59) is nothing but $\langle\langle\ |\ \rangle\rangle_P$. This observation together with Eqs. (58) and (60) implies

$$P = \sum_n (-1)^n |\phi_n\rangle\langle\phi_n|. \tag{63}$$

Comparing this equation with (12), we see that P is an example of the canonical operators η_σ of Eq. (12) with

$$\sigma_n=(-1)^n. \tag{64}$$

This is another verification of the fact that the Hamiltonians (1) are P-pseudo-Hermitian.[3]

Note that as a result of Eq. (56), $\psi_n(-x)^*=\psi_n(x)$. This equation together with (60) implies

$$\phi_n(x)=(-1)^n\psi_n(-x), \tag{65}$$

$$\langle\psi_m|\psi_n\rangle=\int_{\mathbb{R}}dx\,\psi_m(x)^*\psi_n(x)=\int_{\mathbb{R}}dx\,\psi_m(-x)\psi_n(-x)^*=\int_{\mathbb{R}}dx\,\psi_m(x)\psi_n(x)^*=\langle\psi_n|\psi_m\rangle, \tag{66}$$

$$\begin{aligned}\langle\phi_m|\phi_n\rangle&=\int_{\mathbb{R}}dx\,\phi_m(x)^*\phi_n\\&=(-1)^{m+n}\int_{\mathbb{R}}dx\,\psi_m(-x)^*\psi_n(-x)\\&=(-1)^{m+n}\int_{\mathbb{R}}dx\,\psi_m(x)^*\psi_n(x)=(-1)^{m+n}\langle\psi_m|\psi_n\rangle.\end{aligned} \tag{67}$$

In view of Eqs. (64) and (67), the condition (51) of Propositions 6 holds. Therefore, Eq. (63) is consistent with the fact that P is an involution.

Next, we use Eqs. (56) and (8) to calculate

$$PT=\sum_n\ |\psi_n\rangle\star\langle\phi_n|. \tag{68}$$

Then, multiplying both sides of this equation by P and using Eqs. (63) and (8), we find

$$T=\sum_n\ (-1)^n|\phi_n\rangle\star\langle\phi_n|. \tag{69}$$

This shows that the time-reversal operator T is nothing but the canonical antilinear operator (24) with σ_n given by (64). [This is consistent with the known fact[5] that the PT-symmetric standard Hamiltonians of the form $H=p^2+V(x;t)$ which have $\mathbb{R}$ as their configuration space, in general, and the Hamiltonians (1) with $\nu\in[0,2)$ and $\gamma=\mathbb{R}$, in particular, are T-anti-pseudo-Hermitian. See also Ref. 11.] Again, in view of (66) and (67), we see that the condition (48) of Corollary 4 is satisfied and the expression (69) is consistent with $T^2=1$.

Next, we consider the positive operator η_+ for the Hamiltonians (1) with $\nu\in[0,2)$ and $\gamma=\mathbb{R}$. Because these Hamiltonians are pseudo-Hermitian with respect to both η_+ and P, they admit a symmetry generated by $\eta_+^{-1}P$. This is a particular example of the symmetry generators S of Proposition 4, where $\nu_0=n$, $\sigma_{\nu_0}=(-1)^{\nu_0}=(-1)^n$, and $\nu_\pm$ are absent. We can compute $\eta_+^{-1}P$ using Eq. (43). Alternatively, we may use the identity[3]

$$\eta_+^{-1}=\sum_n\ |\psi_n\rangle\langle\psi_n| \tag{70}$$

together with Eqs. (63) and (8). This yields

$$\eta_+^{-1}P=\sum_n\ (-1)^n|\psi_n\rangle\langle\phi_n|. \tag{71}$$

The symmetry generator $\eta_+^{-1}P$ has the following form in the position representation:

$$\langle x|\,\eta_+^{-1}P|y\rangle=\sum_n\,(-1)^n\psi_n(x)^*\phi_n(y)=\sum_n\,\psi_n(x)\psi_n(y). \tag{72}$$

Comparing this equation with Eq. (3), we see that $\eta_+^{-1}P$ coincides with the charge-conjugation operator C of Ref. 1,

$$C=\eta_+^{-1}P. \tag{73}$$

Next, we use Eqs. (70), (69), (8), (67), (66), and (9) to compute

$$\begin{aligned}
T\eta_+&=\sum_{nm}\,(-1)^n|\phi_n\rangle\star\langle\phi_n|\phi_m\rangle\langle\phi_m|\\
&=\sum_{nm}\,(-1)^m|\phi_n\rangle\star\langle\psi_n|\psi_m\rangle\langle\phi_m|\\
&=\sum_{nm}\,(-1)^m|\phi_n\rangle\star\langle\psi_m|\psi_n\rangle\langle\phi_m|\\
&=\sum_{nm}\,(-1)^m|\phi_n\rangle\langle\psi_n|\psi_m\rangle\star\langle\phi_m|\\
&=\sum_{m}\,(-1)^m|\psi_m\rangle\star\langle\phi_m|\\
&=\sum_{nm}\,(-1)^m|\psi_m\rangle\langle\psi_m|\phi_n\rangle\star\langle\phi_n|=\eta_+^{-1}T=\eta_+^{-1}P^2T=CPT.
\end{aligned} \tag{74}$$

Hence,

$$\begin{aligned}
\langle\phi|\psi\rangle_{CPT}&=\int_{\mathbb{R}}dx\,[CPT\phi(x)]\psi(x)\\
&=\int_{\mathbb{R}}dx\,[T\eta_+\phi(x)]\psi(x)\\
&=\int_{\mathbb{R}}dx\,[\eta_+\phi(x)]^*\psi(x)=\int_{\mathbb{R}}dx\;\phi(x)^*[\eta_+\psi(x)]=\langle\phi|\,\eta_+\psi\rangle=\langle\!\langle\phi|\psi\rangle\!\rangle_{\eta_+},
\end{aligned} \tag{75}$$

where we have used the fact that η_+ is Hermitian. Equations (75) show that the CPT-inner product (4) advocated in Ref. 1 is nothing but the positive-definite inner product $\langle\!\langle\ |\ \rangle\!\rangle_{\eta_+}$ that was extensively used in Ref. 9. Moreover, the orthonormality relation (5) is a simple consequence of Eqs. (12) and (8).

Comparing the expressions given in (68) and (74) for the PT and CPT operators with Eq. (28), we see that the PT and CPT operators are specific examples of the canonical antilinear symmetry generators (28).

V. GENERALIZED *P*, *T*, AND *C* OPERATORS FOR QUASI-HERMITIAN OPERATORS

In the preceding section we explored the mathematical basis of the charge conjugation operator (3) for the Hamiltonians (1) with the choice $\gamma=\mathbb{R}$ which is allowed for $\nu\in[0,2)$. In this section we will demonstrate that indeed the approach based on the theory of pseudo-Hermitian operators applies to quasi-Hermitian Hamiltonians with a discrete spectrum in general and the PT-symmetric Hamiltonians (1) with $\nu\in[0,\infty)$ in particular.

As we discussed in Sec. III, every quasi-Hermitian Hamiltonian H with a discrete spectrum is η_+-pseudo-Hermitian for a positive operator η_+, and that H is Hermitian with respect to the inner product $\langle\!\langle\ |\ \rangle\!\rangle_{\eta_+}$. This in turn implies the existence of a complete set of eigenvectors $|\psi_n,a\rangle$ of H such that $|\psi_n\rangle$ are orthonormal with respect to $\langle\!\langle\ |\ \rangle\!\rangle_{\eta_+}$.

Lemma 1: Let H, η_+, and $|\psi_n,a\rangle$ be as in the preceding paragraph, and

$$|\phi_n,a\rangle := \eta_+|\psi_n,a\rangle, \tag{76}$$

$$\mathcal{P} := \sum_n \sum_{a=1}^{d_n} (-1)^n |\phi_n\rangle\langle\phi_n|, \tag{77}$$

$$\mathcal{T} := \sum_n \sum_{a=1}^{d_n} (-1)^n |\phi_n\rangle\star\langle\phi_n|, \tag{78}$$

$$\mathcal{C} := \sum_n \sum_{a=1}^{d_n} (-1)^n |\psi_n\rangle\langle\phi_n|. \tag{79}$$

Then we have the following.

(1) $\{|\psi_n,a\rangle,|\phi_n,a\rangle\}$ forms a complete biorthonormal system.

(2) η_+ satisfies (11) and

$$\eta_+^{-1} = \mathcal{T}\eta_+\mathcal{T}. \tag{80}$$

(3) H is $\mathcal{P}$-pseudo-Hermitian and $\mathcal{T}$-anti-pseudo-Hermitian.

(4) $\mathcal{PT}$ and $\mathcal{CPT}$, which have the form

$$\mathcal{PT} = \sum_n \sum_{a=1}^{d_n} |\psi_n,a\rangle\star\langle\phi_n,a|, \tag{81}$$

$$\mathcal{CPT} = \sum_n \sum_{a=1}^{d_n} (-1)^n |\psi_n,a\rangle\star\langle\phi_n,a|, \tag{82}$$

are antilinear symmetry generators and $\mathcal{C}$ is a linear symmetry generator for H; the corresponding symmetries are exact, in particular $|\psi_n,a\rangle$ satisfy

$$\mathcal{PT}|\psi_n,a\rangle = |\psi_n,a\rangle, \tag{83}$$

$$\mathcal{CPT}|\psi_n,a\rangle = \mathcal{C}|\psi_n,a\rangle = (-1)^n|\psi_n,a\rangle. \tag{84}$$

(5) $\mathcal{P}$, $\mathcal{T}$, and $\mathcal{C}$ satisfy

$$(\mathcal{PT})^2 = \mathcal{C}^2 = 1, \tag{85}$$

$$\mathcal{C} = \eta_+^{-1}P = \mathcal{T}\eta_+\mathcal{TP}. \tag{86}$$

(6) The operators $\mathcal{P}$ and $\mathcal{T}$ are involutions if and only if

$$(-1)^{m+n}\langle\phi_n,a|\phi_m,b\rangle = \langle\psi_n,a|\psi_m,b\rangle = \langle\psi_m,b|\psi_n,a\rangle. \tag{87}$$

(7) If H is a Hermitian Hamiltonian, $\mathcal{C}^{-1}\mathcal{P}$ is a Hermitian invertible linear operator commuting with H. In particular, if for all n and a, $|\phi_n,a\rangle = |\psi_n,a\rangle$, then $\mathcal{C} = \mathcal{P}$.

Proof: Statement 1 may be established by checking Eqs. (8) and (9) directly. Statements 2–4 follow from these equations and (77)–(79). $\mathcal{PT}$ and $\mathcal{CPT}$ are respectively examples of the antilinear symmetry generators $\mathcal{X}_+$ and $\mathcal{X}_\sigma$. Statement 5 is a result of Proposition 4; Eq. (86) may be checked by direct computation. Statement 6 is a consequence of Corollary 4. In order to prove statement 7, we introduce

$$\Lambda := \sum_n \sum_{a=1}^{d_n} |\psi_n,a\rangle\langle\psi_n,a|, \tag{88}$$

which is clearly a Hermitian invertible linear operator commuting with H. Now it suffices to use (8) to establish $\Lambda\mathcal{P}=\mathcal{C}$. Finally, for the case that $|\phi_n,a\rangle=|\psi_n,a\rangle$, Eq. (9) implies $\Lambda=1$. □

In view of the analogy with the systems studied in Sec. IV, we shall respectively call the operators $\mathcal{P}$, $\mathcal{T}$, and $\mathcal{C}$ the *generalized parity, time-reversal*, and *charge conjugation* operators. The following theorem follows as a direct consequence of Lemma 1.

Theorem 1: Every diagonalizable Hamiltonian with a real discrete spectrum is invariant under the action of the generalized charge-conjugation operator $\mathcal{C}$ and the combined action of the generalized parity and time-reversal symmetry ($\mathcal{PT}$). In particular, every such Hamiltonian has exact $\mathcal{PT}$- and $\mathcal{CPT}$-symmetry.

Clearly for the Hamiltonians (1) with $\nu\in[0,2)$, the operators $\mathcal{P}$, $\mathcal{T}$, and $\mathcal{C}$ coincide with P,T, and C. For $\nu\in[2,\infty)$, we define the vectors $|\phi_n\rangle$ according to (60) so that in the position representation

$$\eta_+(x,y)=\sum_n \phi_n(x)\phi_n(y)^*=\sum_n \psi_n(x)^*\psi_n(y), \quad \forall x,y\in\mathbb{R}. \tag{89}$$

Next, we note that Eqs. (56), (60), and consequently (65) also hold for $\nu\in[2,\infty)$. Using (65) and (57), we can show that in the position representation

$$\begin{aligned}\mathcal{P}(x,y)&=\sum_n (-1)^n\phi_n(x)\phi_n(y)^*\\ &=\sum_n (-1)^n\psi_n(-x)\psi_n(-y)^*\\ &=\sum_n (-1)^n\psi_n(-x)\psi_n(y)\\ &=\delta(x+y)=P(x,y) \quad \forall x,y\in\mathbb{R},\end{aligned} \tag{90}$$

i.e., P and $\mathcal{P}$ have the same position representations. Furthermore, we can easily see that in view of (81) and (56), $\mathcal{PT}=P\mathcal{T}$, so that T and $\mathcal{T}$ also have the same position representations. Finally, we can employ (79) and (3) to infer that C and $\mathcal{C}$ have the same position representations as well.

VI. GENERALIZED *P*, *T*, AND *C* OPERATORS FOR PSEUDO-HERMITIAN HAMILTONIANS

The construction of the operators $\mathcal{P}$, $\mathcal{T}$, and $\mathcal{C}$ may be easily generalized to the class of all diagonalized pseudo-Hermitian operators with a discrete spectrum. Comparing the operators η_σ and $\mathcal{X}_\sigma$ for the quasi- and pseudo-Hermitian Hamiltonians discussed in Sec. III, and noting that according to Eqs. (77), (81), and (82), $\mathcal{P}$ is an example of η_σ and $\mathcal{PT}$ and $\mathcal{CPT}$ are examples of $\mathcal{X}_\sigma$, we introduce

$$\mathcal{P}:=\sum_{\nu_0}\sum_{a=1}^{d_{\nu_0}} (-1)^{\nu_0}|\phi_{\nu_0},a\rangle\langle\phi_{\nu_0},a|+\sum_{\nu}\sum_{a=1}^{d_\nu}(|\phi_{\nu_+},a\rangle\langle\phi_{\nu_-},a|+|\phi_{\nu_-},a\rangle\langle\phi_{\nu_+},a|), \tag{91}$$

$$\mathcal{T}:=\sum_{\nu_0}(-1)^{\nu_0}\sum_{a=1}^{d_{\nu_0}}|\phi_{\nu_0},a\rangle\star\langle\phi_{\nu_0},a|+\sum_{\nu}\sum_{a=1}^{d_\nu}(|\phi_{\nu_+},a\rangle\star\langle\phi_{\nu_-},a|+|\phi_{\nu_-},a\rangle\star\langle\phi_{\nu_+},a|), \tag{92}$$

$$\mathcal{C}:=\sum_{\nu_0}(-1)^{\nu_0}\sum_{a=1}^{d_{\nu_0}}|\psi_{\nu_0},a\rangle\langle\phi_{\nu_0},a|+\sum_{\nu}\sum_{a=1}^{d_\nu}(|\psi_{\nu_+},a\rangle\langle\phi_{\nu_-},a|+|\psi_{\nu_-},a\rangle\langle\phi_{\nu_+},a|), \tag{93}$$

where we have used the conventions of Secs. III and IV.

Again we can check that Eqs. (85) and (86) hold. Furthermore,

$$\mathcal{PT}=\sum_{\nu_0}\sum_{a=1}^{d_{\nu_0}}|\psi_{\nu_0},a\rangle\star\langle\phi_{\nu_0},a|+\sum_{\nu}\sum_{a=1}^{d_\nu}(|\psi_{\nu_+},a\rangle\star\langle\phi_{\nu_-},a|+|\psi_{\nu_-},a\rangle\star\langle\phi_{\nu_+},a|), \tag{94}$$

$$\mathcal{CPT}=\sum_{\nu_0}(-1)^{\nu_0}\sum_{a=1}^{d_{\nu_0}}|\psi_{\nu_0},a\rangle\star\langle\phi_{\nu_0},a|+\sum_{\nu}\sum_{a=1}^{d_\nu}(|\psi_{\nu_+},a\rangle\star\langle\phi_{\nu_-},a|+|\psi_{\nu_-},a\rangle\star\langle\phi_{\nu_+},a|). \tag{95}$$

In view of Eqs. (93)–(95), Proposition 4, and the construction given in the proof of Corollary 1, we can check that the operators $\mathcal{C}$, $\mathcal{PT}$, and $\mathcal{CPT}$ are involutions of the Hilbert space commuting with the Hamiltonian H. Therefore, we have the following generalization of Theorem 1.

Theorem 2: Every diagonalizable pseudo-Hermitian Hamiltonian H with a discrete spectrum is invariant under the action of $\mathcal{C}$, $\mathcal{PT}$, and $\mathcal{CPT}$. These operators which are involutions of the Hilbert space generate broken symmetries of H.

We wish to conclude this section by pointing out that the operators $\mathcal{P}$, $\mathcal{T}$, and $\mathcal{C}$ are determined by a complete biorthonormal system associated with the Hamiltonian H. As the latter is unique only up to invertible symmetries of H, so are these operators.

VII. CONCLUSION

In this article, we discussed certain properties of pseudo-Hermitian operators and demonstrated their application in understanding the mathematical origin and exploring generalizations of the findings of Bender, Brody, and Jones.[1] In particular, for arbitrary diagonalizable pseudo-Hermitian Hamiltonians with a discrete spectrum, we introduced generalized parity, time-reversal, and charge-conjugation operators that coincide with the ordinary parity, time-reversal, and charge-conjugation for the PT-symmetric Hamiltonians (1). The generalized parity-time-reversal and charge conjugation operators are examples of generators of a set of generic symmetries of every diagonalizable pseudo-Hermitian Hamiltonians having a discrete spectrum. A common property of these symmetries is that they are generated by involutions. The generalized parity and time-reversal operators are, however, involutions only under certain conditions.

Resolvent convergence of sphere interactions to point interactions[a)]

Shin-ichi Shimada[b)]
Department of Mathematics and Physics, Setsunan University, Ikeda-nakamachi 17-8, Neyagawa, 572-8508, Japan

(Received 2 June 2000; accepted 16 October 2002)

We consider the Hamiltonian $H(a)=-\Delta+a^{-1}\lambda(a)q(\hat{x})\delta(|x|-a)$ which describes a sphere interaction ($\hat{x}=x/|x|$, $\lambda(a)=1+\alpha a+O(a^2)$). We study the convergence of $H(a)$ when $a\downarrow 0$ in the norm resolvent sense. The existence of the zero resonance of $-\Delta+q(\hat{x})\delta(|x|-1)$ affects the form of the limiting operator. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1533834]

I. INTRODUCTION

In this paper we are concerned with the Hamiltonian $H(a)$ describing a sphere interaction in $L_2(\mathbb{R}^3)$. $H(a)$ is formally given by

$$H(a)=-\Delta+a^{-1}\lambda(a)q(\hat{x})\delta(|x|-a), \tag{1.1}$$

where δ denotes the 1-dimensional delta function and $\hat{x}=x/|x|$. $q(\omega)$ is a real and smooth function on the unit sphere S_1. $\lambda(a)$ is a real valued function whose asymptotic behavior near $a=0$ is

$$\lambda(a)=1+\alpha a+O(a^2), \quad \alpha\in\mathbb{R}. \tag{1.2}$$

$H(a)$ is defined rigorously via the quadratic form h:

$$h[u,v]=(\nabla u,\nabla v)+\langle a^{-1}\lambda(a)q\gamma_a u,\gamma_a v\rangle_a,$$

$$\mathrm{Dom}[h]=H^1(\mathbb{R}^3).$$

Here $H^m(\mathbb{G})$ denotes the Sobolev space of order m over $\mathbb{G}$, $(,)$ the $L_2(\mathbb{R}^3)$ inner product, $\langle,\rangle_a$ the $L_2(S_a)$ inner product ($S_a=\{x\in\mathbb{R}^3;|x|=a\}, a>0, \langle,\rangle=\langle,\rangle_1$) and γ_a the trace operator from $H^1(\mathbb{R}^3)$ to $L_2(S_a)$. h is seen to be a lower semibounded closed form, and thus determines the unique self-adjoint operator,

$$H=H(a;a^{-1}\lambda(a)q), \tag{1.3}$$

such that

$$\mathrm{Dom}(H)\subset\mathrm{Dom}[h], \quad h[u,v]=(Hu,v),$$

for $u\in\mathrm{Dom}(H)$, $v\in\mathrm{Dom}[h]$ [(Ikebe, 1991), Theorem 1.4]. $H(a;a^{-1}\lambda(a)q)$ is seen to be $-\Delta$ with the interface condition on S_a:

$$\left(\frac{\partial u}{\partial r}\right)_+(x)-\left(\frac{\partial u}{\partial r}\right)_-(x)=a^{-1}\lambda(a)q(\hat{x})(\gamma_a u)(x), \tag{1.4}$$

[a)]Dedicated to Professor Yoshimi Saitō on his 60th birthday.
[b)]Electronic mail: shimada@mpg.setsunan.ac.jp

where $(\partial u/\partial r)_+(x)$ and $(\partial u/\partial r)_-(x)$ mean the limit of $\partial u/\partial r\,(x)$ obtained by approaching S_a from $\{|x|>a\}$ and $\{|x|<a\}$, respectively [(Ikebe, 1991), Theorem 1.7].

In the present paper we examine to which operator $H(a;a^{-1}\lambda(a)q)$ converges when $a\downarrow 0$. Since we have as $a\downarrow 0$,

$$a^{-2}q(\hat{x})\,\delta(|x|-a)\to\mu\,\delta(x)\quad\left(\mu=\int_{S_1}q(\omega)d\omega\right),\tag{1.5}$$

in the distribution sense, where $\delta(x)$ denotes the 3-dimensional delta function and $d\omega$ the surface measure on S_1, we may expect $-\Delta+a^{-2}q(\hat{x})\,\delta(|x|-a)$ converges to a Hamiltonian describing a point interaction $-\Delta+\mu\,\delta(x)$ in some sense. Contrary to this expectation our results (Theorems 3.3–3.6) show that we should replace a^{-2} in $-\Delta+a^{-2}q(\hat{x})\,\delta(|x|-a)$ by a^{-1} in order to obtain a meaningful limiting operator which describes a point interaction. This operator turns out to be a self-adjoint extension $H_p(\tau)$ parametrized by $\tau\in\mathbb{R}\cup\{\infty\}$ of

$$\hat{H}_{00}=-\Delta\restriction_{C_0^\infty(\mathbb{R}^3\setminus\{0\})}.$$

That is uniquely determined by its resolvent $R_p(z;\tau)$:

$$R_p(\kappa^2;\tau)u(x)=R_0(\kappa^2)u(x)+\left(\tau-\frac{i\kappa}{4\pi}\right)^{-1}(R_0(\kappa^2)u)(0)\,\frac{e^{i\kappa|x|}}{4\pi|x|},\tag{1.6}$$

where $R_0(z)=(H_0-z)^{-1}$ and H_0 the free Hamiltonian:

$$H_0=H_p(\infty)=\overline{(-\Delta\restriction_{C_0^\infty(\mathbb{R}^3)})},$$

$\overline{T}$ being the closure of T [(Albeverio, 1988), Theorem 1.1.1, 1.1.2].

We can let $H(a;a^{-1}\lambda(a)q)$ converge to any $H_p(\tau)$ $(\tau\in\mathbb{R})$ in the norm resolvent sense if taking a suitable α in (1.2) under the condition that $H(1;q)$ has zero resonance. In this case we should note that $a^{-1}\lambda(a)q(\hat{x})$ tends to 0 in the distribution sense as $a\downarrow 0$. A similar situation occurs if we try to approximate $H_p(\tau)$ by short range Hamiltonians [(Albeverio, 1988), Theorem 1.2.10]. On the other hand, we do not have to pay any attention to the zero resonance when we approximate $H(a;q)$ by short range Hamiltonians whose potential converges to $q(\hat{x})\,\delta(|x|-a)$ for a fixed $a>0$ [(Shimada, 1992), Theorem 3].

The resolvent $R(\kappa^2;a)$ of $H(a;a^{-1}\lambda(a)q)$ is given by

$$R(\kappa^2;a)=R_0(\kappa^2)+\lambda(a)T(\kappa;a)(1-\lambda(a)\tilde{T}(\kappa;a))^{-1}\gamma_a R_0(\kappa^2)\tag{1.7}$$

[(Ikebe,1991), (7.2)]. Here, $T(\kappa;a):L_2(S_a)\to L_2(\mathbb{R}^3)$ is defined by

$$T(\kappa;a)u(x)=\frac{-1}{4\pi a}\int_{S_a}\frac{e^{i\kappa|x-y|}}{|x-y|}q(\hat{y})u(y)dS_y$$

for $u\in L_2(S_a)$,$x\in\mathbb{R}^3$ and $\tilde{T}(\kappa;a):L_2(S_a)\to L_2(S_a)$;

$$\tilde{T}(\kappa;a)u(x)=\frac{-1}{4\pi a}\int_{S_a}\frac{e^{i\kappa|x-y|}}{|x-y|}q(\hat{y})u(y)dS_y,$$

for $u\in L_2(S_a)$,$x\in S_a$. Introducing the unitary operator $U_a:L_2(S_1)\to L_2(S_a)$ defined by

$$U_a u(x)=\frac{1}{a}u(\hat{x}),$$

we can rewrite (1.7) as

$$R(\kappa^2;a)=R_0(\kappa^2)+\lambda(a)T(\kappa;a)U_a(1-\lambda(a)\tilde{T}(a\kappa))^{-1}U_a^{-1}\gamma_a R_0(\kappa^2), \tag{1.8}$$

where $\tilde{T}(a\kappa)=\tilde{T}(a\kappa;1)$. We shall derive the asymptotic expansions of $(1-\lambda(a)\tilde{T}(a\kappa))^{-1}$ near $a=0$ in Sec. II. In Sec. III, after examining the asymptotic behavior of $U_a^{-1}\gamma_a R_0(\kappa^2)$ and $\lambda(a)T(\kappa;a)U_a$, we prove the norm resolvent convergence of $H(a;a^{-1}\lambda(a)q)$. We shall also treat the case that q is a constant on S_1, where we can compute the zero resonance function of $H(1;q)$ explicitly.

At the end of this section, we refer to Antoine (1987), Hounkonnau (2000), and Hounkonnau (1999) (and references therein) for a recent development of this area including δ'-sphere and relativistic δ-sphere interactions. All authors mentioned above have treated Hamiltonians reduced into the direct sum of operators by a separation of variables. Among them we should mention the work of Antoine (1987). They have proved the norm resolvent convergence of their δ-sphere Hamiltonian to any Hamiltonian describing point interaction by a suitable choice of parameter. In contrast to our case, no properties of zero resonance enter into their discussion as well as into that of approximating one-dimensional point interactions by scaled short range Hamiltonians [(Albeverio, 1988), Sec. I.3.2]. They have reduced the problem to the one concerning radial Hamiltonians since their Hamiltonian is rotationally invariant. However, the author could not relate these two cases more clearly.

II. THE EXPANSION OF $(1-\lambda(a)\tilde{T}(a\kappa))^{-1}$ NEAR $a=0$

In this section, we derive the asymptotic expansion of $(1-\lambda(a)\tilde{T}(a\kappa))^{-1}$ near $a=0$. It will be done along the line of [(Shimada, 1994), Sec. 4]. The behavior depends heavily on the structure of the null space of $1-\tilde{T}(0)$.

Let us recall some results obtained in [(Shimada, 1994), Sec. 3] (up to the end of this paragraph). First, $L_2(S_1)$ is decomposed into the direct sum of subspaces:

$$L_2(S_1)=\mathcal{N}(1-\tilde{T}(0))\dot{+}\mathcal{R}(1-\tilde{T}(0)), \tag{2.1}$$

where $\mathcal{N}(T)$ means the null space of T, $\mathcal{R}(T)$ the range of T, and $\dot{+}$ the (not necessarily orthogonal) direct sum. Let Q be the projection onto $\mathcal{N}(1-\tilde{T}(0))$ along $\mathcal{R}(1-\tilde{T}(0))$. Then

$$\dim\mathcal{R}(Q)<+\infty.$$

Since $1-\tilde{T}(0)-Q$ is invertible, we define K by

$$K=(1-\tilde{T}(0)-Q)^{-1}Q_0\in\mathbf{B}(L_2(S_1)), \tag{2.2}$$

where $Q_0=1-Q$ and $\mathbf{B}(\mathcal{X},\mathcal{Y})$ denotes the set of all bounded operators from $\mathcal{X}$ to $\mathcal{Y}$ ($\mathbf{B}(\mathcal{X})=\mathbf{B}(\mathcal{X},\mathcal{X})$). We define $A_j\in\mathbf{B}(L_2(S_1))$ by

$$A_j u(\omega)=\frac{-i^j}{4\pi j!}\int_{S_1}|\omega-\omega'|^{j-1}q(\omega')u(\omega')d\omega',$$

for $u\in L_2(S_1)$. Then we have

$$\tilde{T}(\kappa)=\sum_{j=0}^{\infty}\kappa^j A_j \quad in \quad \mathbf{B}(L_2(S_1)) \quad (\kappa\in\mathbb{C}). \tag{2.3}$$

Let P_0 be the orthogonal projection onto $\mathcal{N}(H(1;q))$. Let $\hat{P}_0=\gamma_1 P_0$. Then we have

$$\tilde{P}_0 \in \mathbf{B}(L_2(\mathbb{R}^3), L_2(S_1)), \quad \mathcal{R}(\tilde{P}_0) = \mathcal{N}_2, \tag{2.4}$$

where $\mathcal{N}_2$ is the subspace of $\mathcal{N}(1-\tilde{T}(0))$ defined by

$$\mathcal{N}_2 = \{u \in L_2(S_1); u \in \mathcal{N}(1-\tilde{T}(0)), \langle u, q\rangle = 0\}. \tag{2.5}$$

We put $P = \tilde{P}_0 \tilde{P}_0^*$, where $*$ means the adjoint. We define Q_1 and Q_2 by

$$Q_1 = (1 + PqA_2)Q, \quad Q_2 = -PqA_2Q.$$

Then it is seen that Q_j $(j=0,1,2)$ are (not necessarily orthogonal) projections and satisfy the following relations:

$$Q_1 + Q_2 = Q, \quad Q_0 + Q_1 + Q_2 = 1, \quad Q_iQ_j = \delta_{ij}Q_j \ \ (i,j=0,1,2), \tag{2.6}$$

$$\mathcal{R}(Q_0) = \mathcal{R}(1-\tilde{T}(0)), \quad \mathcal{R}(Q_2) = \mathcal{N}_2. \tag{2.7}$$

If $Q_1 \neq 0$, we can find $f_0 \in \mathcal{R}(Q_1)$ such that

$$\langle f_0, q\rangle = (4\pi)^{1/2}, \quad \mathcal{R}(Q_1) = \{cf_0; c \in \mathbb{C}\}. \tag{2.8}$$

We put

$$\mathcal{N}_1 = \mathcal{R}(Q_1). \tag{2.9}$$

Then, in view of (2.1), (2.6), (2.7) and (2.9) we have the following decompositions:

$$\mathcal{N}(1-\tilde{T}(0)) = \mathcal{N}_1 \dotplus \mathcal{N}_2, \quad L_2(S_1) = \mathcal{N}_1 \dotplus \mathcal{N}_2 \dotplus \mathcal{R}(1-\tilde{T}(0)). \tag{2.10}$$

$\mathcal{N}_1$ corresponds to the zero resonance state of $H(1;q)$ in the following sense. Let $u_0 = T(0;1)f_0$. Then u_0 satisfies

$$\Delta u_0 = 0 \quad on \quad \mathbb{R}^3 \backslash S_1,$$

$$\left(\frac{\partial u_0}{\partial r}\right)_+ - \left(\frac{\partial u_0}{\partial r}\right)_- = qu_0 \quad on \quad S_1,$$

and

$$u_0(x) = -(4\pi)^{-1/2}|x|^{-1} + O(|x|^{-2}) \quad as \quad |x| \to \infty.$$

Thus, u_0 satisfies $H(1;q)u_0 = 0$ formally and does not belong to $L_2(\mathbb{R}^3)$. On the other hand, there exists a bijection between $\mathcal{N}_2$ and $\mathcal{N}(H(1;q))$ by [(Shimada, 1994), Theorem 2.4].

Now we derive the asymptotic expansion of $(1-\lambda(a)\tilde{T}(a\kappa))^{-1}$ near $a=0$ according to the possible four cases of Q_1 and Q_2.

Lemma 2.1: Assume that $Q_1 = Q_2 = 0$. Then we have as $a \downarrow 0$,

$$(1-\lambda(a)\tilde{T}(a\kappa))^{-1} = O(1),$$

where $O(a^s)$ means a bounded linear operator whose norm is $O(a^s)$ as $a \downarrow 0$.

Proof: Since $(1-\tilde{T}(0))^{-1}$ exists by (2.7), (2.9) and (2.10), we have as $a \downarrow 0$,

$$1-\lambda(a)\tilde{T}(a\kappa)=1-\tilde{T}(0)-(\tilde{T}(a\kappa)-\tilde{T}(0))+O(a)$$
$$=1-\tilde{T}(0)+o(1)$$
$$=(1-\tilde{T}(0))[1+(1-\tilde{T}(0))^{-1}o(1)],$$

where we have used (1.2) and the fact that $\tilde{T}(a\kappa)$ is a compact operator valued continuous function in a. The desired result follows immediately. □

To treat cases other than $Q_1=Q_2=0$, we use the following lemma obtained by [(Jensen, 1979), Lemma 3.12].

Lemma 2.2: Let $\mathcal{X}$, $\mathcal{Y}$, X and Y be vector spaces. Let $L:\mathcal{X}\to\mathcal{Y}, B:X\to\mathcal{X}$ and $C:\mathcal{Y}\to Y$ be linear operators. Let $A=CLB$. If A^{-1} exists, B is surjective and C is injective, then L^{-1} exists and $L^{-1}=BA^{-1}C$.

Lemma 2.3: Assume that $Q_1\neq 0$ and $\kappa\neq -i\alpha\langle qf_0,f_0\rangle$. Then $Q_1^*q(\kappa A_1+\alpha A_0)Q_1$ is invertible in $\mathbf{B}(\mathcal{R}(Q_1),\mathcal{R}(Q_1^*))$ with the inverse

$$[Q_1^*q(\kappa A_1+\alpha A_0)Q_1]^{-1}=(-i\kappa+\alpha\langle qf_0,f_0\rangle)^{-1}\langle\cdot,f_0\rangle f_0.$$

Proof: We can take $g_0\in\mathcal{R}(Q_1^*)$ such that

$$\langle f_0,g_0\rangle=1$$

by [(Shimada, 1994), Lemma 3.19]. Then $u\in\mathcal{R}(Q_1)$ is of the form

$$Q_1u=u=\langle u,g_0\rangle f_0. \tag{2.11}$$

Since $A_0=\tilde{T}(0)$ and $A_1=-i/4\pi\langle\cdot,q\rangle$, we have

$$(\kappa A_1+\alpha A_0)f_0=-i(4\pi)^{-1/2}\kappa+\alpha f_0, \tag{2.12}$$

where we used (2.8) and the fact that $f_0\in\mathcal{N}(1-\tilde{T}(0))$. Since $Q_1^*=\langle\cdot,f_0\rangle g_0$, we have by (2.8) and (2.12),

$$Q_1^*q(\kappa A_1+\alpha A_0)f_0=(-i\kappa+\alpha\langle qf_0,f_0\rangle)g_0,$$

and hence, together with (2.11),

$$Q_1^*q(\kappa A_1+\alpha A_0)Q_1u=(-i\kappa+\alpha\langle qf_0,f_0\rangle)\langle u,g_0\rangle g_0.$$

From this, the desired result follows. □

Lemma 2.4: Assume that $Q_1\neq 0$, $Q_2=0$ and $\kappa\neq -i\alpha\langle qf_0,f_0\rangle$. Then we have as $a\downarrow 0$,

$$(1-\lambda(a)\tilde{T}(a\kappa))^{-1}=-a^{-1}(-i\kappa+\alpha\langle qf_0,f_0\rangle)^{-1}\langle\cdot,qf_0\rangle f_0+O(1).$$

We should note that $\langle qf_0,f_0\rangle\neq 0$ holds if $q(\omega)\geqslant 0$ (or $q(\omega)\leqslant 0$) on S_1 under the assumption $Q_1\neq 0$ (in which case $q\not\equiv 0$). In fact, assume that $q\geqslant 0$ and $\langle qf_0,f_0\rangle=0$. Then we have

$$q^{1/2}f_0=0,$$

and hence

$$qf_0=0.$$

Thus we have

$$f_0(\omega)=\frac{-1}{4\pi}\int_{S_1}\frac{1}{|\omega-\omega'|}q(\omega')f_0(\omega')d\omega'=0,$$

which is a contradiction.

Proof: Under our assumption, we have by (2.7) and (2.10)

$$L_2(S_1)=\mathcal{R}(Q_0)\dotplus\mathcal{R}(Q_1). \tag{2.13}$$

As was shown in the proof of [(Shimada, 1994), Lemma 4.3], we have

$$L_2(S_1)=\mathcal{R}(Q_0)\dotplus\mathcal{R}(Q_1^*). \tag{2.14}$$

Now let

$$\mathcal{X}=\mathcal{Y}=L_2(S_1),\quad X=\mathcal{R}(Q_0)\dotplus\mathcal{R}(Q_1),\quad Y=\mathcal{R}(Q_0)\dotplus\mathcal{R}(Q_1^*),$$

$$L=1-\lambda(a)\tilde{T}(a\kappa),$$

$$B=[Q_0\quad a^{-1/2}Q_1],$$

$$C=\begin{bmatrix}Q_0\\ a^{-1/2}Q_1^*q\end{bmatrix}.$$

Then, from (2.13) and (2.14), B and C are well-defined bounded operators on $L_2(S_1)$. B is obviously surjective. From the proof of [(Shimada, 1994), Lemma 4.3] it follows that C is injective. Define $A=CLB$. Then A has the following form:

$$A=\begin{bmatrix}Q_0(1-\lambda(a)\tilde{T}(a\kappa))Q_0 & a^{-1/2}Q_0(1-\lambda(a)\tilde{T}(a\kappa))Q_1\\ a^{-1/2}Q_1^*q(1-\lambda(a)\tilde{T}(a\kappa))Q_0 & a^{-1}Q_1^*q(1-\lambda(a)\tilde{T}(a\kappa))Q_1\end{bmatrix}=\begin{bmatrix}A_{11} & A_{12}\\ A_{21} & A_{22}\end{bmatrix}.$$

We have by (1.2) and (2.3),

$$1-\lambda(a)\tilde{T}(a\kappa)=1-\tilde{T}(0)-a(\kappa A_1+\alpha A_0)+O(a^2). \tag{2.15}$$

We know by [(Shimada, 1994), Lemma 3.15],

$$(1-\tilde{T}(0))Q_j=Q_j^*q(1-\tilde{T}(0))=0\quad(j=1,2). \tag{2.16}$$

Thus, using (2.15) and (2.16) we have

$$A_{11}=Q_0(1-\tilde{T}(0))Q_0+O(a),$$

$$A_{12}=O(a^{1/2})$$

$$A_{21}=O(a^{1/2})$$

$$A_{22}=-Q_1^*q(\kappa A_1+\alpha A_0)Q_1+O(a).$$

So, we can rewrite A as $A=D-E$ with

$$D=\begin{bmatrix}Q_0(1-\tilde{T}(0))Q_0 & 0\\ 0 & -Q_1^*q(\kappa A_1+\alpha A_0)Q_1\end{bmatrix},$$

$$E=\begin{bmatrix} O(a) & O(a^{1/2}) \\ O(a^{1/2}) & O(a) \end{bmatrix}.$$

We know by [(Shimada, 1994), Lemma 3.18],

$$[Q_0(1-\tilde{T}(0))Q_0]^{-1}=K|_{\mathcal{R}(Q_0)} \quad in \quad \mathbf{B}(\mathcal{R}(Q_0)) \tag{2.17}$$

[see (2.2)]. Thus, from Lemma 2.3 and (2.17), D is invertible with the inverse,

$$D^{-1}=\begin{bmatrix} K & 0 \\ 0 & -(-i\kappa+\alpha\langle qf_0,f_0\rangle)^{-1}\langle\cdot,f_0\rangle f_0 \end{bmatrix}.$$

Therefore, since A is invertible with the inverse,

$$A^{-1}=(1-D^{-1}E)^{-1}D^{-1}=D^{-1}+\sum_{j=1}^{\infty}(D^{-1}E)^jD^{-1},$$

we have by Lemma 2.2,

$$L^{-1}=BD^{-1}C+\sum_{j=1}^{\infty}B(D^{-1}E)^jD^{-1}C.$$

Direct computation shows that

$$BD^{-1}C=-a^{-1}(-i\kappa+\alpha\langle qf_0,f_0\rangle)^{-1}\langle\cdot,f_0\rangle f_0+O(1),$$

$$\sum_{j=1}^{\infty}B(D^{-1}E)^jD^{-1}C=O(1).$$

Thus we completed the proof. □

Lemma 2.5: Assuume that $Q_1=0$ *and* $Q_2\neq 0$. *Then* $Q_2^*qQ_2$ *is invertible in* $\mathbf{B}(\mathcal{R}(Q_2),\mathcal{R}(Q_2^*))$.

Proof: Since $Q_2=Q$, we have by [(Shimada, 1994), Lemma 3.3],

$$\mathcal{R}(Q_2)=\mathcal{N}(1-\tilde{T}(0)), \quad \mathcal{R}(Q_2^*)=\mathcal{N}(1-\tilde{T}(0)^*).$$

Now, since q is a bijection from $\mathcal{N}(1-\tilde{T}(0))$ to $\mathcal{N}(1-\tilde{T}(0)^*)$ ([(Shimada, 1994), Lemma 3.1]), the lemma follows. □

When $Q_1=0$ and $Q_2\neq 0$, we put $W=(Q_2^*qQ_2)^{-1}\in\mathbf{B}(\mathcal{R}(Q_2^*),\mathcal{R}(Q_2))$.

Lemma 2.6: Assume that $Q_1=0$, $Q_2\neq 0$ *and* $\alpha\neq 0$ *in* (1.2). *Then we have as* $a\downarrow 0$,

$$(1-\lambda(a)\tilde{T}(a\kappa))^{-1}=-a^{-1}\alpha^{-1}Q_2WQ_2^*q+O(1).$$

Proof: Under our assumption, we have

$$L_2(S_1)=\mathcal{R}(Q_0)\dot{+}\mathcal{R}(Q_2)=\mathcal{R}(Q_0)\dot{+}\mathcal{R}(Q_2^*).$$

Let

$$\mathcal{X}=\mathcal{Y}=L_2(S_1), \quad X=\mathcal{R}(Q_0)\dot{+}\mathcal{R}(Q_2), \quad Y=\mathcal{R}(Q_0)\dot{+}\mathcal{R}(Q_2^*),$$

$$L=1-\lambda(a)\tilde{T}(a\kappa),$$

$$B=[Q_0 \quad a^{-1/2}Q_2],$$

$$C=\begin{bmatrix} Q_0 \\ a^{-1/2}Q_2^* q \end{bmatrix}.$$

Then, from an argument similar to the proof of [(Shimada, 1994), Lemma 4.3], it follows that B is surjective and C is injective. Define $A=CLB$. Then A has the following form:

$$A=\begin{bmatrix} Q_0(1-\lambda(a)\tilde{T}(a\kappa))Q_0 & a^{-1/2}Q_0(1-\lambda(a)\tilde{T}(a\kappa))Q_2 \\ a^{-1/2}Q_2^* q(1-\lambda(a)\tilde{T}(a\kappa))Q_0 & a^{-1}Q_2^* q(1-\lambda(a)\tilde{T}(a\kappa))Q_2 \end{bmatrix}=\begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}.$$

Using (2.15) and (2.16) we have

$$A_{11}=Q_0(1-\tilde{T}(0))Q_0+O(a),$$

$$A_{12}=O(a^{1/2}),$$

$$A_{21}=O(a^{1/2}),$$

$$A_{22}=-Q_2^* q(\kappa A_1+\alpha A_0)Q_2+O(a).$$

Moreover, since $A_1Q_2=0$ [(Shimada, 1994), Lemma 3.6] and $A_0=\tilde{T}(0)$, we have by (2.16),

$$A_{22}=-\alpha Q_2^* q\tilde{T}(0)Q_2+O(a)=\alpha Q_2^* q(1-\tilde{T}(0))Q_2-\alpha Q_2^* qQ_2+O(a)=-\alpha Q_2^* qQ_2+O(a).$$

So, we can rewrite A as $A=D-E$ with

$$D=\begin{bmatrix} Q_0(1-\tilde{T}(0))Q_0 & 0 \\ 0 & -\alpha Q_2^* qQ_2 \end{bmatrix},$$

$$E=\begin{bmatrix} O(a) & O(a^{1/2}) \\ O(a^{1/2}) & O(a) \end{bmatrix}.$$

From Lemma 2.5 and (2.17), D is invertible with the inverse,

$$D^{-1}=\begin{bmatrix} K & 0 \\ 0 & -\alpha^{-1}W \end{bmatrix}.$$

Thus, an application of Lemma 2.2 gives

$$L^{-1}=BD^{-1}C+O(1)=-a^{-1}\alpha^{-1}Q_2WQ_2^* q+O(1).$$

Therefore we completed the proof. □

Lemma 2.7: Assume that $Q_1\neq 0$, $Q_2\neq 0$ *and* $q(\omega)\geqslant 0$ [*or* $q(\omega)\leqslant 0$] *on* S_1. *Then* $Q_2^* qQ_2$ *is invertible in* $\mathbf{B}(\mathcal{R}(Q_2),\mathcal{R}(Q_2^*))$.

Proof: Since $\dim\mathcal{R}(Q_2)=\dim\mathcal{R}(Q_2^*)<+\infty$ [(Shimada, 1994), Theorem 2.4, Lemma 3.19]), we have only to show the injectivity of $Q_2^* qQ_2$. Assume that

$$Q_2^* qQ_2u=0, \quad u\in\mathcal{R}(Q_2).$$

Then

$$0=\langle Q_2^* q Q_2 u,u\rangle=\langle qu,u\rangle=\int_{S_1} q(\omega)|u(\omega)|^2\,d\omega,$$

and hence, by our assumption,

$$q(\omega)u(\omega)=0.$$

Thus we have

$$u(\omega)=\tilde{T}(0)u(\omega)=\frac{-1}{4\pi}\int_{S_1}\frac{1}{|\omega-\omega'|}q(\omega')u(\omega')d\omega'=0. \qquad \square$$

Lemma 2.8: Assume that $q(\omega)\geqslant 0$ [*or* $q(\omega)\leqslant 0$] *on* S_1. *Assume that* $Q_1\neq 0$, $Q_2\neq 0$, $\alpha\neq 0$ *and* $\kappa\neq -i\alpha[\det(\langle f_i,qf_j\rangle)_{0\leqslant i,j\leqslant n}/\det(\langle f_i,qf_j\rangle)_{1\leqslant i,j\leqslant n}]$. *Define the operator* $D_1:\mathcal{R}(Q_1)\dot{+}\mathcal{R}(Q_2)\to\mathcal{R}(Q_1^*)\dot{+}\mathcal{R}(Q_2^*)$ *by*

$$D_1=\begin{bmatrix} Q_1^* q(\kappa A_1+\alpha A_0)Q_1 & \alpha Q_1^* q Q_2 \\ \alpha Q_2^* q Q_1 & \alpha Q_2^* q Q_2 \end{bmatrix}.$$

Then D_1 *is invertible. Here* $\{f_j\}_{1\leqslant j\leqslant n}$ *is a basis of* $\mathcal{R}(Q_2)$.

We put

$$D_1^{-1}=-\begin{bmatrix} B_{11} & B_{12} \\ B_{21} & B_{22}\end{bmatrix}:\mathcal{R}(Q_1^*)\dot{+}\mathcal{R}(Q_2^*)\to\mathcal{R}(Q_1)\dot{+}\mathcal{R}(Q_2).$$

We should remark that

$$(i)\ \det(\langle f_i,qf_j\rangle)_{0\leqslant i,j\leqslant n}\neq 0;\quad (ii)\ \det(\langle f_i,qf_j\rangle)_{1\leqslant i,j\leqslant n}\neq 0;$$

(iii) $\det(\langle f_i,qf_j\rangle)_{0\leqslant i,j\leqslant n}/\det(\langle f_i,qf_j\rangle)_{1\leqslant i,j\leqslant n}$ does not depend on the choice of basis $\{f_j\}_{1\leqslant j\leqslant n}$. In fact, let $x=(c_0,c_1,\ldots,c_n)$. Assume that

$$(\langle f_i,qf_j\rangle)_{0\leqslant i,j\leqslant n}x=0.$$

Then, if we assume $q\geqslant 0$, we have

$$0=((\langle f_i,qf_j\rangle)_{0\leqslant i,j\leqslant n}x)\cdot x=\left\|q^{1/2}\left(\sum_{j=0}^{n}c_j f_j\right)\right\|^2.$$

Thus

$$q\left(\sum_{j=0}^{n}c_j f_j\right)=0.$$

Since $q:\mathcal{R}(Q)\to\mathcal{R}(Q^*)$ is bijective [(Shimada, 1994), Lemma 3.1], we have

$$\sum_{j=0}^{n}c_j f_j=0.$$

Since $f_0,f_1,\ldots,f_n$ are linearly independent, we obtain

$$c_0=c_1=\cdots=c_n=0,$$

and hence

$$x=0.$$

From this, (i) follows. We can show (ii) in a similar way. We show (iii). We use the identity

$$\det(\langle f_i, qf_j\rangle)_{1\leqslant i,j\leqslant n}=|\det(c_{ij})_{1\leqslant i,j\leqslant n}|^2\det(\langle g_i, qg_j\rangle)_{1\leqslant i,j\leqslant n}, \tag{2.18}$$

provided that

$$[f_1 f_2\cdots f_n]=[g_1 g_2\cdots g_n]\begin{bmatrix} c_{11} & c_{12} & \cdots & c_{1n}\\ c_{21} & c_{22} & \cdots & c_{2n}\\ \vdots & \vdots & \ddots & \vdots\\ c_{n1} & c_{n2} & \cdots & c_{nn}\end{bmatrix}. \tag{2.19}$$

Let $\{g_j\}_{1\leqslant j\leqslant n}$ be another basis of $\mathcal{R}(Q_2)$. Then there exists the regular matrix $(c_{ij})_{1\leqslant i,j\leqslant n}$ such that (2.19) holds. On the other hand,

$$[f_0 f_1 f_2\cdots f_n]=[f_0 g_1 g_2\cdots g_n]\begin{bmatrix} 1 & 0 & 0 & \cdots & 0\\ 0 & c_{11} & c_{12} & \cdots & c_{1n}\\ 0 & c_{21} & c_{22} & \cdots & c_{2n}\\ \vdots & \vdots & \vdots & \ddots & \vdots\\ 0 & c_{n1} & c_{n2} & \cdots & c_{nn}\end{bmatrix}, \tag{2.20}$$

holds. Applying (2.18) for (2.19) and (2.20), (iii) follows.

Proof of Lemma 2.8: Since

$$\dim(\mathcal{R}(Q_1)\dot{+}\mathcal{R}(Q_2))=\dim(\mathcal{R}(Q_1^*)\dot{+}\mathcal{R}(Q_2^*))<+\infty,$$

we have only to show that D_1 is injective. We can find $g_0\in\mathcal{R}(Q_1^*), g_j\in\mathcal{R}(Q_2^*)$ $(j=1,2,\ldots,n)$ such that

$$\langle f_0, g_0\rangle=1,\quad \langle f_i, g_j\rangle=\delta_{ij}\quad (i,j=1,2,\ldots,n).$$

Then we have

$$Q_1^*=\langle\cdot, f_0\rangle g_0,\quad Q_2^*=\sum_{j=1}^{n}\langle\cdot, f_j\rangle g_j. \tag{2.21}$$

Let

$$u=c_0 f_0,\quad v=\sum_{j=1}^{n} c_j f_j\ (c_k\in\mathbb{C}, k=0,1,\ldots,n). \tag{2.22}$$

Then, using (2.8), (2.12) and (2.21) we have

$$Q_1^* q(\kappa A_1+\alpha A_0)Q_1 u=c_0(-i\kappa+\alpha\langle f_0, qf_0\rangle)g_0,$$

$$\alpha Q_1^* q Q_2 v=\alpha\left(\sum_{j=1}^{n} c_j\langle f_j, qf_0\rangle\right)g_0, \tag{2.23}$$

$$\alpha Q_2^* q Q_1 u = \alpha c_0 \sum_{j=1}^{n} \langle f_0, q f_j \rangle g_j,$$

$$1\,\alpha Q_2^* q Q_2 v = \alpha \sum_{k=1}^{n} \sum_{j=1}^{n} c_j \langle f_j, q f_k \rangle g_k.$$

Thus the equation

$$D_1 \begin{pmatrix} u \\ v \end{pmatrix} = 0$$

implies

$$\tilde{D}_1 \begin{pmatrix} c_0 \\ c_1 \\ \vdots \\ c_n \end{pmatrix} = 0,$$

where

$$\tilde{D}_1 = \begin{bmatrix} -i\kappa + \alpha\langle f_0, q f_0 \rangle & \alpha\langle f_1, q f_0 \rangle & \cdots & \alpha\langle f_n, q f_0 \rangle \\ \alpha\langle f_0, q f_1 \rangle & \alpha\langle f_1, q f_1 \rangle & \cdots & \alpha\langle f_n, q f_1 \rangle \\ \vdots & \vdots & \ddots & \vdots \\ \alpha\langle f_0, q f_n \rangle & \alpha\langle f_1, q f_n \rangle & \cdots & \alpha\langle f_n, q f_n \rangle \end{bmatrix}. \tag{2.24}$$

Since

$$\det \tilde{D}_1 = \alpha^n (-i\kappa \det(\langle f_i, q f_j \rangle)_{1 \leqslant i,j \leqslant n} + \alpha \det(\langle f_i, q f_j \rangle)_{0 \leqslant i,j \leqslant n}) \neq 0, \tag{2.25}$$

the lemma follows. □

Lemma 2.9: Assume that $q(\omega) \geqslant 0$ [*or* $q(\omega) \leqslant 0$] *on* S_1. *Assume that* $Q_1 \neq 0$, $Q_2 \neq 0$, $\alpha \neq 0$ *and* $\kappa \neq -i\alpha \det(\langle f_i, q f_j \rangle)_{0 \leqslant i,j \leqslant n} / \det(\langle f_i, q f_j \rangle)_{1 \leqslant i,j \leqslant n}$. *Then we have as* $a \downarrow 0$,

$$(1 - \lambda(a)\tilde{T}(a\kappa))^{-1} = a^{-1}(Q_1 B_{11} Q_1^* + Q_1 B_{12} Q_2^* + Q_2 B_{21} Q_1^* + Q_2 B_{22} Q_2^*) q + O(1).$$

Proof: Under our assumption, we have

$$L_2(S_1) = \mathcal{R}(Q_0) \dotplus \mathcal{R}(Q_1) \dotplus \mathcal{R}(Q_2) = \mathcal{R}(Q_0) \dotplus \mathcal{R}(Q_1^*) \dotplus \mathcal{R}(Q_2^*).$$

Let

$$\mathcal{X} = \mathcal{Y} = L_2(S_1), \quad X = \mathcal{R}(Q_0) \dotplus \mathcal{R}(Q_1) \dotplus \mathcal{R}(Q_2),$$

$$Y = \mathcal{R}(Q_0) \dotplus \mathcal{R}(Q_1^*) \dotplus \mathcal{R}(Q_2^*),$$

$$L = 1 - \lambda(a)\tilde{T}(a\kappa),$$

$$B = [\,Q_0 \quad a^{-1/2} Q_1 \quad a^{-1/2} Q_2\,],$$

$$C = \begin{bmatrix} Q_0 \\ a^{-1/2} Q_1^* q \\ a^{-1/2} Q_2^* q \end{bmatrix}.$$

Then, it is seen that B is surjective and C is injective. Define

$$A=CLB=\begin{bmatrix} A_{11} & A_{12} & A_{13} \\ A_{21} & A_{22} & A_{23} \\ A_{31} & A_{32} & A_{33} \end{bmatrix}.$$

Then, using the relations

$$(1-\tilde{T}(0))Q_j=Q_j^*q(1-\tilde{T}(0))=0 \quad (j=1,2),$$

$$A_1Q_2=Q_2^*qA_1=0$$

[(Shimada, 1994), Lemmas 3.15, 3.16], we have

$$A_{11}=Q_0(1-\tilde{T}(0))Q_0+O(a),$$

$$A_{12}=O(a^{1/2}),$$

$$A_{13}=O(a^{1/2}),$$

$$A_{21}=O(a^{1/2}),$$

$$A_{22}=-Q_1^*q(\kappa A_1+\alpha A_0)Q_1+O(a),$$

$$A_{23}=-\alpha Q_1^*qQ_2+O(a),$$

$$A_{31}=O(a^{1/2}),$$

$$A_{32}=-\alpha Q_2^*qQ_1+O(a),$$

$$A_{33}=-\alpha Q_2^*qQ_2+O(a).$$

So, we can rewrite A as $A=D-E$ with

$$D=\begin{bmatrix} Q_0(1-\tilde{T}(0))Q_0 & 0 & 0 \\ 0 & -Q_1^*q(\kappa A_1+\alpha A_0)Q_1 & -\alpha Q_1^*qQ_2 \\ 0 & -\alpha Q_2^*qQ_1 & -\alpha Q_2^*qQ_2 \end{bmatrix},$$

$$E=\begin{bmatrix} O(a) & O(a^{1/2}) & O(a^{1/2}) \\ O(a^{1/2}) & O(a) & O(a) \\ O(a^{1/2}) & O(a) & O(a) \end{bmatrix}.$$

From Lemma 2.8 and (2.17) D is invertible with the inverse,

$$D^{-1}=\begin{bmatrix} K & 0 & 0 \\ 0 & B_{11} & B_{12} \\ 0 & B_{21} & B_{22} \end{bmatrix}.$$

Thus an application of Lemma 2.2 gives the desired result. □

III. RESOLVENT CONVERGENCE OF $H(a;a^{-1}\lambda(a)q)$

In order to prove the norm resolvent convergence of $H(a;a^{-1}\lambda(a)q))$ as $a\downarrow 0$, we prepare the following two lemmas.

Lemma 3.1: Let $z\in\mathbb{C}$ be such that $\mathrm{Im}\, z\neq 0$. Then, for any $\varepsilon>0$, we have as $a\downarrow 0$,

$$U_a^{-1}\gamma_a R_0(z)=a(R_0(z)\cdot)(0)+O(a^{3/2-\varepsilon}) \quad in \quad \mathbf{B}(L_2(\mathbb{R}^3),L_2(S_1)).$$

Proof: Since $U_a^{-1}:L_2(S_a)\to L_2(S_1)$,

$$(U_a^{-1}u)(\omega)=au(a\omega) \quad (\omega\in S_1)$$

is unitary, we have only to show that

$$\gamma_a R_0(z)=(R_0(z)\cdot)(0)+O(a^{3/2-\varepsilon}) \quad in \quad \mathbf{B}(L_2(\mathbb{R}^3),L_2(S_a)), \tag{3.1}$$

as $a\downarrow 0$ for sufficiently small $\varepsilon>0$. Let $u\in\mathcal{S}$ (the Schwartz space of rapidly decreasing functions). Then, for $x\in S_a$ we have

$$(\gamma_a R_0(z)u)(x)=(R_0(z)u)(x)=(2\pi)^{-3/2}\int\frac{e^{ix\cdot\xi}}{|\xi|^2-z}\hat{u}(\xi)d\xi, \tag{3.2}$$

where $\hat{u}=\mathcal{F}u$ is the Fourier transform of u defined by

$$\mathcal{F}u(\xi)=(2\pi)^{-3/2}\int e^{-i\xi\cdot x}u(x)dx.$$

Let μ be such that $0<\mu<1/2$. Then, since

$$|e^{ix\cdot\xi}-1|\leqslant 2^{1-\mu}a^{\mu}|\xi|^{\mu} \quad (|x|=a), \tag{3.3}$$

we have by (3.2) and the Schwarz inequality,

$$|(\gamma_a R_0(z)u)(x)-(R_0(z)u)(0)|\leqslant(2\pi)^{-3/2}2^{1-\mu}a^{\mu}\left\|\frac{|\xi|^{\mu}}{|\xi|^2-z}\right\|\cdot\|u\|, \tag{3.4}$$

and hence

$$\|(\gamma_a R_0(z)u)-(R_0(z)u)(0)\|_{L_2(S_a)}\leqslant\pi^{-1}2^{1/2-\mu}a^{1+\mu}\left\|\frac{|\xi|^{\mu}}{|\xi|^2-z}\right\|\cdot\|u\|, \tag{3.5}$$

which implies (3.1). □

Lemma 3.2: Let $\kappa\in\mathbb{C}$ be such that $\mathrm{Im}\,\kappa\neq 0$. Then, for any $\varepsilon>0$, we have as $a\downarrow 0$,

$$\lambda(a)T(\kappa;a)U_a=-\frac{e^{i\kappa|x|}}{4\pi|x|}\langle\cdot,q\rangle+O(a^{1/2-\varepsilon}) \quad in \quad \mathbf{B}(L_2(S_1),L_2(\mathbb{R}^3)).$$

Proof: In view of (1.2), we have only to show that

$$T(\kappa;a)U_a=-\frac{e^{i\kappa|x|}}{4\pi|x|}\langle\cdot,q\rangle+O(a^{1/2-\varepsilon}) \quad in \quad \mathbf{B}(L_2(S_1),L_2(\mathbb{R}^3)), \tag{3.6}$$

as $a\downarrow 0$ for sufficiently small $\varepsilon>0$. Let $u\in L_2(S_1)$. Then, since

$$\mathcal{F}\left(\frac{e^{i\kappa|\cdot-y|}}{4\pi|\cdot-y|}\right)(\xi)=(2\pi)^{-3/2}\frac{e^{-i\xi\cdot y}}{|\xi|^2-\kappa^2},$$

we have by the Parseval identity,

$$\left\| T(\kappa;a)U_a u + \frac{e^{i\kappa|x|}}{4\pi|x|}\langle u,q\rangle \right\|^2 = \int d\xi \left| \frac{-(2\pi)^{-3/2}}{|\xi|^2-\kappa^2} \int_{S_1} d\omega (e^{-i\xi\cdot a\omega}-1) q(\omega)u(\omega) \right|^2 = I(a). \tag{3.7}$$

Let μ be such that $0<\mu<1/2$. Then, by (3.3) and the Schwarz inequality, we obtain

$$I(a) \leqslant (2\pi)^{-3} 2^{2(1-\mu)} a^{2\mu} \int d\xi \frac{|\xi|^{2\mu}}{||\xi|^2-\kappa^2|^2} \|q\|^2 \|u\|^2. \tag{3.8}$$

Thus (3.7) and (3.8) imply (3.6). □

Now we are in a position to prove the norm resolvent convergence of $H(a)$ as $a\downarrow 0$.

Theorem 3.3: *Assume that $Q_1=Q_2=0$. Then we have as $a\downarrow 0$,*

$$R(\kappa^2;a) = R_0(\kappa^2) + O(a) \quad in \quad \mathbf{B}(L_2(\mathbb{R}^3))$$

for $\kappa\in\mathbb{C}$ such that $Im\ \kappa^2\neq 0$.

Proof: In view of Lemmas 2.1, 3.1 and 3.2 we have

$$\lambda(a)T(\kappa;a)U_a(1-\lambda(a)\tilde{T}(a\kappa))^{-1}U_a^{-1}\gamma_a R_a(\kappa^2) = O(a).$$

Thus, from (1.8) we obtain the required result. □

Theorem 3.4: *Assume that $Q_1\neq 0$ and $Q_2=0$. Let $\kappa\in\mathbb{C}$ be such that $Im\ \kappa^2\neq 0$. Then, for any $\varepsilon>0$, we have as $a\downarrow 0$,*

$$R(\kappa^2;a) = R_p(\kappa^2;\tau) + O(a^{1/2-\varepsilon}) \quad in \quad \mathbf{B}(L_2(\mathbb{R}^3)),$$

where

$$\tau = \frac{\alpha\langle f_0, qf_0\rangle}{4\pi}.$$

Proof: In view of Lemmas 2.4, 3.1 and 3.2 we have by using (2.8),

$$\begin{aligned}&\lambda(a)T(\kappa;a)U_a(1-\lambda(a)\tilde{T}(a\kappa))^{-1}U_a^{-1}\gamma_a R_0(\kappa^2)\\ &\quad = \left(\frac{\alpha\langle f_0,qf_0\rangle}{4\pi} - \frac{i\kappa}{4\pi}\right)^{-1} (R_0(\kappa^2)\cdot)(0)\frac{e^{i\kappa|x|}}{4\pi|x|} + O(a^{1/2-\varepsilon}).\end{aligned}$$

Thus, from (1.8) we obtain the required result. □

Theorem 3.5: *Assume that $Q_1=0$, $Q_2\neq 0$ and $\alpha\neq 0$ in (1.2). Let $\kappa\in\mathbb{C}$ be such that $Im\ \kappa^2\neq 0$. Then, for any $\varepsilon>0$, we have as $a\downarrow 0$,*

$$R(\kappa^2;a) = R_0(\kappa^2) + O(a^{1/2-\varepsilon}) \quad in \quad \mathbf{B}(L_2(\mathbb{R}^3)).$$

Proof: First we show that

$$Q_2^* q\varphi = 0 \quad in \quad L_2(S_1), \tag{3.9}$$

$[\varphi(\omega)\equiv 1$ on $S_1]$. In fact, we have for $u\in L_2(S_1)$,

$$\langle u, Q_2^* q\varphi\rangle = \langle Q_2 u, q\rangle = 0,$$

since $Q_2 u\in\mathcal{N}_2$. Thus (3.9) holds. Now, in view of Lemmas 2.4, 3.1 and 3.2 we have together with (3.9),

$$\lambda(a)T(\kappa;a)U_a(1-\lambda(a)\tilde{T}(a\kappa))^{-1}U_a^{-1}\gamma_a R_0(\kappa^2)$$
$$=\alpha^{-1}(R_0(\kappa^2)\cdot)(0)\frac{e^{i\kappa|x|}}{4\pi|x|}\langle Q_2WQ_2^*q\varphi,q\rangle+O(a^{1/2-\varepsilon})=O(a^{1/2-\varepsilon}).$$

Thus, from (1.8) we obtain the required result. □

Theorem 3.6: *Assume that* $q(\omega)\geqslant 0$ [*or* $q(\omega)\leqslant 0$] *on* S_1. *Assume that* $Q_1\neq 0$, $Q_2\neq 0$ *and* $\alpha\neq 0$. *Let* $\kappa\in\mathbb{C}$ *be such that* $Im\ \kappa^2\neq 0$. *Then, for any* $\varepsilon>0$, *we have as* $a\downarrow 0$,

$$R(\kappa^2;a)=R_p(\kappa^2;\tau)+O(a^{1/2-\varepsilon})\quad in\quad \mathbf{B}(L_2(\mathbb{R}^3)),$$

where

$$\tau=\frac{\alpha\det(\langle f_i,qf_j\rangle)_{0\leqslant i,j\leqslant n}}{4\pi\det(\langle f_i,qf_j\rangle)_{1\leqslant i,j\leqslant n}}$$

and $\{f_1,f_2,\ldots,f_n\}$ *is a basis of* $\mathcal{R}(Q_2)$.

Proof: In view of Lemmas 2.9, 3.1 and (3.9) we have

$$(1-\lambda(a)\tilde{T}(a\kappa))^{-1}U_a^{-1}\gamma_a R_0(\kappa^2)=(R_0(\kappa^2)\cdot)(0)(Q_1B_{11}Q_1^*q\varphi+Q_2B_{21}Q_1^*q\varphi)+O(a^{1/2-\varepsilon}).\tag{3.10}$$

Moreover, we have

$$\lambda(a)T(\kappa;a)U_a(R_0(\kappa^2)\cdot)(0)Q_2B_{21}Q_1^*q\varphi=O(a^{1/2-\varepsilon}).\tag{3.11}$$

In fact, since $Q_2B_{21}Q_1^*q\varphi$ is of the form

$$Q_2B_{21}Q_1^*q\varphi=\sum_{j=1}^{n}c_jf_j\quad(c_j\in\mathbb{C},f_j\in\mathcal{N}_2),$$

we have

$$\langle Q_2B_{21}Q_1^*q\varphi,q\rangle=\sum_{j=1}^{n}c_j\langle f_j,q\rangle=0.$$

Thus, (3.11) holds from Lemma 3.2. Therefore we have

$$\lambda(a)T(\kappa;a)U_a(1-\lambda(a)\tilde{T}(a\kappa))^{-1}U_a^{-1}\gamma_a R_0(\kappa^2)=(R_0(\kappa^2)\cdot)(0)Q_1B_{11}Q_1^*q\varphi+O(a^{1/2-\varepsilon}).\tag{3.12}$$

Let us compute $Q_1B_{11}Q_1^*q\varphi$. We put

$$u=-Q_1B_{11}Q_1^*q\varphi,\quad v=-Q_2B_{21}Q_1^*q\varphi.$$

We note

$$\mathcal{R}(B_{11})\subset\mathcal{R}(Q_1),\quad \mathcal{R}(B_{21})\subset\mathcal{R}(Q_2).$$

Then, by (2.8) and (2.21) we have

$$-(4\pi)^{1/2}B_{11}g_0=u,\quad -(4\pi)^{1/2}B_{21}g_0=v,$$

which implies

$$D_1\begin{pmatrix} u \\ v \end{pmatrix} = \begin{pmatrix} (4\pi)^{1/2} g_0 \\ 0 \end{pmatrix}.$$

Thus, from (2.24) and (2.25) it follows that

$$u = (4\pi)^{1/2}\left(\alpha \frac{\det(\langle f_i, q f_j\rangle)_{0\leqslant i,j\leqslant n}}{\det(\langle f_i, q f_j\rangle)_{1\leqslant i,j\leqslant n}} - i\kappa \right)^{-1} f_0,$$

and hence, by (2.8), (3.12) and Lemma 3.2,

$$\begin{aligned} &\lambda(a) T(\kappa; a) U_a (1 - \lambda(a)\tilde{T}(a\kappa))^{-1} U_a^{-1} \gamma_a R_0(\kappa^2) \\ &\quad = 4\pi \left(\alpha \frac{\det(\langle f_i, q f_j\rangle)_{0\leqslant i,j\leqslant n}}{\det(\langle f_i, q f_j\rangle)_{1\leqslant i,j\leqslant n}} - i\kappa \right)^{-1} (R_0(\kappa^2)\cdot)(0) \frac{e^{i\kappa|x|}}{4\pi|x|} + O(a^{1/2-\varepsilon}), \end{aligned}$$

from which the theorem follows. □

Finally, we will give an example of the zero resonance state of $H(1;q)$. Assume that $q(\omega) = V_0$ (real constant). Then, by [S2, Theorem 7.1] we have the following.

Theorem 3.7: *If* $V_0 \neq -(2l+1)$ $(l = 0,1,2,\ldots)$, *then* $Q_1 = Q_2 = 0$. *If* $V_0 = -1$ $(V_0 = -(2l+1), l = 1,2,\ldots)$, *then* $Q_1 \neq 0$ *and* $Q_2 = 0$ $(Q_1 = 0, Q_2 \neq 0)$.

Moreover, when $V_0 = -1$, f_0 is seen to be of the form

$$f_0(\omega) = -(4\pi)^{-1/2},$$

from the proof of the theorem above. Thus the zero resonance function $u_0(x) = (T(0;1)f_0)(x)$ of $H(1;q)$ is given by

$$u_0(x) = \begin{cases} -(4\pi)^{-1/2} & (|x| \leqslant 1), \\ -(4\pi)^{-1/2}|x|^{-1} & (|x| \geqslant 1). \end{cases}$$

Gauge theories of Yang–Mills vector fields coupled to antisymmetric tensor fields

Stephen C. Anco[a)]
Department of Mathematics, Brock University St Catharines, Ontario L2S 3A1, Canada

(Received 17 July 2002; accepted 10 October 2002)

A non-Abelian class of massless/massive nonlinear gauge theories of Yang–Mills vector potentials coupled to Freedman–Townsend antisymmetric tensor potentials is constructed in four space–time dimensions. These theories involve an extended Freedman–Townsend-type coupling between the vector and tensor fields, and a Chern–Simons mass term with the addition of a Higgs-type coupling of the tensor fields to the vector fields in the massive case. Geometrical, field theoretic, and algebraic aspects of the theories are discussed in detail. In particular, the geometrical structure mixes and unifies features of Yang–Mills theory and Freedman–Townsend theory formulated in terms of Lie algebra valued curvatures and connections associated to the fields and nonlinear field strengths. The theories arise from a general determination of all possible geometrical nonlinear deformations of linear Abelian gauge theory for one-form fields and two-form fields with an Abelian Chern–Simons mass term in four dimensions. For this type of deformation (with typical assumptions on the allowed form considered for terms in the gauge symmetries and field equations), an explicit classification of deformation terms at first-order is obtained, and uniqueness of deformation terms at all higher orders is proven. This leads to a uniqueness result for the non-Abelian class of theories constructed here.
[DOI: 10.1063/1.1528271]

I. INTRODUCTION

Gauge field theories continue to be fundamental in the study of many areas of mathematical physics, ranging from elementary particle interactions, and completely integrable nonlinear differential equations, to topology of three- and four-dimensional manifolds. Consequently, an effort to generalize the important types of gauge field theories is of natural interest. In recent work,[1,2] a new nonlinear gauge theory was found for massless vector fields in three space–time dimensions, describing a novel type of generalization of non-Abelian Yang–Mills theory. Its origin can be understood by considering nonlinear deformations of the Abelian linear gauge theory of one-form potentials in d dimensions.[3–5]

The deformation process considered here consists of adding linear and higher power terms to the Abelian gauge symmetry while also adding quadratic and higher power terms to the linear field equations, such that a gauge invariant action principle exists which is not equivalent to the undeformed linear theory under nonlinear field redefinitions. The property of gauge invariance is very restrictive and can be used to derive determining equations for the allowed form of the deformation terms added order by order in powers of the fields.

Non-Abelian Yang–Mills theory describes one type of allowed deformation, which works for one-form potentials in any dimension $d>1$. Interestingly, in $d=3$ dimensions, another type of deformation is allowed,[1] analogous to the Freedman–Townsend theory of antisymmetric tensor gauge fields.[6] The Freedman–Townsend theory was derived originally only for antisymmetric tensor fields in $d=4$ dimensions but it has a simple geometrical formulation in any dimension

[a)]Electronic mail: sanco@brocku.ca

$d>2$ as a nonlinear gauge theory of $d-2$-form potentials, in particular, one-form potentials in $d=3$ dimensions. Moreover, this formulation of the theory has a further natural extension to a coupled tower of p-form potentials of all ranks $1\leqslant p\leqslant d-2$, in particular, coupled one-form and two-form potentials in $d=4$ dimensions.[7,8]

The novel generalization of non-Abelian Yang–Mills theory in Ref. 2 arises by combining the Yang–Mills-type and Freedman–Townsend-type deformations of the Abelian linear one-form potential gauge theory in $d=3$ dimensions. In the present paper, a similar nonlinear deformation of the Abelian linear gauge theory of one-form and two-form potentials in $d=4$ dimensions is studied, which has been announced in earlier work.[2,9] The resulting nonlinear gauge theory generalizes both non-Abelian Yang–Mills theory and Freedman–Townsend theory, describing coupled massless vector and antisymmetric tensor fields in four space–time dimensions. As a main new result, an interesting extension of this theory to include a Chern–Simons-type mass term involving both the vector and antisymmetric tensor fields is presented.

Physically speaking, the field strengths in this nonlinear gauge theory together represent coupled massive spin-one fields in the case with a Chern–Simons term, and otherwise represent massless spin-one fields coupled to massless spin-zero fields in the case with no Chern–Simons term. The construction and features of these two cases of the theory are given in Secs. II and III. The theory has a very rich and interesting geometrical structure, mixing and unifying features of Yang–Mills theory and Freedman–Townsend theory in terms of curvatures and connections associated with the fields and field strengths, which is discussed in Sec. IV. In Sec. V, the theory is derived from an analysis of allowed nonlinear geometrical deformations of the Abelian linear gauge theory of massless/massive sets of one-form and two-form potentials in four dimensions, with the mass determined by a Chern–Simons-type term. This analysis yields a novel nonlinear gauge theory for coupled massless and massive sets of vector and antisymmetric tensor fields, generalizing the two preceding cases of the new theory from Secs. II and III. Finally, some concluding remarks are made in Sec. VI.

II. DEFORMATION OF NON-ABELIAN YANG–MILLS/FREEDMAN–TOWNSEND GAUGE THEORY

First consider, as a starting point, the formulation of non-Abelian Yang–Mills theory and Freedman–Townsend theory as respective nonlinear gauge theories of massless vector and antisymmetric tensor fields on four-dimensional Minkowski space–time. For simplicity, the gauge groups will be taken to be three dimensional. Recall, in Yang–Mills theory, the Lie algebra underlying the gauge group is required to be compact semisimple, which then fixes it here to be SU(2). In Freedman–Townsend theory, however, no such condition arises on the underlying Lie algebra of the gauge group, and thus here it can be any three-dimensional non-Abelian Lie algebra, $\mathcal{G}$. From the classification of three-dimensional Lie algebras, it then follows that $\mathcal{G}$ either is semisimple and thus $\mathcal{G}=\mathrm{SU}(2)$, $\mathcal{G}=\mathrm{SU}(1,1)$, or is solvable and thus $\mathcal{G}=\mathrm{U}(1)\rtimes\mathrm{U}(1)^2$ which is a semidirect product of Abelian Lie algebras U(1) and $\mathrm{U}(1)^2$.

To formulate Yang–Mills theory with an SU(2) gauge group, introduce as the field variable a vector potential A_μ that takes values in the Lie algebra SU(2). Equivalently, with respect to a fixed SU(2) basis e_a, $a=1,2,3$, the vector potential components $A_\mu=A^a_\mu e_a$ can be regarded as a set of three ordinary vector fields A^a_μ on Minkowski space–time. Let $\varepsilon^a{}_{bc}$ denote the SU(2) structure constants, and let k_{ab} denote an SU(2) positive–definite invariant metric, related to Killing metric by $k_{ab}=-\varepsilon^c{}_{ad}\varepsilon^d{}_{bc}$, and so $\varepsilon_{abc}=\varepsilon^e{}_{bc}k_{ae}$ is totally antisymmetric.

The SU(2) Yang–Mills field strength is given by

$$F^a_{\sigma\mu}=\partial_{[\sigma}A^a_{\mu]}+\tfrac{1}{2}\varepsilon^a{}_{bc}A^b_\sigma A^c_\mu\,. \tag{2.1}$$

It is convenient in four dimensions to work with the dual field strength

$$\tilde{F}^a_{\sigma\mu}=\epsilon_{\sigma\mu}{}^{\tau\nu}F^a_{\tau\nu}, \tag{2.2}$$

which satisfies the Bianchi identity

$$D^\sigma \tilde{F}^a_{\sigma\mu} = 0, \tag{2.3}$$

where

$$D_\sigma = \partial_\sigma + \varepsilon^a{}_{bc} A^b_\sigma \tag{2.4}$$

is the SU(2) covariant derivative operator. The Yang–Mills Lagrangian is given by

$$L_{\rm YM} = \tfrac{1}{2} k_{ab} \tilde{F}^a_{\sigma\mu} \tilde{F}^b_{\tau\nu} \eta^{\sigma\tau} \eta^{\mu\nu} \tag{2.5}$$

yielding the SU(2) Yang–Mills field equation

$$E_{A^a_\tau} = \epsilon_\tau{}^{\sigma\nu\mu} D_\sigma \tilde{F}^a_{\mu\nu} = 0 \tag{2.6}$$

for A^a_τ. Under the Yang–Mills gauge symmetry on A^a_μ, given by the field variation

$$\delta_\xi A^a_\mu = D_\mu \xi^a, \tag{2.7}$$

where ξ^a are arbitrary functions that take values in the Lie algebra SU(2), the Lagrangian is gauge invariant, $\delta_\xi L_{\rm YM} = 0$. These gauge symmetries generate a SU(2) gauge group with commutator structure $[\delta_{\xi_1}, \delta_{\xi_2}] = \delta_{\xi_3}$ such that $\xi_3{}^a = \varepsilon^a{}_{bc} \xi_1{}^b \xi_2{}^c$. The Lagrangian gives rise to a gauge invariant stress-energy tensor

$$T_{\mu\nu}(\tilde{F}) = k_{ab} \eta^{\alpha\beta} (\tilde{F}^a_{\mu\alpha} \tilde{F}^b_{\nu\beta} - \tfrac{1}{4} \eta_{\mu\nu} \eta^{\sigma\tau} \tilde{F}^a_{\sigma\alpha} \tilde{F}^b_{\tau\beta}), \tag{2.8}$$

which yields a causal energy-momentum for the vector potential A^a_μ on spacelike hypersurfaces, i.e., $T_{\mu\nu}(\tilde{F}) t^\nu$ is timelike or null for all unit timelike vectors t^ν on Minkowski space–time. Gauge invariance of the Yang–Mills Lagrangian relies on the property that SU(2) is semisimple. The additional property that SU(2) is compact, corresponding to positive–definiteness of k_{ab}, is essential for causality of the Yang–Mills stress-energy tensor obtained from the Lagrangian.

Next, for formulating Freedman–Townsend theory with gauge group determined by $\mathcal{G}$, introduce as the field variable an antisymmetric tensor potential $B_{\mu\nu}$ that takes values in the Lie algebra $\mathcal{G}$. Hereafter, it is convenient to identify the vector spaces of $\mathcal{G}$ and SU(2), so the SU(2) basis provides a vector-space basis e_a, $a = 1,2,3$, for $\mathcal{G}$. Then the components of the antisymmetric tensor potential $B_{\mu\nu} = B^a_{\mu\nu} e_a$ can be regarded equivalently as a set of three ordinary antisymmetric tensor fields $B^a_{\mu\nu}$ on Minkowski space–time. Finally, introduce the Abelian field strength for $B^a_{\mu\nu}$ given by the curl

$$H^a_{\sigma\mu\nu} = \partial_{[\sigma} B^a_{\mu\nu]}, \tag{2.9}$$

along with its dual

$$\tilde{H}^a_\sigma = \epsilon_\sigma{}^{\tau\mu\nu} H^a_{\tau\mu\nu} \tag{2.10}$$

which satisfies the divergence identity

$$\partial^\sigma \tilde{H}^a_\sigma = 0. \tag{2.11}$$

Let $c^a{}_{bc}$ denote structure constants of $\mathcal{G}$, and let $c_{ab}{}^c = c^e{}_{bd} k_{ae} k^{cd}$, where the SU(2) invariant metric provides a positive–definite metric k_{ab} on $\mathcal{G}$. Note this metric is not invariant with respect to the Lie algebra product in $\mathcal{G}$ unless $\mathcal{G} \simeq$ SU(2).

Now the field strength for Freedman–Townsend theory is defined in terms of $B^a_{\mu\nu}$ and $H^a_{\tau\mu\nu}$ by the relation

$$K^a_{\sigma\mu\nu}+\tilde{K}^b_{[\sigma}B^c_{\mu\nu]}c_{cb}{}^a=H^a_{\sigma\mu\nu}, \tag{2.12}$$

where

$$\tilde{K}^a_\tau=\epsilon_\tau{}^{\sigma\mu\nu}K^a_{\sigma\mu\nu} \tag{2.13}$$

is the dual field strength. This field strength has a nonpolynomial expression in terms of $B^c_{\mu\nu}$ given by

$$\tilde{K}^a_\mu=Y^{-1}{}^{a\nu}_{\mu b}(B)\tilde{H}^b_\nu \tag{2.14}$$

with $Y^{-1}{}^{a\nu}_{\mu b}(B)$ denoting the inverse of the tensor matrix

$$Y^{a\nu}_{\mu b}(B)=\delta_\mu{}^\nu k_b{}^a+\epsilon_\mu{}^{\nu\sigma\tau}c_{cb}{}^aB^c_{\sigma\tau}, \tag{2.15}$$

where $B^c_{\sigma\tau}$ is restricted to satisfy $\det(Y^{a\nu}_{\mu b}(B))\neq 0$. Note the tensor matrix is symmetric $Y^{ab}_{\mu\nu}(B)=Y^{ba}_{\nu\mu}(B)$ due to the antisymmetry of volume tensor $\epsilon_{\mu\nu}{}^{\sigma\tau}$ and the structure constants $c^a{}_{cb}$. Then, the Freedman–Townsend Lagrangian is given by

$$L_{\rm FT}=\tfrac{1}{2}k_{ab}\tilde{K}^a_\mu\tilde{K}^b_\nu Y^{\mu\nu}_{ab}(B). \tag{2.16}$$

This yields the field equation for $B^a_{\sigma\tau}$,

$$E_{\rm B}{}^a_{\sigma\tau}=\epsilon_{\sigma\tau}{}^{\nu\mu}(\partial_\nu\tilde{K}^a_\mu+\tfrac{1}{2}c^a{}_{bc}\tilde{K}^b_\nu\tilde{K}^c_\mu)=0. \tag{2.17}$$

The gauge symmetry on $B^a_{\mu\nu}$ is given by the field variation

$$\delta_\chi B^a_{\mu\nu}=\partial_{[\mu}\chi^a_{\nu]}-c_{cb}{}^a\tilde{K}^b_{[\mu}\chi^c_{\nu]}, \tag{2.18}$$

where χ^a_ν are arbitrary covector functions that take values in the Lie algebra G. These gauge symmetries generate an Abelian gauge group $[\delta_{\chi_1},\delta_{\chi_2}]=0$ on solutions of the field equation. Off solutions, the commutator structure closes to within a trivial symmetry proportional to the field equation. Finally, the Lagrangian is gauge invariant to within a total divergence, $\delta_\chi L_{\rm FT}=\partial_\mu(\epsilon^{\mu\nu\sigma\tau}\tfrac{1}{2}c^d{}_{ab}k_{cd}\tilde{K}^a_\sigma\tilde{K}^b_\tau\chi^c_\nu)$. In particular, gauge invariance holds without the need for $\mathcal{G}$ to be semisimple. Moreover, the stress-energy tensor obtained from the Lagrangian

$$T_{\mu\nu}(\tilde{K})=k_{ab}(\tfrac{1}{2}\tilde{K}^a_\mu\tilde{K}^b_\nu-\tfrac{1}{4}\eta_{\mu\nu}\eta^{\sigma\tau}\tilde{K}^a_\sigma\tilde{K}^b_\tau) \tag{2.19}$$

yields a causal energy-momentum for the antisymmetric tensor potential $B^a_{\mu\nu}$ on spacelike hypersurfaces, i.e., $T_{\mu\nu}(\tilde{K})t^\nu$ is timelike or null for all unit timelike vectors t^ν on Minkowski space–time.

A. Nonlinear generalization

We now construct a massless gauge theory with a nonlinear interaction for the fields A^a_μ, $B^a_{\mu\nu}$, $a=1,2,3$, giving a novel generalization of the Yang–Mills/Freedman–Townsend theories above. The origin of the generalization will be explained by the deformation analysis carried out in Sec. V.

To begin, the following algebraic structure[10] is needed on the Lie algebras SU(2) and $\mathcal{G}$. Let $f_{ab}{}^c$ denote a bilinear map f from $\mathcal{G}\times\mathrm{SU}(2)$ into SU(2) defining a representation of $\mathcal{G}$ on SU(2)

$$2\,f_{[d|c}{}^af_{|e]b}{}^c=f_{cb}{}^ac^c{}_{de} \tag{2.20}$$

such that this representation acts as a derivation preserving the SU(2) commutator

$$f_{ed}{}^{c}\varepsilon^{d}{}_{ab} = 2\, f_{e[a|}{}^{d}\varepsilon^{c}{}_{d|b]}\,. \tag{2.21}$$

Since SU(2) is semisimple, any derivation is given by an adjoint representation map

$$f_{eb}{}^{c} = \varepsilon^{c}{}_{db}h_{e}{}^{d} \tag{2.22}$$

with $h_e{}^d$ denoting some linear map h from $\mathcal{G}$ into SU(2). Then, the relation (2.20) implies that h is a homomorphism (with respect to the Lie algebra product) of $\mathcal{G}$ into SU(2).

Consequently, if $\mathcal{G}$ is semisimple then clearly $h(\mathcal{G}) = \mathrm{SU}(2)$ and so $\mathcal{G} \simeq \mathrm{SU}(2)$ are isomorphic Lie algebras, with the linear map h being one-to-one. If instead $\mathcal{G}$ is solvable then the Abelian two-dimensional Lie subalgebra $\mathrm{U}(1)^2$ in $\mathcal{G}$ is the kernel of h, with $\mathcal{G}/\mathrm{U}(1)^2 \simeq h(\mathcal{G}) = \mathrm{U}(1)$ being any one-dimensional Lie subalgebra in SU(2). Hence there are two different cases allowed for the Lie algebra structures in the construction of the massless nonlinear theory. For the semisimple case when $\mathcal{G} \simeq \mathrm{SU}(2)$, since h is an isomorphism, then without loss of generality it follows that

$$h_{a}{}^{b} = \kappa\delta_{a}{}^{b}, \quad c^{a}{}_{bc} = f_{bc}{}^{a} = \kappa\varepsilon^{a}{}_{bc}\,, \tag{2.23}$$

where κ is an arbitrary nonzero constant. Alternatively, for the solvable case when $\mathcal{G} = \mathrm{U}(1) \rtimes \mathrm{U}(1)^2$, the properties of h and $\mathcal{G}$ lead to

$$h_{a}{}^{b} = v_{a}w^{b}, \quad c^{a}{}_{bc} = c^{a}{}_{[b}v_{c]}\,, \quad f_{bc}{}^{a} = \varepsilon^{a}{}_{dc}w^{d}v_{b} \tag{2.24}$$

for some fixed vectors v^a, w^a in the common vector space of $\mathcal{G}$ and SU(2), and for some fixed linear map $c^a{}_b$ such that

$$c^{a}{}_{b}v_{a} = 0, \quad c^{a}{}_{b}v^{b} = 0. \tag{2.25}$$

To proceed, the construction now follows the pattern of the novel deformation of SU(2) Yang–Mills theory in three dimensions from Ref. 2. Let $c_{ab}{}^{c} = c^{d}{}_{be}k_{ad}k^{ce}$ and $f^{a}{}_{bc} = f_{db}{}^{e}k^{ad}k_{ce}$.

Nonlinear field strengths $P^a_{\mu\nu}$, $Q^a_{\mu\nu\sigma}$ are introduced in terms of A^a_μ, $B^a_{\mu\nu}$ by

$$P^{a}_{\mu\nu} - f_{bc}{}^{a}\tilde{Q}^{b}_{[\mu}A^{c}_{\nu]} = F^{a}_{\mu\nu}\,, \tag{2.26}$$

$$Q^{a}_{\mu\nu\sigma} - f^{a}{}_{cb}\tilde{P}^{b}_{[\mu\nu}A^{c}_{\sigma]} + c_{cb}{}^{a}\tilde{Q}^{b}_{[\mu}B^{c}_{\nu\sigma]} = H^{a}_{\mu\nu\sigma}\,, \tag{2.27}$$

where

$$\tilde{P}^{a}_{\sigma\mu} = \epsilon_{\sigma\mu}{}^{\tau\nu}P^{a}_{\tau\nu}\,, \quad \tilde{Q}^{a}_{\sigma} = \epsilon_{\sigma}{}^{\tau\mu\nu}Q^{a}_{\tau\mu\nu} \tag{2.28}$$

are the duals. These field strengths depend nonpolynomially on A^a_μ, $B^a_{\mu\nu}$ in the following form. Define the tensor matrix

$$Y(A,B) = Y^{T}(A,B) = \begin{pmatrix} \delta_{b}{}^{a}\delta_{\mu}{}^{\sigma}\delta_{\nu}{}^{\alpha} & -f_{bc}{}^{a}\epsilon_{\mu\nu}{}^{\sigma\tau}A^{c}_{\tau} \\ -f^{a}{}_{cb}\epsilon_{\mu}{}^{\sigma\alpha\tau}A^{c}_{\tau} & \delta_{b}{}^{a}\delta_{\mu}{}^{\sigma} + c_{cb}{}^{a}\epsilon_{\mu}{}^{\sigma\tau\nu}B^{c}_{\tau\nu} \end{pmatrix} \tag{2.29}$$

and consider the inverse matrix $Y^{-1}(A,B)$ satisfying

$$Y^{-1}(A,B)Y(A,B) = Y(A,B)Y^{-1}(A,B) = \begin{pmatrix} \delta_{b}{}^{a}\delta_{\tau}{}^{\sigma}\delta_{\nu}{}^{\alpha} & 0 \\ 0 & \delta_{b}{}^{a}\delta_{\tau}{}^{\sigma} \end{pmatrix} \tag{2.30}$$

with A^a_τ and $B^a_{\tau\nu}$ restricted by the condition $\det(Y(A,B)) \neq 0$ necessary for invertibility of $Y(A,B)$. Assemble the field strength duals into tensor matrices

$$N=\begin{pmatrix}\tilde{P}^a_{\mu\nu}\\ \tilde{Q}^a_\mu\end{pmatrix},\quad M=\begin{pmatrix}\tilde{F}^a_{\mu\nu}\\ \tilde{H}^a_\mu\end{pmatrix}. \tag{2.31}$$

Then $N=Y^{-1}(A,B)M$, where $Y^{-1}(A,B)$ is nonpolynomial in terms of A^a_μ, $B^a_{\mu\nu}$.

The Lagrangian for the massless nonlinear theory is constructed by

$$L_{\rm N}=k_{ab}(\eta^{\sigma\tau}\eta^{\mu\nu}\tilde{P}^a_{\sigma\mu}\tilde{F}^b_{\tau\nu}+\eta^{\sigma\tau}\tilde{Q}^a_\sigma\tilde{H}^b_\tau) \tag{2.32}$$

which can be also expressed in a more symmetrical form $L=N^TY(A,B)N=M^TY^{-1}(A,B)M$. The gauge symmetries in this theory consist of the field variations given by

$$\delta_\xi A^a_\mu=D_\mu\xi^a+f_{bc}{}^a\tilde{Q}^b_\mu\xi^c, \tag{2.33}$$

$$\delta_\xi B^a_{\mu\nu}=f^a{}_{cb}\tilde{P}^b_{\mu\nu}\xi^c, \tag{2.34}$$

in terms of arbitrary functions ξ^a, and also

$$\delta_\chi A^a_\mu=0, \tag{2.35}$$

$$\delta_\chi B^a_{\mu\nu}=\partial_{[\mu}\chi^a_{\nu]}-c_{cb}{}^a\tilde{Q}^b_{[\mu}\chi^c_{\nu]}, \tag{2.36}$$

in terms of arbitrary covector functions χ^a_ν. Under both these gauge symmetries the Lagrangian is invariant to within a total divergence,

$$\delta_\xi L_{\rm N}=\partial_\mu(\epsilon^{\mu\nu\sigma\tau}2\,f_{ac}{}^dk_{bd}\tilde{Q}^a_\nu\tilde{P}^b_{\sigma\tau}\xi^c),\quad \delta_\chi L_{\rm N}=\partial_\mu(\epsilon^{\mu\nu\sigma\tau}c^c{}_{ab}k_{cd}\tilde{Q}^a_\nu\tilde{Q}^b_\sigma\chi^d_\tau) \tag{2.37}$$

as shown by results in Sec. V.

In this construction, we refer to the underlying Yang–Mills/Freedman–Townsend algebraic structure $(\mathrm{SU}(2),\mathcal{G})$ as the structure group of the massless nonlinear theory.

B. Features

The field equations for A^a_μ and $B^a_{\mu\nu}$ obtained from the Lagrangian are given by

$$E_{{\rm A}\tau}{}^a=\epsilon_\tau{}^{\nu\sigma\mu}(D_\nu\tilde{P}^a_{\sigma\mu}+f_{bc}{}^a\tilde{Q}^b_\nu\tilde{P}^c_{\sigma\mu})=0, \tag{2.38}$$

$$E_{{\rm B}\tau\sigma}{}^a=\epsilon_{\tau\sigma}{}^{\nu\mu}(\partial_\nu\tilde{Q}^a_\mu+\tfrac{1}{2}c^a{}_{bc}\tilde{Q}^b_\nu\tilde{Q}^c_\mu)=0. \tag{2.39}$$

Both these field equations are of second order in derivatives of A^a_μ, $B^a_{\mu\nu}$, with the second derivatives appearing linearly and first derivatives appearing quadratically, while A^a_μ, $B^a_{\mu\nu}$ appear nonpolynomially. As a consequence of gauge invariance, the field equations satisfy nonlinear divergence identities

$$D^\tau E_{{\rm A}\tau}{}^a=-\eta^{\tau\mu}f_{bc}{}^a\tilde{Q}^b_\mu E_{{\rm A}\tau}{}^c-\eta^{\tau\mu}\eta^{\sigma\nu}f_{cb}{}^a\tilde{P}^b_{\mu\nu}E_{{\rm B}\tau\sigma}{}^c, \tag{2.40}$$

$$\partial^\tau E_{{\rm B}\tau\sigma}{}^a=-\eta^{\tau\mu}c^a{}_{bc}\tilde{Q}^b_\mu E_{{\rm B}\tau\sigma}{}^c. \tag{2.41}$$

There are also nonlinear divergence identities that arise on the dual field strengths

$$\eta^{\sigma\mu}(D_\sigma\tilde{P}^a_{\mu\nu}+f_{bc}{}^a\tilde{Q}^b_\sigma\tilde{P}^c_{\mu\nu})=\eta^{\sigma\mu}f_{bc}{}^aE_{{\rm B}\mu\nu}{}^bA^c_\sigma, \tag{2.42}$$

$$\eta^{\sigma\mu}(\partial_\sigma\tilde{Q}^a_\mu-c_{bc}{}^a\tilde{Q}^b_\sigma\tilde{Q}^c_\mu-f^a{}_{bc}\eta^{\tau\nu}\tilde{P}^b_{\sigma\tau}\tilde{P}^c_{\mu\nu})=-\eta^{\sigma\mu}f^a{}_{bc}E_{{\rm A}\mu}{}^cA^b_\sigma-\eta^{\sigma\mu}\eta^{\tau\nu}c_{bc}{}^aE_{{\rm B}\mu\nu}{}^cB^b_{\sigma\tau}, \tag{2.43}$$

due to the SU(2) Bianchi identity (2.3) on $\tilde{F}^a_{\mu\nu}$ and the linear divergence identity (2.11) on $\tilde{H}^a_{\sigma\mu\nu}$. Consequently, for solutions of the field equations, the field strengths satisfy a system of divergence and curl equations

$$D_{[\nu}\tilde{P}^a_{\sigma\mu]} = -f_{bc}{}^a \tilde{Q}^b_{[\nu}\tilde{P}^c_{\sigma\mu]}, \quad D^\nu \tilde{P}^a_{\mu\nu} = -\eta^{\sigma\nu} f_{bc}{}^a \tilde{Q}^b_\sigma \tilde{P}^c_{\mu\nu}, \tag{2.44}$$

$$\partial_{[\nu}\tilde{Q}^a_{\mu]} = -\tfrac{1}{2} c^a{}_{bc} \tilde{Q}^b_{[\nu}\tilde{Q}^c_{\mu]}, \quad \partial^\mu \tilde{Q}^a_\mu = \eta^{\sigma\mu} c_{bc}{}^a \tilde{Q}^b_\sigma \tilde{Q}^c_\mu + \eta^{\sigma\mu}\eta^{\tau\nu} f^a{}_{bc} \tilde{P}^b_{\sigma\tau}\tilde{P}^c_{\mu\nu}, \tag{2.45}$$

with quadratic source terms. In the divergence equation on $\tilde{Q}^a_\mu$, the source terms identically vanish when $c_{(ab)c} = k_{d(a}c^d{}_{b)c} = 0$, which occurs in the case $\mathcal{G} \simeq \mathrm{SU}(2)$.

In both cases $\mathcal{G} \simeq \mathrm{SU}(2)$ or $\mathrm{U}(1) \rtimes \mathrm{U}(1)^2$, the divergence and curl equations (2.44) and (2.45) together with equations (2.26) and (2.27) constitute a first-order nonlinear field theory for A^a_μ, $B^a_{\mu\nu}$, $\tilde{P}^a_{\mu\nu}$, $\tilde{Q}^a_\nu$. Moreover, its linearization reduces to the Abelian linear gauge theory of vector potentials and antisymmetric tensor potentials (see Sec. V A), whose field strengths represent free massless spin-one and spin-zero fields. Hence, in physical terms, solutions of the nonlinear field strength equations (2.44) and (2.45) describe a set of nonlinearly interacting massless fields of spin-one and spin-zero, respectively, in Minkowski space–time.

Under the gauge symmetries the field strengths have the transformation

$$\delta_\xi \tilde{P}^a_{\mu\nu} = \varepsilon^a{}_{bc}\tilde{P}^b_{\mu\nu}\xi^c + (Y^{-1}\xi\cdot E)^a_{\mu\nu}, \quad \delta_\xi \tilde{Q}^a_\mu = (Y^{-1}\xi\cdot E)^a_\mu, \tag{2.46}$$

$$\delta_\chi \tilde{P}^a_{\mu\nu} = (Y^{-1}\chi\cdot E)^a_{\mu\nu}, \quad \delta_\chi \tilde{Q}^a_\mu = (Y^{-1}\chi\cdot E)^a_\mu, \tag{2.47}$$

where $Y^{-1}\xi\cdot E$ and $Y^{-1}\chi\cdot E$ are the respective products of the inverse of the tensor matrix (2.29) with the field equation tensor matrices

$$\xi\cdot E = \begin{pmatrix} f_{bc}{}^a E_{\mathrm{B}\mu\nu}{}^b \xi^c \\ -f^a{}_{cb} E_{\mathrm{A}\mu}{}^b \xi^c \end{pmatrix}, \quad \chi\cdot E = \begin{pmatrix} 0 \\ \eta^{\sigma\nu} c_{cb}{}^a E_{\mathrm{B}\sigma\mu}{}^b \chi^c_\nu \end{pmatrix}. \tag{2.48}$$

Hence, for solutions of the field equations, $\tilde{P}^a_{\mu\nu}$ and $\tilde{Q}^a_\mu$ are gauge invariant with respect to δ_χ, while with respect to δ_ξ, $\tilde{Q}^a_\mu$ is gauge invariant and $\tilde{P}^a_{\mu\nu}$ transforms homogeneously by the adjoint representation of the Lie algebra SU(2).

The gauge symmetries on solutions of the field equations have the commutator structure

$$[\delta_{\xi_1}, \delta_{\xi_2}] = \delta_{\xi_3}, \quad [\delta_{\chi_1}, \delta_{\chi_2}] = 0, \quad [\delta_{\xi_1}, \delta_{\chi_1}] = 0, \tag{2.49}$$

where $\xi_3{}^a = \varepsilon^a{}_{bc}\xi_1{}^b \xi_2{}^c$. Exponentiating these gauge symmetries leads to a group of finite gauge transformations closed on solutions for A^a_μ, $B^a_{\mu\nu}$. In particular, δ_χ generates a $\mathrm{U}(1)^3$ Abelian group of nonlinear gauge transformations, while δ_ξ generates an SU(2) non-Abelian group of nonlinear gauge transformations, with δ_χ and δ_ξ commuting. Thus the complete gauge group for the nonlinear theory has the direct product structure $\mathrm{SU}(2) \times \mathrm{U}(1)^3$.

The spin-one field strength equations (2.44) lead to conserved electric and magnetic type currents $J_{\mathrm{e}\mu}{}^a = \partial^\nu P^a_{\mu\nu}$, $J_{\mathrm{m}\mu}{}^a = \partial^\nu \tilde{P}^a_{\mu\nu}$ in the nonlinear theory. Corresponding sets of electric and magnetic charges are given by

$$Q_{\mathrm{e}}{}^a = \frac{1}{4\pi}\int_S P^a_{\nu\mu} t^\nu \, dS^\mu, \quad a = 1,2,3, \tag{2.50}$$

$$Q_{\mathrm{m}}{}^a = \frac{1}{4\pi}\int_S \tilde{P}^a_{\nu\mu} t^\nu \, dS^\mu, \quad a = 1,2,3 \tag{2.51}$$

for any closed surface S in a constant time hypersurface in Minkowski space–time, with surface element dS^μ and hypersurface unit normal t^ν. If the closed surface is taken to be a sphere S_∞ at spatial infinity, the resulting enclosed total charges are time-independent constants, $t^\nu \partial_\nu Q_{\mathrm{e}}{}^a = t^\nu \partial_\nu Q_{\mathrm{m}}{}^a = 0$, provided there is no current flow normal to S_∞. These total charges are gauge invariant with respect to δ_χ and transform by the adjoint representation of the Lie algebra SU(2) with respect to δ_ξ if the functions ξ^a are constant on S_∞,

$$\delta_\xi Q_{\mathrm{e}}{}^a = \varepsilon^a{}_{bc} Q_{\mathrm{e}}{}^b \xi^c, \quad \delta_\xi Q_{\mathrm{m}}{}^a = \varepsilon^a{}_{bc} Q_{\mathrm{m}}{}^b \xi^c, \tag{2.52}$$

$$\delta_\chi Q_{\mathrm{e}}{}^a = \delta_\chi Q_{\mathrm{m}}{}^a = 0. \tag{2.53}$$

Similarly, the spin-zero field strength equations (2.45) yield a conserved tensor $J_{\mathrm{s}\sigma\mu}^a = \partial^\nu Q^a_{\sigma\mu\nu}$, which leads to a set of scalar type charges

$$Q_{\mathrm{s}}{}^a = \frac{1}{2\pi} \int_C Q^a_{\sigma\nu\mu} n^\sigma t^\nu \, ds^\mu, \quad a = 1,2,3 \tag{2.54}$$

for any closed curve C on a surface S in a constant time hypersurface in Minkowski space–time, with line element ds^μ, surface unit normal n^σ, and hypersurface unit normal t^ν. If the closed curve is taken to be a circle C_∞ at spatial infinity, the resulting enclosed total charges are time-independent constants, $t^\nu \partial_\nu Q_{\mathrm{s}}{}^a = 0$, provided there is no current flow normal to C_∞. These total charges are gauge invariant with respect to both δ_ξ and δ_χ,

$$\delta_\xi Q_{\mathrm{s}}{}^a = \delta_\chi Q_{\mathrm{s}}{}^a = 0. \tag{2.55}$$

Note that, due to the source terms in the spin-one and spin-zero field strength equations, the total charges (2.50), (2.51), (2.54) are, in general, nonzero for solutions.

The Lagrangian gives rise in the standard manner (under diffeomorphisms on Minkowski space–time) to a stress-energy tensor

$$T_{\mu\nu}(\tilde{P},\tilde{Q}) = k_{ab}(\tilde{P}^a_{\mu\sigma}\tilde{P}^b_{\nu\tau}\eta^{\sigma\tau} + \tfrac{1}{2}\tilde{Q}^a_\mu \tilde{Q}^b_\nu - \tfrac{1}{4}\eta_{\mu\nu}(\tilde{P}^a_{\sigma\alpha}\tilde{P}^b_{\tau\beta}\eta^{\sigma\tau}\eta^{\alpha\beta} + \tilde{Q}^a_\sigma \tilde{Q}^b_\tau \eta^{\sigma\tau})). \tag{2.56}$$

This tensor is conserved and gauge invariant on solutions. The conservation equation $\partial^\mu T_{\mu\nu}(\tilde{P},\tilde{Q}) = 0$ can be derived in a standard manner from the space–time covariance of the theory, while gauge invariance $\delta_\xi T_{\mu\nu}(\tilde{P},\tilde{Q}) = \delta_\chi T_{\mu\nu}(\tilde{P},\tilde{Q}) = 0$ manifestly holds due to the gauge transformation properties of the field strengths.

Conserved currents $J_\mu(\zeta) = \zeta^\nu T_{\mu\nu}(\tilde{P},\tilde{Q})$ are obtained from the stress-energy tensor by contraction with a Killing vector field ζ^ν on Minkowski space–time. These conserved currents define gauge invariant fluxes of energy momentum and stress carried by the fields on a constant time hypersurface Σ, when ζ^ν is taken to be a time translation and space translation, respectively. Fluxes of angular momentum and boost momentum are defined similarly with ζ^ν taken to be a rotation or boost. In particular, for $\zeta^\nu = t^\nu$ given by the timelike unit normal t^μ to Σ, a positive energy $t^\mu t^\nu T_{\mu\nu}(\tilde{P},\tilde{Q})$ and a causal energy-momentum $t^\mu T_{\mu\nu}(\tilde{P},\tilde{Q})$ is obtained for solutions. The corresponding total fluxes are given by

$$Q(\zeta) = \int_\Sigma t^\mu \zeta^\nu T_{\mu\nu}(\tilde{P},\tilde{Q}) dV, \tag{2.57}$$

where dV is the volume element on Σ.

An extension of this theory from an (SU(2),$\mathcal{G}$) structure group to a general non-Abelian structure group is presented in Sec. IV.

III. EXTENDED DEFORMATION WITH CHERN–SIMONS MASS TERM

The nonlinear generalization of Yang–Mills/Freedman–Townsend gauge theories in Sec. II has an interesting extension to include a Chern–Simons mass term. This construction yields a novel gauge theory for massive vector potentials A^a_μ coupled to massive antisymmetric tensor potentials $B^a_{\mu\nu}$, $a=1,2,3$, presented here. For simplicity, the Lie algebra of the underlying Yang–Mills and Freedman–Townsend gauge groups will again be given by the most general three-dimensional possibilities, respectively, SU(2) and $\mathcal{G}\simeq \mathrm{SU}(2)$ or $\mathrm{U}(1)\rtimes \mathrm{U}(1)^2$.

The natural starting point is a non-Abelian Chern–Simons-type term[11]

$$L_{\mathrm{CS}}=m\epsilon^{\nu\mu\sigma\tau}k_{ab}(B^a_{\sigma\tau}\partial_\nu A^b_\mu+\lambda A^d_\nu A^e_\mu B^a_{\sigma\tau}\varepsilon^b{}_{de}), \tag{3.1}$$

where $m\neq 0$ is the Chern–Simons mass, λ is a coupling constant, and, recall, $k_{ab}=-\varepsilon^c{}_{ad}\varepsilon^d{}_{bc}$ is a positive definite metric on the common three-dimensional vector space of the Lie algebras SU(2),$\mathcal{G}$. In the case $\mathcal{G}=\mathrm{SU}(2)$, the addition of this Lagrangian to the pure Yang–Mills and Freedman–Townsend Lagrangians (2.5) and (2.16) gives a gauge invariant Lagrangian $L=L_{\mathrm{YM}}+L_{\mathrm{FT}}+L_{\mathrm{CS}}$ if a SU(2) Yang–Mills–Higgs-type coupling is added between the antisymmetric tensor potentials $B^a_{\mu\nu}$ and the Yang–Mills vector potentials A^a_μ. Gauge invariance also determines the Chern–Simons coupling to be $\lambda=\frac{1}{2}$. This yields a massive SU(2) Yang–Mills/Freedman–Townsend gauge theory[6] with the mass arising from the nonlinear interaction of the fields A^a_μ and $B^a_{\mu\nu}$ through the Chern–Simons Lagrangian. The origin of the Yang–Mills–Higgs coupling of $B^a_{\mu\nu}$ with A^a_μ will be explained by the deformation analysis in Sec. V. Remarkably, this coupling also allows the Chern–Simons Lagrangian (3.1) to be compatible with the nonlinear generalization of massless Yang–Mills/Freedman–Townsend theory constructed in Sec. II A, as we now carry out.

To begin, we replace the ordinary curl (2.9) of $B^a_{\mu\nu}$ in the nonlinear field strengths (2.26) and (2.27) by the Yang–Mills covariant curl

$$H^a_{\sigma\mu\nu}=D_{[\sigma}B^a_{\mu\nu]} \tag{3.2}$$

using the SU(2) covariant derivative operator (2.4). Note the dual (2.10) of $H^a_{\sigma\mu\nu}$ now satisfies an SU(2) divergence identity

$$D^\sigma \tilde{H}^a_\sigma=\tilde{F}^b_{\mu\nu}B^c_{\sigma\tau}\varepsilon^a{}_{bc}\eta^{\mu\sigma}\eta^{\nu\tau}. \tag{3.3}$$

We also covariantly modify the nonlinear gauge symmetries (2.34) and (2.36) on $B^a_{\mu\nu}$ to involve an SU(2) covariant curl $D_{[\mu}\chi^a_{\nu]}$ in $\delta_\chi B^a_{\mu\nu}$ and an SU(2) commutator $\varepsilon^a{}_{bc}B^b_{\mu\nu}\xi^c$ in $\delta_\xi B^a_{\mu\nu}$. The nonlinear gauge symmetries (2.33) and (2.35) on A^a_μ remain unchanged. Furthermore, in the algebraic structure used to construct the massless nonlinear theory, the bilinear map defined by $f_{ab}{}^c$ from $\mathcal{G}\times\mathrm{SU}(2)$ into SU(2) remains a representation of $\mathcal{G}$ and a derivation of SU(2). However, consistency of the Yang–Mills–Higgs coupling between $B^a_{\mu\nu}$ and A^a_μ requires that the SU(2) commutator needs to act as a derivation of $\mathcal{G}$,

$$\varepsilon^c{}_{de}c^d{}_{ab}=2\varepsilon^d{}_{[a|e}c^c{}_{d|b]}. \tag{3.4}$$

This holds only if $\mathcal{G}\simeq\mathrm{SU}(2)$, and therefore excludes the possibility $\mathcal{G}\simeq\mathrm{U}(1)\rtimes\mathrm{U}(1)^2$. Hence, we thereby have

$$c^c{}_{ab}=\kappa\varepsilon^c{}_{ab}, \tag{3.5}$$

where κ is a nonzero constant. Since $f_{ab}{}^c$ is then both a derivation of and representation of $\mathcal{G}$, these properties fix $f_{ab}{}^c$ to be the adjoint representation

$$f_{ab}{}^c=c^c{}_{ab}. \tag{3.6}$$

As a result, with the underlying Yang–Mills/Freedman–Townsend algebraic structure $\mathcal{G} \simeq \mathrm{SU}(2)$, the nonlinear field strengths are given by

$$P^a_{\mu\nu} - \kappa\varepsilon^a{}_{bc}\tilde{Q}^b_{[\mu}A^c_{\nu]} = F^a_{\mu\nu}, \tag{3.7}$$

$$Q^a_{\mu\nu\sigma} - \kappa\varepsilon^a{}_{bc}(\tilde{Q}^b_{[\mu}B^c_{\nu\sigma]} - \tilde{P}^b_{[\mu\nu}A^c_{\sigma]}) = H^a_{\mu\nu\sigma}, \tag{3.8}$$

while the nonlinear gauge symmetries take the form

$$\delta_\xi A^a_\mu = D_\mu\xi^a + \kappa\varepsilon^a{}_{bc}\tilde{Q}^b_\mu\xi^c, \tag{3.9}$$

$$\delta_\chi A^a_\mu = 0, \tag{3.10}$$

and

$$\delta_\xi B^a_{\mu\nu} = \varepsilon^a{}_{bc}(B^b_{\mu\nu} + \kappa\tilde{P}^b_{\mu\nu})\xi^c, \tag{3.11}$$

$$\delta_\chi B^a_{\mu\nu} = D_{[\mu}\chi^a_{\nu]} + \kappa\varepsilon^a{}_{bc}\tilde{Q}^b_{[\mu}\chi^c_{\nu]}, \tag{3.12}$$

in terms of arbitrary scalar functions ξ^a and covector functions χ^a_ν. The complete Lagrangian is then constructed by adding the Chern–Simons Lagrangian (3.1) to the nonlinear field strength Lagrangian (2.32), $L = L_{\mathrm{N}} + L_{\mathrm{CS}}$. This Lagrangian depends on A^a_μ and $B^a_{\mu\nu}$ in the nonpolynomial form

$$L = M^T Y^{-1}(A,B)M + mM^T((2-2\lambda)B + (2\lambda-1)A), \tag{3.13}$$

where $Y(A,B)$ is the symmetric tensor matrix (2.29) constructed linearly from A^a_μ, $B^a_{\mu\nu}$, and M is the tensor matrix (2.31) of the SU(2) field strengths of A^a_μ, $B^a_{\mu\nu}$, and where, in the Chern–Simons term,

$$A = \begin{pmatrix} 0 \\ A^a_\mu \end{pmatrix}, \quad B = \begin{pmatrix} B^a_{\mu\nu} \\ 0 \end{pmatrix}, \tag{3.14}$$

are tensor matrices defined by the fields. Note $N = Y^{-1}(A,B)M$ yields the tensor matrix (2.31) of the nonlinear field strengths.

Under both gauge symmetries (3.9) to (3.12), the Lagrangian (3.13) is invariant to within a total divergence,

$$\delta_\xi L = \partial_\mu(\epsilon^{\mu\nu\sigma\tau}\kappa k_{cd}\varepsilon^c{}_{ba}\tilde{Q}^a_\nu(2\tilde{P}^b_{\sigma\tau} + mB^b_{\sigma\tau})\xi^d), \tag{3.15}$$

$$\delta_\chi L = \partial_\mu(\epsilon^{\mu\nu\sigma\tau}k_{cd}(\kappa\varepsilon^c{}_{ab}\tilde{Q}^a_\nu\tilde{Q}^b_\sigma + m\tilde{F}^c_{\nu\sigma})\chi^d_\tau), \tag{3.16}$$

provided the coupling constants κ and λ are fixed such that

$$\kappa = 1/m, \quad \lambda = 1/2 \tag{3.17}$$

as shown by results in Sec. V. This gauge theory gives a nonlinear deformation of the massive SU(2) Yang–Mills/Freedman–Townsend theory from Ref. 6. We refer to the underlying algebraic structure SU(2) as the structure group of the massive nonlinear theory.

A. Features

The Lagrangian (3.13) yields the following field equations for A^a_μ and $B^a_{\mu\nu}$:

$$E_{\mathrm{A}\tau}{}^a = \epsilon_\tau{}^{\nu\sigma\mu}(D_\nu \tilde{P}^a_{\sigma\mu} + \varepsilon^a{}_{bc}((1/m)\tilde{Q}^b_\nu - A^b_\nu)\tilde{P}^c_{\sigma\mu}) + m\tilde{Q}^a_\tau = 0, \tag{3.18}$$

$$E_{\mathrm{B}\tau\sigma}{}^a = \epsilon_{\tau\sigma}{}^{\nu\mu}(D_\nu \tilde{Q}^a_\mu + \varepsilon^a{}_{bc}((1/(2m))\,\tilde{Q}^b_\nu - A^b_\nu)\tilde{Q}^c_\mu) + m\tilde{P}^a_{\tau\sigma} = 0. \tag{3.19}$$

These field equations are of second order in derivatives of A^a_μ, $B^a_{\mu\nu}$, with the second derivatives appearing linearly and first derivatives appearing quadratically, while A^a_μ, $B^a_{\mu\nu}$ appear nonpolynomially through the nonlinear field strengths. Due to the SU(2) Bianchi identity (2.3) and SU(2) divergence identity (3.3), these field strengths satisfy nonlinear divergence identities

$$\eta^{\nu\sigma}(D_\nu \tilde{P}^a_{\sigma\mu} + \varepsilon^a{}_{bc}((1/m)\,\tilde{Q}^b_\nu - A^b_\nu)\tilde{P}^c_{\sigma\mu}) = (1/m)\,\eta^{\nu\sigma}\varepsilon^a{}_{bc}E_{\mathrm{B}\nu\mu}{}^b A^c_\sigma, \tag{3.20}$$

$$\eta^{\nu\sigma}(D_\nu \tilde{Q}^a_\mu - \varepsilon^a{}_{bc}A^b_\nu \tilde{Q}^c_\sigma) = (1/m)\,\eta^{\nu\sigma}\varepsilon^a{}_{bc}(E_{\mathrm{A}\nu}{}^b A^c_\sigma + \eta^{\mu\tau}E_{\mathrm{B}\nu\mu}{}^b B^c_{\sigma\tau}). \tag{3.21}$$

Consequently, for solutions of the field equations, the field strengths satisfy a system of divergence and curl equations. Here, in contrast to the massless nonlinear theory in Sec. II A, this system can be written in terms of the field strengths alone

$$\partial_{[\sigma}\tilde{P}^a_{\nu\mu]} + mQ^a_{\sigma\nu\mu} = -(1/m)\,\varepsilon^a{}_{bc}\tilde{Q}^b_{[\sigma}\tilde{P}^c_{\nu\mu]}, \quad \partial^\nu \tilde{P}^a_{\nu\mu} = -(1/m)\,\eta^{\sigma\nu}\varepsilon^a{}_{bc}\tilde{Q}^b_\sigma P^c_{\nu\mu}, \tag{3.22}$$

$$\partial_{[\sigma}\tilde{Q}^a_{\nu]} + mP^a_{\sigma\nu} = -(1/(2m))\,\varepsilon^a{}_{bc}\tilde{Q}^b_{[\sigma}\tilde{Q}^c_{\nu]}, \quad \partial^\nu \tilde{Q}^a_\nu = 0, \tag{3.23}$$

constituting a first-order nonlinear field theory for $\tilde{P}^a_{\nu\mu}$, $\tilde{Q}^a_\nu$.

Linearization of the equations (3.22) and (3.23) produces a system of linear massive spin-one field strength equations, with the mass given by m. The corresponding linearization in terms of A^a_μ and $B^a_{\mu\nu}$ thus reduces to the Abelian linear gauge theory of massive vector potentials and antisymmetric tensor potentials (see Sec. V A). Hence, solutions of the nonlinear field theory for A^a_μ and $B^a_{\mu\nu}$ together describe a set of nonlinearly interacting massive spin-one fields in Minkowski space–time, where the coupling constant of the interaction is proportional to the inverse mass. A connection between this massive nonlinear theory and pure massive SU(2) Yang–Mills theory is discussed in Sec. IV.

Some additional features of the massive nonlinear theory will now be highlighted and compared to the massless nonlinear theory from Sec. II A.

The gauge symmetries on solutions of the field equations have the commutator structure

$$[\delta_{\xi_1}, \delta_{\xi_2}] = \delta_{\xi_3}, \quad [\delta_{\chi_1}, \delta_{\chi_2}] = 0, \quad [\delta_{\xi_1}, \delta_{\chi_1}] = \delta_{\chi_3}, \tag{3.24}$$

where $\xi_3{}^a = \varepsilon^a{}_{bc}\xi_1{}^b\xi_2{}^c$ and $\chi_{3\mu}{}^a = \varepsilon^a{}_{bc}\xi_1{}^b\chi_{1\mu}{}^c$. Thus the gauge group generated by exponentiation of these gauge symmetries is the semidirect product $\mathrm{SU}(2) \rtimes \mathrm{U}(1)^3$ which differs from the direct product structure in the massless nonlinear theory. Surprisingly, under this gauge group the nonlinear field strengths for solutions of the field equations are gauge invariant

$$\delta_\xi \tilde{P}^a_{\mu\nu} = \delta_\chi \tilde{P}^a_{\mu\nu} = 0, \quad \delta_\xi \tilde{Q}^a_\nu = \delta_\chi \tilde{Q}^a_\nu = 0. \tag{3.25}$$

Off solutions, the gauge symmetries are closed to within trivial gauge symmetries proportional to the field equations.

Conserved electric, magnetic, and scalar type charges are given by the same currents (2.50), (2.51), and (2.54) as derived for the massless nonlinear theory. These currents are gauge invariant on solutions of the field equations, due to the gauge transformation properties of the field strengths.

More remarkably, the conserved stress-energy tensor obtained from the Lagrangian (3.13) is of the same form (2.56) as in the massless nonlinear theory. In particular, the Chern–Simons term (3.1) makes no contribution to the stress-energy, as it has no dependence on the space–time metric $\eta_{\mu\nu}$ other than through the associated (metric compatible) volume tensor $\epsilon^{\mu\nu\sigma\tau}$. This stress-energy tensor (2.56) is again conserved and gauge invariant on solutions of the field equations in the massive nonlinear theory. Likewise it again yields a positive energy $t^\mu t^\nu T_{\mu\nu}(\tilde{P},\tilde{Q})$ and a causal energy momentum $t^\mu T_{\mu\nu}(\tilde{P},\tilde{Q})$ carried by the fields on any constant time hyperplane, with a unit timelike normal t^μ.

An extension of this theory from an SU(2) structure group to a general non-Abelian structure group is presented in the next section.

IV. GEOMETRICAL ASPECTS

The massless and massive nonlinear deformations of SU(2) Yang–Mills/Freedman–Townsend gauge theory constructed in Secs. II and III have a straightforward extension from a SU(2) structure group to a general non-Abelian structure group. The resulting non-Abelian massless and massive theories of coupled vector and antisymmetric tensor potentials possess a geometrically rich structure involving connections on Lie group bundles and associated covariant derivative operators and curvatures, which blend geometrical features of pure Yang–Mills theory and pure Freedman–Townsend theory, as will be discussed here. In particular, this structure exposes a striking equivalence between the massless/massive Yang–Mills equations for a Lie group connection and the field strength equations in the massless/massive nonlinear deformation. An interesting duality between the massive Yang–Mills equations and massive Freedman–Townsend equations will also be noted.

To begin, recall, the field variables consist of a set of three vector fields A^a_μ and three antisymmetric tensor fields $B^a_{\mu\nu}$, $a=1,2,3$, with which is associated an internal three-dimensional real vector space. We fix a basis e_a, $a=1,2,3$, for the Lie algebra SU(2) on this vector space and formulate the field variables geometrically as an SU(2)-valued one-form $A=A^a_\mu e_a\,dx^\mu$ and an SU(2)-valued two-form $B=B^a_{\mu\nu}e_a\,dx^\mu\,dx^\nu$. Similarly, the nonlinear field strengths are represented geometrically as an SU(2)-valued two-form $P=P^a_{\mu\nu}e_a\,dx^\mu\,dx^\nu$ and an SU(2)-valued three-form $Q=Q^a_{\mu\nu\sigma}e_a\,dx^\mu\,dx^\nu\,dx^\sigma$, whose duals are the two-form $*P=\tilde{P}^a_{\mu\nu}e_a\,dx^\mu\,dx^\nu$ and the one-form $*Q=\tilde{Q}^a_\mu e_a\,dx^\mu$.

We now introduce the following SU(2) covariant derivative operators, using A and $*Q$ as connection one-forms:

$$D_A=d+[A,\cdot\,], \tag{4.1}$$

$$D_{*Q}=d+[\lambda *Q,\cdot\,], \tag{4.2}$$

$$D_{A+*Q}=d+[A+\lambda *Q,\cdot\,], \tag{4.3}$$

where λ is a coupling constant, and $[\,\cdot\,,\cdot\,]$ denotes the SU(2) Lie bracket. The corresponding SU(2) curvatures are given by the two-forms

$$R_A=dA+\tfrac{1}{2}[A,A], \tag{4.4}$$

$$R_{*Q}=\lambda(d*Q+\tfrac{1}{2}\lambda[*Q,*Q]), \tag{4.5}$$

$$R_{A+*Q}=R_A+R_{*Q}+\lambda[A,*Q], \tag{4.6}$$

which satisfy

$$(D_A)^2=[R_A,\cdot], \quad (D_{*Q})^2=[R_{*Q},\cdot], \quad (D_{A+*Q})^2=[R_{A+*Q},\cdot]. \tag{4.7}$$

A. Massless SU(2) theory

The nonlinear massless field equations (2.38) and (2.39) for A,B together with the massless field strength equations (2.26) and (2.27) which define P,Q are given in geometrical form by

$$P=R_{A+*Q}-R_{*Q}, \tag{4.8}$$

$$Q=D_{*Q}B+\lambda[A,*P], \tag{4.9}$$

and

$$D_{A+*Q}*P=0, \tag{4.10}$$

$$R_{*Q}=0. \tag{4.11}$$

Thus, $*Q$ is a zero-curvature connection, while $*P$ is covariantly curl-free.

Hence, on solutions, it follows that

$$P=R_{A+*Q} \tag{4.12}$$

is a curvature, while

$$Q=D_{*Q}(B-\lambda*P) \tag{4.13}$$

is a covariant curl. In addition, the field strength identities (2.42) and (2.43) become

$$D_{A+*Q}P=0 \tag{4.14}$$

due to the SU(2) Bianchi identity, and

$$D_{*Q}Q=dQ=0 \tag{4.15}$$

since $[*Q,Q]=0$ is an identity.

Now, consider the SU(2)-valued one-form,

$$A_{\mathrm{SU}(2)}=A+\lambda*Q. \tag{4.16}$$

Under the gauge symmetry δ_ξ, $A_{\mathrm{SU}(2)}$ transforms as a SU(2) connection

$$\delta_\xi A_{\mathrm{SU}(2)}=D_{A_{\mathrm{SU}(2)}}\xi, \tag{4.17}$$

where

$$D_{A_{\mathrm{SU}(2)}}=d+[A_{\mathrm{SU}(2)},\cdot]. \tag{4.18}$$

This connection is invariant under the gauge symmetry δ_χ,

$$\delta_\chi A_{\mathrm{SU}(2)}=0. \tag{4.19}$$

Moreover, in terms of $A_{\mathrm{SU}(2)}$, the nonlinear field strength equations (4.10) and (4.12) involving P are simply the SU(2) Yang–Mills equations. In particular,

$$F_{\mathrm{SU}(2)} = P \tag{4.20}$$

is the SU(2) curvature of $A_{\mathrm{SU}(2)}$, satisfying the Yang–Mills connection equation

$$D_{A_{\mathrm{SU}(2)}} * F_{\mathrm{SU}(2)} = 0 \tag{4.21}$$

and the Bianchi identity

$$D_{A_{\mathrm{SU}(2)}} F_{\mathrm{SU}(2)} = 0. \tag{4.22}$$

Similarly, consider the SU(2)-valued two-form

$$B_{\mathrm{SU}(2)} = B - \lambda * P. \tag{4.23}$$

From the field strength equation (4.13), note $Q = D_{*Q} B_{\mathrm{SU}(2)}$ is equivalent to

$$*Q = Y^{-1}_{B_{\mathrm{SU}(2)}}(*dB_{\mathrm{SU}(2)}), \tag{4.24}$$

where $Y^{-1}_{B_{\mathrm{SU}(2)}}$ is the inverse of the linear map

$$Y_{B_{\mathrm{SU}(2)}} = \mathbb{I} + \lambda * [B_{\mathrm{SU}(2)}, \cdot\,] \tag{4.25}$$

acting on SU(2)-valued one-forms. Thus,

$$K_{\mathrm{SU}(2)} = *Q \tag{4.26}$$

is the SU(2) Freedman–Townsend three-form field strength of $B_{\mathrm{SU}(2)}$. In particular, under the gauge symmetry δ_χ, $B_{\mathrm{SU}(2)}$ transforms as a Freedman–Townsend antisymmetric tensor potential

$$\delta_\chi B_{\mathrm{SU}(2)} = D_{K_{\mathrm{SU}(2)}} \chi \tag{4.27}$$

and is invariant under the gauge symmetry δ_ξ,

$$\delta_\xi B_{\mathrm{SU}(2)} = 0. \tag{4.28}$$

Here

$$D_{K_{\mathrm{SU}(2)}} = d + [*K_{\mathrm{SU}(2)}, \cdot\,] \tag{4.29}$$

is an SU(2) covariant derivative using the dual field strength as the connection one-form. Moreover, $K_{\mathrm{SU}(2)}$ satisfies both the Freedman–Townsend field equation

$$R_{K_{\mathrm{SU}(2)}} = 0 \tag{4.30}$$

and field strength identity

$$dK_{\mathrm{SU}(2)} = 0, \tag{4.31}$$

which follow from the field strength equations (4.11) and (4.15) involving Q.

Interestingly, we therefore see that pure SU(2) Yang–Mills theory for a vector potential $A_{\mathrm{SU}(2)}$ and pure SU(2) Freedman–Townsend theory for an antisymmetry tensor potential $B_{\mathrm{SU}(2)}$ possess a combined formulation as a massless nonlinear gauge theory given by a nonlinear deformation of SU(2) Yang–Mills gauge theory for $A = A_{\mathrm{SU}(2)} - \lambda K_{\mathrm{SU}(2)}$ and SU(2) Freedman–Townsend gauge theory for $B = \lambda * F_{\mathrm{SU}(2)} + B_{\mathrm{SU}(2)}$.

B. Massive SU(2) theory

Compared to the massless case, the massive nonlinear theory has some significant geometrical differences. The nonlinear massive field equations (3.18) and (3.19) for A, B together with the field strength equations (3.7) and (3.8) which define P, Q take the geometrical form

$$P = R_{A+*Q} - R_{*Q}, \tag{4.32}$$

$$Q = D_{A+*Q}B + \frac{1}{m}[A, *P], \tag{4.33}$$

with $\lambda = 1/m$ in the covariant derivatives (4.2) and (4.3), and

$$\frac{1}{m} D_{*Q} *P = -Q, \tag{4.34}$$

$$R_{*Q} = -P. \tag{4.35}$$

By substitution of equations (4.35) and (4.34), respectively, into expressions (4.32) and (4.33), it follows that

$$R_{A+*Q} = 0 \tag{4.36}$$

and

$$D_{A+*Q}(*P + mB) = 0. \tag{4.37}$$

Hence, on solutions, $A + (1/m)*Q$ is a zero-curvature connection, while $*P + mB$ is covariantly curl-free. In addition, the field strength identities (3.20) and (3.21) become

$$D_{*Q}P = 0 \tag{4.38}$$

due to the SU(2) Bianchi identity, and

$$D_{*Q}Q = dQ = 0 \tag{4.39}$$

since $[*Q, Q] = [*P, P] = 0$ is an identity.

Now, in analogy with the massless case, consider the SU(2)-valued one-form

$$A_{\mathrm{SU}(2)} = \frac{1}{m} *Q. \tag{4.40}$$

In terms of $A_{\mathrm{SU}(2)}$, the nonlinear field strength equations (4.34), (4.35), and (4.38) involving P are simply the massive SU(2) Yang–Mills equations, in particular,

$$*D_{A_{\mathrm{SU}(2)}} *F_{\mathrm{SU}(2)} + m^2 A_{\mathrm{SU}(2)} = 0 \tag{4.41}$$

and the Bianchi identity

$$D_{A_{\mathrm{SU}(2)}} F_{\mathrm{SU}(2)} = 0, \tag{4.42}$$

where

$$F_{\mathrm{SU}(2)} = -P \tag{4.43}$$

is the SU(2) curvature of $A_{\mathrm{SU}(2)}$. Moreover, $A_{\mathrm{SU}(2)}$ satisfies Lorentz gauge

$$d*A_{\mathrm{SU}(2)}=0 \tag{4.44}$$

due to the field strength identity (4.39). Correspondingly, under the SU(2) gauge symmetry δ_ξ, $A_{\mathrm{SU}(2)}$ is gauge invariant

$$\delta_\xi A_{\mathrm{SU}(2)}=0. \tag{4.45}$$

Finally, from the remaining field strength equations (4.36) and (4.37), it follows that the SU(2)-valued one-form

$$A_{\mathrm{flat}}=A+\frac{1}{m}*Q \tag{4.46}$$

is a flat connection, with respect to which the SU(2)-valued two-form

$$B_{\text{curl-free}}=B+\frac{1}{m}*P \tag{4.47}$$

is covariantly curl-free. Thus, up to gauge transformations, $B_{\text{curl-free}}$ is an exact two-form and A_{flat} vanishes. This two-form has no apparent geometrical relation to Freedman–Townsend theory, in contrast to the situation in the massless case.

Interestingly, however, the nonlinear field strength equations (4.34), (4.35), (4.38), (4.39) exhibit a direct relation to massive SU(2) Freedman–Townsend theory as follows. Consider the SU(2)-valued two-form

$$B_{\mathrm{SU}(2)}=-\frac{1}{m}*P. \tag{4.48}$$

From the field strength equation (4.34), we see that

$$K_{\mathrm{SU}(2)}=\frac{1}{m}Q \tag{4.49}$$

is the SU(2) Freedman–Townsend field strength three-form determined by

$$D_{K_{\mathrm{SU}(2)}}B_{\mathrm{SU}(2)}=K_{\mathrm{SU}(2)}, \tag{4.50}$$

and hence

$$Y^{-1}_{B_{\mathrm{SU}(2)}}(*dB_{\mathrm{SU}(2)})=*K_{\mathrm{SU}(2)}. \tag{4.51}$$

We then see that the field strength equation (4.35) is simply the massive Freedman–Townsend field equation

$$R_{K_{\mathrm{SU}(2)}}=m^2*B_{\mathrm{SU}(2)}, \tag{4.52}$$

while the field strength equation (4.38) yields the SU(2) Freedman–Townsend field strength identity

$$dK_{\mathrm{SU}(2)}=0. \tag{4.53}$$

Finally, from the field strength equation (4.39), we obtain

$$D_{K_{\mathrm{SU}(2)}}*B_{\mathrm{SU}(2)}=0, \tag{4.54}$$

which is a nonlinear SU(2) Lorentz gauge on $B_{\mathrm{SU}(2)}$.

It now follows through the duality

$$A_{\mathrm{SU}(2)} = *K_{\mathrm{SU}(2)}, \quad mB_{\mathrm{SU}(2)} = *F_{\mathrm{SU}(2)}, \quad m \neq 0 \tag{4.55}$$

given by Eqs. (4.40), (4.43), (4.48), and (4.49) that this massive Freedman–Townsend theory for $B_{\mathrm{SU}(2)}$ is equivalent to the massive Yang–Mills theory for $A_{\mathrm{SU}(2)}$.

Consequently, we see that pure massive SU(2) Yang–Mills theory for a vector potential $A_{\mathrm{SU}(2)}$ [or equivalently pure massive SU(2) Freedman–Townsend theory for an antisymmetric tensor potential $B_{\mathrm{SU}(2)}$], along with a SU(2) theory of a covariantly exact antisymmetric tensor potential $B_{\text{curl-free}}$ with respect to a flat connection A_{flat}, together possess a reformulation as a massive nonlinear gauge theory given by a nonlinear deformation of SU(2) Yang–Mills/Freedman–Townsend theory with a Chern–Simons mass term for $A = A_{\mathrm{flat}} - A_{\mathrm{SU}(2)}$ and $B = B_{\text{curl-free}} - (1/m)*F_{\mathrm{SU}(2)}$.

C. General non-Abelian theory

The SU(2) massless and massive nonlinear theories are easily generalized so that in place of the SU(2) structure group we have a non-Abelian structure group based on any semisimple Lie algebra, $\mathcal{A}$. Geometrically, A, $*Q$, B, $*P$ thereby are generalized to be $\mathcal{A}$-valued one-forms and two-forms. The field strength equations in Secs. IV A and IV B retain the same geometrical form with $[\cdot,\cdot]$ given by the Lie bracket of $\mathcal{A}$. As shown by the deformation analysis in Sec. V, this provides the most general non-Abelian massless and massive nonlinear theories representing a geometrical deformation of semisimple Yang–Mills/Freedman–Townsend gauge theory for Lie-algebra valued field variables A, B.

A further type of extension arises from considering non-semisimple structure groups. Recall from Sec. II, for the massless nonlinear theory an allowed structure group is $(\mathrm{SU}(2), \mathcal{G} = \mathrm{U}(1) \rtimes \mathrm{U}(1)^2)$, based on using the Lie algebras SU(2) for the Yang–Mills algebraic structure and $\mathcal{G}$ for the Freedman–Townsend algebraic structure underlying the construction of the theory. A more general non-semisimple structure group is allowed for both the massless as well as the massive nonlinear theories, which will now be presented. This extension involves some unexpected, novel algebraic features compared to the SU(2) case.

To proceed, we first introduce two Lie algebras $\mathcal{A}$ and $\mathcal{A}'$ along with a homomorphism h from $\mathcal{A}'$ into $\mathcal{A}$. Thus, $h(\mathcal{A}') \subseteq \mathcal{A}$ is a subalgebra of $\mathcal{A}$ while $\ker(h) \subseteq \mathcal{A}'$ is an invariant subalgebra of $\mathcal{A}'$. (In particular, note $\mathcal{A}' \simeq \mathcal{A}$ are isomorphic Lie algebras iff the kernel of h is empty and h is surjective.) Then the algebraic structure common to both the massless and massive nonlinear theories consists of the Lie brackets $[\cdot,\cdot]_{\mathcal{A}}$, $[\cdot,\cdot]_{\mathcal{A}'}$, and inner products $(\cdot,\cdot)_{\mathcal{A}}$, $(\cdot,\cdot)_{\mathcal{A}'}$ fixed on $\mathcal{A}$ and $\mathcal{A}'$, and a bilinear map $f(\cdot,\cdot) = [\cdot, h(\cdot)]_{\mathcal{A}}$ from $\mathcal{A} \times \mathcal{A}'$ into $\mathcal{A}$. There are additional properties required to hold on this algebraic structure in the separate massless and massive cases. An explanation for the origin of these properties will be provided by the deformation analysis in Sec. V.

We begin with some algebraic preliminaries of a techincal nature. Associated with the Lie brackets and bilinear map, introduce the linear maps $ad_{\mathcal{A}}(\cdot)$ and $ad_{\mathcal{A}'}(\cdot)$ denoting the adjoint representation of the Lie algebras $\mathcal{A}$ and $\mathcal{A}'$,

$$ad_{\mathcal{A}}(v)u = [v,u]_{\mathcal{A}}, \quad ad_{\mathcal{A}'}(v')u' = [v',u']_{\mathcal{A}'}, \tag{4.56}$$

and the additional linear maps $ad_{\mathcal{A}} \circ h(\cdot)$ and $ad_{h,\mathcal{A}}(\cdot)$ defined via $f(\cdot,\cdot)$ by

$$ad_{\mathcal{A}} \circ h(v')u = ad_{\mathcal{A}}(u)h(v') = [u, h(v')]_{\mathcal{A}} = f(u,v'), \tag{4.57}$$

$$ad_{h,\mathcal{A}}(v)u' = ad_{\mathcal{A}} \circ h(u')v = f(v,u'), \tag{4.58}$$

for all u, v in $\mathcal{A}$, and all u', v' in $\mathcal{A}'$. Let $h^T(\cdot)$ denote the adjoint map of $h(\cdot)$ from $\mathcal{A}$ into $\mathcal{A}'$ defined in the natural manner with respect to the inner products on $\mathcal{A}$ and $\mathcal{A}'$. This gives a bilinear map $f^T(\cdot,\cdot)=[\cdot,h^T(\cdot)]_{\mathcal{A}'}$ from $\mathcal{A}'\times\mathcal{A}$ into $\mathcal{A}'$. Now, introduce the associated linear maps $ad_{\mathcal{A}'}\circ h^T(\cdot)$ and $ad_{h,\mathcal{A}'}(\cdot)$, defined via $f^T(\cdot,\cdot)$ by

$$ad_{\mathcal{A}'}\circ h^T(v)u'=ad_{\mathcal{A}'}(u')h^T(v)=[u',h^T(v)]_{\mathcal{A}'}=f^T(u',v), \tag{4.59}$$

$$ad_{h,\mathcal{A}'}(v')u=ad_{\mathcal{A}'}\circ h^T(u)v'=f^T(v',u), \tag{4.60}$$

for all u, v in $\mathcal{A}$, and all u', v' in $\mathcal{A}'$.

Similarly, let $ad^T_{\mathcal{A}}(\cdot)$ and $ad^T_{\mathcal{A}'}(\cdot)$ denote the adjoint maps of $ad_{\mathcal{A}}(\cdot)$,$ad_{\mathcal{A}'}(\cdot)$ and define the related adjoints $ad^*_{\mathcal{A}}(\cdot)$ and $ad^*_{\mathcal{A}'}(\cdot)$ by

$$ad^*_{\mathcal{A}}(v)u=ad^T_{\mathcal{A}}(u)v, \quad ad^*_{\mathcal{A}'}(v')u'=ad^T_{\mathcal{A}'}(u')v', \tag{4.61}$$

as well as the analogous adjoint maps $ad^T_{h,\mathcal{A}}(\cdot)$, $ad^T_{h,\mathcal{A}'}(\cdot)$, $ad^*_{h,\mathcal{A}}(\cdot)$, $ad^*_{h,\mathcal{A}'}(\cdot)$ given via

$$ad^*_{h,\mathcal{A}}(u)v=-h^T(ad^*_{\mathcal{A}}(u)v)=-h^T(ad^T_{\mathcal{A}}(v)u)=ad^T_{h,\mathcal{A}}(v)u, \tag{4.62}$$

$$ad^*_{h,\mathcal{A}'}(u')v'=-h(ad^*_{\mathcal{A}'}(u')v')=-h(ad^T_{\mathcal{A}'}(v')u')=ad^T_{h,\mathcal{A}'}(v')u', \tag{4.63}$$

again for all u, v in $\mathcal{A}$, and all u', v' in $\mathcal{A}'$. Since h is a homomorphism of $\mathcal{A}'$ into $\mathcal{A}$, it follows that

$$ad^*_{h,\mathcal{A}}(\cdot)h=-ad^*_{\mathcal{A}'}(h^T(\cdot)). \tag{4.64}$$

The appearance of these adjoint maps is an essential feature in the general non-Abelian algebraic structure of the massless and massive nonlinear theories. Note, we have $ad^*_{\mathcal{A}}(\cdot)=ad_{\mathcal{A}}(\cdot)$ and $ad^*_{\mathcal{A}'}(\cdot)=ad_{\mathcal{A}'}(\cdot)$ if and only if the inner products are invariant with respect to the Lie brackets, which holds whenever $\mathcal{A}$ and $\mathcal{A}'$ are semisimple and the inner products are given by the Cartan–Killing metrics of $\mathcal{A}$ and $\mathcal{A}'$.

Next, we take A, $*Q$ to be $\mathcal{A}$-,$\mathcal{A}'$-valued one-forms and B, $*P$ to be $\mathcal{A}'$-,$\mathcal{A}$-valued two-forms, respectively. For later use in formulating $*Q$, $*P$ geometrically in terms of A, B, we first introduce the following inner product norm on pairs (α,β) consisting of a $\mathcal{A}$-valued two-form α and a $\mathcal{A}'$-valued one-form β:

$$Y_{A,B}((\alpha,\beta),(\alpha,\beta))=(\alpha,\alpha)_{\mathcal{A}}+(\beta,\beta)_{\mathcal{A}'}-2([h(\beta),A]_{\mathcal{A}},*\alpha)_{\mathcal{A}}-([\beta,\beta]_{\mathcal{A}'},*B)_{\mathcal{A}'}, \tag{4.65}$$

where $(\cdot,\cdot)_{\mathcal{A}}$ and $(\cdot,\cdot)_{\mathcal{A}'}$ are extended to act on $\mathcal{A}$-,$\mathcal{A}'$-valued forms via the Hodge inner product. Then let $Y_{A,B}(\cdot)=Y^{\mathrm{T}}_{A,B}(\cdot)$ be the associated symmetric linear map on pairs (α,β).

Finally, we also introduce the following covariant derivative operators:

$$D_A=d+ad_{\mathcal{A}}(A), \tag{4.66}$$

$$D_{*Q}=d+ad_{\mathcal{A}}\circ h(*Q), \tag{4.67}$$

$$D_{A+*Q}=d+ad_{\mathcal{A}}(A+h(*Q)), \tag{4.68}$$

which act on $\mathcal{A}$-valued functions and forms, and

$$D'_{*Q}=d-ad^T_{\mathcal{A}'}(*Q), \tag{4.69}$$

$$D'_A=d-ad^T_{\mathcal{A}'}\circ h^{-1}(A), \tag{4.70}$$

$$D'_{A+*Q}=d-ad^T_{\mathcal{A}'}(h^{-1}(A)+*Q), \tag{4.71}$$

which act on $\mathcal{A}'$-valued functions and forms, where the last two derivative operators are defined only when h is invertible. The Lie-algebra valued curvature two-forms associated with these connections are determined by

$$R_A=dA+\tfrac{1}{2}[A,A]_{\mathcal{A}}, \tag{4.72}$$

$$R'_{*Q}=d*Q+\tfrac{1}{2}[*Q,*Q]_{\mathcal{A}'}, \tag{4.73}$$

which satisfy

$$(D_A)^2=ad_{\mathcal{A}}(R_A), \tag{4.74}$$

$$(D'_{*Q})^2=-ad^T_{\mathcal{A}'}(R'_{*Q}). \tag{4.75}$$

Moreover, note that since h is a homomorphism of $\mathcal{A}'$ into $\mathcal{A}$, we have

$$R_{*Q}=h(R'_{*Q}), \tag{4.76}$$

while from the property that $-ad^T_{\mathcal{A}'}(\cdot)$ is the coadjoint representation of $\mathcal{A}'$, we also have

$$R'_A=-ad^T_{\mathcal{A}'}\circ h^{-1}(R_A) \tag{4.77}$$

since when h^{-1} exists it gives a homomorphism of $\mathcal{A}$ onto $\mathcal{A}'$.

1. Massless theory

In the massless nonlinear theory, the Lie algebra $\mathcal{A}$ is required to be semisimple, and hence

$$ad^*_{\mathcal{A}}(\cdot)=-ad^T_{\mathcal{A}}(\cdot)=ad_{\mathcal{A}}(\cdot), \tag{4.78}$$

with the inner product $(\cdot,\cdot)_{\mathcal{A}}$ given by the Cartan–Killing metric of $\mathcal{A}$. Note that, consequently,

$$ad^T_{\mathcal{A}'}\circ h^T(\cdot)=h^T\circ ad_{\mathcal{A}}\circ h(\cdot) \tag{4.79}$$

and so

$$h^T(D_{*Q}(\cdot))=D'_{*Q}(h^T(\cdot)). \tag{4.80}$$

No further properties are needed on the Lie algebra structure of $\mathcal{A}$, $\mathcal{A}'$. Now the entire theory can be constructed geometrically in terms of the covariant derivatives (4.66), (4.68), (4.69) and curvatures (4.72) and (4.73) along with the linear map (4.65). First, the massless nonlinear field strengths are defined by

$$(*P,*Q)=Y^{-1}_{A,B}(*R_A,*dB), \tag{4.81}$$

where $Y^{-1}_{A,B}(\cdot)$ is the inverse of the linear map $Y_{A,B}(\cdot)$. In terms of these field strengths, the gauge symmetries on A, B are given by

$$\delta_\xi A=D_{A+*Q}\xi, \quad \delta_\xi B=\Gamma'_{*P}\xi, \tag{4.82}$$

for arbitrary $\mathcal{A}$-valued functions ξ on M, and

$$\delta_\chi A=0, \quad \delta_\chi B=D'_{*Q}\chi, \tag{4.83}$$

for arbitrary $\mathcal{A}'$-valued one-forms χ on M. Here $\Gamma'_{*P}(\cdot)$ is a linear map associated with $*P$ by

$$\Gamma'_{*P}=ad^T_{h,\mathcal{A}'}(*P). \tag{4.84}$$

Finally, the Lagrangian is given by

$$L=\tfrac{1}{2}(*P,R_A)_{\mathcal{A}}+\tfrac{1}{2}(*Q,*dB)_{\mathcal{A}'}=\tfrac{1}{2}(*P,*Q)\cdot Y_{A,B}(*P,*Q), \tag{4.85}$$

where $(\alpha,\beta)\cdot(\alpha,\beta)=(\alpha,\alpha)_{\mathcal{A}}+(\beta,\beta)_{\mathcal{A}'}$ for any $\mathcal{A}$-valued forms α, $\mathcal{A}'$-valued forms β. This yields the field equations for A, B:

$$*E_{\mathrm{A}}=D_{A+*Q}*P=0, \quad *E_{\mathrm{B}}=R'_{*Q}=0. \tag{4.86}$$

Thus, on solutions, $*Q$ is a zero-curvature connection, while $*P$ is covariantly curl-free.

From the field strength equation (4.81), $*P$ and $*Q$ have the form

$$P=R_{A+*Q}-R_{*Q}, \quad Q=D'_{*Q}B-\Gamma'_{*P}A. \tag{4.87}$$

Hence, since $R_{*Q}=h(R'_{*Q})=0$ and $ad_{\mathcal{A}}(*P)A=D_{*Q}*P$ on solutions, it respectively follows that

$$P=R_{A+*Q} \tag{4.88}$$

is a curvature, while

$$Q=D'_{*Q}(B-h^T(*P)) \tag{4.89}$$

is a covariant curl, using in addition the algebraic relation

$$ad^T_{h,\mathcal{A}}(\cdot)=h^T\circ ad_{\mathcal{A}}(\cdot). \tag{4.90}$$

Then, the covariant exterior derivatives D'_{*Q} of Q and D_{A+*Q} of P yield

$$D_{A+*Q}P=0 \tag{4.91}$$

and

$$D'_{*Q}Q=0. \tag{4.92}$$

These are the same geometrical expressions as those in the SU(2) case.

Therefore, geometrically, $ad_{\mathcal{A}}(A+h^T(*Q))=A_{\mathrm{YM}}$ is a Yang–Mills connection one-form, whose curvature $ad_{\mathcal{A}}(P)=F_{\mathrm{YM}}$ satisfies the massless Yang–Mills equations $D_{A_{\mathrm{YM}}}*F_{\mathrm{YM}}=0$ and the Bianchi identity $D_{A_{\mathrm{YM}}}F_{\mathrm{YM}}=0$, with $D_{A_{\mathrm{YM}}}=d+ad_{\mathcal{A}}(A_{\mathrm{YM}})$, based on the gauge group associated to the semisimple Lie algebra $\mathcal{A}$.

2. Massive theory

In the massive nonlinear theory, the homomorphism h is required to be a Lie-algebra isomorphism

$$h(\cdot)=\frac{1}{m}\,\mathrm{id}(\cdot) \tag{4.93}$$

so $\mathcal{A}=h(\mathcal{A}')\simeq\mathcal{A}'$, where $m\neq 0$ is the mass, and id is a linear map identifying the vector spaces of $\mathcal{A}$ and $\mathcal{A}'$. But, $\mathcal{A}$ and $\mathcal{A}'$ need not be semisimple here, and there are no further properties

required on the Lie algebra structure of $\mathcal{A}$, $\mathcal{A}'$. Thus, surprisingly, compared to massive Yang–Mills/Freedman–Townsend theory[6] as well as to pure massless Yang–Mills theory, a more general structure group is allowed for the massive nonlinear theory.

First, the massive nonlinear field strengths are defined by

$$(*P,*Q)=Y^{-1}_{A,B}(*R_A,*D'_AB), \tag{4.94}$$

where $Y^{-1}_{A,B}(\cdot)$ is the inverse of the linear map $Y_{A,B}(\cdot)$. In terms of these field strengths, the gauge symmetries on A, B are given by

$$\delta_\xi A=D_{A+*Q}\xi, \quad \delta_\xi B=\Gamma'_{B+*P}\xi, \tag{4.95}$$

for arbitrary $\mathcal{A}$-valued functions ξ on M, and

$$\delta_\chi A=0, \quad \delta_\chi B=D'_{A+*Q}\chi, \tag{4.96}$$

for arbitrary $\mathcal{A}'$-valued one-forms χ on M, where now

$$\Gamma'_{B+*P}=-ad^*_{h,\mathcal{A}'}(*P)+ad_{h,\mathcal{A}'}(B). \tag{4.97}$$

The Lagrangian is given by

$$L=\tfrac{1}{2}(*P+m^2h(B),R_A)_{\mathcal{A}}+\tfrac{1}{2}(*Q,*D'_AB)_{\mathcal{A}'}, \tag{4.98}$$

which yields the field equations for A, B:

$$*E_{\mathrm{A}}=h(D'_{*Q}h^{-1}(*P))+m^2h(Q)=0, \quad *E_{\mathrm{B}}=R'_{*Q}+h^{-1}(P)=0, \tag{4.99}$$

where h^{-1} is the inverse of the isomorphism h,

$$h^{-1}(\cdot)=m\,\mathrm{id}(\cdot)=m^2h^T(\cdot). \tag{4.100}$$

From the field strength equation (4.94), $*P$ and $*Q$ have the form

$$P=R_{A+*Q}-R_{*Q}, \quad Q=D'_{A+*Q}B-\Gamma'_{*P}A. \tag{4.101}$$

Hence, since

$$R_{*Q}=-P \tag{4.102}$$

holds on solutions, it follows that

$$R_{A+*Q}=0 \tag{4.103}$$

and so $A+*Q$ is a zero-curvature connection. Furthermore, from

$$D'_{*Q}h^T(*P)=-Q \tag{4.104}$$

on solutions, and from $\Gamma'_{*P}A=ad^T_{\mathcal{A}'}\circ h^{-1}(A)h^T(*P)$ through the algebraic relation

$$ad^T_{h,\mathcal{A}}(\cdot)=-ad^T_{\mathcal{A}'}\circ h^{-1}(\cdot)h^T \tag{4.105}$$

obtained from the homomorphism equation (4.64), it follows that

$$D'_{A+*Q}(B+h^T(*P))=0 \tag{4.106}$$

and so $B+h^T(*P)$ is covariantly curl-free. Then, the covariant exterior derivatives D'_{*Q} of Q and D_{*Q} of P yield

$$D_{*Q}P=0 \tag{4.107}$$

and

$$D'_{*Q}Q=h^T(ad^T_{\mathcal{A}}(*P)P). \tag{4.108}$$

Therefore, geometrically, $ad_{\mathcal{A}}\circ h(*Q)=A_{\rm YM}$ is a Yang–Mills connection one-form, whose curvature $-ad_{\mathcal{A}}(P)=F_{\rm YM}$ satisfies an adjoint version of the massive Yang–Mills equations

$$*D^T_{A_{\rm YM}}*F_{\rm YM}+m^2A_{\rm YM}=0 \tag{4.109}$$

and the Bianchi identity

$$D^T_{A_{\rm YM}}F_{\rm YM}=0, \tag{4.110}$$

where

$$D^T_{A_{\rm YM}}=d-ad^T_{\mathcal{A}}(A_{\rm YM}). \tag{4.111}$$

In addition, $A_{\rm YM}$ satisfies a nonlinear covariant gauge condition

$$D^T_{A_{\rm YM}}*A_{\rm YM}=-ad^T_{\mathcal{A}}(*F_{\rm YM})F_{\rm YM}. \tag{4.112}$$

Interestingly, this adjoint modification is based on having a non-semisimple Lie algebra $\mathcal{A}$, so that $ad^*_{\mathcal{A}}(\cdot)\neq ad_{\mathcal{A}}(\cdot)$. Its consistency relies on the property that, for any Lie algebra $\mathcal{A}$, $-ad^T_{\mathcal{A}}(\cdot)$ is the coadjoint representation of $\mathcal{A}$. If $\mathcal{A}$ is chosen to be semisimple, then note the standard massive Yang–Mills theory is obtained.

