Now turning back to the discontinuity of the resolvent with respect to s_2 when $s_1\neq0$ we get from (2.51) for these limits

$$\lim_{s_2\to\pm0\mathbf{k}_{\Im}}(\hat{M}_1(s)|_{s_1=\mathbf{k}_{\Im}})=G_1(\pm0+i\mathbf{k}_{\Im}). \tag{3.32}$$

Relations among Green's functions follow from the bilinear representation (3.16) for the resolvent. For the boundary values of the Green's function of the Jost solutions at the real axis we use notations (2.72). Then by (3.22) they are finite for all finite k but discontinuous at $k=0$ and by (3.31)

$$G_1^{\sigma}(k)-G_{1,\pm}=\frac{\mp1}{2\pi i}\int dk'\,\theta(\mp\sigma(k-k'))\Phi_1(k')\otimes\Psi_1(k')\mp\frac{\theta(\mp\sigma k)}{2\pi i}\varphi_1\otimes\psi_1,\quad \sigma=+,-. \tag{3.33}$$

Other relations of such kind, say, among advanced and retarded Green's functions, can be derived analogously.

IV. INVERSE SCATTERING TRANSFORM ON NONTRIVIAL BACKGROUND: TWO-DIMENSIONAL PERTURBATION OF THE SOLITON SOLUTION

A. Resolvent

We investigate, now, the operator $\mathcal{L}$ in (1.1) with a potential of the form (1.4), where $u_1(x_1)$ is the one-soliton solution (3.2) and $u_2(x)$ is a generic real, smooth and rapidly decaying function on the plane (x_1,x_2), "small" in some sense, so that it can be considered a two-dimensional perturbation of the one-soliton solution. According to our general approach we introduce the extension $L(s)$ of $\mathcal{L}$ and the inverse of this extension, i.e., its extended resolvent $M(s)$. In the previous sections we considered the special case $u_2(x)\equiv 0$ and studied in detail the properties of the corresponding resolvent $M_1(s)$. Therefore, it is convenient to exploit these results and to use for constructing the resolvent $M(s)$, instead of the integral equations (2.37), the following ones,

$$M(s)=M_1(s)+M_1(s)U_2M(s), \quad M(s)=M_1(s)+M(s)U_2M_1(s), \tag{4.1}$$

where $U_2(x,x';s)=u_2(x)\delta(x-x')$. We assume that, thanks to the "smallness" requirement on $u_2(x)$, both equations admit a unique solution $M(x,x';s)$ in $\mathcal{S}'(\mathbb{R}^6)$. This requirement, in addition, guarantees that the solution $M(x,x';s)$ inherits the properties of $M_1(x,x';s)$, in particular that $M(x,x';s)$ is a distribution with respect to $x-x'$, a smooth function with respect to $x+x'$ and a continuous function of s, when $s_1\neq 0$ and $s_2\neq 0$. Therefore, the Hilbert identities (2.40) and (2.42) are valid also in our case, since the composition of operators appearing in them exist and are associative. The Hilbert identity (2.40) can be used for proving that equations (4.1) have the same solution. In fact, if we choose M to be a solution of the first equation in (4.1) [and then solution of the second equation in (2.26)] and M' to obey the second equation in (4.1) [the first in (2.26), correspondingly], then we obtain $M'=M$. Notice that, in addition, this proves that $M(s)$ is Hermitian, i.e., it obeys (2.38) like in the decaying and one-dimensional cases. Instead, the Hilbert identity (2.42) can be used for studying the properties of the resolvent in the s variable. However, as we did for the integral equations (4.1) defining $M(s)$, it is more convenient to rewrite it in terms of the one-dimensional operator $L_1(s)$ and resolvent $M_1(s)$ as follows:

$$M(\mathbf{s}')-M(\mathbf{s})=M(\mathbf{s}')L_1(\mathbf{s}')(M_1(\mathbf{s}')-M_1(\mathbf{s}))L_1(\mathbf{s})M(\mathbf{s}). \tag{4.2}$$

Then, in analogy with (2.44) we get for the derivatives of the hat-kernel of the resolvent

$$\frac{\partial\hat{M}(s)}{\partial s_j}=\hat{M}(s)\overleftarrow{\mathcal{L}}_1\frac{\partial\hat{M}_1(s)}{\partial s_j}\vec{\mathcal{L}}_1\hat{M}(s), \quad j=1,2, \quad s_2\neq 0.$$

Inserting here (3.20) and (3.21) we get for the derivatives of $\hat{M}(s)$ the same equations (2.45) and (2.46) of the decaying case, where the Jost solutions are defined now as [cf. (2.50)]

$$\Phi(\mathbf{k})=G(\mathbf{k})\overleftarrow{\mathcal{L}}_1\Phi_1(\mathbf{k}), \quad \Psi(\mathbf{k})=\Psi_1(\mathbf{k})\vec{\mathcal{L}}_1G(\mathbf{k}), \tag{4.3}$$

with the Green's function $G(x,x',\mathbf{k})$ defined by (2.51) as in the decaying case. We excluded here the value $s_2=0$, where $M_1(s)$ is discontinuous.

For the study of the discontinuity at $s_2=0$ of $M(s)$ inherited from $M_1(s)$, following the results of Sec. III, we have to consider separately the cases $s_1=0$ and $s_1\neq 0$. The boundary values of the resolvent in the first case, $\lim_{s_2\to\pm 0}\hat{M}(s)|_{s_1=0}$, define the advanced/retarded Green's functions like in (2.52). In the case $s_1\neq 0$ for the boundary values of the resolvent thanks to (2.51) we have in analogy with (3.32) that

$$\lim_{s_2\to\pm 0\mathbf{k}_\mathfrak{I}}(\hat{M}(s)|_{s_1=\mathbf{k}_\mathfrak{I}})=G(\pm 0+i\mathbf{k}_\mathfrak{I}). \tag{4.4}$$

Now we consider the properties of these Green's functions in detail.

B. The Green's function of the Jost solutions

1. Properties of $G(\mathbf{k})$

We proved above that the definition (2.51) of the Green's function $G(\mathbf{k})$ of the Jost solutions is applicable in the case we are considering now. Then directly by (4.1) we get that $G(\mathbf{k})$ satisfies the integral equations

$$G(\mathbf{k})=G_1(\mathbf{k})+G_1(\mathbf{k})U_2G(\mathbf{k}),\quad G(\mathbf{k})=G_1(\mathbf{k})+G(\mathbf{k})U_2G_1(\mathbf{k}). \tag{4.5}$$

Taking into account that $\mathcal{L}=\mathcal{L}_1-U_2$ it is easy to check that $G(\mathbf{k})$ obeys the differential equations (2.58) and the conjugation property (2.59). According to the remark we already made above for the resolvent $M(s)$, $G(\mathbf{k})$ has the same domains of analyticity as $G_1(\mathbf{k})$. Precisely, it is analytic in the region $\mathbf{k}_\Re\mathbf{k}_\Im\neq 0$, where it obeys (2.64) and (2.65), and continuous up to the borders, it has a cut at $\mathbf{k}_\Im=0$ as in the decaying case and an additional cut at $\mathbf{k}_\Re=0$ when $|\mathbf{k}_\Im|<\kappa$. Using notation (2.71) for the boundary values of the Green's function at the real axis, we get

$$\lim_{\sigma\mathbf{k}_\Im\to+0} G(\pm 0+i\mathbf{k}_\Im)=\lim_{\pm k\to+0} G^\sigma(k)\equiv G^\sigma(\pm 0),\quad \sigma=+,-. \tag{4.6}$$

Notice that by inserting (4.5) into the definitions (4.3) of the Jost solutions we get the integral equations

$$\Phi(\mathbf{k})=\Phi_1(\mathbf{k})+G_1(\mathbf{k})U_2\Phi(\mathbf{k}),\quad \Psi(\mathbf{k})=\Psi_1(\mathbf{k})+\Psi(\mathbf{k})U_2G_1(\mathbf{k}), \tag{4.7}$$

which can be also considered to define the Jost solutions.

2. Discontinuity of $G(\mathbf{k})$ across the imaginary axis

As always in order to study the properties of the resolvent at a discontinuity we use the Hilbert identity. Choosing in (4.2) both $\mathbf{s}$ and $\mathbf{s}'$ to be real and $s_1=s_1'$, we have

$$\lim_{s_2\to+0}\hat{M}(s)-\lim_{s_2\to-0}\hat{M}(s)=(\lim_{s_2\to\pm 0}\hat{M}(s)\tilde{\mathcal{L}}_1)(\lim_{s_2\to+0}\hat{M}_1(s)-\lim_{s_2\to-0}\hat{M}_1(s))(\vec{\mathcal{L}}_1\lim_{s_2\to\mp 0}\hat{M}(s)),$$

which, by (4.4), is the discontinuity of the Green's function across the imaginary axis. By using (3.22) for the discontinuity of $G_1(\mathbf{k})$ we obtain

$$G(+0+i\mathbf{k}_\Im)-G(-0+i\mathbf{k}_\Im)=\frac{\theta(\kappa-|\mathbf{k}_\Im|)}{2\pi i\ \mathrm{sgn}\,\mathbf{k}_\Im}(G(\pm 0+i\mathbf{k}_\Im)\tilde{\mathcal{L}}_1\varphi_1)\otimes(\psi_1\vec{\mathcal{L}}_1G(\mp 0+i\mathbf{k}_\Im)), \tag{4.8}$$

where in brackets ''vector'' and ''covector'' notation like in (2.50) is used and the direct product is defined as in (2.36). Applying operations $\psi_1\vec{\mathcal{L}}_1$ and $\tilde{\mathcal{L}}_1\varphi_1$ to this equality from the left and from the right, correspondingly, we get in the region $\kappa>|\mathbf{k}_\Im|>0$

$$\left[1-\frac{\psi_1\vec{\mathcal{L}}_1G(-0+i\mathbf{k}_\Im)\tilde{\mathcal{L}}_1\varphi_1}{2\pi i\ \mathrm{sgn}\,\mathbf{k}_\Im}\right]\left[1+\frac{\psi_1\vec{\mathcal{L}}_1G(+0+i\mathbf{k}_\Im)\tilde{\mathcal{L}}_1\varphi_1}{2\pi i\ \mathrm{sgn}\,\mathbf{k}_\Im}\right]=1, \tag{4.9}$$

where the ''expectation values'' in the numerator have explicit expressions analogous to those in (2.99). Under our assumptions on the potential both multipliers on the l.h.s. are regular in this region so they have no zeroes. Denoting the right multiplier as $A(\mathbf{k}_\Im)$ we get

$$A(\mathbf{k}_\Im)=\left(1\pm\frac{\psi_1\vec{\mathcal{L}}_1G(\pm 0+i\mathbf{k}_\Im)\tilde{\mathcal{L}}_1\varphi_1}{2\pi i\mathrm{sgn}\,\mathbf{k}_\Im}\right)^{\pm 1}, \tag{4.10}$$

which has no zeroes for any $|\mathbf{k}_\Im|<\kappa$,

$$A(\mathbf{k}_\jmath)\neq 0, \tag{4.11}$$

and by (2.59) and the second equality in (3.8) obeys the conjugation property

$$\overline{A(\mathbf{k}_\jmath)}=A(-\mathbf{k}_\jmath). \tag{4.12}$$

The function $A(\mathbf{k}_\jmath)$ is defined inside the interval $|\mathbf{k}_\jmath|<\kappa$, it is continuous for all $\mathbf{k}_\jmath\neq 0$ and using for the limiting values at $\mathbf{k}_\jmath=\pm 0$ notation of the type (2.71), $A^\pm=\lim_{\mathbf{k}_\jmath\to\pm 0}A(\mathbf{k}_\jmath)$, we get by (4.6) and (4.10)

$$A^\pm=1\pm\frac{\psi_1\vec{\mathcal{L}}_1G^\pm(+0)\tilde{\mathcal{L}}_1\varphi_1}{2\pi i}. \tag{4.13}$$

Thanks to (4.11) both these constants $A^\pm$ are different from zero and by (4.12) they are mutually conjugate,

$$\overline{A^-}=A^+. \tag{4.14}$$

If we introduce the functions

$$\varphi(\mathbf{k}_\jmath)=G(+0+i\mathbf{k}_\jmath)\tilde{\mathcal{L}}_1\varphi_1,\quad \psi(\mathbf{k}_\jmath)=A(\mathbf{k}_\jmath)(\psi_1\vec{\mathcal{L}}_1G(-0+i\mathbf{k}_\jmath)), \tag{4.15}$$

where the multiplier $A(\mathbf{k}_\jmath)$ in the last equality is introduced for convenience, the discontinuity of the Green's function at the imaginary axis (4.8) can be written in their terms as

$$G(+0+i\mathbf{k}_\jmath)-G(-0+i\mathbf{k}_\jmath)=\theta(\kappa-|\mathbf{k}_\jmath|)\frac{\varphi(\mathbf{k}_\jmath)\otimes\psi(\mathbf{k}_\jmath)}{2\pi iA(\mathbf{k}_\jmath)\operatorname{sgn}\mathbf{k}_\jmath}. \tag{4.16}$$

Thanks to (4.10) this equality gives the following relations symmetric to (4.15),

$$\varphi(\mathbf{k}_\jmath)=A(\mathbf{k}_\jmath)(G(-0+i\mathbf{k}_\jmath)\tilde{\mathcal{L}}_1\varphi_1),\quad \psi(\mathbf{k}_\jmath)=\psi_1\vec{\mathcal{L}}_1G(+0+i\mathbf{k}_\jmath). \tag{4.17}$$

Notice that using the first equality in (4.15) and the second equality in (4.17) we get by (4.5) the integral equations for these functions

$$\varphi(\mathbf{k}_\jmath)=\varphi_1+G_1(+0+i\mathbf{k}_\jmath)U_2\varphi(\mathbf{k}_\jmath),\quad \psi(\mathbf{k}_\jmath)=\psi_1+\psi(\mathbf{k}_\jmath)U_2G_1(+0+i\mathbf{k}_\jmath), \tag{4.18}$$

$|\mathbf{k}_\jmath|<\kappa$, which can also be considered to define them.

The values of the Green's function on the two sides of the cut along the imaginary axis can be obtained by using the derivatives of the Green's function (2.64), whose validity can be extended to the case we are now considering if the Jost solutions are defined as in (4.3). Performing the limits $\mathbf{k}_\mathfrak{R}\to\pm 0$ we get in the strip $|\mathbf{k}_\jmath|<\kappa$

$$G(\pm 0+i\mathbf{k}_\jmath)=G^\sigma(\pm 0)+\frac{\sigma}{2\pi}\int_0^{\mathbf{k}_\jmath}d\alpha\,\Phi(\pm 0+i\alpha)\otimes\Psi(\pm 0+i\alpha),\quad \sigma=\operatorname{sgn}\mathbf{k}_\jmath, \tag{4.19}$$

where we used the second equality in (4.6).

3. Behavior of $G(\mathbf{k})$ at the end points of the cut

In order to study the behavior of the Green's function in the vicinities of the points $\mathbf{k}=\pm i\kappa$ [where $G_1(\mathbf{k})$ is singular] we use (3.27) and introduce the regularized Green's function $G_{\text{reg}}(\mathbf{k})$ as solution of the integral equation

$$G_{\text{reg}}(\mathbf{k})=G_{1,\text{reg}}(\mathbf{k})+G_{1,\text{reg}}(\mathbf{k})U_2G_{\text{reg}}(\mathbf{k}), \tag{4.20}$$

which thanks to properties of $G_{1,\mathrm{reg}}$ has finite limits at points $\mathbf{k}=\pm i\kappa$. Subtracting (4.20) from (4.5) and using (3.27) we get

$$G(\mathbf{k})-G_{\mathrm{reg}}(\mathbf{k})=-2\pi i\gamma(\mathbf{k})(\mathbf{k}\,\mathrm{sgn}\,\mathbf{k}_\mathfrak{I}-i\kappa)\Phi_1(\mathbf{k})\otimes\Psi_1(\mathbf{k})[I+U_2G(\mathbf{k})]$$
$$+G_{1,\mathrm{reg}}(\mathbf{k})U_2[G(\mathbf{k})-G_{\mathrm{reg}}(\mathbf{k})].$$

Under the assumption of unique solvability of (4.20) and thanks to the identity $I+U_2G(\mathbf{k})=\vec{\mathcal{L}}_1G(\mathbf{k})$ we derive from this equality for the Green's function in vicinity of these points the following representation:

$$G(\mathbf{k})=G_{\mathrm{reg}}(\mathbf{k})-\frac{2\pi i\gamma(\mathbf{k})(\mathbf{k}\,\mathrm{sgn}\,\mathbf{k}_\mathfrak{I}-i\kappa)(G_{\mathrm{reg}}(\mathbf{k})\tilde{\mathcal{L}}_1\Phi_1(\mathbf{k}))\otimes(\Psi_1(\mathbf{k})\vec{\mathcal{L}}_1G_{\mathrm{reg}}(\mathbf{k}))}{1+2\pi i\gamma(\mathbf{k})(\mathbf{k}\,\mathrm{sgn}\,\mathbf{k}_\mathfrak{I}-i\kappa)(\Psi_1(\mathbf{k})\vec{\mathcal{L}}_1G_{\mathrm{reg}}(\mathbf{k})\tilde{\mathcal{L}}_1\Phi_1(\mathbf{k}))}. \quad (4.21)$$

In analogy with (4.15), (4.17) we introduce the regular parts of the functions $\varphi(x,\mathbf{k}_\mathfrak{I})$, $\psi(x,\mathbf{k}_\mathfrak{I})$ at $\mathbf{k}_\mathfrak{I}=\pm\kappa$:

$$\varphi_{\mathrm{reg},\pm}=G_{\mathrm{reg}}(\pm i\kappa)\tilde{\mathcal{L}}_1\varphi_1,\quad \psi_{\mathrm{reg},\pm}=\psi_1\vec{\mathcal{L}}_1G_{\mathrm{reg}}(\pm i\kappa) \quad (4.22)$$

and the ''expectation values''

$$B_\pm=\psi_1\vec{\mathcal{L}}_1G_{\mathrm{reg}}(\pm i\kappa)\tilde{\mathcal{L}}_1\varphi_1. \quad (4.23)$$

Then by (3.6), (3.7) we have that

$$2\pi\lim_{\mathbf{k}\to\pm i\kappa}(\mathbf{k}\,\mathrm{sgn}\,\mathbf{k}_\mathfrak{I}-i\kappa)(\Psi_1(\mathbf{k})\vec{\mathcal{L}}_1G_{\mathrm{reg}}(\mathbf{k})\tilde{\mathcal{L}}_1\Phi_1(\mathbf{k}))=iB_\pm,$$

and thus using the above notations we get the asymptotic relation

$$G(\mathbf{k})=G_{\mathrm{reg}}(\pm i\kappa)+\frac{\gamma(\mathbf{k})\varphi_{\mathrm{reg}}(\pm\kappa)\otimes\psi_{\mathrm{reg}}(\pm\kappa)}{1-\gamma(\mathbf{k})B_\pm}+o(1),\quad \mathbf{k}\to\pm i\kappa. \quad (4.24)$$

Summarizing, the Green's function $G(\mathbf{k})$, like $G_1(\mathbf{k})$, has a discontinuity on the segment $|\mathbf{k}_\mathfrak{I}|<\kappa$ of the imaginary axis, but in general it is not necessarily singular at the end points of this segment. Indeed, if $B_+=0$, then at $\mathbf{k}\to i\kappa$ the logarithmic behavior of $\gamma(\mathbf{k})$ in the numerator of (4.24) is not compensated, so the Green's function $G(\mathbf{k})$ has a logarithmic singularity at the point $\mathbf{k}=i\kappa$, like in the special case considered in Sec. II. However, if

$$B_+\neq 0, \quad (4.25)$$

then the logarithmic behaviors of numerator and denominator in (4.24) compensate and we get a finite result. Taking into account the conjugation property $B_-=\overline{B_+}$, this is also valid for the point $\mathbf{k}=-i\kappa$, so in this case at the end points of the cut we have

$$G(\pm i\kappa)=G_{\mathrm{reg}}(\pm i\kappa)-\frac{\varphi_{\mathrm{reg},\pm}\otimes\psi_{\mathrm{reg},\pm}}{B_\pm}. \quad (4.26)$$

Applying to (4.24) the operations $\psi_1\vec{\mathcal{L}}_1$ from the left and $\tilde{\mathcal{L}}_1\varphi_1$ from the right we get for $A(\mathbf{k}_\mathfrak{I})$ by (4.10) that

$$A(\pm\kappa)=1 \quad (4.27)$$

independently of the value of B_+.

C. Jost solutions

1. Properties of Jost solutions

From the properties of the Green's function $G(\mathbf{k})$ studied in Sec. II it follows that the Jost solutions $\Phi(\mathbf{k})$ and $\Psi(\mathbf{k})$ introduced in (4.3) are analytic in the region $\mathbf{k}_{\mathfrak{R}}\mathbf{k}_{\mathfrak{I}}\neq 0$, and continuous up to the borders, have a discontinuity at $\mathbf{k}_{\mathfrak{I}}=0$ as in the decaying case and an additional discontinuity at $\mathbf{k}_{\mathfrak{R}}=0$ when $|\mathbf{k}_{\mathfrak{I}}|<\kappa$. By (2.59) the Jost solutions obey the conjugation property (2.76). Moreover, the functions $\chi(x,\mathbf{k})$ and $\xi(x,\mathbf{k})$ defined as in (2.78) are bounded both in the x-variables and obey condition (2.80).

The discontinuity of the Jost solution $\Phi(\mathbf{k})$ at $\mathbf{k}_{\mathfrak{R}}\to\pm 0$ follows from (4.16) by means of (4.3), i.e., by applying $\check{\mathcal{L}}_1\Phi_1(\pm 0+i\mathbf{k}_{\mathfrak{I}})$ to (4.16) from the right. By (3.30) the discontinuity of $\Phi_1(\mathbf{k})$ at the imaginary axis is proportional to φ_1. Under condition (4.25) we have representation (4.26) thanks to which $G(i\kappa)\check{\mathcal{L}}_1\varphi_1=0$ by (4.22), (4.23). So the discontinuity of $\Phi_1(\mathbf{k})$ in the first equality in (4.3) does not contribute to the discontinuity of $\Phi(\mathbf{k})$ and we get by (4.16)

$$\Phi(x,+0+i\mathbf{k}_{\mathfrak{I}})-\Phi(x,-0+i\mathbf{k}_{\mathfrak{I}})=\theta(\kappa-|\mathbf{k}_{\mathfrak{I}}|)\varphi(x,\mathbf{k}_{\mathfrak{I}})w(\mathbf{k}_{\mathfrak{I}}), \tag{4.28}$$

where

$$w(\mathbf{k}_{\mathfrak{I}})=\frac{\psi(\mathbf{k}_{\mathfrak{I}})\check{\mathcal{L}}_1\Phi_1(i\mathbf{k}_{\mathfrak{I}})}{2\pi iA(\mathbf{k}_{\mathfrak{I}})\operatorname{sgn}\mathbf{k}_{\mathfrak{I}}},\quad |\mathbf{k}_{\mathfrak{I}}|<\kappa, \tag{4.29}$$

and again thanks to (4.25) we can omit specification of the limiting procedure for $\Phi_1(\pm 0+i\mathbf{k}_{\mathfrak{I}})$ in the r.h.s. Below in (4.38) and (4.42) we give the behavior of $\varphi(\mathbf{k}_{\mathfrak{I}})$ and $w(\mathbf{k}_{\mathfrak{I}})$ that enables to prove that in the limit $B(\kappa)\to 0$ one gets $\delta(\mathbf{k}_{\mathfrak{I}}-\kappa)$ in the r.h.s. of (4.28).

If we use for the numerator of (4.29) the explicit expression

$$\psi(\mathbf{k}_{\mathfrak{I}})\check{\mathcal{L}}_1\Phi_1(i\mathbf{k}_{\mathfrak{I}})=\int dx(\mathcal{L}_1^{\mathrm{d}}(x,\partial_x)\psi(x,\mathbf{k}_{\mathfrak{I}}))\Phi_1(x,i\mathbf{k}_{\mathfrak{I}}),$$

we recover the spectral data $w(\mathbf{k}_{\mathfrak{I}})$ describing the discontinuity of the Jost solutions introduced in Ref. 16. Using (4.3) and (4.15)–(4.17) $w(\mathbf{k}_{\mathfrak{I}})$ can be rewritten as

$$w(\mathbf{k}_{\mathfrak{I}})=\frac{\psi_1\vec{\mathcal{L}}_1G(-0+i\mathbf{k}_{\mathfrak{I}})\check{\mathcal{L}}_1\Phi_1(i\mathbf{k}_{\mathfrak{I}})}{2\pi i\ \operatorname{sgn}\mathbf{k}_{\mathfrak{I}}}\equiv\frac{\psi_1\vec{\mathcal{L}}_1\Phi(-0+i\mathbf{k}_{\mathfrak{I}})}{2\pi i\ \operatorname{sgn}\mathbf{k}_{\mathfrak{I}}}, \tag{4.30}$$

or

$$w(\mathbf{k}_{\mathfrak{I}})=\frac{\psi_1\vec{\mathcal{L}}_1G(+0+i\mathbf{k}_{\mathfrak{I}})\check{\mathcal{L}}_1\Phi_1(i\mathbf{k}_{\mathfrak{I}})}{2\pi iA(\mathbf{k}_{\mathfrak{I}})\operatorname{sgn}\mathbf{k}_{\mathfrak{I}}}\equiv\frac{\psi_1\vec{\mathcal{L}}_1\Phi(+0+i\mathbf{k}_{\mathfrak{I}})}{2\pi iA(\mathbf{k}_{\mathfrak{I}})\operatorname{sgn}\mathbf{k}_{\mathfrak{I}}}. \tag{4.31}$$

From the first equality here and the conjugation properties of all the objects involved we have

$$\overline{w(-\mathbf{k}_{\mathfrak{I}})}=\frac{\Psi_1(i\mathbf{k}_{\mathfrak{I}})\vec{\mathcal{L}}_1\varphi(\mathbf{k}_{\mathfrak{I}})}{2\pi iA(\mathbf{k}_{\mathfrak{I}})\operatorname{sgn}\mathbf{k}_{\mathfrak{I}}},\quad |\mathbf{k}_{\mathfrak{I}}|<\kappa. \tag{4.32}$$

Notice that by (2.59), (4.15), and (4.17) we get the conjugation property

$$\overline{\varphi(x,\mathbf{k}_{\mathfrak{I}})}=\psi(x,-\mathbf{k}_{\mathfrak{I}}), \tag{4.33}$$

which motivates the introduction of the multiplier $A(\mathbf{k}_{\mathfrak{I}})$ in (4.15). Then, by conjugation of (4.28) we get for the dual Jost solution

$$\Psi(x,+0+i\mathbf{k}_{\mathfrak{I}})-\Psi(x,-0+i\mathbf{k}_{\mathfrak{I}})=\theta(\kappa-|\mathbf{k}_{\mathfrak{I}}|)\psi(x,\mathbf{k}_{\mathfrak{I}})\overline{w(-\mathbf{k}_{\mathfrak{I}})}. \tag{4.34}$$

Thus we see that the discontinuity of the Jost solutions across the imaginary axis is given not in their terms, but in terms of the functions $\varphi(x,\mathbf{k}_\jmath)$, $\psi(x,\mathbf{k}_\jmath)$ introduced in (4.15) [or (4.17)]. From their definition it follows that they obey equations (2.75): $\tilde{\mathcal{L}}\varphi(\mathbf{k}_\jmath)=0$ and $\psi(\mathbf{k}_\jmath)\tilde{\mathcal{L}}=0$, and can be considered a generalization of the functions $\varphi_1(x)$, $\psi_1(x)$ to the case u_2 different from zero. However, they acquire a nontrivial dependence on $\mathbf{k}_\jmath$ and cannot be obtained as specific values of the Jost solutions. Due to the properties of the Green's function these solutions are discontinuous at $\mathbf{k}_\jmath=0$. In the following we refer to $\varphi(x,\mathbf{k}_\jmath)$ and $\psi(x,\mathbf{k}_\jmath)$ as auxiliary Jost solutions.

2. Behavior of Jost solutions and spectral data at the end points of the cut

The asymptotic behavior of the Jost solutions easily results from the asymptotic property of the Green's function given in (4.24). Applying $\tilde{\mathcal{L}}_1\varphi_1$ from the right and using definitions (4.22) and (4.23) we get

$$G(\mathbf{k})\tilde{\mathcal{L}}_1\varphi_1=\frac{\varphi_{\mathrm{reg},\pm}}{1-\gamma(\mathbf{k})B_\pm}+o(1),\quad \mathbf{k}\to\pm i\kappa. \tag{4.35}$$

Then, from the definitions (4.3) of the Jost solution and properties (3.6), (3.7) of the Jost solutions of the one-soliton case, we derive the asymptotic behavior

$$\Phi(\mathbf{k})=\sqrt{\frac{\kappa}{\pi}}\frac{ie^{\kappa x_0}\varphi_{\mathrm{reg},+}}{(\mathbf{k}-i\kappa)(1-\gamma(\mathbf{k})B_+)}+O(1),\quad \mathbf{k}\to+i\kappa, \tag{4.36}$$

$$\Phi(\mathbf{k})=\frac{e^{-\kappa x_0}\varphi_{\mathrm{reg},-}}{2\sqrt{\kappa\pi}(1-\gamma(\mathbf{k})B_-)}+o(1),\quad \mathbf{k}\to-i\kappa, \tag{4.37}$$

while the behavior of $\Psi(\mathbf{k})$ follows from conjugation property (2.76) and relations $\overline{\varphi_{\mathrm{reg},\pm}}=\psi_{\mathrm{reg},\mp}$ that follow from (4.22). As regards the auxiliary Jost solution $\varphi(\mathbf{k}_\jmath)$, by its definition (4.15) and (4.35) we get in the same way

$$\varphi(\mathbf{k}_\jmath)=\frac{\varphi_{\mathrm{reg},\pm}}{1-\gamma(+0+i\mathbf{k}_\jmath)B_\pm}+o(1),\quad \mathbf{k}_\jmath\to\pm\kappa, \tag{4.38}$$

and asymptotics for $\psi(\mathbf{k}_\jmath)$ follow again by the conjugation property (4.33). We see that the behavior of the Jost and auxiliary Jost solutions at the points $\mathbf{k}_\jmath=\pm\kappa$ is determined by the value of B_+. If $B_+=0$ the behavior of the Jost solutions is like in the case $u_2\equiv 0$ [cf. (3.6) and (3.7)] and the auxiliary Jost solutions are finite and nonzero at these points. If $B_+\neq 0$, the behavior of both types of Jost solutions is modified at these points by the multiplier $(\log||\mathbf{k}_\jmath|-\kappa|)^{-1}$ as follows from (3.26). In particular, in this case we have

$$\varphi(\pm\kappa)=\psi(\pm\kappa)=0. \tag{4.39}$$

Now we apply $\tilde{\mathcal{L}}_1\varphi_1$ from the right to (4.19) with the upper sign and cancel $G^\sigma(\pm 0)\tilde{\mathcal{L}}_1\varphi_1$ thanks to (4.39). Then by (4.31) and the conjugation properties (2.76) and (4.12) we get the following expression of $\varphi(x,\mathbf{k}_\jmath)$ in terms of the Jost solution,

$$\varphi(x,\mathbf{k}_\jmath)=i\int_{\kappa\,\mathrm{sgn}\,\mathbf{k}_\jmath}^{\mathbf{k}_\jmath}d\alpha\,A(\alpha)\overline{w(-\alpha)}\Phi(x,+0+i\alpha), \tag{4.40}$$

which, as we will see below, is necessary for closing the inverse problem.

For the spectral data $A(\mathbf{k}_\jmath)$ in (4.10) we can use the first equality in (4.17) and in the case $B_+\neq 0$ also (4.40), and, then, by (4.27) and (4.31) we obtain the relation

$$A(\mathbf{k}_\jmath)=1+i\int_{\kappa\ \mathrm{sgn}\ \mathbf{k}_\jmath}^{\mathbf{k}_\jmath} d\alpha\, w(\alpha)\overline{w(-\alpha)}A^2(\alpha),$$

giving the explicit expression of $A(\mathbf{k}_\jmath)$ in terms of the spectral data $w(\mathbf{k}_\jmath)$,

$$A(\mathbf{k}_\jmath)=\left(1-i\int_{\kappa\ \mathrm{sgn}\ \mathbf{k}_\jmath}^{\mathbf{k}_\jmath} d\alpha\, w(\alpha)\overline{w(-\alpha)}\right)^{-1}, \tag{4.41}$$

which also is necessary for closing the inverse problem.

For the spectral data $w(\mathbf{k}_\jmath)$ we can use the second equality in (4.31) and taking into account that by (4.22) and (4.23) $\psi_1\vec{\mathcal{L}}_1\varphi_{\mathrm{reg},\pm}=B_\pm$ we get by (4.36) and (4.37) the asymptotic behaviors

$$w(\mathbf{k}_\jmath)=\frac{i\sqrt{\kappa}e^{\kappa x_0}B_+}{2\pi^{3/2}(\kappa-\mathbf{k}_\jmath)(1-\gamma(+0+i\mathbf{k}_\jmath)B_+)}+O(1),\quad \mathbf{k}_\jmath\to\kappa-0, \tag{4.42}$$

$$w(\mathbf{k}_\jmath)=\frac{ie^{-\kappa x_0}B_-}{4\sqrt{\kappa}\pi^{3/2}(1-\gamma(+0+i\mathbf{k}_\jmath)B_-)}+o(1),\quad \mathbf{k}_\jmath\to-\kappa+0. \tag{4.43}$$

Notice that for $B_+=0$ both these asymptotics are equal to zero, while as we mentioned above, in the product on the r.h.s. of (4.28) one gets δ-function in this case.

Concluding this study of the properties of the Jost solutions and spectral data at the points $\mathbf{k}_\jmath=\pm\kappa$, let us emphasize that, in order to get relations among different spectral data, which are crucial for solving the inverse problem, as for instance (4.32) used in getting (4.40), it is necessary to use different representations for the spectral data, like (4.30) and (4.31), in terms of different solutions of the nonstationary Schrödinger equation and its dual. These representations can be obtained in the framework of the resolvent approach, while they cannot be derived if one deals only with equations for the Jost solutions (cf. Ref. 16).

3. Bilinear representation for the resolvent and Green's functions

Now, we can derive a bilinear representation of the resolvent in terms of the Jost solutions. We proved that for $s_2\neq0$ its derivative with respect to s_2 obeys (2.46), so using notations (4.4) for the limiting values at $s_2=0$ we get

$$\hat{M}(x,x';s)=\frac{1}{2\pi i}\int dk\,[\theta(x_2-x_2')-\theta(2ks_1-s_2)]\,\Phi(x,k+is_1)\Psi(x',k+is_1)$$
$$+\mathrm{sgn}\,s_1[\theta(x_2-x_2')-\theta(-s_2)][G(x,x';+0+is_1)-G(x,x';-0+is_1)].$$

Then, thanks to (4.16), we get the following generalization of the bilinear representation (3.16) for the resolvent of the perturbed potential:

$$\hat{M}(x,x';s)=\frac{1}{2\pi i}\int dk\,[\theta(x_2-x_2')-\theta(2ks_1-s_2)]\,\Phi(x,k+is_1)\Psi(x',k+is_1)$$
$$+\frac{\theta(\kappa-|s_1|)}{2\pi iA(s_1)}[\theta(x_2-x_2')-\theta(-s_2)]\varphi(x,s_1)\psi(x',s_1). \tag{4.44}$$

If we consider the kernel $M(x,x';s)$ defined by (2.13), then both terms on the r.h.s. give distributions belonging to $\mathcal{S}'$. For the first term this follows from the mentioned properties of the functions χ and ξ, defined as in the decaying case by (2.78), and for the second term from the fact that $e^{-s_1x_1}\varphi(x,s_1)$ and $e^{s_1x_1}\psi(x,s_1)$ are bounded at space infinity when $|s_1|<\kappa$. Equation (2.45)

at $s_1 \neq 0$ follows from the analyticity of the Jost solutions and from the derivatives of (4.40) and of the analogous equation for $\psi(s_1)$. The absence of a discontinuity at $s_1=0$ in the case $s_2 \neq 0$ like in the derivation of (2.92) is equivalent to the condition

$$\int dk\, \Phi^+(k) \otimes \Psi^+(k) + \frac{\varphi^+ \otimes \psi^+}{A^+} = \int dk\, \Phi^-(k) \otimes \Psi^-(k) + \frac{\varphi^- \otimes \psi^-}{A^-}, \tag{4.45}$$

where we used notation (2.91) also for the limiting values of the auxiliary Jost solutions on the real axis

$$\varphi^{\pm}(x) = \lim_{\pm \mathbf{k}_\Im \to +0} \varphi(x, \mathbf{k}_\Im), \quad \psi^{\pm}(x) = \lim_{\pm \mathbf{k}_\Im \to +0} \psi(x, \mathbf{k}_\Im). \tag{4.46}$$

Thanks to (2.76) and (4.33) these limiting values obey the conjugation properties

$$\overline{\Phi^{\pm}(x,k)} = \Psi^{\mp}(x,k), \quad \overline{\varphi^{\pm}(x)} = \psi^{\mp}(x), \quad k \in \mathbb{R}. \tag{4.47}$$

By (2.49) the bilinear representation (4.44) for the resolvent leads to the following bilinear representation for the Green's function of the Jost solutions:

$$\begin{aligned} G(x,x',\mathbf{k}) = {} & \frac{1}{2\pi i} \int dk' \, [\, \theta(x_2 - x_2') - \theta(\mathbf{k}_\Im k')\,] \, \Phi(x, k' + \mathbf{k}) \Psi(x', k' + \mathbf{k}) \\ & + \frac{\theta(\kappa - |\mathbf{k}_\Im|)}{2\pi i A(\mathbf{k}_\Im)} [\, \theta(x_2 - x_2') - \theta(-\mathbf{k}_\Re \mathbf{k}_\Im)\,] \varphi(x, \mathbf{k}_\Im) \psi(x', \mathbf{k}_\Im), \end{aligned} \tag{4.48}$$

which generalizes (3.22). Below we use this bilinear representation for deriving relations between the Jost and advanced/retarded solutions.

D. Discontinuity of the resolvent at $s=0$

1. The advanced/retarded Green's functions and solutions

Above we investigated the behavior of the resolvent when at least one of the variables s_1 or s_2 is different from zero. As we have seen in the case of decaying potentials, it is just the study of the discontinuity of the resolvent at $s=0$ that leads to relations between Jost and advanced/retarded solutions which can be used for defining the spectral data. In the present case of a perturbed one-soliton potential the method is pretty close and, therefore, we omit details and we mainly present the peculiarities of this case. First, we introduce the advanced/retarded Green's functions as specific limits of the resolvent in the same way as in (2.52). It is straightforward to prove that they obey equations (2.68) and (2.69) and integral equations (2.70). In order to find the difference between the advanced and the retarded Green's function we use the Hilbert identity in the form (4.2), which, according to our previous discussion, in the case of a perturbed one-soliton potential is more convenient than (2.42). So we choose in (4.2) both s and s' real, $s_1' = s_1 = 0$ and consider the limits $s_2' \to \pm 0$, $s_2 \to \mp 0$. We get

$$G_+ - G_- = G_\pm \tilde{\mathcal{L}}_1 (G_{1,+} - G_{1,-}) \vec{\mathcal{L}}_1 G_\mp,$$

which by (3.31) gives for the discontinuity the representation

$$G_+ - G_- = \frac{1}{2\pi i} \left(\int dk\, \Phi_\pm(k) \otimes \Psi_\mp(k) + \varphi_\pm \otimes \psi_\mp \right), \tag{4.49}$$

where we introduced not only, in analogy with (2.57), the advanced/retarded solutions $\Phi_\pm(k)$, $\Psi_\pm(k)$ but also the auxiliary advanced/retarded solutions $\varphi_\pm$, $\psi_\pm$ defined by

$$\Phi_{\pm}(k)=G_{\pm}\tilde{\mathcal{L}}_1\Phi_1(k),\quad \varphi_{\pm}=G_{\pm}\tilde{\mathcal{L}}_1\varphi_1, \tag{4.50}$$

$$\Psi_{\pm}(k)=\Psi_1(k)\vec{\mathcal{L}}_1G_{\pm},\quad \psi_{\pm}=\psi_1\vec{\mathcal{L}}_1G_{\pm}. \tag{4.51}$$

It is easy to check that these functions $\Phi_{\pm}(x,k)$, $\Psi_{\pm}(x,k)$ and $\varphi_{\pm}(x)$, $\psi_{\pm}(x)$ are solutions of the differential equations (2.86) and obey a conjugation property, i.e., (2.87) for $\Phi_{\pm}(x,k)$, $\Psi_{\pm}(x,k)$, and

$$\overline{\varphi_{\pm}}=\psi_{\mp} \tag{4.52}$$

for the auxiliary solutions.

The bilinear representation (4.44) for the resolvent, thanks to (2.52), gives the following representation for the advanced/retarded Green's functions in terms of the Jost and auxiliary Jost solutions on the real axis,

$$G_{\pm}(x,x')=\frac{\pm\theta(\pm(x_2-x_2'))}{2\pi i}\left(\int dk\,\Phi^{\sigma}(x,k)\Psi^{\sigma}(x',k)+\frac{\varphi^{\sigma}(x)\psi^{\sigma}(x')}{A^{\sigma}}\right), \tag{4.53}$$

where we used notations (2.91) for the limiting values of the Jost solutions at the real axis and where the l.h.s. is independent on the sign $\sigma=+,-$ due to condition (4.45).

2. Relations among Green's functions $G^{\pm}(k)$ and $G_{\pm}$

The difference among the limiting values of the Green's function $G(\mathbf{k})$ on the two sides of the real axis and the advanced/retarded Green's functions, like in the case of the decaying potential, can be presented in two forms. The first one follows from (4.48) in the limits $\mathbf{k}\to k\pm i0$ and (4.53):

$$G^{\sigma}(k)-G_{\pm}=\frac{\mp 1}{2\pi i}\left(\int dk'\;\theta(\pm\sigma(k'-k))\,\Phi^{\sigma}(k')\otimes\Psi^{\sigma}(k')+\theta(\mp\sigma k)\,\frac{\varphi^{\sigma}\otimes\psi^{\sigma}}{A^{\sigma}}\right). \tag{4.54}$$

A second type of relation, analogous to (2.74), can be derived from the Hilbert identity (4.2). Taking into account definitions (2.72) and (2.52) we get

$$G^{\sigma}(k)-G_{\pm}=G_{\pm}\tilde{\mathcal{L}}_1(G_1^{\sigma}(k)-G_{1,\pm})\vec{\mathcal{L}}_1G^{\sigma}(k),\quad k\in\mathbb{R},$$

so that we can use (3.33) and definitions (4.50) and (4.51) to derive

$$\begin{aligned}G^{\sigma}(k)-G_{\pm}=&\frac{\mp 1}{2\pi i}\int dk'\;\theta(\mp\sigma(k-k'))\Phi_{\pm}(k')\otimes(\Psi_1(k')\vec{\mathcal{L}}_1G^{\sigma}(k))\\&\mp\frac{\theta(\mp\sigma k)}{2\pi i}\,\varphi_{\pm}\otimes(\psi_1\vec{\mathcal{L}}_1G^{\sigma}(k)),\quad \sigma=+,-.\end{aligned} \tag{4.55}$$

Now we can use relations (4.54) and (4.55) in order to get relations among Jost and advanced/retarded solutions, introduce spectral data and get characterization equations such that, in particular, condition (4.45) is accomplished.

E. Spectral data

1. Relations among Jost and advanced/retarded solutions

In order to derive these relations we again use definitions (4.3) and (4.15) for $\mathbf{k}=k\in\mathbb{R}$ and apply $\tilde{\mathcal{L}}_1\Phi_1(k)$ and $\tilde{\mathcal{L}}_1\varphi_1$ to (4.55) from the right (the latter one to the limit of (4.55) at $k\to+0$). Then by (2.91), (4.13), (4.46), and (4.50) we get

$$\Phi^{\sigma}(k)=\int dk'\;\Phi_{\pm}(k')r_{\pm}^{\sigma}(k',k)+\varphi_{\pm}r_{\pm}^{\sigma}(k),\quad \sigma=+,-, \tag{4.56}$$

$$\varphi^{\sigma}=\int dk'\,\Phi_{\pm}(k')\tau_{\pm}^{\sigma}(k')+\varphi_{\pm}(A^{\sigma})^{\theta(\mp\sigma)}, \tag{4.57}$$

generalizing (2.96), where we introduced spectral data [cf. (2.97) and (2.98)] by means of relations

$$r_{\pm}^{\sigma}(k,k')=\delta(k-k')\mp\theta(\pm\sigma(k-k'))r^{\sigma}(k,k'), \tag{4.58}$$

$$r^{\sigma}(k,k')=\frac{\Psi_1(k)\vec{\mathcal{L}}_1G^{\sigma}(k')\tilde{\mathcal{L}}_1\Phi_1(k')}{2\pi i}\equiv\frac{\Psi_1(k)\vec{\mathcal{L}}_1\Phi^{\sigma}(k')}{2\pi i}, \tag{4.59}$$

$$r_{\pm}^{\sigma}(k)=\mp\theta(\mp\sigma k)r^{\sigma}(k), \tag{4.60}$$

$$r^{\sigma}(k)=\frac{\psi_1\vec{\mathcal{L}}_1G^{\sigma}(k)\tilde{\mathcal{L}}_1\Phi_1(k)}{2\pi i}\equiv\frac{\psi_1\vec{\mathcal{L}}_1\Phi^{\sigma}(k)}{2\pi i}, \tag{4.61}$$

$$\tau_{\pm}^{\sigma}(k)=\mp\theta(\pm\sigma k)\tau^{\sigma}(k), \tag{4.62}$$

$$\tau^{\sigma}(k)=\frac{\Psi_1(k)\vec{\mathcal{L}}_1G^{\sigma}(+0)\tilde{\mathcal{L}}_1\varphi_1}{2\pi i}\equiv\frac{\Psi_1(k)\vec{\mathcal{L}}_1\varphi^{\sigma}}{2\pi i}. \tag{4.63}$$

We write equations (4.56) and (4.57) in a more compact form as

$$(\Phi^{\sigma},\,\varphi^{\sigma})=(\Phi_{\pm},\,\varphi_{\pm})*\mathcal{R}_{\pm}^{\sigma}, \tag{4.64}$$

and omit equations for Ψ and ψ that can be obtained analogously, or by conjugation. Here we introduced the matrix operator

$$\mathcal{R}_{\pm}^{\sigma}(k,k')=\begin{pmatrix} r_{\pm}^{\sigma}(k,k') & \tau_{\pm}^{\sigma}(k) \\ r_{\pm}^{\sigma}(k') & (A^{\sigma})^{\theta(\mp\sigma)} \end{pmatrix}. \tag{4.65}$$

$\mathcal{R}^{\dagger}$ denotes the Hermitian conjugate operator. Solutions $\Phi(x,k)$ and $\varphi(x)$ [$\Psi(x,k)$ and $\psi(x)$] have been combined in a row (correspondingly, column), where only the first element depends on k. For two operators $\mathcal{R}$ and $\mathcal{R}'$ with elements $\mathcal{R}_{ij}$, $\mathcal{R}'_{ij}$ with dependence on the arguments k, k' like in (4.65) we introduce a composition $*$ that gives a matrix of the same form with elements

$$\begin{aligned}
(\mathcal{R}*\mathcal{R}')_{11}(k,k')&=\int dk''\,\mathcal{R}_{11}(k,k'')\mathcal{R}'_{11}(k'',k')+\mathcal{R}_{12}(k)\mathcal{R}'_{21}(k'),\\
(\mathcal{R}*\mathcal{R}')_{12}(k,k')&=\int dk''\,\mathcal{R}_{11}(k,k'')\mathcal{R}'_{12}(k'')+\mathcal{R}_{12}(k)\mathcal{R}'_{22},\\
(\mathcal{R}*\mathcal{R}')_{21}(k,k')&=\int dk''\,\mathcal{R}_{21}(k'')\mathcal{R}'_{11}(k'',k')+\mathcal{R}_{22}\mathcal{R}'_{21}(k'),\\
(\mathcal{R}*\mathcal{R}')_{22}(k,k')&=\int dk''\,\mathcal{R}_{21}(k'')\mathcal{R}'_{12}(k'')+\mathcal{R}_{22}\mathcal{R}'_{22}.
\end{aligned} \tag{4.66}$$

The unity matrix in the set of such operators is given by

$$\mathcal{I}(k,k')=\begin{pmatrix} \delta(k-k') & 0 \\ 0 & 1 \end{pmatrix}. \tag{4.67}$$

In the same way we define the product of the matrix by the row (from the left) and by column (from the right) of the type used in (4.64). This composition is also denoted by an asterisk to emphasize that the integration is performed in the first (upper) element only.

Equation (4.64) gives the boundary values of the Jost solutions in terms of the advanced/retarded ones. In order to get the inverse relations we apply the same procedures as above to Eq. (4.54) and in analogy with (2.102) in terms of the introduced notations we get

$$(\Phi_{\pm}, \varphi_{\pm}) = (\Phi^{\sigma}, \varphi^{\sigma}) * (W^{\sigma})^{-1} (\mathcal{R}_{\pm}^{-\sigma})^{\dagger}, \tag{4.68}$$

where we introduced the constant matrix

$$W^{\sigma} = \begin{pmatrix} 1 & 0 \\ 0 & A^{\sigma} \end{pmatrix}. \tag{4.69}$$

Alternative spectral data that relate values of the Jost solutions computed on the two sides of the real axis appear if we insert $(\Phi_{\pm}, \varphi_{\pm})$ from (4.68) into (4.64) for opposite sign of σ. Thus we get

$$(\Phi^{\sigma}, \varphi^{\sigma}) = (\Phi^{-\sigma}, \varphi^{-\sigma}) * (W^{-\sigma})^{-1} \mathcal{F}^{-\sigma}, \tag{4.70}$$

where we denoted

$$\mathcal{F}^{\sigma} = (\mathcal{R}_{\pm}^{-\sigma})^{\dagger} * \mathcal{R}_{\pm}^{-\sigma}. \tag{4.71}$$

Finally let us note that Eqs. (4.58)–(4.63) together with Eqs. (4.31), (4.40), and (4.41) solve completely the so-called direct problem, furnishing all spectral data and the auxiliary function $\varphi(x, \mathbf{k}_3)$ in terms of the Jost solution $\Phi(x, \mathbf{k})$ and the functions $\Phi_1(x, \mathbf{k})$ and $\varphi_1(x)$ relative to the one-soliton potential.

Below we discuss the properties of these spectral data and relations between them.

2. Characterization equations for spectral data

Inserting (4.68) in (4.64) we get relation $(\Phi^{\sigma}, \varphi^{\sigma}) = (\Phi^{\sigma}, \varphi^{\sigma})(W^{\sigma})^{-1} (\mathcal{R}_{\pm}^{-\sigma})^{\dagger} * \mathcal{R}_{\pm}^{\sigma}$, $\sigma = +, -$, so taking into account the asymptotic behavior of the Jost solutions with respect to the x-variables we derive the characterization equation

$$(\mathcal{R}_{\pm}^{-\sigma})^{\dagger} * \mathcal{R}_{\pm}^{\sigma} (W^{\sigma})^{-1} = \mathcal{I} \tag{4.72}$$

for the spectral data $\mathcal{R}_{\pm}^{\sigma}$. Another characterization equation follows by inserting (4.64) into (4.68):

$$\mathcal{R}_{\pm}^{\sigma} (W^{\sigma})^{-1} * (\mathcal{R}_{\pm}^{-\sigma})^{\dagger} = \mathcal{I}, \tag{4.73}$$

and the third one is the condition that the r.h.s. of (4.71) is independent of the choice of the sign $\pm$:

$$(\mathcal{R}_{+}^{\sigma})^{\dagger} * \mathcal{R}_{+}^{\sigma} = (\mathcal{R}_{-}^{\sigma})^{\dagger} * \mathcal{R}_{-}^{\sigma}. \tag{4.74}$$

These equations generalize the characterization equations of the case of decaying potential.[17] We see that (4.72) and (4.73) are just the condition that the "triangular operators" $\mathcal{R}_{\pm}^{\sigma}$ are invertible and that $(\mathcal{R}_{\pm}^{-\sigma})^{\dagger}$ is the inverse of $\mathcal{R}_{\pm}^{\sigma} (W^{\sigma})^{-1}$. They define, say, $\mathcal{R}_{\pm}^{-}$ if $\mathcal{R}_{\pm}^{+}$ is given. Thus essential restrictions on the spectral data are imposed by (4.74), that is a consequence of the reality condition on the potential $u(x)$. Thanks to (4.64) this equation proves (4.45). By (4.65) we write (4.74) as a system of three equations (for some sign σ):

$$\left(\int_{k'}^{+\infty}-\int_{-\infty}^{k}\right)dk''\,\overline{r^{\sigma}(k'',k)}r^{\sigma}(k'',k')=\operatorname{sgn}k\;\theta(kk')\,\overline{r^{\sigma}(k)}r^{\sigma}(k')+\sigma r^{\sigma}(k,k')+\sigma\overline{r^{\sigma}(k',k)},\tag{4.75}$$

$$[\,\theta(k)A^{\sigma}+\theta(-k)]\overline{r^{\sigma}(k)}=\sigma\left(\int_{0}^{+\infty}-\int_{-\infty}^{k}\right)dk'\,\overline{r^{\sigma}(k',k)}\,\tau^{\sigma}(k')-\tau^{\sigma}(k),\tag{4.76}$$

$$|A^{\sigma}|^{2}=\int dk\,\operatorname{sgn}k\,|\tau^{\sigma}(k)|^{2}+1.\tag{4.77}$$

Characterization equations for the spectral data (4.71) look simpler,

$$(\mathcal{F}^{\sigma})^{\dagger}=\mathcal{F}^{\sigma},\quad (\mathcal{F}^{\sigma})^{-1}=(W^{-\sigma})^{-1}\mathcal{F}^{-\sigma}(W^{\sigma})^{-1},\tag{4.78}$$

to which we have to add the requirement that $\mathcal{F}^{\sigma}$ can be decomposed in the product (4.71) of two sets of triangular operators (4.65).

3. Discontinuities of spectral data

The cuts of the Jost solutions intersect on the complex plane at $k=0$. Thanks to property (4.6) for the Green's function we get by (4.3) that the Jost solution obeys property

$$\lim_{\sigma\mathbf{k}_{\mathfrak{J}}\to+0}\Phi(\pm 0+i\mathbf{k}_{\mathfrak{J}})=\Phi^{\sigma}(\pm 0),\quad \sigma=+,-,\tag{4.79}$$

which means that it is necessary to pay special attention to the properties of the spectral data at this point $k=0$. Thus taking the limits $\mathbf{k}_{\mathfrak{J}}\to\sigma 0$ in (4.28) we get for the boundary values of the Jost and auxiliary Jost solutions the relation

$$\Phi^{\sigma}(+0)-\Phi^{\sigma}(-0)=\varphi^{\sigma}w^{\sigma}.\tag{4.80}$$

The spectral data $r^{\sigma}(k,k')$ are defined in (4.59) in terms of the Jost solution $\Psi_1(k)$, which is a continuous function of k, and of $\Phi^{\sigma}(k')$ which is discontinuous at $k'=0$. Therefore $r^{\sigma}(k,k')$ is continuous with respect to k and k' with a possible discontinuity at $k'=0$. Precisely, by (4.59), (4.63), and (4.80) we get

$$r^{\sigma}(k,+0)-r^{\sigma}(k,-0)=\tau^{\sigma}(k)w^{\sigma}.\tag{4.81}$$

The spectral data $\tau^{\sigma}(k)$ are continuous at $k=0$ and from their definition (4.63) and the definitions (4.10) and (4.29) of A and w we derive

$$\tau^{\sigma}(0)=\sigma A^{\sigma}\overline{w^{-\sigma}}.\tag{4.82}$$

The spectral data $r^{\sigma}(k)$ are discontinuous at $k=0$ as follows from their definition (4.61). Taking into account (4.30) and (4.31), we get the relations

$$r^{\sigma}(+0)=\sigma A^{\sigma}w^{\sigma},\tag{4.83}$$

$$r^{\sigma}(-0)=\sigma w^{\sigma}.\tag{4.84}$$

These behaviors at $k=0$ are compatible with the characterization equations. In fact, choosing $k'=\pm 0$ in (4.75) we get (4.76) and analogously (4.76) at $k=\pm 0$ gives (4.77).

F. Inverse problem and time evolution

Let now be given the spectral data, i.e., function $w(\mathbf{k}_{\mathfrak{J}})$ and, say, $\mathcal{R}^{+}_{\pm}$. Function $w(\mathbf{k}_{\mathfrak{J}})$ is continuously differentiable on the interval $|\mathbf{k}_{\mathfrak{J}}|<\kappa$ except for the point $\mathbf{k}_{\mathfrak{J}}=0$, where it has

bounded limits $w^{\pm}$. Moreover, $w(\mathbf{k}_\mathfrak{I})$ has the asymptotic behaviors (4.42), (4.43) and $A(\mathbf{k}_\mathfrak{I})$ defined by (4.41) is bounded on this interval and has finite limits $A^{\pm}$ at zero. The spectral data $\mathcal{R}_{\pm}^{+}$ obey the characterization equation (4.74), or, more explicitly the characterization equations (4.75)–(4.77) for its elements in (4.65) and relations (4.81)–(4.84). The matrix operator $\mathcal{R}_{\pm}^{+}$ also admits inverse, so that the spectral data $\mathcal{R}_{\pm}^{-}$ can be introduced by (4.72) or (4.73) with the triangularity property given in (4.65), which means that the spectral data $\mathcal{F}^{-}$ can be defined by (4.71). Taking into account that the Jost solution $\Phi(x,\mathbf{k})$ is analytic in the complex $\mathbf{k}$-plane with a discontinuity across the real axis, given by the first equation in (4.70) for $\sigma=+$, and with a discontinuity across the interval $|\mathbf{k}_\mathfrak{I}|<\kappa$ of the imaginary axis, given by (4.28), and has an asymptotic normalization at $\mathbf{k}\to\infty$ given by (2.78) and (2.80), the Cauchy–Green formula yields

$$\Phi(x,\mathbf{k})=e^{-i\mathbf{k}x_1-i\mathbf{k}^2x_2}+\frac{1}{2\pi i}\int dk'\frac{e^{i(k'-\mathbf{k})x_1+i(k'^2-\mathbf{k}^2)x_2}}{k'-\mathbf{k}}\Bigg(\int dk''\Phi^{-}(x,k'')[\mathcal{F}_{11}^{-}(k'',k')-\delta(k''-k')]+\frac{\varphi^{-}(x)}{A^{-}}\mathcal{F}_{21}^{-}(k')\Bigg)-\frac{1}{2\pi i}\int_{-\kappa}^{\kappa}\frac{d\alpha\, w(\alpha)}{\alpha+i\mathbf{k}}e^{-(\alpha+i\mathbf{k})x_1-i(\alpha^2+\mathbf{k}^2)x_2}\varphi(x,\alpha). \tag{4.85}$$

Notice that the singular behavior (4.42) of $w(\alpha)$ at $\alpha=\kappa$ is smoothed by (4.38) and, consequently, the integral on the r.h.s. is well defined. It is necessary to emphasize that equalities (4.40) and (4.85) were derived under condition (4.25) that excludes the case $u_2(x)\equiv 0$. Indeed, in this case $G_{\mathrm{reg}}(i\kappa)=G_{1,\mathrm{reg}}(i\kappa)$ so that by (4.23) $B(\kappa)=0$.

The integral equation (4.85) together with (4.40) solves the inverse problem. In fact, considering (4.40) and the limits of (4.85) as $\mathbf{k}\to k-i0$, $k\in\mathbb{R}$, and as $\mathbf{k}\to+0+i\mathbf{k}_\mathfrak{I}$, we obtain a system of three linear integral equations for $\{\Phi^{-}(x,k),\Phi(x,+0+i\mathbf{k}_\mathfrak{I}),\varphi(x,\mathbf{k}_\mathfrak{I})\}$, whose solution is uniquely determined in terms of the spectral data. When these boundary values are determined, the Jost solution for generic $\mathbf{k}\in\mathbb{C}$ is given by (4.85) and then the potential is reconstructed in the standard way by (2.78), (2.81) as

$$u(x)=\frac{1}{\pi}\frac{\partial}{\partial x_1}\Bigg[\int dk\, e^{ikx_1+ik^2x_2}\Bigg(\int dk'\Phi^{-}(x,k')[\mathcal{F}_{11}^{-}(k',k)-\delta(k'-k)]+\frac{\varphi^{-}(x)}{A^{-}}\mathcal{F}_{21}^{-}(k)\Bigg)-i\int_{-\kappa}^{\kappa}d\alpha\, w(\alpha)\, e^{-\alpha x_1-i\alpha^2x_2}\varphi^{-}(x,\alpha)\Bigg]. \tag{4.86}$$

Since, in the resolvent approach, all spectral data can be given as special reductions of the extended resolvent, one can derive directly (see Ref. 4 for details) the time evolution of the spectral data related to a solution of (1.2). We omit here these calculations and give only the final result on the time evolution of the spectral data:[16]

$$\mathcal{F}^{-}(k,k',t)=\begin{pmatrix} e^{-4ik^3t} & 0\\ 0 & 1\end{pmatrix}\mathcal{F}^{-}(k,k')\begin{pmatrix} e^{4ik'^3t} & 0\\ 0 & 1\end{pmatrix},\quad k,k'\in\mathbb{R}, \tag{4.87}$$

$$w(\mathbf{k}_\mathfrak{I},t)=e^{4\mathbf{k}_\mathfrak{I}^3t}w(\mathbf{k}_\mathfrak{I}), \tag{4.88}$$

$$A(\mathbf{k}_\mathfrak{I},t)=A(\mathbf{k}_\mathfrak{I}). \tag{4.89}$$

Taking the time evolution (4.88) into account we get that (4.42) and (4.43) are preserved under the dynamics and like in the pure one-soliton case

$$\kappa(t)=\kappa,\quad x_0(t)=x_0+4\kappa^2t, \tag{4.90}$$

where $x_0(t)$ is the parameter of the one-soliton solution (3.2).

V. CONCLUSION

We presented the main aspects of what we call the extended resolvent approach to the spectral theory of differential operators and we tested it in the two-dimensional case of the nonstationary Schrödinger equation with decaying and nondecaying potentials at large distances in the plane. We showed that a specific advantage of this approach is that the extended resolvent $M(s)$ of the differential operator (1.1), which depends on a parameter $s \in \mathbb{R}^2$, can be used as a general tool for finding all mathematical objects, such as Green's functions, Jost and auxiliary Jost solutions, advanced/retarded solutions and spectral data, which result to be necessary for developing the spectral theory. In fact, the introduction of all these quantities follow naturally from the study of departure from analyticity of the extended resolvent and of its discontinuities, together with its reductions. In particular, the different Green's functions involved in the theory are values (in general limiting values) of the resolvent $M(s)$ at different specific points s, which are suggested by the behavior in s of $M(s)$ itself. Moreover, the study of the properties of all these objects is reduced to the study of the resolvent $M(s)$, which can be accomplished by using Hilbert-type identities and the bilinear representation (2.90). This representation gives the extended resolvent in terms of the Jost solutions and supplies a simple and straightforward way of deriving relations between different kinds of solutions of the linear problem, constructing spectral data and deriving relations between them, as well as characterization equations.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 8 AUGUST 2003

Novel integrable reductions in nonlinear continuum mechanics via geometric constraints

C. Rogers and W. K. Schief[a)]
School of Mathematics, The University of New South Wales, Sydney, New South Wales 2052, Australia

(Received 15 December 2002; accepted 9 April 2003)

The nonlinear equations that describe solitonic behavior in physical systems have, to-date, typically been derived by approximation or expansion methods. Here, by contrast, hidden integrable structure is revealed in diverse areas of nonlinear continuum mechanics through natural geometric constraints. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1589155]

I. INTRODUCTION

The basic equations of hydrodynamics, magnetohydrodynamics, and finite deformation elasticity are intrinsically nonlinear. The extent to which these and other governing equations of nonlinear continuum mechanics naturally admit integrable structure and are accordingly amenable to the powerful techniques of modern soliton theory remains an important open question. Hitherto, whereas solitonic phenomena have been observed in widely diverse areas in nature, the nonlinear equations that describe solitons have typically been derived by approximation or expansion methods. It is well-established that solitonic equations arise naturally out of the geometry of those privileged classes of surfaces that admit invariance under Bäcklund transformations.[1] Soliton systems that occur, without resort to approximation, in nonlinear physics or continuum mechanics have been relatively unknown. The prime exception is the Ernst equation which constitutes a reduction of Einstein's equations in general relativity.[2] However, the Ernst equation may be formulated as an elliptic counterpart of a classical Bianchi system descriptive of a class of hyperbolic surfaces constrained to admit a Bäcklund transformation.[1] Indeed, the celebrated Harrison transformation for the Ernst equation as set down in Ref. 3 is the counterpart of a classical Bäcklund transformation for the Bianchi system. This important paradigm motivates an investigation into how appropriate geometric constraints imposed on nonlinear physical models might reveal hidden integrable structure. Here, we bring together in a single account recent work by the authors on the application of geometric constraints to reveal hidden integrable structure over a range of nonlinear physical models in

(i) hydrodynamics,
(ii) magnetohydrodynamics,
(iii) the kinematics of ideal fiber-reinforced materials, and
(iv) elastostatics of shell membranes.

Integrable connections in the theory of liquid crystals have recently been uncovered in Ref. 4.

II. HYDRODYNAMICS BACKGROUND. GENESIS OF THE NLS EQUATION

The celebrated nonlinear Schrödinger (NLS) equation

$$\mathrm{i}\frac{\partial q}{\partial t}+\frac{\partial^2 q}{\partial x^2}+\nu|q|^2 q=0 \tag{2.1}$$

a)Author to whom correspondence should be addressed. Electronic mail: schief@maths.unsw.edu.au

models a wide range of physical phenomena. It was originally derived in explicit form in the context of the self-focusing of optical beams in nonlinear media.[5,6] However, the origins of the NLS equation or, equivalently, if $\nu>0$, of the Heisenberg spin equation[7]

$$\frac{\partial \mathbf{S}}{\partial t}=\mathbf{S}\times\frac{\partial^2 \mathbf{S}}{\partial x^2}, \quad \mathbf{S}^2=1, \tag{2.2}$$

go back to work in hydrodynamics at the beginning of the 20th century. Thus, Da Rios,[8] in 1906, in a study of the motion of an isolated inextensible vortex filament in an unbounded fluid, derived, via what is essentially the localized induction approximation (LIA), a pair of nonlinear coupled equations for the temporal evolution of the curvature and torsion of the filament. These equations may be conjugated to produce the NLS equation.[9] The original and subsequent results by Da Rios were collected in a survey by Levi-Civita.[10] An interesting account of the rediscovery of the work of Da Rios has been given by Ricca.[11]

The origins of the NLS equation then seem to reside in hydrodynamics, albeit via approximation. That it arises in hydrodynamics in the guise of the Heisenberg spin equation but rather via a geometric constraint was established only recently by Rogers.[12] The origins of that study go back to a long outstanding problem in hydrodynamics posed by Gilbarg[13] which seeks to delimit the circumstances under which a motion is uniquely determined by its geometry.

It was Prim[14] who established that any steady motion governed by the classical hydrodynamic system

$$\operatorname{div}\mathbf{q}=0, \tag{2.3a}$$

$$\rho(\mathbf{q}\cdot\nabla)\mathbf{q}+\nabla p=\mathbf{0} \tag{2.3b}$$

is uniquely determined by its streamline pattern unless it has constant velocity magnitude $q=|\mathbf{q}|$ along individual streamlines or, equivalently, in the absence of stagnation points, unless

$$\operatorname{div}\mathbf{t}=0, \tag{2.4}$$

where $\mathbf{t}$ is the unit tangent to the streamline. In the above, $\mathbf{q}=q\mathbf{t}$ is the fluid velocity and p,ρ are the pressure and constant density, respectively. If the geometric condition (2.4) holds, then there exists a multiplicity of flows which exhibit the same streamline pattern since the system (2.3) and (2.4) is seen to be invariant under $(p,\mathbf{q})\rightarrow(f(p),\sqrt{f'(p)}\,\mathbf{q})$.

The Gilbarg problem has been investigated by, *inter alia*, not only Prim[14] but also Howard,[15] Wasserman,[16] and Marris.[17] In Ref. 18, it has been established that, remarkably, this classical problem may be decomposed into a study of the solitonic Heisenberg spin equation (2.2) with $\mathbf{S}=\mathbf{t}$ subject to the condition (2.4). The results carry over, *mutatis mutandis*, to the steady motion of an inviscid and thermally nonconducting gas with arbitrary equation of state as well as to magnetohydrostatics.[12,18,19]

In the sequel, an account of the derivation of the Heisenberg spin equation in hydrodynamics and magnetohydrostatics is presented. The classical Gilbarg problem is reformulated as the problem of solving the Heisenberg spin equation subject to the geometric constraint (2.4).

III. GEOMETRIC PRELIMINARIES

The nature of the geometric constraint (2.4) prompts the adoption of a characterization of a three-dimensional vector field $\mathbf{f}$ inherent in a study of anholonomic coordinate systems by Vranceanu.[20] Thus, the orthonormal basis $\{\mathbf{t},\mathbf{n},\mathbf{b}\}$ is introduced along the tangential, principal normal and binormal directions to the vector lines of nonvanishing $\mathbf{f}$. This formulation has been previously used to derive kinematic properties in hydrodynamics by Marris and Passman.[21] In that context, as here, $\mathbf{f}$ is identified with the velocity field $\mathbf{q}$.

Let

$$\frac{\delta}{\delta s}=\mathbf{t}\cdot\nabla,\quad \frac{\delta}{\delta n}=\mathbf{n}\cdot\nabla,\quad \frac{\delta}{\delta b}=\mathbf{b}\cdot\nabla \tag{3.1}$$

denote the directional derivatives in the tangential, principal normal and binormal directions, respectively. It proves convenient to introduce the notation[22]

$$\theta_{ns}=\mathbf{n}\cdot\frac{\delta\mathbf{t}}{\delta n},\quad \theta_{bs}=\mathbf{b}\cdot\frac{\delta\mathbf{t}}{\delta b}, \tag{3.2}$$

in terms of which

$$\operatorname{div}\mathbf{t}=\left(\mathbf{t}\frac{\delta}{\delta s}+\mathbf{n}\frac{\delta}{\delta n}+\mathbf{b}\frac{\delta}{\delta b}\right)\cdot\mathbf{t}=\theta_{ns}+\theta_{bs}. \tag{3.3}$$

In a similar manner,

$$\operatorname{div}\mathbf{n}=-\kappa+\mathbf{b}\cdot\frac{\delta\mathbf{n}}{\delta b},\quad \operatorname{div}\mathbf{b}=\mathbf{n}\cdot\frac{\delta\mathbf{b}}{\delta n}, \tag{3.4}$$

where κ denotes the curvature of the **t**-field. Moreover,

$$\operatorname{curl}\mathbf{t}=\left(\mathbf{t}\times\frac{\delta}{\delta s}+\mathbf{n}\times\frac{\delta}{\delta n}+\mathbf{b}\times\frac{\delta}{\delta b}\right)\mathbf{t}=\Omega_s\mathbf{t}+\kappa\mathbf{b}, \tag{3.5}$$

where

$$\Omega_s=\mathbf{t}\cdot\operatorname{curl}\mathbf{t}=\mathbf{b}\cdot\frac{\delta\mathbf{t}}{\delta n}-\mathbf{n}\cdot\frac{\delta\mathbf{t}}{\delta b}. \tag{3.6}$$

Further,

$$\begin{aligned}\operatorname{curl}\mathbf{n}&=-(\operatorname{div}\mathbf{b})\mathbf{t}+\Omega_n\mathbf{n}+\theta_{ns}\mathbf{b},\\ \operatorname{curl}\mathbf{b}&=(\kappa+\operatorname{div}\mathbf{n})\mathbf{t}-\theta_{bs}\mathbf{n}+\Omega_b\mathbf{b},\end{aligned} \tag{3.7}$$

where

$$\begin{aligned}\Omega_n&=\mathbf{n}\cdot\operatorname{curl}\mathbf{n}=\mathbf{t}\cdot\frac{\delta\mathbf{n}}{\delta b}-\tau,\\ \Omega_b&=\mathbf{b}\cdot\operatorname{curl}\mathbf{b}=-\tau-\mathbf{t}\cdot\frac{\delta\mathbf{b}}{\delta n},\end{aligned} \tag{3.8}$$

with τ the torsion of the **t**-field. The quantities Ω_s, Ω_n, and Ω_b are termed abnormalities of the **t**, **n**, and **b**-fields, in turn. Combination of (3.6) and (3.8) produces the important relation

$$\Omega_s+\Omega_n+\Omega_b=2(\Omega_s-\tau). \tag{3.9}$$

This connection between the abnormalities appears in another guise in the treatise of Weatherburn.[23] Therein, Ω_s, Ω_n, and Ω_b are called the total moments of the **t**, **n**, and **b**-fields, respectively.

The identity curl grad $\phi=\mathbf{0}$, on use of the intrinsic decompositions (3.5) and (3.7), produces the commutator relations

$$\frac{\delta^2}{\delta n\,\delta b}-\frac{\delta^2}{\delta b\,\delta n}=-\Omega_s\frac{\delta}{\delta s}+\operatorname{div}\mathbf{b}\,\frac{\delta}{\delta n}-(\kappa+\operatorname{div}\mathbf{n})\frac{\delta}{\delta b}, \tag{3.10a}$$

$$\frac{\delta^2}{\delta b\,\delta s}-\frac{\delta^2}{\delta s\,\delta b}=-\Omega_n\frac{\delta}{\delta n}+\theta_{bs}\frac{\delta}{\delta b}, \tag{3.10b}$$

$$\frac{\delta^2}{\delta s\,\delta n}-\frac{\delta^2}{\delta n\,\delta s}=-\kappa\frac{\delta}{\delta s}-\theta_{ns}\frac{\delta}{\delta n}-\Omega_b\frac{\delta}{\delta b}. \tag{3.10c}$$

The system governing the directional derivatives of the orthonormal triad $\{\mathbf{t},\mathbf{n},\mathbf{b}\}$ reads

$$\frac{\delta}{\delta s}\begin{pmatrix}\mathbf{t}\\ \mathbf{n}\\ \mathbf{b}\end{pmatrix}=\begin{pmatrix}0 & \kappa & 0\\ -\kappa & 0 & \tau\\ 0 & -\tau & 0\end{pmatrix}\begin{pmatrix}\mathbf{t}\\ \mathbf{n}\\ \mathbf{b}\end{pmatrix},$$

$$\frac{\delta}{\delta n}\begin{pmatrix}\mathbf{t}\\ \mathbf{n}\\ \mathbf{b}\end{pmatrix}=\begin{pmatrix}0 & \theta_{ns} & \Omega_b+\tau\\ -\theta_{ns} & 0 & -\operatorname{div}\mathbf{b}\\ -(\Omega_b+\tau) & \operatorname{div}\mathbf{b} & 0\end{pmatrix}\begin{pmatrix}\mathbf{t}\\ \mathbf{n}\\ \mathbf{b}\end{pmatrix}, \tag{3.11}$$

$$\frac{\delta}{\delta b}\begin{pmatrix}\mathbf{t}\\ \mathbf{n}\\ \mathbf{b}\end{pmatrix}=\begin{pmatrix}0 & -(\Omega_n+\tau) & \theta_{bs}\\ \Omega_n+\tau & 0 & \kappa+\operatorname{div}\mathbf{n}\\ -\theta_{bs} & -(\kappa+\operatorname{div}\mathbf{n}) & 0\end{pmatrix}\begin{pmatrix}\mathbf{t}\\ \mathbf{n}\\ \mathbf{b}\end{pmatrix}.$$

The compatibility of this linear system, on application of the commutator relations (3.10), gives rise to nine conditions on the eight geometric parameters $\kappa,\tau,\Omega_s,\Omega_n,\operatorname{div}\mathbf{n},\operatorname{div}\mathbf{b},\theta_{ns}$, and θ_{bs}, viz.,

$$\frac{\delta\theta_{ns}}{\delta b}+\frac{\delta}{\delta n}(\tau+\Omega_n)=(\kappa+\operatorname{div}\mathbf{n})(\Omega_s-2\Omega_n-2\tau)+\operatorname{div}\mathbf{b}\,(\theta_{bs}-\theta_{ns})+\Omega_s\kappa, \tag{3.12a}$$

$$\frac{\delta}{\delta b}(\tau+\Omega_n-\Omega_s)+\frac{\delta\theta_{bs}}{\delta n}=(\kappa+\operatorname{div}\mathbf{n})(\theta_{ns}-\theta_{bs})+\operatorname{div}\mathbf{b}\,(\Omega_s-2\Omega_n-2\tau), \tag{3.12b}$$

$$\frac{\delta}{\delta b}\operatorname{div}\mathbf{b}+\frac{\delta}{\delta n}(\kappa+\operatorname{div}\mathbf{n})=(\tau+\Omega_n)(\tau+\Omega_n-\Omega_s)-\theta_{ns}\theta_{bs}-\tau\Omega_s-(\operatorname{div}\mathbf{b})^2-(\kappa+\operatorname{div}\mathbf{n})^2, \tag{3.12c}$$

$$\frac{\delta}{\delta s}(\tau+\Omega_n)+\frac{\delta\kappa}{\delta b}=-\Omega_n\theta_{ns}-(2\tau+\Omega_n)\theta_{bs}, \tag{3.12d}$$

$$\frac{\delta\theta_{bs}}{\delta s}=-\theta_{bs}^2+\kappa(\kappa+\operatorname{div}\mathbf{n})-\Omega_n(\tau+\Omega_n-\Omega_s)+\tau(\tau+\Omega_n), \tag{3.12e}$$

$$\frac{\delta}{\delta s}(\kappa+\operatorname{div}\mathbf{n})-\frac{\delta\tau}{\delta b}=-\Omega_n\operatorname{div}\mathbf{b}-\theta_{bs}(2\kappa+\operatorname{div}\mathbf{n}), \tag{3.12f}$$

$$\frac{\delta\kappa}{\delta n}-\frac{\delta\theta_{ns}}{\delta s}=\kappa^2+\theta_{ns}^2+(\tau+\Omega_n)(3\tau+\Omega_n)-\Omega_s(2\tau+\Omega_n), \tag{3.12g}$$

$$\frac{\delta}{\delta s}(\tau+\Omega_n-\Omega_s)=-\theta_{ns}(\Omega_n-\Omega_s)+\kappa\,\mathrm{div}\,\mathbf{b}+\theta_{bs}(-2\tau-\Omega_n+\Omega_s), \tag{3.12h}$$

$$\frac{\delta\tau}{\delta n}+\frac{\delta}{\delta s}\mathrm{div}\,\mathbf{b}=-\kappa(\Omega_n-\Omega_s)-\theta_{ns}\mathrm{div}\,\mathbf{b}+(\kappa+\mathrm{div}\,\mathbf{n})(-2\tau-\Omega_n+\Omega_s). \tag{3.12i}$$

Solitonic equations inherent in subsystems of these compatibility conditions have been isolated via the application of certain geometric constraints in Ref. 24. Here, it is shown how the classical hydrodynamic system (2.3) subject to the geometric constraint (2.4) when adjoined to an appropriate subset of the system (3.12), namely, (3.12d)–(3.12f), produces an integrable Heisenberg spin equation that prevails on the constant pressure surfaces. The residual conditions in (3.12) constrain the foliation of these soliton surfaces.

In what follows, it will emerge that the geometric constraint (2.4) imposed on the hydrodynamic system (2.3) implies the vanishing abnormality condition

$$\Omega_n=0. \tag{3.13}$$

Magnetohydrodynamic motions in which this condition arises in conjunction with (2.4) have been previously investigated by Rogers and Kingston.[25] The geometric constraint (3.13) implies the existence of functions Φ and Ψ such that

$$\mathbf{n}=\Psi\nabla\Phi. \tag{3.14}$$

Since $\mathbf{n}$ is parallel to the normal to the surfaces $\Sigma_n:\Phi=\mathrm{const}$, the vector lines of $\mathbf{t}$ (commonly termed the s-lines) constitute geodesics thereon. The vector lines of $\mathbf{b}$ (the b-lines) are necessarily parallels.[23]

On introduction of a parametrization of the surfaces Σ_n wherein

$$\frac{\delta}{\delta s}=\frac{\partial}{\partial s},\quad \frac{\delta}{\delta b}=\frac{1}{\gamma}\frac{\partial}{\partial b}, \tag{3.15}$$

the commutator relation (3.10b) shows that

$$\theta_{bs}=\frac{\partial}{\partial s}\ln\gamma. \tag{3.16}$$

Thus, with the s-lines and b-lines taken as parametric curves on the surfaces Σ_n, the surface metric of an individual such surface adopts the form

$$\mathrm{I}_n=ds^2+\gamma^2(s,b)db^2, \tag{3.17}$$

where γ is constrained by the relation (3.16).

The Gauss–Weingarten equations for an individual surface Σ_n become

$$\begin{aligned}\frac{\partial}{\partial s}\begin{pmatrix}\mathbf{t}\\ \mathbf{n}\\ \mathbf{b}\end{pmatrix}&=\begin{pmatrix}0 & \kappa & 0\\ -\kappa & 0 & \tau\\ 0 & -\tau & 0\end{pmatrix}\begin{pmatrix}\mathbf{t}\\ \mathbf{n}\\ \mathbf{b}\end{pmatrix},\\ \frac{1}{\gamma}\frac{\partial}{\partial b}\begin{pmatrix}\mathbf{t}\\ \mathbf{n}\\ \mathbf{b}\end{pmatrix}&=\begin{pmatrix}0 & -\tau & \theta_{bs}\\ \tau & 0 & \kappa+\mathrm{div}\,\mathbf{n}\\ -\theta_{bs} & -(\kappa+\mathrm{div}\,\mathbf{n}) & 0\end{pmatrix}\begin{pmatrix}\mathbf{t}\\ \mathbf{n}\\ \mathbf{b}\end{pmatrix}.\end{aligned} \tag{3.18}$$

Moreover, if $\mathbf{r}$ denotes the generic position vector to a surface Σ_n, then

$$\frac{\partial \mathbf{r}}{\partial s}=\mathbf{t}, \quad \frac{\partial \mathbf{r}}{\partial b}=\gamma \mathbf{b}, \tag{3.19}$$

and compatibility requires that the **t**-field be such that

$$\frac{\partial \mathbf{t}}{\partial b}=\frac{\partial}{\partial s}\left(h\mathbf{t}\times\frac{\partial \mathbf{t}}{\partial s}\right), \tag{3.20}$$

where

$$h=\gamma\kappa^{-1}. \tag{3.21}$$

IV. THE HEISENBERG SPIN EQUATION IN HYDRODYNAMICS AND MAGNETOHYDROSTATICS

If we now set $\mathbf{q}=q\mathbf{t}$, then decomposition of the hydrodynamic system (2.3) yields

$$\frac{\delta q}{\delta s}+q\,\mathrm{div}\,\mathbf{t}=0, \tag{4.1}$$

together with

$$\frac{\delta p}{\delta s}=\rho q^2\,\mathrm{div}\,\mathbf{t}, \quad \frac{\delta p}{\delta n}=-\rho q^2\kappa, \quad \frac{\delta p}{\delta b}=0. \tag{4.2}$$

On use of the commutator relations (3.10), it is seen that the compatibility conditions for the pressure field require that

$$2\left(\frac{\delta \ln q}{\delta n}\right)\mathrm{div}\,\mathbf{t}=-\frac{\delta \kappa}{\delta s}+\theta_{bs}\kappa-\frac{\delta}{\delta n}\mathrm{div}\,\mathbf{t}+2\kappa\,\mathrm{div}\,\mathbf{t},$$

$$2\left(\frac{\delta \ln q}{\delta b}\right)\mathrm{div}\,\mathbf{t}=\kappa\Omega_n-\frac{\delta}{\delta b}\mathrm{div}\,\mathbf{t}, \tag{4.3}$$

$$2\kappa\left(\frac{\delta \ln q}{\delta b}\right)=-\mathrm{div}\,(\kappa\mathbf{b})-\Omega_s\,\mathrm{div}\,\mathbf{t}.$$

These relations confirm Prim's result[14] that the hydrodynamic motions described by the classical system (2.3) are completely determined by their geometry except when $\mathrm{div}\,\mathbf{t}=0$. On the other hand, if $\mathrm{div}\,\mathbf{t}=0$, then (4.3) shows that if $\kappa\neq 0$, then

$$\theta_{bs}=\frac{\delta}{\delta s}\ln\kappa=\frac{\partial}{\partial s}\ln\kappa, \tag{4.4a}$$

$$\Omega_n=0. \tag{4.4b}$$

Combination of the relation (3.16) with (4.4a) yields

$$\gamma=\nu\kappa, \tag{4.5}$$

where $\partial\nu/\partial s=0$. Here, we may set $\nu=1$ without loss of generality since ν may be absorbed into the b-coordinate. It is readily shown that the residual condition

$$\frac{\delta}{\delta b}\ln q=-\frac{1}{2\kappa}\mathrm{div}\,\kappa\mathbf{b} \tag{4.6}$$

is compatible with the relation

$$\frac{\delta q}{\delta s}=0 \tag{4.7}$$

on use of the geometric compatibility conditions (3.12). It is noted that (4.7) is equivalent, by virtue of the continuity equation (2.3a), to the geometric condition $\operatorname{div}\mathbf{t}=0$ if stagnation points are excluded. It was with hydrodynamic motions subject to the condition (4.7) that the doctoral thesis of Howard in 1953 was concerned.[15]

The relation (4.5), in view of (3.20) and (3.21), shows that, remarkably, for such hydrodynamic motions, the **t**-field satisfies the integrable Heisenberg spin equation. The result is encapsulated in the following:

Theorem 1: *In steady hydrodynamic motions with*

$$\operatorname{div}\mathbf{t}=0 \tag{4.8}$$

and $\kappa\neq 0$, *the unit tangent to the streamlines on individual constant pressure surfaces is governed by the solitonic Heisenberg spin equation*

$$\frac{\partial \mathbf{t}}{\partial b}=\frac{\partial}{\partial s}\left(\mathbf{t}\times\frac{\partial \mathbf{t}}{\partial s}\right), \tag{4.9}$$

where s denotes arc length of the streamlines and b parametrizes the binormal lines. Conversely, any solution of the Heisenberg spin equation subject to the constraint (4.8) gives rise to steady hydrodynamic motions via integration of the compatible linear system (4.2), (4.6), and (4.7) for p and q^2.

In light of the above result, the classical Gilbarg problem reduces to that of the foliation of NLS soliton surfaces according to the geometric constraint (4.8). The integrable Heisenberg spin equation reduction subject to (4.8) likewise obtains for the steady spatial motion of a Prim gas[12] and indeed for that of a gas with general equation of state

$$\rho=\rho(p,\eta),\quad \left.\frac{\partial \rho}{\partial \eta}\right|_{p}>0. \tag{4.10}$$

Importantly, it also applies *mutatis mutandis* for the equilibrium equations of an infinitely conducting liquid, namely,[26]

$$\operatorname{div}\mathbf{H}=0,\quad -\mu(\mathbf{H}\cdot\nabla)\mathbf{H}+\nabla\Pi=\mathbf{0}, \tag{4.11}$$

subject to the condition

$$\mathbf{H}\cdot\nabla|\mathbf{H}|=0, \tag{4.12}$$

where **H** denotes the magnetic field, μ is the magnetic permeability assumed constant and $\Pi=p+\frac{1}{2}\mu\mathbf{H}^2$ is the total pressure. In this context, the role of the constant pressure surfaces in hydrodynamics is replaced by the constant total pressure surfaces $\Pi=\text{const}$. The Heisenberg spin connection has been recently exploited by Schief[27] to construct geometric configurations wherein the constant total pressure surfaces comprise nested tori which are foliated in accordance with the condition (4.8). In this case, the constant total pressure surfaces and the isobar surfaces are identical. Remarkably, such equilibrium configurations were earlier obtained in a direct manner by Palumbo,[28,29] who asserted that the constant pressure surfaces coincide with the so-called drift surfaces if and only if the magnetic field lines constitute geodesics on these surfaces. Equilibria of this kind are of importance since they are free of neoclassical transport effects causing increased diffusion and heat conduction.

The above-mentioned nested toroidal configurations represent a particular solution of the complete set of compatibility conditions (3.12) subject to the geometric constraints (4.4) and (4.8). The solution of these constrained compatibility conditions in general remains an open and important problem. In terms of complexity, it represents an extension of a classical problem posed by Hamel[30] (vide Ref. 31).

V. INTEGRABLE STRUCTURE IN IDEAL EQUILIBRIUM MAGNETOHYDRODYNAMICS. THE POHLMEYER–LUND–REGGE MODEL

It is natural to pose an analog of the Gilbarg problem in ideal magnetohydrodynamics. Indeed, work in this direction was initiated by Wasserman in Ref. 32. However, it is only recently that it has been established that any solution of the ideal magnetohydrodynamic equations governing the steady motion of an infinitely conducting incompressible fluid which is such that the Maxwellian and constant total pressure surfaces coincide is embedded in a multiplicity of solutions which share the magnetic field line and streamline geometry.[33] Remarkably, in this case, the magnetohydrodynamic equations reduce to the integrable Pohlmeyer–Lund–Regge model subject to a volume-preserving constraint. Moreover, it may be shown that if the magnetic and velocity fields are aligned or either of them vanishes then the Heisenberg spin connection as discussed in the previous section is retrieved. Here, the Pohlmeyer–Lund–Regge connection to ideal magnetohydrodynamics is described.

A. The magnetohydrodynamic system

The system of magnetohydrodynamic equations adopts the form[26]

$$\operatorname{div}\mathbf{q}=0, \tag{5.1a}$$

$$\rho(\mathbf{q}\cdot\nabla)\mathbf{q}+\nabla p=\frac{1}{\mu}\operatorname{curl}\mathbf{B}\times\mathbf{B}, \tag{5.1b}$$

$$\operatorname{div}\mathbf{B}=0, \tag{5.1c}$$

$$\operatorname{curl}(\mathbf{q}\times\mathbf{B})=\mathbf{0}, \tag{5.1d}$$

or, equivalently,

$$\operatorname{div}\mathbf{q}=0, \tag{5.2a}$$

$$\rho(\mathbf{q}\cdot\nabla)\mathbf{q}-\frac{1}{\mu}(\mathbf{B}\cdot\nabla)\mathbf{B}+\nabla\Pi=\mathbf{0}, \tag{5.2b}$$

$$\operatorname{div}\mathbf{B}=0, \tag{5.2c}$$

$$(\mathbf{q}\cdot\nabla)\mathbf{B}=(\mathbf{B}\cdot\nabla)\mathbf{q}, \tag{5.2d}$$

wherein $\Pi=p+\mathbf{B}^2/2\mu$ is the total pressure and μ designates the magnetic permeability. In the following, we set $\rho=\mu=1$ without loss of generality.

The Faraday equation (5.1d) implies that there exist 'Maxwellian' surfaces Σ which bear the streamlines and magnetic field lines. The commutation property

$$[\mathbf{q}\cdot\nabla,\mathbf{b}\cdot\nabla]=0 \tag{5.3}$$

embodied in (5.2d) implies that there exists a coordinate system (χ, ψ, ω) such that the Maxwellian surfaces are given by $\omega=\text{const}$ and

$$\mathbf{q}\cdot\nabla=\partial_\chi, \quad \mathbf{B}\cdot\nabla=\partial_\psi \tag{5.4}$$

so that if $\mathbf{r}$ denotes the Eulerian coordinate vector then

$$\mathbf{q}=\mathbf{r}_\chi, \quad \mathbf{B}=\mathbf{r}_\psi \tag{5.5}$$

are tangent vectors to the χ and ψ coordinate lines, respectively, on the Maxwellian surfaces. In terms of this coordinate system, the continuity and induction equations (5.2a) and (5.2c) in turn, adopt the form

$$\begin{aligned} \operatorname{div}\mathbf{r}_\chi &= \frac{|\mathbf{r}_\chi,\mathbf{r}_\psi,\mathbf{r}_\omega|_\chi}{|\mathbf{r}_\chi,\mathbf{r}_\psi,\mathbf{r}_\omega|}=0, \\ \operatorname{div}\mathbf{r}_\psi &= \frac{|\mathbf{r}_\chi,\mathbf{r}_\psi,\mathbf{r}_\omega|_\psi}{|\mathbf{r}_\chi,\mathbf{r}_\psi,\mathbf{r}_\omega|}=0. \end{aligned} \tag{5.6}$$

Thus, on appropriate reparametrization of the foliation parameter ω, we obtain the volume-preserving condition

$$|\mathbf{r}_\chi,\mathbf{r}_\psi,\mathbf{r}_\omega|=1 \tag{5.7}$$

while the equation of motion (5.2b) becomes

$$\mathbf{r}_{\chi\chi}-\mathbf{r}_{\psi\psi}+\Pi_\chi\mathbf{r}_\psi\times\mathbf{r}_\omega+\Pi_\psi\mathbf{r}_\omega\times\mathbf{r}_\chi+\Pi_\omega\mathbf{r}_\chi\times\mathbf{r}_\psi=0. \tag{5.8}$$

It is concluded that the magnetohydrodynamic system (5.2) is equivalent to the system (5.7), (5.8) with the fluid velocity and magnetic field given by (5.5).

B. The Pohlmeyer–Lund–Regge connection

The preceding canonical formulation of the governing equations has as a consequence the following theorem:[33]

Theorem 2: *If the Maxwellian surfaces coincide with the constant total pressure surfaces so that* $\Pi=\Pi(\omega)$ *then the magnetohydrodynamic system (5.1) or, equivalently, (5.2) reduces to the* integrable *Pohlmeyer–Lund–Regge model*

$$\mathbf{r}_{\chi\chi}-\mathbf{r}_{\psi\psi}=\Omega(\omega)\mathbf{r}_\chi\times\mathbf{r}_\psi \tag{5.9}$$

subject to the volume-preserving condition

$$|\mathbf{r}_\chi,\mathbf{r}_\psi,\mathbf{r}_\omega|=1. \tag{5.10}$$

The fluid velocity, magnetic field, and total pressure are given by

$$\mathbf{q}=\mathbf{r}_\chi, \quad \mathbf{B}=\mathbf{r}_\psi, \quad \Pi=-\int \Omega(\omega)\,d\omega, \tag{5.11}$$

respectively.

The Pohlmeyer–Lund–Regge model constitutes an integrable nonlinear σ-model[34,35] which usually consists of the vector equation (5.9) and the admissible constraints

$$\mathbf{r}_\chi^2+\mathbf{r}_\psi^2=1, \quad \mathbf{r}_\chi\cdot\mathbf{r}_\psi=0. \tag{5.12}$$

The latter normalization may always be achieved by means of a suitable coordinate transformation which leaves (5.9) invariant. However, in the present magnetohydrodynamic context, the new coordinate lines on the Maxwellian surfaces do not necessarily coincide with the streamlines and magnetic field lines and the volume-preserving condition (5.10) adopts a less convenient form.

The assumption that the magnetic field is orthogonal to the velocity field constitutes an additional constraint on the magnetohydrodynamic system. This orthogonality condition is not 'geometric' in that it is not preserved by the invariance

$$\begin{pmatrix} \mathbf{q} \\ \mathbf{B} \end{pmatrix} \to \begin{pmatrix} \cosh\lambda & \sinh\lambda \\ \sinh\lambda & \cosh\lambda \end{pmatrix} \begin{pmatrix} \mathbf{q} \\ \mathbf{B} \end{pmatrix}, \quad \lambda = \text{const} \tag{5.13}$$

of the magnetohydrodynamic system.

C. A substitution principle. Bernoulli integrals of motion

The geometric constraint that the Maxwellian surfaces and constant total pressure surfaces coincide is equivalently characterized by

$$\mathbf{q}\cdot\nabla\Pi = 0, \quad \mathbf{B}\cdot\nabla\Pi = 0. \tag{5.14}$$

If $\mathbf{q}$, $\mathbf{B}$ and Π obey these conditions then a function m which is constant on the Maxwellian surfaces so that

$$\mathbf{q}\cdot\nabla m = 0, \quad \mathbf{B}\cdot\nabla m = 0 \tag{5.15}$$

is associated with the multiplicity of solutions $\{\mathbf{q}^*, \mathbf{B}^*, \Pi^*\}$ of the magnetohydrodynamic system (5.2) embodied in the substitution principle

$$\mathbf{q}^* = m\mathbf{q}, \quad \mathbf{B}^* = m\mathbf{B}, \quad \nabla\Pi^* = m^2\nabla\Pi. \tag{5.16}$$

Thus, any solution of the magnetohydrodynamic system wherein the Maxwellian and constant total pressure surfaces coincide is embedded in a multiplicity of solutions which share the streamline and magnetic field line geometry. This property is reflected by the invariance $(\chi, \psi, \omega) \to (\chi^*, \psi^*, \omega^*)$ of the constrained Pohlmeyer–Lund–Regge system (5.9), (5.10), where

$$\chi^* = \frac{\chi}{m(\omega)}, \quad \psi^* = \frac{\psi}{m(\omega)}, \quad \omega^* = \int m^2(\omega)\, d\omega \tag{5.17}$$

and $\Omega^* = \Omega$. It is noted that the admittance of invariance properties of substitution principle type has been previously investigated in magnetohydrodynamics in Refs. 36–38.

In view of the conditions (5.14), it is seen that scalar multiplication of the equation of motion (5.2b) by $\mathbf{q}$ and $\mathbf{B}$, respectively, yields

$$(\mathbf{q} \mp \mathbf{B})\cdot\nabla(\mathbf{q} \pm \mathbf{B})^2 = 0. \tag{5.18}$$

Accordingly, we obtain the two Bernoulli-type integrals of motion

$$(\mathbf{q} \pm \mathbf{B})^2 = 2\mathbb{B}_\pm(\chi \pm \psi, \omega) \tag{5.19}$$

or, equivalently,

$$\mathbf{q}^2 + \mathbf{B}^2 = \mathbb{B}_+ + \mathbb{B}_-, \quad \mathbf{q}\cdot\mathbf{B} = \tfrac{1}{2}(\mathbb{B}_+ - \mathbb{B}_-). \tag{5.20}$$

The latter correspond to the first integrals

$$\mathbf{r}_\chi^2 + \mathbf{r}_\psi^2 = \mathbb{B}_+ + \mathbb{B}_-, \quad \mathbf{r}_\chi\cdot\mathbf{r}_\psi = \tfrac{1}{2}(\mathbb{B}_+ - \mathbb{B}_-) \tag{5.21}$$

of the Pohlmeyer–Lund–Regge model. These may be reduced to the normal form (5.12) by means of a suitable coordinate transformation.

VI. THE KINEMATICS OF IDEAL FIBER-REINFORCED FLUIDS. INTEGRABLE ADMISSIBLE REDUCTIONS

The notion of an ideal fiber-reinforced fluid was introduced in Ref. 39 as a model in the liquid formation process of fiber-resin materials. This model consists of an incompressible fluid which is inextensible along 'fiber' lines that occupy the volume of the fluid by which they are convected. Resin matrix fiber-reinforced materials enjoy abundant engineering applications, particularly in the construction of light laminated shell structures with complicated geometries.

The kinematic conditions that attend the motion of an ideal fiber-reinforced fluid were set down by Spencer.[40] Thus, if a generic fiber direction is characterized by a unit vector $\mathbf{t}$, the kinematic conditions comprise the usual continuity equation

$$\operatorname{div}\mathbf{v}=0 \tag{6.1}$$

together with the condition

$$\frac{\partial \mathbf{t}}{\partial t}+(\mathbf{v}\cdot\nabla)\mathbf{t}=(\mathbf{t}\cdot\nabla)\mathbf{v}. \tag{6.2}$$

The latter constitutes the commutativity condition

$$\frac{d}{dt}\left(\frac{\delta \mathbf{r}}{\delta s}\right)=\frac{\delta}{\delta s}\left(\frac{d\mathbf{r}}{dt}\right), \tag{6.3}$$

where $\mathbf{r}$ is the position vector to a generic fiber and $d/dt=\partial/\partial t+\mathbf{v}\cdot\nabla$. It is interesting to observe that a similar compatibility condition arises in the derivation of soliton equations via privileged motions of inextensible curves. The kinematic conditions combine to show that

$$\frac{d}{dt}\operatorname{div}\mathbf{t}=0 \tag{6.4}$$

and an important subclass of motions is that with[40]

$$\operatorname{div}\mathbf{t}=0. \tag{6.5}$$

The natural reappearance of the geometric constraint (6.5), albeit now with regard to the fiber field, prompts the search for hidden integrable structure within the kinematic conditions (6.1), (6.2). This motivation is enhanced by the presence of the commutativity condition (6.3) as encountered in soliton theory. Here, attention is restricted to steady motion, in which case the kinematic conditions imply that

$$(\mathbf{v}\times\mathbf{t})\cdot\operatorname{curl}(\mathbf{v}\times\mathbf{t})=0, \tag{6.6}$$

whence the $\mathbf{v}\times\mathbf{t}$-field is complex-lamellar so that

$$\mathbf{v}\times\mathbf{t}=\Psi\nabla\Phi \tag{6.7}$$

for some functions Ψ and Φ. Thus, surfaces $\Sigma:\Phi=\text{const}$ exist which bear both the streamlines and fibers.

It is common in the structure of composite materials to have reinforcement by multiple families of fibers. If there exists a second family of fibers with unit tangent $\mathbf{t}^*$ which are convected by the fluid flow $\mathbf{v}$ and which also lie on the surfaces Σ then there exists the additional kinematic constraint

$$(\mathbf{v}\cdot\nabla)\mathbf{t}^*=(\mathbf{t}^*\cdot\nabla)\mathbf{v}, \tag{6.8}$$

where $\mathbf{t}^*$ may be decomposed according to

$$\mathbf{t}^* = \alpha \mathbf{t} + \beta \mathbf{v}. \tag{6.9}$$

Substitution of (6.9) into (6.8) establishes the following result:

Theorem 3: *In steady fiber-reinforced motion, the surfaces* Σ *bearing the stream lines and* $\mathbf{t}$*-fibers contain a second family of fibers*

$$\mathbf{t}^* = \alpha \mathbf{t} + \beta \mathbf{v}, \quad |\mathbf{t}^*| = 1 \tag{6.10}$$

iff

$$\alpha^2 + \beta^2 v^2 + 2\alpha\beta v(\mathbf{T}\cdot\mathbf{t}) = 1, \tag{6.11}$$

where $\mathbf{T}$ *is the unit tangent to the streamlines and*

$$\frac{\delta\alpha}{\delta S} = \frac{\delta\beta}{\delta S} = 0 \tag{6.12}$$

with $\delta/\delta S = \mathbf{T}\cdot\nabla$.

The following result is readily obtained as a consequence of Theorem 3:[41]

Corollary 1: A multiplicity (>2) *of fibers can exist on the surfaces* Σ *iff the geometry of the streamlines and fibers is constrained by*

$$\operatorname{div}\mathbf{T} = 0, \tag{6.13a}$$

$$\frac{\delta}{\delta S}(\mathbf{T}\cdot\mathbf{t}) = 0. \tag{6.13b}$$

Materials with two, three, or more families of embedded fibers have been discussed in the authoritative monograph of Spencer.[42] It is recalled that it is just the geometric condition (6.13a) which in classical hydrodynamics has been seen to lead to the integrable Heisenberg spin equation.

If the fluid velocity $\mathbf{v}$ is decomposed as

$$\mathbf{v} = v_s \mathbf{t} + v_n \mathbf{n} + v_b \mathbf{b} \tag{6.14}$$

in terms of the fiber direction $\mathbf{t}$ and its principal normal $\mathbf{n}$ and binormal $\mathbf{b}$ then insertion into the kinematic conditions (6.1) and (6.2) yields

$$\frac{\delta v_s}{\delta s} = v_n \kappa, \tag{6.15a}$$

$$\frac{\delta v_n}{\delta s} = v_n \theta_{ns} - v_b \Omega_n, \tag{6.15b}$$

$$\frac{\delta v_b}{\delta s} = v_n \Omega_b + v_b \theta_{bs}, \tag{6.15c}$$

$$\frac{\delta v_n}{\delta n} + \frac{\delta v_b}{\delta b} = -v_s \operatorname{div}\mathbf{t} - v_n(\kappa + \operatorname{div}\mathbf{n}) - v_b \operatorname{div}\mathbf{b}. \tag{6.15d}$$

This constitutes an overdetermined system of linear equations for the velocity components v_s, v_n, and v_b with compatibility condition

$$v_s \frac{\delta}{\delta s} \operatorname{div} \mathbf{t} + v_n \frac{\delta}{\delta n} \operatorname{div} \mathbf{t} + v_b \frac{\delta}{\delta b} \operatorname{div} \mathbf{t} = 0. \tag{6.16}$$

In particular, the latter constraint is satisfied if

$$\operatorname{div} \mathbf{t} = 0 \tag{6.17}$$

in which case the commutator relations (3.10) show that (6.15b)–(6.15d) guarantee the existence of a potential Π such that

$$\frac{\delta \Pi}{\delta s} = 0, \tag{6.18a}$$

$$\frac{\delta \Pi}{\delta n} = -v_b, \tag{6.18b}$$

$$\frac{\delta \Pi}{\delta b} = v_n. \tag{6.18c}$$

Moreover, in the case of geometries with

$$\Omega_n = 0, \quad \theta_{bs} = \frac{\delta}{\delta s} \ln \kappa, \tag{6.19}$$

the solution of the residual condition (6.15a) is given explicitly by

$$\Pi = \frac{\delta \chi}{\delta s}, \tag{6.20a}$$

$$\frac{v_s}{\kappa} = \frac{\delta \chi}{\delta b}, \tag{6.20b}$$

where the function χ is, *a priori*, arbitrary. However, insertion of Π as given by (6.20a) into (6.18a) produces a constraint on χ and we obtain:

Theorem 4: *The kinematic equations (6.1), (6.2) of ideal fiber-reinforced spatial flows with geometric constraints*

$$\operatorname{div} \mathbf{t} = 0, \tag{6.21a}$$

$$\Omega_n = 0, \tag{6.21b}$$

$$\theta_{bs} = \frac{\delta}{\delta s} \ln \kappa \tag{6.21c}$$

admit the general solution

$$\mathbf{v} = \kappa \frac{\delta \chi}{\delta b} \mathbf{t} + \frac{\delta^2 \chi}{\delta b \, \delta s} \mathbf{n} - \frac{\delta^2 \chi}{\delta n \, \delta s} \mathbf{b}, \tag{6.22}$$

where

$$\frac{\delta^2 \chi}{\delta s^2} = 0. \tag{6.23}$$

The fibers constitute geodesics on a family of surfaces Σ_n.

It is recalled that the conditions (6.21b) and (6.21c) encapsulate the integrable Heisenberg spin equation while (6.21a) is identical to the constraint encountered in the Gilbarg problem. In the present context, however, the **t**-lines are the fibers. The nested toroidal solutions obtained in Ref. 27 carry over *mutatis mutandis* to provide particular spatial geometries that adhere to the kinematic conditions (6.1) and (6.2).

A. The geometry of planar motion

It is asserted in Ref. 40 that two-dimensional flows of an ideal fiber-reinforced fluid are essentially determined by kinematical considerations. Thus, the pressure p and tension T in the fiber direction can always be determined such that the equations of motion are satisfied. Accordingly, planar motion is especially privileged and the study of its kinematics assumes an added importance. Here, it is established that the kinematic conditions for the planar motion of an ideal fiber-reinforced fluid can be encoded in a single nonlinear third-order equation. Remarkably, the latter is shown to contain a variant of a well-known integrable system in soliton theory.

In the planar kinematic study of ideal fiber-reinforced fluids, the linear system (3.11) reduces to

$$\frac{\delta}{\delta s}\begin{pmatrix}\mathbf{t}\\ \mathbf{n}\end{pmatrix}=\begin{pmatrix}0 & \kappa\\ -\kappa & 0\end{pmatrix}\begin{pmatrix}\mathbf{t}\\ \mathbf{n}\end{pmatrix},$$
$$\frac{\delta}{\delta n}\begin{pmatrix}\mathbf{t}\\ \mathbf{n}\end{pmatrix}=\begin{pmatrix}0 & \theta\\ -\theta & 0\end{pmatrix}\begin{pmatrix}\mathbf{t}\\ \mathbf{n}\end{pmatrix}, \tag{6.24}$$

where $\theta=\theta_{ns}=\operatorname{div}\mathbf{t}$. The above pair may be interpreted as the Serret–Frenet equations associated with the planar fibers and their orthogonal trajectories, that is the **n**-lines, with $-\theta$ being the curvature of the latter. The nonlinear system of compatibility conditions (3.12) is identically satisfied except for the single condition

$$\frac{\delta\kappa}{\delta n}-\frac{\delta\theta}{\delta s}=\kappa^2+\theta^2. \tag{6.25}$$

Indeed, on use of the commutator relation

$$\frac{\delta^2}{\delta n\,\delta s}-\frac{\delta^2}{\delta s\,\delta n}=\kappa\frac{\delta}{\delta s}+\theta\frac{\delta}{\delta n}, \tag{6.26}$$

it is readily shown that the Serret–Frenet system (6.24) is compatible modulo (6.25). The general solution of the latter geometric condition may be parametrized via

$$\kappa=\frac{\delta\varphi}{\delta s},\quad \theta=\frac{\delta\varphi}{\delta n}, \tag{6.27}$$

where φ is an as yet unspecified function. Moreover, the fluid velocity **v** is now decomposed according to

$$\mathbf{v}=v\,\mathbf{t}+w\,\mathbf{n}, \tag{6.28}$$

whence, on substitution into the kinematic conditions (6.1) and (6.2), one obtains

$$\frac{\delta v}{\delta s}=\kappa w, \tag{6.29a}$$

$$\frac{\delta w}{\delta s} = \theta w, \tag{6.29b}$$

$$\frac{\delta w}{\delta n} = -\theta v, \tag{6.29c}$$

where the relation $\kappa + \operatorname{div}\mathbf{n} = 0$ valid in planar geometry has been employed.

It is natural to take the fiber lines and their orthogonal trajectories as the coordinate lines of an orthogonal system on the plane. Accordingly, if the variables s and n parametrize the **t**- and **n**-lines, respectively, then the metric of the plane adopts the form

$$\mathrm{I} = \phi^2 ds^2 + \psi^2 dn^2, \tag{6.30}$$

where the partial and directional derivatives are related by

$$\frac{\partial}{\partial s} = \phi \frac{\delta}{\delta s}, \quad \frac{\partial}{\partial n} = \psi \frac{\delta}{\delta n}. \tag{6.31}$$

Thus, if **r** is a generic point on the plane then

$$\frac{\delta \mathbf{r}}{\delta s} = \mathbf{t} = \frac{1}{\phi}\frac{\partial \mathbf{r}}{\partial s}, \quad \frac{\delta \mathbf{r}}{\delta n} = \mathbf{n} = \frac{1}{\psi}\frac{\partial \mathbf{r}}{\partial n}. \tag{6.32}$$

In view of (6.27), the geometric quantities κ and θ now admit the parametrization

$$\kappa = \frac{1}{\phi}\frac{\partial \varphi}{\partial s}, \tag{6.33a}$$

$$\theta = \frac{1}{\psi}\frac{\partial \varphi}{\partial n}. \tag{6.33b}$$

Insertion of (6.31) into the commutator relation (6.26) yields

$$\psi_s = \varphi_n \phi, \tag{6.34a}$$

$$\phi_n = -\varphi_s \psi. \tag{6.34b}$$

Here and subsequently, subscripts denote partial derivatives.

It now proves convenient to introduce a quantity ρ according to the relations

$$\frac{\delta \rho}{\delta s} = 1, \tag{6.35a}$$

$$\frac{\delta \rho}{\delta n} = -\frac{v}{w}. \tag{6.35b}$$

Use of the commutator relation (6.26) and the kinematic conditions (6.29a) and (6.29b) shows that the relations (6.35) are indeed compatible. By virtue of (6.35a), the quantity ρ is seen to constitute arc length along the fibers. Moreover, the relations (6.35) combine to yield

$$\mathbf{q} \cdot \nabla \rho = 0 \tag{6.36}$$

while the compatibility of the kinematic conditions (6.29b) and (6.29c) requires, on use of (6.26), that

$$\mathbf{q}\cdot\nabla\theta=0, \tag{6.37}$$

whence we come to the important conclusion that the divergence of the **t**-field constitutes a function of the arc length ρ along the fibers. In fact, in Ref. 41, it has been shown that this geometric property completely characterizes steady planar motions. If we set, for convenience,

$$\theta=\operatorname{div}\mathbf{t}=\frac{\Psi'(\rho)}{\Psi(\rho)} \tag{6.38}$$

then relations (6.33b) and (6.34a) together show that

$$\frac{\psi_s}{\psi}=\frac{\Psi'(\rho)}{\Psi(\rho)}\phi \tag{6.39}$$

while (6.35a) yields

$$\phi=\rho_s, \tag{6.40}$$

whence

$$\psi=\Psi(\rho). \tag{6.41}$$

Herein, an arbitrary function of integration $N(n)$ has been omitted without loss of generality since it may be removed via a suitable reparametrization of the **n**-lines. The relation (6.33b), on use of (6.38) and (6.41), reduces to

$$\varphi_n=\Psi'(\rho) \tag{6.42}$$

while the residual condition (6.34b) shows that

$$\varphi_s=-\frac{\rho_{sn}}{\Psi(\rho)}. \tag{6.43}$$

Elimination of φ between the latter two relations gives rise to the following result:

Theorem 5: *The kinematics of the steady planar motion of an ideal fiber-reinforced fluid is governed by the single third-order nonlinear equation*

$$\left(\frac{\rho_{sn}}{\Psi(\rho)}\right)_n+\Psi''(\rho)\rho_s=0 \tag{6.44}$$

for the arc length ρ along the fibers. Here, Ψ constitutes an arbitrary function of ρ. The one-parameter family of fibers $\mathbf{r}(s,n=\text{const})$ *is obtained by integration of the compatible pair*

$$\mathbf{r}_s=\rho_s\mathbf{t}, \quad \mathbf{r}_n=\Psi(\rho)\mathbf{n} \tag{6.45}$$

while the fluid velocity is given by

$$\mathbf{v}=-\rho_n\mathbf{t}+\Psi(\rho)\mathbf{n}. \tag{6.46}$$

The solution of the Serret–Frenet equations (6.24) reads

$$\mathbf{t}=\begin{pmatrix}\cos\varphi\\ \sin\varphi\end{pmatrix}, \quad \mathbf{n}=\begin{pmatrix}-\sin\varphi\\ \cos\varphi\end{pmatrix}, \tag{6.47}$$

where φ obeys the compatible system

$$\varphi_s = -\frac{\rho_{sn}}{\Psi(\rho)}, \quad \varphi_n = \Psi'(\rho). \tag{6.48}$$

B. An integrable reduction. Generation of fiber distributions

To proceed, it proves convenient to reformulate the third-order equation (6.44) as a coupled system of equations, namely,

$$\rho_{sn} = \mu\Psi(\rho), \quad \mu_n = -\Psi''(\rho)\rho_s. \tag{6.49}$$

The latter admits the first integral

$$\mu^2 - \alpha\rho_s^2 = I(s) \tag{6.50}$$

if Ψ is constrained by

$$\Psi''(\rho) + \alpha\Psi(\rho) = 0, \tag{6.51}$$

where α constitutes an arbitrary constant. On use of an appropriate reparametrization of the fiber lines, the function I may be scaled to $0, \pm 1$. In particular, if $\alpha = I = 1$ and

$$\Psi(\rho) = \sin\rho, \tag{6.52}$$

the parametrization

$$\mu = \epsilon\cosh\omega, \quad \rho_s = \epsilon\sinh\omega, \quad \epsilon^2 = 1 \tag{6.53}$$

of the relation (6.50) results in the following consequence of Theorem 5:

Corollary 2: The specialization $\Psi(\rho) = \sin\rho$ in (6.44) reduces it to the system

$$\rho_s = \epsilon\sinh\omega, \quad \omega_n = \sin\rho \tag{6.54}$$

with associated fluid velocity

$$\mathbf{v} = -\rho_n\mathbf{t} + \sin\rho\,\mathbf{n}, \tag{6.55}$$

where the pair $(\mathbf{t}, \mathbf{n})$ *is given by (6.47) with*

$$\varphi_s = -\epsilon\cosh\omega, \quad \varphi_n = \cos\rho. \tag{6.56}$$

The metric of the plane may be cast into the form

$$\mathrm{I} = \rho_s^2 ds^2 + \omega_n^2 dn^2 \tag{6.57}$$

so that ρ and ω constitute arc length along the **t***-lines and* **n***-lines, respectively.*

If the term $\epsilon\sinh\omega$ in (6.54) is replaced by $\sin\omega$ then the classical Bäcklund equations for surfaces of constant negative Gaussian curvature result.[1] The Gauss equation for such pseudospherical surfaces is the integrable sine-Gordon equation.[43] In the current context, it is readily verified that $\rho + \mathrm{i}\omega$ obey the sine-Gordon equation

$$(\rho + \mathrm{i}\omega)_{sn} = \epsilon\sin(\rho + \mathrm{i}\omega). \tag{6.58}$$

The system (6.54) guarantees that the pair

$$\Phi_s=\frac{\epsilon}{2}\begin{pmatrix}\tan\nu\sinh\omega & -\dfrac{\cosh\omega}{\cos\nu}\\ \dfrac{\cosh\omega}{\cos\nu} & -\tan\nu\sinh\omega\end{pmatrix}\Phi,$$
$$\Phi_n=\frac{1}{2}\begin{pmatrix}0 & \cos(\rho-\nu)\\ -\cos(\rho+\nu) & 0\end{pmatrix}\Phi \tag{6.59}$$

is compatible for any value of the constant parameter ν. In fact, the latter constitutes a 'linear representation' of the nonlinear system (6.54) in the sense of soliton theory and admits an associated Darboux transformation.[1] In this connection, it is noted that, at $\nu=0$, the fundamental solution of (6.59) is given by

$$\Phi|_{\nu=0}=\begin{pmatrix}\cos\varphi/2 & \sin\varphi/2\\ -\sin\varphi/2 & \cos\varphi/2\end{pmatrix}. \tag{6.60}$$

Thus, the 'eigenfunction' Φ encodes the tangent vectors $\mathbf{t}$ and $\mathbf{n}$ via the angle φ. An induced Bäcklund transformation for the fiber distribution on the plane may be obtained in a standard manner by employing the Sym–Tafel formula[1,44] which, in the current context, states that the position vector of the fibers is encapsulated in

$$\Phi^{-1}\frac{\partial\Phi}{\partial\nu}\bigg|_{\nu=0}. \tag{6.61}$$

The above-mentioned results are summarized below:[45]

Theorem 6: *Any solution (ρ,ω) of the integrable system (6.54) together with the associated fiber position vector* $\mathbf{r}$ *and tangent vectors* $\mathbf{t}$, $\mathbf{n}$ *may be mapped to another solution* (ρ',ω') *and fiber distribution* $(\mathbf{r}',\mathbf{t}',\mathbf{n}')$ *by the Bäcklund transformation*

$$\rho'=\rho+2\arctan\left(\cot\nu\frac{1+\xi^2}{1-\xi^2}\right),$$
$$\omega'=-\omega+2\left(\frac{2\xi\sin\nu}{1+\xi^2}\right),$$
$$\varphi'=\varphi+\chi,\quad \chi=-2\arctan\left(\frac{2\xi\cos\nu}{1-\xi^2}\right), \tag{6.62}$$
$$\mathbf{r}'=\mathbf{r}+2\cot\nu\frac{1+\xi^2}{1-\xi^2}\cos\frac{\chi}{2}\left(\cos\frac{\chi}{2}\mathbf{t}+\sin\frac{\chi}{2}\mathbf{n}\right),$$
$$\mathbf{t}'=\cos\chi\,\mathbf{t}+\sin\chi\,\mathbf{n},\quad \mathbf{n}'=-\sin\chi\,\mathbf{t}+\cos\chi\,\mathbf{n},$$

where $\xi=\Phi^1/\Phi^2$ *and* $\epsilon'=-\epsilon$. *Here,* Φ^i *designate the components of a vector-valued solution* Φ *of the linear system (6.59).*

The above Bäcklund transformation may be used to generate explicitly large classes of fiber distributions and associated velocity fields $\mathbf{v}$. This has been discussed in Ref. 45.

In conclusion, it is noted that if we introduce the vector field

$$\mathbf{w}=\sinh\omega\,\mathbf{t}-\epsilon\omega_s\mathbf{n} \tag{6.63}$$

then it is readily shown that

$$(\mathbf{w}\cdot\nabla)\mathbf{n}=(\mathbf{n}\cdot\nabla)\mathbf{w},\quad \operatorname{div}\mathbf{w}=0. \tag{6.64}$$

Consequently, the **n**-lines may also be regarded as inextensible fibers which are convected with the **w**-flow. The inextensibility of the **n**-lines is verified by the relation

$$(\mathbf{w}\cdot\nabla)\omega=0. \tag{6.65}$$

Accordingly, we have established the duality

$$(\mathbf{t},\mathbf{v})\leftrightarrow(\mathbf{n},\mathbf{w}). \tag{6.66}$$

Moreover, it may be shown that such a duality property exists iff the function $\Psi(\rho)$ is constrained by (6.51). Thus, the integrable case is privileged with regard to duality.

C. A Loewner connection. The 2+1-dimensional sine-Gordon system

It has been established that the third-order equation (6.44) embodies the complete set of equations governing steady planar motions. These consist of the geometric system (6.34), that is

$$\psi_s=q\phi,\quad \phi_n=-p\psi, \tag{6.67}$$

where

$$p=\varphi_s,\quad q=\varphi_n, \tag{6.68}$$

along with the kinematic conditions (6.29a) and (6.29c) given by

$$v_s=pw,\quad w_n=-qv \tag{6.69}$$

and the remaining kinematic condition (6.29b) which may be replaced by

$$w=\psi. \tag{6.70}$$

Remarkably, if p and q are arbitrary then the linear system (6.69) may be interpreted as the standard 'scattering problem' associated with the $2+1$-dimensional AKNS hierarchy of soliton equations[46] and (6.67) constitutes its adjoint. The functions v and w may be regarded as eigenfunctions while ψ and ϕ represent adjoint eigenfunctions. Moreover, a 'squared eigenfunction' M may be introduced via the compatible system

$$M_s=\phi w,\quad M_n=-\psi v. \tag{6.71}$$

Squared eigenfunctions play an important role in the construction of binary Darboux transformations in soliton theory.[47]

The reduction (6.68) is admissible and indeed standard in soliton theory. It produces a modified Nizhnik-Veselov-Novikov hierarchy (see, e.g., Ref. 48) which may be regarded as a $2+1$-dimensional version of the potential modified Korteweg–de Vries hierarchy.[46] The latter is compatible with the $2+1$-dimensional sine-Gordon system which constitutes a particular reduction of the so-called LKR system.[48–50] The origins of this master $2+1$-dimensional soliton system reside in gasdynamics in a study by Loewner[51] on the application of infinitesimal Bäcklund transformations to reduce the hodograph equations to appropriate canonical form in subsonic, transsonic and supersonic flow régimes. Indeed, (6.69) is gauge-equivalent to the system as studied by Loewner. It was the discovery of the gasdynamic connection with soliton theory via the LKR system that, in part, motivated the present search for hidden integrability in other classical systems of nonlinear continuum mechanics.

The eigenfunction-adjoint eigenfunction constraint (6.70) appears to be novel. It gives rise to the nonlinearity of the third-order equation (6.44) in that it implicitly relates the function φ to the (adjoint) eigenfunctions.

The above-mentioned $2+1$-dimensional integrable generalization of the classical sine-Gordon equation may be brought into the compact polynomial form

$$\hat{\varphi}_{snt}+\hat{\varphi}_s\eta_{nt}+\hat{\varphi}_n\eta_{st}=0, \tag{6.72a}$$

$$\eta_{sn}=\hat{\varphi}_s\hat{\varphi}_n\,. \tag{6.72b}$$

It arises out of the compatibility conditions associated with the Lax pair[52]

$$\begin{pmatrix} \partial_s & -\hat{\varphi}_s \\ \hat{\varphi}_n & \partial_n \end{pmatrix}\begin{pmatrix} \hat{v} \\ \hat{w} \end{pmatrix}=0, \tag{6.73a}$$

$$\begin{pmatrix} \partial_n\partial_t+\eta_{nt} & -\hat{\varphi}_n\partial_t \\ \hat{\varphi}_s\partial_t & \partial_s\partial_t+\eta_{st} \end{pmatrix}\begin{pmatrix} \hat{v} \\ \hat{w} \end{pmatrix}=0. \tag{6.73b}$$

The 'spatial' part (6.73a) of this Lax pair may be identified with the linear system (6.69) if we set

$$\hat{\varphi}=\varphi, \quad \hat{v}=v, \quad \hat{w}=w. \tag{6.74}$$

It is natural to inquire as to whether the 'temporal' part (6.73b) may also be satisfied in the present context, in which case the angle φ obeys the $2+1$-dimensional sine-Gordon system (6.72) and gives rise to classes of fiber distributions in which t plays the role of a parameter.

Here, we focus on the integrable case as summarized in Corollary 2 with $\epsilon=1$. Thus, insertion of φ_s and φ_n as given by (6.56) into (6.72a) yields

$$(\sinh\omega\sin\rho)_t+\eta_{nt}\cosh\omega-\eta_{st}\cos\rho=0, \tag{6.75}$$

which admits a decomposition into the two equations

$$\eta_{st}=\rho_t\sinh\omega, \quad \eta_{nt}=-\omega_t\sin\rho, \tag{6.76}$$

while the remaining equation (6.72b) reads

$$\eta_{sn}=-\cosh\omega\cos\rho. \tag{6.77}$$

The compatibility conditions $\eta_{stn}=\eta_{nts}=\eta_{snt}$ then produce

$$\rho_{nt}=-\omega_t\cos\rho, \quad \omega_{st}=-\rho_t\cosh\omega. \tag{6.78}$$

These are readily seen to be compatible with the system (6.54). Moreover, if we take into account the relations $v=-\rho_n$ and $w=\psi=\sin\rho$ (cf. (6.55)) then it may be verified that the Lax equation (6.73b) is indeed satisfied. Accordingly, it has been established that the fluid velocity vector $\mathbf{v}$ associated with steady planar motions governed by the integrable system (6.54) and taken with respect to the orthonormal basis ($\mathbf{t}$, $\mathbf{n}$) may be interpreted as an eigenfunction of the $2+1$-dimensional sine-Gordon system (6.72). Even though these integrable motions are not constrained by their parametric dependence on t, the solutions of the sine-Gordon system are special. In fact, the associated specialization of the sine-Gordon system encoded in (6.54), (6.56) and (6.76)–(6.78) may be simplified by the observation that

$$(\rho+\mathrm{i}\omega)_{st}=\mathrm{i}\varphi_s(\rho+\mathrm{i}\omega)_t, \quad (\rho+\mathrm{i}\omega)_{nt}=\mathrm{i}\varphi_n(\rho+\mathrm{i}\omega)_t \tag{6.79}$$

so that

$$\rho_t = \cos\varphi, \quad \omega_t = \sin\varphi \tag{6.80}$$

without loss of generality. Hence, we obtain the compatible systems

$$\begin{gathered}\varphi_s = -\cosh\omega, \quad \varphi_n = \cos\rho,\\ \omega_n = \sin\rho, \quad \rho_s = \sinh\omega,\\ \rho_t = \cos\varphi, \quad \omega_t = \sin\varphi,\end{gathered} \tag{6.81}$$

and

$$\begin{gathered}\eta_{sn} = -\cos\rho\cosh\omega,\\ \eta_{st} = \cos\varphi\sinh\omega,\\ \eta_{nt} = -\sin\varphi\sin\rho,\end{gathered} \tag{6.82}$$

which may directly be shown to constitute a reduction of the sine-Gordon system (6.72). It is interesting that the integrable system (6.81) has been recently discussed by Ferapontov in connection with Laplace transformations and Poisson brackets of hydrodynamic type.[53,54]

VII. INTEGRABILITY IN THE EQUILIBRIUM THEORY OF SHELL MEMBRANES

The study of the equilibrium of shell membranes has a long history going back to work of Lamé and Clapeyron[55] on the symmetric loading of shells of revolution. The classical governing equations of general membrane theory were set down by Lecornu[56] and Beltrami.[57] An extensive account of the membrane theory of shells is presented in the lucid monograph of Novozhilov.[58] Here, a classical system descriptive of the equilibrium of shell membranes under normal loading is investigated. It is established that, remarkably, the nonlinear system comprised of the equilibrium equations augmented by the Gauss–Mainardi–Codazzi equations for the membranes may be located in a large class of integrable systems which has recently been derived in the context of so-called O surfaces.[59]

A. The membrane shell system

In the following, we adopt the standard assumptions of classical shell membrane theory as described in Ref. 58. The geometric properties of the membrane are analyzed in the setting of the classical differential geometry of surfaces Σ embedded in an Euclidean space $\mathbb{R}^3$. If a surface (membrane) $\Sigma:\mathbf{r}=\mathbf{r}(\alpha,\beta)$ with associated normal $\mathbf{N}$ is parametrized in terms of curvature coordinates α, β then the first and second fundamental forms $\mathrm{I}=\mathrm{d}\mathbf{r}\cdot\mathrm{d}\mathbf{r}$, $\mathrm{II}=-\mathrm{d}\mathbf{N}\cdot\mathrm{d}\mathbf{r}$ are given by

$$\begin{gathered}\mathrm{I} = A_1^2 d\alpha^2 + A_2^2 d\beta^2,\\ \mathrm{II} = \kappa_1 A_1^2 d\alpha^2 + \kappa_2 A_2^2 d\beta^2,\end{gathered} \tag{7.1}$$

where $\kappa_1 = 1/R_1$, $\kappa_2 = 1/R_2$ denote the principal curvatures and R_1, R_2 are the corresponding principal radii of curvature. In these coordinates, the Gauss–Mainardi–Codazzi equations adopt the form

$$\left(\frac{A_{2\alpha}}{A_1}\right)_\alpha + \left(\frac{A_{1\beta}}{A_2}\right)_\beta + \kappa_1\kappa_2 A_1 A_2 = 0, \tag{7.2a}$$

$$\kappa_{1\beta} + (\ln A_1)_\beta(\kappa_1 - \kappa_2) = 0, \tag{7.2b}$$

$$\kappa_{2\alpha} + (\ln A_2)_\alpha(\kappa_2 - \kappa_1) = 0, \tag{7.2c}$$

while the classical membrane equilibrium equations reduce to

$$(N_1A_2)_\alpha+\frac{(A_1^2S)_\beta}{A_1}-N_2A_{2\alpha}+A_1A_2p_1=0,$$

$$(N_2A_1)_\beta+\frac{(A_2^2S)_\alpha}{A_2}-N_1A_{1\beta}+A_1A_2p_2=0, \tag{7.3}$$

$$\frac{N_1}{R_1}+\frac{N_2}{R_2}+p_3=0,$$

where N_1,N_2 denote the in-plane normal stress components and $S=N_{12}=N_{21}$ designates the in-plane shear. Here, the functions p_i are the components of the surface loading

$$\mathbf{p}=p_1\mathbf{e}_1+p_2\mathbf{e}_2+p_3\mathbf{e}_3, \tag{7.4}$$

wherein the orthonormal triad $(\mathbf{e}_1,\mathbf{e}_2,\mathbf{e}_3)$ is defined by

$$\mathbf{e}_1=\frac{\mathbf{r}_\alpha}{A_1},\quad \mathbf{e}_2=\frac{\mathbf{r}_\beta}{A_2},\quad \mathbf{e}_3=\mathbf{N}=\frac{\mathbf{r}_\alpha\times\mathbf{r}_\beta}{A_1A_2}. \tag{7.5}$$

The system (7.3) results directly from the general theory of thin shells.[58]

For any given membrane geometry and prescribed external surface loading, the membrane equilibrium equations constitute a well-determined linear system for the in-plane stress. However, if conditions are imposed on the in-plane stress then the equilibrium equations constrain the Gauss–Mainardi–Codazzi equations and thereby the geometry of the membrane. Indeed, in the absence of in-plane shear $(S=0)$ with purely normal loading, the equilibrium equations (7.3) reduce to

$$N_{1\alpha}+(\ln A_2)_\alpha(N_1-N_2)=0, \tag{7.6a}$$

$$N_{2\beta}+(\ln A_1)_\beta(N_2-N_1)=0, \tag{7.6b}$$

$$\kappa_1N_1+\kappa_2N_2+p_3=0. \tag{7.6c}$$

The equilibrium equations together with the Gauss–Mainardi–Codazzi equations (7.2) then form a well-determined *coupled nonlinear* system. Thus, under the above-mentioned circumstances, the shape of a membrane in equilibrium is restricted. It is noted that the condition $S=0$ expresses the requirement that the lines of principal stress on the membrane coincide with the lines of curvature.

In the simplest case of a 'homogeneous' stress distribution, that is,

$$N_1=N_2=c=\text{const}, \tag{7.7}$$

the equilibrium equations (7.6) reduce to the classical Young–Laplace equation[60–62]

$$\kappa_1+\kappa_2=-c^{-1}p_3 \tag{7.8}$$

which expresses the fact that the normal loading p_3 is proportional to the mean curvature

$$\mathcal{H}=\kappa_1+\kappa_2 \tag{7.9}$$

of the membrane. In particular, if

$$p_3=\text{const} \tag{7.10}$$

then the membrane is of constant mean curvature while when $p_3=0$ then the membrane is minimal. This connection with classical constant mean curvature and minimal surfaces suggests the detailed study of the case $p_3=\text{const}$. Accordingly, in the following, we focus on the case of vanishing in-plane shear and constant purely normal loading.

B. The O surface connection

It is observed that the equilibrium equations (7.6a) and (7.6b) and the Gauss–Mainardi–Codazzi equations (7.2b) and (7.2c) are identical in form if the correspondence $(N_1,N_2)\leftrightarrow(\kappa_2,\kappa_1)$ is made. In fact, this observation provides the link with integrability. This is readily seen by reformulation of the governing equations. Thus, the change of variables

$$p=\frac{A_{1\beta}}{A_2},\quad q=\frac{A_{2\alpha}}{A_1},$$

$$H_\circ=-\kappa_1 A_1,\quad K_\circ=-\kappa_2 A_2, \tag{7.11}$$

$$H=A_1,\quad K=A_2$$

takes the Gauss–Mainardi–Codazzi equations (7.2) to the equivalent first-order system

$$p_\beta+q_\alpha+H_\circ K_\circ=0, \tag{7.12a}$$

$$H_\beta=pK, \tag{7.12b}$$

$$H_{\circ\beta}=pK_\circ, \tag{7.12c}$$

$$K_\alpha=qH, \tag{7.12d}$$

$$K_{\circ\alpha}=qH_\circ. \tag{7.12e}$$

The unit tangent vectors $\mathbf{e}_1=\mathbf{X}$, $\mathbf{e}_2=\mathbf{Y}$ to the lines of curvature and the normal $\mathbf{e}_3=\mathbf{N}$ are then obtained by solving the Gauss–Weingarten equations

$$\begin{aligned}\begin{pmatrix}\mathbf{X}\\ \mathbf{Y}\\ \mathbf{N}\end{pmatrix}_\alpha&=\begin{pmatrix}0&-p&-H_\circ\\ p&0&0\\ H_\circ&0&0\end{pmatrix}\begin{pmatrix}\mathbf{X}\\ \mathbf{Y}\\ \mathbf{N}\end{pmatrix},\\ \begin{pmatrix}\mathbf{X}\\ \mathbf{Y}\\ \mathbf{N}\end{pmatrix}_\beta&=\begin{pmatrix}0&q&0\\ -q&0&-K_\circ\\ 0&K_\circ&0\end{pmatrix}\begin{pmatrix}\mathbf{X}\\ \mathbf{Y}\\ \mathbf{N}\end{pmatrix},\end{aligned} \tag{7.13}$$

while the position vector $\mathbf{r}$ of the membrane is constructed by integration of the pair

$$\mathbf{r}_\alpha=H\mathbf{X},\quad \mathbf{r}_\beta=K\mathbf{Y}. \tag{7.14}$$

Here, it is important to note that the triplets $(\mathbf{r},H,K)$ and $(\mathbf{r}_\circ,H_\circ,K_\circ)$, where $\mathbf{r}_\circ=\mathbf{N}$, obey the same linear equations, namely, (7.12b), (7.12d), and (7.14) on the one hand and (7.12c), (7.12e), and

$$\mathbf{r}_{\circ\alpha}=H_\circ\mathbf{X},\quad \mathbf{r}_{\circ\beta}=K_\circ\mathbf{Y} \tag{7.15}$$

on the other.

The additional change of variables

$$\tilde{H}=N_2A_1, \quad \tilde{K}=N_1A_2 \tag{7.16}$$

now reduces the equilibrium equations (7.6) to the pair

$$\tilde{H}_\beta=p\tilde{K}, \quad \tilde{K}_\alpha=q\tilde{H} \tag{7.17}$$

subject to the constraint

$$H_\circ\tilde{K}+K_\circ\tilde{H}-p_3HK=0. \tag{7.18}$$

The relations (7.17) represent nothing but another copy of the equations (7.12b) and (7.12d) or (7.12c) and (7.12e). They imply the compatibility of the pair

$$\tilde{\mathbf{r}}_\alpha=\tilde{H}\mathbf{X}, \quad \tilde{\mathbf{r}}_\beta=\tilde{K}\mathbf{Y} \tag{7.19}$$

for some vector-valued function $\tilde{\mathbf{r}}$. Thus, if we interpret $\tilde{\mathbf{r}}$ as the position vector of a surface $\tilde{\Sigma}$ with principal curvatures $\tilde{\kappa}_1=-H_\circ/\tilde{H}$ and $\tilde{\kappa}_2=-K_\circ/\tilde{K}$ then the relations (7.14), (7.15) and (7.19) show that the tangent vectors to the coordinate lines on the membrane Σ, the sphere $\Sigma_\circ$ and the surface $\tilde{\Sigma}$ are parallel. Moreover, since the Gauss–Weingarten equations (7.13) are formulated in terms of the orthonormal triad ($\mathbf{X}$, $\mathbf{Y}$, $\mathbf{N}$) only, we deduce that the surface $\tilde{\Sigma}$ is likewise parametrized in terms of curvature coordinates. Two surfaces parametrized in terms of curvature coordinates which are such that at corresponding points their tangent vectors are parallel are said to be Combescure transforms of each other.[59] It is observed that even though the Combescure transformation has originally been defined for surfaces parametrized in terms of conjugate coordinates, it may readily be shown that it preserves lines of curvature. Accordingly, the surface $\tilde{\Sigma}$ constitutes a Combescure transform of the membrane Σ. The following theorem therefore holds:[63]

Theorem 7: *A shell membrane Σ with vanishing in-plane shear S and constant purely normal loading $\mathbf{p}=p_3\mathbf{N}$ is in equilibrium iff there exists a Combescure transform $\tilde{\Sigma}$ such that the orthogonality condition*

$$\mathsf{H}^{\mathrm{T}}\Lambda\mathsf{K}=0 \tag{7.20}$$

is satisfied, where

$$\mathsf{H}=\begin{pmatrix} H_\circ \\ H \\ \tilde{H} \end{pmatrix}, \quad \mathsf{K}=\begin{pmatrix} K_\circ \\ K \\ \tilde{K} \end{pmatrix}, \quad \Lambda=\begin{pmatrix} 0 & 0 & 1 \\ 0 & -p_3 & 0 \\ 1 & 0 & 0 \end{pmatrix}. \tag{7.21}$$

The in-plane stress components N_1 and N_2 are given by

$$N_1=\frac{\kappa_2}{\tilde{\kappa}_2}=\frac{\tilde{K}}{K}, \quad N_2=\frac{\kappa_1}{\tilde{\kappa}_1}=\frac{\tilde{H}}{H}. \tag{7.22}$$

If one replaces the three-dimensional vectors H, K by their higher-dimensional analogues corresponding to a collection of Combescure transforms and demands that these vectors be orthogonal with respect to a symmetric constant matrix Λ then the general class of integrable O surfaces is obtained.[59] It is important to remark that O surfaces include and generalize classical surfaces such as isothermic, constant mean curvature, minimal, linear Weingarten, Guichard and Petot surfaces and surfaces of constant Gaussian curvature. The membrane O surfaces as identified above are reminiscent of the classical Guichard surfaces which are associated with the matrix

$$\Lambda = \begin{pmatrix} c & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}. \tag{7.23}$$

In this case, the orthogonality constraint (7.20) reads

$$R_1\tilde{R}_2 + R_2\tilde{R}_1 + c = 0. \tag{7.24}$$

This is precisely the constraint in terms of which Guichard[64] defined his surfaces. In the case of membrane O surfaces, the constraint (7.20) may be written as

$$\tilde{R}_1 + \tilde{R}_2 + p_3 R_1 R_2 = 0, \tag{7.25}$$

which, by construction, is nothing but the normal component equilibrium equation (7.6c).

C. Particular membrane geometries

The above formulation of the governing equations may be exploited to isolate particular classes of membrane O surfaces and investigate their properties.[63] For instance, if the normal loading vanishes, that is $p_3 = 0$, then the orthogonality constraint (7.20) simplifies to

$$\begin{pmatrix} H_\circ \\ \tilde{H} \end{pmatrix}^{\mathrm{T}} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} K_\circ \\ \tilde{K} \end{pmatrix} = 0. \tag{7.26}$$

Thus, the latter imposes a restriction on the surface $\tilde{\Sigma}$ while Σ constitutes an arbitrary Combescure transform of $\tilde{\Sigma}$. Since (7.26) may be cast into the form

$$\tilde{\mathcal{H}} = \tilde{\kappa}_1 + \tilde{\kappa}_2 = 0, \tag{7.27}$$

it is evident that any Combescure transform Σ of a minimal surface $\tilde{\Sigma}$ may be considered a membrane which is in equilibrium.

In the case of non-vanishing normal loading, we may impose the admissible conditions

$$\tilde{H} = \mu H - \lambda H_\circ, \quad \tilde{K} = \mu K - \lambda K_\circ, \tag{7.28}$$

where λ and μ constitute arbitrary constants. The orthogonality constraint (7.20) then reduces to

$$\begin{pmatrix} H_\circ \\ H \end{pmatrix}^{\mathrm{T}} \begin{pmatrix} 2\lambda & -\mu \\ -\mu & p_3 \end{pmatrix} \begin{pmatrix} K_\circ \\ K \end{pmatrix} = 0 \tag{7.29}$$

or, equivalently,

$$2\lambda\mathcal{K} + \mu\mathcal{H} + p_3 = 0, \tag{7.30}$$

where the Gaussian curvature $\mathcal{K}$ of the membrane is defined by

$$\mathcal{K} = \kappa_1\kappa_2. \tag{7.31}$$

Importantly, the relation (7.30) shows that the membrane adopts the shape of a linear Weingarten surface since the principal curvatures κ_1, κ_2 are functionally dependent and their relation is such that the Gauss and mean curvatures are linearly related.[43] It is well-known that linear Weingarten surfaces are 'solitonic,' that is, their underlying Gauss–Mainardi–Codazzi equations constitute an integrable system. In the case $\lambda = 0$, the above-mentioned constant mean curvature surfaces are retrieved while the condition $\mu = 0$ leads to surfaces of constant Gaussian curvature. Linear

Weingarten surfaces are known to be parallel to surfaces of constant Gaussian curvature provided that $\mu^2-2\lambda p_3\neq 0$. Parallel surfaces are of importance in computer-aided engineering design in which context they are termed ''offset surfaces.'' [65,66] Potential applications of Weingarten surfaces in this context are discussed in Ref. 67. Thus, linear Weingarten surfaces may be regarded as inheriting their integrable nature from surfaces of constant Gaussian curvature (vide Ref. 1).

Canal surfaces[68] may also be identified with membranes in equilibrium. These are the envelopes of one-parameter families of spheres of variable radius. They include surfaces of revolution and classical Dupin cyclides. The latter are defined by the requirement that the lines of curvature consist of circles.[43,68] Dupin surfaces constitute particular members of the integrable class of classical isothermic surfaces (see, e.g., Ref. 69). Details of the significance of canal surfaces in shell membrane theory may be found in Refs. 63 and 70.

D. A linear representation and associated Bäcklund transformation

The integrability of O surfaces is reflected by the existence of Lax pairs and Bäcklund transformations.[59] The existence of Lax pairs for O surfaces implies that the *nonlinear* Gauss–Mainardi–Codazzi and equilibrium equations (7.2), (7.6), and (7.10) may be completely encoded in a pair of *linear* matrix equations via compatibility. Indeed, the following result may be established.[63]

Theorem 8: *The linear system*

$$\begin{pmatrix}\mathcal{X}\\ \mathcal{Y}\\ \mathcal{R}_\circ\\ \mathcal{R}\\ \tilde{\mathcal{R}}\end{pmatrix}_\alpha=\begin{pmatrix}0 & -p & m\tilde{H}-H_\circ & -mp_3H & mH_\circ\\ p & 0 & 0 & 0 & 0\\ H_\circ & 0 & 0 & 0 & 0\\ H & 0 & 0 & 0 & 0\\ \tilde{H} & 0 & 0 & 0 & 0\end{pmatrix}\begin{pmatrix}\mathcal{X}\\ \mathcal{Y}\\ \mathcal{R}_\circ\\ \mathcal{R}\\ \tilde{\mathcal{R}}\end{pmatrix},$$

$$\begin{pmatrix}\mathcal{X}\\ \mathcal{Y}\\ \mathcal{R}_\circ\\ \mathcal{R}\\ \tilde{\mathcal{R}}\end{pmatrix}_\beta=\begin{pmatrix}0 & q & 0 & 0 & 0\\ -q & 0 & m\tilde{K}-K_\circ & -mp_3K & mK_\circ\\ 0 & K_\circ & 0 & 0 & 0\\ 0 & K & 0 & 0 & 0\\ 0 & \tilde{K} & 0 & 0 & 0\end{pmatrix}\begin{pmatrix}\mathcal{X}\\ \mathcal{Y}\\ \mathcal{R}_\circ\\ \mathcal{R}\\ \tilde{\mathcal{R}}\end{pmatrix} \tag{7.32}$$

is compatible iff the Gauss–Mainardi–Codazzi equations

$$\begin{gathered}p_\beta+q_\alpha+H_\circ K_\circ=0,\\ H_\beta=pK,\quad H_{\circ\beta}=pK_\circ,\\ K_\alpha=qH,\quad K_{\circ\alpha}=qH_\circ,\end{gathered} \tag{7.33}$$

and the membrane equilibrium equations

$$\begin{gathered}\tilde{H}_\beta=p\tilde{K},\quad \tilde{K}_\alpha=q\tilde{H},\\ H_\circ\tilde{K}+K_\circ\tilde{H}-p_3HK=0\end{gathered} \tag{7.34}$$

are simultaneously satisfied. Here, m is an arbitrary constant parameter.

The Bäcklund transformation for the general class of O surfaces as set down in Ref. 59 is based on the classical fundamental transformation for conjugate nets and its specialization to the classical Ribaucour transformation which preserves lines of curvature.[1] In the case of membrane O surfaces, the associated Bäcklund transformation reads as follows:[63]

Theorem 9: *The Gauss–Mainardi–Codazzi and membrane equilibrium equations (7.33) and (7.34) are invariant under the transformation*

$$\mathsf{H}'=\mathsf{H}-\frac{\overline{H}\mathsf{R}}{M},\quad \mathsf{K}'=\mathsf{K}-\frac{\overline{K}\mathsf{R}}{M},$$
$$p'=p-\frac{\mathcal{Y}\overline{H}}{M},\quad q'=q-\frac{\mathcal{X}\overline{K}}{M},\tag{7.35}$$

where $\mathcal{X},\mathcal{Y},\mathsf{R}=(\mathcal{R}_\circ,\mathcal{R},\tilde{\mathcal{R}})^{\mathrm{T}}$ *constitute a solution of the linear representation (7.32) subject to the admissible quadratic constraint*

$$\mathcal{X}^2+\mathcal{Y}^2+\mathcal{R}_\circ^2=m(2\mathcal{R}_\circ\tilde{\mathcal{R}}-p_3\mathcal{R}^2)\tag{7.36}$$

and

$$\overline{H}=\mathcal{X}_\alpha+p\mathcal{Y}+H_\circ\mathcal{R}_\circ,\quad \overline{K}=\mathcal{Y}_\beta+q\mathcal{X}+K_\circ\mathcal{R}_\circ,$$
$$2M=\mathcal{X}^2+\mathcal{Y}^2+\mathcal{R}_\circ^2.\tag{7.37}$$

The membranes Σ *and* Σ' *are related by*

$$\mathbf{r}'=\mathbf{r}-\frac{\mathcal{R}\mathbf{M}}{M},\quad \mathbf{M}=\mathcal{X}\mathbf{X}+\mathcal{Y}\mathbf{Y}+\mathcal{R}_\circ\mathbf{N}.\tag{7.38}$$

The above Bäcklund transformation may now be used to construct explicitly large classes of membranes in equilibrium with vanishing in-plane shear S and associated in-plane stress components N_1 and N_2 determined by (7.22).

In conclusion, it is noted that if the geometry of the membrane is such that $A_1=A_2$, then the analysis presented here extends to the case $SA_1^2=\text{const}$ since the in-plane shear terms in the equilibrium equations (7.3) vanish. In particular, this applies to membranes of constant mean curvature, membranes of revolution and membranes which adopt the shape of Dupin cyclides. Surfaces constrained by $A_1=A_2$ are ''solitonic'' and termed isothermic surfaces.[43]

(Received 2 December 2002; accepted 9 April 2003)

A Weierstrass-type system of equations corresponding to the CP^{N-1} harmonic maps is presented. The system constitutes a further generalization of our previous construction [J. Math. Phys. **44**, 328 (2003)]. It consists of four first order equations for three complex functions which are shown to be equivalent to the CP^{N-1} harmonic maps. When the harmonic maps are holomorphic (or antiholomorphic) one of the functions vanishes and the system reduces to the previously given generalization of the Weierstrass problem. We also discuss a possible interpretation of our results and show that in our new case the induced metric is proportional to the total energy density of the map and not only to its holomorphic part, as was the case in the previous generalizations. © *2003 American Institute of Physics.*

I. INTRODUCTION

A few years ago Konopelchenko, together with his collaborators,[1,2] introduced the subject of Weierstrass representations of surfaces immersed in multidimensional spaces. This has generated quite a lot of interest[3,4] and has led to the connection with the CP^{N-1} harmonic maps. Exploiting this connection, we have recently proposed a generalization of these ideas to the CP^2 (Ref. 5) case and, more recently, managed to generalize it further—to the CP^{N-1} case.[6]

These generalizations lead to the study of immersed surfaces, whose metric is then related to the properties of the corresponding harmonic maps. In the CP^1 case all harmonic maps (from S^2) are holomorphic (or antiholomorphic) and, as the induced metric is characterized by the holomorphic component of the energy, this characterization is complete. This is also the case for the holomorphic CP^{N-1} maps.

In the CP^{N-1} case (for $N>2$) there are harmonic maps which are not holomorphic[7] and for them the above mentioned construction[6] is not complete, as in the general case we would expect the maps to be characterized by the total energy. Hence a further generalization is called for and such a generalization is provided in this article.

In the next section we briefly review the CP^{N-1} harmonic maps (using the formalism as given in Ref. 7) and in the following sections relate these maps to the various versions of the Weierstrass problem.

II. CP^{N-1} HARMONIC MAPS

A. Formulation

The CP^{N-1} models are, in fact, a generalization of the, perhaps the simplest, sigma model, namely, the S^2 model—also called the vector $O(3)$ model. The CP^{N-1} models involve maps from R^2, or S^2 if a nontrivial topology is required, to CP^{N-1}, i.e.,

a)Electronic mail: grundlan@crm.umontreal.ca
b)Electronic mail: w.j.zakrzewski@durham.ac.uk

$$C \supset \Omega \ni \zeta = \zeta_1 + i\zeta_2 \mapsto z = (z^1, \ldots, z^N) \in C^N, \tag{1}$$

where the homogeneous coordinates $z = (z^1, \ldots, z^N)$ have the following property:

$$z \sim z' = \lambda z \quad \text{for} \quad \lambda \neq 0.$$

Exploiting this projective invariance we can require that

$$z^\dagger \cdot z = 1 \tag{2}$$

holds, where † denotes Hermitian conjugation, and we are still left with the gauge symmetry

$$z \to z' = z e^{i\phi}, \tag{3}$$

where ϕ is a real-valued function.

It is easiest to define the CP^{N-1} models in terms of the Lagrangian density[7]

$$L = \tfrac{1}{4}(D_\mu z)^\dagger \cdot D_\mu z, \quad z^\dagger \cdot z = 1, \tag{4}$$

where the covariant derivatives D_μ act on $z: S^2 \to CP^{N-1}$ according to the formula

$$D_\mu z = \partial_\mu z - (z^\dagger \cdot \partial_\mu z) z. \tag{5}$$

Here the index $\mu = 1,2$ denotes ζ_1 and ζ_2. Note that the covariant derivatives $D_\mu z$ transform under the gauge transformation (3)

$$D_\mu z \to D_\mu z' = (D_\mu z) e^{i\phi}, \tag{6}$$

so that the dependence on the phase ϕ drops out of the Lagrangian density (4) and so the model is really based on CP^{N-1}.

The total Lagrangian is given by

$$\mathcal{L} = \int L \, d\zeta \, d\overline{\zeta} \tag{7}$$

and, if the CP^{N-1} model is defined over S^2, we require that $\mathcal{L}$ is finite.

For the CP^{N-1} sigma model it is convenient to define

$$z = \frac{f}{|f|}, \tag{8}$$

where $|f| = (f^\dagger \cdot f)^{1/2}$. In terms of f the Lagrangian (7) becomes

$$\mathcal{L} = \int \frac{|\overline{\partial} f|^2 + |\partial f|^2}{|f|^4} d\zeta \, d\overline{\zeta}, \tag{9}$$

where $|\partial f|^2 = (\partial f)^\dagger \cdot (\partial f)$ and $|\overline{\partial} f|^2 = (\overline{\partial} f)^\dagger \cdot (\overline{\partial} f)$. The Euler–Lagrange equations for f take the form

$$\left(1 - \frac{f \otimes f^\dagger}{|f|^2}\right)\left[\partial \overline{\partial} f - \partial f \frac{(f^\dagger \cdot \overline{\partial} f)}{|f|^2} - \overline{\partial} f \frac{(f^\dagger \cdot \partial f)}{|f|^2}\right] = 0, \tag{10}$$

where we have introduced the holomorphic and antiholomorphic derivatives

$$\partial = \frac{\partial}{\partial(\zeta_1 + i\zeta_2)} = \frac{\partial}{\partial\zeta}, \quad \overline{\partial} = \frac{\partial}{\partial(\zeta_1 - i\zeta_2)} = \frac{\partial}{\partial\overline{\zeta}}, \tag{11}$$

and bar denotes complex conjugation.

B. Integrability and first conservation laws

As is well known,[8] Eqs. (10) can be written as a compatibility condition for a set of two linear spectral equations for an N-component auxiliary vector Ψ,

$$\begin{aligned} \partial\Psi &= \frac{2}{1+\lambda}[\partial P, P]\,\Psi, \\ \overline{\partial}\Psi &= \frac{2}{1-\lambda}[\overline{\partial} P, P]\,\Psi, \end{aligned} \tag{12}$$

where λ is a spectral parameter and the N by N matrix P is the projector given by

$$P = \frac{1}{|f|^2} f \otimes f^\dagger, \quad P^\dagger = P, \quad P^2 = P. \tag{13}$$

The compatibility conditions for (12) are then

$$[\partial\overline{\partial} P, P] = 0, \tag{14}$$

which, as can be easily checked, are equivalent to Eqs. (10). Note that (14) can be written in the form of a conservation law

$$\partial[\overline{\partial} P, P] + \overline{\partial}[\partial P, P] = 0 \tag{15}$$

or, equivalently, using the tracelessness of the matrix K, as

$$\partial K - \overline{\partial} K^\dagger = 0, \tag{16}$$

where the matrices K and $K^\dagger$ are given by

$$K = [\overline{\partial} P, P] = \frac{\overline{\partial} f \otimes f^\dagger - f \otimes \overline{\partial} f^\dagger}{|f|^2} + \frac{f \otimes f^\dagger}{|f|^4}[(\overline{\partial} f^\dagger \cdot f) - (f^\dagger \cdot \overline{\partial} f)], \qquad \mathrm{Tr}\, K = 0, \tag{17}$$

and consequently

$$K^\dagger = -[\partial P, P] = -\frac{\partial f \otimes f^\dagger - f \otimes \partial f^\dagger}{|f|^2} + \frac{f \otimes f^\dagger}{|f|^4}[(\partial f^\dagger \cdot f) - (f^\dagger \cdot \partial f)].$$

Note that due to the invariance of the Lagrangian (4) under the gauge transformation (3) we can, without any loss of generality, set one of the components of the vector field f, say f_1, to 1. Then, in the CP^1 case, all quantities are expressible through one variable

$$w = \frac{f_2}{f_1} = f_2 \tag{18}$$

and the Euler–Lagrange equations (10) take the form

$$\partial\overline{\partial}w-\frac{2\overline{w}}{(1+|w|^2)}\partial w\overline{\partial}w=0. \tag{19}$$

C. Further conservation laws

Let us note that our matrix K in (17) is given by

$$K=M+L, \tag{20}$$

where

$$M=(1-P)\frac{\overline{\partial}f\otimes f^{\dagger}}{|f|^2} \tag{21}$$

and

$$L=-\frac{f\otimes\overline{\partial}f^{\dagger}}{|f|^2}(1-P). \tag{22}$$

Thus

$$M^{\dagger}=\frac{f\otimes\partial f^{\dagger}}{|f|^2}(1-P),\quad \text{and}\quad L^{\dagger}=-(1-P)\frac{\partial f\otimes f^{\dagger}}{|f|^2}. \tag{23}$$

Next we note that the matrices M and L, separately, satisfy our conservations laws (16). To see this consider

$$\begin{aligned}\partial M-\overline{\partial}M^{\dagger}=&-\partial P\frac{\overline{\partial}f\otimes f^{\dagger}}{|f|^2}+(1-P)\frac{\overline{\partial}\partial f\otimes f^{\dagger}}{|f|^2}+(1-P)\frac{\overline{\partial}f\otimes\partial f^{\dagger}}{|f|^2}-(1-P)\frac{\overline{\partial}f\otimes f^{\dagger}}{|f|^4}\partial|f|^2\\&-\frac{\overline{\partial}f\otimes\partial f^{\dagger}}{|f|^2}(1-P)-\frac{f\otimes\overline{\partial}\partial f^{\dagger}}{|f|^2}(1-P)+\frac{f\otimes\partial f^{\dagger}}{|f|^2}\overline{\partial}P+\frac{f\otimes\partial f^{\dagger}}{|f|^4}(1-P)\overline{\partial}|f|^2.\end{aligned} \tag{24}$$

But

$$\partial P=\frac{\partial f\otimes f^{\dagger}}{|f|^2}+\frac{f\otimes\partial f^{\dagger}}{|f|^2}-\frac{P}{|f|^2}\partial|f|^2 \tag{25}$$

and so we see that all the terms in (24) become

$$\begin{aligned}&(1-P)\left[\partial\overline{\partial}f-\partial f\frac{(f^{\dagger}\cdot\overline{\partial}f)}{|f|^2}-\overline{\partial}f\frac{(f^{\dagger}\cdot\partial f)}{|f|^2}\right]\\&\otimes\frac{f^{\dagger}}{|f|^2}-\frac{f}{|f|^2}\otimes\left[\partial\overline{\partial}f^{\dagger}-\partial f^{\dagger}\frac{(\overline{\partial}f^{\dagger}f)}{|f|^2}-\overline{\partial}f^{\dagger}\frac{(\partial f^{\dagger}\cdot f)}{|f|^2}\right](1-P).\end{aligned} \tag{26}$$

However, due to (10), this is zero. Hence we have two separate conservation laws, namely,

$$\partial M=\overline{\partial}M^{\dagger} \tag{27}$$

and

$$\partial L=\overline{\partial}L^{\dagger}. \tag{28}$$

Next we consider the explicit form of the entries of the matrices M and L. To do this we introduce

$$F_{ij} = f_i \partial f_j - f_j \partial f_i, \tag{29}$$

and

$$G_{ij} = f_i \overline{\partial} f_j - f_j \overline{\partial} f_i. \tag{30}$$

Then, using expressions (29) and (30), we can write the entries of the matrices M and L, equivalently, in the form

$$M_{ij} = \overline{\Phi_i^2} \overline{f_j} \tag{31}$$

and

$$L_{ij} = - f_i \overline{\varphi_j^2}, \tag{32}$$

where we have introduced

$$\varphi_i^2 = \frac{1}{A^2} \overline{f}_k F_{ki}, \quad A = \overline{f_l} f_l \tag{33}$$

and

$$\Phi_i^2 = \frac{1}{A^2} f_k \overline{G_{ki}}, \tag{34}$$

and we have used the convention of implicit summation over repeated indices.

Note that from Eqs. (30), (33), and (34) we have two algebraic constraints, namely,

$$\overline{f_k}\, \varphi_k^2 = 0, \quad f_k \Phi_k^2 = 0, \tag{35}$$

which imply that only $(N-1)$ functions φ_i^2 and $(N-1)$ functions Φ_i^2 are linearly independent. So in our further discussion we take as independent functions $\varphi_2^2, \ldots, \varphi_N^2$ and $\Phi_2^2, \ldots, \Phi_N^2$.

Making use of the symmetry (3) we can set, without any loss of generality, say, $f_1 = 1$, and so we end up with the expressions [for (33), and (34)]

$$\begin{aligned} \varphi_i^2 &= \frac{1}{A^2}[(1 + f_k \overline{f_k})\, \partial f_i - f_i(\overline{f_k}\, \partial f_k)], \\ \overline{\Phi_i^2} &= \frac{1}{A^2}[(1 + f_k \overline{f_k})\, \overline{\partial} f_i - f_i(\overline{f_k}\, \overline{\partial} f_k)], \quad i = 2, \ldots, N, \end{aligned} \tag{36}$$

where

$$A = 1 + |f_2|^2 + \cdots + |f_N|^2.$$

Note that now all the sums over repeated indices run over $k = 2, \ldots, N$.

Next we invert expressions (36) and so express all the derivatives ∂f_i in terms of φ_i^2's and f_i. This way we find that

$$\partial f_i = A\,[\varphi_i^2 + f_i \overline{f}_k \varphi_k^2]. \tag{37}$$

Thus, in particular, for the CP^1 case, Eqs. (37) become

$$\partial f_2 = A^2 \varphi_2^2, \quad A = 1 + |f_2|^2,$$

and f_2 is often denoted by w (see, e.g., Ref. 7), while in the CP^2 case we have

$$\begin{aligned} \partial f_2 &= A[(1+|f_2|^2)\varphi_2^2 + f_2 \overline{f_3}\, \varphi_3^2], \\ \partial f_3 &= A[(1+|f_3|^2)\varphi_3^2 + f_3 \overline{f_2}\, \varphi_2^2], \\ A &= 1 + |f_2|^2 + |f_3|^2. \end{aligned} \tag{38}$$

Note that in Refs. 5 and 6 the functions f_2 and f_3 are denoted by w_1 and w_2, respectively.

Similarly,

$$\overline{\partial} f_i = A\,[\overline{\Phi}_i^2 + f_i\, \overline{f}_k \overline{\Phi}_k^2]. \tag{39}$$

III. THE WEIERSTRASS PROBLEM[1,3]

In the Weierstrass problem we consider two complex functions $\psi = \psi(\zeta, \overline{\zeta})$ and $\phi = \phi(\zeta, \overline{\zeta})$, which satisfy

$$\partial \psi = p\, \phi, \quad \overline{\partial} \phi = -p\, \psi, \quad p = |\phi|^2 + |\psi|^2. \tag{40}$$

Note that we have not specified $\overline{\partial}\psi$, nor $\partial\phi$.

A natural question then arises. Is this problem related to the harmonic maps of the previous sections, presumably corresponding to the case of CP^1?

This is indeed the case as has been discussed in Ref. 4. To see this we put

$$w = \frac{\psi}{\overline{\phi}} \tag{41}$$

and note that

$$\psi = w \frac{(\overline{\partial}\overline{w})^{1/2}}{1+|w|^2}, \quad \phi = \frac{(\partial w)^{1/2}}{1+|w|^2} \tag{42}$$

satisfy (40). In fact, one can show that (19) and (40) are equivalent.

Moreover, we can introduce three real quantities:

$$\begin{aligned} X_1 &= i \int_\gamma [\overline{\psi}^2 + \phi^2] d\zeta - [\psi^2 + \overline{\phi}^2] d\overline{\zeta}, \\ X_2 &= \int_\gamma [\overline{\psi}^2 - \phi^2] d\zeta + [\psi^2 - \overline{\phi}^2] d\overline{\zeta}, \\ X_3 &= -2 \int_\gamma \overline{\psi}\phi d\zeta + \psi \overline{\phi} d\overline{\zeta}, \end{aligned} \tag{43}$$

where γ is any curve from a fixed point to ζ. Then, it is easy to show that if ψ and ϕ satisfy (40), the functions X_i do not depend on the contour of the curve γ but only on its endpoints.

Furthermore, if we treat X_i as components of a vector $\vec{r} = (X_1, X_2, X_3)$ and introduce the metric

$$g_{\zeta\zeta} = (\partial \vec{r}, \partial \vec{r}), \quad g_{\overline{\zeta}\overline{\zeta}} = (\overline{\partial}\vec{r}, \overline{\partial}\vec{r}), \quad g_{\zeta\overline{\zeta}} = (\partial \vec{r}, \overline{\partial}\vec{r}), \tag{44}$$

we find that, for fields which solve (19) on S^2, only $g_{\zeta\bar{\zeta}}$ is nonzero and is given by

$$g_{\zeta\bar{\zeta}} = \frac{|\partial w|^2}{(1+|w|^2)^2} = |Dz|^2, \tag{45}$$

where $D = 1/2(D_1 - iD_2)$, with D_i defined in (5); i.e., is a covariant derivative evaluated with respect to ζ. Note that (45) is a term in the general expression for the energy density of the CP^1 map. However, as all harmonic maps on S^2 satisfy $w = w(\zeta)$,[7] we note that $g_{\zeta\bar{\zeta}}$ is the total energy density of this map. (We are assuming here that we are not dealing with antiholomorphic maps, as in this case we simply interchange the roles of ζ and $\bar{\zeta}$.)

IV. A GENERALIZED WEIERSTRASS REPRESENTATION IN R^M

Having observed that the Weierstrass problem is related to the equations of the CP^1 model, we have in Refs. 5 and 6 presented a CP^{N-1} generalization of the Weierstrass problem. Our generalization was based on the observation that for a generalized Weierstrass system in multi-dimensional spaces we need a set of φ_i and ψ_i which generalize the φ and ψ of the CP^1 case.

Then we noted that the quantities φ_i^2, $i = 2, \ldots, N$, defined in (33), provide such a choice as (37) is a natural CP^{N-1} generalization of (42).

What should we take for the functions ψ_i? In Ref. 6 we argued that (41) suggested that we put

$$\psi_i = f_i \bar{\varphi}_i \tag{46}$$

with no summation over the indices $i = 2, \ldots, N$. Then, to complete the generalization of the Weierstrass system in multi-dimensional spaces, we need relations which would be analogs of (40), i.e., we need to prescribe the first derivatives $\bar{\partial}\varphi_i$ and $\partial\psi_i$ in terms of φ_i and ψ_i.

Note that from (46) we have

$$\partial\psi_i = \partial(f_i \bar{\varphi}_i) = \partial f_i \bar{\varphi}_i + f_i \overline{(\bar{\partial}\varphi_i)}. \tag{47}$$

So, we are left to specify $\bar{\partial}\varphi_i$ in terms of φ_i, f_i and their derivatives. To do this, in Ref. 1, we noted that from (36) we had

$$\bar{\partial}\varphi_i^2 = 2\frac{f_i(\bar{f}_l \partial f_l)}{A^3}(\bar{f}_k \bar{\partial} f_k + f_k \overline{\partial f_k}) + \frac{1}{A^2}[(1+|f|^2)\partial\bar{\partial} f_i - (\bar{f}_k \bar{\partial} f_k)\partial f_i - (f_k \overline{\partial f_k})\partial f_i - \bar{\partial} f_i(\bar{f}_k \partial f_k) - f_i(\overline{\partial f_k}\partial f_k) - f_i(\bar{f}_k\, \partial\bar{\partial} f_k)]. \tag{48}$$

However, Eq. (10) allowed us to eliminate the second derivatives $\partial\bar{\partial} f_i$ from (48) and also we noted that all the terms involving first derivatives $\bar{\partial} f$ and $\partial \bar{f}$ in (48) canceled. Thus we ended up with a simple expression

$$\bar{\partial}\varphi_i = -\frac{\varphi_i}{2A}(f_k \overline{\partial f_k}) - \frac{f_i}{2\varphi_i A^2}(\overline{\partial f_k}\partial f_k) + \frac{f_i}{2\varphi_i A^3}(\overline{\partial f_k} f_k)(\bar{f}_l \partial f_l). \tag{49}$$

Next, taking the complex conjugate of (37),

$$\overline{\partial f_k} = A[\bar{\varphi}_k^2 + \bar{f}_k f_l \bar{\varphi}_l^2], \tag{50}$$

and using (50) we have found

$$\overline{\partial}\varphi_i = -\frac{1}{2}\left\{A\varphi_i(\overline{\varphi}\cdot\psi) + \frac{\psi_i}{\varphi_i\overline{\varphi}_i}[(\overline{\varphi}^2\cdot\varphi^2) + (\overline{\varphi}\cdot\psi)(\overline{\psi}\cdot\varphi)]\right\} \tag{51}$$

(no summation over i). The second pair of equations for ψ_i then followed from (47), i.e.,

$$\partial\psi_i = A\overline{\varphi}_i\varphi_i^2 + \frac{1}{2}A\psi_i(\overline{\psi}\cdot\varphi) - \frac{1}{2}\frac{|\psi_i|^2}{|\varphi_i|^2\overline{\varphi}_i}[(\overline{\varphi}^2\cdot\varphi^2) + (\overline{\varphi}\cdot\psi)(\overline{\psi}\cdot\varphi)] \tag{52}$$

(no summation over i).

Thus, in Ref. 6 we proposed the following form of the generalized Weierstrass system: The **generalized Weierstrass system** in multi-dimensional space is a set of $(2N-2)$ complex functions φ_i and ψ_i, $i=2,\ldots,N$, which obey the following system of equations (no summation over i):

$$\overline{\partial}\varphi_i = -\frac{1}{2}\left\{A\varphi_i(\overline{\varphi}\cdot\psi) + \frac{\psi_i}{\varphi_i\overline{\varphi}_i}[(\overline{\varphi}^2\cdot\varphi^2) + (\overline{\varphi}\cdot\psi)(\overline{\psi}\cdot\varphi)]\right\}$$

and

$$\partial\psi_i = A\overline{\varphi}_i\varphi_i^2 + \frac{1}{2}A\psi_i(\overline{\psi}\cdot\varphi) - \frac{1}{2}\frac{|\psi_i|^2}{|\varphi_i|^2\overline{\varphi}_i}[(\overline{\varphi}^2\cdot\varphi^2) + (\overline{\varphi}\cdot\psi)(\overline{\psi}\cdot\varphi)], \tag{53}$$

where

$$A = 1 + \sum_{k=2}^{N}\frac{|\psi_k|^2}{|\varphi_k|^2}.$$

From our construction it is clear that the above system of equations is equivalent to the equations of the CP^{N-1} sigma model (10). Moreover, it is easy to check that the system of equations (53) reduces to Eq. (19) when $N=2$.

V. A MODIFIED GENERALIZED WEIERSTRASS REPRESENTATION

The generalized Weierstrass representation given in the previous section leads to pairs of functions φ_i, ψ_i, $i=2,\ldots,N$, and, as discussed in Ref. 6, to a geometric interpretation in terms of surfaces in R^M for which their metric is given by $|Dz|^2$ [as in the CP^1 case—see (45)]. This is the case for the holomorphic solutions but we know[7] that CP^{N-1} models have harmonic maps which are not holomorphic (even CP^1 has such maps; in this case, antiholomorphic maps, but these can be considered to be complex conjugates of holomorphic ones). But for CP^{N-1}, $N>2$, we have also maps which are neither holomorphic nor antiholomorphic. So can we generalize the Weierstrass problem differently to bring out this property?

In fact, our discussion of the CP^{N-1} models does tell us what to do. We should use both φ_i and Φ_i. Thus we should consider a larger problem and use Φ_i, φ_i, and f_i.

Then taking (36) and repeating the steps as in (48) (and using φ^2 and Φ^2) we get

$$\overline{\partial}\varphi_i^2 = -A\varphi_i^2(\varphi^{\dagger 2}\cdot f) - f_i[(\varphi^{\dagger 2}\cdot\varphi^2) + (f^\dagger\cdot\varphi^2)(\varphi^{2\dagger}\cdot f)], \tag{54}$$

$$\overline{\partial}\Phi_i^2 = -A\Phi_i^2(f^\dagger\cdot\overline{\Phi}^2) - \overline{f}_i[(\Phi^{\dagger 2}\cdot\Phi^2) + (f^\dagger\cdot\overline{\Phi}^2)(\overline{\Phi}^{\dagger 2}\cdot f)]. \tag{55}$$

These equations should then be supplemented with the expressions for ∂f and $\partial\overline{f}$. The latter are given by (37) and (39) and so take the form

$$\partial f_i = A\,[\varphi_i^2 + f_i\,\overline{f}_k\varphi_k^2],$$
$$\overline{\partial} f_i = A\,[\overline{\Phi}_i^2 + f_i\,\overline{f}_k\overline{\Phi}_k^2], \tag{56}$$

where, as usual, $A=1+(f^\dagger\cdot f)$ and all indices, and summations, go over $(2,\ldots,N)$.

These four sets of equations (54)–(56), for three sets of complex functions, f_i, φ_j and Φ_k, constitute our **modified generalized Weierstrass problem**.

Let us make a few comments.

(i) The equations fall into two sets (those involving ∂f_i and φ_j and those involving $\partial\overline{f_i}$ and Φ_j). Both sets are equivalent to the same equations for f_i, namely, (10).

(ii) Instead of taking f_i we could introduce, in analogy with (46), new functions ψ_i and Ψ_i by, say, $\psi_i=f_i\overline{\varphi_i}$ and $\Psi_i=f_i\overline{\Phi}_i$. Then our set of functions would effectively decouple.

(iii) One can consider what happens when f_i are holomorphic; i.e., $\overline{\partial} f_i=0$. Then, as is easy to check, $f^\dagger\cdot\overline{\Phi}^2=0$, which in turn shows that $|\Phi^2|^2=0$, thus demonstrating that $\Phi_i^2=0$, and we are left with (54) and (56) for f_i, φ_j, i.e., with the previous system (53).

VI. GEOMETRICAL ASPECTS

Next we consider some geometrical aspects of our procedure. This requires the introduction of a real vector $X_i\in R^M$ which is a generalization of the vector (43) constructed for CP^1. In Ref. 6 we have introduced such a vector and showed that its properties generalize those of (43).

However, our approach here generalizes the discussion in Ref. 6 and elucidates some of the points made there. Namely, in our new construction we exploit the matrices M and L. We introduce two matrices

$$V=\int_\gamma M\,d\overline{\zeta}+\int_\gamma M^\dagger\,d\zeta \tag{57}$$

and

$$W=\int_\gamma L\,d\overline{\zeta}+\int_\gamma L^\dagger\,d\zeta, \tag{58}$$

and for the components of our vectors we take individual entries of each matrix. As $\mathrm{Tr}\,M=\mathrm{Tr}\,L=0$ we see that V and W have, each, only N^2-1 independent entries so our construction gives us two vectors in R^{N^2-1}.

Notice also that W and V do not depend on the contour of integration γ. This follows from the fact that for an integral

$$Z=\int_\Gamma F(\zeta,\overline{\zeta})\,d\zeta+\overline{F}(\zeta,\overline{\zeta})\,d\overline{\zeta}$$

to be independent of the integration contour Γ the condition is that F and $\overline{F}$ must satisfy

$$\overline{\partial}F=\partial\overline{F},$$

which is the case for V and W due to, respectively, our conservation laws (27) and (28).

Of course we can reexpress our vectors V and W in terms of the Weierstrass functions φ_i, Φ_j and f_k or in terms of φ_i, ψ_j, Φ_k, and Ψ_l.

Note that in the CP^1 case the matrix W is given by

$$W = -\frac{1}{(1+|w|^2)^2}\begin{pmatrix} w\overline{\partial w} & -\overline{\partial w} \\ w^2\overline{\partial w} & -w\overline{\partial w}\end{pmatrix}, \tag{59}$$

and so, given (42), we see that the integrands of the first terms in X_i of (43) have the form

$$x_1 = -i[\overline{L}_{21} - \overline{L}_{12}], \quad x_2 = -[\overline{L}_{21} + \overline{L}_{12}], \quad x_3 = -\overline{L}_{11} = \overline{L}_{22}. \tag{60}$$

So should we consider a new $2(N^2-1)$ vector, the first half of whose components are various entries of the matrix W, and the second half those of V? In the CP^1 case, as shown in Ref. 5, we can restrict ourselves to a vector with only three components. So we add both contributions and consider an N^2-1 component vector given by all the entries (except the top left hand corner one) of the matrix

$$X = \int_\gamma (M+L)\, d\overline{\zeta} + \int_\gamma (M^\dagger + L^\dagger)\, d\zeta. \tag{61}$$

Next we calculate the components of the induced metric

$$g_{\alpha\beta} = \sum_{lk} \frac{\partial X_{kl}}{\partial \alpha}\frac{\partial X_{lk}}{\partial \beta}, \tag{62}$$

where α and β are ζ or $\overline{\zeta}$. But

$$\frac{\partial X}{\partial \overline{\zeta}} = (M + L), \quad \frac{\partial X}{\partial \zeta} = (M^\dagger + L^\dagger), \tag{63}$$

where we are still using the matrix formulation. Hence

$$g_{\overline{\zeta}\overline{\zeta}} = \mathrm{Tr}\,(M+L)^2, \quad g_{\zeta\zeta} = \mathrm{Tr}\,(M^\dagger + L^\dagger)^2, \quad g_{\zeta\overline{\zeta}} = \mathrm{Tr}\,[(M+L)(M^\dagger + L^\dagger)]. \tag{64}$$

However, given the form of M in (21) and L in (22), we see that

$$\mathrm{Tr}\,M^2 = \mathrm{Tr}\,L^2 = \mathrm{Tr}\,(M^\dagger)^2 = \mathrm{Tr}\,(L^\dagger) = \mathrm{Tr}\,L^\dagger M = \mathrm{Tr}\,M^\dagger L = 0, \tag{65}$$

and so we are left with

$$g_{\overline{\zeta}\overline{\zeta}} = 2\,\mathrm{Tr}\,(ML), \quad g_{\zeta\zeta} = 2\,\mathrm{Tr}\,(M^\dagger L^\dagger), \quad g_{\zeta\overline{\zeta}} = \mathrm{Tr}\,[MM^\dagger + LL^\dagger]. \tag{66}$$

Next we observe that

$$\mathrm{Tr}\,MM^\dagger = \mathrm{Tr}\,(1-P)\frac{\overline{\partial f}\otimes f^\dagger}{|f|^2}\frac{f\otimes \partial f^\dagger}{|f|^2} = \frac{\partial f^\dagger \cdot \overline{\partial f}}{|f|^4} - \frac{(\partial f^\dagger \cdot f)(f^\dagger \cdot \overline{\partial f})}{|f|^6} = |Dz|^2, \tag{67}$$

where, as in (45), D denotes the covariant derivative evaluated with respect to ζ. Similarly,

$$\mathrm{Tr}\,LL^\dagger = |\overline{D}z|^2, \tag{68}$$

where $\overline{D}$ is again the covariant derivative but this time evaluated with respect to $\overline{\zeta}$.

Note that, together, the two terms in $g_{\zeta\overline{\zeta}}$ give the total energy density of the map (i.e., $|Dz|^2 + |\overline{D}z|^2$).

What about $g_{\zeta\zeta}$ and $g_{\overline{\zeta}\overline{\zeta}}$? They are given by

$$g_{\bar{\zeta}\bar{\zeta}} = -\operatorname{Tr}(1-P)\frac{\bar{\partial}f\otimes f^{\dagger}\cdot f\otimes\bar{\partial}f^{\dagger}}{|f|^4} = -\operatorname{Tr}(1-P)\frac{\bar{\partial}f\otimes\bar{\partial}f^{\dagger}}{|f|^2}, \tag{69}$$

$$g_{\zeta\zeta} = -\operatorname{Tr}(1-P)\frac{\partial f\otimes f^{\dagger}\cdot f\otimes\partial f^{\dagger}}{|f|^4} = -\operatorname{Tr}(1-P)\frac{\partial f\otimes\partial f^{\dagger}}{|f|^2}, \tag{70}$$

and, at first sight, they appear to be nonvanishing. However, they do, in fact, vanish on the solutions of the CP^{N-1} model, i.e., on the vectors f which satisfy (10), at least those that are defined on S^2. To see this we note that

$$g_{\bar{\zeta}\bar{\zeta}} = \frac{-|f|^2(\bar{\partial}f^{\dagger}\cdot\bar{\partial}f) + (\bar{\partial}f^{\dagger}\cdot f)(f^{\dagger}\cdot\bar{\partial}f)}{|f|^2} \tag{71}$$

and $g_{\zeta\zeta}$ is its complex conjugate.

However, all solutions of (10) defined on S^2 are[7] of the type

$$f = P_+^k g, \tag{72}$$

where g is a holomorphic vector, i.e., $g\neq g(\bar{\zeta})$, and k is some integer taken from the set $\{0,1,\ldots,N-1\}$, and $P_+^l g$ is defined by the successive, i.e., $P_+^l g = P_+(P_+^{l-1}g)$, repetition of the operation

$$P_+ h = \partial h - h\frac{(h^{\dagger}\cdot\partial h)}{|h|^2}. \tag{73}$$

Then, as is known,[7] $P_+^k g$ satisfy

$$(P_+^l g)^{\dagger}\cdot P_+^k g = 0 \quad \text{if} \quad k\neq l, \tag{74}$$

$$\partial P_+^k g = P_+^{k+1}g + P_+^k g\frac{(P_+^k g^{\dagger}\cdot\partial P_+^k g)}{|P_+^k g|^2}, \tag{75}$$

$$\bar{\partial}P_+^k g = -P_+^{k-1}g\frac{|P_+^k g|^2}{|P_+^{k-1}g|^2}. \tag{76}$$

Thus $(\bar{\partial}f^{\dagger}\cdot\bar{\partial}f)=0$ and $(f^{\dagger}\cdot\bar{\partial}f)=0$ and so we see that $g_{\zeta\zeta}=0$ (and so also $g_{\bar{\zeta}\bar{\zeta}}=0$).

VII. THE CP^1 CASE REVISITED

In the CP^1 case it is convenient to calculate its energy momentum tensor

$$T_{\mu\nu} = (D_\mu z)^{\dagger}\cdot D_\nu z + (D_\nu z)^{\dagger}\cdot D_\mu z - \delta_{\mu\nu}|D_\alpha|^2. \tag{77}$$

Then, as is known[7]

$$\bar{\partial}(T_{11} + iT_{12}) = 0 \tag{78}$$

and in the CP^1 case

$$J = T_{11} + iT_{12} = \frac{\partial w\,\bar{\partial}w}{[1+|w|^2]^2}. \tag{79}$$

When the CP^1 model is defined on S^2 we find that $J=0$, which shows that all the harmonic CP^1 maps on S^2 are either holomorphic or antiholomorphic,[7] but for the CP^1 model on R^2, or for CP^{N-1}, $N>2$, J does not have to vanish.

In the CP^1 model case we have (59),

$$W=-\frac{1}{(1+|w|^2)^2}\begin{pmatrix} w\overline{\partial w} & -\overline{\partial w} \\ w^2\overline{\partial w} & -w\overline{\partial w}\end{pmatrix} \tag{80}$$

and

$$V=\frac{\overline{\partial w}}{(1+|w|^2)^2}\begin{pmatrix} -\bar{w} & -\bar{w}^2 \\ 1 & \bar{w}\end{pmatrix}. \tag{81}$$

This allows us to express $\overline{\partial w}$ in terms of $\overline{\partial \bar{w}}$, J and p given by (40). We find

$$\overline{\partial w}=\frac{J(1+|w|^2)^2}{\partial w}=J\,\overline{\partial \bar{w}}\frac{(1+|w|^2)^2}{|\partial w|^2}. \tag{82}$$

However, using (42), we see that

$$p^2=\frac{|\partial w|^2}{(1+|w|^2)^2} \tag{83}$$

and so we have

$$\overline{\partial w}=\overline{\partial \bar{w}}\frac{J}{p^2}. \tag{84}$$

This allows us to combine the two vectors V and W into

$$V+W=\frac{\overline{\partial \bar{w}}}{(1+|w|^2)^2}\begin{pmatrix} -w-R\bar{w} & 1-R\bar{w}^2 \\ R-w^2 & w+R\bar{w}\end{pmatrix}, \tag{85}$$

where $R=J/p^2$.

This explains the origin of the expressions for the components of X_i given in Ref. 4. However, it is clear that this possibility to gather both terms into one expression does not generalize to higher CP^{N-1} models.

VIII. SUMMARY AND CONCLUDING REMARKS

The main aim of this article has been to derive a generalization of the Weierstrass system to the CP^{N-1} case for which the metric of the induced surfaces is determined by the energy density of the corresponding harmonic map.

This has led us to introduce a set of $3N$ complex functions φ_i, Φ_j and f_k which are required to satisfy a system of four classes of first order equations and which are equivalent to the full system of equations of the CP^{N-1} model.

We have also introduced a set of (N^2-1) real quantities X_i, which can be treated as coordinates of a surface immersed in R^{N^2-1} and we have shown that the induced metric of our map is given by

$$ds^2=(|Dz|^2+|\overline{Dz}|^2)\,d\zeta\,d\bar{\zeta}. \tag{86}$$

The study of the generalized Weierstrass representations for surfaces immersed in multidimensional spaces was initiated by Konopelchenko and Landolfi.[3] Our work here, in which we have adopted an alternative approach based on the CP^{N-1} sigma models, provides a generalization of their results.

(Received 10 December 2002; accepted 9 April 2003)

We apply techniques of Painlevé–Kowalewski analysis to certain ODE reductions of the Ricci-flat equations. We particularly focus on two examples when the hypersurface is an Aloff–Wallach space or a circle bundle over a Fano product. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1584207]

I. INTRODUCTION

The difficulty of the Einstein system of partial differential equations has made it natural to consider reductions of this system to ordinary differential equations (ODEs). One way of performing this reduction is to require the Einstein metrics to be of cohomogeneity one, that is, to be invariant under the action of a group with principal orbits of codimension one. In Dancer and Wang (2003b) we studied the cohomogeneity-one Ricci-flat equations in the situation when the isotropy representation of the principal orbit consists of pairwise inequivalent summands. We showed how to choose variables so that the equations became a constrained flow of an ODE system with quadratic nonlinearities.

In Dancer and Wang (2002) we proved some general results about the Painlevé–Kowalewski analysis of this system. This involves looking for solutions of the equations given by *Painlevé expansions*, i.e., meromorphic expansions in (a rational power of) the independent variable. The general philosophy of this method is that the existence of large families of Painlevé expansions should be associated with ''nice'' properties of the equations. In particular, if for each dependent variable in the equations there is a corresponding family of Painlevé expansions which depends on the full number of parameters and in which that dependent variable actually blows up, then this is regarded as a strong indication that the equations are ''integrable.'' A good summary of the modern treatment of Painlevé–Kowalewski analysis may be found in Ablowitz *et al.* (1980) and Adler and van Moerbeke (1982).

This general theory was applied to some examples in Dancer and Wang (2001, 2002, 2003b). Two features were particularly noteworthy.

(i) The existence of Painlevé expansions is often associated with the existence of a solution to a Diophantine problem (in many cases, the existence of an integral point on an elliptic curve). This may single out certain dimensions as special.
(ii) When Painlevé expansions do exist, they sometimes represent metrics of exceptional holonomy.

In this article we shall analyze some further examples, including one which has recently become relevant in string theory (Cvetič *et al.*, 2002a; Gukov and Sparks, 2002; Kanno and Yasui,

a)Electronic mail: dancer@maths.ox.ac.uk
b)Electronic mail: wang@mcmail.mcmaster.ca

2002). This is the example when the principal orbit is an Aloff–Wallach space SU(3)/U(1). Such spaces depend on two integer parameters, leading to Diophantine questions during the Painlevé analysis. Moreover, the Ricci-flat equations have a subsystem whose solutions represent metrics of Spin(7) holonomy. We find that this Spin(7) subsystem has a family of Painlevé expansions depending on the full number of parameters and representing asymptotically locally conical (ALC) metrics (cf. Theorem 4.5 and Remark 4.6). By contrast, large Painlevé families representing asymptotically conical (AC) metrics are very rare, and their existence imposes strong Diophantine constraints on the Aloff–Wallach space (cf Theorem 4.8).

We also consider the case when the hypersurface belongs to a certain class of circle bundles over a product of two Fano manifolds admitting Kähler–Einstein metrics. These circle bundles are classified by two integers, which, together with the dimensions and first Chern classes of the factors in the base, lead also to Diophantine questions during the Painlevé analysis. As a result, dimension 12 is singled out when considering ALC Ricci-flat metrics. Furthermore, the circle bundles which admit Sasakian–Einstein metrics (up to orientation changes) appear to be singled out in the case of AC Ricci-flat metrics. For this class of bundles, the Ricci-flat equations have a subsystem whose solutions represent Calabi–Yau metrics and can be written down by quadratures.

In order to make this article as self-contained as possible, we include a review of the results of Dancer and Wang (2002, 2003b) on the general cohomogeneity one Ricci-flat system and its Painlevé analysis.

II. THE EQUATIONS

In this section we briefly review the formulation in Dancer and Wang (2003b) of the cohomogeneity one Ricci-flat equations [see also Bérard and Bergery (1982), Dancer and Wang (2000), and Eschenburg and Wang (2000) for background on these equations].

Consider a Riemannian manifold $(\mathcal{M},g)$ with a cohomogeneity one isometric action of a compact Lie group G, whose principal orbit is G/K. We denote by

$$\mathfrak{p}=\mathfrak{p}_1\oplus\cdots\oplus\mathfrak{p}_r$$

the decomposition of the isotropy representation $\mathfrak{p}\approx T_{(K)}(G/K)$ of G/K into irreducible K-representations. We let d_i be the real dimension of $\mathfrak{p}_i$, and let $n=\Sigma_{i=1}^r d_i$ denote the dimension of G/K (so $\dim\mathcal{M}=n+1$). We use d for the vector of dimensions $(d_1,\ldots,d_r)$.

We shall assume that the isotropy representation is *monotypic*, that is, all the $\mathfrak{p}_i$ are distinct as representations of K. In particular if there is a trivial summand it must be one-dimensional. The metric g may now be written as

$$dt^2+g_t, \tag{1}$$

where

$$g_t=e^{q_1(t)}B|_{\mathfrak{p}_1}\perp\cdots\perp e^{q_r(t)}B|_{\mathfrak{p}_r} \tag{2}$$

is a one-parameter family of G-invariant metrics on G/K, B is a fixed background metric on G/K induced from some biinvariant metric on G, and t is a parameter along a geodesic which intersects all principal orbits orthogonally. Note that the factor $\exp(\frac{1}{2}d\cdot q)$ is the ratio of the volume of g_t to that of B.

The scalar curvature of $(G/K,g_t)$ is given by $\mathsf{S}=\Sigma_{w\in\mathcal{W}}A_w e^{w\cdot q}$, where A_w are (nonzero) constants and $\mathcal{W}$ is a finite collection of vectors $w\in\mathbb{Z}^r$ (which depend only on G/K and which we refer to as *weight vectors*).

We shall also assume that the elements of $\mathcal{W}$ span $\mathbb{R}^r$, which is the case when G is semisimple (Dancer and Wang, 2000). We define a non-negative integer ℓ by $r+\ell=|\mathcal{W}|$, and order the weight vectors as $w^{(k)}$ $(1\leqslant k\leqslant r+\ell)$, where $w^{(i+r)}=\Sigma_{j=1}^r \nu_{ij}w^{(j)}(1\leqslant i\leqslant\ell)$, for some constants ν_{ij}.

Note that by the homogeneity properties of the scalar curvature, $w^{(k)}\cdot(1,\ldots,1)=-1$ for all k, so we can deduce that $\Sigma_{j=1}^{r}\nu_{ij}=1$ for all i. We shall refer to the constant $A_{w^{(k)}}$ just as A_k in future.

As explained in Dancer and Wang (2003b), the Ricci-flat equations for g may be viewed as the flow for a Hamiltonian $\bar{H}$ together with the constraint $\bar{H}=0$. The potential term is the scalar curvature S of G/K times the square of the volume distortion factor $\exp(\frac{1}{2}d\cdot q)$. The kinetic energy is given by the signature $(1,r-1)$ quadratic form

$$J(p)=\frac{1}{n-1}\left(\sum_{i=1}^{r}p_i\right)^2-\sum_{i=1}^{r}\frac{p_i^2}{d_i}. \tag{3}$$

In Dancer and Wang (2003b) we showed how to rewrite the Ricci-flat equations as a quadratic system, using ideas from Adler and van Moerbeke (1982). We first define an $(r+\ell)\times r$ matrix $\hat{U}$ by

$$\hat{U}_{ij}=d_j+w_j^{(i)}.$$

Consider the matrix $\Phi:=\hat{U}J\hat{U}^t$, where we have also denoted by J the matrix of the quadratic form given in (3). Now we can choose an $(r+\ell)\times r$ matrix Q satisfying $QDQ^t=\Phi$, where $D=\mathrm{diag}(\epsilon_1,\ldots,\epsilon_r)$ and $\epsilon_1=1$, $\epsilon_i=-1\quad(i>1)$. We may also arrange that Q is of the form

$$\begin{pmatrix} Q_1 \\ \nu Q_1 \end{pmatrix} \tag{4}$$

for some invertible $r\times r$ matrix Q_1.

The Ricci-flat equations for g are now equivalent, after suitable change of dependent and independent variables, to the system

$$z_i'=2z_i\sum_{j=1}^{r}Q_{ij}v_j \qquad (1\leqslant i\leqslant r+\ell), \tag{5}$$

$$v_i'=\epsilon_i\sum_{j=1}^{r+\ell}Q_{ji}z_j \qquad (1\leqslant i\leqslant r), \tag{6}$$

together with the constraints

$$\frac{z_{r+j}}{A_{r+j}}=\prod_{i=1}^{r}\left(\frac{z_i}{A_i}\right)^{\nu_{ji}} \qquad (1\leqslant j\leqslant \ell), \tag{7}$$

and the Hamiltonian constraint

$$\bar{H}\equiv v_1^2-v_2^2-\cdots-v_r^2-\sum_{j=1}^{r+\ell}z_j=0. \tag{8}$$

Remark 2.1: (i) The quantities $z_{r+j}\Pi_{i=1}^{r}z_i^{-\nu_{ji}}$, as well as $\bar{H}$, are conserved by the flow. As discussed in Dancer and Wang (2003b), Eqs. (5) and (6) may be viewed as a Poisson Hamiltonian flow, and the constraints (7) define restriction of this flow to a symplectic leaf. The Ricci-flat equations are then the Hamiltonian flow on this leaf subject to the Hamiltonian constraint (8).

(ii) Note that the choice of Q above is not unique. Indeed, replacing Q by $-Q$ and v_j by $-v_j$ will leave the above system invariant.

(iii) For quadratic systems such as (5) and (6) a general majorization argument shows that formal Painlevé expansions about 0 are convergent in a deleted neighborhood of 0.

III. PAINLEVÉ EXPANSIONS

A. Leading terms

We now review the Painlevé analysis (Dancer and Wang, 2002) of Eqs. (5) and (6). We first look for possible leading terms of the Painlevé expansions of solutions to these equations. Put

$$z_i = \alpha_0^{(i)} s^{m_i} + \cdots, \qquad v_i = \beta_0^{(i)} s^{n_i} + \cdots, \tag{9}$$

where $\alpha_0^{(i)}, \beta_0^{(i)} \neq 0$.

It is straightforward to show that $n_i \geqslant -1$; we shall assume for the moment (see Remark 3.2) that all $m_i \geqslant -2$. Let $S \subset \{1,\ldots,r+\ell\}$ denote the set of indices for which $m_i = -2$ and $T \subset \{1,\ldots,r\}$ denote the set of indices for which $n_i = -1$. It is convenient to introduce an $(r+\ell)\times r$ matrix P defined by

$$P_{ij} = \begin{cases} Q_{ij} & \text{if } i \in S, \\ 0 & \text{if } i \notin S. \end{cases}$$

In Dancer and Wang (2002) we derived the equation

$$m_i = -2\sum_{j\in S} (QDQ^t)_{ij} \quad \alpha_0^{(j)} = -2\sum_{j\in S} (\hat{U}J\hat{U}^t)_{ij} \quad \alpha_0^{(j)} = -2(\Phi^S \hat{\alpha}_0)^{(i)},$$

where Φ^S denotes the $(r+\ell)\times|S|$ matrix obtained by deleting the jth column of $\Phi = \hat{U}J\hat{U}^t$ iff $j \notin S$, and $\hat{\alpha}_0$ denotes the $|S|\times 1$ vector $(\alpha_0^{(i)})_{i\in S}$. Therefore we need

$$(\Phi^S \hat{\alpha}_0)^{(i)} = 1 \quad (i \in S), \tag{10}$$

$$(\Phi^S \hat{\alpha}_0)^{(i)} < 1 \quad (i \notin S). \tag{11}$$

This gives us an algorithm to find the possibilities for S, α_0 and β_0. For each subset S of $\{1,\ldots,r+\ell\}$, we solve (10) for $\hat{\alpha}_0$ and then check if (11) is satisfied. (If $|S| < r+\ell$, then the components $\alpha_0^{(i)}$ with $i \notin S$ will be free.)

Remark 3.1: We showed in Dancer and Wang (2002) that

$$j \in S \quad \text{whenever} \quad w^{(j)} \in \text{Span}\{w^{(i)} \ : \ i \in S\}. \tag{12}$$

This observation drastically reduces the number of sets S to which we have to apply the algorithm.

Remark 3.2: If there are some indices i for which $m_i < -2$, we let $\tilde{S}$ denote the subset of such indices corresponding to the minimal leading power m_i. Remark 3.1 still applies to $\tilde{S}$ and immediately puts some restrictions on $\tilde{S}$.

Now (6) implies that $\Sigma_{j\in\tilde{S}} Q_{ji}\alpha_0^{(j)} = 0$ for $i = 1,\ldots,r$. These r equations are supplemented by the ℓ equations on α_0 coming from the constraints (7). Usually these equations force some or all of the $\alpha_0^{(i)}$ to be zero, giving a contradiction. This is the case in the examples we deal with in this article.

Convergent Painlevé expansions for Eqs. (5)–(8) give local solutions of the cohomogeneity one Ricci-flat equations. In Dancer and Wang (2002) we derived from the leading term behavior (as s tends to 0) of an expansion the behavior of the corresponding Ricci-flat metric.

Theorem 3.3: (Dancer and Wang, 2002) *Let U denote the $r\times r$ matrix consisting of the first r rows of $\hat{U}$. Let ξ be the vector $-dU^{-1}$ and U^{ij} denote the components of U^{-1}. Then $1 - \frac{1}{2}\Sigma_i m_i \xi_i$ is nonzero. Moreover, letting $f_i(t)^2 = e^{q_i(t)}$ in (2), we have the following.*

(I) If $1 - \frac{1}{2}\Sigma_{i=1}^r m_i\xi_i < 0$, then as $s \to 0^+$, we must have $t \to +\infty$ (possibly after changing the sign of t). Asymptotically, we have

$$f_i(t)^2 \sim c_i\, t^{\Sigma_j U^{ij} m_j / (1 - (1/2)\,\Sigma_j m_j \xi_j)}.$$

(II) if $1-\frac{1}{2}\Sigma_{i=1}^{r} m_i\xi_i>0$, *then as* $s\to 0^+$, t *decreases to a finite limit* t^*, *and asymptotically we have*

$$f_i(t)^2 \sim c_i(t-t^*)^{\Sigma_j U^{ij} m_j/(1-(1/2)\,\Sigma_j m_j\xi_j)}.$$

In both (I) and (II), the c_i *are constants which can be explicitly computed in terms of* U^{-1}, m, ξ, α_0 *and the* A_i.

Remark 3.4: Painlevé expansions of type (I) give metrics with a complete end. Two special cases are particularly important in examples.

(a) *AC asymptotics:* If $S=\{1,\ldots,r+\ell\}$ and $T=\{1,\ldots,r\}$, that is, all m_i equal -2 and all n_i equal -1, the leading terms are themselves an exact solution of the equations, corresponding to the Ricci-flat cone over a homogeneous Einstein metric on G/K.
Painlevé expansions with such leading terms will correspond to metrics *asymptotic* to the cone [AC in the terminology of Cvetič *et al.* (2002a)].

(b) *ALC asymptotics:* If we are in case (I) and $\mathfrak{p}_i$ is a *trivial* summand such that $\Sigma_j U^{ij} m_j=0$, then the principal orbits in the Ricci-flat end will be asymptotic to a circle bundle over G/K' with isometric fibers, where K' has Lie algebra $\mathfrak{k}\oplus\mathfrak{p}_i$. An important special case is when the $f_j(t)^2$ for $j\neq i$ grow like t^2. Locally (in t) the metric is now asymptotically that of a circle bundle with isometric fibres over a cone on G/K'. In Cvetič *et al.* (2002a) the terminology *asymptotically locally conical* (or ALC) was introduced to describe such end behavior. The circle is often referred to as the M-theory circle, due to the physical implications discussed, for example, in Brandhuber *et al.* (2001) and Cvetič *et al.* (2002a, b).

B. Resonances

Next one must extend the leading terms of the previous section to full series solutions to Eqs. (5) and (6), in (possibly fractional) powers of s. We write

$$z_i=\sum_{j=0}^{\infty} \alpha_j^{(i)} s^{m_i+(j/N)}, \qquad v_i=\sum_{j=0}^{\infty} \beta_j^{(i)} s^{n_i+(j/N)}, \tag{13}$$

where N is an integer to be determined after all the resonances have been computed.

Equations (5) and (6) will now yield recursion relations involving the α_j,β_j. Schematically, the recursion may be written as

$$\mathcal{T}_j(\alpha_j,\beta_j)=\text{expression} \quad \text{in} \quad \alpha_k,\beta_k \qquad (k<j),$$

where $\mathcal{T}_j$ is a linear operator. The *resonances* of the expansion are the values of j/N for which $\mathcal{T}_j$ is noninvertible; that is, they give the stages in the recursion at which free parameters may enter.

We shall now summarize the calculation of the resonances in Dancer and Wang (2002). The recursion relations are (for $j>0$)

$$\frac{j}{N}\ \alpha_j^{(i)}-2\ \mathrm{diag}(\alpha_0^{(1)},\ldots,\alpha_0^{(r+\ell)})\ Q\widehat{\beta}_j=X_j, \tag{14}$$

$$\left(\frac{j}{N}-1\right)\beta_j^{(p)}-(DP^t\alpha_j)^{(p)}=Y_j^{(p)} \quad (p\in T), \tag{15}$$

$$\left(n_p+\frac{j}{N}\right)\beta_j^{(p)}=\epsilon_p\sum_{i=1}^{r+\ell} Q_{ip}\ \ \alpha_{j-N(m_i-n_p+1)}^{(i)} \quad (p\notin T), \tag{16}$$

where

$$\hat{\beta}_j^{(p)} = \begin{cases} \beta_j^{(p)} & (p \in T), \\ 0 & (p \notin T), \end{cases}$$

$$X_j^{(i)} = \sum_{p \in T} \sum_{k=1}^{j-1} 2Q_{ip}\ \alpha_k^{(i)} \beta_{j-k}^{(p)} + \sum_{p \notin T} \sum_{k=0}^{j-N(n_p+1)} 2Q_{ip}\ \alpha_k^{(i)} \beta_{j-k-N(n_p+1)}^{(p)}, \tag{17}$$

and

$$Y_j^{(p)} = \epsilon_p \sum_{i \notin S} Q_{pi}^t\ \alpha_{j-N(m_i+2)}^{(i)}. \tag{18}$$

Note that $X_j^{(i)}$ and $Y_j^{(p)}$ involve only terms with subscripts $<j$, and the terms $\beta_j^{(p)}$ with $p \notin T$ do not appear on the left-hand side of (14) and (15). Equations (14) and (15) therefore form a subsystem of the full recursion, and in this subsystem we can eliminate α_j by (14).