Similarly to the SU(2) case, the non-semisimple massive Yang–Mills theory (4.109) to (4.112) here is equivalent to a non-semisimple massive Freedman–Townsend theory given by the duality

$$A_{\rm YM}=*K_{\rm YM}, \quad mB_{\rm YM}=*F_{\rm YM} \tag{4.113}$$

as follows from the field strength equations (4.102), (4.104), (4.107), and (4.108).

V. DEFORMATION ANALYSIS

Here a systematic determination of the most general nonlinear geometrical deformation will be given for the linear gauge theory of $n\geqslant 1$ vector potentials A^a_μ, $a=1,\ldots,n$, and $n'\geqslant 1$ antisymmetric tensor potentials $B^{a'}_{\mu\nu}$, $a'=1,\ldots,n'$, with a Chern–Simons-type mass term, on a four-dimensional space–time manifold M. The method used is a geometrical version of the field theoretic approach to deformations developed in Refs. 3, 1, and 12.

A. Linear theory

We formulate the linear theory geometrically, using a set of one-forms $A^a=A^a_\mu\,dx^\mu$ and two-forms $B^{a'}=B^{a'}_{\mu\nu}\,dx^\mu\,dx^\nu$. These field variables are regarded as taking values in respective internal vector spaces $\mathcal{A}$, $\mathcal{A}'$ of dimensions n, n'.

To proceed, the only structure we require on the space–time manifold M is the exterior derivative operator d and the Hodge dual $*$ such that $*^2=\pm 1$ where 1 is the identity operator. Hereafter, products of fields will be understood to be wedge products of forms on M (and tensor products with respect to $\mathcal{A}$, $\mathcal{A}'$). Recall, in terms of $*$, there is a standard Hodge inner product on pairs (α,β) of one-forms and two-forms, $(\alpha,\beta)\cdot(\alpha,\beta)=*(\alpha*\alpha)-*(\beta*\beta)$.

The linear field strengths associated with the field variables are given by the $\mathcal{A}$-valued two-form $F^a = dA^a$ and $\mathcal{A}'$-valued three-form $H^{a'} = dB^{a'}$. Then the Lagrangian is given by the following real-valued four-form:

$$\overset{(2)}{L} = \tfrac{1}{2}\delta_{ab}F^a * F^b - \tfrac{1}{2}\delta_{a'b'}H^{a'} * H^{b'} + m_{aa'}F^a B^{b'}, \tag{5.1}$$

where δ_{ab}, $\delta_{a'b'}$ represent components of respective inner products on $\mathcal{A}$, $\mathcal{A}'$, and $m_{aa'}$ represents components of a bilinear form on $\mathcal{A}\times\mathcal{A}'$. We refer to $m_{aa'}$ as the mass tensor. This Lagrangian is invariant to within an exact four-form under the separate Abelian gauge symmetries given by

$$\overset{(0)}{\delta}_\xi A^a = d\xi^a, \quad \overset{(0)}{\delta}_\xi B^{a'} = 0, \tag{5.2}$$

for arbitrary $\mathcal{A}$-valued functions ξ^a, and

$$\overset{(0)}{\delta}_\chi A^a = 0, \quad \overset{(0)}{\delta}_\xi B^{a'} = d\chi^{a'}, \tag{5.3}$$

for arbitrary $\mathcal{A}'$-valued one-forms $\chi^{a'}$. Under variations of the fields A^a and $B^{a'}$, the Lagrangian yields the Euler–Lagrange field equations

$$*\overset{(1)}{E}_{\mathrm{A}}{}^a = d*F^a + m_{a'}{}^a H^{a'} = 0, \tag{5.4}$$

$$*\overset{(1)}{E}_{\mathrm{B}}{}^{a'} = d*H^{a'} + m_a{}^{a'} F^a = 0, \tag{5.5}$$

where $m_{a'}{}^a = \delta^{ab}m_{ba'}$ and $m_a{}^{a'} = \delta^{a'b'}m_{ab'}$ are components of linear maps $m_{\mathcal{A}}(\cdot)$ from $\mathcal{A}$ into $\mathcal{A}'$, and $m_{\mathcal{A}'}(\cdot)$ from $\mathcal{A}'$ into $\mathcal{A}$.

Note, in the case when the mass tensor vanishes, $m_{aa'} = 0$, the fields A^a and $B^{a'}$ are decoupled and the linear theory reduces to massless Abelian Yang–Mills gauge theory for A^a and massless Abelian Freedman–Townsend gauge theory for $B^{a'}$. The field strengths F^a and $H^{a'}$ obviously then describe free massless spin-one and spin-zero fields.

In contrast, in the opposite case when the mass tensor is fully nondegenerate, $m_{aa'} = m\,\delta_{aa'}$ where $\delta_a{}^{a'}$ is a vector-space isomorphism of $\mathcal{A}$ and $\mathcal{A}'$ (and hence $n = n'$), the fields A^a and $B^{a'}$ are coupled through a Chern–Simons mass term. The linear theory then reduces to massive Abelian Yang–Mills/Freedman–Townsend gauge theory, which is the linearization of the nonlinear theory given in Ref. 6. Consequently, the field strengths F^a and $H^{a'}$ together describe free massive spin-one fields, with the mass given by m. (In particular, A^a supplies two of the three spin-one helicity components while $B^{a'}$ supplies the third.)

To continue, we consider the general case with no conditions assumed on the mass tensor. Let $\mathcal{A}_0$ and $\mathcal{A}'_0$ denote the kernels of the maps $m_{\mathcal{A}}(\cdot)$ and $m_{\mathcal{A}'}(\cdot)$, and let $\mathcal{A}_m$ and $\mathcal{A}'_m$ denote the orthogonal complements of these kernels. Note there is a direct sum decomposition, $\mathcal{A} = \mathcal{A}_0 \oplus \mathcal{A}_m$, $\mathcal{A}' = \mathcal{A}'_0 \oplus \mathcal{A}'_m$, with respect to the inner products on the internal vector spaces. Moreover, $\mathcal{A}_m$ and $\mathcal{A}'_m$ are isomorphic vector subspaces, with a common dimension denoted by $0 \leqslant k \leqslant n, n'$.

Fix a basis for these vector subspaces so that the fields A^a and $B^{a'}$ belong to $\mathcal{A}_0$ and $\mathcal{A}'_0$ for $a = a' = 1,\ldots,k$ and belong to $\mathcal{A}_m$ and $\mathcal{A}'_m$ for $a = k+1,\ldots,n$, $a' = k+1,\ldots,n'$. Then, physically speaking, it follows from the linear field equations that the field strengths F^a and $H^{a'}$ given by $a = a' = 1,\ldots,k$, together describe a set of k free massive spin-one fields with mass equal to the nonzero eigenvalues of $m_{aa'}$, while the remaining field strengths F^a and $H^{a'}$ given by $a = k+1,\ldots,n$ and $a' = k+1,\ldots,n'$ describe separate sets of $n-k$ free massless spin-one fields and $n'-k$ free massless spin-zero fields, respectively.

B. Determining equations for nonlinear deformations

We now consider nonlinear deformations of the linear Abelian gauge theory for A^a and $B^{a'}$, with the deformation terms being locally constructed in a geometrical manner from the fields by using only the exterior derivative d and Hodge dual $*$ on M. Here, a deformation consists of adding linear and higher power terms to the Abelian gauge symmetries (5.2) and (5.3),

$$\delta_\xi A^a = \overset{(0)}{\delta}_\xi A^a + \overset{(1)}{\delta}_\xi A^a + \cdots, \quad \delta_\xi B^{a'} = \overset{(0)}{\delta}_\xi B^{a'} + \overset{(1)}{\delta}_\xi B^{a'} + \cdots, \tag{5.6}$$

and

$$\delta_\chi A^a = \overset{(0)}{\delta}_\chi A^a + \overset{(1)}{\delta}_\chi A^a + \cdots, \quad \delta_\chi B^{a'} = \overset{(0)}{\delta}_\chi B^{a'} + \overset{(1)}{\delta}_\chi B^{a'} + \cdots, \tag{5.7}$$

while simultaneously adding quadratic and higher power terms to the linear field equations (5.4) and (5.5),

$$E_{\mathrm{A}}{}^a = \overset{(1)}{E}_{\mathrm{A}}{}^a + \overset{(2)}{E}_{\mathrm{A}}{}^a + \cdots, \quad E_{\mathrm{B}}{}^{a'} = \overset{(1)}{E}_{\mathrm{B}}{}^{a'} + \overset{(2)}{E}_{\mathrm{B}}{}^{a'} + \cdots, \tag{5.8}$$

such that there exists a locally constructed Lagrangian four-form that is gauge invariant to within an exact four-form. The condition of gauge invariance is expressed by

$$\delta_\xi L = \overset{(0)\ (2)}{\delta}_\xi L + \overset{(1)\ (2)}{\delta}_\xi L + \overset{(0)\ (3)}{\delta}_\xi L + \cdots = d\Theta_\xi, \tag{5.9}$$

$$\delta_\chi L = \overset{(0)\ (2)}{\delta}_\chi L + \overset{(1)\ (2)}{\delta}_\chi L + \overset{(0)\ (3)}{\delta}_\chi L + \cdots = d\Theta_\chi, \tag{5.10}$$

holding for some locally constructed three-forms Θ_ξ and Θ_χ, where the Lagrangian is related to the field equations through

$$\delta L = \delta A^a * E_{\mathrm{A}}{}^b \delta_{ab} + \delta B^{a'} * E_{\mathrm{B}}{}^{b'} \delta_{a'b'} + d\Gamma, \tag{5.11}$$

holding for some locally constructed three-form Γ, under arbitrary variations δA^a, $\delta B^{a'}$.

For writing down deformation terms and analyzing the deformation equations, a precise formal setting is provided by the field space $\mathcal{S}=\{(A^a(x), B^{a'}(x))\}$ defined as the set of all sections of the vector bundle of $\mathcal{A}$-valued one-forms and $\mathcal{A}'$-valued two-forms on M. Hereafter, geometrically, a field variation $(\delta A^a,\ \delta B^{a'})$ is regarded as a vector field on $\mathcal{S}$ while field equations $(E^A{}_a,\ E^B{}_{a'})$ are regarded as a covector field on $\mathcal{S}$, where $E^{\mathrm{A}}{}_a$, $E^{\mathrm{B}}{}_{a'}$ are related to $E_{\mathrm{A}}{}^a$, $E_{\mathrm{B}}{}^{a'}$ by

$$\delta_{ab} * E_{\mathrm{A}}{}^a \cdot \delta A^b = \delta A^a \rfloor E^{\mathrm{A}}{}_a, \quad \delta_{a'b'} * E_{\mathrm{A}}{}^{a'} \cdot \delta B^{b'} = \delta B^{a'} \rfloor E^{\mathrm{B}}{}_{a'}. \tag{5.12}$$

Here the hook $\rfloor$ denotes interior product of a vector field with a covector field on $\mathcal{S}$. Associated to $\mathcal{S}$ is the jet space defined using local coordinates

$$J^{(\infty)}(\mathcal{S}) = (x, A^a, B^{a'}, dA^a, dB^{a'}, d*dA^a, d*dB^{a'}, \ldots), \tag{5.13}$$

where x represents a point in M; A^a, dA^a, $d*dA^a, \ldots$, represent the values of the $\mathcal{A}$-valued one-form field $A^a(x)$ and its exterior derivatives at x; and $B^{a'}$, $dB^{a'}$, $d*dB^{a'}, \ldots$, represent the values of the $\mathcal{A}'$-valued two-form field $B^{a'}(x)$ and its exterior derivatives at x. In this setting, a locally constructed function or p-form on M is a function purely of the jet variables $(A^a, B^{a'}, dA^a, dB^{a'}, d*dA^a, d*dB^{a'}, \ldots)$ and their Hodge duals $(*A^a, *B^{a'}, *dA^a, *dB^{a'}, *d*dA^a, *d*dB^{a'}, \ldots)$, up to some finite order. Let ∂_{A^a}, $\partial_{B^{a'}}$, and $\partial_{(d*)^k dA^a}$, $\partial_{(d*)^k dB^{a'}}$, $k=0,1,2,\ldots$, denote derivatives with respect to the jet variables. Note the derivatives ∂_{A^a}, $\partial_{B^{a'}}$

produce covector fields on $\mathcal{S}$. We define contravariant derivatives $\partial^{\flat}_{A^a}$, $\partial^{\flat}_{B^{a'}}$ that produce vector fields on $\mathcal{S}$ via the natural pairing $\partial^{\flat}_{A^a} g \rfloor \partial_{A^a} f = \delta^{ab} \partial_{A^a} g \cdot \partial_{A^b} f$ and $\partial^{\flat}_{B^{a'}} g \rfloor \partial_{B^{a'}} f = \delta^{a'b'} \partial^{\flat}_{B^{a'}} g \cdot \partial_{B^{b'}} f$, for any locally constructed functions f, g. Likewise we define $\partial^{\flat}_{(d*)^k\, dA^a}$, $\partial^{\flat}_{(d*)^k\, dB^{a'}}$. Then, we introduce Euler–Lagrange operators given by

$$E^{\flat}_{A^a} = \partial^{\flat}_{A^a} - \sum_{k\geqslant 0} (*d*)^{k+1} \partial^{\flat}_{(d*)^k\, dA^a}, \quad E^{\flat}_{B^{a'}} = \partial^{\flat}_{B^{a'}} - \sum_{k\geqslant 0} (*d*)^{k+1} \partial^{\flat}_{(d*)^k\, dB^{a'}}. \tag{5.14}$$

These operators take locally constructed functions f into vector fields $(E^{\flat}_{A^a}(f), E^{\flat}_{B^{a'}}(f))$ on $\mathcal{S}$ and have the property that $E^{\flat}_{A^a}(f) = E^{\flat}_{B^{a'}}(f) = 0$ annihilates a locally constructed function f if and only if $*f = d\Gamma$ for some locally constructed three-form Γ. The related operators

$$E^{\sharp}_{A^a} = \partial_{A^a} - \sum_{k\geqslant 0} (*d*)^{\sharp k+1} \partial_{(d*)^k\, dA^a}, \quad E^{\sharp}_{B^{a'}} = \partial_{B^{a'}} - \sum_{k\geqslant 0} (*d*)^{\sharp k+1} \partial_{(d*)^k\, dB^{a'}} \tag{5.15}$$

yield covector fields on $\mathcal{S}$, where $*^{\sharp}$ and $d^{\sharp}$ denote the contravariant Hodge dual operator and contravariant exterior derivative operator on vectors and antisymmetric tensors on M.

The relation between the deformation terms in the field equations and Lagrangian is most naturally expressed through the Euler–Lagrange operators by

$$\overset{(k)}{E}{}^{\mathrm{A}}{}_a = E^{\sharp}_{A^a}(*\overset{(k+1)}{L}), \quad \overset{(k)}{E}{}^{\mathrm{B}}{}_{a'} = E^{\sharp}_{B^{a'}}(*\overset{(k+1)}{L}), \tag{5.16}$$

which determines

$$\overset{(k+1)}{L} = -\frac{1}{k+1}(\overset{(k)}{E}{}_{\mathrm{A}}{}^a A^b \delta_{ab} - \overset{(k)}{E}{}_{\mathrm{B}}{}^{a'} B^{b'} \delta_{a'b'}) \tag{5.17}$$

to within an exact four-form.

In terms of the Euler–Lagrange operators, the condition for existence of a gauge-invariant Lagrangian is equivalent to the equations

$$E^{\flat}_{A^a}(\delta_\xi A^a \cdot *E_{\mathrm{A}}{}^b \delta_{ab} + \delta_\xi B^{a'} \cdot *E_{\mathrm{B}}{}^{b'} \delta_{a'b'}) = 0, \tag{5.18}$$

$$E^{\flat}_{A^a}(\delta_\chi A^a \cdot *E_{\mathrm{A}}{}^b \delta_{ab} + \delta_\chi B^{a'} \cdot *E_{\mathrm{B}}{}^{b'} \delta_{a'b'}) = 0, \tag{5.19}$$

$$E^{\flat}_{B^{a'}}(\delta_\xi A^a \cdot *E_{\mathrm{A}}{}^b \delta_{ab} + \delta_\xi B^{a'} \cdot *E_{\mathrm{B}}{}^{b'} \delta_{a'b'}) = 0, \tag{5.20}$$

$$E^{\flat}_{B^{a'}}(\delta_\chi A^a \cdot *E_{\mathrm{A}}{}^b \delta_{ab} + \delta_\chi B^{a'} \cdot *E_{\mathrm{B}}{}^{b'} \delta_{a'b'}) = 0. \tag{5.21}$$

These four equations are the determining system for all allowed deformations.

Remark: To proceed, we restrict attention to deformations that involve at most one derivative of A^a, $B^{a'}$, ξ^a, $\chi^{a'}$ in the gauge symmetries and at most two derivatives of A^a, $B^{a'}$ in the field equations. Such deformations automatically preserve the number of gauge degrees of freedom and initial-data degrees of freedom in the nonlinear theory to be the same as those in the linear theory. Also, we consider only nontrivial deformations such that the field equations and gauge symmetries in the nonlinear theory are not equivalent to those in the linear theory by a change either of field variables or of gauge symmetry variables (see Ref. 3).

The determining system can be reformulated more usefully and geometrically as Lie derivative equations. We introduce the Lie derivative $\mathcal{L}_\delta$ with respect to a vector field $(\delta A^a, \delta B^{a'})$ on $\mathcal{S}$ acting on a locally constructed covector field $(f^{\mathrm{A}}_a, f^{\mathrm{B}}_{a'})$ by

$$(\mathcal{L}_\delta f)^{\mathrm{A}}_a = \left(\delta A^b \rfloor \partial_{A^b} f^{\mathrm{A}}_a + \delta B^{b'} \rfloor \partial_{B^{b'}} f^{\mathrm{A}}_a + \sum_{k\geqslant 0} (d*)^k\, d\,\delta A^b \rfloor \partial_{(d*)^k\, dA^b} f^{\mathrm{A}}_a + (d*)^k\, d\,\delta B^{b'} \rfloor \partial_{(d*)^k\, dB^{b'}} f^{\mathrm{A}}_a \right)$$
$$- \left(\partial_{A^a} \delta A^b \rfloor f^{\mathrm{A}}_b + \partial_{A^a} \delta B^{b'} \rfloor f^{\mathrm{B}}_{b'} - \sum_{k\geqslant 0} (*d*)^{\sharp k+1} (\partial_{(d*)^k\, dA^a} \delta A^b \rfloor f^{\mathrm{A}}_b + \partial_{(d*)^k\, dA^a} \delta B^{b'} \rfloor f^{\mathrm{B}}_{b'}) \right), \tag{5.22}$$

$$(\mathcal{L}_\delta f)^{\mathrm{B}}_{a'} = \left(\delta A^b \rfloor \partial_{A^b} f^{\mathrm{B}}_{a'} + \delta B^{b'} \rfloor \partial_{B^{b'}} f^{\mathrm{B}}_{a'} + \sum_{k\geqslant 0} (d*)^k\, d\,\delta A^b \rfloor \partial_{(d*)^k\, dA^b} f^{\mathrm{B}}_{a'} + (d*)^k\, d\,\delta B^{b'} \rfloor \partial_{(d*)^k\, dB^{b'}} f^{\mathrm{B}}_{a'} \right)$$
$$- \left(\partial_{B^{a'}} \delta A^b \rfloor f^{\mathrm{A}}_b + \partial_{B^{a'}} \delta B^{b'} \rfloor f^{\mathrm{B}}_{b'} - \sum_{k\geqslant 0} (*d*)^{\sharp k+1} (\partial_{dB^{a'}} \delta A^b \rfloor f^{\mathrm{A}}_b + \partial_{dB^{a'}} \delta B^{b'} \rfloor f^{\mathrm{B}}_{b'}) \right). \tag{5.23}$$

Theorem 1: *Local gauge invariance holds if and only if the Lie derivative of the field equations with respect to the gauge symmetries vanishes*

$$\mathcal{L}_{\delta_\xi}(E^{\mathrm{A}}{}_a, E^{\mathrm{B}}{}_{a'}) = 0, \quad \mathcal{L}_{\delta_\chi}(E^{\mathrm{A}}{}_a, E^{\mathrm{B}}{}_{a'}) = 0. \tag{5.24}$$

Geometrically, these equations assert that the gauge symmetries are vector fields tangential to the surface in $\mathcal{S}$ corresponding to the field equations. Due to gauge invariance, the commutators of these vector fields have the same property.

Theorem 2: *Local gauge invariance holds only if the Lie derivative of the field equations with respect to the gauge symmetry commutators vanishes*

$$\mathcal{L}_{[\delta_{\xi_1}, \delta_{\xi_2}]}(E^{\mathrm{A}}{}_a, E^{\mathrm{B}}{}_{a'}) = 0, \quad \mathcal{L}_{[\delta_{\chi_1}, \delta_{\chi_2}]}(E^{\mathrm{A}}{}_a, E^{\mathrm{B}}{}_{a'}) = 0, \quad \mathcal{L}_{[\delta_{\xi_1}, \delta_{\chi_1}]}(E^{\mathrm{A}}{}_a, E^{\mathrm{B}}{}_{a'}) = 0. \tag{5.25}$$

An expansion of these equations in powers of A^a and $B^{a'}$ (and their derivatives) gives a hierarchy of determining equations whose solutions yield all allowed deformation terms in the field equations and gauge symmetries. We now find the solution of these determining equations explicitly at the lowest orders to give all first-order deformations and then outline an induction analysis to obtain a uniqueness result for the higher-order deformations.

C. First-order deformations and uniqueness of higher-order deformations

Up to a change of field variables and gauge symmetry variables, the most general possible first-order deformation terms for the gauge symmetries are given by

$$\overset{(1)}{\delta}_\xi A^a = a^a{}_{bc} A^b \xi^c + b^a{}_{b'c} * H^{b'} \xi^c + c^a{}_{b'c} * (B^{b'}\, d\xi^c) + \tilde{c}^a{}_{b'c} * (*B^{b'}\, d\xi^c), \tag{5.26}$$

$$\overset{(1)}{\delta}_\xi B^{a'} = d^{a'}{}_{b'c} B^{b'}\, \xi^c + \tilde{d}^{a'}{}_{b'c} * B^{b'}\, \xi^c + e^{a'}{}_{bc} F^b \xi^c + \tilde{e}^{a'}{}_{bc} * F^b \xi^c + f^{a'}{}_{bc} * (A^b\, d\xi^c), \tag{5.27}$$

with

$$e^{a'}{}_{[bc]} = f^{a'}{}_{[bc]} = 0, \tag{5.28}$$

and by

$$\overset{(1)}{\delta}_\chi A^a = g^a{}_{b'c'} * (B^{b'}\chi^{c'}) + \tilde{g}^a{}_{b'c'} * (*B^{b'}\chi^{c'}) + h^a{}_{bc'} * (F^b\chi^{c'}) + \tilde{h}^a{}_{bc'} * (*F^b\chi^{c'}) + i^a{}_{bc'} A^b * d * \chi^{c'} + \tilde{i}^a{}_{bc'} (*d*A^b)\chi^{c'}, \tag{5.29}$$

$$\overset{(1)}{\delta}_\chi B^{a'} = j^{a'}{}_{bc'} A^b \chi^{c'} + \tilde{j}^{a'}{}_{bc'} * (A^b\chi^{c'}) + k^{a'}{}_{b'c'} * H^{b'}\chi^{c'} + \tilde{k}^{a'}{}_{b'c'} * (*H^{b'}\chi^{c'}) + l^{a'}{}_{b'c'} * d * (B^{b'}\chi^{c'}) + \tilde{l}^{a'}{}_{b'c'} * d * (*B^{b'}\chi^{c'}) + m^{a'}{}_{bc'} B^{b'} * d * \chi^{c'} + \tilde{m}^{a'}{}_{bc'} * B^{b'} * d * \chi^{c'}, \tag{5.30}$$

where the coefficients are constants, which represent the components of bilinear maps from $\mathcal{A}\times\mathcal{A}$, $\mathcal{A}\times\mathcal{A}'$, $\mathcal{A}'\times\mathcal{A}$, $\mathcal{A}'\times\mathcal{A}'$ into $\mathcal{A}$ and $\mathcal{A}'$. These coefficients are determined by solving the zeroth-order part of the Lie derivative commutator equation from Theorem 2 (using the methods of Refs. 3 and 12). This yields the linear algebraic relations

$$a_{a(bc)} = 0, \quad f_{a'(bc)} = 0, \tag{5.31}$$

$$l_{a'b'c'} = \tilde{l}_{a'b'c'} = m_{a'b'c'} = \tilde{m}_{a'b'c'} = 0, \quad g_{ab'c'} = \tilde{g}_{ab'c'} = 0, \tag{5.32}$$

$$c_{ab'c} = \tilde{c}_{ab'c} = 0, \quad \tilde{j}_{a'bc'} = \tilde{d}_{a'cb'} = 0, \quad d_{a'b'c} + j_{a'cb'} = 0. \tag{5.33}$$

Additional linear algebraic relations arise from the first-order part of the Lie derivative equation from Theorem 1 applied to the rigid symmetries

$$(\delta_\xi)_{\text{rigid}} = \delta_\xi|_{d\xi=0}, \quad (\delta_\chi)_{\text{rigid}} = \delta_\chi|_{d\chi=0} \tag{5.34}$$

given by restricting the gauge symmetry variables so that $d\xi^a = d\chi^{a'} = 0$. This leads to (by the methods of Refs. 3 and 12)

$$\tilde{e}_{a'bc} + b_{ba'c} = 0, \tag{5.35}$$

$$m_a{}^{a'} j_{a'cb'} - m_{b'}{}^b a_{bac} = 0, \quad a_{(ab)c} - m_{(b}{}^{b'} b_{a)b'c} = 0, \quad j_{(a'|c|b')} - m_{(a'}{}^a b_{|a|b')c} = 0, \tag{5.36}$$

$$k_{(a'b')e'} = 0, \quad m_a{}^{a'} k_{a'b'c'} + j_{b'ac'} = 0, \tag{5.37}$$

$$h_{abc'} = \tilde{h}_{abc'} = 0, \quad \tilde{k}_{a'b'c'} = 0. \tag{5.38}$$

Then, we return to the first-order part of the Lie derivative equation with ξ^a and $\chi^{a'}$ now taken to be arbitrary, which determines the first-order deformation terms in the field equations (by the methods of Ref. 1). This yields

$$\overset{(2)}{*E}{}_A{}^a = d * (\tfrac{1}{2} a^a{}_{bc} A^b A^c + b^a{}_{b'c} * H^{b'} A^c) - a_{cb}{}^a A^b * F^c - b_{cb'}{}^a * H^{b'} F^c + (2F^b * H^{c'} - A^b d * H^{c'}) e^{a'}{}_{bc} + j_{b'}{}^a{}_{c'} * H^{b'} B^{c'} - m_{c'}{}^c a_{cb}{}^a A^b B^{c'}, \tag{5.39}$$

$$\overset{(2)}{E}{}_B{}^{a'} = d * (j^{a'}{}_{bc'} A^b B^{c'} - k^{a'}{}_{b'c'} * H^{b'} B^{c'} + b_b{}^{a'}{}_c * F^b A^c) + \tfrac{1}{2} k_{b'c'}{}^{a'} * H^{b'} * H^{c'} - d(A^b * F^c) e^{a'}{}_{bc} - j_{c'b}{}^{a'} A^b * H^{c'} + m_a{}^{a'} a^a{}_{bc} A^b A^c, \tag{5.40}$$

together with the linear algebraic relation

$$m_{(a|}{}^{a'} e_{a'b|c)} + m_b{}^{b'} e_{b'ac} = 0. \tag{5.41}$$

The corresponding Lagrangian is given by

$$\overset{(3)}{L} = \tfrac{1}{2} a_{abc} * F^a A^b A^c + j_{a'bc'} * H^{a'} A^b B^{c'} + b_{ab'c} * F^a * H^{b'} A^c - \tfrac{1}{2} k_{a'b'c'} * H^{a'} * H^{b'} B^{c'}$$
$$- e_{a'bc} * H^{a'} F^b A^c + \tfrac{1}{2} m_{aa'} a^a{}_{bc} B^{a'} A^b A^c. \tag{5.42}$$

These deformation terms are related to the deformation terms in the gauge symmetries (as follows from general results in Ref. 3) by being the Noether currents of the rigid symmetries associated to the first-order deformed gauge symmetries

$$\overset{(1)}{\delta}_\xi A^a = a^a{}_{bc} A^b \xi^c + b^a{}_{b'c} * H^{b'} \xi^c, \tag{5.43}$$

$$\overset{(1)}{\delta}_\xi B^{a'} = - j^{a'}{}_{cb'} B^{b'} \xi^c - b_b{}^{a'}{}_c * F^b \xi^c + e^{a'}{}_{bc} F^b \xi^c, \tag{5.44}$$

$$\overset{(1)}{\delta}_\chi A^a = 0, \tag{5.45}$$

$$\overset{(1)}{\delta}_\chi B^{a'} = j^{a'}{}_{bc'} A^b \chi^{c'} + k^{a'}{}_{b'c'} * H^{b'} \chi^{c'}. \tag{5.46}$$

In particular, we have $*d(\overset{(2)}{E}{}_{\rm A}{}^a \xi^b \delta_{ab}) = (\overset{(1)}{\delta}_\xi A^a)_{\rm rigid} \rfloor \overset{(1)}{E}{}^{\rm A}{}_a$ and $*d(\overset{(2)}{E}{}_{\rm B}{}^{a'} \chi^{b'} \delta_{a'b'}) = (\overset{(1)}{\delta}_\xi B^{a'})_{\rm rigid} \rfloor \overset{(1)}{E}{}^{\rm B}{}_{a'}$, where $d\xi^b = d\chi^{b'} = 0$.

We next note that, from (5.43) to (5.46),

$$[\overset{(0)}{\delta}_{\xi_1}, \delta_{\xi_2}] = \overset{(0)}{\delta}_{\xi_3}, \quad \xi_3{}^a = a^a{}_{bc} \xi_1{}^b \xi_2{}^c, \tag{5.47}$$

$$[\overset{(0)}{\delta}_{\chi_1}, \delta_{\chi_2}] = 0, \tag{5.48}$$

$$[\overset{(0)}{\delta}_{\xi_1}, \delta_{\chi_2}] = \overset{(0)}{\delta}_{\chi_3}, \quad \chi_3{}^{a'} = j^{a'}{}_{bc'} \xi_1{}^b \chi_2{}^{c'}. \tag{5.49}$$

Now we consider the first-order part of the Lie derivative commutator equation from Theorem 2 and subtract the first-order part of the Lie derivative equation from Theorem 1 with the gauge symmetry variables given by the commutators (5.47)–(5.49). This combined equation leads to the result (by the methods of Refs. 3 and 12) that the gauge symmetry commutators are closed to first-order when $A^a, B^{a'}$ satisfy the linear field equations $\overset{(1)}{E}{}_{\rm A}{}^a = 0$ and $\overset{(1)}{E}{}_{\rm B}{}^{a'} = 0$. Then if the gauge symmetry variables are taken to be rigid, $d\xi_1{}^a = d\xi_2{}^a = 0$ and $d\chi_1{}^{a'} = d\chi_2{}^{a'} = 0$, we obtain an integrability condition involving just the first-order deformation terms,

$$([\overset{(1)}{\delta}_{\xi_1}, \overset{(1)}{\delta}_{\xi_2}])_{\rm rigid} A^a - (\overset{(1)}{\delta}_{\xi_3})_{\rm rigid} A^a = d\, \overset{(1)}{\xi}{}^a_{(\xi_1,\xi_2)}, \quad ([\overset{(1)}{\delta}_{\xi_1}, \overset{(1)}{\delta}_{\xi_2}])_{\rm rigid} B^{a'} - (\overset{(1)}{\delta}_{\xi_3})_{\rm rigid} B^{a'} = d\, \overset{(1)}{\chi}{}^{a'}_{(\xi_1,\xi_2)}, \tag{5.50}$$

$$([\overset{(1)}{\delta}_{\chi_1}, \overset{(1)}{\delta}_{\chi_2}])_{\rm rigid} A^a = d\, \overset{(1)}{\xi}{}^a_{(\chi_1,\chi_2)}, \quad ([\overset{(1)}{\delta}_{\chi_1}, \overset{(1)}{\delta}_{\chi_2}])_{\rm rigid} B^{a'} = d\, \overset{(1)}{\chi}{}^{a'}_{(\chi_1,\chi_2)}, \tag{5.51}$$

$$([\overset{(1)}{\delta}_{\xi_1}, \overset{(1)}{\delta}_{\chi_2}])_{\rm rigid} A^a - (\overset{(1)}{\delta}_{\chi_3})_{\rm rigid} A^a = d\, \overset{(1)}{\xi}{}^a_{(\xi_1,\chi_2)}, \quad ([\overset{(1)}{\delta}_{\xi_1}, \overset{(1)}{\delta}_{\chi_2}])_{\rm rigid} B^{a'} - (\overset{(1)}{\delta}_{\chi_3})_{\rm rigid} B^{a'} = d\, \overset{(1)}{\chi}{}^{a'}_{(\xi_1,\chi_2)}, \tag{5.52}$$

which hold for some locally constructed $\mathcal{A}$-valued functions $\overset{(1)}{\xi}{}^{a}_{(\cdot,\cdot)}$ and $\mathcal{A}'$-valued one-forms $\overset{(1)}{\chi}{}^{a'}_{(\cdot,\cdot)}$ depending linearly on $\xi_1{}^a, \xi_2{}^a, \chi_1{}^{a'}, \chi_2{}^{a'}$. The solution of these six equations (using the methods of Ref. 12) yields the quadratic algebraic relations

$$a_{adb}a^{b}{}_{ec} - 2a_{ab[c|}a^{b}{}_{d|e]} = 0, \tag{5.53}$$

$$2a_{ab[c}b^{b}{}_{|d'|e]} - b_{ad'b}a^{b}{}_{ec} + 2b_{ab'[c|}b^{db'}{}_{|e]}m_{d'd} - 2b_{ab'[c|}j^{b'}{}_{|e]d'} = 0, \tag{5.54}$$

$$j_{a'be'}a^{b}{}_{dc} - 2j_{a'[d|b'}j^{b'}{}_{|c]e'} = 0, \tag{5.55}$$

plus three others that are redundant as a consequence of (5.36) and (5.37).

Another integrability condition arises for the first-order deformation terms if we consider the second-order part of the Lie derivative equation from Theorem 1 under the previous conditions imposed on $A^a, B^{a'}, \xi^a, \chi^{a'}$. Contracting this equation with $(A^a, B^{a'})$, we obtain

$$(\overset{(1)}{\delta}{}_{\xi})_{\text{rigid}}A^{a}\rfloor\overset{(2)}{E}{}^{\mathrm{A}}{}_{a} + (\overset{(1)}{\delta}{}_{\xi})_{\text{rigid}}B^{a'}\rfloor\overset{(2)}{E}{}^{\mathrm{B}}{}_{a'} = d\overset{(3)}{\Theta}{}_{\xi}, \tag{5.56}$$

$$(\overset{(1)}{\delta}{}_{\chi})_{\text{rigid}}A^{a}\rfloor\overset{(2)}{E}{}^{\mathrm{A}}{}_{a} + (\overset{(1)}{\delta}{}_{\chi})_{\text{rigid}}B^{a'}\rfloor\overset{(2)}{E}{}^{\mathrm{B}}{}_{a'} = d\overset{(3)}{\Theta}{}_{\chi}, \tag{5.57}$$

holding for some locally constructed three-forms $\Theta_{(3)\xi}, \Theta_{(3)\chi}$ which depend linearly on $\xi^a, \chi^{a'}$. The solution of these two equations (again using the methods of Ref. 12) yields the additional quadratic algebraic relations

$$k_{[a'b'|c'}k^{c'}{}_{|d']e'} = 0, \tag{5.58}$$

$$b_{ab'c}k_{d'e'}{}^{b'} - 2b_{a[d'|b}b^{b}{}_{|e']c} = 0, \tag{5.59}$$

$$2e_{a'(b|c}a^{c}{}_{|d)e} - e_{c'bd}j^{c'}{}_{ea'} - 2e_{a'c(d}m_{b)b'}b^{cb'}{}_{e} = 0, \tag{5.60}$$

plus others that reduce to combinations of (5.53) to (5.55) through (5.36) and (5.37). Moreover, the quadratic relation (5.55) itself is a consequence of (5.58) and (5.37).

It can be shown that the integrability relations (5.53)–(5.55) are necessary and sufficient to allow solving for the second order deformation terms in the gauge symmetries from the first-order part of the Lie derivative commutator equation in Theorem 2. The additional integrability relations (5.58)–(5.60) are necessary in then solving the second-order part of the Lie derivative equation from Theorem 1 for the second order deformation terms in the field equations. However, it is found that a solution exists if and only if the following additional algebraic relation holds on the coefficients of the field equation deformation terms,

$$k_{d'e'}{}^{c'}e_{c'ab} - 2e_{[d'|ca}b^{c}{}_{|e']b} - 2e_{[d'|cb}b^{c}{}_{|e']a} = 0. \tag{5.61}$$

This relation imposes in effect a further integrability relation on allowed first-order deformations.

Theorem 3: *Up to a change of field variables and gauge symmetry variables, all first-order geometrical deformations are given by Eqs. (5.43)–(5.46), Eqs. (5.39) and (5.40), with the coefficients satisfying the linear relations (5.36) and (5.37) and the quadratic relations (5.53)–(5.55) and (5.58)–(5.61). There are no further algebraic obstructions to the existence of second-order geometrical deformations.*

These first-order deformations have the following classification: the a_{abc} terms represent a massless Yang–Mills self-coupling of A^a, the $k_{a'b'c'}$ terms represent a massless Freedman–Townsend self-coupling of $B^{a'}$, and the $b_{ab'c}$ terms represent an extended Freedman–Townsend coupling between A^a and $B^{a'}$, while the $j_{a'bc'}$ terms represent a Higgs-type coupling of $B^{a'}$ to A^a

which is nontrivial only when the mass tensor $m_{aa'}$ is nonzero. The $e_{a'bc}$ terms, in contrast, represent a different type of coupling between A^a and $B^{a'}$ unrelated to Yang–Mills and Freedman–Townsend type couplings. It is similar in form to the coupling known for one-form and two-form fields in extended supergravity theory.[13,14] Moreover, the deformation corresponding to the $e_{a'bc}$ terms is characterized by possessing opposite parity compared to the parity of the other deformation terms. In particular, consider the parity operator $\mathcal{P}$ defined by $d\mathcal{P}=\mathcal{P}d$, $*\mathcal{P}=-\mathcal{P}*$. If we assign even parity to A^a and odd parity to $B^{a'}$,

$$\mathcal{P}A^a=A^a, \quad \mathcal{P}B^{a'}=-B^{a'}, \tag{5.62}$$

which thus determines

$$\mathcal{P}*F^a=-F^a, \quad \mathcal{P}*H^{a'}=H^{a'}, \tag{5.63}$$

and

$$\mathcal{P}\xi^a=\xi^a, \quad \mathcal{P}\chi^{a'}=-\chi^{a'}, \tag{5.64}$$

then it follows that all the deformation terms except for the $e_{a'bc}$ terms have even parity.

To proceed, we now consider the uniqueness of the higher-order deformation terms determined by the first-order terms in Theorem 3. Let $\Delta\overset{(k+1)}{E}_{\mathrm{A}}{}^a$, $\Delta\overset{(k+1)}{E}_{\mathrm{B}}{}^{a'}$, $\Delta\overset{(k)}{\delta}_\xi A^a$, $\Delta\overset{(k)}{\delta}_\chi A^a$, $\Delta\overset{(k)}{\delta}_\xi B^{a'}$, $\Delta\overset{(k)}{\delta}_\chi B^{a'}$ denote the difference of any two deformations that agree up to some given order $k\geqslant 1$. Then the $k+1$st-order part of the Lie derivative equation from Theorem 1 yields

$$\overset{(0)}{\delta}_\xi\Delta\overset{(k+2)}{E}_{\mathrm{A}}{}^a=\overset{(0)}{\delta}_\chi\Delta\overset{(k+2)}{E}_{\mathrm{A}}{}^a=0, \quad \overset{(0)}{\delta}_\xi\Delta\overset{(k+2)}{E}_{\mathrm{B}}{}^{a'}=\overset{(0)}{\delta}_\chi\Delta\overset{(k+2)}{E}_{\mathrm{B}}{}^{a'}=0. \tag{5.65}$$

Similarly, the kth order part of the Lie derivative commutator equation from Theorem 2 yields the result that, after a change of field variables and gauge symmetry variables,

$$\overset{(0)}{\delta}_{\xi_2}\Delta\overset{(k+1)}{\delta}_{\xi_1}A^a=\overset{(0)}{\delta}_{\chi_2}\Delta\overset{(k+1)}{\delta}_{\xi_1}A^a=0, \quad \overset{(0)}{\delta}_{\xi_2}\Delta\overset{(k+1)}{\delta}_{\chi_1}A^a=\overset{(0)}{\delta}_{\chi_2}\Delta\overset{(k+1)}{\delta}_{\chi_1}A^a=0, \tag{5.66}$$

$$\overset{(0)}{\delta}_{\xi_2}\Delta\overset{(k+1)}{\delta}_{\xi_1}B^{a'}=\overset{(0)}{\delta}_{\chi_2}\Delta\overset{(k+1)}{\delta}_{\xi_1}B^{a'}=0, \quad \overset{(0)}{\delta}_{\xi_2}\Delta\overset{(k+1)}{\delta}_{\chi_1}B^{a'}=\overset{(0)}{\delta}_{\chi_2}\Delta\overset{(k+1)}{\delta}_{\chi_1}B^{a'}=0. \tag{5.67}$$

Under the assumptions on the number of derivatives considered for possible deformation terms (see Remark in Sec. V B), the solution of Eqs. (5.65)–(5.67) is immediately given by

$$\Delta\overset{(k+2)}{E}_{\mathrm{A}}{}^a=0, \quad \Delta\overset{(k+2)}{E}_{\mathrm{B}}{}^{a'}=0, \quad k\geqslant 1, \tag{5.68}$$

$$\Delta\overset{(k+1)}{\delta}_\xi A^a=\Delta\overset{(k+1)}{\delta}_\chi A^a=0, \quad \Delta\overset{(k+1)}{\delta}_\xi B^{a'}=\Delta\overset{(k+1)}{\delta}_\chi B^{a'}=0, \quad k\geqslant 1. \tag{5.69}$$

Hence, we have established the following uniqueness result.

Theorem 4: *If two deformations agree at all orders* $1\leqslant l\leqslant k$, $\Delta\overset{(l+1)}{E}_{\mathrm{A}}{}^a=\Delta\overset{(l+1)}{E}_{\mathrm{B}}{}^{a'}=0$, $\Delta\overset{(l)}{\delta}_\xi A^a=\Delta\overset{(l)}{\delta}_\chi A^a=0$, $\Delta\overset{(l)}{\delta}_\xi B^{a'}=\Delta\overset{(l)}{\delta}_\chi B^{a'}=0$, *then up to a change of field variables and gauge symmetry variables, the deformations also agree at order* $l=k+1$.

D. Deformations to all orders

Hereafter we restrict attention to parity-invariant and opposite-parity deformations separately and proceed to write down a complete deformation to all orders in each case. A full discussion of the combined parity non-invariant deformations from Theorem 3 is given in Ref. 15.

For a deformation determined at first-order purely by the $e_{a'bc}$ terms, note that the linear algebraic relations (5.28) and (5.41) imply

$$m_{a'}{}^{a}e^{a'}{}_{bc}=0 \tag{5.70}$$

and hence the $e_{a'bc}$ terms are incompatible with a nonzero mass tensor. However, in the massless case, the $e_{a'bc}$ terms produce a nontrivial deformation, which we now write down to all orders.

The algebraic structure on $\mathcal{A},\mathcal{A}'$ associated to $e^{a'}{}_{bc}$ consists of a symmetric product from $\mathcal{A}\times\mathcal{A}$ into $\mathcal{A}'$. Then the gauge symmetries are given by

$$\delta_\xi A^a=d\xi^a,\quad \delta_\xi B^{a'}=e^{a'}{}_{bc}F^b\xi^c, \tag{5.71}$$

$$\delta_\chi A^a=0,\quad \delta_\chi B^{a'}=d\chi^{a'}, \tag{5.72}$$

while the Lagrangian is constructed by

$$L=\tfrac{1}{2}F^a{*}F^b\delta_{ab}-\tfrac{1}{2}H^{a'}{*}H^{b'}\delta_{a'b'}-{*}H^{a'}F^bA^ce_{a'bc}+\tfrac{1}{2}F^bA^c{*}(F^dA^e)e^{a'}{}_{bc}e_{a'de}. \tag{5.73}$$

It is straightforward to see that this Lagrangian is gauge invariant, $\delta_\xi L=\delta_\chi L=0$, and that the gauge symmetries commute, $[\delta_{\xi_1},\delta_{\xi_2}]=[\delta_{\chi_1},\delta_{\chi_2}]=[\delta_{\xi_1},\delta_{\chi_2}]=0$. From the Lagrangian, the field equations are given by

$$E_{\mathrm{A}}{}^{a}=d{*}F^a+(2F^b{*}H^{c'}-A^bd{*}H^{c'})e_{c'b}{}^{a}-(2F^b{*}(F^cA^d)+A^bd{*}(F^cA^d))e^{a'}{}_{cd}e_{a'b}{}^{a}=0, \tag{5.74}$$

$$E_{\mathrm{B}}{}^{a'}=d(*H^{a'}-{*}(F^bA^c))e^{a'}{}_{bc}=0. \tag{5.75}$$

Theorem 5: *The massless nonlinear theory (5.71)–(5.75) is the unique nonlinear geometrical deformation of the Abelian linear theory (5.1)–(5.5) determined by the first-order deformation terms* $e_{a'bc}$.

Next we consider a general deformation determined at first-order by all terms except $e_{a'bc}$. This deformation is more general than the massless/massive nonlinear theories constructed in Secs. II and III, since it includes a mixing of massless and massive fields $A^a,B^{a'}$, controlled by the eigenvalues of the mass tensor $m_{aa'}$.

Let $a^a{}_{bc},b^a{}_{b'c},j^{a'}{}_{bc'},k_{a'b'}{}^{c'}$ be the components of respective bilinear maps from $\mathcal{A}\times\mathcal{A}$ into $\mathcal{A}$, $\mathcal{A}'\times\mathcal{A}$ into $\mathcal{A}$, $\mathcal{A}\times\mathcal{A}'$ into $\mathcal{A}'$, $\mathcal{A}'\times\mathcal{A}'$ into $\mathcal{A}'$, fixed to satisfy the linear and quadratic relations (5.36) and (5.37), (5.53)–(5.55), (5.58), and (5.59). Thus, it follows that $a^a{}_{bc}$ and $k_{a'b'}{}^{c'}$ define the commutator structure constants (5.53) and (5.58) of respective Lie algebras on $\mathcal{A},\mathcal{A}'$, while $j^{a'}{}_{bc'}$ and $b^a{}_{b'c}$ define linear maps that are representations (5.55) and (5.59) of these Lie algebras on the vector spaces of $\mathcal{A}',\mathcal{A}$, respectively. Further discussion of the additional algebraic structure imposed by the relations (5.36), (5.37), (5.54) is given in the next section.

To write down the deformation to all orders, we first define a Yang–Mills field strength two-form and a related antisymmetric tensor field strength three-form by

$$F^a_A=dA^a+\tfrac{1}{2}a^a{}_{bc}A^bA^c,\quad H^{a'}_A=dB^{a'}+j^{a'}{}_{bc'}A^bB^{c'}. \tag{5.76}$$

Geometrically, F^a_A is the curvature of the connection one-form $a^a{}_{bc}A^b$, and $H^{a'}_A$ is the covariant curl of $B^{a'}$ in terms of the associated connection $j^{a'}{}_{bc'}A^b$. Consequently, using the covariant exterior derivative operators given by

$$D_A=d+a^a{}_{bc}A^b,\quad D'_A=d+j^{a'}{}_{bc'}A^b, \tag{5.77}$$

we have

$$D'_A B^{a'} = H_A^{a'}, \tag{5.78}$$

$$[D_A, D_A] = a^a{}_{bc} F_A^b, \quad [D'_A, D'_A] = j^{a'}{}_{bc'} F_A^b, \tag{5.79}$$

due to the algebraic structure (5.53) and (5.55). Next we define a nonlinear field strength two-form P^a and three-form Q^a by the equations

$$P^a - *Q^{b'} A^c b^a{}_{b'c} = F_A^a, \tag{5.80}$$

$$Q^{a'} - *P^b A^c b_b{}^{a'}{}_c - *Q^{b'} B^{c'} k^{a'}{}_{b'c'} = H_A^{a'}. \tag{5.81}$$

These field strengths are nonpolynomial expressions in terms of $A^a, B^{a'}$, as given by

$$(P^a, Q^{a'}) = Y^{-1}{}_{A,B}(F_A^a, H_B^{a'}), \tag{5.82}$$

where $Y^{-1}{}_{A,B}$ is the inverse of the linear map

$$Y_{A,B} = \begin{pmatrix} \mathrm{id} & A^b b^a{}_{c'b} * \\ -A^b b_c{}^{a'}{}_b * & \mathrm{id} - B^{b'} k^{a'}{}_{c'b'} * \end{pmatrix} \tag{5.83}$$

defined to act on the vector space of pairs of $\mathcal{A}$-valued two-forms, $\mathcal{A}'$-valued three-forms.

Now we write down the deformation, using the previous structure. The gauge symmetries on $A^a, B^{a'}$ are given by the field variations

$$\delta_\xi A^a = D_A \xi^a + b^a{}_{b'c} * Q^{b'} \xi^c, \tag{5.84}$$

$$\delta_\xi B^{a'} = -j^{a'}{}_{cb'} B^{b'} \xi^c - b_b{}^{a'}{}_{c} * P^b \xi^c, \tag{5.85}$$

$$\delta_\chi A^a = 0, \tag{5.86}$$

$$\delta_\chi B^{a'} = D'_A \chi^{a'} + k^{a'}{}_{b'c'} * Q^{b'} \chi^{c'}, \tag{5.87}$$

where ξ^a is an arbitrary $\mathcal{A}$-valued function, and $\chi^{a'}$ is an arbitrary $\mathcal{A}'$-valued one-form. The Lagrangian four-form for $A^a, B^{a'}$ is constructed by

$$L = \tfrac{1}{2} * P^a F_A^b \delta_{ab} + \tfrac{1}{2} * Q^{a'} H^{b'}{}_A \delta_{a'b'} + F_A^a B^{b'} m_{ab'}. \tag{5.88}$$

Gauge invariance of this Lagrangian is established as follows.

The variation of L under the gauge symmetry δ_ξ yields

$$\begin{aligned} \delta_\xi L = {} & m_{ab'} (D_A \delta_\xi A^a B^{b'} + F_A^a \delta_\xi B^{b'}) + *P^e (D_A \delta_\xi A^a + b^a{}_{b'c} * Q^{b'} \delta_\xi A^c) \delta_{ae} \\ & + *Q^{e'} (D'_A \delta_\xi B^{a'} + j^{a'}{}_{bc'} \delta_\xi A^b B^{c'} + \tfrac{1}{2} k^{a'}{}_{b'c'} * Q^{b'} \delta_\xi B^{c'}) \delta_{a'e'}. \end{aligned} \tag{5.89}$$

To proceed, collecting all terms $d\xi^c$ we obtain $-(*P^b b_{ba'c} + B^{b'} m_{bb'} b^b{}_{a'c}) * Q^{a'} d\xi^c$. Next we integrate by parts and use the field strength equations (5.76), (5.80), (5.81) to eliminate $dA^a, dB^{a'}$ algebraically in terms of $P^a, Q^{a'}, A^a, B^{a'}$. This yields terms of the type $P^a * P^b \xi^c$, $Q^{a'} * Q^{b'} \xi^c$, $*Q^{a'} * Q^{b'} * P^c \xi^d$, $*P^a * Q^{b'} A^c \xi^d$, $*Q^{a'} * Q^{b'} B^{c'} \xi^d$. Then we find that the coefficients of these terms vanish, respectively, due to the algebraic relations (5.36), (5.59), (5.54), (5.55). Hence, it follows that

$$\delta_\xi L = d((b_{ba'c} P^b + m_{bb'} b^b{}_{a'c} B^{b'}) * Q^{a'} \xi^c). \tag{5.90}$$

Similarly, under the gauge symmetry δ_χ, the variation of L is given by

$$\delta_\chi L = m_{ab'} F^a_A \delta_\chi B^{b'} + *Q^{e'}(D'_A \delta_\chi B^{a'} + \tfrac{1}{2} k^{a'}{}_{b'c'} * Q^{b'} \delta_\chi B^{c'})\delta_{a'e'}. \tag{5.91}$$

Proceeding as before, we find that all $d\chi^{c'}$ terms yield $(-\frac{1}{2} * Q^{a'} * Q^{b'} k_{a'b'c'} + F^a_A m_{ac'}) d\chi^{c'}$. An integration by parts and use of the field strength equations (5.76), (5.80), and (5.81) leaves terms of the type $*Q^{a'} P^b \chi^{c'}$, $*Q^{a'} * Q^{b'} * Q^{c'} \chi^{d'}$, $*Q^{a'} * Q^{b'} A^c \chi^{d'}$, $P^a A^b \chi^{c'}$, $A^a A^b * Q^{c'} \chi^{d'}$. Then we find that the coefficients of these terms vanish, respectively, due to the algebraic relations (5.37), (5.58), (5.55), (5.36). Hence, it follows that

$$\delta_\chi L = d((\tfrac{1}{2} k_{a'b'c'} * Q^{a'} * Q^{b'} + m_{ac'} F^a_A)\chi^{c'}. \tag{5.92}$$

Proposition: The Lagrangian (5.88) *is invariant to within an exact four-form (5.90) and (5.92) under the gauge symmetries (5.84)–(5.87).*

The field equations for $A^a, B^{a'}$ are given by

$$E_{\mathrm{A}}{}^a = D_A * P^a + (b^a{}_{c'b} m_c{}^{c'} A^b - b_{cb'}{}^a * Q^{b'}) * P^c + Q^{b'} m_{b'}{}^a = 0, \tag{5.93}$$

$$E_{\mathrm{B}}{}^{a'} = D'_A * Q^{a'} + \tfrac{1}{2} k_{b'c'}{}^{a'} * Q^{b'} * Q^{c'} - b_c{}^{a'}{}_b m_{c'}{}^c A^b * Q^{c'} + P^b m_b{}^{a'} = 0. \tag{5.94}$$

On solutions of these field equations, the gauge symmetries on $A^a, B^{a'}$ have the commutator structure

$$[\delta_{\xi_1}, \delta_{\xi_2}] = \delta_{\xi_3}, \quad [\delta_{\chi_1}, \delta_{\chi_2}] = 0, \quad [\delta_{\xi_1}, \delta_{\chi_2}] = \delta_{\chi_3}, \tag{5.95}$$

where

$$\xi_3{}^a = a^a{}_{bc} \xi_1{}^b \xi_2{}^c, \quad \chi_3{}^{a'} = j^{a'}{}_{bc'} \xi_1{}^b \chi_2{}^{c'}. \tag{5.96}$$

Off solutions, the commutator structure remains closed to within trivial symmetries proportional to the field equations

$$\delta_E A^a = 2 b^{ab'}{}_{[c|} b_{db'|e]} \xi_1{}^c \xi_2{}^e * E_{\mathrm{A}}{}^d - b^{ab'}{}_c k_{b'd'e'} \xi_1{}^c * (\chi_2{}^{e'} E_{\mathrm{B}}{}^{d'}), \tag{5.97}$$

$$\begin{aligned}\delta_E B^{a'} = {} & 2 b^{a'b}{}_{[c|} b_{bd'|e]} \xi_1{}^c \xi_2{}^e * E_{\mathrm{B}}{}^{d'} + k^{a'b'}{}_{e'} b_{db'c} \xi_1{}^c \chi_2{}^{e'} * E_{\mathrm{A}}{}^d - k^{a'b'}{}_{c'} k_{b'd'e'} \chi_1{}^{c'} * (\chi_2{}^{e'} E_{\mathrm{B}}{}^{d'}) \\ & + k^{a'b'}{}_{e'} k_{b'd'c'} \chi_2{}^{e'} * (\chi_1{}^{c'} E_{\mathrm{B}}{}^{d'}).\end{aligned} \tag{5.98}$$

Theorem 6: *The nonlinear theory (5.84)–(5.94) is the unique nonlinear geometrical deformation of the Abelian linear theory (5.1)–(5.5) determined by the first-order deformation terms* $a^a{}_{bc}, b^a{}_{b'c}, j^{a'}{}_{bc'}, k^{a'}{}_{b'c'}$.

We remark that the pure massless/massive SU(2) case of this theory, given by

$$a^a{}_{bc} = \epsilon_{bc}{}^a, \quad b^a{}_{b'c} = \lambda \epsilon_{b'c}{}^a, \quad j^{a'}{}_{bc'} = \epsilon_{bc'}{}^{a'}, \quad k^{a'}{}_{b'c'} = \lambda \epsilon_{b'c'}{}^{a'} \tag{5.99}$$

(where $a, a', \ldots = 1,2,3$) with $\lambda = 1/m$ and $m = \mathrm{const} \neq 0$ in the massive case, and $\lambda = \mathrm{const} \neq 0$ in the massless case, yields the SU(2) theories from Secs. II and III.

E. Algebraic structure in the nonlinear theory

Finally, we discuss the full algebraic structure on $\mathcal{A}, \mathcal{A}'$ underlying the nonlinear theory (5.84)–(5.94) given by the general parity-invariant deformation.

We start from the vector space decompositions $\mathcal{A} = \mathcal{A}_0 \oplus \mathcal{A}_m$ and $\mathcal{A}' = \mathcal{A}'_0 \oplus \mathcal{A}'_m$ into massless and massive subspaces defined by the mass tensor $m_{aa'}$. Let $\mathcal{P}_0, \mathcal{P}_m, \mathcal{P}'_0, \mathcal{P}'_m$ be the respective

projection operators onto these subspaces in $\mathcal{A},\mathcal{A}'$. Thus we have $m_{\mathcal{A}}(u_0)=m_{\mathcal{A}'}(v'_0)=0$ and $u'_{\rm m}=m_{\mathcal{A}}(u_m)\neq 0$, $v_m=m_{\mathcal{A}'}(v'_{\rm m})\neq 0$, with subscripts denoting subspace projections for all u,v in $\mathcal{A}$ and u',v' in $\mathcal{A}'$. Let $(u,v)_{\mathcal{A}}=u^a v^b \delta_{ab}$ and $(u',v')_{\mathcal{A}'}=u'^a v'^b \delta_{a'b'}$ denote the vector space inner products on $\mathcal{A},\mathcal{A}'$. We denote the Lie algebra multiplication $a^a{}_{bc}u^b v^c$ and $k_{b'c'}{}^{a'}u'^b v'^c$ on $\mathcal{A}$ and $\mathcal{A}'$ by the brackets $[u,v]_{\mathcal{A}}$ and $[u',v']_{\mathcal{A}'}$. In addition we denote the Lie algebra representations $j^{a'}{}_{bc'}u^b$ and $b^a{}_{b'c}u'^b$ by the linear maps $\rho'(u)$ and $\rho(u')$. Similarly, $ad_{\mathcal{A}}(u)$ and $ad_{\mathcal{A}'}(u')$ denote the adjoint representations given by $a^a{}_{bc}u^b$ and $k_{b'c'}{}^{a'}u'^b$ on $\mathcal{A}$ and $\mathcal{A}'$.

We begin by noting Eqs. (5.58) and (5.59) show that ρ' is a derivation of the Lie algebra $\mathcal{A}'$,

$$\rho'(w)[u',v']_{\mathcal{A}'}=[\rho'(w)u',v']_{\mathcal{A}'}+[u',\rho'(w)v']_{\mathcal{A}'}, \tag{5.100}$$

for all w in $\mathcal{A}$, $u'v'$ in $\mathcal{A}'$.

We now consider the additional algebraic structure imposed by the algebraic relations (5.36) and (5.37). To proceed, first note that, by Eq. (5.37),

$$\rho'(u_0)=0, \quad \rho'(u_m)=ad_{\mathcal{A}'}(m_{\mathcal{A}}(u_m)), \tag{5.101}$$

which completely determines ρ' in terms of the adjoint representation of $\mathcal{A}'$. Next, by Eq. (5.36), it follows that

$$m_{\mathcal{A}}([u,v]_{\mathcal{A}})=[m_{\mathcal{A}}(u),m_{\mathcal{A}}(v)]_{\mathcal{A}'}. \tag{5.102}$$

Hence, $\mathcal{A}'_m$ is a Lie subalgebra of $\mathcal{A}'$, and $\mathcal{A}_0$ is an invariant Lie subalgebra of $\mathcal{A}$, namely $[\mathcal{A}'_m,\mathcal{A}'_m]\subseteq\mathcal{A}'_m$, $[\mathcal{A},\mathcal{A}_0]\subseteq\mathcal{A}_0$. Furthermore, it also follows from Eq. (5.36) that

$$(u_0,[v_0,w]_{\mathcal{A}})_{\mathcal{A}}=-(v_0,[u_0,w]_{\mathcal{A}})_{\mathcal{A}} \tag{5.103}$$

and thus the inner product on $\mathcal{A}$ is an invariant metric with respect to the massless subspace $\mathcal{A}_0$. Consequently, since $\mathcal{A}_0$ is a Lie subalgebra, it must be a direct sum of an Abelian Lie algebra $\mathcal{A}_0^c$ and a semisimple Lie algebra $\mathcal{A}_0^s$. However, the inner product is not required to be invariant with respect to the whole Lie algebra $\mathcal{A}$, since

$$(u,[v,w]_{\mathcal{A}})_{\mathcal{A}}+(v,[u,w]_{\mathcal{A}})_{\mathcal{A}}=(u,\rho(m_{\mathcal{A}}(v))w)_{\mathcal{A}}+(v,\rho(m_{\mathcal{A}}(u))w)_{\mathcal{A}}, \tag{5.104}$$

which need not vanish for u,v in $\mathcal{A}_m$. Thus, surprisingly, $\mathcal{A}$ need not be semisimple unless its massive subspace $\mathcal{A}_m$ is empty. Moreover, the inner product on the Lie algebra $\mathcal{A}'$ likewise is not required to be invariant except on the massless subspace $\mathcal{A}'_0$,

$$(u'_0,[v'_0,w']_{\mathcal{A}'})_{\mathcal{A}'}=-(v'_0,[u'_0,w']_{\mathcal{A}'})_{\mathcal{A}'}, \tag{5.105}$$

since, by Eq. (5.37),

$$(u',[v',m_{\mathcal{A}}(w)]_{\mathcal{A}'})_{\mathcal{A}'}+(v',[u',m_{\mathcal{A}}(w)]_{\mathcal{A}'})_{\mathcal{A}'}=(u',m_{\mathcal{A}}(\rho(v')w))_{\mathcal{A}'}+(v',m_{\mathcal{A}}(\rho(u')w))_{\mathcal{A}'}, \tag{5.106}$$

which need not vanish for u',v' in $\mathcal{A}'_m$. Hence, as $\mathcal{A}'_m$ is a Lie subalgebra, it need not be semisimple and therefore, again, the whole Lie algebra $\mathcal{A}'$ is not required to be semisimple unless its massive subspace $\mathcal{A}'_m$ is empty.

Finally, we consider the remaining algebraic relation (5.54). This imposes further structure on the Lie algebras $\mathcal{A},\mathcal{A}'$, and on the representation ρ as follows. We first examine, separately, the pure massless case $m_{aa'}=0$ and pure massive case $m_{aa'}=m\delta_{aa'}$, $m\neq 0$.

In the massless case,

$$\mathcal{A}=\mathcal{A}_0, \quad \mathcal{A}'=\mathcal{A}'_0, \tag{5.107}$$

and so $\mathcal{A}$ and $\mathcal{A}'$ are each a direct sum of Abelian Lie algebras $\mathcal{A}^c,\mathcal{A}'^c$ and semisimple Lie algebras $\mathcal{A}^s,\mathcal{A}'^s$, respectively. Now, Eq. (5.54) reduces to

$$\rho(w')[u,v]_{\mathcal{A}}=[\rho(w')u,v]+[u,\rho(w')v], \tag{5.108}$$

which states that the linear map ρ is a derivation of the Lie algebra $\mathcal{A}'$. Since the quotient of $\mathcal{A}'$ by its center $\mathcal{A}'^c$ is semisimple, ρ must take the form

$$\rho(w')=ad_{\mathcal{A}}(h(w')) \tag{5.109}$$

for some linear map h from $\mathcal{A}'$ into $\mathcal{A}$. It then follows that

$$[h(u'),h(v')]_{\mathcal{A}}=h([u',v']_{\mathcal{A}'}). \tag{5.110}$$

Hence, the kernel of h is an invariant Lie subalgebra of $\mathcal{A}'$. As a consequence of the decomposition $\mathcal{A}'=\mathcal{A}'^c\oplus\mathcal{A}'^s$, any such subalgebra must belong to $\mathcal{A}'^c$. Furthermore, the image of h is a Lie subalgebra of $\mathcal{A}$ isomorphic to $\mathcal{A}'^s$. Hence, $h(\mathcal{A}'^s)\subseteq\mathcal{A}^s$ yields a Lie algebra homomorphism. This now fully describes the structure imposed on $\mathcal{A}$ and $\mathcal{A}'$ by the algebraic relations (5.36) and (5.37), (5.53)–(5.55), (5.58), and (5.59) in the massless case.

In the massive case, note

$$\mathcal{A}=\mathcal{A}_m, \quad \mathcal{A}'=\mathcal{A}'_m \tag{5.111}$$

are isomorphic as vector spaces under the map $m_{\mathcal{A}'}(\mathcal{A}'_m)=m\,\mathrm{id}(\mathcal{A}'_m)=m\mathcal{A}_m$. Since this map is a Lie algebra homomorphism by Eq. (5.102), then $\mathcal{A}$ and $\mathcal{A}'$ are isomorphic Lie algebras. Consequently, Eq. (5.54) becomes

$$\begin{aligned}&[\rho_m(w)u,v]_{\mathcal{A}}+[u,\rho_m(w)v]_{\mathcal{A}}-\rho_m(w)[u,v]_{\mathcal{A}}\\&\quad=\rho_m(\rho_m(w)u)v-\rho_m(\rho_m(w)v)u-\rho_m([w,u]_{\mathcal{A}})v+\rho_m([w,v]_{\mathcal{A}})u,\end{aligned} \tag{5.112}$$

where $\rho_m(w)=\rho(m_{\mathcal{A}}(w))$. Taking into account Eq. (5.36), the relation (5.112) states that the linear map on $\mathcal{A}$ defined by

$$\tilde{\rho}_m(u)v=\rho_m(v)u-ad_{\mathcal{A}}(v)u \tag{5.113}$$

must be a skew-adjoint representation of the Lie algebra $\mathcal{A}$,

$$(u,\tilde{\rho}_m(w)v)_{\mathcal{A}}=-(v,\tilde{\rho}_m(w)u)_{\mathcal{A}}, \quad [\tilde{\rho}_m(u),\tilde{\rho}_m(v)]=\tilde{\rho}_m([u,v]_{\mathcal{A}}). \tag{5.114}$$

This is satisfied if $\rho_m=ad_{\mathcal{A}}$, in which case $\tilde{\rho}_m=0$ is a trivial representation, or if $\rho_m=0$, in which case $\tilde{\rho}_m=-ad^T_{\mathcal{A}}$ is the coadjoint representation. In either case, there is no further algebraic structure imposed by Eq. (5.112). Note then, surprisingly, $\mathcal{A}$ is thus not required to be semisimple in massive case with $\rho_m=ad_{\mathcal{A}}$.

To conclude the discussion, we return to the general situation when $\mathcal{A}$ and $\mathcal{A}'$ contain both massless and massive nonempty subspaces. In this case, from Eq. (5.54), it follows that

$$\begin{aligned}&[\rho(w')u,v]_{\mathcal{A}}+[u,\rho(w')v]_{\mathcal{A}}-\rho(w)[u,v]_{\mathcal{A}}\\&\quad=\rho(m_{\mathcal{A}}(\rho(w')u))v-\rho(m_{\mathcal{A}}(\rho(w')v))u-\rho([w',m_{\mathcal{A}}(u)]_{\mathcal{A}'})v+\rho([w',m_{\mathcal{A}}(v)]_{\mathcal{A}'})u.\end{aligned} \tag{5.115}$$

We now show that this equation is satisfied by

$$\rho(w')=ad_{\mathcal{A}}(h(w')) \tag{5.116}$$

for some linear map h from $\mathcal{A}'$ into $\mathcal{A}$ if

$$h(m_{\mathcal{A}}(\mathcal{A}_m))=\mathcal{A}_m, \quad m_{\mathcal{A}}(h(\mathcal{A}'_m))=\mathcal{A}'_m, \quad h(\mathcal{A}'_0)\subseteq\mathcal{A}_0 \tag{5.117}$$

and if

$$[\mathcal{A}_m,\mathcal{A}_m]\subseteq\mathcal{A}_m, \quad [\mathcal{A}_m,\mathcal{A}_0]\subseteq\mathcal{A}_0^c, \quad [ad_{\mathcal{A}_0}(\mathcal{A}_m),ad_{\mathcal{A}_0}(\mathcal{A}_m)]=0, \tag{5.118}$$

where $\mathcal{A}_0^c$ is the center of the Lie algebra $\mathcal{A}$. To begin the proof, first note that if Eq. (5.116) holds then the left-hand side of Eq. (5.115) directly vanishes for any h since $ad_{\mathcal{A}}$ is a derivation of $\mathcal{A}$. Next, from Eq. (5.59), the last two terms on the right-hand side of Eq. (5.115) become

$$\begin{aligned}&-[ad_{\mathcal{A}}(w_m),ad_{\mathcal{A}}(u_m)]v+[ad_{\mathcal{A}}(w_m),ad_{\mathcal{A}}(v_m)]u\\&\quad=-ad_{\mathcal{A}}([w_m,u_m]_{\mathcal{A}})v+ad_{\mathcal{A}}([w_m,v_m]_{\mathcal{A}})u\\&\quad=-[[w_m,u_m]_{\mathcal{A}},v]_{\mathcal{A}}+[[w_m,v_m]_{\mathcal{A}},v]_{\mathcal{A}},\end{aligned} \tag{5.119}$$

where $w_m=m_{\mathcal{A}'}(w')$. Then, by Eq. (5.118), the first two terms on the right-hand side of Eq. (5.115) reduce to

$$ad_{\mathcal{A}}(ad_{\mathcal{A}}(w_m)u_m)v-ad_{\mathcal{A}}(ad_{\mathcal{A}}(w_m)v_m)u=[[w_m,u_m]_{\mathcal{A}},v]_{\mathcal{A}}-[[w_m,v_m]_{\mathcal{A}},u]_{\mathcal{A}}. \tag{5.120}$$

Hence, the right-hand side of Eq. (5.115) vanishes, which completes the proof.

Consequently, note that Eqs. (5.116)–(5.118) determine

$$\rho(w'_m)=ad_{\mathcal{A}_m}(m_{\mathcal{A}'}^{-1}(w'_m)), \quad \rho(w'_0)=ad_{\mathcal{A}_0}(h_0(w'_0)) \tag{5.121}$$

in terms of some linear map $h_0=h\circ\mathcal{P}'_0$ from $\mathcal{A}'_0$ into $\mathcal{A}_0$, and using the inverse $m_{\mathcal{A}'}^{-1}$ from $\mathcal{A}_m$ into $\mathcal{A}'_m$ of the linear map $m_{\mathcal{A}'}\circ\mathcal{P}'_m$. It then follows that

$$m_{\mathcal{A}'}([u',v']_{\mathcal{A}'})=[m_{\mathcal{A}'}(u'),m_{\mathcal{A}'}(v')]_{\mathcal{A}}. \tag{5.122}$$

Hence, $\mathcal{A}'_0$ is an invariant Lie subalgebra of $\mathcal{A}'$, and $\mathcal{A}_m$ is a Lie subalgebra of $\mathcal{A}$. Consequently, since by Eq. (5.105) the inner product on $\mathcal{A}'_0$ is an invariant metric with respect to $\mathcal{A}'$, the Lie subalgebra $\mathcal{A}'_0$ is a direct sum of an Abelian Lie algebra $\mathcal{A}'^c_0$ and a semisimple Lie algebra $\mathcal{A}'^s_0$. Furthermore, from Eq. (5.122), it follows that $\mathcal{A}_m$ and $\mathcal{A}'_m$ are isomorphic Lie algebras, but note that they are not required to be semisimple. This now gives a complete description of the algebraic structure imposed by the relations (5.36) and (5.37), (5.53)–(5.55), (5.58), and (5.59) in the case given by Eqs. (5.116)–(5.118).

Thus, the previous algebraic analysis leads to an interesting generalization of the massless/massive nonlinear theories in Secs. II and III given by the nonlinear theory (5.84)–(5.94) with the following algebraic structure:

(i) The massless and massive subspaces $\mathcal{A}_0,\mathcal{A}'_0,\mathcal{A}_m,\mathcal{A}'_m$ are Lie subalgebras of $\mathcal{A},\mathcal{A}'$ with $\mathcal{A}'_m$ and $\mathcal{A}_m$ being isomorphic under the linear maps $m_{\mathcal{A}},m_{\mathcal{A}'}$ given by the mass tensor.

(ii) $\mathcal{A}_0$ and $\mathcal{A}'_0$ are semisimple Lie algebras and ideals in $\mathcal{A},\mathcal{A}'$, such that $\mathcal{A}_0$ and $\mathcal{A}_m$ commute; however, the Lie algebras $\mathcal{A}_m\simeq\mathcal{A}'_m$ are not restricted to be semisimple (they may be nilpotent or solvable) and $\mathcal{A}'_m$ is not restricted to commute with $\mathcal{A}'_0$.

(iii) The representation ρ' is the adjoint representation of $\mathcal{A}'_m=m_{\mathcal{A}}(\mathcal{A}_m)$ on $\mathcal{A}'$, while the representation ρ is the sum of the adjoint representations of $\mathcal{A}_m=m_{\mathcal{A}'}^{-1}(\mathcal{A}'_m)$ and of $\mathcal{A}_0=h_0(\mathcal{A}'_0)$ on $\mathcal{A}$, for any linear map h_0.

In physical terms, the resulting nonlinear theory (5.84)–(5.94) is a novel generalization of Yang–Mills gauge theory for vector potentials A^a coupled to Freedman–Townsend gauge theory for antisymmetric tensor potentials $B^{a'}$, involving a Chern–Simons-type mass term. It describes a set of nonlinearly interacting massive spin-one fields and massless spin-one and spin-zero fields, with a mutual interaction between the massive and massless fields.

VI. CONCLUDING REMARKS

This paper has developed in detail the geometrical, field theoretic, and algebraic aspects of an interesting nonlinear generalization of massless/massive Yang–Mills/Freedman–Townsend gauge theory in four dimensions. The generalization involves an extended Freedman–Townsend coupling between the Yang–Mills one-form gauge fields and Freedman–Townsend two-form gauge fields, in addition to a Higgs-type coupling tied to a Chern–Simons mass term, and accompanied by a novel form of generalized Yang–Mills and Freedman–Townsend gauge symmetries and field equations in both the massless and massive cases. In particular, the geometrical structure of the resulting nonlinear gauge theory mixes and unifies well-known features of Yang–Mills theory and Freedman–Townsend theory in terms of Lie algebra valued curvatures and connections associated to the gauge fields and nonlinear field strengths.

This generalization was found by a general determination of the geometrical nonlinear deformations of linear Abelian gauge theory for one-form fields and two-form fields with an Abelian Chern–Simons mass term. The deformation framework used here is a geometrical version of the field theoretic approach developed in Refs. 3, 1, and 12. It exposes clearly the existence of two integrability conditions on the first-order parts of possible deformations and leads to a simple uniqueness argument for the higher-order parts of allowed deformations.

Another approach to deformations (see Ref. 4 for an overview), which is based on BRST cohomology,[5,16,17] has recently yielded important results on the classification of allowed first-order deformations of the free gauge theory for a set of p-form fields, $p=1,\ldots,n-1$, in $n\geqslant 2$ dimensions.[7,18] While this classification analysis is complete for massless p-form fields with $p\geqslant 2$ and lists the extended Freedman–Townsend and Yang–Mills types of first-order deformations, it did not explicitly treat deformations of massive p-form fields with the mass given by an Abelian Chern–Simons term in the free gauge theory. Moreover, integrability conditions (i.e., obstructions to the existence of higher-order deformation terms) associated with combining the distinct types of allowed first-order deformations were not obtained for any $p\geqslant 1$. In the case $p\leqslant 2$, these gaps are closed by the deformation results obtained in Sec. V. In particular, a complete classification of first-order geometrical deformations of the free gauge theory for a massive/massless set of one-form and two-form fields has been obtained in $n=4$ dimensions, including all integrability conditions that arise on such deformations (with typical assumptions on the allowed number of derivatives considered for terms in the gauge symmetries and field equations). Also, uniqueness results on deformations to all orders in this setting have been proved. (Interestingly, if the restriction to geometrical deformations is relaxed, then an additional type of deformation is known to exist in the case $p=1$.[19])

There are several directions in which the main results in this paper could be generalized. First, an extension of the general massless/massive nonlinear theory constructed here for Yang–Mills one-form gauge fields coupled to Freedman–Townsend two-form gauge fields with a Chern–Simons mass term in four dimensions is expected to exist in n dimensions, involving a tower of Lie-algebra valued p-form fields $A_{(p)}$, $p=1,\ldots,n-2$, with a Yang–Mills self-coupling on $A_{(1)}$, a Freedman–Townsend self-coupling on $A_{(n-2)}$, and an extended Freedman–Townsend coupling between $A_{(1)},\ldots,A_{(n-2)}$, in addition to a Higgs coupling of $A_{(2)},\ldots,A_{(n-2)}$ with $A_{(1)}$ in the massive case.

Second, it is straightforward to couple such a geometrical nonlinear gauge theory to gravity. In particular, on a space–time with metric tensor g, the only structure needed is the Hodge dual operator $*$ determined by g, and the exterior derivative d operator (which is independent of g). For the case $n=4$ dimensions, if the Lagrangian of the nonlinear gauge theory given in this paper for $A_{(1)}$ and $A_{(2)}$ is combined with the Einstein gravitational Lagrangian for g, then this achieves an interesting generalization of the Einstein–Yang–Mills theory (and there is obvious extension to n dimensions for $A_{(1)},\ldots,A_{(n-2)}$). Of particular interest would be to consider its field theoretic features, such as black hole solutions, non-Abelian monopole solutions, and critical behavior in the initial value problem.

(Received 17 April 2002; accepted 19 November 2002)

The thermodynamic free energy $F(\beta)$ is calculated for a gas consisting of the transverse oscillations of a piecewise uniform bosonic string. The string consists of $2N$ parts of equal length, of alternating type I and type II material, and is relativistic in the sense that the velocity of sound everywhere equals the velocity of light. The present paper is a continuation of two earlier papers, one dealing with the Casimir energy of a $2N$-piece string [I. Brevik and R. Sollie, J. Math. Phys. **38**, 2774 (1997)], and another dealing with the thermodynamic properties of a string divided into two (unequal) parts [I. Brevik, A. A. Bytsenko, and H. B. Nielsen, Class. Quantum Grav. **15**, 3383 (1998)]. Making use of the Meinardus theorem, we calculate the asymptotics of the level state density, and show that the critical temperatures in the individual parts are equal, for arbitrary space–time dimension D. If $D=26$, we find $\beta=(2/N)\sqrt{2\pi/T_{II}}$, T_{II} being the tension in part II. Thermodynamic interactions of parts related to high genus g is also considered. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1540235]

I. INTRODUCTION

Whereas the bosonic string of length L in D-dimensional space–time is assumed to be uniform, the *composite* string is imagined to consist of two or more uniform pieces. In a Casimir context, such a model was introduced in 1990.[1] The string was assumed to be divided into two pieces, of lengths L_I and L_{II}, and the model was relativistic in the sense that the velocity of sound was everywhere required to be equal to the velocity of light. With this contraint imposed on the model, the Casimir energy of the string, i.e., the zero-point energy associated with its discontinuity properties, was easily calculable as a function of the length ratio $s=L_{II}/L_I$. Later, various aspects of the relativistic piecewise uniform string model were studied.[2–12] One may note, for instance, the paper of Lu and Huang[12] in which the model finds application in relation to the Green–Schwarz superstring.

The present article focuses attention on the thermodynamic free energy $F(\beta)$ at inverse temperature $\beta=1/T$ of a $2N$-piece string, made up of $2N$ parts of equal length, of alternating type I and type II material. The model is relativistic, in the sense explained above. In an earlier paper[7] we developed the Casimir theory for a string of this type, whereas in another paper[8] we considered the free energy for the case where the string consists of *two* pieces only, i.e., the model of Ref. 4. The calculation of $F(\beta)$ for a $2N$-piece string has to our knowledge not been undertaken before.

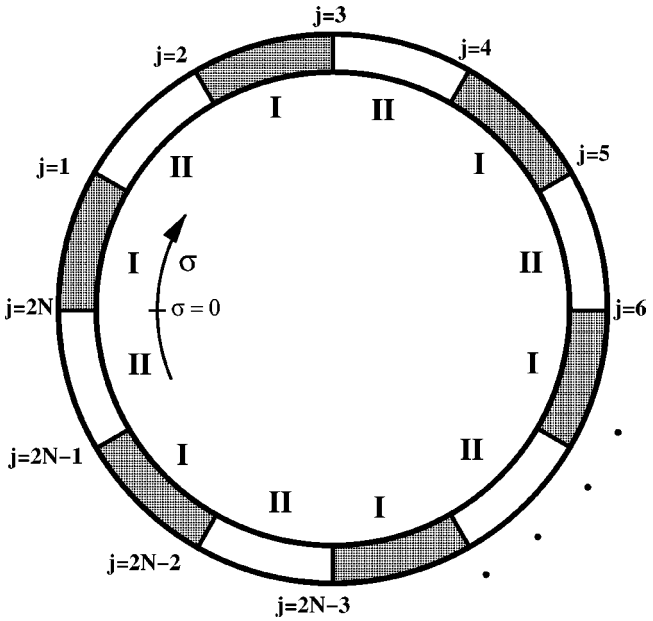

FIG. 1. Sketch of the composite $2N$ string, when $N=6$.

It turns out, similarly as in Ref. 10, that the Meinardus theorem[13–15] is powerful, allowing us to find the asymptotics of the level state density. Using this we find, for a general space–time dimension D, that the critical (Hagedorn) temperatures for the two kinds of pieces are the same. When $D=26$, the common space–time dimension for a bosonic string, we find $\beta_c = (2/N)\sqrt{2\pi/T_{II}}$, T_{II} being the tension in region II. This result is derived in Sec. VI. In Sec. VII, we comment upon the thermodynamic properties of the composite string for arbitrary genus g.

II. RESUMÉ OF THE 2*N*-PIECE STRING THEORY

Assume, as mentioned, that the string of total length L is divided into $2N$ equally large pieces, of alternating type I and type II material; see Fig. 1. The string is relativistic, in the sense that the velocity of sound is everywhere equal to the velocity of light, $v_s=\sqrt{T_I/\rho_I}=\sqrt{T_{II}/\rho_{II}}=c$, where T_I, T_{II} are the tensions and ρ_I, ρ_{II} the mass densities in the two pieces. We will study the transverse oscillations $\psi=\psi(\sigma,\tau)$ of the string, σ denoting as usual the position coordinate and τ the time coordinate of the string. We can thus write in the two regions

$$\begin{aligned}\psi_I &= \xi_I e^{i\omega(\sigma-\tau)} + \eta_I e^{-i\omega(\sigma+\tau)},\\ \psi_{II} &= \xi_{II} e^{i\omega(\sigma-\tau)} + \eta_{II} e^{-i\omega(\sigma+\tau)},\end{aligned} \tag{1}$$

where ξ and η are constants. The junction conditions are that ψ itself as well as the transverse elastic force $T\partial\psi/\partial\sigma$ are continuous, i.e.,

$$\psi_I=\psi_{II}, \quad T_I\partial\psi_I/\partial\sigma = T_{II}\partial\psi_{II}/\partial\sigma, \tag{2}$$

at each of the $2N$ junctions. We define x as the tension ratio, $x=T_I/T_{II}$, and define also the symbols p_N and α by $p_N=\omega L/N$, $\alpha=(1-x)/(1+x)$. Now introduce the matrix Λ,

$$\Lambda(\alpha,p_N)=\begin{pmatrix} a & b \\ b^* & a^* \end{pmatrix}, \tag{3}$$

with

$$a=e^{-ip_N}-\alpha^2, \quad b=\alpha(e^{-ip_N}-1). \tag{4}$$

Then, as shown in Ref. 7, the eigenfrequencies ω are determined from the equation

$$\mathrm{Det}[(1-\alpha^2)^{-N}\Lambda^N(\alpha,p_N)-1]=0. \tag{5}$$

For practical purposes it is convenient to reformulate the condition (5). Let us define two new quantities $\lambda_\pm$:

$$\lambda_\pm(p_N)=\cos p_N-\alpha^2\pm[(\cos p_N-\alpha^2)^2-(1-\alpha^2)^2]^{1/2}. \tag{6}$$

Then, we can reexpress the condition (5) as[7]

$$\lambda_+^N+\lambda_-^N=2(1-\alpha^2)^N. \tag{7}$$

We can now make use of the following recursion formula for the quantity $S_N\equiv\lambda_+^N+\lambda_-^N$:

$$S_N=2(\cos p-\alpha^2)S_{N-1}-(1-\alpha^2)^2S_{N-2}, \quad N\geqslant 2, \tag{8}$$

in which it is assumed that $\omega L/N$ is constant, at all recursive steps. The initial values of S_N are $S_0=2$, $S_1=\lambda_++\lambda_-=2(\cos p-\alpha^2)$.

Assume now that $L=\pi$, in conformity with usual practice. Thus $p_N=\pi\omega/N$. We let $X^\mu(\sigma,\tau)$, with $\mu=0,1,2,...,(D-1)$, specify the coordinates on the world sheet. For each of the eigenvalue branches determined by the dispersion equation (5) we can write X^μ on the form

$$X^\mu=x^\mu+\frac{p^\mu\tau}{\pi T_0}+X_I^\mu, \quad \text{region I}, \tag{9}$$

$$X^\mu=x^\mu+\frac{p^\mu\tau}{\pi T_0}+X_{II}^\mu, \quad \text{region II}, \tag{10}$$

where x^μ is the center-of-mass position, p^μ is the total momentum of the string, and $T_0=\frac{1}{2}(T_I+T_{II})$ is the mean tension. Further, X_I^μ and X_{II}^μ are decomposed into oscillator coordinates,

$$X_I^\mu=\frac{i}{2}\ell_s\sum_{n\neq 0}\frac{1}{n}[\alpha_{nI}e^{i\omega(\sigma-\tau)}+\tilde{\alpha}_{nI}e^{-i\omega(\sigma+\tau)}], \tag{11}$$

$$X_{II}^\mu=\frac{i}{2}\ell_s\sum_{n\neq 0}\frac{1}{n}[\alpha_{nII}e^{i\omega(\sigma-\tau)}+\tilde{\alpha}_{nII}e^{-i\omega(\sigma+\tau)}]. \tag{12}$$

Here, ℓ_s is the fundamental string length, unspecified so far, and $\alpha_n,\tilde{\alpha}_n$ are oscillator coordinates of the right- and left-moving waves, respectively. A characteristic property of the composite string is that the oscillator coordinates have to be specified for each of the various branches determined by Eq. (5). This makes the handling of the formalism complicated, in general. A significant simplification can be obtained if, following Ref. 8, we limit ourselves to the case of extreme string ratios only. Since α occurs quadratically in Eqs. (6) and (7), the eigenvalue spectrum has to be invariant under the transformation $x\to 1/x$. It is sufficient, therefore, to consider the tension ratio interval $0<x\leqslant 1$ only. The case of extreme tensions corresponds to $x\to 0$. We will consider only this case in the following.

III. THE CASE OF EXTREME TENSIONS

We assume that T_{II} has a finite value, so that the limiting case $x\to 0$ corresponds to $T_I\to 0$. Thus $T_0\to\frac{1}{2}T_{II}$. Since now $\alpha\to 1$ we get from Eq. (6) $\lambda_-=0$, $\lambda_+=\cos p_N-1$, so we obtain from

Eq. (7) the remarkable simplification that all the eigenfrequency branches degenerate into one single branch determined by $\cos p_N=1$. That is, the eigenvalue spectrum becomes

$$\omega_n=2Nn, \quad n=\pm 1,\pm 2,\pm 3,\ldots . \tag{13}$$

Then, choosing the fundamental length equal to $\ell_s=(\pi T_I)^{-1/2}$, we can write the expansion (11) in region I as (with subscript I on the α_n's omitted)

$$X_I^\mu=\frac{i}{2\sqrt{\pi T_I}}\sum_{n\neq 0}\frac{1}{n}[\alpha_n^\mu e^{2iNn(\sigma-\tau)}+\tilde{\alpha}_n^\mu e^{-2iNn(\sigma+\tau)}]. \tag{14}$$

The junction conditions (2) permit all waves to propagate from region I to region II. When $x\rightarrow 0$, they reduce to the equations

$$\xi_I+\eta_I=2\xi_{II}=2\eta_{II}, \tag{15}$$

which show that the right- and left-moving amplitudes ξ_I and η_I in region I can be chosen freely and that the amplitudes ξ_{II}, η_{II} in region II are thereafter fixed. This means, in oscillator language, that α_n^μ and $\tilde{\alpha}_n^\mu$ can be chosen freely. The expansion in region II can in view of Eq. (15) be written as

$$X_{II}^\mu=\frac{i}{2\sqrt{\pi T_I}}\sum_{n\neq 0}\frac{1}{n}\gamma_n^\mu e^{-2iNn\tau}\cos(2Nn\sigma), \tag{16}$$

where we have defined γ_n^μ as

$$\gamma_n^\mu=\alpha_n^\mu+\tilde{\alpha}_n^\mu, \quad n\neq 0. \tag{17}$$

The oscillations in region II are thus standing waves. This is the same kind of behavior as that found for the two-piece string.[8]

The action of the string is

$$S=-\frac{1}{2}\int \mathrm{d}\tau\mathrm{d}\sigma T(\sigma)\eta^{\alpha\beta}\partial_\alpha X^\mu\partial_\beta X_\mu, \tag{18}$$

where $\alpha,\beta=0,1$ and $T(\sigma)=T_I$ in region I, $T(\sigma)=T_{II}$ in region II. The momentum conjugate to X^μ is $P^\mu(\sigma)=T(\sigma)\dot{X}^\mu$, and the Hamiltonian is accordingly

$$H=\int_0^\pi [P_\mu(\sigma)\dot{X}^\mu-\mathcal{L}]\mathrm{d}\sigma=\frac{1}{2}\int_0^\pi T(\sigma)(\dot{X}^2+X'^2)\mathrm{d}\sigma, \tag{19}$$

where $\mathcal{L}$ is the Lagrangian.

As for the constraint equation for the string, some care has to be taken. Conventionally, in the classical theory for the uniform string the constraint equation reads $T_{\alpha\beta}=0$, $T_{\alpha\beta}$ being the energy–momentum tensor. As discussed in Ref. 8, the situation is here more complicated, since the junctions restrict the freedom one has to take the variations δX^μ. We thus have to replace the strong condition $T_{\alpha\beta}=0$ by a weaker condition, and the most natural choice, which we will adopt, is to impose that $H=0$ when applied to the physical states.

Let us introduce lightcone coordinates, $\sigma^-=\tau-\sigma$ and $\sigma^+=\tau+\sigma$. The derivatives conjugate to $\sigma^\mp$ are $\partial_\mp=\frac{1}{2}(\partial_\tau\mp\partial_\sigma)$. In region I,

$$\partial_- X^\mu = \frac{N}{\sqrt{\pi T_I}} \sum_{-\infty}^{\infty} \alpha_n^\mu e^{2iNn(\sigma-\tau)},$$
$$\partial_+ X^\mu = \frac{N}{\sqrt{\pi T_I}} \sum_{-\infty}^{\infty} \tilde{\alpha}_n e^{-2iNn(\sigma+\tau)}, \tag{20}$$

and in region II

$$\partial_\mp X^\mu = \frac{N}{2\sqrt{\pi T_I}} \sum_{-\infty}^{\infty} \gamma_n^\mu e^{\pm 2in(\sigma\mp\tau)}, \tag{21}$$

where we have defined

$$\alpha_0^\mu = \tilde{\alpha}_0^\mu = \frac{p^\mu}{NT_{II}} \sqrt{\frac{T_I}{\pi}}, \qquad \gamma_0^\mu = 2\alpha_0^\mu. \tag{22}$$

Inserting these expressions into the Hamiltonian

$$H = \int_0^\pi T(\sigma)(\partial_- X \cdot \partial_- X + \partial_+ X \cdot \partial_+ X)\mathrm{d}\sigma$$
$$= NT_I \int_0^{\pi/(2N)} (\partial_- X \cdot \partial_- X + \partial_+ X \cdot \partial_+ X)\mathrm{d}\sigma$$
$$+ NT_{II} \int_{\pi/(2N)}^{\pi/N} (\partial_- X \cdot \partial_- X + \partial_+ X \cdot \partial_+ X)\mathrm{d}\sigma \tag{23}$$

we get

$$H = \frac{1}{2} N^2 \sum_{-\infty}^{\infty} (\alpha_{-n} \cdot \alpha_n + \tilde{\alpha}_{-n} \cdot \tilde{\alpha}_n) + \frac{N^2}{4x} \sum_{-\infty}^{\infty} \gamma_{-n} \cdot \gamma_n. \tag{24}$$

Now consider the expression for the square M^2 of the mass of the string. One must have $M^2 = -p^\mu p_\mu$, as in the case of a uniform string.[16] We start from the constraint $H=0$ when applied to physical states, making use of Eq. (24) in which we separate out the $n=0$ terms. Using that $\alpha_0 \cdot \alpha_0 = -M^2 x/(\pi N^2 T_{II})$ according to Eq. (22) we obtain in this way, when again observing that $x \ll 1$,

$$M^2 = \pi N^2 T_{II} \sum_{n=1}^{\infty} \left[\alpha_{-n} \cdot \alpha_n + \tilde{\alpha}_{-n} \cdot \tilde{\alpha}_n + \frac{1}{2x} \gamma_{-n} \cdot \gamma_n \right]. \tag{25}$$

The following point ought to be stressed in order to prevent misunderstanding. The reason why we have dealt with the limit of extreme tensions, $x = T_I/T_{II} \to 0$, is merely practical; therewith the eigenvalue branches degenerate into one single branch, Eq. (13). This simplification is however not of fundamental importance; in particular, it has no bearing on the general problem of how to distinguish between the actions for massive and massless particles. We never put T_I exactly equal to zero.

IV. QUANTIZATION

The momentum conjugate to X^μ is at any position on the string equal to $T(\sigma)\dot{X}^\mu$. We accordingly require the commutation rules in region I to be

$$T_I[\dot{X}^\mu(\sigma,\tau), X^\nu(\sigma',\tau)] = -i\,\delta(\sigma-\sigma')\,\eta^{\mu\nu}, \tag{26}$$

and in region II

$$T_{II}[\dot{X}^{\mu}(\sigma,\tau),X^{\nu}(\sigma',\tau)]=-i\,\delta(\sigma-\sigma')\,\eta^{\mu\nu}, \tag{27}$$

$\eta^{\mu\nu}$ being the D-dimensional flat metric. The other commutators vanish. The quantities to be promoted to Fock state operators are $\alpha_{\mp n}$ and $\gamma_{\mp n}$. We insert the expansions for X^{μ} and $\dot{X}^{\mu}$ in regions I and II into Eqs. (26) and (27) and make use of the effective relationship

$$\sum_{n=-\infty}^{\infty} e^{2iNn(\sigma-\sigma')}=2\sum_{n=-\infty}^{\infty}\cos 2Nn\sigma\cos 2Nn\sigma'\rightarrow\frac{\pi}{N}\delta(\sigma-\sigma'). \tag{28}$$

We then get in region I

$$[\alpha_n^{\mu},\alpha_m^{\nu}]=n\,\delta_{n+m,0}\eta^{\mu\nu}, \tag{29}$$

with a similar relation for $\tilde{\alpha}_n$. In region II,

$$[\gamma_n^{\mu},\gamma_m^{\nu}]=4nx\;\delta_{n+m,0}\;\eta^{\mu\nu}. \tag{30}$$

We introduce annihilation and creation operators by

$$\begin{aligned}\alpha_n^{\mu}&=\sqrt{n}\,a_n^{\mu}, \quad \alpha_{-n}^{\mu}=\sqrt{n}\,a_n^{\mu\dagger},\\ \gamma_n^{\mu}&=\sqrt{4nx}\,c_n^{\mu}, \quad \gamma_{-n}^{\mu}=\sqrt{4nx}\,c_n^{\mu\dagger},\end{aligned} \tag{31}$$

and find for $n\geqslant 1$ the standard form

$$\begin{aligned}[a_n^{\mu},a_m^{\nu\dagger}]&=\delta_{nm}\eta^{\mu\nu},\\ [c_n^{\mu},c_m^{\nu\dagger}]&=\delta_{nm}\eta^{\mu\nu}.\end{aligned} \tag{32}$$

These expressions are formally the same as those found for a two-piece string.[8] From Eq. (24) we get, when separating out the $n=0$ term,

$$H=-\frac{M^2}{\pi T_{II}}+\frac{1}{2}N\sum_{n=1}^{\infty}\omega_n(a_n^{\dagger}\cdot a_n+\tilde{a}_n^{\dagger}\cdot\tilde{a}_n+2\,c_n^{\dagger}\cdot c_n). \tag{33}$$

Here $a_n^{\dagger}\cdot a_n\equiv a_n^{\mu\dagger}a_{n\mu}$, and $\omega_n=2Nn$ as before. From the condition $H=0$ we now get

$$M^2=\frac{1}{2}\pi NT_{II}\sum_{i=1}^{24}\sum_{n=1}^{\infty}\omega_n(a_{ni}^{\dagger}a_{ni}+\tilde{a}_{ni}^{\dagger}\tilde{a}_{ni}+2\,c_{ni}^{\dagger}c_{ni}-\mathcal{C}), \tag{34}$$

where we have put $D=26$ and summed over the transverse 24 oscillator operators. Further, we have introduced a constant $\mathcal{C}$ in order to account for ordering ambiguities. Note that in Eq. (20) the denominator goes to zero when T_I does, but the same T_I is restored again in Eqs. (22) and (26). The result is that the commutation rules for the creation and annihilation operators, Eq. (29), take the same form as usual in quantum field theory.

V. QUANTUM THERMODYNAMICS

The constraint for the closed string (fat circles at Fig. 2), expressing the invariance of the theory in the region I under shifts of the origin of the coordinate, has the form

$$\sum_{i=1}^{24}\sum_{n=1}^{\infty}\omega_n[a_{ni}^{\dagger}a_{ni}-\tilde{a}_{ni}^{\dagger}\tilde{a}_{ni}]=0. \tag{35}$$

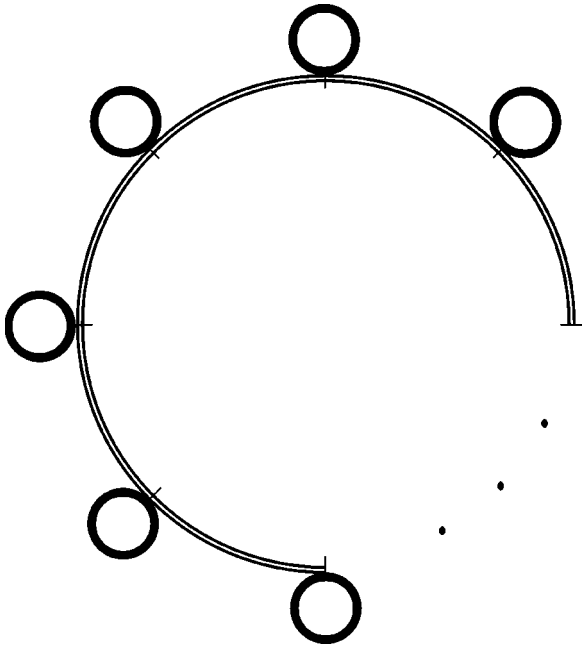

FIG. 2. Fat circles correspond to closed strings, double lines correspond to open strings.

The commutation relations for the above operators are given by Eq. (32). The mass of state (obtained by acting on the Fock vacuum $|0\rangle$ with creation operators) can be written as follows: $(\text{mass})^2 \sim a_{n1}^{\dagger} \cdots a_{ni}^{\dagger} c_{n1}^{\dagger} \cdots c_{ni}^{\dagger} |0\rangle$.

Let us start with the discussion of the free energy in field theory at nonzero temperature $T = \beta^{-1}$ (we put $k_B = 1$). As usual the physical Hilbert space consists of all Fock space states obeying the condition (35), which can be implemented by means of the integral representation for Kronecker deltas. Thus the free energy of the field content in the ''proper time'' representation becomes

$$F(\beta) = \mathcal{F}(\beta = \infty) - \pi (2\pi)^{-14} \int_0^{\infty} \frac{\mathrm{d}\tau_2}{\tau_2^{14}} \left[\theta_3 \left(0 \,\middle|\, \frac{i\beta^2}{2\pi\tau_2} \right) - 1 \right] \mathrm{Tr} \exp\left\{ -\frac{\tau_2 M^2}{2} \right\}$$
$$\times \int_{-\pi}^{\pi} \frac{\mathrm{d}\tau_1}{2\pi} \mathrm{Tr} \exp\left\{ iN\tau_1 \sum_{i=1}^{24} \sum_{n=1}^{\infty} \omega_n [a_{ni}^{\dagger} a_{ni} - \tilde{a}_{ni}^{\dagger} \tilde{a}_{ni}] \right\}, \tag{36}$$

where $\mathcal{F}(\beta = \infty)$ is the temperature independent part of $F(\beta)$ (the Casimir energy), while the second term in (36) presents the temperature dependent part (the statistical sum). Once the free energy has been found, the other thermodynamic quantities can readily be calculated. For instance, the energy U and the entropy S of the system are $U = (\partial/\partial\beta)(\beta F(\beta))$, $S = \beta^2 (\partial/\partial\beta)(F(\beta))$.

VI. THE CRITICAL TEMPERATURE

First we consider some mathematical results on the asymptotics of the level degeneracy which leads to the asymptotics of the level state density. Let

$$\mathcal{G}(z) = \prod_{n=1}^{\infty} [1 - e^{-zn}]^{-a_n} = 1 + \sum_{n=1}^{\infty} \Xi(n) e^{-zn} \tag{37}$$

be the generating function, where $\Re z > 0$ and a_n are non-negative real numbers. Let us consider the associated Dirichlet series

$$\mathcal{D}(s)=\sum_{n=1}^{\infty} a_n n^{-s}, \qquad s=\sigma+it, \tag{38}$$

which converges for $0<\sigma<p$. We assume that $\mathcal{D}(s)$ can be analytically continued in the region $\sigma\geqslant -C_0$ $(0<C_0<1)$ and here $\mathcal{D}(s)$ is analytic except for a pole of order one at $s=p$ with residue A. Besides we assume that $\mathcal{D}(s)=\mathcal{O}(|t|^{C_1})$ uniformly in $\sigma\geqslant -C_0$ as $|t|\to\infty$, where C_1 is a fixed positive real number. The following lemma[13–15] is useful with regard to the asymptotic properties of $\mathcal{G}(z)$ at $z=0$:

Lemma 1: If $\mathcal{G}(z)$ and $\mathcal{D}(s)$ satisfy the above assumptions and $z=y+2\pi ix$, then

$$\mathcal{G}(z)=\exp\left\{A\Gamma(p)\zeta_R(1+p)z^{-p}-\mathcal{D}(0)\log z+\frac{d}{ds}\mathcal{D}(s)\bigg|_{s=0}+\mathcal{O}(y^{C_0})\right\} \tag{39}$$

uniformly in x as $y\to 0$, provided $|\arg z|\leqslant\pi/2$ and $|x|\leqslant\frac{1}{2}$. Moreover, there exists a positive number ε such that

$$\mathcal{G}(z)=\mathcal{O}(\exp\{A\Gamma(p)\zeta_R(1+p)y^{-p}-Cy^{-\varepsilon}\}), \tag{40}$$

uniformly in x with $y^{\alpha}\leqslant|x|\leqslant\frac{1}{2}$ as $y\to 0$, C being a fixed real number and $\alpha=1+p/2-p\nu/4$, $0<\nu<\frac{2}{3}$.

The main result below follows from the lemma and permits one to calculate the complete asymptotics of $\Xi(n)$.

Theorem 1: (Meinardus[13,14]) *For $n\to\infty$ one has*

$$\Xi(n)=C_p n^k \exp\left\{\frac{1+p}{p}[A\Gamma(1+p)\zeta_R(1+p)]^{1/(1+p)}n^{p/(1+p)}\right\}(1+\mathcal{O}(n^{-k_1}))\,, \tag{41}$$

$$C_p=[A\Gamma(1+p)\zeta_R(1+p)]^{(1-2\mathcal{D}(0))/2(1+p)}\frac{\exp((d/\mathrm{d}s)\mathcal{D}(s)|_{s=0})}{[2\pi(1+p)]^{1/2}}, \tag{42}$$

$$k=\frac{2\mathcal{D}(0)-p-2}{2(1+p)}\,, \qquad k_1=\frac{p}{1+p}\min\left(\frac{C_0}{p}-\frac{\nu}{4},\frac{1}{2}-\nu\right). \tag{43}$$

Coming back to the composite string problem, note that the generation function has the form

$$W(\beta)=\mathrm{Tr}[e^{-\beta M^2}]_{(\mathcal{C}=0)}=W^{(I)}(\beta)W^{(II)}(\beta)\equiv\prod_{n=1}^{\infty}[1-e^{-n\beta Q(N)}]^{-48}\prod_{n=1}^{\infty}[1-e^{-2n\beta Q(N)}]^{-24}, \tag{44}$$

where $Q(N)=\pi T_{II}N^2$. Some remarks are in order. Taking into account $a_n=D-2$ [or $a_n=2(D-2)$ in the case of region II], we have $p=1$. In fact, Eq. (38) gives the Riemann zeta function. Therefore, from the Meinardus theorem, Eqs. (41)–(43), it follows that

$$\Xi^{(I)}(n)=C_1^{(I)}n^{k^{(I)}}\exp\left\{\pi\sqrt{\frac{4n\pi(D-2)}{3Q(N)}}\right\}(1+\mathcal{O}(n^{-k_1}))\,, \tag{45}$$

$$\Xi^{(II)}(n)=C_1^{(II)}n^{k^{(II)}}\exp\left\{\pi\sqrt{\frac{2n(D-2)}{3Q(N)}}\right\}(1+\mathcal{O}(n^{-k_1}))\,. \tag{46}$$

Using the mass formula $M^2=n$ (for the sake of simplicity we assume a tension parameter, with dimensions of $(\text{mass})^{p+1}$, equal to 1) we find for the number of bosonic string states of mass M to $M+dM$

$$\nu(M)dM \simeq 2C_1 M^{(1-D)/2}\exp(bM)dM\,, \qquad b=\pi\sqrt{\frac{D-2}{3Q(N)}}\,. \tag{47}$$

One can show that the constant b is the inverse of the Hagedorn temperature.

For the closed bosonic string in the region I the constraint $N_0=\tilde{N}_0$ should be taken into account, where N_0 is a number operator related to M^2. As a result, in Eq. (45) the total degeneracy of the level n is simply the square of $\Xi^{(I)}(n)$. Therefore the critical temperatures of composite string are given by

$$\beta_c^{(I)}=\pi\sqrt{\frac{D-2}{3Q(N)}}=\frac{2}{N}\sqrt{\frac{2\pi}{T_{II}}}\,, \tag{48}$$

$$\beta_c^{(II)}=\pi\sqrt{\frac{D-2}{3Q(N)}}=\frac{2}{N}\sqrt{\frac{2\pi}{T_{II}}}\,, \tag{49}$$

and so $\beta_c^{(I)}=\beta_c^{(II)}=\beta_c$.

VII. HIGH GENERA

The aim of this section is to consider thermodynamic properties of the composite string to arbitrary genus g associated with Riemann surface world-sheet $\Sigma_{\rm g}$. Such considerations allow us to identify the critical temperature at arbitrary loop order. It is well-known that the genus-g temperature contribution to the free energy for the bosonic string can be written as[17]

$$F_{\rm g}(\beta)=\sum_{\mathbf{m},\mathbf{n}\in\mathbf{Z}^{2g}/\{\mathbf{0}\}}\int (d\tau)_{WP}\,(\det P^{+}P)^{1/2}(\det\Delta_{\rm g})^{-13}e^{-\Delta S(\beta;\mathbf{m},\mathbf{n})}\,, \tag{50}$$

where $(\mathrm{d}\tau)_{WP}$ is the Weil–Petersson measure on the Teichmüller space. This measure as well as the factors $\det(P^{+}P)$ and $\det\Delta_{\rm g}$ are each individually modular invariant.[17] In addition,

$$I_{\rm g}(\tau)=(\det P^{+}P)^{1/2}(\det\Delta_{\rm g})^{-13}=e^{c(2{\rm g}-2)}\left(\frac{d}{ds}Z(s)\bigg|_{s=1}\right)^{-13}Z(2)\,, \tag{51}$$

where $Z(s)$ is the Selberg zeta function and c an absolute constant.[18] Furthermore, the winding-number factor has the form of a metric over the space of windings, namely

$$\Delta S(\beta;\mathbf{m},\mathbf{n})=\frac{\pi}{2}NT_{II}\beta^2[m_\ell\Omega_{\ell i}-n_i]((\Im\Omega)^{-1})_{ij}[\overline{\Omega}_{jk}m_k-n_j]={\rm g}^{\mu\nu}(\Omega)\mathcal{N}_\mu\mathcal{N}_\nu\,, \tag{52}$$

where $\mu,\nu=1,2,\ldots,2g$, $\{\mathcal{N}_1,\ldots,\mathcal{N}_{2{\rm g}}\}\equiv\{m_1,n_1,\ldots,m_{\rm g},n_{\rm g}\}$. The periodic matrix Ω, corresponding to the string world-sheet of genus g, is a holomorphic function of the moduli, $\Omega_{ij}=\Omega_{ji}$ and $\Im\Omega>0$. The matrix Ω admits a decomposition into real symmetric g$\otimes$g matrices: $\Omega=\Omega_1+i\Omega_2$. As a result

$${\rm g}(\Omega_1+i\Omega_2)=\begin{pmatrix}\Omega_1\Omega_2^{-1}\Omega_1+\Omega_2 & -\Omega_1\Omega_2^{-1}\\ -\Omega_2^{-1}\Omega_1 & \Omega_2^{-1}\end{pmatrix}. \tag{53}$$

Besides, ${\rm g}(\Omega)=\hat{\Lambda}^t{\rm g}(\Lambda(\Omega))\hat{\Lambda}$,[18] where Λ is an element of the symplectic modular group $Sp(2{\rm g},\mathbf{Z})$ and the associated tranformation of the periodic matrix reads $\Omega\mapsto\Omega'=\Lambda(\Omega)=(A\Omega+B)(C\Omega+D)^{-1}$. As a consequence, the winding factor $\Sigma_{\mathbf{m},\mathbf{n}}\exp[-\Delta S(\beta;\mathbf{m},\mathbf{n})]$ is also modular invariant. It can be shown that the 2g summations present in the expression for $F_{\rm g}(\beta)$ can be

replaced by a single summation together with a change in the region of integration from the fundamental domain to the analog of the strip S_{a_1} related to the cycle a_1, whose choice is entirely arbitrary.[17,19] Then, one has

$$F_{\mathrm{g}}(\beta)=\sum_{r=1}^{\infty}\int (\mathrm{d}\tau)_{WP}\, I_{\mathrm{g}}(\tau)\exp\left\{-\frac{\pi}{2}NT_{II}\beta^2 r^2(\Omega_{1i}((\Im\Omega)^{-1})_{ij}\overline{\Omega}_{j1})\right\}. \tag{54}$$

To make use of the Mellin transform the genus-g free energy can be present in the form[20–22]

$$F_g(\beta)=\frac{1}{2\pi i}\int_{\Re\, s=s_0}\mathrm{d}s\Gamma(s)\zeta(2s)\left(\frac{\pi}{2}NT_{II}\beta^2\right)^{-s} \times\left\{\int (\mathrm{d}\tau)_{WP}\, I_{\mathrm{g}}(\tau)[\Omega_{1i}((\Im\Omega)^{-1})_{ij}\overline{\Omega}_{j1}]^{-s}\right\}_{(\mathrm{Reg})}. \tag{55}$$

In order to deal with Eq. (55) the integrals on a suitable variable in $(\mathrm{d}\tau)_{WP}$ should be understood as the regularized ones. In this way the order of integration may be interchanged.

The critical behaviors of closed and open strings of the composite model coincide (at least at level $\mathrm{g}=1$). Let us consider, for example, the open string genus-g contribution to the free energy. The matrix Ω may be chosen as $\Omega=\mathrm{diag}(\Omega_2,\Omega_2^{-1})$. In the limit $\Omega_2\to 0$, one has

$$\exp\left\{-\frac{\pi}{2}NT_{II}\beta^2(\mathcal{N}^t\Omega\mathcal{N})^{-s}\right\}\to\exp\left\{-\frac{\pi}{2}NT_{II}\beta^2\Omega_2^{-1}\mathcal{N}^t\mathcal{N}\right\}, \tag{56}$$

and

$$\left(\sum_{\mathcal{N}\in\mathbf{Z}^{2g}/\{\mathbf{0}\}}(\mathcal{N}^t\Omega\mathcal{N})^{-s}\right)_{(\Omega_2\to 0)}\to\Omega_2^s\sum_{\mathcal{N}\in\mathbf{Z}^g/\{\mathbf{0}\}}(\mathcal{N}^t\mathcal{N})^{-s}=\Omega_2^s Z_{\mathrm{g}}|^{\mathbf{0}}_{\mathbf{0}}|(2s), \tag{57}$$

where the Epstein zeta function of order g is defined by

$$Z_{\mathrm{g}}|^{\mathbf{b}}_{\mathbf{h}}|(s)=\sum_{\mathcal{N}\in\mathbf{Z}^g/\{\mathbf{0}\}}[(n_1+b_1)^2+\cdots+(n_{\mathrm{g}}+b_{\mathrm{g}})^2]^{-s/2}\exp[2\pi i(\mathcal{N}^t,\mathbf{h})]. \tag{58}$$

The corresponding contribution is given by

$$\frac{1}{2\pi i}\int_{\Re\, s=s_0}\mathrm{d}s\,\Gamma(s)\left(\frac{\pi}{2}NT_{II}\beta^2\right)^{-s}Z_{\mathrm{g}}|^{\mathbf{0}}_{\mathbf{0}}|(2s)\left\{\int \mathrm{d}\tau_{WP}\Omega_2^s I_{\mathrm{g}}(\tau)\right\}_{(\mathrm{Reg})}. \tag{59}$$

Since a tachyon is present in the spectrum, the total free energy will be divergent, for any g. The infrared divergence may be regularized by means of a suitable cutoff parameter. This divergence could be associated with pinching a cycle nonhomologous at zero. The behavior of the factor $(\mathrm{d}\tau)_{WP}\, I_{\mathrm{g}}(\tau)$ is given by the Belavin–Knizhnik double-pole result and has a universal character for any g. It should also be noticed that this divergence is β independent and the meromormphic structure is similar to the genus-one case. As a consequence, the whole genus dependence of the critical temperature is encoded in the Epstein zeta function $Z_{\mathrm{g}}|^{\mathbf{0}}_{\mathbf{0}}|(2s)$ (see for details Ref. 20).

For this reason, we mention the asymptotic properties of function $Z_{\mathrm{g}}|^{\mathbf{0}}_{\mathbf{0}}|(2s)$. The following result holds:

Corollary 1 (Ref. 20):

$$B_g \equiv \lim_{\Re s \to +\infty} \frac{Z_g|^{\mathbf{b}}_{\mathbf{0}}|(2s+2)}{Z_g|^{\mathbf{b}}_{\mathbf{0}}|(2s)} = [(\hat{b}_1 - \eta_1)^2 + \cdots + (\hat{b}_g - \eta_g)^2]^{-1}, \tag{60}$$

where at least one of the b_i *is noninteger,* $\hat{b}_i = b_i - [b_i]$ *with* $[b_i]$ *the noninteger (decimal) part of* b_i *and*

$$\eta_i = \begin{cases} 0\,, & 0 \leqslant \hat{b}_i \leqslant \frac{1}{2}, \\ 1\,, & \frac{1}{2} \leqslant \hat{b}_i < 1. \end{cases} \tag{61}$$

Furthermore, if $\mathbf{b} = (0,0,\ldots,0)$, *then* $B_g = 1$.

As a consequence, the interactions of bosonic strings do not modify the critical temperature. However, one can consider different linear real bundles over compact Riemann surfaces and spinorial structures on them. The procedure of evaluation of the free energy in terms of the path integral over the metrics does not depend on whatever type of real scalars are considered. This fact leads to new contributions to the genus-g integral (50).

One could investigate the role of these contributions for the torus compactification.[2,18,23] In this case, the sum in Eq. (50) should be taken over the vectors on the lattice on which some space dimensions are compactified. The half-lattice vectors can be labelled by the multiplets $(b_1, \ldots, b_p)$, with $b_i = \frac{1}{2}$. The critical temperature related to the multiplet $\mathbf{b} = (b_1, \ldots, b_p, 0, \ldots, 0)$ can be easily evaluated by means of Eq. (60), which gives $B_p = 4p^{-1}$. As a result $\beta_{c,p} = (2/\sqrt{p})\,\beta_c$. As an example, we note the particular multiplets $(0, \ldots, \frac{1}{2}, \ldots, 0)$ and $(0,..\frac{1}{2},\frac{1}{2},...,0)$, where only one b_i and two b_i are different from zero. In this case we have ''minimal'' critical temperatures given by $\beta_{c,1}^{-1} = \beta_c^{-1}/2$ and $\beta_{c,2}^{-1} = \beta_c^{-1}/\sqrt{2}$, respectively.

VIII. CONCLUDING REMARKS

Making use of the Meinardus theorem in Sec. VI, we found the critical temperatures of the two kinds of pieces in the string (I and II) to be equal and to be given by Eqs. (48) and (49) for arbitrary space–time dimension D. The calculation generalizes earlier calculations of the Casimir energy of the $2N$-piece string in Ref. 7, and of thermodynamics of the two-piece string in Ref. 8. Interactions of bosonic parts of a piecewice uniform string do not modify the critical temperatures. However, for the sectors of parts having a spinor structure, the critical temperatures, associated with genus g, depend on the windings.

It ought to be emphasized again that a fundamental property of this kind of string theory is its *relativistic invariance*. It means the velocity of sound is everywhere required to be equal to the velocity of light. If this requirement were to be abandoned, the regularization procedure would be more difficult. The requirement about relativistic invariance makes the string theory quite analogous to the Casimir theory in a continuous medium satisfying the condition $\varepsilon\mu = 1$, ε being the premittivity and μ the permeability (cf., for instance, Refs. 24 and 25, and also the recent discussion in Ref. 26).

The theory above was worked out in explicit form, making the simplifying assumption $x = T_I/T_{II} \to 0$. It should be noted, however, that no important physical property of the string model is lost by going to the case of extreme string tensions. In particular, as already mentioned, this simplification does not prevent one from distinguishing between the actions for massive and massless particles.

As for physical implications of the string model, we note that it can be looked upon as the vacuum state of a quantum field theory in a two-dimensional space–time endowed with special properties. One of the most fundamental properties of the string is the *negativity* of the Casimir energy. Moreover, as we would expect, the Casimir energy can always be made more negative if the string chooses to divide itself into a larger number of pieces. It becomes natural to suggest that the model could be of some importance for cosmology. Perhaps a ''phase transition'' of this sort played a physical role in the early universe.

Let us also mention another argument, taken from the theory of superstrings, which similarly points towards the physical importance of two-dimensional field theory. In Ref. 27 it is argued that at high temperatures, the free energy for a superstring is $F_{\text{string}} \sim -VT^2$, where V is the volume and T is the temperature. One can compare this with the quantum field theory behavior of the free energy in d spatial dimensions, $F_{QFT} \sim -VT^{d+1}$. It becomes natural to interpret this to mean that the fundamental degrees of freedom in string theory are much less than in quantum field theory in the same dimensions, and that the underlying string theory should be like a two-dimensional quantum field theory. See also the recent discussion in Ref. 28.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 3 MARCH 2003

Adjoint operators, gauge invariant perturbations, and covariant symplectic form for black holes in string theory

R. Cartas-Fuentevilla[a)]
Instituto de Física, Universidad Autónoma de Puebla, Apartado postal J-48 72570 Puebla Pue., México

(Received 1 February 2002; accepted 5 December 2002)

Using a scheme of adjoint operators, we give a covariant and gauge invariant treatment for the perturbation theory of static charged black holes in string theory, valid for curvature below the Planck scale; conserved quantities and a covariant symplectic form on the phase space are explicitly constructed. Future extensions of the present results are discussed. © *2003 American Institute of Physics.*

I. INTRODUCTION

At present, the theories of extended objects such as membranes and strings represent the more viable candidates for a quantum theory of gravity. Particularly, there have been many efforts studying black holes in string theory from different points of view, with the main task of elucidating on the problem of quantum gravity embedded in them, since such objects appear to play a crucial role in the subject. However, because of the many technical and conceptual difficulties in treating the full theory, the low-energy limit of string theory has been developed as a more pragmatic approach. This low-energy physics emerges as an effective action obtained from the lowest order in the world-sheet and string loop expansion, where the usual Einstein–Hilbert gravity is supplemented by gauge fields, scalar fields such as the axion and the dilaton, which couple in a nontrivial way to the other matter fields.[1] As it is well known, the presence of the dilaton changes drastically the dynamical properties of the systems, and new features arise in this theory due to the nontrivial coupling of this field. In particular, dilaton black holes have shown to have novel thermodynamics properties,[2,3] and to behave like elementary particles in the sense that the excitation spectrum has an energy gap.[4–6] Besides, it has been explored the viewpoint that quantum black holes are massive excitations of extended objects and also correspond, in this sense, to elementary particles (Ref. 7, and references cited therein).

In all issues discussed above, the first-order perturbation analysis plays a fundamental role. Perturbation theory revels important physical information of the system under study. As we shall see, the adjoint operators approach will cover, in a unified way, various aspects of the same problem (in this case, the perturbation analysis of string black holes), which traditionally have been treated separately. In the remainder of this Introduction, we discuss such aspects, pointing out our aims and successes in the present work, and we make a review of previous works in which the present approach has been employed.

In the scheme of the perturbation theory, the black holes (and other space–times) have been studied from different approaches. The traditional approaches consist of trying to solve the original set of equations for the field perturbations directly. This approach has several disadvantages and difficulties that can be overcome by means of an alternative and more convenient approach based on the concept of the adjoint of a differential operator (Wald's method). The reach and differences of this approach with respect to the usual ones have been already discussed widely in previous works; in fact, in the cases where string fields are involved, the approach has been

a)Electronic mail: rcartas@sirio.ifuap.buap.mx

applied successfully in the setting of the Einstein–Maxwell-dilaton-axion (EMDA) theory, which contains the low-energy limit of string theory as a particular case.[8,9] Additionally, as we shall see, with the connection recently established between adjoint operators and conserved currents,[10–12] Wald's method becomes the more convenient and powerful approach for facing the study of perturbations.

At a more general context, the study of conservation laws in field theories involving gravity becomes particularly interesting because of the lack of conserved currents representing the conservation of energy and momentum. Additionally, in the construction of a *covariant symplectic structure* on the phase space of classical systems, a bilinear product on first-order deformations of classical solutions on such phase space is required.[13–15] In both cases, the problem is to find a local expression physically meaningful and coming from some continuity equation. As we shall see, the present adjoint operators scheme allows us to establish a local continuity law with the features described above, from which conserved quantities and a covariant symplectic structure (in terms of Debye potentials) are derived.

In this manner, the purpose of the present work is to perform an analysis of the first-order perturbations of the dilatonic charged black holes employing Wald's method. Previously, the self-adjointness of the operator governing the field perturbations in the EMDA theory has been demonstrated,[10] leaving only the finding of the corresponding decoupled set of equations in the case where the background space–time corresponds to the solution considered, in order to establish our results.

For this purpose, the outline of this article is as follows. The relevant information on the background solution is given in Sec. II. In Sec. III, a decoupled set of equations for metric, vector potential, and dilaton perturbations is obtained from the original equations for the field perturbations using the Newman–Penrose formulation. Employing the results of Sec. III, the equations for the Debye potentials, and the expressions for the metric, vector potential, and dilaton perturbations in terms of those, are found in Sec. IV A. In Sec. IV B, our fundamental continuity equation is established and a symplectic structure is derived in Sec. IV C. The separation of variables for the equations for the Debye potentials and for the continuity equation is performed in Sec. V, such that two conserved quantities are obtained. Finally, we finish with some concluding remarks and future extensions of the present results.

It is worth pointing out some issues on the notation. The first-order field variations appearing in Refs. 8 and 9 are denoted by a superscript B. On the other hand, the field variations coincide, according to Witten's interpretation,[13,14] with an infinite-dimensional generalization of the usual exterior derivative, which is traditionally represented by the symbol δ. However, in Refs. 8 and 9 and the present work, the Newman–Penrose formalism is used, in which the symbol δ is employed for denoting one of the directional derivatives defined by the null tetrad. In this manner, for avoiding confusion, we will maintain the symbol δ as usual in the Newman–Penrose notation, and the superscript B for the first-order field variations (the exterior derivative of background fields). In the present article, the exterior derivative will not be performed explicitly, and it will be sufficient for our purposes to understand any quantity with the superscript B as a one-form on the phase space. Quantities without such a superscript will correspond to background fields, which mean zero-forms on the phase space. With these previous considerations, formulas and notation of Refs. 8 and 9 will be used throughout this article; the concepts and definitions on differential forms, exterior derivatives, etc., come from Ref. 14.

II. BACKGROUND SPACE–TIME

Static, spherically symmetric solutions of the Einstein–Maxwell-dilaton equations have been found, representing charged black holes for curvature below the Planck scale.[2,3] The solutions for magnetically charged dilaton black holes have, using the metric convention $(+---)$, the line element

$$ds^2=\chi^2 dt^2-\chi^{-2}dr^2-R^2 d\Omega, \tag{1}$$

where χ and R depend only on r:

$$\chi^2=\left(1-\frac{r_+}{r}\right)\left(1-\frac{r_-}{r}\right)^{(1-a^2)/(1+a^2)},\quad R=r\left(1-\frac{r_-}{r}\right)^{a^2/(1+a^2)}, \tag{2}$$

where r_+ and r_- are the values of the parameter r at the outer and the inner horizons, respectively, and are related to the physical mass (M) and charge (Q); a is the dilaton coupling parameter. The Maxwell and dilaton fields are given by

$$F=Q\sin\theta d\theta\wedge d\varphi,\quad e^{-2a\phi}=\left(1-\frac{r_-}{r}\right)^{2a^2/(a^2+1)}\qquad(\xi\equiv -e^{-2a\phi}). \tag{3}$$

There are also electrically charged solutions which may be obtained by a duality rotation. For more details see Refs. 2 and 3.

For our present purpose, it is more convenient to specify the line element (2) by the null tetrad

$$\begin{gathered}D\equiv l^\mu\partial_\mu=\frac{1}{\chi^2}\partial_t+\partial_r,\qquad \Delta\equiv n^\mu\partial_\mu=\frac{1}{2}(\partial_t-\chi^2\partial_r),\\ \delta\equiv m^\mu\partial_\mu=\frac{1}{\sqrt{2}R}(\partial_\theta+i\csc\theta\partial_\varphi),\quad \bar{\delta}\equiv\bar{m}^\mu\partial_\mu=\frac{1}{\sqrt{2}R}(\partial_\theta-i\csc\theta\partial_\varphi).\end{gathered} \tag{4}$$

Using the commutation relations of the tetrad (4), the nonvanishing spin coefficients can be conveniently expressed as

$$\begin{gathered}\rho=D\ln R^{-1},\quad \mu=\Delta\ln R,\quad \gamma=\Delta\ln\chi^{-1},\\ \beta=\delta\ln\sin^{1/2}\theta,\quad \alpha=-\bar{\delta}\ln\sin^{1/2}\theta,\end{gathered} \tag{5}$$

where ρ, μ, and γ depend only on r, and β and α on both r and θ.

On the other hand, considering the first of Eqs. (3) and the definitions $\varphi_0\equiv l^\mu m^\nu F_{\mu\nu}$, $\varphi_1\equiv\frac{1}{2}(l^\mu n^\nu+\bar{m}^\mu m^\nu)F_{\mu\nu}$, and $\varphi_2\equiv\bar{m}^\mu n^\nu F_{\mu\nu}$, the Newman–Penrose components of the electromagnetic field are given by

$$\varphi_0=0=\varphi_2,\quad \varphi_1(r)=\frac{iQ}{2R^2}. \tag{6}$$

Note that $\varphi_1+\bar{\varphi_1}=0=\delta\phi_1$, which will be used implicitly below. On the other hand, from Eqs. (3) and (4), the only nonvanishing derivatives of the dilaton field are $D\phi$ and $\Delta\phi$, which depend only on r, and

$$\delta\phi=0=\bar{\delta}\phi. \tag{7}$$

Thus, the only nonvanishing Ricci scalars are (see Appendix of Ref. 8)

$$\begin{gathered}\Phi_{00}=-(D\phi)^2,\quad \Phi_{22}=-(\Delta\phi)^2,\\ \Phi_{11}=-\tfrac{1}{2}(D\phi)(\Delta\phi)-2\xi\varphi_1^2,\quad \Lambda=-\tfrac{1}{6}(D\phi)(\Delta\phi),\end{gathered} \tag{8}$$

and the only nonvanishing component of the Weyl spinor can be expressed as

$$\Psi_2(r)=2\gamma\rho-\tfrac{2}{3}D\phi\Delta\phi. \tag{9}$$

Furthermore, the background Maxwell equations take the form[8]

$$(D-2\rho)\varphi_1=0, \quad (\Delta+2\mu)\varphi_1=0, \tag{10}$$

and, similarly, the background dilaton equation is

$$D\Delta\phi+2\mu D\phi-2a\xi\varphi_1^2=0. \tag{11}$$

Additionally, using Eqs. (4)–(9) and the commutation relations, we can find the following relations:

$$\begin{aligned}(D+p\rho)(\delta+q\beta)&=(\delta+q\beta)[D+(p+1)\rho],\\ (\Delta+p\gamma+p'\mu)(\delta+q\beta)&=(\delta+q\beta)[\Delta+p\gamma+(p'-1)\mu],\end{aligned} \tag{12}$$

where p, q, and p' are arbitrary constants.

In the Newman–Penrose formalism, the adjoints of the tetrad components (4) are given, in general, by Eqs. (16) of Ref. 8, which reduce to

$$D^\dagger=-(D-2\rho), \quad \Delta^\dagger=-(\Delta-2\gamma+2\mu), \quad \delta^\dagger=-(\delta+2\beta), \quad \overline{\delta}^\dagger=-(\overline{\delta}+2\overline{\beta}), \tag{13}$$

for the present background solution. These equations will be used below.

III. DECOUPLED SET OF EQUATIONS FOR GAUGE INVARIANT PERTURBATIONS

The notation, conventions, and Appendix of Ref. 8 will be used extensively throughout this article. In particular, the metric, vector potential, and dilaton variations are represented by $h_{\mu\nu}$, b_μ, and ϕ^{B}, respectively. The metric and vector potential perturbations are defined modulo gauge transformations. Since the dilaton is a fundamental physical field, no gauge invariance associated with this field exists.

On the other hand, it is well known that when the perturbation analysis is performed using the Newman–Penrose formalism, one is faced with the perturbed tetrad gauge freedom. The traditional approaches make use of this gauge freedom in order to simplify the equations for the perturbations (Ref. 8 and references therein). However, we shall see that in the present case, although including string fields, there is no need to invoke perturbed tetrad rotations, but that appropriate combinations of the perturbed quantities, which are independent on the perturbed tetrad gauge freedom, lead in a natural way to a decoupled set of equations from the original set. Such combinations prove to be also independent on the ordinary gauge transformations of the electromagnetic potential perturbations. This system of equations consists of five second-order linear partial differential equations for five unknowns, Ψ_0^{B}, $\overline{\Psi_4^{\mathrm{B}}}$, $\tilde{\sigma}$, $\tilde{\lambda}$, and $(\delta-2\beta)\tilde{\phi}^{\mathrm{B}}$, and can be expressed in the following matrix form (a detailed derivation of this system is given in Ref. 12):

$$\mathcal{O}(\Psi^{\mathrm{B}})=\mathcal{S}\begin{pmatrix}(T_{\mu\nu})\\(j_\mu)\\ \phi_s\end{pmatrix}, \tag{14}$$

where $\mathcal{O}$ is the 5×5 matrix

$$\mathcal{O}\equiv\begin{pmatrix}\mathcal{O}_{11} & 0 & \mathcal{O}_{13} & -F_1D\phi & F_1\\ 0 & \mathcal{O}_{22} & \frac{\chi^4}{4}\Delta\phi F_1 & \mathcal{O}_{24} & \frac{\chi^4}{4}F_1\\ \mathcal{O}_{31} & 0 & \mathcal{O}_{33} & \mathcal{O}_{34} & \mathcal{O}_{35}\\ 0 & \mathcal{O}_{42} & \mathcal{O}_{43} & \mathcal{O}_{44} & \mathcal{O}_{45}\\ \frac{\chi^4}{8}F_1 & \frac{1}{2}F_1 & \mathcal{O}_{53} & \mathcal{O}_{54} & \mathcal{O}_{55}\end{pmatrix}, \tag{15}$$

$$(\Psi^{\mathrm{B}})\equiv\begin{pmatrix}\dfrac{\Psi_0^{\mathrm{B}}}{\Psi_4^{\mathrm{B}}}\\ \tilde{\sigma}^{\mathrm{B}}\\ \tilde{\lambda}^{\mathrm{B}}\\ (\delta-2\beta)\tilde{\phi}^{\mathrm{B}}\end{pmatrix}, \tag{16}$$

and $\mathcal{S}$ is the 5×3 matrix

$$\mathcal{S}\equiv\begin{pmatrix}\mathcal{S}_{11} & 0 & 0\\ \mathcal{S}_{21} & 0 & 0\\ \mathcal{S}_{31} & \mathcal{S}_{32} & 0\\ \mathcal{S}_{41} & \mathcal{S}_{42} & 0\\ \mathcal{S}_{51} & \mathcal{S}_{52} & \mathcal{S}_{53}\end{pmatrix}, \tag{17}$$

where the entries are given explicitly by

$$\mathcal{O}_{11}=(D-5\rho)(\Delta-4\gamma+\mu)-(\delta-2\beta)(\bar{\delta}+4\bar{\beta})-(3\Psi_2-2\Phi_{11}+2D\phi\Delta\phi),$$

$$\mathcal{O}_{13}=-8\xi\varphi_1^2D-4D\phi(\gamma D\phi-3a\xi\varphi_1^2),$$

$$F_1(r)=8\chi^{-2}D\phi\left(\gamma+\frac{a\xi\varphi_1^2}{D\phi}\right),$$

$$\mathcal{O}_{22}=(\Delta+2\gamma+5\mu)(D-\rho)-(\delta-2\beta)(\bar{\delta}+4\bar{\beta})-(3\Psi_2+2D\phi\Delta\phi-2\Phi_{11}),$$

$$\mathcal{O}_{24}=8\xi\varphi_1^2(\Delta+2\gamma)+4\Delta\phi(\gamma D\phi-3a\xi\varphi_1^2),$$

$$\mathcal{O}_{31}=\Delta-4\gamma+2\mu,$$

$$\mathcal{O}_{33}=(\Delta-4\gamma)(D-2\rho)-aD\phi(\Delta-2\gamma)-(\delta-2\beta)(\bar{\delta}+4\bar{\beta})-2(3\Psi_2+2\Phi_{11}),$$

$$\mathcal{O}_{34}=-aD\phi D+2\Phi_{00},$$

$$\mathcal{O}_{35}=a(D-2\rho)-2D\phi, \tag{18}$$

$$\mathcal{O}_{42}=D-2\rho,$$

$$\mathcal{O}_{43}=a\Delta\phi(\Delta-2\gamma)-2\Phi_{22},$$

$$\mathcal{O}_{44}=-D(\Delta+2\gamma+2\mu)+a\Delta\phi D+(\delta-2\beta)(\bar{\delta}+4\bar{\beta})+2(3\Psi_2+2\Phi_{11}),$$

$$\mathcal{O}_{45}=a(\Delta+2\mu)-2\Delta\phi,$$

$$\mathcal{O}_{53}=-\frac{\chi^4}{8}F_1(D-2\rho)+[\Delta\phi(D-\rho)-2a\xi\varphi_1^2](\Delta-2\gamma+\mu)$$
$$-\Delta\phi(\delta-2\beta)(\bar{\delta}+4\bar{\beta})-\mu F_2-\Phi_{22}D\phi,$$

$$\mathcal{O}_{54}=(F_2-\mu D\phi)(D-\rho)-(D-3\rho)D\phi(\Delta+2\gamma+2\mu)+D\phi(\delta-2\beta)(\bar{\delta}+4\bar{\beta})$$
$$+[(\Delta\phi D-2a\xi\varphi_1^2)\rho]+D\phi(3\Psi_2+2\Phi_{11}),$$

$$\mathcal{O}_{55}=(D-3\rho)(\Delta+3\mu)-(\delta-2\beta)(\overline{\delta}+4\overline{\beta})-3\Psi_2+2\mu\rho-3D\phi\Delta\phi-4(a^2-1)\xi\varphi_1^2,$$

$$F_2\equiv 2D\phi\left(\mu+\frac{a\xi\varphi_1^2}{D\phi}\right),$$

and

$$\mathcal{S}_{11}=2(\delta-2\beta)(D-3\rho)l^{(\mu}m^{\nu)}-[(D-5\rho)(D-\rho)+\Phi_{00}]m^\mu m^\nu-(\delta-2\beta)\delta l^\mu l^\nu,$$

$$\mathcal{S}_{21}=2(\delta-2\beta)(\Delta+2\gamma+3\mu)n^{(\mu}m^{\nu)}-[(\Delta+2\gamma+5\mu)(\Delta+\mu)+\Phi_{22}]m^\mu m^\nu-(\delta-2\beta)\delta n^\mu n^\nu,$$

$$\mathcal{S}_{31}=2(\delta-2\beta)l^{(\mu}m^{\nu)}-2(D-\rho)m^\mu m^\nu,$$

$$\mathcal{S}_{32}=\frac{1}{2\varphi_1}(\delta-2\beta)[(D-3\rho)\xi^{-1}m^\mu-\delta\xi^{-1}l^\mu],$$

$$\mathcal{S}_{41}=2(\delta-2\beta)n^{(\mu}m^{\nu)}-2(\Delta+\mu)m^\mu m^\nu, \tag{19}$$

$$\mathcal{S}_{42}=\frac{1}{2\varphi_1}(\delta-2\beta)[(\Delta+3\mu)\xi^{-1}m^\mu-\delta\xi^{-1}n^\mu],$$

$$\mathcal{S}_{51}=2D\phi(\delta-2\beta)n^{(\nu}m^{\nu)}+2\Delta\phi(\delta-2\beta)l^{(\nu}m^{\nu)}+(4a\xi\varphi_1^2-\Delta\phi D-D\phi\Delta)m^\mu m^\nu,$$

$$\mathcal{S}_{52}=-4a\varphi_1(\delta-2\beta)m^\mu,$$

$$\mathcal{S}_{53}=\tfrac{1}{2}(\delta-2\beta)\delta.$$

Note that both $\mathcal{O}$ and $\mathcal{S}$ depend only on the background fields. As mentioned previously, a gauge-fixing condition on the perturbed tetrad is unnecessary for obtaining the complete system (14). Furthermore, the entries of the matrix (Ψ^{B}) are automatically independent on the gauge transformations of the vector potential variations b_μ: $(\Psi^{\mathrm{B}})(h_{\mu\nu},b_\mu)=(\Psi^{\mathrm{B}})(h_{\mu\nu},b_\mu+\nabla_\mu\varepsilon)$. In this manner, the invariance under the gauge freedoms of the matter fields and the perturbed tetrad is guaranteed. This issue will be particularly important below, when we discuss the bilinear forms on the reduced phase space.

In the traditional approach, the field perturbations are separated in polar and axial perturbations (and some gauge-fixing conditions are imposed) with the purpose of reducing the equations governing the perturbations to Schrödinger-type equations, and then to apply semiclassical methods based on the Hermiticity of such a system of equations. However, as shown in Ref. 11, such treatment is unnecessary, and for many aims one can obtain essentially the same physical results working directly with the original non-Hermitian system of equations. In fact, when string fields are involved, such as the present case, those reductions seem to be very difficult to carry out, or, when possible, the interaction matrix is too complex to be displayed in explicit form.[5] Therefore, Eqs. (14) in their original form, without separations nor reductions, are sufficient for our present purposes.

IV. LOCAL CONTINUITY LAWS ON THE PHASE SPACE AND DEBYE POTENTIALS

A. Equations for the Debye potentials

Following that made in Ref. 12, if the matrix potential (ψ) satisfies $\mathcal{O}^{\dagger}(\psi)=0$, with

$$(\psi)=\begin{pmatrix}\psi_G\\ \psi_H\\ \psi_E\\ \psi_F\\ \psi_D\end{pmatrix}, \tag{20}$$

then the metric, vector potential, and dilaton *real* variations are given by

$$\begin{pmatrix}-\frac{1}{2}h_{\mu\nu}\\ 2b_{\mu}\\ \phi^{\mathrm{B}}\end{pmatrix}=\mathcal{S}^{\dagger}(\psi)=\begin{pmatrix}\mathcal{S}^{\dagger}_{11}\psi_G+\mathcal{S}^{\dagger}_{21}\psi_H+\mathcal{S}^{\dagger}_{31}\psi_E+\mathcal{S}^{\dagger}_{41}\psi_F+\mathcal{S}^{\dagger}_{51}\psi_D+\text{c.c.}\\ \mathcal{S}^{\dagger}_{32}\psi_E+\mathcal{S}^{\dagger}_{42}\psi_F+\mathcal{S}^{\dagger}_{52}\psi_D+\text{c.c.}\\ \mathcal{S}^{\dagger}_{53}\psi_D+\text{c.c.}\end{pmatrix}; \tag{21}$$

from Eqs. (13), and (19), we have explicitly that

$$\mathcal{S}^{\dagger}_{11}=2l_{(\mu}m_{\nu)}(D+\rho)(\delta+4\beta)-m_{\mu}m_{\nu}[(D-\rho)(D+3\rho)+\Phi_{00}]-l_{\mu}l_{\nu}(\delta+2\beta)(\delta+4\beta),$$

$$\mathcal{S}^{\dagger}_{21}=2n_{(\mu}m_{\nu)}(\Delta-4\gamma-\mu)(\delta+4\beta)-m_{\mu}m_{\nu}[(\Delta-2\gamma+\mu)(\Delta-4\gamma-3\mu)+\Phi_{22}]$$
$$-n_{\mu}n_{\nu}(\delta+2\beta)(\delta+4\beta),$$

$$\mathcal{S}^{\dagger}_{31}=2m_{\mu}m_{\nu}(D-\rho)-2l_{(\mu}m_{\nu)}(\delta+4\beta),$$

$$\mathcal{S}^{\dagger}_{41}=2m_{\mu}m_{\nu}(\Delta-2\gamma+\mu)-2n_{(\mu}m_{\nu)}(\delta+4\beta),$$

$$\mathcal{S}^{\dagger}_{51}=-2D\phi n_{(\mu}m_{\nu)}(\delta+4\beta)-2\Delta\phi l_{(\mu}m_{\nu)}(\delta+4\beta)+m_{\mu}m_{\nu}(8a\xi\varphi_1^2+\Delta\phi D+D\phi\Delta), \tag{22}$$

$$\mathcal{S}^{\dagger}_{32}=\frac{1}{2\xi}[m_{\mu}(D+\rho)-l_{\mu}(\delta+2\beta)](\delta+4\beta)\frac{1}{\varphi_1},$$

$$\mathcal{S}^{\dagger}_{42}=\frac{1}{2\xi}[m_{\mu}(\Delta-2\gamma-\mu)-n_{\mu}(\delta+2\beta)](\delta+4\beta)\frac{1}{\varphi_1},$$

$$\mathcal{S}^{\dagger}_{52}=4a\varphi_1 m_{\mu}(\delta+4\beta),$$

$$\mathcal{S}^{\dagger}_{53}=\frac{1}{2}(\delta+2\beta)(\delta+4\beta).$$

In this manner, the complete field variations are given by Eqs. (21) in terms of the Debye potentials, which satisfy a system of five second-order linear partial differential equations:

$$\mathcal{O}^{\dagger}(\psi)=\begin{pmatrix} \mathcal{O}^{\dagger}_{11} & 0 & \mathcal{O}^{\dagger}_{31} & 0 & \frac{\chi^4}{8}F_1 \\ 0 & \mathcal{O}^{\dagger}_{22} & 0 & \mathcal{O}^{\dagger}_{42} & \frac{1}{2}F_1 \\ \mathcal{O}^{\dagger}_{13} & \frac{\chi^4}{4}\Delta\phi F_1 & \mathcal{O}^{\dagger}_{33} & \mathcal{O}^{\dagger}_{43} & \mathcal{O}^{\dagger}_{53} \\ -F_1 D\phi & \mathcal{O}^{\dagger}_{24} & \mathcal{O}^{\dagger}_{34} & \mathcal{O}^{\dagger}_{44} & \mathcal{O}^{\dagger}_{54} \\ F_1 & \frac{\chi^4}{4}F_1 & \mathcal{O}^{\dagger}_{35} & \mathcal{O}^{\dagger}_{45} & \mathcal{O}^{\dagger}_{55} \end{pmatrix}\begin{pmatrix} \psi_G \\ \psi_H \\ \psi_E \\ \psi_F \\ \psi_D \end{pmatrix}=0, \tag{23}$$

where

$$\mathcal{O}^{\dagger}_{11}=(\Delta+2\gamma+\mu)(D+3\rho)-(\bar{\delta}-2\bar{\beta})(\delta+4\beta)-(3\Psi_2-2\Phi_{11}+2D\phi\Delta\phi),$$

$$\mathcal{O}^{\dagger}_{13}=8\xi\varphi_1^2(D+2\rho)+F_1\Delta\phi,$$

$$\mathcal{O}^{\dagger}_{22}=(D-\rho)(\Delta-4\gamma-3\mu)-(\bar{\delta}-2\bar{\beta})(\delta+4\beta)-(3\Psi_2-2\Phi_{11}+2D\phi\Delta\phi),$$

$$\mathcal{O}^{\dagger}_{24}=-8\xi\varphi_1^2(\Delta-4\gamma-2\mu)+\frac{\chi^2}{2}F_1\Delta\phi,$$

$$\mathcal{O}^{\dagger}_{31}=-(\Delta+2\gamma),$$

$$\mathcal{O}^{\dagger}_{33}=D(\Delta+2\gamma+2\mu)+aD\phi(\Delta+2\mu)-(\bar{\delta}-2\bar{\beta})(\delta+4\beta)-2(3\Psi_2+2\Phi_{11})+a\Delta D\phi,$$

$$\mathcal{O}^{\dagger}_{34}=aD\phi(D-2\rho)+aD^2\phi+2\Phi_{00}, \tag{24}$$

$$\mathcal{O}^{\dagger}_{35}=-aD-2D\phi, \quad \mathcal{O}^{\dagger}_{42}=-D, \quad \mathcal{O}^{\dagger}_{43}=-a\Delta\phi(\Delta+2\mu)-a\Delta^2\phi-2\Phi_{22},$$

$$\mathcal{O}^{\dagger}_{44}=-(\Delta-4\gamma+a\Delta\phi)(D-2\rho)+(\bar{\delta}-2\bar{\beta})(\delta+4\beta)+2(3\Psi_2+2\Phi_{11})-aD\Delta\phi,$$

$$\mathcal{O}^{\dagger}_{45}=-a(\Delta-2\gamma)-2\Delta\phi,$$

$$\mathcal{O}^{\dagger}_{53}=\tfrac{1}{8}D\chi^4F_1+(\Delta+\mu)(4a\xi\varphi_1^2-\mu D\phi+\Delta\phi D)-\Delta\phi(\bar{\delta}-2\bar{\beta})(\delta+4\beta)-\Phi_{22}D\phi-\mu F_2,$$

$$\mathcal{O}^{\dagger}_{54}=-(D-\rho)(F_2-\mu D\phi)-(\Delta-4\gamma)D\phi(D+\rho)+D\phi(\bar{\delta}-2\bar{\beta})(\delta+4\beta)$$
$$+[(\Delta\phi D-2a\xi\varphi_1^2)\rho]+D\phi(3\Psi_2+2\Phi_{11}),$$

$$\mathcal{O}^{\dagger}_{55}=(\Delta-2\gamma-\mu)(D+\rho)-(\bar{\delta}-2\bar{\beta})(\delta+4\beta)-3\Psi_2+2\mu\rho-3D\phi\Delta\phi+4(a^2-1)\xi\varphi_1^2,$$

and Eqs. (13), and (18) have been used. Equations (23) are our fundamental equations since, as we shall see, all conserved quantities and bilinear forms on the phase space are defined in terms of the Debye potentials. Although these equations admit separable solutions in a simple way, we will use them first in the form (23) in order to establish a *covariant* conservation law, and subsequently to carry out such separation.

B. Covariant continuity equation and bilinear forms on the phase space

Since the decoupled system (14) and the system of equations for the Debye potentials (23) are adjoints to each other, we have that[12]

$$(\psi)\mathcal{O}(\Psi^{\mathrm{B}})-\mathcal{O}^{\dagger}(\psi)(\Psi^{\mathrm{B}})=\nabla_{\mu}J^{\mu}(\psi,\Psi^{\mathrm{B}}). \tag{25}$$

The left-hand side contains terms of the form $\psi_G\mathcal{O}_{11}\Psi_0^{\mathrm{B}}-\mathcal{O}_{11}^{\dagger}\psi_G\Psi_0^{\mathrm{B}}$ [see Eqs. (15), and (23)], which can be expressed in the following form, considering the explicit forms of the operators $\mathcal{O}_{11}$, and $\mathcal{O}_{11}^{\dagger}$ given in Eqs. (18) and (24), respectively, that $D\equiv l^{\mu}\partial_{\mu}$, $\Delta\equiv n^{\mu}\partial_{\mu}$, $\delta\equiv m^{\mu}\partial_{\mu}$, $\overline{\delta}\equiv\overline{m}^{\mu}\partial_{\mu}$, and that they are acting on scalar fields:

$$\begin{aligned}\psi_G\mathcal{O}_{11}\Psi_0^{\mathrm{B}}-\mathcal{O}_{11}^{\dagger}\psi_G\Psi_0^{\mathrm{B}}=\nabla_{\mu}[&l^{\mu}\psi_G(\Delta-4\gamma+\mu)\Psi_0^{\mathrm{B}}-n^{\mu}(D+3\rho)\psi_G\Psi_0^{\mathrm{B}}-m^{\mu}\psi_G(\overline{\delta}+4\overline{\beta})\Psi_0^{\mathrm{B}}\\&+\overline{m}^{\mu}(\delta+4\beta)\psi_G\Psi_0^{\mathrm{B}}],\end{aligned} \tag{26}$$

and similarly for the remaining terms:

$$\begin{aligned}
&\psi_G\mathcal{O}_{13}\tilde{\sigma}^{\mathrm{B}}-\mathcal{O}_{13}^{\dagger}\psi_G\tilde{\sigma}^{\mathrm{B}}=\nabla_{\mu}(-8\xi\varphi_1^2l^{\mu}\psi_G\tilde{\sigma}^{\mathrm{B}}),\\
&\psi_H\mathcal{O}_{22}\overline{\Psi_4^{\mathrm{B}}}-\mathcal{O}_{22}^{\dagger}\psi_H\overline{\Psi_4^{\mathrm{B}}}=\nabla_{\mu}[n^{\mu}\psi_H(D-\rho)\overline{\Psi_4^{\mathrm{B}}}-l^{\mu}(\Delta-4\gamma-3\mu)\psi_H\overline{\Psi_4^{\mathrm{B}}}-m^{\mu}\psi_H(\overline{\delta}+4\overline{\beta})\overline{\Psi_4^{\mathrm{B}}}\\
&\qquad+\overline{m}^{\mu}(\delta+4\beta)\psi_H\overline{\Psi_4^{\mathrm{B}}}],\\
&\psi_H\mathcal{O}_{24}\tilde{\lambda}^{\mathrm{B}}-\mathcal{O}_{24}^{\dagger}\psi_H\tilde{\lambda}^{\mathrm{B}}=\nabla_{\mu}[8\xi\varphi_1^2n^{\mu}\psi_H\tilde{\lambda}^{\mathrm{B}}),\\
&\psi_E\mathcal{O}_{31}\Psi_0^{\mathrm{B}}-\mathcal{O}_{31}^{\dagger}\psi_E\Psi_0^{\mathrm{B}}=\nabla_{\mu}[n^{\mu}\psi_E\Psi_0^{\mathrm{B}}],\\
&\psi_E\mathcal{O}_{33}\tilde{\sigma}^{\mathrm{B}}-\mathcal{O}_{33}^{\dagger}\psi_E\tilde{\sigma}^{\mathrm{B}}=\nabla_{\mu}[n^{\mu}\psi_E(D-2\rho-aD\phi)\tilde{\sigma}^{\mathrm{B}}-l^{\mu}(\Delta+2\gamma+2\mu)\psi_E\tilde{\sigma}^{\mathrm{B}}\\
&\qquad-m^{\mu}\psi_E(\overline{\delta}+4\overline{\beta})\tilde{\sigma}^{\mathrm{B}}+\overline{m}^{\mu}(\delta+4\beta)\psi_E\tilde{\sigma}^{\mathrm{B}}],\\
&\psi_E\mathcal{O}_{34}\tilde{\lambda}^{\mathrm{B}}-\mathcal{O}_{34}^{\dagger}\psi_E\tilde{\lambda}^{\mathrm{B}}=\nabla_{\mu}(-aD\phi l^{\mu}\psi_E\tilde{\lambda}^{\mathrm{B}}),\\
&\psi_E\mathcal{O}_{35}(\delta-2\beta)\tilde{\phi}^{\mathrm{B}}-\mathcal{O}_{35}^{\dagger}\psi_E(\delta-2\beta)\tilde{\phi}^{\mathrm{B}}=\nabla_{\mu}[al^{\mu}\psi_E(\delta-2\beta)\tilde{\phi}^{\mathrm{B}}],\\
&\psi_F\mathcal{O}_{42}\overline{\Psi_4^{\mathrm{B}}}-\mathcal{O}_{42}^{\dagger}\psi_F\overline{\Psi_4^{\mathrm{B}}}=\nabla_{\mu}(l^{\mu}\psi_F\overline{\Psi_4^{\mathrm{B}}}),\\
&\psi_F\mathcal{O}_{43}\tilde{\sigma}^{\mathrm{B}}-\mathcal{O}_{43}^{\dagger}\psi_E\tilde{\sigma}^{\mathrm{B}}=\nabla_{\mu}[a\Delta\phi n^{\mu}\psi_F\tilde{\sigma}^{\mathrm{B}}],\\
&\psi_F\mathcal{O}_{44}\tilde{\lambda}^{\mathrm{B}}-\mathcal{O}_{44}^{\dagger}\psi_F\tilde{\lambda}^{\mathrm{B}}=\nabla_{\mu}[n^{\mu}(D-2\rho)\psi_F\tilde{\lambda}^{\mathrm{B}}-l^{\mu}\psi_F(\Delta+2\gamma+2\mu-a\Delta\phi)\tilde{\lambda}^{\mathrm{B}}+m^{\mu}\psi_F(\overline{\delta}+4\overline{\beta})\tilde{\lambda}^{\mathrm{B}}\\
&\qquad-\overline{m}^{\mu}(\delta+4\beta)\psi_F\tilde{\lambda}^{\mathrm{B}}],\\
&\psi_F\mathcal{O}_{45}(\delta-2\beta)\tilde{\phi}^{\mathrm{B}}-\mathcal{O}_{45}^{\dagger}\psi_F(\delta-2\beta)\tilde{\phi}^{\mathrm{B}}=\nabla_{\mu}[an^{\mu}\psi_F(\delta-2\beta)\tilde{\phi}^{\mathrm{B}}],\\
&\psi_D\mathcal{O}_{53}\tilde{\sigma}^{\mathrm{B}}-\mathcal{O}_{53}^{\dagger}\psi_D\tilde{\sigma}^{\mathrm{B}}=\nabla_{\mu}\Bigg[-n^{\mu}(\Delta\phi D-\mu D\phi+4a\xi\varphi_1^2)\psi_D\tilde{\sigma}^{\mathrm{B}}+l^{\mu}\Delta\phi\psi_D\left(\Delta+\mu+\frac{2a\xi\varphi_1^2}{D\phi}\right)\tilde{\sigma}^{\mathrm{B}}\\
&\qquad-\Delta\phi m^{\mu}\psi_D(\overline{\delta}+4\overline{\beta})\tilde{\sigma}^{\mathrm{B}}+\Delta\phi\overline{m}^{\mu}(\delta+4\beta)\psi_D\tilde{\sigma}^{\mathrm{B}}\Bigg],\\
&\psi_D\mathcal{O}_{54}\tilde{\lambda}^{\mathrm{B}}-\mathcal{O}_{54}^{\dagger}\psi_D\tilde{\lambda}^{\mathrm{B}}=\nabla_{\mu}\Bigg[D\phi n^{\mu}(D+\rho)\psi_D\tilde{\lambda}^{\mathrm{B}}-D\phi l^{\mu}\psi_D\left(\Delta+2\gamma+\mu-\frac{2a\xi\varphi_1^2}{D\phi}\right)\tilde{\lambda}^{\mathrm{B}}\\
&\qquad+D\phi m^{\mu}\psi_D(\overline{\delta}+4\overline{\beta})\tilde{\lambda}^{\mathrm{B}}-D\phi\overline{m}^{\mu}(\delta+4\beta)\psi_D\tilde{\lambda}^{\mathrm{B}}\Bigg],
\end{aligned} \tag{27}$$

$$\psi_D \mathcal{O}_{55}(\delta-2\beta)\tilde{\phi}^{\mathrm{B}} - \mathcal{O}^{\dagger}_{55}\psi_D(\delta-2\beta)\tilde{\phi}^{\mathrm{B}} = \nabla_\mu[-n^\mu(D+\rho)\psi_D(\delta-2\beta)\tilde{\phi}^{\mathrm{B}} + l^\mu\psi_D(\Delta+3\mu) \times(\delta-2\beta)\tilde{\phi}^{\mathrm{B}} - m^\mu\psi_D(\bar{\delta}+4\bar{\beta})(\delta-2\beta)\tilde{\phi}^{\mathrm{B}} + \bar{m}^\mu(\delta+4\beta)\psi_D(\delta-2\beta)\tilde{\phi}^{\mathrm{B}}].$$

Moreover, from Eqs. (14) and (23) $\mathcal{O}(\Psi^{\mathrm{B}})=0$ and $\mathcal{O}^{\dagger}(\psi)=0$. [The presence of an inhomogeneous term corresponding to the additional sources of the field variations in Eqs. (14) is only a *knack* for finding the operator $\mathcal{S}$. Finally we set $T_{\mu\nu}=0$, $j_\mu=0$, $\phi_s=0$.] Hence, from Eq. (25) we have the local continuity law:

$$\nabla_\mu J^\mu(\Psi^{\mathrm{B}},\psi)=0,$$
$$J^\mu = J^\mu_{11}+J^\mu_{13}+J^\mu_{22}+J^\mu_{24}+J^\mu_{31}+J^\mu_{33}+J^\mu_{34}+J^\mu_{35}+J^\mu_{42}+J^\mu_{43}+J^\mu_{44}+J^\mu_{45}+J^\mu_{53}+J^\mu_{54}+J^\mu_{55}, \tag{28}$$

and, of course, the J^μ_{ij}'s $(i,j=1,2,3,4,5)$ are the components coming from Eqs. (26), and (27); for example, $J^\mu_{34}=-aD\phi l^\mu\psi_E\tilde{\lambda}^{\mathrm{B}}$. Thus, J^μ is a *covariantly* conserved current. We will discuss now the properties and physical meaning of J^μ.

It is easy to verify that, such as (Ψ^{B}) in Eq. (16), the matrix potential (ψ) in Eq. (20) is made out of one-forms. Equations (21) give the field variations $h_{\mu\nu}$, b_μ, and ϕ^{B} (one-forms), in terms of (ψ). Since the operator $\mathcal{S}^\dagger$ is dependent only on background fields (zero-forms), thus (ψ) corresponds to one-forms. This implies automatically that $J^\mu=J^\mu(\Psi^{\mathrm{B}},\psi)$ in Eq. (28) is a (non-degenerate) two-form on the corresponding phase space of the solution considered (the matrix operators $\mathcal{O}$ and $\mathcal{O}^\dagger$ involved in the construction of J^μ are also dependent only on the background fields). In next section, we will demonstrate that J^μ is a *closed* two-form on the phase space, from which a symplectic structure will be constructed.

C. Covariant symplectic structure on the phase space

For demonstrating that J^μ is a closed two-form, we need to rewrite the J^μ_{ij}'s in Eq. (28). For example, J^μ_{11} [see Eq. (26)] can be rewritten as

$$\begin{aligned} &l^\mu\psi_G(\Delta-4\gamma+\mu)\Psi_0^{\mathrm{B}} - n^\mu(D+3\rho)\psi_G\Psi_0{}^{\mathrm{B}} - m^\mu\psi_G(\bar{\delta}+4\bar{\beta})\Psi_0^{\mathrm{B}} + \bar{m}^\mu(\delta+4\beta)\psi_G\Psi_0^{\mathrm{B}} \\ &\quad = -[l^\mu\psi_G(\Delta-4\gamma+\mu)\Psi_0]^{\mathrm{B}} + [n^\mu(D+3\rho)\psi_G\Psi_0]^{\mathrm{B}} + [m^\mu\psi_G(\bar{\delta}+4\bar{\beta})\Psi_0]^{\mathrm{B}} \\ &\qquad -[\bar{m}^\mu(\delta+4\beta)\psi_G\Psi_0]^{\mathrm{B}}, \end{aligned} \tag{29}$$

where we have considered that Ψ_0 vanishes at the background, and the Leibniz rule for the exterior derivative. Eq. (29), implies that J^μ_{11} is an *exact* two-form, and automatically a closed two-form. Similarly, using the fact that $\overline{\Psi_4^{\mathrm{B}}}$, $\tilde{\sigma}^{\mathrm{B}}$, $\tilde{\lambda}^{\mathrm{B}}$, and $(\delta-2\beta)\tilde{\phi}^{\mathrm{B}}$ can be expressed as variations of vanishing background fields, and the property of exterior derivative used above, we can find that

$$(J^\mu_{ij})^{\mathrm{B}}=0, \tag{30}$$

which makes that J^μ itself to be closed. In this manner, the geometrical structure defined as $\omega \equiv \int_\Sigma J^\mu d\Sigma_\mu$, where Σ is an initial value hypersurface, corresponds to a symplectic structure on the phase space. As J^μ is conserved, ω is independent of the choice of Σ and, in particular, is Poincaré invariant. Since (Ψ^{B}) is invariant under gauge transformation of b_μ, J^μ and ω have the same invariance properties. Hence, we have constructed a gauge-invariant closed two-form ω on the reduced phase space, which means the phase space modulo gauge transformations. Similarly, J^μ and ω are independent of the perturbed tetrad gauge freedom.

V. SEPARATION OF VARIABLES AND CONSERVED QUANTITIES

Our fundamental equations for the Debye potentials (23) and the continuity equation (28) admit separation of variables in terms of harmonic time and the spin-weighted spherical harmonics. The first ones are reduced to a system of *ordinary* differential equations for the radial parts of the potentials, the second one yields two conserved quantities expressed in terms of such radial parts.

A. Separable solutions for the potentials

An advantage of using the Newman–Penrose formalism is that each quantity has a type, and its corresponding boost weight and spin weight. This property suggests the separable solutions more convenient for the equations under study.

More specifically, the effect of the (relevant) Geroch–Held–Penrose operators on the spin-weighted spherical harmonics is given by[16]

$$\begin{aligned} \text{Þ}_s Y_{lm} &= (\delta - 2s\beta)\,{}_sY_{lm} = \frac{1}{\sqrt{2}R}[(l-s)(l+s+1)]^{1/2}\,{}_{s+1}Y_{lm}, \\ \text{Þ}'_s Y_{lm} &= (\bar{\delta} + 2s\bar{\beta})\,{}_sY_{lm} = -\frac{1}{\sqrt{2}R}[(l+s)(l-s+1)]^{1/2}\,{}_{s-1}Y_{lm}, \end{aligned} \tag{31}$$

where Eqs. (4) and (5) have been used. On the other hand, from Eqs. (23), it is easy to determine that the potentials ψ_G, ψ_H, ψ_E, ψ_F, and ψ_D have types $\{-4,0\}$, $\{0,4\}$, $\{-3,1\}$, $\{-1,3\}$, and $\{-2,2\}$, respectively. Therefore, all potentials have spin weight -2. Thus, making use of the fact that the background solution is static and spherically symmetric, we seek for solutions for the potentials of the form:

$$\psi_I = \psi_i(r)\,{}_{-2}Y_{lm}(\theta,\varphi)e^{-i\omega t}, \tag{32}$$

where the subscripts $I=G,H,E,F,D$ and $i=g,h,e,f,d$, respectively. Since $(\bar{\delta}-2\bar{\beta})(\delta+4\beta)$ is the only operator appearing in Eqs. (23) that involves angular variables, we only need to know that

$$(\bar{\delta}-2\bar{\beta})(\delta+4\beta)\psi_I = -\frac{L^2}{2R^2}\psi_I, \quad L=[(l-1)(l+2)]^{1/2}, \tag{33}$$

where Eqs. (31) and (32) have been employed. The remaining terms correspond to functions and differential operators involving only radial and time variables. In fact, from Eqs. (4) and (32) we have that

$$D\psi_I = \mathcal{D}\psi_I, \quad \Delta\psi_I = -\frac{\chi^2}{2}\bar{\mathcal{D}}\psi_I \quad \left(D\bar{\psi}_I = \overline{\mathcal{D}\psi_I}, \quad \Delta\bar{\psi}_I = -\frac{\chi^2}{2}\mathcal{D}\bar{\psi}_I\right), \tag{34}$$

where

$$\mathcal{D} = \partial_r - \frac{i\omega}{\chi^2}, \quad \bar{\mathcal{D}} = \partial_r + \frac{i\omega}{\chi^2}. \tag{35}$$

In this manner, it suffices to substitute the operators D and Δ, according to Eqs. (34), by $\mathcal{D}$ and $-(\chi^2/2)\bar{\mathcal{D}}$, respectively, $(\bar{\delta}-2\bar{\beta})(\delta+4\beta)$ by $-(L^2/2R^2)$ [according to Eq. (33)], and ψ_I by ψ_i (the corresponding radial part) into Eqs. (23), for reducing them to a system of ordinary equations for the radial parts ψ_i's of the potentials. Hence, the separation of variables proposed in Eq. (32) applies in a natural and straightforward way.

B. Separation of variables for the continuity equation

In this section we will see that the covariant continuity equation (28), together with the separable solutions admitted for the potentials [Eq. (32)], and the corresponding separation of variables for the field variations[12] (where a more detailed version of the present work is presented), lead to the existence of two conserved quantities.

As we have seen, at each space–time point, J^μ in Eq. (28) is a two-form on the phase space. Regardless of the last interpretation, we can maintain J^μ as a bilinear product on field perturbations on the space–time manifold. In this manner, the covariantly conserved current (28) can be rewritten, grouping conveniently its components on the null tetrad, in the form

$$J^\mu = V_l l^\mu + V_n n^\mu + V_m m^\mu + V_{\bar{m}} \bar{m}^\mu, \tag{36}$$

where

$$\begin{aligned}
V_l \equiv{}& \psi_{\mathrm{G}}(\Delta - 4\gamma + \mu)\Psi_0^{\mathrm{B}} - 8\xi\varphi_1^2\psi_{\mathrm{G}}\tilde{\sigma}^{\mathrm{B}} - \overline{\Psi_4^{\mathrm{B}}}(\Delta - 4\gamma - 3\mu)\psi_H - \tilde{\sigma}^{\mathrm{B}}(\Delta + 2\gamma + 2\mu)\psi_{\mathrm{E}} - aD\phi\psi_E\tilde{\lambda}^{\mathrm{B}} \\
&+ a\psi_E(\delta - 2\beta)\tilde{\phi}^{\mathrm{B}} + \psi_{\mathrm{F}}\overline{\Psi_4^{\mathrm{B}}} - \psi_{\mathrm{F}}(\Delta + 2\gamma + 2\mu - a\Delta\phi)\tilde{\lambda}^{\mathrm{B}} + \Delta\phi\psi_d\left(\Delta + \mu + \frac{2a\xi\varphi_1^2}{D\phi}\right)\tilde{\sigma}^{\mathrm{B}} \\
&- D\phi\psi_d\left(\Delta + 2\gamma + \mu - \frac{2a\xi\varphi_1^2}{D\phi}\right)\tilde{\lambda}^{\mathrm{B}} + \psi_{\mathrm{D}}(\Delta + 3\mu)(\delta - 2\beta)\tilde{\phi}^{\mathrm{B}}, \\
V_n \equiv{}& -\Psi_0^{\mathrm{B}}(D + 3\rho)\psi_{\mathrm{G}} + \psi_{\mathrm{H}}(D - \rho)\overline{\Psi_4^{\mathrm{B}}} + 8\xi\varphi_1^2\psi_{\mathrm{H}}\tilde{\lambda}^{\mathrm{B}} + \psi_{\mathrm{E}}\Psi_0^{\mathrm{B}} + \psi_{\mathrm{E}}(D - 2\rho - aD\phi)\tilde{\sigma}^{\mathrm{B}} \\
&+ a\Delta\phi\psi_{\mathrm{F}}\tilde{\sigma}^{\mathrm{B}} + \tilde{\lambda}^{\mathrm{B}}(D - 2\rho)\psi_{\mathrm{F}} + a\psi_{\mathrm{F}}(\delta - 2\beta)\tilde{\phi}^{\mathrm{B}} - \tilde{\sigma}^{\mathrm{B}}[4a\xi\varphi_1^2 - \mu D\phi + \Delta\phi D]\psi_{\mathrm{D}} \\
&+ D\phi\tilde{\lambda}^{\mathrm{B}}(D + \rho)\psi_{\mathrm{D}} - [(D + \rho)\psi_{\mathrm{D}}](\delta - 2\beta)\tilde{\phi}^{\mathrm{B}}, \\
V_m \equiv{}& -\psi_{\mathrm{G}}(\bar{\delta} + 4\bar{\beta})\Psi_0^{\mathrm{B}} - \psi_{\mathrm{H}}(\bar{\delta} + 4\bar{\beta})\overline{\Psi_4^{\mathrm{B}}} - \psi_{\mathrm{E}}(\bar{\delta} + 4\bar{\beta})\tilde{\sigma}^{\mathrm{B}} + \psi_{\mathrm{F}}(\bar{\delta} + 4\bar{\beta})\tilde{\lambda}^{\mathrm{B}} - \Delta\phi\psi_{\mathrm{D}}(\bar{\delta} + 4\bar{\beta})\tilde{\sigma}^{\mathrm{B}} \\
&+ D\phi\psi_{\mathrm{D}}(\bar{\delta} + 4\bar{\beta})\tilde{\lambda}^{\mathrm{B}} - \psi_{\mathrm{D}}(\bar{\delta} + 4\bar{\beta})(\delta - 2\beta)\tilde{\phi}^{\mathrm{B}}, \\
V_{\bar{m}} \equiv{}& \Psi_0^{\mathrm{B}}(\delta + 4\beta)\psi_{\mathrm{G}} + \overline{\Psi_4^{\mathrm{B}}}(\delta + 4\beta)\psi_{\mathrm{H}} + \tilde{\sigma}(\delta + 4\beta)\psi_{\mathrm{E}} - \tilde{\lambda}^{\mathrm{B}}(\delta + 4\beta)\psi_{\mathrm{F}} + \Delta\phi\tilde{\sigma}^{\mathrm{B}}(\delta + 4\beta)\psi_{\mathrm{D}} \\
&- D\phi\tilde{\lambda}^{\mathrm{B}}(\delta + 4\beta)\psi_{\mathrm{D}} + (\delta + 4\beta)\psi_{\mathrm{D}}(\delta - 2\beta)\tilde{\phi}^{\mathrm{B}}.
\end{aligned} \tag{37}$$

Therefore, considering that in the Newman–Penrose formalism $\partial_\mu l^\mu = -2\rho$, $\partial_\mu n^\mu = 2\mu - 2\gamma$, $\partial_\mu m^\mu = 2\beta$, the continuity equation (28) can be rewritten in the following form:

$$\partial_\mu(V_l l^\mu + V_n n^\mu + V_m m^\nu + V_{\bar{m}}\bar{m}^\mu) = (D - 2\rho)V_l + (\Delta + 2\mu - 2\gamma)V_n = 0, \tag{38}$$

where we have considered that $(\delta + 2\beta)V_m + (\bar{\delta} + 2\bar{\beta})V_{\bar{m}} = 0$, which can be shown using the explicit forms of V_m and $V_{\bar{m}}$ in Eqs. (37), and considering that all components of (Ψ^{B}) have spin weight 2.[12]

Thus, the whole physical information about our conserved quantities is contained in V_l and V_n. Furthermore, direct substitutions of the separable solutions for the potentials [Eq. (32)], and field variations[12] into the expressions for the bilinear products V_l and V_n given in Eqs. (37), lead to a splitting of such products in terms of the form e^0 and $e^{-2i\omega t}$:

$$\begin{aligned}
V_n &= \left[V_n^+ + \frac{i\omega}{\chi^2}G^+\right]{}_{-2}Y_{lm}\,\overline{{}_{-2}Y_{lm}} + e^{-2i\omega t}\left[V_n^- + \frac{i\omega}{\chi^2}G^-\right]{}_{-2}Y_{lm}\,{}_2Y_{lm}, \\
V_l &= \left[V_l^+ + \frac{i\omega}{2}G^+\right]{}_{-2}Y_{lm}\,\overline{{}_{-2}Y_{lm}} + e^{-2i\omega t}\left[V_l^- - \frac{i\omega}{2}G^-\right]{}_{-2}Y_{lm}\,{}_2Y_{lm},
\end{aligned} \tag{39}$$

where

$$
\begin{aligned}
V_n^{\pm} \equiv & \Psi_0^{\mathrm{B}\pm}[\psi_e - R^3\partial_r(R^{-3}\psi_g)] + \psi_h[R^{-1}\partial_r(R\,\overline{\Psi_4^{\mathrm{B}\pm}}) + 8\xi\varphi_1^2\tilde{\lambda}^{\mathrm{B}\pm}] + \psi_e R^{-2}\xi^{-1/2}\partial_r(R^2\xi^{1/2}\tilde{\sigma}^{\mathrm{B}\pm}) \\
& + a\psi_f[\Delta\phi\tilde{\sigma}^{\mathrm{B}\pm} + \tilde{\phi}^{\mathrm{B}\pm}] + \tilde{\lambda}^{\mathrm{B}\pm}R^2\partial_r(R^2\psi_f) - \tilde{\sigma}^{\mathrm{B}\pm}[\Delta\phi R\partial_r(R^{-1}\psi_d) + 4a\xi\varphi_1^2\psi_d] \\
& + R[D\phi\tilde{\lambda}^{\mathrm{B}\pm} - \tilde{\phi}^{\mathrm{B}\pm}]\partial_r(R^{-1}\psi_d), \\
V_l^{\pm} \equiv & \overline{\Psi_4^{\mathrm{B}\pm}}[\psi_f + \tfrac{1}{2}\chi^{-2}R^3\partial_r(R^{-3}\chi^2\psi_h)] - \psi_g[\tfrac{1}{2}\chi^{-2}R^{-1}\partial_r(R\chi^4\Psi_0^{\mathrm{B}\pm}) + 8\xi\varphi_1^2\tilde{\sigma}^{\mathrm{B}\pm}] \\
& + \tfrac{1}{2}\psi_f\chi^4R^{-2}\xi^{-1/2}\partial_r(\xi^{1/2}R^2\chi^{-2}\tilde{\lambda}^{\mathrm{B}\pm}) + a\psi_e[\tilde{\phi}^{\mathrm{B}\pm} - \Delta\phi\tilde{\lambda}^{\mathrm{B}\pm}] + \tfrac{1}{2}\tilde{\sigma}^{\mathrm{B}\pm}\chi^4R^{-2}\partial_r(R^2\chi^{-2}\psi_e) \\
& + \Delta\phi\psi_d\left[-\frac{1}{2}\chi^2R^{-1}\partial_r(R\tilde{\sigma}^{\mathrm{B}\pm}) + \frac{2a\xi\varphi_1^2}{D\phi}\tilde{\sigma}^{\mathrm{B}\pm}\right] \\
& + D\phi\psi_d\left[\frac{1}{2}\chi^4R^{-1}\partial_r(R\chi^{-2}\tilde{\lambda}^{\mathrm{B}\pm}) + \frac{2a\xi\varphi_1^2}{D\phi}\tilde{\lambda}^{\mathrm{B}\pm}\right] - \frac{1}{2}\chi^2R^{-3}\psi_d\partial_r(R^3\tilde{\phi}^{\mathrm{B}\pm}),
\end{aligned}
\tag{40}
$$

and

$$
\begin{aligned}
G^+ &\equiv \psi_g\Psi_0^{\mathrm{B}+} + \psi_h\overline{\Psi_4^{\mathrm{B}+}} + \psi_e\tilde{\sigma}^{\mathrm{B}+} - \psi_f\tilde{\lambda}^{\mathrm{B}+} + \psi_d[\Delta\phi\tilde{\sigma}^{\mathrm{B}+} - D\phi\tilde{\lambda}^{\mathrm{B}+} + \tilde{\phi}^{\mathrm{B}+}], \\
G^- &\equiv \psi_g\Psi_0^{\mathrm{B}-} - \psi_h\overline{\Psi_4^{\mathrm{B}-}} - \psi_e\tilde{\sigma}^{\mathrm{B}-} - \psi_f\tilde{\lambda}^{\mathrm{B}-} + \psi_d[\Delta\phi\tilde{\sigma}^{\mathrm{B}-} - D\phi\tilde{\lambda}^{\mathrm{B}-} + \tilde{\phi}^{\mathrm{B}-}] = \frac{L^2l(l+1)}{8R^4}\psi_d^2
\end{aligned}
\tag{41}
$$

are only functions of r. Since the components $(\Psi^{\mathrm{B}})^-$ are directly proportional to the potentials,[12] V_n^- and V_l^- in Eqs. (40) have remarkable reductions (unlike V_n^+ and V_l^+):

$$
\begin{aligned}
V_n^- &= -\frac{L^2l(l+1)}{8R^4}\left[-2\psi_g\psi_h\partial_r\ln R^3 + R\psi_d\partial_r\left(\frac{\psi_d}{R}\right)\right], \\
V_l^- &= -\frac{L^2l(l+1)\chi^2}{16R^4}\left[2\psi_g\psi_h\partial_r\ln R^3 + R\psi_d\partial_r\left(\frac{\psi_d}{R}\right)\right],
\end{aligned}
\tag{42}
$$

therefore, from Eqs. (41), and (42), is very easy to show that

$$
\begin{aligned}
& V_n^- + 2\chi^{-2}V_l^- + R^{-2}\partial_r(R^2G^-) = 0, \\
& V_l^- - \frac{\chi^2}{2}V_n^- = -\frac{L^2l(l+1)\chi^2}{4R^4}(\partial_r\ln R^3)\psi_g\psi_h,
\end{aligned}
\tag{43}
$$

which will be useful below.

C. Conserved quantities

Substituting expressions (39) into Eq. (38), using the explicit form for D, Δ, ρ, μ, and γ we obtain, after some simplification and suitably grouping, that

$$
\begin{aligned}
& \frac{1}{R^2}\partial_rR^2\left[V_l^+ - \frac{\chi^2}{2}V_n^+\right]\,{}_{-2}Y_{lm}\,\overline{{}_{-2}Y_{lm}} + \frac{e^{-2i\omega t}}{R^2}\partial_rR^2\left[V_l^- - \frac{\chi^2}{2}V_n^-\right]\,{}_{-2}Y_{lm}\,{}_2Y_{lm} \\
& \quad - i\omega e^{-2i\omega t}\left[2\frac{V_l^-}{\chi^2} + V_n^- + R^{-2}\partial_r(R^2G^-)\right]\,{}_{-2}Y_{lm}\,{}_2Y_{lm} = 0,
\end{aligned}
\tag{44}
$$

the last term vanishes according to the first of Eqs. (43), thus Eq. (44) reduces to

$$\partial_r R^2\left[V_l^+ - \frac{\chi^2}{2}V_n^+\right]{}_{-2}Y_{lm}\,\overline{{}_{-2}Y_{lm}} + e^{-2i\omega t}\partial_r R^2\left[V_l^- - \frac{\chi^2}{2}V_n^-\right]{}_{-2}Y_{lm}\,{}_{2}Y_{lm} = 0, \tag{45}$$

which implies (using the linear independence of terms of the form $e^{i\omega t}$ and $e^{-i\omega t}$) that there exist two conserved quantities, which we denote by $K^{(\pm)}$:

$$R^2\left[V_l^{(\pm)} - \frac{\chi^2}{2}V_n^{(\pm)}\right] \equiv K^{(\pm)}. \tag{46}$$

Although K^+ has a complicated form in terms of the potentials, K^- has a remarkably simple form, in accordance with the last expression in Eq. (43):

$$K^- \equiv R^2\left[V_l^- - \frac{\chi^2}{2}V_n^-\right] = -\frac{L^2 l(l+1)}{4}\,\frac{\chi^2(\partial_r \ln R^3)}{R^2}\,\psi_g\psi_h\,. \tag{47}$$

Note that, since $(\Psi^{\mathrm{B}})^+$ depends on $(\overline{\psi_i})$, K^+ depends on (ψ_i) and $(\overline{\psi_i})$, whereas K^- directly on the potentials without involving its complex conjugates.

The existence of these two conserved quantities deserves some important comments. First: although the equations used for obtaining such quantities are not Hermitian ones (for which the constancy of the Wronskian yields traditionally conserved quantities), one can obtain, without any restrictions and full generality, conserved quantities, provided that the original system of equations and its adjoint system are used. Second: as we have seen, if the potentials have a time dependence of the form $e^{-i\omega t}$, the field perturbations appearing in the decoupled system contain terms proportional to $e^{-i\omega t}$ and $e^{i\omega t}$ (in the classical cases, unlike the present case involving string fields, only terms proportional to $e^{i\omega t}$ are present[11]), which lead finally to two conserved quantities. In the classical cases, only a conserved quantity analogous to the present K^+ is obtained. In fact, the bilinear terms depending on $\Psi_0^{\mathrm{B}+}$ and ψ_g in the expression for K^+ [see the explicit forms for V_n^+ and V_l^+ in Eqs. (40)] yield a conservation relation for the energy of gravitational perturbations in the classical Schwarzschild black hole (and something similar for electromagnetic perturbations).[11] In this manner, it is possible that K^+ has the same physical meaning for the present string black hole: the conservation of the energy for the coupled field perturbations. However, this question will require a long asymptotic analysis and will be studied in a subsequent work. On the other hand, K^- is a novel conserved quantity apparently without classical analogy; it is also an open question to investigate its physical meaning.

VI. CONCLUDING REMARKS

We summarize some questions that remain open and will be the subject of forthcoming works.

First, although string black holes are considered as classical black holes plus Planck-scale corrections, they are not actually *quantum black holes*. Hence, for example, the thermodynamics properties argued in Refs. 2 and 3 are limited in this sense; a proper quantization will give a more complete and satisfactory description of such objects (see the paragraph before final comments of Ref. 5). The idea is, of course, that the symplectic structure constructed in the present work is to be the starting point for such a (canonical) quantization, which will give us a consistent quantum extension of string black holes.

Second, as mentioned, the physical meaning of the conserved quantities obtained in the present work remains to be worked out. This subject will include the calculation of physical quantities such as scattering amplitudes, reflection and transmission coefficients, etc.

Finally, the scheme of adjoint operators employed in the present work can be understood as an important extension of the original Wald's method: wherever there exists an appropriate decoupled equation, it is not only possible to express the complete solution in terms of scalar potentials, but also to find automatically a corresponding (covariantly) conserved current.

(Received 28 October 2002; accepted 9 December 2002)

In this article we study spherically symmetric monopoles, which are critical points for the Yang–Mills–Higgs functional over a disk in three dimensions, with prescribed degree and covariant constant at the boundary. This is a three-dimensional gauge-theory generalization of the Ginzburg-Landau model in two dimensions. [DOI: 10.1063/1.1543226]

I. INTRODUCTION

In this article we treat a three-dimensional analog of the vortex equations in two dimensions and look for solutions with spherical symmetry as described in Sec. II. The domain considered is a three-dimensional disk and we prescribe the degree of the monopole at the boundary. Unlike in two dimensions, where Ginzburg–Landau-type functionals appear either with or without gauge potentials, the problem in three dimensions is well-posed only in gauge theory. Without a curvature term in the action, a minimizing sequence for the action would yield a trivial limit.[2] In the presence of a gauge potential, this problem is well-posed, natural and has physical meaning.

The most general Yang–Mills–Higgs functional takes the form

$$\mathcal{YMH}(A,\phi)=\frac{\epsilon}{2}\|F\|_{L^2}^2+\frac{\rho}{2}\|D_A\phi\|_{L^2}^2+\frac{\lambda}{8}\|\,|\phi|^2-a^2\|_{L^2}^2\ , \tag{1.1}$$

for appropriate constants ϵ, ρ, λ and a. Working on $\mathbb{R}^3$, one usually applies a rescaling of ϕ, a rescaling of space, and a rescaling of the action to set $\epsilon=\rho=a=1$, so the action functional depends on a single parameter, λ. On the unit ball, however, we cannot rescale space, so we can only eliminate two of the four parameters. We set $\rho=a=1$, and obtain a two-parameter family of functionals

$$\mathcal{YMH}_{\epsilon,\lambda}(A,\phi)=\frac{\epsilon}{2}\|F\|_{L^2(B^3)}^2+\frac{1}{2}\|D_A\phi\|_{L^2(B^3)}^2+\frac{\lambda}{8}\|\,|\phi|^2-1\|_{L^2(B^3)}^2. \tag{1.2}$$

(Alternatively, we could work on a sphere of radius R. One can then rescale to set $\epsilon=1$, at the cost of varying R. We then obtain a two-parameter family of functionals indexed by λ and R.) We know from the general theory for monopoles (cf. Ref. 2 for $\epsilon=1$, $\lambda\geqslant 0$) that there exists a minimum for this functional which satisfies the Euler Lagrange equations

$$\begin{aligned}\epsilon *D_A *F&=[D_A\phi,\phi],\\ *D_A *D_A\phi&=\frac{\lambda}{2}(|\phi|^2-1)\phi,\end{aligned} \tag{1.3}$$

b)Electronic mail: sadun@math.utexas.edu

and suitable boundary conditions on $\partial B^3 \equiv S^2$ (cf. Sec. IV and Refs. 2 and 3), and is smooth. In this article we prove the existence, and describe the form, of spherically symmetric solutions to these equations.

We note that, even for $\lambda = 0$, these are not solutions to the Bogomolnyi equations found in Ref. 1. The Bogomolnyi solutions are obtained only in the limit $\lambda \to 0$, $R \to \infty$, or equivalently $\lambda \to 0$, $\epsilon \to 0$.

II. SPHERICALLY SYMMETRIC CONNECTIONS, MONOPOLES, AND GAUGE TRANSFORMATIONS

We work on the trivial principal SU(2)-bundle $P = B^3 \times \mathrm{SU}(2)$ and its associated vector bundles. A is a connection on P, which can be viewed as a one-form on B^3 with values in su(2). The Higgs field ϕ is a section of the adjoint bundle, i.e., a map $\phi : B^3 \to \mathrm{su}(2)$. Here $\mathrm{su}(2) \equiv \{X \in \mathcal{M}_{2\times 2} : tr\, X = 0\, ;\, X + \overline{X^T} = 0\}$ is the Lie algebra of SU(2). We identify su(2) with the imaginary quaternions $\mathrm{Im}\,\mathbb{H} \equiv \{x_1 i + x_2 j + x_3 k : (x_1, x_2, x_3) \in \mathbb{R}^3\}$ by identifying the matrices

$$\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad \begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix} \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix},$$

with i, j, k, respectively, and extending this mapping to a Lie-algebra isomorphism. It is also convenient to define the three-vector of Lie-algebra elements $\vec{\sigma} = (i, j, k)$.

The symmetry group SO(3) acts on pairs (A, ϕ), simultaneously rotating the three-dimensional base space and the three-dimensional Lie algebra. That is, the triple (i, j, k) transforms in the same way as the triple (x_1, x_2, x_3), so quantities such as $\vec{\sigma} \cdot \vec{x}$ are invariant.

We are interested in finding Yang–Mills–Higgs fields (A, ϕ) which are invariant under this group action. To this purpose, one needs to specify the value of the connection one-form $A : B^3 \to \Lambda^1(B^3) \otimes \mathrm{Im}\,\mathbb{H}$ and of the Higgs field $\phi : B^3 \to \mathrm{Im}\,\mathbb{H}$ at one point of each group orbit (on the base) and impose invariance under the isotropy group of that point. We find it convenient to fix the values of (A, ϕ) on the slice $L \equiv \{\vec{x} \in B^3 : x_2 = x_3 = 0, x_1 \in (0,1]\}$. The isotropy group at $(x,0,0) \in L$ is SO(2), i.e., rotations about the x_1-axis (and about the i axis in the Lie algebra). For the Higgs field ϕ one has in general

$$\phi(x,0,0) = \varphi_1(x) i + \varphi_2(x) j + \varphi_3(x) k \in \mathrm{Im}\,\mathbb{H} \simeq \mathrm{su}(2)\,,$$

where $\varphi_l(x)$, $l = 1,2,3$ are real-valued functions. Imposing invariance under SO(2) forces $\varphi_2(x) = \varphi_3(x) = 0$ for all $x \in (0,1]$. Applying the action of SO(3), one obtains the symmetric form of the Higgs field ϕ

$$\phi = \frac{\varphi(r)}{r} \vec{\sigma} \cdot \vec{x} \equiv \frac{\varphi(r)}{r} (x_1 i + x_2 j + x_3 k)\,, \tag{2.1}$$

with $r \equiv |\vec{x}|$, $\vec{x} \equiv (x_1, x_2, x_3) \in \mathbb{R}^3$, $\vec{\sigma} \equiv (i, j, k) \in \mathrm{Im}\,\mathbb{H}$.

An su(2)-valued connection on the slice L is given in general by

$$\begin{aligned} A(x,0,0) = {} & a_{11}(x) i\, dx_1 + a_{12}(x) i\, dx_2 + a_{13}(x) i\, dx_3 + a_{21}(x) j\, dx_1 + a_{22}(x) k\, dx_2 + a_{23}(x) j\, dx_3 \\ & + a_{31}(x) k\, dx_1 + a_{32}(x) k\, dx_2 + a_{33}(x) k\, dx_3\,. \end{aligned} \tag{2.2}$$

Imposing SO(2)-invariance yields $a_{12} = a_{13} = a_{21} = a_{31} = 0$, $a_{22} = a_{33}$, and $a_{23} = -a_{32}$. Thus the final form of the SO(2)-invariant connection evaluated at the points $(x,0,0) \in L$ is

$$A(x,0,0) = a(x) i\, dx_1 + b(x)(j\, dx_2 + k\, dx_3) + c(x)(k\, dx_2 - j\, dx_3)\,.$$

Transporting this slice via the SO(3) group action on B^3 one obtains the invariant version

$$A(x_1,x_2,x_3)=\frac{\alpha(r)}{r}\vec{\sigma}\cdot\vec{dx}+\frac{\beta(r)}{r^3}(\vec{x}\times\vec{dx})\cdot(\vec{x}\times\vec{\sigma})+\frac{\gamma(r)}{r^2}\vec{\sigma}\cdot(\vec{x}\times\vec{dx}), \tag{2.3}$$

where "×" denotes the cross product of vectors and $\vec{dx}\equiv(dx_1,dx_2,dx_3)$.

At this point there is still some gauge freedom available to further specify the connection A, namely that provided by "symmetric" gauge transformations. Such a transformation g is determined by its values on the slice L, which must be SO(2)-invariant. This yields $i\,g(x,0,0)=g(x,0,0)\,i$, thus $g(x,0,0)=\exp(i\,h(x))$. Therefore, symmetric gauge transformations are of the type

$$g(x_1,x_2,x_3)=\exp\left(h(r)\frac{\vec{\sigma}\cdot\vec{x}}{|\vec{x}|}\right), \tag{2.4}$$

where $h(r)$ is an arbitrary function of the radius r. Performing such a gauge transformation does not change the form (2.1) of the Higgs field ϕ. However, A transforms nontrivially. In particular, setting $h(r)\equiv\int\alpha(r)/r\,dr$ exactly cancels the α-piece in $g^{-1}dg+g^{-1}A\,g$. Thus, one can impose $\alpha(r)=0$. The final version of A is then

$$A(x_1,x_2,x_3)=\frac{\beta(r)}{r^3}(\vec{x}\times\vec{dx})\cdot(\vec{x}\times\vec{\sigma})+\frac{\gamma(r)}{r^2}\vec{\sigma}\cdot(\vec{x}\times\vec{dx}). \tag{2.5}$$

The only gauge freedom remaining is from the constant of integration in the indefinite integral $\int[\alpha(r)/r]\,dr$ (cf. Sec. IV).

Note that the β and γ terms have opposite parities. The isometry $\vec{x}\to-\vec{x}$ sends β to $-\beta$ but sends γ to $+\gamma$.

III. THE YANG–MILLS–HIGGS FUNCTIONAL ON SPHERICALLY SYMMETRIC CONFIGURATIONS

In this section we explicity compute the Yang–Mills–Higgs functional, and the resulting equations of motion, for symmetric pairs (A,ϕ). Our connection is a sum of two terms,

$$A=B+C,$$

where

$$\begin{aligned}B&=\frac{\beta(r)}{r^3}(\vec{x}\times\vec{dx})\cdot(\vec{x}\times\vec{\sigma})\\&=\frac{\beta(r)}{r^3}[(r^2-x_1^2)i-x_1x_3k-x_1x_2j]\,dx_1+\frac{\beta(r)}{r^3}[(r^2-x_2^2)j-x_2x_3k-x_1x_2i]\,dx_2\\&\quad+\frac{\beta(r)}{r^3}[(r^2-x_3^2)k-x_1x_3i-x_2x_3j]\,dx_3,\end{aligned} \tag{3.1}$$

and

$$\begin{aligned}C&=\frac{\gamma(r)}{r^2}\vec{\sigma}\cdot(\vec{x}\times\vec{dx})\\&=\frac{\gamma(r)}{r^2}(x_3j-x_2k)\,dx_1+\frac{\gamma(r)}{r^2}(x_1k-x_3i)\,dx_2+\frac{\gamma(r)}{r^2}(x_2i-x_1j)\,dx_3.\end{aligned} \tag{3.2}$$

A. Preliminary computations

The curvature of A is given by

$$F = dA + A \wedge A = dB + dC + B \wedge B + C \wedge C ,$$

since the cross term $B \wedge C + C \wedge B$ is identically zero.

Computing F_{12}, the various nonzero terms are

$$(d\,B)_{12} = \frac{\beta'}{r^2}(-x_2 i + x_1 j), \tag{3.3}$$

$$(d\,C)_{12} = \left(\frac{-\gamma}{r^2}\right)' \left(\frac{x_1 x_3}{r} i + \frac{x_2 x_3}{r} j\right) + \left(\frac{2\gamma}{r^2} + \left(\frac{\gamma}{r^2}\right)' \left(\frac{x_2^2}{r} + \frac{x_1^2}{r}\right)\right) k, \tag{3.4}$$

$$(B \wedge B)_{12} = \frac{2\beta^2}{r^4}[x_1 x_3 i + x_2 x_3 j + x_3^2 k], \tag{3.5}$$

$$(C \wedge C)_{12} = \frac{2\gamma^2}{r^4}[x_1 x_3 i + x_2 x_3 j + x_3^2 k]. \tag{3.6}$$

By rotational symmetry, the contributions to F_{13} and F_{23} are similar.

The covariant derivative of the monopole $\phi = [\varphi(r)/r]\vec{\sigma} \cdot \vec{x}$ is given by

$$D_A \phi \equiv d\phi + [B, \phi] + [C, \phi] , \tag{3.7}$$

where

$$d\phi = \frac{\vec{\sigma} \cdot \vec{x}}{r} d\varphi + \varphi\, d\left(\frac{\vec{\sigma} \cdot \vec{x}}{r}\right) \quad , \tag{3.8}$$

$$[B, \phi] \equiv B\phi - \phi B = \frac{2\beta\varphi}{r^2}(-x_3 j + x_2 k)\, d\,x_1 + \text{cyclic permutations}, \tag{3.9}$$

$$[C, \phi] \equiv C\phi - \phi C = \frac{2\gamma\varphi}{r^3}[(r^2 - x_1^2) i - x_1 x_3 k - x_1 x_2 j] d\,x_1 + \text{cyclic permutations}. \tag{3.10}$$

At this point we are ready to compute the three terms involved in the Yang–Mills–Higgs functional (1.2). They are

(1) $|F|^2 \equiv F \wedge *F$,
(2) $|D\phi|^2 \equiv D\phi \wedge *D\phi$,
(3) $(|\phi|^2 - 1)^2$.

Computation of (1): One shows easily that

$$dB \wedge *dC = dC \wedge *dB = 0 ,$$

$$dB \wedge *(B \wedge B) = (B \wedge B) \wedge *dB = 0 ,$$

$$dB \wedge *(C \wedge C) = (C \wedge C) \wedge *dB = 0 ,$$

thus

$$
\begin{aligned}
|F|^2 &= |dB|^2 + |dC|^2 + dC\wedge *(B\wedge B) + dC\wedge *(C\wedge C) + (B\wedge B)\wedge *(B\wedge B) \\
&\quad + (B\wedge B)\wedge *(C\wedge C) + (C\wedge C)\wedge *(C\wedge C) \\
&= 2\frac{\beta'^2}{r^2} + 2\frac{\gamma'^2}{r^2} + 4\frac{\gamma^2}{r^4} + 4\frac{\beta^2\gamma}{r^4} + 4\frac{\gamma^3}{r^4} + 4\frac{\beta^4}{r^4} + 8\frac{\beta^2\gamma^2}{r^4} + 4\frac{\gamma^4}{r^4} \\
&= \frac{2\beta'^2}{r^2} + \frac{2\gamma'^2}{r^2} + \frac{4(\beta^2+\gamma^2+\gamma)^2}{r^4}. \qquad (3.11)
\end{aligned}
$$

Computation of (2): One shows that

$$d\phi\wedge *[B,\phi] = [B,\phi]\wedge *d\phi = 0\,,$$

$$[B,\phi]\wedge *[C,\phi] = [C,\phi]\wedge *[B,\phi] = 0\,,$$

thus

$$|D\phi|^2 = |d\phi|^2 + |[B,\phi]|^2 + |[C,\phi]|^2 + 2\,d\phi\wedge *[C,\phi] \qquad (3.12)$$

$$= \left(\varphi'^2 + 2\frac{\varphi^2}{r^2}\right) + 8\frac{\beta^2\varphi^2}{r^2} + 8\frac{\gamma^2\varphi^2}{r^2} + 8\frac{\gamma\varphi^2}{r^2}. \qquad (3.13)$$

Computation of (3): One easily obtains

$$(|\phi|^2 - 1)^2 = \left(\frac{\varphi^2}{r^2} - 1\right)^2.$$

Collecting terms, the Yang–Mills–Higgs functional calculated on spherically symmetric configurations is given by

$$
\begin{aligned}
\mathcal{SYMH}(\gamma,\varphi) = 4\pi\int_0^1 \Bigg[& 2\epsilon\left(\beta'^2 + \gamma'^2 + \frac{2}{r^2}(\beta^2+\gamma^2+\gamma)^2\right) + r^2\varphi'^2 \\
& + 2\varphi^2[1 + 4(\beta^2+\gamma^2+\gamma)] + \lambda r^2(\varphi^2-1)^2 \Bigg] \mathrm{d}r\ . \qquad (3.14)
\end{aligned}
$$

IV. FURTHER GAUGE TRANSFORMATIONS AND THE EULER–LAGRANGE EQUATIONS

We want to search for absolute minima of the functional (3.14) among all finite-action spherically symmetric configurations (β, γ, φ). The following theorem restricts the possibilities:

Theorem 4.1: *If the functional (3.14) has a minimum, then this minimum is achieved by functions* (β, γ, φ) *with* β *identically zero and* $\gamma(0) = 0$.

Proof: First we find a gauge transformation that yields $\beta(0) = \gamma(0) = 0$. In that gauge, we then show that minimization requires $\beta/(\gamma + \frac{1}{2})$ to be constant, hence for β to be identically zero.

If $\mathcal{SYMH}(\beta,\gamma,\varphi) < \infty$, then β and γ much approach well-defined limits as $r \to 0$, and $\beta^2(0) + \gamma^2(0) + \gamma(0) = 0$. If $\beta(0)$ and $\gamma(0)$ are not already zero, we let θ be the argument of the complex number $\beta(0) + i\,\gamma(0)$, and define

$$g = \exp\left(\theta\frac{\vec{\sigma}\cdot\vec{x}}{|\vec{x}|}\right) \equiv \exp\left(\theta\frac{x_1 i + x_2 j + x_3 k}{|\vec{x}|}\right) \equiv \cos(\theta) + \sin(\theta)\frac{\vec{\sigma}\cdot\vec{x}}{|\vec{x}|}\,. \qquad (4.1)$$

Then

$$d\,g(x_1,x_2,x_3)=\sin(\theta)\left[\frac{\vec{\sigma}\cdot\vec{dx}}{|\vec{x}|}+d\left(\frac{1}{|\vec{x}|}\right)\vec{\sigma}\cdot\vec{x}\right]\ , \tag{4.2}$$

and evaluating on our slice gives

$$d\,g(r,0,0)=\frac{\sin(\theta)}{r}(j\,d\,x_2+k\,d\,x_3). \tag{4.3}$$

Our transformed connection on the slice is then

$$\begin{aligned}[g^{-1}d\,g+g^{-1}A\,g](r,0,0)&=\left[\frac{\cos(2\theta)\,\beta(r)}{r}+\frac{\sin(2\theta)\,\gamma(r)}{r}+\frac{\cos(\theta)\sin(\theta)}{r}\right](j\,d\,x_2+k\,d\,x_3)\\&\quad+\left[-\frac{\sin(2\theta)\,\beta(r)}{r}+\frac{\cos(2\theta)\,\gamma(r)}{r}-\frac{\sin^2(\theta)}{r}\right](k\,d\,x_2-j\,d\,x_3)\\&\equiv\frac{\hat{\beta}(r)}{r}(j\,d\,x_2+k\,d\,x_3)+\frac{\hat{\gamma}(r)}{r}(k\,d\,x_2-j\,d\,x_3).\end{aligned} \tag{4.4}$$

Plugging in the values of $\sin(\theta)$, $\cos(\theta)$, etc., gives

$$\hat{\beta}(r)=\frac{(\beta^2(0)-\gamma^2(0))\beta(r)+2\beta(0)\gamma(0)\gamma(r)+\beta(0)\gamma(0)}{\beta^2(0)+\gamma^2(0)}, \tag{4.5}$$

$$\hat{\gamma}(r)=\frac{(-2\beta(0)\gamma(0))\beta(r)+(\beta^2(0)-\gamma^2(0))\gamma(r)-\gamma^2(0)}{\beta^2(0)+\gamma^2(0)}. \tag{4.6}$$

As $r\to 0$, both these terms go to zero, since $\beta^2(0)+\gamma^2(0)+\gamma(0)=0$.

Having set $\beta(0)=\gamma(0)=0$, we now show that β must be identically zero. We choose polar coordinates in the $(\beta,\gamma+\frac{1}{2})$-plane:

$$\begin{aligned}\beta&=\nu\cos t,\\ \gamma+\tfrac{1}{2}&=\nu\sin t.\end{aligned} \tag{4.7}$$

In these coordinates, the functional (3.14) becomes

$$\mathcal{SYMH}(\nu,t)=4\pi\int_0^1\left[\ 2\epsilon\left(\nu'^2+t'^2\nu^2+\frac{2}{r^2}\left(\nu^2-\frac{1}{4}\right)^2\right)+r^2\varphi'^2+8\varphi^2\nu^2+\lambda r^2(\varphi^2-1)^2\ \right]dr, \tag{4.8}$$

with $\nu^2(0)=\frac{1}{4}$. The only dependence on t is in the $t'^2\nu^2$ term, which is minimized by setting $t=$const. But then $\cot(t)=\beta/(\gamma+\frac{1}{2})$ must be constant, and equal to $\beta(0)/(\gamma(0)+\frac{1}{2})=0$, so β is identically zero. □

We may therefore restrict our attention to the functional

$$\mathcal{S}(\gamma,\varphi)=4\pi\int_0^1\left[\ 2\epsilon\left(\gamma'^2+\frac{2}{r^2}(\gamma^2+\gamma)^2\right)+r^2\varphi'^2+2\varphi^2(1+2\gamma)^2+\lambda r^2(\varphi^2-1)^2\ \right]dr. \tag{4.9}$$

The Euler–Lagrange equations for this functional together with the appropriate boundary conditions are then

$$\gamma'' - \frac{2}{\epsilon}\varphi^2(1+2\gamma) - \frac{2}{r^2}(\gamma^2+\gamma)(1+2\gamma) = 0 \quad \text{on } (0,1),$$

$$\varphi'' + \frac{2\varphi'}{r} - \frac{2\varphi}{r^2}(1+2\gamma)^2 - 2\lambda\varphi(\varphi^2-1) = 0 \quad \text{on } (0,1),$$

$$\gamma(1) = -\tfrac{1}{2}, \tag{4.10}$$

$$\gamma(0) = 0,$$

$$\varphi(1) = +1 \quad (\text{or } \varphi(1) = -1).$$

The boundary conditions above come directly from the variational principle. In fact, to cancel the boundary terms one needs to either restrict the space of connections to those with prescribed boundary data, or to impose Neumann-type boundary conditions. The boundary condition $\varphi(1) = \pm 1$ comes from $|\phi| = 1$ on ∂B^3 and $\gamma(1) = -\frac{1}{2}$ comes from

$$(D\phi)_\tau = (d\phi)_\tau + [A_\tau, \phi] = (1+2\gamma)\phi \quad d\left(\frac{\vec{\sigma}\cdot\vec{x}}{r}\right) = 0 \tag{4.11}$$

on ∂B^3, where the subscript τ denotes tangential components (cf. Refs. 2 and 3).

Observation: After some computation, the system (4.10) could also be obtained by imposing spherical symmetry in (1.3), thus critical symmetric points for the action (4.9) are symmetric critical points (not necessarily minima) for (1.2). This is also known *a priori* from the ''principle of symmetric criticality.'' [4]

V. EXISTENCE OF SPHERICALLY SYMMETRIC MONOPOLES

Our basic existence result is the following.

Theorem 5.1: *For all values of* $\lambda \geqslant 0$, $\epsilon > 0$, *there exists a symmetric solution of*

$$\begin{gathered} \epsilon * D_A * F = [D_A\phi, \phi] \quad \text{on } B^3, \\ * D_A^* D_A \phi = \frac{\lambda}{2}(|\phi|^2 - 1)\phi \quad \text{on } B^3, \\ (D\phi)_\tau = 0 \quad \text{on } \partial B^3, \\ |\varphi| = 1 \quad \text{on } \partial B^3. \end{gathered} \tag{5.1}$$

Observation: These equations do not reduce to the Bogomolnyi equations, even if $\lambda = 0$. The Bogolmolnyi argument involves an integration by parts; on a finite domain, this results in a boundary contribution.[1]

Proof: Because of the derivative terms in the action, the natural space for γ (denoted $\mathcal{H}_\gamma$) is $H^1(0,1)$, while the natural space $\mathcal{H}_\varphi$ for φ is the weighted Sobolev space $H^1((0,1), r^2 dr)$. By the Sobolev embedding theorem, functions in $\mathcal{H}_\gamma$ are continuous on $[0,1]$. Functions in $\mathcal{H}_\varphi$ are continuous on $(0,1]$, but may not have a limit at $r = 0$. We may therefore apply boundary conditions to γ at $r = 0$ and at $r = 1$, and to φ at $r = 1$.

Let

$$\mathcal{F} = \{(\gamma, \varphi) \in \mathcal{H}_\gamma \times \mathcal{H}_\varphi \ : \ \gamma(1) = -\tfrac{1}{2},\ \gamma(0) = 0, \varphi(1) = 1\}. \tag{5.2}$$

The action functional (4.9) is well-defined on $\mathcal{F}$, and is finite whenever φ is bounded. In particular, $\mu \equiv Inf_{\mathcal{F}} \mathcal{S}$ is finite. We follow the direct method in the calculus of variations. That is, take a minimizing sequence for $\mathcal{S}$, show that it converges weakly in $\mathcal{F}$, and then show that the weak limit minimizes the action and so solves the Euler–Lagrange equations.

Let (γ_n, φ_n) be a minimizing sequence for $\mathcal{S}$. Since $\lambda \geqslant 0$, the action is not increased if we make the replacement

$$\varphi(r) \to \begin{cases} -1, & \text{if } \varphi(r) < -1; \\ \varphi(r), & \text{if } -1 \leqslant \varphi(r) \leqslant 1; \\ 1, & \text{if } \varphi(r) > 1. \end{cases} \tag{5.3}$$

As a result, we can assume that each $\varphi_n(r)$ is bounded in magnitude by 1. Under these circumstances, the sequence (γ_n, φ_n) is bounded in $\mathcal{F} \subset \mathcal{H}_\gamma \times \mathcal{H}_\varphi$. However, balls in $\mathcal{H}_\gamma$ are weakly compact, as are balls in $\mathcal{H}_\varphi$, so the pair (γ_n, φ_n) converges weakly in $\mathcal{H}_\gamma \times \mathcal{H}_\varphi$ to a limit $(\gamma_\infty, \varphi_\infty)$.

By Sobolev, $\gamma_n(r)$ and $\varphi_n(r)$ converge pointwise to $\gamma_\infty(r)$ and $\varphi_\infty(r)$, so the limiting values $\gamma(0)$, $\gamma(1)$, and $\varphi(1)$ are preserved, and $(\gamma_\infty, \varphi_\infty) \in \mathcal{F}$. Moreover, terms in $\mathcal{S}(\gamma_n, \varphi_n)$ that do not involve derivatives converge to the corresponding terms in $\mathcal{S}(\gamma_\infty, \varphi_\infty)$. The derivative terms are quadratic, hence weakly semicontinuous. As a result, $\mathcal{S}(\gamma_\infty, \varphi_\infty)$ is bounded above by μ, and therefore must equal μ.

Showing that γ_∞ and φ_∞ satisfy the Euler–Lagrange equations (4.10) is then a standard exercise in the calculus of variations. Smoothness of $(\gamma_\infty, \varphi_\infty)$ away from $r=0$ follows by elliptic regularity of the equations (4.10). Smoothness at $r=0$ follows from regular singular-point analysis, combined with the fact that both functions are bounded (see Sec. VI for details). This in turn implies that the connection and Higgs field (A, ϕ) constructed from $(\gamma_\infty, \varphi_\infty)$ comprise a smooth, symmetric classical solution to the PDE system (5.1). [Alternatively, one can establish regularity of (A, ϕ) from the ellipticity of the PDE system (5.1), since we are working in a gauge with $d^*A = 0$.]

VI. REGULAR SINGULAR POINT ANALYSIS

In Sec. V we demonstrated the existence of symmetric monopoles for arbitrary $\lambda \geqslant 0$ and $\epsilon > 0$. In this section we explore their form near the regular singular point of the equations (4.10), namely $r=0$.

Theorem 6.1: *Let (γ, φ) be a bounded finite-action solution to the ODE system (4.10) for some fixed $\epsilon > 0$ and $\lambda \geqslant 0$. Then there exist constants a_1 and b_2 such that*

$$\begin{aligned} \varphi(r) &= a_1 r + O(r^3), \\ \gamma(r) &= b_2 r^2 + O(r^4), \\ \gamma'(r) &= 2 b_2 r + O(r^3), \end{aligned} \tag{6.1}$$

near $r=0$. In particular, $\varphi(0) = \gamma'(0) = 0$.

Proof: We begin with the equation for φ, which we write as

$$\varphi'' + \frac{2\varphi'}{r} - \frac{2\varphi}{r^2} = \frac{8\varphi}{r^2}(\gamma + \gamma^2) + 2\lambda\varphi(\varphi^2 - 1). \tag{6.2}$$

Since φ is bounded and $\gamma(0) = 0$, the terms on the right hand side are less singular than those on the left hand side, and to leading order φ resembles the solution to the homogeneous equation

$$\varphi'' + \frac{2\varphi'}{r} - \frac{2\varphi}{r^2} = 0. \tag{6.3}$$

The general solution to this equation is $\varphi = a_1 r + a_{-2} r^{-2}$. However, φ is bounded by assumption, so $a_{-2} = 0$. Thus the solution to (6.2) is, to leading order, $a_1 r$.

Next we turn to the equation for γ, namely

$$\gamma'' - \frac{2\gamma}{r^2} = \frac{2}{\epsilon}\varphi^2(1+2\gamma) + \frac{2\gamma}{r^2}(2\gamma^2+3\gamma). \tag{6.4}$$

Again, since φ is bounded and $\gamma(0)=0$, this may be viewed as a perturbation of the homogeneous linear equation

$$\gamma'' - \frac{2\gamma}{r^2} = 0, \tag{6.5}$$

whose solution is $\gamma = b_{-1} r^{-1} + b_2 r^2$. Since γ is bounded, $b_{-1} = 0$. Thus our solution to (6.4) is, to leading order, $b_2 r^2$.

With these basic results, we can estimate the right hand sides of (6.2) and (6.4). The right hand side of (6.2) is $O(r)$, which gives an $O(r)$ correction to φ'', hence an $O(r^3)$ correction to φ. The right hand side of (6.4) is $O(r^2)$, thus giving an $O(r^3)$ correction to γ' and an $O(r^4)$ correction to γ. □

One can do an expansion for φ and γ in powers of r. Indeed, only odd powers contribute to φ and only even powers contribute to γ. This is seen by induction. By Theorem 6.1, φ is odd and γ is even through order r^2. However, if φ is odd and γ is even through order r^k, then the right hand sides of (6.2) and (6.4) are odd and even, respectively, to order r^k, and so φ and γ are odd and even, respectively, to order r^{k+2}. Thus φ and γ are odd and even to all orders in r.

We can therefore write an asymptotic expansion

$$\begin{aligned} \varphi(r) &\sim \sum_{n \text{ odd}} a_n r^n, \\ \gamma(r) &\sim \sum_{n \text{ even}} b_n r^n. \end{aligned} \tag{6.6}$$

Plugging this expansion into Eqs. (6.2) and (6.4) and equating coefficients of r^{n-2} gives recursion relations of the form

$$\begin{aligned} (2k)(2k+3)a_{2k+1} &= \text{algebraic expression involving } a_1, b_2, \ldots, b_{2k}, \\ (2k+1)(2k-2)b_{2k} &= \text{algebraic expression involving } a_1, b_2, \ldots, b_{2k-2}. \end{aligned} \tag{6.7}$$

These relations do not constrain a_1 or b_2. However, once we have a_1 and b_2, the remaining coefficients are determined. The first few are

$$\begin{aligned} a_3 &= (4a_1 b_2 - \lambda a_1)/5, \\ b_4 &= (3b_2^2 + \epsilon^{-1} a_1^2)/5, \\ a_5 &= (4a_1 b_4 + 4a_3 b_2 + 4a_1 b_2^2 + \lambda(a_1^3 - a_3))/14, \\ b_6 &= (b_2^3 + 3b_2 b_4 + \epsilon^{-1}(a_1 a_3 + a_1^2 b_2))/7, \\ a_7 &= [4(a_1 b_6 + a_3 b_4 + a_5 b_2 + a_3 b_2^2 + 2a_1 b_2 b_4) + \lambda(3a_1^2 a_3 - a_5)]/27, \\ b_8 &= [3(2b_2^2 b_4 + b_4^2 + 2b_2 b_6) + \epsilon^{-1}(a_3^2 + 2a_1 a_5 + 2a_1^2 b_4 + 4a_1 a_3 b_2)]/27, \end{aligned} \tag{6.8}$$

TABLE I. Taylor coefficients (a_1, b_2) for various values of (ϵ, λ).

VII. SYMMETRIES AND STABILITY

The action functional and the resulting Euler–Lagrange equations are invariant under two natural symmetries,

$$\varphi(r)\to-\varphi(r),\quad \gamma(r)\to+\gamma(r); \tag{7.1}$$

$$\varphi(r)\to\varphi(r),\quad \gamma(r)\to-1-\gamma(r). \tag{7.2}$$

The first symmetry (7.1) comes from the isometry $\vec{x}\to-\vec{x}$ of B^3, which of course respects rotational symmetry. Since $\vec{\sigma}\cdot\vec{x}$ is odd and $\vec{\sigma}\cdot(\vec{x}\times\overrightarrow{dx})$ is even, pulling the pair (A,ϕ) back by this isometry flips the sign of φ while preserving γ. Using this symmetry, we can fix the sign of $\varphi(1)$, which we henceforth take to be positive.

The second symmetry (7.2) is a gauge transformation by $(\vec{\sigma}\cdot\vec{x})/r$. This is of the form of (4.2), with $\theta=\pi/2$. From (4.4) it is clear that this transformation sends γ to $-1-\gamma$ without generating a β term or changing φ. Applying this to a connection with $\gamma(0)=0$ yields a new connection with $\gamma(0)=-1$. This connection has finite action but is singular at the origin, reflecting the singular gauge transformation that generated it.

We now consider stability properties of the ODE system (4.10). These ODEs have several fixed points, namely

$$(\gamma,\varphi)=(-\tfrac{1}{2},1),\ (-\tfrac{1}{2},-1),\ (-\tfrac{1}{2},0),\ (0,0)\ \text{ or }\ (-1,0). \tag{7.3}$$

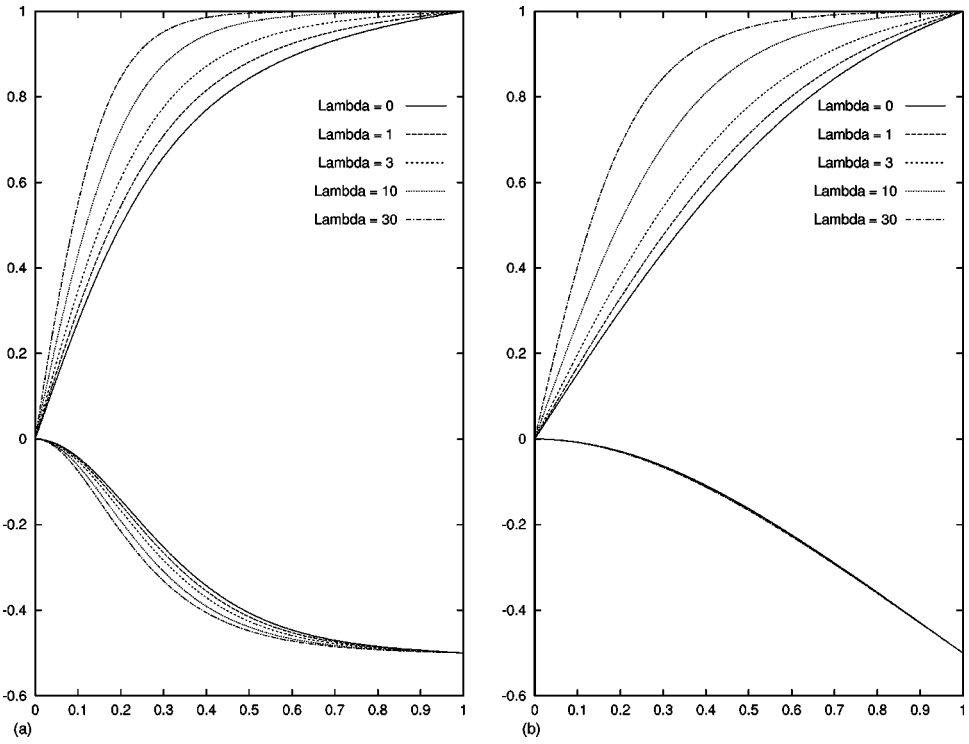

FIG. 1. Trajectories with fixed ϵ.

The point $(-\frac{1}{2},-1)$ is related to $(-\frac{1}{2},1)$ by the symmetry (7.1), while $(-1,0)$ is related to $(0,0)$ by (7.2), so we do not need to study these. What remains is $(-\frac{1}{2},1)$, $(-\frac{1}{2},0)$, and $(0,0)$.

For the $\gamma=-1/2$ fixed points, we define $\delta=\gamma+1/2$, and the equation for γ becomes

$$\delta''=4\delta\left(\frac{\varphi^2}{\epsilon}-\frac{1}{4r^2}+\frac{\delta^2}{r^2}\right). \tag{7.4}$$

The fixed point $\gamma=-\frac{1}{2}$ is stable for $\varphi=1$ when $r^2<\epsilon/4$, but is unstable if $r^2>\epsilon/4$. This defines a natural length scale to the problem, namely $\sqrt{\epsilon}/2$. We should expect our solutions to behave qualitatively differently for r less than or greater than this length scale. Of course, if $\epsilon>4$, then all radii r are less than this length scale. In the case of $\varphi=0$, the value $\gamma=\frac{1}{2}$ is always stable, regardless of ϵ or r.

Near $\gamma=-\frac{1}{2}$, the equation for φ becomes

$$\varphi''+2\frac{\varphi'}{r}=2\varphi\left(\frac{4\delta^2}{r^2}+\lambda(\varphi^2-1)\right). \tag{7.5}$$

The behavior of this fixed point depends on the value of φ. Near $\varphi=0$ we have

$$(r\varphi)''=-2\lambda r\varphi+O(\delta^2)+O(\varphi^2),$$

which is stable for all positive values of r. Near $\varphi=1$, however, we write $\varphi=1+\zeta$ and have

$$(r\zeta)''=4\lambda(r\zeta)+O(\zeta^2)+O(\delta^2).$$

This is unstable as long as $\lambda>0$, and has natural length scale $1/\sqrt{4\lambda}$.

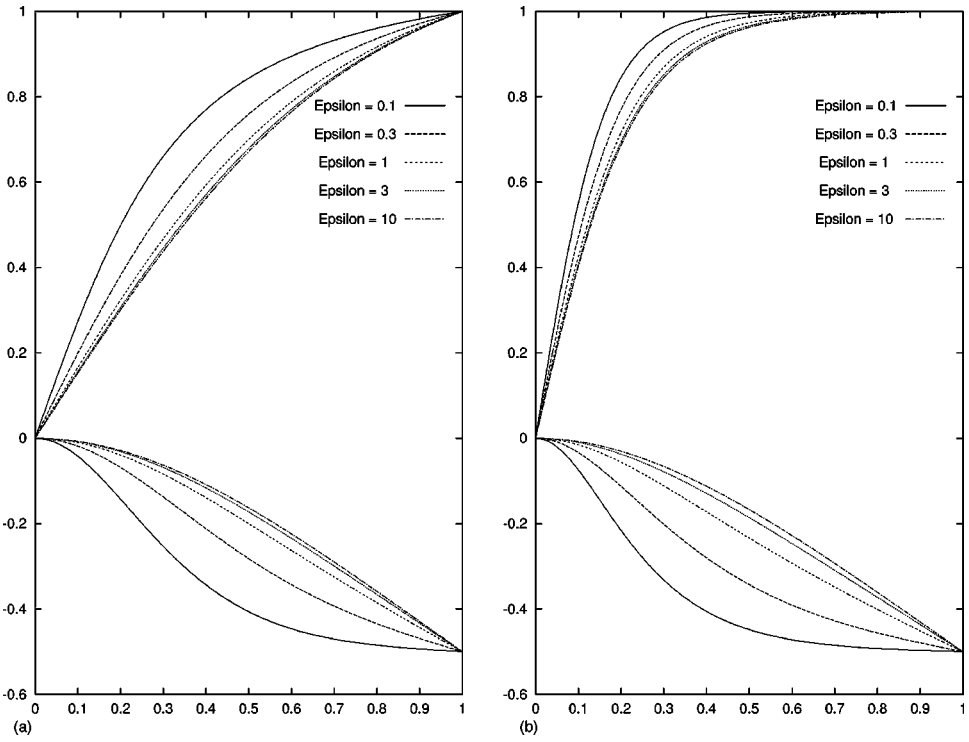

FIG. 2. Trajectories with λ fixed.

To summarize, the fixed point $(-\frac{1}{2},0)$ is stable, while the fixed point $(-\frac{1}{2},1)$ is unstable. If $r^2<\epsilon/4$, then there is one unstable mode, corresponding to growth of $\varphi-1$. If $r^2>\epsilon/4$, then there are two unstable modes, one for φ and one for γ.

Finally, there is the fixed point (0,0). Near (0,0) we have

$$\begin{aligned}\gamma'' &= 2\gamma/r^2 + \text{higher order},\\ \varphi'' + 2\varphi'/r &= 2\varphi(r^{-2}-\lambda) + \text{higher order}.\end{aligned} \tag{7.6}$$

This fixed point is always unstable, with γ growing rapidly. φ will grow exponentially if $r<1/\sqrt{\lambda}$, and will oscillate if $r>1/\sqrt{\lambda}$.

VIII. NUMERICAL RESULTS AND QUALITATIVE ANALYSIS

For any fixed ϵ and λ, and given a_1 and b_2, one can in principle integrate the differential equations out to $r=1$. In practice, numerical errors due to the discretization of the interval [0,1] can be very bad near the origin, due to the singular nature of the ODE system there. A better method is to use the power series (6.6) in a neighborhood of the origin and to numerically integrate from there. In a discretization of 10 000 points, we use the power series out to $r=0.01$, or 100 lattice spacings from the origin.

In this way we get a pair $(\gamma(1),\varphi(1))$ for each (a_1,b_2). Using Newton's method, we then find values of (a_1,b_2) such that $(\gamma(1),\varphi(1))=(-\frac{1}{2},1)$. Table I lists the correct values of a_1 and b_2 for several values of ϵ and λ.

The resulting functions $\varphi(r)$ and $\gamma(r)$ are sketched in Figs. 1 and 2. Figure 1 shows the functions for different values of λ and ϵ fixed at 0.1 or at 10. Figure 2 is similar, only with λ fixed and ϵ variable. In each case the positive function is φ and the negative function is γ.

From these figures several qualitative features are clear. Although φ depends significantly on both ϵ and λ, γ is practically independent of λ, especially when ϵ is large. The length scale on

which γ changes from 0 to $-\frac{1}{2}$ is the smaller of $\sqrt{\epsilon}$ and 1. The length scale on which φ changes from 0 to 1 is the smallest of $\sqrt{\epsilon}$, $1/\sqrt{\lambda}$, and 1. Thus changing λ has the greatest effect when λ is greater than 1, while changing ϵ has the greatest effect when $\epsilon<1$.

The source code for these numerical results can be obtained from the authors.

(Received 4 September 2001; accepted 2 December 2002)

The separated radial part of a massive complex scalar wave equation in the Kerr–Sen geometry is shown to satisfy the generalized spheroidal wave equation which is, in fact, a confluent Heun equation up to a multiplier. The Hawking evaporation of scalar particles in the Kerr–Sen black hole background is investigated by the Damour–Ruffini–Sannan method. It is shown that quantum thermal effect of the Kerr–Sen black hole has the same character as that of the Kerr–Newman black hole. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1539899]

I. INTRODUCTION

In a recent paper,[1] we have investigated exact solution of a massive complex scalar field equation in the Kerr–Newman black hole background, and demonstrated that both its radial part and its angular part can be transformed into the form of a generalized spheroidal wave equation.[2] Previous work on solution of a massive scalar wave equation in the Kerr(–Newman) space–time had been completed in Refs. 3 and 4. It is interesting to extend our analysis to solution of a scalar wave equation in a Kerr–Sen black hole background.[5] The Kerr–Sen solution arising in the low energy effective string field theory is a rotating charged black hole generated from the Kerr solution. The thermodynamic property of this twisted Kerr black hole was discussed in Ref. 6 by using separation of the Hamilton–Jacobi equation of a test particle. The aim of this paper is to study some exact solutions to a massive charged scalar wave equation and to find its connection to the confluent Heun equation[7] as well as to investigate quantum thermal effect of scalar particles on the Kerr–Sen space–time.

The paper is organized as follows: In Sec. II, we separate a massive charged scalar field equation on the Kerr–Sen black hole background into the radial and angular parts. Section III is devoted to transforming the radial part into a generalized spheroidal wave equation and to relating it to the confluent Heun equation. Then, we investigate quantum thermal effect of scalar particles in the Kerr–Sen space–time in Sec. IV. Finally, we summarize our discussions in the conclusion section.

II. SEPARATING VARIABLES OF KLEIN–GORDON EQUATION ON THE KERR–SEN BLACK HOLE BACKGROUND

Constructed from the charge neutral rotating (Kerr) black hole solution, the Kerr–Sen solution[5] is an exact classical four dimensional black hole solution in the low energy effective heterotic string field theory. In the Boyer–Lindquist coordinates, the Kerr–Sen metric and the electromagnetic field vector potential can be rewritten as[6]

[a)]Electronic mail: sqwu@ustc.edu.cn
[b)]Electronic mail: xcai@ccnu.edu.cn

$$ds^2=-\frac{\Delta}{\Sigma}(dt-a\sin^2\theta\, d\varphi)^2+\frac{\sin^2\theta}{\Sigma}[a\,dt-(\Sigma+a^2\sin^2\theta)d\varphi]^2+\Sigma\left(\frac{dr^2}{\Delta}+d\theta^2\right),$$
$$\mathcal{A}=\frac{-Qr}{\Sigma}(dt-a\sin^2\theta\, d\varphi), \tag{1}$$

where $\Delta=r^2+2(b-M)r+a^2=(r-r_+)(r-r_-)$, $\Sigma=r^2+2br+a^2\cos^2\theta$ and $r_\pm=M-b\pm\epsilon$ with $\epsilon=\sqrt{(M-b)^2-a^2}$.

This metric describes a black hole carrying mass M, charge Q, angular momentum $J=Ma$, and magnetic dipole moment Qa. The twist parameter b is related to the Sen's parameter α via $b=Q^2/2M=M\tanh^2(\alpha/2)$. Because $M\geqslant b\geqslant 0$, $r=r_-$ is a new singularity in the region $r\leqslant 0$, the event horizon of the Kerr–Sen black hole is located at $r=r_+$. The area of the outer event horizon of the twisted Kerr solution[5] is given by $A_+=4\pi(r_+^2+2br_++a^2)=8\pi Mr_+$.

We consider the solution of a massive charged test scalar field on the Kerr–Sen black hole background (we use Planck unit system $G=\hbar=c=k_B=1$ throughout the paper). Because the Kerr–Sen metric (1) only differs from the Kerr(–Newman) solution by the form of two functions Δ and Σ, the minimal electromagnetic coupling Klein–Gordon field equation satisfied by the complex scalar wave function Φ with mass μ and charge q in such a space–time can be separated as $\Phi(t,r,\theta,\varphi)=R(r)S^{\not<}_{m,0}(ka,\theta)e^{i(m\varphi-\omega t)}$, in which the angular part $S^{\not<}_{m,0}(ka,\theta)$ is an ordinary spheroidal angular wave function with spin weight $s=0$, while the radial part can be given as follows:

$$\partial_r[\Delta\,\partial_r R(r)]+\left[\frac{(Ar-ma)^2}{\Delta}+k^2\Delta+2Dr-\lambda\right]R(r)=0, \tag{2}$$

here λ is a separation constant, $A=2M\omega-qQ$, $D=A\omega-M\mu^2$, $k=\sqrt{\omega^2-\mu^2}$ (we assume that $\omega>\mu$). For later convenience, we also denote $\epsilon B=A(M-b)-ma$ and introduce $W_\pm=(A\pm B)/2$.

With further substitution $R(r)=(r-r_+)^{i(A+B)/2}(r-r_-)^{i(A-B)/2}F(r)$, we can transform Eq. (2) for $R(r)$ into a modified generalized spheroidal wave equation with imaginary spin weight iA and boost weight iB for $F(r)$,[1]

$$\Delta\partial_r^2F(r)+2[i\epsilon B+(1+iA)(r-M+b)]\partial_rF(r)+[k^2\Delta+2Dr+iA-\lambda]F(r)=0. \tag{3}$$

Equation (2) has two regular singular points $r=r_\pm$ with indices $\pm iW_+$ and $\pm iW_-$, respectively, whereas Eq. (3) has indices $\rho_+=0$, $-2iW_+$ and $\rho_-=0$, $-2iW_-$ at two singularities $r=r_\pm$, respectively. The infinity is an irregular singularity of Eqs. (2) and (3). Equation (3) has the same form as the radial part of the massive complex scalar wave equation in the Kerr–Newman geometry[1] with its solution (when $\mu=0$) named as the generalized spheroidal wave function.[2] It is interesting to note that a special solution of function $F(r)$ satisfies the Jacobi equation of imaginary index when $\omega=\pm\mu=qQ/M$ (namely, $k=D=0$).

III. GENERALIZED SPHEROIDAL WAVE FUNCTION AND HEUN EQUATION

In this section, we shall show that the generalized spheroidal wave equation (3) of imaginary number order is, in fact, a confluent form of Heun equation.[7] To this end, let us make a coordinate transformation $r=M-b+\epsilon z$ and substitute $R(r)=(z-1)^{i(A+B)/2}(z+1)^{i(A-B)/2}F(z)$ into Eq. (2), then we can reduce it to the following standard forms of a generalized spheroidal wave equation:[1,7]

$$(z^2-1)R''(z)+2zR'(z)+\left[(\epsilon k)^2(z^2-1)+2D\epsilon z+\frac{(Az+B)^2}{z^2-1}+2D(M-b)-\lambda\right]R(z)=0 \tag{4}$$

and

$$(z^2-1)F''(z)+2[iB+(1+iA)z]F'(z)+[(\epsilon k)^2(z^2-1)+2D\epsilon z+2D(M-b)+iA-\lambda]F(z)=0\,, \tag{5}$$

where a prime denotes the derivative with respect to its argument.

The spin-weighted spheroidal wave function $F(z)$ is symmetric under the reflect $k\to -k$. Letting $F(z)=e^{i\epsilon kz}G(z)$ without loss of generality, we can transform Eq. (5) to

$$(z^2-1)G''(z)+2[iB+(1+iA)z+i\epsilon k(z^2-1)]G'(z)+[2i\epsilon k(1+iA-iD/k)z-2\epsilon kB+iA+2D(M-b)-\lambda]G(z)=0\,. \tag{6}$$

By means of changing variable $z=1-2x$, we arrange the singularities $r=r_+$ $(z=1)$ to $x=0$ and $r=r_-$ $(z=-1)$ to $x=1$, respectively, and reduce Eq. (6) to a confluent form of Heun's equation[7,8]

$$G''(x)+\left(\beta+\frac{\gamma}{x}+\frac{\delta}{x-1}\right)G'(x)+\frac{\alpha\beta x-h}{x(x-1)}G(x)=0\,, \tag{7}$$

with $\gamma=1+2iW_+$, $\delta=1+2iW_-$, $\beta=4i\epsilon k$, $\alpha=-(1+iA)+iD/k$, $h=\lambda-2i\epsilon k-iA+4\epsilon kW_+-2Dr_+$.

This confluent Heun equation (7), with h its accessory parameter, has two regular singular points at $x=0,\ 1$ with exponents $(0,\ 1-\gamma)$ and $(0,\ 1-\delta)$, respectively, as well as an irregular singularity at the infinity point. The power series solution in the vicinity of the point $x=0$ for Eq. (7) can be written as

$$G(\alpha,\beta,\gamma,\delta,h;x)=\sum_{n=0}^{\infty} g_n x^n\,, \tag{8}$$

and the coefficient g_n satisfies a three-term recurrence relation[7,8]

$$\begin{gathered} g_0=1\,,\quad g_1=-h/\gamma\,,\\ (n+1)(n+\gamma)g_{n+1}-\beta(n-1+\alpha)g_{n-1}=[n(n-1-\beta+\gamma+\delta)-h]g_n\,. \end{gathered} \tag{9}$$

It is not difficult to deduce the exponent $1-\gamma$ solution[8] for $x=0$ and obtain the power series solution in the vicinity of the point $x=1$ by a linear transformation interchanging the regular singular points $x=0$ and $x=1$: $x\to 1-x$. Expansion of solutions to the confluent Heun's equation in terms of hypergeometric and confluent hypergeometric functions has been presented in Refs. 2 and 7. The confluent Heun's functions can be normalized to constitute a group of orthogonal complete functions.[7] It should be noted that Heun's confluent equation also admits quasipolynomial solutions for particular values of the parameters.[7,8] It follows from the three-term recurrence relation that $G(\alpha,\beta,\gamma,\delta,h;x)$ is a polynomial solution if

$$\begin{gathered} \alpha=-N\,,\quad \text{with integer } N\geqslant 0\,,\\ g_{N+1}(h)=0\,, \end{gathered} \tag{10}$$

where g_{N+1} being a polynomial of degree $N+1$ in h, that is, there are $N+1$ eigenvalues h_i for h such that $g_{N+1}(h_i)\equiv 0$.

IV. HAWKING RADIATION OF SCALAR PARTICLES

Now we investigate the Hawking evaporation[9] of scalar particles in the Kerr–Sen black hole by using the Damour–Ruffini–Sannan's (DRS) method.[10] This approach only requires the exis-

tence of a future horizon and is completely independent of any dynamical details of the process leading to the formation of this horizon. The DRS method assumes analyticity properties of the wave function in the complexified manifold.

In the following, we shall consider a wave outgoing from the event horizon r_+ over interval $r_+<r<\infty$. According to the DRS method, a correct outgoing wave $\Phi^{\text{out}}=\Phi^{\text{out}}(t,r,\theta,\varphi)$ is an adequate superposition of functions $\Phi^{\text{out}}_{r>r_+}$ and $\Phi^{\text{out}}_{r<r_+}$,

$$\Phi^{\text{out}}=C[\,\eta(r-r_+)\Phi^{\text{out}}_{r>r_+}+\eta(r_+-r)\Phi^{\text{out}}_{r<r_+}e^{2\pi W_+}], \tag{11}$$

where η is the conventional unit step function, C is a normalization factor.

In fact, components $\Phi^{\text{out}}_{r>r_+}$ and $\Phi^{\text{out}}_{r<r_+}$ have asymptotic behaviors,

$$\Phi^{\text{out}}_{r>r_+}=\Phi^{\text{out}}_{r>r_+}(t,r,\theta,\varphi)\to c_1(r-r_+)^{iW_+}S^{\swarrow}_{m,0}(ka,\theta)e^{i(m\varphi-\omega t)}\quad(r\to r_+), \tag{12}$$

$$\Phi^{\text{out}}_{r<r_+}=\Phi^{\text{out}}_{r<r_+}(t,r,\theta,\varphi)\to c_2(r-r_+)^{-iW_+}S^{\swarrow}_{m,0}(ka,\theta)e^{i(m\varphi-\omega t)}\quad(r\to r_+) \tag{13}$$

when $r\to r_+$. Clearly, the outgoing wave $\Phi^{\text{out}}_{r>r_+}$ cannot be directly extended from $r_+<r<\infty$ to $r_-<r<r_+$, but it can be analytically continued to an outgoing wave $\Phi^{\text{out}}_{r<r_+}$ that inside event horizon r_+ by the lower half complex r-plane around unit circle $r=r_+-i0$:

$$r-r_+\to(r_+-r)e^{-i\pi}.$$

By this analytical treatment, we have

$$\Phi^{\text{out}}_{r<r_+}\sim c_2(r-r_+)^{-iW_+}S^{\ell}_{m,0}(ka,\theta)e^{i(m\varphi-\omega t)}. \tag{14}$$

Equation (13) just takes one solution to the radial equation inside the event horizon r_+, it has the same form of Eq. (14) generated by the analytical method. As $\Phi^{\text{out}}_{r>r_+}$ differs $\Phi^{\text{out}}_{r<r_+}$ by a factor $(r-r_+)^{-2iW_+}$, then a difference factor $e^{2\pi W_+}$ emerges due to the above analytical treatment. Thus we can derive the relative scattering probability of the scalar wave at the event horizon

$$\left|\frac{\Phi^{\text{out}}_{r>r_+}}{\Phi^{\text{out}}_{r<r_+}}\right|^2=e^{-4\pi W_+}, \tag{15}$$

and obtain the thermal radiation spectrum with the Hawking temperature $T=\kappa/2\pi$.

$$\begin{aligned}\langle\mathcal{N}\rangle&=|C|^2=\frac{1}{e^{4\pi W_+}-1},\\ W_+&=\frac{Ar_+-ma}{2\epsilon}=\frac{\omega-m\Omega-q\Phi}{2\kappa},\end{aligned} \tag{16}$$

where the angular velocity at the horizon is $\Omega=a/2Mr_+$, the electric potential is $\Phi=Q/2M=b/Q$, the surface gravity at the pole is $\kappa=(r_+-M+b)/2Mr_+=\epsilon/2Mr_+$.

The black body radiation spectrum (16) demonstrates that the thermal property of Kerr–Sen black hole is similar to that of Kerr–Newman black hole though its geometry character is like that of the Kerr solution.[6] Correspondingly, there exist four thermodynamical laws of the Kerr–Sen black hole, similar to those of Kerr–Newman black hole thermodynamics.

V. CONCLUSION

In this paper, we have shown that the separation of variables of the scalar wave equation in the Kerr–Newman black hole background can apply completely to the case of the twisted Kerr solution. The separated radial part can be recast into the generalized spheroidal wave equation, which is, in fact, a confluent form of Heun equation.

In addition, we find that the thermal property of the twisted Kerr black hole resembles that of Kerr–Newman black hole though its geometry character likes that of the Kerr solution. The Kerr–Sen solution shares similar four black hole thermodynamical laws and quantum thermal effect as the Kerr–Newman space–time does.

Quasi-homogeneous thermodynamics and black holes

F. Belgiorno[a)]
Dipartimento di Fisica, Università Degli Studi di Milano, Via Celoria 16, 20133 Milano, Italy

(Received 14 October 2002; accepted 29 November 2002)

We propose a generalized thermodynamics in which quasi-homogeneity of the thermodynamic potentials plays a fundamental role. This thermodynamic formalism arises from a generalization of the approach presented in Ref. 1, and it is based on the requirement that quasi-homogeneity is a nontrivial symmetry for the Pfaffian form $\delta Q_{\text{rev.}}$ It is shown that quasi-homogeneous thermodynamics fits the thermodynamic features of at least some self-gravitating systems. We analyze how quasi-homogeneous thermodynamics is suggested by black hole thermodynamics. Then, some existing results involving self-gravitating systems are also shortly discussed in the light of this thermodynamic framework. The consequences of the lack of extensivity are also recalled. We show that generalized Gibbs–Duhem equations arise as a consequence of quasi-homogeneity of the thermodynamic potentials. An heuristic link between this generalized thermodynamic formalism and the thermodynamic limit is also discussed. © *2003 American Institute of Physics.*

I. INTRODUCTION

In Ref. 1 we have shown that, by choosing the extensive variables $(U,V,X^1,\ldots,X^n)$ as independent variables, and by postulating that the integrable Pfaffian form δQ_{rev} representing the infinitesimal heat exchanged reversibly is homogeneous of degree one and that the homogeneity symmetry is nontrivial (for the definition of nontrivial symmetry see the next section), it is possible to find immediately an integrating factor for δQ_{rev}. In fact, if $Y=U\partial_U+V\partial_V+\Sigma_i X^i\partial_{X^i}$ is the Liouville vector field associated with the homogeneity symmetry, one has that an integrating factor is given by $f=\delta Q_{\text{rev}}(Y)=i_Y\delta Q_{\text{rev}}\not\equiv 0$ (see Ref. 1 and references therein). The entropy $S(U,V,X^1,\ldots,X^n)$, which represents the fundamental equation in the entropy representation, is then straightforwardly recovered. The framework presented in Ref. 1 can be generalized in the following sense. A generalized thermodynamics where δQ_{rev} is a quasi-homogeneous integrable Pfaffian form is proposed. Quasi-homogeneity is realized to be a property which characterizes the behavior of thermodynamic functions like, e.g., the entropy in the black hole case, in some statistical mechanical models involving nonrelativistic matter interacting via the Newtonian potential and also in the case of self-gravitating radiation. When gravity plays an important role the standard extensivity property of thermodynamics does not hold; nevertheless, one can still find a form of thermodynamics in which each thermodynamic variable follows a power scaling law where the power can be different from one or zero, i.e., the variables are allowed to be neither extensive nor intensive. Black hole thermodynamics is the most evident and special thermodynamics belonging to this framework.

The plan of the paper is the following. In Sec. II we give some definitions and then in Sec. III, we propose a theoretical framework for quasi-homogeneous thermodynamics, by generalizing the standard thermodynamics case.[1] In Secs. IV, V, and VI examples displaying a quasi-homogeneous thermodynamics are discussed. In Sec. IV, the role of quasi-homogeneity in black hole thermodynamics is shown; in Sec. V, we discuss a model of fermionic nonrelativistic matter with Newtonian interaction which displays a quasi-homogeneous behavior. In Sec. VI, the general relativistic case of thermal geons and self-gravitating radiation are discussed. Sec. VII concerns the

a)Electronic mail: belgiorno@mi.infn.it

discussion of the physical consequences for thermodynamics when the requirement of homogeneity is relaxed. In Sec. VIII a summary of constructive assumptions is made. In Sec. IX the generalized Gibbs–Duhem identities are discussed. In Sec. X the energy representation and the Legendre transform are analyzed. In Sec. XI some further suggestions from black hole thermodynamics are discussed. Section XII has an heuristic nature, a link between the thermodynamic limit and the formalism of quasi-homogeneous thermodynamics is proposed. In the Appendix further mathematical and physical aspects are explored.

II. QUASI-HOMOGENEOUS PFAFFIAN FORMS

Given a set of real coordinates $x \equiv (x^1,\ldots,x^n)$ and a set of weights $\boldsymbol{\alpha} \equiv (\alpha_1,\ldots,\alpha_n) \in \mathbb{R}^n$, a real-valued function $G(x^1,\ldots,x^n)$ is quasi-homogeneous of degree r and type $\boldsymbol{\alpha}$ if, under the action of the one-parameter group of quasi-homogeneous dilatations

$$g^\tau : (x^1,\ldots,x^n) \to (e^{\alpha_1 \tau} x^1,\ldots,e^{\alpha_n \tau} x^n), \tag{1}$$

where $\tau \in \mathbb{R}$, one finds

$$G(g^\tau x) = e^{r\tau} G(x). \tag{2}$$

A differentiable function G on a open connected domain

$$\mathcal{D} = \{x \in \mathcal{D} \,|\, g^\tau x \in \mathcal{D} \;\; \forall \;\; x \in \mathcal{D}, \tau \in \mathbb{R}\} \subseteq \mathbb{R}^n \tag{3}$$

is quasi-homogeneous of degree r, if and only if,[2,3]

$$DG = rG, \tag{4}$$

where the Euler vector field

$$D \equiv \alpha_1 x^1 \frac{\partial}{\partial x^1} + \cdots + \alpha_n x^n \frac{\partial}{\partial x^n} \tag{5}$$

is the infinitesimal generator of the transformation. Notice that a quasi-homogeneous transformation is also called ''similarity transformation'' and ''stretching transformation.'' [4] The identity (4) is a generalization of the Euler identity for homogeneous functions. Quasi-homogeneity for functions and vector fields is defined in Ref. 2. Notice that, according to the definition given above, one cannot avoid specifying, together with the degree of quasi-homogeneity, the type of the quasi-homogeneous object one is considering.

Homogeneous functions are a subset of quasi-homogeneous functions, in fact they have all the weights equal to 1. We define *strictly quasi-homogeneous functions* the functions which satisfy the above definition with weights which cannot be all equal. A quasihomogeneous function of n variables is characterized by n weights and its degree. If all the weights are undetermined and arbitrary, or if they are in part undetermined and in part equal to 1, then all the weights can be set equal to 1, and then the function is actually homogeneous. The vice versa is not true, because there are homogeneous functions which do not admit different weights (i.e., they are not strictly quasi-homogeneous). A trivial example is given by $g(x,y) = x^2 + y^2$, which is homogeneous of degree 2 but it is not also strictly quasihomogeneous. Instead, the function $h(x,y) = xy$ is homogeneous of degree 2 and it is also quasi-homogeneous with undetermined weights. In the following, ''quasi-homogeneous'' is used as synonymous of strictly quasi-homogeneous, unless a more general discussion is required.

A Pfaffian form

$$\omega = \sum_{i=1}^{n} \omega_i(x) dx^i \tag{6}$$

is defined to be quasi-homogeneous of degree $r \in \mathbb{R}$ if, under the scaling

$$x^1,\ldots,x^n \mapsto \lambda^{\alpha_1} x^1,\ldots,\lambda^{\alpha_n} x^n \tag{7}$$

one finds

$$\omega \mapsto \lambda^r \omega. \tag{8}$$

This happens if and only if the degree of quasi-homogeneity $\deg(\omega_i(x))$ of $\omega_i(x)$ is such that $\deg(\omega_i(x)) = r - \alpha_i \ \forall i = 1,\ldots,n$. Let us assume that a quasi-homogeneous ω is integrable, i.e., $\omega \wedge d\omega = 0$. A quasi-homogeneous transformation is a symmetry for ω (see, e.g., Refs. 5 and 6), in the sense that

$$(L_D \omega) \wedge \omega = 0 \tag{9}$$

where L_D is the Lie derivative associated with D defined in (5). An integrating factor f such that the form ω/f is closed can then be constructed by contracting the vector field D with ω:

$$f \equiv \omega(D) = i_D(\omega), \tag{10}$$

and $\omega(D) \not\equiv 0$ is to be assumed. This means that the symmetry generated by D is nontrivial, in the sense that it does not belong to the distribution of codimension one which is associated with the kernel of ω. Then, the symmetry is not tangent to each leaf of the foliation associated with the integrable one-form ω, but it carries leaves onto other leaves. In this sense, a nontrivial symmetry is transversal with respect to the foliation.
One gets

$$d\left(\frac{\omega}{f}\right) = 0. \tag{11}$$

The integrating factor f is a quasi-homogeneous function of degree r, because $D i_D(\omega) = i_D L_D \omega = r i_D(\omega)$ (due to the Cartan formula $L_X i_Y - i_Y L_X = i_{[X,Y]}$ and to $i_0 = 0$). Then ω/f is of degree zero and its integral can be found only by quadratures (cf. Sec. III); one gets

$$\hat{S} - \hat{S}_0 \equiv \int_\Gamma \frac{\omega}{f}. \tag{12}$$

It can be shown that there exists a quasi-homogeneous function F of degree one with respect to D such that

$$\hat{S} = \log(F), \tag{13}$$

$$DF = F, \tag{14}$$

thus it holds $D\hat{S} = 1$ and $\hat{S}$ is not quasi-homogeneous. On this topic see Appendix A, where the case of a generic transversal symmetry is treated. The above construction is completely analogous to the construction developed for homogeneous integrable Pfaffian forms in Ref. 1.

III. A GENERAL FRAMEWORK

Quasi-homogeneous thermodynamics (recall that we mean strictly quasi-homogeneous) overcomes the standard distinction between extensive and intensive variables. We propose the following generalization for the integrable Pfaffian form δQ_{rev} which represents the infinitesimal heat exchanged by the system:

$$\delta Q_{\mathrm{rev}} = dU^* - \sum_{i=1}^{n} \xi_i^* \, dX^{i*} \tag{15}$$

where the asterisk indicates that both the independent variables $U^*, X^{1*}, \ldots, X^{n*}$ and the dependent ones $\xi_1^*, \ldots, \xi_n^*$ in (15) are generalizations of the usual ones in the sense that they are not simply intensive and/or extensive but quasi-homogeneous, in such a way that the Pfaffian form δQ_{rev} is quasi-homogeneous of degree r. Moreover, for the sake of definiteness and in order to fit some requirements for the validity of Frobenius' theorem, δQ_{rev} is assumed to be of class at least C^1 in the thermodynamic domain (except, maybe, on the boundary as, e.g., the surface $T=0$).

The thermodynamic domain $\mathcal{D}$ is assumed to be a simply connected set which satisfies (3). A further requirement for $\mathcal{D}$ has to be introduced if the entropy S^* is required to be superadditive: $\mathcal{D}$ has to be closed with respect to the sum (see Sec. VII for further details). Compare also Sec. III B. [In standard homogeneous thermodynamics, the thermodynamic domain can be assumed to be a convex cone,[1] which is a cone with the property to be closed under addition (Ref. 7, pp. 13–14). One can also assume that the domain $\mathcal{D}$ is still a convex cone with the further requirement that it has to be invariant under quasi-homogeneous transformations. This can be obtained by considering a set $\mathcal{C} \subset \mathbb{R}^{n+1}$ which is invariant under quasi-homogeneous transformations and then the set $\mathcal{K}$ of all the positive linear combinations of elements of $\mathcal{C}$. The set $\mathcal{K}$ is the smallest convex cone containing $\mathcal{C}$ (Ref. 7, p. 14). This cone $\mathcal{K}$ is trivially still invariant under quasi-homogeneous transformations.]

In the following, it is useful to refer to the variables $U^*, X^{1*}, \ldots, X^{n*}$ as would-be extensive variables, and to the variables $\xi_1^*, \ldots, \xi_n^*$ (and also T^*) as would-be intensive variables. The variables $U^*, X^{1*}, \ldots, X^{n*}$ could also be chosen to be such that they are additive, i.e., if one considers a system which is composed by two noninteracting subsystems, then $X^* = X_1^* + X_2^*$. See also Ref. 8.

We assume that the X^{i*} are of degree α_i; notice that the degree of U^* is $\alpha = r$, i.e., the degree r of δQ_{rev} and the weight α of U^* have to coincide in every case. The Euler vector field is

$$D = \alpha U^* \frac{\partial}{\partial U^*} + \sum_i \alpha_i X^{i*} \frac{\partial}{\partial X^{i*}}. \tag{16}$$

An integrating factor for δQ_{rev} is given by

$$f^* = \alpha U^* - \sum_i \alpha_i \xi_i^* X^{i*}, \tag{17}$$

and it is assumed that $f^* \not\equiv 0$ as in standard thermodynamics and, moreover, it is assumed that $f^* \geqslant 0$, which is related to the positivity of the absolute temperature. Then, it is possible to show that, as in standard thermodynamics, the potential $\hat{S}^*$, which is not quasi-homogeneous, is associated with a positive definite potential S^* which is a quasi-homogeneous function of degree 1 with respect to the Euler vector field D:

$$\hat{S}^* - \hat{S}_0^* = \int_\Gamma \frac{\omega}{f^*} = \log\left(\frac{S^*}{S_0^*}\right). \tag{18}$$

The proof is found in Appendix A.

Before continuing our analysis, we recall that a detailed and important study on quasi-homogeneous functions and their application to scaling and universality is the subject of Refs. 9 and 10 (therein, quasi-homogeneous functions are called ''generalized homogeneous functions,'' which is a better denomination, but we adopt a common mathematical denomination). See also Ref. 11. Further mathematical properties are found in Ref. 12 [note that, therein, quasi-homogeneous functions are called ''almost-homogeneous functions'' (Ref. 12, p. 231), whereas

the definition ''generalized homogeneous functions'' is assigned to a further generalization of the equation defining homogeneous and almost-homogeneous functions (Ref. 12, p. 304)].

A. Metrical entropy

By analogy with the construction for standard thermodynamics, a possibility is that S^* is the metrical entropy for the system. This is what happens in standard homogeneous thermodynamics and also in black hole thermodynamics, and we conjecture that this occurrence is not special. See however the discussion at the end of this section.

We define $T^* \geqslant 0$ by means of

$$\frac{\partial S^*}{\partial U^*} \equiv \frac{1}{T^*} > 0, \tag{19}$$

which means that S^* is assumed to be monotonically increasing in U^*. T^* is another integrating factor for (15), it is such that

$$\delta Q_{\text{rev}} = T^* \, dS^*. \tag{20}$$

T^* is a quasi-homogeneous function of degree $r-1$ (see theorem 1 of Ref. 9, where it is shown that the partial derivative $\partial g/\partial X$ of a quasi-homogeneous function g of degree a with respect to a variable X of weight b is a quasi-homogeneous function of degree $a-b$ and the same type as g). When $r \neq 1$, the function T is not intensive, but changes under quasi-homogeneous rescalings of the system. In the case of a Kerr–Newman black hole, one finds, e.g., that, by doubling the mass and the charge, and by quadruplicating the angular momentum, the temperature becomes one-half the temperature of the original black hole state. This behavior is well justified in the light of the Hawking effect.

As a consequence of (19) and of (18), one finds

$$\frac{\partial \hat{S}^*}{\partial U^*} = \frac{1}{f^*} = \frac{1}{S^*} \, \frac{\partial S^*}{\partial U^*} = \frac{1}{T^* S^*}, \tag{21}$$

thus

$$f^* = T^* S^*, \tag{22}$$

as in standard thermodynamics. From (20) it is easy to show that the quasi-homogeneous entropy can be written as

$$S^* = \alpha \frac{U^*}{T^*} - \sum_i \alpha_i \frac{\xi_i^*}{T^*} X^{i*}. \tag{23}$$

In fact, T^* is an integrating factor of degree $r-1$ for δQ_{rev}, and $dS^* \equiv \delta Q_{\text{rev}}/T^*$ is an exact quasi-homogeneous Pfaffian form of degree 1. Then, as a consequence of lemma 1 in Appendix A (cf. also result 1 therein), one finds $S^* = i_D(\delta Q_{\text{rev}}/T^*)$, i.e., Eq. (23) holds. When all the weights in (23) are equal to 1, the well-known expression for the homogeneous thermodynamic entropy is recovered.

B. Thermodynamic foliation

As in the case of standard thermodynamics, one can require that the thermodynamic foliation is defined by the leaves $\hat{S}^* = \text{const}$ everywhere in the thermodynamic manifold, except maybe on the boundary. Singularities for $\hat{S}^*$ can occur where $f^* = 0$, i.e., in the set $Z(f^*) = Z(T^*) \cup Z(S^*)$.

The surface $T^*=0$ is expected to represent an adiabatic boundary of the thermodynamic manifold. Notice that, as in the case of standard thermodynamics, the set $Z(S^*)$ of zeroes of the function S^*, if nonempty, is assumed to be contained in the set $Z(T^*)$. In standard thermodynamics the occurrence of a zero for S at a temperature $T>0$ can be considered pathological, a system in such a state should necessarily absorb heat in a neighborhood of this state, whichever reversible process could be considered. Compare Ref. 1. The same would happen in the quasi-homogeneous case.

Because of (18), the singular values for the thermodynamic foliation are represented by the points where $S^*=0$ (if any).

A stronger assumption on the domain: One could also assume that

$$f^*\geqslant 0 \Leftrightarrow U^*\geqslant b(X^{1*},\ldots,X^{n*}), \tag{24}$$

where $b(X^{1*},\ldots,X^{n*})$ is a quasi-homogeneous function of degree α and weights $(\alpha_1,\ldots,\alpha_n)$. This function $b(X^{1*},\ldots,X^{n*})$ plays the role of lowest energy for the system, because by definition $U^*\geqslant b$. The domain $\mathcal{D}$ has to include the following set:

$$epi(b)\equiv\{(U^*,X^{1*},\ldots,X^{n*})|(X^{1*},\ldots,X^{n*})\in\mathcal{K}_{(n)},\ \ U^*\geqslant b(X^{1*},\ldots,X^{n*})\}, \tag{25}$$

where $\mathcal{K}_{(n)}\subseteq\mathbb{R}^n$ is an open connected set. $epi(b)$ is by definition the epigraph of the function b. If $\mathcal{K}_{(n)}$ is closed under quasi-homogeneous dilatations $(X^{1*},\ldots,X^{n*})\mapsto(\lambda^{\alpha_1}X^{1*},\ldots,\lambda^{\alpha_n}X^{n*})$, then $epi(b)$ is closed under quasi-homogeneous dilatations involving also U^*, because $b(\lambda^{\alpha_1}X^{1*},\ldots,\lambda^{\alpha_n}X^{n*})=\lambda^{\alpha}b(X^{1*},\ldots,X^{n*})\leqslant\lambda^{\alpha}U^*$. Moreover, if $\mathcal{K}_{(n)}$ is also closed under the sum and if b is subadditive, then $epi(b)$ is closed under the sum too, thus the closure of $\mathcal{K}_{(n)}$ under quasi-homogeneous dilatations and under the sum allows us to choose $\mathcal{D}=epi(b)$, in analogy with the standard homogeneous case. (Notice that if, e.g., $\mathcal{K}_{(n)}=\mathbb{R}^n_+$, then it is a convex cone which is invariant under quasi-homogeneous dilatations.) An example where the domain $\mathcal{D}$ coincides with the epigraph of a quasi-homogeneous function is furnished by black hole thermodynamics.

Under this assumption on the structure of the domain, one finds that it is not possible to find a state having $S^*=0$ at $T^*>0$, because by introducing

$$B^*\equiv U^*-b(X^{1*},\ldots,X^{n*})\geqslant 0 \tag{26}$$

one finds

$$S^*(B^*,X^{1*},\ldots,X^{n*})=S^*(0,X^{1*},\ldots,X^{n*})+\int_0^{B^*}dY\,\frac{1}{T^*(Y,X^{1*},\ldots,X^{n*})}, \tag{27}$$

which cannot be zero for any $B^*>0$ (in the last formula mathematical conditions ensuring a continuous entropy at $T^*=0$ have been implicitly assumed, cf. Ref. 1).

As far as the reference state is concerned, we assume that states like the one where all the variables $U^*,X^{1*},\ldots,X^{n*}$ are zero, and any states which imply the absence of the system, are unphysical. The thermodynamic description starts being meaningful if a statistically relevant number of degrees of freedom is available. Compare Sec. II of Ref. 1.

C. Possible ambiguities

One may wonder what should happen if one finds that ω is quasi-homogeneous but the exact weights are not *a priori* known. In particular, one can assume that their ratio is known, i.e., α/α_i and α_j/α_i are known for all $i\neq j$; then, there is an overall undetermined multiplicative constant $q\neq 0$, in the sense that these ratios do not change if one multiplies all the weights by the same constant. One could, e.g., know $r^{(1)}\equiv\alpha/\alpha_1$ and $r_j^{(1)}\equiv\alpha_j/\alpha_1$ for $\alpha_1\neq 0$ and for all $j\neq 1$, but the absolute weight α_1 is not known, thus the weights are $(\alpha_1 r^{(1)},\alpha_1,\alpha_1 r_2^{(1)},\ldots,\alpha_1 r_n^{(1)})$. An example where this ambiguity appears is represented by black hole thermodynamics (see Sec. IV). One can

also assign the weights with respect to a scale λ whose absolute weight could be unknown. The absolute weights are then of the form $(q\alpha, q\alpha_1, \ldots, q\alpha_n)$ with q undetermined. We treat the latter case without loss of generality, being the former equivalent to it under the map $\alpha_1 \mapsto q\alpha_1$, $q\alpha_1 r^{(1)} \mapsto q\alpha, q\alpha_1 r_i^{(1)} \mapsto q\alpha_i$ for all $i \neq 1$. As a consequence of the undetermined overall factor q, one has a one-parameter family of Euler vector fields $\{D_{(q)}\}$, with

$$D_{(q)} = q\alpha U^* \frac{\partial}{\partial U^*} + \sum_i q\alpha_i X^{i*} \frac{\partial}{\partial X^{i*}}. \tag{28}$$

Thus, there exist a one-parameter family $\{f^*_{(q)}\}$ of integrating factors, with $f^*_{(q)} = \delta Q_{\text{rev}}(D_{(q)})$, and a one-parameter family $\{\hat{S}_{(q)}\}$ of potentials such that

$$\frac{\delta Q_{\text{rev}}}{f^*_{(q)}} = d\hat{S}_{(q)} \tag{29}$$

and a one-parameter family of entropies $\{S^*_{(q)}\}$ satisfying

$$d\hat{S}_{(q)} = \frac{dS^*_{(q)}}{S^*_{(q)}}, \tag{30}$$

$$D_{(q)} S^*_{(q)} = S^*_{(q)}. \tag{31}$$

The true metrical entropy S^*, according to our conjecture, belongs to the family $\{S^*_{(q)}\}$ but is undetermined because the overall factor q is undetermined. In order to see which relation occurs between the various entropies in this family, let us consider a fixed value $\overline{q}$ of the parameter q. Then we obtain the entropy $S^*_{(\overline{q})}$. If one considers a generic $\hat{q} \neq \overline{q}$, one has

$$D_{(\hat{q})} = \frac{\hat{q}}{\overline{q}} D_{(\overline{q})} \tag{32}$$

and

$$f^*_{(\hat{q})} = \frac{\hat{q}}{\overline{q}} f^*_{(\overline{q})}. \tag{33}$$

Then,

$$\frac{\delta Q_{\text{rev}}}{f^*_{(\hat{q})}} = \frac{\overline{q}}{\hat{q}} \frac{\delta Q_{\text{rev}}}{f^*_{(\overline{q})}} \tag{34}$$

$$\Leftrightarrow$$

$$d \log(S^*_{(\hat{q})}) = \frac{\overline{q}}{\hat{q}} d \log(S^*_{(\overline{q})}). \tag{35}$$

As a consequence, by assuming in the integral of $\delta Q_{\text{rev}}/f$ the same reference state $(U_0^*, X_0^{1*}, \ldots, X_0^{n*})$, one finds

$$S^*_{(\hat{q})}(U^*, X^{1*}, \ldots, X^{n*}) = \frac{S^*_{(\hat{q})}(U_0^*, X_0^{1*}, \ldots, X_0^{n*})}{(S^*_{(\overline{q})}(U_0^*, X_0^{1*}, \ldots, X_0^{n*}))^{\overline{q}/\hat{q}}} \; (S^*_{(\overline{q})}(U^*, X^{1*}, \ldots, X^{n*}))^{\overline{q}/\hat{q}}, \tag{36}$$

i.e.,

$$S^*_{(\hat{q})} = \zeta_{\hat{q},\overline{q}} (S^*_{(\overline{q})})^{\overline{q}/\hat{q}}, \tag{37}$$

where $\zeta_{\hat{q},\overline{q}} \equiv S^*_{(\hat{q})}(U^*_0, X^1_0{}^*, \ldots, X^n_0{}^*)/(S^*_{(\overline{q})}(U^*_0, X^1_0{}^*, \ldots, X^n_0{}^*))^{\overline{q}/\hat{q}}$ is a constant, once one has fixed the reference state. The metrical entropy S^* is related with the entropy $S^*_{(\overline{q})}$ by a simple power law. Compare also Appendix A.

The one-parameter family of temperatures $\{T^*_{(q)}\}$, with

$$\frac{1}{T^*_{(q)}} \equiv \frac{\partial S^*_{(q)}}{\partial U^*}, \tag{38}$$

is such that

$$\frac{1}{T^*_{(\hat{q})}} = \zeta_{\hat{q},\overline{q}} \frac{\overline{q}}{\hat{q}} (S^*_{(\overline{q})})^{\overline{q}/\hat{q}-1} \frac{1}{T^*_{(\overline{q})}}. \tag{39}$$

Analogous relations exist for the other partial derivatives of $S^*_{(\overline{q})}$ and $S^*_{(\hat{q})}$. Notice that it holds $f^*_{(q)} = T^*_{(q)} \; S^*_{(q)}$, because

$$\frac{\partial \hat{S}^*_{(q)}}{\partial U^*} = \frac{1}{f^*_{(q)}} = \frac{1}{S^*_{(q)}} \frac{\partial S^*_{(q)}}{\partial U^*} = \frac{1}{T^*_{(q)} S^*_{(q)}}. \tag{40}$$

1. Phenomenological resolution of the ambiguity

The metrical entropy S^* could be phenomenologically identified by means of an absolute temperature thermometer, made of standard matter, allowing to find, as the parameters $U^*, X^1{}^*, \ldots, X^n{}^*$ are varied, the function T^* describing the absolute temperature of the system. As a consequence, also S^* can be recovered. We remark that the resolution of the above ambiguity by means of a phenomenological input is completely in the spirit of thermodynamics, which has a phenomenological nature as far as statistical mechanics is not taken into account.

2. How to fix the absolute weights by means of statistical mechanics

A priori, even in statistical mechanics, there is a scaling ambiguity, unless the absolute weights are somehow fixed. On this topic, see also Sec. XII. In fact, let us assume that the statistical mechanical entropy (calculated by means of some sort of thermodynamic limit or by means of some mean field approximation; cf. Sec. XII) under rescaling by means of a scale λ is a quasi-homogeneous function of degree α_S and weights $\alpha_1, \ldots, \alpha_n$. This means that $S_{sm}(\lambda^{\alpha} U, \lambda^{\alpha_1} X^1, \ldots, \lambda^{\alpha_n} X^n) = \lambda^{\alpha_S} S_{sm}(U, X^1, \ldots, X^n)$. By changing the scale $\lambda = \overline{\lambda}^{q}$, the scaling of the variables becomes $\overline{\lambda}^{q\alpha_i}$. Thus, there is an overall factor q of ambiguity. Such a redefinition of the scale, unless the absolute weights are somehow fixed, allows to remap any quasi-homogeneous function of degree $\alpha \neq 0$ into a quasi-homogeneous function of degree one, as noticed in Ref. 10. The statistical mechanical entropy is then assumed to satisfy

$$S_{sm}(\lambda^{q\alpha} U, \lambda^{q\alpha_1} X^1, \ldots, \lambda^{q\alpha_n} X^n) = \lambda^{q\alpha_S} S_{sm}(U, X^1, \ldots, X^n), \tag{41}$$

where the overall factor ambiguity is enhanced. With respect to the Euler vector field $D_{(q)}$ which corresponds to the above weights it holds $D_{(q)} S_{sm} = q \alpha_S S_{sm}$.

We know that from a thermodynamic point of view there is a one-parameter family of possible metrical entropies, each of which is of degree one. The statistical mechanical entropy S_{sm} has to coincide with the metrical thermodynamic entropy S^* and it has to hold $T \, dS_{sm} = T^* \, dS^* = \delta Q_{\text{rev}}$. As a consequence, the statistical mechanical entropy has to be a degree one quasi-homogeneous function. This requirement fixes $q \alpha_S = 1$, and fixes unambiguously the weights (then, it eliminates also the ambiguity in the one-parameter family of thermodynamic entropies).

We could also relax our conjecture about the identification of S^* in formula (18) as the metrical entropy. The Clausius-type formula (18) gives in general an empirical entropy which is to be uniquely related with the metrical entropy by identifying the absolute temperature scale as in the standard procedure. One could still assume that the metrical entropy is quasi-homogeneous, but it would be possible in line of principle to require that its degree is q, with q non-necessarily equal to 1. Then, even in the case where all the weights are known, one would find $S^*_{\text{metric}} \propto (S^*)^q$, where S^* is obtained from formula (18). Compare also Appendix A. The above phenomenological procedure could be still allowed. Compare also Sec. XII and the conclusions herein.

A further consideration is in order, and it concerns the possible presence of variables of weight zero. All the mathematical approach developed in this section remains unaltered. It is to be noted that, if a variable I^* having weight zero is present, the term $I^* \partial / I^*$ does not appear in the Euler operator and in the integrating factor f the term proportional to I^* is missing.

Notice that it is possible that the thermodynamic description allows a reducing/enlarging of the thermodynamic space as the one discussed in Ref. 1. This means that part of the variables X^i* appearing in δQ_{rev} and in S^* could be set equal to zero consistently, which means that a meaningful thermodynamic description is still allowed when $X^i* = 0$ (in standard thermodynamics such variables play, e.g., the role of external fields[1]); consistency requires that, if $X^i* = 0$ is allowed, then $\xi_i^* = 0$ as $X^i* = 0$.[1] Black hole thermodynamics represents a good example, and this topic is discussed in Sec. XI.

We underline that this kind of generalization of thermodynamics can be considered as a subcase of a generalization proposed by Landsberg in Ref. 13. Therein, a discussion of generalized ideal gases appears, where the properties of the following generalized entropy are analyzed:

$$S = bN \log\left(a \frac{UV^g}{N^h} \right). \tag{42}$$

Given the Euler field

$$D_{\alpha\beta\gamma} = \alpha U \frac{\partial}{\partial U} + \beta V \frac{\partial}{\partial V} + \gamma N \frac{\partial}{\partial N}, \tag{43}$$

it is easy to show that S in (42) is quasi-homogeneous (of degree γ) if and only if $\alpha + g\beta - h\gamma = 0$. If the latter constraint is not implemented, then S is not quasi-homogeneous. Homogeneity requires $h = g + 1$.

IV. THE BLACK HOLE CASE

We summarize herein the results obtained in Ref. 14 in the black hole case (we set $\hbar = c = G = k_b = 1$, where k_b is the Boltzmann constant; moreover, we work with unrationalized electrical units). For a general discussion about black hole thermodynamics see, e.g., Refs. 15 and 16. Herein, as well as in Sec. V and in Sec. VI, we do not use the asterisk, which is in general used only in theoretical sections. The Pfaffian form of black hole thermodynamics for black holes of the Kerr–Newman family is

$$\delta Q_{\text{rev}} \equiv dM - \Phi\, dQ - \Omega\, dJ, \tag{44}$$

where the parameters M, Q, J are the mass M, the angular momentum J and the charge Q of the black hole; the angular velocity

$$\Omega = \frac{J}{M} \frac{1}{2M^2 - Q^2 + 2M\sqrt{M^2 - Q^2 - J^2/M^2}} \tag{45}$$

and the electric potential

$$\Phi = \frac{Q(M + \sqrt{M^2 - Q^2 - J^2/M^2})}{2M^2 - Q^2 + 2M\sqrt{M^2 - Q^2 - J^2/M^2}} \tag{46}$$

are associated with the black hole horizon. M in (44) plays the role of internal energy, the remaining terms in (44) being ''standard'' work terms. Each black hole of the Kerr–Newman family is a stationary solution of the Einstein equations, and it can be considered, from the thermodynamic point of view we develop here, rather loosely speaking, as an ''equilibrium state of the geometry.'' The variation occurring in (44) is taken along such stationary solutions. The thermodynamic domain for the nonextremal black holes is the (open) nonextremal manifold implicitly defined by the inequality $M^4 - M^2Q^2 - J^2 > 0$; the extremal submanifold $M^4 - M^2Q^2 - J^2 = 0$ is a boundary of the former, and its status is analyzed in Ref. 17 (therein a discussion of the third law of thermodynamics also in the light of this approach is found). (We limit ourselves to recall that in black hole thermodynamics the entropic form of the third law is violated[18] but still the unattainability of $T = 0$ holds under suitable hypotheses.)

The Pfaffian form (44) is integrable, it satisfies the condition $\delta Q_{\text{rev}} \wedge d(\delta Q_{\text{rev}}) = 0$, i.e.,

$$-\partial_J \Phi + \partial_Q \Omega + \Phi \partial_M \Omega - \Omega \partial_M \Phi = 0. \tag{47}$$

Moreover, the Pfaffian form (44) is quasi-homogeneous. In fact, under $M \to \lambda^{\alpha} M$; $Q \to \lambda^{\alpha} Q$; $J \to \lambda^{2\alpha} J$, one obtains $\delta Q_{\text{rev}} \to \lambda^{\alpha} \delta Q_{\text{rev}}$, where $\lambda > 0$. The weights α, α, 2α are not known, only their ratio is determined. Then, the degree of δQ_{rev} is not fixed.[14] Nevertheless, a thermodynamic construction is allowed. One finds that the integrating factor for δQ_{rev} is given by $f = \alpha(M - \Phi Q - 2\Omega J)$, that is

$$f = \alpha \sqrt{M^2 - Q^2 - J^2/M^2} \tag{48}$$

(it is interesting to notice that this integrating factor is proportional to the horizon coordinate c introduced by Carter in Ref. 19, thus, it is constant on the horizon). Then, one gets[14]

$$\int \frac{\delta Q_{\text{rev}}}{f} \equiv \hat{S} - \hat{S}_0 = \frac{1}{2\alpha} \log\left(\frac{A}{A_0}\right), \tag{49}$$

where $A = 4\pi(M^2(1 + \sqrt{1 - Q^2/M^2 - J^2/M^4})^2 + J^2/M^2)$ is the black hole area and is positive definite. The main difficulty is in finding the metrical entropy, because of the undetermined overall multiplicative constant α. Both $\alpha = 1/2$ and a undetermined proportionality constant c_0 appearing in the Bekenstein–Hawking law $S = c_0 A$ are recovered, e.g., by comparing the temperature of the black hole with the Hawking temperature, and one finds $c_0 = 1/4$; also the Euclidean path integral method can be used with this aim[20] (see also the papers collected in Ref. 21), as well as a phenomenological plot of the temperature as a function of M, Q, J. [Moreover, we notice that the same result $S \propto A$ could be obtained by requiring that the metrical entropy is quasi-homogeneous of degree one with respect to the Euler field D which is obtained by normalizing to one the biggest weight 2α:

$$D = \frac{1}{2} M \frac{\partial}{\partial M} + \frac{1}{2} Q \frac{\partial}{\partial Q} + J \frac{\partial}{\partial J}. \tag{50}$$

But this normalization rule should be justified on a general thermodynamic footing, and the case $J = 0$ (Reissner–Nordström solution), being homogeneous in M, Q, shows that the physically correct value $\alpha = 1/2$ cannot be found on the ground of such a rule.]

S is quasi-homogeneous of degree one and of type (1/2,1/2,1) and it is well defined everywhere in the thermodynamic manifold. It is such that $S = 0$ only for $M = Q = J = 0$, which should not be considered as a state belonging to the thermodynamic manifold (see the discussion in Sec. III; moreover, near $M = 0$ quantum gravity effects are non-negligible and general relativity is

expected to be nonviable). Thus, $Z(S)=\varnothing$ and one finds $Z(f)=Z(T)$, and $\hat{S}$ is regular everywhere; as a consequence, $\hat{S}$ and S could be continued even on the extremal submanifold (but see Ref. 17 for arguments against this continuation). All nonextremal states have $T>0$, whereas the extremal boundary corresponds to $T=0$. As it is well-known, one obtains an entropy which is not concave, but simply strictly superadditive when the merging of two black holes is considered. This ensures the second law of thermodynamics.[13,22,23] See also Sec. VII.

By introducing

$$b(Q,J)\equiv\frac{1}{\sqrt{2}}\sqrt{Q^2+\sqrt{Q^4+4J^2}}, \tag{51}$$

which is a quasi-homogeneous function of degree 1/2 and weights (1/2,1), as it can be easily verified (see also Ref. 17), the domain can be also written as follows:

$$\mathcal{D}=\{(M,Q,J)|(Q,J)\in\mathbb{R}^2,M\geqslant b(Q,J)\}\equiv \mathrm{epi}(b). \tag{52}$$

In fact, $M=b(Q,J)$ is the physical (i.e., having positive mass) solution of $M^4-M^2Q^2-J^2=0$ and the black hole manifold is $M^4-M^2Q^2-J^2\geqslant 0$, which means $M\geqslant b$. The function $b(Q,J)$ indicates, for given values of Q,J, which is the lowest mass such that a black hole solution can exist. The lowest mass coincides with the mass of the extremal black hole having Q,J as charge and angular momentum, respectively.

We point out that the quasi-homogeneous behavior of black hole thermodynamics is not a special feature of the Kerr–Newman family. In fact, it can be realized easily, e.g., in the case of the Kerr–Newman–anti–de-Sitter (KN–AdS) case.[24] A peculiar feature arises, one has to define a thermodynamic angular velocity Ω as the difference between the angular velocity of the horizon and the angular velocity at infinity, and the same is true in the case of the electric potential.[24] Nevertheless, these definitions are necessary, e.g., the ''electric'' work term has to involve the difference between the potential at the horizon and the potential at infinity when the latter is not zero, and, on the same footing, the redefinition of Ω is due to the fact that the angular velocity is not zero at infinity. The change in the energy associated with these work terms has to involve such a difference, which does not appear in the KN case because of the vanishing of Φ and of Ω at infinity.

General relativity is surprising from a thermodynamic point of view. Black hole solutions of the Einstein equations are involved with an integrability condition (47), and they allow a fine explicit thermodynamic construction via Carathéodory. One finds a link with thermodynamics which is *a priori* unexpected and it is not simply the formal analogy between laws of thermodynamics and laws of black hole mechanics, because the above construction belongs to the thermodynamic framework, apart from the geometric inputs Ω, Φ, which come from general relativity. See also the discussion in Ref. 14.

V. NEWTONIAN GRAVITY. A MODEL OF HERTEL, NARNHOFER, AND THIRRING

There exists an interesting statistical mechanical calculation for gravitating fermions which corroborates the idea that, in presence of gravity, a quasi-homogeneous thermodynamics is allowed.[25–27] The model (HNT model in the following) involves nonrelativistic fermions interacting by means of a Coulomb potential and a Newtonian potential, with vanishing (or small) total charge. Thus, the calculation does not involve general relativity but only Newtonian gravity. Nevertheless, the result is still interesting and, to some extent, puzzling. The quantum mechanical Hamiltonian which is considered is

$$H=\sum_{i=1}^{N}\frac{\vec{p}_i^{\,2}}{2M_i}+\sum_{i<j}\frac{e_ie_j-Gm_im_j}{|\vec{x}_i-\vec{x}_j|}. \tag{53}$$

The authors state that a thermodynamic limit exists if the following asymptotic behavior is allowed for U,V: $V\sim 1/N$, $U\sim N^{7/3}$, and the microcanonical entropy is of degree 1 in the number N of fermions. The scaling properties of U, V with N are peculiar, they are homogeneous of degree 1 if the potential term in (53) is suppressed by means of a multiplicative factor $1/N^{2/3}$, which means that, as the system gets larger, the interaction becomes weaker.[27] If this suppression is not in agreement with the physics, and if the fermions do not become relativistic, then the microcanonical entropy $S(U,V,N)$ is a quasi-homogeneous function of degree 1, and the weights of U,V,N are $7/3,-1,1$, respectively. Compare also Sec. XII, where the notion of quasi-homogeneous thermodynamic limit is introduced. The Euler field is

$$D_{UVN}=\frac{7}{3}\,U\,\frac{\partial}{\partial U}-V\,\frac{\partial}{\partial V}+N\,\frac{\partial}{\partial N}. \tag{54}$$

For details of the highly nontrivial calculations, see Refs. 25,26 and 28. We are interested here in pointing out that, as stressed in Ref. 25, there is a one-parameter family of equivalent limits $N\to\infty$, whose parameter γ remains fixed by the requirement that the ground state energy goes like $N^{7/3}$, according to a result of Ref. 29. A scaling ambiguity, which would reflect itself in the undetermined weights $(-2\gamma+5/3,3\gamma,1)$ of (U,V,N), respectively, is thus solved by comparing with the scaling behavior of the ground state. See also Ref. 28. Another important point is that the temperature-dependent Thomas–Fermi equation, which allows these scaling properties, becomes exact in the thermodynamic limit for the system under discussion.[25] We limit ourselves to underline that Newtonian gravity furnishes a statistical mechanical example where unusual scaling laws for the ''extensive'' variables are allowed. The purely attractive nature of gravity plays a major role, because it does not saturate, i.e., it does not allow to obtain a ground state proportional to the number of particles.[29] Notice also that a lack of concavity is allowed.[27]

It is interesting to notice that another model involving different scaling relations has been developed in Ref. 30. Therein, a classical gas of nonrelativistic particles which interact by means of Newtonian gravity is considered in a diluted regime where particles of mass m are enclosed in a box; the following behavior is recovered in a nonconventional thermodynamic limit where $V/N^3\to$const. as $N\to\infty$. A dilution parameter

$$\xi\equiv\frac{1}{Gm^2}\,\frac{UV^{1/3}}{N^2} \tag{55}$$

is kept constant in the thermodynamic limit. One finds that $S(U,V,N)$ is quasi-homogeneous of degree 1 and weights (1,3,1), as can be inferred from Ref. 30. Compare also Sec. XII. This model differs from the previous one because it involves classical matter, the gas is kept diluted in the thermodynamic limit, no collapse is considered. Note that even the HNT model can be related with the parameter ξ introduced in (55), in fact even in HNT model this parameter is constant in the appropriate thermodynamic limit. ξ can be qualitatively interpreted as the ratio between the internal energy and the Newtonian gravitational energy, in fact the gravitational energy of a homogeneous sphere of mass $M\equiv N^2m$ is proportional to $GM^2/V^{1/3}$. Thus, in both cases, the requirement of a non-negligible contribution of the gravitational energy to the internal energy is realized in the thermodynamic limit. In the HNT model, a self-bounded system is considered, like a (cold) star, where V contracts as the mass is increased; in the model of Ref. 30, the physical conditions are different, a gaseous system is considered, the energy per particle remains constant and small, and the systems remains gaseous in the thermodynamic limit.

In the regime where gravitational forces cannot be neglected, one can expect that a different kind of quasi-homogeneous thermodynamics can arise, with different weights, depending on the actual physical conditions, e.g., the amount and the type of matter. Semirelativistic matter is expected to behave in a different manner (cf. Ref. 29). The point is that a different scaling behavior of the ground state of the matter can be expected if relativistic effects in the kinetic energy are non-negligible. A self-consistent calculation taking into account general relativity is

expected to give another kind of contribution. An approach, combining in a self-consistent way general-relativistic equations and finite-temperature Thomas–Fermi approximation for the thermodynamic functionals would be required. In this direction, see Ref. 31. It is also interesting to point out that such an approach probably would not be useful for understanding black hole thermodynamics, in fact no stable ground state for the matter could exist by hypothesis (a collapse of the matter beyond the possible stable states represented by white dwarf and neutron stars should take place, with no possibility to prevent the formation of an event horizon).

VI. A LOOK AT THE THERMAL GEON AND AT SELF-GRAVITATING RADIATION

We discuss naively the scaling properties of the so-called thermal geons.[32] A geon is a ''gravitational electromagnetic entity'' which consists in a self-gravitating ensemble of electromagnetic modes.[33] The most stable configuration is such that the photons are distributed within a toroidal region of the space–time, but also a spherical distribution can be allowed. Geons do not represent strictly stationary solutions of the Einstein equations, because a leakage of photons to infinity is allowed. Nevertheless, they can be considered as metastable quasistationary solutions. Moreover, sizes are considered where no contribution of electron physics, due to pair creation by the electromagnetic field, is considered, and no zero-point energy is taken into account. In Ref. 32 the idea of a geon has been generalized to the case of thermally distributed electromagnetic modes. The main assumptions are the following ones: (a) the metric is a spherosymmetric static diagonal metric in the Schwarzschild gauge; (b) there exist two separate classes of electromagnetic modes; the first class is constituted by bounded null geodesics which represent modes whose energy cannot escape to infinity (the actual rate of flux to infinity goes to zero exponentially with the ratio between the dimensions of the geon and the wavelength λ). The second class is constituted by free electromagnetic modes, i.e., by null geodesics which reach infinity. (c) The energy of the free modes is zero, the energy of the bounded modes of frequency Ω is (in natural units)

$$E_\Omega = \Omega \frac{1}{\exp\left(\frac{\Omega}{T}\right) - 1}, \tag{56}$$

which is the usual distribution for black-body radiation and T is the temperature. See also Ref. 32 on this topic. The active region of the geon is defined as the region where the metric coefficient g_{00} satisfies $|g_{00}| < 1$. By defining R as the radius of the active region and M as its mass, the following scaling laws can be deduced:[32]

$$R \sim R_T \equiv \left(\frac{15\hbar^3 c^7}{8\pi^3 G}\right)^{1/2} \frac{1}{(k_b T)^2} \propto \frac{1}{T^2}, \tag{57}$$

$$M \sim M_T \equiv \left(\frac{15\hbar^3 c^{11}}{8\pi^3 G^3}\right)^{1/2} \frac{1}{(k_b T)^2} \propto \frac{1}{T^2}. \tag{58}$$

As an order of magnitude estimation on the same footing of the previous evaluations, one can see that the entropy behaves as $S \propto VT^3$, where V is the volume of the active region, thus $S \propto T^{-3}$. From the above naive considerations, one finds that S is a quasi-homogeneous function

$$S(\lambda^{-2}M, \lambda^{-6}V) = \lambda^{-3} S(M, V). \tag{59}$$

In the case of a massless gas, there is an ambiguity in the identification of the absolute weights of the variables. There is an overall multiplicative factor to be determined in the Euler vector field. Let us assume that S is of degree 1, as suggested by the formal picture of thermodynamics (cf. Sec. III and Sec. XII); then T has degree $-1/3$ and the scaling law for the fundamental equation is

$$S(\lambda^{2/3}M,\lambda^2 V)=\lambda S(M,V), \tag{60}$$

i.e., M has weight 2/3 and V has weight 2. We note that the ratio $M/V^{1/3}$ is scale-invariant and it is the same ratio which is kept constant in the thermodynamic limit discussed in Ref. 30. The above result about thermal radiation can be confirmed by comparing it with the study of Ref. 34. Black-body self-gravitating radiation enclosed in a spherical box of radius R is considered in Ref. 34. It is shown that the maximization of the entropy in a spherosymmetric geometry leads to the following results: (i) the metric is static; (ii) the perfect fluid of photons satisfies the Tolman–Oppenheimer–Volkov (TOV) equation. In particular, the TOV equation one obtains is scale invariant. By introducing the density $\rho(r)$, the mass $m(r)=\int_0^r dy\, 4\pi y^2\rho(y)$ (r is the radial coordinate) one can define, by following Ref. 34, the dimensionless variables

$$\mu=m(r)/r, \tag{61}$$

$$q=dm/dr=4\pi r^2\rho(r), \tag{62}$$

and the TOV becomes equivalent to the following couple of equations:

$$r\frac{dq}{dr}=\frac{2q}{1-2\mu}\left(1-4\mu-\frac{2}{3}\,q\right), \tag{63}$$

$$r\frac{d\mu}{dr}=q-\mu. \tag{64}$$

No equilibrium is attained if $\mu>0.25$.[34] We are interested here in the scaling properties of the Pfaffian form

$$\delta Q_{\mathrm{rev}}=dM+p\,dV, \tag{65}$$

where $M\equiv m(R)$ is the mass, V is the volume (as seen from infinity) and $p=\rho(R)/3$ is the pressure as a function of the box radius. These variations are to be intended, as in the black hole case, as ''on shell,'' i.e., along static spherosymmetric equilibrium solutions of the TOV. Each solution represents a thermodynamic equilibrium state. Under the scaling $M\to\lambda M$; $V\to\lambda^3 V$; $p\to\lambda^{-2}p$, which corresponds to (30) of Ref. 34 and is allowed by the scale invariance of the TOV, one finds $\delta Q_{\mathrm{rev}}\to\lambda\,\delta Q_{\mathrm{rev}}$. Particularly, one has

$$D=\alpha\left(M\,\frac{\partial}{\partial M}+3V\,\frac{\partial}{\partial V}\right), \tag{66}$$

where α has to be determined. From $dV=4\pi R^2\,dR$ and from (64) one finds

$$\delta Q_{\mathrm{rev}}=\tfrac{4}{3}\,q\,dR \tag{67}$$

and the integrating factor

$$\delta Q_{\mathrm{rev}}(D)=\alpha(M+3pV)=\alpha\tfrac{1}{3}(3\mu+q)R. \tag{68}$$

Thus,

$$\frac{\omega}{f}=\frac{4}{\alpha}\,\frac{q}{3\mu+q}\,\frac{dR}{R}. \tag{69}$$

By comparing this result with the ratio dS/S which can be obtained by the exact result (34) of Ref. 34, one finds that $\alpha=2/3$. As the consequence, the weights of D are the same as in the case of

thermal geons [notice that the requirement for S to be quasi-homogeneous of degree one in the scale factor λ would lead to the scaling $r\to\lambda^{2/3}r$; $m\to\lambda^{2/3}m$; $\rho\to\lambda^{-4/3}\rho$ in (30) of Ref. 34].

VII. CONSEQUENCES OF THE NONEXTENSIVITY OF *S*

We have to underline that the lack of extensivity has important consequences on the properties of the entropy. In fact, if one considers for a continuous entropy S superadditivity (S), concavity (C) and homogeneity (H), one finds:
(a) (H) and (S) imply (C);[35]
(b) (H) and (C) imply (S);[36]
(c) (S), with the condition $S(0)=0$, and (C) imply (H).[8,22]

We recall that a function $h(x)$ of n variables, collectively indicated with x in this section, is superadditive if $h(x+y)\geqslant h(x)+h(y)$ for all x,y in its domain. Superadditivity, in the case of entropy, means that the principle of entropy increase in a irreversible adiabatic process is respected. Moreover, (C) requires a convex domain, (S) a domain which has to be closed under addition, and (H) a domain which has to be closed under multiplication of x by a real scalar $\lambda>0$ (a cone).

Notice that the condition $S(0)=0$ appearing in (c) is a mathematical condition which could be required even if the state $x=0$ does not belong to the thermodynamic space, in the light of our discussion in Sec. III; see however also Ref. 22, where $x=0$ is included in the thermodynamic space. One could consider an extended domain including $x=0$, on a purely mathematical ground, even if the thermodynamic formalism at such a point is meaningless. Moreover, S is required to be a continuous function. Then, if homogeneity does not hold and $S(0)=0$, either superadditivity or concavity has to be violated. It can be easily shown that the condition $S(0)=0$ in (c) can be replaced by the (natural) requirement that $S(x)\geqslant 0$ for any state x in the thermodynamic domain. In fact, (C) implies

$$S(\tfrac{1}{2}y+\tfrac{1}{2}z)\geqslant\tfrac{1}{2}S(y)+\tfrac{1}{2}S(z) \tag{70}$$

for any y,z; moreover, (S) implies

$$S(2x)\geqslant 2S(x). \tag{71}$$

If $z=0$ and $y=2x$, from (70) one obtains

$$S(x)\geqslant\tfrac{1}{2}S(2x)+\tfrac{1}{2}S(0). \tag{72}$$

Then, $1/2\ S(2x)+1/2\ S(0)\leqslant S(x)\leqslant 1/2\ S(2x)$, which implies $S(0)\leqslant 0$. As a consequence, the requirement of a non-negative entropy S, together with (S) and (C), implies $S(0)=0$, thus also (H) has to hold. This shows that the condition $S(0)=0$, in the framework of thermodynamics, where $S\geqslant 0$, cannot be actually considered as a true restriction leaving room for a thermodynamics in which a concave and superadditive but nonhomogeneous entropy is allowed if S is defined in $x=0$ (of course, this holds as far as negative values of S are forbidden). Notice that $S^*(0)=0$ for a continuous quasi-homogeneous entropy defined in 0.

Superadditivity of the entropy means that for the thermodynamic system the entropy does not increase by fragmenting the system.[8] From the point of view of the energy representation, to be discussed in Sec. X, superadditivity of the entropy is equivalent to the subadditivity of the energy under the condition (19) (for a proof, see Refs. 35 and 36). [This equivalence holds even if conditions (C), (H) are violated.] Subadditivity of the energy means that exploding is not energetically advantageous for the system.[37,38] The relevance of (S) for the second law of thermodynamics is discussed and underlined in Ref. 13. Accordingly, one should privilege the superadditivity property against the concavity, and superadditivity should be required as a fundamental property for the quasi-homogeneous picture of thermodynamics. Notice that a lack of concavity for thermodynamics in presence of gravity is verified in Refs. 39 and 40, where negative heat

capacities in presence of gravity are calculated. Therein, a discussion on how to deal with the lack of the standard stability properties of thermodynamics is sketched. See also Refs. 41 and 42. It is to be noted that this lack of concavity in presence of gravity forces to abandon the usual Gibbsian scheme for thermodynamics, and the homogeneity property has to be withdrawn because of (a), if one adopts the superadditivity as a fundamental property for the metrical entropy of a system. Due to the above equivalence between superadditivity of the entropy and subadditivity of the internal energy, one can naively justify this choice by underlining that, because of the purely attractive nature of gravity, internal energy of a self-gravitating system should be strictly subadditive, in fact energy decreases as the accretion of matter increases. Thus, there is an implosive instability of gravity, which eventually leads to the formation of black holes, to be identified as very long-lived metastable states. By passing, we note that there is another instability which is opposite in character with respect to the one implied by gravity. It involves system fragmentation/explosion because of a superadditive energy.[37,38] It should be characterized only by unstable states (systems with a suitable charge excess would be explosive[28]). (See also the works of Lieb collected in Ref. 43, in particular the review in Ref. 44; see also Ref. 45.)

VIII. SUMMARY OF CONSTRUCTIVE ASSUMPTIONS

We summarize the set of constructive assumptions upon which our approach is based. They correspond to the assumptions leading to standard homogeneous thermodynamics,[1] the difference consists in the substitution of the homogeneity symmetry with the quasihomogeneity symmetry and also in the explicit request that the entropy is superadditive. We comment only some assumptions which require further remarks with respect to the discussion developed in the text.

(**a1**) The quasi-homogeneity symmetry which characterizes the thermodynamic system is translated into the quasi-homogeneity of the Pfaffian form $\delta Q_{\mathrm{rev}}=dU^*-\Sigma_{i=1}^{n}\xi_i^*\,dX^{i*}$.

(**a2**) The quasi-homogeneity symmetry of δQ_{rev} is nontrivial.

(**a3**) The thermodynamic foliation is defined by the leaves $\hat{S}^{*-1}(c)$, where $c\in\mathbb{R}$ is a constant, everywhere in $\mathcal{D}$.

This assumption does not leave room for foliations which are based on a quasi-homogeneous S^* which is allowed to be negative. Compare the discussion in Ref. 1 for the homogeneous case.

(**a4**) The integrating factor f^* is non-negative.

(**a5**) The metrical entropy S^* is quasi-homogeneous of degree 1.

This assumption could also be weakened, as discussed in the text.

(**a6**) The metrical entropy S^* is superadditive.

This assumption substitutes the requirement for a concave entropy occurring in standard homogeneous thermodynamics. Notice that in standard thermodynamics it would lead again to a concave metrical entropy, because of the implication (a) of Sec. VII (cf. Ref. 35).

(**a7**) We require that $Z(S^*)\subseteq Z(T^*)$.

This assumption is, e.g., implemented as in Sec. III B. One can also add the following assumptions which appear to be physically appealing.

(**a8**) We require that to each level set $S^*=\mathrm{const}$ corresponds a unique leaf.

This assumption means that two states of the same quasi-homogeneous system lying on the same isoentropic surface are path-connected, i.e., it is possible to find a reversible adiabatic path connecting each other.

(**a9**) We require that $\partial S^*/\partial V^*$ is positive if V^* is the volume of the system.

This simply means that the pressure p^* is positive whenever it is definite.

(**a10**) We require that $f^*=0$ corresponds to an integral manifold of δQ_{rev}.

This assumption is natural and is related to the problem of the third law. Compare Ref. 1 for standard thermodynamics; see also Ref. 17 for the black hole case and also Appendix B.

IX. GENERALIZED GIBBS–DUHEM EQUATION

Quasi-homogeneity of S^* allows to find a generalization of the standard Gibbs–Duhem equation.[46]

A. Case where none independent variable of weight zero appears

We first discuss the case where none independent variable of weight zero appears. By differentiating (23) one finds

$$dS^*=\alpha\,\frac{1}{T^*}\,dU^*+\alpha U^* d\left(\frac{1}{T^*}\right)-\sum_i \alpha_i\,\frac{\xi_i^*}{T^*}dX^{i*}-\sum_i \alpha_i X^{i*} d\left(\frac{\xi_i^*}{T^*}\right) \tag{73}$$

and by comparing with

$$dS^*=\frac{1}{T^*}\,dU^*-\sum_i\,\frac{\xi_i^*}{T^*}\,dX^{i\ *} \tag{74}$$

one finds that the following generalized Gibbs–Duhem equation has to hold:

$$\alpha U^{*-[(\alpha-1)/\alpha]+1} d\left(\frac{U^{*[(\alpha-1)/\alpha]}}{T^*}\right)-\sum_i \alpha_i X^{i*-[(\alpha_i-1)/\alpha_i]+1} d\left(\frac{X^{i*[(\alpha_i-1)/\alpha_i]}\xi_i^*}{T^*}\right)=0. \tag{75}$$

This equation, as in the usual thermodynamic case, allows to express the differential of a would-be intensive variable as a function of all the other ones, and then to find such a would-be intensive variable apart from a integration constant (cf. Ref. 46 for the case of standard thermodynamics). In fact, one could, e.g., find for $1/T^*$:

$$d\log\left(\frac{1}{T^*}\right)=-\frac{\alpha-1}{f^*}\;\;dU^*+\frac{1}{f^*}\sum_i \alpha_i X^{i*-[(\alpha_i-1)/\alpha_i]+1} d(X^{i*[(\alpha_i-1)/\alpha_i]}\xi_i^*). \tag{76}$$

Notice that

$$d\log\left(\frac{1}{T^*}\right)=-d\log(f^*)+\frac{\delta Q_{\rm rev}}{f^*}. \tag{77}$$

Equation (76) is implemented if (18) and (74) hold. Let us consider the inverse problem where one assigns n would-be intensive functions $\xi_1^*,\ldots,\xi_n^*$ which are quasi-homogeneous in $U^*,X^{1*},\ldots,X^{n*}$ and such that $\delta Q_{\rm rev}$ is quasi-homogeneous as well. Equation (76), or, equivalently, Eq. (77) can be used for recovering T^*, and then for reconstructing S^* by means of (18), if and only if one has ensured that $\delta Q_{\rm rev}/f^*$ is an exact differential, i.e., that $\delta Q_{\rm rev}$ is integrable and f^* is an integrating factor for $\delta Q_{\rm rev}$. Otherwise, (76) is not even meaningful [a closed form on the left-hand side of (77) should be equal to a nonclosed form on the right-hand side of the same equation]. Compare also Ref. 1.

Notice that, if S^* has degree q, then (75) becomes

$$\frac{\alpha}{q}\,U^{*-[(\alpha-q)/\alpha]+1} d\left(\frac{U^{*[(\alpha-q)/\alpha]}}{T^*}\right)-\sum_i\,\frac{\alpha_i}{q}\,X^{i*-[(\alpha_i-q)/\alpha_i]+1} d\left(\frac{X^{i*[(\alpha_i-q)/\alpha_i]}\xi_i^*}{T^*}\right)=0. \tag{78}$$

See also Appendix C.

B. Case where independent variables of weight zero appear

Let us assume that, the independent variables X^{i*} have weight zero for $i=p+1,\ldots,n$, with $p<n$. This means that ξ_i^* have degree α for $i=p+1,\ldots,n$. The Euler vector field is

$$D=\alpha U^*\frac{\partial}{\partial U^*}+\sum_{i\leqslant p}\alpha_i X^{i*}\frac{\partial}{\partial X^{i*}}, \tag{79}$$

and the integrating factor is

$$f^* = \alpha U^* - \sum_{i \leqslant p} \alpha_i \xi_i^* X^{i*}. \tag{80}$$

Then, one has

$$S^* = \frac{1}{T^*} \left(\alpha U^* - \sum_{i \leqslant p} \alpha_i \xi_i^* X^{i*} \right). \tag{81}$$

It is easy to show that the Gibbs–Duhem equation in this case is

$$\alpha U^{*-[(\alpha-1)/\alpha]+1} d\left(\frac{U^{*[(\alpha-1)/\alpha]}}{T^*} \right) - \sum_{i \leqslant p} \alpha_i X^{i*-[(\alpha_i-1)/\alpha_i]+1} d\left(\frac{X^{i*[(\alpha_i-1)/\alpha_i]} \xi_i^*}{T^*} \right)$$
$$+ \sum_{p<i \leqslant n} \frac{\xi_i^*}{T^*} dX^{i*} = 0. \tag{82}$$

One can also obtain the analogous of Eq. (76),

$$d \log\left(\frac{1}{T^*} \right) = -\frac{\alpha-1}{f^*} dU^* + \frac{1}{f^*} \sum_{i \leqslant p} \alpha_i X^{i*-[(\alpha_i-1)/\alpha_i]+1} d(X^{i*[(\alpha_i-1)/\alpha_i]} \xi_i^*) - \frac{1}{f^*} \sum_{p<i \leqslant n} \xi_i^* dX^{i*}. \tag{83}$$

Equation (77) still holds.

Concerning the Gibbs–Duhem equation in standard thermodynamics, see Ref. 47.

C. Examples

In the black hole case, as well known, one has (we do not write the asterisk in what follows)

$$S = \frac{M}{2T} - \frac{\Phi Q}{2T} - \frac{\Omega J}{T} \tag{84}$$

and

$$dS = \frac{1}{T} dM - \frac{\Phi}{T} dQ - \frac{\Omega}{T} dJ; \tag{85}$$

the generalized Gibbs–Duhem equation, associated with the quasi-homogeneity of S, is

$$-\frac{1}{2T} dM + \frac{M}{2} d\left(\frac{1}{T} \right) + \frac{\Phi}{2T} dQ - \frac{Q}{2} d\left(\frac{\Phi}{T} \right) - J d\left(\frac{\Omega}{T} \right) = 0, \tag{86}$$

which can be rewritten as[14]

$$\frac{1}{2} M^2 d\left(\frac{1}{MT} \right) - \frac{1}{2} Q^2 d\left(\frac{\Phi}{QT} \right) - J d\left(\frac{\Omega}{T} \right) = 0. \tag{87}$$

Then, one can find $1/T$ from

$$d \log\left(\frac{1}{T} \right) = \frac{1}{f} \left(\frac{1}{2} dM + \frac{1}{2} Q^2 d\left(\frac{\Phi}{Q} \right) + J \, d\Omega \right). \tag{88}$$

It can be easily shown that $1/T$ can be determined apart from an undetermined multiplicative constant.

X. ENERGY REPRESENTATION AND LEGENDRE TRANSFORM

In the energy representation, the fundamental equation is $U^*=U^*(S^*,X^{1*},\ldots,X^{n*})$. One has

$$dU^*=T^*\,dS^*+\sum_i \xi_i^* dX^{i*}. \tag{89}$$

U^* is a quasi-homogeneous function of degree r and type $(1,\alpha_1,\ldots,\alpha_n)$; T^* is quasi-homogeneous of degree $r-1$, ξ_i^* are quasi-homogeneous of degree α_i-r. Equation (89) represents an exact quasi-homogeneous Pfaffian form of degree r. The Euler operator is

$$D=S^*\,\frac{\partial}{\partial S^*}+\sum_i \alpha_i X^{i*}\,\frac{\partial}{\partial X^{i*}}. \tag{90}$$

One has then

$$U^*=\frac{1}{r}\left(T^*S^*+\sum_i \alpha_i \xi_i^* X^{i*}\right). \tag{91}$$

(Notice that the generalization to the case where S^* is quasi-homogeneous of degree q is trivial.)

As far as the Gibbs–Duhem equation is concerned, one easily finds (we shift to the case where S^* has degree q)

$$\frac{q}{r}\;S^{*-[(q-r)/q]+1}d(S^{*[(q-r)/q]}T^*)+\sum_i \frac{\alpha_i}{r}\,X^{i*-[(\alpha_i-r)/\alpha_i]+1}d(X^{i*[(\alpha_i-r)/\alpha_i]}\xi_i^*)=0. \tag{92}$$

For a proof see Appendix C. One can, e.g., determine T^* from

$$d(S^{*[(q-r)/q]}T^*)=-S^{*[(q-r)/q]-1}\,\frac{1}{q}\sum_i \alpha_i X^{i*-[(\alpha_i-r)/\alpha_i]+1}d(X^{i*[(\alpha_i-r)/\alpha_i]}\xi_i^*). \tag{93}$$

A formula analogous to (82) can be obtained if some independent zero-weight variables appear; one obtains (cf. Appendix C)

$$\frac{q}{r}\,S^{*-[(q-r)/q]+1}d(S^{*[(q-r)/q]}T^*)+\sum_{i\leqslant p}\frac{\alpha_i}{r}\,X^{i*-[(\alpha_i-r)/\alpha_i]+1}d(X^{i*[(\alpha_i-r)/\alpha_i]}\xi_i^*)$$

$$-\sum_{p<i\leqslant n}\xi_i^* dX^{i*}=0. \tag{94}$$

A. Legendre transforms

Legendre transforming of the potentials involves the usual procedure. A noticeable difference, with respect to standard thermodynamics, is that, if, between the $n+1$ independent variables, no variable of weight zero appears and no intensive dependent variable occurs, then one can iterate the Legendre transformations of the potential $n+1$ times and find a potential which is not identically vanishing. Moreover, the would-be intensive variables appear in the Euler operator involving the new independent variables. Let us, e.g., consider the quasi-homogeneous free energy

$$F^*(T^*,X^{1*},\ldots,X^{n*})=U^*-T^*\quad S^*. \tag{95}$$

It is a quasi-homogeneous function of degree r with respect to the Euler operator

$$D_1=(r-1)T^*\,\frac{\partial}{\partial T^*}+\sum_i \alpha_i X^{i*}\,\frac{\partial}{\partial X^{i*}}. \tag{96}$$

One can Legendre transform also with respect to the remaining n variables $X^{1*},\ldots,X^{n*}$:

$$G^*_{n+1}(T^*,\xi^*_1,\ldots,\xi^*_n)=U^*-T^*S^*-\sum_{i=1}^{n} X^{i*}\xi^*_i\not\equiv 0. \tag{97}$$

The corresponding Euler operator is

$$D_{n+1}=(r-1)T^*\,\frac{\partial}{\partial T^*}+\sum_i\,(r-\alpha_i)\xi^*_i\,\frac{\partial}{\partial \xi^*_i}. \tag{98}$$

Notice that, all the potentials which are obtained by Legendre transforming the internal energy U^* are quasi-homogeneous of degree r with respect to the corresponding Euler operator; all the Massieu–Planck potentials, which are obtained by Legendre transforming the entropy S^*, are quasi-homogeneous of degree 1. In other terms, the Legendre transform preserves the degree of quasi-homogeneity [but it changes variables and weights: the function

$$h^*(\xi^*,Y^*)=g^*-\xi^*X^* \tag{99}$$

which is obtained by a Legendre transform with respect to a variable ξ of weight α of a function $g(X^*,Y^*)$ which is quasi-homogeneous of degree r and weights $(r-\alpha,r-\beta)$, has weight $(\alpha,r-\beta)$]. For a proof, see Ref. 9 (theorem 2, Appendix A therein).