The following theorem describes the nonzero resonances of the recursion.

Theorem 3.5: (Dancer and Wang, 2002):

(a) The (nonzero) resonances $R = j/N$ of the subsystem (14) and (15) are the roots of the quadratic equation

$$R(R-1) = \lambda, \tag{19}$$

where λ runs over all the eigenvalues of the $|T| \times |T|$ matrix M_T obtained from $M := 2DP^t \operatorname{diag}(\alpha_0^{(1)}, \ldots, \alpha_0^{(r+\ell)})\, Q$ by deleting the pth row and pth column for all p not in T.

(b) If the following conditions,

(i) $m_i \geqslant n_p - 1$ for all $p \notin T$ and $i \notin S$ with $Q_{ip} \neq 0$,

(ii) $Q_{ip} = 0$ for all $p \notin T$ and $i \in S$,

hold, then Eq. (16) reduces to

$$\left(n_p + \frac{j}{N}\right) \beta_j^{(p)} = \epsilon_p \sum_{i \notin S} Q_{ip}\ \alpha_{j-N(m_i-n_p+1)}^{(i)}, \quad p \notin T, \tag{20}$$

where the terms on the right have subscript $\leqslant j$, so the only additional nonzero resonances from (16) are $R = -n_p$ for $p \notin T$.

Remark 3.6: (1) Equations (14)–(16) are valid for $j > 0$. We may also have additional zero resonances, associated to free parameters in α_0, β_0.

(2) In the examples of this article the only case where conditions (i) and (ii) do not hold is $S = \{4,6\}$ in the example of Sec. IV. In this case we can perform a reindexing $j \mapsto j - N(n_p+1)$ for the terms $\beta_j^{(p)}$ where $p \notin T$, and bring the system back into the form considered above. [cf. $S = \{4,5\}$ in Example 5.2 of Dancer and Wang (2002)].

Remark 3.7: As mentioned in Dancer and Wang (2002), $(\beta_0^{(p)})_{p \in T}$ is an eigenvector of M_T with eigenvalue 2, and hence -1, 2 are resonances. The appearance of -1 as a resonance is typical for autonomous systems of differential equations, and is associated to the degree of freedom coming from translating the independent variable. For the Einstein system under consideration, it can be shown that this freedom corresponds to homothetic changes of the metric. We shall see below (Proposition 3.10) that the Hamiltonian constraint fixes one free parameter at $R = 2$.

Existence of nontrivial Painlevé expansions (that is, expansions with free parameters other than translation) therefore requires, at least in the case $|T| = r$, the existence of rational roots of (19) other than -1,2. This can impose constraints on the principal orbit G/K, and in particular can lead to Diophantine conditions involving, for example, the dimension of G/K.

One common situation is that we have a family of principal orbit types indexed by an integer k (often dimension), and that the eigenvalues of M_T are given by rational functions $P_i(k)/Q_i(k)$, where $P_i, Q_i \in \mathbb{Z}[k]$. The condition that the associated resonance should be rational is that

$$Q_i(k)(Q_i(k)+4P_i(k)) \quad \text{is a perfect square.}$$

We are therefore looking for an integral point (k,y) on the hyperelliptic curve

$$y^2=Q_i(k)(Q_i(k)+4P_i(k)). \tag{21}$$

A theorem of Siegel tells us that there are only finitely many solutions [provided that all the roots of $Q_i(Q_i+4P_i)$ are distinct].

In Dancer and Wang (2002, 2003b) we encountered examples of this situation where the orbit G/K is $\mathrm{Sp}(k+1)/\mathrm{Sp}(k)\mathrm{U}(1)$, $\mathrm{Sp}(k+1)\mathrm{Sp}(1)/\mathrm{Sp}(k)\mathrm{Sp}(1)$, and $\mathrm{Sp}(k+1)\mathrm{U}(1)/\mathrm{Sp}(k)\mathrm{U}(1)$. The right-hand side of (21) factorized into polynomials of degree $\leqslant 3$, and we were able to reduce the problem of finding integral points on (21) to that of finding integral points (satisfying certain extra conditions) on an elliptic curve.

C. Compatibility conditions and constraints

By definition, the resonances correspond to the steps in the recursion at which the recursion operator is noninvertible. This means that at each resonance there are compatibility conditions which must be satisfied if the recursion is to proceed.

It often happens that these conditions may only be satisfied by setting to zero free parameters arising from earlier resonances.

However, in all of our examples compatibility holds *automatically* at the top resonance $R=2$. In most cases we can see this from the following proposition.

Proposition 3.8: (Dancer and Wang, 2002) *Suppose that all compatibility conditions hold for* $R=j/N<2$, *and we have*

(i) $m_i \geqslant n_p-1$ *for all* $p\notin T$, $i\notin S$ *with* $Q_{ip}\neq 0$,

(ii) $Q_{ip}=0$ *for all* $p\notin T$ *and* $i\in S$, *and*

(iii) the 2-eigenspace of M_T *is one-dimensional.*

Suppose in addition that **either**

(iv) $m_i+n_p+1>0$ *for all* $p\notin T$ *and* $i\notin S$ *with* $Q_{ip}\neq 0$, **or**

(v) $m_i-n_p+1=0$ *for all* $p\notin T$ *and* $i\notin S$ *with* $Q_{ip}\neq 0$.

Then the compatibility condition holds at $R=2$.

Remark 3.9: Note that condition (iv) holds if $m_i\geqslant 0$ for all $i\notin S$, which is true for all cases in the examples of Secs. IV and V [and the examples of Dancer and Wang (2002)] except the ALC ones.

Condition (v) holds if there exist constants ν_1 and ν_2 such that $\nu_1-\nu_2+1=0$ and $m_i=\nu_1$ for all $i\notin S$, $n_p=\nu_2$ for all $p\notin T$. This situation occurs in the ALC cases of the examples in Secs. IV and V, and in Dancer and Wang (2002).

The Hamiltonian constraint (8) is related to the resonance at $R=2$, as we now explain. After substituting the Painlevé expansion into the Hamiltonian (8), one sees that the constant term in the Hamiltonian is given by a linear combination of $\beta_{2N}^{(p)}$ $(p\in T)$ and $\alpha_{2N}^{(i)}$ $(i\in S)$ plus terms with subscripts less than $2N$. Substituting in an element of the kernel of the recursion operator at $R=2$ (that is, $j=2N$) we have the following:

Proposition 3.10: (Dancer and Wang, 2002) *If all compatibility conditions hold at* $R=2$, *and if*

$$2\sum_{p\in T}\epsilon_p(\beta_0^{(p)})^2+\sum_{i\in S}\alpha_0^{(i)}\neq 0,$$

then the Hamiltonian constraint may always be satisfied by choosing α_{2N},β_{2N} *appropriately. In this situation the Hamiltonian constraint fixes one of the degrees of freedom coming from the resonance* $R=2$.

As $z_{r+j}\Pi_{i=1}^{r} z_i^{-\nu_{ji}}$ $(j=1,\ldots,\ell)$ are constants of the flow, the remaining constraints (7) are equivalent to imposing on α_0 the constraints

$$\frac{\alpha_0^{(r+j)}}{A_{r+j}} = \prod_{i=1}^{r} \left(\frac{\alpha_0^{(i)}}{A_i} \right)^{\nu_{ji}} \quad (1 \leqslant j \leqslant \ell). \tag{22}$$

IV. ALOFF–WALLACH SPACES AS PRINCIPAL ORBITS

We shall now look at a specific example, where the principal orbit G/K is the Aloff–Wallach space $N(k,l)$ (Aloff and Wallach, 1975). Here $N(k,l)$ is defined to be the quotient $\mathrm{SU}(3)/\mathrm{U}(1)_{k,l}$ where $\mathrm{U}(1)_{k,l}$ denotes $\mathrm{U}(1)$ embedded as

$$e^{i\theta} \mapsto \mathrm{diag}(e^{ik\theta}, e^{il\theta}, e^{im\theta})$$

and k,l,m are coprime integers with $k+l+m=0$. Notice that permuting k,l,m does not change the diffeomorphism type of the space. For example $N(1,-1) \approx N(1,0) \approx N(-1,0)$. We exclude the case $\{k,l,m\}=\{1,1,-2\}$ as in this case the isotropy representation does not split as the direct sum of inequivalent irreducible summands.

The second author (Wang, 1982) showed that every $N(k,l)$ admits a homogeneous Einstein metric. It was subsequently shown (Page and Pope, 1984) that there are exactly two such metrics on each $N(k,l)$, except for $N(1,-1)$ and the spaces obtained from it by permutation, when the metric is unique. Explicit formulas are given in Castellani and Romans (1984) [see Cvetič *et al.* (2002b) for a more detailed derivation]. Both Einstein metrics are in fact of weak holonomy G_2, so the cone over them has holonomy contained in Spin(7).

The isotropy representation of $N(k,l)$ is

$$\mathfrak{su}(3)/\mathfrak{u}(1) = \mathfrak{p}_0 \oplus \mathfrak{p}_1 \oplus \mathfrak{p}_2 \oplus \mathfrak{p}_3,$$

where $\mathfrak{p}_0$ is a trivial summand of real dimension one, $\mathfrak{p}_i$ $(i=1,2,3)$ are of real dimension 2, and $\mathrm{U}(1)$ acts on them with weights

$$\pm(k-l), \pm(k-m), \pm(l-m),$$

respectively. We write $\Gamma = k^2+m^2+km = k^2+l^2+kl = l^2+m^2+lm$. We take the background metric B to be the normal metric induced by the trace form $-\mathrm{tr}(XY)$.

The weight vectors in the scalar curvature formula are now as follows:

$$w^{(1)}=(0,-1,0,0), \quad w^{(2)}=(0,0,-1,0), \quad w^{(3)}=(0,0,0,-1),$$

$$w^{(4)}=(1,-2,0,0), \quad w^{(5)}=(1,0,-2,0), \quad w^{(6)}=(1,0,0,-2),$$

$$w^{(7)}=(0,1,-1,-1), \quad w^{(8)}=(0,-1,1,-1), \quad w^{(9)}=(0,-1,-1,1),$$

and the corresponding coefficients are $(A_1,\ldots,A_9)=(6,6,6,-3m^2/4\Gamma,-3l^2/4\Gamma,-3k^2/4\Gamma,-1,-1,-1)$. We give Φ and a choice of Q below:

$$\Phi=\begin{pmatrix}
\frac{1}{2} & 1 & 1 & 0 & 1 & 1 & \frac{3}{2} & \frac{1}{2} & \frac{1}{2}\\
1 & \frac{1}{2} & 1 & 1 & 0 & 1 & \frac{1}{2} & \frac{3}{2} & \frac{1}{2}\\
1 & 1 & \frac{1}{2} & 1 & 1 & 0 & \frac{1}{2} & \frac{1}{2} & \frac{3}{2}\\
0 & 1 & 1 & -2 & 0 & 0 & 2 & 0 & 0\\
1 & 0 & 1 & 0 & -2 & 0 & 0 & 2 & 0\\
1 & 1 & 0 & 0 & 0 & -2 & 0 & 0 & 2\\
\frac{3}{2} & \frac{1}{2} & \frac{1}{2} & 2 & 0 & 0 & -\frac{1}{2} & \frac{3}{2} & \frac{3}{2}\\
\frac{1}{2} & \frac{3}{2} & \frac{1}{2} & 0 & 2 & 0 & \frac{3}{2} & -\frac{1}{2} & \frac{3}{2}\\
\frac{1}{2} & \frac{1}{2} & \frac{3}{2} & 0 & 0 & 2 & \frac{3}{2} & \frac{3}{2} & -\frac{1}{2}
\end{pmatrix},$$

$$Q=\begin{pmatrix}
\frac{1}{\sqrt{2}} & 0 & 0 & 0\\
\sqrt{2} & \frac{\sqrt{6}}{2} & 0 & 0\\
\sqrt{2} & \frac{\sqrt{6}}{3} & \frac{\sqrt{30}}{6} & 0\\
0 & -\frac{\sqrt{6}}{3} & -\frac{\sqrt{30}}{15} & \frac{\sqrt{30}}{5}\\
\sqrt{2} & \frac{2\sqrt{6}}{3} & -\frac{\sqrt{30}}{15} & \frac{\sqrt{30}}{5}\\
\sqrt{2} & \frac{\sqrt{6}}{3} & \frac{4\sqrt{30}}{15} & \frac{\sqrt{30}}{5}\\
\frac{3}{\sqrt{2}} & \frac{5}{\sqrt{6}} & \frac{\sqrt{30}}{6} & 0\\
\frac{1}{\sqrt{2}} & -\frac{1}{\sqrt{6}} & \frac{\sqrt{30}}{6} & 0\\
\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{6}} & -\frac{\sqrt{30}}{6} & 0
\end{pmatrix}.$$

Applying the algorithm of Sec. III we can now find the possible leading terms. It is straightforward to check from Remark 3.2 that no m_i can be less than -2. The subgroup C_3 of permu-

tations of {1,...,9} generated by the order three element (123)(456)(789) acts on the set of possible S, so we list only one possibility from each orbit. The vectors m are similarly permuted. Note that the last three entries in our table are fixed by C_3.

S	m	$\alpha_0^{(i)}$ $(i\in S)$
{4}	$(0,1,1,-2,0,0,2,0,0)$	$-\frac{1}{2}$
{7}	$(6,2,2,8,0,0,-2,6,6)$	-2
{4,5}	$(1,1,2,-2,-2,0,2,2,0)$	$-\frac{1}{2},-\frac{1}{2}$
{4,8}	$(2,7,3,-2,8,0,8,-2,6)$	$-\frac{1}{2},-2$
{4,9}	$(2,3,7,-2,0,8,8,6,-2)$	$-\frac{1}{2},-2$
{4,5,9}	$(3,3,8,-2,-2,8,8,8,-2)$	$-\frac{1}{2},-\frac{1}{2},-2$
{4,5,6}	$(2,2,2,-2,-2,-2,2,2,2)$	$-\frac{1}{2},-\frac{1}{2},-\frac{1}{2}$
{1,...,9}	$(-2,...,-2)$	see below
{1,2,3,7,8,9}	$(-2,-2,-2,-\frac{8}{5},-\frac{8}{5},-\frac{8}{5},-2,-2,-2)$	see below

Remark 4.1: The AC case is when $S=\{1,\ldots,9\}$, and the ALC case is $S=\{1,2,3,7,8,9\}$. For all other choices of S, letting s tend to 0 corresponds to letting arclength t tend to a finite limit, as in (II) of Theorem 3.3.

A. AC case

As mentioned in Remark 3.4(a) the possibilities for α_0 may be computed from the homogeneous Einstein metrics on the principal orbits. Using the formulas of Castellani and Romans (1984) and Cvetič *et al.* (2002b) we find the explicit formula

$$\alpha_0=\left(\frac{2(3+2\cos\phi+\sin\phi)}{3(2+\cos\phi)^2},\frac{2(3+2\cos\phi-\sin\phi)}{3(2+\cos\phi)^2},\frac{(3+2\cos\phi+\sin\phi)(3+2\cos\phi-\sin\phi)}{3(2+\cos\phi)^2},\right.$$
$$-\frac{(\cos\phi-2\sin\phi)^2}{18(2+\cos\phi)^2},-\frac{(\cos\phi+2\sin\phi)^2}{18(2+\cos\phi)^2},-\frac{(2+3\cos\phi)^2}{18(2+\cos\phi)^2},-\frac{(3+2\cos\phi-\sin\phi)^2}{18(2+\cos\phi)^2},$$
$$\left.-\frac{(3+2\cos\phi+\sin\phi)^2}{18(2+\cos\phi)^2},-\frac{2}{9(2+\cos\phi)^2}\right),$$

where

$$\frac{l}{m}=\frac{(3+2\cos\phi+\sin\phi)(\cos\phi+2\sin\phi)}{(3+2\cos\phi-\sin\phi)(\cos\phi-2\sin\phi)}=\frac{4+6\cos\phi+12\sin\phi+5\sin 2\phi}{4+6\cos\phi-12\sin\phi-5\sin 2\phi}. \tag{23}$$

If $\{k,l,m\}\neq\{1,0,-1\}$ there are, for each choice of *ordered* triple (k,l,m), two choices of ϕ in $[0,2\pi)$, corresponding to the two Einstein metrics on $N(k,l)$. Note that the degenerate case $\{k,l,m\}=\{1,1,-2\}$ (that is, $l/m=1,-2$ or $-\frac{1}{2}$) occurs iff $\cos\phi=-1,0,1$ or $-\frac{4}{5}$.

It follows from (23) that $\cos\phi$ is a root of the quartic

$$H(t)=(l+m)^2(5t^2-4)(5t^2+12t+8)-4lm(3t+2)^2. \tag{24}$$

B. ALC case

There are four possibilities for α_0:

(i) $\alpha_0=(\frac{12}{25},\frac{12}{25},\frac{12}{25},m^2\omega,l^2\omega,k^2\omega,-\frac{2}{25},-\frac{2}{25},-\frac{2}{25})$, and

(ii) $\alpha_0=(\frac{3}{5},\frac{3}{5},\frac{3}{10},m^2\omega,l^2\omega,k^2\omega/4,-\frac{1}{20},-\frac{1}{20},-\frac{1}{5})$, and the two other vectors obtained by applying the permutation (123)(789) and shifting the $\frac{1}{4}$ factor cyclically in the middle three indices.

In both cases ω is a free parameter.

The corresponding cohomogeneity one metrics will asymptotically approach a circle bundle of constant radius c_1 over a cone over a homogeneous Einstein metric on $\mathrm{SU}(3)/T^2$. Cases (i)

and (ii) correspond to the four homogeneous Einstein metrics on $SU(3)/T^2$, that is, (i) the normal metric and (ii) the three Kähler–Einstein metrics. As in Theorem 3.3, we may calculate that ω controls the radius c_1 of the M-theory circle.

We can now calculate the resonances, check the compatibility conditions, and find the Painlevé expansions.

S	Rational resonances (multiplicities)	No. of parameters in expansion
{4}	-1,0 (three times), 1 (twice), 2 and $-n_1$	7
{5} or {6}	-1,0 (three times), 1 (three times), 2	7
{7}	-1,0 (three times), 1 (twice), 2 and $-n_4$	7

{1,2,3,7,8,9} (ii)	-1,0,2 and $\frac{3}{5}$	3

Remark 4.2: (i) As before, we have listed one choice of S from each orbit of the permutation group C_3. The exception is when $S=\{4\}$, $\{5\}$ or $\{6\}$, where we have listed each case separately because $S=\{4\}$ is slightly different from the other two (this reflects the fact that the choice of Q to some extent breaks the C_3 symmetry).

(ii) The entry in the final column is the maximum number of parameters among Painlevé families with given set S, after all constraints, including the Hamiltonian constraint, have been imposed. Note that the degree of freedom coming from translation of s is included as a parameter (cf. Remark 3.7).

(iii) The resonances after ''and'' are those arising from Theorem 3.5 (b); that is, they are $-n_a$ $(a \notin T)$ in the cases where $|T|<4$. In the ALC case, $T=\{1,2,3\}$ and the value of n_4 follows from the fourth equation in (6). In the remaining cases we obtain the maximal number of parameters in the expansion by taking n_a $(a \notin T)$ to be zero. If $S=\{7\}$, then n_4 must be 0 or 1.

(iv) Expansions with $N=1$ (i.e., expansions meromorphic in s rather than a fractional power of s) are obtained except when S is $\{1,\ldots,9\}$ or $\{1,2,3,7,8,9\}$.

Let us discuss the AC and ALC cases in more detail.

C. AC case: $S=\{1,\ldots,9\}$

On computing the characteristic polynomial of M_T and applying Theorem 3.5(a), we find that the resonances are the roots of the polynomial

$$f(t)f(1-t),$$

where f is the quartic polynomial

$$f(t)=(t+1)\left(t^3-\frac{4}{3}t^2-\frac{1}{9}t+\frac{4}{27}\left(14\frac{\cos^2\phi(\cos\phi+1)}{(\cos\phi+2)^3}+1\right)\right). \tag{25}$$

The number of nontrivial rational resonances is therefore twice the number of rational roots of the cubic factor in $f(t)$.

We write

$$E_x(t)=t^3-\frac{4}{3}t^2-\frac{1}{9}t+\frac{4}{27}\left(14\frac{x^2(x+1)}{(x+2)^3}+1\right)$$

so that the cubic factor is $E_{\cos\phi}(t)$.

The discriminant of $E_x(t)$ is

$$\left(\frac{2}{27(x+2)^3}\right)^2 F(x),$$

where

$$F(x) = -19\,375x^6 - 28\,660x^5 + 20\,556x^4 + 67\,360x^3 + 66\,544x^2 + 43\,200x + 14\,400. \quad (26)$$

Theorem 4.3: *For all but a finite number of Aloff–Wallach spaces $N(k,l)$, the cubic $E_{\cos\phi}(t)$ has at most one rational root, hence the number of parameters in the AC Painlevé expansion is at most three.*

Proof: Observe that if $E_{\cos\phi}(t)$ has more than one rational root, then all its roots are rational.

We first claim that

$$\{x \in \mathbb{Q} : E_x(t) \text{ has more than one root in } \mathbb{Q}\}$$

is *finite*. This is because the discriminant of $E_x(t)$ must now be the square of a rational, and so we have a rational point on the smooth genus two curve $y^2 = F(x)$, where $F(x)$ is given by (26). Faltings's proof of the Mordell conjecture shows there are only finitely many such points.

Now consider the case of general $\cos\phi$. If $E_{\cos\phi}(t)$ has more than one rational root, then, from above, all its coefficients are rational. Therefore there exists a rational q (depending on ϕ) such that $\cos\phi$ is a root of the cubic

$$c_{q(\phi)}(t) = q(t+2)^3 - t^2(t+1) = (q-1)t^3 + (6q-1)t^2 + 12qt + 8q.$$

Also, we saw earlier that $\cos\phi$ is a root of the quartic $H(t)$ given by (24).

If $c_{q(\phi)}(t)$ is irreducible over $\mathbb{Q}$, then up to a scale factor $H(t)$ must be the product of $c_{q(\phi)}(t)$ and a linear factor. It is straightforward to show, by equating coefficients, that this cannot occur for l/m rational.

It follows that $c_{q(\phi)}(t)$ has a root in $\mathbb{Q}$, which means that the cubic $E_{\cos\phi}(t)$ is $E_x(t)$ for some $x \in \mathbb{Q}$. Hence $\{\cos\phi : E_{\cos\phi}(t)$ has more than one root $\in \mathbb{Q}\}$ is finite, and the claim now follows. □

Remark 4.4: The program Ratpoints of Elkies, Stahlke, and Stoll was used to search for rational points on the curve $y^2 = F(x)$ in the range where the denominator of x is $\leqslant 10^5$. The only points found were $(x,y) = (-1, \pm 15), (0, \pm 120), (1, \pm 405), (-\frac{4}{5}, \pm \frac{648}{25})$. As remarked earlier, these possibilities for $x = \cos\phi$ correspond precisely to the degenerate case $\{k,l,m\} = \{1,1,-2\}$.

D. ALC case: $S = \{1,2,3,7,8,9\}$

The eigenvalues of M_T are given as follows:
case (i): $2, -\frac{4}{25}$ (twice),
case (ii): $2, \frac{1}{5}, -\frac{2}{5}$.

In case (i) we have a full set of rational resonances: $-1, \frac{1}{5}$(twice), $\frac{4}{5}$(twice),2 from the eigenvalues of M_T, 0 as in Remark 3.6 (1) and $\frac{3}{5}$ from 3.5(b), as $n_4 = m_4 + 1 = -\frac{3}{5}$.

In case (ii), $-1,2$ are the only rational resonances from the eigenvalues of M_T. We also have resonances 0 and $\frac{3}{5}$ as in (i).

The compatibility conditions are computed using MAPLE. In (i) we have a free parameter ω_0 at $j=0$, and pick up two more ω_1, ω_2 at $j=1$. (The compatibility condition is vacuous here as $X_1 = Y_1 = 0$.) The compatibility condition at $j=3$ forces ω_0 to equal a certain rational function of ω_1, ω_2, homogeneous of degree two. We pick up a free parameter ω_3 from the kernel of the recursion operator at $j=3$. The compatibility conditions at $j=4$ are now the vanishing of two homogeneous polynomials of degree six in ω_1, ω_2. These polynomials have a common linear factor, so we lose only one free parameter at $j=4$. Now the kernel of the recursion operator at

$j=4$ gives two new free parameters ω_4,ω_5. Now Proposition 3.8 ensures that we can solve the recursion at $j=10$, and the Hamiltonian constraint fixes the parameter here.

The upshot is that $\omega_3,\omega_4,\omega_5$ and one of $\omega_0,\omega_1,\omega_2$ may be regarded as free. We therefore have five free parameters in all (including the position of the singularity).

In (ii) the recursion operator for (14) and (15) is invertible for $j<10$ and we find that $\alpha_1=\hat{\beta}_1=0$ and hence $X_3=Y_3=0$. Therefore $\alpha_3=0$, the compatibility condition holds at $j=3$ and we pick up one free parameter here. The other free parameters are from $j=0$ and the position of the singularity.

Now, the equations for the cohomogeneity one metric to be of Spin(7) holonomy will be a subsystem of the Ricci-flat equations (5) and (6).

Transforming the Spin(7)-equations in Gukov and Sparks (2002) to the variables we use, we find that this subsystem may be written as

$$\zeta_i'=\zeta_i\sum_j C_{ij}\zeta_j \quad (i,j=4,5,6,7,8,9) \tag{27}$$

with the constraints

$$\zeta_4\zeta_7=\zeta_5\zeta_8=\zeta_6\zeta_9. \tag{28}$$

Here ζ_i is the positive square root of x_i and C is the matrix

$$-\begin{pmatrix} m\sqrt{\frac{3}{2\Gamma}} & 0 & 0 & 2\sqrt{2} & 0 & 0 \\ 0 & l\sqrt{\frac{3}{2\Gamma}} & 0 & 0 & 2\sqrt{2} & 0 \\ 0 & 0 & k\sqrt{\frac{3}{2\Gamma}} & 0 & 0 & 2\sqrt{2} \\ -m\sqrt{\frac{3}{2\Gamma}} & 0 & 0 & -1/\sqrt{2} & 3/\sqrt{2} & 3/\sqrt{2} \\ 0 & -l\sqrt{\frac{3}{2\Gamma}} & 0 & 3/\sqrt{2} & -1/\sqrt{2} & 3/\sqrt{2} \\ 0 & 0 & -k\sqrt{\frac{3}{2\Gamma}} & 3/\sqrt{2} & 3/\sqrt{2} & -1/\sqrt{2} \end{pmatrix}.$$

We can now look for Painlevé expansions

$$\zeta_i=\sum_{j=0}^{\infty}\gamma_j^{(i)}s^{\mu_i+j/N} \qquad (i=4,5,6,7,8,9),$$

for (27). If we let S denote the set of indices for which the leading power is -1, we can form matrices $\tilde{C}$ and $\hat{C}$ defined by

$$\text{if } j\in S, \quad \tilde{C}_{ij}=C_{ij}, \quad \hat{C}_{ij}=0;$$

$$\text{if } j\notin S, \quad \tilde{C}_{ij}=0, \quad \hat{C}_{ij}=C_{ij}.$$

It is straightforward to check that

$$\tilde{C}\gamma_0=\mu,$$

and that the recursion relation is

$$\frac{j}{N}\gamma_j^{(i)} - \gamma_0^{(i)}(\tilde{C}\gamma_j)^{(i)} = \sum_{k=1}^{j-1}(\tilde{C}\gamma_{j-k})^{(i)}\gamma_k^{(i)} + \sum_{p\notin S}\sum_{k=0}^{j-N(1+\mu_p)} C_{ip}\gamma_k^{(i)}\gamma_{j-k-N(1+\mu_p)}^{(p)}.$$

In particular the resonances $R=j/N$ are the eigenvalues of $\mathrm{diag}(\gamma_0^{(4)},\ldots,\gamma_0^{(9)})\tilde{C}$ [two of the zero eigenvalues should be removed, as the corresponding free parameters are fixed by the constraints (28)].

We can thus compare the Painlevé expansions of the exceptional holonomy system (27) with those of the full Ricci-flat system having the corresponding leading terms.

Theorem 4.5: *Consider the cohomogeneity one Ricci-flat system for the principal orbit* $N(k,l)=\mathrm{SU}(3)/\mathrm{U}(1)_{k,l}$. *The non-AC Painlevé expansions of the associated quadratic system (5)–(8) which contain metrics of* Spin(7)*-holonomy are given by*

(*I*) *a five-parameter family of ALC metrics containing a four-parameter family of ALC* Spin(7)*-metrics,*

(*II*) *a six-parameter family of metrics with* $S=\{4,5\}$ (*or* $\{5,6\}$ *or* $\{4,6\}$) *containing a three-parameter family of* Spin(7)*-metrics,*

(*III*) *a seven-parameter family of metrics with* $S=\{4\}$ (*or* $\{5\}$ *or* $\{6\}$) *containing a four-parameter family of* Spin(7)*-metrics.*

(See Theorem 4.8 for the AC case.) □

Remark 4.6: The expansion for (27) representing ALC metrics has resonances at $-1,0$ and $\frac{4}{5}$ (twice) (cf. the resonances for the ALC expansion in the full Ricci-flat system). A calculation with MAPLE shows that the compatibility conditions at $\frac{4}{5}$ hold automatically, so we have a four-parameter family of expansions. The metrics are asymptotic to a circle of constant radius c_1 over a cone over the standard normal Einstein metric on $\mathrm{SU}(3)/T^2$.

It is interesting to compare this with the equations studied in Dancer and Wang (2002, 2003a) [see also Cvetič *et al.* (2002b) and Cleyton and Swann (2002)] for cohomogeneity one G_2 metrics with principal orbit $\mathrm{SU}(3)/T^2$. These equations form a three-dimensional system, and there is a Painlevé expansion representing metrics asymptotic to a cone over the standard normal Einstein metric on $\mathrm{SU}(3)/T^2$. The eigenvalues are now $-1,\frac{4}{5}(\text{twice})$, all compatibility conditions hold, and we obtain a three-parameter expansion. In fact, the equations may be explicitly solved in terms of Jacobi functions.

The extra parameter in the Spin(7) system comes from the free parameter at $j=0$, that is, the free leading term $\gamma_0^{(4)}=\gamma_0^{(5)}=\gamma_0^{(6)}$. This parameter determines the radius c_1 of the M-theory circle. The existence of our four-parameter ALC Painlevé expansion suggests that it may be possible to find a more general solution in closed form to the Spin(7) system than the ones discovered in Cvetič *et al.* (2002b) and Kanno and Yasui (2002).

Remark 4.7: In the AC case, we find that the resonances are the roots of the polynomial $f(t)$ that we encountered in (25). [Recall that the AC resonances for the full Ricci-flat system are the roots of $f(t)f(1-t)$.] Theorem 4.3 therefore has the following corollary.

Theorem 4.8: *For all but finitely many Aloff–Wallach spaces, the* Spin(7) *equations have at most one nontrivial rational resonance in the AC case. The corresponding Painlevé expansions have at most two free parameters.* □

V. U(1) BUNDLES OVER PRODUCTS OF EINSTEIN FANO VARIETIES

In this section we examine Painlevé expansions of our Ricci-flat equations (5)–(8) in the case when the ''principal orbits'' are certain circle bundles over a product of two Fano varieties studied in Wang and Ziller (1990). When the Fano varieties are homogeneous, then the principal circle bundles we consider are homogeneous, and so are genuine principal orbits of a cohomogeneity one action on the manifold $\mathcal{M}$. In general, however, there are no symmetries on the Fano varieties or the circle bundles. Nevertheless, it is well known that if we use the Kaluza–Klein construction

for the metrics on the circle bundles, the formalism of cohomogeneity one Einstein metrics leads to the same system of ordinary differential equations as in the homogeneous case.

Let $V_i (i=2,3)$ be respectively smooth Fano varieties admitting Kähler–Einstein metrics h_i. The cohomology group $H^2(V_i,\mathbb{Z})$ is torsion free and so we can write the first Chern class of V_i as $c_i\gamma_i$ where γ_i is an indivisible class and c_i is a positive integer—the first Chern number. The principal circle bundles we will consider are circle bundles over $V_2\times V_3$ whose Euler class is $e_2\gamma_2+e_3\gamma_3\in H^2(V_2,\mathbb{Z})\oplus H^2(V_3,\mathbb{Z})$, where e_i are arbitrary nonzero integers. Note that if e_2 and e_3 have greatest common divisor e_1, then the circle bundle has the bundle whose Euler class is $(e_2/e_1)\,\gamma_2+(e_3/e_1)\,\gamma_3$ as its universal cover. Also, bundles whose Euler classes give rise to the same ordered pair $(|e_2|,|e_3|)$ are related by pull-back via diffeomorphisms of the base. So it is natural and convenient to introduce the quantity

$$\tau:=\left|\frac{e_2}{c_2}\left(\frac{e_3}{c_3}\right)^{-1}\right| \tag{29}$$

and not to distinguish bundles with the same invariant τ.

We will let $d_i=2l_i$ be the real dimension of V_i. Without loss of generality, we may assume that $d_2\leqslant d_3$. We will also normalize the Kähler–Einstein metric h_i so that its Ricci form is $2\pi c_i$ times its Kähler form.

Next we describe the one-parameter families of metrics we will consider on our principal circle bundles. For each such bundle, we choose a connection θ so that its curvature form is harmonic with respect to the product metric $h_2\perp h_3$ on the base. Then we consider one-parameter families of metrics of the form

$$g_t=f_1(t)^2\ (\theta\otimes\theta)\perp\pi^*(f_2(t)^2h_2\perp f_3(t)^2h_3), \tag{30}$$

where π denotes the bundle projection map and f_i are smooth positive functions of the transverse variable t. The scalar curvature of g_t is given by

$$\mathsf{S}(g_t)=\frac{d_2c_2}{f_2(t)^2}+\frac{d_3c_3}{f_3(t)^2}-\frac{1}{4}\left(d_2e_2^2\frac{f_1(t)^2}{f_2(t)^4}+d_3e_3^2\frac{f_1(t)^2}{f_3(t)^4}\right). \tag{31}$$

We shall need some information about Einstein metrics of the form (30) (without the parameter t) on our circle bundles. It was shown by an abstract degree argument in Wang and Ziller (1990) that up to homothety there is a unique Einstein metric in this class of metrics. The special case of these bundles where $V_2=\mathbb{CP}^1$ and $V_3=\mathbb{CP}^2$ was first studied in Witten (1982). These are homogeneous seven-dimensional manifolds with $\mathrm{SU}(3)\cdot\mathrm{SU}(2)\cdot\mathrm{U}(1)$ symmetry. For these manifolds, Castellani, D'Auria, and Fré (1984, p. 627) independently showed the existence of a unique homogeneous Einstein metric (up to homothety). Furthermore, they parametrized the Einstein metrics in terms of the roots of a cubic polynomial whose coefficients depend on a rational expression of c_i and e_i. Finally, they showed that the Einstein manifolds admit a nontrivial Killing spinor only when this rational expression is 1. In our notation, this is the case when $e_i=-c_i$ $(i=2,3)$. Another way to phrase this observation is that the circle bundles with $e_i=-c_i$ $(i=2,3)$ are the only ones where the unique Einstein metric of bundle type is Sasakian–Einstein. This observation holds generally in the situation of Wang and Ziller (1990), and in an even more general context, and is due to Boyer and Galicki (2000). Thus the metric cones over these Einstein circle bundles admit a Calabi–Yau metric.

In the Appendix we will give a similar parametrization (in terms of τ) of the unique Einstein metric on the circle bundles under study. This parametrization will be used in this section.

With the above preliminaries, we are now ready to discuss the Painlevé analysis of (5)–(8) for the present case.

Note first that from (31) we have the weight vectors

$$w^{(1)}=(0,-1,0),\quad w^{(2)}=(0,0,-1),$$

$$w^{(3)}=(1,-2,0),\quad w^{(4)}=(1,0,-2),$$

and corresponding coefficients $(A_1,A_2,A_3,A_4)=(d_2c_2,d_3c_3,-d_2e_2^2/4,-d_3e_3^2/4)$. So $r=3$ and $\ell=1$. It follows that the matrix Φ and a choice of the matrix Q are given by

$$\Phi=\begin{pmatrix} 1-\frac{1}{d_2} & 1 & 1-\frac{2}{d_2} & 1 \\ 1 & 1-\frac{1}{d_3} & 1 & 1-\frac{2}{d_3} \\ 1-\frac{2}{d_2} & 1 & -\frac{4}{d_2} & 0 \\ 1 & 1-\frac{2}{d_3} & 0 & -\frac{4}{d_3} \end{pmatrix},$$

$$Q=\begin{pmatrix} \sqrt{\frac{d_2-1}{d_2}} & 0 & 0 \\ \sqrt{\frac{d_2}{d_2-1}} & \sqrt{\frac{d_2+d_3-1}{d_3(d_2-1)}} & 0 \\ \frac{d_2-2}{\sqrt{d_2(d_2-1)}} & -\sqrt{\frac{d_3}{(d_2-1)(d_2+d_3-1)}} & \sqrt{\frac{d_2+d_3}{d_2+d_3-1}} \\ \sqrt{\frac{d_2}{d_2-1}} & \frac{2d_2+d_3-2}{\sqrt{d_3(d_2-1)(d_2+d_3-1)}} & \sqrt{\frac{d_2+d_3}{d_2+d_3-1}} \end{pmatrix}.$$

The vector ξ in Theorem 3.3 is equal to $[1/(d_2+d_3)](-(d_2+2),-d_3,1)$.

Applying the algorithm in Sec. III, one easily checks that possible leading terms of Painlevé expansions for Eqs. (5) and (6) are as given in the following table.

S	T	m	$\alpha_0^{(i)}$ $(i\in S)$	Remarks
$\{3\}(i)$	$\{2,3\}$	$(0,1,-2,0)$	$-\frac{1}{2}$	$d_2=2$
$\{3\}(ii)$	$\{1,2,3\}$	$\left(\frac{d_2-2}{2},\frac{d_2}{2},-2,0\right)$	$-\frac{d_2}{4}$	$d_2>2$
$\{4\}$	$\{1,2,3\}$	$\left(\frac{d_3}{2},\frac{d_3-2}{2},0,-2\right)$	$-\frac{d_3}{4}$	
$\{3,4\}$	$\{1,2,3\}$	$\left(\frac{d_2+d_3-2}{2},\frac{d_2+d_3-2}{2},-2,-2\right)$	$-\frac{d_2}{4},-\frac{d_3}{4}$	
$\{1,2,3,4\}$	$\{1,2,3\}$	$(-2,-2,-2,-2)$	see below	AC
$\{1,2\}$	$\{1,2\}$	$\left(-2,-2,-2\left(\frac{d_2+d_3-2}{d_2+d_3-1}\right),-2\left(\frac{d_2+d_3-2}{d_2+d_3-1}\right)\right)$	$\frac{d_2}{d_2+d_3-1},\frac{d_3}{d_2+d_3-1}$	ALC

In the above table, we have not yet imposed the constraint (7). When $S=\{1,2,3,4\}$, using (10) and the parametrization of the Einstein metrics on our circle bundles given in the Appendix, we find that

$$\begin{aligned} \alpha_0^{(1)}&=\frac{d_2}{d_2+d_3}\left(\frac{d_3\mu^2+d_2+2}{d_3\mu^2+d_2}\right),\quad \alpha_0^{(2)}=\frac{d_3}{d_2+d_3}\left(\frac{(d_3+2)\mu^2+d_2}{d_3\mu^2+d_2}\right), \\ \alpha_0^{(3)}&=\frac{-d_2}{d_2+d_3}\left(\frac{1}{d_3\mu^2+d_2}\right),\quad \alpha_0^{(4)}=\frac{-d_3}{d_2+d_3}\left(\frac{1}{d_3\mu^2+d_2}\right), \end{aligned} \tag{32}$$

where μ is the parameter introduced in the Appendix and the constraint condition (7) is precisely the requirement that μ is a root of the cubic polynomial φ given by (A1).

When $S=\{1,2\}$, we may let $\alpha_0^{(4)}$ be a free parameter $\omega_0<0$, and the constraint (7) implies that $\alpha_0^{(3)}=(d_2/d_3)\,\tau^2\omega_0$.

Regarding the asymptotics of the metrics corresponding to Painlevé expansions with the above leading term behavior, the AC and ALC cases are as indicated in the table, with $f_1(t)$ approaching a positive constant in the latter case. In the remaining cases, as s approaches 0, the transverse parameter t tends to a finite limit, and the volume of the circle bundles tends to 0. There is always an $f_j(t)$ which blows up, and when $S=\{3\}$ or $\{4\}$ there is always another $f_j(t)$ which tends to a positive constant.

We discuss next the resonances and compatibility conditions for our Painlevé expansions. The results are summarized in the table below.

S	Resonances (multiplicities)	No. of parameters in expansion
$\{3\}$ (i)	-1,0 (twice), 1,2 and $-n_1$	5
$\{3\}$ (ii)	-1,0 (twice), 1 (twice), 2	5
$\{4\}$	-1,0 (twice), 1 (twice), 2	5
$\{3,4\}$	-1 (twice), 0,1,2 (twice)	4
$\{1,2,3,4\}$	$-1,\frac{-2}{n-1},\frac{2}{n-1},\frac{n-3}{n-1},\frac{n+1}{n-1},2$ when $\tau=1$ otherwise see below	4 or 3
$\{1,2\}$	$-1,0,2$, roots of $R(R-1)=\frac{-2}{n-2}$	4 $(n=11)$
	and $-n_3=\frac{n-4}{n-2}$	3 (n$\neq$11)

Remark 5.1: We follow the same conventions as those in Remark 4.2.

(i) Recall that $n=1+d_2+d_3$ *is the dimension of our hypersurfaces and* τ *is given by* (29).

(ii) We may choose $N=1$ in the first four cases, and so we obtain expansions meromorphic in s.

(iii) We have again listed the maximum number of parameters among Painlevé expansions with the same S in the third column. For example, when $S=\{3\}$ and $d_2=2$, we get five parameters when $n_1=0$, four parameters when $n_1=1$ and three parameters when $n_1>1$.

We now give more details regarding the AC and ALC cases.

A. AC cases

When $S=\{1,2,3,4\}$, one finds using MAPLE that the eigenvalues of the matrix M (cf. Theorem 3.5) are 2 and $2(1+\mu^2\pm\sqrt{\delta})/[(d_2+d_3)(d_3\mu^2+d_2)]$ where

$$\delta=(d_3+1)^2\mu^4+2(d_2d_3-d_2-d_3-1)\mu^2+(d_2+1)^2.$$

Hence the rationality conditions for the resonances are that

$$\Delta_{\pm}=1+\left(\frac{8}{d_2+d_3}\right)\left(\frac{1+\mu^2\pm\sqrt{\delta}}{d_3\mu^2+d_2}\right) \tag{33}$$

should be squares in $\mathbb{Q}$.

By the discussion in the Appendix, in the special case when $\tau=1$ (the Sasakian–Einstein case), we have $\mu=1$, and $\delta=(n-1)^2$. Corresponding to Δ_+ we obtain resonances $-2/(n-1)$ and $(n+1)/(n-1)$, and corresponding to Δ_- we obtain resonances $2/(n-1)$ and $(n-3)/(n-1)$ (which are equal when $n=5$).

Lemma 5.2: In the AC case, in order that we have a full set of rational resonances, μ must be rational.

Proof: Note that besides the cubic equation $\varphi(x)=0$, where φ is given by (A1), μ also satisfies the quartic equation

$$F(x)=((d_3+1)^2-r_*^2d_3^2)x^4+2(d_2d_3(1-r_*^2)-d_2-d_3-1)x^2+((d_2+1)^2-r_*^2d_2^2)=0,$$

where r_* is some rational number, because $\sqrt{\delta}/(d_3\mu^2+d_2)$ has to be rational. Let $\eta(x)$ be the minimal polynomial of μ. If η has degree 1, μ is rational, so we may assume that η has degree 2 or 3. In the former case, since it divides φ, we get a contradiction to the fact that φ has a unique real root, as was indicated in the Appendix. In the latter case, up to a constant, φ is the minimal polynomial of μ. If F genuinely has degree 4, since φ must divide F, F has a nonzero rational root in addition to the roots of φ. Since F is even in x, the negative of this root must be μ, which would then be rational. If the coefficient of x^4 in F vanishes, then φ cannot be the minimal polynomial of μ unless the coefficient of x^2 in F vanishes as well. But this leads immediately to a contradiction. □

We do not know if the above lemma remains true under the assumption that there is at least one nontrivial rational resonance.

In any case, let us assume that μ is rational in (33). This imposes a restriction on the circle bundles through (A2). In this situation, if one of $\Delta_\pm$ is a square in $\mathbb{Q}$, then δ must be a square, too. We shall analyze this condition in two steps. First, note that $(\mu^2,\pm\sqrt{\delta})$ are rational points on the curve whose equation is

$$y^2=(d_3+1)^2x^2+2(d_2d_3-d_2-d_3-1)x+(d_2+1)^2.$$

Since $(1,d_2+d_3)$ is also a rational point on this curve it follows that we can parametrize all of its rational points (x_ρ,y_ρ) by lines with rational slope ρ passing through $(1,d_2+d_3)$. Explicitly we have

$$x_\rho=1+\frac{2(d_3(d_2+d_3)+d_3-d_2-(d_2+d_3)\rho)}{\rho^2-(d_3+1)^2}, \tag{34}$$

$$y_\rho=(d_2+d_3)+\rho(x_\rho-1). \tag{35}$$

Second, in order for $x_\rho=\mu^2$ for some positive rational number μ, we must have a rational point (ρ_0,w_0) on the curve

$$\mathcal{C}_\delta: w^2=F_\delta(\rho):=(\rho+d_3+1)(\rho-d_3-1)(\rho-d_3+1)(\rho-2d_2-d_3-1). \tag{36}$$

Note that the underlying circle bundle must then have Euler class satisfying (A2) with $\mu=\sqrt{x_{\rho_0}}$.

Assuming now that δ is a square in $\mathbb{Q}$ as above, it follows by a straightforward computation that requiring Δ_+ or Δ_- to be a square in $\mathbb{Q}$ is equivalent to the existence of a rational point *having first coordinate* ρ_0 on one of the two curves $\mathcal{C}_\pm$ whose respective equations are

$$\mathcal{C}_+: w^2=F_+(\rho):=(d_2+d_3)F_1(\rho)G(\rho), \tag{37}$$

$$\mathcal{C}_-: w^2=F_-(\rho):=(d_2+d_3)F_2(\rho)G(\rho), \tag{38}$$

where

$$F_1(\rho)=(d_2+d_3-4)^2\rho^2-2(d_3(d_2+d_3-4)^2+16(d_2-d_3))\rho+(d_2+d_3-4)^2(d_3^2-1)$$
$$-4(d_2+d_3)(d_2d_3+8)-32d_3^2, \tag{39}$$

$$F_2(\rho)=(d_2+d_3+4)^2\rho^2-2d_3(d_2+d_3+4)^2\rho+(d_2+d_3+4)^2(d_3^2-1)-4d_2d_3(d_2+d_3-8), \tag{40}$$

$$G(\rho)=(d_2+d_3)\rho^2-2d_3(d_2+d_3)\rho+(d_2+d_3)(d_3^2-1)-4d_2d_3. \tag{41}$$

In particular, there is a full set of rational resonances iff there are rational points on all three curves $\mathcal{C}_\delta,\mathcal{C}_\pm$ with the *same* first coordinate ρ.

Note that we do not really need both curves $\mathcal{C}_\pm$ in the above analysis. For a fixed value of x_ρ in (34), there are two corresponding values of ρ, for which the values of y_ρ are negatives of each other. So searching for rational points having the same first coordinate on the two curves is the same as searching for rational points on one of the curves whose first coordinates determine the same x_ρ.

One can check that the right-hand side of (37) has four distinct real roots except when $d_2=d_3=2$, and the right-hand side of (38) always has four distinct real roots. Furthermore, the polynomial $F_\delta(\rho)\cdot F_-(\rho)$ has distinct roots except when $d_2+d_3=8$, in which case there are precisely two roots with multiplicity 2 and the rest have multiplicity 1. The genus of the curve

$$\mathcal{C}:\quad w^2=F_\delta(\rho)\cdot F_-(\rho)$$

is therefore 3 when $d_2+d_3\neq 4$ or 8, and in this situation Faltings' theorem implies that $\mathcal{C}$ has only finitely many rational points. Now consider the situation where (ρ_0,w_1) and (ρ_0,w_2) are rational points on $\mathcal{C}_\delta$ and $\mathcal{C}_-$, respectively. Then (ρ_0,w_1w_2) is a rational point on the curve $\mathcal{C}$. This proves the first assertion in the following theorem.

Theorem 5.3: *Among all the circle bundles under study over a fixed base whose dimension is different from* 4 *or* 8, *there are only finitely many for which the AC Painlevé expansions can have a full set of rational resonances. When the base has dimension* 4 *this happens only for the bundles such that* $\tau=1$, *i.e., the bundles which admit a Sasakian–Einstein metric of bundle type after suitable changes in orientation.*

We now discuss some low-dimensional cases in more detail and along the way prove the second assertion of the above theorem.

Let us first consider the case where $d_2=d_3=2$. In this situation we have circle bundles over $\mathbb{CP}^1\times\mathbb{CP}^1$, and $(c_2,c_3)=(2,2)$. If e_2 and e_3 are coprime, then all the circle bundles are diffeomorphic to $S^2\times S^3$ by a well-known theorem of Smale (1962). Equations (37) and (38) become respectively

$$w^2=-4\cdot 16^2\cdot 5\cdot(\rho^2-4\rho-1),$$

$$w^2=4\cdot 16^2\cdot(\rho-2)^2(\rho^2-4\rho-1).$$

(Note that F_+ reduces to a constant in this case, so the first equation is quadratic in ρ.) Obviously, the same ρ cannot be the first coordinate of two rational points, one on each curve, unless $\rho=2$, which occurs iff $x_\rho=\mu^2=1$. By (A2), we must have $|e_2|=|e_3|$. The total spaces of these bundles are related by pull-back via a diffeomorphism of the base which sends one or both of the first Chern classes of the base factors to their negatives. Thus modulo this pull-back, these are precisely the bundles admitting a Sasakian–Einstein metric of bundle type. This gives the second claim in Theorem 5.3.

If $d_2=2$ and $d_3=4$, the respective curves are given by

$$\mathcal{C}_\delta: w^2=(\rho-5)(\rho+5)(\rho-3)(\rho-9),$$

$$\mathcal{C}_+: w^2=48(\rho-11)(\rho+19)(3\rho^2-24\rho+29),$$

$$\mathcal{C}_-: w^2 = 48(5\rho - 23)(5\rho - 17)(3\rho^2 - 24\rho + 29).$$

Using the program Ratpoints with a bound of 10^5 on $|\rho|$ and on its denominator, we find 14 rational points on $\mathcal{C}_+$, 16 rational points on $\mathcal{C}_-$, and 17 rational points on $\mathcal{C}_\delta$, not counting the point at infinity. Comparing the ρ-coordinates of the rational points found for $\mathcal{C}_\pm$ and $\mathcal{C}_\delta$, we find $\rho = \frac{13}{3}$ as the only common value. By (34), $x_\rho = 1$, and so $\tau = 1$.

The same phenomenon is observed for $(d_2, d_3) = (2,6),(4,4),(2,8),(4,6)$. In other words, for the AC Painlevé expansions under consideration, the requirement of having a full set of rational resonances appears to single out (when $d_2 + d_3 + 1 = n \leqslant 11$) the circle bundles on which the bundle-type Einstein metric is Sasakian–Einstein, modulo orientation change and pull-back. In view of the above numerical evidence and Proposition 5.3, it is tempting to conjecture that this is true in general, perhaps even under the weaker requirement that there is at least one nontrivial rational resonance.

We turn now to the compatibility conditions when $\tau = 1$ (the Sasakian–Einstein case). The positive resonances are at $j/N = 1/(l_2 + l_3)$, $(l_2 + l_3 - 1)/(l_2 + l_3)$, $(l_2 + l_3 + 1)/(l_2 + l_3)$ and 2. We take N to be $l_2 + l_3$, the complex dimension of the base of our bundles. The compatibility condition at $j = 1$ is trivially satisfied since the right-hand side of the recursion relations is zero. We therefore obtain a free parameter ω_1. If compatibility holds up to and including $j = l_2 + l_3 + 1$, then compatibility at the top resonance follows from Proposition 3.8, and one checks that the free parameter entering at that stage can be used to satisfy the Hamiltonian constraint. Hence we get at most a four-parameter Painlevé family.

When $d_2 = d_3 = 2$, we have $N = 2$. The first two nonzero resonances coincide, and the compatibility condition at $j = 3$ is also satisfied. So we obtain a three-parameter family of expansions.

When $d_2 = 2$, $d_3 = 4$, we have $N = 3$. The compatibility condition at $j = 2$ is satisfied, giving rise to a free parameter ω_2. Using MAPLE, one sees that the compatibility condition at $j = 4$ is satisfied iff

$$(10\omega_2 + 97\sqrt{2}\omega_1^2)(-10\omega_2 + 3\sqrt{2}\omega_1^2) = 0.$$

Hence we obtain two three-parameter families of Painlevé expansions by setting one of the two factors in the above equal to 0.

When $d_2 = d_3 = 4$, we have $N = 4$. This time, using MAPLE one sees that the compatibility conditions always hold and we obtain a four-parameter Painlevé family. On the other hand, when $d_2 = 2, d_3 = 6$, the compatibility condition at $j = 3$ holds while that at $j = 5$ is given by

$$\omega_1^2\left(\tfrac{1024}{63}\omega_1^3 + \sqrt{21}\omega_2\right) = 0.$$

So we have two three-parameter Painlevé families.

Exactly the same phenomena occur for the two cases where $d_2 + d_3 = 10$ and we obtain two three-parameter families in each case.

B. ALC cases

When $S = \{1,2\}$, the eigenvalues of the 2×2 matrix M_T are 2 and $-2/(n-2)$. The equation $R(R-1) = -2/(n-2)$ has rational solutions iff $(n-10)/(n-2)$ is a square in $\mathbb{Q}$. By Lemma 4.1 in Dancer and Wang (2001), this happens precisely when $n = 10$ or 11. Since n must be odd in our situation, we have $n = 11$, and the resonances in this case are $-1, 0, \frac{1}{3}, \frac{2}{3}, \frac{7}{9}$ and 2. We therefore take $N = 9$ in the recursion, which we perform using MAPLE.

Recall that we have a free parameter ω_0 in the leading coefficients. At step $j = 3$ the right-hand sides of the recursion relations (14) and (15) vanish and we pick up a free parameter ω_1. At $j = 6$ the compatibility condition requires ω_1 to vanish, and we pick up a free parameter ω_2. It follows then that at $j = 7$ the right-hand sides of (14) and (15) vanish, and we pick up a free parameter ω_3 from (16). The compatibility condition at the top resonance then follows from Proposition 3.8, and as usual the free parameter entering at that point is used to satisfy the

Hamiltonian constraint. Thus, adding in the singularity position, we obtain a four-parameter Painlevé family. If $n \neq 11$, then the only positive rational resonances are $(n-4)/(n-2)$ and 2, and we can let $N=n-2$. The compatibility condition at $(n-4)/(n-2)$ is satisfied because we can show by induction that the right-hand sides of (14) and (15) are zero when j is odd and $\leqslant n-4$. The compatibility condition holds at the top resonance again by Proposition 3.8, and the Hamiltonian constraint is satisfied by fixing the parameter entering at the top resonance. Thus ω_0, the free parameter entering at $j=n-4$, and the singularity position account for a three-parameter Painlevé family.

Finally, we discuss situations in which the metrics represented by the Painlevé expansions we obtained above exhibit special geometry.

Recall from Dancer and Wang (1998, Sec. 2) and Wang and Wang (1998) that when $e_i = -c_i$ for $i=2,3$, the cohomogeneity one Ricci-flat equations have a three-parameter family of explicit (local) Kähler–Einstein solutions, if we include the freedom to add a constant to the independent variable. [Note that $e_i=-c_i, (i=2,3)$ is a *necessary* condition for Ricci-flat Kähler-Einstein metrics.] In the above three-parameter family, there is a one-parameter subfamily of *complete* Calabi–Yau metrics. One can easily check that the ends in this subfamily are asymptotic to the metric cone over the Sasakian–Einstein metric of bundle-type on the circle bundle.

It turns out that when $e_i=-c_i (i=2,3)$, the solution curves of the Ricci-flat system (5)–(8) which lie in the subvariety given by

$$\frac{v_1}{\sqrt{d_2(d_2-1)}}+\frac{\sqrt{d_3}\ v_2}{\sqrt{(d_2-1)(d_2+d_3-1)}}-\frac{v_3}{\sqrt{(d_2+d_3)(d_2+d_3-1)}}=\frac{\sqrt{-z_3}}{\sqrt{d_2}},$$

$$-\frac{\sqrt{d_2-1}}{\sqrt{d_3(d_2+d_3-1)}}v_2-\frac{v_3}{\sqrt{(d_2+d_3)(d_2+d_3-1)}}=\frac{\sqrt{-z_4}}{\sqrt{d_3}},$$

$$\frac{2\sqrt{d_2+d_3-1}}{\sqrt{d_2+d_3}}\ v_3=\frac{1}{\sqrt{d_2}}\frac{z_1}{\sqrt{-z_3}}-\sqrt{d_2}\sqrt{-z_3}-\sqrt{d_3}\sqrt{-z_4}$$

correspond to Calabi–Yau metrics. If we let $\zeta_1=z_1/\sqrt{-z_3}$, $\zeta_2=\sqrt{-z_3}$ and $\zeta_3=\sqrt{-z_4}$, then these variables parametrize the subvariety of Calabi–Yau solutions and (5) and (6) induce on it the system

$$\zeta_i'=\zeta_i\sum_j C_{ij}\zeta_j, \quad i,j=1,2,3,$$

where C is the matrix

$$\begin{pmatrix} 0 & \sqrt{d_2} & \sqrt{d_3} \\ \dfrac{1}{\sqrt{d_2}} & -\dfrac{2}{\sqrt{d_2}} & 0 \\ \dfrac{1}{\sqrt{d_2}} & 0 & -\dfrac{2}{\sqrt{d_3}} \end{pmatrix}.$$

By comparing the Painlevé expansions of this system which have the same leading terms as those of the full Ricci-flat system, we obtain the following.

Theorem 5.4: *Consider the quadratic system (5)–(8) associated to principal circle bundles over a product of two Kähler–Einstein Fano varieties V_2, V_3 with $e_i=-c_i$, $i=2,3$.*

(*I*) *There are two five-parameter families of meromorphic Painlevé expansions representing local Ricci-flat metrics, within each of which is a three-parameter subfamily of Painlevé expansions representing Calabi–Yau metrics.*

(*II*) *There is a four-parameter family of meromorphic Painlevé expansions representing local Ricci-flat metrics, within which lies a two-parameter subfamily representing Calabi–Yau metrics.*

(*III*) *If the base dimension is* $\leqslant 10$*, there is a three-parameter family of Painlevé expansions (four parameters if* V_i *have the same dimension) representing complete Ricci-flat ends with AC asymptotics, within which lies a two-parameter subfamily representing Calabi–Yau metrics.*

The remaining ALC Painlevé families do not contain Calabi-Yau metrics.

□

Remark 5.5: (i) We expect that part (III) of the above theorem should be true without the dimension restriction.

(ii) We can relate our Painlevé expansions to another geometric condition that was first explored by Alfred Gray (1976). This concerns Riemannian metrics which are almost Hermitian with respect to a complex structure J and for which the curvature four-tensor is totally invariant under J. The Kähler condition is a special case of this condition. In Wang and Wang (1998), this condition was used to integrate the Einstein equations of cohomogeneity-one type where the hypersurfaces are circle bundles over a product of Fano manifolds. In particular, it was shown in Lemma 2.14 in Wang and Wang (1998) that local solutions satisfying the above geometric condition depend in general on three-parameters. The Ricci-flat equations we are studying in this section by Painlevé analysis are a special case of the Ricci-flat equations in Wang and Wang (1998). Hence the fact that in dimension 12 we obtained a four-parameter family of ALC Painlevé expansions implies that in that dimension there is a one-parameter family of complete Ricci-flat ends with ALC asymptotics whose curvature four-tensor is not totally invariant under the natural complex structure arising in that situation. On the other hand, MAPLE computations seem to indicate that Gray's condition in our situation is closely related to ALC asymptotics and it is quite probable that our three-parameter families of ALC Painlevé expansions in dimensions $\neq 12$ all satisfy Gray's condition.

APPENDIX: EXPLICIT PARAMETRIZATION OF EINSTEIN METRICS ON CIRCLE BUNDLES

In this section we indicate how we parametrize the Einstein metrics on the total spaces of the circle bundles we considered in Sec. V. The method is similar to that used in Castellani *et al.* (1984) and in Cvetic (2002b).

We start with the Einstein equations (1.5), (1.6) on p. 222 of Wang and Ziller (1990). In our notation, and in the case when the base consists of two factors, these are

$$x_1\left(\frac{d_2e_2^2}{x_2^2}+\frac{d_3e_3^2}{x_3^2}\right)=4\Lambda,$$

$$\frac{4c_2}{x_2}-2x_1\frac{e_2^2}{x_2^2}=4\Lambda,$$

$$\frac{4c_3}{x_3}-2x_1\frac{e_3^2}{x_3^2}=4\Lambda,$$

where Λ is the Einstein constant and $x_i=f_i^2$ for $i=1,2,3$. Let us multiply all three of the above equations by the factor $x_2x_3/c_2c_3x_1$. For $i=2,3$ let $\sigma_i=e_i/c_i$ (so $\tau=|\sigma_2/\sigma_3|$) and $y_i=x_i/c_ix_1$, and set $W_2^2=\sigma_2^2y_3/y_2$, $W_3^2=\sigma_3^2y_2/y_3$. After subtracting the resulting equations, we obtain

$$d_2W_2^2+(d_3+2)W_3^2=4y_2,$$

$$(d_2+2)W_2^2+d_3W_3^2=4y_3.$$

It follows that

$$(d_2+d_3+2)W_2^2=2(-d_3y_2+(d_3+2)y_3),$$

$$(d_2+d_3+2)W_3^2=2((d_2+2)y_2-d_2y_3).$$

The relation $W_2^2W_3^2=\sigma_2^2\sigma_3^2$ now gives

$$(d_2+d_3+2)^2\sigma_2^2\sigma_3^2=2(F_1^2-F_2^2),$$

where

$$F_1=\frac{1}{\sqrt{2}}(((d_2+2)y_2-d_2y_3)+(-d_3y_2+(d_3+2)y_3))$$

and

$$F_2=\frac{1}{\sqrt{2}}(((d_2+2)y_2-d_2y_3)-(-d_3y_2+(d_3+2)y_3)).$$

We can therefore write

$$F_1=\frac{1}{\sqrt{2}}(d_2+d_3+2)|\sigma_2\sigma_3|\cosh\theta,$$

$$F_2=\frac{1}{\sqrt{2}}(d_2+d_3+2)|\sigma_2\sigma_3|\sinh\theta,$$

for some parameter θ and set $\mu=\exp\theta$. One easily checks now that the Einstein equations become the condition that μ should be a positive root of the cubic polynomial

$$\varphi(x)=\tau d_3x^3-(d_3+2)x^2+\tau(d_2+2)x-d_2. \tag{A1}$$

The x_i in the original Einstein equations are then given by

$$x_2=\frac{x_1}{4}c_2|\sigma_2\sigma_3|((d_3+2)\exp\theta+d_2\exp(-\theta)),$$

$$x_3=\frac{x_1}{4}c_3|\sigma_2\sigma_3|(d_3\exp\theta+(d_2+2)\exp(-\theta)).$$

Since roots of a cubic polynomial are given by Cardano's formula, we may regard the above Einstein metrics as ''explicit.''

Note that for $\mu \leqslant 0$ we have $\varphi(\mu) < 0$, and one easily checks also that φ has a unique positive root. Hence we recover the fact that up to homothety there is a unique solution of the Einstein equations. Our interest here is to parametrize the Einstein metrics in terms of τ. Note that when $\tau = 1$, φ has the unique positive root $\mu = 1$, which represents the unique Sasakian–Einstein metric in the family.

From $\varphi(\mu) = 0$ we obtain the relation

$$\tau = \frac{(d_3+2)\mu^2 + d_2}{\mu(d_3\mu^2 + (d_2+2))}. \tag{A2}$$

One can check that as a function of $\mu > 0$, τ is strictly decreasing, with $\lim_{\mu \to 0} \tau = +\infty$ and $\lim_{\mu \to +\infty} \tau = 0$.

Progress in relativistic gravitational theory using the inverse scattering method

G. Neugebauer[a] and R. Meinel
Theoretisch-Physikalisches Institut, Friedrich-Schiller-Universität Jena, Max-Wien-Platz 1, 07743 Jena, Germany

(Received 9 April 2003; accepted 9 April 2003)

The increasing interest in compact astrophysical objects (neutron stars, binaries, galactic black holes) has stimulated the search for rigorous methods, which allow a systematic general relativistic description of such objects. This article is meant to demonstrate the use of the inverse scattering method, which allows, in particular cases, the treatment of rotating body problems. The idea is to replace the investigation of the matter region of a rotating body by the formulation of boundary values along the surface of the body. In this way we construct solutions describing rotating black holes and disks of dust (''galaxies''). Physical properties of the solutions and consequences of the approach are discussed. Among other things, the balance problem for two black holes can be tackled. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1590419]

I. INTRODUCTION

The systematic investigation of neutron stars and binaries consisting of pulsars and other compact objects and the increasing evidence for the existence of (rotating) black holes have stimulated theoretical and numerical studies on rapidly rotating bodies in general relativity. No doubt, realistic stellar models (e.g., neutron star models) require a careful physical analysis of their interior states and processes and, as a consequence, extensive *numerical* calculations. On the other hand, there is widespread interest for explicit solutions of the rotating body problem under simplifying assumptions. Such solutions could provide a deeper insight into physical phenomena connected with spinning matter configurations and, moreover, serve as test beds for the numerical investigations mentioned before. A good example is the Kerr solution, which has enriched our knowledge of rotating black holes in an inestimable way. However, rigorous results for rotating bodies are relatively rare in general relativity. Among other things, this is due to the mathematical difficulties with ''free boundary value problems,'' already known from Newton's gravitational theory, and to the specific complexity of the differential equations of Einstein's theory inside the body. Namely, the shape of the surface of a rotating self-gravitating fluid ball—the best model for astrophysical applications—is a ''compromise'' between gravitational, centrifugal, and pressure forces and not known *a priori*. (The surface is ''free,'' i.e., not fixed from the very beginning.) Though there are powerful (soliton-) techniques to generate (formal) stationary axisymmetric solutions of Einstein's vacuum equations, no algorithm to integrate the interior field equations is available. Hence, at first glance, a boundary value description of rotating bodies seems to be questionable and inadequate. However, there are exceptional cases, in which the surface of the body has a known shape and the surface values provide enough information to construct the complete solution of the vacuum field equations. It is the intention of this article to show that this is true for stationary black holes and disks of dust, which may be considered to be extremely flattened perfect fluid bodies. Moreover, it should become clear that our procedure, which is based

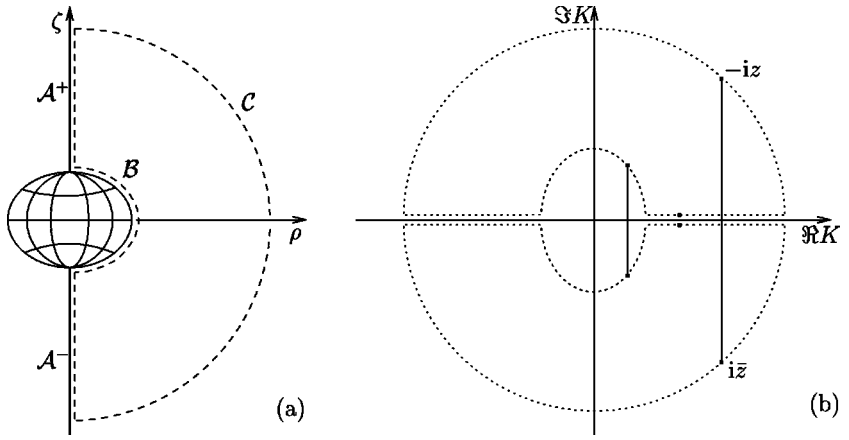

FIG. 1. (a) A slice $\phi=\text{const}$, $t=\text{const}$, (b) two-sheeted Riemann K-surface with branch points (dots) and two cuts (solid lines).[2]

on the inverse scattering method, opens an access to the not yet solved problem of the balance of two black holes and enables, in principle, the construction of black holes surrounded by dust rings (''AGN models'').

Another interesting domain of application for the inverse scattering method is colliding gravitational waves. This theory is out of the scope of our article. We refer to Ref. 1 and references therein.

The present work is mainly based on the Refs. 2 and 3, but it also contains substantial material not published before.

II. THE BOUNDARY VALUE PROBLEM

We consider a simply connected axisymmetric and stationary body and describe its exterior vacuum gravitational field in Weyl–Lewis–Papapetrou coordinates

$$ds^2=e^{-2U}[e^{2k}(d\rho^2+d\zeta^2)+\rho^2 d\phi^2]-e^{2U}(dt+a\,d\phi)^2, \tag{1}$$

where the ''Newtonian'' gravitational potential U, the ''gravitomagnetic'' potential a, and the ''superpotential'' k are functions of ρ and ζ alone. Figure 1(a) shows the boundaries of the vacuum region: $\mathcal{A}^{\pm}$ are the regular parts of the axis of symmetry ($\rho=0$), $\mathcal{B}$ is the surface of the body and $\mathcal{C}$ stands for spatial infinity. Later on, we will integrate along the dashed line and pick up information from the boundary values of the gravitational fields at $\mathcal{A}^{\pm}$, $\mathcal{B}$ and $\mathcal{C}$. The metric (1) allows an Abelian group of motions G_2 with the generators (Killing vectors)

$$\begin{aligned} &\xi^i=\delta^i_t, \quad \xi^i\xi_i<0 \quad \text{(stationarity)},\\ &\eta^i=\delta^i_\phi, \quad \eta^i\eta_i>0 \quad \text{(axisymmetry)}, \end{aligned} \tag{2}$$

where the Kronecker symbols δ^i_t and δ^i_ϕ indicate that ξ^i has only a t-component whereas η^i points in the azimuthal ϕ-direction (its trajectories are closed circles!). Obviously,

$$e^{2U}=-\xi^i\xi_i, \quad a=-e^{-2U}\eta_i\xi^i \tag{3}$$

is a coordinate-free representation of the two relativistic gravitational fields U (generalization of the Newtonian gravitational potential) and a (gravitomagnetic potential). To get a unique definition of U and a, we prescribe their behavior at infinity. Assuming that the space–time has to be flat at large distances from the body and can be described by a Minkowskian line element (1) in cylindrical coordinates, we are led to the boundary conditions

$$\mathcal{C}: \quad U\to 0, \quad a\to 0, \quad k\to 0. \tag{4}$$

Any linear transformation

$$t'=t, \quad \phi'=\phi-\omega t \tag{5}$$

introduces a frame of reference which rotates with a constant angular velocity ω with respect to that asymptotic Minkowski space.

To describe stationarity and axixymmetry in that rotating system one would use the Killing vectors

$$\tilde{\xi}^{i'}=\xi^{i'}+\omega\,\eta^{i'}, \quad \tilde{\eta}^{i'}=\eta^{i'} \tag{6}$$

instead of (2).

Regularity of the metric along $\mathcal{A}^{\pm}$ means

$$\mathcal{A}^{\pm}: \quad a=0, \quad k=0. \tag{7}$$

These conditions express the fact that $\mathcal{A}^{\pm}$ is an axis of symmetry ($a=0$) and ensure elementary flatness along the axis ($k=0$). The behavior of U and a at the surface $\mathcal{B}$ of the body depends on the physical nature of it. Rotating *perfect fluids* are characterized by a *four-velocity field* u^i consisting of a linear combination of the two Killing vectors,

$$u^i=\mathrm{e}^{-V}(\xi^i+\Omega\,\eta^i), \quad u^iu_i=-1, \tag{8}$$

where Ω is the angular velocity of the body, and an *invariant scalar pressure* p, which is, for rigid rotation,

$$\Omega=\Omega_0 \quad (\Omega_0 \text{ a constant}), \tag{9}$$

a function of V alone,

$$p=p(V), \tag{10}$$

as a consequence of the Euler equations. Along the surface of the body (if it exists) the pressure has to vanish, $p(V_0)=0$, i.e., V must be a constant along $\mathcal{B}$,

$$\mathcal{B}: \quad \mathrm{e}^{2V}\equiv-(\xi^i+\Omega_0\,\eta^i)(\xi_i+\Omega_0\,\eta_i)=\mathrm{e}^{2V_0}. \tag{11}$$

That is a further boundary condition. When identifying ω in (5) and Ω_0 we introduce a frame of reference co-rotating with the body and may interprete V as the co-rotating ''Newtonian'' potential, cf. (3) and (11). Interestingly, the event horizon $\mathcal{H}$ of a stationary (axisymmetric) black hole behaves like an ''ordinary'' perfect fluid surface (11). Namely, one can show that a linear combination of the two Killing vectors, $\xi^i+\Omega_{\mathrm{H}}\eta^i$, has a vanishing norm along $\mathcal{H}$,

$$\mathcal{H}: \quad \mathrm{e}^{2V}\equiv(\xi^i+\Omega_{\mathrm{H}}\eta^i)(\xi_i+\Omega_{\mathrm{H}}\eta_i)=0, \tag{12}$$

where Ω_{H} is the angular velocity of the horizon. Hence we may include black holes in our scheme, see Fig. 1(a), for $V_0\to-\infty$ and $\mathcal{H}\equiv\mathcal{B}$. It will turn out that (12) together with the correct positioning of the horizon $\mathcal{H}$ in Weyl–Lewis–Papapetrou coordinates together with the asymptotic behavior (4) of the (invariant) potentials (3) suffices for an explicit construction of the Kerr solution—thus providing a simple constructive uniqueness proof for stationary axisymmetric black holes. On the other hand, the condition (11) is not sufficient to calculate the gravitational field of rotating *perfect fluid balls*. However, in the disk of dust limit of such fluid configurations the

field equations themselves will provide the missing boundary condition along the surface $\mathcal{B}$ of the disk, see Ref. 3. Starting with that completed set of boundary conditions we will be able to construct the global solution for the rigidly rotating disk of dust.

III. THE FIELD EQUATIONS

The vacuum Einstein equations for the metric coefficients k, U, a are equivalent to the Ernst equation

$$(\Re f)\left(f_{,\rho\rho}+f_{,\zeta\zeta}+\frac{1}{\rho}f_{,\rho}\right)=f_{,\rho}^2+f_{,\zeta}^2 \tag{13}$$

for the complex function

$$f(\rho,\zeta)=\mathrm{e}^{2U}+\mathrm{i}b, \tag{14}$$

where b replaces a via

$$a_{,\rho}=\rho\mathrm{e}^{-4U}b_{,\zeta}, \quad a_{,\zeta}=-\rho\mathrm{e}^{-4U}b_{,\rho} \tag{15}$$

and k can be calculated from

$$k_{,\rho}=\rho[U_{,\rho}^2-U_{,\zeta}^2+\tfrac{1}{4}\mathrm{e}^{-4U}(b_{,\rho}^2-b_{,\zeta}^2)], \quad k_{,\zeta}=2\rho[U_{,\rho}U_{,\zeta}+\tfrac{1}{4}\mathrm{e}^{-4U}b_{,\rho}b_{,\zeta}]. \tag{16}$$

As a consequence of the Ernst equation (13), the integrability conditions $a_{,\rho\zeta}=a_{,\zeta\rho}$ and $k_{,\rho\zeta}=k_{,\zeta\rho}$ are automatically satisfied such that the metric functions a and k may be calculated via line integration from the Ernst potential f. Thus, it is sufficient to discuss the Ernst equation alone.

IV. THE LINEAR PROBLEM

The existence of a linear problem (LP) for the Ernst equation[4–9] is the cornerstone of our analysis since it provides a suitable instrument for tackling boundary value problems: the inverse scattering method (ISM). Here we will use a ''local'' version[10] of the linear problem,

$$\begin{aligned}\mathbf{\Phi}_{,z}&=\left\{\begin{pmatrix}B & 0\\ 0 & A\end{pmatrix}+\lambda\begin{pmatrix}0 & B\\ A & 0\end{pmatrix}\right\}\mathbf{\Phi},\\ \mathbf{\Phi}_{,\bar{z}}&=\left\{\begin{pmatrix}\bar{A} & 0\\ 0 & \bar{B}\end{pmatrix}+\frac{1}{\lambda}\begin{pmatrix}0 & \bar{A}\\ \bar{B} & 0\end{pmatrix}\right\}\mathbf{\Phi},\end{aligned} \tag{17}$$

where $\mathbf{\Phi}(z,\bar{z},\lambda)$ is a 2×2 matrix depending on the spectral parameter

$$\lambda=\sqrt{\frac{K-\mathrm{i}\bar{z}}{K+\mathrm{i}z}} \tag{18}$$

as well as on the complex coordinates $z=\rho+\mathrm{i}\zeta$, $\bar{z}=\rho-\mathrm{i}\zeta$, whereas A,B and the complex conjugate quantities $\bar{A}$, $\bar{B}$ are functions of $z,\bar{z}$ (or ρ, ζ) and do not depend on K. From the integrability condition and the formulas

$$\lambda_{,z}=\frac{\lambda}{4\rho}(\lambda^2-1), \quad \lambda_{,\bar{z}}=\frac{1}{4\rho\lambda}(\lambda^2-1) \tag{19}$$

it follows that a matrix polynomial in λ has to vanish. This yields the set of first order differential equations

$$A_{,\bar{z}}=A(\bar{B}-\bar{A})-\frac{1}{4\rho}(A+\bar{B}),\quad B_{,\bar{z}}=B(\bar{A}-\bar{B})-\frac{1}{4\rho}(B+\bar{A}). \tag{20}$$

The system has the ''first integrals''

$$A=\frac{f_{,z}}{f+\bar{f}},\quad B=\frac{\bar{f}_{,z}}{f+\bar{f}}. \tag{21}$$

Resubstituting A and B in the equations (20) one obtains the Ernst equation (13). Thus, the Ernst equation is the integrability condition of the LP (17). Vice versa, if f is a solution to the Ernst equation, the matrix $\mathbf{\Phi}$ calculated from (17) does not depend on the path of integration. The idea of the inverse scattering method (ISM) is to discuss $\mathbf{\Phi}$, for fixed but arbitrary values of $z,\bar{z}$, as a holomorphic function of λ (or K) and to calculate A,B and finally f afterwards. To obtain the desired information about the holomorphic structure in λ, we will integrate the linear system along the dashed line in Fig. 1(b) making use of the conditions (4), (7), (11) or (12). In this way, we will solve the *direct problem* of the ISM and obtain $\mathbf{\Phi}(z,\bar{z},\lambda)$ for $z,\bar{z}\in\mathcal{A}^{\pm},\mathcal{B},\mathcal{C}$. It turns out that the holomorphic structure remains unchanged by an extension of $z,\bar{z}$ off the axis of symmetry into the entire vacuum region such that one can construct functions $\mathbf{\Phi}$ with prescribed properties in λ from which one obtains the desired solution $f(z,\bar{z})$ everywhere in the vacuum region. This second step can be very technical and will, in general, lead to linear integral equations for $\mathbf{\Phi}$. In some circumstances, λ may be replaced by K. For this purpose, it may be helpful to discuss the mapping (18) of the two-sheeted Riemann surface of K onto the λ-plane for different values of ρ, ζ (or equivalently $z,\bar{z}$). Figure 1(b) shows the position of the branch points $K_{\mathrm{B}}=\mathrm{i}\bar{z}$, $\bar{K}_{\mathrm{B}}=-\mathrm{i}z$ for the marked path $\mathcal{A}^{+}\mathcal{C}\mathcal{A}^{-}\mathcal{B}$ of Fig. 1(a). It reflects the slice $\phi=\mathrm{const}$, $t=\mathrm{const}$ [Fig. 1(a)] and indicates, in particular, the position and shape of the body. Note that $\mathbf{\Phi}$ is not defined in the nonvacuum domain inside the circular contour around the origin.

Consider now a Riemann surface with confluent branch points $K_{\mathrm{B}}=\bar{K}_{\mathrm{B}}=\zeta\in\mathcal{A}^{+}$. Here λ degenerates and takes the values $\lambda=-1$ for K's in the lower sheet, say, and $\lambda=+1$ for K's in the upper sheet ($K\neq K_{\mathrm{B}}$).

We will now travel along the dashed line of Fig. 1(a) starting from and returning to any point $\rho=0$, $\zeta\in\mathcal{A}^{+}$. [In Fig. 1(b) this corresponds to the bold faced points on the real axis.] Note that $\lambda=-1$ for all K's ($K\neq\zeta$) in the lower and $\lambda=+1$ for all K's ($K\neq\zeta$) in the upper sheet of the Riemann K-surface belonging to axis values $\rho=0$, $\zeta\in\mathcal{A}^{\pm}$ [the corresponding branch points cling to either side of the real axis in Fig. 1(b)]. For $\rho,\zeta\in\mathcal{C}$, the cut between the branch points [e.g., right solid line in Fig. 1(b)] points over the entire K-surface and puts ''upper'' K values into the lower sheet and ''lower'' K values into the ''upper'' sheet. As a consequence, λ will change from ±1 to ∓1 between $\rho=0$, $\zeta=+\infty$ and $\rho=0$, $\zeta=-\infty$.[11] This ''exchange of sheets'' is important for the solution of the linear problem: The initial value $\mathbf{\Phi}(\rho_0,\zeta_0,\lambda)$ can (and must) be fixed only in *one* sheet of the K-surface. The dependence on K in the other sheet follows by integration of the LP (17) along a suitable path.[11]

We will divide the integration of the LP (17) along the closed dashed line of Fig. 1(a) into two steps:

(i) Integrating along $\mathcal{A}^{+}\mathcal{C}\mathcal{A}^{-}$: This step can be performed without particular knowledge about the body and leads to a ''*general* solution'' for $\mathbf{\Phi}$ on the regular parts $\mathcal{A}^{\pm}$ of the symmetry axis.

(ii) Integrating along $\mathcal{B}$: Here we confine ourselves to black holes and disks of dust.

V. SOLUTION OF THE DIRECT PROBLEM

A. Axis and infinity

Without loss of generality the matrix $\mathbf{\Phi}$ may be assumed to have the structure

$$\mathbf{\Phi}=\begin{pmatrix}\psi(\rho,\zeta,\lambda) & \psi(\rho,\zeta,-\lambda)\\ \chi(\rho,\zeta,\lambda) & -\chi(\rho,\zeta,-\lambda)\end{pmatrix} \tag{22}$$

together with

$$\overline{\psi\left(\rho,\zeta,\frac{1}{\bar{\lambda}}\right)}=\chi(\rho,\zeta,\lambda). \tag{23}$$

Note that both columns of $\mathbf{\Phi}$ are independent solutions of (17). The particular form of (22) is equivalent to

$$\mathbf{\Phi}(-\lambda)=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}\mathbf{\Phi}(\lambda)\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix}. \tag{24}$$

For $K\to\infty$ and $\lambda=-1$ the functions ψ, χ may be normalized by

$$\psi(\rho,\zeta,-1)=\chi(\rho,\zeta,-1)=1. \tag{25}$$

Finally, the solution to the Ernst equation can be read off at $\lambda=1$ $(K\to\infty)$,

$$f(\rho,\zeta)=\chi(\rho,\zeta,1),\quad (\overline{f(\rho,\zeta)}=\psi(\rho,\zeta,1)). \tag{26}$$

Remarkably enough, the Ernst equation retains its form in the frame of reference co-rotating with the body $(\omega=\Omega_0)$. This is a consequence of (3) and (6) and implies the existence of a linear problem (17) in the co-rotating system. In particular, the $\mathbf{\Phi}$-matrices of both systems of reference are connected by the relation

$$\mathbf{\Phi}'=\left[\begin{pmatrix}1+\Omega_0 a-\Omega_0\rho e^{-2U} & 0\\ 0 & 1+\Omega_0 a+\Omega_0\rho e^{-2U}\end{pmatrix}+i(K+iz)\Omega_0 e^{-2U}\begin{pmatrix}-1 & -\lambda\\ \lambda & 1\end{pmatrix}\right]\mathbf{\Phi}. \tag{27}$$

Henceforth, a prime marks ''co-rotating'' quantities. We can now realize our program and integrate the linear problem (17) along the part $\mathcal{A}^+\mathcal{C}\mathcal{A}^-$ of the dashed line in Fig. 1(a). Using (17) along $\mathcal{A}^\pm$ and (21) one finds for the axis values of $\mathbf{\Phi}$

$$\mathcal{A}^+:\quad \mathbf{\Phi}=\begin{pmatrix}\overline{f(\zeta)} & 1\\ f(\zeta) & -1\end{pmatrix}\begin{pmatrix}F(K) & 0\\ G(K) & 1\end{pmatrix}, \tag{28}$$

$$\mathcal{A}^-:\quad \mathbf{\Phi}=\begin{pmatrix}\overline{f(\zeta)} & 1\\ f(\zeta) & -1\end{pmatrix}\begin{pmatrix}1 & G(K)\\ 0 & F(K)\end{pmatrix}, \tag{29}$$

where $f(\zeta)=f(\rho=0,\zeta)$ is the axis value of the Ernst potential and $F(K),G(K)$ are integration ''constants'' depending on K alone. The particular form of (28) is due to the initial condition $\psi=\chi=1$ for some $\rho_0=0$, $\zeta=\zeta_0\in\mathcal{A}^+$, $\lambda=-1$ (K in the lower sheet), which fixes the second column of $\mathbf{\Phi}$ in (28), cf. (22). The first column corresponds to the upper $(\lambda=1)$ sheet and represents a general integral with the two integration ''constants'' $F(K),G(K)$ which cannot be specified here. Along $\mathcal{C}$, $\mathbf{\Phi}=\mathbf{\Phi}(K)$ does not depend on ρ and ζ, since A and B vanish, cf. (21). The ''exchange of sheets'' along $\mathcal{C}$, see Fig. 1(b), together with (24) leads to the particular form of $\mathbf{\Phi}$

on $\mathcal{A}^-$. The representations (28) and (29) describe the behavior of ψ and χ in both sheets. Nevertheless, one may wish to consider the matrix $\mathbf{\Phi}$ as a whole as a unique function of λ, which is therefore defined on both sheets of the K-surface. From this point of view, the equations (28) and (29) describe $\mathbf{\Phi}$ on one sheet only (say, on the upper sheet). Its values on the other (lower) sheet follow from (24).

Combining (28) and (29) with (27) we obtain the axis values in the co-rotating system,

$$\mathcal{A}^+: \quad \mathbf{\Phi}' = \left[\mathbf{1} + \mathrm{i}(K-\zeta)\Omega_0 \mathrm{e}^{-2U}\begin{pmatrix} -1 & -1 \\ 1 & 1 \end{pmatrix}\right] \times \left[\begin{pmatrix} \overline{f(\zeta)} & 1 \\ f(\zeta) & -1 \end{pmatrix}\begin{pmatrix} F(K) & 0 \\ G(K) & 1 \end{pmatrix}\right], \tag{30}$$

$$\mathcal{A}^-: \quad \mathbf{\Phi}' = \left[\mathbf{1} + \mathrm{i}(K-\zeta)\Omega_0 \mathrm{e}^{-2U}\begin{pmatrix} -1 & -1 \\ 1 & 1 \end{pmatrix}\right] \times \left[\begin{pmatrix} \overline{f(\zeta)} & 1 \\ f(\zeta) & -1 \end{pmatrix}\begin{pmatrix} 1 & G(K) \\ 0 & F(K) \end{pmatrix}\right], \tag{31}$$

where $\mathbf{1}$ ist the 2×2 unit matrix. At the branch points $K_\mathrm{B}=\zeta$ of K-surfaces belonging to axis values $\rho=0, \zeta \in \mathcal{A}^\pm$, ψ and χ must be unique, i.e.,

$$\mathcal{A}^+(K_\mathrm{B}=\zeta): \quad \mathbf{\Phi} = \begin{pmatrix} \psi & \psi \\ \chi & -\chi \end{pmatrix} = \begin{pmatrix} \overline{f(\zeta)} & 1 \\ f(\zeta) & -1 \end{pmatrix}\begin{pmatrix} F(\zeta) & 0 \\ G(\zeta) & 1 \end{pmatrix}, \tag{32}$$

$$\mathcal{A}^-(K_\mathrm{B}=\zeta): \quad \mathbf{\Phi} = \begin{pmatrix} \psi & \psi \\ \chi & -\chi \end{pmatrix} = \begin{pmatrix} \overline{f(\zeta)} & 1 \\ f(\zeta) & -1 \end{pmatrix}\begin{pmatrix} 1 & G(\zeta) \\ 0 & F(\zeta) \end{pmatrix}, \tag{33}$$

whence

$$\mathcal{A}^+: \quad F(\zeta) = \frac{2}{f(\zeta)+\overline{f(\zeta)}}, \quad G(\zeta) = \frac{f(\zeta)-\overline{f(\zeta)}}{f(\zeta)+\overline{f(\zeta)}}, \tag{34}$$

$$\mathcal{A}^-: \quad F(\zeta) = \frac{2\, f(\zeta)\overline{f(\zeta)}}{\overline{f(\zeta)}+f(\zeta)}, \quad G(\zeta) = \frac{\overline{f(\zeta)}-f(\zeta)}{f(\zeta)+\overline{f(\zeta)}}. \tag{35}$$

Thus, $F(K)$ and $G(K)$ consist in a unique way of analytic continuations of the real and imaginary parts of the axis values of the Ernst potential $f(\zeta)$. Vice versa, $f(\zeta)$ follows from $F(K), G(K)$ for $K=\zeta$. Interestingly, the determinants of $\mathbf{\Phi}$ and $\mathbf{\Phi}'$ can be expressed in terms of $\Re f$, $\Re f'$ and $F(K)$. From (17) $[\mathrm{Tr}\mathbf{\Phi}_{,z}\mathbf{\Phi}^{-1} = (\ln\det\mathbf{\Phi})_{,z}]$, (21) and (28)–(31), we have

$$\det\mathbf{\Phi} = -2\mathrm{e}^{2U}F(K), \quad \det\mathbf{\Phi}' = -2\mathrm{e}^{2V}F(K), \tag{36}$$

where $\mathrm{e}^{2U}=\Re f$ and $\mathrm{e}^{2V}=\Re f'$ $[U=U(\rho,\zeta), V=V(\rho,\zeta)]$.

We may now interpret the result of (30)–(35) of the integration of the LP along $\mathcal{A}^+\mathcal{C}\mathcal{A}^-$: On the regular parts $\mathcal{A}^\pm$ of the symmetry axis, $\mathbf{\Phi}$ and $\mathbf{\Phi}'$ can explicitly be expressed in terms of the axis values $f(\zeta)$ of the Ernst potential and its analytic continuations $F(K), G(K)$. To calculate $f(\zeta)$ one needs boundary values on $\mathcal{B}$. Accordingly, the integration along $\mathcal{B}$ depends on the physical nature of the rotating body and can be performed in particular cases only. In the next section we will discuss black holes and rigidly rotating disks of dust.

B. Surface

1. One black hole

We identify the surface $\mathcal{B}$ with the horizon $\mathcal{H}$. In Weyl coordinates, the event horizon $\mathcal{H}$ of a single black hole covers the domain,[12]

$$\mathcal{H}: \quad \rho=0, \quad K_1 \geqslant \zeta \geqslant K_2. \tag{37}$$

[In Fig. 1(a), the surface $\mathcal{B}$ degenerates to a "straight line" connecting the regular parts $\mathcal{A}^-, \mathcal{A}^+$ of the axis of symmetry.] Along $\mathcal{H}$, e^{2V} has to vanish [see (12)],

$$\mathcal{H}: \quad e^{2V} \equiv (\xi^i + \Omega_0 \eta^i)(\xi_i + \Omega_0 \eta_i) = 0 \quad (\Omega_0 = \Omega_H). \tag{38}$$

Because of

$$e^{2V} = e^{2U}([1 + \Omega_0 a]^2 - \Omega_0^2 \rho^2 e^{-4U}), \tag{39}$$

cf. (3), this implies

$$\mathcal{H}: \quad 1 + \Omega_0 a = 0. \tag{40}$$

$\mathbf{\Phi}$ and $\mathbf{\Phi}'$ can now be calculated along the horizon $\mathcal{H}$. From (17), (37), (38), (40) and (27) we obtain

$$\mathbf{\Phi} = \begin{pmatrix} \overline{f(\zeta)} & 1 \\ f(\zeta) & -1 \end{pmatrix} \begin{pmatrix} U(K) & V(K) \\ W(K) & X(K) \end{pmatrix},$$

$$\mathcal{H}: \tag{41}$$

$$\mathbf{\Phi}' = 2i\Omega_0 (K - \zeta) \begin{pmatrix} -1 & 0 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} U(K) & V(K) \\ W(K) & X(K) \end{pmatrix}.$$

The Ernst equations have to hold at K_1 and K_2 too. Hence, $\mathbf{\Phi}$ and $\mathbf{\Phi}'$ must be continuous in K_1 and K_2. Considering (28)–(31) and (41), we are led to the conditions

$$\begin{aligned} \begin{pmatrix} f_1 & -1 \\ f_1 + 2i\Omega_0(K - K_1) & -1 \end{pmatrix} \begin{pmatrix} F & 0 \\ G & 1 \end{pmatrix} &= \begin{pmatrix} f_1 & -1 \\ 2i\Omega_0(K - K_1) & 0 \end{pmatrix} \begin{pmatrix} U & V \\ W & X \end{pmatrix}, \\ \begin{pmatrix} f_2 & -1 \\ f_2 + 2i\Omega_0(K - K_2) & -1 \end{pmatrix} \begin{pmatrix} 1 & G \\ 0 & F \end{pmatrix} &= \begin{pmatrix} f_2 & -1 \\ 2i\Omega_0(K - K_2) & 0 \end{pmatrix} \begin{pmatrix} U & V \\ W & X \end{pmatrix}, \end{aligned} \tag{42}$$

where $f_1 = f(\zeta = K_1)$ and $f_2 = f(\zeta = K_2)$. Note that f_1 and f_2 are imaginary, see (36).

Eliminating the $UVWX$ matrix, we obtain

$$\mathcal{N} = \left(\mathbf{1} + \frac{\mathbf{F}_1}{2i\Omega_0(K - K_1)} \right) \left(\mathbf{1} + \frac{\mathbf{F}_2}{2i\Omega_0(K - K_2)} \right), \tag{43}$$

where

$$\mathbf{F}_1 = \begin{pmatrix} -f_1 & 1 \\ -f_1^2 & f_1 \end{pmatrix}, \quad \mathbf{F}_2 = \begin{pmatrix} f_2 & -1 \\ f_2^2 & -f_2 \end{pmatrix}, \tag{44}$$

$$\mathcal{N} = \begin{pmatrix} F & -G \\ G & (1 - G^2)/F \end{pmatrix}. \tag{45}$$

Obviously, the elements of $\mathcal{N}$ are regular everywhere in the complex K-plane with the exception of the two simple poles at K_1 and K_2 ($\Im K_1 = 0 = \Im K_2$). The sum of the off-diagonal elements in (45) must be zero. This requirement leads to the constraints

$$f_1 = -f_2, \quad \Omega_0 = \frac{i f_1 (1 + f_1^2)}{(K_1 - K_2)(1 - f_1^2)}. \tag{46}$$

$F(K)$ and $G(K)$ take the form

$$F(K)=\frac{4\Omega_0^2(K^2-K_1^2)+4\mathrm{i}\Omega_0 f_1 K-2f_1^2}{4\Omega_0^2(K^2-K_1^2)},\quad G(K)=\frac{4\mathrm{i}\Omega_0 K_1+2f_1}{4\Omega_0^2(K^2-K_1^2)}. \tag{47}$$

Here we have chosen $K_1=-K_2$, i.e., we have set the horizon in a symmetric position in the ρ, ζ-plane. Making use of (34) and (35) and eliminating Ω_0 by the second constraint equation we obtain the axis potential

$$\mathcal{A}^+:\quad f=\frac{\zeta(1+f_1^2)+(f_1^2-1+2f_1)K_1}{\zeta(1+f_1^2)+(1-f_1^2+2f_1)K_1}. \tag{48}$$

It can be useful to introduce the multipole moments mass M and angular momentum J by an asymptotic expansion of f,

$$M=\frac{1-f_1^2}{1+f_1^2}K_1,\quad \frac{J}{M}=\alpha=\frac{2\mathrm{i}f_1K_1}{1+f_1^2}, \tag{49}$$

and to replace f_1, K_1 in (47), (48) and (46):

$$F(K)=\frac{(K+M)^2+\alpha^2}{K^2+\alpha^2-M^2},\quad G(K)=\frac{2\mathrm{i}M\alpha}{K^2+\alpha^2-M^2}. \tag{50}$$

To represent $f(\zeta)$, a simplifying parametrization is advisible,

$$f_1=\mathrm{i}\tan\varphi/2,\quad \alpha=-M\sin\varphi,\quad K_1=-K_2=\sqrt{M^2-\alpha^2}=M\cos\varphi,\quad \varphi=\overline{\varphi}. \tag{51}$$

This yields

$$\mathcal{A}^+:\quad f=\frac{(\zeta-M)+\mathrm{i}M\sin\varphi}{(\zeta+M)+\mathrm{i}M\sin\varphi}. \tag{52}$$

Finally, the second constraint equation (46) becomes the well-known equation of state of black hole thermodynamics,

$$2M\Omega_0=\frac{M}{\alpha}-\sqrt{\frac{M^2}{\alpha^2}-1}, \tag{53}$$

connecting the angular velocity of the horizon with mass and angular momentum.

2. Two aligned black holes

The same procedure can be used to tackle the balance problem for two black holes. The question is whether the spin-spin repulsion of two aligned stationary black holes can compensate their gravitational attraction.

Here we have two horizons $\mathcal{H}_1$ and $\mathcal{H}_2$,

$$\mathcal{H}_1:\quad \rho=0,\ K_1\geqslant\zeta\geqslant K_2,\quad \mathcal{H}_2:\rho=0,\ K_3\geqslant\zeta\geqslant K_4, \tag{54}$$

separated by a piece of the regular symmetry axis $\mathcal{A}^0$,

$$\mathcal{A}^0:\quad K_2\geqslant\zeta\geqslant K_3. \tag{55}$$

As a characteristic black hole property, the norm of the Killing vectors of the co-rotating frameworks has to vanish along the horizons,

$$\mathcal{H}_1: \quad (\xi_i+\Omega_0^1\eta_i)(\xi^i+\Omega_0^1\eta^i)=0, \quad \mathcal{H}_2: \quad (\xi_i+\Omega_0^2\eta_i)(\xi^i+\Omega_0^2\eta^i)=0, \tag{56}$$

where Ω_0^1,Ω_0^2 are the constant angular velocities of the respective horizons.

Following the arguments for one black hole, we arrive at[13]

$$\mathcal{N}=\prod_{i=1}^{4}\left(\mathbf{1}+\frac{\mathbf{F}_i}{2\mathrm{i}\Omega_i(K-K_i)}\right), \tag{57}$$

where $\Omega_1=\Omega_2=\Omega_0^2$, $\Omega_3=\Omega_4=\Omega_0^2$ and

$$\mathbf{F}_i=(-1)^i\begin{pmatrix} f_i & -1 \\ f_i^2 & -f_i \end{pmatrix}, \tag{58}$$

whence

$$\begin{aligned} F(K)&=\frac{p_4(K)}{(K-K_1)(K-K_2)(K-K_3)(K-K_4)}, \\ G(K)&=\frac{p_2(K)}{(K-K_1)(K-K_2)(K-K_3)(K-K_4)}, \end{aligned} \tag{59}$$

where $p_4(K)$ and $p_2(K)$ are polynomials in K of the indicated orders. From (59) together with (34) and (35) we may read off the axis values of the Ernst potential. For the upper axis we obtain the structure

$$\mathcal{A}^+: \quad f(\zeta)=\frac{q_2(\zeta)}{Q_2(\zeta)}. \tag{60}$$

We need not use the representation of the explicit form of the second order polynomials $q_2(\zeta),Q_2(\zeta)$ and of the constraints resulting from $G=\mathcal{N}_{21}=-\mathcal{N}_{12}$. Namely, from the fact that $f(\zeta)$ is a quotient of polynomials of the same (even) order, it is clear that the desired two black hole solution can be generated by a Bäcklund transformation (in our case by a twofold Bäcklund transformation) from the Minkowski space. (Note that the axis values of the Ernst potential determine solutions of the Ernst equation in a unique way.)

The four constraints $\mathcal{N}_{21}=-\mathcal{N}_{12}$ ensure that the constants K_i, $f_i=-\overline{f_i}$ $(i=1,\ldots,4)$, Ω_0^1,Ω_0^2 may be expressed by two position parameters and the masses and angular momenta of the two black holes.

The Bäcklund generated solution belonging to (60) known as the ''double Kerr solution'' was intensively discussed by several authors.[14,15] It turned out that there are necessarily struts between the ''horizons.'' Since we have shown, by solving the boundary value problem, that Bäcklund generated solutions are the *only* candidates to describe aligned balanced black holes, we may now assert that black holes cannot be balanced at all.

3. Rigidly rotating disks of dust

Disks of dust can be considered to be extremely flattened spheroids [Fig. 2(a)] consisting of perfect fluid matter.[3] One can show that, for rigidly rotating dust, the boundary conditions (4) and (11) have to be complemented by the condition $b'=\mathfrak{I}f'=0$ on the disk ($\mathcal{B}$). This condition follows from the Einstein equations as a transition condition from a divergence-free part of those equations via Gauss's theorem.[3] Thus we have to take into consideration

$$\mathcal{A}^{\pm}: \text{ regularity of } f, \quad \mathcal{B}: \ f'=\mathrm{e}^{2V_0}, \quad \mathcal{C}: \ f\to 1, \tag{61}$$

see Fig. 2(a). On the disk, the linear problem of the co-rotating system of reference takes the form

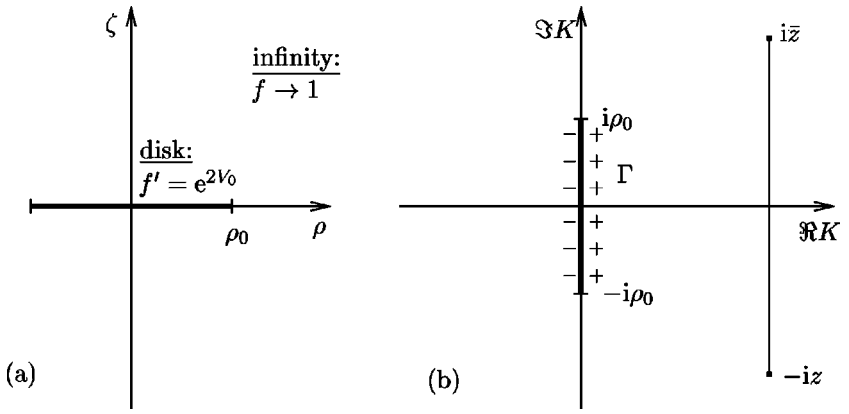

FIG. 2. (a) Boundary value problem for the rotating disk of dust, (b) two-sheeted K-surface of the rotating disk with branch points at $-iz, i\bar{z}$.[2]

$$\mathcal{B}: \quad \mathbf{\Phi}'_{,\rho} = -\frac{\rho}{\sqrt{K^2+\rho^2}(f'+\overline{f'})}\begin{pmatrix} 0 & \overline{f'}_{,\zeta} \\ f'_{,\zeta} & 0 \end{pmatrix}\mathbf{\Phi}', \tag{62}$$

where $\mathbf{\Phi}'$ and f' are the "co-rotating" $\mathbf{\Phi}$-matrix and the "co-rotating" Ernst potential on the disk. This relation must be discussed under the "boundary conditions"

$$\mathbf{\Phi}'(\rho=0,\zeta=0^+,\lambda)|_{\mathcal{B}} = \mathbf{\Phi}'(\rho=0,\zeta=0^+,\lambda)|_{\mathcal{A}^+},$$

cf. (30) and

$$\mathbf{\Phi}'(\rho=0,\zeta=0^-,\lambda)|_{\mathcal{B}} = \mathbf{\Phi}'(\rho=0,\zeta=0^-,\lambda)|_{\mathcal{A}^-},$$

cf. (31).

Again, this discussion allows the construction of $F(K)$ and $G(K)$ and, via (34) and (35), the construction of the axis values $f(\zeta)$ of the Ernst potential. We first take advantage of the symmetry of the problem which implies $\overline{f(\rho,\zeta)} = f(\rho,-\zeta)$ and connects the ζ-derivatives of f' above ($\zeta = 0^+$) and below ($\zeta = 0^-$) the disk

$$\mathcal{B}: \quad \overline{f'}_{,\zeta}|_{\zeta=0^+} = -f'_{,\zeta}|_{\zeta=0^-}. \tag{63}$$

As a consequence, the LP (62) connects the matrix $\overset{\mathrm{A}}{\mathbf{\Phi}}$ above the disk, $\overset{\mathrm{A}}{\mathbf{\Phi}} = \mathbf{\Phi}'(\rho,\zeta=0^+,K)$, with the matrix $\overset{\mathrm{B}}{\mathbf{\Phi}}$ below the disk, $\overset{\mathrm{B}}{\mathbf{\Phi}} = \mathbf{\Phi}'(\rho,\zeta=0^-,K)$,

$$\mathcal{B}: \quad \overset{\mathrm{A}}{\mathbf{\Phi}} = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}\overset{\mathrm{B}}{\mathbf{\Phi}}\mathbf{H}(K), \tag{64}$$

where the matrix $\mathbf{H}(K)$ (the "integration constant") does not depend on $\rho \in \mathcal{B}$. At the rim of the disk we have

$$\overset{\mathrm{A}}{\mathbf{\Phi}}(\rho_0,0,K) = \overset{\mathrm{B}}{\mathbf{\Phi}}(\rho_0,0,K) = \overset{\mathrm{r}}{\mathbf{\Phi}}. \tag{65}$$

Because of (64), the rim matrix $\overset{\mathrm{r}}{\mathbf{\Phi}}{}^{-1}\left(\begin{smallmatrix}0 & -1\\ 1 & 0\end{smallmatrix}\right)\overset{\mathrm{r}}{\mathbf{\Phi}}$ can be expressed in terms of $\overset{\mathrm{A}}{\mathbf{\Phi}}=\mathbf{\Phi}'(\rho,\zeta=0^+,K)$, $\overset{\mathrm{B}}{\mathbf{\Phi}}=\mathbf{\Phi}'(\rho,\zeta=0^-,K)$. Note that $\mathbf{\Phi}$ is considered to be a holomorphic function of λ and therefore a function living on the two-sheeted Riemann K-surface of Fig. 1(b). Hence we have to discuss the rim matrix as a function of K on both sheets.

Any $\mathbf{\Phi}$ multiplied from the right by a matrix function of K is again a solution of the LP. The discussion of the rim matrix simplifies after the following redefinition

$$\mathcal{R}=\begin{pmatrix}0 & 1\\ -1 & 0\end{pmatrix}\begin{pmatrix}F & 0\\ G & 1\end{pmatrix}\overset{\mathrm{r}}{\mathbf{\Phi}}{}^{-1}\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}\overset{\mathrm{r}}{\mathbf{\Phi}}\begin{pmatrix}F & 0\\ G & 1\end{pmatrix}^{-1}\begin{pmatrix}0 & 1\\ -1 & 0\end{pmatrix}^{-1}. \tag{66}$$

Using (30) and (31) we obtain

$$\mathcal{R}=\begin{cases}\mathrm{e}^{2V_0}\mathcal{M}\mathcal{S}^{-1} & \text{on the upper sheet,}\\ -\mathrm{e}^{2V_0}\mathcal{S}^{-1}\mathcal{M} & \text{on the lower sheet,}\end{cases} \tag{67}$$

where

$$\mathcal{M}=\begin{pmatrix}G(K) & (G^2-1)/F\\ -F(K) & -G(K)\end{pmatrix},\quad \mathcal{S}=\begin{pmatrix}f_0\overline{f_0}-4\Omega_0^2K^2 & \mathrm{i}b_0+2\mathrm{i}\Omega_0K\\ \mathrm{i}b_0-2\mathrm{i}\Omega_0K & -1\end{pmatrix} \tag{68}$$

and

$$f_0=\mathrm{e}^{2V_0}+\mathrm{i}b_0=f(\zeta=0^+). \tag{69}$$

Note that $\mathcal{M}=\left(\begin{smallmatrix}0 & -1\\ 1 & 0\end{smallmatrix}\right)\mathcal{N}\left(\begin{smallmatrix}-1 & 0\\ 0 & 1\end{smallmatrix}\right)$.

Obviously, $\operatorname{Tr}\mathcal{R}=\operatorname{Tr}\mathcal{R}^{-1}=0$ and $\mathcal{M}^2=\mathbf{1}$, whence

$$\operatorname{Tr}\mathcal{M}\mathcal{S}^{-1}=\operatorname{Tr}\mathcal{S}\mathcal{M}=0. \tag{70}$$

This relation interlinks $F(K)$ and $G(K)$ and, because of (34) and (35), real and imaginary parts of the axis values $f(\zeta)$ of the Ernst potential.[16,17]

We next wish to determine $F(K)$ and $G(K)$ which in turn determine $f(\zeta)$. To this end we consider $\mathbf{\Phi}(\rho,\zeta,\lambda)$, for fixed coordinates ρ, ζ as a function of λ. We have already used the initial conditions $\psi=\chi=1$ for some $\rho=\rho_0=0$, $\zeta=\zeta_0\in\mathcal{A}^+$ prescribed in one sheet ($\lambda=-1$) of the K-plane. In principle the behavior of $\mathbf{\Phi}$ in both sheets and at all points in the ρ, ζ-plane can be calculated by integrating the LP along a suitable path. However, the coefficients $A(\rho,\zeta)$, $B(\rho,\zeta)$ in the LP (17) are not explicitly known. Nevertheless, their regular behavior outside the disk together with the boundary values on the disk, cf. (61), provides us with defining properties for $\mathbf{\Phi}$. One of them may be taken from Fig. 1(b) together with Fig. 2(b): Since the domain of the disk, $0\leqslant\rho\leqslant\rho_0$, $\zeta=0^{\pm}$, is a nonvacuum domain, where the LP fails, $\mathbf{\Phi}$ at the branch point pairs $K=\mathrm{i}\rho+0^{\pm},-\mathrm{i}\rho+0^{\pm}$, $0\leqslant\rho\leqslant\rho_0$, cannot "pass" through the contour(s) $\Gamma:\Re K=0,-\rho_0\leqslant\Im K\leqslant\rho_0$, i.e., $\mathbf{\Phi}$ has a well-defined jump between opposite points along the contour(s) Γ, see Fig. 2. A careful discussion would show that $\mathbf{\Phi}(\rho,\zeta,\lambda)$, for fixed coordinate values ρ, ζ outside the disk ($\rho,\zeta\notin\mathcal{B}$), is a regular function in λ outside Γ and jumps along Γ, i.e., $\mathbf{\Phi}$ satisfies a (regular) Riemann–Hilbert problem.

Consider now the jump $\mathbf{\Phi}_+^{-1}\mathbf{\Phi}_-$, where the signs indicate the two sides of Γ, cf. Fig. 2(b). The LP tells us that $\mathbf{\Phi}_+^{-1}\mathbf{\Phi}_-$ does not depend on the coordinates and is therefore a function $\mathcal{D}$ of the contour alone,

$$\begin{aligned}\mathbf{\Phi}_+^{-1}\mathbf{\Phi}_-&=\mathcal{D}_{\mathrm{u}}(K),\quad K\in\Gamma_{\mathrm{u}},\\ \mathbf{\Phi}_+^{-1}\mathbf{\Phi}_-&=\mathcal{D}_{\mathrm{l}}(K),\quad K\in\Gamma_{\mathrm{l}},\end{aligned} \tag{71}$$

where u marks the upper and l the lower sheet. Since the jump contours Γ_u, Γ_l and the jump matrices $\mathcal{D}_u$, $\mathcal{D}_l$ are the same for all values of ρ, ζ (i.e., for all Riemann surfaces with different branch points), we may express $\mathcal{D}_u$ and $\mathcal{D}_l$ in terms of the axis values of $\mathbf{\Phi}$,

$$\mathcal{D}_u(K)=\begin{pmatrix} F_+ & 0 \\ G_+ & 1 \end{pmatrix}^{-1}\begin{pmatrix} F_- & 0 \\ G_- & 1 \end{pmatrix}, \quad K\in\Gamma_u. \tag{72}$$

A similar relation for $\mathcal{D}_l$ may be obtained via (24). As a consequence of (71) and (72) the matrix $\mathbf{\Phi}\left(\begin{smallmatrix} F & 0 \\ G & 1 \end{smallmatrix}\right)^{-1}$ does not jump along Γ_u. Because of (27) the same holds for $\mathbf{\Phi}'\left(\begin{smallmatrix} F & 0 \\ G & 1 \end{smallmatrix}\right)^{-1}$ and, finally, for $\mathcal{R}$ as defined in (66). Consider now the Riemann K-surface of the disk rim $\rho=\rho_0$, $\zeta=0$. The cut between the branch points $K_B=\pm i\rho_0$ coincides with the contour Γ_u, Γ_l which are on the two "bridges" connecting crosswise the upper with the lower sheet. Since $\mathcal{R}$ does not jump on Γ_u, we have, according to (67), $(\mathcal{M}\mathcal{S}^{-1})_-=-(\mathcal{S}^{-1}\mathcal{M})_+$. Though $\mathcal{R}$ does not jump, F and G do jump, cf. (72). Note that $F(K)$ and $G(K)$ are unique functions of K. Hence, there is only one contour $\Gamma:\Re K=0,-\rho_0\leqslant\Im K\leqslant\rho_0$, where $\mathcal{M}$ [with the elements $F(K)$, $G(K)$] does jump. Since $\mathbf{\Phi}$ is analytic outside Γ_u,Γ_l, the matrix $\mathcal{M}$ must be analytic outside Γ. Thus we obtain $F(K)$ and $G(K)$ from the Riemann–Hilbert problem,

$$\begin{aligned} &K\in\Gamma: \quad \mathcal{S}\mathcal{M}_-=-\mathcal{M}_+\mathcal{S}, \\ &K\notin\Gamma: \quad \mathcal{M}(K) \text{ analytic in } K, \end{aligned} \tag{73}$$

$\mathcal{S}$ and $\mathcal{M}$ as in (68). (Note that the elements of $\mathcal{S}$, which are polynomials, and the elements of $\mathcal{S}^{-1}$, which are rational functions in K, do not jump along Γ.) There is no jump at the end points of the contour $K=\pm i\rho_0$, $\mathcal{M}(\pm i\rho_0)_-=\mathcal{M}(\pm i\rho_0)_+$. As a consequence, one obtains $\operatorname{Tr}\mathcal{S}(\pm i\rho_0)=0$, i.e., the parameter relation

$$f_0\overline{f_0}+4\Omega_0^2\rho_0^2=1. \tag{74}$$

It turns out that the Riemann–Hilbert problem (73) has a unique solution $\mathcal{M}(K)$ in the parameter region

$$0\leqslant\mu=2\Omega_0^2e^{-2V_0}\rho_0^2<\mu_0=4.629\,661\,84\ldots\,. \tag{75}$$

An important step on the way to this solution is the diagonalization of $\mathcal{S}$. Finally, one obtains $F(K)$, $G(K)$ and the axis values of the Ernst potential $f(\zeta)$ in terms of elliptic theta functions. We need not go this road. As we shall see in the next section, we can use the Riemann–Hilbert problem (73) to formulate a more general Riemann–Hilbert problem which will yield the complete disk of dust solution in terms of hyperelliptic theta functions.

VI. ERNST POTENTIAL EVERYWHERE

A. Kerr solution

In the preceding section, we analyzed the axis values of the Ernst potential. We will now construct the complete solutions $f(\rho,\zeta)$ of our boundary value problems from the information about the behavior along the axis of symmetry gained by the discussion of the direct problem.

There is, of course, no question that the discussion of the black hole case in Sec. V B 1 will lead to the famous Kerr solution [in Weyl coordinates (1)]. The point made here is that this solution describing the stationary rotating black hole can be derived from a boundary value problem.

To achieve our goal it is useful to exploit the gauge freedom of multiplying $\mathbf{\Phi}$ from the right by an arbitrary matrix funktion of K. The transformation

$$\tilde{\mathbf{\Phi}}=\frac{K^2-\alpha^2-M^2}{K[(K+M)^2+\alpha^2]}\mathbf{\Phi}\begin{pmatrix}K+m & \mathrm{i}\alpha\\ \mathrm{i}\alpha & K+m\end{pmatrix} \tag{76}$$

preserves the properties (22)–(25) and enables the calculation of f via (26). Because of (36), (50), (28) and (18), the determinant of $\tilde{\mathbf{\Phi}}$ becomes

$$\det\tilde{\mathbf{\Phi}}=\gamma\frac{(K+\mathrm{i}z)^2}{K^2}(\lambda^2-\lambda_1^2)(\lambda^2-\lambda_2^2),\quad \gamma=\gamma(\rho,\zeta)=-\frac{2\mathrm{e}^{2U(\rho,\zeta)}}{(1-\lambda_1^2)(1-\lambda_2^2)}, \tag{77}$$

where

$$\lambda_i^2=\frac{K_i-\mathrm{i}\overline{z}}{K_i+\mathrm{i}z}\quad (i=1,2). \tag{78}$$

This form of the determinant together with the axis values of $\tilde{\mathbf{\Phi}}$ tells us that $\tilde{\mathbf{\Phi}}$ must be a quadratic matrix polynomial of λ,

$$\tilde{\mathbf{\Phi}}=\frac{K+\mathrm{i}z}{K}(\mathbf{C}+\mathbf{D}\lambda+\mathbf{E}\lambda^2), \tag{79}$$

where the 2×2 matrices $\mathbf{C}$, $\mathbf{D}$, $\mathbf{E}$ are functions of ρ, ζ alone. It can be shown[18] that $\tilde{\mathbf{\Phi}}$ with (77) satisfies the LP. (It is a Bäcklund transformation of the trivial solution $f=1$.)

According to (77), $\tilde{\mathbf{\Phi}}(\rho,\zeta,\lambda_i)$ $(i=1,2)$ must have a null eigenvector b_i in the zeros λ_i,

$$\tilde{\mathbf{\Phi}}(\rho,\zeta,\lambda_i)b_i=0\quad (i=1,2). \tag{80}$$

From the LP it follows that the elements of b_i have to be constants. Hence, the quotient

$$\frac{\tilde{\chi}(\rho,\zeta,\lambda)}{\tilde{\chi}(\rho,\zeta,-\lambda)}=-\frac{C_{21}+D_{21}\lambda+E_{21}\lambda^2}{C_{21}-D_{21}\lambda+E_{21}\lambda^2}, \tag{81}$$

where the coefficients are elements of the matrices $\mathbf{C}$, $\mathbf{D}$, $\mathbf{E}$ must be a constant at $\lambda=\lambda_i$ $(i=1,2)$. The values of the two constants $(i=1,2)$ can be read off from the axis values of $\tilde{\mathbf{\Phi}}$ resulting from (81) together with (28), (29), (50), (51) and (76),

$$\frac{\tilde{\chi}(\lambda_1)}{\tilde{\chi}(-\lambda_1)}=-\mathrm{i}\cot\frac{\varphi}{2},\quad \frac{\tilde{\chi}(\lambda_2)}{\tilde{\chi}(-\lambda_2)}=\mathrm{i}\cot\frac{\varphi}{2}. \tag{82}$$

Note that $\tilde{\chi}(-1)=1$ implies

$$C_{21}-D_{21}+E_{21}=1. \tag{83}$$

These three conditions fix the coefficients C_{21}, D_{21}, E_{21} via a linear algebraic system. Finally, we obtain the Ernst potential everywhere from $f=\tilde{\chi}(1)/\tilde{\chi}(-1)$,

$$f(\rho,\zeta)=\frac{r_1\mathrm{e}^{\mathrm{i}\varphi}+r_2\mathrm{e}^{\mathrm{i}\varphi}-2M\cos\varphi}{r_1\mathrm{e}^{\mathrm{i}\varphi}+r_2\mathrm{e}^{\mathrm{i}\varphi}+2M\cos\varphi}, \tag{84}$$

where

$$r_i^2=(K_i-\zeta)^2+\rho^2\quad (i=1,2)$$

with $K_1=-K_2$ and φ as in (51). This is the Ernst potential f of the Kerr solution in Weyl–Papapetrou coordinates. By virtue of (15) and (16), this potential determines all metric coefficients in the line element (1).

B. Disk of dust solution

In order to construct the $\mathbf{\Phi}$-matrix for arbitrary values of ρ, ζ and λ, let us return to the Riemann–Hilbert problem (73). As we have seen, the matrix $\mathbf{\Phi}\left(\begin{smallmatrix}F & 0\\ G & 1\end{smallmatrix}\right)^{-1}$ does not jump along Γ_u. Analogously, $\mathbf{\Phi}\left(\begin{smallmatrix}1 & G\\ 0 & F\end{smallmatrix}\right)^{-1}$ does not jump along Γ_l. The images Γ_λ of Γ_u and $\Gamma_{-\lambda}$ of Γ_l inherit these properties, which are essential to the following deductions.

To formulate a Riemann-Hilbert problem in the λ-plane, we define two matrices,

$$\begin{aligned}\mathcal{L}:&=\mathbf{\Phi}\begin{pmatrix}1 & G\\ 0 & F\end{pmatrix}^{-1}\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}\mathcal{M}\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}\begin{pmatrix}1 & G\\ 0 & F\end{pmatrix}\mathbf{\Phi}^{-1}\\ &=\mathbf{\Phi}\begin{pmatrix}F & 0\\ G & 1\end{pmatrix}^{-1}\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}\mathcal{M}\begin{pmatrix}0 & 1\\ -1 & 0\end{pmatrix}\begin{pmatrix}F & 0\\ G & 1\end{pmatrix}\mathbf{\Phi}^{-1}\\ &=\mathbf{\Phi}\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix}\mathbf{\Phi}^{-1},\end{aligned}\tag{85}$$

$$\begin{aligned}\mathcal{Q}:&=\mathrm{e}^{-2V_0}\mathbf{\Phi}\begin{pmatrix}1 & G\\ 0 & F\end{pmatrix}^{-1}\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}(\mathcal{S}+w\mathbf{1})\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}\begin{pmatrix}1 & G\\ 0 & F\end{pmatrix}\mathbf{\Phi}^{-1}\\ &=\mathrm{e}^{-2V_0}\mathbf{\Phi}\begin{pmatrix}F & 0\\ G & 1\end{pmatrix}^{-1}\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}(\mathcal{S}+w\mathbf{1})\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}\begin{pmatrix}F & 0\\ G & 1\end{pmatrix}\mathbf{\Phi}^{-1},\end{aligned}\tag{86}$$

where

$$w=-\tfrac{1}{2}\mathrm{Tr}\,\mathcal{S}=2\Omega_0^2(K^2+\rho_0^2).$$

Here we have made use of the parameter relation (74). Since $\mathcal{S}$ and w are polynomials in K and therefore rational functions in λ, the matrix $\mathcal{Q}$ has no jump at all. Taking the asymptotics of S and w into account, $\mathcal{Q}$ must take the following polynomial structure in λ:

$$\mathcal{Q}=(K+\mathrm{i}z)^2\begin{pmatrix}q_1 & q_2\\ q_3 & -q_2\end{pmatrix},\quad q_1=k\lambda+l\lambda^3,\quad q_2=m+n\lambda^2+p\lambda^4,\quad q_3=q+r\lambda^2+s\lambda^4,\tag{87}$$

where $k,l,m,n,p;q,r,s$ are functions of ρ, ζ alone. From the definitions (85), (86) and the condition (70), we may derive

$$\mathcal{Q}\mathcal{L}=-\mathcal{L}\mathcal{Q},\tag{88}$$

whereas the particular Riemann-Hilbert problem (73) has the continuation

$$\begin{aligned}&\lambda\in\Gamma_\lambda:\quad(\mathcal{Q}+\mathrm{e}^{-2V_0}w\mathbf{1})\mathcal{L}_-=-\mathcal{L}_+(\mathcal{Q}+\mathrm{e}^{-2V_0}w\mathbf{1}),\\ &\lambda\in\Gamma_{-\lambda}:\quad(\mathcal{Q}-\mathrm{e}^{-2V_0}w\mathbf{1})\mathcal{L}_-=-\mathcal{L}_+(\mathcal{Q}-\mathrm{e}^{-2V_0}w\mathbf{1}),\\ &\lambda\notin\Gamma_\lambda,\Gamma_{-\lambda}:\quad\mathcal{L}\ \text{analytic in}\ \lambda.\end{aligned}\tag{89}$$

The following solution of the regular Riemann–Hilbert problem (89) is based on the diagonalization of $\mathcal{Q}$.

We consider a function Ψ defined by

$$\Psi := \frac{1}{\sqrt{w^2+\mathrm{e}^{4V_0}}} \ln \frac{\hat{\mathcal{L}}_{22}+\sqrt{1+w^2\mathrm{e}^{-4V_0}}\,\hat{\mathcal{L}}_{21}}{\hat{\mathcal{L}}_{22}-\sqrt{1+w^2\mathrm{e}^{-4V_0}}\hat{\mathcal{L}}_{21}}, \tag{90}$$

where

$$\hat{\mathcal{L}} = \mathcal{L}\begin{pmatrix} 1 & \mathcal{Q}_{11} \\ 0 & \mathcal{Q}_{21} \end{pmatrix}. \tag{91}$$

Note that Ψ has no branch points at the zeroes K_1, K_2, $\overline{K_1}=-K_2$ and $\overline{K_2}=-K_1$ of $w^2+\mathrm{e}^{4V_0}$,

$$K_1^2=\rho_0^2\frac{\mathrm{i}-\mu}{\mu},\quad K_2^2=\rho_0^2\frac{\mathrm{i}+\mu}{\mu}\,[\Re K_1<0,\ \Re K_2>0,\quad \mu \text{ as in (75)}] \tag{92}$$

(Ψ is unaffected by a change in the sign of $\sqrt{w^2+\mathrm{e}^{4V_0}}$). It is an odd function of λ (vanishing at $\lambda=0$ and at $\lambda=\infty$). Therefore, the function

$$\hat{\Psi}=\Psi/[\lambda(K+\mathrm{i}z)]=\Psi/\sqrt{(K-\mathrm{i}\overline{z})(K+\mathrm{i}z)} \tag{93}$$

can be discussed as a unique function of K with the following properties:

(i) Along Γ, because of (89), it jumps according to

$$\hat{\Psi}_-=\hat{\Psi}_+ + \frac{2}{\sqrt{(K-\mathrm{i}\overline{z})(K+\mathrm{i}z)}\sqrt{w^2+\mathrm{e}^{4V_0}}} \ln \frac{\sqrt{w^2+\mathrm{e}^{4V_0}}+w}{\sqrt{w^2+\mathrm{e}^{4V_0}}-w}. \tag{94}$$

(ii) Because of

$$\hat{\mathcal{L}}_{21}^2(1+w^2\mathrm{e}^{-4V_0})-\hat{\mathcal{L}}_{22}^2=\mathcal{Q}_{21}^2, \tag{95}$$

$$\mathcal{Q}_{21}=-\frac{2\,f\Omega_0^2\mathrm{e}^{-2V_0}}{f+\overline{f}}(K-K_a)(K-K_b), \tag{96}$$

the behavior for $K\to K_{a/b}$ is given by

$$\hat{\Psi}\to\frac{\pm 2}{\sqrt{(K_{a/b}-\mathrm{i}\overline{z})(K_{a/b}+\mathrm{i}z)(w_{a/b}^2+\mathrm{e}^{4V_0})}}\ln(K-K_{a/b}) \quad \text{as} \quad K\to K_{a/b}. \tag{97}$$

(The ambiguity of sign can be compensated for by the square root.)

(iii) The behavior for $K\to\infty$, because of the definitions of $\mathcal{Q}$ and $\mathcal{L}$, is given by

$$\hat{\Psi}\to\frac{\ln f}{\Omega^2K^3}\text{as}\quad K\to\infty. \tag{98}$$

These properties are realized by the following representation of $\hat{\Psi}$:

$$\hat{\Psi}=\frac{1}{\pi \mathrm{i}}\int_{-\mathrm{i}\rho_0}^{\mathrm{i}\rho_0}\frac{\ln[(\sqrt{w'^2+\mathrm{e}^{4V_0}}+w')/(\sqrt{w'^2+\mathrm{e}^{4V_0}}-w')]}{\sqrt{(K'-\mathrm{i}\bar{z})(K'+\mathrm{i}z)}\sqrt{w'^2+\mathrm{e}^{4V_0}}(K'-K)}\,\mathrm{d}K'$$
$$-2\int_{K_1}^{K_a}\frac{1}{\sqrt{(K'-\mathrm{i}\bar{z})(K'+\mathrm{i}z)(w'^2+\mathrm{e}^{4V_0})}(K'-K)}\,\mathrm{d}K'$$
$$-2\int_{K_2}^{K_b}\frac{1}{\sqrt{(K'-\mathrm{i}\bar{z})(K'+\mathrm{i}z)(w'^2+\mathrm{e}^{4V_0})}(K'-K)}\,\mathrm{d}K', \tag{99}$$

where K_a and K_b have to be determined such that $\hat{\Psi}=\mathcal{O}(K^{-3})$. The lower limits of integration in the last two integrals have been fixed to obtain the correct result in the Newtonian limit $\mu\to 0$ where $K_a/K_1=1+\mathcal{O}(\mu^2)$ and $K_b/K_2=1+\mathcal{O}(\mu^2)$. (A systematic post-Newtonian expansion of the solution is given in Ref. 19.) Note that the last two terms in Eq. (99) may also be interpreted as follows,

$$2\left(\int_{K_1}^{K_a}+\int_{K_2}^{K_b}\right)=2\left(\int_{K_a}^{K_1}\{-\}+\int_{K_2}^{K_b}\right)=\int_{K_a}^{K_b}\{1\}+\int_{K_a}^{K_b}\{2\}, \tag{100}$$

showing that nothing special happens at K_1 and K_2. In this symbolic notation $\{-\}$ indicates that the square root is meant to have the opposite sign with reference to the first term; $\{1\}$ and $\{2\}$ denote different paths in the complex K-plane, which are chosen such that the closed integral

$$\oint=\int_{K_a}^{K_b}\{1\}-\int_{K_a}^{K_b}\{2\}=2\int_{K_1}^{K_2} \tag{101}$$

is performed around a contour enclosing the branch points K_1 and K_2 of $\sqrt{w^2+\mathrm{e}^{4V_0}}$. In the subsequent formulas we normalize K and introduce

$$X=\frac{K}{\rho_0},\quad X_{a/b}=\frac{K_{a/b}}{\rho_0},\quad X_{1/2}=\frac{K_{1/2}}{\rho_0}. \tag{102}$$

An asymptotic expansion of Eq. (99) for $X\to\infty$ $(K\to\infty)$ leads, according to (98), to

$$\ln f=\mu\left[\int_{X_1}^{X_a}\frac{X^2\,\mathrm{d}X}{W}+\int_{X_2}^{X_b}\frac{X^2\,\mathrm{d}X}{W}-\int_{-\mathrm{i}}^{\mathrm{i}}\frac{hX^2\,\mathrm{d}X}{W_1}\right], \tag{103}$$

$$\int_{X_1}^{X_a}\frac{\mathrm{d}X}{W}+\int_{X_2}^{X_b}\frac{\mathrm{d}X}{W}=\int_{-\mathrm{i}}^{\mathrm{i}}\frac{h\mathrm{d}X}{W_1},\qquad \int_{X_1}^{X_a}\frac{X\,\mathrm{d}X}{W}+\int_{X_2}^{X_b}\frac{X\,\mathrm{d}X}{W}=\int_{-\mathrm{i}}^{\mathrm{i}}\frac{hX\mathrm{d}X}{W_1}, \tag{104}$$

where the lower integration limits X_1, X_2 are given by

$$X_1^2=\frac{\mathrm{i}-\mu}{\mu},\quad X_2^2=-\frac{\mathrm{i}+\mu}{\mu}\quad(\Re X_1<0,\quad \Re X_2>0), \tag{105}$$

whereas the upper limits X_a, X_b must be calculated from the integral equations (104). Here we have introduced the abbreviations

$$W=W_1W_2,\quad W_1=\sqrt{(X-\zeta/\rho_0)^2+(\rho/\rho_0)^2},\quad W_2=\sqrt{1+\mu^2(1+X^2)^2}, \tag{106}$$

and

$$h=\frac{\ln(\sqrt{1+\mu^2(1+X^2)^2}+\mu(1+X^2))}{\pi\mathrm{i}\sqrt{1+\mu^2(1+X^2)^2}}. \tag{107}$$

The third integral in (103) as well as the integrals on the right-hand sides in (104) have to be taken along the imaginary axis in the complex X-plane with h and and W_1 fixed according to $\Re W_1<0$ (for ρ, ζ outside the disk) and $\Re h=0$. The task of calculating the upper limits X_a, X_b in (104) from

$$u=\int_{-\mathrm{i}}^{\mathrm{i}}\frac{h\,dX}{W_1},\quad v=\int_{-\mathrm{i}}^{\mathrm{i}}\frac{hXdX}{W_1} \tag{108}$$

is known as Jacobi's inversion problem. Göpel[20] and Rosenhain[21] were able to express the hyperelliptic functions $X_a(u,v)$ and $X_b(u,v)$ in terms of (hyperelliptic) theta functions. Later on it turned out that even the first two integrals in (103) can be expressed by theta functions in u and v! A detailed introduction into the related mathematical theory which was founded by Riemann and Weierstraß may be found in Refs. 22–24. The representation of the Ernst potential (103) in terms of theta functions can be be taken from Stahl's book [see Ref. 22, p. 311, Eq. (5)]. Here is the result: Defining a theta function $\vartheta(x,y;p,q,\alpha)$ by

$$\vartheta(x,y;p,q,\alpha)=\sum_{m=-\infty}^{\infty}\sum_{n=-\infty}^{\infty}(-1)^{m+n}p^{m^2}q^{n^2}\mathrm{e}^{2mx+2ny+4mn\alpha} \tag{109}$$

one can reformulate the expressions (103) and (104) to give

$$f=\frac{\vartheta(\alpha_0u+\alpha_1v-C_1,\beta_0u+\beta_1v-C_2;p,q,\alpha)}{\vartheta(\alpha_0u+\alpha_1v+C_1,\beta_0u+\beta_1v+C_2;p,q,\alpha)}\,\mathrm{e}^{-(\gamma_0u+\gamma_1v+\mu w)} \tag{110}$$

with u and v as in (108) and

$$w=\int_{-\mathrm{i}}^{\mathrm{i}}\frac{hX^2\mathrm{d}X}{W_1}. \tag{111}$$

The normalization parameters α_0, α_1; β_0, β_1; γ_0, γ_1, the moduli p, q, α of the theta function and the quantities C_1, C_2 are defined on the two sheets of the hyperelliptic Riemann surface related to

$$W=\mu\sqrt{(X-X_1)(X-\overline{X_1})(X-X_2)(X-\overline{X_2})(X-\mathrm{i}\overline{z}/\rho_0)(X+\mathrm{i}z/\rho_0)}, \tag{112}$$

see Fig. 3. There are two normalized Abelian differentials of the first kind,

$$\mathrm{d}\omega_1=\alpha_0\frac{\mathrm{d}X}{W}+\alpha_1\frac{X\mathrm{d}X}{W}, \tag{113}$$

$$\mathrm{d}\omega_2=\beta_0\frac{\mathrm{d}X}{W}+\beta_1\frac{X\mathrm{d}X}{W}, \tag{114}$$

defined by

$$\oint_{a_m}\mathrm{d}\omega_n=\pi\mathrm{i}\,\delta_{mn}\quad(m=1,2;\,n=1,2). \tag{115}$$

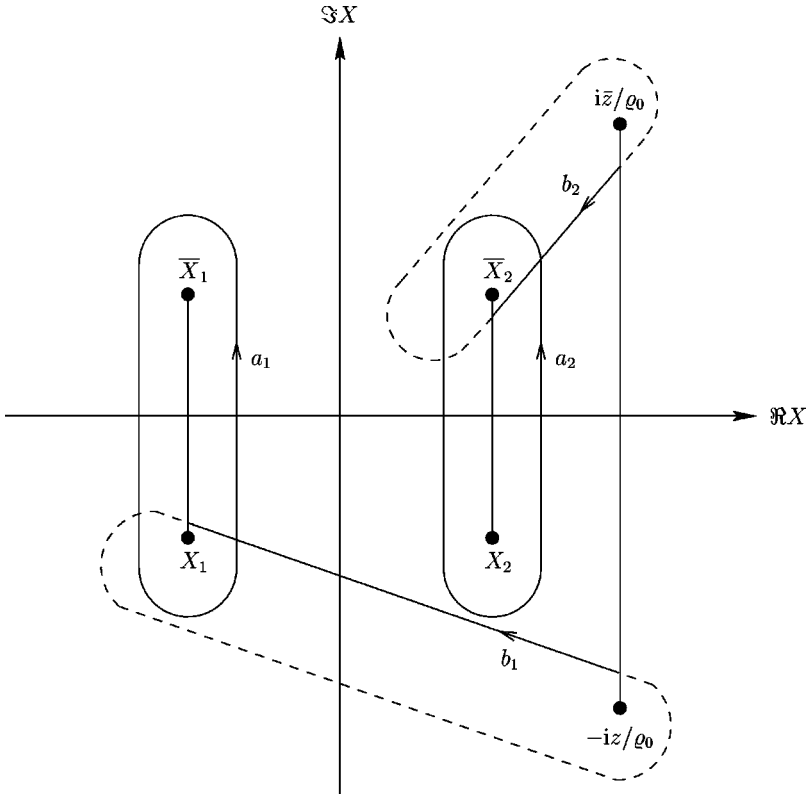

FIG. 3. Riemann surface with cuts between the branch points X_1 and $\overline{X}_1$, X_2 and $\overline{X}_2$, $-\mathrm{i}z/\rho_0$ and $\mathrm{i}\overline{z}/\rho_0$. Also shown are the four periods a_i and b_i $(i=1,2)$. (Continuous/dashed lines belong to the upper/lower sheet defined by $W\to\pm\mu X^3$ as $X\to\infty$.)[3]

Equation (115) consists of four linear algebraic equations and yields the four parameters α_0, α_1, β_0, β_1 in terms of integrals extending over the closed (deformable) curves a_1, a_2. It can be shown that there is one normalized Abelian differential of the third kind,

$$\mathrm{d}\omega=\gamma_0\frac{\mathrm{d}X}{W}+\gamma_1\frac{X\mathrm{d}X}{W}+\mu\frac{X^2\mathrm{d}X}{W}, \tag{116}$$

with vanishing a-periods,

$$\oint_{a_j}\mathrm{d}\omega=0 \qquad (j=1,2). \tag{117}$$

This equation defines γ_0, γ_1 (again via a linear algebraic system). The Riemann matrix

$$(B_{ij})=\begin{pmatrix}\ln p & 2\alpha\\ 2\alpha & \ln q\end{pmatrix} \qquad (i=1,2;\ j=1,2) \tag{118}$$

(with negative definite real part) is given by

$$B_{ij}=\oint_{b_i}d\omega_j \tag{119}$$

and defines the moduli p, q, α of the theta function (109). Finally, the quantities C_1, C_2 can be calculated by

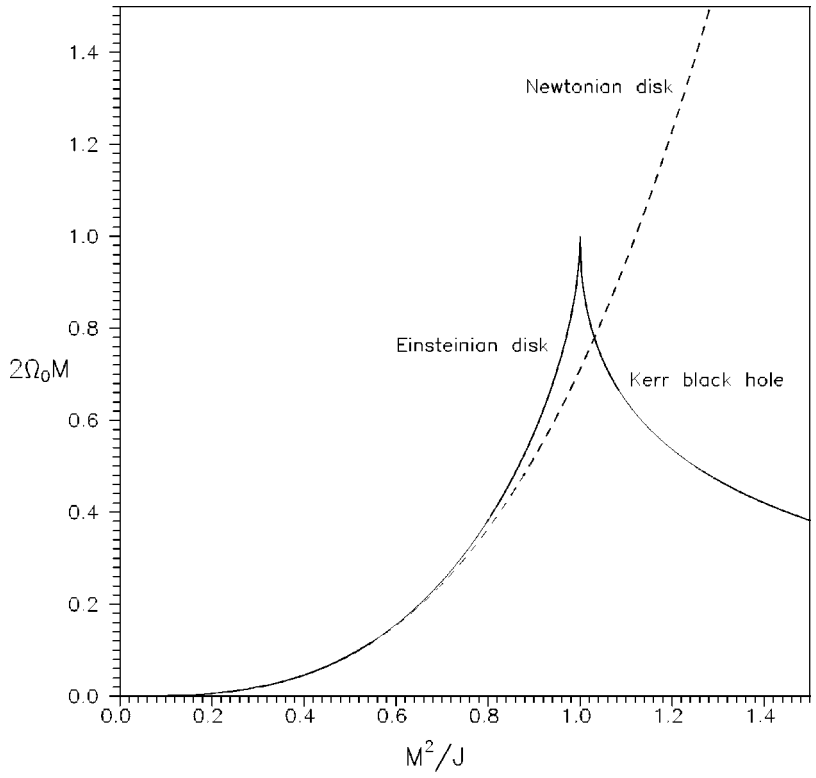

FIG. 4. Relation between $2\Omega_0 M$ and M^2/J for the classical Maclaurin disk (dashed line), the general-relativistic dust disk and the Kerr black-hole.[17]

$$C_i = -\int_{-\mathrm{i}z/\rho_0}^{\infty^+} \mathrm{d}\omega_i \quad (i=1,2), \tag{120}$$

where $+$ denotes the upper sheet. Obviously, all the quantities entering the theta functions and the exponential function in (110) can be expressed in terms of well-defined integrals and depend on the three parameters ρ/ρ_0, ζ/ρ_0, μ. The corresponding "tables" for α_i, β_i, γ_i, C_i, B_{ij}, u, v, w can easily be calculated by numerical integrations. Fortunately, theta series like (109) converge rapidly. For $0<\mu<\mu_0$, the solution (110) is analytic *everywhere* outside the disk—even at the rings $-\mathrm{i}z/\rho_0 = X_1$, X_2. The complete metric, calculated according to (1) and (14)–(16), is given in the Appendix.

In the framework of the completely integrable evolution equations, the solution (110) may be interpreted as a "Bäcklund-like" transformation of well-defined "seed" solutions u,v,w satisfying axisymmetric Laplace equations. The transformation "parameters" $\alpha_0,\beta_0;\alpha_1,\beta_1;\gamma_0,\gamma_1;$ $p,q,\alpha;C_1,C_2$ depend on the six branch points of the two-sheeted Riemann K-surface associated with the function $W=W(X)$, cf. (106), and do not depend on u,v,w. All in all, f is a function of the two parameters ρ_0 and μ and the two cylindrical coordinates ρ and ζ. For $\mu \ll 1$ we obtain the Maclaurin disk as the Newtonian limit.

VII. PHYSICAL DISCUSSION

Since the Kerr black hole is also a two-parameter solution, it might be interesting to compare the behavior of both solutions in dependence on common parameters, say, on mass M and angular momentum J. It must be possible to express the area of the horizon and the disk, the radius ρ_0 of the disk or other physical quantities in terms of M and J. A very illustrative relation is the angular

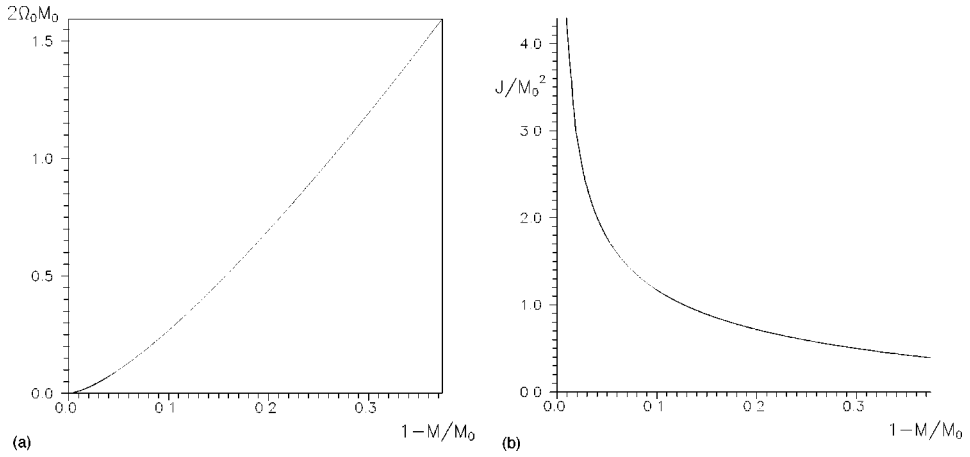

FIG. 5. (a) $\Omega_0 M_0$ and (b) J/M_0^2 as functions of the relative binding energy $(M_0-M)/M_0$ for the disk of dust.[2]

velocity Ω_0 as a function of M and J, since Ω_0 is defined in both cases. For black holes, we have derived the explicit expression (53). Surprisingly, the corresponding disk of dust relation has the same scaling behavior, i.e., $M\Omega_0$ is a function of M^2/J alone. Figure 4 shows this dependence for both solutions.[17] For $M^2/J \to 1$ (corresponding to $\mu \to \mu_0$), where the disk solution becomes identical with the extreme Kerr solution outside the horizon $(\rho^2+\zeta^2>0)$, there is a "phase transition" between the disk and the black hole. Note that for nonvanishing Ω_0, $\rho_0 \to 0$ as $\mu \to \mu_0$. A detailed analysis of the disk solution for $\mu \to \mu_0$, including the discussion of a different, nonasymptotically flat limit of space–time, which is obtained for finite ρ/ρ_0 and ζ/ρ_0 $(\rho^2+\zeta^2 = 0\,!)$, can be found in Ref. 25.

We remark that (110) solves the Bardeen–Wagoner problem[26] explicitly. All metric coefficients in (1) are analytic in ρ, ζ outside the disk and continuous through the disk. From a physical point of view we have an extremely flattened rigidly rotating body and, likewise, a rotating continuous distribution of mass points interacting via gravitational forces alone ("galaxy" model). Figure 5 illustrates the "parametric" collapse of a disk with the total mass-energy M, the baryonic mass M_0, the angular velocity Ω_0 and the angular momentum J towards the black hole limit $(1-M/M_0 = 0.373\,283\,5\ldots)$. Imagine a disk consisting of a fixed number of baryons (fixed M_0): Occupying states with decreasing energy M, it would shrink, thereby shedding angular momentum but increasing its angular velocity. The above mentioned limit of the relative binding energy $1-M/M_0$ corresponds to the extreme black hole limit. Additional physical effects (ergozones, dragging effects, surface mass density,...) as well as further parameter relations have been discussed in Refs. 3 and 27.

The methods outlined in this article could be used to construct self-gravitating disks around a central black hole.

ACKNOWLEDGMENTS

We wish to thank Andreas Kleinwächter for numerous discussions and Jörg Hennig for technical assistance.

APPENDIX: METRIC OF THE RIGIDLY ROTATING DISK OF DUST

The metric functions e^{2U}, a, e^{2k} calcutated from the Ernst potential (110) via (14)–(16) are given as follows:

$$e^{2U}=\frac{\vartheta(\mathbf{c})\vartheta^*(\mathbf{c})\vartheta(\mathbf{a})\vartheta^*(\mathbf{a})}{\vartheta(\mathbf{0})\vartheta^*(\mathbf{0})\vartheta(\mathbf{a}+\mathbf{c})\vartheta^*(\mathbf{a}+\mathbf{c})}e^{-(\gamma_0 u+\gamma_1 v+\mu w)},$$

$$1+\frac{(1+\Omega_0 a)e^{2U}}{\Omega_0\rho}=\frac{\vartheta(\mathbf{0})\vartheta^*(\mathbf{0})\vartheta(\mathbf{a}+2\mathbf{c})\vartheta^*(\mathbf{a})}{\vartheta(\mathbf{c})\vartheta^*(\mathbf{0})\vartheta(\mathbf{a}+\mathbf{c})\vartheta^*(\mathbf{a}+\mathbf{c})},$$

$$e^{2k(\rho,\zeta)}=\frac{\kappa(\rho,\zeta)}{\kappa(0,0)},$$

with

$$\kappa(\rho,\zeta)=\frac{\vartheta(\mathbf{a})\vartheta^*(\mathbf{a})}{\vartheta(\mathbf{0})\vartheta^*(\mathbf{0})}\exp\left(2k_0-\frac{1}{2}\sum_{i,k=1}^{2}a_i a_k\frac{\partial^2\ln\vartheta(\mathbf{x})\vartheta^*(\mathbf{x})}{\partial x_i\partial x_k}\bigg|_{\mathbf{x}=\mathbf{0}}\right),$$

where

$$2k_0=\frac{\mu^2}{4}\int_{-i}^{i}\int_{-i}^{i}dX\,dX'\frac{(\lambda-\lambda')^2}{\lambda\lambda'}\frac{h(X)h(X')(X-X_1)(X-X_2)(X'+X_1)(X'+X_2)}{(X-X')^2},$$

$$\lambda=\sqrt{\frac{X-iz/\rho_0}{X+iz/\rho_0}},\quad \lambda'=\sqrt{\frac{X'-iz/\rho_0}{X'+iz/\rho_0}},$$

$$\vartheta(\mathbf{x})=\vartheta(\mathbf{x};p,q,\alpha)=\vartheta(x_1,x_2;p,q,\alpha),$$

$$\vartheta^*(\mathbf{x})=\vartheta\left(x_1+\frac{i\pi}{2},x_2+\frac{i\pi}{2};p,q,\alpha\right),$$

$$\mathbf{a}=(a_1,a_2)=(\alpha_0 u+\alpha_1 v,\beta_0 u+\beta_1 v),\quad \mathbf{0}=(0,0),\quad \mathbf{c}=(C_1,C_2).$$

(Received 15 January 2003; accepted 9 April 2003)

We review the hierarchy for the hyper-Kähler equations and define a notion of symmetry for solutions of this hierarchy. A four-dimensional hyper-Kähler metric admits a hidden symmetry if it embeds into a hierarchy with a symmetry. It is shown that a hyper-Kähler metric admits a hidden symmetry if it admits a certain Killing spinor. We show that if the hidden symmetry is tri-holomorphic, then this is equivalent to requiring symmetry along a higher time and the hidden symmetry determines a ''twistor group'' action as introduced by Bielawski [*Twistor Quotients of Hyper-Kähler Manifolds* (World Scientific, River Edge, NJ, 2001)]. This leads to a construction for the solution to the hierarchy in terms of linear equations and variants of the generalized Legendre transform for the hyper-Kähler metric itself given by Ivanov and Rocek [Commun. Math. Phys. **182**, 291 (1996)]. We show that the ALE spaces are examples of hyper-Kähler metrics admitting three tri-holomorphic Killing spinors. These metrics are in this sense analogous to the ''finite gap'' solutions in soliton theory. Finally we extend the concept of a hierarchy from that of our earlier work [Commun. Math. Phys. **213**, 641 (2000)] for the four-dimensional hyper-Kähler equations to a generalization of the conformal anti-self-duality equations and briefly discuss hidden symmetries for these equations. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1588466]

I. INTRODUCTION

It is well known that finding exact solutions to a nonlinear partial differential equation (PDE) is greatly simplified by the existence of symmetries. In differential geometric language the symmetries of a hyper-Kähler structure or, more generally, anti-self-dual conformal structures in four dimensions, correspond to (conformal) Killing vectors. Equations for hyper-Kähler four-manifolds with conformal Killing vectors have been studied and, in many cases, solved.[11,31,9,10]

Apart from natural Lie-point symmetries, integrable soliton equations possess infinitely many hidden symmetries, which can also be effectively used to construct solutions. It is less well known how to find such solutions in hyper-Kähler geometry (although we will see that such solutions have indeed been found in another guise[3,17,20]). In this article we shall show that hidden symmetries correspond to Killing tensors and spinors (which, classically, occur in Riemannian geometry as additional integrals of the geodesic flow) and propose two methods of finding hyper-Kähler metrics with such symmetries.

We start by briefly reviewing a beautiful construction of Novikov[24] which we shall posit as a motivation and a guiding principle. Consider the Korteveg–de Vries (KdV) equation

$$u_{t_1}=6uu_x-u_{xxx}, \quad \text{where} \quad u=u(x,t_1), \tag{1}$$

a)Electronic mail: m.dunajski@damtp.cam.ac.uk

together with the associated hierarchy of equations for $u(x,t_1,t_2,\dots)$

$$\frac{\partial u}{\partial t_i}=\frac{\partial}{\partial x}\frac{\delta H_i}{\delta u}. \tag{2}$$

Here

$$H_0=\int \frac{1}{2}u^2\mathrm{d}x, \quad H_1=\int\left(\frac{1}{2}u_x^2+u^3\right)\mathrm{d}x, \quad H_2=\int\left(\frac{1}{2}u_{xx}^2-\frac{5}{2}u^2u_{xx}+\frac{5}{2}u^4\right)\mathrm{d}x, \ \dots$$

are constants of motions which can be found recursively by solving the Riccati equation. Imposing a constraint

$$\frac{\partial u}{\partial t_k}+c_1\frac{\partial u}{\partial t_{k-1}}+\ \cdots\ +c_k\frac{\partial u}{\partial t_0}=c_0 \tag{3}$$

reduces (1) to an ordinary differential equation (ODE). This ODE is a completely integrable Hamiltonian system with k first integrals in involution. In the simplest nontrivial case the solution is

$$x=\int\frac{\mathrm{d}u}{\sqrt{2u^3+c_1u^2+2c_0u+E}}.$$

In the case of the KdV equation, it is then possible to proceed to obtain explicit formulas for such solutions in terms of theta functions.

For a general integrable system, hidden symmetries are constructed systematically by studying a hierarchy of commuting flows associated to the original equations. A hidden symmetry is then an explicit point symmetry of the hierarchy which, in particular, include the higher flows themselves.

In this article we shall propose an analogous construction of hidden symmetries for the hyper-Kähler equations in four dimensions and its integrable generalizations, which include quaternionic structures in $4k$ dimensions. Recall that a four-dimensional Riemannian manifold $(\mathcal{M},g)$ is hyper-Kähler if it admits three Kähler structures Σ_I, Σ_J, and Σ_K compatible with g and such that the endomorphisms I, J, K given by $g(IX,Y)=\Sigma_I(X,Y)$, etc., satisfy $IJ=K=-JI$. To impose higher symmetries on this system one needs to

(1) reformulate the hyper-Kähler condition on a metric as an integrable PDE (the *heavenly equation*),
(2) construct the associated hierarchy, and
(3) look for solutions invariant under the hidden symmetries, and characterize twistor spaces corresponding to these solutions.

Steps (**1**) and (**2**) were taken in Ref. 27, and Refs. 5, 30, 29, and 8, respectively. We shall review the approach taken in Ref. 8 in Sec. II which focuses on hierarchies associated to four-dimensional hyper-Kähler spaces. This is generalized in Sec. VI to give a hierarchy associated to general conformally ASD spaces both in four dimensions and their higher dimensional generalizations such as quaternion Kähler spaces. The other sections deal with (**3**).

In Secs. III and IV we discuss symmetry and hidden symmetry reduction in the context of the four-dimensional hyper-Kähler equations. In Sec. III we first discuss and classify symmetries of solutions to the hyper-Kähler hierarchy. We use the well known twistor description[31] of the Gibbons–Hawking solution as a guiding example in our analysis of the case of the hierarchy; we show that when the symmetry is triholomorphic, the solutions of the reduced equations are linear and we briefly discuss the corresponding twistor theory. The hyper-Kähler hierarchy is in particular foliated by four-dimensional hyper-Kähler manifolds that admit a hidden symmetry in a variant of the Ivanov and Rocek construction.[17]

In Sec. IV we discuss hyper-Kähler spaces with a hidden symmetry, defined to be a space that embeds into a hierarchy that has a symmetry. In the general case, we show that a hidden symmetry corresponds to the existence of a spinor $K^{B}_{B'_0\dots B'_k}$ satisfying

$$\nabla^{(A}{}_{(A'}K^{B)}_{B'_0\dots B'_k)}=0. \tag{4}$$

When the hidden symmetry is ''triholomorphic'' in an appropriate sense, we find that $K^{B}_{B'_0\dots B'_k}=\nabla^{B}_{(B'_0}L_{B'_1\dots B'_k)}$ for some spinor field $L_{B'_1\dots B'_k}$ satisfying

$$\nabla_{A(A'}L_{B'_1\dots B'_k)}=0. \tag{5}$$

A nonconstant solution $L_{A'_1\dots A'_k}$ to the Killing-spinor equation (5) is said to be a Killing spinor of type $(0,k)$ and is also sometimes known as a solution to the valence-$(0,k)$ twistor equation. If $k=2$, then $K_{AA'}=\nabla^{B'}_{A}L_{A'B'}$ is a triholomorphic Killing vector of the given hyper-Kähler space, and the corresponding metric is of the Gibbons–Hawking form.[12]

If the metric admits a hyper-Kähler hidden symmetry and hence Killing spinor, then the corresponding twistor space admits a globally defined twistor function Q homogeneous of degree k. This is because the existence of a Killing spinor implies that the twistor space of the hyper-Kähler hierarchy admits an action of a Hamiltonian vector field with Hamiltonian Q and factor space $\mathcal{O}(k)$. The hyper-Kähler twistor space therefore arises as an affine bundle over $\mathcal{O}(k)$, described by a cohomology class $f\in H^1(\mathbb{CP}^1,\mathcal{O}(2-k))$. The corresponding space–time can be determined directly and the construction followed through to give explicit formulas for a basis of the self-dual two-forms (and therefore for the metric).

In Sec. V, we demonstrate that the asymptotically locally Euclidean (ALE) spaces constructed by Hitchin[15] and Kronheimer[18,19] admit three triholomorphic hidden symmetries. We show that the corresponding twistor spaces are elliptic fibrations over $\mathcal{O}(k)$ for some k, and the transition functions defining these bundles can be found in terms of elliptic integrals.

Finally in Sec. VI we extend the concept of a hierarchy from that of Ref. 8 for the four-dimensional hyper-Kähler equations to a generalization of the conformal anti-self-duality equations and give a brief discussion of hidden symmetries in this context.

The two-component spinor notation used in the article is summarized in the Appendix.

II. THE HYPER-KÄHLER HIERARCHY

Let $\mathcal{M}$ be a complex four-manifold equipped with a holomorphic metric g and compatible volume form ν; we shall refer to this triple as a *space–time*. For a four-manifold with metric, we have that $T\mathcal{M}=\mathbb{S}\otimes\tilde{\mathbb{S}}$ where $\mathbb{S}$ and $\tilde{\mathbb{S}}$ are the bundles of self-dual and anti-self-dual spinors, respectively, each being rank two complex vector bundles on $\mathcal{M}$. The metric connection necessarily preserves this factorization, and the hyper-Kähler condition is equivalent to the condition that the induced connection on $\tilde{\mathbb{S}}$ be flat. (The I, J, and K act trivially on the $\tilde{\mathbb{S}}$ factor and on the $\mathbb{S}$ factor by Pauli σ matrices.) This implies that, on translation of the one-form indices to indices $A,B,\dots$ denoting membership of $\mathbb{S}$ and $A',B',\dots$ denoting membership of $\tilde{\mathbb{S}}$, the curvature has the form

$$R_{AA'BB'CC'DD'}=\varepsilon_{A'B'}C_{ABCD}\varepsilon_{C'D'}, \quad C_{ABCD}=C_{(ABCD)},$$

where ε_{AB} and $\varepsilon_{A'B'}$ are skew, and $\varepsilon_{AB}\varepsilon_{A'B'}$ induces the metric under $T\mathcal{M}=\mathbb{S}\otimes\tilde{\mathbb{S}}$. In four dimensions this amounts to the ASD vacuum equations

$$\Phi_{ABA'B'}=0, \quad R=0, \quad C_{A'B'C'D'}=0. \tag{6}$$

Here R is the Ricci scalar, $\Phi_{ABA'B'}$ is the trace-free part of the Ricci tensor, and $C_{A'B'C'D'}$ is the SD part of the Weyl tensor (we use the conventions of Penrose and Rindler[26]).

We now show how the geometrical characterization of the hyper-Kähler equations and its hierarchy can be reduced to differential equations. We use a potential formulation, due to Plebański,[27] based on the fact that the equations locally imply the existence of a complex-valued function Θ and coordinate system (w,z,x,y) such that the metric is given by

$$g=2\mathrm{d}w\mathrm{d}x+2\mathrm{d}z\mathrm{d}y-2\Theta_{xx}\mathrm{d}z^2-2\Theta_{yy}\mathrm{d}w^2+4\Theta_{xy}\mathrm{d}w\mathrm{d}z, \tag{7}$$

and Θ satisfies so-called second heavenly equation

$$\Theta_{xw}+\Theta_{yz}+\Theta_{xx}\Theta_{yy}-\Theta_{xy}^2=0. \tag{8}$$

The associated hierarchy is a differential equation with higher times generalizing one of the formulations of the hyper-Kähler equations in terms of potentials. We introduce the coordinates $x^{Ai}, A=0,1, i=0,\ldots n$, on a $(2n+2)$-dimensional manifold $\mathcal{N}$. The dependent variable $\Theta(x^{Ai})$ satisfies the equations

$$\partial_{Ai}\partial_{Bj-1}\Theta-\partial_{Bj}\partial_{Ai-1}\Theta+\{\partial_{Ai-1}\Theta,\partial_{Bj-1}\Theta\}_{yx}=0, \qquad i,j=1,\ldots,n. \tag{9}$$

Here $\{\ldots,\ldots\}_{yx}$ is the Poisson bracket with respect to the Poisson structure $\partial/\partial x^{A0}\wedge\partial/\partial x_{A0}$. [In order to make contact with the above for $n=1$, put $x^{A0}=(y,-x)$ and $x^{A1}=(w,z)$ and note that (8) is (9) with $i=j=1$.]

This hierarchy has a Lax representation

$$L_{Ai}\Phi=\partial_{Ai-1}\Phi+\lambda(\partial_{Ai}\Phi+\{\partial_{Ai-1}\Theta,\Phi\})=0, \tag{10}$$

where $A=0,1$, $i=1,\ldots,n$, λ is an affine coordinate on $\mathbb{CP}^1$ and $\Phi(x^{Ai},\lambda)$ is a function on $\mathcal{N}\times\mathbb{CP}^1$. It is clear that this provides the point of contact with the abstract definition.

It is clear from the form of the equations (10) that the space $\mathcal{N}$ is foliated by four-dimensional hyper-Kähler manifolds parametrized by $x^{Ai}=\text{const}$ for $i\geqslant 2$.

In Ref. 8 the hierarchies were obtained both via a rescursion operator construction and via a twistor construction. We shall summarize these constructions in the remaining part of this section.

Let

$$\Box_\Theta=\partial_x\partial_w+\partial_y\partial_z+\Theta_{yy}\partial_x^2+\Theta_{xx}\partial_y^2-2\Theta_{xy}\partial_x\partial_y$$

denote the wave operator on the ASD background determined by Θ, and let $\mathcal{W}_\Theta=\mathrm{Ker}\ \Box_\Theta$.

Proposition 2.1:[8]

(i) Elements of $\mathcal{W}_\Theta$ can be identified with linearized solutions $\delta\Theta$ [i.e., $(\Theta+\delta\Theta)$ satisfies (8) up to the linear terms in $\delta\Theta$] of the heavenly equation (8).

(ii) Let $(\delta\Theta_1\delta\Theta_2)\in\mathcal{W}_\Theta\times\mathcal{W}_\Theta$. The "recursion operator" $\mathcal{R}$ is defined to be the subspace $\mathcal{R}\subset\mathcal{W}_\Theta\times\mathcal{W}_\Theta$ on which

$$\partial_y(\delta\Theta_2)=(\partial_w-\Theta_{xy}\partial_y+\Theta_{yy}\partial_x)\delta\Theta_1, \qquad -\partial_x(\delta\Theta_2)=(\partial_z+\Theta_{xx}\partial_y-\Theta_{xy}\partial_x)\delta\Theta_1. \tag{11}$$

Note that the recursion operator is only an operator in the usual sense when the subspace $\mathcal{R}$ can be realized as a graph of a genuine operator $R:\mathcal{W}_\Theta\to\mathcal{W}_\Theta$ given by the recursion relations

$$R\,\delta\Theta=\partial_y^{-1}((\partial_w-\Theta_{xy}\partial_y+\Theta_{yy}\partial_x)\delta\Theta), \qquad R\,\delta\Theta=-\partial_x^{-1}((\partial_z+\Theta_{xx}\partial_y-\Theta_{xy}\partial_x)\delta\Theta). \tag{12}$$

This identification with a genuine operator will only be possible when we impose appropriate boundary conditions. However, for the definition of the hierarchy as a local system of equations, we will need only the definition of $\mathcal{R}$ above.

The first few iterations can be explicitly integrated to give

$$w\to y\to -\Theta_x\to\Theta_z\to\cdots,\quad z\to -x\to -\Theta_y\to -\Theta_w\to\cdots.$$

We introduce the new coordinates x^{Ai}, $A=0,\ 1$, $i=0,\ldots,n$. For $i=0,\ 1$, $x^{Ai}=x^{AA'}=(w,z,x,y)$ are coordinates on $\mathcal{M}$, and for $1<i\leqslant n, x^{Ai}$ are the parameters for the new flows (with $2n-2$ dimensional parameter space $\mathbb{X}$). The propagation of Θ along these parameters is determined by the recursion relations $\partial_{Ai+1}\Theta=R\partial_{Ai}\Theta$. However, the consistency conditions imply that in addition Θ satisfies the equations (9) with the Lax system generated by the operators (10).

The twistor theory is summarized in the following:

Theorem 2.2:[8] *There is a 1-1 correspondence between solutions to (9) on $\mathcal{M}\times\mathbb{X}$ and twistor spaces $\mathcal{PT}_n$ defined as follows.*

The twistor space $\mathcal{PT}_n$ is a three-dimensional complex manifold with the following structures:

(1) a projection $\mu:\mathcal{PT}\to\mathbb{CP}^1$,

(2) a section $s:\mathbb{CP}^1\mapsto\mathcal{PT}$ of μ with normal bundle $\mathcal{O}(n)\oplus\mathcal{O}(n)$,

(3) a nondegenerate two-form Σ on the fibers of μ, with values in the pullback from $\mathbb{CP}^1$ of $\mathcal{O}(2n)$.

(4) The choice of coordinate systems and potential Θ in the second Plebanski form for the hierarchy corresponds on the twistor space to a choice of point $[o^{A'}]\in\mathbb{CP}^1$ and canonical homogeneous degree n coordinates ω^A (i.e., $\Sigma=\mathrm{d}\omega^0\wedge\mathrm{d}\omega^1$) on a neighborhood of the fiber of $\mathcal{PT}_n$ over $[o^{A'}]$ defined up to $2n$th order away from this fiber.

Briefly, the space $\mathcal{M}\times\mathbb{X}$ is reconstructed as the moduli space $\mathcal{N}$ of deformations of the section s given in condition (2) above. Then $\mathcal{N}$ is $2n+2$-dimensional and we can introduce coordinates and the function Θ as follows:

We use homogeneous coordinates $\pi_{A'}=(\pi_{0'},\pi_{1'})$ and affine coordinate $\lambda=\pi_{0'}/\pi_{1'}$ on $\mathbb{CP}^1$ so that the point o is represented by $o_{A'}=(0,1)$, or $\lambda=0$. The homogeneous coordinates ω^A [i.e., $(\omega^A,\pi_{A'})\simeq(c^n\omega^A,c\pi_{A'})$ for $c\in\{\mathbb{C}-0\}$] can be pulled back to $\mathcal{N}\times\mathbb{CP}^1$ and the expansion $\omega^A=\pi_{1'}^n\Sigma_{i=0}^n x^{A,i}\lambda^i+O(\lambda^{n+1})$ and this defines coordinates $x^{A,i}$ on $\mathcal{N}$.

Expanding ω^A further, we discover, as shown in Ref. 8, that the twistor coordinates ω^A pulled back to the correspondence space $\mathbb{CP}^1\times\mathcal{N}$ can be expanded further as

$$\omega_n^0=(\pi_{1'})^n\left[x^{0n}+\lambda x^{0n-1}+\cdots+\lambda^n x^{00}+\lambda^{n+1}\frac{\partial\Theta}{\partial x^{10}}+\lambda^{n+2}\frac{\partial\Theta}{\partial x^{11}}+\cdots+\lambda^{2n+1}\frac{\partial\Theta}{\partial x^{1n}}+\cdots\right],$$
$$\omega_n^1=(\pi_{1'})^n\left[x^{1n}+\lambda x^{1n-1}+\cdots+\lambda^n x^{10}+\lambda^{n+1}\frac{\partial\Theta}{\partial x^{00}}+\lambda^{n+2}\frac{\partial\Theta}{\partial x^{01}}+\cdots+\lambda^{2n+1}\frac{\partial\Theta}{\partial x^{0n}}+\cdots\right], \tag{13}$$

and this determines $\Theta(x^{Ai})$ (up to a constant) satisfying (9). The form of the Lax system (10) is determined by the fact that ω^B are solutions to $L_{Ai}\omega^B=0$.

The form of the expansions (13) and Eqs. (9) can be obtained from the fact that the expansion of $\Sigma=\mathrm{d}\omega^0\wedge\mathrm{d}\omega^1$ on $\mathcal{N}\times\mathbb{CP}^1$ in powers of λ must truncate after λ^{2n}.

There is a $2n$-dimensional distribution on the "spin bundle" $D\subset T(\mathcal{N}\times\mathbb{CP}^1)$ that is tangent to the fibers of the projection $\mathcal{N}\times\mathbb{CP}^1\to\mathcal{PT}_n$. The distribution D has an identification with $\mathcal{O}(-1)\otimes\mathbb{C}^{2n}$ and is generated by the Lax system (10).

This correspondence is stable under small perturbations of the complex structure on $\mathcal{PT}_n$ preserving (1)–(3).

One can find the twistor spaces for the four-dimensional hyper-Kähler slices given by $x^{Ai}=\mathrm{const}, i\geqslant 2$, by taking a sequence of $n-1$ blowups of points in the fiber over $o_{A'}\in\mathbb{CP}^1$, the choice of point in the fiber to blow up at the $(n-i+1)$th blowup corresponding precisely to the choice of the values of x^{Ai}. If one wishes to respect Euclidean reality conditions, one can instead blow up complex conjugate points in the fibers over $o_{A'}$ and $\hat{o}_{A'}$.

III. SYMMETRIES OF HYPER-KÄHLER HIERARCHIES

For a hyper-Kähler space, we can characterize conformal symmetries as follows: let $\Sigma^{A'B'}=(\Sigma^{0'0'},\Sigma^{0'1'},\Sigma^{1'1'})$ be a basis of SD two-forms, and let $\Sigma=\Sigma^{A'B'}\pi_{A'}\pi_{B'}$.

Definition 3.1: A solution to the hyper-Kähler equations admits a symmetry if there exists a vector field K on $\mathcal{N}$ together with a lift $\tilde{K}$ to $S^{A'}$ over $\mathcal{N}$ such that $\mathcal{L}_{\tilde{K}}\Sigma=0$.

Here the lift must be $\tilde{K}=K+\phi_{B'}^{A'}\pi_{A'}\partial/\partial\pi_{B'}$ where $\phi_{B'}^{A'}=-\frac{1}{2}\nabla_{BB'}K^{BA'}-\frac{1}{2}\nabla_c K^c\varepsilon_{B'}^{A'}$ according to the standard theory of Lie derivatives of spinors, see Ref. 26.

We will use this also as a definition for symmetries of the hyper-Kähler hierarchy where now Σ will be the pull-back from twistor space to the spin bundle of the corresponding two-form that is homogeneous of degree $2n$ in $\pi_{A'}$.

Definition 3.2: A solution to the hyper-Kähler hierarchy admits a symmetry if there exists a vector field K on $\mathcal{N}$ together with a lift $\tilde{K}$ to $S^{A'}$ over $\mathcal{N}$ such that $\mathcal{L}_{\tilde{K}}\Sigma=0$.

Again, by homogeneity, we must have that the lift must be $\tilde{K}=K+\phi_{B'}^{A'}\pi_{A'}\partial/\partial\pi_{B'}$ where $\phi_{B'}^{A'}$ will be determined by K.

In particular, $\tilde{K}$ is therefore in involution with the Lax distribution D so that it projects down to a global holomorphic vector field $\mathcal{K}$ on the twistor space $\mathcal{PT}$.

We can classify symmetries according to the extent to which they preserve the various structures on $S^{A'}$ or on the twistor space. This is most easily seen by examining the vertical part $\phi=\phi_{A'}^{B'}\pi_{B'}\partial/\partial\pi_{A'}=\tilde{K}-K$ (where here $\tilde{K}$ denotes the horizontal lift of K). The matrix $\phi_{A'}^{B'}$ generically has two constant eigenvalues (the space–time must be of Petrov type N for nonconstant eigenvalues to be admissable).

(1) K will be said to be *triholomorphic* if the eigenvalues of $\phi_{A'}^{B'}$ are equal. The projection of $\tilde{K}$ to the projective spin bundle, $PS^{A'}$, is then horizontal, and the vertical part ϕ of $\tilde{K}$ on $S^{A'}$ is a multiple of the Euler homogeneity operator $\pi^{A'}\partial/\partial\pi^{A'}$, i.e., $\phi_{A'}^{B'}=\mu\,\delta_{A'}^{B'}$. Equivalently, it is triholomorphic if $\mathcal{K}$ is tangent to the fibers of the projection $p:\mathcal{PT}_n\mapsto\mathbb{CP}^1$.

(2) K is said to be Killing if the trace of ϕ vanishes, $\phi_{A'}^{A'}=0$. Then ϕ preserves the form $\pi_{A'}d\pi^{A'}$ on the spin bundle.

(3) K is said to be a homothety if the trace of ϕ, $\phi_{A'}^{A'}$ is constant, i.e., $\mathcal{L}_{\tilde{K}}\varepsilon^{A'B'}\pi_{A'}\mathrm{d}\pi_{B'}=\mu\varepsilon^{A'B'}\pi_{A'}\mathrm{d}\pi_{B'}$ for some constant $\mu\neq0$.

In the case that the symmetry is not triholomorphic, we can further distinguish the case where ϕ, on projection to the projective spin bundle, has one or two zeroes. In the single zero case in particular, $\phi_{A'}^{B'}$ will not be diagonalizable. We will not pursue this distinction here but see Refs. 7 and 10 for a study of such symmetries on $(++--)$ hyper-Kähler space.

A. Examples with triholomorphic Killing symmetry

We first consider well known reductions of the hyper-Kähler equations, and then analogous reductions of the hierarchy.

1. Gibbons–Hawking metrics revisited

The heavenly equation (8) with $R(\Theta_x)=\Theta_z=0$ can be expressed as

$$\mathrm{d}\Theta_x\wedge\mathrm{d}x\wedge\mathrm{d}y+\mathrm{d}w\wedge\mathrm{d}\Theta_x\wedge\mathrm{d}\Theta_y=0. \tag{14}$$

Introduce $p:=\Theta_x$ and perform a Legendre transform

$$F(p,y,w):=px(w,y,p)-\Theta(w,z,y,x(w,y,p)).$$

Then $x=F_p$, $\Theta_y=-F_y$ and (14) yields the wave equation[11]

$$F_{pw}+F_{yy}=0. \tag{15}$$

Implicit differentiation gives

$$\Theta_{yy}=-F_{yy}+\frac{F_{py}}{F_{pp}},\quad \Theta_{xy}=-\frac{F_{py}}{F_{pp}},\quad \Theta_{xx}=\frac{1}{F_{pp}},$$

and so [with the help of (7) and (15)]

$$g=F_{pp}\left(\frac{1}{4}\mathrm{d}y^2+\mathrm{d}w\mathrm{d}p\right)-\frac{1}{F_{pp}}\left(\mathrm{d}z-\frac{F_{pp}}{2}\mathrm{d}y+F_{py}\mathrm{d}w\right)^2=\psi\left(\frac{1}{4}\mathrm{d}y^2+\mathrm{d}w\mathrm{d}p\right)-\psi^{-1}(\mathrm{d}z+\Omega)^2, \tag{16}$$

where $\psi=F_{pp}$ and $\Omega=F_{py}\mathrm{d}w-(F_{pp}/2)\mathrm{d}y$ satisfy the monopole equation $*\mathrm{d}\psi=\mathrm{d}\Omega$ from (15). Thus (16) is of the Gibbons–Hawking form.[12]

The twistor description is as follows: the twistor coordinates pull back to the spin bundle as

$$\omega^0=\pi_{1'}[w+\lambda y-\lambda^2\Theta_x+\lambda^3\Theta_z+\cdots],$$

$$\omega^1=\pi_{1'}[z-\lambda x-\lambda^2\Theta_y-\lambda^3\Theta_w+\cdots]. \tag{17}$$

The vanishing of Θ_z implies that the whole series for ω^0 truncates at second order. Thus the twistor space admits a global section of $\mathcal{O}(2)$, and this is the Hamiltonian with respect to Σ, for the holomorphic vector field corresponding to the Killing field $\partial_z=K^{AA'}\partial_{AA'}$. Conversely, given a triholomorphic symmetry, the triholomorphicity condition means that its lift to the spin bundle $\mathcal{M}$ is horizontal and so, on twistor space, the corresponding holomorphic vector field is tangent to the fibers of μ. It also preserves Σ and so is Hamiltonian with Hamiltonian given by a homogeneity degree-2 global function. We can choose ω^0 to be this preferred section divided by $\pi_{1'}$ so that the series for ω^0 terminates after λ^2.

Substituting the Legendre transform into (17) yields

$$\omega^0=\pi_{1'}[w+\lambda y-\lambda^2 p], \tag{18}$$

$$\omega^1=\pi_{1'}[z-\lambda F_p+\lambda^2 F_y+\lambda^3 F_w+\cdots]\ . \tag{19}$$

With the definition $\Sigma=\mathrm{d}\omega^0\wedge\mathrm{d}\omega^1|_{\lambda=\mathrm{const}}$ the equation (15) can be rewritten as $\Sigma\wedge\Sigma=0$. The basis of SD two-forms can be read off from $\Sigma=\Sigma^{A'B'}\pi_{A'}\pi_{B'}$:

$$\Sigma^{0'0'}=-\mathrm{d}z\wedge\mathrm{d}p+\mathrm{d}y\wedge\mathrm{d}F_p-\mathrm{d}w\wedge\mathrm{d}F_y,\quad \Sigma^{0'1'}=\mathrm{d}z\wedge\mathrm{d}y+\mathrm{d}w\wedge\mathrm{d}F_p,\quad \Sigma^{1'1'}=\mathrm{d}z\wedge\mathrm{d}w,$$

and these determine the metric above.

2. Triholomorphic symmetry reductions of the hierarchy

In this subsection we shall generalize the construction of Gibbons–Hawking metrics described in the last subsection, and generate solutions to the hyper-Kähler hierarchy such that $R^n\Theta_x=\partial_{1n}\Theta=0$. These are the cases of a triholomorphic Killing symmetry.

Proposition 3.3: The hyper-Kähler hierarchy (9) with symmetry $\partial\Theta/\partial x^{1n}=0$ reduces (in appropriate coordinates) to an overdetermined system of $n(2n-1)$ linear equations for $F(t^0,\ldots,t^{2n})$:

$$\frac{\partial^2 F}{\partial t^{i+1}\partial t^j}=\frac{\partial^2 F}{\partial t^i\partial t^{j+1}},\quad i,j=0,\ldots,2n-1. \tag{20}$$

Proof: Let $\mathcal{PT}_n$ be the twistor space from Proposition 2.2, and let $(\omega_n^A, \pi_{A'})$ be homogeneous coordinates on the neighborhood of $\pi_{A'} = o_{A'}$. (In the previous section $\mathcal{PT} := \mathcal{PT}_1$ and $\omega^A := \omega_1^A$ correspond to the standard situation of the nonlinear graviton construction.)

Now impose the symmetry condition, i.e., assume that $R^n\Theta_x = \partial_{1n}\Theta = 0$. Again, the vanishing of $\partial_{1n}\Theta$ implies that the series (13) in λ for ω^0 truncates at degree $2n$. [Thus, $\pi_{1'}^n \omega^0$ is a global holomorphic function of homogeneity degree-$2n$ on $\mathcal{PT}_n$. Conversely, again, this symmetry corresponds to a global holomorphic vector field on $\mathcal{PT}_n$ that is vertical up the fibers of μ and preserves Σ. It therefore is generated by a global Hamiltonian Q homogeneous of degree $2n$, and we can take as before $\omega^0 = Q/\pi_{1'}^n$.]

We can now perform the Legendre transform

$$p^i = \partial_{1i}\Theta, \qquad i = 0, \ldots, n-1, \quad F(p^j, x^{0j}) = \sum_{i=0}^{n-1} p^i x^{1i}(p^j, x^{0j}) - \Theta(x^{0j}, x^{1i}(p^j, x^{0j})), \quad x^{1n} = T. \tag{21}$$

Therefore $\partial_{0i}F = -\partial_{0i}\Theta, \partial_{p_i}F = x^{1i}$. Define 2n+1 functions $(t^0, \ldots, t^{2n})$ by

$$t^{n-i-1} = p^i, \quad i = 0, \ldots, n-1, \quad t^{n+i} = x^{0i}, \quad i = 0, \ldots n.$$

This implies

$$\omega_n^0 = (\pi_{1'})^n [t^{2n} + \lambda t^{2n-1} + \cdots + \lambda^{2n} t^0], \tag{22}$$

$$\omega_n^1 = (\pi_{1'})^n \left[T + \lambda \frac{\partial F}{\partial t^0} + \lambda^2 \frac{\partial F}{\partial t^1} + \cdots + \lambda^{2n+1} \frac{\partial F}{\partial t^{2n}} + \cdots \right] . \tag{23}$$

Equations (20) arise from the vanishing of coefficient λ^{2n+2} in $\mathrm{d}\omega_n^0 \wedge \mathrm{d}\omega_n^1$:

$$\sum_{i=0}^{2n-1} \mathrm{d}t^i \wedge \mathrm{d} \frac{\partial F}{\partial t^{i+1}} = 0.$$

It can also be verified by cross-differentiating that all integrability conditions for the system (20) are satisfied. □

The geometry on twistor space can be understood as follows. The section Q of $\mathcal{O}(2n)$ generates a Hamiltonian flow

$$\mathcal{K} = \varepsilon^{AB} \frac{\partial Q}{\partial \omega^A} \frac{\partial}{\partial \omega^B}, \quad \varepsilon^{AB} = -\varepsilon^{BA}, \quad \varepsilon^{01} = 1,$$

on the extended twistor space $\mathcal{PT}_n$. This flow corresponds to $\mathcal{K}^{AA_1' \ldots A_n'} \partial_{AA_1' \ldots A_n'} = \partial/\partial x^{1n}$ on $\mathcal{N}$. Since Q is constant along $\mathcal{K}$, the quotient space $\mathcal{PT}_n/\mathcal{K}$ is the total space of $\mathcal{O}(2n) \to \mathbb{CP}^1$ where the map to $\mathcal{O}(2n)$ is furnished by $(\omega^A, \pi_{A'}) \to (Q, \pi_{A'})$.

The full twistor space $\mathcal{PT}_n$ is an affine line bundle with trivial underlying translation bundle and so it corresponds to an element $G(Q, \pi_{A'})$ of $H^1(\mathcal{O}(2n), \mathcal{O})$.

Sections of $\mathcal{O}(2n) \to \mathbb{CP}^1$ are parametrized by $\mathbb{C}^{2n+1}$ with coordinates $\mathbf{t} = (t^0, \ldots, t^{2n})$. The $2n+2$-dimensional space of sections of $\mathcal{PT}_n \to \mathbb{CP}^1$ maps onto this with fiber $\mathbb{C}$ parametrized by T. Choosing linear coordinates up the line bundle η and $\tilde{\eta}$ over open sets U and $\tilde{U}$, the problem of lifting a curve $L_{\mathbf{t}}$ in $\mathcal{O}(2n)$ to one in $\mathcal{PT}_n$ is one of finding a trivialization of the line bundle over L_t, i.e., of finding functions $g(\mathbf{t}, \pi_{A'})$ and $\tilde{g}(\mathbf{t}, \pi_{A'})$ such that, on $U \cap \tilde{U}$, $g - \tilde{g} = G$ on restriction to L_t where G is the log of the patching function for the line bundle, and therefore has homogeneity degree zero. We can then take $\eta = T + g$. We can give a formula for g as

$$g(\mathbf{t},\lambda)=\oint_\gamma G(t^{2n}+\zeta t^{2n-1}+\cdots+\zeta^{2n}t^0,\zeta)\mathrm{d}\zeta/(\zeta-\lambda),$$

where the contour γ is taken in $L_t\cap U\cap\tilde{U}$ surrounding ζ in U. With an identical expression for $\tilde{g}$ but with contour $\tilde{\gamma}$ such that $\gamma-\tilde{\gamma}$ surrounds ζ, we see that $g-\tilde{g}=G$ follows from Cauchy's integral formula. Then the expression for the expansion of the coordinate $\eta=T+g$ about $\lambda=0$ is

$$\eta=T+\sum_{i=0}\lambda^i\oint G(Q(t,\zeta),\zeta)\mathrm{d}\zeta/\zeta^{i+1}.$$

It can then be seen that if we define

$$F(\mathbf{t})=\oint_\Gamma\frac{G(t^{2n}+\lambda t^{2n-1}+\cdots+\lambda^{2n}t^0,\lambda)}{\lambda^2}\mathrm{d}\lambda,$$

then F clearly satisfies the equations of (20) and we obtain the expansions (22) for $(\omega^0,\omega^1)=(Q/\pi_1^n,,\pi_1^n,\eta)$. These can then be used to obtain concrete expressions for $\Sigma=\mathrm{d}\omega^0\wedge\mathrm{d}\omega^1$ to determine the geometric structures of the hyper-Kähler hierarchy.

Clearly we have the following.

Lemma 3.4: The full space of the hierarchy is foliated by hyper-Kähler four-manifolds with $x^{Ai}=constant$ *for* $i>1$ *and metric*

$$2\mathrm{d}x^{10}\mathrm{d}x^{01}+2\mathrm{d}x^{11}\mathrm{d}x^{00}-2\frac{\partial^2\Theta}{\partial(x^{10})^2}(\mathrm{d}x^{11})^2-2\frac{\partial^2\Theta}{\partial(x^{00})^2}(\mathrm{d}x^{01})^2-4\frac{\partial^2\Theta}{\partial x^{00}\partial x^{10}}\mathrm{d}x^{01}\mathrm{d}x^{11}. \quad (24)$$

This gives a variant of the Legendre transform of Ivanov and Rocek[17] (see also Ref. 3).

B. Example for $n=2$

We saw above that for $n=1$ the construction is equivalent to the Gibbons–Hawking anzatz. The $n=2$ case goes as follows:

Let $F_i:=\partial_{t^i}F$. Implicit differentiation of $\partial_{0i}F=-\partial_{0i}\Theta,\partial_{p_i}F=x^{1i}$ with respect to p_0,p_1,y yields

$$\Theta_{xx}=-\frac{F_{00}}{M},\quad \Theta_{xy}=\frac{-F_{01}F_{02}+F_{00}F_{12}}{M},\quad \Theta_{yy}=-F_{22}-\frac{F_{00}(F_{12})^2-2F_{01}F_{12}F_{02}+F_{11}(F_{02})^2}{M},$$

where $M:=(F_{01})^2-F_{00}F_{11}$. The metric (7) with $x=x(t^i),z=z(t^i)$ is defined on the surface $F_4=0$. The formula for the metric in terms of F is not very illuminating, but we shall give it for the sake of completeness:

$$\begin{aligned}g=&M^{-1}(F_{10}N\mathrm{d}t^1\mathrm{d}t^2+F_{00}N\mathrm{d}t^0\mathrm{d}t^2+F_{11}(F_{01})^2(\mathrm{d}t^2)^2+F_{11}^3(\mathrm{d}t^3)^2+2F_{01}(F_{11})^2\mathrm{d}t^2\mathrm{d}t^3\\&+2F_{01}(F_{00})^2\mathrm{d}t^0\mathrm{d}t^1+F_{00}^3(\mathrm{d}t^0)^2+F_{00}(F_{01})^2(\mathrm{d}t^1)^2+[F_{11}N+F_{01}F_{00}F_{03}]\mathrm{d}t^1\mathrm{d}t^3\\&+[3F_{01}F_{00}F_{11}-(F_{01})^3+(F_{00})^2F_{03}]\mathrm{d}t^0\mathrm{d}t^3),\end{aligned} \quad (25)$$

where $N:=(F_{01})^2+F_{00}F_{11}$.

IV. HYPER-KÄHLER SPACES WITH HIDDEN SYMMETRIES

If we have a hyper-Kähler space that embeds into a hyper-Kähler hierachy that admits a symmetry we will say that that the original hyper-Kähler space admits a *hidden symmetry*.

The first question we wish to address is of how to recognize when a hyper-Kähler space admits such a hidden symmetry.

Proposition 4.1: If a hyper-Kähler space $\mathcal{M}$ admits a hidden symmetry, then it admits a solution to the equation

$$\nabla^{(A}_{(A'_1}K^{B)}_{A'_2\cdots A'_n)}=0. \tag{26}$$

Proof: This result is most easily seen from the twistor theory. The symmetry vector K gives rise to a global holomorphic vector field $\mathcal{K}$ on the twistor space for $\mathcal{N}$, $\mathcal{PT}_n$. The twistor space $\mathcal{PT}_1$ for $\mathcal{M}$ is a region in the blowup of $\mathcal{PT}_n$ at a number of points. Thus we have a map $p:\mathcal{PT}_1 \to \mathcal{PT}_n$. So rather than consider $\mathcal{K}$ itself, we consider the two-form $\mathcal{K}\lrcorner\nu_n$ weight $2n+2$ where $\nu_n\in\Gamma(\mathcal{PT}_n,\Omega^3(2n+2))$ is given by $\Sigma_n\wedge\pi_{A'}\mathrm{d}\pi^{A'}$.

This two-form can be pulled back to give $p^*\mathcal{K}\lrcorner\nu_n$ a global two-form of weight $2n+2$ on the twistor space $\mathcal{PT}_1$ for $\mathcal{M}$. This two-form can then be pulled back to give a two-form on the spin-bundle $\mathbb{S}^{A'}$ which must take the form

$$\mathcal{K}\lrcorner\nu_n=(K^{AA'_1\cdots A'_{2n-1}}e^{A'_{2n}}_{A}\pi_{A'_1}\cdots\pi_{A'_{2n}}\wedge\pi_{B'}\mathrm{d}\pi^{B'}+\chi_{A'_1\cdots A'_{2n}}\pi^{A'_1}\cdots\pi^{A'_{2n}})\Sigma_1$$

for some $K^{AA'_1\cdots A'_{2n-1}}$ and $\chi_{A'_1\cdots A'_{2n}}$.

The condition that this two-form descends to twistor space is the condition that

$$\pi^{A'}\nabla_{AA'}\lrcorner\mathrm{d}(\mathcal{K}\lrcorner\nu_n)=0.$$

This leads to Eq. (26) and

$$\nabla^{A}_{(A'_1}K_{A'_2\cdots A'_{2n})A}=\chi_{A'_1\cdots A'_{2n}}, \quad \nabla_{A(A'}\chi_{A'_1\cdots A'_{2n})}=0\,.$$

However, it can be checked that these two equations are a consequence of (26), if the first equation is taken to be the definition of $\chi_{A'_1\cdots A'_{2n}}$. □

A. The case of a hidden triholomorphic Killing symmetry

The case of a hidden triholomorphic Killing symmetry reduces to linear equations and can be worked through completely modulo some intergations and solving for implicit functions. This is effectively the case studied by Ivanov and Rocek[17] and generalized by Bielawski.[3]

In the triholomorphic Killing case, we have the following.

Lemma 4.2: Suppose $\mathcal{M}$ admits a hidden triholomorphic Killing symmetry. Then $\chi_{A'_1\cdots A'_{2n}}=0$ and there exists a spinor $\phi_{A'_2\cdots A'_{2n}}$ such that

$$\nabla_{AA'}\phi_{A'_1\cdots A'_{2n}}=K_{A(A'_1\cdots A'_{2n-1}}\varepsilon_{A'_{2n})A'}\,.$$

Proof: The vanishing of $\chi_{A'_1\cdots A'_{2n}}=0$ follows from the fact that $\mathcal{K}$ is tangent to the fibers of twistor space over $\mathbb{CP}^1$. The existence of $\phi_{A'_1\cdots A'_{2n}}$ follows from the fact that $\mathcal{K}$ is Hamiltonian with respect to the symplectic forms Σ_n up the fibers of μ and so is generated by a Hamiltonian $Q\in\Gamma(\mathcal{O}(2n))$. On pullback to the spin bundle $Q=\phi_{A'_1\cdots A'_{2n}}\pi^{A'_1}\cdots\pi^{A'_{2n}}$ and the condition that Q descends to twistor space is $\pi^{A'}\nabla_{AA'}Q=0$ and this gives the equation above. □

The above lemma shows that a Killing spinor on an ASD vacuum determines a function Q homogeneous of degree k on its twistor space $\mathcal{PT}$. This in turn implies the following lemma.

Lemma 4.3: If an ASD vacuum space–time admits a Killing spinor, its twistor space $\mathcal{PT}$ is an affine line bundle over $\mathcal{O}(k)$ with underlying translation bundle $\mathcal{O}(2-k)$.

Proof: The existence of a global twistor function homogeneous of degree k on $\mathcal{PT}$ gives a projection onto $p:\mathcal{PT}\to\mathcal{O}(k)$. Furthermore, the fiber is spanned by the Hamiltonian vector field of Q with respect to Σ, in local coordinates,

$$\mathcal{K}=\varepsilon^{AB}\frac{\partial Q}{\partial \omega^A}\frac{\partial}{\partial \omega^B}.$$

This is a vector field with values in $O(k-2)$. This gives each fiber an affine linear structure which is twisted globally by $\mathcal{O}(2-k)$, since, if a is a local section of $\mathcal{O}(2-k)$ over $\mathbb{CP}^1$, then $a\mathcal{K}$ is a vector whose flows determine an action of $\mathbb{C}$. Thus $\mathcal{PT}\to\mathcal{O}(k)$ is an affine line bundle over $\mathcal{O}(k)$ with underlying translation bundle $\mathcal{O}(2-k)$. □

Such affine line bundles are classified by elements $[f]$ of $H^1(\mathcal{O}(k),\mathcal{O}(2-k))$. In a Cech description, cover $\mathcal{O}(k)$ by open sets, U_i, and represent $[f]$ by its Cech representative $f_{ij}\in\Gamma(\mathcal{O}(2-k),U_i\cap U_j)$. Then $\mathcal{PT}$ is constructed by patching together the total space of $\mathcal{O}(2-k)\to U_i$ to $\mathcal{O}(2-k)\to U_j$ by translating the zero section by f_{ij}. The data $[f]$ therefore determines the twistor space. This proves the first part of the following theorem.

Theorem 4.4: *There is a one-to-one correspondence between ASD vacuum space–times* $(\mathcal{M},g)$ *admitting a valence* $(0,k)$ *Killing spinor and elements* $[f]$ *of* $H^1(\mathcal{O}(k),\mathcal{O}(2-k))$.

In this case, for $k\geqslant 3$, $\mathcal{M}$ *admits a natural map into* $\mathbb{C}^{k+1}=\odot^k\mathbb{S}^{A'}$ *which we coordinate with* $t^{A'_1\cdots A'_k}$. *The hyper-Kähler space* $\mathcal{M}$ *is determined as a subset of* $\mathbb{C}^{k+1}$ *by the* $k-3$ *constraints*

$$f_{A'_1\cdots A'_{k-4}}:=\oint_\Gamma \pi_{A'_1}\cdots\pi_{A'_{k-4}}f(Q,\pi_{A'})\pi\cdot \mathrm{d}\pi=0.$$

The basis of SD two-forms for g *is then given by the restriction of the forms*

$$\Sigma^{A'_1B'_1}=\psi_{B'_2\cdots B'_kA'_2\cdots A'_{k-2}}\mathrm{d}t^{A'_1\cdots A'_k}\wedge \mathrm{d}t^{B'_2\cdots B'_k}{}_{A'_k}, \tag{27}$$

to $\mathcal{M}$, *where*

$$\psi_{A'_1\cdots A'_{2k-4}}=\frac{1}{2\pi i}\oint_\Gamma \pi_{A'_1}\cdots\pi_{A'_{2k-4}}\frac{\partial f}{\partial Q}\pi\cdot\mathrm{d}\pi \tag{28}$$

is a field determined by an arbitrary element of $H^1(\mathcal{O}(k),\mathcal{O}(2-k))$.

Proof: If one wishes to obtain the space–time $(\mathcal{M},g,\nu)$ determined by a given twistor space, the first task is to locate the four-dimensional family of sections of the fibration $\mathcal{PT}\to\mathbb{CP}^1$.

Let $t^{A'_1\cdots A'_k}=t^{(A'_1\cdots A'_k)}$ be coordinates on the $\mathbb{C}^{k+1}=\odot^k\mathbb{S}^{A'}$ parameter space of sections $\sigma_t:\pi_{A'}\to Q=t^{A'_1\cdots A'_k}\pi_{A'_1}\cdots\pi_{A'_k}\in\Gamma(\mathcal{O}(k))$. Sections of $\mathcal{PT}\to\mathbb{CP}^1$ determine sections of $\mathcal{O}(k)$ by projection onto $\mathcal{O}(k)$. However, the affine line bundle $\mathcal{PT}$ only admits a section over some σ_t if the cohomology class $[f]$ vanishes on restriction to σ_t. If $[f]$ vanishes on restriction to σ_t, $\mathcal{PT}$ restricts to become the line bundle $\mathcal{O}(2-k)$ so that there is a $3-k$-dimensional family of sections over σ_t for $3-k>0$ or just the zero-section otherwise.

To obtain explicit formulas, we first note that $[f]$ determines a field

$$f_{A'_1\cdots A'_{k-4}}(t^{B'_1\cdots B'_k})=\oint_{\gamma\subset\sigma_t}\pi_{A'_1}\cdots\pi_{A'_{k-4}}f\pi_{B'}\mathrm{d}\pi^{B'}$$

on $\mathbb{C}^{k+1}$ (here we express the natural pairing as a contour integral over some contour γ_t in σ_t where here χ is a Cech representative). This vanishes at some $t^{A'_1\cdots A'_k}$ iff $[f]$ vanishes on the corresponding σ_t. Thus, for $3-k>0$, $\mathcal{M}$ is fibered over the zero set of $\chi_{A'_1\cdots A'_{k-4}}$ in $\mathbb{C}^{k+1}$ with $3-k$-dimensional fibers, and is simply identified with this zero set for $k\geqslant 3$.

In order to calculate the SD two-forms associated to the space–time, we use the method of Gindikin,[13] and pullback Σ to the spin-bundle. To this end, introduce local homogeneous coordi-

nates $(\pi_{A'},Q,\zeta_i)=(c\pi_{A'},cQ,c^{2-k}\zeta_i)$ on each set U_i of some Stein cover twistor space; here ζ_i is a fiber coordinate up the fibers of the affine line bundle $\mathcal{PT}\to\mathcal{O}(k)$ on U_i with patching relations $\zeta_i=\zeta_j+f_{ij}$ on $U_i\cap U_j$. In these coordinates

$$\Sigma=\mathrm{d}_h Q\wedge\mathrm{d}_h\zeta_i\,,$$

where d_h denotes the exterior derivative in which $\pi_{A'}$ is held constant, i.e., horizontal on the spin bundle over space–time (although slightly confusingly, vertical with respect to the fibration $\mathcal{PT}\to\mathbb{CP}^1$). This form Σ is globally defined on vector fields tangent to the fibers of $\mathcal{PT}\to\mathbb{CP}^1$ as f_{ij} does not depend on ζ_i.

In order to evaluate this, we need to find the values of ζ_i on the sections of $\mathcal{PT}\to\mathbb{CP}^1$. These are obtained by a splitting formula due to Sparling.

On a σ_t for which $f_{A'_1\cdots A'_{k-4}}(t^{B'_1\cdots B'_k})=0$, we can find $\zeta_i(t,\pi_{A'})$ such that

$$\zeta_i(t,\pi_{A'})=\zeta_j(t,\pi_{A'})+f_{ij}(t^{A'_1\cdots A'_k}\pi_{A'_1}\cdots\pi_{A'_k},\pi_{B'})\,. \tag{29}$$

For $k\geqslant 3$ this solution will be unique, but for $k<3$ we will be free to add $x^{A'_1\cdots A'_{k-2}}\pi_{A'_1}\cdots\pi_{A'_{k-2}}$ to the solution.

In the formula for Σ we can rearrange so that we have

$$\Sigma=\mathrm{d}_h Q\wedge\mathrm{d}_h\zeta_i=\mathrm{d}t^{A'_1\cdots A'_k}\wedge\mathrm{d}_h(\pi_{A'_1}\cdots\pi_{A'_k}\zeta_i)\,.$$

Applying d_h to Eq. (29), and multiplying by $k-3$ of the π's, we obtain

$$\mathrm{d}_h(\pi_{A'_1}\cdots\pi_{A'_{k-3}}\zeta_i)=\mathrm{d}_h(\pi_{A'_1}\cdots\pi_{A'_{k-3}}\zeta_j)+\frac{\partial f_{ij}}{\partial Q}\pi_{A'_1}\cdots\pi_{A'_{k-3}}\pi_{B'_1}\cdots\pi_{B'_k}\mathrm{d}t^{B'_1\cdots B'_k}\,.$$

The cocycle $\partial f_{ij}/\partial Q$ defines a class in $H^1(\mathcal{O}(k),\mathcal{O}(2-2k))$ so that the expression above takes values in $\mathcal{O}(-1)$ on $\mathbb{CP}^1$ for each fixed t. Thus the splitting as stated exists and is unique since $H^0(\mathbb{CP}^1,\mathcal{O}(-1))=H^1(\mathbb{CP}^1,\mathcal{O}(-1))=0$. This gives

$$\mathrm{d}_h(\pi_{A'_1}\cdots\pi_{A'_{k-3}}\zeta_i)=k_{i,A'_1\cdots A'_{k-3}B'_1\cdots B'_k}\mathrm{d}t^{B'_1\cdots B'_k}\,,$$

where $k_{i,A'_1\cdots A'_{2k-3}}$ is defined by the splitting relation

$$k_{i,A'_1\cdots A'_{2k-3}}-k_{j,A'_1\cdots A'_{2k-3}}=\pi_{A'_1}\cdots\pi_{A'_{2k-3}}\frac{\partial f_{ij}}{\partial Q}$$

or alternatively the contour integral formula

$$k_{i,A_1,\cdots A'_{2k-3}}=\oint_{\Gamma_i}\rho_{A'_1}\cdots\rho_{A'_{2k-3}}\frac{1}{\pi\cdot\rho}\frac{\partial f_{ij}(Q,\rho_{A'})}{\partial Q}\rho\cdot\mathrm{d}\rho, \tag{30}$$

where for simplicity we assume a two set cover and the contour γ_i is chosen so that $\gamma_i-\gamma_j$ surrounds $\pi=\rho$. It follows that

$$\psi_{A'_1\cdots A'_{2k-4}}=\pi^{A'_{2k-3}}k_{A'_1\cdots A'_{2k-4}A'_{2k-3}}=\oint_{\gamma_i}\rho_{A'_1}\cdots\rho_{A'_{2k-4}}\frac{\partial f_{ij}(Q,\rho_{A'})}{\partial Q}\rho\cdot\mathrm{d}\rho \tag{31}$$

is the field on $\mathbb{C}^{k+1}$ naturally associated to $\partial f/\partial Q$.