1. Case where weight-zero independent variables appear

Let us consider the case where a variable η^* of degree r and a variable I^* of weight zero appears:

$$dU^*=T^*\,dS^*+\xi^*\,dX^*+\eta^*\,dI^*. \tag{100}$$

The Euler operator is

$$D=S^*\,\frac{\partial}{\partial S^*}+\beta X^*\,\frac{\partial}{\partial X^*}. \tag{101}$$

One can Legendre transform three times, obtaining

$$G_3(T^*,\xi^*,\eta^*)=\frac{1}{r}\,[(1-r)T^*S^*-(r-\beta)\xi^*X^*-r\,\eta^*I^*] \tag{102}$$

and

$$D_3=(r-1)T^*\,\frac{\partial}{\partial T^*}+(r-\beta)\xi^*\,\frac{\partial}{\partial \xi^*}+r\,\eta^*\,\frac{\partial}{\partial \eta^*}. \tag{103}$$

2. Case with would-be intensive variable of degree zero

Let us consider the case where a variable ζ^* of degree zero and a variable Z^* of weight r appears,

$$dU^*=T^*\,dS^*+\xi^*\,dX^*+\zeta^*\,dZ^*. \tag{104}$$

The Euler operator is

$$D = S^* \frac{\partial}{\partial S^*} + \beta X^* \frac{\partial}{\partial X^*} + rZ^* \frac{\partial}{\partial Z^*}. \tag{105}$$

One can Legendre transform three times, obtaining

$$G_3(T^*, \xi^*, \zeta^*) = \frac{1}{r}[(1-r)T^*S^* - (r-\beta)\xi^* X^*] \tag{106}$$

and

$$D_3 = (r-1)T^* \frac{\partial}{\partial T^*} + (r-\beta)\xi^* \frac{\partial}{\partial \xi^*}. \tag{107}$$

This case is analogous to what happens in standard thermodynamics, e.g., when one passes from $U(S,V,N)$ to $F(T,V,N)$ and then to $G(T,p,N)$.

B. From the entropy to the energy representation and further considerations

In order to pass from the entropy representation $S^*(U^*, X^{1\,*}, \ldots, X^{n\,*})$ to the energy representation $U^*(S^*, X^{1*}, \ldots, X^{n*})$, one inverts the first relation with respect to U^*, which is possible because $\partial S^*/\partial U^* > 0$. If S^* has degree 1 and weights $(r, \alpha_1, \ldots, \alpha_n)$, then U^* has degree r and weights $(1, \alpha_1, \ldots, \alpha_n)$. Analogous considerations hold when passing from the energy to the entropy representation. We show that, when it is possible to invert, at least locally, a quasi-homogeneous function with respect to one variable, a quasi-homogeneous function is obtained again, having obvious degree and weights.

In the general case, let us consider a quasi-homogeneous function $w = g(x^1, \ldots, x^n)$ of degree r and weights $(a_1, \ldots, a_n)$; the partial derivatives

$$p_i \equiv \frac{\partial w}{\partial x^i} \tag{108}$$

are quasi-homogeneous functions of degree $r - a_i$ for $i = 1, \ldots, n$. Let us assume, e.g., that $p_1 \neq 0$. Then, at least locally, one can invert w with respect to x^1 and find $x^1 = h(w, x^2, \ldots, x^n)$ such that $g(h(w, x^2, \ldots, x^n), x^2, \ldots, x^n) = w$. The inverse function h (where it exists and it is sufficiently smooth) is easily shown to be a quasi-homogeneous function of degree a_1 and weights $(r, a_2, \ldots, a_n)$. In fact, one has

$$g(\lambda^{a_1} x^1, \lambda^{a_2} x^2, \ldots, \lambda^{a_n} x^n) = g(\lambda^{a_1} h(w, x^2, \ldots, x^n), \lambda^{a_2} x^2, \ldots, \lambda^{a_n} x^n) = \lambda^r g(x^1, \ldots, x^n). \tag{109}$$

Moreover, one has

$$g(h(\lambda^r w, \lambda^{a_2} x^2, \ldots, \lambda^{a_n} x^n), \lambda^{a_2} x^2, \ldots, \lambda^{a_n} x^n) = \lambda^r w = \lambda^r g(x^1, \ldots, x^n), \tag{110}$$

thus it has to hold

$$h(\lambda^r w, \lambda^{a_2} x^2, \ldots, \lambda^{a_n} x^n) = \lambda^{a_1} h(w, x^2, \ldots, x^n). \tag{111}$$

Compare Ref. 35, where an analogous property is shown in passing from the entropy representation to the energy representation in standard (homogeneous) thermodynamics. See also Ref. 48.

As a further example, let us consider Kerr–Newman black holes. By inverting (where possible) the relation $T = T(M,Q,J)$ with respect to M, one obtains (at least formally) $M = M(T,Q,J)$. We know that M and Q have degree 1/2, J has degree one and T has degree $-1/2$. In the new variables, $M = M(T,Q,J)$ is a quasi-homogeneous function of degree 1/2 and weights $(-1/2, 1/2, 1)$. The Euler operator corresponding to the independent variables (T,Q,J) is

$$\overline{D} = -\frac{1}{2} T \frac{\partial}{\partial T} + \frac{1}{2} Q \frac{\partial}{\partial Q} + J \frac{\partial}{\partial J} \tag{112}$$

and it holds

$$\overline{D} M = \tfrac{1}{2} M. \tag{113}$$

XI. FURTHER INSIGHTS FROM BLACK HOLES

A feature of quasi-homogeneous thermodynamics, shared also with homogeneous thermodynamics, is that in the expression of the metrical entropy and of the absolute temperature a undetermined multiplicative constant appears (cf. also Ref. 1). Such a constant is phenomenologically fixed once the absolute scale of temperature is chosen. From the point of view of the actual analytic expression of this constant, it should be furnished by a statistical mechanical calculation. The black hole case can be again useful. By dimensional analysis, if we make the hypothesis that the entropy of a black hole can depend only on $\hbar, c, G, k_b$, we find that

$$S \propto \frac{k_b c^3}{\hbar G} A; \tag{114}$$

this is the same procedure as in the original proposal of Bekenstein.[49] For the temperature one obtains

$$T \propto \frac{\hbar c}{k_b} \left(\frac{\partial A}{\partial (GM/c^2)} \right)^{-1}. \tag{115}$$

A dimensionless constant has still to be determined.

If one considers standard thermodynamics cases, this hypothesis which allows to recover the dimensions of the entropy by involving only the above constants works for the photon gas but it does not work in other cases; e.g., in the case of a Fermi gas of electrons, the electron mass represents a further scale, related to a microscopic analysis of the system, to be taken into account. In our case, the confirmation of the above hypothesis comes from the Hawking effect, which gives us the behavior of the black hole temperature, to be compared with (115). Then, because of the absence of a particle mass scale and, e.g., in the Schwarzchild and in the Kerr cases being involved only vacuum solutions of the Einstein equations, one could be tempted to think about some sort of ''graviton gas,'' but, actually, this is far from being evident. See also Ref. 14.

Black holes represent an example of the the procedure of reducing/enlarging consistently the thermodynamics space discussed in Sec. III. In fact, the construction of the fundamental equation sketched in Sec. IV is allowed also in the case of a black hole with $J=0$ and of a black hole with $Q=0$. Two parameters appear, M,Q and M,J, respectively. The integrability condition is then trivially satisfied, but a well-defined potential S is obtained everywhere. Moreover, black holes of the Kerr–Newman family are a consistent extension of the black holes of the Reissner–Nordström family (by adding J) or of the Kerr family (by adding Q). To this family belong also a thermodynamically degenerate case: the Schwarzschild case $J=0=Q$, which is described only by one variable M. Notice also that the Kerr–Newman family can be obtained by setting $\Lambda=0$ in the KN–AdS family.

In the case of black hole thermodynamics, it is tempting to conjecture that the quasi-homogeneous behavior of the thermodynamic potentials could be related to an explanation, to some extent, analogous to the one for the quasi-homogeneous behavior of the thermodynamic potentials in standard thermodynamics near the critical point:[50,51] As in standard thermodynamics the (leading order) quasi-homogeneous behavior can be related to the conformal invariance of the underlying quantum field theory near criticality,[51] one could conjecture that the quasi-homogeneous behavior of black hole thermodynamics could be related to some sort of conformal invariance of the quantum theory underlying general relativity (superstring theory). This field

deserves further investigation. We however point out that it does not seem to be necessary that quasi-homogeneous thermodynamics should be related to some sort of conformal invariance in every case. For black holes, as well as for the general case, one should determine the reason of a quasi-homogeneous behavior by means of statistical mechanical calculations. In the following section, a further discussion is found.

XII. HEURISTICS: QUASI-HOMOGENEOUS THERMODYNAMICS AND THERMODYNAMIC LIMIT

In this section we suggest that the thermodynamic limit, under suitable hypotheses, can lead only to quasi-homogeneous thermodynamics. The thermodynamic limit should not be intended in a literal sense, of course, but as a tool which allows to determine the leading terms in the statistical mechanical functionals as large systems occur. Compare e.g., Ref. 52, Chap. 4, and also Ref. 53. Thermodynamics of macrosystems emerges as an asymptotic law which is extrapolated from the asymptotic behavior of statistical mechanics. To some extent, the thermodynamic limit is also a tool by means of which the vague notion of ''macroscopic system'' is meant to be implemented, and a proper thermodynamic behavior recovered. Such a behavior depends on the interactions and on the nature of the system involved (e.g., fermionic or bosonic matter), together with a dependence on the initial conditions (from a quantum-mechanical point of view, a sort of ''preparation'' of the system, even if it is of ''astrophysical size''). As far as the gravitational interaction can be neglected, the standard thermodynamic behavior emerges, with the usual asymptotic laws which justify the extensivity of standard thermodynamics. At the same time, extensivity cannot be considered as an absolute and unmodifiable property of thermodynamics, because of the purely attractive nature of gravity. One can also expect a different asymptotic behavior for different systems at different scales. See also the discussion in the following sections.

The basic set (B) of assumptions is the following.

Assumptions (B): Let $\{Z_i\}$ *be the set of the thermodynamic variables, both independent* $(Z_i^{(I)})$ *and dependent* $(Z_i^{(D)})$ *ones. Let the independent variables describe the Gibbs thermodynamic space. Let* λ *be the parameter such that, by taking* $\lambda \to \infty$*, one recovers the thermodynamic limit. Assume that the thermodynamic limit properly describes the bulk properties of the system under consideration.*

Assume that the thermodynamic limit of the statistical mechanical quantities, like, e.g., the entropy or the free energy, exists under the hypothesis that, in the limit $\lambda \to \infty$*, the independent thermodynamic variables* $Z_i^{(I)}(\lambda)$ *are rescaled as*

$$Z_i^{(I)} = g_i^{(I)}(\lambda) Z_i^{(I)\ 0}, \tag{116}$$

where $g_i^{(I)}(\lambda)$ *is a positive function which is either an invertible function of* λ *or it is one (or a constant), and* $Z_i^{(I)\ 0}$ *is the value of the i-esime variable* $Z_i^{(I)}$ *at an arbitrary reference state (cf. Ref. 53 for the extensive case).*

We now state the following result (R-group).

Result (R-group): Let us assume the set of assumptions (B) and that for the rescalings of the independent variables the group property holds,

$$g_i^{(I)}(\lambda\mu) = g_i^{(I)}(\lambda) g_i^{(I)}(\mu). \tag{117}$$

This implies that for each independent variable there exists a real number $\alpha_i^{(I)}$ *such that* $g_i^{(I)}(\lambda) = \lambda^{\alpha_i^{(I)}}$.

Let us assume that the dependent thermodynamic variables

$$Z_i^{(D)} = Z_i^{(D)}(Z_1^{(I)}, \ldots, Z_n^{(I)}), \tag{118}$$

are obtained as leading terms in the asymptotic expansion of the corresponding statistical mechanical functionals $\mathcal{Z}_i^{(D)}$ *in the following sense: for each* i *there exists a positive continuous function* $\rho_i(\lambda)$ *such that*

$$\lim_{\lambda\to\infty}\frac{1}{\rho_i(\lambda)}\,\mathcal{Z}_i^{(D)}(g_1^{(I)}(\lambda)Z_1^{(I)},\ldots,g_n^{(I)}(\lambda)Z_n^{(I)})=Z_i^{(D)}(Z_1^{(I)},\ldots,Z_n^{(I)}),\tag{119}$$

and let us assume that the domain of the functionals $\mathcal{Z}_i^{(D)}$ *is invariant under the above rescalings. Then, the dependent thermodynamic variables are quasi-homogeneous, i.e., they satisfy*

$$Z_i^{(D)}(g_1^{(I)}(\lambda)Z_1^{(I)},\ldots,g_n^{(I)}(\lambda)Z_n^{(I)})=g_i^{(D)}(\lambda)Z_i^{(D)}(Z_1^{(I)},\ldots,Z_n^{(I)}),\tag{120}$$

where $g_i^{(D)}(\lambda)=\lambda^{\alpha_i^{(D)}}$ *and* $\alpha_i^{(D)}\in\mathbb{R}$.

Moreover, for all i, *the functions* $\rho_i(\lambda)$ *are regularly varying functions*:[54] *for all* $\mu\in\mathbb{R}_+$,

$$\lim_{\lambda\to\infty}\frac{\rho_i(\lambda\mu)}{\rho_i(\lambda)}=\mu^{\alpha_i^{(D)}}\tag{121}$$

($\alpha_i^{(D)}$ *is also called degree of* ρ_i).

In order to be more explicit, let us consider (R-group) for a specific case. Let us, e.g., assume that the thermodynamic limit for the statistical mechanical functional $\mathcal{S}$ representing the entropy exists in the sense that

$$\lim_{\lambda\to\infty}\frac{1}{\rho_S(\lambda)}\,\mathcal{S}(\lambda^{\alpha_U}U,\lambda^{\alpha_V}V,\lambda^{\alpha_N}N)=S(U,V,N),\tag{122}$$

where the function ρ_S is positive and $\alpha_U,\alpha_V,\alpha_N$ are real numbers. Then for each real $\mu>0$ the function ρ_S satisfies

$$\lim_{\lambda\to\infty}\frac{\rho_S(\lambda\mu)}{\rho_S(\lambda)}=\mu^{\gamma}\tag{123}$$

for some $\gamma\in\mathbb{R}$. Moreover, S is quasi-homogeneous of degree γ. In fact, from (122) it follows

$$\lim_{\lambda\to\infty}\frac{1}{\rho_S(\lambda\mu)}\,\mathcal{S}((\lambda\mu)^{\alpha_U}U,(\lambda\mu)^{\alpha_V}V,(\lambda\mu)^{\alpha_N}N)=S(U,V,N).\tag{124}$$

Moreover, it holds

$$\lim_{\lambda\to\infty}\frac{1}{\rho_S(\lambda)}\,\mathcal{S}(\lambda^{\alpha_U}(\mu^{\alpha_U}U),\lambda^{\alpha_V}(\mu^{\alpha_V}V),\lambda^{\alpha_N}(\mu^{\alpha_N}N))=S(\mu^{\alpha_U}U,\mu^{\alpha_V}V,\mu^{\alpha_N}N).\tag{125}$$

Then

$$\lim_{\lambda\to\infty}\frac{\rho_S(\lambda)}{\rho_S(\lambda\mu)}\,\frac{\mathcal{S}((\lambda\mu)^{\alpha_U}U,(\lambda\mu)^{\alpha_V}V,(\lambda\mu)^{\alpha_N}N)}{\mathcal{S}(\lambda^{\alpha_U}(\mu^{\alpha_U}U),\lambda^{\alpha_V}(\mu^{\alpha_V}V),\lambda^{\alpha_N}(\mu^{\alpha_N}N))}$$

$$=\frac{S(U,V,N)}{S(\mu^{\alpha_U}U,\mu^{\alpha_V}V,\mu^{\alpha_N}N)}=\lim_{\lambda\to\infty}\frac{\rho_S(\lambda)}{\rho_S(\lambda\mu)},\tag{126}$$

which is possible only if the above conditions are implemented. A general proof is found in Appendix E. Compare Ref. 55, where a rigorous approach for asymptotics of tempered distributions is developed.

The case where one or more variables are ''intensive,'' i.e., are not rescaled, presents no difficulty. The above reasoning about the leading order in the asymptotic law identified in the thermodynamic limit is corroborated b y the standard thermodynamic limit, which allows to find a leading-order homogeneous thermodynamics. We define *quasi-homogeneous thermodynamic limit* the thermodynamic limit satisfying the group property.

Moreover, we notice that, if, e.g., for the thermodynamic entropy $S(U,V,N)$ it holds

$$S(g_U(\lambda)U_0,g_V(\lambda)V_0,g_N(\lambda)N_0)=g_S(\lambda)S_0=g_S(\lambda)S(U_0,V_0,N_0), \tag{127}$$

where the functions g_U,g_V,g_N,g_S are positive and the group property holds, then S has to be quasi-homogeneous and the g_i are power-like functions. The key point is that a behavior like the one in (127) under the group property is necessarily quasi-homogeneous; as it is shown in Ref. 9, ''powers need no generalization'' (see Appendix A in Ref. 9 and Appendix C in Ref. 10). A different proof is sketched in Appendix D for the sake of completeness. The aforementioned theorem implies that actually one has

$$S(g(\lambda)^{\alpha_U}U,g(\lambda)^{\alpha_V}V,g(\lambda)^{\alpha_N}N)=g(\lambda)^{\alpha_S}S(U,V,N) \tag{128}$$

with the same scaling function $g(\lambda)$. By defining

$$\overline{\lambda}\equiv g(\lambda) \tag{129}$$

one finds $S(\overline{\lambda}^{\alpha_U}U,\overline{\lambda}^{\alpha_V}V,\overline{\lambda}^{\alpha_N}N)=\overline{\lambda}^{\alpha_S}S(U,V,N)$, i.e., the standard definition of quasi-homogeneous behavior for a function. A generalization of the quasi-homogeneous behavior of a function under rescaling with the group property is not allowed.

We now relax the requirement for the group property, one can still make a conjecture (C-reg) which would allows a quasi-homogeneous behavior under rather general conditions.

Conjecture (C-reg): Let us assume the set (B) and that g,g_i (for $i=1,\ldots,n$) are positive and continuous functions which are regularly varying functions of real degree $\gamma,\alpha_1,\ldots,\alpha_n$ respectively.

Assume that the statistical mechanical functional $\mathcal{Z}$ satisfies

$$\lim_{\lambda\to\infty}\frac{1}{g(\lambda)}\,\mathcal{Z}(g_1(\lambda)Z^1,\ldots,g_n(\lambda)Z^n)=Z(Z^1,\ldots,Z^n), \tag{130}$$

where Z^i are the independent thermodynamic variables [we omit the suffix (I)].

We conjecture that, under suitable hypotheses, the asymptotic $Z(Z^1,\ldots,Z^n)$ is quasi-homogeneous of degree γ and weights $(\alpha_1,\ldots,\alpha_n)$.

For each positive real μ one should find

$$\lim_{\lambda\to\infty}\frac{1}{g(\lambda\mu)}\,\mathcal{Z}(g_1(\lambda\mu)Z^1,\ldots,g_n(\lambda\mu)Z^n)=Z(Z^1,\ldots,Z^n) \tag{131}$$

$$\text{``}=\text{''}\lim_{\lambda\to\infty}\frac{1}{g(\lambda)\mu^{\gamma}}\,\mathcal{Z}(g_1(\lambda)\mu^{\alpha_1}Z^1,\ldots,g_n(\lambda)\mu^{\alpha_n}Z^n) \tag{132}$$

$$=\frac{1}{\mu^{\gamma}}\,Z(\mu^{\alpha_1}Z^1,\ldots,\mu^{\alpha_n}Z^n), \tag{133}$$

where "=" indicates that further hypotheses on the statistical mechanical functional should be satisfied. Notice that the case $g_i(\lambda)=\lambda^{\alpha_i}$ is a subcase of the preceding one and requires only that the limit (130) exists and that the state $(\mu^{\alpha_1}Z^1,\ldots,\mu^{\alpha_n}Z^n)$ belongs to the domain of the statistical mechanical functional $\mathcal{Z}$.

From a physical point of view, it can be noticed that, when passing from the statistical mechanical functional $\mathcal{S}$ representing the entropy to its asymptotic S_{sm} under dilatations, as in the standard thermodynamic limit, it would be not strictly necessary, *a priori*, to impose that $g(\lambda)=\lambda$ in order to obtain an homogeneous S_{sm} [herein we indicate by S_{sm} the asymptotic which is indicated by S in (122)]. (S_{sm} corresponds to the statistical mechanical entropy one takes into account in Sec. III C 2.) A generic regularly varying function of degree one could also be allowed [e.g., $g(\lambda)=\lambda\log(\lambda)$ could be allowed]. The requirement

$$\lim_{\lambda\to\infty}\frac{1}{\lambda}\,\mathcal{S}(\lambda x)=S_{\mathrm{sm}}(x) \tag{134}$$

amounts to the requirement that in some sense also $\mathcal{S}$ is extensive.

We have found that, under rather general hypotheses, the only possible outcome of the thermodynamic limit is a form of quasi-homogeneous thermodynamics. The thermodynamic limit, at the same time, is not expected to describe all possible systems; e.g., it cannot be applied to a thin (molecular thickness) metallic film.[56] Nevertheless, it can be safely applied to a huge class of macroscopic systems, and, in the nonrelativistic case, it allows to conclude that the Thomas–Fermi approximation becomes exact in the limit.

In partially concluding these heuristic considerations, we point out that a relation between a so-called pseudoextensive thermodynamics and the thermodynamic limit has been postulated in Ref. 57 and an analysis of Newtonian self-gravitating systems is made in Ref. 58. We limit ourselves to refer the reader to the aforementioned papers.

A. Nonconventional thermodynamic limit

A nonconventional thermodynamic limit has already been proposed. A very interesting discussion of the thermodynamic limit in physical systems is found in Ref. 59. Therein, physical systems are divided into two classes each of which can be associated with its own thermodynamic limit; one can distinguish between the standard thermodynamic limit (STL) and the inhomogeneous mean field thermodynamic limit (IMFTL) which occurs, e.g., in self-gravitating systems as the one of HNT model. The latter kind of thermodynamic limit can be related with the presence of long-range forces.[59] In order to identify the correct limit, the key notion of characteristic bulk length scale is introduced, which corresponds to a typical length scale λ_{typ} resulting from the interaction of many particles in the system. Such length scale λ_{typ} plays the role of characteristic invariant in the thermodynamic limit. In the case of a classical self-gravitating isothermal gas, the Jeans length λ_{Jeans} is such a typical length. Moreover, the requirement that mean thermodynamic quantities exist almost everywhere in the thermodynamic limit is a tool for selecting the appropriate thermodynamic limit at constant λ_{typ}.[59] A complementarity between STL and IMFTL can also be allowed for the same system, in the sense that STL and IMFTL can describe complementary asymptotic properties for the same large but finite system (the case of classical Coulomb systems is discussed). We do not discuss further on this approach herein, we limit ourselves to point out that one obtains the same limit, in the case of classical self-gravitating matter, if one keeps λ_{Jeans} fixed or ξ fixed (cf. Sec. V). Notice that ξ is an intensive function with respect to the Euler operator relative to the HNT model. At an heuristic level one expects that in general there exists a physically meaningful function which is left invariant under a quasi-homogeneous thermodynamic limit and which is intensive under the corresponding Euler operator.

A nonconventional discussion of the thermodynamic limit is found also in Secs. 1.2 and 4.2 of Ref. 27. Both for stable and for unstable interactions are discussed, and the criterion for selecting the limit is a comparison between the kinetic and the potential energies involved in the system. According to Ref. 28 (pp. 1–3), a nonconventional thermodynamic limit has to be associated with

the peculiar scaling behavior for ''nonstable interactions;'' the notion of ''Thomas–Fermi thermodynamic limit'' is also introduced for nonextensive systems. Note that a more general thermodynamic limit can also be allowed, where also the coupling constants are allowed to vary in the limit. Compare Refs. 25, 28, and 59.

B. Absolute weights again

It is evident that one has a reference quantity with respect to which all the others are ''weighted'' in the thermodynamic limit. Then an overall undetermined scale factor q is expected to appear, unless an absolute weight is known.

In the standard homogeneous case, the problem of assigning absolute weights does not arise, they are all equal to 1 for extensive variables and 0 for intensive ones, the thermodynamic limit is performed with the aim of studying bulk properties of the system, and the ratios U/N and V/N are kept constant. Roughly, one fixes the energy per particle and the volume per particle (or, equivalently, the density N/V and the energy density U/V) and then performs the limit with the aim of neglecting any finite-size effect. The same is true also for a massless particle gas, like the photon gas, where the limit $U,V\to\infty, U/V=\text{const}$ is performed.

If a strict quasi-homogeneous picture is required, then the above problem is instead present. When N is available, as it is when nonzero rest-mass particles are considered, it is to some extent natural to assume that its weight is 1. Such a special role of N can be justified. In the model of Hertel, Narnhofer, and Thirring, the existence of the Boltzmann's entropy per particle in the thermodynamic limit $\lim_{N\to\infty}\log(\Omega)/N$ is ensured, in agreement with Boltzmann's postulate, which states that the entropy per particle $\log(\Omega)/N$ exists for an equilibrium system. As a consequence of the coincidence of $\lim_{N\to\infty}\log(\Omega)/N$ with the thermodynamic entropy density (per particle), one can justify *a posteriori* the assumption that N has weight 1, in fact $\log(\Omega)$ in the thermodynamic limit coincides with the thermodynamic entropy which has degree 1. The other weights α_i appropriate to the physical condition one is considering for the system are recovered in the asymptotic limit. Then, no ambiguity for an overall multiplicative constant in the definition of the weight like the one discussed in Sec. III C appears. Note also that the Boltzmann's entropy, being the logarithm of the number of microstates compatible with a given macrostate, by involving the (vague) concept of macrostate and thus of macroscopic system can legitimately related to the thermodynamic limit (again in the sense of asymptotic law). [About Boltzmann's entropy and its coincidence with the Gibbs entropy (which, in the quantum case, corresponds to the von Neumann entropy) see, e.g., Ref. 60.] A more puzzling case is represented by a self-gravitating massless gas, but weights can be still fixed. See Sec. VI.

In general, if $\lambda\to\infty$ corresponds to the thermodynamic limit, one could also require the existence of the Boltzmann entropy density functional as $\lambda\to\infty$, to be defined as

$$s_{\text{boltz}}\equiv\lim_{\lambda\to\infty}\frac{1}{\lambda^{\alpha_S}}\log(\Omega), \tag{135}$$

where α_S is a constant which is fixed by the requirement of finiteness of the above limit. α_S has to be introduced because the scale λ can also be such that λ/N is not asymptotically a positive constant, i.e., $\lambda\not\sim N$ in the sense of the asymptotic behavior. This more general choice for the scale is also necessary if N is not a good thermodynamic variable (as in the massless gas case). We know that it is consistent to fix the weights by choosing the Boltzmann entropy to be of degree 1.

If another variable, e.g., the internal energy, would be used as reference variable, the relative weights could be still recovered in line of principle, but the aforementioned ambiguity would emerge in absence of a criterion for finding the absolute weight of at least one (independent or dependent) variable.

One could also choose to work in the energy representation, and decide to fix the weight of the internal energy to be 1. Then the entropy in general would not be a degree 1 quasi-homogeneous function; in the HNT model, one would obtain $\deg(V)=-3/7$; $\deg(N)=3/7$; $\deg(S)=3/7$,

against the weight 7/3 of U resulting by assuming that N has weight 1. This procedure, although legitimate because of the overall ambiguity, is less satisfactory, because the thermodynamic construction, in the case the entropy is a quasi-homogeneous function and the weights present the overall factor ambiguity, allows naturally the thermodynamic entropy to be of degree 1. The only exception which, in line of principle could be admitted, is given by the case where the weights in the Gibbs space are all fixed and the statistical-mechanical entropy is not of degree 1, but it is apparently not allowed (unless some reason for fixing the absolute weight of a variable appears).

C. Thermodynamics, weights and gravity

As far as gravity is negligible, one finds the standard extensivity property for the fundamental equation in the entropy (energy) representation; when the scale of the system is such that is no more possible to neglect self-gravity effects, then the weights of the thermodynamic variables change according to the nature of the system and to the scale itself. The quasi-homogeneous character of thermodynamics with fixed weights $(\alpha_1,\ldots,\alpha_n)$ has to be intended as relative to the validity range of the asymptotic expansion which leads to those particular $(\alpha_1,\ldots,\alpha_n)$, whose nature is thus nonabsolute. [One could also be tempted to write $\alpha_i=\alpha_i(\lambda)$, in order to recall that the weights can change with the scale. Nevertheless, in light of the above theorem about quasi-homogeneity, such a dependence is not allowed. The quasi-homogeneity is extrapolated at each fixed scale, and it is made ''absolute'' by the thermodynamic formalism.] Also an estimate of the error for finite λ should be allowed.[52] One could think also to a sort of ''evolving picture'' for the formalism, in which one starts from standard homogeneous systems, characterized by stable interactions, and then, as far as gravity becomes non-negligible, a quasi-homogeneous behavior is allowed. Weights can change, even in a discontinuous way, depending on the physical conditions leading to the new stationary equilibrium state. Because of the Hawking effect, the ''end of the story'' does not occur even when the scale and the physical conditions are such that a black hole forms, whose ''classical'' weights are the ones presented in Sec. IV.

It is interesting to underline again that ordinary thermodynamics implements the picture described above, as discussed in several fundamental papers on the stability of matter.[29,61–63] See also Refs. 43 and 64. Strict quasi-homogeneity is expected to be effective when gravitation begins playing an essential role in the physics of the system. Moreover, the so-called fourth law of thermodynamics[13] should be generalized in such a way to include the general quasi-homogeneous behavior of the thermodynamic variables (dependent as well as independent ones).

XIII. CONCLUSIONS

Quasi-homogeneous thermodynamics is proposed as the unifying picture for thermodynamics where both stationary black holes, fermionic nonrelativistic matter, and self-gravitating electromagnetic radiation are found.

We have chosen to introduce quasi-homogeneity in thermodynamics by generalizing the formalism developed for standard homogeneous thermodynamics.[1] The basic requirement is that the Euler vector field which generates quasi-homogeneous dilatations in the Gibbs' thermodynamic space is a nontrivial symmetry for the integrable Pfaffian form δQ_{rev}. This means that the symmetry maps leaves of the thermodynamic foliation onto other leaves. The leaves of the foliation are naturally associated with a quasi-homogeneous function S^* of degree 1, which is suggested to be the (unique apart from a multiplicative constant) metrical entropy corresponding to the fundamental equation in the entropy representation. This is true also in the case one knows the weights of the thermodynamics variables apart from an overall unknown factor. Notice that quasi-homogeneity could be introduced also at the level of the fundamental equation in the entropy representation or in the energy one, but, in the case where only the relative weights of the independent thermodynamic variables are known, it should be considered equivalent the choice of a degree one internal energy with respect to the choice of a degree 1 entropy (cf. also Ref. 9), whereas the aforementioned approach privileges a degree 1 entropy.

The consequences of the lack of homogeneity are recalled, and superadditivity of the metrical entropy is a privileged property ensuring the second law even in absence of concavity for S^*.

The generalized Gibbs–Duhem identities are also derived, and the energy representation and the behavior under Legendre transforms is analyzed.

An heuristic argument which can relate quasi-homogeneous thermodynamics to the thermodynamic limit in statistical mechanics (even if in a nonconventional framework) has been introduced. According to this argument, under the group property only a form of quasi-homogeneous thermodynamics can be recovered in the thermodynamic limit. Moreover, a mean field thermodynamic limit appears to be appropriate; the suggestion from the existing models is that one has to search for asymptotic scaling properties of the equations allowing to find out the mean field thermodynamics for the system, in fact the scaling properties of a finite temperature Thomas–Fermi equation appears to be involved in the quasi-homogeneity of the HNT model, whereas the scaling properties of the TOV equations are related with the quasi-homogeneity of self-gravitating radiation.

Gravity appears to play a fundamental role in allowing a generalization of the standard scheme for thermodynamics. The purely attractive nature of gravity, as well-known, is the reason for the failure of the extensivity property in thermodynamics of self-gravitating systems, because of the absence of saturation which leads to an implosive instability, and matter systems eventually can implode into a black hole if the mass is sufficiently large. Moreover, the thermodynamic ensembles become inequivalent,[28] and the lack of concavity leads to phase transitions in matter systems in the canonical ensemble.[27,28] Negative heat capacities arise in the microcanonical ensemble. Also black holes present this feature.

Black hole thermodynamics requires some special comments. From the point of view of thermodynamic formalism, black hole thermodynamics can be realized to be a rather straightforward generalization of the formalism developed for standard thermodynamics in Ref. 1; moreover, its quasi-homogeneous behavior can no more be considered as exceptional, because self-gravitating systems exist where quasi-homogeneous scaling laws are satisfied. Nevertheless, from other points of view black hole thermodynamics is still to be considered special, also because it is still unclear which statistical mechanics should lie beyond it.

We limit ourselves herein to this proposal for a generalization of the thermodynamic formalism, without pursuing it further on (apart from a note on the third law in Appendix B). For future investigations, it would be interesting to develop a statistical mechanical formalism where general relativity is self-consistently included.

It would be also interesting to explore, if other long range forces are allowed to be included in the framework of quasi-homogeneous thermodynamics. Classical two-component Coulomb matter seems to belong to this framework,[59] further investigations are required in order to see if this is true also for quantum Coulomb matter.

APPENDIX A: INTEGRAL OF ω/μ AND POTENTIALS ASSOCIATED WITH QUASI-HOMOGENEOUS EXACT PFAFFIAN FORMS

We first present some results in the general case of a generic symmetry X for a Pfaffian form ω. Then we translate the results for the case of the quasi-homogeneity symmetry. We recall that a vector field X is defined to be a symmetry for a Pfaffian form ω if

$$(L_X\omega)\wedge\omega=0. \tag{A1}$$

This means that there exists a function h such that

$$L_X\omega=h\omega. \tag{A2}$$

See Refs. 5 and 6.

We need the following two lemmas.

Lemma 1: Let $\overline{\omega}$ be an exact Pfaffian form; let X be a symmetry such that

$$L_X\overline{\omega}=q\,\overline{\omega}, \tag{A3}$$

where $q\neq 0$ *is a constant. Then, one finds that* $\overline{\omega}=d\phi$ *is implemented by*

$$\phi\equiv\frac{1}{q}\,i_X\overline{\omega}. \tag{A4}$$

Proof: The proof is elementary. One has trivially

$$d\phi=\frac{1}{q}\,d(i_X\overline{\omega})=-\frac{1}{q}\,i_X(d\overline{\omega})+\frac{1}{q}\,L_X\overline{\omega}. \tag{A5}$$

From $d\overline{\omega}=0$ because $\overline{\omega}$ is closed and from the symmetry of $\overline{\omega}$, which implies $L_X\overline{\omega}=q\,\overline{\omega}$ the thesis follows. Notice that ϕ satisfies $X\phi=q\phi$. □

Lemma 2: Let $\omega_{(0)}$ *be an exact Pfaffian form; let* $\hat{W}$ *be the associated potential:* $d\hat{W}\equiv\omega_{(0)}$*; let* X *be a symmetry such that* $L_X\omega_{(0)}=0$*. Then*

$$d\hat{W}=\frac{dF}{F}, \tag{A6}$$

where F *satisfies*

$$XF=qF, \tag{A7}$$

with $q\in\mathbb{R}$ *constant. Moreover,*

$$i_X\omega_{(0)}=q. \tag{A8}$$

As a consequence, $q=0$ *is allowed if and only if the symmetry is tangent (i.e., trivial).*

Proof: We have

$$0=L_X\omega_{(0)}=L_X\,d\hat{W}=dL_X\hat{W}. \tag{A9}$$

As a consequence,

$$L_X\hat{W}=X\hat{W}=q, \tag{A10}$$

where q is a constant. We can define a positive definite function F such that

$$\hat{W}\equiv\log(F). \tag{A11}$$

Then we get that (A10) is equivalent to the following equation for F:

$$XF=qF; \tag{A12}$$

moreover

$$d\hat{W}=\frac{dF}{F}, \tag{A13}$$

and

$$i_X\omega_{(0)}=i_X\,d\hat{W}=L_X\hat{W}=\frac{1}{F}\,XF=q. \tag{A14}$$

If the symmetry is tangent, then $i_X\omega_{(0)}\equiv 0$. Then $q=0$ necessarily. If $q=0$, then F and $\hat{W}$ satisfy $XF=0$ and $X\hat{W}=0$, respectively. As a consequence, $i_X\omega_{(0)}=i_X\,d\hat{W}=L_X\hat{W}=0$, which completes the proof. □

Notice that $\hat{W}$ has to be found by quadratures, the contraction of the Pfaffian form with the vector field X is not useful in order to find a potential without explicit integration.

One can in general show that the following theorem holds.

Theorem 1: *Let ω be a integrable Pfaffian form which is defined in a simply connected domain; let X be a nontrivial symmetry for ω; let $\mu=i_X\omega$. Then μ is an integrating factor for ω and the foliation corresponding to the Pfaffian equation $\omega=0$ is associated with a potential F which satisfies the following equation*:

$$XF=F. \tag{A15}$$

Proof: The proof that ω/μ is closed is trivial. See also Refs. 6 and 1. Moreover

$$L_X\,\frac{\omega}{\mu}=0, \tag{A16}$$

being X a symmetry for ω. In fact,

$$L_X\,\frac{\omega}{\mu}=\frac{1}{\mu^2}((L_X\omega)\mu-(L_X\mu)\omega)=\frac{1}{(i_X\omega)^2}((L_X\omega)(i_X\omega)-(L_Xi_X\omega)\omega) \tag{A17}$$

$$=\frac{1}{(i_X\omega)^2}\,i_X(\omega\wedge(L_X\omega)), \tag{A18}$$

where the rules $i_XL_X=L_Xi_X$ and $i_X(\alpha\wedge\beta)=(i_X\alpha)\wedge\beta+(-)^n\alpha\wedge(i_X\beta)$ for a n-form α and a m-form β are used. Compare Ref. 65.

As a consequence, ω/μ is an exact one-form such that the previous lemma applies. One has

$$\frac{\omega}{\mu}=d\hat{W}=\frac{dF}{F}, \tag{A19}$$

where F satisfied Eq. (A7) with $q\neq 0$, because of the hypothesis of nontrivial symmetry. Then one finds

$$dF=\frac{F}{\mu}\,\omega, \tag{A20}$$

which satisfies $L_X\,dF=q\,dF$ and is closed. Then, from (A4), we obtain

$$F=\frac{1}{q}\,\frac{F}{\mu}\,i_X\omega, \tag{A21}$$

which, because of the definition of μ, implies $q=1$. □

Notice that the integrating factor satisfies

$$L_X\mu=L_Xi_X\omega=i_XL_X\omega=h\mu. \tag{A22}$$

It is interesting to underline that this theorem allows to construct a general theory of thermodynamics if δQ_{rev} has a nontrivial symmetry. It is easy to see that the constructions of Secs. III A and III B remain unaltered, and also the constructive assumptions of Sec. VIII can be trivially generalized [it is sufficient to delete "quasi-homogeneous" in (a1) and (a2) and to change (a5) into "the metrical entropy S satisfies $X\ \ S=S$"]. The case of quasi-homogeneous symmetry is immediately

obtained by requiring that each independent variable in the thermodynamic space has the same kind of symmetry as the potential S. More general symmetries can also be introduced. Further details will be given elsewhere.[66]

1. The quasi-homogeneous case

The following results are immediate consequences of the previous lemmas and theorem in the case of quasi-homogeneous symmetry.

Result 1: Let

$$\omega=\sum_{i=1}^{n}\omega_i\,dx^i \tag{A23}$$

be an exact quasi-homogeneous Pfaffian form of degree $r\neq 0$ *and weights* $(\alpha_1,\ldots,\alpha_n)$; *let*

$$D\equiv\sum_{i=1}^{n}\alpha_i x^i\,\frac{\partial}{\partial x^i} \tag{A24}$$

be the Euler operator; let the symmetry be nontrivial (or transversal), i.e.,

$$\omega(D)=i_D\omega=\sum_{i=1}^{n}\alpha_i\omega_i x^i\not\equiv 0. \tag{A25}$$

Then, one finds that $\omega=d\phi$ *is implemented by*

$$\phi\equiv\frac{1}{r}\,\omega(D). \tag{A26}$$

The above result can be used even when some zero weights occur. It cannot be used if $r=0$, in which case the potential can be found only by quadratures. When one considers, e.g., $\delta Q_{\mathrm{rev}}/f$, the potential has to be found by integrating the exact form.

Result 2: Let $\omega_{(0)}$ *be an exact quasi-homogeneous Pfaffian form of degree* $r=0$; *let* W *be the associated potential:* $d\hat{W}\equiv\omega_{(0)}$. *Then*

$$d\hat{W}=\frac{dF}{F}, \tag{A27}$$

where F *is a quasi-homogeneous function of degree* q *with respect to the Euler vector field* D. *Moreover,*

$$i_D\omega_{(0)}=q. \tag{A28}$$

As a consequence, $q=0$ *is allowed if and only if the symmetry is tangent.*

Notice that $\hat{W}$ has to be found by quadratures, the contraction of the Pfaffian form with the Euler vector field is not useful in order to find a potential without explicit integration.

Result 3: If $\omega_{(r)}$ *is a quasi-homogeneous integrable Pfaffian form of degree* r *defined in a connected, simply connected domain, if the symmetry is nontrivial and if* μ *is the corresponding integrating factor* $\omega(D)$, *then*

$$d\hat{W}\equiv\frac{\omega_{(r)}}{\mu}=\frac{dF}{F}, \tag{A29}$$

where F *is a quasi-homogeneous function of degree 1 with respect to the Euler vector field* D.

The degree r of $\omega_{(r)}$ can also be zero in the case where at least one weight, say α_1, is different from zero (the would-be intensive variable ω_1 has then weight $-\alpha_1$). Herein examples are given where $0<r<\infty$. It would be interesting to see if $r\leqslant 0$ is physically meaningful.

Notice that the fact that the case $q=0$ is not allowed by the requirement of nontriviality for the symmetry can be verified by direct inspection, in fact from Eq. (A20) it follows

$$\partial_i F=\frac{F}{\mu}\,\omega^i \quad \forall i=1,\ldots,n, \tag{A30}$$

thus $DF=0$ becomes

$$\sum_{i=1}^{n}\alpha_i x^i\,\frac{F}{\mu}\,\omega^i=0, \tag{A31}$$

which is not allowed, in fact, because of $\mu=\Sigma_{i=1}^{n}\alpha_i x^i\omega^i$, it would imply $F\equiv 0$. It is interesting to note that, from a mathematical point of view, $\hat{W}$ is an almost quasi-homogeneous function of degree zero with first order deficiency index identically equal to 1 (cf. Ref. 3), i.e., its behavior under quasi-homogeneous scaling is

$$\hat{W}(\lambda^{\alpha_1}x^1,\ldots,\lambda^{\alpha_n}x^n)=\hat{W}(x^1,\ldots,x^n)+\log(\lambda). \tag{A32}$$

This property of $\hat{W}$ is to be related with the nontriviality of the symmetry, which allows to find an integrating factor $\mu\not\equiv 0$.

2. Some more results on quasi-homogeneous integrable Pfaffian forms

We have found that, for nontrivial symmetry,

$$\omega_{(r)}=g_{(r-1)}dF, \tag{A33}$$

where $g_{(r-1)}$ is quasi-homogeneous of degree $r-1$. If G is a quasi-homogeneous function of degree q such that

$$\omega_{(r)}=g_{(r-q)}\,dG \tag{A34}$$

then necessarily

$$G=\zeta F^q, \tag{A35}$$

where $\zeta=\text{const}$. In fact, one has

$$\omega_{(r)}=g_{(r-q)}\,dG=g_{(r-1)}\,dF \tag{A36}$$

and

$$g_{(r-q)}=\frac{g_{(r-1)}}{dG/dF}. \tag{A37}$$

Moreover, the quasi-homogeneity of $G(F)$ implies

$$DG=qG=\frac{dG}{dF}\,F, \tag{A38}$$

that is,

$$\frac{dG}{dF} = q\,\frac{G}{F}, \tag{A39}$$

whose solution is (A35). For $q=1$, one obtains that the quasi-homogeneous function F of degree one implementing (A33) is unique apart from a multiplicative constant. [Notice that this result can be generalized easily to the case of a generic symmetry X. By referring to theorem 1, if G satisfies $XG=qG$ and $\omega = b\,dG$, then $G=G(F)$, where F is the potential (A15), and $G=\kappa F^q$, where κ is a constant.]

It is evident that, if D is a symmetry generator, $D_q = qD$ is another symmetry generator for $q \in \mathbb{R}-\{0\}$. It is also interesting that, by changing q, the integrating factor f_q changes in such a way that $\omega/f_q = d\log(F_q)$, where $F_q = F^{1/q}$ is quasi-homogeneous of degree 1 with respect to D_q (i.e., $D_q F_q = F_q$). In fact, one has $f_q = qf$ and

$$\frac{\omega}{f_q} = \frac{1}{q}\,\frac{\omega}{f} = \frac{1}{q}\,d\log(F) = d\log(F^{1/q}); \tag{A40}$$

then, $D_q F^{1/q} = qDF^{1/q} = q1/qF^{1/q-1}DF = F^{1/q}$.

APPENDIX B: *S* AS A FUNCTION OF *T* IN QUASI-HOMOGENEOUS THERMODYNAMICS AND THE THIRD LAW IN ENTROPIC FORM

We assume that the metrical entropy S^* is quasi-homogeneous of degree 1, and that $\alpha, \alpha_1, \ldots, \alpha_n$ are the weights of the independent variables $U^*, X^{1*}, \ldots, X^{n*}$. The temperature is then a quasi-homogeneous function of degree $\alpha - 1$. Let us consider $S^* = S^*(T^*, X^{1*}, \ldots, X^{n*})$. The entropic form of the third law, for standard thermodynamics, states that $S \to S_0$ as $T \to 0$, where S_0 is a constant which has to be zero.[1] Planck's restatement of the third law $S \to 0$ as $T \to 0$ is mandatory, if the third law holds, also in the case of quasi-homogeneous thermodynamics. In fact, if, for any fixed value of $X^{1*}, \ldots, X^{n*}$,

$$\lim_{T^* \to 0} S^*(T^*, X^{1*}, \ldots, X^{n*}) = S^*(0, X^{1*}, \ldots, X^{n*}) \equiv S_0^* \tag{B1}$$

holds, then, from

$$\lim_{T^* \to 0} S^*(\lambda^{\alpha-1}T^*, \lambda^{\alpha_1}X^{1*}, \ldots, \lambda^{\alpha_n}X^{n*}) = \lambda \lim_{T^* \to 0} S^*(T^*, X^{1*}, \ldots, X^{n*}) = \lambda \quad S_0^* \tag{B2}$$

and

$$\lim_{T^* \to 0} S^*(\lambda^{\alpha-1}T^*, \lambda^{\alpha_1}X^{1*}, \ldots, \lambda^{\alpha_n}X^{n*}) = S^*(0, \lambda^{\alpha_1}X^{1*}, \ldots, \lambda^{\alpha_n}X^{n*}) = S_0^* \tag{B3}$$

one finds $S_0^* = 0$. In the above formulas, continuity of S^* at $T^* = 0$ is assumed (otherwise the third law is violated[67]).

We know that black hole thermodynamics violates the entropic form of the third law. This behavior is not a general feature of quasi-homogeneous thermodynamics. We construct a toy-entropy which is both quasi-homogeneous and superadditive and implements the third law. Herein, as in Sec. VII, with x we indicate collectively the n variables appearing in S. Our starting point consists in realizing that, given two non-negative superadditive functions $g(x), h(x)$, the function

$$F(x) \equiv g(x)h(x) \tag{B4}$$

is superadditive too. In fact,

$$F(x_1+x_2) = g(x_1+x_2)h(x_1+x_2) \geqslant (g(x_1)+g(x_2))(h(x_1)+h(x_2)) \tag{B5}$$

$$= g(x_1)h(x_1) + g(x_2)h(x_2) + g(x_1)h(x_2) + g(x_2)h(x_1) \tag{B6}$$

$$\geqslant g(x_1)h(x_1) + g(x_2)h(x_2) = F(x_1) + F(x_2). \tag{B7}$$

Then, let us consider $g = 2\sqrt{U^* X^*}$ and $h = X^{*2}$. Both are superadditive functions (g is superadditive because of its homogeneity and concavity). Then $S^* \equiv 2\sqrt{U^* X^* X^{*2}}$ is superadditive and quasi-homogeneous. For S^* as a function of T^*, one finds

$$S^* = 2T^* X^{*5} \tag{B8}$$

which satisfies $S^* \to 0$ as $T^* \to 0$.

It is also interesting to notice that, in general, if S is a strictly superadditive function everywhere (i.e., also on the boundary $T=0$) then the entropic version of the third law in Planck's form has to be violated; in fact, if $(U_0, X_0^1, \ldots, X_0^n)$ is such that $T(U_0, X_0^1, \ldots, X_0^n) = 0$, then

$$S(U + U_0, X^1 + X_0^1, \ldots, X^n + X_0^n) > S(U_0, X_0^1, \ldots, X_0^n) + S(U, X_1, \ldots, X^n) \tag{B9}$$

is possible with the strict inequality only if $S(U_0, X_0^1, \ldots, X_0^n) > 0$. In the case of a self-gravitating system belonging to quasi-homogeneous thermodynamics framework, if the energy is strictly subadditive everywhere, then the third law cannot hold.

As far as mathematical properties of the Pfaffian form δQ_{rev} ensuring the validity of the entropic form of the third law are concerned, it can be shown that a quasi-homogeneous δQ_{rev} which is C^1 everywhere is a sufficient condition, in analogy with standard thermodynamics.[1,67] In fact, a superadditive non-negative function $S: \mathcal{D} \to \mathbb{R}_+ \cup \{\infty\}$ cannot be divergent at a limit point x_0 of its domain (we mean that all the points x in the domain satisfy $\|x\| < \infty$, where $\|\cdot\|$ stays for the Euclidean norm and that x_0 can be included in the domain by setting $S(x_0) = \infty$). This is evident if one translates rigidly the domain in such a way that $x_0 \equiv 0$. Then, if z_0 is another point in the domain of S one has $S(z_0) = S(z_0 + 0) \geqslant S(0) + S(z_0) = \infty$. Thus, if $S \not\equiv \infty$, then S has to be finite. Then S has to be finite in the limit as $T \to 0$. As a consequence, if f^* is the integrating factor, one has

$$\frac{\partial f}{\partial U^*} = 1 + S^* \frac{\partial T^*}{\partial U^*} \tag{B10}$$

and $\partial T^*/\partial U^* = 1/C$, where C is the heat capacity at fixed parameters X^{i*}, which has to tend to zero if S^* is finite and non-negative as $T^* \to 0$. Then, if f^* is everywhere C^1 (and it is such if δQ_{rev} is C^1 everywhere), it holds $S^* \to 0$ as $T^* \to 0$. Moreover, it is evident from (18) that $\lim_{T^* \to 0} S^* = 0$ holds if and only if $\int_\gamma \delta Q_{\text{rev}}/f^* \to -\infty$ as $T^* \to 0$ whichever path is chosen in approaching $T^* = 0$. Even the latter is an extension to the quasi-homogeneous case of the standard case.[1,67] See also Ref. 68 for further conditions.

APPENDIX C: GIBBS–DUHEM EQUATION REVISITED

Let us consider a quasi-homogeneous function $g(x^1, \ldots, x^n)$ of degree $q \neq 0$ and of weights $(\alpha_1, \ldots, \alpha_p, 0, \ldots, 0)$ where $1 \leqslant p \leqslant n$ is an integer and the last $n-p$ weights are all zero. It satisfies

$$Dg = qg, \tag{C1}$$

where

$$D = \sum_{i \leqslant p} \alpha_i x^i \frac{\partial}{\partial x^i}. \tag{C2}$$

If one defines

$$g_i \equiv \frac{\partial g}{\partial x^i} \quad \forall i = 1,\ldots,n, \tag{C3}$$

and

$$\omega_g \equiv \sum_i g_i \, dx^i = dg, \tag{C4}$$

one finds

$$g = \frac{1}{q} \, i_D \omega_g \, . \tag{C5}$$

This formal manipulation is useful in order to derive the Gibbs–Duhem equation. In fact, one has

$$dg = d\left(\frac{1}{q} \, i_D \omega_g\right) = \frac{1}{q} \, (-i_D \, d\omega_g + L_D \omega_g), \tag{C6}$$

where $L_D \omega_g = q \omega_g$ holds. Moreover, $d\omega_g = 0$ because $dg = \omega_g$ by construction. The Gibbs–Duhem equation is shown to be equivalent to

$$-\frac{1}{q} \, i_D \, d\omega_g = 0. \tag{C7}$$

One can easily see that

$$d\omega_g = \sum_i dg_i \wedge dx^i \tag{C8}$$

and that

$$\begin{aligned} i_D \, d\omega_g &= \sum_i (i_D \, dg_i) dx^i - \sum_i dg_i (i_D \, dx^i) \\ &= \sum_i (Dg_i) dx^i - \sum_{i \leqslant p} dg_i (\alpha_i x^i) \\ &= \sum_{i \leqslant p} (q - \alpha_i) g_i \, dx^i - \sum_{i \leqslant p} dg_i (\alpha_i x^i) + \sum_{p < i \leqslant n} q g_i \, dx^i. \end{aligned} \tag{C9}$$

As a consequence, (C7) becomes

$$\sum_{i \leqslant p} \frac{\alpha_i}{q} \, (x^i)^{q/\alpha_i} d((x^i)^{1 - q/\alpha_i} g_i) - \sum_{p < i \leqslant n} g_i \, dx^i = 0. \tag{C10}$$

If none independent variable of weight zero appears, then one finds

$$\sum_i \frac{\alpha_i}{q} \, (x^i)^{q/\alpha_i} d((x^i)^{1 - q/\alpha_i} g_i) = 0. \tag{C11}$$

Let us consider the inverse problem, where one assigns n would-be intensive variables g_i and the quasi-homogeneous one-form of degree $\omega_g = \Sigma_i g_i \, dx^i$ such that $L_D \omega_g = q \omega_g$ [one has to require

that $\deg(g_i)=q-\alpha_i$, where the weights of the independent variables x^i are the same as above]. Then one can also define a function $g\equiv i_D\omega_g/q$. From $dg=(-i_D\,d\omega_g)/q+\omega_g$ follows that ω_g is closed if $i_D\,d\omega_g=0$, i.e., if the Gibbs–Duhem equation is satisfied.

We limit ourselves to point out that more general Gibbs–Duhem equations are obtained in the generic symmetric case.[66] The generalization of (83) is

$$(i_X\delta Q_{\rm rev})d\log\left(\frac{1}{T}\right)-i_X\,d\,\delta Q_{\rm rev}+(L_X-1)\,\delta Q_{\rm rev}=0. \tag{C12}$$

APPENDIX D: QUASI-HOMOGENEITY (SCALING) CANNOT BE GENERALIZED

We show that, if $f(x^1,\ldots,x^n)$ is a C^1 function on a open connected set which satisfies the following identity:

$$f(g_1(\lambda)x^1,\ldots,g_n(\lambda)x^n)=g(\lambda)f(x^1,\ldots,x^n) \tag{D1}$$

and the functions $g(\lambda),g_i(\lambda)$ for $i=1,\ldots,n$ are positive definite and invertible, then $f(x^1,\ldots,x^n)$ is necessarily quasi-homogeneous. The above transformation is meant to be obtained by a "generalized similarity transformation" which carries $x^1,\ldots,x^n$ into $g_1(\lambda)x^1,\ldots,g_n(\lambda)x^n$. Let us consider $u\equiv g(\lambda)$ and the inverse $\lambda=g^{-1}(u)$. Define

$$h_i(u)\equiv g_i(g^{-1}(u))\quad\forall i=1,\ldots,n. \tag{D2}$$

It is also useful to define

$$u\equiv e^s. \tag{D3}$$

Then we obtain

$$f(h_1(e^s)x^1,\ldots,h_n(e^s)x^n)=e^sf(x^1,\ldots,x^n). \tag{D4}$$

Note that, for $s=0$, one finds

$$f(h_1(1)x^1,\ldots,h_n(1)x^n)=f(x^1,\ldots,x^n). \tag{D5}$$

This *a priori* does not imply that $h_i(1)=1\ \forall i=1,\ldots,n$, but the one-parameter $s\in\mathbb{R}_+$ "generalized similarity transformation" $\mathcal{T}_s$: $(x^1,\ldots,x^n)\to(h_1(e^s)x^1,\ldots,h_n(e^s)x^n)$ is consistently defined if $\mathcal{T}_{s=0}$ is the identity, i.e., if $h_i(1)=1\ \forall i=1,\ldots,n$.

We introduce the auxiliary function

$$F(s;x^1,\ldots,x^n)\equiv e^{-s}f(h_1(e^s)x^1,\ldots,h_n(e^s)x^n). \tag{D6}$$

It is such that $\partial_sF=0$, i.e.,

$$F=\sum_{i=1}^n e^sh_i'(e^s)x^i\left(\frac{\partial F}{\partial x^i}\right)(h_1(e^s)x^1,\ldots,h_n(e^s)x^n), \tag{D7}$$

where $h_i'(u)\equiv dh_i/du$. For $s=0$ one obtains

$$f(x^1,\ldots,x^n)=\sum_{i=1}^n h_i'(1)x^i\left(\frac{\partial f}{\partial x^i}\right)(x^1,\ldots,x^n). \tag{D8}$$

Thus, $f(x^1,\ldots,x^n)$ is a quasi-homogeneous function of degree 1 and weights $(h_1'(1),\ldots,h_n'(1))\equiv(\alpha_1,\ldots,\alpha_n)$. As a consequence, one has

$$f(e^{\alpha_1s}x^1,\ldots,e^{\alpha_ns}x^n)=e^sf(x^1,\ldots,x^n), \tag{D9}$$

i.e.,

$$h_i(e^s)=e^{\alpha_i s} \quad \forall i=1,\ldots,n. \tag{D10}$$

By resorting the original dependence on λ, one finds

$$f((g(\lambda))^{\alpha_1}x^1,\ldots,(g(\lambda))^{\alpha_n}x^n)=g(\lambda)f(x^1,\ldots,x^n), \tag{D11}$$

i.e.,

$$g_i(\lambda)=(g(\lambda))^{\alpha_i} \quad \forall i=1,\ldots,n. \tag{D12}$$

If some $g_i=1$ above, then one simply finds that the variable x^i is quasi-homogeneous of degree zero, i.e., it has weight zero. If instead $g(\lambda)=1$, then f is quasi-homogeneous of degree zero. The proof is straightforward. Let λ_0 be such that $g_i(\lambda_0)=1 \ \forall i=1,\ldots,n$. We have that

$$\frac{\partial f}{\partial \lambda}=0=\sum_{i=1}^{n} g_i'(\lambda)x^i\left(\frac{\partial f}{\partial x^i}\right)(g_1(\lambda)x^1,\ldots,g_n(\lambda)x^n). \tag{D13}$$

By setting $\lambda=\lambda_0$, one finds

$$0=\sum_{i=1}^{n} g_i'(\lambda_0)x^i\left(\frac{\partial f}{\partial x^i}\right)(x^1,\ldots,x^n), \tag{D14}$$

i.e., f is quasi-homogeneous of degree zero and weights $(g_1'(\lambda_0),\ldots,g_n'(\lambda_0))$.

APPENDIX E: SCALING AND ASYMPTOTICS

Let us assume that $f(x)$ is a function of n variables collectively indicated with x. Let the domain of f be invariant under quasi-homogeneous transformations. Let $\{\mathcal{T}_\lambda\}$ be a one-parameter quasi-homogeneous transformation. If we require that there exist a positive continuous function $\rho(\lambda)$ and a continuous function $g(x)\not\equiv 0$ such that g is an asymptotic of f in the following sense:

$$\lim_{\lambda\to\infty}\frac{1}{\rho(\lambda)}f(\mathcal{T}_\lambda x)=g(x), \tag{E1}$$

where the limit is assumed to exist. Then, (a) the function $\rho(\lambda)$ is a regularly varying function, i.e., it satisfies for all $a>0$,

$$\lim_{\lambda\to\infty}\frac{\rho(\lambda a)}{\rho(\lambda)}\equiv C(a), \tag{E2}$$

where $C(a)C(b)=C(ab)$, i.e., $C(a)=a^\gamma$ for some $\gamma\in\mathbb{R}$; γ is also defined the order of the regularly varying function $\rho(\lambda)$; (b) the function satisfies the ''homogeneity'' relation

$$g(\mathcal{T}_\mu x)=\mu^\gamma g(x), \tag{E3}$$

i.e., $g(x)$ is quasi-homogeneous of degree γ.

Proof: for each real $s>0$ it holds

$$\lim_{\lambda\to\infty}\frac{1}{\rho(\lambda s)}f(\mathcal{T}_{\lambda s}x)=g(x), \tag{E4}$$

and, because of $\mathcal{T}_{\lambda s}=\mathcal{T}_\lambda\mathcal{T}_s$,

$$\lim_{\lambda\to\infty}\frac{1}{\rho(\lambda)}\,f(\mathcal{T}_\lambda(\mathcal{T}_s x))=g(\mathcal{T}_s x). \tag{E5}$$

As a consequence,

$$\lim_{\lambda\to\infty}\frac{\rho(\lambda)}{\rho(\lambda s)}\,\frac{f(\mathcal{T}_{\lambda s}x)}{f(\mathcal{T}_\lambda(\mathcal{T}_s x))}=\frac{g(x)}{g(\mathcal{T}_s x)}=\lim_{\lambda\to\infty}\frac{\rho(\lambda)}{\rho(\lambda s)}. \tag{E6}$$

This is possible only if the following conditions:

$$\lim_{\lambda\to\infty}\frac{\rho(\lambda s)}{\rho(\lambda)}=C(s) \tag{E7}$$

and

$$g(\mathcal{T}_s x)=C(s)g(x) \tag{E8}$$

are both satisfied. Moreover, it is easy to see that it holds

$$C(st)=C(s)C(t), \tag{E9}$$

which implies that there exists a real number γ such that $C(s)=s^\gamma$. Thus, one obtains

$$g(\mathcal{T}_s x)=s^\gamma g(x), \tag{E10}$$

which concludes the proof. □

Leibnizian, Galilean and Newtonian structures of space–time[a)]

Antonio N. Bernal and Miguel Sánchez[b)]
Dpto. de Geometría y Topología, Universidad de Granada, Facultad de Ciencias, Fuentenueva s/n, E-18071 Granada, Spain

(Received 28 October 2002; accepted 2 December 2002)

The following three geometrical structures on a manifold are studied in detail: *Leibnizian*: a nonvanishing one-form Ω plus a Riemannian metric $\langle\cdot,\cdot\rangle$ on its annhilator vector bundle. In particular, the possible dimensions of the automorphism group of a Leibnizian G-structure are characterized. *Galilean*: Leibnizian structure endowed with an affine connection ∇ (gauge field) which parallelizes Ω and $\langle\cdot,\cdot\rangle$. For any fixed vector field of observers $Z(\Omega(Z)\equiv 1)$, an explicit Koszul-type formula which reconstructs bijectively all the possible ∇'s from the gravitational $\mathcal{G}:=\nabla_Z Z$ and vorticity $\omega:=\frac{1}{2}$ rot Z fields (plus eventually the torsion) is provided. *Newtonian*: Galilean structure with $\langle\cdot,\cdot\rangle$ flat and a field of observers Z which is inertial (its flow preserves the Leibnizian structure and $\omega\equiv 0$). Classical concepts in Newtonian theory are revisited and discussed. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1541120]

I. INTRODUCTION

It is well-known since Cartan's era[2] that Newtonian theory can be stated in the language of differential geometry, and many authors have studied this geometrization on its own and in comparison with (or as a limit of) Einstein's general relativity [see for example, Refs. 3–8, 11, 12, 13 (Box 12.4), 14–16, 18, and 21]. The aim of this article is to carry out a geometrization from a more general viewpoint, which arises from the fundamental considerations on measurements of space and time in Ref. 1.

A *Leibnizian* structure on an m-manifold M is a pair $(\Omega,\langle\cdot,\cdot\rangle)$ consisting of a nonvanishing one-form Ω and a (positive definite) Riemannian metric $\langle\cdot,\cdot\rangle$ on its kernel. When $m=4$, this structure appears naturally as a consequence of our methods of measurement of space–time; in fact, it is natural to assume the existence of a Leibnizian (or dual *anti-Leibnizian*) structure in the degenerate part of a signature-changing metric from Lorentzian to Riemannian.[1] When Ω is exact, i.e., $\Omega=dT$ for an *absolute time* function T, the intuitive idea ''at each instant of time there exist a Riemannian metric on space'' is geometrized. Given the Leibnizian space–time a *Galilean* connection is an affine connection which parallelizes Ω and $\langle\cdot,\cdot\rangle$. As a difference with the Levi-Civita connection for a semi-Riemannian (Riemannian, Lorentzian or with any index) manifold, symmetric Galilean connections are not univocally determined by the Leibnizian structure. Moreover, there exists a symmetric Galilean connection if and only if Ω is closed (i.e., locally, $\Omega=dT$). Galilean connections can be seen as gauge fields, which are necessary to preserve the covariance of physical laws under the change of ''Galilean reference frames.'' A Newtonian space–time will be a Galilean one $(M,\Omega,\langle\cdot,\cdot\rangle,\nabla)$ where ∇ satisfies certain symmetries. In the present article we study the mathematical properties of each level (Leibnizian/Galilean/Newtonian) and the corresponding physical interpretations.

From the purely mathematical viewpoint, some questions arise naturally: which are the pos-

[a)]Part of the results of this article has been announced at the RSME meeting ''Encuentros de Otoño de Geometría y Física'' Miraflores de la Sierra (Madrid), September 2001.

[b)]Author to whom correspondence should be addressed. Electronic mail: sanchezm@goliat.ugr.es

sible dimensions of the group of automorphisms of a Leibnizian space–time? How many Galilean connections admit a Leibnizian structure? Is there an explicit way to construct them? The answers to such questions are interesting also from the physical viewpoint. The cornerstone of our approach can be stated as follows (see Lemma 25, Theorem 27, and Corollary 28): *given a Leibnizian space–time, a field of observers Z and an (unknown) Galilean connection ∇, the gravitational field $\mathcal{G}$ and the vorticity/Coriolis field ω measured by Z* (plus, eventually, any skew-symmetric tensor Tor representing the torsion, subject to the restriction $\Omega\circ \mathrm{Tor}=d\Omega$) *permit us to reconstruct univocally the connection ∇*. Even though partial versions of this result are well-known (*ad nauseam* if $\langle\cdot,\cdot\rangle$ is flat and Z determines an ''inertial reference frame''), the full result is new, as far as we know. In fact, it relies on formula (13), which plays a similar role to Koszul's formula in semi-Riemannian geometry, and introduces a type of ''sub-Riemannian'' geometry with interest of its own. Then, classical Newtonian concepts are revisited under this viewpoint.

In the comparison with classical geometrizations of Newtonian theory (see, e.g., Refs. 21, 13, Box 12.4, and 5), where one assumes first that the space is flat and then some sort of assumptions to make inertial references frames appear, the advantages of our approach become apparent not only for its bigger generality but also for the sake of clarity: the detailed study of the structures at each level Leibnizian/Galilean/Newtonian clarifies both the mathematical results and the physical interpretations. It is also worth pointing out that Kunzle and some co-workers[11,12,4] have also studied some Leibnizian structures; in fact, they call $(M,\Omega,\langle\cdot,\cdot\rangle)$ with Ω closed ''Galilei structure'' and the corresponding compatible connections ''Galilei connections.'' Nevertheless, our constructive procedure of all Galilean connections and associated physical interpretations go further [see Remark 29(2)]. (In fact, our study led us to put different names to the structures depending on if ∇ was fixed or not, as in Ref. 5. The names Leibnizian, Galilean and Newtonian are suggested by some famous historical facts–Galilean studies on freely moving bodies, controversy between Leibniz and Newton, and Newton's discussion of the spinning water-bucket.)

The present article is divided into three parts. In the first one (Sec. II), the properties of pure Leibnizian structures are studied. Leibnizian vector fields and fields of Leibnizian observers (FLOs) are introduced, as infinitesimal generators of automorphisms. In Theorem 8, the possible dimensions of these vector fields are characterized, in agreement with some known properties of classical *kinematical group*.

The second part (Sec. III) is devoted to Galilean structures. Apart from the commented results on our Koszul-type formula (13), we introduce both Galilean vector fields and fields of Galilean observers (i.e., the corresponding Leibnizian fields which preserve infinitesimally the connection ∇), see Table I. In Sec. III C, coordinate expressions for the connection, geodesics and curvature (for coordinates adapted to general fields of observers as well as more restricted ones: Leibnizian, Galilean or *inertial*) are also provided.

Finally, in the third part (Sec. IV) the Newtonian case is specifically revised, discussing the classical concepts. In fact, our definition of Newtonian space–time is a Galilean one which admits an inertial field of observers and with $(\mathrm{an}\Omega,\langle\cdot,\cdot\rangle)$ flat. This definition avoids conditions at infinity, which are discussed in relation to the properties of gravitational fields and the uniqueness of Poisson's equation. Even though from the mathematical viewpoint the results are clearer when nonsymmetric connections are also taken into account [see Remark 29(1)], we restrict to symmetric connections for physical concepts or coordinate expressions, in particular along all the third part.

II. LEIBNIZIAN STRUCTURES

A. Leibnizian space–times

1. Setup

A *Leibnizian* space–time is a triad, $(M,\Omega,\langle\cdot,\cdot\rangle)$, consisting of a smooth connected manifold M, of any dimension $m=n+1\geqslant 2$, a differential one-form $\Omega\in\Lambda^1(M)$, nowhere null ($\Omega_p\neq 0, \forall p\in M$), and a smoth, bilinear, symmetric and positive definite map

TABLE I. Semi-Riemannian versus Leibnizian/Galilean.

● Structure	Semi-Riemannian, (M,g) $\dim M=m$, index $g=s$	Leibnizian, $(M,\Omega,<,>)$ $\dim M=m\ (=n+1)$
● Structural group	Orthonormal, $O_s(m)$ $\dim O_s(m)=m(m-1)/2$	Galilean, $G_m(\mathbb{R})$ $\dim G_m(\mathbb{R})=m(m-1)/2$
● Infinitesimal automorphisms	Killing vector fields Possible dimensions: $0,1,\ldots,m(m+1)/2$	Leibnizian vector fields Possible dimensions $(d\Omega=0)$: 0, 1 or ∞
● Possible connections ∇ which parallelize the structure	Determined by all torsion tensors, bijective correspondence: Connections$\leftrightarrow$two-covar. one-contrav. skew-symmetric tensors Unique connection without torsion (Levi-Civita)	Determined by: (a) Possible torsions: $\Omega\circ$ Tor$=d\,\Omega$ (b) Fixed Z $(\Omega(Z)=1)$: $\nabla_Z Z$ and $\omega=rot\,Z/2$ Existence of ∇ without Tor $\Leftrightarrow d\,\Omega=0$
● Fixed a connection ∇ which parallelizes the structure	Canonically, Tor$=0$ Killing$\Rightarrow$Affine No new definition of vector fields required	Even if Tor$=0$, Leibnizian$\not\Rightarrow$Affine Galilean vector fields: Leibnizian+affine Dimension Galilean: $0,1,\ldots,m(m+1)/2$

$$\langle\cdot,\cdot\rangle:\Gamma(\mathrm{an}\Omega)\times\Gamma(\mathrm{an}\Omega)\to C^\infty(M),\quad (V,W)\mapsto\langle V,W\rangle,$$

where $\mathrm{an}\Omega=\{v\in TM\,|\,\Omega(v)=0\}$, is the n-distribution induced by Ω, and the symbol Γ denotes the corresponding vector fields, so $\Gamma(\mathrm{an}\Omega)=\{V\in\Gamma(TM)\,|\,V_p\in\mathrm{an}\Omega,\ \forall p\in M\}$. [As usual, M will be assumed Hausdorff and paracompact; "smooth" will mean C^∞ (even though C^2 is enough).] Summing up, the Leibnizian structure on M is the nonvanishing one-form Ω plus the Riemannian vector bundle $(\mathrm{an}(\Omega),\langle\cdot,\cdot\rangle)$.

Note: Let the superscript * denote dual space. For any $p\in M$ there exists a canonical isomorphism between $(\mathrm{an}\Omega_p)^*$ and the quotient vector space $(T_pM)^*/\mathrm{Span}\Omega_p$. Therefore, the metric $\langle\cdot,\cdot\rangle_p$ induces a canonical Euclidean product on $(T_pM)^*/\mathrm{Span}\Omega_p$, as well as a positive semidefinite metric on $(T_pM)^*$, with radical generated by Ω_p. Thus, a Leibnizian structure is equivalent to a degenerate semidefinite positive metric of constant rank n in the cotangent bundle TM^*, plus a one-form generating its radical. In Ref. 1, an *anti-Leibnizian* structure on M is defined as a degenerate semidefinite positive metric of constant rank n in the tangent bundle TM, plus a vector field Z generating its radical. Thus, the study of anti-Leibnizian structures is analogous (dual) to the study of the Leibnizian ones.

According to Ref. 1, Euclidean space $(\mathrm{an}(\Omega_p),\langle\cdot,\cdot\rangle_p)$ is called the *absolute space* at $p\in M$, and the linear form Ω_p is the *absolute clock* at p. A tangent vector $Z_p\in T_pM$ is *timelike*, if $\Omega_p(Z_p)\neq 0$ (*spacelike*, otherwise). If, additionally, $\Omega_p(Z_p)>0$ [resp. $\Omega_p(Z_p)<0$], Z_p *points out the future* (resp. *the past*). Any normalized timelike vector Z_p [that is, with $\Omega_p(Z_p)=1$] is a *standard timelike unit* (or *instantaneous observer*) at p; any (ordered) orthonormal base of the absolute space at p is a *set of standard spacelike units* at p.

Let us introduce definitions for the concepts of observer and field of observers (or reference frame) analogous to the Lorentzian ones; compare with Ref. 17, Chap. 2. An *observer* is a smooth curve, $\gamma:I\to M$ ($I\subseteq\mathbb{R}$, interval), such that its velocity is always a standard timelike unit, $\Omega_{\gamma(s)}(\gamma'(s))=1$, $\forall s\in I$. The parameter of this curve is the *proper time* of the observer γ. A *field of (instantaneous) observers* (FO) is a vector field $Z\in\Gamma(TM)$ with $\Omega(Z)\equiv 1$, that is, integral curves of Z are observers. The existence of a FO on any Leibnizian space–time is straightforward from the paracompactness of M. [Conversely, if we assume the existence of a FO, then Lemma 25 and Remark 26 permit us to construct an affine connection on M; thus, we could deduce the

paracompactness of M by using Ref. 19, Vol. II, Addendum 1, p. 8-52.] Let $\mathcal{Z}(M)\equiv\mathcal{Z}(M,\Omega)$ be the set of all the FOs. Clearly, $\mathcal{Z}(M)$ has a structure of affine space with associated vector field $\Gamma(\mathrm{an}\Omega)$. For each FO, $Z\in\mathcal{Z}(M)$, define the field of endomorphisms:

$$P^Z(v)=v-\Omega(v)Z, \qquad \forall v\in TM, \tag{1}$$

or *spacelike projection along* Z. Obviously, the image of P^Z is $\mathrm{an}(\Omega)$.

When the absolute clock Ω satisfies $\Omega\wedge d\Omega=0$ (i.e., the distribution $\mathrm{an}\Omega$ is involutive: $[V,W]\in\Gamma(\mathrm{an}\Omega),\forall V,W\in\Gamma(\mathrm{an}\Omega)$), we say that $(M,\Omega,\langle\cdot,\cdot\rangle)$ is *locally sincronizable*; if $d\Omega=0$ (Ω is closed), then $(M,\Omega,\langle\cdot,\cdot\rangle)$ is *proper time locally syncronizable*. In fact, it is well-known that the equality $\Omega\wedge d\Omega=0$ is equivalent, locally, to $\Omega=f\,dt$, for some smooth functions $f>0$, t. That is, in the domain of f and t, hipersuperfaces $t\equiv$const are tangent to the absolute space at each point. Thus, in principle, any observer could be "syncronized," that is, it can regard t as a compromise time, obtained by rescaling its proper time. In the more restrictive case $d\Omega=0$, one has locally $\Omega=dt$. Thus, any observer γ is direcly "syncronized," up to a constant c_γ [i.e., $t\circ\gamma(s)=s+c_\gamma,\forall s\in I$]. Notice that these concepts about local syncronizability are intrinsic to the Leibnizian structure and, then, applicable to each particular observer γ. This is a clear difference with the Lorenzian case, where the analogous concepts have meaning only for fields of observers. [If (M,g) is a time-oriented Lorentzian manifold, a FO is a unit future-pointing timelike vector field Z. If $Z^\flat$ is the metrically associated one-form, Z is said locally syncronizable (resp. proper time locally sincronizable) if $Z^\flat\wedge dZ^\flat=0$ (resp. $dZ^\flat=0$). It is not difficult to prove that, in the neighborhood of any point, *a proper time locally syncronizable vector field can be always constructed* (compare with Ref. 17, Sec. 2.3).]

When Ω is exact, that is, $\Omega=dT$ for some (unique up to a constant) $T\in C^\infty(M)$, T will be called the function *absolute time*. In this case, any observer γ will be assumed to be parametrized with T ($T\circ\gamma(s)=s,\forall s\in I$). When M is simply connected, local proper time synchronizability is equivalent to the existence of such an absolute time function.

2. Coordinates

Given a Leibnizian space–time $(M,\Omega,\langle\cdot,\cdot\rangle)$ and a FO, $Z\in\mathcal{Z}(M)$, for each $p\in M$ there exist charts $(U,y^0,\ldots,y^n)$ such that $\partial_{y^0}=Z|_U$. We can wonder if, additionally, these charts may be adapted to the absolute spaces. More precisely, we have the following.

Definition 1: Let $(M,\Omega,\langle\cdot,\cdot\rangle)$ *a Leibnizian space–time and* $(U',t,x^1,\ldots,x^n)$ *a coordinate system in* M. $(U',t,x^1,\ldots,x^n)$ *is* adapted to the absolute space *if*

$$\Omega(\partial_{x_i})=0, \qquad \forall i\in\{1,\ldots,n\}$$

(in particular, hipersuperfaces $t\equiv$const *are integral manifolds of the distribution* $\mathrm{an}\Omega$*).*

Given a FO, $Z\in\mathcal{Z}(M)$, $(U',t,x^1,\ldots,x^n)$ *is* adapted to Z *if, on* U',

$$\partial_t=Z \quad and \quad \Omega=dt.$$

If the chart is adapted to the absolute space, then $\Omega=\Omega(\partial_t)dt$; if it is adapted to Z, then it is adapted to the absolute space too. Clearly, if $(U',t,x^1,\ldots,x^n)$ is adapted to the absolute space (resp. a Z), then $\Omega\wedge d\Omega=0$ (resp. $d\Omega=0$) on U'. The converse also holds; in fact, the following result yields adapted charts constructively.

Proposition 2: Let Z *be a FO on a Leibnizian space–time* $(M,\Omega,\langle\cdot,\cdot\rangle)$. *Fix a chart* $(U,y^0,\ldots,y^n)$ *such that* $\partial_{y^0}=Z|_U$, *and put*

$$V_k=P^Z(\partial_{y^k})\in\mathrm{an}\Omega, \quad \forall k\in\{1,\ldots,n\}, \tag{2}$$

with P^Z *in (1). Then*

(i) $(Z,V_1,\ldots,V_n)$ *is a local base of vector fields* (moving frame) *with* $\Omega(V_k)=0$ *and*

$$d\Omega(Z,V_j)=-\Omega([Z,V_j]),\qquad d\Omega(V_i,V_j)=-\Omega([V_i,V_j]),\qquad \forall i,j\in\{1,\dots n\}. \tag{3}$$

(ii) If $\Omega\wedge d\Omega=0$, *then, at some neighborhood* U' *of each* $p\in U$, *there exist coordinates* $(t,x^1,\dots,x^n)$ *satisfying on* U':

$$\Omega=\Omega(\partial_t)dt,\quad \partial_{x^k}=V_k,\quad \forall k\in\{1,\dots,n\}.$$

Thus, such coordinates are adapted to the absolute space.

(iii) If $d\Omega=0$, *then, in addition to (ii), one has*

$$\partial_t=Z,$$

on U' (*i.e., the coordinates are adapted to* Z).

Proof: (i) Obvious.

(ii) As the distribution anΩ is involutive, $\Omega([V_i,V_j])=0$ and, from (2), $[V_i,V_j]=0$. Thus, it is enough to apply classical Frobenius' theorem (see, for example, Ref. 23 Chap. 1).

(iii) By using (3), one checks $[Z,V_j]=0$ and, again, the result follows from Frobenius' theorem. □

From now on, Latin indexes i, j, k will vary in $1,\dots,n$. We will simplify the notation, too: $\partial_{x^k}\equiv\partial_k$.

3. Galilean group at a point

Fix $p\in M$. An (ordered) base $B=(Z_p,e_1,\dots,e_n)$ of T_pM is a *Galilean base at* p if $\Omega(Z_p)=1$ and $\{e_1,\dots,e_n\}$ is an orthonormal base of an(Ω_p), that is, if Z_p is a standard timelike unit at p and $e_1,\dots,e_n$ are standard spacelike units.

A *Galilean transformation at* p is a linear map, $A:T_pM\to T_pM$, which maps some (and thus, any) Galilean base onto a Galilean base. Or, equally, $\Omega_p(A(X_p))=\Omega_p(X_p)$ *and* $\langle A(V_p),A(W_p)\rangle_p=\langle V_p,W_p\rangle_p$, $\forall X_p\in T_pM$, $\forall V_p,W_p\in$ an(Ω_p). The group of all such transformations will be called the *Galilean group* at p.

Matricial Galilean group $G_m(\mathbb{R})$, $m=n+1$, is the group of the matrixes

$$\begin{pmatrix}1 & 0\\ a & A\end{pmatrix},\qquad \text{where}\quad a=\begin{pmatrix}a^1\\ \vdots\\ a^n\end{pmatrix}\in\mathbb{R}^n\quad\text{and}\quad A\cdot A^t=I_n \tag{4}$$

(A is an orthogonal matrix $n\times n$).

It is straightforward to check that, given a Galilean base B and any other base $B'=(Z'_p,e'_1,\dots,e'_n)$ in T_pM, the base B' is Galilean if and only if the transition matrix belongs to $G_m(\mathbb{R})$, that is,

$$Z'_p=Z_p+\sum_{i=1}^{n}a^ie_i,\qquad e'_j=\sum_{i=1}^{n}a^i_je_i,\quad \forall j\in\{1,\dots,n\},$$

where $A=(a^i_j)$ is a orthogonal matrix. In this case, $v=\Sigma_j a^je_j$ is the *velocity of* Z'_p *measured by* Z_p.

B. Leibnizian vector fields

1. Automorphisms of Leibnizian G-structures

Let LM be the linear frame bundle of M, that is, each element of LM can be seen as a (ordered) base of the tangent space at some point of M. The Leibnizian structure $(\Omega,\langle\cdot,\cdot\rangle)$ on M determines the fiber bundle of all the Galilean bases $GM\subset LM$. As $G_m(\mathbb{R})$ acts freely and transively on each fiber, GM is a G-structure with $G=G_m(\mathbb{R})$ [i.e., a principal fiber bundle with structural group $G_m(\mathbb{R})$, obtained as a reduction of LM]. Recall that the set of the orthonormal

bases for any semi-Riemannian metric (in particular, Riemannian or Lorentzian) is a well-known example of G-structure; the dimension of its structural group is equal to the dimension of $G_m(\mathbb{R})$, i.e., $m(m-1)/2$ $(m=n+1)$. G-structures have mathematical interest in their own right (see, for example, Ref. 9), and we will be interested in two properties of Leibnizian G-structures with striking differences with respect to the semi-Riemannian case: their infinitesimal automorphisms (studied below) and the set of all the compatible affine connections (Sec. III B).

An infinitesimal automorphism of a G-structure is a vector field K generating a group of automorphisms of the principal fiber bundle. In the semi-Riemannian case, such a K is called a Killing vector field. In the Leibnizian one, the following definition is equivalent.

Definition 3: Given $(M,\Omega,\langle\cdot,\cdot\rangle)$, *a vector field* $K\in\Gamma(TM)$ *is* Leibnizian (Killing) *if its local flows* ψ_s *preserve the absolute clock and space, that is,*

$$\psi_s^*\Omega=\Omega \qquad \text{and} \qquad \psi_s^*\langle\cdot,\cdot\rangle=\langle\cdot,\cdot\rangle.$$

$\mathrm{Leib}(M)\equiv\mathrm{Leib}(M,\Omega,\langle\cdot,\cdot\rangle)$ *will denote the set of all the Leibnizian vector fields.*

As $\mathcal{L}_K$, the Lie derivative along K, can be recovered from the local flows of K, the following characterizations of Leibnizian vector fields are straightforward.

Proposition 4: Let $(M,\Omega,\langle\cdot,\cdot\rangle)$ *be a Leibnizian space–time, and* $K\in\Gamma(TM)$ *be a vector field. The following assertions are equivalent:*

(1) K *is a Leibnizian vector field.*
(2) $\mathcal{L}_K\Omega=0$ *and* $\mathcal{L}_K\langle\cdot,\cdot\rangle=0$,
(3) The following two properties hold:
(a) $\Omega([K,Y])=K(\Omega(Y))$, $\forall Y\in\Gamma(TM)$ *[equally:* $-d\Omega(K,Y)=Y(\Omega(K))$*].*
(b) $K\langle V,W\rangle=\langle[K,V],W\rangle+\langle V,[K,W]\rangle$, $\forall V,W\in\Gamma(\mathrm{an}\Omega)$.

In particular, $\mathrm{Leib}(M)$ *is a Lie algebra.*

Remark 5: (1) The right hand side of *3(b)* makes sense [i.e., $[K,V]$, $[K,W]\in\Gamma(\mathrm{an}\Omega)$] when *3(a)* holds.

(2) When $d\Omega=0$, property $3(a)$ holds if and only if $\Omega(K)=cte$. We will put then, for each $c\in\mathbb{R}$,

$$\mathrm{Leib}_c(M)=\{K\in\mathrm{Leib}(M)\,|\,\Omega(K)=c\} \tag{5}$$

(clearly, the relevant cases will be $c=0,1$).

(3) As we will see, the dimension of $\mathrm{Leib}(M)$ may be infinite. This was expected from a purely algebraic viewpoint: a straightforward computation from (4) shows that the Lie algebra $G_m(\mathbb{R})$ contains elements of rank 1 and, thus, this algebra is of finite type (see Ref. 9, Proposition 1.4). As a consequence, the automorphisms of a Leibnizian manifold are not necessarily a (finite dimensional) Lie group.

2. Fields of Leibnizian observers

Consider now the case that Z is a *field of Leibnizian observers (FLO)*, that is, $Z\in\mathcal{Z}(M)$, and Z is Leibnizian. (The name of *rigid vector fields* is also natural for FLO's, see Ref. 17, Sec. 2.3). We will be interested in the classical interpretations of these vector fields; thus, we assume now $d\Omega=0$. According to formula (5) the set of all the FLOs will be denoted as $\mathrm{Leib}_1(M)$.

From Proposition 2, given $Z\in\mathcal{Z}(M)$ a chart $(t,x^1,\ldots,x^n)$ adapted to Z exists. Put

$$h_{ij}=\langle\partial_i,\partial_j\rangle, \qquad h\equiv\langle\cdot,\cdot\rangle.$$

The following characterization of the FLOs is immediate from its definition and Proposition 4.

Proposition 6: Let $(M,\Omega,\langle\cdot,\cdot\rangle)$ *be a Leibnizian space–time with* $d\Omega=0$ *and* $Z\in\mathcal{Z}(M)$. *The field of observers* Z *is a FLO if and only if for each* $p\in M$ *there exists a chart* $(t,x^1,\ldots,x^n)$ *adapted to* Z *such that*

$$\partial_t h_{ij}=0, \quad \forall i,j\in\{1,\dots n\}. \tag{6}$$

Remark 7: Of course, in this case equality (6) holds for any chart adapted to Z. Thus, the FLOs are those fields of observers satisfying the following: their observers see that, locally, the metric $\langle\cdot,\cdot\rangle$ does not change with the local absolute time t (they are always at the same distance of the neighboring observers).

3. Main result

Now, let us characterize the dimension of the Lie algebra Leib(M). For simplicity, we will assume the existence of a globally defined time function T (of course, the results hold locally if only $d\Omega=0$).

Notice first that $\mathrm{Leib}_1(M)$ may be empty [and then $\mathrm{Leib}(M)=\mathrm{Leib}_0(M)$], no matter the dimension of $\mathrm{Leib}_0(M)$ be. Recall also that a vector field $Z\in\Gamma(TM)$ is called *complete* if it admits a globally defined flow ϕ, i.e., $\phi_t: M\to M$, for all $t\in\mathbb{R}$ [for $Z\in\mathcal{Z}(M)$, one can say, equally, that the—inextendable—observers in Z are defined on all $\mathbb{R}$].

Theorem 8: *Consider the Leibnizian space–time* $(M,dT,\langle\cdot,\cdot\rangle)$.

(1) (a) Let $K\in\mathrm{Leib}_0(M)$ *be. The restriction of* K *to each hypersurface* $T\equiv T_0$ *(constant) is a Killing vector field of the Riemannian manifold* $(T^{-1}(T_0),\langle\cdot,\cdot\rangle)$.
(b) If $\mathrm{Leib}_0(M)\neq 0$, *then* $\dim(\mathrm{Leib}_0(M)=\infty)$.
(2) If $\mathrm{Leib}_1(M)$ *is not empty, then it is an affine space of associated vector space* $\mathrm{Leib}_0(M)$. *Thus,* $\dim(\mathrm{Leib}(M))\in\{0,1,\infty\}$.
(3) If there exists a complete FLO, $Z\in\mathrm{Leib}_1(M)$, *then we have the following.*
(a) All the hypersurfaces $T\equiv$ const *are isommetric*.
(b) If one of the $T^{-1}(T_0)$ *admits a Killing vector field* $K_0(\not\equiv 0)$, *then* $dim\,\mathrm{Leib}_0(M)=\infty$.

Proof: (1) Assertion (a) is obvious. For (b) take any $K\in\mathrm{Leib}_0(M)$. Notice that, for any function $a:\mathbb{R}\to\mathbb{R}$, the vector field

$$K^a(p)=a(T(p))K(p), \quad \forall p\in M,$$

satisfies $K^a\in\mathrm{Leib}_0(M)$ too. If $K\not\equiv 0$, one can choose a neighborhood U where K does not vanish, and some interval $]T_1,T_2[$, $T_1<T_2$ included in $T(U)$. Now, just take infinite independient functions $a(T)$ vanishing outside of $]T_1,T_2[$.

(2) Obvious.

(3) For (a) recall that the flow ϕ_t of Z generates an isommetry between $T^{-1}(T_0)$ and $T^{-1}(T_0+t),\forall t\in\mathbb{R}$. For (b), we have just to find some $K\in\mathrm{Leib}_0(M)$, $K\not\equiv 0$ and apply *1(b)*. Such a vector field can be constructed from K_0 and the flow of Z as follows:

$$K_p=d\phi_{(T(p)-T_0)}(K_0[\phi_{-(T(p)-T_0)}(p)]) \tag{7}$$

{with the notation: $K_0[q]\equiv(K_0)_q$, for $q=\phi_{-(T(p)-T_0)}(p)$}, □

Remark 9: Choosing $M=\mathbb{R}\times S$ (S any manifold) with $T:\mathbb{R}\times S\to\mathbb{R}$ the natural projection, it is not difficult to prove that all the dimensions of $\mathrm{Leib}_c(M)$ permited by Theorem 8 can occur. Substracting a small neighborhood of some point, the importance of the hypothesis of completeness in *(3)* can be easily verified (even though this result is always true locally, for any FLO).

Moreover, locally, when there exists a FLO and there are r independent Killing vector fields $K_{01},\dots,K_{0r}$ in the neighborhood of some point at a hypersurface $T\equiv T_0$, then infinitely many new FLOs can be constructed, type $Z^*=Z+\Sigma_i a^i(T)K_i$, for any functions $a^1,\dots,a^r$ and K_i's as in (7). That is, as the time T varies, all the observers in Z^* can move in the direction of a spacelike Killing vector field with a speed which depends arbitrarily on T; this generalizes well-known properties of the *kinematical group*, see Ref. 5.

III. GALILEAN STRUCTURES

A. Galilean space–times

1. Galilean connections

As already commented, a Leibnizian structure has no canonical affine connection associated. Now, affine connections preserving the Leibnizian structure will be studied. The existence of such a fixed connection can be seen as a physical requirement from gauge covariance. In fact, if no connection is fixed, then all the the sections of the principal fiber bundle GM, or *Galilean reference frames*, are physically equivalent. But, in this case, physical laws as Newton's second one should be covariant under changes of Galilean reference frames. This forces the existence of a gauge field (i.e., a compatible connection) which restates covariance. Recall that general relativity can also be seen as a gauge theory, where the gauge invariance under different choices of sections in the principle fiber bundle of the orthonormal basis must be preserved. Nevertheless, in this theory the gauge field (the gravitational field) is canonically fixed as the unique torsionless connection of the bundle.

Definition 10: A Galilean connection *in a Leibnizian space–time* $(M,\Omega,\langle\cdot,\cdot\rangle)$, *is a connection* ∇ *such that its parallel transport maps Galilean bases onto Galilean bases.*

A Galilean space–time $(M,\Omega,\langle\cdot,\cdot\rangle,\nabla)$ *is a Leibnizian space–time* $(M,\Omega,\langle\cdot,\cdot\rangle)$ *endowed with a Galilean connection* ∇.

As the connection can be reconstructed from the parallel transport, it is not difficult to check the following characterization.

Proposition 11: An affine connection ∇ *on a Leibnizian space–time* $(M,\Omega,\langle\cdot,\cdot\rangle)$ *is Galilean if and only if the following two conditions hold:*

(1) $\nabla\Omega=0$ [i.e., $\nabla_X\Omega=0, \quad \forall X\in\Gamma(TM)$].
(2) $\nabla\langle\cdot,\cdot\rangle=0$, *that is,* $X\langle V,W\rangle=\langle\nabla_X V,W\rangle+\langle V,\nabla_X W\rangle, \quad \forall X\in\Gamma(TM), \quad \forall V,W\in\Gamma(\mathrm{an}\Omega)$.

Remark 12: Item (*1*) holds if and only if $\Omega(\nabla_X Y)=X(\Omega(Y)), \ \forall Y\in\Gamma(TM)$. Thus, if $\Omega(Y)$ is constant, then $\nabla_X Y\in\Gamma(\mathrm{an}\Omega), \forall X\in\Gamma(TM)$. In particular, this happens if $Y=Z\in\mathcal{Z}(M)$ or if $Y=V,W\in\Gamma(\mathrm{an}\Omega)$; therefore, the right-hand side of item (*2*) is well defined.

Equally, a Galilean connection can be seen as a connection in the fiber bundle of the Galilean bases GM. As any principal fiber bundle, GM admits connections, but it does not admit necessarily a symmetric connection. Thus, in principle, Galilean connections are not assumed symmetric. Even more, our results on existence of Galilean connections will be mathematically clearer without this restriction. Thus, the *torsion*

$$\mathrm{Tor}(X,Y)=\nabla_X Y-\nabla_Y X-[X,Y],$$

which measures the lack of symmetry of the connection, will be relevant. The existence of a symmetric Galilean connection implies restrictions on the one-form Ω, as the following result shows.

Lemma 13: For any Galilean space–time $(M,\Omega,\langle\cdot,\cdot\rangle,\nabla)$,

$$\Omega\circ\mathrm{Tor}=d\Omega. \tag{8}$$

Therefore, if there exists a symmetric Galilean connection, then $d\Omega=0$.

Proof: By using Remark 12,

$$\begin{aligned} d\Omega(X,Y)&=X(\Omega(Y))-Y(\Omega(X))-\Omega([X,Y])\\ &=\Omega(\nabla_X Y)-\Omega(\nabla_Y X)-\Omega([X,Y])\\ &=\Omega(\mathrm{Tor}(X,Y)), \quad \forall X,Y\in\Gamma(TM), \end{aligned}$$

which proves (8). □

Remark 14: If a G-structure is parallelizable, then it admits a symmetric connection (Ref. 9, Proposition 1.2), but the converse is clearly false. Nevertheless, as we will see in Sec. III B, if $d\Omega=0$, then there are symmetric connections. Thus, for Leibnizian G-structures one can say: *there exists a symmetric connection if and only if* "Ω *is parallelizable*" (i.e., locally $\Omega=dt$).

When $d\Omega\neq 0$, only "connections symmetric for a field of observers" can be defined:

Definition 15: Let $Z\in\mathcal{Z}(M)$ *be a FO, and* P^Z *its associated projection [formula (1)]. A Galilean connection is* Z-symmetric, *if*

$$P^Z\circ \mathrm{Tor}\equiv 0.$$

If $d\Omega=0$, then $\Omega\circ\mathrm{Tor}\equiv 0$ and, therefore, $P^Z\circ\mathrm{Tor}\equiv\mathrm{Tor}$; that is symmetric and Z-symmetric connections are equal. More precisely, we have the following.

Proposition 16: Let $(M,\Omega,\langle\cdot,\cdot\rangle,\nabla)$ *be a Galilean space–time. The following assertions are equivalent:*

(1) ∇ *is symmetric.*
(2) $d\Omega=0$ *and, given any point* $p\in M$*, there exist a neighborhood* U *and a FO on* U*,* $Z\in\mathcal{Z}(U)$*, such that* ∇ *is* Z*-symmetric on* U*.*
(3) Fix any point $p\in M$*; there exists a neighborhood* U *and two FOs* Z,Z' *on* U*, which are independent at* p *and such that* ∇ *is* Z *and* Z'*-symmetric on* U*.*
(4) ∇ *is* Z*-symmetric for any FO,* $Z\in\mathcal{Z}(M)$*.*

Proof: By using Lemma 13 and the above comments, the implications $1\Rightarrow 2\Rightarrow 1\Rightarrow 4\Rightarrow 3$ are obvious. For $3\Rightarrow 2$, notice that

$$0=(P^Z-P^{Z'})\circ\mathrm{Tor}(v,w)=(Z-Z')_p\,d\Omega(v,w),\quad \forall v,w\in T_pM. \qquad \square$$

Finally, let us define the following fundamental concepts (see Sec. III A 3 for interpretations).

Definition 17: Let $Z\in\mathcal{Z}(M)$*, a FO in a Galilean space–time,* $(M,\Omega,\langle\cdot,\cdot\rangle,\nabla)$*. The gravitational field induced by* ∇ *in* Z *is the vector field:*

$$\mathcal{G}=\nabla_Z Z.$$

The vorticity *or* Coriolis field *induced by* ∇ *in* Z *is the skew-symmetric two covariant tensor field* $\omega\equiv\frac{1}{2}\mathrm{rot}Z$ *defined by*

$$\omega(V,W)=\tfrac{1}{2}(\langle\nabla_V Z,W\rangle-\langle V,\nabla_W Z\rangle),\quad \forall V,W\in\Gamma(\mathrm{an}\Omega).$$

An observer $\gamma:I\to M$*,* $\Omega(\gamma')\equiv 1$*, is freely falling if it is a geodesic for* ∇*.*

Remark 18: Recall that $\Omega(\mathcal{G})=\Omega(\nabla_Z Z)=Z(\Omega(Z))=0$, that is, as the Galilean connection parallelizes Ω, the gravitational field is always spacelike.

Analogously, the definition of ω makes sense because ω is applied only on spacelike vector fields (Remark 12). In general, the *rotational* of a vector field $\mathrm{rot}X$, as in Definition 17, makes sense when $\Omega(X)$ is constant (in particular, if X is spacelike or a FO) and it is applied on pairs of spacelike tangent vectors.

2. Galilean vector fields

As for the Leibnizian case, vector fields (and, in particular, FOs) with flows preserving the Galilean structure become natural now. Recall first that, given an affine conection ∇, a vector field K with local flows preserving ∇ (i.e., $\mathcal{L}_K\nabla=0$) is called affine (Killing) and is characterized by the equality

$$[K,\nabla_Y X]=\nabla_{[K,Y]}X+\nabla_Y[K,X],\quad \forall X,Y\in\Gamma(TM) \tag{9}$$

(when K, X and Y are coordinate vector fields, this means that the Christoffel symbols are independent of the coordinate associated to K).

Definition 19: Given a Galilean structure $(M,\Omega,\langle\cdot,\cdot\rangle,\nabla)$, *a vector field* $K\in\Gamma(TM)$ *is* Galilean *(Killing) if* K *is Leibnizian for* $(M,\Omega,\langle\cdot,\cdot\rangle)$ *and affine for* ∇. *If, additionally,* K *is a FO, then* K *is a* field of Galilean observers *(FGO).*

Denote by $\mathrm{Gal}(M)\equiv\mathrm{Gal}(M,\Omega,\langle\cdot,\cdot\rangle,\nabla)$ the Lie algebra of all the Galilean vector fields. If $d\Omega=0$, $\mathrm{Gal}_1(M)$ will denote the affine space of all the FGOs, in agreement with the notation in Remark 5(2). Although Leibnizian vector fields might have infinite dimension, this cannot hold for the Galilean ones, which are always affine; recall that the maximum dimension for affine vector fields is $m(m+1)$. Therefore, from the classical results by Palais, the diffeomorphisms of M preserving the Galilean structure are a (finite dimensional) Lie group, and its associated algebra is the subalgebra of $\mathrm{Gal}(M)$ generated by its complete vector fields (see, for example, Ref. 10, Vol. I, Note 9). It is not difficult to find the best bound for the dimension of $\mathrm{Gal}(M)$:

Proposition 20: If $m=\dim M$, *then* $\dim(\mathrm{Gal}(M))\leqslant m(m+1)/2$.

Proof: Choose $p\in M$ and take coordinates $(t,x^1,\ldots,x^n)$ such that the corresponding set of coordinate vector fields (∂_μ) is a Galilean base at p. Each Galilean vector field $K\in\mathrm{Gal}(M)$ is determined by the values of $K^\mu(p)$ and $\partial_\nu K^\mu(p)$. (This holds for any affine vector field. The proof is analogous to the one for the Killing case in Ref. 22 p. 442-3.) Condition *3(b)* of Proposition 4 imposes $m(m-1)/2$ independent linear equations for the values of $\partial_i K^j(p)$; Condition *3(a)* fixes the values of $\partial_\nu K^0,\forall\,\nu\in\{0,1,\ldots,n\}$, that is, it imposes m independent conditions more. □

Remark 21: This bound for $\dim(\mathrm{Gal}(M))$ is the best one, as one can check in the standard example: $(\mathbb{R}^{n+1},dt^2,\langle\cdot,\cdot\rangle_0,\nabla^0)$, t being the usual projection on the first variable and $\langle\cdot,\cdot\rangle_0$ (resp. ∇^0) the usual metric on each hypersuperface (resp. usual connection).

Remarkably, the maximum dimension of $\mathrm{Gal}(M)$ is equal to the maximum dimension for the Killing vector fields of a semi-Riemannian metric on M. This was expected because, on one hand, the groups $G_m(\mathbb{R})$ and orthogonal $O_s(n+1,\mathbb{R})$ have the same dimensión and, on the other, Killing vector fields are automatically affine for the Levi-Civita connection of the semi-Riemannian metric.

Finally, we give the following consequence on gravitational and Coriolis fields (Definition 17), interesting for its classical physical interpretation.

Proposition 22: Let $Z\in\mathcal{Z}(M)$ *be a FGO of* $(M,\Omega,\langle\cdot,\cdot\rangle,\nabla)$. *Then*

$$\mathcal{L}_Z\mathcal{G}(=[Z,\mathcal{G}])=0,\quad \mathcal{L}_Z\omega=0,\quad \mathcal{L}_Z\mathrm{Tor}=0.$$

If $d\Omega=0$, *then the first (resp. second, third) equality is equivalent to the following fact: for any chart* $(t,x^1,\ldots,x^n)$ *adapted to* Z, *the field* $\mathcal{G}$ *(resp.* ω, *Tor) is independent of the coordinate* t.

Proof: The first equality is a consequence of (9) with $K=X=Y=Z$. From this formula one also has

$$[Z,\nabla_X Z]=\nabla_{[Z,X]}Z. \tag{10}$$

Then, for any spacelike vector fields V,W,

$$2\mathcal{L}_Z\omega(V,W)=2(Z(\omega(V,W))-\omega([Z,V],W)-\omega(V,[Z,W]))=Z(\langle\nabla_V Z,W\rangle-\langle V,\nabla_W Z\rangle)$$
$$-\langle\nabla_{[Z,V]}Z,W\rangle+\langle[Z,V],\nabla_W Z\rangle-\langle\nabla_V Z,[Z,W]\rangle+\langle V,\nabla_{[Z,W]}Z\rangle.$$

But this expression vanishes, by using Proposition 4 [formula *3(b)*] and (10). For the torsion, we can assume that X, Y, Z, at any fixed point, commute and then

$$\mathcal{L}_Z\mathrm{Tor}(X,Y)=[Z,\nabla_X Y]-[Z,\nabla_Y X].$$

By (9), the last two terms vanish.

Finally, the last assertion is straightforward from the expressions in coordinates. □

3. Classical physical interpretations

Next, some definitions will suggest the classical interpretations for observers in $(M,\Omega,\langle\cdot,\cdot\rangle,\nabla)$. For simplicity, we will consider the case $d\Omega=0$ and ∇ symmetric, but the definitions can be extended formally to the general case.

Fix a FO, $Z\in\mathcal{Z}(M)$. Denote, as usual,

$$A_Z:\mathrm{an}\Omega\to\mathrm{an}\Omega,\quad A_Z(V)=-\nabla_V Z,\quad \forall V\in\Gamma(\mathrm{an}\Omega),$$

and decompose $-A_Z$ in its symmetric $\hat{S}$ and skew-symmetric $\hat{\omega}$ parts. [The sign $-$ in the definition of A_Z is a usual convention differential geometry: A_Z is then the Weingarten endomorphism for the hypersuperficies $t\equiv\mathrm{const}$ (see, for example, Ref. 10). Nevertheless, this sign is ruled out in the decomposition.] That is,

$$-A_Z=\hat{S}+\hat{\omega}$$

where $\hat{S}$ is self-adjoint for $\langle\cdot,\cdot\rangle$, and $\hat{\omega}$ skew-adjoint. Denote by S,ω the corresponding fields of two-covariant associated tensors:

$$S(V,W)=\langle\hat{S}(V),W\rangle=\tfrac{1}{2}(\langle\nabla_V Z,W\rangle+\langle V,\nabla_W Z\rangle),$$

$$\omega(V,W)=\langle\hat{\omega}(V),W\rangle=\tfrac{1}{2}(\langle\nabla_V Z,W\rangle-\langle V,\nabla_W Z\rangle).$$

Tensor ω is, then, the vorticity or Coriolis field in Definition 17. The name ''vorticity'' means that, if Z represents the trajectories of the particles of a fluid, then ω measures how, given a fixed trajectory, the others turn around. The name ''Coriolis field'' appears because ω measures the ''lack of inerciality'' of Z due to the spinning of the observers (even though this lack of inerciality maybe intrinsic, see Remark 36). In fact, when $n=3$ and M (or, equally, anΩ) is orientable, ω can be represented by a *Coriolis vector field* C_ω in a standard way. Indeed, fix an orientation continuously at each fiber of anΩ; the metric $\langle\cdot,\cdot\rangle$ yields a standard *oriented volume element*, dv, which is a skew-symmetric three-covariant tensor. Now, define C_ω by the equality $\omega(V,W)=dv(C_\omega,V,W),\forall V,W\in\Gamma(\mathrm{an}\Omega)$. $\hat{S}$ (or, S) will be called the *intrinsic Leibnizian part of* A_Z, because of the following result.

Proposition 23: Fix $Z\in\mathcal{Z}(M)$. The endomorphism field $\hat{S}$ (and, thus, S) depends only on the Leibnizian structure $(M,\Omega,\langle\cdot,\cdot\rangle)$; thus, it is independent of the Galilean connection ∇.

Moreover, Z is Leibnizian if and only if $\hat{S}=0$.

Proof: From the definition of S (recall that we assume now Tor$=0$)

$$S(V,V)=\langle\nabla_V Z,V\rangle=(\langle[V,Z],V\rangle+\langle\nabla_Z V,V\rangle)=-\langle[Z,V],V\rangle+\tfrac{1}{2}Z\langle V,V\rangle,\tag{11}$$

and the first assertion holds. The last assertion is straightforward from (11), the third characterization in Proposition 4, and Remark 5(2). □

Now, $\hat{S}$ can be decomposed as

$$\hat{S}=\frac{\theta}{n}I+\sigma,$$

where I is the identity endomorphism, σ is the *shear*, characterized because it must be traceless, and θ is the *expansion*. So, θ measures how, with an observer fixed, neighboring observers go away on average, and σ is the deviations of this average. From Proposition 23, each observer γ in a FLO, Z, stands at a constant distance from any other observer $\overline{\gamma}$ in Z; nevertheless, depending on the Galilean connection, they may rotate when $\omega\neq 0$. Then, the gravitational field of a FLO Z

measures the forces which must be used, in order to compensate gravity and maintain a constant distance between its observers. Alternatively, Z may represent a *rigid solid*, and $\mathcal{G}$ measures gravitational tensions.

Finally, fields of inertial observers will be defined. Notice that, from a classical physical viewpoint, it is natural to assume that they are FLOs without ''rotations.'' But, under our mathematical approach, it is also natural to assume that they are FGO. Thus, we give two definitions.

Definition 24: Let $(M,\Omega,\langle\cdot,\cdot\rangle,\nabla)$ *be a Leibnizian space–time with symmetric* ∇, *and* $Z \in \mathcal{Z}(M)$. *We will say that* Z *is a* field of inertial observers (FIO) *if* Z *is a FLO and* $\omega=0$.

In this case, the FIO Z *is* proper *if it is a FGO.*

B. Existence of Galilean connections: Fundamental theorem

Next, we determine all the Galilean connections compatible with a fixed Leibnizian structure.

Recall that, for a semi-Riemannian metric g, all the connections which parallelize g can be computed from their torsion, Tor and Koszul's formula (which determines the Levi-Civita connection, i.e., the unique one with $\mathrm{Tor}=0$). The only condition for Tor is to be a two-skew-symmetric covariant, one-contravariant tensor field, $\mathrm{Tor}\in\Lambda^2(TM,TM)$. Thus, there exists a natural bijection between the connections which parallelize g and the tensors field in $\Lambda^2(TM,TM)$.

On the contrary, formula (8) does represent an obstruction for the possible torsions associated to a Galilean connection. As a consequence, we will have to consider tensors fields in $\Lambda^2(TM,TM)$ under a restriction type (8). In addition, we will need so many new parameters as restrictions in (8). As we will see, gravitational and Coriolis fields will be these new parameters.

Our study will be carried out in two steps. In the first one (Sec. III B 1) we will see how, given a Galilean structure and fixed Z, the values of $\mathcal{G}$, ω and Tor fix the Galilean connection. In the second step (Sec. III B 2) we will see how, given a Leibnizian structure and fixed Z, the permitted values of $\mathcal{G}$, ω and Tor are in bijective correspondence with the space of all the Galilean connections.

1. Formula "à la Koszul"

Our aim is to prove formula (13), which plays a role similar to the Koszul formula in semi-Riemannian geometry. Our next result is, then, the ''fundamental lemma of the Galilean geometry'' (compare, for example, with Ref. 19, Vol. IV, Chap. 6). As in previous notation, put, for any Galilean connection ∇,

$$A(X,Y)=\mathrm{Tor}(X,Y)+[X,Y]=\nabla_X Y-\nabla_Y X, \qquad \forall X,Y\in\Gamma(TM). \tag{12}$$

That is, A is two times the skew-symmetric part of ∇, and it depends just on its torsion. Notice that $A(Z,W)\in\Gamma(\mathrm{an}\Omega)$, $\forall Z\in\mathcal{Z}(M),\forall W\in\Gamma(\mathrm{an}\Omega)$ and $A(W_1,W_2)\in\Gamma(\mathrm{an}\Omega)$, $\forall W_1,W_2\in\Gamma(\mathrm{an}\Omega)$.

Lemma 25: Let $(M,\Omega,\langle\cdot,\cdot\rangle,\nabla)$ *be a Galilean space–time, and* $Z\in\mathcal{Z}(M)$ *a FO with gravitational field* $\mathcal{G}$ *and Coriolis* ω. *Then,* ∇ *satisfies the following formula:*

$$\begin{aligned}2\langle P^Z(\nabla_X Y),V\rangle=&X\langle P^Z(Y),V\rangle+Y\langle P^Z(X),V\rangle-V\langle P^Z(X),P^Z(Y)\rangle+2(\Omega(X)\,\Omega(Y)\langle\mathcal{G},V\rangle\\&+\Omega(X)\,\omega(P^Z(Y),V)+\Omega(Y)\,\omega(P^Z(X),V))+\Omega(X)(\langle A(Z,P^Z(Y)),V\rangle\\&-\langle A(Z,V),P^Z(Y)\rangle)-\Omega(Y)(\langle A(Z,P^Z(X)),V\rangle+\langle A(Z,V),P^Z(X)\rangle)\\&+\langle A(P^Z(X),P^Z(Y)),V\rangle-\langle A(P^Z(Y),V),P^Z(X)\rangle-\langle A(P^Z(X),V),P^Z(Y)\rangle,\end{aligned} \tag{13}$$

where $X,Y\in\Gamma(TM)$ *and* $V\in\Gamma(\mathrm{an}\Omega)$ *is any spacelike vector field.*

Proof: From the cyclic identities,

$$V\langle P^Z(X),P^Z(Y)\rangle=\langle\nabla_V P^Z(X),P^Z(Y)\rangle+\langle P^Z(X),\nabla_V P^Z(Y)\rangle, \tag{14}$$

$$P^Z(X)\langle P^Z(Y),V\rangle=\langle\nabla_{P^Z(X)}P^Z(Y),V\rangle+\langle P^Z(Y),\nabla_{P^Z(X)}V\rangle, \tag{15}$$

$$P^Z(Y)\langle V, P^Z(X)\rangle = \langle \nabla_{P^Z(Y)} V, P^Z(X)\rangle + \langle V, \nabla_{P^Z(Y)} P^Z(X)\rangle, \tag{16}$$

compute (15)+(16)−(14) to obtain

$$\begin{aligned}\langle \nabla_{P^Z(X)} P^Z(Y) + \nabla_{P^Z(Y)} P^Z(X), V\rangle = {} & P^Z(X)\langle P^Z(Y), V\rangle + P^Z(Y)\langle V, P^Z(X)\rangle - V\langle P^Z(X), P^Z(Y)\rangle \\ & - \langle A(P^Z(Y), V), P^Z(X)\rangle - \langle A(P^Z(X), V), P^Z(Y)\rangle. \end{aligned}\tag{17}$$

On the other hand, using (1) and (12),

$$\begin{aligned} 2\langle \nabla_X P^Z(Y), V\rangle &= 2\langle \nabla_{P^Z(X)} P^Z(Y), V\rangle + 2\,\Omega(X)\langle \nabla_Z P^Z(Y), V\rangle \\ &= \langle \nabla_{P^Z(X)} P^Z(Y), V\rangle + \langle \nabla_{P^Z(Y)} P^Z(X), V\rangle + \langle A(P^Z(X), P^Z(Y)), V\rangle \\ &\quad + 2\,\Omega(X)\langle \nabla_Z P^Z(Y), V\rangle. \end{aligned}\tag{18}$$

Substituing (17) in (18),

$$\begin{aligned} 2\langle \nabla_X P^Z(Y), V\rangle = {} & P^Z(X)\langle P^Z(Y), V\rangle + P^Z(Y)\langle V, P^Z(X)\rangle - V\langle P^Z(X), P^Z(Y)\rangle \\ & - \langle A(P^Z(Y), V), P^Z(X)\rangle - \langle A(P^Z(X), V), P^Z(Y)\rangle + \langle A(P^Z(X), P^Z(Y)), V\rangle \\ & + 2\,\Omega(X)\langle \nabla_Z P^Z(Y), V\rangle. \end{aligned}\tag{19}$$

Substituting also, in the two first terms on the right-hand side of (19), the values of $P^Z(X), P^Z(Y)$ by its expresion (1),

$$\begin{aligned} 2\langle \nabla_X P^Z(Y), V\rangle = {} & \Omega(X)\langle \nabla_Z P^Z(Y), V\rangle - \Omega(X)\langle P^Z(Y), \nabla_Z V\rangle - \Omega(Y)\langle \nabla_Z V, P^Z(X)\rangle \\ & - \Omega(Y)\langle V, \nabla_{P^Z(X)} Z\rangle - \Omega(Y)\langle V, A(Z, P^Z(X))\rangle + \{\text{Koszul}\}, \end{aligned}\tag{20}$$

where

$$\begin{aligned} \{\text{Koszul}\} = {} & X\langle P^Z(Y), V\rangle + Y\langle V, P^Z(X)\rangle - V\langle P^Z(X), P^Z(Y)\rangle + \langle A(P^Z(X), P^Z(Y)), V\rangle \\ & - \langle A(P^Z(Y), V), P^Z(X)\rangle - \langle A(P^Z(X), V), P^Z(Y)\rangle. \end{aligned}$$

But, using $\nabla_X(\Omega(Y)Z) = \Omega(\nabla_X Y)Z + \Omega(Y)(\Omega(X)\nabla_Z Z + \nabla_{P^Z(X)} Z)$, one has

$$\begin{aligned} P^Z(\nabla_X Y) = \nabla_X Y - \Omega(\nabla_X Y)Z &= \nabla_X(\Omega(Y)Z) + \nabla_X P^Z(Y) - \Omega(\nabla_X Y)Z \\ &= \Omega(X)\Omega(Y)\mathcal{G} + \Omega(Y)\nabla_{P^Z(X)} Z + \nabla_X P^Z(Y). \end{aligned}\tag{21}$$

Thus, substitute (20) in (21):

$$\begin{aligned} 2\langle P^Z(\nabla_X Y), V\rangle = {} & 2\,\Omega(X)\,\Omega(Y)\langle \mathcal{G}, V\rangle + \Omega(Y)\langle \nabla_{P^Z(X)} Z, V\rangle + \Omega(X)\langle \nabla_{P^Z(Y)} Z, V\rangle \\ & + \Omega(X)\langle A(Z, P^Z(Y)), V\rangle - \Omega(X)\langle P^Z(Y), \nabla_V Z\rangle - \Omega(X)\langle P^Z(Y), A(Z, V)\rangle \\ & - \Omega(Y)\langle \nabla_V Z, P^Z(X)\rangle - \Omega(Y)\langle A(Z, V), P^Z(X)\rangle - \Omega(Y)\langle V, A(Z, P^Z(X))\rangle \\ & + \{\text{Koszul}\} \\ = {} & 2\,\Omega(X)\,\Omega(Y)\langle \mathcal{G}, V\rangle + 2\,\Omega(X)\,\omega(P^Z(Y), V) + 2\,\Omega(Y)\,\omega(P^Z(X), V) \\ & + \Omega(X)(\langle A(Z, P^Z(Y)), V\rangle - \langle A(Z, V), P^Z(Y)\rangle) - \Omega(Y)(\langle A(Z, P^Z(X)), V\rangle \\ & + \langle A(Z, V), P^Z(X)\rangle) + \{\text{Koszul}\}, \end{aligned}$$

as required. □

Remark 26: As $\nabla_X Y = P^Z(\nabla_X Y) + X(\Omega(Y))Z$, *formula (13) permits us to reconstruct* ∇ *from* $\Omega, \langle\cdot,\cdot\rangle$, Tor, *and the values of* $\mathcal{G}, \omega$ *associated to* Z.

2. Natural bijection

Let us see how, for fixed FO, formula (13) determines all the Galilean connections of a Leibnizian space–time. As in previous notation, let (i) $\Lambda^2(\mathrm{an}\Omega)$ be the vector space of all the two-covariant skew-symmetric tensors defined on spacelike vectors [that is, $\vartheta\in\Lambda^2(\mathrm{an}\Omega)$, if and only if, $\vartheta:\mathrm{an}\Omega\times\mathrm{an}\Omega\to C^\infty(M)$, ϑ is $C^\infty(M)$–bilinear and skew-symmetric] and (ii) $\Lambda^2(TM,\mathrm{an}\Omega)$ be the vector space of all the two-covariant skew-symmetric tensors, one-contravariant spacelike valued [that is, $\Theta\in\Lambda^2(TM,\mathrm{an}\Omega)$, if and only if, $\Theta:\Gamma(TM)\times\Gamma(TM)\to\Gamma(\mathrm{an}\Omega)$, Θ is $C^\infty(M)$–bilinear and skew-symmetric].

Theorem 27: *Given a Leibnizian space–time* $(M,\Omega,\langle\cdot,\cdot\rangle)$, *let* $\mathcal{D}(\Omega,\langle\cdot,\cdot\rangle)$ *be the set of all its Galilean connections. For fixed FO, Z, the map,* $D^Z:\mathcal{D}(\Omega,\langle\cdot,\cdot\rangle)\to\Gamma(\mathrm{an}\Omega)\times\Lambda^2(\mathrm{an}\Omega)\times\Lambda^2(TM,\mathrm{an}\Omega)$, *given by*

$$D^Z(\nabla)=(\mathcal{G}(\equiv\nabla_Z Z),\ \omega(\equiv\tfrac{1}{2}\mathrm{rot}Z),\ P^Z\circ\mathrm{Tor}),\qquad\forall\nabla\in\mathcal{D}(\Omega,\langle\cdot,\cdot\rangle),$$

is one-to-one and onto.

Proof: Obviously, this map is well-defined. Let us prove that it is one-to-one. By using (8) and (12)

$$P^Z\circ\mathrm{Tor}=A(\cdot,\cdot)-d\,\Omega(\cdot,\cdot)Z-[\cdot,\cdot]\tag{22}$$

and

$$D^Z(\tilde{\nabla})=D^Z(\nabla)\Rightarrow\tilde{\mathcal{G}}=\mathcal{G},\quad\tilde{\omega}=\omega,\quad\tilde{A}=A.$$

Thus, from formula (13),

$$\langle P^Z(\tilde{\nabla}_X Y)-P^Z(\nabla_X Y),V\rangle=0,\qquad\forall X,Y\in\Gamma(TM),\forall V\in\Gamma(\mathrm{an}\Omega)\Rightarrow\tilde{\nabla}_X Y-\nabla_X Y=P^Z(\tilde{\nabla}_X Y)-P^Z(\nabla_X Y)=0,\qquad\forall X,Y\in\Gamma(TM),$$

as required.

In order to check that D^Z is onto, fix $\mathcal{G}\in\mathrm{an}\Omega$, $\omega\in\Lambda^2(\mathrm{an}\Omega)$ and $\Theta\in\Lambda^2(TM,\mathrm{an}\Omega)$. Taking into account (22), define

$$A(X,Y)=\Theta(X,Y)+d\,\Omega(X,Y)Z+[X,Y],\qquad\forall X,Y\in\Gamma(TM).$$

Then

$$\Omega(A(X,Y))=d\,\Omega(X,Y)+\Omega([X,Y])=X(\Omega(Y))-Y(\Omega(X)),$$

and $A(Z,W)\in\Gamma(\mathrm{an}\Omega)$, $\forall W\in\Gamma(\mathrm{an}\Omega)$, $A(W_1,W_2)\in\Gamma(\mathrm{an}\Omega)$, $\forall W_1,W_2\in\Gamma(\mathrm{an}\Omega)$. As a consequence, there exists an unique map $\Pi:\Gamma(TM)\times\Gamma(TM)\to\Gamma(\mathrm{an}\Omega)$, such that

$$2\,\langle\Pi(X,Y),V\rangle,\qquad\forall X,Y\in\Gamma(TM),\forall V\in\Gamma(\mathrm{an}\Omega),$$

satisfies formula (13) for previously fixed $\mathcal{G}$, ω and A. Define then

$$\nabla_X Y=X(\Omega(Y))Z+\Pi(X,Y),\qquad\forall X,Y\in\Gamma(TM).$$

A straightforward computation shows that the so-defined ∇ is a Galilean connection, with $D^Z(\nabla)$ equal to the initial $(\mathcal{G},\omega,\Theta)$. □

According to this theorem, there exists a canonical way to construct a Galilean connection from $Z\in\mathcal{Z}(M)$, and a gravitational and Coriolis field: the unique ∇ such that $D^Z(\nabla)=(\mathcal{G},\omega,0)$. If, additionally, the space–time satisfies $d\Omega=0$, we can consider only symmetric connections, that is, as in the following.

Corollary 28: Let $(M,\Omega,\langle\cdot,\cdot\rangle)$ *be a Leibnizian space–time, and fix* $Z\in\mathcal{Z}(M)$. *The set of all the Z-symmetric Galilean connections is mapped bijectively onto the set of all the possible gravitational* $\mathcal{G}\in\Gamma(\mathrm{an}\Omega)$ *and Coriolis* $\omega\in\Lambda^2(\mathrm{an}\Omega)$ *fields.*

In particular, if $d\Omega=0$, *then the set of all the symmetric Galilean connections is also mapped bijectively onto* $\Gamma(\mathrm{an}\Omega)\times\Lambda^2(\mathrm{an}\Omega)$.

Notice also that, when $d\Omega=0$, if nonsymmetric connections are considered, then Theorem 27 can be rewritten putting Tor instead of $P^Z\circ\mathrm{Tor}$.

Remark 29: (1) It is well-known that the set of all the affine connections on a manifold M has a natural structure of affine space, the associated vector space being the one of all the two-covariant, one-contravariant tensors fields. As commented at the beginning of this section, if a semi-Riemannian metric g is fixed, the set of all the connections parallelizing g has a natural structure of vector space (the Levi-Civita connection would play the role of vector 0), isomorphic to the vector space of all the possible torsions, i.e., the space $\Lambda^2(TM,TM)$. Recall that $\Lambda^2(TM,TM)$ is a vector fiber bundle, with fiber of dimension $m^2(m-1)/2$. Theorem 27 shows that, for fixed Z, the space $\mathcal{D}(\Omega,\langle\cdot,\cdot\rangle)$ admits a natural structure of vector space (the Z-symmetric connection with null gravitational and Coriolis fields would play the role of vector 0), isomorphic to the vector space $\Gamma(\mathrm{an}\Omega)\times\Lambda^2(\mathrm{an}\Omega)\times\Lambda^2(TM,\mathrm{an}\Omega)$. Recall that this vector space is also a vector fiber bundle, with fiber of equal dimension $n+n(n-1)/2+n^2(n+1)/2=m^2(m-1)/2$.

(2) Corollary 28 can be seen as an improved version of Ref. 11, Theorem 7. In fact, this result asserts that the degrees of freedom for the symmetric Galilean connections can be put in one-to-one correspondence with the set $\Lambda^2(TM)$ of all two-forms on M. Thus, we obtain not only the further splitting of such two forms in $\mathcal{G}$ and ω but also the more precise associated physical interpretations, which are developed in the remainder of the article.

C. Formulas for the connection, geodesics and curvature

Next, we will give explicit formulas in coordinates for the different geometric elements (Christoffel symbols, geodesics, curvature) associated to a Galilean connection. By using Lemma 25, these formulas can be given in terms of the Leibnizian estructure, and the fields $\mathcal{G}$, ω, Tor. For simplicity, we will assume that the connection is symmetric and, thus, $d\Omega=0$, but it is not difficult to give general expressions (see the computations following Remark 33).

Thus, fix $(M,\Omega,\langle\cdot,\cdot\rangle,\nabla)$ with a symmetric ∇, and a FO, $Z\in\mathcal{Z}(M)$. Let $(t,x^1,\ldots,x^n)$ be a chart adapted to Z as in Proposition 2, and let $\mathcal{G}^k$ (resp. ω_{ij}) be the components of the gravitational field $\mathcal{G}$ (resp. Coriolis field ω) for Z. Let $(h^{kl})_{n\times n}$, be the smooth local functions obtained from the inverse of the matrix $(h_{ij}=\langle\partial_i,\partial_j\rangle)_{n\times n}$ at each point. Indices will be raised as usual, thus $\omega_i^k(=\omega_i{}^k)=\Sigma_l\omega_{il}h^{kl}$.

Theorem 30: *The Christoffel symbols of* ∇ *in any chart adapted to* $Z\in\mathcal{Z}(M)$ *are*

$$\Gamma^0_{\mu\nu}=0,\quad \Gamma^k_{00}=\mathcal{G}^k,\quad \Gamma^k_{i0}=\omega_i^k+\frac{1}{2}\sum_{l=1}^{n}h^{kl}\frac{\partial h_{il}}{\partial t},$$

$\forall\,\mu,\nu\in\{0,1,\ldots,n\}$, $\forall\,i,k\in\{1,\ldots,n\}$, *the remainder being equal to the symbols for the hypersurfaces* $t\equiv\mathrm{const}$ *with the induced metric, i.e.,*

$$\Gamma^k_{ij}=\frac{1}{2}\sum_{l=1}^{n}h^{kl}\left(\frac{\partial h_{il}}{\partial x^j}+\frac{\partial h_{jl}}{\partial x^i}-\frac{\partial h_{ij}}{\partial x^l}\right),\qquad \forall\,i,j,k\in\{1,\ldots,n\}.$$

As a consequence, for any freely falling observer $\gamma:I\to M$ *(Definition 17), the following equations of the motion hold, putting* $\gamma^i=x^i\circ\gamma$:

$$\frac{d^2\gamma^k}{dt^2}+\frac{1}{2}\sum_{i,j,l=1}^{n}(h^{kl}\circ\gamma)\left(\frac{\partial h_{il}}{\partial x^j}+\frac{\partial h_{jl}}{\partial x^i}-\frac{\partial h_{ij}}{\partial x^l}\right)\circ\gamma\cdot\frac{d\gamma^i}{dt}\frac{d\gamma^j}{dt}$$

$$=-\mathcal{G}^k\circ\gamma-\sum_{i,l=1}^{n}(h^{kl}\circ\gamma)\left(\frac{\partial h_{il}}{\partial t}\circ\gamma\right)\frac{d\gamma^i}{dt}-2\sum_{i=1}^{n}(\omega_i^k\circ\gamma)\frac{d\gamma^i}{dt}, \tag{23}$$

for all $k\in\{1,\ldots,n\}$.

Proof: From Remark 26, one has $\Gamma^0_{\mu\nu}=0$. For the remainder, just apply formula (13) with $P^Z(\partial_i)=\partial_i$ and $A(\partial_\mu,\partial_\nu)=0$, [recall that $A(X,Y)=[X,Y]$, $\forall X,Y\in\Gamma(TM)$, because of the symmetry of ∇]. □

Notice that, if h_{ij} is independent of t (i.e., Z is a FLO, Proposition 6), the left-hand side of (23) yields the acceleration of the curve obtained as the projection of γ in a hypersurface $t\equiv$const (acceleration computed with the metric $\langle\cdot,\cdot\rangle$ on this hypersurface). Denote this left-hand side as $D^h(\gamma^k)'/dt$. On the other hand, recall that Z is an affine vector field if and only if

$$\partial_t\Gamma^\rho_{\mu\nu}=0,$$

for all μ, ν, ρ. Thus, the following characterization of a previously defined field of observers is straightforward (see also Propositions 6 and 22).

Corollary 31: Let $(M,\Omega,\langle\cdot,\cdot\rangle,\nabla)$ *be a Galilean space–time with symmetric* ∇, *and* $Z\in\mathcal{Z}(M)$. *Then, in the domain of any chart adapted to* Z,

(1) Z *is a FLO if and only if* $\partial_t h_{ij}=0$.

In this case, $\Gamma^k_{i0}=\omega_i^k$ *and, for freely falling observers,*

$$\frac{D^h(\gamma^k)'}{dt}=-\mathcal{G}^k\circ\gamma-2\sum_{i}^{n}(\omega_i^k\circ\gamma)\frac{d\gamma^i}{dt}. \tag{24}$$

(2) Z *is a FGO if and only if* $\partial_t h_{ij}=\partial_t\omega_{ij}=\partial_t\mathcal{G}^k=0$.

In this case, (24) holds with $\mathcal{G}^k=\mathcal{G}^k(x^1,\ldots,x^n),\omega_i^k=\omega_i^k(x^1,\ldots,x^n)$.

(3) Z *is a FIO if and only if* $\partial_t h_{ij}=0,\omega_{ij}=0$.

In this case, $\Gamma^k_{i0}=0$ *and, for freely falling observers,*

$$\frac{D^h(\gamma^k)'}{dt}=-\mathcal{G}^k\circ\gamma. \tag{25}$$

(4) Z *is a proper FIO if and only if* $\partial_t h_{ij}=\partial_t\mathcal{G}^k=0,\omega_{ij}=0$.

In this case, (25) holds with $\mathcal{G}^k=\mathcal{G}^k(x^1,\ldots,x^n)$.

From the Christoffel symbols one can readily compute the curvature tensor R (we will follow the convention of sign $R(X,Y)=[\nabla_X,\nabla_Y]-\nabla_{[X,Y]}$). As

$$\Omega(R(X,Y)Q)=0,\ \forall X,Y,Q\in\Gamma(M), \tag{26}$$

the operator R is spacelike-valued; moreover,

$$\langle V,R(X,Y)W\rangle=-\langle R(X,Y)V,W\rangle,\quad \forall X,Y\in\Gamma(TM),\forall V,W\in\mathrm{an}\Omega \tag{27}$$

[notice that (26) and (27) are also valid if ∇ is not symmetric]. Recall that, in a Galilean space–time, neither the four-covariant curvature tensor nor the scalar curvature make sense, but the Ricci tensor, Ric, does make sense. For each Riemanian hypersurface $t\equiv$const, the symbol ∇^h will denote the Levi-Civita connection (as well as the gradient), and the corresponding curvature and Ricci tensors (defined on spacelike vectors) will be R^h, Ric^h, resp. If $R^h\equiv 0$, we will say that the space $(\mathrm{an}\Omega,\langle\cdot,\cdot\rangle)$ is flat. In this case, if Z is a FLO, we can assume that the spacelike coordinates are parallel, i.e., $\Gamma^k_{ij}\equiv 0$ (see Proposition 35 for a general result).

Corollary 32: Given a Galilean space–time $(M,\Omega,\langle\cdot,\cdot\rangle,\nabla)$ *with symmetric* ∇*, for any chart adapted to* $Z\in\mathcal{Z}(M)$ *we have the following.*

(1) $R(\partial_i,\partial_j)\partial_k=R^h(\partial_i,\partial_j)\partial_k$ *and* $\mathrm{Ric}(\partial_i,\partial_j)=\mathrm{Ric}^h(\partial_i,\partial_j)$.

(2) If Z is a FLO, $R(\partial_i,\partial_t)\partial_t=\nabla^h_{\partial_i}\mathcal{G}-\Sigma_k(\partial_t\omega^k_i+\Sigma_l\omega^l_i\omega^k_l)\partial_k$. *[In particular, if Z is a FIO,* $R(\partial_i,\partial_t)\partial_t=\nabla^h_{\partial_i}\mathcal{G}$.*]*

Moreover, $\mathrm{Ric}(\partial_t,\partial_t)=\mathrm{div}^h\mathcal{G}+\|\omega\|^2$, *where* div^h *denotes the divergence with respect to* $\langle\cdot,\cdot\rangle$ *in the corresponding hypersurface* $t\equiv\mathrm{const}$, *and* $\|\omega\|^2=-\Sigma_{i,j}\omega^i_j\omega^j_i$. *[In particular, if Z is a FIO,* $\mathrm{Ric}(\partial_t,\partial_t)=\mathrm{div}^h\mathcal{G}$.*]*

(3) If Z is a FLO, $R(\partial_t,\partial_i)\partial_j=\Sigma_k(-\partial_i\omega^k_j+\Sigma_l(\Gamma^l_{ij}\omega^k_l-\Gamma^k_{il}\omega^l_j))\partial_k$.

In particular, (a) if Z is a FIO, then $R(\partial_t,\partial_i)\partial_j=0$, *and (b) if the space is flat, and parallel spacelike coordinates are taken,* $R(\partial_t,\partial_i)\partial_j=-\Sigma_k\partial_i\omega^k_j\partial_k$.

(4) If Z is a FLO, $R(\partial_i,\partial_j)\partial_t=\Sigma_k(\partial_i\omega^k_j-\partial_j\omega^k_i+\Sigma_l(\Gamma^k_{il}\omega^l_j-\Gamma^k_{jl}\omega^l_i))\partial_k$.

In particular, (a) if Z is a FIO, then $R(\partial_i,\partial_j)\partial_t=0$, *and (b) if the space is flat, and parallel spacelike coordinates are taken,* $R(\partial_i,\partial_j)\partial_t=\Sigma_k(\partial_i\omega^k_j-\partial_j\omega^k_i)\partial_k$.

Remark 33: Item (*1*) makes it natural to define the *sectional curvature* of a tangent plane included in an absolute space $\pi_p\subset\mathrm{an}\Omega_p$ as the curvature of π_p for the hypersurface $T\equiv T(p)$ endowed with the Riemannian metric $\langle\cdot,\cdot\rangle$, i.e., $K(\pi_p)=\langle R^h(v,w)w,v\rangle$, where v,w is any orthonormal base of π_p. If $\pi_p\subset T_pM$ does not lie in the absolute space $\mathrm{an}\Omega_p$, we can define:

$$K(\pi_p)=\langle R(v,Z_p)Z_p,v\rangle,$$

where v is any unit vector of $\pi_p\cap\mathrm{an}\Omega_p$ and $Z_p\in\pi_p$ satisfies $\Omega(Z_p)=1$. Thus, from a purely geometrical viewpoint, a rich ''sub-Riemannian'' geometry is introduced in this way, with interest on its own (compare with Ref. 20).

Alternatively, it is not difficult to study the curvature tensor by means of moving frames *à la Cartan*. For the sake of completeness, we sketch the structural equations. Locally, fix a field of observers Z and an orthonormal base of vector fields $E_1,\ldots,E_n$ of $\mathrm{an}\Omega$, and consider the dual base $(\Omega,\varphi^1,\ldots,\varphi^n)$ of $(E_0=Z,E_1,\ldots,E_n)$, plus the one-forms $\varphi^i{}_\rho$:

$$\varphi^i{}_\rho(X)=\varphi^i(\nabla_X E_\rho),\qquad \forall i\in\{1,\ldots,n\},\ \forall\rho\in\{0,1,\ldots,n\},\ \forall X\in\Gamma(TM).$$

Then, a straightforward computation shows the following three properties, valid even if ∇ is not symmetric:

(1) The curvature tensor

$$R(X,Y)E_\rho=\sum_{k=1}^{n}\Upsilon^k{}_\rho(X,Y)E_k$$

is univocally determined by the *second structural equation:*

$$\Upsilon^k{}_\rho=d\,\varphi^k{}_\rho+\sum_{l=1}^{k}\varphi^k{}_l\wedge\varphi^l{}_\rho,\qquad \forall k\in\{1,\ldots,n\},\ \forall\rho\in\{0,1,\ldots,n\}.$$

(2) For the gravitational and Coriolis fields $\mathcal{G}$, ω of the FO, Z, the one-forms $\varphi^i{}_0$ satisfy

$$2P^{Z^*}\omega=P^{Z^*}\mathcal{G}^\flat\wedge\Omega+\sum_{k=1}^{n}\varphi^k{}_0\wedge\varphi^k,$$

where $\mathcal{G}^\flat(V)=\langle\mathcal{G},V\rangle$, for all $V\in\mathrm{an}\Omega$.

(3) $\Upsilon^j{}_i=-\Upsilon^i{}_j$ and $\varphi^j{}_i=-\varphi^i{}_j$, for all $i,j\in\{1,\ldots,n\}$.

Therefore, if ∇ is Z-symmetric, the *connection one-forms* $\varphi^i{}_\rho$, are the unique one-forms satisfying the *first structural equation:*

$$2P^{Z^*}\omega = P^{Z^*}\mathcal{G}^\flat \wedge \Omega + \sum_{k=1}^{n} \varphi^k{}_0 \wedge \varphi^k,$$

$$d\,\varphi^i = -\varphi^i{}_0 \wedge \Omega - \sum_{k=1}^{n} \varphi^i{}_k \wedge \varphi^k,$$

plus the skew-symmetry relations $\varphi^j{}_i = -\varphi^i{}_j$.

IV. NEWTONIAN STRUCTURES

A. Newtonian space–times

As a difference with most previous references, our definition of Newtonian space–time is independent of hypotheses at infinity, i.e., it would be locally testable.

Definition 34: A Galilean space–time $(M,\Omega,\langle\cdot,\cdot\rangle,\nabla)$ *with symmetric* ∇ *is* Newtonian *if its space is flat and it admits a FIO.*

In this case, the Newtonian space–time will be proper *if some of its FIOs are proper.*

Now, it is natural to wonder: (a) which hypotheses imply the existence of a FIO? and (b) under these hypotheses, how many FIO's exist? In order to answer (a), we will assume for simplicity some global hypotheses, as the existence of a function absolute time T.

Proposition 35: Let $(M,dT,\langle\cdot,\cdot\rangle,\nabla)$ *be a Galilean space–time with* ∇ *symmetric and geodesically complete. Assume that each hypersurface* $T\equiv$const *is flat and simply connected. Then we have the following.*

(1) There exist a FLO, Z*, and the Leibnizian structure* $(M,dT,\langle\cdot,\cdot\rangle)$ *isomorphic to the standard one* $(\mathbb{R}^{n+1},dt,\langle\cdot,\cdot\rangle_0)$ [*with* $\langle\cdot,\cdot\rangle_0=\Sigma_{i=1}^n(dx^i)^2$ *and* $(t,x^1,\ldots,x^n)$ *the usual coordinates of* $\mathbb{R}^{n+1}$], *being identifiable under the isomorphism* $T\equiv t, Z\equiv\partial_t$.

(2) For fixed FLO Z *with vorticity* ω*, there exists a FIO (and, then, the space–time is Newtonian) if and only if there exists a spacelike vector field* $A\in\Gamma(\mathrm{an}\Omega)$ *such that* $2\omega=\mathrm{rot}A$.

Equally, under the identification with $(\mathbb{R}^{n+1},dt,\langle\cdot,\cdot\rangle_0)$*, there exists a FIO if and only if there exist* n *functions* $a^i:\mathbb{R}^{n+1}\to\mathbb{R}$ *such that* $2\omega_{ji}(\equiv 2\omega^i_j)=\partial_j a^i-\partial_i a^j$.

(3) If there exists a FLO, Z*, with vorticity* ω *depending only on* T $(\partial_i\omega_{jk}\equiv 0)$*, then there exists a FIO.*

Proof: Recall first that $\Omega(\beta')$ is a constant c_β for any geodesic β. Taking β with $c_\beta\neq 0$, the range of T must be all $\mathbb{R}$. By using geodesics with $c_\beta=0$, each hypersurface $T\equiv$const must be isommetric to $\mathbb{R}^n$.

(1) The flow ϕ_s of Z can be defined directly as follows. Fix any geodesic $\gamma(s)$ parametrized by T, i.e., $T\circ\gamma(s)=s,\forall s\in\mathbb{R}$. For each $p\in M$, take the unique spacelike geodesic $\alpha:[0,1]\to T^{-1}(T(p))$ connecting $\gamma(T(p))$ with p. Let $v_s, s\in\mathbb{R}$, be the vector field along γ obtained by parallel transport of $\alpha'(0)$ along γ, from $\gamma(T(p))$ to $\gamma(T(p)+s)$. If α_s^* is the geodesic with initial velocity v_s, define $\phi_s(p)=\alpha_s^*(1)$. It is straightforward to check that the infinitesimal generator Z of ϕ_s is a FLO and, fixing an orthonormal base of the absolute space at $\gamma(0)$, the isomorphism with the standard Leibnizian structure is straightforward.

(2) Fix the FLO Z. Put $\overline{Z}=Z-A$, where, using the isomorphism of item *(1)*, $A=\Sigma_k a^k\partial_k$ for some functions a^k on $\mathbb{R}^{n+1}$. Easily, $\mathrm{rot}\overline{Z}(\partial_i,\partial_j)=2\omega_{ij}-\partial_i a^j+\partial_j a^i$, and the result follows.

(3) Use item *(2)* with $a^j=-\Sigma_k\omega_{jk}x^k$. □

Remark 36: (1) For all Newtonian space–times the Leibnizian structure must be locally isomorphic to the standard one on $\mathbb{R}^m$. For the sake of simplicity, we will assume from now on that this standard Leibnizian structure underlies globally on any Newtonian space–time.

(2) From item *(2)* it is clear that if, for some indexes i,j,k, one has $\partial_i\omega_{jk}+\partial_k\omega_{ij}+\partial_j\omega_{ki}\neq 0$, ($\omega$ is not "spatially closed"), then there are no FIOs. Notice that, when Z is a FLO but not a FIO, (i) if the space–time is Newtonian (i.e., there exists a FIO), then ω represents "inertial (Coriolis) forces," (ii) otherwise, ω represents "true" gravitational forces (which cannot be "gauged away").

(3) An alternative formulation of Definition 34 is to impose the "gyroscope principle:" $R(X,Y)V=0$ whenever V is spacelike [see, for example, Ref. 13, Box 12.4, Axiom (3); and Ref. 14, Def. 1.1, Axiom 5]. In this case, Corollary 32(*1*) implies that the space is flat and Corollary 32(*4*) plus Proposition 35(*3*) implies the existence of a FIO.

Next, we will focus on the question (b) at the beginning of this section. Recall first the following straighforward result.

Lemma 37: Let $(\mathbb{R}^{n+1},dt,\langle\cdot,\cdot\rangle_0,\nabla)$ *be a Newtonian space–time and fix a FIO,* $Z\in\mathcal{Z}(M)$. *Consider a generic FO,* $\overline{Z}=Z+\Sigma_i a^i\partial_i$ *for some functions* a^i *on* $\mathbb{R}^{n+1}$.

(1) The relation between the gravitational fields $\mathcal{G},\overline{\mathcal{G}}$ *of* Z, $\overline{Z}$ is

$$\overline{\mathcal{G}}=\mathcal{G}+\sum_{i=1}^{n}\partial_t a^i\partial_i+\sum_{i,j=1}^{n}(a^i\partial_i a^j)\partial_j. \tag{28}$$

(2) $\overline{Z}$ *is a FIO if and only if the* a^i*'s are independent of* x, $a^i\equiv a^i(t)$, *and, thus,*

$$\overline{\mathcal{G}}=\mathcal{G}+(a^i)'(t)\partial_i. \tag{29}$$

(3) If Z *and* $\overline{Z}$ *are proper FIOs then (28) and (29) hold with constant derivatives* $(a^i)'$, *for all* i.

Therefore, if Z is a FIO, then $\overline{Z}=Z+\Sigma_i a^i(t)\partial_i$ is a FIO for any $a^i(t)$, and the FIOs have infinite dimension. If Z is proper, $\overline{Z}$ will be proper if and only if $a^i(t)=\alpha_1^i\cdot t+\alpha_0^i$ for some constants α_1^i,α_0^i. And if Z and $\overline{Z}$ are FIOs (proper or not) with the same gravitational field, then $a^i(t)\equiv\alpha_0^i$ for all i. Summing up, we have the following.

Theorem 38: *Let* $(\mathbb{R}^{n+1},dt,\langle\cdot,\cdot\rangle_0,\nabla)$ *be a Newtonian space–time.*

(1) The set of all the FIOs is an affine space of infinite dimension.
(2) If the Newtonian space–time is proper, proper FIOs are a $2n$*-dimensional subspace.*
(3) For fixed FIO, Z, *with gravitational field* $\mathcal{G}$, *the set* $FIO(\mathcal{G})=\{\overline{Z}\in\mathcal{Z}(M)|\overline{Z}$ *is a FIO and* $\overline{\mathcal{G}}=\mathcal{G}\}$ *is an* n*-dimensional subspace.*

Remark 39: (1) When Z is a proper FIO, one can also put $\mathrm{FIO}(\mathcal{G})=\{\overline{Z}\in\mathcal{Z}(M)|\overline{Z}$ is a FIO and $[Z,\overline{Z}]=0\}$. In this case, $\mathrm{FIO}(\mathcal{G})$ is the set of all the FOs *whose observers move with constant velocity respect to* Z. Of course, there are only n independent directions for such velocities. Any other proper FIO $\overline{Z}$ measures a gravitational field $\overline{\mathcal{G}}=\mathcal{G}+\mathcal{G}_0$, where $\mathcal{G}_0$ is parallel ("a uniform gravitational field cannot be distinguished from a uniform acceleration").

(2) Any possible gravitational field $\mathcal{G}$ for ∇ fixes the n-dimensional set of fields of observers $\mathrm{FIO}(\mathcal{G})$. One of such gravitational fields $\mathcal{G}_0$ maybe privileged by some physical or mathematical reason. For example, $\mathcal{G}_0$ may be the unique gravitational field vanishing at infinity (this is a natural condition for Poisson's equation) or the unique one vanishing along a concrete observer γ_0. (This observer can be called "the center of the Universe" following ideas of Newton himself—"the center of the Universe is not accelerated by gravitation.") In this case, $\mathrm{FIO}(\mathcal{G}_0)$ is a distinguished n-dimensional set of fields of inertial observers.

(3) It is commonly accepted that "inertial reference frames" [see (4) below] can be defined only if there exist a privileged $\mathcal{G}_0$ which vanishes at infinity (see, for example, Ref. 21). Under our viewpoint, it is preferable to maintain our definition of FIOs and, when necessary, to speak about proper FIOs or $\mathrm{FIO}(\mathcal{G}_0)$ (as in the next section). Recall that, under our definition, the question whether a field of observers is inertial or not is *purely local* and can be determined, in principle, from Corollaries 31 and 32. In any case, those who prefer more classical names can call our inertial observers "Newtonian observers" and reserve the name "inertial" for our $\mathrm{FIO}(\mathcal{G}_0)$ when $\mathcal{G}_0$ vanishes at infinity.

(4) From our definition of FIO, we can give a natural definition of *inertial reference frame* (IRF), as a particular case of Galilean reference frame (see Sec. III A 1), i.e., as the choice of a

privileged gauge. Consider a Newtonian space–time, and fix any $p \in M$. Each orthonormal base $(e_1,\ldots,e_n)$ of the absolute space $(\mathrm{an}\Omega_p, \langle\cdot,\cdot\rangle_p)$ can be parallelly propagated to obtain a orthonormal base of vector fields $(E_1,\ldots,E_n)$. A *IRF* is a base of vector fields (moving frame) $(Z,E_1,\ldots,E_n)$ where Z is a FIO and $E_1,\ldots,E_n \in \Gamma(\mathrm{an}\Omega)$ is a parallel orthonormal base of vector fields. The gravitational field of the IRF is, by definition, the one of Z (the IRF will be *proper* if Z is a proper FIO). [Notice that this gravitational field is a gauge field; thus, FIO($\mathcal{G}$) characterizes all the IRFs with the same gauge field $\mathcal{G}$.] For fixed $\mathcal{G}_0$, all the IRF's with gravitational field equal to $\mathcal{G}_0$ are determined by the value of $(Z,E_1,\ldots,E_n)$ at p. Thus, the Galilean group $G_m(\mathbb{R})$ acts freely and transitively on the set of all the IRF's with gravitational field $\mathcal{G}_0$ (*classical homogeneous Galilean transformations*).

B. Poisson's equation

Up to now, Newtonian space–times have been described in a purely geometric way. Notice that the knowledge of a FIO Z and its corresponding $\mathcal{G}$ allows one to reconstruct ∇ [as a very particular case of formula (13)]. Poisson's equation relates geometry to the ''source'' of the gravitational field, by connecting $\mathcal{G}$ to the density of mass. Units with gravitational Newton's constant $G=1$ will be assumed. Recall first the following result [straightforward from (29) and Corollary 32]:

Lemmma 40: For any Newtonian space–time, we have the following.

(1) The spatial divergence of the gravitational field $\mathrm{div}^h\mathcal{G}$ *is equal for all the FIOs.*

Moreover, $Ric(Z_p,Z_p)=\mathrm{div}^h\mathcal{G}(p)$ *for all* Z_p with $dt(Z_p)=1$ *and, thus,* $Ric=4\pi\rho dt\otimes dt$ *where* ρ *is the* density of mass *defined as*

$$\rho(t,x)=\mathrm{div}^h\mathcal{G}(t,x)/4\pi.$$

(2) If, for some FIO Z, the gravitational field $\mathcal{G}$ *is a spatial gradient, i.e.,* $\mathcal{G}=\nabla^h\Phi$ *for some function* Φ*, then the gravitational field* $\overline{\mathcal{G}}$ *of any other FIO* $\overline{Z}=Z+\Sigma_i a^i(t)\partial_i$ *is the spatial gradient* $\overline{\mathcal{G}}=\nabla^h\overline{\Phi}$ *with*

$$\overline{\Phi}(t,x)=\Phi(t,x)+\sum_{i=1}^{n}(a^i)'(t)x^i+b^0(t)$$

and $b^0(t)$ *arbitrary.*

Thus, classical Newton's gravitational law and Poisson's equation suggest the following.

Definition 41: A Newtonian (resp. proper Newtonian) space–time $(\mathbb{R}^{n+1},dt,\langle\cdot,\cdot\rangle_0,\nabla)$ *is* Poissonian *(resp.* proper Poissonian*) if the following two conditions hold:*

(i) The density of mass is non-negative, $\rho\geqslant 0$.

(ii) The gravitational field $\mathcal{G}$ *of a FIO is a spatial gradient* $\mathcal{G}=\nabla^h\Phi$*, for some* $\Phi \in C^2(\mathbb{R}^{n+1})$.

Remark 42: An alternative assumption to *(ii)* is to impose the conservative character of gravitational forces by means of an assumption on the curvature, say, for some $Z\in\mathcal{Z}(M)$, $\langle R(V,Z)Z,W\rangle=\langle R(W,Z)Z,V\rangle$ whenever V,W are spacelike [use Corollary 32; compare with Ref. 14 [Def. 1, Axiom 4], and Ref. 13, Box 12.4, Axiom (7)]. From Lemma 40, assumption (i) can also be formulated as $\mathrm{Ric}(v,v)\geqslant 0$ for all v. Recall that, in any case, our axioms avoid any type of redundancy (as, for example, those in Ref. 13, Box 12.4).

In any Poissonian space–time, denoting by Δ^h the spacelike Laplacian, intrinsic *Poisson's equation*

$$\Delta^h\Phi=4\pi\rho \tag{30}$$

holds. Taking coordinates adapted to some FIO Z (and spacelike parallel), it is well-known that if $\Phi(t,x)$ is a solution of (30), then $\Phi^*(t,x)=\Phi(t,x)+\Sigma_i b^i(t)x^i+b^0(t)$ is a new solution. Thus, Poisson's equation does not determine univocally the value of $\mathcal{G}$ for $Z=\partial_t$, but the value of all the

possible $\mathcal{G}$'s for all the FIOs [this happens even in the proper case, where ρ is necessarily independent of t, and the solutions of (30) can be chosen independent of t]. But this is not surprising, because, in principle, (30) should not privilege any particular inertial gauge.

In order to avoid this difficulty, one assumes usually that (30) can be written in coordinates such that $Z=\partial_t$ is not an arbitrary FIO but one in a priviledged set FIO($\mathcal{G}_0$). The classical assumption for $\mathcal{G}_0$ is to assume that it vanishes at spatial infinity [thus, if such a $\mathcal{G}_0$ exists, then (29) implies that it is unique], and this can be always assumed if ρ has spatial compact support.

Nevertheless, when $\rho(t,\cdot)$ does not have compact support for some t, perhaps no $\mathcal{G}_0$ vanishes at spatial infinity. The simplest case happens for a nonempty spatially homogeneous Universe, i.e., when $\rho(t,x)\equiv\rho_0(t)$ with $\rho_0(t)\not\equiv 0$ [even though perhaps $\rho_0(t)\equiv$const]. Then, a typical solution of (30) when $n=3$ is, in spatial spherical coordinates, $\Phi(t,x)=2\pi\rho_0(t)r^2/3$. The corresponding gravitational field $\mathcal{G}_0$ is null at $r=0$, i.e., along the observer $\gamma_0(t)=(t,0)$ (the ''center of the Universe''). Thus, if one chooses such a γ_0, then a tridimensional set of fields of inertial observers FIO($\mathcal{G}_0$) is privileged, and $\mathcal{G}_0$ can be reconstructed from ρ.

Reciprocal transformations of Hamiltonian operators of hydrodynamic type: Nonlocal Hamiltonian formalism for linearly degenerate systems

E. V. Ferapontov[a] and M. V. Pavlov
Department of Mathematical Sciences, Loughborough University, Loughborough, Leicestershire LE11 3TU, United Kingdom

(Received 7 February 2002; accepted 9 December 2002)

Reciprocal transformations of Hamiltonian operators of hydrodynamic type are investigated. The transformed operators are generally nonlocal, possessing a number of remarkable algebraic and differential-geometric properties. We apply our results to linearly degenerate semi-Hamiltonian systems in Riemann invariants, a typical example being $R^i_t=(\Sigma^n_{m=1}R^m-R^i)R^i_x$, $\quad i=1,2,\ldots,n$. Since all such systems are linearizable by appropriate (generalized) reciprocal transformations, our formulas provide an infinity of mutually compatible nonlocal Hamiltonian structures, explicitly parametrized by n arbitrary functions of one variable. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1542921]

I. INTRODUCTION

Equations of hydrodynamic type,

$$u^i_t=v^i_j(u)u^j_x, \qquad i,j=1,\ldots,n,$$

naturally arise in applications such as gas dynamics, hydrodynamics, chemical kinetics, the Whitham averaging procedure, differential geometry and topological field theory (see, e.g., Refs. 9, 10, 27, 28, 8, 21, and 22). In this article we study Hamiltonian systems,

$$u^i_t=v^i_j(u)u^j_x=J^{ij}\frac{\partial h}{\partial u^j}, \quad i=1,2,\ldots,n, \tag{1}$$

where

$$J^{ij}=g^{ij}(u)\frac{d}{dx}-g^{is}(u)\Gamma^j_{sk}(u)u^k_x \tag{2}$$

is the Hamiltonian operator and $h(u)$ is the density. As pointed out by Dubrovin and Novikov,[9] expression (2) defines a Hamiltonian operator if and only if the metric g^{ij} ($g^{ij}=g^{ji}$, $\det g^{ij}\neq 0$) is flat and Γ^j_{sk} are the Christoffel symbols of the corresponding Levi-Civita connection. Notice that Eqs. (1) and (2) imply that v^i_j is the matrix of second covariant derivatives of the density h,

$$v^i_j=\nabla^i\nabla_j h,$$

where $\nabla^i\equiv g^{ij}\nabla_j$. The theory of integrability of Hamiltonian systems of hydrodynamic type was proposed by Tsarev.[27,28] He demonstrated that if a Hamiltonian system (1) is diagonalizable, that is, can be written in the diagonal form

$$R^i_t=v^i(R)R^i_x$$

[a]Electronic mail: e.v.ferapontov@lboro.ac.uk

(the corresponding coordinates R^i are called the Riemann invariants), then it necessarily possesses an infinity of conservation laws and commuting flows and, moreover, is integrable by the so-called "generalized hodograph transform." In Riemann invariants R^i, the flat metric g^{ij} also becomes diagonal, $g^{ij}=g^{ii}\delta^{ij}$, thus establishing a correspondence between Hamiltonian diagonalizable systems (1) and n-orthogonal curvilinear coordinates in flat spaces. This shows that the theory of Hamiltonian systems of hydrodynamic type is deeply rooted in classical differential geometry.

There exists an important class of nonlocal transformations which act on hydrodynamic-type systems. Unlike the classical Bäcklund transformations (Miura-type transformations) familiar from the soliton theory, these transformations change the *independent* variables of a system. They are defined as follows. Let $B(u)dx+A(u)dt$ and $N(u)dx+M(u)dt$ be two conservation laws of system (1), understood as one-forms which are closed by virtue of (1). In the new independent variables $\tilde{x}$ and $\tilde{t}$ defined by

$$d\tilde{x}=B(u)dx+A(u)dt, \quad d\tilde{t}=N(u)dx+M(u)dt, \tag{3}$$

Eqs. (1) take the form

$$u^i_{\tilde{t}}=\tilde{v}^i_j(u)u^j_{\tilde{x}}, \tag{4}$$

where the transformed matrix $\tilde{v}$ is $\tilde{v}=(Bv-AE)(ME-Nv)^{-1}$, $E=id$. Transformations of the type (3) originate from gas dynamics and are known as *reciprocal*.[26] The simplest example is, probably, the passage from Eulerian to Lagrangian coordinates in one-dimensional gas dynamics. Reciprocal transformations are known to preserve the class of diagonalizable systems, which is an immediate corollary of the form of the transformed matrix $\tilde{v}$. Moreover, all conservation laws and commuting flows of the initial system can easily be recalculated in the new independent variables. Therefore, reciprocal transformations preserve the whole class of integrable systems of hydrodynamic type.

The only object which, under reciprocal transformations, behaves in a nontrivial way is the Hamiltonian structure. Generic reciprocal transformations destroy the local Hamiltonian formalism of the form (2). To the best of our knowledge, the behavior of Hamiltonian structures under reciprocal transformations (and their appropriate generalizations) has not been discussed in the literature. Investigation of this problem is, thus, the main objective of our article.

In Secs. III and IV we study the behavior of Hamiltonian structures (2) under reciprocal transformations (3). The main conclusion is that local Hamiltonian structures generally become nonlocal, so that the transformed system (4) is still Hamiltonian, $u^i_{\tilde{t}}=\tilde{J}^{ij}\partial\tilde{h}/\partial u^j$, however, with the nonlocal Hamiltonian operator

$$\tilde{J}^{ij}=\tilde{g}^{ij}\frac{d}{d\tilde{x}}-\tilde{g}^{is}\tilde{\Gamma}^j_{sk}u^k_{\tilde{x}}+\sum \varepsilon^\alpha w^i_{(\alpha)k}u^k_{\tilde{x}}\left(\frac{d}{d\tilde{x}}\right)^{-1}w^j_{(\alpha)s}u^s_{\tilde{x}}. \tag{5}$$

Here $\varepsilon^\alpha=\pm 1$; the explicit form of the transformed metric $\tilde{g}^{ij}$ and the nonlocal terms is stated in Secs. III and IV.

Remark: In the particular case of constant A, B, M, N, transformations (3) reduce to linear changes of the independent variables, $\tilde{x}=bx+at$, $\tilde{t}=nx+mt$, (a, b, m, n are constants). As pointed out by Tsarev,[28] transformations of this type preserve the locality of Hamiltonian structures of hydrodynamic type (see also Ref. 24).

Nonlocal operators of the form (5) have been extensively investigated in Refs. 20, 11, 13, 25, 1, 18, 5, and 2, and have a remarkable differential-geometric interpretation. The general theory is briefly recalled in Sec. II. As an illustration of our approach, we discuss Hamiltonian formalism of linearly degenerate semi-Hamiltonian systems in Riemann invariants,

$$R^i_t=v^i(R)R^i_x,$$

where the characteristic speeds $v^i(R)$ satisfy the identities

(1) $\partial_i v^i = 0$ for any $i = 1,2,\ldots n$, $\partial_i = \partial/\partial R^i$ (linear degeneracy);
(2) $\partial_k[\partial_j v^i/(v^j - v^i)] = \partial_j[\partial_k v^i/(v^k - v^i)]$ for any $i \neq j \neq k$ (semi-Hamiltonian property).

Linearly degenerate semi-Hamiltonian systems have interesting interrelations with separable (Stäckel) systems in classical mechanics[15,16,4,12,14] and finite-gap solutions of integrable soliton equations. For instance, the linearly degenerate semi-Hamiltonian system $R^i_t = (\Sigma R^m - R^i)R^i_x$ governs the evolution of zeros of the n-gap ψ-function in the KdV theory.[6,7,12] For $n=2$ we have essentially one nontrivial linearly degenerate system,

$$u_t = v u_x, \quad v_t = u v_x, \tag{6}$$

arising in gas dynamics (Chaplygin gas), field theory (Born–Infeld equation) and classical differential geometry (minimal surfaces in Minkowski three-space, improper affine spheres). Theorem 1 of Sec. III provides infinitely many Hamiltonian representations of system (6),

$$\begin{pmatrix} u \\ v \end{pmatrix}_t = J \begin{pmatrix} \partial h/\partial u \\ \partial h/\partial v \end{pmatrix}, \tag{7}$$

with nonlocal operators

$$\begin{aligned} J = {} & (u-v)^2 \begin{pmatrix} f(u) & 0 \\ 0 & \varphi(v) \end{pmatrix} \frac{d}{dx} + (u-v) \\ & \times \begin{pmatrix} \frac{1}{2}(u-v)f'(u)u_x + f(u)(u_x - v_x) & \varphi(v)u_x + f(u)v_x \\ -\varphi(v)u_x - f(u)v_x & \frac{1}{2}(u-v)\varphi'(v)v_x + \varphi(v)(u_x - v_x) \end{pmatrix} \\ & + \begin{pmatrix} w^1 u_x & u_x \\ w^2 v_x & v_x \end{pmatrix} \begin{pmatrix} d \\ \overline{dx} \end{pmatrix}^{-1} \begin{pmatrix} u_x & v_x \\ w^1 u_x & w^2 v_x \end{pmatrix}, \end{aligned}$$

where $w^1 = \frac{1}{2}[(u-v)f'(u) - f(u) - \varphi(v)]$ and $w^2 = \frac{1}{2}[(v-u)\varphi'(v) - f(u) - \varphi(v)]$ are the characteristic speeds of commuting flows of system (6), and the corresponding Hamiltonian densities

$$h = \frac{1}{4(v-u)} \left(\left[\int^u \frac{\mathrm{d}\nu}{\sqrt{f(\nu)}} \right]^2 - \left[\int^v \frac{\mathrm{d}\nu}{\sqrt{\varphi(\nu)}} \right]^2 \right),$$

parametrized by two arbitrary functions $f(u)$ and $\varphi(v)$. In view of the linearity of J in $f(u)$ and $\varphi(v)$, all these Hamiltonian structures are mutually compatible. Notice that the local part of the operator J is of the form (2), corresponding to the metric

$$(u-v)^{-2} \left(\frac{du^2}{f(u)} + \frac{dv^2}{\varphi(v)} \right),$$

which is not flat for generic $f(u)$ and $\varphi(v)$. Particular choices of $f(u)$ and $\varphi(v)$ lead to local Hamiltonian structures which were first discovered in Refs. 23 and 3 (see Example 1 in Sec. III).

Another example of this type is the three-component linearly degenerate semi-Hamiltonian system

$$u_t = (v+w)u_x, \quad v_t = (u-w)v_x, \quad w_t = \tfrac{1}{2}(u+v)w_x, \tag{8}$$

which is the Riemann invariant form of non-isentropic gas dynamics with the special equation of state $P(\rho,s)=s-1/\rho$ (see Refs. 29 and 19). Our approach provides infinitely many nonlocal Hamiltonian structures of the form

$$J=\frac{4}{\rho^2}\begin{pmatrix} f(u) & 0 & 0\\ 0 & \varphi(v) & 0\\ 0 & 0 & \psi(w)\end{pmatrix}\frac{d}{dx}$$
$$+\frac{2}{\rho}\begin{pmatrix} \frac{1}{\rho}f'(u)u_x+2f(u)\left(\frac{1}{\rho}\right)_x & -\varphi(v)u_x-f(u)v_x & -2\psi(w)u_x-f(u)w_x\\ \varphi(v)u_x+f(u)v_x & \frac{1}{\rho}\varphi'(v)v_x+2\varphi(v)\left(\frac{1}{\rho}\right)_x & -2\psi(w)v_x+\varphi(v)w_x\\ 2\psi(w)u_x+f(u)w_x & 2\psi(w)v_x-\varphi(v)w_x & \frac{1}{\rho}\psi'(w)v_x+2\psi(w)\left(\frac{1}{\rho}\right)_x\end{pmatrix}$$
$$+\begin{pmatrix} w^1u_x & u_x\\ w^2v_x & v_x\\ w^3w_x & w_x\end{pmatrix}\left(\frac{d}{dx}\right)^{-1}\begin{pmatrix} u_x & v_x & w_x\\ w^1u_x & w^2v_x & w^3w_x\end{pmatrix},\quad \rho=\left(w+\frac{v-u}{2}\right)^{-1}.$$

Here the local part is of the form (2), generated by the diagonal metric

$$(2w+v-u)^{-2}\left(\frac{du^2}{f(u)}+\frac{dv^2}{\varphi(v)}+\frac{dw^2}{\psi(w)}\right),\tag{9}$$

which is not flat in general, and w^1, w^2, w^3 are the characteristic speeds of commuting flows of system (8):

$$w^1=-\tfrac{1}{2}(2w+v-u)f'(u)-\tfrac{1}{2}[f(u)+\varphi(v)+4\psi(w)],$$
$$w^2=\tfrac{1}{2}(2w+v-u)\varphi'(v)-\tfrac{1}{2}[f(u)+\varphi(v)+4\psi(w)],$$
$$w^3=(2w+v-u)\psi'(w)-\tfrac{1}{2}[f(u)+\varphi(v)+4\psi(w)].$$

These Hamiltonian operators depend linearly on three arbitrary functions $f(u)$, $\varphi(v)$ and $\psi(w)$, and are mutually compatible (Example 2 in Sec. III).

Similar arguments applied to the three-component linearly degenerate semi-Hamiltonian system

$$u_t=(v+w)u_x,\quad v_t=(u+w)v_x,\quad w_t=(u+v)w_x\tag{10}$$

provide infinitely many nonlocal Hamiltonian structures

$$J=\begin{pmatrix} g^{11} & 0 & 0\\ 0 & g^{22} & 0\\ 0 & 0 & g^{33}\end{pmatrix}\frac{d}{dx}$$
$$+\begin{pmatrix} g^{11}\left[\frac{f'(u)}{2f(u)}u_x+\frac{u_x-v_x}{u-v}+\frac{u_x-w_x}{u-w}\right] & \frac{g^{22}u_x+g^{11}v_x}{u-v} & \frac{g^{33}u_x+g^{11}w_x}{u-w}\\ -\frac{g^{22}u_x+g^{11}v_x}{u-v} & g^{22}\left[\frac{\varphi'(v)}{2\varphi(v)}v_x+\frac{u_x-v_x}{u-v}+\frac{v_x-w_x}{v-w}\right] & \frac{g^{33}v_x+g^{22}w_x}{v-w}\\ -\frac{g^{33}u_x+g^{11}w_x}{u-w} & -\frac{g^{33}v_x+g^{22}w_x}{v-w} & g^{33}\left[\frac{\psi'(w)}{2\psi(w)}w_x+\frac{w_x-v_x}{w-v}+\frac{u_x-w_x}{u-w}\right]\end{pmatrix}$$

$$+\begin{pmatrix} \lambda^1 u_x & \mu^1 u_x & \eta^1 u_x & u_x \\ \lambda^2 v_x & \mu^2 v_x & \eta^2 v_x & v_x \\ \lambda^3 w_x & \mu^3 w_x & \eta^3 w_x & w_x \end{pmatrix} \left(\frac{d}{dx}\right)^{-1} \begin{pmatrix} u_x & v_x & w_x \\ \eta^1 u_x & \eta^2 v_x & \eta^3 w_x \\ \mu^1 u_x & \mu^2 v_x & \mu^3 w_x \\ \lambda^1 u_x & \lambda^2 v_x & \lambda^3 w_x \end{pmatrix}.$$

Here the metric components are

$$g^{11}=(u-v)^2(u-w)^2 f(u), \quad g^{22}=(v-u)^2(v-w)^2\varphi(v), \quad g^{33}=(w-u)^2(w-v)^2\psi(w),$$

the coefficients $\eta^1=v+w$, $\eta^2=u+w$ and $\eta^3=v+w$ are the characteristic speeds of system (10), and μ^k, λ^k are the characteristic speeds of its commuting flows:

$$\mu^1=-\frac{1}{2}(u-v)(u-w)f'(u)+uf(u)+v\varphi(v)+w\psi(w)-\int^u f(\nu)\mathrm{d}\nu-\int^v \varphi(\nu)\mathrm{d}\nu$$
$$-\int^w \psi(\nu)\mathrm{d}\nu-\frac{1}{2}(v+w)(f(u)+\varphi(v)+\psi(w)),$$

$$\lambda^1=(u-v)(u-w)[2f(u)+uf'(u)]-2[u^2f(u)+v^2\varphi(v)+w^2\psi(w)]$$
$$+(v+w)\left[uf(u)+v\varphi(v)+w\psi(w)+\int^u f(\nu)\mathrm{d}\nu+\int^v \varphi(\nu)\mathrm{d}\nu+\int^w \psi(\nu)\mathrm{d}\nu\right].$$

(μ^2, μ^3 and λ^2, λ^3 can be obtained by a cyclic permutation of u, v, w and f, φ, ψ.) These operators depend linearly on three arbitrary functions $f(u)$, $\varphi(v)$ and $\psi(w)$ and are mutually compatible. The details can be found in Example 3 in Sec. IV.

Generalized reciprocal transformations and their action on the local Poisson brackets of Dubrovin–Novikov type are discussed in Sec. V.

II. NONLOCAL HAMILTONIAN OPERATORS OF HYDRODYNAMIC TYPE. NONLOCAL HAMILTONIAN FORMALISM FOR SEMI-HAMILTONIAN SYSTEMS

In this section we recall the necessary information about nonlocal Hamiltonian operators of hydrodynamic type

$$J^{ij}=g^{ij}\frac{d}{dx}-g^{is}\Gamma^j_{sk}u^k_x+\sum_\alpha \varepsilon^\alpha w^i_{(\alpha)k}u^k_x\left(\frac{d}{dx}\right)^{-1} w^i_{(\alpha)n}u^n_x, \quad \varepsilon^\alpha=\pm 1, \tag{11}$$

which are defined by a metric g^{ij} ($g^{ij}=g^{ji}$, $\det g^{ij}\neq 0$), the corresponding Levi-Civita connection Γ^j_{sk} and a set of affinors $w_{(\alpha)}$ forming the nonlocal "tail."

Theorem 1:[11] *The operator J^{ij} is Hamiltonian if and only if the affinors $w_{(\alpha)}$ satisfy the equations*

$$g_{ik}w^k_{(\alpha)j}=g_{jk}w^k_{(\alpha)i}, \tag{12}$$

$$\nabla_k w^i_{(\alpha)j}=\nabla_j w^i_{(\alpha)k}, \tag{13}$$

and the curvature tensor of the metric g^{ij} has the expansion

$$R^{ij}_{kl}=\sum_\alpha \varepsilon^\alpha(w^i_{(\alpha)k}w^j_{(\alpha)l}-w^i_{(\alpha)l}w^j_{(\alpha)k}). \tag{14}$$

Moreover, the set of affinors $w_{(\alpha)}$ must be commutative,

$$[w_{(\alpha)}, \quad w_{(\beta)}]=0. \tag{15}$$

As pointed out in Ref. 11, Eqs. (12)–(15) constitute the Gauss–Codazzi–Ricci equations of submanifolds of pseudo-Euclidean spaces with flat normal bundle. There are three particularly interesting special cases of the general formula (11).

Hamiltonian operators associated with *constant curvature* metrics, first introduced in Ref. 20 (see also Ref. 25), are of the form

$$J^{ij}=g^{ij}\frac{d}{dx}-g^{is}\Gamma^j_{sk}u^k_x+cu^i_x\left(\frac{d}{dx}\right)^{-1}u^j_x. \tag{16}$$

Here g^{ij} is a metric of constant curvature c, so that the Gauss equation (14) takes the form

$$R^{ij}_{kl}=c(\delta^i_k\delta^j_l-\delta^i_l\delta^j_k).$$

Hamiltonian operators associated with *conformally flat* metrics are of the form[13]

$$J^{ij}=g^{ij}\frac{d}{dx}-g^{is}\Gamma^j_{sk}u^k_x+w^i_ku^k_x\left(\frac{d}{dx}\right)^{-1}u^j_x+u^i_x\left(\frac{d}{dx}\right)^{-1}w^j_ku^k_x. \tag{17}$$

The corresponding equations (12)–(14) reduce to

$$g_{ik}w^k_j=g_{jk}w^k_i,$$

$$\nabla_kw^i_j=\nabla_jw^i_k,$$

while the curvature tensor of the metric g^{ij} has the expansion

$$R^{ij}_{kl}=w^i_k\delta^j_l+w^j_l\delta^i_k-w^j_k\delta^i_l-w^i_l\delta^j_k,$$

implying that the metric g^{ij} is conformally flat.

Hamiltonian operators associated with *hypersurfaces of the Euclidean space* are[11]

$$J^{ij}=g^{ij}\frac{d}{dx}-g^{is}\Gamma^j_{sk}u^k_x+w^i_ku^k_x\left(\frac{d}{dx}\right)^{-1}w^j_nu^n_x. \tag{18}$$

The corresponding equations (12)–(14),

$$g_{ik}w^k_j=g_{jk}w^k_i,$$

$$\nabla_kw^i_j=\nabla_jw^i_k,$$

$$R^{ij}_{kl}=w^i_kw^j_l-w^i_lw^j_k,$$

are the Gauss–Codazzi equations governing the first fundamental form g^{ij} and the shape operator w^i_j of a hypersurface in the Euclidean space.

Nonlocal Hamiltonian operators of the form (11) and their particular instances (16)–(18) appear in a variety of applications including the Whitham theory [where operators of the form (11) arise as a result of the Whitham averaging of nonlocal higher order Poisson brackets of integrable PDEs[1,2]], recursion scheme, Dirac reduction, etc.[11] Canonical coordinates for these operators were introduced in a recent paper by Maltsev and Novikov.[18] The corresponding nonlocal symplectic structures were investigated in Ref. 17.

Notice that Eqs. (11)–(14) simplify if the metric g and affinors $w_{(\alpha)}$ are diagonal, $g^{ij}=g^{ii}\delta^{ij}$, $w^i_{(\alpha)j}=w^i_{(\alpha)}\delta^i_j$. In this case the operator (11) takes the form

$$J^{ij}=g^{ii}\delta^{ij}\frac{d}{dx}-g^{ii}\Gamma^j_{ik}u^k_x+\sum_\alpha\varepsilon^{(\alpha)}w^i_{(\alpha)}u^i_x\left(\frac{d}{dx}\right)^{-1}w^j_{(\alpha)}u^j_x, \tag{19}$$

while Eqs. (12)–(14) reduce to

$$\partial_j \ln \sqrt{g_{ii}} = \frac{\partial_j w^i_{(\alpha)}}{w^j_{(\alpha)} - w^i_{(\alpha)}}, \tag{20}$$

$$R^{ij}_{ij} = \sum_\alpha \varepsilon^{(\alpha)} w^i_{(\alpha)} w^j_{(\alpha)} \tag{21}$$

for any $i \neq j$. Nonlocal Hamiltonian operators of the form (19) naturally arise as Hamiltonian structures of semi-Hamiltonian systems in Riemann invariants.[11,5] Let us recall the main construction. Following Tsarev,[28] a system in Riemann invariants

$$R^i_t = v^i(R) R^i_x, \quad i = 1,2,\ldots,n, \tag{22}$$

is called semi-Hamiltonian if the characteristic speeds $v^i(R)$ satisfy the identities

$$\partial_k \frac{\partial_j v^i}{v^j - v^i} = \partial_j \frac{\partial_k v^i}{v^k - v^i}$$

for any triple $i \neq j \neq k$. Let us introduce the diagonal metric $g_{ii} dR^{i^2}$ by the formulas

$$\partial_j \ln \sqrt{g_{ii}} = \frac{\partial_j v^i}{v^j - v^i} \tag{23}$$

for any $i \neq j$. Notice that g_{ii} is defined up to a multiple $g_{ii} \to g_{ii}/f^i(R^i)$, where $f^i(R^i)$ is an arbitrary function of R^i.

Although the metric g_{ii} may happen to be flat for particular choices of $f^i(R^i)$ (in this case our system is Hamiltonian with the local Hamiltonian operator of Dubrovin–Novikov type corresponding to the metric g_{ii}), it is not flat in general. Suppose one can find the expansion of the curvature tensor of this metric in the form (21), where $w^i_{(\alpha)}$ are characteristic speeds of commuting flows of system (22):

$$R^i_{t^\alpha} = w^i_{(\alpha)}(R) R^i_x. \tag{24}$$

Notice that the flows (22) and (24) commute if and only if

$$\frac{\partial_j v^i}{v^j - v^i} = \frac{\partial_j w^i_{(\alpha)}}{w^j_{(\alpha)} - w^i_{(\alpha)}} \tag{25}$$

for any $i \neq j$. In this case the system (22) will be Hamiltonian with the nonlocal Hamiltonian operator (19) [indeed, both conditions (20) and (21) are satisfied]. The main problem is thus to find the expansion (21) for a metric satisfying (23). We point out that the sum in (21) is infinite in general.

Remarkably, there exist semi-Hamiltonian systems for which one can explicitly construct the expansion (21) for an arbitrary metric g_{ii} satisfying (23). Moreover, for any choice of $f^i(R^i)$ the summation in (21) is *finite*, so that the corresponding systems possess infinitely many Hamiltonian structures explicitly parametrized by n arbitrary functions of one variable. Among the most interesting examples of this type are systems of Temple's class and linearly degenerate semi-Hamiltonian systems. The construction of nonlocal Hamiltonian formalism for linearly degenerate semi-Hamiltonian systems is based on the formulas for reciprocal transformations of local Hamiltonian operators which we derive in Secs. III–V.

III. RECIPROCAL TRANSFORMATIONS WHICH CHANGE ONLY THE SPACE VARIABLE *x*

Consider a Hamiltonian system (1),

$$u_t^i = v_j^i(u)u_x^j = (\nabla^i\nabla_j h)u_x^j = J^{ij}\frac{\partial h}{\partial u^j},$$

with the local Hamiltonian operator (2),

$$J^{ij} = g^{ij}\frac{d}{dx} - g^{is}\Gamma_{sk}^j u_x^k.$$

In this section we discuss special reciprocal transformations of the form (3) which change the space variable x only,

$$d\tilde{x} = B(u)dx + A(u)dt, \quad \tilde{t} = t. \tag{26}$$

Notice that an arbitrary reciprocal transformation (3) can be represented as a composition

$$R_1 \circ T \circ R_2$$

where R_1 and R_2 are reciprocal transformations of the form (26) and T is the transformation interchanging the independent variables: $\tilde{x} = t$, $\tilde{t} = x$. After the transformation (26), system (1) takes the form

$$u_t^i = \tilde{v}_j^i(u)u_{\tilde{x}}^j = (\nabla^i\nabla_j h \cdot B - \delta_j^i A)u_{\tilde{x}}^j, \tag{27}$$

while the Hamiltonian operator J^{ij} undergoes a nontrivial transformation and becomes nonlocal. To write down the transformed operator $\tilde{J}^{ij}$, we introduce the Hamiltonian system

$$u_\tau^i = w_j^i(u)u_x^j = J^{ij}\frac{\partial B}{\partial u^j} = (\nabla^i\nabla_j B)u_x^j \tag{28}$$

generated by the Hamiltonian operator J^{ij} and the density B. Clearly, systems (1) and (28) commute. Since the flux of the conserved density B corresponding to the flow (28) is given by the formula $\frac{1}{2}(\nabla B)^2$ [here $\nabla B = B_i du^i$ is the gradient of B and $(\nabla B)^2 = g^{ij}B_iB_j$], we can incorporate the time τ into the reciprocal transformation (26) as follows:

$$d\tilde{x} = Bdx + Adt + \tfrac{1}{2}(\nabla B)^2 d\tau.$$

Therefore, the transformed system (28) takes the form

$$u_\tau^i = \tilde{w}_j^i(u)u_{\tilde{x}}^j = (\nabla^i\nabla_j B \cdot B - \tfrac{1}{2}\delta_j^i(\nabla B)^2)u_{\tilde{x}}^j. \tag{29}$$

The transformed systems (27) and (29) commute. Now we can formulate the main result of this section.

Theorem 2: *The transformed system (27) is Hamiltonian,*

$$u_t^i = \tilde{J}^{ij}\frac{\partial \tilde{h}}{\partial u^j},$$

with the nonlocal operator

$$\tilde{J}^{ij}=\tilde{g}^{ij}\frac{d}{d\tilde{x}}-\tilde{g}^{is}\tilde{\Gamma}^{j}_{sk}u^{k}_{\tilde{x}}+\tilde{w}^{i}_{k}u^{k}_{\tilde{x}}\left(\frac{d}{d\tilde{x}}\right)^{-1}u^{j}_{\tilde{x}}+u^{i}_{\tilde{x}}\left(\frac{d}{d\tilde{x}}\right)^{-1}\tilde{w}^{j}_{k}u^{k}_{\tilde{x}} \tag{30}$$

and the Hamiltonian density $\tilde{h}(u)=h(u)/B(u)$. *Here the transformed metric is* $\tilde{g}^{ij}=B^2g^{ij}$, $\tilde{\Gamma}$ *is the Levi-Civita connection of* $\tilde{g}$, *and* $\tilde{w}^{i}_{j}$ *is given by (29). Notice that the transformed metric is conformally flat with the curvature tensor*

$$\tilde{R}^{ij}_{kl}=\tilde{w}^{i}_{k}\delta^{j}_{l}+\tilde{w}^{j}_{l}\delta^{i}_{k}-\tilde{w}^{j}_{k}\delta^{i}_{l}-\tilde{w}^{i}_{l}\delta^{j}_{k}.$$

The proof follows directly from results of Ref. 13 where nonlocal Hamiltonian operators of the form (30) associated with conformally flat metrics were investigated. As an illustration of the procedure outlined in Theorem 1, we explicitly construct nonlocal Hamiltonian formalism for the two-component linearly degenerate system (6).

Example 1: The linear system

$$u_t=u_x,\quad v_t=-v_x \tag{31}$$

possesses infinitely many Hamiltonian representations

$$\begin{pmatrix}u\\v\end{pmatrix}_t=J\begin{pmatrix}\partial h/\partial u\\ \partial h/\partial v\end{pmatrix} \tag{32}$$

with local Hamiltonian operators J of the type (2),

$$J=4\begin{pmatrix}f(u)&0\\0&\varphi(v)\end{pmatrix}\frac{d}{dx}+2\begin{pmatrix}f'(u)u_x&0\\0&\varphi'(v)v_x\end{pmatrix}, \tag{33}$$

corresponding to flat metrics

$$ds^2=\frac{du^2}{4f(u)}+\frac{dv^2}{4\varphi(v)} \tag{34}$$

[here $f(u)$ and $\varphi(v)$ are arbitrary functions]. The corresponding Hamiltonian densities are

$$h(u,v)=\frac{1}{8}\left[\int^{u}\frac{\mathrm{d}\nu}{\sqrt{f(\nu)}}\right]^2-\frac{1}{8}\left[\int^{v}\frac{\mathrm{d}\nu}{\sqrt{\varphi(\nu)}}\right]^2. \tag{35}$$

Consider the reciprocal transformation

$$d\tilde{x}=Bdx+Adt=\tfrac{1}{2}(v-u)dx-\tfrac{1}{2}(v+u)dt,\quad \tilde{t}=t, \tag{36}$$

mapping the linear system (31) to the linearly degenerate system

$$u_t=vu_{\tilde{x}},\quad v_t=uv_{\tilde{x}}. \tag{37}$$

To write down the transformed Hamiltonian operators (33), we first introduce the transformed metric

$$d\tilde{s}^2=\frac{ds^2}{B^2}=(u-v)^{-2}\left(\frac{du^2}{f(u)}+\frac{dv^2}{\varphi(v)}\right), \tag{38}$$

which is no longer flat for generic $f(u)$ and $\varphi(v)$. Following the procedure outlined in Theorem 1, we calculate the Hamiltonian flow generated by the Hamiltonian operator (33) and the Hamiltonian density $B=\frac{1}{2}(v-u)$. A simple computation gives the system

$$u_\tau = -f'(u)u_x, \quad v_\tau = \varphi'(v)v_x, \tag{39}$$

which clearly commutes with (31). To incorporate the time τ into the reciprocal transformation (36), we calculate the flux of the density B corresponding to the flow (39),

$$\tfrac{1}{2}(\nabla B)^2 = \tfrac{1}{2}[f(u)+\varphi(v)].$$

Thus, reciprocal transformation (36) takes the form

$$d\tilde{x} = Bdx + Adt + \tfrac{1}{2}(\nabla B)^2 d\tau = \tfrac{1}{2}(v-u)dx - \tfrac{1}{2}(v+u)dt + \tfrac{1}{2}[f(u)+\varphi(v)]d\tau, \quad \tilde{t} = t,$$

so that the transformed system (39) is

$$u_\tau = w^1 u_{\tilde{x}}, \quad v_\tau = w^2 v_{\tilde{x}}, \tag{40}$$

where

$$w^1 = \tfrac{1}{2}[(u-v)f'(u) - f(u) - \varphi(v)], \quad w^2 = \tfrac{1}{2}[(v-u)\varphi'(v) - f(u) - \varphi(v)] \tag{41}$$

[notice that Eqs. (40) and (41) constitute a general commuting flow of the linearly degenerate system (37)]. According to Theorem 1, system (37) is Hamiltonian,

$$\begin{pmatrix} u \\ v \end{pmatrix}_t = \tilde{J}\begin{pmatrix} \partial\tilde{h}/\partial u \\ \partial\tilde{h}/\partial v \end{pmatrix},$$

with nonlocal operators $\tilde{J}$ of the form

$$\begin{aligned} &(u-v)^2\begin{pmatrix} f(u) & 0 \\ 0 & \varphi(v) \end{pmatrix}\frac{d}{d\tilde{x}} + (u-v) \\ &\quad\times\begin{pmatrix} \tfrac{1}{2}(u-v)f'(u)u_{\tilde{x}} + f(u)(u_{\tilde{x}} - v_{\tilde{x}}) & \varphi(v)u_{\tilde{x}} + f(u)v_{\tilde{x}} \\ -\varphi(v)u_{\tilde{x}} - f(u)v_{\tilde{x}} & \tfrac{1}{2}(u-v)\varphi'(v)v_{\tilde{x}} + \varphi(v)(u_{\tilde{x}} - v_{\tilde{x}}) \end{pmatrix} \\ &\quad+\begin{pmatrix} w^1 u_{\tilde{x}} & u_{\tilde{x}} \\ w^2 v_{\tilde{x}} & v_{\tilde{x}} \end{pmatrix}\left(\frac{d}{d\tilde{x}}\right)^{-1}\begin{pmatrix} u_{\tilde{x}} & v_{\tilde{x}} \\ w^1 u_{\tilde{x}} & w^2 v_{\tilde{x}} \end{pmatrix} \end{aligned} \tag{42}$$

and the Hamiltonian densities

$$\tilde{h} = h/B = \frac{1}{4(v-u)}\left(\left[\int^u \frac{d\nu}{\sqrt{f(\nu)}}\right]^2 - \left[\int^v \frac{d\nu}{\sqrt{\varphi(\nu)}}\right]^2\right).$$

All these operators are mutually compatible. Let us discuss some particular cases. For $f(u)=1$, $\varphi(v)=-1$ and $f(u)=u$, $\varphi(v)=-v$ we have $w^1=w^2=0$, so that the transformed operators take local forms

$$(u-v)^2\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}\frac{d}{d\tilde{x}} + (u-v)\begin{pmatrix} u_{\tilde{x}} - v_{\tilde{x}} & v_{\tilde{x}} - u_{\tilde{x}} \\ u_{\tilde{x}} - v_{\tilde{x}} & v_{\tilde{x}} - u_{\tilde{x}} \end{pmatrix} \tag{43}$$

and

$$(u-v)^2\begin{pmatrix} u & 0 \\ 0 & -v \end{pmatrix}\frac{d}{d\tilde{x}}+(u-v)\begin{pmatrix} (\frac{3}{2}u-\frac{1}{2}v)u_{\tilde{x}}-uv_{\tilde{x}} & uv_{\tilde{x}}-vu_{\tilde{x}} \\ vu_{\tilde{x}}-uv_{\tilde{x}} & (\frac{3}{2}v-\frac{1}{2}u)v_{\tilde{x}}-vu_{\tilde{x}} \end{pmatrix}, \tag{44}$$

the corresponding Hamiltonian densities being

$$h(u,v)=\frac{u^2+v^2}{4(v-u)} \quad \text{and} \quad h(u,v)=\frac{u+v}{v-u},$$

respectively. In the case $f(u)=u^2$, $\varphi(v)=-v^2$ we have $w^1=-w^2=\frac{1}{2}(u-v)^2$ so that the operator $\tilde{J}$ takes the form

$$\begin{aligned}(u-v)^2\begin{pmatrix} u^2 & 0 \\ 0 & -v^2 \end{pmatrix}\frac{d}{d\tilde{x}}+(u-v)\begin{pmatrix} u(2u-v)u_{\tilde{x}}-u^2v_{\tilde{x}} & u^2v_{\tilde{x}}-v^2u_{\tilde{x}} \\ v^2u_{\tilde{x}}-u^2v_{\tilde{x}} & v(2v-u)v_{\tilde{x}}-v^2u_{\tilde{x}} \end{pmatrix} \\ +\begin{pmatrix} \frac{1}{2}(u-v)^2u_{\tilde{x}} & u_{\tilde{x}} \\ -\frac{1}{2}(u-v)^2v_{\tilde{x}} & v_{\tilde{x}} \end{pmatrix}\left(\frac{d}{d\tilde{x}}\right)^{-1}\begin{pmatrix} u_{\tilde{x}} & v_{\tilde{x}} \\ \frac{1}{2}(u-v)^2u_{\tilde{x}} & -\frac{1}{2}(u-v)^2v_{\tilde{x}} \end{pmatrix}\end{aligned} \tag{45}$$

with the corresponding density

$$h(u,v)=\frac{(\ln u)^2+(\ln v)^2}{4(v-u)}.$$

Notice that the local part of the Hamiltonian operator (45),

$$(u-v)^2\begin{pmatrix} u^2 & 0 \\ 0 & -v^2 \end{pmatrix}\frac{d}{d\tilde{x}}+(u-v)\begin{pmatrix} u(2u-v)u_{\tilde{x}}-u^2v_{\tilde{x}} & u^2v_{\tilde{x}}-v^2u_{\tilde{x}} \\ v^2u_{\tilde{x}}-u^2v_{\tilde{x}} & v(2v-u)v_{\tilde{x}}-v^2u_{\tilde{x}} \end{pmatrix}, \tag{46}$$

is itself Hamiltonian, indeed, the metric

$$(u-v)^{-2}\left(\frac{du^2}{u^2}-\frac{dv^2}{v^2}\right)$$

is flat.

One can show that the operators (43), (44) and (46) (are arbitrary linear combinations thereof) are the only local Hamiltonian structures of Dubrovin–Novikov type of the system (37). This follows from the fact that the metric

$$(u-v)^{-2}\left(\frac{du^2}{f(u)}-\frac{dv^2}{\varphi(v)}\right)$$

is flat if and only if

$$f(u)=\alpha u^2+\beta u+\gamma, \quad \varphi(v)=-\alpha v^2-\beta v-\gamma,$$

where α, β and γ are arbitrary constants. These local structures were first discovered in Refs. 23 and 3, and subsequently generalized to polytropic gas dynamics in Refs. 21 and 22. The general nonlocal operator (42) first appeared in Ref. 5.

Example 2: The linear system

$$u_t = u_x, \quad v_t = -v_x, \quad w_t = 0 \tag{47}$$

possesses infinitely many Hamiltonian representations

$$\begin{pmatrix} u \\ v \\ w \end{pmatrix}_t = J \begin{pmatrix} \partial h/\partial u \\ \partial h/\partial v \\ \partial h/\partial w \end{pmatrix}$$

with local operators

$$J = 4\begin{pmatrix} f(u) & 0 & 0 \\ 0 & \varphi(v) & 0 \\ 0 & 0 & \psi(w) \end{pmatrix} \frac{d}{dx} + 2\begin{pmatrix} f'(u)u_x & 0 & 0 \\ 0 & \varphi'(v)v_x & 0 \\ 0 & 0 & \psi'(w)w_x \end{pmatrix}.$$

corresponding to flat metrics

$$ds^2 = \frac{du^2}{4f(u)} + \frac{dv^2}{4\varphi(v)} + \frac{dw^2}{4\psi(w)}$$

[here $f(u)$, $\varphi(v)$ and $\psi(w)$ are arbitrary functions]. The corresponding Hamiltonian densities are

$$h(u,v) = \frac{1}{8}\left[\int^u \frac{\mathrm{d}\nu}{\sqrt{f(\nu)}}\right]^2 - \frac{1}{8}\left[\int^v \frac{\mathrm{d}\nu}{\sqrt{\varphi(\nu)}}\right]^2.$$

Consider the reciprocal transformation

$$d\tilde{x} = B\,dx + A\,dt = [w + \tfrac{1}{2}(v-u)]\,dx - \tfrac{1}{2}(u+v)\,dt, \quad \tilde{t} = t, \tag{48}$$

mapping the system (47) to the linearly degenerate semi-Hamiltonian system

$$u_t = (v+w)u_{\tilde{x}}, \quad v_t = (u-w)v_{\tilde{x}}, \quad w_t = \tfrac{1}{2}(u+v)w_{\tilde{x}}. \tag{49}$$

Notice that under the change of variables

$$u = -c + s - \frac{1}{\rho}, \quad v = -c - s + \frac{1}{\rho}, \quad w = s, \tag{50}$$

system (49) takes the form of equations of gas dynamics

$$\rho_t + \partial_{\tilde{x}}(\rho c) = 0, \quad c_t + c c_{\tilde{x}} + \frac{1}{\rho}\partial_{\tilde{x}} P(\rho, s) = 0, \quad s_t + c s_{\tilde{x}} = 0 \tag{51}$$

with the special equation of state $P = s - 1/\rho$ generalizing isentropic Chaplygin gas [see Refs. 29 and 19].

To calculate the transformed Hamiltonian operators (3), we introduce the conformal metric (9),

$$d\tilde{s}^2 = \frac{ds^2}{B^2} = (2w + v - u)^{-2}\left(\frac{du^2}{f(u)} + \frac{dv^2}{\varphi(v)} + \frac{dw^2}{\psi(w)}\right),$$

which is no longer flat in general. Following the recipe of Theorem 1, we introduce the Hamiltonian flow generated by the Hamiltonian operator (3) and the Hamiltonian density $B = w + \frac{1}{2}(v - u)$. A simple computation gives the system

$$u_\tau=-f'(u)u_x,\quad v_\tau=\varphi'(v)v_x,\quad w_\tau=2\psi'(w)w_x, \tag{52}$$

which commutes with (47). To incorporate the time τ into the reciprocal transformation (48), we calculate the flux of the density B corresponding to the flow (52),

$$\tfrac{1}{2}(\nabla B)^2=\tfrac{1}{2}[f(u)+\varphi(v)+4\psi(w)].$$

Thus, transformation (48) takes the form

$$d\tilde{x}=Bdx+Adt+\tfrac{1}{2}(\nabla B)^2d\tau=[w+\tfrac{1}{2}(v-u)]dx-\tfrac{1}{2}(v+u)dt+\tfrac{1}{2}[f(u)+\varphi(v)+4\psi(w)]d\tau,$$

$$\tilde{t}=t,$$

so that the transformed flow (52) is

$$u_\tau=w^1u_{\tilde{x}},\quad v_\tau=w^2v_{\tilde{x}},\quad w_\tau=w^3w_{\tilde{x}}, \tag{53}$$

where

$$\begin{aligned}
w^1&=-\tfrac{1}{2}(2w+v-u)f'(u)-\tfrac{1}{2}[f(u)+\varphi(v)+4\psi(w)],\\
w^2&=\tfrac{1}{2}(2w+v-u)\varphi'(v)-\tfrac{1}{2}[f(u)+\varphi(v)+4\psi(w)],\\
w^3&=(2w+v-u)\psi'(w)-\tfrac{1}{2}[f(u)+\varphi(v)+4\psi(w)].
\end{aligned} \tag{54}$$

Notice that Eqs. (53) and (54) constitute a general commuting flow of the linearly degenerate system (49). According to Theorem 1, the system (49) is Hamiltonian,

$$\begin{pmatrix} u\\ v\\ w\end{pmatrix}_t=\tilde{J}\begin{pmatrix}\partial\tilde{h}/\partial u\\ \partial\tilde{h}/\partial v\\ \partial\tilde{h}/\partial w\end{pmatrix},$$

with nonlocal operators $\tilde{J}$ of the form

$$\begin{aligned}
&\frac{4}{\rho^2}\begin{pmatrix} f(u) & 0 & 0\\ 0 & \varphi(v) & 0\\ 0 & 0 & \psi(w)\end{pmatrix}\frac{d}{d\tilde{x}}\\
&\quad+\frac{2}{\rho}\begin{pmatrix} \frac{1}{\rho}f'(u)u_{\tilde{x}}+2f(u)\left(\frac{1}{\rho}\right)_{\tilde{x}} & -\varphi(v)u_{\tilde{x}}-f(u)v_{\tilde{x}} & -2\psi(w)u_{\tilde{x}}-f(u)w_{\tilde{x}}\\ \varphi(v)u_{\tilde{x}}+f(u)v_{\tilde{x}} & \frac{1}{\rho}\varphi'(v)v_{\tilde{x}}+2\varphi(v)\left(\frac{1}{\rho}\right)_{\tilde{x}} & -2\psi(w)v_{\tilde{x}}+\varphi(v)w_{\tilde{x}}\\ 2\psi(w)u_{\tilde{x}}+f(u)w_{\tilde{x}} & 2\psi(w)v_{\tilde{x}}-\varphi(v)w_{\tilde{x}} & \frac{1}{\rho}\psi'(w)v_{\tilde{x}}+2\psi(w)\left(\frac{1}{\rho}\right)_{\tilde{x}}\end{pmatrix}\\
&\quad+\begin{pmatrix} w^1u_{\tilde{x}} & u_{\tilde{x}}\\ w^2v_{\tilde{x}} & v_{\tilde{x}}\\ w^3w_{\tilde{x}} & w_{\tilde{x}}\end{pmatrix}\left(\frac{d}{d\tilde{x}}\right)^{-1}\begin{pmatrix} u_{\tilde{x}} & v_{\tilde{x}} & w_{\tilde{x}}\\ w^1u_{\tilde{x}} & w^2v_{\tilde{x}} & w^3w_{\tilde{x}}\end{pmatrix}
\end{aligned} \tag{55}$$

and the Hamiltonian densities

$$\tilde{h}=h/B=\frac{\rho}{8}\left(\left[\int^{u}\frac{d\nu}{\sqrt{f(\nu)}}\right]^2-\left[\int^{v}\frac{d\nu}{\sqrt{\varphi(\nu)}}\right]^2\right),$$

where $2w+v-u=2/\rho$ [see (50)]. We point out that the corresponding metric (9) is flat if and only if

$$f(u)=\varepsilon u+\alpha,\quad \varphi(v)=\varepsilon v+\beta,\quad \psi(w)=-\frac{\varepsilon}{2}w+\gamma,$$

where the constants α, β, γ and ε are constrained by $\alpha+\beta+4\gamma=0$. In this case $w^1=w^2=w^3=0$, so that the corresponding operators (55) are local, thus providing three nonequivalent Hamiltonian structures of Dubrovin–Novikov type.

IV. RECIPROCAL TRANSFORMATIONS WHICH CHANGE BOTH *x* AND *t*

Consider again the Hamiltonian system (1),

$$u^i_t=v^i_j(u)u^j_x=(\nabla^i\nabla_j h)u^j_x=J^{ij}\frac{\partial h}{\partial u^j},$$

with the local Hamiltonian operator

$$J^{ij}=g^{ij}\frac{d}{dx}-g^{is}\Gamma^j_{sk}u^k_x$$

corresponding to the flat metric g^{ij}. In this section we discuss the behavior of Hamiltonian operators (2) under general reciprocal transformations

$$d\tilde{x}=B(u)dx+A(u)dt,\quad d\tilde{t}=N(u)dx+M(u)dt$$

of the form (3) which map system (1) to the system (4),

$$u^i_{\tilde{t}}=\tilde{v}^i_j(u)u^j_{\tilde{x}},\quad \tilde{v}=(Bv-AE)(ME-Nv)^{-1},\quad E=id.$$

First of all, we introduce the transformed metric

$$\tilde{g}_{ij}=\frac{(M\delta^s_i-Nv^s_i)(M\delta^r_j-Nv^j_r)}{(BM-AN)^2}g_{sr},\tag{56}$$

which is no longer flat in general. This metric will generate the local part of the transformed Hamiltonian operator $\tilde{J}$.

Remark: In the particular case of reciprocal transformations changing only the variable x, we have $N=0$, $M=1$ so that formula (56) reduces to the conformal transformation

$$\tilde{g}_{ij}=g_{ij}/B^2.$$

Similarly, if we interchange the independent variables (that is, if $A=N=1$, $B=M=0$), we have

$$\tilde{g}_{ij}=v^s_i g_{sr}v^r_j,$$

which coincides with the formula proposed in Ref. 28. Notice that in the second case the metric $\tilde{g}_{ij}$ is automatically flat, which means that the local Hamiltonian formalism is invariant under the interchange of independent variables.

To calculate the nonlocal "tail" of the transformed operator $\widetilde{J}$, we introduce the Hamiltonian flows

$$u^i_\tau=(\nabla^i\nabla_j N)u^j_x=J^{ij}\frac{\partial N}{\partial u^j} \tag{57}$$

and

$$u^i_\zeta=(\nabla^i\nabla_j B)u^j_x=J^{ij}\frac{\partial B}{\partial u^j}, \tag{58}$$

generated by the Hamiltonian operator J^{ij} and the Hamiltonian densities N and B which enter the reciprocal transformation (3). Clearly, systems (57) and (58) commute with (1). To incorporate the times τ and ζ into the reciprocal transformation (3), we calculate the fluxes P, Q and R, S of the Hamiltonian densities B and N,

$$d\tilde{x}=Bdx+Adt+Pd\tau+Qd\zeta,$$

$$d\tilde{t}=Ndx+Mdt+Rd\tau+Sd\zeta,$$

that is, the coefficients which make these one-forms closed by virtue of (1), (57) and (58). Here

$$Q=\tfrac{1}{2}(\nabla B)^2=\tfrac{1}{2}g^{ij}B_iB_j,$$

$$R=\tfrac{1}{2}(\nabla N)^2=\tfrac{1}{2}g^{ij}N_iN_j,$$

(see Ref. 28) and P, S are normalized as

$$P+S=(\nabla B,\nabla N)=g^{ij}B_iN_j.$$

Therefore, the transformed flows (57) and (58) take the forms

$$u^i_\tau=\mu^i_j(u)u^j_{\tilde{x}} \tag{59}$$

and

$$u^i_\zeta=\lambda^i_j(u)u^j_{\tilde{x}}, \tag{60}$$

where the matrices μ^i_j and λ^i_j are

$$\mu^i_j=B\nabla^i\nabla_jN-P\delta^i_j+N\tilde{v}^k_j\nabla^i\nabla_kN-R\tilde{v}^i_j \tag{61}$$

and

$$\lambda^i_j=B\nabla^i\nabla_jB-Q\delta^i_j+N\tilde{v}^k_j\nabla^i\nabla_kB-S\tilde{v}^i_j, \tag{62}$$

respectively [these formulas readily follow from (57) and (58) after one changes from x, t, τ, ζ to $\tilde{x}$, $\tilde{t}$, τ, ζ]. The transformed flows (59) and (60) commute with (4). Now we can formulate the main result of this section.

Theorem 3: *After the reciprocal transformation* (3), *the local Hamiltonian operator* (2) *corresponding to the flat metric* g^{ij} *becomes nonlocal of the form*

$$\tilde{J}^{ij}=\tilde{g}^{ij}\frac{d}{d\tilde{x}}-\tilde{g}^{is}\tilde{\Gamma}^{j}_{sk}u^{k}_{\tilde{x}}+\lambda^{i}_{k}u^{k}_{\tilde{x}}\left(\frac{d}{d\tilde{x}}\right)^{-1}u^{j}_{\tilde{x}}+u^{i}_{\tilde{x}}\left(\frac{d}{d\tilde{x}}\right)^{-1}\lambda^{j}_{k}u^{k}_{\tilde{x}}$$
$$+\mu^{i}_{k}u^{k}_{\tilde{x}}\left(\frac{d}{d\tilde{x}}\right)^{-1}\tilde{v}^{j}_{n}u^{n}_{\tilde{x}}+\tilde{v}^{i}_{n}u^{n}_{\tilde{x}}\left(\frac{d}{d\tilde{x}}\right)^{-1}\mu^{j}_{k}u^{k}_{\tilde{x}}.$$

Here the local part is defined by the metric $\tilde{g}^{ij}$ given by (56), $\tilde{\Gamma}$ is the Levi-Civita connection of $\tilde{g}$, and the nonlocal terms λ^{i}_{j}, μ^{i}_{j} and $\tilde{v}^{i}_{j}$ are defined in (61), (62) and (4). In particular, the curvature tensor of $\tilde{g}^{ij}$ is

$$\tilde{R}^{ij}_{kl}=\lambda^{i}_{k}\delta^{j}_{l}+\lambda^{j}_{l}\delta^{i}_{k}-\lambda^{j}_{k}\delta^{i}_{l}-\lambda^{i}_{l}\delta^{j}_{k}+\mu^{i}_{k}\tilde{v}^{j}_{l}+\mu^{j}_{l}\tilde{v}^{i}_{k}-\mu^{j}_{k}\tilde{v}^{i}_{l}-\mu^{i}_{l}\tilde{v}^{j}_{k}.$$

The proof of Theorem 3 will follow from general results of Sec. V.

As an illustration of this procedure, we explicitly calculate nonlocal Hamiltonian operators associated with the three-component linearly degenerate system (10).

Example 3: We start with the same linear system (47) as in Example 2,

$$u_t=u_x,\qquad v_t=-v_x,\qquad w_t=0,$$

which possesses infinitely many Hamiltonian structures with operators

$$J=\begin{pmatrix} f(u) & 0 & 0\\ 0 & \varphi(v) & 0\\ 0 & 0 & \frac{1}{4}\psi(w)\end{pmatrix}\frac{d}{dx}+\frac{1}{2}\begin{pmatrix} f'u_x & 0 & 0\\ 0 & \varphi'v_x & 0\\ 0 & 0 & \frac{1}{4}\psi'w_x\end{pmatrix} \tag{63}$$

corresponding to flat metrics

$$ds^2=\frac{du^2}{f(u)}+\frac{dv^2}{\varphi(v)}+4\frac{dw^2}{\psi(w)} \tag{64}$$

[here $f(u)$, $\varphi(v)$ and $\psi(w)$ are arbitrary functions; the multiple 4 is chosen for convenience].

Consider the reciprocal transformation

$$\begin{aligned} d\tilde{x}&=Bdx+Adt=(2w^2-u^2-v^2)dx+(v^2-u^2)dt,\\ d\tilde{t}&=Ndx+Mdt=(u+v-2w)dx+(u-v)dt,\end{aligned} \tag{65}$$

which maps system (47) to the three-component linearly degenerate semi-Hamiltonian system

$$u^{\sim}_{\tilde{t}}=(v+w)u_{\tilde{x}},\quad v^{\sim}_{\tilde{t}}=(u+w)v_{\tilde{x}},\quad w^{\sim}_{\tilde{t}}=(u+v)w_{\tilde{x}}. \tag{66}$$

The transformed metric (64) [apply formula (56)],

$$d\tilde{s}^2=\frac{du^2}{(u-v)^2(u-w)^2f(u)}+\frac{dv^2}{(v-u)^2(v-w)^2\varphi(v)}+\frac{dw^2}{(w-u)^2(w-v)^2\psi(w)}, \tag{67}$$

is no longer flat for generic $f(u)$, $\varphi(v)$ and $\psi(w)$. The commuting flows of system (47) generated by the Hamiltonian densities $N=u+v-2w$ and $B=2w^2-u^2-v^2$ are

$$u_\tau=\tfrac{1}{2}f'u_x,\quad v_\tau=\tfrac{1}{2}\varphi'v_x,\quad w_\tau=-\tfrac{1}{4}\psi'w_x \tag{68}$$

and

$$u_\zeta=-(2f+uf')u_x,\quad v_\zeta=-(2\varphi+v\varphi')v_x,\quad w_\zeta=(\psi+\tfrac{1}{2}w\psi')w_x, \tag{69}$$

respectively. To incorporate the times τ and ζ into the reciprocal transformation (65), we have to calculate the fluxes P, Q and R, S of the Hamiltonian densities B and N,

$$\begin{aligned} d\tilde{x}&=Bdx+Adt+Pd\tau+Qd\zeta,\\ d\tilde{t}&=Ndx+Mdt+Rd\tau+Sd\zeta, \end{aligned} \tag{70}$$

that is, the coefficients which make these one-forms closed by virtue of (47), (68) and (69). Here

$$Q=\tfrac{1}{2}(\nabla B)^2=2[u^2f(u)+v^2\varphi(v)+w^2\psi(w)],$$

$$R=\tfrac{1}{2}(\nabla N)^2=\tfrac{1}{2}[f(u)+\varphi(v)+\psi(w)],$$

while P and S are of the form

$$P=-uf-v\varphi-w\psi+\int^u f(\nu)\mathrm{d}\nu+\int^v \varphi(\nu)\mathrm{d}\nu+\int^w \psi(\nu)\mathrm{d}\nu,$$

$$S=-uf-v\varphi-w\psi-\int^u f(\nu)\mathrm{d}\nu-\int^v \varphi(\nu)\mathrm{d}\nu-\int^w \psi(\nu)\mathrm{d}\nu,$$

respectively. Notice that $P+S=(\nabla B,\,\nabla N)=g^{ij}B_iN_j$. Under the extended reciprocal transformation (70), the commuting flows (68) and (69) take the form

$$u_\tau=\mu^1u_{\tilde{x}},\quad v_\tau=\mu^2v_{\tilde{x}},\quad w_\tau=\mu^3w_{\tilde{x}} \tag{71}$$

and

$$u_\zeta=\lambda^1u_{\tilde{x}},\quad v_\zeta=\lambda^2v_{\tilde{x}},\quad w_\zeta=\lambda^3w_{\tilde{x}}, \tag{72}$$

where the characteristic speeds are

$$\mu^1=-\tfrac{1}{2}(u-v)(u-w)f'-(v+w)R-P,$$

$$\mu^2=-\tfrac{1}{2}(v-u)(v-w)\varphi'-(u+w)R-P,$$

$$\mu^3=-\tfrac{1}{2}(w-u)(w-v)\psi'-(u+v)R-P,$$

and

$$\lambda^1=(u-v)(u-w)(2f+uf')-(v+w)S-Q,$$

$$\lambda^2=(v-u)(v-w)(2\varphi+v\varphi')-(u+w)S-Q,$$

$$\lambda^3=(w-u)(w-v)(2\psi+w\psi')-(u+v)S-Q,$$

respectively. The transformed flows (71) and (72) commute with (66). According to Theorem 2, the transformed metric (67) and the transformed flows (71) and (72) generate the nonlocal Hamiltonian operator which, in matrix form, is

$$\tilde{J}=\begin{pmatrix}\tilde{g}^{11}&0&0\\0&\tilde{g}^{22}&0\\0&0&\tilde{g}^{33}\end{pmatrix}\frac{d}{d\tilde{x}}$$
$$+\begin{pmatrix}\tilde{g}^{11}\left[\frac{f'(u)}{2f(u)}u_{\tilde{x}}+\frac{u_{\tilde{x}}-v_{\tilde{x}}}{u-v}+\frac{u_{\tilde{x}}-w_{\tilde{x}}}{u-w}\right] & \frac{\tilde{g}^{22}u_{\tilde{x}}+\tilde{g}^{11}v_{\tilde{x}}}{u-v} & \frac{\tilde{g}^{33}u_{\tilde{x}}+\tilde{g}^{11}w_{\tilde{x}}}{u-w}\\ -\frac{\tilde{g}^{22}u_{\tilde{x}}+\tilde{g}^{11}v_{\tilde{x}}}{u-v} & \tilde{g}^{22}\left[\frac{\varphi'(v)}{2\varphi(v)}v_{\tilde{x}}+\frac{u_{\tilde{x}}-v_{\tilde{x}}}{u-v}+\frac{v_{\tilde{x}}-w_{\tilde{x}}}{v-w}\right] & \frac{\tilde{g}^{33}v_{\tilde{x}}+\tilde{g}^{22}w_{\tilde{x}}}{v-w}\\ -\frac{\tilde{g}^{33}u_{\tilde{x}}+\tilde{g}^{11}w_{\tilde{x}}}{u-w} & -\frac{\tilde{g}^{33}v_{\tilde{x}}+\tilde{g}^{22}w_{\tilde{x}}}{v-w} & \tilde{g}^{33}\left[\frac{\psi'(w)}{2\psi(w)}w_{\tilde{x}}+\frac{w_{\tilde{x}}-v_{\tilde{x}}}{w-v}+\frac{u_{\tilde{x}}-w_{\tilde{x}}}{u-w}\right]\end{pmatrix}$$
$$+\begin{pmatrix}\lambda^1u_{\tilde{x}}&\mu^1u_{\tilde{x}}&\eta^1v_{\tilde{x}}&u_{\tilde{x}}\\ \lambda^2v_{\tilde{x}}&\mu^2v_{\tilde{x}}&\eta^2v_{\tilde{x}}&v_{\tilde{x}}\\ \lambda^3w_{\tilde{x}}&\mu^3w_{\tilde{x}}&\eta^3w_{\tilde{x}}&w_{\tilde{x}}\end{pmatrix}\left(\frac{d}{d\tilde{x}}\right)^{-1}\begin{pmatrix}u_{\tilde{x}}&v_{\tilde{x}}&w_{\tilde{x}}\\ \eta^1u_{\tilde{x}}&\eta^2v_{\tilde{x}}&\eta^3w_{\tilde{x}}\\ \mu^1u_{\tilde{x}}&\mu^2v_{\tilde{x}}&\mu^3w_{\tilde{x}}\\ \lambda^1u_{\tilde{x}}&\lambda^2v_{\tilde{x}}&\lambda^3w_{\tilde{x}}\end{pmatrix},$$

where $\tilde{g}^{ii}$ are components of the transformed metric (67), $\eta^1=v+w$, $\eta^2=u+w$ and $\eta^3=u+v$ are the characteristic speeds of system (66), and λ^k, μ^k are the characteristic speeds of its commuting flows (71) and (72). In the particular case $f(u)=\alpha$, $\varphi(v)=\beta$ and $\psi(w)=\gamma$, where α, β, γ are constants subject to a single constraint $\alpha+\beta+\gamma=0$, we have $\lambda^k=\mu^k=0$, so that the transformed operator takes the local Dubrovin–Novikov form, the corresponding flat metric being

$$d\tilde{s}^2=\frac{du^2}{\alpha(u-v)^2(u-w)^2}+\frac{dv^2}{\beta(v-u)^2(v-w)^2}+\frac{dw^2}{\gamma(w-u)^2(w-v)^2}.$$

As shown in Ref. 23, these are the only local Hamiltonian structures of hydrodynamic type of the three-component system (66).

Remark: Modifying the reciprocal transformation (65) from Example 3 as

$$d\tilde{x}=[2R(w)-P(u)-Q(v)]dx+[Q(v)-P(u)]dt,$$

$$d\tilde{t}=[A(u)+B(v)-2C(w)]dx+[A(u)-B(v)]dt,$$

we obtain the transformed system

$$u_{\tilde{t}}=\frac{R(w)-Q(v)}{C(w)-B(v)}u_{\tilde{x}},\quad v_{\tilde{t}}=\frac{P(u)-R(w)}{A(u)-C(w)}v_{\tilde{x}},\quad w_{\tilde{t}}=\frac{Q(v)-P(u)}{B(v)-A(u)}w_{\tilde{x}},\tag{73}$$

where $A(u)$, $B(v)$, $C(w)$ and $P(u)$, $Q(v)$, $R(w)$ are arbitrary functions. As shown in Ref. 12, formulas (73) define a general three-component linearly degenerate semi-Hamiltonian system. Repeating the construction of Example 3, one can obtain the associated family of nonlocal Hamiltonian structures.

V. GENERALIZED RECIPROCAL TRANSFORMATIONS

Consider N commuting flows of hydrodynamic type

$$R^i_{t^\beta}=v^i_\beta(R)R^i_{t^1},\quad i=1,2,\ldots n,\quad \beta=1,2,\ldots,N,\tag{74}$$

where we have set $t^1\equiv x$ and $t^2\equiv t$ (so that $v^i_1\equiv 1$). We assume that the flows (74) are Hamiltonian with the local Hamiltonian operator (2) generated by the flat metric $ds^2=g_{ii}(R)dR^{i^2}$, so that $v^i_\beta=\nabla^i\nabla_i h_\beta$, where h_β are the corresponding Hamiltonian densities. Let us change from t^1, $t^2,\ldots,t^N$ to the new independent variables $\tilde{t}^1$, $\tilde{t}^2,\ldots,\tilde{t}^N$ defined as

$$d\tilde{t}^\gamma=a^\gamma_\beta(R)dt^\beta,\quad \gamma,\beta=1,2,\ldots N,\tag{75}$$

where $a_1^\gamma(R)$ are the conserved densities of systems (74), and $a_\beta^\gamma(R)$ are the corresponding fluxes:

$$\partial_{t^\beta} a_1^\gamma = \partial_{t^1} a_\beta^\gamma. \tag{76}$$

Transformations of the type (75) naturally generalize reciprocal transformations (the case $N=2$). Under the *generalized* reciprocal transformation (75), the commuting flows (74) transforms to

$$R^i_{\tilde{t}^\beta} = \tilde{v}^i_\beta(R) R^i_{\tilde{t}^1}, \tag{77}$$

where

$$\tilde{v}^i_\beta = \frac{A^\gamma_\beta v^i_\gamma}{A^\nu_1 v^i_\nu}, \tag{78}$$

while the metric ds^2 transforms to

$$d\tilde{s}^2 = \tilde{g}_{ii} dR^{i^2}, \quad \tilde{g}_{ii} = g_{ii}(A^\nu_1 v^i_\nu)^2. \tag{79}$$

Here A^β_γ is the inverse of a^ν_β,

$$dt^\beta = A^\beta_\gamma d\tilde{t}^\gamma. \tag{80}$$

We emphasize that the transformed metric $d\tilde{s}^2$ is no longer flat in general. In the particular case $N=2$ formula (79) reduces to (56). To calculate the curvature tensor of the metric $d\tilde{s}^2$ we introduce N extra flows

$$R^i_{\tau^\gamma} = w^i_\gamma(R) R^i_{t^1}, \quad i=1,2,\ldots,n, \quad \gamma=1,2,\ldots,N, \tag{81}$$

generated by the Hamiltonian operator (2) and the Hamiltonian densities $a_1^\beta(R)$:

$$w^i_\beta = \nabla^i \nabla_i a_1^\beta.$$

Clearly, the flows (81) commute with (74). To calculate the transformed flows (81), we have to incorporate the times τ^β into the generalized reciprocal transformation (75), namely,

$$d\tilde{t}^\gamma = a^\gamma_\beta dt^\beta + c^\gamma_\beta d\tau^\beta, \quad \gamma,\beta = 1,2,\ldots,N.$$

Here the fluxes c^γ_β are restricted by

$$c^\beta_\gamma + c^\gamma_\beta = (\nabla a_1^\beta, \quad \nabla a_1^\gamma) = \sum g^{kk} (\partial_k a_1^\beta)(\partial_k a_1^\gamma), \tag{82}$$

where $(\nabla f, \nabla g)$ denotes a scalar product of the gradients of f and g in the metric ds^2. Finally, the transformed flows (81) take the form

$$R^i_{\tau^\gamma} = \tilde{w}^i_\gamma(R) R^i_{\tilde{t}^1}, \tag{83}$$

with

$$\tilde{w}^i_\gamma = \frac{w^i_\gamma - c^\beta_\gamma A^\varepsilon_\beta v^i_\varepsilon}{A^\nu_1 v^i_\nu}. \tag{84}$$

Theorem 4: *The curvature tensor of the transformed metric $d\tilde{s}^2$ is*

$$\tilde{R}^{ij}_{ij}=\sum_{\beta=1}^{N}(\tilde{v}^i_\beta\tilde{w}^j_\beta+\tilde{v}^j_\beta\tilde{w}^i_\beta).$$

The metric $d\tilde{s}^2$ generates the nonlocal Hamiltonian operator

$$\tilde{J}^{ij}=\tilde{g}^{ii}\delta^{ij}\frac{d}{d\tilde{x}}-\tilde{g}^{ii}\tilde{\Gamma}^j_{ik}R^k_{\tilde{x}}+\sum_{\beta=1}^{N}\tilde{v}^i_\beta R^i_{\tilde{x}}\left(\frac{d}{d\tilde{x}}\right)^{-1}\tilde{w}^j_\beta R^j_{\tilde{x}}+\sum_{\beta=1}^{N}\tilde{w}^i_\beta R^i_{\tilde{x}}\left(\frac{d}{d\tilde{x}}\right)^{-1}\tilde{v}^j_\beta R^j_{\tilde{x}}.$$

Proof: Let us introduce the Lame coefficients $H_{1i}=\sqrt{g_{ii}}$ and the rotation coefficients $\beta_{ik}=\partial_i H_{1k}/H_{1i}$ (for any $i\neq k$). According to Ref. 28, the linear problem

$$\partial_i H_k=\beta_{ik}H_i,\quad i\neq k,$$

has N particlular solutions $H_{\beta i}$, where $H_{\beta i}=v^i_\beta H_{1i}$, and N other solutions H^β_i, where $H^\beta_i=w^i_\beta H_{1i}$. Since commuting flows (74) and (81) are locally Hamiltonian ($v^i_\beta=\nabla^i\nabla_i h_\beta$ and $w^i_\beta=\nabla^i\nabla_i a^\beta_1$), the relationship between conserved densities (h_β and a^β_1) and the corresponding commuting flows (v^i_β and w^i_β) can be written as

$$H_{\beta i}=\psi_{\beta i,i}+\sum_{m\neq i}\beta_{mi}\psi_{\beta m},\quad H^\beta_i=\psi^\beta_{i,i}+\sum_{m\neq i}\beta_{mi}\psi^\beta_m, \tag{85}$$

where $\psi_{\beta i}$ and ψ^β_i are defined by the equations $\partial_i h_\beta=\psi_{\beta i}H_{1i}$ and $\partial_i a^\beta_1=\psi^\beta_i H_{1i}$. In this notation the formulas (78), (84) and (79) become

$$\tilde{H}_{\beta i}=A^\gamma_\beta H_{\gamma i},\quad \tilde{H}^\beta_i=H^\beta_i-\tilde{H}_{\gamma i}c^\gamma_\beta$$

(where $\tilde{v}^i_\beta=\tilde{H}_{\beta i}/\tilde{H}_{1i}$ and $\tilde{w}^i_\beta=\tilde{H}^\beta_i/\tilde{H}_{1i}$) and the transformed rotation coefficients are

$$\tilde{\beta}_{ik}=\beta_{ik}-\psi^\beta_i\tilde{H}_{\beta k}.$$

Since the metric ds^2 is flat, the curvature components R^i_{jik} ($i\neq j\neq k$) vanish identically, that is, $\partial_i\beta_{jk}=\beta_{ji}\beta_{ik}$ ($i\neq j\neq k$). This identity is preserved under generalized reciprocal transformations: $\partial_i\tilde{\beta}_{jk}=\tilde{\beta}_{ji}\tilde{\beta}_{ik}$. However, the components $\tilde{R}^{ij}_{ij}$ defined as

$$\tilde{R}^{ij}_{ij}=-\frac{\tilde{\Delta}_{ij}}{\tilde{H}_{1i}\tilde{H}_{1j}},$$

where

$$\tilde{\Delta}_{ij}\equiv\partial_i\tilde{\beta}_{ij}+\partial_j\tilde{\beta}_{ji}+\sum_{m\neq i}\tilde{\beta}_{mi}\tilde{\beta}_{mj},$$

will no longer be zero. Indeed,

$$\begin{aligned}\tilde{\Delta}_{ij}&=\partial_i\tilde{\beta}_{ij}+\partial_j\tilde{\beta}_{ji}+\sum_{m\neq i\neq k}\tilde{\beta}_{mi}\tilde{\beta}_{mj}\\&=\partial_i[\beta_{ij}-\psi^\gamma_i\tilde{H}_{\gamma j}]+\partial_j[\beta_{ji}-\psi^\gamma_j\tilde{H}_{\gamma i}]+\sum_{m\neq i\neq j}(\beta_{mi}-\psi^\gamma_m\tilde{H}_{\gamma i})(\beta_{mj}-\psi^\beta_m\tilde{H}_{\beta j})\\&=\Delta_{ij}-\tilde{H}_{\gamma j}\left[\psi^\gamma_{i,i}+\sum_{m\neq i}\beta_{mi}\psi^\gamma_m\right]\end{aligned}$$

$$-\tilde{H}_{\gamma i}\left[\psi^{\gamma}_{j,j}+\sum_{m\neq j}\beta_{mj}\psi^{\gamma}_{m}\right]+\tilde{H}_{\beta i}\tilde{H}_{\gamma j}\sum\ \psi^{\beta}_{m}\psi^{\gamma}_{m}.$$

Since $\Delta_{ij}\equiv 0$, Eqs. (85) and (82) imply

$$\begin{aligned}\tilde{\Delta}_{ij}&=-\tilde{H}_{\gamma j}H^{\gamma}_{i}-\tilde{H}_{\gamma i}H^{\gamma}_{j}+\tilde{H}_{\gamma i}\tilde{H}_{\beta j}(c^{\beta}_{\gamma}+c^{\gamma}_{\beta})\\&=-\tilde{H}_{\beta j}[H^{\beta}_{i}-\tilde{H}_{\gamma i}c^{\gamma}_{\beta}]-\tilde{H}_{\beta j}[H^{\beta}_{i}-\tilde{H}_{\gamma i}c^{\gamma}_{\beta}]\\&=-\tilde{H}_{\beta j}\tilde{H}^{\beta}_{i}-\tilde{H}_{\beta i}\tilde{H}^{\beta}_{j}.\end{aligned}$$

Thus, the transformed curvature tensor is

$$\tilde{R}^{ij}_{ij}=-\frac{1}{\tilde{H}_{1i}\tilde{H}_{1j}}\tilde{\Delta}_{ij}=\frac{\tilde{H}_{\beta j}\tilde{H}^{\beta}_{i}+\tilde{H}_{\beta i}\tilde{H}^{\beta}_{j}}{\tilde{H}_{1i}\tilde{H}_{1j}}=\tilde{v}^{i}_{\beta}\tilde{w}^{j}_{\beta}+\tilde{v}^{j}_{\beta}\tilde{w}^{i}_{\beta}.$$

For $N=2$ this proves Theorem 2 formulated in Sec. IV.

As shown in Ref. 12, any linearly degenerate semi-Hamiltonian system in Riemann invariants can be linearized by a generalized reciprocal transformation. Applying the results of Sec. V to local Hamiltonian structures of a linear system, one can explicitly construct an infinity of mutually compatible nonlocal Hamiltonian structures for an arbitrary linearly degenerate semi-Hamiltonian system in the same way as it was done in Examples 1–3. In the example below we explicitly construct nonlocal Hamiltonian formalism for the n-component linearly degenerate system mentioned in the abstract.

Example 4: As shown in Ref. 12, the linearly degenerate semi-Hamiltonian system

$$R^{i}_{\tilde{t}^2}=\left(R^{i}-\sum_{m=1}^{n}R^{m}\right)R^{i}_{\tilde{t}^1},\quad i=1,2,\ldots,n, \tag{86}$$

and its linearly degenerate commuting flows

$$R^{i}_{\tilde{t}^{\beta}}=(-1)^{\beta+1}(\partial_i\tilde{h}_{\beta})R^{i}_{\tilde{t}^1},\quad i=1,2,\ldots,n,\quad \beta=3,4,\ldots,n,$$

where

$$\tilde{h}=\prod_{k=1}^{n}(1+\lambda R^{k})=1+\lambda\tilde{h}_1+\lambda^2\tilde{h}_2+\lambda^3\tilde{h}_3+\cdots+\lambda^n\tilde{h}_n,$$

can be obtained from a set of commuting linear flows

$$R^{i}_{t^{\beta}}=(\varepsilon^{i})^{\beta-1}R^{i}_{t^1},\quad \beta=1,2,\ldots,n$$

(ε^{i} are arbitrary constants) by a generalized reciprocal transformation,

$$d\tilde{t}^{\beta}=a^{\beta}_{\gamma}dt^{\gamma},$$

where

$$a^{\beta}_{\gamma}=\sum_{k=1}^{n}(\varepsilon^{k})^{\gamma-1}(R^{k})^{n-\beta}.$$

In the two- and three-component cases the explicit form of this transformation is stated in Examples 1 and 3. The inverse reciprocal transformation is

$$dt^{\beta}=A^{\beta}_{\gamma}d\tilde{t}^{\gamma},$$

where

$$A^{\beta}_{\gamma}=\sum_{k=1}^{n}(-1)^{n+\gamma+\beta+1}\frac{\partial_k\tilde{\varepsilon}_{n+1-\gamma}}{\Pi^{n}_{m\neq k}(\varepsilon^k-\varepsilon^m)}\frac{\partial_k\tilde{h}_{\beta}}{\Pi^{n}_{s\neq k}(R^k-R^s)}$$

and

$$\tilde{\varepsilon}=\prod_{k=1}^{n}(1+\lambda\varepsilon^k)=1+\lambda\tilde{\varepsilon}_1+\lambda^2\tilde{\varepsilon}_2+\lambda^3\tilde{\varepsilon}_3+\cdots+\lambda^n\tilde{\varepsilon}_n.$$

Applying Theorem 4 to local Hamiltonian structures of the corresponding linear systems, we obtain infinitely many nonlocal Hamiltonian operators associated with the system (86):

$$A^{ij}=g^{ii}\delta^{ij}\frac{d}{dx}-g^{ii}\Gamma^{j}_{ik}R^k_x+\sum_{\beta=1}^{n-1}\left[\tilde{v}^i_{\beta}R^i_x\left(\frac{d}{dx}\right)^{-1}\tilde{w}^j_{\beta}R^j_x+\tilde{w}^i_{\beta}R^i_x\left(\frac{d}{dx}\right)^{-1}\tilde{v}^j_{\beta}R^j_x\right]. \tag{87}$$

Here $g_{ii}(dR^i)^2$ is the diagonal metric of the form

$$\frac{dR^{1^2}}{\Pi_{k\neq 1}(R^1-R^k)f^1(R^1)}+\cdots+\frac{dR^{n^2}}{\Pi_{k\neq n}(R^n-R^k)f^n(R^n)}, \tag{88}$$

with the curvature tensor

$$\tilde{R}^{ik}_{ik}=\sum_{\beta=1}^{n-1}(\tilde{v}^i_{\beta}\tilde{w}^k_{\beta}+\tilde{v}^k_{\beta}\tilde{w}^i_{\beta}),$$

where

$$\tilde{v}^i_{\beta}=\partial_i\tilde{h}_{\beta},$$

$$\tilde{w}^i_{\beta}=(n-\beta)\prod_{k\neq i}(R^i-R^k)\left[\frac{1}{2}f_i'(R^i)(R^i)^{n-\beta-1}+(n-\beta-1)f_i(R^i)(R^i)^{n-\beta-2}\right]-\sum_{\gamma=1}^{n-1}\tilde{v}^i_{\gamma}c^{\gamma}_{\beta},$$

$$\partial_i c^{\gamma}_{\beta}=(n-\beta)(n-\gamma)\left[\tfrac{1}{2}f_i'(R^i)(R^i)^{2n-\beta-\gamma-2}+(n-\beta-1)f_i(R^i)(R^i)^{2n-\beta-\gamma-3}\right].$$

Operators (87) depend on n arbitrary functions $f^1(R^1),\ \ldots,\ f^n(R^n)$, and are mutually compatible. It was demonstrated in Ref. 23 that the metric (88) is not flat for $n\geqslant 4$, whatever $f^i(R^i)$ are.

(Received 4 February 2002; accepted 8 November 2002)

In a recent article, certain underdetermined linear systems of partial differential equations connected with Lie–Poisson structures have been studied. They were constructed via power series solutions of the evolution equation for a given Hamiltonian. We extend the results to arbitrary Poisson manifolds, correct an error in the case of degenerate Poisson structures, and show that these linear systems simply characterize Hamiltonian vector fields. Our basic tool is the formal theory of differential equations with its central concept of an involutive system. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1536021]

I. INTRODUCTION

In a recent article, Bender *et al.*[1] studied certain underdetermined linear systems of partial differential equations connected with Lie–Poisson structures. These systems arose from considering power series solutions of the corresponding evolution equations. In the present work their results are extended to arbitrary Poisson manifolds and the relation to Poisson geometry is clarified. In particular, it turns out that these systems are simply the equations characterizing the Hamiltonian vector fields on the manifold.

Furthermore, we correct an error in the cited work. For degenerate Poisson structures, i.e., if the Poisson matrix J is singular, the claimed expression is *not* the general solution of the underdetermined system; further solutions exist. Let us take for example the system related to the Lie–Poisson structure induced by the Lie algebra E_2:

$$\begin{aligned} y\frac{\partial G}{\partial z}+x\frac{\partial F}{\partial z}&=0\,,\\ y\frac{\partial H}{\partial z}+y\frac{\partial F}{\partial x}-x\frac{\partial F}{\partial y}-G&=0\,,\\ x\frac{\partial H}{\partial z}-y\frac{\partial G}{\partial x}+x\frac{\partial G}{\partial y}-F&=0\,. \end{aligned} \tag{1}$$

Bender *et al.*[1] claimed that its general solution was

$$F=-y\frac{\partial K}{\partial z},\quad G=x\frac{\partial K}{\partial z},\quad H=y\frac{\partial K}{\partial x}-x\frac{\partial K}{\partial y}, \tag{2}$$

with an arbitrary function $K(x,y,z)$. However, one easily checks that $F=c_1/x$, $G=c_2/y$ and $H=(c_1/x^2+c_2/y^2)z$ solves (1) for arbitrary values of the constants c_1, c_2 and only for $c_1=-c_2=c$ these expressions are contained in the solution family (2), namely for the choice $K=-cz/xy$. We will show that (2) represents the general solution only, if we augment (1) by the algebraic constraint $xF+yG=0$.

a)Electronic mail: werner.seiler@math.uni-mannheim.de

Our basic tool will be the formal theory of differential equations.[2–4] Some elements of this theory are about a century old, but it still seems to be fairly unknown. In fact, Bender *et al.*[1] mentioned a number of questions concerning the arbitrariness of the general solution of a system of partial differential equations many of which can be answered with the help of the formal theory (see, e.g., Ref. 5).

A key concept within the formal theory is *involution*. For lack of space, we cannot give a detailed introduction but must refer to the above cited works. Any serious analysis of a system of differential equations not in Cauchy–Kovalevskaya form requires usually that the system is involutive. Involution comprises in particular the absence of integrability conditions. Any system can be completed to an involutive one (under some mild regularity assumptions). Fortunately, we do not have to bother with a completion, as it turns out that due to the properties of Poisson manifolds our system is already involutive.

In the next section those basic properties of Poisson manifolds that are needed later are reviewed. In Sec. III an underdetermined system of partial differential equations characterizing Hamiltonian vector fields is derived and the conditions under which it is involutive are analyzed. The relation to the work of Bender *et al.*[1] is found in Sec. IV, studying the fundamental power series solutions of the Hamiltonian evolution equation. Finally, after considering explicitly the case of the Lie–Poisson structure of E_2, some conclusions are given in Sec. VI.

II. POISSON MANIFOLDS

For easier comparison with the results presented by Bender *et al.*,[1] we use throughout local coordinates; the intrinsic theory of Poisson manifolds can be found in the book of Vaisman[6] (with an emphasis on the geometry; see also Ref. 7) or in the books of Marsden and Ratiu,[8] resp., Libermann and Marle[9] (with an emphasis on applications in mechanics).

A *Poisson manifold* is a (smooth) manifold M equipped with a bracket structure on the ring $\mathcal{F}(M)$ of smooth functions on M. This bracket $\{\cdot,\cdot\}:\mathcal{F}(M)\times\mathcal{F}(M)\to\mathcal{F}(M)$ must satisfy four axioms for arbitrary functions $F,G,H\in\mathcal{F}(M)$ and real constants λ,μ:

(i) $\{F,G\}=-\{G,F\}$ (skew-symmetry),
(ii) $\{\lambda F+\mu G,H\}=\lambda\{F,H\}+\mu\{G,H\}$ (linearity),
(iii) $\{FG,H\}=F\{G,H\}+\{F,H\}G$ (Leibniz rule),
(iv) $\{F,\{G,H\}\}+\{G,\{H,F\}\}+\{H,\{F,G\}\}=0$ (Jacobi identity).

Thus the ring $\mathcal{F}(M)$ acquires the structure of an infinite-dimensional Lie algebra.

In terms of local coordinates $(z^1,\ldots,z^n)$ on the manifold M, the bracket is uniquely determined by the *Poisson matrix* $J^{kl}=\{z^k,z^l\}$. For two arbitrary functions $F,G\in\mathcal{F}(M)$ we find $\{F,G\}=(\nabla F)^t J\nabla G$. The matrix J is obviously skew-symmetric and the Jacobi identity induces the following differential equations for its components:

$$J^{kl}\frac{\partial J^{ij}}{\partial z^l}+J^{il}\frac{\partial J^{jk}}{\partial z^l}+J^{jl}\frac{\partial J^{ki}}{\partial z^l}=0\,,\quad 1\leqslant i,j,k\leqslant n\,. \tag{3}$$

In an intrinsic language, the Poisson bracket is defined in terms of the Poisson bivector $w\in\Lambda^2(TM)$ by $\{F,G\}=w(dF,dG)$. The matrix J is a coordinate representation of this bivector, $w=J^{kl}\partial_{z^k}\wedge\partial_{z^l}$, and the Jacobi identity (3) expresses the vanishing of the Schouten–Nijenhuis bracket of w with itself.

If the matrix J is regular (which obviously can only happen on even-dimensional manifolds), then M is in fact a symplectic manifold with the symplectic structure locally defined by the inverse of J. If $\mathcal{A}$ is an n-dimensional Lie algebra, then its dual space $\mathcal{A}^*$ carries a canonical *Lie–Poisson structure*. Since $T\mathcal{A}^*\cong\mathcal{A}^*\times\mathcal{A}^*$, we may identify for any smooth function $\phi\in\mathcal{F}(\mathcal{A}^*)$ at the point $\lambda\in\mathcal{A}^*$ the tangent map $T_\lambda\phi:\mathcal{A}^*\to\mathbb{R}$ with an element of $\mathcal{A}^{**}=\mathcal{A}$ and define for $\phi,\psi\in\mathcal{F}(\mathcal{A}^*)$,

$$\{\phi,\psi\}(\lambda)=\lambda([T_\lambda\phi,T_\lambda\psi])\,.$$

If C_{kl}^i denotes the structure constants of $\mathcal{A}$ for some basis $\{A_1,\ldots,A_n\}$, i.e. $[A_k,A_l]=C_{kl}^i A_i$, then in coordinates $(z_1,\ldots,z_n)$ with respect to the dual basis $\{A^1,\ldots,A^n\}$ of $\mathcal{A}^*$ the Poisson matrix is given by $J_{kl}=C_{kl}^i z_i$. It is trivial to check that it satisfies (3). Bender *et al.*[1] considered exclusively Poisson structures of this form.

A Poisson structure defines a homomorphism $\sharp: T^*M\to TM$ by $\omega_1(\omega_2^\sharp)=w(\omega_1,\omega_2)$ for arbitrary one-forms $\omega_1,\omega_2\in T^*M$. The structure w is *nondegenerate*, if $\sharp$ is an isomorphism or, equivalently, the Poisson matrix J is regular. More generally, the rank of a Poisson structure is defined as the dimension of $\operatorname{im}\sharp$ (we restrict here and in the sequel to the case that $\operatorname{im}\sharp$ defines a regular distribution on M). If $\operatorname{rank} w=n-r$, then r linearly independent one-forms $\chi^{(a)}=\chi_k^{(a)}\,dz^k$ exist on M such that $\ker\sharp=\langle\chi^{(1)},\ldots,\chi^{(r)}\rangle$. If a function $C\in\mathcal{F}(M)$ is such that $dC\in\ker\sharp$, then $\{C,F\}=0$ for all $F\in\mathcal{F}(M)$ and C is called a *Casimir function.*

We associate with any function $H\in\mathcal{F}(M)$ its *Hamiltonian vector field*,

$$X_H=(dH)^\sharp=\{\cdot,H\}=J^{kl}\frac{\partial H}{\partial z^l}\frac{\partial}{\partial z^k}.$$

For a Casimir function C, X_C is obviously the zero vector field. For later use, we introduce as a special case the short hand

$$X^{(k)}=X_{-z^k}=\{z^k,\cdot\}=J^{kl}\frac{\partial}{\partial z^l}.$$

The Poisson bracket may now conveniently be expressed with these fields:

$$\{F,G\}=\frac{\partial F}{\partial z^k}X^{(k)}G=-\frac{\partial G}{\partial z^k}X^{(k)}F.$$

The Hamiltonian vector fields form a Lie algebra under the Lie bracket. Indeed, one easily obtains for arbitrary functions $F,G,H\in\mathcal{F}(M)$ with the help of the Jacobi identity,

$$X_{\{F,G\}}(H)=\{H,\{F,G\}\}=\{\{H,F\},G\}-\{\{H,G\},F\}=[X_G,X_F](H). \tag{4}$$

Thus the mapping $F\mapsto X_F$ defines a Lie algebra *anti*homomorphism between $\mathcal{F}(M)$ and the Hamiltonian vector fields (if we had defined $X_F=\{F,\cdot\}$, we would have obtained a homomorphism[6]). It follows from (4) that the distribution $\operatorname{im}\sharp$ is involutive and thus defines a foliation of the manifold M. By a classical result in Poisson geometry, the leaves are $(n-r)$-dimensional symplectic manifolds, i.e., they carry a nondegenerate Poisson structure. Obviously, the codistribution $\ker\sharp$ is just the annihilator of $\operatorname{im}\sharp$.

A Hamiltonian vector field X_H may be written either in the form $X_H=(X^{(k)}H)\partial_{z^k}$ or as $X_H=-H_{z^k}X^{(k)}$. Thus the fields $X^{(k)}$ span the distribution $\operatorname{im}\sharp$ and (4) takes the form

$$[X^{(k)},X^{(l)}]=\frac{\partial J^{kl}}{\partial z^j}X^{(j)}. \tag{5}$$

Note that in the special case of a Lie–Poisson structure the vector fields $X^{(k)}$ provide us with a representation of the underlying Lie algebra, as then $\partial J_{kl}/\partial z_j=C_{kl}^j$.

The vector field X_H defines a dynamical system on the Poisson manifold M. We denote its flow by ϕ, i.e., ϕ is a map $\mathbb{R}\times M\to M$ (as we are only interested in local properties, we do not bother about the precise domain of definition of ϕ) and $\phi_z(t)=\phi(t,z)$ yields the integral curve of X_H passing through the point $z\in M$. A central property of Hamiltonian flows is that they preserve the Poisson structure. Indeed, it follows again from the Jacobi identity that for arbitrary functions $F,G,H\in\mathcal{F}(M)$,

$$(L_{X_H}w)(dF,dG)=X_H(w(dF,dG))-w(L_{X_H}dF,dG)-w(dF,L_{X_H}dG)$$
$$=X_H(\{F,G\})-\{X_HF,G\}-\{F,X_HG\}=0,$$

where L_X denotes the Lie derivative with respect to the vector field X. Thus $L_{X_H}w=0$ for every Hamiltonian vector field X_H.

If we consider how functions $F\in\mathcal{F}(M)$ vary along the integral curves of the Hamiltonian vector field X_H, then we find for arbitrary points $z\in M$,

$$\frac{d}{dt}(\phi_z^*F)(t)=\phi_z^*(dF(X_H))(t)=\phi_z^*(\{F,H\})(t)\,. \tag{6}$$

Often this equation is briefly written as $\dot{F}=\{F,H\}$.

Let us expand the function ϕ^*F in a formal power series in t,

$$(\phi^*F)(t,z)=\sum_{\alpha=0}^{\infty}F_\alpha(z)t^\alpha, \tag{7}$$

with coefficients $F_\alpha\in\mathcal{F}(M)$. A trivial computation shows then that

$$(\{F,G\})_\alpha=\sum_{\beta=0}^{\alpha}\{F_{\alpha-\beta},G_\beta\}\,. \tag{8}$$

Since, by definition of a flow, $(\phi^*F)(0,z)=F(z)$, we may express the coefficients F_α in a closed form: entering the expansion (7) into the differential equation (6) yields the relation $\alpha F_\alpha=\{F_{\alpha-1},H\}$ and thus

$$F_0=F\,,\quad F_1=\{F,H\}\,,\quad F_2=\tfrac{1}{2}\{\{F,H\},H\}\,,$$
$$F_\alpha=\frac{1}{\alpha!}\{\cdots\{\{F,\underbrace{H\},H\}\cdots,H\}}_{\alpha\ \text{brackets}}\,. \tag{9}$$

III. A PARTIAL DIFFERENTIAL SYSTEM AND ITS INVOLUTION ANALYSIS

Assume we are given an arbitrary vector field X on the Poisson manifold M. A natural question is whether or not a function $H\in\mathcal{F}(M)$ exists such that $X=X_H=(dH)^\sharp$. By the results of Sec. II, this corresponds in local coordinates where $X=\xi^k\partial_{z^k}$ to studying the solvability of the following overdetermined inhomogeneous linear first-order system for H:

$$X^{(k)}H=J^{kl}\frac{\partial H}{\partial z^l}=\xi^k\,. \tag{10}$$

It should be noted that we consider in the sequel only the *formal* solvability, i.e., the existence of formal power series solutions H.

In the language of the formal theory, conditions on the right hand side $\vec{\xi}$ for the existence of solutions are called *compatibility conditions*. They are determined by rendering (10) involutive. For linear first-order systems with one unknown function this is a classical problem much studied in the 19th century (see, e.g., the references in the textbooks[10,11]); in modern geometric language it leads to the Frobenius theorem. The system (10) is involutive, if and only if the vector fields $X^{(k)}$ span an involutive distribution, i.e., if the distribution is closed under the Lie bracket.

But we have already determined in (5) that this is indeed the case. Applying these commutator relations to the function H and using (10) immediately yields the following compatibility conditions for the right hand side $\vec{\xi}$:

$$X^{(k)}\xi^l - X^{(l)}\xi^k = \frac{\partial J^{kl}}{\partial z^j}\xi^j, \quad 1 \leqslant k < l \leqslant n. \tag{11}$$

Restricted to the special case of a Lie–Poisson manifold, this is the underdetermined system studied by Bender *et al.*[1] In general, (11) does *not* contain all compatibility conditions of (10). If the Poisson structure is degenerate, the vector fields $X^{(k)}$ are not linearly independent, as trivially $\chi_k^{(a)} X^{(k)} = 0$ for the one-forms $\chi^{(a)}$ spanning $\ker \sharp$. Thus we find in addition,

$$\chi_k^{(a)}\xi^k = 0, \quad 1 \leqslant a \leqslant r. \tag{12}$$

Bender *et al.*[1] ignored these equations and they are the reason for the problem mentioned in the Introduction.

In an intrinsic language, (11) is (up to a constant factor) the local coordinate form of $L_X w = 0$ and (12) of $\chi^{(a)}(X) = 0$. This observation is not too surprising: by definition of the one-forms $\chi^{(a)}$, the second equation simply says that the vector field X must lie in $\operatorname{im} \sharp$ and we showed above that for every Hamiltonian vector field the Lie derivative of the Poisson bivector w vanishes. Thus both conditions are obviously *necessary* for X being Hamiltonian. Because of the involution of the linear system (10), they are also *sufficient* for the vector field X being (formally) Hamiltonian.

It follows from these considerations that the general formal solution of (11), (12) is

$$\xi^k = X^{(k)}H = J^{kl}\frac{\partial H}{\partial z^l},$$

where the function $H \in \mathcal{F}(M)$ is arbitrary. Hence (11), (12) indeed always represents an underdetermined system, although it comprises more equations than unknown functions.

We proceed with an involution analysis of the combined system (11), (12). We first analyze whether it is possible to generate integrability conditions via cross-differentiations within the differential equations (11). We introduce the short hand $A^{kl} = X^{(k)}\xi^l - X^{(l)}\xi^k - (\partial J^{kl}/\partial z^j)\xi^j$ (the antisymmetric tensor corresponding to the bivector $L_X w$) and thus (11) may be written as $A^{kl} = 0$. If we take the cyclic combination

$$X^{(m)}A^{kl} + X^{(k)}A^{lm} + X^{(l)}A^{mk} = 0, \tag{13}$$

all second-order derivatives vanish and thus an integrability condition might be hidden here.

Here (13) contains the difference $(X^{(m)}X^{(k)} - X^{(k)}X^{(m)})\xi^l$ (and cyclic permutations of it). Here we enter the commutation relation (5). The arising equation contains expressions of the form $(\partial J^{mk}/\partial z^j)(X^{(j)}\xi^l - X^{(l)}\xi^j)$ which are simplified using (11). These operations finally yield the algebraic integrability conditions

$$\left(\frac{\partial J^{mk}}{\partial z^i}\frac{\partial J^{il}}{\partial z^n} + \frac{\partial J^{lm}}{\partial z^i}\frac{\partial J^{ik}}{\partial z^n} + \frac{\partial J^{kl}}{\partial z^i}\frac{\partial J^{im}}{\partial z^n} + J^{il}\frac{\partial^2 J^{mk}}{\partial z^n \partial z^i} + J^{ik}\frac{\partial^2 J^{lm}}{\partial z^n \partial z^i} + J^{im}\frac{\partial^2 J^{kl}}{\partial z^n \partial z^i} \right)\xi^n = 0.$$

As the coefficient of ξ^n is just the z^n-derivative of the Jacobi identity (3), this condition is always satisfied. If our Poisson structure is nondegenerate [so that the equations (12) do not arise], this result suffices to conclude that (11) is involutive, as (13) is the only linear combination of differentiated equations where all second-order derivatives vanish.

In the case of a degenerate Poisson structure we must also analyze prolongations of the algebraic equations (12). We first consider the application of one of the vector fields $X^{(l)}$. Upon entering the differential equations (11), a trivial computation yields

$$X^{(l)}(\chi_k^{(a)}\xi^k) = \left(J^{lm}\frac{\partial \chi_k^{(a)}}{\partial z^m} + \frac{\partial J^{lm}}{\partial z^k}\chi_m^{(a)} \right)\xi^k.$$

Exploiting the relation $J^{lm}\chi_m^{(a)}=0$ we have thus found the integrability conditions

$$J^{lm}\left(\frac{\partial\chi_k^{(a)}}{\partial z^m}-\frac{\partial\chi_m^{(a)}}{\partial z^k}\right)\xi^k=0\,,\quad 1\leqslant l\leqslant n\,. \tag{14}$$

A necessary condition for involution is that these conditions are linearly dependent of the algebraic equations (12) or, equivalently, that contracting the coefficients with J^{nk} yields zero. Relabeling the indices m and k in the second term, we arrive at the condition

$$(J^{nk}J^{lm}-J^{lk}J^{nm})\frac{\partial\chi_k^{(a)}}{\partial z^m}=0\,.$$

Exploiting again the relation $J^{lm}\chi_m^{(a)}=0$ and using the Jacobi identity (3) we find

$$(J^{nk}J^{lm}-J^{lk}J^{nm})\frac{\partial\chi_k^{(a)}}{\partial z^m}=\left(J^{lm}\frac{\partial J^{kn}}{\partial z^m}+J^{nm}\frac{\partial J^{lk}}{\partial z^m}\right)\chi_k^{(a)}=J^{km}\frac{\partial J^{ln}}{\partial z^m}\chi_k^{(a)}=0,$$

and hence this condition is always satisfied by the definition of the one-forms $\chi^{(a)}$.

As the vector fields $X^{(l)}$ are not linearly independent, the analysis above does not cover all possible prolongations of the constraints (12). Let $Y^{(b)}$ be r further vector fields such that together with the fields $X^{(l)}$ they span the full tangent space TM. This implies the existence of functions A_k^{lb} and B_c^{lb} such that

$$[X^{(l)},Y^{(b)}]=A_k^{lb}X^{(k)}+B_c^{lb}Y^{(c)}\,. \tag{15}$$

Applying the vector fields $Y^{(b)}$ to (12) yields differential equations

$$Y^{(b)}(\chi_k^{(a)}\xi^k)=0, \tag{16}$$

which are obviously algebraically independent of the system (11). In a strict geometric sense, they represent integrability conditions, albeit of a rather trivial nature. The more interesting question is whether it is possible to derive further integrability conditions via cross-differentiations between equations in (16) and (11), respectively. But one fairly easily sees that this cannot be the case.

A further integrability condition could only be generated by applying one of the vector fields $X^{(l)}$ to (16) and eliminating all arising second-order derivatives using equations obtained by applying some of the fields $Y^{(b)}$ to (11). But according to (15) we may write

$$X^{(l)}Y^{(b)}(\chi_k^{(a)}\xi^k)=(Y^{(b)}X^{(l)}+A_k^{lb}X^{(k)}+B_c^{lb}Y^{(c)})(\chi_k^{(a)}\xi^k)\,.$$

The second and the third terms on the right hand side consist of linear combinations of equations already present in the augmented system (11), (12), (16). In the first term we find the expression $X^{(l)}(\chi_k^{(a)}\xi^k)$ of which we have shown above that it may also be written as a linear combination of equations in (11), (12). Thus the right hand side is algebraically dependent of (11), (12), (16) plus the equations obtained by applying $Y^{(b)}$ to (11) and there are no further integrability conditions hidden.

Hence we have proven that for nondegenerate Poisson structures the system (11) is directly involutive, whereas in the degenerate case we must only add the trivial integrability conditions (16) to the system (11), (12) in order to achieve involution.

The Schouten–Nijenhuis bracket allows us to reformulate these lengthy coordinate calculations in an intrinsic language. As already mentioned, the system (11) is equivalent to $L_Xw=-[X,w]=0$. Let Y be an arbitrary vector field; then the prolongation of (11) in the direction Y is simply given by $L_YL_Xw=[Y,[X,w]]=0$. The graded Jacobi identity of the Schouten–Nijenhuis bracket yields $L_YL_Xw=L_XL_Yw-L_{[X,Y]}w$. On the right hand side, all second-order derivatives of

X are located in the second term. It vanishes if Y is a Hamiltonian vector field (i.e., a linear combination of the fields $X^{(k)}$), as $[X,Y]$ is then Hamiltonian, too. However, in this case we also have $L_Y w=0$, so that no integrability conditions appear.

In a similar manner, we can analyze the prolongation of the equations $\chi^{(a)}(X)=0$. If Y is a Hamiltonian vector field, then $L_Y(\chi^{(a)}(X))=(L_Y\chi^{(a)})(X)-\chi^{(a)}([X,Y])=(L_Y\chi^{(a)})(X)$. By Cartan's formula, $L_Y\chi^{(a)}=\iota_Y d\chi^{(a)}+d(\iota_Y\chi^{(a)})$ where ι_Y denotes the interior derivative with respect to Y. The second term vanishes, as Y is Hamiltonian and thus $\iota_Y\chi^{(a)}=0$. For the first term, we exploit that the codistribution $\ker\sharp$ spanned by the forms $\chi^{(a)}$ is involutive, as it annihilates the involutive distribution $\operatorname{im}\sharp$. This implies by the Frobenius theorem that $d\chi^{(a)}=\omega_b^{(a)}\wedge\chi^{(b)}$ for some one-forms $\omega_b^{(a)}$ and hence $\iota_X\iota_Y d\chi^{(a)}=0$. Thus no integrability conditions appear in the prolongation with respect to a Hamiltonian vector fields and the trivial ones (16) in any other prolongation.

IV. THE FUNDAMENTAL POWER SERIES SOLUTIONS

Bender *et al.*[1] derived the underdetermined system (11) differently. They considered in some local coordinate chart the n special functions $F^{(k)}\in\mathcal{F}(M)$ given by $F^{(k)}(z)=z^k$. We may call the functions $\phi^*F^{(k)}$ the *fundamental solutions* of the differential equation (6), as it obeys a kind of nonlinear superposition principle: for any function $F\in\mathcal{F}(M)$ we have

$$(\phi^*F)(t,z)=F((\phi^*F^{(1)})(t,z),\ldots,(\phi^*F^{(n)})(t,z)).$$

Indeed, the functions $\phi^*F^{(k)}$ are obviously nothing but the components of the flow in the local coordinates $(z^1,\ldots,z^n)$.

Bender *et al.*[1] expanded the fundamental solutions into power series of the form (7) and determined partial differential equations for the coefficients $F_\alpha^{(k)}$. Using our results above it is straightforward to find these equations. We first apply the relation (8) for $\alpha=1$:

$$(\{F^{(k)},F^{(l)}\})_1=\{F_1^{(k)},F_0^{(l)}\}+\{F_0^{(k)},F_1^{(l)}\}.$$

By the definition of the functions $F^{(k)}$, the right hand side may obviously be written in the form $X^{(k)}F_1^{(l)}-X^{(l)}F_1^{(k)}$. Because of $(\{F^{(k)},F^{(l)}\})_0=\{F_0^{(k)},F_0^{(l)}\}=J^{kl}$, the left hand side evaluates to

$$(\{F^{(k)},F^{(l)}\})_1=\{J^{kl},H\}=\frac{\partial J^{kl}}{\partial z^j}\{z^j,H\}=\frac{\partial J^{kl}}{\partial z^j}\{F_0^{(j)},H\}=\frac{\partial J^{kl}}{\partial z^j}F_1^{(j)}.$$

Putting the pieces together, we find that the first-order coefficients $F_1^{(k)}$ satisfy the compatibility conditions (11). This is of course not surprising: by definition of the flow ϕ and the functions $F^{(k)}$, the coefficients $F_1^{(k)}$ are nothing but the components ξ^k of the Hamiltonian vector field X_H in the given local coordinates.

We may derive similarly systems of partial differential equations for the higher-order coefficients $F_k^{(i)}$. In second order, the starting point is the relation

$$(\{F^{(k)},F^{(l)}\})_2=\{F_2^{(k)},F_0^{(l)}\}+\{F_1^{(k)},F_1^{(l)}\}+\{F_0^{(k)},F_2^{(l)}\}.$$

The right hand side equals $X^{(k)}F_2^{(l)}-X^{(l)}F_2^{(k)}+\{F_1^{(k)},F_1^{(l)}\}$. Using the results above we evaluate the left hand side to

$$(\{F^{(k)},F^{(l)}\})_2=\{(\{F^{(k)},F^{(l)}\})_1,H\}=\left\{\frac{\partial J^{kl}}{\partial z^j}F_1^{(j)},H\right\}=\frac{\partial J^{kl}}{\partial z^j}F_2^{(j)}+\left\{\frac{\partial J^{kl}}{\partial z^j},H\right\}F_1^{(j)}.$$

Thus we obtain the following system for the second-order coefficients:

$$X^{(k)}F_2^{(l)}-X^{(l)}F_2^{(k)}-\frac{\partial J^{kl}}{\partial z^j}F_2^{(j)}=\left\{\frac{\partial J^{kl}}{\partial z^j},H\right\}F_1^{(j)}-\{F_1^{(k)},F_1^{(l)}\}. \tag{17}$$

Note that the homogeneous part of this linear system is identical with our compatibility conditions (11). It is easy to see that if we continue in this manner, the homogeneous part always remains unchanged. Only the right hand side becomes a more and more complicated expression in the coefficients of lower order. More precisely, we find

$$X^{(k)}F_\alpha^{(l)}-X^{(l)}F_\alpha^{(k)}-\frac{\partial J^{kl}}{\partial z^j}F_\alpha^{(j)}=R_\alpha^{kl}-\sum_{\beta=1}^{\alpha-1}\{F_{\alpha-\beta}^{(k)},F_\beta^{(l)}\}, \tag{18}$$

where the term R_α^{kl} is determined by the recurrence relation

$$R_{\alpha+1}^{kl}=\left\{\frac{\partial J^{kl}}{\partial z^j},H\right\}F_\alpha^{(j)}+\{R_\alpha^{kl},H\}, \quad R_1^{kl}=0\,.$$

It should be noted that so far we have only shown that the functions $F_\alpha^{(k)}$ satisfy certain differential equations. We have *not* shown that they form their respective general solution. Indeed, we already know from the last section that this is the case only for nondegenerate Poisson structures. It is trivial to see that

$$\chi_k^{(a)}F_1^{(k)}=\chi_k^{(a)}\{F_0^{(k)},H\}=\chi_k^{(a)}X^{(k)}H=0\,, \quad 1\leqslant a\leqslant r\,.$$

Thus we recover (12). However, using the power series approach we still have no rigorous proof that we have found all equations satisfied by the first-order coefficients $F_1^{(\alpha)}$ whereas this followed trivially from our compatibility analysis in the last section.

The higher-order coefficients $F_\alpha^{(k)}$ also satisfy some algebraic constraints which may be determined recursively. If we set $G_\alpha^{(a)}=\chi_k^{(a)}F_\alpha^{(k)}$, then a trivial computation yields

$$G_{\alpha+1}^{(a)}=\{G_\alpha^{(a)},H\}-\{\chi_k^{(a)},H\}F_\alpha^{(k)}\,. \tag{19}$$

Of course, such a relation holds for arbitrary one-forms χ. The special property of the one-forms $\chi^{(a)}\in\ker\sharp$ is that for them $G_1^{(a)}=0$.

Bender *et al.*,[1] explicitly determined and solved for several concrete instances of a Lie-Poisson manifold the inhomogeneous system (17) for the second-order coefficients. They used the traditional approach of finding a particular solution of the inhomogeneous system and adding the general solution of the homogenous system. But obviously, (9) provides us with simpler closed form expressions for the general solution of the combined system (18), (19) for any order α.

V. AN EXPLICIT EXAMPLE

We detail the calculations presented so far for the Lie–Poisson structure associated with the three-dimensional Lie algebra E_2 generating the Euclidean motions in $\mathbb{R}^2$. This structure is characterized by the Poisson matrix

$$J=\begin{pmatrix}0 & 0 & -y\\ 0 & 0 & x\\ y & -x & 0\end{pmatrix}.$$

If we exclude the origin and confine ourselves to $M=\mathbb{R}^2\backslash\{0\}$, its constant rank is 2 and $\ker\sharp$ is spanned by the single one-form $\chi=x\,dx+y\,dy$. The vector fields $X^{(k)}$ have the form

$$X^{(1)}=-y\partial_z\,, \quad X^{(2)}=x\partial_z\,, \quad X^{(3)}=y\partial_x-x\partial_y\,.$$

They yield a representation of E_2 on $\mathbb{R}^3$, as the only nonvanishing Lie brackets are

$$[X^{(1)},X^{(3)}]=-X^{(2)}\,, \quad [X^{(2)},X^{(3)}]=X^{(1)}\,.$$

If we write $\xi^1=F$, $\xi^2=G$, $\xi^3=H$, then the evaluation of (11) yields the system (1).

Obviously, $X^{(1)}$ and $X^{(2)}$ are linearly dependent: $\chi_k X^{(k)}=xX^{(1)}+yX^{(2)}=0$. Hence (12) takes the form $xF+yG=0$ and all solutions given by (2) satisfy this equation. However, the system (1) implies only the relations $\partial/\partial z(xF+yG)=0$ and $(y\partial/\partial x-x\partial/\partial y)(xF+yG)=0$. Thus it possesses further solutions for which $xF+yG\neq 0$; one example has been given in the Introduction.

The Hamiltonian vector field X_K associated to an arbitrary function K is of the form $X_K=-yK_z\partial_x+xK_z\partial_y+(yK_x-xK_y)\partial_z$. As expected, the components are just the components of the general solution (2). A direct compatibility analysis yields that a general vector field $X=F\partial_x+G\partial_y+H\partial_z$ is Hamiltonian, if and only if its components satisfy

$$xF+yG=0\,,\quad F_x+G_y+H_z=0\,.$$

This system is equivalent to (1) *plus* the algebraic constraint $xF+yG=0$.

Let us perform an involution analysis of the system consisting of (1) and the constraint $xF+yG=0$. Cross-differentiations of the equations within (1) do not lead to any new equations. There is not short-cut for showing this; one must perform some lengthy computations which are equivalent to our analysis of (13).

The z-prolongation of the constraint is already contained in (1); thus applying neither $X^{(1)}$ nor $X^{(2)}$ to the constraint yields an integrability condition. If we apply $X^{(3)}$ to it, we obtain an equation which is a linear combination of the second and the third equation in the system (1). Indeed, it is easy to see that in our special case the one-form χ is such that in (14) the expression in the parentheses vanishes.

However, the vector fields $X^{(k)}$ do not form a basis of TM. Thus we must also study either the x- or the y-prolongation of the constraint. Either one leads to a trivial integrability condition, say, $xF_x+yG_x+F=0$, if we choose $Y=\partial_x$. Now, as a last step, we must check whether a cross-differentiation of this equation with some equation contained in (1) yields something nontrivial. But it is easy to see that this is not the case and we have arrived at an involutive system.

VI. CONCLUSIONS

We rederived the results of Bender *et al.*[1] on Lie–Poisson structures in a more geometric fashion using the formal theory of differential equations and generalized them to arbitrary Poisson manifolds. It turned out that their system simply describes necessary and sufficient conditions on the components of a vector field for the field to be Hamiltonian with respect to the given Poisson structure. We also corrected an error of Bender *et al.*,[1] in the case of degenerate Poisson structures where the Poisson matrix admits nontrivial null vectors.

We studied only the formal solvability of our differential systems. In the analytic category we could use the Cartan–Kähler theorem for proving the existence of analytic solutions (because of the linearity of the systems, the Holmgren theorem ensures that these solutions are unique even in much larger function spaces). The assumption that the Poisson matrix is analytic is not so restrictive, as it is for example trivially true for any Lie–Poisson structure. In contrast, the restriction to analytic vector fields is surely too severe for applications.

An existence theory in more general function spaces would require a deeper analysis of the systems. In the case of a nondegenerate Poisson structure it is not difficult to prove that both (10) and (11), (12) form elliptic systems in the sense that their symbol maps are injective. Thus one could apply the results outlined in the encyclopaedia article by Dudnikov and Samborski.[12] But as for our purposes the formal analysis was sufficient, we refrain from going further in this direction.

It is very instructive to see how deeply the involution analysis of our partial differential system (11), (12) is related to Poisson geometry. The two characteristic properties of the Poisson matrix J, skew-symmetry and the Jacobi identity (3), must be applied repeatedly for showing the vanishing of all integrability conditions. It is tempting to conjecture that conversely the system has the wanted properties, if and only if the matrix J defines a Poisson structure, but we have not been able to prove this. Such a proof would require to solve the *inverse* problem of compatibility for the

system (11), (12). Fairly recently, an algorithmic solution of this inverse problem has been developed.[13,14] However, the involved computations are rather tedious and it seems hopeless to perform them for our system.

We studied in this article only classical Poisson systems. Bender *et al.*[1] also considered quantum systems where the coordinates z^j become noncommutative. We developed recently a theory of involutive bases in a fairly large class of algebras, the polynomial algebras of solvable type.[4] This class contains in particular the universal enveloping algebras of finite-dimensional Lie algebras. The latter should provide the right setting for an analogous analysis of the quantum version of the evolution equation (6).

Discrete symmetry's chains and links between integrable equations

A. V. Yurov[a)]
Theoretical Physics Department, Kaliningrad State University, 236041, Al.Nevsky St., 14, Kaliningrad, Russia

(Received 13 August 2002; accepted 5 September 2002)

We consider the discrete symmetry's dressing chains of the nonlinear Schrödinger equation (NLS) and Davey–Stewartson equations (DS). The modified NLS (mNLS) equation and the modified DS (mDS) equations are obtained. The explicitly reversible Bäcklund auto-transformations for the mNLS and mDS equations are constructed. We demonstrate discrete symmetry's conjugate chains of the KP and DS models. The two-dimensional generalization of the P_4 equation is obtained. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1523641]

I. INTRODUCTION

Darboux transformations (DT) are very useful method to construct exact solutions of integrable PDE.[1] Some time ago a new approach to the DT (called dressing chains of discrete symmetries) emerged at the horizon of soliton's mathematics. This approach to proliferate integrable equations was proposed in the example of the Korteweg–de Vries (KdV) and sine-Gordon equations.[2] The scheme to proliferate the integrable equation (we choose the KdV for definiteness) starts out from Lax pair and DT of this equation. After very simple transformations (see Sec. II) we obtain new integrable equations with their Lax pairs. The modified KdV (mKdV$=$m^{1}KdV), m^{2}KdV, and m^{3}KdV equations were thus constructed, the second of which can be reduced to the exponential Calogero–Degasperis (CD) equation by an exponential point change of variables and the third contains the elliptic CD equation. The only price we have to pay for this simplicity is a rapidly growing amount of calculation.

Despite its apparent simplicity, the method of dressing chains is an extremely powerful method, as can be illustrated in following example (see details in Refs. 2–4): as noted in Refs. 2 and 3, the m^{n}KdV equations ($n=0,\ldots,3$), together with the Krichever–Novikov equation, exhaust all the integrable equations of the form $u_t+u_{xxx}+f(u_{xx},u_x,u)=0$. In Ref. 4 we generalized the dressing-chain method to considerably $(1+2)$-dimensional nonlinear equations: the Kadomtsev–Petviashvili (KP) and the Boiti–Leon–Pempinelli (BLP) equations. A new result, which is characteristic precisely of multidimensional equations, is the discovery of two types of dressing chains for the KP equation (we call these the conjugate chains). The new chain can be constructed with the help of binary DT.

The aim of this work is the generalization of the dressing-chains method for the nonlinear Schrödinger (NLS) and Davey–Stewartson (DS) equations. The plan of this paper is as follows. In Secs. II and III we review the dressing-chains method for the higher and lower KdV equations and for the higher KP equations. The dressing chains for the NLS and for the DS equations are discussed in Secs. IV and V. In Sec. VI we develop a technique for constructing exact localized solution of DS equations with a reduction constraint imposed and give some of these solutions. We conclude with a discussion on possible role of discrete symmetry's dressing chains in the theory of integrable PDE.

Last but not least, the dressing-chains method allows us to construct new integrable equations and, on the other hand, to find a link between known ones. For example, the sine-Gordon, KdV,

a)Electronic mail: yurov@freemail.ru

and CD equations can be constructed starting out from the KdV equation via dressing chains. *Maybe it is really only one integrable equation*?

II. 2D-P_4 EQUATION

Let us begin our discussion of the Borisov–Zykov method by analyzing the simplest of all possible integrable systems, the KdV equation. The starting point is the Lax pair for the KdV equation

$$\psi_{xx}=(u-\lambda)\psi, \quad \psi_t=2(u+2\lambda)\psi_x-u_x\psi, \tag{1}$$

where the KdV equation

$$u_t-6uu_x+u_{xxx}=0. \tag{2}$$

Setting $\tau=\phi_x/\phi$, where ϕ is a partial solution of (2) with the $\lambda=\mu$, we can write the Lax pair as

$$\tau_x=-\tau^2+u-\mu, \quad \tau_t=[2(u+2\mu)\tau-u_x]_x. \tag{3}$$

Exempting u from (4), we get

$$\tau_t=6\tau^2\tau_x-\tau_{xxx}+6\mu\tau_x. \tag{4}$$

If $\mu=0$ then we have the well-known mKdV equation. To construct Lax pair for (4) we use the DT

$$u_1=u-2\tau_x, \quad \psi_1=\psi_x-\tau\psi.$$

Setting $\sigma=\psi_{1,x}/\psi_1$, we get the x chain

$$(\sigma+\tau)_x=-\sigma^2+\tau^2-\lambda+\mu \tag{5}$$

and t chain

$$(\sigma+\tau)_t=[2(-\tau_x+\tau^2+\mu+2\lambda)\sigma-2\tau\tau_x+6\mu\tau+2\tau^3]_x.$$

At last, after introduction of the auxiliary function (denoted by Ψ)

$$\sigma+\tau=\Psi,$$

we obtain the Lax pair for (4)

$$\Psi_x=-\Psi^2+2\tau\Psi-\lambda+\mu, \quad \Psi_t=2[(\tau^2-\tau_x+\mu+2\lambda)\Psi+2(\mu-\lambda)\tau]_x. \tag{6}$$

Starting out from (6), we can find the m^{2}KdV (which can be reduced to the exponential CD equation by an exponential point change of variables) with its Lax pair. Continuing this procedure, we obtain the elliptic CD equation (m^{3}KdV) and *it is the end of this way*. The m^{3}KdV equation is the last equation which can be obtained by this method.

At first, one may wonder why the limitation appears by the $n=3$. However, we can write the Lax pairs for the m^{n}KdV with $n<4$ as two Riccati equations. It is incorrect for the m^{4}KdV.[2] This equation, therefore, is different from the ones found earlier and cannot be used by the old scheme. On the other hand, as we have mentioned in the Introduction, the m^{n}KdV equations ($n=0,\ldots,3$), together with the Krichever–Novikov equation, exhaust all the integrable equations of the form $u_t+u_{xxx}+f(u_{xx},u_x,u)=0$. So, this limitation is something beyond that. We can understand the triviality of this limitation with the help of the Painleve property. Let consider the m^{1}KdV equation (4). The function τ is the solution of both this equation and two Riccati equations

(3) [inserting τ_x from the first equation (3) in the second one we obtain the second Riccati equation], so it is obvious that the function τ has the Painleve property and that it is incorrect for the solutions of the m^{3}KdV with $n>3$.

In Ref. 5 the continuation of the KdV equation hierarchy in the direction corresponding to the negative power of the spectral parameter is constructed in the following way: let the L operator have the form (1)

$$L=-\partial_x^2+u(x,t),$$

and the nonlinear equations are

$$L_t=[L,A_N].$$

The operators A_N have the form

$$A_N=\sum_{m=-1}^{N} K_m(L)^m,$$

where $N=-1,-2,\ldots,$ and K_m are some operators.

The first lower KdV ($N=-1$) equation has the form (see Ref. 5),

$$\mathrm{KdV}_{-1}(\sigma)\equiv(\sigma_x^2+\sigma_{xx})_t-(e^{2\sigma})_x=0,$$

where σ is connected with u in the following way:

$$u=-\sigma_{xx}-\sigma_x^2.$$

Let $\sigma=iq/2$, where $q=q(x,t)$. It easy to see that

$$\mathrm{KdV}_{-1}(\sigma)=\tfrac{1}{2}(i\partial_x-q_x)(q_{xt}-2\sin q)=0, \tag{7}$$

so we have the Miura transformation between the KdV_{-1} equation and the sine-Gordon equation.

Lax pair for the (7) has the form

$$\psi_{xx}=\left(\frac{iq_{xx}}{2}-\frac{q_x^2}{4}+\lambda^2\right)\psi,\quad \psi_t=\frac{1}{2\lambda^2}e^{iq}\left(\psi_x-\frac{iq_x}{2}\psi\right). \tag{8}$$

Starting out from (8), we can find the Lax pair for the sine-Gordon equation. To do this we introduce a new function $\tilde{\psi}$

$$\tilde{\psi}=\frac{1}{\lambda}\left(\psi_x-\frac{i}{2}q_x\psi\right). \tag{9}$$

Therefore

$$\tilde{\psi}_x=\lambda\psi-\frac{i}{2}q_x\tilde{\psi},\quad \psi_t=\frac{1}{2\lambda}e^{iq}\tilde{\psi},\quad \tilde{\psi}_t=-\frac{1}{2\lambda}(iq_{xt}-e^{iq})\psi. \tag{10}$$

Substituting $2\sin q$ in place of q_{xt} (in the equation for the $\tilde{\psi}_t$) we can see that (9) and (10) are the well-known Lax pair for the sine-Gordon equation.

Thus, we can use the method of dressing chains for both higher and lower KdV equations. The sine-Gordon, KdV, and CD equations can be constructed starting out from the KdV equation via dressing chains of discrete symmetries. These are simply different representations of the same equation. From this standpoint, *the difference between sine-Gordon, KdV, mKdV, and CD equations is similar to the difference between the Maxwell equations in different gauges*!

Surprisingly, much of the analysis of the simple system carries over directly to the multidimensional case. The KP equations are given by

$$u_t+6uu_x+u_{xxx}=-3\alpha^2v_y, \quad v_x=u_y,$$

where $u=u(x,y,t)$, $v=v(x,y,t)$, $\alpha^2=\pm1$. The Lax pair for the KP equations is

$$\alpha\psi_y+\psi_{xx}+u\psi=0, \quad \psi_t+4\psi_{xxx}+6u\psi_x+3(u_x-\alpha v)\psi=0. \tag{11}$$

Setting $f\equiv\log\phi$, $\tau\equiv f_x$, where ϕ is a partial solution of (11), we can write Lax pair (11) as

$$\begin{gathered}\alpha\tau_y+(\tau_x+\tau^2+u)_x=0,\\ \tau_t+(4\tau_{xx}+12\tau\tau_x+4\tau^3+6u\tau+3u_x-3\alpha v)_x=0.\end{gathered} \tag{12}$$

It follows from the first equation in (12) that

$$u=-\tau_x-\tau^2-\alpha F, \quad F_x=\tau_y. \tag{13}$$

Substituting (12) into the second equation in (13) and making some simple transformations, we obtain the well-known mKP equation[6]

$$\tau_t-6\tau^2\tau_x+\tau_{xxx}=3\alpha(2\tau_xF-\alpha F_y), \quad F_x-\tau_y=0. \tag{14}$$

We now construct dressing chains of discrete symmetries. The KP equation admits the Darboux transformation[1]

$$\psi_1=\psi-\tau\psi, \quad u_1=u+2\tau_x, \quad v_1=v+2\tau_y. \tag{15}$$

Setting $s\equiv\log\psi_1$, $\sigma=s_x$, we see that σ satisfies the system of equations obtained from (12) by replacing $u\to u_1$ and $v\to v_1$. Comparing these equations with (12) and eliminating the potentials u and v, we obtain

$$\begin{gathered}\alpha(s-f)_y+(s+f)_{xx}+s_x^2-f_x^2=0,\\ (s-f)_t+[2(2s+f)_{xx}+6s_x^2-3f_x^2]_x+4s_x^3+6(f_{xx}-f_x^2-\alpha f_y)s_x-6\alpha(f_{xy}-f_xf_y)+2f_x^3=0.\end{gathered} \tag{16}$$

The first equation in (16) determines the y chain and the second determines the t chain, denoted by $C_y^{(+)}$ and $C_t^{(+)}$, respectively. Later (in Sec. III) we will generalize the Borisov–Zykov approach for the case of the KP equation, and we will find that the results of Borisov–Zykov carry over with only one important change.

As we have seen, the Painleve property is connected with the dressing chains. The approach of using dressing chain (5) to construct the P_4 equation was proposed in Ref. 7. It is interesting to apply this method to the chain (16).

To do this, it is helpful to insert the periodic condition. It is well known that the periodic condion for (5) led to the P_4 equations. Let us consider the dressing chain $C_y^{(+)}$ (16). Setting $f=f_n$, $s=f_{n+1}$, we use the condition of periodic

$$f_{n+N}=f_n+c(y). \tag{17}$$

It easy to see that

$$u_{n+N}=u_n+\alpha c',$$

so the condition (17) gets us some generalization of the harmonic oscillator. We choose $N=3$ and $c=-2y/\alpha$. Introducing new fields g_n, $n=1,2,3$

$$f_1=\tfrac{1}{2}(g_1-g_2+g_3+c),\quad f_2=\tfrac{1}{2}(g_1+g_2-g_3-c),\quad f_3=\tfrac{1}{2}(-g_1+g_2+g_3+c),$$

we can now rewrite the equations for the f_n in the following way:

$$\alpha(g_{2_y}-g_{3_y}-c_y)+(g_{2_x}-g_{3_x})g_{1_x}+g_{1_{xx}}=0,$$

$$\alpha(-g_{1_y}+g_{3_y}+c_y)+(g_{3_x}-g_{1_x})g_{2_x}+g_{2_{xx}}=0,$$

$$\alpha(g_{1_y}-g_{2_y}-c_y)+(g_{1_x}-g_{2_x})g_{3_x}+g_{3_{xx}}=0.$$

Excluding g_3, and using thecompatibility condition $\partial_y(g_{2,xx})=\partial_x^2(g_{2,y})$, we get the nonlinear equation which can be written via some transformation as

$$z_{xx}=\frac{1}{2}\frac{z_x^2}{z}+\frac{3}{2}z^3+4xz^2+2(x^2-2)z+\frac{\beta}{z}+\frac{3\alpha^2q^2}{2z}-3\alpha qz+\frac{\alpha}{z}\partial_x^{-1}\partial_y(z^3+2xz^2-3\alpha qz),$$

$$z_y=q_x, \tag{18}$$

where $z=g_{1_x}$ and $q=g_{1_y}$. The one-dimensional limit (where $\partial_y=q=0$) of Eq. (18) is the P_4 equation, so (18) is the two-dimensional generalization of the P_4 equation and should be called the 2D-P_4 equation.

The price we pay for the D=2 is that locality in x is lost, that is, in the usual run of things for the multidimensional integrable systems.

III. CONJUGATE CHAINS FOR THE KP EQUATIONS

The correspondence between the KdV dressing-chains formalism that we developed in the previous section and the KP dressing-chains formalism is quite remarkable. We find that almost the entire KdV formalism can be imported into the KP chains.

Chains (16) involve two Lax pairs for Eqs. (14), which arise after introducting the auxiliary function (denoted by Ψ) according to one of two rules

$$\Psi=s-f,\quad \Psi=s+f. \tag{19}$$

Using the first rule, we obtain

$$\alpha\Psi_y+(2f+\Psi)_{xx}+2f_x\Psi_x+\Psi_x^2=0,$$

$$\Psi_t+2(2\Psi_{xx}+6f_x\Psi_x+3\Psi_x^2+3\theta)_x+6\theta\Psi_x+4(3f+\Psi)_x\Psi_x^2=0, \tag{20}$$

$$\theta\equiv f_{xx}+f_x^2-\alpha f_y,$$

from (16). The compatibility condition for these equations is

$$(f_t-2f_x^3+f_{xxx})_x=3\alpha(2f_{xx}f_y-\alpha f_{yy}), \tag{21}$$

which is merely another form of the mKP equation (for $\tau=f_x$ and $F=f_y$).

This process can be repeated. In particular, the system (20) contains a new nonlinear equation obtained by eliminating the potential f. For this purpose, we linearize the first equation in (20) by substituting

$$f=-\tfrac{1}{2}(\Psi+\alpha\xi), \tag{22}$$

where $\xi=\xi(x,y,t)$. Inserting (22) in the second equation in (20), differentiating it with respect to x, and introducing $S\equiv\Psi_x$, we obtain the system

$$S_t+S_{xxx}-\tfrac{3}{2}S^2S_x=-3\alpha^2[(\tfrac{1}{2}\xi_x^2+\xi_y)S+(\tfrac{1}{2}\xi_x^2+\xi_y)_x]_x,$$
$$S_y=(\xi_{xx}+\xi_xS)_x. \tag{23}$$

Although Eq. (23) looks like a two-dimensional generalization of the mKdV equation, the one-dimensional limit (where $\partial_y=0$) of (20) is

$$g_t+\left(g_{xx}-\frac{\alpha^2}{2}g^3-\frac{3}{2}\frac{g_x^2}{g}\right)_x=0$$

[where $g(x,t)\equiv\xi_x=\exp(-\Psi)$] rather than the mKdV equation. After an exponential point change of variable, this equation reduced to the exponential CD equation. Therefore, Eq. (23) should be called the two-dimensional CD equation rather than the two-dimensional mKdV equation.

In Ref. 2, another representation for Ψ was used in the derivation of the CD equation, namely, the representation determined by the second formula in (19). We have used this representation in Ref. 4.

In addition to the usual DT, the KP equations admit the so-called binary Darboux transformations,[1] which, as we now show, allow us to construct new KP dressing chains.

It is obvious that the KP equation admits the Lax pair

$$-\alpha\chi_y+\chi_{xx}+u\chi=0,\quad \chi_t+4\chi_{xxx}+6u\chi_x+3(u_x+\alpha v)\chi=0, \tag{24}$$

which can be obtained from (11) by simply replacing $\alpha\to-\alpha$. Let

$$dQ(\chi,\psi)=\chi\psi dx+\frac{1}{\alpha}(\chi_x\psi-\chi\psi_x)dy+4\left(\psi_x\chi_x-\chi_{xx}\psi-\chi\psi_{xx}-\frac{3}{2}u\chi\psi\right)dt,$$

$$Q(\chi,\psi)\equiv\int dQ(\chi,\psi).$$

It is easy to see that the one-form $dQ(\chi,\psi)$ is closed if ψ and χ are solutions of Eqs. (11) and (24). Pair (24) also admits the Darboux transformation

$$\chi_{-1}=\chi-\rho\chi,\quad u_{-1}=u+2\rho_x,\quad v_{-1}=v+2\rho_y, \tag{25}$$

where $\rho=(\log\tilde{\chi})_x$, and $\tilde{\chi}$ is a partial solution of (24). Applying DT (15), we have

$$\chi_1=\frac{A+BQ(\chi,\psi)}{\psi},$$

where A and B are arbitrary constants. Now, using (25) we obtain

$$u_{1,-1}=u+2[\log(A+BQ(\chi,\psi))]_{xx},\quad v_{1,-1}=v+2[\log(A+BQ(\chi,\psi))]_{xy}.$$

We set $\sigma\equiv\chi_{1,x}/\chi_1$. This function satisfies the equations obtained from (12) by replacing $u\to u_1$, $v\to v_1$, and $\alpha\to-\alpha$. In other words, this yields new integrable y- and t-chains ($C_y^{(-)}$ and $C_t^{(-)}$), which can be called *conjugate* to the $C^{(+)}$ chains discussed above

$$-\alpha(s+f)_y+(s+f)_{xx}+s_x^2-f_x^2=0,$$

$$(s+f)_t+[4(s+f)_{xx}+6s_x^2-3f_x^2]_x+4s_x^3+6(f_{xx}-f_x^2-\alpha f_y)s_x-6\alpha f_xf_y-2f_x^3=0,$$

where we still have $\tau=f_x$ and $\sigma=s_x$. Comparing the expressions for $C^{(-)}$ and $C^{(+)}$ from (16), we see that these chains do not reduce to each other, thereby justifying the term "conjugate." This implies that the chains $C^{(-)}$ lead to new integrable equations and also to the corresponding Lax

pairs. To construct these, we should again use two possibilities to define Ψ; see Eq. (19). In the present case, it is convenient to choose the second formula. As a result, we obtain yet another Lax pair for the mKP equation (21)

$$-\alpha\Psi_y+\Psi_{xx}-2f_x\Psi_x+\Psi_x^2=0,$$

$$\Psi_t+2(2\Psi_{xx}-3f_x\Psi_x+3\Psi_x^2)_x+6(f_x^2-\alpha f_y)\Psi_x-6f_x\Psi_{xx}+4(\Psi-3f)_x\Psi_x^2=0.$$

Linearizing the first equation by the substitution that differs from (22) only by the sign of the right-hand side and defined as $S\equiv\Psi_x$, we get

$$\begin{gathered}S_t+4S_{xxx}-\tfrac{3}{2}S^2S_x=3\alpha[\xi_{xx}S+2\xi_xS_x+\alpha(\xi_y-\tfrac{1}{2}\xi_x^2)S]_x,\\ \alpha S_y=(S_x-\alpha\xi_xS)_x.\end{gathered}\tag{26}$$

Equations (26) are similar to (23) and also reduce to the CD equation in the one-dimensional limit (for $\alpha^2=1$). At the same time, as follows from the method of their construction, Eqs. (26) do not reduce to system (23) via a 1:1 change of dependent variables (by a gauge transformation); therefore, Eqs. (26) can be called conjugate to the Eqs. (23).

IV. DRESSING CHAINS FOR THE NLS EQUATION

The results in the last section indicate that generalizing the dressing-chain method to considerably more complicated NLS and DS equations can be very fruitful. In this section we use the dressing chains of discrete symmetries to proliferate the NLS equation. Recently, Shabat has studied such chains for the Zakharov–Shabat spectral problem in some unusual gauge.[8] We have another aim: to construct higher mNLS equations. We can do it in two gauges, each with its own advantages and disadvantages.

(1) *Standard symmetric Zakharov–Shabat gauge*. In this gauge we have very clear connections between NLS and m^{n}NLS equations. The disadvantage of this gauge is a very rapidly growing amount of calculations. For the $n>2$ we obtain very cumbersome equations.
(2) *New Shabat gauge*.[8] The advantage of this gauge is that the equations have more compact form. However, the connection between real NLS and real mNLS equations is not obvious in this gauge. The reconstruction of the m^{n}NLS for a $n>2$ must be checked tediously.

Here, we choose the standard gauge for the spectral problem; therefore, the Lax pair for the NLS equation is

$$\Psi_t=-2i\sigma_3\Psi\Lambda^2+2iU\Psi\Lambda+V\Psi,\quad \Psi_x=-i\sigma_3\Psi\Lambda+iU\Psi,\tag{27}$$

where

$$U=\begin{pmatrix}0 & u\\ v & 0\end{pmatrix},\quad \sigma_3=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix},\quad V=\sigma_3(iU^2-U_x),$$

and Λ is an arbitrary constant matrix. The compatibility condition gets us the NLS equations

$$iu_t+u_{xx}+2u^2v=0,\quad -iv_t+v_{xx}+2v^2u=0.$$

Let Φ is a partial solution of (27) with the $\Lambda=\mathrm{diag}((\lambda+\mu)/2,(\lambda-\mu)/2)$, Ψ is the same for the $\Lambda_1=\mathrm{diag}((\lambda_1+\mu_1)/2,(\lambda_1-\mu_1)/2)$ and $\tau\equiv\Phi\Lambda\Phi^{-1}$. This matrix function is the solution of the system

$$\tau_x=i[\tau,\sigma_3]\tau+i[U,\tau],\quad \tau_t=2\tau_x\tau+[V,\tau].\tag{28}$$

The Darboux transformation has the form

$$\Psi\to\Psi_1=\Psi\Lambda_1-\tau\Psi,\quad U\to U_1=U+[\tau,\sigma_3]. \tag{29}$$

There are two discrete symmetries of the Zakharov–Shabat spectral problem: S- and T symmetries. The transformation (29) is S^2 symmetry. We must use squared S symmetry because an elementary S symmetries are insufficient to construct exact solutions of the NLS.

Using (29), we obtain

$$u\to u_1=u-2b,\quad v\to v_1=v+2c, \tag{30}$$

where

$$\tau=\begin{pmatrix} a & b \\ c & d \end{pmatrix}. \tag{31}$$

Substituting (31) into (28), we get

$$a_x=-d_x=-i(2bc-uc+vb),\quad b_x=-i(2bd+(a-d)u), \tag{32}$$

$$c_x=i(2ac+(a-d)v),$$

and

$$\begin{gathered} a_t=(a^2)_x+2b_xc-bv_x-cu_x,\quad d_t=(d^2)_x+2bc_x+bv_x+cu_x, \\ b_t=2(ibuv+a_xb+b_xd)+(a-d)u_x,\quad c_t=2(-icuv+ac_x+cd_x)+(a-d)v_x. \end{gathered} \tag{33}$$

Calculating the determinant and trace of matrix τ we get

$$ad-bc=\frac{\lambda^2-\mu^2}{4},\quad a+d=\lambda. \tag{34}$$

Using (34), we get

$$a=\tfrac{1}{2}(\lambda\pm\sqrt{\mu^2-4bc}). \tag{35}$$

Eliminating u and v from the last two Eqs. (32) and putting everything together, we find mNLS (m^1NLS) equation

$$\begin{gathered} (\mu^2-4bc)(ib_t+b_{xx}-2b^2c)+2\lambda(\lambda c+2ic_x)b^2+2(b_xc+2bc_x)b_x\equiv(\mu^2-4bc)\beta(b,c)=0, \\ (\mu^2-4bc)(-ic_t+c_{xx}-2c^2b)+2\lambda(\lambda b-2ib_x)c^2+2(bc_x+2b_xc)c_x\equiv(\mu^2-4bc)\gamma(b,c)=0. \end{gathered} \tag{36}$$

The designations $\beta(b,c)$ and $\gamma(b,c)$ will be useful [see (41), (42)].

As we have mentioned above, the NLS equation has a broader set of symmetries. In addition to the Darboux transformations, the discrete symmetries include the Schlesinger transformations or T symmetries. The T symmetries produce an explicity invertible Bäcklund auto-transformations for the NLS equation

$$u\to u_1=u_{xx}+u^2v-\frac{u_x^2}{u},\quad v\to v_1=\frac{1}{u},$$

and

$$u\to u_{-1}=\frac{1}{v},\quad v\to v_{-1}=v_{xx}+v^2u-\frac{v_x^2}{v},$$

where

$$(u_1)_{-1}=(u_{-1})_1=u,\quad (v_1)_{-1}=(v_{-1})_1=v.$$

These symmetries are related to the Toda chain and some of its generalizations.[9]

The mNLS equation (36) has the similar property. We have very cumbersome Schlesinger transformations for (36) so we show ones when $\lambda=\mu=0$. In this case, (36) has an elegant form

$$\begin{aligned} &ib_t+b_{xx}-2b^2c-\frac{b_xc_x}{c}-\frac{1}{2}\frac{b_x^2}{b}=0,\\ &-ic_t+c_{xx}-2bc^2-\frac{b_xc_x}{b}-\frac{1}{2}\frac{c_x^2}{c}=0. \end{aligned} \tag{37}$$

The explicity invertible Bäcklund auto-transformations for (37) are

$$b\to b_1=\frac{1}{4}\frac{(2cb_x^2-2cbb_{xx}+c_xb_xb+4c^2b^3)^2}{c^2b(b_x^2-4cb^3)},\quad c\to c_1=\frac{4cb^2}{b_x^2-4cb^3},$$

$$b\to b_{-1}=\frac{4bc^2}{c_x^2-4bc^3},\quad c\to c_{-1}=\frac{1}{4}\frac{(2bc_x^2-2bcc_{xx}+b_xc_xc+4b^2c^3)^2}{b^2c(c_x^2-4bc^3)}.$$

It is easy to verify that

$$(b_1)_{-1}=(b_{-1})_1=b,\quad (c_1)_{-1}=(c_{-1})_1=c.$$

To obtain dressing chains of discrete symmetries S^2, we construct new matrix function $\tau_1=\Psi_1\Lambda_1\Psi_1^{-1}$ with Ψ_1 from (29). Its elements a_1, b_1, c_1, and d_1 are solutions of (32)–(35) by replacing $\lambda\to\lambda_1$, $\mu\to\mu_1$, $u\to u_1$, and $v\to v_1$ [see (30)]. Eliminating potentials u and v, we obtain our chains

$$\begin{aligned} &(\lambda-2a)b_{1,x}-(\lambda_1-2a_1)b_x+2i(\lambda_1-a_1)(\lambda-2a)b_1-2i(\lambda_1-2a_1)ab=0,\\ &(\lambda-2a)c_{1,x}-(\lambda_1-2a_1)c_x-2i(\lambda-2a)a_1c_1+2i(\lambda_1-2a_1)(\lambda-a)c=0,\\ &b_{1,t}b-b_1b_t+2[(\lambda-a)b_1b_x-(\lambda_1-a_1)b_{1,x}b]+(\lambda_1-2a_1)(b^2)_x+K_1b_1+M_1b=0,\\ &c_{1,t}c-c_1c_t+2(ac_1c_x-a_1c_{1,x}c)+(\lambda_1-2a_1)(c^2)_x+K_2c_1+M_2c=0, \end{aligned} \tag{38}$$

where

$$\begin{aligned} &K_1=4iC(2,2)b^2+2[(a-a_1)_x+2iB(-2,-2)c]b-(\lambda-2a)B_x(-2,-2),\\ &K_2=-4iB(0,2)c^2-2[(a-a_1)_x+2iC(0,-2)b]c-(\lambda-2a)C_x(0,-2),\\ &M_1=(\lambda_1-2a_1)B_x(-2,-2),\quad M_2=(\lambda_1-2a_1)C_x(0,-2),\\ &B(n,k)=\frac{ib_x+(n\lambda-ka)b}{\lambda-2a},\quad C(n,k)=\frac{ic_x+(n\lambda-ka)c}{\lambda-2a}, \end{aligned}$$

and fields a, d (a_1, d_1) are expressed in term of b, c (b_1, c_1) via (34)–(35).

Chains (38) involve Lax pair for the mNLS (36), which arise after introducing the auxiliary fields

$$\psi \equiv \frac{b_1}{b}, \quad \phi \equiv \frac{c_1}{c}, \quad A \equiv a_1 .$$

After some calculations, we obtain

$$\psi_x = \left(2i(A-\lambda_1) - \frac{b_x}{b} \right) \psi + \frac{i(2A-\lambda_1)}{b} B(0,2),$$

$$\phi_x = \left(2iA - \frac{c_x}{c} \right) \phi + \frac{i(2A-\lambda_1)}{c} C(2,2),$$

$$\begin{aligned}
\psi_t &= 2(\lambda_1 - A)\psi_x - 4ibc\phi\psi^2 - 2i(bC(2,2)\psi + cB(0,2)\phi)\psi + P\psi + \frac{\lambda_1 - 2A}{b} B_x(0,2), \\
\phi_t &= 2A\phi_x + 4ibc\psi\phi^2 + 2i(bC(2,2)\psi + cB(0,2)\phi)\phi + Q\phi - \frac{\lambda_1 - 2A}{c} C_x(2,2),
\end{aligned} \tag{39}$$

$$A_x = -i[2bc\phi\psi + bC(2,2)\psi + cB(0,2)\phi],$$

$$A_t = -4i\lambda_1 bc\phi\psi - b[2iAC(2,2) + C_x(2,2)]\psi + c[2i(A-\lambda_1)B(0,2) + B_x(0,2)]\phi,$$

where

$$P = \frac{[2b_x(\lambda_1 - A) - ib_{xx}](\mu^2 - 4bc) + 2(bc)_x[2b(\lambda - a) - ib_x]}{b(\mu^2 - 4bc)},$$

$$Q = \frac{(2c_x A + ic_{xx})(\mu^2 - 4bc) + 2(bc)_x(2ca + ic_x)}{c(\mu^2 - 4bc)}.$$

The mNLS equation (36) arises from the compatibility condition of (39)

$$(\psi_x)_t = (\psi_t)_x, \quad (\phi_x)_t = (\phi_t)_x, \quad (A_x)_t = (A_t)_x . \tag{40}$$

From the first two equations (40), we get two nonlinear equations

$$\beta_1(b,c) = 0, \quad \gamma_1(b,c) = 0.$$

The connection between these equations and the mNLS (36) is given by

$$\beta_1(b,c) = b\left(\frac{\beta(b,c)}{b} \right)_x, \quad \gamma_1(b,c) = c\left(\frac{\gamma(b,c)}{c} \right)_x , \tag{41}$$

so we have not (36) but

$$\beta(b,c) = mb, \quad \gamma(b,c) = m'c, \tag{42}$$

where m and m' are arbitrary constants. Substituting b_t and c_t [which are expressed from (42)] into the third equation of the system (40), we obtain $m' = m$. Thus, using the gauge transformation

$$b \to e^{-imt} b, \quad c \to e^{imt} c,$$

we can reduce (42) to mNLS (36)

$$\beta(b,c)-mb\to e^{-imt}\beta(b,c)=0,\quad \gamma(b,c)-mc\to e^{-imt}\gamma(b,c)=0.$$

This completes the proof that the system (39) is the Lax pair of mNLS. We are giving two formulas (for convenience of reader) which are useful to check for this Lax pair

$$a_x=\frac{(bc)_x}{\lambda-2a},\quad a_t=\lambda a_x+b_xc-bc_x-bC_x(0,-2)+cB_x(-2,-2).$$

We will shortly see the advantage of carefully working out the details of the NLS dressing chains. We will find that almost all of this formalism carried over directly into the more complicated DS dressing chains. Formulas for the DS dressing chains are very bulky but have the same structure.

V. CONJUGATE CHAINS OF THE DS EQUATIONS

The DS equations has the form

$$iu_t+u_{xx}+\frac{1}{\alpha^2}u_{yy}-\frac{2}{\alpha^2}u^2v+qu=0,\quad -iv_t+v_{xx}+\frac{1}{\alpha^2}v_{yy}-\frac{2}{\alpha^2}v^2u+qv=0, \tag{43}$$

$$q_{yy}-\alpha^2q_{xx}=-4(uv)_{xx},$$

where $u=u(x,y,t)$, $v=v(x,y,t)$, $q=q(x,y,t)$. We have the DS-I system if $\alpha=1$, and DS-II if $\alpha=i$. Under the reduction $v=\pm\bar{u}$, one obtains a known model that describes the propagation of a small amplitude wave packet that is quasi-one-dimensional and quasi-monochromatic over the surface of a nonviscous curl-free liquid.[10] The quantity u is the envelope of the velocity potential, while q describes the nonlocal flow generated by the wave packet. A different application of (43) is related to the dynamics of plasma waves.[11] We will not use this reduction restriction in this section.

Lax pair for the (43) has the form

$$\begin{gathered}\psi_y=\alpha\psi_x+u\phi,\quad \phi_y=-\alpha\phi_x+v\psi,\\ \psi_t=2i\psi_{xx}+\frac{2i}{\alpha}u\phi_x+\left(\frac{1}{2}\left[\frac{1}{\alpha}F_y+F_x\right]-\frac{i}{\alpha^2}uv\right)\psi+\frac{i}{\alpha^2}(\alpha u_x+u_y)\phi,\\ \phi_t=-2i\phi_{xx}+\frac{2i}{\alpha}v\psi_x+\left(\frac{1}{2}\left[\frac{1}{\alpha}F_y-F_x\right]+\frac{i}{\alpha^2}uv\right)\phi+\frac{i}{\alpha^2}(\alpha v_x-v_y)\psi,\end{gathered} \tag{44}$$

where $q=-iF_x$.

Let $\{\psi_1,\phi_1;\psi_2,\phi_2;\psi,\phi\}$ be solutions of (44) for the same u, v, and F. DT is given by

$$\begin{gathered}\psi\to\psi_1=\psi_x-a\psi-b\phi,\quad \phi\to\phi_1=\phi_x-c\psi-d\phi,\\ u\to u_1=u+2\alpha b,\quad v\to v_1=v-2\alpha c,\quad F\to F_1=F+4i(a+d),\end{gathered} \tag{45}$$

where

$$a=\frac{\psi_{1,x}\phi_2-\psi_{2,x}\phi_1}{\Delta},\quad b=\frac{\psi_{2,x}\psi_1-\psi_{1,x}\psi_2}{\Delta},\quad c=\frac{\phi_{1,x}\phi_2-\phi_{2,x}\phi_1}{\Delta}, \tag{46}$$

$$d=\frac{\phi_{2,x}\psi_1-\phi_{1,x}\psi_2}{\Delta},\quad \Delta=\psi_1\phi_2-\psi_2\phi_1.$$

The quantities a, b, c, d are solutions of the system

$$
\begin{aligned}
&a_y=\alpha(a_x+2bc)+uc-vb,\quad b_y=\alpha(b_x+2bd)+(d-a)u+u_x,\\
&c_y=-\alpha(c_x+2ac)+(a-d)v+v_x,\quad d_y=-\alpha(d_x+2bc)-uc+vb,\\
&a_t=2i\left[\left(a_x+2bc+a^2+\frac{q}{4}\right)_x+2(a+d)bc\right]+\frac{i}{\alpha^2}[bv_y+cu_y-(uv)_x]\\
&\quad+\frac{i}{\alpha}\left[cu_x-bv_x+2(cdu-abv+(uc)_x)+\frac{q_y}{2}\right],\\
&b_t=2i\left[(b_x+2bd)_x+2\left(a_x+bc+d^2+\frac{q}{4}\right)b\right]+\frac{i}{\alpha^2}[u_{xy}+(d-a)u_y-2buv]\\
&\quad+\frac{i}{\alpha}[u_{xx}+(3d-a)u_x+2(d_x+d^2-ad+bc)u-2b^2v],\\
&c_t=-2i\left[(c_x+2ac)_x+2\left(d_x+bc+a^2+\frac{q}{4}\right)c\right]-\frac{i}{\alpha^2}[v_{xy}+(a-d)v_y-2cuv]\\
&\quad+\frac{i}{\alpha}[v_{xx}+(3a-d)v_x+2(a_x+a^2-ad+bc)v-2c^2u],\\
&d_t=-2i\left[\left(d_x+2bc+d^2+\frac{q}{4}\right)_x+2(a+d)bc\right]-\frac{i}{\alpha^2}[bv_y+cu_y-(uv)_x]\\
&\quad-\frac{i}{\alpha}\left[cu_x-bv_x+2(cdu-abv-(bv)_x)-\frac{q_y}{2}\right].
\end{aligned}
\tag{47}
$$

These equations can be obtained from (44). Equations (47) are similar to (32) and (33). The Lax pair (44) and Eqs. (47) are simply two different representations of the same equation. To construct mDS equations we must first express fields a and d via one function $\theta=\theta(x,y,t)$, defined by the relations

$$
a=\frac{\alpha\theta_x+\theta_y}{2\alpha},\quad d=\frac{\alpha\theta_x-\theta_y}{2\alpha}. \tag{48}
$$

It is easy to check the accuracy of this representation by the substitution (48) into the first and fourth equations (47). Second, we must exclude potentials u and v from the first four equations (47). Introducing new fields $\xi=\xi(x,y,t)$, $X=\theta_x$, $Y=\theta_y$

$$
q=-2X_x-X^2-4bc+\frac{1}{\alpha^2}(\xi-Y^2),
$$

and putting everything together, we find mDS (mDS-I if $\alpha=1$ and mDS-II if $\alpha=i$) equations as the system of five equations for the five functions b, c, ξ, X, and Y:

$$
\begin{aligned}
&ib_t+2(bX+b_x)_x+\frac{1}{\alpha}[(UX+U_x)_x+2b(Uc-Vb)-2Y(bX+b_x)]\\
&\quad+\frac{1}{\alpha^2}[U_{xy}-U(X_y+XY)-2(U_xY+bUV)+\xi b]+\frac{1}{\alpha^3}Y(UY-U_y)=0,
\end{aligned}
$$

$$
\begin{aligned}
&-ic_t+2(cX+c_x)_x-\frac{1}{\alpha}[(VX+V_x)_x-2c(Uc-Vb)-2Y(cX+c_x)]\\
&\quad+\frac{1}{\alpha^2}[V_{xy}-V(X_y+XY)-2(V_xY+cUV)+\xi c]-\frac{1}{\alpha^3}Y(VY-V_y)=0,\\
&iX_t+4[(bc)_x+2Xbc]-\frac{2}{\alpha}[X(Vb-Uc)+4cb_y-2(cU)_x+bV_x-cU_x-YX_x]\\
&\quad-\frac{2}{\alpha^2}[(UV)_x-Vb_y-Uc_y+Y(bV+cU)]-\frac{1}{\alpha^3}(Y^2-\xi)_y=0,\\
&iY_t+4(b_yc-bc_y)+\frac{1}{\alpha}[2(U_yc-Uc_y+V_yb-Vb_y)+\xi_x]=0,\\
&X_y-Y_x=0,
\end{aligned}
\tag{49}
$$

where

$$
U=\frac{G_1}{2\alpha(2bcY+\alpha(bc_x-b_xc))},\quad V=\frac{G_2}{2\alpha(2bcY+\alpha(bc_x-b_xc))},
$$

$$
\begin{aligned}
G_1&=\alpha^3[b_xX_x-bX_{xx}+2b(2bcX+b_xc-bc_x)]\\
&\quad+\alpha^2[2(bc_y-b_yc)-(X_x+4bc)Y]b+\alpha(bX_{yy}-b_xY_y)+bYY_y,\\
G_2&=\alpha^3[c_xX_x-cX_{xx}+2c(2bcX-b_xc+bc_x)]\\
&\quad+\alpha^2[2(bc_y-b_yc)+(X_x+4bc)Y]c+\alpha(cX_{yy}-c_xY_y)-cYY_y.
\end{aligned}
$$

As we have mentioned above, the NLS equation has two types of discrete symmetries: Darboux and Schlesinger transformations. In just the same way, the discrete symmetries of the DS equations include T symmetry. These transformations are given by[12,13]

$$
u\to u_1=u(uv+\alpha^2(\log u)_{xx}-(\log u)_{yy}),\quad v\to v_1=\frac{1}{u},\quad q\to q_1=q+4(\log u)_{xx},
$$

$$
u\to u_{-1}=\frac{1}{v},\quad v\to v_{-1}=v(uv+\alpha^2(\log v)_{xx}-(\log v)_{yy}),\quad q\to q_{-1}=q+4(\log v)_{xx}.
$$

Similar transformations for (49) are given by

$$
b\to b_1=\frac{M_1}{\alpha U(U+2\alpha b)},\quad c\to c_1=\frac{b}{U(U+2\alpha b)},
$$

$$
X\to X_1=X+2\alpha\frac{Ub_x-U_xb}{U(U+2\alpha b)},\quad Y\to Y_1=\frac{-U^2Y+2\alpha[UU_x-bU_y+\alpha U(b_x+bX)]}{U(U+2\alpha b)},
$$

$$
\xi\to\xi_1=\xi+4\alpha\frac{\alpha^2U(b_{xx}+(bX)_x)+\alpha[b(UY_x-U_{xy})+U(U_{xx}-b_xY)]-UU_xY}{U(U+2\alpha b)},
$$

and

$$c\to c_{-1}=\frac{M_{-1}}{\alpha V(V-2\alpha c)},\quad b\to b_{-1}=\frac{c}{V(V-2\alpha c)},$$

$$X\to X_{-1}=X-2\alpha\frac{Vc_x-V_xc}{V(V-2\alpha c)},\quad Y\to Y_{-1}=\frac{V^2Y+2\alpha[VV_x-cV_y-\alpha V(c_x+cX)]}{V(V-2\alpha c)},$$

$$\xi\to\xi_{-1}=\xi-4\alpha\frac{\alpha^2V(c_{xx}+(cX)_x)-\alpha[c(VY_x-V_{xy})+V(V_{xx}-c_xY)]-VV_xY}{V(V-2\alpha c)},$$

where

$$\begin{aligned}M_1=&\alpha^3[U^2b(2X_x-X^2)+2U((U_xb-Ub_x)X+(U^2)_xb_x+4(Ub)^2c+(U_x^2-2UU_{xx})b]\\&+\alpha^2U[U(UX_x+2bY_x)+(2U_yb-UU_x)X-2Ub_xY+4U^2cb-2U_{xy}b-UU_{xx}+2b_xU_y\\&+2U_x^2]+\alpha[U^3(Y_x+XY+Uc)+U^2(bY^2-2U_xY-U_{xy})+U_y((U^2)_x-bU_y)]\\&+U^2Y(UY-U_y),\end{aligned}$$

$$\begin{aligned}M_{-1}=&\alpha^3[V^2c(X^2-2X_x)-2V(V_xc-Vc_x)X-(V^2)_xc_x-4(Vc)^2b-(V_x^2-2VV_{xx})c]\\&+\alpha^2V[V(VX_x+2cY_x)+(2V_yc-VV_x)X-2Vc_xY+4V^2bc-2V_{xy}c-VV_{xx}+2c_xV_y\\&+2V_x^2]-\alpha[V^3(Y_x+XY+Vb)+V^2(cY^2-2V_xY-V_{xy})+V_y((V^2)_x-cV_y)]\\&+V^2Y(VY-V_y).\end{aligned}$$

It is possible to verify that $X_{\pm1,y}=Y_{\pm1,x}$, $(b_1)_{-1}=(b_{-1})_1=b$, and so on.