We therefore obtain the formula

$$\Sigma = \mathrm{d}t^{A'_1\cdots A'_k} \wedge \pi_{A'_1}\pi_{A'_2}\pi_{A'_3} k_{A'_4\cdots A'_{2k}} \mathrm{d}t^{A'_{k+1}\cdots A'_{2k}}.$$

Define the indexed two-forms $\Sigma^{(B'_1B'_2)|(A'_5\cdots A'_{2k})}$ by

$$\mathrm{d}t^{B'_1\cdots B'_3(A'_4\cdots A'_k} \wedge \mathrm{d}t^{A'_{k+1}\cdots A'_{2k})} = \varepsilon^{(A'_4|(B'_1} \Sigma^{B'_2B'_3)|A'_5\cdots A'_{2k})C'}.$$

(This indexed two-form can be represented as

$$\Sigma^{(B'_1B'_2)|(A'_5\cdots A'_{2k})} = \frac{3k}{2} \mathrm{d}t^{(B'_1B'_2)|(A'_5\cdots A'_{k+1}}_{C'} \wedge \mathrm{d}t^{A'_{k+2}\cdots A'_{2k})C'}$$

$$+ a_k \varepsilon^{(A'_5|(B'_1} \varepsilon^{B'_2)|A'_6} \mathrm{d}t^{A'_7\cdots A'_{k+1}}_{C'D'E'} \wedge \mathrm{d}t^{A'_{k+2}\cdots A'_{2k})C'D'E'},$$

where a_k is a conbinatorial constant depending on k.) With this, we find that a $\pi_{A'}$ is contracted onto $k_{i,A'_1\cdots A'_{2k-3}}$ so that (31) gives

$$\Sigma = \pi_{A'_1}\pi_{A'_2}\psi_{A'_3\cdots A'_{2k-2}} \Sigma^{A'_1\cdots A'_{2k-2}}.$$

Thus, the result follows. □

Remarks:

(i) If $k>3$, then there exists a potential for $\psi_{A'_1\cdots A'_{2k-4}}$,

$$\psi_{A'_1\cdots A'_{2k-4}} = \partial_{A'_{k-3}\cdots A'_{2k-4}} f_{A'_1\cdots A'_{k-4}},$$

where

$$f_{A'_1\cdots A'_{k-4}} = \oint_\Gamma \rho_{A'_1}\cdots\rho_{A'_{k-4}} f \rho\cdot\mathrm{d}\rho.$$

The space–time is a four-dimensional surface $\chi_{A'_1\cdots A'_{k-4}}=0$ in $k+1$-dimensional moduli space of $\mathcal{O}(k)$ sections coordinatized by $x^{A'_1\cdots A'_k}$.

(ii) $k=3$: The field $\psi_{A'_1A'_2}$ does not have a potential, and no conditions have to be imposed on the moduli space of $\mathcal{O}(3)$ to find the space–time. This is because $H^0(\mathbb{CP}^1,\mathcal{O}(3)) = H^0(\mathbb{CP}^1,\mathcal{O}(1)\oplus\mathcal{O}(1))$, and $x^{A'_1A'_2A'_3}$ has as many components as $x^{AA'}$. Ward[32] regards $\psi_{A'_1A'_2}$ as a self-dual Maxwell field on $\mathbb{C}^4$.

(iii) The case $k=2$ implies the existence of a triholomorphic Killing vector and was considered by Tod and Ward in Ref. 31. Now

$$\psi = \oint_\Gamma \frac{\partial f}{\partial Q} \rho\cdot\mathrm{d}\rho$$

is a solution to the three-dimensional wave equation. The relation between our construction and the description of the Gibbons–Hawking metric form in Sec. III A 1 is given by

$$F(x^{A'B'}) = \oint_\Gamma \frac{G(\pi_{A'},Q)}{(\pi\cdot o)^2}\pi\cdot\mathrm{d}\pi, \quad \psi = F_{pp} = \oint_\Gamma (\pi\cdot o)^2 \frac{\partial^2 G}{\partial Q^2}\pi\cdot\mathrm{d}\pi,$$

where

$$x^{A'B'} := \begin{pmatrix} -p & y/2 \\ y/2 & w \end{pmatrix}.$$

B. Relation between the two constructions

In this section we relate the hyper-Kähler slices (4) of the symmetric hierarchy introduced in Sec. III to the method described above.

Proposition 4.5: Let $f \in H^1(\mathcal{O}(2n),\mathcal{O}(2-2n))$ *give rise to the ZRM field* (28) *with* $k=2n$. *Then hyper-Kähler metrics arising from Proposition 3.3 form a subclass of metrics from Proposition 4.4 if*

$$F=\oint_\Gamma (\pi\cdot o)^{-2}G(Q,\pi_{A'})\pi\cdot \mathrm{d}\pi, \quad \textit{where} \quad (\pi\cdot o)^2\frac{\partial G}{\partial Q}=f\in H^1(\mathcal{O}(2n),\mathcal{O}(2-2n)),$$

where $o_{A'}$ *is a constant spinor*.

Proof: Let $(Q,\pi_{A'})$ be homogeneous coordinates on the total space of $\mathcal{O}(2n)$ bundle. Let us choose a constant spinor $o_{A'}$ and parametrize a section of the $\mathcal{O}(2n)\to\mathbb{CP}^1$ by $2n+1$ complex numbers

$$x^{A'_1\cdots A'_{2n}}=\left.\frac{\partial^{2n}Q}{\partial\pi_{A'_1}\cdots\partial\pi_{A'_{2n}}}\right|_{\pi_{A'_i}=o_{A'}}.$$

The coordinates $x^{A'_1\cdots A'_{2n}}$ on $\mathbb{C}^{2n+1}$ correspond to $t^0,\ldots,t^{2n}$ by

$$t^i=\binom{2n}{i}x^{A'_1A'_2\cdots A'_{2n}}o_{A'_1}\cdots o_{A'_i}\iota_{A'_{i+1}}\cdots\iota_{A'_{2n}}(-1)^{n-i}, \quad i=0,\ldots,2n.$$

Define

$$\frac{\partial}{\partial t^i}=\iota^{A'_1}\cdots\iota^{A'_i}o^{A'_{i+1}}\cdots o^{A'_{2n}}\frac{\partial}{\partial x^{A'_1\cdots A'_{2n}}}.$$

Let

$$F=\oint_\Gamma (\pi\cdot o)^{-2}G(Q,\pi_{A'})\pi\cdot \mathrm{d}\pi, \quad \text{where} \quad (\pi\cdot o)^2\frac{\partial G}{\partial Q}=f\in H^1(\mathcal{O}(2n),\mathcal{O}(2-2n)).$$

We have

$$\begin{aligned} f_{A'_1\cdots A'_{2n-4}} &= \oint_\Gamma \pi_{A'_1}\cdots\pi_{A'_{2n-4}}f\pi\cdot\mathrm{d}\pi \\ &= \oint_\Gamma \pi_{A'_1}\cdots\pi_{A'_{2n-4}}(\pi\cdot o)^2\frac{\partial G}{\partial Q}\pi\cdot\mathrm{d}\pi \\ &= o^{A'_{2n-3}}\cdots o^{A'_{2n}}\frac{\partial}{\partial x^{A'_1\cdots A'_{2n}}}\oint_\Gamma(\pi\cdot o)^{-2}G\pi\cdot\mathrm{d}\pi=\frac{\partial F}{\partial x^{A'_1\cdots A'_{2n-4}0'0'0'0'}}. \end{aligned}$$

Therefore fixing $f_{A'_1\cdots A'_{2n-4}}$ is equivalent to fixing $\partial F/\partial t^i$ for $i<2n-3$. Moreover, the global twistor function is given by

$$Q=(\omega_n\cdot\iota)(\pi\cdot\iota)^n=(\pi\cdot\iota)^{2n}\sum_{i=0}^{2n}\lambda^i t^{2n-i}.$$

□

V. ALE SPACES REVISITED; FINITE-GAP SOLUTIONS OF ASD VACUUM EQUATIONS

One way to generalize the Novikov construction of finite gap solutions of the Korteweg–de Vries equation to hyper-Kähler equations would be to study solutions to (8) which are invariant under three commuting hidden symmetries that we shall take to be triholomorphic:

$$\partial_{T_1} := \sum_{i=1}^{k} a_i \frac{\partial}{\partial t_i}, \quad \partial_{T_2} := \sum_{i=1}^{l} b_i \frac{\partial}{\partial t_i}, \quad \partial_{T_3} := \sum_{i=1}^{m} c_i \frac{\partial}{\partial t_i}, \qquad \text{where } a_i, b_i, c_i \text{ are constant,}$$

and the propagation of Θ along the parameters t_i is determined by the recursion relations (9). This would reduce (8) down to an ODE.

Rather than performing the explicit reduction to an ODE, we see from the twistor picture that the twistor space must have three projections onto the total space of the line bundle $\mathcal{O}(n)$ for three values of n. Thus we have a map of the twistor space $\mathcal{PT}$ into $\mathcal{O}(p)\oplus\mathcal{O}(q)\oplus\mathcal{O}(r)$ and so $\mathcal{PT}$ can be realized as a hypersurface in this space (although there may need to be some blowup or resolution of singularities where the map fails to be an embedding). If we realize $\mathcal{PT}$ as the zero set of a function F taking values in a line bundle of degree s, then we must have, for rational curves to have the appropriate normal bundle, that $p+q+r=2+s$.

We will now see that the ALE hyper-Kähler spaces fall precisely into this above class.

It is well known that hyper-Kähler manifolds $(\mathcal{M},g)$, which have the topology of $\mathbb{R}^4$ at infinity, and approach the flat Euclidean metric $\eta=\mathrm{d}x_1^2+\cdots+\mathrm{d}x_4^2$ sufficiently fast, in the sense that

$$g_{ab}=\eta_{ab}+O(r^{-4}), \quad (\partial_a)^p(g_{bc})=O(r^{-4-p}), \quad r^2=x_1^2+\cdots+x_4^2 \tag{32}$$

have to be flat. A weaker asymptotic condition one can impose on g is assymptoticaly locally Euclidean (ALE).

The ALE spaces are noncompact, complete hyper-Kähler manifolds which satisfy (32) only locally for $r\to\infty$. Globally the neighborhood of infinity must look like $S^3/\Gamma\times\mathbb{R}$, where Γ is a finite group of isometries acting freely on S^3 (a Kleinian group). These manifolds belong to the class of *gravitational instantons* because their curvature is localized in a "finite region" of a space–time.

Finite subgroups of $\Gamma\subset\mathrm{SU}(2)$ correspond Platonic solids in $\mathbb{R}^3$. They are the cyclic groups, and the binary dihedral, tetrahedral, octahedral and icosahedral groups (one can think about the last three as Möbius transformations of $S^2=\mathbb{CP}^1$ which leave the points corresponding to vertices of a given Platonic solid fixed). Each of them can be related to a Dynkin diagram of a simple Lie algebra. All Kleinian groups act on $\mathbb{C}^2$, and the "infinity" $S^3\subset\mathbb{C}^2$. Let $(z_1,z_2)\in\mathbb{C}^2$. For each Γ there exist three invariants x,y,z which are polynomials in (z_1,z_2) invariant under Γ. These invariants satisfy some algebraic relations which we list below:

Group	**Dynkin diagram**	**Relation** $F_\Gamma(x,y,z)=0$
cyclic	A_k	$xy-z^k=0$
dihedral	D_{k-1}	$x^2+y^2z+z^k=0$
tetrahedral	E_6	$x^2+y^3+z^4=0$
octahedral	E_7	$x^2+y^3+yz^3=0$
icosahedral	E_8	$x^2+y^3+z^5=0$

In each case

$$\mathbb{C}^2/\Gamma\subset\mathbb{C}^3=\{(x,y,z)\in\mathbb{C}^3, F_\Gamma(x,y,z)=0\}.$$

The manifold $\mathcal{M}$ on which an ALE metric is defined is obtained by minimally resolving the singularity at the origin of $\mathbb{C}^2/\Gamma$. This desingularization is achieved by taking $\mathcal{M}$ to be the zero set of

$$\tilde{F}_\Gamma(x,y,z)=F_\Gamma(x,y,z)+\sum_{i=1}^{r} a_i f_i(x,y,z),$$

where f_i span the ring of polynomials in (x,y,z) which do not vanish when $\partial_x F_\Gamma=\partial_y F_\Gamma=\partial_z F_\Gamma=0$. The dimension r of this ring is equal to the number of nontrivial conjugacy classes of Γ which is $k-1,\ k+1,\ 6,\ 7$ and 8, respectively.[6] Kronheimer[18,19] proved that for each Γ a unique hyper-Kähler metric exists on a minimal resolution $\mathcal{M}$, and that this metric is precisely the ALE metric with $\mathbb{R}^4/\Gamma$ as its infinity. His construction was a combination of the hyper-Kähler quotient[16] with twistor theory.

In each case the twistor space is the three-dimensional hyper-surface $\tilde{F}_\Gamma(x,y,z,\lambda)=0$ in the rank-three bundle $\mathcal{O}(p)\oplus\mathcal{O}(q)\oplus\mathcal{O}(r)\to\mathbb{CP}^1$. Now $x(\lambda)\in\mathcal{O}(p), y(\lambda)\in Q(q), z(\lambda)\in O(r)$ are polynomials in λ, $f_i=f_i(x,y,z)$, and $a_i=a_i(\lambda)$. Therefore

$$\mathcal{PT}\to\mathcal{O}(p),\quad \mathcal{PT}\to\mathcal{O}(q),\quad \mathcal{PT}\to\mathcal{O}(r),$$

and Lemma 4.2 implies that the corresponding hyper-Kähler metrics admit three commuting hidden symmetries, and the heavenly equation (8) reduces to an ODE.

The degrees p,q and r are such that $\tilde{F}_\Gamma(x,y,z,\lambda)$ is a function homogeneous of some degree s. Therefore

$$\tilde{F}_\Gamma:\mathcal{O}(p)\oplus\mathcal{O}(q)\oplus\mathcal{O}(r)\to\mathcal{O}(s).$$

To determine the integers p,q,r,s take the determinants of the above, and notice that the normal bundle to an $\mathcal{O}(1)\oplus\mathcal{O}(1)$ section of $\mathcal{PT}\to\mathbb{CP}^1$ will have the Chern class $p+q+r-s=2$. This gives us the following:

$$\begin{aligned}
A_k\quad & \mathcal{PT}=\{(x,y,z,\lambda)\in\mathcal{O}(k)\oplus\mathcal{O}(k)\oplus\mathcal{O}(2)\to\mathbb{CP}^1,\\
& xy-z^k-a_1z^{k-2}-\cdots-a_{k-1}=0\},\\
D_{k-1}\quad & \mathcal{PT}=\{(x,y,z,\lambda)\in\mathcal{O}(2k)\oplus\mathcal{O}(2k-2)\oplus\mathcal{O}(4)\to\mathbb{CP}^1,\\
& x^2+y^2z+z^k+a_1y^2+a_2y+a_3z^{k-2}+\cdots+a_kz+a_{k+1}=0\},\\
E_6\quad & \mathcal{PT}=\{(x,y,z,\lambda)\in\mathcal{O}(12)\oplus\mathcal{O}(8)\oplus\mathcal{O}(6)\to\mathbb{CP}^1,\\
& x^2+y^3+z^4+y(a_1z^2+a_2z+a_3)+a_4z^2+a_5z+a_6=0\},\\
E_7\quad & \mathcal{PT}=\{(x,y,z,\lambda)\in\mathcal{O}(18)\oplus\mathcal{O}(12)\oplus\mathcal{O}(8)\to\mathbb{CP}^1,\\
& x^2+y^3+yz^3+y^2(a_1z+a_2)+y(a_3z+a_4)+a_5z^2+a_6z+a_7=0\},\\
E_8\quad & \mathcal{PT}=\{(x,y,z,\lambda)\in\mathcal{O}(30)\oplus\mathcal{O}(20)\oplus\mathcal{O}(12)\to\mathbb{CP}^1,\\
& x^2+y^3+z^5+y(a_1z^3+a_2z^2+a_3z+a_4)+a_5z^3+a_6z^2+a_7z+a_8=0\}.
\end{aligned}\tag{33}$$

Note that these spaces are not quite the full nonsingular twistor space as there will be singular points where $\tilde{F}_\Gamma$ vanishes together with its first derivatives. These singularities can, however, be resolved, see Ref. 19.

We observe that these twistor spaces have projections onto $\mathcal{O}(2n)$ for $2n=p,q,r$ and this corresponds to the existence of three independent commuting triholomorphic hidden symmetries. The simplest description along the lines of Sec. IV arises for the lowest value of n, i.e., when we

project onto the z coordinates in the above construction. It is clear from the above formulas that the fibers of this projection are affine conics in the A_k and D_k cases, and affine elliptic curves in the E_k cases.

From now on we shall drop the subscript Γ, because the construction we shall describe applies to all cases. These twistor spaces can all be described as affine line bundles over $\mathcal{O}(r)$ in effect by uniformizing the affine conics or elliptic curves that make up the fibers of $\mathcal{PT}\to\mathcal{O}(r)$. The affine line bundle is determined by a cohomology class in $H^1(\mathcal{O}(r),\mathcal{O}(2-r)$ which can be evaluated as a linear field on $\mathbb{C}^{r+1}$. The ALE space can then be realized as (a branched cover of) the zero set of this linear field in the real slice $\mathbb{R}^{r+1}$ as in Theorem 4.4.

To make the description more concrete, we now find a patching description of the relevant cohomology class in $H^1(\mathcal{O}(r),\mathcal{O}(2-r)$. We exclude the curve(s) on which both $\tilde{F}_x=0$ and $\tilde{F}_y=0$ so that we can cover the twistor space by the two open sets $U,\tilde{U}$ such that $\tilde{F}_x\neq 0$ in U and $\tilde{F}_y\neq 0$ in $\tilde{U}$. We use (y,z,λ) and (x,z,λ) as local coordinates in U and $\tilde{U}$, respectively. The symplectic form Σ on each fiber of $\mathcal{PT}\to\mathbb{CP}^1$ is given by

$$\frac{dy\wedge dz}{\tilde{F}_x} \quad \text{in } U, \quad \text{or} \quad \frac{-dx\wedge dz}{\tilde{F}_y} \quad \text{in } \tilde{U}.$$

These arise from the formula $\Sigma=\oint dx\wedge dy\wedge dz/\tilde{F}$ with the contour being a small circle surrounding $\tilde{F}=0$. The global homogeneous function z gives rise to a homogeneity $r-2$ Hamiltonian vector field X_z tangent to the fibers of $\mathcal{PT}\to\mathcal{O}(r)$. From the formula $X_z\lrcorner\Sigma=dz$ we deduce that

$$X_z=\tilde{F}_x\frac{\partial}{\partial y} \quad \text{in } U, \quad X_z=-\tilde{F}_y\frac{\partial}{\partial x} \quad \text{in } \tilde{U}.$$

We now introduce new coordinates (u,z,λ) and $(\tilde{u},z,\lambda)$ on U and $\tilde{U}$, respectively, where the fiber coordinates in u in $U\to\mathcal{O}(r)$ and $\tilde{u}$ in $\tilde{U}\to\mathcal{O}(r)$ satisfy $X_z(u)=X_z(\tilde{u})=1$. Therefore

$$u(y,z)=\int_\sigma^{\tilde{F}_x=1}\frac{dy}{\tilde{F}_x}, \quad \tilde{u}(x,z)=-\int_\sigma^{\tilde{F}_y=1}\frac{dx}{\tilde{F}_y}$$

for some σ, and the patching function is given on the overlap by

$$f(z,\lambda)=u-\tilde{u}=\int_{\tilde{F}_y=1}^{\tilde{F}_x=1}\frac{dy}{\tilde{F}_x}. \tag{34}$$

In the above formula x should be determined in terms of (y,z,λ) using $\tilde{F}=0$ before the integral is evaluated. The upper and lower limits will then involve $y=y(z,\lambda)$.

In the case of A_k ALE space we can assume that

$$z^k+a_1z^{k-2}+\cdots+a_{k-1}=\prod_{j=1}^{k}(z-p_j(\lambda)), \quad \text{where } p_j\in\Gamma(\mathcal{O}(2)).$$

(See Refs. 15 and 6 for further discussion of this point.) A simple integration yields $f=\ln\Pi_{j=1}^k(z-p_j(\lambda))$, and from Proposition 4.5 we find

$$G=\sum_{j=1}^{k}(z-p_j)(\ln(z-p_j)-1).$$

For D_{k-1} we can redefine z and a_j to get rid of terms linear and quadratic in y, and write

$$\tilde{F}=x^2-y^2z-\prod_{j=1}^{k}(z-q_j(\lambda)) \quad \text{where } q_j\in\Gamma(\mathcal{O}(4)).$$

Now (34) yields

$$f=\frac{1}{\sqrt{z}}\ln\frac{(z-4z\Pi_{j=1}^{k}(z-q_j(\lambda)))^{1/2}+\sqrt{z}}{(1+4z\Pi_{j=1}^{k}(z-q_j(\lambda)))^{1/2}-1}.$$

In the remaining cases E_6, E_7 and E_8 the fibers of $\mathcal{PT}\to\mathcal{O}(r)$ are elliptic curves $x^2=4y^2+g_1y+g_2$ (in case of E_7 one needs to redefine y,z,a_i to obtain this canonical form). The periods g_1,g_2 are polynomials in z of order less or equal to 5 which can be determined from (33). The fibers can therefore be parametrized by the Weierstrass elliptic function. The cohomology class is represented by an elliptic integral

$$f=\frac{1}{2}\int_{y_0}^{y_1}\frac{\mathrm{d}y}{\sqrt{4y^3+g_1y+g_2}},$$

where y_1 and y_0 are roots of $4y^3+g_1y+g_2-\frac{1}{4}=0$ and $12y^2+g_1-1=0$, respectively.

One can now, in principal, take these cohomology classes and integrate them to obtain a linear field with $r-3$ components on $\mathbb{C}^{r+1}$ the vanishing of which will determine the complexified ALE space as a submanifold. This above description is not completely satisfactory for two related reasons. First, the description of the ALE space will not be global; the projection from the true ALE space to $\mathbb{C}^{r+1}$ can be many to one, and can have irregular values. Second, the limits of integration above defining the cohomology classes actually branch and are not completely well defined.

Further work is required to make this a useful description of ALE spaces. It seems likely that these are the only complete hyper-Kähler metrics with three triholomorphic hidden symmetries.

VI. HIERARCHIES FOR THE GENERALIZED CONFORMAL ANTI-SELF-DUALITY EQUATIONS

In this section we extend the concept of a hierarchy from that of Ref. 8 for the four-dimensional hyper-Kähler equations to a generalization of the conformal anti-self-duality equations (and in the process give new and more geometric formulations for the hyper-Kähler hierarchy than in Ref. 8). The guiding motivation for these definitions comes from the twistor theory. However, we first define the various concepts in space–time terms, and then discuss the twistor theory subsequently. We shall, for convenience, work in the holomorphic category. Real versions of the various structures and equations can then be obtained subsequently by demanding the existence of an antiholomorphic involution σ fixing a real slice and with specified action on the various geometric structures.

We will abbreviate the term conformal anti-self-duality to CASD and generalized CASD to GCASD. Unfortunately this terminology is nonstandard but is designed to be consistent with the corresponding discussion for the anti-self-dual Yang–Mills equations given in Ref. 21. The generalization of the CASD case is a mild generalization of quaternionic structures discussed in Ref. 28 and they have been termed paraconformal structures, see Ref. 2, and Grassman structures,[1,4] where many properties, including the twistor theory, of these spaces are studied. Here we shall refer to them as generalized CASD, GCASD, spaces. The hierarchies defined here are a special case of the $\mathcal{P}$-structures of Gindikin (Ref. 14, and references therein).

Definition 6.1: A solution to the GCASD hierarchy consists of the data $(\mathcal{M},\mathbb{S},\tilde{\mathbb{S}},e^{AA'_1\cdots A'_n})$ *defined as follows:* $\mathcal{M}$ *is a manifold of dimension* $r(n+1)$, $\mathbb{S}$ *and* $\tilde{\mathbb{S}}$ *are vector bundles of rank* r *and* 2, *respectively, we use abstract indices* A *and* A' *to denote membership of* $\mathbb{S}$ *and* $\tilde{\mathbb{S}}$, *respec-*

tively; when realized concretely, $A=0,1,\ldots,r-1$ *and* $A'=0',1'$. *The indexed one-form* $e^{AA'_1\cdots A'_n}$, *symmetric over its primed indices, determines an isomorphism* $T\mathcal{M}=\mathbb{S}\otimes\odot^n\tilde{\mathbb{S}}$ *at every point.*

An element $\pi_{A'}$ *of* $\tilde{\mathbb{S}}^*$ *at* $m\in\mathcal{M}$ *determines an* rn*-plane element*

$$z(m)_\pi=\{V\in T_m\mathcal{M}, V\lrcorner e^{AA'_1\cdots A'_n}\pi_{A'_1}\cdots\pi_{A'_n}=0\}.$$

Such an rn*-plane element will be said to be an* α*-plane element at* m. *An* α*-surface is an* rn*-dimensional surface whose tangent space defines an* α*-plane element at each of its points.*

The GCASD hierarchy equations are the requirement that there exists a full family of α*-surfaces, with a unique* α*-surface through each* $z(m)_\pi$.

The notation derives from the identification of these bundles with the spin bundles of a conformal structure in four-dimensions, $r=2$, $n=1$. It will also be convenient to introduce a "clumped" index i for the $n+1$-dimensional vector space $\odot^n\tilde{\mathbb{S}}$. When the indices are realized concretely by a choice of a frame for $\tilde{\mathbb{S}}$ with components labeled by 0 and 1, there is a standard correspondence between the ith component for the clumped index and the component with i 1's and $n-i$ 0's, so that i naturally goes from 0 to n.

We now assume that we have a solution to the CASD hierarchy so that we have a full complement of α-surfaces and that, shrinking $\mathcal{M}$ to a convex neighborhood of a point if necessary, the space of these α-surfaces is a manifold. We can then define the following.

Definition 6.2: The space of such α*-surfaces will be called the twistor space and is denoted* $\mathcal{PT}$.

Twistor space is an $r+1$-dimensional complex manifold.

Theorem 6.3: *The twistor space determines and is determined by the GCASD hierarchy. The correspondence is stable under small deformations of the complex structure of* $\mathcal{PT}$ *or of the GCASD hierarchy.*

Proof: This is a straightforward extension of Penrose's nonlinear graviton construction. The correspondence can be studied by means of the double fibration

$$\begin{array}{ccc} & P\tilde{\mathbb{S}} & \\ p\swarrow & & \searrow q \\ \mathcal{M} & & \mathcal{PT}. \end{array}$$

Points $m\in M$ correspond to rational curves $L_m:=q(p^{-1}(m))\equiv\mathbb{CP}^1$ in $\mathcal{PT}$. The normal bundle of these rational curves is $N=\mathbb{S}\otimes\mathcal{O}(n)$ where $\mathcal{O}(n)$ is the line bundle of Chern class n on $\mathbb{CP}^1$; this follows from the fact that, since the tangent space of $z(m)_\pi$ is the kernel of $e^{AA'_1\cdots A'_n}\pi_{A'_1}\cdots\pi_{A'_n}$, the section of the normal bundle corresponding to a vector V can be identified with $V\lrcorner e^{AA'_1\cdots A'_n}\pi_{A'_1}\cdots\pi_{A'_n}$, a function with values in $\mathbb{S}$ with homogeneity n. However, sections of $\mathcal{O}(n)$ can be identified with functions homogeneous degree n, and so the normal bundle is $\mathbb{S}\otimes\mathcal{O}(n)$ as claimed.

With knowledge of the normal bundle, Kodaira theory can now be applied and shows that, since $H^1(\mathbb{CP}^1,N)=H^1(\mathbb{CP}^1,\mathrm{End}(N))=0$, the moduli space of curves has $\dim(H^0(\mathbb{CP}^1,\mathbb{S}\otimes\mathcal{O}(n))=r(n+1)$ dimensions, contains $\mathcal{M}$ and $T_m\mathcal{M}\equiv\Gamma(\mathbb{S}\otimes\mathcal{O}(n))\equiv\mathbb{S}\otimes\odot^n\tilde{\mathbb{S}}$. Points of $\mathcal{PT}$ clearly then correspond to integrable α-surfaces in $\mathcal{M}$. Kodaira theory also provides the stability of the correspondence under small deformations. See Refs. 22 and 23 for general constructions that apply to these situations. □

Remark: The $\mathcal{P}$-structures of Gindikin are more general but can be understood easily in this context as arising naturally on moduli spaces of rational curves in some complex manifold whose normal bundles are $\mathcal{O}(k_1)\oplus\cdots\oplus\mathcal{O}(k_r)$ with the k_i not being required to be equal. Such prescriptions for the normal bundle are unstable under deformations of the underlying complex manifold

unless no two of the k_i differ by more than one. Under deformations of the complex structure, in the moduli space of such rational curves, the normal bundle will jump so that a dense open set will be the stable case where the normal bundle will be $E\otimes\mathcal{O}(k)\oplus F\otimes\mathcal{O}(k+1)$ with E and F trivial bundles.

This additional generality can be important. For example, if we wish to discuss generalizations of the Ward construction, the twistor space has the structure of a holomorphic vector bundle over a lower dimensional space. In this case, the normal bundle of the rational curves along the fibers is usually taken to have degree 0, whereas the normal bundle of its projection into the bases will usually be required to have a higher degree normal bundle.

These geometric structures fall into the category of involutive G-structures studied by Merkulov.[22,23] In particular, one can exploit his theorems to deduce the existence of connections compatible with the geometric structure. However, for the most part, they must have torsion, although they fall into Merkulov's category of "G-structures with very little torsion."[23]

Lemma 6.4: For $r\geqslant 2$, $n\geqslant 1$, there exists connections on $\mathbb{S}$ and $\widetilde{\mathbb{S}}$ such that the induced connection on TM has torsion with nonvanishing irreducible parts only in $\mathbb{S}\otimes\odot^2\mathbb{S}^*\otimes\odot^{n-2}\widetilde{\mathbb{S}}$ and $\mathbb{S}^*\otimes\odot^{n-4}\widetilde{\mathbb{S}}$ where we take $\odot^n\widetilde{\mathbb{S}}=\mathbb{C}$ for $n=0$ or zero for $n<0$. There exists a unique choice for such a connection when $n>1$ and unique up to a one-form for $n=1$ (which can be taken to be exact with appropriate choices).

Proof: Merkulov reformulates the moduli spaces considered above as Legendrian moduli spaces of holomorphically embedded $\mathbb{CP}^1\times\mathbb{CP}^{r-1}$'s in the projective cotangent bundle $PT^*\mathcal{PT}$ of twistor space. A rational curve, $\mathbb{CP}^1$ in $\mathcal{PT}$ determines its projective conormal bundle in $PT^*\mathcal{PT}$, i.e., the one-forms up to scale that annihilate the tangent space of $\mathbb{CP}^1$. This correspondence is studied by means of the following double fibration

$$\begin{array}{ccc} & P\widetilde{\mathbb{S}}\times P\mathbb{S}\subset P(T^*M) & \\ & \mu\swarrow \qquad \searrow\nu & \\ M & & P(T^*\mathcal{PT})\,. \end{array}$$

Merkulov's method uses the contact line bundle L which is the dual to the tautological line bundle $T^*\mathcal{PT}\to P(T^*\mathcal{PT})$. On restriction to a $\mathbb{CP}^1\times\mathbb{CP}^{r-1}$, it gives $\mathcal{O}(n,1)$ where $\mathcal{O}(p,q)$ is the product of the pullback of $\mathcal{O}(p)$ from $\mathbb{CP}^1$ with the pullback of $\mathcal{O}(q)$ frpm $\mathbb{CP}^{r-1}$.

Merkulov shows that the minimal torsion of an affine connection preserving the G-structure (or obstruction to obtaining a torsion free connection preserving the tensor decomposition of the tangent space) is then measured by a geometrically obtained class in $H^1(\mathbb{CP}^1\times\mathbb{CP}^{r-1},L\otimes\odot^2(J^1L)^*)$ and the freedom in the resulting connection is given by $H^0(\mathbb{CP}^1\times\mathbb{CP}^{r-1},L\otimes\odot^2(J^1L)^*)$.

These groups can be computed as follows. The first jet of a section of $\mathcal{O}(n)$, $n\neq 0$, at a point of $\mathbb{CP}^{r-1}$ can be encoded into the derivative of a homogeneous degree n function with respect to the $r+1$ homogeneous coordinates. The value of the function is then retrieved from this by Euler's homogeneity equations, $\pi_A\partial f/\partial\pi_A=nf$. Thus, the sheaf J^1L on $\mathbb{CP}^1\times\mathbb{CP}^r$ can be understood as the kernel

$$0\to J^1L\to\mathbb{S}^*(n-1,1)\oplus\widetilde{\mathbb{S}}^*(n,0)\xrightarrow{(\pi_A,-\pi_{A'})}\mathcal{O}(n,1)\to 0$$

since, in the third map, we are imposing the requirement that the Euler homogeneity relation for each factor leads to the same value for f.

The cohomology groups $H^i(\mathbb{CP}^1\times\mathbb{CP}^{r-1},L\otimes\odot^2(J^1L)^*)$ can therefore be calculated by consideration of the long exact cohomology sequence arising from the short exact sequence

$$0\to \mathbb{S}^*(-n,0)\oplus\tilde{\mathbb{S}}^*(1-n,-1)\xrightarrow{\odot(\pi_B,\pi_{B'})}\odot^2\mathbb{S}^*(-n,1)\oplus\mathbb{S}\otimes\tilde{\mathbb{S}}(1-n,0)\oplus\odot^2\tilde{\mathbb{S}}(2-n,-1)$$
$$\to L\otimes\odot^2(J^1L^*)\to 0,$$

where π_A and $\pi_{A'}$ are the homogenous coordinates on $\mathbb{CP}^{r-1}$ and $\mathbb{CP}^1$, respectively. □

Note that the Merkulov framework is not quite equivalent to ours in the sense that it only requires knowledge of the total space $P(T^*\mathcal{PT})$ but does not require that it be realized as the projective cotangent bundle of some $\mathcal{PT}$. The results are only inequivalent for $r=1$, $n<3$ and $r=2$, $n=1$. In these cases the results are well known, for example, the full theory of the latter case goes back to Penrose in 1976.[25] The Merkulov framework does not see the curvature conditions that arise from existence of $\mathcal{PT}$, but gives the correct result for the existence of and freedom in choosing compatible torsion-free affine connections.

The cases $r=1$ are also well known, but for $n=1,2$ do not fall satisfactorily into the Merkulov framework. For $n=1$, there is a projective structure, i.e., an equivalence class of torsion-free connections that share the same unparametrized geodesics, with freedom given by a one-form. For $n=2$ there exists a unique torsion-free connection compatible with a conformal structure. For $n=3$ the connection is still torsion-free, but not subsequently for higher n.

The general $n=1$ case was studied in Refs. 28 and 2. It also follows from the calculations of Ref. 2 that the torsion must be nonzero for a nonflat structure in the $n>1$, $r>2$ cases as a consequence of the fact that in these cases the decomposition of the tangent space as a tensor product of $\mathbb{S}$ with $\odot^n\tilde{\mathbb{S}}$ determines a paraconformal structure in which both factors have dimension greater than two, and in that case the torsion-free condition implies flatness.

Lemma 6.5: For $r>1$, the requirement of uniqueness for the α surface through $z(m)_\pi$ is redundant.

Proof: The integrability equations in particular give a propagation equation for π across the α-surface. □

There are a number of specializations of the GCASD equations: hypercomplex, scalar-flat Kähler, Einstein, hyper-Kähler. The hypercomplex and hyper-Kähler cases have straightforward extensions to the hierarchy.

(i) The hyper-complex case for r even, $n=1$, where there exists a flat connection on $\tilde{\mathbb{S}}$ such that the distribution D on $P\tilde{\mathbb{S}}$ is horizontal. This is equivalent to the existence of a fibration $\mathcal{PT}\mapsto\mathbb{CP}^1$. This condition (flatness of the induced connection of 6.4 or a fibration of the associated twistor space over $\mathbb{CP}^1$) can clearly be imposed consistently on any $\mathcal{M}_{r,n}$ to give a hypercomplex hierarchy.

(ii) In case of the hyper-Kähler hierarchy, we require that there exists a connection compatible with 6.4 that induces a flat connection on $\tilde{\mathbb{S}}$ and preserves skew forms ε_{AB} on $\mathbb{S}$ and $\varepsilon_{A'B'}$ on $\tilde{\mathbb{S}}$ such that the forms $\varepsilon_{AB}e^{A(A'_1\cdots A'_n}\wedge e^{B'_1\cdots B'_n)B}$ are closed. This then implies that $\eta=\varepsilon^{A'B'}\pi_{A'}D\pi_{B'}$ and $\eta\wedge\varepsilon_{AB}\pi_{A'_1}\cdots\pi_{A'_n}e^{AA'_1\cdots A'_n}\wedge\pi_{B'_1}\cdots\pi_{B'_n}e^{BB'_1\cdots B'_n}$ descend to $\mathcal{PT}$, in such a way that η is the annihilator of an integrable distribution determining a fibration over $\mathbb{CP}^1$.

A. Reality structures

The imposition of reality conditions is standard; it is imposed by requiring the existence of an anti-holomorphic involution σ on $\mathcal{M}$ that fixes a real slice and preserves the geometric structures (i.e., sends α-surfaces to α-surfaces). In the hyper-Kähler case, we can talk in terms of the signature of the associated metric (although the following conditions can be applied more generally). For Euclidean signature, we require that it induces a quaternionic involution on $\tilde{\mathbb{S}}$ given by $\sigma^2=-1$. In particular there are no nonzero fixed points. It will then also induce a quaternionic involution on $\mathbb{S}$ which will have to be even dimensional and we must also require that the

Hermitian form $\pi^A\hat{\pi}^B\varepsilon_{AB}$ be definite (it is trivially definite for $r=2$). For non-Euclidean signature we can have different signatures for $\pi^A\hat{\pi}^B\varepsilon_{AB}$, or impose a conjugation whose action on $\mathbb{S}$ snf $\widetilde{\mathbb{S}}$ is an ordinary complex conjugation.

The conjugation will also lead to an antiholomorphic involution on the twistor space, without fixed points in the quaternionic case, and with a fixed real slice otherwise. Points of the real slice of $\mathcal{M}$ will then correspond to σ invariant rational curves.

B. Embedding into hierarchies

In the usual definition of a hierarchy, the hierarchy is an overdetermined, but compatible, system of equations which contains the original system. A given solution to the original system may not actually extend to a solution of the hierarchy in general (there can be obstructions, see p. 249 and p. 253, footnote 2, of Ref. 21 for some discussion of this behavior for the Drinfeld Sokolov hierarchies). Furthermore, if such an extension does exist, it will not in general be unique without the imposition of boundary conditions.

Our definition of a hidden symmetry in Sec. IV requires the existence of an extension of a solution to the original equation to the hierarchy that happens to admit a symmetry, but only when thought of as a solution to the hierarchy.

We state the embedding definition in slightly greater generality as for one hierarchy into another:

Definition 6.6: A solution $\mathcal{M}_{r_1,n_1}$ to the GCASD hierarchy embeds into another solution $\mathcal{M}_{r_2,n_2}$, $n_1<n_2$, $r_1\leqslant r_2$, if $\mathcal{M}_{r,n_1}$ embeds into $\mathcal{M}_{r,n_2}$ as a manifold in such a way that the α-surfaces of $\mathcal{M}_{r,n_2}$ intersect $\mathcal{M}_{r,n_1}$ in the α-surfaces of $\mathcal{M}_{r,n_1}$ and all α-surfaces of $\mathcal{M}_{r,n_1}$ arise in this way.

Due to a remarkable theorem of Bernstein and Gindikin,[14] the twistor characterization of such an embedding in the most interesting case, $r_1=r_2$, is remarkably simple:

Theorem 6.7 (Bernstein and Gindikin): *A solution $\mathcal{M}_{r,n_1}$ to the GCASD hierarchy embeds into $\mathcal{M}_{r,n_2}$ iff the twistor space $\mathcal{PT}_{n_1}$ for $\mathcal{M}_{r,n_1}$ is obtained from that $\mathcal{PT}_{n_2}$ for $\mathcal{M}_{r,n_2}$ by choosing submanifolds Γ_1, Γ_2,... of codimension greater than one and S_1, S_2,... of $codimension=1$ and blowing up along each Γ_1, Γ_2,... and taking a branch covers branching with some multiplicity over each S_i.*

In Ref. 8 (see also Sec. III), we embedded $\mathcal{M}_{2,n_1}$ into $\mathcal{M}_{2,n_2}$ by blowing up the twistor space $\mathcal{PT}_{n_2}$ at one point n_2-n_1 times.

Note that it is natural in the quaternionic cases, or in the hyper-CASD cases, to require that the additional structures be compatible. This is straightforward in the hypercomplex case in which one wishes the embedded twistor space to inherit a fibration over $\mathbb{CP}^1$, but when line bundle valued forms need to be pulled back also, there is the problem that the forms that have been pulled back will in general take values in an inappropriate line bundle unless particular care has been taken.

C. Symmetries and hidden symmetries

We can define a symmetry for a GCASD structure to be the requirement that the twistor space admits a global holomorphic vector field $\mathcal{K}$. This will in turn determine global holomorphic vector fields $\widetilde{K}$ on the correspondence space and K on $\mathcal{M}$, such that $\widetilde{K}$ projects to K. The essential requirement on $\widetilde{K}$ will be that it preserves the twistor distribution and this will lead to a generalization of the conformal Killing vector equations on K whose precise form will depend on r and n.

Clearly the concept of hidden symmetry can be applied as before but with greater generality; a solution $\mathcal{M}_{r,n}$ admits a hidden symmetry if it can be embedded as above into an $\mathcal{M}_{r,m}$ that admits an explicit symmetry. This will, as in the proof of Proposition 4.1, lead to a global vector field on $\mathcal{PT}_{r,n}$ with values in a line bundle $\mathcal{L}$ of degree $m-n$ (the restriction of the canonical bundle of $\mathcal{PT}_{r,m}$ tensored with the inverse of that of $\mathcal{PT}_{r,n}$). There will also be a generalization of Theorem 4.4: this global vector field with values in $\mathcal{L}$ will lead to the realization of $\mathcal{PT}_{r,n}$ as the total space of an affine line bundle, with underlying translation bundle $\mathcal{L}^*$, over some reduced

twistor space which will generically be $\mathcal{PT}_{r-1,l}$ where $l=n+m/(r-1)$, if l is an integer, although if l is fractional, or in nongeneric situations, the normal bundle of lines in the reduced twistor space must be $\mathcal{O}(k_1)\oplus\cdots\oplus\mathcal{O}(k_{r-1})$ with $\Sigma k_i=(r-1)n+m$. Thus the original $\mathcal{PT}_{r,n}$ with a hidden symmetry can be determined in terms of a lower dimensional twistor space together with a linear cohomology class on that space.

ACKNOWLEDGMENTS

We are grateful to Nigel Hitchin for helpful comments and for showing us his notes on D_k ALE manifolds. We would also like to thank Toby Bailey, Roger Bielawski, David Calderbank, Simon Gindikin and George Sparling for useful discussions. Both authors are members of EDGE, Research Training Network HPRN-CT-2000-00101. M.D. was partly supported by NATO Grant No. PST.CLG.978984.

APPENDIX: TWO-COMPONENT SPINOR NOTATION

In four complex dimensions orthogonal transformations decompose into products of ASD and SD rotations $\mathrm{SO}(4,\mathbb{C})=(\mathrm{SL}(2,\mathbb{C})\times\widetilde{\mathrm{SL}}(2,\mathbb{C}))/\mathbb{Z}_2$. The spinor calculus in four dimensions is based on this isomorphism. We use the conventions of Penrose and Rindler.[26] The tangent space at each point of $\mathcal{M}$ is isomorphic to a tensor product of the two spin spaces $T^a\mathcal{M}=S^A\otimes S^{A'}$. Spin dyads (o^A,ι^A) and $(o^{A'},\iota^{A'})$ span S^A and $S^{A'}$, respectively. The spin spaces S^A and $S^{A'}$ are equipped with symplectic forms ε_{AB} and $\varepsilon_{A'B'}$ such that $\varepsilon_{01}=\varepsilon_{0'1'}=1$. These antisymmetric objects are used to raise and lower the spinor indices via $\iota_A=\iota^B\varepsilon_{BA}$, $\iota^B=\varepsilon^{AB}\iota_B$. Let Γ_{AB} and $\Gamma_{A'B'}$ be the $\mathrm{SL}(2,\mathbb{C})$ and $\widetilde{\mathrm{SL}}(2,\mathbb{C})$ spin connections. The curvature of the unprimed spin connection $R^A{}_B=\mathrm{d}\Gamma^A{}_B+\Gamma^A{}_C\wedge\Gamma^C{}_B$ decomposes as

$$R^A{}_B=C^A{}_{BCD}\Sigma^{CD}+(1/12)R\Sigma^A{}_B+\Phi^A{}_{BC'D'}\Sigma^{C'D'},$$

and similarly for $R^{A'}{}_{B'}$. Here R is the Ricci scalar, $\Phi_{ABA'B'}$ is the trace-free part of the Ricci tensor R_{ab}, and C_{ABCD} is the ASD part of the Weyl tensor

$$C_{abcd}=\varepsilon_{A'B'}\varepsilon_{C'D'}C_{ABCD}+\varepsilon_{AB}\varepsilon_{CD}C_{A'B'C'D'},$$

and the two-forms $\Sigma^{A'B'}$ span the three-dimensional space of SD two-forms.

Given a complex four-dimensional manifold $\mathcal{M}$ with curved metric g, a twistor in $\mathcal{M}$ is an α-surface, i.e., a null two-dimensional surface whose tangent space at each point is an α plane (a null two-dimensional plane with a SD bi-vector). There are Frobenius integrability conditions for the existence of such α-surfaces through each α-plane element at each point and these are equivalent, after some calculation, to the vanishing of the self-dual part of the Weyl curvature, $C_{A'B'C'D'}$. Thus, given $C_{A'B'C'D'}=0$, we can define a twistor space $\mathcal{PT}$ to be the three complex dimensional manifold of α-surfaces in $\mathcal{M}$. If g is also Ricci flat, then $\mathcal{PT}$ has further structures which are listed in the nonlinear graviton theorem:

Theorem A.1 (Penrose[25]): *There is a 1-1 correspondence between complex ASD vacuum metrics on complex four-manifolds and three-dimensional complex manifolds $\mathcal{PT}$ such that the following hold.*

(i) *There exists a holomorphic projection $\mu:\mathcal{PT}\to\mathbb{CP}^1$.*
(ii) *$\mathcal{PT}$ is equipped with a four complex parameter family of sections of μ each with a normal bundle $\mathcal{O}(1)\oplus\mathcal{O}(1)$ (this will follow from the existence of one such curve by Kodaira theory).*
(iii) *Each fiber of μ has a symplectic structure $\Sigma_\lambda\in\Gamma(\Lambda^2(\mu^{-1}(\lambda))\otimes\mathcal{O}(2))$, where $\lambda\in\mathbb{CP}^1$.*

To obtain real metrics on a real four-manifold, we can require further that the twistor space admit an antiholomorphic involution.

The correspondence space $\mathcal{F}=\mathcal{M}\times\mathbb{CP}^1$ is coordinatized by (x,λ), where x denotes the coordinates on $\mathcal{M}$ and λ is the coordinate on $\mathbb{CP}^1$ that parametrizes the α-surfaces through x in $\mathcal{M}$. We represent $\mathcal{F}$ as the quotient of the primed-spin bundle $S^{A'}$ with fiber coordinates $\pi_{A'}$ by the Euler vector field $\Upsilon=\pi^{A'}\partial/\partial\pi^{A'}$. We relate the fiber coordinates to λ by $\lambda=\pi_{0'}/\pi_{1'}$. A form with values in the line bundle $\mathcal{O}(n)$ on $\mathcal{F}$ can be represented by a homogeneous form α on the nonprojective spin bundle satisfying $\Upsilon\lrcorner\alpha=0$, $\mathcal{L}_\Upsilon\alpha=n\alpha$.

The correspondence space has the alternate definition

$$\mathcal{F}=\mathcal{PT}\times\mathcal{M}\big|_{Z\in l_x}=\mathcal{M}\times\mathbb{CP}^1,$$

where l_x is the line in $\mathcal{PT}$ that corresponds to $x\in\mathcal{M}$ and $Z\in\mathcal{PT}$ lies on l_x. This leads to a double fibration

$$\mathcal{M}\overset{p}{\leftarrow}\mathcal{F}\overset{q}{\rightarrow}\mathcal{PT}. \tag{A1}$$

Points in $\mathcal{M}$ correspond to rational curves in $\mathcal{PT}$ with normal bundle $\mathcal{O}^A(1):=\mathcal{O}(1)\oplus\mathcal{O}(1)$. The normal bundle to l_x consists of vectors tangent to x (horizontally lifted to $T_{(x,\lambda)}\mathcal{F}$) modulo the twistor distribution. We have a sequence of sheaves over $\mathbb{CP}^1$:

$$0\rightarrow D\rightarrow\mathbb{C}^4\rightarrow\mathcal{O}^A(1)\rightarrow 0.$$

The map $\mathbb{C}^4\rightarrow\mathcal{O}^A(1)$ is given by $V^{AA'}\rightarrow V^{AA'}\pi_{A'}$. Its kernel consists of vectors of the form $\pi^{A'}\lambda^A$ with λ^A varying. The twistor distribution is therefore $D=O(-1)\otimes S^A$ and so there is a canonical $L_A\in\Gamma(D\otimes\mathcal{O}(1)\otimes S_A)$ given by $L_A=\pi^{A'}\nabla_{AA'}$. The projective twistor space $\mathcal{PT}$ arises as a quotient of $\mathcal{F}$ by the twistor distribution. Functions on $\mathcal{F}$ which are constant along $L_{A'}$ are called twistor functions.

Hexagonal circle patterns with constant intersection angles and discrete Painlevé and Riccati equations

S. I. Agafonov[a] and A. I. Bobenko[b]
Fachbereich Mathematik, Technische Universität Berlin, Strasse des 17. Juni 136, 10623 Berlin, Germany

(Received 15 January 2003; accepted 9 April 2003)

Hexagonal circle patterns with constant intersection angles mimicking holomorphic maps z^c and $\log(z)$ are studied. It is shown that the corresponding circle patterns are immersed and described by special separatrix solutions of discrete Painlevé and Riccati equations. The general solution of the Riccati equation is expressed in terms of the hypergeometric function. Global properties of these solutions, as well as of the discrete z^c and $\log(z)$, are established. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1586966]

I. INTRODUCTION. HEXAGONAL CIRCLE PATTERNS AND z^c

The theory of circle patterns is a rich fascinating area having its origin in the classical theory of circle packings. Its fast development in recent years is caused by the mutual influence and interplay of ideas and concepts from discrete geometry, complex analysis and the theory of integrable systems.

The progress in this area was initiated by Thurston's idea[24,17] of approximating the Riemann mapping by circle packings. Classical circle packings consisting of disjoint open disks were later generalized to circle patterns where the disks may overlap (see, for example, Ref. 14). Different underlying combinatorics were considered. Circle patterns with the combinatorics of the square grid were introduced in Ref. 22; hexagonal circle patterns were studied in Refs. 7 and 9.

The striking analogy between circle patterns and the classical analytic function theory is underlined by such facts as the uniformization theorem concerning circle packing realizations of cell complexes with prescribed combinatorics,[4] a discrete maximum principle and Schwarz's lemma,[20] rigidity properties[17,14] and a discrete Dirichlet principle.[22]

The convergence of discrete conformal maps represented by circle packings was proven in Ref. 21. For prescribed regular combinatorics this result was refined. C^∞-convergence for hexagonal packings is shown in Ref. 15. The uniform convergence for circle patterns with the combinatorics of the square grid and orthogonal neighboring circles was established in Ref. 22.

The approximation issue naturally leads to the question about analogs to standard holomorphic functions. Computer experiments give evidence for their existence,[12,16] however not very much is known. For circle packings with hexagonal combinatorics the only explicitly described examples are Doyle spirals,[11,5] which are discrete analogs of exponential maps, and conformally symmetric packings, which are analogs of a quotient of Airy functions.[6] For patterns with overlapping circles more explicit examples are known: discrete versions of $\exp(z)$, $\mathrm{erf}(z)$,[22] z^c, $\log(z)$ (Ref. 3) are constructed for patterns with underlying combinatorics of the square grid; z^c, $\log(z)$ are also described for hexagonal patterns.[7,9]

It turned out that an effective approach to the description of circle patterns is given by the theory of integrable systems (see Refs. 7–9). For example, Schramm's circle patterns are governed by a difference equation which is the stationary Hirota equation (see Ref. 22). This approach proved to be especially useful for the construction of discrete z^c and $\log(z)$ in Refs. 3 and 7–9 with

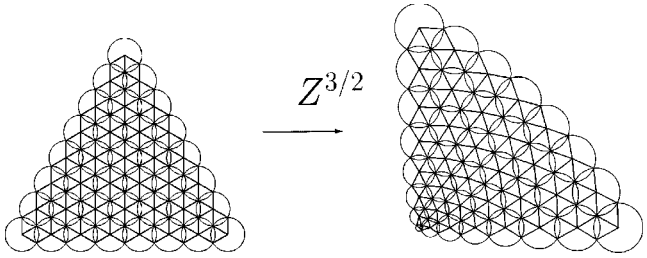

FIG. 1. Hexagonal circle patterns as a discrete conformal map.

the aid of some isomonodromy problem. Another connection with the theory of discrete integrable equations was revealed in Refs. 1–3: embedded circle patterns are described by special solutions of discrete Painlevé II and discrete Riccati equations.

In this article we carry the results of Ref. 3 for square grid combinatorics over to hexagonal circle patterns with constant intersection angles introduced in Ref. 7.

Hexagonal combinatorics are obtained on a sublattice of $\mathbb{Z}^3$ as follows: consider the subset

$$H=\{(k,l,m)\in\mathbb{Z}^3:\ |k+l+m|\leqslant 1\}$$

and join by edges those vertices of H whose (k,l,m)-labels differ by 1 only in one component. The obtained quadrilateral lattice QL has two types of vertices: for $k+l+m=0$ the corresponding vertices have six adjacent edges, while the vertices with $k+l+m=\pm 1$ have only three. Suppose that the vertices with six neighbors correspond to centers of circles in the complex plane $\mathbb{C}$ and the vertices with three neighbors correspond to intersection points of circles with the centers in neighboring vertices. Thus we obtain a circle pattern with hexagonal combinatorics.

Circle patterns where the intersection angles are constant for each of three types of (quadrilateral) faces (see Fig. 1) were introduced in Ref. 7. A special case of such circle patterns mimicking holomorphic map z^c and $\log(z)$ is given by the restriction to an H-sublattice of a special isomonodromic solution of some *integrable system* on the lattice $\mathbb{Z}^3$. Equations for the field variable $z:\mathbb{Z}^3\to\mathbb{C}$ of this system are

$$\begin{aligned}
&q(z_{k,l,m},z_{k,l+1,m},z_{k-1,l+1,m},z_{k-1,l,m})=e^{-2i\alpha_1},\\
&q(z_{k,l,m},z_{k,l,m-1},z_{k,l+1,m-1},z_{k,l+1,m})=e^{-2i\alpha_2},\\
&q(z_{k,l,m},z_{k+1,l,m},z_{k+1,l,m-1},z_{k,l,m-1})=e^{-2i\alpha_3},
\end{aligned}\tag{1}$$

where $\alpha_i>0$ satisfy $\alpha_1+\alpha_2+\alpha_3=\pi$ and

$$q(z_1,z_2,z_3,z_4)=\frac{(z_1-z_2)(z_3-z_4)}{(z_2-z_3)(z_4-z_1)}$$

is the cross-ratio of elementary quadrilaterals of the image of $\mathbb{Z}^3$. Equations (1) mean that the cross-ratios of images of faces of elementary cubes are constant for each type of face, while the restriction $\alpha_1+\alpha_2+\alpha_3=\pi$ ensures their compatibility.

The isomonodromic problem for this system (see Sec. II for the details, where we present the necessary results from Ref. 7) specifies the nonautonomous constraint

$$\begin{aligned}
cz_{k,l,m}=&2k\frac{(z_{k+1,l,m}-z_{k,l,m})(z_{k,l,m}-z_{k-1,l,m})}{z_{k+1,l,m}-z_{k-1,l,m}}+2l\frac{(z_{k,l+1,m}-z_{k,l,m})(z_{k,l,m}-z_{k,l-1,m})}{z_{k,l+1,m}-z_{k,l-1,m}}\\
&+2m\frac{(z_{k,l,m+1}-z_{k,l,m})(z_{k,l,m}-z_{k,l,m-1})}{z_{k,l,m+1}-z_{k,l,m-1}},
\end{aligned}\tag{2}$$

which is compatible with (1) (this constraint in the two-dimensional case with $c=1$ first appeared in Ref. 19). In particular, a solution to (1) and (2) in the subset

$$Q=\{(k,l,m)\in\mathbb{Z}^3 |\ \ k\geqslant 0,\ \ l\geqslant 0,\ \ m\leqslant 0\} \tag{3}$$

is uniquely determined by its values

$$z_{1,0,0},\ \ z_{0,1,0},\ \ z_{0,0,-1}.$$

Indeed, the constraint (2) gives $z_{0,0,0}=0$ and defines z along the coordinate axis $(n,0,0)$, $(0,n,0)$, $(0,0,-n)$. Then all other $z_{k,l,m}$ with $(k,l,m)\in Q$ are calculated through the cross-ratios (1).

Proposition 1:[7] *The solution $z:Q\to\mathbb{C}$ of the system (1) and (2) with the initial data*

$$z_{1,0,0}=1,\ \ z_{0,1,0}=e^{i\phi},\ \ z_{0,0,-1}=e^{i\psi} \tag{4}$$

determines a circle pattern. For all $(k,l,m)\in Q$ with even $k+l+m$ the points $z_{k\pm 1,l,m}$, $z_{k,l\pm 1,m}$, $z_{k,l,m\pm 1}$ lie on a circle with the center $z_{k,l,m}$, i.e., all elementary quadrilaterals of the Q-image are of kite form.

Moreover, Eqs. (1) (see Lemma 1 in Sec. III) ensure that for the points $z_{k,l,m}$ with $k+l+m=\pm 1$, where three circles meet intersection angles are α_i or $\pi-\alpha_i$, $i=1,2,3$ (see Fig. 1 where the isotropic case $\alpha_i=\pi/3$ of regular and $Z^{3/2}$-pattern are shown).

According to Proposition 1, the discrete map $z_{k,l,m}$, restricted on H, defines a circle pattern with circle centers $z_{k,l,m}$ for $k+l+m=0$, each circle intersecting six neighboring circles. At each intersection point three circles meet.

However, for most initial data $\phi,\psi\in\mathbb{R}$, the behavior of the obtained circle pattern is quite irregular: inner parts of different elementary quadrilaterals intersect and circles overlap. Define $Q_H=Q\cap H$.

Definition 1:[7] *The hexagonal circle pattern Z^c, $0<c<2$ with intersection angles $\alpha_1,\alpha_2,\alpha_3$, $\alpha_i>0$, $\alpha_1+\alpha_2+\alpha_3=\pi$ is the solution $z:Q\to\mathbb{C}$ of (1) subject to (2) and with the initial data*

$$z_{1,0,0}=1,\ \ z_{0,1,0}=e^{ic(\alpha_2+\alpha_3)},\ \ z_{0,0,-1}=e^{ic\alpha_3} \tag{5}$$

restricted to Q_H.

Definition 2: A discrete map $z:Q_H\to\mathbf{C}$ is called an immersion if inner parts of adjacent elementary quadrilaterals are disjoint.

The main result of this article is the following theorem.

Theorem 1: *The hexagonal Z^c with constant positive intersection angles and $0<c<2$ is an immersion.*

The proof of this property follows from an analysis of the geometrical properties of the corresponding circle patterns and analytical properties of the corresponding discrete Painlevé and Riccati equations.

The crucial step is to consider equations for the radii of the studied circle patterns in the whole Q-sublattice with even $k+l+m$. In Sec. III, these equations are derived and the geometrical property of immersedness is reformulated as the positivity of the solution to these equations. Using discrete Painlevé and Riccati equations in Sec. IV we present the proof of the existence of a positive solution and thus complete the proof of immersedness. In Sec. VI, we discuss possible generalizations and corollaries of the obtained results. In particular, circle patterns Z^2 and Log with both square grid and hexagonal combinatorics are considered. It is also proved that they are immersions.

II. DISCRETE Z^c VIA A MONODROMY PROBLEM

Equations (1) have the Lax representation:[7]

$$\Phi_{k+1,l,m}(\mu)=L^{(1)}(e,\mu)\Phi_{k,l,m}(\mu),$$

$$\Phi_{k,l+1,m}(\mu)=L^{(2)}(e,\mu)\Phi_{k,l,m}(\mu), \tag{6}$$

$$\Phi_{k,l,m+1}(\mu)=L^{(3)}(e,\mu)\Phi_{k,l,m}(\mu),$$

where μ is the spectral parameter and $\Phi(\mu):\mathbb{Z}^3\to \mathrm{GL}(2,\mathbb{C})$ is the wave function. The matrices $L^{(n)}$ are defined on the edges $e=(p_{out},p_{in})$ of $\mathbb{Z}^3$ connecting two neighboring vertices and oriented in the direction of increasing $k+l+m$:

$$L^{(n)}(e,\mu)=\begin{pmatrix} 1 & z_{in}-z_{out} \\ \mu\dfrac{\Delta_n}{z_{in}-z_{out}} & 1 \end{pmatrix}, \tag{7}$$

with parameters Δ_n fixed for each type of edges. The zero-curvature condition on the faces of elementary cubes of $\mathbb{Z}^3$ is equivalent to Eqs. (1) with $\Delta_n=e^{i\delta_n}$ for properly chosen δ_n. Indeed, each elementary quadrilateral of $\mathbb{Z}^3$ has two consecutive positively oriented pairs of edges e_1,e_2 and e_3,e_4. Then the compatibility condition

$$L^{(n_1)}(e_2)L^{(n_2)}(e_1)=L^{(n_2)}(e_4)L^{(n_1)}(e_3)$$

is exactly one of the equations (1). This Lax representation is a generalization of the one found in Ref. 19 for the square lattice.

A solution $z:\mathbb{Z}^3\to\mathbb{C}$ of Eqs. (1) is called *isomonodromic* if there exists a wave function $\Phi(\mu):\mathbf{Z}^3\to\mathrm{GL}(2,\mathbf{C})$ satisfying (6) and the following linear differential equation in μ:

$$\frac{d}{d\mu}\Phi_{k,l,m}(\mu)=A_{k,l,m}(\mu)\Phi_{k,l,m}(\mu), \tag{8}$$

where $A_{k,l,m}(\mu)$ are some 2×2 matrices meromorphic in μ, with the order and position of their poles being independent of k,l,m. Isomonodromic solutions are important in many applications, in particular, for the first time the isomonodromy method was used to solve a discrete equation appearing in quantum gravity.[13]

The simplest nontrivial isomonodromic solutions satisfy the constraint

$$\begin{aligned} bz_{k,l,m}^2+cz_{k,l,m}+d=&2(k-a_1)\frac{(z_{k+1,l,m}-z_{k,l,m})(z_{k,l,m}-z_{k-1,l,m})}{z_{k+1,l,m}-z_{k-1,l,m}} \\ &+2(l-a_2)\frac{(z_{k,l+1,m}-z_{k,l,m})(z_{k,l,m}-z_{k,l-1,m})}{z_{k,l+1,m}-z_{k,l-1,m}} \\ &+2(m-a_3)\frac{(z_{k,l,m+1}-z_{k,l,m})(z_{k,l,m}-z_{k,l,m-1})}{z_{k,l,m+1}-z_{k,l,m-1}}. \end{aligned} \tag{9}$$

Theorem 2:[7] *Let $z:\mathbf{Z}^3\to\mathbf{C}$ be an isomonodromic solution to (1) with the matrix $A_{k,l,m}$ in (8) of the form*

$$A_{k,l,m}(\mu)=\frac{C_{k,l,m}}{\mu}+\sum_{n=1}^{3}\frac{B^{(n)}_{k,l,m}}{\mu-1/\Delta_n} \tag{10}$$

with μ-independent matrices $C_{k,l,m}$, $B^{(n)}_{k,l,m}$ and normalized by $\mathrm{tr}\,A_{0,0,0}(\mu)=0$. *Then these matrices have the following form:*

$$C_{k,l,m}=\frac{1}{2}\begin{pmatrix} -bz_{k,l,m}-c/2 & bz_{k,l,m}^2+cz_{k,l,m}+d \\ b & bz_{k,l,m}+c/2 \end{pmatrix},$$

$$B^{(1)}_{k,l,m}=\frac{k-a_1}{z_{k+1,l,m}-z_{k-1,l,m}}\begin{pmatrix} z_{k+1,l,m}-z_{k,l,m} & (z_{k+1,l,m}-z_{k,l,m})(z_{k,l,m}-z_{k-1,l,m}) \\ 1 & z_{k,l,m}-z_{k-1,l,m}\end{pmatrix}+\frac{a_1}{2}I,$$

$$B^{(2)}_{k,l,m}=\frac{l-a_2}{z_{k,l+1,m}-z_{k,l-1,m}}\begin{pmatrix} z_{k,l+1,m}-z_{k,l,m} & (z_{k,l+1,m}-z_{k,l,m})(z_{k,l,m}-z_{k,l-1,m}) \\ 1 & z_{k,l,m}-z_{k,l-1,m}\end{pmatrix}+\frac{a_2}{2}I,$$

$$B^{(3)}_{k,l,m}=\frac{m-a_3}{z_{k,l,m+1}-z_{k,l,m-1}}\begin{pmatrix} z_{k,l,m+1}-z_{k,l,m} & (z_{k,l,m+1}-z_{k,l,m})(z_{k,l,m}-z_{k,l,m-1}) \\ 1 & z_{k,l,m}-z_{k,l,m-1}\end{pmatrix}+\frac{a_3}{2}I,$$

and $z_{k,l,m}$ satisfies (9).

Conversely, any solution $z:\mathbb{Z}^3\to\mathbb{C}$ to the system (1) and (9) is isomonodromic with $A_{k,l,m}(\mu)$ given by the formulas above.

The special case $b=a_1=a_2=a_3=0$ with shift $z\to z-d/c$ implies (2).

III. EUCLIDEAN DESCRIPTION OF HEXAGONAL CIRCLE PATTERNS

In this section we describe the circle pattern z^c in terms of the radii of the circles. Such characterization proved to be quite useful for the circle patterns with combinatorics of the square grid.[1,3] In what follows, we say that the triangle (z_1,z_2,z_3) has *positive (negative) orientation* if

$$\frac{z_3-z_1}{z_2-z_1}=\left|\frac{z_3-z_1}{z_2-z_1}\right|e^{i\phi}\quad\text{with}\quad 0\leqslant\phi\leqslant\pi\quad(-\pi<\phi<0).$$

Lemma 1: Let $q(z_1,z_2,z_3,z_4)=e^{-2i\alpha}$, $0<\alpha<\pi$.

(i) *If $|z_1-z_2|=|z_1-z_4|$ and the triangle (z_1,z_2,z_4) has positive orientation, then $|z_3-z_2|=|z_3-z_4|$ and the angle between $[z_1,z_2]$ and $[z_2,z_3]$ is $(\pi-\alpha)$.*

(ii) *If $|z_1-z_2|=|z_1-z_4|$ and the triangle (z_1,z_2,z_4) has negative orientation, then $|z_3-z_2|=|z_3-z_4|$ and the angle between $[z_1,z_2]$ and $[z_2,z_3]$ is α.*

(iii) *If the angle between $[z_1,z_2]$ and $[z_1,z_4]$ is α and the triangle (z_1,z_2,z_4) has positive orientation, then $|z_3-z_2|=|z_1-z_2|$ and $|z_3-z_4|=|z_4-z_1|$.*

(iv) *If the angle between $[z_1,z_2]$ and $[z_1,z_4]$ is $(\pi-\alpha)$ and the triangle (z_1,z_2,z_4) has negative orientation, then $|z_3-z_2|=|z_1-z_2|$ and $|z_3-z_4|=|z_4-z_1|$.*

Lemma 1 and Proposition 1 imply that each elementary quadrilateral of the studied circle pattern has one of the forms enumerated in the lemma.

Proposition 1 allows us to introduce the radius function

$$r(K,L,M)=|z_{k,l,m}-z_{k\pm1,l,m}|=|z_{k,l\pm1,m}-z_{k,l,m}|=|z_{k,l,m}-z_{k,l,m\pm1}|,\tag{11}$$

where (k,l,m) belongs to the sublattice of Q with even $k+l+m$ and (K,L,M) label this sublattice:

$$K=k-\frac{k+l+m}{2},\quad L=l-\frac{k+l+m}{2},\quad M=m-\frac{k+l+m}{2}.\tag{12}$$

The function r is defined on the sublattice

$$\tilde{Q}=\{(K,L,M)\in\mathbf{Z}^3|L+M\leqslant 0,\quad M+K\leqslant 0,\quad K+L\geqslant 0)\}$$

corresponding to Q. Consider this function on

$$\tilde{Q}_H=\{(K,L,M)\in\mathbf{Z}^3|K\geqslant 0,\quad L\geqslant 0,\quad M\leqslant 0,\quad K+L+M=0,+1\}.$$

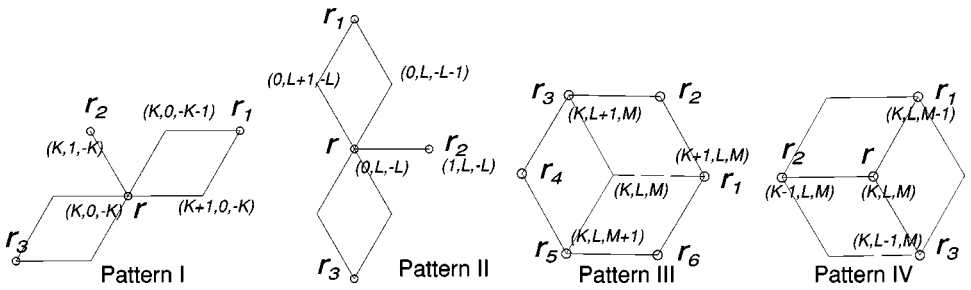

FIG. 2. Equation patterns.

Theorem 3: *Let the solution $z:Q_H\to\mathbb{C}$ of the system (1) and (2) with initial data (4) be an immersion. Then function $r(K,L,M):\tilde{Q}_H\to\mathbb{R}_+$, defined by (11), satisfies the following equations:*

$$(r_1+r_2)(r^2-r_2r_3+r(r_3-r_2)\cos\alpha_i)+(r_3+r_2)(r^2-r_2r_1+r(r_1-r_2)\cos\alpha_i)=0 \tag{13}$$

on the patterns of type I and II as in Fig. 2, with $i=3$ and $i=2$, respectively;

$$(L+M+1)\frac{r_4-r_1}{r_4+r_1}+(M+K+1)\frac{r_6-r_3}{r_6+r_3}+(K+L+1)\frac{r_2-r_5}{r_2+r_5}=c-1 \tag{14}$$

on the patterns of type III, and

$$r(r_1\sin\alpha_3+r_2\sin\alpha_1+r_3\sin\alpha_2)=r_1r_2\sin\alpha_2+r_2r_3\sin\alpha_3+r_3r_1\sin\alpha_1 \tag{15}$$

on the patterns of type IV. Conversely, $r(K,L,M):\tilde{Q}_H\to\mathbb{R}_+$ satisfying Eqs. (13)–(15) is the radius function of an immersed hexagonal circle pattern with constant intersection angles [i.e., corresponding to some immersed solution $z:Q_H\to\mathbb{C}$ of (1) and (2)], which is determined by r uniquely.

Proof: The map $z_{k,l,m}$ is an immersion if and only if all triangles $(z_{k,l,m},z_{k+1,l,m},z_{k,l,m-1})$, $(z_{k,l,m},z_{k,l,m-1},z_{k,l+1,m})$ and $(z_{k,l,m},z_{k+1,l,m},z_{k,l+1,m})$ of elementary quadrilaterals of the map $z_{k,l,m}$ have the same orientation (for brevity we call it the orientation of the quadrilaterals).

Necessity: To get Eq. (14), consider the configuration of two starlike figures with centers at $z_{k,l,m}$ with $k+l+m=1\,(\mathrm{mod}\,2)$ and at $z_{k+1,l,m}$, connected by five edges in the k-direction as shown on the left part of Fig. 3. Let r_i, $i=1,\ldots,6$, be the radii of the circles with the centers at the vertices neighboring $z_{k,l,m}$ as in Fig. 3. As follows from Lemma 1, the vertices $z_{k,l,m}$, $z_{k+1,l,m}$ and $z_{k-1,l,m}$ are collinear. For immersed z^c, the vertex $z_{k,l,m}$ lies between $z_{k+1,l,m}$ and $z_{k-1,l,m}$. Similar facts are true also for the l- and m-directions. Moreover, the orientations of elementary quadrilaterals with the vertex $z_{k,l,m}$ coincides with one of the standard lattice. Lemma 1 defines all angles at $z_{k,l,m}$ of these quadrilaterals. Equation (2) at (k,l,m) gives $z_{k,l,m}$:

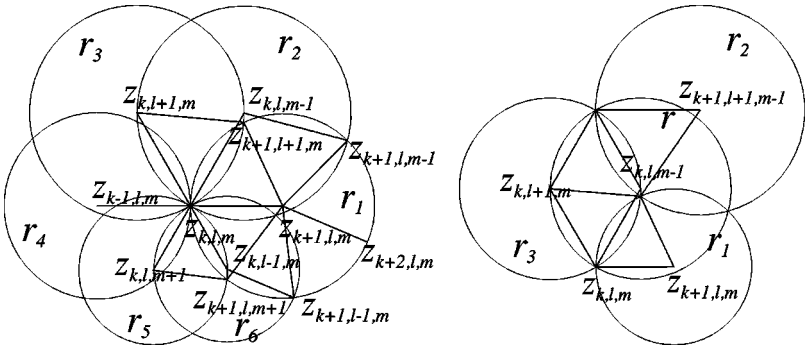

FIG. 3. Circles.

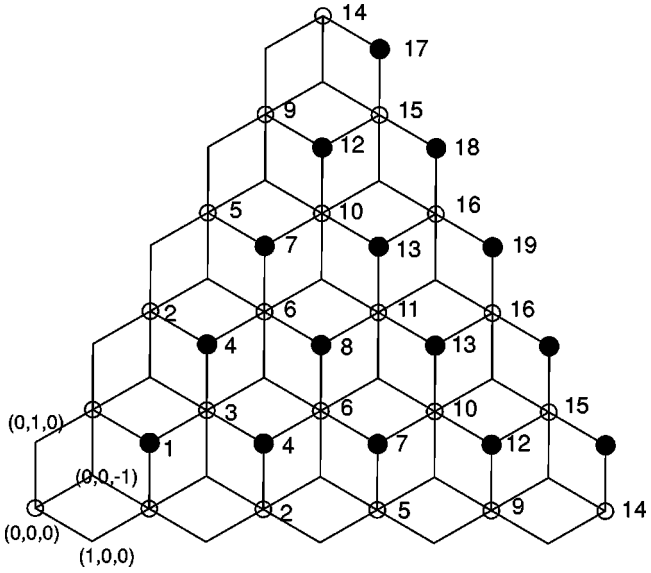

FIG. 4. Computing r in $\tilde{Q}_H$.

$$z_{k,l,m}=\frac{2e^{is}}{c}\left(k\frac{r_1r_4}{r_1+r_4}+l\frac{r_3r_6}{r_3+r_6}e^{i(\alpha_2+\alpha_3)}+m\frac{r_2r_5}{r_2+r_5}e^{i(\alpha_1+\alpha_2+2\alpha_3)}\right),$$

where $e^{is}=(z_{k+1,l,m}-z_{k,l,m})/r_1$. Lemma 1 allows one to compute $z_{k+1,l,m-1}$, $z_{k+1,l+1,m}$, $z_{k+1,l,m+1}$ and $z_{k+1,l-1,m}$ using the form of quadrilaterals (they are shown in Fig. 3). Now Eq. (2) at $(k+1,l,m)$ defines $z_{k+2,l,m}$. Condition $|z_{k+2,l,m}-z_{k+1,l,m}|=r_1$ with the labels (12) yields Eq. (14).

For $l=0$ values $z_{k+1,0,m}$, $z_{k+2,0,m}$, $z_{k+1,0,m-1}$ and the equation for the cross-ratio with α_3 give the radius R with the center at $z_{k+2,0,m-1}$. Note that for $l=0$ the term with r_6 and r_5 drops out of Eq. (14). Using this equation and the permutation $R\to r_1$, $r_1\to r$, $r_2\to r_2$, $r_5\to r_3$, one gets Eq. (13) with $i=3$. The equation for pattern II is derived similarly.

To derive (15), consider the figure on the right part of Fig. 3 where $k+l+m=1\ (\mathrm{mod}\ 2)$ and r_1, r_2, r_3 and r are the radii of the circles with the centers at $z_{k+1,l,m}$, $z_{k+1,l+1,m-1}$, $z_{k,l+1,m}$ and $z_{k,l,m-1}$, respectively. Elementary geometrical considerations and Lemma 1 applied to the forms of the shown quadrilaterals give Eq. (15).

Remark: Equation (15) is derived for $r=r(K,L,M)$, $r_1=r(K,L,M-1)$, $r_2=r(K-1,L,M)$, $r_3=r(K,L-1,M+1)$. However, it holds true also for $r_1=r(K,L,M+1)$, $r_2=r(K+1,L,M)$, $r_3=r(K,L+1,M+1)$ since it gives the radius of the circle through the three intersection points of the circles with radii r_1, r_2, r_3 intersecting at prescribed angles as shown in the right part of Fig. 3. Later, we refer to this equation also for this pattern.

Sufficiency: Now let $r(K,L,M):\tilde{Q}_H\to\mathbf{R}_+$ be some positive solution to (13)–(15). We can rescale it so that $r(0,0,0)=1$. Starting with $r(1,0,-1)$ and $r(0,1,-1)$ one can compute r everywhere in $\tilde{Q}_H$: r in a "black" vertex (see Fig. 4) is computed from (14). [Note that only r at "circled" vertices is used: so to compute $r_{1,1,-1}$ one needs only $r(1,0,-1)$ and $r(0,1,-1)$.] The function r in "white" vertices on the border $\partial\tilde{Q}_H=\{(K,0,-K)|K\in\mathbf{N}\}\cup\{(0,L,-L)|L\in\mathbf{N}\}$ is given by (13). Finally, r in "white" vertices in $Q_H^{int}=Q_H\backslash\partial\tilde{Q}_H$ is computed from (15). In Fig. 4 labels show the order of computing r.

Lemma 2: Any solution $r(K,L,M):\tilde{Q}_H\to\mathbf{R}$ to (13)–(15) with $0\leqslant c\leqslant 2$, which is positive for inner vertices of $\tilde{Q}_H$ defines some $z_{k,l,m}$ satisfying (1) in Q. Moreover, all the triangles $(z_{k,l,m},z_{k+1,l,m},z_{k,l,m-1})$, $(z_{k,l,m},z_{k,l,m-1},z_{k,l+1,m})$ and $(z_{k,l,m},z_{k+1,l,m},z_{k,l+1,m})$ have positive orientation.

Proof of the lemma: One can place the circles with radii $r(K,L,M)$ into the complex plane $\mathbb{C}$ in the way prescribed by the hexagonal combinatorics and the intersection angles. Taking the circle centers and the intersection points of neighboring circles, one recovers $z_{k,l,m}$ for $k+l+m=0,\pm 1$ up to a translation and rotation. Reversing the arguments used in the derivation of (13)–(15), one observes from the forms of the quadrilaterals that Eqs. (1) are satisfied. Now using (1), one recovers z in the whole Q. Equation (15) ensures that the radii r remain positive, which implies the positive orientations of the triangles $(z_{k,l,m},z_{k+1,l,m},z_{k,l,m-1})$, $(z_{k,l,m},z_{k,l,m-1},z_{k,l+1,m})$ and $(z_{k,l,m},z_{k+1,l,m},z_{k,l+1,m})$.

Consider a solution $z:Q\to\mathbb{C}$ of the system (1) and (2) with initial data (4), where ϕ and ψ are chosen so that the triangles $(z_{0,0,0)},z_{1,0,0},z_{0,0,-1})$ and $(z_{0,0,0)},z_{0,0,-1},z_{0,1,0})$ have positive orientations and satisfy conditions $r(1,0,-1)=|z_{1,0,-1}-z_{1,0,0}|$ and $r(0,1,-1)=|z_{0,1,-1}-z_{0,0,-1}|$. The map $z_{k,l,m}$ defines circle pattern due to Proposition 1 and coincides with the map defined by Lemma 2 due to the uniqueness of the solution uniqueness. Q.E.D.

Since the cross-ratio equations and the constraint are compatible, the equations for the radii are also compatible. Starting with $r(0,0,0)$, $r(1,0,-1)$ and $r(0,1,-1)$, one can compute $r(K,L,M)$ everywhere in $\tilde{Q}$.

Lemma 3: Let a solution $r(K,L,M):\tilde{Q}\to\mathbb{R}$ of (13)–(15) be positive in the planes given by equations $K+M=0$ and $L+M=0$. Then it is positive everywhere in $\tilde{Q}$.

Proof: As follows from Eq. (15), r is positive for positive r_i, $i=1,2,3$. As r at $(K,K,-K)$, $(K+1,K,-K-1)$ and $(K,K+1,-K-1)$ is positive, r at $(K,K,K-1)$ is also positive. Now starting from r at $(K,K,-K-1)$ and having $r>0$ at $(N,K+1,-K-1)$ and $(N,K,-K)$, one obtains positive r at $(N,K,-K-1)$ for $0\leqslant N<K$ by the same reason. Similarly, r at $(K,N,-K-1)$ is positive. Thus from positive r at the planes $K+M=0$ and $L+M=0$, we get positive r at the planes $K+M=-1$ and $L+M=-1$. Induction completes the proof.

Lemma 4: Let a solution $r(K,L,M):\tilde{Q}\to\mathbb{R}$ of (13)–(15) be positive in the lines parametrized by n as $(n,0,-n)$ and $(0,n,-n)$. Then it is positive in the border planes of $\tilde{Q}$ specified by $K+M=0$ and $L+M=0$.

Proof: We prove this lemma for $K+M=0$. For the other border plane it is proved similarly. Equation (14) for $(K,L,-K-1)$ gives

$$r_2=r_5\frac{(2L+c)r_1+(2K+c)r_4}{(2K+2-c)r_1+(2L+2-c)r_4}, \tag{16}$$

therefore r_2 is positive provided r_1, r_5 and r_4 are positive. For $K=L$ it reads as

$$r_2=r_5\frac{(2K+c)}{(2K+2-c)}. \tag{17}$$

It allows us to compute recursively r at $(K,K,-K)$ starting with r at $(0,0,0)$. Obviously, $r>0$ for $(K,K,-K)$ if $r>0$ at $(0,0,0)$. This property together with the condition $r>0$ at $(n,0,-n)$ implies the conclusion of the lemma since Eq. (16) gives r everywhere in the border plane of $\tilde{Q}$ specified by $K+M=0$.

Lemmas 3 and 4 imply that the circle pattern z^c is an immersion if $r>0$ at $(N,0,-N)$ and $(0,N,-N)$.

IV. PROOF OF THE MAIN THEOREM. DISCRETE PAINLEVÉ AND RICCATI EQUATIONS

In this section, we prove that all $r(n,0,-n)$, $\forall n\in\mathbb{N}$ are positive only for the initial data $z_{1,0,0}=1$, $z_{0,0,-1}=e^{c\alpha_3}$. For the line $r(0,n,-n)$ the proof is the same. Our strategy is as follows: first, we prove the existence of an initial value $z_{0,0,-1}$ such that $r(n,0,-n)>0$, $\forall n\in\mathbb{N}$. Finally we will show that this value is unique and is $z_{0,0,-1}=e^{c\alpha_3}$.

Proposition 2: Suppose the equation

$$(n+1)(x_n^2-1)\left(\frac{x_{n+1}+x_n/\varepsilon}{\varepsilon+x_nx_{n+1}}\right)-n(1-x_n^2/\varepsilon^2)\left(\frac{x_{n-1}+\varepsilon x_n}{\varepsilon+x_{n-1}x_n}\right)=cx_n\frac{\varepsilon^2-1}{2\varepsilon^2}, \tag{18}$$

where $\varepsilon=e^{i\alpha_3}$, *has a unitary solution* $x_n=e^{i\beta_n}$ *in the sector* $0<\beta_n<\alpha_3$. *Then* $r(n,0,-n)$, $n\geqslant 0$ *is positive.*

Proof: For $z_{1,0,0}=1$ and unitary $z_{1,0,-1}$, the equation for the cross-ratio with α_3 and (2) reduce to (18) with unitary $x_n^2=(z_{n,0,-n-1}-z_{n,0,n})/(z_{n+1,0,-n}-z_{n,0,n})$. Note that for $n=0$ the term with x_{-1} drops out of (18); therefore the solution for $n>0$ is determined by x_0 only. The condition $0<\beta_n<\alpha_3$ means that all triangles $(z_{n,0,-n},z_{n+1,0,n},z_{n,0,-n-1})$ have positive orientation. Hence $r(n,0,-n)$ are all positive. Q.E.D.

Remark: Equation (18) is a special *discrete Painlevé equation*. For a more general reduction of cross-ratio equation see Ref. 18. The case $\varepsilon=i$, corresponding to the orthogonally intersecting circles, was studied in detail in Ref. 3. Here we generalize these results to the case of arbitrary unitary ε. Below we omit the index of α so that $\varepsilon=e^{i\alpha}$.

Theorem 4: *There exists a unitary solution* $x_n=e^{i\beta_n}$ *to (18) in the sector* $0<\beta_n<\alpha$.

Proof: Equation (18) allows us to represent x_{n+1} as a function of n,x_{n-1} and x_n: $x_{n+1}=\Phi(n,x_{n-1},x_n)$. $\Phi(n,u,v)$ maps the torus $T^2=S^1\times S^1=\{(u,v)\in\mathbb{C}:|u|=|v|=1\}$ into S^1 and has the following properties:

(i) For all $n\in\mathbb{N}$ it is a continuous map on $A_I\times\overline{A_I}$ where $A_I=\{e^{i\beta}:\beta\in(0,\alpha)\}$ and $\overline{A_I}$ is the closure of A_I. Values of Φ on the border of $A_I\times\overline{A_I}$ are defined by continuity: $\Phi(n,u,\varepsilon)=-1$, $\Phi(n,u,1)=-\varepsilon$.

(ii) For $(u,v)\in A_I\times A_I$ one has $\Phi(n,u,v)\in A_I\cup A_{II}\cup A_{IV}$, where $A_{II}=\{e^{i\beta}:\beta\in(\alpha,\pi]\}$ and $A_{IV}=\{e^{i\beta}:\beta\in[\alpha-\pi,0)\}$, i.e., x cannot jump in one step from A_I into $A_{III}=\{e^{i\beta}:\beta\in(-\pi,\alpha-\pi)\}$.

Let $x_0=e^{i\beta_0}$. Then $x_n=x_n(\beta_0)$. Define $S_n=\{\beta_0:\ x_k(\beta_0)\in\overline{A_I}\forall\,0\leqslant k\leqslant n\}$. Then S_n is a closed set since Φ is continuous on $A_I\times\overline{A_I}$. As a closed subset of a segment it is a collection of disjoint segments S_n^l.

Lemma 5: There exists sequence $\{S_n^{l(n)}\}$ *such that*

(i) $S_n^{l(n)}$ *is mapped by* $x_n(\beta_0)$ *onto* $\overline{A_I}$ *and*
(ii) $S_{n+1}^{l(n+1)}\subset S_n^{l(n)}$.

The lemma is proved by induction. For $n=0$ it is trivial. Suppose it holds for n. As $S_n^{l(n)}$ is mapped by $x_n(\beta_0)$ onto $\overline{A_I}$, continuity considerations and $\Phi(n,u,\varepsilon)=-1$, $\Phi(n,u,1)=-\varepsilon$ imply $x_{n+1}(\beta_0)$ maps $S_n^{l(n)}$ onto $A_I\cup A_{II}\cup A_{IV}$ and at least one of the segments $S_{n+1}^l\subset S_n^{l(n)}$ is mapped into $\overline{A_I}$. This proves the lemma.

Since the segments of $\{S_n^{l(n)}\}$ constructed in Lemma 5 are nonempty, there exists $\overline{\beta_0}\in S_n$ for all $n\geqslant 0$. For this $\overline{\beta_0}$, the value $x_n(\overline{\beta_0})$ is not on the border of $\overline{A_0}$ since then $x_{n+1}(\beta_0)$ would jump out of $\overline{A_I}$. Q.E.D.

Let r_n and R_n be the radii of the circles of the circle patterns defined by $z_{k,l,m}$ with the centers at $z_{2n,0,0}$ and $z_{2n+1,0,-1}$, respectively. Constraint (2) gives

$$r_{n+1}=\frac{2n+c}{2(n+1)-c}r_n,$$

which is exactly formula (17). From elementary geometric considerations (see Fig. 5) one gets

$$R_{n+1}=\frac{r_{n+1}-R_n\cos\alpha}{R_n-r_{n+1}\cos\alpha}r_{n+1}$$

(recall that $\alpha=\alpha_3$). Define

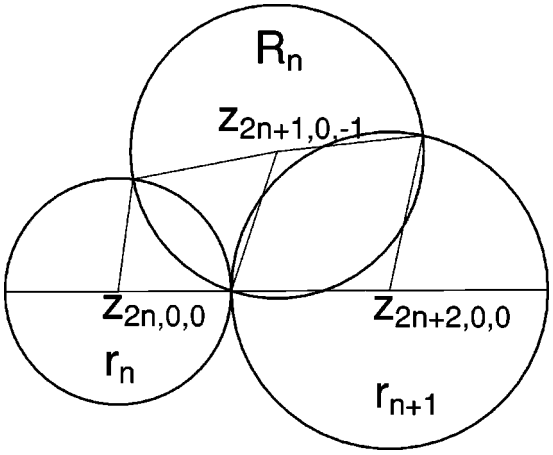

FIG. 5. Circles on the border.

$$p_n=\frac{R_n}{r_n},\quad g_n(c)=\frac{2n+c}{2(n+1)-c}$$

and denote $t=\cos\alpha$. Now, the equation for the radii R, r takes the form

$$p_{n+1}=\frac{g_n(c)-tp_n}{p_n-tg_n(c)}. \tag{19}$$

Remark: Equation (19) can be seen as a discrete version of a *Riccati* equation. This is motivated by the following properties:

(i) The cross-ratio of each four-tuple of its solutions is constant as p_{n+1} is a Möbius transform of p_n.

(ii) The general solution is expressed in terms of solutions of some linear equation: the standard ansatz

$$p_n=\frac{y_{n+1}}{y_n}+tg_n(c) \tag{20}$$

transforms (19) into

$$y_{n+2}+t(g_{n+1}(c)+1)y_{n+1}+(t^2-1)g_n(c)y_n=0. \tag{21}$$

As follows from Theorem 4, Proposition 2, and Lemma 4, Eq. (19) has a positive solution. One may conjecture that there is only one initial value p_0 such that $p_n>0,\ \forall n\in\mathbb{N}$ from the consideration of the asymptotics. Indeed, $g_n(c)\to 1$ as $n\to\infty$, and the general solution of Eq. (21) with limit values of coefficients is $y_n=c_1(-1)^n(1+t)^n+c_2(1-t)^n$. Thus $p_n=y_{n+1}/y_n+tg_n(c)\to -1$ for $c_1\neq 0$. However c_1,c_2 define only the asymptotics of a solution. To relate it to the initial value p_0 is a more difficult problem. Fortunately, it is possible to find the general solution to (21).

Proposition 3: The general solution to (21) is

$$y_n=\frac{\Gamma\left(n+\frac{1}{2}\right)}{\Gamma\left(n+1-\frac{c}{2}\right)}\left(c_1\lambda_1^{n+1-c/2}F\left(\frac{3-c}{2},\frac{c-1}{2},\frac{1}{2}-n,z_1\right)\right.$$
$$\left.+c_2\lambda_2^{n+1-c/2}F\left(\frac{3-c}{2},\frac{c-1}{2},\frac{1}{2}-n,z_2\right)\right), \tag{22}$$

where $\lambda_1=-t-1$, $\lambda_2=1-t$, $z_1=(t-1)/2$, $z_2=-(1+t)/2$ *and* F *is the hypergeometric function.*

Proof: The solution was found by a slightly modified *symbolic method* (see Ref. 10 for the method description and Ref. 2 for the detail). Here, $F(a,b,c,z)$ denotes the standard hypergeometric function which is a solution of the hypergeometric equation

$$z(1-z)F_{zz}+[c-(a+b+1)z]F_z-abF=0 \tag{23}$$

holomorphic at $z=0$. Due to linearity, the general solution of (21) is given by a superposition of any two linearly independent solutions. Direct computation with the series representation of the hypergeometric function

$$\begin{aligned}F&\left(1-\frac{\gamma-1}{2},\frac{\gamma-1}{2},1-\left(x+\frac{\gamma-1}{2}\right),z\right)\\&=1+z\frac{(1-(\gamma-1)/2)(\gamma-1)/2}{(1-(x+(\gamma-1)/2))}+\cdots\\&\quad+z^k\frac{[(1-(\gamma-1)/2)(2-(\gamma-1)/2)\cdots(k-(\gamma-1)/2)][((\gamma-1)/2)(1+(\gamma-1)/2)\cdots(k-1(\gamma-1)/2)]}{(1-(x(\gamma-1)/2))\cdots(k-(x+(\gamma-1)/2))}+\cdots\end{aligned} \tag{24}$$

shows that each summand in (22) satisfies Eq. (21). To finish the proof of Proposition 3, one has to show that the particular solutions with $c_1=0$, $c_2\neq 0$ and $c_1\neq 0$, $c_2=0$ are linearly independent. This fact follows from the following lemma.

Lemma 6: As $n\to\infty$, *function (22) has the asymptotics*

$$y_n\simeq(n+1-\gamma/2)^{(\gamma-1)/2}(c_1\lambda_1^{n+1-\gamma/2}+c_2\lambda_2^{n+1-\gamma/2}). \tag{25}$$

For $n\to\infty$ the series representation (24) implies $F((3-\gamma)/2,(\gamma-1)/2,\frac{1}{2}-n,z_1)\simeq 1$. Stirling's formula

$$\Gamma(x)\simeq\sqrt{2\pi}e^{-x}x^{x-1/2} \tag{26}$$

yields the asymptotics of the factor $\Gamma(n+\frac{1}{2})/\Gamma(n+1-\gamma/2)$. This completes the proof of the lemma and of Proposition (3).

Proposition 4: A solution of the discrete Riccati equation (19) with $\alpha\neq\pi/2$ *is positive for all* $n\geqslant 0$ *if and only if*

$$p_0=\frac{\sin c\alpha/2}{\sin(2-c)\alpha/2}. \tag{27}$$

Proof: For positive p_n, it is necessary that $c_1=0$: this follows from asymptotics (25) substituted into (20). Let us define

$$\begin{aligned}s(z)&=1+z\frac{(1-(\gamma-1)/2)((\gamma-1)/2)}{\frac{1}{2}}+\cdots\\&\quad+z^k\frac{(k-(\gamma-1)/2)\cdots(1-(\gamma-1)/2)((\gamma-1)/2)(k-1+(\gamma-1)/2)}{k!\left(k-\frac{1}{2}\right)\cdots\frac{1}{2}}\cdots.\end{aligned} \tag{28}$$

This is the hypergeometric function $F((3-\gamma)/2,(\gamma-1)/2,\frac{1}{2}-n,z)$ with $n=0$. A straightforward computation with series shows that

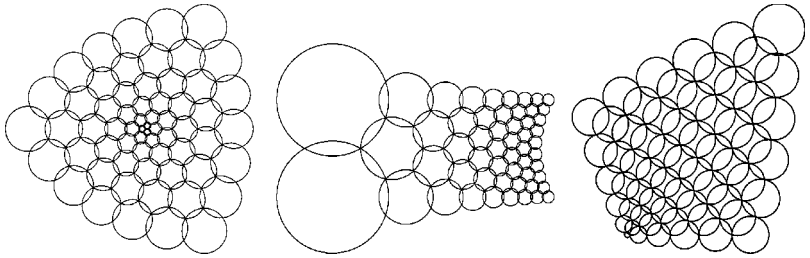

FIG. 6. Hexagonal z^2, Log and square grid $z^{3/2}$.

$$p_0 = 1 + \frac{2(\gamma-1)}{2-\gamma} z + \frac{4z(z-1)}{2-\gamma} \frac{s'(z)}{s(z)}, \tag{29}$$

where $z=(1+t)/2$. Note that p_0 as a function of z satisfies an ordinary differential equation of first order since $s'(z)/s(z)$ satisfies the Riccati equation obtained by a reduction of (23). A computation shows that $[\sin(\gamma\alpha/2)]/[\sin(2-\gamma)\alpha/2]$ satisfies the same ordinary differential eqiation. Since both expression (29) and (27) are equal to 1 for $z=0$, they coincide everywhere.

Q.E.D.

Proof of Theorem 1: Proposition (4) implies that the initial x_0 for which (18) gives positive r is unique and implies the initial values (5) for z^c if $\alpha_i \neq \pi/2$. For the case $\alpha=\pi/2$, any solution for (19) with $p_0>0$ is positive. Nevertheless, as was proved in Ref. 3, x_0 is in this case also unique and is specified by (27). Thus for all $n \in \mathbb{N}$ we have $r(n,0,-n)>0$, $r(0,n,-n)>0$ for the circle pattern z^c. Lemmas 4 and 3 complete the proof.

V. HEXAGONAL CIRCLE PATTERNS z^2 AND Log

For $c=2$, formula (17) gives infinite $r(1,1,-1)$. The way around this difficulty is renormalization $z \to (2-c)z/c$ and a limit procedure $c \to 2-0$, which leads to the renormalization of initial data (see Ref. 7). As follows from (27), this renormalization implies

$$r(0,0,0)=0,\ r(1,0,-1)=\frac{\sin\alpha_3}{\alpha_3}, r(0,1,-1)=\frac{\sin\alpha_2}{\alpha_2},\ r(1,1,-1)=1. \tag{30}$$

Proposition 5: The solution to (13)–(15) with $c=2$ and initial data (30) is positive.

Proof: This follows from Lemmas 3 and 4 since Theorem 4 is true also for the case $c=2$. Indeed, solution x_n is a continuous function of c. Therefore it has a limit value as $c \to 2-0$ and it lies in the sector A_I.

Lemma 2 implies that there exists a hexagonal circle pattern with radius function r.

Definition 3: The hexagonal circle pattern Z^2 has a radius function specified by Proposition 5.

Equations (13)–(15) have the symmetry

$$r \to \frac{1}{r},\ \ c \to 2-c, \tag{31}$$

which is the *duality transformation* (see Ref. 8). The smooth analog $f \to f^*$ for holomorphic functions $f(w), f^*(w)$ is

$$\frac{df(w)}{dw}\frac{df^*(w)}{dw}=1.$$

Note that $\log^*(w)=w^2/2$. The hexagonal circle pattern Log is defined[7] as a circle pattern dual to Z^2. Discrete z^2 and Log are the first two images in Fig. 6.

Theorem 5: *The hexagonal circle patterns Z^2 and* Log *are immersions.*

Proof: For z^2 this follows from Proposition 5. Hence the values of $1/r$, where r is radius function for z^2, are positive except for $r(0,0,0)=\infty$. Lemma 2 completes the proof.

VI. CONCLUDING REMARKS

In this section we discuss corollaries of the obtained results and possible generalizations

A. Square grid circle patterns z^c and Log

Equations (1) extend $z_{k,l,m}$ corresponding to the hexagonal z^2 and Log from Q_H into the three-dimensional lattice Q. The r-function of this extension satisfies Eq. (15). Consider $z_{k,l,m}$ for the hexagonal z^c and Log restricted to one of the coordinate planes, e.g., $l=0$. Then Proposition 1 states that $z_{k,0,m}$ defines some circle pattern with combinatorics of the square grid: each circle has four neighboring circles intersecting it at angles α_3 and $\pi-\alpha_3$. It is natural to call it *square grid* z^c (see the third image in Fig. 6). Such circle patterns are natural generalization of those with orthogonal neighboring and tangent half-neighboring circles introduced and studied in Ref. 22.

Theorem 6: *Square grid* z^c, $0<c\leqslant 2$ *and* Log *are immersions.*

Proof easily follows from Lemma 2.

It is interesting to note that the square grid circle pattern z^c can be obtained from hexagonal one by limit procedure $\alpha_3\to+0$ and by $\alpha_1\to\pi-\alpha_2$. These limit circle patterns still can be defined by (1) and (2) by imposing the self-similarity condition $z_{k,l,m}=f_{l,k-m}$.

B. Square grid circle patterns Erf

For square grid combinatorics and $\alpha=\pi/2$, Schramm[22] constructed circle patterns mimicking holomorphic function $\mathrm{erf}(z)=(2/\pi)\int e^{-z^2}dz$ by giving the radius function explicitly. Namely, let n,m label the circle centers so that the pairs of circles $c(n,m)$, $c(n+1,m)$ and $c(n,m)$, $c(n,m+1)$ are orthogonal and the pairs $c(n,m)$, $c(n+1,m+1)$ and $c(n,m+1)$, $c(n+1,m)$ are tangent. Then

$$r(n,m)=e^{nm} \tag{32}$$

satisfies the equation for a radius function:

$$R^2(r_1+r_2+r_3+r_4)-(r_2r_3r_4+r_1r_3r_4+r_1r_2r_4+r_1r_2r_3)=0, \tag{33}$$

where $R=r(n,m)$, $r_1=r(n+1,m)$, $r_2=r(n,m+1)$, $r_3=r(n-1,m)$, $r_4=r(n,m-1)$. For square grid circle patterns with intersection angles α for $c(n,m)$, $c(n+1,m)$ and $\pi-\alpha$ for $c(n,m)$, $c(n,m+1)$ the governing Eq. (33) becomes

$$R^2(r_1+r_2+r_3+r_4)-(r_2r_3r_4+r_1r_3r_4+r_1r_2r_4+r_1r_2r_3)+2R\cos\alpha(r_1r_3-r_2r_4)=0. \tag{34}$$

It is easy to see that (34) has the same solution (32) and it therefore defines a square grid circle pattern, which is a discrete Erf. A hexagonal analog of Erf is not known.

C. Circle patterns with quasi-regular combinatorics

One can deregularize the prescribed combinatorics by a projection of $\mathbb{Z}^n$ into a plane as follows (see Ref. 23). Consider $\mathbb{Z}^n_+\subset\mathbb{R}^n$. For each coordinate vector $\mathbf{e}_i=(e_i^1,\ldots,e_i^n)$, where $e_i^j=\delta_i^j$ define a unit vector ξ_i in $\mathbb{C}=\mathbb{R}^2$ so that for any pair of indices i,j, vectors ξ_i,ξ_j form a basis in $\mathbb{R}^2$. Let $\Omega\in\mathbb{R}^n$ be some two-dimensional simply connected cell complex with vertices in $\mathbb{Z}^n_+$. Choose some $x_0\in\Omega$. Define the map $P:\Omega\to\mathbb{C}$ by the following conditions:

(i) $P(x_0)=P_0$.
(ii) If x,y are vertices of Ω and $y=x+\mathbf{e}_i$, then $P(y)=P(x)+\xi_i$.

It is easy to see that P is correctly defined and unique.

We call Ω a *projectable* cell complex if its image $\omega = P(\Omega)$ is embedded, i.e., intersections of images of different cells of Ω do not have inner parts. Using projectable cell complexes one can obtain combinatorics of Penrose tilings.

It is natural to define ''discrete conformal map on ω'' as a discrete complex immersion function z on vertices of ω preserving the cross-ratios of the ω-cells. The argument of z can be labeled by the vertices x of Ω. Hence for any cell of Ω, constructed on $\mathbf{e}_k, \mathbf{e}_j$, the function z satisfies the following equation for the cross-ratios:

$$q(z_x, z_{x+\mathbf{e}_k}, z_{x+\mathbf{e}_k+\mathbf{e}_j}, z_{x+\mathbf{e}_j}) = e^{-2i\alpha_{k,j}}, \tag{35}$$

where $\alpha_{k,j}$ is the angle between $\boldsymbol{\xi}_k$ and $\boldsymbol{\xi}_j$, taken positively if (ξ_k, ξ_j) has positive orientation and taken negatively otherwise. Now suppose that z is a solution to (35) defined on the whole $\mathbb{Z}^n_+$. We can define a discrete $z^c: \omega \to \mathbb{C}$ for projectable Ω as a solution to (35) and (36) restricted to Ω. Initial conditions for this solution are of the form (5) so that the restrictions of z to each two-dimensional coordinate lattice is an immersion defining a circle pattern with prescribed intersection angles. This definition naturally generalizes the definition of discrete hexagonal and square grid z^c considered above.

We finish this section with the natural conjecture formulated in Ref. 2.

Conjecture: The discrete $z^c: \omega \to \mathbb{C}$ is an immersion.

The first step in proving this claim is to show that Eq. (35) is compatible with the constraint

$$c f_x = \sum_{s=1}^{n} 2x_s \frac{(f_{x+\mathbf{e}_s} - f_x)(f_x - f_{x-\mathbf{e}_s})}{f_{x+\mathbf{e}_s} - f_{x-\mathbf{e}_s}}. \tag{36}$$

For $n = 3$ this fact is proven in Ref. 7.

The most fruitful approach to studying low energy soliton dynamics in field theories of Bogomol'nyi type is the geodesic approximation of Manton. In the case of vortices and monopoles, Stuart has obtained rigorous estimates of the errors in this approximation, and hence proved that it is valid in the low speed regime. His method employs energy estimates which rely on a key coercivity property of the Hessian of the energy functional of the theory under consideration. In this article we prove an analogous coercivity property for the Hessian of the energy functional of a general sigma model with compact Kähler domain and target. We go on to prove a continuity property for our result, and show that, for the $\mathbb{C}P^1$ model on S^2, the Hessian fails to be globally coercive in the degree 1 sector. We present numerical evidence which suggests that the Hessian is globally coercive in a certain equivariance class of the degree n sector for $n \geqslant 2$. We also prove that, within the geodesic approximation, a single $\mathbb{C}P^1$ lump moving on S^2 does not generically travel on a great circle. © *2003 American Institute of Physics.*

I. INTRODUCTION

Many field theories arising naturally in theoretical high energy physics may be said to be of Bogomol'nyi type. For such theories there is a topological lower bound on the energy of field configurations, and this bound is attained only by solutions of a first order ''self-duality'' equation, the so-called solitons of the theory. The solitons are stable by virtue of their energy-minimizing property, and are generically spatially localized lumps of energy with strongly particlelike characteristics. When static they exert no net force on one another, so the structure of the space of static multisoliton solutions is rather rich. Examples within the context of gauge theory are given by the Yang–Mills–Higgs and Abelian–Higgs models, whose solitons are called monopoles and vortices, respectively. In both these cases, the static models are very well understood and the structure of M_n, the moduli space of static n-soliton solutions, is known in great detail. For monopoles, in particular, the static system is integrable and there are several constructions which generate exact solutions of various degrees of explicitness. Once one introduces time dependence, however, things get much more difficult. No Bogomol'nyi-type field theory (indeed, no Lorentz invariant field theory) in more than $(1+1)$ dimensions is integrable, and the construction of nontrivial exact time-dependent solutions seems impossible.

How then is one to understand the dynamics of moving solitons in these models? The most fruitful approach has turned out to be the geodesic approximation of Manton.[11] Here one argues on physical grounds that the solution of any initial value problem in the n-soliton sector whose initial field is a static solution, and whose initial kinetic energy is small, should be forced to stay close to M_n by energy conservation. Manton suggested that the dynamics should be well approximated by

[a)]Electronic mail: mhaskin@math.jhu.edu
[b)]Electronic mail: j.m.speight@leeds.ac.uk

a solution of the reduced variational problem where the field configuration is *constrained* to lie on M_n at all times. This reduced dynamics turns out to be geodesic flow on M_n with respect to a natural metric called the L^2 metric, so one has the appealing suggestion that low energy soliton dynamics in Bogomol'nyi-type theories may be understood by studying the Riemannian geometry of their moduli spaces. This is still a highly nontrivial problem, and it was some time before the L^2 metrics on the two-monopole and two-vortex moduli spaces were well understood.[2,17] Since first being proposed, the method of Manton has been extended to deal with dynamical issues other than classical multisoliton scattering. Quantum soliton states[5] are thought to be well approximated by eigenstates of the Laplacian on M_n, for example, and the thermodynamics of soliton gases[12] has been analyzed in terms of the geometry of M_n.

Not all Bogomol'nyi-type field theories are gauge theories. Another class is given by nonlinear sigma models with Kähler target space, for example the $\mathbb{C}P^N$ models. These models are nonlinear in the most fundamental way: the field takes values in a space with no linear structure. However, they have many features in common with the gauge theories mentioned above. There is again a topological lower bound on energy, attained only by solutions of a first order partial differential equation, namely the $\pm$-holomorphic maps—the Cauchy–Riemann conditions play the role of the self-duality equation. The static model is integrable and the structure of M_n is again well understood. The solitons in this case are usually called ''lumps.''

Given the similarities between lumps and their gauge theoretic counterparts, it was natural for Ward to suggest, in the specific context of the $\mathbb{C}P^1$ model on the plane, that the geodesic approximation should be applicable to classical lump dynamics too.[26] A detailed numerical analysis of two-lump scattering within the geodesic approximation followed,[7] as well as generalizations to the $\mathbb{C}P^N$ models.[22] One technical problem encountered in all these studies is that $\mathbb{C}P^N$ lumps have L^2-infinite zero modes on $\mathbb{C}$, so the L^2 metric is only well-defined on the leaves of a foliation of M_n, rather than M_n itself. One interprets this physically as saying that certain parameters in the static n-lump solution are frozen to constant values by infinite inertia. For example, the width of a single $\mathbb{C}P^1$ lump is a free parameter, but is frozen in this fashion. Unfortunately, this freezing appears to be an artifact of the approximation—numerical solutions suggest that a single lump may expand or contract according to the genuine field dynamics. So the geodesic approximation is rather pathological for these models. It is therefore interesting to consider situations where physical space is compact, since the L^2 metric is then guaranteed to be well-defined. In particular, $\mathbb{C}P^1$ lumps on S^2 and T^2 have been studied, and quite a lot is known about the corresponding L^2 geometries.[19–21]

The question remains, of course, whether geodesic flow in M_n really does closely approximate low-energy n-lump dynamics in these theories. For two-vortex and two-monopole dynamics, rigorous results supporting the geodesic approximation have been proved by Stuart.[23,24] He has shown that the solution with initial data $\phi(0) \in \mathsf{M}_2$, $\dot{\phi}(0) \in T_{\phi(0)}\mathsf{M}_2$ of order ϵ (where $\epsilon > 0$ is small), stays pointwise close (order ϵ^2) to its corresponding geodesic in M_2 for a time of order ϵ^{-1}. The key idea in Stuart's analysis is to separate the dynamics into slow and fast time-varying modes by means of the following projection: the true solution $\phi(t)$ is projected onto M_2 to obtain a slow trajectory $\tilde{\phi}$,

$$\phi(t) = \tilde{\phi}(\epsilon t) + \epsilon^2 V(t), \tag{1.1}$$

and a fast varying ''error'' $V(t)$, the projection being chosen so that $V(t)$ is always L^2 orthogonal to $T_{\tilde{\phi}(\epsilon t)}\mathsf{M}_2$. Stuart goes on to prove that an appropriate Sobolev norm of $V(t)$ remains bounded for times of order ϵ^{-1} by bounding this norm in terms of $\mathsf{Hess}_{\tilde{\phi}}$, the quadratic form associated with the second variation of the potential energy functional of the model, which is slowly varying by virtue of energy conservation. It follows that, as expected, the true solution remains close to M_2. That the projected trajectory $\tilde{\phi}$ remains close to geodesic is proved as a separate step.

The whole analysis relies on one's ability to control Sobolev norms of the error in terms of the Hessian. More precisely, the following coercivity property of Hess is crucial:

There exists a constant $\tau>0$ *such that for all* $\tilde{\phi}\in \mathsf{M}_2$ *and all* $V\in H^1$ *with* $V\perp_{L^2} T_{\tilde{\phi}}\mathsf{M}_2$, $\mathsf{Hess}_{\tilde{\phi}}(V,V)\geqslant \tau\|V\|^2_{H^1}$.

This turns out to be slightly easier to prove for vortices than monopoles since the L^2 spectrum of small oscillations about a static vortex has a mass gap due to the Higgs mechanism. No such gap occurs for monopoles.

How much of this framework carries over to sigma models? Since the target space has no linear structure, Eq. (1.1) makes no sense as it stands, and must be replaced. We suggest here that the correct replacement is

$$\phi(t)=\exp_{\tilde{\phi}(\epsilon t)}\epsilon^2 V(t), \tag{1.2}$$

where $\exp{:}TN\to N$ is the exponential map on the target space N. Once again, we should choose $V(t)$ always to be L^2 orthogonal to $T_{\tilde{\phi}(\epsilon t)}\mathsf{M}_n$. In this context, we will prove an analog of Stuart's coercivity lemma for any holomorphic map $\tilde{\phi}$ between compact Kähler manifolds, namely, there exists $\tau(\tilde{\phi})>0$ such that for all $V\in H^1$, $V\perp_{L^2} T_{\tilde{\phi}}\mathsf{M}_n$,

$$\mathsf{Hess}_{\tilde{\phi}}(V,V)\geqslant \tau(\tilde{\phi})\|V\|^2_{H^1}. \tag{1.3}$$

The important difference from Stuart's result is that the constant τ depends on $\tilde{\phi}$, that is, varies with position in M_n. We may define the optimal constant

$$\tau(\tilde{\phi})=\inf\left\{\frac{\mathsf{Hess}_{\tilde{\phi}}(V,V)}{\|V\|^2_{H^1}}: V\neq 0, V\perp_{L^2} T_{\tilde{\phi}}\mathsf{M}_n\right\}>0. \tag{1.4}$$

We prove a result (Theorem 6) which gives sufficient conditions that τ depends continuously on $\tilde{\phi}$, and verify that those conditions hold in the main examples of interest to us. It turns out that M_n for sigma models is generically noncompact, so continuity of $\tau(\tilde{\phi})$ does not guarantee a global bound. In fact, we will show by means of an explicit counterexample that $\tau(\tilde{\phi})>0$ is *not* necessarily bounded away from zero. The counterexample occurs in the simplest nontrivial case, namely the one-lump moduli space of the $\mathbb{C}P^1$ model on S^2, but we believe it is indicative of a generic phenomenon for the $\mathbb{C}P^N$ models on any compact Riemann surface. Roughly speaking, $\tau(\tilde{\phi})\to 0$ as the lump $\tilde{\phi}$ shrinks to zero size. One would expect this to happen quite generically in M_n, wherever a family of holomorphic maps degenerates so that a single isolated lump collapses. This suggests we are never likely to have a global bounding constant τ on M_n as obtained by Stuart for vortices and monopoles. Consequently, the best result one could hope for from an analysis of this type for lumps is that the geodesic approximation is good for a time of order $T\epsilon^{-1}$, where T is some increasing function of $\inf_t \tau(\tilde{\phi}(\epsilon t))$. In this case, the approximation would work well (in the usual sense) so long as the projected geodesic stays away from $\partial_\infty \mathsf{M}_n$, the boundary at infinity of M_n, where $\tau\to 0$. In particular it seems very unlikely that geodesic flow provides a good approximation to the process of single lump collapse itself. Two independent numerical studies of singularity formation in the $\mathbb{C}P^1$ model on the plane support this pessimistic assessment.[3,10]

If we impose extra symmetry on our system, in other words, restrict attention to an admissible equivariance class, then the projected map $\tilde{\phi}$ is confined to a totally geodesic submanifold M_n^{eq} of M_n, and the error V is confined to an infinite dimensional subspace H^1_{eq} of $H^1(\tilde{\phi}^*TN)$. We may define an equivariant version τ^{eq} of τ by taking the infimum only over sections $V\in H^1_{eq}$. Clearly $\tau^{eq}(\tilde{\phi})\geqslant\tau(\tilde{\phi})>0$. For a certain equivariance class for n-lump dynamics in the $\mathbb{C}P^1$ model on S^2, one can prove that τ^{eq} is continuous on M_n^{eq}, which is again noncompact. We will present numerical evidence that $\tau^{eq}(\tilde{\phi})$ *is* globally bounded away from zero for $n\geqslant 2$ in this class. The point is that only *coincident* n-lump collapse can occur within this particular equivariance class, and the problem of vanishing τ does not appear to happen for such collapse. It is possible,

therefore, that the geodesic approximation does give a good model of equivariant multilump collapse, though one should be cautious: there is ample scope for other aspects of Stuart's method to break down as singularities form. There are some grounds for optimism. A recent careful numerical study of lump collapse by Linhart and Sadun found that single lump collapse on the plane differed significantly from that predicted by a truncated geodesic approximation, while coincident two-lump collapse did not.[10]

The rest of this article is structured as follows. In Sec. II we introduce the nonlinear sigma models of interest and briefly review some of their standard properties. We focus in particular on the $\mathbb{C}P^1$ model on S^2, describing what is known about the L^2 geometry on M_n in this case, especially for $n=1$. We present a new result on generic behavior of the geodesic flow in M_1 which implies that (within the geodesic approximation) a single lump generically does *not* travel along great circles on S^2. Precise restrictions on the set of nongeneric initial data are given. In Sec. III we formulate and prove the main result of the article, that the Hessian for these models is coercive on H^1, in the sense described above. In Sec. IV we establish a simple sufficient condition for $\tau(\phi)$ to depend continuously on $\tilde{\phi}\in\mathsf{M}_n$. In Sec. V we show that this condition is met in the case of M_1 for the $\mathbb{C}P^1$ model on S^2. We go on to prove that $\tau\to 0$ as $\tilde{\phi}$ approaches $\partial_\infty \mathsf{M}_1$, so global coercivity fails in this case. Finally, in Sec. VI we consider the case of the n-lump sector of the $\mathbb{C}P^1$ model on S^2 within a given equivariance class, showing that τ^{eq} is continuous. We conjecture that Hess^{eq} is globally coercive for $n\geqslant 2$ and present some numerical results in support of this conjecture.

II. THE $\mathbb{C}P^1$ MODEL ON S^2

For our purposes, a nonlinear sigma model consists of a single field $\phi:\mathbb{R}\times M\to N$, where (M,g) and (N,h) are compact Kähler manifolds, M represents physical space, $\mathbb{R}\times M$ is space–time, equipped with the Lorentzian pseudometric $\eta=dt^2-g$, and N is the target space. Solutions of the model are local extremals of the action,

$$S[\phi]=\frac{1}{2}\int_{\mathbb{R}\times M}\sum_{\alpha}\frac{|d\phi E_\alpha|^2}{|E_\alpha|^2}=\int_{\mathbb{R}}\left(\frac{1}{2}\int_M|\dot{\phi}|^2-E[\phi]\right), \tag{2.1}$$

where $E_0=\partial/\partial t, E_1,\ldots,E_m$ is an orthonormal basis of vector fields on $\mathbb{R}\times M$ and $E[\phi]$ is the harmonic map energy functional for maps $M\to N$. Such solutions are called wave maps in the geometric analysis literature, by analogy with harmonic maps.[18] Indeed, static wave maps are precisely harmonic maps and hence have been the focus of intense study. In particular, Lichnerowicz showed that if a homotopy class $[\phi]$ contains $\pm$-holomorphic representatives, then these minimize energy within that class.[9] So the moduli space of interest within a given class is $\mathsf{M}_{[\phi]}=\mathsf{Hol}_{[\phi]}(M,N)$. For the sake of generality, we will state and prove the coercivity lemma for the Hessian in this general context.

It is important when using the geodesic approximation to know that $\mathsf{M}_{[\phi]}$ is a finite dimensional smooth manifold. This is not always true in the general case of holomorphic maps between Kähler manifolds. We discuss this question in more detail in Sec. III, briefly summarizing some results in the harmonic maps and algebraic geometry literature which allow us to identify classes of sigma model whose moduli spaces are smooth manifolds. For the moment we note that the particular case we have most directly in mind, namely $M=N=S^2$, the $\mathbb{C}P^1$ model on the two-sphere, certainly does have this property.

We now consider the case $M=N=S^2$ in more detail. Each homotopy class $[\phi]\in\pi_2(S^2)$ is labeled by the degree of ϕ, an integer n, which without loss of generality we may assume is nonnegative. The degree n is interpreted physically as the net lump number of the configuration ϕ. The space M_n of degree n holomorphic maps $S^2\to S^2$ is easily constructed explicitly. Choosing stereographic coordinates $z,W\in\mathbb{C}$ on both M and N, such a map is rational of degree n,

$$\phi: z \mapsto W = \frac{a_1 z^n + \cdots + a_{n+1}}{a_{n+2} z^n + \cdots + a_{2n+2}}, \tag{2.2}$$

where a_i are $2n+2$ complex constants, a_1 and a_{n+2} do not both vanish, and the numerator and denominator have no common roots. Since $(a_1,\ldots,a_{2n+2})$ and $(\xi a_1,\ldots,\xi a_{2n+2})$ give the same map for all $\xi \in \mathbb{C}\backslash\{0\}$, we have a natural identification of M_n with a dense open subset of $\mathbb{C}P^{2n+1}$, whence it inherits a natural topology and complex structure.

The metric of interest γ does not descend from the inclusion $\mathsf{M}_n \subset \mathbb{C}P^{2n+1}$, however. To define it, one must think of a tangent vector $X \in T_\phi \mathsf{M}_n$ as a zero mode of the Cauchy–Riemann equations for maps $M \to N$ at the map ϕ. Such a zero mode is a smooth section of $\phi^* TN$, the pullback of the tangent bundle of N by the map ϕ, that is, a rule which assigns to each $p \in M$ a vector $V(p) \in T_{\phi(p)} N$. We may define the L^2 inner product between any pair of sufficiently regular sections X, Y of $\phi^* TN$ by taking their fibrewise inner product in $T_{\phi(p)} N$, then integrating over M,

$$\langle X, Y \rangle_{L^2} = \int_M h(X,Y). \tag{2.3}$$

The L^2 metric on M_n is simply the restriction of $\langle \cdot, \cdot \rangle_{L^2}$ to zero modes. In more concrete terms, one can in principle compute explicit formulas for γ by choosing local coordinates q^i on M_n (for example, the real and imaginary parts of a_i/a_1, on the chart where $a_1 \neq 0$) and expressing the map $\phi(\{q^i\})$ as an explicit function $W(z,\{q^i\})$, so that

$$\gamma = \sum_{ij} \gamma_{ij} dq^i dq^j, \quad \gamma_{ij} = \int_{\mathbb{C}} \frac{dz d\overline{z}}{(1+|z|^2)^2} \frac{1}{(1+|W|^2)^2} \frac{\partial W}{\partial q^i} \frac{\overline{\partial W}}{\partial q^j}. \tag{2.4}$$

In practice, of course, the integrals involved are almost always intractable.

Certainly, the L^2 metric is a natural way of geometrizing M_n. More importantly, it is the Riemannian metric descending from the restriction of the kinetic energy functional $\frac{1}{2}\int_M |\dot{\phi}|^2$ to M_n, and hence the metric whose geodesics are thought to model slow lump dynamics. We shall briefly review what is known about the Riemannian manifold (M_n, γ), and prove a new result about the generic behavior of geodesics in (M_1, γ).

First, (M_n, γ) is manifestly Hermitian, and is in fact Kähler. This was long suspected, owing to a rather general formal argument of Ruback,[15] and has recently been proved rigorously.[21] It is also known that (M_n, γ) is geodesically incomplete.[16] For odd n, (M_n, γ) contains a totally geodesic Lagrangian submanifold naturally identified with the moduli space of static $\mathbb{R}P^2$ n-lumps on $\mathbb{R}P^2$; for $n \geqslant 3$ this submanifold is also incomplete.

There is an isometric action of $G = \mathrm{SO}(3) \times \mathrm{SO}(3)$ on M_n, induced by the natural SO(3) actions on the domain and target spheres, which on M_1 has cohomogeneity 1 (generic G orbits have codimension 1), and in fact, almost completely determines γ. Consequently, an explicit formula for γ is known in this case, and the geometry is particularly well understood. For $n=1$, the no common roots condition on the rational map $W(z) = (a_1 z + a_2)/(a_3 z + a_4)$ is $a_1 a_4 - a_2 a_3 \neq 0$, so we may identify each map with a projective equivalence class $[L]$ of $\mathrm{GL}(2,\mathbb{C})$ matrices. Hence $\mathsf{M}_1 \cong \mathrm{PL}(2,\mathbb{C})$. By identifying S^2 with the unit sphere in $\mathbb{R}^3 \cong \mathfrak{su}(2)$ in the usual way, we may identify the SO(3) action on S^2 with the adjoint SU(2) action, so that γ regarded as a metric on $\mathrm{PL}(2,\mathbb{C})$ is invariant under the left and right PU(2) actions:

$$([U_1],[U_2]): [L] \mapsto [U_1 L U_2]. \tag{2.5}$$

Now every $[L] \in \mathrm{PL}(2,\mathbb{C})$ has a unique polar decomposition

$$[L] = [U(\sqrt{1+\lambda^2}\,\mathbb{I}_2 + \boldsymbol{\lambda}\cdot\boldsymbol{\tau})] \tag{2.6}$$

where $([U],\boldsymbol{\lambda})\in \mathrm{PU}(2)\times\mathbb{R}^3$, $\lambda=|\boldsymbol{\lambda}|$, and τ_1,τ_2,τ_3 are the Pauli spin matrices. Hence $\mathsf{M}_1 \cong \mathrm{PU}(2)\times\mathbb{R}^3\cong \mathrm{SO}(3)\times\mathbb{R}^3$. Physically, the lump corresponding to $([U],\boldsymbol{\lambda})$ has maximum energy density at $-\boldsymbol{\lambda}/\lambda\in S^2$, sharpness proportional to λ and internal orientation $[U]$. The $\lambda=0$ lumps have uniform energy density. The G action in this coordinate system is

$$([U_1],[U_2]):([U],\boldsymbol{\lambda})\mapsto([U_1UU_2],Ad_{U_2}\boldsymbol{\lambda}), \tag{2.7}$$

where again we have used $\mathbb{R}^3\cong\mathfrak{su}(2)$ to identify the fundamental SO(3) action on $\mathbb{R}^3$ with the adjoint SU(2) action on $\mathfrak{su}(2)$. From this we see that the G-orbits are level sets of λ, generically diffeomorphic to $\mathrm{SO}(3)\times S^2$ (when $\lambda>0$), the only exception being $\lambda=0$, which is diffeomorphic to SO(3).

In Ref. 21 it was proved that every G invariant Kähler metric on M_1 may be written

$$\gamma=A_1\,d\boldsymbol{\lambda}\cdot d\boldsymbol{\lambda}+A_2(\boldsymbol{\lambda}\cdot d\boldsymbol{\lambda})^2+A_3\,\boldsymbol{\sigma}\cdot\boldsymbol{\sigma}+A_4(\boldsymbol{\lambda}\cdot\boldsymbol{\sigma})^2+A_1\boldsymbol{\lambda}\cdot(\boldsymbol{\sigma}\times d\boldsymbol{\lambda}), \tag{2.8}$$

where $A_1,\ldots,A_4$ are smooth functions of λ only, all determined from the single function $A_1=A(\lambda)$ by the relations

$$A_2=\frac{A(\lambda)}{1+\lambda^2}+\frac{A'(\lambda)}{\lambda},\quad A_3=\frac{1}{4}(1+2\lambda^2)A(\lambda),\quad A_4=\frac{1}{4\lambda}(1+\lambda^2)A'(\lambda). \tag{2.9}$$

Here $\sigma_1,\sigma_2,\sigma_3$ are the left invariant one-forms on SO(3) dual to the basis $\{i/2\,\tau_a : a=1,2,3\}$ for $\mathfrak{su}(2)\cong\mathfrak{so}(3)$. For the L^2 metric, one finds that

$$A=\frac{4\pi\mu[\mu^4-4\mu^2\log\mu-1]}{(\mu^2-1)^3},\quad \mu=(\sqrt{1+\lambda^2}+\lambda)^2. \tag{2.10}$$

It follows from these formulas that (M_1,γ) has finite volume and diameter, is Ricci positive and has unbounded scalar and holomorphic sectional curvatures. Examining the large λ behavior of γ, one finds that $\partial_\infty\mathsf{M}_1$, the boundary at infinity of M_1, is $S^2\times S^2$. This is natural in two ways: a point in $\partial_\infty\mathsf{M}_1$ should be thought of as a collapsed lump whose width has shrunk to zero. Such a lump is specified by a pair of points p,p' in S^2 because every point except one, p, in the domain gets mapped to the same point p' in the codomain, while p gets mapped to the antipodal point $-p'$. Second, the complex codimension 1 algebraic variety $a_1a_4-a_2a_3=0$ complementary to M_1 in $\mathbb{C}P^3$ is biholomorphic to $\mathbb{C}P^1\times\mathbb{C}P^1$, being the image of the holomorphic embedding

$$([x_1,x_2],[y_1,y_2])\mapsto[x_1y_2,x_1y_1,x_2y_2,x_2y_1]. \tag{2.11}$$

Since $\mathrm{diam}(\mathsf{M}_1,\gamma)<\infty$, $\partial_\infty\mathsf{M}_1$ lies at finite proper distance, so geodesics may reach it in finite time, the origin of the incompleteness already noted. Given that $\partial_\infty\mathsf{M}_1$ has (real) codimension 2, however, one would expect geodesics to miss $\partial_\infty\mathsf{M}_1$ generically. More precisely, one would expect the subset of $T\mathsf{M}_1$ consisting of initial data of geodesics which *do* escape to infinity to have zero measure with respect to the natural measure inherited from γ.

Geodesic flow in (M_1,γ) was studied in detail in Ref. 19. It turns out to be surprisingly complicated given the homogeneity and isotropy of the domain of the sigma model, S^2. Geodesics were found for which the lump spins internally and oscillates between antipodal points. Other geodesics were found where the lump travels along a great circle in S^2, its speed and shape undergoing complicated periodic oscillations. Geodesics do exist for which the lump simply traverses a great circle at constant speed and shape, but the initial data to generate such motion must be chosen very carefully. Nevertheless, all the geodesics found in Ref. 19 confined the lump's position $-\boldsymbol{\lambda}/\lambda$ to some great circle for all time. More precisely, they all confined $\boldsymbol{\lambda}(t)$ to some plane through the origin. The geodesics themselves were obtained by reducing the geodesic problem to low dimensional totally geodesic submanifolds, the fixed point sets of discrete isom-

etries. The question arises, then, whether this "planar property" of the geodesic flow is an artifact of the exceptional symmetries enjoyed by these geodesics, or is a general feature of the dynamics. We shall now prove that the former is the case.

By the G invariance of the metric, it suffices to determine which initial velocities $u \in T_{x(0)}H$ at the point $x(0)=([\mathbb{I}_2],(0,0,\lambda))$ tangent to the hypersurface $H=\{([U],\boldsymbol{\lambda}):\lambda_2=0\}$ generate geodesics which remain in H. We shall call such an initial velocity u a "good" vector. Clearly the set of good initial velocities is conical by time-scaling invariance of geodesic flow. By this we mean that if $u \in T_{x(0)}H$ is good, so is every vector $\xi u \in T_{x(0)}H$, $\xi \in [0,\infty)$, on the ray containing u. The question is then whether the *link* of this cone of good velocity vectors, that is, its intersection with the unit four-sphere in $T_{x(0)}H$, has nonvanishing measure in S^4.

Theorem 1: *Let $u \in T_{x(0)}H$ generate a geodesic through $x(0)$ which remains in H. Then u lies in a codimension 1 cone in $T_{x(0)}H$. For generic $x(0) \in H$, the link of this cone is the suspension of a two-torus. There is at most a nowhere dense subset of H on which the link of the cone is $S^3 \cup S^3$, two three-spheres intersecting in an equatorial two-sphere.*

Proof: Let N be a nonvanishing (but not necessarily unit) normal on H. Then if $x(t)$ remains in H, $\gamma(\dot{x}(t),N(x(t)))=0$ for all t. Differentiating this at $t=0$ and using the fact that $\dot{x}(t)$ is parallel for a geodesic, one finds that $\gamma(\dot{x}(0),\nabla_{\dot{x}(0)}N)=0$, where ∇ is the Levi-Civita connection. Hence, $u=\dot{x}(0)$ must lie in the null space of the symmetric bilinear form

$$B(u,v)=\gamma(u,\nabla_v N), \tag{2.12}$$

that is, $B(u,u)=0$. Clearly this null space is conical. We seek to understand the link of this cone. In this case ($H=\{\lambda_2=0\}$), we may choose

$$N=A_3\frac{\partial}{\partial\lambda_2}+\frac{1}{2}A_1(-\lambda_3\theta_1+\lambda_1\theta_3) \tag{2.13}$$

as our normal field, where θ_a are the left-invariant vector fields on SO(3) dual to σ_a. We may compute $B(u,v)$ by extending u,v to vector fields U,V on M_1, then using the usual formula for ∇ and symmetry of B,[27] to yield

$$B(u,v)=\tfrac{1}{2}N[\gamma(U,V)]|_{x(0)}+\tfrac{1}{2}\gamma([U,N]|_{x(0)},v)+\tfrac{1}{2}\gamma([V,N]|_{x(0)},u). \tag{2.14}$$

A straightforward but lengthy calculation then shows that

$$B=f_1(\lambda)d\lambda_1\sigma_3+f_2(\lambda)d\lambda_3\sigma_1+f_3(\lambda)\sigma_2\sigma_3, \tag{2.15}$$

where

$$f_1=\tfrac{1}{8}(1+\lambda^2)(2A+\lambda A'),\quad f_2=-\tfrac{1}{4}(1+2\lambda^2)A(A+\lambda A'),\quad f_3=\tfrac{1}{16}(1+\lambda^2)AA', \tag{2.16}$$

at the specific point $x(0)=([\mathbb{I}_2],(0,0,\lambda))$. By computing eigenvalues, one sees that, with respect to some orthonormal basis for $T_{x(0)}H$,

$$B(u,u)=f_2(\lambda)(u_2^2-u_3^2)+\sqrt{f_1(\lambda)^2+f_3(\lambda)^2}(u_4^2-u_5^2). \tag{2.17}$$

Note that

$$\frac{8f_1(\lambda)}{1+\lambda^2}=2A+\lambda A'>\frac{2\lambda^1+1}{\lambda^2+1}A+\lambda A'=\gamma\left(\frac{\partial}{\partial\lambda_3},\frac{\partial}{\partial\lambda_3}\right)>0 \tag{2.18}$$

so $f_1(\lambda)$ never vanishes. Consider the set $L=f_2^{-1}(0)\subset[0,\infty)$. If L were dense at λ_0, then by continuity of $A+\lambda A'$, there would be an open interval containing λ_0 such that $A=-\log\lambda+\text{const}$. Given the formula (2.10), A clearly does not coincide with $-\log\lambda+\text{const}$ on any interval, so no such λ_0 exists. Hence the set L is nowhere dense.

Let $\lambda\notin L$. By means of a λ dependent rescaling of the basis, we see that the null space is the locus of the equation

$$\tilde{u}_2^2+\tilde{u}_4^2=\tilde{u}_3^2+\tilde{u}_5^2. \tag{2.19}$$

Clearly $\tilde{u}_1$ may take any value, while $(\tilde{u}_2,\tilde{u}_3,\tilde{u}_4,\tilde{u}_5)$ lies on a cone in $\mathbb{R}^4$ whose link is a two-torus. Alternatively, we may think of the unit sphere in $\mathbb{R}^5$ as the suspension of the unit sphere in $\mathbb{R}^4$ along the $\tilde{u}_1$ direction. Then the intersection of the link of the null space with each three-sphere of constant $\tilde{u}_1\in[-1,1]$ is a scaled two-torus. Assembling the slices together we see that the whole null space has a link which is topologically the suspension of a two-torus.[6] Either way of viewing the null set, it is clearly a codimension 1 cone in $T_{x(0)}H$ as claimed.

It remains to consider the nongeneric case, $\lambda\in L$, for which $f_2(\lambda)=0$. In this case, since $f_1(\lambda)\neq 0$, the cone consists of all vectors for which $u_4=\pm u_5$. The link is the intersection of S^4 with the union of the two orthogonal hyperplanes $(u_4\pm u_5)=0$, which is manifestly a union of two three-spheres intersecting in an equatorial two sphere $(u_4=u_5=0)$. □

We should point out that $u\in\text{null}\,B$ is a necessary but not sufficient condition for the geodesic with initial velocity u to stay in H. It is not certain that the cone of good velocities is all of null B, therefore. Given the explicit formula for A, one would expect to be able to improve the characterization of the nongeneric subset of H (on which null B has link $S^3\cup S^3$) from nowhere dense to discrete or finite. Indeed, one may check graphically that $f_2(\lambda)=0$ has only one solution ($\lambda=0.881$ to three decimal places), so the nongeneric set consists of a single G orbit, $S^1\times\text{SO}(3)$, in H.

Corollary 2: Generically geodesics in (M_1,γ) *do not confine* $\mathbf{\lambda}(t)$ *to a plane through* $\mathbf{0}$. *Consequently, single lumps generically do not stay on great circles while moving on* S^2.

Of course, this corollary refers to the lump dynamics within the geodesic approximation. The question remains: does this give a good model of the full field dynamics?

III. COERCIVITY OF THE HESSIAN

We wish to consider the wave map problem for maps $(\mathbb{R}\times M,dt^2-g)\to(N,h)$, where $(M,g),(N,h)$ are compact Kähler, and the initial data have a certain Sobolev regularity and are close to holomorphic, in a sense to be made precise. The eventual aim is to prove that such wave maps stay close to $\mathsf{Hol}_{[\phi]}(M,N)$ and that their closest trajectory in $\mathsf{Hol}_{[\phi]}(M,N)$ is close to a geodesic. In this section we will prove the main analytic ingredient needed for such a program, along the lines of Stuart's work on vortices.

The first thing to note is that the Cauchy problem for such wave maps with initial data $(\phi_0,\dot{\phi}_0)\in H^k\oplus H^{k-1}$ on the time slice $\{0\}\times M$ is well posed, that is, has a unique solution in the same Sobolev space, with $t\mapsto(\phi(t),\dot{\phi}(t))$ continuous, at least on some open time interval, $t\in(-\epsilon,\epsilon)$, by work of Choquet-Bruhat.[4] Here H^k denotes the space of maps $M\to\mathbb{R}^p$ which are H^k in the usual sense ($\phi,\nabla\phi,\ldots,\nabla^k\phi$ are all L^2) and which take values on $N\subset\mathbb{R}^p$ (isometrically embedded in $\mathbb{R}^p$) almost everywhere. For our purposes, it is convenient to use an alternative intrinsic definition of $H^k(M,N)$, which is only well-defined for $k>\frac{1}{2}\dim M$. With this restriction on k, $H^k(M,N)$ naturally has the structure of a Hilbert manifold. Below we give a brief treatment of both the intrinsic definition and the Hilbert manifold structure of $H^k(M,N)$. For a complete treatment we refer the reader to Ref. 14.

A map $\phi:M\to N$ is said to belong to $H^k(M,N)$ if for any $p\in M$ and any chart (U,Φ) containing p, and any chart (V,Ψ) containing $\phi(p)$, the map $\Psi\circ\phi\circ\Phi^{-1}:\Phi(U)\to\mathbb{R}^n$ belongs to $H^k(\Phi(U),\mathbb{R}^n)$. For this notion to be well-defined we need to ensure that composition by C^∞ diffeomorphisms on the left and on the right takes an H^k map to an H^k map. For composition on the right this is true without any restriction on k. However, for left composition the same result

only holds if we assume $k>\frac{1}{2}\dim M$ (for a discussion of both points see B.1.7 and B.1.9 on p. 182 in Ref. 13). From now on we make a standing assumption that $k>\frac{1}{2}\dim M$, so that the intrinsic definition of $H^k(M,N)$ given above makes sense.

We now exhibit the structure of an infinite dimensional Hilbert manifold on $H^k(M,N)$. Standard facts on embeddings of Sobolev spaces and the density of smooth maps in Sobolev spaces prove the following: There are continuous inclusions $C^\infty(M,N)\hookrightarrow H^k(M,N)\hookrightarrow C^0(M,N)$ and the first inclusion has dense image. From the latter fact it follows that it is sufficient to exhibit charts for $H^k(M,N)$ around only the C^∞ maps.

Given $\phi\in C^\infty(M,N)$ the pullback bundle ϕ^*TN (i.e., the vector bundle over M whose fibre at m is the vector space $T_{\phi(m)}N$) comes equipped with a natural inner product $h\circ(\phi\times\phi)$ and compatible connexion ∇^ϕ, the pullback of the Levi-Civita connection on TN. For any vector bundle E over compact M equipped with an inner product $\langle\ ,\ \rangle$ and compatible connection ∇ there is a natural H^k inner product on smooth sections of E:

$$\langle V,W\rangle_{H^k}=\int_M\langle V,W\rangle+\int_M\langle\nabla V,\nabla W\rangle+\cdots+\int_M\langle\nabla^k V,\nabla^k W\rangle. \tag{3.1}$$

$H^k(E)$ is then defined as the set of finite H^k norm elements of the completion of $C^\infty(E)$ with respect to the norm $\|\cdot\|_{H^k}$. For M compact, this definition of $H^k(E)$ is equivalent to the following alternative definition: given any choice of local coordinates on M and associated bundle trivializations for E, a section belongs to $H^k(E)$ if it is represented by locally H^k functions in these trivializations. The difference is that the connection-dependent definition gives a preferred inner product on $H^k(E)$, i.e., $(H^k(E),\|\cdot\|_{H^k})$ is naturally a Hilbert space.

The point is that $H^k(\phi^*TN)$ is the local model space for the Hilbert manifold $H^k(M,N)$. For each $\phi\in C^\infty(M,N)$, there is a map $\exp_\phi:H^k(\phi^*TN)\to H^k(M,N)$ given by $V(p)\mapsto\exp_{\phi(p)}V(p)$, where $\exp:TN\to N$ is the exponential map on (N,h). It can be shown that $\exp_\phi$ maps a neighborhood of 0 in the Hilbert space $H^k(\phi^*TN)$ bijectively to a neighborhood of ϕ in $H^k(M,N)$. Hence for each $\phi\in C^\infty(M,N)$ there exists some $\epsilon>0$, so that one can define a chart $(U_\phi,\exp_\phi^{-1})$ based at ϕ where

$$U_\phi=\{\exp_\phi(V):V\in H^k(\phi^*TN),\|V\|_{H^k}<\epsilon\}.$$

The local homeomorphism $U_\phi\to B_\epsilon(0)\subset H^k(\phi^*TN)$ is simply given by $\exp_\phi^{-1}$. So we identify H^k maps close to ϕ with H^k sections of ϕ^*TN by deforming ϕ: the deformed map $\exp_\phi(V)$ maps each $p\in M$ to the point in N reached by traveling for unit time along the geodesic with initial data $(\phi(p),V(p))$.

It can be shown that for any two maps $\phi_1,\phi_2\in C^\infty(M,N)$ the change of charts map $\exp_{\phi_2}^{-1}\circ\exp_{\phi_1}:\exp_{\phi_1}^{-1}(U_{\phi_1}\cap U_{\phi_2})\to\exp_{\phi_2}^{-1}(U_{\phi_1}\cap U_{\phi_2})$ is a diffeomorphism between open sets in the Hilbert spaces $H^k(\phi_1^*TN)$ and $H^k(\phi_2^*TN)$. It follows that the collection of charts $\{(U_\phi,\exp_\phi^{-1})|\ \phi\in C^\infty(M,N)\}$ defines a differentiable structure on $H^k(M,N)$ with local model a Hilbert space, i.e., $H^k(M,N)$ is a Hilbert manifold. In fact, the differentiable structure can be shown to be independent of the metric h on N used to define $\exp_\phi$.

Given

(i) a holomorphic map $\tilde{\phi}_0\in\mathsf{Hol}(M,N)$, and
(ii) sections $V_0,X_0,Y_0\in H^k(\tilde{\phi}_0^*TN)$, such that
(iii) V_0,Y_0 are L^2 orthogonal to $T_{\tilde{\phi}_0}\mathsf{Hol}(M,N)$, and
(iv) $X_0\in T_{\tilde{\phi}_0}\mathsf{Hol}(M,N)$,

and $\epsilon>0$ small, the initial value problem with initial data

$$\phi_0=\exp_{\tilde{\phi}_0}\epsilon^2V_0,\quad \dot{\phi}_0=\epsilon X_0+\epsilon^3Y_0 \tag{3.2}$$

has a unique solution in H^k. The idea is to decompose this solution into $\tilde{\phi}(t) \in \mathsf{Hol}(M,N)$ and $V(t) \in H^k(\tilde{\phi}(t)^*TN) \cap T_{\tilde{\phi}(t)}\mathsf{Hol}(M,N)^{\perp_{L^2}}$ by

$$\phi(t) = \exp^{\sim}_{\tilde{\phi}(t)} \epsilon^2 V(t), \tag{3.3}$$

and then show that $\|V\|_{H^k}$ remains bounded for times of order ϵ^{-1}. The starting point is to show that $\|V\|_{H^1}$ is controlled by $\mathsf{Hess}^{\sim}_{\tilde{\phi}}(V,V)$. From now on, all quantities will be considered at a fixed time, and we will denote the holomorphic base map of our local chart in H^k by ϕ rather than $\tilde{\phi}$, to simplify notation.

$\mathsf{Hess}_\phi(X,Y)$ is the second variation of the harmonic map energy E at the holomorphic (hence harmonic) map ϕ. Precisely, given a two-parameter variation $\phi_{s,t}$ of the map ϕ through smooth maps, with $d\phi_{0,0}\partial/\partial s = X, d\phi_{0,0}\partial/\partial t = Y \in \Gamma(\phi^*TN)$,

$$\mathsf{Hess}_\phi(X,Y) = \left.\frac{\partial^2 E[\phi_{s,t}]}{\partial s \partial t}\right|_{s=t=0}. \tag{3.4}$$

There are two useful explicit formulas for Hess.[25] The first uses only compactness of M, not the Kähler property. To write it down we must introduce two new objects. Let $E_i, i = 1,\ldots,m$, be a local frame of smooth orthonormal vector fields on M. Then the rough Laplacian on sections of ϕ^*TN is the second order linear elliptic differential operator

$$\Delta^\phi V = -\operatorname{tr}(\nabla^\phi \nabla^\phi V) = -\sum_{i=1}^m (\nabla^\phi \nabla^\phi V)(E_i, E_i). \tag{3.5}$$

Like the usual Laplacian (on functions or forms) Δ^ϕ is a positive self-adjoint operator. Positivity follows from the identity

$$\int_M h(V, \Delta^\phi V) = \frac{1}{2}\int_M \sum_i h(\nabla^\phi_{E_i} V, \nabla^\phi_{E_i} V). \tag{3.6}$$

We may define a (fiberwise linear) bundle map $\mathfrak{R}^\phi$ on ϕ^*TN by

$$\mathfrak{R}^\phi V = \sum_{i=1}^m R^N(V, d\phi E_i) d\phi E_i, \tag{3.7}$$

where R^N is the curvature tensor on N. Given these, the Hessian is

$$\mathsf{Hess}_\phi(X,Y) = \int_M h(X, \mathfrak{J}^\phi Y) = \langle X, \mathfrak{J}^\phi Y\rangle_{L^2}, \quad \mathfrak{J}^\phi = \Delta^\phi - \mathfrak{R}^\phi. \tag{3.8}$$

The operator $\mathfrak{J}^\phi$, called the Jacobi operator, is itself second order, linear, elliptic and self-adjoint. It follows immediately from this formula that every harmonic map into a manifold of nonpositive sectional curvature is weakly stable [meaning $\mathsf{Hess}_\phi(V,V) \geqslant 0$].

In the case of interest to us, namely M,N compact Kähler, and ϕ holomorphic, one can obtain a more useful and rather simpler formula for Hess. First one defines the Urakawa connection on ϕ^*TN,

$$(\mathfrak{D}^\phi V)(X) := \nabla^\phi_{J^M X} V - J^N \nabla^\phi_X V, \tag{3.9}$$

J^M, J^N being the almost complex structures on M and N.[25] Then

$$\mathsf{Hess}_\phi(V,V) = \tfrac{1}{2}\|\mathfrak{D}^\phi V\|^2_{L^2}. \tag{3.10}$$

Weak stability of holomorphic maps follows immediately from (3.10).

$\mathfrak{D}^\phi V=0$ should be thought of as the linearized Bogomol'nyi equation, so every $V\in\ker\mathfrak{D}^\phi=\ker\mathfrak{J}^\phi$ is a zero mode of the holomorphic map ϕ. For the geodesic approximation to make sense, the space of holomorphic maps close to ϕ must be a smooth manifold whose tangent space at ϕ equals $\ker\mathfrak{J}^\phi$. Sections of ϕ^*TN in the kernel of $\mathfrak{J}^\phi$ are called Jacobi fields along ϕ. A Jacobi field is said to be integrable if it may be generated by a variation of ϕ through harmonic maps, and the map itself is said to be Jacobi integrable if all its Jacobi fields have this property. A fundamental theorem of Adams and Simon[1] states that a harmonic map ϕ between real analytic manifolds is Jacobi integrable if and only if the space of harmonic maps $C^{2,\alpha}$ close to ϕ is a smooth manifold with tangent space $\ker\mathfrak{J}^\phi$ at ϕ. Similar results hold in suitable Sobolev spaces of maps also. In the case where M,N are Kähler (hence real analytic), Lichnerowicz showed that all harmonic deformations of a holomorphic map ϕ are holomorphic,[9] so the space of interest to us, the space of *holomorphic* maps close to ϕ, is a smooth manifold with tangent space $\ker\mathfrak{J}^\phi$ at ϕ, if and only if ϕ is Jacobi integrable. Jacobi integrability of harmonic maps is an active field of research whose current state is summarized in Ref. 8. Particularly relevant to the present article is a theorem of Wood and Lemaire which states that every holomorphic map $S^2\to\mathbb{C}P^N$ is Jacobi integrable. So the moduli space of holomorphic maps for the $\mathbb{C}P^N$ model on S^2 is smooth with tangent space $\ker\mathfrak{J}^\phi$, as we require. A similar result holds for degree n holomorphic maps $\Sigma\to\mathbb{C}P^1$, Σ being a compact Riemann surface of genus g, provided $n>2g-2$, by a standard application of the Riemann–Roch theorem. So the n-lump moduli space of the $\mathbb{C}P^1$ model on Σ also has the required property, with some low degree exceptions.

We may now state and prove our main result.

Theorem 3 [Coercivity of the Hessian]: *Let $\phi:M\to N$ be a holomorphic map between compact Kähler manifolds and Hess_ϕ be the Hessian of the harmonic map energy functional at ϕ. Then there exists a constant $\tau(\phi)>0$ such that for all $V\in H^1(\phi^*TN)$ with $\langle V,\ker\mathfrak{D}^\phi\rangle_{L^2}=0$,*

$$\mathsf{Hess}_\phi(V,V)\geqslant\tau(\phi)\|V\|^2_{H^1}.$$

Proof: Both H^1 and L^2 are Hilbert spaces. We will use $\to$ and $\rightharpoonup$ to denote strong and weak convergence, respectively, the space concerned being explicitly specified. Define the subset $S=\{V\in H^1:\|V\|^2_{H^1}=1,V\perp_{L^2}\ker\mathfrak{D}^\phi\}$ and the quantity

$$\tau(\phi)=\inf_{V\in S}\mathsf{Hess}_\phi(V,V)=\inf_{V\in S}\tfrac{1}{2}\|\mathfrak{D}^\phi V\|^2_{L^2}\geqslant 0. \tag{3.11}$$

We claim that $\tau(\phi)\neq 0$. Assume this is false. Then there exists a sequence $V_i\in S$ such that $\mathfrak{D}^\phi V_i\overset{L^2}{\to}0$. We will repeatedly extract (nested) subsequences from V_i, which we will always denote by the same symbol, V_i. Now V_i is bounded in H^1 so, by the Alaoglu theorem, there exists a subsequence $V_i\overset{H^1}{\rightharpoonup}V$, to some weak limit V. Since $\mathfrak{D}^\phi:H^1\to L^2$ is a bounded linear map, it is continuous with respect to the weak (and strong) topologies on H^1,L^2. It follows that $\mathfrak{D}^\phi V_i\overset{L^2}{\rightharpoonup}\mathfrak{D}^\phi V$. But $\mathfrak{D}^\phi V_i\overset{L^2}{\to}0\Rightarrow\mathfrak{D}^\phi V_i\overset{L^2}{\rightharpoonup}0\Rightarrow\mathfrak{D}^\phi V=0$ by uniqueness of weak limits. Hence $V_i\overset{H^1}{\rightharpoonup}V\in\ker\mathfrak{D}^\phi$.

Now the inclusion $\iota:H^1\hookrightarrow L^2$ is compact by Rellich's lemma, so the bounded set $\{V_i\}\subset H^1$ is compact in L^2. Hence, any sequence in $\{V_i\}$, for example V_i itself, has a subsequence which is strongly convergent in L^2. Once again, denoting this subsequence by V_i, we have $V_i\overset{L^2}{\to}\tilde{V}$. But then $V_i\overset{L^2}{\rightharpoonup}\tilde{V}$ so

$$0=\langle V_i,\ker\mathfrak{D}^\phi\rangle_{L^2}\to\langle\tilde{V},\ker\mathfrak{D}^\phi\rangle_{L^2}. \tag{3.12}$$

Hence $V_i \overset{L^2}{\to} \tilde{V} \in (\ker \mathfrak{D}^\phi)^{\perp_{L^2}}$.

But $\iota: H^1 \hookrightarrow L^2$ is continuous, so $V_i \overset{H^1}{\rightharpoonup} V \Rightarrow \iota V_i \overset{L^2}{\rightharpoonup} \iota V$, and so $\tilde{V} = V$ by uniqueness of weak limits. So $V \in \ker \mathfrak{D}^\phi$ and $V \in (\ker \mathfrak{D}^\phi)^{\perp_{L^2}}$, and hence $V = 0$, so $V_i \overset{L^2}{\to} 0$. Then, by (3.6) and (3.8),

$$
\begin{aligned}
1 &= \|V_i\|_{H^1}^2 = \|V_i\|_{L^2}^2 + \sum_\alpha \|\nabla^\phi_{E_\alpha} V_i\|_{L^2}^2 \\
&= 2\,\mathrm{Hess}_\phi(V_i, V_i) + \|V_i\|_{L^2}^2 + \sum_\alpha 2\langle R^N(d\phi E_\alpha, V_i) d\phi E_\alpha, V_i\rangle_{L^2} \\
&\leqslant 2\,\mathrm{Hess}_\phi(V_i, V_i) + \|V_i\|_{L^2}^2 + C_\phi \|V_i\|_{L^2}^2, \qquad (3.13)
\end{aligned}
$$

where $C_\phi > 0$ is a constant, by compactness of N and the tensorial property of $\mathfrak{R}^N$. Taking limits of both sides of (3.13) and using $\tau(\phi) = 0$ and $V_i \overset{L^2}{\to} 0$, one sees that $1 \leqslant 0$, a contradiction. □

We remark that the L^2 version of this result, that there exists a constant $\tau(\phi) > 0$ such that $\mathrm{Hess}_\phi(V,V) \geqslant \tau(\phi)\|V\|_{L^2}^2$ for all $V \perp_{L^2} \ker \mathfrak{J}^\phi$, is much easier to prove. Since $\mathfrak{J}^\phi$ is elliptic, self-adjoint and positive definite (for weakly stable ϕ), and M is compact, we know immediately that the spectrum of $\mathfrak{J}^\phi$ is discrete and, normal to its kernel, bounded away from 0. The result immediately follows. In fact the optimal constant $\tau_{L^2}(\phi)$ in this case is just the lowest nonvanishing eigenvalue of $\mathfrak{J}^\phi$. Hence the optimal bound is attained in this case, by any eigensection with this eigenvalue. We remark also that the spectrum of $\mathfrak{J}^\phi$ is of independent physical interest since it gives the semiclassical meson spectrum of the sigma model in the topological sector $[\phi]$.

IV. CONTINUITY OF $\tau(\phi)$

Let $\phi_n : M \to N$ be a sequence of smooth holomorphic maps between compact Kähler manifolds, converging in C^1 to a smooth holomorphic map $\phi: M \to N$. From Theorem 3 we have for each n a positive constant $\tau(\phi_n)$ and the positive constant $\tau(\phi)$, which give lower bounds for the ratio $\mathrm{Hess}(V,V)/\langle V, V\rangle_{H_1}$ for any H^1 section of the pullback bundle L^2 orthogonal to all Jacobi fields. In this section we will establish conditions sufficient to guarantee that $\lim_{n\to\infty} \tau(\phi_n) = \tau(\phi)$. In subsequent sections we will show that these conditions are met in the cases of interest to us.

In order to compare various quantities (especially the Hessian and H^1 norm) at different maps, it is convenient to make various identifications so that we can treat all geometric quantities and operators as being defined on the fixed bundle $E = \phi^* TN$. Since $\phi_n \to \phi$, for sufficiently large n each pullback bundle $E_n = \phi_n^* TN$ is topologically equivalent to E. However, since each bundle E_n comes naturally equipped with both an inner product and a compatible connection (both of which occur in the Hessian and the H^1-norm of a section) we would also like to transfer these geometric structures to the bundle E.

Again since $\phi_n \to \phi$, for each $x \in M$ (and for each sufficiently large n) there is a unique minimizing geodesic joining $\phi_n(x)$ to $\phi(x)$. By parallel transporting vectors along this unique geodesic we construct a canonical isometry between the fibers of E and the fibers of E_n at each point $x \in M$, and hence a natural L^2 isometry between E and E_n. Using this isometry we can interpret the natural connection on each E_n as a connection on E, which we shall write ∇_n. Using the connection ∇_n and the (fixed) L^2 metric on E we can now interpret each of the Jacobi operators $\mathfrak{J}^{\phi_n}$ (and hence also the associated symmetric bilinear form Hess_{ϕ_n}) as an operator on sections of the fixed bundle E. Similarly, for each n we get an $H^1_{\phi_n}$ norm on sections of E, by using the connection ∇_n and the fixed L^2 metric. Since the difference of any two connections on E is tensorial, it is clear that for each n (sufficiently large) the $H^1_{\phi_n}$ norm is equivalent to the H^1_ϕ norm on sections of E.

Suppose now that the difference between the connections ∇_n and ∇ tends to zero in the following pointwise sense,

$$|\nabla V - \nabla_n V| \leq a_n |V|, \tag{4.1}$$

where each a_n is a positive number, $a_n \to 0$ as $n \to \infty$, and $|.|$ refers to the natural pointwise norms on the bundles $E \otimes T^*M$ and E, and V is a smooth section of E.

Lemma 4: Suppose that (4.1) holds. Then the following inequalities also hold:

(i) $\quad | \, \|\nabla V\|^2 - \|\nabla_n V\|^2 \, | \leq b_n \|V\|_1^2,$
(ii) $\quad | \, \|V\|_1^2 - \|V\|_{H^1_{\phi_n}}^2 \, | \leq b_n \|V\|_1^2,$
(iii) $\quad | \, \mathrm{Hess}_\phi(V,V) - \mathrm{Hess}_{\phi_n}(V,V) \, | \leq c_n \|V\|_1^2,$

where b_n, c_n are positive numbers which tend to zero as $n \to \infty$, and $\|\cdot\|$ is the L^2 norm on $\Gamma(E)$, $\|\cdot\|_1$ is the H^1 norm on $\Gamma(E)$ defined using the connection ∇ and $\|\cdot\|_{H^1_{\phi_n}}$ is the H^1 norm on $\Gamma(E)$ defined using the connection ∇_n.

Proof: (i) Elementary manipulations involving the triangle inequality, inequality (4.1) and the Cauchy–Schwarz inequality yield the following chain of inequalities:

$$\begin{aligned}
\left| \int_M (|\nabla V|^2 - |\nabla_n V|^2) \right| &\leq \int_M \|\nabla V|^2 - |\nabla_n V|^2| \\
&\leq \int_M | \; |\nabla V| - |\nabla_n V| \; | \cdot | \; |\nabla V| + |\nabla_n V| \; | \\
&\leq \int_M | \; |\nabla V| - |\nabla_n V| \; | \cdot (| \; 2|\nabla V| + |\nabla V - \nabla_n V| \; |) \\
&\leq 2a_n \int_M |V| \; |\nabla V| \; + a_n^2 \int_M |V|^2 \\
&\leq 2a_n \| \; |V| \; \| \cdot \| \; |\nabla V| \; \| + a_n^2 \|V\|^2 \\
&\leq (2a_n + a_n^2) \; \|V\|_1^2.
\end{aligned}$$

Hence the result follows with $b_n = a_n(2 + a_n)$.

(ii) This is immediate from the definition of the H^1 norm and part (i).

(iii) The definition of $\mathfrak{R}^\phi$ [see Eq. (3.7)], together with the compactness of M and the fact that $\phi_n \to \phi$ in C^1 implies that

$$\lim_{n \to \infty} \|\mathfrak{R}^\phi - \mathfrak{R}^{\phi_n}\| = 0. \tag{4.2}$$

Using part (i) and the definition of Hess we have

$$\begin{aligned}
|\mathrm{Hess}_\phi(V,V) - \mathrm{Hess}_{\phi_n}(V,V)| &= |\tfrac{1}{2}\|\nabla V\|^2 - \tfrac{1}{2}\|\nabla_n V\|^2 - \langle \mathfrak{R}^\phi V, V\rangle + \langle \mathfrak{R}^{\phi_n} V, V\rangle| \\
&\leq \tfrac{1}{2} |\|\nabla V\|^2 - \|\nabla_n V\|^2| + |\langle \mathfrak{R}^\phi V, V\rangle - \langle \mathfrak{R}^{\phi_n} V, V\rangle| \\
&\leq b_n \|V\|_1^2 + \|(\mathfrak{R}^\phi - \mathfrak{R}^{\phi_n})V\| \; \|V\| \\
&\leq b_n \|V\|_1^2 + \|\mathfrak{R}^\phi - \mathfrak{R}^{\phi_n}\| \; \|V\|^2.
\end{aligned}$$

The result now follows from (4.2). □

We will also need the following simple proposition on the continuity of L^2 orthogonal projection operators.

Proposition 5: Let $H^k(E)$ denote the H^k sections of E. Let V_n be a sequence of finite dimensional vector subspaces of $H^k(E)$ of constant dimension p which converge to another p-dimensional subspace V of $H^k(E)$ in the following sense: there exists an L^2-orthonormal basis $e_1^n,\ldots,e_p^n$ of V_n and an L^2-orthonormal basis $e_1,\ldots,e_p$ of V so that for each $i=1,\ldots p$, $e_i^n\to e_i$ in H^k as $n\to\infty$. Denote by P_n and P the L^2 orthogonal projections onto $V_n^\perp$ and $V^\perp$, respectively. Then $P_n\to P$ in the operator norm on $B(H^k(E),H^k(E))$, the bounded linear maps between $H^k(E)$ and itself.

Proof: In this proof, norms and inner products without subscripts will refer to L^2 norms and inner products, while H^k norms and inner products will be referred to with the subscript k. Since $P_n v=v-\Sigma_i\langle v,e_i^n\rangle e_i^n$ and $Pv=v-\Sigma_i\langle v,e_i\rangle e_i$ we have

$$\begin{aligned}\|P_n v-Pv\|_k&=\left\|\sum_i\ \langle v,e_i^n\rangle e_i^n-\sum_i\ \langle v,e_i\rangle e_i\right\|_k\\&\leqslant\sum_i\ \|\langle v,e_i^n\rangle e_i^n-\langle v,e_i\rangle e_i\|_k\\&\leqslant\sum_i\ \|\langle v,e_i^n\rangle e_i^n-\langle v,e_i^n\rangle e_i+\langle v,e_i^n\rangle e_i-\langle v,e_i\rangle e_i\|_k\\&\leqslant\sum_i\ |\langle v,e_i^n\rangle|\ \ \|e_i^n-e_i\|_k+\|e_i\|_k|\langle v,e_i^n-e_i\rangle|\\&\leqslant\|v\|\ \left(\sum_i\ \|e_i^n\|\ \ \|e_i^n-e_i\|_k+\|e_i\|_k\|e_i^n-e_i\|\right)\leqslant\|v\|\left(\sum_i\ (1+\|e_i\|_k)\ \ \|e_i^n-e_i\|_k\right).\end{aligned}\tag{4.3}$$

So for all $v\neq 0\in H^k$ we have

$$\frac{\|(P_n-P)v\|_k}{\|v\|_k}\leqslant\frac{\|(P_n-P)v\|_k}{\|v\|}\leqslant\left(\sum_i\ (1+\|e_i\|_k)\ \ \|e_i^n-e_i\|_k\right).\tag{4.4}$$

Since by assumption $e_i^n\to e_i$ strongly in H^k for each i, (4.4) implies that

$$\limsup_{n\to\infty v\neq 0}\frac{\|(P_n-P)v\|_k}{\|v\|_k}=0\tag{4.5}$$

as required. □

We now state the main result of this section, a theorem giving sufficient conditions for $\tau(\phi)$ to depend continuously on the holomorphic map ϕ. The analogous result in Stuart's analysis of slowly moving Abelian Higgs vortices is Lemma 3.2 of Ref. 23 Our proof of Theorem 6 is inspired by Stuart's argument.

Theorem 6: *Let $\phi_n:M\to N$ be a sequence of smooth holomorphic maps between compact Kähler manifolds converging in C^1 to the smooth holomorphic map $\phi:M\to N$. Suppose all the Jacobi fields of ϕ are integrable and that the conclusions of Lemma 4 hold. Then*

$$\lim_{n\to\infty}\tau(\phi_n)=\tau(\phi).$$

Proof: Let $P_n,P:H^1(E)\to H^1(E)$ denote L^2 orthogonal projection onto $\ker\mathfrak{D}^{\phi_n\perp}$ and $\ker\mathfrak{D}^{\phi\perp}$, respectively. Since ϕ is Jacobi integrable, the space of sufficiently C^1-close holomorphic maps is a C^∞ manifold of dimension equal to dim $\ker\mathfrak{D}^\phi$. This also holds for all ϕ_n for all n

sufficiently large. In particular, the subspaces $\ker\mathfrak{D}^{\phi_n}$ satisfy the hypotheses of the previous proposition for any k, and in particular for $k=1$. Hence by the previous proposition we have

$$\|P-P_n\|_1=d_n,$$

for some positive numbers d_n tending to 0 as $n\to\infty$.

We will prove (i) $\tau(\phi)\geqslant\limsup_{n\to\infty}\tau(\phi_n)$ and (ii) $\tau(\phi)\leqslant\liminf_{n\to\infty}\tau(\phi_n)$. From (i) and (ii) it follows that $\lim_{n\to\infty}\tau(\phi_n)$ exists and equals $\tau(\phi)$.

Proof of (i): Consider for any $V\in H^1(E)\cap(\ker\mathfrak{D}^{\phi})^{\perp}$, the section $V_n:=P_nV\in H^1(E)\cap(\ker\mathfrak{D}^{\phi_n})^{\perp}$. Since $\|V-V_n\|_{H^1_\phi}=\|(P-P_n)V\|_{H^1_\phi}\leqslant d_n\|V\|_{H^1_\phi}$ we get

$$|\langle V_n,V_n\rangle_{H^1_\phi}-\langle V,V\rangle_{H^1_\phi}|\leqslant\|V-V_n\|_{H^1_\phi}(\|V\|_{H^1_\phi}+\|V_n\|_{H^1_\phi})\leqslant d_n(d_n+2)\langle V,V\rangle_{H^1_\phi}. \tag{4.6}$$

Using the previous inequality and inequality (ii) of Lemma 4 we have

$$\begin{aligned}|\langle V,V\rangle_{H^1_\phi}-\langle V_n,V_n\rangle_{H^1_{\phi_n}}|&\leqslant|\langle V_n,V_n\rangle_{H^1_{\phi_n}}-\langle V_n,V_n\rangle_{H^1_\phi}|+|\langle V_n,V_n\rangle_{H^1_\phi}-\langle V,V\rangle_{H^1_\phi}|\\&\leqslant b_n\langle V_n,V_n\rangle_{H^1_\phi}+d_n(d_n+2)\langle V,V\rangle_{H^1_\phi}\\&\leqslant f_n\langle V,V\rangle_{H^1_\phi},\end{aligned} \tag{4.7}$$

where $f_n:=(b_n+d_n(d_n+2)(1+b_n))$ is another sequence of positive numbers tending to zero as $n\to\infty$.

Since $V=V_n+K_n$ for some $K_n\in\ker\mathfrak{D}^{\phi_n}$, we have $\mathrm{Hess}_{\phi_n}(V_n,V_n)=\mathrm{Hess}_{\phi_n}(V,V)$. Hence

$$\begin{aligned}&\left|\frac{\mathrm{Hess}_\phi(V,V)}{\langle V,V\rangle_{H^1_\phi}}-\frac{\mathrm{Hess}_{\phi_n}(V_n,V_n)}{\langle V_n,V_n\rangle_{H^1_{\phi_n}}}\right|\\&\quad=\left|\frac{\mathrm{Hess}_\phi(V,V)}{\langle V,V\rangle_{H^1_\phi}}-\frac{\mathrm{Hess}_{\phi_n}(V,V)}{\langle V_n,V_n\rangle_{H^1_{\phi_n}}}\right|\\&\quad\leqslant\frac{\mathrm{Hess}_\phi(V,V)|\langle V,V\rangle_{H^1_\phi}-\langle V_n,V_n\rangle_{H^1_{\phi_n}}|+\langle V,V\rangle_{H^1_\phi}|\mathrm{Hess}_\phi(V,V)-\mathrm{Hess}_{\phi_n}(V,V)|}{\langle V,V\rangle_{H^1_\phi}\langle V_n,V_n\rangle_{H^1_{\phi_n}}}\\&\quad\leqslant\frac{f_n\mathrm{Hess}_\phi(V,V)+c_n\langle V,V\rangle_{H^1_\phi}}{\langle V,V\rangle_{H^1_{\phi_n}}}\leqslant\frac{f_n}{1-f_n}\frac{\mathrm{Hess}_\phi(V,V)}{\langle V,V\rangle_{H^1_\phi}}+\frac{c_n}{1-f_n}.\end{aligned} \tag{4.8}$$

Let $\{V^j\}_{j=1}^{\infty}\in H^1(E)\cap(\ker\mathfrak{D}^{\phi})^{\perp}$ be a minimizing sequence for $\tau(\phi)$ with unit H^1_ϕ norm, that is

$$\lim_{j\to\infty}\frac{\mathrm{Hess}_\phi(V^j,V^j)}{\langle V^j,V^j\rangle_{H^1_\phi}}=\lim_{j\to\infty}\mathrm{Hess}_\phi(V^j,V^j)=\tau(\phi).$$

Hence there exists a positive constant C and numbers ϵ_j tending to zero as $j\to\infty$, such that

$$\mathrm{Hess}_\phi(V^j,V^j)=\tau(\phi)+\epsilon_j$$

and

$$\mathrm{Hess}_{\phi_n}(V^j,V^j)\leqslant C$$

for all j and n. Define $V_n^j = P_n V^j \in H^1(E) \cap (\ker \mathfrak{D}^{\phi_n})^{\perp}$. The two previous facts together with (4.8) imply that

$$\left| \tau(\phi) + \epsilon_j - \frac{\mathrm{Hess}_{\phi_n}(V_n^j, V_n^j)}{\langle V_n^j, V_n^j \rangle_{H^1_{\phi_n}}} \right| \leqslant \frac{C f_n + c_n}{1 - f_n}$$

holds for all j and n. For any fixed n, taking the limit as $j \to \infty$ we see that

$$\tau(\phi_n) \leqslant \tau(\phi) + \frac{C f_n + c_n}{1 - f_n}.$$

Hence for any limit point l of the sequence $\{\tau(\phi_n)\}_{n=1}^{\infty}$ we have $l \leqslant \tau(\phi)$. In particular we have

$$\limsup_{n \to \infty} \tau(\phi_n) \leqslant \tau(\phi)$$

as required.

Proof of (ii): Since the proof of (ii) is very similar in character to the proof of (i) we shall omit some details. Consider the projection PV_n of an element $V_n \in H^1(E) \cap (\ker \mathfrak{D}^{\phi_n})^{\perp}$ into $H^1(E) \cap (\ker \mathfrak{D}^{\phi})^{\perp}$. Several applications of the triangle inequality, together with the inequalities in Lemma 4 and the fact that $P_n \to P$ in H^1, show that there exist two sequences of positive numbers $\{g_n\}$ and $\{h_n\}$ with $\lim_{n \to \infty} g_n = \lim_{n \to \infty} h_n = 0$ so that

$$\left| \langle V_n, V_n \rangle_{H^1_{\phi_n}} - \langle PV_n, PV_n \rangle_{H^1_{\phi}} \right| \leqslant g_n \langle PV_n, PV_n \rangle_{H^1_{\phi}} \tag{4.9}$$

and

$$\left| \langle V_n, V_n \rangle_{H^1_{\phi}} - \langle PV_n, PV_n \rangle_{H^1_{\phi}} \right| \leqslant h_n \langle V_n, V_n \rangle_{H^1_{\phi}} \tag{4.10}$$

hold for any $V_n \in H^1(E) \cap (\ker \mathfrak{D}^{\phi_n})^{\perp}$. These two inequalities, combined with the inequalities of Lemma 4 and the fact that $\mathrm{Hess}_{\phi}(PV_n, PV_n) = \mathrm{Hess}_{\phi}(V_n, V_n)$, prove that

$$\begin{aligned}
&\left| \frac{\mathrm{Hess}_{\phi}(PV_n, PV_n)}{\langle PV_n, PV_n \rangle_{H^1_{\phi}}} - \frac{\mathrm{Hess}_{\phi_n}(V_n, V_n)}{\langle V_n, V_n \rangle_{H^1_{\phi_n}}} \right| \\
&\quad = \left| \frac{\mathrm{Hess}_{\phi}(V_n, V_n)}{\langle PV_n, PV_n \rangle_{H^1_{\phi}}} - \frac{\mathrm{Hess}_{\phi_n}(V_n, V_n)}{\langle V_n, V_n \rangle_{H^1_{\phi_n}}} \right| \\
&\quad \leqslant \frac{\mathrm{Hess}_{\phi_n}(V_n, V_n) \left| \langle V_n, V_n \rangle_{H^1_{\phi_n}} - \langle PV_n, PV_n \rangle_{H^1_{\phi}} \right| + \langle V_n, V_n \rangle_{H^1_{\phi_n}} \left| \mathrm{Hess}_{\phi}(V_n, V_n) - \mathrm{Hess}_{\phi_n}(V_n, V_n) \right|}{\langle V_n, V_n \rangle_{H^1_{\phi_n}} \langle PV_n, PV_n \rangle_{H^1_{\phi}}} \\
&\quad \leqslant \frac{g_n \mathrm{Hess}_{\phi_n}(V_n, V_n) \ \langle PV_n, PV_n \rangle_{H^1_{\phi}} + c_n \langle V_n, V_n \rangle_{H^1_{\phi_n}} \langle V_n, V_n \rangle_{H^1_{\phi}}}{\langle V_n, V_n \rangle_{H^1_{\phi_n}} \langle PV_n, PV_n \rangle_{H^1_{\phi}}} \\
&\quad \leqslant g_n \frac{\mathrm{Hess}_{\phi_n}(V_n, V_n)}{\langle V_n, V_n \rangle_{H^1_{\phi_n}}} + c_n \frac{\langle V_n, V_n \rangle_{H^1_{\phi}}}{\langle PV_n, PV_n \rangle_{H^1_{\phi}}} \leqslant g_n \frac{\mathrm{Hess}_{\phi_n}(V_n, V_n)}{\langle V_n, V_n \rangle_{H^1_{\phi_n}}} + \frac{c_n}{1 - h_n}
\end{aligned} \tag{4.11}$$

holds for any $V_n \in H^1(E) \cap (\ker \mathfrak{D}^{\phi_n})^{\perp}$.

Let $\{V_n^j\}_{j=1}^{\infty} \in H^1(E) \cap (\ker \mathfrak{D}^{\phi_n})^{\perp}$ be a minimizing sequence for $\tau(\phi_n)$ with unit $H^1_{\phi_n}$ norm, that is

$$\lim_{j\to\infty}\frac{\mathsf{Hess}_{\phi_n}(V_n^j,V_n^j)}{\langle V_n^j,V_n^j\rangle_{H^1_{\phi_n}}}=\lim_{j\to\infty}\ \mathsf{Hess}_{\phi_n}(V_n^j,V_n^j)=\tau(\phi_n).$$

Hence there exists a positive constant C and numbers ϵ_n^j tending to zero as $j\to\infty$, such that

$$\mathsf{Hess}_{\phi}(V_n^j,V_n^j)=\tau(\phi_n)+\epsilon_n^j$$

and

$$\mathsf{Hess}_{\phi}(V_n^j,V_n^j)\leqslant C$$

for all j and n. Consider the sequence $\tilde{V}_n^j=PV_n^j\in H^1(E)\cap(\ker\mathfrak{D}^{\phi})^{\perp}$. The two previous facts together with (4.11) imply that

$$\left|\frac{\mathsf{Hess}_{\phi}(\tilde{V}_n^j,\tilde{V}_n^j)}{\langle\tilde{V}_n^j,\tilde{V}_n^j\rangle_{H^1_{\phi}}}-(\tau(\phi)+\epsilon_n^j)\right|\leqslant Cg_n+\frac{c_n}{1-h_n}$$

holds for all j and n. For any fixed n, taking the limit as $j\to\infty$ we see that

$$\tau(\phi)\leqslant\tau(\phi_n)+Cg_n+\frac{c_n}{1-h_n}.$$

Hence for any limit point l of the sequence $\{\tau(\phi_n)\}_{n=1}^{\infty}$ we have $\tau(\phi)\leqslant l$. In particular,

$$\tau(\phi)\leqslant\liminf_{n\to\infty}\tau(\phi_n)$$

as claimed. □

V. THE CASE OF Rat_1

It is interesting to consider the simplest nontrivial case, namely $\mathsf{M}_1=\mathsf{Hol}_1(S^2,S^2)=\mathsf{Rat}_1$, in detail. Although $M=N=S^2$ in this case, it is often helpful to distinguish between domain and codomain by continuing to denote them M,N, respectively. We shall do this when clarity requires. The G action on M_n introduced in Sec. II extends naturally to $C^{\infty}(S^2,S^2)$, and leaves $E[\phi]$ invariant. It follows that $\tau(\phi)$ is constant on G orbits in M_n. Since G acts with cohomogeneity 1 on M_1, it suffices to consider $\tau(\phi)$ for the one-parameter family of maps

$$\phi_{\mu}:z\mapsto\mu z,\quad \mu\in[1,\infty),\tag{5.1}$$

lying on the curve $\Gamma=\{([\mathbb{I}_2],(0,0,\lambda)):\lambda\geqslant 0\}$ in M_1 (so $\mu=(\sqrt{1+\lambda^2}+\lambda)^2$ as in Sec. II). We may think of τ as a positive function $\tau(\mu)$ on $[1,\infty)$. We will first use the results of Sec. IV to prove that $\tau(\mu)$ is continuous. Positivity and continuity of τ ensure that it is bounded away from zero on any compact set. The domain of τ (whether thought of as a function on M_1 or on $[1,\infty)$) is noncompact, however, so we cannot conclude that τ is globally bounded away from zero. The essential question is, then, how does $\tau(\mu)$ behave as $\mu\to\infty$, that is, as the lump collapses to zero width? We will prove that $\tau(\mu)\to 0$.

First we address the issue of continuity. By symmetry, it suffices to consider a sequence of degree 1 holomorphic maps ϕ_n in the curve Γ, labeled by a sequence μ_n in $[1,\infty)$. If $\mu_n\to\hat{\mu}$, then the corresponding maps $\phi_n:z\mapsto\mu_n z$ converge in C^1 to $\hat{\phi}:z\mapsto\hat{\mu}z$. Since every holomorphic map $S^2\to S^2$ is Jacobi integrable, we may apply the results of Sec. IV. We merely need to prove that the pointwise inequality (4.1) on the pullback connexions ∇_n (∇^{ϕ_n} transfered to $\hat{\phi}^*TN$) holds for any such sequence μ_n. Then Lemma 4 applies, and continuity of τ follows from Theorem 6.

We must first construct the canonical isometry between each bundle $\phi_n^* TN$ and the fixed bundle $\hat{\phi}^* TN$ equipped with their L^2 inner products. To this end, it is convenient to define an orthonormal frame $E_1 = \partial/\partial\theta$, $E_2 = \operatorname{cosec}\theta\, \partial/\partial\varphi$ on S^2, where (θ,φ) are the usual polar coordinates, and the corresponding sections $\tilde{E}_i^n = E_i \circ \phi_n \in \Gamma(\phi_n^* TN)$, $\hat{E}_i = E_i \circ \phi \in \Gamma(\phi^* TN)$, $i = 1,2$. Note that varying ϕ within the family Γ sends each fixed $p \in M$ along a geodesic of constant φ in N. Note also that the frame E_1, E_2 is parallel along geodesics of constant φ, so the canonical isometry between $\phi_n^* TN$ and $\hat{\phi}^* TN$ is simply given by the identification

$$\tilde{E}_1^n \equiv \hat{E}_1, \quad \tilde{E}_2^n \equiv \hat{E}_2. \tag{5.2}$$

It is this property which makes polar coordinates particularly natural for our purposes.

In this coordinate system, a holomorphic map $\phi: z \mapsto \mu z$ is

$$(\theta,\varphi) \mapsto (f_\mu(\theta),\varphi), \quad f_\mu(\theta) = 2\cot^{-1}\left(\mu \cot\frac{\theta}{2}\right). \tag{5.3}$$

We will construct the pullback connexion ∇^ϕ by computing its action on $\tilde{E}_i = E_i \circ \phi$, $i = 1,2$. The Levi-Civita connection on S^2 is

$$\nabla E_1 = \cot\theta\, e_2 \otimes E_2, \quad \nabla E_2 = -\cot\theta\, e_2 \otimes E_1, \tag{5.4}$$

or equivalently,

$$\nabla e_1 = \cot\theta\, e_2 \otimes e_2, \quad \nabla e_2 = -\cot\theta\, e_2 \otimes e_1, \tag{5.5}$$

where e_1, e_2 is the coframe dual to E_1, E_2. The following properties of ∇^ϕ are essential for computations:

(a) If $u \in T_p M$, $Y \in \Gamma(\phi^* TN)$ and $f \in C^\infty(M)$, then $\nabla_u^\phi fY = u[f]Y + f\nabla_u^\phi Y$.

(b) If $Y \in \Gamma(\phi^* TN)$ may locally be identified with a vector field $\tilde{Y}$ on N (i.e., $Y = \tilde{Y} \circ \phi$, on a neighborhood of p), then $\nabla_u^\phi Y = \nabla_{d\phi u}^N \tilde{Y}$.

Now $d\phi E_1 = f'_\mu \tilde{E}_1$ and $d\phi E_2 = \operatorname{cosec}\theta \sin f_\mu \tilde{E}_2$, where $'$ denotes differentiation with respect to θ. Hence

$$\nabla_{\tilde{E}_1}^\phi \tilde{E}_1 = \nabla_{\tilde{E}_1}^\phi \tilde{E}_2 = 0,$$

$$\nabla_{\tilde{E}_2}^\phi \tilde{E}_1 = \frac{\sin f_\mu}{\sin\theta} \nabla_{\tilde{E}_2} \tilde{E}_1 = \frac{\sin f_\mu}{\sin\theta} \cot f_\mu \tilde{E}_2 = \frac{\cos f_\mu}{\sin\theta} \tilde{E}_2, \tag{5.6}$$

$$\nabla_{\tilde{E}_2}^\phi \tilde{E}_2 = \frac{\sin f_\mu}{\sin\theta} \nabla_{\tilde{E}_2} \tilde{E}_2 = -\frac{\sin f_\mu}{\sin\theta} \cot f_\mu \tilde{E}_2 = -\frac{\cos f_\mu}{\sin\theta} \tilde{E}_2.$$

Note that when $\mu = 1$, $\phi = \mathrm{Id}$, and $\nabla^{\mathrm{Id}} = \nabla$, so (5.6) should reduce to (5.4), which it does.

Any section of $\phi^* TN$ may be written

$$W = V + J^N U, \quad V = \mathcal{V}(\theta,\varphi)\tilde{E}_1, \quad U = \mathcal{U}(\theta,\varphi)\tilde{E}_1. \tag{5.7}$$

Note that ∇^ϕ commutes with J^N by the Kähler property. By the defining property (a), above, and (5.6), one sees that

$$\nabla^\phi V = \mathcal{V}_\theta\, e_1 \otimes \tilde{E}_1 + \frac{1}{\sin\theta} \mathcal{V}_\varphi\, e_2 \otimes \tilde{E}_2 + \mathcal{V} \frac{\cos f_\mu}{\sin\theta} e_2 \otimes \tilde{E}_2, \tag{5.8}$$

where subscripts θ,φ denote partial derivatives. This gives us explicit formulas for $\nabla^{\hat{\phi}}$ and ∇^{ϕ_n}. Using the identification (5.2) we may transfer a section W of $\hat{\phi}^*TN$ to ϕ_n^*TN, act with ∇^{ϕ_n}, then transfer back using the same identification, calling the result $\nabla_n W$. The difference between $\nabla_n W$ and $\nabla^{\hat{\phi}}W=\hat{\nabla}W$ is, by (5.8),

$$(\hat{\nabla}-\nabla_n)W=\frac{\cos f_{\hat{\mu}}-\cos f_{\mu_n}}{\sin\theta}(\mathcal{V}e_2\otimes\hat{E}_2-\mathcal{U}e_2\otimes\hat{E}_1)=\frac{\cos f_{\hat{\mu}}-\cos f_{\mu_n}}{\sin\theta}J^N W. \tag{5.9}$$

An elementary calculation shows that

$$\frac{\cos f_{\hat{\mu}}-\cos f_{\mu_n}}{\sin\theta}=\frac{(\hat{\mu}^2-\mu_n^2)\sin 2\theta}{2(\hat{\mu}^2\cos^2(\theta/2)+\sin^2(\theta/2))(\mu_n^2\cos^2(\theta/2)+\sin^2(\theta/2))}$$

$$\Rightarrow\left|\frac{\cos f_{\hat{\mu}}-\cos f_{\mu_n}}{\sin\theta}\right|\leqslant\frac{1}{2}\left(1+\frac{1}{\hat{\mu}^2}+\frac{1}{\mu_n^2}+\frac{1}{\hat{\mu}^2\mu_n^2}\right)|\hat{\mu}^2-\mu_n^2|. \tag{5.10}$$

Hence, we have a pointwise bound of the form (4.1),

$$|(\hat{\nabla}-\nabla_n)W|\leqslant a_n|W|, \tag{5.11}$$

where

$$a_n=\frac{1}{2}\left(1+\frac{1}{\hat{\mu}^2}+\frac{1}{\mu_n^2}+\frac{1}{\hat{\mu}^2\mu_n^2}\right)|\hat{\mu}^2-\mu_n^2|\to 0 \tag{5.12}$$

as $n\to\infty$, as required.

Having shown that $\tau(\mu)$ is continuous, we now address its behavior as $\mu\to\infty$. In particular, we will prove that $\lim_{\mu\to\infty}\tau(\mu)=0$. To do this, it suffices to consider only sections of ϕ^*TN of a certain type, which we will call "irrotational," namely those of the form

$$V=\mathcal{V}(\theta)\tilde{E}_1. \tag{5.13}$$

It is straightforward to compute $\mathfrak{D}^\phi V$ for such sections, and hence obtain $\mathsf{Hess}_\phi(V,V)$ as an explicit integral functional of $\mathcal{V}$. It follows from (5.8) that

$$\mathfrak{D}^\phi V=-\left(\mathcal{V}'-\frac{\cos f_\mu}{\sin\theta}\mathcal{V}\right)(e_1\otimes\tilde{E}_2+e_2\otimes\tilde{E}_1). \tag{5.14}$$

The Hessian for irrotational sections is

$$\mathsf{Hess}_\phi(V,V)=\frac{1}{2}\|\mathfrak{D}^\phi V\|_{L^2}^2=2\pi\int_0^\pi d\theta\sin\theta\left(\mathcal{V}'-\frac{\cos f_\mu}{\sin\theta}\mathcal{V}\right)^2. \tag{5.15}$$

We seek to compare this quantity, for irrotational sections L^2 orthogonal to $\ker\mathfrak{D}^\phi$, with $\|V\|_{H^1}^2$. Note that $\ker\mathfrak{D}^\phi$ is six-dimensional, and is spanned by

$$K_\mu^m=-\frac{2\cot^m(\theta/2)}{1+\mu^2\cot^2(\theta/2)}[\cos(1-m)\varphi\,\tilde{E}_1+\sin(1-m)\varphi\,\tilde{E}_2],\quad m=-1,0,1, \tag{5.16}$$

and their images under J^N. This basis is obtained by considering curves in M_1 through ϕ generated by altering the real part of one of the coefficients of the rational map. Every irrotational section V is automatically L^2 orthogonal to $K_\mu^{-1}, K_\mu^0, J^N K_\mu^{-1}, J^N K_\mu^0$ and $J^N K_\mu^1$, so we need only insist that V is L^2 orthogonal to the one and only irrotational section in the basis, K_μ^1, which we will henceforth denote K_μ. Explicitly, we require that

$$\langle V, K_\mu \rangle_{L^2} = -2\pi \int_0^\pi d\theta \sin\theta \frac{\mathcal{V}(\theta)\sin\theta}{\sin^2(\theta/2) + \mu^2 \cos^2(\theta/2)} = 0, \tag{5.17}$$

having rearranged K_μ slightly.

We shall also need an explict formula for $\|V\|_{H_1}$. Equation (5.8) implies that

$$\nabla^\phi V = \mathcal{V}' e_1 \otimes \tilde{E}_1 + \mathcal{V} \frac{\cos f_\mu}{\sin\theta} e_2 \otimes \tilde{E}_2, \tag{5.18}$$

so

$$\begin{aligned} \|V\|_{H^1}^2 = \|\nabla^\phi V\|_{L^2}^2 + \|V\|_{L^2}^2 &= 2\pi \int_0^\pi d\theta \sin\theta \left((\mathcal{V}')^2 + \frac{\cos^2 f_\mu}{\sin^2\theta} \mathcal{V}^2 + \mathcal{V}^2 \right) \\ &= \mathsf{Hess}_\phi(V,V) + \|V\|_{L^2}^2 + 2\pi \int_0^\pi d\theta \, 2\mathcal{V}\mathcal{V}' \cos f_\mu \\ &= \mathsf{Hess}_\phi(V,V) + \|V\|_{L^2}^2 + \langle V, \mathcal{E}_\mu V \rangle_{L^2}, \end{aligned} \tag{5.19}$$

where $\mathcal{E}_\mu \in C^\infty(S^2)$ is the energy density of the map ϕ. To see the last equality, note that ϕ is holomorphic, hence conformal, so

$$f_\mu' = |d\phi E_1| = |d\phi E_2| = \frac{\sin f_\mu}{\sin\theta}. \tag{5.20}$$

Equation (5.19) follows from (5.20) and integration by parts.

It also proves useful to write down the formulas above using cylindrical coordinates instead of spherical polar coordinates on the domain. That is in place of (θ,φ) we use (s,φ) where $s := \log\cot\theta/2$. First notice that with respect to these cylindrical coordinates $f_\mu(s)$ arises by translating one fixed profile by a μ dependent amount. More precisely,

$$f_\mu(s) = f_1(s + \log\mu), \tag{5.21}$$

where

$$f_1(s) = 2\cot^{-1}(\exp s). \tag{5.22}$$

We have an analogous formula for K_μ the irrotational part of the kernel of $\mathfrak{D}^\phi$:

$$K_\mu(s) = \operatorname{sech}(s + \log\mu)\tilde{E}_1. \tag{5.23}$$

It is a routine computation to obtain the following formulas for $\mathsf{Hess}_{\phi_\mu}(V,V)$, $\langle V, \mathcal{E}_\mu V \rangle_{L^2}$ and the L^2, H^1 norms of an irrotational section V from the corresponding formulas using spherical polars already presented

$$\langle V, V \rangle_{L^2} = \int_{-\infty}^\infty ds \operatorname{sech}^2 s \;\; \mathcal{V}^2, \tag{5.24}$$

$$\langle V,\mathcal{E}_\mu V\rangle_{L^2}=\int_{-\infty}^{\infty} ds\,\operatorname{sech}^2(s+\log\mu)\mathcal{V}^2, \tag{5.25}$$

$$\langle V,V\rangle_{H^1}=\int_{-\infty}^{\infty} ds\left(\left(\frac{d\mathcal{V}}{ds}\right)^2+\tanh^2(s+\log\mu)\ \ \mathcal{V}^2+\operatorname{sech}^2 s\ \ \mathcal{V}^2\right), \tag{5.26}$$

$$\mathsf{Hess}_{\phi_\mu}(V,V)=\int_{-\infty}^{\infty} ds\ \ \left(\frac{d\mathcal{V}}{ds}+\tanh(s+\log\mu)\mathcal{V}\right)^2. \tag{5.27}$$

We may now state and prove the main result of this section. We shall denote the map $z\mapsto\mu z$ by ϕ_μ to emphasize its parametric dependence.

Theorem 7 (Global coercivity of the Hessian fails on Rat_1): $\lim_{\mu\to\infty}\tau(\phi_\mu)=0$.

Proof: Define the following sequence of smooth irrotational sections $V_\mu=\mathcal{V}_\mu\tilde{E}_1$ of $\phi_\mu^*TS^2$ where

$$\mathcal{V}_\mu(s)=\operatorname{sech} s-c_\mu K_\mu(s) \tag{5.28}$$

and c_μ is a constant determined by the requirement that $\langle V_\mu,K_\mu\rangle_{L^2}=0$. By our previous remarks, this suffices to ensure that $\mathcal{V}_\mu$ is orthogonal to $\ker\mathfrak{D}^{\phi_\mu}$. Since $V_\mu\in H^1(\phi_\mu^*TS^2)\cap\ker\mathfrak{D}^{\phi_\mu}$ it suffices to prove that

$$\lim_{\mu\to\infty}\frac{\mathsf{Hess}_{\phi_\mu}(V_\mu,V_\mu)}{\langle V_\mu,V_\mu\rangle_{H^1}^2}=0. \tag{5.29}$$

In fact, we will show that

$$\lim_{\mu\to\infty}\frac{\mathsf{Hess}_{\phi_\mu}(V_\mu,V_\mu)}{\langle V_\mu,\mathcal{E}_\mu V_\mu\rangle_{L^2}}=0, \tag{5.30}$$

which implies (5.29) since

$$\|V\|_{H^1}^2=\mathsf{Hess}_{\phi_\mu}(V,V)+\|V\|_{L^2}^2+\langle V,\mathcal{E}_\mu V\rangle_{L^2}>\langle V,\mathcal{E}_\mu V\rangle_{L^2}.$$

To prove (5.30), first notice that since $K_\mu\in\ker\mathfrak{D}^{\phi_\mu}$ we have

$$\mathsf{Hess}_{\phi_\mu}(V_\mu,V_\mu)=\mathsf{Hess}_{\phi_\mu}(\operatorname{sech} s,\operatorname{sech} s).$$

Using the explicit expression for the Hessian in cylindrical coordinates we find

$$\mathsf{Hess}_{\phi_\mu}(\operatorname{sech} s,\operatorname{sech} s)=\int_{-\infty}^{\infty} ds\,\operatorname{sech}^2 s(\tanh s_\mu-\tanh s)^2,$$

where $s_\mu:=s+\log\mu$. Since $|(\tanh s_\mu-\tanh s)^2|<4$ holds for all s,

$$\mathsf{Hess}_{\phi_\mu}(\operatorname{sech} s,\operatorname{sech} s)<4\int_{-\infty}^{\infty} ds\,\operatorname{sech}^2 s=8$$

holds for all μ. Since $\mathsf{Hess}_{\phi_\mu}(V_\mu,V_\mu)$ is bounded for all μ, (5.30) is implied by

$$\lim_{\mu\to\infty}\langle V_\mu,\mathcal{E}_\mu V_\mu\rangle_{L^2}=+\infty. \tag{5.31}$$

To establish (5.31), first introduce for each non-negative pair of integers (m,n) the positive function

$$I_{m,n}(\mu)=\int_{-\infty}^{\infty} ds\,\mathrm{sech}^m s\,\mathrm{sech}^n s_\mu .$$

Clearly, the function $I_{m,n}(\mu)$ is bounded above by the constant $I_{m,0}$. From the definition of c_μ we have

$$c_\mu=\frac{\langle \mathrm{sech}\,,K_\mu\rangle}{\langle K_\mu,K_\mu\rangle}=\frac{I_{3,1}}{I_{2,2}}\ ,$$

and from Eq. (5.25) and the definition of V_μ we have

$$\langle V_\mu,\mathcal{E}_\mu V_\mu\rangle_{L^2}=c_\mu(c_\mu I_{4,0}-2I_{1,3})+I_{2,2}.$$

Since $I_{4,0}$ is a positive constant and $I_{1,3}$, $I_{2,2}$ are positive and bounded above, (5.31) will follow if we can establish that $\lim_{\mu\to\infty}c_\mu=+\infty$. In fact, one can explicitly evaluate the integrals which appear in the definition of c_μ to obtain

$$c_\mu=\frac{I_{3,1}}{I_{2,2}}=\frac{\mu^4-4\mu^2\log\mu-1}{4\mu(\mu^2\log\mu-\mu^2+\log\mu+1)}.$$

Clearly, this implies that $\lim_{\mu\to\infty}c_\mu=+\infty$ as required. □

VI. THE CASE OF Rat_n^{eq}

Staying in the context of the $\mathbb{C}P^1$ model on S^2, but generalizing to any degree sector, $n\geqslant 1$, things become rather more difficult. The reason is that the isometric action of G on $\mathsf{M}_n=\mathsf{Rat}_n$ does not have cohomogeneity 1, except for $n=1$. In general, then, to understand the global behavior of τ one must consider the $4(n-1)$-dimensional orbifold M_n/G, not simply a curve, as in Sec. V. Reduction to a curve *is* possible, however, provided we restrict attention to dynamics within a certain equivariance class. Employing stereographic coordinates z,W on domain and codomain as usual, and defining polar coordinates such that $z=re^{i\varphi}$, one may write the field equation for the $\mathbb{C}P^1$ model on space–time $S^2\times\mathbb{R}$ as

$$\frac{W_{tt}}{(1+r^2)^2}-\left(W_{rr}+\frac{1}{r}W_r+\frac{1}{r^2}W_{\varphi\varphi}\right)-\frac{2\overline{W}}{1+|W|^2}\left(\frac{W_t^2}{(1+r^2)^2}-W_r^2-\frac{1}{r^2}W_\varphi^2\right)=0. \tag{6.1}$$

This supports equivariant solutions within the ansatz

$$W(r,\varphi,t)=r^n q(r,t)e^{in\varphi}. \tag{6.2}$$

Provided $q:[0,\infty)\times(-\epsilon,\epsilon)\to\mathbb{C}$ is nowhere vanishing and has suitable boundary behavior, solutions within this ansatz have degree n. Substituting (6.2) into (6.1) one obtains a $(1+1)$-dimensional hyperbolic partial differential equation for q. The space of static solutions is simply $q(r,t)=c\neq 0$, a complex constant. So the equivariant moduli space is $\mathsf{M}_n^{eq}=\mathsf{Rat}_n^{eq}=\{z\mapsto cz^n: c\neq 0\}\cong\mathbb{C}^\times$, the punctured complex plane. Note that M_n^{eq} is one connected component of the fixed point set in M_n of the isometry group $G^{eq}=\{([\exp -in(\psi/2)\,\tau_3],[\exp i(\psi/2)\,\tau_3]):\psi\in\mathbb{R}\}\cong\mathrm{SO}(2)$, so we are assured that $\mathsf{M}_n^{eq}\subset\mathsf{M}_n$ is totally geodesic. Both the true wave map flow and its geodesic approximant stay within the equivariance class, therefore, and one can again ask to what extent the analytic method of Stuart applies. The equivariant configuration space enjoys a residual U(1) symmetry, namely $W(z)\mapsto e^{i\psi}W(z)$, and the discrete symmetry $W(z)\mapsto 1/W(1/z)$, both of which leave the harmonic map energy unchanged, so we may again restrict attention to a curve in M_n^{eq}, namely $\Gamma=\{z\mapsto\mu z^n:\mu\in[1,\infty)\}$. The situation is actually *simpler* than in the full

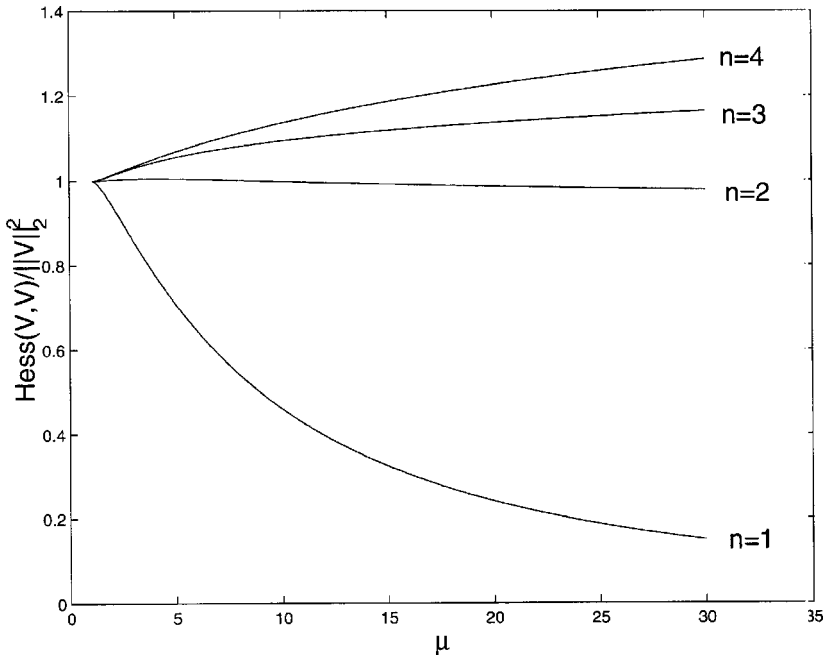

FIG. 1. Plots of the ratio $\mathrm{Hess}_{\phi_\mu}(V_\mu,V_\mu)/\|V_\mu\|^2_{H^1}$ against μ for the first excited state V_μ of the Sturm–Liouville problem (6.8) with $\phi_\mu: z\to\mu z^n$, $n=1,2,3,4$. To facilitate comparison of the curves, in each case the ratio has been normalized by its value at $\mu=1$ (0.30, 0.74, 1.17 and 1.55 respectively, to two decimal places). Note that only for $n=1$ does the ratio tend to 0 as $\mu\to\infty$.

degree 1 case, because now the error, that is, the section of ϕ^*TN along which we exponentiate to get from the holomorphic approximant to the true solution at time t, must also lie within the equivariance class. The only sections of relevance, therefore, are irrotational sections and their J^N images. We may define a new optimal constant $\tau^{eq}(\phi)$, again the infimium of the Hessian for H^1 unit sections L^2 orthogonal to $\ker\mathfrak{D}^\phi$, but now we include only equivariant sections. Since these form a subset of all sections, we have trivially that $\tau^{eq}(\phi)\geqslant\tau(\phi)>0$ by Theorem 3.

Once again, we may think of τ^{eq} as a function of $\mu\in[1,\infty)$. We first show that $\tau^{eq}(\mu)$ is continuous. Since the setup is very similar to Sec. V we use equivalent notation and conventions, and omit several details. In spherical polar coordinates, the map $\phi: z\mapsto\mu z^n$ is

$$(\theta,\varphi)\mapsto(f_\mu(\theta),n\varphi),\quad f_\mu(\theta)=2\cot^{-1}\left(\mu\cot^n\frac{\theta}{2}\right),\tag{6.3}$$

so $d\phi E_1=f'_\mu\tilde{E}_1$ and $d\phi E_2=n\,\mathrm{cosec}\,\theta\cos f_\mu\tilde{E}_2$. It follows that

$$\nabla^\phi\tilde{E}_1=n\frac{\cos f_\mu}{\sin\theta}e_2\otimes\tilde{E}_2,\quad \nabla^\phi\tilde{E}_2=-n\frac{\cos f_\mu}{\sin\theta}e_2\otimes\tilde{E}_1.\tag{6.4}$$

Hence, on an irrotational section $V=\mathcal{V}(\theta)\tilde{E}_1$,

$$\nabla^\phi V=V'e_1\otimes\tilde{E}_1+Vn\frac{\cos f_\mu}{\sin\theta}e_2\otimes\tilde{E}_2.\tag{6.5}$$

Given a general equivariant section $W=V+J^NU$, where V,U are irrotational, we may transfer W to a neighboring bundle $\hat{\phi}^*TN$ (where $\hat{\phi}: z\mapsto\hat{\mu}z$) using the canonical isometry (5.2), act with $\nabla^{\hat{\phi}}$, then transfer back again, to obtain $\hat{\nabla}W$. The difference between this and $\nabla^\phi W$ is

$$(\nabla^{\phi}-\hat{\nabla})W=n\frac{\cos f_{\mu}-\cos f_{\hat{\mu}}}{\sin\theta}J^{N}W. \tag{6.6}$$

Now

$$\begin{aligned}\alpha(\theta)&=\frac{\cos f_{\mu}-\cos f_{\hat{\mu}}}{\sin\theta}\\&=\frac{(\mu^2-\hat{\mu}^2)(\cos(\theta/2)\sin(\theta/2))^{2n-1}}{(\sin^{2n}(\theta/2)+\mu^2\cos^{2n}(\theta/2))(\sin^{2n}(\theta/2)+\hat{\mu}^2\cos^{2n}(\theta/2))}\\&\Rightarrow|\alpha(\theta)|\leqslant\left(1+\frac{1}{\hat{\mu}^2}+\frac{1}{\mu^2}+\frac{1}{\hat{\mu}^2\mu^2}\right)|\hat{\mu}^2-\mu^2|.\end{aligned} \tag{6.7}$$

So the pullback connexion satisfies a pointwise bound of the correct type ($|(\nabla^{\phi}-\hat{\nabla})W|<c(\mu,\hat{\mu})|W|$ where $c\to 0$ as $\mu\to\hat{\mu}$) and we may conclude from the results of Sec. IV that $\tau^{eq}(\mu)$ is continuous.

As for Rat_1, the interesting issue is the large μ behavior of $\tau^{eq}(\mu)$. We are so far unable to prove anything rigorous about $\lim_{\mu\to\infty}\tau^{eq}(\mu)$ (if, indeed, it exists). However, we make the following conjecture:

Conjecture 8: For all $n\geqslant 1$, $\lim_{\mu\to\infty}\tau^{eq}(\mu)$ *exists and is finite. For all* $n>1$, *this limit is not zero.*

If true, the equivariant Hessian is globally coercive for degree n greater than unity. One could at least hope, therefore, to model equivariant lump collapse accurately within the geodesic approximation in the case $n>1$.

To motivate this conjecture, we should describe some numerical work which led directly to the proof of its $n=1$ counterpart, Theorem 7. It is straightforward to write the Jacobi operator on irrotational sections as an explicit ordinary differential operator acting on $\mathcal{V}(\theta)$. The eigenvalue problem for $\mathfrak{J}^{\phi}$ then reduces to a singular Sturm–Liouville problem on $(0,\pi)$, namely

$$-\mathcal{V}''-\cot\theta\mathcal{V}'+n^2\frac{\cos 2f_{\mu}}{\sin^2\theta}\mathcal{V}=\omega^2\mathcal{V}. \tag{6.8}$$

Here $\omega^2\geqslant 0$ is the eigenvalue. The eigenfunctions of this problem form an L^2 orthogonal basis for the space of irrotational sections. In particular, the eigenfunctions outside the kernel, which we shall refer to as "excited states," in analogy with quantum mechanics, form a basis for the irrotational sections orthogonal to $\ker\mathfrak{J}^{\phi}$. If we could prove that $\mathsf{Hess}_{\phi}(V,V)/\|V\|^2_{H^1}=\omega^2\|V\|^2_{L^2}/\|V\|^2_{H^1}$ is bounded uniformly away from zero for all μ and all excited states V, global coercivity of Hess^{eq} would follow. Conversely, if for one of the excited states, $\omega^2\|V\|^2_{L^2}/\|V\|^2_{H^1}\to 0$ as $\mu\to\infty$, global coercivity must fail: the one parameter family of excited states itself provides a counterexample. Unfortunately, the (μ families) of eigensections are rather inaccessible analytically (except in the special case $\mu=n=1$, where they are known exactly). However, they are quite easy to construct numerically, either by employing a specialist Sturm–Liouville solver package, or by using a shooting method. We have tried both strategies, obtaining compatible results from each.

The pertinent results may be summarized as follows. For $n=1,2,3,4$ and for all excited states from second to sixth (ordered by increasing ω^2), the ratio $\mathsf{Hess}_{\phi}(V,V)/\|V\|^2_{H_1}$ appears to remain bounded away from zero as $\mu\to\infty$. More interesting is the first excited state. Here the ratio remains bounded away from zero for $n=2,3,4$, but not for $n=1$. It was by examining the graphs of the $n=1$ first excited eigenstates that the explicit family V_{μ} of the proof of Theorem 7 was devised: the family is designed to have the same qualitative behavior as the numerically generated

eigenstates. In Fig. 1 we present a graph showing the ratio $\mathrm{Hess}_\phi(V,V)/\|V\|^2_{H_1}$ as a function of μ for the first excited states for $n=1,2,3,4$. These data were generated by a shooting method using a fourth order Runge–Kutta scheme with variable θ step. The singularities at $\theta=0,\pi$ were handled by series expansions, so the scheme shot forwards from $\theta=\delta$ and backwards from $\theta=\pi-\delta$, applying a matching condition at $\theta=(\pi/2)$ (δ being a small positive number, typically 0.001). The difference between $n=1$ and the other cases is quite clear. Although it is impossible to be exhaustive numerically, the results suggest that $\mathrm{Hess}_\phi(V,V)/\|V\|^2_{H_1}$ is bounded away from zero for $n>1$, as we have conjectured. Linhart and Sadun in a recent numerical study of lump collapse in the $\mathbb{C}P^1$ model on $\mathbb{C}$ imposed the analogous equivariance condition on their field equation.[10] It is an intriguing coincidence that they found that single lump collapse differs greatly from the predictions of the geodesic approximation (truncated to a finite disk in $\mathbb{C}$), whereas the collapse of two coincident lumps is quite well modeled by the geodesic flow.

(Received 1 August 2002; accepted 9 April 2003)

The explicit solutions of the Bogomolny equations for N vortices on a sphere of radius $R^2>N$ are not known. In particular, this has prevented the use of the geodesic approximation to describe the low energy vortex dynamics. In this article we introduce an approximate general solution of the equations, valid for $R^2 \gtrsim N$, which has many properties of the true solutions, including the same moduli space $\mathbb{CP}^N$. Within the framework of the geodesic approximation, the metric on the moduli space is then computed to be proportional to the Fubini–Study metric, which leads to a complete description of the particle dynamics. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1584526]

I. INTRODUCTION

The Abelian Higgs model in the plane is one of the most studied examples of a field theory with topological solitons. The solitons are vortices. At critical coupling there are Bogomolny equations, and it is known that there is a $2N$-dimensional manifold of gauge-inequivalent N-vortex solutions.[6] This is known as the N-vortex moduli space, and denoted $\mathcal{M}_N$. As a manifold, $\mathcal{M}_N \cong \mathbb{C}^N$. There is a natural metric on $\mathcal{M}_N$, arising from the kinetic terms in the Lagrangian of the model, and it has been proved by Stuart[13] that, at least for finite time intervals, geodesic trajectories on the moduli space give a good approximation to the true dynamics of slowly moving vortices.

It is convenient to introduce the standard complex coordinate z on the plane. The locations of the vortices are the N unordered points where the Higgs field vanishes. These points may be regarded as the roots of a monic polynomial in z (monic means that the coefficient of z^N is 1), and the natural coordinates on moduli space are the N complex coefficients of such a polynomial. If a particular geodesic motion is known, then the time dependence of the polynomial is known, and hence the time dependence of the roots can be calculated.

Now, a general formula for the metric on moduli space has been given by Samols,[12] but it is not explicit, so only very special geodesics, with a high degree of symmetry, are understood in detail for $N>2$.[1,9] One vortex just moves at constant speed along a straight line. The geodesic motion for two vortices has been calculated by Samols numerically. The most interesting phenomenon is that, in a head-on collision, two vortices scatter at right angles. Recently, Manton and Speight[11] have found an explicit metric for N well separated vortices, from which the geodesic motion could be computed.

In this article we are interested in the opposite limit. It is possible to consider the Abelian Higgs model with fields defined on any compact surface. We shall only consider the case of a two-sphere with its standard round metric, parametrized by its radius R. There are again Bogomolny equations and a $2N$-dimensional moduli space of N-vortex solutions. As a manifold this is $\mathbb{CP}^N$. However, there is an important geometrical constraint, discovered by Bradlow.[2] This is that the area of the sphere must be greater than $4\pi N$ for nontrivial solutions of the Bogomolny equations to exist. Equivalently, $R^2>N$. The metric on moduli space is known to collapse to zero size as the Bradlow limit $R^2 \searrow N$ is approached. We shall be interested here in the case where R^2

[a]Electronic mail: j.m.baptista@damtp.cam.ac.uk
[b]Electronic mail: n.s.manton@damtp.cam.ac.uk

is slightly greater than N. One should think of this as a situation where the vortices are densely squeezed together. We shall present an approximate general solution of the Bogomolny equations, and, using this, calculate the metric on moduli space directly from its definition. Again the solutions involve a polynomial, and the natural coordinates are the complex coefficients of the polynomial. We shall find that the metric is that of Fubini–Study, with an overall scale factor that depends on R^2-N.

The geodesics on Fubini–Study are quite simple, and hence, in principle, the motion of vortices can be calculated straightforwardly. However, this does involve finding the roots of polynomials with time-varying coefficients, which is not algebraically trivial for three or more vortices. We shall present examples, mainly of two vortex motion. We should also remark that Stuart's proof of the validity of the geodesic approximation for vortex motion does not extend automatically to this regime of being close to the Bradlow limit, so our results on vortex motion remain rather formal at this stage. The particle dynamics we obtain at the end is, nevertheless, quite ''physical.''

The article is structured as follows. In Sec. II we introduce the Bogomolny equations on S^2, which is identified with $\mathbb{CP}^1$. As in Refs. 2 and 4, the equations are defined on complex line bundles over this surface. In Secs. III and IV we explain our approximation for R^2 close to N, and proceed to compute the metric on the moduli space of the approximate solutions. The geodesics of this Fubini–Study metric are then used in Sec. V to give an explicit description of the N-vortex dynamics. Some examples of motions are presented in Sec. VI, and finally in Sec. VII a general result concerning the number of vortex collisions is proved.

II. THE BOGOMOLNY EQUATIONS

According to Bradlow's generalization of the classical vortices over $\mathbb{R}^2$,[2] when the base manifold is the sphere $S^2\cong\mathbb{CP}^1$, the setup for the problem is a complex line bundle $\pi:E\to S^2$ of degree N equipped with a Hermitian metric h. The Higgs field ϕ is now a section of this bundle, and the gauge potentials are the local one-forms of an h-compatible connection D on the bundle. We will take the metric on S^2 to be $g_R:=R^2\times(\text{standard metric on } S^2)$, so that the volume of (S^2,g_R) is $4\pi R^2$.

Letting $\mathcal{A}:=\{h\text{-compatible connections on } E\}$ and $\Gamma(E):=\{\text{global } C^\infty \text{ sections of } E\}$, the Bogomolny equations for $(D,\phi)\in\mathcal{A}\times\Gamma(E)$ are[2,4]

$$D^{0,1}\phi=0, \tag{1}$$

$$F+\tfrac{1}{2}(|\phi|_h^2-1)\,\mathrm{vol}_R=0, \tag{2}$$

where $D^{0,1}$ is the anti-holomorphic part of D, $\mathrm{vol}_R\in\Omega^2(S^2,\mathbb{R})$ is the volume form of the metric g_R, and $-iF$ is the globally defined curvature form of D, so that $F\in\Omega^2(S^2,\mathbb{R})$.

We remark that the problem does not depend essentially on (E,h), because all complex line bundles over S^2 of a given degree N are isomorphic. In fact, for another choice (E',h') there will always be an isomorphism $f:E\to E'$ such that $f^*(h')=h$. It is then not difficult to check that (D,ϕ) is a solution of (1) and (2) on (E',h') if and only if $(f^*D, f^{-1}\circ\phi)$ is a solution on (E,h), where f^*D is the pull-back connection on E. Notice in particular that $\phi\in\Gamma(E')$ and $f^{-1}\circ\phi\in\Gamma(E)$ have the same zeros on S^2, and hence correspond to the same vortex configuration.

We will now define the particular pair (E,h) which is to be used in the remainder of this article. Let $U_1=\mathbb{CP}^1\backslash\{[0,1]\}$, $U_2=\mathbb{CP}^1\backslash\{[1,0]\}$, where we use the standard homogeneous coordinates $[z_0,z_1]$ for points on $\mathbb{CP}^1$, and let $\varphi_i:U_i\to\mathbb{C}$ be the standard complex charts of $\mathbb{CP}^1$ with transition functions $\varphi_1\circ\varphi_2^{-1}=\varphi_2\circ\varphi_1^{-1}:z\mapsto 1/z$. Define $g_{ij}:U_i\cap U_j\to U(1)$ by

$$g_{21}\circ\varphi_2^{-1}(z)=(z/|z|)^N, \qquad g_{12}=1/g_{21}\ , \quad g_{11}=g_{22}=1.$$

Since the g_{ij} satisfy the usual cocycle conditions, it is possible to construct a complex line bundle $\pi: E \to \mathbb{CP}^1$ with trivializations $\psi_i : \pi^{-1}(U_i) \to U_i \times \mathbb{C}$ such that $\psi_i \circ \psi_j^{-1}(p,y) = (p, g_{ij}(p)\, y)$. The Hermitian metric h on E is defined by requiring the unitarity of the trivializations ψ_i, that is, $|\psi_i^{-1}(p,y)|_h^2 = |y|^2$; it is well defined because g_{ij} has values in $U(1)$.

We should now check that $\deg E = N$. Define the real valued one-forms $A_i \in \Omega^1(U_i, \mathbb{R})$ by

$$A_i = \varphi_i^* A \qquad \text{with} \qquad A := \frac{-iN}{2(1+|z|^2)} (\bar{z}\, dz - z\, d\bar{z}) \in \Omega^1(\mathbb{C}, \mathbb{R}). \tag{3}$$

On $U_1 \cap U_2$ one has

$$(\varphi_2^{-1})^*(A_1 - A_2) = \left(\frac{1}{z}\right)^* A - A = i \left(\frac{|z|}{z}\right)^N d\left(\frac{z}{|z|}\right)^N = i\, (\varphi_2^{-1})^*(g_{12}\, dg_{21}),$$

or equivalently

$$(-iA_1) - (-iA_2) = g_{12}\, dg_{21} \ ,$$

which shows that the local forms $-iA_1$ and $-iA_2$ define a connection D_N on E. The curvature $-iF_N$ of D_N is a global two-form on $\mathbb{CP}^1$ determined by $F_N = dA_j$ on U_j. In particular, one can compute that

$$(\varphi_1^{-1})^* F_N = dA = \frac{iN}{(1+|z|^2)^2}\, dz \wedge d\bar{z} = (\varphi_1^{-1})^* \left(\frac{1}{2} \mathrm{vol}_{\sqrt{N}}\right),$$

and hence

$$\deg E := \frac{i}{2\pi} \int_{\mathbb{CP}^1} (-iF_N) = \frac{1}{2\pi} \int_{\mathbb{C}} (\varphi_1^{-1})^* F_N = N.$$

Integrating Eq. (2) over $\mathbb{CP}^1$, and using that $\int_{\mathbb{CP}^1} F = 2\pi \deg E = 2\pi N$, it is clear that for $R^2 < N$ the Bogomolny equations have no solution, and that for $R^2 = N$ any solution (D, ϕ) must satisfy $\phi = 0$ and $F = 1/2\, \mathrm{vol}_{\sqrt{N}} = F_N$. Since we have already constructed a connection D_N on E with curvature $-iF_N$, we have an explicit solution of the Bogomolny equations for the case $R^2 = N$ (which is called the Bradlow limit), and it can be shown that it is unique up to gauge transformations.

For $R^2 > N$ Bradlow has shown,[2] in a more general context, that for any solution (D, ϕ) of (1) and (2), the section ϕ has exactly N zeros (which are called vortices), counting multiplicities. Moreover, the moduli space $\mathcal{M}_N$ of these solutions up to gauge tranformations is parametrized by the positions in $\mathbb{CP}^1$ of these N vortices. Since the vortices are indistinguishable, this moduli space is identified with $(\mathbb{CP}^1)^N / S_N$, where S_N is the group of permutations of N elements.

Now consider the map $\Upsilon : (\mathbb{CP}^1)^N / S_N \to \mathbb{CP}^N$ defined in homogeneous coordinates by

$$[\,[u^1, v^1], \ldots, [u^N, v^N]\,] \mapsto \left[\ \ldots, \sum_{\sigma \in S_N} v^{\sigma(1)} \cdots v^{\sigma(k)} u^{\sigma(k+1)} \cdots u^{\sigma(N)}, \ldots\ \right]_{0 \le k \le N} .$$

With some care, one can verify that Υ is a bijection. In fact, its inverse may be described in the following way. Given $[w_0, \ldots, w_N] \in \mathbb{CP}^N$, consider the nonzero polynomial

$$P(z) = \sum_{k=0}^{N} (-1)^k \frac{N!}{k!(N-k)!} w_k\, z^{N-k} \ ,$$

which has degree $l \leqslant N$. Calling $z_1, \ldots, z_l$ the complex roots of $P(z)$, one has

$$\Upsilon^{-1}([w_0,\ldots,w_N])=[[1,z_1],\ldots,[1,z_l],[0,1],\ldots,[0,1]].$$

Using this bijection, $\mathcal{M}_N$ can also be identified with $\mathbb{CP}^N$.

III. VORTICES NEAR THE BRADLOW LIMIT

Although we have an accurate description of the moduli space $\mathcal{M}_N$, the explicit form of the solutions (D,ϕ) of (1) and (2) is not known. In particular, this has prevented any successful attempt to describe the dynamics of the vortices by means of the well-known geodesic approximation. The purpose of this article is to show that by replacing the exact Bogomolny equations by two other conditions, which should be a good approximation near the Bradlow limit $R^2 \searrow N$, one can obtain the solutions explicitly; they also have $\mathbb{CP}^N$ as their moduli space, and furthermore the dynamics of these ''pseudo-vortices'' is completely computable in the framework of the geodesic approximation.

Since for $R^2=N$ the pair $(D_N,0)\in\mathcal{A}\times\Gamma(E)$ is an exact solution of (1) and (2), we may expect that for R^2 close to N the solutions (D,ϕ) will have $D\approx D_N$ (after a gauge transformation if necessary). We therefore impose $D=D_N$ and look for $\phi\in\Gamma(E)$ such that

$$(D_N,\phi) \text{ is a solution of (1), i.e., } D_N^{0,1}\phi=0; \tag{4}$$

$$(D_N,\phi) \text{ satisfies (2) ''on average,'' i.e., } \int_{\mathbb{CP}^1}\left(F_N+\frac{1}{2}(|\phi|_h^2-1)\,\mathrm{vol}_R\right)=0. \tag{5}$$

[We note in passing that Eq. (4) is analogous to the equation for electron wavefunctions of the first Landau level in the uniform background magnetic field F_N; Eq. (5) is then a wavefunction normalization condition.]

We will now find the explicit solutions of (4) and (5), and then describe their moduli space. Using the local trivialization ψ_1 of E and the chart φ_1 of $\mathbb{CP}^1$ defined before, the equation $D_N^{0,1}\phi=0$ over the domain U_1 is the same as $(\overline{\partial}-iA^{0,1})\phi_1=0$, or, explicitly, using (3),

$$\frac{\partial\phi_1}{\partial\bar{z}}=\frac{-Nz}{2(1+|z|^2)}\phi_1, \tag{6}$$

where $\phi_1\in C^\infty(\mathbb{C})$ is the representative of ϕ with respect to ψ_1.

Equation (6) has the general solution $\phi_1=f(z)(1+|z|^2)^{-N/2}$, with f holomorphic on $\mathbb{C}$. The section ϕ of E determined by ϕ_1, which is only defined over U_1, has a representative ϕ_2 with respect to ψ_2 given by $\phi_2(z)=g_{12}(z)\phi_1(1/z)$, which is smooth on $\mathbb{C}\backslash\{0\}$. But since we are looking for global solutions of (4), ϕ must be extensible to all of $\mathbb{CP}^1$, and this will happen iff $\phi_2(z)$ is smoothly extensible to $\mathbb{C}$. Writing f as a Taylor series, it is then not difficult to check that this requires that the coefficient of z^n vanishes for all $n>N$. Thus any solution ϕ of (4) must have a representative ϕ_1 over U_1 of the form

$$\phi_1(z)=\frac{a_0z^N+\cdots+a_N}{(1+|z|^2)^{N/2}}, \tag{7}$$

and conversely any ϕ_1 of this form determines a global section ϕ of E which is a solution of (4) over U_1, and by continuity over all of $\mathbb{CP}^1$.

If ϕ is represented by ϕ_1 as in (7), then the representative ϕ_2 will be

$$\phi_2(z)=\frac{a_0+\cdots+a_Nz^N}{(1+|z|^2)^{N/2}}$$

and hence, as for (1) and (2), any solution ϕ of (4) has exactly N zeros over $\mathbb{CP}^1$, counting multiplicities.

We now turn to condition (5). Using that $-iF_N$ is the curvature form of a degree N bundle, (5) is equivalent to

$$4\pi(R^2-N)=\int_{\mathbb{CP}^1}|\phi|_h^2\,\mathrm{vol}_R=\int_{\mathbb{C}}|\phi_1|^2\frac{2iR^2}{(1+|z|^2)^2}\,dz\wedge d\bar{z}=4\pi R^2\sum_{k=0}^{N}\frac{k!(N-k)!}{(N+1)!}|a_k|^2\ ,$$

where the last integral is calculated in the Appendix for ϕ_1 of the form (7). We can therefore conclude that ϕ_1 represents a solution ϕ of (4) and (5) iff ϕ_1 is of the form (7) and satisfies the normalization condition

$$\sum_{k=0}^{N}\frac{k!(N-k)!}{(N+1)!}|a_k|^2=1-\frac{N}{R^2}.$$

Calling $\mathcal{D}\subset\mathcal{A}\times\Gamma(E)$ the subspace of solutions of (4) and (5), we thus get a bijection $\alpha:\mathcal{D}\to S^{2N+1}\subset\mathbb{C}^{N+1}$ that maps each $\phi\in\mathcal{D}$, represented by a ϕ_1 like in (7), to the point

$$\left(1-\frac{N}{R^2}\right)^{-1/2}\left(\ldots,\left(\frac{k!(N-k)!}{(N+1)!}\right)^{1/2}a_k,\ldots\right)_{0\leqslant k\leqslant N}. \tag{8}$$

The following step is to determine when two solutions in $\mathcal{D}$ are gauge equivalent. Let therefore (D_N,ϕ) and $(D_N,\tilde{\phi})$ be a pair of solutions, and suppose $g:\mathbb{CP}^1\to U(1)$ is a gauge transformation on E that takes one into the other. Using the usual transformation rule for connection forms under g, and the key fact that the connection is fixed, it is readily shown that g must be constant. So $\tilde{\phi}=e^{i\beta}\phi$ for some $\beta\in\mathbb{R}$. Since the converse is clear, we conclude that (D_N,ϕ) and $(D_N,\tilde{\phi})$ are gauge equivalent iff

$$\tilde{\phi}=e^{i\beta}\phi\ \Leftrightarrow\ \tilde{\phi}_1=e^{i\beta}\phi_1\ \Leftrightarrow\ \tilde{c}=e^{i\beta}c$$

for some $\beta\in\mathbb{R}$, where $c,\tilde{c}\in S^{2N+1}$ are the images of (D_N,ϕ) and $(D_N,\tilde{\phi})$ under the bijection α. Furthermore, notice that this last condition is also equivalent to $\pi(\tilde{c})=\pi(c)$ in $\mathbb{CP}^N$, where $\pi:S^{2N+1}\to\mathbb{CP}^N$ is the usual principal $U(1)$-bundle.

Calling $\mathcal{M}_N$ the moduli space of solutions of (4) and (5) up to gauge transformations, and $p:\mathcal{D}\to\mathcal{M}_N$ the natural projection, we therefore have

$$\begin{array}{ccc}\mathcal{D} & \xrightarrow{\ \alpha\ } & S^{2N+1}\\ \downarrow p & & \downarrow\pi\\ \mathcal{M}_N & \xrightarrow{\ \tilde{\alpha}\ } & \mathbb{CP}^N\end{array} \tag{9}$$

where $\tilde{\alpha}$, defined by the commutativity of the diagram, is, like α, a bijection. The right-hand side of this diagram is a concrete model for the space of solutions $\mathcal{D}$ and its moduli space.

IV. THE METRIC ON THE MODULI SPACE

Using the usual prescriptions of the geodesic approximation (first described in Ref. 10), we will now obtain the metric m on $\mathcal{M}_N$ which, within the framework of this approximation, determines the dynamics of the "pseudo-vortices" (which from now on will be just called vortices).

Suppose one has a curve γ in $\mathcal{D}$:

$$t\overset{\gamma}{\mapsto}(D_N,\phi(t))\in\mathcal{D}\overset{\alpha}{\mapsto}(w_0(t),\ldots,w_N(t))\in S^{2N+1}\ .$$

A natural Hermitian metric on $\mathcal{D}$ is defined by

$$\left\langle \frac{d\gamma}{dt}, \frac{d\gamma}{dt} \right\rangle_{\gamma(t)} := \frac{1}{2} \int_{\mathbb{CP}^1} h(\dot{\phi}(t), \dot{\phi}(t)) \mathrm{vol}_R , \tag{10}$$

where the dot stands for the time derivative. Notice that in this case, as opposed to what happens in Ref. 12, the gauge potentials do not contribute to the metric, since the connection in our space $\mathcal{D}$ is fixed, and thus time independent.

Writing

$$\phi_1(t) = \frac{a_0(t)\, z^N + \cdots + a_N(t)}{(1+|z|^2)^{N/2}}$$

for the usual representative of $\phi(t)$, using the unitarity of ψ_1, and noting that $\dot{\phi}_1 = (1+|z|^2)^{-N/2}(\dot{a}_0 z^N + \cdots + \dot{a}_N)$, one has that

$$\begin{aligned} \left\langle \frac{d\gamma}{dt}, \frac{d\gamma}{dt} \right\rangle_{\gamma(t)} &= \frac{1}{2} \int_{\mathbb{C}} |\dot{\phi}_1|^2 \frac{2iR^2}{(1+|z|^2)^2} dz \wedge d\bar{z} \\ &= 2\pi R^2 \sum_{k=0}^{N} \frac{k!(N-k)!}{(N+1)!} \dot{a}_k \dot{\bar{a}}_k = 2\pi (R^2 - N) \sum_{k=0}^{N} \dot{w}_k \dot{\bar{w}}_k , \end{aligned}$$

again using the integral calculated in the Appendix. We conclude that the Hermitian L^2 metric on $\mathcal{D}$ corresponds via the map α to the restriction to S^{2N+1} of the canonical Hermitian metric on $\mathbb{C}^{N+1}$, up to the constant factor $2\pi(R^2-N)$. This metric will also be called $\langle \cdot, \cdot \rangle$.

According to the usual procedure, the metric m on $\mathcal{M}_N$ is induced from $\langle \cdot, \cdot \rangle$ on $\mathcal{D}$ in the following way. Given $q \in \mathcal{D}$ and a tangent vector $d\gamma/dt \in T_q\mathcal{D}$, let $(d\gamma/dt)_\perp$ be its component perpendicular to the subspace of $T_q\mathcal{D}$ formed by the vectors tangent to curves on $\mathcal{D}$ which are pure gauge transformations, that is, perpendicular to $\ker(p_*)_q$. Then

$$(p^* m)_q \left(\frac{d\gamma}{dt}, \frac{d\gamma}{dt} \right) := \left\langle \left(\frac{d\gamma}{dt} \right)_\perp , \left(\frac{d\gamma}{dt} \right)_\perp \right\rangle_q .$$

We will now compute the metric on $\mathbb{CP}^N$ corresponding to m by the identification $\tilde{\alpha}$. It will also be called m.

Using the diagram (9), the subspace $\ker(p_*)_q \subset T_q\mathcal{D}$ corresponds to the subspace $\ker(\pi_*)_{\alpha(q)} \subset T_{\alpha(q)} S^{2N+1}$. Given $w \in S^{2N+1} \subset \mathbb{C}^{N+1}$, we have that $\ker(\pi_*)_w$ is the one-dimensional real subspace generated by the vector $(d/dt)(e^{it}w)(0) = iw$. Therefore, given a tangent vector $d\gamma/dt = (\dot{\gamma}_0, \ldots, \dot{\gamma}_N) \in T_w S^{2N+1} \subset T_w \mathbb{C}^{N+1}$, we have

$$\left(\frac{d\gamma}{dt} \right)_\perp = \frac{d\gamma}{dt} - \frac{\langle d\gamma/dt, w \rangle}{\langle w, w \rangle} w,$$

so

$$\begin{aligned} \left\langle \left(\frac{d\gamma}{dt} \right)_\perp , \left(\frac{d\gamma}{dt} \right)_\perp \right\rangle_w &= \left\langle \frac{d\gamma}{dt}, \frac{d\gamma}{dt} \right\rangle - \frac{\langle d\gamma/dt, w \rangle \langle w, d\gamma/dt \rangle}{\langle w, w \rangle} \\ &= 2\pi (R^2 - N) \sum_{j,k=0}^{N} (\delta_{jk} - \bar{w}_j w_k)\, \dot{\gamma}_j \dot{\bar{\gamma}}_k , \end{aligned}$$

where the computation in the last step uses that $\langle w, w \rangle = 2\pi(R^2-N)$, since $w \in S^{2N+1}$. Thus $\pi^* m$ is the restriction to S^{2N+1} of the two-tensor in $\mathbb{C}^{N+1}$,

$$2\pi(R^2-N)\sum_{j,k=0}^{N}(\delta_{jk}-\overline{w}_j w_k)\,dw_j\otimes d\overline{w}_k.$$

Now consider the Kähler form μ associated to m. It is defined, as usual, using the imaginary part of m: $\mu=-\operatorname{Im} m\in\Omega^2(\mathbb{CP}^N,\mathbb{R})$. We have

$$\begin{aligned}
\pi^*\mu &= \pi^*(-\operatorname{Im} m)\\
&= -\operatorname{Im}(\pi^* m)\\
&= 2\pi(R^2-N)\frac{i}{2}\sum_{j,k=0}^{N}(\delta_{jk}-\overline{w}_j w_k)\,dw_j\wedge d\overline{w}_k\Big|_{S^{2N+1}}\\
&= 2\pi(R^2-N)\frac{i}{2}\sum_{j,k=0}^{N}\left(\frac{\delta_{jk}}{|w_0|^2+\cdots+|w_N|^2}-\frac{\overline{w}_j w_k}{(|w_0|^2+\cdots+|w_N|^2)^2}\right)dw_j\wedge d\overline{w}_k\Big|_{S^{2N+1}}\\
&= 2\pi(R^2-N)\frac{i}{2}\partial\overline{\partial}\log(|w_0|^2+\cdots+|w_N|^2)\Big|_{S^{2N+1}}\\
&= 2\pi(R^2-N)\,\pi^*\mu_{\mathrm{FS}},
\end{aligned}$$

where μ_{FS} is the Fubini–Study form on $\mathbb{CP}^N$, and the last equality is a well-known result (Ref. 8, p. 160). Since π and $(\pi_*)_w$ are both surjective,

$$\pi^*\mu=\pi^*(2\pi(R^2-N)\mu_{\mathrm{FS}})\qquad\text{implies}\qquad\mu=2\pi(R^2-N)\mu_{\mathrm{FS}}.$$

Therefore $m=2\pi(R^2-N)m_{\mathrm{FS}}$, where m_{FS} is the Fubini–Study metric on $\mathbb{CP}^N$, because a Hermitian metric is uniquely determined by its Kähler form.

V. VORTEX DYNAMICS

Having determined the metric m on the moduli space $\mathcal{M}_N\cong\mathbb{CP}^N$, we will now proceed to explicitly describe its geodesics, which provide an approximate description of the low-energy particle dynamics. Note that $m\propto m_{\mathrm{FS}}$ implies that the geodesics of m are exactly the Fubini–Study geodesics. These are well known (Ref. 8, p. 277) but nevertheless we will rederive them here.

Let $\pi:\mathbb{C}^{N+1}\backslash\{0\}\to\mathbb{CP}^N$ be the natural projection and $\chi_0:U_0\to\mathbb{C}^N$ one of the standard charts of $\mathbb{CP}^N$, where $U_0=\{[w^0,\ldots,w^N]\in\mathbb{CP}^N:w^0\neq 0\}$. Calling $(c^1,\ldots,c^N)$ the coordinate functions of this chart, then by definition of the Fubini–Study metric we have on U_0

$$\mu_{\mathrm{FS}}=\frac{i}{2}\partial\overline{\partial}\log(1+|c^1|^2+\cdots+|c^N|^2)=\frac{i}{2}h_{j\bar{k}}dc^j\wedge d\overline{c}^{\bar{k}}$$

and

$$m_{\mathrm{FS}}=h_{j\bar{k}}dc^j\otimes d\overline{c}^{\bar{k}},$$

with

$$h_{j\bar{k}}=\frac{\delta_{jk}}{1+|c|^2}-\frac{c^k\overline{c}^j}{(1+|c|^2)^2}.\tag{11}$$

For a general Kähler metric the geodesic equations have the simplified form (Ref. 14, p. 4):

$$\ddot{c}^k=-\frac{\partial h_{j\bar{s}}}{\partial c^l}h^{k\bar{s}}\dot{c}^l\dot{c}^j,\qquad\text{where}\qquad h^{k\bar{s}}:=(sk\ \text{entry of}\ [h_{i\bar{j}}]^{-1}).$$

In our case $h^{k\bar{s}}=(1+|c|^2)(\delta^{sk}+c^k\overline{c^s})$, and so the geodesic equations for $(\mathbb{CP}^N,m_{\mathrm{FS}})$ in the chart χ_0 are

$$\ddot{c}=\frac{2\langle\dot{c}\,,c\rangle}{1+\langle c\,,c\rangle}\dot{c}, \tag{12}$$

where $c(t)$ is a curve in $\mathbb{C}^N$ and $\langle\cdot\,,\cdot\rangle$ is the canonical Hermitian product.

Now consider curves in $S^{2N+1}\subset\mathbb{C}^{N+1}$ of the form

$$\gamma(t)=\sin(\omega t)\,y+\cos(\omega t)\,x, \qquad t\in\mathbb{R}, \tag{13}$$

where $x,y\in\mathbb{C}^{N+1}$ are orthonormal with respect to the canonical Hermitian product of $\mathbb{C}^{N+1}$. If $x^0\neq 0$, then $\pi\circ\gamma(t)\notin U_0$ only for a discrete set D of nonzero values of t, and a short computation shows that, in $\mathbb{R}\backslash D$,

$$c(t):=\chi_0\circ\pi\circ\gamma(t)=c(0)+\dot{c}(0)\frac{x^0\sin(\omega t)}{\omega(y^0\sin(\omega t)+x^0\cos(\omega t))}, \tag{14}$$

where

$$c^k(0)=\frac{x^k}{x^0} \quad\text{and}\quad \dot{c}^k(0)=\frac{\omega(y^kx^0-x^ky^0)}{(x^0)^2}, \qquad k=1,\ldots,N. \tag{15}$$

One can verify directly that this $c(t)$ satisfies (12), and therefore $\pi\circ\gamma(t)$ is a geodesic for t in $\mathbb{R}\backslash D$, and by continuity for all t. If $x^0=0$, a similar computation in one of the other standard charts of $\mathbb{CP}^N$ would establish that, also in this case, $\pi\circ\gamma(t)$ is a geodesic.

On the other hand, it is not difficult to verify that every geodesic of $(\mathbb{CP}^N,m_{\mathrm{FS}})$ can be written as $\pi\circ\gamma$, where γ has the form (13). Although one could give a general, chart-independent argument for this, for later convenience we will proceed unnaturally. Namely, using (15), one may simply check that given any $c(0)\in\mathbb{C}^N$ and $\dot{c}(0)\in T_{c(0)}\mathbb{C}^N\cong\mathbb{C}^N$, the geodesic $\pi\circ\gamma(t)$ with

$$\begin{aligned}
x&=(1+|c(0)|^2)^{-1/2}\ (\,1\,,c(0)\,),\\
y&=\omega^{-1}(1+|c(0)|^2)^{-1/2}\left(-\frac{\langle\dot{c}(0),c(0)\rangle}{1+|c(0)|^2},\ \dot{c}(0)-\frac{\langle\dot{c}(0),c(0)\rangle}{1+|c(0)|^2}c(0)\right),\\
\omega&=(1+|c(0)|^2)^{-1/2}\left(|\dot{c}(0)|^2-\frac{|\langle\dot{c}(0),c(0)\rangle|^2}{1+|c(0)|^2}\right)^{1/2},
\end{aligned} \tag{16}$$

has initial position and velocity $\chi_0^{-1}(c(0))$ and $(\chi_0^{-1})_*(\dot{c}(0))$, respectively. This shows that every geodesic starting in U_0 is of the form $\pi\circ\gamma(t)$. Similar calculations in the other standard charts would extend the result to all of $\mathbb{CP}^N$.

We now note two general properties of the geodesics $\pi\circ\gamma(t)$. First, using (11) and (15), one can compute that the velocity of the geodesic, which is a constant of motion, is $|\omega|$. Second, notice that all the geodesics of $(\mathbb{CP}^N,m_{\mathrm{FS}})$ are periodic. It is not difficult to show that for $\omega\neq 0$ the period is $\pi/|\omega|$.

We will now use our knowledge of the geodesics on the moduli space $(\mathbb{CP}^N,m)$ to give an explicit description of the vortex dynamics.

Recall from Sec. III that the solutions $(D_N\,,\phi)\in\mathcal{D}$ with the vortices (zeros of ϕ) in positions $\varphi_1^{-1}(z_1),\ldots,\varphi_1^{-1}(z_N)$ in $\mathbb{CP}^1$ are represented by a function ϕ_1 of the form (7), where we now have

$$a_0z^N+\cdots+a_N\propto(z-z_1)\cdots(z-z_N),$$

and therefore

$$a_k = A\,(-1)^k S_k(z_1,\ldots,z_N), \qquad k=0,\ldots,N,$$

where the S_j are the usual elementary symmetric polynomials, and A is a normalization factor which is nonzero for $R^2>N$. Thus such solutions $(D_N,\phi)\in\mathcal{D}$ correspond by $\pi\circ\alpha$ to [see (8)]

$$\left[\ \ldots,(-1)^k\left(\frac{k!(N-k)!}{(N+1)!}\right)^{1/2} S_k(z_1,\ldots,z_N),\ldots\ \right]_{0\leqslant k\leqslant N}\in\mathbb{CP}^N\cong\mathcal{M}_N$$

and by $\chi_0\circ\pi\circ\alpha$ to $c=(c^1,\ldots,c^N)\in\mathbb{C}^N$, where

$$c^k=(-1)^k\binom{N}{k}^{-1/2} S_k(z_1,\ldots,z_N). \tag{17}$$

Inverting these relations, we can obtain the positions of the N vortices as a function of the coordinates c^k of a given point in the moduli space $\mathbb{CP}^N$. In particular, to the geodesics $c(t)$ of the form (14) corresponds a motion of the vortices determined by

$$w^N+\sum_{k=1}^{N}\binom{N}{k}^{1/2} c^k(t)\,w^{N-k}=(w-z_1(t))\cdots(w-z_N(t)), \tag{18}$$

where the $z_i(t)$ are the coordinates of the vortices in the chart (φ_1,U_1) of $\mathbb{CP}^1$. Thus, since we know all the geodesics of $(\mathbb{CP}^N,m)$, we can determine all the possible N-vortex motions by finding the roots of polynomials of degree N—either analytically for $N\leqslant 4$ or numerically for $N>4$.

Now suppose we are given initial positions $z_i(0)$ and initial velocities $\dot z_i(0)$ for the vortices, where we assume that the $z_i(0)$ are all different. Through (17) and its derivative we can get the corresponding values $c(0),\dot c(0)\in\mathbb{C}^N$, then use (16) to determine which geodesic $c(t)$ corresponds to this initial data, and finally solve (18) to get the motions $z_i(t)$. This general procedure has been used to obtain the various special vortex motions shown below.

We remark that, because (17) is a local diffeomorphism only in the region where the vortices do not coincide, only in this region can we guarantee that the final result $z_i(t)$ has indeed the prescribed initial velocities. This is why we take the $z_i(0)$ all different. If the $z_i(0)$ are not all different, there are some values of $\dot z_i(0)$ that do not correspond to any $z_i(t)$ coming from a geodesic motion.

VI. EXAMPLES OF MOTIONS

Using the method described in the previous section, we now give a few examples of two- and three-vortex motions on the sphere. Figures 1–3 show the initial positions and trajectories in the complex plane via the stereographic projection $\varphi_1:S^2\backslash\{N\}\to\mathbb{C}$. The particular initial positions and velocities used in each case are listed in Table I.

To help with the interpretation of the figures, we recall that the stereographic projection has the property of mapping circles of S^2 (not necessarily great circles) to circles and straight lines in the plane. The inverse φ_1^{-1} has the converse property. Also the circle of unit radius is always shown as a dashed curve; the northern (southern) hemisphere of S^2 projects to the exterior (interior) of that circle.

During the motion shown in Fig. 3, the coordinate $c^1(t)$ of expressions (14) and (18) is always zero. The coordinate $c^2(t)$ is of the form $-a^2+2a(1+a^4)/[2a^3+i\omega\cot(\omega t)]$. Taking one of the roots $z(t)=x(t)+iy(t)$ of (18) and eliminating t from the system $x(t),y(t)$, one obtains that the trajectory on the plane has the simple equation $(x^2+y^2)^2+(1/a^2-a^2)(x^2-y^2)-1=0$. These are special cases of Cassini's ovals and, when projected back to the sphere, look like the joint of a tennis ball.

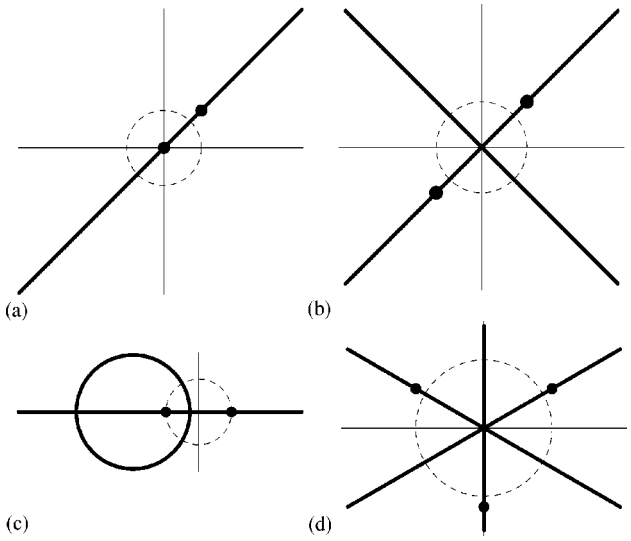

FIG. 1. (a) Two colliding vortices, one of which is at rest. One of the vortices describes a great circle on the sphere that passes through the static position of the other. (b) Head-on collision of two vortices with the same speed. There are two collisions at antipodal points. The total trajectory is the union of two great circles. (c) Head-on collision of two vortices with different initial speeds. Again two collisions occur. The total trajectory is the union of a great circle and another circle. (d) Symmetrical collision of three vortices with equal speeds. The three vortices collide twice at antipodal points. The total trajectory is the union of three great circles.

VII. COINCIDENT PARTICLES AND COLLISIONS

In this section we start by finding an algebraic condition which determines when a point in the moduli space $\mathcal{M}_N \cong \mathbb{CP}^N$ corresponds to a vortex configuration where at least two of the vortices coincide. We then use this condition to show that, for a system of N vortices starting in different positions with arbitrary initial velocities, there are at most $2N-2$ collisions during one period of the motion.

Using diagram (9) and the definition (8) of the bijection α, it is not difficult to recognize that a point $[w_0,\ldots,w_N] \in \mathbb{CP}^N$ corresponds by $\tilde{\alpha}^{-1}$ to the equivalence class in $\mathcal{M}_N$ of a solution ϕ represented by

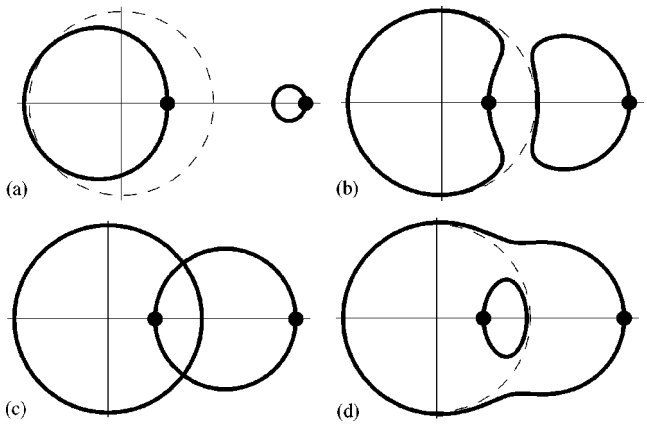

FIG. 2. (a),(b),(d) No collisions occur, and each vortex returns to its initial position after one period. (c) This degenerate case is the same as Fig. 1(c)—one great circle and another circle—in a different orientation.

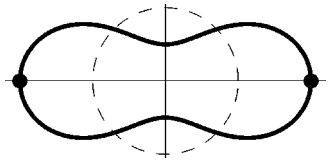

FIG. 3. (*with* $a=2$) No collision takes place and the vortices exchange positions after one period.

$$\phi_1(z) = A\,(1+|z|^2)^{-N/2} \sum_{k=0}^{N} \frac{w_k}{(k!(N-k)!)^{1/2}} z^{N-k},$$

where A is a nonzero normalization factor. Thus, asserting that $[w_0, \ldots, w_N]$ corresponds to a solution with at least two coincident vortices is equivalent to saying that one of the following conditions holds:

(i) $P(z) := \Sigma_{k=0}^{N}[w_k/(k!(N-k)!)^{1/2}]\, z^{N-k}$ has a root of multiplicity at least two;
(ii) $w_0 = w_1 = 0$, which corresponds to a double zero of ϕ at $[0,1] \in \mathbb{CP}^1$.

We now use the following result, whose proof is at the end of this section.

Lemma: For any $n \in \mathbb{N}$, *there is a homogeneous polynomial* S *in* $n+1$ *variables of degree* $2n-2$, *such that* $S(a_0,\ldots,a_n)=0$ *if and only if* $\Sigma_{k=0}^{n} a_k z^{n-k}$ *has a multiple root or* $a_0=a_1=0$.

An explicit formula for S is given in the proof and we note that, up to a sign, S coincides with the discriminant of $\Sigma_k a_k z^{N-k}$ whenever $a_0 \neq 0$.

Using this lemma, it is clear that the points $[w_0,\ldots,w_N] \in \mathbb{CP}^N$, which correspond to at least two coincident vortices, are exactly those of the algebraic hypersurface H of degree $2N-2$ in $\mathbb{CP}^N$ determined by the equation

$$\tilde{S}(\ldots,w_k,\ldots) := S\left(\ldots, \frac{w_k}{(k!(N-k)!)^{1/2}}, \ldots \right) = 0.$$

As we have seen in Sec. V, any motion of N vortices in S^2 corresponds to a Fubini–Study geodesic in $\mathbb{CP}^N$, and these are all of the form $t \mapsto \pi(\sin(\omega t)y + \cos(\omega t)x)$, with $x,y \in \mathbb{C}^{N+1}$ orthonormal and π being the projection from $\mathbb{C}^{N+1}$ to $\mathbb{CP}^N$. By the discussion above, it is also clear that this motion will have a collision of two or more vortices iff the corresponding geodesic intersects H. But since this geodesic lies on the projective line $L = \pi(\mathrm{span}_{\mathbb{C}}\{x,y\}) \subset \mathbb{CP}^N$, and does not intersect itself during one period, we conclude that the number of collisions is not bigger than the cardinality of $L \cap H$.

It is, however, a standard result in algebraic geometry that either $L \subset H$ or $\#(L \cap H) \leqslant \deg H = 2N-2$. In fact, denoting $x=(x_0,\ldots,x_N)$ and $y=(y_0,\ldots,y_N)$ in $\mathbb{C}^{N+1}$, it follows that a point $\pi(ux+vy)$ in L, with $(u,v) \in \mathbb{C}^2 \setminus \{0\}$, belongs to H iff

TABLE I. Initial positions and velocities.

	1(a)	**1(b)**	**1(c)**	**1(d)**	**2(a)**	**2(b)**	**2(c)**	**2(d)**	**3**
$\mathbf{z_1(0)}$	$1+i$	$1+i$	1	$-2i/\sqrt{3}$	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$	$a>0$
$\dot{\mathbf{z}}_1\mathbf{(0)}$	$-1-i$	$-1-i$	-3	$2i/\sqrt{3}$	i	i	i	i	i
$\mathbf{z_2(0)}$	0	$-1-i$	-1	$1+i/\sqrt{3}$	2	2	2	2	$-a$
$\dot{\mathbf{z}}_2\mathbf{(0)}$	0	$1+i$	1	$-1-i/\sqrt{3}$	$0.6\,i$	$3.7\,i$	$4\,i$	$4.5\,i$	$-i$
$\mathbf{z_3(0)}$	$\cdots$	$\cdots$	$\cdots$	$-1+i/\sqrt{3}$	$\cdots$	$\cdots$	$\cdots$	$\cdots$	$\cdots$
$\dot{\mathbf{z}}_3\mathbf{(0)}$	$\cdots$	$\cdots$	$\cdots$	$1-i/\sqrt{3}$	$\cdots$	$\cdots$	$\cdots$	$\cdots$	$\cdots$

$$Q(u,v) := \widetilde{S}(ux_0+vy_0,\ldots,ux_N+vy_N)=0.$$

But since $\widetilde{S}$ is homogeneous of degree $2N-2$, so is Q, and therefore there is a factorization (see Ref. 7, p. 31)

$$Q(u,v)=\prod_{i=1}^{2N-2}(\alpha_i u+\beta_i v), \quad \text{for some } (\alpha_i,\beta_i)\in\mathbb{C}^2 .$$

If Q is identically zero we have $L\subset H$. If Q is not identically zero, then the roots of Q are $(\beta_i,-\alpha_i)\neq 0\,\forall i$, and it is apparent that $L\cap H$ consists of the points $\pi(\beta_i x-\alpha_i y)$, which are at most $2N-2$.

We finally conclude that, either the vortices have a motion with at least two of them coincident for all time, which corresponds to $L\subset H$, or there are at most $2N-2$ collisions in one period.

Proof of the lemma: This lemma is a slight generalization of well-known algebraic results, as stated for example in Ref. 5, p. 168, or Ref. 3, p. 178. Consider $P(z)=\Sigma_{k=0}^{n}a_k z^{n-k}$ and its derivative $P'(z)=\Sigma_{k=1}^{n}(n-k+1)a_{k-1}z^{n-k}$, and form the usual resultant

$$\mathcal{R}_{P,P'}(a_0,\ldots,a_n):=\begin{vmatrix} a_0 & & \cdots & a_n & & \\ & \ddots & & & \ddots & \\ & & a_0 & \cdots & & a_n \\ na_0 & & \cdots & a_{n-1} & & \\ & \ddots & & & \ddots & \\ & & na_0 & \cdots & & a_{n-1} \end{vmatrix}$$

where there are $n-1$ rows with the coefficients of P and n rows with the coefficients of P', so that the matrix is $(2n-1)\times(2n-1)$. Applying the usual expansion to the first column of this determinant we get

$$\mathcal{R}_{P,P'}(a_0,\ldots,a_n)=a_0\,S(a_0,\ldots,a_n)$$

with

$$S(a_0,\ldots,a_n) = \begin{vmatrix} a_0 & \cdots & & a_n & & \\ & \ddots & & & \ddots & \\ & & a_0 & \cdots & & a_n \\ (n-1)a_1 & \cdots & a_{n-1} & & & \\ na_0 & \cdots & & a_{n-1} & & \\ & \ddots & & & \ddots & \\ & & na_0 & \cdots & & a_{n-1} \end{vmatrix}$$

$$+(-1)^n n \begin{vmatrix} a_1 & \cdots & a_n & & & \\ a_0 & \cdots & & a_n & & \\ & & \ddots & & \ddots & \\ & & a_0 & \cdots & & a_n \\ na_0 & \cdots & & a_{n-1} & & \\ & \ddots & & & \ddots & \\ & & na_0 & \cdots & & a_{n-1} \end{vmatrix} .$$

Expanding again the first columns of the determinants in $S(0,a_1,\ldots,a_n)$ we get

$$S(0,a_1,\ldots,a_n)=(-1)^n(n-1)\,a_1\,\mathcal{R}_{Q,Q'}+(-1)^n n\,a_1\,\mathcal{R}_{Q,Q'}=(-1)^n(2n-1)\,a_1\,\mathcal{R}_{Q,Q'}$$

where $Q(z)=\Sigma_{k=1}^{n}a_k z^{n-k}$.

Now, if $a_0\neq 0$, by standard results in basic algebra (see Refs. 5 and 3),

$$\mathcal{R}_{P,P'}=(-1)^{n(n-1)/2}a_0\,D(P),$$

where $D(P)$ is the discriminant of P, and therefore

$$S(a_0,\ldots,a_n)=0\Leftrightarrow D(P)=0\Leftrightarrow P \text{ has a multiple root.}$$

If $a_0=0$, then $P(z)=Q(z)$ and

$$S(a_0,\ldots,a_n)=S(0,a_1,\ldots,a_n)=0\Leftrightarrow a_1=0 \text{ or } \mathcal{R}_{Q,Q'}=0.$$

But when $a_1\neq 0$, by the same algebraic results, $\mathcal{R}_{Q,Q'}=0\Leftrightarrow Q=P$ has a multiple root.

We finally conclude that

$$S(a_0,\ldots,a_n)=0\Leftrightarrow P \text{ has a multiple root or } a_0=a_1=0\,.$$

APPENDIX

In this appendix we compute integrals of the form

$$\int_{\mathbb{C}}\phi\,\overline{\psi}\frac{2iR^2}{(1+|z|^2)^2}\,dz\wedge d\overline{z}=\int_{\mathbb{R}^2}\phi\,\overline{\psi}\frac{4R^2}{(1+x^2+y^2)^2}\,dx\,dy,$$

where $\phi=(1+|z|^2)^{-N/2}(a_0z^N+\cdots+a_N)$ and $\psi=(1+|z|^2)^{-N/2}(b_0z^N+\cdots+b_N)$.

Write

$$\phi\,\overline{\psi}=\sum_{k,j=0}^{N}a_{N-j}\,\overline{b}_{N-k}\,f_{kj}(z),\quad \text{with}\qquad f_{kj}(z)=\overline{z}^k z^j(1+|z|^2)^{-N}\ .$$

Using polar coordinates and integration by parts,

$$\begin{aligned}I(k,j,N)&:=\int_{\mathbb{R}^2}\frac{f_{kj}(z)}{(1+|z|^2)^2}=\int_0^{2\pi}e^{i(j-k)\theta}\,d\theta\int_0^{\infty}\frac{r^{k+j}}{(1+r^2)^{N+2}}\,r\,dr\\&=2\pi\,\delta_{jk}\int_0^{\infty}\frac{r^{2k+1}}{(1+r^2)^{N+2}}\,dr\\&=\delta_{jk}\frac{-\pi}{N+1}\int_0^{\infty}r^{2k}\frac{d}{dr}\left(\frac{1}{(1+r^2)^{N+1}}\right)dr\\&=\delta_{jk}\frac{2k\pi}{N+1}\int_0^{\infty}\frac{r^{2k-1}}{(1+r^2)^{N+1}}\,dr=\delta_{jk}\frac{k}{N+1}I(k-1,k-1,N-1),\end{aligned}$$

where the vanishing of the boundary terms in the integration by parts is valid for $N\geqslant k\geqslant 1$. Since

$$I(0,0,N-k) = 2\pi \int_0^\infty \frac{r}{(1+r^2)^{N-k+2}}\, dr = \frac{-\pi}{N-k+1}\left[\frac{1}{(1+r^2)^{N-k+1}}\right]_0^\infty = \frac{\pi}{N-k+1},$$

we have

$$I(k,j,N) = \delta_{jk}\frac{k(k-1)\cdots 1}{(N+1)\cdots(N+2-k)}\ I(0,0,N-k) = \frac{k!(N-k)!}{(N+1)!}\,\pi\,\delta_{jk} \quad .$$

The final result is therefore

$$\int_{\mathbb{C}} \phi\,\overline{\psi}\frac{2iR^2}{(1+|z|^2)^2}\, dz\wedge d\overline{z} = 4R^2 \sum_{k=0}^{N} I(k,k,N)\, a_{N-k}\,\overline{b}_{N-k} = 4\pi R^2 \sum_{k=0}^{N} \frac{k!(N-k)!}{(N+1)!}\, a_k\,\overline{b}_k .$$

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 8 AUGUST 2003

The moduli space of noncommutative vortices

David Tong[a)]
Center for Theoretical Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139

(Received 26 September 2002; accepted 9 April 2003)

The Abelian Higgs model on the noncommutative plane admits both BPS vortices and non-BPS fluxons. After reviewing the properties of these solitons, we discuss several new aspects of the former. We solve the Bogomoln'yi equations perturbatively, to all orders in the inverse noncommutivity parameter, and show that the metric on the moduli space of k vortices reduces to the computation of the trace of a $k\times k$-dimensional matrix. In the limit of large noncommutivity, we present an explicit expression for this metric. © *2003 American Institute of Physics.*

I. INTRODUCTION AND RESULTS

Vortices are enigmatic objects. Despite the apparent simplicity of the first order equations, no analytic expression for the solution has been found. Moreover, the metric on the moduli space, encoding the interactions of two or more vortices, remains unknown. This is in stark contrast to higher co-dimension solitons, such as monopoles and instantons, where seemingly more complicated equations readily yield results.

Progress may be made in the limit of far separated vortices. By considering the leading order forces experienced by moving vortices, Manton and Speight determined the asymptotic form of the low-energy dynamics.[1] Their expression contains an unknown coefficient that characterizes the exponential return to vacuum of the Higgs field. Although a direct analytic computation of this coefficient appears difficult, a prediction has been given based on T-duality in string theory,[2] and is in agreement with previous numerical results.[3]

Another approach to understanding the dynamics is to deform the background space on which the vortices live. A cunning choice of deformation may ensure that the Bogomoln'yi equations become tractable. For example, it was discovered long ago that the tricky vortex equation is replaced by Liouville's equation when the background is taken to be hyperbolic space.[4] Strachan subsequently showed that this simplification is sufficient to allow an explicit calculation of the moduli space metric.[5] More recently, Baptista and Manton considered the case of k vortices interacting on a sphere of area $A\sim 4\pi k$.[6] An analytic expression for the metric was given in the limit as the area of the sphere shrinks to a critical value, $A\rightarrow 4\pi k$. Curiously, in this limit, the vortex motion exhibits a symmetry enhancement, from the underlying SU(2) symmetry of the sphere to SU$(k+1)$. The physics behind this enhancement remains somewhat puzzling.

Here, we shall again deform the background space so that the dynamics of vortices becomes tractable. This time, we take space to be the flat, noncommutative plane. In two spatial dimensions, noncommutivity is rather natural since it breaks only the discrete parity symmetry, leaving the continuous rotational symmetry intact. Solitons in noncommutative geometry have been extensively studied in recent times (see Ref. 7 for reviews). In particular, aspects of vortices in the noncommutative Abelian Higgs model have been discussed in Refs. 8–10. As we shall review, noncommutivity yields a one-parameter family of metrics on the vortex moduli space, depending on γ, a dimensionless combination of the gauge coupling constant e^2, the Higgs expectation value v and the noncommutivity parameter θ,

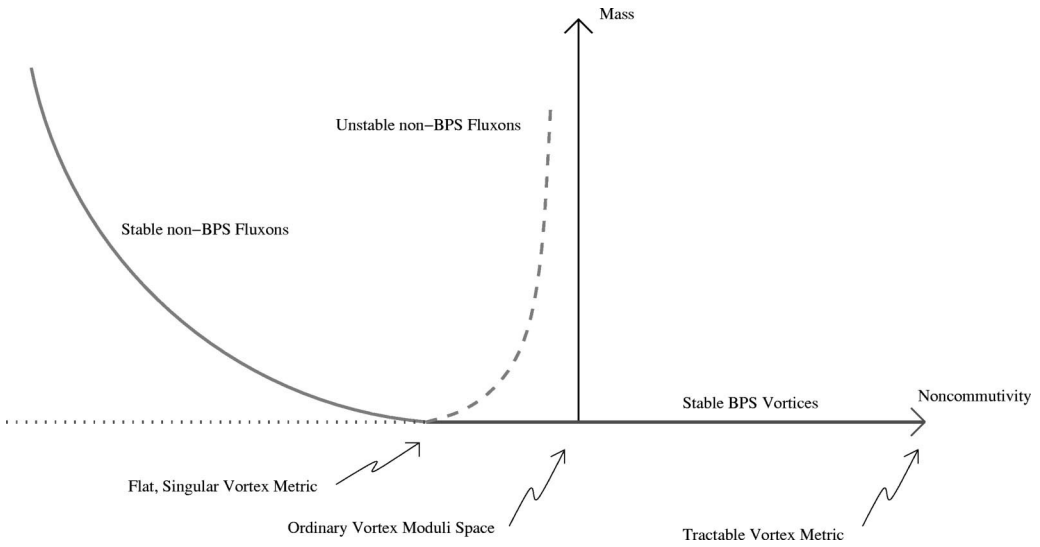

FIG. 1. The vortex phase diagram: BPS vortices exist for $-1\leqslant\gamma\leqslant\infty$, while non-BPS fluxons exist for $\gamma<0$, but are stable only for $\gamma\leqslant-1$.

$$\gamma=\theta e^2 v^2. \tag{1}$$

It was shown by Bak, Lee, and Park[9] that solutions to the Bogomoln'yi equations exist only for $-1\leqslant\gamma\leqslant+\infty$. At the critical point $\gamma=-1$, the vortex solutions coincide with the fluxon solutions discovered in Ref. 11. Here, the moduli space of vortices is endowed with the flat, singular metric on $\mathbf{C}^k/S_k$, and the moduli space approximation breaks down.[9] For $\gamma<-1$, there are no further solutions to the first order vortex equations, but the non-BPS fluxon solutions survive as localized solitons carrying magnetic flux. In contrast, for $-1<\gamma<0$, these non-BPS fluxon solutions are unstable to decay into the BPS vortices which have lower mass. For $\gamma>0$, only the BPS vortex solutions exist. This scenario, which was developed in Ref. 9, is summarized in Fig. 1.

Here we consider only $\gamma>0$, and present three, related, results. First, we derive a $2k$-parameter formal solution to the vortex equations as an all-orders perturbative expansion in γ^{-1}. For arbitrary γ, we then show that the metric on the moduli space of k vortices is given by the trace of a $k\times k$ matrix. This provides the noncommutative extension of Samols' expression in the ordinary commutative case.[12] Finally, in the limit $\gamma\to\infty$, we present an explicit expression for the metric on the moduli space of vortices. For k vortices centered at $z_a\in\mathbb{C}$, $a=1,\ldots,k$, the Kähler potential for the multi-cover of the moduli space is given by

$$\mathcal{K}=\log\det\exp(\overline{z}_a z_b). \tag{2}$$

Modding out by the permutation group S_k, exchanging the z_a, results in the true moduli space metric. This metric has appeared before in the study of noncommutative scalar solitons,[13–16] and we explain the similarities and differences with its appearance in the Abelian Higgs model.

The limit $\gamma\to\infty$ is customarily taken to mean large noncommutivity. However, as is clear from (1), it may also be taken to be the strong coupling limit $e^2\to\infty$, which is commonly used in the context of gauged linear sigma models. Indeed, as we shall see, it is only in this limit that the proper kinetic energy of the noncommutative vortices remains finite. In the ordinary, commutative, Abelian Higgs model, vortices become vanishingly small in this limit but, nevertheless, play an important role as singular worldsheet instantons.[17] We shall see that noncommutivity on the worldsheet resolves these singular vortices, in a manner similar to the resolution of singular U(1) Yang–Mills instantons.

II. THE VORTEX EQUATIONS

The Lagrangian of the Abelian Higgs model at critical coupling is

$$\mathcal{L}=-\frac{1}{4e^2}F_{ij}F^{ij}+\mathcal{D}_i\phi\mathcal{D}^i\phi-\frac{e^2}{2}(\phi\phi^\dagger-v^2)^2.$$

The model admits BPS vortices of mass $2\pi v^2 k$, for any positive integer k, satisfying the first order equations of motion,

$$F_{12}+e^2(\phi\phi^\dagger-v^2)=0,\ \mathcal{D}_{\bar{z}}\phi=0,\ \int F_{12}=2\pi k>0, \tag{3}$$

where we have introduced the complex structure $z=x_1+ix_2$ on the background space. Here we wish to consider the Abelian Higgs model defined on the noncommutative complex plane, such that

$$[z,\bar{z}]=2\theta.$$

It is common practice (see Ref. 7) to take z to be an operator on the Hilbert space $\mathcal{H}$, isomorphic to the Hilbert space of a single harmonic oscillator. We define the usual creation and annihilation operators, satisfying $[a,a^\dagger]=1$, whose action on the orthonormal basis $|n\rangle=0,1,2,\ldots$ is given by

$$a|n\rangle=\sqrt{n}|n-1\rangle,\qquad a^\dagger|n\rangle=\sqrt{n+1}|n+1\rangle.$$

For $\theta>0$, the action of all spatial operators may thus be reexpressed as

$$z=\sqrt{2\theta}a,\quad \partial_z\cdot=-\frac{1}{\sqrt{2\theta}}[a^\dagger,\cdot],\quad \int d^2x=2\pi\theta\mathrm{Tr},$$

where Tr is the trace over $\mathcal{H}$. Complex conjugation of the space–time coordinate z is identified with Hermitian conjugation of operators on $\mathcal{H}$. The fields A_z and ϕ are themselves promoted to operators on $\mathcal{H}$. To simplify the equations, we rescale the Higgs field $\phi\to v\phi$, and decompose the gauge potential operator as

$$A_z=\frac{i}{\sqrt{2\theta}}(a^\dagger+C^\dagger).$$

The advantage of this notation is that the magnetic field F_{12} is independent of a and $a^\dagger$, and the vortex equations (3) become the operator equations,

$$1+[C^\dagger,C]=\gamma(\phi\phi^\dagger-1),$$

$$\phi a+C\phi=0, \tag{4}$$

$$\mathrm{Tr}(1+[C^\dagger,C])=-k<0.$$

As promised, the equations depend only on the dimensionless combination $\gamma=\theta e^2v^2$. They are valid only for $\gamma>0$. The rest of this article will be devoted to analyzing these equations. However, for completeness, we first mention the extension to $\theta<0$. Defining $z=\sqrt{-2\theta}a^\dagger$, and $A_z=-i(a+C)/\sqrt{-2\theta}$, we have

$$1+[C^\dagger,C]=\gamma(\phi\phi^\dagger-1),$$

$$\phi a^\dagger+C^\dagger\phi=0, \tag{5}$$

$$\mathrm{Tr}(1+[C^\dagger,C])=+k>0.$$

As depicted in Fig. 1, while the equations (4) are thought to have solutions for all $\gamma>0$,[8] Eqs. (5) have solutions only for $-1\leqslant\gamma\leqslant 0$.[9,10]

Note that under a CP transformation, which is a symmetry of the theory, vortices are mapped to antivortices, while $\theta\to-\theta$. The phase diagram for antivortices is therefore given by reflecting Fig. 1 in the vertical axis. The theory admits both BPS vortex and BPS antivortex solutions only for $|\gamma|\leqslant 1$.

III. THE SOLUTION

We turn now to the solution of the vortex equations (4). Perturbative progress can be made when the dimensionless parameter γ is large. For coincident vortices, the solution to first order in $1/\gamma$ was given in Ref. 8. Here we present an iterative solution, for arbitrary vortex positions, to all orders in $1/\gamma$.

Let us first consider the limit $\gamma\to\infty$. The first equation in (4) now simply becomes $\phi_0\phi_0^\dagger=1$, which can be partially inverted to give

$$\phi_0^\dagger\phi_0=(1-P),$$

where P, a projection operator on $\mathcal{H}$, determines the kernel of ϕ_0: $Ker(\phi_0)=P\mathcal{H}$. In this limit, the gauge potential is given by $C_0=-\phi_0 a\phi_0^\dagger$. After some manipulation, the second and third vortex equations (4) give further constraints on P,

$$(1-P)aP=0,\ \mathrm{Tr}P=k. \tag{6}$$

(In analyzing this final equation, it appears necessary to employ a suitable regularization of the trace over $\mathcal{H}$. We choose $Tr_N\cdot\equiv\Sigma_{n=1}^N\langle n|\cdot|n\rangle$, subsequently taking the limit $N\to\infty$.) Thus the kernel of ϕ_0 is constrained to be a k-dimensional eigenspace of the annihilation operator a. Eigenvectors of a are provided by the coherent states,

$$|z\rangle=\exp(za^\dagger)|0\rangle=\sum_{n=0}^{\infty}\frac{z^n}{\sqrt{n!}}|n\rangle,$$

which satisfy $a|z\rangle=z|z\rangle$ for any $z\in\mathbb{C}$. Thus, in general, solutions to the vortex equations in the limit $\gamma\to\infty$ are parametrized by k complex vectors $|z_a\rangle$, $a=1,\ldots,k$, spanning $P\mathcal{H}$, with

$$P=\sum_{a,b=1}^{k}|z_a>(h^{-1})^{ab}\langle z_b|, \tag{7}$$

where the overlap matrix h is defined by

$$h_{ab}=\langle z_a|z_b\rangle=\exp(\overline{z}_a z_b). \tag{8}$$

We therefore find a $2k$ (real) parameter family of solutions. Hearteningly, the number of moduli is in agreement with the ordinary, commutative, vortex equations.[18] In the limit of far-separated vortices, we may think of the z_a as the positions of k unit-flux solitons. Note that this description of $P\mathcal{H}$ becomes singular in the limit as $|z_a\rangle\to|z_b\rangle$ for $a\neq b$. However, as explained nicely in Ref. 15, the underlying eigen-subspace remains smooth in this limit, and is spanned by $|z_a\rangle$ and $a^\dagger|z_a\rangle$.

To extend this analysis away from the $\gamma\to\infty$ limit, we make the expansion

$$\phi=\sum_{m=0}^{\infty}\gamma^{-m}\phi_m, \qquad C=\sum_{m=0}^{\infty}\gamma^{-m}C_m.$$

The resulting iterative equations do not immediately determine the action of ϕ_1 on the eigenspace $P\mathcal{H}$. To resolve this, we make the ansatz that the kernel of ϕ is independent of γ. In other words,

$$\mathrm{Ker}(\phi)=P\mathcal{H}.$$

I have not been able to derive this explicitly from (4), but have been unable to find solutions in which it is not the case. Proceeding with this assumption, we may express the solution to (4) as

$$C_m=-\phi_0 d_m\phi_0^\dagger, \qquad \phi_m=\phi_0\psi_m(1-P),$$

where the operator coefficients ψ_m and d_m are determined by induction, starting from $\psi_0=1$, and with

$$\begin{aligned} d_m&=\psi_m a+\sum_{l=0}^{m-1} d_l(1-P)\psi_{m-l},\\ \psi_m&=\frac{1}{2}(1-P)\sum_{l=0}^{m-1}(d_l^\dagger(1-P)d_{m-l-1}-d_{m-l-1}(1-P)d_l^\dagger)-\frac{1}{2}\sum_{l=1}^{m-1}\psi_l\psi_{m-l}^\dagger. \end{aligned} \tag{9}$$

To summarize, this perturbative solution is uniquely determined by a choice of projector (7) from among the $2k$ parameter family of suitable projectors. An important, open, problem is to determine the radius of convergence of this expansion.

IV. THE LOW-ENERGY DYNAMICS

Let us turn now to the low-energy dynamics of the noncommutative vortices. As usual, we consider the moduli space approximation, in which only the collective coordinates z_a, which determine the projection operator P, are allowed to vary in time. The linearized Bogomoln'yi equations (4) are

$$\begin{aligned} [\dot{C}^\dagger,C]+[C^\dagger,\dot{C}]&=\gamma(\dot{\phi}\phi^\dagger+\phi\dot{\phi}^\dagger),\\ \dot{\phi}a+\dot{C}\phi+C\dot{\phi}&=0, \end{aligned} \tag{10}$$

and are to be augmented with Gauss' law, the equation of motion for A_0. In our operator notation, this reads

$$-[\dot{C}^\dagger,C]+[C^\dagger,\dot{C}]=\gamma(\dot{\phi}\phi^\dagger-\phi\dot{\phi}^\dagger), \tag{11}$$

which can therefore be combined with the first of the Bogomoln'yi equations to give

$$[C^\dagger,\dot{C}]=\gamma\dot{\phi}\phi^\dagger.$$

The low-energy dynamics of the solitons is inherited from the kinetic energy terms of the original field theory in the standard Manton manner,

$$T=2\pi\theta v^2\mathrm{Tr}\left(\frac{1}{\gamma}\dot{C}^\dagger\dot{C}+\dot{\phi}^\dagger\phi\right)\equiv 2\pi\theta v^2 g_{ab}(z)\dot{z}^a\dot{\bar{z}}^b. \tag{12}$$

In the second equality above, we have anticipated the Kählerity of the metric. This property is guaranteed by supersymmetry. To see this, a standard trick is to embed the theory in one with

maximal supersymmetry, living in the maximal space–time dimension. The Abelian Higgs model may be embedded in a $d=5+1$ dimensional theory which is endowed with $\mathcal{N}=1$ supersymmetry (or eight supercharges). The vortex solutions under consideration now become BPS three-branes which preserve half of the supersymmetry. The addition of noncommutivity in two, transverse, spatial directions does not alter this fact, and the low-energy dynamics is thus described by a $d=3+1$, $\mathcal{N}=1$ (four supercharges) nonlinear sigma-model with target space given by the noncommutative vortex moduli space. The metric on the target space is necessarily Kähler.

We start our analysis of the moduli space metric by once again taking the limit $\gamma\to\infty$. As is clear from (12), the low-energy Lagrangian remains finite if we interpret this as $e^2\to\infty$. Since the kinetic terms for the gauge field become negligible in this limit, we have simply

$$\frac{T_0}{2\pi\theta v^2}=\mathrm{Tr}\ \dot{\phi}_0^\dagger\dot{\phi}_0.$$

From (10) and (11) we find that $\dot{\phi}_0=\dot{\phi}_0 P=-\phi_0\dot{P}$, from which we derive the low-energy dynamics purely in terms of the projection operator P,

$$\frac{T_0}{2\pi\theta v^2}=\mathrm{Tr}\ P\ \dot{\phi}_0^\dagger\dot{\phi}_0=\frac{1}{2}\mathrm{Tr}\ \dot{P}\dot{P}. \tag{13}$$

From the definition of the projection operator (7) in terms of the overlap matrix (8) it is simple to derive the explicit form of the metric,

$$\frac{T_0}{2\pi\theta v^2}=\mathrm{tr}\,(\partial_a\overline{\partial_b}\log h)\,\dot{z}^a\dot{\bar{z}}^b, \tag{14}$$

where tr denotes the trace over the $k\times k$ matrix indices of h. The Kähler potential is therefore given by the expression (2) as promised. The expressions (13) and (14) have appeared before in the context of noncommutative solitons.[13–16] Let us pause briefly to review that work and explain the differences with the present case. The seminal work[13] considered pure scalar field theories in noncommutative space–times. It was shown that, in the limit $\theta\to\infty$, *any* projection operator solves the equation of motion. To proceed to finite theta one may work, as we have above, perturbatively in $1/\tilde{\gamma}=1/m^2\theta$ where m is some mass scale of the theory. It was shown that, at first order in $1/\tilde{\gamma}$, only some projection operators survive as solutions to the equations of motion.[15,16] These are precisely those operators satisfying (6) above. At next-to-leading order in $1/\tilde{\gamma}$, these projectors too are lifted, and only isolated solutions remain. This scenario left certain aesthetic puzzles. For example, it was unclear why, *a priori*, the moduli space need be Kähler since the original field theory could not be embedded in a supersymmetric context and the solitons were not BPS. Moreover, the relevant solitons were not the most general solutions to any equations of motion, but rather the surviving approximate solutions at first order in perturbation theory.

In contrast, the appearance of the moduli space in the current context is more natural. It now appears at *zeroth* order in perturbation theory, rather than first, and the solitons are therefore solutions to certain equations of motion (namely those derived in the strict $\gamma\to\infty$ limit). Furthermore, as explained above, the Kähler nature of the target space finds an explanation in terms of supersymmetry.

The explicit metric for noncommutative vortices may be easily extracted from (14). For $k\geqslant 3$, the algebra becomes somewhat entangled, but for $k=2$ it is simple and was given previously in Refs. 14–16. Factoring off an overall center of mass, we have the relative moduli space described in terms of the separation $z=z^1-z^2$ with metric,

$$ds^2=\left(\frac{1}{2}\coth(|z|^2/2)-\frac{|z|^2}{4\sinh^2(|z|^2/2)}\right)dz\,d\bar{z}.$$

Since the two vortices are indistinguishable, we should orbifold this space by the Z_2 action $z \to -z$. It is simple to see that this renders the metric nonsingular at the origin $z=0$.

We would like to extend this discussion beyond the $\gamma \to \infty$ limit. One may consider proceeding by calculating the contributions to the low-energy dynamics perturbatively in $1/\gamma$. Unlike the case of scalar field theories, where these effects induce a potential on the moduli space,[15,16] for the case of vortices they merely correct the metric on the moduli space. The leading order contribution is given by $T = T_0 + T_1/\gamma$ where

$$\frac{T_1}{2\pi\theta v^2} = \mathrm{Tr} P(\dot{P}\dot{P}a(1-P)a^\dagger - a(1-P)\dot{P}\dot{P}a^\dagger).$$

However, this perturbative path appears tedious and illuminates little.

Instead, we finish by deriving the noncommutative extension of Samols' localization theorem.[12] Recall that Samols analyzed the dynamics of k vortices in the ordinary, commutative, Abelian Higgs model. Upon integrating the usual overlap of zero modes over the complex plane, he found that all contributions vanish apart from those arising at the k zeroes of the Higgs field.

Examining our expressions for T_0 and T_1 above, we see that a similar phenomenon has occurred. The trace over the infinite dimensional Hilbert space $\mathcal{H}$ has been reduced to a more manageable trace over a k-dimensional subspace $P\mathcal{H}$. Here we show that this property holds for all values of γ. In order to derive this result, I have found it necessary to introduce the operator ϕ^{-1}. Since $\mathrm{Ker}(\phi) \neq 0$, we must define this operator with care. We require,

$$\phi\phi^{-1} = 1, \quad \phi^{-1}\phi = 1 - P.$$

While the existence of such an operator in not guaranteed for all γ, it is a simple matter to construct it explicitly within the perturbative context of the solution (9),

$$\phi^{-1} = \sum_{m=1}^{\infty} \gamma^{-m} \tilde{\psi}_m \phi_0^\dagger,$$

where the operators $\tilde{\psi}_m$ are defined iteratively as $\tilde{\psi}_0 = 1$ and $\tilde{\psi}_1 = -\psi_1$ with the remainder given by $\tilde{\psi}_m = -\Sigma_{l=1}^m \psi_l \tilde{\psi}_{m-l}$. The result below is therefore only strictly valid for γ within the radius of convergence of the series (9). Wielding this operator allows us to invert the Bogomoln'yi equation to $C = -\phi a \phi^{-1}$, supplying the leverage necessary to pry open the expression for the kinetic energy (12). A little algebra reveals the final result,

$$T = 2\pi\theta v^2 \ \mathrm{Tr}\ P\left(\dot{\phi}^\dagger\dot{\phi} - \frac{1}{\gamma} a \phi^{-1}\dot{C}^\dagger\dot{\phi} \right),$$

which indeed reduces to the trace over the k-dimensional subspace $P\mathcal{H}$ as advertised.

(Received 10 December 2002; accepted 9 April 2003)

We discuss the structure of the framed moduli space of Bogomolny monopoles for arbitrary symmetry breaking and extend the definition of its stratification to the case of arbitrary compact Lie groups. We show that each stratum is a union of submanifolds for which we conjecture that the natural L^2 metric is hyper-Kähler. The dimensions of the strata and of these submanifolds are calculated, and it is found that for the latter, the dimension is always a multiple of four. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1590056]

I. INTRODUCTION

Recently there has been much interest in monopoles with nonmaximal symmetry breaking at infinity. In particular questions have been raised as to when they are manifolds and when they have hyper-Kähler metrics. This note gathers together some mathematical results concerning the structure of the moduli spaces and their L^2 metrics. These range from theorems which have been proved in full generality through partially proved theorems to outright conjectures.

Recall that we generally expect that moduli spaces of solutions of the self-duality equations and their reductions such as the Bogomolny equations and Nahm's equations should be hyper-Kähler manifolds. One reason for this is that formally such moduli spaces arise as hyper-Kähler quotients. To recall this, fix a compact, connected Lie group G, with Lie algebra $\mathfrak{g}$, and consider the space $\mathcal{A}$ of G-connections (vector potentials) on the trivial G-bundle over flat $\mathbb{R}^4$. By identifying

$$A_0 dx_0 + A_1 dx_1 + A_2 dx_2 + A_3 dx_3$$

with the $\mathfrak{g}\otimes\mathbb{H}$-valued function

$$A_0 + iA_1 + jA_2 + kA_3,$$

where i, j, and k are unit quaternions, $\mathcal{A}$ becomes a quaternionic vector space. Formally, $\mathcal{A}$ can be equipped with the L^2 metric, making it a flat hyper-Kähler manifold. Because $\mathbb{R}^4$ is not compact, the convergence of this metric will depend upon subjecting our connections to suitable asymptotic conditions, and these will be considered in detail below. Setting this aside for the moment, it is a straightforward exercise to check that the hyper-Kähler moment map for the action of the gauge group $\mathcal{G}$ on $\mathcal{A}$ is given by

$$A \mapsto F_A^+ \in \Omega^2(X, \mathfrak{g}) \otimes \mathrm{Im}\,\mathbb{H}.$$

a)Electronic mail: mmurray@maths.adelaide.edu.au
b)Electronic mail: michael@maths.ed.ac.uk

Hence the hyper-Kähler quotient $\mathcal{A}///\mathcal{G}$ should be the same as the space of anti-self-dual connections divided by the action of the gauge group, and the L^2-metric will descend to define a hyper-Kähler metric on the moduli space.

A monopole on $\mathbb{R}^3$ is a pair $c=(A,\Phi)$, where A is a connection on the trivial G-bundle $E \to \mathbb{R}^3$, and Φ is a section of the adjoint bundle $E\times_G\mathfrak{g}$. The monopole c satisfies the Bogomolny equations

$$\mathrm{d}_A\Phi = *F_A \tag{1.1}$$

if and only if the connection $\Phi dx_0 + A$ is anti-self-dual on $\mathbb{R}\times\mathbb{R}^3$. In particular, from this four-dimensional point of view, Φ cannot vanish at infinity, because it is independent of x_0. Thus the convergence of the L^2 metric and the nondegeneracy of the hyper-Kähler symplectic forms are important issues in this case.

These issues were fully resolved when $G=\mathrm{SU}(2)$ by Atiyah and Hitchin:[2] they showed that the moduli space of (framed) monopoles of charge k is, indeed, a complete hyper-Kähler manifold. Its dimension is $4k$ where the charge of the monopole is k.

For a general compact Lie group of rank r it is expected that the moduli space of monopoles with *maximal symmetry* breaking is a hyper-Kähler manifold although this has not been proved in generality. Except for very simple low charge cases, there are mostly partial results which compute the metric asymptotically near the edge of the moduli space; see, for example, Refs. 4, 5, and 17, and references therein.

The real complications, however, arise when there is *nonmaximal symmetry breaking* which is our primary interest below. The case of SU(3) monopoles with minimal symmetry breaking was treated in detail in Ref. 7, but beyond this little seems to be known.

We shall present here a summary of the results discussed in the article: the reader will have to refer forward for precise definitions.

The full moduli space of (framed) monopoles of mass μ and charge m is denoted by $\mathcal{M}(u,\mu,[\phi]=m)$. Here $0\neq\mu\in\mathfrak{g}$ is arbitrary (*maximal* symmetry breaking is precisely the condition that μ should be regular) and u is a unit vector in $\mathbb{R}^3$. m is a homotopy class, essentially a string of integers. The boundary conditions imposed guarantee that for some $k\in\mathfrak{g}$,

$$\Phi(tu)=\mu-\frac{k}{2t}+o(t^{-1}) \quad \text{for} \quad t\gg 0. \tag{1.2}$$

There is therefore a map $e:\mathcal{M}(u,\mu,[\phi]=m)\to\mathfrak{g}$ which assigns k to (A,Φ). The image $\mathcal{K}$ of e in $\mathfrak{g}$ is not the whole of $\mathfrak{g}$, but rather a disjoint union of $C(\mu)$-orbits

$$\mathcal{K}=C(\mu)k_1\cup C(\mu)k_2\cup\cdots\cup C(\mu)k_n. \tag{1.3}$$

It turns out that the k_j are *integral* elements of $\mathfrak{g}$. The set of all monopoles (A,Φ) with $e(A,\Phi)\in C(\mu)k_j$ is the jth stratum $\mathcal{M}_j$, say, of the moduli space. This was defined in a different way for $G=\mathrm{SU}(r+1)$ in Ref. 19. In general, $\mathcal{M}_j$ does not have dimension divisible by 4, so it cannot be hyper-Kähler. However, if we define, for $k\in\mathcal{K}$,

$$\mathcal{M}(u,\mu,k)=\{(A,\Phi)\in\mathcal{M}(u,\mu,[\phi]=m):e(A,\Phi)=k\} \tag{1.4}$$

[the moduli space of framed monopoles of *type* (μ,k)], then we shall see that $\mathcal{M}(u,\mu,k)$ has dimension divisible by 4 and the natural conjecture is that the L^2 metric makes $\mathcal{M}(u,\mu,k)$ into a hyper-Kähler manifold.

At least one of the strata, $\mathcal{M}_1$, say, must be open, hence of the same dimension as $\mathcal{M}(u,\mu,[\phi]=m)$, but this stratum need not be hyper-Kähler. If, however, $C(\mu)k_1=k_1$, then $\mathcal{M}_1=\mathcal{M}(u,\mu,k_1)$ and then this stratum *is* a candidate to be hyper-Kähler. Notice more generally that if k and k' lie in $C(\mu)k_j$, an element $g\in C(\mu)$ with $\mathrm{ad}(g)k=k'$ can be regarded as a constant gauge transformation which maps $\mathcal{M}(u,\mu,k)$ diffeomorphically to $\mathcal{M}(u,\mu,k')$.

In Sec. IV, magnetic charges $m_1,\ldots,m_s$ and holomorphic charges $h_1,\ldots,h_{r-s}$ are defined for monopoles in $\mathcal{M}(u,\mu,k)$. The information in the magnetic charges is topological and is equivalent to the homotopy class m. In particular, the magnetic charges do not vary from stratum to stratum. By contrast the holomorphic charges determine the stratum $\mathcal{M}_j$. (The number s of magnetic charges is completely determined by the mass μ.)

We shall show that if $\mathcal{M}(u,\mu,k)$ is nonempty, then the charges are all nonnegative, and that

$$\dim \mathcal{M}(u,\mu,k)=4(m_1+\cdots+m_s+h_1+\cdots+h_{r-s}). \tag{1.5}$$

Dimensions of the strata and full moduli space are also determined in Sec. VI.

II. THE MODULI SPACE AS A MANIFOLD

In this section we shall introduce various different monopole moduli spaces and explain carefully which of them are smooth manifolds, and which are likely to admit hyper-Kähler metrics. Throughout we shall be considering *Euclidean* monopoles, that is to say, monopoles on flat $\mathbb{R}^3$. Note that the metric enters the Bogomolny equation (1.1) through the Hodge star operator. Some work has also been done on hyperbolic monopoles, where $\mathbb{R}^3$ is replaced by hyperbolic three-space $\mathcal{H}^3$. It is expected that moduli spaces of hyperbolic monopoles will be diffeomorphic to the corresponding moduli spaces of Euclidean monopoles, but this has not been proved in general. On the other hand, the issue of natural metrics on moduli spaces of hyperbolic monopoles is completely open: all that is known for certain is that the L^2 metric is infinite in this case.

There are two reasons why there are so many different monopole moduli spaces. The first is that the monopoles must be *framed*, and this can be done either at a base-point in $\mathbb{R}^3$ or "at infinity." The second has to do with the specification of the asymptotics of the Higgs field Φ.

A. Notation

In order to discuss monopoles, we shall fix the following:

(i) G is a compact, connected, semi-simple Lie group of rank r. The complexification is denoted G^c and Lie algebra $\mathfrak{g}$.
(ii) If $a\in\mathfrak{g}$, $O_a\subset\mathfrak{g}$ is the orbit of a in $\mathfrak{g}$ under the adjoint action of G. $C(a)\subset G$ is the centralizer of a, with Lie algebra $\mathfrak{c}(a)$.
(iii) As a homogeneous space, $O_a=G/C(a)=G^c/P_a$, where P_a is the appropriate parabolic subgroup. The latter description gives O_a the structure of a compact complex manifold.
(iv) μ and k are commuting elements of $\mathfrak{g}$, $[\mu,k]=0$.
(v) $E\to\mathbb{R}^3$ will denote the trivial principal G-bundle over $\mathbb{R}^3$.

B. Boundary conditions and moduli spaces

The physically natural condition to impose on a solution of the Bogomolny equations is the finite-energy condition

$$\int |F_A|^2=\int |\mathrm{d}_A\Phi|^2<\infty. \tag{2.1}$$

We shall impose apparently rather stronger asymptotic conditions. It follows from the work of Taubes if $G=\mathrm{SU}(2)$, that (2.1) together with (1.1) implies these stronger conditions, but for general groups this must remain a conjecture.

Following Jarvis, we assume the following.

(BC1) Along each straight line, there is a gauge in which

$$\Phi=\mu-\frac{k}{2r}+O\left(\frac{1}{r^{1+\delta}}\right)$$

for all sufficiently large r.

(BC2) In this same gauge,

$$d_A\Phi = \frac{k}{2r^2}\,dr + O\left(\frac{1}{r^{2+\delta}}\right)$$

for all sufficiently large r.

These conditions are closely related to the Bogomolny–Prasad–Sommerfield (BPS) boundary conditions of Ref. 12.

Define

$$\mathcal{C} = \{(A,\Phi): d_A\Phi = *F_A,\ \ (A,\Phi) \text{satisfies BC1 and BC2}\}.$$

Notice that we do not yet fix μ and k: we merely assert that the boundary conditions are satisfied for *some* elements μ and k satisfying

$$\mu \neq 0, \quad [\mu,k] = 0. \tag{2.2}$$

Denote by $\mathcal{G}$ the group of all automorphisms g of E that preserve the boundary conditions (i.e., g and ∇g have limits as r goes to infinity along any straight line, and the limiting values are continuously differentiable when viewed as functions on the sphere at infinity). Then $\mathcal{G}$ acts on $\mathcal{C}$ and we would like to define the monopole moduli space as the quotient $\mathcal{M} = \mathcal{C}/\mathcal{G}$. This will have singularities because $\mathcal{G}$ does not act freely. In addition it will contain components of arbitrarily high dimension. We shall now explain how these two problems are eliminated.

C. The degree of a monopole

The asymptotic value of Φ is a section ϕ, say, of $\mathrm{ad}(E_\infty)$, where E_∞ is the restriction of E to the two-sphere at infinity. Since $\mathrm{ad}(E_\infty)$ is a trivial bundle, we can view ϕ as a continuous map into $\mathfrak{g}$. By BC1, this takes values in the adjoint orbit O_μ. This orbit is preserved by the action of gauge transformations g on E_∞, but $g(\phi) = \mathrm{ad}(g)\phi$, so that this map is not gauge-invariant. However, its homotopy class $m = [\phi]$ *is* gauge invariant, because $\pi_2(G) = 0$, so that any gauge transformation can be deformed to the identity. The homotopy class m is called the *degree* of the monopole. This discussion suggests the definition of spaces

$$\mathcal{C}(O_\mu, [\phi] = m),$$

where the adjoint orbit as well as the homotopy class of ϕ are fixed. This is referred to as the set of monopoles of mass μ and charge m. Note that $O_\mu = G/C(\mu)$.

D. Radial scattering and interior framing

Let $x \in \mathbb{R}^3$ be any point. The moduli space of monopoles framed at x, of mass μ and charge m, is the quotient

$$\mathcal{M}(x, O_\mu, [\phi] = m) = \mathcal{C}(O_\mu, [\phi] = m)/\mathcal{G}(x),$$

where

$$\mathcal{G}(x) = \{g \in \mathcal{G}: g(x) = 1\}.$$

In Ref. 15 Jarvis proved the following:

Theorem 2.1: *There is a natural bijection*

$$r_x : \mathcal{M}(x, O_\mu, [\phi] = m) \to \mathcal{R}(O_\mu, m)$$

where the set on the RHS is the space of all holomorphic maps $v: S^2 \to O_\mu$, *with* $[v] = m$.

In defining $\mathcal{R}(O_\mu, m)$ recall from Sec. II A that O_μ is in a natural way a complex manifold. It is known[6] that $\mathcal{R}(O_\mu, m)$ is a finite-dimensional smooth manifold, often referred to as a space of rational maps. It follows that our framed moduli space can be identified with a smooth manifold. It should be the case that r_x is naturally a diffeomorphism, but to prove that one would have to equip $\mathcal{M}(x, O_\mu, [\phi]=m)$ with a smooth structure. Although this should be possible, we are not aware of a detailed treatment of this issue.

E. Framing at infinity and parallel scattering

To frame monopoles "at infinity" we pick a point $u \in S^2$, viewed as the sphere at infinity in $\mathbb{R}^3$. Returning to BC1, we define

$$\mathcal{C}(u, \mu, [\phi]=m) = \{(A,\Phi) \in \mathcal{C}: \lim_{t\to\infty} \Phi(tu) = \mu, [\phi]=m\}$$

and

$$\mathcal{C}(u, \mu, k) = \{(A,\Phi) \in \mathcal{C}: \Phi(tu) = \mu - k/2t + o(t^{-1})\}$$

and introduce the corresponding gauge group

$$\mathcal{G}(u) = \{g \in \mathcal{G}: \lim_{t\to\infty} g(tu) = 1\}.$$

The corresponding moduli spaces are

$$\mathcal{M}(u, \mu, [\phi]=m) = \mathcal{C}(u, \mu, [\phi]=m)/\mathcal{G}(u) \quad \text{and} \quad \mathcal{M}(\mu, k) = \mathcal{C}(u, \mu, k)/\mathcal{G}(u).$$

The first of these is called the moduli space of (framed) monopoles with mass μ and degree m. The second is called the moduli space of (framed) monopoles of type (μ, k).

These can also be identified with spaces of rational maps:

Theorem 2.2: *(a) There is a natural bijection* $r_u : \mathcal{M}(u, \mu, m) \to \tilde{\mathcal{R}}(O_\mu, m)$. *(b) There is a natural bijection* $\hat{r}_u : \mathcal{M}(u, \mu, k) \to \tilde{\mathcal{R}}(O_{\mu k}, m)$.

Here $\tilde{\mathcal{R}}(O_\mu, m) \subset \mathcal{R}(O_\mu, m)$ is the set of *based* rational maps, that is, those which send $u \in S^2$ to μ. In part (b),

$$O_{\mu k} = G/H_{\mu k} = G^c/P_{\mu k}, \quad \text{where} \quad H_{\mu k} = C(\mu) \cap C(k), \tag{2.3}$$

and $P_{\mu k}$ is the corresponding parabolic subgroup.

Part (a) of this result was proved first by Donaldson[8] for $G = \mathrm{SU}(2)$, then by Hurtubise[11] for classical groups by a generalization of Donaldson's approach. Both parts were proved for general G by Jarvis[13,14] using parallel scattering to associate a rational map to a monopole, and nonlinear analysis to invert this procedure.

We note in passing that Jarvis shows that the restriction of r_u to $\mathcal{M}(u, \mu, k)$ is the composition of $\hat{r}_u$ with the projection $\tilde{\mathcal{R}}(O_{\mu k}, m) \to \tilde{\mathcal{R}}(G^c/P, m)$.

Once again, it is not clear that smooth structures have been defined on these framed moduli spaces. One conjectures that natural smooth structures should exist, such that these bijections are diffeomorphisms.

As we indicated in the Introduction, it is the moduli spaces $\mathcal{M}(u, \mu, k)$ that have dimensions divisible by 4 and which are therefore candidates to be hyper-Kähler spaces. In Proposition 6.2 the dimension of $\tilde{\mathcal{R}}(O_{\mu k}, m)$ will be explicitly computed.

F. Discussion

Let $x(t) = ut$, and consider the bijection $r_{x(t)}$, for t large, of Theorem 2.1. It is tempting to believe that this should approach the map r_u of Theorem 2.2. However, they cannot be compared

directly since they have different targets. But we could divide both sides by the appropriate groups to get bijections

$$\tilde{r}_u : \mathcal{M}(O,[\phi]=m) \to \tilde{\mathcal{R}}(O_\mu, m)/C(\mu) \quad \text{and} \quad \tilde{r}_{x(t)} : \mathcal{M}(O_\mu,[\phi]=m) \to \mathcal{R}(O_\mu, m)/G$$

and then compare them via the natural isomorphism induced by the inclusion of based maps into unbased maps. A straightforward calculation shows that the limit of $\tilde{r}_{tu}(A,\Phi)$ typically does not exist because evaluated in coordinates it blows up. Some kind of renormalization or scaling must be required to find the relationship between the limit of $\tilde{r}_{x(t)}$ and $\tilde{r}_u$.

III. THE L^2 METRIC

Formally, a tangent vector to (A,Φ) in $\mathcal{C}$ is a pair $(\dot{A},\dot{\Phi})$ satisfying the linearization at (A,Φ) of the Bogomolny equations. The L^2 metric gives this vector length-squared equal to

$$\int_{\mathbb{R}^3} (|\dot{A}|^2 + |\dot{\Phi}|^2) \mathrm{d}x; \tag{3.1}$$

due to the noncompactness of $\mathbb{R}^3$, this need not converge. Looking back at BC1 and BC2, it is clear that (3.1) cannot converge if the variation $\dot{\Phi}$ changes μ or k in BC1. It is natural, therefore, to focus on $\mathcal{M}(u,\mu,k)$ as the obvious candidate to carry a hyper-Kähler metric. Our first task is to show that if the Bogomolny equations hold asymptotically, then the pair (μ,k) determines the leading asymptotics of the monopole on the whole of the two-sphere at infinity.

We begin by noting that the boundary conditions imply that the connection A restricts to give a connection a on E_∞ and that BC1 gives

$$\Phi(tz) = \phi(z) - \frac{f(z)}{2t} + o(t^{-1}), \tag{3.2}$$

where ϕ and f are smooth functions of $z \in S^2$ and the framing condition is

$$\phi(u) = \mu, \qquad f(u) = k. \tag{3.3}$$

The Bogomolny equations reduce to

$$\nabla f = 0, \quad \nabla \phi = 0, \quad F_a = \frac{f}{2} \mathrm{dvol}, \tag{3.4}$$

where dvol denotes the standard area-form of the unit two-sphere. A pair (ϕ,f) satisfying (3.3) and (3.4) are called *monopole boundary data*.

We now prove that, up to gauge, the pair (ϕ,f) is completely determined by its value $(\mu,k/2)$ at the base-point u.

Proposition 3.1: Let (ϕ,f) and (ϕ',f') be boundary data for a monopole:

(i) If u and v are in S^2, then there is a $g \in G$ such that $\phi(u) = \mathrm{ad}(g)(\phi(v))$ and $f(u) = \mathrm{ad}(g)(f(v))$.

(ii) If there is an $h \in G$ such that $\phi(u) = \mathrm{ad}(h)(\phi'(u))$ and $f(u) = \mathrm{ad}(h)(f'(u))$, then there is a $g : S^2 \to G$ such that $\phi^g = \phi'$ and $f^g = f'$.

Proof: If $\phi = 0$, this is a trivial case of the results of Ref. 1 classifying equivalence classes or Yang–Mills connections over a Riemann surface. We follow the proof in Ref. 1. Recall that $E_\infty \to S^2$ is a principal G-bundle. Then ϕ and f can be viewed as equivariant maps $E_\infty \to \mathfrak{g}$. Fix a point $p_0 \in E_\infty$ and let $\phi(p_0) = \mu$ and $f(p_0) = k$. Because ϕ and f are covariantly constant they are constant along any horizontal path. If $p \in P$, we can join p_0 to some point pg with a horizontal curve and then $\phi(p) = \mathrm{ad}(g)(\mu)$ and $f(p) = \mathrm{ad}(g)(k)$ as required.

From the discussion in the preceding paragraph it follows that we have a map

$$(\phi,f):E_\infty\to O_{\mu k}=G/H_{\mu k},\quad H_{\mu k}=C(\mu)\cap C(k).$$

Here $O_{\mu k}$ is the orbit of (μ,k). The preimage of the coset $H_{\mu k}$, i.e., the set of all points p in E_∞ at which $\phi(p)=\mu$ and $f(p)=k$, is a reduction of E_∞ to $H_{\mu k}$ which we denote by $E_{\mu k}$. If $p\in E_{\mu k}$, then any horizontal curve is also in $E_{\mu k}$ because ϕ and k are constant along horizontal curves so the connection also reduces to $P_{\mu k}$.

Because S^2 is simply connected, standard results on reduction of bundles to their holonomy subgroups can be used.[16] It follows from the Ambrose–Singer theorem that the holonomy subgroup at p_0 is the subgroup $H\subset H_{\mu k}$ obtained by exponentiating k and that $E_{\mu k}$ reduces to a bundle E_0 with structure group H.

For the final point we need to know that k is an integral element of the Lie algebra. This is done in Ref. 9 and in a different fashion in Ref. 13. We proceed as follows. Because $[\mu,k]=0$ the closure of the subgroup generated by $\exp(t\mu+sk)$ for any t and s will be an Abelian subgroup of G so a torus and hence inside a maximal torus containing H. If λ is any weight of this maximal torus, we can form an associated line bundle which will have integer chern class $\lambda(k)$. It follows that k is an integer element of $\mathfrak{g}$ and that it exponentiates to define a circle subgroup and a homomorphism $\chi:U(1)\to G$.

We have now reduced our original bundle to a subbundle $Q\to S^2$ which is a circle bundle. It has a connection A and a curvature F with $*F=k/2$ a constant so that it is a circle bundle of degree 1. If A' is another connection with curvature $F'=F$, then $A-A'=a$ with $da=0$ so $a=d(\exp(g))$ for $g:S^2\to \mathrm{U}(1)$ and hence the connections A and A' are equal after a gauge transformation.

This gives us a method of constructing the original bundle, connection and Higgs field from the data μ and k. First take the standard U(1) bundle $Q\to S^2$ with its SU(2) invariant connection and fix $q_0\in Q$ in the fiber over the point u. Let $\chi:\mathrm{U}(1)\to G_{\mu k}\subset G$ be the homomorphism defined by exponentiating k. We can then form $Q\times_\chi G$, the associated bundle, using the action $(q,k)z=(qz,\chi(z)^{-1}k)$ for $z\in\mathrm{U}(1)$. This inherits a connection and the Higgs field is defined by $\hat{\phi}([q,k])=\mathrm{ad}(k)(\mu)$. □

Let $\mathcal{C}^\infty$ denote the set of all monopole boundary data (ϕ,f) and let $\mathcal{G}^\infty$ be the space of all gauge transformations at infinity, that is maps $g:S^2\to G$. Define the *moduli space of boundary data* to be the quotient $\mathcal{M}^\infty=\mathcal{C}^\infty/\mathcal{G}^\infty$. We have the boundary map

$$\partial:\mathcal{M}\to\mathcal{M}^\infty, \tag{3.5}$$

which sends (A,Φ) to the value of the Higgs field and curvature at infinity. Our reason for introducing the boundary map is that we believe that the methods of Atiyah and Hitchin[2] can be adapted to show that

Conjecture 3.2: If $\partial(A,\Phi)=\partial(A',\Phi')$, then there is a gauge transformation g such that A^g-A' and $\Phi^g-\Phi'$ are L^2.

The idea here is that if the condition holds, then for some gauge transformation g, Φ^g and Φ' should agree up to order $1/r$, so that $\Phi^g-\Phi'$ will be square integrable. Similar considerations should apply to the difference between the connections.

Let $\mathcal{G}^\infty(u)$ be all gauge transformations which are the identity at u and let $\mathcal{C}^\infty(u,\mu,m)$ be all pairs (ϕ,f) with $\phi(u)=\mu$ and $[\phi]=m$. Denote $\mathcal{M}^\infty(u,\mu,m)=\mathcal{C}^\infty(u,\mu,m)/\mathcal{G}^\infty(u)$. We have the commuting diagram

$$\begin{array}{ccc}\mathcal{M}(u,\mu,m) & \to & \mathcal{M}^\infty(u,\mu,m)\\ \downarrow & & \downarrow\\ \mathcal{M}(O,m) & \to & \mathcal{M}^\infty(O,m)\end{array}$$

where both vertical maps are quotienting by the group $C(\mu)$.

Conjecture 3.2 would imply that the L^2 metric is finite on each of the moduli spaces $\mathcal{M}(u,\mu,k)$ of monopoles of type (μ,k). This suggests the following.

Conjecture 3.3: The spaces $\mathcal{M}(u,\mu,k)$ are hyper-Kähler manifolds.

A natural approach to these conjectures is the analysis of the linearization $\mathcal{D}$ at $(A,\Phi) \in \mathcal{M}(u,\mu,k)$ of (1.1). Combined with the Coulomb gauge-fixing condition, $\mathcal{D}$ becomes a coupled Dirac operator on $\mathbb{R}^3$,

$$\mathcal{D}: C^\infty(\mathbb{R}^3, \mathbb{H}\otimes\mathbb{H}\otimes \mathrm{ad}(E)) \to C^\infty(\mathbb{R}^3, \mathbb{H}\otimes\mathbb{H}\otimes \mathrm{ad}(E)),$$

where $\mathbb{H}$ is regarded as the spin-bundle of $\mathbb{R}^3$. Unfortunately this operator is not "invertible at infinity" and so it is not automatically a Fredholm operator in L^2. Taubes analyzed it in detail when $G=\mathrm{SU}(2)$, but in general, rigorous results about this operator are not available. Nonetheless, it should be possible to find a suitable space of functions such that $\mathcal{D}$ becomes a Fredholm operator, with index calculable in terms of the type data (μ,k). Formally $\mathcal{D}$ is quaternionic, so its L^2 null space will automatically be a quaternionic vector space with compatible inner product. The reader is referred to Ref. 2, Chaps. 3 and 4, for a detailed discussion of the case $G=\mathrm{SU}(2)$.

A. Group actions

Consider $\mathcal{E}$, the group of Euclidean transformations of $\mathbb{R}^3$, which is the semi-direct product of SO(3), the group of rotations and $\mathbb{R}^3$ the group of translations. As the monopole bundle $E\to\mathbb{R}^3$ is trivial the group $\mathcal{E}$ acts on the connection and Higgs field, preserves the Bogomolny equations and commutes with gauge transformations so it acts on the full-unframed moduli space. In general this action disturbs the framings. If $x\in\mathbb{R}^3$, then the subgroup $\mathcal{E}_x$ of transformations preserving x, which is isomorphic to SO(3), acts naturally on the moduli space of monopoles framed at x. If $u\in S^2$, then the subgroup of $\mathcal{E}_u$ of transformations preserving the line through u, which is isomorphic to $\mathrm{SO}(2)\times\mathbb{R}^2$, will act naturally on the moduli space of monopoles framed at u.

As well as these straightforward actions the moduli space $\mathcal{M}(u,\mu,k)$ also carries an action of the full group of Euclidean transformations. For this we need a different description of this moduli space (cf. Ref. 2, pp. 15 and 16). Note that Proposition 3.1 shows that k defines a representation of the circle in G, hence an associated G-bundle over the two-sphere. This carries a natural SO(3)-action and has a unique SO(3)-equivariant connection a and Higgs field ϕ such that $\phi(u)=\mu$ and $f(u)=k$. The moduli space $\mathcal{M}(\mu,k)$ is now defined to consist of configurations (A,Φ,q) where (A,ϕ) is a monopole and q is an isomorphism between $\partial(A,\Phi)$ and (ϕ,f), modulo the group of gauge transformations that approach the identity at infinity. Then $\mathcal{M}(\mu,k)$ has a natural SO(3)-action and can be shown to be diffeomorphic to $\mathcal{M}(u,\mu,k)$. The subtlety is [as in the case $G=\mathrm{SU}(2)$] that the diffeomorphism between $\mathcal{M}(\mu,k)$ and $\mathcal{M}(u,\mu,k)$ is not equivariant with respect to the copy of $\mathrm{SO}(2)\subset\mathrm{SO}(3)$ which fixes the direction u.

B. Discussion

Assuming that the L^2 metric does define a genuine hyper-Kähler metric on $\mathcal{M}(u,\mu,k)$, there are many interesting open questions surrounding it. First of all, there is the issue of whether it is complete for all μ and k. Second, there are questions relating to variation of the parameters μ and k. It is natural to conjecture that the metrics will vary smoothly with μ as long as the corresponding orbit O_μ does not jump. An interesting conjecture of Lee, Weinberg, and Yi[18] suggests that these hyper-Kähler metrics should also behave well with respect to specialization of μ. To state the conjecture, call a path $\mu:[0,\delta]\to\mathfrak{g}$ a *regular* deformation of $\mu_0=\mu(0)$ if $\mu(t)$ is *regular* for all $t>0$. Let $\mathcal{M}_t=\mathcal{M}(u,\mu_t,k)$, and let g_t be the L^2 metric on $\mathcal{M}_t$.

Conjecture 3.4: Given any $0\neq\mu_0\in\mathfrak{g}$, there is a regular deformation μ_t, such that $(\mathcal{M}_t,g_t)$ tends to $(\mathcal{M}_0,g_0)$ as $t\to 0$.

Note that Jarvis[13] describes a "filling-out procedure" which associates to any holomorphic map $v:S^2\to O_{\mu,k}$ a new map $\tilde{v}:S^2\to G/T$ where T is a maximal torus. This would appear to be closely related to the idea of regular deformation of a general element μ, but it says nothing about the behavior of the metrics.

We have now filled in the details of our account in the Introduction up to Eq. (1.4), though we have not yet shown that $\mathcal{K}$ has the structure claimed in (1.3). We turn to that in the next section.

IV. MAGNETIC AND HOLOMORPHIC CHARGES

We will now show how to calculate explicitly the *magnetic charges* of a monopole which determine the homotopy class m and the *holomorphic charges* which determine the strata. We will also make some conjectures about the possible values these can take.

In this section, μ and k are as before. In addition, T is a maximal torus whose Lie algebra $\mathfrak{t}$ contains both μ and k. Recall that a choice of Weyl chamber C in $\mathfrak{t}$ gives rise to a set of simple roots $\alpha_1,\ldots,\alpha_r$ and the corresponding fundamental weights $\lambda_1,\ldots,\lambda_r$ defined by

$$2\frac{\langle\alpha_i,\lambda_j\rangle}{\langle\alpha_i,\alpha_i\rangle}=\delta_{ij}. \tag{4.1}$$

We can always choose a fundamental Weyl chamber C satisfying

$$\alpha_1(\mu)>0,\ldots,\alpha_s(\mu)>0, \text{ and } \alpha_{s+1}(\mu)=0,\ldots,\alpha_r(\mu)=0, \tag{4.2}$$

because this is just the condition that μ is in the closure of C and a particular ordering of the simple roots.

We would like to apply the corresponding fundamental weights to k but this is not possible as we only know that k is in the Lie algebra of the centralizer of μ. We can conjugate k by $C(\mu)$ until it is inside the torus but then we find that $\mathfrak{t}\cap C(\mu)k$ is not a single point but an orbit under $\mathcal{W}_\mu$ the subgroup of the Weyl group stabilising μ. Our first result resolves this problem by showing that we can pick out a unique element $\tilde{k}$ of $\mathfrak{t}\cap C(\mu)k$.

Proposition 4.1: Suppose that the moduli space $\mathcal{M}(u,\mu,k)$ is nonempty and we have fixed a maximal torus containing μ, a fundamental Weyl chamber C with μ in its closure and have ordered the simple roots so they satisfy (4.2). Then there exists a uniquely determined $\tilde{k}\in\mathfrak{t}\cap C(\mu)k$, such that

$$\alpha_{s+1}(\tilde{k})\leqslant 0,\ldots,\alpha_r(\tilde{k})\leqslant 0.$$

Moreover, we have $\lambda_j(\tilde{k})\geqslant 0$ for $j=1,\ldots,r$.

We shall give the proof of this proposition in a moment. For now, we shall use it to define the *charges* of the monopole to be the non-negative integers

$$\lambda_1(\tilde{k}),\ldots,\lambda_r(\tilde{k}).$$

They are naturally divided into *magnetic charges*

$$m_1=\lambda_1(\tilde{k}),\ldots,m_s=\lambda_s(\tilde{k})$$

and the *holomorphic charges*:

$$h_1=\lambda_{s+1}(\tilde{k}),\ldots,h_{r-s}=\lambda_r(\tilde{k}).$$

In some examples the simple roots have a natural ordering and it is convenient not to reorder them. In that case we just choose $\tilde{k}$ to be the unique $\tilde{k}\in\mathfrak{t}\cap C(\mu)k$ such that whenever $\alpha_i(\mu)=0$ we have $\alpha_i(\tilde{k})\leqslant 0$. We then say that $\lambda_i(\tilde{k})$ is a magnetic charge if $\alpha_i(\mu)>0$ and a holomorphic charge if $\alpha_i(\mu)=0$.

The most important point to be made here is that it is easy to show that $\pi_2(O_\mu)=\mathbb{Z}^s$ and the magnetic charges determine the homotopy class of ϕ the Higgs field at infinity (see, for example,

Ref. 3). The magnetic charges therefore cannot change under continuous deformation of a monopole. By contrast, the holomorphic charges can jump under continuous deformation of the monopole.

Note that the strata in the moduli space are all those monopoles with the same $\tilde{k}$.

As well as being non-negative the holomorphic charges satisfy the additional constraint that $\alpha_i(\tilde{k}) \leqslant 0$ for all $i = s+1, \ldots, r$. This is equivalent to

$$\sum_{l=1}^{r-s} \frac{2\langle \alpha_i, \alpha_{l+s} \rangle}{\langle \alpha_{l+s}, \alpha_{l+s} \rangle} h_l + \sum_{j=1}^{s} \frac{2\langle \alpha_i, \alpha_j \rangle}{\langle \alpha_j, \alpha_j \rangle} m_j \leqslant 0, \quad \text{for} \quad i = s+1, \ldots, r. \tag{4.3}$$

We conjecture the following.

Conjecture 4.2: For a given μ there are monopoles with any collection of non-negative magnetic charges $(m_1, \ldots, m_s)$. Given a choice of magnetic charges there are monopoles with any collection of holomorphic charges $(h_1, \ldots, h_{r-s})$ satisfying (4.3).

It should be possible to prove this result using rational maps but it has eluded us. We can prove, however, the following.

Proposition 4.3: For a given μ and choice of magnetic charges there are at most a finite number of possible holomorphic charges satisfying (4.3).

We defer the proof to the next section but note that this gives the following.

Corollary 4.4: There are only a finite number of strata and in particular there must be an open stratum.

Note that this approach gives a nice picture in terms of Dynkin diagrams. For maximal symmetry-breaking, all charges are magnetic (i.e., topological) and the heuristic is that there are m_i fundamental monopoles of type i for each i a node on the Dynkin diagram. For nonmaximal symmetry breaking mark each node i with $\alpha_i(\mu) = 0$. Now each Dynkin node still has associated to it the non-negative integer $\lambda_i(\tilde{k})$. This number is a magnetic charge m_i if i is unmarked, and again the heuristic is that there are m_i fundamental monopoles of type i. If i is a marked node, then $\lambda_i(\tilde{k})$ is a holomorphic charge. This labels the strata and can jump under continuous deformation of the monopole. The possible holomorphic charges are constrained by inequalities which can be deduced from the Dynkin diagram and (4.3).

A. Proof of Proposition 4.1

Let $\mathcal{W}_\mu$ be the subgroup of the Weyl group fixing μ and note that it acts transitively on the set of all fundamental Weyl chambers with μ in their closure.[10]

To prove first that a $\tilde{k}$ exists we follow Jarvis[13] and consider the condition $\alpha(\mu - tk') > 0$ for large enough t and any $k' \in \mathfrak{t} \cap C(\mu)k$. As there are only a finite number of roots we can find an $\epsilon > 0$ such that for all $t \in (0, \epsilon]$ we have that $\alpha(\mu - tk') = 0$ if and only if $\alpha(\mu) = 0$ and $\alpha(k') = 0$ and $\alpha(\mu - tk') > 0$ implies $\alpha(k') = 0$ and $\alpha(k') < 0$. For any such t choose a fundamental Weyl chamber with $\mu - tk'$ in its closure. As $t \to 0$ we see that this has μ in its closure as well. If this is not the fundamental Weyl chamber we first thought of we can move it by $\sigma \in \mathcal{W}_\mu$ until it is and then let $\tilde{k} = \sigma(k')$. Then $\mu - t\tilde{k}$ is in the closure of our fundamental Weyl chamber so that $\alpha_i(\mu) > 0$ for $i = 1, \ldots, s$ and $\alpha_j(\mu) = 0$ and $\alpha_j(\tilde{k}) \leqslant 0$ for $j = s+1, \ldots, r$.

We will see in a moment that $\tilde{k}$ is unique but for now we show that $\lambda_i(\tilde{k}) \geqslant 0$ for all $i = 1, \ldots, r$.

Consideration of the twistor construction for monopoles shows that ϕ and f satisfy the following non-negativity constraint for any direction u. Choose any maximal torus T so that $\phi(u), f(u) \in \mathfrak{t}$. Choose a fundamental Weyl chamber whose closure contains $\phi(u)$ and let $\alpha_1, \ldots, \alpha_r$ be the corresponding simple roots. Define the fundamental weights $\lambda_1, \ldots, \lambda_r$ by (4.1). Then

$$\lambda_i(f(z)) \geqslant 0 \quad \text{for all} \quad i = 1, \ldots, r$$

independent of all the choices made. Note that $\tilde{k}$ is a conjugate of k under an element of $C(\mu)$ and hence corresponds to the k for some different monopole which also satisfies the positivity constraint. Hence we must have $\lambda_i(\tilde{k}) \geqslant 0$ for all $i=1,\ldots,r$.

Consider lastly the uniqueness of $\tilde{k}$. So assume we have $\tilde{k}$ and $\sigma(\tilde{k})$ for $\sigma \in \mathcal{W}_\phi$ and $\alpha_j(\tilde{k}) \leqslant 0$ and $\alpha_j(\sigma(\tilde{k})) \leqslant 0$ for every $i=s+1,\ldots,r$. Let V be the span of the roots $\alpha_{s+1},\ldots,\alpha_r$. This is a root system with Weyl group $\mathcal{W}_\mu$. Let C_{ij} be the inverse of the matrix $D_{ij}=\langle \alpha_i, \alpha_j \rangle$. Then both C and D are symmetric. Define

$$\chi: \mathfrak{t} \to V$$

by

$$\chi(h) = \sum_{j,k=s+1}^{r} \alpha_j(h) C_{jk} \alpha_k .$$

Let σ_l be a simple root reflection for $s+1 \leqslant l \leqslant r$. Then

$$\begin{aligned}
\chi(\sigma_l(h)) &= \sum_{j,k=s+1}^{r} \sigma_l(\alpha_j)(h) C_{jk} \alpha_k \\
&= \chi(h) - \sum_{j,k=s+1}^{r} \frac{2\langle \alpha_j, \alpha_l \rangle}{\langle \alpha_l, \alpha_l \rangle} C_{jk} \alpha_k(h) \\
&= \chi(h) - \frac{2\alpha_l(h)}{\langle \alpha_l, \alpha_l \rangle} \alpha_l .
\end{aligned}$$

Moreover,

$$\begin{aligned}
\sigma_l(\chi(h)) &= \chi(h) - \frac{2\langle \chi(h), \alpha_l \rangle}{\langle \alpha_l, \alpha_l \rangle} \\
&= \chi(h) - \sum_{j,k=s+1}^{r} \alpha_j(h) C_{jk} \frac{2\langle \alpha_k, \alpha_l \rangle}{\langle \alpha_l, \alpha_l \rangle} \\
&= \chi(h) - \frac{2\alpha_l(h)}{\langle \alpha_l, \alpha_l \rangle} \alpha_l \\
&= \chi(\sigma_l(h)).
\end{aligned}$$

It follows that if $\sigma \in \mathcal{W}_\mu$, then $\chi(\sigma(\tilde{k})) = \sigma(\chi(\tilde{k}))$. We also have $\langle \alpha_l, \chi(h) \rangle = \alpha_l(h)$ so that $\chi(\tilde{k})$ and $\chi(\sigma(\tilde{k}))$ are in the closure of the same Weyl chamber in V. Applying Humphreys' 10.3 Lemma B[10] we see that $\chi(\sigma(\tilde{k})) = \sigma(\chi(\tilde{k})) = \chi(\tilde{k})$ and hence $\alpha_i(\tilde{k} - \sigma(\tilde{k})) = 0$ for $i = s+1,\ldots,r$. We have previously seen that $\lambda_i(\tilde{k} - \sigma(\tilde{k})) = 0$ for $i=1,\ldots,s$. Moreover, the span of the $\lambda_1,\ldots,\lambda_s$ is orthogonal to the span of the $\alpha_{s+1},\ldots,\alpha_r$, so together they must span $\mathfrak{t}^*$ and hence $\tilde{k} = \sigma(\tilde{k})$.

B. Proof of Proposition 4.3

Let ϵ be the sum of all the positive roots which are in the span of the simple roots $\alpha_{s+1},\ldots,\alpha_r$. Notice that $\epsilon(\tilde{k}) \leqslant 0$. Recall[10] that a simple root reflection σ_i permutes all the positive roots except α_i which it sends to $-\alpha_i$. So if $s+1 \leqslant i \leqslant r$, we have $\sigma_i(\epsilon) = \epsilon - 2\alpha_i$ so that

$$2\frac{\langle \epsilon, \alpha_i \rangle}{\langle \alpha_i, \alpha_i \rangle} = 2.$$

So we have

$$\epsilon = \sum_{j=1}^{r} 2\frac{\langle \epsilon, \alpha_i \rangle}{\langle \alpha_i, \alpha_i \rangle}\lambda_i = \sum_{j=1}^{s} 2\frac{\langle \epsilon, \alpha_i \rangle}{\langle \alpha_i, \alpha_i \rangle}\lambda_i + \sum_{i=s+1}^{r} 2\lambda_i = \sum_{j=1}^{s} -p_j\lambda_j + \sum_{i=s+1}^{r} 2\lambda_i,$$

where $p_j \geqslant 0$ because if $1 \leqslant j \leqslant s$ we have $\langle \epsilon, \alpha_j \rangle \leqslant 0$. Applying ϵ to $\tilde{k}$ gives

$$0 \leqslant \sum_{i=1}^{r-s} h_i \leqslant \sum_{j=1}^{s} p_j m_j$$

and, as each h_j is non-negative, this means there can only be a finite number of possibilities.

V. EXAMPLES

Let $G = \mathrm{SU}(N)$ and μ be a diagonal matrix with eigenvalues $i\mu_1, i\mu_2, \ldots, i\mu_q$ with multiplicities $n_1, \ldots, n_q$ and assume that $\mu_1 > \mu_2 > \cdots > \mu_q$. Choose the usual fundamental Weyl chamber. That is, if d is any diagonal matrix with entries $id_1, \ldots, id_N$, then it is in the fundamental Weyl chamber if $d_1 > d_2 > \cdots > d_N$. Clearly this has μ in its closure. Define $x_j(d) = d_j$. Then the simple roots are $\alpha_i = x_{i+1} - x_i$ for $i = 1, \ldots, N-1$. The fundamental weights satisfy

$$\lambda_j(d) = d_1 + \cdots + d_j$$

and a weight is magnetic if $j = n_1, n_2, \ldots, n_{q-1}$ and holomorphic otherwise.

Let $\mathbb{C}^N = \mathbb{C}^{n_1} \oplus \cdots \oplus \mathbb{C}^{n_q}$ be the corresponding eigenvalue decomposition of $\mathbb{C}^N$. Assume that on $\mathbb{C}^{n_j}$ the eigenvalues of k are

$$k_{n_1+\cdots+n_{j-1}+1} \leqslant k_{n_1+\cdots+n_{j-1}+2} \leqslant \cdots \leqslant k_{n_1+\cdots+n_j}.$$

Then $\tilde{k}$ is the diagonal matrix with entries $ik_1, \ldots, ik_N$.

Let $\mathcal{M}_j$ be the stratum containing $\mathcal{M}(u, \mu, k)$. It was shown in Ref. 19 that

$$\dim\ \mathcal{M}_j = 4\sum_{i=1}^{N} (k_1 + \cdots + k_i) + \dim\ C(\mu)k,$$

and hence from the definition of the strata in the Introduction,

$$\dim\ (\mathcal{M}(u, \mu, k)) = 4\sum_{i=1}^{N} (k_1 + \cdots + k_i),$$

so the dimension is divisible by four as required for a hyper-Kähler manifold. In Proposition 6.2 we shall show that this result is always true.

Notice that we could find a deformation μ_t of μ by choosing μ_t to be diagonal with entries $i\mu_j(t)$ such that

$$\mu_1(t) > \mu_2(t) > \mu_3(t) > \cdots > \mu_N(t),$$

and, of course, with $\mu(0) = \mu$. It follows from known results on the moduli spaces[12,20] that $\dim \mathcal{M}(u, \mu_t, k) = \dim \mathcal{M}(u, \mu, k)$. In fact, the method used in Ref. 19 to calculate the dimension formula shows that $\mathcal{M}(u, \mu(t), k))$ and $\mathcal{M}(u, \mu, k)$ are diffeomorphic spaces of holomorphic maps. This result was generalized to arbitrary G by Jarvis.[13]

VI. DIMENSIONS

In this section we compute the dimension of the moduli space $\mathcal{M}(u,\mu,m)$ by computing the dimension of $\tilde{\mathcal{R}}(O_\mu,m)$. We shall also compute the dimensions of the strata and the moduli space $\mathcal{M}(u,\mu,k)$ of monopoles of type (μ,k), by computing the dimension of $\tilde{\mathcal{R}}(O_{\mu k},m)$.

Fix a maximal torus T, a fundamental Weyl chamber and a set of simple roots $\alpha_1,\ldots,\alpha_r$. For a root α let $\mathfrak{g}_\alpha$ be the α root space. Denote by B the standard Borel determined by this choice of simple roots. That is the Lie algebra of B contains the root space of every simple root. The parabolic P is determined by the fact that its Lie algebra $\mathfrak{p}$ contains the root spaces for the negative roots $\alpha_{s+1},\ldots,\alpha_r$.

If $f:S^2\to G^c/P$ is a holomorphic map, then we can use it to pull back the tangent bundle to G^c/P and the Riemann–Roch theorem tell us that

$$\dim(H^0(S^2,f^{-1}(TG^c/P)))-\dim(H^1(S^2,f^{-1}(TG^c/P)))=\dim(G^c/P)+c_1(\det(f^{-1}TG^c/P)),$$

where $\det(TG^c/P)$ is the determinant line bundle of $f^{-1}TG^c/P$ and c_1 denotes the first Chern class. Because the group G acts holomorphically on G^c/P every element of $\mathfrak{g}$ defines a holomorphic vector field on G^c/P so we have a surjection of holomorphic vector bundles over S^2

$$\mathfrak{g}\times S^2\to f^{-1}TG^c/P\to 0$$

and it follows from the short exact sequence in cohomology that

$$\dim(H^1(S^2,f^{-1}(TG^c/P)))=0.$$

The tangent space to $\tilde{\mathcal{R}}(G^c/P,m)$ at the function f is just the subset of sections in $H^0(S^2,f^{-1}(TG^c/P))$ which vanish at the base point, say $P\in G^c/P$. This has *real* dimension

$$\dim\mathcal{R}(G^c/P,m)=2(\dim(H^0(S^2,f^{-1}(TG^c/P)))-\dim(G^c/P))=2c_1(\det(f^{-1}TG^c/P)).$$

Each of the fundamental weights $\lambda_1,\ldots,\lambda_s$ extend to one-dimensional representations of P and hence define homogeneous line bundles $L(\lambda_i)$ over G^c/P. The magnetic charges of a holomorphic map f are $m_i=-c_1(f^{-1}(L(\lambda_i)))$. Choose $\tilde{k}$ so that $m_i=\lambda_i(\tilde{k})$. Then $c_1(f^{-1}(L(-\lambda)))=\lambda(\tilde{k})$ for any weight λ.

Let ϵ be the weight defined by the adjoint representation of P on $\mathfrak{p}$. Then the weight defined by the adjoint representation of P on $\mathfrak{g}/\mathfrak{p}$ is $-\epsilon$. The bundle $\det(T(G^c/P)$ is then a homogeneous bundle over G^c/P induced by the character $-\epsilon$ so that

$$c_1(f^{-1}(\det(TG^c/P)))=c_1(f^{-1}(L(-\epsilon)))=\epsilon(\tilde{k}).$$

Hence

$$\dim\tilde{\mathcal{R}}(G^c/P,m)=2\epsilon(\tilde{k}).$$

In the case of maximal symmetry breaking where the parabolic P is a Borel B

$$\epsilon=\sum_{\alpha>0}\alpha=2\sum_{i=1}^{r}\lambda_i,$$

so that

$$\dim\tilde{\mathcal{R}}(G/B,m)=4\sum_{i=1}^{r}m_i.$$

In the nonmaximal symmetry breaking case we can proceed further. Because ϵ is a weight we know that $\epsilon=\Sigma_{i=1}^{r}-n_i\lambda_i$ for some integers n_i. We also know that ϵ is a character of P so invariant under the simple root reflections σ_i for $i=s+1,\ldots,r$. But $\sigma_j(\epsilon)=\epsilon+n_j\alpha_j$ so that we must have

$$\epsilon=\sum_{i=1}^{s}-n_i\lambda_i$$

and hence

$$\dim\tilde{\mathcal{R}}(G^c/P,m)=2\sum_{i=1}^{s}n_im_i.$$

We can obtain some further information about the n_i. First we note that

$$n_i=-2\frac{\langle\epsilon,\alpha_i\rangle}{\langle\alpha_i,\alpha_i\rangle}.$$

Also, if ρ is one-half the sum of the positive roots and $\rho_{\mathfrak{p}}$ is one-half the sum of the positive roots α for which $\mathfrak{g}_{-\alpha}\subset\mathfrak{p}$, then we have that $\epsilon=-2\rho+2\rho_{\mathfrak{p}}$ and hence

$$n_i=2\frac{\langle 2\rho-2\rho_{\mathfrak{p}},\alpha_i\rangle}{\langle\alpha_i,\alpha_i\rangle}=2\left(1-2\frac{\langle\rho_{\mathfrak{p}},\alpha_i\rangle}{\langle\alpha_i,\alpha_i\rangle}\right)\lambda_i$$

using the standard fact that $\rho=\Sigma_{i=1}^{r}\lambda_i$. Hence

$$\dim(\tilde{\mathcal{R}}(G^c/P,m))=4\sum_{i=1}^{s}\left(1-2\frac{\langle\rho_{\mathfrak{p}},\alpha_i\rangle}{\langle\alpha_i,\alpha_i\rangle}\right)m_i,$$

which agrees with the result in Ref. 20. So we have the following proposition.

Proposition 6.1: The dimension of the moduli space $\mathcal{M}(u,\mu,m)$ is

$$4\sum_{i=1}^{s}\left(1-2\frac{\langle\rho_{\mathfrak{p}},\alpha_i\rangle}{\langle\alpha_i,\alpha_i\rangle}\right)m_i.$$

Notice that while the Lie theory guarantees ρ is a weight, the same may not be true of $\rho_{\mathfrak{p}}$ and hence expressions such as

$$2\frac{\langle\rho_{\mathfrak{p}},\alpha_i\rangle}{\langle\alpha_i,\alpha_i\rangle}$$

may not be integers. This is consistent with the fact that for nonmaximal symmetry breaking the moduli space may not be hyper-Kähler for the simple reason that its dimension is not a multiple of four.

Next we calculate $\dim\tilde{\mathcal{R}}(O_{\mu k},m)$ where $P_{\mu k}$ is the parabolic subgroup containing all the positive roots and the negative roots α where $\alpha(\mu)=\alpha(\tilde{k})=0$ and we let $O_{\mu k}=G^c/P_{\mu k}$. This is the parabolic subgroup occurring in (2.3).

Then ϵ is the sum of all these roots so that

$$\epsilon(\tilde{k})=\sum_{\alpha>0}\alpha(\tilde{k})$$

and we have

$$\dim\tilde{\mathcal{R}}(G^c/P_{\mu k},k)=4\left(\sum_{i=1}^{s} m_i+\sum_{j=1}^{r-s} h_j\right).$$

Hence we deduce the following.

Proposition 6.2: The dimension of the moduli space $\mathcal{M}(u,\mu,k)$ is

$$4\left(\sum_{i=1}^{s} m_i+\sum_{j=1}^{r-s} h_j\right).$$

In particular it is divisible by four.

Similarly for the strata, we have the following Corollary.

Corollary 6.3: The dimension of the stratum $\mathcal{M}_j$ containing $\mathcal{M}(u,\mu,k)$ is

$$4\left(\sum_{i=1}^{s} m_i+\sum_{j=1}^{r-s} h_j\right)+\dim C(\mu)-\dim C(\mu)\cap C(k).$$

The dynamics of n slowly moving fundamental monopoles in the SU($n+1$) BPS Yang–Mills–Higgs theory can be approximated by geodesic motion on the $4n$-dimensional hyperkähler Lee–Weinberg–Yi manifold. In this article we apply a variational method to construct some scaling geodesics on this manifold. These geodesics describe the scattering of n monopoles which lie on the vertices of a bouncing polyhedron; the polyhedron contracts from infinity to a point, representing the spherically symmetric n-monopole, and then expands back out to infinity. For different monopole masses the solutions generalize to form bouncing nested polyhedra. The relevance of these results to the dynamics of well separated SU(2) monopoles is also discussed. © *2003 American Institute of Physics.*

I. INTRODUCTION

The dynamics of slowly moving BPS monopoles can be approximated by geodesic motion on the moduli space of static solutions, with the metric determined by the kinetic part of the Lagrangian.[20,23] For two centered SU(2) monopoles the moduli space is the Atiyah–Hitchin manifold and the simplest geodesic corresponds to the 90° scattering of two monopoles in a head-on collision.[3] Unfortunately, for more than two SU(2) monopoles the moduli space metric is not known explicitly, except in the region where all the monopoles are well separated.[12] Despite this fact some geodesics are known.[13,15,16,24] They are obtained by the imposition of appropriate spatial symmetries to yield a one-dimensional manifold of static solutions, which is then automatically a geodesic, since the fixed point set of a group action is always a totally geodesic submanifold.

For BPS monopoles with gauge group SU($n+1$) and maximal symmetry breaking there are n topological charges and correspondingly n types of fundamental monopole, each of which carries a single unit of one of these charges.[25] If there is precisely one fundamental monopole of each type, then the moduli space is $4n$-dimensional and equipped with the hyperkähler Lee–Weinberg–Yi metric,[18] which is known explicitly. The explicit form of the metric allows the possibility of computing some geodesics and hence n-monopole scattering processes for any value

of n. In this article we apply a variational method to construct some scaling geodesics on this manifold. The approach is to look for central configurations in which the time dependence is only in the form of an overall scaling of the monopole positions. The resulting algebraic equations can then be written as the critical points of a certain energy function,[22] which we minimize using numerical methods. As examples, we find minimal energy configurations, and hence geodesics, for all $n \leqslant 20$. The symmetries of these configurations are analyzed and suggest the existence of icosahedral minima at $n=32$ and $n=72$, which are also constructed. In all cases the associated geodesics describe the scattering of n monopoles which lie on the vertices of a bouncing polyhedron, in the following sense. The polyhedron first contracts from infinity to a point, which in the moduli space represents the spherically symmetric n-monopole. The evolution then reverses with the monopoles located on the vertices of the same polyhedron, but which is now expanding back out to infinity.

For different monopole masses the above solutions generalize to form bouncing nested polyhedra. Our solutions also provide geodesics of the Gibbons–Manton metric,[12] and hence describe the scattering of n SU(2) monopoles, valid in the region where the monopoles are well separated. This reveals a connection with some geodesics obtained earlier using symmetry arguments.

II. POLYHEDRAL SCATTERING

The $4n$-dimensional hyperkähler Lee–Weinberg–Yi manifold is a T^n bundle over a $3n$-dimensional base space. For $i=1,...,n$ let $\theta_i \in S^1$ be the fiber coordinates and $\mathbf{x}_i \in \mathbb{R}^3$ be local coordinates in the base, which may be thought of as the positions in $\mathbb{R}^3$ of each of the n monopoles. The purely kinetic Lagrangian associated with the metric has the form

$$L = g_{ij}\dot{\mathbf{x}}_i \cdot \dot{\mathbf{x}}_j + g_{ij}^{-1}(\dot{\theta}_i + \mathbf{W}_{ik}\cdot\dot{\mathbf{x}}_k)(\dot{\theta}_j + \mathbf{W}_{jl}\cdot\dot{\mathbf{x}}_l)\,, \tag{2.1}$$

where we have used the Einstein summation convention, though this is not to be used in the rest of the article unless explicitly stated. The quantities appearing in the above are given by

$$g_{ii} = m_i + \sum_{j\neq i} \frac{1}{|\mathbf{x}_i - \mathbf{x}_j|}, \tag{2.2}$$

$$g_{ij} = \frac{-1}{|\mathbf{x}_i - \mathbf{x}_j|}, \quad i \neq j, \tag{2.3}$$

$$\mathbf{W}_{ii} = \sum_{j\neq i} \mathbf{w}_{ij}\,, \tag{2.4}$$

$$\mathbf{W}_{ij} = -\mathbf{w}_{ij}\,, \quad i \neq j, \tag{2.5}$$

and $\mathbf{w}_{ij}$ is the value at $\mathbf{x}_i$ of the Dirac potential due to the monopole at $\mathbf{x}_j$, that is,

$$\boldsymbol{\nabla}_j \times \mathbf{w}_{ji} = \frac{\mathbf{x}_i - \mathbf{x}_j}{|\mathbf{x}_i - \mathbf{x}_j|^3}. \tag{2.6}$$

In the above we have scaled out the magnetic charge of a monopole and the positive constants m_i are related to the monopole masses.

The T^n isometry of the metric yields the n conserved charges (here we use the summation convention once more)

$$Q_i = g_{ij}^{-1}(\dot{\theta}_j + \mathbf{W}_{jk}\cdot\dot{\mathbf{x}}_k)\,, \tag{2.7}$$

so that the fiber coordinates are nondynamical degrees of freedom. In this article we shall be concerned with monopoles with no electric charge, so we set $Q_i=0$, for all $i=1,...,n$. In this case the Lagrangian describing the motion in the base space is simply

$$L=\sum_i \left(m_i+\sum_{j\neq i}\frac{1}{x_{ij}}\right)\dot{\mathbf{x}}_i^2-\sum_i\sum_{j\neq i}\frac{1}{x_{ij}}\dot{\mathbf{x}}_i\cdot\dot{\mathbf{x}}_j\,, \tag{2.8}$$

where we have defined $\mathbf{x}_{ij}=\mathbf{x}_i-\mathbf{x}_j$, and $x_{ij}=|\mathbf{x}_{ij}|$. The geodesic equations which follow from (2.8) are

$$m_k\ddot{\mathbf{x}}_k=\sum_{j\neq k}\left(\frac{\ddot{\mathbf{x}}_{jk}}{x_{jk}}+\frac{\mathbf{x}_{jk}|\dot{\mathbf{x}}_{jk}|^2}{2x_{jk}^3}-\frac{\dot{\mathbf{x}}_{jk}\dot{x}_{jk}}{x_{jk}^2}\right). \tag{2.9}$$

As suggested in Ref. 22 we now look for time dependent homothetic solutions of these equations, that is, solutions of the form $\mathbf{x}_k(t)=\alpha(t)\mathbf{y}_k$, with constant $\mathbf{y}_k$. Clearly, such solutions describe monopoles in a fixed configuration, but with the overall scale of the configuration evolving dynamically. Substituting this ansatz into (2.9) yields the equations

$$m_k\mathbf{y}_k+C\sum_{j\neq k}\frac{\mathbf{y}_{jk}}{y_{jk}}=0\,, \tag{2.10}$$

where C is defined to be the quantity

$$C=\frac{\dot{\alpha}^2}{2\ddot{\alpha}\alpha^2}-\frac{1}{\alpha}. \tag{2.11}$$

Obviously, for a nontrivial solution of (2.10) to exist the quantity C must be a constant, and it turns out that only a positive constant produces a physically acceptable solution. By a rescaling of the time variable we may, without loss of generality, set $C=1$. The two constants which appear in the general solution of (2.11) may be absorbed by a linear transformation of t, and the solution we require is given implicitly by

$$t=\sqrt{\alpha+\alpha^2}+\tfrac{1}{2}\log(1+2\alpha+2\sqrt{\alpha+\alpha^2})\,, \tag{2.12}$$

for $t\geqslant 0$. It is clear from (2.12) that the scale $\alpha(t)$ is a monotonically increasing function of t, which for small t has the expansion $\alpha=t^2/4+\cdots$ and for large t has the asymptotic form $\alpha\sim t$.

Note that Eqs. (2.9) are invariant under time reversal $t\mapsto -t$ and also spatial inversion of all the points $\mathbf{x}_k\mapsto-\mathbf{x}_k$. So far we have only addressed the second part of the geodesic motion, when $t\geqslant 0$ and the monopoles are moving away from each other, but the first part with $t<0$ is simply obtained by time reversal in Eq. (2.12), so that the monopoles approach the origin from spatial infinity. Thus the monopoles bounce back off each other, rather than passing through each other, which would have been the result if the time inversion was accompanied by the spatial inversion $\mathbf{x}_k\mapsto-\mathbf{x}_k$. The fact that the first of these scenarios is the correct one can be seen by studying the Lee–Weinberg–Yi manifold in the neighborhood of the origin $\mathbf{x}_k=0$, for all k. Although the metric appears to be singular at the origin, this is merely a coordinate singularity, and if new coordinates are chosen appropriately (these are essentially polar coordinates but with the radial variables related to the monopole positions by $r_k=\sqrt{|\mathbf{x}_k|}$) the metric is seen to be flat in these new coordinates. The fact that the squares of the monopole positions are related to the flat coordinates is the reason that fundamental monopoles of different types bounce back upon collision; had the metric been flat around the origin in the coordinates $\mathbf{x}_k$ then the monopoles would have passed through each other.

The problem of finding scaling geodesics has now been reduced to the algebraic problem of finding sets of n points $\mathbf{y}_k$, which satisfy (2.10) with $C=1$. Our method is to use a variational approach, based on the fact that (2.10) are the equations for critical points of the energy function

$$E=\frac{1}{2}\sum_i m_i|\mathbf{y}_i|^2-\sum_i\sum_{j<i} y_{ij}. \tag{2.13}$$

In this formulation the problem has obvious similarities with the classical problem of finding central configurations[5] (which arise in a similar way when a time dependent homothetic ansatz is used in Newton's equations of motion for gravitating point particles) or equivalently solutions of the one component plasma (OCP) model.[6] The OCP model describes point charges immersed in a uniform background of charge with the opposite sign. Hence there are two competing forces. The first is an attraction towards the origin, represented by exactly the same expression as the first term in (2.13), and repulsion between the points, which in the OCP case is described by the Coulomb energy. The second term in (2.13) plays a similar role in our problem as the Coulomb energy does in the OCP model. The contribution of this nonpositive term produces two-body particle repulsions which can balance the attractive central force, producing stable minimal energy configurations with finite nonzero separations.

In the remainder of this section we shall restrict to the case when all the monopole masses are equal. By rescaling the positions $\mathbf{y}_k$ by the inverse of this common mass we obtain the situation in which all monopole masses are equal to unity, so for the rest of this section we set $m_i=1$ for all $i=1,\ldots,n$.

Although any critical point of the energy (2.13) will provide us with a geodesic on the Lee–Weinberg–Yi manifold we shall concentrate only on local minima, since these are the easiest to find numerically, and ignore any saddle point solutions. Presumably Leech's symmetric configurations,[19] which are sets of particles on a sphere in equilibrium under any force law between pairs of particles, will also yield critical points of (2.13) if the particles are allowed to move off the sphere, but are required to maintain all symmetries of the spherical configuration. Leech's configurations consist of an infinite family of polygons and bipyramids and a finite family with Platonic symmetry.

TABLE I. For $2\leqslant n\leqslant 20$ we list the energy E of the minimizing configuration, its symmetry group G, the distance from the origin of the closest point $r_{\min}$, and the distance from the origin of the furthest point $r_{\max}$.

n	E	G	$r_{\min}$	$r_{\max}$

The numerical scheme employed is a multi-start gradient flow algorithm with randomly distributed initial conditions. The energy function (2.13) has the obvious SO(3) invariance associated with a spatial rotation of all n points, and also reflection symmetries which change the sign of any one of the three Cartesian components of all the points. Up to the action of these symmetry groups, all the minimal energy solutions we find are unique.

The case $n=1$ is trivial; the minimal energy solution is a single point at the origin, with $E=0$, and hence the scaling solution is time independent, so no geodesic is obtained. For two points the minimal energy is $E=-1$ which occurs if $\mathbf{y}_1=-\mathbf{y}_2=(0,0,1)$, or any spatial rotation of this configuration. In other words, the two monopoles are at antipodal points on the unit sphere. The associated geodesic describes the head-on collision of two monopoles, in which the spherically symmetric two-monopole is formed, after which the monopoles bounce back off each other. This scattering process was first described by Connell,[9] who discovered that the metric on the centered moduli space of two different fundamental SU(3) monopoles is Taub-NUT with a positive mass parameter.

In Table I we present, for $2\leqslant n\leqslant 20$, the energy E of the minimizing configuration, its symmetry group G, the distance from the origin of the closest point $r_{\min}$, and the distance from the origin of the furthest point $r_{\max}$.

In the examples in Table I where $r_{\min}$ is equal to $r_{\max}$, to the accuracy presented they are in fact precisely equal, indicating that all the points lie on the surface of a sphere of radius $r_{\min}=r_{\max}$. For all the other cases it can be seen that $r_{\min}$ and $r_{\max}$ are very close in value, showing that all n points lie close to, but not exactly on, a sphere. As we shall see later, this feature appears to persist for arbitrarily large values of n, which contrasts sharply with traditional central configurations with a Coulomb interaction, where this property exists only for $n<13$ and beyond this value there are multiple shells.[5] It is interesting to note that a scale invariant geometric energy function exists which also yields minimal energy configurations on a single shell for all numbers

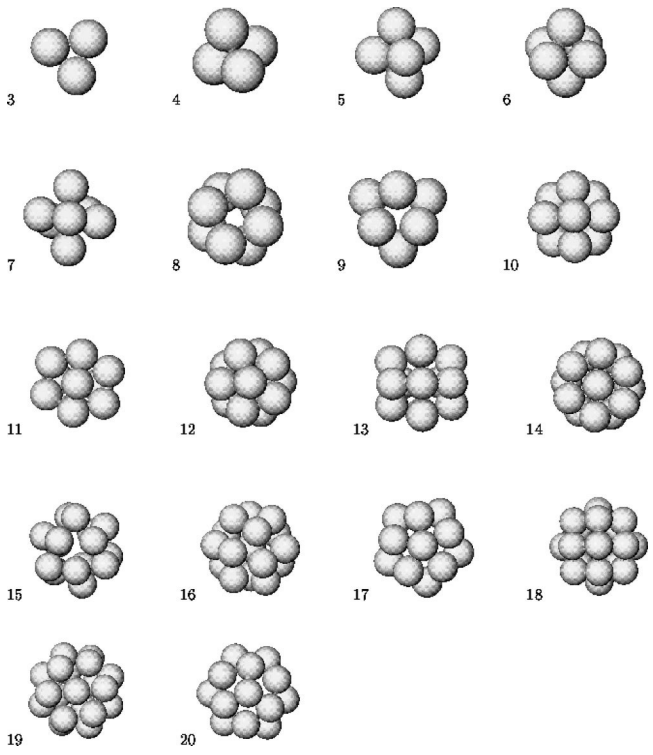

FIG. 1. For $3\leqslant n\leqslant 20$ we display the configurations of n points (not to scale) by plotting spheres around each of the points. In each case the diameter of the spheres is equal to the minimal separation between points, to emphasize the sphere packing behavior.

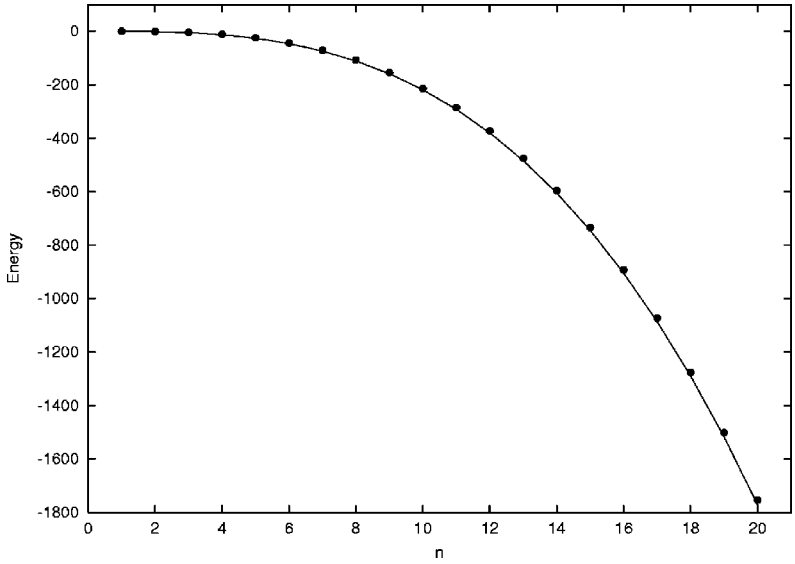

FIG. 2. The energy as a function of n (circles) and the estimate described in the text (curve).

of points.[4] It would be interesting to try and classify the properties of interaction potentials which produce only a single shell.

In Fig. 1 we present, for $3 \leqslant n \leqslant 20$, the minimal energy configurations of n points by plotting spheres around each of the points and in Fig. 2 we plot their energy as a function of n, for $n \leqslant 20$. In each case the diameter of the spheres is equal to the minimal separation between points, to emphasize the sphere packing behavior. As seen from Table I, the size of the configuration (as measured by $r_{\max}$) grows with n, so for clarity we do not display the configurations to scale. Three points lie on the vertices of an equilateral triangle, with edge length equal to 3. For $n > 3$ the points may be considered as forming the vertices of a polyhedron, which generically is a deltahedron, that is, all faces are triangular. For example, four points lie on the vertices of a tetrahedron with edge length equal to 4. For $n = 4,6,8,12$ all points lie exactly on the surface of a sphere, and in fact on the vertices of a tetrahedron, octahedron, square antiprism and icosahedron, respectively.

As can be seen from Table I and Fig. 1 the points are often arranged symmetrically, though the case $n = 7$ is rather anomalous. There is an obvious D_{5h} symmetric candidate for the minimal energy $n = 7$ configuration, in which five points lie on the vertices of a regular pentagon and the two remaining points lie on the fivefold symmetry axis equidistant from the origin. This regular bipyramid is the obvious generalization of the minimal $n = 5$ configuration, which is a bipyramid with a triangular base. However, the minimal energy solution for $n = 7$ is a symmetry breaking perturbation of the bipyramid. There are points at the north and south poles of a sphere of radius 4.5635, and the remaining five points lie in a roughly pentagonal distribution, but all with slightly different heights above or below the equatorial plane and different distances from the origin, which range from 4.4782 to 4.4825. Clearly this prohibits any exact symmetry, even reflection symmetries, so we label the symmetry group as C_1, indicating no point symmetries. As a check it is possible to minimize within the family of D_{5h} symmetric configurations, yielding an energy of $E = -71.0156$, which is indeed slightly higher than the asymmetric minimum with $E = -71.0162$.

To gain insight into minimizing the energy function (2.13) (with $m_k = 1$) it is useful to consider the restricted problem in which all the points are constrained to lie on a sphere of a given radius ρ. The energy of this restricted problem is given by

$$E_\rho = \tfrac{1}{2}\rho^2 n + \rho U, \tag{2.14}$$

where

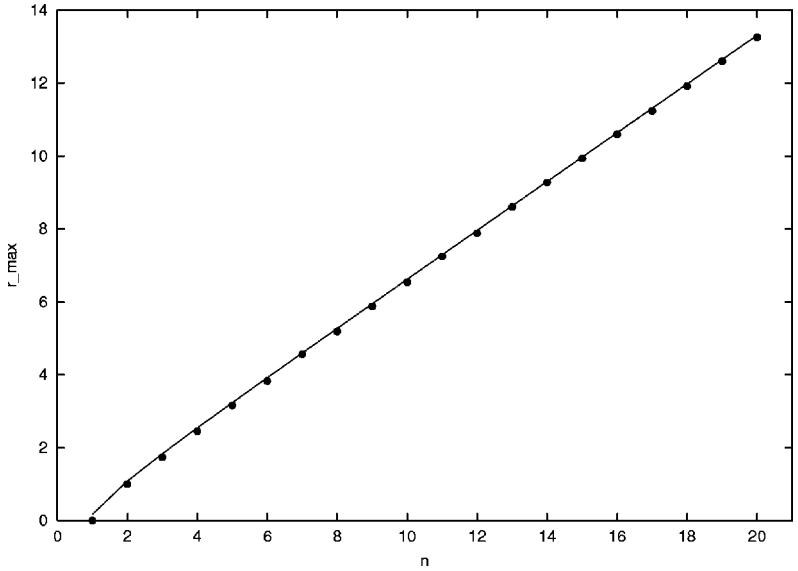

FIG. 3. The size of the configuration $r_{\max}$ as a function of n (circles) and the estimate ρ described in the text (curve).

$$U=-\sum_i \sum_{j<i} |\mathbf{Y_i}-\mathbf{Y_j}|\,, \tag{2.15}$$

for n points $\mathbf{Y_k}=\mathbf{y}_k/\rho$ restricted to lie on the surface of the unit sphere. Minimization of the function U for points on the unit sphere is a problem in discrete geometry which was first posed almost 50 years ago by Fejes Tóth,[11] though it is usually phrased in terms of maximizing the sum of the mutual separations $-U$. There are a number of theorems proved about the extrema of this energy function and in particular there is the lower bound[1]

$$U>\tfrac{1}{2}-\tfrac{2}{3}n^2. \tag{2.16}$$

Using this result in (2.14) we obtain a lower bound for E_ρ which we can then minimize over the radius ρ, finding a minimum value at

$$\rho=\frac{2n}{3}-\frac{1}{2n}, \tag{2.17}$$

to obtain the lower bound

$$E_{\text{sphere}}>-(\tfrac{2}{9}n^3-\tfrac{1}{3}n+\tfrac{1}{8})\,, \tag{2.18}$$

where E_{sphere} denotes the energy (2.13) (with $m_k=1$) under the restriction that all points lie at the same distance from the origin. Clearly when we drop this restriction we have no rigorous lower bound for the unrestricted energy (2.13) which is our main concern, but since our numerical results suggest that in all the minimal energy configurations the points lie very close to the surface of a sphere, then we expect that the quantity in (2.18) will be a good estimate of the minimal energy value, though it will tend to be slightly lower. In Fig. 2 we plot this estimate as the curved line. Clearly the above expectations appear to be realized, in that the estimate is close to the true value, but bounds it from below. In Fig. 3 we compare the estimate (2.17) (curve) for the size of the configuration with the numerical values as measured by $r_{\max}$ (circles). Again it can be seen that the estimate is quite accurate.

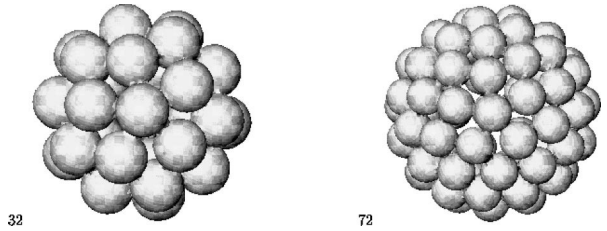

FIG. 4. For $n=32$ and $n=72$ we display the icosahedrally symmetric minimal energy configurations by drawing spheres around the monopoles.

The above discussion suggests that our minimal energy solutions are closely related to those which maximize the sum of the mutual separations for points on a sphere. For $n=2,3,4,8,12$ it is proved that the extremal configurations for this sphere problem are the dipole, triangle, tetrahedron, octahedron and icosahedron, respectively (see Ref. 2 and references therein), which agrees with our results. For $n\leqslant 10$ this problem was investigated numerically by Berman and Hanes[7] and more recently a comprehensive numerical investigation has been performed by Rakhmanov, Saff, and Zhou,[21] who studied all $n\leqslant 200$ and obtained the symmetry groups of the extremal configurations. A comparison of the symmetry groups in Table I with those that appear in Ref. 21 reveals that the groups agree for all cases except $n=7$. (In Ref. 21 the symmetry group for 18 points should read D_{4d} not D_{4h}.) In Ref. 21 the symmetry group for $n=7$ is given as C_2 and in Ref. 7 the configuration is described as two almost antipodal points with the remaining five points sprinkled around an equatorial band. Our configuration for $n=7$ is therefore consistent with a small deformation of the spherical extremal solution, which itself has little symmetry.

For all $1\leqslant n\leqslant 20$ we found only one local minimum of the energy for each value of n, except for $n=16$. For $n=16$ the global minimum with $E=-892.7338$ has tetrahedral symmetry T, but we also found a local minimum with energy $E=-892.7256$ and symmetry D_{4h}. Once again this mirrors the situation in studying extremal problems for points on a sphere.[10]

In order to further investigate the similarites between our solutions and points on the sphere which maximize the sum of the mutual separations we turn our attention to configurations with icosahedral symmetry. For the sphere problem extremal configurations with icosahedral symmetry occur for a sequence of points[21] which begins $n=12,32,72,...$ As we have seen, for $n=12$ our solution has icosahedral symmetry, with the points lying on the vertices of an icosahedron, so it is interesting to compute the minimal energy solutions for $n=32$ and $n=72$, to see if they are icosahedrally symmetric.

In Fig. 4 we display the minimal energy configurations for $n=32$ and $n=72$, using the same method as in Fig. 1. Both configurations contain a single shell and have icosahedral symmetry, as predicted by analogy with the sphere problem. For $n=32$ there are 12 points on the vertices of an icosahedron at a distance of 21.2516 from the origin and a further 20 points at a distance of 21.2680 from the origin. The associated polyhedron is the dual of a truncated icosahedron and the energy is $E=-7233.0539$. For $n=72$ the energy is $E=-82\,780.0335$. There are 12 points at a distance of 47.9338 and 60 points at a distance of 47.9563.

III. DISTINCT MASSES AND SU(2) MONOPOLES

In this section we mention two extensions of the study we have described so far. The first is the obvious generalization to monopoles which are not all of equal mass. As stated earlier, if all monopoles have the same mass, then varying this mass produces the same configuration but scaled by the inverse common mass. Thus, the expectation for sets of distinct masses is that multiple shells will arise, with monopoles grouped into shells according to their mass, so that the heaviest monopoles sit closest to the origin, and with each set of monopoles in a given shell being arranged on the vertices of the polyhedron which arises in the minimization of the relevant number of equal mass monopoles. This nested polyhedron picture is consistent with the numerical results we have

obtained. For example, in the case of two distinct masses and four monopoles of each mass, we set $m_i=1$, for $i=1,..,4$ and $m_i=2$, for $i=5,..,8$; the resulting configuration is that the four heavy monopoles sit on the vertices of a tetrahedron at a distance 1.5940 from the origin and the four light monopoles sit on the vertices of the dual tetrahedron scaled so that they are at a distance 6.3543 from the origin. As another example, with 12 light monopoles (with mass one) and six heavy monopoles (with mass two) the nested polyhedra are an octahedron and an icosahedron with scales 2.6954 and 13.8057, respectively, and oriented so as to preserve their common tetrahedral subgroups. Clearly the relative orientations of sets of nested polyhedra, together with their deformation as very distinct monopole masses are varied towards equality, are interesting problems which are likely to need substantial investigation in each specific case.

The second extension we consider is to relate our results to the dynamics of well separated SU(2) monopoles. Although, for $n>2$, the moduli space metric for n SU(2) monopoles is not known explicitly, the asymptotic metric is known, which is valid in the region where all the monopoles are well separated.[12] This is the Gibbons–Manton metric and it is related to the Lee–Weinberg–Yi metric through some sign changes. Explicitly, the Gibbons–Manton metric is obtained by replacing Eqs. (2.2)–(2.5) by the equations

$$g_{ii}=m_i-\sum_{j\neq i}\frac{1}{|\mathbf{x}_i-\mathbf{x}_j|}, \tag{3.1}$$

$$g_{ij}=\frac{1}{|\mathbf{x}_i-\mathbf{x}_j|}, \quad i\neq j, \tag{3.2}$$

$$\mathbf{W}_{ii}=-\sum_{j\neq i}\mathbf{w}_{ij}, \tag{3.3}$$

$$\mathbf{W}_{ij}=\mathbf{w}_{ij}, \quad i\neq j. \tag{3.4}$$

If the approach of the previous section is now applied to this metric to find time dependent homothetic solutions then, due to the sign changes, the upshot is that Eq. (2.10) is once again obtained, but with the replacement $C\mapsto -C$. In this case the physically acceptable solution is therefore to choose $C=-1$. With this choice both the function $\alpha(t)$ and the positions $\mathbf{y}_k$ that we have found to provide geodesics for the Lee–Weinberg–Yi metric carry over unchanged to produce geodesics of the Gibbons–Manton metric. The difference now is that these geodesics are only valid in the region where all the monopole are well separated, so the solutions break down before they can describe the collision of the monopoles.

For example, for $n=4$, the scaling geodesic describes the scattering of four monopoles on the vertices of a contracting tetrahedron. In fact, by using symmetry arguments, the full geodesic, to which this is a good approximation in the well separated regime, has been found and shows that as the monopoles approach they pass through a monopole solution with cubic symmetry and emerge on the vertices of an expanding tetrahedron which is dual to the incoming one.[15] For this example, even the metric is known exactly in terms of elliptic integrals.[8]

It might be amusing to attempt to identify the outcomes of the various SU(2) monopole scatterings that begin as the contracting polyhedra that we have identified, particularly those with high symmetry. However, a note of caution must be applied in this situation. The Gibbons–Manton metric possesses an n-torus isometry which the true monopole metric does not have for any finite separation. This means that the symmetry of a contracting polyhedron may only be realized in the true SU(2) monopole solution at the limit of infinite separation. As an example of this situation consider the case $n=6$, where the contracting polyhedron is an octahedron. Using the one-to-one correspondence[17] between SU(2) n-monopoles and (an equivalence class of) rational maps between Riemann spheres of degree n we may determine the dimension of the moduli space of octahedrally symmetric SU(2) monopoles of charge six. Degree six polynomials form the carrier space for the 7-dimensional irreducible representation of SU(2) and when this representa-

tion is restricted to the octahedral group it decomposes into irreducible representations of the octahedral group of dimensions one, three and three. Since two polynomials are required to form a rational map this shows that there are no octahedrally symmetric rational maps of degree six, and hence no octahedrally symmetric charge six monopoles. Thus six SU(2) monopoles placed on the vertices of an octahedron break the octahedral symmetry for any finite value of the separation, no matter how large. This contrasts with the above mentioned case of $n=4$ with tetrahedral symmetry. The five-dimensional irreducible representation of SU(2) when restricted to the tetrahedral group decomposes into two one-dimensional representations and a three-dimensional representation. The basis polynomials for the two one-dimensional representations yield a one-parameter family of tetrahedrally symmetric degree three rational maps, which corresponds to the geodesic describing the tetrahedral scattering of four monopoles.[14] Thus, in some cases the symmetry of the scaling geodesics of the Gibbons–Manton metric may be true symmetries of related geodesics in the true moduli space and in others they may not.

IV. CONCLUSION

The scattering of n distinct fundamental monopoles can be approximated by geodesic motion on the Lee–Weinberg–Yi manifold. We have described a variational method to construct some geodesics on this manifold for arbitrary values of n, and applied it to obtain a number of examples. The energy function used in this approach has features similar to that which arises in the classic problem of determining central configurations, but in contrast to central configurations it yields points which lie on a single shell for arbitrary values of n. The geodesics constructed by our method describe the scattering of monopoles on the vertices of a contracting, and then expanding, polyhedron, which generically is a deltahedron. We have found, and exploited, similarities between the deltahedra obtained here and those which arise in the problem of maximizing the sum of the mutual separations for points on a sphere.

(Received 17 October 2002; accepted 9 April 2003)

In this article we aim to determine the baryon numbers at which the minimal energy Skyrmion has icosahedral symmetry. By comparing polyhedra which arise as minimal energy Skyrmions with the dual of polyhedra that minimize the energy of Coulomb charges on a sphere, we are led to conjecture a sequence of magic baryon numbers, $B=7,17,37,67,97,\ldots$, at which the minimal energy Skyrmion has icosahedral symmetry and unusually low energy. We present evidence for this conjecture by applying a simulated annealing algorithm to compute energy minimizing rational maps for all degrees up to 40. Further evidence is provided by the explicit construction of icosahedrally symmetric rational maps of degrees 37, 47, 67 and 97. To calculate these maps we introduce two new methods for computing rational maps with Platonic symmetries. © *2003 American Institute of Physics.*

I. INTRODUCTION

Skyrmions are topological solitons in three space dimensions which are candidates for an effective description of nuclei, with an identification between soliton and baryon numbers.[10] Recently, the minimal energy Skyrmions for all baryon numbers $1\leqslant B\leqslant 22$ were computed and their symmetries identified.[3] The baryon density of these Skyrmions is localized around the vertices and edges of polyhedra, which are almost always trivalent, and for $B\geqslant 7$ are composed of 12 pentagons and $2B-14$ hexagons, with only a few exceptions (which can be understood by a symmetry enhancement principle). These Skyrmions have discrete point group symmetries, including occasional Platonic symmetries. For $B=7$ and $B=17$ the minimal energy Skyrmion is particularly symmetric, having icosahedral symmetry Y_h, and the value of the energy is unusually low. However, there are other baryon numbers at which icosahedral Skyrme fields exist, but the minimal energy Skyrmion has less symmetry. This motivates the main question addressed in this article, namely, what are the magic baryon numbers at which the minimal energy Skyrmion has icosahedral symmetry with a resulting unusually low energy?

To gain some insight into this problem we note that, as first observed in Ref. 2, there is a close relationship between the polyhedra which arise as minimal energy Skyrmions and the duals of polyhedra which occur in the problem of minimizing point Coulomb charges on a sphere. This latter problem is often known as the Thomson problem, even though he appears not to have posed it explicitly, and we shall use this nomenclature here. The Thomson problem is well studied for up to 200 points on the sphere[9] and generically the n points sit at the vertices of a combinatoric

deltahedron. Taking the dual of a deltahedron leads to a trivalent polyhedron, which is the class of polyhedra which generically arise for Skyrmions. A Skyrmion polyhedron with baryon number B has $2B-2$ faces, so to identify this with the dual of a Thomson polyhedron requires that we consider $n=2B-2$ Coulomb charges on the sphere. Let us denote by G_B the symmetry of the minimal energy Skyrmion with baryon number B and by H_B the symmetry of the minimal energy Thomson configuration of $2B-2$ points on the sphere. Extracting the information from Refs. 3 and 5 we obtain Table I, in which we compare the symmetries of the minimal energy configurations for each problem.

From Table I it is clear that although a variety of different Platonic, dihedral and cyclic symmetry groups occur, there is a remarkable match for the two problems in 17 out of the 22 cases. Moreover, a closer inspection reveals that in these 17 cases not only do the symmetry groups match, but the combinatorial types of the Skyrmion polyhedron and the dual of the Thomson polyhedron are identical. The five examples that do not coincide, $B=5,9,10,19,22$, show that the topography of the two energy functions is slightly different and suggest that the same factors which determine the polyhedron (or its dual) are important, but perhaps with slightly different weightings. For example, for $B=9$ and $B=10$, which are not particularly low in energy, it is known that Skyrmion configurations exist which have the symmetries required to match to those of the Thomson problem, but that they have very slightly higher energy than the minimal energy Skyrmion. The fact that there is so often an agreement for the two problems leads us to believe that, in the cases where particularly symmetric low energy configurations arise, they will be the minima in both problems. Thus, as a working hypothesis to test, we shall postulate that G_B is the icosahedral group only if H_B is also the icosahedral group. Although the Thomson problem is a difficult one to study numerically, it is certainly much easier than finding minimal energy Skyrmions, so we can take advantage of the known numerical results. Minimal energy configurations are currently available for up to 200 points, that is, $B\leqslant 101$, and of these the values $B=7,17,37,62,67,97$ are selected as magic numbers at which the configuration has icosahedral symmetry and unusually low energy when compared to a numerical fit of all 200 configurations.[9] As we describe later, the case $B=62$ is rather different from the others in the sequence, so we shall leave this example out for the moment. We are thus led to conjecture that there is a sequence $B=7,17,37,67,97,\ldots$ at which the minimal energy Skyrmion has icosahedral symmetry and unusually low energy. In the rest of this article we perform some investigations to test this conjecture, and hence the connection between Skyrmions and the Thomson problem.

II. MINIMIZING RATIONAL MAPS

A static Skyrme field, $\mathrm{U}(\mathbf{x})$, is an SU(2) matrix defined throughout $\mathbb{R}^3$ and satisfying the boundary condition that $U\to 1$ as $|\mathbf{x}|\to\infty$. This boundary condition implies a compactification of space so that the Skyrme field becomes a mapping $U:S^3\mapsto \mathrm{SU}(2)$, and so can be classified by an integer valued winding number

$$B=\frac{1}{24\pi^2}\int \epsilon_{ijk}\,\mathrm{Tr}(\partial_i U\,U^{-1}\partial_j U\,U^{-1}\partial_k U\,U^{-1})\,d^3x, \tag{2.1}$$

which is a topological invariant. This winding number counts the number of solitons in a given field configuration and is identified with baryon number in the application to modeling nuclei.

The energy of a static Skyrme field is given by

$$E=\frac{1}{12\pi^2}\int \mathrm{Tr}\left(-\frac{1}{2}(\partial_i U\,U^{-1})^2-\frac{1}{16}[\partial_i U\,U^{-1},\partial_j U\,U^{-1}]^2\right)d^3x \tag{2.2}$$

and, for each integer B, the problem is to minimize this energy within the class of fields with baryon number B in order to find the minimal energy Skyrmion. This problem has been solved numerically for all $B\leqslant 22$ (Ref. 3) yielding the results presented in Table I for the symmetries of the minimal energy Skyrmions. When we refer to the symmetry of a Skyrmion we do not mean that the Skyrme field itself is invariant under particular spatial rotations, but rather that the effect of a spatial rotation can be undone by the application of the global SO(3) symmetry of the Skyrme model, which acts through the conjugation $U\mapsto \mathcal{O}U\mathcal{O}^{\dagger}$, where $\mathcal{O}\in \mathrm{SU}(2)$ is a constant matrix. In particular this means that the baryon and energy densities [the integrands in (2.1) and (2.2)] are strictly invariant.

It is computationally prohibitive to apply the full numerical scheme to larger values of B at the present time, but fortunately an approximation method has been developed which provides very accurate results. This is the rational map ansatz,[7] where a Skyrme field with baryon number B is constructed from a degree B rational map between Riemann spheres. Although this ansatz does not give exact solutions of the static Skyrme equations, it produces approximations which have energies only a few percent above the numerically computed solutions. Briefly, use spherical coordinates in $\mathbb{R}^3$, so that a point $\mathbf{x}\in\mathbb{R}^3$ is given by a pair (r,z), where $r=|\mathbf{x}|$ is the distance from the origin, and z is a Riemann sphere coordinate giving the point on the unit two-sphere which intersects the half-line through the origin and the point $\mathbf{x}$. Now, let $R(z)$ be a degree B rational map between Riemann spheres, that is, $R=p/q$ where p and q are polynomials in z such that $\max[\deg(p),\deg(q)]=B$, and p and q have no common factors. Given such a rational map the ansatz for the Skyrme field is

$$U(r,z)=\exp\left[\frac{if(r)}{1+|R|^2}\begin{pmatrix}1-|R|^2 & 2\overline{R}\\ 2R & |R|^2-1\end{pmatrix}\right], \tag{2.3}$$

where $f(r)$ is a real profile function satisfying the boundary conditions $f(0)=\pi$ and $f(\infty)=0$, which is determined by minimization of the Skyrme energy of the field (2.3) given a particular rational map R.

Substitution of the rational map ansatz (2.3) into the Skyrme energy functional results in the following expression for the energy

$$E=\frac{1}{3\pi}\int\left(r^2f'^2+2B(f'^2+1)\sin^2 f+\mathcal{I}\frac{\sin^4 f}{r^2}\right)dr\,, \tag{2.4}$$

where $\mathcal{I}$ denotes the integral

$$\mathcal{I}=\frac{1}{4\pi}\int\left(\frac{1+|z|^2}{1+|R|^2}\left|\frac{dR}{dz}\right|\right)^4\frac{2i\;dz\,d\overline{z}}{(1+|z|^2)^2}. \tag{2.5}$$

To minimize the energy (2.4) one first determines the rational map which minimizes $\mathcal{I}$, then given the minimum value of $\mathcal{I}$ it is a simple exercise to find the minimizing profile function. Thus, within the rational map ansatz, the problem of finding the minimal energy Skyrmion reduces to the simpler problem of calculating the rational map which minimizes the function $\mathcal{I}$.

The baryon density of the rational map $R=p/q$ is proportional to the Wronskian

$$w(p,q)=p'q-q'p \tag{2.6}$$

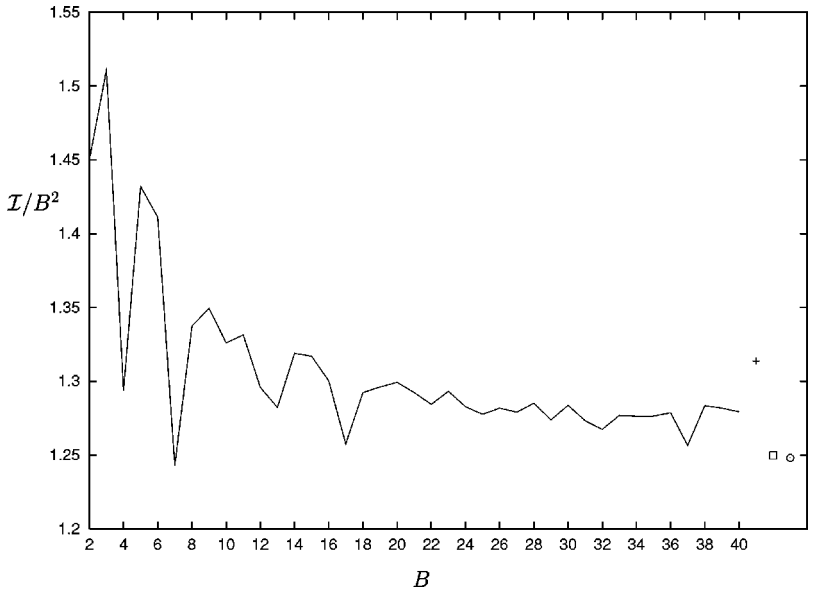

FIG. 1. $\mathcal{I}/B^2$ for $2 \leqslant B \leqslant 40$, as calculated by $\mathcal{I}$ minimizing simulated annealing computations. Also shown are the values of $\mathcal{I}/B^2$ for the icosahedrally symmetric Skyrmions with $B=47$ (cross), $B=67$ (square) and $B=97$ (circle), discussed in the text.

which has $2B-2$ roots, giving the points on the Riemann sphere for which the baryon density vanishes along the corresponding half-lines through the origin. These $2B-2$ points on the sphere give the face-centers of the Skyrmion polyhedron, or equivalently the vertices of the dual polyhedron which is associated with the Thomson problem.

Using a simulated annealing algorithm the $\mathcal{I}$ minimizing rational maps for $1 \leqslant B \leqslant 22$ have been computed[3] and found to be in good agreement with the results of full Skyrme field minimization. Here we extend the simulated annealing computation to $B \leqslant 40$, in an attempt to determine particularly low energy magic numbers. In the Thomson problem the magic numbers are determined by comparing the energy of minimal solutions with the energy of a numerical fit to the data of all known minimal energy solutions—thereby isolating cases where the energy is lower than the expected fit. In the problem of minimizing rational maps it turns out that there is a more natural approach, due to the fact that a useful lower bound exists. Using a simple inequality it is shown in Ref. 7 that $\mathcal{I} \geqslant B^2$. It turns out that examining the excess above this bound, by computing the quantity $\mathcal{I}/B^2$, is a good diagnostic tool for highlighting low energy maps, and in particular is more useful than simply calculating the energy of the associated Skyrme field. We illustrate this in Fig. 1 by plotting $\mathcal{I}/B^2$ for the results of our simulated annealing computations for $2 \leqslant B \leqslant 40$. There are clear dips at the magic numbers $B=7$ and $B=17$, corresponding to the already known low energy icosahedral Skyrmions (see Table I). There are also dips at $B=4$ and $B=13$, where it is known that the Skyrmions also have Platonic symmetry, but this time octahedral (see Table I). However, there is one more major dip at $B=37$, and this is precisely the value predicted as the next magic number in the icosahedral sequence suggested by comparison with the Thomson problem. This result, therefore, provides strong support for our conjectured sequence, providing we can prove that this low energy degree 37 map obtained from simulated annealing does indeed have icosahedral symmetry. This will be discussed in the next section.

Note that the quantity $\mathcal{I}/B^2$ appears to be tending towards an asymptotic value of around 1.28, apart from magic numbers where it drops to around 1.25. It would be interesting to understand this approach to a relatively constant value, as well as its magnitude.

In Fig. 2 we plot the energy per baryon E/B of the Skyrmions constructed from the minimizing maps with $1 \leqslant B \leqslant 40$. The dips at the magic numbers are clearly visible in Fig. 2, reproducing the sequence displayed in Fig. 1. However, in this case the dips are superimposed upon a general

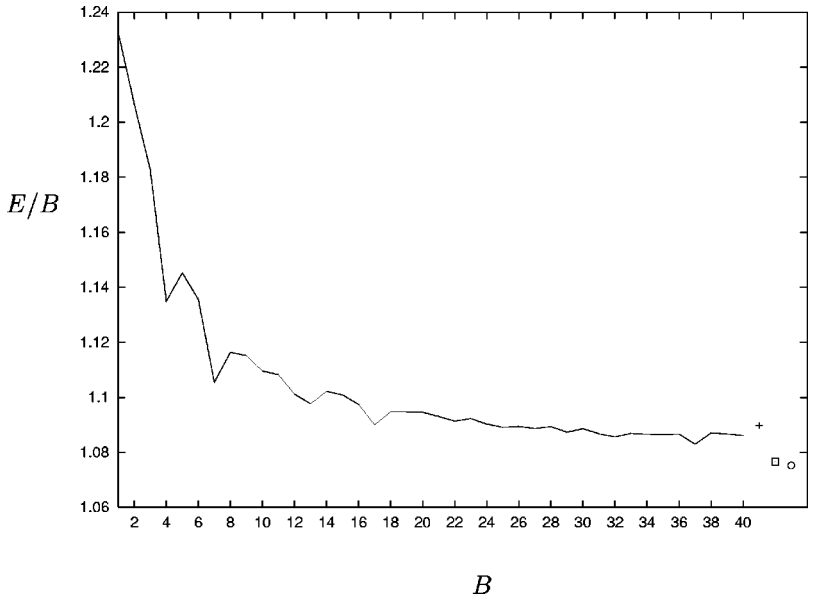

FIG. 2. The energy per baryon E/B of the Skyrmions constructed from the minimizing maps with $1 \leqslant B \leqslant 40$. Also shown are the values of E/B for the icosahedrally symmetric Skyrmions with $B=47$ (cross), $B=67$ (square) and $B=97$ (circle), discussed in the text.

decrease of E/B with increasing B, which is why we regard the quantity $\mathcal{I}/B^2$ as a more useful diagnostic than E/B.

The radius of a Skyrmion produced from the rational map ansatz can be defined as the radial value, r_*, at which the profile function is equal to $\pi/2$. In Fig. 3 we plot r_*^2 as a function of B for $1 \leqslant B \leqslant 40$. This clearly shows that the radius has a $\sqrt{B}$ dependence, and given that all these configurations are reasonably close to the Faddeev–Bogomolny energy bound $E \geqslant |B|$, this means that the energy grows like the square of the radius, as expected for a shell-like structure. Note that

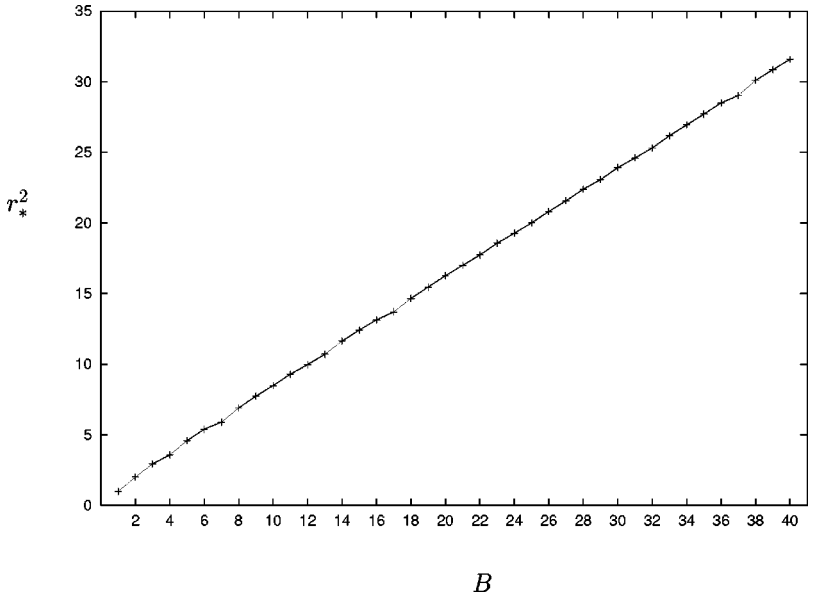

FIG. 3. r_*^2, the squared radius of the Skyrmion, as a function of baryon number B.

at the magic numbers the radius of the Skyrmion is slightly less than expected, presumably due to a more compact arrangement of a particularly symmetric energy density.

III. COMPUTING ICOSAHEDRAL MAPS

Recall that a Skyrmion is symmetric under a group $G \subset \mathrm{SO}(3)$, if a spatial rotation $g \in \mathrm{SO}(3)$ can be compensated by an action of the global SO(3) symmetry. In terms of the rational map approach a spatial rotation acts on the Riemann sphere coordinate z as an SU(2) Möbius transformation. Similarly the global symmetry acts on the Riemann sphere coordinate R of the target two-sphere as an SU(2) Möbius transformation. Hence, a map is G-symmetric if, for each $g \in G$, there exists a target space rotation D_g such that $R(g(z)) = D_g(R(z))$. Since we are dealing with SU(2) transformations the set of target space rotations will form a representation of the double group of G, but we shall continue to call this G.

To determine the existence and compute particular symmetric rational maps is a matter of classical group theory. We are concerned with degree B polynomials which form the carrier space for $B+1$, the $(B+1)$-dimensional irreducible representation of SU(2). Now, as a representation of SU(2) this is irreducible, but if we only consider the restriction to a subgroup G, $\underline{B+1}|_G$, this will, in general, be reducible. What we are interested in is the irreducible decomposition of this representation and tables of these subductions can be found, for example, in Ref. 1.

The simplest case in which a G-symmetric degree B rational map exists is if

$$\underline{B+1}|_G = E + \cdots, \tag{3.1}$$

where E denotes a two-dimensional representation. Here, and in the following, the dots denote other representations which are not relevant. In this case a basis for E consists of two degree B polynomials which can be taken to be the numerator and denominator of the rational map. A subtle point which needs to be addressed is that the two basis polynomials may have a common root, in which case the resulting rational map is degenerate and does not correspond to a genuine degree B map.

More complicated situations can arise, for example, if

$$\underline{B+1}|_G = A_1 + A_2 + \cdots, \tag{3.2}$$

where A_1 and A_2 denote two one-dimensional representations, then a whole one-parameter family of maps can be obtained by taking a constant multiple of the ratio of the two polynomials which are a basis for A_1 and A_2, respectively. An m-parameter family of G-symmetric maps can be constructed if the decomposition contains $(m+1)$ copies of a two-dimensional representation, that is,

$$\underline{B+1}|_G = (m+1)E + \cdots, \tag{3.3}$$

where the m (complex) parameters correspond to the freedom in the choice of one copy of E from $(m+1)E$.

A detailed explanation of how to explicitly calculate any required symmetric map is given in Ref. 7. However, this approach involves computing appropriate projectors which are matrices of size $(B+1)\times(B+1)$, and even with the use of symbolic computational packages this procedure becomes cumbersome for the large values of B that we are interested in here. In this section we therefore describe and apply two new, more convenient, methods for calculating symmetric maps. We shall concentrate on the situation of relevance to this article, where $G = Y$, the icosahedral group, but the methods are applicable for any G.

Before we describe our new approaches we need to recall some facts about representations of the icosahedral group and Klein polynomials of the icosahedron. The icosahedral group Y has the trivial one-dimensional representation A and two two-dimensional representations, which we de-

note by E_1' and E_2', with a prime denoting the fact that these are proper representations of the double group. There are also three-, four-, five- and six-dimensional representations, but we shall not need these here.

Klein polynomials are strictly invariant polynomials for the Platonic groups.[8] Since

$$\underline{13}|_Y = A + \cdots, \tag{3.4}$$

this implies that there is degree 12 invariant polynomial. This is the Klein polynomial given by

$$k_v = z^{11} + 11z^6 - z \tag{3.5}$$

and although it appears to have degree 11, it should be thought of as having degree 12 with one root at infinity. The roots of this polynomial, considered as points on the Riemann sphere, are located at the vertices of a suitably oriented and scaled icosahedron. The same construction, but using the face-centers and mid-points of the edges of the icosahedron, in place of the vertices, produces the Klein polynomials

$$k_f = z^{20} - 228z^{15} + 494z^{10} + 228z^5 + 1, \tag{3.6}$$

$$k_e = z^{30} + 522z^{25} - 10\,005z^{20} - 10\,005z^{10} - 522z^5 + 1, \tag{3.7}$$

which are also Y-invariant, by construction.

A. Polarization

In this subsection we describe our polarization method for computing symmetric maps. It has similar features to the polarization technique used to construct symmetric Nahm data.[6]

Suppose we wish to obtain the symmetric degree B map associated with the decomposition

$$\underline{B+1}|_Y = E + \cdots, \tag{3.8}$$

where E denotes one of the two-dimensional representations. The above fact implies that

$$E \otimes \underline{B+1}|_Y = A + \cdots, \tag{3.9}$$

and, in our polarization method, the invariant polynomial corresponding to this one-dimensional representation is used to construct a basis for the E in (3.8).

It is convenient to work with homogeneous coordinates x,y on the Riemann sphere, that is, $z = x/y$, so that a polynomial in z of degree B corresponds to a homogeneous degree B polynomial in x and y.

Let $(p_L(x,y), q_L(x,y))$ be known degree L polynomials which form a basis for the representation E and let $k(x,y)$ be a degree $B+L$ invariant polynomial which is a basis for the one-dimensional representation in (3.9). Then, since the pair $(\partial_y, -\partial_x)$ transform in the same way as the pair (x,y) under linear SU(2) transformations, this means that the polynomials $p_B(x,y), q_B(x,y)$ defined by

$$p_B(x,y) = p_L(\partial_y, -\partial_x)k(x,y), \quad q_B(x,y) = q_L(\partial_y, -\partial_x)k(x,y) \tag{3.10}$$

have degree B and are the required basis for the two-dimensional representation occuring in (3.8).

As an example of this scheme we now construct the icosahedrally symmetric degree 17 rational map, in an orientation that we shall require later. The relevant decomposition is

$$\underline{18}|_Y = E_2' + \cdots, \tag{3.11}$$

so we first require a known Y-symmetric rational map that is a basis for the representation E_2'. The simplest known example is the degree 7 map[7] (corresponding to the $B=7$ Y_h-symmetric minimal energy Skyrmion)

$$p_7(x,y)=x^7-7x^5y^2-7x^2y^5-y^7, \quad q_7(x,y)=x^7+7x^5y^2-7x^2y^5+y^7. \tag{3.12}$$

Hence we have $B=17$ and $L=7$, so now we require an invariant polynomial $k(x,y)$ of degree $B+L=24$. This is easily found by using an appropriate combination of Klein polynomials, in this case $k(x,y)=k_v^2(x,y)$ is the degree 24 invariant where $k_v(x,y)=x^{11}y+11x^6y^6-xy^{11}$ is the degree 12 Klein polynomial given earlier, when written in terms of homogeneous coordinates. The formula (3.10) then produces

$$\begin{aligned} p_{17}&=z^{17}+17z^{15}+119z^{12}-187z^{10}+187z^7+119z^5+17z^2-1, \\ q_{17}&=z^{17}-17z^{15}+119z^{12}+187z^{10}+187z^7-119z^5+17z^2+1, \end{aligned} \tag{3.13}$$

when written in terms of the inhomogeneous coordinate z. This map is equivalent, after a change of spatial and internal orientation, to the Y_h-symmetric map presented in Ref. 7 that corresponds to the $B=17$ Y_h-symmetric minimal energy Skyrmion. In the following subsection we shall require this map in the orientation presented in (3.13).

Although this method is much easier to implement than the projector algorithm, it turns out that for the icosahedral maps we require in this article there is yet another approach, which is even more effecient.

B. Klein leapfrog

From the previous section we already have two Y-symmetric rational maps, which are $R_7=p_7/q_7$ and $R_{17}=p_{17}/q_{17}$. Here we describe how the other Y-symmetric maps that we require can be obtained from these two by the simple multiplication of invariant Klein polynomials. This way of obtaining higher degree invariant rational maps we refer to as the Klein leapfrog method.

Recall that we wish to determine whether the low energy $\mathcal{I}$ minimizing map of degree 37 that we found earlier is icosahedrally symmetric. The relevant decomposition is

$$\underline{38}|_Y=E_1'+2E_2'+\cdots. \tag{3.14}$$

Both the maps (p_7,q_7) and (p_{17},q_{17}) are a basis for the representation E_2', and the multiplication of these maps by any (integer power of a) Klein polynomial does not change the transformation properties, since Klein polynomials are invariants. Thus, both (k_ep_7,k_eq_7) and (k_fp_{17},k_fq_{17}) are degree 37 Y-symmetric maps. Each map alone is not a valid degree 37 rational map, since the numerator and denominator contain common factors, but taken together they form an acceptable basis for the $2E_2'$ in (3.14). Explicitly,

$$R_{37}=\frac{p_{37}}{q_{37}}=\frac{k_fp_{17}+ck_ep_7}{k_fq_{17}+ck_eq_7}, \tag{3.15}$$

where c is a complex parameter. For $c=0$ or $c=\infty$ the map is clearly degenerate, having degree lower than 37, but for generic values of c the numerator and denominator are coprime.

The Wronskian of this map must be strictly invariant, and indeed it is given by the following combination of Klein polynomials:

$$w(p_{37},q_{37})=k_e^2k_v(80c+28c^2)-k_f^3k_v(68+120c). \tag{3.16}$$

The 72 roots of this polynomial give the face-centers of the Skyrmion polyhedron. Minimizing the integral $\mathcal{I}$ over the one- (complex) parameter family of maps (3.15) results in a minimum at $c=-0.829+0.545i$, where $\mathcal{I}/B^2=1.255$. This is precisely the value found by the minimization

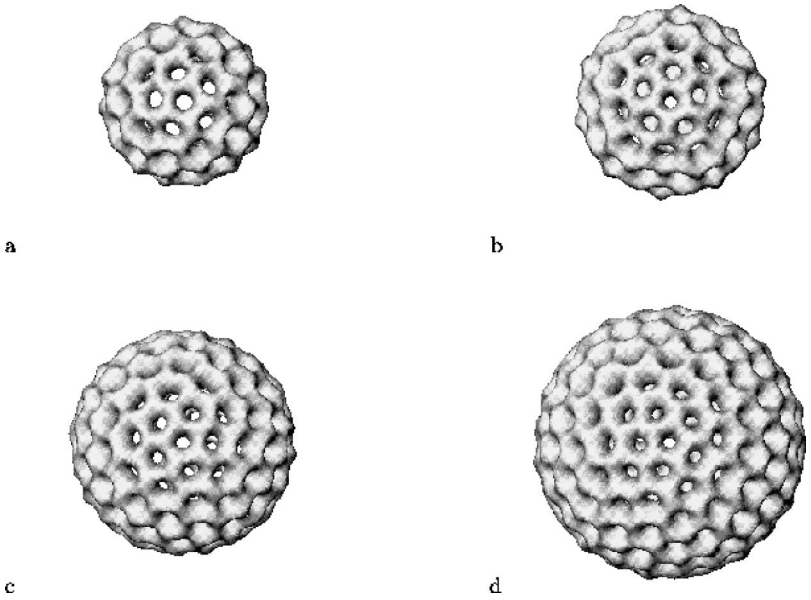

FIG. 4. Baryon density isosurface plots (to scale) for icosahedral Skyrmions with baryon numbers (a) $B=37$, (b) $B=47$, (c) $B=67$, and (d) $B=97$.

over all degree 37 maps, so we confirm that the $\mathcal{I}$ minimizing degree 37 map, and hence the minimal energy $B=37$ Skyrmion, has icosahedral symmetry. Note that the symmetry group is only Y and not Y_h since c is not real. A baryon density isosurface plot for the associated Skyrmion is displayed in Fig. 4(a).

The next magic number in our conjectured icosahedral list is $B=67$. The application of our simulated annealing scheme to extend the results presented in Fig. 1 to such a large value of B would require unreasonable computing resources. We therefore make use of the fact that the quantity $\mathcal{I}/B^2$ appears to approach an asymptotic value of around 1.28, whereas for icosahedral magic numbers the value is closer to 1.25. Therefore we aim to present evidence in support of our conjecture by finding an icosahedral map of degree 67 with $\mathcal{I}/B^2 \approx 1.25$.

The relevant decomposition is

$$\underline{68}|_Y = 2E_1' + 3E_2' + \cdots, \tag{3.17}$$

so we require three degree 67 maps to form a basis for the second component in the above decomposition. These are given by a Klein leapfrog as

$$(k_e k_f p_{17}, k_e k_f q_{17}), \quad (k_e^2 p_7, k_e^2 q_7), \quad (k_f^3 p_7, k_f^3 q_7). \tag{3.18}$$

It might seem strange that $(k_v^5 p_7, k_v^5 q_7)$ is not included, but because $\underline{61}|_Y = 2A + \cdots$, there must be a linear relationship between k_e^2, k_f^3 and k_v^5. In fact, it is given by $1728 k_v^5 = k_e^2 - k_f^3$.[8]

Minimizing over the two- (complex) parameter family of maps

$$R_{67} = \frac{k_e k_f p_{17} + c_1 k_e^2 p_7 + c_2 k_f^3 p_7}{k_e k_f q_{17} + c_1 k_e^2 q_7 + c_2 k_f^3 q_7} \tag{3.19}$$

yields a minimum at $c_1 = -0.292 - 0.816i$, $c_2 = -0.491 + 1.008i$, for which $\mathcal{I}/B^2 = 1.250$. This value is plotted as the square in Fig. 1, and it is clearly consistent with being an icosahedral magic number, as is the energy per baryon of the associated Skyrmion which is plotted as the square in Fig. 2. A baryon density isosurface derived from the minimal Y-symmetric map is displayed in Fig. 4(c).

The next magic number on our list is $B=97$. The required decomposition is

$$\underline{98}|_Y = 3E_1' + 4E_2' + \cdots, \tag{3.20}$$

so there is a three- (complex) parameter family of Y-symmetric maps. Three of the required basis maps are obtained by a Klein leapfrog of the three degree 67 basis maps given above, through the multiplication by k_e. The fourth basis map is a Klein leapfrog of (p_{17}, q_{17}) through the multiplication by k_f^4. The full map is therefore

$$R_{97} = \frac{k_e^2 k_f p_{17} + c_1 k_e^3 p_7 + c_2 k_e k_f^3 p_7 + c_3 k_f^4 p_{17}}{k_e^2 k_f q_{17} + c_1 k_e^3 q_7 + c_2 k_e k_f^3 q_7 + c_3 k_f^4 q_{17}}. \tag{3.21}$$

A minimization over the three complex parameters yields a minimum for $c_1 = 0.705 + 0.699i, c_2 = -0.554 - 1.701i, c_3 = -0.967 + 0.930i$, at which $\mathcal{I}/B^2 = 1.248$. This value is plotted as the circle in Fig. 1, and again it is consistent with being the minimal degree 97 map, producing another icosahedral magic number at $B=97$. A baryon density isosurface of the Skyrmion derived from this minimal Y-symmetric map is displayed in Fig. 4(d). The energy per baryon of this Skyrmion is plotted as the circle in Fig. 2. Given that the rational map ansatz tends to overestimate the energy by around 1% or 2%, then the true energy per baryon of this Skyrmion must be very close to that of the hexagonal lattice,[4] which has $E/B = 1.061$.

Icosahedrally symmetric rational maps, and hence Skyrme fields, exist for many values of B, but rarely are these symmetric configurations those of minimal energy. The simplest example is the degree 11 rational map presented in Ref. 7. For this map $\mathcal{I}/B^2 = 3.84$, which is clearly very large, and indeed the associated $B=11$ Skyrme field has larger energy than 11 well-separated single Skyrmions. This is not very surprising, given that the associated polyhedron is an icosahedron—clearly violating the favorable trivalent property at all vertices. However, in the Thomson problem there are more subtle examples, where there is an icosahedrally symmetric configuration which has reasonably low energy, but not quite as low as a less symmetric minimal energy solution. This situation occurs for the values $B = 22, 47, 82, \ldots$.[9] We shall see if this situation is also mirrored in the Skyrmion problem, by studying Y-symmetric rational maps of degree 47.

The required decomposition is

$$\underline{48}|_Y = E_1' + 2E_2' + \cdots, \tag{3.22}$$

and a basis for the $2E_2'$ is obtained by the Klein leapfrog of R_{17} by k_e and the Klein leapfrog of R_7 by k_f^2. Therefore, the one-parameter family of Y-symmetric maps is

$$R_{47} = \frac{k_e p_{17} + c k_f^2 p_7}{k_e q_{17} + c k_f^2 q_7}. \tag{3.23}$$

Minimizing over c yields a minimum when c is real (so the symmetry extends to Y_h) and takes the value $c = -1.425$, at which $\mathcal{I}/B^2 = 1.314$. This value is plotted as the cross in Fig. 1, and it can be seen that, even though it is reasonably low, it is not consistent with the general trend for minimal energy maps. The associated energy per baryon is plotted as the cross in Fig. 2 and provides further evidence that this is not a minimal energy Skyrmion. This suggests that the same phenomenon of nonminimal icosahedral maps exists in both the Thomson and Skyrme problems, providing yet more evidence for the similarity of these two systems. A baryon density isosurface is displayed in Fig. 4(b) for the Y_h-symmetric Skyrmion obtained from the above map with the minimal value of c. From this figure it can be seen that the Skyrmion polyhedron fits into the required class, as a trivalent polyhedron with 12 pentagonal faces and the remaining faces hex-

agonal. Therefore, the reason for it not to be the minimal energy Skyrmion must be subtle, and probably involves the placement of the pentagons within the polyhedron, when compared to a more favorable but less symmetric distribution.

Finally, we turn to the anomalous case of $B=62$. In the Thomson problem there is an icosahedral magic number at $B=62$, but the relevant decomposition for rational maps is

$$\underline{63}|_Y = A + \text{ irreps of dimension greater than } 2, \tag{3.24}$$

so there is certainly no Y-symmetric degree 62 rational map, and probably no Y-symmetric $B=62$ Skyrmion either. The resolution of this problem is the fact that the polyhedron associated with a Skyrmion is derived from the baryon density, and it is possible that the baryon and energy density of a Skyrmion could have more symmetry than the Skyrme field itself. In terms of the rational map ansatz this corresponds to an enhanced symmetry of the Wronskian, not shared by the rational map.

Recall that the Wronskian is a polynomial of degree $2B-2$, so to see if this is a possible explanation for the case $B=62$ we need to look for Y-invariant polynomials of degree 122. The decomposition

$$\underline{123}|_Y = 2A + \cdots \tag{3.25}$$

reveals that there are two invariants, and in fact they are given by $k_v k_f k_e^3$ and $k_v k_f^4 k_e$. Thus, to address this case we would need to find the family of degree 62 rational maps, (p_{62}, q_{62}), so that the Wronskian takes the form

$$w(p_{62}, q_{62}) = k_v k_f k_e (c_1 k_e^2 + c_2 k_f^3), \tag{3.26}$$

where c_1 and c_2 are arbitrary complex constants. It is difficult to see how to explicitly construct this family, given we do not know the symmetry of the rational map, but it would be interesting if this could be done, to see whether a map with a Y-invariant Wronskian is likely to be the minimal map. However, as far as our definition of icosahedral magic number is concerned, the value $B=62$ does not qualify because the map is not Y-symmetric.

The example of a nonminimal icosahedral $B=22$ Thomson configuration, briefly mentioned above, also appears to fall into the same class.[4] There are no Y-symmetric degree 22 maps, but there is a degree 42 invariant, given by $k_v k_e$, to which the Wronskian of a degree 22 map could be proportional.

IV. CONCLUSION

In this article we have used a comparison between Skyrmion polyhedra and the duals of Thomson polyhedra to predict a sequence of magic baryon numbers at which the Skyrmion has icosahedral symmetry and unusually low energy. We have presented some evidence for our conjecture, through the minimization of the most general rational maps for all degrees up to 40, and by the explicit construction, using two new methods, of some high degree rational maps with icosahedral symmetry.

Our methods could also be used to find other possible minimal energy rational maps and Skyrme fields, with octahedral and tetrahedral symmetries. It is likely that these other Platonic symmetries are more prevalent than icosahedral symmetry, and may account for some of the less pronounced dips in Fig. 1.

Finally, a comparison between the Skyrme crystal and the Skyrme lattice[4] suggests that for large enough baryon numbers the shell-like structure of Skyrmions may give way to a crystal structure. However, even the order of magnitude of B at which this transition might take place is not known, so whether all the icosahedral Skyrmions we have constructed will survive this possible transition remains an open question.

Topological Q-solitons

R. S. Ward[a)]
Department of Mathematical Sciences, University of Durham, Durham DH1 3LE, United Kingdom

(Received 18 November 2002; accepted 9 April 2003)

Static topologically-nontrivial configurations in sigma-models, for spatial dimension $D \geqslant 2$, are unstable. The question addressed here is whether such sigma-model solitons can be stabilized by steady rotation in internal space; that is, rotation in a global SO(2) symmetry. This is the mechanism which stabilizes Q-balls (nontopological solitons). The conclusion is that the Q-mechanism can stabilize topological solitons in $D=2$ spatial dimensions, but not for $D=3$. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1584527]

I. INTRODUCTION

Topological solitons (stable, localized, topologically nontrivial solutions in a field theory) have long been of great interest, both for their mathematical properties and for their applications in many areas of physics. In any system admitting such solitons, the nontrivial topology is not sufficient to ensure that the solitons are stable. One obvious reason for this is that topology is, by definition, a nonmetric structure, and so it cannot determine the size of the solitons; for that, one needs to balance the forces acting on the soliton in such a way that it has a preferred size. Recall, for example, the O(n) sigma model in $D+1$ dimensions (with trivial boundary condition at spatial infinity), which is the subject of this article. This system admits topological configurations (textures) whenever the homotopy group $\pi_D(S^{n-1})$ is nontrivial; in particular, for (D,n) equal to (2, 3), (3, 3) or (3, 4). If $D=3$, then solitons tend to shrink—in the pure sigma model, there are no static solutions. In the $D=2$ case, there are static solutions, for example, the Belavin–Polyakov solitons[1] in the O(3) system, but these are unstable.[2,3]

A soliton can always be prevented (or rather discouraged) from spreading out by the addition, if necessary, of a potential (a term involving only the field, and not its gradient). In order to stabilize the soliton size, we also need to introduce something which prevents it from shrinking. There are several possibilities for such an antishrinking mechanism: for example, a Skyrme term involving four (or more) powers of the field gradient, or a gauge field suitably coupled to the sigma-field, or periodic time-dependence (rotation in an internal space). This third possibility also underlies nontopological solitons (Q-balls). In this article, we investigate to what extent the Q-ball mechanism is effective at stabilizing topological sigma-model solitons. We shall see that stationary topological Q-solitons exist in $D=2$ spatial dimensions, but not for $D=3$. This result is analogous to that for the Landau–Lifshitz equation (Heisenberg model of ferromagnetism), as one might have surmised since the static Landau–Lifshitz system is identical to the static sigma model.