To obtain dressing chains of discrete symmetries, we must exclude potentials u, v, q from the two systems: (47) and the system of equations obtained from (47) by replacing $a\to a_1$, $b\to b_1$, $c\to c_1$, $d\to d_1$, $q\to q_1=q+4(a+d)_x$, $u\to u_1$, $v\to v_1$ [it is necessary to use (45)]. As a result, we have y chains

$$\begin{aligned}&[2bc(d-a)+b_xc-bc_x](a_{1,y}-\alpha a_{1,x})+(bc_1-b_1c)(a_y-\alpha a_x)_x+(bc_1-b_1c)(bc_y-b_yc)\\&+\alpha[(b_1c+2b_1c_1+bc_1)(bc_x-b_xc)+4bc(ac_1(b+b_1)-b_1d(c+c_1))]\\&+[(bc_1+b_1c)(a-d)+b_1c_x-b_xc_1](a_y-\alpha a_x)=0,\\&(bc_1-b_1c)[(b_1-b)_y-\alpha(b+b_1)_x]+(a-a_1-d+d_1)[\alpha(a_{1,x}b-a_xb_1)+a_yb_1-a_{1,y}b]\\&+2\alpha[(b+b_1)(abc_1+cb_1d_1)-bb_1(c+c_1)(a_1+d)]=0,\\&(b_1c-bc_1)[(c_1-c)_y+\alpha(c+c_1)_x]+(a-a_1-d+d_1)[\alpha(a_{1,x}c-a_xc_1)+a_yc_1-a_{1,y}c]\\&-2\alpha[(c+c_1)(a_1c_1b+cdb_1)-cc_1(b+b_1)(a+d_1)]=0,\\&(a_1+d_1)_y-\alpha(a_1-d_1)_x=0,\end{aligned}\tag{50}$$

and t chains

$$\begin{aligned}&\alpha^2(a_1-a)_t+i[2\alpha^2((a^2-a_1^2-2b_1c_1-a_{1,x}-d_x)_x+2((a+d)bc-(b+b_1)c_1d_1-(c+c_1)a_1b_1\\&-(bc_1)_x)-b_xc_1-b_1c_x)+\alpha((c-3c_1)U_x+(b+b_1)V_x+2(b_1c_y-b_yc_1-(a+d)_{xy}\\&+(b_x+a_1b_1-ab)V-(c_{1,x}+c_1d_1-cd)U))+(b-b_1)V_y+(c-c_1)U_y]=0,\end{aligned}$$

$$
\begin{aligned}
&\alpha^2(bb_{1,t}-b_tb_1)+i[2\alpha^2(2b^2(a_1d_1-b_1c_1)-2bb_1^2(c_1+c)+b_{xx}b_1-b_{1,xx}b-2bd_{1,x}(b+b_1)\\
&\quad+2(b_xdb_1-b_{1,x}d_1b)+b[a_1b_x-2a_{1,x}b_1-b_{xx}-3b_xd_1+2(b_1(d^2-bc)-d_1^2(b+b_1))])\\
&\quad+\alpha((b_1-b)U_{xx}+(3(b_1d-bd_1)+a_1b-ab_1)U_x+2[b_1bV(b+b_1)+bb_y(a_1-d_1)-bb_{xy}\\
&\quad+U(b_1d_x-bd_{1,x}+b_1d^2-bd_1^2-bb_1(c+c_1)+ba_1d_1-b_1ad)])+U_{xy}(b_1-b)+U_y(b(a_1\\
&\quad-d_1)-b_1(a-d))]=0,\\
&\alpha^2(cc_{1,t}-c_tc_1)+i[2\alpha^2(2c^2(b_1c_1-a_1d_1)+2cc_1^2(b_1+b)+c_{1,xx}c-c_1c_{xx}+2ca_{1,x}(c+c_1)\\
&\quad+2(ca_1c_{1,x}-c_1ac_x)+c[2c_1d_{1,x}-d_1c_x+c_{xx}+3c_xa_1+2(c_1(bc-a^2)+a_1^2(c+c_1))])\\
&\quad+\alpha((c_1-c)V_{xx}+(3(ac_1-a_1c)+cd_1-c_1d)V_x+2[c_1cU(c+c_1)+cc_y(d_1-a_1)-cc_{xy}\\
&\quad+V(c_1a_x-ca_{1,x}+c_1a^2-ca_1^2-cc_1(b+b_1)+ca_1d_1-c_1ad)])+V_{xy}(c-c_1)+V_y(c(a_1-d_1)\\
&\quad-c_1(a-d))]=0,\\
&\alpha^2(d_1-d)_t+i[2\alpha^2((d_1^2-d^2+2b_1c_1+a_x+d_{1,x})_x-2((a+d)bc-(b+b_1)c_1d_1-(c+c_1)a_1b_1\\
&\quad-(b_1c)_x)+b_xc_1+b_1c_x)+\alpha((b-3b_1)V_x+(c+c_1)U_x+2(c_1b_y-b_1c_y-(a+d)_{xy}\\
&\quad+(c_x+c_1d_1-cd)U-(b_{1,x}+a_1b_1-ab)V))+(c_1-c)U_y+(b_1-b)V_y]=0.
\end{aligned}
\tag{51}
$$

These formulas are an awful sight! Unfortunately, I don't know how to write them in more compact form in our gauge. Equation (51) has the best form I could imagine.

Although these equations are long and difficult, the end result is quite simple. We can see that all of the $(1+1)$ NLS formalism carried over directly into the $(2+1)$ DS dressing chains. In particular, the chains (51) involve Lax pair for the mDS (49). We do not give it here.

As noted in Sec. III, the KP equations admit two types of chains, which we call conjugate. It is a new result, which is characteristic precisely of multidimensional systems. Of course, it is true for the DS equations.

To construct the chains which are conjugate to (50)–(51), we must introduce the new Lax pair for the DS equations $[p=p(x,y,t),\ f=f(x,y,t)]$

$$
\begin{aligned}
&p_y=\alpha p_x-vf,\quad f_y=-\alpha f_x-up,\\
&p_t=-2ip_{xx}+\frac{2i}{\alpha}vf_x-\left(\frac{1}{2}\left[\frac{1}{\alpha}F_y+F_x\right]-\frac{i}{\alpha^2}uv\right)p+\frac{i}{\alpha^2}(\alpha v_x+v_y)f,\\
&f_t=2if_{xx}+\frac{2i}{\alpha}up_x-\left(\frac{1}{2}\left[\frac{1}{\alpha}F_y-F_x\right]+\frac{i}{\alpha^2}uv\right)f+\frac{i}{\alpha^2}(\alpha u_x-u_y)p,
\end{aligned}
\tag{52}
$$

two matrix functions

$$
\Psi=\begin{pmatrix}\psi_1 & \psi_2\\ \phi_1 & \phi_2\end{pmatrix},\quad \Phi=\begin{pmatrix}p_1 & f_1\\ p_2 & f_2\end{pmatrix},
$$

and one form

$$
d\Omega=\Phi\Psi\,dx+\alpha\Phi\sigma_3\Psi\,dy+2i\left(\Phi\sigma_3\Psi_x-\Phi_x\sigma_3\Psi+\frac{1}{\alpha}\Phi\sigma_3\Psi\right),\quad \Omega=\int d\Omega.
$$

This one form is closed if $\psi_{1,2}$, $\phi_{1,2}$, $p_{1,2}$, and $f_{1,2}$ are solutions of Eqs. (44) and (52) for the same u, v, F. It is easy to see that the quantities

$$A=\frac{p_{1,x}f_2-p_{2,x}f_1}{\Delta},\quad B=\frac{f_{1,x}f_2-f_{2,x}f_1}{\Delta},\quad C=\frac{p_{2,x}p_1-p_{1,x}p_2}{\Delta},$$

$$D=\frac{f_{2,x}p_1-f_{1,x}p_2}{\Delta},\quad \Delta=p_1f_2-p_2f_1.$$

are solutions of the y system

$$\begin{gathered}A_y=\alpha(A_x+2BC)+uC-vB,\quad B_y=-\alpha(B_x+2AB)+(D-A)u-u_x,\\ C_y=\alpha(C_x+2CD)+(A-D)v-v_x,\quad D_y=-A_y+\alpha(A-D)_x.\end{gathered}\tag{53}$$

Here, we don't need t system (four equations for the A_t, B_t, C_t, and D_t).

The Darboux transformation (45) [for the system (44)] give us the transformation rule for the functions A, B, C, D

$$A\to a_1=\Lambda_{11}-a,\quad B\to b_1=\Lambda_{12}-b,\quad C\to c_1=\Lambda_{21}-c,\quad D\to d_1=\Lambda_{22}-d,$$

where a, b, c, and d are defined in (46), and Λ_{ik} are elements of the matrix $\Lambda=\Psi\Omega^{-1}\Phi$, $i,k=1,2$. Transforming the system (53) and exluding potentials u and v from this system and from the first four equations (47), we get y chains which are conjugate to (50). There are four equations; two of them are equaivalent to the first and fourth equations (50). The remaining two equations are given by

$$\begin{aligned}&(bc_1-b_1c)[(b+b_1)_y+\alpha(b+b_1)_x]+(a+a_1-d-d_1)[\alpha(a_xb_1-a_{1,x}b)+a_{1,y}b-a_yb_1]\\&\quad-2\alpha[(b+b_1)(abc_1+a_1b_1c)-bb_1(c+c_1)(d+d_1)]=0,\end{aligned}$$

$$\begin{aligned}&(b_1c-bc_1)[(c+c_1)_y-\alpha(c+c_1)_x]+(a+a_1-d-d_1)[\alpha(a_xc_1-a_{1,x}c)+a_{1,y}c-a_yc_1]\\&\quad+2\alpha[(c+c_1)(bc_1d_1+b_1cd)-cc_1(b+b_1)(a+a_1)]=0.\end{aligned}$$

The conjugate t chains can be obtained by the same way. We do not give them here.

VI. ON THE LOCALIZED SOLUTIONS OF THE DS EQUATIONS

Discrete symmetries are a good way to obtain exact solutions of the nonlinear integrable equations. In Ref. 14 we applied the DT (S symmetry) to construct exact solutions to the DS-I and DS-II equations (the same to the BLP equations; see Ref. 15). In particular, we have obtained the dromion solutions of the DS-I equations. In this section we use the T symmetry to construct nonsingular solutions to the DS-I that fall off according to the exponential and/or rational low along *all* directions in the plan (see also Ref. 16). In the rest of this section we present (via S symmetry) novel exact solution of the DS-II equations describing the soliton on the plane-wave background.

A. DS-I equations

To study the DS-I equations it is convenient to use the following change of variables:

$$\partial_x\to\frac{1}{\sqrt{2}}(\partial_x+\partial_y),\quad \partial_y\to\frac{1}{\sqrt{2}}(\partial_x-\partial_y),\quad v\to-\frac{\overline{u}}{2}.$$

We are interested in localized solutions to the DS-I equations which move without shape distortions, and we look for these solutions in the form

$$u(t,x,y)=\overline{v(t,x,y)}=U(\xi,\eta)\exp(i\theta),\quad q(t,x,y)=Q(\xi,\eta),$$

where

$$\xi = x - 2at, \quad \eta = x - 4bt, \quad \theta = ax + by - (a^2 + b^2)t,$$

and $U(\xi, \eta)$ is the real function. It was shown in Ref. 16 that a solution to the DS-I equations can be found in this setting from the nonlinear Liouville equation

$$\partial_x \partial_y \Phi = \tfrac{1}{2} \exp(\Phi), \tag{54}$$

for the function $\Phi \equiv \log(U^2)$. This result was obtained via the T symmetries (see the previous section).

It is convenient to introduce the boundary conditions for the $U(x,y)$ as

$$U(x,0) = A(x), \quad U(0,y) = B(y), \quad A(0) = B(0) = C, \tag{55}$$

where $A(x)$ and $B(y)$ are the given functions. Now, we can use the solution to the Gousat problem for (54) given in Ref. 17, from which we find

$$U(x,y) = \frac{4CA(x)B(y)}{4C^2 - \int_0^x dp A^2(p) \int_0^y dq B^2(q)}. \tag{56}$$

Using T symmetries, one can also find the explicit expression for the $Q(x,y)$ field

$$Q(x,y) = \frac{1}{2}\left(P'\left(\frac{1}{P'}\right)'' + G'\left(\frac{1}{G'}\right)''\right) - \frac{3}{4}([(\log P')']^2 + [(\log G')']^2) + \frac{2}{PG-4}\left(PG'' + P''G - \frac{(PG')^2 + (P'G)^2 + 8P'G'}{PG-4}\right),$$

where

$$P(x) = \frac{1}{C}\int_0^x dp A^2(p), \quad G(y) = \frac{1}{C}\int_0^y dq\, B^2(q).$$

Expression (56) also allows us to construct localized solutions. For example, choosing the boundary functions in the form of two solutions of the NLS equation, we obtain the well-known ''one-dromion'' solution.[18] Other localized objects are found by choosing the boundary conditions appropriately. Thus, assuming $A(x)$ and $B(y)$ to be solutions of the KdV equation, we obtain a new solution that decays exponentially in **all directions**.[16] It is possible to show that these equations are different from the (L,M) dromions[19] and N^2-soliton solutions built in Refs. 20 and 21.

The rational localized solutions (''lamps'') are obtained in the same way. We get the two-lamp solution and the four-lamp solution in Ref. 16. One can always choose the parameters such that the solutions falling off in all directions according to rational law are nonsingular. Finally, we can obtain the localized solution falling off according to the exponential law as a function of x and according to the ratianol law as a function of x.

B. DS-II equations

We couldn't find a localized nonstationary solution of the DS-II equation. We present only soliton on the plane-wave background. We choose the initial solution of the DS-II equations as

$$u = A\exp(iS), \quad S = -(2A^2 + a^2 - b^2)t + ax + by, \quad q = 0,$$

where A, a and b are real constants. The solutions of the Lax pair (44)

$$\psi_1 = f \exp\left(i\frac{S}{2} + M \right), \quad \psi_2 = \frac{\overline{i(2m-b)-p}}{2A}\left(f - 2i\frac{\alpha_1}{p} \right)\exp\left(i\frac{S}{2} + \overline{M} \right),$$

where

$$f = \alpha_1\left[x + \frac{1}{p}((b-2m)y + 2(2(bm - A^2 - 2m^2) - ap)t) \right] + \alpha_2,$$

$$M = mx + \tfrac{1}{2}((p-a)y + [p(b+2m) - 4am]t), \quad p^2 + [4A^2 + (b-2m)^2]^2 = 0.$$

Using (45) (with $\overline{m} = m$, $\overline{\alpha_1} = \alpha_1$, and $\alpha_2 = 0$) we get nonsingular solution u_1 which is the soliton on the plane-wave background

$$|u_1|^2 \to A^2 \quad \text{at} \quad x^2 + y^2 \to \infty.$$

This solution is a two-dimensional generalization of the ''exulton'' solution of the NLS built in Ref. 1.

VII. CONCLUSION

The past years of intense theoretical research have made it increasingly clear that the secret to integrability most likely lies in the power of discrete symmetries. Let us summarize some of the promising features of the discrete symmetries.

(1) It is an extremely powerful method to construct exact solutions of integrable equations.
(2) This approach includes all ''soliton miracles:'' finite-gap solutions, the Painleve property, etc.
(3) Discrete symmetries allow us to proliferate integrable equations. For example, the whole MKdV theory can be considered as the DT theory and the Toda–Volterra theory can be considered as the theory of S- and T symmetries of the NLS equations (Ref. 9).
(4) Discrete symmetries led to a connection between integrable system and supersymmetry.
(5) Discrete symmetries allow us to construct discrete integrable systems.

Ideally, we would want a unified theory to unite and understand all soliton miracles. There are two ways to find this unified theory. The first path is connected with the Hirota bilinear difference equation.[22] This famous equation is known to provide a canonical integrable discretization for most important types of soliton equation.

The second path is the theory of dressing chains. This approach allows us to proliferate integrable equations and, at the same time, to establish a link between known integrable equations (it is clear that the Miura map can be obtained from the dressing chains). Ideally, we want to show that all integrable equations are nothing but different forms of a single equation!

Even if this direction is right, it is still a long way off. Now, the theory itself often seems like a confused jumble of random (but useful) rules and random (but remarkable) observations. It remains to be seen how useful the dressing chains will become in the future.

Long-time asymptotics are established for finite energy solutions of the scalar Klein–Gordon equation coupled to a relativistic classical particle: any ''scattering'' solution is asymptotically a sum of a soliton and of a dispersive free wave packet as $t \to \pm\infty$. These asymptotics mean the nonlinear scattering of free wave packets by the soliton. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1539900]

I. INTRODUCTION: KLEIN–GORDON FIELD COUPLED TO A CLASSICAL PARTICLE

In this paper we consider the classical scalar Klein–Gordon equation coupled (noncovariantly) to a relativistic classical particle subjected to an external potential V of compact support. The system is a finite-range perturbation of the corresponding translation-invariant system without V that admits soliton-type solutions describing a particle traveling with constant velocity that is dressed by a comoving wave field. The set of all such solutions forms a finite-dimensional manifold, called the *soliton manifold*, in the phase space (a Hilbert space) of the unperturbed system. We are interested in *scattering* solutions of the perturbed system in which the particle travels to infinity as $t \to \pm\infty$.

The reason for the name *soliton manifold* resides the fact, proven in this paper, that it is an attracting set for the scattering solutions of the perturbed dynamical system. The attraction holds in the Fréchet topology defined by the local energy seminorms.

Our main result is the long-time asymptotics in the global energy norm: each scattering solution is asymptotically the sum of a soliton and a dispersive free wave as $t \to \pm\infty$. This means that the solution is scattering of the free wave by a soliton. This representation of the solutions gives a mathematical description of the wave-particle duality: for $t = -\infty$ such solution is a union of a ''particle'' = soliton and ''photon'' = free wave, for finite t the solution in general does not admit such a representation, and for $t = \infty$ the representation again appears.

Previously similar results have been proved for relativistic charged particles coupled, respectively, to the wave equation corresponding to $m = 0$ (Refs. 11 and 13) and to Maxwell's equations.[2,10,16] The proof of these results is based on the nonautonomous integral inequality method[19] that uses essentially the strong Huygen's principle. In the case of the Klein–Gordon equation with $m > 0$ the strong Huygen's principle fails. That is why we develop a new more general version of the integral inequality method that does not use the strong Huygen's principle. An important role play the known time decay of the Green function for the Klein–Gordon equation and a sufficiently fast spatial decay of the solitons in the case $m > 0$.

[b)]Electronic mail: komech@mathematik.tu-muenchen.de
[c)]Electronic mail: peter.markowich@univie.ac.at

We consider a scalar wave field $\psi(x)\in\mathbb{R}$, $x\in\mathbb{R}^3$, coupled to a relativistic particle with position q and momentum p, governed by

$$\dot{\psi}(x,t)=\pi(x,t),\quad \dot{\pi}(x,t)=\Delta\psi(x,t)-m^2\psi(x,t)-\rho(x-q(t)),$$
$$\dot{q}(t)=p(t)/(1+p^2(t))^{1/2},\quad \dot{p}(t)=-\nabla V(q(t))+\int d^3x\ \psi(x,t)\,\nabla\rho(x-q(t)) \tag{1}$$

subject to appropriate initial conditions determining the dynamics. This is a Hamiltonian system with the Hamiltonian functional

$$\mathcal{H}(\psi,\pi,q,p)=(1+p^2)^{1/2}+V(q)+\frac{1}{2}\int d^3x(|\nabla\psi(x)|^2+m^2|\psi(x)|^2+|\pi(x)|^2)$$
$$+\int d^3x\ \psi(x)\rho(x-q). \tag{2}$$

We have set the mechanical mass of the particle and the speed of wave propagation equal to one. The case of the point particle corresponds to $\rho(x)=\delta(x)$ and then the interaction term in the Hamiltonian is simply $\psi(q)$. This would result however in an energy which is not bounded from below implying for the scattering theory the well-known ultraviolet divergence. Therefore we smooth the coupling by the function $\rho(x)$ following the strategy proposed by Abraham[1] for the Maxwell field. Respectively, the system (1) is not relativistic covariant. In analogy to the Maxwell–Lorentz equations we call ρ the ''charge distribution.'' We assume the real-valued function ρ to be in the Sobolev space H^1 and of compact support, i.e.,

$$\rho,\nabla\rho\in L^2(\mathbb{R}^3),\quad \rho(x)=0\ \text{ for }\ |x|\geqslant R_\rho. \tag{C}$$

An important assumption is that the norm of ρ in L^2 is sufficiently small,

$$\gamma_\rho:=\|\rho\|_{L^2}\ll 1 \tag{3}$$

meaning *weak* field-particle interaction.

For the potential V we introduce two sets of assumptions: smooth and bounded from below,

$$V\in C^2(\mathbb{R}^3),\quad V_0:=\inf_{q\in\mathbb{R}^3}V(q)>-\infty; \tag{$P_{\min}$}$$

and of a compact support,

$$V(x)\equiv 0\quad \text{for }\ |x|>R_V>0. \tag{K}$$

Consider the corresponding nonperturbed system with $V\equiv 0$:

$$\dot{\psi}(x,t)=\pi(x,t),\quad \dot{\pi}(x,t)=\Delta\psi(x,t)-m^2\psi(x,t)-\rho(x-q(t)),$$
$$\dot{q}(t)=p(t)/(1+p^2(t))^{1/2},\quad \dot{p}(t)=\int d^3x\ \psi(x,t)\,\nabla\rho(x-q(t)). \tag{4}$$

The system (4) has solutions traveling with constant velocity $v,|v|<1$. Up to spatial translations they are given by

$$S_v(t)=(\psi_v(x-vt),\pi_v(x-vt),vt,p_v) \tag{5}$$

with

$$\psi_v(x) = -\frac{1}{4\pi}\int \frac{e^{-m|(y-x)_\parallel + \lambda(y-x)_\perp|}\rho(y)d^3y}{|(y-x)_\parallel + \lambda(y-x)_\perp|},$$
$$\pi_v(x) = -v\cdot\nabla\psi_v(x), \quad p_v = v/\lambda. \tag{6}$$

Here we set $\lambda = \sqrt{1-v^2}$ and $x = x_\parallel + x_\perp$, where $v \| x_\parallel \in \mathbb{R}^3$ and $v \perp x_\perp \in \mathbb{R}^3$ for $x \in \mathbb{R}^3$. We call $S_v(t)$ the *soliton* with velocity v centered at $q(t) = vt$.

Let us discuss and summarize now our main results, the precise theorems to be stated in the following sections. Consider the set of scattering solutions to (1) for which $|q(t)| \to \infty$ as $t \to \infty$. Below we discuss the properties of these solutions. Since only a finite amount of energy can be dissipated to infinity, we shall show the relaxation of acceleration,

$$\ddot{q}(t) \to 0, \quad t \to \pm\infty. \tag{7}$$

More precisely, we shall establish the rate of convergence $|\ddot{q}(t)| \sim t^{-1-\sigma}$ with a $\sigma > 0$. This is a crucial point of our asymptotic analysis. It implies that

$$\dot{q}(t) \to v_\pm, \quad t \to \pm\infty. \tag{8}$$

Also we show that the fields are asymptotically traveling waves in the sense

$$(\psi(x,t), \pi(x,t)) \sim (\psi_{v_\pm}(x - q(t)), \pi_{v_\pm}(x - q(t))), \quad t \to \pm\infty. \tag{9}$$

Since the energy is conserved, the convergence here is in the sense of local energy seminorms, cf. Sec. II. Further, we shall establish the corresponding asymptotics in the *global* energy norm,

$$(\psi(x,t), \pi(x,t)) \sim (\psi_{v_\pm}(x - q(t)), \pi_{v_\pm}(x - q(t))) + U(t)\Psi_\pm, \quad t \to \pm\infty, \tag{10}$$

where $U(t)$ is the unitary group generated by the free Klein–Gordon equation, and $\Psi_\pm$ are the scattering states. At last we suggest simple sufficient conditions for solutions to be scattering. Note that all finite energy solutions are scattering if $V(x) \equiv 0$. We prove (8), (9), and (10) with the assumption (3), however we suggest the same asymptotics hold in more general framework.

We mention now some previous results which reflect the gradual progress in investigating the long-time asymptotics for coupled field-particle equations.

The results of Ref. 14 for the wave equation, $m = 0$, imply the long-time convergence to the set of solitons of type (5) in the sense of local energy seminorms, as in (9).

Soliton-type asymptotics were proved for certain translation invariant completely integrable 1D equations.[18] Soliton-type asymptotics in *local* energy seminorms was proved for a translation invariant 3D system of a scalar field coupled to a particle[15] and for translation invariant 1D kinetic-reaction systems.[8]

Soliton-type asymptotics of type (10) in *global* energy norm were proved initially for *small perturbations* of soliton-type solutions of 1D nonlinear Schrödinger equations.[3,4]

Soliton-type asymptotics of type (10) in the energy norm for all finite energy scattering solutions is proved here for the first time for coupled particle-field equations (1). The asymptotics is provided by radiation of the energy to infinity which leads to the relaxation (7). The relaxation in classical electrodynamics is known as ''radiative damping'' studied by Lorentz,[17] Dirac,[5] Feynman[7] and others.[9]

Note that a lot of numerical experiments[12] confirm the long-time convergence of an arbitrary finite energy solution of a general relativistic equation to a finite sum of solitons with velocities less than the light speed and of ''photons'' propagating at the light speed. Nevertheless the proof remains an absolutely open problem.

II. EXISTENCE OF DYNAMICS, *A PRIORI* ESTIMATES

To formulate our results precisely, we need some definitions. We introduce the phase space suitable for the Cauchy problem corresponding to (1) and (2). Let L^2 be the real Hilbert space $L^2(\mathbb{R}^3)$ with scalar product $\langle\cdot,\cdot\rangle$ and norm $|\cdot|$, and let H^1 be the Sobolev space $H^1=\{\psi \in L^2: |\nabla\psi| \in L^2\}$ with the norm $\|\psi\|=|\psi|+|\nabla\psi|$. Let $|\psi|_R$ denote the norm in $L^2(B_R)$ for $R>0$, where $B_R=\{x\in\mathbb{R}^3:|x|\leqslant R\}$. Then the seminorms $\|\psi\|_R=|\psi|_R+|\nabla\psi|_R$ are continuous on H^1.

Definition 1: (i) The phase space $\mathcal{E}$ is the Hilbert space $H^1\times L^2\times\mathbb{R}^3\times\mathbb{R}^3$ of states $Y=(\psi,\pi,q,p)$ with finite norm

$$\|Y\|_{\mathcal{E}}=\|\psi\|+|\pi|+|q|+|p|\,.$$

(ii) $\mathcal{E}_F$ is the space $\mathcal{E}$ endowed with the Fréchet topology defined by the local energy seminorms

$$\|Y\|_R=\|\psi\|_R+|\pi|_R+|q|+|p|,\quad \forall R>0\,.$$

(iii) $\mathcal{F}$ is the Hilbert space $H^1\times L^2$ of fields $\Psi=(\psi,\pi)$ with finite norm

$$\|\Psi\|_{\mathcal{F}}=\|\psi\|+|\pi|\,.$$

(iv) $\mathcal{F}_F$ is the space $\mathcal{F}$ endowed with the Fréchet topology defined by the local energy seminorms

$$\|\Psi\|_R=\|\psi\|_R+|\pi|_R\,,\quad \forall R>0\,.$$

Note that both spaces $\mathcal{E}$ and $\mathcal{E}_F$ are metrisable. For $\psi\in L^2$ we have

$$-\frac{1}{2m^2}|\rho|^2\leqslant\frac{m^2}{2}|\psi|^2+\langle\psi,\rho(\cdot-q)\rangle\leqslant\frac{m^2+1}{2}|\psi|^2+\frac{1}{2}|\rho|^2. \tag{11}$$

Therefore $\mathcal{E}$ is the space of finite energy states. The Hamiltonian functional $\mathcal{H}$ is continuous on the space $\mathcal{E}$ and the lower bound in (11) implies that the energy functional (2) is bounded from below, namely,

$$\inf_{Y\in\mathcal{E}}\mathcal{H}(Y)\geqslant 1+V_0-\frac{1}{2m^2}|\rho|^2. \tag{12}$$

We consider the Cauchy problem for the Hamiltonian system (1), which we write as

$$\dot{Y}(t)=\mathcal{V}_0(Y(t))+\mathcal{V}_1(Y(t)),\quad t\in\mathbb{R},\quad Y(0)=Y^0. \tag{13}$$

All derivatives are understood in the sense of distributions. Here $Y(t)=(\psi(t),\pi(t),q(t),p(t))$, $Y^0=(\psi^0,\pi^0,q^0,p^0)\in\mathcal{E}$, and $\mathcal{V}_0: Y\mapsto(\pi,\Delta\psi-m^2\psi,0,0)$. Recall that we are interested in situations where the particle is allowed to travel to infinity, e.g., when the external potential $V(q)$ vanishes identically. The existence of dynamics is true under such conditions ($P_{\min}$).

Theorem 2: *Let (C) and $(P_{\min})$ hold. Then (i) for every $Y^0\in\mathcal{E}$ the Cauchy problem (13) has a unique solution $Y(t)\in C(\mathbb{R},\mathcal{E})$. (ii) For every $t\in\mathbb{R}$ the map $W_t: Y^0\mapsto Y(t)$ is continuous both on $\mathcal{E}$ and on $\mathcal{E}_F$. (iii) The energy is conserved, i.e.,*

$$\mathcal{H}(Y(t))=\mathcal{H}(Y^0)\quad \text{for } t\in\mathbb{R}. \tag{14}$$

(iv) The speed is bounded,

$$|\dot{q}(t)|\leqslant\overline{v}<1\quad \text{for } t\in\mathbb{R}. \tag{15}$$

Proof: We follow Ref. 14, where the case $m=0$ is considered. Let us fix an arbitrary $b>0$ and prove (i)–(iii) for $\|Y^0\|_{\mathcal{E}}\leqslant b$ and $|t|\leqslant\varepsilon=\varepsilon(b)$ for some sufficiently small $\varepsilon(b)>0$.

ad (i) Fourier transform provides the existence and uniqueness of solution $Y_0(t) \in C(\mathbb{R},\mathcal{E})$ to the linear problem (13) with $\mathcal{V}_1 = 0$. Let $W_t^0 : Y^0 \mapsto Y_0(t)$ be the corresponding strongly continuous group of bounded linear operators on $\mathcal{E}$. Then uniqueness of solution to the (inhomogeneous) linear problem implies that (13) for $Y(t) \in C(\mathbb{R},\mathcal{E})$ is equivalent to

$$Y(t) = W_t^0 Y^0 + \int_0^t ds\, W_{t-s}^0 \mathcal{V}_1(Y(s)), \tag{16}$$

because $\mathcal{V}_1(Y(\cdot)) \in C(\mathbb{R},\mathcal{E})$ in this case. The latter follows from a local Lipschitz continuity of the map $\mathcal{V}_1$ in $\mathcal{E}$: for each $b>0$ there exist a $\kappa = \kappa(b) > 0$ such that for all $Y, Z \in \mathcal{E}$ with $\|Y\|_{\mathcal{E}}, \|Z\|_{\mathcal{E}} \leqslant b$,

$$\|\mathcal{V}_1(Y) - \mathcal{V}_1(Z)\|_{\mathcal{E}} \leqslant \kappa \|Y - Z\|_{\mathcal{E}}. \tag{17}$$

For example, we have

$$\left| \int d^3x\, (\psi_1(x) - \psi_2(x)) \nabla \rho(x-q) \right| \leqslant |\nabla(\psi_1 - \psi_2)||\rho|.$$

Moreover, by the contraction mapping principle, Eq. (16) has a unique local solution $Y(\cdot) \in C([-\varepsilon,\varepsilon],\mathcal{E})$ with $\varepsilon > 0$ depending only on b. Then the existence of the global dynamics will follow from the *a priori* estimate, see in *ad (iii)* below.

ad (ii) The map $W_t : Y^0 \mapsto Y(t)$ is continuous in the norm $\|\cdot\|_{\mathcal{E}}$ for $|t| \leqslant \varepsilon$ and $\|Y^0\| \leqslant b$. To prove continuity of W_t in $\mathcal{E}_F$, let us consider Picard's successive approximation scheme

$$Y^N(t) = W_t^0 Y^0 + \int_0^t ds\, W_{t-s}^0 \mathcal{V}_1(Y^{N-1}(s)), \quad N = 1,2,\ldots .$$

The equation for q^N in this system implies $|\dot{q}^N(t)| < 1$ and therefore $|q(t)| < |q^0| + |t|$. Now we fix $t \in \mathbb{R}$ and choose $R > |q^0| + |t| + R_\rho$ with R_ρ from (C). From the explicit solution of the free Klein–Gordon equation $W_t^0 Y^0$ (see Sec. III) we conclude that every Picard's approximation $Y^N(t)$ and hence the solution $Y(t) = (\psi(x,t), \pi(x,t), q(t), p(t))$ for $|x| < R$ depends only on the initial data $(\psi^0(x), \pi^0(x), q^0, p^0)$ with $|x| < R + |t|$. Thus the continuity of W_t in $\mathcal{E}_F$ follows from the continuity in $\mathcal{E}$.

ad (iii) For $k = 0,1,\ldots$ denote by $C_0^k(\mathbb{R}^3)$ the space of functions $\psi(x) \in C^k(\mathbb{R}^3)$ with compact support. For initial data $(\psi^0, \pi^0) \in C^3(\mathbb{R}^3) \times C^2(\mathbb{R}^3)$ the solution $\psi = \psi(x,t)$ satisfies $\psi \in C^2(\mathbb{R}^3 \times \mathbb{R})$. Indeed, this is well known for the solution $W_t^0 Y^0$ of the linear Klein–Gordon equation. The integral representation (16) then implies the same property for ψ. In addition, let Y^0 have compact support, i.e.,

$$\psi^0(x) = \pi^0(x) = 0 \quad \text{for} \quad |x| > R^0 \tag{18}$$

with some $R^0 > 0$. Since $|q(t)| < |q^0| + |t|$, (16) implies

$$\psi(x,t) = 0 \quad \text{for } |x| \geqslant |t| + \max\{R^0, R_\rho + |q^0| + |t|\}.$$

Thus, for such initial data energy conservation can be shown by integration by parts. Hence (iii) follows from the continuity of W_t and the fact that $C_0^3(\mathbb{R}^3) \oplus C_0^2(\mathbb{R}^3) \oplus \mathbb{R}^3 \oplus \mathbb{R}^3$ is dense in $\mathcal{E}$.

We use now energy conservation to ensure the existence of a global solution and its continuity. Similar to (11) we have

$$\mathcal{H}(Y) \geqslant \frac{1}{2}|\pi|^2 + \frac{1}{2}|\nabla\psi|^2 + \frac{m^2}{4}|\psi|^2 + \sqrt{1+p^2} + V(q) - \frac{1}{m^2}|\rho|^2,$$

and by energy conservation, for $|t| \leqslant \varepsilon$,

$$\frac{1}{2}|\pi(t)|^2+\frac{1}{2}|\nabla\psi(t)|^2+\frac{m^2}{4}|\psi|^2+\sqrt{1+p^2(t)}+V(q(t))-\frac{1}{m^2}|\rho|^2\leqslant\mathcal{H}(Y(t))=\mathcal{H}(Y^0). \quad (19)$$

Therefore $(P_{\min})$ implies the *a priori* estimate

$$\|\psi(t)\|+|\pi(t)|+|p(t)|\leqslant B \text{ for } t\in\mathbb{R} \quad (20)$$

with B depending only on the norm $\|Y^0\|_{\mathcal{E}}$ of the initial data and on $|\rho|$. Properties (i)–(iii) for arbitrary $t\in\mathbb{R}$ now follow from the same properties for small $|t|$ and from the *a priori* bound (20).

ad (iv) Note first that (20) implies $|p(t)|\leqslant p_0<\infty$. Hence

$$|\dot{q}(t)|/(1-\dot{q}^2(t))^{1/2}=|p(t)|\leqslant p_0<\infty,$$

which yields $|\dot{q}(t)|\leqslant q_1=:\overline{v}<1$. □

III. INTEGRAL INEQUALITY ARGUMENT

Definition 3: Let $0<\sigma<1/2$ *and let* $\alpha=(1-2\sigma)/3$. *The set* $\mathcal{E}^\sigma$ *is the set of the states* $(\psi,\pi,q,p)\in\mathcal{E}$ *such that*

$$\int_{R\leqslant|x|}d^3x(R^2|\psi(x)|^2+|\nabla\psi(x)|^2)=\mathcal{O}(R^{-(4+2\sigma)}) \quad (21)$$

and

$$\int_{R^\alpha\leqslant|x|}d^3x\ (|\psi(x)|^2+|\pi(x)|^2)=\mathcal{O}(R^{-(4+2\sigma)}) \quad (22)$$

as $R\to+\infty$.

If the soliton-type asymptotics is approximately valid, then the field should be close to the soliton centered at $q(t)$ with velocity $v(t)=\dot{q}(t)$. We therefore consider the difference

$$Z(x,t)=\Psi(x,t)-\Psi_{v(t)}(x-q(t)), \quad (23)$$

where

$$\Psi(x,t)=(\psi(x,t),\pi(x,t))$$

and $\Psi_v(x)=(\psi_v(x),\pi_v(x))$ is the field part of the soliton. Defining $\overline{\rho}(x)=(0,\rho(x))$ and $A(\psi,\pi)=(\pi,\Delta\psi-m^2\psi)$, it follows that Ψ obeys the equations of motion:

$$\dot{\Psi}(x,t)=A\Psi(x,t)-\overline{\rho}(x-q(t)). \quad (24)$$

On the other hand, for the soliton field Ψ_v with a fixed v, the equation

$$-\frac{\partial\Psi_v}{\partial x}(x-q(t))v=A\Psi_v(x-q(t))-\overline{\rho}(x-q(t)) \quad (25)$$

holds. Then (24) and (25) imply the following equation for Z:

$$\dot{Z}(x,t)=AZ(x,t)-\frac{\partial\Psi_{v(t)}}{\partial p}(x-q(t))\dot{p}(t). \quad (26)$$

Here, according to the chain rule,

$$\frac{\partial \Psi_v}{\partial p} = \frac{\partial \Psi_v}{\partial v}\frac{\partial v}{\partial p}, \tag{27}$$

where $\partial v/\partial p$ is the Jacobi matrix of the map $p \mapsto v(p) = p/\sqrt{1+p^2}$.

Proposition 4: Let (C), $(P_{\min})$, (K) *hold, let the solution* $Y(t)$ *to the system (1) be scattering and* $Y(0) \in \mathcal{E}^\sigma$ *for a certain* $\sigma \in (0;1/2)$. *Then for any* $R>0$ *and sufficiently small* $\gamma_\rho := |\rho|$,

$$\|Z(\cdot + q(t),t)\|_R \leqslant C_R(Z(0),q^0,\overline{v},R_\rho)(1+|t|)^{-1-\sigma}. \tag{28}$$

Proof: First, we prove the estimate with $R = R_\rho$. Definition (23) implies $Z(\cdot,t) \in \mathcal{F}$. Solving the equations (26) we get the mild solution representation,

$$Z(t) = U(t)Z(0) - \int_0^t U(t-s)\left[\frac{\partial \Psi_{v(s)}}{\partial p}(\cdot - q(s))\dot{p}(s)\right] ds, \tag{29}$$

with $U(t)$ the group generated by the free Klein–Gordon equation in $H^1 \oplus L^2$, see the explicit formulas in Sec. III A below.

Thus, the proof consists of two essential parts: (1) estimating, in local seminorms, the action of the free Klein–Gordon group $U(t)Z(0)$ and (2) estimating, in local seminorms, the free Klein–Gordon group applied to the Jacobian of the soliton field, $U(t-s)[\partial \Psi_{v(s)}/\partial p(\cdot - q(s))]$.

A. Local decay for the free Klein–Gordon group

Let us denote $S_t(x) = \{y\colon |y-x| = t\}$, $B_t(x) = \{y\colon |y-x| \leqslant t\}$. For sufficiently smooth initial data, say $u_0, v_0 \in C_0^\infty(\mathbb{R}^3)$, the action of the free Klein–Gordon group in $\mathbb{R}^3$ reads [Ref. 6, Chap. 5, formulas (6.4), (6.11), (6.12)],

$$U(t)(u_0(x),v_0(x)) = (u(x,t),v(x,t)) = (u_w(x,t) - u_m(x,t), v_w(x,t) - v_m(x,t))$$

with

$$u_w(x,t) = \frac{1}{4\pi t^2}\int_{S_t(x)} d^2y\, u_0(y) + \frac{1}{4\pi t}\int_{S_t(x)} d^2y \frac{\partial u_0(y)}{\partial n} + \frac{1}{4\pi t}\int_{S_t(x)} d^2y\, v_0(y), \tag{30}$$

$$u_m(x,t) = \frac{m^2}{8\pi}\int_{S_t(x)} d^2y\, u_0(y) + \frac{m}{4\pi}\int_{B_t(x)} d^3y\, \dot{F}(t,x-y)u_0(y) + \frac{m}{4\pi}\int_{B_t(x)} d^3y\, F(t,x-y)v_0(y), \tag{31}$$

and

$$\begin{aligned} v_w(x,t) = \dot{u}_w(x,t) = {} & \frac{1}{2\pi t^2}\int_{S_t(x)} d^2y \frac{\partial u_0(y)}{\partial n} + \frac{1}{4\pi t}\int_{S_t(x)} d^2y \frac{\partial^2 u_0(y)}{\partial n^2} \\ & + \frac{1}{4\pi t^2}\int_{S_t(x)} d^2y\, v_0(y) + \frac{1}{4\pi t}\int_{S_t(x)} d^2y \frac{\partial v_0(y)}{\partial n}, \end{aligned} \tag{32}$$

$$\begin{aligned} v_m(x,t) = \dot{u}_m(x,t) = {} & \frac{m^2}{4\pi t}\int_{S_t(x)} d^2y\, u_0(y) - \frac{m^4 t}{32\pi}\int_{S_t(x)} d^2y\, u_0(y) + \frac{m^2}{8\pi}\int_{S_t(x)} d^2y \frac{\partial u_0(y)}{\partial n} \\ & + \frac{m}{4\pi}\int_{B_t(x)} d^3y\, \ddot{F}(t,x-y)u_0(y) + \frac{m^2}{8\pi}\int_{S_t(x)} d^2y\, v_0(y) \\ & + \frac{m}{4\pi}\int_{B_t(x)} d^3y\, \dot{F}(t,x-y)v_0(y). \end{aligned} \tag{33}$$

Here $n = (y-x)/|y-x|$ is the exterior unit normal vector of the sphere $S_t(x)$ at a point y,

$$F(t,z)=\frac{J_1(m\sqrt{t^2-z^2})}{\sqrt{t^2-z^2}},$$

J_1 being the Bessel function of order 1. Note that $(u_w(x,t),v_w(x,t))$ is the solution to the free wave equation corresponding to $m=0$, with the same initial conditions (u_0,v_0). From the well-known asymptotics

$$|J_1(s)|+|J_1'(s)|+|J_1''(s)|=\mathcal{O}(|s|^{-1/2}) \quad \text{as } s\to\infty$$

of the Bessel function, see Ref. 20, Chap. XVII, it follows that

$$|F(t,z)|+|\dot{F}(t,z)|+|\ddot{F}(t,z)|+|\nabla_z F(t,z)|=\mathcal{O}(|t|^{-3/2}) \quad \text{as } t\to\infty, \tag{34}$$

if $|z|\leqslant\nu|t|$ with $0<\nu<1$. However, near the boundary of the cone $|z|=|t|$ only some weaker decay is valid, namely for $|z|\leqslant|t|-1$,

$$|F(t,z)|+|\dot{F}(t,z)|+|\ddot{F}(t,z)|+|\nabla_z F(t,z)|=\mathcal{O}(|t|^{-3/4}) \quad \text{as } t\to\infty, \tag{35}$$

Definition 5: The set $\mathcal{F}^\sigma$ for $0<\sigma<1/2$ is the set of the fields $(\psi,\pi)\in\mathcal{F}$ satisfying the conditions (21),(22).

Lemma 6: Let $(u_0,v_0)\in\mathcal{F}^\sigma$ with some $\sigma\in(0;1/2)$. Then $\forall R>0$,

$$\|U(t)(u_0,v_0)\|_R\leqslant C(u_0,v_0,R)(1+|t|)^{-1-\sigma}. \tag{36}$$

Proof: Note that for any fixed t the map $U(t):(u_0,v_0)\to(u(t),v(t))$ is continuous in $\mathcal{F}$. For initial data $(u_0,v_0)\in\mathcal{F}^\sigma$ we can approximate them with u_0^n, $v_0^n\in C_0^\infty$ such that the bounds (21), (22) hold for u_0, v_0 uniformly in n. Hence, it is sufficient to obtain the estimate (36) for $u_0,v_0\in C_0^\infty$, with $C(u_0,v_0,R)$ depending only on the constant of (21), (22) and on the norm of u_0,v_0 in $\mathcal{F}$. Thus, we may use the integral representation (30) to (33).

At first consider (u_w,v_w). For the free wave equation the following energy inequality is well known:

$$\int_{B_R}d^3x(|\nabla u_w(x,t)|^2+|v_w(x,t)|^2)\leqslant\int_{B_{t+R}}d^3x(|\nabla u_0(x)|^2+|v_0(x)|^2).$$

Further, from the strong Huygen's principle it follows that for $t>R$ the solution $(u_w(x,t),v_w(x,t))$ does not change if one replaces $u_0(x)$, $v_0(x)$ by zero inside the ball B_{t-R}. Hence,

$$\int_{B_R}d^3x(|\nabla u_w(x,t)|^2+|v_w(x,t)|^2)\leqslant\int_{B_{t-R,t+R}}d^3x(|\nabla u_0(x)|^2+|v_0(x)|^2),$$

where $B_{t-R,t+R}=\{x\in\mathbb{R}^3: t-R\leqslant|x|\leqslant t+R\}$. Then the conditions (21), (22) imply, for sufficiently large t,

$$|\nabla u_w(\cdot,t)|_R+|v_w(\cdot,t)|_R\leqslant C(R,u_0,v_0)(1+|t|)^{-1-\sigma}. \tag{37}$$

It remains to estimate $|u_w(\cdot,t)|_R$, $\|u_m(\cdot,t)\|_R$, and $|v_m(\cdot,t)|_R$. We claim that if $(u_0,v_0)\in\mathcal{F}^\sigma$, then for sufficiently large t any of the norms $|I(\cdot,t)|_R$, $\|J(\cdot,t)\|_R$, $|K(\cdot,t)|_R$ is bounded by $C(u_0,v_0,R)(1+|t|)^{-1-\sigma}$ for any integral $I(x,t)$ of (30), $J(x,t)$ of (31), $K(x,t)$ of (33). At first consider the spherical integrals. For example, let us prove these estimates for the integrals

$$I(x,t)=\frac{1}{4\pi t}\int_{S_t(x)}d^2y\,\frac{\partial u_0(y)}{\partial n},\quad J(x,t)=\frac{m^2}{8\pi}\int_{S_t(x)}d^2y\,u_0(y),\quad K(x,t)=\frac{m^4t}{32\pi}\int_{S_t(x)}d^2y\,u_0(y).$$

For $I(x,t)$ we should estimate $|I(\cdot,t)|_R$. We have

$$|I(\cdot,t)|_R^2=\int_{B_R} d^3x(I(x,t))^2$$
$$=\frac{C}{t^2}\int_{B_R} d^3x\left(\int_{S_t(x)} d^2y\,\frac{\partial u_0(y)}{\partial n}\right)^2$$
$$\leqslant\frac{C}{t^2}\int_{B_R} d^3x\ 4\pi t^2\int_{S_t(x)} d^2y\left(\frac{\partial u_0(y)}{\partial n}\right)^2=C_1\int_{B_R} d^3x\int_{S_t(x)} d^2y\left(\frac{\partial u_0(y)}{\partial n}\right)^2.$$

For a non-negative continuous function u and $t\geqslant R$ the following bound follows by integration in polar coordinates and geometric argument:

$$\int_{B_R} d^3x\int_{S_t(x)} d^2y\,u(y)\leqslant 8\pi R^2\int_{B_{t-R,t+R}} d^3x\,u(x). \tag{38}$$

Hence

$$|I(\cdot,t)|_R^2\leqslant C_2R^2\int_{B_{t-R,t+R}} d^3x\left(\frac{\partial u_0(x)}{\partial n}\right)^2 \tag{39}$$

for $t>R$. Thus, from the condition (21) the stated bound follows.

For $J(x,t)$ we should estimate $\|J(\cdot,t)\|_R=|J(\cdot,t)|_R+|\nabla J(\cdot,t)|_R$. Consider $|J(\cdot,t)|_R$. Similar to (39) we obtain

$$|J(\cdot,t)|_R^2\leqslant CR^2t^2\int_{B_{t-R,t+R}} d^3x(u_0(x))^2.$$

Then from the condition (21) the required estimate follows. For $\nabla J(x,t)=(m^2/8\pi)\int_{S_t(x)}d^2y\,\nabla u_0(y)$ the estimate is analogous. Consider $|K(\cdot,t)|_R$. Similarly to (39) we obtain

$$|K(\cdot,t)|_R^2\leqslant CR^2t^4\int_{B_{t-R,t+R}} d^3x(u_0(x))^2.$$

Then the estimate we need follows from the condition (21).

Now estimate the integrals over the balls. For example, consider the integral

$$J(x,t)=\frac{m}{4\pi}\int_{B_t(x)} d^3y\,F(t,x-y)v_0(y).$$

We should estimate $|J(\cdot,t)|_R$ and $|\nabla J(\cdot,t)|_R$. We have

$$|J(x,t)|=C\left|\int_{B_t(x)} d^3y\,F(t,x-y)v_0(y)\right|$$
$$\leqslant C\left|\int_{B_{t^\alpha}(x)} d^3y\,F(t,x-y)v_0(y)\right|+C\left|\int_{B'_{t^\alpha}(x)} d^3y\,F(t,x-y)v_0(y)\right|,$$

where $B_{t^\alpha}(x)=\{y:|y-x|\leqslant t^\alpha\}$, $B'_{t^\alpha}(x)=\{y:t^\alpha\leqslant|y-x|\leqslant t\}$. The first integral is bounded by

$$\left(\int_{B_{t^\alpha}(x)} d^3y\,F^2(t,x-y)\right)^{1/2}\left(\int_{B_{t^\alpha}(x)} d^3y\,v_0^2(y)\right)^{1/2}\leqslant C_1t^{(3\alpha-3)/2}|v_0|\leqslant C_1t^{-1-\sigma}|v_0|$$

for $\alpha=(1-2\sigma)/3$. The second integral is bounded by

$$\left|\int_{B_{t^\alpha,t-1}(x)} d^3y\, F(t,x-y)v_0(y)\right| + \left|\int_{B_{t-1,t}(x)} d^3y\, F(t,x-y)v^0(y)\right|, \tag{40}$$

where $B_{t^\alpha,t-1}(x)=\{y:t^\alpha\leqslant|y-x|\leqslant t-1\}$, $B_{t-1,t}(x)=\{y:t-1\leqslant|y-x|\leqslant t\}$. Further, for sufficiently large t the first integral of (40) is bounded by

$$\left(\int_{B_{t^\alpha,t-1}(x)} d^3y\, F^2(t,x-y)\right)^{1/2}\left(\int_{B_{t^\alpha,t-1}(x)} d^3y\, v_0^2(y)\right)^{1/2}\leqslant C(t^{3-3/2})^{1/2}(t^{-7/2-2\sigma})^{1/2}=Ct^{-1-\sigma},$$

due to (35) and (22). The second integral of (40) is bounded by

$$C\,t\left(\int_{B_{t-1,t}(x)} d^3y\, v_0^2(y)\right)^{1/2}\leqslant Ct^{-1-\sigma}$$

by (22). Thus we have the pointwise bound $|J(x,t)|\leqslant Ct^{-1-\sigma}$ that implies the stated integral bound.

Now let us estimate $|\nabla J(\cdot,t)|_R$. Note that

$$\nabla J(x,t)=\frac{m}{4\pi}\int_{B_t(x)} d^3y\, F(t,x-y)\nabla v_0(y).$$

Since $F(t,x-y)=m/2$ for $|x-y|=t$, the partial integration gives

$$\left|\int_{B_t(x)} d^3y\, F(t,x-y)\frac{\partial}{\partial y_i}v_0(y)\right|\leqslant\frac{m}{2}\int_{S_t(x)} d^2y\,|v_0(y)|+\int_{B_t(x)} d^3y\left|\frac{\partial}{\partial x_i}F(t,x-y)v_0(y)\right|.$$

Then the estimates for both the spherical integral and the integral over the ball are made as above. Hence, the bound $|\nabla J(\cdot,t)|_R\leqslant C(v_0,R)(1+|t|)^{-1-\sigma}$ follows from the condition (22).

Altogether, we obtain that for sufficiently large t the estimate (36) is true. For bounded t this estimate follows from the energy conservation for the free Klein–Gordon equation.

□

Remark: The statement of the lemma is true under some weaker conditions on initial data, than (21), (22). Namely, it suffices to assume that

$$\int_{R\leqslant|x|\leqslant R+1} d^3x(R^2|u_0(x)|^2+|\nabla v_0(x)|^2)=\mathcal{O}(R^{-(4+2\sigma)}),$$

$$\int_{R^\alpha\leqslant|x|\leqslant R} d^3x\ (|u_0(x)|^2+|v_0(x)|^2)=\mathcal{O}(R^{-(4+2\sigma)})$$

as $R\to+\infty$; $\alpha=(1-2\sigma)/3$.

Thus, for the first term on the right-hand side of (29) we have

$$\|U(t)Z(0)\|_{R_\rho}\leqslant\frac{C(Z(0),\overline{v},R_\rho)}{(1+|t|)^{1+\sigma}}.$$

Then from (15) the estimate

$$\|U(t)Z(0)(\cdot+q(t))\|_{R_\rho}\leqslant\frac{C(Z(0),q^0,\overline{v},R_\rho)}{(1+|t|)^{1+\sigma}} \tag{41}$$

follows.

B. Decay of the soliton field subject to free Klein–Gordon group

Denote by $Z_1(x,t)=\psi(x,t)-\psi_{v(t)}(x-q(t))$ the first component of $Z(x,t)$ and observe that $\langle \psi_v, \nabla\rho\rangle=0$ for $|v|<1$ because the soliton (5) is a solution to (4). Note that for scattering solutions, for sufficiently large $|t|$, the fourth equation of the system (1) transforms to the fourth nonperturbed equation of the system (4) Then for these $|t|$,

$$\dot p(t)=\langle Z_1(x+q(t),t),\nabla\rho(x)\rangle\,. \tag{42}$$

Thus we obtain,

$$|\dot p(t)|\leqslant C\|Z(\cdot+q(t),t)\|_{R_\rho}\gamma_\rho\,. \tag{43}$$

Denote $S_{t-s}(x)=\{y\colon |y-x|=t-s\}$, $B_{t-s}(x)=\{y\colon |y-x|\leqslant t-s\}$, $\psi_v^p=\partial\psi_v/\partial p$, $\pi_v^p=\partial\pi_v/\partial p$, and

$$(\psi^U(\cdot,t,s),\pi^U(\cdot,t,s))=U(t-s)\left[\frac{\partial\Psi_{v(s)}}{\partial p}(\cdot-q(s))\right]. \tag{44}$$

Then the formulas (30), (31) for $U(t-s)$ imply

$$\begin{aligned}\psi^U(x,t,s)=&\frac{1}{4\pi(t-s)}\int_{S_{t-s}(x)}d^2y\;\pi^p_{v(s)}(y-q(s))-\frac{m}{4\pi}\int_{B_{t-s}(x)}d^3y\,F(t-s,x-y)\,\pi^p_{v(s)}(y-q(s))\\&+\frac{1}{4\pi(t-s)^2}\int_{S_{t-s}(x)}d^2y\;\psi^p_{v(s)}(y-q(s))+\frac{1}{4\pi(t-s)}\int_{S_{t-s}(x)}d^2y\,\frac{\partial}{\partial n}\psi^p_{v(s)}(y-q(s))\\&-\frac{m^2}{8\pi}\int_{S_{t-s}(x)}d^2y\;\psi^p_{v(s)}(y-q(s))-\frac{m}{4\pi}\int_{B_{t-s}(x)}d^3y\,\dot F(t-s,x-y)\,\psi^p_{v(s)}(y-q(s)).\end{aligned} \tag{45}$$

From this one derives the explicit formula for $\nabla\psi^U(x,t,s)$; (32) and (33) give the formula for $\pi^U(x,t,s)$.

Now $\psi^U(x+q(t),t,s)$ can be represented as the sum of type (45) of integrals over the shifted sphere $S_{t-s}(x+q(t))$ and ball $B_{t-s}(x+q(t))$ and with $x+q(t)$ replacing x in F and $\dot F$. Denote $\psi^U_S(x+q(t),t,s)$ the sum of the integrals over the sphere $S_{t-s}(x+q(t))$ and $\psi^U_B(x+q(t),t,s)$ the sum of the integrals over the ball $B_{t-s}(x+q(t))$. Let us estimate $\psi^U_S(x+q(t),t,s)$. If $|x|\leqslant R_\rho$, we have on the sphere $S_{t-s}(x+q(t))$,

$$|y-q(s)|=|(y-x-q(t))+(x+q(t)-q(s))|\geqslant(t-s)-|x|-\overline{v}(t-s)\geqslant(1-\overline{v})(t-s)-R_\rho \tag{46}$$

by the bound (15) on $\dot q(t)$. On the other hand, the integral representation (6) yields by Cauchy–Schwartz inequality,

$$\sup_{|v|\leqslant\overline{v}}\sup_{|x|\geqslant 2R_\rho} e^{m|x|}(|\partial^\alpha\psi^p_v(x)|+|\partial^\beta\pi^p_v(x)|)\leqslant C(\overline{v},R_\rho)\,\gamma_\rho<\infty \tag{47}$$

for all multi-indices α,β with $|\alpha|\leqslant 2$, $|\beta|\leqslant 1$, recall that $\gamma_\rho:=|\rho|$. Then (47) and (46) imply the following pointwise bound for $\psi^U_S(x+q(t),t,s)$:

$$|\psi^U_S(x+q(t),t,s)|\leqslant C_1(\overline{v},R_\rho)\,\gamma_\rho e^{-m(t-s)} \tag{48}$$

for $|x|\leqslant R_\rho$ and provided $t-s\geqslant 3R_\rho/(1-\overline{v})$.

Now let us estimate $\psi^U_B(x+q(t),t,s)$. Set $\mu=(1-2\sigma)/6$ and consider two regions $B_\mu=\{y\colon |y-q(s)|\leqslant(t-s)^\mu\}$ and

$$B'_\mu = B_{t-s}(x+q(t)) - B_\mu = \{y : |y-(x+q(t))| \leqslant (t-s) \ \& \ |y-q(s)| > (t-s)^\mu\}.$$

Represent every integral over the ball $B_{t-s}(x+q(t))$ as the sum of the integrals over B_μ and B'_μ. Note that the volume of B_μ is of order $(t-s)^{3\mu}$, the volume of B'_μ is of order $(t-s)^3-(t-s)^{3\mu}$. Furthermore, for sufficiently large $t-s$ and $y \in B_\mu$ we have $|y-x| \leqslant \nu|t|$ with some positive $\nu<1$. Hence, by (34) the following estimate is true:

$$|F(t-s,x-y)| + |\dot{F}(t-s,x-y)| + |\ddot{F}(t-s,x-y)| \leqslant C|t-s|^{-3/2}.$$

Then for the integrals over B_μ we have

$$\left| \int_{B_\mu} \cdots \right| \leqslant C_1(t-s)^{3\mu}(t-s)^{-3/2} C_2 \gamma_\rho = C_3 \gamma_\rho (t-s)^{3\mu-3/2} = C_3 \gamma_\rho (t-s)^{-1-\sigma}$$

for $\mu = (1-2\sigma)/6$.

For the integrals over B'_μ we obtain, due to (47), provided $t-s \geqslant (2R_\rho)^{1/\mu}$,

$$\left| \int_{B'_\mu} \cdots \right| \leqslant C_4((t-s)^3-(t-s)^{3\mu}) C_5 \exp(-m(t-s)^\mu)\, \gamma_\rho \leqslant \frac{C_6 \gamma_\rho}{(t-s)^{1+\sigma}}$$

for sufficiently large $t-s$. Thus, the sum of the integrals over B'_μ is bounded by $(C_7(\overline{v},R_\rho)\gamma_\rho)/(1+(t-s)^{1+\sigma})$. So we come to

$$|\psi_B^U(x+q(t),t,s)| \leqslant \frac{C_8(\overline{v},R_\rho)\gamma_\rho}{1+(t-s)^{1+\sigma}} \tag{49}$$

for $|x| \leqslant R_\rho$ and sufficiently large $t-s$. Therefore (48) and (49) imply for large $t-s$, together with similar bounds for $\nabla\psi^U(x+q(t),t,s)$ and $\pi^U(x+q(t),t,s)$, the integral estimate

$$\|(\psi^U(\cdot+q(t),t,s), \pi^U(\cdot+q(t),t,s))\|_{R_\rho} \leqslant \frac{C_9(\overline{v},R_\rho)\gamma_\rho}{1+(t-s)^{1+\sigma}}. \tag{50}$$

On the other hand, for bounded $t-s$ this integral estimate follows from (44) by energy conservation for the group $U(t-s)$ since $\|\partial\Psi_v/\partial p\|_{\mathcal{F}} \leqslant C(\overline{v},R_\rho)\gamma_\rho$ by (C). Finally, (43) and (50) imply

$$\|\dot{p}(s)\cdot(\psi^U(\cdot+q(t),t,s), \pi^U(\cdot+q(t),t,s))\|_{R_\rho} \leqslant C_{10}(\overline{v},R_\rho)\gamma_\rho \frac{\|Z(\cdot+q(s),s)\|_{R_\rho}\gamma_\rho}{1+(t-s)^{1+\sigma}}. \tag{51}$$

C. Completing the proof of Proposition 4

The method was initially developed in Ref. 13 for $m=0$, see also Ref. 11. Combining (29) to (51) and (41) we arrive at

$$\|Z(\cdot+q(t),t)\|_{R_\rho} \leqslant \frac{C(Z(0),q^0,\overline{v},R_\rho)}{(1+|t|)^{1+\sigma}} + \gamma_\rho^2 C_{10}(\overline{v},R_\rho) \int_0^t \frac{\|Z(\cdot+q(s),s)\|_{R_\rho}}{1+(t-s)^{1+\sigma}} ds, \quad t \geqslant 0. \tag{52}$$

Therefore, setting $M(t) = \max_{0\leqslant s\leqslant t}(1+|s|)^{1+\sigma}\|Z(\cdot+q(s),s)\|_{R_\rho}$, we have

$$M(t) \leqslant C_0(Z(0),q^0,\overline{v},R_\rho) + \gamma_\rho^2 C(\overline{v},R_\rho) I_\sigma M(t),$$

where

$$I_\sigma = \sup_{t\geqslant 0}(1+|t|)^{1+\sigma} \int_0^t \frac{(1+|s|)^{-1-\sigma}}{(1+|t-s|^{1+\sigma})}\, ds < \infty.$$

It remains to choose $\gamma_\rho^2 C(\overline{v},R_\rho)I_\sigma<1$, then (28) with $R=R_\rho$ follows.

Remark: It is important that $\overline{v}$ is bounded for bounded γ_ρ and fixed initial data.

At last, we claim that the bound (28) with $R=R_\rho$ implies (28) for any $R>0$. Indeed, (50)–(52) hold with the norm $\|\cdot\|_R$ instead of $\|\cdot\|_{R_\rho}$ on the *left*-hand sides and with $C_i(\overline{v},\rho,R)$ instead of $C_i(\overline{v},R_\rho)$ on the *right*-hand sides. Then (52) with this generalization and (28) with $R=R_\rho$ imply (28) for any $R>0$. □

IV. SCATTERING

Theorem 7: *Under the conditions of Proposition 4, for sufficiently small γ_ρ, the convergence (7) holds, and the solution $Y(t)$ displays the following long-time asymptotics:*

(i) There exist $v_\pm=\lim_{t\to\pm\infty}\dot q(t)\in\mathcal{V}$ such that

$$|\dot q(t)-v_\pm| \leqslant C\ (1+|t|)^{-\sigma}, \tag{53}$$

$$\|\Psi(\cdot+q(t),t)-\Psi_{v_\pm}\|_R\leqslant C_R(1+|t|)^{-\sigma},\quad \forall R>0. \tag{54}$$

(ii) There exist $\Psi_\pm\in\mathcal{F}$ such that

$$\|\Psi(\cdot,t)-\Psi_{v(t)}(\cdot-q(t))-U(t)\Psi_\pm\|_{\mathcal{F}}\leqslant C(1+|t|)^{-\sigma}. \tag{55}$$

Proof: (i) Equation (28) with $R=R_\rho$ and (43) imply

$$|\dot p(t)|\leqslant C(1+|t|)^{-1-\sigma}\Leftrightarrow|\ddot q(t)|\leqslant C_1(1+|t|)^{-1-\sigma}. \tag{56}$$

Then the limits (8) exist, and (53) follows. Therefore, (28) implies (54).

(ii) We have to prove that $\|Z(x,t)-U(t)F_\pm\|_{\mathcal{F}}\leqslant C(1+|t|)^{-\sigma}$. This is equivalent to $\|U(-t)Z(x,t)-F_\pm\|_{\mathcal{F}}\leqslant C(1+|t|)^{-\sigma}$ since the group $U(t)$ is isometric in $\mathcal{F}$. Apply $U(-t)$ to the integral equation (29). We obtain

$$U(-t)Z(t)=Z(0)-\int_0^t U(-s)\left[\frac{\partial\Psi_{v(s)}}{\partial p}(\cdot-q(s))\dot p(s)\right]ds.$$

The condition (15) implies that the norm of $\Psi_{v(s)}(\cdot-q(s))$ in $\mathcal{F}$ is bounded uniformly with respect to s. Then (56) implies the convergence of the integral in $\mathcal{F}$ at the stated rate and Theorem 7 is proved. □

A. Constructing scattering solutions

Let us formulate a criterion for a solution $Y(t)$ to be scattering. Introduce the energy of the field part of a solution

$$h(t)=\frac{1}{2}\int d^3x(|\nabla\psi(x,t)|^2+m^2|\psi(x,t)|^2+|\pi(x,t)|^2).$$

Set $G=\sup_{x\in\mathbb{R}^3}|\nabla V(x)|$ and $v(t)=\dot q(t)$.

Theorem 8: *Let (C), $(P_{\min})$, (K) hold. Consider solutions $Y(t)$ to the system (1) with initial data $Y(0)\in\mathcal{E}^\sigma$, $0<\sigma<1/2$. Let $R_V,G,h(0),|q(0)|$ be finite. Then for $|\dot q(0)|$ close enough to 1 and sufficiently small γ_ρ, we have*

$$\lim_{t\to\pm\infty}|q(t)|=\infty. \tag{57}$$

Proof: Since the system (1) is time invertible, we consider only the case $t\to+\infty$. Consider the particle with initial data $q(0),v(0):=\dot q(0)$. Introduce $e=v(0)/|v(0)|$. The orthogonal projection of the vectors $v(t),p(t),q(t)$ onto e read $v_e(t)e$, $p_e(t)e$, $q_e(t)e$, respectively, with $v_e(t):=v(t)\cdot e$, $p_e(t):=p(t)\cdot e$, $q_e(t):=q(t)\cdot e$, here the dot means the scalar product in $\mathbb{R}^3$. Note that

the vectors $v(t)$ and $p(t)$, $v_e(t)$ and $p_e(t)$ are of the same directions and $v_e(0)=|v(0)|$, $p_e(0)=|p(0)|$. Introduce the layer in $\mathbb{R}^3$, $L(e,R_V)=\{x:|x\cdot e|\leqslant R_V\}$, then $\operatorname{supp} V\subset L(e,R_V)$.

The statement of the theorem follows from the three propositions below. Since the system (1) is invariant with respect to time translations, we start from $t=0$ in either proposition.

Proposition 9: Let $|q(0)|>R_V$, $|v(0)|$ be close enough to 1, let e be directed toward $L(e,R_V)$. Then the particle enters $L(e,R_V)$ at a certain moment τ with $|v_e(\tau)|$ close to 1.

Proposition 10: Let $|q(0)|\leqslant R_V$, let $|v(0)|$ be close to 1. Then the particle leaves $L(e,R_V)$ at a certain moment τ such that $|v_e(\tau)|>0$ and $v_e(\tau)e$ is directed outside $L(e,R_V)$.

Proposition 11: Let $|q(0)|\geqslant R_V$, $|v(0)|>0$ and e is directed outside $L(e,R_V)$. Then the particle never enters $L(e,R_V)$ and $|q_e(t)|\to\infty$ as $t\to+\infty$.

Proof of Proposition 9: For $v_e(t)$ we have the estimate

$$v_e(t)\geqslant v_e(0)-\int_0^t|\dot v(s)|ds=|v(0)|-\int_0^t|\dot v(s)|ds.$$

Since outside $L(e,R_v)$ the free equations (4) are satisfied, the following estimate (see [28) and (43)] is valid:

$$|\dot v(t)|\leqslant\frac{C(Z(0),q(0),\overline{v},R_\rho)\,\gamma_\rho}{(1+|t|)^{\sigma+1}}. \tag{58}$$

Here $C(Z(0),q(0),\overline{v},R_\rho)$ is bounded uniformly with respect to the values $q(0),\psi(0),\pi(0)$ under consideration. Thus,

$$v_e(t)\geqslant|v(0)|-\int_0^\infty\frac{C\gamma_\rho\,dt}{(1+|t|)^{\sigma+1}}=|v(0)|-\frac{C\gamma_\rho}{\sigma},$$

and we obtain the required result for sufficiently small γ_ρ. □

Proof of Proposition 10: First we check that the growth of the field energy is not very fast.

Lemma 12: The following bound holds:

$$h(t)\leqslant(\sqrt{h(0)}+\sqrt{2}\,\gamma_\rho t)^2. \tag{59}$$

Proof: Multiply the equation $\ddot\psi=\Delta\psi-m^2\psi-\rho$ by $\dot\psi$ and integrate over $\mathbb{R}^3$. We obtain $\dot h(t)=-\int d^3x\,\rho\dot\psi$ and hence $\dot h(t)\leqslant\sqrt{2}\,\gamma_\rho\sqrt{h}$. Integrating this differential inequality in t we come to $\sqrt{h(t)}\leqslant\sqrt{h(0)}+\sqrt{2}\,\gamma_\rho t$ which proves (59). □

Let us now prove the proposition. Recall that $v=p/\sqrt{1+p^2}$ and hence, $p=v/\sqrt{1-v^2}$. Thus, $|v|$ is close to 1 if and only if $|p|$ is large. From the equation

$$\dot p(t)=-\nabla V(q(t))+\int d^3x\,\psi(x,t)\,\nabla\rho(x-q(t))$$

we obtain, due to (59), $|\dot p|\leqslant G+\|\psi\|\gamma_\rho\leqslant G+(2h(t))^{1/2}\gamma_\rho\leqslant G+((2h(0))^{1/2}+2\gamma_\rho t)\gamma_\rho=G_1+2\gamma_\rho^2 t$ with $G_1=G+(2h(0))^{1/2}\gamma_\rho$. The conditions of the theorem imply that G_1 is bounded. We obtain the following lower and upper bounds:

$$p_e(t)\geqslant p_e(0)-\int_0^t|\dot p(s)|ds\geqslant|p(0)|-G_1t-\gamma_\rho^2t^2=P-f(t),$$

$$|p(t)|\leqslant|p(0)|+\int_0^t|\dot p(s)|ds\leqslant|p(0)|+G_1t+\gamma_\rho^2t^2=P+f(t),$$

where $P:=|p(0)|$, $f(t):=G_1t+\gamma_\rho^2t^2$. These estimates imply for $v_e(t)$,

$$v_e(t)=\frac{p_e(t)}{|p(t)|}\left(1+\frac{1}{|p(t)|^2}\right)^{-1/2}\geqslant\frac{P-f(t)}{P+f(t)}\left(1-\frac{1}{(P-f(t))^2}\right)$$
$$=\frac{1-a^2-2af(t)+a^2f^2(t)}{1-a^2f^2(t)}$$
$$\geqslant(1-a^2-2af(t)+a^2f^2(t))(1+a^2f^2(t))=1-a^2+g(t), \tag{60}$$

where $a:=P^{-1}$, $g(t):=-2af(t)+(2a^2-a^4)f^2(t)-2a^3f^3(t)+a^4f^4(t)$. The corresponding estimate for $q_e(t)$ is

$$q_e(t)\geqslant q_e(0)+(1-a^2)t+\int_0^t g(s)ds. \tag{61}$$

Take sufficiently large P, that is small a, then from the estimates (61), (60) the statement of the proposition follows. □

Proof of Proposition 11: We claim that there exist such small $\gamma_\rho>0,\underline{v}>0$ that $\forall\, t>0 v_e(t)\geqslant\underline{v}$. Indeed, set $T=\sup\{t>0\colon v_e(t)>\underline{v}\}$. If $\underline{v}<v_e(0)/2$, then, by continuity, $T>0$. We claim that it is possible to choose such small $\gamma_\rho>0$, $\underline{v}>0$ that $T=+\infty$. Indeed, for $t\in[0,T]$ the free equations (4) are satisfied, hence the estimate (58) is valid. Take

$$0<\underline{v}<v_e(0)-\int_0^\infty\frac{C\gamma_\rho}{(1+|t|)^{\sigma+1}}=v_e(0)-\frac{C\gamma_\rho}{\sigma};$$

this choice is possible for sufficiently small γ_ρ. If $T<+\infty$, then $v_e(T)>\underline{v}$, hence, by continuity, $v_e(T+\varepsilon)>\underline{v}$ for some $\varepsilon>0$. This contradicts to the definition of T. Thus, $T=+\infty$. Hence, for $t>0$ one obtains $q_e(t)\geqslant q_e(0)+\underline{v}t$. □

Note that from the proof of the theorem the following statement follows.

Corollary 13: Let (C), ($P_{\min}$), (K) hold, let $Y(0)\in\mathcal{E}^\sigma,0<\sigma<1/2$. Let $R_V,h(0),|q(0)|$ be finite. Then for $\dot{q}(0)\neq0$ and sufficiently small γ_ρ, G the solution $Y(t)$ is scattering.

Transport of energy in dissipative advection phenomena

Manuel Núñez[a)]
Departamento de Análisis Matemático, Universidad de Valladolid, 47005 Valladolid, Spain

(Received 4 November 2002; accepted 26 November 2002)

A study of the distribution of energy among the different scales is performed for several systems in fluid mechanics, including the Navier–Stokes, magnetohydrodynamics and active scalars equations. It is found that all these systems possess a common structure which enables us to deduce how the energy introduced by the forcing is transferred to the scales present in the flow. It is also shown that in special cases an energy cascade will occur. The limits of this method are also considered. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1540237]

I. INTRODUCTION

It is well known that the energy injected into a fluid by some forcing will be distributed among all the scales of the flow. In a general sense this is true for all phenomena governed by nonlinear equations: for every decomposition of the solution in different modes representing the scales, the nonlinearity will make interact different modes so that they do not evolve independently. The details of how this interaction occurs depend essentially on the particular equation modeling the phenomenon. However, for certain equations, prevalent in several processes in fluid mechanics, the transfer of energy may be studied with some generality. These equations could be called dissipative advection phenomena by the two terms of their expression:

$$\frac{\partial w}{\partial t} = Aw + Tw + f, \tag{1}$$

where w is the magnitude under study. It is assumed that the solution of our initial value problem exists for all time, and that $w(t)$ belongs to a certain Hilbert space H. A is a linear self-adjoint dissipative operator; it is defined in a dense domain

$$A: D(A) \to H,$$

and it satisfies, for some constant $\alpha > 0$ and all $w \in D(A)$,

$$-(Aw, w) \geqslant \alpha \|w\|^2. \tag{2}$$

Thus the whole spectrum of A is contained in $(-\infty, -\alpha]$. For simplicity purposes we will assume that H is separable and the spectrum of A discrete, although it is not really necessary. T is a generally nonlinear and time-dependent operator densely defined in H, satisfying the orthogonality property:

$$(Tw, w) = 0, \tag{3}$$

for every w in the domain of T. A represents the dissipation and T the advective effect in the evolution of w. As we will see, condition (3) means that the energy injected by the forcing f will be distributed without loss by this advective term among all scales, while dissipation acts in a different way on each of them.

a)Electronic mail: mnjmhd@am.uva.es

The present article represents a simplification of the arguments advanced in Ref. 1 for the study of hydrodynamics turbulence. The Navier–Stokes case is analyzed there in more generality and depth, without making use of some of our hypotheses concerning uniqueness of the solution, which in fact are not proved in general. While it is probably overoptimistic to think that Ref. 1 answers all the questions on the origin and behavior of cascades in turbulence, it represents a valuable attempt to rigorize a classical and difficult problem. The method developed there is not difficult and we have been able to extend its range beyond the original hydrodynamic problem: in addition to the Navier–Stokes equations, the magnetohydrodynamics (MHD) system possesses also the required form, along with several equations describing passive and active scalars. Among the latter we may mention the vorticity in plane flows, the magnetic potential in two-dimensional plasmas, the temperature in Bénard convection, the salinity in oceanic waters and other magnitudes relevant in geophysical phenomena.

In a limit case we can prove something similar to energy cascades in the sense of Kolmogorov: energy is transferred without loss to smaller (direct cascade) or larger scales (inverse cascade) in a form independent of A, i.e., of viscosity.[2] However, the assumptions needed to prove this are probably excessive and the fact that there is no discernible influence of the space dimension, unlike what is experimentally known, seems to indicate that physical cascades have their own phenomenology not covered by this case.

II. THE MAIN RESULTS

Let (e_n) be a basis of H formed by eigenfunctions of A, $-Ae_n=\lambda_n e_n$, with $\lambda_1=\alpha$, $\lambda_1 \leqslant \lambda_2 \leqslant \cdots$. We will consider that the scales of the problem are given by the orthogonal decomposition $w=\Sigma(w,e_n)e_n$, so that a large-scale function is one limited to the lower eigenfunctions. When, as usual, A is essentially the Laplacian, certainly the higher eigenfunctions are more irregular than the lower ones. In particular, if H is formed by periodic functions, the basis is formed by the trigonometric functions $\mathbf{x}\rightarrow\exp(i\mathbf{k}\cdot\mathbf{x})$ and the spectral decomposition is the Fourier one, so that the concept coincides with the classical one.

The energy estimates are classical: by making the scalar product of (1) with w,

$$\frac{1}{2}\frac{\partial}{\partial t}(w,w)-(Aw,w)=(Tw,w)+(f,w)=(f,w). \tag{4}$$

Thus

$$\frac{1}{2}\frac{d}{dt}\|w\|^2-(Aw,w)=(f,w)\leqslant\|f\|\,\|w\|\leqslant\frac{1}{2\alpha}\|f\|^2+\frac{\alpha}{2}\|w\|^2. \tag{5}$$

Since $-(Aw,w)\geqslant\alpha\|w\|^2$,

$$\frac{d}{dt}\|w\|^2+\alpha\|w\|^2\leqslant\frac{1}{\alpha}\|f\|^2, \tag{6}$$

so that

$$\|w(t)\|^2\leqslant\|w(0)\|^2e^{-\alpha t}+\frac{1}{\alpha}\int_0^t e^{-\alpha(t-s)}\|f(s)\|^2\,ds, \tag{7}$$

which is bounded in particular if $\|f\|$ is bounded for all time: e.g., if it does not depend on time. In the absence of forcing the solution tends exponentially to zero. We will only need to assume

$$\lim_{t\rightarrow\infty}\frac{1}{T}\|w(T)\|^2=0, \tag{8}$$

which certainly happens if w remains bounded. Our remaining hypotheses are as follows: let us denote by $\langle\ \rangle$ the time mean of a magnitude:

$$\langle g\rangle = \lim_{T\to\infty}\frac{1}{T}\int_0^T g(s)\,\mathrm{d}s, \tag{9}$$

provided it exists. We will assume that the time mean of all the magnitudes occurring in Eqs. (11)–(16) exists. This is not an unreasonable hypothesis, since turbulent phenomena are usually considered decaying or statistically stationary.

Let H_1 be the finite-dimensional subspace of H whose basis is $\{e_k, e_{k+1}, \ldots, e_l\}$. We will consider that H_1 is the space of some intermediate range of scales, called the injection range because we will assume that f lies within this range for all time; if f is large-scale, then $k=1$. Let H_2 be the subspace orthogonal to H_1, a Hilbert basis of whom is formed by the remaining e_j. Let $w = w_1 + w_2$ be the orthogonal decomposition of an element of H in the subspaces H_1 and H_2. The condition $(Tw,w)=0$ means therefore

$$(Tw,w_2) = -(Tw,w_1). \tag{10}$$

By taking the scalar product of (1) with w_1 and w_2 we obtain, analogously to (4),

$$\begin{aligned} \frac{1}{2}\frac{d}{dt}\|w_1\|^2 - (Aw_1,w_1) &= (Tw,w_1) + (f,w_1), \\ \frac{1}{2}\frac{d}{dt}\|w_2\|^2 - (Aw_2,w_2) &= (Tw,w_2) = -(Tw,w_1), \end{aligned} \tag{11}$$

since $(f,w_2)=0$. We also have

$$\left\langle \frac{d}{dt}\|w_i\|^2 \right\rangle = \lim_{T\to\infty}\frac{1}{T}(\|w_i(T)\|^2 - \|w_i(0)\|^2) = 0, \tag{12}$$

and therefore

$$\begin{aligned} \langle(-Aw_1,w_1)\rangle &= \langle(Tw,w_1)\rangle + \langle(f,w_1)\rangle, \\ \langle(-Aw_2,w_2)\rangle &= \langle(Tw,w_2)\rangle = -\langle(Tw,w_1)\rangle. \end{aligned} \tag{13}$$

Now $(-Aw_i,w_i)\geqslant 0$ may be regarded as the dissipation of the component w_i, whereas (Tw,w_i) is the energy transferred by the advection to that component. Therefore the mean energy transferred to the noninjective scales is positive and identical to the mean dissipation of them, and also equal to the energy lost by the injective scales. Notice that this does not yield any information about if the energy goes to larger or smaller scales than the injective range, or more likely to both. If we decompose again w_2 in $w_2^+ + w_2^-$, formed respectively by smaller scales (projection in the $e_j : j>l$) and larger (projection in $e_i : i<k$), what we can deduce is

$$\langle(Tw,w_2^+)\rangle + \langle(Tw,w_2^-)\rangle = \langle(-Aw_2,w_2)\rangle = \langle(-Aw_2^+,w_2^+)\rangle + \langle(-Aw_2^-,w_2^-)\rangle. \tag{14}$$

Cascades are not merely energy transfer. In the Kolmogorov[2] theory of homogeneous turbulence, it is admitted that there exists a range of scales (called inertial) where energy is transferred without viscous loss. To prove something similar we need to make an additional hypothesis, also made in Ref. 3: we assume that there is a range outside the injection one such that the projection of w there is zero, or very small. Take the injection range generated by $e_k, \ldots, e_l$, and assume that from e_l to e_n there is no projection of w. Let E_h^+ be the energy transferred to modes larger than e_h, i.e., the product of Tw with the projection $w_h^+ = \Sigma_{j>h}(w,e_j)e_j$. Then

$$\langle(-Aw_2^+,w_2^+)\rangle=E_{l+1}^+=E_{l+2}^+=\cdots=E_n^+=\langle(Tw,w_2^+)\rangle. \tag{15}$$

Thus the energy passes without loss through this inertial range. Since it goes to smaller scales, it is called a direct cascade. The same could be done for larger scales if we assume that the projection of w in some range e_i, $e_{i+1},\ldots,e_{k-1}$ is zero: then, with an obvious notation,

$$\langle(-Aw_2^-,w_2^-)\rangle=E_{k-1}^-=E_{k-2}^-=\cdots=E_i^-=\langle(Tw,w_2^-)\rangle. \tag{16}$$

This should be an inverse cascade. For the direct one, however, there is a more manageable criterion to ascertain that the projection of w in small ranges is itself small: if the energy satisfies the inequality

$$\|w\|^2=\sum\ |(w,e_n)|^2\ll\sum\ \lambda_n|(w,e_n)|^2=(-Aw,w), \tag{17}$$

it is because large λ_n must play the main role, i.e., w is localized at the higher frequencies. Thus a much larger ''enstrophy'' $(-Aw,w)$ than energy means that a direct cascade is more likely, as stated in Ref. 3. This, however, does not seem to be a prerequisite for the actual cascades observed in turbulent phenomena.

III. EXAMPLES

A. The Navier–Stokes equations

The original example, developed as stated in much more depth and detail in Ref. 1, is the Navier–Stokes system for incompressible Newtonian fluids. It is worth to study how the abstract framework applies to this classical case. The Navier–Stokes equations are

$$\begin{gathered}\frac{\partial\mathbf{u}}{\partial t}=\nu\Delta\mathbf{u}-\mathbf{u}\cdot\nabla\mathbf{u}-\nabla p+\mathbf{f},\\ \nabla\cdot\mathbf{u}=0,\end{gathered} \tag{18}$$

where $\mathbf{u}$ represents the fluid velocity, ν the viscosity, p the kinetic pressure and $\mathbf{f}$ the forcing. Boundary conditions determine the space H. By taking the divergence of the first equation, one finds that p is in fact a (nonlocal) function of the velocity gradient, the solution of an elliptic problem (see, e.g., Ref. 1). We may either define

$$\begin{gathered}T\mathbf{u}=-\mathbf{u}\cdot\nabla\mathbf{u}+\nabla p(\mathbf{u}),\\ A=\nu\Delta,\end{gathered} \tag{19}$$

or, as usual, project (18) into the space of functions with null divergence. Denoting by P this projection, one gets the Stokes system:

$$\frac{\partial\mathbf{u}}{\partial t}=\nu P\Delta\mathbf{u}-P\mathbf{u}\cdot\nabla\mathbf{u}+P\mathbf{f}. \tag{20}$$

Then we may define $T\mathbf{u}=-P\mathbf{u}\cdot\nabla\mathbf{u}$, $A=\nu P\Delta$. The space H is defined by the boundary conditions. For periodic ones in a box Ω, one sets

$$H=\left\{\mathbf{u}\in L^2(\Omega)^N:\nabla\cdot\mathbf{u}=0,\ \int_\Omega\mathbf{u}\,dV=\mathbf{0},\mathbf{u}\cdot\mathbf{n}\Big|_{\partial\Omega}\ \text{antiperiodic}\right\}. \tag{21}$$

N is the space dimension. The condition $\nabla \cdot \mathbf{u}=0$ is to be understood in the sense of distributions. For these functions the trace of $\mathbf{u}\cdot\mathbf{n}$ at the boundary makes sense. The domain of A is defined as $D(A)=H^2(\Omega)^N \cap H$.

For no-slip boundary conditions, the velocity at the boundary of the smooth bounded domain Ω is taken as zero: we therefore set

$$\begin{aligned} H&=\{\mathbf{u}\in L^2(\Omega)^N:\nabla\cdot\mathbf{u}=0,\mathbf{u}\cdot\mathbf{n}|_{\partial\Omega}=0\},\\ D(A)&=H^2(\Omega)^N\cap H_0^1(\Omega)^N\cap H. \end{aligned} \tag{22}$$

That T and A satisfy the previous conditions is classical (see, e.g., Ref. 1 or 4).

B. Magnetohydrodynamics

The MHD system for an incompressible plasma with velocity $\mathbf{u}$ and magnetic field $\mathbf{B}$ are

$$\begin{aligned} \frac{\partial \mathbf{u}}{\partial t}&=\nu\Delta\mathbf{u}-\mathbf{u}\cdot\nabla\mathbf{u}+\mathbf{B}\cdot\nabla\mathbf{B}-\nabla\left(p+\frac{B^2}{2}\right)+\mathbf{f}_1,\\ \frac{\partial \mathbf{B}}{\partial t}&=\eta\Delta\mathbf{B}-\mathbf{u}\cdot\nabla\mathbf{B}+\mathbf{B}\cdot\nabla\mathbf{u}+\mathbf{f}_2,\\ \nabla\cdot\mathbf{u}&=0,\\ \nabla\cdot\mathbf{B}&=0. \end{aligned} \tag{23}$$

$\eta>0$ is the plasma resistivity. Again a projection P to the space of fields with null divergence is applied to the equations, obtaining

$$\begin{aligned} \frac{\partial \mathbf{u}}{\partial t}&=\nu P\Delta\mathbf{u}-P\mathbf{u}\cdot\nabla\mathbf{u}+P\mathbf{B}\cdot\nabla\mathbf{B}+P\mathbf{f}_1,\\ \frac{\partial \mathbf{B}}{\partial t}&=\eta P\Delta\mathbf{B}-P\mathbf{u}\cdot\nabla\mathbf{B}+P\mathbf{B}\cdot\nabla\mathbf{u}+P\mathbf{f}_2. \end{aligned} \tag{24}$$

Now we define $\mathbf{w}=(\mathbf{u};\mathbf{B})$,

$$\begin{aligned} T\mathbf{w}&=(-P\mathbf{u}\cdot\nabla\mathbf{u}+P\mathbf{B}\cdot\nabla\mathbf{B};\ -P\mathbf{u}\cdot\nabla\mathbf{B}+P\mathbf{B}\cdot\nabla\mathbf{u}),\\ A\mathbf{w}&=(\nu P\Delta\mathbf{u};\ \eta P\Delta\mathbf{B}). \end{aligned} \tag{25}$$

The space H again depends on the boundary conditions. It is defined essentially as (21) for periodic problems, with the exception that now both components $\mathbf{u}$ and $\mathbf{B}$ of $\mathbf{w}$ must be periodic. $D(A)$ is defined as $H^2(\Omega)^{2N}\cap H$. For Dirichlet homogeneous problems, the analog of (22) is used; in this case $D(A)=H^2(\Omega)^{2N}\cap H_0^1(\Omega)^{2N}\cap H$. For the case where the boundary of Ω is supposed to be a perfect conductor, i.e., $\mathbf{u}|_{\partial\Omega}=\mathbf{0}$, $\mathbf{B}\cdot\mathbf{n}|_{\partial\Omega}=0$, $(\nabla\times\mathbf{B})\times\mathbf{n}|_{\partial\Omega}=\mathbf{0}$, one sets

$$\begin{aligned} H&=\{(\mathbf{u};\mathbf{B})\in L^2(\Omega)^{2N}:\nabla\cdot\mathbf{u}=\nabla\cdot\mathbf{B}=0,\mathbf{u}\cdot\mathbf{n}|_{\partial\Omega}=\mathbf{B}\cdot\mathbf{n}|_{\partial\Omega}=0\},\\ D(A)&=\{(\mathbf{u};\mathbf{B})\in H^2(\Omega)^{2N}\cap H:\mathbf{u}\in H_0^1(\Omega)^N,\ (\nabla\times\mathbf{B})\times\mathbf{n}|_{\partial\Omega}=\mathbf{0}\}. \end{aligned} \tag{26}$$

(See, e.g., Refs. 4, 5.) Again A and T satisfy the main conditions and therefore one should expect an analogous transfer of energy for MHD problems. However, it is known that cascades in MHD are very different from the hydrodynamic ones (see, e.g., Ref. 6), which is a warning not to expect fine details from our calculations on energy transfer.

C. Passive scalars

These are magnitudes ϕ that are transported and diffused by an incompressible flow with a given velocity $\mathbf{u}$. They evolve according to

$$\frac{\partial \phi}{\partial t} = \kappa \Delta \phi - \mathbf{u} \cdot \nabla \phi + f. \tag{27}$$

The velocity is a datum of the problem. It satisfies $\nabla \cdot \mathbf{u} = 0$, $\mathbf{u} \cdot \mathbf{n}|_{\partial\Omega} = 0$. $\kappa > 0$ is a diffusion coefficient; as we see ϕ has no influence on $\mathbf{u}$. Boundary conditions depend on the meaning of ϕ, and these define the domain of $A = \kappa\Delta$. Set $H = L^2(\Omega)$; for Dirichlet problems, $D(A) = H^2(\Omega) \cap H_0^1(\Omega)$; for periodic ones, $D(A) = \{\phi \in H^2(\Omega) : \phi|_{\partial\Omega} \text{ periodic}\}$; for Neumann ones, $D(A) = \{\phi \in H^2(\Omega) : \partial\phi/\partial n \in H_0^1(\Omega)\}$. The condition of symmetry for A,

$$\int_{\partial\Omega} \phi \frac{\partial \phi}{\partial n} \mathrm{d}\sigma = 0,$$

is satisfied for all $\phi \in D(A)$. Tracers in a fluid are assumed to behave as passive scalars, provided they are not dense enough to modify the density or other properties of the fluid. For instance, salt in ocean water is not taken as a passive, but as an active scalar.

D. Active scalars

The equation is formally similar to (27), but now $\mathbf{u}$ depends on ϕ through some other equation, making $\mathbf{u}$ a (usually nonlocal) function of ϕ. These equations are rather common in fluid mechanics (see, e.g., Ref. 7). We will consider two examples: the magnetic potential in two-dimensional MHD and the temperature in Bénard convection.

E. Magnetic potential

Two-dimensional magnetic fields $\mathbf{B} = (B_1, B_2)$ in a simply connected domain Ω are of the form $B_1 = \partial A/\partial x_2$, $B_2 = -\partial A/\partial x_1$ for some scalar field A, called the magnetic potential. With this variable the MHD equations (without forcing on the magnetic field) become

$$\frac{\partial A}{\partial t} = \eta \Delta A - \mathbf{u} \cdot \nabla A + C(t),$$

$$\frac{\partial \mathbf{u}}{\partial t} = \nu \Delta \mathbf{u} - \mathbf{u} \cdot \nabla \mathbf{u} + \Delta A \nabla A + f, \tag{28}$$

$$\nabla \cdot \mathbf{u} = 0.$$

$C(t)$ is some time-dependent constant depending on the choosing of A, which is indifferent to the addition of any gradient. Boundary conditions and the gauge constant C are linked. We may choose $C = 0$, but at the expense of not being able to precise the values of A at any point. If $\mathbf{B} \cdot \mathbf{n}|_{\partial\Omega} = 0$, A is constant along every connected component of $\partial\Omega$. By allowing $C \neq 0$ and choosing $A = 0$ at a given point of $\partial\Omega$, we have $A|_{\partial\Omega} = 0$. Thus we may take $H = L^2(\Omega)$, $A = \eta\Delta$, $D(A) = H^2(\Omega) \cap H_0^1(\Omega)$. The second equation of (28) is ignored; we may study the transfer of energy without knowing the full evolution of the system. The magnetic potential is reputed to possess an inverse cascade,[6] such as the velocity in two-dimensional turbulence.

F. Temperature in Bénard convection

In a simple model, this satisfies

$$\frac{\partial T}{\partial t}=\kappa\Delta T-\mathbf{u}\cdot\nabla T+f,$$

$$\frac{\partial \mathbf{u}}{\partial t}=\nu\Delta\mathbf{u}-\mathbf{u}\cdot\nabla\mathbf{u}-\nabla p+\mathbf{e}_2(T-T_1), \tag{29}$$

$$\nabla\cdot\mathbf{u}=0.$$

T is the temperature in a box $[0,1]\times[0,1]$, κ is a thermal diffusion constant, $\mathbf{e}_2=(1,0)$, T_1 is the temperature at the upper lid $x_2=1$, and T_1+1 is the temperature at the lower one $x_2=0$. p, $\mathbf{u}$, T, $\partial\mathbf{u}/\partial x_1$ and $\partial T/\partial x_1$ are assumed one-periodic in the x_1-direction, $\mathbf{u}=\mathbf{0}$ at $x_2=0$ and $x_2=1$.[4,8] f is a possible injection of temperature.

These conditions make it possible to find $\mathbf{u}$ as a nonlocal function of T (since $\mathbf{u}$ satisfies a parabolic equation on a cylinder) so that we may define for the temperature the spaces

$$H=L^2[0,1]\times L^2[0,1], \tag{30}$$

$$D(A)=D(\kappa\Delta)$$
$$=\left\{T\in H^2(\Omega):\, T(x,1)=T_1,\, T(x,0)=T_1+1, T(0,y)=T(1,y),\, \frac{\partial T}{\partial x_1}(0,y)=\frac{\partial T}{\partial x_1}(1,y)\right\}.$$

Neumann conditions on the lateral walls are also admissible. Conditions are easily seen to be satisfied (the integral at the boundary of $T\partial T/\partial n$ always vanishes) so that we may ignore $\mathbf{u}$ to see that the temperature is transferred to the different scales according to our model.

IV. CONCLUSIONS

It is found that the transfer of energy among the different scales acts in a similar way in several processes of fluid mechanics, including the Navier–Stokes equations, the magnetohydrodynamics system, and passive and active scalar equations. The essence of this fact is that these magnitudes follow an evolution equation formed by the addition of a linear dissipative term which determines the scales of the flow and an advective one which distributes the energy injected by the forcing among the different scales. In some extreme cases the presence of a direct or inverse cascade, where energy is transferred without dissipative loss through some inertial range, may also be proved. However, it is pointed that these results do not yield precise information on the transfer of energy in some specific direction, which is known to differ according to the magnitude and the space dimension.

(Received 28 October 2002; accepted 5 December 2002)

The partial averaging technique is defined and used in conjunction with the random series implementation of the Feynman–Kaç formula. It enjoys certain properties such as good rates of convergence and convergence for potentials with coulombic singularities. In this work, I introduce the reader to the technique and I analyze the basic mathematical properties of the method. I show that the method is convergent for all Kato class potentials that have finite Gaussian transform. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1541933]

I. INTRODUCTION

The thermodynamic properties of a monodimensional spinless quantum system characterized by the inverse temperature $\beta=1/(k_BT)$ are completely determined by the canonical partition function

$$Z(\beta)=\int_{\mathbb{R}}\rho(x,x;\beta)\mathrm{d}x, \tag{1}$$

where the (unnormalized) density matrix

$$\rho(x,x';\beta)=\langle x|e^{-\beta H}|x'\rangle$$

can be computed with the help of the Feynman–Kaç representation formula[1,2]

$$\frac{\rho(x,x';\beta)}{\rho_{fp}(x,x';\beta)}=\mathbb{E}\exp\left\{-\beta\int_0^1 V[x_0(u)+\sigma B_u^0]\mathrm{d}u\right\} \tag{2}$$

for a large class of potentials. In Eq. (2), m_0 is the mass of the particle, $x_0(u)$ is a shorthand for $x+(x'-x)u$, $\sigma=(\hbar^2\beta/m_0)^{1/2}$, and

$$\rho_{fp}(x,x';\beta)=\frac{1}{\sqrt{2\pi\sigma^2}}\exp\left[-\frac{(x-x')^2}{2\sigma^2}\right]$$

is the density matrix of a similar free particle. The stochastic element that appears in Eq. (2), $\{B_u^0, 0\leqslant u\leqslant 1\}$, is a so-called standard Brownian bridge defined as follows: if $\{B_u, u\geqslant 0\}$ is a standard Brownian motion starting at zero, then the Brownian bridge is the stochastic process $\{B_u-uB_1, 0\leqslant u\leqslant 1\}$. Unless otherwise stated, in this article, we shall reserve the symbol $\mathbb{E}$ to denote the expected value (average value) of a certain random variable against the underlying probability measure of the Brownian bridge B_u^0.

The generalization of Eq. (2) to a d-dimensional system is straightforward. The symbol B_u^0 now denotes a d-dimensional standard Brownian bridge, which is a vector $(B_{u,1}^0, B_{u,2}^0, \ldots, B_{u,d}^0)$ with the components being independent standard Brownian bridges. The symbol σ stands for the

a)Electronic mail: cristian_predescu@brown.edu

vector $(\sigma_1,\sigma_2,\ldots,\sigma_d)$ with components defined by $\sigma_i^2=\hbar^2\beta/m_{0,i}$. The product σB_u^0 is interpreted as the d-dimensional vector of components $\sigma_i B_{u,i}^0$. Finally, x and x' are points in the configuration space $\mathbb{R}^d$ connected by the line $x_0(u)=x+(x'-x)u$.

As emphasized in Ref. 3, the success of the Feynman–Kaç formula in the computation of the thermodynamic properties of quantum systems is fortuitously due to another remarkable result: the Metropolis *et al.*[4] sampling algorithm of arbitrary finite-dimensional probability distributions, which lies at the heart of the Monte Carlo integration schemes.[5] This leads to the related but separate problem of finding a rapidly convergent sequence of finite-dimensional approximations of the stochastic integral (2). The main techniques found in literature can be classified in two categories: the discrete path integral methods and the random series techniques (for reviews, see Refs. 6 and 7, respectively). The latter methods lend themselves to various modifications which result in convergence for a wider class of potentials $V(x)$ or/and improved asymptotic convergence. One such method is the partial averaging (PA) technique, which was initially introduced by Doll, Coalson, and Freeman[8] as a way to accelerate the convergence of the ''primitive'' Fourier path integral method (FPI).[9]

As we shall see, the partial averaging method requires the Gaussian transform of the potential V for its implementation. For real life potentials this is a difficult but not impossible task. However, it was generally considered that the improvement the technique brings in does not warrant the effort of computing the Gaussian transform of the potential and therefore, the so-called gradient corrected partial averaging method was used instead. It has been shown that this latter method has general $\mathcal{O}(1/n^2)$ asymptotic behavior for sufficiently smooth potentials and it has been argued that there is not much reason to suspect a better convergence rate for the full partial averaging method.[10] However, more accurate numerical evidence recently presented in Ref. 7 suggests that the full partial averaging method does have in fact a better behavior: if the technique is used in conjunction with the FPI approach and if the potential is smooth enough, the asymptotic convergence is $\mathcal{O}(1/n^3)$. The importance of the partial averaging method resides also in the fact that it acts as a prototypical strategy for improving the asymptotic rate of convergence of the random series path integral methods. As such, the reweighted random series technique[7] achieves superior asymptotic convergence by simulating the partial averaging approach.

In this work, I shall argue for one more property of the partial averaging method which is not shared by the gradient corrected version and in general by the nonaveraged methods. More specifically, I shall show that the method can be employed for potentials having negative coulombic singularities, for which standard discrete path integral techniques (and also the primitive random series ones) fail to converge.[11,12] In this respect, it is quite surprising that the technique has been scarcely used for this purpose, despite the fact that in several instances its application for the polaron problem[13,14] and for the computation of statistical properties of quantum systems[15] was numerically successful. Though several other methods for dealing with the coulombic singularities have been proposed (see, for instance, Ref. 16), I appreciate that the advantage of the partial averaging strategy can be best emphasized by its ability of handling such systems.

In this article, I establish a sufficiently large class of potentials for which the partial averaging sequence of approximations converges to the correct Feynman–Kaç result, though I only study the convergence of the density matrix and of the partition function. This class includes most of the smooth and bounded from below potentials as well as most of the potentials having coulombic singularities. The proofs I perform are of a rather trivial nature, as they are direct consequences of well established convergence theorems from general probability theory. In fact, they exploit the martingale property of the partial averaging method. Besides their intrinsic value, these convergence theorems are important because they set the proper mathematical context in which the partial averaging method should be further discussed or utilized.

II. FORMULATION OF THE PROBLEM

A. A chemically relevant class of (scalar) potentials

A sufficiently large class of potentials for which the Feynman–Kaç formula (2) and its multidimensional analog hold is the so-called Kato class, which we define below. If

$$g(y)=\begin{cases}|y|, & d=1,\\ \ln(\|y\|^{-1}), & d=2,\\ \|y\|^{2-d}, & d\geqslant 3,\end{cases}$$

then the Kato class K_d is made up of all measurable functions $f:\mathbb{R}^d\to\mathbb{R}$ such that

$$\limsup_{\alpha\downarrow 0}\sup_{x\in\mathbb{R}^d}\int_{\|x-y\|\leqslant\alpha}|f(y)g(x-y)|\mathrm{d}y=0. \tag{3}$$

We also say that f is in K_d^{loc} if $1_D f\in K_d$ for all bounded domains $D\subset\mathbb{R}^d$. We say that the potential $V(x)$ is of Kato class if its negative part $V_-=\max\{0,-V\}$ is in K_d, while its positive part $V_+=\max\{0,V\}$ is in K_d^{loc}. In these conditions, as shown in Refs. 17 and 18, the Feynman–Kaç formula (2) holds. Moreover, Theorem B.7.5 of Ref. 18 shows that the density matrix $\rho(x,x';\beta)$ is continuous on $\mathbb{R}^d\times\mathbb{R}^d\times(0,\infty)$, while Theorem B.6.7 of the same reference shows that for a given $\beta>0$, the density matrix is uniformly bounded in the variables (x,x').

A remarkable theorem due to Aizenman and Simon[19] gives an alternative definition for the Kato class K_d. More precisely, Theorem 4.5 of Ref. 19 says that $V\in K_d$ if and only if

$$\limsup_{\epsilon\downarrow 0}\sup_{x\in\mathbb{R}^d}\mathbb{E}\left[\int_0^{\epsilon}|V(x+\sigma B_u)|\mathrm{d}u\right]=0, \tag{4}$$

where $\mathbb{E}$ denotes the expectation value against the d-dimensional Brownian motion B_u. Inverting the order of integration in Eq. (4) and remembering that B_u is a Gaussian distributed variable of variance u, we obtain the equivalent condition

$$\limsup_{\epsilon\downarrow 0}\sup_{x\in\mathbb{R}^d}\int_0^{\epsilon}\mathrm{d}u\int_{\mathbb{R}^d}(2\pi u)^{-d/2}e^{-\|z\|^2/(2u)}|V(x+\sigma z)|\mathrm{d}z=0. \tag{5}$$

We leave it for the reader to perform the substitutions $u'=u/\epsilon$ and then $z'=z/\sqrt{\epsilon}$ in successive order and prove the following reformulation of the condition given by Eq. (5):

$$\limsup_{\epsilon\downarrow 0}\sup_{x\in\mathbb{R}^d}\epsilon\int_0^{1}\mathrm{d}u\int_{\mathbb{R}^d}(2\pi u)^{-d/2}e^{-\|z\|^2/(2u)}|V(x+\sigma\sqrt{\epsilon}z)|\mathrm{d}z=0. \tag{6}$$

In the Appendix, we shall use Eq. (4) in the proof of Theorem 5 and Eq. (6) in the proof of Theorem 4, respectively.

As far as the chemical physicist is concerned, the Kato class of potentials is sufficiently general. It contains, for instance, the coulombic potential as it appears in electronic structure calculations. For another example, the *ab initio* intermolecular potential computed at the level of the Born-Oppenheimer approximation cannot have singularities worse than the coulombic ones and therefore it is of Kato class. However, we do not consider certain empirical potentials which are not of Kato class, as for example the Leonard-Jones potential. Nevertheless, this can be brought into the Kato class if the unphysical r^{-12} singularity is removed by truncation or by other approximations.

Let us anticipate a little and also demand that the potential V have finite Gaussian transform. The reader may read ahead in the next subsection and see that this condition is natural for the proper definition of the partial averaging method. More precisely, we require that

$$\overline{|V|}_{\alpha}(x)=\left(\prod_{i=1}^{d}\frac{1}{2\pi\alpha_i^2}\right)^{1/2}\int_{\mathbb{R}}\mathrm{d}z_1\cdots\int_{\mathbb{R}}\mathrm{d}z_d\exp\left(-\sum_{i=1}^{d}\frac{z_i^2}{2\alpha_i^2}\right)|V(x+z)|<\infty, \tag{7}$$

for all $x \in \mathbb{R}^d$ and $\alpha \in \mathbb{R}_+^d$. [In this article, $\mathbb{R}_+ = (0,\infty)$.] Certain properties of the potentials having finite Gaussian transform are given by Theorem 3 of the Appendix.

From the thermodynamic point of view, only the diagonal density matrix $\rho(x,x;\beta)$ is of interest. Moreover, in order to have a physically relevant statistics, the condition

$$0 < Z(\beta) < \infty, \quad \forall \beta > 0 \tag{8}$$

must hold, but the inequality (8) is not a requirement for the results obtained in this article to be valid. In practice, the condition is achieved by the addition of a *constraining* potential, which is usually a continuous and bounded from below function (thus still in the Kato class). The constraining potential is intended to simulate, for example, the effect of the container in which a reaction takes place. A sufficient condition for the quantum partition function to be finite is that the analog classical partition function be finite. This follows from the following inequality:

Proposition 1: Set

$$Z_{cl}(\beta) = \frac{1}{\sqrt{2\pi\sigma^2}} \int_{\mathbb{R}} e^{-\beta V(x)} \mathrm{d}x.$$

Then, $Z(\beta) \leqslant Z_{cl}(\beta)$.

Proof: By Jensen's inequality and Tonelli theorem,

$$\begin{aligned} Z(\beta) &= \frac{1}{\sqrt{2\pi\sigma^2}} \int_{\mathbb{R}} \mathrm{d}x\, \mathbb{E}\, e^{-\beta \int_0^1 V(x+\sigma B_u^0)\mathrm{d}u} \\ &\leqslant \frac{1}{\sqrt{2\pi\sigma^2}} \int_{\mathbb{R}} \mathrm{d}x\, \mathbb{E} \int_0^1 \mathrm{d}u\, e^{-\beta V(x+\sigma B_u^0)} \\ &= \frac{1}{\sqrt{2\pi\sigma^2}} \mathbb{E} \int_0^1 \mathrm{d}u \int_{\mathbb{R}} \mathrm{d}x\, e^{-\beta V(x+\sigma B_u^0)} = Z_{cl}(\beta). \end{aligned}$$

□

As stated, Proposition 1 remains true for multidimensional systems. In this article, we shall perform the proofs only for monodimensional systems. The reader should notice that our arguments are purely measure theoretic, in fact irrespective of the dimensionality of the physical systems. On the other hand, in the chemical physics literature it is customary to perform the analysis in ''monodimensional'' notation. I consider that the mathematician will have little trouble generalizing the proofs, yet the chemist may find it hard to accommodate a more complicated notation.

B. The partial averaging strategy

In this section, we shall give a short review of the partial averaging method for monodimensional systems (the multidimensional generalization is straightforward). For a more complete discussion, the reader should consult Ref. 7. The most general series representation of the Brownian bridge is given by the Ito-Nisio theorem,[20] the statement of which is reproduced below. Assume given $\{\lambda_k(\tau)\}_{k \geqslant 1}$ a system of functions on the interval $[0,1]$ which, together with the constant function $\lambda_0(\tau) = 1$, makes up an orthonormal basis in $L^2[0,1]$. Let $\Lambda_k(u)$ denote the primitives

$$\Lambda_k(u) = \int_0^u \lambda_k(\tau)\mathrm{d}\tau$$

of the functions $\lambda_k(u)$. If Ω is the space of infinite sequences $\overline{a} \equiv (a_1, a_2, \ldots)$ and

$$P[\overline{a}] = \prod_{k=1}^{\infty} \mu(a_k) \tag{9}$$

is the (unique by the Kolmogorov extension theorem) probability measure on Ω such that the coordinate maps $\overline{a}\to a_k$ are independent identically distributed (i.i.d.) variables with distribution probability

$$\mu(a_k\in A)=\frac{1}{\sqrt{2\pi}}\int_A e^{-z^2/2}\,\mathrm{d}z, \tag{10}$$

then

$$B_u^0(\overline{a})=\sum_{k=1}^{\infty} a_k\Lambda_k(u),\quad 0\leqslant u\leqslant 1 \tag{11}$$

is equal in distribution to a standard Brownian bridge. Moreover, the convergence of the above series is almost surely uniform on the interval [0,1].

Using the Ito–Nisio representation of the Brownian bridge, the Feynman–Kaç formula (2) takes the form

$$\frac{\rho(x,x';\beta)}{\rho_{fp}(x,x';\beta)}=\int_\Omega \mathrm{d}P[\overline{a}]\exp\left\{-\beta\int_0^1 V\left[x_0(u)+\sigma\sum_{k=1}^{\infty} a_k\Lambda_k(u)\right]\mathrm{d}u\right\}.$$

The independence of the coordinates a_k, which physically amounts to choosing those representations in which the kinetic energy operator is diagonal, is the key to the use of the partial averaging method. Denoting by $\mathbb{E}_n$ the average over the coefficients beyond the rank n, the partial averaging formula reads

$$\frac{\rho_n^{PA}(x,x';\beta)}{\rho_{fp}(x,x';\beta)}=\int_{\mathbb{R}}\mathrm{d}\mu(a_1)\ldots\int_{\mathbb{R}}\mathrm{d}\mu(a_n)\exp\left\{-\beta\ \ \mathbb{E}_n\int_0^1 V\left[x_0(u)+\sigma\sum_{k=1}^{\infty} a_k\Lambda_k(u)\right]\mathrm{d}u\right\}. \tag{12}$$

Assuming that the Fubini theorem holds (this is proved in the next section), one may invert the order of integration in the exponent and compute

$$\mathbb{E}_n\int_0^1 V[x_0(u)+\sigma B_u^0(\overline{a})]\mathrm{d}u=\int_0^1 \mathbb{E}_n V[x_0(u)+\sigma B_u^0(\overline{a})]\mathrm{d}u=\int_0^1 \overline{V}_{u,n}\left[x_0(u)+\sigma\sum_{k=1}^{n} a_k\Lambda_k(u)\right]\mathrm{d}u, \tag{13}$$

where

$$\overline{V}_{u,n}(y)=\int_{\mathbb{R}}\frac{1}{\sqrt{2\pi\Gamma_n^2(u)}}\exp\left[-\frac{z^2}{2\Gamma_n^2(u)}\right]V(y+z)\mathrm{d}z. \tag{14}$$

The function $\Gamma_n^2(u)$ is defined by

$$\Gamma_n^2(u)=\sigma^2\sum_{k=n+1}^{\infty}\Lambda_k(u)^2=\sigma^2\left[u(1-u)-\sum_{k=1}^{n}\Lambda_k(u)^2\right]. \tag{15}$$

[Again, the reader is referred to Ref. 7 for additional explanations. It is customary to use the notation $\Gamma_n^2(u)$ to mean the square of $\Gamma_n(u)$.] To summarize, we *define* the nth order partial averaging approximation to the diagonal density matrix by the formula

$$\frac{\rho_n^{PA}(x,x';\beta)}{\rho_{fp}(x,x';\beta)} = \int_{\mathbb{R}} \mathrm{d}\mu(a_1)\ldots \int_{\mathbb{R}} \mathrm{d}\mu(a_n) \exp\left\{ -\beta \int_0^1 \overline{V}_{u,n}\left[x_0(u) + \sigma \sum_{k=1}^{n} a_k \Lambda_k(u) \right] \mathrm{d}u \right\}. \tag{16}$$

III. MARTINGALE PROPERTY AND CONVERGENCE RESULTS

This section establishes the martingale property of the partial averaging method. One may notice that we obtain some important convergence results without actually doing much work other than citing some well-established theorems. The chemical physicist will probably be more interested in Corollary 1, which is for that matter presented separately.

On the set Ω of sequences $\overline{a} \equiv (a_1, a_2, \ldots)$, consider the σ-algebra generated by the finite-dimensional Borel sets $\mathcal{F}_\infty = \sigma(\cup_{n \geqslant 0} \mathcal{F}_n)$, where $\mathcal{F}_n = \sigma(a_1, a_2, \ldots, a_n)$ and $\mathcal{F}_0 = \{\varnothing, \Omega\}$. By construction, $\{\mathcal{F}_n\}_{n \geqslant 0}$ is a filtration. Also, the probability measure $\mathrm{d}P[\overline{a}]$ introduced in the previous section is, of course, defined over $\mathcal{F}_\infty$ so that the default probability space we refer to in this work is $(\Omega, \mathcal{F}_\infty, P)$. If f is an integrable random variable on Ω, we shall sometimes denote the conditional expectation $\mathbb{E}[f \,|\, \mathcal{F}_n]$ simply by $\mathbb{E}_n f$.

To continue with the introduction of the notations, we define

$$U_n(x,x',\beta;\overline{a}) = \int_0^1 \overline{V}_{u,n}\left[x_0(u) + \sigma \sum_{k=1}^{n} a_k \Lambda_k(u) \right] \mathrm{d}u$$

and

$$U_\infty(x,x',\beta;\overline{a}) = \int_0^1 V\left[x_0(u) + \sigma \sum_{k=1}^{\infty} a_k \Lambda_k(u) \right] \mathrm{d}u.$$

The variables x, x', and β are interpreted here as parameters and, just as a reminder, we separate them by a semicolon from the "true" variable $\overline{a}$. By construction, $U_n(x,x',\beta;\overline{a})$ is $\mathcal{F}_n$ measurable, while $U_\infty(x,x',\beta;\overline{a})$ is $\mathcal{F}_\infty$ measurable. Let us prove that $U_n(x,x',\beta;\overline{a}) = \mathbb{E}_n[U_\infty(x,x',\beta;\overline{a})]$ for P-almost every $\overline{a}$. As shown in the previous section, this boils down to proving

$$\mathbb{E}_n \int_0^1 V[x_0(u) + \sigma B_u^0(\overline{a})]\mathrm{d}u = \int_0^1 \mathbb{E}_n V[x_0(u) + \sigma B_u^0(\overline{a})]\mathrm{d}u$$

P-almost surely. The relation follows from the Fubini–Tonelli theorem provided that

$$\int_0^1 \mathbb{E}_n |V[x_0(u) + \sigma B_u^0(\overline{a})]| \mathrm{d}u \tag{17}$$

is finite P-a.s. Since the above integrand is non-negative, it is enough to show that its P-expectation is finite. Let

$$\mathrm{d}\mu_\epsilon(z) = \frac{1}{\sqrt{2\pi\epsilon^2}} e^{-z^2/(2\epsilon^2)} \mathrm{d}z$$

denote the respective Gaussian measure on $\mathbb{R}$. Using the Tonelli theorem to invert the order of integration, one computes

$$\mathbb{E}\left\{\int_0^1 \mathbb{E}_n\left|V[x_0(u)+\sigma B_u^0(\overline{a})]\right|\mathrm{d}u\right\}=\int_0^1 \mathbb{E}|V[x_0(u)+\sigma B_u^0(\overline{a})]|\mathrm{d}u$$

$$=\int_0^1 \mathrm{d}u\int_{\mathbb{R}}|V[x_0(u)+z]|\mathrm{d}\mu_{\Gamma_0(u)}(z)<\infty. \tag{18}$$

The last expression is finite for all $(x,x';\beta)\in\mathbb{R}^2\times\mathbb{R}_+$ by Theorem 4 of the Appendix. Equation (18) also shows that $U_\infty(x,x',\beta;\overline{a})$ is P-integrable for all $(x,x';\beta)$. Then, standard theorems from martingale theory show [see Theorem 5.7 of Ref. 21] the following:

Theorem 1: *For all $(x,x',\beta)\in\mathbb{R}^2\times\mathbb{R}_+$, the sequence $U_n(x,x',\beta;\overline{a})$ is a martingale adapted to the filtration $\mathcal{F}_n$ and is a.s. and L^1 convergent to $\mathbb{E}[U_\infty(x,x',\beta;\overline{a})|\mathcal{F}_\infty]=U_\infty(x,x',\beta;\overline{a})$.*

Let us define

$$X_n(x,x',\beta;\overline{a})=\rho_{fp}(x,x';\beta)\exp[-\beta\,U_n(x,x',\beta;\overline{a})]$$

and

$$X_\infty(x,x',\beta;\overline{a})=\rho_{fp}(x,x';\beta)\exp[-\beta\,U_\infty(x,x',\beta;\overline{a})].$$

Then, we have

$$\rho(x,x';\beta)=\mathbb{E}[X_\infty(x,x',\beta;\overline{a})] \tag{19}$$

and

$$\rho_n^{PA}(x,x';\beta)=\mathbb{E}[X_n(x,x',\beta;\overline{a})], \tag{20}$$

respectively.

Theorem 2: *(PA Convergence Theorem) For all $(x,x',\beta)\in\mathbb{R}^2\times\mathbb{R}_+$, the sequence $X_n(x,x',\beta;\overline{a})$ is a submartingale adapted to the filtration $\mathcal{F}_n$ and is a.s. and L^1 convergent to $X_\infty(x,x',\beta;\overline{a})$.*

Proof: We notice that $X_n(x,x',\beta;\overline{a})$ is the exponential of a martingale. Thus, by the conditional Jensen's inequality (see p. 225 of Ref. 21), we have

$$X_n\leqslant\mathbb{E}[X_{n+1}|\mathcal{F}_n]\leqslant\mathbb{E}[X_\infty|\mathcal{F}_n]. \tag{21}$$

The above inequality establishes the submartingale property because, as mentioned in Sec. II A,

$$\rho(x,x';\beta)=\mathbb{E}[\mathbb{E}[X_\infty|\mathcal{F}_n]]=\mathbb{E}X_\infty$$

is uniformly bounded in the variables (x,x') for all $\beta>0$. An elementary proof of this assertion is given in the Appendix (see Theorem 5). Finally, the a.s. convergence follows directly from Theorem 1, while the L^1 convergence follows from the Dominated convergence theorem and the inequality (21). □

We define the nth order partial averaging partition function by the formula

$$Z_n^{PA}(\beta)=\int_{\mathbb{R}}\rho_n^{PA}(x,x;\beta)\mathrm{d}x.$$

Using the symbol ↑ to mean "monotonically increasing to," a direct consequence of Theorem 2 is the following.

Corollary 1: As $n\to\infty$,

$$\rho_n^{PA}(x,x';\beta)\uparrow\rho(x,x';\beta)\text{ and }Z_n^{PA}(\beta)\uparrow Z(\beta). \tag{22}$$

Proof: The pointwise monotonic convergence of the density matrix is a direct consequence of the submartingale property and of the $L^1(\Omega,P)$ convergence of the partial averaging method. Then, the convergence of the partition functions follows from the monotone convergence theorem. □

IV. SUMMARY

In this article, I presented the basic properties of the partial averaging method. I demonstrated that the method can be employed for a quite general class of potentials by proving several convergence results of interest for the chemical physicist. In particular, I proved that the PA method is convergent for most of the potentials having negative coulombic singularities. The value of the convergence theorems deduced in the present article consists of the fact that they establish the mathematical context in which the partial averaging method should be utilized or discussed. I also anticipate that the martingale property will play an important role in establishing the asymptotic rates of convergence for different partial averaging schemes and, in fact, it may explain the superior asymptotic behavior of these methods.

APPENDIX: SOME USEFUL THEOREMS

The following theorem consists of well known facts about the Gaussian transform and I present it here for ease of reference.

Theorem 3: *Let* $f:\mathbb{R}^d\to\mathbb{R}$ *be a Borel measurable function, let* $\alpha=(\alpha_0,\ldots,\alpha_d)\in\mathbb{R}_+^d$, *and let* $\|\alpha\|=\max_{1\leqslant i\leqslant d}\alpha_i$. *Consider the d-dimensional Gaussian measure*

$$\mathrm{d}\mu_\alpha(z)=\prod_{i=1}^{d}\left[\frac{1}{\sqrt{2\pi\alpha_i^2}}e^{-z_i^2/(2\alpha_i^2)}\mathrm{d}z_i\right] \tag{A1}$$

and let

$$F(x,\alpha)=\int_{\mathbb{R}^d}|f(x+z)|\mathrm{d}\mu_\alpha(z)$$

be defined on $\mathbb{R}^d\times\mathbb{R}_+^d$. *Assume there is* $(y,\eta)\in\mathbb{R}^d\times\mathbb{R}_+^d$ *such that* $F(y,\eta)<\infty$ *and let* $D=\mathbb{R}^d\times\Pi_{i=1}^d(0,\eta_i)$. *Then the following are true:*

(a) f *is locally integrable.*

(b) $F(x,\alpha)<\infty$ *for all* $(x,\alpha)\in D$.

(c)

$$G(x,\alpha)=\int_{\mathbb{R}^d}f(x+z)\mathrm{d}\mu_\alpha(z)$$

is well defined, continuous and infinitely differentiable in both arguments on D.

(d) $\lim_{\|\alpha\|\to 0}G(x,\alpha)=f(x)$ *a.e. More strongly,*

$$\lim_{\|\alpha\|\to 0}\int_{\mathbb{R}^d}|f(x+z)-f(x)|\mathrm{d}\mu_\alpha(z)=0 \quad \text{a.e.}$$

Theorem 4: *Let x and x' be arbitrary points in $\mathbb{R}^d$, let $\beta>0$, and let B_u^0 be a standard d-dimensional Brownian bridge on $[0,1]$. Pick some arbitrary $\sigma=(\sigma_1,\ldots,\sigma_d)\in\mathbb{R}_+^d$ and set $y=x'-x$. If $V\in K_d^{loc}$ and V has finite Gaussian transform, then*

$$\int_0^1 \mathbb{E}|V(x+yu+\sigma B_u^0)|\mathrm{d}u=\int_0^1 \mathrm{d}u\int_{\mathbb{R}^d}|V(x+yu+z)|\mathrm{d}\mu_{\Gamma_0(u)}(z)<\infty, \tag{A2}$$

where $\Gamma_0^2(u)=u(1-u)(\sigma_1^2,\ldots,\sigma_d^2)$ and the Gaussian measure $\mathrm{d}\mu_\alpha(z)$ is defined by the relation (A1).

Observation: We stated this theorem separately because its proof depends upon the dimensionality of the problem. More precisely, if the system is monodimensional, one may use $\Gamma_0^2(u)\leqslant\sigma^2$ to show that the integral (A2) is smaller than

$$\int_0^1 \mathrm{d}u\,\frac{1}{\sqrt{u(1-u)}}\int_{\mathbb{R}}|V(x+yu+z)|\mathrm{d}\mu_\sigma(z). \tag{A3}$$

By Theorem 3(c), the integral

$$\int_{\mathbb{R}}|V(x+yu+z)|\mathrm{d}\mu_\sigma(z)$$

as a function of u is continuous on $[0,1]$, thus bounded. Then, by the integrability of $[u(1-u)]^{-1/2}$, it follows that the integral (A3) is finite. However, this reasoning is not valid for higher dimensions because $[u(1-u)]^{-d/2}$ is not integrable for $d\geqslant 2$ and the additional condition $V\in K_d^{loc}$ is needed.

Proof of the theorem: The equality (A2) was discussed in the text. From Theorem 3(c), it follows that

$$\int_{\mathbb{R}^d}|V(x+yu+z)|\mathrm{d}\mu_{\Gamma_0(u)}(z)$$

as a function of u is continuous on all compact intervals $[\epsilon,1-\epsilon]$ with $0<\epsilon<\frac{1}{2}$, thus bounded and integrable. It is then enough to show that

$$I_\epsilon(x,y)=\int_0^\epsilon \mathrm{d}u\int_{\mathbb{R}^d}|V(x+yu+z)|\mathrm{d}\mu_{\Gamma_0(u)}(z)=\int_0^\epsilon \mathrm{d}u\int_{\mathbb{R}^d}|V(x+z)|\mathrm{d}\mu_{\Gamma_0(u)}(z-yu)<\infty$$

for all x and y and small enough ϵ. This is so because the integral over the end $[1-\epsilon,1]$ can be shown to equal $I_\epsilon(x+y,-y)$ by the change of variable $u'=1-u$. We shall prove the above inequality in two steps.

Step 1: In the first step, we prove the inequality

$$I_\epsilon(x,y)\leqslant 2^d\exp\left(\sum_{i=1}^d\frac{y_i^2}{4\sigma_i^2}\right)\int_0^\epsilon \mathrm{d}u\int_{\mathbb{R}^d}|V(x+z)|\mathrm{d}\mu_{\sigma\sqrt{2u}}(z). \tag{A4}$$

The inequality $0<u<\frac{1}{2}$ implies

$$\prod_{i=1}^d\left\{\frac{1}{\sqrt{2\pi\sigma_i^2u(1-u)}}\exp\left[-\frac{(z_i-y_iu)^2}{2\sigma_i^2u(1-u)}\right]\right\}\leqslant 2^{d/2}\prod_{i=1}^d\left\{\frac{1}{\sqrt{2\pi\sigma_i^2u}}\exp\left[-\frac{(z_i-y_iu)^2}{2\sigma_i^2u}\right]\right\}. \tag{A5}$$

On the other hand, the minimum of the expression

$$z_i^2/2-2z_iy_iu+y_i^2u^2$$

as a quadratic function of z_i is attained at $z_i=2y_iu$ and has the value $-y_i^2u^2$. Therefore,

$$\frac{(z_i-y_iu)^2}{2\sigma_i^2u}=\frac{z_i^2/2+z_i^2/2-2z_iy_iu+y_i^2u^2}{2\sigma_i^2u}\geqslant\frac{z_i^2}{4\sigma_i^2u}-\frac{y_i^2u}{2\sigma_i^2}\geqslant\frac{z_i^2}{4\sigma_i^2u}-\frac{y_i^2}{4\sigma_i^2},$$

where we used again the condition $u<\frac{1}{2}$. Replacing the last inequality in Eq. (A5), we obtain

$$\prod_{i=1}^{d}\left\{\frac{1}{\sqrt{2\pi\sigma_i^2u(1-u)}}\exp\left[-\frac{(z_i-y_iu)^2}{2\sigma_i^2u(1-u)}\right]\right\}\leqslant 2^d\exp\left(\sum_{i=1}^{d}\frac{y_i^2}{4\sigma_i^2}\right)\prod_{i=1}^{d}\left[\frac{1}{\sqrt{4\pi\sigma_i^2u}}\exp\left(-\frac{z_i^2}{4\sigma_i^2u}\right)\right]$$

and, consequently, the inequality given by Eq. (A4) is proven.

Step 2: By the results from the first step, it suffices to show that the last integral in Eq. (A4) is finite. By appropriate transformation of coordinates, we may rewrite this last integral as

$$\begin{aligned}\int_0^{\epsilon}du\int_{\mathbb{R}^d}|V(x+z)|\,d\mu_{\sigma\sqrt{2u}}(z)&=\epsilon\int_0^1du\int_{\mathbb{R}^d}|V(x+z)|\,d\mu_{\sigma\sqrt{2\epsilon u}}(z)\\&=\epsilon\int_0^1du\int_{\mathbb{R}^d}|V(x+z\sigma\sqrt{2\epsilon})|\,d\mu_{\sqrt{u}}(z).\end{aligned}$$

Even more, the integral over $\mathbb{R}^d$ in the last relation can be restricted to the ball $\|z\|<1$. Indeed if $\|z\|\geqslant 1$, we have

$$\begin{aligned}(2\pi u)^{-d/2}\exp\left\{-\frac{\|z\|^2}{2u}\right\}&=u^{-d/2}\exp\left\{-\frac{\|z\|^2}{2}\left(\frac{1}{u}-1\right)\right\}(2\pi)^{-d/2}\exp(-\|z\|^2/2)\\&\leqslant u^{-d/2}e^{1/2}e^{-1/(2u)}(2\pi)^{-d/2}\exp(-\|z\|^2/2).\end{aligned}$$

Notice that

$$M_0=\sup_{u>0}\ e^{1/2}u^{-d/2}\exp[-1/(2u)]<\infty.$$

Then, a little calculus and Theorem 3(c) show that

$$\epsilon\int_0^1du\int_{\|z\|\geqslant 1}|V(x+z\sigma\sqrt{2\epsilon})|\,d\mu_{\sqrt{u}}(z)\leqslant\epsilon M_0\int_{\mathbb{R}^d}|V(x+z\sigma\sqrt{2\epsilon})|\,d\mu_1(z)<\infty.$$

To conclude the theorem, we only need to prove that

$$\epsilon\int_0^1du\int_{\|z\|<1}|V(x+z\sigma\sqrt{2\epsilon})|\,d\mu_{\sqrt{u}}(z)<\infty$$

for ϵ small enough. Pick an arbitrary $\eta>0$. Remembering that $\epsilon<\frac{1}{2}$ and taking x such that $\|x\|<\eta$, we notice that in order to compute the integral over z in the above formula, we only need to know the potential over the ball D of radius $\eta+\max_{1\leqslant i\leqslant d}\sigma_i$ centered at origin. Therefore, if we set $V_D=1_DV$, then

$$\epsilon\int_0^1du\int_{\|z\|<1}|V(x+z\sigma\sqrt{2\epsilon})|\,d\mu_{\sqrt{u}}(z)\leqslant\epsilon\int_0^1du\int_{\mathbb{R}^d}|V_D(x+z\sigma\sqrt{2\epsilon})|\,d\mu_{\sqrt{u}}(z)\qquad\text{(A6)}$$

for all x such that $\|x\|<\eta$. Since D is bounded and $V\in K_d^{\mathrm{loc}}$, it follows that $V_D\in K_d$ and then Eq. (6) guarantees that there is $\epsilon_0>0$ such that the last integral in Eq. (A6) is uniformly bounded for all x. Consequently,

$$\epsilon_0 \int_0^1 \mathrm{d}u \int_{\|z\|<1} |V(x+z\sigma\sqrt{2\epsilon_0})| \mathrm{d}\mu_{\sqrt{u}}(z)$$

is bounded for all x such that $\|x\|<\eta$. Since η is arbitrary, we are done. □

Theorem 5: *Assume V is a Kato-class potential. Then there is $M_\beta>0$ a constant depending upon the inverse temperature β such that $\rho(x,x';\beta)\leqslant M_\beta$ for all $(x,x')\in\mathbb{R}^d\times\mathbb{R}^d$.*

Observation: The proof of this theorem will show why the Kato class is the natural class for the treatment of Feynman–Kaç semigroups. Most of the arguments used in the proof are borrowed from Aizenman and Simon.[19]

Proof of the theorem: If V_- denotes the negative part of V, we notice that

$$\mathbb{E}\exp\left\{-\beta\int_0^1 V[x_0(u)+\sigma B_u^0]\right\}\leqslant \mathbb{E}\exp\left\{\beta\int_0^1 V_-[x_0(u)+\sigma B_u^0]\right\},$$

so, without loss of generality, we may assume that V is of class K_d. The proof of this theorem is organized in three steps, each step reducing the problem to a simpler statement.

Step 1: In the first step, we prove that it suffices to show that

$$\sup_x \int_{\mathbb{R}^d} \rho(x,x';\beta)\mathrm{d}x'<\infty \tag{A7}$$

for all $\beta>0$ and $V\in K_d$.

In this part of the proof, it is convenient to denote the density matrix by $\rho_V(x,x';\beta)$, the index V indicating the potential from which the density matrix is derived. For the proof, we need two well-known properties of the density matrix $\rho_V(x,x';\beta)$: it is symmetrical

$$\rho_V(x,x';\beta)=\rho_V(x',x;\beta)$$

and it satisfies the Trotter product rule

$$\rho_V(x,x';\beta)=\int_{\mathbb{R}^d}\rho_V(x,y;\beta/2)\rho_V(y,x';\beta/2)\mathrm{d}y.$$

These two properties can be established by direct computation starting with the definition of the Brownian bridge. The first one is a consequence of the symmetry of the standard Brownian bridge, that is $\{B_{1-u}^0:0\leqslant u\leqslant 1\}$ is also a Brownian bridge and is equal in distribution to $\{B_u^0:0\leqslant u\leqslant 1\}$. The Trotter product rule is a consequence of the Markov property of the Brownian motion B_u entering the definition of the Brownian bridge. The simple proofs are left to the reader.

Now, the Cauchy–Schwartz inequality gives the estimate

$$\rho_V(x,x';\beta)\leqslant\left[\int_{\mathbb{R}^d}\rho_V(x,y;\beta/2)^2\mathrm{d}y\right]^{1/2}\left[\int_{\mathbb{R}^d}\rho_V(y,x';\beta/2)^2\mathrm{d}y\right]^{1/2}.$$

Taking the supremum over x and x' and using the symmetry of the density matrix, one concludes that

$$\sup_{x,x'}\ \rho_V(x,x';\beta)\leqslant\sup_x\int_{\mathbb{R}^d}\rho_V(x,y;\beta/2)^2\mathrm{d}y. \tag{A8}$$

Again by the Cauchy–Schwartz inequality,

$$\frac{\rho_V(x,x';\beta/2)^2}{\rho_{fp}(x,x';\beta/2)^2}=\left(\mathbb{E}\exp\left\{-\frac{\beta}{2}\int_0^1 V\left[x_0(u)+\frac{\sigma}{\sqrt{2}}B_u^0\right]\mathrm{d}u\right\}\right)^2$$
$$\leqslant\mathbb{E}\exp\left\{-\frac{\beta}{2}\int_0^1 2V\left[x_0(u)+\frac{\sigma}{\sqrt{2}}B_u^0\right]\mathrm{d}u\right\}.$$

Next, we combine the last equation with the bound

$$\rho_{fp}(x,x';\beta/2)^2\leqslant\left(\prod_{i=1}^d\frac{1}{\sqrt{\pi\sigma_i^2}}\right)\rho_{fp}(x,x';\beta/2)$$

to obtain the inequality

$$\rho_V(x,x';\beta/2)^2\leqslant\left(\prod_{i=1}^d\frac{1}{\sqrt{\pi\sigma_i^2}}\right)\rho_{2V}(x,x';\beta/2). \tag{A9}$$

Substituting Eq. (A9) in Eq. (A8), one obtains

$$\sup_{x,x'}\ \rho_V(x,x';\beta)\leqslant\left(\prod_{i=1}^d\frac{1}{\sqrt{\pi\sigma_i^2}}\right)\sup_x\int_{\mathbb{R}^d}\rho_{2V}(x,y;\beta/2)\mathrm{d}y$$

and the claim of Step 1 is concluded because $\beta/2>0$ and $2V\in K_d$.

Step 2: Simple transformations of coordinates show that

$$\int_{\mathbb{R}^d}\rho(x,x';\beta)\mathrm{d}x'=\int_{\mathbb{R}^d}\mathrm{d}\mu_1(z)\,\mathbb{E}\,e^{-\beta\int_0^1 V[x+zu\sigma+\sigma B_u^0]\mathrm{d}u}$$

and from the very definition of the Brownian bridge, we learn that $zu+B_u^0$ is in fact a Brownian motion B_u starting at zero. Thus,

$$\int_{\mathbb{R}^d}\rho(x,x';\beta)\mathrm{d}x'=\mathbb{E}\,e^{-\beta\int_0^1 V(x+\sigma B_u)\mathrm{d}u}.$$

For the remainder of the proof, $\mathbb{E}$ stands for the expectation value with respect to the underlying measure of the standard Brownian motion B_u.

In this second step, we use the Markov property of the Brownian motion to show that if there is $\epsilon_0>0$ such that the inequality

$$\sup_x\ \mathbb{E}\ \ e^{-\beta\int_0^\epsilon V(x+\sigma B_u)\mathrm{d}u}<\infty$$

holds for all $\epsilon<\epsilon_0$, then Eq. (A7) also holds.

Let θ and τ be some positive real numbers such that $\theta+\tau=1$. We break the integrand in the above equation in two parts:

$$e^{-\beta\int_0^1 V(x+\sigma B_u)\mathrm{d}u}=e^{-\beta\int_0^\theta V(x+\sigma B_u)\mathrm{d}u}e^{-\beta\int_\theta^1 V(x+\sigma B_u)\mathrm{d}u}=e^{-\beta\int_0^\theta V(x+\sigma B_u)\mathrm{d}u}e^{-\beta\int_0^\tau V(x+\sigma B_{\theta+u})\mathrm{d}u}.$$

Using the Markov property, we learn that the expected value of the above integrand conditioned on the random variables B_u with $u\in[0,\theta]$ is

$$e^{-\beta\int_0^\theta V(x+\sigma B_u)\mathrm{d}u}\mathbb{E}'\,e^{-\beta\int_0^\tau V(x+\sigma B_\theta+\sigma B'_u)\mathrm{d}u}.$$

Here, the symbol $\mathbb{E}'$ denotes the expected value against the standard Brownian motion starting at zero B'_u, Brownian motion that is independent from B_u. The above conditional expectation is smaller than or equal to

$$e^{-\beta\int_0^\theta V(x+\sigma B_u)\mathrm{d}u}\sup_x \mathbb{E}\, e^{-\beta\int_0^\tau V(x+\sigma B_u)\mathrm{d}u},$$

where the prime sign becomes superfluous and is therefore dropped. Taking the total expectation and then the supremum over x, we obtain the inequality

$$\sup_x \mathbb{E}\, e^{-\beta\int_0^1 V(x+\sigma B_u)\mathrm{d}u}\leqslant \sup_x \mathbb{E}\, e^{-\beta\int_0^\theta V(x+\sigma B_u)\mathrm{d}u}\times\sup_x \mathbb{E}\, e^{-\beta\int_0^\tau V(x+\sigma B_u)\mathrm{d}u}.$$

A simple inductive argument then shows that

$$\sup_x \mathbb{E}\, e^{-\beta\int_0^1 V(x+\sigma B_u)\mathrm{d}u}\leqslant\left\{\sup_x \mathbb{E}\, e^{-\beta\int_0^{1/n} V(x+\sigma B_u)\mathrm{d}u}\right\}^n \tag{A10}$$

for all $n\geqslant 1$. Clearly, the claim of Step 2 is concluded because the right-hand side of Eq. (A10) is finite for all n such that $1/n<\epsilon_0$.

Step 3: In this final step, we prove that there is ϵ_0 small enough such that

$$\sup_x \mathbb{E}\, e^{-\beta\int_0^\epsilon V(x+\sigma B_u)\mathrm{d}u}<\infty$$

for all $\epsilon<\epsilon_0$. Equation (4) allows us to pick some $\epsilon_0>0$ such that

$$\sup_x \mathbb{E}\left[\beta\int_0^\epsilon |V|(x+\sigma B_u)\mathrm{d}u\right]<\frac{1}{2} \tag{A11}$$

for all $\epsilon<\epsilon_0$. Next, we consider the inequality

$$\sup_x \mathbb{E}\, e^{-\beta\int_0^\epsilon V(x+\sigma B_u)\mathrm{d}u}\leqslant\sup_x \mathbb{E}\, e^{\beta\int_0^\epsilon |V|(x+\sigma B_u)\mathrm{d}u}=\sup_x\sum_{k=1}^\infty \frac{\beta^k}{k!}\mathbb{E}\left[\int_0^\epsilon |V|(x+\sigma B_u)\mathrm{d}u\right]^k\leqslant\sum_{k=0}^\infty A_k, \tag{A12}$$

where

$$A_k=\sup_x\frac{\beta^k}{k!}\mathbb{E}\left[\int_0^\epsilon |V|(x+\sigma B_u)\mathrm{d}u\right]^k=\beta^k\mathbb{E}\int_{0\leqslant s_1\leqslant\ldots\leqslant s_k\leqslant\epsilon}|V|(x+\sigma B_{s_1})\cdots|V|(x+\sigma B_{s_k})\mathrm{d}s_1\cdots\mathrm{d}s_k. \tag{A13}$$

Notice that the term by term integration of the first series appearing in Eq. (A12) is guaranteed by the monotone convergence theorem. The last equality in Eq. (A13) follows by symmetry arguments.

To construct a bound for the terms A_k, we first condition on the random variables B_u with $u\in[0,s_{k-1}]$ and use the Markov property of B_u to show that this conditional expectation has the value

$$\beta^{k-1}\int_{0\leqslant s_1\leqslant\ldots\leqslant s_{k-1}\leqslant\epsilon}|V|(x+\sigma B_{s_1})\cdots|V|(x+\sigma B_{s_{k-1}})\times\left[\mathbb{E}'\beta\int_0^{\epsilon-s_{k-1}}|V|(x+\sigma B_{s_{k-1}}+\sigma B'_u)\mathrm{d}u\right]\mathrm{d}s_1\cdots\mathrm{d}s_{k-1}. \tag{A14}$$

Equation (A11) shows that the quantity in the square brackets is bounded by $\frac{1}{2}$. Therefore, the conditional expectation given by Eq. (A14) is bounded by

$$\frac{1}{2}\beta^{k-1}\int_{0\leqslant s_1\leqslant\ldots\leqslant s_{k-1}\leqslant\epsilon}|V|(x+\sigma B_{s_1})\cdots|V|(x+\sigma B_{s_{k-1}})\mathrm{d}s_1\cdots\mathrm{d}s_{k-1}. \tag{A15}$$

Taking the total expectation in Eqs. (A14) and (A15) and then the supremum over x, we learn that

$$A_k\leqslant A_{k-1}/2,$$

from which the inequality $A_k\leqslant 1/2^k$ follows by induction. Substituting this last inequality in Eq. (A12), we obtain

$$\sup_x \mathbb{E}\, e^{-\beta\int_0^\epsilon V(x+\sigma B_u)\mathrm{d}u}\leqslant\sum_{k=0}^{\infty}\frac{1}{2^k}=2<\infty$$

for all $\epsilon<\epsilon_0$ and the proof of Step 3 and of the theorem is concluded. □

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 3 MARCH 2003

Limits of a Ginzburg–Landau model with codimension-one defects

J. Rubinstein and P. Sternberg[a)]
Department of Mathematics, Indiana University, Bloomington, Indiana 47405

(Received 11 December 2002; accepted 20 December 2002)

We derive a nondimensional Ginzburg–Landau energy functional that does not use temperature-dependent scaling quantities. Using the machinery of gamma-convergence, the asymptotic limits of the functional are computed in the presence of thin defects centered around co-dimension 1 manifolds. We classify the defects into three groups depending on the L^1-norm of the defect potential. We show that each group has its own distinguished asymptotic limit as the thickness of the defect converges to zero. © *2003 American Institute of Physics.*

I. INTRODUCTION

The Ginzburg–Landau model has successfully captured a wide range of phenomena associated with the behavior of a superconducting material subjected to external magnetic fields. This includes the analysis of the relation between the transition temperature below which one first observes superconductivity and the strength of the applied field. In this article we present a modification of the standard Ginzburg–Landau model that incorporates the presence of normal—that is, non-superconducting—material appearing as thin inclusions within the superconducting bulk. We study the effect of this modification in the asymptotic regime where the thickness of the normal inclusions is small. Particular attention is paid to the effect on the transition temperature of the material.

As we shall see, in our model the normal inclusions are broken into three distinct regimes involving a weak, critical and strong influence on the behavior of the superconductor. Previous attempts by physicists to model the presence of normal defects in a superconducting material via Ginzburg–Landau theory include Refs. 1 and 9. In Refs. 2, 5 and 6, a modification of the Ginzburg–Landau model is studied which corresponds in our language to the case of weak inclusions only. The identification of the three regimes was set forth in Ref. 7 for the case of a one-dimensional superconductor and a primary purpose of the present study is to extend this model and analysis to the more physically interesting cases of two- and three-dimensional samples.

Because a central application we have in mind concerns the temperature versus external field transition curve, we shall begin our analysis with a careful nondimensionalization of the unmodified Ginzburg–Landau model. Commonly used nondimensionalizations typically involve scaling space as well as the order parameter and field by temperature-dependent quantities. This can lead to inappropriate formulations for our purposes. Consequently, in Sec. II we present in some detail a nondimensionalization that involves scaling only by temperature-independent quantities. We believe this formulation may prove useful in other investigations stressing temperature dependence in superconducting materials.

We follow this in Sec. III with a presentation of the modified Ginzburg–Landau model to incorporate the normal inclusions. A central component of the standard Ginzburg–Landau energy[11] is a bulk term depending on the complex-valued order parameter $\tilde{u}$ of the form

[a)]Author to whom correspondence should be addressed. Electronic mail: sternber@indiana.edu

$$\int_{\tilde{\Omega}} -\alpha|\tilde{u}|^2+\frac{\beta}{2}|\tilde{u}|^4\,\mathrm{d}\tilde{x},$$

where $\tilde{\Omega}$ is the region occupied by the superconductor. The factor β is a positive, temperature-independent constant but α is a factor depending on temperature. For temperatures below the critical temperature T_c, where onset first occurs in the absence of magnetic fields, α is positive, while it is negative above this value where superconductivity is precluded. Since the physically relevant quantity here is $|\tilde{u}|^2$, which measures the density of superconducting electron pairs, this sign change in α allows for the emergence of the stable state $|\tilde{u}|^2=\alpha/\beta$ signaling the presence of superconductivity in the model. In the modification we pursue, we model the presence of normal regions within $\tilde{\Omega}$ by taking α to be negative, regardless of temperature, in certain small portions of the sample. It is the size of the positive factor $-\alpha$, taken to be of the form $-\alpha=a/\delta^p$, that distinguishes the three different asymptotic regimes alluded to earlier. Here a is a positive constant, p is non-negative and $0<\delta\ll 1$ corresponds to the thickness of the normal region. What turns out to be relevant is the L^1-norm of this factor a/δ^p taken over the normal region, thus leading to the regimes $p<1$, $p=1$ and $p>1$.

In Sec. IV we invoke the theory of gamma-convergence (cf. Ref. 4) to study the limit of the modified Ginzburg–Landau energy for small δ. We review the definition of this convergence at the outset of the section. The identification of the gamma-limits allows one to characterize minimizers, both global and local, of the original energies as being minimizers of the identified limiting energies.

Finally, in Sec. V we focus on the issue of transition temperatures in the presence of normal inclusions by calculating the second variation of the limiting energies taken about the purely normal state. This leads to concrete eigenvalue problems whose first eigenvalue corresponds to the shift down in transition temperature due to the presence of applied magnetic fields for this superconducting/normal sample in the $\delta\to 0$ first approximation.

II. FORMULATION OF THE NONDIMENSIONAL PROBLEM FOR A CLEAN SUPERCONDUCTOR

The dimensional Ginzburg–Landau functional is given by

$$G(\tilde{u},\tilde{\mathbf{A}})=\int_{\tilde{D}}\frac{1}{2m}\left|\left(i\hbar\tilde{\nabla}-\frac{e}{c}\tilde{\mathbf{A}}\right)\tilde{u}\right|^2-\alpha|\tilde{u}|^2+\frac{\beta}{2}|\tilde{u}|^4\mathrm{d}\tilde{x}+\int_{\mathbb{R}^n}\frac{1}{8\pi}|\tilde{\nabla}\times\tilde{\mathbf{A}}-\tilde{\mathbf{H}}_{\mathbf{e}}|^2\mathrm{d}\tilde{x}. \tag{2.1}$$

Here $\tilde{D}\subset\mathbb{R}^n$ ($n=1$, 2 or 3) is the bounded domain occupied by the superconducting sample, c is the speed of light, $\hbar$ is Planck's constant, e and m are the electron's charge and half-mass, $\tilde{\mathbf{H}}_{\mathbf{e}}:\mathbb{R}^n\to\mathbb{R}^n$ and $\tilde{\mathbf{A}}:\mathbb{R}^n\to\mathbb{R}^n$ are the applied magnetic field and the total magnetic potential, respectively, $u:\tilde{D}\to\mathbb{C}$ is the order parameter, and α and β are material parameters. The dependence of β on the temperature T is weak. Since in most applications one works at temperatures that are not too far from the critical temperature, we can assume that β is temperature-independent. The parameter α, on the other hand, is sensitive to the temperature. The standard model is to take

$$\alpha\sim\alpha_0(T_c-T)\quad\text{for}\quad T_c-T\ll 1, \tag{2.2}$$

where α_0 is a positive constant and T_c is the critical temperature for the material, below which superconductivity is observable in the absence of any applied field (cf. Ref. 3).

We wish to nondimensionalize the various terms in the energy functional (2.1) without scaling by any temperature-dependent quantities. We start with generic scalings: $\overline{H}$ for the magnetic field, l for lengthscale, and $\sqrt{M}$ for u, and later we shall make judicious choices for these three factors. It is useful to recall the definitions of four fundamental parameters that appear frequently in superconductivity: the coherence length

$$\xi = \sqrt{\frac{\hbar^2}{2m\alpha}}, \tag{2.3}$$

the penetration depth

$$\lambda = \sqrt{\frac{m\beta c^2}{4\pi\alpha e^2}}, \tag{2.4}$$

the (dimensionless) Ginzburg–Landau parameter

$$\kappa = \frac{\lambda}{\xi}, \tag{2.5}$$

and the basic flux quantum

$$\Phi_0 = 2\pi\frac{\hbar c}{e}. \tag{2.6}$$

We now scale:

$$u = \frac{\tilde{u}}{\sqrt{M}}, \quad x = \frac{\tilde{x}}{l}, \quad \mathbf{H_e} = \frac{\tilde{\mathbf{H}}_\mathbf{e}}{2(2\pi)^{1/2}\overline{H}}, \quad \mathbf{A} = \frac{\tilde{\mathbf{A}}}{2(2\pi)^{1/2}l\overline{H}}. \tag{2.7}$$

Under this scaling, the Ginzburg–Landau functional becomes

$$G(u,\mathbf{A}) = \int_D \left(\frac{M\hbar^2}{2m}\frac{1}{l^2}\left| \left(i\nabla - \frac{2(2\pi)^{1/2}\overline{H}el^2}{c\hbar}\mathbf{A} \right) u \right|^2 - \alpha M|u|^2 + \frac{\beta M^2}{2}|u|^4 \right) l^n \, \mathrm{d}x$$

$$+ \int_{\mathbb{R}^n} \overline{H}^2 |\nabla\times\mathbf{A} - \mathbf{H_e}|^2 \, l^n \, \mathrm{d}x$$

$\Rightarrow$

$$\frac{1}{l^n\overline{H}^2}G(u,\mathbf{A}) = \int_D \left(\frac{M\hbar^2}{2m\overline{H}^2}\frac{1}{l^2}\left| \left(i\nabla - \frac{2(2\pi)^{1/2}\overline{H}el^2}{c\hbar}\mathbf{A} \right) u \right|^2 - \frac{\alpha M}{\overline{H}^2}|u|^2 + \frac{\beta M^2}{2\overline{H}^2}|u|^4 \right) \mathrm{d}x$$

$$+ \int_{\mathbb{R}^n} |\nabla\times\mathbf{A} - \mathbf{H_e}|^2 \, \mathrm{d}x. \tag{2.8}$$

Here D denotes the original domain $\tilde{D}$ scaled by l.

Again, our goal is to find a nondimensionalization such that M, $\overline{H}$ and l are not temperature-dependent. Before proceeding, we should perhaps mention that in addition to the coherence length and the penetration depth, there is another length-scale in the problem given by

$$\zeta = \frac{2m\beta}{\hbar^2}.$$

An elementary calculation shows that ζ and κ are related through

$$\zeta = 4\pi\kappa r_0, \tag{2.9}$$

where $r_0 = e^2/mc^2$ is the classical radius of the electron. Since λ and ξ depend on temperature through α, we are left with only two choices for scaling length in a temperature-independent manner. One is ζ and the other one is some typical length l associated with the domain $\tilde{D}$ such as

its diameter. The former choice is not desirable since $r_0 \sim 10^{-15}$ m, which is much smaller than any other length in the problem. We therefore opt for the latter choice that *uses the problem's specific geometry to fix its length-scale*. Thus we are guaranteed to end up working with a domain D whose size is $\mathcal{O}(1)$.