II. Q-SOLITONS IN THE O(3) SIGMA MODEL

The O(3) sigma model involves a scalar field taking values on S^2; this field can be represented as a unit three-vector $\vec{\phi}=(\phi_1,\phi_2,\phi_3)$ with $\vec{\phi}\cdot\vec{\phi}=1$. The Lagrangian is

$$\mathcal{L}=\tfrac{1}{2}(\partial_\mu\vec{\phi})\cdot(\partial^\mu\vec{\phi})-V(\phi_3), \tag{1}$$

a)Electronic mail: richard.ward@durham.ac.uk

where V is some potential function (which, for simplicity, we take to depend only on ϕ_3). The space–time coordinates are $x^\mu=(t,x^j)$, with $j=1,\ldots,D$. The system has a global SO(3) symmetry which is broken, by the potential term, to SO(2). This SO(2) acts only on ϕ_1 and ϕ_2, namely, by changing the phase of $\phi:=\phi_1+\mathrm{i}\phi_2$. The corresponding conserved quantity is

$$Q=\int \mathrm{Im}(\dot{\phi}\overline{\phi})d^Dx. \tag{2}$$

Minimizing the energy of a configuration subject to Q being fixed implies,[4] in particular, that $\vec{\phi}$ has the form

$$\phi(t,x^j)=\psi(x^j)\mathrm{e}^{\mathrm{i}\omega t},\quad \phi_3=\psi_3(x^j), \tag{3}$$

with $|\psi|^2+(\psi_3)^2=1$. Without loss of generality, we shall assume that $\omega\geqslant 0$. Note that $Q=\omega I$, where $I=\int|\psi|^2d^Dx$. The energy of a configuration of the form (3) is $E=E_d+E_k+E_p$, where

$$E_d=\frac{1}{2}\int[|\partial_j\psi|^2+(\partial_j\psi_3)^2]d^Dx,$$

$$E_k=\tfrac{1}{2}I\omega^2=\tfrac{1}{2}Q^2/I,$$

$$E_p=\int V(\psi_3)d^Dx.$$

The boundary condition is $\psi_3\to 1$ as $r\to\infty$, so we need $V(1)=0$.

A stationary Q-lump is a critical point of the energy functional $E[\vec{\psi}]$, subject to Q having some fixed value. Such a Q-lump is (classically) stable if this critical point is a local minimum of E. The usual (Derrick) scaling argument shows that any stationary Q-lump must satisfy

$$(2-D)E_d-DE_p+DE_k=0. \tag{4}$$

Let the positive constant m be defined by $V'(1)=-m^2$; in other words, $V(\psi_3)\approx m^2(1-\psi_3)\approx\frac{1}{2}m^2|\psi|^2$ for $\psi_3\approx 1$. Then, near spatial infinity, the Euler–Lagrange equations corresponding to E imply that

$$\nabla^2\psi-(m^2-\omega^2)\psi=0.$$

So in order to satisfy the boundary condition $\psi\to 0$ as $r\to\infty$, we need $\omega\leqslant m$. The solitons are exponentially localized if $\omega<m$, but less-localized solitons with $\omega=m$ may also exist.

The parameter m is part of the specification of the system, and the parameter Q is set by the initial data. Each of these two parameters has dimensions; the combination Qm^{D-1} is dimensionless, whereas the combination $(Q/m)^{1/D}$ has dimension of length, and determines the size of the soliton. Configurations in this system are classified topologically by their topological charge N (an integer); if $D=2$, then N is the winding number, while if $D=3$, then N is the Hopf number. Let $E(N,Q)$ denote the energy of a configuration (or rather, of data $\vec{\phi},\vec{\phi}_t$) with topological charge N and Noether charge Q.

Let V_0 be the normalized potential function $V_0:=2V/m^2$. Note that $V_0(\psi_3)/|\psi|^2\to 1$ as $\psi_3\to 1$. It is clear from (4) that if $V_0\geqslant|\psi|^2$ everywhere, with $V_0>|\psi|^2$ somewhere, then there can be no solution. So the constant K defined by $K=\min[V_0(\psi_3)/|\psi|^2]$ should satisfy $K\leqslant 1$. It then follows that

$$E_p=m^2\int V_0\geqslant m^2KI=(Km^2/\omega^2)E_k\geqslant(Km^2/\omega^2)E_p, \tag{5}$$

where the final inequality comes from (4). As a consequence, we have

$$Km^2 \leqslant \omega^2 \leqslant m^2. \tag{6}$$

In the $D=3$ case, the first inequality is strict: $Km^2 < \omega^2 \leqslant m^2$.

In two spatial dimensions, it is possible to have $K=1$, which corresponds to the choice $V(\psi_3)=\frac{1}{2}m^2(1-\psi_3^2)$. So here $\omega=m$. This system,[5] and generalizations in which the target space is some other Kähler manifold, arise naturally by dimensional reduction from "pure" sigma models in one dimension higher.[6] The energy satisfies a Bogomolny bound $E(N,Q) \geqslant 4\pi N + mQ$, which (for $N \geqslant 2$) can be saturated: for each value of $N \geqslant 2$ and Q, there is an explicit family $\mathcal{M}$ of stationary multi-soliton solutions such that $E(N,Q)=4\pi N+mQ$. There is no force between the individual solitons: in particular, the total energy has the additive property $E(N_1,Q_1)+E(N_2,Q_2)=E(N_1+N_2,Q_1+Q_2)$. One may use moduli-space methods (as was done in Refs. 7–9 for other sigma-model systems) to investigate the scattering of moving solitons;[5] this involves finite-dimensional mechanics on $\mathcal{M}$. The dynamics turns out to be rather exotic (as is also the case[10–12] for nontopological Q-balls). The solitons are only polynomially localized, and the nonexistence of an $N=1$ soliton is related to this; an $N=1$ configuration tends to shrink in size, and there is no stationary $N=1$ solution.

On the other hand, if $K<1$, then one-solitons can exist. Different choices of V (having $K<1$) seem to lead to similar behavior, but this has yet to be fully investigated; in what follows, we take $V_0=\frac{1}{2}(1-\psi_3^4)$, so $K=\frac{1}{2}$. Let us consider, first, the thin-wall limit,[13] where $Qm^{D-1} \gg 1$. In this limit, the (bulk) contributions E_p and E_k to the energy are very much greater than the (surface) contribution E_d. So, the energy is approximately $E \approx \frac{1}{4}m^2 \int (1-\psi_3^4) + \frac{1}{2}Q^2/\int (1-\psi_3^2)$. Without loss of generality, we may assume that $\psi_3=1$ outside of some compact set. So space is partitioned into three regions: one (with infinite volume) where $\psi_3=1$, the second (with volume A) where $|\psi_3| \neq 1$, and the third (with volume B) where $\psi_3=-1$. Note that E depends on A (and on the value that ψ_3 takes on A), but not on B, and that

$$\frac{\delta E}{\delta \psi_3} = (\omega^2 - m^2\psi_3^2)\psi_3.$$

So for fixed A, the function E has a minimum for $\psi_3=0$ ($\psi_3=\pm\omega/m$ are local maxima). Hence we should set $\psi_3=0$ on A, and the energy becomes

$$E = \tfrac{1}{2}Q^2/A + \tfrac{1}{4}m^2A.$$

Thus for a given value of Q, the energy has the minimum value $E_{\min}=mQ/\sqrt{2}$ when $A=Q\sqrt{2}/m$. Note that $\omega=m/\sqrt{2}$, at the lower end of its allowed range (6).

To make further progress, we need to include the effect of surface tension, in other words include the term E_d. Let us consider, first, the planar case $D=2$. For simplicity, we assume rotational symmetry about a point in the plane: the field is taken to have the form $\psi = \sin(f)\exp(\mathrm{i}N\theta)$ and $\psi_3=\cos(f)$, where $f=f(r)$. The boundary conditions are $f(0)=\pi$ and $f(\infty)=0$, and N is the topological charge. The energy functional $E=E_d+E_k+E_p$ was minimized numerically, for various values of m, Q and N. The term E_k was used in the form $E_k=Q^2/I$, so that one can minimize while keeping Q fixed; the quantity ω does not enter explicitly, but can be derived (via the formula $\omega=Q/I$) once the minimum has been found. In each case that was investigated, a smooth minimum was reached. For $N=1$ and $Qm=3200\pi$ (close to the thin-wall limit), the profile function $f(r)$ is plotted in Fig. 1. We see that there is a region around $r=0$ where $f(r)$ drops rapidly from π to $\pi/2$ (the term E_d prevents this region from shrinking further in size), and then a region (corresponding to A in the argument above) where $f=\pi/2 \Leftrightarrow \psi_3=0$. Outside of this region, the field takes on its asymptotic value $f=0 \Leftrightarrow \psi_3=1$.

Figure 2 displays results for $N=1$, $m=1$ and a range of values of Q. We see that E is very close to being linear in Q (recall that in the Bogomolny case, it is exactly linear): to a very good

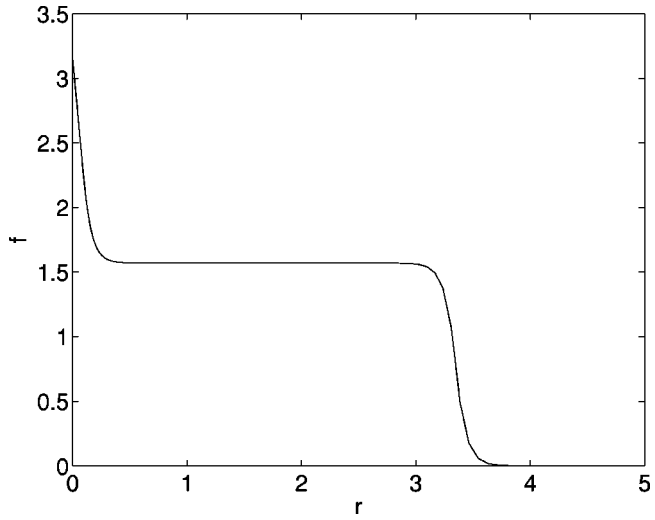

FIG. 1. The profile function $f(r)$ for the one-soliton solution on the plane, with $m=20$ and $Q=160\pi$.

approximation, we have $E=4\pi+3Q/4$. As for ω, we know from (6) that ω has to be in the range $1/\sqrt{2}<\omega<1$, and we see from the figure that this is so; furthermore, $\omega\to 1/\sqrt{2}$ as $Q\to\infty$ (the thin-wall limit[13]), while $\omega\to 1$ as $Q\to 0$ (the thick-wall limit[14]).

In the Bogomolny case[5] mentioned previously, the energy $E(N,Q)$ of a stationary soliton has the feature that, for a given Q, the quantity $E_N:=(4\pi N)^{-1}E(N,NQ)$ is independent of N; in fact, $E_N=1+mQ/4\pi$. This corresponds to the fact that in this Bogomolny-type system, there is no force between stationary solitons. For the potential $V=\frac{1}{4}m^2(1-\psi_3^4)$, however, there are such forces. This can be seen by examining E_N for fixed $Q=4\pi$ and for various values of N. Table I shows the results for $1\leqslant N\leqslant 7$. The energy density of the one-soliton is peaked at the point $r=0$, whereas that for the rotationally-symmetric N-soliton is peaked on a ring. Note that E_N is a decreasing function of N, which suggests that this N-soliton is stable against breakup into solitons of lower topological charge. But this remains to be checked; in particular, one should investigate the vibrational modes about these rotationally-symmetric solutions.

Finally, let us turn to the case of $D=3$ spatial dimensions. Configurations with nonzero Hopf number N look like closed loops, which may be linked or knotted. Static knot-solitons are have been studied in the Faddeev–Skyrme system, where a Skyrme term is added to the Lagrangian: this extra term stabilizes the solitons, which would otherwise shrink.[15–18] The question here is whether there exist stationary Hopf solitons which are stabilized by internal rotation rather than by

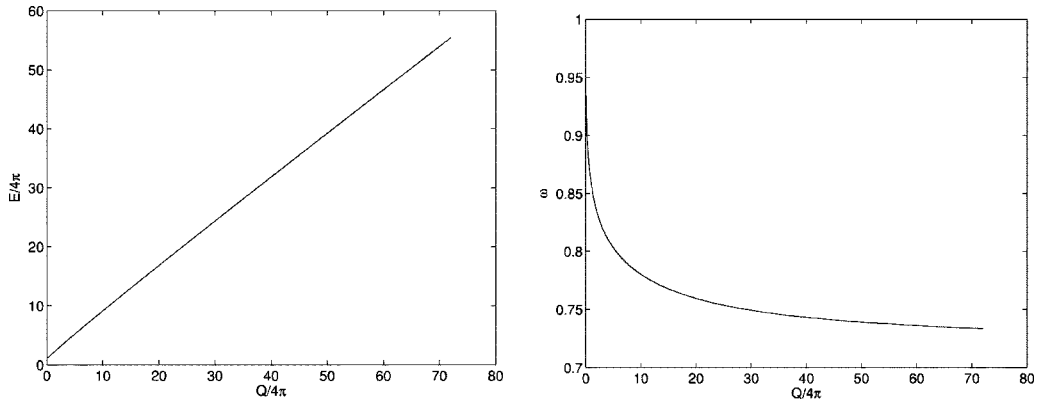

FIG. 2. The energy E and angular frequency ω of the one-soliton, as functions of Q.

TABLE I. Energy $E_N=E(N,NQ)/(4\pi N)$ and frequency ω/m, for $m=1$ and $Q=4\pi$.

N	1	2	3	4	5	6	7
E_N	1.888	1.840	1.826	1.820	1.817	1.816	1.815
ω/m	0.859	0.826	0.817	0.814	0.882	0.811	0.810

a Skyrme term. The answer to this question appears to be negative; what happens is as follows. Consider an $N=1$ configuration. Typically, $\psi_3=1$ at spatial infinity and on a curve which extends to infinity; let us visualize this curve as the z-axis. Second, $\psi_3=-1$ on a closed loop L around the z-axis. Finally, $\psi_3=0$ on a torus around the z-axis, with the loop L in its interior. So the region A in the previous thin-wall analysis is a thickened torus (with the B-region in its interior) resembling a closed string. Numerical experiments indicate that, roughly speaking, the Q-effect supports the thickness of the string, but not its length; the string has a tension which causes its length to shrink. So the configuration collapses, and there is no stationary Hopf soliton in this system. In principle it remains a possibility that for some potential function V, some value of Q, and some nonzero value of the Hopf number N, there might exist a stationary solution, but this seems rather unlikely.

Another way of viewing the situation is as follows. The Q-mechanism provides a lower bound on the quantity I (since ω is bounded above, and $Q=I\omega$ is fixed); this in turn means that the volume of the soliton is bounded below. But surface tension then acts to make the soliton spherical. So we are led to the following conjecture: any stationary Q-ball (whether topological or not) with $\omega<m$, in D spatial dimensions, has O(D) symmetry. (In the Bogomolny case, where $\omega=m$, rotational symmetry is not essential.[5]) For standard Q-balls, this conjecture is known to be true,[13] but it is not immediately clear that the result extends to cases (such as the present one) where the target space is nontrivial. The instability of Hopf Q-solitons is an immediate consequence of the conjecture, since O(3) symmetry implies that the Hopf number is zero.

III. THE O(4) SIGMA MODEL IN 3+1 DIMENSIONS

In this section, we investigate the analogous problem for the O(4) sigma model in three space dimensions. The details of the system are similar to those of the previous section. The field takes values on S^3, and is represented as a unit four-vector $\vec{\phi}=(\phi_0,\phi_1,\phi_2,\phi_3)$. The Lagrangian is (1), as before, but with the potential being allowed to depend on ϕ_0 and ϕ_3: $V=V(\phi_0,\phi_3)$. In general, this breaks the global O(4) symmetry to O(2), the subgroup which rotates ϕ_1 and ϕ_2, leaving ϕ_0 and ϕ_3 fixed. The expressions for E_d, E_k and E_p are the same as before, with $D=3$, except that in E_d there is an extra term involving $(\partial_j\psi_0)^2$.

We take the boundary condition to be $\psi_0\to 1$ as $r\to\infty$ in $\mathbf{R}^3$. The mass m is defined by $V(\psi_0,\psi_3)\approx m^2(1-\psi_0)\approx\frac{1}{2}m^2(|\psi|^2+\psi_3^2)$ for $\psi_0\approx 1$; the function V_0 and the constant K are defined as before. The virial relation from (4) with $D=3$ holds as before, as does the inequality $Km^2<\omega^2\leqslant m^2$.

In Ref. 19, this system was studied, with the potential $V_0=2(1-\psi_0)$. Since in that case we have $K=1$, no soliton solution can exist. The authors of Ref. 19 reach this conclusion for the topologically trivial case $N=0$; they report numerical evidence for a nontrivial solution with $N=1$, but this cannot be correct.

In order to allow the possibility of nontrivial solutions, we need a potential V_0 which has $K<1$; for what follows, we shall take $V_0=\frac{1}{2}(1-\psi_0^4)$ as in the previous section. Then there are solutions, but it appears that they all have trivial topology ($N=0$). One way to see what happens is to consider the thin-wall limit, where $m^2Q\gg 1$. So, the energy is approximately $E\approx\frac{1}{4}m^2\int(1-\psi_0^4)+\frac{1}{2}Q^2/\int|\psi|^2$, and the corresponding variational equations are

$$\xi\psi_0-m^2\psi_0^3=0,\quad \xi\psi-\omega^2\psi=0,\quad \xi\psi_3=0, \tag{7}$$

where $\xi:=m^2\psi_0^4+\omega^2|\psi|^2$ (the ξ-term arises from enforcing the constraint $\vec{\phi}\cdot\vec{\phi}=1$). These equations (7) have a number of solutions, namely,

(i) $\psi_0=0,\ \psi=0,\ \psi_3=\pm 1;$
(ii) $\psi=0,\ \psi_3=0,\ \psi_0=\pm 1;$
(iii) $\psi_0=\psi_3=0,\ |\psi|^2=1;$
(iv) $\psi_3=0,\ \psi_0=\pm\omega/m,\ |\psi|^2=1-\omega^2/m^2.$

So to construct a mimimum-energy configuration, we must partition space $\mathbf{R}^3$ into regions (separated by infinitesimally-thin walls), on each of which one of these relations holds. It is clear that regions on which $\psi_3\neq 0$ contribute only to E_p, and that we can reduce the total energy by instead setting $\psi_3=0,\ \psi_0=1$ on these regions. In other words, ψ_3 ''collapses'' to zero, and is replaced by ψ_0.

This is exactly what one sees in numerical simulations. For example, we may start with the O(3)-symmetric ''hedgehog'' ansatz

$$\psi_0+\mathrm{i}\psi_j\sigma_j=\exp[\mathrm{i}f(r)x^j\sigma_j/r]; \tag{8}$$

here σ_j denotes the Pauli matrices, and the profile function $f(r)$ satisfies the usual boundary conditions $f(0)=\pi,\ f(\infty)=0$. The winding number is $N=1$. Note that $\psi=\psi_1+\mathrm{i}\psi_2$ vanishes on the x^3-axis, and that $\psi_0(0)=-1$. If we now relax the configuration by flowing down the energy gradient, then ψ_3 approaches zero everywhere except at the single point $r=0$; in other words, there is no continuous minimum in this topological class. By contrast, there is a smooth minimum which has $\psi_3\equiv 0$: this is topologically trivial, and is essentially a standard (nontopological) Q-ball.

IV. CONCLUDING REMARKS

We begin with a few remarks on the similarities with stationary topological soliton solutions of the Landau–Lifshitz equation

$$\frac{\partial\vec{\phi}}{\partial t}=-\vec{\phi}\times\frac{\delta E}{\delta\vec{\phi}}. \tag{9}$$

Here $\vec{\phi}$ is a unit three-vector representing the local orientation of magnetization, and the energy E is given by

$$E=\int\left[\frac{1}{2}(\partial_j\vec{\phi})\cdot(\partial_j\vec{\phi})+U(\phi_3)\right]d^Dx. \tag{10}$$

A typical choice for the function U is $U=A(1-\phi_3^2)$, where A is a constant; this corresponds to an easy-axis anisotropy. The boundary condition is $\phi_3\to 1$ as $r\to\infty$. The total magnetization

$$M=\int(1-\phi_3)d^Dx \tag{11}$$

is a conserved quantity. It is clear from scaling that the only static solutions are the Belavin–Polyakov solitons[1] in spatial dimension $D=2$, with $U\equiv 0$. But by allowing time dependence, more solutions are possible. In particular, we may allow periodic time dependence, and look for stationary solutions such that

$$\phi_1+\mathrm{i}\phi_2=\psi(x^j)\mathrm{e}^{\mathrm{i}\nu t},\quad \phi_3=\psi_3(x^j). \tag{12}$$

With this ansatz, the Landau–Lifshitz equation (9) is equivalent to

$$\frac{\delta}{\delta\vec{\phi}}\left(E-\frac{1}{2}\nu M\right)=0. \tag{13}$$

We may think of the solutions as critical points of E, subject to the constraint that M has a given value.[20] The simplest example occurs if $U=\frac{1}{2}\nu(1-\psi_3)$, for then the functional appearing in (13) consists of only the gradient term, and the Belavin–Polyakov solitons are solutions (in $D=2$); these correspond, of course, to the Bogomolny-type Q-lump solitons.[5] The analysis of stationary topological Landau–Lifshitz solitons leads to rather similar results as for Q-solitons (although the dynamics of moving solitons is quite different). In $D=2$, there are topological solutions (called magnetic bubbles—see Ref. 21 for a review); a single soliton is pinned in space, and cannot move.[22] In $D=3$, on the other hand, there are no stationary Hopf solitons;[23] however, such solitons can be stabilized by allowing them to move at constant velocity.[23,24]

Returning to sigma-model dynamics, we have seen that the Q-mechanism stabilizes topological solitons in $D=2$ spatial dimensions, but not in $D=3$. Stabilizing vortex rings (Hopf textures) in $D=3$ is particularly difficult, since there are two length-scales (the length of the loop and its width), each of which has to be fixed. The Q-effect can stabilize the latter, but not the former. One does get stable loops in systems with a Skyrme term,[15,16] and also in systems with a magnetic field sufficiently strongly coupled to the scalar field (minimal coupling is not enough).[25] But in the basic versions of each of these systems, there is only one length-scale; and so the length of the loop is of the same order as (and only slightly greater than) its thickness. It remains an open question as to whether there is a system admitting a stable Hopf soliton in which the two length-scales are significantly different.

A sigma-model soliton in $D=2$ can be thought of as a (straight) sigma-model string in three spatial dimensions. So, for example, the Q-stabilized solitons discussed in this article may find application as cosmic strings. Given an appropriate potential V, long strings with internal rotational energy will be stable, although closed loops will eventually shrink and decay. In this connection, it is worth recalling that, on a cosmological scale, both the width and the length of sigma-model strings are stabilized by cosmological expansion; but stabilizing the length requires a greater rate of expansion than stabilizing the width.[26]

I. INTRODUCTION

The existence of Q-balls is a general feature of scalar field theories carrying a conserved U(1) charge.[1,2] Q-balls can be understood as bound states of scalar particles and appear as stable classical solutions (nontopological solitons) carrying a rotating time dependent internal phase. They are characterized by a conserved nontopological charge Q (Noether charge) which is responsible for their stability (see, for example, Refs. 3 and 4). These features differentiate the Q-ball interaction properties from those of the topological solitons since here the charge Q can take arbitrary values in a specific range, allowing for the possibility of charge transfer between solitons during the interaction process.

Up till now, comprehensive studies of these objects have been made by using either numerical simulations[3–5] or some analytic considerations.[1,6,7] Recently, in Ref. 8 the explicit relation between the energy and the charge of the Q-balls has been derived using analytic arguments. In particular, a semi-Bogomolny argument in the energy density led to a first order differential equation whose solution, however, did not satisfy the correct boundary conditions and differed considerably from its exact form. In this work, we present a method to obtain an analytic form for the Q-ball profile function which is in good agreement with the numerical results.

We consider the U(1) Goldstone model, given by the Lagrangian

$$\mathcal{L}=\tfrac{1}{2}\partial_\mu\phi\,\partial^\mu\overline{\phi}-\mathrm{U}(|\phi|), \tag{1}$$

where ϕ is a single complex scalar field in three spatial dimensions while the potential $\mathrm{U}(|\phi|)$ is a function of $|\phi|$ only and has a single minimum at $\phi=0$. This is equivalent of stating that there is a sector of scalar particles (mesons) which carry U(1) charge and have mass squared equal to $\frac{1}{2}\mathrm{U}''(0)$. The corresponding energy functional is given by

$$E=\int\left(\frac{1}{2}|\partial_t\phi|^2+\frac{1}{2}|\nabla\phi|^2+\mathrm{U}(|\phi|)\right)d^3x. \tag{2}$$

The model has a global U(1) symmetry and an associated conserved Noether current J_μ exists whose covariant conservation $\partial^\mu J_\mu=0$ leads to the existence of the conserved Noether charge Q given by

a)Permanent address: Insitute of Mathematics, University of Kent, Canterbury CT2 7NF, UK. Electronic mail: t.ioannidou@ukc.ac.uk
b)Electronic mail: vlachos@physics.auth.gr

$$Q=\frac{1}{2i}\int(\bar{\phi}\,\partial_t\phi-\phi\,\partial_t\bar{\phi})d^3x. \tag{3}$$

A stationary Q-ball solution has the form

$$\phi=e^{i\omega t}f(r), \tag{4}$$

where $f(r)$ is a real radial profile function which satisfies the ordinary differential equation

$$f''(r)+\frac{2}{r}f'(r)=-\omega^2 f(r)+\mathrm{U}'(f) \tag{5}$$

with the condition $f(\infty)=0$ and $f'(0)=0$. This equation can either be interpreted as describing the motion of a point particle moving in a potential with friction,[1] or in terms of Euclidean bounce solutions.[9] In each case the effective potential being $\mathrm{U}_{\mathrm{eff}}(f)=\omega^2 f^2/2-\mathrm{U}(f)$ leads to constraints on the potential $\mathrm{U}(f)$ and the frequency ω in order for a Q-ball solution to exist. First, the effective mass of f must be negative. If we consider a potential $\mathrm{U}(f)$ which is non-negative and satisfies $\mathrm{U}(0)=\mathrm{U}'(0)=0$, $\mathrm{U}''(0)=\omega_+^2>0$, then one can deduce that $\omega<\omega_+$. Furthermore, the minimum of $\mathrm{U}(f)/f^2$ must be attained at some positive value of f, say $0<f_0<\infty$, and existence of the solution requires that $\omega>\omega_-$ where $\omega_-^2=2\mathrm{U}(f_0)/f_0^2$. Hence, Q-balls exist for all ω in the range $\omega_-<|\omega|<\omega_+$.

Then, the charge and the energy of a stationary Q-ball solution simplify to

$$Q=4\pi\omega\int r^2 f^2(r)\,dr, \tag{6}$$

$$E=4\pi\int\left(\frac{1}{2}\omega^2 f^2(r)+\frac{1}{2}f^{*2}(r)+\mathrm{U}(f)\right)r^2\,dr. \tag{7}$$

It has been observed using numerical and analytic methods that the classical stability of a Q-ball is related with the dependence of its charge on the internal frequency ω. For small internal frequency, close to its minimal value ω_-, the profile function is almost constant, which implies that the charge (6) is large and this corresponds to the so-called thin-wall approximation. On the other hand, for large internal frequency (close to its maximal value ω_+) the profile function (and thus the charge) tends to zero and this corresponds to the thick-wall approximation. In fact, for $\omega\to\omega_+$, the behavior of the charge Q depends on the particular form of the potential and the number of dimensions.[7] In the case studied here we show that $Q\to\infty$ as $\omega\to\omega_+$.

The choice of the potential is not unique; the standard requirement is that the function $\mathrm{U}(f)/f^2$ has a local minimum at some value of f different from zero. For simplicity, we consider the following form,

$$\mathrm{U}(f)=f^2(1+(1-f^2)^2), \tag{8}$$

which implies that in terms of the earlier notation we have that $\omega_+=2$ and $\omega_-=\sqrt{2}$, and therefore stable Q-balls exist for $\sqrt{2}<\omega<2$. In this case, the energy-charge dependence of the Q-balls, obtained in Ref. 8 using a semi-Bogomolny argument, is given by the analytic expression

$$E_{\mathrm{Bog}}=\sqrt{2}\,Q_{\mathrm{Bog}}+\frac{3^{2/3}\pi^{1/3}}{2^{7/6}}Q_{\mathrm{Bog}}^{2/3}+\frac{5\pi^{2/3}}{2^{11/6}3^{2/3}}Q_{\mathrm{Bog}}^{1/3}-\frac{\pi(4+3\pi^2)}{36\sqrt{2}}+\frac{\pi^{4/3}(17-216\pi^2)}{2592\;\;2^{1/6}\;\;3^{1/3}}Q_{\mathrm{Bog}}^{-1/3}$$
$$+\frac{\pi^{5/3}(20-54\pi^2+27\pi^4)}{1944\;\;2^{5/6}\;\;3^{2/3}}Q_{\mathrm{Bog}}^{-2/3}+O(Q_{\mathrm{Bog}}^{-1}). \tag{9}$$

For large Q, the above equation corresponds to the upper energy bound. The same result can be obtained by representing the Q-ball profile function by the Woods–Saxon distribution (i.e., a generalization of the semi-Bogomolny solution) as presented in Ref. 8.

Let us emphasize that neither the semi-Bogomolny nor the Woods–Saxon ansatz describe accurately the Q-ball profile function. In particular, in both cases the derivative of the profile function at the origin is nonzero (that is, different from the required boundary conditions) while the corresponding profile function differs from the exact one obtained by solving numerically the equation of motion. In the next section, we show that the symmetrized Woods–Saxon distribution describes accurately the Q-ball profile function and satisfies the correct boundary conditions.

II. EQUATION OF MOTION

The Q-ball equation of motion (5) for the specific potential (8) is given by

$$f''(r)+\frac{2}{r}f'(r)=(4-\omega^2)f(r)-8f^3(r)+6f^5(r) \tag{10}$$

and satisfies the boundary conditions $f'(0)=0$, $f(\infty)=0$. For large values of the argument r the nonlinear terms in (10) can be neglected and we get the asymptotic behavior $f(r) \sim \exp(-\sqrt{4-\omega^2}\,r)$. The exact solution of (10) should contain only one free parameter ω so that the charge Q, the energy E and the initial value $f(0)$ should in principle be expressed as functions of this parameter. Since Eq. (10) is too complicated to be tackled by analytic methods, we shall seek a suitable ansatz for the profile function and search for relations connecting E, Q and $f(0)$ with ω.

As mentioned earlier, a test profile of the Woods–Saxon type cannot reasonably approximate the Q-ball solution since it fails to satisfy the correct boundary conditions. Nevertheless, it implies an energy-charge relation (9) which holds remarkably well for a wide range of energies, a fact that certainly requires some further investigation. A more general test function that satisfies the correct boundary conditions and has the correct asymptotic behavior is given by the symmetrized Woods–Saxon distribution

$$f(r)=\frac{c}{\sqrt{1+c_1\cosh(\alpha r)}}\,. \tag{11}$$

The values of the arbitrary parameters c, c_1, and α can then be determined by fitting the data of the numerically solved (10). Having done that, we got a very satisfactory agreement in all cases. It is interesting to realize that $f(r)$ satisfies the following differential equation,

$$f''(r)+\frac{2}{r}f'(r)=\frac{\alpha^2}{4}\left(1-\frac{4}{\alpha r}\right)f(r)-\frac{\alpha^2}{c^2}\left(1-\frac{1}{\alpha r}\right)f^3(r)+\frac{3\alpha^2}{4c^4}\left((1-c_1^2)+\frac{2}{3}\frac{c_1^2}{\alpha r}\right)f^5(r)+\mathrm{O}(f^7), \tag{12}$$

which in the limit $\alpha r \gg 4$ looks exactly like (10). It is then quite reasonable to expect that there must be a critical value of $r=r_c$ beyond which the following equations must approximately hold true:

$$\frac{\alpha^2}{4}\left(1-\frac{4}{\alpha r_c}\right)\simeq 4-\omega^2, \tag{13}$$

$$\frac{\alpha^2}{c^2}\left(1-\frac{1}{\alpha r_c}\right)\simeq 8, \tag{14}$$

$$\frac{3\alpha^2}{4c^4}\left((1-c_1^2)+\frac{2}{3}\frac{c_1^2}{\alpha r_c}\right)\simeq 6 \quad . \tag{15}$$

The thin-wall approximation is reached when $c_1\to 0$, so we will assume that $c_1<1$ and we shall neglect the last term on the left hand side of (15). Then the system above gives the approximate solutions

$$c\simeq\sqrt{\frac{2}{3}}\sqrt{1-c_1^2}\sqrt{1+\sqrt{1-\frac{3}{8}\frac{4-\omega^2}{1-c_1^2}}}, \tag{16}$$

$$\alpha\simeq\frac{4\sqrt{2}}{3}\sqrt{1-c_1^2}\left(1+\sqrt{1-\frac{3}{8}\frac{4-\omega^2}{1-c_1^2}}\right), \tag{17}$$

$$\alpha r_c\simeq\frac{1+\sqrt{1-\frac{3}{8}(4-\omega^2)/(1-c_1^2)}}{-\frac{1}{2}+\sqrt{1-\frac{3}{8}(4-\omega^2)/(1-c_1^2)}} \quad . \tag{18}$$

A comparison with values obtained by a direct fit shows that the relations above are quite good. In fact, Eq. (16) is excellent, while Eq. (17) gives the right shape but the actual values for α are on the average 10% higher than expected, implying a faster drop of the profile function. Note that both c and a are slowly varying functions of ω.

The equation of motion (10) can be written as

$$\frac{d}{dr}\left(\frac{1}{2}f^{*2}(r)+\frac{1}{2}\omega^2 f^2(r)-\mathrm{U}(f)\right)=-\frac{2}{r}f'^2(r) \quad . \tag{19}$$

In the absence of the friction term, Eq. (19) would simply imply the conservation of energy for the corresponding mechanical problem. In the presence of friction and upon integrating (19) we get that the initial potential energy equals the work done by friction. This relation can be used to provide a further constraint on the form of (11):

$$\frac{1}{2}\omega^2 f^2(0)-\mathrm{U}(f(0))=-2\int_0^\infty\frac{f'^2(r)}{r}dr \quad . \tag{20}$$

Recall that $f(0)=c/\sqrt{1+c_1}$. Finally, using the symmetrized Woods–Saxon distribution (11), the charge (6) and the energy (7) of the Q-ball can be explicitly evaluated in terms of the parameters c, c_1, and α:

$$Q=4\pi\omega\frac{c^2}{3\alpha^3\sqrt{1-c_1^2}}\cosh^{-1}\left(\frac{1}{c_1}\right)\left(\pi^2+\cosh^{-1}\left(\frac{1}{c_1}\right)^2\right), \tag{21}$$

$$E=4\pi\left[\frac{\alpha^2+4(4+\omega^2)}{8}I_0-\left(2+\frac{\alpha^2}{4c^2}\right)I_1+\left(1+\frac{\alpha^2}{8c^4}(1-c_1^2)\right)I_2\right], \tag{22}$$

where the integrals I_0, I_1, and I_2 are given by

$$I_0=\frac{Q}{4\pi\omega}, \tag{23}$$

TABLE I. Values of the parameters c, c_1, α and $f(0)$ obtained from (11) and numerically $[f(0)_{\text{num}}]$ for different values of ω.

Q	ω	c	c_1	α	$f(0)$	$f(0)_{\text{num}}$
23.68	1.79	1.097	0.12	2.66	1.037	1.024
35	1.72	1.087	0.068	2.60	1.052	1.055
61.6	1.64	1.068	0.0243	2.54	1.056	1.065
149.3	1.57	1.049	0.0031	2.53	1.048	1.056

$$I_1 = c^2 I_0 + c^2 c_1 \frac{d}{dc_1} I_0, \tag{24}$$

$$I_2 = c^4 I_0 + 2c^4 c_1 \frac{d}{dc_1} I_0 + \frac{1}{2} c^4 c_1^2 \frac{d^2}{dc_1^2} I_0 \ . \tag{25}$$

It is readily seen that the actual values for Q and E depend strongly on the value of c_1 especially for small values of c_1. In this region, c_1 can be eliminated in favor of Q to get

$$E = \left(\frac{1}{\omega} + \frac{\omega}{2}\right) Q + \frac{24 + 3\alpha^2}{16\omega} (q\omega)^{1/3} Q^{2/3} + \frac{24 + 3\alpha^2}{8\omega} (q\omega)^{2/3} Q^{1/3} - \frac{(8 + \alpha^2)\,\pi^2}{8\omega} q\omega \ + O(Q^{-1/3}), \tag{26}$$

where

$$q = \frac{4\pi c^2}{3\alpha^3} \ . \tag{27}$$

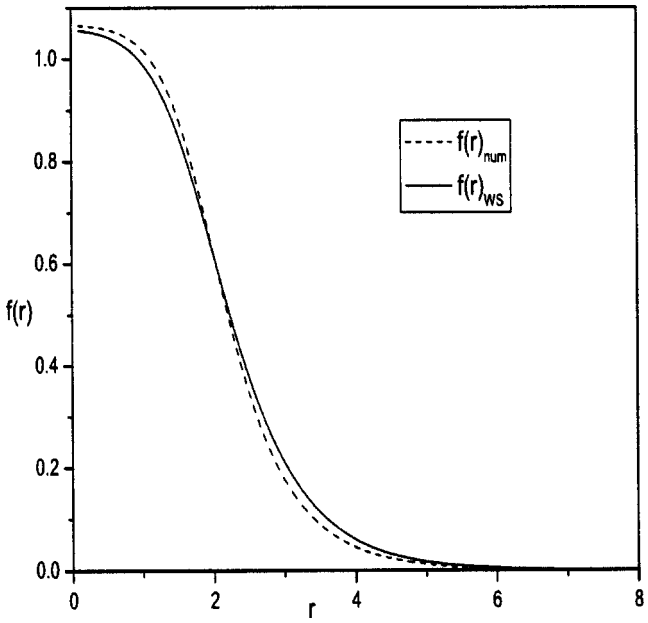

FIG. 1. The profile function $f(r)$ as a function of r for $\omega = 1.64$.

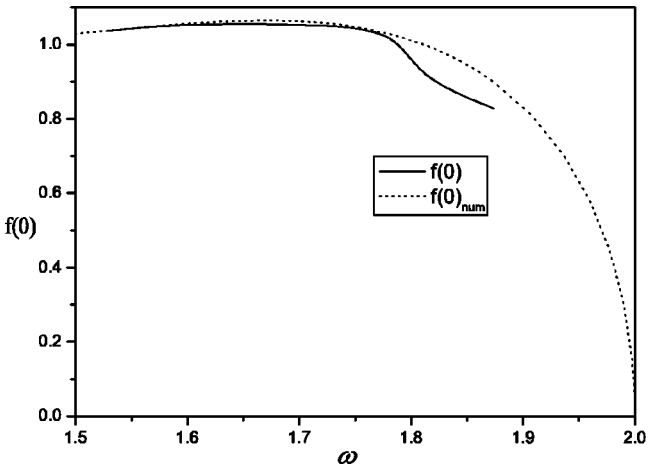

FIG. 2. The frequency dependence of the profile function at the origin $f(0)$.

It is interesting to see that the leading terms of (26) are identical to those of (9) for $\alpha=2\sqrt{2}$, $c=1$, $\omega=\sqrt{2}$. Taking into account the fact that α and c are slowly varying functions of ω helps to explain the wide range of applicability of (9).

As a result, the parameters c, c_1, α, and ω for specific values of the charge Q can be uniquely determined by solving the system of equations: (16), (20), (21), and (22) provided that the energy-charge dependence of the Q-ball is given by (9). We expect the values obtained that way to be quite accurate as long as (9) remains reasonably accurate. In practice, this means that $Q\gtrsim 16$, a value far distant from the values normally associated with the region of the thin-wall approximation. In Table I the values of the arbitrary constants in (11) are presented for different values of Q (or ω). That way, the initial value $f(0)$ can be determined explicitly; a comparison with values obtained numerically show that the symmetrized Woods–Saxon distribution describes accurately the Q-ball profile function.

Finally, Fig. 1 presents the profile function obtained analytically and numerically for $\omega=1.64$. Figure 2 presents the values of the profile function at the origin for different ω obtained numerically and analytically.

III. CONCLUSIONS

In this work, the basic properties of the Q-ball profile function have been extensively studied by means of mainly analytic methods. In particular, it has been shown that the profile function can be accurately approximated by the symmetrized Woods–Saxon distribution, while the corresponding energy and charge can be explicitly evaluated. The approach presented here might prove to be particularly useful in understanding the basic properties of Q-balls such as existence, small vibrations and stability. We believe that a similar line of argument can be applied to study the profile function and the energy-charge dependence in other types of potentials. In fact, we expect that the symmetrized Woods–Saxon distribution will accurately describe all types of Q-balls independently of the exact form of the scalar potential. Work in this direction is currently in progress.

Topics in quantum integrable systems

Kazuhiro Hikami[a] and Miki Wadati
Department of Physics, Graduate School of Science, University of Tokyo, Tokyo 113, Japan

(Received 15 December 2002; accepted 9 April 2003)

Recent developments in the theory of quantum integrable particle systems in one-dimension with inverse square interactions are reviewed. First the Yangian symmetry is introduced and the energy spectra of the related spin models are discussed. The character of the su$(n)_1$ WZNW theory is shown to be closely related with the Rogers–Szegö polynomial. Second, the infinite dimensional representation for solutions of the Yang–Baxter equation and the reflection equation is given. Based on the representation, the Dunkl operators associated with the classical root systems are constructed. The Macdonald polynomial and its generalization are discussed in connection with the eigenstates for the trigonometric case. Finally, some results on short-range interacting systems are mentioned. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1588743]

I. INTRODUCTION

We define the integrability of quantum systems as an extension of the Liouville theorem for classical systems. The quantum system is integrable when it has M independent mutually commuting conserved operators (M being the number of degrees of freedom). Quantum integrable systems[1] can be classified by the range of interaction. One is short-range interacting systems including the δ-function gas, the Heisenberg XYZ spin chain and the Toda lattice. The other is long-range interacting systems: the most famous systems are due to Calogero,[2] Sutherland,[3] and Moser.[4] See also references in Ref. 5

We consider a system of N identical particles on a line. The Hamiltonians of the Calogero–Sutherland–Moser (CSM) models are written as follows:

$$\mathcal{H}=-\sum_{j=1}^{N}\frac{\partial^2}{\partial z_j{}^2}+2\sum_{1\leqslant j<k\leqslant N}\wp(z_{jk})\cdot(\beta^2-\beta P_{jk}), \tag{1.1}$$

$$\begin{aligned}\mathcal{H}=&-\sum_{j=1}^{N}\frac{\partial^2}{\partial z_j{}^2}+2\sum_{1\leqslant j<k\leqslant N}(\wp(z_{jk})\cdot(\beta^2-\beta P_{jk})+\wp(z_j+z_k)\cdot(\beta^2-\beta Q_jQ_kP_{jk}))\\&+\sum_{j=1}^{N}(\wp(z_j)\cdot(4\alpha^2+4\alpha\overline{\alpha}-2\alpha Q_j)+\wp(2z_j)\cdot(4\overline{\alpha}^2-4\overline{\alpha}Q_j)),\end{aligned} \tag{1.2}$$

where $z_{jk}=z_j-z_k$ and $\wp(z)$ is the Weierstrass $\wp$-function. Note that the original CSM models do not contain internal degrees of freedom expressed by operators P_{jk} and Q_j. The models (1.1) and (1.2) are related to the root system. In this sense, the first one is the A-type, and the second is the BC-type. Another interesting extension is a model confined in an external harmonic potential,

$$\mathcal{H}=-\sum_{j=1}^{N}\frac{\partial^2}{\partial z_j{}^2}+2\sum_{1\leqslant j<k\leqslant N}\frac{\beta^2-\beta P_{jk}}{z_{jk}^2}+\sum_{j=1}^{N}\omega^2 z_j{}^2. \tag{1.3}$$

[a]Electronic mail: hikami@phys.s.u-tokyo.ac.jp

Operators P_{jk} and Q_j act on the spin space of the jth and kth particles, and satisfy the relations

$$P_{jk}P_{kl}=P_{kl}P_{jl}=P_{jl}P_{jk}, \quad P_{jk}Q_j=Q_kP_{jk}, \quad Q_jQ_k=Q_kQ_j,$$

$$P_{jk}^2=Q_j{}^2=\mathbb{1}, \quad \text{for } j,k,l \text{ are distinct.}$$

In the case of su(2) spin-$\frac{1}{2}$, these operators may be chosen nontrivially as $P_{jk}=\frac{1}{2}(1+\boldsymbol{\sigma}_j\cdot\boldsymbol{\sigma}_k)$, $Q_j=\sigma_j^z$, where $\boldsymbol{\sigma}=(\sigma^x,\sigma^y,\sigma^z)$ are Pauli spin matrices. Hereafter we use su(n) spin generator E_j^{ab} $(a,b=1,2,\ldots,n)$ for the jth spin, $E^{ab}=|a\rangle\langle b|$, satisfying the commutation relations

$$[E_j^{ab},E_k^{cd}]=\delta_{jk}(\delta^{bc}E_j^{ad}-\delta^{da}E_j^{cb}). \tag{1.4}$$

It is noted that the permutation operator P_{jk} is written as

$$P_{jk}=\sum_{a,b=1}^{n}E_j^{ab}E_k^{ba}.$$

Studies of the long-ranged interaction systems have made remarkable developments since the discovery of the integrable variants for spin system.[6,7] A well-known example is the Haldane–Shastry (HS) model,

$$\mathcal{H}_{\mathrm{HS}}=\sum_{1\leqslant j<k\leqslant N}\frac{P_{jk}}{\sin^2(\pi(j-k)/N)}. \tag{1.5}$$

As will be discussed later, the Yangian symmetry is revealed for the HS model with *finite* lattice. This fact gives new insights on interesting subjects such as the fractional statistics, the character formula for the WZNW model, and the affine Hecke algebra.

This article presents some recent results related with the quantum CSM models. In Sec. II the Yangian symmetry is explained. We show that the Haldane–Shastry-type spin chains have the Yangian symmetry, and that the character formula for the level-1 WZNW model is related with the HS chain. Section III deals with the infinite-dimensional representation for solutions of the Yang–Baxter equation (YBE) and the reflection equation (RE). We propose a simple method to give matrix solutions of YBE and RE. In Sec. IV the elliptic Dunkl operator is constructed by use of the infinite-dimensional representation. The Hamiltonians for the elliptic CSM model are expressed in terms of the Dunkl operators. The trigonometric limit is discussed in Sec. V. The trigonometric CSM models are studied from the representation of the affine Hecke algebra. In Sec. VI the Macdonald polynomial associated with the root systems is discussed in relation with the q-deformed trigonometric CSM models. Section VIII is devoted to concluding remarks.

II. YANGIAN SYMMETRY AND CHARACTER FORMULA

A. Yangian symmetry

The Yangian symmetry was first defined by Drinfeld[8] as a Hopf algebra associated with the rational solution of the Yang–Baxter equation. The YBE reads (Fig. 1)

$$R^{12}(\xi_{12})\,R^{13}(\xi_{13})\,R^{23}(\xi_{23})=R^{23}(\xi_{23})\,R^{13}(\xi_{13})\,R^{12}(\xi_{12}), \tag{2.1}$$

where the conventional notation, e.g., $\xi_{ij}=\xi_i-\xi_j$, is used. We call ξ_j spectral parameters.

Operator R^{jk} acts on space $V^{\otimes N}$ as R on the jth and kth space, and as identity on the other spaces. For solutions of the YBE, we can define a monodromy matrix $T(\xi)$, which satisfies the quadratic relation

$$R^{12}(\xi_{12})\overset{1}{T}(\xi_1)\overset{2}{T}(\xi_2)=\overset{2}{T}(\xi_2)\overset{1}{T}(\xi_1)R^{12}(\xi_{12}), \tag{2.2}$$

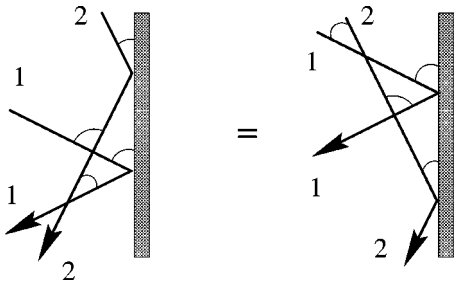

FIG. 1. Yang–Baxter equation (2.1).

where we use the standard notation, $\overset{1}{T}(\xi)=T(\xi)\otimes\mathbb{1}$ and $\overset{2}{T}(\xi)=\mathbb{1}\otimes T(\xi)$. As solutions of the YBE, there are three types of R-matrices: rational, trigonometric, and elliptic ones. When we substitute in the quadratic relation (2.2) a rational su(n) R-matrix $R(u)=u+\hbar P$, we find that matrix elements of the monodromy matrix satisfy commutation relations

$$[T^{ab}(\xi_1),T^{cd}(\xi_2)]=\frac{\hbar}{\xi_{12}}(T^{cb}(\xi_2)\,T^{ad}(\xi_1)-T^{cb}(\xi_1)\,T^{ad}(\xi_2)). \tag{2.3}$$

We refer to $\hbar$ as a ''deformation parameter.'' One defines a set of generators $\{T_l\}$ as a mode expansion of the monodromy matrix $T(\xi)$,

$$T^{ab}(\xi)=\delta^{ab}-\hbar\sum_{k=0}^{\infty}T_k^{ab}\,\xi^{-k-1}. \tag{2.4}$$

The Yangian Y(su(n)) is the algebra constructed from operators T_k^{ab} with commutation relations,

$$[T_l^{ab},T_m^{cd}]=\delta^{bc}\,T_{l+m}^{ad}-\delta^{ad}\,T_{l+m}^{cb}+\hbar\sum_{k=0}^{l-1}(T_{k+m}^{cb}\,T_{l-k-1}^{ad}-T_{l-k-1}^{cb}\,T_{k+m}^{ad}).$$

The above defining relations are simplified when one introduces new generators (Yangian currents) by

$$\begin{aligned}Q_0^{ab}&=T_0^{ab},\\ Q_1^{ab}&=T_1^{ab}+\frac{\hbar}{2}(T_0\,T_0)^{ab},\end{aligned} \tag{2.5}$$

where the notation $(T_0\,T_0)^{ab}=\Sigma_{c=1}^{n}T_0^{ac}\,T_0^{cb}$ is used for brevity. We can show that these currents satisfy the following commutation relations:

$$\begin{aligned}[Q_0^{ab},Q_0^{cd}]&=\delta^{bc}Q_0^{ad}-\delta^{da}Q_0^{cb},\\ [Q_0^{ab},Q_1^{cd}]&=\delta^{bc}Q_1^{ad}-\delta^{da}Q_1^{cb},\\ [Q_0^{ab},[Q_1^{cd},Q_1^{ef}]]&-[Q_1^{ab},[Q_0^{cd},Q_1^{ef}]]\\ &=\frac{\hbar^2}{4}([Q_0^{ab},[(Q_0Q_0)^{cd},(Q_0Q_0)^{ef}]]-[(Q_0Q_0)^{ab},[Q_0^{cd},(Q_0Q_0)^{ef}]]).\end{aligned} \tag{2.6}$$

These are the defining relations for the Yangian Y(su(n)).[8] It is noted that in the limit $\hbar\to 0$ the Yangian algebra Y(su(n)) reduces to the loop algebra for Lie algebra su(n). Due to this, we can

regard the Yangian as the ''deformed Lie algebra.'' The third equation in (2.6) is called the deformed Serre relation. In a precise sense for the Yangian algebra Y(su(n)), we should set the quantum determinant qdet$T(\xi)$ as unity, where the quantum determinant is defined as a center of the Yangian,[9]

$$\mathrm{qdet}T(\xi)=\sum_{\sigma}(-)^{\sigma}T^{1\,\sigma(1)}(\xi)\,T^{2\,\sigma(2)}(\xi+\hbar)\cdots T^{n\,\sigma(n)}(\xi+(n-1)\hbar), \tag{2.7}$$

$$[\mathrm{qdet}T(\xi_1),T^{ab}(\xi_2)]=0,\quad \text{for } a,b=1,2,\ldots,n. \tag{2.8}$$

By definition the Yangian symmetry Y(su(n)) is associated with the quantum integrable colored systems formulated by the rational solution of the YBE, for instance, the XXX–Heisenberg model.[10] The Yangian symmetry in the XXX–Heisenberg spin chain is revealed for the thermodynamical limit. It is a remarkable fact that the Yangian symmetry is realized in the finite-size HS model.[11] As an integrable variant of the HS model, we have the Polychronakos–Frahm (PF) model,[12] which also possesses the Yangian symmetry.[13] The Hamiltonians for these models are respectively written as follows:

$$\mathcal{H}_{\mathrm{HS}}=\sum_{1\leqslant j<k\leqslant N}\frac{z_j z_k}{z_{jk}z_{kj}}P_{jk}, \tag{2.9}$$

$$\mathcal{H}_{\mathrm{PF}}=\sum_{1\leqslant j<k\leqslant N}\frac{1}{z_{jk}^2}P_{jk}. \tag{2.10}$$

We can explicitly construct the Yangian currents $\{Q_0^{ab},Q_1^{ab}\}$ which satisfy the Yangian commutation relations (2.6) and commute with Hamiltonian.

(a) HS model:

$$Q_0^{ab}=\sum_{j=1}^{N}E_j^{ab},$$

$$Q_1^{ab}=\sum_{j,k=1}^{N}{}'\,(E_j E_k)^{ab}\frac{z_j+z_k}{z_{jk}}, \tag{2.11}$$

where Σ' means any two indices do not coincide. For the Yangian currents $\{Q_0^{ab},Q_1^{ab}\}$ to commute with the Hamiltonian $\mathcal{H}_{\mathrm{HS}}$ (2.9), it is required that the coordinates $\{z_j\}$ satisfy

$$\sum_{l=1,\ l\neq j}^{N}\frac{z_j z_l(z_j+z_l)}{z_{jl}^3}=0,\quad \text{for } j=1,2,\ldots,N.$$

This condition is satisfied when

$$z_k=\exp(2\pi\mathrm{i}k/N),\quad \text{for finite } N,$$

$$z_k=\exp(2\gamma k),\quad \text{for } N\to\infty,\ \gamma\in\mathbb{R}.$$

The first case corresponds to the HS model (1.5); all spins are fixed equidistantly on a circle. The second one was studied by Inozemtsev;[14] each spin is on the infinite one-dimensional regular lattice. This model reduces to the XXX–Heisenberg spin chain in a certain limit.

(b) PF model:

$$Q_0^{ab}=\sum_{j=1}^{N}E_j^{ab},$$

$$Q_1^{ab}=-\sum_{j,k=1}^{N}{}' E_j^{ab}\frac{1}{z_{jk}^2}+\sum_{j,k,l=1}^{N}{}' (E_jE_kE_l)^{ab}\frac{1}{z_{jk}z_{kl}}-\sum_{j=1}^{N} E_j^{ab}z_j{}^2. \tag{2.12}$$

In this case the Hamiltonian $\mathcal{H}_{\mathrm{PF}}$ in (2.10) commutes with the Yangian currents $\{Q_0^{ab},Q_1^{ab}\}$ when we set the coordinates as

$$z_j=\sum_{l=1,\ l\neq j}^{N}\frac{2}{z_{jl}^3},\quad \text{for } j=1,2,\ldots,N.$$

This condition means that each spin is fixed on the equilibrium position of the Calogero model (1.3), i.e., $\{z_j\}$ are zeros of the Nth order Hermite polynomial $h_N(x)$:

$$h_N''(x)-2x\,h_N'(x)+2N\,h_N(x)=0.$$

B. Motif

The spectra and their degeneracies of these spin chains can be obtained from Haldane's "motif."[11,15,16] We briefly explain it for the su(2) spin case with N sites. Let us consider a set of pseudo-momenta $m_j\in\{1,2,\ldots,N-1\}$. In terms of pseudo-momenta the energies for HS and PF models are, respectively, given by

$$E_{\mathrm{HS}}=\sum_j m_j(m_j-N), \tag{2.13}$$

$$E_{\mathrm{PF}}=\sum_j (-m_j). \tag{2.14}$$

Remark that the eigenvalues are additive. A set $\{m_j\}$ can be represented by an $(N+1)$-term sequence of 0's and 1's, where a 0 (resp. 1) indicates the absence (presence) of the integer corresponding to the position in the sequence. It is required that consecutive 1's do not occur and that both ends are 0's. These two 0's are sometimes replaced by parenthesis '(' and ')'. This sequence is called "motif." This selection rule shows that motifs are decomposed into a product of "elementary motifs," a series of $(M+1)$ consecutive 0's. Each elementary motif is represented by the Young diagram

$$[M]=\underbrace{\square\square\cdots\square}_{M}$$

and the multiplicities of each motif is calculated as a tensor product of representations of elementary motifs. It is seen that the ground state of the spin chain with $2M$ sites is expressed by motif

$$\underbrace{(101010\ldots0101)}_{2M-1}.$$

For su(n) case, the representation is more involved.[15]

In the following we show that the representation of motif is derived from the Rogers–Szegö polynomial.[17] This polynomial is a special case of the Macdonald polynomial, which will be shown in Sec. VI.

The spectrum of the PF model is simple; energy levels are equally spaced as in (2.14). This fact makes it possible to calculate the partition function $Z_N^{(n)}(q)$ of the N-site su(n) PF spin chain; *modding* the su(n) Calogero model confined in the harmonic potential by the spinless model, the partition function for the PF model is calculated.[18] In the case of su(2), we get

$$Z_N(q)=\sum_{k=0}^{N} q^{(N/2-k)^2}\begin{bmatrix} N \\ k \end{bmatrix}_q, \tag{2.15}$$

where we used the Gaussian q-binomial coefficient (Appendix A),

$$\begin{bmatrix} N \\ k \end{bmatrix}_q=\begin{cases} \dfrac{(q;q)_N}{(q;q)_k\,(q;q)_{N-k}}, & \text{for } 0\leqslant k\leqslant N, \\ 0, & \text{otherwise,} \end{cases}$$

with the q-product $(a;q)_k=(1-a)\,(1-a\,q)\,\cdots(1-a\,q^{k-1})$, $(a;q)_0=1$. The partition function $Z_N(q)$ can be written in a compact form as

$$Z_N(q)=q^{N^2/4}\cdot H_N(x_1=x_2=1;q^{-1}), \tag{2.16}$$

where a function $H_N(x;q)$ is the Rogers–Szegö (RS) polynomial[19] defined by

$$H_N(x;q)=\sum_{k=0}^{N}\begin{bmatrix} N \\ k \end{bmatrix}_q x_1^k\,x_2^{N-k}. \tag{2.17}$$

The RS polynomial is regarded as the q-deformed Hermite polynomial, and we have a generating function,

$$\sum_{N=0}^{\infty}\frac{H_N(x;q)}{(q;q)_N}\,t^N=\frac{1}{(x_1\,t;q)_\infty\,(x_2\,t;q)_\infty}. \tag{2.18}$$

By setting $t\to q\,t$ in the above formula, one obtains the three-term recurrence relation for the RS polynomial,

$$H_N(x;q)=s_{[1]}(x)\,H_{N-1}(x;q)-(1-q^{N-1})\,s_{[1^2]}(x)\,H_{N-2}(x;q), \tag{2.19}$$

where $s_\lambda(x)$ is the Schur function for the Young diagram λ. As the RS polynomial is essentially the partition function of the PF model and the energy of the PF model is additive for the Yangian invariant bases, we obtain the representation for motifs from the recurrence relation (2.19):[17]

$$(\ldots 11)=0,\ (\ldots 10)=\square\otimes(\ldots 1),$$

$$(\ldots 01)=\begin{smallmatrix}\square\\\square\end{smallmatrix}\otimes(\ldots),\quad (\ldots 00)=\square\otimes(\ldots 0)-\begin{smallmatrix}\square\\\square\end{smallmatrix}\otimes(\ldots),$$

with the first three motifs,

$$(\ )=\square,\quad (0)=\square\square,\quad (1)=\begin{smallmatrix}\square\\\square\end{smallmatrix}.$$

One sees that these recurrence relations give the same representation found by Haldane. The first identity means that consecutive 1's are forbidden. This shows that the quasi-particle of the HS and PF models has a fractional exclusion statistics *a là* Haldane.[20] Also one sees that the motif

$$\underbrace{(101010\ldots01)}_{2M-1}$$

gives a trivial representation $[M^2]$. As this motif corresponds to the ground state of the HS and PF models with $2M$ sites, we conclude that the ground state is nondegenerate.

Representation for su(n) motif is related with the generalized RS polynomial $H_N^{(n)}(x;q)$ defined by

$$H_N^{(n)}(x;q)=\sum_{\substack{k_1+\cdots+k_n=N\\ k_j\geqslant 0}}\begin{bmatrix} N \\ k_1,k_2,\ldots,k_n\end{bmatrix}_q x_1^{k_1}x_2^{k_2}\cdots x_n^{k_n}. \tag{2.20}$$

Here we use the q-multinomial coefficients,

$$\begin{bmatrix} N \\ k_1,k_2,\ldots,k_n\end{bmatrix}_q=\begin{cases}\dfrac{(q;q)_N}{(q;q)_{k_1}\cdots(q;q)_{k_n}}, & \text{for } k_1+\cdots+k_n=N,\ k_j\geqslant 0,\\ 0, \quad \text{otherwise.}\end{cases}$$

The partition function $Z_N^{(n)}(q)$ of the PF spin chain is written in terms of the generalized RS polynomial as

$$Z_N^{(n)}(q)=q^{(n-1)/2n\,N^2}\cdot H_N^{(n)} \quad (x_1=\cdots=x_n=1;q^{-1}). \tag{2.21}$$

The generating function of the generalized RS polynomial is given by

$$\sum_{N=0}^{\infty}\frac{H_N^{(n)}(x;q)}{(q;q)_N}t^N=\frac{1}{(x_1t;q)_\infty(x_2t;q)_\infty\cdots(x_nt;q)_\infty}. \tag{2.22}$$

In the same manner for the su(2) case, by setting $t\to q\,t$ in the above equality one gets a recurrence relation for any $(n+1)$-consecutive generalized RS polynomials $H_N^{(n)}(x;q)$,

$$H_N^{(n)}(x;q)=\sum_{k=1}^{n}(-)^{k-1}\frac{(q;q)_{N-1}}{(q;q)_{N-k}}s_{[1^k]}(x)\,H_{N-k}^{(n)}(x;q). \tag{2.23}$$

It is straightforward to translate the above recurrence relation into a language of motifs. We take an example from su(3) case:

$$(\ldots 111)=0, \quad (\ldots 110)=\square\otimes(\ldots 11),$$

$$(\ldots 011)=\begin{array}{|c|}\hline\ \\ \hline\end{array}\otimes(\ldots), \quad (\ldots 001)=\begin{array}{|c|}\hline\ \\ \hline\end{array}\otimes(\ldots 0)-\begin{array}{|c|}\hline\ \\ \hline\ \\ \hline\end{array}\otimes(\ldots),$$

$$(\ldots 101)=\begin{array}{|c|}\hline\ \\ \hline\end{array}\otimes(\ldots 1), \quad (\ldots 010)=\square\otimes(\ldots 01)-\begin{array}{|c|}\hline\ \\ \hline\ \\ \hline\end{array}\otimes(\ldots 0),$$

$$(\ldots 100)=\square\otimes(\ldots 10)-\begin{array}{|c|}\hline\ \\ \hline\end{array}\otimes(\ldots 1),$$

$$(\ldots 000)=\square\otimes(\ldots 00)-\begin{array}{|c|}\hline\ \\ \hline\end{array}\otimes(\ldots 0)+\begin{array}{|c|}\hline\ \\ \hline\ \\ \hline\end{array}\otimes(\ldots).$$

First several motifs are given by

$$(\ )=\square, \quad (0)=\square\square, \quad (1)=\begin{array}{|c|}\hline\ \\ \hline\end{array}, \quad (00)=\square\square\square, \quad (10)=(01)=\begin{array}{|c|}\hline\ \\ \hline\end{array}\square, \quad (11)=\begin{array}{|c|}\hline\ \\ \hline\ \\ \hline\end{array}.$$

In su(3) case the three consecutive 1's are forbidden, and the ground state for a $(3M)$-site spin chain is denoted by motif $(110110110\ldots011)$. In general, one sees that the N-site spin is represented by the Young diagram with N boxes, and that n consecutive 1's cannot occur for the su(n) motif. It should be seen that the ground state for an $(n\times M)$-site spin chain is nondegenerate and given by motif

$$(\underbrace{11\ldots1}_{n-1}0\underbrace{11\ldots1}_{n-1}0\,11\ldots\ldots11\,0\underbrace{11\ldots1}_{n-1}).$$

TABLE I. Representation for motifs, $N=4$.

Motif	$\{m_j\}$	Young diagram	E_{PF}	E_{HS}
(111)	{1,2,3}	$[1^4]$	-6	-10
(011)	{2,3}	$[2^1 1^2]$	-5	-7
(110)	{1,2}	$[2^1 1^2]$	-3	-7
(101)	{1,3}	$[2^1 1^2]\oplus[2^2]$	-4	-6
(010)	{2}	$[2^2]\oplus[3^1 1^1]$	-2	-4
(001)	{3}	$[3^1 1^1]$	-3	-3
(100)	{1}	$[3^1 1^1]$	-1	-3
(000)	{}	$[4^1]$	0	0

One sees also that the motif

$$\underbrace{011\ldots10}_{r}$$

corresponds to the Young diagram $[1^{r+1}]$, but the representation is not given from simple tensor products of each motifs.

Solution of those recurrence relations is explicitly solved as a skew Schur function for the borderstrip which is no 2×2 squares.[21]

In Table I, we list a representation for motifs $N=4$. The representation for the su(n) case ($n<4$) is given by removing the forbidden Young tableaus.

C. Character formula

The Yangian currents $\{Q_0^{ab},Q_1^{ab}\}$ can be constructed from the current operators for level-1 su(n) WZNW theory,[22]

$$[J_l^a,J_m^b]=f^{abc}J_{l+m}^c+\delta^{ab}\,l\,\delta_{l+m,0}. \tag{2.24}$$

In terms of the currents J_m^a, the Yangian currents are expressed as

$$\begin{aligned} Q_0^a&=J_0^a,\\ Q_1^a&=\frac{1}{2}f^{abc}\sum_{m>0}J_{-m}^bJ_m^c-\frac{n}{2(n+2)}W_0^a. \end{aligned} \tag{2.25}$$

We used the zero-mode of the W-current,

$$W^a(z)=\tfrac{1}{2}d^{abc}{:}J^bJ^c{:}(z),$$

where : : denotes the normal ordering. The conserved operators H_m for the Yangian currents are also given in terms of the currents for the su$(n)_1$ WZNW theory. The first two are explicitly written as

$$H_1=L_0\equiv\frac{1}{2(n+1)}\sum_m{:}J_{-m}^aJ_m^a{:}, \tag{2.26a}$$

$$H_2=\sum_{m>0}m\,J_{-m}^aJ_m^a+\frac{n}{(n+1)(n+2)}W_0, \tag{2.26b}$$

where W_0 is the zero-mode of the third order Casimir operator $W(z)$,

$$W(z)=\tfrac{1}{6}d^{abc}{:}J^a{:}J^bJ^c{::}(z).$$

The fact that the energy levels of the PF chain are equally spaced suggests that the Hamiltonian of the PF spin chain can be identified as the Virasoro generator L_0. Through this observation we can show that the partition function $Z_N^{(n)}(q)$ for the large-N limit is realized as the affine character for the level-1 su(n) WZNW theory,

$$\chi_\ell^{(n)}(q)=\lim_{\substack{N\to\infty \\ N\equiv\ell(\mathrm{mod}\ n)}} Z_N^{(n)}(q). \tag{2.27}$$

For the su(2) case we obtain a well-known character formula ($\ell=0,1$),

$$\chi_\ell^{(2)}(q)=\frac{1}{(q;q)_\infty}\sum_{k=-\infty}^{\infty} q^{(k+\ell/2)^2}=\sum_{n^++n^-=\ell(\mathrm{mod}\ 2)}\frac{q^{(n^++n^-)^2/4}}{(q;q)_{n^+}(q;q)_{n^-}}.$$

The second equality is proved in Ref. 23 by using spinon bases.

In the general su(n) case, we can obtain the affine character as the large-N limit of $Z_N^{(n)}(q)$,

$$\chi_{\ell=0}^{(n)}(q)=\frac{1}{(q;q)_\infty^{n-1}}\sum_{k_1=-\infty}^{\infty}\cdots\sum_{k_{n-1}=-\infty}^{\infty} q^{\mathbf{k}^t\cdot\mathbf{A}\cdot\mathbf{k}/2}=1+(n^2-1)\,q+\cdots, \tag{2.28}$$

where $\mathbf{k}^t=(k_1,\ldots,k_{n-1})$ and $\mathbf{A}$ is the Cartan matrix for su(n). A supersymmetric extension of the PF spin chain is also an interesting subject and has been studied in Ref. 24.

III. INFINITE-DIMENSIONAL REPRESENTATION

A. Infinite-dimensional representation

We investigate solutions of the Yang–Baxter equation (2.1). Each solution of the YBE corresponds to an integrable spin chain. Here we shall consider the infinite-dimensional representation for solutions.[25]

We make an ansatz that the R-operator acts on functional space in the following way:

$$(R^{12}(\xi)\,f)(z_1,z_2)=A(z_{12})\,f(z_1,z_2)-B(\xi,z_{12})\,f(z_2,z_1),$$

where functions $A(z)$ and $B(\xi,z)$ are to be determined. By using this ansatz in the YBE (2.1), we get functional equations

$$\begin{aligned}&B(\xi_{12},z_{12})\cdot(A(z_2)\,A(-z_2)-A(z_1)\,A(-z_1))\\&\quad=B(\xi_1,z_1)\,B(\xi_{12},-z_2)\,B(-\xi_2,z_1)-B(-\xi_2,-z_2)\,B(\xi_{12},z_1)\,B(\xi_1,-z_2),\end{aligned} \tag{3.1a}$$

$$B(\xi_1,z_1)\,B(-\xi_2,z_{12})=B(\xi_{12},z_{12})\,B(\xi_1,z_2)+B(-\xi_2,-z_2)\,B(\xi_{12},z_1). \tag{3.1b}$$

One finds that elliptic function solves the above functional equations,

$$A(z)=\sigma_\mu(z),\qquad B(\xi,z)=\sigma_\xi(z),$$

where μ is an arbitrary parameter. See Appendix B for definition and properties of the elliptic function $\sigma_\mu(z)=\sigma_\mu(z;\tau)$. For our convention, we take $R^{jk}(\xi)$ as

$$(R^{12}(\xi)\,f)(z_1,z_2)=\frac{1}{\sigma_\mu(\xi)}(\sigma_\mu(z_{12})\,f(z_1,z_2)-\sigma_\xi(z_{12})\,f(z_2,z_1)), \tag{3.2}$$

which satisfies the unitarity condition, $R^{12}(\xi)\,R^{21}(-\xi)=\mathbb{1}$, and the quasi-classical condition, $R^{12}(\xi)|_{\mu=0}=\mathbb{1}$.

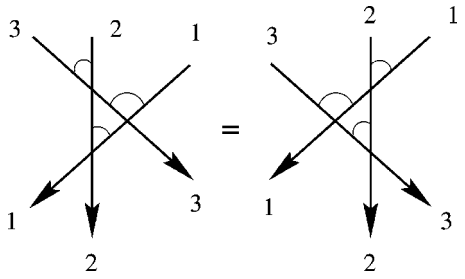

FIG. 2. Reflection equation (3.3).

The YBE is used to formulate integrable systems with the periodic or twisted boundary condition. Recently much attention has been paid on the effects of the boundary condition. In general, the boundary condition should be carefully fixed to keep the integrability; the ''choice'' of the boundary condition is determined by the reflection equation (RE).[26] The RE is written as (see Fig. 2)

$$R^{12}(\xi_{12})\overset{1}{K}(\xi_1)R^{21}(\xi_1+\xi_2)\overset{2}{K}(\xi_2)=\overset{2}{K}(\xi_2)R^{12}(\xi_1+\xi_2)\overset{1}{K}(\xi_1)R^{21}(\xi_{12}), \tag{3.3}$$

where R is a solution of the YBE (2.1). To give the solution of the RE (3.3) associated with the elliptic R-operator (3.2), we make an ansatz that the boundary K-operator acts on functional space as

$$(K(\xi)f)(z)=G(\xi,z)f(z)-H(z)f(-z), \tag{3.4}$$

with functions $G(\xi,z)$ and $H(z)$ to be fixed. Then from the RE (3.3), one obtains functional equations[27]

$$\begin{aligned}
&G(\xi_2,z_2)\sigma_{\xi_1+\xi_2}(z_{12})\sigma_{\xi_{12}}(z_1+z_2)+G(\xi_1,z_1)\sigma_{\mu}(z_1+z_2)\sigma_{\mu}(-z_1-z_2)\\
&\quad+G(\xi_1,-z_2)\sigma_{\xi_1+\xi_2}(z_1+z_2)\sigma_{\xi_{12}}(z_1+z_2)\\
&\quad=G(\xi_1,z_1)\sigma_{\mu}(z_{12})\sigma_{\mu}(z_{21})+G(\xi_1,z_2)\sigma_{\xi_{12}}(z_{12})\sigma_{\xi_1+\xi_2}(z_{12})\\
&\qquad+G(\xi_2,-z_2)\sigma_{\xi_{12}}(z_{12})\sigma_{\xi_1+\xi_2}(z_1+z_2),
\end{aligned} \tag{3.5a}$$

$$\begin{aligned}
&G(\xi_1,z_1)G(\xi_2,z_2)\sigma_{\xi_{12}}(z_{21})+G(\xi_1,z_2)G(\xi_2,z_2)\sigma_{\xi_1+\xi_2}(z_{12})+H(-z_2)H(z_2)\sigma_{\xi_1+\xi_2}(z_1+z_2)\\
&\quad=G(\xi_1,z_1)G(\xi_2,z_1)\sigma_{\xi_1+\xi_2}(z_{21})+G(\xi_1,z_2)G(\xi_2,z_1)\sigma_{\xi_{12}}(z_{12})\\
&\qquad+H(z_1)H(-z_1)\sigma_{\xi_1+\xi_2}(z_1+z_2),
\end{aligned} \tag{3.5b}$$

$$\begin{aligned}
&G(\xi_1,z_1)\sigma_{\xi_1+\xi_2}(z_{21})+G(\xi_1,z_2)\sigma_{\xi_{12}}(z_{12})+G(\xi_2,-z_1)\sigma_{\xi_1+\xi_2}(z_1+z_2)\\
&\quad=G(\xi_2,z_2)\sigma_{\xi_{12}}(z_1+z_2).
\end{aligned} \tag{3.5c}$$

The solution is written as[27]

$$G(\xi,z)=\sum_{r=0}^{3}g_r\sigma_{2\xi}^{r}(z),\qquad H(z)=\sum_{r=0}^{3}g_r\sigma_{2\nu}^{r}(z), \tag{3.6}$$

where parameters g_r and ν are arbitrary. Correspondingly, we have explicit forms for the K-operators,

$$K(\xi)=\sum_{r=0}^{3} g_r\,(\sigma_{2\xi}^r(z)-\sigma_{2\nu}^r(z)\cdot\hat{t}\,). \tag{3.7}$$

As a simple solution we have

$$(K^{\mathrm{I}}(\xi)\,f\,)(z)=\frac{1}{\sigma_{2\nu}(2\xi)}(\sigma_{2\xi}(z)\,f(z)-\sigma_{2\nu}(z)\,f(-z)). \tag{3.8}$$

Here the K-operators are normalized to satisfy the unitarity condition, $K^{\mathrm{I}}(\xi)\,K^{\mathrm{I}}(-\xi)=\mathbb{1}$, and the quasi-classical condition, $K^{\mathrm{I}}(\xi=0)=\mathbb{1}$.

B. Belavin elliptic solutions

In the remainder of this section, we shall show that the Belavin elliptic solutions of the YBE[28] are constructed from the infinite-dimensional R-operator,[29] and that the associated boundary K-matrix is calculated in the same way.[27] The strategy is to restrict the functional space to the finite-dimensional one. We set a positive integer $k\in\mathbb{Z}_+$, and introduce the shift operator $T_k(\xi)$, which acts on the functional space as

$$(T_k(\xi)\,f\,)(z)=f\left(z-\frac{\xi}{k}\right). \tag{3.9}$$

The shift operators satisfy the relations

$$\begin{aligned} &T_k(\xi+\eta)=T_k(\xi)\,T_k(\eta),\\ &[R(\xi),T_k(\eta)\otimes T_k(\eta)]=0. \end{aligned} \tag{3.10}$$

The first one is trivial, and the second follows from the fact that the R-operator (3.2) only depends on the difference z_{12}.

To restrict the functional space to be finite-dimensional, we define the functional space $\mathbf{V}_k(\xi)$ of the theta function; a function $f(z)\in\mathbf{V}_k(\xi)$ is a doubly quasi-periodic function,

$$f(z+1)=f(z),\qquad f(z+\tau)=\alpha_k(z,\xi)\,f(z),$$

where $\alpha_k(z,\xi)\equiv\exp(-2\,\pi\,\mathrm{i}\,k\,z-\pi\,\mathrm{i}\,k\,\tau+2\,\pi\,\mathrm{i}\,\xi)$. It is seen that the elliptic R-operator (3.2), the K-operator (3.7) and the shift operator (3.9) map the functional space in the following way:

$$R(\xi_{12}):\mathbf{V}_k(\xi_1)\otimes\mathbf{V}_k(\xi_2+\mu)\to\mathbf{V}_k(\xi_1+\mu)\otimes\mathbf{V}_k(\xi_2),$$

$$K(\xi):\mathbf{V}_k(\nu-\xi)\to\mathbf{V}_k(\nu+\xi),$$

$$T_k(\xi):\mathbf{V}_k(0)\to\mathbf{V}_k(\xi).$$

Motivated by these properties, we introduce modified elliptic operators $R_k(\xi)$ and $K_k(\xi)$ by

$$R_k(\xi_{12})=T_k(-\xi_1-\mu)\otimes T_k(-\xi_2)\cdot R(\xi)\cdot T_k(\xi_1)\otimes T_k(\xi_2+\mu), \tag{3.11}$$

$$K_k(\xi)=T_k(-\nu-\xi)\cdot K(\xi)\cdot T_k(\nu-\xi), \tag{3.12}$$

both of which preserve the functional space $\mathbf{V}_k(0)$,

$$R_k(\xi):\mathbf{V}_k(0)\otimes\mathbf{V}_k(0)\to\mathbf{V}_k(0)\otimes\mathbf{V}_k(0),$$

$$K_k(\xi):\mathbf{V}_k(0)\to\mathbf{V}_k(0).$$

It is important that a set of the modified operators, $R_k(\xi)$ and $K_k(\xi)$, satisfies both the YBE (2.1) and the RE (3.3). We write explicit forms of the modified operators:

$$(R_k(\xi)\,f)(z_1,z_2)=\sigma_\mu\left(z_{12}+\frac{\mu+\xi}{k};\tau\right)f\left(z_1+\frac{\mu}{k},z_2-\frac{\mu}{k}\right)-\sigma_\xi\left(z_{12}+\frac{\mu+\xi}{k};\tau\right)f\left(z_2-\frac{\xi}{k},z_1+\frac{\xi}{k}\right),$$

$$(K_k(\xi)\,f)(z)=\sum_{r=0}^{3} g_r\left(\sigma^r_{2\xi}\left(z+\frac{\xi+\nu}{k};\tau\right)f\left(z+\frac{2\xi}{k}\right)-\sigma^r_{2\nu}\left(z+\frac{\xi+\nu}{k};\tau\right)f\left(-z-\frac{2\nu}{k}\right)\right).$$

The dimension of the space $\mathbf{V}_k(0)$ is k, and therefore we choose as a basis the θ-function for $a\in\mathbb{Z}_k\equiv\mathbb{Z}/k\mathbb{Z}$:

$$\theta_a(z)=\sum_{n\in\mathbb{Z}}\exp\left(\pi\,\mathrm{i}\,(k\,n+a)^2\frac{\tau}{k}+2\,\pi\,\mathrm{i}\,(k\,n+a)\,z\right)=\vartheta\begin{bmatrix}\alpha/k\\0\end{bmatrix}(kz;k\tau). \tag{3.13}$$

Since the modified R- and K-operators preserve the space $\mathbf{V}_k(0)$, we can define matrix elements of operators by expanding with the θ_a-bases. For the R-operator, we define the $k^2\times k^2$-matrix elements by

$$R_k(\xi)\;\theta_a\otimes\theta_b=\sum_{c,d\in\mathbb{Z}_k}R_k(\xi)_{ac,bd}\,\theta_c\otimes\theta_d\,. \tag{3.14}$$

The boundary K-matrix is also fixed as $k\times k$-matrix,

$$K_k(\xi)\;\theta_a=\sum_{c\in\mathbb{Z}_k}K_k(\xi)_{a,c}\,\theta_c\,. \tag{3.15}$$

Using the property (B5) of the function $\sigma_\mu(z)$, we calculate the matrix elements,

$$R_k(\xi)_{ac,bd}=\delta_{a+b,c+d}\cdot\frac{\vartheta[^{1/2}_{1/2}]'(0;k\,\tau)\;\vartheta[^{(b-a)/k+1/2}_{1/2}](\xi-\mu;k\,\tau)}{\vartheta[^{(b-c)/k+1/2}_{1/2}](\xi;k\,\tau)\;\vartheta[^{(c-a)/k+1/2}_{1/2}](-\mu;k\,\tau)}. \tag{3.16}$$

The same computation results in the elliptic boundary K-matrices[27]

$$K_k(\xi)_{a,c}=\sum_{r=0}^{3}g_r\frac{\vartheta[^{1/2}_{1/2}]'(0;k\,\tau)\;\vartheta[^{-2a/k+1/2}_{1/2}](2\nu-2\xi;k\,\tau)}{\vartheta[^{-(c+a)/k+1/2}_{1/2}](2\nu;k\,\tau)\;\vartheta[^{(c-a)/k+1/2}_{1/2}](-2\xi;k\,\tau)}\times\frac{\vartheta[^{-c/k+\beta_r/2}_{k\alpha_r/2}](\nu+\xi;k\,\tau)}{\vartheta[^{-a/k+\beta_r/2}_{k\alpha_r/2}](\nu-\xi;k\,\tau)}. \tag{3.17}$$

See Appendix B for definitions of α_r and β_r.

To close this section, we note the trigonometric limit of the above results.[30] We set bases e_a for k-dimensional space, $a\in\{-(k-1)/2,-(k-1)/2+1,\ldots,(k-1)/2\}$. The R-matrix is calculated as

$$R(\theta)\,e_a\otimes e_b=\begin{cases}-q^{-1/2}(\theta^{1/2}-\theta^{-1/2})\,e_a\otimes e_b+\theta^{1/2}(q^{1/2}-q^{-1/2})\,e_b\otimes e_a\,, & \text{for } a>b,\\ (\theta^{-1/2}q^{1/2}-\theta^{1/2}q^{-1/2})\,e_a\otimes e_b\,, & \text{for } a=b,\\ -q^{1/2}(\theta^{1/2}-\theta^{-1/2})\,e_a\otimes e_b+\theta^{-1/2}(q^{1/2}-q^{-1/2})\,e_b\otimes e_a\,, & \text{for } a<b.\end{cases} \tag{3.18}$$

This matrix is the Drinfeld's triangular R-matrix. A simple solution of associated boundary K-matrices is computed as

$$K^{\mathrm{I}}(\theta)\, e_a = \begin{cases} -\theta^{-1/2}(p^{1/2}-p^{-1/2})\, e_a + p^{1/2}(\theta^{1/2}-\theta^{-1/2})\, e_{-a}, & \text{for } a>0, \\ (\theta^{1/2}p^{-1/2}-\theta^{-1/2}p^{1/2})\, e_0, & \text{for } a=0, \\ -\theta^{1/2}(p^{1/2}-p^{-1/2})\, e_a + p^{-1/2}(\theta^{1/2}-\theta^{-1/2})\, e_{-a}, & \text{for } a<0. \end{cases} \tag{3.19}$$

We take a simple example from the case of $n=2$. These matrices are written in terms of constant matrices,

$$\begin{aligned} R(\theta) &= \theta^{-1/2}\cdot R - \theta^{1/2}\cdot P\, R^{-1}\, P, \\ K^{\mathrm{I}}(\theta) &= \theta^{1/2}\cdot K^{-1} - \theta^{-1/2}\cdot K, \end{aligned} \tag{3.20}$$

where, with constants p and q, R and K are

$$R = \begin{pmatrix} q^{1/2} & & & \\ & q^{1/2} & q^{1/2}-q^{-1/2} & \\ & & q^{-1/2} & \\ & & & q^{1/2} \end{pmatrix}, \quad K = \begin{pmatrix} 0 & p^{-1/2} \\ p^{1/2} & p^{1/2}-p^{-1/2} \end{pmatrix}.$$

One finds that the following relations are satisfied:

$$\begin{aligned} & R^{12}\, R^{13}\, R^{23} = R^{23}\, R^{13}\, R^{12}, \\ & R - P\, R^{-1}\, P = (q^{1/2}-q^{-1/2})\, P, \\ & K - K^{-1} = p^{1/2}-p^{-1/2}, \\ & (1\otimes K)\, R^{21}\, (K\otimes 1)\, R^{12} = R^{21}\, (K\otimes 1)\, R^{12}\, (1\otimes K). \end{aligned} \tag{3.21}$$

Those are the defining relations for the Hecke algebra of type-B.

IV. ELLIPTIC DUNKL OPERATOR

In this section we consider the integrability of the elliptic CSM models associated with the classical root systems. The integrability is proved, in classical theory, by using the Lax matrix formalism.[31] The Lax matrix formalism has been applied to the quantum theory of the rational and trigonometric models.[7,31] Instead, we shall employ a slightly different approach, namely the Dunkl operator. The Dunkl operator was originally defined as integrable differential-difference operator associated with the root systems[32] and applied to the CSM model.[13,16,33,34] We shall construct the elliptic Dunkl operators based on the infinite-dimensional representation for solutions of the Yang–Baxter equation and the reflection equation discussed in the previous section.

In addition to the YBE (2.1) and the RE (3.3), we introduce the ''conjugate'' reflection equation (RE2, for short),

$$R^{12}(\xi_{21})\, \overset{2}{\overline{K}}(\xi_2)\, R^{21}(\xi_1+\xi_2)\, \overset{1}{\overline{K}}(\xi_1) = \overset{1}{\overline{K}}(\xi_1)\, R^{12}(\xi_1+\xi_2)\, \overset{2}{\overline{K}}(\xi_2)\, R^{21}(\xi_{21}). \tag{4.1}$$

Solutions for the RE2 and for the RE, that is, $\overline{K}(\xi)$ and $K(\xi)$, are related by

$$\overline{K}(\xi) = \hat{t} K(\xi)\, \hat{t}, \tag{4.2}$$

where the operator $\hat{t}$ means the reflection on a single-variable functional space,

$$(\hat{t}_j f)(\ldots, z_j, \ldots) = f(\ldots, -z_j, \ldots). \tag{4.3}$$

Hereafter we shall use the exchange operator $\hat{s}_{j,k}$,

$$(\hat{s}_{j,k} f)(\ldots,z_j,\ldots,z_k,\ldots)=f(\ldots,z_k,\ldots,z_j,\ldots), \tag{4.4}$$

and a parameter $\overline{\nu}$ for solutions of the RE2 [cf. (3.7)].

Based on the method of Refs. 30 and 35, we shall construct the elliptic Dunkl difference operator as variants of the quantum Knizhnik–Zamolodchikov–Bernard equation. For brevity we redefine the shift operator from (3.9) as $\hat{T}=T_{\beta}(\mu)$,

$$(\hat{T} f)(z)=f\left(z-\frac{\mu}{\beta}\right),$$

where β is an arbitrary constant. We recall the commutativity between the R-operator and the shift operator,

$$[R(\xi),\hat{T}\otimes\hat{T}]=0. \tag{4.5}$$

In terms of the infinite-dimensional representations for the R- and K-operators, we can define two sets of the elliptic Dunkl operators by

$$\hat{D}_j(\xi)=R^{j\,j-1}(\xi_{j\,j-1})\cdots R^{j\,1}(\xi_{j\,1})\cdot\hat{T}_j\cdot R^{j\,N}(\xi_{jN})\cdots R^{j\,j+1}(\xi_{j\,j+1}), \tag{4.6}$$

$$\begin{aligned}\hat{Y}_j(\xi)=&R^{j\,j-1}(\xi_{j\,j-1})\cdots R^{j\,1}(\xi_{j\,1})\cdot\hat{T}_j\cdot\overset{j}{K}(\xi_j)\cdot\hat{T}_j^{-1}\times R^{1\,j}(\xi_1+\xi_j)\cdots R^{j-1\,j}(\xi_{j-1}+\xi_j)\\&\cdot R^{j+1\,j}(\xi_{j+1}+\xi_j)\cdots R^{N\,j}(\xi_N+\xi_j)\times\overline{\overset{j}{K}}(\xi_j)\cdot R^{j\,N}(\xi_{j\,N})\cdots R^{j\,j+1}(\xi_{j\,j+1}),\end{aligned} \tag{4.7}$$

where $\overset{j}{K}$ and $\overline{\overset{j}{K}}$ act on the jth space. Using the YBE (2.1) and the RE (3.3) with (4.5), one finds that each set of the quantum Knizhnik–Zamolodchikov (qKZ) type difference operators constitutes a commuting family of operators (an integrable family, hereafter),

$$\begin{aligned}[\hat{D}_j(\xi),\hat{D}_k(\xi)]=0,\\ [\hat{Y}_j(\xi),\hat{Y}_k(\xi)]=0.\end{aligned} \tag{4.8}$$

We assume a parameter μ to be infinitesimal and take a quasi-classical limit in the difference operators. For the A-type operator $\hat{D}_j(\xi)$, we see that

$$\hat{D}_j(\xi)=1-\frac{\mu}{\beta}\left(\frac{\partial}{\partial z_j}-\beta\sum_{k:k\neq j}^{N}(\sigma_{\xi_{jk}}(z_{jk})\,\hat{s}_{j,k}+\rho(\xi_{jk})-\rho(z_{jk}))\right)+O(\mu^2),$$

where the elliptic function $\rho(z)$ is defined by $\rho(z)=(\mathrm{d}/\mathrm{d}z)\log\vartheta_1(z;\tau)$. With a product of functions,

$$\Delta^{\mathrm{A}}(z)=\prod_{1\leqslant j<k\leqslant N}(\vartheta_1(z_{jk};\tau))^{\beta},$$

we gauge-transform the operator $\hat{D}_j(\xi)$ as $\hat{D}_j(\xi)\to\Delta^{\mathrm{A}}(z)\cdot\hat{D}_j(\xi)\cdot\Delta^{\mathrm{A}}(z)^{-1}$. As a result one obtains the A-type elliptic Dunkl operators,

$$\hat{d}_j=\frac{\partial}{\partial z_j}-\beta\sum_{k:k\neq j}^{N}\sigma_{\xi_{jk}}(z_{jk})\,\hat{s}_{j,k},\quad\text{for } j=1,2,\ldots,N, \tag{4.9}$$

which constitute an integrable family,

$$[\hat{d}_j,\hat{d}_k]=0. \tag{4.10}$$

Subtracting terms of order ξ^{-2} (which is a c-number) and setting all rapidities to zero ($\xi\to 0$), we obtain the Hamiltonian of the elliptic CSM model,

$$\mathcal{H}^{\mathrm{A}}=\lim_{\xi\to 0}\sum_{j=1}^{N}\pi(\hat{d}_j^2)=\sum_j\frac{\partial^2}{\partial z_j^2}-\sum_{j,k}\wp(z_{jk})\cdot(-\beta P_{jk}+\beta^2), \tag{4.11}$$

where π means a projection to symmetric functional space, $\hat{s}_{j,k}P_{jk}=\mathbb{1}$. The next-order conserved operator is computed as

$$\lim_{\xi\to 0}\sum_{j=1}^{N}\pi(\hat{d}_j^3)=\sum_j\frac{\partial^3}{\partial z_j^3}+\frac{3}{2}\sum_{j,k}\wp(z_{jk})\cdot\left(\frac{\partial}{\partial z_j}+\frac{\partial}{\partial z_k}\right)\cdot(\beta P_{jk}-\beta^2).$$

For the BC-type, we see that the difference operator is calculated in the quasi-classical limit $\mu\to 0$ as

$$\begin{aligned}\hat{Y}_j(\xi)=1-\frac{\mu}{\beta}\Bigg\{&\frac{\partial}{\partial z_j}-\beta\sum_{k:k\neq j}(\sigma_{\xi_{jk}}(z_{jk})\,\hat{s}_{j,k}+\rho(\xi_{jk})-\rho(z_{jk}))-\beta\sum_{k:k\neq j}(\sigma_{\xi_j+\xi_k}(z_j+z_k)\,\hat{t}_j\hat{t}_k\hat{s}_{j,k}\\&+\rho(\xi_j+\xi_k)-\rho(z_j+z_k))-2\alpha(\sigma_{2\xi_j}(z_j)\,\hat{t}_j+\rho(2\xi_j)-\rho(z_j))-2\overline{\alpha}(\sigma_{\xi_j}(2z_j)\,\hat{t}_j+\rho(\xi_j)\\&-\rho(2z_j))\Bigg\}+O(\mu^2).\end{aligned}$$

Here we have substituted explicit forms of $K(\xi)$ and $\overline{K}(\xi)$. By transforming this operator $\hat{Y}_j^{\mathrm{BC}}\to\Delta^{\mathrm{BC}}(z)\cdot\hat{Y}_j^{\mathrm{BC}}\cdot\Delta^{\mathrm{BC}}(z)^{-1}$ by a product of functions,

$$\Delta^{\mathrm{BC}}(z)=\prod_{1\leqslant j<k\leqslant N}(\vartheta_1(z_{jk};\tau)\,\vartheta_1(z_j+z_k;\tau))^{\beta}\cdot\prod_{j=1}^{N}(\vartheta_1(z_j;\tau))^{2\alpha}(\vartheta_1(2z_j;\tau))^{\overline{\alpha}},$$

we get the BC-type elliptic Dunkl operator,

$$\hat{y}_j=\frac{\partial}{\partial z_j}-\beta\sum_{k:k\neq j}^{N}\{\sigma_{\xi_{jk}}(z_{jk})\,\hat{s}_{j,k}+\sigma_{\xi_j+\xi_k}(z_j+z_k)\,\hat{t}_j\hat{t}_k\hat{s}_{j,k}\}+(-2\alpha\,\sigma_{2\xi_j}(z_j)-2\overline{\alpha}\,\sigma_{\xi_j}(2z_j))\cdot\hat{t}_j. \tag{4.12}$$

It is easily seen that this differential-difference operator is also integrable,

$$[\hat{y}_j,\hat{y}_k]=0. \tag{4.13}$$

The first nontrivial conserved operator, the Hamiltonian of the BC-type, is given by

$$\begin{aligned}\mathcal{H}^{\mathrm{BC}}=\lim_{\xi\to 0}\sum_{j=1}^{N}\pi(\hat{y}_j{}^2)=&\sum_j\frac{\partial^2}{\partial z_j{}^2}-{\sum_{j,k}}'\{\wp(z_{jk})\cdot(-\beta P_{jk}+\beta^2)+\wp(z_j+z_k)\cdot(-\beta Q_jQ_kP_{jk}\\&+\beta^2)\}-\sum_j\{\wp(z_j)\cdot(-2\alpha Q_j+4\alpha^2+4\alpha\overline{\alpha})+\wp(2z_j)\cdot(-4\overline{\alpha}Q_j+4\overline{\alpha}^2)\},\end{aligned} \tag{4.14}$$

where we denote the projection operator π as a restriction to the symmetric space; $\hat{s}_{j,k}P_{jk}=\mathbb{1}$, $\hat{t}_jQ_j=\mathbb{1}$.

V. AFFINE HECKE ALGEBRA

A. Affine Hecke algebra

Mathematical studies for elliptic cases as a well-defined algebra are not completed. On the other hand, the trigonometric case can be formulated in terms of the affine Hecke algebra. We take the trigonometric limit for solutions of the YBE and RE, $\sigma_\mu(z)\to\pi\cot(\pi z)-\pi\cot(\pi\mu)$. In this limit the R- and K-operators are given by

$$R(\theta)=\frac{-1}{q-q^{-1}\theta}(\theta\hat{g}-\hat{g}^{-1})\cdot\hat{s}, \tag{5.1}$$

$$K(\theta)=-\theta^2\hat{r}+\theta(a-a^{-1}-b+b^{-1})+\hat{r}^{-1}, \tag{5.2}$$

where a, b, and q are arbitrary constants. We have introduced the exponential variables for coordinate and rapidity, and defined the so-called Demazure–Lusztig (DL) operators as

$$\hat{g}_{j,k}=\frac{q^{-1}z_j-q\,z_k}{z_j-z_k}\hat{s}_{j,k}+(q-q^{-1})\frac{z_k}{z_j-z_k}, \tag{5.3}$$

$$\hat{r}_j=\frac{-a+a^{-1}-(b-b^{-1})z_j}{1-z_j^{\,2}}+\frac{a+(b-b^{-1})z_j-a^{-1}z_j^{\,2}}{1-z_j^{\,2}}\cdot\hat{t}_j. \tag{5.4}$$

Remark that for the exponential variables, the reflection operator acts as

$$(\hat{t}\,f)(z)=f(z^{-1}).$$

These difference operators satisfy the following relations;

$$\begin{gathered}\hat{g}_{j,j+1}\hat{g}_{j+1,j+2}\hat{g}_{j,j+1}=\hat{g}_{j+1,j+2}\hat{g}_{j,j+1}\hat{g}_{j+1,j+2},\\ \hat{r}_j\hat{g}_{j,j+1}\hat{r}_j\hat{g}_{j,j+1}=\hat{g}_{j,j+1}\hat{r}_j\hat{g}_{j,j+1}\hat{r}_j,\\ (\hat{g}_{j,k}+q)(\hat{g}_{j,k}-q^{-1})=0,\\ (\hat{r}_j+a)(\hat{r}_j-a^{-1})=0.\end{gathered} \tag{5.5}$$

As for the conjugate operator $\overline{K}(\xi)$, we define the operator $\hat{\bar{r}}_j$ which has the same form with the operator $\hat{r}_j$ replacing parameters a and b with c and d, respectively. As we use exponential variables, the action of the shift operator $\hat{T}_j$ is given by

$$(\hat{T}_j f)(\ldots,z_j,\ldots)=f(\ldots,p\,z_j,\ldots), \tag{5.6}$$

where p is an arbitrary parameter.

The difference operators are defined by[36,37]

$$\hat{D}_j=\hat{g}_{j,j-1}\hat{g}_{j-1,j-2}\cdots\hat{g}_{2,1}\cdot\hat{T}_1\cdot\hat{g}_{1,N}^{-1}\hat{g}_{N,N-1}^{-1}\cdots\hat{g}_{j+2,j+1}^{-1}\hat{s}_{1,N}\hat{s}_{1,N-1}\cdots\hat{s}_{1,2}, \tag{5.7}$$

$$\hat{Y}_j=\hat{g}_{j,j-1}\hat{g}_{j-1,j-2}\cdots\hat{g}_{2,1}\cdot\hat{T}_1\hat{\bar{r}}_1\hat{T}_1^{-1}\cdot\hat{g}_{2,1}\hat{g}_{3,2}\cdots\hat{g}_{N,N-1}\times\hat{r}_N^{-1}\cdot\hat{g}_{N,N-1}^{-1}\hat{g}_{N-1,N-2}^{-1}\cdots\hat{g}_{j+1,j}^{-1}. \tag{5.8}$$

Notice that no spectral parameters ξ_j are included. These two operators are given from the qKZ-type difference operators (4.6) and (4.7) by taking limits of the spectral parameters as

$$0\ll\xi_1\ll\xi_2\ll\cdots\ll\xi_N.$$

By construction, trivial is the integrability for these q-difference operators,

$$[\hat{D}_j,\hat{D}_k]=0, \tag{5.9}$$

$$[\hat{Y}_j,\hat{Y}_k]=0. \tag{5.10}$$

We note that the q-difference operators $\hat{D}_j$ and $\hat{Y}_j$ satisfy the relations

$$\hat{g}_{j+1,j}\,\hat{D}_j\,\hat{g}_{j+1,j}=\hat{D}_{j+1}, \tag{5.11}$$

$$\hat{g}_{j+1,j}\,\hat{Y}_j\,\hat{g}_{j+1,j}=\hat{Y}_{j+1},$$

$$\hat{Y}_1^{-1}\cdot(\hat{T}_1\,\hat{r}_1\,\hat{T}_1^{-1})=(\hat{T}_1\,\hat{r}_1\,\hat{T}_1^{-1})^{-1}\cdot\hat{Y}_1-(c-c^{-1}). \tag{5.12}$$

Algebra generated from a set of operators $\{\hat{g}_{j,j+1},\hat{D}_j|j=1,\ldots,N\}$ is called the affine Hecke algebra of type-A while algebra from $\{\hat{g}_{j,j+1},\hat{Y}_j,\hat{T}_1\,\hat{r}_1\hat{T}_1^{-1},\hat{r}_N\}$ is of type-B. We can construct the integrable Hamiltonian systems by

$$\hat{I}_n=\sum_{j=1}^{N}\hat{D}_j{}^n,\quad \hat{J}_n=\sum_{j=1}^{N}\hat{Y}_j{}^n. \tag{5.13}$$

B. A-type

Let us see that the A-type difference operators $\hat{I}_n$ are difference analogue of the trigonometric CSM model. We shall take the quasi-classical limit,

$$p\to 1+\varepsilon+O(\varepsilon^2). \tag{5.14}$$

When we introduce a parameter β by $q=p^{-\beta/2}$, we find that the q-difference operator has a form

$$\hat{D}_j\to 1+\varepsilon\,\hat{d}_j+O(\varepsilon^2),$$

where the differential-difference operator $\hat{d}_j$ is defined by

$$\hat{d}_j=z_j\frac{\partial}{\partial z_j}-\beta\sum_{k<j}\frac{z_k}{z_j-z_k}(\hat{s}_{jk}-1)-\beta\sum_{k>j}\frac{z_j}{z_j-z_k}(\hat{s}_{jk}-1)+\beta\left(j-\frac{N+1}{2}\right). \tag{5.15}$$

The (trigonometric) Dunkl operator satisfies the relations

$$[\hat{d}_j,\hat{d}_k]=0,\quad \hat{s}_{j,j+1}\,\hat{d}_j-\hat{d}_{j+1}\,\hat{s}_{j,j+1}=-\beta, \tag{5.16}$$

which are the quasi-classical limits of (5.9) and (5.11). The Hamiltonians without spin degrees of freedom ($P_{jk}=\mathbb{1}$) are calculated from the operators $\hat{d}_j$ as

$$\mathcal{H}^{\mathrm{A}}=\Delta^{\mathrm{A}}(z)\cdot\sum_{j=1}^{N}\pi(\hat{d}_j{}^2)\cdot\Delta^{\mathrm{A}}(z)^{-1}=\sum_{j=1}^{N}\left(z_j\frac{\partial}{\partial z_j}\right)^2-\beta(\beta-1)\sum_{j,k=1}^{N}\frac{z_j z_k}{(z_j-z_k)^2}, \tag{5.17}$$

where $\Delta^{\mathrm{A}}(z)$ is the ground state wave-function,

$$\Delta^{\mathrm{A}}(z)=\prod_{j=1}^{N}z_j^{-\beta(N-1)}\cdot\prod_{1\leqslant j<k\leqslant N}(z_j-z_k)^{2\beta}.$$

Eigenvalues are computed in the following way.[37,36] We define the ordering for a monomial basis, $z^m = z_1^{m_1} z_2^{m_2} \cdots z_N^{m_N}$. For this basis we define a partition, $|m| = (m_1 \geqslant m_2 \geqslant \cdots \geqslant m_N)$. Ordering is defined as

$$|m| \geqslant |m'| \Leftrightarrow \begin{cases} m_1 \geqslant m_1', \\ m_1 + m_2 \geqslant m_1' + m_2', \\ \cdots \\ m_1 + \cdots + m_N \geqslant m_1' + \cdots + m_N'. \end{cases} \tag{5.18}$$

We recall that the DL operators have forms

$$\hat{g}_{j,k} = q^{-1} \hat{s}_{j,k} - (q - q^{-1}) \frac{z_k}{z_{jk}} (\hat{s}_{j,k} - 1), \quad \hat{g}_{j,k}^{-1} = q \hat{s}_{j,k} - (q - q^{-1}) \frac{z_j}{z_{jk}} (\hat{s}_{j,k} - 1).$$

Thus for the partition $|m|$, the eigenvalue D_j for operator $\hat{D}_j$ is given by

$$D_j = p^{m_j} q^{-N+2j-1}, \tag{5.19}$$

where $\{m_j\}$ is a partition in nonincreasing order, $m_1 \geqslant m_2 \geqslant \cdots \geqslant m_N$. The eigenstates are in fact related with the Macdonald polynomials, which will be discussed later. The eigenvalue E for the A-type CSM model (5.17) is

$$E = \sum_{j=1}^{N} k_j{}^2, \tag{5.20}$$

where the quasi-momenta k_j are given by

$$k_j = m_j + \beta \left(\frac{N+1}{2} - j \right). \tag{5.21}$$

This means that the momenta k_j for the quasi-particles satisfy a condition,

$$k_j - k_{j+1} \geqslant \beta. \tag{5.22}$$

The momenta for bosons and fermions correspond to cases $\beta = 0$ and $\beta = 1$, respectively. One realizes from the Hamiltonian (5.17) that interactions vanish in both cases. In this sense the CSM model with generic β realizes a free particle with "fractional exclusion statistics." A quasi-particle excludes β energy levels, i.e., has a statistical interaction β,[20]

$$\delta G = -\beta \, \delta N, \tag{5.23}$$

where G and N are the number of energy levels and the number of particles, respectively. Remark that the character for the (chiral) A-type CSM model is calculated as[38]

$$Z_\beta(q) = \sum_{n=0}^{\infty} \frac{q^{\beta(n^2-n)/2+n}}{(q;q)_n} x^n. \tag{5.24}$$

This character coincides with the grand partition function for the spinless CSM model confined in the harmonic potential (1.3). It is interesting to see that the cases of $\beta = 0$ and 1 correspond to the free bosons and fermions, respectively,

$$Z_{\beta=0}(q) = \prod_{n=1}^{\infty} \frac{1}{1 - x q^n}, \quad Z_{\beta=1}(q) = \prod_{n=1}^{\infty} (1 + x q^n).$$

The character formula (5.24) suggests that the scattering matrix $S(\xi)$ is related with the statistical interaction by a formula

$$\beta = 1 - \frac{1}{2\pi}\int \mathrm{d}\xi \cdot \left(-\mathrm{i}\frac{\mathrm{d}}{\mathrm{d}\xi}\log S(\xi)\right). \tag{5.25}$$

This supports the result of the asymptotic Bethe ansatz,[39] by which the S-matrix for the CSM model is computed as

$$S(\xi) = \exp(-\mathrm{i}\pi(\beta-1)\mathrm{sgn}(\xi)). \tag{5.26}$$

C. BC-type

In the following we demonstrate the same calculation for the BC-type. We set $q = p^{-\beta}$, and take a limit $p \to 1+\varepsilon$. The quasi-classical limit (5.14) results in

$$\hat{Y}_j \to 1 + 2\varepsilon\, \hat{y}_j + O(\varepsilon^2),$$

where the BC-type differential-difference operator $\hat{y}_j$ is given by

$$\begin{aligned}\hat{y}_j = {} & z_j\frac{\partial}{\partial z_j} - \beta\sum_{k<j}\frac{z_k}{z_j - z_k}(\hat{s}_{j,k}-1) - \beta\sum_{k>j}\frac{z_j}{z_j-z_k}(\hat{s}_{j,k}-1) - \beta\sum_{k:k\neq j}\frac{1}{z_j z_k - 1}(\hat{t}_j\hat{t}_k\hat{s}_{j,k}-1) \\ & + \beta(j-1) - \left(\frac{\overline{\alpha}}{z_j^{\,2}-1} + \alpha\frac{2}{z_j-1}\right)\hat{t}_j + \left(\frac{\overline{\alpha}}{z_j^{\,2}-1} + \alpha\frac{z_j+1}{z_j-1}\right).\end{aligned} \tag{5.27}$$

The BC-type Dunkl operator $\hat{y}_j$ satisfies the following relations, which may be checked from the properties for $\hat{Y}_j$;

$$[\hat{y}_j, \hat{y}_k] = 0, \quad \hat{s}_{j,j+1}\hat{y}_j - \hat{y}_{j+1}\hat{s}_{j,j+1} = -\beta, \quad \hat{t}_1\hat{y}_1 + \hat{y}_1\hat{t}_1 = 2(\alpha+\overline{\alpha}). \tag{5.28}$$

The Hamiltonian for the trigonometric CSM model is obtained from the Dunkl operator $\hat{y}_j$. A lengthy calculation leads us to

$$\begin{aligned}\mathcal{H}^{\mathrm{BC}} = {} & \Delta^{\mathrm{BC}}(z)\cdot\sum_{j=1}^{N}\pi(\hat{y}_j^{\,2})\cdot\Delta^{\mathrm{BC}}(z)^{-1} \\ = {} & \sum_{j=1}^{N}\left(z_j\frac{\partial}{\partial z_j}\right)^2 - \beta(\beta-1)\sum_{j,k=1}^{N}{}'\left(\frac{z_j z_k}{(z_j-z_k)^2} + \frac{z_j z_k}{(z_j z_k - 1)^2}\right) \\ & - \sum_{j=1}^{N}\left(2\alpha(2\overline{\alpha}+2\alpha-1)\frac{z_j}{(z_j-1)^2} + 4\overline{\alpha}(\overline{\alpha}-1)\frac{z_j^{\,2}}{(z_j^{\,2}-1)^2}\right),\end{aligned} \tag{5.29}$$

where we suppose that there is no internal degree of freedom ($P_{jk} = Q_j = \mathbb{1}$) and define the BC-type ground state wave-function by

$$\Delta^{\mathrm{BC}}(z) = \prod_{j=1}^{N} z_j^{-\beta(N-1)-\overline{\alpha}-\alpha}(z_j-1)^{2\alpha}(z_j^{\,2}-1)^{\overline{\alpha}}\cdot\prod_{1\le j<k\le N}(z_j-z_k)^{\beta}(z_j z_k - 1)^{\beta}.$$

The eigenvalues are calculated in the same method as for the case of the A-type. We recall the DL operators,

$$\hat{r}^{-1} = a + \frac{a + (b-b^{-1})z - a^{-1}z^2}{1-z^2}(\hat{t}-1),$$

$$\hat{T}\,\hat{\bar{r}}\,\hat{T}^{-1}=c^{-1}+\frac{c+(d-d^{-1})\,p\,z-c^{-1}p^2\,z^2}{1-p^2\,z^2}(\hat{T}^2\,\hat{t}-1).$$

One can show that the eigenvalue Y_j for $\hat{Y}_j$ is given by

$$Y_j=q^{2j-2N}\,p^{2m_j}\,c^{-1}\,a. \tag{5.30}$$

Here $\{m_j\}$ is in a nonincreasing order, $m_1\geqslant m_2\geqslant\cdots\geqslant m_N\geqslant 0$. The energy for the BC-type CSM model (5.29) is expressed as

$$E=\sum_{j=1}^{N}(k_j^{\mathrm{BC}})^2, \tag{5.31}$$

where we choose the quasi-momenta k_j^{BC} as

$$k_j^{\mathrm{BC}}=m_j+\beta\,(N-j)+\alpha+\overline{\alpha}. \tag{5.32}$$

One sees that the quasi-particle has a statistical interaction β,

$$k_j^{\mathrm{BC}}-k_{j+1}^{\mathrm{BC}}\geqslant\beta. \tag{5.33}$$

The ''boundary interactions,'' α and $\overline{\alpha}$, only shift the quasi-momenta by a constant, and do not change the statistical interaction. To summarize, the statistical interaction in (5.23) is determined from the bulk property, and is not affected by the boundary effects.

VI. MACDONALD POLYNOMIAL

The difference operators $\hat{D}_j$ and $\hat{Y}_j$ introduced in the previous section are closely related with the Macdonald polynomial.[40] The Macdonald polynomial is defined as the orthogonal polynomial associated with the root system. For the case of the BC-type, it can be generalized to the Koornwinder–Macdonald (KM) polynomial, which contains five arbitrary parameters.[41]

The A_N-type Macdonald polynomial is defined as an eigen-polynomial of the difference operators,

$$\hat{M}_n=\sum_{I\subset\{1,2,\ldots,N\}\atop |I|=n}\prod_{j\in I\atop k\notin I}\frac{q^{-1}\,z_j-q\,z_k}{z_j-z_k}\prod_{j\in I}\hat{T}_j, \tag{6.1}$$

where the operator $\hat{T}_j$ is defined in (5.6). In fact these operators are given from the quantum Dunkl operators $\hat{D}_j$. For example, we have

$$\hat{M}_1=\pi(\hat{I}_1)=\sum_{j=1}^{N}\left(\prod_{k=1\atop k\neq j}^{N}\frac{q^{-1}\,z_j-q\,z_k}{z_j-z_k}\right)\hat{T}_j, \tag{6.2}$$

where $\hat{I}_1=\Sigma_{j=1}^{N}\hat{D}_j$.

On the other hand, the BC-type KM polynomial is introduced as a generalization of the Askey-Wilson polynomial.[42] The KM polynomial is defined as an eigen-polynomial of the operator,

$$\hat{M}_1^{\mathrm{BC}}=\sum_{j=1}^{N}\Psi_j(z)\,(\hat{T}_j-1)+\sum_{j=1}^{N}\Psi_j(z^{-1})\,(\hat{T}_j{}^{-1}-1), \tag{6.3}$$

where functions $\Psi_j(z)$ are defined as

$$\Psi_j(z)=\frac{(1-a_1 z_j)(1-a_2 z_j)(1-a_3 z_j)(1-a_4 z_j)}{(1-z_j{}^2)(1-p z_j{}^2)}\cdot\prod_{\substack{k=1\\k\neq j}}^{N}\frac{(t z_j-z_k)(1-t z_j z_k)}{(z_j-z_k)(1-z_j z_k)}.$$

It should be remarked that we have five arbitrary parameters $\{a_j,t\}$ besides p. It is straightforward to check that the KM operator $\hat{M}_1^{\mathrm{BC}}$ is also given by using the representation of the affine Hecke algebra $\hat{Y}_j$,[43]

$$\hat{W}_1\equiv\pi(\hat{J}_1+\hat{J}_{-1})=\Phi_0+\sum_{j=1}^{N}\Phi_j(z)\cdot(\hat{T}_j{}^2-1)+\sum_{j=1}^{N}\Phi_j(z^{-1})\cdot(\hat{T}_j^{-2}-1). \tag{6.4}$$

In the above equation, functions Φ_0 and $\Phi_j(z)$ are computed as

$$\Phi_j(z)=c\,a^{-1}\frac{(1+c^{-1}d\,p\,z_j)(1-c^{-1}d^{-1}p\,z_j)(1+a\,b^{-1}z_j)(1-a\,b\,z_j)}{(1-z_j{}^2)(1-p^2 z_j{}^2)}$$
$$\times\prod_{\substack{k=1\\k\neq j}}^{N}\frac{q^{-1}z_j-q\,z_k}{z_j-z_k}\cdot\frac{q^{-1}z_j z_k-q}{z_j z_k-1},$$

$$\Phi_0=(c^{-1}a\,q^{1-N}+c\,a^{-1}q^{N-1})\frac{q^{N-1}-q^{-N+1}}{q^2-1}.$$

One thus sees that the KM operator is constructed based on the affine Hecke algebra of type-BC.[44]

Some of eigenfunctions of the Macdonald operator $\hat{M}_1$ are simply calculated from the generating function $F^{(N)}(z;t)$,

$$F^{(N)}(z;t)=\prod_{j=1}^{N}\frac{(q^{-2}z_j t;p)_\infty}{(z_j t;p)_\infty}. \tag{6.5}$$

We can show that the function $F^{(N)}(z;t)$ satisfies a difference equation,

$$(\hat{M}_1 F^{(N)})(z;t)=\left(\sum_{j=1}^{N-1}q^{2j-N+1}\right)F^{(N)}(z;t)+q^{-N+1}F^{(N)}(z;p\,t).$$

Thus when one defines the "generalized Rogers–Askey–Ismail (RAI) polynomial" $C_n^{(N)}(z)$ as

$$F^{(N)}(z;t)=\sum_{n=0}^{\infty}\frac{(q^{-2};p)_n}{(p;p)_n}\cdot C_n^{(N)}(z)\,t^n,$$

one sees that the polynomial is indeed an eigenfunction of $\hat{M}_1$,

$$(\hat{M}_1 C_n^{(N)})(z)=\left(\sum_{j=1}^{N-1}q^{2j-N+1}+q^{-N+1}p^n\right)C_n^{(N)}(z). \tag{6.6}$$

The generalized RAI polynomial $C_n^{(N)}(z)$ coincides with the A-type Macdonald polynomial $P_\lambda(z)$ for Young diagram $\lambda=[n]$.[40] The RS polynomial, which appeared in Sec. II as a generating function for the Yangian invariant spin chain, is a special case of the RAI polynomial,

$$H_n^{(N)}(p)=\lim_{q^{-2}\to 0}C_n^{(N)}(z). \tag{6.7}$$

VII. ELLIPTIC RUIJSENAARS MODEL

The Ruijsenaars model[45] is an elliptic generalization of the Macdonald difference operator (6.1),

$$\hat{\mathcal{D}}_n=\sum_{|I|=n}\prod_{\substack{j\in I\\ k\notin I}}\frac{\vartheta_1(z_{jk}-\mu)}{\vartheta_1(z_{jk})}\prod_{j\in I}\hat{T}_j(\beta), \tag{7.1}$$

where we have used the shift operator, $(\hat{T}_j(\beta)\,f)(\ldots,z_j,\ldots)=f(\ldots,z_j+\beta,\ldots)$.

These integrable operators can be constructed as follows.[46] We rescale the R-operator (3.2) and redefine it by

$$R^{jk}(\xi)=\sigma_\mu(z_{jk})-\sigma_\xi(z_{jk})\,\hat{s}_{jk}. \tag{7.2}$$

We first consider the two-body case. Simple calculation gives

$$R^{21}(\xi)\,\hat{T}_2(\beta)=\frac{\vartheta_1(z_{21}-\mu)\,\vartheta_1'(0)}{\vartheta_1(z_{21})\,\vartheta_1(-\mu)}\hat{T}_2(\beta)+\frac{\vartheta_1(z_{12}+\xi)\,\vartheta_1'(0)}{\vartheta_1(z_{12})\,\vartheta_1(\xi)}\hat{T}_1(\beta)\,\hat{s}_{12},$$

which coincides with the Ruijsenaars operator $\hat{\mathcal{D}}_1$ up to a constant if we set $\xi=-\mu$ and the operator acts on the symmetric space (we replace permutation operators $\hat{s}$ with unity when they are moved to the rightmost). As a generalization of this observation, we have the integrable difference operator defined by

$$\hat{D}(\boldsymbol{\xi})=R^{N,N-1}(\xi_{NN-1})\cdots R^{N,1}(\xi_{N1})\,\hat{T}_N(\beta), \tag{7.3}$$

which reduces to the first order Ruijsenaars operator (up to constant) by suitably setting the spectral parameters,[46]

$$\hat{\mathcal{D}}_1=\lim_{\xi_{jk}\to(k-j)\mu}\hat{D}(\boldsymbol{\xi}). \tag{7.4}$$

This construction can be applied to a generalized elliptic Ruijsenaars model[47] as well. Using a solution of the reflection equation (3.7) and (4.2), the integrable difference operator can be written as

$$\hat{\mathcal{Y}}(\boldsymbol{\xi})=\left(\prod_{k=1}^{\overleftarrow{N-1}}R^{N,k}(\xi_{Nk})\right)^{N}K(\xi_N)\left(\prod_{l=1}^{N-1}R^{l,N}(\xi_l+\xi_N)\right)\hat{T}_N(-\beta)\,\overline{\overset{N}{K}}(\xi_N)\,\hat{T}_N(\beta). \tag{7.5}$$

When we set $\xi_k=-\nu-(k-1)\mu$ in this integrable operator, we obtain an elliptic generalization of the Macdonald–Koornwinder operator,[46]

$$\begin{aligned}\hat{\mathcal{D}}_1^{\mathrm{BC}}=&\sum_{j=1}^{N}\left(\prod_{\substack{k=1\\k\neq j}}^{N}\sigma_\mu(z_{jk})\sigma_\mu(z_j+z_k)\right)\left(\sum_{r=0}^{3}g_r\,\sigma_{2\nu}^r(z_j)\right)\\&\times\left(\sum_{r=0}^{3}\overline{g_r}\,\sigma_{2\nu}^r(z_j+\beta)\,\hat{T}_j^2(\beta)-\sum_{r=0}^{3}\overline{g_r}\,\sigma_{-2(N-1)\mu-2\nu}^r(z_j+\beta)\right)\\&+\sum_{j=1}^{N}\left(\prod_{\substack{k=1\\k\neq j}}^{N}\sigma_\mu(z_{kj})\sigma_\mu(-z_j-z_k)\right)\left(\sum_{r=0}^{3}g_r\,\sigma_{2\nu}^r(-z_j)\right)\end{aligned}$$

$$\times\left(\sum_{r=0}^{3}\overline{g_r}\,\sigma^r_{2\nu}(-z_j+\beta)\,\hat{T}_j^{-2}(\beta)-\sum_{r=0}^{3}\overline{g_r}\,\sigma^r_{-2(N-1)\mu-2\nu}(-z_j+\beta)\right). \tag{7.6}$$

Higher conserved operators for these generalized elliptic Ruijsenaars models are obtained explicitly.[46] Such an approach is further extended to the quantum integrability of elliptic Ruijsenaars models associated with all affine Lie algebras.[48] It was also discussed that for a certain setting of parameters integrable difference operators $\hat{\mathcal{D}}_1$ in (7.4) and $\hat{\mathcal{D}}_1^{\mathrm{BC}}$ in (7.6) preserve a finite dimensional space as in Sec. III B and that we can compute the eigenvalues/eigenfunctions.

VIII. CONCLUDING REMARKS

We have reviewed some salient properties of quantum integrable models with long-range interactions.

In what follows, short-range interaction models are briefly discussed. We remark that the Yangian symmetry is revealed in the Hubbard model[49] and the two-component δ-function interacting fermi gas.[50] In the case of the δ-function interacting fermi gas, one can construct the Dunkl operator as well. We find that the YBE (2.1) is solved by the R-operator,[51]

$$R(\xi)=1-U(\mathrm{sgn}(z)-\coth(\xi))\hat{s}_{j,k}, \tag{8.1}$$

where the function sgn(z) denotes a signature of z,

$$\mathrm{sgn}(z)=\lim_{\gamma\to\infty}\coth(\gamma z)=\begin{cases}+1, & \text{for } z>0,\\ -1, & \text{for } z<0.\end{cases}$$

Almost all the properties studied in Sec. V are preserved for this R-operator; with a shift operator, $(\hat{T}f)(z)=f(z+1)$, one can construct the integrable difference operator,

$$\hat{I}=-\sum_{j=1}^{N}(\hat{T}_j+\hat{T}_j^{-1})+U\sum_{1\leqslant j<k\leqslant N}(\mathrm{sgn}(z_{jk}+1)-\mathrm{sgn}(z_{jk}))(\hat{T}_j+\hat{T}_k^{-1})\,\hat{s}_{j,k}. \tag{8.2}$$

This difference operator corresponds, in the su(2) case, to the strongly correlated electron system[52]

$$\mathcal{H}^{\mathrm{Bariev}}=-\sum_j\{(c^\dagger_{j,\uparrow}c_{j+1,\uparrow}+c^\dagger_{j+1,\uparrow}c_{j,\uparrow})(1-Un_{j,\downarrow})+(c^\dagger_{j,\downarrow}c_{j+1,\downarrow}+c^\dagger_{j+1,\downarrow}c_{j,\downarrow})(1-Un_{j+1,\uparrow})\}, \tag{8.3}$$

where $c_{j,\sigma}$ and $c^\dagger_{j,\sigma}$ are fermion annihilation and creation operators, respectively. It is interesting to see a distinction from the Hubbard model,

$$\mathcal{H}^{\mathrm{Hubbard}}=-\sum_j\sum_{\sigma=\uparrow,\downarrow}(c^\dagger_{j,\sigma}c_{j+1,\sigma}+c^\dagger_{j+1,\sigma}c_{j,\sigma})+U\sum_j\left(n_{j,\uparrow}-\frac{1}{2}\right)\left(n_{j,\downarrow}-\frac{1}{2}\right). \tag{8.4}$$

As a continuum limit of (8.3), we obtain the Dunkl operator and the Hamiltonian as follows:

$$\hat{d}_j^{\mathrm{NLS}}=-\mathrm{i}\frac{\partial}{\partial z_j}+\frac{\mathrm{i}\beta}{2}\sum_{k<j}(\mathrm{sgn}(z_{jk})-1)\,\hat{s}_{j,k}+\frac{\mathrm{i}\beta}{2}\sum_{k>j}(\mathrm{sgn}(z_{jk})+1)\,\hat{s}_{j,k}, \tag{8.5}$$

$$\mathcal{H}^{\mathrm{NLS}}=\sum_{j=1}^{N}\pi((\hat{d}_j^{\mathrm{NLS}})^2)=-\sum_{j=1}^{N}\frac{\partial^2}{\partial z_j^{\,2}}+2\beta\sum_{1\leqslant j<k\leqslant N}\delta(z_{jk})\,P_{j,k}. \tag{8.6}$$

We call this system the multi-component nonlinear Schrödinger (NLS) model. This is a generalization of the δ-function gas.

APPENDIX A: GAUSSIAN q-BINOMIAL

The q-binomial satisfies the following relations:

$$\begin{bmatrix} n \\ m \end{bmatrix}_q = \begin{bmatrix} n \\ n-m \end{bmatrix}_q, \quad \begin{bmatrix} n+m \\ m \end{bmatrix}_{q^{-1}} = q^{-mn} \begin{bmatrix} m+n \\ m \end{bmatrix}_q,$$

$$\lim_{q\to 1} \begin{bmatrix} n \\ m \end{bmatrix}_q = \begin{pmatrix} n \\ m \end{pmatrix}, \quad \lim_{n\to\infty} \begin{bmatrix} n \\ m \end{bmatrix}_q = \frac{1}{(q;q)_m}, \tag{A1}$$

$$\begin{bmatrix} n \\ m \end{bmatrix}_q = \begin{bmatrix} n-1 \\ m-1 \end{bmatrix}_q + q^m \begin{bmatrix} n-1 \\ m \end{bmatrix}_q = q^{n-m} \begin{bmatrix} n-1 \\ m-1 \end{bmatrix}_q + \begin{bmatrix} n-1 \\ m \end{bmatrix}_q.$$

We note that the Euler series-product identity is satisfied for infinite q-product series,

$$\sum_{N=0}^{\infty} \frac{t^N}{(q;q)_N} = \frac{1}{(t;q)_\infty}. \tag{A2}$$

APPENDIX B: ELLIPTIC FUNCTION

The elliptic function $\sigma_\mu^r(z) = \sigma_\mu^r(z;\tau)$ is a doubly quasi-periodic function,

$$\sigma_\mu^r(z+1) = \sigma_\mu^r(z), \quad \sigma_\mu^r(z+\tau) = \mathrm{e}^{2\pi \mathrm{i}\mu} \sigma_\mu^r(z), \quad \text{for } \Im\tau > 0. \tag{B1}$$

Here we have defined the function $\sigma_\mu^r(z)$ for $r = 0,1,2,3$ by

$$\sigma_\mu^r(z) = \frac{\vartheta_{r+1}(z-\mu;\tau)\ \vartheta_1'(0;\tau)}{\vartheta_{r+1}(z;\tau)\ \vartheta_1(-\mu;\tau)}, \tag{B2}$$

where

$$\vartheta_1(z) = -\mathrm{i} \sum_{n\in\mathbb{Z}} \exp\left(\mathrm{i}\pi \left(n+\frac{1}{2} \right)^2 \tau + 2\pi \mathrm{i} \left(n+\frac{1}{2} \right) z + \mathrm{i}\pi n \right),$$

$$\vartheta_2(z) = \sum_{n\in\mathbb{Z}} \exp\left(\mathrm{i}\pi \left(n+\frac{1}{2} \right)^2 \tau + 2\pi \mathrm{i} \left(n+\frac{1}{2} \right) z \right),$$

$$\vartheta_3(z) = \sum_{n\in\mathbb{Z}} \exp(\mathrm{i}\pi n^2 \tau + 2\pi \mathrm{i} n z),$$

$$\vartheta_0(z) = \sum_{n\in\mathbb{Z}} \exp(\mathrm{i}\pi n^2 \tau + 2\pi \mathrm{i} n z + \mathrm{i}\pi n),$$

and $\vartheta_4(z) = \vartheta_0(z)$. We mean $\sigma_\mu(z) = \sigma_\mu^0(z)$. Functions $\sigma_\mu^r(z)$ have simple poles at $z = \mathbb{Z} + \tau\mathbb{Z} + \omega_r$ where $\omega_r \equiv (\alpha_r + \beta_r \tau)/2$ are given by $(\omega_0, \omega_1, \omega_2, \omega_3) = (0, 1/2, (1+\tau)/2, \tau/2)$. We summarize some useful formulas for the function $\sigma_\mu(z)$:

$$\begin{gathered} \sigma_\mu(z) = -\sigma_z(\mu), \quad \sigma_\mu(z) = -\sigma_{-\mu}(-z), \\ \sigma_\mu(z)\ \sigma_{-\mu}(z) = \wp(z) - \wp(\mu), \\ \sigma_\lambda(z)\ \sigma_\mu(w) = \sigma_{\lambda+\mu}(w)\ \sigma_\lambda(z-w) + \sigma_\mu(w-z)\ \sigma_{\lambda+\mu}(z), \\ \sigma_\lambda(z)\ \sigma_\mu(z) = \sigma_{\lambda+\mu}(z) \cdot (\zeta(z) - \zeta(\lambda) - \zeta(\mu) - \zeta(z-\lambda-\mu)). \end{gathered} \tag{B3}$$

We also use

$$\vartheta\begin{bmatrix} a \\ b \end{bmatrix}(z;\tau)=\sum_{n\in\mathbb{Z}} \exp(\pi \mathrm{i}(n+a)^2\tau+2\pi\mathrm{i}(n+a)(z+b)). \tag{B4}$$

It is proved by checking the periodicity and the residues that the following equality is satisfied:[29]

$$\sigma_\mu(z;\tau)=\frac{1}{k}\sum_{a=0}^{k-1} \sigma_{\mu+a/k}\left(z;\frac{\tau}{k}\right), \tag{B5}$$

where k is an arbitrary positive integer, $k\in\mathbb{Z}_+$.

We use the general $\mathcal{N}=1$ supersymmetric formulation of one dimensional sigma models on nontrivial manifolds and its subsequent quantization to formulate the classical and quantum dynamics of the $\mathcal{N}=2$ supersymmetric charged particle moving on a sphere in the field of a monopole. The factorization method is accommodated with the general covariance and it is used to integrate the corresponding system. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1586476]

I. INTRODUCTION

The factorization method was first used by Schrödinger[1] to diagonalize the harmonic oscillator. It may work when the Hamiltonian of the system can be cast as a product of two operators:

$$H=AB. \tag{1.1}$$

A c-number can also be added to the above operator. Most systems treated by this method are one dimensional systems,[2,3] but it has also been considered in other situations.[4]

Recently, Ferapontov and Veselov[5] used factorization to look for integrable Schrödinger operators with magnetic fields on two dimensional surfaces. In the following we will use their approach to the monopole harmonics of Wu and Yang[6] to construct the super-symmetric monopole harmonics. We will show that factorization can be readily used for integrating the $\mathcal{N}=2$ supersymmetric nonrelativistic quantum mechanics[7] of a particle with spin moving on a sphere in the field of a monopole placed at its center. This can be inferred from the fact that the supersymmetric charge of the classical σ-model quantizes as the Dirac operator[8,9] on the manifold. Because the sphere is a two dimensional manifold, in a convenient basis the Dirac operators do not mix the components of the spinors and therefore the Hamiltonian of the system will be

$$H=\frac{1}{2}(Q\overline{Q}+\overline{Q}Q)=\begin{pmatrix} AB & 0 \\ 0 & BA \end{pmatrix},$$

and, because of this, the factorization method will be the natural method to integrate H.

As the factorization method is very simple we will recall some of its features here, in order to make the following computations easier to follow. Therefore, along with (1.1), one considers the reverse order product:

$$\tilde{H}=BA.$$

Then $\tilde{H}$ and H have the same nonzero eigenvalues. Indeed, if λ is an eigenvalue $(\lambda\neq 0)$ of $\tilde{H}$,

$$\tilde{H}|\tilde{\Psi}_\lambda\rangle=\lambda|\tilde{\Psi}_\lambda\rangle,$$

then

$$|\Psi_\lambda\rangle=A|\tilde{\Psi}_\lambda\rangle$$

obeys

$$H|\Psi_\lambda\rangle=\lambda|\Psi_\lambda\rangle.$$

For the harmonic oscillator,

$$H=a^\dagger a+\tfrac{1}{2}$$

with

$$[a,a^\dagger]=1,$$

introduce

$$\tilde{H}=aa^\dagger+\tfrac{1}{2}=a^\dagger a+\tfrac{3}{2}.$$

The operators H and $\tilde{H}$ are positive operators, and it follows that the vector $|0\rangle$,

$$a|0\rangle=0,$$

is an eigenvector of H, with $\lambda=\frac{1}{2}$, and of $\tilde{H}$, with $\lambda=\frac{3}{2}$, and therefore

$$a^\dagger|0\rangle$$

is an eigenvector of H, corresponding to $\lambda=\frac{3}{2}$. The procedure can be continued:

$$\tilde{\tilde{H}}=H^{(2)}=\tilde{H}+1=H+2.$$

At the nth step

$$H^{(n)}=H+n,$$

with $|0\rangle$ being an eigenvector of $H^{(n)}$ corresponding to

$$\lambda=n+\tfrac{1}{2}.$$

Then H has the same eigenvalue and the corresponding eigenvector is

$$|\Psi_\lambda\rangle=(a^\dagger)^n|0\rangle.$$

We emphasize that the factorization method involves three steps: First, write the Hamiltonian in a factorized way; second, use a trick to cast $\tilde{H}$ in a form similar to that of H (i.e., move the destruction operators to the right in the previous example). The third step is to find the necessary recurrence procedure that yields all the eigenvalues and eigenvectors. This is also the pattern we are going to follow.

In Sec. II we reformulate the method of Ref. 5 for the scalar wave function in the einbein formalism. We show that the recurrence relations are obtained as a consequence of the requirement that the reverse order product BA has the same covariance properties acting on scalar wave vectors as the original product AB. On the sphere this happens because the spin connection

associated with the U(1) gauge group in the tangent space can be chosen to be proportional to the gauge connection corresponding to the monopole at its center,[10] the proportionality factor being exactly the number entering into the Dirac quantization condition.

In Sec. III we formulate the maximal classical supersymmetric action associated with the motion of a charge on a sphere, in the field of a monopole located at its center. The same action can be obtained by considering the supersymmetric one dimensional SU(2)/U(1) nonlinear model and coupling it with the electromagnetic field through a gauge potential equal with the connection, generated by the nonlinear transformation law.[11] The equivalence of these two formulations stems from the aforementioned property: the spin connection and the gauge connection are proportional. Alternatively, the same result follows by restricting the $\mathcal{N}=1$ supersymmetric action corresponding to a charge in the field of a monopole through Lagrange super-multipliers.[12,13] However, we prefer to obtain our model from the existing general superspace σ-model actions,[14,15] by fixing the field content, and choosing the appropriate background. In this way we can follow the natural way of solving models of this sort. We will need only two real anticommuting classical degrees of freedom for the formulation of the classical supersymmetric action. After quantization these real anticommuting degrees of freedom become the gamma matrices. This suggests that the two bosonic degrees of freedom combine with the anticommuting ones in two type-B superfields. Then we fix the appropriate background in the most general renormalizable $\mathcal{N}=1$ type-B superspace σ-model action.[14,15] The quantization of the general superspace σ-models produces the component approach to supersymmetric quantum mechanics, the general formulation of which was pursued in Ref. 16. To quantize our model we use the procedure of Refs. 17 and 18 in which the reparametrization covariance can be obtained with the help of the appropriately defined Noether supercharge.

Section IV is devoted to the diagonalization of this quantum system, while in Sec. V we give some concluding remarks.

II. FACTORIZATION METHOD

The Hamiltonian for the motion of a charge e, on a sphere, in the field of a monopole of strength g, localized at the center of the sphere, is

$$H_N=-\tfrac{1}{4}g^{ab}\nabla_a^{(N)}\nabla_b^{(N)}, \tag{2.1}$$

where g^{ab} is the inverse metric on a sphere

$$ds^2=g_{ab}dx^a dx^b=R^2\sin^2\theta d\phi^2+R^2 d\theta^2, \tag{2.2}$$

and the covariant derivatives are

$$\nabla_b^{(N)}=\partial_b-iA_b^{(N)}, \tag{2.3}$$

and

$$\nabla_a^{(N)}\nabla_b^{(N)}=\partial_a\nabla_b^{(N)}-iA_a^{(N)}\nabla_b^{(N)}-\Gamma_{ab}^c\nabla_c^{(N)}, \tag{2.4}$$

where ∂_a are the derivatives with respect to the coordinates in a patch on the sphere. The gauge connection A_a^N is

$$A_\phi=\frac{eg}{R\sin\theta}(\pm 1-\cos\theta), \tag{2.5}$$

where $\theta<\pi$ for the upper sign and $\theta>0$ for the lower sign. Γ_{ab}^c is the standard Christoffel connection for a sphere, and $N=eg$.

The desired factorization of (2.1) will be obtained by introducing the stereographic projection:

$$\cos\theta = 1 - \frac{2}{1+(x^2+y^2)/4R^2}, \tag{2.6}$$

$$\tan\phi = \frac{y}{x}. \tag{2.7}$$

Defining the complex coordinate

$$z = x + iy, \tag{2.8}$$

the only nonvanishing components of g^{ab} are $g^{z\bar{z}} = g^{\bar{z}z}$ with

$$g^{z\bar{z}} = 2h^{-2} = 2\left(1 + \frac{z\bar{z}}{4R^2}\right)^2. \tag{2.9}$$

Now, in the new coordinates, the Hamiltonian is

$$H_N = -\frac{1}{2} g^{z\bar{z}} \nabla_{\bar{z}}^{(N)} \nabla_z^{(N)} + \frac{N}{4R^2}, \tag{2.10}$$

where

$$\nabla_z^{(N)} = \partial_z - iA_z^{(N)}, \tag{2.11}$$

$$\nabla_{\bar{z}}^{(N)} = \partial_{\bar{z}} - iA_{\bar{z}}^{(N)}, \tag{2.12}$$

and

$$A_z^{(N)} = \tfrac{1}{2}(A_1^{(N)} - iA_2^{(N)}) = -iN\partial_z \ln h, \quad A_{\bar{z}}^{(N)} = A_z^{(N)*}. \tag{2.13}$$

The Christoffel connection does not appear in (2.10) anymore, because its only nonvanishing components are Γ_{zz}^{z} and $\Gamma_{\bar{z}\bar{z}}^{\bar{z}}$. In (2.10) we have used the relation

$$g^{z\bar{z}}[\nabla_z^{(N)}, \nabla_{\bar{z}}^{(N)}] = -\frac{N}{R^2}, \tag{2.14}$$

in order to exhibit the ''destruction operators'' $\nabla_z^{(N)}$ to the right and the ''creation operators'' $\nabla_{\bar{z}}^{(N)}$ to the left. The lowest eigenvalues of H_N are defined by the zero modes of the operators $\nabla_z^{(N)}$. Moreover, as it will be shown, the excited levels of H_N are related to the lowest levels of H_K, with $K > N$. These zero modes are related by the index theorem to topological properties of the manifold, see Ref. 5. Thus we may regard the present method of integrating H_N as a topological one.

In our case the wave vector is a scalar under the reparametrizations of the manifold. In a more general setting we might consider different assignments of spinorial (tensorial) properties to the wave vector. This is the case when one deals with the motion of a charged spin $\frac{1}{2}$ particle on a sphere, when the wave function is a spinor. Then, for a manifestly covariant approach, the appropriate language is the vielbein formalism of general relativity. This is not actually necessary for the case of the scalar wave functions. However, as we will show, even in this case, it allows one to avoid the use of the correct, but rather artificial, similarity transformations[5] in establishing the recurrence relations necessary to apply the factorization method.

Let us now introduce the einbeins for our complex manifold:

$$g_{z\bar{z}} = e_z^{+} e_{\bar{z}}^{-} \eta_{+-}, \tag{2.15}$$

where η_{+-} is the metric in the tangent space in an appropriate basis:

$$\eta_{+-}=\eta_{-+}=\tfrac{1}{2}, \quad \eta^{+-}=\eta^{-+}=2. \tag{2.16}$$

We have

$$e_z^+=e_{\bar{z}}^-=h, \quad e_z^-=e_{\bar{z}}^+=0. \tag{2.17}$$

Using the constant covariance of the einbein

$$\nabla_a e_b^\alpha=\partial_a e_b^\alpha+\omega_a{}^\alpha{}_\beta e_b^\beta-\Gamma_{ab}^c e_c^\alpha=0, \tag{2.18}$$

(2.10) becomes

$$H_N=-\mathcal{D}_-^{(N)}\mathcal{D}_+^{(N)}+\frac{N}{4R^2}, \tag{2.19}$$

where

$$\mathcal{D}_-^{(N)}=e_-^{\bar{z}}(\nabla_{\bar{z}}^{(N)}+\omega_{\bar{z}+}{}^+), \tag{2.20}$$

and

$$\mathcal{D}_+^{(N)}=e_+^z\nabla_z^{(N)}. \tag{2.21}$$

Above, one has

$$e_+^z=e_-^{\bar{z}}=h^{-1}, \tag{2.22}$$

and the nonvanishing components of the spin connection are

$$\omega_z{}^+{}_+=-\omega_{z+}{}^+=\partial_z\ln h, \tag{2.23}$$

$$\omega_{\bar{z}}{}^+{}_+=-\omega_{\bar{z}+}{}^+=-\partial_{\bar{z}}\ln h. \tag{2.24}$$

Consider now the tilde of (2.19):

$$\tilde{H}_N=-[\mathcal{D}_+^{(N)}]_{nc}[\mathcal{D}_-^{(N)}]_{nc}+\frac{N}{4R^2}. \tag{2.25}$$

While (2.19) is manifestly generally covariant (assuming that the wave vector is a world scalar), (2.25) is not manifestly so. By reversing the order of covariant derivatives, the spin connection terms in the covariant derivatives do not match the tensor properties of the terms ahead of them. This is why, in considering the reverse order product above, we appended the nc index to the covariant derivatives, even if their definition (2.20) and (2.21) did not change.

In order to obtain a recurrence relation one would expect (as explained in the Introduction) the operator $\tilde{H}_N$ to be a scalar and act on a scalar wave function. However, then $\tilde{H}_N$ is not manifestly covariant. The manifest covariance of $\tilde{H}_N$ is restored by noting that the gauge connection and the spin connection can be chosen to be proportional:[10]

$$A_a^{(N)}=N\omega_a, \tag{2.26}$$

where $N=eg$ appears in the Dirac quantization condition. Therefore we have the following identity:

$$[\mathcal{D}_+^{(N)}]_{nc}[\mathcal{D}_-^{(N)}]_{nc}=e_+^z\nabla_z^{(N)}e_-^{\bar{z}}(\nabla_{\bar{z}}^{(N)}+\omega_{z+}{}^+)=e_+^z(\nabla_z^{(N+1)}+\omega_{z-}{}^-)e_-^{\bar{z}}\nabla_{\bar{z}}^{(N+1)}=\mathcal{D}_+^{(N+1)}\mathcal{D}_-^{(N+1)}. \tag{2.27}$$

Here the expressions for $\mathcal{D}_+^{(N+1)}$, $\mathcal{D}_-^{(N+1)}$ can be read in the above formula and the expression to the right, above, is fully covariant. Substituting this in $\tilde{H}_N$ and moving the destruction operators to the right with the help of (2.14) we have

$$\tilde{H}_N = H_N{}^{(1)} = H_{N+1} + \frac{2N+1}{4R^2}. \tag{2.28}$$

Therefore the next eigenvalue of H_N is $(3N+2)/4R^2$. The corresponding eigenvector can be obtained from that of $\tilde{H}_N$, given by the condition

$$\nabla_z^{(N+1)} \tilde{\Psi}_1 = 0. \tag{2.29}$$

One has

$$\Psi_1 = \mathcal{D}_-^{(N)} \tilde{\Psi}_1, \tag{2.30}$$

with $\mathcal{D}_-^{(N)}$ defined by (2.20). Even if we deal with two covariant problems, that of H_N and that of $\tilde{H}_N$, the connection between the two sets of eigenvectors is not generally covariant.

The procedure described above can be continued, and at the lth step we get

$$H_N^{(l)} = H_{N+l} + \frac{(2N-1)+l(l+1)}{4R^2}, \tag{2.31}$$

with the eigenvalue

$$\lambda_l = \frac{1}{4R^2}[(2l+1)N + l(l+1)], \tag{2.32}$$

and the corresponding eigenvector of H_N

$$\Psi_l = \mathcal{D}_-^{(N)} \cdots \mathcal{D}_-^{(N+l-1)} \tilde{\Psi}_l, \tag{2.33}$$

where $\mathcal{D}_-^{(P)}$ was defined in (2.20). $\tilde{\Psi}_l$ is the solution of

$$\nabla_z^{(N+l)} \tilde{\Psi}_l = 0. \tag{2.34}$$

The multiplicity of the state Ψ_l is obtained from the condition of finite norm of the states:

$$\int \frac{dz d\bar{z}}{2} h^2 |\tilde{\Psi}_l|^2 < \infty. \tag{2.35}$$

Indeed, the solution of (2.34) is

$$\tilde{\Psi}_l = h^{N+l} f(\bar{z}), \tag{2.36}$$

where $f(\bar{z})$ is an arbitrary polynomial of degree $\leqslant 2(N+l)$, making the degeneracy of the corresponding state $2(N+l)+1$. From the asymptotic behavior of (2.33) in the radial variable, one sees that there are potential problems with normalizability of such states. However, as we checked on examples, due to cancellations of unwanted terms the vector Ψ_l is normalizable. We point out that this result is valid for integer $2N \geqslant 0$. Otherwise ($N<0$) the creation and annihilation operators must be interchanged.

Hence imposing the manifest general covariance of $\tilde{H}_N$ led us to rederive the recurrence relations[5] necessary in order to completely integrate the Hamiltonian H_N. In the next section, using the canonical quantization we will obtain the Hamiltonian for the supersymmetric particle which will be subsequently diagonalized by the factorization method.

III. $\mathcal{N}=2$ SUPERSYMMETRIC QUANTUM MECHANICS ON A SPHERE

We will approach the supersymmetrization of a given bosonic action in the following way. Given the target manifold (whose local coordinates are the bosonic fields which appear in the formulation of the one dimensional σ-model of the system), we look at the dimensionality of the Clifford algebra supported by the tangent space; for the sphere this is two. Therefore, in the present case, the Γ-matrices will be Hermitian matrices and therefore can be obtained from the quantization of the two real anticommuting degrees of freedom. Thus the minimal content of the fields realizing the representation of the supersymmetry algebra will be two real bosonic (the coordinate on the target manifold) and two real anticommuting degrees of freedom. We can fit these degrees of freedom in two type-B superfields. Because the tangent space is two dimensional and the supersymmetry charges must be constructed with the help of the Γ-matrices, one expects the maximal supersymmetry allowable for the system to be $\mathcal{N}=2$. Thus with the help of two type-B superfields we must formulate an $\mathcal{N}=2$ supersymmetric action. This is automatic since our target space manifold admits a complex structure. The above argument is somehow circular because one formulates the problem on the basis of the outcome of the quantization procedure.

Therefore, with the help of the metric $g_{ab}(X^a)$, the gauge connection $A_a{}^{(N)}(X^a)$ and the type-B superfield $X^a(x,\theta)$, we construct the following $\mathcal{N}=1$, one dimensional σ-model:[14,15]

$$S=-i\int dt\,d\theta\left\{\frac{g_{z\bar{z}}}{2}(DX^z\dot{X}^{\bar{z}}+DX^{\bar{z}}\dot{X}^z)+A_zDX^z+A_{\bar{z}}DX^{\bar{z}}\right\}. \tag{3.1}$$

Here

$$D=\frac{\partial}{\partial\theta}+i\theta\frac{d}{dt},\quad D^2=i\frac{d}{dt} \tag{3.2}$$

is the covariant supersymmetric derivative. The superfields, X^z and $X^{\bar{z}}$, are connected through $X^{\bar{z}}=(X^z)^\dagger$ and have the components

$$z=X^z|_{\theta=0},\quad \lambda^z=(DX^z)|_{\theta=0}, \tag{3.3}$$

with

$$\lambda^{z\dagger}=-\lambda^{\bar{z}} \tag{3.4}$$

and

$$\int d\theta\{\cdots\}=D\{\cdots\}|_{\theta=0}. \tag{3.5}$$

The action (3.1) is invariant under the supersymmetry transformations

$$\delta_\epsilon X^{\bar{z}}=\epsilon QX^{\bar{z}}, \tag{3.6}$$

$$\delta_\epsilon X^z=\epsilon QX^z, \tag{3.7}$$

where the supersymmetry shift operator Q is

$$Q=\frac{\partial}{\partial\theta}-i\theta\frac{d}{dt}, \tag{3.8}$$

with

$$Q^2=-i\frac{d}{dt}, \quad \{Q,D\}=0. \tag{3.9}$$

As mentioned before, because of the fact that the target space manifold is complex we will automatically have a second supersymmetry

$$\delta_\eta X^{\bar z}=-i\eta DX^{\bar z}, \tag{3.10}$$

$$\delta_\eta X^{z}=i\eta DX^{z}. \tag{3.11}$$

The two supersymmetry transformations above can be combined in one complex supersymmetry which in component fields $z,\bar z,\lambda^z,\lambda^{\bar z}$ takes the form

$$\delta z=\delta\mu\lambda^z, \quad \delta\lambda^z=i\delta\bar\mu\dot z, \tag{3.12}$$

and

$$\delta\bar z=\delta\bar\mu\lambda^{\bar z}, \quad \delta\lambda^{\bar z}=i\delta\mu\dot{\bar z}, \tag{3.13}$$

where

$$\delta\mu^\dagger=\delta\bar\mu. \tag{3.14}$$

The action (3.1) can also be written in terms of component fields, and the Lagrangian is

$$\mathcal{L}=g_{z\bar z}\dot z\dot{\bar z}+i\frac{g_{z\bar z}}{2}(\lambda^z D\lambda^{\bar z}+\lambda^{\bar z}D\lambda^z)-iF^{(N)}_{z\bar z}\lambda^z\lambda^{\bar z}+A^{(N)}_z\dot z+A^{(N)}_{\bar z}\dot{\bar z}, \tag{3.15}$$

where

$$F_{z\bar z}=\partial_z A_{\bar z}-\partial_{\bar z}A_z, \tag{3.16}$$

and

$$D\lambda^z=\dot\lambda^z+\dot z\Gamma^z_{zz}\lambda^z, \quad D\lambda^{\bar z}=\dot\lambda^{\bar z}+\dot{\bar z}\Gamma^{\bar z}_{\bar z\bar z}\lambda^{\bar z}, \tag{3.17}$$

where Γ^z_{zz} and $\Gamma^{\bar z}_{\bar z\bar z}$ are the only nonvanishing components of the Christoffel connection for the sphere. Equation (3.15) is invariant under (3.12) and (3.13) and by the Noether procedure one can deduce the corresponding supercharges:

$$\bar Q=-\lambda^z g_{z\bar z}\dot{\bar z}, \tag{3.18}$$

$$Q=\lambda^{\bar z}g_{\bar z z}\dot z. \tag{3.19}$$

From (3.15) one infers that one can go to the tangent space indices by making the redefinition

$$\lambda^z=ie^z_+\lambda^+, \tag{3.20}$$

$$\lambda^{\bar z}=ie^{\bar z}_-\lambda^-. \tag{3.21}$$

Then the fermions in (3.15) acquire a standard form:

$$\mathcal{L}=g_{z\bar{z}}\dot{z}\dot{\bar{z}}-\frac{i}{4}(\lambda^{+}\dot{\lambda}^{-}+\lambda^{-}\dot{\lambda}^{+})+\cdots, \tag{3.22}$$

and one concludes that $\lambda^{\pm}$ quantizes as the corresponding $(1/\sqrt{2})\,\Gamma^{\pm}$ matrices:

$$\Gamma^{+}=(\Gamma^{-})^{\dagger}=\begin{pmatrix}0 & 2\\ 0 & 0\end{pmatrix}. \tag{3.23}$$

The canonical conjugate momentum is given by

$$\mathrm{P}_z=g_{z\bar{z}}\dot{\bar{z}}+\frac{i}{2}(\omega_z)_{\alpha\beta}\lambda^{\alpha}\lambda^{\beta}+A_z^{(N)}. \tag{3.24}$$

With the notation

$$\Pi_z=g_{z\bar{z}}\dot{\bar{z}}=\mathrm{P}_z-\frac{i}{2}(\omega_z)_{\alpha\beta}\lambda^{\alpha}\lambda^{\beta}-A_z^{(N)}, \tag{3.25}$$

the corresponding Noether charge can be written

$$Q=\lambda^{z}\Pi_z=ie_{+}^{z}\lambda^{+}\left(\mathrm{P}_z-\frac{i}{2}(\omega_z)_{\alpha\beta}\lambda^{\alpha}\lambda^{\beta}-A_z^{(N)}\right). \tag{3.26}$$

Let us now quantize the supercharge Q.[17,18] As mentioned before $\lambda^{\pm}$ quantizes as the corresponding $(1/\sqrt{2})\,\Gamma^{\pm}$, further P_z goes into $(1/i)(\partial/\partial z)$; therefore in order to maintain the general covariance under quantization we can take the minimal Q:

$$Q=\frac{\Gamma^{+}}{\sqrt{2}}e_{+}^{z}\nabla_z^{(N)}, \tag{3.27}$$

where $\nabla_z^{(N)}$ is the covariant derivative on the spinor wave function:

$$\nabla_z^{(N)}=\partial_z-iA_z^{(N)}-\tfrac{1}{4}\omega_z^{\alpha\beta}\Gamma_{\alpha\beta}, \tag{3.28}$$

and the matrices $\Gamma_{\alpha\beta}$ are

$$\Gamma_{\alpha\beta}=\tfrac{1}{2}[\Gamma_{\alpha},\Gamma_{\beta}], \tag{3.29}$$

where

$$\{\Gamma_{\alpha},\Gamma_{\beta}\}=2\,\eta_{\alpha\beta}. \tag{3.30}$$

Once we have the quantum expression for Q we can define

$$\overline{Q}=Q^{\dagger}, \tag{3.31}$$

with respect to the scalar product corresponding to (2.35), where of course now the scalar wave vector is replaced by the two component wave function. The adjoint of Q is

$$Q^{\dagger}=-\frac{\Gamma^{-}}{\sqrt{2}}e_{-}^{\bar{z}}\nabla_{\bar{z}}^{(N)}, \tag{3.32}$$

with

$$\nabla_{\bar{z}}^{(N)} = \partial_{\bar{z}} - iA_{\bar{z}}^{(N)} - \tfrac{1}{4}\omega_{\bar{z}}^{\alpha\beta}\Gamma_{\alpha\beta}. \tag{3.33}$$

The Q and $\bar{Q}$ so defined obey automatically

$$Q^2 = \bar{Q}^2 = 0, \tag{3.34}$$

because they contain the matrices $\Gamma^{\pm}$ in their definition. Defining the quantum Hamiltonian by

$$H = \tfrac{1}{2}(Q\bar{Q} + \bar{Q}Q), \tag{3.35}$$

H commutes automatically with the supercharges Q and $\bar{Q}$. Thus the quantum ordering in H is completely fixed by supersymmetry and reparametrization covariance. The expression for H is also covariant under the reparametrizations of the manifold and the system has $\mathcal{N}=2$ supersymmetry.

Finally, it might be worth mentioning that by this procedure H is defined from the supersymmetry algebra (3.35) without any recourse to the standard ways of defining it.

IV. SUPERSYMMETRIC MONOPOLE HARMONICS

Diagonalization of the Hamiltonian (3.35) follows now in a rather simple way. Using the constant covariance of the Γ-matrices with respect to vector and spinor indices, (3.35) can be cast in the following form:

$$H = -\tfrac{1}{4}e_+^z e_-^{\bar{z}}[\Gamma^+\Gamma^-\nabla_z^{(N)}\nabla_{\bar{z}}^{(N)} + \Gamma^-\Gamma^+\nabla_{\bar{z}}^{(N)}\nabla_z^{(N)}], \tag{4.1}$$

the products $\Gamma^+\Gamma^-$ and $\Gamma^-\Gamma^+$ being scalars under local rotations in the tangent plane. Moreover, they are projectors:

$$\Gamma^+\Gamma^- = \begin{pmatrix} 4 & 0 \\ 0 & 0 \end{pmatrix}, \quad \Gamma^-\Gamma^+ = \begin{pmatrix} 0 & 0 \\ 0 & 4 \end{pmatrix}. \tag{4.2}$$

Therefore, H is a sum of factorized terms. We recognize that the operators multiplying the products $\Gamma^+\Gamma^-$ and $\Gamma^-\Gamma^+$ are connected with the Laplacian appearing in (2.1) with a modified spin connection, due to the nonzero spin of the wave function. In fact, we have

$$H = \left[H_{(N+1/2)} + \frac{(N+\frac{1}{2})}{4R^2}\right]\frac{\Gamma^+\Gamma^-}{4} + \left[H_{(N-1/2)} - \frac{(N-\frac{1}{2})}{4R^2}\right]\frac{\Gamma^-\Gamma^+}{4}. \tag{4.3}$$

This is due to the fact that the spinor components transform with an effective charge $\pm\frac{1}{2}$ under local rotations. As remarked before, one can absorb this ''Lorentz charge'' in the gauge connection leading to a modification of the effective charge of the corresponding components. Using (2.28), it is easy to show that

$$\tilde{H}_{(N-1/2)} - \frac{(N-\frac{1}{2})}{4R^2} = H_{(N+1/2)} + \frac{(N+\frac{1}{2})}{4R^2}. \tag{4.4}$$

However, by the same procedure $\tilde{H}_{(N+1/2)}$ gets connected with $H_{(N+3/2)}$. The connection between $\tilde{H}_{(N+1/2)}$ and $H_{(N-1/2)}$ is the result of a different factorization of H_N in Sec. II. From (2.1) one has

$$H_N = -\mathcal{D}_+^{(N)}\mathcal{D}_-^{(N)} - \frac{N}{4R^2}, \tag{4.5}$$

where

$$\mathcal{D}_{+}^{(N)}=e_{+}^{z}(\nabla_{z}^{(N)}+\omega_{z-}{}^{-}), \tag{4.6}$$

and

$$\mathcal{D}_{-}^{(N)}=e_{-}^{\bar{z}}\nabla_{\bar{z}}^{(N)}. \tag{4.7}$$

Therefore, with respect to this factorization we have

$$\tilde{H}_N=-[\mathcal{D}_{-}^{(N)}]_{nc}[\mathcal{D}_{+}^{(N)}]_{nc}-\frac{N}{4R^2}=-\mathcal{D}_{-}^{(N-1)}\mathcal{D}_{+}^{(N-1)}-\frac{N}{4R^2}=H_{N-1}-\frac{2N-1}{4R^2}, \tag{4.8}$$

and using the identities just derived one has

$$\tilde{H}_{(N+1/2)}+\frac{(N+\frac{1}{2})}{4R^2}=H_{(N-1/2)}-\frac{(N-\frac{1}{2})}{4R^2}. \tag{4.9}$$

We prefer to start with the eigenfunctions of $H_{(N+1/2)}$, because this operator appears in a manifestly positive definite combination in the Hamiltonian.

Therefore, given the eigenvector Ψ of $H_{(N+1/2)}+(N+\frac{1}{2})$, with nonzero eigenvalue, we obtain the corresponding eigenvector of $H_{(N-1/2)}-(N-\frac{1}{2})$ by taking

$$\mathcal{D}_{-}^{(N-1/2)}\Psi, \tag{4.10}$$

with $\mathcal{D}_{-}^{(N-1/2)}$ defined by (2.20). From (4.3) the eigenvalues of H are

$$E_l=\frac{1}{4R^2}(l+1)(l+2N+1), \tag{4.11}$$

with the eigenvector being given by

$$\Psi_l=\begin{pmatrix} \mathcal{D}_{-}^{(N+1/2)}\cdots\mathcal{D}_{-}^{(N+l-1/2)}\tilde{\Psi}_l \\ \mathcal{D}_{-}^{(N-1/2)}\mathcal{D}_{-}^{(N+1/2)}\cdots\mathcal{D}_{-}^{(N+l-1/2)}\tilde{\Psi}_l \end{pmatrix}. \tag{4.12}$$

Therefore we have found the eigenvalues and eigenvectors of the $\mathcal{N}=2$ supersymmetric spinning particle moving on a sphere in the field of a monopole. They are analogous to the eigenfunctions determined in Ref. 19.

V. CONCLUSIONS

Restating the main result, we have supersymmetrized and solved the motion of a charge on a sphere in the field of a monopole at its center.

The factorization method appears to be the natural way to solve this problem. This is because in order to formulate a supersymmetric problem one is basically compelled to use the complex structure of the target space manifold. The quantization scheme for the problem is manifestly taking into account the reparametrizations of the manifold; therefore it is covariant with respect to these reparametrizations. One should remember that one is dealing basically with the algebra of angular momentum and it is quite interesting that following the manifest symmetries of the problem one is led to an alternative integration method. In this context, even if algebraic, this method appears somewhat strange, albeit natural.

One should also stress that the degeneracies of the levels are all finite and it is well known that we deal with a regularization of the Landau electrons. Taking the limit $R^2,N\to\infty$ (with N/R^2 fixed) one obtains the infinitely degenerate states of a planar electron in a constant magnetic field.

In a rather different context, the eigenfunctions obtained in this article may also be studied by methods similar to those used for the harmonic superspace.[20]

ACKNOWLEDGMENTS

We wish to thank Willy Fischler for the question which led to this problem and for subsequent discussions. We have also benefited from discussions with S. Barnes, E. A. Ivanov, A. I. Pashnev, V. Rittenberg and A. B. Zamolodchikov. G.A.M. gratefully ackowledges financial support from a grant by Army Research Laboratory, BAE Systems. L.M. wishes to thank E. Paschos for hospitality at the University of Dortmund, while this work was in progress and is also indebted to A. T. Filippov for making possible his participation in the Symposium of Quantum Gravity and Superstrings, 18–28 June 2001, Dubna, where part of this work was presented. L.M. was supported in part by the National Science Foundation under Grant No. PHY-9870101.

NOTE ADDED

These computations have been posted on the web as a preprint hep-th/0109002. We however did not submit the article as we intended to perform some further checks, which were a little outside the main direction of the paper, to illustrate the usefulness of the factorization method in problems in which general covariance plays an important role. Three months after posting the article on the web a lot of our results have been reobtained by Ref. 21.

While in the process of finalizing our paper, on 21 December 2001, my beloved brother and coauthor on this article suddenly and unexpectedly passed away. For some time afterwards I was unable to touch this article, and this explains the delay by which this article is submitted.

There remains a topic which is not discussed above and it was not covered in Ref. 21 either; it is the action of the rotation group which is a symmetry of the model,[11] and which completely fixes the spin of the excitations in the model. I defer this study to a later publication. (I am indebted to L. Susskind for a discussion of this point.)

It should also be mentioned that the usefulness of the holomorphic approach to closely related problems was recently emphasized in Refs. 22–24.

Yang Institute for Theoretical Physics, State University of New York, Stony Brook, New York 11794-3840 and Theoretical Physics Group, Stanford Linear Accelerator Center, Menlo Park, California 94025 and Center for Theoretical Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139

(Received 10 December 2002; accepted 9 April 2003)

The phenomenon of fractional charge has come to prominence in recent decades through theoretical and experimental discoveries of isolable objects which carry fractions of familiar charge units—electric charge Q, spin S, baryon number B and lepton number L. It is shown here on the basis of a few simple assumptions that all these effects may be described using a generalized version of *charge renormalization* for locally conserved charges, in which many-body correlations can produce familiar adiabatic, continuous renormalization, and in some circumstances nonadiabatic, discrete renormalization. The fractional charges may be carried either by *fundamental particles* or by *fundamental solitons*. This excludes nontopological solitons and also skyrmions: The only known fundamental solitons in three or fewer space dimensions d are the kink ($d=1$), the vortex ($d=2$), and the magnetic monopole ($d=3$). Further, for a charge which is not intrinsically coupled to the topological charge of a soliton, only the kink and the monopole may carry fractional values. The same reasoning enforces fractional local values of $B-L$ for electrically charged elementary particles. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1586793]

I. INTRODUCTION

The ascendancy of elementary particles in thinking about microscopic physics began with atoms and molecules, followed by electrons, photons, and nuclei, then nucleons and neutrinos, quarks, gluons, and W and Z bosons. The pattern of a hierarchy of length scales, with the particles of one scale being compounds of those found at a shorter scale, has replayed itself several times over. Even today there is no observational evidence that this pattern terminates at some scale.

Nevertheless, reasons to question the pattern have emerged. String theory and its developments raise the prospect that at sufficiently short scales the elementary objects are not particles, but rather extended entities. While such studies give exciting directions for discovery at those new scales, they actually support rather than undermine the notion of elementary particles: The additional structure ''inside'' the particles does not change the fact that they still look structureless at sufficiently long scales.

A different reason to worry about the universal validity of the particle description at currently accessible scales has come from theoretical and experimental discoveries of fractional charge. If at the beginning of microscopic physics all kinds of different charges had been observed, with no rational relation among them, progress in understanding would have been impeded seriously indeed. We know that did not happen, but in principle the recent discoveries might herald a new era where precisely such chaos in the pattern of charges could emerge. The purpose of this work is to present some simple definitions and theorems, based on minimal assumptions, from which it follows that fractional charge fits into the familiar framework of charge renormalization, and

a)Electronic mail: goldhab@insti.physics.sunysb.edu

consequently is so tightly constrained that any threat of ''charge chaos'' is precluded.

In the standard model of strong and electroweak interactions there are three isolable, quantized charges observable in vacuum at zero temperature that may be locally conserved, electric charge Q, measured in units of the electron charge e, spin $\vec{S}$, whose projection onto a fixed axis has integer or half-integer values in units of $\hbar$, and the difference between baryon and lepton charge $B-L$, which usually is assumed to have the value 1 for a proton or neutron, and -1 for an electron or neutrino. Despite the existence of an exponentially small effect associated with electroweak instantons, which 't Hooft[1] recognized would produce baryon decay through the Adler–Bell–Jackiw chiral anomaly,[2] and possible additional interactions associated with very high energy scales, B+L also may be treated as conserved in many contexts. If electroweak effects and the difference of light quark masses may be ignored, so that attention is focused exclusively on the strong interactions, then also isospin $\vec{I}$ may be treated as conserved. Even if electromagnetic interactions are included, still I_3, as well as flavor charges of higher generations of quarks—strangeness, charm, bottom, and top—are conserved.

Thus, many isolable, quantized charges observable in the laboratory are exactly or at least quite accurately conserved. It should be noted that besides these charges there are the continuous (i.e., nonquantized), locally conserved charges corresponding to energy and momentum, which precisely because they have a continuum of allowed values need not concern us further here.

At this point it may be worthwhile to discuss a bit more what is meant by the concept ''charge.'' Of course, the prototype example is electric charge, whose conservation follows from the Maxwell equations. Already in classical physics it was understood that the existence of a conserved charge could be deduced from a symmetry of the dynamics. In quantum physics, this is expressed in terms of a unitary (or in the case of time reversal symmetry, antiunitary) operator which commutes with the Hamiltonian. If that symmetry be continuous, then the generators of the symmetry must be self-adjoint operators. In certain cases, such as the generators of the rotation group in three space dimensions, which are identified as the angular momentum or spin of a system under study, the commutation relations among the generators lead directly to the quantization of the allowed values of the charge. However, for electric charge such a deduction has not yet been possible, while for $B-L$ there is not even a framework to discuss the symmetry beyond the statement that phenomenologically established couplings conserve the charge, i.e., all terms in the Lagrangian are invariant under the unitary transformation generated by the operator $B-L$. Thus, in terms of current knowledge, symmetries imply conservation and sometimes even quantization of observable charges, but there is at this point no assurance that all cases of apparently conserved and quantized charges are consequent to symmetries which can be identified in any way other than by recognizing that the charges seem to be conserved.

In relativistic physics, a conserved charge whose local density is defined must be locally conserved. That is, if the charge in some volume changes, the immediately surrounding volume must experience an equal and opposite change in charge, or expressed differently, the rate of change of the charge in a volume is equal and opposite to the net current flowing out of the volume. The reason is easily found by assuming the contradiction to this assertion: If in one inertial frame a conserved charge disappeared in one place and reappeared instantly at a distant place, then in different frames of reference boosted by velocity shifts from the original frame the total charge at certain times either would vanish or would be double the original value, evidently violating charge conservation.

How may charges be measured or observed? Again, the prototype is electric charge, which may be measured through the electromagnetic interaction, either by determining the influence on a particle of a specified electromagnetic field (thus measuring the Lorentz-force charge), or by using test particles with known charges to measure the electric flux coming out of the particle (thus measuring the Gauss-law charge). In the quantum context, these two may be called the Aharonov–Bohm (AB) charge and the local charge, respectively.[3] For other types of charge (i.e., not coupled to gauge fields), one must use more indirect methods, such as counting different spin states of an object, To help understand the conceptual structure, one may introduce hypothetical Abelian gauge fields weakly coupled to any conserved, localizable charge one wishes to measure.

Are there any circumstances in which fractional values of charges may be found, and if so, what are the precise conditions for this to occur? Let us turn to that issue.

II. DEFINITIONS AND THEOREMS

Definition 1 (Elementary particle): In a given medium, and for a given range of length scales, an isolable particle is called *elementary* if its set of conserved charges cannot be constructed from any finite assembly of particles which individually carry fractions and/or subsets of that charge set.

Remarks: In ordinary vacuum at zero temperature, the known elementary particles according to this definition are the proton and neutron, the π^+ and π^0 mesons, the electron, the neutrino, the photon, and the W^+ and Z bosons, plus their antiparticles (the photon, π^0 and Z certainly, and the neutrino possibly, are their own antiparticles). Among this set, all are isolable, but several are unstable against decay to two or more others. These nevertheless are properly considered elementary under the definition, because the summed absolute values of certain charges of the decay products are greater in magnitude than the corresponding charge of the particle, for example, the electrically neutral neutron decays to proton, electron, and antineutrino, of which the first two each carry unit electric charge.

It is significant that protons, and hadrons in general, exhibit strong short-range interactions, so that they really are isolable only at long distance scales. Nevertheless, in nuclear matter it is possible to make an accurate description of the dynamics including quasiparticles with the same charges as neutrons and protons, suitably redefined so that these ''nucleon quasiparticles'' interact weakly. It is a useful perspective to consider these quasiparticles as nucleons whose effective interactions are renormalized by the strong, short-range correlations of the nuclear medium: Each quasinucleon may be viewed as having a nucleon kernel surrounded by a cloud of medium polarization. A very similar approach has been most successful in describing electron quasiparticles in many different condensed-matter systems. Thus, while the definition of an elementary particle may be medium-dependent, there often is a simple correspondence between a set of elementary particles in one medium and a set in a different medium.

Definition 2 (Fundamental particle): A particle is called *fundamental* if it obeys all the criteria for an elementary particle except possibly that of being isolable, and in addition it has no discernible internal structure. This means that at the shortest distance scales such particles correspond to fields appearing in the Lagrangian.

Remarks: This new criterion removes the nucleons and pions from the list above, and introduces instead the quarks and gluons. While these particles are not isolable in vacuum, the fact that quantum chromodynamics (QCD) exhibits asymptotic freedom,[4] meaning weak coupling at short distance scales, implies that at those scales they may be detected and (for quarks) their electric charges measured. As the term ''fundamental'' suggests, the charges of all the known elementary particles in vacuum can be constructed from those of the fundamental particles. In other media, there may be additional fundamental particles in the sense described, and there may be also fundamental solitons, discussed in the theorems below. Again, all elementary particles in these media have charges which may be constructed from those of the fundamental particles and solitons. In this sense, the fundamental objects may be considered the building blocks for everything else.

Definition 3 (Fractional charge): An object which carries only a portion of the charges of finite combinations of elementary particles may be said to carry *fractional charge*. In principle, such a particle might have, for example, the same spin as the electron, but an electric charge which is an irrational fraction of e. There is no known instance like this for particles in vacuum, but in any insulating medium exactly such a phenomenon is found, and in the accepted interpretation this fractional value is treated as a *renormalization* of the electron charge from its value in vacuum. By this definition, the electric charges of quarks are examples of fractional charge, but the fractional values arise because these fundamental particles carry a smaller unit of charge than any (isolable) elementary particle.

Remarks: This definition invites two thought experiments which illuminate it, and also will be useful later. First, imagine a massive particle such as a proton slowly entering an insulating

medium. As it enters, its local charge is reduced and, by the time it has penetrated far inside, the extra charge is found on the surface of the insulator. Thus, total charge is locally conserved throughout the process, but it ends up fractionated between the charge localized on the particle and the charge on the surface. The second experiment, even in vacuum, invokes a slow increase from zero in the value of α, the electromagnetic coupling. As this occurs, the electric field measurable at some distance from a charged particle increases in strength, but not quite proportionally to α, because vacuum polarization increasingly screens the field. Again, charge is locally conserved, because as the coupling increases there is an outward flow of current, with the current density proportional to the electric field at each point.

As mentioned already, the charge which is fractionated is the local charge, while the AB charge remains invariant. This is illustrated by another thought experiment. Imagine a capacitor stuffed with dielectric and set at voltage V. Then an electron of charge $-e$ passing through the capacitor will acquire from the electric field a net energy $-eV$, regardless of the magnitude of the dielectric response. Of course the presence of the dielectric implies an increase in the amount of surface charge on the capacitor plates to achieve the same V as for the plates in vacuum, but once this V is established the effect on the electron is not further modified by the dielectric.

Definition 4 (Breakup): On passing from one medium to another, a particle may undergo *charge breakup*, meaning that on the other side there are several particles instead of one, each with only a portion of the set of charges carried by the one particle in the original medium. This evidently is an intrinsically nonadiabatic process, as the number of mobile degrees of freedom changes discontinuously. Note that charge breakup may occur when, for example, a fast electron enters a conventional insulator, knocking loose a number of electrons each of which penetrates far into the medium. As a result, very little charge may be left on the surface. Nevertheless, there is a big distinction between such a case and one where the surface simply cannot take up charge at all, as occurs when an electron enters from above a two-dimensional layer exhibiting the fractional quantum Hall effect.

Now we are ready for the first theorem.

Theorem 1 (Conservation of particles with fractional charge): An isolable particle that has fractional charge with respect to previously identified elementary particles in its medium must itself be an elementary or a fundamental particle of that medium. (As indicated above, a particle may carry fractional charge with respect to particles in *different* media, as a consequence of medium-dependent charge renormalization.)

Proof: This statement follows directly from the definition of elementary particles, because the charges of this object cannot be produced by any finite assembly of particles carrying integer values of the same charge.

Theorem 2 (Fundamental solitons): The possible soliton carriers of charges which are fractional with respect to those of other elementary particles in a given medium for spatial dimension $d \leqslant 3$ are *fundamental solitons*, of which the known examples are the kink $(d=1)$, the vortex $(d=2)$, and the magnetic monopole $(d=3)$.

Proof: A soliton is an object which in first approximation could be described as a classical field configuration that is classically stable. However, classical stability clearly is not enough because, if addition of energy to the system could enable the disintegration of the soliton, then its conserved charges would have no unconventional carrier, and hence obviously could not be fractional. Furthermore, a soliton in a class all with the same low-energy properties could not carry fractional charge if some other members of the class were capable of disintegration, because all solitons in the class would have the same influence on the medium polarization which determines possible fractional charge.

The kink in $d=1$ may be described by a classical scalar field which has equal potential energy density minima for two or more distinct values of the field. Thus the field can go asymptotically to one value as $x \to +\infty$ and another value as $x \to -\infty$. No finite-action process could destroy this structure, which nevertheless possesses a finite, localized energy in the region between the two asymptotic zones. Consequently the kink has a conserved *topological charge*, and so there would be no contradiction if it carried fractional values of other charges.

In $d=2$, a vortex may be described by a complex scalar field which rotates in phase by $2n\pi$ at large distances from its center as the radial direction rotates by 2π, while the field magnitude approaches a fixed value with increasing radius, again to minimize a potential energy density. In the Abelian Higgs model for such a vortex, gradient energy is kept finite through coupling of the scalar field to a gauge field, which makes the covariant azimuthal gradient negligible at large distances and implies a magnetic flux stored near the center. There is an alternate description of the asymptotic fields, in which the scalar field goes to a fixed constant and the gauge field (pure gauge) corresponds to an Aharonov–Bohm phase factor $e^{2\pi iq/Q}$ relating the phase of a charged particle wave function at, e.g., azimuthal angles $\phi=0$ and $\phi=2\pi$, where Q is the charge of the scalar field and q is the charge of a particle which experiences a nontrivial Aharonov–Bohm effect upon diffraction around the flux. Again, no finite-action process could destroy this structure.

In $d=3$, a configuration again containing a gauge field and perhaps also a scalar field generates a long-range magnetic monopole field, which cannot be destroyed with finite action, regardless of the precise details of the monopole interior. Thus any of these three solitons potentially would be able to carry charges that are pieces or fractions of those carried by elementary particles in the same medium.

Remarks: From the above argument, no other solitons can carry fractional charge, a fact already understood for nontopological solitons.[5] A type of nontopological soliton much discussed recently is the "Q ball,"[6] a configuration of a charged scalar field which carries a very large electric charge, stabilized by the attractive self-interaction of the scalar field. Such a system evidently can be made to disintegrate, and therefore could not carry a fraction of elementary charges.

Perhaps the most famous topological soliton, which according to the above criterion is not fundamental, is the skyrmion, described in the nonlinear sigma model by a four-component scalar field with fixed magnitude. The soliton corresponds to a map from R_3 (with spatial infinity treated as a single point) to S_3. The winding number of the map is an exactly conserved integer, which Skyrme proposed should be identified with baryon number.[7] However, in its coupling to light fermions the skyrmion must have effects equivalent to those of a similar object in the linear sigma model, where a fourth-order polynomial potential density is minimized for a specified magnitude of the Skyrme field. For this structure the topological quantum number could be destroyed with finite action by temporarily creating a zero in the Skyrme field at the center of the skyrmion, and then allowing the topological charge to flow into the zero and disappear.

MacKenzie and Wilczek[8] and D'Hoker and Goldstone[9] each computed flows of baryon current involved in the adiabatic creation of a skyrmion and found integer baryon number, but implicitly left open the possibility that some exotic circumstance might produce a fractional result instead. Their construction works exactly the same way for the original skyrmions or for the almost-stable objects in the linear sigma model, and therefore the argument here shows that one never could obtain fractional charge for this system. There is one apparent way out: Insist that the high-energy behavior indeed is governed by the strict nonlinear sigma model, with fixed magnitude of the Skyrme field. The trouble now is that this theory is well-known to be nonrenormalizable, so that this option is undefined—one only may use the theory with an energy cutoff, which is equivalent to replacing the model with a linear sigma model. Stated differently, using the nonlinear sigma model is making a statement about the behavior at arbitrarily high energies of what should be only an effective field theory. This would be tantamount to introducing new particles associated with those high energy scales.

Theorem 3 (Fractional charge from conventional renormalization): For a fractional charge to be associated with conventional renormalization, the particle must be an electric charge or a magnetic monopole in $d=3$, or a kink in $d=1$. Otherwise (in particular for the vortex in $d=2$), the fractional charge must be intrinsic to the structure of the particle or fundamental soliton.

Proof: For conventional renormalization, as some coupling parameter changes adiabatically there must be a current flow of the relevant charge into or out of the particle in question. Far away from the $d=3$ electric charge, or the magnetic monopole, there is a radial $1/r^2$ field. Thus, a local current density proportional to that field and to the time rate of change of some scalar or pseudo-

scalar parameter would provide a steady net current into the particle. Clearly the long-range field is necessary to give direction as well as the correct radial dependence to the current density. In one space dimension, the different asymptotic behaviors to right and left of the kink field can determine locally the sign and magnitude of a current, again proportional to the time rate of change for some suitable coupling parameter.

Remarks: Thus, in these cases the possibility of creating fractional charge by continuous variation of a suitable parameter is open, while for other isolable objects it is not. In particular, the vortex exhibits no locally observable long-range field, only the globally defined vector potential, so that it cannot guide a continuous current flow from infinity. Note that electrically charged particles in $d=1$ or $d=2$ are not isolable, because the energy for a particle–antiparticle pair diverges with separation. In all cases except the two in $d=3$ and the one in $d=1$ just described, the renormalization cannot be accomplished by a flow from infinity, and therefore must be intrinsic to the structure of the particle. For description of such intrinsic fractional charge as due to discrete renormalization to be meaningful, it must be possible to identify some ''core'' of the particle, with its characteristic conserved charge, to which the medium polarization (leading to net fractional charge) is attached. That turns out to be possible, and therefore at least a useful perspective, for all known cases.

We have seen that among solitons only the fundamental ones (stabilized by long-range physics) can nucleate fractional charge. The obvious corollary is that the only other possible ''kernels'' are those elementary particles which can be taken as given (i.e., determined by short-range physics). Blankenbecler and Boyanovsky[10] have presented another perspective which leads to the same conclusion as the one here for the case of fractional fermion charge induced by topology. They argue that the high-energy coupling of fermions carrying integer values of such a charge is influenced by the asymptotic field of the soliton, and this directly determines the fractional part of the charge localized on the soliton.

III. ILLUSTRATIONS AND COMMENTS

Before going on, it is important to emphasize that the above theorems give necessary conditions for fractional charge—they do not demonstrate that it occurs. Such demonstrations were the important content of works to be cited below.

It has been shown here that the only solitons whose topological charges could have a conventional renormalization to produce fractional values of certain other charges are kinks and monopoles, the two types of object first found by Jackiw and Rebbi (JR)[11] to carry fractional charge—to be precise, fermion number $F=\frac{1}{2}$. Their results were verified elegantly using adiabatic flow methods by Goldstone and Wilczek[12] and by Seiberg and Witten.[13] These methods can be implemented in such a way that the soliton remains intact, while variation of certain couplings ''decorates'' the object with fractional F and perhaps also fractional electric charge.

Fractional local charges are significant only if they are eigenvalues rather than expectation values; they must be ''sharp'' quantum observables. For charges to be sharp, in one space dimension spatial smearing of the corresponding charge density operator is required,[14] while in higher dimensions temporal smoothing is needed as well.[15,3]

Perhaps the most dramatic observation of fractional charge is associated with the fractional quantum Hall effect (FQHE) discovered by Tsui, Störmer, and Gossard.[16] Here Laughlin[17] concluded that the quasiparticles carry a simple fraction of an electron charge, so that an electron entering the medium could break up into several quasiparticles (something dramatically different from the breakup into reduced quasiparticle charge and remnant surface charge when an electron enters a conventional insulator). This result was vindicated in several experiments, by Goldman and Su, de Picciotto *et al.*, Seminadayar *et al.*, and Reznikov *et al.*[18]

Jain's composite-fermion description[19] of odd-denominator FQHE states identifies the composite fermions as electrons whose strong repulsive mutual correlations renormalize their charges to the observed fractional values associated with the quasiparticles, so that it is natural to identify the quasiparticles as electrons dressed by the medium. In that perspective, the AB charge of a quasiparticle should be the same as that of an electron, but it is accepted that the force on the

particle due to a Maxwell electric field $\vec{E}$ parallel to the Hall plane may be obtained by using precisely the fractional local charge already mentioned. In the dressed-electron picture, this is understood as resulting from an induced Chern–Simons field in the Hall plane which partly compensates the effect of the Maxwell field.[20] The large conceptual advantage of this perspective, embodied in composite-fermion theory,[19] is that it not only unifies the description of different FQHE regimes, but also provides a close correspondence with previously familiar condensed-matter systems and their quasielectron excitations.

The original description of a quasihole for simple Hall fractions was given by Laughlin[17] in terms of a fundamental soliton in the form of a special type of vortex—a vortex in the many-body ground-state wave function. This vortex requires neither Higgs nor gauge field, but only is possible under the special conditions for which the Laughlin ansatz gives the ground state wave function. Now one describes the quasihole as a soliton with local charge and AB charge both equal to the same fraction. The ability to describe a quasiparticle either as a fundamental soliton or a dressed electron may be unique to this particular case. Depending on which one chooses, the local charge always is the same fraction, but the AB charge either has fractional or unit value. Of course, all observables are identical in the two descriptions, but as mentioned the electron description has wider and easier application. In these terms, the experiment of Goldman and Su mentioned above was a meaurement of fractional effective AB charge, while the other experiments measuring shot noise were sensitive to fractional local charge.

After JR, besides the independent work of Su, Schrieffer, and Heeger (SSH) on kinks in polyacetylene,[21] there were a number of studies confirming and elaborating on the original finding that solitons can carry fractional charge. Shankar and Witten[22] used bosonization to put fermions and bosons on the same footing in the kink system, taking account of possible back-reaction by fermion on boson degrees of freedom, and confirming the JR result. Su and Schrieffer[23] found examples of kinks in condensed matter models with other rational fractions. Earlier, Witten[24] showed that magnetic monopoles could have fractional electric charge determined by the vacuum angle (or equally well by a crossed electric-magnetic susceptibility like that for a medium with dipolar molecules carrying both electric and magnetic moments). Sikivie[25] put this in the context of conventional insulator behavior, showing that if a monopole passes through a domain wall between different values of the vacuum angle θ, then the change in electric charge of the monopole is exactly compensated by a change in the surface charge spread over the wall.

The work of Witten[24] had two parts. First was a demonstration that the very gauge transformation which has a compact U(1) action on conventional charged particles with quantized electric charge can have a noncompact action on a magnetic monopole, a necessary condition for fractional electric charge on the monopole. (For an extended treatment of this point, see Ref. 26.) The noncompact action of the electric-charge gauge transformation on the dyon is consistent with gauge invariance because in the mutual interaction of two dyons there is besides the normal gauge interaction an extra term, gauge-variant but not contributing to the equations of motion for the pair.[27,28] The conclusion in Theorem 3 above that the monopole satisfies a necessary condition to possess fractional local electric charge is based on a space–time picture of the magnetic field configuration of the monopole (corresponding by a magnetic Gauss law to an absolutely conserved charge), complementary to the topological analysis just mentioned. The second part of Witten's work was a direct construction of the fractional charge from the vacuum angle. Thus he found both necessary and sufficient conditions for the monopole to carry fractional electric local and AB charge. Note that the latter clearly is not conserved when the monopole passes through a domain wall.

As mentioned, Goldstone and Wilczek[12] developed an adiabatic flow analysis showing that F for the JR monopole must change by $\Delta F = \frac{1}{2}$ as the fermion mass is chirally rotated from isoscalar to isovector. Callan[29] considered fermions light even compared to the Coulomb energy required to confine a unit of electric charge within a monopole radius, finding $F = \frac{1}{2}$ appears in a natural way. Over a long period, the notions of electric-magnetic duality, supersymmetry, and JR fermion zero modes were locked together, mutually reinforcing all three.[30,13] In particular, Seiberg and Witten[13] used an adiabatic flow analysis (complementary to that of Goldstone and Wilczek), which allowed

them to follow the change of F and electric charge Q as the isoscalar part of the fermion mass is lowered from infinity, where the fermion is totally decoupled (meaning any fractional part of F must vanish), to a point where the net mass of one member of the fermion isodoublet goes through zero. They were able to establish directly that F becomes fractional, while explicitly treating the electric charge as a discrete quantum variable.

This subject of adiabatic flow brings attention to the beautiful thought experiment of Laughlin,[17] who imagined piercing a fractional quantum Hall layer with an infinitely thin tube of flux, gradually increased from zero to one flux quantum. Through the Faraday effect and the Hall effect this assures the localization of a fractional charge, immediately showing that the quasiparticles of this system must have fractional charge with respect to electrons in a different medium—free ($d=3$) space. The fractional value in itself should not be a surprise, in view of the behavior of normal insulators. However, if we imagine inserting an electron into the layer from above there is no surface in which to leave part of its locally conserved electric charge, so that the charge instead must be deposited on several quasiparticles. This inevitable breakup into many particles was a new and theoretically unanticipated phenomenon.

The concept of fractional soliton charge was at least implicit in the work of Skyrme,[7] who argued that his classical field configuration could be quantized with half-integer isospin and spin (a possibility shown consistent with the usual spin-statistics connection in Ref. 31). Half-integer values would allow the skyrmion to be identified with the nucleon, but by Theorem 2 are impossible without elementary or fundamental isospinor fermions: Modification of the short-distance, high-energy part of the Skyrme action (e.g., replacing the nonlinear constraint in his sigma model with a quartic action in the chiral field) could destabilize the skyrmion, so that its ''topological'' charge would be ''unwound'' in a process with finite action, and therefore in principle is not absolutely conserved. Microscopic analyses agree, indicating that the spin and isospin of the skyrmion will be integer or half-integer as the number of colors of up and down quarks is even or odd,[32] and therefore integer if there are no quarks.

These considerations may be put more dramatically. The fact that the skyrmion is in a class of objects some of which are not conserved immediately implies that there must be some underlying structure to account for spin and isospin charge values that are fractional with respect to the meson charges of the sigma model. Thus at best the skyrmion could be a useful description for reasonably low-energy and long-distance properties of the nucleon. That indeed is the case, but this simple reasoning could have been made at any time after Skyrme's original work. Perhaps an intuitive appreciation of this point contributed to initial resistance to his model. Paradoxically, if the model had been embraced, it might have slowed the approach to quarks and QCD which now gives an intellectual basis for the skyrmion's success in the appropriate domain.

Skyrme's model describes the nucleon entirely in terms of an SU(2) matrix function $\mathrm{U}(\mathbf{r},t)$, while in a ''hybrid'' model the U function is used outside a chosen ''bag'' radius R, and inside are free quarks with angle-dependent boundary condition parametrized by $\mathrm{U}(\mathbf{r})$ at the bag wall.[33] Goldstone and Jaffe[34] showed that the simple boundary condition guessed in Ref. 33 meets the requirement of net integer baryon number B. Thus, for the nucleon it becomes possible to interpolate smoothly between soliton and fundamental-particle (quark) descriptions, and neither can involve intrinsically fractional charges.

An analogous interpolation has been found for FQHE quasiparticles, which for $\nu=1/(2n+1)$ can blow up into arbitrarily spread-out ''baby skyrmions'' when the Zeeman splitting between the two possible electron spin orientations becomes negligible. Thus, adjusting the Zeeman splitting allows interpolation between microscopic quasiparticles and macroscopic solitons. Of course, the charges of the soliton and the quasiparticle are the same. This theoretical result for FQHE follows well-established results for skyrmions of the integer quantum Hall effect with small Zeeman splitting.[35]

The SSH kink analysis[21] shows that in one space dimension ''spinons'' with spin $\frac{1}{2}$ but no charge and ''holons'' with charge $\pm e$ but no spin can travel independently. Kivelson *et al.*[36] proposed that such objects might play a role in the planar dynamics which appears to be critical in high T_C superconductivity. Detailed studies suggested that if so, either these fractional objects are

connected by strings[37] or are able to move only along particular lines in the plane.[38] However, Senthil and Fisher[39] observed that a dynamics which leads to vortices in terms of some effective gauge field could allow the string connecting a spinon and a holon to exhibit zero tension, because the precise path of that string is simply a gauge choice. Hence it becomes imaginable that the two types of particle could move freely in the plane.

The uniqueness of magnetic monopoles among solitons in $d=3$ as possible carriers of fractional particle charge is connected with other special properties, such as the ability to convert the dynamics of the lowest fermion partial wave into a one-dimensional problem on a half-line. This is an example of the fact that the chiral anomaly for electrodynamics with $d=3$ may be written as the product of a magnetic-field contribution which reduces the problem to $d=1$, and an electric-field contribution just like that for QED in $d=1$.[40] The same long-range magnetic field is responsible for the possibility of creating an object with half-integer spin[41] and Fermi–Dirac statistics[42] from spinless bosons in a world with no fundamental fermons, a possibility that we have seen is *not* available to the skyrmion, contrary to casual statements in the literature.

An interesting example of fractional charge is the Higgs–Chern–Simons vortex in Abelian $2+1$ D gauge theory, a soliton which carries a conserved topological charge, the quantized magnetic flux. There is a locally conserved Gauss-law electric charge $Q=\kappa\Phi+q_H$, with κ the Chern–Simons (CS) coupling,[43] Φ the quantized magnetic flux, and q_H the Noether charge of the Higgs field. Evidently Q vanishes by the Gauss law, but of course q_H does not, and is not even conserved if κ varies. Indeed, with the gauge kinetic term F^2 omitted, the resulting ''self-dual'' vortex[44] has vanishing Q density everywhere! This system manifestly violates electric charge conjugation symmetry, and generates fractional values for q_H. The fact that q_H would vary if κ changed implies that κ must be constant if one is to interpret q_H as a conserved fractional charge. With this assumption, one sees that a given value of κ, which is crucial to the dynamics of this soliton, indeed enforces an intrinsic relation between the charge and the soliton structure, maintaining consistency with Theorem 3. For non-Abelian CS theory there must be quantization of κ,[45] but for the Abelian case relevant here there may be some flexibility in the allowed values. The self-dual vortex has been proposed, though without explicit identification as such, to be the charge carrying quasiparticle of the $\nu=5/2$ FQHE state.[46]

Up to now we have not considered fractional spin in this discussion. Of course, in $d=1$ spin is not defined, while in $d=3$ the non-Abelian character of the rotation group assures spin quantization. However, in $d=2$ the logical possibility of fractional spin is open. Paranjape[47] realized that such spin indeed could be induced for solitons carrying both electric charge and magnetic flux; Blankenbecler and Boyanovsky[48] gave a simple exposition of the mechanism. That the familiar connection between spin and statistics holds in $d=2$ for the fractional, charge-conjugation-even part of the spin and the associated part of the statistics was suggested already by Wilczek,[27] and follows from elementary conservation laws:[49,20] To be precise, if one defines $s_e=(s+\overline{s})/2$, the part of the spin symmetric under particle$\leftrightarrow$antiparticle, with $0<|s_e|<\frac{1}{2}$, then there is a contribution to the phase factor on exchange of two indistinguishable particles given by $e^{2\pi i s_e}$.

The one example of fractional charge by conventional renormalization that remains to be discussed is that of the familiar electrically charged elementary particles mentioned at the beginning, the proton and the electron. Suppose we say that the neutron has $B-L=1$, and the neutrino has $B-L=-1$. What is the value of $B-L$ for the charged particles? In first approximation, one may neglect all contributions to QED vacuum polarization except that of electron loops. As a result, the proton is accompanied by a tenuous cloud of electron vacuum polarization, and so has still $B=1$, but $L=\epsilon$. Meanwhile, charge renormalization of the electron implies that it has $L=1-\epsilon$. Thus, $B-L$ for the proton is $1-\epsilon$, and $B-L$ for the electron is $\epsilon-1$. For neutron decay, this gives initial $B-L=1$, and final $B-L=(1-\epsilon)_{\mathrm{p}}+(\epsilon-1)_{\mathrm{e}}-(-1)_{\overline{\nu}}=1$. In principle, it would be consistent with all we know to introduce a new gauge field, weakly coupled to $B-L$. This would allow direct observation of the different local values of $B-L$ for the neutral and the electrically charged particles. However, the main point to make here is that if there is some conserved charge carried by a particle, then it can consistently generate a fractional shift in another

charge carried by that particle. The fact that in some cases this fractional shift is quantized, while in others it can be varied continuously, is important, but the parallelism between the two types of cases may be even more important.

There is a complementary way to view the above discussion, exemplified by consideration of the weak coupling through the new $B-L$ gauge field between a neutron and a proton. What was discussed already shows that the neutron would see a somewhat weaker field due to electron vacuum polarization. Alternately, if one considers the influence of the neutron on the proton, the neutron's $B-L$ field mixes with the electromagnetic field due to the same vacuum polarization, so that it couples to the combination of AB charges $B-\epsilon Q$. The AB charges do not change, but the field acting on them is modified in a nontrivial way. Of course, in line with the principle of reciprocity, either way of calculating the interaction between neutron and proton gives the same answer.

Note that (assuming the neutrino is its own antiparticle) the nonconservation of $B+L$, combined with the conservation of $B-L$, assures that the magnitudes of the electric charges of proton and electron must be equal. This is very close to the assertion that there is a single elementary unit of electric charge (which quarks are able to fractionate because they also possess the additional conserved quantum number triality).

IV. CONCLUSION

This work is designed both as codification and development of an extensive if not entirely coherent literature on fractional charge. The principal results are as follows.

(1) Gauge charge, which in the case of a charge coupled to a local gauge field is the Lorentz-force charge of a particle in classical mechanics or the Aharonov–Bohm charge in quantum mechanics, is a fundamental, quantized attribute of a fundamental particle or an elementary particle built of fundamental particles, never renormalized or fractionated by change in medium, scale, or coupling strength. Gauge charge is not necessarily conserved; for example, there may be processes conserving local charge while allowing excitation of the vacuum to mobilize previously latent particles carrying gauge charge. For a fundamental soliton, there may be gauge charges carrying fractional values compared to those found on elementary particles in the same medium, if so with the fractions equal to the corresponding values for local or Gauss-law charge.
(2) The (locally conserved) local charge of a particle with specified AB charge may have a fractional value in one medium or at one scale with respect to its value in a different medium or at a different scale.
(3) In a given medium an isolable particle may carry a fraction of the local charge of another isolable particle only if the first one is itself elementary, which includes the possibility that it is a fundamental soliton.
(4) Fractional charge may result from conventional, continuous flow if the particle is a $d=1$ kink, or a $d=3$ electric charge or magnetic monopole. Otherwise the fractional value must arise from the intrinsic structure of the particle. In particular, this is the only possible fractional-charge case for a $d=2$ vortex.

The considerations in this work about elementary particles and fundamental solitons show a striking (and typical) duality. The particles and their constituents are established in the dynamics of the smallest distance and highest energy scales, while the stability of the solitons is assured by the dynamics of the largest distance and lowest energy scales.

It is interesting to wonder about possible extensions of this analysis. There may well be novel charges for $d>3$, and in certain circumstances fractional values of these charges. Even within the domain of $d\leqslant 3$ there is a class of issues that remains a matter of art rather than systematic deduction, namely, the determination of the discrete renormalizations which by definition are not directly susceptible to the well-developed techniques used for conventional renormalization. It is

possible that consistency relations of the type developed by Su[50] for the fractional quantum Hall effect would permit this sort of determination.

It may be in order to say something about the role of this article (in a journal issue devoted to exact methods for solitons), which has almost no equations and deals as well with solitons which do and ones which do not exhibit exact integrability, the latter evidently violating the original definition of the term by Zabusky and Kruskal.[51] Mathematical physics uses the notion of exactness in many ways. On one side, emphasized in this issue, one has exactly soluble systems, which can be used to infer generic properties that may be compared with real systems whose dynamics generally will not be exactly soluble. On the other side one finds systems which may not be fully soluble, but the existence of certain local conservation laws still may permit some useful—and exact—statements. This work manifestly is intended as a contribution to the latter category, by determining from mild assumptions some stringent requirements for the occurrence of fractional charge.

ACKNOWLEDGMENTS

A sceptical remark by Jeffrey Goldstone about skyrmions with fractional B was an early stimulus for this study, supported in part by the National Science Foundation under Grant No. PHY-0140192. Michael Dine, Roman Jackiw, Jainendra Jain, Vladimir Korepin, Barry McCoy, and Mikhail Stephanov gave instructive comments and criticisms. The Theoretical Physics Group at the Stanford Linear Accelerator Center (Department of Energy Contract No. DE–AC03–76SF00515) and the Center for Theoretical Physics at the Massachusetts Institute of Technology (Department of Energy Cooperative Agreement No. DF-FC02-94ER40818) provided generous hospitality during a sabbatical leave from Stony Brook.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 8 AUGUST 2003

Sphalerons, spectral flow, and anomalies

Frans R. Klinkhamer[a] and Christian Rupp[b]
Institut für Theoretische Physik, Universität Karlsruhe (TH), 76128 Karlsruhe, Germany

(Received 8 January 2003; accepted 9 April 2003)

The topology of configuration space may be responsible in part for the existence of sphalerons. Here, sphalerons are defined to be static but unstable finite-energy solutions of the classical field equations. Another manifestation of the nontrivial topology of configuration space is the phenomenon of spectral flow for the eigenvalues of the Dirac Hamiltonian. The spectral flow, in turn, is related to the possible existence of anomalies. In this review, the interconnection of these topics is illustrated for three particular sphalerons of SU(2) Yang–Mills–Higgs theory. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1590420]

I. INTRODUCTION

One of the main themes of the present special issue concerns the so-called topological solitons. The field configurations of these classical solutions are characterized by a topologically nontrivial map of the space manifold (or part of it) into some internal space of the model considered. A well-known example is the Skyrme soliton,[1] for which the space manifold S^3 (i.e., the compactified Euclidean space $\mathbb{R}^3$) is mapped into the internal space SU(2). Another example is the magnetic monopole,[2] for which the ''sphere at infinity'' S^2 is mapped into the Higgs vacuum manifold SO(3)/SO(2).

There exist, however, other classical solutions, the so-called sphalerons, which themselves have trivial topology but trace back to nontrivial topology in the configuration space of the fields.[3,4] In this contribution, we intend to give an elementary discussion of sphaleron solutions in Yang–Mills–Higgs theory and the underlying topology. In order to get a clear picture of what goes on, we focus on a single Yang–Mills–Higgs theory and three specific sphalerons.[5–7]

Physically, the topological solitons and the sphalerons play a different role. Solitons are primarily relevant to the equilibrium properties of the theory (e.g., the existence of certain stable asymptotic states), whereas sphalerons are of importance to the dynamics of the theory. The sphaleron[5] of the electroweak standard model,[8] for example, is believed to play a crucial role for baryon-number-violating processes in the early universe (see, e.g., Refs. 9 and 10 for two reviews).

The outline of this article is as follows. In Sec. II, we present the theory considered, to wit, SU(2) Yang–Mills theory with a single complex isodoublet of Higgs fields. This particular Yang–Mills–Higgs theory forms the core of the electroweak standard model of elementary particle physics. In Sec. III, we recall some basic facts about the mapping of spheres into spheres, in particular their homotopy classes. In Sec. IV, we describe three sphaleron solutions and their topological *raison d'être*. In Sec. V, we discuss another manifestation of the nontrivial topology of configuration space, namely the spectral flow of the eigenvalues of the Dirac Hamiltonian. The word ''spectral flow'' is used in a generalized sense, meaning *any* type of rearrangement of the energy levels. Loosely speaking, the spectral flow makes it possible for a sphaleron to acquire a fermion zero-mode. In Sec. VI, we link the spectral flow to the possible occurrence of anomalies (which signal the loss of one or more classical symmetries). In Sec. VII, finally, we present some concluding remarks.

II. SU(2) YANG–MILLS–HIGGS THEORY

In this article, we consider a simplified version of the electroweak standard model[8] without the hypercharge U(1) gauge field. This means, basically, that we set the weak mixing angle $\theta_w \equiv \arctan(g'/g)$ to zero, where g' and g are the coupling constants of the U(1) and SU(2) gauge groups, respectively. Also, we take only one family of quarks and leptons instead of the three known experimentally.

In general, the fields are considered to propagate in Minkowski space–time with coordinates $x^\mu \in \mathbb{R}$, $\mu = 0,1,2,3$, and metric $g_{\mu\nu}(x) = \text{diag}(+1,-1,-1,-1)$. But occasionally we go over to Euclidean space–time with metric $g_{\mu\nu}(x) = \delta_{\mu\nu}$. Natural units with $\hbar = c = 1$ are used throughout.

The SU(2) Yang–Mills gauge field is denoted by $A_\mu(x) \equiv A^a_\mu(x)\, \tau^a/(2\text{i})$, where the τ^a are the three Pauli matrices acting on weak isospin space and the component fields $A^a_\mu(x)$ are real. (Repeated indices are summed over, unless stated otherwise.) The complex Higgs field transforms as an isodoublet under the SU(2) gauge group and is given by $\Phi(x) = (\Phi_1(x), \Phi_2(x))^t$, where the suffix t stands for transpose [cf. Eq. (5.5) below]. The fermion fields will be discussed in Sec. V.

The classical action of the gauge and Higgs fields reads

$$\Gamma_{\text{YMH}} = \int_{\mathbb{R}^4} \mathrm{d}^4x \, \left\{ \frac{1}{2} \text{tr}\, F_{\mu\nu} F^{\mu\nu} + (D_\mu \Phi)^\dagger (D^\mu \Phi) - \lambda\, (\Phi^\dagger \Phi - \eta^2)^2 \right\}, \tag{2.1}$$

where $F_{\mu\nu} \equiv \partial_\mu A_\nu - \partial_\nu A_\mu + g[A_\mu, A_\nu]$ is the SU(2) Yang–Mills field strength and $D_\mu \Phi \equiv (\partial_\mu + g A_\mu)\Phi$ is the covariant derivative of the Higgs field. The theory has Yang–Mills coupling constant g and quartic Higgs coupling constant λ, but the classical dynamics depends only on the ratio λ/g^2. The parameter η has the dimension of mass and sets the scale of the Higgs expectation value. The three W vector bosons then have equal mass, $M_W = g\,\eta/\sqrt{2}$. The single Higgs scalar boson has a mass $M_H = 2\,\sqrt{\lambda}\,\eta$.

The action (2.1) is invariant under a local gauge transformation

$$\Phi'(x) = \Lambda(x)\, \Phi(x), \quad g A'_\mu(x) = \Lambda(x)\, (\, g A_\mu(x) + \partial_\mu\,)\, \Lambda(x)^{-1}, \tag{2.2}$$

for an arbitrary gauge function $\Lambda(x) \in \text{SU}(2)$. In addition, there are certain global SU(2) and U(1) symmetry transformations which operate solely on the Higgs field.

III. MAPS OF SPHERES INTO SPHERES

Let us consider continuous maps from a connected manifold M to a connected manifold N. Two such maps, f_1 and f_2, are called *homotopic* if the one can be obtained from the other by continuous deformation. More specifically, f_1 and f_2 are homotopic if there exists a continuous map $h:[0,1]\times M \to N$ such that $h(0,m) = f_1(m)$ and $h(1,m) = f_2(m)$ for all $m \in M$. All maps $M \to N$ can be divided into equivalence classes, where two maps are equivalent if they are homotopic (see, e.g., Ref. 11).

We are particularly interested in the case where M and N are the spheres S^m and S^n, respectively. The set of homotopy classes is called the *homotopy group* and is denoted by $\pi_m(S^n)$. Figure 1 shows two maps $S^1 \to S^1$ which are not homotopic. It is clear that in this particular case

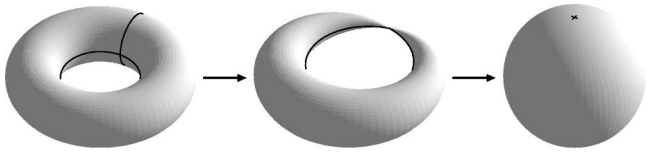

FIG. 2. Left: Cartesian product space $S^1\times S^1$ drawn as a torus, with two circles representing the sets $\{x_0\}\times S^1$ and $S^1\times\{y_0\}$ for some arbitrarily chosen points x_0 and y_0. Middle: surface after shrinking the first of these sets to a point. Right: surface after shrinking the second set to a point, which gives the smash product $S^1\wedge S^1\sim S^2$.

the homotopy classes can be labeled by integer numbers which describe how often the original circle S^1 is wrapped around the target circle S^1. This explains the result $\pi_1(S^1)=\mathbb{Z}$, where $\mathbb{Z}$ denotes the group of integers under addition. The two maps shown in Fig. 1 have winding numbers 1 and 0.

The homotopy classes of $S^n\to S^n$, for $n>1$, can be pictured analogously, since the representation of a sphere S^n in spherical coordinates contains exactly one azimuthal angle $\phi\in[0,2\pi]$. The result is $\pi_n(S^n)=\mathbb{Z}$. Further homotopy groups are $\pi_m(S^n)=\{0\}$ for $m<n$, $\pi_3(S^2)=\mathbb{Z}$, and $\pi_4(S^3)=\mathbb{Z}_2$, where $\mathbb{Z}_2$ denotes the group of integers $\{0,1\}$ under addition modulo 2.

Next, consider families of maps $S^m\to S^n$, where the family parameters themselves form a sphere S^p. In short, consider $S^p\times S^m\to S^n$. Imposing certain constraints, these families of maps can be viewed as maps $S^{p+m}\to S^n$ and classified according to the homotopy groups of spheres.

To this end, we introduce the *smash product*[11] of two spheres S^p and S^m. The smash product $S^p\wedge S^m$ is defined as the Cartesian product $S^p\times S^m$ with the set $(\{x_0\}\times S^m)\cup(S^p\times\{y_0\})$ considered as a single point, for some arbitrarily chosen $x_0\in S^p$ and $y_0\in S^m$. It can be shown that $S^p\wedge S^m$ is homeomorphic to the sphere S^{p+m} (see Fig. 2 for a sketch of the proof).

A simple corollary will be important in the following. Any map $f:S^p\times S^m\to S^n$ can effectively be considered as a map defined on $S^p\wedge S^m$ if $f(x_0,y)$ is independent of y and $f(x,y_0)$ is independent of x, for an appropriate choice of $x_0\in S^p$ and $y_0\in S^m$.

IV. SPHALERONS

The word sphaleron is of Greek origin and means "ready to fall" (see Ref. 5 for the etymology). It is used to denote a static but unstable solution of the classical field equations with finite total energy of the fields.

In this article, only finite-energy configurations of the fields will be considered. By analogy to Morse theory,[12] sphalerons can then be looked for by a minimax procedure[3] if the configuration space of the underlying field theory is multiply connected.

The procedure runs as follows: first, construct a noncontractible p-dimensional sphere S^p in configuration space, then determine its maximal energy configuration, and, finally, "shrink" the sphere to minimize this maximal energy. If the configuration space were compact, this procedure would be guaranteed to give a saddle point. But configuration space is infinite-dimensional and noncompact, so that the minimax procedure produces at best only a candidate solution. It has to be checked explicitly that the appropriate minimax-configuration solves the classical field equations. If this is the case, the minimax-configuration is a genuine sphaleron.

A. Sphaleron S

For the sphaleron S[4,5,13] of the SU(2) Yang–Mills–Higgs theory (2.1), we consider three-space to be compactified by adding the "sphere at infinity." Configuration space is then the space of all static three-dimensional gauge and Higgs field configurations in a particular gauge which have finite energy. The static gauge field can be written as a Lie-algebra-valued one-form,

$$A(x^1,x^2,x^3)\equiv A_m^a(x^1,x^2,x^3)\,\tau^a/(2\mathrm{i})\,\mathrm{d}x^m\,, \tag{4.1}$$

with implicit sums of a and m over $1,2,3$. Furthermore, we use spherical coordinates (r,θ,ϕ) over $\mathbb{R}^3$ and employ the radial gauge condition $A_r=0$, together with $A_0=0$.

Since the energy has to be finite, only those configurations are admissible for which the gauge field tends towards a pure-gauge configuration as $r\to\infty$ and the Higgs field towards its associated vacuum value,

$$g\,A^{\infty}=-\,\mathrm{d}\omega\;\omega^{-1}\,,\quad \Phi^{\infty}=\eta\;\omega\begin{pmatrix}0\\1\end{pmatrix}, \tag{4.2}$$

for a map ω of the "sphere at infinity" S^2 into the gauge group SU(2).

Any loop in configuration space induces a loop in the space of these mappings ω. The corresponding map is denoted by

$$U{:}S^1\times S^2\to \mathrm{SU}(2)\,,\quad (\mu,\theta,\phi)\mapsto U(\mu,\theta,\phi)\,, \tag{4.3}$$

where $\mu\in[0,\pi]$ is the parameter of the loop of configurations and $\theta\in[0,\pi]$ and $\phi\in[0,2\pi]$ are spherical coordinates in three-space.

By imposing certain constraints on this map, we may effectively reduce the set of allowed loops, so that U becomes a map $S^3\to\mathrm{SU}(2)\sim S^3$ which falls into homotopy classes according to $\pi_3(\mathrm{SU}(2))=\pi_3(S^3)=\mathbb{Z}$. To be specific, the map U for $\mu=0$ and $\mu=\pi$ must not depend on θ and ϕ, and the map U for $\theta=0$ has to be independent of μ. Then U is effectively defined on the smash product $S^1\wedge S^2\sim S^3$, as explained in the last paragraph of Sec. III. Now there exist noncontractible loops of field configurations for which the minimax procedure can be performed.

An appropriate expression for the map (4.3) is given by[4]

$$U(\mu,\theta,\phi)=y^1\,(-\mathrm{i}\tau_1)+y^2\,(-\mathrm{i}\tau_2)+y^3\,(-\mathrm{i}\tau_3)+y^4\,\mathbb{1}_2\,, \tag{4.4}$$

with

$$\begin{pmatrix}y^1\\y^2\\y^3\\y^4\end{pmatrix}=\begin{pmatrix}-\sin\mu\,\sin\theta\,\sin\phi\\-\sin\mu\,\sin\theta\,\cos\phi\\\sin\mu\,\cos\mu\,(\cos\theta-1)\\\cos^2\mu+\sin^2\mu\,\cos\theta\end{pmatrix}. \tag{4.5}$$

In order to calculate the winding number of this particular map U, we examine its relation to the standard spherical coordinates on S^3,

$$\begin{pmatrix}z^1\\z^2\\z^3\\z^4\end{pmatrix}=\begin{pmatrix}\cos\theta_2\\\sin\theta_2\,\cos\theta_1\\\sin\theta_2\,\sin\theta_1\,\sin\phi_1\\\sin\theta_2\,\sin\theta_1\,\cos\phi_1\end{pmatrix}, \tag{4.6}$$

with polar angles $\theta_1,\theta_2\in[0,\pi]$ and azimuthal angle $\phi_1\in[0,2\pi]$.

We first observe that the two-vector

$$\vec{w}=\begin{pmatrix}\cos\mu\\\sin\mu\,\cos\theta\end{pmatrix} \tag{4.7}$$

sweeps over the unit disk if μ and θ run from 0 to π. Since rotations map the unit disk onto itself and leave the length of $\vec{w}$ invariant,

$$|\vec{w}|^2=1-\sin^2\mu\,\sin^2\theta\,, \tag{4.8}$$

the relation

$$\begin{pmatrix}\cos\theta_2\\\sin\theta_2\,\cos\theta_1\end{pmatrix}=\begin{pmatrix}\cos\alpha&-\sin\alpha\\\sin\alpha&\cos\alpha\end{pmatrix}\begin{pmatrix}\cos\mu\\\sin\mu\,\cos\theta\end{pmatrix} \tag{4.9}$$

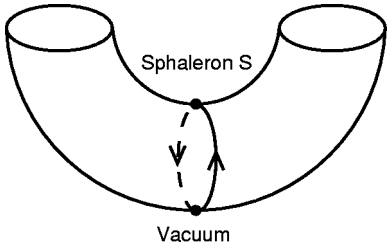

FIG. 3. Sphaleron S on top of a noncontractible loop in configuration space. The field energy is zero for the vacuum and positive for the sphaleron S.

describes an admissible reparametrization of the disc. By choosing $\alpha=-\mu$, we find $y^4=z^1$ and $y^3=z^2$. With $\sin\theta_1\sin\theta_2=\sin\mu\sin\theta$ and $\phi_1=\phi$, we have also $y^1=-z^3$ and $y^2=-z^4$.

The conclusion is that the map U as defined by Eqs. (4.4) and (4.5) covers the target sphere S^3 exactly once. The map U has winding number one (or minus one, depending on the definition of the winding number) and corresponds to a nontrivial element of the homotopy group $\pi_3(S^3)=\mathbb{Z}$.

For the static SU(2) gauge and Higgs fields of the noncontractible loop (NCL), we make the ansatz[4]

$$g\,A(\mu,r,\theta,\phi)=-\,f(r)\;\mathrm{d}U(\mu,\theta,\phi)\;U(\mu,\theta,\phi)^{-1}\,, \tag{4.10a}$$

$$\Phi(\mu,r,\theta,\phi)=\eta\,h(r)\;U(\mu,\theta,\phi)\begin{pmatrix}0\\1\end{pmatrix}+\eta\,(1-h(r))\begin{pmatrix}0\\ \exp(-\mathrm{i}\,\mu)\cos\mu\end{pmatrix}, \tag{4.10b}$$

with the following boundary conditions for the radial functions f and h:

$$\lim_{r\to 0} f(r)/r=0\,,\quad \lim_{r\to\infty} f(r)=1\,, \tag{4.11a}$$

$$\lim_{r\to 0} h(r)=0\,,\quad \lim_{r\to\infty} h(r)=1\,. \tag{4.11b}$$

The energy density of the fields (4.10) turns out to be spherically symmetric. Indeed, the fields of the NCL can also be written in a manifestly spherically symmetric form.[14]

The fields (4.10) of the NCL at $\mu=0$ or π correspond to the Higgs vacuum with $A(x)=0$ and $\Phi(x)=(0,\eta)^t$. This particular configuration is independent of the radial functions f and h and has zero energy according to Eq. (2.1). The NCL configuration at $\mu=\pi/2$ is distinguished by having parity reflection symmetry (the only other configuration of the NCL with this property is the vacuum at $\mu=0$). For given functions f and h, this $\mu=\pi/2$ configuration is also the maximum energy configuration over the NCL. The minimax procedure now consists of adjusting the radial functions f and h while maintaining the boundary conditions (4.11), so that the energy at $\mu=\pi/2$ is minimized. The resulting configuration is the sphaleron S, as sketched in Fig. 3.

Using numerical methods, one finds for the sphaleron energy the value[5]

$$E_{\mathrm{S}}\approx 3.04\times(4\pi/g^2)\,M_W\,, \tag{4.12}$$

which holds for the case of vanishing quartic Higgs coupling constant ($\lambda/g^2=0$). [The sphaleron energy E_{S} has also been calculated for the full SU(2)×U(1) Yang–Mills–Higgs theory of the electroweak standard model. The energy E_{S} is found to be weakly dependent on the mixing angle θ_w, at least near $\theta_w=0$. The emergence of a large magnetic dipole moment $\mu_{\mathrm{S}}\propto(4\pi/g^2)\,g\tan\theta_w/M_W$ is perhaps more interesting. See Refs. 5, 15, and 16 for details.] For large

enough values of λ/g^2, additional solutions appear, the so-called ''deformed sphalerons.'' [17,18] The appearance of these extra sphalerons can be explained[14] by a simple deformation of the energy surface in Fig. 3.

The sphaleron S by itself has trivial topology, with the ''sphere at infinity'' S^2 mapped into the Higgs vacuum manifold $\mathrm{SU}(2)\sim S^3$; cf. Sec. III. [As mentioned in the Introduction, the magnetic monopole[2] in SU(2) Yang–Mills theory with a real isotriplet of Higgs is based on the nontrivial map $S^2\to\mathrm{SO}(3)/\mathrm{SO}(2)\sim S^2$.] Note that the original S ansatz, with the so-called hedgehog structure, was discovered[13] 10 years before the construction of S via the NCL.[4,5]

In the radial gauge, the vacuum configuration of the SU(2) gauge field is uniquely fixed, $gA_m^{\mathrm{vac}}(x^1,x^2,x^3)=0$. If this gauge condition is abandoned, any pure-gauge configuration $gA_m=-\partial_m U\,U^{-1}$, for arbitrary time-independent SU(2)-valued field U, is a possible vacuum configuration. Depending on the topology of three-space, these vacuum configurations may or may not fall into different unconnected classes. This does not happen for our compactification $\mathbb{R}^3\cup S^2_\infty$. But the situation changes if, instead, we choose a one-point compactification $\mathbb{R}^3\cup\{\infty\}$, with all fields approaching a single direction-independent value as $r\to\infty$. Each vacuum configuration then corresponds to a map $S^3\to S^3$ and there are topologically distinct vacuum classes, since $\pi_3(S^3)=\mathbb{Z}$.

In fact, it is possible to perform a gauge transformation on the NCL (4.10) which changes the asymptotic behavior of the gauge fields, so that they can be considered to live on $S^3=\mathbb{R}^3\cup\{\infty\}$. Let $\omega(\mu,r,\theta,\phi)$ be an SU(2)-valued map which approaches $U(\mu,\theta,\phi)$ for $r\to\infty$ and $\mathbb{1}_2$ for $r\to 0$. The radial dependence of $\omega(\mu,r,\theta,\phi)$ implements a path which connects the map $U(\mu,\theta,\phi)=\omega(\mu,\infty,\theta,\phi)$ to the constant map $\mathbb{1}_2=\omega(\mu,0,\theta,\phi)$. [Note that $U(\mu,\theta,\phi)$ for *fixed* μ is a map $S^2\to S^3$ and therefore contractible.]

The crucial point, now, is that the map $\omega(0,r,\theta,\phi)$ is homotopically different from the map $\omega(\pi,r,\theta,\phi)$. [Otherwise, the radial dependence of $\omega(\mu,r,\theta,\phi)$ would yield a contraction of $\omega(\mu,\infty,\theta,\phi)$, considered as a μ-dependent map $S^3\to S^3$, which is impossible.] Both maps $\omega(0,r,\theta,\phi)$ and $\omega(\pi,r,\theta,\phi)$ can also be viewed as maps $S^3\to S^3$, since $\omega(\mu,\infty,\theta,\phi)=U(\mu,\theta,\phi)=\mathbb{1}_2$ for $\mu=0$ and $\mu=\pi$. The conclusion is then that the corresponding vacuum configurations $A_m(x^1,x^2,x^3)$ at $\mu=0$ and $\mu=\pi$ belong to different homotopy classes. This result will be discussed further in Sec. VI A.

B. Sphaleron S*

The three-space of our SU(2) Yang–Mills–Higgs theory (2.1) is again compactified by adding the ''sphere at infinity.'' This time, however, we do not consider one-parameter families (loops) of static finite-energy configurations but two-parameter families (spheres). At spatial infinity, these families are characterized by the map

$$U:S^2\times S^2\to\mathrm{SU}(2)\,,\quad (\mu,\nu,\theta,\phi)\mapsto U(\mu,\nu,\theta,\phi)\,, \tag{4.13}$$

where (μ,ν) are the parameters of the sphere of configurations and (θ,ϕ) are the polar and azimuthal angles of the spherical coordinates in three-space. The parameters μ and ν run from $-\pi/2$ to $+\pi/2$ and the boundary of the (μ,ν)-square at $|\mu|=\pi/2$ or $|\nu|=\pi/2$ is mapped to the same element of SU(2).

Next, restrict the class of mappings U by requiring that $U(\mu,\nu,0,\phi)$ is independent of (μ,ν,ϕ) and $U(-\pi/2,-\pi/2,\theta,\phi)$ independent of (θ,ϕ). Then U is effectively a mapping from S^4 to S^3, which has a nontrivial homotopy structure, $\pi_4(S^3)=\mathbb{Z}_2$. The general idea, now, is to construct a noncontractible sphere, to determine the maximal energy configuration on that sphere and to continuously deform the sphere so that its maximal energy is minimized.[19]

The construction of the required nontrivial map $S^4\to S^3$ is done in two steps. First, a nontrivial map $S^3\to S^2$ is found and, second, an operation is performed to increase the dimension of both spheres.

The relevant map $S^3\to S^2$ is given by the well-known *Hopf fibration*,[11] which can be ex-

plained as follows. Consider the three-sphere S^3 to be a subset of $\mathbb{C}^2$, namely, $\{(z_1,z_2)\,|\,\ |z_1|^2+|z_2|^2=1\}$. Each $\mathbb{C}$-line through the origin in $\mathbb{C}^2$ then intersects with this three-sphere in a great circle S^1. These great circles S^1 form a pairwise disjoint covering of S^3. Two points of S^3 are defined to be equivalent ($\simeq$), if they lie on the same great circle S^1. The corresponding projection,

$$S^3 \to S^3/\simeq , \tag{4.14}$$

is the desired Hopf map, since the topological space $S^3/\simeq$ is homeomorphic to S^2.

The topological equivalence of $S^3/\simeq$ and S^2 can be shown by considering the $\mathbb{C}$-lines which label the great circles S^1 discussed in the previous paragraph. All but one of these $\mathbb{C}$-lines can be parametrized by complex numbers $c \in \mathbb{C}$. Specifically, the coordinates of such a line read

$$(z_1\,,z_2)=(w\,,cw)\,, \quad \text{for} \quad w\in\mathbb{C}\,. \tag{4.15}$$

In addition, there is the single $\mathbb{C}$-line given by

$$(z_1\,,z_2)=(0\,,w)\,, \quad \text{for} \quad w\in\mathbb{C}\,. \tag{4.16}$$

Hence, the total parameter space of $S^3/\simeq$ is given by the one-point-compactified plane, i.e., the Riemann sphere S^2.

The *suspension* of a sphere S^n is essentially the same as the smash product $S^1\wedge S^n$. It can be used to increase the dimension of the spheres appearing in the above discussion. The resulting suspension of the Hopf map corresponds to a nontrivial element of the homotopy group $\pi_4(S^3)=\mathbb{Z}_2$.

In a particular parametrization, the required map (4.13) takes the form[19]

$$\begin{aligned} U(\mu,\nu,\hat{x}) = &(\sin\mu + \mathrm{i}\cos\mu\ \exp[\,+\mathrm{i}(\nu+\pi/2)\,\tau_3\,]\ \hat{x}\cdot\vec{\tau}\ \exp[\,-\mathrm{i}(\nu+\pi/2)\,\tau_3\,])\\ &\times(\sin\mu - \mathrm{i}\cos\mu\ \hat{x}\cdot\vec{\tau})\,, \end{aligned} \tag{4.17}$$

where μ and ν range over $[-\pi/2,\pi/2]$ and describe a two-sphere, as does the unit three-vector $\hat{x}\equiv(\sin\theta\cos\phi,\sin\theta\sin\phi,\cos\theta)$. The map $U(\mu,\nu,\hat{x})$ is effectively defined on the smash product $S^2\wedge S^2$, since U is independent of $\hat{x}$ for $\mu=\pm\pi/2$ or $\nu=\pm\pi/2$ and independent of μ and ν for $\hat{x}=(0,0,1)$. (Note that the suspended Hopf map also plays a role in the physics of Skyrme solitons.[20])

With the map (4.17) in hand, it is possible to construct a noncontractible sphere (NCS) of static Yang–Mills–Higgs configurations and to obtain the corresponding nontrivial classical solution, the sphaleron S*, just as for the NCL and the sphaleron S of the previous subsection. The construction of S* is, however, rather subtle. Here, we only describe the four basic steps and refer the reader to Ref. 6 for more information.

First, we observe that the map (4.17) singles out the x^3 axis, which suggests the use of the cylindrical coordinates ρ, ϕ, and z, defined by $(x^1,x^2,x^3)=(\rho\cos\phi,\rho\sin\phi,z)$. Then, it is not difficult to construct a NCS of static SU(2) Yang–Mills–Higgs configurations, whose behavior at infinity is governed by the SU(2) matrix (4.17). Specifically, the NCS configurations can be written in terms of six axial functions $f_i(\rho,z)$ and $h_j(\rho,z)$, for $i=0,1,2,3$ and $j=1,2$, with appropriate boundary conditions [for example, $f_0(\rho,z)\to 1$ and $h_1(\rho,z)\to 1$ as $\rho^2+z^2\to\infty$]. The SU(2) gauge and Higgs field configuration of the NCS are by construction axially symmetric.

Second, the configuration at $\mu=\nu=0$ is also invariant under parity reflection and gives the maximum energy of the NCS. Moreover, it can be verified that this $\mu=\nu=0$ configuration, in terms of the six axial functions $f_i(\rho,z)$ and $h_j(\rho,z)$, provides a *self-consistent ansatz* for the SU(2) Yang–Mills–Higgs field equations. Concretely, this means that the ansatz reduces the field equations to precisely six partial differential equations (PDEs) for the six functions $f_i(\rho,z)$ and $h_j(\rho,z)$, with appropriate boundary conditions which trace back in part to the finite-energy condition. (This result agrees with the so-called principle of symmetric criticality,[21] which

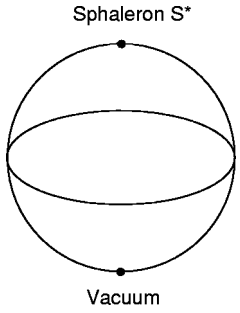

FIG. 4. Sphaleron S* on top of a noncontractible sphere in configuration space.

states that, under certain conditions, it suffices to consider variations that respect the symmetry of the ansatz.) The solution of these PDEs then determines the field configurations of the sphaleron S*. See Fig. 4 for a sketch of configuration space.

Third, the reduced field equations for the sphaleron S* can be solved numerically. For approximately vanishing quartic Higgs coupling constant ($\lambda/g^2 = 1/800$), the numerical solution of the six PDEs with the correct boundary conditions gives the following value for the energy:

$$E_{S^*} \approx 1.91 \times E_S \,, \tag{4.18}$$

where E_S denotes the corresponding energy of the sphaleron S [cf. Eq. (4.12) above]. In fact, the sphaleron S* is found to have the structure of a di-atomic molecule, binding together a sphaleron S and an "anti-sphaleron" $\overline{\text{S}}$. See Ref. 6 for a plot of the energy density and further discussion.

Fourth, the construction of S* via the NCS can be extended to the full $\text{SU}(2)\times\text{U}(1)$ theory of the electroweak standard model by the introduction of one more axial function, $f_4(\rho,z)$, with trivial boundary conditions at infinity. But for nonvanishing weak mixing angle θ_w, there are only preliminary numerical results for the sphaleron S* and it would be worthwhile to obtain accurate results over the full range of values of λ/g^2 and θ_w.

C. *Z*-string

Now consider static field configurations of the SU(2) Yang–Mills–Higgs theory (2.1) which are independent of one spatial coordinate, the z-coordinate, and have vanishing gauge potential in that direction, $A_z = 0$. In order to have finite total energy, the z-direction has to be compact and three-space is taken to be $\mathbb{R}^2 \times S^1$ instead of $\mathbb{R}^3$. Also, choose cylindrical polar coordinates (ρ,ϕ, z) and work in the polar gauge for which $A_\rho = 0$.

Since the energy density in a plane with fixed z has to be finite, the remaining gauge field component A_ϕ reduces to a pure-gauge configuration asymptotically,

$$g\, A_\phi \to -\,(\partial_\phi\, \omega)\;\omega^{-1}\,, \quad \text{as} \quad \rho \to \infty\,, \tag{4.19}$$

for a map $\omega: S^1 \to \text{SU}(2)$. Basically, this means that the plane $\mathbb{R}^2$ is compactified by adding the "circle at infinity."

It is possible to construct a noncontractible sphere of these field configurations by restricting the corresponding maps

$$U: S^2 \times S^1 \to \text{SU}(2)\,, \quad (\mu,\nu,\phi) \mapsto U(\mu,\nu,\phi)\,, \tag{4.20}$$

in such a way that they are effectively defined on the smash product $S^2 \wedge S^1 \sim S^3$. Specifically, the sphere is parametrized by μ and ν which take values in $[-\pi/2, +\pi/2]$. The rim of the (μ,ν)-square is identified and corresponds to a single point on S^2. The map U is restricted to be independent of ϕ if (μ,ν) lies on this rim and independent of (μ,ν) if $\phi = 0$.

An appropriate expression for the map (4.20) is given by[7]

$$U(\mu,\nu,\phi)=V(\mu,\nu,0)^{-1}\,V(\mu,\nu,\phi)\,, \tag{4.21a}$$

$$V(\mu,\nu,\phi)=z^1\,(-\mathrm{i}\tau_1)+z^2\,(-\mathrm{i}\tau_2)+z^3\,(-\mathrm{i}\tau_3)+z^4\,\mathbb{1}_2\,, \tag{4.21b}$$

$$\begin{pmatrix} z^1\\ z^2\\ z^3\\ z^4\end{pmatrix}=\begin{pmatrix} \sin\mu\\ \cos\mu\sin\nu\\ \cos\mu\cos\nu\sin\phi\\ \cos\mu\cos\nu\cos\phi\end{pmatrix}. \tag{4.21c}$$

Note that the factor $V(\mu,\nu,0)^{-1}$ in (4.21a) serves a dual purpose. First, it assures that the rim of the (μ,ν)-square is mapped to a single element, since $V(\mu,\nu,\phi)$ is independent of ϕ on this boundary. Second, it makes U independent of μ and ν if $\phi=0$.

For the two-dimensional SU(2) gauge and Higgs fields of the noncontractible sphere (NCS), we make the ansatz[7]

$$g\,A(\mu,\nu,\rho,\phi)=-f(\rho)\;\mathrm{d}U(\mu,\nu,\phi)\,U(\mu,\nu,\phi)^{-1}\,, \tag{4.22a}$$

$$\Phi(\mu,\nu,\rho,\phi)=\eta\,h(\rho)\,U(\mu,\nu,\phi)\begin{pmatrix}0\\1\end{pmatrix}, \tag{4.22b}$$

with parameters $|\mu|,|\nu|\leqslant\pi/2$. The polar functions f and h have the following boundary conditions:

$$\lim_{\rho\to 0} f(\rho)/\rho=0\,,\quad \lim_{\rho\to\infty} f(\rho)=1, \tag{4.23a}$$

$$\lim_{\rho\to 0} h(\rho)=0\,,\quad \lim_{\rho\to\infty} h(\rho)=1. \tag{4.23b}$$

But no point on this NCS corresponds to a vacuum configuration, since the Higgs field in Eq. (4.22b) vanishes at $\rho=0$ for all values of (μ,ν). Therefore, the point of the NCS at the boundary of the (μ,ν)-square must be connected to the vacuum by an additional line segment. The corresponding ansatz is simply

$$g\,A(\mu,\nu,\rho,\phi)=0\,, \tag{4.24a}$$

$$\Phi(\mu,\nu,\rho,\phi)=\eta\,(1-\sin[\mu\nu]+h(\rho)\sin[\mu\nu]\,)\begin{pmatrix}0\\1\end{pmatrix}, \tag{4.24b}$$

for $[\mu\nu]\equiv\max\{|\mu|,|\nu|\}>\pi/2$ with the parameter range of μ and ν extended to $[-\pi,+\pi]$. The set of configurations (4.21)–(4.24) is like a ''balloon'' which is tied to the ground by a rope.

The energy of the NCS has a global maximum at $\mu=\nu=0$. By minimizing this maximal energy with respect to the functions f and h, one finds the coupled differential equations

$$\rho\,f''-f'=\frac{1}{2}g^2\eta^2\,\rho\,h^2\,(f-1)\,, \tag{4.25a}$$

$$\rho^2\,h''+\rho\,h'=h\,(1-f\,)^2+2\lambda\,\eta^2\,\rho^2 h\,(h^2-1)\,, \tag{4.25b}$$

where the prime indicates a derivative with respect to ρ. The same differential equations, with boundary conditions (4.23), hold for the so-called Z-string,[22–24] which excites the Z boson and Higgs fields of the electroweak standard model.

The Z-string is thus the sphaleron on the NCS given by Eqs. (4.21)–(4.24); see Fig. 5. This particular sphere (balloon) in configuration space will be discussed further in Sec. VI C. Note,

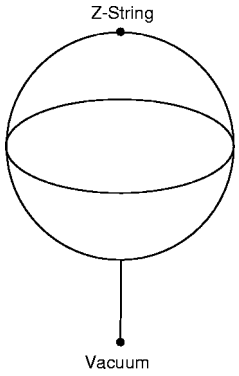

FIG. 5. Z-string on top of a noncontractible sphere (balloon) in configuration space.

finally, that the configurations of the NCS can also be embedded in the full $\mathrm{SU}(2)\times U(1)$ gauge theory of the electroweak standard model; see Ref. 7 for details and numerical results.

V. SPECTRAL FLOW

The classical field configurations of the previous section may serve as background fields for massless Dirac fermions, whose left-handed components form an isodoublet under the SU(2) gauge group and whose right-handed components are gauge singlets. The Dirac equation for the spinor $\Psi(x)$ reads in this case

$$(\mathrm{i}\not{D} - k\,(\Phi_M^\dagger P_L + \Phi_M P_R))\Psi = 0\,, \tag{5.1}$$

with the Yukawa coupling constant k, the Feynman slash notation $\not{D} \equiv \gamma^\mu D_\mu$, and the covariant derivative

$$D_\mu \Psi(x) \equiv [\,\partial_\mu + g A_\mu(x) P_L\,]\Psi(x)\,, \tag{5.2}$$

which shows that only the left-handed fermions interact with the SU(2) gauge field.

The left- and right-handed projectors are, as usual, defined by $P_L \equiv \frac{1}{2}(\mathbb{1} - \gamma_5)$ and $P_R \equiv \frac{1}{2}(\mathbb{1} + \gamma_5)$. With the Minkowski metric of Sec. II, the Dirac matrices obey the following Clifford algebra and Hermiticity conditions:

$$\gamma^\mu \gamma^\nu + \gamma^\nu \gamma^\mu = 2\, g^{\mu\nu}\,, \qquad \gamma^{\mu\,\dagger} = \gamma^0 \gamma^\mu \gamma^0\,, \qquad \gamma_5 \equiv \mathrm{i}\,\gamma^0\gamma^1\gamma^2\gamma^3 = \gamma_5^\dagger\,. \tag{5.3}$$

(For the Euclidean metric, all Dirac matrices are chosen Hermitian, $\gamma^{\mu\,\dagger} = \gamma^\mu$.) The space–time manifold considered in this article is flat and there is no need to use the vierbeins (tetrads) explicitly.

The matrix Φ_M in (5.1) contains the two Higgs field components Φ_1 and Φ_2,

$$\Phi_M = \begin{pmatrix} \Phi_2^* & \Phi_1 \\ -\Phi_1^* & \Phi_2 \end{pmatrix}, \tag{5.4}$$

so that

$$\Phi_M \cdot \begin{pmatrix} 0 \\ 1 \end{pmatrix} = \begin{pmatrix} \Phi_1 \\ \Phi_2 \end{pmatrix} = \Phi\,. \tag{5.5}$$

For the Higgs vacuum with $A_\mu(x) = 0$ and $\Phi_M(x) = \mathrm{diag}(\eta, \eta)$, the effective fermion mass is given by $m = k\,\eta$.

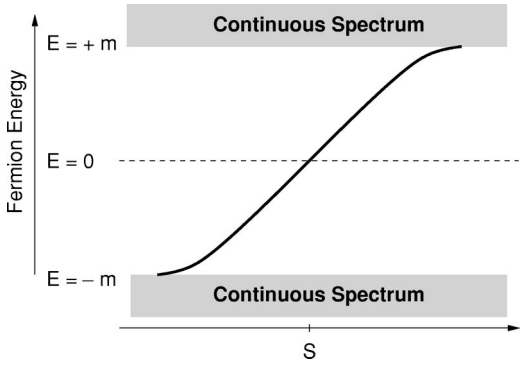

FIG. 6. Spectral flow for a path over the sphaleron barrier (cf. Fig. 3).

The model considered may serve as the starting point for a consistently renormalized quantum field theory with gauge group $SU(2)\times U(1)$ if we include three colors of left-handed quark isodoublets for each left-handed lepton isodoublet, so that the perturbative gauge anomalies[25–28] cancel between the quarks and the leptons.[29,30] (A similar cancellation occurs for the nonperturbative SU(2) anomaly[31] to be discussed in Sec. VI B.) But, for our purpose, it suffices to consider a *single* isodoublet of left-handed fermions, since the fermion isodoublets of the full theory behave identically.

The time-dependent solutions of the Dirac equation (5.1) are, however, not our main interest. Rather, we are interested in the eigenvalues E of the corresponding Dirac Hamiltonian,

$$H=-\mathrm{i}\gamma^0\gamma^m D_m+k\,\gamma^0(\,\Phi_M^\dagger P_L+\Phi_M P_R\,)\,, \tag{5.6}$$

where use has been made of the fact that $A_0=0$ for our gauge field configurations and the covariant derivative D_m, for $m=1,2,3$, has already been given in Eq. (5.2). The eigenvalues E are real, since the Dirac Hamiltonian H is Hermitian.

Now consider periodic one-parameter families (loops) of static background fields. The spectral flow invariant[32] is then defined as the number of eigenvalues that cross zero from below minus the number of eigenvalues that cross zero from above as the loop parameter varies over its range (in a prescribed direction). See, e.g., Ref. 33 for an elementary introduction to the concept of spectral flow.

Even if the spectral flow invariant vanishes, there may still be a nontrivial rearrangement (permutation) of the energy levels. We speak about ''spectral flow'' also in this case. (Mathematicians would perhaps say that there is no spectral flow if the spectral flow invariant is zero.) In addition, we will look for ''spectral flow'' in two-parameter families of background fields (which may be characterized by a different topological invariant).

A. Spectral flow for the sphaleron S

Consider the noncontractible loop (NCL) used in Sec. IV A to construct the sphaleron S, with parameter μ running from 0 to π. At the beginning of the loop ($\mu=0$) and at the end ($\mu=\pi$), the static background field (4.10) is the same vacuum configuration and the spectrum of the Dirac Hamiltonian (5.6) is purely continuous with a mass gap $2m$ according to the Higgs mechanism ($m\propto\eta$). For the sphaleron S at $\mu=\pi/2$, on the other hand, it has been shown[34–38] that the Dirac Hamiltonian H has a single normalizable eigenfunction with eigenvalue zero.

The overall picture, starting from $\mu=0$, is that a negative eigenvalue $E(\mu)$ of the Dirac Hamiltonian H rises above the negative continuous spectrum, crosses zero when the background fields pass the sphaleron barrier ($\mu=\pi/2$), and finally reaches the positive continuous spectrum for $\mu=\pi$. See Fig. 6 for a sketch and Ref. 38 for numerical results.

The nonvanishing spectral flow over the NCL is guaranteed by the Atiyah–Singer index theorem,[39] which relates the analytic index of the four-dimensional Dirac operator (the loop

parameter μ playing the role of an imaginary time) to the topological charge associated with the NCL. Further details will be given in Sec. VI A. Here, we only remark that the NCL gauge field (4.10), defined in Minkowski space, has essentially the same topology as the BPST instanton solution of Euclidean Yang–Mills theory.[40,41]

B. Spectral flow for the sphaleron S*

For the fermion behavior over the noncontractible sphere (NCS) through S*, we need to resort to more abstract reasoning, since no complete numerical or analytic solution has been obtained up till now.

First, consider massless Dirac fermions with *equal* gauge couplings for the right- and left-handed components. It has then been shown that there exist two fermion zero-modes of the four-dimensional Euclidean Dirac operator $i\not{D}_4$, one of each chirality, if the fermions are placed in the background of the constrained instanton I*.[42–44] [Note that a particular time slice through I* corresponds to the three-dimensional configuration of the S* sphaleron. For practical purposes, one may consider I* as a bound state of a BPST instanton I and an anti-instanton $\overline{\text{I}}$, just as the sphaleron S* may be viewed as a composite of a sphaleron S and an anti-sphaleron $\overline{\text{S}}$; see Eq. (4.18) and the lines below.]

Now the instanton I*, which depends on four Euclidean space–time coordinates, can be viewed as a path in configuration space which passes over the S* barrier. (In other words, this path is homotopic to a particular closed loop on the S*-NCS modulo gauge transformations; cf. Fig. 4.) The two zero-modes of $i\not{D}_4$ in the I* background, being time-dependent solutions of the Dirac equation (with imaginary time), can be calculated in the adiabatic approximation, where the state at time t is an eigenstate of the Dirac Hamiltonian with energy $E(t)$. The corresponding "phase factor" is given by

$$\exp\left(-\int_0^t \mathrm{d}t'\, E(t')\right). \tag{5.7}$$

From the normalizability of the zero-mode, it follows that $E(t)$ is positive for $t\to+\infty$ and negative for $t\to-\infty$.

With left- and right-handed chiralities, there are then two energy levels $E^{(1,2)}(t)$ crossing zero from below (these energy levels may, of course, be degenerate). In addition, there are two eigenvalues $E^{(3,4)}(t)$ which cross zero from above, so that the total spectral flow invariant is zero (note that the loop through S* over the NCS is contractible). For these last two eigenvalues, there are no zero-modes of $i\not{D}_4$ because the corresponding four-dimensional wave functions are not normalizable. Thus we have two pairs of levels which cross at zero energy, one left-handed pair and one right-handed pair. Returning to the Dirac Hamiltonian (5.6) with only left-handed fermions interacting with the SU(2) gauge fields, we have the spectral flow of the eigenvalues $E^{(1)}(t)$ and $E^{(3)}(t)$ as shown in Fig. 7.

Recently, numerical results[45] have been obtained for the eigenvalues of the $i\not{D}_4$ operator along a particular path over the I* barrier. It would be interesting to use similar methods to calculate the spectral flow related to S* and also to consider fermion representations other than isodoublet.

C. Spectral flow for the *Z*-string

Finally, we turn to the fermion behavior over the noncontractible sphere (NCS) with the Z-string at the top.[46] First, we choose a path on the NCS (4.21)–(4.24), which starts in the vacuum, passes over the Z-string and ends up in the vacuum.

To be concrete, we put $\nu=0$ in (4.21) and let μ run from $-\pi/2$ to $+\pi/2$. Such a loop is contractible and there is no net spectral flow to be expected (just as for the loop through S* considered in the previous subsection). What happens instead is that one negative eigenvalue $E^{(1)}(\mu,0)$ is raised from the negative continuous spectrum and one positive eigenvalue $E^{(2)}(\mu,0)$ is lowered from the positive continuous spectrum. Both eigenvalues meet at energy zero when the

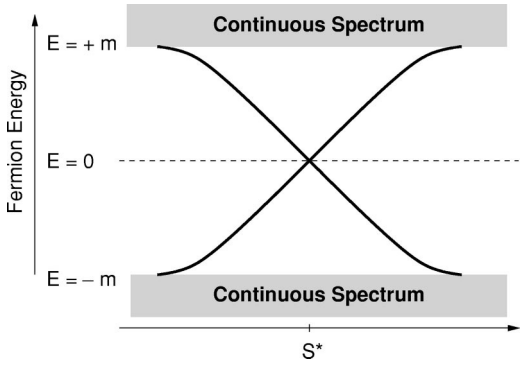

FIG. 7. Spectral flow for a path through the sphaleron S* (cf. Fig. 4).

background fields pass the Z-string configuration ($\mu=\nu=0$), cross and reach the opposite region of continuous eigenvalues (see the picture on the left in Fig. 8). The fermion zero-modes of the Z-string have been studied in Refs. 47 and 48.

We can also consider the behavior of the Dirac eigenvalues over the whole two-parameter family (4.22). Plotted over the (μ,ν)-square, the eigenvalues $E(\mu,\nu)$ form a double cone meeting at $\mu=\nu=0$ (see the picture on the right in Fig. 8).

VI. ANOMALIES

In this section, we review the relation between the sphalerons presented in Sec. IV and so-called anomalies. The connection between sphalerons and anomalies is precisely the spectral flow discussed in Sec. V.

A. Chiral anomaly and fermion number violation

The chiral U(1) anomaly, which turns out to be related to the sphaleron S, eliminates a rigid U(1) symmetry of the classical action, viz., chiral invariance. This anomaly can be found in theories with *massless* fermions, for which there is a classical Ward identity

$$\sum_f \left(\frac{\delta\Gamma_{\rm cl}}{\delta\Psi_f}\ \delta\Psi_f - \delta\bar{\Psi}_f\ \frac{\delta\Gamma_{\rm cl}}{\delta\bar{\Psi}_f} \right) = \partial^\mu j^5_\mu\,, \tag{6.1}$$

where $\Gamma_{\rm cl}$ is the classical action and $\Psi_f(x)$ denotes a Dirac fermion field, with f labeling the different flavors (fermion species). The rigid chiral transformation of the fermion fields is given by

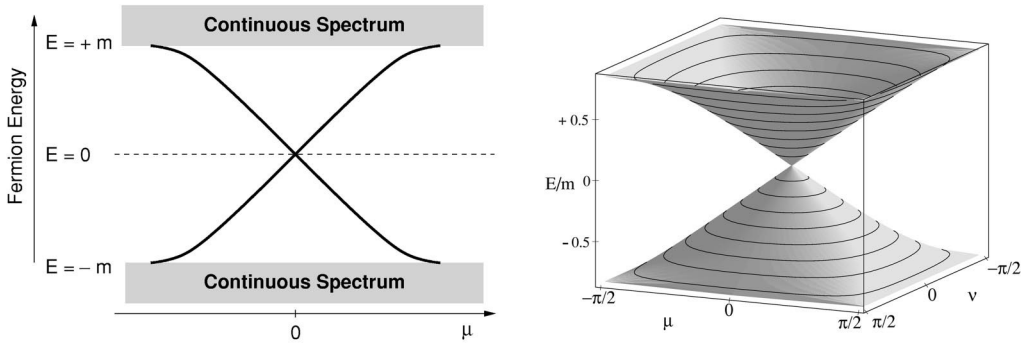

FIG. 8. Spectral flow over the noncontractible sphere (NCS) through the Z-string (cf. Fig. 5). In the picture on the left, the NCS parameter ν is held fixed at the value 0 and μ is varied. In the picture on the right, the Dirac eigenvalues are shown for the NCS patch $|\mu|,|\nu|\leqslant\pi/2$.

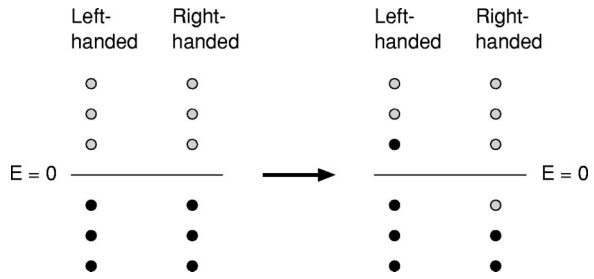

FIG. 9. Opposite spectral flow for left- and right-handed fermions, which leads to the creation of two units of chiral charge. Filled states are drawn black, empty states gray.

$$\delta\Psi_f(x) = \mathrm{i}\gamma_5\,\Psi_f(x)\,, \quad \delta\overline{\Psi}_f(x) = \overline{\Psi}_f(x)\,\mathrm{i}\gamma_5\,. \tag{6.2}$$

Since the left-hand side of (6.1) vanishes for solutions of the classical equations of motion, the current $j^5_\mu(x) \equiv \Sigma_f \overline{\Psi}_f(x)\,\gamma_5\gamma_\mu\Psi_f(x)$ is conserved classically. This implies that the chiral charge $Q_5 \equiv \int \mathrm{d}^3x\, j^5_0(x)$ does not change with time ($t \equiv x^0$),

$$\left.\frac{\mathrm{d}Q_5}{\mathrm{d}t}\right|_{\text{classical}} = 0\,. \tag{6.3}$$

Now suppose that the SU(2) gauge field couples equally to left- and right-handed fermions in the fundamental representation [as is the case for the SU(3) gauge field which is believed to be responsible for quark confinement in the standard model]. Then the spectral flow for a path over the sphaleron S with unit winding number is as shown in Fig. 9: for each isodoublet of fermions a left-handed state crosses zero from below and a right-handed one crosses zero from above. (Essentially the same type of spectral flow has been found[49] in the Schwinger model, i.e., two-dimensional quantum electrodynamics with a massless Dirac fermion.) In the Dirac-sea picture of the second-quantized vacuum, this means that a pair of fermions is created from an initial vacuum state, namely one chiral fermion and one chiral antiparticle corresponding to a hole in the Dirac sea of antichiral negative-energy states. Hence, the total chiral charge Q_5 *changes* by two units per isodoublet, which contradicts the classical conservation equation (6.3).

This result is supported by the Atiyah–Singer index theorem[39] for the four-dimensional chiral Dirac operator (see, e.g., Refs. 50–52). For N isodoublets, the relation between the change of chiral charge and the appropriate characteristic of the background gauge field is simply the integrated version of the perturbative Ward identity for the chiral current containing the Adler–Bell–Jackiw anomaly,[25,26]

$$\sum_{f=1}^{N}\left(\frac{\delta\Gamma}{\delta\Psi_f}\;\delta\Psi_f - \delta\overline{\Psi}_f\;\frac{\delta\Gamma}{\delta\overline{\Psi}_f}\right) = [\,\partial^\mu j^5_\mu\,]\cdot\Gamma + \frac{g^2N}{8\,\pi^2}\,[\,\mathrm{tr}\,\widetilde{F}_{\mu\nu}F^{\mu\nu}]\cdot\Gamma\,, \tag{6.4}$$

where Γ is now the fully quantized vertex functional and the dot denotes an operator insertion.

The anomalous term in Eq. (6.4) includes the Pontryagin density

$$q(x) \equiv -\frac{g^2}{16\,\pi^2}\,\mathrm{tr}\,\widetilde{F}_{\mu\nu}(x)\,F^{\mu\nu}(x)\,, \tag{6.5}$$

with $\widetilde{F}_{\mu\nu} \equiv \frac{1}{2}\epsilon_{\mu\nu\rho\sigma}F^{\rho\sigma}$. The integral of this density over the space–time manifold M is a *topological invariant* called the Pontryagin index,

$$Q \equiv \int_M \mathrm{d}^4x\;\; q(x)\,. \tag{6.6}$$

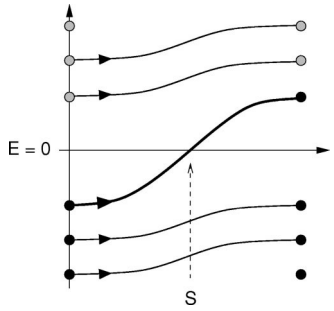

FIG. 10. Spectral flow in the electroweak standard model, where only left-handed fermions interact with the SU(2) gauge fields. S denotes the sphaleron, which has a single fermion zero-mode. The spectral flow leads to a change of fermion number between initial and final states (see text).

For compact space–time manifolds M, the Pontryagin index is an integer number and is also called the winding number or topological ''charge'' (hence, the notation Q).

Next, turn to the simplified version of the electroweak standard model, as described in Secs. II and V. Here, the fermion fields are fundamentally massless, even though they behave as massive particles in the Higgs vacuum. More importantly, the gauge field now couples only to the left-handed parts of the fermion fields; cf. Eqs. (5.1) and (5.2). Hence, the spectral flow for a single fermion flavor is made up of only one state which crosses zero from below. This implies that *fermion number conservation* is violated.[53,54] See Fig. 10 and compare with Fig. 9. (It is, of course, important to define carefully what is meant by ''the fermion number'' of a given state;[55–57] see also the discussion in the last three paragraphs of this subsection.)

The map U given in Sec. IV A essentially provides a map $S^3 \to S^3$, characterized by the topological charge $|Q|=1$. The above considerations can be generalized to other (integer) values of Q and to a model with N_{fam} families of quarks and leptons. The sum of baryon number B and lepton number L is then found to be nonconserved,[53]

$$\Delta(B-L)=0\,, \quad \Delta(B+L)=2\,N_{\text{fam}}\,Q\,, \tag{6.7}$$

where ΔB denotes the change of baryon number between initial and final states and similarly for ΔL.

As explained at the end of Sec. IV A, the NCL can be transformed into a path connecting two topologically distinct vacua in one-point-compactified three-space. The general form of such a vacuum is given by a static pure-gauge configuration,

$$g\,A=-\mathrm{d}\chi\,\chi^{-1}\,, \quad \Phi=\eta\,\chi\begin{pmatrix}0\\1\end{pmatrix}, \tag{6.8}$$

for a map $\chi:\mathbb{R}^3\to \mathrm{SU}(2)$ which approaches $\mathbb{1}_2$ at spatial infinity. The homotopy class to which χ belongs is characterized by the integer *Chern–Simons number*

$$N_{\mathrm{CS}}[\,\chi\,]=-\frac{1}{24\,\pi^2}\int \mathrm{d}^3x\;\epsilon^{klm}\;\mathrm{tr}\{(\partial_k\chi\,\chi^{-1})\,(\partial_l\chi\,\chi^{-1})\,(\partial_m\chi\,\chi^{-1})\}\,. \tag{6.9}$$

The topological charge Q of the map $\omega(\mu,r,\theta,\phi)$, as discussed in the last two paragraphs of Sec. IV A, is then the difference of the Chern–Simons numbers of the vacua at the start and end of the associated path,

$$Q=\Delta N_{\mathrm{CS}}\equiv N_{\mathrm{CS}}[\,\omega(\pi,r,\theta,\phi)\,]-N_{\mathrm{CS}}[\,\omega(0,r,\theta,\phi)\,]\,. \tag{6.10}$$

Of course, it is also possible to map the μ-interval $[0,\pi]$ on the time interval $[-\infty,+\infty]$.

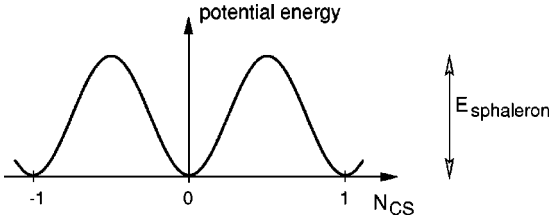

FIG. 11. Potential energy over a slice of configuration space, parametrized by the Chern–Simons number N_{CS}. The height of the energy barrier between topologically different vacua ($N_{\mathrm{CS}}=n\in\mathbb{Z}$) is set by the sphaleron S, which appears in different gauge copies ($N_{\mathrm{CS}}=\frac{1}{2}+n$, for $n\in\mathbb{Z}$). This figure essentially "unwraps" the loop of Fig. 3.

The sphaleron now corresponds to an energy barrier between these vacua, as sketched in Fig. 11. The transition between different vacua can, for example, take place by tunneling *through* the sphaleron barrier[53,54] or by passing *over* the barrier due to a thermal fluctuation of the fields.[5,58] Especially the latter mechanism is expected to contribute significantly to fermion-number-violating processes in the early universe (see, e.g., Refs. 9 and 10).

The rate of fermion-number-violating processes at relatively low energies ($E\ll E_{\mathrm{S}}\approx 10$ TeV) can be calculated from the Euclidean path integral.[54,59] But for a reliable discussion of these processes at high energies ($E\gtrsim E_{\mathrm{S}}$) it is advisable to remain in Minkowski space–time. The problem, then, is that the compactification of four-space which we used as the starting point of our topological considerations is not really physically sensible for Minkowski space–time. The topological charge Q, in particular, need not be an integer quantity in Minkowski space–time. The crucial point here is the role of *energy conservation* for background fields that solve the equations of motion; see, e.g., Ref. 60. The general question of which type of gauge field leads to nontrivial spectral flow remains unanswered for the moment.

There exists, however, a result for *strongly dissipative* SU(2) gauge fields.[55–57] In this case, the spectral flow is given by the difference in winding numbers of the asymptotic vacuum configurations for $t\to\pm\infty$. Roughly speaking, this coincides with the previous result in Euclidean space–time, namely Eq. (6.10) inserted into Eq. (6.7).

For the case of spherically symmetric fields, there is also a result for *generic* (i.e., nondissipative) gauge fields,

$$\Delta(B-L)=0\,,\quad \Delta(B+L)=2\,N_{\mathrm{fam}}\,(\Delta N_{\mathrm{winding}}+\Delta N_{\mathrm{twist}})\,\big|_{\mathrm{spher.\ symm.}}\,. \tag{6.11}$$

The change of $B+L$ is now determined by two integers. The first, $\Delta N_{\mathrm{winding}}$, again corresponds to Eq. (6.10). But the second, $\Delta N_{\mathrm{twist}}$, is an entirely new characteristic of spherically symmetric SU(2) gauge fields, which is related to the asymptotic behavior of the solutions of a (nonlinear) Riccati equation embedded in the (linear) zero-energy Dirac equation.[61] The integer $\Delta N_{\mathrm{twist}}$ is zero for strongly dissipative SU(2) gauge fields. See Ref. 62 for further discussion of the issues involved.

B. Witten's global gauge anomaly

The global SU(2) gauge anomaly, which turns out to be related to the sphaleron S*, differs from the case discussed in the previous subsection in that not just a symmetry of the theory is eliminated but the theory itself.

As mentioned in Sec. V B, the crossing of energy levels for paths over the S* barrier is related to the existence of two normalizable zero-modes of the four-dimensional Euclidean Dirac operator $i\not{D}_4$, one of each chirality. The noncontractible sphere of three-dimensional configurations can also be viewed as a noncontractible loop of four-dimensional configurations. Furthermore, as explained at the end of Sec. IV A, it is possible to pass from a *loop* of gauge field configurations in the radial gauge to a *path* of gauge field configurations without the radial gauge condition. The resulting path has topologically inequivalent vacua at the start and at the end.

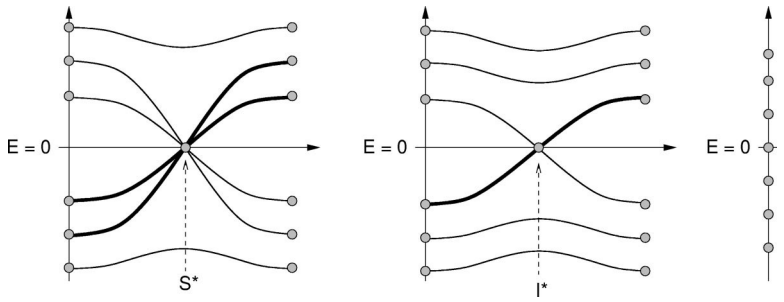

FIG. 12. Left: sketch of the eigenvalues of the Dirac Hamiltonian for a particular path over the S* noncontractible sphere (the theory considered has both left- and right-handed fermions interacting with the SU(2) gauge fields, which is not the case in Fig. 7). Middle: eigenvalues of $i\not{D}_4$ for the corresponding noncontractible loop through the constrained instanton I*. Right: eigenvalues of $i\not{D}_5$ for the corresponding five-dimensional configuration. Each path with an energy level crossing zero from below (thick line) corresponds to a normalizable fermion zero-mode one dimension higher. The sphaleron S* has four fermion zero-modes, the constrained instanton I* two, and the five-dimensional configuration one.

Now consider the change of eigenvalues of $i\not{D}_4$ along such a path. Since for one ''point'' of the path (i.e., the I*-configuration) there are known zero-modes,[44] it is to be expected that some level crossing is occurring also here.

That this is indeed the case has been shown in Ref. 31 by increasing the dimension once more. The one-parameter family of four-dimensional Dirac operators can also be considered as a single five-dimensional one. (In other words, the whole NCS serves as a single background configuration.) It then follows from the so-called mod-2 Atiyah-Singer index theorem[63] that the corresponding five-dimensional Dirac operator has a normalizable zero-mode. For $i\not{D}_4$, this implies that an eigenvalue is crossing zero from negative to positive values as the path is traversed. Simultaneously, there is a second eigenvalue which passes from positive to negative values. This discussion is summarized in Fig. 12, which also gives the corresponding spectral flow in three dimensions. (The mod-2 index theorem guarantees only an odd number of zero-modes for the five-dimensional configuration, but for simplicity we have assumed there is just one. See Ref. 45 for numerical results and further discussion.)

Witten also argued that the spectral flow of $i\not{D}_4$ leads to a global gauge anomaly.[31] In the Euclidean path integral of SU(2) Yang–Mills theory with a single isodoublet of Weyl fermions, there effectively appears a square root of the Dirac determinant,

$$\int \mathcal{D}A_\mu \quad \sqrt{\det i\not{D}_4} \quad \exp\left(\frac{1}{2} \int d^4x \ \mathrm{tr} F_{\mu\nu} F^{\mu\nu} \right), \tag{6.12}$$

if one recalls that two Weyl fermions of opposite chiralities make a single Dirac fermion.

The Dirac determinant in Eq. (6.12) depends on the background gauge fields $A_\mu(x)$ and its square root can be defined as the product of the positive eigenvalues [starting from a given gauge field configuration, say $A_\mu(x)=0$]. The above considerations then show that for a particular *continuous* variation of the gauge fields we end up with gauge fields, which are related to the starting configuration by a large gauge transformation and which have a $\sqrt{\det i\not{D}_4}$ of opposite sign (one positive eigenvalue having become negative; cf. the middle picture of Fig. 12). In the path integral, one has to integrate over all gauge fields (taking out the infinite factor due to gauge invariance afterwards). Hence, for every contribution $\sqrt{\det i\not{D}_4}$ there is also a contribution $-\sqrt{\det i\not{D}_4}$ arising from the gauge-transformed background fields. This implies that the path integral (6.12) vanishes.

More precisely, the path integral over the gauge fields is not well defined, because there is no satisfactory way to restrict the integration over the gauge fields so that a single Weyl isodoublet

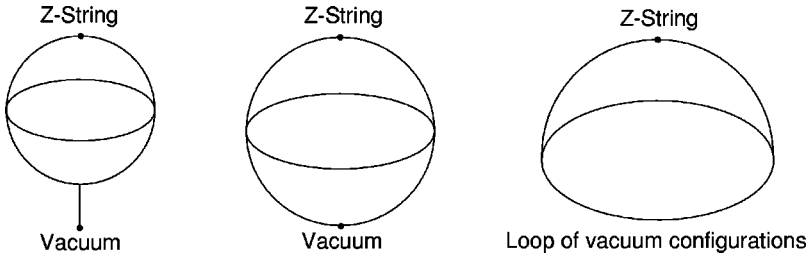

FIG. 13. Z-balloon, Z-sphere and Z-disc.

gives a continuous gauge-invariant contribution. This, then, is the Witten anomaly, which can also be proven without the mod-2 Atiyah–Singer index theorem but with the perturbative Bardeen anomaly instead.[64,65]

C. Z-string global gauge anomaly

Just as for the Witten anomaly and the S* sphaleron of the previous subsection, there exists a global gauge anomaly related to the Z-string sphaleron.[46] In order to explain this anomaly, we need a modified noncontractible sphere (NCS), obtained by continuous deformation of the balloon as given in Sec. IV C. This modification has the advantage of being a real sphere, that is, without degenerate points. The modified NCS still has one point corresponding to the vacuum and one point corresponding to the Z-string (see the picture in the middle of Fig. 13).

For the modified NCS, the z-independent SU(2) gauge field is in the polar gauge $A_\rho = 0$. But like the case of the sphalerons S and S*, it is possible to relax the polar gauge condition and to demand instead that the vacuum reached for $\rho \to \infty$ is the trivial one. Then one ends up with a disc of configurations with a loop of pure-gauge configurations on the boundary (see the picture on the right of Fig. 13). Considering the compactified radial coordinate ρ to be a polar angle θ, the fields are effectively defined on a sphere S^2. The loop of vacuum configurations on this two-sphere, restricted to the smash product $S^1 \wedge S^2$, corresponds to a nontrivial element of the homotopy group $\pi_3(S^3)$.

We keep this in mind for later and turn to the eigenvalues of the four-dimensional Euclidean Dirac operator $i\not{D}_4$, where the time-dependent background fields are taken to be paths over the Z-disc, with the start and end point (not necessarily the same) lying on the rim of vacuum configurations. For any such path passing through the Z-string, we know from Sec. V C that $i\not{D}_4$ has a single normalizable zero-mode corresponding to the eigenvalue of the Dirac Hamiltonian which crosses zero from below.

Now consider a particular family of operators $i\not{D}_4$ corresponding to a family of paths over the Z-disc, which starts from a constant path corresponding to a point on the rim of the disc, passes through a path via the Z-string, and ends up in a pure vacuum path formed by the boundary of the disc (see Fig. 14, where the Z-disc of Fig. 13 has been flattened). This family of four-dimensional Dirac operators sweeps over the whole Z-disc and we expect that there is spectral flow corresponding to the winding number of the underlying map $S^3 \to S^3$. In our case, this means that a single eigenvalue of $i\not{D}_4$ crosses zero. The zero crossing can be expected to occur for the path labeled (3) in Fig. 14.

Like the case of the Witten anomaly in Sec. VI B, this prevents us from defining the square root of the fermion determinant as a continuous gauge-invariant function of the bosonic background fields. Note that our path of four-dimensional configurations begins in a time-independent, topologically trivial vacuum and ends up in a gauge-transformed, time-dependent and topologically nontrivial one.

It is particularly interesting to see how this global gauge anomaly manifests itself in the space of time-independent fermion states. Since the Dirac Hamiltonian is a *real* Hermitian operator, we may choose real energy-eigenstates. Concretely, look at the one-dimensional subspace spanned by

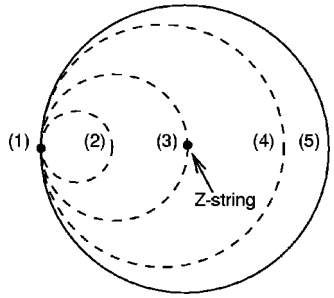

FIG. 14. Five closed loops on the Z-disc (cf. Fig. 13). Loop (1) corresponds to a single point on the boundary, loop (3) passes through the Z-string, and loop (5) consists of the whole boundary of the disc.

the eigenstate which crosses zero from below in the picture on the left in Fig. 8. For the background fields, we use an arbitrary loop on the Z-disc, which circumnavigates the Z-string exactly once and which is parametrized by $\alpha \in [0,2\pi]$. Then the energy eigenstate defines a *real* line bundle over S^1.

It has been shown in Ref. 46 that this bundle is, in fact, the Möbius bundle. A normalized eigenstate $|\Phi(0)\rangle$ transported around the loop ends up as $|\Phi(2\pi)\rangle = -|\Phi(0)\rangle$; see Fig. 15. The phase factor found is determined by the Berry phase for adiabatic transport.[66] The Berry phase π (mod 2π) is of topological origin and does not change under continuous deformation of the loop, as long as the loop of configurations does not touch the fermion degeneracy ''point'' corresponding to the Z-string. This observation also shows that the boundary of the Z-disc (Fig. 13) is a noncontractible loop of vacuum configurations, since the real Berry phase factor -1 on it cannot be continuously changed to $+1$.

The variation of the eigenstate along the rim of the Z-disc defines a projective action of the gauge group on the fermionic matter. There is then a global gauge anomaly, because it is impossible to define a real, continuous, and proper (i.e., nonprojective) representation of the local gauge group on the fermion states. Since the vacuum of quantum field theory is the Dirac sea with all negative-energy eigenstates filled, this also means that the second-quantized vacuum state acquires the Berry phase factor -1. See Sec. 6 of Ref. 46 for further discussion. (We take the opportunity to correct a slip of the pen. In the last sentence of Footnote 6 in Ref. 46, the words ''and vice versa'' must be deleted.)

A similar interpretation of the Witten anomaly in terms of a Berry phase has been given in Ref. 67. There is, however, a crucial difference between the Z-string global gauge anomaly and the Witten anomaly. For the Z-string anomaly, namely, there *does* exist a local counterterm in the action which restores gauge invariance, but at the price of violating Lorentz and CPT invariance.[68] More generally, if gauge invariance is enforced, there appears a new anomaly, the so-called CPT anomaly (see Refs. 69 and 70 for the main result and Ref. 71 for a review).

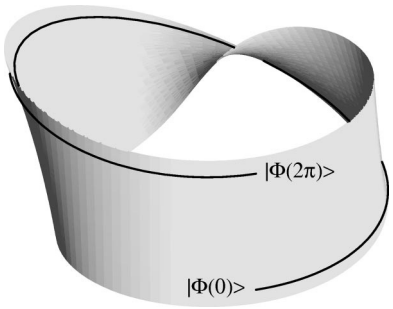

FIG. 15. Möbius bundle structure of the gauge orbit, with loop parameter $\alpha \in [0,2\pi]$. The line represents a normalized real eigenstate $|\Phi(\alpha)\rangle$ of the Dirac Hamiltonian, with $|\Phi(2\pi)\rangle = -|\Phi(0)\rangle$.

VII. CONCLUSION

The space of finite-energy three-dimensional field configurations of SU(2) Yang–Mills–Higgs theory (in short, configuration space) has nontrivial topology,[3,4] which leads to the existence of a new type of classical solutions, the so-called sphalerons. Sphalerons are unstable static finite-energy solutions of the classical field equations, whereas solitons are stable solutions.

In Sec. IV, we have explained the topology behind the S, S*, and Z-string sphalerons[5–7] of the SU(2) Yang–Mills–Higgs theory (2.1). Precisely this theory appears in the electroweak standard model of elementary particle interactions.[8] Knowledge of these classical solutions may, therefore, be of great importance to physics.

Adding chiral fermions to the SU(2) Yang–Mills–Higgs theory, the nontrivial topology of configuration space makes itself felt by the occurence of spectral flow,[32] as discussed in Sec. V. In turn, the general phenomenon of spectral flow is related to the possible existence of anomalies which invalidate certain properties of the classical theory, as discussed in Sec. VI.

The spectral flow over a noncontractible loop through the sphaleron S is related to the chiral U(1) anomaly,[25,26] which corresponds to a breakdown of baryon and lepton number conservation in the electroweak standard model.[53] The spectral flow through the S* and Z-string sphalerons does *not* lead to a global SU(2) gauge anomaly,[31,46] because the electroweak standard model has an *even* number of chiral isodoublets. Still, there is nontrivial spectral flow (more precisely, spectral rearrangement) over configuration space, but its physical implications remain to be clarified (cf. Refs. 44 and 69). Indeed, we need a better understanding of the role of configuration space topology in concrete physical problems, such as the behavior of elementary particle fields at high energies or temperatures.

(Received 28 November 2002; accepted 9 April 2003)

We examine the low-energy dynamics of four-dimensional supersymmetric gauge theories and calculate the values of the gluino condensate for all simple gauge groups. By initially compactifying the theory on a cylinder we are able to perform calculations in a controlled weakly coupled way for a small radius. The dominant contributions to the path integral on the cylinder arise from magnetic monopoles which play the role of instanton constituents. We find that the semi-classically generated superpotential of the theory is the affine Toda potential for an associated twisted affine algebra. We determine the supersymmetric vacua and calculate the values of the gluino condensate. The number of supersymmetric vacua is equal to c_2, the dual Coxeter number, and in each vacuum the monopoles carry a fraction $1/c_2$ of topological charge. As the results are independent of the radius of the circle, they are also valid in the strong coupling regime where the theory becomes decompactified. For gauge groups SU(N), SO(N) and USp($2N$) our results for the gluino condensate are in precise agreement with the ''weak coupling instanton'' expressions (and not with the ''strong coupling instanton'' calculations). For the exceptional gauge groups we calculate the values of the gluino condensate for the first time. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1586477]

I. INTRODUCTION AND SUMMARY OF RESULTS

The goal of this article is to provide new calculations of the values of the gluino condensate $\langle \mathrm{tr}\,\lambda^2 \rangle$ in four-dimensional $\mathcal{N}=1$ supersymmetric Yang-Mills theory for all the simple gauge groups. Our approach is based on the idea[1] that when the space-time is partially compactified on the cylinder $\mathbb{R}^3 \times S^1$, magnetic monopoles play the role of instanton constituents, directly contribute to the path integral and completely determine the values of the gluino condensate. Our results for the gluino condensate are summarized in Table I and a universal formula in terms of Lie algebra data is given in (56). For classical gauge groups our results are in precise agreement with the known expressions derived in the ''weak-coupling instanton'' approach in Refs. 2–5. For the exceptional gauge groups the condensates are calculated for the first time.

It is somewhat of a miracle that some features of gauge theories which have supersymmetry can be understood exactly. Sometimes this success arises from viewing these theories as being embedded in string theory, a classical example being the duality of Maldacena.[6] Generally, however, we can make use of the fact that supersymmetry leads to very restrictive Ward identities, giving rise to powerful holomorphy properties (see the review in Ref. 7). Regarding this later point, the full functional form of certain correlators is fixed up to an overall constant. Sometimes these correlators have a dependence on the couplings which can be identified with specific gauge theory configurations, in particular with instantons, but in other cases this is not so.[8] In the former case, it is tempting to suppose that a semi-classical instanton calculation will yield the value of the correlator. In particular, we have in mind multi-point functions of the gluino operator $\mathrm{tr}\,\lambda^2$ in $\mathcal{N}=1$ supersymmetric gauge theory. It is our thesis that one must be very careful in applying a semi-classical analysis to a strongly-coupled theory and such calculations will only be correct if

TABLE I. The values of the gluino condensate in the Pauli-Villars scheme (2).

Gauge group	$\langle \mathrm{tr}\,\lambda^2\rangle/(\Lambda^3 16\pi^2)$
SU(N)	1
SO(N)	$2^{4/(N-2)-1}$
USp($2N$)	$2^{1-2/(N+1)}$
G_2	$2^{-1/2}3^{1/4}$
F_4	$2^{-1/9}3^{-1/3}$
E_6	$2^{-1/2}3^{-1/4}$
E_7	$2^{-7/9}3^{-1/3}$
E_8	$2^{-13/15}3^{-2/5}5^{-1/6}$

they are performed in a weakly-coupled phase, where semi-classical methods are rigorously justified. It is then possible to infer the value of the correlator in a strongly-coupled phase, if that phase is continuously connected to the weakly-coupled phase by using holomorphicity. It was the misuse of a semi-classical analysis directly in a strongly-coupled phase that led to the gluino condensate puzzle.

This famous puzzle is the inconsistency between two conceptually different approaches followed in the early literature of calculating the gluino condensate in pure $\mathcal{N}=1$ supersymmetric gauge theory. In the first methodology[9–11]—and in the present context the ''suspect'' method, because it involves a semi-classical analysis directly in the strongly-coupled confining phase of the gauge theory—the so-called strong-coupling instanton (SCI) approach, the gluino condensate $\langle \mathrm{tr}\,\lambda^2\rangle$ is determined via an explicit one-instanton calculation of a certain multi-point function of $\mathrm{tr}\,\lambda^2$. Cluster decomposition arguments are then invoked in order to extract the one-point function $\langle \mathrm{tr}\,\lambda^2\rangle$. In the second methodology,[2] the so-called weak-coupling instanton (WCI) approach—and for us the safe method—the calculation is performed with additional matter fields whose presence ensures that the non-Abelian gauge group is broken and the theory is in a weakly-coupled Higgs phase and a ''constrained instanton'' calculation is justified.[12] Holomorphicity is then used to decouple the matter fields and to flow continuously to the confining phase of the original gauge theory. As is well known, these two methods give two different values for the gluino condensate:[2,13,11,5]

$$\left\langle \frac{\mathrm{tr}\,\lambda^2}{16\pi^2}\right\rangle_{\mathrm{SU}(N)} = \begin{cases} \dfrac{2}{[(N-1)!(3N-1)]^{1/N}}\Lambda^3 & \text{SCI,} \\ \Lambda^3 & \text{WCI.} \end{cases} \tag{1}$$

[These results are quoted for an SU(N) gauge theory in the Pauli-Villars scheme with Λ being the corresponding dimensional transmutation scale of the theory defined in Eq. (2) below.] The reason for the discrepancy between the SCI and WCI calculations, as well as the question as to which is correct, has been a long-standing controversy.[2,11,14,15] This controversy was reexamined in Ref. 16 using recently developed multi-instanton methods,[17,18] for a comprehensive review see Ref. 19. By evaluating the k-instanton contribution to gluino correlation functions in the large number of colors limit it was shown that an essential step in the SCI calculation of the gluino condensate, namely the use of cluster decomposition in the instanton sector, is actually invalid. The central idea pursued in Ref. 1 and in the present paper is that there are additional configurations which contribute to the gluino condensate implying that the SCI calculation only gives part of the answer. The existence of other contributions to multi-point correlators of $\mathrm{tr}\,\lambda^2$, which are non-instantonic invalidates the application of cluster decomposition to a purely instantonic contribution.

In Ref. 1 we provided an alternative way to deform the theory in order to connect the confining phase continuously to a weak-coupled phase: in this case a Coulomb rather than a Higgs phase. The idea is to consider the theory partially compactified on the cylinder $\mathbb{R}^3\times S^1$. In this scenario, the gauge field can have a non-trivial Wilson loop around the circle which acts like an

adjoint-valued Higgs field breaking the gauge group to its maximal Abelian subgroup and so the theory is in a Coulomb phase. For small enough radius, the resulting theory is arbitrarily weakly coupled and the gluino condensate can be reliably calculated. It is then argued, based on the usual argument of holomorphy, that the result is actually independent of the radius and is therefore easily extrapolated to the confining phase where the radius goes to infinity and the theory becomes decompactified.

However, there is a significant bonus in this scenario: the additional configurations missing in the instanton calculation can explicitly be identified at small radius with BPS monopoles in the gauge theory with the component of the gauge field around the circle playing the role of a Higgs field. However, we should point out that this in no way means that BPS monopoles quantitatively describe the physics in the decompactification limit. In this scenario, the one-point function $\langle \mathrm{tr}\,\lambda^2\rangle$ directly receives a semi-classical contribution from single monopoles, unlike the SCI situation in $\mathbb{R}^4$, where, as described above, only multi-functions receive contributions. (There are precisely 2 gluino zero modes in the single-monopole background. These are supersymmetric fermion zero modes of the monopole. In distinction with instanton configurations on $\mathbb{R}^4$, there are no, e.g., superconformal gluino zero modes in the monopole background. In fact, classical conformal invariance of the theory is explicitly broken by the compactification on the cylinder.) The monopoles consequently carry fractional topological charge. Hence, the theory on the cylinder uncovers a very pleasing picture of instanton constituents, or instanton partons, that were argued to play an important role in confinement of ordinary QCD.[20–24] The fact that an instanton configuration on the cylinder is actually a composite of fundamental monopoles has been the subject of number of earlier works.[25–30] These generalize the notion of a periodic instanton, or "caloron,"[31–33] to the case when the gauge field has a non-trivial Wilson line around the circle. It is only in this case that the instanton constituents can be pulled apart and identified with monopoles. It turns out that in ordinary QCD the Wilson line of the gauge field around the circle is energetically favored to vanish: in this case the monopoles have no role to play in the physics. On the contrary, as we shall explicitly show, in $\mathcal{N}=1$ supersymmetric gauge theories, a non-trivial superpotential is generated by the monopoles whose supersymmetric vacua have a non-trivial value for the Wilson line and hence monopole effects are important. Other recent references which consider supersymmetric gauge theories on a cylinder and monopole effects are to be found in Refs. 34–36.

In $\mathcal{N}=1$ supersymmetric gauge theories, the first coefficient of the β-function is $b_0=3c_2$, where c_2 is the dual Coxeter number of the gauge group listed in the table in Appendix A. We will use a definition of the dynamical scale Λ in the Pauli–Villars renormalization scheme via the RG-invariant exact relation

$$\Lambda^3=\mu^3\frac{1}{g^2(\mu)}\exp\frac{2\pi i\tau(\mu)}{c_2}. \tag{2}$$

[If one chooses to use instead another exact definition of Λ,[15] more in line with standard QCD conventions, $\tilde{\Lambda}^3=(\mu^3 16\pi^2/3c_2g^2)\exp(-8\pi^2/c_2g^2)$, then the values of the gluino condensate in Table I have to be adjusted accordingly.] Here μ is the Pauli–Villars regulator mass and τ is the usual complexified coupling incorporating both the gauge coupling constant g and the theta angle ϑ:

$$\tau=\frac{\vartheta}{2\pi}+\frac{4\pi i}{g^2}\,. \tag{3}$$

The article is organized in the following way. In Sec. II we consider, in general terms, the effect of compactifying the $\mathcal{N}=1$ gauge theory on $\mathbb{R}^3\times S^1$. In Sec. III we discuss the various semi-classical configurations that can contribute to the functional integral and explain the relation between monopoles and instantons on the cylinder. Regarding this point, our considerations in this article are purely field-theoretical; for an elegant D-brane discussion of the SU(N) dynamics on $\mathbb{R}^3\times S^1$ see Refs. 1 and 25. In Sec. IV we derive the form of the superpotential in the low energy

TABLE II. The associated affine algebra.

Gauge group	Lie algebra	Affine Toda potential
G(Simply-laced)	g	$g^{(1)}$
SO($2r+1$)	b_r	$a^{(2)}_{2r-1}$
USp($2r$)	c_r	$d^{(2)}_{r+1}$
G_2	g_2	$d^{(3)}_4$
F_4	f_4	$e^{(2)}_6$

effective three-dimensional theory generated by monopoles (46). It turns out that this potential is precisely the affine Toda potential for a specific affine algebra. For the simply-laced cases the affine algebra is the untwisted affinization of the Lie algebra of the gauge group while for the non-simply-laced cases it is affine algebra whose Kac–Dynkin diagram is obtained from the untwisted affine diagram with long roots changed to short roots, and vice versa. The affine algebras (in Kac's notation[37]) are listed in Table II. The Toda potential is in complete agreement with M(F)-theory considerations,[38–40] although we will find some additional prefactors that feed into the calculation of the gluino condensate in an essential way. From the superpotential, we find that the number of supersymmetric vacua is equal to dual Coxeter number of the gauge group in complete agreement with the Witten index.[41] The values of the gluino condensate in each vacuum are then found and the results are summarized in Table I. For all classical groups these are in agreement with the WCI results of Refs. 2–5. In Appendix A we summarize our Lie algebra conventions and Appendix B contains a brief discussion of the measure needed for integrating over the collective coordinate space of fundamental monopoles.

II. $\mathcal{N}=1$ GAUGE THEORY ON THE CYLINDER

In this section, we consider the effect of compactifying the pure $\mathcal{N}=1$ gauge theory on a cylinder of radius R. To this end, let us take x_0 to be periodic with period $2\pi R$. We then impose periodic boundary conditions on the gauge field and gluino:

$$v_m(x_\mu,x_0)=v_m(x_\mu,x_0+2\pi R),\quad \lambda(x_\mu,x_0)=\lambda(x_\mu,x_0+2\pi R). \tag{4}$$

(In our notation the four-dimensional indices run over $m,n,\ldots=0,1,2,3$ while our three-dimensional indices run over $\mu,\nu,\ldots=1,2,3$.) Notice that the periodicity of the fermions preserves supersymmetry.

Smooth finite-action gauge fields on the cylinder were classified in Ref. 33. In particular, at finite radius instanton configurations do not exhaust the set of semi-classical contributions. The complete set of semi-classical configurations is characterized by three pieces of data. First, there is a topological or instanton charge (or second Chern class) generalized from $\mathbb{R}^4$ to the cylinder:

$$k=\frac{1}{16\pi^2}\int_{\mathbb{R}^3\times S^1} d^4x\ \ \mathrm{tr}\, v_{mn}{}^*v^{mn}. \tag{5}$$

An important feature of the cylinder is that k is not quantized in integer units. However, when k is an integer there are solutions with action $S=8\pi^2k/g^2-ik\vartheta$ that, for scale size much smaller than R, are identifiable as instantons of the uncompactified theory. The second piece of data involves the Wilson loop of the gauge field around the circle:

$$\oint_{S^1} dx_m\, v_m=\int_0^{2\pi R} dx_0\, v_0\equiv\varphi. \tag{6}$$

We will then define the VEV of φ as the asymptotic value at spatial infinity in $\mathbb{R}^3$:

$$\langle \varphi \rangle = \lim_{|x_\mu| \to \infty} \boldsymbol{\varphi} \cdot \mathbf{H}, \tag{7}$$

where we have fixed a portion of the global gauge symmetry by choosing the Wilson loop (7) to lie within the Cartan subalgebra of the Lie algebra g associated to the gauge group G. (Our Lie algebra conventions are summarized in Appendix A. We will denote $r = \operatorname{rank} G$ vectors in boldface.) This still leaves the freedom to perform global gauge transformations from the Weyl group W_g of G.

A nonzero value for $\langle \varphi \rangle$ acts as an adjoint-valued Higgs field that generically breaks the gauge group to its maximal Abelian subalgebra $\mathrm{U}(1)^r$. The classical moduli space $\mathcal{M}_{\mathrm{cl}}$, parametrized by the vector $\langle \boldsymbol{\varphi} \rangle$, is the quotient

$$\mathcal{M}_{\mathrm{cl}} = \frac{\mathbb{R}^r}{2\pi \cdot \Lambda_W^* \rtimes W_g}, \tag{8}$$

where Λ_W^* is the co-weight lattice. The form of the quotient is explained in the following way: we have already noted that fixing $\langle \varphi \rangle$ to be in the Cartan subalgebra leaves the freedom to perform global gauge transformations in the Weyl group. On top of this, theories with $\langle \boldsymbol{\varphi} \rangle$ differing by 2π times any co-weight vector are equivalent. To see this last point, consider the following topologically nontrivial gauge transformation

$$U(x_0) = \exp\left(\frac{i x_0}{R} \boldsymbol{\omega}^* \cdot \mathbf{H} \right), \tag{9}$$

for any co-weight $\boldsymbol{\omega}^* \in \Lambda_W^*$. This transforms the component of the gauge field around the circle as $v_0 \to v_0 + \boldsymbol{\omega}^* \cdot \mathbf{H}/R$, and hence $\langle \boldsymbol{\varphi} \rangle \to \langle \boldsymbol{\varphi} \rangle + 2\pi \boldsymbol{\omega}^*$. The transformation (9) is periodic in the adjoint representation of the gauge group and consequently in the pure gauge theory where all fields are adjoint-valued $\langle \boldsymbol{\varphi} \rangle$ is identified with $\langle \boldsymbol{\varphi} \rangle + 2\pi \boldsymbol{\omega}^*$. (Because $\boldsymbol{\alpha} \cdot \boldsymbol{\omega}^* \in \mathbb{Z}$ for *any* root $\boldsymbol{\alpha}$ and co-weight $\boldsymbol{\omega}^*$.)

We will find it convenient to choose the VEV $\langle \boldsymbol{\varphi} \rangle$ to lie in a "fundamental cell"

$$0 \leqslant \langle \boldsymbol{\varphi} \rangle \cdot \boldsymbol{\alpha}_i < 2\pi \quad , \quad i = 1, \ldots, r, \tag{10}$$

where $\boldsymbol{\alpha}_i$ are the simple roots of g. [Notice that this region is still an over-parametrization of the quotient (8).] The regions where $\langle \boldsymbol{\varphi} \rangle \cdot \boldsymbol{\alpha}_i = 0$, for some set of i's, correspond to submanifolds of $\mathcal{M}_{\mathrm{cl}}$ where a non-Abelian subgroup of the gauge symmetry is restored.

The final piece of data arises from the fact that finite action configurations can also carry three-dimensional magnetic charge. This is an r-vector-valued quantity $\mathbf{g}$ in the charge space of the unbroken $\mathrm{U}(1)^r$ Abelian symmetry that can be defined via a surface integral over the two-sphere at spatial infinity in $\mathbb{R}^3$ of the magnetic field $B_\mu = \frac{1}{2} \epsilon_{\mu\nu\rho} v_{\nu\rho}$:

$$-\frac{1}{2\pi} \int_{S^2} dS_\mu B_\mu \equiv \mathbf{g} \cdot \mathbf{H}. \tag{11}$$

The magnetic charge is subject to the usual generalization of the Dirac quantization rule[42,43] which requires that

$$\mathbf{g} \in \Lambda_R^*, \tag{12}$$

the co-root lattice of g.

Classically, the Wilson loop $\langle \boldsymbol{\varphi} \rangle$ is not determined and, so, as we have explained, there is a moduli space $\mathcal{M}_{\mathrm{cl}}$ of inequivalent theories. An important question is whether this classical degeneracy persists in the quantum theory. At this point, the behavior depends crucially on whether one has periodic or anti-periodic boundary conditions on the fermions. In the latter—thermal—case,

Ref. 33 argued that nontrivial values of the asymptotic Wilson loop (7) are suppressed in the infinite volume limit. Consequently, the classically flat directions are lifted by thermal quantum corrections and the true vacuum of the theory is $\langle \boldsymbol{\varphi} \rangle = 0$. In this case, the configurations with magnetic charges are not relevant, since they require nonvanishing VEV, and the semi-classical physics is described by instantons only. Remarkably, for the theory on the cylinder, with periodic boundary conditions on the fermions, the argument of Ref. 33 does not apply and, as we shall see in the following sections, the opposite scenario ensues; namely, the following.

(i) The semi-classical physics of the theory on the cylinder is described by configurations of BPS monopoles. There are $r+1$ types of ''fundamental'' monopole which carry only four bosonic and two (adjoint) fermionic zero modes. To those who are sufficiently initiated into monopole calculus in gauge theories with arbitrary gauge group, this will be a surprise: one would expected to have only r such monopoles (each with a magnetic charge equal to one of the r simple roots). The additional monopole, needed to make up the full complement of $r+1$ types, is specific to the compactification on the cylinder since, unlike the other, it is a nontrivial function of ''time'' x_0.[25,26,29,30] The magnetic charge of the new monopole is such that when all $r+1$ types of monopoles are present with a specific degeneracy, the magnetic charges cancel and the resulting configuration carries only a unit of instanton charge. Hence, remarkably, instantons on the cylinder can be understood as composite configurations of monopoles.[25–30]

(ii) The classical moduli space of the gauge theory on the cylinder (6) is lifted in the quantum theory in a nontrivial way. The quantum vacua correspond to a single point in $\mathcal{M}_{\rm cl}$ cell along with an additional c_2-fold degeneracy, which has no counterpart in the classical theory, and corresponds precisely to the expectations based on a refined Witten index[41] and the WCI counting.[44,4]

III. SEMI-CLASSICAL CONFIGURATIONS

In the weak-coupling limit, the path integral is dominated by field configurations which are of minimal action in each topological sector. These configurations satisfy the four-dimensional self-dual, or anti-self-dual, equations $v_{mn} = \pm {}^*v_{mn}$. As we have explained there are two quantum numbers carried by semi-classical configurations: the topological charge and the magnetic charge.

First of all, let us consider solutions which are independent of the coordinate around the circle x_0. These are simply BPS monopoles in the three-dimensional theory[45–48] with the time direction taken to be along x_0. Monopole solutions in a gauge theory with a simple gauge group G can in turn be constructed out of the SU(2) BPS monopole in the following way.[43] The idea is to take a regular embedding $\mathrm{SU}(2) \subset G$, associated to a positive root $\boldsymbol{\alpha}$ of G:

$$\tau^1 = \frac{1}{2}(E_\alpha + E_{-\alpha}), \quad \tau^2 = \frac{1}{2i}(E_\alpha - E_{-\alpha}), \quad \tau^3 = \frac{1}{2}\boldsymbol{\alpha}^* \cdot \mathbf{H}, \tag{13}$$

which obey the SU(2) algebra

$$[\tau^a, \tau^b] = i\epsilon_{abc}\tau^c. \tag{14}$$

(Here, $\boldsymbol{\alpha}^* = 2\boldsymbol{\alpha}/\boldsymbol{\alpha}^2$ is the co-root associated to $\boldsymbol{\alpha}$.) The monopole solution is then

$$v_0(x_\nu) = \Phi^c(v; x_\nu)\tau^c + \frac{1}{2\pi R}\left(\langle \boldsymbol{\varphi} \rangle - \frac{1}{2}(\langle \boldsymbol{\varphi} \rangle \cdot \boldsymbol{\alpha})\boldsymbol{\alpha}^*\right) \cdot \mathbf{H}, \quad v_\mu(x_\nu) = v_\mu^c(v; x_\nu)\tau^c, \tag{15}$$

where $\Phi^c(v; x_\nu)$ is the Higgs field and $v_\mu^c(v; x_\nu)$ are the spatial components of the gauge field (in the gauge $v_0 = 0$) of the SU(2) BPS monopole. The long distance behavior of this solution is

$$\lim_{|x_\mu| \to \infty} \Phi^c(v; x_\nu)\tau^c = \frac{v}{2}\boldsymbol{\alpha}^* \cdot \mathbf{H}, \tag{16}$$

where

$$v = \frac{\boldsymbol{\alpha}\cdot\langle\boldsymbol{\varphi}\rangle}{2\pi R}. \tag{17}$$

For this solution to be well defined, we must have $v>0$, which is automatic if $\boldsymbol{\alpha}$ is a positive root and $\langle\boldsymbol{\varphi}\rangle$ lies in the fundamental cell (10), in which case it has magnetic charge, topological charge and action given by

$$\mathbf{g}=\boldsymbol{\alpha}^*, \quad k=\boldsymbol{\alpha}^*\cdot\frac{\langle\boldsymbol{\varphi}\rangle}{2\pi}, \quad S=\frac{4\pi}{g^2}\,\boldsymbol{\alpha}^*\cdot\langle\boldsymbol{\varphi}\rangle. \tag{18}$$

For completeness, we give the explicit solution for the SU(2) BPS monopole in ''hedgehog'' gauge,

$$v^c_\mu(v;x_\nu)=\epsilon_{\mu\nu c}\frac{x_\nu}{|x|^2}\left(1-\frac{v|x|}{\sinh v|x|}\right), \tag{19a}$$

$$\Phi^c(v;x_\nu)=\frac{x_c}{|x|^2}(v|x|\coth v|x|-1). \tag{19b}$$

The asymptotic value of the magnetic field of the hedgehog solution, as $|x|\to\infty$, is

$$B^c_\mu\to-\frac{x_\mu x^c}{|x|^4}, \tag{20}$$

while in unitary gauge

$$B^c_\mu\to-\frac{x_\mu}{|x|^3}\,\delta^{c3}, \quad B_\mu\equiv B^c_\mu\tau^c\to-\frac{x_\mu}{2|x|^3}\,\boldsymbol{\alpha}^*\cdot H. \tag{21}$$

However, these x_0-independent solutions do not exhaust the set of solutions with a given magnetic charge $\boldsymbol{\alpha}^*$.[25] A whole tower of other solutions which *are* x_0 dependent can be generated in the following way. First of all, we start with the solution (15) with $\langle\boldsymbol{\varphi}\rangle$ lying in the fundamental cell (10). We then write down the same solution with a shifted VEV $\langle\boldsymbol{\varphi}'\rangle=\langle\boldsymbol{\varphi}\rangle+\pi n\boldsymbol{\alpha}^*$, where $n\in\mathbb{Z}$. For this solution to be well defined we must have

$$v'=\frac{\boldsymbol{\alpha}\cdot\langle\boldsymbol{\varphi}'\rangle}{2\pi R}=\frac{\boldsymbol{\alpha}\cdot\langle\boldsymbol{\varphi}\rangle}{2\pi R}+\frac{n}{R}>0\,. \tag{22}$$

For $\boldsymbol{\alpha}=\boldsymbol{\alpha}_i$, a simple root, (10) implies that $n\geqslant 0$. Acting on the solution with the (nonperiodic) gauge transformation,

$$V_n(x_0)=\exp\left(\frac{inx_0}{2R}\,\boldsymbol{\alpha}^*\cdot\mathbf{H}\right), \tag{23}$$

has the effect of restoring the VEV $\langle\boldsymbol{\varphi}\rangle$ to its original value. The new solution is then given by

$$\begin{aligned} v_0(x_\nu)&=\Phi^c(v+n/R;x_\nu)\tilde{\tau}^c+\frac{1}{2\pi R}\left(\langle\boldsymbol{\varphi}\rangle-\frac{1}{2}(\langle\boldsymbol{\varphi}\rangle\cdot\boldsymbol{\alpha}+2\pi n)\,\boldsymbol{\alpha}^*\right)\cdot\mathbf{H},\\ v_\mu(x_\nu)&=v^c_\mu(v+n/R;x_\nu)\tilde{\tau}^c, \end{aligned} \tag{24}$$

where v is given as in (17) and the SU(2) generators are conjugated with $V_n(x_0)$:

$$\tilde{\tau}^c = V_n(x_0)\tau^c V_n(x_0)^{-1}. \tag{25}$$

Notice although $V_n(x_0)$ is not a periodic gauge transformation the generators $\tilde{\tau}^c$ *are* periodic functions of x_0. The solution (24) has the same magnetic charge as (15), but the topological charge is $k=\boldsymbol{\alpha}^*\cdot\langle\boldsymbol{\varphi}\rangle/2\pi+n$. This solution can be interpreted as a composite configuration of the original monopole plus an instanton of charge n.

However, there are also towers of solutions of the self-dual equations that have a magnetic charge equal to some *negative* root.[25] We should emphasize that these solutions are *not* anti-monopoles which would satisfy the *anti*-self-dual equations. To construct these solutions we can start with our solution (15) with $\langle\boldsymbol{\varphi}\rangle$ lying in the fundamental cell. We now define a new solution with a VEV $\langle\boldsymbol{\varphi}'\rangle=\kappa_{\boldsymbol{\alpha}}(\langle\boldsymbol{\varphi}\rangle)+\pi n\boldsymbol{\alpha}^*$, where $\kappa_{\boldsymbol{\alpha}}$ is the Weyl reflection in $\boldsymbol{\alpha}$. For the solution to be well defined we must have

$$v'=\frac{\boldsymbol{\alpha}\cdot\langle\boldsymbol{\varphi}'\rangle}{2\pi R}=-\frac{\boldsymbol{\alpha}\cdot\langle\boldsymbol{\varphi}\rangle}{2\pi R}+\frac{n}{R}>0. \tag{26}$$

For $\boldsymbol{\alpha}=\boldsymbol{\alpha}_i$, a simple root, this means $n>0$. To reinstall the original VEV, we then perform a Weyl reflection in $\boldsymbol{\alpha}$ and the gauge transformation (23). The resulting solution is

$$\begin{aligned} v_0(x_\nu)&=\Phi^c(n/R-v;x_\nu)\tilde{\tau}^c+\frac{1}{2\pi R}\left(\langle\boldsymbol{\varphi}\rangle-\frac{1}{2}(-\langle\boldsymbol{\varphi}\rangle\cdot\boldsymbol{\alpha}+2\pi n)\boldsymbol{\alpha}^*\right)\cdot\mathbf{H},\\ v_\mu(x_\nu)&=v_\mu^c(n/R-v;x_\nu)\tilde{\tau}^c, \end{aligned} \tag{27}$$

where v is given in (17) and the SU(2) generators are now conjugated with $V_n(x_0)\kappa_{\boldsymbol{\alpha}}$:

$$\tilde{\tau}^c=V_n(x_0)\kappa_{\boldsymbol{\alpha}}\tau^c\kappa_{\boldsymbol{\alpha}}V_n(x_0)^{-1}. \tag{28}$$

It can be easily verified that this solution is again periodic in x_0. The resulting solution has magnetic charge $-\boldsymbol{\alpha}^*$ and topological charge $k=-\boldsymbol{\alpha}^*\cdot\langle\boldsymbol{\varphi}\rangle/2\pi+n$.

It will be important for later to determine the number of adjoint fermion, or gluino, zero modes of these monopole solutions. Each classical solution has at least two adjoint fermion zero modes protected by supersymmetry. These modes can be generated from the purely bosonic solution by acting with the generators of supersymmetry that do not leave the configuration invariant. This gives the universal expression for these supersymmetric modes

$$\lambda_\alpha=\sigma_\alpha^{mn\beta}\xi_\beta v_{mn}, \tag{29}$$

where v_{mn} is the field strength. For future reference we give the long-distance behavior of the supersymmetric fermion zero modes (29) of our fundamental monopole solutions (15) and (27) with $n=1$:

$$\lambda_\alpha=\sigma_\alpha^{mn\beta}\xi_\beta v_{mn}=-2(\sigma^\nu\xi)_\alpha B_\nu\to 4\pi(\mathcal{S}_{\mathrm{F}}\xi)_\alpha\boldsymbol{\alpha}^*\cdot\mathbf{H}, \tag{30}$$

where $\mathcal{S}_{\mathrm{F}}(x)=\sigma_\mu x_\mu/(4\pi|x_\mu|^3)$ is the massless fermion propagator in three dimensions.

Solutions with only the supersymmetric zero modes have four associated bosonic zero modes which correspond to moving the center-of-mass of the monopole in $\mathbb{R}^3$ as well as performing global gauge rotations by $\exp((i/2)\,\Omega\,\boldsymbol{\alpha}^*\cdot\mathbf{H})$. Hence these solutions are special in that they are elementary or ''fundamental'': the other solutions have additional moduli that correspond to pulling the configuration apart into their fundamental constituents.

As might have been expected there are r solutions of the form (15) where $\boldsymbol{\alpha}$ is a simple root $\boldsymbol{\alpha}_i$ lying at the bottom of the more general tower of solutions (24). This gives us $i=1,\ldots,r$ fundamental monopole solutions with two adjoint-valued fermion zero modes, magnetic charge $\boldsymbol{\alpha}_i^*$, and the topological charge $k=\boldsymbol{\alpha}_i^*\cdot\langle\boldsymbol{\varphi}\rangle/2\pi$. Solutions higher in the tower, with $n>0$, have

$2(1+nc_2)$ fermion zero modes,[25,26] as we expect for a configuration of a fundamental monopole and n instantons. In addition to these r fundamental monopoles, there is one other solution that is fundamental.[25,26] This is a solution which has a negative magnetic charge equal to the lowest root $\boldsymbol{\alpha}_0^* \equiv \boldsymbol{\alpha}_0$ (although the solution, as we explained above is *not* an anti-monopole) lying in the second tower (27) with $n=1$ and hence with topological charge $k=-\boldsymbol{\alpha}_0^* \cdot \langle \boldsymbol{\varphi} \rangle / 2\pi + 1$.

Since $\Sigma_{i=0}^{r} k_i^* \boldsymbol{\alpha}_i^* = 0$, the quantum numbers of the solutions suggest that a pure instanton solution, carrying zero magnetic charge and unit topological charge, is a composite configuration with k_i^* fundamental $\boldsymbol{\alpha}_i$ monopoles, for each $i=0,\ldots,r$. (Here k_i^* are the dual "Kac labels," or co-marks, defined in Appendix A.) This turns out to be the case[25,26] and the resulting configuration has exactly $2c_2$ $(4c_2)$ exact fermionic (bosonic) zero modes as expected for a singly-charged instanton with gauge group G.

IV. MONOPOLE CONTRIBUTIONS TO THE SUPERPOTENTIAL

In this section, we will explain how the fundamental monopoles described in the last section lift the classical degeneracy of the theory parametrized by the asymptotic value of the Wilson loop $\langle \boldsymbol{\varphi} \rangle$ (7). The idea is to consider the low energy three-dimensional effective theory corresponding to the massless Abelian components of the fields formed by integrating out all the massive fields.

For this analysis to hold we must first assume there is no root $\boldsymbol{\alpha}$ such that $\langle \boldsymbol{\varphi} \rangle \cdot \boldsymbol{\alpha} = 0$, so that the unbroken gauge group is maximally Abelian $\mathrm{U}(1)^r$. We will also assume that the Wilson line VEV $\langle \boldsymbol{\varphi} \rangle$ lies in the fundamental region (10). After that we can integrate out (1) all non-Abelian fields on $\mathbb{R}^3 \times S^1$, and (2) all the massive Kaluza–Klein modes on S^1, i.e., the modes with nonzero Matsubara frequency $\omega_m = m/R$, to flow to the Abelian theory on $\mathbb{R}^3$. We emphasize that the periodicity in $\langle \boldsymbol{\varphi} \rangle \sim \langle \boldsymbol{\varphi} \rangle + 2\pi \boldsymbol{\omega}^*$, $\boldsymbol{\omega}^* \in \Lambda_W^*$, is a property of the full microscopic theory but not of the low-energy theory on $\mathbb{R}^3$. Indeed, the large gauge transformation (9) is x_0-dependent and has the effect of mixing up the massless and massive Kaluza–Klein modes.

The fields of the low energy theory consist of the Wilson loop $\boldsymbol{\varphi}$, i.e., the component v_0 of the gauge field averaged over the circle, along with r massless photons corresponding to the components of v_μ in the Cartan subalgebra of the gauge group. Along with these bosonic fields there are superpartners corresponding to the Abelian components of the gluino.

It turns out to be convenient to use the fact that massless Abelian gauge fields in three dimensions can be eliminated in favor of scalar fields by a duality transformation. To construct the classical effective action, we start with the action of the pure gauge theory in four dimensions and dimensionally reduce to three dimensions keeping only the Abelian components of the fields. From (6), the component v_0 of the four-dimensional gauge field is replaced by $\boldsymbol{\varphi} \cdot \mathbf{H}/(2\pi R)$ and the resulting three-dimensional effective action is

$$S_{\mathrm{cl}} = \frac{2\pi R}{g^2} \int d^3x \left\{ \frac{1}{4\pi^2 R^2} (\partial_\mu \boldsymbol{\varphi})^2 - \frac{1}{2} (\mathbf{v}_{\mu\nu})^2 + 2i \overline{\boldsymbol{\lambda}} \cdot \overline{\sigma}_\mu \mathcal{D}_\mu \boldsymbol{\lambda} \right\} - \frac{i\vartheta}{8\pi^2} \int d^3x \, \epsilon_{\mu\nu\rho} \partial_\mu \boldsymbol{\varphi} \cdot \mathbf{v}_{\nu\rho} . \tag{31}$$

[It is useful to notice that in our normalization $\mathrm{tr}(\mathbf{a}\cdot\mathbf{H}\ \mathbf{b}\cdot\mathbf{H}) = \mathbf{a}\cdot\mathbf{b}$.] In order to construct the dual description of the three-dimensional gauge field one adds a new term to the action involving a field $\boldsymbol{\sigma}$ which serves as a Lagrange multiplier for the Bianchi identity constraint:

$$S_{\mathrm{cst}} = -\frac{i}{4\pi} \int d^3x \, \epsilon_{\mu\nu\rho} \partial_\mu \boldsymbol{\sigma} \cdot \mathbf{v}_{\nu\rho} = -\frac{i}{2\pi} \int_{S^2} dx_\mu \, \boldsymbol{\sigma} \cdot \mathbf{B}_\mu . \tag{32}$$

The Abelian field strength $\mathbf{v}_{\mu\nu}$ can now be integrated-out of the path integral as a Gaussian field to obtain the classical effective action, whose bosonic part is

$$S_{\mathrm{cl}}^{\mathrm{bos}} = \frac{1}{2\pi R} \int d^3x \left\{ \frac{1}{g^2} (\partial_\mu \boldsymbol{\varphi})^2 + \frac{g^2}{16\pi^2} \left(\partial_\mu \boldsymbol{\sigma} + \frac{\vartheta}{2\pi} \partial_\mu \boldsymbol{\varphi} \right)^2 \right\} . \tag{33}$$

This can be written compactly in terms of the single complex field

$$\mathbf{z}=i(\tau\boldsymbol{\varphi}+\boldsymbol{\sigma}), \tag{34}$$

as

$$S_{\rm cl}^{\rm bos}=\frac{1}{8\pi^2R}\int d^3x\,\frac{1}{\operatorname{Im}\tau}\,\partial^\mu\mathbf{z}^+\cdot\partial_\mu\mathbf{z}. \tag{35}$$

We have eliminated the r massless photons in favor of an r-vector scalar field $\boldsymbol{\sigma}$. Notice that since the magnetic charge $\mathbf{g}$ is quantized in the co-root lattice it follows from (32) that $\boldsymbol{\sigma}$ is physically equivalent to $\boldsymbol{\sigma}+2\pi\boldsymbol{\omega}$ for any weight $\boldsymbol{\omega}\in\Lambda_W$. Once again, we also have the freedom to perform Weyl reflections and so $\boldsymbol{\sigma}$ is valued in the quotient

$$\frac{\mathbb{R}^r}{2\pi\cdot\Lambda_W\rtimes W_g}, \tag{36}$$

to compare with $\boldsymbol{\varphi}$ which is valued in the slightly different quotient (8). Obviously these spaces are the same for the simply-laced groups.

The fact that both (real) scalar fields $\boldsymbol{\varphi}$ and $\boldsymbol{\sigma}$ can be amalgamated into a single complex field $\mathbf{z}$ is no coincidence. Since the original four-dimensional theory was $\mathcal{N}=1$ supersymmetric, the effective theory written in terms of the bosonic fields $\boldsymbol{\varphi}$ and $\boldsymbol{\sigma}$, along with the Abelian components of the gluino $\boldsymbol{\lambda}_\alpha$, must form a representation of four-dimensional $\mathcal{N}=1$ supersymmetry (corresponding to $\mathcal{N}=2$ in three dimensions) which must be a chiral superfield since we have taken the dual of all the vector fields. In particular the bosonic fields must be expressible in terms of a single complex field as we have found in (34).

The $\mathcal{N}=2$ (in 3D) supersymmetric completion of the classical action (35) can be most succinctly expressed in terms of a four-dimensional $\mathcal{N}=1$ chiral superfield $\mathbf{X}$ with scalar component $\mathbf{z}$ and fermionic component $\boldsymbol{\lambda}_\alpha$, the Abelian component of the gluino. The supersymmetric version of (35) written in superspace is then

$$S_{\rm cl}=\frac{1}{8\pi^2R}\int d^3x\,\frac{1}{\operatorname{Im}\tau}\,\mathbf{X}^+\cdot\mathbf{X}\big|_{\theta\theta\overline{\theta\theta}}. \tag{37}$$

Quantum effects can modify the classical expression (37). However, modifications must preserve supersymmetry. As long as we are at a generic point in the classical moduli space, we expect to be able to integrate out all the massive fields to be left with an effective theory in terms of the superfield $\mathbf{X}$. The most general possible low energy effective action, i.e., involving at most two derivatives or four fermions, and preserving $\mathcal{N}=2$ supersymmetry in three dimensions, is

$$S_{\rm eff}=\int d^3x\,\{\mathcal{K}(\mathbf{X},\mathbf{X}^+)\big|_{\theta\theta\overline{\theta\theta}}+\mathcal{W}(\mathbf{X})\big|_{\theta\theta}+\overline{\mathcal{W}}(\mathbf{X}^+)\big|_{\overline{\theta\theta}}\}, \tag{38}$$

which involves an arbitrary D-term $\mathcal{K}(\mathbf{X},\mathbf{X}^+)$ as well as a superpotential $\mathcal{W}(\mathbf{X})$. It is the superpotential that is responsible for lifting the classical degeneracy and which we must determine.

In the classical theory (37) the superpotential vanishes identically. Quantum corrections will modify the theory in a complicated way depending on the couplings. However, the superpotential, by the standard arguments,[49,7,34] must be holomorphic in the fields $\mathbf{X}$ and the complexified coupling τ. In particular, up to the overall factor, the superpotential can only depend on R through the running of τ via the dimensionless quantity $R|\Lambda|$, where Λ is the usual Pauli–Villars scale of strong coupling effects in the pure gauge theory in $\mathbb{R}^4$. [This appears when the fields are not canonically normalized. In our case scalar fields arise from the Wilson line and the dual photon, which are dimensionless. This leads to an overall factor of R/g^2 in Eq. (46) below.] We intend to compute the superpotential at weak-coupling, for which $R\ll|\Lambda|^{-1}$ and the VEV of the effective

Higgs field (17) is large and a semi-classical analysis should be reliable. In this regime the superpotential will receive contributions from the minimal action configurations in each topological sector which have exactly two gluino zero modes; in other words, from the $r+1$ fundamental monopoles described in the last section. As usual holomorphy then forbids any perturbative corrections to the semi-classical contributions and, as a consequence, fixes the R dependence, a fact that ultimately will allow us to take R to be large.

In the presence of the dual photon field $\boldsymbol{\sigma}$, the action of the fundamental monopole associated to the root $\boldsymbol{\alpha}_j$, $j=0,\ldots,r$, is given in terms of the VEV of the scalar field z by

$$S_j = -2\pi i\tau\delta_{j0} - i\tau\boldsymbol{\alpha}_j^*\cdot\langle\boldsymbol{\varphi}\rangle - i\boldsymbol{\alpha}_j^*\cdot\langle\boldsymbol{\sigma}\rangle \equiv -2\pi i\tau\delta_{j0} - \boldsymbol{\alpha}_j^*\cdot\langle\mathbf{z}\rangle. \tag{39}$$

Here τ is the complexified coupling (3).

We determine the form of the superpotential by calculating the monopole contribution to the large distance behavior of the correlator of two components of the massless gluino field

$$\langle\boldsymbol{\lambda}_\alpha(x)\otimes\boldsymbol{\lambda}_\beta(0)\rangle. \tag{40}$$

In the background of the $\boldsymbol{\alpha}_j$ monopole, only the component $\boldsymbol{\lambda}_\alpha \propto \boldsymbol{\alpha}_j$ is nontrivial; in fact from (30) one finds the long-distance behavior to be

$$\boldsymbol{\lambda}_\alpha^{LD}(x) = 4\pi\boldsymbol{\alpha}_j^*\mathcal{S}_{\mathrm{F}}(x-a)_\alpha^\gamma\xi_\gamma, \tag{41}$$

where $\mathcal{S}_{\mathrm{F}}(x)=\sigma_\mu x_\mu/(4\pi|x_\mu|^3)$ is the massless fermion propagator in three dimensions, a_μ is the position of the monopole in $\mathbb{R}^3$ and ξ_α are the Grassmann collective coordinates corresponding to the two supersymmetric zero modes.

In order to evaluate the contribution to the superpotential from the monopole, we need the measure for integrating over the moduli space of the monopole derived in Appendix B. A fundamental monopole has a moduli space that is parametrized by a_μ, the position in $\mathbb{R}^3$ and by the U(1) phase angle $0\leqslant\Omega\leqslant 2\pi$. Along with this, there are two Grassmann collective coordinates ξ_α, corresponding to the two supersymmetric zero modes. From Eq. (79) the measure is

$$\int d\mu_{\mathrm{mon}}^{(\mathrm{j})} = \frac{2}{\boldsymbol{\alpha}_j^2}\frac{\mu^3 R}{g^2}e^{-S_j}\int d^3a\, d\Omega\, d^2\xi. \tag{42}$$

Performing the integrals over the phase angle and the Grassmann collective coordinates, we find that

$$\langle\boldsymbol{\lambda}_\alpha(x)\otimes\boldsymbol{\lambda}_\beta(0)\rangle = \frac{2^6\pi^3\mu^3 R}{g^2\boldsymbol{\alpha}_j^2}\boldsymbol{\alpha}_j^*\otimes\boldsymbol{\alpha}_j^* e^{2\pi i\tau\delta_{j0}+\boldsymbol{\alpha}_j^*\cdot\langle\mathbf{z}\rangle}\int d^3a\,\mathcal{S}_{\mathrm{F}}(x-a)_\alpha^\gamma\mathcal{S}_{\mathrm{F}}(a)_{\beta\gamma}. \tag{43}$$

Amputating this correlator we find the associated vertex in the effective action:

$$\left(\frac{2\pi R}{g^2}\right)^2\frac{2^5\pi^3\mu^3 R}{g^2\boldsymbol{\alpha}_j^2}e^{2\pi i\tau\delta_{j0}+\boldsymbol{\alpha}_j^*\cdot\langle\mathbf{z}\rangle}\ (\boldsymbol{\alpha}_j^*\cdot\boldsymbol{\lambda})^2. \tag{44}$$

In the above, the numerical factor in the bracket reflects our normalization for the kinetic term of $\boldsymbol{\alpha}\cdot\boldsymbol{\lambda}$ which follows from (31). The vertex (44) is generated by a term in the effective potential of the form

$$\frac{4\pi\mu^3 R}{g^2\boldsymbol{\alpha}_j^2}e^{2\pi i\tau\delta_{j0}+\boldsymbol{\alpha}_j^*\cdot\mathbf{X}}. \tag{45}$$

[In order to get the correct numerical factor, notice that the fermionic component of $\mathbf{z}$ and the gluino $\boldsymbol{\lambda}$ are related via $\boldsymbol{\psi}=2^{5/2}\pi^2 g^{-2} R\,\boldsymbol{\lambda}$. This follows from the fact[50] that the superpartner of $\mathbf{v}_0$ is $(\boldsymbol{\lambda}+\overline{\boldsymbol{\lambda}})/\sqrt{2}$.] Hence, summing over the effects of all $r+1$ fundamental monopoles we deduce that the monopole-generated superpotential of the theory is

$$\mathcal{W}_{\text{mono}}(\mathbf{X})=\frac{2\pi\mu^3 R}{g^2}\left(\sum_{j=1}^{r}\frac{2}{\boldsymbol{\alpha}_j^2}e^{\boldsymbol{\alpha}_j^*\cdot\mathbf{X}}+\frac{2}{\boldsymbol{\alpha}_0^2}e^{2\pi i\tau+\boldsymbol{\alpha}_0^*\cdot\mathbf{X}}\right). \tag{46}$$

This is an affine Toda potential for an associated affine algebra. Notice that to give the usual expression for a Toda potential one can remove the pre-factors $2/\boldsymbol{\alpha}_j^2$ by a shift in the field:

$$\mathbf{X}\to\mathbf{X}+\sum_{j=1}^{r}\ln(\boldsymbol{\alpha}_j^2/2)\boldsymbol{\omega}_j+\frac{\boldsymbol{\rho}}{c_2}\left(2\pi i\tau-\sum_{j=0}^{r}\ln(\boldsymbol{\alpha}_j^2/2)\right), \tag{47}$$

where $\boldsymbol{\rho}=\Sigma_{j=1}^{r}\boldsymbol{\omega}_j$ is the Weyl vector. For the simply-laced groups, the associated affine algebra is the untwisted affinization of the original Lie algebra, $g^{(1)}$ in Kac's notation,[37] while for the non-simply-laced groups the corresponding affine algebra is twisted in the way described in Table II. In these cases, the Kac–Dynkin diagram of the affine algebra is obtained from the Kac–Dynkin diagram of the untwisted affinization $g^{(1)}$ by changing long roots into short roots, and vice versa. In Kac's notation[37] this leads to the twisted affinization of a different algebra. The same superpotential has been deduced from entirely different considerations involving M theory compactified on certain eight-dimensional manifolds,[38–40,51,52] although the $2/\boldsymbol{\alpha}_j^2$ prefactors, that we shall find crucial in order to get results for the gluino condensate that agree with other calculations, are absent. It is also interesting that the integrable systems related to the Toda potentials that we have found above are precisely those that appear in the "Seiberg–Witten theory" of the $\mathcal{N}=2$ gauge theory with the same gauge group in four dimensions.[53,54] Naturally this is no accident since the $\mathcal{N}=1$ theory can be obtained from the $\mathcal{N}=2$ theory by soft breaking mass terms.

Importantly, although we have calculated the superpotential in the limit $R\ll|\Lambda^{-1}|$, at weak coupling, there can be no additional dependence on R and the result can be continued to any R, and in particular to the decompactification limit.[34,35]

One may wonder how the superpotential relates to that calculated in Ref. 55 for the three-dimensional $\mathcal{N}=2$ supersymmetric gauge theory. The way that this superpotential arises from the $R\to 0$ limit of our superpotential is explained in a slightly different context in Ref. 34. The point is that to take the three-dimensional limit, one should take it in such a way that the three-dimensional gauge coupling, which is classically given by $g_3^2=g^2/(2\pi R)$, is fixed. In other words, as $R\to 0$, we should simultaneously take the limit $g\to 0$ in the superpotential (46). In this limit, the additional term corresponding to the affine root is removed to give

$$\mathcal{W}_{3\text{-d}}=\frac{\mu^3}{g_3^2}\sum_{j=1}^{r}\frac{2}{\boldsymbol{\alpha}_j^2}e^{\boldsymbol{\alpha}_j^*\cdot\mathbf{X}}. \tag{48}$$

In other words, in this limit, the affine Toda potential becomes the Toda potential for a nonaffine algebra. This is what one expects because the affine term in the superpotential on the cylinder is generated by the additional monopole solution that only exists on the cylinder and not in $\mathbb{R}^3$. The genuinely three-dimensional superpotential (48) is the generalization of that of Ref. 55 from SU(2) to arbitrary gauge group. Just as in the SU(2) case, it does not have a stationary point and therefore the theory does not have a vacuum state.

V. VACUUM STRUCTURE AND THE GLUINO CONDENSATE

The superpotential (46) gives rise to a number of supersymmetric vacua which satisfy

$$\frac{2}{\boldsymbol{\alpha}_j^2} e^{\boldsymbol{\alpha}_j^* \cdot \mathbf{X}} = \frac{2}{\boldsymbol{\alpha}_0^2} k_j^* e^{2\pi i \tau} e^{\boldsymbol{\alpha}_0^* \cdot \mathbf{X}}, \tag{49}$$

for $j=1,\ldots,r$. Writing $\mathbf{X}=\sum_{j=1}^r a_j \boldsymbol{\omega}_j$ we have

$$e^{a_j} = \frac{k_j^* \boldsymbol{\alpha}_j^2 e^{2\pi i \tau}}{2\kappa}, \tag{50}$$

where $\kappa = e^{\sum_{j=1}^r a_j k_j^*}$ is determined self-consistently as the solution of the equation

$$\kappa^{c_2} = e^{2\pi i (c_2-1)\tau} \prod_{j=0}^{r} \left(\frac{k_j^* \boldsymbol{\alpha}_j^2}{2} \right)^{k_j^*}. \tag{51}$$

There are consequently c_2 supersymmetric ground states given by the c_2 roots of (51) which are related by $\mathbf{X} \to \mathbf{X} + 2\pi i \boldsymbol{\rho}/c_2$. (The vector $\boldsymbol{\rho}=\sum_{j=1}^r \boldsymbol{\omega}_j$ is the Weyl vector and recall that $\mathbf{X}$ is identified with $\mathbf{X}+2\pi i \boldsymbol{\rho}$ as a consequence of the fact that $\boldsymbol{\sigma}$ is identified with $\boldsymbol{\sigma}+2\pi\boldsymbol{\rho}$, since $\boldsymbol{\rho} \in \Lambda_W$.) These vacua correspond to a fixed value of $\boldsymbol{\varphi}$:

$$\boldsymbol{\varphi} = \left(\frac{2\pi}{c_2} + \frac{g^2}{4\pi} \ln|\kappa| \right) \boldsymbol{\rho} - \frac{g^2}{4\pi} \sum_{j=1}^{r} \ln(k_j^* \boldsymbol{\alpha}_j^2/2)\, \boldsymbol{\omega}_j, \tag{52}$$

and c_2 values of $\boldsymbol{\sigma}$ given by

$$\boldsymbol{\sigma} = -\frac{\vartheta}{2\pi} \boldsymbol{\varphi} + \frac{\vartheta + 2\pi u}{c_2} \boldsymbol{\rho}, \tag{53}$$

where $u=1,2,\ldots,c_2$. Notice that as expected the c_2 vacua are related by $\vartheta \to \vartheta + 2\pi$.

The value of the superpotential in one of the vacua is

$$\langle \mathcal{W}_{\text{mono}} \rangle = \frac{2\pi\mu^3 R}{g^2} \cdot \frac{e^{2\pi i \tau} c_2}{\kappa} = \frac{2\pi\mu^3 R}{g^2} \cdot \frac{c_2 e^{2\pi i \tau/c_2 + 2\pi i u/c_2}}{\Pi_{j=0}^r (k_j^* \boldsymbol{\alpha}_j^2/2)^{k_j^*/c_2}} = 2\pi R \Lambda^3 \cdot \frac{c_2 e^{2\pi i u/c_2}}{\Pi_{j=0}^r (k_j^* \boldsymbol{\alpha}_j^2/2)^{k_j^*/c_2}}, \tag{54}$$

where in the final expression we have eliminated the Pauli–Villars mass scale μ in favor of the Lambda parameter using the exact relation (2). The value of the gluino condensate in each vacuum can be extracted by using the general relation

$$\left\langle \frac{\operatorname{tr} \lambda^2}{16\pi^2} \right\rangle = b_0^{-1} \Lambda \frac{\partial}{\partial \Lambda} \left\langle \frac{1}{2\pi R} \mathcal{W}_{\text{mono}} \right\rangle, \tag{55}$$

adapted to the three-dimensional superpotential. The first coefficient of the beta-function is $b_0 = 3c_2$ giving

$$\left\langle \frac{\operatorname{tr} \lambda^2}{16\pi^2} \right\rangle = \frac{\Lambda^3 e^{2\pi i u/c_2}}{\Pi_{j=0}^r (k_j^* \boldsymbol{\alpha}_j^2/2)^{k_j^*/c_2}}. \tag{56}$$

The gluino condensate can also be evaluated directly without having to rely on the identity (55). The idea is to consider the fundamental monopole contributions to the one-point function $\langle \operatorname{tr} \lambda^2/16\pi^2 \rangle$ in a given vacuum, say the u^{th}. The contribution of the $\boldsymbol{\alpha}_j$ monopole to the condensate in this vacuum is

$$\left\langle \frac{\mathrm{tr}\,\lambda^2}{16\pi^2} \right\rangle_{j\text{-mono}} = \int d\mu^{(j)}_{\mathrm{mon}} \left. \frac{\mathrm{tr}\,\lambda^2}{16\pi^2} \right|_{j\text{-mono}} . \tag{57}$$

To evaluate (57), we can use the normalization of the adjoint fermion zero modes from Ref. 50,

$$\int d^3a\, d^2\xi \left. \frac{\mathrm{tr}\,\lambda^2}{16\pi^2} \right|_{j\text{-mono}} = \frac{g^2\,\mathrm{Re}\,S_j}{8\boldsymbol{\alpha}_j^2\pi^3 R}. \tag{58}$$

Computing the remaining integral over the phase angle gives

$$\left\langle \frac{\mathrm{tr}\,\lambda^2}{16\pi^2} \right\rangle_{j\text{-mono}} = \frac{\mu^3\,\mathrm{Re}\,S_j}{4\pi^2\boldsymbol{\alpha}_j^2} e^{-S_j}. \tag{59}$$

In the supersymmetric vacua

$$S_j = -2\pi i\tau - \ln\left(\frac{k_j^*\boldsymbol{\alpha}_j^2}{2\kappa} \right) \tag{60}$$

and so inserting the value for κ in (51) we have

$$\left\langle \frac{\mathrm{tr}\,\lambda^2}{16\pi^2} \right\rangle_{j\text{-mono}} = \frac{k_j^*\Lambda^3 e^{2\pi i u/c_2}}{c_2} \cdot \frac{1}{\prod_{j=0}^{r} (\boldsymbol{\alpha}_j^2 k_j^*/2)^{k_j^*/c_2}}. \tag{61}$$

Summing over the contributions from the $r+1$ fundamental monopoles gives (56).

We conclude the section with the observation that in the supersymmetric vacua the $r+1$ fundamental monopoles have equal topological charge

$$\boldsymbol{\alpha}_j \cdot \frac{\langle \boldsymbol{\varphi} \rangle}{2\pi} = 1 - \boldsymbol{\alpha}_0 \cdot \frac{\langle \boldsymbol{\varphi} \rangle}{2\pi} = \frac{1}{c_2} \tag{62}$$

(for $j=1,\ldots,r$) independent of j. In addition, as we have discussed in Sec. III, the configuration which becomes the singly-charged instanton in the uncompactified theory is obtained by considering a multi-monopole solution which consists of k_j^* of the jth fundamental monopole. In this very precise sense they realize the old dream of thinking of the instanton in terms of a set of constituents, or instanton quarks.[20–24] It was anticipated that the instanton quarks would cause, or at least play a major role in, confinement. In the theory on the cylinder this old idea again receives confirmation. Notice that in the quantum vacuum states the dual photon becomes massive which is equivalent to the confinement of the original Abelian electric photons.

APPENDIX A: SOME LIE ALGEBRA CONVENTIONS

In this appendix we give a brief review of particular details of Lie algebras that we will need. For more details on Lie algebras the reader may consult Refs. 56.

Let $\{H^i\}$ be a maximal set of simultaneously diagonalizable, mutually commuting generators, $[H^i,H^j]=0$. The indices i,j run from 1 to r, the *rank* of the Lie algebra. We normalize the Cartan generators to one,

$$\mathrm{tr}(H^iH^j) = \delta^{ij}, \tag{A1}$$

and often think of the r-vector $\mathbf{H}$. The remainder of the generators are the step operators E_α with

$$[\mathbf{H},E_\alpha] = \boldsymbol{\alpha}E_{\boldsymbol{\alpha}}. \tag{A2}$$

The normalization condition (A1) makes the length squared of any long root to be equal to 2.

TABLE III. Lie algebra data.

G	g	c_2	$\{k_i^*\}$	$\{\alpha_i^2\}$
SU($r+1$)	a_r	$r+1$	{1,1,...,1}	{2,...,2}
SO($2r+1$)	b_r	$2r-1$	{1,1,2,...,2,1}	{2,...,2,1}
USp($2r$)	c_r	$r+1$	{1,...,1}	{2,1,...,1,2}
SO($2r$)	d_r	$2r-2$	{1,1,2,...,2,1,1}	{2,...,2}
G_2	g_2	4	{1,2,1}	{2,2,2/3}
F_4	f_4	9	{1,2,3,2,1}	{2,2,2,1,1}
E_6	e_6	12	{1,1,1,2,2,2,3}	{2,...,2}
E_7	e_7	18	{1,1,2,2,2,3,3,4}	{2,...,2}
E_8	e_8	30	{1,2,2,3,3,4,4,5,6}	{2,...,2}

We will denote a set of simple roots as $\boldsymbol{\alpha}_j$, $j=1,\ldots,r$. These span the root lattice Λ_R. The lowest root is then denoted as $\boldsymbol{\alpha}_0$. The co-roots are defined via

$$\boldsymbol{\alpha}^* \equiv \frac{2}{\boldsymbol{\alpha}^2}\boldsymbol{\alpha} \tag{A3}$$

and these span the co-root lattice Λ_R^*. The weight lattice Λ_W is dual to the co-root lattice and is spanned by the fundamental weights $\boldsymbol{\omega}_j$ where

$$\boldsymbol{\omega}_i \cdot \boldsymbol{\alpha}_j^* = \delta_{ij}. \tag{A4}$$

Similarly one can define the co-weight lattice Λ_W^* which is dual to the root lattice and is spanned by the co-weights $\boldsymbol{\omega}_i^*$ where

$$\boldsymbol{\omega}_i^* \equiv \frac{2}{\boldsymbol{\alpha}_i^2}\boldsymbol{\omega}_i. \tag{A5}$$

We will also need to define the dual Kac labels, or co-marks, k_i^*. By definition $k_0^*=1$ and the remaining co-marks are given by the expansion of the lowest co-root in terms of the co-simple-roots:

$$\boldsymbol{\alpha}_0^* = -\sum_{i=1}^{r} k_i^* \boldsymbol{\alpha}_i^*. \tag{A6}$$

Finally

$$c_2 \equiv \sum_{i=0}^{r} k_i^* \tag{A7}$$

is the *dual Coxeter number*. (The Kac labels, or marks, and Coxeter number are similarly defined but will not be needed here.)

In Table III we summarize all the Lie algebra data that we need. As well as listing the dual Kac labels and dual Coxeter number we also list the root lengths $\boldsymbol{\alpha}_j^2$ for $j=0,\ldots,r$. (Note that the set of dual Kac labels and root lengths are ordered in the same way.)

APPENDIX B: THE MONOPOLE COLLECTIVE COORDINATE MEASURE

In this appendix we briefly discuss the measure for integrating over the collective coordinates of a fundamental monopole. A fundamental monopole has a moduli space that is identical to the BPS monopole in SU(2). Therefore, it is parametrized by a_μ, the position in $\mathbb{R}^3$, and by the U(1) phase angle $0\leqslant\Omega\leqslant 2\pi$. Along with this, there are two Grassmann collective coordinates ξ_α,

corresponding to the two supersymmetric zero modes. The measure for integrating over the monopole moduli space is obtained in the standard way by changing variables in the path integral from field fluctuations around the monopole to the monopole's collective coordinates:

$$\int d\mu_{\rm mon} = \mu^3 e^{-S} \int \frac{d^3a}{(2\pi)^{3/2}} J_a \int_0^{2\pi} \frac{d\Omega}{(2\pi)^{1/2}} J_\Omega \int \frac{d^2\xi}{J_F}, \tag{B1}$$

where S is the monopole action (39) and μ is the Pauli–Villars mass scale. The Jacobian factors J_a and J_F were calculated in Ref. 50:

$$J_a = (\mathrm{Re}\, S)^{3/2}, \quad J_F = 2\,\mathrm{Re}\, S, \tag{B2}$$

and S is the monopole action. The remaining Jacobian J_Ω is given by

$$J_\Omega = \frac{2\pi R (\mathrm{Re}\, S)^{1/2}}{\boldsymbol{\alpha}\cdot\langle\boldsymbol{\varphi}\rangle}. \tag{B3}$$

To derive this, we start with the general expression for the bosonic zero mode,

$$Z_m = \frac{\partial v_m^{(\Omega)}}{\partial\Omega} + D_m\Lambda, \tag{B4}$$

where $v_m^{(\Omega)}$ is the Ω-rotated monopole solution in the singular gauge,

$$v_m^{(\Omega)} = e^{i\Omega\tau^3} v_m e^{-i\Omega\tau^3}, \tag{B5}$$

and $D_m\Lambda$ is added to keep the zero mode in the covariant background gauge. Since

$$\frac{\partial v_m^{(\Omega)}}{\partial\Omega} = i\left[\frac{1}{2}\boldsymbol{\alpha}^*\cdot\mathbf{H},\ v_m\right], \tag{B6}$$

the choice of Λ is obvious [recall (16)]:

$$\Lambda = \frac{2\pi R}{\boldsymbol{\alpha}\cdot\langle\boldsymbol{\varphi}\rangle}\ \Phi^c\tau^c - \frac{1}{2}\boldsymbol{\alpha}^*\cdot\mathbf{H}. \tag{B7}$$

This gives

$$Z_m = \frac{2\pi R}{\boldsymbol{\alpha}\cdot\langle\boldsymbol{\varphi}\rangle}\ D_m(\Phi^c\tau^c) = \frac{2\pi R}{\boldsymbol{\alpha}\cdot\langle\boldsymbol{\varphi}\rangle}\ v_{m0}, \tag{B8}$$

and

$$J_\Omega \equiv \sqrt{\langle Z_m | Z_m\rangle} = \frac{2\pi R (\mathrm{Re}\, S)^{1/2}}{\boldsymbol{\alpha}\cdot\langle\boldsymbol{\varphi}\rangle}. \tag{B9}$$

Gathering all factors together, we find that the measure is

$$\frac{\mu^3 R}{g^2}\cdot\frac{2}{\boldsymbol{\alpha}^2}\cdot e^{-S}\int d^3a\ \ d\Omega\ \ d^2\xi. \tag{B10}$$

In contradistinction with the three-dimensional calculation of Ref. 50, our present calculation is locally four-dimensional, i.e., in the path integral we have integrated over the fluctuations around the monopole configuration in $\mathbb{R}^3\times S^1$. Thus, the UV-regularized determinants over nonzero eigenvalues of the quadratic fluctuation operators cancel between fermions and bosons due to supersymmetry as in Ref. 57. The ultra-violet divergences are regularized in the Pauli–Villars scheme, which explains the appearance of the Pauli–Villars mass scale μ.

I. INTRODUCTION

In random matrix theory, unitary ensembles of $N\times N$ matrices $\{H\}$ play a central role.[15] Such ensembles are described by a measure $d\alpha$ with finite moments $\int_{\mathrm{R}}|x|^k\,d\alpha(x)<\infty$, $k=0,1,2,...$, and the associated distribution function for the eigenvalues $\{x_i=x_i(H)\}$ of matrices H in the ensembles has the form

$$dP_{\alpha,N}(x)=\frac{1}{Z_N}\Delta(x)^2\,d\alpha(x), \tag{1.1}$$

where $d\alpha(x)=\Pi_{i=1}^{N}d\alpha(x_i)$, $\Delta(x)=\Pi_{N\geqslant i>j\geqslant 1}(x_i-x_j)$ is the Vandermonde determinant for the x_i's, and $Z_N=\int\cdots\int\Delta(x)^2\,d\alpha(x)$ is the normalization constant. The special case $d\alpha(x)=e^{-x^2}dx$ is known as the Gaussian unitary ensemble (GUE). For symmetric functions $f(x)=f(x_1,\ldots,x_N)$ of the x_i's,

$$\langle f\rangle_\alpha\equiv\frac{1}{Z_N}\int\cdots\int f(x)\Delta(x)^2\,d\alpha(x) \tag{1.2}$$

denotes the average of f with respect to $dP_{\alpha,N}$.

Recently there has been considerable interest in the averages of products and ratios of the characteristic polynomials $D_N[\mu,H]=\Pi_{i=1}^{N}(\mu-x_i(H))$ of random matrices with respect to various ensembles. Such averages are used, in particular, in making predictions about the moments of the Riemann-zeta function [see Refs. 12–14 (circular ensembles) and 3 (unitary ensembles)]. Many other uses are described, for example, in Refs. 1, 12, and 17.

By (1.2), for unitary ensembles, such averages have the form

a)Electronic mail: jbaik@math.princeton.edu
b)Electronic mail: deift@cims.nyu.edu
c)Electronic mail: eugene.strahov@brunel.ac.uk

$$\left\langle \frac{\prod_{j=1}^{K} D_N[\mu_j,H]}{\prod_{j=1}^{M} D_N[\epsilon_j,H]} \right\rangle_\alpha = \frac{1}{Z_N}\int\cdots\int \frac{\prod_{j=1}^{K}\prod_{i=1}^{N}(\mu_j-x_i)}{\prod_{j=1}^{M}\prod_{j=1}^{N}(\epsilon_j-x_i)}\Delta(x)^2\,d\alpha(x). \tag{1.3}$$

In this article we consider certain explicit determinantal formulas for (1.3)—see (2.6), (2.24), (2.36), (3.3), and (3.12) below. Formula (2.6) is due to Brezin and Hikami[3] (see also Ref. 16, and when all the μ_j's are equal, see Ref. 10), whereas (2.24), (2.36), (3.3), and (3.12) are due to Fyodorov and Strahov.[17,11] References 17 and 11 also contain a discussion of the history of these formulas. The formulas (3.3) and (3.12) are particularly useful in proving universality results for the ratios (1.3) in the Dyson limit as $N\to\infty$ (see Ref. 17). For a discussion of other universality results, particularly the work of Brezin–Hikami and Fyodorov in special cases, we again refer the reader to Ref. 17. The asymptotic analysis in Ref. 17 is based on the reformulation of the orthogonal polynomial problem as a Riemann–Hilbert problem by Fokas, Its, and Kitaev.[9] The Riemann–Hilbert problem is then analyzed asymptotically using the noncommutative steepest-descent method introduced by Deift and Zhou,[5] and further developed with Venakides in Ref. 6 to allow for fully nonlinear oscillations, and in Refs. 7 and 8.

Our goal in this article is to give new, streamlined proofs of (2.6)–(3.12), using only the properties of orthogonal polynomials and a minimum of combinatorics. Along the way we will also need an integral version of the classical Binet–Cauchy-formula due to C. Andréief dating back to 1883 (see Lemma 2.1 below).

Let $\pi_j(z)=x^j+\cdots$ denote the jth monic orthogonal polynomial with respect to the measure $d\alpha$,

$$\int_{\mathrm{R}} \pi_j(x)\pi_k(x)d\alpha(x)=c_jc_k\delta_{jk};\quad j,k\geqslant 0, \tag{1.4}$$

where the norming constants c_j's are positive. The key observation in our approach is that for $K=1$ and $M=0$ in (1.3),

$$\langle D_N[\mu,H]\rangle_\alpha=\pi_N(\mu) \tag{1.5}$$

(see Ref. 18). In our words, the orthogonal polynomial $\pi_N(\mu)$ with respect to $d\alpha$ is also precisely the average polynomial $\Pi_{i=1}^{N}(\mu-x_i)$ with respect to $d\mathrm{P}_{\alpha,N}$. Formula (1.5) appears already in the work of Heine in the 1880s (see Ref. 18). Set

$$d\alpha^{[\ell,m]}(t)\equiv \frac{\prod_{j=1}^{\ell}(\mu_j-t)}{\prod_{j=1}^{m}(\epsilon_j-t)}d\alpha(t),\quad \ell,m\geqslant 0, \tag{1.6}$$

$[d\alpha^{[0,0]}(t)\equiv d\alpha(t)]$, and let $\pi_j^{[\ell,m]}(t)$ denote the jth monic orthogonal polynomial with respect to $d\alpha^{[\ell,m]}$. With this notation we see immediately from (1.3) and (1.5) that $\langle \mathrm{Q}_{j=1}^{K}D_N[\mu_j,H]/\mathrm{Q}_{j=1}^{M}D_N[\epsilon_j,H]\rangle_\alpha$ is proportional to $\pi_N^{[K-1,M]}(\mu_K)$. Using a classical determinantal formula of Christoffel (see Ref. 18) for $\pi_N^{[\ell,0]}(\mu)$ and a more recent formula of Uvarov[19] for $\pi_N^{[0,m]}(\mu)$, we are then led (see Sec. II) to (2.6), (2.24), and (2.36) in a rather straightforward way. Formula (3.3) appears to have a different character from (2.6), (2.24), and (2.36), and relies on Lemma 2.1 mentioned above, which computes the integral of the product of two determinants: formula (3.12) follows (see Sec. III) by combining (3.3) with (2.6) and (2.36). In Ref. 17 the authors present a variety of additional formulas for $\langle \mathrm{Q}_{j=1}^{K}D_N[\mu_j,H]/\mathrm{Q}_{j=1}^{M}D_N[\epsilon_j,H]\rangle_\alpha$ for cases of K and M not covered by (2.6)–(3.12): we leave it to the interested reader to verify that the method of this article can also be used to derive these formulas in a straightforward manner.

Remark 1.1: As is well known (see, e.g., Ref. 18), each measure $d\alpha$ gives rise to a tridiagonal operator

$$J=J(d\alpha)=\begin{pmatrix} a_1 & b_1 & 0 & \\ b_1 & a_2 & b_2 & \\ 0 & b_2 & a_3 & \ddots \\ & & \ddots & \ddots \end{pmatrix}, \quad b_i>0, \tag{1.7}$$

with generalized eigenfunctions given by the orthonormal polynomials

$$p_j(x)=c_j^{-1}\pi_j(x), \quad j=0,1,..., \tag{1.8}$$

i.e.,

$$b_{j-1}p_{j-1}(x)+a_jp_j(x)+b_jp_{j+1}(x)=xp_j(x), \quad j\geqslant 1, \tag{1.9}$$

where $b_0\equiv 0$. Conversely, modulo certain essential self-adjointness issues, $d\alpha$ is the spectral measure for J in the cyclic subspace generated by J and the vector $e_1(1,0,0,...)^T$ (see, e.g., Ref. 4). It follows that the transformation of measures

$$d\alpha\rightarrow d\alpha^{[\ell,m]} \tag{1.10}$$

leads to the transformation of operators

$$J(d\alpha)\rightarrow J(d\alpha^{[\ell,m]}). \tag{1.11}$$

For appropriate choices of $\mu_1,\ldots,\mu_m$ and $\epsilon_1,\ldots,\epsilon_\ell$, such transformations correspond to removing m points from the spectrum of $J(d\alpha)$ and inserting ℓ points: in the spectral theory literature, such transformations are known as Darboux transformations. The formulas in this article clearly provide formulas for the generalized eigenfunctions $p_j^{[\ell,m]}(x)$ of the Darboux-transformed operator $J(d\alpha^{[\ell,m]})$, as well as the matrix entries, $a_j^{[\ell,m]}$ and $b_j^{[\ell,m]}$, in terms of the corresponding objects for $J(d\alpha)$. Again we leave the details to the reader. Here the elementary formulas

$$b_n^2(d\alpha)=\frac{n+1}{n+2}\frac{Z_n(d\alpha)Z_{n+2}(d\alpha)}{(Z_{n+1}(d\alpha))^2}, \quad a_n(d\alpha)=\frac{d}{dt}\bigg|_{t=0}\log\frac{Z_n(d\alpha_t)}{Z_{n+1}(d\alpha_t)}, \tag{1.12}$$

where $d\alpha_t(x)=e^{tx}d\alpha(x)$, are useful.

Technical Remark 1.2: Formulas (2.6)–(3.12) clearly do not make sense for all values of the parameters. In **all the calculations that follow, we will assume that** $d\alpha$ **has compact support, support** $(d\alpha)=[-Q,Q]$, **say, and that the** μ_i**'s and** ϵ_j**'s are distinct real numbers greater than** Q: under these assumptions, $d\alpha^{[\ell,m]}(t)$ becomes, in particular, a bona fide measure, etc. By analytic continuation one sees that the formulas remain true for complex values of $\{\mu_i\}$ and $\{\epsilon_j\}$, as long as they remain distinct. Furthermore, if the μ_j's and ϵ_j's are distinct, and $\mathrm{Im}(\epsilon_j)\neq 0$ for all j, then we can let $Q\rightarrow\infty$ and so the formulas are true for measures $d\alpha$ with unbounded support. Finally, we can, for example, let $\mu_j\rightarrow\mu_k$ for some $j\neq k$, which leads to formulas involving derivatives of the π_j's, etc.

II. FORMULAS OF CHRISTOFFEL–UVAROV TYPE

We use the notations $d\alpha$, π_j, $d\alpha^{[\ell,m]}$, $\pi_j^{[\ell,m]}$,... of Sec. I. In addition, in all the calculations that follow we assume that $d\alpha$, $\{\mu_j\}$, $\{\epsilon_k\}$ satisfy the conditions described in Technical Remark 1.2 above: the natural analytical continuation of the formulas obtained to complex values of the parameters, and the limit $Q\rightarrow\infty$, is left to the reader.

The following result of Christoffel (see Ref. 18) plays a basic role in what follows.

Lemma 2.1: Consider the measure $d\alpha^{[\ell,0]}(t)=\Pi_{j=1}^{\ell}(\mu_j-t)d\alpha(t)$, *where* $\ell=1,2,...$. *Then the* n*th monic orthogonal polynomial* $\pi_n^{[\ell,0]}(t)$ *associated with the new measure* $d\alpha^{[\ell,0]}(t)$ *can be expressed as follows:*

$$\pi_n^{[\ell,0]}(t)=\frac{1}{(t-\mu_1)\cdots(t-\mu_\ell)}\frac{\begin{vmatrix}\pi_n(\mu_1) & \cdots & \pi_{n+\ell}(\mu_1)\\ \vdots & & \\ \pi_n(\mu_\ell) & \cdots & \pi_{n+\ell}(\mu_\ell)\\ \pi_n(t) & \cdots & \pi_{n+\ell}(t)\end{vmatrix}}{\begin{vmatrix}\pi_n(\mu_1) & \cdots & \pi_{n+\ell-1}(\mu_1)\\ \vdots & & \\ \pi_n(\mu_\ell) & \cdots & \pi_{n+\ell-1}(\mu_\ell)\end{vmatrix}}. \tag{2.1}$$

Proof: Set

$$q_n^{[\ell,0]}(t)=\begin{vmatrix}\pi_n(\mu_1) & \cdots & \pi_{n+\ell}(\mu_1)\\ \vdots & & \\ \pi_n(\mu_\ell) & \cdots & \pi_{n+\ell}(\mu_\ell)\\ \pi_n(t) & \cdots & \pi_{n+\ell}(t)\end{vmatrix}. \tag{2.2}$$

We note that $q_n^{[\ell,0]}(t)$ satisfies the condition $\int t^j q_n^{[\ell,0]}(t)d\alpha(t)=0$ for all $j\in\{0,...,n-1\}$. Also $q_n^{[\ell,0]}(\mu_j)=0$, $j=1,...,\ell$, and so $q_n^{[\ell,0]}(t)/[(\mu_1-t)\cdots(\mu_\ell-t)]$ is a polynomial of degree at most n. Now observe that

$$\int t^j\left[\frac{q_n^{[\ell,0]}(t)}{(\mu_1-t)\cdots(\mu_\ell-t)}\right]d\alpha^{[\ell,0]}(t)=0,\quad 0\leqslant j<n, \tag{2.3}$$

which means that $q_n^{[\ell,0]}(t)$ divided by the product $(\mu_1-t)\cdots(\mu_\ell-t)$ is proportional to the nth monic orthogonal polynomial $\pi_n^{[\ell,0]}(t)$ associated with the new measure $d\alpha^{[\ell,0]}(t)$. Now $q_n^{[\ell,0]}\times(t)$ cannot vanish for any $t=\mu_{\ell+1}>Q$, $\mu_{\ell+1}\notin\{\mu_1,...,\mu_\ell\}$. Indeed, if $q_n^{[\ell,0]}(\mu_{\ell+1})=0$, then there exist $\{\alpha_i\}_{i=0}^{\ell}$, not all zero, such that $p(t)\equiv\Sigma_{i=0}^{\ell}\alpha_i\pi_{n+i}(t)$ vanishes at $\{\mu_i\}_{i=1}^{\ell+1}$. Thus $\tilde{p}(t)\equiv p(t)/\Pi_{i=1}^{\ell+1}(\mu_i-t)$ is a polynomial of order $<n$, and as above, $\tilde{p}(t)$ is orthogonal to t^j, $0\leqslant j<n$, with respect to the measure $d\alpha^{[\ell+1,0]}(t)$. Thus $\tilde{p}(t)\equiv 0$ and hence $\alpha_0=\cdots=\alpha_\ell=0$, which is a contradiction. Replacing ℓ by $\ell-1$, we conclude that

$$\begin{vmatrix}\pi_n(\mu_1) & \cdots & \pi_{n+\ell-1}(\mu_1)\\ \vdots & & \\ \pi_n(\mu_\ell) & \cdots & \pi_{n+\ell-1}(\mu_\ell)\end{vmatrix}\neq 0. \tag{2.4}$$

Taking the limit $t\to\infty$ and noting that the coefficient of the highest degree of $\pi_n^{[\ell,0]}(t)$ should be equal to 1, we find the coefficient of proportionality and establish formula (2.1). □

Representation (2.1) for the monic orthogonal polynomials associated with the measure $d\alpha^{[\ell,0]}(t)$ immediately leads to the following result:

Corollary 2.2: The product of monic orthogonal polynomials $\Pi_{j=0}^{\ell}\pi_n^{[j,0]}(\mu_{j+1})$ *defined with respect to the different measures* $d\alpha^{[j,0]}(t)\equiv(\mu_j-t)\cdots(\mu_1-t)d\alpha(t)$ *is given by the formula*

$$\prod_{j=0}^{\ell}\pi_n^{[j,0]}(\mu_{j+1})=\frac{1}{\Delta(\mu)}\begin{vmatrix}\pi_n(\mu_1) & \cdots & \pi_{n+\ell}(\mu_1)\\ \vdots & & \\ \pi_n(\mu_{\ell+1}) & \cdots & \pi_{n+\ell}(\mu_{\ell+1})\end{vmatrix}, \tag{2.5}$$

where $\Delta(\mu)=\Pi_{\ell+1\geqslant i>j\geqslant 1}(\mu_i-\mu_j)$.

We observe that Corollary 2.2 gives the identity for the average of products of random characteristic polynomials obtained first by Brezin and Hikami.[3]

Theorem 2.3: *Let* $D_N[\mu,H]$ *be the characteristic polynomial of the Hermitian matrix H. The following identity is valid:*

$$\left\langle \prod_{j=1}^{L} D_N[\mu_j,H] \right\rangle_\alpha = \frac{1}{\Delta(\mu)} \begin{vmatrix} \pi_N(\mu_1) & \cdots & \pi_{N+L-1}(\mu_1) \\ \vdots & & \\ \pi_N(\mu_L) & \cdots & \pi_{N+L-1}(\mu_L) \end{vmatrix}, \tag{2.6}$$

where the average is defined by (1.2).

Proof: To prove formula (2.6) we use the representation for the monic orthogonal polynomials in the case $L=1$ given in (1.5),

$$\pi_N(\mu) = \frac{1}{Z_N} \int \cdots \int \prod_{i=1}^{N} (\mu - x_i) \Delta^2(x) d\alpha(x). \tag{2.7}$$

Let $Z_N^{[\ell,0]}$ be defined by

$$Z_N^{[\ell,0]} = \int \cdots \int \Delta^2(x) d\alpha^{[\ell,0]}(x), \quad \ell = 1,2,..., \tag{2.8}$$

where $d\alpha^{[\ell,0]}(x) = \Pi_{i=1}^{N} d\alpha^{[\ell,0]}(x_i)$. With this notation, we have

$$\left\langle \prod_{j=1}^{L} D_N[\mu_j,H] \right\rangle_\alpha = \frac{Z_N^{[L,0]}}{Z_N} = \frac{Z_N^{[L,0]}}{Z_N^{[L-1,0]}} \frac{Z_N^{[L-1,0]}}{Z_N^{[L-2,0]}} \cdots \frac{Z_N^{[1,0]}}{Z_N}. \tag{2.9}$$

Equation (2.7) implies that $\pi_n^{[\ell-1,0]}(\mu_\ell)$ can be represented as the ratio $Z_N^{[\ell,0]}/Z_N^{[\ell-1,0]}$, where $\pi_N^{[0,0]}(\mu) \equiv \pi_N(\mu)$, and $Z_N^{[0,0]} \equiv Z_N$. Thus we obtain

$$\left\langle \prod_{j=1}^{L} D_N[\mu_j,H] \right\rangle_\alpha = \prod_{j=0}^{L-1} \pi_N^{[j,0]}(\mu_{j+1}). \tag{2.10}$$

The above equation together with Corollary 2.2 proves formula (2.6). □

Remark 2.4: Notice [see Eqs. (2.7) and (2.10)] that the average of products of characteristic polynomials can be rewritten as a product of averages. Namely,

$$\left\langle \prod_{j=1}^{L} D_N[\mu_j,H] \right\rangle_\alpha = \prod_{j=1}^{L} \langle D_N[\mu_j,H] \rangle_{\alpha^{[j-1,0]}}, \tag{2.11}$$

where $\langle \cdots \rangle_{\alpha^{[j-1,0]}}$ means the average defined by Eq. (1.2) but with respect to the new measure $d\alpha^{[j-1,0]}(x)$, and $d\alpha(x) \equiv d\alpha^{[0,0]}(x)$.

The formula of Christoffel [Eq. (2.1)] enables us to construct the orthogonal polynomials associated with the measure $d\alpha^{[\ell,0]}(t) = \Pi_{j=1}^{\ell}(\mu_j - t) d\alpha(t)$ in terms of the orthogonal polynomials associated with the measure $d\alpha(t)$. Now we derive a formula due to Uvarov[19] expressing the monic orthogonal polynomials $\pi_n^{[0,m]}(t)$ associated with the measure $d\alpha^{[0,m]}(t) = \Pi_{j=1}^{m}(\epsilon_j - t)^{-1} d\alpha(t)$, again in terms of the monic orthogonal polynomials $\pi_n(t)$ associated with the measure $d\alpha(t)$.

Lemma 2.5: Suppose $0 \leqslant m \leqslant n$. *The monic orthogonal polynomials* $\pi_n^{[0,m]}(t)$ *associated with the measure* $d\alpha^{[0,m]}(t)$ *can be expressed as ratios of determinants.*

$$\pi_n^{[0,m]}(t)=\frac{\begin{vmatrix} h_{n-m}(\epsilon_1) & \cdots & h_n(\epsilon_1) \\ \vdots & & \\ h_{n-m}(\epsilon_m) & \cdots & h_n(\epsilon_m) \\ \pi_{n-m}(t) & \cdots & \pi_n(t) \end{vmatrix}}{\begin{vmatrix} h_{n-m}(\epsilon_1) & \cdots & h_{n-1}(\epsilon_1) \\ \vdots & & \\ h_{n-m}(\epsilon_m) & \cdots & h_{n-1}(\epsilon_m) \end{vmatrix}}. \tag{2.12}$$

Here the $h_k(\epsilon_j)$'s are the Cauchy transformations of the monic orthogonal polynomials $\pi_k(t)$.

$$h_k(\epsilon_j)=\frac{1}{2\pi i}\int \frac{\pi_k(t)d\alpha(t)}{t-\epsilon_j}. \tag{2.13}$$

Proof: Set

$$q_n^{[0,m]}(t)=\begin{vmatrix} h_{n-m}(\epsilon_1) & \cdots & h_n(\epsilon_1) \\ \vdots & & \\ h_{n-m}(\epsilon_m) & \cdots & h_n(\epsilon_m) \\ \pi_{n-m}(t) & \cdots & \pi_n(t) \end{vmatrix}. \tag{2.14}$$

Now $q_n^{[0,m]}(t)$ is proportional to the nth monic orthogonal polynomial $\pi_n^{[0,m]}(t)$ with respect to the measure $d\alpha^{[0,m]}(t)$. Indeed, first observe that

$$\int \frac{q_n^{[0,m]}(t)}{t-\epsilon_j}d\alpha(t)=0, \quad j=1,...,m. \tag{2.15}$$

Also, for $0\leqslant k<n$,

$$\frac{t^k}{\Pi_{\ell=1}^m(\epsilon_\ell-t)}=\sum_{\ell=1}^m \frac{\beta_\ell}{\epsilon_\ell-t}+p(t) \tag{2.16}$$

for suitable constants $\{\beta_\ell\}$ and for some polynomial $p(t)$ of degree $<n-m$. But for $0\leqslant k<n$,

$$\int t^k q_n^{[0,m]}(t)d\alpha^{[0,m]}(t)=-\sum_{\ell=1}^m \beta_\ell\int \frac{q_n^{[0,m]}(t)}{t-\epsilon_\ell}d\alpha(t)+\int p(t)q_n^{[0,m]}(t)d\alpha(t). \tag{2.17}$$

The terms in the sum are zero by (2.15) and the final integral is zero by the construction (2.14) of $q_n^{[0,m]}(t)$ and the fact that deg $p(t)<n-m$. Thus $q_n^{[0,m]}(t)$ is proportional to $\pi_n^{[0,m]}(t)$. An argument similar to the proof in Lemma 2.1, that

$$\begin{vmatrix} \pi_n(\mu_1) & \cdots & \pi_{n+\ell-1}(\mu_1) \\ \vdots & & \\ \pi_n(\mu_\ell) & \cdots & \pi_{n+\ell-1}(\mu_\ell) \end{vmatrix}\neq 0, \tag{2.18}$$

shows that the denominator in (2.12) does not vanish. Letting $t\to\infty$ in (2.14), and matching leading terms, we prove Lemma 2.5. □

Remark 2.6: In Ref. 19, Uvarov obtains formulas for $\pi_n^{[0,m]}(t)$ of type (2.12) also in the case $m>n$. These formulas can be used to obtain analogs of (2.24) and (2.36) below in the case $M>N$.

Remark 2.7: As noted in Refs. 11 and 17, the Cauchy transformations $h_k(\epsilon)$ of the π_k's occur explicitly, together with the π_k's, in the solution of the Fokas–Its–Kitaev Riemann–Hilbert problem for orthogonal polynomials.[9]

Lemma 2.5 implies the following analog of the Christoffel formula for the Cauchy transforms of monic orthogonal polynomials.

Corollary 2.8: Let $h_k^{[0,m]}(\epsilon)$ be the Cauchy transform of the monic polynomial $\pi_k^{[0,m]}(t)$. with respect to the measure $d\alpha^{[0,m]}(t)$,

$$h_k^{[0,m]}(\epsilon)=\frac{1}{2\pi i}\int \frac{\pi_k^{[0,m]}(t)}{t-\epsilon}d\alpha^{[0,m]}(t). \tag{2.19}$$

Let also $0\leqslant m\leqslant n$. Then $h_n^{[0,m]}(\epsilon)$ has a representation similar to that for the monic orthogonal polynomials $\pi_n^{[\ell,0]}(t)$ [Eq. (2.1)],

$$h_n^{[0,m]}(\epsilon)=\frac{(-1)^m}{(\epsilon-\epsilon_m)\cdots(\epsilon-\epsilon_1)}\frac{\begin{vmatrix} h_{n-m}(\epsilon_1) & \cdots & h_n(\epsilon_1)\\ \vdots & & \\ h_{n-m}(\epsilon_m) & \cdots & h_n(\epsilon_m)\\ h_{n-m}(\epsilon) & \cdots & h_n(\epsilon)\end{vmatrix}}{\begin{vmatrix} h_{n-m}(\epsilon_1) & \cdots & h_{n-1}(\epsilon_1)\\ \vdots & & \\ h_{n-m}(\epsilon_m) & \cdots & h_{n-1}(\epsilon_m)\end{vmatrix}}. \tag{2.20}$$

Proof: The above representation follows from formula (2.12) and from the fact that

$$\frac{1}{(t-\epsilon_{m+1})\cdots(t-\epsilon_1)}=\sum_{j=1}^{m+1}\frac{1}{t-\epsilon_j}\prod_{k\neq j}\frac{1}{\epsilon_j-\epsilon_k}. \tag{2.21}$$

Indeed we find from formula (2.12) that $h_n^{[0,m]}(\epsilon)$ is the ratio of the determinants. The elements of the last row of the determinant in the numerator are the integrals

$$\frac{1}{2\pi i}\int\frac{\pi_{n-k}(t)d\alpha(t)}{(t-\epsilon)(t-\epsilon_m)\cdots(t-\epsilon_1)},\quad 0\leqslant k\leqslant m.$$

Using identity (2.21) and noting that the only term

$$\frac{1}{t-\epsilon}\frac{1}{(\epsilon-\epsilon_m)\cdots(\epsilon-\epsilon_1)} \tag{2.22}$$

of the sum (2.21) contributes to the determinant, (2.20) follows. □

Equation (2.20) immediately implies the following analogy of (2.5) for the $h_k^{[0,m]}$'s.

Corollary 2.9: Let $0\leqslant m\leqslant n$. Then the product of the Cauchy transforms of monic orthogonal polynomials with respect to the measures $d\alpha^{[0,j]}(t)$, $0\leqslant j\leqslant m$, can be written as a determinant,

$$\prod_{j=0}^{m}h_{n-m+j}^{[0,j]}(\epsilon_{j+1})=\frac{(-1)m(m+1)/2}{\Delta(\epsilon)}\begin{vmatrix} h_{n-m}(\epsilon_1) & \cdots & h_n(\epsilon_1)\\ \vdots & & \\ h_{n-m}(\epsilon_{m+1}) & \cdots & h_n(\epsilon_{m+1})\end{vmatrix}. \tag{2.23}$$

Now we derive the identity for the average of the product of inverse random characteristic polynomials.

Theorem 2.10: *Suppose $1\leqslant M\leqslant N$ and let $\gamma_n=-2\pi i/c_n^2$, where c_n is the normality constant defined by Eq. (1.4). Then we have the following formula:*

$$\left\langle \prod_{j=1}^{M} D_N^{-1}[\epsilon_j,H] \right\rangle_\alpha = (-1)^{M(M-1)/2} \frac{\prod_{j=N-M}^{N-1} \gamma_j}{\Delta(\epsilon)} \begin{vmatrix} h_{N-M}(\epsilon_1) & \cdots & h_{N-1}(\epsilon_1) \\ \vdots & & \\ h_{N-M}(\epsilon_M) & \cdots & h_{N-1}(\epsilon_M) \end{vmatrix}. \quad (2.24)$$

Proof: When $M=1$, we use the identity (2.21) together with (2.7) and the relation (see, e.g., Ref. 18)

$$\gamma_{n-1} = -2\pi i n \frac{Z_{n-1}}{Z_n} \quad (2.25)$$

to obtain

$$\langle D_N^{-1}[\epsilon,H] \rangle_\alpha = \gamma_{N-1} h_{N-1}(\epsilon). \quad (2.26)$$

We rewrite the average in Eq. (2.24) as follows:

$$\left\langle \prod_{j=1}^{M} D_N^{-1}[\epsilon_j,H] \right\rangle_\alpha = \frac{Z_N^{[0,M]}}{Z_{N-1}^{[0,M-1]}} \frac{Z_{N-1}^{[0,M-1]}}{Z_{N-2}^{[0,M-2]}} \cdots \frac{Z_{N-M}^{[0,0]}}{Z_N^{[0,0]}}, \quad (2.27)$$

where

$$Z_N^{[0,M]} = \int \cdots \int \Delta^2(x) d\alpha^{[0,M]}(x), \quad (2.28)$$

$Z_N^{[0,0]} \equiv Z_N$ and $d\alpha^{[0,0]}(x) = d\alpha(x)$. The following relation can be observed from Eqs. (2.26) and (2.25):

$$\frac{Z_{N-K}^{[0,m]}}{Z_{N-K-1}^{[0,m-1]}} = -2\pi i (N-K) h_{N-K-1}^{[0,m-1]}(\epsilon_m). \quad (2.29)$$

Inserting this relation in (2.27) we find

$$\left\langle \prod_{j=1}^{M} D_N^{-1}[\epsilon_j,H] \right\rangle_\alpha = \prod_{j=1}^{M} \gamma_{N-j} h_{N-j}^{[0,M-j]}(\epsilon_{M-j+1}). \quad (2.30)$$

Our result (2.24) immediately follows from the above equation and formula (2.23). □

We now repeat the above considerations for the case

$$d\alpha^{[\ell,m]}(t) = \frac{(\mu_1 - t)\cdots(\mu_\ell - t)}{(\epsilon_1 - t)\cdots(\epsilon_m - t)} d\alpha(t). \quad (2.31)$$

The first result is a Christoffel-type formula for the measure (2.31), which is due to Uvarov.[19]

Lemma 2.11: Suppose $0 \leqslant m \leqslant n$. *Then the monic orthogonal polynomials* $\pi_n^{[\ell,m]}(t)$'s *with respect to the measure* $d\alpha^{\ell,m]}(t)$ *have the following representation:*

$$\pi_n^{[\ell,m]}(t)=\frac{1}{(t-\mu_\ell)\cdots(t-\mu_1)}\frac{\begin{vmatrix} h_{n-m}(\epsilon_1) & \cdots & h_{n+\ell}(\epsilon_1)\\ \vdots & & \\ h_{n-m}(\epsilon_m) & \cdots & h_{n+\ell}(\epsilon_m)\\ \pi_{n-m}(\mu_1) & \cdots & \pi_{n+\ell}(\mu_1)\\ \vdots & & \\ \pi_{n-m}(\mu_\ell) & \cdots & \pi_{n+\ell}(\mu_\ell)\\ \pi_{n-m}(t) & \cdots & \pi_{n+\ell}(t)\end{vmatrix}}{\begin{vmatrix} h_{n-m}(\epsilon_1) & \cdots & h_{n+\ell}(\epsilon_1)\\ \vdots & & \\ h_{n-m}(\epsilon_m) & \cdots & h_{n+\ell}(\epsilon_m)\\ \pi_{n-m}(\mu_1) & \cdots & \pi_{n+\ell}(\mu_1)\\ \vdots & & \\ \pi_{n-m}(\mu_\ell) & \cdots & \pi_{n+\ell}(\mu_\ell)\end{vmatrix}}. \tag{2.32}$$

Proof: As in the previous cases we define $q_n^{[\ell,m]}(t)$ to be the determinant in the numerator of (2.32). Observe that

$$q_n^{[\ell,m]}(\mu_1)=\cdots=q_n^{[\ell,m]}(\mu_\ell)=0 \tag{2.33}$$

and that

$$\int \frac{q_n^{[\ell,m]}(t)d\alpha(t)}{\epsilon_1-t}=\cdots=\int \frac{q_n^{[\ell,m]}(t)d\alpha(t)}{\epsilon_m-t}=0. \tag{2.34}$$

The next steps are the same as in the proofs of Lemma 2.1 and Lemma 2.5. □

Corollary 2.12:

$$\left\langle \prod_{j=1}^{K} D_N[\mu_j,H] \right\rangle_{\alpha^{[0,M]}}=\frac{1}{\Delta(\mu)}\frac{\begin{vmatrix} h_{N-M}(\epsilon_1) & \cdots & h_{N+K-1}(\epsilon_1)\\ \vdots & & \\ h_{N-M}(\epsilon_M) & \cdots & h_{N+K-1}(\epsilon_M)\\ \pi_{N-M}(\mu_1) & \cdots & \pi_{N+K-1}(\mu_1)\\ \vdots & & \\ \pi_{N-M}(\mu_K) & \cdots & \pi_{N+K-1}(\mu_K)\end{vmatrix}}{\begin{vmatrix} h_{N-M}(\epsilon_1) & \cdots & h_N(\epsilon_1)\\ \vdots & & \\ h_{N-M}(\epsilon_M) & \cdots & h_N(\epsilon_M)\end{vmatrix}}. \tag{2.35}$$

Proof: Identity (2.35) follows from Eqs. (2.10) and (2.32) once we note that Eq. (2.32) can be rewritten in a similar manner as Eq. (2.5). □

Finally we generalize Theorems 2.3 and 2.10 and obtain a formula for the average of ratios of characteristic polynomials.

Theorem 2.13: *Suppose* $0\leqslant M\leqslant N$. *Then the average of ratios of characteristic polynomials of* $N\times N$ *Hermitian matrices H is given by the following formula:*

$$\left\langle \frac{\prod_{j=1}^{K} D_N[\mu_j,H]}{\prod_{j=1}^{M} D_N[\epsilon_j,H]} \right\rangle_{\alpha} = \frac{(-1)^{M(M-1)/2} \prod_{j=N-M}^{N-1} \gamma_j}{\Delta(\mu)\Delta(\epsilon)} \begin{vmatrix} h_{N-M}(\epsilon_1) & \cdots & h_{N+K-1}(\epsilon_1) \\ \vdots & & \\ h_{N-M}(\epsilon_M) & \cdots & h_{N+K-1}(\epsilon_M) \\ \pi_{N-M}(\mu_1) & \cdots & \pi_{N+K-1}(\mu_1) \\ \vdots & & \\ \pi_{N-M}(\mu_K) & \cdots & \pi_{N+K-1}(\mu_K) \end{vmatrix}. \tag{2.36}$$

Proof: Let $\alpha^{[0,0]} \equiv \alpha$, $Z_n^{[0,0]} \equiv Z_n$. Then we have

$$\left\langle \frac{\prod_{j=1}^{K} D_N[\mu_j,H]}{\prod_{j=1}^{M} D_N[\epsilon_j,H]} \right\rangle_{\alpha} = \frac{Z_N^{[K,M]}}{Z_N^{[0,0]}} = \frac{Z_N^{[K,M]}}{Z_N^{[0,M]}} \frac{Z_N^{[0,M]}}{Z_N^{[0,0]}}, \tag{2.37}$$

i.e.,

$$\left\langle \frac{\prod_{j=1}^{K} D_N[\mu_j,H]}{\prod_{j=1}^{M} D_N[\epsilon_j,H]} \right\rangle_{\alpha} = \left\langle \prod_{j=1}^{K} D_N[\mu_j,H] \right\rangle_{\alpha^{[0,M]}} \left\langle \prod_{j=1}^{M} D_N^{-1}[\epsilon_j,H] \right\rangle_{\alpha}. \tag{2.38}$$

We use Corollary 2.12 and Theorem 2.10 to obtain formula (2.36). □

Remark 2.14: Observe that formulas (2.6) and (2.24) do not follow immediately as special cases of (2.36): some further algebraic manipulation is required. Similarly, the process of adding and removing zeros is clearly reciprocal. More precisely, given $\epsilon_1,\ldots,\epsilon_\ell$, we can construct the polynomials $\pi_n^{[0,\ell]}(t;d\alpha^{[0,\ell]})$ associated with the measure $d\alpha^{[0,\ell]}(t) = (\Pi_{i=1}^{\ell}(\epsilon_i - t)^{-1})dt$ by (2.12): We can then construct $\pi_n^{[\ell,0]}(t;d(\alpha^{[0,\ell]})^{[\ell,0]})$ with $\mu_i = \epsilon_i$, inserting $\pi_n^{[0,\ell]}(t;d\alpha^{[0,\ell]})$ for $\pi_n(t)$ on the right-hand side of (2.1). We should find that $\pi_n^{[\ell,0]}(t;d(\alpha^{[0,\ell]})^{[\ell,0]}) = \pi_n(t;d\alpha)$. However, again, this relation is not immediately clear, and requires further algebraic manipulation.

III. FORMULAS OF TWO-POINT FUNCTION TYPE

The following integral version of the Binet–Cauchy formula is due to Andréief,[2] and plays a basic role in our calculations.

Lemma 3.1: Let $(X,d\mu)$ be a measure space and suppose f_i, $g_j \in L^2(X,d\mu)$ for $1 \leqslant i,j \leqslant k$. Then

$$\int_X \cdots \int_X \det(f_i(x_j))_{1\leqslant i,j\leqslant k} \det(g_i(x_j))_{1\leqslant i,j\leqslant k}\, d\mu(x_1)\cdots d\mu(x_k)$$

$$= k!\, \det\left(\int_X f_i(x) g_j(x) d\mu(x) \right)_{1\leqslant i,j\leqslant k}. \tag{3.1}$$

Proof: Set $c_{ij} = \int_X f_i(x) g_j(x) d\mu(x)$. Then

$$\int_X \cdots \int_X \det(f_i(x_j))_{1\leqslant i,j\leqslant k} \det(g_i(x_j))_{1\leqslant i,j\leqslant k}\, d\mu(x_1)\cdots d\mu(x_k)$$

$$= \sum_{\sigma,\tau\in S_k} \operatorname{sgn}(\sigma)\operatorname{sgn}(\tau) c_{\sigma(1)\tau(1)}\cdots c_{\sigma(k)\tau(k)} = \sum_{\sigma} \operatorname{sgn}(\sigma) \sum_{\tau} \operatorname{sgn}(\tau\circ\sigma) c_{\sigma(1)\tau\circ\sigma(1)}\cdots c_{\sigma(k)\tau\circ\sigma(k)}$$

$$= \sum_{\sigma} (\operatorname{sgn}(\sigma))^2 \sum_{\tau} \operatorname{sgn}(\tau) c_{1\tau(1)}\cdots c_{k\tau(k)} = k!\, \det(c_{ij})_{1\leqslant i,j\leqslant k} \tag{3.2}$$

as desired. In (3.2) we used $\mathrm{sgn}(\tau\circ\sigma)=(\mathrm{sgn}\,\tau)(\mathrm{sgn}\,\sigma)$ and the fact that $c_{\sigma(1)\tau\circ\sigma(1)}\cdots c_{\sigma(k)\tau\circ\sigma(k)}=c_{1\tau(1)}\cdots c_{k\tau(k)}$ for all σ. □

Theorem 3.2: *Let $K\geqslant 1$. Then the following identity is valid:*

$$\left\langle \prod_{j=1}^{K} D_N[\lambda_j,H]D_N[\mu_j,H]\right\rangle_\alpha = \frac{C_{N,K}}{\Delta(\lambda)\Delta(\mu)}\det(W_{I,N+K}(\lambda_i,\mu_j))_{1\leqslant i,j\leqslant K}, \tag{3.3}$$

where

$$W_{I,N+K}(x,y)=\frac{\pi_{N+K}(x)\pi_{N+K-1}(y)-\pi_{N+K}(y)\pi_{N+K-1}(y)}{x-y} \tag{3.4}$$

and

$$C_{N,K}=\frac{\prod_{\ell=N}^{N+K-1} c_\ell^2}{(c_{N+K-1})^{2K}} \tag{3.5}$$

where c_ℓ is again the norming constant for π_ℓ given in (1.4).

Proof: Let $p_j(x)=c_j^{-1}\pi_j(x)$, $j\geqslant 0$, denote the orthonormal polynomials with respect to $d\alpha$. From (1.2) we obtain

$$\left\langle \prod_{j=1}^{K} D_N[\lambda_j,H]D_N[\mu_j,H]\right\rangle_\alpha = \frac{1}{Z_N\Delta(\lambda)\Delta(\mu)}\int\cdots\int \Delta(x,\lambda)\Delta(x,\mu)\,d\alpha(x). \tag{3.6}$$

Adding columns, we see that the Vandermonde determinant $\Delta(x,\lambda)$ has the form

$$\begin{vmatrix} \pi_0(x_1) & \pi_1(x_1) & \cdots & \pi_{N+K-1}(x_1)\\ \vdots & & & \\ \pi_0(x_N) & \pi_1(x_N) & \cdots & \pi_{N+K-1}(x_N)\\ \pi_0(\lambda_1) & \pi_1(\lambda_1) & \cdots & \pi_{N+K-1}(\lambda_1)\\ \vdots & & & \\ \pi_0(\lambda_K) & \pi_1(\lambda_K) & \cdots & \pi_{N+K-1}(\lambda_K)\end{vmatrix} \tag{3.7}$$

and similarly for $\Delta(x,\mu)$. Here $\pi_j(t)=\pi_j^{[0,0]}(t)$. The determinant $\Delta(x,\lambda)$ can be evaluated by a Lagrange expansion of the form

$$\sum_{0\leqslant i_1<i_2<\cdots<i_k\leqslant N+K-1}\sigma_{i_1,\ldots,i_K}\begin{vmatrix}\pi_{i_1}(\lambda_1) & \cdots & \pi_{i_K}(\lambda_1)\\ \vdots & & \\ \pi_{i_1}(\lambda_K) & \cdots & \pi_{i_K}(\lambda_K)\end{vmatrix}\begin{vmatrix}\pi_{j_1}(x_1) & \cdots & \pi_{j_N}(x_1)\\ \vdots & & \\ \pi_{j_1}(x_N) & \cdots & \pi_{j_N}(x_N)\end{vmatrix}, \tag{3.8}$$

where $\sigma_{i_1,\ldots,i_K}=\pm 1$ is an appropriate signature and $\{(j_1,\ldots,j_N):0\leqslant j_1<j_2<\cdots<j_N\leqslant N+K-1\}$ is the complement of $\{i_1,\ldots,i_K\}$ in $\{0,1,\ldots,N+K-1\}$. Multiplying (3.8) by a similar expansion for $\Delta(x,\mu)$, and inserting in (3.6), we obtain a sum of terms of the form

$$\int\cdots\int\begin{vmatrix}\pi_{j_1}(x_1) & \cdots & \pi_{j_K}(x_1)\\ \vdots & & \\ \pi_{j_1}(x_N) & \cdots & \pi_{j_K}(x_N)\end{vmatrix}\begin{vmatrix}\pi_{j_1'}(x_1) & \cdots & \pi_{j_N'}(x_1)\\ \vdots & & \\ \pi_{j_1'}(x_N) & \cdots & \pi_{j_N'}(x_N)\end{vmatrix} d\alpha(x), \tag{3.9}$$

which is equal by Lemma 3.1 to $N!\det(\int \pi_{j_i'}(x)\pi_{j_k}(x)d\alpha(x))_{1\leqslant i,k\leqslant N}=N!\det(\delta_{j_i' j_k}c_{j_k}^2)_{1\leqslant i,k\leqslant N}$. From this we see that

$$\begin{aligned}
&\left\langle \prod_{j=1}^{K} D_N[\lambda_j,H]D_N[\mu_j,H]\right\rangle_\alpha \\
&\quad=\frac{N!}{Z_N\Delta(\lambda)\Delta(\mu)}\sum_{0\leqslant i_1<\cdots<i_k\leqslant N+K-1}\sigma_{i_1,\ldots,i_K}^2\begin{vmatrix}\pi_{i_1}(\lambda_1) & \cdots & \pi_{i_K}(\lambda_1)\\ \vdots & & \\ \pi_{i_1}(\lambda_K) & \cdots & \pi_{i_K}(\lambda_K)\end{vmatrix}\\
&\qquad\times\prod_{k=1}^{N}c_{j_k}^2\begin{vmatrix}\pi_{i_1}(\mu_1) & \cdots & \pi_{i_K}(\mu_1)\\ \vdots & & \\ \pi_{i_1}(\mu_K) & \cdots & \pi_{i_K}(\mu_K)\end{vmatrix}\\
&\quad=\frac{N!\Pi_{q=N}^{N+K-1}c_q^2}{Z_N\Delta(x,\lambda)\Delta(x,\mu)}\sum_{0\leqslant i_1<\cdots<i_k\leqslant N+K-1}\det(p_{i_j}(\lambda_k))_{1\leqslant j,k\leqslant K}\det(p_{i_j}(\mu_k))_{1\leqslant j,k\leqslant K}\\
&\quad=\frac{N!\Pi_{q=N}^{N+K-1}c_q^2}{Z_N\Delta(x,\lambda)\Delta(x,\mu)}\det\left(\sum_{0\leqslant i\leqslant N+K-1}p_i(\lambda_j)p_i(\mu_k)\right)_{1\leqslant j,k\leqslant K},
\end{aligned}\tag{3.10}$$

where the last line follows by applying Lemma 3.1 to the discrete measure $d\mu=\Sigma_{i=0}^{N+K-1}\delta_i$. But, by the Christoffel–Darboux formula,

$$\sum_{0\leqslant i\leqslant N+K-1}p_i(\lambda_j)p_i(\mu_k)=\frac{\pi_{N+K}(\lambda_j)\pi_{N+K-1}(\mu_k)-\pi_{N+K}(\mu_k)\pi_{N+K-1}(\lambda_j)}{\lambda_j-\mu_k},\tag{3.11}$$

which then implies (3.3) as $Z_N=N!\Pi_{\ell=0}^{N-1}c_\ell^2$ (see, e.g., Ref. 18). □

Theorem 3.3: *Suppose* $1\leqslant K\leqslant N$. *Then the following identity is valid:*

$$\left\langle \prod_{j=1}^{K}\frac{D_N[\mu_i,H]}{D_N[\epsilon_j,H]}\right\rangle_\alpha=(-1)^{K(K-1)/2}\gamma_{N-1}^K\frac{\Delta(\epsilon,\mu)}{\Delta^2(\epsilon)\Delta^2(\mu)}\det(W_{H,N}(\epsilon_i,\mu_j))_{1\leqslant i,j\leqslant K},\tag{3.12}$$

where

$$W_{H,N}(x,y)=\frac{h_N(\epsilon)\pi_{N-1}(\mu)-h_{N-1}(\epsilon)\pi_N(\mu)}{\epsilon-\mu}\tag{3.13}$$

and again $h_k(\epsilon)=(1/2\pi i)\int\pi_k(t)d\alpha(t)/(t-\epsilon)$ *is the Cauchy transform of* $\pi_k(t)$ *and* $\gamma_{N-1}=-2\pi i/C_{N-1}^2$. Observe first that by linearity

$$\begin{vmatrix} h_{N-M}(\epsilon_1) & \cdots & h_{N+L-1}(\epsilon_1) \\ \vdots & & \\ h_{N-M}(\epsilon_M) & \cdots & h_{N+L-1}(\epsilon_M) \\ \pi_{N-M}(\mu_1) & \cdots & \pi_{N+L-1}(\mu_1) \\ \vdots & & \\ \pi_{N-M}(\mu_1) & \cdots & \pi_{N+L-1}(\mu_L) \end{vmatrix} = \int \cdots \int \frac{d\alpha(\lambda)}{(2\pi i)^M \prod_{j=1}^{M} (\lambda_j - \epsilon_j)}$$

$$\times \begin{vmatrix} \pi_{N-M}(\lambda_1) & \cdots & \pi_{N+L-1}(\lambda_1) \\ \vdots & & \\ \pi_{N-M}(\lambda_M) & \cdots & \pi_{N+L-1}(\lambda_M) \\ \pi_{N-M}(\mu_1) & \cdots & \pi_{N+L-1}(\mu_1) \\ \vdots & & \\ \pi_{N-M}(\mu_1) & \cdots & \pi_{N+L-1}(\mu_L) \end{vmatrix}. \tag{3.14}$$

Inserting (2.36) on the left-hand side, and using (2.5) to reexpress the integrand on the right-hand side, we obtain the following result, which is of independent interest. The result expresses averages of ratios of characteristic polynomials in terms of averages of products of such polynomials.

Proposition 3.4: Let $1 \leqslant M \leqslant N$. *Then*

$$\left\langle \frac{\prod_{j=1}^{L} D_N[\mu_i, H]}{\prod_{j=1}^{M} D_N[\epsilon_j, H]} \right\rangle_\alpha = \frac{(-1)^{M(M-1)/2} \prod_{j=N-M}^{N-1} \gamma_j}{\Delta(\mu)\Delta(\epsilon)} \int \cdots \int \frac{d\alpha(\lambda)}{(2\pi i)^M \prod_{j=1}^{M} (\lambda_j - \epsilon_j)} \Delta(\lambda, \mu)$$

$$\times \left\langle \prod_{j=1}^{M} D_{N-M}[\lambda_j, H] \prod_{j=1}^{L} D_{N-M}[\mu_j, H] \right\rangle_\alpha. \tag{3.15}$$

Proof of Theorem 3.2: For $M = L = K \leqslant N$, by (3.15) and (3.3),

$$\frac{\Delta(\mu)\Delta(\epsilon)}{(-1)^{K(K-1)/2} \prod_{j=N-K}^{N-1} \gamma_j} \left\langle \frac{\prod_{j=1}^{K} D_N[\mu_i, H]}{\prod_{j=1}^{K} D_N[\epsilon_j, H]} \right\rangle_\alpha$$

$$= \int \cdots \int \frac{d\alpha(\lambda)}{(2\pi i)^M \prod_{j=1}^{M} (\lambda_j - \epsilon_j)} C_{N-K,K} \prod_{i=1}^{K} \prod_{j=1}^{K} (\mu_i - \lambda_j) \det(W_{I,N}(\lambda_i, \mu_j))_{1 \leqslant i,j \leqslant K}. \tag{3.16}$$

But

$$\frac{1}{2\pi i} \int \frac{d\alpha(\lambda_j)}{\lambda_j - \epsilon_j} \prod_{i=1}^{K} (\mu_i - \lambda_j) \frac{\pi_N(\lambda_j)\pi_{N-1}(\mu_k) - \pi_{N-1}(\lambda_j)\pi_N(\mu_k)}{\lambda_j - \mu_k}$$

$$= \frac{1}{2\pi i} \int d\alpha(\lambda_j) \left(1 - \frac{\mu_1 - \epsilon_j}{\lambda_j - \epsilon_j}\right) \left(\prod_{\substack{i=2 \\ i \neq k}}^{K} (\mu_i - \lambda_j) \right) (\pi_N(\lambda_j)\pi_{N-1}(\mu_k) - \pi_{N-1}(\lambda_j)\pi_N(\mu_k))$$

$$= -\frac{1}{2\pi i} \int d\alpha(\lambda_j) \frac{\mu_1 - \epsilon_j}{\lambda_j - \epsilon_j} \left(\prod_{\substack{i=2 \\ i \neq k}}^{K} (\mu_i - \lambda_j) \right) (\pi_N(\lambda_j)\pi_{N-1}(\mu_k) - \pi_{N-1}(\lambda_j)\pi_N(\mu_k)) \tag{3.17}$$

as $\int d\alpha(\lambda_j)\lambda_j^{\ell}\pi_{N-1}(\lambda_j)=\int d\alpha(\lambda_j)\lambda_j^{\ell}\pi_N(\lambda_j)=0$ for $0\leqslant \ell \leqslant K-2<N-1$. Continuing in this way, the integral reduces to $\Pi_{i=1}^{K}(\mu_i-\epsilon_j)W_{H,N}(\epsilon_i,\mu_k)$. Thus we find

$$\frac{\Delta(\mu)\Delta(\epsilon)}{(-1)^{K(K-1)/2}\prod_{j=N-K}^{N-1}\gamma_j}\left\langle \frac{\prod_{j=1}^{K} D_N[\mu_i,H]}{\prod_{j=1}^{K} D_N[\epsilon_j,H]}\right\rangle_{\alpha}=\frac{\Delta(\epsilon,\mu)}{\Delta(\epsilon)\Delta(\mu)}\det(W_{I,N+K}(\lambda_i,\mu_k))_{1\leqslant i,k\leqslant K} \tag{3.18}$$

and (3.12) follows. □

Monotone Riemannian metrics on density matrices with non-monotone scalar curvature

Attila Andai
Department for Mathematical Analysis, Budapest University of Technology and Economics, H-1521 Budapest XI. Sztoczek u. 2, Hungary

(Received 28 November 2002; accepted 20 May 2003)

The theory of monotone Riemannian metrics on the state space of a quantum system was established by Dénes Petz in 1996. In a recent paper he argued that the scalar curvature of a statistically relevant—monotone—metric can be interpreted as an average statistical uncertainty. The present paper contributes to this subject. It is reasonable to expect that states which are more mixed are less distinguishable than those which are less mixed. The manifestation of this behavior could be that for such a metric the scalar curvature has a maximum at the maximally mixed state. We show that not every monotone metric fulfils this expectation, some of them behave in a very different way. A mathematical condition is given for monotone Riemannian metrics to have a local minimum at the maximally mixed state and examples are given for such metrics. © *2003 American Institute of Physics.*

I. INTRODUCTION

The quantum mechanical Hilbert space formalism gives a mathematical description of particles with spin of $(n-1)/2$. Concentrating on the spin part of nonrelativistic particles one can build a proper mathematical model in an n dimensional complex Hilbert space. This is the simplest physical realization of an n-level quantum system. The states of an n-level system are identified with the set of positive semidefinite self-adjoint $n\times n$ matrices of trace 1. The states form a closed convex set in the space of matrices and its interior, the set of all strictly positive self-adjoint matrices of trace 1 becomes naturally a differentiable manifold.

The idea in mathematical statistics that a statistical or informational distance between probability measures gives rise to a Riemannian metric is due to Rao[1] and was developed by Amari[2] and Streater[3] among others. Let us see how can one measure the statistical distance between the simplest probability distributions in classical case Ref. 4. Assume, that we have two probability distributions $(p_1,1-p_1)$ and $(p_2,1-p_2)$. Let us now suppose that an experimenter, in making his determination of the value p_1, has only n trials. Because of the unavoidable statistical fluctuations associated with a finite sample, the experimenter cannot know p_1 exactly. After these measurements the experimenter's uncertainty is the size of a typical fluctuation

$$\Delta p_1 = \sqrt{\frac{p_1(1-p_1)}{n}}.$$

We can say that the distributions $(p_1,1-p_1)$ and $(p_2,1-p_2)$ are distinguishable in n trials if the regions of uncertainty do not overlap, that is, if

$$|p_1-p_2| \geqslant \Delta p_1 + \Delta p_2 .$$

Let $k(n,p_1,p_2)$ denote the number of the probability distributions of the form $(p_i,1-p_i)$ between p_1 and p_2 (that is $p_1<p_i<p_2$) each of which is distinguishable in n trials from its neighbors. The statistical distance between the given probability distributions is

$$d(p_1,p_2)=\lim_{n\to\infty}\frac{k(n,p_1,p_2)}{\sqrt{n}}.$$

From the previous equations we find that

$$d(p_1,p_2)=\int_{p_1}^{p_2}\frac{1}{2\sqrt{p(1-p)}}dp=\arccos(\sqrt{p_1p_2}+\sqrt{(1-p_1)(1-p_2)}).$$

This distance function was introduced by Fisher in 1922.

The Fisher informational metric is unique in some sense (i.e., it is the only Markovian monotone distance) in the classical case Ref. 5. A family of Riemannian metrics are called monotone if they are decreasing under stochastic mappings (the exact definition is given below). These metrics play the role of Fisher metric in the quantum case. Monotone Riemannian metrics are important for information-theoretical and statistical considerations on the state space. The study of monotone metrics for parametric statistical manifolds was initiated by Chentsov and Morozova.[6] Petz's classification theorem[7] establishes a correspondence between monotone metrics and operator monotone $f:[0,\infty[\to\mathbb{R}$ functions, such that $f(x)=xf(x^{-1})$ hold for all positive x. In the simplest quantum case, dealing with 2×2 matrices we can use the Stokes parametrization, that is every state D can be uniquely written in the

$$D=\tfrac{1}{2}(I+x_1\sigma_1+x_2\sigma_2+x_2\sigma_2)$$

form, where $(\sigma_i)_{i=1,2,3}$ are the Pauli matrices and $(x_1,x_2,x_3)\in\mathbb{R}^3$ with $x_1^2+x_2^2+x_3^2\leqslant1$. The interior of the set of states can be identified with the open unit ball in $\mathbb{R}^3$ by this parametrization. In this case a monotone Riemannian metric on this manifold can be written in the

$$ds^2=\frac{1}{1-r^2}dr^2+\frac{r^2}{(1+r)f\left(\frac{1-r}{1+r}\right)}d\vartheta^2+\frac{r^2\sin^2\vartheta}{(1+r)f\left(\frac{1-r}{1+r}\right)}d\varphi^2$$

form in polar coordinates.

There is a strong connection between the scalar curvature of these manifolds at a given state and statistical distinguishability and uncertainty of the state. If D_0 is a $n\times n$ density matrix we call geodesic ball the set

$$B_r(D_0)=\{Dn\times n \text{ density matrix: } d(D_0,D)<r\}.$$

The volume of this ball is given by

$$V(B_r(D_0))=\frac{\sqrt{\pi^{n^2-1}}r^{n^2-1}}{\Gamma\left(\frac{n^2+1}{2}\right)}\cdot\left(1-\frac{r(D_0)r^2}{6(n^2+1)}+O(r^4)\right),$$

where $r(D_0)$ is the scalar curvature at the point D_0. According to Ref. 8, the quantity $V(B_r(D_0))$ measures the statistical uncertainty and the scalar curvature measures the average statistical uncertainty. A general explicit formula for the scalar curvature was given by Dittmann[10] (particular cases have been discussed in Refs. 11 and 12). There are many Riemannian metrics on the state space which are statistically relevant in different ways. The state A is more mixed than the state B if for their decreasingly ordered set of eigenvalues $(a_1,\ldots,a_n)$ and $(b_1,\ldots,b_n)$ the inequality

$$\sum_{l=1}^{k}a_l\leqslant\sum_{l=1}^{k}b_l$$

holds for every $1 \leqslant k \leqslant n$.

It is reasonable to expect that the most mixed states are less distinguishable than the less mixed states; for details see Refs. 13 and 14. It means mathematically that in this case the scalar curvature of a Riemann structure should have the following monotonicity property: if D_1 is more mixed than D_2 then $r(D_2)$ should be less then $r(D_1)$, where $r(D)$ denotes the scalar curvature of the manifold at the state D. It has been shown that the Bures metric does not have this monotonicity property for the scalar curvature and moreover it has a global minimum at the most mixed state. Actually in Ref. 9 it was proved that for the Bures metric for every $n \times n$ density matrix D the inequality

$$r(D) \geqslant \frac{(5n^2-4)(n^2-1)}{4}$$

holds. If $n>3$, equality holds iff $D=(1/n)I$. If $n=2$, then $r(D)=24$. This implies that the Bures metric is (trivially) monotone for $n=2$. Indeed all metrics studied thus far in two level quantum systems have monotone scalar curvature. This means that these metrics are compatible with one's statistical view. Do all monotone metrics have this property in the two level quantum system? The answer is no; in this paper we show a family of monotone metrics with non-monotone scalar curvature and we give a condition for monotone metric to have a local minimum at the maximally mixed state.

II. SCALAR CURVATURE ON THE TWO LEVEL QUANTUM SYSTEMS

A. The setup

Let $\mathcal{M}_n^+$ be the space of all complex self-adjoint positive definite $n \times n$ matrices of trace 1 and let $\mathcal{M}_n$ be the real vector space of all self-adjoint traceless $n \times n$ matrices. The space $\mathcal{M}_n^+$ can be endowed with a differentiable structure.[15]

The tangent space T_D at $D \in \mathcal{M}_n^+$ can be identified with $\mathcal{M}_n$. A map

$$K: \mathcal{M}_n^+ \times \mathcal{M}_n \times \mathcal{M}_n \to \mathbb{C}, \quad (D,X,Y) \mapsto K_D(X,Y)$$

will be called a Riemannian metric if the following condition holds: For all $D \in \mathcal{M}_n^+$ the map

$$K_D: \mathcal{M}_n \times \mathcal{M}_n \to \mathbb{C}, \quad (X,Y) \mapsto K_D(X,Y)$$

is a scalar product and for all $X \in \mathcal{M}_n$ the map

$$K_\cdot(X,X): \mathcal{M}_n^+ \to \mathbb{C}, \quad D \mapsto K_D(X,X)$$

is smooth.

We now use differential geometrical notation to define the scalar curvature of the $(\mathcal{M}_n^+, K)$ Riemannian manifold. In this case the Riemannian metric is a

$$K: \mathcal{M}_n^+ \to \mathrm{LIN}(\mathcal{M}_n \times \mathcal{M}_n, \mathbb{R}), \quad D \mapsto ((X,Y) \mapsto K_D(X,Y))$$

map, where $\mathrm{LIN}(U,V)$ denotes the set of linear maps from the vector space U to the vector space V. The derivative of the metric K is a map

$$\mathrm{d}K: \mathcal{M}_n^+ \to \mathrm{LIN}(\mathcal{M}_n, \mathrm{LIN}(\mathcal{M}_n \times \mathcal{M}_n, \mathbb{R})), \quad D \mapsto (X \mapsto ((Y,Z) \mapsto \mathrm{d}K_D(X)(Y,Z))).$$

At a given $D \in \mathcal{M}_n^+$ point for given $X,Y \in \mathcal{M}_n$ tangent vectors the map

$$\tau_{D,X,Y}: \mathcal{M}_n \to \mathbb{R}, \quad Z \mapsto \tfrac{1}{2}(\mathrm{d}K_D(Y)(X,Z) + \mathrm{d}K_D(X)(Z,Y) - \mathrm{d}K_D(Z)(X,Y))$$

is a linear functional. It means that there exists a unique $V_{D,X,Y}\in\mathcal{M}_n$ tangent vector such that for all $Z\in\mathcal{M}_n$ vector

$$K_D(V_{D,X,Y},Z)=\tau_{D,X,Y}(Z)$$

holds. One can define the map

$$\Gamma:\mathcal{M}_n^+\to\mathrm{LIN}(\mathcal{M}_n\times\mathcal{M}_n,\mathcal{M}_n),\quad D\mapsto((X,Y)\mapsto V_{D,X,Y})$$

which is called covariant differentiation. Its derivative is a map

$$\mathrm{d}\Gamma:\mathcal{M}_n^+\to\mathrm{LIN}(\mathcal{M}_n,\mathrm{LIN}(\mathcal{M}_n\times\mathcal{M}_n,\mathcal{M}_n)),\quad D\mapsto(X\mapsto((Y,Z)\mapsto\mathrm{d}\Gamma_D(X)(Y,Z))).$$

The Riemann curvature tensor defined to be

$$R:\mathcal{M}_n^+\to\mathrm{LIN}(\mathcal{M}_n\times\mathcal{M}_n\times\mathcal{M}_n,\mathcal{M}_n),\quad (D,X,Y,Z)\mapsto R_D(X,Y,Z),$$

where

$$R_D(X,Y,Z)=\mathrm{d}\Gamma_D(X)(Y,Z)-\mathrm{d}\Gamma_D(Y)(X,Z)+\Gamma_D(X,\Gamma_D(Y,Z))-\Gamma_D(Y,\Gamma_D(X,Z)).$$

The map

$$\alpha:\mathcal{M}_n^+\times\mathcal{M}_n\times\mathcal{M}_n\to\mathrm{LIN}(\mathcal{M}_n,\mathcal{M}_n),\quad (D,X,Y)\mapsto\alpha_{D,X,Y}=(Z\mapsto R_D(Z,X,Y)),$$

is needed to define the Ricci tensor

$$\mathrm{Ric}:\mathcal{M}_n^+\to\mathrm{LIN}(\mathcal{M}_n\times\mathcal{M}_n,\mathbb{R}),\quad D\mapsto((X,Y)\mapsto\mathrm{Ric}_D(X,Y)),$$

where

$$\mathrm{Ric}_D(X,Y)=\mathrm{Tr}\,\alpha_{D,X,Y}.$$

At a given $D\in\mathcal{M}_n^+$ point for given $X\in\mathcal{M}_n$ tangent vector the map

$$\beta_{D,X}:\mathcal{M}_n\to\mathbb{R},\quad Y\mapsto\mathrm{Ric}_D(X,Y)$$

is a linear functional. It means that there exists a unique $U_{D,X}\in\mathcal{M}_n$ tangent vector such that for all $Y\in\mathcal{M}_n$ vector

$$K_D(U_{D,X},Y)=\beta_{D,X}(Y)$$

holds. From the map

$$\rho:\mathcal{M}_n^+\to\mathrm{LIN}(\mathcal{M}_n,\mathcal{M}_n),\quad D\mapsto\rho_D=((X)\mapsto U_{D,X})$$

we get the scalar curvature of the manifold

$$\mathrm{Scal}:\mathcal{M}_n^+\to\mathbb{R},\quad D\mapsto\mathrm{Tr}\,\rho_D.$$

For further differential geometry details see, for example, Ref. 16.

Let $M_n(\mathbb{C})$ denote the set of complex $n\times n$ matrices and $M_k(M_n)$ denote the set of $k\times k$ matrices with entries $M_n(\mathbb{C})$. If $T:M_n(\mathbb{C})\to M_m(\mathbb{C})$ is a linear map, it induces a linear map $T^{(k)}:M_k(M_n)\to M_k(M_m)$ by

$$T^{(k)}([A_{ij}])=[T(A_{ij})].$$

The map T is called positive if it takes positive operators to positive operators. Say that T is k-positive if $T^{(k)}$ is positive and T is completely positive if it is k-positive for all $k \geqslant 1$.

A linear mapping $T: M_n(\mathbb{C}) \to M_m(\mathbb{C})$ is defined to be stochastic if T is completely positive and trace preserving. For more information on completely positive and stochastic maps see Refs. 13 and 14.

Let $(K^m)_{m \in \mathbb{N}}$ be a family of metrics, such that K^m is a Riemannian metric on $\mathcal{M}_m^+$ for all m. This family of metrics is defined to be monotone if

$$K^m_{T(D)}(T(X),T(X)) \leqslant K^n_D(X,X)$$

for every stochastic mapping $T: M_n(\mathbb{C}) \to M_m(\mathbb{C})$, for every $D \in \mathcal{M}_n^+$ and for all $X \in \mathcal{M}_n$ and for all $m,n \in \mathbb{N}$.

Theorem 2.1: *Petz classification theorem:*[7] *There exists a bijective correspondence between the monotone family of metrics* $(K^n)_{n \in \mathbb{N}}$ *and operator monotone* $f: \mathbb{R}^+ \to \mathbb{R}$ *functions such that* $f(x) = xf(x^{-1})$ *hold for all positive* x. *The metric is given by*

$$K^n_D(X,Y) = \mathrm{Tr}(X(R^{1/2}_{n,D} f(L_{n,D} R^{-1}_{n,D}) R^{1/2}_{n,D})^{-1}(Y)) \tag{1}$$

for all $n \in \mathbb{N}$ *where* $L_{n,D}(X) = DX$, $R_{n,D}(X) = XD$ *for all* $D,X \in M_n(\mathbb{C})$.

A Riemannian metric K is said to be monotone if there is a monotone family of metrics $(K^m)_{m \in \mathbb{N}}$ such that $K = K^n$ for an n. We use the normalization condition for the function f in the previous theorem $f(1) = 1$. Here are some examples of operator monotone functions which generate monotone metrics from Refs. 17 and 18,

$$\frac{1+x}{2}, \quad \frac{2x}{1+x}, \quad \frac{x-1}{\log x}, \quad \frac{2(x-1)^2}{(1+x)(\log x)^2}, \quad \frac{2(x-1)\sqrt{x}}{(1+x)\log x}, \quad \frac{2x^{\alpha+1/2}}{1+x^{2\alpha}}, \quad \frac{\beta(1-\beta)(x-1)^2}{(x^\beta-1)(x^{1-\beta}-1)},$$

where $0 \leqslant \alpha \leqslant 1/2$ and $0 < |\beta| < 1$.