Choosing a value for M is trickier. It is not desirable to use the geometrical quantity l. If we choose ζ, we end up with a representation for G that has terms such as r_0/l that are extremely small as explained above. We cannot use ξ and λ since this will lead to a formulation where the temperature appears implicitly in u, and this causes difficulties in any phase transition analysis. To remedy the situation we use the formula (2.2) to define

$$\xi_0 = \sqrt{\frac{\hbar^2}{2m\alpha_0}} \quad \text{and} \quad \lambda_0 = \sqrt{\frac{m\beta c^2}{4\pi\alpha_0 e^2}}. \tag{2.10}$$

These definitions imply that $\lambda = \lambda_0 \rho(T)$ and $\xi = \xi_0 \rho(T)$, with $\rho(T) \sim (T_c - T)^{-1/2}$. We can therefore use ξ_0, or, even better, α_0, as a natural scaling length for M:

$$M = \frac{\overline{H}^2}{\alpha_0}. \tag{2.11}$$

Scaling H is to a large extent dependent on the specific problem at hand. For example, if we are interested in mesoscopic domains, we can use the number of fluxoids in $\tilde{D}$ as a scaling parameter and set

$$\overline{H} = \frac{\Phi_0}{2(2\pi)^{3/2} l^2} = \frac{\hbar c}{2(2\pi)^{1/2} e l^2}. \tag{2.12}$$

Up to a factor and an additive constant, we obtain that the energy is given by

$$G(u, \mathbf{A}) = \int_D \left(\left(\frac{\xi_0}{l} \right)^2 |(i\nabla - \mathbf{A})u|^2 + \frac{\nu^2}{2} (|u|^2 - \mu^2)^2 \right) dx + \int_{\mathbb{R}^n} |\nabla \times \mathbf{A} - \mathbf{H_e}|^2 \, dx. \tag{2.13}$$

Here

$$\nu^2 = \frac{\beta \overline{H}^2}{\alpha_0^2} \tag{2.14}$$

and is independent of temperature, while the temperature dependence is captured in the parameter μ^2 given by

$$\mu^2 \sim \frac{\alpha_0^2 (T_c - T)}{\beta \overline{H}^2} \quad \text{for} \quad T_c - T \ll 1. \tag{2.15}$$

It is also useful to write the energy in another form that exposes the parameter κ. It follows from (2.10) and (2.12) that

$$\frac{l^2 \nu^2}{\xi_0^2} = \frac{\lambda_0^2}{l^2}.$$

Substituting this into (2.13) and noting that $\kappa = \lambda_0 / \xi_0$ we obtain (after multiplying G by a constant)

$$G(u,\mathbf{A})=\int_D\left(|(i\nabla-\mathbf{A})u|^2+\frac{\sigma}{2}(|u|^2-\mu^2)^2\right)\,dx+\sigma^{-1}\kappa^2\int_{\mathbb{R}^n}|\nabla\times\mathbf{A}-\mathbf{H_e}|^2\,dx, \tag{2.16}$$

where $\sigma=(\lambda_0/l)^2$.

III. FORMULATION OF THE VARIATIONAL PROBLEM WITH NORMAL INCLUSIONS

In this section we discuss the incorporation of normal inclusions into the Ginzburg–Landau model. This will be carried out through an appropriate modification of the nondimensional energy (2.13). We wish to consider three possible geometries for the region occupied by the superconductor: that of a thin film, an infinite cylinder and an arbitrary smooth, bounded three-dimensional domain. For the first two, we denote by $D\subset\mathbb{R}^2$ a smooth, bounded, connected open set. In the case of the film, D will represent the planar region covered by the film. In the case of an infinite cylinder, D represents the $2d$ cross-section. In all cases, we study the behavior of the superconductor when exposed to an applied magnetic field $\mathbf{H_e}$. In the first two cases, we take $\mathbf{H_e}$ to be directed orthogonally to D, that is, $\mathbf{H_e}$ takes the form $(0,0,h_e)$ for some $h_e:\mathbb{R}^2\to\mathbb{R}^1$, while $\mathbf{H_e}:\mathbb{R}^3\to\mathbb{R}^3$ is at this point taken to be arbitrary in the fully $3d$ case.

To model the normal inclusions in the sample, we first introduce $\Gamma=(\cup_{i=1}^N\Gamma_i)\subset D$ to be a finite union of nonintersecting C^2 curves (surfaces) for $D\subset\mathbb{R}^2$ ($\subset\mathbb{R}^3$). We assume that for each i, either Γ_i has no boundary or else that its boundary lies in ∂D. We shall denote by $d_\Gamma:D\to\mathbb{R}^1$ the Euclidean distance from a point in D to Γ and we note that under the assumption that $\Gamma\in C^2$ we can conclude that $d_\Gamma\in C^2$ in a sufficiently small neighborhood of Γ. We also note that the (mean) curvature of Γ, denoted by κ_Γ, is bounded in L^∞. Then, for $\delta>0$ and small, define a δ-neighborhood D_δ around Γ by

$$D_\delta=\{x\in D:\, d_\Gamma(x)<\delta\}. \tag{3.1}$$

In what follows, D_δ will represent the region taken up by the normal inclusions.

The impurity is modeled by the potential V_δ defined through

$$V_\delta=\frac{a}{\delta^p}\chi_{D_\delta}, \tag{3.2}$$

where a is a fixed positive constant, p is a positive parameter that characterizes the ''strength'' of the impurity, and χ_{D_δ} denotes the characteristic function of the set D_δ.

We begin with the case of a thin film. In this case, to leading order in the film thickness, one may ignore the field induced by any supercurrents[10] and thereby obtain the following modified Ginzburg–Landau model with inclusions:

$$E_\delta(u)=\int_D|(i\nabla-\mathbf{A}_e)u|^2dx+\int_D V_\delta(x)|u|^2dx+\int_{D\setminus D_\delta}\frac{\nu^2}{2}(|u|^2-\mu^2)^2dx. \tag{3.3}$$

Here $\mathbf{A}_e:\mathbb{R}^2\to\mathbb{R}^2$ is the magnetic potential associated with $\mathbf{H_e}$; that is,

$$\nabla\times\mathbf{A}_e=\mathbf{H_e}. \tag{3.4}$$

To simplify the presentation of the asymptotic analysis we take $\xi_0/l=1$ in (2.13).

For the case of an infinite cylinder with cross-section $D\subset\mathbb{R}^2$ and the case where $D\subset\mathbb{R}^3$, we may not ignore the induced magnetic field and so the energy includes the total magnetic potential $\mathbf{A}$ and takes the form

$$G_\delta(u,\mathbf{A})=\int_D|(i\nabla-\mathbf{A})u|^2dx+\int_D V_\delta(x)|u|^2dx+\int_{D\setminus D_\delta}\frac{\nu^2}{2}(|u|^2-\mu^2)^2dx+\int_{R^n}|\nabla\times\mathbf{A}-\mathbf{H_e}|^2\,dx, \tag{3.5}$$

for $n=2,3$.

We note that the functional E_δ is well-defined for Sobolev functions $u \in H^1(D;\mathbb{C})$ consisting of all square-integrable, complex-valued functions having (weak) square-integrable gradients. The functional G_δ makes sense for $u \in H^1(D;\mathbb{C})$ and $\mathbf{A}$ such that $\mathbf{A} \in H^1_{\mathrm{loc}}(\mathbb{R}^n;\mathbb{R}^n)$ ($n=2$ or 3) and such that $\nabla \times \mathbf{A} - \mathbf{H_e} \in L^2(\mathbb{R}^n;\mathbb{R}^n)$. We will denote this space of admissible magnetic potentials by $H^1_e(\mathbb{R}^n;\mathbb{R}^n)$.

IV. ASYMPTOTIC LIMITS OF E_δ AND G_δ

The characterization of the minimizers of the functionals E_δ and G_δ depends on the value taken by the parameter p. We investigate the asymptotic limits using the method of gamma-convergence.

To describe these asymptotic limits, we need to recall the notion of the trace of a Sobolev function (cf. Ref. 12). The trace of a Sobolev function is a measure-theoretic means to describe the restriction of a Sobolev function defined on $\mathbb{R}^n$ to an $(n-1)$-dimensional set. It is not obvious that such a restriction is sensible since Sobolev functions are only defined up to sets of n-measure zero. However, for $u \in H^1(D;\mathbb{C})$, one can define the trace of u on the smooth curves (surfaces) Γ previously introduced, which we denote by $\mathrm{tr}_\Gamma u$. In particular, one has $\mathrm{tr}_\Gamma u \in L^2(\Gamma;\mathbb{C})$ and there exists a positive constant $C=C(\Gamma,D)$ such that

$$\int_\Gamma |\mathrm{tr}_\Gamma u|^2 \, dH^{n-1}(x) \leqslant C \int_D |u|^2 + |\nabla u|^2 \, dx. \tag{4.1}$$

Here dH^{n-1} corresponds to $(n-1)$-dimensional Hausdorf measure, that is, essentially d(arc length) in two dimensions and d(surface area) in three dimensions. Of course, (4.1) in particular implies that if a sequence of functions defined on D converges in $H^1(D;\mathbb{C})$, then necessarily their traces converge in $L^2(\Gamma;\mathbb{C})$. We also record here the fact that the $L^2(\Gamma;\mathbb{C})$-norm of the trace can be approached through integral averages in the sense that for any $u \in H^1(D;\mathbb{C})$ one has

$$\int_\Gamma |\mathrm{tr}_\Gamma u|^2 \, dH^{n-1}(x) = \lim_{\delta \to 0} \frac{1}{2\delta} \int_{D_\delta} |u|^2 \, dx. \tag{4.2}$$

Throughout the article, we shall generally suppress the notation $\mathrm{tr}_\Gamma u$ and write simply u when considering the restriction of a Sobolev function u to the set Γ. However, it should be interpreted in terms of trace.

We now recall the characterization of gamma-convergence of a sequence of functionals (cf., e.g., Ref. 4). A family of functionals $\{F_\delta\}$, all defined on Banach space X and mapping into $\mathbb{R}^1$, are said to gamma-converge to a functional $F: X \to \mathbb{R}^1$ with respect to the topology of X if

$$\forall u \in X, \exists \text{a sequence } \{u_\delta\} \subset X \quad \text{such that } u_\delta \overset{X}{\to} u \quad \text{and } \lim_{\delta \to 0} F_\delta(u_\delta) = F(u), \tag{4.3}$$

and

$$\forall u \in X, \quad \forall \{v_\delta\} \subset X \quad \text{such that } v_\delta \overset{X}{\to} u, \text{ we have } \liminf F_\delta(v_\delta) \geqslant F(u). \tag{4.4}$$

A useful consequence of this definition is that if a class of functionals $\{F_\delta\}$ has a gamma-limit F, then any limit u of minimizers $\{u_\delta\}$ of F_δ must minimize the limiting functional F.

We shall apply this machinery to the sequence $\{E_\delta\}$ in the topology $X=H^1(D;\mathbb{C})$, to obtain the following result:

Theorem 4.1: *(i) For $0 \leqslant p < 1$, the $H^1(D;\mathbb{C})$ gamma-limit of the sequence $\{E_\delta\}$ as $\delta \to 0$ is the functional $E^{(0)}$ given by*

$$E^{(0)}(u)=\int_D|(i\nabla-\mathbf{A}_e)u|^2\mathrm{d}x+\int_D\frac{\nu^2}{2}(|u|^2-\mu^2)^2\mathrm{d}x. \tag{4.5}$$

(ii) For $p=1$, the gamma-limit of the $\{E_\delta\}$ as $\delta\to0$ is $E^{(1)}$ given by

$$E^{(1)}(u)=E^{(0)}(u)+2a\int_\Gamma|u|^2\mathrm{d}H^1(x). \tag{4.6}$$

(iii) For $p>1$, the gamma-limit of the $\{E_\delta\}$ as $\delta\to0$ is $E^{(2)}$ given by

$$E^{(2)}(u)=\begin{cases}E^{(0)}(u), & \text{if } \mathrm{tr}_\Gamma u(x)=0 \quad \text{for} \quad H^{n-1}\,a.e.\,x\in\Gamma,\\ +\infty, & \text{otherwise.}\end{cases} \tag{4.7}$$

In a similar fashion, we shall obtain the gamma-limit of $\{G_\delta\}$. In this case, we take the $H^1(D;\mathbb{C})$ topology for u, and the $H^1_{\mathbf{e}}$ topology for $\mathbf{A}$.

Theorem 4.2: *(i) For $0\leqslant p<1$, the $H^1(D;\mathbb{C})\times H^1_{\mathbf{e}}(\mathbb{R}^n;\mathbb{R}^n)$ gamma-limit of the sequence $\{G_\delta\}$ as $\delta\to0$ is the functional $G^{(0)}$ given by*

$$G^{(0)}(u,\mathbf{A})=\int_D|(i\nabla-\mathbf{A})u|^2\mathrm{d}x+\int_D\frac{\nu^2}{2}(|u|^2-\mu^2)^2\mathrm{d}x+\int_{\mathbb{R}^n}|\nabla\times\mathbf{A}-\mathbf{H}_e|^2\,\mathrm{d}x. \tag{4.8}$$

(ii) For $p=1$, the gamma-limit of the $\{G_\delta\}$ as $d\to0$ is $G^{(1)}$ given by

$$G^{(1)}(u,\mathbf{A})=G^{(0)}(u,\mathbf{A})+2a\int_\Gamma|u|^2\mathrm{d}H^{n-1}(x). \tag{4.9}$$

(iii) For $p>1$, the gamma-limit of the $\{G_\delta\}$ as $\delta\to0$ is $G^{(2)}$ given by

$$G^{(2)}(u,\mathbf{A})=\begin{cases}G^{(0)}(u,\mathbf{A}), & \text{if } \mathrm{tr}_\Gamma u(x)=0 \quad \text{for} \quad H^{n-1}\,a.e.\,x\in\Gamma,\\ +\infty, & \text{otherwise.}\end{cases} \tag{4.10}$$

Proof of Theorems 4.1 and 4.2: Since the two theorems are proved in a similar manner, we shall present both proofs simultaneously.

Case 1: $0\leqslant p<1$.

We begin with the construction required by (4.3). For both E_δ and G_δ we choose the trivial sequence. That is, given any $u\in H^1(D;\mathbb{C})$ and $\mathbf{A}$ such that $\mathbf{A}-\mathbf{A}_e\in H^1(\mathbb{R}^n;\mathbb{R}^n)$ we take for the required construction $\{u_\delta\}$ simply $u_\delta=u$ and for $\{\mathbf{A}_\delta\}$ simply $\mathbf{A}_\delta=\mathbf{A}$ for all δ. Then the properties

$$\lim_{\delta\to0}E_\delta(u_\delta)=E^{(0)}(u) \quad \text{and} \quad \lim_{\delta\to0}G_\delta(u_\delta,\mathbf{A}_\delta)=G^{(0)}(u,\mathbf{A})$$

follow immediately from (4.1) and (4.2) since

$$\int_D V_\delta(x)|u_\delta|^2\mathrm{d}x=\frac{a}{\delta^p}\int_{D_\delta}|u|^2\,\mathrm{d}x=a\,\delta^{1-p}\left(\frac{1}{\delta}\int_{D_\delta}|u|^2\,\mathrm{d}x\right)\approx2a\,\delta^{1-p}\int_\Gamma|u|^2\,\mathrm{d}H^{n-1}(x)\to0$$
$$\text{as} \quad \delta\to0.$$

The convergence of the other terms in E_δ and G_δ to the appropriate terms in $E^{(0)}$ and $G^{(0)}$ are trivial. The lower semi-continuity property (4.4) follows at once since the non-negative term in the energies E_δ and G_δ involving V_δ can be ignored and all other terms are in fact continuous in the H^1 topology.

Case 2: $p=1$.

In light of (4.2), one may again take the trivial sequences $u_\delta = u$ and $\mathbf{A}_\delta = \mathbf{A}$ in order to establish the construction (4.3) for E_δ and G_δ.

The lower semi-continuity condition (4.4)—in fact, continuity under in the H^1 topology—will follow from (4.1) and (4.2) and the fact that if $u_\delta \to u$ in $H^1(D;\mathbb{C})$, then

$$\lim_{\delta\to 0}\left|\frac{1}{\delta}\int_{D_\delta}|u_\delta|^2\,\mathrm{d}x - 2\int_\Gamma |u_\delta|^2\,\mathrm{d}H^{n-1}(x)\right| = 0. \tag{4.11}$$

To verify (4.11), we use the co-area formula to compute

$$\begin{aligned}
&\left|\frac{1}{\delta}\int_{\{0<d_\Gamma(x)<\delta\}}|u_\delta|^2\,\mathrm{d}x - \int_\Gamma |u_\delta|^2\,\mathrm{d}H^{n-1}(x)\right| \\
&\quad = \left|\frac{1}{\delta}\int_0^\delta \int_{\{d_\Gamma(x)=\eta\}} |u_\delta|^2\,\mathrm{d}H^{n-1}(x)\,\mathrm{d}\eta - \int_\Gamma |u_\delta|^2\,\mathrm{d}H^{n-1}(x)\right| \\
&\quad = \frac{1}{\delta}\left|\int_0^\delta \left\{\int_{\{d_\Gamma(x)=\eta\}} |u_\delta|^2\,\mathrm{d}H^{n-1}(x) - \int_{\{d_\Gamma(x)=0\}}\right\}\right| |u_\delta|^2\,\mathrm{d}H^{n-1}(x)\,\mathrm{d}\eta.
\end{aligned}$$

This last difference is controlled using the divergence theorem, yielding

$$\begin{aligned}
&\left|\frac{1}{\delta}\int_{\{0<d_\Gamma(x)<\delta\}}|u_\delta|^2\,\mathrm{d}x - \int_\Gamma |u_\delta|^2\,\mathrm{d}H^{n-1}(x)\right| \\
&\quad \leqslant \frac{1}{\delta}\left|\int_0^\delta \int_{\{0<d_\Gamma(x)<\eta\}} \mathrm{div}(|u_\delta|^2\nabla d_\Gamma)\,\mathrm{d}x\right| \\
&\qquad + \frac{1}{\delta}\left|\int_0^\delta \int_{\partial D\cap\{0<d_\Gamma(x)<\eta\}} |u_\delta|^2\,(\nabla d_\Gamma\cdot \nu_{\partial D})\,\mathrm{d}H^{n-1}(x)\,\mathrm{d}\eta\right| \\
&\quad \leqslant \frac{1}{\delta}\int_0^\delta \int_{\{0<d_\Gamma(x)<\eta\}} (|u_\delta|^2\|\kappa_\Gamma\|_{L^\infty(\Gamma)} + 2|u_\delta||\nabla u_\delta|)\,\mathrm{d}x + \int_{\partial D\cap\{0<d_\Gamma(x)<\delta\}} |u_\delta|^2\,\mathrm{d}H^{n-1}(x) \\
&\quad \leqslant (\|\kappa_\Gamma\|_{L^\infty(\Gamma)}+1)\|u_\delta\|^2_{H^1(\{0<d_\Gamma(x)<\delta\})} \\
&\qquad + \|u_\delta\|^2_{L^2(\partial D\cap\{0<d_\Gamma(x)<\delta\})} \to 0 \quad \text{as} \quad \delta\to 0.
\end{aligned}$$

Case 3: $p>1$.

To establish property (4.3), fix any $u\in H^1(D;\mathbb{C})$. If $u(x)\neq 0$ for H^{n-1} a.e. $x\in\Gamma$, then take the trivial sequence $u_\delta = u$ for the constructive part (4.3). Using (4.2), one finds

$$\int_D V_\delta |u_\delta|^2\,\mathrm{d}x = \frac{\alpha}{\delta^{p-1}}\left(\frac{1}{\delta}\int_{D_\delta}|u|^2\right) \approx \frac{2\alpha}{\delta^{p-1}}\int_\Gamma |u|^2\,\mathrm{d}H^{n-1}(x) \to \infty. \tag{4.12}$$

Hence, $\lim_{\delta\to 0} E_\delta(u_\delta) = E^{(2)}(u) = \infty$ and the same reasoning applies to G_δ.

If, on the other hand, $u(x)=0$, then we introduce a smooth sequence $\rho_\delta:[0,\infty)\to[0,\infty)$ such that (i) $\rho_\delta(s)=0$ for $0\leqslant s\leqslant\delta$, (ii) $\rho_\delta(s)=1$ for $s\geqslant\delta^{1/2}$ and (iii) $|\rho_\delta'(s)|\leqslant 2/\delta^{1/2}$ for all s. Then define the sequence $\{u_\delta\}$ through the formula

$$u_\delta(x) = u(x)\rho_\delta(d_\Gamma(x)).$$

Clearly $u_\delta\to u$ in $L^2(D;\mathbb{C})$ and since

$$|\nabla u_\delta|^2 \leq 2\left(|\nabla u|^2 + \frac{1}{\delta}|u|^2\right)$$

one finds that

$$\int_{\{\delta<d_\Gamma(x)<\delta^{1/2}\}} |\nabla u_\delta|^2 \, dx \leq 2\left(\int_{\{\delta<d_\Gamma(x)<\delta^{1/2}\}} |\nabla u|^2 \, dx + \frac{1}{\delta}\int_{\{d_\Gamma(x)<\delta^{1/2}\}} |u|^2 \, dx\right). \quad (4.13)$$

Since $u \in H^1(D;\mathbb{C})$, the first term on the right in (4.13) clearly approaches zero with δ. Now since smooth functions are dense in H^1, we may assume that $u \in H^1(D;\mathbb{C}) \cap C^1(D;\mathbb{C})$. Then the assumption $u=0$ implies that for any $\eta>0$ and any $x \in D$ such that $d_\Gamma(x)=\eta$ one has

$$u(x) = \int_0^\eta \frac{d}{dt} u(y + t\nu(y)) \, dt,$$

where $y=y(x)$ is the closest point of Γ to x and $\nu(y)$ is the unit normal of Γ at y pointing towards x. Consequently, we have

$$|u(x)|^2 \leq \eta \int_0^\eta |\nabla u(y + t\nu(y))|^2 \, dt \quad \text{for any } x \text{ such that } d_\Gamma(x)=\eta. \quad (4.14)$$

We then handle the second term in (4.13) again through an appeal to the co-area formula, Fubini's theorem and (4.14) as follows:

$$\begin{aligned}
\frac{1}{\delta}\int_{\{\delta<d_\Gamma(x)<\delta^{1/2}\}} |u(x)|^2 \, dx &\leq \frac{1}{\delta}\int_\delta^{\delta^{1/2}} \int_{\{d_\Gamma(x)=\eta\}} \eta \int_0^\eta |\nabla u(y+t\nu(y))|^2 \, dt \, dH^{n-1}(x) \, d\eta \\
&\leq \frac{1}{\delta}\int_0^{\delta^{1/2}} \eta \int_{\{d_\Gamma(x)=\eta\}} \int_0^{\delta^{1/2}} |\nabla u(y+t\nu(y))|^2 \, dt \, dH^{n-1}(x) \, d\eta \\
&= \frac{1}{\delta}\int_0^{\delta^{1/2}} \eta \int_0^{\delta^{1/2}} \int_{\{d_\Gamma(x)=\eta\}} |\nabla u(y+t\nu(y))|^2 \, dH^{n-1}(x) \, dt \, d\eta \\
&\leq \frac{1}{\delta}\int_0^{\delta^{1/2}} \eta \int_0^{\delta^{1/2}} \int_{\{d_\Gamma(x)=t\}} |\nabla u(x)|^2 (1 + C_0\delta^{(n-1)/2}) \, dH^{n-1}(x) \, dt \, d\eta,
\end{aligned}$$

where the factor of $C_0\delta^{(n-1)/2}$ appearing in the last integral arises from the difference in dH^{n-1} along $\{d_\Gamma(x)=\eta\}$ versus $\{d_\Gamma(x)=t\}$ where $|t-\eta| \leq \delta^{1/2}$. We conclude that

$$\frac{1}{\delta}\int_{\{\delta<d_\Gamma(x)<\delta^{1/2}\}} |u(x)|^2 \, dx \leq C \int_{\{d_\Gamma(x)<\delta^{1/2}\}} |\nabla u|^2 \, dx \to 0 \text{ as } \delta \to 0.$$

It easily follows that $u_\delta \to u$ in $H^1(D;\mathbb{C})$ as well. Then, since

$$\int_D V_\delta(x)|u_\delta|^2 \, dx = \int_{\{d_\Gamma(x)<\delta\}} \frac{a}{\delta^p} \cdot 0 \, dx = 0,$$

one concludes that $E_\delta(u_\delta) \to E^{(2)}(u)$ and $G_\delta(u_\delta, \mathbf{A}) \to G^{(2)}(u, \mathbf{A})$ as $\delta \to 0$, thus establishing (4.3) in this case.

The lower semi-continuity property (4.4) is clear in the case where $u=0$ since again one may simply ignore the non-negative term involving the potential V_δ. To establish the lower semi-continuity for the case $u \not\equiv 0$, we let $\{u_\delta\}$ be any sequence converging in $H^1(D;\mathbb{C})$ to u, and use (4.1) and (4.2) to see that

$$\frac{1}{\delta^p}\int_{D_\delta}|u_\delta|^2\,dx=\frac{1}{\delta^{p-1}}\left\{\left(\frac{1}{\delta}\int_{D_\delta}|u_\delta|^2\,dx-2\int_\Gamma|u_\delta|^2\,dH^{n-1}(x)\right)\right\}$$
$$+\frac{2}{\delta^{p-1}}\left\{\left(\int_\Gamma|u_\delta|^2-|u|^2\,dH^{n-1}(x)\right)+\int_\Gamma|u|^2\,dH^{n-1}(x)\right\}$$
$$=\frac{1}{\delta^{p-1}}\left(2\int_\Gamma|u|^2\,dH^{n-1}(x)+o(1)\right)\to\infty=E^{(2)}(u)=G^{(2)}(u,\mathbf{A}).$$

□

V. VARIATIONAL CHARACTERIZATION OF TRANSITION TEMPERATURE WITH NORMAL INCLUSIONS

One application of the analysis of the previous section concerns the transition temperature $T=T(\mathbf{H_e})$ below which the normal state in a superconductor with normal inclusions loses stability. Recall that within Ginzburg–Landau theory, the normal state prevails when the order parameter vanishes identically while the applied magnetic field completely penetrates the sample so that $\mathbf{A}=\mathbf{A_e}$ where $\mathbf{A_e}$ is given by (3.4). Then the loss of stability of the state $u=0$ in (3.3) or of the pair $(u,\mathbf{A})=(0,\mathbf{A_e})$ in (3.5) for $\delta\ll 1$ should be related to the corresponding loss of stability of their gamma-limits given by Theorems 4.1 and 4.2. This claim is supported by the fact that limits of minimizers of a gamma-converging sequence will minimize the gamma-limit and even an isolated local minimizer of a gamma-limit will be a limit point of a sequence of local minimizers of the gamma-converging sequence (see Ref. 8 in this regard).

Stability or instability of a critical point is most easily classified in terms of the sign of the second variation taken about the point in question. Starting from (4.5) and (4.7), a straightforward calculation yields the second variation formula for the gamma-limits of E_δ when $p<1$ or $p>1$:

$$\delta^2E^{(j)}(0;u)\equiv\left.\frac{d^2E^{(j)}(0+\varepsilon u)}{d\varepsilon^2}\right|_{\varepsilon=0}=2\int_D\{|(i\nabla-\mathbf{A}_e)u|^2-\nu^2\mu^2|u|^2\}\,dx \tag{5.1}$$

for $j=0$ or 2 where for $j=0$ $(p<1)$, the variation is taken over arbitrary functions in $u\in H^1(D;\mathbb{C})$ while for $j=2$ $(p>1)$, we additionally require $u=0$ on Γ in the sense of traces.

For E_δ in the critical case $p=1$, we obtain from (4.6) that

$$\delta^2E^{(1)}(0;u)=2\int_D\{|(i\nabla-\mathbf{A}_e)u|^2-\nu^2\mu^2|u|^2\}\,dx+4a\int_\Gamma|u|^2\,dH^{n-1}(x) \tag{5.2}$$

for any $u\in H^1(D;\mathbb{C})$.

Now if our goal is to understand the phase transition curve $T=T(\mathbf{H_e})$, we can capture this through the parameter μ [cf. (2.15)]. Loss of stability of the normal state corresponds to the value of μ where the second variations calculated above vanish. Hence we can characterize $\mu^2(\mathbf{H_e})$ and through (2.15) obtain $T(\mathbf{H_e})$ via the formulas

$$\mu^2(\mathbf{H_e})=\inf_{\{u\in H^1(D;\mathbb{C})\}}\frac{\int_D|(i\nabla-\mathbf{A}_e)u|^2\,dx}{\nu^2\int_D|u|^2\,dx}\quad\text{for}\quad p<1,$$

$$\mu^2(\mathbf{H_e})=\inf_{\{u\in H^1(D;\mathbb{C})\}}\frac{\int_D|(i\nabla-\mathbf{A}_e)u|^2\,dx+2a\int_\Gamma|u|^2\,dH^{n-1}(x)}{\nu^2\int_D|u|^2\,dx}\quad\text{for}\quad p=1, \tag{5.3}$$

$$\mu^2(\mathbf{H_e})=\inf_{\{u\in H^1(D;\mathbb{C}),\ u=0\ \text{on}\ \Gamma\}}\frac{\int_D|(i\nabla-\mathbf{A}_e)u|^2\,dx}{\nu^2\int_D|u|^2\,dx}\quad\text{for}\quad p>1.$$

A similar set of calculations on the three gamma-limits of G_δ given by (4.8)–(4.10) yield corresponding formulas

$$\delta^2 G^{(j)}(0,\mathbf{A_e};u,\mathbf{A}) \equiv \left.\frac{d^2 G^{(j)}(0+\varepsilon u,\mathbf{A_e}+\varepsilon \mathbf{A})}{d\varepsilon^2}\right|_{\varepsilon=0}$$

$$= 2\int_D \{|(i\nabla - \mathbf{A}_e)u|^2 - \nu^2\mu^2|u|^2\}\,dx + 2\int_{\mathbb{R}^n} |\nabla\times\mathbf{A}|^2\,dx \tag{5.4}$$

for $j=0$ or 2 where for $j=0$ $(p<1)$, the variation is taken over arbitrary functions $u \in H^1(D;\mathbb{C})$ and $\mathbf{A}\in H^1_e(\mathbb{R}^n;\mathbb{R}^n)$ while for $j=2$ $(p>1)$, we additionally require $u=0$ on Γ in the sense of traces.

For the second variation of $G^{(1)}$ in the critical case $p=1$ we obtain from (4.9) that

$$\delta^2 G^{(1)}(0,\mathbf{A_e};u,\mathbf{A}) = 2\int_D \{|(i\nabla - \mathbf{A}_e)u|^2 - \nu^2\mu^2|u|^2\}\,dx + 4a\int_\Gamma |u|^2\,dH^{n-1}(x) + 2\int_{\mathbb{R}^n} |\nabla\times\mathbf{A}|^2\,dx$$

for any $u\in H^1(D;\mathbb{C})$ and $\mathbf{A}\in H^1_{\mathbf{e}}(\mathbb{R}^n;\mathbb{R}^n)$.

Since the convex term $\int_{\mathbb{R}^n}|\nabla\times\mathbf{A}|^2\,dx$ will never lead to instability, the value of $\mu^2(\mathbf{H_e})$ yielding zero second variation will again be achieved by (5.3) for the cases $p<1$, $p=1$ and $p>1$ by taking $\mathbf{A}=0$.

We point out that in the absence of any applied field where one can take $\mathbf{A_e}=0$, the presence of the normal junction will still cause a shift down in the critical temperature when $p\geqslant 1$, that is, when the junction is sufficiently strong. In other words, $\mu^2(0)>0$ in (5.3) for E_δ or G_δ for the cases $p=1$ and $p>1$. On the other hand, for a weak junction $(p<1)$, one finds that $\mu^2(0)=0$ so that to leading order in δ, there is no shift in the critical temperature in the absence of applied fields.

VI. SUMMARY

We have calculated several canonical limits of the Ginzburg–Landau energy functional for superconducting samples with defects. The defect is centered around a co-dimension-one manifold in the domain. The defect is defined through a penalizing potential in a small neighborhood of that manifold. The different limits are distinguished by the strength of the defect, which, in turn, is controlled by the L_1-norm of the penalizing potential.

One of the interesting conclusions we obtain is that when the defect is sufficiently strong, the minimizer must vanish along the defect. This result has a number of consequences; in particular, it affects the phase transition temperature. It is well known that this temperature is determined by the first eigenvalue of the magnetic Schrödinger operator. Typically one considers this spectral problem under Neumann boundary conditions. Our results indicate that in the presence of strong defects, one should compute the leading eigenvalue of the magnetic Schrödinger operator for functions that satisfy Dirichlet boundary conditions along the defect and Neumann boundary conditions along the rest of the sample boundary.

(Received 18 November 2002; accepted 22 November 2002)

Starting with the super-Yangian $Y(M|N)$ based on $\mathrm{gl}(M|N)$, we define twisted super-Yangians $Y(M|N)^{\pm}$. Only $Y^{+}(M|2n)$ and $Y^{-}(2m|N)$ can be defined, and appear to be isomorphic one with each other. We study their finite-dimensional irreducible highest weight representations. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1542662]

I. INTRODUCTION

Quite recently, a revival of interest has been put on coideal algebras of Hopf algebras, both from mathematical and physical points of view. Among these algebras, let us note the twisted Yangians $Y^{\pm}(N)$, introduced by Olshanski[1] and widely studied (see, for instance Ref. 2 and references therein), or the reflection algebras, introduced by Sklyanin[3] and studied in Refs. 4 and 5.

From the mathematical point of view, it seems that such coideal condition is quite restrictive, leading to a very small class of subalgebras, for a given Hopf algebra.[6,7] Indeed, for quantum algebras $\mathcal{U}_q(\mathrm{gl}_N)$, it has been proven that they are natural deformations of symmetric spaces.[6]

From a physical point of view, such ideals appear to play an important role in integrable systems with boundaries.[4,8,9] They appear to be the integrals of motion of such systems,[4,9] and also naturally deduced from the boundary condition.[8]

It thus appears natural to look for such coideals when the underlying algebra is not gl_N anymore. Such types of algebras have been introduced in Ref. 10 for the case of Yangians based on orthogonal and symplectic algebras, and orthosymplectic superalgebras. They are defined as the ''twist'' of the (super)Yangian based on the corresponding Lie (super)algebra.

The aim of the present work is to complete the picture with the case of super-Yangians based on $\mathrm{gl}(M|N)$. After recalling the basic definitions and properties of the super-Yangians $Y(\mathrm{gl}(M|N)) \equiv Y(M|N)$ in Sec. II, we will define the twisted super-Yangians $Y(M|N)^{+}$ in Sec. III. Their finite-dimensional irreducible representations are studied in Sec. IV. We conclude in Sec. V.

II. SUPER-YANGIANS $Y(M|N)$

The super-Yangian $Y(M|N)$ based on the $\mathrm{gl}(M|N)$ superalgebra has been introduced in Ref. 11, and its irreducible finite-dimensional representations studied in Ref. 12. Since it is a $\mathbb{Z}_2$-graded (Hopf) algebra, different conventions can be chosen: the ones we choose are given below. We will rephrase the properties given in Ref. 12 in this context.

A. Graded spaces

We start with $K\times K$ matrices acting on the vector space $\mathbb{C}^K$, and introduce a $\mathbb{Z}_2$-grading $[.]$ on these spaces. We will denote by E_{ij} the usual $K\times K$ matrices which have 1 in position (i,j), and by e_i the basic vectors of $\mathbb{C}^K$ which have 1 in position i:

$$E_{ij}e_k = \delta_{jk}e_i\,. \tag{2.1}$$

[a)]Author to whom correspondence should be addressed. Electronic mail: ragoucy@lapp.in2p3.fr
[b)]URA 14-36 du CNRS, associée à l'Université de Savoie.

The $\mathbb{Z}_2$-grade is defined by

$$[E_{ij}]=[i]+[j];\ \ [e_i]=[i]\ \text{ and }\ [i]\in\{0,1\}\ \ \forall i,\ \ j=1,\ldots,K. \tag{2.2}$$

We will call even the matrices and vectors such that

$$A=A_{ij}E_{ij}\quad\text{ with }\quad [A_{ij}]=[i]+[j];\quad u=u_ie_i\quad\text{ with }\quad [u_i]=[i]. \tag{2.3}$$

The tensor product of graded matrices is chosen to be graded:

$$(E_{ij}\otimes E_{kl})(E_{ab}\otimes E_{cd})=(-1)^{([k]+[l])([a]+[b])}(E_{ij}E_{ab})\otimes(E_{kl}E_{cd}). \tag{2.4}$$

On the tensor product of $\mathbb{C}^K$ vector spaces, one has

$$(E_{ij}\otimes E_{kl})(e_a\otimes e_b)=(-1)^{([k]+[l])[a]}(E_{ij}e_a)\otimes(E_{kl}e_b). \tag{2.5}$$

We introduce the graded permutation operator:

$$P_{12}=\sum_{i,j}(-1)^{[j]}E_{ij}\otimes E_{ji}, \tag{2.6}$$

which obeys $P^2=\mathbb{I}$ and

$$P(e_i\otimes e_j)=(-1)^{[i][j]}e_j\otimes e_i,\ P(E_{ij}\otimes E_{kl})P=(-1)^{([i]+[j])([k]+[l])}E_{kl}\otimes E_{ij}. \tag{2.7}$$

B. Definition and first properties of $Y(M|N)$

We set $K=M+N$ and define the $\mathbb{Z}_2$-grade by

$$\begin{gathered}[i]=0\ \ \text{for}\ \ 1\leqslant i\leqslant M,\\ [i]=1\ \ \text{for}\ \ M+1\leqslant i\leqslant M+N.\end{gathered} \tag{2.8}$$

The super-Yangian $Y(M|N)$ has generators $T^{ab}_{(n)}$ (of $\mathbb{Z}_2$-grade $[a]+[b]$), gathered in

$$T(u)=\sum_{a,b=1}^{K}\sum_{n\geqslant 0}u^{-n}T^{ab}_{(n)}E_{ab}=\sum_{a,b=1}^{K}T^{ab}(u)E_{ab}=\sum_{n\geqslant 0}u^{-n}T_{(n)}\ \ \text{with}\ \ T_{(0)}=\mathbb{I}_K. \tag{2.9}$$

The even matrix $T(u)\in M_K[Y(M|N)]$ obeys

$$R_{12}(u-v)\,T_1(u)\,T_2(v)=T_2(v)\,T_1(u)\,R_{12}(u-v), \tag{2.10}$$

$$\text{with } R_{12}(u-v)=\mathbb{I}\otimes\mathbb{I}-\frac{1}{u-v}P_{12}, \tag{2.11}$$

or equivalently

$$[T^{ab}(u)\,,T^{cd}(v)\}=\frac{(-1)^{[a][b]+([a]+[b])[c]}}{u-v}(T^{cb}(u)T^{ad}(v)-T^{cb}(v)T^{ad}(u)), \tag{2.12}$$

where the graded commutator is defined by

$$[A,B\}=AB-(-1)^{[A][B]}BA. \tag{2.13}$$

It is a Hopf algebra:

$$\Delta(T^{ab}(u))=\sum_{c=1}^{M+N} T^{ac}(u)\otimes T^{cb}(u);\quad \epsilon(T^{ab}(u))=\delta^{ab};\quad S(T^{ab}(u))=(T^{-1}(u))^{ab}. \tag{2.14}$$

Note that $Y(M|N)$ contains several subalgebras:[12]

Property 2.1 (Subalgebras of $Y(M|N)$):

(i) *The generators $T^{ab}(u)$ with $a,b=1,\ldots,M$ (resp. $T^{ab}(u)$, $a,b=M+1,\ldots,M+N$) define the algebra inclusion $Y(M)\subset Y(M|N)$ [resp. $Y(N)\subset Y(M|N)$].*

(ii) *The generators $T^{ab}_{(1)}$ with $a,b=1,\ldots,M+N$ form a $\mathrm{gl}(M|N)$ Lie sub-superalgebra of $Y(M|N)$.*

(iii) *The generators $T^{ab}(u)$ with $a,b\in\{M,M+1\}$ define the algebra inclusion $Y(1|1)\subset Y(M|N)$.*

Remark: The above subalgebras are *not* Hopf subalgebras of $Y(M|N)$. Indeed, the coproduct (2.14) is based on all the generators of $Y(M|N)$, so that it does not induce the coproduct of $Y(M)$ and $Y(N)$.

We have also the following property.

Property 2.2 (Isomorphism between $Y(M|N)$ and $Y(N|M)$): Let

$$\widetilde{T}^{ab}(u)=(-1)^{[\overline{a}]([\overline{b}]+1)}T^{\overline{b}\,\overline{a}}(u)\quad with\quad \overline{a}=K+1-a,$$
$$[a]'=[\overline{a}]+1. \tag{2.15}$$

$\widetilde{T}(u)$ obey the Hopf algebra relations of $Y(N|M)$, with $\Delta'(x)=P\Delta(x)P$. We have thus a Hopf algebra isomorphism between $Y(M|N)$ and $Y(N|M)$.

Proof: One first proves that $\widetilde{T}(u)$ satisfies the commutation relations of $Y(N|M)$.

To prove that, we need

$$T^{cb}(u)T^{ad}(v)-T^{cb}(v)T^{ad}(u)=-(-1)^{([a]+[d])([b]+[c])}(T^{ad}(u)T^{cb}(v)-T^{ad}(v)T^{cb}(u)),$$

which can be proven either by a direct calculation, or by using the graded antisymmetry of the commutator,

$$[T^{ab}(u),T^{cd}(v)\}=-(-1)^{([a]+[d])([b]+[c])}[T^{cd}(v),T^{ab}(u)\}, \tag{2.16}$$

and computing $[T^{cd}(v),T^{ab}(u)\}$ using (2.12) with the replacements $(a,b,u)\leftrightarrow(c,d,v)$.

With the help of the above calculation one gets

$$\begin{aligned}
[\widetilde{T}^{ab}(u),\widetilde{T}^{cd}(v)\} &= (-1)^{[\overline{a}][\overline{b}]+[\overline{c}][\overline{d}]}[T^{\overline{b}\,\overline{a}}(u),T^{\overline{d}\,\overline{c}}(v)\}\\
&= \frac{(-1)^{[\overline{a}][\overline{b}]+[\overline{c}][\overline{d}]+[\overline{b}][\overline{a}]+([\overline{b}]+[\overline{a}])[\overline{d}]}}{u-v}(T^{\overline{d}\,\overline{a}}(u)T^{\overline{b}\,\overline{c}}(v)-T^{\overline{d}\,\overline{a}}(v)T^{\overline{b}\,\overline{c}}(u))\\
&= \frac{(-1)^{([\overline{a}]+[\overline{b}]+[\overline{c}])[\overline{d}]+([\overline{b}]+[\overline{c}])([\overline{a}]+[\overline{d}])}}{u-v}(T^{\overline{b}\,\overline{c}}(u)T^{\overline{d}\,\overline{a}}(v)-T^{\overline{b}\,\overline{c}}(v)T^{\overline{d}\,\overline{a}}(u))\\
&= \frac{(-1)^{[a]'[b]'+([a]'+[b]')[c]'}}{u-v}(\widetilde{T}^{cb}(u)\widetilde{T}^{ad}(v)-\widetilde{T}^{cb}(v)\widetilde{T}^{ad}(u)),
\end{aligned}$$

which is the correct expression for the commutator in $Y(N|M)$, since $[\ ]'$ is the correct gradation of $Y(N|M)$.

For the Hopf structure, one has

$$\begin{aligned}\Delta_{M|N}\tilde{T}^{ab}(u)&=\sum_{c=1}^{K}(-1)^{[\bar{a}]([\bar{b}]+1)}T^{\bar{b}\bar{c}}(u)\otimes T^{c\bar{a}}(u)\\&=\sum_{c=1}^{K}(-1)^{[\bar{a}]([\bar{b}]+1)+[\bar{c}]([\bar{b}]+1)+[\bar{a}]([\bar{c}]+1)}\tilde{T}^{cb}(u)\otimes\tilde{T}^{ac}(u)\\&=P\,\tilde{T}^{ac}(u)\otimes\tilde{T}^{cb}(u)\,P\\&=\Delta'_{N|M}\,\tilde{T}^{ab}(u),\end{aligned}$$

where we have denoted by $\Delta_{M|N}$ (resp. $\Delta_{N|M}$) the coproduct on $Y(M|N)$ [resp. on $Y(N|M)$].

A simple calculation shows

$$\epsilon_{M|N}(\tilde{T}^{ab}(u))=\epsilon'_{N|M}(\tilde{T}^{ab}(u)),\tag{2.17}$$

where $\epsilon'=\epsilon$ is the counit associated to Δ', while for the antipode

$$S'_{M|N}(\tilde{T}^{ab}(u))=(-1)^{[\bar{a}]([\bar{b}]+1)}\theta_a\theta_b(T^{-1}(u))^{\bar{a}\bar{b}}=S'_{N|M}(\tilde{T}^{ab}(u))=(\tilde{T}^{-1\prime}(u))^{ab},\tag{2.18}$$

where, in the last equality, the inverse $\tilde{T}^{-1\prime}(u)$ is computed using m' instead of m:

$$m'(\tilde{T}^{ab}(u)\otimes\tilde{T}^{-1\prime}(u)^{bc})=(-1)^{([a']+[b'])([b']+[c'])}\tilde{T}^{-1\prime}(u)^{bc}\cdot\tilde{T}^{ab}(u)=\delta^{ac}.\tag{2.19}$$

$S'_{M|N}$ obeys the relations

$$m'(S'\otimes id)\Delta'=\epsilon'=m'(id\otimes S')\Delta'.\tag{2.20}$$

■

C. Finite-dimensional irreducible representations of $Y(M|2n)$

The finite-dimensional irreducible representations of the super-Yangian $Y(M|N)$ have been studied in Ref. 12. We recall here its main results, referring to Ref. 12 for the proofs.

We will specify to the case $N=2n$, for it is the only case that is needed for twisted super-Yangians. Moreover, in order to be able to deal with the twisted super-Yangians, we need to choose a positive root system different from the one chosen in Ref. 12. Indeed, the situation is analogous to the one encountered in the case of simple Lie superalgebras, which admit different *inequivalent* systems of simple roots (see, for instance, Ref. 13). For our purpose, we define the following.

Definition 2.3 (Positive roots): Let $\Phi^{\pm,0}\subset\mathbb{N}_K^2$, *where* $\mathbb{N}_K=\mathbb{N}_{M+2n}=[1,M+2n]\cap\mathbb{N}$, *be defined by*

$$\Phi^+=\left\{(a,b)\in\mathbb{N}_K^2,\ \text{with either}\ \left|\begin{array}{c}1\leqslant a<b\leqslant M\\ M+1\leqslant a<b\leqslant M+2n\\ 1\leqslant a\leqslant M,\ M+n+1\leqslant b\leqslant M+2n\\ M+1\leqslant a\leqslant M+n,\ 1\leqslant b\leqslant M\end{array}\right.\right.\tag{2.21}$$

$$\Phi^-=\{(a,b)\in\mathbb{N}_{M+2n}^2,\ \text{such that}\ (b,a)\in\Phi^+\},\tag{2.22}$$

$$\Phi^0=\{(a,a),\ with\ a\in\mathbb{N}_{M+2n}\}.\tag{2.23}$$

We have $\mathbb{N}_{M+2n}^2=\Phi^-+\Phi^0+\Phi^+$, *and the positive roots will be associated to* $T^{ab}(u)$ *with* $(a,b)\in\Phi^+$.

Once a positive root system is chosen, one can introduce the notion of highest weight vectors:

Definition 2.4 (Highest weight vectors): Let $\mathcal{M}$ be a module of $Y(M|2n)$. A highest weight vector $\xi \in \mathcal{M}$ is defined by

$$T^{aa}(u)\xi = \lambda^a(u)\xi, \quad \forall a = 1,\ldots,M+2n,$$
$$T^{ab}(u)\xi = 0, \quad \forall (a,b) \in \Phi^+. \tag{2.24}$$

$\lambda(u) = (\lambda^1(u),\ldots,\lambda^{M+2n}(u)) \in \mathbb{C}[[u^{-1}]]$ *is the highest weight associated to* ξ.

The notion of highest weight vectors grounds in the following properties:

Property 2.5: Any irreducible finite-dimensional representation of $Y(M|N)$ admits a unique (up to multiplication by scalars) highest weight vector.

Property 2.6: The irreducible representation of $Y(M|N)$ with highest weight $\lambda(u)$ is finite dimensional if and only if we have

$$\frac{\lambda^a(u)}{\lambda^{a+1}(u)} = \frac{P_a(u+1)}{P_a(u)}, \quad 1 \leqslant a \leqslant M+N-1, \quad a \neq M, \tag{2.25}$$

$$\frac{\lambda^M(u)}{\lambda^{M+1}(u)} = \frac{P_M(u)}{P_{M+N}(u)}, \tag{2.26}$$

where $P_a(u)$ are monic polynomials.

Let us remark that some signs differ between our presentation and the presentation given in Ref. 12 because of the definition for $T(u)$: the relation between these two notations is given by $T^{ab}_{(n)} = (-1)^{[b]} t^a_b[n]$.

Definition 2.7 (Evaluation representations): Let J^{ab} be the generators of the gl$(M|N)$ *superalgebra and $\pi^{ab} = \pi(J^{ab})$ a finite-dimensional representation of* gl$(M|N)$. *Then, the morphism*

$$ev(T(u)) = 1 + \frac{\mathbb{E}}{u} \quad \textit{with} \quad \mathbb{E} = \pi^{ab} E_{ab} \tag{2.27}$$

provides a finite-dimensional representation of $Y(M|N)$, called an evaluation representation.

The usefulness of evaluation representations reveals in the following theorem:

Theorem 2.8: *Any irreducible finite-dimensional representation of $Y(M|N)$ is isomorphic to the irreducible part of tensor products of evaluation representations.*

III. TWISTED SUPER-YANGIANS

A. Introduction to $Y(M|N)^\tau$

We now introduce the notion of twisted super-Yangian, in the same way twisted Yangians have been defined from the Yangians $Y(N)$.

We first introduce the transposition t on matrices:

$$E^t_{ab} = (-1)^{[a]([b]+1)} \theta_a \theta_b E_{\bar{b}\bar{a}} \text{ with } \quad \theta_a = \pm 1,$$
$$\bar{a} = M+1-a \quad \text{for } 1 \leqslant a \leqslant M, \tag{3.1}$$
$$\bar{a} = 2M+N+1-a \quad \text{for } M+1 \leqslant a \leqslant M+N,$$

which satisfies

$$(AB)^t = B^t A^t. \tag{3.2}$$

Demanding the transposition to be of order 2 leads to the constraint

$$(-1)^{[a]}\, \theta_a \theta_{\bar{a}} = \theta_0 = \pm 1 \quad \forall \quad a. \tag{3.3}$$

Note that for superalgebras, one could ask the transposition to be of order 4 only. We will not consider this case in the following.

Let us stress that $\overline{a}$ has *not* the same meaning as in Sec. II: from now on, we will use this notation to denote (3.1). These new $\overline{a}$ satisfy $[a]=[\overline{a}]$.

Let us also note that there is a freedom on the definition of the transposition, $\theta_a \to (-1)^{[a]}\theta_a$: this freedom is fixed when imposing $\mathbb{I}^t=\mathbb{I}$. Remark also the useful identity

$$(-1)^{[a]([b]+1)}\theta_a\theta_b=(-1)^{[\overline{a}]([\overline{b}]+1)}\theta_{\overline{a}}\theta_{\overline{b}}. \tag{3.4}$$

Then, we define on $Y(M|N)$

$$\tau[T(u)]=\sum_{a,b}\tau[T^{ab}(u)]\,E_{ab}=\sum_{a,b}T^{ab}(-u)\,E^t_{ab}, \tag{3.5}$$

which reads for the super-Yangian generators

$$\tau(T^{ab}(u))=(-1)^{[a]([b]+1)}\theta_a\theta_b\;T^{\overline{b}\overline{a}}(-u). \tag{3.6}$$

Property 3.1: τ is an algebra automorphism for $Y(M|2n)$ and $Y(2m|N)$ only.
In that case, one must choose $\theta_0=+1$ for $Y(M|2n)$ and $\theta_0=-1$ for $Y(2m|N)$.

Proof: Considering subalgebras mentioned in Property 2.1, one can see that τ acts as an automorphism of $Y(M)$ of the type defined in Ref. 14, with $\theta_a\theta_{\overline{a}}=\theta_0$, and an automorphism of $Y(N)$ with $\theta_a\theta_{\overline{a}}=-\theta_0$. Using the results of Ref. 14, where it is proved that when M is odd, one must have $\theta_0=+1$ in $Y(M)$, one immediately concludes that we cannot have MN odd, and that the values for θ_0 are the ones given in the property.

Then, it is a simple matter of calculation to show that τ is an automorphism of the superalgebra $Y(M|N)$:

$$\tau([T^{ab}(u),T^{cd}(v)\})=[\tau(T^{ab}(u)),\tau(T^{cd}(v))\}. \tag{3.7}$$

■

One then defines in $Y(M|N)$ (we take MN even):

$$S(u)=T(u)\,\tau[T(u)]=\sum_{a,b=1}^{M+N}S^{ab}(u)E_{ab}=\mathbb{I}+\sum_{a,b=1}^{M+N}\sum_{n>0}u^{-n}S^{ab}_{(n)}E_{ab}, \tag{3.8}$$

$$S^{ab}_{(n)}=\sum_{c=1}^{M+N}\sum_{p=0}^{n}(-1)^p(-1)^{[c]([b]+1)}\theta_c\theta_b T^{ac}_{(n-p)}T^{\overline{b}\overline{c}}_{(p)}, \tag{3.9}$$

$$S^{ab}(u)=\sum_{c=1}^{M+N}(-1)^{[c]([b]+1)}\theta_c\theta_b T^{ac}(u)T^{\overline{b}\overline{c}}(-u). \tag{3.10}$$

$S(u)$ defines a subalgebra of the super-Yangian:

Theorem 3.2: *$S(u)$ obey the following relations:*

$$R_{12}(u-v)\,S_1(u)\,R'_{12}(u+v)\,S_2(v)=S_2(v)\,R'_{12}(u+v)\,S_1(u)\,R_{12}(u-v), \tag{3.11}$$

$$\tau(S(u))=S(u)+\frac{\theta_0}{2u}(S(u)-S(-u)), \tag{3.12}$$

where $R(x)$ is the super-Yangian R-matrix,

$$R'(x)=\mathbb{I}+\frac{1}{x}Q=R^{t_1}(-x) \quad with \quad Q=P^{t_1}, \tag{3.13}$$

and t_1 is the transposition (3.1) in the first space. These two relations uniquely define a subalgebra $Y(M|N)^\tau$ in the super-Yangian.

Proof: One starts with the relation (2.10) and applies the transposition t_1 and the sign operation $(u,v)\to(-u,-v)$ to get

$$\tau[T_1(u)]R'_{12}(u+v)T_2(v)=T_2(v)R'_{12}(u+v)\tau[T_1(u)]. \tag{3.14}$$

A direct calculation shows that

$$P\,Q=Q\,P=\theta_0 Q;\quad P^2=\mathbb{I} \text{ and } \quad Q^2=(M-N)Q. \tag{3.15}$$

Thus, applying $P(.)P$ on (3.14) leads to (after the exchange $u\leftrightarrow v$)

$$T_1(u)R'_{12}(u+v)\tau[T_2(v)]=\tau[T_2(v)]R'_{12}(u+v)T_1(u). \tag{3.16}$$

Finally, applying once again the transposition t_1 and $(u,v)\leftrightarrow(-u,-v)$, we obtain

$$R_{12}(u-v)\tau[T_1(u)]\tau[T_2(v)]=\tau[T_2(v)]\tau[T_1(u)]R_{12}(u-v), \tag{3.17}$$

which is another way to prove that τ is an automorphism. A simple calculation using (2.10), (3.14), (3.16) and (3.17) shows then that (3.11) is satisfied.

The second relation is also proved directly:

$$(\tau[S(u)])^{ab}=\sum_{c=1}^{M+N}(-1)^{[a]([b]+1)+[c]([a]+1)}\theta_a\theta_b\theta_{\bar{a}}\theta_{\bar{c}}T^{\bar{b}\bar{c}}(-u)T^{a\bar{c}}(u) \tag{3.18}$$

$$=S(u)+\sum_{c=1}^{M+N}(-1)^{[a]([b]+[c])}\theta_b\theta_c[T^{\bar{b}\bar{c}}(-u),T^{a\bar{c}}(u)\} \tag{3.19}$$

$$=\left(S(u)+\frac{\theta_0}{2u}(S(u)-S(-u))\right)^{ab}, \tag{3.20}$$

where, in the last step, we have used the graded commutator (2.12).

Conversely, let us start with an abstract algebra $\mathcal{A}$ whose generators $\sigma^{ab}_{(n)}$ obey (3.11) and (3.12). There is an obvious surjective morphism j from $\mathcal{A}$ to $Y(M|N)^\tau$. Thus, it remains to show that this morphism is injective. We follow the argumentation done in Ref. 15 for the case of (non-super) twisted Yangians.

We first introduce a filtration on $Y(M|N)$ induced by

$$\deg(T^{ab}_{(p)})=p \quad \text{and} \quad \deg(XY)=\deg(X)\deg(Y),\ \ \forall X,Y\in Y(M|N). \tag{3.21}$$

The graded algebra $grY(M|N)$ is defined as usual by

$$Y_p(M|N)=\{X\in Y(M|N),\quad \text{with}\quad \deg(X)\leqslant p\};\ \ p>0, \tag{3.22}$$

$$Y_0(M|N)=\mathbb{C};\ \ gr_0Y(M|N)=\mathbb{C}, \tag{3.23}$$

$$gr_pY(M|N)=Y_p(M|N)\,/\,Y_{p-1}(M|N);\ \ p>0, \tag{3.24}$$

$$grY(M|N)=\oplus_{p\geqslant 0}gr_pY(M|N). \tag{3.25}$$

Since for $X \in gr_p Y(M|N)$ and $Y \in gr_q Y(M|N)$, we have $[X,Y\} \in gr_{p+q-1} Y(M|N)$, we deduce that $grY(M|N)$ is commutative. (During this proof, and to avoid confusion with the gradation deg, we will write commutative and commutator where one should has written $\mathbb{Z}_2$-graded commutative and $\mathbb{Z}_2$-graded commutator.) The same is true for $grY(M|N)^\tau$; here the filtration is induced by the $Y(M|N)$ one.

Similarly, on $\mathcal{A}$, we introduce a filtration given by

$$\deg(\sigma_{(n)}^{ab}) = n. \tag{3.26}$$

This makes $gr\mathcal{A}$ a commutative algebra, for the same reasons as above. Moreover, since the morphism j preserves the filtration, it is enough to show that the induced morphism $\overline{j}$ between graded algebras is injective.

Let $\overline{T}_{(p)}^{ab}$ and $\overline{S}_{(p)}^{ab}$ be the image of $T_{(p)}^{ab}$ and $S_{(p)}^{ab}$ in $grY(M|N)^\tau$. The expression (3.9) is still valid for the elements of $grY(M|N)^\tau$, so that we deduce

$$\overline{S}_{(p)}^{ab} = \overline{T}_{(p)}^{ab} + (-1)^p (-1)^{[a]([b]+1)} \theta_a \theta_b \overline{T}_{(p)}^{\overline{b}\overline{a}} = (-1)^p (-1)^{[a]([b]+1)} \theta_a \theta_b \overline{S}_{(p)}^{\overline{b}\overline{a}}. \tag{3.27}$$

In Ref. 12, it has been proven that the generators $\overline{T}_{(p)}^{ab}$ are independent. [Strictly speaking, the proof is lacking in Ref. 12, but it can be done following the steps given in Ref. 15 for Yangians $Y(N)$.] Thus, we conclude that $grY(M|N)^\tau$ is isomorphic to the algebra of polynomials in the ($\mathbb{Z}_2$-graded) letters $x_{(p)}^{ab}$ submitted to the constraints (3.27).

Finally, the symmetry relation (3.12) in the algebra $gr\mathcal{A}$ just takes the form (3.27), so that $gr\mathcal{A}$ is also isomorphic to the algebra of polynomials in the ($\mathbb{Z}_2$-graded) letters $x_{(p)}^{ab}$ submitted to the constraints (3.27). Hence, $\overline{j}$ is injective. ■

Corollary 3.3 (PBW basis for $Y(M|N)^\tau$): Given an arbitrary linear order on the following set of generators (for $p=1,2,\ldots$),

$$\begin{gathered}
S_{(2p)}^{ij} \ \text{for } 1 \leqslant i,j \leqslant M \quad \text{and} \quad i+j \leqslant M+1, \\
S_{(2p+1)}^{ij} \ \text{for } 1 \leqslant i,j \leqslant M \quad \text{and} \quad i+j < M+1, \\
S_{(2p)}^{ij} \ \text{for } M+1 \leqslant i,j \leqslant M+2n \ \text{ and } \ i+j < 2M+2+2n, \\
S_{(2p+1)}^{ij} \ \text{for } M+1 \leqslant i,j \leqslant M+2n \ \text{ and } \ i+j \leqslant 2M+2+2n, \\
S_{(2p)}^{ij} \ \text{for } M+1 \leqslant i \leqslant M+2n \ \text{ and } \ 1 \leqslant j \leqslant M,
\end{gathered} \tag{3.28}$$

any element of $Y(M|2n)^\tau$ is uniquely written as a linear combination of the ordered monomials in these generators.

The same type of basis exists for $Y(2m|N)^\tau$ with an obvious exchange of M and N (and m and n).

Proof: It is a direct consequence of the proof of Theorem 3.2. Indeed, considering $grY(M|2n)^\tau$, it is sufficient to find a basis for it, i.e., for the algebra of polynomials in the ($\mathbb{Z}_2$-graded) letters $x_{(p)}^{ab}$ submitted to the constraints (3.27). From the property $a+b \leqslant M+1 \Leftrightarrow \overline{a}+\overline{b} \geqslant M+1$, $\overline{a}=b \Leftrightarrow a+b=M+1$ when $a,b \leqslant M$, and $a+b \leqslant M+n+2 \Leftrightarrow \overline{a}+\overline{b} \geqslant M+n+2$, $\overline{a}=b \Leftrightarrow a+b=M+n+2$ when $a,b \geqslant M+1$, an analysis of these constraints lead to the above basis. ■

Although several automorphisms τ can be defined (depending upon the choices for the θ's), they all lead to the same subalgebra $Y(M|N)^\tau$:

Property 3.4: All the θ_a dependence, but the value of θ_0, can be removed in the commutation relations of $Y(M|N)^\tau$.

Proof: We prove the property by exhibiting a basis in which the θ dependence has disappeared. We give this basis for the case $Y(M|2n)^{\tau}$ and $\theta_0=+1$, the other case being similar. When restricted to the bosonic part, it is the same basis as the one given in Ref. 14 for (bosonic) twisted Yangians.

For $Y^-(2n)$,

$$J^{ij}(u)=\theta^i\theta^j S^{ij}(u);\quad K^{ij}(u)=\theta^i S^{i,\bar{j}}(u);\quad \overline{K}^{ij}(u)=\theta^j S^{\bar{i},j}(u);\quad i,j=1,\ldots,n. \tag{3.29}$$

For $Y^+(M)$, the redefinition is the same as before, plus for the remaining generators which appear when $M=2m+1$ (we set $\tilde{m}=m+1$):

$$J_0(u)=\theta^{\tilde{m}} S^{\tilde{m}\tilde{m}}(u);\quad L^i(u)=\theta^i S^{\tilde{m},i}(u);\quad \overline{L}^i(u)=\theta^{\tilde{m}}\theta^i S^{i,\tilde{m}}(u);\quad i=1,\ldots,m. \tag{3.30}$$

This proves that the commutation relations among generators of $Y^-(2n)$ and those among $Y^+(M)$ are free from θ's in this basis. Commuting an element of $Y^-(2n)$ with one of $Y^+(M)$ provides the change of basis for the fermionic generators:

$$\begin{aligned} &F^{ai}(u)=\theta_a\theta_i S^{ai}(u),\quad \overline{F}^{ia}(u)=\theta_a\theta_i S^{ai}(u),\quad i=M+1,\ldots,M+n,\\ &G^{ai}(u)=\theta_a S^{\bar{ai}}(u),\quad \overline{G}^{ia}(u)=\theta_i S^{\bar{ai}}(u)\quad a=1,\ldots,M,\\ &H^i(u)=\theta_i S^{m+1,i}(u),\quad \overline{H}^i(u)=\theta_{m+1}\theta_i S^{i,m+1}(u),\quad \text{if } M=2m+1. \end{aligned} \tag{3.31}$$

All the $Y(M|2n)^+$-generators are expressible in terms of the generators (3.29)–(3.31) using the symmetry relation (3.12). Then, one can check that all the graded commutators in this basis are free from θ. ■

Using the isomorphism 2.2, one can focus on either one of the two cases given in Proposition 3.1. From now on, we will consider the case $Y(M|2n)$ and $\theta_0=+1$. Since it is only the value of θ_0 which is relevant for our study, we will use it to label the automorphism τ.

Definition 3.5: The twisted super-Yangian $Y(M|2n)^+\equiv Y(2n|M)^-$ is the subalgebra generated by $S(u)=T(u)\tau[T(u)]$, with τ given in (3.6) and

$$\begin{aligned} &\theta_a=1\quad for\ 1\leqslant a\leqslant M,\\ &\theta_a=sg\left(\frac{2M+2n+1}{2}-a\right)\quad for\ M+1\leqslant a\leqslant M+2n. \end{aligned} \tag{3.32}$$

B. Few properties of $Y(M|2n)^+$

Proposition 3.6: The relation (3.11) is equivalent to the following commutator:

$$\begin{aligned} [S_1(u),S_2(v)]=&\frac{1}{u-v}(P_{12}S_1(u)S_2(v)-S_2(v)S_1(u)P_{12})-\frac{1}{u+v}(S_1(u)Q_{12}S_2(v)\\ &-S_2(v)Q_{12}S_1(u))+\frac{1}{u^2-v^2}(P_{12}S_1(u)Q_{12}S_2(v)-S_2(v)Q_{12}S_1(u)P_{12}) \end{aligned} \tag{3.33}$$

and also to

$$
\begin{aligned}
[S^{ab}(u),S^{cd}(v)\}=&\frac{(-1)^{([a]+[b])[c]}}{u-v}(-1)^{[a][b]}(S^{cb}(u)S^{ad}(v)-S^{cb}(v)S^{ad}(u))\\
&-\frac{(-1)^{([a]+[b])[c]}}{u+v}((-1)^{[a][c]}\theta_b\theta_{\bar{c}}S^{a\bar{c}}(u)S^{\bar{b}d}(v)\\
&-(-1)^{[b][d]}\theta_{\bar{a}}\theta_d S^{c\bar{a}}(v)S^{\bar{d}b}(u))\\
&+\frac{(-1)^{([a]+[b])[c]}}{u^2-v^2}(-1)^{[a]}\theta_a\theta_b(S^{c\bar{a}}(u)S^{\bar{b}d}(v)\\
&-S^{c\bar{a}}(v)S^{\bar{b}d}(u)).
\end{aligned}
\tag{3.34}
$$

Proof: Equation (3.33) follows from a direct calculation using (3.11), (2.11) and (3.13). ■

As an obvious consequence, we get the following.

Corollary 3.7: The twisted super-Yangian $Y(M|2n)^+$ *contains* osp$(M|2n)$ *as Lie subsuperalgebra. It is generated by*

$$
S^{ab}_{(1)}=T^{ab}_{(1)}-(-1)^{[a]([b]+1)}\theta_a\theta_b T^{\bar{b}\bar{a}}_{(1)} \quad a,b=1,\ldots,M+2n, \tag{3.35}
$$

which obey

$$
S^{ab}_{(1)}=-(-1)^{[a]([b]+1)}\theta_a\theta_b S^{\bar{b}\bar{a}}_{(1)}, \tag{3.36}
$$

and defines a morphism of algebra $\mathcal{U}[\text{osp}(M|2n)]\to Y(M|2n)^+$.

The action of the osp$(M|2n)$ *generators on the twisted Yangian is given by*

$$
\begin{aligned}
[S^{ab}_{(1)},S^{cd}(v)\}=&(-1)^{([a]+[b])[c]}\{(-1)^{[a][b]}(\delta_{cb}S^{ad}(v)-\delta_{ad}S^{cb}(v))\\
&-\theta_{\bar{a}}\theta_b(\delta_{a\bar{c}}S^{\bar{b}d}(v)-\delta_{\bar{d}b}S^{c\bar{a}}(v))\}.
\end{aligned}
\tag{3.37}
$$

Proof: Expanding $(u\pm v)^{-1}=u^{-1}(1\mp vu^{-1}+\cdots)$ and taking the coefficient of $u^{-1}v^{-1}$ in (3.33) leads to

$$
[S_{1(1)},S_{2(1)}\}=P_{12}S_{2(1)}-S_{2(1)}P_{12}-Q_{12}S_{2(1)}+S_{2(1)}Q_{12}, \tag{3.38}
$$

where the subscript (1) refers to the coefficient of u^{-1} and v^{-1}, while the indices 1,2 label the auxiliary spaces. The symmetry relation projected on the u^{-1} term reads

$$
S^t_{(1)}=-S_{(1)}. \tag{3.39}
$$

Equations (3.38) and (3.39) are just the defining relations of osp$(M|2n)$.

Starting now from (3.34) and taking the coefficient of u^{-1} gives the relation (3.37). Note that taking the coefficient of v^{-1} in this last relation gives again the commutation relations of osp$(M|2n)$. ■

Let us denote the osp$(M|2n)$ generators by J^{ab} and gather them in the matrix

$$
F=\sum_{a,b=1}^{M+N}J^{ab}F_{ab} \quad \text{with} \quad F_{ab}=E_{ab}-(-1)^{[a]([b]+1)}\theta_a\theta_b E^{\bar{b}\bar{a}}. \tag{3.40}
$$

It satisfies

$$
\begin{aligned}
F^t&=-F,\\
[F_1,F_2\}&=P_{12}F_2-F_2P_{12}+F_2Q_{12}-Q_{12}F_2,
\end{aligned}
\tag{3.41}
$$

where t is the transposition (3.1).

Property 3.8: The following map defines an algebra homomorphism:

$$\begin{aligned} &Y(M|2n)^+ \to \mathcal{U}[\mathrm{osp}(M|2n)], \\ &S(u) \to \mathbb{F}(u) = \mathbb{I} + \frac{1}{u+\frac{1}{2}} F. \end{aligned} \tag{3.42}$$

Proof: We have to prove that $\mathbb{F}$ obeys to the relations (3.11) and (3.12). A direct calculation shows

$$\mathbb{F}^t(-u) = \mathbb{I} + \frac{1}{u-\frac{1}{2}} F = \mathbb{F}(u) + \frac{1}{2u}(\mathbb{F}(u) - \mathbb{F}(-u)).$$

Moreover, using (3.15), the commutator (3.41) and the relations

$$\begin{aligned} &P_{12}F_2 = F_1 P_{12} \Rightarrow Q_{12}F_2 = -Q_{12}F_1, \\ &P_{12}F_1 = F_2 P_{12} \Rightarrow F_1 Q_{12} = -F_2 Q_{12}, \end{aligned} \tag{3.43}$$

one proves that we have

$$\begin{aligned} [\mathbb{F}_1(u), \mathbb{F}_2(v)\} = &\frac{1}{u-v}(P_{12}\mathbb{F}_1(u)\mathbb{F}_2(v) - \mathbb{F}_2(v)\mathbb{F}_1(u)P_{12}) - \frac{1}{u+v}(\mathbb{F}_1(u)Q_{12}\mathbb{F}_2(v) \\ &- \mathbb{F}_2(v)Q_{12}\mathbb{F}_1(u)) + \frac{1}{u^2-v^2}(P_{12}\mathbb{F}_1(u)Q_{12}\mathbb{F}_2(v) - \mathbb{F}_2(v)Q_{12}\mathbb{F}_1(u)P_{12}). \end{aligned}$$

■

The relation between $\mathrm{osp}(M|2n)$ and $Y(M|2n)^+$ also reveals in the following.

Property 3.9: $Y(M|2n)^+$ is a deformation of $\mathcal{U}(\mathrm{osp}(M|2n)[x])$, the (positive modes) loop algebra based on $\mathrm{osp}(M|2n)$.

Proof: We start with $S(u) = \mathbb{I} + s(u)$, and make a change of basis $\tilde{s}(u) = \hbar^{-1} s(u/\hbar)$. In this basis, the commutation relations read

$$\begin{aligned} [\tilde{s}_1(u), \tilde{s}_2(v)\} = &\frac{1}{u-v}(P_{12}\tilde{s}_1(u) + P_{12}\tilde{s}_2(v) - \tilde{s}_1(u)P_{12} - \tilde{s}_2(v)P_{12}) - \frac{1}{u+v}(\tilde{s}_1(u)Q_{12} + Q_{12}\tilde{s}_2(v) \\ &- Q_{12}\tilde{s}_1(u) - \tilde{s}_2(v)Q_{12}) + \frac{\hbar}{u-v}(P_{12}\tilde{s}_1(u)\tilde{s}_2(v) - \tilde{s}_2(v)\tilde{s}_1(u)P_{12}) \\ &- \frac{\hbar}{u+v}(\tilde{s}_1(u)Q_{12}\tilde{s}_2(v) - \tilde{s}_2(v)Q_{12}\tilde{s}_1(u)) + \frac{\hbar}{u^2-v^2}(P_{12}\tilde{s}_1(u)Q_{12} + P_{12}\tilde{s}_2(v) \\ &- Q_{12}\tilde{s}_1(u)P_{12} - \tilde{s}_2(v)P_{12}) + \frac{\hbar^2}{u^2-v^2}(P_{12}\tilde{s}_1(u)Q_{12}\tilde{s}_2(v) - \tilde{s}_2(v)Q_{12}\tilde{s}_1(u)P_{12}). \end{aligned}$$

For $\hbar \neq 0$ all the algebras $Y_\hbar(M|2n)^+$ are isomorphic, while in the limit $\hbar \to 0$, $Y_{\hbar=0}(M|2n)^+$ reduces to $\mathcal{U}(\mathrm{osp}(M|2n)[x])$. ■

Note also the following isomorphism.

Property 3.10 (Automorphism of $Y(M|2n)^+$): The transformations

$$S(u) \to g(u)\, S(u) \quad \textit{with } g(u) \textit{ even } \mathbb{C}\textit{-function} \tag{3.44}$$

are automorphisms of $Y(M|2n)^+$.

Proof: Multiplying (3.11) by $g(u)g(v)$ shows that it is invariant under the transformation (3.44), for any function g. The symmetry relation (3.12) is preserved for $g(u)$ even only. ■

There is another of type of automorphism that we will need when looking at the representations of twisted super-Yangians:

Definition 3.11 (# involution): For any index $i=1,\ldots,M+N$, *we define* i' *by*

$$i'=\begin{cases}\tilde{m}+1 & \text{if} \quad i=m,\\ m & \text{if} \quad i=\tilde{m}+1 \qquad \text{where} \quad m=\left[\frac{M}{2}\right] \quad \text{and} \quad \tilde{m}=\left[\frac{M+1}{2}\right]\\ i & \text{otherwise}.\end{cases} \tag{3.45}$$

The # involution acts on $S(u)$ *by*

$$S^{ij}_{\#}(u)=S^{i'j'}(u) \tag{3.46}$$

and is an order 2 automorphism of $Y(M|2n)^+$.

Proof: Obvious direct calculation from the relations (3.34) and (3.12). ■

For the Hopf structure, and mimicking again the case of twisted Yangians, one can show the following.

Property 3.12: $Y(M|2n)^+$ *is a left coideal of* $Y(M|2n)$*:*

$$\Delta(Y(M|2n)^+)\subset Y(M|2n)\otimes Y(M|2n)^+. \tag{3.47}$$

More precisely,

$$\Delta(S^{ab}_{(p)})=\sum_{y=0}^{p}\sum_{q=0}^{y}\sum_{d,e=1}^{M+2n}(-1)^q(-1)^{[d]([e]+[b])}\theta_b\theta_e T^{ad}_{(y-q)}\overline{T^{be}_{(q)}}\otimes S^{de}_{(y)},$$

$$\Delta[S^{ab}(u)]=\sum_{d,e=1}^{M+2n}(-1)^{[d]([e]+[b])}\theta_b\theta_e T^{ad}(u)\overline{T^{be}}(-u)\otimes S^{de}(u).$$

Proof: Direct calculation using (2.14) and (3.9). ■

C. Subalgebras of $Y(M|2n)^+$

Property 3.13: The twisted super-Yangian $Y(M|N)^+$ *contains as subalgebras* $Y(M)^+$, $Y(N)^-$ *and* $\mathrm{osp}(M|N)$.

Proof: A direct examination on the commutator (2.12) and the symmetry relation (3.12) shows that $S^{ab}(u)$ with $a,b=1,\ldots,M$ (resp. $a,b=M+1,\ldots,M+N$) generates the twisted Yangian $Y(M)^+$ [resp. $Y(N)^-$]. The last inclusion has been proved in Corollary 3.7. ■

Property 3.14: As algebra embeddings, we have

$$Y(1|2)^+\subset Y(2m+1|2n)^+ \quad \text{and} \quad Y(2|2)^+\subset Y(2m|2n)^+. \tag{3.48}$$

Proof: We consider the generators $S^{ij}(u)$, with $i,j=m+1,2m+n+1,2m+n+2$ in $Y(2m+1|2n)^+$ and $S^{ij}(u)$, with $i,j=m,m+1,2m+n,2m+n+1$ in $Y(2m|2n)^-$: they obey the commutation and symmetry relations of $Y(1|2)^+$ and $Y(2|2)^+$, respectively. ■

Note that there is no regular embedding of $Y(1|2)^+$ into $Y(2m|2n)^+$. The circumstances are here different from both simple superalgebras and non-super twisted Yangians cases: in the first case, it always exists a regular $\mathrm{osp}(1|2)$ embedding, and in the second case, one can always construct a regular $Y(2)^{\pm}$ embedding in the twisted Yangian $Y(M)^{\pm}$. It is the symmetry relation which causes this unusual situation.

Property 3.15: As algebra embedding, we have

$$Y(2m|2n)^+ \subset Y(2m+1|2n)^+. \tag{3.49}$$

Let us stress, however, that $Y(2m|2n)^+$ is not a Hopf coideal of $Y(2m+1|2n)^+$.

The same results apply for $Y(2m)^+$ and $Y(2m+1)^+$.

Proof: Let $s^{ij}(u)$ be the generators of $Y(2m+1|2n)^+$. We set $M=2m+1$ and introduce

$$\sigma^{ij}(u)=s^{ij}(u) \quad \text{for } 1\leqslant i,j\leqslant m \text{ and } M+1\leqslant i,j\leqslant M+n+1,$$

$$\sigma_{i,j}(u)=s^{i-1,j-1}(u) \quad \text{for } m+2\leqslant i,j\leqslant M \text{ and } M+n+2\leqslant i,j\leqslant M+2n,$$

$$\sigma^{ij}(u)=s^{i-1,j}(u) \quad \text{for } \begin{cases} 1\leqslant j\leqslant m \text{ or } M+1\leqslant j\leqslant M+n+1, \\ m+2\leqslant i\leqslant M \text{ or } M+n+2\leqslant i\leqslant M+2n, \end{cases}$$

$$\sigma^{ij}(u)=s^{i,j-1}(u) \quad \text{for } \begin{cases} 1\leqslant i\leqslant m \text{ or } M+1\leqslant i\leqslant M+n+1, \\ m+2\leqslant j\leqslant M \text{ or } M+n+2\leqslant j\leqslant M+2n. \end{cases}$$

We prove that the generators $\sigma^{ij}(u)$ generate $Y(2m|2n)^+$. We denote by $x\to\overline{x}$ the "bar" operator introduced in (3.6) for $Y(2m+1|2n)^+$, and by $x\to\tilde{x}$ this "bar" operator for $Y(2m|2n)^+$. In the same way, we call τ and θ (resp. $\tilde{\tau}$ and $\tilde{\theta}$) the corresponding operations in $Y(2m+1|2n)^+$ [resp. $Y(2m|2n)^+$]. It is easy to see that

$$\overline{\imath}=\tilde{\imath}, \quad \theta_i=\tilde{\theta}_i, \quad \text{for } i\leqslant m \text{ and } M+1\leqslant i\leqslant M+n+1,$$

$$\overline{\imath-1}=\tilde{\imath}, \qquad \theta_{i-1}=\tilde{\theta}_i, \quad \text{for } m+2\leqslant i\leqslant M \text{ and } M+n+2\leqslant i,j\leqslant M+2n,$$

so that the action of τ on $s(u)$ is equivalent to the action of $\tilde{\tau}$ on $\sigma(u)$. It also proves that the symmetry relation of $s(u)$ [coming from $Y(2m+1|2n)^+$] implies the symmetry relation for $\sigma(u)$ [as $Y(2m|2n)^+$ generator].

In the same way, one shows, starting with the commutation relations of $s(u)$, that the commutation relations of $\sigma(u)$ are those of $Y(2m|2n)^+$.

Finally, computing $\Delta\sigma^{ij}(u)$ as it is induced from the $Y(2m+1|2n)^+$ coproduct does not lead to the coproduct formula for $Y(2m|2n)^+$. ■

IV. FINITE-DIMENSIONAL IRREDUCIBLE REPRESENTATIONS OF $Y(M|2n)^+$

We study here the finite-dimensional irreducible representations of $Y(M|2n)^+$ starting from $Y(M|2n)$ in the same way those of $Y(M)^\pm$ have been studied starting from $Y(M)$.[16]

As a shorthand notation, we note irreps for irreducible representations.

A. Generalities

Definition 4.1 (Highest weight vector): Let $\mathcal{M}$ be a module of $Y(M|2n)^+$. A nonzero vector $\xi\in\mathcal{M}$ is called highest weight if it satisfies

$$S^{ij}(u)\xi=0 \quad \textit{for } (i,j)\in\Phi^+, \tag{4.1}$$

$$S^{ii}(u)\xi=\mu_i(u)\xi \quad \textit{for } i=1,\ldots,M+2n, \tag{4.2}$$

for some formal series $\mu_i(u)\in 1+u^{-1}\mathbb{C}[[u^{-1}]]$. The set $\mu(u)\equiv(\mu_1(u),\ldots,\mu_{M+2n}(u))$ is the highest weight of $\mathcal{M}$.

Remark 1: Due to the symmetry relation (3.12), some of the relations (4.1) are redundant, and one could reduce Φ^+: we keep it as it is to make the comparison with the $Y(M|N)$ case.

Note also that, in the basis of Ref. 12, the symmetry relation would have led to $S^{ij}(u)\xi=0$, $\forall i\neq j$, hence the present choice for the positive root system.

Remark 2: The symmetry relation also implies for the highest weight

$$\mu_{\bar{a}}(u)=\frac{1}{2u}\mu_a(u)+\frac{2u-1}{2u}\mu_a(-u), \tag{4.3}$$

so that, in the $Y(2m+1|2n)^+$ case, $\mu_{m+1}(u)$ is an even function of u.

Definition 4.2 (Highest weight representations): A representation V of the twisted super-Yangian $Y(M|2n)^+$ is called highest weight if it is generated by a highest weight vector ξ. If $\mu(u)$ is the highest weight of ξ, we will use the notation $V[\mu(u)]$ for V.

Theorem 4.3: *Every finite-dimensional irrep V of $Y(M|2n)^+$ is highest weight. Moreover, V contains a unique (up to scalar multiples) highest weight vector.*

Proof: We define

$$V_+=\{v\in V|S^{ab}_{(p)}v=0,\ \forall(a,b)\in\Phi^+ \ \text{ and } \ p>0\}. \tag{4.4}$$

We first prove that V_+ is not empty.

Let $m\equiv[M/2]$. The generators $S^{11}_{(1)},\ldots,S^{mm}_{(1)},S^{M+1,M+1}_{(1)},\ldots,S^{M+n,M+n}_{(1)}$ form a Cartan subalgebra of $\mathrm{Osp}(M|2n)$, so there exists at least one eigenvector v common to all $S^{aa}_{(1)}$ and with eigenvalue $\mu=(\mu^{(1)}_1,\ldots,\mu^{(1)}_{M+2n})$.

If $v\in V_+$, then we have $V_+\neq\varnothing$. If $v\notin V_+$, by applying $S^{ab}_{(p)},(a,b)\in\Phi^+$, to v we obtain an other common eigenvector of the $S^{aa}_{(1)}$ with eigenvalue $\mu+\omega$, where ω is a $\mathbb{Z}_{>0}$-linear combination of the positive roots. As V is finite dimensional, repeated applications of generators $S^{ab}_{(n)}$, $(a,b)\in\Phi^+$, $n>0$, will lead to a nonvanishing vector $v_+\in V$ such that

$$S^{ab}_{(p)}v_+=0\ \forall(a,b)\in\Phi^+,\ \ p>0, \tag{4.5}$$

$$S^{aa}_{(1)}v_+=\lambda^{(1)}v_+\ \forall a. \tag{4.6}$$

So $v_+\in V_+$ and V_+ contains at least one nonzero element.

One defines

$$\mathcal{T}_\pm=\{S^{ab}(u),\forall(a,b)\in\Phi^\pm\} \tag{4.7}$$

and L (resp. R) the left (resp. right) ideal generated by $\mathcal{T}_+$ (resp. $\mathcal{T}_-$). We also introduce the subalgebra

$$\mathcal{Y}_0=\{y\in Y(M|2n)^+,\ \text{such that}\ \ [S^{aa}_{(1)},y]=0\ \forall a=1,\ldots,M+2n\} \tag{4.8}$$

and correspondingly

$$L_0=\mathcal{Y}_0\cap L\quad\text{and}\quad R_0=\mathcal{Y}_0\cap R. \tag{4.9}$$

Using the PBW Theorem 3.3, one shows that $L_0=R_0\equiv I_0$ is a two-sided ideal so that $\mathcal{G}=\mathcal{Y}_0/I_0$ is an algebra. From the commutation relations (3.34), one gets that $[S^{aa}(u),S^{bb}(v)]\in I_0$, i.e., $\mathcal{G}$ is a commutative algebra.

By construction, $\forall v\in V_+$ and $i\in I_0$, one has $iv=0$, so that V_+ is a $\mathcal{G}$-module. Since $\mathcal{G}$ is commutative, there exists a nonzero common eigenvector $\xi\in V_+$. Now, let $V'=\mathcal{U}(\mathcal{T}_-)\xi$: it is a nonzero submodule of V, and since V is supposed irreducible, it must equal V. Thus, ξ is a highest weight vector of V.

Finally, if there is another highest weight vector ξ', the above construction ensures that $V=\mathcal{U}(\mathcal{T}_-)\xi=\mathcal{U}(\mathcal{T}_-)\xi'$ which is possible only for ξ and ξ' proportional. ■

Theorem 4.4: *(Necessary conditions for finite-dimensional irreps) If the irreducible highest weight representation $V[\mu(u)]$ of $Y(M|2n)^+$ is finite dimensional, then the following relations hold*:

$$\frac{\mu_i(u)}{\mu_{i+1}(u)}=\frac{P_{i+1}(u+1)}{P_{i+1}(u)}\quad \textit{for}\quad \begin{cases} m+2\leqslant i\leqslant M-1,\\ M+n+1\leqslant i\leqslant M+2n-1, \end{cases} \tag{4.10}$$

$$\frac{\mu_{M+n+1}(-u)}{\mu_{M+n+1}(u)}=\frac{P_{M+n+1}(u+1)P_{M+n+1}(-u)}{P_{M+n+1}(u)P_{M+n+1}(1-u)}. \tag{4.11}$$

If $M=2m+1$, we have also the relation

$$\gamma(u)\frac{\mu_{m+1}(u)}{\mu_{m+2}(u)}=\frac{P_{m+1}(u+1)}{P_{m+1}(u)}, \quad \textit{where} \quad \gamma(u) \quad \textit{is either} \quad 1 \quad \textit{or} \quad \frac{2u}{2u+1}. \tag{4.12}$$

If $M=2$, we have the additional condition

$$\frac{\mu_2(-u)}{\mu_2(u)}=\frac{P(u+1)P(-u)}{P(u)P(1-u)}\frac{(u+\gamma)(2u-1)}{(u-\gamma)(2u+1)}, \quad \textit{with} \quad P(-\gamma)P(\gamma+1)\neq 0. \tag{4.13}$$

Finally, for $M=2m>2$, we have the relations

$$\frac{\mu^o_{m+1}(u)}{\mu_{m+2}(u)}=\frac{P_{m+2}(u+1)}{P_{m+2}(u)},$$

$$\gamma(u)\frac{\mu^o_{m+1}(-u)}{\mu^o_{m+1}(u)}=\frac{P_{m+1}(u+1)P_{m+1}(-u)}{P_{m+1}(u)P_{m+1}(1-u)}, \tag{4.14}$$

where $\gamma(u)$ is either 1 or $(2u-1)/(2u+1)$, and $\mu^o_{m+1}(u)$ is either $\mu_{m+1}(u)$ or $\mu^{\#}_{m+1}(u)$. We have introduced $\mu^{\#}_{m+1}(u)$, which is deduced from $\mu_{m+1}(u)$ by the action of the # automorphism (see Definition 3.11 and Ref. 16 for more details).

Proof: It is a direct consequence of the classification of finite-dimensional irreps for the algebras $Y(M)^{\pm}$ done in Ref. 16. Since $Y(M)^{+}$ and $Y(2n)^{-}$ are subalgebras of $Y(M|2n)^{+}$, starting with an $Y(M|2n)^{+}$-irrep with highest weight ξ and considering the cyclic span of ξ with each of these subalgebras leads to the result. ■

B. Finite-dimensional irreps of $Y(1|2)^{+}$

Let $V[\mu(u)]$ be an irrep of $Y(1|2)^{+}$ with highest weight $\mu(u)\equiv(\mu_1(u),\mu_2(u),\mu_3(u))$. From the symmetry relation (4.3) we obtain that $\mu_1(u)$ is an even series in u^{-1} and $\mu_2(u)$ can be deduced from $\mu_3(u)$.

Property 4.5: If $V[\mu_1(u),\mu_3(u)]$ is finite dimensional, then there exists a formal even series $\psi(u)$ in u^{-1} such that

$$\psi(u)\mu_1(u)=(1-\alpha_1^2u^{-2})\cdots(1-\alpha_k^2u^{-2}), \tag{4.15}$$

$$\psi(u)\mu_3(u)=(1-\alpha_1u^{-1})\cdots(1-\alpha_ku^{-1})(1+\beta_1u^{-1})\ldots(1+\beta_ku^{-1}). \tag{4.16}$$

Proof: Let ξ be the highest weight vector of $V[\mu(u)]$.

Under $(S^{22}_{(1)},S^{33}_{(1)})$, $S^{32}_{(l_1)}\cdots S^{32}_{(l_s)}S^{31}_{(p_1)}\cdots S^{31}_{(p_r)}\xi$ has weight $(\mu_2^{(1)}+2s+r,\mu_3^{(1)}-2s-r)$ whereas $S^{31}_{(i)}\xi$ has weight $(\mu_2^{(1)}+1,\mu_3^{(1)}-1)$. So $S^{31}_{(i)}\xi$ can only be written as a linear combination of vectors $S^{31}_{(j)}\xi$. Let k be the minimum non-negative integer such that $S^{31}_{(k+1)}\xi$ is a linear combination of the vectors $\xi_1\equiv S^{31}_{(1)}\xi,\ldots,\xi_k\equiv S^{31}_{(k)}\xi$ (such k exists because $V[\mu(u)]$ is finite dimensional).

We will prove that for any vector $S^{31}_{(r)}\xi$ with $r\geqslant k+1$ we have

$$S^{31}_{(r)}\xi=a_1^{(r)}\xi_1+\cdots+a_k^{(r)}\xi_k, \tag{4.17}$$

where the $a_i^{(r)}$ are complex numbers.

Equation (4.17) is true for $r=k+1$ by definition of k. Taking $i=k=l=3$, $j=1$ in the commutation relation and exchanging u and v, we get

$$[S^{33}(u),S^{31}(v)]=-\frac{1}{u-v}(S^{31}(v)S^{33}(u)-S^{31}(u)S^{33}(v))-\frac{1}{u+v}S^{32}(u)S^{21}(v)$$
$$+\frac{1}{u^2-v^2}S^{32}(u)S^{13}(v)+\frac{-1+u-v}{u^2-v^2}S^{32}(v)S^{13}(u). \tag{4.18}$$

We multiply by (u^2-v^2) and take the coefficient at u^0v^{-p} $(p\geqslant 1)$. Using the fact that $S^{21}(u)\xi=S^{13}(u)\xi=0$ we obtain

$$S^{33}_{(2)}S^{31}_{(p)}\xi=-S^{31}_{(p+1)}\xi+S^{31}_{(1)}S^{33}_{(p)}\xi+S^{31}_{(p)}(S^{33}_{(2)}-S^{33}_{(1)})\xi. \tag{4.19}$$

For $i=1,\ldots,k-1$ (4.19) gives

$$S^{33}_{(2)}\xi_i=-\xi_{i+1}+\mu_3^{(i)}\xi_1+(\mu_3^{(2)}-\mu_3^{(1)})\xi_i\,. \tag{4.20}$$

For $i=k$, using $S^{31}_{(k+1)}\xi=a_1^{(k+1)}\xi_1+\cdots+a_k^{(k+1)}\xi_k$ in (4.19) gives

$$S^{33}_{(2)}\xi_k=-(a_1^{(k+1)}\xi_1+\cdots+a_k^{(k+1)}\xi_k)+\mu_3^{(k)}\xi_1+(\mu_3^{(2)}-\mu_3^{(1)})\xi_k\,. \tag{4.21}$$

So $\forall i\in\{1,\ldots,k\}$, $S^{33}_{(2)}\xi_i$ is a linear combination of the $\{\xi_j\}_{j=1,\ldots,k}$.

Now suppose that $\forall r\in\{k+1,\ldots,p\}$ (where $p\geqslant k+1$), Eq. (4.17) holds. We then have

$$S^{31}_{(p+1)}\xi=-S^{33}_{(2)}S^{31}_{(p)}+\mu_3^{(p)}\xi_1+(\mu_3^{(2)}-\mu_3^{(1)})S^{31}_{(p)}\xi$$
$$=-\sum_{i=1}^{k}(a_i^{(p)}S^{33}_{(2)}\xi_i)+\mu_3^{(p)}\xi_1+(\mu_3^{(2)}-\mu_3^{(1)})\sum_{i=1}^{k}(a_i^{(p)}\xi_i), \tag{4.22}$$

so $S^{31}_{(p+1)}\xi$ is a linear combination of the $\{\xi_j\}_{j=1,\ldots,k}$ and Eq. (4.17) is proved by induction on p. We can therefore write

$$S^{31}(u)\xi=a_1(u)\xi_1+\cdots+a_k(u)\xi_k\,, \tag{4.23}$$

where $a_i(u)=u^{-i}+\Sigma_{s=k+1}^{\infty}a_i^{(s)}u^{-s}$.

We can rewrite (4.19) as

$$S^{33}_{(2)}S^{31}(v)\xi=-vS^{31}(v)\xi+\mu_3(v)\xi_1+(\mu_3^{(2)}-\mu_3^{(1)})S^{31}(v)\xi. \tag{4.24}$$

On the other hand, applying $S^{33}_{(2)}$ on (4.23) and using (4.20) and (4.21) we have

$$S^{33}_{(2)}S^{31}(v)\xi=\sum_{i=1}^{k}a_i(v)S^{33}_{(2)}\xi_i$$
$$=\left(\sum_{i=1}^{k}(a_i(v)\mu_3^{(i)})+(\mu_3^{(2)}-\mu_3^{(1)})-a_k(v)a_1^{(k+1)}\right)\xi_1$$
$$+\sum_{i=2}^{k}(-a_{i-1}(v)+(\mu_3^{(2)}-\mu_3^{(1)})a_i(v)-a_k(v)a_i^{(k+1)})\xi_i\,. \tag{4.25}$$

Taking the coefficient at ξ_i for $i=2,\ldots,k$ in (4.24) and (4.25) leads to

$$-a_{i-1}(v)+va_i(v)-a_i^{k+1}a_k(v)=0, \tag{4.26}$$

so that

$$a_i(v)=a_k(v)\underbrace{(v^{k-i}-v^{k-1-i}a_k^{k+1}-v^{k-i-2}a_{k-1}^{(k+1)}-\cdots-va_{i+2}^{(k+1)}-a_{i+1}^{(k+1)}}_{A_i(v)} \tag{A27}$$

for $i=1,\ldots,k-1$. The coefficient at ξ_1 in (4.24) and (4.25) leads to

$$\mu_3(v)=\underbrace{\sum_{i=1}^{k}\mu_3^{(i)}a_k(v)A_i(v)}_{\text{pol. of degree } k-1}-a_1^{(k+1)}a_k(v)+\underbrace{va_k(v)A_1(v)}_{\text{monic pol. of degree } k} \tag{4.28}$$

So $\mu_3(v)=a_k(v)B(v)$ where $B(v)$ is a monic polynomial in v of degree k.

For $\mu_1(v)$ we use

$$[S^{11}(u),S^{31}(v)]=\frac{u+v+1}{u^2-v^2}S^{31}(u)S^{11}(v)-\frac{1}{u+v}S^{12}(u)S^{11}(v)-\frac{2v+1}{u^2-v^2}S^{31}(v)S^{11}(u).$$

Notice that $S^{11}(u)$ is an even series in u^{-1}. Using the same procedure we find that $\mu_1(v)=a_k(v)C(v)$ where $C(v)$ is a monic polynomial in v of degree k.

Defining $\varphi(u)=(a_k(u)u^k)^{-1}$, we have

$$\varphi(u)\mu_1(u)=(1+\alpha_1u^{-1})\cdots(1+\alpha_ku^{-1}), \tag{4.29}$$

$$\varphi(u)\mu_3(u)=(1+\beta_1u^{-1})\cdots(1+\beta_ku^{-1}), \tag{4.30}$$

where the α_i's and the β_i's are complex numbers.

The formal series

$$\psi(u)\equiv\varphi(u)(1-\alpha_1u^{-1})\cdots(1-\alpha_ku^{-1})=\frac{(1-\alpha_1^2u^{-2})\cdots(1-\alpha_k^2u^{-2})}{\mu_1(u)}. \tag{4.31}$$

is an even series in u^{-1}. The composition of the automorphism $S(u)\to\psi(u)S(u)$ with $V[\mu(u)]$ is an irrep with the following highest weight which we shall again denote by $\mu(u)$:

$$\mu_1(u)=(1-\alpha_1^2u^{-2})\cdots(1-\alpha_k^2u^{-2}), \tag{4.32}$$

$$\mu_3(u)=(1-\alpha_1u^{-1})\cdots(1-\alpha_ku^{-1})(1+\beta_1u^{-1})\cdots(1+\beta_ku^{-1}). \tag{4.33}$$

■

Thus, up to an automorphism of $Y(1|2)^+$, we can assume that $\mu_1(u)$ and $\mu_3(u)$ are polynomials in u^{-1}.

Theorem 4.6: *Let $V[\mu_1(u),\mu_3(u)]$ be an irrep of $Y(1|2)^+$. Suppose $\mu_1(u)$ and $\mu_3(u)$ satisfy*

$$\frac{\mu_1(u)}{\mu_3(u)}=\frac{P(u+1)}{P(u)}\frac{R(u)}{Q(u)}, \tag{4.34}$$

$$\frac{\mu_3(-u)}{\mu_3(u)}=\frac{P(u+1)P(-u)}{P(u)P(1-u)}, \tag{4.35}$$

where $P(u)$, $Q(u)$ and $R(u)$ are a monic polynomial, $Q(u)$ and $R(u)$ are even in u and of same degree.

Then V is finite-dimensional.

Proof: We call p (resp. $2r$) the degree of $P(u)$ [resp. $Q(u)$ and $R(u)$]. Since $R(u)$ and $Q(u)$ are even, they write

$$R(u)=R_0(u)R_0(-u); \quad Q(u)=Q_0(u)Q_0(-u) \quad \text{with} \quad dg(R_0)=dg(Q_0)=r. \tag{4.36}$$

We introduce

$$\lambda_1(u)=u^{-s-r}P(u+1)R_0(u), \tag{4.37}$$

$$\lambda_2(u)=u^{-s-r}P(u+1)Q_0(u), \tag{4.38}$$

$$\lambda_3(u)=u^{-s-r}P(u)Q_0(u). \tag{4.39}$$

Let $L[\lambda(u)]$ be the corresponding irreducible highest weight module of $Y(1|2)$. Since $\lambda_1(u)/\lambda_2(u)=R_0(u)/Q_0(u)$ and $\lambda_2(u)/\lambda_3(u)=P(u+1)/P(u)$, according to Ref. 12 $L[\lambda(u)]$ is finite dimensional. The cyclic $Y(1|2)^+$-span of its highest weight vector is a finite-dimensional representation $V[\mu'(u)]$ of $Y(1|2)^+$ with $\mu_1'(u)=\lambda_1(u)\lambda_1(-u)$ and $\mu_3'(u)=\lambda_3(u)\lambda_2(-u)$. By construction, the polynomials $\mu_i'(u)$ satisfy (4.34) and (4.35). This implies that

$$\psi(u)\equiv\frac{\mu_3(u)}{\mu_3'(u)}=\frac{\mu_3(-u)}{\mu_3'(-u)} \tag{4.40}$$

is an even series in u^{-1} and

$$\mu_1(u)=\frac{\mu_3(u)}{\mu_3'(u)}\mu_1'(u)=\psi(u)\mu_1'(u). \tag{4.41}$$

Thus, there exists an automorphism $S(u)\to\psi(u)S(u)$ of $Y(1|2)^+$ such that its composition with the representation $V[\mu'(u)]$ is isomorphic to $V[\mu(u)]$:$V[\mu(u)]$ is therefore finite dimensional. ■

Conjecture 1: The sufficient condition (4.34) of Theorem 4.6 for the existence of finite-dimensional irreps of $Y(1|2)^+$ is also a necessary condition.

We remind that the condition (4.35) has been proved to be necessary (see Theorem 4.6), so that Conjecture 1 just says that Theorem 4.6 states necessary and sufficient conditions for finite-dimensional irreps of $Y(1|2)^+$.

C. The general case $Y(2m+1|2n)^+$

Theorem 4.7: *Let $V=V[\mu_{m+1}(u),\ldots,\mu_{2m+1}(u),\mu_{M+n+1}(u),\ldots,\mu_{M+2n}(u)]$ be an irrep of $Y(2m+1|2n)^+$. We take $m\geqslant 1$ and note $M=2m+1$.*

Suppose the weights $\mu_i(u)$ obey

$$\frac{\mu_i(u)}{\mu_{i+1}(u)}=\frac{P_{i+1}(u+1)}{P_{i+1}(u)} \quad \textit{for} \quad \begin{cases} m+2\leqslant i\leqslant 2m, \\ M+n+1\leqslant i\leqslant M+2n-1, \end{cases} \tag{4.42}$$

$$\frac{\mu_{M+n+1}(-u)}{\mu_{M+n+1}(u)}=\frac{P_{M+n+1}(u+1)P_{M+n+1}(-u)}{P_{M+n+1}(u)P_{M+n+1}(1-u)}, \tag{4.43}$$

$$\gamma(u)\frac{\mu_{m+1}(u)}{\mu_{m+2}(u)}=\frac{P_{m+2}(u+1)}{P_{m+2}(u)}, \tag{4.44}$$

$$\frac{\mu_{m+1}(u)}{\mu_{M+n+1}(u)}=\frac{P_{M+n+1}(u+1)}{P_{M+n+1}(u)}\frac{R(u)}{Q(u)}, \tag{4.45}$$

with $R(u)$ and $Q(u)$ even and of same degree. In the above formulas, $\gamma(u)$ is either 1 *or* $2u/(2u+1)$.

Then V is finite dimensional.

Under the assumption of Conjecture 1, the above sufficient conditions are also necessary ones.

Proof: First, let $\gamma(u)$ be 1. We note s_i the degree of the polynomials $P_i(u)$, decompose $R(u)$ and $Q(u)$ as in (4.36), and note

$$P_+(u)=\prod_{a=m+2}^{M} P_a(u); \quad P_-(u)=\prod_{a=M+n+1}^{M+2n} P_a(u); \quad s_0=r+\sum_{i=m+1}^{M} s_i+\sum_{i=M+n+1}^{M+2n} s_i. \tag{4.46}$$

We also define

$$\lambda_i(u)=u^{-s_0}P_+(u+1)P_-(u+1)R_0(u), \qquad i=1,\ldots,m+1, \tag{4.47}$$

$$\lambda_i(u)=u^{-s_0}P_-(u+1)R_0(u)\prod_{a=m+2}^{i} P_a(u)\prod_{a=i+1}^{2m+1} P_a(u+1), \qquad i=m+2,\ldots,M, \tag{4.48}$$

$$\lambda_i(u)=u^{-s_0}P_+(u+1)P_-(u+1)Q_0(u), \qquad i=M+1,\ldots,M+n, \tag{4.49}$$

$$\lambda_i(u)=u^{-s_0}P_+(u+1)Q_0(u)\prod_{a=M+n+1}^{i} P_a(u)\prod_{a=i+1}^{M+2n} P_a(u+1),$$

$$i=M+n+1,\ldots,M+2n. \tag{4.50}$$

We therefore have

$$\frac{\lambda_i(u)}{\lambda_{i+1}(u)}=\frac{P_{i+1}(u+1)}{P_{i+1}(u)} \quad \text{for} \quad \begin{cases} i=m+1,\ldots,M-1, \\ i=M+n,\ldots,M+2n-1, \end{cases} \tag{4.51}$$

$$\frac{\lambda_i(u)}{\lambda_{i+1}(u)}=1 \quad \text{for} \quad \begin{cases} i=1,\ldots,m, \\ i=M+1,\ldots,M+n-1, \end{cases} \tag{4.52}$$

$$\frac{\lambda_M(u)}{\lambda_{M+1}(u)}=\frac{R_0(u)}{Q_0(u)}\frac{P_+(u)}{P_+(u+1)}. \tag{4.53}$$

We consider the highest weight irrep $L[\lambda(u)]$ of $Y(2m+1|2n)$. According to Property 2.6, the relations (4.51)–(4.53) ensure that $L[\lambda(u)]$ is finite dimensional. The cyclic $Y(2m+1|2n)^+$-span of its highest weight vector is a finite-dimensional representation with highest weights $\mu_i'(u)=\lambda_i(u)\overline{\lambda_i}(-u)$ for $i=m+1,\ldots,2m+1$ and $i=M+n+1,\ldots,M+2n$. Its irreducible quotient is a finite-dimensional irrep $V[\overline{\mu}(u)]$ of $Y(2m|2n)^+$.

Moreover, the $\mu_i'(u)$ verify

$$\frac{\mu_i'(u)}{\mu_{i+1}'(u)}=\frac{P_{i+1}(u+1)}{P_{i+1}(u)}=\frac{\mu_i(u)}{\mu_{i+1}(u)}, \quad \begin{cases} i=m+1,\ldots,M-1, \\ i=M+n+1,\ldots,M+2n-1, \end{cases} \tag{4.54}$$

$$\frac{\mu'_{M+n+1}(-u)}{\mu'_{M+n+1}(u)}=\frac{P_{M+n+1}(u+1)P_{M+n+1}(-u)}{P_{M+n+1}(u)P_{M+n+1}(1-u)}=\frac{\mu_{M+n+1}(-u)}{\mu_{M+n+1}(u)}, \tag{4.55}$$

$$\frac{\mu'_{m+1}(u)}{\mu'_{M+n+1}(u)}=\frac{P_{M+n+1}(u+1)}{P_{M+n+1}(u)}\frac{R(u)}{Q(u)}=\frac{\mu_{m+1}(u)}{\mu_{M+n+1}(u)}. \tag{4.56}$$

The formal series

$$\psi(u)=\frac{\mu_{M+n+1}(-u)}{\mu'_{M+n+1}(u)} \tag{4.57}$$

is an even series in u^{-1} and we have

$$\frac{\mu_i(u)}{\mu'_i(u)}=\psi(u), \quad \forall i. \tag{4.58}$$

Hence there exists an automorphism $S(u)\to\psi(u)S(u)$ of $Y(2m+1|2n)^+$ such that its composition with $V[\mu'(u)]$ is isomorphic to $V[\mu(u)]$. The latter is thus finite dimensional.

Now, let $\gamma(u)=2u/(2u+1)$ holds. We introduce the osp$(2m+1|2n)$ representation V_0, of highest weight $l_i=-\frac{1}{2}$ for $i=m+2,\ldots,2m+1$ and $l_i=0$ for $i=m+1,M+n+1,\ldots,M+2n$ and promote it to a $Y(2m+1|2n)^+$ representation using the evaluation map. The corresponding highest weight has components $l_i(u)=2u/(2u+1)$ for $i=m+2,\ldots,2m+1$, and $l_i(u)=1$ for $i=m+1,M+n+1,\ldots,M+2n$.

Moreover, making the same construction as for the case $\gamma(u)=1$, and considering the tensor product $L[\lambda(u)]\otimes V_0$, we get a finite-dimensional representation $V[\mu''(u)]$ obeying the relations (4.42)–(4.45) with $\gamma(u)=2u/(2u+1)$. Its irreducible subquotient is isomorphic to $V[\mu(u)]$, which is therefore finite dimensional.

Conversely, let us suppose that the irrep $V[\mu(u)]$ is finite dimensional. From Theorem 4.4, one already knows that the conditions (4.42)–(4.44) must be satisfied.

Suppose also that Conjecture 1 holds. The subalgebra generated by the coefficients of $S^{ij}(u)$, $i,j=m+1,M+n,M+n+1$, is isomorphic to $Y(1|2)^+$. The cyclic span of the highest weight vector of $V[\mu(u)]$ with respect to this subalgebra is a representation with highest weight $(\mu_{m+1}(u),\mu_{M+n+1}(u))$. Its irreducible quotient is finite dimensional and, so, we have relation (4.45). ■

D. Finite-dimensional irreps of $Y(2|2)^+$

Let $V=V[\mu(u)]$ be an irrep of $Y(2|2)^+$ with highest weight $\mu(u)$.

Proposition 4.8: If $V[\mu(u)]$ is finite dimensional, then there exists a formal even series $\psi(u)$ in u^{-1} such that

$$\psi(u)\mu_2(u)=(1-\alpha_1u^{-1})\cdots(1-\alpha_ku^{-1}), \tag{4.59}$$

$$\psi(u)\mu_4(u)=(1-\beta_1u^{-1})\cdots(1-\beta_ku^{-1}). \tag{4.60}$$

Proof: The proof is very similar to the case of $Y(1|2)^+$, and we leave it to the reader. Note that for the calculation being achieved using the fermionic generator $S_{13}(u)$ [instead of the even bosonic one $S_{12}(u)$], there is no difference in the proof for $Y(1|2)^+$ and $Y(2|2)^+$, in opposition with the $Y(2)^+$ and $Y(2)^-$ cases.[16] ■

Theorem 4.9: *Let $V[\mu_2(u),\mu_4(u)]$ be an irrep of $Y(2|2)^+$. If $\mu_2(u)$ and $\mu_4(u)$ satisfy*

$$\frac{\mu_2(u)}{\mu_4(u)}=\frac{u-\gamma}{u+\frac{1}{2}}\frac{P_4(u+1)\,P_2(u)}{P_4(u)\,P_2(u+1)}\frac{R(u)}{Q(u)}, \tag{4.61}$$

$$\frac{\mu_4(-u)}{\mu_4(u)}=\left(\frac{u+\frac{1}{2}}{u-\frac{1}{2}}\right)^2\frac{P_4(u+1)\,P_4(-u)}{P_4(u)\,P_4(1-u)}, \tag{4.62}$$

then V is finite dimensional.

In the above formulas, $P_2(u)$, $P_4(u)$, $Q(u)$ and $R(u)$ are monic polynomials, $Q(u)$ and $R(u)$ are even in u and of same degree, and $\gamma \in \mathbb{C}$.

Proof: We call p_2 (resp. p_4, resp. $2r$) the degree of $P_2(u)$ [resp. $P_4(u)$, resp. $Q(u)$ and $R(u)$] and decompose $Q(u)$ and $R(u)$ as in (4.36). Let $L[\lambda(u)]$ be the irrep of $Y(2|2)$ with weights

$$\lambda_1(u) = u^{-p_2-p_4-r} P_4(u+1) P_2(u+1) R_0(u), \tag{4.63}$$

$$\lambda_2(u) = u^{-p_2-p_4-r} P_4(u+1) P_2(u) R_0(u), \tag{4.64}$$

$$\lambda_3(u) = u^{-p_2-p_4-r} P_4(u+1) P_2(u+1) Q_0(u), \tag{4.65}$$

$$\lambda_4(u) = u^{-p_2-p_4-r} P_4(u) P_2(u+1) Q_0(u). \tag{4.66}$$

Since we have

$$\frac{\lambda_1(u)}{\lambda_2(u)} = \frac{P_2(u+1)}{P_2(u)}, \quad \frac{\lambda_2(u)}{\lambda_3(u)} = \frac{P_2(u+1) R_0(u)}{P_2(u)\, Q_0(u)}, \quad \frac{\lambda_3(u)}{\lambda_4(u)} = \frac{P_4(u+1)}{P_4(u)}, \tag{4.67}$$

$L[\lambda(u)]$ is finite dimensional. The $Y(2|2)^+$-cyclic span of its highest weight vector is a finite-dimensional $Y(2|2)^+$-representation $V[\mu'(u)]$ of weights $\mu_2'(u) = \lambda_2(u)\lambda_1(-u)$ and $\mu_4'(u) = \lambda_4(u)\lambda_3(-u)$. These weights obey the relations

$$\frac{\mu_2'(u)}{\mu_4'(u)} = \frac{P_4(u+1)\, P_2(u)}{P_4(u)\, P_2(u+1)} \frac{R(u)}{Q(u)}, \tag{4.68}$$

$$\frac{\mu_4'(-u)}{\mu_4'(u)} = \frac{P_4(u+1)\, P_4(-u)}{P_4(u)\, P_4(1-u)}. \tag{4.69}$$

We now consider the osp(2|2) finite-dimensional irrep V_0 with weights $l_2 = -\gamma - \frac{1}{2}$ and $l_4 = -1$. Through the evaluation map, its provides a finite-dimensional representation of $Y(2|2)^+$ with weights

$$l_2(u) = \frac{u-\gamma}{u+\frac{1}{2}} \quad \text{and} \quad l_4(u) = \frac{u-\frac{1}{2}}{u+\frac{1}{2}}. \tag{4.70}$$

The tensor product $L[\lambda(u)] \otimes V_0$ is thus a finite-dimensional representation of $Y(2|2)^+$, with weights $\mu_i''(u) = \mu_i'(u) l_i(u)$, $i = 2,4$. They obey relations (4.61) and (4.62), so that the irreducible quotient provide a finite-dimensional irrep isomorphic to V. Thus, V finite dimensional. ■

Note that the polynomial $P(u) = (u - \frac{1}{2})^2$ obeys the relation $P(1-u) = P(u)$, so that the condition on $\mu_4(u)$ does not differ from the one obtained for $Y(2)^-$.

Conjecture 2: The sufficient condition (4.61) *of Theorem 4.9 for the existence of finite-dimensional irreps of $Y(2|2)^+$ is also a necessary condition.*

E. The general case $Y(2m|2n)^+$

Theorem 4.10: *(Case of $Y(2|2m)^+$) Let $V = V[\mu_2(u), \mu_{n+3}(u), \ldots, \mu_{2+2n}(u)]$ be an irrep of $Y(2|2n)^+$.*

Suppose the weights $\mu_i(u)$ obey

$$\frac{\mu_i(u)}{\mu_{i+1}(u)} = \frac{P_{i+1}(u+1)}{P_{i+1}(u)} \quad \text{for} \quad n+3 \leqslant i \leqslant 2n+1, \tag{4.71}$$

$$\frac{\mu_{n+3}(-u)}{\mu_{n+3}(u)}=\left(\frac{u-\frac{1}{2}}{u+\frac{1}{2}}\right)^2\frac{P_{n+3}(u+1)P_{n+3}(-u)}{P_{n+3}(u)P_{n+3}(1-u)}, \tag{4.72}$$

$$\frac{\mu_2(u)}{\mu_{n+3}(u)}=\frac{u-\gamma}{u+\frac{1}{2}}\frac{P_{n+3}(u+1)\,P_2(u)}{P_{n+3}(u)\,P_2(u+1)}\frac{R(u)}{Q(u)}, \tag{4.73}$$

with $R(u)$ and $Q(u)$ even and of same degree, and $\gamma\in\mathbb{C}$.

Then V is finite dimensional.

Under the assumption of Conjecture 2, the conditions (4.71)–(4.73) are necessary and sufficient conditions for V to be a finite-dimensional irrep.

Proof: The proof is similar to the previous ones. One constructs a finite-dimensional irrep for $Y(2|2n)^+$ which fulfills the conditions (4.71)–(4.73). It takes the form $V'=L[\lambda(u)]\otimes V_\gamma$. $L[\lambda(u)]$ is constructed as in Theorem 4.7. The finite-dimensional osp$(2|2n)$-irrep V_γ has weight

$$l_2=-\gamma-\tfrac{1}{2}\quad\text{and}\quad l_i=-1,\quad\text{for}\quad n+3\leqslant i\leqslant 2n. \tag{4.74}$$

Looking at the osp$(2|2n)$-span of the highest weight vector and taking the irreducible subquotient, we get a finite-dimensional irrep V' with highest weight obeying (4.71)–(4.73). V being isomorphic to V', it is therefore finite dimensional.

Conversely, assuming Conjecture 2, and looking at the subalgebras $Y(2|2)^+$ and $Y(2n)^-$, one easily proves that the conditions (4.71)–(4.73) are necessary conditions. ■

Theorem 4.11: *(Case of $m>1$) Let $V=V[\mu_{m+1}(u),\ldots,\mu_M(u),\mu_{M+n+1}(u),\ldots,\mu_{M+2n}(u)]$ be an irrep of $Y(2m|2n)^+$. We note $M=2m$ and take $m>1$.*

Suppose the weights $\mu_i(u)$ obey

$$\frac{\mu_i(u)}{\mu_{i+1}(u)}=\frac{P_{i+1}(u+1)}{P_{i+1}(u)}\quad\text{for}\quad\begin{cases}m+1\leqslant i\leqslant 2m-1,\\ M+n+1\leqslant i\leqslant M+2n-1,\end{cases} \tag{4.75}$$

$$\frac{\mu_{M+n+1}(-u)}{\mu_{M+n+1}(u)}=\frac{P_{M+n+1}(u+1)P_{M+n+1}(-u)}{P_{M+n+1}(u)P_{M+n+1}(1-u)}, \tag{4.76}$$

$$\gamma(u)\frac{\mu_{m+1}(u)}{\mu_{M+n+1}(u)}=\frac{P_{M+n+1}(u+1)\,P_{m+1}(u)}{P_{M+n+1}(u)\,P_{m+1}(u+1)}\frac{R(u)}{Q(u)}, \tag{4.77}$$

with $R(u)$ and $Q(u)$ even and of same degree, and $\gamma(u)$ is either 1 or $(2u-1)/(2u+1)$.

Then V is finite dimensional.

Proof: We start with the case $\gamma(u)=1$, and do the same construction as in Theorem 4.7, to get weights $\lambda_i(u)$ defined as in Eqs. (4.47)–(4.50), with now $M=2m$. We introduce

$$\lambda_i'(u)=P_{m+1}(u+1)\lambda_i(u)\quad\text{for}\quad\begin{cases}i=1,\ldots,m,\\ i=M+1,\ldots,M+2n,\end{cases} \tag{4.78}$$

$$\lambda_i'(u)=P_{m+1}(u)\lambda_i(u)\quad\text{for}\quad i=m+1,\ldots,M. \tag{4.79}$$

For these new weights, the relations (4.51)–(4.53) are still valid when $i\neq m,M$. In these latter cases, we get

$$\frac{\lambda_m'(u)}{\lambda_{m+1}'(u)}=\frac{P_{m+1}(u+1)}{P_{m+1}(u)}, \tag{4.80}$$

$$\frac{\lambda_M'(u)}{\lambda_{M+1}'(u)}=\frac{P_{m+1}(u)}{P_{m+1}(u+1)}\frac{P_+(u)}{P_+(u+1)}\frac{R_0(u)}{Q_0(u)}. \tag{4.81}$$

Thus, the $Y(2m|2n)$-irrep $L[\lambda'(u)]$ is still finite dimensional. The cyclic $Y(2m|2n)^+$-span of its highest weight vector is a representation with highest weight $\overline{\mu}_i(u)=\lambda'_i(u)\lambda'_i(-u)$ for $i=m+1,\ldots,2m$ and $i=M+n+1,\ldots,M+2n$. Its irreducible quotient is a finite-dimensional irrep $V[\overline{\mu}(u)]$ of $Y(2m|2n)^+$.

Moreover, the weights $\overline{\mu}_i(u)$ for $i=m+1,\ldots,M-1$ on the one hand, and $i=M+n+1,..,M+2n-1$ on the other hand, verify the same relations as the $\mu'_i(u)$, i.e., the conditions (4.75) and (4.76). For the remaining relation, one computes

$$\frac{\overline{\mu}_{m+1}(u)}{\overline{\mu}_{M+n+1}(u)}=\frac{P_{m+1}(u)}{P_{m+1}(u+1)}\,\frac{\mu'_{m+1}(u)}{\mu'_{M+n+1}(u)}, \tag{4.82}$$

which gives the relation (4.77).

The weights $\mu_i(u)$ and $\overline{\mu}_i(u)$ both obeying the relations (4.75)–(4.77), there exists an automorphism $S(u)\to\psi(u)S(u)$ of $Y(2m|2n)^+$ such that its composition with $V[\overline{\mu}(u)]$ is isomorphic to $V[\mu(u)]$. The latter is thus finite dimensional.

If now $\gamma(u)=2u/(2u-1)$, we construct the tensor product of the above representation by the osp$(2m|2n)$ finite-dimensional irrep V_0 with weights $l_i=-\frac{1}{2}$ for $m+1\leqslant i\leqslant 2m$ and $l_i=-1$ for $2m+n+1\leqslant i\leqslant 2m+2n$. V_0 provides a finite-dimensional representation for $Y(2m|2n)^+$ with weights $l_i(u)=2u/(2u+1)$ for $m+1\leqslant i\leqslant 2m$ and $l_i(u)=2u/(2u-1)$ for $2m+n+1\leqslant i\leqslant 2m+2n$. The weights of the tensor product obey the relations (4.75)–(4.77), and we conclude as in Theorem 4.7. ■

Remark: Conversely, let us suppose that the irrep $V[\mu(u)]$ is finite dimensional and that Conjecture 2 holds. From Theorem 4.4, one already knows that the conditions (4.75) and (4.76) must be satisfied (for $i\neq m+1$). Moreover, we get also

$$\gamma(u)\,\frac{\mu^o_{m+1}(-u)}{\mu^o_{m+1}(u)}=\frac{P_m(u+1)P_m(-u)}{P_m(u)P_m(1-u)} \tag{4.83}$$

with $\gamma(u)$ and $\mu^o_{m+1}(u)$ defined as in Theorem 4.4.

We suppose also that $\mu^o_{m+1}(u)=\mu_{m+1}(u)$, which turns out to suppose that (4.75) is valid for $i=m+1$.

The subalgebra generated by the coefficients of $S^{ij}(u)$, $i,j=m,m+1,M+n,M+n+1$, is isomorphic to $Y(2|2)^+$. The cyclic span of the highest weight vector of $V[\mu(u)]$ with respect to this subalgebra is a representation with highest weight $(\mu_{m+1}(u),\mu_{M+n+1}(u))$. Its irreducible quotient is finite dimensional and, so, we have

$$\frac{\mu_{m+1}(u)}{\mu_{M+n+1}(u)}=\frac{u-\gamma}{u+\frac{1}{2}}\,\frac{P_{M+n+1}(u+1)\,P_{m+1}(u)}{P_{M+n+1}(u)\,P_{m+1}(u+1)}\,\frac{R(u)}{Q(u)}. \tag{4.84}$$

We look at the osp$(2m|2n)$ irrep induced by the generators $S^{ab}_{(1)}$ acting on the highest weight vector. It is finite dimensional, so we must have

$$l_{i+1}-l_i\in\mathbb{Z}_+ \quad \text{for} \begin{cases} m+2\leqslant i\leqslant 2m, \\ M+n+1\leqslant i\leqslant M+2n-1, \end{cases} \tag{4.85}$$

$$-(l_{m+2}+l_{m+1})\in\tfrac{1}{2}\mathbb{Z}_+ \quad \text{and} \quad -l_{M+n+1}\in\mathbb{Z}_+, \tag{4.86}$$

$$l_{m+1}-l_{M+n+1}\in\tfrac{1}{2}\mathbb{Z}_+, \tag{4.87}$$

where $\mu_i(u)=1+u^{-1}l_i+\cdots$. The above relations [on the weights $\mu_i(u)$] imply the following constraints:

$$l_{i+1}-l_i\in\mathbb{Z}_+ \quad \text{for} \quad \begin{cases} m+2\leqslant i\leqslant 2m, \\ M+n+1\leqslant i\leqslant M+2n-1, \end{cases} \tag{4.88}$$

$$-(l_{m+1}+l_{m+2})\in\mathbb{Z}_+ \quad \text{and} \quad -l_{M+n+1}\in\mathbb{Z}_+, \tag{4.89}$$

$$l_{m+1}-l_{M+n+1}\in\mathbb{Z}_+ +(-\gamma-\tfrac{1}{2}). \tag{4.90}$$

This implies in particular that $\gamma\in-\frac{1}{2}\mathbb{Z}_+$, so that we are back to the conditions (4.77). Thus, we are led to the following:

Conjecture 3: The sufficient conditions of Theorem 4.11 for the existence of finite-dimensional irreps of $Y(2m|2n)^+$ are also necessary conditions.

V. CONCLUSION

We have defined the notion of twisted Yangians in the context of superalgebra gl$(M|N)$. It appears that most of the properties of the twisted Yangians $Y^{\pm}(N)$ can be exhibited in the superalgebra case. However, only $Y^+(M|2n)$ and $Y^-(2m|N)$ can be defined, and appear to be isomorphic. We thus concentrate on $Y^+(M|2n)$. Its finite-dimensional irreducible representations have been studied. $Y^+(M|2n)$ is also a coideal subalgebra of $Y(M|2n)$, and is a deformation of the polynomial superalgebra $\mathcal{U}(\mathrm{osp}(M|2n)[x])$.

From a mathematical point of view, the center of this algebra remains to be studied, and in particular the notion of Sklyanin determinant (which appears in the context of twisted Yangians) has to be generalized to this case. Note that the notion of quantum Berezinian, which generates central elements of $Y(M|N)$, has been introduced in Ref. 11.

From the physical of view, the integrable systems with boundary that could be relevant for such an algebra has to be determined. Nonlinear sigma models based on a supergroup seem to be a good candidate.

ACKNOWLEDGMENTS

(Received 25 March 2002; accepted 10 December 2002)

In this article, we give the general forms of the minimal L matrix (the elements of the L-matrix are c numbers) associated with the Boltzmann weights of the A_{n-1}^{1} interaction-round-a-face (IRF) model and the minimal representation of the A_{n-1} series elliptic quantum group given by Felder and Varchenko. The explicit dependence of elements of L-matrices on spectral parameter z are given. They are of five different forms [A(1-4) and B]. The algebra for the coefficients (which do not depend on z) are given. The algebra of form A is proved to be trivial, while that of form B obeys Yang–Baxter equation (YBE). We also give the PBW base and the centers for the algebra of form B. © *2003 American Institute of Physics.*

I. INTRODUCTION

Recently, many papers have focused on the many-body long-distance integrable dynamical system, such as the Ruijsenaar Schneider model and the Calogero Moser (CM) model.[1–3] They are closely connected with the quantum Hall effect in the condense matter physics and the Seiberg Witten (SW) theory in the field theory, especially for the equations of the spectral curve in the SW theory, namely, the modified eigenvalue equations of the Lax matrices in the above integrable models.[4–6] These Lax matrices are the classical limit of the L matrices which is associated with the interaction-round-a-face (IRF) model of Lie group[7–9] and the modified Yang–Baxter relation (NSF equation).[10–13] All these L-matrices are corresponding to the representation of the elliptic quantum group which was proposed by Felder and Varchenko.[11,12] So it is very interesting to study the general solution of the L-matrices.

In this article, we study the simplest case of L-matrices which satisfy the dynamical Yang–Baxter relation (DYBR) for the A_{n-1} group. The deep study of the A_{n-1} group case can help us to understand the other Lie group cases because a subset of the other Lie groups can be constructed by the A_{n-1} group. We only study the simplest case of L matrices, that is to say, the Hilbert space of the L-operator is a scale function space. We find that the L matrices can only have five possible forms, form A(1), A(2), A(3), A(4) and form B. The form A(1) and B can be constructed by the factorized L matrices.[14–17] And the coefficient part of form B obeys a set of quadratic equations which can be related to the Shibukawa–Ueno operator.[18] The algebra of these quadratic relations have explicit PBW base and satisfy the YBE without spectral parameter z. We find that all known L-matrices[9,12,16] of related problem are equivalent to one representation of this algebra. But it is still an open question as to whether it is the unique one.

The present article is organized as follows. In Sec. II, we study the dependence of the elements of L-matrix with spectral parameter z. In Sec. III, we study the dependence of the essential

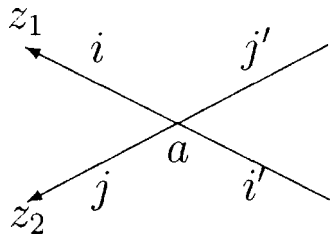

FIG. 1. The element of R-matrix $R(a|z_1-z_2)_{ij}^{i'j'}$.

part of these elements, which are functions of both z and (a,b), with respect to the indices of the elements. We prove that there are five possible classes of the minimal L-matrices. We then relate the elements of adjacent lattice points (a,b) and $(a+\hat{i}',b+\hat{i})$ in the end of this section. Section IV is written for the equations of the coefficient part of the elements of L-matrices, as a necessary and sufficient condition of L-matrices to satisfy the DYBR. This leads to two kinds of algebras. The A algebra, which is corresponding to the form A(i) ($i=1,2,3,4$), is trivially commutative and thus the coefficients of form A(i) can be determined completely. The algebra for form B coefficients is studied further in Sec. V, which satisfies YBE, and we establish the PBW base for it. We also give center elements for this algebra. In the last section, we give a known solution to the equations of form B. Throughout this article, we always assume all elements of L-matrix are c number functions which are not identically zero and $n\geqslant 4$.

II. DYBR AND THE RELATION BETWEEN FACTORIZED *L*-MATRIX AND MINIMAL *L*-MATRIX

It is well known that the Boltzmann weight of the $A_{n-1}^{(1)}$ IRF[7–9] model can be written as

$$R(a|z)_{ii}^{ii}=\frac{\sigma(z+w)}{\sigma(w)},\quad R(a|z)_{ij}^{ij}=\frac{\sigma(z)\sigma(a_{ij}-w)}{\sigma(w)\sigma(a_{ij})}\qquad \text{for}\qquad i\neq j,$$
$$R(a|z)_{ij}^{ji}=\frac{\sigma(z+a_{ij})}{\sigma(a_{ij})}\qquad \text{for}\qquad i\neq j,\quad R(a|z)_{i'j'}^{ij}=0\quad \text{for other cases,} \tag{1}$$

where $a\equiv(m_0,m_1,\ldots,m_{n-1})$ is an n-vector, and $a_{ij}=a_i-a_j$, $a_i=w(m_i-(1/n)\Sigma_l m_l+w_i)$, m_i ($i=0,1,\ldots,n-1$) are integers which describe the state of model, while $\{w,w_i\}$ are generic c-numbers which are the parameters of the model, and $\sigma(z)\equiv\theta[{}^{1/2}_{1/2}](z,\tau)$, with

$$\theta[{}^{a}_{b}](z,\tau)\equiv\sum_{m\in Z}e^{i\pi(m+a)^2\tau+2i\pi(m+a)(z+b)}.$$

We define an n-dimension vector $\hat{j}=(0,0,\ldots,0,1,0,\ldots)$, in which the jth component is 1.

We consider a matrix whose elements are linear operators. We denote the elements of the matrix as $L({}^{a}_{b}|z)_{i}^{j}$. The R-matrix and the L-matrix can also be depicted by Figs. 1 and 2.

The dynamical Yang–Baxter relation (DYBR) is written as (also see Fig. 3)

$$\sum_{i',j'}R(b|z_1-z_2)_{ij}^{i'j'}L({}^{a}_{b}|z_1)_{i'}^{i''}L({}^{a+\hat{i}''}_{b+\hat{i}'}|z_2)_{j'}^{j''}=\sum_{i',j'}L({}^{a}_{b}|z_2)_{j}^{j'}L({}^{a+\hat{j}'}_{b+\hat{j}}|z_1)_{i}^{i'}R(a|z_1-z_2)_{i'j'}^{i''j''},\tag{2}$$

where $b\equiv(m_0^b,m_1^b,\ldots,m_{n-1}^b)$, $a\equiv(m_0^a,m_1^a,\ldots,m_{n-1}^a)$. We note that Eq. (2) gives the quadratic relation of the elements of L. If we let $b=a+h$, the form of the equation will be the same as that given in Refs. 11 and 12, and the relation which L satisfies is the definition relation of the elliptic quantum group proposed by Felder and Varchenko. Here, the elements of the L-matrix are operators, and Eq. (2) is the algebra of these operators. In this article, we only discuss the minimal form

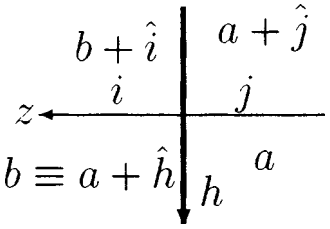

FIG. 2. The element of L-matrix, $L(a,h|z)^j_i \equiv L(^a_b|z)^j_i$.

of the operators, namely, we only consider the simplest case that all elements are c numbers. In this situation, the $L(^a_b|z)^j_i$ is scalar functions of (a,b,z,i,j). We will try to find the general form of such L-matrix. From Eq. (2), we have

$$\frac{L(^{a+\hat{i}'}_{b+\hat{i}}|z_1)^{i'}_i}{L(^a_b|z_1)^{i'}_i}=\frac{L(^{a+\hat{i}'}_{b+\hat{i}}|z_2)^{i'}_i}{L(^a_b|z_2)^{i'}_i}, \tag{3}$$

$$R(b|z_1-z_2)^{ii}_{ii}=R(a|z_1-z_2)^{i'j'}_{i'j'}\frac{L(^a_b|z_2)^{j'}_i}{L(^{a+\hat{i}'}_{b+\hat{i}}|z_2)^{j'}_i}\frac{L(^{a+\hat{j}'}_{b+\hat{i}}|z_1)^{i'}_i}{L(^a_b|z_1)^{i'}_i}$$

$$+R(a|z_1-z_2)^{i'j'}_{j'i'}\frac{L(^a_b|z_2)^{i'}_i}{L(^{a+\hat{i}'}_{b+\hat{i}}|z_2)^{j'}_i}\frac{L(^{a+\hat{i}'}_{b+\hat{i}}|z_1)^{j'}_i}{L(^a_b|z_1)^{i'}_i}\quad (i'\neq j'), \tag{4}$$

$$R(a|z_1-z_2)^{i'i'}_{i'i'}=R(b|z_1-z_2)^{ij}_{ij}\frac{L(^a_b|z_1)^{i'}_i}{L(^{a+\hat{i}'}_{b+\hat{j}}|z_1)^{i'}_i}\frac{L(^{a+\hat{i}'}_{b+\hat{i}}|z_2)^{i'}_j}{L(^a_b|z_2)^{i'}_j}$$

$$+R(b|z_1-z_2)^{ji}_{ij}\frac{L(^a_b|z_1)^{i'}_j}{L(^{a+\hat{i}'}_{b+\hat{j}}|z_1)^{i'}_i}\frac{L(^{a+\hat{i}'}_{b+\hat{j}}|z_2)^{i'}_i}{L(^a_b|z_2)^{i'}_j}\quad (i\neq j). \tag{5}$$

By solving Eqs. (4) and (5), we can determine $L(^a_b|z)^j_i$ as the function of z. Let

$$\frac{L(^a_b|z_2)^{j'}_i}{L(^{a+\hat{i}'}_{b+\hat{i}}|z_2)^{j'}_i}\equiv g(z_2),\quad \frac{L(^{a+\hat{j}'}_{b+\hat{i}}|z_1)^{i'}_i}{L(^a_b|z_1)^{i'}_i}\equiv h(z_1),\qquad \frac{L(^{a+\hat{i}'}_{b+\hat{i}}|z)^{j'}_i}{L(^a_b|z)^{i'}_i}\equiv f(z), \tag{6}$$

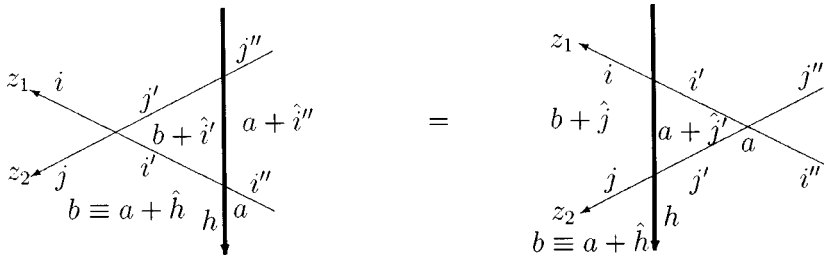

FIG. 3. The dynamical Yang–Baxter relation.

$$\frac{R(b|z_1-z_2)^{ii}_{ii}}{R(a|z_1-z_2)^{i'j'}_{i'j'}}\equiv A(z_1-z_2), \qquad -\frac{R(a|z_1-z_2)^{i'j'}_{j'i'}}{R(a|z_1-z_2)^{i'j'}_{i'j'}}\equiv B(z_1-z_2). \tag{7}$$

We then rewrite Eq. (4) as

$$g(z_2)h(z_1)=A(z_1-z_2)+B(z_1-z_2)f(z_1)/f(z_2)\equiv F(z_1,z_2). \tag{8}$$

We find that the left hand side of the above equation is factorized by the functions of z_1 and z_2. So taking logarithm to the both sides of the above equation and taking the derivative with respect to z_1 and z_2, we have

$$\frac{\partial^2}{\partial z_1\partial z_2}\ln F(z_1,z_2)=0. \tag{9}$$

Hence the above equation gives

$$F(z_1,z_2)\frac{\partial^2}{\partial z_1\partial z_2}F(z_1,z_2)-\frac{\partial}{\partial z_1}F(z_1,z_2)\frac{\partial}{\partial z_2}F(z_1,z_2)=0. \tag{10}$$

By using Eqs. (8) and (10), we can get an algebraic equation of second order about $f(z_1)$,

$$\begin{aligned} &f(z_1)^2[d_1f'(z_2)+d_2f(z_2)]+f(z_1)[d_3f'(z_2)^2+d_4f'(z_2)f(z_2)+d_5f(z_2)^2]\\ &\quad+d_6f'(z_2)f(z_2)^2+d_7f(z_2)^3=0, \end{aligned} \tag{11}$$

where d_i $(i=1, 2, \ldots, 7)$ are known functions of z_1-z_2. Define

$$y=\frac{f(z_1)}{f(z_2)},$$

$$\theta\equiv\frac{f'(z_2)}{f(z_2)}=\frac{\partial}{\partial z_2}\ln\left\{\frac{L(^{a+\hat{i}'}_{b+\hat{i}}|z_2)^{j'}_{i}}{L(^{a}_{b}|z_2)^{i'}_{i}}\right\}.$$

Then, Eq. (11) can be rewritten as

$$y^2(d_1\theta+d_2)+y(d_3\theta^2+d_4\theta+d_5)+(d_6\theta+d_7)=0. \tag{12}$$

When z_2 is fixed, the coefficients of Eq. (12) are the functions of z_1. So y is also a function of z_1. Since Eq. (12) is of second order, the y can only have two solutions $y_1(z_1,z_2)$ and $y_2(z_1,z_2)$ at most. If we can find two different L-matrices $L_1(^a_b|z)$ and $L_2(^a_b|z)$ which satisfy the DYBR with same θ, we must have $f(z_1)/f(z_2)=f_1(z_1)/f_1(z_2)$ or $f(z_1)/f(z_2)=f_2(z_1)/f_2(z_2)$, where f_1 and f_2 are obtained by the two different L's. Then, we can obtain $f(z_1)\sim f_1(z_1)$ or $f(z_1)\sim f_2(z_1)$, where ''$\sim$'' implies that, as the function of z_1, two sides of it can only be different with a constant respect to z_1. Thus, we can conclude that if there are two $L_i(^a_b|z)$ $(i=1,2)$ which satisfy the DYBR and are not proportional to each other, and when $z=z_2$, they have the same $\theta=\theta_1(z_2)=\theta_2(z_2)$, then every $f(z)$ related with $L(^a_b|z)$ satisfying $f'(z)/f(z)=\theta$ when $z=z_2$ must satisfy

$$f(z)=f_1(z)\text{const} \quad \text{or} \quad f(z)=f_2(z)\text{const}, \tag{13}$$

where the constants do not depend on z.

Now we consider the factorized L-matrix[14–17] which has an adjustable parameter δ. We will show that for the given z_2 and θ, there are generally two different δ's which can give $f'_{\delta_1}(z_2)/f_{\delta_1}(z_2)=f'_{\delta_2}(z_2)/f_{\delta_2}(z_2)=\theta$.

Considering the intertwiner of the Z_n Belavin model and the $A_{n-1}^{(1)}$ IRF model,[19,20] we have

$$\varphi^{(j)}_{a+\hat{i},a}(z)=\theta\begin{bmatrix}\frac{1}{2}-\frac{j}{n}\\ \frac{1}{2}\end{bmatrix}(z+n(a+\hat{i})_i,n\tau)\equiv\theta^{(j)}(nz_i),$$

$$(a+\hat{i})_i=w\left(m_i+1-\frac{1}{n}\sum_l(m_l+\delta_{il})+w_i\right)=a_i+w\left(1-\frac{1}{n}\right).$$

Define $\tilde{\varphi}^{(j)}_{a+\hat{\nu},a}(z)$ which satisfies

$$\sum_{j=0}^{n-1}\tilde{\varphi}^{(j)}_{a+\hat{\nu},a}(z)\varphi^{(j)}_{a+\hat{\mu},a}(z)=\delta_{\mu\nu}.$$

Let

$$\overline{L}_s\left(\begin{matrix}a\\ b\end{matrix}|z\right)^{\nu}_{\mu}=\sum_{j=0}^{n-1}\tilde{\varphi}^{(j)}_{a+\hat{\nu},a}(z)\varphi^{(j)}_{b+\hat{\mu},b}(z+s),\tag{14}$$

where s is an arbitrary parameter. Then by using the correspondence relation between face and vertex,[20] we can prove that the L-matrix above satisfies the DYBR Eq. (2). After some derivation, we have[17]

$$\overline{L}_s\left(\begin{matrix}a\\ b\end{matrix}|z\right)^{\nu}_{\mu}=\frac{\sigma(z+\Delta+(n-1)w-(n-1)/2+s/n+b_\mu-a_\nu)}{\sigma(z+\Delta+(n-1)w-(n-1)/2)}\prod_{j(\neq\nu)}\frac{\sigma(s/n+b_\mu-a_j)}{\sigma(a_\nu-a_j)}$$

with $\Delta=w\Sigma_j w_j$. Let $\delta=\Delta+(n-1)w-(n-1)/2+s/n=\delta(s)$, $\delta'=s/n$. Since $\sigma(z+\Delta+(n-1)w-(n-1)/2)$ is irrelevant with a,b,μ,ν, from the above formula, we can prove that

$$L_\delta\left(\begin{matrix}a\\ b\end{matrix}|z\right)^{\nu}_{\mu}=\overline{L}_s\left(\begin{matrix}a\\ b\end{matrix}|z\right)^{\nu}_{\mu}\sigma\left(z+\Delta+(n-1)w-\frac{n-1}{2}\right)=\sigma(z+\delta+b_\mu-a_\nu)\prod_{j\neq\nu}\frac{\sigma(\delta'+b_\mu-a_j)}{\sigma(a_\nu-a_j)}\tag{15}$$

also satisfy the DYBR [Eq. (2)].

Considering the definition of θ, we have

$$\theta(z)=\frac{f'_\delta(z)}{f_\delta(z)}=\frac{\sigma'(z+\delta+b_i-a_{j'}+w)}{\sigma(z+\delta+b_i-a_{j'}+w)}-\frac{\sigma'(z+\delta+b_i-a_{i'})}{\sigma(z+\delta+b_i-a_{i'})}.\tag{16}$$

By using the properties of the θ-function, one can show that for a given θ, there generally exist two different δ's satisfying Eq. (16).

From Eq. (13), we know that for the L-matrix which satisfies the DYBR,

$$f(z)\sim f_\delta(z)\tag{17}$$

must be held for certain δ. And from Eq. (8), we know that $g(z)$ and $h(z)$ can be determined completely by $f(z)$ up to a scale. So we have

$$g(z)\sim g_\delta(z),\quad h(z)\sim h_\delta(z).\tag{18}$$

Here the parameter δ is the same as that in Eq. (17). Then, from Eqs. (17) and (18), we have

$$\frac{L(^{a+\hat{i}'}_{b+\hat{i}}|z)^{j'}_{i}}{L(^{a}_{b}|z)^{i'}_{i}}\sim\frac{\sigma(z+\delta+b_i-a_{j'}+w)}{\sigma(z+\delta+b_i-a_{i'})}, \tag{19}$$

$$\frac{L(^{a+\hat{j}'}_{b+\hat{i}}|z)^{i'}_{i}}{L(^{a}_{b}|z)^{i'}_{i}}\sim\frac{\sigma(z+\delta+b_i-a_{i'}+w)}{\sigma(z+\delta+b_i-a_{i'})}, \tag{20}$$

$$\frac{L(^{a}_{b}|z)^{j'}_{i}}{L(^{a+\hat{i}'}_{b+\hat{i}}|z)^{j'}_{i}}\sim\frac{\sigma(z+\delta+b_i-a_{j'})}{\sigma(z+\delta+b_i-a_{j'}+w)}. \tag{21}$$

So from Eqs. (19) and (21), we can obtain

$$\frac{L(^{a}_{b}|z)^{j'}_{i}}{L(^{a}_{b}|z)^{i'}_{i}}\sim\frac{\sigma(z+\delta+b_i-a_{j'})}{\sigma(z+\delta+b_i-a_{i'})}. \tag{22}$$

In Eqs. (19)–(22), all δ's are the same. We note here that the δ may depend on i,i',j',a,b, but it does not depend on z, i.e., $\delta=\delta_i(abi'j')$. One sees from Eqs. (19), (20) and (22) $\delta_i(i'j')\cong\delta_i(j'i')\ (\mathrm{mod}\ \Lambda_\tau)$.

Similarly, from Eq. (5), we have

$$\frac{L(^{a+\hat{i}'}_{b+\hat{j}}|z)^{i'}_{i}}{L(^{a}_{b}|z)^{i'}_{j}}\sim\frac{\sigma(z+\delta+b_i-a_{i'}-w)}{\sigma(z+\delta+b_j-a_{i'})}, \tag{23}$$

$$\frac{L(^{a+\hat{i}'}_{b+\hat{i}}|z)^{i'}_{j}}{L(^{a}_{b}|z)^{i'}_{j}}\sim\frac{\sigma(z+\delta+b_j-a_{i'}-w)}{\sigma(z+\delta+b_j-a_{i'})}, \tag{24}$$

$$\frac{L(^{a+\hat{i}'}_{b+\hat{j}}|z)^{i'}_{i}}{L(^{a}_{b}|z)^{i'}_{i}}\sim\frac{\sigma(z+\delta+b_i-a_{i'}-w)}{\sigma(z+\delta+b_i-a_{i'})}, \tag{25}$$

$$\frac{L(^{a}_{b}|z)^{i'}_{j}}{L(^{a}_{b}|z)^{i'}_{i}}\sim\frac{\sigma(z+\delta+b_j-a_{i'})}{\sigma(z+\delta+b_i-a_{i'})}. \tag{26}$$

Here the dependence of the δ's are similar with the former. We also have $\delta=\delta^{i'}(abij)$ and $\delta^{i'}(ij)\cong\delta^{i'}(ji)\ (\mathrm{mod}\ \Lambda_\tau)$.

III. DEPENDENCE OF ELEMENTS OF *L*-MATRIX WITH SPECTRAL PARAMETER *z*

In this section, we study the dependence of $L(^{a}_{b}|z)^{j}_{i}$ with respect to z. It is found that there are only five possible forms of L-matrices in the whole lattice. We prove this in the following steps.

Step 1: Assume $i\neq i'$, $j\neq j'$. From Eqs. (22) and (26), we have

$$\frac{L(^{a}_{b}|z)^{j}_{i}}{L(^{a}_{b}|z)^{j'}_{i'}}=\frac{L(^{a}_{b}|z)^{j}_{i}L(^{a}_{b}|z)^{j'}_{i'}}{L(^{a}_{b}|z)^{j'}_{i}L(^{a}_{b}|z)^{j'}_{i'}}\sim\frac{\sigma(z+\delta_i+b_i-a_j)}{\sigma(z+\delta_i+b_i-a_{j'})}\frac{\sigma(z+\delta^{j'}+b_i-a_{j'})}{\sigma(z+\delta^{j'}+b_{i'}-a_{j'})}, \tag{27}$$

$$\frac{L(^{a}_{b}|z)^{j}_{i}}{L(^{a}_{b}|z)^{j'}_{i'}}=\frac{L(^{a}_{b}|z)^{j}_{i}L(^{a}_{b}|z)^{j}_{i'}}{L(^{a}_{b}|z)^{j}_{i'}L(^{a}_{b}|z)^{j'}_{i'}}\sim\frac{\sigma(z+\delta^{j}+b_i-a_j)}{\sigma(z+\delta^{j}+b_{i'}-a_j)}\frac{\sigma(z+\delta_{i'}+b_{i'}-a_j)}{\sigma(z+\delta_{i'}+b_{i'}-a_{j'})}, \tag{28}$$

giving

$$\frac{\sigma(z+\delta_i+b_i-a_j)}{\sigma(z+\delta_i+b_i-a_{j'})}\frac{\sigma(z+\delta_{i'}+b_{i'}-a_{j'})}{\sigma(z+\delta_{i'}+b_{i'}-a_j)}\frac{\sigma(z+\delta^{j'}+b_i-a_{j'})}{\sigma(z+\delta^{j'}+b_{i'}-a_{j'})}\frac{\sigma(z+\delta^{j}+b_{i'}-a_j)}{\sigma(z+\delta^{j}+b_i-a_j)}$$

$$\equiv\frac{(1)\ (2)\ (3)\ (4)}{(1')(2')(3')(4')}\sim 1, \tag{29}$$

where

$$\delta_i=\delta_i(a,b,j,j'),\quad \delta^j=\delta^j(a,b,i,i'),$$

$$\delta_{i'}=\delta_{i'}(a,b,j,j'),\quad \delta^{j'}=\delta^{j'}(a,b,i,i').$$

Obviously in Eq. (29), the zeroes of the numerator must coincide with those of the denominator. From this fact and noticing that a_j and $a_{j'}$, b_i and b_i' are generic complex numbers, we analyze all cases and obtain

$$\delta_i-\delta_{i'}\cong K(b_{i'}-b_i)\quad\text{and}\quad \delta^j-\delta^{j'}\cong K(a_j-a_{j'}),\quad K=0,1,2, \tag{30}$$

where $\delta_i=\delta_i(j\ j')$, $\delta_{i'}=\delta_{i'}(j\ j')$, $\delta^j=\delta^j(i\ i')$, $\delta^{j'}=\delta^{j'}(i\ i')$ and $K=K(i\ i'\ j\ j')$. From Eq. (29), we also have

$$\delta_i\cong\delta^{j'}\cong\delta_{i'}\cong\delta^j,\quad\text{when}\ \ K=0, \tag{31}$$

$$\delta_i(j\ \ j')-\delta^{j'}(i\ \ i')\cong b_{i'}-b_i+a_j-a_{j'},\quad\text{when}\ \ K=2. \tag{32}$$

Step 2: Since the dimension $n\geqslant 4$, we may choose three different i_1,i_2,i_3 and substitute $\{i_1,i_2\}$, $\{i_2,i_3\}$, $\{i_1,i_3\}$ as $\{i,i'\}$ into Eq. (30). This leads to the conclusion that K is independent of the indices i,i',j and j'.

These are the rules for the differences between $\delta_i(jj')$ and $\delta_{i'}(jj')$ and for the differences between $\delta^j(ii')$ and $\delta^{j'}(ii')$.

Step 3: Now let us study the differences between $\delta_i(j_1j_2)$ and $\delta_i(j_3j_4)$. Consider different indices j_1, j_2, j_3. We have from Eq. (22)

$$\frac{L(^a_b|z)^{j_1}_i}{L(^a_b|z)^{j_2}_i}\frac{L(^a_b|z)^{j_2}_i}{L(^a_b|z)^{j_3}_i}\sim\frac{\sigma(z+\delta_i(j_1j_2)+b_i-a_{j_1})}{\sigma(z+\delta_i(j_1j_2)+b_i-a_{j_2})}\frac{\sigma(z+\delta_i(j_2j_3)+b_i-a_{j_2})}{\sigma(z+\delta_i(j_2j_3)+b_i-a_{j_3})},$$

$$LHS=\frac{L(^a_b|z)^{j_1}_i}{L(^a_b|z)^{j_3}_i}\sim\frac{\sigma(z+\delta_i(j_1j_3)+b_i-a_{j_1})}{\sigma(z+\delta_i(j_1j_3)+b_i-a_{j_3})}.$$

This implies

$$\frac{\sigma(z+\delta_i(j_1j_2)+b_i-a_{j_1})}{\sigma(z+\delta_i(j_1j_2)+b_i-a_{j_2})}\frac{\sigma(z+\delta_i(j_2j_3)+b_i-a_{j_2})}{\sigma(z+\delta_i(j_2j_3)+b_i-a_{j_3})}\frac{\sigma(z+\delta_i(j_1j_3)+b_i-a_{j_3})}{\sigma(z+\delta_i(j_1j_3)+b_i-a_{j_1})}$$

$$\equiv\frac{(1)\ (2)\ (3)}{(1')\ (2')\ (3')}\sim 1.$$

From this equation, we obtain

$$\delta_i(j_1j_2)-k(a_{j_1}+a_{j_2})\cong\delta_i(j_2j_3)-k(a_{j_2}+a_{j_3})\cong\delta_i(j_1j_3)-k(a_{j_1}+a_{j_3}),\quad k=0,1, \tag{33}$$

where $k=k(ij_1j_2j_3)$.

Step 4: Consider unequal j_a, j_b, j_c, j_d, and substitute $\{j_a, j_b, j_c\}, \{j_b, j_c, j_d\}, \{j_a, j_c, j_d\}$ as $\{j_1, j_2, j_3\}$ into Eq. (33), we may show that k is also independent of the indices.

Therefore, from Eqs. (30) and (33), we conclude that one can always find a number C independent of indices $i\ j\ j'$ such that

$$C \cong \delta_i(jj') - k_0(a_j + a_{j'}) + Kb_i. \tag{34}$$

Similarly, we also find a number D satisfying

$$D \cong \delta^j(ii') + k^0(b_i + b_{i'}) - Ka_j, \tag{35}$$

where D, K, k_0, k^0 are independent of indices, and are fixed for a given lattice point (a,b).

Step 5: In the following, we discuss the cases $K=0$ and 2. For $K=0$, one has from Eqs. (30), (31), (34) and (35),

$$\delta_i(jj') \cong C + k_0(a_j + a_{j'}) \cong \delta^j(ii') \cong D - k^0(b_i + b_{i'}) \Rightarrow D - C = k_0(a_j + a_{j'}) + k^0(b_i + b_{i'}).$$

Thus, the k_0 and k^0 must be zero since C and D are independent of the indices. We have

$$\delta \cong C \cong D \cong \delta_i \cong \delta^j. \tag{36}$$

When $K=2$, from Eq. (32), we can find a number E satisfying

$$E \cong C \cong D \quad \text{and} \quad k_0 = k^0 = 1. \tag{37}$$

Step 6: We next study the relations for C, D, K, k_0, K^0 between adjacent lattice point (a,b) and $(a+\hat{i}', b+\hat{i})$. Equations (19) and (23) intertwine two lattice points. Notice that in Eqs. (19)–(22) [or in Eqs. (23)–(26)] the δ's are the same. By using these equations, we can prove that k, k_0, k^0 are unchanged for adjacent lattice points while

$$C(a+\hat{i}', b+\hat{i}) - C(a,b) = C' - C \cong -k_0 w\left(1 - \frac{2}{n}\right) + Kw\left(1 - \frac{1}{n}\right), \tag{38}$$

$$D(a+\hat{i}', b+\hat{i}) - D(a,b) = D' - D \cong k^0 w\left(1 - \frac{2}{n}\right) - Kw\left(1 - \frac{1}{n}\right). \tag{39}$$

These equations imply that Eq. (37) cannot be realized in two adjacent lattice points. Thus $K=2$ must be discarded.