B. Curvature and eigenvalues on $\mathcal{M}_2^+$

There is an explicit formula for scalar curvature in a given $D \in \mathcal{M}_2^+$ state using a monotone metric coming from a suitable f function defined by Eq. (1). To use that result to build up a more explicit formula to our $\mathcal{M}_2^+$ manifold, first introduce the Morozova–Chentsov function related to the monotone function f defined by

$$c(x,y) := \frac{1}{yf(x/y)}. \tag{2}$$

Let us denote by $\partial_1 c(x,y)$ the partial derivative of $c(x,y)$ with respect to its first variable. Define four new functions (as in Ref. 10)

$$h_1(x,y,z) := \frac{c(x,y) - zc(x,z)c(y,z)}{(x-z)(y-z)c(x,z)c(y,z)}, \quad h_3(x,y,z) := \frac{z}{x-y}(\partial_1(\log c)(z,x) - \partial_1(\log c)(z,y)),$$

$$h_2(x,y,z) := \frac{(c(x,z)-c(y,z))^2}{(x-y)^2 c(x,y)c(x,z)c(y,z)}, \quad h_4(x,y,z) := z\partial_1(\log c)(z,x)\partial_1(\log c)(z,y). \tag{3}$$

The terms like $h_i(x,x,z)$ can be computed as a

$$\lim_{y \to x} h_i(x,y,z)$$

limit. We will need a linear combination of these functions

$$h(x,y,z)=h_1(x,y,z)-\tfrac{1}{2}h_2(x,y,z)+2h_3(x,y,z)-h_4(x,y,z). \tag{4}$$

Theorem 2.2: *(see Ref. 10.) Let $\sigma(D)$ be the spectrum of the state $D\in\mathcal{M}_n^+$. Then for the scalar curvature one has the expression*

$$r(D)=\sum_{x,y,z\in\sigma(D)}h(x,y,z)-\sum_{x\in\sigma(D)}h(x,x,x)+\frac{1}{4}(n^2-1)(n^2-2).$$

Corollary 2.1: The scalar curvature at the state $D\in\mathcal{M}_2^+$ with eigenvalues λ_1,λ_2 is given by

$$r(D)=h(\lambda_1,\lambda_1,\lambda_2)+h(\lambda_1,\lambda_2,\lambda_1)+h(\lambda_2,\lambda_1,\lambda_1)+h(\lambda_2,\lambda_2,\lambda_1)+h(\lambda_2,\lambda_1,\lambda_2)$$
$$+h(\lambda_1,\lambda_2,\lambda_2)+\tfrac{3}{2}.$$

Theorem 2.3: *Let $D\in\mathcal{M}_2^+$ and $a=2\lambda_1-1$ where λ_1 is an eigenvalue of D and assume that the monotone metric of $\mathcal{M}_2^+$ comes from a function f. Then the scalar curvature at D is*

$$r(a)=\frac{14(a-1)\left[f'\left(\frac{1-a}{1+a}\right)\right]^2}{(1+a)^3\left[f\left(\frac{1-a}{1+a}\right)\right]^2}+\frac{2(a^2+7a-6)f'\left(\frac{1-a}{1+a}\right)}{(1+a)^2af\left(\frac{1-a}{1+a}\right)}+\frac{8(1-a)f''\left(\frac{1-a}{1+a}\right)}{(1+a)^3f\left(\frac{1-a}{1+a}\right)}$$
$$+\frac{2(1+a)f\left(\frac{1-a}{1+a}\right)}{a^2}+\frac{3a^3+5a^2+8a-4}{2(1+a)a^2}. \tag{5}$$

Proof 1: Through the computation we will use the identities $f'(1)=\frac{1}{2}$ and $2f^{(3)}(1)+3f^{(2)}(1)=0$ which come from the equations $f(x)=xf(1/x)$ and $f(1)=1$. It is easy to recognize that $h_i(y,x,x)=h_i(x,y,x)$ for $i=1,2,3,4$. First let us note the following identities:

$$c(x,x)=\frac{1}{x},\quad c(x,y)=c(y,x),\quad c(x,y)=tc(tx,ty),\quad \forall t\in\mathbb{R}^+,$$
$$\partial_1c(x,x)=-\frac{1}{2x^2},\quad \partial_1^k\partial_2^lc(x,y)=\partial_1^l\partial_2^kc(y,x),\quad c(x,y)=-x\partial_1c(x,y)-y\partial_2c(x,y), \tag{6}$$

which will be used through the computation.

The $h_i(x,x,y)$ and $h_i(x,y,x)$ like limit functions can be computed. For example,

$$h_1(x,x,y)=\lim_{q\to x}h_1(x,q,y)=\lim_{q\to x}\frac{c(x,q)-yc(x,y)c(q,y)}{(x-y)(q-y)c(x,y)c(q,y)}=\frac{c(x,x)-y[c(x,y)]^2}{(x-y)^2[c(x,y)]^2},$$

$$h_4(x,y,x)=\lim_{q\to x}h_4(x,y,q)=\lim_{q\to x}q\frac{\partial_1c(q,x)}{c(q,x)}\frac{\partial_1c(q,y)}{c(q,y)}=x\frac{\partial_1c(x,x)}{c(x,x)}\frac{\partial_1c(x,y)}{c(x,y)}.$$

After taking into account the identities (6) these limit functions can be simplified,

$$h_1(x,x,y)=\frac{1-xy[c(x,y)]^2}{x(x-y)^2[c(x,y)]^2},\quad h_1(x,y,x)=-\frac{1}{2}\frac{c(x,y)+2x\partial_1c(x,y)}{(x-y)c(x,y)}, \tag{7}$$

$$h_2(x,x,y)=x\left(\frac{\partial_1c(x,y)}{c(x,y)}\right)^2,\quad h_2(x,y,x)=\frac{1}{x}\left(\frac{1-xc(x,y)}{(x-y)c(x,y)}\right)^2,$$

$$h_3(x,x,y)=-\frac{y^2c(x,y)[\partial_1c(y,x)]^2+2yc(x,y)\partial_1c(y,x)+xy\partial_1c(x,y)\partial_1c(y,x)}{x[c(x,y)]^2},$$

$$h_3(x,y,x)=-\frac{c(x,y)+2x\partial_1c(x,y)}{2(x-y)c(x-y)},$$

$$h_4(x,x,y)=y\left(\frac{\partial_1c(y,x)}{c(x,y)}\right)^2,\quad h_4(x,y,x)=-\frac{1}{2}\frac{\partial_1c(x,y)}{c(x,y)}.$$

Introducing the suitable sum functions for h_i $(i=1,2,3,4)$,

$$sh_i(x,y):=h_i(x,x,y)+2h_i(x,y,x)+h_i(y,y,x)+2h_i(y,x,y), \tag{8}$$

we get that

$$sh_1(x,y)=\frac{(x+y)(1-xy[c(x,y)]^2)}{xy(x-y)^2[c(x,y)]^2}-\frac{4x\partial_1c(x,y)+2c(x,y)}{(x-y)c(x,y)},$$

$$sh_2(x,y)=\frac{x[\partial_1c(x,y)]^2+y[\partial_1c(y,x)]^2}{[c(x,y)]^2}+2\frac{(x+y)+xy(x+y)[c(x,y)]^2-4xyc(x,y)}{xy(x-y)^2[c(x,y)]^2},$$

$$sh_3(x,y)=\frac{(x+y)(c(x,y)[\partial_{1,2}c(x,y)]^2-\partial_1c(x,y)\partial_1c(y,x))}{[c(x,y)]^2}-\frac{4x\partial_1c(x,y)+2c(x,y)}{(x-y)c(x,y)}, \tag{9}$$

$$sh_4(x,y)=\frac{x[\partial_1c(x,y)]^2+y[\partial_1c(y,x)]^2}{[c(x,y)]^2}-\frac{\partial_1c(x,y)+\partial_1c(y,x)}{c(x,y)}.$$

These sum functions can be expressed by the operator monotone function $f(x)$:

$$sh_1(x,y)=\frac{1}{(x-y)^2}\left(\frac{y(x+y)}{x}[f(x/y)]^2+y-3x+\frac{4x(x-y)}{y}\frac{f'(x/y)}{f(x/y)}\right),$$

$$sh_2(x,y)=\frac{x}{y^2}\left(\frac{f'(x/y)}{f(x/y)}\right)^2+\frac{y^3}{x^4}\left(\frac{f(x/y)f'(y/x)}{[f(y/x)]^2}\right)^2+\frac{2y(x+y)}{x(x-y)^2}[f(x/y)]^2$$
$$-\frac{8y}{(x-y)^2}f(x/y)+\frac{2(x+y)}{(x-y)^2},$$

$$sh_3(x,y)=\frac{-2x(x+y)}{y^3}\left(\frac{f'(x/y)}{f(x/y)}\right)^2-\frac{(x+y)}{x^2}\frac{f'(x/y)f'(y/x)}{[f(x/y)]^2} \tag{10}$$
$$+\frac{2(x^2+2xy-y^2)}{y^2(x-y)}\frac{f'(x/y)}{f(x/y)}+\frac{x(x+y)}{y^3}\frac{f''(x/y)}{f(x/y)}-\frac{2}{x-y},$$

$$sh_4(x,y)=\frac{x}{y^2}\left(\frac{f'(x/y)}{f(x/y)}\right)^2+\frac{y^3}{x^4}\left(\frac{f(x/y)f'(y/x)}{[f(y/x)]^2}\right)^2+\frac{1}{y}\frac{f'(x/y)}{f(x/y)}+\frac{y}{x^2}\frac{f(x/y)f'(y/x)}{[f(y/x)]^2}.$$

The scalar curvature is given by the linear combination of the functions $sh_i(x,y)$:

$$r(D)=sh_1(x,y)-\tfrac{1}{2}sh_2(x,y)+2sh_3(x,y)-sh_4(x,y).$$

The result is the following:

$$r(D)=2\frac{2yf(x/y)-1}{(x-y)^2}+6\frac{2xf'(x/y)-yf(x/y)}{y(x-y)f(x/y)}-\frac{1}{2}\frac{x(8+3y)}{y^3}\left(\frac{f'(x/y)}{f(x/y)}\right)^2-\frac{3}{2}\frac{y}{x^2}\left(\frac{f'(y/x)}{f(y/x)}\right)^2$$
$$+\frac{(3+x)f'(x/y)}{y^2f(x/y)}+2\frac{xf''(x/y)}{y^3f(x/y)}-\frac{f'(y/x)}{xf(y/x)}-\frac{2f'(x/y)f'(y/x)}{x^2[f(y/x)]^2}+\frac{3}{2}. \tag{11}$$

The eigenvalues of D can be expressed by a as

$$\lambda_1=\frac{1+a}{2},\quad \lambda_2=\frac{1-a}{2}.$$

Substituting these into the previous formula and collecting the terms we get Eq. (5). □

Since the scalar curvature formula Eq. (5) is a rather complicated one it is worth mentioning that there is a completely different proof (which is based on Sec. II A) for Theorem 2.3.

Proof 2: There is another parametrization of the state as it was mentioned in the introduction. Let us use the following parametrization for the 2×2 density matrices:

$$\frac{1}{2}\begin{pmatrix}1+r\cos\theta & (r\sin\theta\cos\phi)+i(r\sin\theta\sin\phi)\\ (r\sin\theta\cos\phi)-i(r\sin\theta\sin\phi) & 1-r\cos\theta\end{pmatrix},$$

where (r,θ,ϕ) denote the spherical coordinates, but now $0\leqslant r<1$. In this case the metric is

$$ds^2=\frac{1}{1-r^2}dr^2+\frac{r^2}{(1+r)f\left(\frac{1-r}{1+r}\right)}d\theta^2+\frac{r^2\sin^2\theta}{(1+r)f\left(\frac{1-r}{1+r}\right)}d\phi^2.$$

Let us use the order (r,θ,ϕ) for the coordinates. [For example $\partial_2 t(r,\theta,\phi)$ denotes the partial derivative of $t(r,\theta,\phi)$ with respect to θ.] The g_{ik} metric can be written in the form $g_{ik}=\delta_{ik}\alpha_i(r,\theta,\phi)$. The identities

$$\partial_2\alpha_1=\partial_3\alpha_1=0,\quad \partial_2\alpha_2=\partial_3\alpha_2=0,\quad \partial_3\alpha_3=0$$

will simplify the computation. The Christoffel symbols of the second kind for this Riemannian manifold is

$$\Gamma_{ij}^{\cdot\cdot m}=\sum_{k=1}^{3}\frac{1}{2}g^{km}(\partial_i g_{jk}+\partial_j g_{ik}-\partial_k g_{ij}), \tag{12}$$

where g^{ij} denotes the inverse matrix of g_{ij}. Since $\Gamma_{ij}^{\cdot\cdot m}=\Gamma_{ji}^{\cdot\cdot m}$, there are only seven nonzero independent Christoffel symbols in this case

$$\Gamma_{1,1}^{\cdot\cdot 1}=\frac{r}{1-r^2},\quad \Gamma_{2,2}^{\cdot\cdot 1}=\frac{-r(1-r)}{2(1+r)^2f(c(r))}\left(r^2+3r+2+2r\frac{f'(c(r))}{f(c(r))}\right),\quad \Gamma_{3,3}^{\cdot\cdot 1}=\sin^2\theta\,\Gamma_{2,2}^{\cdot\cdot 1},$$

$$\Gamma_{1,2}^{\cdot\cdot 2}=\frac{-f(c(r))}{r^2(1-r)}\Gamma_{2,2}^{\cdot\cdot 1},\quad \Gamma_{3,3}^{\cdot\cdot 2}=-\sin\theta\cos\theta,\quad \Gamma_{1,3}^{\cdot\cdot 3}=\Gamma_{1,2}^{\cdot\cdot 2},\quad \Gamma_{2,3}^{\cdot\cdot 3}=\frac{\cos\theta}{\sin\theta}, \tag{13}$$

where $c(r)=(1-r)/(1+r)$.

The Riemannian curvature tensor is given by the equation

$$R_{ijkl}=\sum_{n=1}^{3}g_{ln}\left(\partial_i\Gamma_{jk}^{\cdot\cdot n}-\partial_j\Gamma_{ik}^{\cdot\cdot n}+\sum_{m=1}^{3}(\Gamma_{jk}^{\cdot\cdot m}\Gamma_{im}^{\cdot\cdot n}-\Gamma_{ik}^{\cdot\cdot m}\Gamma_{jm}^{\cdot\cdot n})\right). \tag{14}$$

Since $R_{ijkl}=-R_{jikl}$, $R_{ijkl}=-R_{ijlk}$, and $R_{ijkl}=R_{klij}$, there are only three nonzero independent elements of the curvature tensor,

$$R_{1212}=\frac{-r}{(1+r)^4(1-r^2)f(c(r))}\left(2r(1-r)\frac{f''(c(r))}{f(c(r))}-3r(1-r)\left(\frac{f'(c(r))}{f(c(r))}\right)^2+(1+r)(3r-2)\frac{f'(c(r))}{f(c(r))}+\frac{(r^2+r+4)(1+r)^2}{4}\right),$$

$$R_{1313}=\sin^2\theta\ R_{1212}, \tag{15}$$

$$R_{2323}=\frac{r^2(1-r)\sin^2\theta}{(1+r)^4[f(c(r))]^2}\left(r(r+2)\frac{f'(c(r))}{f(c(r))}+\frac{r^2}{1+r}\left(\frac{f'(c(r))}{f(c(r))}\right)^2-\frac{(1+r)^3}{1-r}f(c(r))+\frac{(1+r)(2+r)^2}{4}\right).$$

The Ricci curvature tensor is

$$\mathrm{Ric}_{ij}=\sum_{k,l=1}^{3}g^{kl}R_{lijk}. \tag{16}$$

It is symmetric $\mathrm{Ric}_{ij}=\mathrm{Ric}_{ji}$, and it has three nonzero elements,

$$\mathrm{Ric}_{1,1}=\frac{1}{(1+r)^4}\left(4\frac{f''(c(r))}{f(c(r))}-6\left(\frac{f'(c(r))}{f(c(r))}\right)^2+\frac{2(1+r)(3r-2)}{(1-r)}\frac{f'(c(r))}{f(c(r))}+\frac{(r^2+r+4)(1+r)^2}{2r(1-r)}\right),$$

$$\mathrm{Ric}_{2,2}=\frac{r^2(1-r)}{(1+r)^4f(c(r))}\left(2\frac{f''(c(r))}{f(c(r))}-4\left(\frac{f'(c(r))}{f(c(r))}\right)^2+\frac{(1+r)(r^2+4r-4)}{r(1-r)}\frac{f'(c(r))}{f(c(r))}+\frac{(1+r)^4}{r^2(1-r)}f(c(r))+\frac{(r^3+2r^2+2r-2)(1+r)^2}{2r^2(1-r)}\right), \tag{17}$$

$$\mathrm{Ric}_{3,3}=\sin^2\theta\,\mathrm{Ric}_{2,2}.$$

The scalar curvature at point D is

$$r(D)=\sum_{i,j=1}^{3}g^{ij}\,\mathrm{Ric}_{ji}. \tag{18}$$

Computing $r(D)$ we get Eq. (5). □

The state D is maximally mixed if its eigenvalues are equal, in this case $a=0$. So the scalar curvature has local minimum or maximum at the maximally mixed state if and only if the function $r(a)$ has local minimum or maximum at the origin.

C. Curvature formula at the origin and Radon measures

To find an operator monotone function f such that the scalar curvature has local minimum at the origin we start from the following representation theorem in Ref. 19.

The map $\mu\mapsto f$ defined by

$$f(x)=\int_0^\infty \frac{x(1+t)}{x+t}\,\mathrm{d}\mu(t) \quad \text{for } x>0$$

establishes an affine isomorphism from the class of positive Radon measures $[0,\infty]$ onto the class of operator monotone functions.

We use a modified version of the previous theorem Ref. 20.

Theorem 2.4: *The map $\mu\mapsto f$, defined by*

$$f(x)=\int_0^1 \frac{x}{(1-t)x+t}\,\mathrm{d}\mu(t), \quad \text{for } x>0, \tag{19}$$

establishes a bijection between the class of positive Radon measures on [0,1] and the class of operator monotone functions.

From this representation we get that

$$xf(x^{-1})=\int_0^1 \frac{x}{(1-t)+tx}\,\mathrm{d}\mu(t)=\int_0^1 \frac{x}{(1-t)x+t}\,\mathrm{d}\mu(1-t) \quad .$$

Thus $f(x)=xf(x^{-1})$ holds iff $\mu([0,t])=\mu([1-t,1])$ for all $t\in[0,1]$ and the $f(1)=1$ normalization means that $\mu([0,1])=1$. Let T denote the set of all positive Radon measures on the $[0,1]$ interval such that $\mu(X)=\mu(1-X)$ for every measurable X subset of $[0,1]$ and $\mu([0,1])=1$. Theorem 2.1 and 2.4 imply that there is bijective correspondence between monotone metrics and T.

III. SCALAR CURVATURE

A. Scalar curvatures with local minimum at the origin

For detailed verification of Theorem 3.1 and 3.3 the *Maple* program was used. The Maple worksheet, containing these proofs is available at Ref. 21.

Theorem 3.1: *The series expansion of $r(a)$ at the origin leads to the*

$$r(a)=(6+36f''(1))+a^2\left(\tfrac{100}{3}f^{(4)}(1)-140f''(1)-120f''(1)^2\right)+a^4(352f''(1)^3+616f''(1)^2$$
$$+1092f''(1)-\tfrac{1288}{3}f^{(4)}(1)+\tfrac{392}{45}f^{(6)}(1)-160f''(1)f^{(4)}(1))+O(a^6) \tag{20}$$

approximation.

Proof: From Eq. (5) one may expect that the $1/a$ and $1/a^2$ type divergences occur in this expansion but the behavior derivatives of f not allow this. It is obvious that $r(a)=r(-a)$ from symmetric reasons (not from the formula) this means that the coefficient of $a^{(2n+1)}$ will be zero for all $n\in\mathbb{N}$. We proof this series expansion only up to the order $O(a^4)$ because the coefficient of a^4 can be derived in a similar way, but it needs more complicated formulas. Through the computation we will use the identities

$$f'(1)=\frac{1}{2}, \quad f^{(3)}(1)=-\frac{3}{2}f^{(2)}(1), \quad f^{(5)}(1)=-\frac{15f^{(4)}(1)+60f^{(3)}(1)+60f^{(2)}(1)}{2}$$

which come from the equations $f(x)=xf(1/x)$ and $f(1)=1$. We consider the scalar curvature as a sum of five functions according to the Eq. (5). The series expansion of the summands can be computed in elementary way, but the intermediate formulas are rather complicated. The series expansions of the five summands from Eq. (5) after simplifications are the following:

(1) $-\frac{7}{2}+7(4f''(1)+1)\cdot a-7(8f''(1)^2+4f''(1)+1)\cdot a^2$.
(2) $-6\cdot\frac{1}{a}+(24f''(1)+13)-(28f''(1)+12)\cdot a+(16f^{(4)}(1)-48f''(1)^2-52f''(1)+12)\cdot a^2$.
(3) $8f''(1)+(16f^{(4)}(1)-16f''(1)^2-56f''(1))\cdot a^2$.

(4) $2\cdot\frac{1}{a}^2+4f''(1)+(4/3\,f^{(4)}(1)-4f''(1))\cdot a^2$.
(5) $-2\cdot\frac{1}{a}^2+6\cdot\frac{1}{a}-5+5\cdot a-5\cdot a^2$.

The sum of these expansions leads to Eq. (5) in this theorem. □

Combining Eqs. (19) and (20) we conclude that the scalar curvature has local minimum at the origin if

$$12\left(\int_0^1 t(1-t)\ \mathrm{d}\mu(t)\right)^2-\int_0^1 t(t-1)(20t^2-40t+13)\mathrm{d}\mu(t)<0 \tag{21}$$

holds for a $\mu\in T$. The scalar curvature at the origin is given by

$$6+72\int_0^1 (t^2-t)\ \mathrm{d}\mu(t).$$

It has maximum when $\mu=(1/2)\,\delta_0+(1/2)\,\delta_1$, the corresponding operator monotone function is $f(x)=(1+x)/2$ and then $r(0)=6$. It has minimum when $\mu=\delta_{1/2}$, the corresponding operator monotone function is $f(x)=2x/(1+x)$ and then $r(0)=-12$.

The measure $\mu\in T$ can be transformed into a probability measure μ' on the [0,1] interval such that

$$\int_0^{-1/2} t(1-t)\ \mathrm{d}\mu(t)=\frac{1}{8}\int_0^1 x\ \mathrm{d}\mu'(x)$$

because the $4t(1-t)$ function maps the $2\mu|_{[0,1/2]}$ measure into a probability measure on [0,1]. If λ denotes the Lebesgue measure and

$$\mu(t)|_{[0,1/2]}=\rho(t)\ \mathrm{d}\lambda(t)+\sum a_i\delta_{p_i}$$

then

$$\mu'(x)=\frac{1}{2}\rho\left(\frac{1-\sqrt{1-x}}{x}\right)\frac{1}{\sqrt{1-x}}\mathrm{d}\lambda(x)+\sum 2a_i\delta_{4p_i(1-p_i)}.$$

There is one to one correspondence between probability measures on [0,1] and T. Let m_μ denote the expectation σ_μ^2 the variance and $E_{n,\mu}$ the nth momentum of the μ' measure. Using Eq. (19) and the previous notation one can check the following equalities:

$$f''(1)=-\frac{m_\mu}{2},\quad f^{(4)}(1)=-3m_\mu+\frac{3}{2}E_{2,\mu},\quad f^{(6)}(1)=-90m_\mu-\frac{45}{4}E_{3,\mu}+90E_{2,\mu}.$$

Substituting this into the approximation Eq. (20) one gets the following theorem.

Theorem 3.2: *If for a measure $\mu\in T$ the inequality*

$$m_\mu(3-2m_\mu)<5\sigma_\mu^2$$

holds or if

$$m_\mu(3-2m_\mu)=5\sigma_\mu^2\quad\text{and}\quad -44m_\mu^3+70m_\mu^2+114m_\mu<98E_{3,\mu}$$

then the scalar curvature of the metric induced by the measure μ by the Eq. (19) has local minimum at the origin.

We give examples for monotone metrics which satisfies the previous conditions so the scalar curvature of them has local minimum at the maximally mixed state.

Theorem 3.3: *Let*

$$\frac{7-\sqrt{7}}{14}<p\leqslant\frac{1}{2}$$

and

$$h(p)=\frac{\sqrt{14p^2-14p+4+\sqrt{-640p^4+1280p^3-880p^2+240p+9}}}{2\sqrt{7}} \tag{22}$$

and $0\leqslant q<\frac{1}{2}-h(p)$. *Then the scalar curvature of the* $\mathcal{M}_2^+$ *manifold coming from the operator monotone function*

$$f(x)=\frac{x}{4}\left(\frac{1}{px+1-p}+\frac{1}{(1-p)x+p}+\frac{1}{qx+1-q}+\frac{1}{(1-q)x+q}\right) \tag{23}$$

has local minimum at the origin.

Proof: First one can try to find a $\mu\in T$ measure such that Eq. (21) holds in

$$\mu_p=\tfrac{1}{2}\delta_p+\tfrac{1}{2}\delta_{1-p} \tag{24}$$

form where δ_p is a Dirac measure. Let

$$t_\mu:=12\left(\int_0^1 t(1-t)\ \mathrm{d}\mu(t)\right)^2-\int_0^1 t(t-1)(20t^2-40t+13)\ \mathrm{d}\mu(t) \tag{25}$$

and $t(p)=t_{\mu_p}$. We get that

$$t(p)=p(1-p)(8p^2-8p+3).$$

For all $p\in[0,1/2]$ we have $t(p)>0$. This means that the scalar curvature has local maximum at the origin for all μ_p measures.

Let $p\in[0,1/2]$, $q\in[p,1/2]$, and

$$\mu_{p,q}=\tfrac{1}{4}\delta_p+\tfrac{1}{4}\delta_q+\tfrac{1}{4}\delta_{1-p}+\tfrac{1}{4}\delta_{1-q}. \tag{26}$$

Let $t(p,q)=t_{\mu_{p,q}}$ then

$$t(p,q)=-7(p^4+q^4)+14(p^3+q^3)-6pq(p+q-pq-1)-\tfrac{17}{2}(p^2+q^2)+\tfrac{3}{2}(p+q). \tag{27}$$

After substituting into Eq. (27) the

$$p=\frac{v+\sqrt{v^2-4u}}{2},\quad q=\frac{v-\sqrt{v^2-4u}}{2} \tag{28}$$

formulas one derives that

$$t(u,v)=-8u^2+(28v^2-48v+23)u-(7v^4-14v^3+\tfrac{17}{2}v^2-\tfrac{3}{2}v). \tag{29}$$

The equation $t(u,v)=0$ has two solutions for a given v. Taking into account that $u=pq$ we get the condition $0<u<\frac{1}{4}$. The only solution of the equation $t(u,v)=0$ which fulfills this condition is

$$u(v)=\tfrac{7}{4}v^2-3v+\tfrac{23}{16}-\tfrac{1}{16}\sqrt{560v^4-2240v^3+3320v^2-2160v+529}. \tag{30}$$

If the parameter p is given then q can be computed from the equation $u(p+q)=pq$. There are four solutions for q but only one of them is admissible

$$q(p)=\tfrac{1}{2}-\tfrac{1}{14}\sqrt{84p^2-84p+28+7\sqrt{-640p^4+1280p^3-880p^2+240p+9}} \tag{31}$$

because of the conditions for q. This equation gives positive parameter q if

$$\frac{7-\sqrt{7}}{14}<p\leqslant\frac{1}{2}.$$

One can check that if $0<q<q(p)$ then the function $t(p,q)$ is negative. Then we use Eq. (19) defining a desired $f(z)$ operator monotone function from the $\mu_{p,q}$ measures. □

If we choose $(7-\sqrt{7})/14<p\leqslant\frac{1}{2}$ arbitrary and $q=0$ in the previous theorem then we get that the scalar curvature coming from the operator monotone function

$$f(x)=\frac{x}{4}\left(\frac{1}{(1-p)x+p}+\frac{1}{px+1-p}+\frac{1}{x}+1\right)$$

has local minimum at the origin. In this case series expansion of the scalar curvature at the origin is

$$r(a)=(\tfrac{9}{2}-36p(1-p))-20p(1-p)(14p^2-14p+3)\cdot a^2+O(a^4).$$

One can prove that the minimum at the origin is not only local but global for these functions. The greatest value of the scalar curvature in this case is

$$r(1)=\frac{7}{2}+\frac{1}{p(1-p)}.$$

Here some other examples for operator monotone functions, such that the scalar curvature derived from them has local, but not global minimum at the maximally mixed state,

$$f(x)=\frac{x}{4}\left(\frac{4}{x+1}+\frac{50}{x+49}+\frac{50}{49x+1}\right),\quad f(x)=\frac{250x}{999x+1}+\frac{250x}{x+999}+\frac{x}{x+1}.$$

Numerical computations suggest that the scalar curvature of the Riemannian metric of a three level quantum system induced by the second function has local minimum at the maximally mixed state.

IV. CONCLUSIONS

The Riemannian metrics so far studied on the manifold $\mathcal{M}_n^+$ come from special operator monotone functions according to Theorem 2.1. The metric carries all differential geometrical properties of the manifold, this means that from a suitable function f one can derive all geometrical quantities of the manifold. One of the basic phenomenological problems is to give physical interpretation of differential geometrical quantities.

One can expect that the greatest statistical uncertainty should belong to the most mixed states. This expectation means that the scalar curvature of Riemannian metrics should have a global maximum at the maximally mixed state. We gave several examples for suitable operator monotone functions such that the derived scalar curvatures do not fulfill this expectation and have even a local minimum at the maximally mixed state.

The Kubo–Mori (or Bogoliubov) metric comes from the function $f(x)=(x-1)/\log x$. This is one of the statistically most relevant metrics. It was conjectured in Ref. 17 that the scalar curvature of this metric is monotone in the following sense. If D_1, $D_2 \in \mathcal{M}_n^+$, and D_1 is more mixed than D_2 then $r(D_1) \geqslant r(D_2)$.

(Received 30 August 2002; accepted 13 May 2003)

The conditions for spontaneous localization of electrons in an isotropic two-dimensional electron–phonon lattice are investigated within the zero adiabatic approximation. It is shown that the localization occurs when the electron–phonon coupling takes values within certain finite interval of values $g_{c,1}<g<g_{c,2}$. At $g<g_{c,1}$ the energy minimum is attained for the delocalized states and at $g>g_{c,2}$ the strong localization on one lattice site takes place. In this paper we introduce an ansatz which, under a variational principle, allows us to describe all three regimes at the same time. The radius of the electron localization, as a function of electron–phonon coupling constant, is evaluated analytically and shown to fit well the numerical data. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1592873]

I. INTRODUCTION

Low-dimensional systems in general, and electron–phonon systems in particular, attract significant attention both from the experimental and theoretical points of view.[1–8] It is known that in such systems the electron–phonon coupling can be significant and can lead to the formation of localized modes, due to which the electroconducting and/or optical properties of the system can change drastically. In particular, in one-dimensional systems (1DSs) solitonlike states of quasiparticles (electron, hole, exciton) can be formed[9] under certain conditions, namely, when the parameters of the system satisfy the conditions of an adiabatic approximation. The latter is valid when the nonadiabaticity parameter, which is determined as the ratio between the width of the electron band and the characteristic energy of the phonons, is small and when the electron–phonon coupling takes values within a certain finite interval $g_{cr,1}<g<g_{cr,2}$.[10] At weak coupling, when $g<g_{cr,1}$, the quasiparticle is almost free, while at strong coupling, when $g>g_{cr,2}$, a small polaron state is formed which corresponds to the self-trapping of this quasiparticle within one lattice site. Although both solitons and small polarons correspond to the localized quasiparticle states, their transport and stability properties differ significantly: the small polaron motion corresponds to a jumping mechanism and is sensitive to temperature, presence of impurities in the compound, etc., while a soliton, which is localized within several lattice sites, can propagate coherently almost without emitting phonons and is stable due to the mutual compensation between the dispersion and the nonlinearity.

Much less is known about the possibility of spontaneous localization, i.e., the formation of solitonlike states, in 2DSs. First, it is known that in other 2DSs (in plasma, magnetic systems, etc.) 2D solitons might be unstable under the interaction with weak perturbations and, as a result, collapse, i.e., shrink infinitely.[11–13] This shrinking might turn out to be even more important for 'molecular solitons with nonzero velocity, since it is known that the amplitude and the inverse

radius of localization of 1D solitons increase with the increase of their velocity.[9,14] On the other hand, it is clear that such shrinking of the soliton size is restricted by the discreteness of the system. Some aspects of this problem have been studied for isotropic[15–17] and anisotropic[18,19] 2D crystals. In particular, the possibility of the existence of solitonlike states in 2D lattices has been demonstrated numerically and analytically within various variational schemes. It has turned out that, even within the adiabatic approximation, when the wave vector of the state is chosen to be given by the product of the electron and the renormalized phonon wave functions, the formation of soliton states occurs only within a certain range of the parameters. In the isotropic case this parametric domain can be characterized again by the dimensionless electron–phonon coupling constant: the soliton exists if the condition $g_{c,1}<g<g_{c,2}$ is valid, where the constants $g_{c,1}$ and $g_{c,2}$ are, in general, different from the corresponding constant for the 1DSs. This differs from the 1D case where, once the adiabatic approximation is assumed, the spontaneous localization takes place *formally* for an arbitrary value of the electron–phonon coupling constant.

To understand this better here we present, within the adiabatic approximation, a variational function for a 2D isotropic lattice in such a form that it allows us to describe in a self-consistent way all three electron states: delocalized, spontaneously localized and strongly localized (nearly on one lattice site). We calculate the radius of localization as a function of the electron–phonon coupling constant, and compare these values with the results of the direct numerical calculations of the system of discrete equations. The analytical results show distinctly the existence of the lower critical value $g_{c,1}$ for the formation of solitonlike states, and the transition from soliton states to the small polaron states when $g\to g_{c,2}$.

II. GENERAL DESCRIPTION OF THE MODEL

The quasiparticle states in a 2D lattice where the electron–phonon interaction is taken into account are described by the following Hamiltonian in the site representation

$$\hat{H}=\sum_{\vec{m}}\ \mathcal{E}_0 A^{+}_{\vec{m}}A_{\vec{m}}+\sum_{\vec{m},\vec{n}}\ [-J_{\vec{m},\vec{n}}(A^{+}_{\vec{m}}A_{\vec{n}}+A^{+}_{\vec{n}}A_{\vec{m}})+\chi_{\vec{m},\vec{n}}A^{+}_{\vec{m}}A_{\vec{m}}(\hat{u}_{\vec{m}}-\hat{u}_{\vec{n}})]$$
$$+\sum_{\mu,\vec{n}}\ \frac{\hat{p}^2_{\mu}(\vec{n})}{2M}+\frac{1}{2}\sum_{\mu,\nu,\vec{n},\vec{m}}\ w_{\mu,\nu}(\vec{n},\vec{m})\hat{u}_{\mu}(\vec{n})\hat{u}_{\nu}(\vec{m}). \tag{1}$$

Here $A^{+}_{\vec{m}}$ ($A_{\vec{m}}$) are the creation (annihilation) operators of the quasiparticle on the site $\vec{m}$ with the corresponding radius-vector coordinate $\vec{R}_{\vec{n}}=\vec{e}_x a_x m+\vec{e}_y a_y n,\ m,n=0,\pm 1,\pm 2,\ldots,\ \hat{u}_{\vec{m}}$ and $\hat{p}_{\vec{m}}$ are the molecule displacements operators and the corresponding conjugate momenta, $\mathcal{E}_0$ is the quasiparticle on-site energy, $J_{\vec{m},\vec{n}}$ are the exchange interaction energies, $\chi_{\vec{m},\vec{n}}$ are the electron–phonon coupling constants, $\vec{e}_{\mu}$ is the unit vector along μ axis, $\mu=x,y$. Moreover, a_{μ} is the corresponding lattice spacing, M is the atom mass and $w_{\mu,\nu}(\vec{n},\vec{m})$ are the lattice elasticity coefficients which are assumed to be constant on the grid: $w_{\mu\mu}(\vec{n},\vec{n}\pm\vec{e}_x)=w_{\mu\mu}(\vec{n},\vec{n}\pm\vec{e}_y)=w$.

In the adiabatic approximation the vector state of the system, $|\Psi\rangle$, can be chosen in the multiplicative form[20,18] which, after substitution into the Schrödinger equation

$$i\hbar\frac{\partial}{\partial t}|\Psi\rangle=\hat{H}|\Psi\rangle, \tag{2}$$

leads to the following system of discrete equations describing the dynamics of a quasiparticle in a self-consistent deformational potential on a 2D lattice in the nearest neighbor approximation:

$$i\frac{d\varphi_{m,n}}{d\tau}=E_0\varphi_{m,n}-(\varphi_{m+1,n}+\varphi_{m-1,n}+\varphi_{m,n+1}+\varphi_{m,n-1})$$
$$+[U_{m+1,n}-U_{m-1,n}+V_{m,n+1}-V_{m,n-1}]\varphi_{m,n}, \tag{3}$$

$$\frac{d^2U_{m,n}}{d\tau^2} = -K[4U_{m,n} - U_{m+1,n} - U_{m-1,n} - U_{m,n+1} - U_{m,n-1}] + X(|\varphi_{m+1,n}|^2 - |\varphi_{m-1,n}|^2), \quad (4)$$

$$\frac{d^2V_{m,n}}{d\tau^2} = -K[4V_{m,n} - V_{m+1,n} - V_{m-1,n} - V_{m,n+1} - V_{m,n-1}] + X(|\varphi_{m,n+1}|^2 - |\varphi_{m,n-1}|^2). \quad (5)$$

Here we have introduced the dimensionless parameters

$$\tau = \frac{Jt}{\hbar}, \quad U = \frac{u_x\chi}{J}, \quad V = \frac{u_y\chi}{J},$$
$$E_0 = \frac{\mathcal{E}_0 + \mathcal{W}}{J}, \quad K = \frac{\hbar^2 w}{M J^2}, \quad X = \frac{\hbar^2 \chi^2 \hbar^2}{M J^3}, \quad (6)$$

where $u_\mu(\vec{n},t)$ are the average values of the molecule displacements in the μ direction, and $\varphi_{\vec{n}}$ is the probability amplitude of the quasiparticle being located on the $\vec{n}$th site. The total probability is normalized to unity.

The total energy of the system governed by Eqs. (3)–(5) is conserved and can be represented as the following functional:

$$\mathcal{H} = \sum_{\vec{n}} \left\{ \mathcal{E}_0 \varphi_{\vec{n}}^* \varphi_{\vec{n}} - J[\varphi_{\vec{n}}^*(\varphi_{\vec{n}+\vec{e}_x} + \varphi_{\vec{n}-\vec{e}_x}) - \varphi_{\vec{n}}^*(\varphi_{\vec{n}+\vec{e}_y} + \varphi_{\vec{n}-\vec{e}_y})] \right.$$
$$\left. + \varphi_{\vec{n}}^* \varphi_{\vec{n}} \chi \sum_\mu [u_\mu(\vec{n}+\vec{e}_\mu) - u_\mu(\vec{n}-\vec{e}_\mu)] \right\} + \mathcal{W}. \quad (7)$$

Here $\mathcal{W}$, the phonon energy, is the sum of the lattice kinetic and potential energies

$$\mathcal{W} = \frac{1}{2} \sum_{\vec{n},\mu} \left\{ \frac{p_\mu^2(\vec{n})}{M} + w_x[u_\mu(\vec{n}) - u_\mu(\vec{n}-\vec{e}_x)]^2 + w_y[u_\mu(\vec{n}) - u_\mu(\vec{n}-\vec{e}_y)]^2 \right\}. \quad (8)$$

In this paper we consider a square lattice $N_x = N_y = N$ and introduce the quasimomentum representation

$$\vec{k} = k_x\vec{e}_x + k_y\vec{e}_y, \quad k_\mu = \frac{2\pi l_\mu}{N}, \quad l_\mu = 0, \pm 1, \pm 2, \ldots, N/2, \quad (9)$$

using the following transformation:

$$\varphi_{\vec{n}} = \frac{1}{\sqrt{N}} \sum_{\vec{k}} \Phi(\vec{k}) e^{i\vec{k}\vec{n}}, \quad u_\mu(\vec{n}) = \frac{1}{\sqrt{N}} \sum_{\vec{k}} Q_\mu(\vec{k}) e^{i\vec{k}\vec{n}}. \quad (10)$$

The quasiparticle wave function, after excluding the deformational variables in the stationary case, satisfies in this representation the following nonlinear equation:

$$[E(\vec{k}) - E]\Phi(\vec{k}) - \frac{1}{N} \sum_{\vec{k}',\vec{q}} G(\vec{q}) \Phi^*(\vec{k}') \Phi(\vec{k}' + \vec{q}) \Phi(\vec{k} - \vec{q}) = 0, \quad (11)$$

and the corresponding energy functional takes the form

$$E_{\text{tot}} = \sum_{\vec{k}} E(\vec{k}) |\Phi(\vec{k})|^2 - \frac{1}{2N} \sum_{\vec{k}} G(\vec{k}) |\wp(\vec{k})|^2, \quad (12)$$

where

$$E(\vec{k}) = \mathcal{E}_0 - 2J(\cos(k_x) + \cos(k_y)), \tag{13}$$

$$G(\vec{k}) = \frac{\chi^2}{w} \frac{\sin^2(k_x) + \sin^2(k_y)}{\sin^2(k_x/2) + \sin^2(k_y/2)}, \tag{14}$$

$$\wp(\vec{k}) = \sum_{\vec{q}} \Phi^*(\vec{q})\Phi(\vec{q}-\vec{k}) = \sum_{\vec{n}} e^{i\vec{k}\vec{n}} |\varphi_{\vec{n}}|^2. \tag{15}$$

In view of their complexity, Eqs. (3)–(5) can be studied numerically or by using a variational scheme. The numerical studies[18,17] have shown that, depending on the value of electron–phonon coupling, three types of electron ground states occur. To perform an analytical study different forms of the variational functions have been tried, and it has turned out, that the variational functions which had been used, can describe numerical data satisfactorily only in some finite intervals of the coupling constant. Namely, the decreasing exponential function describes the regime of strong localization (strong coupling),[21,17] while hyperbolic[17] and Gaussian[17,16] functions describe the soliton regime (intermediate coupling). But the transition itself from one regime to the other, up to now, has not been described analytically. Here we present a trial function in a form which allows us to describe all three regimes of the coupling constant.

III. VARIATIONAL STUDY

First we note that discrete structures that are periodic in space are characterized by functions which are periodic also in the reciprocal space. Moreover, for $N \gg 1$, the quasimomentum $\vec{k}$ varies as a quasicontinuous function, which allows us to replace the infinite sums by the corresponding integration in the first Brillouin zone. Taking into account these two arguments, we choose the trial function in the form

$$\Phi(\vec{k}) = \Phi(k_x)\Phi(k_y), \quad \Phi(k_\mu) = \frac{2AK(k)}{\pi\sqrt{N}} \mathrm{d}n(u_\mu, k), \tag{16}$$

where $\mathrm{d}n(u_\mu, k)$ is the elliptic Jacobi function of the argument u_μ and of the modulus k, which is assumed to be the variational parameter. The argument of the elliptic function, u, is related to the quasimomentum k_μ by the relation $u_\mu = K(k)ak_\mu/\pi$ where $K(k)$ is the complete elliptic integral of the first kind. Note that we use the standard notations k_μ for the quasimomentum and k for the modulus of the elliptic functions and therefore k_μ and k should be distinguished. The parameter A in (16) can be found from the normalization condition

$$\sum_{\vec{n}} |\varphi_{\vec{n}}|^2 = \sum_{k_\mu} |\Phi(k_\mu)|^2 = 1, \quad A^2 = \frac{\pi^2}{4KE}, \tag{17}$$

where E is the complete elliptic integral of the second kind.

Due to the periodicity of the elliptic function (with period $2K$), the function (16) is also a periodic function (with period 2π) and it describes a spatially localized distribution $\varphi_n = A\cosh^{-1}(\kappa n)$ whose width is controlled by κ. Indeed,

$$\Phi(k_\mu) = \frac{A}{\sqrt{N}} \sum_{n=-(N-1)/2}^{(N-1)/2} \frac{e^{-ik_\mu n}}{\cosh(\kappa n)} = \frac{A}{\sqrt{N}} \left[1 + 4 \sum_{n=1}^{(N-1)/2} \frac{e^{-\kappa n}\cos(k_\mu n)}{1 + e^{-2\kappa n}} \right]. \tag{18}$$

Taking the limit $N \to \infty$ and using the Fourier series of the elliptic function $\mathrm{d}n$, leads to the expression (16) with the Jacobi parameter $q = \exp(i\pi\tau)$, where $\tau = i\kappa/\pi$.

The modulus of the elliptic functions, k, is related to the localization parameter, κ, by

$$\kappa=\pi\frac{K'(k)}{K(k)},\quad K'(k)=K(k'),\quad k'^2=1-k^2. \tag{19}$$

The width of the localized structure, κ, as the variational parameter can be determined by minimizing the energy

$$\frac{dE_{\mathrm{tot}}(\kappa)}{d\kappa}=0. \tag{20}$$

Note that function (16) for large κ is close to a decreasing exponent, and at small κ it reduces to the hyperbolic function. Therefore, such a choice of the trial function generalizes these two limiting cases.

The evaluation of (15) with (16) after integrating over the quasimomentum space gives

$$\wp(k_\mu)=\frac{K}{E}\left[\mathrm{d}n(u)-\frac{cn(u)}{sn(u)}Z(u)\right], \tag{21}$$

where $Z(u)=E(u)-uE/K$ is the Jacobi Z-function and where, according to the normalization condition, $\wp(0)=1$.

To perform further calculations analytically it is convenient to use the representation of the elliptic functions in terms of the ϑ-functions $\vartheta_j(z,q)$, $j=1,2,3,4$ defined by the following standard relations:[22,23]

$$\mathrm{d}n(u)=\frac{\vartheta_4\vartheta_3(z)}{\vartheta_3\vartheta_4(z)},\quad cn(u)=\frac{\vartheta_4\vartheta_2(z)}{\vartheta_2\vartheta_4(z)},\quad sn(u)=\frac{\vartheta_3\vartheta_1(z)}{\vartheta_2\vartheta_4(z)},\quad Z(u)=\frac{\pi}{2K}\frac{\vartheta_4'(z)}{\vartheta_4(z)}. \tag{22}$$

Here $z=\pi u/2K=k_\mu/2$, $\vartheta_j=\vartheta_j(0)$, and $\vartheta_j'(z)=\mathrm{d}\vartheta_j(z)/\mathrm{d}z$.

Next we substitute (22) into (21) and, using the differential relation,[22]

$$\vartheta_4(z)\vartheta_2'(z)-\vartheta_2(z)\vartheta_4'(z)=-\vartheta_3^2\vartheta_1(z)\vartheta_3(z), \tag{23}$$

we obtain the following representation for $\wp(k_\mu)$:

$$\wp(k_\mu)=-\frac{\pi\vartheta_4}{2E\vartheta_3}\frac{\vartheta_2'(z)}{\vartheta_1(z)}. \tag{24}$$

To proceed further with the calculations that involve the complete elliptic integrals it is convenient to use their representation in terms of the ϑ-functions of zero-argument. For the complete elliptic integral of the first kind we have $K=\pi\vartheta_3^2/2$, and for the complete elliptic integral of the second kind several representations are given in textbooks. From (24), using the relation $\vartheta_1'=\vartheta_2\vartheta_3\vartheta_4$, we obtain a new representation,

$$E=-\frac{\pi^2}{4K}\frac{\vartheta_2''}{\vartheta_2}, \tag{25}$$

which is more convenient than others, and, to our knowledge, is absent from most handbooks (see, e.g., Refs. 22–24). This relation will be used below.

The calculation of the first term in the energy expression (12) is straightforward, while the second term requires an approximation. For this we note that the function (14) can be rewritten in several equivalent ways, one of which contains a term that vanishes on the lines $k_x=\pm k_y$ in the $\vec{k}$ plane, while the other vanishes on the lines $k_x=0$ and $k_y=0$. Combining these two representations with different weights α and β, such that $\alpha+\beta=1$, we can set a corresponding weight as a free parameter to be determined by the requirement of producing the best fit to the numerical data.

Taking all this into account, we obtain the following expression for the energy as a function of the variational parameter (12):

$$E_{\rm tot}=\mathcal{E}_0-J\left\{4L+\frac{g}{2}F_1[\alpha F_1+(2-\alpha)F_2]\right\}, \tag{26}$$

where g is the dimensionless electron–phonon coupling constant

$$g=\frac{2\chi^2a^2}{Jw}, \tag{27}$$

and where

$$L=\sum_{k_\mu}|\Phi(k_\mu)|^2\cos(k_\mu)=-\frac{2\vartheta_2}{\vartheta_2''\sinh\kappa}, \tag{28}$$

$$F_1=\frac{1}{N}\sum_{k_\mu}|\wp(k_\mu)|^2=\frac{1}{6}\left(3-4\frac{\vartheta_2}{\vartheta_2''}-\frac{\vartheta_2\vartheta_2'''}{(\vartheta_2'')^2}\right), \tag{29}$$

$$F_2=\frac{1}{N}\sum_{k_\mu}|\wp(k_\mu)|^2\cos(k_\mu)=\frac{L(L\cosh\kappa-1)}{\sinh\kappa}. \tag{30}$$

Substituting (26) into (20), we obtain the following equation for the localization parameter κ as a function of g:

$$g=-\frac{8\,{\rm d}L/{\rm d}\kappa}{2\alpha F_1F_{1,\kappa}+(2-\alpha)(F_{1,\kappa}F_2+F_1F_{2,\kappa})}, \tag{31}$$

where $F_{j,\kappa}={\rm d}F_j/{\rm d}\kappa$.

To analyze Eq. (31), it is necessary to calculate explicitly the derivatives of the functions with respect to the localization parameter. For this one can use equations for ϑ-functions which, when $\tau=i\kappa/\pi$, have the form[22–24]

$$\frac{\partial^2\vartheta_j}{\partial z^2}=4\frac{\partial\vartheta_j}{\partial\kappa},\quad j=\overline{1,4}. \tag{32}$$

In this case the functions in (31) are expressed via the ϑ-functions and their zero argument derivatives. To calculate the functions appearing in (31) at small κ, when the Jacobi parameter $q=\exp(-\kappa)$ is not small, it is convenient to use the ϑ-functions as functions of the small parameter $q'=\exp(-i\pi/\tau)=\exp(-\pi^2/\kappa)$, performing the imaginary Jacobi transformation. Thus, for instance,[22,23]

$$\vartheta_2(z,q)=(-i\tau)^{-1/2}\exp\left(\frac{i\tau'z^2}{\pi}\right)\vartheta_4(z\tau',q'),\quad \tau'=-\frac{1}{\tau}. \tag{33}$$

This allows us to determine the dependence of the localization parameter κ, as a function of g given by Eq. (31), numerically. Our result is presented in Fig. 1, where we see that at $g<g_{c,1}=6$ the localization does not occur, $\kappa=0$, and the ground electron state corresponds to a delocalized state. At $g>g_{c,1}$ there are two different regimes of the localization with the distinct transition from one regime, which corresponds to $\kappa<1$, to the other one with $\kappa>1$. This transition manifests itself as a sharp change of the curve $\kappa(g)$.

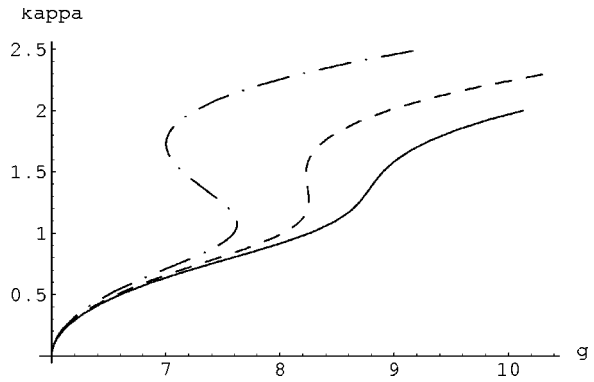

FIG. 1. Dependence of the localization parameter κ on the nonlinearity parameter g as the solution of (20) at $\alpha=0.45$ (solid line), $\alpha=0.5$ (dashed line), and $\alpha=0.6$ (dotted–dashed line).

To compare the results of the variational analysis presented above with the direct numerical calculations of the initial system of discrete equations (3)–(5) it is necessary to calculate the radius of the localization. For the latter the following definition can be used:

$$R^2=\sum_{n,m}(n^2+m^2)|\varphi_{n,m}|^2=-\frac{\mathrm{d}^2}{\mathrm{d}\vec{k}^2}\wp(\vec{k})\bigg|_{\vec{k}=0}. \tag{34}$$

Substituting the explicit expression (24) in (34), we obtain

$$R^2=\frac{2K^2}{3\pi^2}\left[1-\left(\frac{2K}{E}-1\right)k'^2\right]=\frac{1}{6}\left(\frac{\vartheta_1'''}{\vartheta_1'}-\frac{\vartheta_2^{IV}}{\vartheta_2''}\right). \tag{35}$$

The analysis of the last expression shows that at small κ the radius equals $R=\pi/(\sqrt{6}\kappa)$, i.e., it coincides with the radius of the hyperbolic trial function, while at large values of κ it takes the form $R=\sinh^{-1}(\kappa)$ which is equal to the width of localization of the trial function chosen in the form of a decreasing exponential.[17]

In Fig. 2 we present this dependence of the radius of localization as a function of the nonlinearity constant, g, together with the numerical results. The numerical curve shows that $g_{c,1}\approx 5.85$ and $g_{c,2}\approx 7.5$.

While $g_{c,1}$ is well defined as the critical value below which stationary solutions of the model do not exist, $g_{c,2}$ is more difficult to define explicitly: The transition between localized and very strongly localized (small polaron) solutions is not very sharp but one observes that during the transition, the second derivative of the inverse radius of the localization, $d^2(1/R)/dg^2$, is positive near $g_{c,2}$ but negative elsewhere (see Fig. 2 or Ref. 17). If we call $g_{z,1}$ and $g_{z,2}$ the values of g where $d^2(1/R)/dg^2=0$, then we can define $g_{c,2}=(g_{z,1}+g_{z,2})/2$ and from Fig. 2. we see that $R(g_{c,2})\approx 1$ as one would expect intuitively: the solution is essentially localized on one lattice site.

The variational curve, shown in Fig. 2 corresponds to $\alpha=0.45$ and from it one sees that the self-trapped state extends over a few lattice sites when $6<g<8$. In this case the envelope function of the electron distribution changes smoothly from site to site, and the long-wave (continuum) approximation is valid. When $g>9$, the localization is very narrow, virtually, within one lattice site and therefore the lattice discretness is essential and the continuum approximation, obviously, is not valid.

In general, the value of the parameter α introduced in (26) (notice, α is always <1), changes the position of the transition from the soliton regime to the regime of strong localization with respect to g in the interval 8–9 and influences the steepness of the transition. Moreover at $\alpha>0.5$ a bistability takes place, as shown in Fig. 1. Although this bistability can possibly be thought of as an artifact of the variational analysis, its presence indicates that, within the region of the

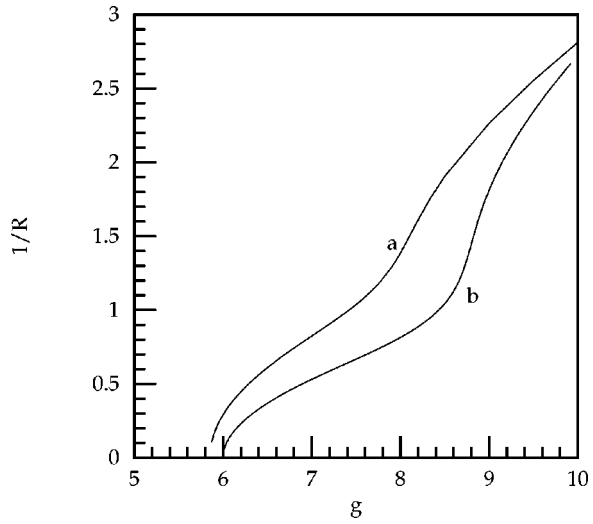

FIG. 2. Inverse radius of localization, $1/R$, as a function of g: (a) Numerical solution of Eqs. (3)–(5), (b) variational curve corresponding to Eq. (35) for $\alpha=0.45$.

transition, $g\approx 8.5$, the self-trapped states are sensitive to the influence of various perturbations, temperature, inclusion of other vibrational modes [i.e., presence of optical mode(s), complex elementary cell of a crystal, account of long-range interactions], etc. Therefore, this bistability can manifest itself in other models. It can possibly be treated as a potential barrier which separates solitonlike states from strongly localized states (the latter ones tend to collapse in the continuum 2D NLSE model).

IV. CONCLUSIONS

We have shown that a 2D lattice with an electron–phonon interaction admits solitonic solutions when the coupling constant g is larger than its lower critical value, $g_{c,1}\approx 5.85$, and lower than its upper critical value, $g_{c,2}\approx 7.5$ ($g_{c,2}\approx 8.5$ for the variational curve). In this interval a solitonic solution is stable with respect to finite and not too large perturbations. The stabilization of such a 2D soliton, which stops it from collapsing or dispersion over the whole lattice, is due to the mutual influence of the nonlinearity, the wave dispersion and the lattice discreteness. As g gets larger than $g_{c,2}$, the self-trapping changes into the regime of strong localization. This transition also manifests itself by the appearance of a bend of the numerical dependence $1/R(g)$, Fig. 2. When the initial function is slightly different from the stationary state its width oscillates around the value that corresponds to the width of the stationary state.[17] A study of the dynamics of such a soliton and its stability with respect to collisions with boundaries is in progress.

Generally speaking, at various values of the electron–phonon coupling different types of electron ground states are realized: small polarons, solitons (large polarons) or almost free electrons.[10] Between the almost free electron states at a weak coupling and the small polaron states at a strong coupling there is a region of the coupling parameter where a soliton state exists and which arises in systems that satisfy the adiabatic approximation. But the properties of the zero adiabatic description of 1D and 2D systems with respect to the self-trapping are qualitatively different. While in 1DS the self-trapping *formally* occurs at an arbitrary value of the coupling constant within the adiabatic approximation, in 2DS, even within the adiabatic approximation, all these three different regimes can be realized depending on the strength of the coupling.

The comparison of the results obtained here with the conditions of the soliton existence in 1D chains[10] shows that solitons in 2D lattices exist at larger values of the electron–phonon coupling constant. Therefore, the properties of systems of similar compounds but possessing a 1D rather than a 2D structure, could differ qualitatively. Indeed, such an example is given by the compara-

tive study of the vibrational modes of double C═O bond of the peptide group, called Amide-I vibrational modes, in biological macromolecules of myoglobin and in photoactive yellow protein, respectively.[25] While myoglobin, which is essentially α-helical, i.e., is a quasi-1D protein and admits the existence of a long-lived photoexcited Amide-I mode with a lifetime >15 ps, photoactive yellow protein, which is predominantly a β-sheet protein, does not, under the same conditions of photoexcitation. Let us add here, that Davydov and Kislukha[26] were the first to predict the self-trapping of Amide-I excitation in a soliton state in α-helical macromolecules due to the electron–phonon coupling with the hydrogen bonds along polypeptide chains, with the lifetime of such a soliton state much higher than that of an isolated Amide-I excitation.[20]

On integrable Hamiltonians for higher spin *XXZ* chain

Andrei G. Bytsko[a)]
Institut für Theoretische Physik, Freie Universität Berlin, Arnimallee 14, 14195 Berlin, Germany

(Received 9 May 2002; accepted 6 May 2003)

Integrable Hamiltonians for higher spin periodic XXZ chains are constructed in terms of the spin generators; explicit examples for spins up to $\frac{3}{2}$ are given. Relations between Hamiltonians for some $U_q(sl_2)$-symmetric and $U(1)$-symmetric universal r-matrices are studied; their properties are investigated. A certain modification of the higher spin periodic chain Hamiltonian is shown to be an integrable $U_q(sl_2)$-symmetric Hamiltonian for an open chain. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1591054]

I. INTRODUCTION

XXZ spin chains have numerous connections with two-dimensional statistical physics and $(1+1)$-dimensional quantum field theory. They describe interaction of q-deformed spins sitting at the nodes of a one-dimensional lattice. The spin generators S^+, S^-, and S^3 obey the commutation relations of the quantum Lie algebra $U_q(sl_2)$,[1]

$$[S^+,S^-]=\frac{\sin(2\gamma S^3)}{\sin\gamma},\quad [S^3,S^\pm]=\pm S^\pm. \tag{1}$$

We will consider only integrable XXZ spin models. The simplest example in this class is a spin-$\frac{1}{2}$ chain with the Hamiltonian given by

$$H=\sum_n \left(\frac{1}{2}(S_n^+S_{n+1}^-+S_n^-S_{n+1}^+)+(\cos\gamma)\,S_n^3S_{n+1}^3\right).$$

Higher spin XXZ chains have also been studied[2,3] but the technique of the "R-matrix fusion" used in these works, although sufficient for application of the Bethe ansatz, did not yield explicit expressions for the corresponding Hamiltonians. In fact, only in the spin-1 case such expression was given in the literature.[2] Another method of constructing the higher spin Hamiltonians, based on consideration of the universal (spectral parameter dependent) R-matrix, was proposed in Ref. 4 but lacked at the time important ideas of the Hopf algebra approach to the quantum groups that was developed later. In the present paper we will combine these two ingredients together and construct local integrable Hamiltonians for higher spin XXZ chains explicitly, i.e., in terms of the spin generators. This, in particular, will allow us to give a rigorous derivation of the properties of the Hamiltonians and to prove integrability of a certain open higher spin chain.

The paper is organized as follows. In Sec. II we recall some facts about $U_q(sl_2)$-symmetric universal r-matrix $r(\lambda)$. In Sec. III we construct a $U_q(sl_2)$-symmetric local Hamiltonian $H_{n,n+1}$. Its properties and properties of the corresponding closed chain Hamiltonian $\mathcal{H}$ are discussed in Sec. IV. In particular, we observe that $H_{n,n+1}$ decomposes into a $U(1)$-symmetric bulk Hamiltonian $\hat{H}_{n,n+1}$ plus a universal local boundary term. Section V contains explicit expressions for $H_{n,n+1}$ for spins $\frac{1}{2}$, 1, and $\frac{3}{2}$. In Sec. VI we find a family of universal r-matrices and Hamiltonians

a)Alexander von Humboldt Fellow, on leave from Steklov Mathematics Institute, St. Petersburg, Russia; electronic mail: bytsko@physik.fu-berlin.de

corresponding to an alternative choice of the co-multiplication. In Sec. VII we construct another family of [$U(1)$-symmetric] universal r-matrices and local Hamiltonians which contains the Hamiltonian $\hat{H}_{n,n+1}$ and the corresponding reflection-symmetric universal r-matrix $r_0(\lambda)$. In Sec. VIII we employ our construction to establish the integrability of certain [$U_q(sl_2)$-symmetric] Hamiltonians for an open chain. Appendix A contains technical details related to $r(\lambda)$ and $r_0(\lambda)$. Appendix B provides some details on computation of the spin-1 and spin-$\frac{3}{2}$ Hamiltonians presented in Sec. V. Appendix C explains a q-trace formula for $H_{n,n+1}$ used in Sec. VIII.

For compactness of notations, we will use in the text both the deformation parameter γ introduced in (1) and $q \equiv e^{i\gamma}$. We assume that q is either real or takes values on the unit circle. In the latter case q is assumed to be generic, i.e., it is not a root of unity.

II. UNIVERSAL *r*-MATRIX

The starting point of the quantum inverse scattering method is the exchange relation

$$R(\lambda)\, L(\lambda+\mu)\otimes L(\mu) = L(\mu)\otimes L(\lambda+\mu)\, R(\lambda)\,, \tag{2}$$

with $\otimes$ understood as the tensor product with respect to an auxiliary space V (below it is the space of 2×2 matrices) and the usual product of operators in the quantum space $\mathfrak{H}$. The R-matrix belongs to $V\otimes V$. Thus (2) is an equation in $V\otimes V\otimes \mathfrak{H}$.

The following L-operator, i.e., an element of $V\otimes\mathfrak{H}$, is consistent with the algebra (1)

$$L(\lambda) = \frac{1}{\sin\gamma}\begin{pmatrix} \sinh[\,\gamma(\lambda+iS^3)\,] & i\sin\gamma\, e^{\gamma\lambda}\, S^- \\ i\sin\gamma\, e^{-\gamma\lambda}\, S^+ & \sinh[\,\gamma(\lambda-iS^3)\,] \end{pmatrix} \tag{3}$$

in the sense that it satisfies Eq. (2) provided that $R(\lambda)=P_V\check{R}(\lambda)$, where

$$\check{R}(\lambda) = i\, e^{\gamma\lambda}\,\sigma^+\otimes\sigma^- + i\, e^{-\gamma\lambda}\,\sigma^-\otimes\sigma^+ + \frac{1}{\sin\gamma}\sinh\left(\gamma\lambda + \frac{i\,\gamma}{2}(1\otimes 1+\sigma^3\otimes\sigma^3)\right). \tag{4}$$

Here σ^a denote the Pauli matrices, $\sigma^\pm=\sigma^1\pm i\sigma^2$, and $P_V=\frac{1}{2}(1\otimes 1+\Sigma_a\sigma^a\otimes\sigma^a)$ is the permutation matrix in $V\otimes V$.

The L-operator (3) decomposes into two λ-independent Borel components,

$$(2\sin\gamma)\, L(\lambda) = e^{\gamma\lambda}L_+ - e^{-\gamma\lambda}L_-\,, \tag{5}$$

which can be utilized to define[5] the co-multiplication (a linear homomorphism $\Delta: U_q(sl_2)\to[U_q(sl_2)]^{\otimes 2}$) in the matrix form,

$$\Delta(L_\pm) = L_\pm \dot{\otimes} L_\pm\,, \tag{6}$$

where Δ acts on the quantum space and $\dot{\otimes}$ denotes the tensor product with respect to $\mathfrak{H}$ and the usual matrix product in V. In explicit form (6) reads

$$\Delta(S^\pm) = S^\pm\otimes q^{-S^3} + q^{S^3}\otimes S^\pm\,,\quad \Delta(S^3) = S^3\otimes 1 + 1\otimes S^3\,. \tag{7}$$

Observe that (4) can be obtained by evaluating the quantum space of $L(\lambda+i/2)$ in the fundamental representation, where $S^\pm=q^{\pm 1/2}\sigma^\pm$ and $S^3=\frac{1}{2}\sigma^3$. In fact, $\check{R}(\lambda)$ and $L(\lambda)$ are, respectively, $V\otimes V$ and $V\otimes\mathfrak{H}$ representations of a more general object, $\check{\mathbf{R}}(\lambda)\in[U_q(sl_2)]^{\otimes 2}$, that satisfies the Yang–Baxter equation in $\mathfrak{H}\otimes\mathfrak{H}\otimes\mathfrak{H}$,

$$\check{\mathbf{R}}_{12}(\lambda)\,\check{\mathbf{R}}_{13}(\lambda+\mu)\,\check{\mathbf{R}}_{23}(\mu) = \check{\mathbf{R}}_{23}(\mu)\,\check{\mathbf{R}}_{13}(\lambda+\mu)\,\check{\mathbf{R}}_{12}(\lambda)\,. \tag{8}$$

Relation (2) is then a particular case of (8) with the first and second spaces evaluated in the fundamental representation. Evaluating (8) in the $V\otimes\mathfrak{H}\otimes\mathfrak{H}$ representation (and interchanging λ with μ), we obtain

$$r(\lambda)\,L(\lambda+\mu)\dot{\otimes}L(\mu)=L(\mu)\dot{\otimes}L(\lambda+\mu)\,r(\lambda)\,, \tag{9}$$

with $r(\lambda)\equiv\check{\mathbf{R}}(\lambda)\mathbf{P}$, where $\mathbf{P}$ is the permutation in $\mathfrak{H}\otimes\mathfrak{H}$. For a given L-operator, (9) can be regarded as a defining equation on the element $r(\lambda)\in[U_q(sl_2)]^{\otimes 2}$ which we will call the universal r-matrix. Using (5), Eq. (9) can be equivalently rewritten as follows:

$$r(\lambda)\;\;L_{\pm}\dot{\otimes}L_{\pm}=L_{\pm}\dot{\otimes}L_{\pm}\;\;r(\lambda)\,, \tag{10}$$

$$r(\lambda)\,(e^{\gamma\lambda}L_+\dot{\otimes}L_-+e^{-\gamma\lambda}L_-\dot{\otimes}L_+)=(e^{-\gamma\lambda}L_+\dot{\otimes}L_-+e^{\gamma\lambda}L_-\dot{\otimes}L_+)\,r(\lambda)\,. \tag{11}$$

In view of (6), the first line implies that for any element $\xi\in U_q(sl_2)$ we have

$$r(\lambda)\,\Delta(\xi)=\Delta(\xi)\,r(\lambda)\,. \tag{12}$$

Recall that, for a generic q, the tensor product of two irreducible highest weight $U_q(sl_2)$-representations of spin S is completely reducible and decomposes into the sum

$$D_S\otimes D_S=\sum_{j=0}^{2S}D_j\,, \tag{13}$$

where each subspace D_j is a highest weight $U_q(sl_2)$-module with respect to the action of the operators $\Delta(S^{\pm})$ and $\Delta(S^3)$.

Equation (12) implies that $r(\lambda)$ is a function of an operator J such that

$$J\,|j,m\rangle=j\,|j,m\rangle \tag{14}$$

for any vector $|j,m\rangle$ from D_j. In other words,

$$r(\lambda)=\sum_{j=0}^{2S}r_j(\lambda)\,\mathcal{P}_j\,, \tag{15}$$

where $\mathcal{P}_j$ is the projector onto D_j, i.e., $\mathcal{P}_k|j,m\rangle=\delta_{jk}\,|j,m\rangle$. Taking (15) into account, one can solve Eq. (11) explicitly (Refs. 6 and 7 and see also Appendix A),

$$r(\lambda)=\mathcal{P}_0+\sum_{j=1}^{2S}\left(\prod_{k=1}^{j}\frac{\sin[\,\gamma(k-i\lambda)\,]}{\sin[\,\gamma(k+i\lambda)\,]}\right)\mathcal{P}_j\,. \tag{16}$$

Two obvious consequences of this formula are

$$r(\lambda)\,r(-\lambda)=1\otimes 1\,,\quad r(\lambda)\,r(\mu)=r(\mu)\,r(\lambda)\,. \tag{17}$$

Introduce a q-analogue of the gamma function satisfying the relation

$$(q^x-q^{-x})\,\Gamma_q(x)=(q-q^{-1})\,\Gamma_q(x+1)$$

and normalized such that $\Gamma_q(1)=1$. If $|q|\neq 1$, this equation can be solved in terms of a convergent infinite product. For instance, for $|q|<1$, the solution is given by

$$\Gamma_q(x)=q^{1/2\,x(1-x)}(q^{-1}-q)^{1-x}\prod_{n=0}^{\infty}\frac{1-q^{2n+2}}{1-q^{2n+2x}}\,. \tag{18}$$

In terms of the q-gamma function Eq. (16) can be rewritten as follows:

$$r(\lambda)=\frac{\Gamma_q(J+1-i\lambda)}{\Gamma_q(J+1+i\lambda)}\,\frac{\Gamma_q(1+i\lambda)}{\Gamma_q(1-i\lambda)} \tag{19}$$

with J defined by (14). Equations (16) and (19) are q-deformations of their XXX counterparts found in (Refs. 8 and 4) (see also Ref. 9). [Actually, Refs. 8 and 4 dealt with the XXX analogue of $\check{\mathbf{R}}(\lambda)$. In the XXZ case, $\mathbf{P}$ and $\check{\mathbf{R}}(\lambda)$ do not commute with Δ and therefore cannot be represented as combinations of the projectors $\mathcal{P}_j$.]

III. HAMILTONIAN

Having a solution $\check{\mathbf{R}}(\lambda)$ to Eq. (8) such that $\check{\mathbf{R}}(0)=\mathbf{P}$ [equivalently, $r(0)=1\otimes 1$], one can construct an integrable Hamiltonian for a closed chain in the following way[10,4,7,9] (the normalization is chosen for later convenience):

$$\mathcal{H}=i\,\frac{\sin\gamma}{2\gamma}\sum_{n=1}^{N}\mathbf{P}_{n,n+1}\frac{\mathrm{d}}{\mathrm{d}\lambda}\check{\mathbf{R}}_{n,n+1}(\lambda)\bigg|_{\lambda=0}=\sum_{n=1}^{N}\mathbf{P}_{n,n+1}H_{n,n+1}\mathbf{P}_{n,n+1}=\sum_{n=1}^{N}H_{n+1,n}\,,$$
$$H_{n,n+1}=i\,\frac{\sin\gamma}{2\gamma}\,\frac{\mathrm{d}}{\mathrm{d}\lambda}\ln r_{n,n+1}(\lambda)\bigg|_{\lambda=0} \tag{20}$$

with $H_{N,N+1}\equiv H_{N,1}$ (the periodic boundary conditions). Although $H_{n,n+1}\neq H_{n+1,n}$, we will show in the following that for the total Hamiltonian we have

$$\mathcal{H}=\sum_{n=1}^{N}H_{n+1,n}=\sum_{n=1}^{N}H_{n,n+1}\,. \tag{21}$$

The Hamiltonian $\mathcal{H}$ commutes with the higher quantum integrals of motion which are constructed as higher derivatives of $\ln r(\lambda)$. Moreover, if the reference state ω for an L-operator in question is such that $\omega\otimes\omega$ is an eigenvector of $r(\lambda)$, then the corresponding Bethe vectors are eigenvectors of the Hamiltonian.[11,10,4,9] In particular, this is the case for the L-operator (3), for which the reference state ω is just the highest weight vector.

Combining (19) with (20), we obtain a compact formula for the Hamiltonian,

$$H_{n,n+1}=\frac{\sin\gamma}{\gamma}\left(\Psi_q(J_{n,n+1}+1)-\Psi_q(1)\right), \tag{22}$$

where $\Psi_q(x)$ stands for the logarithmic derivative of $\Gamma_q(x)$.

In order to find the Hamiltonian explicitly in terms of the spin generators we first substitute Eq. (16) into Eq. (20) and derive

$$H_{n,n+1}=(\sin\gamma)\sum_{j=1}^{2S}\left(\sum_{k=1}^{j}\frac{\cos\gamma k}{\sin\gamma k}\right)\mathcal{P}_j\,. \tag{23}$$

Next, we have to construct the projectors $\mathcal{P}_j$ explicitly. Recall that the Casimir operator of the algebra (1) is given by

$$C=S^-S^+ +\frac{\sin\gamma S^3\sin\gamma(S^3+1)}{\sin^2\gamma}\,. \tag{24}$$

Its value in the highest weight representation of spin S is

$$C_S=\frac{\sin\gamma S\sin\gamma(S+1)}{\sin^2\gamma}=\frac{\cos\gamma-\cos\gamma(2S+1)}{2\sin^2\gamma}.$$

Applying the co-multiplication (7) to the Casimir operator (24), we obtain an operator that acts in the tensor product $D_S\otimes D_S$,

$$\begin{aligned}\mathbf{X}_S&=\frac{1}{2}\Delta C\\&=\frac{1}{2}(q^{S^3}S^+)\otimes(S^-q^{-S^3})+\frac{1}{2}(q^{S^3}S^-)\otimes(S^+q^{-S^3})\\&\quad+\frac{1}{4\sin^2\gamma}((1\otimes1+q^{2S^3}\otimes q^{-2S^3})\cos\gamma-(1\otimes q^{-2S^3}+q^{2S^3}\otimes1)\cos(\gamma(2S+1))).\end{aligned}\tag{25}$$

Here we employed the commutation relations (1) and used (as reflected in the subscript of $\mathbf{X}_S$) that on $D_S\otimes D_S$ we have $C\otimes1=1\otimes C=(1\otimes1)C_S$. It is now easy to see that

$$\mathbf{X}_S=\frac{\sin\gamma J\sin\gamma(J+1)}{2\sin^2\gamma}\tag{26}$$

with J defined by (14). Indeed, by construction, $\mathbf{X}_S$ commutes with $\Delta(S^\pm)$. Bearing this in mind, (26) follows from computing the action of $\mathbf{X}_S$ on highest weight vectors.

For a generic q, the eigenvalues of (26) on different subspaces D_j in (13) do not coincide. Therefore, we can utilize (26) to construct the projectors $\mathcal{P}_j$ by means of the Lagrange interpolation,

$$\mathcal{P}_j=\prod_{\substack{l=0\\l\neq j}}^{2S}\frac{2\mathbf{X}_S-[l]_q[l+1]_q}{[j-l]_q[j+l+1]_q}.\tag{27}$$

Here we used the q-numbers defined as

$$[k]_q\equiv(q^k-q^{-k})/(q-q^{-1})=\frac{\sin(\gamma k)}{\sin\gamma}.$$

Note that the denominator in (27) can be written differently with the help of the identity $[j-l]_q[j+l+1]_q=[j]_q[j+1]_q-[l]_q[l+1]_q$. We have chosen the first expression to indicate singularities that can occur if q is a root of unity.

Combining (27) with (23), we obtain a local integrable Hamiltonian for the XXZ spin chain (we call $H_{n,n+1}$ local because it is a lattice analogue of the Hamiltonian density. But $H_{n,n+1}$ is also local in the sense that it involves spines only at two nearest sites of the lattice. We hope that this mixed terminology will not lead to a confusion):

$$H_{n,n+1}=(\sin\gamma)\sum_{j=1}^{2S}\left[\left(\sum_{k=1}^{j}\frac{\cos\gamma k}{\sin\gamma k}\right)\prod_{\substack{l=0\\l\neq j}}^{2S}\frac{2(\sin\gamma)^2\mathbf{X}_S-\sin\gamma l\sin\gamma(l+1)}{\sin\gamma(j-l)\sin\gamma(j+l+1)}\right]\tag{28}$$

with $\mathbf{X}_S\in\mathfrak{H}_n\otimes\mathfrak{H}_{n+1}$ given by (25) which can also be rewritten as follows:

$$\begin{aligned}\mathbf{X}_S=e^{i\gamma S_n^3}\Bigg(&\frac{1}{2}S_n^+S_{n+1}^-+\frac{1}{2}S_n^-S_{n+1}^++\sin\gamma S_n^3\sin\gamma S_{n+1}^3\frac{\cos\gamma S\cos\gamma(S+1)}{\sin^2\gamma}\\&+\cos\gamma S_n^3\cos\gamma S_{n+1}^3\frac{\sin\gamma S\sin\gamma(S+1)}{\sin^2\gamma}\Bigg)e^{-i\gamma S_{n+1}^3}.\end{aligned}\tag{29}$$

We remark that $2\mathbf{X}_S$ is a q-deformation of square of the sum of two spins in the sense that in the $\gamma\to 0$ limit Eq. (29) simplifies to

$$\mathbf{X}_S^0 = S(S+1) + \mathbf{S}_n^0 \cdot \mathbf{S}_{n+1}^0 = \tfrac{1}{2}(\mathbf{S}_n^0 + \mathbf{S}_{n+1}^0)^2 ,$$

where S_a^0 are the generators of sl_2. In this limit Eq. (28) turns into the integrable *XXX* Hamiltonian constructed in Refs. 12 and 4.

Let us consider the large spin S asymptotics of the Hamiltonian (22)–(23) in terms of the spin operator J defined by (14). Recall first that for the logarithmic derivative of the (nondeformed) gamma function we have

$$\Psi(j+1) = \Psi(1) + \sum_{k=1}^{j} \frac{1}{k} = \ln\left(j + \frac{1}{2}\right) + O(j^{-2}) .$$

Therefore the large spin approximation of the *XXX* Hamiltonian is

$$H_{n,n+1} = \ln(J + \tfrac{1}{2}) + \text{const} . \tag{30}$$

In the *XXZ* case, if q is real, Eq. (18) (or its counterpart for $|q|>1$) yields $\Psi_q(x) \approx x\,|\gamma|$ for large x. More precisely, we infer from (22) and (23) that

$$\Psi_q(j+1) = \Psi_q(1) + |\gamma| \sum_{k=1}^{j} \tanh(k|\gamma|) = |\gamma|\, j + \varkappa_\gamma + O(e^{-2|\gamma| j}) , \tag{31}$$

where $\varkappa_\gamma$ is a γ-dependent constant. Hence the large spin asymptotics of the *XXZ* Hamiltonian is

$$H_{n,n+1} = J \sinh|\gamma| + \text{const} . \tag{32}$$

Here we should remind that the spin operator in (32) is not the same as in (30), Indeed, it is always given by $J = \Sigma_j\, j\mathcal{P}_j$ but the projectors are different for different γ. Notice also that the correction to the leading order in (31) decays very fast [because $\tanh(x) = 1 + O(e^{-2x})$]. So, if $|\gamma| S$ is not too small, (32) is a good approximation even for not too large S.

Thus, the large spin asymptotics of $H_{n,n+1}$ in the *XXZ* case differs from that in the *XXX* case. Moreover, for real γ, i.e., when $|q| = 1$, the function $\Psi_q(x)$ is not monotonous [as seen from (23)] and does not have an asymptotics at all.

IV. PROPERTIES

Global symmetry: Recall that the co-associativity property, $(\Delta \otimes 1)\Delta = (1 \otimes \Delta)\Delta$, leads to a natural notion of an nth power of the co-multiplication: $\Delta^{(n+1)} \equiv (\Delta \otimes 1^{\otimes n})\Delta^{(n)}$ with $\Delta^{(1)} \equiv \Delta$. Then the global spin generators for a chain with N nodes are naturally introduced[6] as $\mathcal{S}^{\pm} = \Delta^{(N-1)}(S^{\pm})$ and $\mathcal{S}^3 = \Delta^{(N-1)}(S^3)$; which in explicit form reads

$$\mathcal{S}^3 = \sum_{n=1}^{N} S_n^3 , \quad \mathcal{S}^{\pm} = \sum_{n=1}^{N} q^{S_1^3} \cdots q^{S_{n-1}^3} S_n^{\pm} q^{-S_{n+1}^3} \cdots q^{-S_N^3} . \tag{33}$$

By construction [see (12) and (23)], the local Hamiltonian $H_{n,n+1}$ is $U_q(sl_2)$-symmetric, i.e., it commutes with $\Delta(\xi)$ for any $\xi \in U_q(sl_2)$. Furthermore, it is easy to check that

$$[\, H_{n,n+1}, \mathcal{S}^3 \,] = 0 \quad \text{for } n = 1,\ldots,N , \tag{34}$$

$$[\, H_{n,n+1}, \mathcal{S}^{\pm} \,] = 0 \quad \text{for } n = 1,\ldots,N-1 . \tag{35}$$

Since $H_{N,1}$ does not satisfy (35), the total Hamiltonian enjoys only the $U(1)$-symmetry,

$$[\,\mathcal{H},\mathcal{S}^3\,]=0\,. \tag{36}$$

Actually, the higher quantum integrals of motion also commute with $\mathcal{S}^3$. Therefore in the presence of a constant magnetic field h the corresponding Hamiltonian, $\mathcal{H}_h=\mathcal{H}+h\mathcal{S}^3$, remains integrable and $U(1)$-symmetric.

C and P symmetries: Recall that $\mathbf{P}$ denotes the permutation in $\mathfrak{H}\otimes\mathfrak{H}$. Since the comultiplication Δ does not commute with $\mathbf{P}$, neither does $r(\lambda)$, $\mathbf{X}_S$ or $H_{n,n+1}$. However, we observe that (here and in the following dependence on γ is shown explicitly only if it is affected by a transformation)

$$\mathbf{P}\,\mathbf{X}_S(\gamma)\,\mathbf{P}=\mathbf{X}_S(-\gamma)\,,\quad \mathbf{P}\,r(\lambda,\gamma)\,\mathbf{P}=r(\lambda,-\gamma)\,. \tag{37}$$

The first relation is obvious from (29) and yields the second one upon noticing that both the projectors $\mathcal{P}_j(x,\gamma)$ and the coefficients $r_j(\lambda,\gamma)$ in (15) are even functions in γ. Further, the second relation in (37) implies readily that

$$\mathbf{P}_{n,n+1}\,H_{n,n+1}(\gamma)\,\mathbf{P}_{n,n+1}=H_{n,n+1}(-\gamma)\,. \tag{38}$$

Thus $H_{n,n+1}$ does not have the P (reflection) symmetry. But, if q is real, it has the C-symmetry (invariance with respect to the complex conjugation). If $|q|=1$, then Eq. (38) shows that $H_{n,n+1}$ has no C- or P-symmetry separately but it has the CP-symmetry.

Local bulk and boundary terms: As we will see in the following, $H_{n,n+1}$ decomposes into two parts (which we will refer to as the local bulk term and the local boundary term):

$$H_{n,n+1}=\hat{H}_{n,n+1}+i\,\frac{\sin\gamma}{2}(S^3_n-S^3_{n+1})\,. \tag{39}$$

The local bulk term, $\hat{H}_{n,n+1}$, has the following properties (see Sec. VII):

$$\mathbf{P}_{n,n+1}\hat{H}_{n,n+1}\mathbf{P}_{n,n+1}=\hat{H}_{n,n+1}\,,\quad \hat{H}_{n,n+1}(\gamma)=\hat{H}_{n,n+1}(-\gamma)\,. \tag{40}$$

Thus, $\hat{H}_{n,n+1}$ is P- and C-symmetric for real q as well as for $|q|=1$. In fact (see Sec. VII), $\hat{H}_{n,n+1}$ is a local Hamiltonian associated with the L-operator

$$\hat{L}(\lambda)=\frac{1}{\sin\gamma}\begin{pmatrix}\sinh[\,\gamma(\lambda+iS^3)\,] & i\,S^-\sin\gamma\\ i\,S^+\sin\gamma & \sinh[\,\gamma(\lambda-iS^3)\,]\end{pmatrix}. \tag{41}$$

Notice that $\hat{H}_{n,n+1}$ is not $U_q(sl_2)$-symmetric but only $U(1)$-symmetric.

The local boundary term in (39) has the same form for all positive (half-) integer spins. In the total Hamiltonian of a closed chain all these boundary terms mutually cancel, hence

$$\mathcal{H}=\sum_{n=1}^{N}H_{n,n+1}=\sum_{n=1}^{N}\hat{H}_{n,n+1}\,. \tag{42}$$

This together with (40) explains why the two sums in (21) coincide.

Properties with respect to $*$-operation: The $*$-structure on $U_q(sl_2)$ corresponding to the compact real form $U_q(su(2))$ is defined as an antiautomorphism such that

$$(S^\pm)^*=\eta^{\pm1}S^\mp\,,\quad (S^3)^*=S^3 \tag{43}$$

with some real η. Of course, the prefactor $\eta^{\pm1}$ can be eliminated by rescaling the generators. However it may be convenient to keep it. For instance, we saw in Sec. II that, in the spin-$\frac{1}{2}$ case,

it is natural to put $S^{\pm}=q^{\pm 1/2}\sigma^{\pm}$. Then $\eta=1$ if $|q|=1$ but $\eta=q$ if q is real. In fact, the choice of η is not important for our purposes since $H_{n,n+1}$ and $\hat{H}_{n,n+1}$ contain $S^{\pm}$ only in homogeneous combinations like $(S^{+}\otimes S^{-})$.

The action of the $*$-operation extends on a tensor product as $(\xi\otimes\zeta)^*=\xi^*\otimes\zeta^*$. It must be remarked that properties of the co-multiplication with respect to the action of the $*$-operation depend on the choice of q, namely we infer from (7) and (43) that [a $*$-structure satisfying $(\Delta(\xi))^*=\Delta(\xi^*)$ for $|q|=1$ is the *noncompact* real form $U_q(sl(2,\mathbb{R}))$, see Ref. 13]

$$(\Delta(\xi))^*=\Delta(\xi^*) \quad \text{if } q\in\mathbb{R} \quad \text{but} \quad (\Delta(\xi))^*=\mathbf{P}\Delta(\xi^*)\mathbf{P} \quad \text{if } |q|=1\,.$$

Therefore the local Hamiltonian (28) has the following properties:

$$(H_{n,n+1})^*=H_{n,n+1} \quad \text{for } q\in\mathbb{R}, \tag{44}$$

$$(H_{n,n+1})^*=\mathbf{P}_{n,n+1}H_{n,n+1}\mathbf{P}_{n,n+1} \quad \text{for } |q|=1\,. \tag{45}$$

Nevertheless, we see from Eq. (23) that the eigenvalues of $H_{n,n+1}$ are real in the both cases. Furthermore, it follows from (39)–(40) and (44)–(45) that

$$(\hat{H}_{n,n+1})^*=\hat{H}_{n,n+1} \tag{46}$$

for both regimes of q. In combination with (42) this implies that the relation

$$\mathcal{H}^*=\mathcal{H} \tag{47}$$

holds also in the both regimes of q.

It is worth emphasizing that, for $|q|=1$, objects which have the global $U_q(sl_2)$-symmetry, like $H_{n,n+1}$ for $n\neq N$, are in general not self-conjugate with respect to the $*$-operation (43). Indeed, if $\mathcal{O}^*=\mathcal{O}$ and it commutes with the global spin generators $\mathcal{S}^{\pm}$ given by (33), then it must also commute with $(\mathcal{S}^{\pm})^*$. This imposes a strong extra condition on the structure of $\mathcal{O}$ since for $|q|=1$ the conjugate of $\mathcal{S}^{\pm}$ belongs to $U_{q^{-1}}(sl_2)$ rather than to $U_q(sl_2)$. Conversely, objects that are self-conjugate for $|q|=1$ are in general not $U_q(sl_2)$-symmetric, for instance $\hat{H}_{n,n+1}$ and $\mathcal{H}$.

T symmetry: The definition $(\xi\otimes\zeta)^*=\xi^*\otimes\zeta^*$ is consistent with the property of the matrix transposition, $(\xi\otimes\zeta)^t=\xi^t\otimes\zeta^t$, if ξ and ζ are regarded as matrices. Thus the $*$-operation can be realized as the matrix Hermitian conjugation, $\xi^*=\overline{\xi^t}$ (bar denotes the complex conjugation).

From (44), (45), and (38) we deduce that $(H_{n,n+1})^*=\overline{H}_{n,n+1}$ in both regimes of q. Therefore finite dimensional matrix representations of the above-considered Hamiltonians are symmetric matrices,

$$(H_{n,n+1})^t=H_{n,n+1}\,, \quad (\hat{H}_{n,n+1})^t=\hat{H}_{n,n+1}\,, \quad (\mathcal{H})^t=\mathcal{H}\,. \tag{48}$$

Here the first equality leads to the second and the third due to (39) and (42), respectively.

V. EXAMPLES ($S=\frac{1}{2},1,\frac{3}{2}$)

For the spin $S=\frac{1}{2}$, the Hamiltonian (28) is very simple:

$$H_{n,n+1}=(\cos\gamma)\,\mathcal{P}_1=\mathbf{X}_{1/2}\,, \tag{49}$$

and the spin generators are given by $S^{\pm}=q^{\pm 1/2}\sigma^{\pm}$ and $S^3=\frac{1}{2}\sigma^3$. Using the relations

$$e^{t\sigma^3}\sigma^{\pm}=\sigma^{\pm}e^{-t\sigma^3}=e^{\pm t}\sigma^{\pm}\,, \quad e^{it\sigma^3}=\cos t+i\sigma^3\sin t\,, \tag{50}$$

it is easy to check that (49) acquires the following form:

$$H_{n,n+1}=\frac{1}{2}(S_n^+S_{n+1}^-+S_n^-S_{n+1}^+)+(\cos\gamma)\,S_n^3S_{n+1}^3+\frac{3}{4}\cos\gamma+i\,\frac{\sin\gamma}{2}(S_n^3-S_{n+1}^3)\,. \tag{51}$$

The bulk term here is the well-known XXZ deformation of the Heisenberg spin chain.

For $S=1$ the Hamiltonian (28) looks as follows:

$$H_{n,n+1}=(\cos\gamma)\,\mathcal{P}_1+\frac{\sin 3\gamma}{\sin 2\gamma}\mathcal{P}_2=\frac{1}{4(\cos\gamma)^3}((\cos\gamma+4\cos^3\gamma)\,\mathbf{X}_1-(\mathbf{X}_1)^2)\,. \tag{52}$$

In this case the spin generators are given by (B1); they are related to the spin-1 sl_2-generators as $S^{\pm}=(\cos\gamma)^{1/2}S_0^{\pm}$, $S^3=S_0^3$. Rewriting $\mathbf{X}_1$ and its square as polynomials in the spin generators (see Appendix B), we obtain

$$H_{n,n+1}=\frac{1}{4\cos\gamma}(\mathbf{\Omega}_1-(\mathbf{\Omega}_1)^2+\mathbf{F}_1)+i\,\frac{\sin\gamma}{2}(S_n^3-S_{n+1}^3)\,, \tag{53}$$

where

$$\mathbf{\Omega}_1=\frac{1}{2\cos\gamma}(S_n^+S_{n+1}^-+S_n^-S_{n+1}^+)+(2\cos\gamma-1)\,S_n^3S_{n+1}^3\,, \tag{54}$$

$$\begin{aligned}\mathbf{F}_1=&\,2\cos\gamma(\cos\gamma-1)S_n^3S_{n+1}^3+2(\cos\gamma-1)^2(S_n^3S_{n+1}^3)^2\\&-2(\sin\gamma)^2\,((S_n^3)^2+(S_{n+1}^3)^2)+4+2\cos 2\gamma\,.\end{aligned} \tag{55}$$

The bulk term of the Hamiltonian (53) [i.e., (53) without the last term] coincides (up to a constant) with the Fateev–Zamolodchikov (FZ) Hamiltonian.[2] The FZ Hamiltonian is usually written in a slightly different way in terms of the spin-1 sl_2-generators; we have chosen the above form since it allows for better comparison with the $S=\frac{3}{2}$ case.

In the limit $\gamma\to 0$, (52)–(53) simplifies to the well-know spin-1 XXX Hamiltonian:

$$H_{n,n+1}^0=\tfrac{5}{4}\mathbf{X}_1^0-\tfrac{1}{4}(\mathbf{X}_1^0)^2=\tfrac{1}{4}\mathbf{S}_n^0\cdot\mathbf{S}_{n+1}^0-\tfrac{1}{4}(\mathbf{S}_n^0\cdot\mathbf{S}_{n+1}^0)^2+\tfrac{3}{2}\,.$$

In the $S=\frac{3}{2}$ case the Hamiltonian (23) is given by

$$H_{n,n+1}=(\cos\gamma)\,\mathcal{P}_1+\frac{\sin 3\gamma}{\sin 2\gamma}\mathcal{P}_2+\left(\frac{\sin 3\gamma}{\sin 2\gamma}+(\sin\gamma)\,\frac{\cos 3\gamma}{\sin 3\gamma}\right)\mathcal{P}_3\,. \tag{56}$$

Rewriting the corresponding expression (28) in the polynomial (with respect to the spin generators) form (see Appendix B), we obtain

$$\begin{aligned}H_{n,n+1}=&\frac{1}{12(\cos\gamma)^3(1+2\cos 2\gamma)^3}\Big(12(\cos\gamma)\,(\mathbf{\Omega}_{3/2})^3+(5\cos 4\gamma-\cos 2\gamma+2)\,(\mathbf{\Omega}_{3/2})^2\\&+\frac{1}{2\cos\gamma}(\mathbf{\Omega}_{3/2}\mathbf{Q}+\mathbf{Q}\,\mathbf{\Omega}_{3/2})+\frac{1+2\cos 2\gamma}{64\cos^2\gamma}\mathbf{F}_{3/2}\Big)+i\,\frac{\sin\gamma}{2}(S_n^3-S_{n+1}^3)\,,\end{aligned} \tag{57}$$

where $\mathbf{Q}$ and $\mathbf{F}_{3/2}$ are real symmetric polynomials in S_n^3 and S_{n+1}^3 (see Appendix B) and

$$\mathbf{\Omega}_{3/2}=\frac{1}{2}(S_n^+S_{n+1}^-+S_n^-S_{n+1}^+)+(1+2\cos 2\gamma)\,\frac{\cos 2\gamma}{3\cos\gamma}S_n^3S_{n+1}^3\,. \tag{58}$$

Let us remark that in both Hamiltonians (53) and (57) the two ''most non-diagonal'' terms are powers of an operator $\mathbf{\Omega}$ which is quadratic in generators. To clarify this fact, we observe that, like for $S=\frac{1}{2}$, the corresponding Casimir operators (24) are actually quadratic:

$$\tfrac{1}{2}(S^+S^-+S^-S^+)+(\cos\gamma)(S^3)^2=2\cos\gamma \quad \text{for } S=1\,, \tag{59}$$

$$\tfrac{1}{2}(S^+S^-+S^-S^+)+(\cos\gamma)^2(S^3)^2=\tfrac{1}{4}(17\cos^2\gamma-2) \quad \text{for } S=\tfrac{3}{2} \tag{60}$$

(the last expression differs from $C_{3/2}$ by a constant). Equation (59) is due to the first relation in (B2); Eq. (60) follows from relation (B10) and the identity $2(\sin\gamma S^3)^2=1-\cos 2\gamma S^3$.

VI. ANOTHER CO-MULTIPLICATION

As we saw in Sec. II, the co-multiplication operation Δ plays a key role in the construction of the Hamiltonian $\mathcal{H}$. However, Eq. (7) does not exhaust possible definitions of Δ for $U_q(sl_2)$. In fact, a homomorphism $\Delta_\alpha: U_q(sl_2)\to[U_q(sl_2)]^{\otimes 2}$ such that

$$\Delta_\alpha(S^\pm)=S^\pm\otimes q^{(\pm\alpha-1)S^3}+q^{(\pm\alpha+1)S^3}\otimes S^\pm\,, \quad \Delta_\alpha(S^3)=S^3\otimes 1+1\otimes S^3 \tag{61}$$

satisfies all the properties of the co-multiplication for any real α. We had before $\alpha=0$, which is the most ''symmetric'' choice. But we may prefer $\alpha=1$ (or $\alpha=-1$) if we want the regime $q<0$ to be on equal footing with $q>0$ in the sense that the terms $q^{(\pm\alpha\pm 1)S^3}$ in (61) take only real values.

Notice that Δ_α is obtained from the co-multiplication (7) by twisting:

$$\Delta_\alpha(\xi)=F_\alpha\,\Delta(\xi)\,(F_\alpha)^{-1}\,, \quad F_\alpha=q^{\alpha S^3\otimes S^3}\in\mathfrak{H}\otimes\mathfrak{H}\,. \tag{62}$$

This twist is rather specific in that it preserves the co-associativity of the co-multiplication (more general twists give rise to the so-called quasi-Hopf algebras;[14] see Ref. 15 for their applications in integrable spin models).

In order to construct an integrable Hamiltonian using the new co-multiplication Δ_α in the same way as we used Δ in Secs. II and III, we should first find an L-operator, $\tilde{L}_\alpha(\lambda)$, that satisfies (6) with Δ_α. For this purpose we observe that

$$F_\alpha=(\phi_\alpha\otimes\phi_\alpha)^{-1}\,\Delta(\phi_\alpha),$$

where

$$\phi_\alpha=q^{(\alpha/2)(S^3)^2}\in\mathfrak{H}\,. \tag{63}$$

Therefore we can rewrite the left-hand side of (6) for $\tilde{L}_\alpha(\lambda)$ as

$$\Delta_\alpha(\tilde{L}_\alpha(\lambda))=(\phi_\alpha\otimes\phi_\alpha)^{-1}\,\Delta(\phi_\alpha\tilde{L}_\alpha(\lambda)\,\phi_\alpha^{-1})\,(\phi_\alpha\otimes\phi_\alpha),$$

which makes it obvious that $\tilde{L}_\alpha(\lambda)$ satisfies (6) with Δ_α if it is related to the L-operator (3) as follows:

$$\tilde{L}_\alpha(\lambda)=\phi_\alpha^{-1}\,L(\lambda)\,\phi_\alpha \tag{64}$$

$$=\frac{1}{\sin\gamma}\begin{pmatrix}\sinh[\,\gamma(\lambda+iS^3)\,] & i\sin\gamma\, e^{\gamma\lambda}q^{\alpha/2}q^{\alpha S^3}S^-\\ i\sin\gamma\, e^{-\gamma\lambda}q^{\alpha/2}q^{-\alpha S^3}S^+ & \sinh[\,\gamma(\lambda-iS^3)\,]\end{pmatrix}. \tag{65}$$

Since the map $\xi \to \phi_\alpha^{-1} \xi \phi_\alpha$ is an automorphism of $U_q(sl_2)$, it is clear that the exchange relation (2) holds for $\widetilde{L}_\alpha(\lambda)$ with the same R-matrix as for $L(\lambda)$. Consequently, the Bethe ansatz equations for $\widetilde{L}_\alpha(\lambda)$ coincide with those for $L(\lambda)$ (the reference state ω has also not changed).

Substituting (64) into (9), we find a universal r-matrix for the new L-operator:

$$\tilde{r}_\alpha(\lambda) = (\phi_\alpha \otimes \phi_\alpha)^{-1}\, r(\lambda)\, (\phi_\alpha \otimes \phi_\alpha) = F_\alpha\, r(\lambda)\, (F_\alpha)^{-1}. \tag{66}$$

The second equality is due to relation (63) and the property (12). The same twists relate the corresponding solutions of the Yang–Baxter equation (8), i.e.,

$$\check{\mathbf{R}}_\alpha(\lambda) = (\phi_\alpha \otimes \phi_\alpha)^{-1} \check{\mathbf{R}}(\lambda) (\phi_\alpha \otimes \phi_\alpha) = F_\alpha\, \check{\mathbf{R}}(\lambda) (F_\alpha)^{-1}. \tag{67}$$

Notice that the first equality is consistent with (64) since ϕ_α in the fundamental representation is just a constant. Further, evaluating the right-hand side of (67) in $V \otimes \mathfrak{H}$ representation, we see that $\widetilde{L}_\alpha(\lambda)$ can be constructed also as a twist by 2×2 matrix,

$$\widetilde{L}_\alpha(\lambda) = f_\alpha L(\lambda)\, f_\alpha^{-1}, \quad f_\alpha = q^{(\alpha/2)\,\sigma^3 \otimes S^3}.$$

Let us underline that existence of the two ways of constructing $\widetilde{L}_\alpha(\lambda)$ and, as a consequence, of the relation

$$[L(\lambda), \phi_\alpha f_\alpha] = 0$$

is due to the property of the universal r-matrix (12) applied to $\xi = \phi_\alpha$ [indeed, $q^{\alpha/2} \phi_\alpha f_\alpha$ is $\Delta(\phi_\alpha)$ evaluated in $V \otimes \mathfrak{H}$].

According to (20), the local Hamiltonian corresponding to the universal r-matrix (66) is

$$\widetilde{H}^{(\alpha)}_{n,n+1} = (\phi_n^\alpha\, \phi_{n+1}^\alpha)^{-1}\, H_{n,n+1}\, (\phi_n^\alpha\, \phi_{n+1}^\alpha) = F^\alpha_{n,n+1}\, H_{n,n+1}\, (F^\alpha_{n,n+1})^{-1}. \tag{68}$$

This transformation does not modify the $S = \frac{1}{2}$ Hamiltonian (49) since in this case ϕ_α is trivial. But already for $S = 1$ we find (see Appendix B)

$$\widetilde{H}^{(\alpha)}_{n,n+1} - H_{n,n+1} = \frac{1 - \cos(\alpha\gamma)}{2\cos\gamma} \{\Upsilon_{n,n+1}, S^3_n S^3_{n+1}\} - i\, \frac{\sin(\alpha\gamma)}{2\cos\gamma} [\Upsilon_{n,n+1}, S^3_n S^3_{n+1}], \tag{69}$$

where $[,]$ and $\{,\}$ stand for commutator and anticommutator, respectively, and $\Upsilon_{n,n+1} \equiv \frac{1}{2}(S^+_n S^-_{n+1} + S^-_n S^+_{n+1})$. Notice that the terms on the right-hand side of (69) are nondiagonal.

Finally, the total Hamiltonian is given by

$$\widetilde{\mathcal{H}}^{(\alpha)} = \sum_{n=1}^{N} \widetilde{H}^{(\alpha)}_{n,n+1} = (\Phi_\alpha)^{-1}\, \mathcal{H}\, \Phi_\alpha = \mathcal{F}_\alpha\, \mathcal{H}\, (\mathcal{F}_\alpha)^{-1}, \quad \Phi_\alpha \equiv \prod_{n=1}^{N} \phi_\alpha, \quad \mathcal{F}_\alpha \equiv q^{\alpha \Sigma_{n<m} S^3_n S^3_m}.$$

The Φ-twist here follows easily from (68). The $\mathcal{F}$-twist yields the same result because $\mathcal{H}$ commutes with $\mathcal{S}^3$ (36) and hence with $\Phi_\alpha \mathcal{F}_\alpha = q^{(\alpha/2)(\mathcal{S}^3)^2}$. Since $\widetilde{\mathcal{H}}^{(\alpha)}$ and $\mathcal{H}$ are related by a twist they have the same set of eigenvalues; this agrees with the fact that the Bethe ansatz equations have not changed.

Let us conclude this section with a remark: Eqs. (66), (67), and (68) may appear to suggest that $\widetilde{L}_\alpha(\lambda)$ and $\tilde{r}_\alpha(\lambda)$ are related to another twisted co-multiplication, $\widetilde{\Delta}_\theta(\xi) \equiv \theta^{-1}\, \Delta(\xi)\, \theta$, where $\theta = \phi_\alpha \otimes \phi_\alpha$. But $\widetilde{\Delta}_\theta$ fails to satisfy the necessary property of a co-multiplication,[14] $(\epsilon \otimes 1)\Delta(\xi) = \xi$, where ϵ is the co-unit. So $\widetilde{\Delta}_\theta$ is not a co-multiplication of a (quasi) Hopf algebra. (Moreover, $\widetilde{\Delta}_\theta$ is not co-associative.)

VII. FROM $H_{n,n+1}$ TO $\hat{H}_{n,n+1}$

Consider now another family of L-operators,

$$\hat{L}_\beta(\lambda)=\frac{1}{\sin\gamma}\begin{pmatrix}\sinh[\gamma(\lambda+iS^3)] & i\sin\gamma\, e^{(\gamma-\beta)\lambda}S^- \\ i\sin\gamma\, e^{(\beta-\gamma)\lambda}S^+ & \sinh[\gamma(\lambda-iS^3)]\end{pmatrix}, \tag{70}$$

which are obtained from the L-operator (3) as twists by certain 2×2 matrices,

$$\hat{L}_\beta(\lambda)=K_\lambda^{-1}L(\lambda)K_\lambda, \quad K_\lambda=e^{(1/2)\beta\lambda\sigma^3}\in V. \tag{71}$$

For $\beta=\gamma$ this gives the L-operator (41) (which is most often used in applications of the Bethe ansatz). The map $S^\pm\to e^{\pm\beta\lambda}S^\pm$, $S^3\to S^3$ is an automorphism of $U_q(sl_2)$ but, unlike the case treated in Sec. VI, it is λ-dependent. Therefore, the $\check{R}$-matrix corresponding to $\hat{L}_\beta(\lambda)$ differs from (4). Namely, as seen from (71), exchange relation (2) holds for $\hat{L}_\beta(\lambda)$ with $R_\beta(\lambda)=(1\otimes K_\lambda^{-1})R(\lambda)(K_\lambda\otimes 1)$, i.e., $R_\beta(\lambda)=P\check{R}_\beta(\lambda)$, where

$$\check{R}_\beta(\lambda)=i\,e^{(\gamma-\beta)\lambda}\,\sigma^+\otimes\sigma^-+i\,e^{(\beta-\gamma)\lambda}\,\sigma^-\otimes\sigma^+ +\frac{1}{\sin\gamma}\sinh\left(\gamma\lambda+\frac{i\gamma}{2}(1\otimes 1+\sigma^3\otimes\sigma^3)\right). \tag{72}$$

In order to find a universal r-matrix for $\hat{L}_\beta(\lambda)$, we will apply the approach which we used in Sec. VI. Namely, we observe that $\varphi_\lambda\equiv e^{\beta\lambda S^3}\in\mathfrak{H}$ is a complementary twist to (71) in the sense that

$$[L(\lambda),K_\lambda\,\varphi_\lambda]=0$$

as follows from the property of the universal r-matrix (12) for $\xi=\varphi_\lambda$ (in fact, K_λ is just φ_λ evaluated in the fundamental representation; hence $K_\lambda\varphi_\lambda$ is $\Delta(\varphi_\lambda)$ evaluated in $V\otimes\mathfrak{H}$).

Thus, instead of the twist (71) in the auxiliary space V, the L-operator (70) can be obtained as a twist in the quantum space $\mathfrak{H}$,

$$\hat{L}_\beta(\lambda)=\varphi_\lambda L(\lambda)\varphi_\lambda^{-1}, \quad \varphi_\lambda=e^{\beta\lambda S^3}\in\mathfrak{H}. \tag{73}$$

Substituting (73) into (9) and taking again into account that $[r(\lambda),\Delta(\varphi_\mu)]=0$, we find a universal r-matrix for $\hat{L}_\beta(\lambda)$,

$$\hat{r}_\beta(\lambda)=(1\otimes\varphi_\lambda)\,r(\lambda)\,(\varphi_\lambda^{-1}\otimes 1). \tag{74}$$

Unlike Eq. (66) this relation is not a twist. Notice however that the corresponding solutions of the Yang–Baxter equation (8) are related by a twist,

$$\check{\mathbf{R}}_\beta(\lambda)=(1\otimes\varphi_\lambda)\check{\mathbf{R}}(\lambda)(1\otimes\varphi_\lambda^{-1}). \tag{75}$$

It must be stressed now that $\hat{L}_\beta(\lambda)$ does not possess a decomposition of the type (5)–(6), and $\hat{r}_\beta(\lambda)$ does not commute with Δ (or Δ_α), i.e., (12) does not hold for $\hat{r}_\beta(\lambda)$ for a generic ξ. As a consequence, $\hat{r}_\beta(\lambda)$ does not have a representation of the type (15). Moreover, for $\beta\neq 0$ we have in general $[\hat{r}_\beta(\lambda),\hat{r}_\beta(\mu)]\neq 0$ (except for the fundamental representation in the case $\beta=\gamma$). Nevertheless, the general recipe for constructing a local integrable Hamiltonian applies [because the Yang–Baxter equation for $\check{\mathbf{R}}_\beta(\lambda)$ is valid]. So we substitute (74) into the formula (20) and derive

$$\hat{H}^{(\beta)}_{n,n+1}=H_{n,n+1}-i\frac{\beta\sin\gamma}{2\gamma}(S^3_n-S^3_{n+1}). \tag{76}$$

Thus the new local Hamiltonian differs from $H_{n,n+1}$ only in the local boundary term. Hence the total Hamiltonian $\hat{\mathcal{H}}=\Sigma_{n=1}^{N}\hat{H}^{\beta}_{n,n+1}$ coincides with $\mathcal{H}$. Note that the Bethe ansatz equations, describing the spectrum of $\hat{\mathcal{H}}$, have also not changed, which is not entirely trivial since the corresponding R-matrix has changed. The reason is that in the derivation of the Bethe ansatz equations the nondiagonal entries of (72) appear only in the so-called ''unwanted terms'' that cancel each other.[10,11,9]

In Sec. IV we asserted that the local Hamiltonian $H_{n,n+1}$ decomposes into a local boundary term and a local bulk term $\hat{H}_{n,n+1}$ which is associated with the L-operator (41). Now this is obvious from (70) and (76) if we put $\beta=\gamma$. Since we have found the corresponding universal r-matrix, we are in a position to prove the properties of $\hat{H}_{n,n+1}$ stated in Sec. IV. For brevity we denote $r_0(\lambda)\equiv\hat{r}_{\gamma}(\lambda)$.

As seen from (72) for $\beta=\gamma$, the auxiliary R-matrix associated with the L-operator (41) is P-symmetric, i.e., it commutes with the 4×4 permutation matrix P_V. The corresponding universal r-matrix, $r_0(\lambda)$, has analogous properties. Namely, (as we prove in Appendix A) $r_0(\lambda)$ satisfies the following relations:

$$\mathbf{P}\,r_0(\lambda)\,\mathbf{P}=r_0(\lambda)\,,\quad r_0(\lambda,\gamma)=r_0(\lambda,-\gamma)\,, \tag{77}$$

$$(r_0(\lambda))^t=r_0(\lambda)\,,\quad r_0(\lambda)\,r_0(-\lambda)=1\otimes1\,, \tag{78}$$

where $\mathbf{P}$ is the permutation in $\mathfrak{H}\otimes\mathfrak{H}$ and t denotes transposition. The last equality follows from the formula (74), the first relation in (17) for $r(\lambda)$, and the relation $[r(\lambda),\Delta(\varphi_\lambda)]=0$. Taking logarithmic derivative of (77) at $\lambda=0$, we establish the symmetries (40) of the local bulk term $\hat{H}_{n,n+1}$. The first relation in (78) yields in the same way the second relation in (48).

VIII. OPEN CHAIN

Integrable *open* spin chains have also been intensively studied,[16–21] in particular, from the point of view of the fusion procedure and quantum group symmetries.

As we saw in Sec. IV, $H_{N,1}$ is the only term in $\mathcal{H}$ which does not commute with the global spin generators $\mathcal{S}^{\pm}$. Omitting it, we obtain a Hamiltonian for an open spin chain,

$$\mathcal{H}'=\sum_{n=1}^{N-1}H_{n,n+1}=\sum_{n=1}^{N-1}\hat{H}_{n,n+1}+i\,\frac{\sin\gamma}{2}(S_1^3-S_N^3), \tag{79}$$

which is apparently $U_q(sl_2)$-symmetric, i.e., $[\mathcal{H}',\mathcal{S}^{\pm}]=[\mathcal{H}',\mathcal{S}^3]=0$. It is however not immediately evident whether the Hamiltonian (79) remains *integrable*.

Let us refer to the sum on the right-hand side of (79) as the bulk Hamiltonian, $\hat{\mathcal{H}}'$. The remaining part can be called the surface term; it is a sum of $(N-1)$ local boundary terms we dealt with before. As we discussed earlier, the bulk Hamiltonian $\hat{\mathcal{H}}'$ corresponds to the L-operator (41) and it is only $U(1)$-symmetric. The fact that adding the surface term to $\hat{\mathcal{H}}'$ restores the $U_q(sl_2)$-symmetry was observed for spin $\frac{1}{2}$ in Ref. 16 and for spin 1 in Ref. 17. Integrability of the corresponding total Hamiltonians was established in Refs. 18–20 in the framework of boundary integrable lattice models. We will prove in the following that $\mathcal{H}'$ is integrable for the higher spins as well.

Let us briefly recall the construction of an integrable Hamiltonian for a chain with boundaries.[18] Let $\check{\mathbf{R}}(\lambda)$ be a solution of the Yang–Baxter equation (8), and $T(\lambda)$ be a monodromy matrix obeying the exchange relation (2) with R-matrix $\mathbf{P}\check{\mathbf{R}}(\lambda)$. Introduce a boundary monodromy matrix, $Z(\lambda)\equiv T(\lambda)\mathcal{K}^-(\lambda)(T(-\lambda))^{-1}$. The boundary matrix, $\mathcal{K}^-(\lambda)\in\mathfrak{H}$, represents nonperiodic boundary conditions ($\check{\mathbf{R}}$ and $\mathcal{K}^-$ are close analogues of the bulk and boundary scattering

matrices[22]). [Strictly speaking, $\mathcal{K}^-(\lambda)$ is an element of $\mathfrak{H}\otimes\mathfrak{H}$ but with trivial second component. We had a similar situation in Sec. VII where the twist φ_λ had trivial first component, see Eq. (73).] Now, if $\mathcal{K}^-(\lambda)$ satisfies the so-called reflection equation, namely,

$$\begin{aligned}&\check{\mathbf{R}}(\lambda-\mu)\,(\mathcal{K}^-(\lambda)\otimes 1)\,(\check{\mathbf{R}}(-\lambda-\mu))^{-1}\,(1\otimes\mathcal{K}^-(\mu))\\&\quad=(1\otimes\mathcal{K}^-(\mu))\,\check{\mathbf{R}}(\lambda+\mu)\,(\mathcal{K}^-(\lambda)\otimes 1)\,(\check{\mathbf{R}}(-\lambda+\mu))^{-1},\end{aligned}\tag{80}$$

then $Z(\lambda)$ also satisfies this equation. Using this fact one can show that a special trace of $Z(\lambda)$, $\tau(\lambda)=\mathrm{tr}_0\mathcal{K}^+(\lambda)Z(\lambda)$, is a generating function for quantum integrals of motion if the boundary matrix $\mathcal{K}^+(\lambda)\in\mathfrak{H}$ satisfies a "dual" reflection equation,[18,23]

$$\begin{aligned}&\check{\mathbf{R}}(-\lambda+\mu)\,((\mathcal{K}^+)^t(\lambda)\otimes 1)\,\check{\mathbf{R}}(-\lambda-\mu-2\delta)\,(1\otimes(\mathcal{K}^+)^t(\mu))\\&\quad=(1\otimes(\mathcal{K}^+)^t(\mu))\,\check{\mathbf{R}}(-\lambda-\mu-2\delta)\,((\mathcal{K}^+)^t(\lambda)\otimes 1)\,\check{\mathbf{R}}(-\lambda+\mu),\end{aligned}\tag{81}$$

and $\check{\mathbf{R}}$ has the following properties:

$$\mathbf{P}\,\check{\mathbf{R}}(\lambda)\,\mathbf{P}=\check{\mathbf{R}}(\lambda),\quad \check{\mathbf{R}}(\lambda)\,\check{\mathbf{R}}(-\lambda)=\rho_1(\lambda)\,(1\otimes 1),\quad (\check{\mathbf{R}}(\lambda))^t=\check{\mathbf{R}}(\lambda),\tag{82}$$

$$(\check{\mathbf{R}}(\lambda))^{t_1}\,(\check{\mathbf{R}}(-\lambda-2\delta))^{t_1}=\rho_2(\lambda)\,(1\otimes 1),\tag{83}$$

where δ is a constant, and $\rho_1(\lambda)$ and $\rho_2(\lambda)$ are scalar functions.

With all these conditions, an integrable Hamiltonian is given Ref. 18 by the following analogue of the formula (20) [we keep the same normalization as in (20)]:

$$\begin{aligned}&\mathcal{H}''=\sum_{n=1}^{N-1}h_{n,n+1}+i\,\frac{\sin\gamma}{4\gamma}\,\frac{\mathrm{d}}{\mathrm{d}\lambda}\mathcal{K}_1^-(\lambda)\Big|_{\lambda=0}+\frac{\mathrm{tr}_0(\mathcal{K}_0^+(0)\,h_{0,N})}{\mathrm{tr}\,\mathcal{K}^+(0)},\\&h_{n,n+1}=i\,\frac{\sin\gamma}{2\gamma}\,\mathbf{P}_{n,n+1}\frac{\mathrm{d}}{\mathrm{d}\lambda}\check{\mathbf{R}}_{n,n+1}(\lambda)\Big|_{\lambda=0}.\end{aligned}\tag{84}$$

Deriving (84) one assumes that $\check{\mathbf{R}}_{n,n+1}(0)=\mathbf{P}$ and $\mathcal{K}^-(0)=1$, which is consistent with (80).

Let us try to identify the Hamiltonian (79) as a particular case of (84). First, we can put $h_{n,n+1}=\hat{H}_{n,n+1}$ if we choose $\check{\mathbf{R}}(\lambda)=\check{\mathbf{R}}_\gamma(\lambda)$, where $\check{\mathbf{R}}_\gamma(\lambda)=r_0(\lambda)\mathbf{P}$ is given by (75) with $\beta=\gamma$. For this R-matrix the properties (82) follow from (77); in particular, the second relation (unitarity) holds with $\rho_1(\lambda)=1$. The crossing unitarity (83) holds for $\check{\mathbf{R}}_\gamma(\lambda)$ with $\delta=i$.

The derivation of the reflection equation (80) for $\mathcal{K}^-$ does not use the conditions (82) and (83). So, let us look first for an R-matrix for which the reflection equation has a trivial solution, $\mathcal{K}^-(\lambda)=1$. In this case (80) turns into

$$\check{\mathbf{R}}(\lambda-\mu)\,(\check{\mathbf{R}}(-\lambda-\mu))^{-1}=\check{\mathbf{R}}(\lambda+\mu)\,(\check{\mathbf{R}}(-\lambda+\mu))^{-1}.\tag{85}$$

A solution to this equation is given by $\check{\mathbf{R}}(\lambda)=r(\lambda)\mathbf{P}$, where $r(\lambda)$ is the universal r-matrix we discussed in Sec. II. Indeed, (85) follows from the second relation in (17). Using this observation, we can find a solution to the reflection equation for any R-matrix $\check{\mathbf{R}}_\beta(\lambda)$ given by (75). Indeed, substituting (75) in (85), we derive

$$\begin{aligned}&\check{\mathbf{R}}_\beta(\lambda-\mu)\,(1\otimes\varphi_\lambda^2)\,(\check{\mathbf{R}}_\beta(-\lambda-\mu))^{-1}\,(1\otimes\varphi_{-\mu}^2)\\&\quad=(1\otimes\varphi_{-\mu}^2)\,\check{\mathbf{R}}_\beta(\lambda+\mu)\,(1\otimes\varphi_\lambda^2)\,(\check{\mathbf{R}}_\beta(-\lambda+\mu))^{-1}.\end{aligned}\tag{86}$$

Multiplying this relation by $\Delta(\varphi_\lambda^{-2})=(\varphi_\lambda\otimes\varphi_\lambda)^{-2}$ [which commutes with $\check{\mathbf{R}}_\beta(\lambda)$], we bring it to the form of (80). Thus, a solution of the reflection equation for $\check{\mathbf{R}}_\beta$ is

$$\mathcal{K}^-_\beta(\lambda)=(\varphi_\lambda)^{-2}=e^{-2\beta\lambda S^3}.$$

Notice that for $\beta=\gamma$ the R-matrix $\check{\mathbf{R}}$ is symmetric with respect to γ [the second relation in (77)]. Therefore in this case we have another solution [which can be derived directly from (86) by applying the permutation and then multiplying by $(\varphi_\mu\otimes\varphi_\mu)^2$],

$$\mathcal{K}^-(\lambda)=e^{2\gamma\lambda S^3}. \tag{87}$$

This is the boundary matrix we need since its derivative in (84) gives exactly the S_1^3 term in (79).

In general, solutions of the reflection equation and of its ''dual'' are independent of each other. However, as was noted already in Ref. 18, there exist several isomorphisms that allow us to construct $\mathcal{K}^+$ if we know $\mathcal{K}^-$. In particular, it is easy to see that a possible solution for (81) is $\mathcal{K}^+(\lambda)=(\mathcal{K}^-(-\lambda-\delta))^t$. For $\mathcal{K}^-$ given by (87) this yields

$$\mathcal{K}^+(\lambda)=e^{-2\gamma(\lambda+i)S^3}. \tag{88}$$

It turns out that substitution of $\mathcal{K}^+(0)=q^{-2S^3}$ into (84) gives exactly the S_N^3 term in (79). To prove this assertion, we first observe (see Appendix C) that for the q-trace of the local Hamiltonian $H_{n,n+1}$ we have

$$\mathrm{tr}_n(q^{2S_n^3}H_{n,n+1})=\tilde{\rho}_S\,1_{n+1}, \tag{89}$$

where $\tilde{\rho}_S$ is a scalar constant.

Taking into account the relation (39) between $H_{n,n+1}$ and $\hat{H}_{n,n+1}$, we infer from (89) that

$$\mathrm{tr}_0(q^{2S_0^3}\hat{H}_{0,N})=(\mathrm{tr}\,q^{2S^3})\,i\,\frac{\sin\gamma}{2}S_N^3+\mathrm{const}.$$

Now replacing q with q^{-1} and using that $\hat{H}_{n,n+1}$ is an even function of γ (40), we find that

$$\frac{\mathrm{tr}_0(\mathcal{K}^+(0)\,\hat{H}_{0,N})}{\mathrm{tr}\,\mathcal{K}^+(0)}=\frac{\mathrm{tr}_0(q^{-2S_0^3}\hat{H}_{0,N})}{\mathrm{tr}\,q^{-2S^3}}=-\,i\,\frac{\sin\gamma}{2}S_N^3 \tag{90}$$

holds (up to an additive constant). Thus, the boundary matrix (88) gives the S_N^3 term in (79). This completes the proof that the $U_q(sl_2)$-symmetric open chain Hamiltonian (79) is integrable for all (half-) integer spins.

IX. CONCLUSION

In summary, we have constructed explicitly (in terms of the spin generators) higher spin closed chain Hamiltonians for two families of XXZ-type L-operators including the two L-operators most often used in the literature. We have investigated properties of these Hamiltonians, described their interrelations, and discussed the connection with $U_q(sl_2)$-symmetric open chain Hamiltonians.

We have emphasized a key role of the underlying quantum algebraic structure, especially the universal r-matrix and the co-multiplication, for constructing integrable Hamiltonians and investigating their symmetries. The technique presented in this paper can be applied also for constructing the higher quantum integrals of motion. Also, with certain modifications, this technique can be extended to models based on (the quantum deformation of) the superalgebra $osp(1|2)$; the corresponding basic ingredients are known.[24]

The presented construction applies also to the case of q being a root of unity, $q^p=1$, if p is sufficiently large in comparison with the spin S. Indeed, the denominator of (27) does not vanish if $p>8S$ and therefore the projectors $\mathcal{P}_j$ can be used in the usual way. For $p\leqslant 8S$ the construction needs to be modified because eigenvalues of the tensor Casimir operator become degenerate and the so-called cyclic representations appear.

ACKNOWLEDGMENTS

I am grateful to H.M. Babujian for useful discussions and to L.D. Faddeev, P.P. Kulish, and J. Teschner for valuable comments. This work was supported by Alexander von Humboldt Foundation.

APPENDIX A

Here we give some technical details on the universal r-matrices used in the text. First we recall the derivation of the universal r-matrix (16) along the lines of Refs. 6 and 7 (see also Refs. 9 and 25). The explicit form of the off-diagonal entries of Eq. (11) is

$$r(\lambda)\,(e^{\mp\gamma\lambda}S^{\pm}\otimes q^{S^3}+e^{\pm\gamma\lambda}q^{-S^3}\otimes S^{\pm})=(e^{\pm\gamma\lambda}S^{\pm}\otimes q^{S^3}+e^{\mp\gamma\lambda}q^{-S^3}\otimes S^{\pm})\,r(\lambda)\,. \tag{A1}$$

A solution to this equation is unique up to a scalar factor.[7] Notice that the co-multiplication (7) satisfies the following relations:

$$[S^{\varepsilon}\otimes q^{S^3},\Delta(S^{\varepsilon})]=[q^{-S^3}\otimes S^{\varepsilon},\Delta(S^{\varepsilon})]=0\,,\quad \varepsilon=\pm\,.$$

Therefore, for the highest/lowest weight vectors we deduce that

$$S^{\pm}\otimes q^{S^3}\,|j,\pm j\rangle=g_{\pm}(j)|j+1,\pm(j+1)\rangle\,,\quad q^{-S^3}\otimes S^{\pm}\,|j,\pm j\rangle=h_{\pm}(j)|j+1,\pm(j+1)\rangle\,, \tag{A2}$$

where $g_{\pm}(j)$ and $h_{\pm}(j)$ are scalar functions. Furthermore, we have

$$\begin{aligned}&(S^{\pm}\otimes q^{S^3}+q^{\pm(2+2j)}q^{-S^3}\otimes S^{\pm})\,|j,\pm j\rangle\\&\quad=((1\otimes q^{2S^3})\,S^{\pm}\otimes q^{-S^3}+q^{\pm(2+2j)}(q^{S^3}\otimes S^{\pm}q^{2S^3})q^{-2S^3}\otimes q^{-2S^3})\,|j,\pm j\rangle\\&\quad=(1\otimes q^{2S^3})\,\Delta(S^{\pm})\,|j,\pm j\rangle=0\,.\end{aligned} \tag{A3}$$

Applying now (A1) to $|j,j\rangle$ (for the upper signs) or to $|j,-j\rangle$ (for the lower signs) and using (15), (A2), and (A3), we deduce that

$$r_{j+1}(\lambda)\,(e^{\pm\gamma\lambda}-q^{\pm(2+2j)}e^{\mp\gamma\lambda})=(e^{\mp\gamma\lambda}-q^{\pm(2+2j)}e^{\pm\gamma\lambda})\;\;r_j(\lambda)\,. \tag{A4}$$

Both relations in (A4) yield the same functional equation on $r_j(\lambda)$ (which arises also for universal r-matrices in the lattice sine-Gordon model[26] and in the lattice Virasoro algebra[27])

$$r_{j+1}(\lambda)=\frac{\sin[\,\gamma(j+1-i\lambda)]}{\sin[\,\gamma(j+1+i\lambda)]}\,r_j(\lambda)\,. \tag{A5}$$

Upon imposing the normalization condition $r(0)=1$, we obtain expression (16). A proof that this $r(\lambda)$ does satisfy all the relations in (11) is given in Refs. 6 and 7. Of course, one is still free to multiply $r(\lambda)$ by a scalar function, $\rho(\lambda)$, such that $\rho(0)=1$. For instance, the spin-$\frac{1}{2}$ representation of $\check{R}(\lambda)$ given by (4) corresponds to $\rho(\lambda)=\sin[\gamma(1+i\lambda)]/\sin\gamma$.

Consider now the universal r-matrix $r_0(\lambda)$ introduced in Sec. VII. It is a solution to Eq. (9) for the L-operator (41). Unlike the previous case, this L-operator does not have a Borel decomposition of the type (5). Therefore the off-diagonal entries of (9) give us four λ-dependent relations:

$$r_0(\lambda)\,(S^{\pm}\otimes q^{S^3}+e^{\pm\gamma\lambda}q^{-S^3}\otimes S^{\pm})=(e^{\pm\gamma\lambda}S^{\pm}\otimes q^{S^3}+q^{-S^3}\otimes S^{\pm})\,r_0(\lambda)\,, \tag{A6}$$

$$r_0(\lambda)\,(S^{\pm}\otimes q^{-S^3}e^{\pm\gamma\lambda}+q^{S^3}\otimes S^{\pm})=(e^{\pm\gamma\lambda}q^{S^3}\otimes S^{\pm}+S^{\pm}\otimes q^{-S^3})\,r_0(\lambda)\,. \tag{A7}$$

It can be proven along the lines of Ref. 7 that solution to this equation is unique up to a scalar factor. As we have already shown in Sec. VII, this solution is given by $r_0(\lambda)=(1\otimes e^{\gamma\lambda S^3})r(\lambda)\times(e^{-\gamma\lambda S^3}\otimes 1)$, where $r(\lambda)$ solves (A1).

Now we observe that $r_1(\lambda)\equiv\mathbf{P}r_0(\lambda)\mathbf{P}$ and $r_2(\lambda)\equiv(r_0(\lambda))^t$ solve the same set of equations (A6) and (A7). By the above-mentioned uniqueness, this implies that $r_i(\lambda)=c_i(\lambda)r_0(\lambda)$, where $c_i(\lambda)$, $i=1,2$ are scalar functions. Since $\mathbf{P}^2=1\otimes 1$, and $((r_0)^t)^t=r_0$, we conclude that $c_i(\lambda)=\pm 1$. Imposing the condition $r_0(0)=1\otimes 1$, we have to put $c_i(\lambda)=1$. Thus, we have proven the relations on the left-hand side of (77) and (78). Employing the first of them and the property (37) of $r(\lambda)$, we prove the second relation in (77) as follows:

$$\begin{aligned}
r_0(\lambda,-\gamma)&=(1\otimes e^{-\gamma\lambda S^3})r(\lambda,-\gamma)(e^{\gamma\lambda S^3}\otimes 1)\\
&=(1\otimes e^{-\gamma\lambda S^3})\mathbf{P}r(\lambda,\gamma)\mathbf{P}(e^{\gamma\lambda S^3}\otimes 1)\\
&=\mathbf{P}(e^{-\gamma\lambda S^3}\otimes 1)r(\lambda,\gamma)(1\otimes e^{\gamma\lambda S^3})\mathbf{P}\\
&=\mathbf{P}(1\otimes e^{\gamma\lambda S^3})r(\lambda,\gamma)(e^{-\gamma\lambda S^3}\otimes 1)\mathbf{P}\\
&=\mathbf{P}r_0(\lambda,\gamma)\mathbf{P}=r_0(\lambda,\gamma)\,.
\end{aligned}$$

In the fourth line we used that $[r(\lambda),\Delta(e^{\gamma\lambda S^3})]=0$.

APPENDIX B

Here we provide some details on computation of the Hamiltonians in the cases of spin 1 and spin $\frac{3}{2}$. For $S=1$, a matrix representation of the spin generators is (as was discussed in Sec. IV, one has a freedom of rescaling $S^{\pm}\to\eta^{\mp 1/2}S^{\pm}$ with any real $\eta\neq 0$)

$$S^+=\begin{pmatrix}0&a&0\\0&0&a\\0&0&0\end{pmatrix},\quad S^-=(S^+)^t,\quad S^3=\begin{pmatrix}1&0&0\\0&0&0\\0&0&-1\end{pmatrix}, \tag{B1}$$

where t denotes transposition and $a=\sqrt{2\cos\gamma}$. Since $(S^3)^3=S^3$, any function of S^3 is a polynomial in S^3 of a degree not exceeding two. In particular, we have

$$\sin(tS^3)=S^3\sin t\,,\quad \cos(tS^3)=1-2(S^3)^2\sin^2\frac{t}{2}\,. \tag{B2}$$

Denote $\Upsilon=\frac{1}{2}(S_n^+S_{n+1}^-+S_n^-S_{n+1}^+)$. With the help of formulas (B2) we rewrite (29) as follows:

$$\begin{aligned}
\mathbf{X}_1&=q^{S_n^3}\Upsilon\,q^{-S_{n+1}^3}+(\cos\gamma)\,(\Lambda+\tfrac{1}{2}+2(\cos\gamma)^2)\,,\\
\Lambda&=\tfrac{3}{2}-2(\cos\gamma)^2+(\cos\gamma)^2(S_n^3S_{n+1}^3)+(\sin\gamma)^2((S_n^3S_{n+1}^3)^2-2(S_n^3)^2-2(S_{n+1}^3)^2)\\
&\quad+i(\sin 2\gamma)(S_n^3-S_{n+1}^3+\tfrac{1}{2}(S_n^3)^2S_{n+1}^3-\tfrac{1}{2}S_n^3(S_{n+1}^3)^2)\,.
\end{aligned} \tag{B3}$$

Substituting (B3) into (52), applying several times formulas (B2) and (59), we obtain the Hamiltonian in the following form:

$$\begin{aligned}
H_{n,n+1}=\frac{1}{4\cos\gamma}\Bigg(&-\frac{1}{\cos^2\gamma}(\Upsilon)^2-\frac{1}{\cos\gamma}q^{S_n^3}(\Upsilon\,\Lambda+\Lambda\,\Upsilon)\,q^{-S_{n+1}^3}+4+2\cos 2\gamma+(\cos 2\gamma)\\
&\times(S_n^3S_{n+1}^3-(S_n^3S_{n+1}^3)^2)-2(\sin\gamma)^2((S_n^3)^2+(S_{n+1}^3)^2)\Bigg)+i\frac{\sin\gamma}{2}(S_n^3-S_{n+1}^3)\,.
\end{aligned} \tag{B4}$$

Deriving the first term here we used the following analogue of relation (50):

$$e^{tS^3}(S^{\pm})^2=(S^{\pm})^2 e^{-tS^3}=e^{\pm t}(S^{\pm})^2 . \tag{B5}$$

Next, we observe that the following identity holds (as can be checked directly in terms of matrices):

$$-F_\alpha (q^{S_n^3}(\Upsilon\,\Lambda+\Lambda\,\Upsilon)\,q^{-S_{n+1}^3})\,(F_\alpha)^{-1}=\Theta_\alpha^-\,\Upsilon+\Upsilon\,\Theta_\alpha^+ , \tag{B6}$$

with F_α as in (62) and

$$\Theta_\alpha^{\pm}=\tfrac{1}{2}(1\otimes 1)+(1-2q^{\pm\alpha}\cos\gamma)\,S_n^3 S_{n+1}^3 . \tag{B7}$$

Substituting (B6) and (B7) with $\alpha=0$ into (B4), we obtain the Hamiltonian (53).

The Hamiltonian $\widetilde{H}_{n,n+1}^{(\alpha)}$ discussed in Sec. VI is obtained from (B4) by the twist (68). Notice that the term $(\Upsilon)^2$ in (B4) is not affected due to (B5). The diagonal part of Hamiltonian apparently commutes with the twist. So the only part of (B4) which changes is the second term. It transforms according to (B6), which yields the Hamiltonian (69).

Consider now the case $S=\frac{3}{2}$. The spin generators are given by

$$S^+=\begin{pmatrix} 0 & a_1 & 0 & 0\\ 0 & 0 & a_2 & 0\\ 0 & 0 & 0 & a_1\\ 0 & 0 & 0 & 0 \end{pmatrix},\quad S^-=(S^+)^t,\quad S^3=\begin{pmatrix} \frac{3}{2} & 0 & 0 & 0\\ 0 & \frac{1}{2} & 0 & 0\\ 0 & 0 & -\frac{1}{2} & 0\\ 0 & 0 & 0 & -\frac{3}{2} \end{pmatrix}, \tag{B8}$$

with $a_1=(2\cos 2\gamma+1)^{1/2}$ and $a_2=2\cos\gamma$. Any function of S^3 is a polynomial in S^3 of a degree not exceeding three. In particular,

$$\sin(tS^3)=\left(2\sin\frac{t}{2}+\frac{1}{3}\sin^3\frac{t}{2}\right)S^3-\frac{4}{3}\left(\sin^3\frac{t}{2}\right)(S^3)^3 , \tag{B9}$$

$$\cos(tS^3)=\cos\frac{t}{2}+\frac{1}{4}\sin\frac{t}{2}\sin t-\left(\sin\frac{t}{2}\sin t\right)(S^3)^2 . \tag{B10}$$

The Hamiltonian (56) for $S=\frac{3}{2}$ takes the following form in terms of $\mathbf{X}_{3/2}$:

$$H_{n,n+1}=\frac{1}{4(\cos\gamma)^3(1+2\cos 2\gamma)^3}(4(\cos\gamma)(\mathbf{X}_{3/2})^2-(\mathbf{X}_{3/2})^2(13+20\cos 2\gamma+8\cos 4\gamma +2\cos 6\gamma)+\mathbf{X}_{3/2}(68\cos\gamma+48\cos 3\gamma+23\cos 5\gamma+7\cos 7\gamma+\cos 9\gamma)) . \tag{B11}$$

This Hamiltonian can be rewritten in the same way as we did for $S=1$ using, in particular, relations (60), (B9) and (B10), and appropriate analogues of (B5) and (B6). The final form is given by (57), with

$$\mathbf{Q}=\frac{1}{192}(1\otimes 1)\,(815-5832\cos\gamma+2352\cos 2\gamma-3888\cos 3\gamma+2542\cos 4\gamma-1620\cos 5\gamma$$
$$+1600\cos 6\gamma-324\cos 7\gamma+467\cos 8\gamma)+\frac{2}{3}\left(\sin\frac{\gamma}{2}\right)^2 S_n^3S_{n+1}^3\,(106+37\cos\gamma+186\cos 2\gamma$$
$$+29\cos 3\gamma+88\cos 4\gamma+13\cos 5\gamma+28\cos 6\gamma+5\cos 7\gamma)+\left(\sin\frac{\gamma}{2}\right)^2 (S_n^3S_{n+1}^3)^2\,(28$$
$$-53\cos\gamma+54\cos 2\gamma-31\cos 3\gamma+28\cos 4\gamma-11\cos 5\gamma+10\cos 6\gamma-\cos 7\gamma)$$
$$+\frac{1}{12}\left(\sin\frac{\gamma}{2}\right)^2 ((S_n^3)^2+(S_{n+1}^3)^2)\,(412+1687\cos\gamma+606\cos 2\gamma+1085\cos 3\gamma+268\cos 4\gamma$$
$$+433\cos 5\gamma+58\cos 6\gamma+83\cos 7\gamma)\,,$$

$$\mathbf{F}_{3/2}=\frac{\cos^2\gamma}{4}(1\otimes 1)\,(10328+17080\cos 2\gamma+9071\cos 4\gamma+3220\cos 6\gamma+621\cos 8\gamma)$$
$$-\frac{1}{9}\left(\sin\frac{\gamma}{2}\right)^2 S_n^3S_{n+1}^3\,(8364+5020\cos\gamma+12752\cos 2\gamma+2499\cos 3\gamma+7150\cos 4\gamma$$
$$+1023\cos 5\gamma+3320\cos 6\gamma+447\cos 7\gamma+814\cos 8\gamma+83\cos 9\gamma)$$
$$-\frac{4}{3}\left(\sin\frac{\gamma}{2}\right)^2 (S_n^3S_{n+1}^3)^2\,(536-472\cos\gamma+864\cos 2\gamma-347\cos 3\gamma+650\cos 4\gamma$$
$$-163\cos 5\gamma+272\cos 6\gamma-65\cos 7\gamma+78\cos 8\gamma-9\cos 9\gamma)-\frac{64}{9}\left(\sin\frac{\gamma}{2}\right)^4 (S_n^3S_{n+1}^3)^3\,(50$$
$$-200\cos\gamma+48\cos 2\gamma-168\cos 3\gamma+45\cos 4\gamma-76\cos 5\gamma+28\cos 6\gamma-20\cos 7\gamma$$
$$+13\cos 8\gamma)-(\sin 2\gamma)^2\,((S_n^3)^2+(S_{n+1}^3)^2)\,(169+274\cos 2\gamma+106\cos 4\gamma+27\cos 6\gamma)$$
$$+\frac{4}{9}\left(\sin\frac{\gamma}{2}\right)^2 ((S_n^3)^3S_{n+1}^3+S_n^3(S_{n+1}^3)^2)\,(444-2516\cos\gamma+560\cos 2\gamma-2037\cos 3\gamma$$
$$+334\cos 4\gamma-1137\cos 5\gamma+200\cos 6\gamma-417\cos 7\gamma+46\cos 8\gamma-85\cos 9\gamma)\,.$$

The equivalence of (B11) and (57) as 16×16 matrices has been verified with the help of the program MATHEMATICA.

APPENDIX C

Here we explain the origin of Eq. (89) that was important for our discussion on the open chain Hamiltonian in Sec. VIII.

Recall that, by definition (see, e.g., Refs. 14 and 28), a Hopf algebra $\mathcal{A}$ possesses the antipode map $s:\mathcal{A}\to\mathcal{A}$ which is an antihomomorphism consistent with the co-multiplication and the co-unit in the sense that $m((s\otimes id)\Delta(\xi))=m((id\otimes s)\Delta(\xi))=\epsilon(\xi)\cdot 1$ (here $m:\mathcal{A}^{\otimes 2}\to\mathcal{A}$ is the multiplication). Assume that there exists an element $\chi\in\mathcal{A}$ which realizes the square of the antipode (which is a homomorphism) as an inner automorphism, i.e., $s(s(\xi))=\chi\,\xi\,\chi^{-1}$ for any $\xi\in\mathcal{A}$. Then, as was proven in Ref. 28,

$$\mathrm{tr}_1((\chi^{-1}\otimes 1)\,b) \tag{C1}$$

belongs to the center of $\mathcal{A}$ if an element $b\in\mathcal{A}^{\otimes 2}$ satisfies $[b,\Delta(\xi)]=0$ for any $\xi\in\mathcal{A}$.

For $\mathcal{A}=U_q(sl_2)$ the antipode consistent with the co-multiplication (7) is given by

$$s(S^{\pm}) = -q^{\mp 1} S^{\pm}, \quad s(S^3) = -S^3.$$

It is easy to see that in this case $\chi = q^{-2S^3}$. Since the universal r-matrix $r(\lambda)$ has the property (12), we can apply (C1) and infer that its q-trace, $\mathrm{tr}_1((q^{2S^3} \otimes 1)\, r(\lambda))$, belongs to the center of $U_q(sl_2)$. Consequently, the same holds for the local Hamiltonian $H_{n,n+1}$ constructed as in (20). Being evaluated in an irreducible representation, the q-trace of $H_{n,n+1}$ becomes just a constant, as was stated in Eq. (89).

Quantum mechanics of damped systems

Dariusz Chruściński[a)]
Department of Mathematics and Statistics, University of Calgary, Calgary, Alberta, Canada

(Received 21 January 2003; accepted 16 May 2003)

We show that the quantization of a simple damped system leads to a self-adjoint Hamiltonian with a family of complex generalized eigenvalues. It turns out that they correspond to the poles of energy eigenvectors when continued to the complex energy plane. Therefore, the corresponding generalized eigenvectors may be interpreted as resonant states. We show that resonant states are responsible for the irreversible quantum dynamics of our simple model. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1599074]

I. INTRODUCTION

Standard textbooks on quantum mechanics investigate mainly the Hamiltonian system, i.e., by a quantum system one usually means a Hilbert space $\mathcal{H}$ which describes physical quantum states and a self-adjoint operator (Hamiltonian) in $\mathcal{H}$ which governs dynamics of the system. However, most of the classical systems are not Hamiltonian and the quantum mechanics of such systems is poorly understood. In the present paper we are going to investigate one of the simplest non-Hamiltonian systems corresponding to a damped motion in one dimension:

$$\dot{x} = -\gamma x, \tag{1.1}$$

where $x \in \mathbb{R}$, and $\gamma > 0$ stands for the damping constant. Classically, the damping behavior is described by the exponential law

$$x(t) = e^{-\gamma t} x. \tag{1.2}$$

As is well known[1] (see also Ref. 2), within the standard Hilbert space formulation of quantum mechanics there is no room for such behavior on a quantum level. Therefore, in order to deal with this problem, we shall use the rigged Hilbert space approach to quantum mechanics which generalizes the standard Hilbert space version.[3–5] A rigged Hilbert space (or a Gelfand triplet) is a collection of spaces:[6,7]

$$\Phi \subset \mathcal{H} \subset \Phi', \tag{1.3}$$

where $\mathcal{H}$ is a Hilbert space, Φ is a dense nuclear subspace of $\mathcal{H}$, and Φ' denotes its dual, i.e., the space of continuous functionals on Φ (see Sec. II for a brief review).

The quantization of our simple model (1.1) leads to a self-adjoint Hamiltonian $\hat{H}$ in $\mathcal{H} = L^2(\mathbb{R})$. Interestingly, $\hat{H}$ being self-adjoint, gives rise to the family of generalized complex eigenvalues. Clearly, these eigenvalues are not elements of the spectrum $\sigma(\hat{H}) = (-\infty, \infty)$. The corresponding eigenvectors do not belong to $L^2(\mathbb{R})$ but to Φ' for an appropriately chosen Φ. We show that these complex eigenvalues have many remarkable properties analogous to the point spectrum of a self-adjoint operator. In particular, they give rise to the spectral decomposition of $\hat{H}$. Moreover, they are closely related to the continuous spectrum of $\hat{H}$. It turns out that they corre-

spond to the poles of the energy eigenvectors ψ^E when continued to the complex energy plane.[8] Physicists usually called the corresponding eigenvectors resonant states[3,9,10] (see also Ref. 11). It is widely believed that resonant states are responsible for the irreversible dynamics of physical systems (see, e.g., the recent collection of papers[3]). Indeed, it is true in our simple model. To see this we construct two Gelfand triples:

$$\Phi_{\pm} \subset L^2(\mathbb{R}) \subset \Phi'_{\pm}, \tag{1.4}$$

such that $\Phi_+ \cap \Phi_- = \{\varnothing\}$. Obviously, the time evolution is perfectly reversible when considered on $L^2(\mathbb{R})$. It is given by the one-parameter group of unitary transformations $U(t) = e^{-i\hat{H}t}$. However, when restricted to $\Phi_{\pm}$, it defines only two semigroups: $U(t \geqslant 0)$ on Φ_-, and $U(t \leqslant 0)$ on Φ_+. Therefore, the evolution on $\Phi_{\pm}$ is irreversible. This irreversibility is caused by quantum damping, or, equivalently, by the presence of resonances.

II. RIGGED HILBERT SPACE

Consider a rigged Hilbert space, i.e., the following collection (Gelfand triplet):

$$\Phi \subset \mathcal{H} \subset \Phi', \tag{2.1}$$

where $\mathcal{H}$ is a Hilbert space with the standard norm topology $\tau_{\mathcal{H}}$, Φ is a topological vector space with a topology, τ_{Φ}, stronger than $\tau_{\mathcal{H}}$, and Φ' is the dual space of continuous linear functionals on Φ.[6,7] We denote the action of Φ' on Φ using Dirac notation, i.e., for any $\phi \in \Phi$ and $F \in \Phi'$,

$$\langle \phi | F \rangle := F(\phi). \tag{2.2}$$

Any self-adjoint operator $\hat{A}$ in $\mathcal{H}$ may be extended to an operator on Φ':

$$\hat{A}: \Phi' \to \Phi', \tag{2.3}$$

by

$$\langle \phi | \hat{A} F \rangle := \langle \hat{A}\phi | F \rangle. \tag{2.4}$$

Now, if for any $\phi \in \Phi$,

$$\langle \phi | \hat{A} F_{\lambda} \rangle = \lambda \langle \phi | F_{\lambda} \rangle, \tag{2.5}$$

then $F_{\lambda} \in \Phi'$ is called a generalized eigenvector corresponding to a generalized eigenvalue λ. Omitting ϕ one simply writes

$$\hat{A} | F_{\lambda} \rangle = \lambda | F_{\lambda} \rangle. \tag{2.6}$$

Note that a generalized eigenvalue λ may be complex. Now, if the spectrum of $\hat{A}$,

$$\sigma(\hat{A}) = \sigma_p(\hat{A}) \cup \sigma_c(\hat{A}) \subset \mathbb{R}, \tag{2.7}$$

with $\sigma_p(\hat{A}) = \{\lambda_1, \lambda_2, \ldots\}$, then the Gelfand–Maurin theorem[6,7] implies the following spectral decompositions:

$$\mathbb{1}_{\Phi} = \sum_n |F_n\rangle\langle F_n| + \int_{\sigma_c(\hat{A})} d\lambda \, |F_{\lambda}\rangle\langle F_{\lambda}|, \tag{2.8}$$

and of $\hat{A}$ itself:

$$\hat{A}=\sum_n \lambda_n |F_n\rangle\langle F_n| + \int_{\sigma_c(\hat{A})} d\lambda\, \lambda |F_\lambda\rangle\langle F_\lambda|. \tag{2.9}$$

This way the rigged Hilbert space approach fully justifies the standard Dirac notation.

The choice of Φ depends on the particular problem one deals with. In the present paper we shall consider the following functional spaces: $\mathcal{D}$—the space of $C^\infty(\mathbb{R})$ functions with compact supports equipped with the convex Schwartz topology,[12] $\mathcal{S}$—the space of $C^\infty(\mathbb{R})$ functions vanishing at infinity faster than any polynomial.[12] Moreover, let us define

$$\mathcal{Z} := \{F[\phi] \mid \phi \in \mathcal{D}\}, \tag{2.10}$$

where $F[\phi]$ denotes the Fourier transform of ϕ. It turns out[13] that $\mathcal{Z}$ is isomorphic to the space of entire functions of fast decrease along $\mathbb{R}$. More precisely, let

$$F_L[\phi](z) := \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{izx}\phi(x)\, dx, \tag{2.11}$$

be the Fourier–Laplace transform of $\phi \in \mathcal{D}$. One proves[12,13] the following

Theorem 1: *(Paley–Wiener–Schwartz) Let $a>0$. An entire function $U(z)$ is a Fourier–Laplace transform of a function $u \in \mathcal{D}$ with support*

$$\mathrm{supp}(u) = \{x \in \mathbb{R} \mid |x| \leqslant a\},$$

if and only if

$$|z|^n |U(z)| \leqslant C_n e^{a|\mathrm{Im}\, z|}, \quad n = 1,2,\ldots .$$

Now, for $z=x \in \mathbb{R}$, i.e., $\mathrm{Im}\, z=0$, $F_L[\phi]=F[\phi]$, and the above theorem implies

$$|x|^n |F[\phi](x)| \leqslant C_n, \qquad n = 1,2,\ldots . \tag{2.12}$$

Clearly, $\mathcal{Z} \cap \mathcal{D} = \{\varnothing\}$. Moreover, one has

$$\mathcal{D} \subset \mathcal{S} \subset L^2(\mathbb{R}), \tag{2.13}$$

and

$$\mathcal{Z} \subset \mathcal{S} \subset L^2(\mathbb{R}), \tag{2.14}$$

and both $\mathcal{D}$ and $\mathcal{Z}$ are dense in $\mathcal{S}$. One proves[13] that the Fourier transformation which defines the unitary operator

$$F : L^2(\mathbb{R}) \to L^2(\mathbb{R}), \tag{2.15}$$

establishes an isomorphism between $\mathcal{D}$ and $\mathcal{Z}$.

III. QUANTIZATION OF DAMPED SYSTEMS

Let us quantize a classical damped system described by (1.1). Clearly this system is not Hamiltonian. However, it is well known (cf. Ref. 14) that any dynamical system may be rewritten in a Hamiltonian form. Consider a dynamical system on n-dimensional configuration space Q:

$$\dot{x} = X(x)\ , \tag{3.1}$$

where X is a vector field on Q. Now, define the following Hamiltonian on the cotangent bundle $\mathcal{P}=T^*Q$:

$$H(\alpha_x) := \alpha_x(X(x)), \tag{3.2}$$

where $\alpha_x \in T_x^*Q$. Using canonical coordinates $(x^1,\ldots,x^n,p_1,\ldots,p_n)$ one obtains

$$H(x,p) = \sum_{k=1}^{n} p_k X^k(x), \tag{3.3}$$

where X^k are components of X in the coordinate basis $\partial/\partial x^k$. The corresponding Hamilton equations take the following form:

$$\dot{x}^k = \{x^k, H\} = X^k(x), \tag{3.4}$$

$$\dot{p}_k = \{p_k, H\} = -\sum_{l=1}^{n} p_l \frac{\partial X^l(x)}{\partial x^k}, \tag{3.5}$$

for $k=1,\ldots,n$. In the above formulas $\{\ ,\ \}$ denotes the canonical Poisson bracket on T^*Q:

$$\{F,G\} = \sum_{k=1}^{n} \left(\frac{\partial F}{\partial x^k}\frac{\partial G}{\partial p_k} - \frac{\partial G}{\partial x^k}\frac{\partial F}{\partial p_k} \right). \tag{3.6}$$

Clearly, the formula (3.4) reproduces our initial dynamical system (3.1) on Q.

Let us apply the above procedure to the damped system (1.1). One obtains for the Hamiltonian

$$H(x,p) = -\gamma x p, \tag{3.7}$$

and hence the corresponding Hamilton equations

$$\dot{x} = -\gamma x, \quad \dot{p} = \gamma p, \tag{3.8}$$

give rise to the following Hamiltonian flow on $\mathbb{R}^2$:

$$(x,p) \to (e^{-\gamma t}x, e^{t\gamma}p). \tag{3.9}$$

Now, the quantization is straightforward: one has for the Hilbert space $\mathcal{H} = L^2(\mathbb{R})$, and for the Hamiltonian

$$\hat{H} = -\frac{\gamma}{2}(\hat{x}\hat{p} + \hat{p}\hat{x}). \tag{3.10}$$

It is evident that (3.10) defines a symmetric operator on $L^2(\mathbb{R})$. In Sec. IV we show that $\hat{H}$ is self-adjoint and hence it gives rise to a well-defined quantum mechanical problem. Actually, this Hamiltonian is well known in quantum optics in connection with the squeezed states of light.[15] Introducing $\hat{a}$ and $\hat{a}^*$: $\hat{x} = (\hat{a} + \hat{a}^*)/\sqrt{2}$, $\hat{p} = (\hat{a} - \hat{a}^*)/\sqrt{2}i$, the Hamiltonian (3.10) may be rewritten as follows: $\hat{H} = (\gamma/2i)(\hat{a}^{*2} - \hat{a}^2)$, which is exactly a generator of squeezing.

Let us observe that performing the canonical transformation

$$x = \frac{-1}{\sqrt{2\gamma}}(P + \gamma X), \quad p = \frac{1}{\sqrt{2\gamma}}(P - \gamma X), \tag{3.11}$$

the classical Hamiltonian (3.10) takes the following form:

$$\hat{H} = \tfrac{1}{2}(\hat{P}^2 - \gamma^2 \hat{X}^2), \tag{3.12}$$

that is, it corresponds to the so-called reversed harmonic oscillator. This system was analyzed in Ref. 16 and recently in Refs. 17–19 (see also Refs. 20 and 21).

IV. PROPERTIES OF THE HAMILTONIAN

Let us investigate the basic properties of the Hamiltonian defined in (3.10).

Proposition 1: The operator $\hat{H}=-(\gamma/2)(\hat{x}\hat{p}+\hat{p}\hat{x})$ *is self-adjoint in* $L^2(\mathbb{R})$.

Proof: To prove that $\hat{H}$ is self-adjoint we show that $e^{-i\hat{H}}$ is unitary in $L^2(\mathbb{R})$. One has

$$\hat{H}=-\frac{\gamma}{2}(\hat{x}\hat{p}+\hat{p}\hat{x})=i\gamma\left(x\frac{\mathrm{d}}{\mathrm{d}x}+\frac{1}{2}\right). \tag{4.1}$$

Let us define

$$U=e^{-i\hat{H}}=e^{\gamma/2}e^{\gamma x\partial_x}. \tag{4.2}$$

Clearly,

$$U\psi(x)=e^{\gamma/2}\psi(e^{\gamma}x), \tag{4.3}$$

for any $\psi\in L^2(\mathbb{R})$. The operator U defines an isometry:

$$\langle U\psi|U\phi\rangle=\int_{-\infty}^{\infty}\overline{U\psi(x)}U\phi(x)\,\mathrm{d}x=\int_{-\infty}^{\infty}e^{\gamma}\overline{\psi(e^{\gamma}x)}\phi(e^{\gamma}x)\,\mathrm{d}x=\int_{-\infty}^{\infty}\overline{\psi(y)}\phi(y)\,\mathrm{d}y=\langle\psi|\phi\rangle. \tag{4.4}$$

Moreover, due to (4.3), U is onto, and hence it is unitary in $L^2(\mathbb{R})$. Therefore, Stone's theorem implies that $\hat{H}$ is self-adjoint (see, e.g., Ref. 12). □

Obviously, $\hat{H}$ is parity invariant:

$$\mathbf{P}\hat{H}\mathbf{P}^{-1}=\hat{H}, \tag{4.5}$$

where the parity operator P is defined by

$$\mathbf{P}\hat{x}\mathbf{P}^{-1}=-\hat{x},\quad \mathbf{P}\hat{p}\mathbf{P}^{-1}=-\hat{p}. \tag{4.6}$$

Now, let us turn to the time reversal operator $\mathbf{T}$. The theory invariant under the time reversal has the following property: if $\psi(t)$ is a solution of the Schrödinger equation given by

$$\psi(t)=U(t)\psi, \tag{4.7}$$

with $U(t)=e^{-i\hat{H}t}$, then $\mathbf{T}\psi$ evolves into

$$(\mathbf{T}\psi)(-t)=U(t)(\mathbf{T}\psi), \tag{4.8}$$

or, equivalently

$$\mathbf{T}(U(t)\psi)=U(-t)(\mathbf{T}\psi), \tag{4.9}$$

for any $\psi\in\mathcal{H}$. Now, following Wigner,[22] $\mathbf{T}$ is either unitary or anti-unitary. If $\mathbf{T}$ is unitary, then (4.9) implies

$$\mathbf{T}\hat{H}+\hat{H}\mathbf{T}=0\,. \tag{4.10}$$

It means that if

$$\hat{H}\psi^E = E\psi^E, \tag{4.11}$$

then

$$\hat{H}\,\mathbf{T}\psi^E = -E\,\mathbf{T}\psi^E, \tag{4.12}$$

that is, any eigenvector ψ^E with the energy E is accompanied by $\mathbf{T}\psi^E$ with energy $-E$. Usually, this case is excluded since one expects that the Hamiltonian is bounded from below. If this is the case, then $\mathbf{T}$ is anti-unitary and (4.9) implies:

$$\mathbf{T}\hat{H} - \hat{H}\mathbf{T} = 0. \tag{4.13}$$

However, the Hamiltonian defined in (3.10) is not bounded from below, and, as we show in Sec. VI its spectrum $\sigma(\hat{H}) = (-\infty, \infty)$. Therefore, we take $\mathbf{T}$ to be unitary in $L^2(\mathbb{R})$.

Proposition 2: The time reversal operator $\mathbf{T}$ *is realized by the Fourier transformation:*

$$\mathbf{T}\psi := F[\psi], \tag{4.14}$$

i.e.,

$$F^{-1}\hat{H}F\psi = -\hat{H}\psi, \tag{4.15}$$

for all $\psi \in L^2(\mathbb{R})$. *Moreover,*

$$\mathbf{T}^2\psi(x) = \mathbf{P}\phi(x) = \psi(-x). \tag{4.16}$$

Denoting by $\mathbf{C}$ the complex conjugation $\mathbf{C}\psi = \overline{\psi}$, one immediately finds

Proposition 3: The Hamiltonian (3.10) is $\mathbf{CT}$ *and* $\mathbf{PCT}$ *invariant, i.e.,*

$$[\hat{H}, \mathbf{CT}] = [\hat{H}, \mathbf{PCT}] = 0\,. \tag{4.17}$$

Therefore, if

$$\hat{H}\psi^E = E\psi^E, \tag{4.18}$$

then

$$\hat{H}F[\overline{\psi^E}] = EF[\overline{\psi^E}]. \tag{4.19}$$

Clearly, $\mathbf{CT}$ invariance does not produce any conserved quantity since $\mathbf{CT}$ is anti-unitary.

V. COMPLEX EIGENVALUES

Interestingly, $\hat{H}$ being self-adjoint admits generalized eigenvectors with complex eigenvalues.[19,23,20,21] Let $f_0^{\pm}$ be distributions satisfying

$$\hat{x}\,f_0^- = 0, \quad \hat{p}\,f_0^+ = 0. \tag{5.1}$$

Clearly,

$$f_0^-(x) = \delta(x), \quad f_0^+(x) = 1. \tag{5.2}$$

Its easy to see that

$$\hat{H}\,f_0^{\pm} = \pm i\frac{\gamma}{2}f_0^{\pm}. \tag{5.3}$$

Let us define two families:

$$f_n^- := \frac{(-i)^n}{\sqrt{n!}}\hat{p}^n f_0^-, \quad f_n^+ := \frac{1}{\sqrt{n!}}\hat{x}^n f_0^+. \tag{5.4}$$

One finds

$$f_n^-(x) = \frac{(-1)^n}{\sqrt{n!}}\delta^{(n)}(x), \quad f_n^+(x) = \frac{x^n}{\sqrt{n!}}. \tag{5.5}$$

Moreover,

$$\hat{H} f_n^\pm = \pm E_n f_n^\pm, \tag{5.6}$$

where

$$E_n := i\gamma(n+\tfrac{1}{2}). \tag{5.7}$$

Clearly, both f_n^- and f_n^- are tempered distributions, i.e., $f_n^\pm \in \mathcal{S}'$. Evidently, they are related by the Fourier transformation:

$$F[f_n^+] = \sqrt{2\pi} i^n f_n^-, \quad F[f_n^-] = \frac{i^n}{\sqrt{2\pi}} f_n^+. \tag{5.8}$$

Let us observe that these two families of generalized eigenvectors have two remarkable properties:

$$\int_{-\infty}^{\infty} f_n^+(x)\, f_m^-(x)\, \mathrm{d}x = \delta_{nm}, \tag{5.9}$$

and

$$\sum_{n=0}^{\infty} f_n^+(x)\, f_n^-(x') = \delta(x-x'). \tag{5.10}$$

These formulas remind one of the basic properties of proper (Hilbert space) eigenvectors: if $\hat{A}$ is a self-adjoint operator in $\mathcal{H}$ and

$$\hat{A}\psi_k = \lambda_k \psi_k, \tag{5.11}$$

where ψ_k are normalized vectors in $\mathcal{H}$, then

$$\int \overline{\psi_n}(x)\psi_m(x)\, \mathrm{d}x = \delta_{nm}, \tag{5.12}$$

and

$$\sum_n \overline{\psi_n}(x)\psi_n(x')\, \mathrm{d}x = \delta(x-x'). \tag{5.13}$$

Obviously, there is no complex conjugation in (5.9) and (5.10) since $f_n^\pm$ are real functions.

Now, for any $\phi \in \mathcal{Z}$ one has

$$\phi(x)=\sum_n \frac{\phi^{(n)}(0)}{n!}(-1)^n x^n=\sum_n f_n^+(x)\langle f_n^-|\phi\rangle. \tag{5.14}$$

On the other hand, for any $\phi\in\mathcal{D}$, its Fourier transform $F[\phi]\in\mathcal{Z}$, and

$$\begin{aligned}\phi(x)&=\frac{1}{\sqrt{2\pi}}\int e^{ikx}F[\phi](k)\mathrm{d}k\\&=\frac{1}{\sqrt{2\pi}}\int e^{ikx}\sum_n \frac{F[\phi]^{(n)}(0)}{n!}(-1)^n k^n\,\mathrm{d}k\\&=\sum_n F[f_n^+](x)\langle f_n^-|F[\phi]\rangle\\&=\sum_n F[f_n^+](x)\langle F[f_n^-]|\phi\rangle\\&=\sum_n f_n^-(x)\langle f_n^+|\phi\rangle.\end{aligned} \tag{5.15}$$

Hence, we have two spectral decompositions:

$$|\phi\rangle=\sum_n |f_n^+\rangle\langle f_n^-|\phi\rangle \quad \text{in} \quad \mathcal{Z}, \tag{5.16}$$

and

$$|\psi\rangle=\sum_n |f_n^-\rangle\langle f_n^+|\psi\rangle \quad \text{in} \quad \mathcal{D}. \tag{5.17}$$

In Sec. VII we derive (5.16) and (5.17) from the spectrum of $\hat{H}$. So let us look for $\sigma(\hat{H})$.

VI. SPECTRUM

The Hamiltonian (3.10) has a continuous spectrum $\sigma(\hat{H})=(-\infty,\infty)$. Since the Hamiltonian (3.10) is parity invariant each generalized eigenvalue $E\in\mathbb{R}$ is doubly degenerated:

$$\hat{H}\psi_\pm^E=E\psi_\pm^E. \tag{6.1}$$

The above equation may be rewritten as the following differential equation for $\psi_\pm^E$:

$$x\frac{\mathrm{d}}{\mathrm{d}x}\psi_\pm^E(x)=-\left(i\frac{E}{\gamma}+\frac{1}{2}\right)\psi_\pm^E. \tag{6.2}$$

To solve (6.2) let us introduce the following distributions[13] (see also Ref. 24):

$$x_+^\lambda:=\begin{cases}x^\lambda, & x\geqslant 0,\\ 0, & x<0,\end{cases}\qquad x_-^\lambda:=\begin{cases}0, & x\geqslant 0,\\ |x|^\lambda, & x<0,\end{cases} \tag{6.3}$$

with $\lambda\in\mathbb{C}$ (basic properties of $x_\pm^\lambda$ are collected in the Appendix). It is, therefore, clear that the generalized eigenvectors $\psi_\pm^E$ may be written as follows:

$$\psi_{\pm}^{E}(x) := \frac{1}{\sqrt{2\pi\gamma}} x_{\pm}^{-(iE/\gamma+1/2)}. \tag{6.4}$$

It turns out that $\psi_{\pm}^{E}$ are well-defined tempered distributions for all $E \in \mathbb{R}$. Actually, instead of $\psi_{\pm}^{E}$ one may work with eigenvectors of the parity operator **P**:

$$\psi_{\text{even}}^{E} = \tfrac{1}{2}(\psi_{+}^{E} + \psi_{-}^{E}), \tag{6.5}$$

$$\psi_{\text{odd}}^{E} = \tfrac{1}{2}(\psi_{+}^{E} - \psi_{-}^{E}). \tag{6.6}$$

Obviously

$$\mathbf{P}\,\psi_{\text{even}}^{E} = \psi_{\text{even}}^{E}, \quad \mathbf{P}\,\psi_{\text{odd}}^{E} = -\psi_{\text{odd}}^{E}. \tag{6.7}$$

These distributions of definite parity are given by

$$\psi_{\text{even}}^{E} = \frac{1}{\sqrt{2\pi\gamma}} |x|^{-(iE/\gamma+1/2)}, \quad \psi_{\text{odd}}^{E} = \frac{1}{\sqrt{2\pi\gamma}} \operatorname{sign}(x)|x|^{-(iE/\gamma+1/2)} \tag{6.8}$$

(see Refs. 13 and 24 for the properties of $|x|^{\lambda}$ and $\operatorname{sign}(x)|x|^{\lambda}$).

With the normalization used in (6.4) one proves[25] orthonormality:

$$\int \overline{\psi_{\pm}^{E_1}(x)}\,\psi_{\pm}^{E_2}(x)\,dx = \delta(E_1 - E_2), \tag{6.9}$$

and completeness:

$$\int \overline{\psi_{\pm}^{E}(x)}\,\psi_{\pm}^{E}(x')\,dE = \delta(x - x'). \tag{6.10}$$

Therefore, due to the Gelfand–Maurin spectral theorem one has

$$\phi(x) = \sum_{\pm} \int dE\; \psi_{\pm}^{E}(x) \langle\, \psi_{\pm}^{E} | \phi \,\rangle, \tag{6.11}$$

for any $\phi \in \mathcal{S}$, and the corresponding spectral resolution of the Hamiltonian has the following form:

$$\hat{H} = \sum_{\pm} \int dE\; E\, |\psi_{\pm}^{E}\rangle\langle\, \psi_{\pm}^{E}|. \tag{6.12}$$

There is another family of energy eigenvectors directly related to $\psi_{\pm}^{E}$. Due to (4.19) one has

$$\hat{H}\, F[\psi_{\pm}^{-E}] = E F[\psi_{\pm}^{-E}]. \tag{6.13}$$

The Fourier transform of $\psi_{\pm}^{E}$ is given by (cf. Ref. 13 and the Appendix):

$$F[\psi_{\pm}^{-E}](k) = \pm \frac{i}{2\pi\sqrt{\gamma}} \exp\left[\pm \frac{i\pi}{2}\left(i\frac{E}{\gamma} - \frac{1}{2}\right)\right] \Gamma\left(i\frac{E}{\gamma} + \frac{1}{2}\right)(k \pm i0)^{-(iE/\gamma+1/2)}. \tag{6.14}$$

One shows[13] that $F[\psi_{\pm}^{E}]$ are well-defined tempered distributions for any $E \in \mathbb{R}$. Moreover,

$$\int \overline{F[\psi_{\pm}^{E_1}]}(x)\, F[\psi_{\pm}^{E_2}](x)\,dx = \delta(E_1 - E_2), \tag{6.15}$$

and

$$\int \overline{F[\psi_{\pm}^{E}]}(x)\, F[\psi_{\pm}^{E}](x')\, \mathrm{d}E = \delta(x-x'). \tag{6.16}$$

Hence, following the Gelfand–Maurin theorem, we have further spectral decompositions: for any $\psi \in \mathcal{S}$,

$$\psi(x) = \sum_{\pm} \int \mathrm{d}E\, F[\psi_{\pm}^{-E}](x) \langle F[\psi_{\pm}^{-E}] | \psi \rangle, \tag{6.17}$$

and for the Hamiltonian itself:

$$\hat{H} = \sum_{\pm} \int \mathrm{d}E\, E |F[\psi_{\pm}^{-E}]\rangle\langle F[\psi_{\pm}^{-E}]|. \tag{6.18}$$

VII. ANALYTICITY OF ENERGY EIGENVECTORS

Let us continue the energy eigenvectors $\psi_{\pm}^{E}$ and $F[\psi_{\pm}^{-E}]$ into the energy complex plane $E \in \mathbb{C}$. It turns out[13] (see also the Appendix) that $\psi_{\pm}^{E}$ has simple poles at $E = -E_n$, whereas $F[\psi_{\pm}^{-E}]$ has simple poles at $E = +E_n$, with E_n defined in (5.7). Therefore, the poles of energy eigenvectors considered as functions of the complex energy correspond exactly to the complex eigenvalues of $\hat{H}$ which we found in Sec. V. One easily computes the corresponding residues:

$$\mathrm{Res}(\psi_{\pm}^{E}(x); -E_n) = i\sqrt{\frac{\gamma}{2\pi}} \frac{\delta^{(n)}(x)}{n!} \begin{cases} (-1)^n & (+) \\ 1 & (-), \end{cases} \tag{7.1}$$

and

$$\mathrm{Res}(F[\psi_{\pm}^{-E}(x)]; +E_n) = \pm \frac{\sqrt{\gamma}}{2\pi} (\mp i)^{n+1} \frac{(-1)^n}{n!} x^n. \tag{7.2}$$

Hence, residues of $\psi_{\pm}^{E}$ and $F[\psi_{\pm}^{-E}]$ correspond, up to numerical constants, to the eigenvectors $f_n^{\pm}$ (5.5):

$$\mathrm{Res}(\psi_{\pm}^{E}(x); -E_n) \sim f_n^{-}, \tag{7.3}$$

and

$$\mathrm{Res}(F[\psi_{\pm}^{-E}(x)]; +E_n) \sim f_n^{+}. \tag{7.4}$$

Any function $\phi \in \mathcal{S} \subset L^2(\mathbb{R})$ gives rise to the following functions of energy:

$$\mathbb{R} \ni E \to \langle \psi_{\pm}^{E} | \phi \rangle \in \mathbb{C},$$

and

$$\mathbb{R} \ni E \to \langle F[\psi_{\pm}^{-E}] | \phi \rangle \in \mathbb{C}.$$

Let us introduce two important classes of functions:[26] a smooth function $f = f(E)$ is in the Hardy class from above $\mathcal{H}_{+}^{2}$ (from below $\mathcal{H}_{-}^{2}$) if $f(E)$ is a boundary value of an analytic function in the upper, i.e., $\mathrm{Im}\, E \geqslant 0$ (lower, i.e., $\mathrm{Im}\, E \leqslant 0$) half complex E-plane vanishing faster than any power of E at the upper (lower) semi-circle $|E| \to \infty$. Now, define

$$\Phi_{-} := \{\phi \in \mathcal{S} \,|\, \langle \psi_{\pm}^{E} | \phi \rangle \in \mathcal{H}_{-}^{2}\}, \tag{7.5}$$

and

$$\Phi_+ := \{\phi \in \mathcal{S} \,|\, \langle F[\psi_\pm^{-E}] | \phi \rangle \in \mathcal{H}_+^2\}. \tag{7.6}$$

Proposition 4: $\Phi_+ \cap \Phi_- = \{\varnothing\}$.

Proof: Clearly, if $\phi \in \Phi_-$, then $\langle \psi_\pm^E | \phi \rangle$ is a smooth function of $E \in \mathbb{R}$. Suppose that $\phi \in \Phi_+$, that is

$$\langle F[\psi_\pm^{-E}] | \phi \rangle = \langle \psi_\pm^{-E} | F[\phi] \rangle \in \mathcal{H}_+^2. \tag{7.7}$$

Now, due to the Paley–Wiener theorem[12] the inverse Fourier transform of $F[\phi]$,

$$F^{-1}[F[\phi]](E) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} F[\phi](t)\, e^{-itE}\, \mathrm{d}t, \tag{7.8}$$

vanishes for $E>0$. Therefore, $\phi(E)=0$ for $E>0$, and hence $f(E)$ cannot be a smooth function of E. □

Our main result consists in the following.

Theorem 2: *For any* $\phi^\pm \in \Phi_\pm$ *one has*

$$\phi^-(x) = \sum_n f_n^-(x) \langle f_n^+ | \phi^- \rangle, \tag{7.9}$$

and

$$\phi^+(x) = \sum_n f_n^+(x) \langle f_n^- | \phi^+ \rangle. \tag{7.10}$$

Proof: Due to the spectral formula (6.11) one has, for $\phi^- \in \Phi_- \subset \mathcal{S}$:

$$\phi^-(x) = \sum_\pm \int_{-\infty}^{\infty} \mathrm{d}E\, \psi_\pm^E(x) \langle \psi_\pm^E | \phi^- \rangle\ . \tag{7.11}$$

Now, since $\langle \psi_\pm^E | \phi^- \rangle \in \mathcal{H}_-^2$, we may close the integration contour along the lower semi-circle $|E| \to \infty$. Hence, due to the residue theorem one obtains

$$\phi^-(x) = -2\pi i \sum_\pm \sum_n \mathrm{Res}(\psi_\pm^E(x); -E_n) \langle \psi_\pm^E | \phi^- \rangle |_{E=-E_n}. \tag{7.12}$$

Using the definition of $\psi_\pm^E$,

$$\langle \psi_\pm^E | \phi^- \rangle = \frac{1}{\sqrt{2\pi\gamma}} \int \overline{x_\pm^{-(iE/\gamma+1/2)}}\, \phi^-(x) dx = \frac{1}{\sqrt{2\pi\gamma}} \int x_\pm^{-(-iE/\gamma+1/2)}\, \phi^-(x)\, \mathrm{d}x, \tag{7.13}$$

one finds

$$\langle \psi_\pm^E | \phi^- \rangle |_{E=-E_n} = \frac{1}{\sqrt{2\pi\gamma}} \int x_\pm^n \phi^-(x)\, \mathrm{d}x. \tag{7.14}$$

Therefore, inserting into (7.12) the value of the residue given in (7.1) one gets finally

$$\phi^-(x)=\sum_n \frac{\delta^{(n)}(x)}{n!}\int [(-1)^n x_+^n + x_-^n]\phi^-(x)\,\mathrm{d}x$$

$$=\sum_n (-1)^n \frac{\delta^{(n)}(x)}{n!}\int x^n \phi^-(x)\,\mathrm{d}x$$

$$=\sum_n f_n^-(x)\langle f_n^+|\phi^+\rangle. \tag{7.15}$$

To prove (7.10) let us use another spectral formula (6.17): for any $\phi^+\in\Phi_+\subset\mathcal{S}$,

$$\phi^+(x)=\sum_{\pm}\int_{-\infty}^{\infty}\mathrm{d}E\, F[\psi_\pm^{-E}](x)\langle F[\psi_\pm^{-E}]|\phi^-\rangle. \tag{7.16}$$

Now, since $\langle F[\psi_\pm^{-E}]|\phi^-\rangle\in\mathcal{H}_+^2$, we may close the integration contour along the upper semicircle $|E|\to\infty$. Hence the residue theorem implies

$$\phi^+(x)=+2\pi i\sum_{\pm}\sum_n \mathrm{Res}(F[\psi_\pm^{-E}(x)];+E_n)\,\langle F[\psi_\pm^{-E}]|\phi^+\rangle|_{E=+E_n}. \tag{7.17}$$

Now, using once more the formula for $\psi_\pm^E$ one finds

$$\langle F[\psi_\pm^{-E}]|\phi^+\rangle|_{E=+E_n}=\frac{1}{\sqrt{2\pi\gamma}}\langle F[x_\pm^n]|\phi^+\rangle. \tag{7.18}$$

Hence, inserting the values of residues (7.2) into (7.17) and using the formula for $F[x_\pm^n]$ [see (A9)] one has

$$\phi^+(x)=\frac{i}{\sqrt{2\pi}}\sum_n (-1)^n\frac{x^n}{n!}[(-i)^{n+1}\langle F[x_+^n]|\phi^+\rangle - i^{n+1}\langle F[x_-^n]|\phi^+\rangle]$$

$$=\frac{i}{\sqrt{2\pi}}\sum_n (-1)^n\frac{x^n}{n!}\int [(-i)^{n+1}\overline{F[x_+^n](k)}-i^{n+1}\overline{F[x_-^n](k)}]\phi^+(k)\,\mathrm{d}k$$

$$=\frac{i}{2}\sum_n (-1)^n\frac{x^n}{n!}[(-i)^{n+1}i^n - i^{n+1}(-i)^n]\int \delta^{(n)}(k)\phi^+(k)\,\mathrm{d}k$$

$$=\sum_n f_n^+(x)\langle f_n^-|\phi^+\rangle, \tag{7.19}$$

which ends the proof. □

This way we have recovered (5.16) and (5.17). It is not surprising, due to the following.

Proposition 5: $\Phi_+=\mathcal{Z}$ *and* $\Phi_-=\mathcal{D}$.

Corollary 1: We have two spectral decomposition of $\hat{H}$*:*

$$\hat{H}=\sum_n \overline{E_n}|f_n^-\rangle\langle f_n^+| \quad \text{on} \quad \Phi_-, \tag{7.20}$$

and

$$\hat{H}=\sum_n E_n|f_n^+\rangle\langle f_n^-| \quad \text{on} \quad \Phi_+. \tag{7.21}$$

VIII. RESONANCES AND THE QUANTUM DAMPING

Finally, let us turn to the evolution generated by the Hamiltonian (3.10). Obviously, it generates a one-parameter unitary group

$$U(t)=e^{-i\hat{H}t}, \tag{8.1}$$

on $L^2(\mathbb{R})$. It follows from (4.3) that

$$\psi_t(x)=U(t)\psi(x)=e^{\gamma t/2}\psi(e^{\gamma t}x). \tag{8.2}$$

The above formula is well defined for any $t\in\mathbb{R}$ and clearly, as we already showed, the theory is time-reversal invariant: if $\psi(t)$ solves the Schrödinger equation so does $\mathbf{T}\psi(t):=\psi(-t)$. Therefore, working in $L^2(\mathbb{R})$ we do not see any damping at all. Now, let us construct two natural Gelfand triplets:

$$\Phi_{\pm}\subset L^2(\mathbb{R})\subset\Phi_{\pm}'. \tag{8.3}$$

If $\phi^-\in\Phi_-$, then

$$\langle\,\psi_{\pm}^E|U(t)\phi^-\,\rangle=\langle\,U^*(t)\,\psi_{\pm}^E|\phi^-\,\rangle=e^{-iEt}\langle\,\psi_{\pm}^E|\phi^-\,\rangle. \tag{8.4}$$

Hence $\phi^-(t)\in\Phi_-$ only for $t\geqslant 0$. Similarly, if $\phi^+\in\Phi_+$, then $\phi^+(t)\in\Phi_+$ only for $t\leqslant 0$. Therefore, the restriction of the unitary group $U(t)$ on $L^2(\mathbb{R})$ to $\Phi_{\pm}$ no longer defines a group. It gives rise to two semigroups:

$$U_-(t):\Phi_-\to\Phi_- \quad \text{for } t\geqslant 0,$$

and

$$U_+(t):\Phi_+\to\Phi_+ \quad \text{for } t\leqslant 0.$$

Due to (7.20) and (7.21) one has

$$\phi^+(t)=U(t)\phi^+=\sum_n e^{\gamma(n+1/2)t}|f_n^+\,\rangle\langle\,f_n^-|\phi^+\,\rangle, \tag{8.5}$$

for $t\leqslant 0$, and

$$\phi^-(t)=U(t)\phi^-=\sum_n e^{-\gamma(n+1/2)t}|f_n^-\,\rangle\langle\,f_n^+|\phi^-\,\rangle, \tag{8.6}$$

for $t\geqslant 0$. We stress that ϕ_t^- (ϕ_t^+) does belong to $L^2(\mathbb{R})$ also for $t<0$ ($t>0$). However, $\phi_t^-\in\Phi_-$ ($\phi_t^+\in\Phi_+$) only for $t\geqslant 0$ ($t\leqslant 0$). This way the irreversibility enters on a purely Hamiltonian level by restricting dynamics to the dense subspace $\Phi_{\pm}$ of $L^2(\mathbb{R})$.

Formulas (8.5) and (8.6) are quantum analogues of the classical damping laws:

$$x(t)=e^{-\gamma t}x\ , \quad p(t)=e^{+\gamma t}p. \tag{8.7}$$

Finally, let us recall that the time reversal operator $\mathbf{T}$ establishes an isomorphism between Φ_- and Φ_+. Therefore, each solution

$$\phi_t^- = U_-(t)\phi^-, \tag{8.8}$$

with $\phi^- \in \Phi_-$ is mapped into

$$\mathbf{T}(\phi_t^-) = U_-(-t)\mathbf{T}(\phi^-) = U_+(t)\mathbf{T}(\phi^-), \quad t \leqslant 0. \tag{8.9}$$

Conversely, any solution

$$\phi_t^+ = U_+(t)\phi^+, \tag{8.10}$$

with $\phi^+ \in \Phi_+$ is mapped into

$$\mathbf{T}(\phi_t^+) = U_+(-t)\mathbf{T}(\phi^+) = U_-(t)\mathbf{T}(\phi^+), \quad t \geqslant 0. \tag{8.11}$$

Summarizing, quantum dynamics is irreversible on Φ_- and Φ_+. This irreversibility is caused by quantum damping, or, equivalently, by the presence of resonant states $f_n^{\pm}$ (5.5). It should be stressed that it is not an energy that is dissipated. Clearly, the Hamiltonian (3.10) cannot be interpreted as a system energy—it was used to define a Hamiltonian dynamics of the enlarged system on $L^2(\mathbb{R})$. The quantum damped system is not defined on the entire $L^2(\mathbb{R})$ but rather on a dense subset $\Phi_- \subset L^2(\mathbb{R})$. As we saw it imposes the restriction upon the time evolution such that it is defined only for positive t. Another aspect of dissipation may be seen as follows: let $\phi_0^- \in \Phi_-$ be an initial state then the probability of finding a particle in the interval $[-a,a]$ at time t is given by

$$\mathcal{P}_t([-a,a]) = \int_{-a}^{a} p_t(x)\,\mathrm{d}x, \tag{8.12}$$

where

$$p_t(x) = |\phi_t^-(x)|^2 = e^{+\gamma t}|\phi_0^-(e^{+\gamma t}x)|^2 = e^{+\gamma t}p_0(e^{+\gamma t}x). \tag{8.13}$$

Therefore,

$$\mathcal{P}_t([-a,a]) \to 1, \tag{8.14}$$

in the limit $t \to +\infty$. Hence $p_t(x) \to \delta(x)$.

In a forthcoming paper we are going to show that also more complicated damped systems, e.g., the damped harmonic oscillator, give rise to irreversible dynamics.

APPENDIX

The regular tempered distribution x_+^λ (with $\lambda \in \mathbb{C}$) given by

$$\langle \phi | x_+^\lambda \rangle := \int_0^\infty x^\lambda \phi(x) \mathrm{d}x, \tag{A1}$$

for any $\phi \in \mathcal{S}$, is well defined for $\mathrm{Re}\,\lambda > -1$. However, it may be easily extended to the region $\mathrm{Re}\,\lambda > -2$ due to the following regularization formula:

$$\int_0^\infty x^\lambda \phi(x) \mathrm{d}x = \int_0^1 x^\lambda [\phi(x) - \phi(0)] \mathrm{d}x + \int_1^\infty x^\lambda \phi(x) \mathrm{d}x + \frac{\phi(0)}{\lambda+1}, \tag{A2}$$

which holds for $\lambda \neq -1$. In the same way one may extend the distribution x_+^λ to the region $\mathrm{Re}\,\lambda > -n-1$ using the formula

$$\int_0^\infty x^\lambda \phi(x) \mathrm{d}x = \int_0^1 x^\lambda \left[\phi(x) - \phi(0) - x\phi'(0) - \cdots - \frac{x^{n-1}}{(n-1)!} \phi^{(n-1)}(0) \right] \mathrm{d}x + \int_1^\infty x^\lambda \phi(x) \mathrm{d}x + \sum_{k=1}^n \frac{\phi^{(k-1)}(0)}{(k-1)!(\lambda+k)}, \tag{A3}$$

which holds for $\lambda \neq -1, -2, \ldots, -n$. The above formula shows that $\langle \phi | x_+^\lambda \rangle$ as a function of $\lambda \in \mathbb{C}$ has simple poles at $\lambda = -1, -2, \ldots$, and the corresponding residue at $\lambda = -k$ equals $\phi^{(k-1)}(0)/(k-1)!$.

Using the same arguments one shows that the distribution x_-^λ may be extended to the region $\mathrm{Re}\,\lambda > -n-1$ via

$$\int_{-\infty}^0 x^\lambda \phi(x) \mathrm{d}x = \int_0^\infty x^\lambda \phi(-x) \mathrm{d}x = \int_1^\infty x^\lambda \left[\phi(-x) - \phi(0) + x\phi'(0) - \cdots - \frac{(-1)^{n-1} x^{n-1}}{(n-1)!} \phi^{(n-1)}(0) \right] \mathrm{d}x + \int_1^\infty x^\lambda \phi(x) \mathrm{d}x + \sum_{k=1}^n \frac{(-1)^{k-1} \phi^{(k-1)}(0)}{(k-1)!(\lambda+k)}, \tag{A4}$$

which holds for $\lambda \neq -1, -2, \ldots, -n$. Hence, $\langle \phi | x_-^\lambda \rangle$ has simple poles at $\lambda = -1, -2, \ldots$, and the corresponding residue at $\lambda = -k$ equals $(-1)^{k-1} \phi^{(k-1)}(0)/(k-1)!$.

The Fourier transforms of $x_\pm^\lambda$,

$$F[x_\pm^\lambda](k) = \frac{1}{\sqrt{2\pi}} \int e^{ikx} x_\pm^\lambda \, \mathrm{d}x, \tag{A5}$$

are given by the following formula:[13]

$$F[x_\pm^\lambda](k) = \pm \frac{i}{\sqrt{2\pi}} e^{\pm i\lambda\pi/2} \Gamma(\lambda+1)(k+i0)^{-\lambda-1}, \tag{A6}$$

where $(k \pm i0)^\alpha$ is a distribution defined by

$$(k \pm i0)^\alpha = k_+^\alpha + e^{\pm i\alpha\pi} k_-^\alpha. \tag{A7}$$

Due to the Euler Γ-function the formula (A6) has single poles at $\lambda=-1,-2,\ldots$. Note, that although both k_+^α and k_-^α have poles at $\alpha=-1,-2,\ldots$, the distribution $(k\pm i0)^\alpha$ is well defined for all $\alpha\in\mathbb{C}$. Indeed

$$\lim_{\alpha\to -n}(k\pm i0)^\alpha=\lim_{\alpha\to -n}(k_+^\alpha+(-1)^n k_-^\alpha), \tag{A8}$$

and, due to (A3) and (A4), the singular parts of k_+^α and k_-^α, at $\alpha=-n$, cancel out. In particular, for $\lambda=n\in\mathbb{N}$, one obtains (cf. Ref. 13)

$$F[x_\pm^n](k)=\frac{1}{\sqrt{2\pi}}[(\pm i)^{n+1}n!k^{-n-1}+(\mp i)^n\pi\delta^{(n)}(k)]. \tag{A9}$$

Extended edge states in finite Hall systems

Christian Ferrari[a] and Nicolas Macris[b]
Institute for Theoretical Physics, Ecole Polytechnique Fédérale, CH-1015 Lausanne, Switzerland

(Received 18 July 2002; accepted 6 May 2003)

We study edge states of a random Schrödinger operator for an electron submitted to a magnetic field in a finite macroscopic two dimensional system of linear dimensions equal to L. The y direction is L-periodic and in the x direction the electron is confined by two smoothly increasing parallel boundary potentials. We prove that, with large probability, for an energy range in the first spectral gap of the bulk Hamiltonian, the spectrum of the full Hamiltonian consists only on two sets of eigenenergies whose eigenfuntions have average velocities which are strictly positive/negative, uniformly with respect to the size of the system. Our result gives a well defined meaning to the notion of edge states for a finite cylinder with two boundaries, and extends previous studies on systems with only one boundary. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1598642]

I. INTRODUCTION

In this paper we investigate spectral properties of random Hamiltonians describing the dynamics of a spinless quantum particle on a cylinder of circumference L and confined along the cylinder axis by two boundaries separated by the distance L. The particle is subject to an external homogeneous magnetic field and a weak random potential. A precise statement of the model is given in Sec. II. The physical interest of the model comes from the integral quantum Hall effect occurring in disordered two dimensional electronic systems subject to a uniform magnetic field, for example, in the interface of a heterojunction [v. Klitzing (1980), Prange (1987)]. In his treatment of this effect, Halperin (1982) pointed out the fundamental role played by edge states carrying boundary diamagnetic currents, and it is therefore important to understand the spectral properties of finite but macroscopic quantum Hall samples with boundaries. A short review of the spectral properties of finite quantum Hall systems can be found in Ferrari (2001).

Random Landau Hamiltonians on an infinite plane have been analyzed in the last decade [Dorlas (1995), Dorlas (1996), Combes (1996), Barbaroux (1997), Wang (1997), Dorlas (1997), Dorlas (1999), and Germinet (2002)].

The study of random magnetic Hamiltonians with boundaries is more recent and, before we address the case of a (finite) cylinder, we wish to briefly discuss a few existing results. The case of a semi-infinite plane with one planar boundary, modeled by a smooth confining potential U or a Dirichlet condition at $x=0$, is satisfactorily understood. In this case it is proven that the spectrum of the Hamiltonian $H_\omega^e = H_0 + U + V_\omega$, H_0 being the Landau Hamiltonian for a uniform magnetic field B and V_ω an Anderson-type random potential, has absolutely continuous components inside the complement of Landau bands, for $\|V_\omega\|_\infty \ll B$ [Fröhlich (2000), de Bièvre (1999), and Macris (1999)]. The proof of this statement is essentially based on Mourre theory with conjugate operator y. The positivity of $i[H_\omega^e, y]$ in suitable spectral subspaces of H_ω^e leads to the absolutely continuous nature of the spectrum. Since this commutator is equal to the velocity v_y this means that states in the corresponding spectral subspaces propagate in the y-direction along the edge with positive velocity.

For the case of an infinite strip with two boundaries, separated by a distance L, few results are

[a]Electronic mail: christian.ferrari@epfl.ch
[b]Institut de Physique, Université de Neuchâtel, Neuchâtel, Switzerland.

known. For a general (random) potential we expect that there is no absolutely continuous component in the spectrum, because the impurities may induce a tunneling (or backscattering) between the two boundaries and thus propagating edge states along each boundary cannot persist for an infinite time. In Combes (2002), the authors have shown that such states survive, for a finite time related to the quantum tunneling time between the two edges. In Exner (2001), the authors consider a parabolic channel in the y-direction. They show that if the perturbation V is periodic, or if V is small enough and decays fast enough in the y-direction, then the absolutely continuous spectrum survives in certain intervals, but their analysis does not cover true Anderson like potentials.

In this work, as in our previous work [Ferrari (2002)], we address the case of a macroscopic finite systems with two confining walls separated by a distance L along the x-direction and with the y-direction of length L made periodic (i.e., the geometry is that of a cylinder). The *left* (resp., *right*) *walls* are modeled by a smooth confining potential U_ℓ (resp., U_r) separated by a distance L, and the *bulk* between them contains impurities modeled by a random Anderson-like potential V_ω. Although the spectrum consists of discrete isolated eigenvalues, we show that there is a well defined notion of edge states associated to each boundary.

Let us explain our main new result expressed in Theorem 1 and compare it with that of Ferrari (2002). We show that, with large probability, the spectrum of the random Hamiltonian,

$$H_\omega = H_0 + V_\omega + U_\ell + U_r,$$

in an energy interval $\Delta \subset (\frac{1}{2}B + \|V_\omega\|_\infty, \frac{3}{2}B - \|V_\omega\|_\infty)$ consists in the union of two sets Σ_ℓ and Σ_r, which are small perturbations of the spectra $\sigma(H_0 + U_\ell + V_\omega^\ell)$ and $\sigma(H_0 + U_r + V_\omega^r)$, of the two edge random Hamiltonians (see Sec. II for their precise definition). The eigenvalues in Σ_ℓ and Σ_r are characterized by their average velocity along the periodic direction $J_E = (\psi_E, v_y \psi_E)$: the eigenfunctions corresponding to the eigenvalues in Σ_ℓ (resp., Σ_r) have a uniformly, negative (resp., positive) velocity, with respect to L. These are the so-called edge states and from the constructions in the proofs it is possible to see that the eigenvalues in Σ_ℓ (resp., Σ_r) correspond to eigenfunctions localized in the x-direction near the left (resp., right) boundary. The number of eigenvalues in Σ_ℓ and Σ_r is of order $O(L)$.

We briefly comment about our paper [Ferrari (2002)] where energies inside the Landau bands are considered. We proved that with large probability, for a similar model (where no disorder is present in a thin strip along the boundaries) the spectrum of H_ω in $\Delta_\varepsilon = [\frac{1}{2}B + \varepsilon, \frac{1}{2}B + V_0]$ is given by $\Sigma_\ell \cup \Sigma_b \cup \Sigma_r$. The eigenfunctions corresponding to the eigenvalues in $\Sigma_\ell \cup \Sigma_r$ have strictly positive/negative velocity, and Σ_b is intermixed in between $\Sigma_\ell \cup \Sigma_r$ and the corresponding eigenfunctions have an infinitesimal velocity of order $O(e^{-B(\log L)^2})$. The number of eigenvalues in Σ_ℓ and Σ_r is $O(L)$ while that in Σ_b is $O(L^2)$.

Although our analysis is presented for a sample of size $L \times L$ the same results can be straightforwardly extended to all geometries where the two boundaries are separated by any distance D at least $O(\ln L)$ (assuming the length of the periodic direction is fixed to L) [Ferrari (2003)]. For distances $D = O(1)$ our analysis does not hold, a fact which is consistent with Combes (2002). In fact, we expect that by using the results in the present paper one could prove that a wave packet localized on the left boundary and with appropriate energy, will propagate along the left boundary up to a finite tunneling time and, then, backscatter and propagate along the right boundary and so forth. The tunneling time is set by V_ω and the distance D between the two boundaries. Thus, if $D = O(1)$ with respect to L, this tunneling time is also $O(1)$, and always remains much smaller than $O(L)$ which is the time needed for a ballistic flight around the whole periodic direction y. In Combes (2002) the randomness of the potential is not needed. We suspect that this may also be the case in the present problem, but in order to study the nonrandom situation one should appeal to other arguments not relying on the Wegner estimate.

The paper is organized as follows. In Sec. II we present the precise definition of the model and state the main theorem. Section III is concerned with the main mathematical tools used in our

analysis: a Wegner estimate and a decoupling scheme of the cylinder into two semi-infinite ones. The proof of the main theorem is then completed in Sec. IV. Some useful estimates and more technical material are collected in the Appendixes.

II. THE MODEL AND MAIN RESULT

We study the spectral properties of the family of random Hamiltonians,

$$H_\omega = H_0 + U_\ell + U_r + V_\omega, \quad \omega \in \Omega_\Lambda, \tag{2.1}$$

acting in the Hilbert space $L^2(\mathbb{R}\times[-L/2, L/2])$ with periodic boundary conditions along y: $\psi(x,-L/2)=\psi(x,L/2)$. The Hamiltonians H_ω, and all the Hamiltonians defined below, are densely defined self-adjoint operators.

We choose the Landau gauge in which the kinetic part has the form $H_0=\frac{1}{2}p_x^2+\frac{1}{2}(p_y-Bx)^2$ with a spectrum given by the Landau levels: $\sigma(H_0)=\{(n+\frac{1}{2})B; n\in\mathbb{N}\}$. The potentials U_ℓ and U_r representing the confinement along the x-direction at $x=\pm L/2$ are independent of y and are supposed strictly monotonic, twice differentiable and satisfy

$$c_1\left|x+\frac{L}{2}\right|^{m_1} \leqslant U_\ell(x) \leqslant c_2\left|x+\frac{L}{2}\right|^{m_2}, \quad \text{for } x\leqslant -\frac{L}{2}, \tag{2.2}$$

$$c_1\left|x-\frac{L}{2}\right|^{m_1} \leqslant U_r(x) \leqslant c_2\left|x-\frac{L}{2}\right|^{m_2}, \quad \text{for } x\geqslant \frac{L}{2}, \tag{2.3}$$

for some constants $0<c_1<c_2$, $2\leqslant m_1<m_2<\infty$ and $U_\ell(x)=0$ for $x\geqslant -L/2$, $U_r(x)=0$ for $x\leqslant L/2$. The random potential V_ω is given by the sum of local perturbations located at the sites of a finite lattice $\Lambda=\{(n,m)\in\mathbb{Z}^2; n\in[-L/2, L/2], m\in[-L/2, L/2]\}$. Let $V\geqslant 0$, with $V\in C^2$, $\|V\|_\infty\leqslant V_0$, $\mathrm{supp}V\subset\mathbb{B}(\mathbf{0},\frac{1}{4})$ (the open ball centered at (0,0) of radius $\frac{1}{4}$) and $X_{n,m}$ i.i.d. random variables with common bounded density $h\in C^2([-1,1])$ representing the random strength of each local perturbation. Then V_ω has the form

$$V_\omega(x,y)=\sum_{(n,m)\in\Lambda} X_{n,m}(\omega)V(x-n,y-m). \tag{2.4}$$

We denote by $\mathbb{P}_\Lambda$ the product measure defined on the set of all possible realizations $\Omega_\Lambda=[-1,1]^\Lambda$. Clearly for each realization $\omega\in\Omega_\Lambda$ we have $\|V_\omega\|\leqslant V_0$ and we suppose $V_0\ll B$.

For future use we collect some properties of three simpler random Hamiltonians. Let us first consider the pure edge Hamiltonians,

$$H_\alpha^0 = H_0 + U_\alpha, \quad \alpha=\ell, r. \tag{2.5}$$

In the half-plane case studied in Macris (1999) [H_α^0 acting in $L^2(\mathbb{R}^2)$ with U_α a confining wall at $x=0$] we deduce, from translation invariance along y, that the spectrum consists of analytic and monotone decreasing (resp., increasing) branches $\varepsilon_n^\ell(k)$ [resp., $\varepsilon_n^r(k)$] where $k\in\mathbb{R}$ is the quantum number associated to p_y. One has $\lim_{k\to+\infty}\varepsilon_n^\ell(k)=\lim_{k\to-\infty}\varepsilon_n^r(k)=(n+\frac{1}{2})B$ and $\lim_{k\to-\infty}\varepsilon_n^\ell(k)=\lim_{k\to+\infty}\varepsilon_n^r(k)=+\infty$. For the present case (2.5) because of periodic boundary conditions along y the quantum number k takes discrete values $2\pi m/L$, $m\in\mathbb{Z}$. For L finite the spectrum consists of discrete eigenvalues $E_{n,m}^\alpha=\varepsilon_n^\alpha(2\pi m/L)$ on the spectral branches. Moreover from the mean value theorem we deduce

$$|E^{\alpha}_{0,m+1}-E^{\alpha}_{0,m}|\geqslant \frac{C_0}{L}, \quad \alpha=\ell,r, \tag{2.6}$$

for each m such that $E^{\alpha}_{0,m}\in\Delta_{\varepsilon}=(\frac{1}{2}B+V_0+\varepsilon,\frac{3}{2}B-V_0-\varepsilon)$, where $C_0>0$ is independent of m and depends only on the spectral branch ε^{α}_0.

We will suppose that the following hypothesis is fulfilled.

Hypothesis 1: *There exists L_0 and $d_0>0$ such that for all $L>L_0$,*

$$\mathrm{dist}(\sigma(H^0_{\ell})\cap\Delta_{\varepsilon},\sigma(H^0_r)\cap\Delta_{\varepsilon})\geqslant \frac{d_0}{L}. \tag{2.7}$$

In order to fulfill this hypothesis one must take nonsymmetric boundary potentials U_{ℓ} and U_r. We expect that in fact our result still holds for $U_{\ell}(x)=U_r(-x)$ because physically the random potential V_{ω} removes with high probability any degeneracy, but in order to control this case one should improve the Wegner estimate in Sec. III. In Appendix C we give an example for a situation where this hypothesis is satisfied.

We will make use of the random edge Hamiltonians,

$$H_{\alpha}=H_0+U_{\alpha}+V^{\alpha}_{\omega}, \tag{2.8}$$

where $V^{\alpha}_{\omega}=V_{\omega}|_{\Lambda_{\alpha}}$ with $\Lambda_r=\{(n,m)\in\mathbb{Z}^2;n\in[L/2-3D/4-1,L/2],m\in[-L/2,L/2]\}$ and $\Lambda_{\ell}=\{(n,m)\in\mathbb{Z}^2;n\in[-L/2,-L/2+3D/4+1],m\in[-L/2,L/2]\}$, where $D=\sqrt{L}$. This choice of D turns out to be convenient in the next sections, but (2.9) and (2.10) below are still true for $D=O(L)$.

Since the perturbation has compact support and the essential spectrum of H^0_{α} is given by the Landau levels, the spectrum of H_{α} is discrete with the Landau levels as only accumulation points. We denote it by $\sigma(H_{\alpha})=\{E^{\alpha}_{\kappa}\}$. One can prove [Macris (2003)] that, for each $\omega\in\Omega_{\Lambda_{\alpha}}=[-1,1]^{\Lambda_{\alpha}}$ (the restriction of the configurations ω to the sublattice Λ_{α}) and for each κ such that $E^{\alpha}_{\kappa}\in\Delta=(B-\delta,B+\delta)\subset\Delta_{\varepsilon}$, for L large enough and V_0/B small but independent of L, the distance between two consecutive eigenvalues satisfies

$$|E^{\alpha}_{\kappa+1}-E^{\alpha}_{\kappa}|\geqslant \frac{C}{L}, \quad \alpha=\ell,r, \tag{2.9}$$

where $C>0$ is uniform in κ, ω. Moreover for each $E^{\ell}_{\kappa}\in\Delta$ (resp., $E^{r}_{\kappa}\in\Delta$) the average velocity associated to the corresponding eigenfunctions is strictly negative (resp., positive) uniformly in L,

$$|J_{E^{\alpha}_{\kappa}}|\geqslant C'>0, \quad \alpha=\ell,r. \tag{2.10}$$

The constant C' is estimated in Appendix B (B17) in terms of the parameters of the model.

Finally we remark that the Hamiltonian $H_0+V_{\omega}|_{\tilde{\Lambda}}$ ($\tilde{\Lambda}\subset\Lambda$) has a point spectrum contained in Landau bands (since $V_{\omega}|_{\tilde{\Lambda}}$ has bounded support and $\|V_{\omega}|_{\tilde{\Lambda}}\|=V_0$),

$$\sigma(H_0+V_{\omega}|_{\tilde{\Lambda}})\subset\bigcup_{n\geqslant 0}[(n+\tfrac{1}{2})B-V_0,(n+\tfrac{1}{2})B+V_0]. \tag{2.11}$$

When $\tilde{\Lambda}$ is given by

$$\Lambda_b\equiv\tilde{\Lambda}=\left\{(n,m)\in\mathbb{Z}^2;n\in\left[-\frac{L}{2}+\left(\frac{D}{4}-1\right),\frac{L}{2}-\left(\frac{D}{4}-1\right)\right],m\in\left[-\frac{L}{2},\frac{L}{2}\right]\right\},$$

we call the Hamiltonian $H_b\equiv H_0+V_{\omega}|_{\Lambda_b}$ the bulk Hamiltonian.