According to K, k_0, k^0, when (a,b) is given, the elements of the L-matrix can take five forms.

(1) Form A(1). $K=1$, $k_0 = k^0 = 0$, from Eqs. (22), (34) and (35), we have

$$\frac{L\left(\begin{smallmatrix} a \\ b \end{smallmatrix}|z\right)_i^j}{L\left(\begin{smallmatrix} a \\ b \end{smallmatrix}|z\right)_i^0} \sim \frac{\sigma(z + \delta_i(0j) + b_i - a_j)}{\sigma(z + \delta_i(0j) + b_i - a_0)} \sim \frac{\sigma(z + C - b_i + b_i - a_j)}{\sigma(z + C - b_i + b_i - a_0)} = \frac{\sigma(z + C - a_j)}{\sigma(z + C - a_0)},$$

and from Eq. (26), we have

$$\frac{L\left(\begin{smallmatrix} a \\ b \end{smallmatrix}|z\right)_i^0}{L\left(\begin{smallmatrix} a \\ b \end{smallmatrix}|z\right)_0^0} \sim \frac{\sigma(z + \delta^0(i0) + b_i - a_0)}{\sigma(z + \delta^0(i0) + b_0 - a_0)} \sim \frac{\sigma(z + D + a_0 + b_i - a_0)}{\sigma(z + D + a_0 + b_0 - a_0)} = \frac{\sigma(z + D + b_i)}{\sigma(z + D + b_0)}.$$

Therefore, we obtain

$$L\left(\begin{smallmatrix} a \\ b \end{smallmatrix}|z\right)_i^j \sim \frac{\sigma(z + C - a_j)}{\sigma(z + C - a_0)} \frac{\sigma(z + D + b_i)}{\sigma(z + D + b_0)} L\left(\begin{smallmatrix} a \\ b \end{smallmatrix}|z\right)_0^0 \sim \sigma(z + C - a_j)\sigma(z + D + b_i) F\left(\begin{smallmatrix} a \\ b \end{smallmatrix}|z\right). \tag{40}$$

By using Eqs. (27), (34) and (35), we can similarly derive other forms as follows.
(2) Form A(2). $K=1$, $k_0=0$, $k^0=1$, we have

$$L\left(\begin{smallmatrix}a\\b\end{smallmatrix}|z\right)_i^j \sim \frac{\sigma(z+C-a_j)}{\sigma(z+D-b_i)} F\left(\begin{smallmatrix}a\\b\end{smallmatrix}|z\right). \tag{41}$$

(3) Form A(3). $K=1$, $k_0=1$, $k^0=1$, we have

$$L\left(\begin{smallmatrix}a\\b\end{smallmatrix}|z\right)_i^j \sim \frac{1}{\sigma(z+C+a_j)\sigma(z+D-b_i)} F\left(\begin{smallmatrix}a\\b\end{smallmatrix}|z\right). \tag{42}$$

(4) Form A(4). $K=1$, $k_0=1$, $k^0=0$, we have

$$L\left(\begin{smallmatrix}a\\b\end{smallmatrix}|z\right)_i^j \sim \frac{\sigma(z+D+b_i)}{\sigma(z+C+a_j)} F\left(\begin{smallmatrix}a\\b\end{smallmatrix}|z\right). \tag{43}$$

(5) Form B. $K=0$, $k_0=0$, $k^0=0$; from Eqs. (27) and (36), one obtains

$$L\left(\begin{smallmatrix}a\\b\end{smallmatrix}|z\right)_i^j \sim \sigma(z+\delta+b_i-a_j) F\left(\begin{smallmatrix}a\\b\end{smallmatrix}|z\right). \tag{44}$$

The relation of $F(z)$ between adjacent lattice points (a,b) and (a',b') is discussed in Appendix A.

In conclusion, there can be at most five classes of L-matrices in the whole lattice. Each of them is of the same form at all lattice points.

We must check if these inductive relations are integrable in the whole lattice. That is, if one goes from (a,b) to $(a''=a+\hat{i}'+\hat{j}', b''=b+\hat{i}+\hat{j})$ via different paths, the resulting C'' D'' $F''(z)$ should be the same. The conclusion is affirmative.

For $a\equiv(m_0,m_1,\ldots,m_{n-1})$, define $m\equiv\Sigma_i m_i$. Thus $m(a'=a+\hat{i}', b'=b+\hat{i})=m(a,b)+1$. We can express five forms as follows, which satisfy all relations of adjacent lattice points,
(1) Form A(1). Let $C=C_0+mw(1-1/n)$, $D=D_0-mw(1-1/n)$. Then

$$L\left(\begin{smallmatrix}a\\b\end{smallmatrix}|z\right)_k^l \sim \sigma\left(z+C_0+mw\left(1-\frac{1}{n}\right)-a_l\right)\sigma\left(z+D_0-mw\left(1-\frac{1}{n}\right)+b_k\right)F_0(z) \tag{45}$$

and C_0, D_0, $F_0(z)$ are unchanged in the whole lattice.
(2) Form A(2). Let

$$C=C_0+mw\left(1-\frac{1}{n}\right), \qquad D=D_0-m\frac{w}{n},$$

$$F(z)=F_0(z)\prod_{j=0}^{n-1}\sigma\left(z+D_0-m\frac{w}{n}-b_j\right).$$

We then have

$$\frac{F'(z)}{F(z)}=\frac{\sigma(z+D_0-(m+1)\,w/n-b_i-w(1-1/n))}{\sigma(z+D_0-m\,w/n-b_i)}=\frac{\sigma(z+D-b_i-w)}{\sigma(z+D-b_i)}.$$

Thus,

$$L\left(\begin{smallmatrix}a\\b\end{smallmatrix}|z\right)_k^l \sim \sigma\left(z+C_0+mw\left(1-\frac{1}{n}\right)-a_l\right)\prod_{j(\neq k)}\sigma\left(z+D_0-m\frac{w}{n}-b_j\right)F_0(z) \tag{46}$$

and C_0, D_0, $F_0(z)$ are unchanged in the whole lattice.

(3) Form A(3). Let

$$C=C_0+m\frac{w}{n},\qquad D=D_0-m\frac{w}{n},$$

$$F(z)=F_0(z)\prod_{j=0}^{n-1}\sigma\left(z+C_0+m\frac{w}{n}+a_j\right)\sigma\left(z+D_0-m\frac{w}{n}-b_j\right).$$

We then have

$$\frac{F'(z)}{F(z)}=\frac{\sigma(z+C+a_{i'}+w)}{\sigma(z+C+a_{i'})}\frac{\sigma(z+D-b_i-w)}{\sigma(z+D-b_i)}.$$

Thus,

$$L\left(\begin{smallmatrix}a\\b\end{smallmatrix}|z\right)_k^l\sim\prod_{j(\neq l)}\sigma\left(z+C_0+m\frac{w}{n}+a_j\right)\prod_{j(\neq k)}\sigma\left(z+D_0-m\frac{w}{n}-b_j\right)F_0(z) \tag{47}$$

and C_0, D_0, $F_0(z)$ are unchanged in the whole lattice.

(4) Form A(4). Let

$$C=C_0+m\frac{w}{n},\qquad D=D_0-mw\left(1-\frac{1}{n}\right),$$

$$F(z)=F_0(z)\prod_{j=0}^{n-1}\sigma\left(z+C_0+m\frac{w}{n}+a_j\right).$$

We then have

$$L\left(\begin{smallmatrix}a\\b\end{smallmatrix}|z\right)_k^l\sim\sigma\left(z+D_0-mw\left(1-\frac{1}{n}\right)+b_k\right)\prod_{j(\neq l)}\sigma\left(z+C_0+m\frac{w}{n}+a_j\right)F_0(z) \tag{48}$$

and C_0, D_0, $F_0(z)$ are unchanged in the whole lattice.

(5) Form B.

$$L\left(\begin{smallmatrix}a\\b\end{smallmatrix}|z\right)_k^l\sim\sigma(z+\delta_0+b_k-a_l)F_0(z) \tag{49}$$

and δ_0, $F_0(z)$ are unchanged in the whole lattice.

Thus we can establish the L-matrix in the whole lattice, if we can properly choose the coefficients of the elements of L-matrix. We will discuss this problem in the next section.

IV. THE COEFFICIENTS IRRELEVANT WITH *z* OF THE ELEMENTS OF *L*-MATRIX

In this section, we study the sufficient condition of L-matrices for DYBR and derive the equations satisfied by the coefficients irrelevant with z of the elements of L-matrix.

As an example, we study the form B which is useful in the later. From Eq. (44) for the form B, the L-matrix takes the form

$$L\left(\begin{smallmatrix}a\\b\end{smallmatrix}|z\right)_i^j=\left(\begin{smallmatrix}a\\b\end{smallmatrix}\right)_i^j\sigma(z+\delta+b_i-a_j)F(z), \tag{50}$$

$$L\left(\begin{smallmatrix}a+\hat{i}'\\b+\hat{i}\end{smallmatrix}|z\right)_j^{j'}=\left(\begin{smallmatrix}a+\hat{i}'\\b+\hat{i}\end{smallmatrix}\right)_j^{j'}\sigma(z+\delta+b'_j-a'_{j'})F(z). \tag{51}$$

Then, substituting the above equation and Eq. (1) for the R-matrix into the DYBR Eq. (2) and noticing the fact

$$a'_{j'}=a_{j'}+w\left(\delta_{i'j'}-\frac{1}{n}\right),\quad b'_j=b_j+w\left(\delta_{ij}-\frac{1}{n}\right)\quad(\text{for } a'=a+\hat{i}',\ b'=b+\hat{i}),$$

we obtain the equations for the coefficients:

$$\binom{a}{b}_i^{i'}\binom{a+\hat{i}'}{b+\hat{i}}_i^{i'}=\binom{a}{b}_i^{i'}\binom{a+\hat{i}'}{b+\hat{i}}_i^{i'},\tag{52}$$

which is trivially satisfied, and

$$\binom{a}{b}_i^{i'}\binom{a+\hat{i}'}{b+\hat{i}}_{i'}^{j'}-\frac{\sigma(a_{i'j'}-w)}{\sigma(a_{i'j'}+w)}\binom{a}{b}_i^{j'}\binom{a+\hat{j}'}{b+\hat{i}}_i^{i'}=0\quad(i'\neq j'),\tag{53}$$

$$\binom{a}{b}_i^{i'}\binom{a+\hat{i}'}{b+\hat{i}}_j^{i'}-\binom{a}{b}_j^{i'}\binom{a+\hat{i}'}{b+\hat{j}}_i^{i'}=0\quad(i\neq j),\tag{54}$$

$$\begin{aligned}&\binom{a}{b}_j^{i'}\binom{a+\hat{i}'}{b+\hat{j}}_i^{j'}\sigma(a_{i'j'}+b_{ij})\sigma(w)+\binom{a}{b}_i^{i'}\binom{a+\hat{i}'}{b+\hat{i}}_j^{j'}\sigma(b_{ij}-w)\sigma(a_{i'j'})\\&-\binom{a}{b}_j^{j'}\binom{a+\hat{j}'}{b+\hat{j}}_i^{i'}\sigma(a_{i'j'}-w)\sigma(b_{ij})=0\quad(i\neq j,\ i'\neq j'),\end{aligned}\tag{55}$$

respectively. In the derivation, we have used the addition formula

$$\begin{aligned}&\sigma(u+x)\sigma(u-x)\sigma(v+y)\sigma(v-y)-\sigma(u+y)\sigma(u-y)\sigma(v+x)\sigma(v-x)\\&=\sigma(u+v)\sigma(u-v)\sigma(x+y)\sigma(x-y).\end{aligned}\tag{56}$$

Define

$$\begin{aligned}&\binom{a}{b}_i^{i'}\times\prod_{l(\neq i')}\sigma(a_l-a_{i'})=\left[\begin{smallmatrix}a\\b\end{smallmatrix}\right]_i^{i'},\\&\left[\begin{smallmatrix}a\\b\end{smallmatrix}\right]_i^{i'}\left[\begin{smallmatrix}a+\hat{i}'\\b+\hat{i}\end{smallmatrix}\right]_{j'}^{j'}=Y_i^{i'j'}{}_{j'}.\end{aligned}\tag{57}$$

Then for form B, we rewrite Eqs. (53)–(55) as

$$Y_i^{i'j'}{}_{i'}-Y_i^{j'i'}{}_{i'}=0\quad(i'\neq j'),\tag{58}$$

$$Y_i^{i'i'}{}_{j'}-Y_j^{i'i'}{}_{i'}=0\quad(i\neq j),\tag{59}$$

$$\sigma(w)\sigma(a_{i'j'}+b_{ij})Y_j^{i'j'}{}_{i'}+\sigma(a_{i'j'})\sigma(b_{ij}-w)Y_i^{i'j'}{}_{j'}-\sigma(a_{i'j'}+w)\sigma(b_{ij})Y_j^{j'i'}{}_{i'}=0\quad(i\neq j,\ i'\neq j').\tag{60}$$

With the same procedure, one can also show that all A forms [forms A(1)–A(4)] share common coefficient relations

$$Y_i^{i'j'}{}_{i'}-\frac{\sigma(a_{i'j'}-w)}{\sigma(a_{i'j'}+w)}Y_i^{j'i'}{}_{i'}=0\quad(i'\neq j'),\tag{61}$$

$$Y_i^{i'i'}{}_{j'}-Y_j^{i'i'}{}_{i'}=0\quad(i\neq j),\tag{62}$$

$$Y_j^{i'j'}{}_{i'}=Y_i^{i'j'}{}_{j'}=\frac{\sigma(a_{i'j'}-w)}{\sigma(a_{i'j'}+w)}Y_j^{j'i'}{}_{i'}\quad(i\neq j,\ i'\neq j').\tag{63}$$

For the coefficients of form A(i) ($i=1,2,3,4$), we can easily find the rule. Consider a function $G(a,b)$ on a lattice points ($a=\Sigma_j m_j^a \hat{j}, b=\Sigma_i m_i^b \hat{i}$). From the lattice (a,b), by using the relation $G(a+\hat{i}',b+\hat{i})=G(a,b)[{}_b^a]_i^{i'}$, we can construct the function on the other lattice point. Because of Eqs. (61)–(63), we can obtain the same $G(a+\hat{i}'+\hat{j}',b+\hat{i}+\hat{j})$ through different paths from (a,b) to $(a+\hat{i}'+\hat{j}',b+\hat{i}+\hat{j})$. So this procedure is integrable. This implies that there must exist a function $G(a,b)$ which can determine $[{}_b^a]_i^{i'}$ with

$$[{}_b^a]_i^{i'}=G(a+\hat{i}',b+\hat{i})/G(a,b). \tag{64}$$

Hence, we can solve the problem of form A completely. However, to the coefficients of the form B, its rule is more complicated and we will discuss it in the next section.

Obviously, if we take a gauge transformation

$$[{}_b^a]_i^j \to \overline{[{}_b^a]}_i^j = [{}_b^a]_i^j \frac{g(a+\hat{j},b+\hat{i})}{g(a,b)},$$

and if $[{}_b^a]_i^j$ satisfies Eqs. (61)–(63), $\overline{[{}_b^a]}_i^j$ also satisfies these equations. In this sense, all form A coefficients are gauge equivalent to a constant.

V. THE ALGEBRA FOR FORM B COEFFICIENTS

A. The PBW base of the algebra

In this section, we give the PBW base of the algebra for form B coefficients. The main result is Theorem 1. We also give the center of this algebra. Equations (58)–(60) can be regarded as the algebraic relations which are satisfied by the operators in the lattice ($a=\Sigma_{j=0}^{n-1} m_j^a \hat{j}, b=\Sigma_{i=0}^{n-1} m_i^b \hat{i}$). We define a new operator

$$A_i^{i'} \equiv [{}_b^a]_i^{i'} \Gamma_i^{i'}, \tag{65}$$

where

$$\Gamma_i^{i'} f(a,b) = f(a+\hat{i}',b+\hat{i}) \Gamma_i^{i'}. \tag{66}$$

Namely, we regard the a,b as operators; $\Gamma_i^{i'}$ is not commutative with the function of a,b. In this way, we have the following exchange relations of the operators $\{A_i^{i'}\}$

$$A_i^{i'} A_i^{j'} = A_i^{j'} A_i^{i'} \qquad (i' \neq j'), \tag{67a}$$

$$\sigma(a_{i'j'}+w)\sigma(b_{ij}) A_j^{j'} A_i^{i'} = \sigma(a_{i'j'})\sigma(b_{ij}-w) A_i^{i'} A_j^{j'} + \sigma(w)\sigma(a_{i'j'}+b_{ij}) A_j^{i'} A_i^{j'} \qquad (i \neq i',\ j \neq j'), \tag{67b}$$

$$A_i^{i'} A_j^{i'} = A_j^{i'} A_i^{i'} \qquad (i \neq j). \tag{67c}$$

These equations are equivalent relations to the Felder and Varchenko elliptic quantum algebra under special condition. It is worth noting that in Eq. (67b), the coefficients should be regarded as the functions of operators and they do not commute with A_i^j. These equations are irrelevant with the parameter z. This situation is similar to the relation between the Sklyanin algebra[21–25] and the YBR of the Belavin model.[26–28] In formulation, Eq. (67b) is also similar to the function R-matrices given by Shibukawa and Ueno.[18]

Using the (a) and (b) of Eq. (67), we can exchange the order of the up-indices of a pair of operators $A_i^{j'} A_j^{i'}$. So $A_i^{j'} A_j^{i'}$ can be written as linear combination of $A_i^{i'} A_j^{j'}$ and $A_j^{i'} A_i^{j'}$. Therefore,

we can write the product of three operators $A_i^{i'}A_j^{j'}A_k^{k'}$ as the linear combination of $A_\cdot^{k'}A_\cdot^{j'}A_\cdot^{i'}$. This procedure can be done in two different ways. For the two ways, by using Eqs. (58)–(60), we can show that according to the rules (67a) and (67b) [we will simplify it as (ab)], if the product of three operators $A_i^{i'}A_j^{j'}A_k^{k'}$ is changed to the linear combination of $A_\cdot^{k'}A_\cdot^{j'}A_\cdot^{i'}$ by two different paths, their results are equal. The paths are as follows:

$$(A)\quad i'j'k'\to i'k'j'\to k'i'j'\to k'j'i',$$

$$(B)\quad i'j'k'\to j'i'k'\to j'k'i'\to k'j'i'.$$

In the above transformation, we think that the result of the (ab) transformation on two adjacent operators with the same up-indices does not change the order of them, namely, $A_i^{i'}A_j^{i'}\Rightarrow A_i^{i'}A_j^{i'}$. And we think the associative and the distributive law are satisfied in the transformation.

Furthermore, if we consider the rule (67c), the linear expansions of operator products $A_i^{i'}A_j^{j'}A_k^{j'}$ and $A_i^{i'}A_k^{j'}A_j^{j'}$ by $A_\cdot^{j'}A_\cdot^{j'}A_\cdot^{i'}$ via the (ab) transformation are equal. Therefore, we also call this fact the Yang–Baxter equation (YBE).

Similarly, after $A_i^{j'}A_j^{j'}A_k^{i'}$ and $A_j^{j'}A_i^{j'}A_k^{i'}$ change to the linear combination of the $A_\cdot^{i'}A_\cdot^{j'}A_\cdot^{j'}$ by (ab), these two expansion are equal via the rule (67c).

For the coefficient algebra (or Yang–Baxter algebra) which we discussed above, we will give it a PBW base in the following. We first give some definitions for establishing the base.

Definition 1: Bunch: A bunch is a polynomial (or monomial) of operator A's, in which all terms have the same number of A's and the upper indices of A's in all terms are arranged in the same way.

Example:

$$B=\sum_{i_1i_2i_3i_4} C_{i_1i_2i_3i_4}A_{i_1}^{j_1}A_{i_2}^{j_2}A_{i_3}^{j_3}A_{i_4}^{j_4}$$

is a bunch. A polynomial is always a bunch.

Definition 2: Inverse order number: To any two integers i',j' with a given order, we say the inverse order number is 1 if $i'>j'$ and it is 0 if $i'\leqslant j'$. And the inverse order number of a successive product $A_\cdot^{i'}A_\cdot^{j'}A_\cdot^{k'}\cdots$ is the sum of the inverse order numbers of all up-index pairs.

Definition 3: Normal order product: The (ab) normal order product is a successive product of operators in which the up-indices are arranged from smaller to bigger when inspecting from the left to the right, while the arrangement of the down-indices can be arbitrary. The (abc) normal order product is that the up-indices are arranged from the smaller to the bigger and the down-indices of the operators with the same up-indices are also arranged from smaller to bigger. Their inverse order numbers are zero.

Example: $A_2^1A_1^1A_1^2A_3^2A_5^3A_1^4A_3^5A_1^5$ is an (ab) normal order product but is not an (abc) normal order product. By using the rule (67c), we can change it to the (abc) normal order product $A_1^1A_2^1A_1^2A_3^2A_5^3A_1^4A_1^5A_3^5$.

Definition 4: Normal order expansion: The (ab) normal order expansion of a polynomial of A's is a procedure in which we change each term of the polynomial into a bunch of (ab) normal order products by only using rules (67a) and (67b). We also call the final resulting polynomial as the (ab) normal expansion of the original polynomial.

The (abc) normal order expansion is a procedure, in which we first perform the (ab) normal order expansion and then we rearrange each term of the resulting polynomial into (abc) normal order product by using rule (67c). We also call the final result as an (abc) normal expansion of the original polynomial.

Then, we have a theorem.

Theorem 1: *Transforming on a polynomial of operators A_i^j by using the rules (abc) of Eq. (67) does not change its (abc) normal order expansion.*

It is worth noting that the coefficients of the expansions are functions of the parameters $\{a,b\}$, and they do not commute with operator A_i^j.

The detailed proof of the theorem will be given in Appendix B.

Corollary: The (abc) normal order products are linearly independent.

Proof: If there were a linear relation $\Sigma C_i g_i=0$, where g_i are (abc) normal order products, the LHS must be able to be changed to zero via Eq. (67). However, each operation does not change the (abc) expansion. Thus it is impossible since C_i are not all zero. □

Thus the set of all (abc) normal order products is the PBW base of the algebra defined by Eq. (67).

B. The center of the algebra

By standard procedure, we may obtain the center of elliptic quantum group (the detail will be given elsewhere),

$$I=\frac{\Delta(a)}{\Delta(b)}\mathrm{Det}\ L\left(\begin{smallmatrix}a\\b\end{smallmatrix}|z\right),$$

where $\Delta(a)=\Pi_{i<j}\sigma(a_{ij}),\Delta(b)=\Pi_{i<j}\sigma(b_{ij})$,

$$\mathrm{Det}\ L\left(\begin{smallmatrix}a\\b\end{smallmatrix}|z\right)=\sum_P (-1)^{[\mathrm{Sign}P\left(\begin{smallmatrix}0&1&\cdots&n-1\\ \mu_0&\mu_1&\cdots&\mu_{n-1}\end{smallmatrix}\right)]}\ L\left(\begin{smallmatrix}a\\b\end{smallmatrix}|z\right)^0_{\mu_0}L\left(\begin{smallmatrix}a+\hat{0}\\b+\hat{\mu}_0\end{smallmatrix}|z+w\right)^1_{\mu_1}\cdots L\left(\begin{smallmatrix}a+\hat{0}+\hat{1}+\cdots+\widehat{n-2}\\b+\hat{\mu}_0+\hat{\mu}_1+\cdots+\hat{\mu}_{n-2}\end{smallmatrix}|z+(n-1)w\right)^{n-1}_{\mu_{n-1}},$$

and P's are permutations of integers 0, 1, …, $n-1$. This agrees with that of Ref. 12 for $n=2$.

In the case of

$$L\left(\begin{smallmatrix}a\\b\end{smallmatrix}|z\right)^{i'}_i=\sigma(z+\delta+b_i-a_{i'})A_i^{i'},$$

the quantum determinant can be written as

$$I\left(\begin{smallmatrix}a\\b\end{smallmatrix}|z\right)=\sum_P (-1)^{[\mathrm{Sign}P\left(\begin{smallmatrix}0&1&\cdots&n-1\\ \mu_0&\mu_1&\cdots&\mu_{n-1}\end{smallmatrix}\right)]}\sigma(z+\delta+b_{\mu_0}-a_0)\sigma(z+w+\delta+b_{\mu_1}-a_1)\cdots$$
$$\times\sigma(z+(n-1)w+\delta+b_{\mu_{n-1}}-a_{n-1})A^0_{\mu_0}A^1_{\mu_1}\cdots A^{n-1}_{\mu_{n-1}}.$$

It is easy to check

$$\Phi(z)_{\mu_0\cdots\mu_{n-1}}\equiv\sigma(z+\delta+b_{\mu_0}-a_0)\cdots\sigma(z+(n-1)w+\delta+b_{\mu_{n-1}}-a_{n-1})$$

is quasi-doubly periodic in τ and 1:

$$\Phi(z+1)=(-1)^n\Phi(z),$$

$$\Phi(z+\tau)=\exp\left[-2\pi i\left(\frac{n\tau}{2}+n\delta+nz+\frac{n(n-1)}{2}w+\frac{n}{2}+\sum_i b_{\mu_i}-\sum_i a_i\right)\right]\Phi(z)$$
$$=\exp\left[-2\pi i\left(\frac{n\tau}{2}+n\delta+nz+\frac{n(n-1)}{2}w+\frac{n}{2}\right)\right]\Phi(z)$$

for all $\mu_0,\ldots,\mu_{n-1}$ being a permutation of $(0,1,\ldots,n-1)$. Therefore, from a theorem of such function (see Ref. 29), we have

$$\Phi(z)_{\mu_0,\ldots,\mu_{n-1}}=\sum_{i=0}^{n-1} C^i_{\mu_0,\ldots,\mu_{n-1}} f_i(z), \tag{68}$$

where $\{f_i(z)\}$ are base functions of the space of such quasi-double periodic function. For example, we may choose

$$f_i(z)=\theta\begin{bmatrix}\frac{1}{2}-\frac{i}{n}\\ \frac{1}{2}\end{bmatrix}\left(nz+n\delta+\frac{n(n-1)w}{2}+\frac{n-1}{2},\ n\tau\right).$$

One can obtain $C^i_{\mu_0,\ldots,\mu_{n-1}}$ by choosing n points $z_1,\ldots,z_n$ in the above equation and solve a set of n linear equations. We then derive the n center elements for the algebra. From

$$I(^a_b|z)=\sum_i f_i(z)\left\{\sum_P (-1)^{[\mathrm{Sign}P(^{0\ 1\ \cdots n-1}_{\mu_0\mu_1\cdots\mu_{n-1}})]} C^i_{\mu_0,\ldots,\mu_{n-1}} A^0_{\mu_0}A^1_{\mu_1}\cdots A^{n-1}_{\mu_{n-1}}\right\}\equiv\sum_i f_i(z)J_i,$$

we see that $[\Delta(a)/\Delta(b)]J_i$ are the center elements of the algebra.

VI. A KNOWN SOLUTION FOR THE FORM B COEFFICIENTS

The equations [Eqs. (58)–(60)] of form B coefficients seem simple but they interrelate the values of the coefficients $[^a_b]^{i'}_i$ between different lattice points. To our best knowledge, we only know the analytic solution

$$[^a_b]^{i'}_i=\prod_{j(\neq i')}\sigma(\delta'+b_i-a_{j'}), \tag{69}$$

which can be derived by the factorized operator of Eq. (15),

$$L_\delta(^a_b|z)^{i'}_i=\sigma(z+\delta+b_i-a_{i'})\prod_{j(\neq i')}\frac{\sigma(\delta'+b_i-a_j)}{\sigma(a_{i'}-a_j)}\equiv(-1)^{n-1}\sigma(z+\delta+b_i-a_{i'})(^a_b)^{i'}_i$$

and

$$[^a_b]^{i'}_i=(^a_b)^{i'}_i\prod_{j(\neq i')}\sigma(a_j-a_{i'}).$$

The corresponding $Y^{i'j'}_i$ is

$$Y^{i'j'}_i=[^a_b]^{i'}_i[^{a+\hat{i}'}_{b+\hat{i}}]^{j'}_j=\prod_{l(\neq i')}\sigma(\delta'+b_i-a_l)\prod_{m(\neq j')}\sigma(\delta'+b'_j-a'_m). \tag{70}$$

By using the addition formula (56), we can check that the solution satisfies Eqs. (58)–(60) directly.

This solution can be proved to be equivalent with the results obtained by using the symmetry fusion method for the $A^{(1)}_{n-1}$ model in Ref. 9. And it is also equivalent with the evaluation modules $(n=2)$ obtained by Felder and Varchenko in Ref. 12.

Equation (69) is the only known solution for the form B coefficients. We do not know if there are other analytic solutions. This is still an open question worthy of study.

APPENDIX A: THE RELATION $F(z)$ BETWEEN ADJACENT LATTICE POINTS

Suppose we go from (a,b) to $(a+\hat{i}',b+\hat{i})$. Then we have $a_j'=a_j+w(\delta_{i'j}-1/n)$, $b_j'=b_j+w(\delta_{ij}-1/n)$. From Eqs. (38) and (39), we may choose

$$C'-C=-k_0w\left(1-\frac{2}{n}\right)+Kw\left(1-\frac{1}{n}\right), \tag{A1}$$

$$D'-D=k^0w\left(1-\frac{2}{n}\right)-Kw\left(1-\frac{1}{n}\right) \tag{A2}$$

without loss of generality. This is the explicit relation of CD (δ E) between adjacent lattice points for each form of L-matrices. From Eq. (19)

$$\frac{L\binom{a+\hat{i}'}{b+\hat{i}}|z)_i^{j'}}{L\binom{a}{b}|z)_i^{i'}}\sim\frac{\sigma(z+\delta_i(i'j')+b_i-a_{j'}+w)}{\sigma(z+\delta_i(i'j')+b_i-a_{i'})}$$

and from Eq. (34)

$$\delta_i(i'j')\cong C-Kb_i+k_0(a_{i'}+a_{j'}),$$

we have

$$\frac{L\binom{a+\hat{i}'}{b+\hat{i}}|z)_i^{j'}}{L\binom{a}{b}|z)_i^{i'}}\sim\frac{\sigma(z+C+(1-K)b_i+k_0a_{i'}+(k_0-1)a_{j'}+w)}{\sigma(z+C+(1-K)b_i+(k_0-1)a_{i'}+k_0a_{j'})}. \tag{A3}$$

The relations of $F(z)$ and $F'(z)$ [the new function at lattice point (a',b')] can be obtained by putting the explicit forms of five forms of L-matrices [Eqs. (40)–(44)] into Eq. (A3). For example, we study the A(1) form.

(1) $A(1)\overset{i\,i'}{\rightarrow}A(1)$ $K=1$, $k_0=k^0=0$.

From Eqs. (A1) and (A2), one has

$$C'=C+w\left(1-\frac{1}{n}\right),\quad D'=D-w\left(1-\frac{1}{n}\right). \tag{A4}$$

Then Eqs. (40) and (A3) yield

$$\begin{aligned}\frac{L\binom{a'}{b'}|z)_i^{j'}}{L\binom{a}{b}|z)_i^{i'}}&\sim\frac{\sigma(z+C'-a_{j'}')\sigma(z+D'+b_i')F'(z)}{\sigma(z+C-a_{i'})\sigma(z+D+b_i)F(z)}\\&\sim\frac{\sigma(z+C-a_{j'}+w)\sigma(z+D+b_i)F'(z)}{\sigma(z+C-a_{i'})\sigma(z+D+b_i)F(z)}\\&\sim\frac{\sigma(z+C-a_{j'}+w)}{\sigma(z+C-a_{i'})}\Rightarrow\frac{F'(z)}{F(z)}\sim1.\end{aligned} \tag{A5}$$

Other A(i)'s are similar. We list them in the following.

(2) $A(2)\overset{i\,i'}{\rightarrow}A(2)$ $K=1$, $k_0=0$, $k^0=1$.

Equations (A1) and (A2) give

$$C'=C+w\left(1-\frac{1}{n}\right),\quad D'=D-\frac{w}{n}. \tag{A6}$$

From Eqs. (41) and (A3), we have

$$\frac{F'(z)}{F(z)} \sim \frac{\sigma(z+D-b_i-w)}{\sigma(z+D-b_i)}.$$

(3) $A(3) \overset{i\,i'}{\to} A(3)$ $K=1,\ k_0=k^0=1.$

$$\frac{F'(z)}{F(z)} \sim \frac{\sigma(z+C+a_{i'}+w)\sigma(z+D-b_i-w)}{\sigma(z+C+a_{i'})\sigma(z+D-b_i)}. \tag{A7}$$

(4) $A(4) \overset{i\,i'}{\to} A(4)$ $K=1,\ k_0=1,\ k^0=0.$

$$\frac{F'(z)}{F(z)} \sim \frac{\sigma(z+C+a_{i'}+w)}{\sigma(z+C+a_{i'})}. \tag{A8}$$

(5) $B \overset{i\,i'}{\to} B$ $K=0,\ k_0=k^0=0.$

From Eq. (A1) and noting $\delta \cong C \cong D$ for this class, we have $C' \cong D' \cong \delta' \cong C \cong D \cong \delta$. We may choose $\delta' = \delta$ without loss of generality. Equations (44) and (A3) imply

$$\begin{aligned}\frac{L(^{a'}_{b'}|z)^{j'}_{i}}{L(^{a}_{b}|z)^{i'}_{i}} &\sim \frac{\sigma(z+\delta'+b'_i-a'_{j'})F'(z)}{\sigma(z+\delta+b_i-a_{i'})F(z)} \\ &= \frac{\sigma(z+\delta+b_i-a_{j'}+w)F'(z)}{\sigma(z+\delta+b_i-a_{i'})F(z)} \\ &\sim \frac{\sigma(z+\delta+b_i-a_{j'}+w)}{\sigma(z+\delta+b_i-a_{i'})} \\ \Rightarrow \frac{F'(z)}{F(z)} &\sim 1. \end{aligned} \tag{A9}$$

APPENDIX B: THE PROOF OF THEOREM 1

To prove the theorem, first, we prove the following lemma.

Lemma 1: To any successive product of operators, if we transform it by using Eqs. (67a) and (67b) such that at each step its inverse order number is reduced (the adjacent up-indices are exchanged when the left one is bigger than that of the right one), the final result of the (ab) normal order expansion is unique.

Here we assume that in this transformation, two adjacent operators with the same up-indices do not change the order. And we think that in every step of the transformation, the location of two exchanged operators in all terms of the linear combination after the previous step are same.

Proof: We can do the procedure by different paths. For example, if we want to obtain (ab) normal order expansion of $A^4_{\cdot}A^4_{\cdot}A^6_{\cdot}A^5_{\cdot}A^2_{\cdot}A^2_{\cdot}$, we may do this in following different paths:

(1) $$A^4_{\cdot}A^4_{\cdot}A^6_{\cdot}A^5_{\cdot}A^2_{\cdot}A^2_{\cdot} \equiv (446522) \underset{Q_{2,3}}{\to} (446252) \underset{Q_{1,2}}{\to} (442652) \underset{Q_{2,3}}{\to} (442625) \underset{Q_{5,6}}{\to} (442265) \underset{Q_{4,5}}{\to} (424265) \underset{Q_{3,4}}{\to} (422465) \underset{Q_{4,5}}{\to} (242465) \underset{Q_{3,4}}{\to} (224465) \underset{Q_{2,3}}{\to} (224456),$$

(2) $$A^4_{\cdot}A^4_{\cdot}A^6_{\cdot}A^5_{\cdot}A^2_{\cdot}A^2_{\cdot} \equiv (446522) \underset{Q_{1,2}}{\to} (445622) \underset{Q_{5,6}}{\to} (445262) \underset{Q_{4,5}}{\to} (442562) \underset{Q_{3,4}}{\to} (424562) \underset{Q_{2,3}}{\to} (244562) \underset{Q_{3,4}}{\to} (244526) \underset{Q_{4,5}}{\to} (244256) \underset{Q_{3,4}}{\to} (242456) \underset{Q_{2,3}}{\to} (224456),$$

where $Q_{i,i+1}$ denotes the exchange of the ith operator A and $i+1$th operator A by using rules (67a) and (67b). We may denote such a procedure by the product of a set of exchange operators $\{Q_{i,i+1}\}$ acting on the bunch. For the path (1) in the example, we have

$$Q_{5,6}Q_{2,3}Q_{1,2}Q_{3,4}Q_{2,3}Q_{4,5}Q_{5,6}Q_{3,4}Q_{4,5}A^4_{\cdot}A^4_{\cdot}A^6_{\cdot}A^5_{\cdot}A^2_{\cdot}A^2_{\cdot} = \sum \cdots A^2_{\cdot}A^2_{\cdot}A^4_{\cdot}A^4_{\cdot}A^5_{\cdot}A^6_{\cdot}.$$

For the path (2), we have

$$Q_{2,3}Q_{3,4}Q_{4,5}Q_{5,6}Q_{1,2}Q_{2,3}Q_{3,4}Q_{4,5}Q_{3,4}A^4_{\cdot}A^4_{\cdot}A^6_{\cdot}A^5_{\cdot}A^2_{\cdot}A^2_{\cdot}=\sum \cdots A^2_{\cdot}A^2_{\cdot}A^4_{\cdot}A^4_{\cdot}A^5_{\cdot}A^6_{\cdot}.$$

In general cases, a path of such procedure is denoted by

$$Q_{i_1,i_1+1}Q_{i_2,i_1+1}\cdots Q_{i_s,i_s+1}(A^{j_1}_{k_1}A^{j_2}_{k_2}\cdots A^{j_l}_{k_l})=\sum_{j'k'} c^{t_1\cdots k'_1\cdots}_{j_1\cdots k_1\cdots}A^{j_{t_1}}_{k'_1}A^{j_{t_2}}_{k'_2}\cdots A^{j_{t_l}}_{k'_l} \tag{B1}$$

with $j_{t_1}\leqslant j_{t_2}\leqslant\cdots\leqslant j_{t_l}$. Note that the original arrangement $\{j_1j_2\cdots j_l\}$ and the final arrangement $\{j_{t_1}j_{t_2}\cdots j_{t_l}\}$ are same for whatever path of the (ab) normal product expansion we choose.

Assume there is another path for (ab) normal product expansion

$$Q_{i'_1,i'_1+1}Q_{i'_2,i'_1+1}\cdots Q_{i'_s,i'_s+1}(A^{j_1}_{k_1}A^{j_2}_{k_2}\cdots A^{j_l}_{k_l})=\sum_{j'k'} d^{t_1\cdots k'_1\cdots}_{j_1\cdots k_1\cdots}A^{j_{t_1}}_{k'_1}A^{j_{t_2}}_{k'_2}\cdots A^{j_{t_l}}_{k'_l}. \tag{B2}$$

Consider the corresponding two products of exchange operators in the permutation group

$$P^{(1)}=P_{i_1,i_1+1}P_{i_2,i_2+1}\cdots P_{i_s,i_s+1}$$

and

$$P^{(2)}=P_{i'_1,i'_1+1}P_{i'_2,i'_2+1}\cdots P_{i'_s,i'_s+1}.$$

They must all be able to permute the arrangement $\{j_1\cdots j_l\}$ into $\{j_{t_1}j_{t_2}\cdots j_{t_l}\}$. Although some of the j's may be the same, the permutation $\{^{1\,2\cdots l}_{t_1t_2\cdots t_l}\}$ is unique, however. This is due to the rule we do not exchange adjacent operators with same upper indices. In permutation group, we can express an arbitrary element by product of exchange operators in different ways. However, we can always make them equal step by step using the following equations:

$$P_{i,i+1}P_{i,i+1}=id, \tag{B3}$$

$$P_{i,i+1}P_{j,j+1}=P_{j,j+1}P_{i,i+1}\quad (i+1<j), \tag{B4}$$

$$P_{i,i+1}P_{i+1,i+2}P_{i,i+1}=P_{i+1,i+2}P_{i,i+1}P_{i+1,i+2}. \tag{B5}$$

Thus $P^{(1)}$ can be changed to $P^{(2)}$ by using these equations step by step.

On the other hand, the $\{Q_{i,i+1}\}$ operators have the same properties. We have checked

$$Q_{i,i+1}Q_{i,i+1}=id \tag{B6}$$

for two adjacent operators $A^{j_1}_{k_1}A^{j_2}_{k'_2}$ $(j_1\neq j_2)$, and thus it is also valid for all bunches due to distribution law. We also have

$$Q_{i,i+1}Q_{j,j+1}=Q_{j,j+1}Q_{i,i+1}\quad (i+1<j) \tag{B7}$$

because of the distribution law. Finally we have

$$Q_{i,i+1}Q_{i+1,i+2}Q_{i,i+1}=Q_{i+1,i+2}Q_{i,i+1}Q_{i+1,i+2} \tag{B8}$$

due to YBE for any polynomial $A^{j_1}_{k_1}A^{j_2}_{k_2}A^{j_3}_{k_3}$ with different indices. Due to distribution law, this equation is also true for any bunch. Therefore, we can also change $Q^{(1)}=Q_{i_1,i_1+1}Q_{i_2,i_2+1}\cdots Q_{i_s,i_s+1}$ into $Q^{(2)}=Q_{i'_1,i'_1+1}Q_{i'_2,i'_2+1}\cdots Q_{i'_s,i'_s+1}$ in Eqs. (B1) and (B2), re-

spectively, by using Eqs. (B6)–(B8) step by step since $P^{(1)}$ and $P^{(2)}$ can be equaled in such a way by using Eqs. (B3)–(B5), respectively. Thus we have $c^{j_{t_1}\cdots k_1'\cdots}_{j_1\cdots k_1\cdots}=d^{j_{t_1}\cdots k_1'\cdots}_{j_1\cdots k_1\cdots}$.

We then conclude that the resulting (ab) normal order expansion of the two paths gives the same result. Therefore, all paths give the same result. □

Corollaries then follow:

Corollary 1: If in a product of successive product of operators $CA_i^{i'}A_j^{j'}D$ where C,D are all products of operators, we obtain the combination of $CA_\cdot^{j'}A_\cdot^{i'}D$ [it is $C(\alpha A_i^{j'}A_j^{i'}+\beta A_j^{j'}A_i^{i'})D$]. By changing [with rule (ab) in Eq. (67)] two adjacent operators whose up-indices are unequal, the results of their (ab) normal order expansions are same, if the procedure is done according to the rules described in Lemma 1.

Proof: If $i'>j'$, we can regard this changing procedure as the first step of the (ab) normal order expansion. Thus, we can prove it. If $i'<j'$, we can do the (ab) normal order expansion of $C(\alpha A_i^{j'}A_j^{i'}+\beta A_j^{j'}A_i^{i'})D$, and let the first step as the changing of $A_\cdot^{j'}A_\cdot^{i'}$ into $A_\cdot^{i'}A_\cdot^{j'}$. Then, by using the rule (ab), we can prove that $i'j'\to j'i'\to i'j'$ is the identical transformation. So with the distributive law, the (ab) normal order expansion of bunch $C(\alpha A_i^{j'}A_j^{i'}+\beta A_j^{j'}A_i^{i'})D=$the (ab) normal order expansion of $CA_i^{i'}A_j^{j'}D$. Therefore, this corollary is proved. □

Corollary 2: With the rules of Eqs. (67a) and (67b), if a polynomial (a linear combination of products) of operators C can be changed to D ($C\overset{(ab)}{\to}D$), the (ab) normal order expansions of C and D are same, if the expansion is done according to the rules described in Lemma 1.

Proof: Because each step of the transformation does not affect the result of the expansion.□

Thus Eqs. (67a) and (67b) are compatible with the (ab) normal order expansion and the (abc) normal order expansion.

Here we note that same results of the (ab) normal order expansion give the same results of the (abc) normal order expansion, so the above two corollaries are also true for the (abc) normal order expansion.

Next, we prove the following lemma.

Lemma 2: The (abc) normal order expansion of the bunch $CA_j^{i'}A_k^{i'}D$ and the bunch $CA_k^{i'}A_j^{i'}D$ are same.

Proof: We need only to prove this when they are monomials. We prove the following propositions by using the mathematical inductive method:

Proposition (i): This lemma is true when the inverse order number is zero.

Proposition (ii): If the lemma is true when the inverse order number is smaller than m, it is also true when the inverse order number is equal to m.

The first proposition is obvious, because in this case, $CA_j^{i'}A_k^{i'}D$ and $CA_k^{i'}A_j^{i'}D$ are all (ab) normal order products. To obtain the (abc) normalization, we only need to rearrange the down-indices of the part of the product where the up-indices are the same from the smaller to the bigger by rule (67c). Both of the bunches have the same sets of the down-indices for up-indices i'. Therefore, the (abc) normal order products of them are same.

To the second proposition, we have the following cases:

(α). If in C or D, we can rearrange the up-indices $\{i'\}$ of them to reduce the inverse order number, for example, $D\overset{(ab)}{\to}D'$, we can obtain $CA_j^{i'}A_k^{i'}D'$ and $CA_k^{i'}A_j^{i'}D'$. According to Corollary 2 of Lemma 1, the (ab) normal order expansions of both of them will keep unchanged. However, because the inverse order number must be smaller that m now, according to assumption of proposition (ii), their (abc) normal order expansions are same. Therefore, the (abc) normal order expansions of the $CA_j^{i'}A_k^{i'}D$ and the $CA_k^{i'}A_j^{i'}D$ are same.

(β). If C and D have already been normalized but the inverse order number of the bunch as a whole can be reduced, namely, the bunch is not an (ab) normal order product. We can let $C=C_1A_{i_c}^{i_c'}$, $D=A_{i_d}^{i_d'}D_1$. Then we must have $i_c'>i'$ or (and) $i'>i_d'$. Let us assume $i_c'>i'$. These two

bunches can be rewritten as $T_1=C_1A_{i_c}^{i_c'}A_j^{i'}A_k^{i'}D$ and $T_2=C_1A_{i_c}^{i_c'}A_k^{i'}A_j^{i'}D$, respectively. According to the rule (ab) in Eq. (67), we can change them as $T_1\Rightarrow T_1'=C_1\Sigma_{rst}a_{rst}A_r^{i'}A_s^{i'}A_t^{i_c'}D$ and $T_2\Rightarrow T_2'=C_1\Sigma_{rst}b_{rst}A_r^{i'}A_s^{i'}A_t^{i_c'}D$, where a_{rst} and b_{rst} are some coefficients. With the help of the YBE which we studied in Sec. V, one can see that these two combinations $\Sigma_{rst}a_{rst}A_r^{i'}A_s^{i'}A_t^{i_c'}$ and $\Sigma_{rst}b_{rst}A_r^{i'}A_s^{i'}A_t^{i_c'}$ are the same if we take the rule (67c) into account. Thus we must have

$$\sum_{rst}a_{rst}A_r^{i'}A_s^{i'}A_t^{i_c'}-\sum_{rst}b_{rst}A_r^{i'}A_s^{i'}A_t^{i_c'}=\sum_t\left(\sum_{rs}(a_{rst}-b_{rst})A_r^{i'}A_s^{i'}\right)A_t^{i_c'}$$

with $\Sigma_{rs}(a_{rst}-b_{rst})A_r^{i'}A_s^{i'}=0$ if we take the rule (67c) into account. This is to say

$$a_{rst}+a_{srt}=b_{rst}+b_{srt}=2c_{rst}\quad\text{for each } t. \tag{B9}$$

Thus we have

$$T_1'=\sum_{rst}C_1a_{rst}A_r^{i'}A_s^{i'}A_t^{i_c'}D\equiv\sum_t\sum_{rs}(C_1a_{rst}A_r^{i'}A_s^{i'}D_t)$$

and

$$T_2'=\sum_{rst}C_1b_{rst}A_r^{i'}A_s^{i'}A_t^{i_c'}D\equiv\sum_t\sum_{rs}(C_1b_{rst}A_r^{i'}A_s^{i'}D_t).$$

From Eq. (B9) and due to the assumption of proposition (ii), the (abc) normal order expansions of T_1' and T_2' are the same. According to the procedure of the (abc) normal order expansion, we see that the (abc) normal order expansions of T_1 and T_2 are same.

If $i'>i_d'$, the proof is similar. So we see that proposition (ii) is true.

Thus, with the mathematical inductive method, we prove Lemma 2. □

From Corollary 2 of Lemmas 1 and 2, we obtain Theorem 1.

(Received 20 August 2002; accepted 16 September 2002)

We show that the braided tensor product algebra $\mathcal{A}_1 \underline{\otimes} \mathcal{A}_2$ of two module algebras $\mathcal{A}_1, \mathcal{A}_2$ of a quasitriangular Hopf algebra H is isomorphic to the ordinary tensor product $\mathcal{A}_1 \otimes \mathcal{A}_2$, provided there exists a realization of H within $\mathcal{A}_1$. In other words, under this assumption we construct a transformation of generators which decouples $\mathcal{A}_1, \mathcal{A}_2$ (i.e., makes them commuting). We apply the theorem to the braided tensor product algebras of two or more quantum group covariant quantum spaces, deformed Heisenberg algebras and q-deformed fuzzy spheres. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1522818]

I. INTRODUCTION AND MAIN THEOREM

As is well known, given two associative unital algebras $\mathcal{A}_1, \mathcal{A}_2$ (over the field $\mathbb{C}$, say), one can build a new module algebra $\mathcal{A}$ which is as a vector space the tensor product $\mathcal{A} = \mathcal{A}_1 \otimes \mathcal{A}_2$ of the two vector spaces (over the same field) by postulating the product law

$$(a_1 \otimes a_2)(b_1 \otimes b_2) = a_1 b_1 \otimes a_2 b_2 . \tag{1.1}$$

The resulting algebra is the ordinary tensor product algebra. Equation (1.1) is equivalent to the set of relations

$$(a_1 \otimes \mathbf{1}_2)(b_1 \otimes \mathbf{1}_2) = a_1 b_1 \otimes \mathbf{1}_2 , \tag{1.2}$$

$$(a_1 \otimes \mathbf{1}_2)(\mathbf{1}_1 \otimes a_2) = a_1 \otimes a_2 , \tag{1.3}$$

$$(\mathbf{1}_1 \otimes a_2)(\mathbf{1}_1 \otimes b_2) = \mathbf{1}_1 \otimes a_2 b_2 , \tag{1.4}$$

$$(\mathbf{1}_1 \otimes a_2)(a_1 \otimes \mathbf{1}_2) = (a_1 \otimes \mathbf{1}_2)(\mathbf{1}_1 \otimes a_2). \tag{1.5}$$

However, in many cases the same goal can be reached also by replacing (1.5) by some suitable nontrivial commutation relations. With a standard abuse of notation we shall denote in the sequel $a_1 \otimes a_2$ by $a_1 a_2$ for any $a_1 \in \mathcal{A}_1$, $a_2 \in \mathcal{A}_2$ and omit all units $\mathbf{1}_i$ when multiplied by non-unit elements; consequently (1.2)–(1.4) take trivial forms, whereas (1.5) becomes the commutation relation

$$a_2 a_1 = a_1 a_2 . \tag{1.6}$$

If $\mathcal{A}_1,\mathcal{A}_2$ are module algebras of a Lie algebra $\mathbf{g}$, and we require $\mathcal{A}$ to be too, then (1.6) has essentially no alternative (apart from the case of superalgebras, where a minus sign may appear at the right-hand side, according to the Grassman parity of a_1,a_2), because any $g\in\mathbf{g}$ acts as a derivation on the (algebra as well as tensor) product of any two elements or, in Hopf algebra language, because the coproduct $\Delta(g)=g_{(1)}\otimes g_{(2)}$ [at the right-hand side (rhs) we have used Sweedler notation] of the Hopf algebra $H\equiv U\mathbf{g}$ is cocommutative. In the main part of this paper we shall work with right-module algebras (instead of left ones), and denote by $\triangleleft:(a_i,g)\in\mathcal{A}_i\times H\to a_i\triangleleft g\in\mathcal{A}_i$ the right action; the reason is that they are equivalent to left comodule algebras, which are used in much of the literature. In Sec. V we shall give the formulas for left module algebras. We recall that a right action $\triangleleft:(a,g)\in\mathcal{A}\times H\to a\triangleleft g\in\mathcal{A}$ by definition fulfills

$$a\triangleleft(gg')=(a\triangleleft g)\triangleleft g', \tag{1.7}$$

$$(aa')\triangleleft g=(a\triangleleft g_{(1)})(a'\triangleleft g_{(2)}). \tag{1.8}$$

If we "q-deform" this setting by taking as Hopf algebra H the quantum group $U_q\mathbf{g}$, and as $\mathcal{A}_i$ the corresponding q-deformed module algebras, then it is also known[21,24,25] that although $\Delta(g)$ is no longer cocommutative, it is still possible to build the deformed counterpart of $\mathcal{A}$ if one replaces (1.6) with nontrivial commutation relations of the form

$$a_2a_1=(a_1\triangleleft\mathcal{R}^{(1)})(a_2\triangleleft\mathcal{R}^{(2)}). \tag{1.9}$$

Here $\mathcal{R}\equiv\mathcal{R}^{(1)}\otimes\mathcal{R}^{(2)}\in H^+\otimes H^-$ denotes the so-called universal R-matrix of $H\equiv U_q\mathbf{g}$,[10] and $H^\pm$ denote the Hopf positive and negative Borel subalgebras of H. This yields instead of $\mathcal{A}$ a *braided* tensor product algebra $\mathcal{A}^+=\mathcal{A}_1\underline{\otimes}^+\mathcal{A}_2$.[25] An alternative one $\mathcal{A}^-=\mathcal{A}_1\underline{\otimes}^-\mathcal{A}_2$ is obtained by replacing in the previous formula $\mathcal{R}$ by $\mathcal{R}_{21}^{-1}$:

$$a_2a_1=(a_1\triangleleft\mathcal{R}^{-1(2)})(a_2\triangleleft\mathcal{R}^{-1(1)}). \tag{1.10}$$

Both $\mathcal{A}^+$ and $\mathcal{A}^-$ go to the ordinary tensor product algebra $\mathcal{A}$ in the limit $q\to1$.

This is a particular example of a more general notion, that of a *crossed (or twisted) tensor product*[3] of two unital associative algebras.

In view of (1.9) or (1.10) studying representations of $\mathcal{A}^\pm$ is a more difficult task than just studying the representations of $\mathcal{A}_1,\mathcal{A}_2$, taking their tensor products and studying the irreducible ones there contained. The degrees of freedom of $\mathcal{A}_1,\mathcal{A}_2$ are so to say "coupled." One might ask whether one can "decouple" them by a transformation of generators.

In this work we present a sufficient condition for the construction of a transformation making $\mathcal{A}^+$ isomorphic to the ordinary tensor product algebra $\mathcal{A}_1\otimes\mathcal{A}_2$, more precisely equal to the product $\mathcal{A}_1\tilde{\mathcal{A}}_2^+$, with $\tilde{\mathcal{A}}_2^+$ a subalgebra of $\mathcal{A}^+$ isomorphic to $\mathcal{A}_2$ and *commuting* [in the sense (1.6)] with $\mathcal{A}_1$, although—of course—no longer a H-submodule; and similarly for $\mathcal{A}^-$. In a quantum theory framework one could thus interpret the generators of $\mathcal{A}_1,\tilde{\mathcal{A}}_2^\pm$ as pertaining to decoupled degrees of freedom, describing, e.g., some composite or "quasiparticle" excitations. Reducing $\mathcal{A}^\pm$ to a form $\mathcal{A}_1\tilde{\mathcal{A}}_2^\pm$ will be called an *unbraiding* of the braided tensor product algebra $\mathcal{A}^\pm=\mathcal{A}_1\underline{\otimes}^\pm\mathcal{A}_2$. The sufficient condition is that there, respectively, exists an algebra homomorphism φ_1^+ or an algebra homomorphism φ_1^-

$$\varphi_1^\pm:\mathcal{A}_1\rtimes H^\pm\to\mathcal{A}_1, \tag{1.11}$$

acting as the identity on $\mathcal{A}_1$, namely for any $a_1\in\mathcal{A}_1$,

$$\varphi_1^\pm(a_1)=a_1. \tag{1.12}$$

[Note that, as a consequence of (1.12), $\varphi_1^{\pm}$ is idempotent, $(\varphi_1^{\pm})^2=\varphi_1^{\pm}$.] Here $\mathcal{A}_1 \rtimes H^{\pm}$ denotes the cross product between $\mathcal{A}_1$ and $H^{\pm}$. In other words, this amounts to assuming that $\varphi_1^{+}(H^{+})$ [respectively, $\varphi_1^{-}(H^{-})$] provides a *realization* of H^{+} (respectively, H^{-}) within $\mathcal{A}_1$. In fact, $\tilde{\mathcal{A}}_2$ is found using the main result of this work.

Theorem 1: *Let $\{H,\mathcal{R}\}$ be a quasitriangular Hopf algebra and H^{+},H^{-} be Hopf subalgebras of H such that $\mathcal{R}\in H^{+}\otimes H^{-}$. Let $\mathcal{A}_1,\mathcal{A}_2$ be, respectively, a H^{+}- and a H^{-}-module algebra, so that we can define $\mathcal{A}^{+}$ as in (1.9), and φ_1^{+} be a homomorphism of the type (1.11), (1.12), so that we can define the "unbraiding" map $\chi^{+}:\mathcal{A}_2\to\mathcal{A}^{+}$ by*

$$\chi^{+}(a_2):=\varphi_1^{+}(\mathcal{R}^{(1)})(a_2\triangleleft\mathcal{R}^{(2)}). \tag{1.13}$$

Alternatively, let $\mathcal{A}_1,\mathcal{A}_2$ be, respectively, a H^{-}- and a H^{+}-module algebra, so that we can define $\mathcal{A}^{-}$ as in (1.10), and φ_1^{-} be a homomorphism of the type (1.11), (1.12), so that we can define the "unbraiding" map $\chi^{-}:\mathcal{A}_2\to\mathcal{A}^{-}$ by

$$\chi^{-}(a_2):=\varphi_1^{-}(\mathcal{R}^{-1(2)})(a_2\triangleleft\mathcal{R}^{-1(1)}). \tag{1.14}$$

In either case $\chi^{\pm}$ are then injective algebra homomorphisms and

$$[\chi^{\pm}(a_2),\mathcal{A}_1]=0, \tag{1.15}$$

namely the subalgebras $\tilde{\mathcal{A}}_2^{\pm}:=\chi^{\pm}(\mathcal{A}_2)\approx\mathcal{A}_2$ commute with $\mathcal{A}_1$. Moreover $\mathcal{A}^{\pm}=\mathcal{A}_1\tilde{\mathcal{A}}_2^{\pm}$.

Proof: We start by recalling the content of the hypotheses stated in the theorem. The algebra $\mathcal{A}_1\rtimes H^{\pm}$ as a vector space is the tensor product of $\mathcal{A}_1$ and $H^{\pm}$, whereas its product law is obtained combining the product laws of these two tensor factors with the cross-product law,

$$a_1 g=g_{(1)}(a_1\triangleleft g_{(2)}), \tag{1.16}$$

for any $a_1\in\mathcal{A}_1$ and $g\in H^{\pm}$. $\varphi_1^{\pm}$ being an algebra homomorphism means that for any $\xi,\xi'\in\mathcal{A}_1\rtimes H^{\pm}$,

$$\varphi_1^{\pm}(\xi\xi')=\varphi_1^{\pm}(\xi)\varphi_1^{\pm}(\xi'). \tag{1.17}$$

For $\xi\equiv a\in\mathcal{A}_1\subset\mathcal{A}_1\rtimes H^{\pm}$, $\xi'\equiv g\in H^{\pm}\subset\mathcal{A}_1\rtimes H^{\pm}$ this implies

$$a\varphi^{\pm}(g)=\varphi^{\pm}(g_{(1)})(a\triangleleft g_{(2)}). \tag{1.18}$$

Hereby we have also used (1.12) and (1.16). After these preliminaries, note that under the assumption (1.9), for any $a_1\in\mathcal{A}_1$ and $a_2\in\mathcal{A}_2$

$$\begin{aligned}
a_1\chi^{+}(a_2) &\overset{(1.13)}{=} a_1\varphi_1^{+}(\mathcal{R}^{(1)})(a_2\triangleleft\mathcal{R}^{(2)})\\
&\overset{(1.18)}{=} \varphi^{+}(\mathcal{R}^{(1)}_{(1)})(a_1\triangleleft\mathcal{R}^{(1)}_{(2)})(a_2\triangleleft\mathcal{R}^{(2)})\\
&\overset{(A3)}{=} \varphi^{+}(\mathcal{R}^{(1)})(a_1\triangleleft\mathcal{R}^{(1')})(a_2\triangleleft\mathcal{R}^{(2)}\mathcal{R}^{(2')})\\
&\overset{(1.9)}{=} \varphi^{+}(\mathcal{R}^{(1)})(a_2\triangleleft\mathcal{R}^{(2)})a_1\\
&\overset{(1.13)}{=} \chi^{+}(a_2)a_1,
\end{aligned}$$

which proves (1.15) in this case. Moreover

$$\begin{aligned}
\chi^+(a_2a_2') &\overset{(1.13)}{=} \varphi_1^+(\mathcal{R}^{(1)})(a_2a_2'\triangleleft\mathcal{R}^{(2)})\\
&\overset{(1.8)}{=} \varphi^+(\mathcal{R}^{(1)})(a_2\triangleleft\mathcal{R}^{(2)}_{(1)})(a_2'\triangleleft\mathcal{R}^{(2)}_{(2)})\\
&\overset{(A4)}{=} \varphi^+(\mathcal{R}^{(1')}\mathcal{R}^{(1)})(a_2\triangleleft\mathcal{R}^{(2)})(a_2'\triangleleft\mathcal{R}^{(2')})\\
&\overset{(1.17)}{=} \varphi^+(\mathcal{R}^{(1')})\varphi(\mathcal{R}^{(1)})(a_2\triangleleft\mathcal{R}^{(2)})(a_2'\triangleleft\mathcal{R}^{(2')})\\
&\overset{(1.13)}{=} \varphi^+(\mathcal{R}^{(1')})\chi^+(a_2)(a_2'\triangleleft\mathcal{R}^{(2')})\\
&\overset{(1.15)}{=} \chi^+(a_2)\varphi(\mathcal{R}^{(1')})(a_2'\triangleleft\mathcal{R}^{(2')})\\
&\overset{(1.13)}{=} \chi^+(a_2)\chi^+(a_2'),
\end{aligned}$$

proving that χ^+ is a homomorphism. To prove injectivity we show that χ^+ can be inverted on $\chi^+(\mathcal{A}_2)$, and the inverse is given by

$$(\chi^+)^{-1}(\tilde{a}_2)=V^{-1}([\varphi^+(S^{-1}\mathcal{R}^{(1)})\tilde{a}_2]\triangleleft\mathcal{R}^{(2)}), \tag{1.19}$$

where $V\in\mathcal{A}_1$ is the invertible element defined by $V:=\varphi_1^+(S^{-1}\mathcal{R}^{(1)})\triangleleft\mathcal{R}^{(2)}$ (V is invertible because $\mathcal{R}$ is). In fact,

$$\begin{aligned}
&V^{-1}[\varphi_1^+(S^{-1}\mathcal{R}^{(1)})\chi^+(a_2)]\triangleleft\mathcal{R}^{(2)}\\
&\overset{(1.13)}{=} V^{-1}[\varphi_1^+(S^{-1}\mathcal{R}^{(1)})\varphi_1^+(\mathcal{R}^{(1')})(a_2\triangleleft\mathcal{R}^{(2')})]\triangleleft\mathcal{R}^{(2)}\\
&\overset{(A.1.5),(1.17)}{=} V^{-1}\{\varphi_1^+[S^{-1}(\mathcal{R}^{-1(1')}\mathcal{R}^{(1)})](a_2\triangleleft\mathcal{R}^{-1(2')})\}\triangleleft\mathcal{R}^{(2)}\\
&\overset{(1.8)}{=} V^{-1}\varphi_1^+[S^{-1}(\mathcal{R}^{-1(1')}\mathcal{R}^{(1)})]\triangleleft\mathcal{R}^{(2)}_{(1)}(a_2\triangleleft\mathcal{R}^{-1(2')})\triangleleft\mathcal{R}^{(2)}_{(2)}\\
&\overset{(A.1.4)}{=} V^{-1}\varphi_1^+[S^{-1}(\mathcal{R}^{-1(1')}\mathcal{R}^{(1)}\mathcal{R}^{(1'')})]\triangleleft\mathcal{R}^{(2'')}(a_2\triangleleft\mathcal{R}^{-1(2')})\triangleleft\mathcal{R}^{(2)})\\
&\overset{(1.7)}{=} V^{-1}\varphi_1^+[S^{-1}(\mathcal{R}^{(1'')})]\triangleleft\mathcal{R}^{(2'')}a_2=V^{-1}Va_2=a_2.
\end{aligned}$$

In fact, if φ_1^+ can be extended to an algebra homomorphism $\varphi_1:\mathcal{A}_1\rtimes H\to\mathcal{A}_1$ a little calculation with the help of Eqs. (A32) and (A7) shows that $V=\varphi_1(v)$, where $v\in H$ is the invertible central element defined by (A8). We know that $\mathcal{A}_1\tilde{\mathcal{A}}_2^+\subset\mathcal{A}^+$. To prove that $\mathcal{A}^+=\mathcal{A}_1\tilde{\mathcal{A}}_2^+$ note first that by (1.9) any element in $\mathcal{A}^+$ can be written as a sum of products a_1a_2, with $a_1\in\mathcal{A}_1$ and $a_2\in\mathcal{A}_2$. So we need to show that

$$a_1a_2=b^{(1)}\chi^+(b^{(2)}) \tag{1.20}$$

for some $b^{(1)}\in\mathcal{A}_1$, $b^{(2)}\in\mathcal{A}_2$ (at the rhs a sum of many terms is implicitly understood). Now this can be proved as follows:

$$\begin{aligned}
a_1a_2&=a_1\varphi_1^+(\mathbf{1}_H)(a_2\triangleleft\mathbf{1}_H)=a_1\varphi_1^+(\mathcal{R}^{-1(1)}\mathcal{R}^{(1')})[a_2\triangleleft(\mathcal{R}^{-1(2)}\mathcal{R}^{(2')})]\\
&\overset{(1.7)}{=} a_1\varphi_1^+(\mathcal{R}^{-1(1)})\varphi_1^+(\mathcal{R}^{(1')})(a_2\triangleleft\mathcal{R}^{-1(2)})\triangleleft\mathcal{R}^{(2')}\overset{(1.13)}{=}a_1\varphi_1^+(\mathcal{R}^{-1(1)})\chi^+(a_2\triangleleft\mathcal{R}^{-1(2)}),
\end{aligned}$$

which is of the form (1.20).

The proof for χ^- under the corresponding assumptions is completely analogous. □

In the next section we shall need an alternative expression for $\chi^\pm$, which we prove in the appendix:

Proposition 1:

$$\chi^+(a_2)=(a_2\triangleleft\mathcal{R}^{-1(2)})\varphi_1^+(S\mathcal{R}^{-1(1)}), \tag{1.21}$$

$$\chi^-(a_2)=(a_2\triangleleft\mathcal{R}^{(1)})\varphi_1^-(S\mathcal{R}^{(2)}). \tag{1.22}$$

The rest of the paper is essentially devoted to illustrate the application of Theorem 1 to some algebras $\mathcal{A}_i$ for which homomorphisms $\varphi_1^\pm$ are known. In Ref. 5 algebra homomorphisms $\varphi_1^\pm$ have been found for (a slightly enlarged version $\mathcal{A}_1$ of) the algebra of functions on the N-dimensional quantum Euclidean space[13] $\mathbb{R}_q^N$, corresponding to $H=U_q\,\mathrm{so}(N)$. The explicit forms of $\varphi_1^\pm$ on the Faddeev–Reshetikhin–Takhtadjan (FRT) generators $\mathcal{L}_j^{\pm i}$ of $U_q\,\mathrm{so}(N)$ are recalled in the third part of the Appendix. The maps $\varphi_1^\pm$ for $N=3$ are given also in Refs. 6 and 7. The same maps do the job also on the quotient spaces obtained by setting $x^i x_i=1$ [quantum $(N-1)$-dimensional spheres S_q^{N-1}], and the appropriate maps for the q-deformed fuzzy sphere $S_{q,M}^2$ have been found in Ref. 20. Therefore $U_q\,\mathrm{so}(N)$ and the quantum Euclidean spaces/spheres provide nontrivial H and $\mathcal{A}_1$ for the application of the above theorem. In fact, the constructions of the frame given in Refs. 18 and 5 can be interpreted as an application of the theorem with $\mathcal{A}_1\equiv\mathbb{R}_q^N$ and $\mathcal{A}_2$ the $N!$-dim exterior algebra generated by the differentials dx^i of the $U_q\,\mathrm{so}(N)$-covariant differential calculus (although with a universal R-matrix $\mathcal{R}$ slightly modified by multiplication by the coproduct $\Delta(\Lambda)=\Lambda\otimes\Lambda$ of a new element Λ generating dilatations); consequently, in agreement with the philosophy of Ref. 26, the algebra of differential forms on $\mathbb{R}_q^N$ can be written as $\mathbb{R}_q^N\otimes\tilde{\mathcal{A}}_2$, where $\tilde{\mathcal{A}}_2$ is the $N!$-dim exterior algebra generated by the frame elements. On the other hand, the existence of algebra homomorphisms $\varphi:\mathcal{A}_1\rtimes H\to\mathcal{A}_1$, for $H=U_q\,\mathrm{so}(N), U_q\mathrm{sl}(N)$ and $\mathcal{A}_1$, respectively, equal to (a suitable completion of) the $U_q\,\mathrm{so}(N)$-covariant Heisenberg algebra or the $U_q\,\mathrm{sl}(N)$-covariant Heisenberg or Clifford algebras, has been known for even a longer time,[14,9,22] so the theorem also applies if we choose as $(H,\mathcal{A}_1)$ one of these pairs of algebras.

Of course the above theorem can be used iteratively to completely unbraid an algebra $\mathcal{A}$ obtained by repeated braided tensor product [through prescription (1.9), or prescription (1.10)] of an arbitrary number of H-module algebras $\mathcal{A}_1,\mathcal{A}_2,\ldots,\mathcal{A}_M$. We shall explicitly consider the particular case that the latter be M identical copies of the $U_q\,\mathrm{so}(N)$-covariant quantum space/sphere (Sec. III), of the $U_q\,\mathrm{so}(3)$-covariant q-fuzzy sphere (Sec. VI), or of the $U_q\,\mathrm{so}(N)$- or $U_q\,\mathrm{sl}(N)$-covariant Heisenberg algebra (Sec. IV). There we shall explicitly write down the generators of $\tilde{\mathcal{A}}_2^\pm$ for the lowest N examples. Also the results appeared in Section 3.3 of Ref. 2 can be reinterpreted as an application (at the representation level) of the above iterated unbraiding procedure to a particular iterated braided tensor product algebra, namely a lattice current algebra. In the latter both H and all the $\mathcal{A}_i$ are copies of one and the same quasitriangular semisimple Hopf algebra $\mathcal{G}$.

In the third part of the Appendix we analyze the properties of $\varphi^\pm$ under the main real sections of $U_q\,\mathrm{so}(N)$, what was left aside in Ref. 5. In Sec. II we investigate in the context of general position the properties of $\chi^\pm$ under the $*$-structures.

II. THE UNBRAIDING UNDER THE $*$-STRUCTURES

Assume H is a Hopf $*$-algebra, namely the coproduct Δ and counit ε are $*$-homomorphisms,

$$\Delta(g^*)\equiv(g^*)_{(1)}\otimes(g^*)_{(2)}=(g_{(1)})^*\otimes(g_{(2)})^*, \tag{2.1}$$

and $\mathcal{A}_1$, $\mathcal{A}_2$ are H-module $*$-algebras, namely for any $a_i\in\mathcal{A}_i$,

$$(a_i \triangleleft g)^* = a_i^* \triangleleft S^{-1} g^* \tag{2.2}$$

(here S denotes the antipode of H); we have used and shall use the same symbol $*$ for the $*$-structure on all algebras $H, \mathcal{A}_1$, etc. Then $*$ is a $*$-structure also for $\mathcal{A}_1 \rtimes H$. The same statement is not automatically true for the braided tensor product algebra $\mathcal{A}^{\pm} = \mathcal{A}_1 \underline{\otimes}^{\pm} \mathcal{A}_2$, because the basic requirement that the latter be antimultiplicative

$$(a_2 a_1)^* = a_1^* a_2^* \tag{2.3}$$

(note that this would make $\mathcal{A}^{\pm}$ also a H-module $*$-algebra) is not automatically guaranteed. In fact, applying this would-be $*$ to rhs of (1.9) one finds

$$\begin{aligned}
(a_2 a_1)^* &\overset{(1.9)}{=} [(a_1 \triangleleft \mathcal{R}^{(1)})(a_2 \triangleleft \mathcal{R}^{(2)})]^* \\
&\overset{(2.3)}{=} (a_2 \triangleleft \mathcal{R}^{(2)})^* (a_1 \triangleleft \mathcal{R}^{(1)})^* \\
&\overset{(2.2)}{=} (a_2^* \triangleleft S^{-1}\mathcal{R}^{(2)*})(a_1^* \triangleleft S^{-1}\mathcal{R}^{(1)*}) \\
&\overset{(1.9)}{=} (a_1^* \triangleleft S^{-1}\mathcal{R}^{(1)*}\mathcal{R}^{(1')})(a_2^* \triangleleft S^{-1}\mathcal{R}^{(2)*}\mathcal{R}^{(2')});
\end{aligned} \tag{2.4}$$

in order that this be equal to the rhs of (2.3) it is necessary that $(S^{-1} \otimes S^{-1})\mathcal{R}^* = \mathcal{R}^{-1}$, which upon use of (A5) is equivalent to

$$\mathcal{R}^* = \mathcal{R}^{-1} \tag{2.5}$$

(here $\mathcal{R}^*$ means $\mathcal{R}^{(1)*} \otimes \mathcal{R}^{(2)*}$). This condition is fulfilled only for the standard noncompact sections (A28) of $U_q\mathbf{g}$, for $|q| = 1$; as a consequence, $\mathcal{A}^+ = \mathcal{A}_1 \underline{\otimes}^+ \mathcal{A}_2$ becomes a H-module $*$-algebra if one extends the $*$-structures of the tensor factors to $\mathcal{A}$ using (2.3). The same holds for $\mathcal{A}^-$.

On the contrary, the compact section, which requires $q \in \mathbb{R}$, is characterized by

$$\mathcal{R}^* = \mathcal{R}_{21}. \tag{2.6}$$

In the latter case the map $*$ introduced through (2.3) makes sense only as an involutive antimultiplicative antilinear map $\mathcal{A}^+ \to \mathcal{A}^-$, if both $\mathcal{A}^+$ and $\mathcal{A}^-$ exist. In fact, in this case the last line in (2.4) will be replaced by

$$\overset{(1.10),(2.6)}{=} (a_1^* \triangleleft S^{-1}\mathcal{R}^{(2)}\mathcal{R}^{-1(2')})(a_2^* \triangleleft S^{-1}\mathcal{R}^{(1)}\mathcal{R}^{-1(1')}) \overset{(A5)}{=} a_1^* a_2^*,$$

as required. Alternatively, if $\mathcal{A}_1, \mathcal{A}_2$ are two copies of the same algebra and we denote by $\psi: \mathcal{A}_1 \to \mathcal{A}_2$ the map associating to each $a_1 \in \mathcal{A}_1$ the equivalent element in $\mathcal{A}_2$, one can define an alternative $*$-structure $\star$ in $\mathcal{A}^{\pm}$ by setting

$$a_1^\star = \psi(a_1^*), \quad a_2^\star = \psi^{-1}(a_2^*), \tag{2.7}$$

since this is instead compatible with (1.9). In fact, (2.4) will become

$$
\begin{aligned}
(a_2 a_1)^{\star} &\overset{(1.9)}{=} [(a_1 \triangleleft \mathcal{R}^{(1)})(a_2 \triangleleft \mathcal{R}^{(2)})]^{\star} \\
&\overset{(2.3)}{=} (a_2 \triangleleft \mathcal{R}^{(2)})^{\star}(a_1 \triangleleft \mathcal{R}^{(1)})^{\star} \\
&\overset{(2.2)}{=} \psi^{-1}(a_2^{*} \triangleleft S^{-1}\mathcal{R}^{(2)*})\psi(a_1^{*} \triangleleft S^{-1}\mathcal{R}^{(1)*}) \\
&\overset{(1.9)}{=} \psi(a_1^{*} \triangleleft S^{-1}\mathcal{R}^{(2)}\mathcal{R}^{-1(2')})\psi^{-1}(a_2^{*} \triangleleft S^{-1}\mathcal{R}^{(1)}\mathcal{R}^{-1(1')}) \\
&\overset{(A5)}{=} \psi(a_1^{*})\psi^{-1}(a_2^{*})a_1 \\
&\overset{(2.7)}{=} a_1^{\star}a_2^{\star}. \qquad (2.8)
\end{aligned}
$$

A similar trick can be used also if one considers an iterated braided tensor product of $M>2$ copies of the same algebra, see next section. However, such $\star$'s have not the standard commutative limit, because of the presence of the map ψ.

Inspired by the applications of the next two sections, we now assume that $\varphi_1^{\pm}$ fulfill some specific conditions relating its action before and after the application of the involution $*$, and analyze the identities relating the action of $\chi^{\pm}$ before and after the application of $*$ which follow herefrom.

Proposition 2: Assume that the conditions of Theorem 1 for defining χ^{+} or χ^{-} are fulfilled. If $\mathcal{R}^{*}=\mathcal{R}^{-1}$ and for any $g^{\pm}\in H^{\pm}$,

$$[\varphi_1^{\pm}(g^{\pm})]^{*}=\varphi_1^{\pm}(g^{\pm *}), \qquad (2.9)$$

in other words $\varphi_1^{\pm}$ are $*$-homomorphisms, then

$$[\chi^{\pm}(a_2)]^{*}=\chi^{\pm}(a_2^{*}). \qquad (2.10)$$

If $\mathcal{R}^{*}=\mathcal{R}_{21}$ and $*:H^{\pm}\to H^{\mp}$ fulfills

$$[\varphi_1^{\pm}(g)]^{*}=\varphi_1^{\mp}(g^{*}), \qquad (2.11)$$

then

$$[\chi^{\pm}(a_2)]^{*}=\chi^{\mp}(a_2^{*}). \qquad (2.12)$$

Proof: Under the first assumptions, for any $a_2\in\mathcal{A}_2$,

$$
\begin{aligned}
[\chi^{+}(a_2)]^{*} &\overset{(1.21)}{=} [(a_2 \triangleleft \mathcal{R}^{-1(2)})\varphi_1^{+}(S\mathcal{R}^{-1(1)})]^{*} \\
&= [\varphi_1^{+}(S\mathcal{R}^{-1(1)})]^{*}(a_2 \triangleleft \mathcal{R}^{-1(2)})^{*} \\
&\overset{(2.9),(2.2)}{=} \varphi_1^{+}(S^{-1}\mathcal{R}^{-1(1)*})(a_2^{*} \triangleleft S^{-1}\mathcal{R}^{-1(2)*}) \\
&\overset{(2.5)}{=} \varphi_1^{+}(S^{-1}\mathcal{R}^{(1)})(a_2^{*} \triangleleft S^{-1}\mathcal{R}^{(2)})
\end{aligned}
$$

$$\overset{(A5)}{=} \varphi_1^+(\mathcal{R}^{(1)})(a_2^* \triangleleft \mathcal{R}^{(2)})$$

$$\overset{(1.13)}{=} \chi^+(a_2^*).$$

Similarly one proves (2.10) for χ^-. Under the second assumptions, for any $a_2 \in \mathcal{A}_2$,

$$[\chi^+(a_2)]^* \overset{(1.21)}{=} [(a_2 \triangleleft \mathcal{R}^{-1(2)})\varphi_1^+(S\mathcal{R}^{-1(1)})]^*$$
$$= [\varphi_1^+(S\mathcal{R}^{-1(1)})]^*(a_2 \triangleleft \mathcal{R}^{-1(2)})^*$$

$$\overset{(2.11),(2.2)}{=} \varphi_1^-(S^{-1}\mathcal{R}^{-1(1)*})(a_2^* \triangleleft S^{-1}\mathcal{R}^{-1(2)*})$$

$$\overset{(2.6)}{=} \varphi_1^-(S^{-1}\mathcal{R}^{-1(2)})(a_2^* \triangleleft S^{-1}\mathcal{R}^{-1(1)})$$
$$\overset{(A5)}{=} \varphi_1^-(\mathcal{R}^{-1(2)})(a_2^* \triangleleft \mathcal{R}^{-1(1)})$$

$$\overset{(1.14)}{=} \chi^-(a_2^*).$$

By similar arguments one proves the claim for χ^-. □

It should be noted that there also exist nonstandard star structures on $U_q\mathbf{g}$ for $|q|=1$, in particular the compact form $X_i^{\pm *} = X_i^{\mp}$, $K_i^* = K_i^{-1}$ in terms of the Cartan–Weyl generators. Then

$$\mathcal{R}^* = \mathcal{R}_{21}^{-1}, \tag{2.13}$$

while the coproduct does not fulfill (2.1) as in a standard Hopf $*$-algebra but becomes flipped under the star. This nevertheless has the correct classical limit, because the coproduct is cocommutative for $q=1$. In certain cases (in particular on the fuzzy quantum sphere[20] discussed in Sec. VI, but see also Ref. 31), it is then possible to define a star structure on each $\mathcal{A}_i$, which takes the form $a_{i;k}^* = \pm \Omega_i a_{i;k} \Omega_i^{-1}$ on the generators $a_{i;k}$ of $\mathcal{A}_i$. Here $\Omega_i = \sqrt[4]{v_i}^{-1}\omega_i$, where v_i and ω_i are the realizations in $\mathcal{A}_i$ (using an algebra map from $U_q\mathbf{g}$ to $\mathcal{A}_i$ as above) of the central element $v \in U_q\mathbf{g}$ (A8) and the "universal Weyl element" ω in an extension of $U_q\mathbf{g}$.[23] All this must be defined in some representation of $\mathcal{A}_i$; for more details see Refs. 20 and 31. (The v in Refs. 20 and 31 is the square root of our v here.) If moreover there exists an element Ω which realizes $\sqrt[4]{v}^{-1}\omega$ in $\mathcal{A}^+ = \mathcal{A}_1 \otimes^+ \mathcal{A}_2$ or a "physical" subspace thereof, then it follows easily from (2.13) that the star structure $a_{i;k}^* = \pm \Omega a_{i;k} \Omega^{-1}$ on $\mathcal{A}^+$ is consistent with the commutation relations of the braided tensor product algebra $\mathcal{A}^+$. This star then has the correct classical limit, and the same construction also works for $\mathcal{A}^-$.

III. UNBRAIDING CHAINS OF BRAIDED QUANTUM EUCLIDEAN SPACES OR SPHERES

In this section we consider the braided tensor product of $M \geqslant 2$ copies $\mathcal{A}_1, \mathcal{A}_2, \ldots, \mathcal{A}_M$ of the quantum Euclidean space $\mathbb{R}_q^N$ (Ref. 13) [the U_q so(N)-covariant quantum space], i.e., of the unital associative algebra generated by x^i fulfilling the relations

$$\mathcal{P}^{ij}_{a_{hk}} x^h x^k = 0, \tag{3.1}$$

where $\mathcal{P}_a$ denotes the q-deformed antisymmetric projector appearing in the decomposition of the braid matrix $\hat{R}$ of $U_q\,\mathrm{so}(N)$ [given in formula (A23)], or of the quotient space of the latter obtained by setting $r^2 := x^i x_i = 1$ [the quantum $(N-1)$-dimensional sphere S_q^{N-1}]. The multiplet (x^i) carries the fundamental vector representation ρ of $U_q\,\mathrm{so}(N)$: for any $g \in U_q\,\mathrm{so}(N)$

$$x^i \triangleleft g = \rho^i_j(g) x^j. \tag{3.2}$$

We shall enumerate the different copies of the quantum Euclidean space or sphere by attaching an additional greek index to them, e.g., $\alpha = 1,2,\ldots,M$. The prescription (1.10) to glue $\mathcal{A}_1,\ldots,\mathcal{A}_M$ into a $U_q\,\mathrm{so}(N)$-module associative algebra $\mathcal{A}^-$ gives the following cross commutation relations between their respective generators:

$$x^{\alpha,i} x^{\beta,j} = \hat{R}^{ij}_{hk} x^{\alpha,h} x^{\beta,k} \tag{3.3}$$

whenever $\alpha < \beta$. Note that prescriptions (1.10) and (1.9) go into each other under the inverse reordering $1,2,\ldots,M \to M,\ldots,2,1$. Applying iteratively Theorem 1 we shall be able to completely unbraid this iterated tensor product.

To define $\varphi_1^{\pm}$ one actually needs a slightly enlarged version[5] of $\mathbb{R}_q^N$ (or S_q^{N-1}). One has to introduce some new generators $\sqrt{r_a}$, with $1 \leqslant a \leqslant N/2$, together with their inverses $(\sqrt{r_a})^{-1}$, requiring that

$$r_a^2 = \sum_{h=-a}^{a} x^h x_h = \sum_{h=-a}^{a} g_{hk} x^h x^k \tag{3.4}$$

(note that, having set $n := [N/2]$, r_n^2 coincides with r^2). Moreover for odd N we add also $\sqrt{x^0}$ and its inverse as new generators. In fact, the commutation relations involving these new generators can be fixed consistently, and turn out to be simply q-commutation relations. r plays the role of deformed Euclidean distance of the generic point of coordinates (x^i) of $\mathbb{R}_q^N$ from the origin; r_a is the projection of r on the subspace $x^i = 0$, $|i| > a$. In the previous equation g_{hk} denotes the metric matrix of $\mathrm{SO}_q(N)$:

$$g_{ij} = g^{ij} = q^{-\rho_i} \delta_{i,-j}\,. \tag{3.5}$$

It is a $\mathrm{SO}_q(N)$-isotropic tensor and is a deformation of the ordinary Euclidean metric. Here and in the sequel $n := [N/2]$ is the rank of $\mathrm{so}(N)$, the indices take the values $i = -n,\ldots,-1,0,1,\ldots n$ for N odd, and $i = -n,\ldots,-1,1,\ldots n$ for N even. Moreover, we have introduced the notation $(\rho_i) = (n - \frac{1}{2},\ldots,\frac{1}{2},0,-\frac{1}{2},\ldots,\frac{1}{2}-n)$ for N odd, $(n-1,\ldots,0,0,\ldots,1-n)$ for N even. In the case of even N one needs to include also the FRT generator $\mathcal{L}_1^{-1}$ and its inverse $\mathcal{L}_1^{+1}$ [which are generators of $U_q\,\mathrm{so}(N)$ belonging to the Cartan subalgebra] among the generators of $\mathcal{A}_1$. They satisfy the commutation relations

$$\mathcal{L}_1^{-1} x^{\pm 1} = q^{\pm 1} x^{\pm 1} \mathcal{L}_1^{-1}, \quad \mathcal{L}_1^{-1} x^{\pm i} = x^{\pm i} \mathcal{L}_1^{-1} \quad \text{for} \quad i > 1 \tag{3.6}$$

with $\mathcal{A}_1$, and the standard FRT relations with the rest of $U_q\,\mathrm{so}(N)$. One can easily show that the extension of the action of $U_q\,\mathrm{so}(N)$ to $\sqrt{r_a}$ $(\sqrt{r_a})^{-1}$ is uniquely determined by the constraints the latter fulfill; it is a bit complicated and therefore will be omitted, since we will not need its explicit expression. The action of H on $\mathcal{L}_1^{-1}$ is the standard (right) adjoint action. Note that the maps $\varphi_1^{\pm}$ have no analog in the "undeformed" case $(q=1)$, because $\mathcal{A}_1 \equiv \mathbb{R}^N$ is abelian, whereas $H \equiv U_q\,\mathrm{so}(N)$ is not.

The unbraiding procedure is recursive. We use the homomorphism φ_1 found in Ref. 5 and start by unbraiding the first copy from the others. Following Theorem 1, we perform the following change of generators in $\mathcal{A}^-$,

$$y^{1,i} := x^{1,i},$$

$$y^{\alpha,i}:=\chi^{-}(x^{\alpha,i}) \overset{(1.14)}{=} \varphi_1(\mathcal{R}^{-1(2)})\rho^i_j(\mathcal{R}^{-1(1)})x^{\alpha,j}=\varphi_1(\mathcal{L}^{-i}_{\ j})x^{\alpha,j},\quad \alpha>1.$$

In the last equality we have used the definition (A15) of the FRT generators[13] of $U_q\,\mathrm{so}(N)$. In the third part of the Appendix we recall the $\varphi^{\pm}$ images of the latter. In view of formula (A36) we thus find

$$y^{1,i}:=x^{1,i},$$

$$y^{\alpha,i}:=g^{ih}[\mu^1_h,x^{1,k}]_q g_{kj}x^{\alpha,j},\quad \alpha>1. \tag{3.7}$$

The suffix 1 in μ^1_a means that the special elements μ_a defined in (A37) must be taken as elements of the first copy of $\mathbb{R}^N_q$. In view of (A37) we see that $g^{ih}[\mu^1_h,x^{1,k}]_q g_{kj}$ are rather simple polynomials in x^i and r_a^{-1}, homogeneous of total degree 1 in the coordinates x^i and r_a. Hence (3.7) is a transformation of polynomial type and therefore likely to be implemented as a well-defined operator transformation also when representing $\mathcal{A}^-$ as an algebra of operators on some linear space. Using the results (A42) given in the appendix we give now the explicit expression of (3.7) for $N=3$:

$$y^{\alpha,-}=-qh\gamma_1\frac{r}{x^0}x^{\alpha,-},$$

$$y^{\alpha,0}=\sqrt{q}(q+1)\frac{1}{x^0}x^+x^{\alpha,-}+x^{\alpha,0}, \tag{3.8}$$

$$y^{\alpha,+}=\frac{\sqrt{q}(q+1)}{h\gamma_1 r x^0}(x^+)^2x^{\alpha,-}+\frac{q^{-1}+1}{h\gamma_1 r}x^+x^{\alpha,0}-\frac{1}{qh\gamma_1 r}x^0x^{\alpha,+}$$

for any $\alpha=2,\ldots,M$. Here we have set $x^i\equiv x^{1,i}$, $h\equiv\sqrt{q}-1/\sqrt{q}$, replaced for simplicity the values $-1,0,1$ of the indices by the ones $-,0,+$ and denoted by $\gamma_1\in\mathbb{C}$ a free parameter.

As a consequence of the theorem we find the following.

Corollary 1:

$$[y^{1,i},y^{\alpha,j}]=0,\quad \alpha>1, \tag{3.9}$$

$$y^{\alpha,i}y^{\beta,j}=\hat{R}^{ij}_{hk}y^{\alpha,h}y^{\beta,k},\quad 1<\alpha<\beta, \tag{3.10}$$

$$\mathcal{P}^{ij}_{a_{hk}}y^{\alpha,h}y^{\alpha,k}=0. \tag{3.11}$$

By (3.9) the subalgebra $\tilde{\mathcal{A}}_1^-\equiv\mathcal{A}_1$ of $\mathcal{A}^-$ generated by $y^{1,i}\equiv x^{1,i}$ commutes with the subalgebra generated by $y^{2,i},\ldots,y^{M,i}$, which we shall call $\tilde{\mathcal{A}}^-$. This was the first step of the unbraiding procedure. Now we can reiterate the latter for $\tilde{\mathcal{A}}^-$, with $y^{2,i}$ playing the role of $x^{1,i}$. After $M-1$ steps, we shall have determined M independent commuting subalgebras of $\mathcal{A}^-$ which we shall call $\tilde{\mathcal{A}}^-_\alpha$, $\alpha=1,\ldots,M$.

The unbraiding procedure for the alternative braided tensor product stemming from prescription (1.9) arises by iterating the change of generators

$$y'^{M,i}:=x^{M,i},$$

$$y'^{\alpha,i}:=\varphi_M(\mathcal{L}^{+i}_{\ j})x^{\alpha,j}=g^{ih}[\overline{\mu}^M_h,x^{M,k}]_{q^{-1}}g_{kj}x^{\alpha,j},\quad \alpha<M. \tag{3.12}$$

$\overline{\mu}_a^M$ are the special elements defined in (A40) belonging to the Mth copy of $\mathbb{R}_q^N$. Using the results (A43) given in the appendix we give the explicit expression of (3.12) for $N=3$: for any $\alpha=1,\ldots,M-1$,

$$y'^{\alpha,-}=-h\overline{\gamma}_1\frac{z^0}{r_z}x^{\alpha,-}+\frac{k\overline{\gamma}_1}{\sqrt{q}r_z}z^-x^{\alpha,0}+\frac{q^{-2}k\overline{\gamma}_1}{r_z z^0}(z^-)^2x^{\alpha,+},$$

$$y'^{\alpha,0}=x^{\alpha,0}+q^{-1/2}(q^{-1}+1)\frac{1}{z^0}z^-x^{\alpha,+}, \tag{3.13}$$

$$y'^{\alpha,+}=-\frac{r_z}{h\overline{\gamma}_1 z^0}x^{\alpha,+}.$$

Here we have set $z^i\equiv x^{M,i}$, $r_z^2\equiv x^{M,i}x_i^M$, $k\equiv q-q^{-1}$, and $\overline{\gamma}_1\in\mathbb{C}$ is a free parameter.

Again, the subalgebra $\tilde{\mathcal{A}}_M^+\approx\mathbb{R}_q^N$ of $\mathcal{A}^+$ generated by $y^{M,i}\equiv x^{M,i}$ commutes with the subalgebra generated by $y^{1,i},\ldots,y^{M-1,i}$, which we shall call $\tilde{\mathcal{A}}^+$. This was the first step of the unbraiding procedure. Now we can reiterate the latter for $\tilde{\mathcal{A}}^+$, with $y^{M-1,i}$ playing the role of $x^{M,i}$. After $M-1$ steps, we shall have determined M independent commuting subalgebras of $\mathcal{A}^+$ which we shall call $\tilde{\mathcal{A}}_\alpha^+$.

We summarize the results of this section.

Proposition 3: Let $\mathcal{A}_1,\mathcal{A}_2,\ldots,\mathcal{A}_M$ be M copies of the U_q so(N)-covariant quantum Euclidean space (or sphere). Then $\mathcal{A}_1\underline{\otimes}^{\pm}\mathcal{A}_2\underline{\otimes}^{\pm}\cdots\underline{\otimes}^{\pm}\mathcal{A}_M=\mathcal{A}_1\tilde{\mathcal{A}}_2^{\pm}\cdots\tilde{\mathcal{A}}_M^{\pm}$, where $\tilde{\mathcal{A}}_2^{\pm},\ldots,\tilde{\mathcal{A}}_M^{\pm}$ are subalgebras of the left-hand side (lhs) isomorphic to $\mathcal{A}_1$ and commuting with each other.

By a suitable choice of $\gamma_1,\overline{\gamma}_1$, as well as of the other free parameters appearing in the definitions of $\varphi^{\pm}$ for $N>3$ (see Part 3 of the Appendix), one can make $\varphi^{\pm}$ into $*$-homomorphisms when $|q|=1$, and make them satisfy the relation

$$[\varphi^{\pm}(g)]^*=\varphi^{\mp}(g^*) \tag{3.14}$$

when $q\in\mathbb{R}^+$. Since these relations are of the type considered in proposition 2, the claims of the latter for $\chi^{\pm}$ and their consequences hold. In particular, when $|q|=1$ one has a well-defined $*$ on the braided tensor product of $\mathcal{A}_1,\ldots,\mathcal{A}_M$ mapping each of the independent, commuting subalgebras $\tilde{\mathcal{A}}_i^{\pm}$ into itself. On the contrary for real q one can consider the map $*:\mathcal{A}^+\to\mathcal{A}^-$ defined by (2.3) or a $*$-structure on $\mathcal{A}^{\pm}$ defined in a way similar to what we have done in (2.7),

$$(x^{\alpha,i})^\star=x^{M-\alpha+1,j}g_{ji}. \tag{3.15}$$

The latter has not the standard classical limit. A short calculation shows that the latter implies

$$(y^{\alpha,i})^\star=y'^{M-\alpha+1,j}g_{ji}. \tag{3.16}$$

IV. UNBRAIDING CHAINS OF BRAIDED HEISENBERG ALGEBRAS

In this section we consider the braided tensor product of $M\geqslant 2$ copies $\mathcal{A}_1,\mathcal{A}_2,\ldots,\mathcal{A}_M$ of the $U_q\mathbf{g}$-covariant deformed Heisenberg algebra $\mathcal{D}_{\epsilon,\mathbf{g}}$, $\mathbf{g}=\mathrm{sl}(N)$, so$(N)$,[29,32,4] i.e., the unital associative algebra generated by x^i,∂_j fulfilling the relations

$$\mathcal{P}^{ij}_{a_{hk}}x^hx^k=0,$$

$$\mathcal{P}^{ij}_{a_{hk}}\partial_j\partial_i=0, \tag{4.1}$$

$$\partial_ix^j=\delta_j^i+(q\gamma\hat{R})^{\epsilon jk}_{ih}x^h\partial_k,$$

where $\gamma=q^{1/N}$,1 respectively, for $\mathbf{g}=\mathrm{sl}(N)$, $\mathrm{so}(N)$, and the exponent ϵ can take either value $\epsilon=1,-1$. $\hat{R}$ denotes the braid matrix of $U_q\mathbf{g}$ [given in formulas (A22) and (A23)], and again $\mathcal{P}_a$ the antisymmetric projector appearing in the decomposition of the latter. The coordinates x^i transform according to the fundamental vector representation of $U_q\mathbf{g}$, as in (3.2), whereas the partial derivatives trasform according to the contragredient representation,

$$\partial_i \triangleleft g = \partial_h \rho_i^h(S^{-1}g). \tag{4.2}$$

The indices will take the values $i=1,\ldots,N$ if $\mathbf{g}=\mathrm{sl}(N)$, the same values considered in the preceding section if $\mathbf{g}=\mathrm{so}(N)$. Clearly in the latter case $\mathcal{D}_\epsilon,\mathbf{g}$ has the quantum Euclidean space generated by x^i as a module subalgebra.

Again, we shall enumerate the different copies by attaching to them an additional greek index, e.g., $\alpha=1,2,\ldots,M$. The prescription (1.9) to glue $\mathcal{A}_1,\ldots,\mathcal{A}_M$ into a $U_q\mathbf{g}$-module associative algebra $\mathcal{A}^+$ (see also Ref. 15) gives the following cross commutation relations between their respective generators:

$$\begin{aligned} &x^{\alpha,i}x^{\beta,j}=\hat{R}^{ij}_{hk}x^{\beta,h}x^{\alpha,k}, \quad \partial_{\alpha,i}\partial_{\beta,j}=\hat{R}^{kh}_{ji}\partial_{\beta,h}\partial_{\alpha,k}, \\ &\partial_{\alpha,i}x^{\beta,j}=\hat{R}^{-1\,jh}_{ik}x^{\beta,k}\partial_{\alpha,h}, \quad \partial_{\beta,i}x^{\alpha,j}=\hat{R}^{jh}_{ik}x^{\alpha,k}\partial_{\beta,h} \end{aligned} \tag{4.3}$$

when $\alpha>\beta$. With respect to Ref. 15 we have called the generators x^i,∂_j instead of A^i,A^+_j, inverted the order of the product due to covariance with respect to the *right* (instead of the *left*) $U_q\mathbf{g}$-action, and for the sake of simplicity we have put equal to one possible factors at the rhs of (4.3).

In Refs. 14 and 9 algebra homomorphisms $\varphi:\mathcal{D}_\epsilon,\mathbf{g}\rtimes H\to\mathcal{D}_\epsilon,\mathbf{g}$ have been determined for $\mathbf{g}=\mathrm{so}(n)$ and $\mathbf{g}=\mathrm{sl}(N),\mathrm{so}(N)$, respectively. This is the q-analog of vector field realization of $\mathbf{g}$ on the corresponding $\mathbf{g}$-covariant (undeformed) space, e.g., $\varphi_1(E^i_j)=x^i\partial_j-(1/N)\,\delta^i_j$ in the $\mathbf{g}=\mathrm{sl}(N)$ case. The searched maps $\varphi^\pm$ will be simply the restrictions of φ to $\mathcal{D}_\epsilon,\mathbf{g}\rtimes H^\pm$. In Ref. 14 there are among others the φ-images of the Chevalley generators of $U_q\,\mathrm{so}(N)$ [one should take care of the fact that in Ref. 14 we considered $U_q\,\mathrm{so}(N)$ acting by a *left* action, instead of a right one, what manifests itself in a replacement $q\to q^{-1}$, or equivalently in an opposite coproduct; the rules for passing from right to left are described in Sec. V], in Ref. 9 there are the φ-images of the generators of $U_q\mathbf{g}$ playing the role of "vector fields" on G_q. By the change of generators described in Ref. 13 one can easily pass from the Chevalley to the FRT generators $\mathcal{L}^{\pm i}_j$ (A15), whereas the relation between the latter and the vector fields is recalled in (A52). The FRT generators are the ones explicitly needed in writing down $\chi^\pm(x^i)$ and $\chi^\pm(\partial_i)$. For example, for $\mathbf{g}=\mathrm{sl}(2)$ and $\epsilon=1$ one finds

$$\begin{aligned} &\varphi(\mathcal{L}_1^{+1})=\varphi(\mathcal{L}_2^{-2})=[\varphi(\mathcal{L}_1^{-1})]^{-1}=[\varphi(\mathcal{L}_2^{+2})]^{-1}=\alpha\Lambda^{1/2}[1+(q^2-1)x^2\partial_2]^{1/2}, \\ &\varphi(\mathcal{L}_2^{+1})=-\alpha k q^{-1}\Lambda^{1/2}[1+(q^2-1)x^2\partial_2]^{-1/2}x^1\partial_2, \\ &\varphi(\mathcal{L}_1^{-2})=\alpha k q^3\Lambda^{1/2}[1+(q^2-1)x^2\partial_2]^{-1/2}x^2\partial_1, \end{aligned} \tag{4.4}$$

where α is fixed by (A14) to be $\alpha=\pm1,\pm i$ and we have set

$$\Lambda^{-2}:=1+(q^2-1)x^i\partial_i. \tag{4.5}$$

Whereas for $\mathbf{g}=\mathrm{so}(3)$ and $\epsilon=1$ one finds on the positive Borel subalgebra

$$\begin{aligned} &\varphi(\mathcal{L}_-^{+-})=-\alpha\Lambda[1+(q-1)x^0\partial_0+(q^2-1)x^+\partial_+], \\ &\varphi(\mathcal{L}_0^{+-})=\alpha k\Lambda(x^-\partial_0-\sqrt{q}x^0\partial_+), \end{aligned}$$

$$\begin{gathered}\varphi(\mathcal{L}_{+}^{+-})=\frac{1}{1+q^{-1}}\varphi(\mathcal{L}_{0}^{+-})\varphi(\mathcal{L}_{+}^{+0}),\\ \varphi(\mathcal{L}_{0}^{+0})=1,\\ \varphi(\mathcal{L}_{+}^{+0})=-q^{-1/2}[\varphi(\mathcal{L}_{-}^{+-})]^{-1}\varphi(\mathcal{L}_{0}^{+-}),\\ \varphi(\mathcal{L}_{+}^{++})=[\varphi(\mathcal{L}_{-}^{+-})]^{-1},\end{gathered}\tag{4.6}$$

and on the negative Borel subalgebra

$$\begin{gathered}\varphi(\mathcal{L}_{-}^{--})=-(\alpha\Lambda[1+(q-1)x^0\partial_0+(q^2-1)x^+\partial_+])^{-1},\\ \varphi(\mathcal{L}_{-}^{-0})=-\alpha q^2 k\varphi(\mathcal{L}_{-}^{--})\Lambda(x^0\partial_- -\sqrt{q}x^+\partial_0),\\ \varphi(\mathcal{L}_{-}^{-+})=\frac{1}{1+q}\varphi(\mathcal{L}_{0}^{-+})\varphi(\mathcal{L}_{-}^{-0}),\\ \varphi(\mathcal{L}_{0}^{-0})=1,\\ \varphi(\mathcal{L}_{0}^{-+})=-\alpha q^{3/2}k\Lambda(x^0\partial_- -\sqrt{q}x^+\partial_0),\\ \varphi(\mathcal{L}_{+}^{-+})=[\varphi(\mathcal{L}_{-}^{--})]^{-1}.\end{gathered}\tag{4.7}$$

Here we have set

$$\Lambda^{-2}:=\left[1+(q^2-1)x^i\partial_i+\frac{(q^2-1)^2}{\omega_1^2}(g_{ij}x^ix^j)(g^{hk}\partial_k\partial_h)\right],\tag{4.8}$$

where

$$\omega_a:=(q^{\rho_a}+q^{-\rho_a}),$$

and replaced for simplicity the values $-1,0,1$ of the indices by the ones $-,0,+$. In either case the φ-images of $\mathcal{L}_{j}^{+i}$ and $\mathcal{L}_{i}^{-j}$ for $i>j$ vanish, because the latter do.

We see that strictly speaking φ takes values in some appropriate completion of $\mathcal{D}_{\epsilon,\mathbf{g}}$, containing at least the square root and inverse square root of the polynomial Λ^{-2}, respectively, defined in (4.5), (4.8), as well as the square root of $[1+(q^2-1)x^2\partial_2]$ and its inverse, when $\mathbf{g}=\mathrm{sl}(2)$, and the inverses $(4.6)_6$, $(4.7)_6$, when $\mathbf{g}=\mathrm{so}(3)$. Apart from this minimal completion, another possible one is the so-called h-adic, namely the ring of formal power series in $h=\log q$ with coefficients in $\mathcal{D}_{\epsilon,\mathbf{g}}$. Other completions, e.g., in operator norms, can be considered according to the needs. One can easily show that the extension of the action of H to any such completion is uniquely determined (we omit to write down its explicit expression, since we do not need it).

According to the main theorem, we set

$$\begin{gathered}y^{1,i}\equiv x^{1,i},\\ \partial_{y,1,a}\equiv\partial_{1,a},\\ y^{\alpha,i}\equiv\chi^-(x^{\alpha,i})=\varphi_1(\mathcal{L}_{j}^{-1})x^{\alpha,j},\quad \alpha>1,\\ \partial_{y,\alpha,a}\equiv\chi^-(\partial_{\alpha,a})=\varphi_1(S\mathcal{L}_{a}^{-d})\partial_{\alpha,d},\quad \alpha>1,\end{gathered}\tag{4.9}$$

and we find the following.

Corollary 2:

$$\mathcal{P}^{ij}_{a_{hk}} y^{\alpha,h} y^{\alpha,k} = 0,$$

$$\mathcal{P}^{hk}_{a_{ij}} \partial_{y\alpha,k} \partial_{y,\alpha,h} = 0, \tag{4.10}$$

$$\partial_{y,\alpha,i} y^{\alpha,j} = \delta^j_i + (q\hat{R})^{\epsilon_\alpha jl}_{im} y^{\alpha,m} \partial_{y,\alpha,l}$$

for all $\alpha = 1, \ldots, M$, *together with*

$$[y^{1,i}, y^{\alpha,j}] = 0, \quad [\partial_{y,1,i}, y^{\alpha,j}] = 0,$$
$$[\partial_{y,\alpha,i}, y^{1,j}] = 0, \quad [\partial_{y,1,i}, \partial_{y,\alpha,j}] = 0 \tag{4.11}$$

when $\alpha > 1$, *and*

$$y^{\alpha,i} y^{\beta,j} = \hat{R}^{ij}_{hk} y^{\beta,h} y^{\alpha,k},$$

$$\partial_{y,\alpha,i} \partial_{y,\beta,j} = \hat{R}^{kh}_{ji} \partial_{y,\beta,h} \partial_{y,\alpha,k},$$

$$\partial_{y,\alpha,i} y^{\beta,j} = \hat{R}^{-1\,jh}_{ik} y^{\beta k} \partial_{y,\alpha,h}, \tag{4.12}$$

$$\partial_{y,\beta,i} y^{\alpha,j} = \hat{R}^{jh}_{ik} y^{\alpha,k} \partial_{y,\beta,h}$$

when $1 < \beta < \alpha$.

By (4.11) $y^{1,i} \equiv x^{1,i}$ and $\partial_{y,1,i} \equiv \partial_{1,i}$ commute with the subalgebra generated by $y^{2,i}, \ldots, y^{M,i}$ and $\partial_{y,2,i}, \ldots, \partial_{y,M,i}$ which we shall call $\tilde{\mathcal{A}}^+$. This was the first step of the unbraiding procedure. Now we can reiterate the latter for $\tilde{\mathcal{A}}^+$, with $y^{2,i}, \partial_{y,2,i}$ playing the role of $x^{1,i}, \partial_{1,i}$. After $M-1$ steps, we shall have determined M independent commuting subalgebras of $\mathcal{A}^+$ which we shall call $\tilde{\mathcal{A}}^+_\alpha$.

For the sake of brevity we omit the unbraiding procedure for the alternative braided tensor product algebra stemming from prescription (1.10), which can be found following arguments completely analogous to the ones presented at the end of Sec. III. We summarize the results of this section by the following.

Proposition 4: Let $\mathcal{A}_1, \mathcal{A}_2, \ldots, \mathcal{A}_M$ *be M copies of the* $U_q\mathbf{g}$*-covariant Heisenberg algebra* $\mathcal{D}_{\epsilon,\mathbf{g}}$, $\mathbf{g} = \mathrm{sl}(N)$, $\mathrm{so}(N)$. *Then* $\mathcal{A}_1 \underline{\otimes}^{\pm} \mathcal{A}_2 \underline{\otimes}^{\pm} \ldots \underline{\otimes}^{\pm} \mathcal{A}_M = \mathcal{A}_1 \tilde{\mathcal{A}}^{\pm}_2 \cdots \tilde{\mathcal{A}}^{\pm}_M$, *where* $\tilde{\mathcal{A}}^{\pm}_2, \ldots, \tilde{\mathcal{A}}^{\pm}_M$ *are subalgebras of the lhs isomorphic to* $\mathcal{D}_{\epsilon,\mathbf{g}}$ *and commuting with each other*.

Relations (A28), (2.2), (3.2), (4.2) and (4.1) fix the $*$-structure of $\mathcal{A}_1$ to be

$$(x^i)^* = x^i, \quad (\partial_i)^* = -\partial_i \begin{cases} q^{\pm 2(N-i+1)} & \text{if } H = U_q\,\mathrm{sl}(N), \\ q^{\pm N + \rho_i} & \text{if } H = U_q \mathrm{so}(N), \end{cases} \tag{4.13}$$

if $|q| = 1$, and

$$(x^h)^* = x^k g_{kh}, \quad (\partial_i)^* = -\frac{\Lambda^{\pm 2}}{q^{\pm N} + q^{\pm 2}} [(g^{jh}\partial_h \partial_j), x^i], \tag{4.14}$$

if $H = U_q\,\mathrm{so}(N)$ and $q \in \mathbb{R}^+$. The upper or lower sign, respectively, refer to the choices $\epsilon = 1$, -1 in $(4.1)_3$, and $\Lambda^{\pm 2}$ are, respectively, defined by

$$\Lambda^{\pm 2} := \left[1 + (q^{\pm 2} - 1) x^i \partial_i + \frac{(q^{\pm 2} - 1)^2}{\omega_n^2} r^2 (g^{ji} \partial_i \partial_j) \right]^{-1}. \tag{4.15}$$

The map φ is a $*$-homomorphism both for q real and $|q|=1$. If we denote by $\varphi^{\pm}$ its restrictions to $\mathcal{A}\rtimes H^{\pm}$, then they are $*$-homomorphisms when $|q|=1$ (see the fourth part of the Appendix), and fulfill the relation

$$[\varphi^{\pm}(g)]^*=\varphi^{\mp}(g^*) \tag{4.16}$$

when $q\in\mathbb{R}^+$.[14] Since these relations are of the type considered in proposition 2, the claims of the latter for $\chi^{\pm}$ and their consequences hold. In particular, when $|q|=1$ one has a well-defined $*$ on the braided tensor product of $\mathcal{A}_1,\ldots,\mathcal{A}_M$ mapping each of the independent, commuting subalgebras $\tilde{\mathcal{A}}_\alpha^{\pm}$ into itself.

Finally, the above results have an important corollary. According to Hochschild cohomology arguments developed by Gerstenhaber[19] and applicable to Heisenberg algebras because of the results found by Du Cloux in Ref. 12, any deformed Heisenberg algebra, in particular the braided tensor products of $\mathcal{A}_1,\ldots,\mathcal{A}_M$ considered in this section, can be realized simply by a change of generators in the h-adic completion, $h=\log q$, of its undeformed counterpart (but in general *not* in other, e.g., *operator-norm*, completions). However explicit realizations are not provided by these results. The results presented here, combined to some older ones, allow to determine one such realization. In Ref. 27 Ogievetsky found an explicit realization ϕ or deforming map of the elements of $\mathcal{D}_\epsilon,\mathbf{g}$ in terms of formal power series in $h=\log q$ with coefficients in the corresponding undeformed Heisenberg algebra. Another, less explicit, one was found in Ref. 16. The composition of the unbraiding map found in this section, which allows to decouple M different copies of $\mathcal{D}_\epsilon,\mathbf{g}$ from each other, with the map ϕ provides an explicit realization or deforming map of the larger Heisenberg algebra $\mathcal{A}$ (what we have called the braided chain of Heisenberg algebras), in the h-adic completion of the undeformed $(N\cdot M)$-dimensional Heisenberg algebra.

V. FORMULAS FOR THE LEFT ACTION

For psychological reasons we often prefer to work with a left action rather than with a right one. In this section we give the analogs for left H-module algebras of the main results found so far for right H-module algebras. The left action of $g\in H$ on a product fulfills

$$(gg')\triangleright a=g\triangleright(g'\triangleright a), \tag{5.1}$$

$$g\triangleright(aa')=(g_{(1)}\triangleright a)(g_{(2)}\triangleright a'). \tag{5.2}$$

The product laws in the braided tensor product algebras $\hat{\mathcal{A}}^+,\hat{\mathcal{A}}^-$ are, respectively, given by

$$a_2a_1=(\mathcal{R}^{-1(1)}\triangleright a_1)(\mathcal{R}^{-1(2)}\triangleright a_2), \tag{5.3}$$

$$a_2a_1=(\mathcal{R}^{(2)}\triangleright a_1)(\mathcal{R}^{(1)}\triangleright a_2). \tag{5.4}$$

The analog of Theorem 1 reads as follows.

Theorem 2: *Let $\{H,\mathcal{R}\}$ be a quasitriangular Hopf algebra and H^+,H^- be Hopf subalgebras of H such that $\mathcal{R}\in H^+\otimes H^-$. Let $\hat{\mathcal{A}}_1,\hat{\mathcal{A}}_2$ be, respectively, a (left) H^+- and a H^--module algebra, so that we can define $\hat{\mathcal{A}}^+$ as in (5.3), and $\hat{\varphi}_1^+:H^+\ltimes\hat{\mathcal{A}}_1\to\hat{\mathcal{A}}_1$ be an algebra homomorphism fulfilling (1.12), so that we can define a map $\hat{\chi}^+:\hat{\mathcal{A}}_2\to\hat{\mathcal{A}}^+$ by*

$$\hat{\chi}^+(a_2):=(\mathcal{R}^{(2)}\triangleright a_2)\,\hat{\varphi}_1^+(\mathcal{R}^{(1)}). \tag{5.5}$$

Alternatively, let $\hat{\mathcal{A}}_1,\hat{\mathcal{A}}_2$ be, respectively, a (left) H^--and a H^+-module algebra, so that we can define $\hat{\mathcal{A}}^-$ as in (5.4), and $\hat{\varphi}_1^+:H^+\ltimes\hat{\mathcal{A}}_1\to\hat{\mathcal{A}}_1$ be an algebra homomorphism fulfilling (1.12), so that we can define a map $\hat{\chi}^-:\hat{\mathcal{A}}_2\to\hat{\mathcal{A}}^-$ by

$$\hat{\chi}^-(a_2):=(\mathcal{R}^{-1(1)}\triangleright a_2)\,\hat{\varphi}_1^-(\mathcal{R}^{-1(2)}). \tag{5.6}$$

In either case $\hat{\chi}^{\pm}$ *are then injective algebra homomorphisms and*

$$[\hat{\chi}^{\pm}(a_2),\hat{\mathcal{A}}_1]=0, \tag{5.7}$$

namely the subalgebras $\tilde{\hat{\mathcal{A}}}_2^{\pm}:=\hat{\chi}^{\pm}(\hat{\mathcal{A}}_2)\approx\hat{\mathcal{A}}_2$ *commute with* $\hat{\mathcal{A}}_1$. *Moreover* $\hat{\mathcal{A}}^{\pm}=\hat{\mathcal{A}}_1\tilde{\hat{\mathcal{A}}}_2^{\pm}$.

The results of Sec. II apply without modifications (one just has to place a $\hat{}$ in the appropriate places).

To enumerate the generators of the algebras considered in Secs. III and IV we shall exchange lower with upper indices, so the generators will read $x_{\alpha,i}, \partial^{\alpha,i}$. This is necessary if we wish the x's to carry what we shall consider the fundamental (vector) representation ρ of $U_q\mathbf{g}$,

$$g\triangleright x_i=x_j\rho_i^j(g), \tag{5.8}$$

rather than its contragredient $\rho^T\circ S$, because this follows from the row×column multiplication law $\rho_h^i(gg')=\rho_j^i(g)\rho_h^j(g')$. Apart from this replacement, all the commutation relations remain the same, but can be rephrased in an equivalent way exchanging lower with upper indices also in the braid matrices and in the projectors $\mathcal{P}_a$, because $\hat{R}^T=\hat{R}$, ${\mathcal{P}_a}^T=\mathcal{P}_a$. For instance, the analog of (3.1) will read

$$\mathcal{P}_{aij}^{hk}x_hx_k=0. \tag{5.9}$$

The analogs of (3.2) and (4.2) read

$$g\triangleright x_i=\rho_i^j(g)x_j, \tag{5.10}$$

$$g\triangleright \partial^i=\partial^h\rho_h^i(Sg). \tag{5.11}$$

Algebra homomorphisms $\hat{\varphi}_1^{\pm}$ for the algebras considered in Secs. III and IV are immediately obtained in terms of the $\varphi_1^{\pm}$ described there, according to the rule

$$\hat{\varphi}_1^{\pm}(\mathcal{L}_j^{\pm h})=U_a^{-1j}\varphi_1^{\mp}(\mathcal{L}_b^{\mp a})U_h^b. \tag{5.12}$$

Here

$$U_c^b:=\rho_c^b(u), \tag{5.13}$$

$u\in H$ is a special element as in (A6), and at the rhs the correct expression in the new notation has lower and upper indices exchanged. If $\hat{\mathcal{A}}_1$ is the quantum Euclidean space $\mathbb{R}_q^N$ one finds, for instance,

$$\hat{\varphi}_1^-(\mathcal{L}_j^{-h})=U_a^{-1j}g_{ac}[\overline{\mu}^c,x_k]_{q^{-1}}g^{kb}U_b^h \overset{(A30)}{=} g_{cj}[\overline{\mu}^c,x_k]_qg^{hk}, \tag{5.14}$$

where μ^c is the same as μ_c [see (A3)], but in the new notation. For instance, when $|c|>1$ it reads

$$\overline{\mu}^c=\overline{\gamma}_cr_{|c|}^{-1}r_{|c|-1}^{-1}x_{-c}, \tag{5.15}$$

with γ_c defined as in (A41) and r_a $(a\geqslant 0)$ defined by the condition

$$r_a^2=\sum_{h=-a}^{a}x_hx^h=\sum_{h=-a}^{a}g^{hk}x_hx_k.$$

The analog of (3.7) is therefore (with $\alpha>1$)

$$y_{1,i}:=x_{1,i}, \tag{5.16}$$

$$y^{\alpha,i} := \hat{\chi}^-(x_{\alpha,i}) = x_{\alpha,j}\hat{\varphi}_1(\mathcal{L}_i^{-j}) = x_{\alpha,j} g_{hi}[\overline{\mu}^{1,h}, x_{1,k}]_{q^{-1}} g^{jk}. \tag{5.17}$$

VI. UNBRAIDING CHAINS OF FUZZY QUANTUM SPHERES

As a last example, we consider the braided tensor product of M copies $\mathcal{A}_1, \ldots, \mathcal{A}_M$ of the q-deformed fuzzy sphere $\hat{S}^2_{q,N}$ (Ref. 20) (to relate this to our conventions, the q in Ref. 20 should be replaced by $q^{-1/2}$), which we consider as a left $U_q\,\mathrm{so}(3)$ module algebra. It is generated by x_i fulfilling the relations

$$\begin{aligned} \varepsilon_k^{ij} x_i x_j &= \Lambda_N \;\; x_k, \\ g^{ij} x_i x_j &= R^2. \end{aligned} \tag{6.1}$$

Here $R>0$,

$$C_N = \frac{[N]_q[N+2]_q}{[2]_q^2}, \quad \Lambda_N = R\,\frac{[2]_{q^{N+1}}}{\sqrt{[N]_q[N+2]_q}}, \tag{6.2}$$

where $[n]_q := (q^{n/2} - q^{-n/2})/(q^{1/2} - q^{-1/2})$, and

$$\begin{gathered} \varepsilon_1^{10} = q^{1/2}, \quad \varepsilon_1^{01} = -q^{-1/2}, \\ \varepsilon_0^{00} = q^{1/2} - q^{-1/2}, \quad \varepsilon_0^{1-1} = 1 = -\varepsilon_0^{-11}, \\ \varepsilon_{-1}^{0-1} = q^{1/2}, \quad \varepsilon_{-1}^{-10} = -q^{-1/2} \end{gathered} \tag{6.3}$$

are the spin-1 Clebsch–Gordan coefficients. The multiplet (x_i) carries the fundamental vector representation ρ of $H = U_q\,\mathrm{so}(3)$:

$$g \triangleright x_i = x_j \rho_i^j(g). \tag{6.4}$$

There is no obvious generalization to higher dimensions, but this algebra appears to be relevant, e.g., to D-branes on the SU(2) WZW model.[1] It has a unique irreducible representation, which is equivalent to $\mathrm{Mat}(N+1)$. Here we only consider the case $q \in \mathbb{R}^+$, where the star structure is given by $x_i^* = g^{ij} x_j$. Then $\hat{S}^2_{q,N}$ is simply the "discrete series" of Podles's spheres.[28] It was shown in Ref. 20 that there is a star-algebra homomorphism $\hat{\varphi}: H \ltimes \hat{S}^2_{q,N} \to \hat{S}^2_{q,N}$, which takes a particularly simple form

$$\hat{\varphi}(E^+) = \frac{1}{R}\sqrt{q^{-1}[2]_q C_N}\, x_1, \quad \hat{\varphi}(E^-) = -\frac{1}{R}\sqrt{q[2]_q C_N}\, x_{-1},$$

$$\hat{\varphi}(q^{H/2}) = \frac{[2]_{q^{N+1}}}{[2]_q}\left(1 - \frac{q^{1/2} - q^{-1/2}}{\Lambda_N} x_0\right)$$

where $E^\pm = X^\pm q^{H/4} \in U_q\,\mathrm{so}(3)$. Note that $(1 - [(q^{1/2} - q^{-1/2})/\Lambda_N] x_0)$ is invertible since the eigenvalues of $q^{H/2}$ are positive (assuming $q>0$), therefore $\hat{\varphi}(q^{-H/2}) \in \hat{S}^2_{q,N}$ is well-defined also. Hence the algebra homomorphisms $\hat{\varphi}$ is defined on the entire algebra $U_q\,\mathrm{so}(3)$. Using the definition (A15) and the explicit form for the universal $\mathcal{R}$ (see, e.g., Ref. 8), one finds

$$[\mathcal{L}_j^{-i}] = \begin{bmatrix} q^{H/2}, & 0, & 0 \\ -(1-q^{-1})\sqrt{[2]_q}E^-, & 1, & 0 \\ q^{-1/2}(1-q^{-1})^2 q^{-H/2}(E^-)^2, & -(1-q^{-1})\sqrt{[2]_q} q^{-H/2} E^-, & q^{-H/2} \end{bmatrix} \tag{6.6}$$

and

$$[\mathcal{L}_j^{+i}]=\begin{bmatrix} q^{-H/2}, & (q-1)\sqrt{[2]_q}q^{-H/2}E^+, & (q-1)^2q^{-H/2}(E^+)^2, \\ 0, & 1, & q^{-1/2}(q-1)\sqrt{[2]_q}E^+ \\ 0, & 0, & q^{H/2} \end{bmatrix}. \tag{6.7}$$

The unbraiding procedure then works as in Theorem 2. To be specific, assume that the braided tensor product algebra is as in (5.3). Then we set

$$y_{1,i}:=x_{1,i}\,, \tag{6.8}$$

$$y_{\alpha,i}:=\hat{\chi}(x_{\alpha,i})=x_{\alpha,j}\hat{\varphi}_1(\mathcal{L}_i^{+j}), \quad \alpha>1, \tag{6.9}$$

without spelling out these expressions further. According to Theorem 2, they satisfy

Corollary 3:

$$\varepsilon_k^{ij}y_{\alpha,i}y_{\alpha,j}=\Lambda_N y_{\alpha,k}\,,$$

$$g^{ij}y_{\alpha,i}y_{\alpha,j}=R^2$$

for all $\alpha=1,\ldots,M$, *together with*

$$[y_{1,i}\,,y_{\alpha,j}]=0, \tag{6.10}$$

$$y_{\alpha,i}y_{\beta,j}=\hat{R}_{ij}^{hk}y_{\beta,h}y_{\alpha,k} \tag{6.11}$$

when $1<\alpha$ *and* $\alpha\beta$.

Iterating this procedure as before, we find the following.

Proposition 5: Let $\mathcal{A}_1,\mathcal{A}_2,\ldots,\mathcal{A}_M$ *be M copies of the* $U_q\mathrm{so}(3)$*-covariant fuzzy quantum sphere. Then* $\mathcal{A}_1\underline{\otimes}^{\pm}\mathcal{A}_2\underline{\otimes}^{\pm}\cdots\ \underline{\otimes}^{\pm}\mathcal{A}_M=\mathcal{A}_1\tilde{\mathcal{A}}_2^{\pm}\cdots\ \tilde{\mathcal{A}}_M^{\pm}$, *where* $\tilde{\mathcal{A}}_2^{\pm},\ldots,\tilde{\mathcal{A}}_M^{\pm}$ *are subalgebras of the lhs isomorphic to* $\mathcal{A}_1$ *and commuting with each other.*

APPENDIX

1. The universal *R*-matrix

In this appendix we recall the basics about the universal R-matrix[10] of the quantum groups $U_q\mathbf{g}$, while fixing our conventions. Recall that the universal R-matrix $\mathcal{R}$ is a special element

$$\mathcal{R}\equiv\mathcal{R}^{(1)}\otimes\mathcal{R}^{(2)}\in U_q\mathbf{g}\otimes U_q\mathbf{g} \tag{A1}$$

intertwining between Δ and opposite coproduct Δ^{op}, and so does also $\mathcal{R}_{21}^{-1}$:

$$\begin{aligned}\mathcal{R}(g_{(1)}\otimes g_{(2)})&=(g_{(2)}\otimes g_{(1)})\mathcal{R},\\ \mathcal{R}_{21}^{-1}(g_{(1)}\otimes g_{(2)})&=(g_{(2)}\otimes g_{(1)})\mathcal{R}_{21}^{-1}\,.\end{aligned} \tag{A2}$$

In (A1) we have used a Sweedler notation with upper indices: the right-hand side is a short-hand notation for a sum $\Sigma_I\mathcal{R}_I^{(1)}\otimes\mathcal{R}_I^{(2)}$ of infinitely many terms. We recall some useful formulas

$$(\Delta\otimes\mathrm{id})\mathcal{R}=\mathcal{R}_{13}\mathcal{R}_{23}\,, \tag{A3}$$

$$(\mathrm{id}\otimes\Delta)\mathcal{R}=\mathcal{R}_{13}\mathcal{R}_{12}\,, \tag{A4}$$

$$(S\otimes\mathrm{id})\mathcal{R}=\mathcal{R}^{-1}=(\mathrm{id}\otimes S^{-1})\mathcal{R}, \tag{A5}$$

$$S^{-1}(g)=u^{-1}S(g)u. \tag{A6}$$

Here u is any of the elements $u_1,u_2,\ldots,u_8$ defined below

$$\begin{aligned} u_1&:=(S\mathcal{R}^{(2)})\mathcal{R}^{(1)}, \quad u_2:=(S\mathcal{R}^{-1(1)})\mathcal{R}^{-1(2)},\\ u_3&:=\mathcal{R}^{(2)}S^{-1}\mathcal{R}^{(1)}, \quad u_4:=\mathcal{R}^{-1(1)}S^{-1}\mathcal{R}^{-1(2)},\\ (u_5)^{-1}&:=\mathcal{R}^{(1)}S\mathcal{R}^{(2)}, \quad (u_6)^{-1}:=(S^{-1}\mathcal{R}^{(1)})\mathcal{R}^{(2)},\\ (u_7)^{-1}&:=\mathcal{R}^{-1(2)}S\mathcal{R}^{-1(1)}, \quad (u_8)^{-1}:=(S^{-1}\mathcal{R}^{-1(2)})\mathcal{R}^{-1(1)}. \end{aligned} \tag{A7}$$

In fact, using the results of Drinfel'd[10,11] one can show that

$$u_1=u_3=u_7=u_8=vu_2=vu_4=vu_5=vu_6, \tag{A8}$$

where v is a suitable element belonging to the center of $U_q\,\mathrm{so}(N)$.

From (A2) and (A3), (A4) it follows the universal Yang–Baxter relation

$$\mathcal{R}_{12}\mathcal{R}_{13}\mathcal{R}_{23}=\mathcal{R}_{23}\mathcal{R}_{13}\mathcal{R}_{12}, \tag{A9}$$

whence the other two relations follow

$$\mathcal{R}^{-1}{}_{12}\mathcal{R}^{-1}{}_{13}\mathcal{R}^{-1}{}_{23}=\mathcal{R}^{-1}{}_{23}\mathcal{R}^{-1}{}_{13}\mathcal{R}^{-1}{}_{12}, \tag{A10}$$

$$\mathcal{R}_{13}\mathcal{R}_{23}\mathcal{R}^{-1}{}_{12}=\mathcal{R}^{-1}{}_{12}\mathcal{R}_{23}\mathcal{R}_{13}. \tag{A11}$$

As before, let ρ be the fundamental N-dimensional representation of $\mathbf{g}=\mathrm{sl}(N),\mathrm{so}(N),\mathrm{sp}(N)$. By applying $\mathrm{id}\otimes\rho^a_c\otimes\rho^b_d$ to (A9), $\rho^a_c\otimes\rho^b_d\otimes\mathrm{id}$ to (A10) and $\rho^a_c\otimes\mathrm{id}\otimes\rho^b_d$ to (A11) we, respectively, find the commutation relations

$$\hat{R}^{ab}_{cd}\mathcal{L}^{+d}_f\mathcal{L}^{+c}_e=\mathcal{L}^{+b}_c\mathcal{L}^{+a}_d\hat{R}^{dc}_{ef}, \tag{A12}$$

$$\hat{R}^{ab}_{cd}\mathcal{L}^{-d}_f\mathcal{L}^{-c}_e=\mathcal{L}^{-b}_c\mathcal{L}^{-a}_d\hat{R}^{dc}_{ef}, \tag{A13}$$

$$\hat{R}^{ab}_{cd}\mathcal{L}^{+d}_f\mathcal{L}^{-c}_e=\mathcal{L}^{-b}_c\mathcal{L}^{+a}_d\hat{R}^{dc}_{ef}, \tag{A14}$$

where $\mathcal{L}^{\pm a}_l$ are the Faddeev–Reshetikin–Takhtadjan generators[13] of $U_q\mathbf{g}$, defined by

$$\mathcal{L}^{+a}_l:=\mathcal{R}^{(1)}\rho^a_l(\mathcal{R}^{(2)}), \quad \mathcal{L}^{-a}_l:=\rho^a_l(\mathcal{R}^{-1(1)})\mathcal{R}^{-1(2)}. \tag{A15}$$

It is known[13] that $\{\mathcal{L}^{+i}_j,\mathcal{L}^{-i}_j\}$ and the square roots of the elements $\mathcal{L}^{\pm i}_i$ provide a (overcomplete) set of generators of $U_q\mathbf{g}$. Since in our conventions

$$\mathcal{R}\in H^+\otimes H^-, \tag{A16}$$

then $\mathcal{L}^{+a}_l\in H^+$ and $\mathcal{L}^{-a}_l\in H^-$. Beside (A12)–(A14) these generators fulfill

$$\mathcal{L}^{+i}_j=0, \quad \text{if } i>j, \tag{A17}$$

$$\mathcal{L}^{-i}_j=0, \quad \text{if } i<j, \tag{A18}$$

$$\mathcal{L}^{-i}_i\mathcal{L}^{+i}_i=\mathcal{L}^{+i}_i\mathcal{L}^{-i}_i=1, \quad \forall i \tag{A19}$$

$$\mathcal{L}^{\pm-n}_{-n}\cdots\ \mathcal{L}^{\pm n}_n=1, \tag{A20}$$

and, when $\mathbf{g}=\mathrm{so}(N),\mathrm{sp}(N)$, some additional relations. When $\mathbf{g}=\mathrm{so}(N)$ the latter read

$$\mathcal{L}_j^{\pm i}\mathcal{L}_k^{\pm h}g^{kj}=g^{hi},\quad \mathcal{L}_i^{\pm j}\mathcal{L}_h^{\pm k}g_{kj}=g_{hi}, \tag{A21}$$

where g_{ij} has been defined in (3.5). The braid matrix $\hat{R}$ is related to $\mathcal{R}$ by $\hat{R}^{ij}_{hk}\equiv R^{ji}_{hk}:=(\rho^j_h\otimes\rho^i_k)\mathcal{R}$. With the indices' convention described in Secs. III and IV $\hat{R}$ is given by

$$\hat{R}=q^{-1/N}\left[q\sum_i e^i_i\otimes e^i_i+\sum_{i\neq j}e^j_i\otimes e^i_j+k\sum_{i<j}e^i_i\otimes e^j_j\right] \tag{A22}$$

when $\mathbf{g}=\mathrm{sl}(N)$, and by

$$\hat{R}=q\sum_{i\neq 0}e^i_i\otimes e^i_i+\sum_{\substack{i\neq j,-j\\ \text{or } i=j=0}}e^j_i\otimes e^i_j+q^{-1}\sum_{i\neq 0}e^{-i}_i\otimes e^i_{-i}+k\left(\sum_{i<j}e^i_i\otimes e^j_j-\sum_{i<j}q^{-\rho_i+\rho_j}e^{-j}_i\otimes e^j_{-i}\right) \tag{A23}$$

when $\mathbf{g}=\mathrm{so}(N)$. Here e^i_j is the $N\times N$ matrix with all elements equal to zero except for a 1 in the ith column and jth row. The braid matrix of $\mathrm{sl}(N)$ admits the orthogonal projector decomposition

$$\hat{R}=q\mathcal{P}_S-q^{-1}\mathcal{P}_a,\quad \mathbf{g}=\mathrm{sl}(N); \tag{A24}$$

$\mathcal{P}_a$, $\mathcal{P}_S$ are the $U_q\,\mathrm{sl}(N)$-covariant deformed antisymmetric and symmetric projectors. The braid matrix of $\mathrm{so}(N)$ admits the orthogonal projector decomposition

$$\hat{R}=q\mathcal{P}_s-q^{-1}\mathcal{P}_a+q^{1-N}\mathcal{P}_t,\quad \mathbf{g}=\mathrm{so}(N); \tag{A25}$$

$\mathcal{P}_a$, $\mathcal{P}_t$, $\mathcal{P}_s$ are the q-deformed antisymmetric, trace, trace-free symmetric projectors.

The compact section of $U_q\mathbf{g}$ requires $q\in\mathbb{R}^+$ if $\mathbf{g}=\mathrm{so}(N)$, $q\in\mathbb{R}$ if $\mathbf{g}=\mathrm{sl}(N)$ and is characterized by the $*$-structure,

$$(\mathcal{L}_j^{\pm i})^*=S\mathcal{L}_i^{\mp j}. \tag{A26}$$

For $\mathbf{g}=\mathrm{so}(N)$ this amounts to

$$(\mathcal{L}_j^{\pm i})^*=g_{ih}\mathcal{L}_k^{\mp h}g^{kj}. \tag{A27}$$

The noncompact sections of $U_q\mathbf{g}$ require $|q|=1$ and are characterized by the $*$-structure,

$$(\mathcal{L}_j^{\pm i})^*=U_r^{-1i}\mathcal{L}_s^{\pm r}U_j^s=u\mathcal{L}_j^{\pm i}u^{-1}. \tag{A28}$$

This can be checked using the property $(\hat{R}^{ij}_{hk})^*=\hat{R}^{-1ji}_{kh}$. Here we have defined

$$U^i_j=\rho^i_j(u) \tag{A29}$$

with u any of the elements defined in (A7). For $\mathbf{g}=\mathrm{so}(N)$ one can take

$$U^i_j:=g^{ih}g_{jh}. \tag{A30}$$

From formulas (A3) and (A4) in the Appendix one finds that the coproducts are given by

$$\Delta(\mathcal{L}_j^{+i})=\mathcal{L}_h^{+i}\otimes\mathcal{L}_j^{+h},\quad \Delta(\mathcal{L}_j^{-i})=\mathcal{L}_h^{-i}\otimes\mathcal{L}_j^{-h}. \tag{A31}$$

2. Proof of proposition 1

We make use of the identity

$$\varphi^{\pm}(g^{\pm})\triangleleft h^{\pm}=\varphi^{\pm}(g^{\pm}\triangleleft h^{\pm}), \tag{A32}$$

for any $g^{\pm}$, $h^{\pm}\in H^{\pm}$, which we prove in Ref. 17. The right action appearing at the rhs is the (right) adjoint action on itself

$$h\triangleleft g=Sg_{(1)}hg_{(2)}, \quad g,h\in H; \tag{A33}$$

where S denotes the antipode of the Hopf algebra H. We shall also need the inverse of (1.9),

$$a_1a_2=(a_2\triangleleft\mathcal{R}^{-1(2)})(a_1\triangleleft\mathcal{R}^{-1(1)}). \tag{A34}$$

Now,

$$\begin{aligned}
\chi^{+}(a_2) &\overset{(1.13)}{=} \varphi_1^{+}(\mathcal{R}^{(1)})(a_2\triangleleft\mathcal{R}^{(2)})\\
&\overset{(A34)}{=} (a_2\triangleleft\mathcal{R}^{(2)}\mathcal{R}^{-1(2')})[\varphi_1^{+}(\mathcal{R}^{(1)})\triangleleft\mathcal{R}^{-1(1')}]\\
&\overset{(A32)}{=} (a_2\triangleleft\mathcal{R}^{(2)}\mathcal{R}^{-1(2')})\varphi_1^{+}(\mathcal{R}^{(1)}\triangleleft\mathcal{R}^{-1(1')})\\
&\overset{(A33)}{=} (a_2\triangleleft\mathcal{R}^{(2)}\mathcal{R}^{-1(2')})\varphi_1^{+}(S\mathcal{R}_{(1)}^{-1(1')}\mathcal{R}^{(1)}\mathcal{R}_{(2)}^{-1(1')})\\
&\overset{(A3)}{=} (a_2\triangleleft\mathcal{R}^{(2)}\mathcal{R}^{-1(2')}\mathcal{R}^{-1(2'')})\varphi_1^{+}(S\mathcal{R}^{-1(1'')}\mathcal{R}^{(1)}\mathcal{R}^{-1(1')})\\
&=(a_2\triangleleft\mathcal{R}^{-1(2'')})\varphi_1^{+}(S\mathcal{R}^{-1(1'')}),
\end{aligned}$$

which proves (1.21). Similarly one proves (1.22).

3. The maps $\varphi^{\pm}$ for the quantum Euclidean spaces or spheres

We introduce the short-hand notation

$$[A,B]_x=AB-xBA. \tag{A35}$$

In Ref. 5 we have found algebra homomorphisms $\varphi^{\pm}:\mathbb{R}_q^N\rtimes U_q^{\pm}\,\mathrm{so}(N)\to\mathbb{R}_q^N$. The images of φ^{-} on the negative FRT generators read

$$\varphi^{-}(\mathcal{L}_j^{-i})=g^{ih}[\mu_h,x^k]_q g_{kj}, \tag{A36}$$

where

$$\begin{aligned}
\mu_0&=\gamma_0(x^0)^{-1} \quad \text{for } N \text{ odd},\\
\mu_{\pm1}&=\gamma_{\pm1}(x^{\pm1})^{-1}\mathcal{L}_1^{\pm1} \quad \text{for } N \text{ even},\\
\mu_a&=\gamma_a r_{|a|}^{-1}r_{|a|-1}^{-1}x^{-a} \quad \text{otherwise},
\end{aligned} \tag{A37}$$

and $\gamma_a\in\mathbb{C}$ are normalization constants fulfilling the conditions

$$\gamma_0=-q^{-1/2}h^{-1} \quad \text{for } N \text{ odd},$$
$$\gamma_1\gamma_{-1}=\begin{cases}-q^{-1}h^{-2} & \text{for } N \text{ odd},\\ k^{-2} & \text{for } N \text{ even},\end{cases} \tag{A38}$$
$$\gamma_a\gamma_{-a}=-q^{-1}k^{-2}\omega_a\omega_{a-1} \quad \text{for } a>1.$$

h, k, ω_a are defined as in Secs. III and IV. On the other hand, the images of φ^+ on the positive FRT generators read

$$\varphi^+(\mathcal{L}_j^{+i})=g^{ih}[\overline{\mu}_h,x^k]_{q^{-1}}g_{kj}, \tag{A39}$$

where

$$\overline{\mu}_0=\overline{\gamma}_0(x^0)^{-1} \quad \text{for } N \text{ odd},$$
$$\overline{\mu}_{\pm1}=\overline{\gamma}_{\pm1}(x^{\pm1})^{-1}\mathcal{L}_1^{\pm1} \quad \text{for } N \text{ even}, \tag{A40}$$
$$\overline{\mu}_a=\overline{\gamma}_a r_{|a|}^{-1}r_{|a|-1}^{-1}x^{-a} \quad \text{otherwise},$$

and $\overline{\gamma}_a\in\mathbb{C}$ normalization constants fulfilling the conditions

$$\overline{\gamma}_0=q^{1/2}h^{-1} \quad \text{for } N \text{ odd},$$
$$\overline{\gamma}_1\overline{\gamma}_{-1}=\begin{cases}-qh^{-2} & \text{for } N \text{ odd},\\ k^{-2} & \text{for } N \text{ even},\end{cases} \tag{A41}$$
$$\overline{\gamma}_a\overline{\gamma}_{-a}=-qk^{-2}\omega_a\omega_{a-1} \quad \text{for } a>1.$$

If we require $\varphi^+=\varphi^-$ on the Cartan subalgebra $H_c=H^+\cap H^+$ then it must be

$$\overline{\gamma}_i=-\gamma_{-i}\begin{cases}1 & \text{if } i>1, \text{ or } i=1 \text{ and } N \text{ odd}\\ q^2 & \text{if } i<-1, \text{ or } i=-1 \text{ and } N \text{ odd}.\end{cases}$$

Incidentally, for odd N one can choose the free parameters $\gamma_a,\overline{\gamma}_a$ in such a way that in addition φ^+,φ^- can be glued into an algebra homomorphism $\varphi:\mathbb{R}_q^N\rtimes U_q\,\mathrm{so}(N)\to\mathbb{R}_q^N$:[5] It must be $\gamma_1{}^2=-q^{-2}h^{-2}$, $\gamma_{-1}{}^2=-h^{-2}$, $\gamma_a{}^2=-q^{-2}k^{-2}\omega_a\omega_{a-1}$, $\gamma_{-a}{}^2=-k^{-2}\omega_a\omega_{a-1}$ $(a>1)$, and $\overline{\gamma_i}=-q\gamma_i$, $i=-n,1-n,\ldots,n$.

We give the following explicit expression for $\varphi^{\pm}(\mathcal{L}_j^{\pm i})$ in the case $N=3$:

$$[\varphi^-(\mathcal{L}_j^{-i})]=\begin{bmatrix}-qh\gamma_1(x^0)^{-1}r & & \\ q^{1/2}(q+1)(x^0)^{-1}x^+ & 1 & \\ q^{1/2}(q+1)(h\gamma_1 rx^0)^{-1}(x^+)^2 & (1+q^{-1})(h\gamma_1 r)^{-1} & -(qh\gamma_1 r)^{-1}x^0\end{bmatrix} \tag{A42}$$

and

$$[\varphi^+(\mathcal{L}_j^{+i})]=\begin{bmatrix}-h\overline{\gamma}_1 r^{-1}x^0 & q^{-1/2}\overline{\gamma}_1 kr^{-1}x^- & q^{-2}k\overline{\gamma}_1(rx^0)^{-1}(x^-)^2\\ & 1 & q^{-1/2}(q^{-1}+1)(x^0)^{-1}x^-\\ & & -(h\overline{\gamma}_1x^0)^{-1}r\end{bmatrix}. \tag{A43}$$

When $q\in\mathbb{R}^+$ the real structure of $\mathbb{R}_q^N$ is given by

$$(x^i)^*=x^jg_{ji}. \tag{A44}$$

Note that when N is odd $\mu_0,\overline{\mu}_0$, which are completely determined by their definitions, are such that $\mu_0^*=-q^{-1}\overline{\mu}_0$. We fix the other $\gamma_a,\overline{\gamma}_a$ so that for any a

$$\mu_a^*=-q^{-1}g_{ab}\overline{\mu}_b. \tag{A45}$$

This was already considered in Ref. 5 and requires

$$\gamma_{\pm 1}^* = -\overline{\gamma}_{\mp 1} \quad \text{if } N \text{ even},$$

$$\gamma_a^* = -\overline{\gamma}_{-a} \begin{cases} 1 & \text{if } a<0, \\ q^{-2} & \text{if } a>0, \end{cases} \quad \text{otherwise.} \tag{A46}$$

As a consequence,

$$[\varphi^-(\mathcal{L}_j^{-i})]^* \overset{(A36)}{=} (g^{ih}[\mu_h, x^k]_q g_{kj})^*$$

$$\overset{(A44)}{=} g^{ih}[x^j, \mu_h^*]_q$$

$$\overset{(A45)}{=} [\overline{\mu}_i, x^j]_{q^{-1}}$$

$$\overset{(A39)}{=} g_{ih}\varphi^+(\mathcal{L}_k^{+h})g^{kj}$$

$$\overset{(A27)}{=} \varphi^+[(\mathcal{L}_j^i)^*].$$

In other words

$$[\varphi^{\pm}(g)]^* = \varphi^{\mp}(g^*). \tag{A47}$$

When $|q|=1$

$$(x^i)^* = x^i. \tag{A48}$$

Note that when N is odd $\mu_0, \overline{\mu}_0$, which are completely determined by their definitions, are such that $\mu_0^* = -q\mu_0 = \overline{\mu}_0$. We fix the other $\gamma_a, \overline{\gamma}_a$ so that for any a

$$\mu_a^* = -q\mu_a, \quad \overline{\mu}_a^* = -q^{-1}\overline{\mu}_a. \tag{A49}$$

This requires

$$\gamma_{\pm 1}^* = -\gamma_{\pm 1} \quad \text{if } N \text{ even},$$

$$\gamma_a^* = -\gamma_a \begin{cases} 1 & \text{if } a<0 \\ q^{+2} & \text{if } a>0 \quad \text{otherwise.} \end{cases} \tag{A50}$$

As a consequence,

$$[\varphi^-(\mathcal{L}_j^{-i})]^* \overset{(A36)}{=} (g^{ih}[\mu_h, x^k]_q g_{kj})^*$$

$$\overset{(A48)}{=} -q^{-1}g^{hi}[\mu_h^*, x^k]_q g_{jk}$$

$$\overset{(A49)}{=} g^{hi}[\mu_h, x^k]_q g_{jk}$$

$$\overset{(A30),(A36)}{=} U_r^{-1i}\varphi^-(\mathcal{L}_s^{-r})U_r^i$$

$$\overset{(A28)}{=} \varphi^-[(\mathcal{L}_j^{-i})^*].$$

Similarly one proves that $[\varphi^-(\mathcal{L}_j^{-i})]^*=\varphi^-[(\mathcal{L}_j^{-i})^*]$. In other words, $\varphi^\pm$ are $*$-homomorphisms.

4. The maps φ for the deformed Heisenberg algebras

In Ref. 14 we constructed an algebra homomorphism $\varphi: U_q\,\mathrm{so}(N)\ltimes\mathcal{A}_1\to\mathcal{A}_1$, where $\mathcal{A}_1$ denotes the $U_q\,\mathrm{so}(N)$-covariant (deformed) Heisenberg algebra, such that φ is a $*$-homomorphism

$$\varphi(g^*)=\varphi(g)^* \tag{A51}$$

on the compact section of $U_q\,\mathrm{so}(N)$ (what requires $q\in\mathbb{R}^+$). One can easily prove the same result also for the noncompact section (A28) of $\mathbf{g}=\mathrm{so}(N)$ as well as the compact and noncompact sections of $\mathbf{g}=\mathrm{sl}(N)$. This can be done maybe most rapidly using as a set of generators the so-called vector fields Z_j^i,[30] which are related to the FRT generators by

$$Z_j^i=\mathcal{L}_h^{+i}S\mathcal{L}_j^{-h}. \tag{A52}$$

From (A26) and (A28) one immediately finds

$$(Z_j^i)^*=Z_i^j \quad \text{if } q\in\mathbb{R}^+, \tag{A53}$$

$$(Z_j^i)^*=U_a^{-1i}(S^{-1}\mathcal{L}_b^{-h})\mathcal{L}_h^{+a}U_j^b \quad \text{if } |q|=1; \tag{A54}$$

if $\mathbf{g}=\mathrm{so}(N)$ the second relation reduces to

$$(Z_j^i)^*=U_b^{-1a}Z_c^b\hat{R}_{aj}^{-1ci}. \tag{A55}$$

In Ref. 9 the explicit expression of $\varphi(Z_j^i)$ in terms of the x's and ∂'s is given both for $g=\mathrm{sl}(N)$ and $\mathbf{g}=\mathrm{so}(N)$, and it is not difficult to show that on these generators (and therefore on all of $U_q\mathbf{g}$) (A51) is satisfied. In performing the calculations one has to keep in mind that the authors of Ref. 9 work with the left action, rather than with the right, so one has to switch to the conventions described in Sec. V, but, as explained there, this wil not modify the result (A51). As an intermediate step, we give the action of the $*$-structure on the coordinates and derivatives for the case $\mathbf{g}=\mathrm{so}(N)$, in the notation used there:

$$(x_h)^*=g^{hk}x_k, \quad (\partial^i)^*=-q^{-N}\hat{\partial}_i \quad \text{if } q\in\mathbb{R}^+, \tag{A56}$$

$$(x_h)^*=x_h, \quad (\partial^i)^*=-q^N U_j^{-1i}\partial^j, \quad (\hat{\partial}_i)^*=-q^{-N}\partial_i \quad \text{if } |q|=1. \tag{A57}$$

(Received 25 June 2002; accepted 12 September 2002)

Spin networks are a natural generalization of Wilson loop functionals. They have been extensively studied in the case where the gauge group is compact and it has been shown that they naturally form a basis of gauge invariant observables. Physically the restriction to compact gauge groups is enough for the study of Yang–Mills theories, however it is well known that noncompact groups naturally arise as internal gauge groups for Lorentzian gravity models. In this context, a proper construction of gauge invariant observables is needed. The purpose of the present work is to define the notion of spin network states for noncompact groups. We first build, by a careful gauge fixing procedure, a natural measure and a Hilbert space structure on the space of gauge invariant graph connections. Spin networks are then defined as generalized eigenvectors of a complete set of hermitic commuting operators. We show how the delicate issue of taking the quotient of a space by noncompact groups can be address in term of algebraic geometry. We finally construct the full Hilbert space containing all spin network states. Having in mind applications to gravity, we illustrate our results for the groups SL(2,**R**) and SL(2,**C**). © *2003 American Institute of Physics.* [DOI: 10.1063/1.1521522]

I. INTRODUCTION

The purpose of this paper is to generalize the construction of an Hilbert space of spin network states to the case in which the gauge group is noncompact. Spin network states arise naturally in many fields of physics since they form a basis of gauge invariant functionals in Yang–Mills-type theories.[1] In the context of gravity they were introduced by Rovelli and Smolin[2,3] and they were promoted as a basis of an Hilbert space of gauge and diffeomorphism invariant functionals in works by Ashtekar and Lewandowski[4–6] and by Baez.[7] This series of works have been focused on the case where the gauge group is compact. Compact gauge groups are natural as symmetry groups of gauge theory and Euclidean gravity, however noncompact gauge groups arise as symmetry groups of Lorentzian gravity.

For instance, SL(2,**C**) arises in the original Ashtekar formulation of $3+1$ gravity in terms of self-dual variables. However, in this context, the lack of properly well-defined spin network states has forced the community to work with the real SU(2) Barbero[8] connection at the price of introducing a new constant (Immirzi parameter), a more complicated dynamics[9] and the loss of a natural four-dimensional geometrical interpretation of the phase space variables.[10] In the case of $2+1$ Lorentzian gravity, the partition function and the transition amplitudes have been computed in terms of spin networks (recoupling coefficients) of SL(2,**R**).[11] In this context, geometrical

interpretation of the representation labels has led to the conclusion that space is continuous whereas time is discrete,[11,12] in agreement with former results from 't Hooft.[13]

In order to put these results on a firmer basis and construct geometrical operators in the Lorentzian context, one needs to understand better the nature of noncompact spin networks and how they form a natural Hilbert space related to the Hilbert space of gauge and diffeomorphism invariant connections. This is the purpose of this work.

Several issues concerning noncompact spin network have already been raised in the literature. First, Ashtekar and Lewandowski have already addressed the issue of completeness of the spin network functionals[14] versus the separability of the space of gauge invariant connections. We shall come back to these issues in Sec. III B. There also has been some attempts to define noncompact spin networks. Marolf[15] was the first one to show, in the context of $2+1$ gravity on the torus, that the loop transform using finite dimensional representation is ill defined when the group is noncompact. He and, Ashtekar and Loll,[16] have studied the possibility to overcome this difficulty at the price of introducing additional and non-natural structures.

Our approach shed new lights on this problem, it leads to a different point of view since we do not insist on having spin networks labeled by finite dimensional representations. We show that one should work instead with the infinite dimensional unitary representations of the group. The emergence of spin networks labeled by infinite dimensional representation is not new. They already appeared in the context of spin foams models for Lorentzian 3D gravity[11,17] and 4D gravity.[18,19]

Moreover our formalism is more general since it sets a framework for all noncompact groups. Indeed, our purpose is to give a general account of the construction of noncompact spin networks and the structure of the stratified space of gauge invariant connections. Our presentation is valid for any semisimple reductive group. The general exposition is therefore quite mathematical. Having in mind further application to gravity we will illustrate the main problems and results in the context of SL(2,**C**) and SL(2,**R**).

Connection space and cylindrical functions: We choose once for all a manifold Σ and P a locally trivial smooth principal G-bundle over Σ, with G a semisimple reductive group. We denote by $\mathcal{A}$ the space of gauge G-connections and by $\mathcal{G}$ the gauge group acting on connection by $A^k = k^{-1}Ak + k^{-1}\,dk$. The theories we are interested in are Yang–Mills type in the sense that the phase space conjugate variables are given by a G-connection A (a magnetic potential) and a $a\,dP$ valued densitized vector field E, both are anti-Hermitian. This phase space is the cotangent bundle to the space of connection $T^*(\mathcal{A})$. On such a phase space we want to impose the Gauss laws (gauge invariance) and eventually the diffeomorphism constraint. The representation of the operator algebra is done in the polarization where the wave functionals depend on the connection and therefore the Hilbert space structure is formally $L^2(\mathcal{A}/\mathcal{G}, d\mu)$. The purpose of this work is to study the structure of this space. In fact we will first restrict our intention to special gauge invariant functionals of the connections called cylindrical functionals and we will study the possibility to give the space of cylindrical functions an Hilbert space structure. In the gauge invariant context, cylindrical functions are associated with graphs. Given a smooth *oriented* graph Γ composed of E oriented edges and V vertices we have the holonomy map:

$$\Gamma:\ \mathcal{A} \to G^{\otimes E}$$

$$A \to (g_{e_1}, \ldots, g_{e_E}), \tag{1.1}$$