We now state the main result of this paper.

Theorem 1: *Let V_0 small enough, fix $\varepsilon>0$ and let $0<\delta<B/2-V_0-\varepsilon$. Suppose that $(H1)$ hold. Then there exists $\mu>0$, $\overline{L}$ such that if $L>\overline{L}$ one can find a set $\hat{\Omega}\subset\Omega_\Lambda$ of realizations of the random potential V_ω with $\mathbb{P}_\Lambda(\hat{\Omega})\geqslant 1-L^{-\nu}$ $(\nu\gg 1)$ such that for all $\omega\in\hat{\Omega}$ the spectrum of H_ω in $\Delta=(B-\delta,B+\delta)$ is the union of two sets Σ_ℓ and Σ_r with the following properties:*

(a) *$\mathcal{E}_\kappa^\alpha\in\Sigma_\alpha(\alpha=\ell,r)$ are a small perturbation of $E_\kappa^\alpha\in\sigma(H_\alpha)\cap\Delta$ with*

$$|\mathcal{E}_\kappa^\alpha-E_\kappa^\alpha|\leqslant e^{-\mu\sqrt{B}\sqrt{L}}. \tag{2.12}$$

(b) *For $\mathcal{E}_\kappa^\alpha\in\Sigma_\alpha$ the average velocity $J_{\mathcal{E}_\kappa^\alpha}$ of the associated eigenstate satisfies*

$$|J_{\mathcal{E}_\kappa^\alpha}-J_{E_\kappa^\alpha}|\leqslant e^{-\mu\sqrt{B}\sqrt{L}}. \tag{2.13}$$

That is, the eigenfunctions associated to the eigenvalues (of H_ω) *in Δ have an $\mathcal{O}(1)$ velocity.*

The main tools for the proof of Theorem 1 are developed in Sec. III. Basically they consist of a Wegner estimate for the random Hamiltonians H_α $(\alpha=\ell,r)$ and a decoupling scheme that links the resolvent of the full Hamiltonian H_ω with those of H_ℓ, H_r and H_b. In Sec. IV we prove two propositions that lead to parts (a) and (b) of Theorem 1. Finally in Appendix A we prove some technical results; in Appendix B we prove (2.10) and in Appendix C we discuss the Hypothesis 1.

Let $\mathbf{x},\mathbf{x}'\in\mathbb{R}\times[-L/2,L/2]$, then one can check that

$$|\mathbf{x}-\mathbf{x}'|_\star\equiv\inf_{n\in\mathbb{Z}}\sqrt{(x-x')^2+(y-y'-nL)^2} \tag{2.14}$$

has the properties of a distance on $\mathbb{R}\times\mathbb{S}_L$ ($\mathbb{S}_L$ being the circle of circumference L) and that it is related to the Euclidian distance $|\mathbf{x}-\mathbf{x}'|\equiv\sqrt{(x-x')^2+(y-y')^2}$ by

$$|\mathbf{x}-\mathbf{x}'|_\star\leqslant|\mathbf{x}-\mathbf{x}'|. \tag{2.15}$$

The interest of $|\cdot|_\star$ is that, since we are working with a cylindrical geometry, all decay estimates are naturally expressed in terms of this distance. In particular, it permits us to express in a convenient way decay in the y-direction that occurs on a scale much smaller than L.

III. WEGNER ESTIMATES AND DECOUPLING SCHEME

We first give a Wegner estimate for the Hamiltonians H_α $(\alpha=\ell,r)$. Denote by $P_{0,m}^\alpha$ the projector of H_α^0 onto the eigenvalue $E_{0,m}^\alpha$ and by $P_\alpha(I)$ the projector of H_α on an interval I. Let $I_m=(E_{0,m-1}^\alpha+\delta_0,E_{0,m}^\alpha-\delta_0)$ and $\Delta_\alpha=\cup_{m_0\leqslant m\leqslant m_1}I_m$, for some $-\infty\ll m_0<m_1\ll\infty$ and $\delta_0\ll C_0/L$, where C_0 is the constant defined in (2.6). The local potentials $V(x-n,y-m)$ will also be denoted by $V_\mathbf{i}$, $\mathbf{i}=(m,n)\in\Lambda$.

Proposition 1: Let $V_0=\|V_\omega\|$ sufficiently small with respect to B, $E\in\Delta_\alpha\cap\Delta_\varepsilon$ and $I=[E-\overline{\delta},E+\overline{\delta}]\subset I_m$. Then

$$\mathbb{P}_{\Lambda_\alpha}\{\mathrm{dist}(\sigma(H_\alpha),E)<\overline{\delta}\}\leqslant\|h\|_\infty\overline{\delta}\,\mathrm{dist}(I,E_{0,\overline{m}}^\alpha)^{-2}V_0^2L^4, \tag{3.1}$$

where $E_{0\overline{m}}^\alpha$ is the closest eigenvalue of $\sigma(H_\alpha^0)$ to the interval I.

Proof: We first observe that $V_\mathbf{i}^{1/2}P_{0,m}^\alpha V_\mathbf{j}^{1/2}$ is trace class. Indeed, using $\|AB\|_i\leqslant\|A\|\|B\|_i$ $(i=1,2)$ and $\|AB\|_1\leqslant\|A\|_2\|B\|_2$ we get $\|V_\mathbf{i}^{1/2}P_{0,m}^\alpha V_\mathbf{j}^{1/2}\|_1\leqslant\|V_\mathbf{i}^{1/2}P_{0,m}^\alpha\|_2\|P_{0,m}^\alpha V_\mathbf{j}^{1/2}\|_2\leqslant V_0\|P_{0,m}^\alpha\|_1^2\leqslant V_0$.

We have $E \in \Delta_\alpha \cap \Delta_\varepsilon$, and $I=[E-\overline{\delta},E+\overline{\delta}]$ for $\overline{\delta}$ small enough (we require that $I \subset \Delta_\alpha \cap \Delta_\varepsilon$). By the Chebyshev inequality we have

$$\mathbb{P}_{\Lambda_\alpha}\{\mathrm{dist}(\sigma(H_\alpha),E)<\overline{\delta}\}=\mathbb{P}_{\Lambda_\alpha}\{\mathrm{Tr}P_\alpha(I)\geqslant 1\}\leqslant \mathbb{E}_{\Lambda_\alpha}\{\mathrm{Tr}P_\alpha(I)\}, \tag{3.2}$$

where $\mathbb{E}_{\Lambda_\alpha}$ is the expectation with respect to the random variables in Λ_α.

We first give an estimate on $\mathrm{Tr}P_\alpha(I)$. Let $E^\alpha_{0,\overline{m}}$ the closest eigenvalue of $\sigma(H^0_\alpha)$ to I and m_i $(i=0,1)$ s.t. $\mathrm{dist}(E^\alpha_{0,\overline{m}},E^\alpha_{0,m_i})=\mathcal{O}(B)$. Let also $P^\alpha_>=\Sigma_{m>m_1}P^\alpha_{0,m}$ and $P^\alpha_<=\Sigma_{m<m_0}P^\alpha_{0,m}$.

Using $P^\alpha_>(H^0_\alpha-E)P^\alpha_>\geqslant 0$ and $P^\alpha_>R^0_\alpha(E)P^\alpha_>\leqslant \mathrm{dist}(E^\alpha_{0,m_1+1},E)^{-1}P^\alpha_>$ we can write

$$\begin{aligned} P_\alpha(I)P^\alpha_>P_\alpha(I)&=P_\alpha(I)P^\alpha_>(H^0_\alpha-E)^{1/2}R^0_\alpha(E)(H^0_\alpha-E)^{1/2}P^\alpha_>P_\alpha(I)\\ &\leqslant \mathrm{dist}(E^\alpha_{0,m_1+1},E)^{-1}[P_\alpha(I)(H_\alpha-E)P^\alpha_>P_\alpha(I)-P_\alpha(I)V^\alpha_\omega P^\alpha_>P_\alpha(I)], \end{aligned} \tag{3.3}$$

and thus

$$\|P_\alpha(I)P^\alpha_>P_\alpha(I)\|\leqslant \mathrm{dist}(E^\alpha_{0,m_1+1},E)^{-1}\left(\frac{|I|}{2}+V_0\right)\leqslant\frac{1}{4}, \tag{3.4}$$

if, as we can suppose, V_0 is sufficiently small $[\mathrm{dist}(E^\alpha_{0,m_1+1},E)^{-1}V_0=\mathcal{O}(V_0/B)]$. In a similar way we get

$$\|P_\alpha(I)P^\alpha_<P_\alpha(I)\|\leqslant \mathrm{dist}(E^\alpha_{0,m_0-1},E)^{-1}\left(\frac{|I|}{2}+V_0\right)\leqslant\frac{1}{4}. \tag{3.5}$$

Now

$$\mathrm{Tr}\ P_\alpha(I)P^\alpha_<=\mathrm{Tr}\ P_\alpha(I)P^\alpha_<P_\alpha(I)\leqslant\|P_\alpha(I)P^\alpha_<P_\alpha(I)\|\mathrm{Tr}\ P_\alpha(I), \tag{3.6}$$

and similarly for $\mathrm{Tr}P_\alpha(I)P^\alpha_>$. Therefore, using $1=P^\alpha_<+P^\alpha_>+\Sigma_{m_0\leqslant m\leqslant m_1}P^\alpha_{0,m}$, together with (3.4) and (3.5), we obtain

$$\mathrm{Tr}\ P_\alpha(I)\leqslant 2\sum_{m_0\leqslant m\leqslant m_1}\mathrm{Tr}P_\alpha(I)P^\alpha_{0,m}P_\alpha(I). \tag{3.7}$$

Since

$$\mathrm{dist}(I,E^\alpha_{0,m})^2P_\alpha(I)^2\leqslant(P_\alpha(I)(H_\alpha-E^\alpha_{0,m})P_\alpha(I))^2, \tag{3.8}$$

and $\mathrm{dist}(I,E^\alpha_{0,m})^{-1}\leqslant\mathrm{dist}(I,E^\alpha_{0,\overline{m}})^{-1}$ for all $m_0\leqslant m\leqslant m_1$, it follows that

$$\begin{aligned} \mathrm{Tr}\ P^\alpha_{0,m}P_\alpha(I)P^\alpha_{0,m}&\leqslant\mathrm{dist}(I,E^\alpha_{0,\overline{m}})^{-2}\mathrm{Tr}(P^\alpha_{0k}P_\alpha(I)(H_\alpha-E^\alpha_{0,m})P_\alpha(I)(H_\alpha-E^\alpha_{0,m})P_\alpha(I)P^\alpha_{0,m})\\ &=\mathrm{dist}(I,E^\alpha_{0,\overline{m}})^{-2}\mathrm{Tr}(P^\alpha_{0,m}V^\alpha_\omega P_\alpha(I)V^\alpha_\omega P^\alpha_{0,m}). \end{aligned} \tag{3.9}$$

Thus, taking the expectation value in (3.7) and using that there are $\mathcal{O}(L)$ m's between m_0 and m_1, we get

$$\mathbb{E}_{\Lambda_\alpha}\{\mathrm{Tr}\ P_\alpha(I)\}\leqslant 2\cdot\mathcal{O}(L)\cdot\mathrm{dist}(I,E^\alpha_{0,\overline{m}})^{-2}\sup_{m_0\leqslant m\leqslant m_1}\mathbb{E}_{\Lambda_\alpha}\{\mathrm{Tr}(P^\alpha_{0,m}V^\alpha_\omega P_\alpha(I)V^\alpha_\omega P^\alpha_{0,m})\}. \tag{3.10}$$

It remains to estimate the expectation value on the right hand side of (3.10). Here we follow a method of Combes and Hislop (1996). Writing $V^\alpha_\omega=\Sigma_{\mathbf{i}\in\Lambda_\alpha}X_{\mathbf{i}}(\omega)V_{\mathbf{i}}$,

$$\begin{aligned}\mathrm{Tr}\ P^{\alpha}_{0,m}V^{\alpha}_{\omega}P_{\alpha}(I)V^{\alpha}_{\omega}P^{\alpha}_{0,m} &= \sum_{\mathbf{i},\mathbf{j}\in\Lambda^2_{\alpha}} X_{\mathbf{i}}(\omega)X_{\mathbf{j}}(\omega)\mathrm{Tr}\ P^{\alpha}_{0,m}V_{\mathbf{i}}P_{\alpha}(I)V_{\mathbf{j}}P^{\alpha}_{0,m}\\ &= \sum_{\mathbf{i},\mathbf{j}\in\Lambda^2_{\alpha}} X_{\mathbf{i}}(\omega)X_{\mathbf{j}}(\omega)\mathrm{Tr}V^{1/2}_{\mathbf{j}}P^{\alpha}_{0,m}V^{1/2}_{\mathbf{i}}V^{1/2}_{\mathbf{i}}P_{\alpha}(I)V^{1/2}_{\mathbf{j}}. \end{aligned} \tag{3.11}$$

Since $V^{1/2}_{\mathbf{j}}P^{\alpha}_{0,m}V^{1/2}_{\mathbf{i}}$ is trace class, we can introduce the singular value decomposition,

$$V^{1/2}_{\mathbf{j}}P^{\alpha}_{0,m}V^{1/2}_{\mathbf{i}} = \sum_{n=0}^{\infty}\mu_n(u_n,.)v_n, \tag{3.12}$$

where $\Sigma^{\infty}_{n=0}\mu_n = \|V^{1/2}_{\mathbf{j}}P^{\alpha}_{0,m}V^{1/2}_{\mathbf{i}}\|_1$. Then

$$\begin{aligned}\mathrm{Tr}\,V^{1/2}_{\mathbf{j}}P^{\alpha}_{0k}V^{1/2}_{\mathbf{i}}V^{1/2}_{\mathbf{i}}P_{\alpha}(I)V^{1/2}_{\mathbf{j}} &= \sum_{n=0}^{\infty}\mu_n(u_n,V^{1/2}_{\mathbf{i}}P_{\alpha}(I)V^{1/2}_{\mathbf{j}}v_n)\\ &\leqslant \sum_{n=0}^{\infty}\mu_n(v_n,V^{1/2}_{\mathbf{j}}P_{\alpha}(I)V^{1/2}_{\mathbf{j}}v_n)^{1/2}(u_n,V^{1/2}_{\mathbf{i}}P_{\alpha}(I)V^{1/2}_{\mathbf{i}}u_n)^{1/2}\\ &\leqslant \frac{1}{2}\sum_{n=0}^{\infty}\mu_n\{(v_n,V^{1/2}_{\mathbf{j}}P_{\alpha}(I)V^{1/2}_{\mathbf{j}}v_n)+(u_n,V^{1/2}_{\mathbf{i}}P_{\alpha}(I)V^{1/2}_{\mathbf{i}}u_n)\}. \end{aligned} \tag{3.13}$$

An application of the spectral averaging theorem [see Combes and Hislop (1996)] shows that

$$\mathbb{E}_{\Lambda_{\alpha}}\{(v_n,V^{1/2}_{\mathbf{j}}P_{\alpha}(I)V^{1/2}_{\mathbf{j}}v_n)\}\leqslant\|h\|_{\infty}2\overline{\delta}, \tag{3.14}$$

as well as for the term with $\mathbf{j}$ replacing $\mathbf{i}$ and v_n replacing u_n. Combining (3.10), (3.13), (3.14), and (3.11) we get

$$\begin{aligned}\mathbb{E}_{\Lambda_{\alpha}}\{\mathrm{Tr}\ P_{\alpha}(I)\} &\leqslant 4\cdot\mathcal{O}(L)\cdot\|h\|_{\infty}\overline{\delta}\,\mathrm{dist}(I,E^{\alpha}_{0,\overline{m}})^{-2}V_0^2\sum_{\mathbf{i},\mathbf{j}\in\Lambda^2_{\alpha}}\|V^{1/2}_{\mathbf{j}}P^{\alpha}_{0,m}V^{1/2}_{\mathbf{i}}\|_1\\ &\leqslant 4\cdot\mathcal{O}(L)\cdot\|h\|_{\infty}\overline{\delta}\,\mathrm{dist}(I,E^{\alpha}_{0,\overline{m}})^{-2}V_0^2|\Lambda_{\alpha}|^2. \end{aligned} \tag{3.15}$$

□

We now turn to the decoupling scheme. By a decoupling formula [Bentosela (1991), Briet (1989)] the resolvent $R(z)=(z-H_{\omega})^{-1}$ can be expressed, up to a small term, as the sum of $R_{\alpha}(z)=(z-H_{\alpha})^{-1}$ $(\alpha=\ell,r)$ and $R_b(z)=(z-H_b)^{-1}$. We set $D=\sqrt{L}$ and introduce the characteristic functions

$$\tilde{J}_{\ell}(x)=\chi_{]-\infty,-L/2+D/2]}(x),\quad \tilde{J}_b(x)=\chi_{[-L/2+D/2,L/2-D/2]}(x),$$

$$\tilde{J}_r(x)=\chi_{[L/2-D/2,+\infty[}(x). \tag{3.16}$$

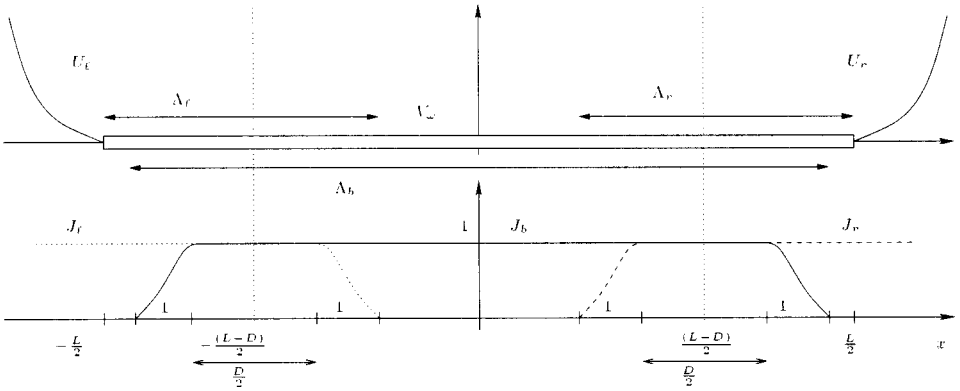

FIG. 1. The system of decoupling functions J_i ($i \in \mathcal{I}$).

We will also use three bounded $C^\infty(\mathbb{R})$ functions $|J_i(x)| \leqslant 1$, $i \in \mathcal{I} \equiv \{\ell, b, r\}$ (see Fig. 1), with bounded first and second derivatives $\sup_x |\partial_x^n J_i(x)| \leqslant 2$, $n = 1,2$, and such that

$$J_\ell(x) = \begin{cases} 1 & \text{if } x \leqslant -\dfrac{L}{2} + \dfrac{3D}{4}, \\ 0 & \text{if } x \geqslant -\dfrac{L}{2} + \dfrac{3D}{4} + 1, \end{cases} \qquad J_b(x) = \begin{cases} 1 & \text{if } |x| \leqslant \dfrac{L}{2} - \dfrac{D}{4}, \\ 0 & \text{if } |x| \geqslant \dfrac{L}{2} - \dfrac{D}{4} + 1, \end{cases}$$

$$J_r(x) = \begin{cases} 1 & \text{if } x \geqslant \dfrac{L}{2} - \dfrac{3D}{4}, \\ 0 & \text{if } x \leqslant \dfrac{L}{2} - \dfrac{3D}{4} - 1. \end{cases} \tag{3.17}$$

For $i \in \mathcal{I}$ we have $H_\omega J_i = H_i J_i$ and the decoupling formula is [Bentosela (1991)]

$$R(z) = \left(\sum_{i \in \mathcal{I}} J_i R_i(z) \tilde{J}_i \right) (1 - \mathcal{K}(z))^{-1}, \tag{3.18}$$

where

$$\mathcal{K}(z) = \sum_{i \in \mathcal{I}} K_i(z) = \sum_{i \in \mathcal{I}} \frac{1}{2} [p_x^2, J_i] R_i(z) \tilde{J}_i. \tag{3.19}$$

The main result of this part is a lemma about $\|\mathcal{K}(z)\|$ for z such that $\operatorname{dist}(z, \sigma(H_\alpha)) \geqslant e^{-\bar{\mu}\sqrt{B}\sqrt{L}}$, for a suitable $\bar{\mu} > 0$ and $\operatorname{dist}(z, \sigma(H_b)) \geqslant \varepsilon$.

Proposition 2: Let $\varepsilon > 0$, *and* $z \in \Delta_\varepsilon$ *such that* $\operatorname{dist}(z, \sigma(H_\ell) \cup \sigma(H_r)) \geqslant e^{-\bar{\mu}\sqrt{B}\sqrt{L}}$ *with* $\bar{\mu} < 1/192$. *Then for* L *large enough there exists* $C(B, V_0, \varepsilon) > 0$ *and* $\tilde{\gamma} > 0$ *independent of* L *such that*

$$\|\mathcal{K}(z)\| \leqslant C(B, V_0, \varepsilon) e^{-\tilde{\gamma}\sqrt{B}\sqrt{L}}. \tag{3.20}$$

Proof: Computing the commutator in the definition of $K_i(z)$ we have

$$K_i(z) = -\tfrac{1}{2} (\partial_x^2 J_i) R_i(z) \tilde{J}_i - (\partial_x J_i) \partial_x R_i(z) \tilde{J}_i. \tag{3.21}$$

Then

$$\|K_b(z)\| \leqslant \tfrac{1}{2}\|(\partial_x^2 J_b)R_b(z)\widetilde{J}_b\| + \|(\partial_x J_b)\partial_x R_b(z)\widetilde{J}_b\|, \tag{3.22}$$

$$\|K_\alpha(z)\| \leqslant \tfrac{1}{2}\|(\partial_x^2 J_\alpha)R_\alpha^b(z)\widetilde{J}_\alpha\| + \tfrac{1}{2}\|(\partial_x^2 J_\alpha)R_\alpha^b(z)U_\alpha\|\,\mathrm{dist}(z,\sigma(H_\alpha))^{-1} + \|(\partial_x J_\alpha)\partial_x R_\alpha^b(z)\widetilde{J}_\alpha\| + \|(\partial_x J_\alpha)\partial_x R_\alpha^b(z)U_\alpha\|\,\mathrm{dist}(z,\sigma(H_\alpha))^{-1}, \tag{3.23}$$

where for the second term we used the second resolvent identity and where $R_\alpha^b(z)=(z-[H_0+V_\omega^\alpha])^{-1}$.

We have to estimate norms of the form $\|f\partial_x^\alpha \widetilde{R}(z)g\|$ ($\alpha=0,1$) where here $\widetilde{R}(z)$ is $R_b(z)$ or $R_\alpha^b(z)$, $f=\partial_x^m J_i$ and $g=\widetilde{J}_i$ or $g=U_\alpha$.

Using the second resolvent formula we develop $\widetilde{R}(z)$ in its Neumann series, denote $V_\omega|_{\tilde{\Lambda}} \equiv W$ ($\tilde{\Lambda}=\Lambda_b$ or Λ_α),

$$\widetilde{R}(z)=\sum_{n=0}^{\infty} R_0(z)[WR_0(z)]^n, \tag{3.24}$$

where $R_0(z)=(z-H_0)^{-1}$. The norm convergence is ensured since we are in a spectral gap, indeed

$$\|WR_0(z)\| \leqslant V_0\ \mathrm{dist}(z,\sigma(H_0))^{-1} \leqslant \frac{V_0}{V_0+\varepsilon} < 1. \tag{3.25}$$

Therefore

$$\|f\partial_x^\alpha \widetilde{R}(z)g\| \leqslant \sum_{n=1}^{\infty} \|f\partial_x^\alpha R_0(z)[WR_0(z)]^n g\|, \tag{3.26}$$

and we have to control the operator norms $\|f\partial_x^\alpha R_0(z)[WR_0(z)]^n g\|$.

For any vector $\varphi \in L^2(\mathbb{R}\times[-L/2, L/2])$ with $\|\varphi\|=1$,

$$\|f\partial_x^\alpha R_0(z)[WR_0(z)]^n g\varphi\|^2 = \int_{\mathrm{supp}\, f} |f(\mathbf{x})|^2 |(\partial_x^\alpha R_0(z)[WR_0(z)]^n g\varphi)(\mathbf{x})|^2\, \mathrm{d}\mathbf{x}. \tag{3.27}$$

For the integrand in (3.27) we have

$$\begin{aligned}\mathcal{T} &\equiv |(\partial_x^\alpha R_0(z)[WR_0(z)]^n g\varphi)(\mathbf{x})| \\ &\leqslant \int_{\mathrm{supp}\, g} \mathrm{d}\mathbf{x}' \int \mathrm{d}\mathbf{x}_1 \cdots \mathrm{d}\mathbf{x}_n \\ &\quad \times |\partial_x^\alpha R_0(\mathbf{x},\mathbf{x}_1;z)||W(\mathbf{x}_1)||R_0(\mathbf{x}_1,\mathbf{x}_2;z)|\cdots|W(\mathbf{x}_n)||R_0(\mathbf{x}_n,\mathbf{x}';z)||g(\mathbf{x}')||\varphi(\mathbf{x}')|.\end{aligned} \tag{3.28}$$

Now, taking out $\|W\|_\infty$ and using Lemma 1, Appendix A, we get

$$\begin{aligned}\mathcal{T} &\leqslant \left(cB^2\frac{V_0}{V_0+\varepsilon}\right)^n \int_{\mathrm{supp}\, g} \mathrm{d}\mathbf{x}' \int \mathrm{d}\mathbf{x}_1 \cdots \mathrm{d}\mathbf{x}_n \exp\Big(-\overline{\gamma}\sqrt{B}\sum_{i=0}^{n} |\mathbf{x}_i-\mathbf{x}_{i+1}|_\star\Big) \\ &\quad \times |\Phi^1(|\mathbf{x}-\mathbf{x}_1|_\star)|\cdots|\Phi^0(|\mathbf{x}_n-\mathbf{x}'|_\star)||g(\mathbf{x}')||\varphi(\mathbf{x}')|,\end{aligned} \tag{3.29}$$

where $\mathbf{x}_0=\mathbf{x}$ and $\mathbf{x}_{n+1}=\mathbf{x}'$. Splitting the exponential and making the change of variables $\mathbf{x}-\mathbf{x}_1=-\mathbf{z}_1,\ldots,\ \mathbf{x}_{n-1}-\mathbf{x}_n=-\mathbf{z}_n$, we get [with $\mathbf{x}_n=\mathbf{x}_n(\{\mathbf{z}_i\},\mathbf{x})$ and $A=cB^2[V_0/(V_0+\varepsilon)]$

$$\mathcal{T}\leqslant A^n \sup_{\mathbf{z}_1\cdots\mathbf{z}_n}\left\{\int_{\operatorname{supp} g} e^{-2/3\overline{\gamma}\sqrt{B}|\mathbf{x}-\mathbf{x}'|_\star}|g(\mathbf{x}')||\varphi(\mathbf{x}')||\Phi^0(|\mathbf{x}_n-\mathbf{x}'|_\star)|e^{-(1/3)\overline{\gamma}\sqrt{B}|\mathbf{x}_n-\mathbf{x}'|_\star}\,d\mathbf{x}'\right\}$$
$$\times\left[\int_{\mathbb{R}^2}|\Phi^1(|\mathbf{z}|)|e^{-(1/3)\overline{\gamma}\sqrt{B}|\mathbf{z}|}\,d\mathbf{z}\right]\left[\int_{\mathbb{R}^2}|\Phi^0(|\mathbf{z}|)|e^{-(1/3)\overline{\gamma}\sqrt{B}|\mathbf{z}|}\,d\mathbf{z}\right]^{n-1} \tag{3.30}$$

$$\equiv A^n \sup_{\mathbf{z}_1\cdots\mathbf{z}_n}\{\mathcal{X}\}[\mathcal{Y}][\mathcal{Z}]^{n-1}. \tag{3.31}$$

Splitting the exponential and using the Schwartz inequality we have the estimate

$$\sup_{\mathbf{z}_1\cdots\mathbf{z}_n}\mathcal{X}\leqslant \sup_{\mathbf{x}'\in\operatorname{supp} g} e^{-(1/3)\overline{\gamma}\sqrt{B}|\mathbf{x}-\mathbf{x}'|_\star}\left\{\int_{\mathbb{R}^2}|\Phi^0(|\mathbf{w}|)|^2e^{-(2/3)\overline{\gamma}\sqrt{B}|\mathbf{w}|}\,d\mathbf{w}\right\}^{1/2}$$
$$\times\left(\sup_{\mathbf{x}'\in\operatorname{supp} g} e^{-(2/3)\overline{\gamma}\sqrt{B}|x-x'|}|g(x')|^2\right)^{1/2}\|\varphi\|. \tag{3.32}$$

Now, since U_α do not grow too fast [see (2.2), (2.3)] $(\sup_{\mathbf{x}'\in\operatorname{supp} g}e^{-(2/3)\overline{\gamma}\sqrt{B}|x-x'|}|g(x')|^2)^{1/2}$ is bounded by a numerical constant. On the other hand the term $\int_{\mathbb{R}^2}|\Phi^0(|\mathbf{w}|)|^2e^{-(2/3)\overline{\gamma}\sqrt{B}|\mathbf{w}|}\,d\mathbf{w}$ is bounded by a constant depending only on B.

Moreover, the terms $\mathcal{Y}$ and $\mathcal{Z}$ are also bounded by a constant depending only on B and not on L. This leads to

$$\|f\partial_x^\alpha[R_0(z)]^n g\varphi\|\leqslant\|f\|_\infty\hat{C}(B)(\tilde{C}(B)A)^n e^{-(1/2)\overline{\gamma}\sqrt{B}D}\|\varphi\|. \tag{3.33}$$

Therefore, if V_0 is small enough the series (3.26) converges and

$$\|f\partial_x^\alpha\tilde{R}(z)g\|\leqslant\tilde{C}(B,V_0)\sqrt{L}e^{-(1/12)\overline{\gamma}\sqrt{B}D}. \tag{3.34}$$

This implies

$$\|K_b(z)\|\leqslant\varepsilon^{-1}\sqrt{L}C(B,V_0)e^{-(1/12)\overline{\gamma}\sqrt{B}\sqrt{L}}, \tag{3.35}$$

$$\|K_\alpha(z)\|\leqslant\sqrt{L}e^{\overline{\mu}\sqrt{B}\sqrt{L}}C(B,V_0)e^{-(1/12)\overline{\gamma}\sqrt{B}\sqrt{L}},\quad \alpha=\ell,r; \tag{3.36}$$

thus $\|\mathcal{K}(z)\|\leqslant C(B,V_0,\varepsilon)e^{-\tilde{\gamma}\sqrt{B}\sqrt{L}}$, where $2\tilde{\gamma}=\overline{\gamma}/12-\overline{\mu}$. Since $\overline{\gamma}=1/16$ in Lemma 1, Appendix A, we must take $\overline{\mu}<1/192$. □

We remark that in the proof above we have proved the following statement [see (3.34)] that will be useful in the next section,

$$\|(1-\tilde{J}_\alpha)\tilde{R}_b(z)g\|\leqslant\overline{C}(B,V_0,\varepsilon)e^{-\tilde{\gamma}\sqrt{B}\sqrt{L}}, \tag{3.37}$$

where $g=U_\alpha$ or $g=\chi_B$ ($B\subset\mathbb{R}\times[-L/2,L/2]$) with $\operatorname{dist}(\operatorname{supp} g,\operatorname{supp}(1-\tilde{J}_\alpha))=\mathcal{O}(D)$ and $\tilde{R}_b(z)$ a resolvent associated to a generic bulk Hamiltonian $(H_0+V_\omega|_{\tilde{\Lambda}})$.

IV. PROJECTOR ESTIMATES AND THE PROOF OF THEOREM 1

In this section we prove two propositions that lead to Theorem 1. Let $\mathcal{D}'=\{\kappa:E_\kappa^\alpha\in\Delta,\alpha=\ell,r\}$, $\operatorname{card}(\mathcal{D}')=\mathcal{O}(L)$, where $\Delta\subset\Delta_\varepsilon$ is given in Sec. II.

Proposition 3: For L large enough, with probability greater than $1-L^{-\nu}$ $(\nu\gg1)$, *we have for all* $\kappa\in\mathcal{D}'$,

$$\|P-P_\alpha(E_\kappa^\alpha)\|\leqslant e^{-\gamma\sqrt{B}\sqrt{L}}, \tag{4.1}$$

where $P_\alpha(E_\kappa^\alpha)$ is the projector associated to H_α onto E_κ^α and P is the projector associated to H_ω onto $\{z\in\mathbb{C}:|z-E_\kappa^\alpha|\leqslant e^{-\overline{\mu}\sqrt{B}\sqrt{L}}\}$.

Proof: (1) Let $\mathcal{E}=\{m:E_{0,m}^\alpha\in\Delta,\alpha=\ell,r\}$, $\mathrm{card}(\mathcal{E})=\mathcal{O}(L)$, and let

$$\hat{\Omega}_\ell=\{\omega\in\Omega_{\Lambda_\ell}:\mathrm{dist}(E_{0,m}^r,\sigma(H_\ell))\geqslant L^{-\sigma},\forall m\in\mathcal{E}\},\tag{4.2}$$

with $\sigma>11$, this set has probability

$$\mathbb{P}_{\Lambda_\ell}(\hat{\Omega}_\ell)\geqslant 1-L^{-(\sigma-8)}.\tag{4.3}$$

Indeed, for a fixed $m\in\mathcal{E}$, using Proposition 1 and $(H1)$ one gets

$$\begin{aligned}&\mathbb{P}_{\Lambda_\ell}\{\omega\in\Omega_{\Lambda_\ell}:\mathrm{dist}(E_{0,m}^r,\sigma(H_\ell))\geqslant L^{-\sigma},\ \text{for one } m\in\mathcal{E}\}\\&\quad\geqslant 1-C'(h,V_0)L^{-\sigma}L^4\left(\frac{d_0}{L}-L^{-\sigma}\right)^{-2}\geqslant 1-C(h,V_0)L^{6-\sigma}.\end{aligned}\tag{4.4}$$

For a given realization $\omega_\ell\in\hat{\Omega}_\ell$ let

$$\hat{\Omega}_r(\omega_\ell)=\{\omega\in\Omega_{\Lambda_r}:\mathrm{dist}(E_\kappa^\ell,\sigma(H_r))\geqslant L^{-3\sigma},\quad\forall\kappa\in\mathcal{D}'\},\tag{4.5}$$

this set has the probability

$$\mathbb{P}_{\Lambda_r}(\hat{\Omega}_r(\omega_\ell)|\omega_\ell)\geqslant 1-L^{-(\sigma-6)}\tag{4.6}$$

uniformly with respect to the realizations of $\hat{\Omega}_\ell$. Indeed,

$$\begin{aligned}&\mathbb{P}_{\Lambda_r}\{\omega\in\Omega_{\Lambda_r}:\mathrm{dist}(E_\kappa^\ell,\sigma(H_r))\geqslant L^{-3\sigma},\ \text{for one } \kappa\in\mathcal{D}'\}\\&\quad\geqslant 1-C'(h,V_0)L^{-3\sigma}L^4(L^{-\sigma}-L^{-3\sigma})^{-2}\geqslant 1-C(h,V_0)L^{4-\sigma}.\end{aligned}\tag{4.7}$$

It follows that the set

$$\hat{\Omega}^{(\ell)}=\{\omega=(\omega_\ell,\omega_b,\omega_r)\in\Omega:\omega_\ell\in\hat{\Omega}_\ell,\omega_b\in\Omega_b,\omega_r\in\hat{\Omega}_r(\omega_\ell)\}\tag{4.8}$$

$\Omega_b=\Omega|_{\Lambda_b\setminus(\Lambda_\ell\cup\Lambda_r)}$ has probability

$$\mathbb{P}_\Lambda(\hat{\Omega}^{(\ell)})=\mathbb{P}_{\Lambda_b}(\hat{\Omega}_b)\mathbb{E}_{\Lambda_\ell}\{\mathbb{P}_{\Lambda_r}(\hat{\Omega}_r|\omega_\ell)|\omega_\ell\in\hat{\Omega}_\ell\}\geqslant(1-L^{-(\sigma-6)})\mathbb{P}_{\Lambda_\ell}(\hat{\Omega}_\ell)\geqslant 1-L^{-(\sigma-9)}.\tag{4.9}$$

(2) We now work with a given $\omega\in\hat{\Omega}^{(\ell)}$. Take $\overline{\mu}>0$ as in Proposition 2 and L large enough such that for all $\kappa\in\mathcal{D}'$ $\Gamma_\kappa=\{z\in\mathbb{C}:|z-E_\kappa^\ell|\leqslant e^{-\overline{\mu}\sqrt{B}\sqrt{L}}\}\cap\sigma(H_r)=\varnothing$, and remark that $\mathrm{Tr}\,P_b(\Delta)=0$ (P_b the projector associated to H_b).

We need to introduce two auxiliary Hamiltonians H_1 and H_2 defined as follows:

$$H_1=H_0+V_\omega^\ell|_{\Lambda_1},\tag{4.10}$$

$$H_2=H_0+V_\omega^\ell|_{\Lambda_2}+U_\ell,\tag{4.11}$$

where $\Lambda_2=\{(n,m)\in\mathbb{Z}^2;n\in[-L/2,-L/2+(D/4-1)],m\in[-L/2,L/2]\}$, and $\Lambda_1=\Lambda_\ell\setminus\Lambda_2$, of course, $H_\ell=H_2+V_\omega^\ell|_{\Lambda_1}$.

From the decoupling formula (3.18) we have

$$R(z)-R_\ell(z)=\left(\sum_{i\in\mathcal{I}} J_i R_i(z)\tilde{J}_i\right)\left(\sum_{n=1}^{\infty}\mathcal{K}(z)^n\right)-(1-J_\ell)R_\ell(z)$$
$$-J_\ell R_\ell(z)(1-\tilde{J}_\ell)+J_b R_b(z)\tilde{J}_b+J_r R_r(z)\tilde{J}_r, \tag{4.12}$$

integrating over $\partial\Gamma_\kappa$ and taking the operator norm we get

$$\|P-P_\ell(E_\kappa^\ell)\|\leqslant e^{-\bar{\mu}\sqrt{B}\sqrt{L}}\left(\sum_{i\in\mathcal{I}}\sup_{z\in\partial\Gamma_\kappa}\|R_i(z)\|\right)\frac{\sup_{z\in\partial\Gamma_\kappa}\|\mathcal{K}(z)\|}{1-\sup_{z\in\partial\Gamma_\kappa}\|\mathcal{K}(z)\|}+\|(1-J_\ell)P_\ell(E_\kappa^\ell)\|$$
$$+\|J_\ell P_\ell(E_\kappa^\ell)(1-\tilde{J}_\ell)\|=a+b+c. \tag{4.13}$$

For the first term we note that for L large enough $e^{-\bar{\mu}\sqrt{B}\sqrt{L}}\sup_{z\in\partial\Gamma_\kappa}\|R_i(z)\|\leqslant 1$ $(i\in\mathcal{I})$. Indeed, for $i=\ell$ we have $\sup_{z\in\partial\Gamma_\kappa}\|R_\ell(z)\|=e^{\bar{\mu}\sqrt{B}\sqrt{L}}$ by construction, for $i=b$ we have $\sup_{z\in\partial\Gamma_\kappa}\|R_b(z)\|=\varepsilon^{-1}$ and for $i=r$ $\sup_{z\in\partial\Gamma_\kappa}\|R_r(z)\|=(L^{-3\sigma}-e^{-\bar{\mu}\sqrt{B}\sqrt{L}})^{-1}$. Then, applying Proposition 2 we get

$$a\leqslant 2C(B,V_0,\varepsilon)e^{-\tilde{\gamma}\sqrt{B}\sqrt{L}}. \tag{4.14}$$

For the second and third terms we first observe that by the second resolvent formula,

$$\frac{P_\ell(E_\kappa^\ell)}{(z-E_\kappa^\ell)}=(z-H_1)^{-1}P_\ell(E_\kappa^\ell)+(z-H_1)^{-1}[V_\omega^\ell|_{\Lambda_2}+U_\ell]\frac{P_\ell(E_\kappa^\ell)}{(z-E_\kappa^\ell)}, \tag{4.15}$$

and integrating (4.15) along $\partial\Gamma_\kappa$ we obtain [using $\sigma(H_1)\cap\Delta_\varepsilon=\varnothing$]

$$P_\ell(E_\kappa^\ell)=R_1(E_\kappa^\ell)[V_\omega^\ell|_{\Lambda_2}+U_\ell]P_\ell(E_\kappa^\ell) \tag{4.16}$$
$$=P_\ell(E_\kappa^\ell)[V_\omega^\ell|_{\Lambda_2}+U_\ell]R_1(E_\kappa^\ell). \tag{4.17}$$

Therefore, using (4.16) for b and (4.17) for c we get

$$b\leqslant\|(1-J_\ell)R_1(E_\kappa^\ell)[V_\omega^\ell|_{\Lambda_2}+U_\ell]\|\leqslant\|(1-\tilde{J}_\ell)R_1(E_\kappa^\ell)[V_\omega^\ell|_{\Lambda_2}+U_\ell]\|, \tag{4.18}$$

$$c\leqslant\|(1-\tilde{J}_\ell)R_1(E_\kappa^\ell)[V_\omega^\ell|_{\Lambda_2}+U_\ell]\|. \tag{4.19}$$

Using (3.37) we get

$$b+c\leqslant 2(V_0L^2\|(1-\tilde{J}_\ell)R_1(E_\kappa^\ell)\chi_{\Lambda_2}\|+\|(1-\tilde{J}_\ell)R_1(E_\kappa^\ell)U_\ell\|)\leqslant 2\bar{C}(B,V_0,\varepsilon)L^2e^{-\tilde{\gamma}\sqrt{B}\sqrt{L}}. \tag{4.20}$$

Thus

$$\|P-P_\ell(E_\kappa^\ell)\|\leqslant e^{-\gamma\sqrt{B}\sqrt{L}}. \tag{4.21}$$

By repeating the above proof in a symmetrical way we get for ω in a set $\hat{\Omega}^{(r)}$ similar to $\hat{\Omega}^{(\ell)}$,

$$\|P-P_r(E_\kappa^r)\|\leqslant e^{-\gamma\sqrt{B}\sqrt{L}}. \tag{4.22}$$

Finally we have both (4.21) and (4.22) for $\omega\in\hat{\Omega}=\hat{\Omega}^{(\ell)}\cap\hat{\Omega}^{(r)}$ with $\mathbb{P}_\Lambda\geqslant 1-L^{-\nu}$, $\nu=\sigma-10$. Note that we can take $\nu'\gg 1$ by taking $\sigma\gg 11$. □

The estimate on the norm difference of the projectors implies that their dimensions are the same and that $\mathcal{E}_\kappa^\alpha\in\sigma(H_\omega)$ is a small perturbation of E_κ^α: this gives part (a) of Theorem 1.

Proposition 4: Let $\omega \in \hat{\Omega}$. Then there exists $\hat{\mu} > 0$ such that the velocity associated to each eigenvalue $\mathcal{E}_\kappa^\alpha$ of H_ω in Δ satisfies

$$|J_{\mathcal{E}_\kappa^\alpha} - J_{E_\kappa^\alpha}| \leq e^{-\hat{\mu}\sqrt{B}\sqrt{L}}. \tag{4.23}$$

Proof: Let $J_{\mathcal{E}_\kappa^\alpha} = \mathrm{Tr}\, v_y P(\mathcal{E}_\kappa^\alpha)$ the average velocity associated to the eigenvalue $\mathcal{E}_\kappa^\alpha \in \sigma(H_\omega)$ and $J_{E_\kappa^\alpha} = \mathrm{Tr}\, v_y P_\alpha(E_\kappa^\alpha)$ that associated to the eigenvalue E_κ^α of H_α. First we observe that $v_y P(\mathcal{E}_\kappa^\alpha)$ is trace class. Indeed, $v_y P(\mathcal{E}_\kappa^\alpha) = v_y P(\mathcal{E}_\kappa^\alpha) P(\mathcal{E}_\kappa^\alpha)$ with $v_y P(\mathcal{E}_\kappa^\alpha)$ bounded and $\|P(\mathcal{E}_\kappa^\alpha)\|_1 = \mathrm{Tr}\, P(\mathcal{E}_\kappa^\alpha) = \mathrm{Tr}\, P_\alpha(E_\kappa^\alpha) = 1$:

$$\|v_y P(\mathcal{E}_\kappa^\alpha)\|_1^2 \leq \|v_y P(\mathcal{E}_\kappa^\alpha)\|^2 \leq \|P(\mathcal{E}_\kappa^\alpha) v_y^2 P(\mathcal{E}_\kappa^\alpha)\| \leq 2\|P(\mathcal{E}_\kappa^\alpha)(H_\omega - V_\omega) P(\mathcal{E}_\kappa^\alpha)\| \leq (3B + 2V_0). \tag{4.24}$$

To get the second inequality one has simply added positive terms to v_y^2. Similarly,

$$\|v_y P_\alpha(E_\kappa^\alpha)\|_1^2 \leq (3B + 2V_0). \tag{4.25}$$

With the help of the identity

$$\begin{aligned} P(\mathcal{E}_\kappa^\alpha) - P_\alpha(E_\kappa^\alpha) = {} & [P(\mathcal{E}_\kappa^\alpha) - P_\alpha(E_\kappa^\alpha)]^2 + [P(\mathcal{E}_\kappa^\alpha) - P_\alpha(E_\kappa^\alpha)] P_\alpha(E_\kappa^\alpha) \\ & + P_\alpha(E_\kappa^\alpha)[P(\mathcal{E}_\kappa^\alpha) - P_\alpha(E_\kappa^\alpha)], \end{aligned} \tag{4.26}$$

we get

$$\begin{aligned} |J_{\mathcal{E}_\kappa^\alpha} - J_{E_\kappa^\alpha}| &= |\mathrm{Tr}\, v_y [P(\mathcal{E}_\kappa^\alpha) - P_\alpha(E_\kappa^\alpha)]| \\ &\leq |\mathrm{Tr}\, v_y [P(\mathcal{E}_\kappa^\alpha) - P_\alpha(E_\kappa^\alpha)]^2| + |\mathrm{Tr}\, v_y [P(\mathcal{E}_\kappa^\alpha) - P_\alpha(E_\kappa^\alpha)] P_\alpha(E_\kappa^\alpha)| \\ &\quad + |\mathrm{Tr}\, v_y P_\alpha(E_\kappa^\alpha)[P(\mathcal{E}_\kappa^\alpha) - P_\alpha(E_\kappa^\alpha)]|, \end{aligned} \tag{4.27}$$

and then, from (4.24) and (4.25), we get

$$\begin{aligned} |J_{\mathcal{E}_\kappa^\alpha} - J_{E_\kappa^\alpha}| &\leq 2(\|v_y P(\mathcal{E}_\kappa^\alpha)\|_1 + \|v_y P_\alpha(E_\kappa^\alpha)\|_1)\|P(\mathcal{E}_\kappa^\alpha) - P_\alpha(E_\kappa^\alpha)\| \\ &\leq 4(3B + 2V_0)^{1/2}\|P(\mathcal{E}_\kappa^\alpha) - P_\alpha(E_\kappa^\alpha)\|. \end{aligned} \tag{4.28}$$

Combining this last inequality with Proposition 3 we get the result. □

From Proposition 4 and the result of Appendix B given in (2.10) we obtain part (*b*) of Theorem 1.

ACKNOWLEDGMENTS

We wish to thank F. Bentosela, J. M. Combes, P. Exner, J. Fröhlich, and P. A. Martin for helpful discussions. The work of C. F. was supported by a grant from the Fonds National Suisse de la Recherche Scientifique No. 20-55654.98.

APPENDIX A: ESTIMATE OF THE GREEN'S FUNCTION $R_0(\mathbf{x},\mathbf{x}';z)$

In this appendix we give the necessary decay property of the kernel $R_0(\mathbf{x},\mathbf{x}';z)$ with periodic boundary conditions along y. The exact formula for $R_0(\mathbf{x},\mathbf{x}';z)$ can be found in Ferrari (2002). We introduce the following notation:

$$\Phi^{\alpha}(|\mathbf{x}-\mathbf{x}'|_{\star})=\begin{cases}1+\left|\ln\left(\frac{B}{2}|\mathbf{x}-\mathbf{x}'|_{\star}^{2}\right)\right|, & \alpha=0,\\ 1+\left[\left|\ln\left(\frac{B}{2}|\mathbf{x}-\mathbf{x}'|_{\star}^{2}\right)\right|+\left(1+\left|\ln\left(\frac{B}{2}|\mathbf{x}-\mathbf{x}'|_{\star}^{2}\right)\right|\right)|\mathbf{x}-\mathbf{x}'|_{\star}^{-1}\right], & \alpha=1.\end{cases} \tag{A1}$$

Lemma 1: If $|\mathcal{I}m\, z|\leqslant 1$, $\mathcal{R}e\, z\in\,]\frac{1}{2}B,\frac{3}{2}B[$ *then, for* L *large enough, there exists* $C(z,B)$ *positive constant independent of* L *such that* $(\alpha=0,1)$

$$|\partial_x^{\alpha}R_0(\mathbf{x},\mathbf{x}';z)|\leqslant C'(z,B)e^{-(B/8)|\mathbf{x}-\mathbf{x}'|_{\star}^{2}}\Phi^{\alpha}(|\mathbf{x}-\mathbf{x}'|_{\star})\leqslant C(z,B)e^{-\overline{\gamma}\sqrt{B}|\mathbf{x}-\mathbf{x}'|_{\star}}\Phi^{\alpha}(|\mathbf{x}-\mathbf{x}'|_{\star}), \tag{A2}$$

where $C(z,B)=cB^{2}\mathrm{dist}(z,\sigma(H_0))^{-1}$ *with* c *a numerical positive constant and* $\overline{\gamma}=\frac{1}{16}$.

Proof: As in Ferrari (2002) we can prove that (for L large enough the logarithmic divergences appear only for $|m|\leqslant 1$ and the sum over $|m|>1$ converge)

$$|\partial_x^{\alpha}R_0(\mathbf{x},\mathbf{x}';z)|\leqslant\frac{C'(z,B)}{3}e^{-(B/8)|\mathbf{x}-\mathbf{x}'|^{2}}+\sum_{|m|\leqslant 1}|\partial_x^{\alpha}R_0^{\infty}(xy-mL,\mathbf{x}';z)|, \tag{A3}$$

with

$$|\partial_x^{\alpha}R_0^{\infty}(\mathbf{x},\mathbf{x}';z)|\leqslant\begin{cases}\frac{C'(z,B)}{3}e^{-(B/8)|\mathbf{x}-\mathbf{x}'|^{2}}\left\{1+\mathbf{1}_{\mathbb{B}(\mathbf{0},\sqrt{2B^{-1}})}(|\mathbf{x}-\mathbf{x}'|)\left|\ln\left(\frac{B}{2}|\mathbf{x}-\mathbf{x}'|^{2}\right)\right|\right\}, & \alpha=0,\\ \frac{C'(z,B)}{3}e^{-B/8|\mathbf{x}-\mathbf{x}'|^{2}}\left\{1+\mathbf{1}_{\mathbb{B}(\mathbf{0},\sqrt{2B^{-1}})}(|\mathbf{x}-\mathbf{x}'|)\left[\left|\ln\left(\frac{B}{2}|\mathbf{x}-\mathbf{x}'|^{2}\right)\right|\right.\right.\\ \quad\left.\left.+\left(1+\left|\ln\left(\frac{B}{2}|\mathbf{x}-\mathbf{x}'|^{2}\right)\right|\right)|\mathbf{x}-\mathbf{x}'|^{-1}\right]\right\}, & \alpha=1.\end{cases} \tag{A4}$$

Now, using $|\mathbf{x}-\mathbf{x}'|_{\star}\leqslant|\mathbf{x}-\mathbf{x}'|$, we can replace the Euclidean distance with the distance $|\cdot|_{\star}$ in all the terms on the rhs of (A3), since all these functions are decreasing. To obtain the same bound for the terms $|m|\leqslant 1$ in the sum we just drop the characteristic functions $\mathbf{1}_{\mathbb{B}(\mathbf{0},\sqrt{2B^{-1}})}$. □

APPENDIX B: AVERAGE VELOCITY OF THE EIGENSTATE ASSOCIATED TO E_{κ}^{α}

In this appendix we prove following Ferrari (1999) that the eigenstates corresponding to the eigenvalues of H_{α} $(\alpha=\ell,r)$ in a energy interval $\Delta=(B-\delta,B+\delta)\subset\Delta_{\varepsilon}$ have an average velocity that is strictly positive/negative uniformly in L, that is, if we have $H_{\alpha}\psi_{\kappa}^{\alpha}=E_{\kappa}^{\alpha}\psi_{\kappa}^{\alpha}$ then

$$|(\psi_{\kappa}^{\alpha},v_y\psi_{\kappa}^{\alpha})|\geqslant C'>0. \tag{B1}$$

From the eigenvalue equation we have

$$\|(H_{\alpha}^{0}-E_{\kappa}^{\alpha})\psi_{\kappa}^{\alpha}\|^{2}=\|V_{\omega}^{\alpha}\psi_{\kappa}^{\alpha}\|^{2}\leqslant V_0^{2}. \tag{B2}$$

We now expand ψ_{κ}^{α} on the eigenfunctions of H_{α}^{0} denoted $\{\phi_{n,m}(x,y)=(e^{iky}/\sqrt{L})\,\varphi_{nk}(x)\}_{n\in\mathbb{N},k\in(2\pi/L)\mathbb{Z}}$ where φ_{nk} is the solution on the eigenvalue problem $[\frac{1}{2}p_x^{2}+\frac{1}{2}(k-Bx)^{2}+U_{\alpha}]\varphi_{nk}=E_{nk}^{\alpha}\varphi_{nk}$:

$$\psi_{\kappa}^{\alpha}(x,y)=\sum_{n=0}^{\infty}\sum_{m\in\mathbb{Z}}\psi_n(m)\,\phi_{n,m}(x,y), \tag{B3}$$

and of course,

$$\|\psi_\kappa^\alpha\|^2=\sum_{n=0}^{\infty}\sum_{m\in\mathbb{Z}}|\psi_n(m)|^2=1. \tag{B4}$$

From (B3) the equation (B2) becomes

$$\sum_{n=0}^{\infty}\sum_{m\in\mathbb{Z}}|\psi_n(m)|^2(E_{n,m}^\alpha-E_\kappa^\alpha)^2\leqslant V_0^2, \tag{B5}$$

thus since each term in the sum is positive we have

$$\sum_{m\in\mathbb{Z}}|\psi_0(m)|^2(E_{0,m}^\alpha-E_\kappa^\alpha)^2\leqslant V_0^2. \tag{B6}$$

We remark that for $n\geqslant 1$ one has $|E_{n,m}^\alpha-E_\kappa^\alpha|\geqslant B/2-\delta$, this leads to

$$\|\psi_\star\|^2\equiv\sum_{n=1}^{\infty}\sum_{m\in\mathbb{Z}}|\psi_n(m)|^2\leqslant\frac{V_0^2}{\left(\frac{B}{2}-\delta\right)^2}. \tag{B7}$$

Let $m^\star$ such that $|E_{0,m^\star}^\alpha-E_\kappa^\alpha|$ is minimal, and for a fixed a independent of L let $\mathcal{A}=[m^\star-a,m^\star+a]$. Then from (B5),

$$\begin{aligned}V_0^2&\geqslant\sum_{m\in\mathbb{Z}}|\psi_0(m)|^2(E_{0,m}^\alpha-E_\kappa^\alpha)^2\\&\geqslant\sum_{m\in\mathcal{A}^c}|\psi_0(m)|^2(E_{0,m}^\alpha-E_\kappa^\alpha)^2\geqslant\inf_{m\in\mathcal{A}^c}(E_{0,m}^\alpha-E_\kappa^\alpha)^2\sum_{m\in\mathcal{A}^c}|\psi_0(m)|^2,\end{aligned} \tag{B8}$$

thus

$$\sum_{m\in\mathcal{A}^c}|\psi_0(m)|^2\leqslant V_0^2\sup_{m\in\mathcal{A}^c}(E_{0,m}^\alpha-E_\kappa^\alpha)^{-2}. \tag{B9}$$

From (B4) and (B7) we get

$$1\geqslant\sum_{m\in\mathbb{Z}}|\psi_0(m)|^2\geqslant 1-\frac{V_0^2}{\left(\frac{B}{2}-\delta\right)^2}. \tag{B10}$$

Combining the last equation and (B9) we get

$$\sum_{m\in\mathcal{A}}|\psi_0(m)|^2\geqslant 1-V_0^2\left[\frac{1}{\left(\frac{B}{2}-\delta\right)^2}+\sup_{m\in\mathcal{A}^c}(E_{0,m}^\alpha-E_\kappa^\alpha)^{-2}\right]. \tag{B11}$$

Decompose now ψ_κ^α as $\psi_\kappa^\alpha=\psi_0+\psi_\star$; then

$$|(\psi_\kappa^\alpha,v_y\psi_\kappa^\alpha)|\geqslant|(\psi_0,v_y\psi_0)|-|(\psi_\star,v_y\psi_\star)|-2|(\psi_\star,v_y\psi_0)|; \tag{B12}$$

the first term can be written as

$$\int_{\mathbb{R}} \mathrm{d}x \int_{-L/2}^{L/2} \mathrm{d}y \left\{ \sum_{m' \in \mathbb{Z}} \psi_0^*(m') \frac{e^{-i(2\pi m'/L)y}}{\sqrt{L}} \varphi_{0,m'}^*(x) \sum_{m \in \mathbb{Z}} \psi_0(m) v_y \frac{e^{i(2\pi m/L)y}}{\sqrt{L}} \varphi_{0,m}(x) \right\}$$

$$= \sum_{m \in \mathbb{Z}} |\psi_0(m)|^2 \int_{\mathbb{R}} \mathrm{d}x (k - Bx) |\varphi_{0,m}(x)|^2 = \sum_{m \in \mathbb{Z}} |\psi_0(m)|^2 \partial_k E_0^\alpha(k)|_{k=2\pi m/L}. \tag{B13}$$

The partial derivative of E_0^α is the average velocity $\partial_k E_0^\alpha(k)|_{k=2\pi m/L} = J_{E_{0,m}^\alpha}$; thus

$$|(\psi_0, v_y \psi_0)| \geqslant \left| \sum_{m \in \mathbb{Z}} |\psi_0(m)|^2 J_{E_{0,m}^\alpha} \right| \geqslant |J_{E_{0\overline{m}}^\alpha}| \left\{ 1 - V_0^2 \left[\frac{1}{\left(\frac{B}{2} - \delta \right)^2} + \sup_{m \in \mathcal{A}^c} (E_{0,m}^\alpha - E_\kappa^\alpha)^{-2} \right] \right\}, \tag{B14}$$

for a suitable $\overline{m} \in \mathcal{A}$, and we have $|J_{E_{0,\overline{m}}^\alpha}| > 0$. The second term can be bounded as follows: $|(\psi_\star, v_y \psi_\star)| \leqslant \|\psi_\star\| \|v_y \psi_\star\| \leqslant V_0 / B/2 - \delta \|v_y \psi_\star\|$ and

$$\begin{aligned} \|v_y \psi_\star\|^2 &= 2(\psi_\star, \tfrac{1}{2}(p_y - Bx)^2 \psi_\star) \\ &\leqslant 2(\psi_\star, [\tfrac{1}{2}p_x^2 + \tfrac{1}{2}(p_y - Bx)^2 + U_\alpha]\psi_\star) + 2(\psi_0, [\tfrac{1}{2}p_x^2 + \tfrac{1}{2}(p_y - Bx)^2 + U_\alpha]\psi_0) \\ &= 2(\psi_\kappa^\alpha, H_\alpha^0 \psi_\kappa^\alpha) = 2(\psi_\kappa^\alpha, H_\alpha \psi_\kappa^\alpha) - 2(\psi_\kappa^\alpha, V_\omega^\alpha \psi_\kappa^\alpha) \leqslant 2(E_\kappa^\alpha + V_0). \end{aligned} \tag{B15}$$

This leads to the bound

$$|(\psi_\star, v_y \psi_\star)| \leqslant \frac{V_0}{\frac{B}{2} - \delta} \sqrt{2(E_\kappa^\alpha + V_0)}. \tag{B16}$$

A similar argument gives the same bound for the third term.

Finally,

$$|(\psi_\kappa^\alpha, v_y \psi_\kappa^\alpha)| \geqslant |J_{E_{0,\overline{m}}^\alpha}| \left\{ 1 - V_0^2 \left[\frac{1}{\left(\frac{B}{2} - \delta \right)^2} + \sup_{m \in \mathcal{A}^c} (E_{0,m}^\alpha - E_\kappa^\alpha)^{-2} \right] \right\} - 3 \frac{V_0}{\frac{B}{2} - \delta} \sqrt{2(E_\kappa^\alpha + V_0)}. \tag{B17}$$

The right hand side of (B17) is greater than

$$J \left[1 - O\left(\frac{V_0^2}{B^2} \right) \right] - \sqrt{B} O\left(\frac{V_0}{B} \right), \tag{B18}$$

where the strictly positive constant J depends only on B and U_α. For a sufficiently small $V_0 > 0$ the right hand side of (B17) is strictly positive.

APPENDIX C: DISCUSSION OF HYPOTHESIS 1

In this section we indicate a way in which hypothesis $(H1)$ can be achieved explicitly. We thank Bentosela for pointing out this possibility to one of us. We take two symmetric confining walls $U_\ell(-x) = U_r(x) \equiv U(x)$ and add a magnetic flux tube of intensity $0 \leqslant \Phi \leqslant 2\pi$ along the cylinder axis. Below we check that the magnetic flux lifts the degeneracy of the levels on the two sides of the sample. In this case the pure edge Hamiltonians are

$$H_\ell^0[\Phi]=\frac{1}{2}p_x^2+\frac{1}{2}\left(p_y-Bx+\frac{\Phi}{L}\right)^2+U(-x), \tag{C1}$$

$$H_r^0[\Phi]=\frac{1}{2}p_x^2+\frac{1}{2}\left(p_y-Bx+\frac{\Phi}{L}\right)^2+U(x). \tag{C2}$$

The spectra of these Hamiltonians are

$$\sigma(H_\alpha^0[\Phi])=\{E_{n,m}^\alpha(\Phi):n\in\mathbb{N},m\in\mathbb{Z}\}, \tag{C3}$$

with $E_{n,m}^\alpha(\Phi)=\varepsilon_n^\alpha(2\pi m/L+\Phi/L)$. We consider here only the first spectral branches and note that from the symmetry of the walls, for $\Phi=0$,

$$\varepsilon_0^\ell\left(-\frac{2\pi}{L}m\right)=\varepsilon_0^r\left(\frac{2\pi}{L}m\right),\quad \forall\quad m\in\mathbb{Z}. \tag{C4}$$

We have

$$\varepsilon_0^\ell\left(-\frac{2\pi m}{L}+\frac{\Phi}{L}\right)=\varepsilon_0^\ell\left(-\frac{2\pi m}{L}\right)+\partial_k\varepsilon_0^\ell(k_\ell)\frac{\Phi}{L}, \tag{C5}$$

$$\varepsilon_0^r\left(\frac{2\pi m}{L}+\frac{\Phi}{L}\right)=\varepsilon_0^r\left(\frac{2\pi m}{L}\right)+\partial_k\varepsilon_0^r(k_r)\frac{\Phi}{L}, \tag{C6}$$

for a suitable $(2\pi/L)(-m)\leqslant k_\ell\leqslant(2\pi/L)(-m)+\Phi/L$ and $(2\pi/L)m\leqslant k_r\leqslant(2\pi/L)m+\Phi/L$. Thus

$$\left|\varepsilon_0^\ell\left(-\frac{2\pi m}{L}+\frac{\Phi}{L}\right)-\varepsilon_0^r\left(\frac{2\pi m}{L}+\frac{\Phi}{L}\right)\right|=\frac{\Phi}{L}|\partial_k\varepsilon_0^r(k_r)-\partial_k\varepsilon_0^\ell(k_\ell)|\geqslant 2\frac{\Phi}{L}|\partial_k\varepsilon_0^\ell(k_\ell)|\geqslant 2\mathcal{C}\frac{\Phi}{L}, \tag{C7}$$

where $\mathcal{C}>0$. A similar argument shows that

$$\begin{aligned}\left|\varepsilon_0^\ell\left(-\frac{2\pi(m+1)}{L}+\frac{\Phi}{L}\right)-\varepsilon_0^r\left(\frac{2\pi m}{L}+\frac{\Phi}{L}\right)\right|&=\left|\frac{\Phi}{L}[\partial_k\varepsilon_0^\ell(k_\ell)-\partial_k\varepsilon_0^r(k_r)]-\frac{2\pi}{L}\partial_k\varepsilon_0^\ell(k_\ell)\right|\\&\geqslant\left|2\frac{\Phi}{L}\left|\partial_k\varepsilon_0^\ell(k_\ell)\right|-\frac{2\pi}{L}\left|\partial_k\varepsilon_0^\ell(k_\ell)\right|\right|\geqslant 2\mathcal{C}\frac{|\Phi-\pi|}{L}.\end{aligned} \tag{C8}$$

Then, by fixing $\Phi^\star$ such that $0<\Phi^\star<\pi$ or $\pi<\Phi^\star<2\pi$ we achieve (2.7).

(Received 10 April 2003; accepted 3 May 2003)

In the search of appropriate Riemannian metrics on quantum state space, the concept of statistical monotonicity, or contraction under coarse graining, has been proposed by Chentsov. The metrics with this property have been classified by Petz. All the elements of this family of geometries can be seen as quantum analogs of Fisher information. Although there exists a number of general theorems shedding light on this subject, many natural questions, also stemming from applications, are still open. In this paper we discuss a particular member of the family, the Wigner–Yanase information. Using a well-known approach that mimics the classical pull-back approach to Fisher information, we are able to give explicit formulas for the geodesic distance, the geodesic path, the sectional and scalar curvatures associated to Wigner–Yanase information. Moreover, we show that this is the only monotone metric for which such an approach is possible. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1598279]

I. INTRODUCTION

The notion of information proposed by Fisher is fundamental in probability and statistics for a number of reasons; here we mention only the Cramer–Rao inequality and the asymptotic behavior of maximum lilkelihood estimators for exponential models (one can see Ref. 5 for unexpected features and applications of Fisher information). In classical statistics Rao was the first to point out that Fisher information can be seen as a Riemannian metric on the space of probability densities. This point of view was nicely complemented by the results of Chentsov, saying that (on the simplex of probability vectors) Fisher information is the unique Riemannian metric contracting under Markov morphisms. This can be rephrased in a more suggestive way. Markov morphisms, or positive mappings, are the mathematical counterpart of the notion of noise. Now suppose that we want to use a distance to distinguish different states (probability densities) in a statistically relevant way. Then the effect of noise must be that of contracting the metric. Chentsov theorem says therefore that in the classical case there is only one choice, the Fisher information (another argument producing Fisher information can be found in Ref. 43).

In the quantum case one deals with density operators instead of density vectors and completely positive mappings play the role of Markov morphisms. As often happens in the quantum counterpart of a classical theory, instead of a uniqueness result, one has a classification theorem, due to Petz. This result states that there is bijection between statistically monotone metrics on quantum state space and the operator monotone functions: we have therefore a rich ''garden'' of candidates for the role of Fisher information in quantum physics. Among the elements of this family of metrics one can find, in a certain sense, the most relevant Riemannian metrics appeared in the literature.[35,37]

[a)]Electronic mail: gibilisc@sci.unich.it
[b)]Electronic mail: isola@mat.uniroma2.it

Despite the existence of general results for the theory[13,17,19,26,27,28,30,40,41] a number of open problems resists investigation. For example, it does not exist yet a general formula for the geodesic path and the geodesic distance associated to an arbitrary monotone metric. For the use of this kind of distances see, for example Ref. 32. Because of the absence of a general formula, inequalities (giving bounds for the geodesic distance) have been proved.[38]

In this paper we discuss the Wigner–Yanase skew information. To find the formulas for geodesic path and geodesic distance we mimic the classical approach to Fisher information via sphere geometry (one should note the importance of determining the geodesic path in the study of the 2-Wasserstein metric[6]). Indeed Wigner–Yanase information appears as the pull-back of the square root map.[18] Next we prove the formula for the scalar curvature. One proof, due to Dittmann, uses the general formula[13] and requires a long calculation. The second one just uses the pull-back approach. One should emphasize that, since the scalar curvature determines the asymptotic behavior of the volume (for a Riemannian metric) then it has also a statistical meaning in relation to the quantum analog of Jeffrey's rule for determining prior probability distributions (see Ref. 35). Finally we prove, as a corollary of the results in Refs. 25, 26, and 19 that the Wigner–Yanase information is the only monotone metric that can be seen as a pull-back metric.

The paper is organized as follows. In Sec. II we review the geometric approach to Fisher information. Sec. III one finds an introduction to the general theory of statistical monotone metrics. Sec. IV shows how the Wigner–Yanase information can be seen as a monotone Riemannian metric. In Sec. V we show that the Wigner–Yanase geometry can be seen as the sphere geometry transposed on the space of density matrices; moreover, we characterize it as the unique pull-back metric. Section VI contains some comments on the main results and on some open problems.

II. FISHER INFORMATION AND ITS GEOMETRY

The classical definition of Fisher information for an indexed family of densities p_θ is given by the variance of the score. In the case of a family indexed by only one parameter θ it is the number

$$I(\theta)=\mathrm{E}_\theta\left[\left(\frac{\partial}{\partial\theta}\log p_\theta\right)^2\right], \tag{2.1}$$

assigned to the parameter θ. For n parameters, say $\theta=(\theta^1,\ldots,\theta^n)$, it is a matrix defined on the parameter manifold given by

$$I(\theta)_{ij}=\mathrm{E}_\theta\left[\left(\frac{\partial}{\partial\theta^i}\log p_\theta\right)\left(\frac{\partial}{\partial\theta^j}\log p_\theta\right)\right]. \tag{2.2}$$

Geometrically this means that $I(\theta)$ is a symmetric bilinear form on the tangent spaces of the parameter manifold. In a coordinate free language it reads as

$$I(\theta)(U,V)=\mathrm{E}_\theta[U(\log p_\theta)\,V(\log p_\theta)], \tag{2.3}$$

where U and V are vectors tangent to the parameter manifold and $U(\log p_\theta)$ is the derivative of $\log p_\theta$ along the direction U, which means $U(\log p_\theta)=(\mathrm{d}/\mathrm{d}t)\log p_{\theta+tU|_{t=0}}$.

$I(\theta)$ is a measure for the statistical distinguishabilty of distribution parameters. Under certain regularity conditions for $\theta\mapsto p_\theta$ the image of this mapping is a manifold of distributions. This manifold is the actual object of interest in information geometry rather than the space of distribution parameters and formula (2.3) defines a Riemannian metric g on it (for a general reference see Ref. 1). Indeed, a vector u tangent to this manifold is of the form

$$u=\frac{\mathrm{d}}{\mathrm{d}t}p_{\theta+tU|_{t=0}},$$

and the right hand side of (2.3) now reads as

$$g(u,v) := \mathrm{E}_p\left[\frac{u}{p}\,\frac{v}{p}\right], \tag{2.4}$$

defining the Fisher metric on the manifold of densities.

We restrict now to $\mathcal{P}_n \subset \mathbb{R}^n$, the simplex of strictly positive probability vectors, that is, $\mathcal{P}_n := \{\rho \in \mathbb{R}^n : \Sigma_{i=1}^n \rho_i = 1, \rho_i > 0, i = 1,\ldots,n\}$. An element $\rho \in \mathcal{P}_n$ is a density on the n-point set $\{1,\ldots,n\}$ with $\rho(i) = \rho_i$. We regard an element u of the tangent space $\mathrm{T}_\rho \mathcal{P}_n \equiv \{u \in \mathbb{R}^n : \Sigma_{i=1}^n u_i = 0\}$ as a function u on $\{1,\ldots,n\}$ with $u(i) = u_i$.

Definition 2.1: The Fisher–Rao Riemannian metric on $\mathrm{T}_\rho \mathcal{P}_n$ is given by

$$\langle u,v \rangle_\rho^F := \sum_{i=1}^n \frac{u_i v_i}{\rho_i}, \tag{2.5}$$

for $u,\ v \in \mathrm{T}_\rho \mathcal{P}_n$.

To see the relation between this metric and the Fisher metric, let $u,v \in \mathrm{T}_\rho \mathcal{P}_n$. We obtain from (2.4),

$$g(u,v) = \sum_{i=1}^n \frac{u(i)}{\rho_i}\,\frac{v(i)}{\rho_i}\,\rho_i = \sum_{i=1}^n \frac{u_i v_i}{\rho_i},$$

in accordance with (2.5).

The following result is well known and is a very special case of a far more general situation (see Ref. 15, for example).

Theorem 2.2: *The manifold $\mathcal{P}_n$ equipped with the Fisher–Rao Riemannian metric $\langle \cdot,\cdot \rangle^F$ is isometric with an open subset of the sphere of radius 2 in $\mathbb{R}^n$.*

Proof: We consider the mapping $\varphi : \mathcal{P}_n \to S_2^{n-1} \subset \mathbb{R}^n$,

$$\varphi(\rho) := 2(\sqrt{\rho_1}, \ldots, \sqrt{\rho_n}).$$

Then $D_\rho \varphi(u) = (u_1/\sqrt{\rho_1}, \ldots, u_n/\sqrt{\rho_n})$ and we get

$$D_\rho \varphi(\langle \cdot,\cdot \rangle^F)(u,v) := \langle D_\rho \varphi(u), D_\rho \varphi(v) \rangle^{\mathbb{R}^n} = \sum_{i=1}^n \frac{u_i v_i}{\rho_i} = \langle u,v \rangle_\rho^F.$$

Hence the standard metric on the sphere of radius 2 is pulled back to the Fisher–Rao Riemannian metric. □

This identification of $\mathcal{P}_n$ with an open subset of a radius 2 sphere allows for obtaining differential geometrical quantities of the Riemannian manifold $(\mathcal{P}_n, \langle \cdot,\cdot \rangle^F)$. From the very definition of geodesic distance, geodesic path and scalar curvature, one has for S_r^{n-1}, with $P_1, P_2 \in S_r^{n-1}$, the following:

(1) geodesic distance,

$$d(P_1,P_2) = r \cdot \arccos\left(\frac{\langle P_1,P_2 \rangle}{r^2}\right);$$

(2) geodesic path connecting P_1 and P_2,

$$\gamma^{P_1,P_2}(t) = r\,\frac{(1-t)P_1 + tP_2}{\|(1-t)P_1 + tP_2\|}$$

(of course, t is not the arc length parameter);

(3) scalar curvature,

$$\mathrm{Scal}(v)=\frac{1}{r^2}(n-1)(n-2),$$

because S_r^{n-1} has constant sectional curvature equal to $1/r^2$.

Let us denote by d_F, γ_F, Scal_F, respectively, the corresponding quantities for the Fisher information. The above considerations give, for $\rho,\sigma\in\mathcal{P}_n$, the following:

(1) Bhattacharya distance,

$$d_{\mathrm{F}}(\rho,\sigma)=2\arccos\left(\sum_i \rho_i^{1/2}\sigma_i^{1/2}\right);$$

(2) geodesic path connecting ρ and σ,

$$\gamma_{\mathrm{F}}^{\rho,\sigma}(t)=2\frac{((1-t)\sqrt{\rho}+t\sqrt{\sigma})^2}{\sum_i ((1-t)\sqrt{\rho_i}+t\sqrt{\sigma_i})^2};$$

(3) scalar curvature,

$$\mathrm{Scal}_{\mathrm{F}}(\rho)=\frac{1}{4}(n-1)(n-2),\quad \forall\rho\in\mathcal{P}_n.$$

The Levi–Civita connection associated to Fisher metric can be decomposed using the geometry of mixture and exponential models. In the rest of the section we explain how.

Definition 2.3: A dualistic structure on a manifold $\mathcal{M}$ is a triple $(\langle\cdot,\cdot\rangle,\nabla,\tilde{\nabla})$, where $\langle\cdot,\cdot\rangle$ is a Riemannian metric on $\mathcal{M}$ and $\nabla,\tilde{\nabla}$ are affine connections on $\mathcal{M}$ such that

$$X\langle Y,Z\rangle=\langle\nabla_X Y,Z\rangle+\langle Y,\tilde{\nabla}_X Z\rangle,$$

where X,Y,Z are vector fields. If $U^{\nabla},U^{\tilde{\nabla}}$ are the parallel transport associated to $\nabla,\tilde{\nabla}$ then the above equation is equivalent to

$$\langle U^{\nabla}(u),U^{\tilde{\nabla}}(v)\rangle=\langle u,v\rangle.$$

A divergence on a manifold is a smooth non-negative function $D:\mathcal{M}\times\mathcal{M}\to\mathbb{R}$ such that $D(\rho,\sigma)=0$ iff $\rho=\sigma$. To each divergence D one may associate a dualistic structure $(\langle\cdot,\cdot\rangle,\nabla,\tilde{\nabla})$ (see Refs. 1 and 14).

Let ∇^2 be the Levi–Civita connection of Fisher information. The Kullback–Leibler relative entropy $K(\rho,\sigma)=\Sigma_i\rho_i(\log\rho_i-\log\sigma_i)$ gives a dualistic structure $(\langle\cdot,\cdot\rangle^F,\nabla^m,\nabla^e)$ such that

$$\nabla^2=\tfrac{1}{2}(\nabla^m+\nabla^e),$$

where ∇^m,∇^e are the mixture and exponential connections. These connections are torsion free and flat: once the representation by scores is used for the tangent spaces, the associated parallel transports are given by

$$U^m_{\rho\sigma}:T_\rho\mathcal{P}\to T_\sigma\mathcal{P},\quad U^m_{\rho\sigma}(u)=\frac{\rho}{\sigma}u,$$

$$U^e_{\rho\sigma}:T_\rho\mathcal{P}\to T_\sigma\mathcal{P},\quad U^e_{\rho\sigma}(u)=u-\mathrm{E}_\sigma(u).$$

The geodesics of ∇^m,∇^e are, respectively, the mixture and exponential models.

III. METRIC CONTRACTION UNDER COARSE GRAINING

In the commutative case a Markov morphism (or stochastic map) is a stochastic matrix $T:\mathbb{R}^n\to\mathbb{R}^k$. In the noncommutative case a stochastic map is a completely positive and trace preserving operator $T:M_n\to M_k$ where M_n denotes the space of n by n complex matrices. We shall denote by $\mathcal{D}_n$ the manifold of strictly positive elements of M_n and by $\mathcal{D}_n^1\subset\mathcal{D}_n$ the submanifold of density matrices.

In the commutative case a monotone metric is a family of Riemannian metrics $g=\{g^n\}$ on $\{\mathcal{P}_n\}$, $n\in\mathbb{N}$ such that

$$g^m_{T(\rho)}(TX,TX)\leqslant g^n_\rho(X,X)$$

holds for every stochastic mapping $T:\mathbb{R}^n\to\mathbb{R}^m$ and all $\rho\in\mathcal{P}_n$ and $X\in T_\rho\mathcal{P}_n$.

In perfect analogy, a monotone metric in the noncommutative case is a family of Riemannian metrics $g=\{g^n\}$ on $\{\mathcal{D}_n^1\}$, $n\in\mathbb{N}$ such that

$$g^m_{T(\rho)}(TX,TX)\leqslant g^n_\rho(X,X)$$

holds for every stochastic mapping $T:M_n\to M_m$ and all $\rho\in\mathcal{D}_n^1$ and $X\in T_\rho\mathcal{D}_n^1$.

Let us recall that a function $f:(0,\infty)\to\mathbb{R}$ is called operator monotone if for any $n\in\mathbb{N}$, any A, $B\in M_n$ such that $0\leqslant A\leqslant B$, the inequalities $0\leqslant f(A)\leqslant f(B)$ hold. An operator monotone function is said to be symmetric if $f(x):=xf(x^{-1})$ and normalized if $f(1)=1$. In what follows by operator monotone we mean normalized symmetric operator monotone. With each operator monotone function f one associates also the so-called Chentsov–Morotzova function (see Ref. 8),

$$c_f(x,y):=\frac{1}{yf\left(\frac{x}{y}\right)},\quad \text{for } x,y>0.$$

Define $L_\rho(A):=\rho A$, and $R_\rho(A):=A\rho$. Since L_ρ,R_ρ commute we may define $c(L_\rho,R_\rho)$. Now we can state the fundamental theorems about monotone metrics (uniqueness and classification are up to scalars).

Theorem 3.1: (Ref. 7) *There exists a unique monotone metric on $\mathcal{P}_n$ given by the Fisher information.*

Theorem 3.2: (Ref. 34) *There exists a bijective correspondence between monotone metrics on $\mathcal{D}_n^1$ and operator monotone functions given by the formula*

$$\langle A,B\rangle_{\rho,f}:=\mathrm{Tr}(A\cdot c_f(L_\rho,R_\rho)(B)).$$

The tangent space to $\mathcal{D}_n^1$ at ρ is given by $T_\rho\mathcal{D}_n^1\equiv\{A\in M_n:A=A^*,\mathrm{Tr}(A)=0\}$, and can be decomposed as $T_\rho\mathcal{D}_n^1=(T_\rho\mathcal{D}_n^1)^c\oplus(T_\rho\mathcal{D}_n^1)^o$, where $(T_\rho\mathcal{D}_n^1)^c:=\{A\in T_\rho\mathcal{D}_n^1:[A,\rho]=0\}$, and $(T_\rho\mathcal{D}_n^1)^o$ is the orthogonal complement of $(T_\rho\mathcal{D}_n^1)^c$, with respect to the Hilbert–Schmidt scalar product $\langle A,B\rangle:=\mathrm{Tr}(A^*B)$. Each statistically monotone metric has a unique expression (up to a constant) given by $\mathrm{Tr}(\rho^{-1}A^2)$, for $A\in(T_\rho\mathcal{D}_n^1)^c$. The following result will be used in Sec. V.

Proposition 3.3: (see Ref. 3) *Let $A\in T_\rho\mathcal{D}_n^1$ be decomposed as $A=A^c+i[\rho,U]$ where $A^c\in(T_\rho\mathcal{D}_n^1)^c$ and $i[\rho,U]\in(T_\rho\mathcal{D}_n^1)^o$. Suppose $\varphi\in\mathcal{C}^1(0,+\infty)$. Then*

$$(D_\rho\varphi)(A)=\varphi'(\rho)A^c+i[\varphi(\rho),U].$$

As proved by Lesniewski and Ruskai each monotone metric is the Hessian of a suitable relative entropy; to state this result more precisely, we introduce some notation. In what follows g is an operator convex function defined on $(0,+\infty)$ and such that $g(1)=0$. The formula

$$f(x)\equiv f_g(x):=\frac{(x-1)^2}{g(x)+xg(x^{-1})},$$

associates a normalized, symmetric operator monotone function $f=f_g$ to each g. We denote by $\Delta_{\sigma,\rho}=L_\sigma R_\rho^{-1}$ the relative modular operator. The relative g–entropy of ρ and σ is defined as

$$H_g(\rho,\sigma):=\mathrm{Tr}(\rho^{1/2}g(\Delta_{\sigma,\rho})(\rho^{1/2})).$$

H_g is a divergence on $\mathcal{D}_n$ in the sense of Refs. 14, and 1. If ρ,σ are diagonal, H_g reduces to the commutative relative g–entropy (see Ref. 9).

Theorem 3.4: (Ref. 30) *Let g be operator convex, $g(1)=0$, $f=f_g$ and $\rho\in\mathcal{D}_n$. Then*

$$-\frac{\partial}{\partial t}\frac{\partial}{\partial s}H_g(\rho+tA,\rho+sB)\Big|_{t=s=0}=\mathrm{Tr}(A\cdot c_f(L_\rho,R_\rho)(B)).$$

To state the general formula for the scalar curvature of a monotone metric we need some auxiliary functions. In what follows c',$(\log c)'$ denote derivatives with respect to the first variable, and $c=c_f$:

$$\begin{aligned}
h_1(x,y,z)&:=\frac{c(x,y)-z\,c(x,z)\,c(y,z)}{(x-z)(y-z)c(x,z)c(y,z)},\\
h_2(x,y,z)&:=\frac{(c(x,z)-c(y,z))^2}{(x-y)^2c(x,y)c(x,z)c(y,z)},\\
h_3(x,y,z)&:=z\,\frac{(\ln c)'(z,x)-(\ln c)'(z,y)}{x-y},\\
h_4(x,y,z)&:=z\,(\ln c)'(z,x)\quad(\ln c)'(z,y),\\
h&:=h_1-\tfrac{1}{2}h_2+2h_3-h_4.
\end{aligned}\tag{3.1}$$

The functions h_i have no essential singularities if arguments coincide.

Note that $\langle A,B\rangle_\rho^f:=\mathrm{Tr}(A\cdot c_f(L_\rho,R_\rho)(B))$ defines a Riemannian metric also over $\mathcal{D}_n$ ($\mathcal{D}_n^1$ is a submanifold of codimension 1). Let $\mathrm{Scal}_f(\rho)$ be the scalar curvature of $(\mathcal{D}_n,\langle\cdot,\cdot\rangle_\rho^f)$ at ρ and $\mathrm{Scal}_f^1(\rho)$ be the scalar curvature of $(\mathcal{D}_n^1,\langle\cdot,\cdot\rangle_\rho^f)$.

Theorem 3.5: (Ref. 13) *Let $\sigma(\rho)$ be the spectrum of ρ. Then*

$$\begin{aligned}
\mathrm{Scal}_f(\rho)&=\sum_{x,y,z\in\sigma(\rho)}h(x,y,z)-\sum_{x\in\sigma(\rho)}h(x,x,x),\\
\mathrm{Scal}_f^1(\rho)&=\mathrm{Scal}_f(\rho)+\tfrac{1}{4}(n^2-1)(n^2-2).
\end{aligned}\tag{3.2}$$

IV. WIGNER–YANASE INFORMATION AS A RIEMANNIAN METRIC

Let $\rho\in\mathcal{D}_n^1$ be a density matrix and let A be a self-adjoint matrix. The Wigner–Yanase information (or skew information, information content relative to A) was defined as

$$I(\rho,A):=-\mathrm{Tr}([\rho^{1/2},A]^2),$$

where $[\cdot,\cdot]$ denotes the commutator (see Ref. 42). Consider now $g(x):=g_{wy}(x):=4(1-\sqrt{x})$. In this case

$$H_g(\rho,\sigma)=4(1-\mathrm{Tr}(\rho^{1/2}\sigma^{1/2})).$$

The associated operator monotone and Chentsov–Morotzova functions are

$$f_{wy}(x) := \frac{1}{4}(\sqrt{x}+1)^2, \quad c_{wy}(x,y) := \frac{1}{y f_{wy}\left(\frac{x}{y}\right)} = \frac{4}{(\sqrt{x}+\sqrt{y})^2}.$$

Let us consider the monotone metric,

$$\langle A,B\rangle_\rho^{wy} := \mathrm{Tr}(A\, c_{wy}(L_\rho,R_\rho)(B)).$$

A typical element of $(T_\rho D_n)^o$ has the form $\mathrm{i}[\rho,A]$, where A is self-adjoint. We have

$$\begin{aligned}
\langle \mathrm{i}[\rho,A],\mathrm{i}[\rho,A]\rangle_\rho^{wy} &= \mathrm{Tr}\,(\mathrm{i}[\rho,A]4(L_\rho^{1/2}+R_\rho^{1/2})^{-2}(\mathrm{i}[\rho,A])) \\
&= -4\,\mathrm{Tr}\,((L_\rho^{1/2}+R_\rho^{1/2})^{-1}([\rho,A])\ \ (L_\rho^{1/2}+R_\rho^{1/2})^{-1}([\rho,A])) \\
&= -4\,\mathrm{Tr}\,((L_\rho^{1/2}+R_\rho^{1/2})^{-1}\circ(L_\rho-R_\rho)(A)\ \ (L_\rho^{1/2}+R_\rho^{1/2})^{-1}\circ(L_\rho-R_\rho)(A)) \\
&= -4\,\mathrm{Tr}\,((L_\rho^{1/2}-R_\rho^{1/2})(A)\ \ (L_\rho^{1/2}-R_\rho^{1/2})(A)) \\
&= -4\,\mathrm{Tr}([\rho^{1/2},A]^2) \\
&= 4I(\rho,A),
\end{aligned}$$

and this explains why the monotone metric associated with the function $\frac{1}{4}(\sqrt{x}+1)^2$ is called the Wigner–Yanase monotone metric.

V. THE MAIN RESULT

First of all, we calculate the scalar curvature of Wigner–Yanase information using Theorem 3.5. If $f_{wy}(x) := \frac{1}{4}(\sqrt{x}+1)^2$, we write Scal^1_{wy} for Scal^1_f.

Theorem 5.1:

$$\mathrm{Scal}^1_{wy}(\rho) = \tfrac{1}{4}(n^2-1)(n^2-2).$$

Proof: Let us calculate the auxiliary functions for $c_{wy}(x,y) := 4(\sqrt{x}+\sqrt{y})^{-2}$. We get

$$h_1(x,y,z) = \frac{\sqrt{x}\,\sqrt{y}+3\,\sqrt{x}\,\sqrt{z}+3\,\sqrt{y}\,\sqrt{z}+z}{4\,(\sqrt{x}+\sqrt{y})^2\,(\sqrt{x}+\sqrt{z})\,(\sqrt{y}+\sqrt{z})},$$

$$h_2(x,y,z) = \frac{(\sqrt{x}+\sqrt{y}+2\,\sqrt{z})^2}{4\,(\sqrt{x}+\sqrt{z})^2\,(\sqrt{y}+\sqrt{z})^2},$$

$$h_3(x,y,z) = \frac{\sqrt{z}}{(\sqrt{x}+\sqrt{y})\,(\sqrt{x}+\sqrt{z})\,(\sqrt{y}+\sqrt{z})},$$

$$h_4(x,y,z) = \frac{1}{(\sqrt{x}+\sqrt{z})\,(\sqrt{y}+\sqrt{z}).}$$

Now one can verify by calculation that the symmetrization of $h_1-\frac{1}{2}h_2$ and the symmetrization of $2\,h_3-h_4$ vanish. Hence, by (3.1), the symmetrization of h vanishes, too. Since we sum up in formula (3.2) over all triples of eigenvalues we may replace h with its symmetrization without changing the summation result. Therefore

$$\mathrm{Scal}_{wy}(\rho)=0\,, \quad \mathrm{Scal}^1_{wy}(\rho) = \tfrac{1}{4}(n^2-1)(n^2-2), \quad \forall \rho \in \mathcal{D}_n^1.$$

□

Remark 5.2: The fact that $\mathrm{Scal}_{wy}(\rho)=0$ can be seen by a different approach (look at the Wigner–Yanase metric over $\mathcal{D}_n$ as the 0-geometry; see Refs. 21 and 27).

In what follows we use the pull-back approach to derive (and explain) the above formula in a direct way. Furthermore we deduce the geodesic distance and geodesic equation.

Let us denote by $\mathcal{S}$ the manifold $\{A \in M_n : \mathrm{Tr}\, A\, A^* = 4,\ A = A^*\}$. Clearly, since $\mathcal{S}$ is the intersection of the radius 2 sphere in $\mathbb{C}^{n\times n}$ and the subspace of Hermitian matrices, it is isometric with a radius 2 sphere $S_2^{n^2-1}$.

Now, let $\varphi : \mathcal{D}_n^1 \to \mathcal{S} \subset \mathbb{C}^{n\times n}$, $\varphi(\rho) := 2\sqrt{\rho}$. Then we have the following result (see Refs. 25, 18, 27, and 21).

Theorem 5.3: *The pull-back by the map φ of the natural metric on $\mathcal{S} \equiv S_2^{n^2-1}$ coincides with the Wigner–Yanase monotone metric.*

Proof: Let A and B be vectors tangent to $\mathcal{D}_n^1$ at ρ. Because $\varphi(\rho)\,\varphi(\rho) = 4\,\rho$ we get from the Leibniz rule $D_\rho\varphi(A)\sqrt{\rho} + \sqrt{\rho}\, D_\rho\varphi(A) = 2A$. Thus, the differential of φ at the point ρ is given by

$$D_\rho\varphi(A) = 2(L_\rho^{1/2} + R_\rho^{1/2})^{-1}(A)\,.$$

Therefore the pull-back of the real part of the Hilbert–Schmidt metric yields

$$\begin{aligned} D_\rho\varphi(\mathrm{Re}\langle\cdot,\cdot\rangle)(A,B) &= \mathrm{Re}\,\langle D_\rho\varphi(A), D_\rho\varphi(B)\rangle \\ &= 4\,\mathrm{Re}\langle (L_\rho^{1/2} + R_\rho^{1/2})^{-1}(A), (L_\rho^{1/2} + R_\rho^{1/2})^{-1}(B)\rangle \\ &= 4\,\langle A, (L_\rho^{1/2} + R_\rho^{1/2})^{-2}(B)\rangle \\ &= 4\,\mathrm{Tr}\, A\, (L_\rho^{1/2} + R_\rho^{1/2})^{-2}(B) \\ &= \mathrm{Tr}\, A\, c_{wy}(L_\rho, R_\rho)(B) = \langle A, B\rangle_\rho^{wy}\,, \end{aligned}$$

which was to be proved. □

From this result one can deduce the following.

Theorem 5.4: *For the geodesic distance, the geodesic path and the scalar curvature of Wigner–Yanase information the following formulas hold:*

(1) geodesic distance,

$$d_{wy}(\rho,\sigma) = 2\,\arccos(\mathrm{Tr}(\rho^{1/2}\sigma^{1/2}))\,; \tag{5.1}$$

(2) geodesic path,

$$\gamma_{wy}^{\rho,\sigma}(t) = 2\,\frac{((1-t)\sqrt{\rho} + t\sqrt{\sigma})^2}{\mathrm{Tr}(((1-t)\sqrt{\rho} + t\sqrt{\sigma})^2)}\,; \tag{5.2}$$

(3) scalar curvature

$$\mathrm{Scal}_{wy}^1(\rho) = \tfrac{1}{4}(n^2-1)(n^2-2). \tag{5.3}$$

Proof: The formulas are immediate consequences of the preceding theorem and of sphere geometry. Indeed by the pull-back argument the Wigner–Yanase metric looks locally like a sphere of radius 2 of dimension (n^2-1). But for a sphere of this kind the sectional curvatures are all equal to $\frac{1}{4}$ and therefore the scalar curvature is given by $\frac{1}{4}(n^2-1)(n^2-2)$. □

One may ask if other monotone metrics are the pull-back of some function φ different from the square root. The rest of the section answers this question.

Definition 5.5: A monotone metric $\langle\cdot,\cdot\rangle_{\rho,f}$ is a pull-back metric if there exists a manifold $\mathcal{S} \subset M_n$ and a function $\varphi \in \mathcal{C}^1(0,+\infty)$ such that the pull-back metric of $\varphi : \mathcal{D}_n^1 \to \mathcal{S} \subset M_n$ coincides with $\langle\cdot,\cdot\rangle_{\rho,f}$.

Proposition 5.6: Let $\langle\cdot,\cdot\rangle_{\rho,f}$ be a monotone metric, let $c = c_f$ be the associated CM-function and let $\varphi \in \mathcal{C}^1(0,+\infty)$. We have that $\langle\cdot,\cdot\rangle_{\rho,f}$ is a pull-back metric by φ if and only if

$$\left(\frac{\varphi(x)-\varphi(y)}{x-y}\right)^2 = c(x,y). \tag{5.4}$$

Proof: Apply the proposition (3.3) to tangent vectors in $(T_\rho \mathcal{D}_n^1)^o$. □

Definition 5.7: Let $\varphi,\chi \in \mathcal{C}^1(0,+\infty)$. We say that (φ,χ) is a dual pair if there exists an operator monotone f such that

$$\frac{\varphi(x)-\varphi(y)}{x-y}\cdot\frac{\chi(x)-\chi(y)}{x-y} = c(x,y), \tag{5.5}$$

where $c=c_f$ is the CM-function associated with f.

In such a case we say that f (or c_f) is a dual function. If (φ,φ) is a dual pair with respect to f (or c_f) we say that f (or c_f) is self-dual. Obviously one has the following.

Proposition 5.8: To say that $\langle\cdot,\cdot\rangle_{\rho,f}$ is a pull-back metric by φ it is equivalent to say that f (or c_f) is self-dual with respect to φ.

Definition 5.9: Two dual pairs $(\varphi,\chi),(\tilde{\varphi},\tilde{\chi})$ are equivalent if there exist constants A_1,A_2,B_1,B_2 such that $A_1A_2=1$,

$$\tilde{\varphi}=A_1\varphi+B_1,$$

$$\tilde{\chi}=A_2\chi+B_2.$$

Obviously equivalent pairs define the same CM-function. In what follows we consider dual pairs up to this equivalence relation with the traditional abuse of language. We are ready to state the fundamental result of the theory that classifies dual pairs.

Theorem 5.10: (Refs. 23, 24, 25, 26, 36, and 19) *Let $\varphi,\chi \in \mathcal{C}^1(0,+\infty)$. Then (φ,χ) is a dual pair if and only if one of the following two possibilities hold:*

$$(\varphi(x),\chi(x)) = \left(\frac{x^p}{p},\frac{x^{1-p}}{1-p}\right), \quad p\in[-1,2]\backslash\{0,1\},$$

$$(\varphi(x),\chi(x)) = (x,\log(x)).$$

Corollary 5.11: The function $f(x)=\frac{1}{4}(\sqrt{x}+1)^2$ is the only self-dual operator monotone function, that is: the Wigner–Yanase metric is the only pull-back metric among statistically monotone metrics.

VI. CONCLUSIONS

Remark 6.1: Note that the formula (5.1) implies $d^{wy}(\rho,\sigma)\leqslant 2\pi$. An analogous inequality holds for the Bures metric (see Ref. 10, p. 311), also known as the SLD-metric: this is the monotone metric associated with $f(x)=\frac{1}{2}(1+x)$. Indeed the formula,

$$d_{\text{Bures}}(\rho,\sigma) = \sqrt{2-2\,\text{Tr}(\rho^{1/2}\sigma\rho^{1/2})^{1/2}}, \tag{6.1}$$

seems to be the only other explicit formula for a geodesic distance (in the family of statistically monotone metrics).

Remark 6.2: In general it is difficult to give explicit formulas for geodesic paths of monotone metrics. In the case of the Bures metric these geodesics can be given because they are projections of large circles on a sphere in the purifying space (see Ref. 10, p. 311 and Refs. 12, 4, and 39). For a discussion of geodesics for α-connections see Refs. 27, 28.

Remark 6.3: A classical theorem classifies the spaces of costant curvature.[29] It is not known at the moment if there are other monotone metrics of costant sectional and scalar curvature.

Remark 6.4: We have seen in the commutative case that for the Levi–Civita connection of the pull-back of the square root the decomposition is available,

$$\nabla^2=\frac{1}{2}(\nabla^m+\nabla^e).$$

In the noncommutative case an analogous decomposition for the pull-back of the square root no longer holds. Indeed, on one hand, the use of Umegaki relative entropy $H(\rho,\sigma)=\mathrm{Tr}(\rho(\log\rho-\log\sigma))$ produces a similar decomposition, but for the Bogoliubov–Kubo–Mori metric.[31,1,22,33] On the other hand, if one uses $H_{wy}(\rho,\sigma)=4(1-\mathrm{Tr}(\rho^{1/2}\sigma^{1/2}))$ as a divergence on $\mathcal{D}_n^1$ and constructs the associated dualistic structure $(\langle\cdot,\cdot\rangle^{H_{wy}},\nabla^{H_{wy}},\nabla^{H_{wy}})$ (again following the lines of Refs. 14 and 1), then the construction is trivial, namely, the dual connections both coincide with the Levi–Civita connection of the Wigner–Yanase information. This is easily seen on $\mathcal{P}_n$ where $H_g(\rho,\sigma)$ reduces to Csiszar relative g-entropy: it is known that such an entropy induces the α-geometry where α is given by the formula $\alpha=3+2g'''(1)/g''(1)$ (see Ref. 1, p. 57). For $g=4(1-\sqrt{x})$ this gives $\alpha=0$, that is, the Fisher information case (see also Ref. 21).

(Received 11 March 2003; accepted 6 May 2003)

By the method of generalized spherical harmonic polynomials, the Schrödinger equation for a four-body system in *D*-dimensional space is reduced to the generalized radial equations where only six internal variables are involved. The problem on separating the rotational degrees of freedom from the internal ones for a quantum *N*-body system in *D* dimensions is generally discussed. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1599956]

I. INTRODUCTION

Recent years have witnessed a flurry of investigations into the arbitrary *D*-dimensional problems[1–5] in many branches of physical chemistry and chemical physics. The problems associated with the *D*-dimensional hydrogen atom,[6–8] the *D*-dimensional harmonic oscillator,[9–11] and the connection between the two[12–16] have been thoroughly discussed. During the past few years, with the application of dimensional scaling to the quantum theory of atomic and molecular structure, large-*D* helium problem has also been studied by many authors.[17–21] This approach requires solving the few-body Schrödinger equation in a *D*-dimensional coordinate space and has been applied to a large number of physically interesting problems.[22–25] Due to the complexity of the problem for an *N*-body system in *D* dimensions, so far there is no complete theoretical solution when $N>3$.

In our recent work,[26] a new method for separating the rotational degrees of freedom from the internal ones in a few-body system was proposed. The power of this new approach is in its ability of great simplification in calculation of energy levels of a few-body system in terms of the generalized radial equations involving only internal variables, which are derived from the Schrödinger equation without any approximation. Some typical three-body system in three-dimensional space, such as a helium atom[27–29] and a positronium negative ion[30] have been solved numerically with high precision. The key to the approach is that we have found a complete set of independent eigenfunctions of angular momentum for the system, which are homogeneous polynomials in the components of Jacobi coordinate vectors and satisfy the Laplace equation, and chosen a suitable set of internal variables. Any wave function with a given angular momentum can be expanded with respect to the basis functions where the coefficients, called the generalized radial functions, depend only upon the internal variables. The generalized radial equations satisfied by the generalized radial functions are easily derived owing to the nice property of the basis functions.[26] This method has been generalized to the arbitrary dimensional space for a three-body system.[31] The exact interdimensional degeneracies in the system can be obtained directly from the generalized radial equations.[32]

To further this study, we expect to apply this approach to an *N*-body system in *D* dimensions. As noticed in our previous paper,[31] the cases with $N<D$ are very different from the cases with

[b]Electronic mail: mazq@sun.ihep.ac.cn
[c]Electronic mail: sunjq@mail.ihep.ac.cn

$N \geqslant D$. The general formulas are hard to express uniformly due to arbitrariness of D and N. However, the main characters are manifested fully in a four-body system of D dimensions, but not fully in a three-body system. The four-body problems also play a fundamental role in nuclear and hypernuclear physics.[33–35] In this paper we will study the problem of separating the rotational degrees of freedom from the internal ones for a quantum four-body system in D dimensions in some detail. The general case (N-body system) will be summarized.

The plan of this paper is as follows: In Sec. II, after separating the motion of the center of mass by Jacobi coordinate vectors, we will define the generalized spherical harmonic polynomials for a four-body system in D dimensions and prove that they constitute a complete set of independent basis functions for a given total orbital angular momentum in the system. Some new features in comparison with the three-body case are also discussed in this section. The generalized radial equations satisfied by the generalized radial functions are established in Sec. III. In Sec. IV, we will generalize this method to separate the rotational degrees of freedom from the internal ones for an N-body system in D dimensions. Some conclusions will be given in Sec. V.

II. THE GENERALIZED SPHERICAL HARMONIC POLYNOMIALS

For a quantum N-body system in an arbitrary D-dimensional space, we denote the position vectors and the masses of N particles by $\mathbf{r}_k$ and by m_k, $k=1, 2,\ldots, N$, respectively. $M=\Sigma_k m_k$ is the total mass. The Schrödinger equation for the N-body system with a pair potential V, depending upon the distance of each pair of particles, $|\mathbf{r}_j-\mathbf{r}_k|$, is

$$-\frac{1}{2}\nabla^2\Psi+V\Psi=E\Psi, \quad \nabla^2=\sum_{k=1}^{N} m_k^{-1}\nabla_{\mathbf{r}_k}^2, \tag{1}$$

where $\nabla_{\mathbf{r}_k}^2$ is the Laplace operator with respect to the position vector $\mathbf{r}_k$. For simplicity, the natural units $\hbar=c=1$ are employed throughout this paper. The total orbital angular momentum operators L_{ab} in D dimensions are defined as[21,36]

$$L_{ab}=-L_{ba}=-i\sum_{k=1}^{N}\left\{r_{ka}\frac{\partial}{\partial r_{kb}}-r_{kb}\frac{\partial}{\partial r_{ka}}\right\}, \quad a,b=1,2,\ldots,D, \tag{2}$$

where r_{ka} denotes the ath component of the position vector $\mathbf{r}_k$. Now, we replace the position vectors $\mathbf{r}_k$ with the Jacobi coordinate vectors $\mathbf{R}_j$,

$$\mathbf{R}_0=M^{-1/2}\sum_{k=1}^{N} m_k\mathbf{r}_k, \quad \mathbf{R}_j=\left(\frac{m_{j+1}M_j}{M_{j+1}}\right)^{1/2}\left(\mathbf{r}_{j+1}-\sum_{k=1}^{j}\frac{m_k\mathbf{r}_k}{M_j}\right),$$

$$1\leqslant j\leqslant(N-1), \quad M_j=\sum_{k=1}^{j} m_k, \quad M_N=M, \tag{3}$$

where $\mathbf{R}_0$ describes the position of the center of mass, $\mathbf{R}_1$ describes the mass-weighted separation from the second particle to the first particle, $\mathbf{R}_2$ describes the mass-weighted separation from the third particle to the center of mass of the first two particles, and so on. It is straightforward to illustrate that the potential V is a function of $\mathbf{R}_j\cdot\mathbf{R}_k$ and is rotationally invariant.

In the center-of-mass frame, $\mathbf{R}_0=0$. A straightforward calculation by replacement of variables shows that the Laplace operator in Eq. (1) and the total orbital angular momentum operator L_{ab} in Eq. (2) are directly expressed in $\mathbf{R}_j$,

$$\nabla^2=\sum_{j=1}^{N-1}\nabla_{\mathbf{R}_j}^2, \quad L_{ab}=\sum_{j=1}^{N-1}L_{ab}^{(j)}=-i\sum_{j=1}^{N-1}\left\{R_{ja}\frac{\partial}{\partial R_{jb}}-R_{jb}\frac{\partial}{\partial R_{ja}}\right\},$$

$$\mathbf{L}^2=\sum_{a<b=2}^{D} L_{ab}^2, \quad (\mathbf{L}^{(j)})^2=\sum_{a<b=2}^{D} (L_{ab}^{(j)})^2. \tag{4}$$

For a four-body system, there are three Jacobi coordinate vectors $\mathbf{R}_1$, $\mathbf{R}_2$, and $\mathbf{R}_3$, which will be denoted for simplicity by $\mathbf{x}$, $\mathbf{y}$, and $\mathbf{z}$, respectively,

$$\begin{aligned}
\mathbf{x}&=\left[\frac{m_1m_2}{m_1+m_2}\right]^{1/2}\{\mathbf{r}_2-\mathbf{r}_1\},\\
\mathbf{y}&=\left[\frac{(m_1+m_2)m_3}{m_1+m_2+m_3}\right]^{1/2}\left\{\mathbf{r}_3-\frac{m_1\mathbf{r}_1+m_2\mathbf{r}_2}{m_1+m_2}\right\},\\
\mathbf{z}&=\left[\frac{(m_1+m_2+m_3+m_4)m_4}{m_1+m_2+m_3}\right]^{1/2}\mathbf{r}_4.
\end{aligned} \tag{5}$$

Hence,

$$\begin{aligned}
&\nabla^2=\nabla_{\mathbf{x}}^2+\nabla_{\mathbf{y}}^2+\nabla_{\mathbf{z}}^2, \quad L_{ab}=L_{ab}^{(x)}+L_{ab}^{(y)}+L_{ab}^{(z)},\\
&\mathbf{L}^2=\sum_{a<b=2}^{D} L_{ab}^2, \quad [\mathbf{L}^{(x)}]^2=\sum_{a<b=2}^{D} [L_{ab}^{(x)}]^2,\\
&[\mathbf{L}^{(y)}]^2=\sum_{a<b=2}^{D} [L_{ab}^{(y)}]^2, \quad [\mathbf{L}^{(z)}]^2=\sum_{a<b=2}^{D} [L_{ab}^{(z)}]^2.
\end{aligned} \tag{6}$$

The Schrödinger equation (1) for $D\geqslant N=4$ reduces to

$$\begin{aligned}
&\{\nabla_{\mathbf{x}}^2+\nabla_{\mathbf{y}}^2+\nabla_{\mathbf{z}}^2\}\Psi(\mathbf{x},\mathbf{y},\mathbf{z})=-2\{E-V(\xi_j,\eta_j,\zeta_j)\}\Psi(\mathbf{x},\mathbf{y},\mathbf{z}),\\
&\xi_1=\mathbf{x}\cdot\mathbf{x}, \quad \xi_2=\eta_1=\mathbf{x}\cdot\mathbf{y}, \quad \xi_3=\zeta_1=\mathbf{x}\cdot\mathbf{z},\\
&\eta_2=\mathbf{y}\cdot\mathbf{y}, \quad \eta_3=\zeta_2=\mathbf{y}\cdot\mathbf{z}, \quad \zeta_3=\mathbf{z}\cdot\mathbf{z},
\end{aligned} \tag{7}$$

where ξ_j, η_j, and ζ_j are internal variables. It is worth noticing that for the cases $3=D<N$ two Jacobi coordinate vectors $\mathbf{x}$ and $\mathbf{y}$ can determine the body-fixed frame and this set of internal variables is not complete because two configurations with different directions of $\mathbf{z}$ reflecting to the plane spanned by $\mathbf{x}$ and $\mathbf{y}$ are described by the same internal variables. As pointed in Ref. 26, the variable ζ_3 has to be changed to $(\mathbf{x}\times\mathbf{y})\cdot\mathbf{z}$. We will further discuss this problem in Sec. IV.

Since Eq. (7) is rotational invariant, the total orbital angular momentum is conserved. As discussed in Ref. 31, in D-dimensional space, the wave function $\Psi(\mathbf{x},\mathbf{y},\mathbf{z})$ with a given total angular momentum has to belong to an irreducible representation of SO(D), and the angular momentum is also denoted by the representation. For a four-body system, there are only three Jacobi coordinate vectors so that the possible irreducible representation is described by a three-row Young pattern $[\mu,\nu,\tau]$ of SO(D), or its highest weight $\mathbf{M}=(M_1,M_2,M_3,0,\ldots,0)$, where

$$M_1=\mu-\nu, \quad M_2=\nu-\tau, \quad M_3=\tau. \tag{8}$$

We only need to consider the highest weight state $\Psi_{\mathbf{M}}^{[\mu,\nu,\tau]}(\mathbf{x},\mathbf{y},\mathbf{z})$ because its partners can be calculated from it by the lowering operators. In this paper the highest weight state will be simply called the wave functions with the given angular momentum $[\mu,\nu,\tau]$ for simplicity.

Now we are going to find a complete set of independent eigenfunctions of total orbital angular momentum, where ''independent'' means that each one in the set cannot be expressed as a combination of the remaining with coefficients only depending on the internal variables. As discussed

in our previous paper,[31] the spherical harmonic polynomials $\mathcal{Y}^{(l)}_{\mathbf{m}}(\hat{\mathbf{x}})$ are homogeneous polynomials in the components of $\mathbf{x}$ of degree l, spanning an irreducible traceless tensor space described by the Young pattern $(l)\equiv[l,0,0]$. When $D>6$, the explicit forms for some polynomials with higher weights $\mathbf{m}$ are as follows:[37]

$$\begin{aligned}
\mathcal{Y}^{(l)}_{(l)}(\mathbf{x}) &= N_{D,l}(x_1+ix_2)^l,\\
\mathcal{Y}^{(l)}_{(l-2,1,0,\ldots,0)}(\mathbf{x}) &= -\sqrt{l}N_{D,l}(x_1+ix_2)^{l-1}(x_3+ix_4),\\
\mathcal{Y}^{(l)}_{(l-4,2,0,\ldots,0)}(\mathbf{x}) &= \sqrt{l(l-1)/2}N_{D,l}(x_1+ix_2)^{l-2}(x_3+ix_4)^2,
\end{aligned} \tag{9}$$

where the last equality holds for $l>1$, and $N_{D,l}$ denotes the normalization factor given in Ref. 37. The product of two spherical harmonic polynomials $\mathcal{Y}^{(l)}_{\mathbf{m}}(\hat{\mathbf{x}})$ and $\mathcal{Y}^{(l')}_{\mathbf{m}'}(\hat{\mathbf{y}})$ belongs to the direct product of two representation (l) and (l'), which is a reducible representation. It can be reduced by the Littlewood–Richardson rule and contraction of a pair of x_a and y_a, where the latter relates to the internal variables,

$$(l)\otimes(l')\simeq \bigoplus_{s=0}^{\min\{l,l'\}} \bigoplus_{t=0}^{\min\{l,l'\}-s} [l+l'-s-2t,s,0]. \tag{10}$$

Since a basis function containing a factor depending on internal variables is not independent, only those representations $[l+l'-s,s,0]$ [$t=0$ in Eq. (10)] calculated by the Littlewood–Richardson rule are related to the independent basis functions.[31] Calculating by the Clebsch–Gordan coefficients and removing the normalization factor, we obtain the independent basis functions for the representations $[l+l'-s,s,0]$, called the generalized spherical harmonic polynomial $Q_l^{(l+l'-s)s}(\mathbf{x},\mathbf{y})$. Changing the parameters $\mu=l+l'-s$, $\nu=s$, and $q=l$, we define the generalized spherical harmonic polynomial $Q_q^{\mu\nu}(\mathbf{x},\mathbf{y})$ for the representation $[\mu,\nu]$ (Ref. 31) as

$$\begin{aligned}
Q_q^{\mu\nu}(\mathbf{x},\mathbf{y}) &= \frac{X_{12}^{q-\nu}Y_{12}^{\mu-q}}{(q-\nu)!(\mu-q)!}(X_{12}Y_{34}-Y_{12}X_{34})^{\nu}, \quad 0\leqslant\nu\leqslant q\leqslant\mu,\\
X_{12} &= x_1+ix_2, \quad X_{34}=x_3+ix_4, \quad Y_{12}=y_1+iy_2, \quad Y_{34}=y_3+iy_4.
\end{aligned} \tag{11}$$

For the product of three spherical harmonic polynomials, Eq. (10) is generalized to

$$(l)\otimes(l')\otimes(l'')\simeq \bigoplus_{r=0}^{\min\{l,l'\}} \bigoplus_{\nu=r}^{\min\{(l+l'-r),(r+l'')\}} \bigoplus_{\tau=0}^{\min\{r,(l''-\nu+r)\}} [l+l'+l''-\nu-\tau,\nu,\tau]\oplus\cdots. \tag{12}$$

The ellipsis denotes those representations related to the basis functions which are not independent.

Filling the digits 1, 2, and 3 arbitrarily into a given Young pattern $[\mu,\nu,\tau]$ ($\mu\geqslant\nu\geqslant\tau$) we obtain a young tableau. A Young tableau is called standard if the digit in every column of the tableau increases downwards and the digit in every row does not decrease from left to right. In fact, the digits "1," "2," and "3" denote the components of $\mathbf{x}$, $\mathbf{y}$, and $\mathbf{z}$, respectively. Obviously, the representation $[l+l'+l''-\nu-\tau,\nu,\tau]$ listed in Eq. (12) corresponds to a standard Young tableau, where the number of digit "1" in the first row is l, the numbers of digit "2" in the first and the second rows are respectively $(l'-r)$ and r, and the numbers of digit "3" in the first, second, and third rows are, respectively, $(l''+r-\nu-\tau)$, $\nu-r$, and τ. The basis functions in the remaining representation spaces, which correspond to nonstandard Young tableaux, are not independent.

For a given pattern $[\mu,\nu,\tau]$, each standard Young tableau is determined by three parameters q, p, and r, where q is the number of digit "1" in the first row, p and r are the numbers of digit "2"

in the first and the second rows, respectively. q, p, and r should satisfy the constraints, $\tau \leqslant r \leqslant q$ and $r \leqslant \nu \leqslant q+p \leqslant \mu$. The number of standard Young tableaux for the given Young pattern $[\mu,\nu,\tau]$ is equal to the dimension of the representation $[\mu,\nu,\tau]$ of the SU(3) group,

$$d_{[\mu,\nu,\tau]}(\mathrm{SU}(3)) = \tfrac{1}{2}(\mu-\tau+2)(\nu-\tau+1)(\mu-\nu+1). \tag{13}$$

For a given representation $[\mu,\nu,\tau]$ of SO(D), each standard Young tableau denoted by (q,p,r) corresponds to a representation space. The highest weight state in the representation space (q,p,r) is the generalized spherical harmonic polynomial $Q^{\mu\nu\tau}_{qpr}(\mathbf{x},\mathbf{y},\mathbf{z})$,

$$Q^{\mu\nu\tau}_{qpr}(\mathbf{x},\mathbf{y},\mathbf{z}) = \begin{cases} \dfrac{X_{12}^{q-\nu} Y_{12}^{p} Z_{12}^{\mu-q-p} T_{12}^{r-\tau} T_{13}^{\nu-r} T^{\tau}}{(q-\nu)!\,p!\,(\mu-q-p)!\,(r-\tau)!\,(\nu-r)!}, & \text{when } q \geqslant \nu, \\ \dfrac{Y_{12}^{q+p-\nu} Z_{12}^{\mu-q-p} T_{12}^{r-\tau} T_{13}^{q-r} T_{23}^{\nu-q} T^{\tau}}{(q+p-\nu)!\,(\mu-q-p)!\,(r-\tau)!\,(q-r)!\,(\nu-q)!}, & \text{when } q < \nu, \end{cases}$$

$$\tau \leqslant r \leqslant q, \quad r \leqslant \nu \leqslant q+p \leqslant \mu,$$

$$X_{12} = x_1 + i x_2, \quad Y_{12} = y_1 + i y_2, \quad Z_{12} = z_1 + i z_2,$$

$$X_{34} = x_3 + i x_4, \quad Y_{34} = y_3 + i y_4, \quad Z_{34} = z_3 + i z_4,$$

$$X_{56} = x_5 + i x_6, \quad Y_{56} = y_5 + i y_6, \quad Z_{56} = z_5 + i z_6,$$

$$T_{12} = X_{12}Y_{34} - X_{34}Y_{12}, \quad T_{13} = X_{12}Z_{34} - X_{34}Z_{12}, \quad T_{23} = Y_{12}Z_{34} - Y_{34}Z_{12},$$

$$T = X_{12}Y_{34}Z_{56} + X_{34}Y_{56}Z_{12} + X_{56}Y_{12}Z_{34} - X_{12}Y_{56}Z_{34} - X_{34}Y_{12}Z_{56} - X_{56}Y_{34}Z_{12}. \tag{14}$$

It is evident that $Q^{\mu\nu\tau}_{qpr}(\mathbf{x},\mathbf{y},\mathbf{z})$ do not contain a function of the internal variables as a factor, nor do their partners due to the rotational symmetry. Therefore, $Q^{\mu\nu\tau}_{qpr}(\mathbf{x},\mathbf{y},\mathbf{z})$ are independent basis functions for the given angular momentum described by $[\mu,\nu,\tau]$. Due to Eq. (12), the set of $Q^{\mu\nu\tau}_{qpr}(\mathbf{x},\mathbf{y},\mathbf{z})$ is complete. The reason why the generalized spherical harmonic polynomial denoted by a nonstandard Young tableau is not independent can be seen from the following identity:

$$T_{23}X_{12} = T_{13}Y_{12} - T_{12}Z_{12}, \quad \begin{array}{|c|c|}\hline 2 & 1 \\ \hline 3 \\ \cline{1-1} \end{array} = \begin{array}{|c|c|}\hline 1 & 2 \\ \hline 3 \\ \cline{1-1} \end{array} - \begin{array}{|c|c|}\hline 1 & 3 \\ \hline 2 \\ \cline{1-1} \end{array}. \tag{15}$$

This identity is similar to the Fock's cyclic symmetry condition.[38] The left-hand side of Eq. (15) corresponds to a nonstandard Young tableau, and two terms in the right-hand side correspond to two standard Young tableaux, respectively.

Since the problem on completeness of the set is very important, we are going to prove this problem by another method. On the one hand, because the basis function $Q^{\mu\nu\tau}_{qpr}(\mathbf{x},\mathbf{y},\mathbf{z})$ is a homogeneous polynomial of degree $\mu+\nu+\tau$ in the components of $\mathbf{x}$, $\mathbf{y}$, and $\mathbf{z}$, we calculate the number $R_D(l)$ of basis functions in the sets for the representations $[\mu,\nu,\tau]$ with $\mu+\nu+\tau=l$. Namely, we want to calculate how many homogeneous polynomials of degree l exist in the sets of the independent basis functions. We first calculate how many basis functions exist in the set for a given representation $[\mu,\nu,\tau]$. The dimension of the representation $[\mu,\nu,\tau]$ of SO(D) is $d_D([\mu,\nu,\tau])$,

$$\begin{aligned} d_D([\mu,\nu,\tau]) = {} & (D+2\mu-2)(D+\mu+\nu-3)(D+\mu+\tau-4)(D+2\nu-4) \\ & \times (D+\nu+\tau-5)(D+2\tau-6)(\mu-\tau+2)(\mu-\nu+1)(\nu-\tau+1) \\ & \times \frac{(D+\mu-5)!\,(D+\nu-6)!\,(D+\tau-7)!}{(D-2)!\,(D-4)!\,(D-6)!\,(\mu+2)!\,(\nu+1)!\,\tau!}. \end{aligned} \tag{16}$$

Thus, the number of basis functions in the set for the representation $[\mu,\nu,\tau]$ is $d_{[\mu,\nu,\tau]}(\mathrm{SU}(3))d_D(\mu,\nu,\tau)$. Then, the number $R_D(l)$ of basis functions in the sets for the representation $[\mu,\nu,\tau]$ with $\mu+\nu+\tau=l$ is

$$R_D(l)=\sum_{\tau=0}^{[l/3]}\sum_{\nu=\tau}^{[(l-\tau)/2]} d_{[(l-\nu-\tau),\nu,\tau]}(\mathrm{SU}(3))d_D([(l-\nu-\tau),\nu,\tau]), \tag{17}$$

where $[x]$ denotes the largest integer less than or equal to x.

On the other hand, the number of linear independent homogeneous polynomials of degree l in the components of $\mathbf{x}$, $\mathbf{y}$, and $\mathbf{z}$ is $M_D(l)$,

$$M_D(l)=\begin{pmatrix} l+3D-1 \\ 3D-1 \end{pmatrix}.$$

After removing those polynomials in the form $\xi_j f(\mathbf{x},\mathbf{y},\mathbf{z})$, $\eta_j f(\mathbf{x},\mathbf{y},\mathbf{z})$, and $\zeta_j f(\mathbf{x},\mathbf{y},\mathbf{z})$, where $f(\mathbf{x},\mathbf{y},\mathbf{z})$ is a polynomial of degree $(l-2)$, the number $M_D(l)$ reduces to $K_D(l)$,

$$\begin{aligned} K_D(l)=&\ M_D(l)-6M_D(l-2)+15M_D(l-4)-20M_D(l-6)+15M_D(l-8) \\ &-6M_D(l-10)+M_D(l-12) \\ =&\{(3D-7)(3D-8)(3D-9)(3D-10)(3D-11)(3D-12)+12l(D-4) \\ &\times[72+(3D-10)(3D-11)(27D^2-153D+236)]+4l^2[184+45(D-4)(3D-11) \\ &\times(9D^2-57D+98)]+480l^3(D-4)(9D^2-63D+126)+80l^4(27D^2-207D+404) \\ &+576l^5(D-4)+64l^6\}\frac{(l+3D-13)!}{l!(3D-7)!}, \end{aligned} \tag{18}$$

where $l+3D\geqslant 13$ and $K_4(0)=1$. It is checked by MATHEMATICA that

$$R_D(l)=K_D(l). \tag{19}$$

Thus, we have proved again that $d_{[\mu,\nu,\tau]}(\mathrm{SU}(3))$ polynomials $Q^{\mu\nu\tau}_{qpr}(\mathbf{x},\mathbf{y},\mathbf{z})$ construct a complete set of independent basis functions for the angular momentum $[\mu,\nu,\tau]$.

The generalized spherical harmonic polynomial $Q^{\mu\nu\tau}_{qpr}(\mathbf{x},\mathbf{y},\mathbf{z})$ is a homogeneous polynomial of degrees q, $(p+r)$ and $(\mu+\nu+\tau-q-p-r)$ in the components of $\mathbf{x}$, $\mathbf{y}$, and $\mathbf{z}$, respectively. It is a simultaneous eigenfunction of $\nabla^2_{\mathbf{x}}$, $\nabla^2_{\mathbf{y}}$, $\nabla^2_{\mathbf{z}}$, $\nabla_{\mathbf{x}}\cdot\nabla_{\mathbf{y}}$, $\nabla_{\mathbf{x}}\cdot\nabla_{\mathbf{z}}$, $\nabla_{\mathbf{y}}\cdot\nabla_{\mathbf{z}}$, and the angular momentum operators $\mathbf{L}^2$, $[\mathbf{L}^{(x)}]^2$, $[\mathbf{L}^{(y)}]^2$, $[\mathbf{L}^{(z)}]^2$,

$$\nabla^2_{\mathbf{x}}Q^{\mu\nu\tau}_{qpr}(\mathbf{x},\mathbf{y},\mathbf{z})=\nabla^2_{\mathbf{y}}Q^{\mu\nu\tau}_{qpr}(\mathbf{x},\mathbf{y},\mathbf{z})=\nabla^2_{\mathbf{z}}Q^{\mu\nu\tau}_{qpr}(\mathbf{x},\mathbf{y},\mathbf{z})=0,$$

$$\nabla_{\mathbf{x}}\cdot\nabla_{\mathbf{y}}Q^{\mu\nu\tau}_{qpr}(\mathbf{x},\mathbf{y},\mathbf{z})=\nabla_{\mathbf{x}}\cdot\nabla_{\mathbf{z}}Q^{\mu\nu\tau}_{qpr}(\mathbf{x},\mathbf{y},\mathbf{z})=\nabla_{\mathbf{y}}\cdot\nabla_{\mathbf{z}}Q^{\mu\nu\tau}_{qpr}(\mathbf{x},\mathbf{y},\mathbf{z})=0,$$

$$\mathbf{L}^2Q^{\mu\nu\tau}_{qpr}(\mathbf{x},\mathbf{y},\mathbf{z})=C_2([\mu,\nu,\tau])Q^{\mu\nu\tau}_{qpr}(\mathbf{x},\mathbf{y},\mathbf{z}),$$

$$C_2([\mu,\nu,\tau])=\mu(\mu+D-2)+\nu(\nu+D-4)+\tau(\tau+D-6), \tag{20}$$

$$[\mathbf{L}^{(x)}]^2Q^{\mu\nu\tau}_{qpr}(\mathbf{x},\mathbf{y},\mathbf{z})=q(q+D-2)Q^{\mu\nu\tau}_{qpr}(\mathbf{x},\mathbf{y},\mathbf{z}),$$

$$[\mathbf{L}^{(y)}]^2Q^{\mu\nu\tau}_{qpr}(\mathbf{x},\mathbf{y},\mathbf{z})=(p+r)(p+r+D-2)Q^{\mu\nu\tau}_{qpr}(\mathbf{x},\mathbf{y},\mathbf{z}),$$

$$[\mathbf{L}^{(z)}]^2Q^{\mu\nu\tau}_{qpr}(\mathbf{x},\mathbf{y},\mathbf{z})=(\mu+\nu+\tau-q-p-r)(\mu+\nu+\tau-q-p-r+D-2)\times Q^{\mu\nu\tau}_{qpr}(\mathbf{x},\mathbf{y},\mathbf{z}),$$

where $C_2([\mu,\nu])$ is the Casimir invariant calculated by a general formula [see (1.131) in Ref. 39]. The parity of $Q_{qpr}^{\mu\nu\tau}(\mathbf{x},\mathbf{y},\mathbf{z})$ is obviously equal to $(-1)^{\mu+\nu+\tau}$.

Now, we turn to discuss the case $D\leqslant 6$. As is well known, the irreducible traceless tensor space of SO(D) described by a Young pattern has the following properties. It is a null space if sum of the lengths of the first two columns of the Young pattern is larger than D. It reduces into the selfdual and antiselfdual tensor spaces if the row number of the Young pattern is equal to $D/2$. Two representations are equivalent if their Young patterns are the same as each other except for the first column and the sum of their row numbers is equal to D. Those properties cause the situation for $D\leqslant 6$ different from that for $D>6$.

When $D=6$, there is no problem for the representation $[\mu,\nu,\tau]$ with $\tau=0$, but when $\tau\neq 0$, the representation is reducible. We denote the generalized spherical harmonic polynomials for the self-dual and anti-self-dual representations by $Q_{qpr}^{(S)\mu\nu\tau}(\mathbf{x},\mathbf{y},\mathbf{z})$ and $Q_{qpr}^{(A)\mu\nu\tau}(\mathbf{x},\mathbf{y},\mathbf{z})$, respectively. $Q_{qpr}^{(S)\mu\nu\tau}(\mathbf{x},\mathbf{y},\mathbf{z})$ is the same as that given in Eq. (14), and $Q_{qpr}^{(A)\mu\nu\tau}(\mathbf{x},\mathbf{y},\mathbf{z})$ can be obtained from $Q_{qpr}^{(S)\mu\nu\tau}(\mathbf{x},\mathbf{y},\mathbf{z})$ by replacing X_{56}, Y_{56}, and Z_{56} with X'_{56}, Y'_{56}, and Z'_{56},

$$X'_{56}=x_5-ix_6,\quad Y'_{56}=y_5-iy_6,\quad Z'_{56}=z_5-iz_6. \tag{21}$$

The formula (16) for the dimension of the representation $[\mu,\nu,\tau]$ of SO(D) holds for $D=6$ when $\tau=0$. When $\tau\neq 0$, $d_D([\mu,\nu,\tau])$ in Eq. (16) is equal to the sum of the dimensions of the self-dual and antiselfdual representations such that the equality (19) still holds for $D=6$.

When $D=5$, in the possible Young pattern $[\mu,\nu,\tau]$, τ has to be 0 or 1. The representation $[\mu,\nu,1]$ is equivalent to the representation $[\mu,\nu,0]$. Their dimensions calculated from Eq. (16) are also the same. The generalized spherical harmonic polynomials $Q_{qpr}^{\mu\nu\tau}(\mathbf{x},\mathbf{y},\mathbf{z})$ given in Eq. (14) hold for $D=5$ except for $x_6=y_6=z_6=0$ and $\tau=0$ or 1. Therefore, the equality (19) holds for $D=5$.

For $D=3$, two Jacobi coordinate vectors, say $\mathbf{x}$ and $\mathbf{y}$, can completely determine the body-fixed frame so that the variables ζ_3 has to be changed as $(\mathbf{x}\times\mathbf{y})\cdot\mathbf{z}$ in order to distinguish two configurations with different directions of $\mathbf{z}$. We have discussed in detail the four-body system in three dimensions in our previous paper.[26]

The case of $D=4$ is quite complicated because SO(4) is not a simple group. The representation $[\mu,\nu,0]$ reduces to a direct sum of a self-dual representation $[(S)\mu,\nu,0]$ and an anti-self-dual one $[(A)\mu,\nu,0]$. The generalized spherical harmonic polynomials $Q_{qpr}^{(S)\mu\nu 0}(\mathbf{x},\mathbf{y},\mathbf{z})$ for the self-dual representations is the same as $Q_{qpr}^{\mu\nu\tau}(\mathbf{x},\mathbf{y},\mathbf{z})$ with $\tau=0$ given in Eq. (14). The generalized spherical harmonic polynomials $Q_{qpr}^{(A)\mu\nu 0}(\mathbf{x},\mathbf{y},\mathbf{z})$ for the anti-self-dual representation can be obtained from $Q_{qpr}^{(S)\mu\nu 0}(\mathbf{x},\mathbf{y},\mathbf{z})$ by replacing X_{34}, Y_{34}, and Z_{34} with X'_{34}, Y'_{34}, and Z'_{34},

$$X'_{34}=x_3-ix_4,\quad Y'_{34}=y_3-iy_4,\quad Z'_{34}=z_3-iz_4. \tag{22}$$

If $\tau=1$, then $\nu=1$ and the representation $[\mu,1,1]$ is equivalent to the representation $[\mu,0,0]$. The standard Young tableau is described by the parameters q and p $(r=1)$, where q and p are, respectively, the numbers of digits ''1'' and ''2'' in the first row of the Young tableau. The generalized spherical harmonic polynomials for two representations $[\mu,\lambda,\lambda]$, $\lambda=0$, or 1, are

$$Q_{qp}^{\mu\lambda\lambda}(\mathbf{x},\mathbf{y},\mathbf{z})=\frac{X_{12}^{q-\lambda}Y_{12}^{p}Z_{12}^{\mu-q-p}T^{\lambda}}{(q-\lambda)!p!(\mu-q-p)!},$$

$$T=X_{12}Y_{34}Z'_{34}+X_{34}Y'_{34}Z_{12}+X'_{34}Y_{12}Z_{34}-X_{12}Y'_{34}Z_{34}-X_{34}Y_{12}Z'_{34}-X'_{34}Y_{34}Z_{12}. \tag{23}$$

The surprising thing is that Eq. (19) is not satisfied for $D=4$ and $l\geqslant 6$. For example,

$l=$	6	7	8	9	10
$R_4(l)$	5346	10908	20550	36332	60996
$K_4(l)$	5336	10836	20256	35436	58728.

(24)

The reason is that the formula (18) for $K_D(l)$ does not hold for $D=4$ and $l\geqslant 6$. For $D=4$ we find an identity with respect to the polynomials of degree 6 checked by MATHEMATICA,

$$\xi_1 T_{23}^2+\eta_2 T_{13}^2+\zeta_3 T_{12}^2-2\xi_2 T_{13}T_{23}+2\xi_3 T_{12}T_{23}-2\eta_3 T_{12}T_{13}=0. \tag{25}$$

The identity obtained from Eq. (25) by replacing X_{34}, Y_{34}, and Z_{34}, respectively, with X'_{34}, Y'_{34}, and Z'_{34} still holds. Those equalities obtained by applying the lowering operators and (or) by multiplying a factor to above two identities are also identities. Thus, the forms $\xi_j f(\mathbf{x},\mathbf{y},\mathbf{z})$, $\eta_j f(\mathbf{x},\mathbf{y},\mathbf{z})$, and $\zeta_j f(\mathbf{x},\mathbf{y},\mathbf{z})$, where $f(\mathbf{x},\mathbf{y},\mathbf{z})$ is a homogeneous polynomial of $\mathbf{x}$, $\mathbf{y}$, and $\mathbf{z}$ of degree $(l-2)$, are not independent when $l\geqslant 6$. It is easy to count by MATHEMATICA that the revised $K_4(l)$ by considering the identities coincides with $R_4(l)$.

III. GENERALIZED RADIAL EQUATIONS

In the preceding section we proved that $d_{[\mu,\nu,\tau]}(\mathrm{SU}(3))$ polynomials $Q_{qpr}^{\mu\nu\tau}(\mathbf{x},\mathbf{y},\mathbf{z})$ construct a complete set of independent basis functions for the angular momentum $[\mu,\nu,\tau]$. Thus, any function $\Psi_{\mathbf{M}}^{[\mu,\nu,\tau]}(\mathbf{x},\mathbf{y},\mathbf{z})$ with angular momentum $[\mu,\nu,\tau]$ in the system can be expanded with respect to the basis functions $Q_{qpr}^{\mu\nu\tau}(\mathbf{x},\mathbf{y},\mathbf{z})$, where the coefficients are functions of internal variables,

$$\Psi_{\mathbf{M}}^{[\mu,\nu,\tau]}(\mathbf{x},\mathbf{y},\mathbf{z})=\sum_{q=\tau}^{\mu}\sum_{p=\max\{(\nu-q),0\}}^{\mu-q}\sum_{r=\tau}^{\min\{q,\nu\}}\psi_{qpr}^{\mu\nu\tau}(\xi_j,\eta_j,\zeta_j)Q_{qpr}^{\mu\nu\tau}(\mathbf{x},\mathbf{y},\mathbf{z}), \tag{26}$$

where the coefficients $\psi_{qpr}^{\mu\nu\tau}(\xi_j,\eta_j,\zeta_j)$ are called the generalized radial functions. When substituting Eq. (26) into the Schrödinger equation (5), the main calculation is to apply the Laplace operator (4) to the function $\Psi_{\mathbf{M}}^{[\mu,\nu,\tau]}(\mathbf{x},\mathbf{y},\mathbf{z})$. The calculation consists of three parts. In the following, we remove the arguments (ξ_j,η_j,ζ_j) and $(\mathbf{x},\mathbf{y},\mathbf{z})$ for simplicity. The first is to apply the Laplace operator to the generalized radial functions $\psi_{qpr}^{\mu\nu\tau}(\xi_j,\eta_j,\zeta_j)$, which can be calculated by replacement of variables,

$$\begin{aligned}\nabla^2\psi_{qpr}^{\mu\nu\tau}=&\{4\xi_1\partial_{\xi_1}^2+4\eta_2\partial_{\eta_2}^2+4\zeta_3\partial_{\zeta_3}^2+2D(\partial_{\xi_1}+\partial_{\eta_2}+\partial_{\zeta_3})+(\xi_1+\eta_2)\partial_{\xi_2}^2\\&+(\xi_1+\zeta_3)\partial_{\xi_3}^2+(\eta_2+\zeta_3)\partial_{\eta_3}^2+4\xi_2(\partial_{\xi_1}+\partial_{\eta_2})\partial_{\xi_2}+4\xi_3(\partial_{\xi_1}+\partial_{\zeta_3})\partial_{\xi_3}\\&+4\eta_3(\partial_{\eta_2}+\partial_{\zeta_3})\partial_{\eta_3}+2\eta_3\partial_{\xi_2}\partial_{\xi_3}+2\xi_3\partial_{\xi_2}\partial_{\eta_3}+2\xi_2\partial_{\xi_3}\partial_{\eta_3}\}\psi_{qpr}^{\mu\nu\tau},\end{aligned} \tag{27}$$

where ∂_ξ denotes $\partial/\partial\xi$ and so on. The second is to apply the Laplace operator to the generalized spherical harmonic polynomials $Q_{qpr}^{\mu\nu\tau}$. This part is vanishing because $Q_{qpr}^{\mu\nu\tau}$ satisfies the Laplace equation. The last is the mixed application

$$\begin{aligned}&2\{(\partial_{\xi_1}\psi_{qpr}^{\mu\nu\tau})2\mathbf{x}+(\partial_{\xi_2}\psi_{qpr}^{\mu\nu\tau})\mathbf{y}+(\partial_{\xi_3}\psi_{qpr}^{\mu\nu\tau})\mathbf{z}\}\cdot\nabla_{\mathbf{x}}Q_{qpr}^{\mu\nu\tau}+2\{(\partial_{\xi_2}\psi_{qpr}^{\mu\nu\tau})\mathbf{x}+(\partial_{\eta_2}\psi_{qpr}^{\mu\nu\tau})2\mathbf{y}\\&+(\partial_{\eta_3}\psi_{qpr}^{\mu\nu\tau})\mathbf{z}\}\cdot\nabla_{\mathbf{y}}Q_{qpr}^{\mu\nu\tau}+2\{(\partial_{\xi_3}\psi_{qpr}^{\mu\nu\tau})\mathbf{x}+(\partial_{\eta_3}\psi_{qpr}^{\mu\nu\tau})\mathbf{y}+(\partial_{\zeta_3}\psi_{qpr}^{\mu\nu\tau})2\mathbf{z}\}\cdot\nabla_{\mathbf{z}}Q_{qpr}^{\mu\nu\tau}.\end{aligned} \tag{28}$$

From the definition (14) for $Q_{qpr}^{\mu\nu\tau}$ we have

$$\mathbf{x}\cdot\nabla_{\mathbf{x}}Q_{qpr}^{\mu\nu\tau}=qQ_{qpr}^{\mu\nu\tau},\quad \mathbf{y}\cdot\nabla_{\mathbf{y}}Q_{qpr}^{\mu\nu\tau}=(p+r)Q_{qpr}^{\mu\nu\tau},$$

$$\mathbf{z}\cdot\nabla_{\mathbf{z}}Q_{qpr}^{\mu\nu\tau}=(\mu+\nu+\tau-q-p-r)Q_{qpr}^{\mu\nu\tau},$$

$$\mathbf{y}\cdot\nabla_{\mathbf{x}}Q_{qpr}^{\mu\nu\tau}=\begin{cases}\dfrac{(p+1)(q-r)}{q-\nu}Q_{(q-1)(p+1)r}^{\mu\nu\tau}-\dfrac{(\mu-q-p+1)(r-\tau+1)}{q-\nu}Q_{(q-1)p(r+1)}^{\mu\nu\tau},\\ \quad\text{when}\quad q>\nu,\\ (\nu-q+1)Q_{(q-1)(p+1)r}^{\mu\nu\tau},\quad\text{when}\quad q\leqslant\nu,\end{cases}$$

$$\mathbf{x}\cdot\nabla_{\mathbf{y}}Q^{\mu\nu\tau}_{qpr}=\begin{cases}(q-\nu+1)Q^{\mu\nu\tau}_{(q+1)(p-1)r}, & \text{when } q\geqslant\nu,\\ \dfrac{p(q-r+1)}{\nu-q}Q^{\mu\nu\tau}_{(q+1)(p-1)r}-\dfrac{(\mu-q-p+1)(r-\tau+1)}{\nu-q}Q^{\mu\nu\tau}_{(q+1)(p-2)(r+1)}, & \text{when } q<\nu,\end{cases}$$

$$\mathbf{z}\cdot\nabla_{\mathbf{x}}Q^{\mu\nu\tau}_{qpr}=\begin{cases}\dfrac{(\mu-q-p+1)(q-\nu+r-\tau)}{q-\nu}Q^{\mu\nu\tau}_{(q-1)pr}-\dfrac{(p+1)(\nu-r+1)}{q-\nu}\\ \quad\times Q^{\mu\nu\tau}_{(q-1)(p+1)(r-1)}, & \text{when } q>\nu,\\ -(\nu-q+1)Q^{\mu\nu\tau}_{(q-1)(p+1)(r-1)}, & \text{when } q\leqslant\nu,\end{cases}$$

$$\mathbf{x}\cdot\nabla_{\mathbf{z}}Q^{\mu\nu\tau}_{qpr}=\begin{cases}(q-\nu+1)Q^{\mu\nu\tau}_{(q+1)pr}, & \text{when } q\geqslant\nu,\\ \dfrac{(q+p-\nu+1)(q-r+1)}{\nu-q}Q^{\mu\nu\tau}_{(q+1)pr}-\dfrac{(r-\tau+1)(\mu+\nu-2q-p)}{\nu-q}\\ \quad\times Q^{\mu\nu\tau}_{(q+1)(p-1)(r+1)}, & \text{when } q<\nu,\end{cases}$$

$$\mathbf{z}\cdot\nabla_{\mathbf{y}}Q^{\mu\nu\tau}_{qpr}=\begin{cases}(\mu-q-p+1)Q^{\mu\nu\tau}_{q(p-1)r}+(\nu-r+1)Q^{\mu\nu\tau}_{qp(r-1)}, & \text{when } q\geqslant\nu,\\ (\mu-q-p+1)Q^{\mu\nu\tau}_{q(p-1)r}+(q-r+1)Q^{\mu\nu\tau}_{qp(r-1)}, & \text{when } q<\nu,\end{cases}$$

$$\mathbf{y}\cdot\nabla_{\mathbf{z}}Q^{\mu\nu\tau}_{qpr}=\begin{cases}(p+1)Q^{\mu\nu\tau}_{q(p+1)r}+(r-\tau+1)Q^{\mu\nu\tau}_{qp(r+1)}, & \text{when } q\geqslant\nu,\\ (q+p-\nu+1)Q^{\mu\nu\tau}_{q(p+1)r}+(r-\tau+1)Q^{\mu\nu\tau}_{qp(r+1)}, & \text{when } q<\nu.\end{cases}\tag{29}$$

Hence, we obtain the generalized radial equation, satisfied by the functions $\psi^{\mu\nu\tau}_{qpr}(\xi,\eta,\zeta)$,

$$\begin{aligned}&\nabla^2\psi^{\mu\nu\tau}_{qpr}+4q\partial_{\xi_1}\psi^{\mu\nu\tau}_{qpr}+4(p+r)\partial_{\eta_2}\psi^{\mu\nu\tau}_{qpr}+4(\mu+\nu+\tau-p-q-r)\partial_{\zeta_3}\psi^{\mu\nu\tau}_{qpr}\\ &\quad+\frac{2p(q-r+1)}{q-\nu+1}\partial_{\xi_2}\psi^{\mu\nu\tau}_{(q+1)(p-1)r}-\frac{2(\mu-q-p)(r-\tau)}{q-\nu+1}\partial_{\xi_2}\psi^{\mu\nu\tau}_{(q+1)p(r-1)}\\ &\quad+2(q-\nu)\partial_{\xi_2}\psi^{\mu\nu\tau}_{(q-1)(p+1)r}+\frac{2(\mu-q-p)(q-\nu+r-\tau+1)}{q-\nu+1}\partial_{\xi_3}\psi^{\mu\nu\tau}_{(q+1)pr}-\frac{2p(\nu-r)}{q-\nu+1}\\ &\quad\times\partial_{\xi_3}\psi^{\mu\nu\tau}_{(q+1)(p-1)(r+1)}+2(q-\nu)\partial_{\xi_3}\psi^{\mu\nu\tau}_{(q-1)pr}+2(\mu-q-p)\partial_{\eta_3}\psi^{\mu\nu\tau}_{q(p+1)r}+2(\nu-r)\\ &\quad\times\partial_{\eta_3}\psi^{\mu\nu\tau}_{qp(r+1)}+2p\partial_{\eta_3}\psi^{\mu\nu\tau}_{q(p-1)r}+2(r-\tau)\partial_{\eta_3}\psi^{\mu\nu\tau}_{qp(r-1)}=-2(E-V)\psi^{\mu\nu\tau}_{qpr},\quad\text{for } q>\nu,\end{aligned}\tag{30a}$$

$$\begin{aligned}&\nabla^2\psi^{\mu\nu\tau}_{qpr}+4q\partial_{\xi_1}\psi^{\mu\nu\tau}_{qpr}+4(p+r)\partial_{\eta_2}\psi^{\mu\nu\tau}_{qpr}+4(\mu+\tau-p-r)\partial_{\zeta_3}\psi^{\mu\nu\tau}_{qpr}+2p(q-r+1)\partial_{\xi_2}\psi^{\mu\nu\tau}_{(q+1)(p-1)r}\\ &\quad-2(\mu-q-p)(r-\tau)\partial_{\xi_2}\psi^{\mu\nu\tau}_{(q+1)p(r-1)}+2(p+1)(q-r)\partial_{\xi_2}\psi^{\mu\nu\tau}_{(q-1)(p+1)r}-2(\mu-q-p)(r-\tau)\\ &\quad\times\partial_{\xi_2}\psi^{\mu\nu\tau}_{(q-1)(p+2)(r-1)}+2(\mu-q-p)(r-\tau+1)\partial_{\xi_3}\psi^{\mu\nu\tau}_{(q+1)pr}-2p(q-r)\partial_{\xi_3}\psi^{\mu\nu\tau}_{(q+1)(p-1)(r+1)}\\ &\quad+2p(q-r)\partial_{\xi_3}\psi^{\mu\nu\tau}_{(q-1)pr}-2(r-\tau)(\mu-q-p+1)\partial_{\xi_3}\psi^{\mu\nu\tau}_{(q-1)(p+1)(r-1)}+2(\mu-q-p)\\ &\quad\times\partial_{\eta_3}\psi^{\mu\nu\tau}_{q(p+1)r}+2(q-r)\partial_{\eta_3}\psi^{\mu\nu\tau}_{qp(r+1)}+2p\partial_{\eta_3}\psi^{\mu\nu\tau}_{q(p-1)r}+2(r-\tau)\partial_{\eta_3}\psi^{\mu\nu\tau}_{qp(r-1)}\\ &\quad=-2(E-V)\psi^{\mu\nu\tau}_{qpr},\quad\text{for } q=\nu,\end{aligned}\tag{30b}$$

$$\nabla^2\psi^{\mu\nu\tau}_{qpr}+4q\partial_{\xi_1}\psi^{\mu\nu\tau}_{qpr}+4(p+r)\partial_{\eta_2}\psi^{\mu\nu\tau}_{qpr}+4(\mu+\nu+\tau-p-q-r)\partial_{\zeta_3}\psi^{\mu\nu\tau}_{qpr}+2(\nu-q)$$
$$\times\partial_{\xi_2}\psi^{\mu\nu\tau}_{(q+1)(p-1)r}+\frac{2(p+1)(q-r)}{\nu-q+1}\partial_{\xi_2}\psi^{\mu\nu\tau}_{(q-1)(p+1)r}-\frac{2(\mu-q-p)(r-\tau)}{\nu-q+1}$$
$$\times\partial_{\xi_2}\psi^{\mu\nu\tau}_{(q-1)(p+2)(r-1)}-2(\nu-q)\partial_{\xi_3}\psi^{\mu\nu\tau}_{(q+1)(p-1)(r+1)}+\frac{2(q+p-\nu)(q-r)}{\nu-q+1}$$
$$\times\partial_{\xi_3}\psi^{\mu\nu\tau}_{(q-1)pr}-\frac{2(r-\tau)(\mu+\nu-2q-p+1)}{\nu-q+1}\partial_{\xi_3}\psi^{\mu\nu\tau}_{(q-1)(p+1)(r-1)}+2(\mu-q-p)$$
$$\times\partial_{\eta_3}\psi^{\mu\nu\tau}_{q(p+1)r}+2(q-r)\partial_{\eta_3}\psi^{\mu\nu\tau}_{qp(r+1)}+2(q+p-\nu)\partial_{\eta_3}\psi^{\mu\nu\tau}_{q(p-1)r}+2(r-\tau)\partial_{\eta_3}\psi^{\mu\nu\tau}_{qp(r-1)}$$
$$=-2(E-V)\psi^{\mu\nu\tau}_{qpr},\quad \text{for } q<\nu, \tag{30c}$$

where $\nabla^2\psi^{\mu\nu\tau}_{qpr}$ is given in Eq. (27). Only six internal variables ξ_1, ξ_2, ξ_3, η_2, η_3, and ζ_3 are involved both in the equations and in the functions. Equation (30) holds either for $D>6$ or for $4\leqslant D\leqslant 6$. For the latter cases some self-dual representation, anti-self-dual representation, or equivalent representations may occur. Especially, for a four-body system in $D=4$ dimensions, the representation $[\mu,1,1]$ is equivalent to the representation $[\mu,0,0]$, but the generalized radial equations for them are decoupled. They will be coupled for the N-body system with $N>D=4$.

IV. QUANTUM *N*-BODY SYSTEM IN *D* DIMENSIONS

It is hard to write unified formulas of the generalized radial equations for an N-body system in arbitrary D-dimensions. However, from the study of the three-body[26,31] and four-body system, we are able to summarize the main features on separating the rotational degrees of freedom from the internal ones for an N-body Schrödinger equation in D dimensions.

First, after removing the motion of the center of mass, there are $(N-1)$ Jacobi coordinate vectors $\mathbf{R}_j$ for an N-body system. On the other hand, in a D-dimensional space one needs $(D-1)$ vectors to determine the body-fixed frame. When $D\geqslant N$, all Jacobi coordinate vectors are used to determine the body-fixed frame, and all internal variables can be chosen as $\mathbf{R}_j\cdot\mathbf{R}_k$. The numbers of the rotational variables and the internal variables are $(N-1)(2D-N)/2$ and $N(N-1)/2$, respectively. When $D<N$, only $(D-1)$ Jacobi coordinate vectors are involved to determine the body-fixed frame, and the remaining can be expressed by the first $(D-1)$ Jacobi coordinate vectors and the internal variables. The set of internal variables $\mathbf{R}_j\cdot\mathbf{R}_k$ is no longer complete because it could not distinguish two configurations, say with different $\mathbf{R}_D$ reflecting to the superplane spanned by the first $(D-1)$ Jacobi coordinate vectors. The correct choice for the internal variables are

$$\xi_{jk}=\mathbf{R}_j\cdot\mathbf{R}_k,\quad \zeta_\alpha=\sum_{a_1\cdots a_D}\epsilon_{a_1\cdots a_D}R_{1a_1}\cdots R_{(D-1)a_{D-1}}R_{\alpha a_D},$$
$$1\leqslant j\leqslant D-1,\quad j\leqslant k\leqslant N-1,\quad D\leqslant\alpha\leqslant N-1. \tag{31}$$

The numbers of the rotational variables and the internal variables are $D(D-1)/2$ and $D(2N-D-1)/2$, respectively.

Second, for an N-body system in D-dimensions $(D\geqslant N)$, the angular momentum is described by an irreducible representation of SO(D) denoted by an $(N-1)$-row Young pattern $[\mu]\equiv[\mu_1,\mu_2,\ldots,\mu_{N-1}]$, $\mu_1\geqslant\mu_2\geqslant\cdots\geqslant\mu_{N-1}$. Due to the rotational symmetry, one only needs to discuss the eigenfunctions of angular momentum with the highest weight. The complete set of independent basis functions with the highest weight consists of the eigenfunctions $Q^{[\mu]}_{(q)}(\mathbf{R}_1,\ldots,\mathbf{R}_{N-1})$ identified by the standard Young tableau (q). Filling the digits 1, 2, ..., $N-1$ arbitrarily into a given Young pattern $[\mu]$ we obtain a Young tableau. A Young tableau is called standard if the digit in every column of the tableau increases downwards and the digit in

every row does not decrease from left to right. Any standard Young tableau is described by a set of parameters (q) which contains $(N-1)(N-2)/2$ parameters q_{jk}, $1\leqslant k\leqslant j\leqslant N-1$, denoting the number of the digit j in the kth row in the standard Young tableau. The number of independent basis functions $Q_{(q)}^{[\mu]}(\mathbf{R}_1,\ldots,\mathbf{R}_{N-1})$ in the complete set is equal to the dimension $d_{[\mu]}[\mathrm{SU}(N-1)]$ of the irreducible representation $[\mu]$ of the SU$(N-1)$ group. $Q_{(q)}^{[\mu]}(\mathbf{R}_1,\ldots,\mathbf{R}_{N-1})$ is a homogeneous polynomial of degree $\Sigma\mu_k$ with respect to the components of $(N-1)$ Jacobi coordinate vectors $\mathbf{R}_j$, and satisfies the generalized Laplace equations [see Eq. (20)]. The explicit form of $Q_{(q)}^{[\mu]}(\mathbf{R}_1,\ldots,\mathbf{R}_{N-1})$ for the given standard Young tableau (q) is very easy to write. In the Young tableau, for each column with the length t, filled by digits $j_1<j_2<\cdots<j_t$, $Q_{(q)}^{[\mu]}(\mathbf{R}_1,\ldots,\mathbf{R}_{N-1})$ contains a determinant as a factor. The rth row and sth column in the determinant is $R_{j_r(2s-1)}+iR_{j_r(2s)}$ if $D>2(N-1)$. $Q_{(q)}^{[\mu]}(\mathbf{R}_1,\ldots,\mathbf{R}_{N-1})$ also contains a numerical coefficient for convenience. When $N\leqslant D\leqslant 2(N-1)$, some self-dual representation, anti-self-dual representation and equivalent representations have to be considered just like the discussion given in the end of Sec. II. When $D<N$, only the first $(D-1)$ Jacobi coordinate vectors are involved in the basis functions $Q_{(q)}^{[\mu]}(\mathbf{R}_1,\ldots,\mathbf{R}_{D-1})$, which are the same as those for smaller $N=D$.

At last, when $D\geqslant N$, any wave function $\Psi_{\mathbf{M}}^{[\mu]}(\mathbf{R}_1,\ldots,\mathbf{R}_{N-1})$ with the given angular momentum $[\mu]$ can be expanded with respect to the complete and independent basis functions $Q_{(q)}^{[\mu]}(\mathbf{R}_1,\ldots,\mathbf{R}_{N-1})$,

$$\Psi_{\mathbf{M}}^{[\mu]}(\mathbf{R}_1,\ldots,\mathbf{R}_{N-1})=\sum_{(q)}\psi_{(q)}^{[\mu]}(\xi)Q_{(q)}^{[\mu]}(\mathbf{R}_1,\ldots,\mathbf{R}_{N-1}), \tag{32}$$

where the coefficients $\psi_{(q)}^{[\mu]}(\xi)$, called the generalized radial functions, only depend upon the internal variables. When $D<N$, $\psi_{(q)}^{[\mu]}(\xi)$ and $Q_{(q)}^{[\mu]}(\mathbf{R}_1,\ldots,\mathbf{R}_{N-1})$ in Eq. (32) have to be replaced with $\psi_{(q)}^{[\mu]}(\xi,\zeta)$ and $Q_{(q)}^{[\mu]}(\mathbf{R}_1,\ldots,\mathbf{R}_{D-1})$, respectively. Substituting Eq. (32) into the N-body Schrödinger equation in the center-of-mass frame,

$$\sum_{j=1}^{N-1}\nabla_{\mathbf{R}_j}^2\Psi_{\mathbf{M}}^{[\mu]}(\mathbf{R}_1,\ldots,\mathbf{R}_{N-1})=-2\{E-V(\xi)\}\Psi_{\mathbf{M}}^{[\mu]}(\mathbf{R}_1,\ldots,\mathbf{R}_{N-1}), \tag{33}$$

one is able to obtain the generalized radial equations. The main calculation is to apply the Laplace operator to the function $\Psi_{\mathbf{M}}^{[\mu,\nu,\tau]}(\mathbf{x},\mathbf{y},\mathbf{z})$. The calculation consists of three parts. The first is to apply the Laplace operator to the generalized radial functions $\psi_{(q)}^{[\mu]}(\xi)$, which can be calculated by replacement of variables. When $D\geqslant N$ we have

$$\begin{aligned}\nabla^2\psi_{(q)}^{[\mu]}(\xi)=\Bigg\{&\sum_{j=1}^{N-1}(4\xi_{jj}\partial_{\xi_{jj}}^2+2D\partial_{\xi_{jj}})+\sum_{j=1}^{N-1}\sum_{k=j+1}^{N-1}[(\xi_{jj}+\xi_{kk})\partial_{\xi_{jk}}^2+4\xi_{jk}(\partial_{\xi_{jj}}+\partial_{\xi_{kk}})\partial_{\xi_{jk}}]\\&+2\sum_{j=1}^{N-1}\sum_{j\neq k=1}^{N-1}\sum_{j\neq t=k+1}^{N-1}\xi_{kt}\partial_{\xi_{jk}}\partial_{\xi_{jt}}\Bigg\}\psi_{(q)}^{[\mu]}(\xi),\end{aligned} \tag{34}$$

where $\xi_{jk}=\xi_{kj}$ and ∂_ξ denotes $\partial/\partial\xi$ and so on. The second is to apply the Laplace operator to the generalized spherical harmonic polynomials. This part is vanishing because the polynomials satisfy the Laplace equation. The last is the mixed application. When $D\geqslant N$ we have

$$2\sum_{j=1}^{N-1}\left\{(\partial_{\xi_{jj}}\psi_{(q)}^{[\mu]})2\mathbf{R}_j+\sum_{j\neq k=1}^{N-1}(\partial_{\xi_{jk}}\psi_{(q)}^{[\mu]})\mathbf{R}_k\right\}\cdot\nabla_{\mathbf{R}_j}Q_{(q)}^{[\mu]}, \tag{35}$$

where the formulas for $\mathbf{R}_j\cdot\nabla_{\mathbf{R}_j}Q_{(q)}^{[\mu]}$ and $\mathbf{R}_k\cdot\nabla_{\mathbf{R}_j}Q_{(q)}^{[\mu]}$ can be calculated from the property of the polynomial $Q_{(q)}^{[\mu]}(\mathbf{R}_1,\ldots,\mathbf{R}_{N-1})$. When $D<N$, the internal variables have to be chosen as those given in Eq. (31) so that Eq. (34) becomes more complicated and Eq. (35) contains more terms of $(\partial\zeta_\alpha/\partial\mathbf{R}_j)\cdot\nabla_{\mathbf{R}_j}Q_{(q)}^{[\mu]}$.[26]

V. CONCLUSIONS

In this paper, the problem of separating the rotational degrees of freedom from the internal ones for the Schrödinger equation of a four-body system in D dimensions is studied in detail by the method of the generalized spherical harmonic polynomials. We have found a complete set of independent basis functions with the given angular momentum described by an irreducible representation $[\mu,\nu,\tau]$ of SO(D). This set of basis functions have different form for the case $D>6$, $4\leqslant D\leqslant 6$, and $D=3$. We have provided an appropriate choice of internal variables for this system and derived the generalized radial equations depending solely on internal variables. The main features on the problem of separating the rotational degrees of freedom from the internal ones for the Schrödinger equation of a N-body system in D dimensions is summarized.

Global symmetries of time-dependent Schrödinger equations

Susumu Okubo[a)]
Department of Physics and Astronomy, University of Rochester, Rochester, New York 14627

(Received 28 October 2002; accepted 27 April 2003)

Some symmetries of time-dependent Schrödinger equations for inverse quadratic, linear, and quadratic potentials have been systematically examined by using a method suitable to the problem. Especially, the symmetry group for the case of the linear potential turns out to be a semidirect product $SL(2,R)\circledS T_2(R)$ of the $SL(2,R)$ with a two-dimensional real translation group $T_2(R)$. Here, the time variable t transforms as $t\to t'=(ct+d)/(at+b)$ for real constants a, b, c, and d satisfying $bc-ad=1$ with an accompanying transformation for the space coordinate x. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1591992]

I. FORMULATION

Many solutions of Schrödinger equations are known (Refs. 1–4 and earlier references quoted therein) to possess dynamical (or hidden) symmetries which are not apparent at first glance.

In a different approach, Eastwood[5] in his study of symmetry of Laplace equation has observed the following: Suppose that a pair of functions $U(\mathbf{x},\boldsymbol{\partial})$ and $W(\mathbf{x},\boldsymbol{\partial})$ of the coordinate $\mathbf{x}$ and its derivative $\boldsymbol{\partial}$ satisfies

$$W(\mathbf{x},\boldsymbol{\partial})\Delta=\Delta U(\mathbf{x},\boldsymbol{\partial}),\quad \left(\Delta=\sum_{j=1}^{n}\frac{\partial^2}{\partial x_j^2}\right)$$

for the Laplacian Δ. Then, if $\psi(\mathbf{x})$ is a solution of the Laplace equation $\Delta\psi(\mathbf{x})=0$, then so will be

$$\psi'(\mathbf{x})=U(\mathbf{x},\boldsymbol{\partial})\psi(\mathbf{x}).$$

The purpose of this note is to utilize an analogous method to systematically find global symmetries of time-independent Schrödinger equations. We consider the equation of motion of the form:

$$\frac{\partial}{\partial t}\psi(t,\mathbf{x})=k\{\Delta-V(\mathbf{x})\}\psi(t,\mathbf{x}). \tag{1.1}$$

If k is purely imaginary with $k=-i\hbar/2m$, then it describes the standard Schrödinger equation, while the case of k being real implies a diffusion-type equation. In what follows, we will always assume that the parameter k is either real or purely imaginary with t and $\mathbf{x}$ being real unless it is stated otherwise.

Consider now a vector space of all suitably smooth functions of t and $\mathbf{x}$, which may be complex. Suppose that we can find a pair of linear operators U and W in this space to satisfy the condition

$$W\left\{\frac{\partial}{\partial t}-k\Delta+kV(\mathbf{x})\right\}=\left\{\frac{\partial}{\partial t}-k\Delta+kV(\mathbf{x})\right\}U. \tag{1.2}$$

a)Electronic mail: okubo@pas.rochester.edu

Then, if $\psi(t,\mathbf{x})$ satisfies Eq. (1.1), the new function given by

$$\psi'(t,\mathbf{x}) = (U\psi)(t,\mathbf{x}) \equiv U\psi(t,\mathbf{x}) \tag{1.3}$$

will also obey the same relation, i.e., we have

$$\frac{\partial}{\partial t}\psi'(t,\mathbf{x}) = k\{\Delta - V(\mathbf{x})\}\psi'(t,\mathbf{x}). \tag{1.4}$$

Some explicit forms of U and W can be found as follows. Let us consider the coordinate transformation of form for $\mathbf{x}=(x_1,x_2,\ldots,x_n)$,

$$t \to t' = \phi(t), \tag{1.5a}$$

$$x_j \to x_j' = F_j(t,\mathbf{x}) \quad (j=1,2,\ldots,n) \tag{1.5b}$$

for some differentiable functions $\phi(t)$ and $F_j(t,\mathbf{x})$ to be determined. The action of the linear operator U to a function $\psi(t,\mathbf{x})$ is then assumed to be given as a multiplication of a function after the coordinate transformation, i.e.,

$$\psi'(t,\mathbf{x}) = U\psi(t,\mathbf{x}) = K(t,\mathbf{x})\psi(t',\mathbf{x}'), \tag{1.6}$$

where $K(t,\mathbf{x})$ is a function of t and $\mathbf{x}$ to be determined. When we note

$$\frac{\partial}{\partial t} = \dot{\phi}(t)\frac{\partial}{\partial t'} + \sum_{j=1}^{n}\frac{\partial F_j(t,\mathbf{x})}{\partial t}\frac{\partial}{\partial x_j'},$$

$$\frac{\partial}{\partial x_j} = \sum_{k=1}^{n}\frac{\partial F_k(t,\mathbf{x})}{\partial x_j}\frac{\partial}{\partial x_k'},$$

then we calculate

$$\begin{aligned}
\left\{\frac{\partial}{\partial t} - k\Delta + kV(\mathbf{x})\right\}\psi'(t,\mathbf{x}) &= \left\{\frac{\partial}{\partial t} - k\Delta + kV(\mathbf{x})\right\}[K(t,\mathbf{x})\psi(t',\mathbf{x}')] \\
&= \left\{\left[\frac{\partial}{\partial t} - k\Delta + kV(\mathbf{x})\right]K(t,\mathbf{x})\right\}\psi(t',\mathbf{x}') \\
&\quad + K(t,\mathbf{x})\sum_{j=1}^{n}\left\{\frac{\partial F_j(t,\mathbf{x})}{\partial t} - k\Delta F_j(t,\mathbf{x})\right. \\
&\quad \left. - 2k\sum_{\ell=1}^{n}\frac{\partial \log K(t,\mathbf{x})}{\partial x_\ell}\frac{\partial F_j(t,\mathbf{x})}{\partial x_\ell}\right\}\frac{\partial}{\partial x_j'}\psi(t',\mathbf{x}') \\
&\quad + K(t,\mathbf{x})\left\{\dot{\phi}(t)\frac{\partial}{\partial t'} - k\sum_{j,\ell=1}^{n}\left(\sum_{i=1}^{n}\frac{\partial F_j}{\partial x_i}\frac{\partial F_\ell}{\partial x_i}\right)\frac{\partial^2}{\partial x_j'\partial x_\ell'}\right\}\psi(t',\mathbf{x}').
\end{aligned} \tag{1.7}$$

If $F_j(t,\mathbf{x})$, and $K(t,\mathbf{x})$ satisfy relations:

$$\text{(i)} \quad \sum_{i=1}^{n}\frac{\partial F_j(t,\mathbf{x})}{\partial x_i}\frac{\partial F_\ell(t,\mathbf{x})}{\partial x_i} = \delta_{j\ell}\dot{\phi}(t)\left(\equiv \delta_{j\ell}\frac{\mathrm{d}}{\mathrm{d}t}\phi(t)\right), \tag{1.8a}$$

$$\text{(ii)} \quad \left(\frac{\partial}{\partial t}-k\Delta\right)F_j(t,\mathbf{x})=2k\sum_{\ell=1}^{n}\frac{\partial \log K(t,\mathbf{x})}{\partial x_\ell}\,\frac{\partial F_j(t,\mathbf{x})}{\partial x_\ell}, \tag{1.8b}$$

$$\text{(iii)} \quad \left\{\frac{\partial}{\partial t}-k\Delta+kV(\mathbf{x})\right\}K(t,\mathbf{x})=k\dot{\phi}(t)V(\mathbf{x}')K(t,\mathbf{x}), \tag{1.8c}$$

then Eq. (1.7) becomes

$$\left\{\frac{\partial}{\partial t}-k\Delta+kV(\mathbf{x})\right\}\psi'(t,\mathbf{x})=\dot{\phi}(t)K(t,\mathbf{x})\left\{\frac{\partial}{\partial t'}-k\Delta'+kV(\mathbf{x}')\right\}\psi(t',\mathbf{x}'), \tag{1.9}$$

which reproduces Eq. (1.2) with actions of U and W given by

$$U\psi(t,\mathbf{x})=K(t,\mathbf{x})\psi(t',\mathbf{x}'), \tag{1.10a}$$

$$W\hat{\psi}(t,\mathbf{x})=\dot{\phi}(t)K(t,\mathbf{x})\hat{\psi}(t',\mathbf{x}'), \tag{1.10b}$$

for any two functions ψ and $\hat{\psi}$. For the present problem, we have

$$\hat{\psi}(t,\mathbf{x})=\left(\frac{\partial}{\partial t}-k\Delta+kV(\mathbf{x})\right)\psi(t,\mathbf{x}).$$

Summarizing, we have proved the following Theorem.

Theorem 1.1: Let functions $\phi(t)$, $F_j(t,\mathbf{x})$, and $K(t,\mathbf{x})$ satisfy Eq. (1.8) with t' and x_j' being given by Eq. (1.5). Then for any function $\psi(t,\mathbf{x})$ which satisfies Eq. (1.1), i.e.,

$$\frac{\partial}{\partial t}\psi(t,\mathbf{x})=k\{\Delta-V(\mathbf{x})\}\psi(t,\mathbf{x}),$$

the new function given by

$$\psi'(t,\mathbf{x})=K(t,\mathbf{x})\psi(t',\mathbf{x}')=K(t,\mathbf{x})\psi(\phi(t),F_j(t,\mathbf{x}))$$

is also a solution of the same generalized Schrödinger equation, Eq. (1.1).

Remark 1.2: We may call the pair of linear operators (U,W) satisfying Eq. (1.2) admissible. Then, for the second admissible pair (U',W') their product (UU',WW') is clearly also admissible. Moreover, the special pair (1,1) acts as the identity. Therefore, a set of all admissible pairs form a semigroup. If the pair is invertible, then they present a symmetry group of Eq. (1.1). More explicitly, if the transformation with certain $V(\mathbf{x})$ are chosen as in Eq. (1.16), one gets a set S of possible ϕ, F, and K with elements $s \in S$ parametrized by real numbers a, $b,\ldots,$ i.e., $s=s(a,b,\ldots)$ and a set of solutions $\psi(t,\mathbf{x};a,b,\ldots)$. It will be shown in subsequent sections that the $s \in S$ and hence the corresponding solutions can be transformed into each other formally via e.g., $SL(2,R)$ depending upon $V(\mathbf{x})$.

We can modify Theorem 1.1 slightly as follows. Let $V_0(\mathbf{x})$ and $V(\mathbf{x})$ be two potentials, and suppose that the pair of linear operators (U,W) now satisfies

$$W\left\{\frac{\partial}{\partial t}-k\Delta+kV_0(\mathbf{x})\right\}=\left\{\frac{\partial}{\partial t}-k\Delta+kV(\mathbf{x})\right\}U \tag{1.11}$$

instead Eq. (1.2). We can proceed exactly in the same way as in the previous case, and we prove the following theorem.

Theorem 1.3: Let functions $\phi(t)$, $F_j(t,\mathbf{x})$, and $K(t,\mathbf{x})$, as in Theorem 1.1 except that Eq. (1.8c) is now replaced by

$$\left\{\frac{\partial}{\partial t}-k\Delta+kV(\mathbf{x})\right\}K(t,\mathbf{x})=k\dot{\phi}(t)V_0(\mathbf{x}')K(t,\mathbf{x}). \tag{1.12}$$

Then, for any function $\psi_0(t,\mathbf{x})$ satisfying

$$\left\{\frac{\partial}{\partial t}-k\Delta+kV_0(\mathbf{x})\right\}\psi_0(t,\mathbf{x})=0, \tag{1.13}$$

the function given by

$$\psi(t,\mathbf{x})=U\psi_0(t,\mathbf{x})=K(t,\mathbf{x})\psi_0(t',\mathbf{x}') \tag{1.14}$$

satisfies

$$\left\{\frac{\partial}{\partial t}-k\Delta+kV(\mathbf{x})\right\}\psi(t,\mathbf{x})=0. \tag{1.15}$$

Remark 1.4: Examples satisfying Theorem 1.3 for $V_0(\mathbf{x})=0$ will be given in Secs. III and IV. If U^{-1} and W^{-1} exist, then we can conversely express $\psi_0(t,\mathbf{x})$ in terms of $\psi(t,\mathbf{x})$.

Returning now to the original discussion of Theorem 1.1, it is in general difficult to find solutions of differential equations, Eq. (1.8). However, for three cases of $V(\mathbf{x})$ being inverse square, linear, and quadratic potentials, we can solve them as follows. The explicit forms of $F_j(t,\mathbf{x})$ and $K(t,\mathbf{x})$ can then be assumed to be

$$t'=\phi(t), \tag{1.16a}$$

$$x_j'=F_j(t,\mathbf{x})=\xi(t)x_j+f_j(t), \tag{1.16b}$$

$$K(t,\mathbf{x})=\exp\left\{A(t)+\sum_{j=1}^{n}B_j(t)x_j+C(t)\mathbf{x}^2\right\}, \tag{1.16c}$$

for some functions $\phi(t)$, $\xi(t)$, $f_j(t)$, $A(t)$, $B_j(t)$, and $C(t)$ of t to be determined as in the following Proposition.

Proposition 1.5: Equation (1.8) will be satisfied for the ansatz Eq. (1.16), if we have

$$\text{(i)}\quad \dot{\phi}(t)=\xi^2(t), \tag{1.17a}$$

$$\text{(ii)}\quad B_j(t)=\frac{1}{2k}\,\frac{\dot{f}_j(t)}{\xi(t)}, \tag{1.17b}$$

$$\text{(iii)}\quad C(t)=\frac{1}{4k}\,\frac{\dot{\xi}(t)}{\xi(t)}, \tag{1.17c}$$

provided that $K(t,\mathbf{x})$ satisfies Eq. (1.8c), i.e.,

$$\left\{\frac{\partial}{\partial t}-k\Delta+kV(\mathbf{x})\right\}K(t,b)=k\dot{\phi}(t)V(\mathbf{x}')K(t,\mathbf{x}). \tag{1.18}$$

We will solve these differential equations, Eqs. (1.17) and (1.18), in subsequent sections. The simplest case of the inverse quadratic potential will be discussed in Sec. II, where the symmetry group is $SL(2,R)$. By contrast, the symmetry of the linear potential is a larger one of $SL(2,R)\,\textcircled{S}\,T_2(R)$ which is the semidirect product of $SL(2,R)$ with a real two-dimensional translation group $T_2(R)$. This will be presented in Sec. III. For the case of the quadratic potential in

Sec. IV, the symmetry is now either a semigroup or a subgroup of $SL(2,C)\,\textcircled{S}\,T_2(C)$, depending upon choices of parameters involved in theory. In Sec. V, we will discuss the associated Lie algebras of these groups.

Last, we simply remark that the present method will also be applicable when the potential is time-dependent. In that case, we simply replace all $V(\mathbf{x})$, $V(\mathbf{x}')$, $V_0(\mathbf{x})$, and $V_0(\mathbf{x}')$ in Theorem 1.1 and 1.3, respectively, by $V(t,\mathbf{x})$, $V(t',\mathbf{x}')$, $V_0(t,\mathbf{x})$, and $V_0(t',\mathbf{x}')$. Also, we may generalize the present method by replacing $K(t,\mathbf{x})$ by $K(t,\mathbf{x},\boldsymbol{\partial},\partial_t)$ which may depend upon both space and time derivatives, $\boldsymbol{\partial}$ and $\partial_t(\equiv \partial/\partial t)$.

II. INVERSE QUADRATIC POTENTIAL

In this section, we assume that the potential $V(\mathbf{x})$ is a homogeneous function of $\mathbf{x}$ of degree -2, i.e., it satisfies an identity

$$V(\lambda\mathbf{x})=\frac{1}{\lambda^2}V(\mathbf{x}) \tag{2.1}$$

for any nonzero real number λ. For example, we may assume

$$V(\mathbf{x})=\frac{\alpha}{x_1^2+x_2^2+\cdots+x_n^2}+\sum_{j=1}^{n}\frac{a_j}{(x_j)^2}+\sum_{j,k=1}^{n}\frac{b_{jk}}{(x_j-x_k)^2},$$

etc., for some constants α, a_j, and b_{jk}.

We must choose $f_j(t)=0$ with $x_j'=\xi(t)x_j$ in this case. Then Eq. (2.1) implies the validity of

$$V(\mathbf{x})=\xi^2(t)V(\mathbf{x}')=\dot{\phi}(t)V(\mathbf{x}')$$

for $\lambda=\xi(t)$ so that Eq. (1.18) becomes

$$\left\{\frac{\partial}{\partial t}-k\Delta\right\}K(t,\mathbf{x})=0,$$

which gives

$$\dot{A}(t)=2nkC(t),$$

$$\dot{C}(t)=4k(C(t))^2.$$

Solving these with Eq. (1.17) for $\xi(t)$ and $\phi(t)$, we find:

Proposition 2.1: For any function $\psi(t,\mathbf{x})$ satisfying

$$\frac{\partial}{\partial t}\psi(t,\mathbf{x})=k\{\Delta-V(\mathbf{x})\}\psi(t,\mathbf{x}) \tag{2.2}$$

with the condition Eq. (2.1) for $V(\mathbf{x})$, a new function given by

$$\psi'(t,\mathbf{x})=\left(\frac{1}{at+b}\right)^{n/2}\exp\left\{-\frac{a}{4k(at+b)}\mathbf{x}^2\right\}\psi(t',\mathbf{x}') \tag{2.3}$$

also satisfies the same equation, i.e.,

$$\frac{\partial}{\partial t}\psi'(t,\mathbf{x})=k\{\Delta-V(\mathbf{x})\}\psi'(t,\mathbf{x}), \tag{2.4}$$

where t' and $\mathbf{x}'$ are given by

$$t' = \frac{ct+d}{at+b}, \quad \mathbf{x}' = \frac{1}{at+b}\mathbf{x}. \tag{2.5}$$

Here, a, b, c, and d are arbitrary real constants satisfying the condition

$$bc - ad = 1. \tag{2.6}$$

We will show next that the admissible pair (U,W) of Sec. I will offer infinite dimensional realizations of the $SL(2,R)$ group. For this purpose, it is more convenient to consider 2×2 $SL(2,R)$ matrix M by

$$M = \begin{pmatrix} c & d \\ a & b \end{pmatrix}, \quad \det M = 1. \tag{2.7}$$

Moreover, we collectively write the coordinates as

$$Z = \{t, \mathbf{x}\} \tag{2.8}$$

on which M is assumed to act as

$$MZ = M\{t,\mathbf{x}\} = \{t',\mathbf{x}'\} = \left\{ \frac{ct+d}{at+b} \ , \ \frac{\mathbf{x}}{at+b} \right\}. \tag{2.9}$$

Since $K(t,\mathbf{x})$ depends upon parameters a, b, c, and d, we will write it as $K(t,\mathbf{x}|M)$ so that

$$K(t,\mathbf{x}|M) \equiv K(Z|M) = \left(\frac{1}{at+b} \right)^{n/2} \exp\left\{ -\frac{a}{4k(at+b)}\mathbf{x}^2 \right\}. \tag{2.10}$$

It is then easy to verify.

Proposition 2.2: For any two $SL(2,R)$ matrices M and M', we have

$$\text{(i)} \quad M(M'Z) = (MM')Z, \tag{2.11a}$$

$$\text{(ii)} \quad K(Z|M')K(M'Z|M) = K(Z|MM'), \tag{2.11b}$$

where MM' implies the standard matrix product of M and M'.

The linear operators U and W introduced in Sec. I also depend upon M. However, it is more convenient to rewrite them as $U(M^{-1})$ and $W(M^{-1})$ instead of $U(M)$ and $W(M)$ for a reason which will become clear shortly, so that Eq. (2.3) is rewritten as

$$U(M^{-1})\psi(Z) = K(Z|M)\psi(MZ). \tag{2.12}$$

Note that

$$M^{-1} = \begin{pmatrix} b & -d \\ -a & c \end{pmatrix} \quad \text{for} \quad M = \begin{pmatrix} c & d \\ a & b \end{pmatrix}.$$

Then, Eq. (2.11) is immediately translated into the following:

Proposition 2.3: Linear operators $U(M)$ and $W(M)$ satisfy

$$U(MM') = U(M)U(M'), \tag{2.13a}$$

$$W(MM') = W(M)W(M'). \tag{2.13b}$$

In other words, they offer (infinite dimensional) realizations of the $SL(2,R)$ group.

In ending this section, it may be of interest to note the following:

Remark 2.4: The transformation, Eq. (2.5), contains both time translation and dilatation as special cases. If we choose

$$M=\begin{pmatrix} 1 & \lambda \\ 0 & 1 \end{pmatrix},$$

then Eq. (2.5) gives the time translation,

$$t\to t'=t+\lambda, \quad \mathbf{x}\to\mathbf{x}'=\mathbf{x}.$$

On the other side, the choice of

$$M=\begin{pmatrix} c & 0 \\ 0 & \dfrac{1}{c} \end{pmatrix} \quad (c\neq 0) \tag{2.14a}$$

leads to the dilatation

$$t\to t'=c^2 t, \quad \mathbf{x}\to\mathbf{x}'=c\mathbf{x}. \tag{2.14b}$$

Remark 2.5: For some subgroup of $SL(2,R)$, the linear operator $U(M)$ may possess a non-trivial fixed point in the function space. Consider the one-dimensional case of $n=1$ with $V(\mathbf{x})=0$. The Jacobi's theta function $\theta_1(x|t)$ is given[6] by

$$\theta_1(x|t)=i\sum_{n=-\infty}^{\infty}(-1)^n \exp\left\{ i\pi\left(n-\frac{1}{2}\right)^2 t+i\pi(2n-1)x\right\}, \tag{2.15}$$

which satisfies the one-dimensional Schrödinger equation

$$4\pi i\frac{\partial}{\partial t}\theta_1(x|t)=\frac{\partial^2}{\partial x^2}\theta_1(x|t) \tag{2.16}$$

with $k=-i/4\pi$. Moreover, if a, b, c, d are all integers with $bc-ad=1$, we then have the identity[6]

$$\theta_1\left(\frac{x}{at+b}\,\middle|\,\frac{ct+d}{at+b}\right)=\epsilon(at+b)^{1/2}\exp\left(\frac{i\pi a x^2}{at+b}\right)\theta_1(x|t), \tag{2.17}$$

where ϵ is a constant satisfying $\epsilon^8=1$, whose particular value depends upon the specification of branches of $(at+b)^{1/2}$ in the complex t plane. Setting $\epsilon=1$. Eq. (2.17) is rewritten as

$$U(M_0)\theta_1(x|t)=\theta_1(x|t) \tag{2.18}$$

for any modular matrix M_0. Therefore, the $SL(2,R)$ orbit of $\theta_1(x|t)$ is the homogeneous space

$$SL(2,R)/SL(2,Z),$$

where $SL(2,Z)$ is the modular subgroup of $SL(2,R)$ in which all a, b, c, and d are integers.

Remark 2.6: For the one-dimensional case with $V(\mathbf{x})=0$, the symmetry group is actually a larger one of $SL(2,R)\,\textcircled{S}\,T_2(R)$ which is a semidirect product of $SL(2,R)$ with a two-dimensional translation group $T_2(R)$. This will be shown as a special case of $\alpha=\beta=0$ in Eqs. (3.5)–(3.10) in the following.

III. LINEAR POTENTIAL

In this section, we will consider the case of the linear potential. For a while, we restrict ourselves to one-dimensional space and set

$$V(x)=\alpha+\beta x \tag{3.1}$$

for constants α and β. Dropping all subindices such as j's in $f_j(t)$, $B_j(t)$, etc. (since $n=1$), Eqs. (1.18) and (1.16c) then gives [with $\dot{A}(t)\equiv(\mathrm{d}/\mathrm{d}t)\,A(t)$, etc.]

$$\text{(i)}\quad \dot{C}(t)=4kC^2(t), \tag{3.2a}$$

$$\text{(ii)}\quad \dot{B}(t)=4kB(t)C(t)+k\beta[\xi^3(t)-1], \tag{3.2b}$$

$$\text{(iii)}\quad \dot{A}(t)=k\{B^2(t)+2C(t)\}+k\alpha(\xi^2(t)-1)+k\beta\xi^2(t)f(t). \tag{3.2c}$$

Together with Eq. (1.17), which gives $2kB(t)=\dot{f}(t)/\xi(t)$ and $4kC(t)=\dot{\xi}(t)/\xi(t)$, we can solve these equations. In this case, the general solution contains five independent real parameters. It is convenient for our purpose to parametrize them as

$$\Lambda=\left\{M,\begin{pmatrix}\mu\\ \nu\end{pmatrix}\right\}, \tag{3.3a}$$

$$M=\begin{pmatrix}c & d\\ a & b\end{pmatrix},\quad \det M=1, \tag{3.3b}$$

where M is the real 2×2 unimodular matrix just as in Sec. II, which acts now on a two-dimensional real vector $\binom{\mu}{\nu}$ in the parameter space. We write $C(t)$, $B(t)$, etc., now as $C(t|\Lambda)$, $B(t|\Lambda)$, etc., in order to indicate their dependence on parameters involved in Λ. We also rewrite $K(t,x)$ of Sec. I as

$$K(t,x|\Lambda)=\frac{1}{\sqrt{at+b}}\exp\{A(t|\Lambda)+B(t|\Lambda)x+C(t|\Lambda)x^2\}, \tag{3.4}$$

where we changed however $A(t)$ there into $A(t|\Lambda)-\frac{1}{2}\log(at+b)$ for simplicity. Then, their explicit forms are found to be

$$\text{(i)}\quad C(t|\Lambda)=-\frac{1}{4k}\,\frac{a}{at+b}, \tag{3.5a}$$

$$\text{(ii)}\quad B(t|\Lambda)=-\frac{\nu}{2k}\,\frac{1}{at+b}+\frac{k\beta}{2}\left\{\frac{2(ct+d)}{(at+b)^2}-t-\frac{bt}{at+b}\right\}, \tag{3.5b}$$

$$\begin{aligned}\text{(iii)}\quad A(t|\Lambda)=&-\frac{1}{4k}\mu\nu+\alpha k\left(\frac{ct+d}{at+b}-t\right)+\frac{\nu^2}{4k}\,\frac{ct+d}{at+b}+k\beta\left\{\mu\,\frac{ct+d}{at+b}-\nu\left[\left(\frac{ct+d}{at+b}\right)^2\right.\right.\\ &\left.\left.-\frac{1}{2}\,\frac{t^2}{at+b}\right]\right\}+k^3\beta^2\left\{\frac{2}{3}\left(\frac{ct+d}{at+b}\right)^3+\frac{1}{12}t^3+\frac{b}{4}\,\frac{t^3}{at+b}-\frac{t^2(ct+d)}{(at+b)^2}\right\}.\end{aligned} \tag{3.5c}$$

In Eq. (3.5c), the constant term $-\mu\nu/4k$ has been added to simplify the expression of $\omega(\Lambda,\Lambda')$ given in Eq. (3.16) shortly. We then have the following Proposition.

Proposition 3.1: For any function $\psi(t,x)$ satisfying

$$\frac{\partial}{\partial t}\psi(t,x)=k\left\{\frac{\partial^2}{\partial x^2}-\alpha-\beta x\right\}\psi(t,x), \tag{3.6}$$

the new wave function given by

$$\psi'(t,x)=K(t,x|\Lambda)\psi(t',x') \tag{3.7}$$

satisfies the same, i.e.,

$$\frac{\partial}{\partial t}\psi'(t,x)=k\left\{\frac{\partial^2}{\partial x^2}-\alpha-\beta x\right\}\psi'(t,x), \tag{3.8}$$

where t' and x' are defined by

$$t'=\frac{ct+d}{at+b}, \tag{3.9a}$$

$$x'=\frac{x}{at+b}+\mu-\nu\frac{ct+d}{at+b}+k^2\beta\left\{\left(\frac{ct+d}{at+b}\right)^2-\frac{t^2}{at+b}\right\}. \tag{3.9b}$$

Next we will show that the underlying symmetry group is now the semidirect product

$$G=SL(2,R)\ \ \textcircled{S}T_2(R). \tag{3.10}$$

Let $\Lambda' \in G$ with

$$\Lambda'=\left\{M',\begin{pmatrix}\mu'\\ \nu'\end{pmatrix}\right\},\quad \det M'=1$$

be the second generic element of G in addition to Λ given by Eq. (3.3). We introduce the product $\Lambda\circ\Lambda'$ by

$$\Lambda\circ\Lambda'=\left\{MM',\begin{pmatrix}\mu\\ \nu\end{pmatrix}+M\begin{pmatrix}\mu'\\ \nu'\end{pmatrix}\right\}, \tag{3.11}$$

which can easily be verified to be associative and defines the desired group product of the group G. Note that the unit element 1 and the inverse Λ^{-1} are then given by

$$1=\left\{\begin{pmatrix}1&0\\0&1\end{pmatrix},\quad\begin{pmatrix}0\\0\end{pmatrix}\right\}, \tag{3.12a}$$

$$\Lambda^{-1}=\left\{M^{-1},-M^{-1}\begin{pmatrix}\mu\\ \nu\end{pmatrix}\right\}, \tag{3.12b}$$

respectively. Again, it is convenient to write

$$Z=\{t,x\} \tag{3.13}$$

collectively for coordinates and assume the action of $\Lambda \in G$ to Z to be given by

$$\Lambda Z=\Lambda\{t,x\}=\{t',x'\}, \tag{3.14}$$

in terms of t' and x' given by Eqs. (3.9). We then find

Proposition 3.2: We have

$$\text{(i)}\quad \Lambda\{\Lambda' Z\}=(\Lambda\circ\Lambda')Z, \tag{3.15a}$$

$$\text{(ii)} \quad K(Z|\Lambda')K(\Lambda' Z|\Lambda) = \exp\{\omega(\Lambda,\Lambda')\}K(Z|\Lambda\circ\Lambda'). \tag{3.15b}$$

Here, $\omega(\Lambda,\Lambda')$ is a constant given by

$$\omega(\Lambda,\Lambda') = \frac{1}{4k}\{(\mu a - \nu c)\mu' + (\mu b - \nu d)\nu'\}, \tag{3.16}$$

which satisfies the cycle condition

$$\omega(\Lambda_1,\Lambda_2) + \omega(\Lambda_1\circ\Lambda_2,\Lambda_3) = \omega(\Lambda_2,\Lambda_3) + \omega(\Lambda_1,\Lambda_2\circ\Lambda_3) \tag{3.17a}$$

as well as

$$\omega(\Lambda_2^{-1},\Lambda_1^{-1}) = -\omega(\Lambda_1,\Lambda_2) \tag{3.17b}$$

for $\Lambda_j \in G$ $(j=1,2,3)$.

The proof of this Proposition requires unfortunately long computations, although it is straightforward. First, we set

$$\Lambda' Z = \Lambda'\{t,x\} \equiv \{\overline{t},\overline{x}\}$$

so that

$$\overline{t} = \phi(t|\Lambda') = \frac{c't+d'}{a't+b'},$$

$$\overline{x} = \xi(t|\Lambda')x + f(t|\Lambda')$$

with

$$\xi(t|\Lambda') = \frac{1}{a't+b'},$$

$$f(t|\Lambda') = \mu' - \nu'\frac{c't+d'}{a't+b'} + k^2\beta\left\{\left(\frac{c't+d'}{a't+b'}\right)^2 - \frac{t^2}{a't+b'}\right\}.$$

Since

$$K(Z|\Lambda') = \frac{1}{\sqrt{a't+b'}}\exp\{A(t|\Lambda') + B(t|\Lambda')x + C(t|\Lambda')x^2\}$$

and

$$K(\Lambda' Z|\Lambda) = \frac{1}{\sqrt{a\overline{t}+b}}\exp\{A(\overline{t}|\Lambda) + B(\overline{t}|\Lambda)\overline{x} + C(\overline{t}|\Lambda)\overline{x}^2\},$$

we must now evaluate the product

$$K(Z|\Lambda')K(\Lambda' Z|\Lambda) = \frac{1}{\sqrt{a''t+b''}}\exp\{A_0(t) + B_0(t)x + C_0(t)x^2\},$$

with

$$A_0(t) = A(t|\Lambda') + A(\overline{t}|\Lambda) + B(\overline{t}|\Lambda)f(t|\Lambda') + C(\overline{t}|\Lambda)[f(t|\Lambda')]^2,$$

$$B_0(t)=B(t|\Lambda')+B(\overline{t}|\Lambda)\xi(t|\Lambda')+2C(\overline{t}|\Lambda)\xi(t|\Lambda')f(t|\Lambda'),$$

$$C_0(t)=C(t|\Lambda')+C(\overline{t}|\Lambda)[\xi(t|\Lambda')]^2.$$

Using expressions given in Eq. (3.5), we can then verify the validity of Eq. (3.15b) after long calculations. For its computation, the following identities are however quite useful to simplify the proof. Let us set

$$M''=MM'=\begin{pmatrix} c & d \\ a & b \end{pmatrix}\begin{pmatrix} c' & d' \\ a' & b' \end{pmatrix}=\begin{pmatrix} c'' & d'' \\ a'' & b'' \end{pmatrix} \tag{3.18}$$

for $M,\ M'\in SL(2,R)$. We then find

$$\text{(i)}\quad a\left(\frac{c't+d'}{a't+b'}\right)+b=\frac{a''t+b''}{a't+b'},\quad c\left(\frac{c't+d'}{a't+b'}\right)+d=\frac{c''t+d''}{a't+b'}, \tag{3.19a}$$

$$\text{(ii)}\quad \frac{a}{(a't+b')(a''t+b'')}=\frac{a''}{a''t+b''}-\frac{a'}{a't+b'}, \tag{3.19b}$$

$$\text{(iii)}\quad a't+b'=c(a''t+b'')-a(c''t+d''),$$

$$c't+d'=-d(a''t+b'')+b(c''t+d''). \tag{3.19c}$$

Also, for the proof at Eq. (3.17), it is more convenient to rewrite Eq. (3.16) in the matrix notation of

$$4k\omega(\Lambda,\Lambda')=\begin{pmatrix} \mu \\ \nu \end{pmatrix}^T JM\begin{pmatrix} \mu' \\ \nu' \end{pmatrix}, \tag{3.20}$$

where $\binom{\mu}{\nu}^T$ is the transpose of $\binom{\mu}{\nu}$, and J is given by

$$J=\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \tag{3.21a}$$

which satisfies

$$M^TJM=MJM^T=J \tag{3.21b}$$

for any $M\in SL(2,R)$ and its transpose matrix M^T.

Rewriting U and W of Sec. I as $U(\Lambda^{-1})$ and $W(\Lambda^{-1})$ so that

$$U(\Lambda^{-1})\psi(Z)=\psi'(Z)=K(Z|\Lambda)\psi(Z'), \tag{3.22}$$

Proposition 3.2 immediately leads to:

Corollary 3.3: We have

$$U(\Lambda\circ\Lambda')=\exp\{-\omega(\Lambda,\Lambda')\}U(\Lambda)U(\Lambda'), \tag{3.23a}$$

$$W(\Lambda\circ\Lambda')=\exp\{-\omega(\Lambda,\Lambda')\}W(\Lambda)W(\Lambda'). \tag{3.23b}$$

In other words, both $U(\Lambda)$ and $W(\Lambda)$ offer projective representations of $G=SL(2,R)\circledS T_2(R)$. We note here that the cycle condition, Eq. (3.17a), ensures the compatibility of Eq. (3.23) with the associativity of products $U(\Lambda)U(\Lambda')$ and $W(\Lambda)W(\Lambda')$.

Before going into further detail, it may be worthwhile to make the following remark.

Remark 3.4: The group $G=SL(2,R)\circledS T_2(R)$ contains, in some sense, the Galilean group. Consider a set of all $\Lambda \in G$ of form

$$\Lambda=\left\{\begin{pmatrix}1 & \lambda\\ 0 & 1\end{pmatrix},\ \begin{pmatrix}\mu\\ \nu\end{pmatrix}\right\}, \tag{3.24}$$

which causes the coordinate transformation,

$$\begin{aligned} t&\to t'=t+\lambda,\\ x&\to x'=x+\sigma+vt \end{aligned} \tag{3.25a}$$

with

$$\begin{aligned} \sigma&=\mu-\nu\lambda+k^2\beta\lambda^2,\\ v&=2k^2\beta\lambda-\nu \end{aligned} \tag{3.25b}$$

by Eq. (3.9). We note that the classical Newton's equation $m\ddot{x}=F$ is invariant under the Galilean transformation since the Newtonian force F is constant for the linear potential. Therefore, in some sense, the group $G=SL(2,R)\circledS T_2$ together with Eq. (3.9) may be said to be a quantum-mechanical generalization of the Galilean transform.

We will next give examples of Theorem 1.3 for the case of $V_0(\mathbf{x})=0$ and $V(\mathbf{x})=\alpha+\beta x$. For simplicity, we set

$$\mathcal{H}_0=\left\{\psi_0(t,x)\middle|\left(\frac{\partial}{\partial t}-k\Delta\right)\psi_0(t,x)=0\right\}, \tag{3.26a}$$

$$\mathcal{H}=\left\{\psi(t,x)\middle|\left(\frac{\partial}{\partial t}-k\Delta+k\alpha+k\beta x\right)\psi(t,x)=0\right\}. \tag{3.26b}$$

First, we note that Eq. (1.12) for $V_0(\mathbf{x})=0$ implies $K(t,x)\in\mathcal{H}$. Solving conditions stated in Theorem 1.3, we then have two distinct solutions, corresponding to $C(x)=0$ or $\neq 0$. Rewriting these $K(t,x)$ now as $f_j(t,x)$ $(j=1,2)$. We have:

Proposition 3.5: Let us set

$$f_1(t,x)=\exp\{-k(\alpha+\beta x)t+\tfrac{1}{3}k^3\beta^2t^3\}, \tag{3.27a}$$

$$f_2(t,x)=\sqrt{\frac{1}{t}}\exp\left\{-kt\left(\alpha+\frac{\beta}{2}x\right)+\frac{1}{12}k^3\beta^2t^3-\frac{x^2}{4kt}\right\}, \tag{3.27b}$$

both of which are elements of $\mathcal{H}$. Then, for any $\psi_0(t,x)\in\mathcal{H}_0$, the functions defined by

$$\psi_j(t,x)=f_j(t,x)\psi_0(t_j',x_j') \quad (j=1,2) \tag{3.28}$$

are elements of $\mathcal{H}$, where

$$t_1'=t, \quad x_1'=x-k^2\beta t^2, \tag{3.29a}$$

$$t_2'=-\frac{1}{t}, \quad x_2'=\frac{x}{t}-k^2\beta t. \tag{3.29b}$$

Conversely, suppose $\psi(t,x)\in\mathcal{H}$. Then, new functions defined by

$$\psi_0^{(j)}(t,x)=\phi_j(t,x)\psi(\tilde{t}_j,\tilde{x}_j) \quad (j=1,2) \tag{3.30}$$

are elements of $\mathcal{H}_0$, where we have set

$$\phi_1(t,x)=\exp\{k[\alpha+\beta x]t+\tfrac{2}{3}k^2\beta^3t^3\}, \tag{3.31a}$$

$$\phi_2(t,x)=\frac{1}{\sqrt{t}}\exp\left\{-\frac{k\alpha}{t}-\frac{2}{3}\frac{k^2\beta^3}{t^3}-\frac{k\beta x}{t^2}-\frac{x^2}{4kt}\right\}, \tag{3.31b}$$

with

$$\tilde{t}_1=t, \quad \tilde{x}_1=x+k^2\beta t^2, \tag{3.32a}$$

$$\tilde{t}_2=-\frac{1}{t}, \quad \tilde{x}_2=\frac{x}{t}+\frac{k^2\beta}{t^2}. \tag{3.32b}$$

So far, we have considered only one-dimensional problems. However, we can find some examples for multidimensional cases with the same symmetry group $G=SL(2,R)\,\textcircled{S}\,T_2(R)$.

Example 3.6: Suppose that $\psi(t,\mathbf{x})$ with $\mathbf{x}=(x_1,x_2,\ldots,x_n)$ satisfy

$$\frac{\partial}{\partial t}\psi(t,\mathbf{x})=k\left\{\Delta-\sum_{j=1}^{n}(\alpha+\beta x_j)-\sum_{j,k=1}^{n}\frac{a_{jk}}{(x_j-x_k)^2}\right\}\psi(t,\mathbf{x}), \tag{3.33}$$

where a_{jk} with $a_{jj}=0$ are some constants. We also set

$$\tilde{K}(t,\mathbf{x}|\Lambda)=\prod_{j=1}^{n}K(t,x_j|\Lambda), \tag{3.34}$$

where $K(t,x|\Lambda)$ is given by Eqs. (3.4) and (3.5). Moreover, we consider the transformation

$$\psi(t,\mathbf{x})\to\psi'(t,\mathbf{x})=\tilde{K}(t,\mathbf{x}|\Lambda)\psi(t',\mathbf{x}'), \tag{3.35}$$

where t' and x_j' are given by Eq. (3.9) by replacing x there by x_j' for each $j=1,2,\ldots,n$. When we note

$$x_j'-x_k'=\frac{1}{at+b}(x_j-x_k),$$

for $j,k=1,2,\ldots,n$, we can readily verify the validity of Eq. (1.9) so that $\psi'(t,\mathbf{x})$ is another solution of Eq. (3.33).

Example 3.7: As we will see in the following, the two-dimensional nonlinear Schrödinger equation (see Refs. 4 and 7–9 on the subject)

$$\frac{\partial}{\partial t}\psi(t,x_1,x_2)=k\left\{\frac{\partial^2}{\partial x_1^2}+\frac{\partial^2}{\partial x_2^2}+\lambda|\psi(t,x_1,x_2)|^2\right\}\psi(t,x_1,x_2) \tag{3.36}$$

possesses also $G=SL(2,R)\,\textcircled{S}\,T_2(R)$ symmetry in spite of the nonlinearity of Eq. (3.36), provided that the parameter k is purely imaginary. Let $\tilde{K}(t,x_1,x_2)$ be given again by Eq. (3.34) with $\alpha=\beta=0$ for $n=2$ so that

$$\tilde{K}(t,x_1,x_2|\Lambda)=\frac{1}{at+b}\exp\left\{-\frac{1}{2k}\mu\nu+\frac{\nu^2}{2k}\,\frac{ct+d}{at+b}-\frac{\nu}{2k}\,\frac{1}{at+b}(x_1+x_2)-\frac{1}{4k}\,\frac{a}{at+b}(x_1^2+x_2^2)\right\}. \tag{3.37}$$

We note then that we have

$$|\tilde{K}(t,x_1,x_2|\Lambda)|^2=\frac{1}{(at+b)^2}$$

if k is purely imaginary. Then, the new function $\psi'(t,x_1,x_2)$ given by Eq. (3.35) for $n=2$ also satisfies

$$|\psi'(t,x_1,x_2)|^2=\frac{1}{(at+b)^2}|\psi(t',x_1',x_2')|^2.$$

As the consequence, it satisfies the analog of Eq. (1.9), i.e.,

$$\left\{\frac{\partial}{\partial t}-k\Delta+k\lambda|\psi'(t,x_1,x_2)|^2\right\}\psi'(t,x_1,x_2)$$
$$=\frac{1}{(at+b)^2}\tilde{K}(t,x_1,x_2)\left\{\frac{\partial}{\partial t'}-k\Delta'+k\lambda|\psi(t',x_1',x_2')|^2\right\}\psi(t',x_1',x_2')=0.$$

Remark 3.8: Let us return now to the function $f_1(t,x)$ given by Eq. (3.27a). One thing interesting about this function is that it is intimately related to a bound state problem. Consider the eigenvalue problem of

$$\left\{-\frac{\mathrm{d}^2}{\mathrm{d}x^2}+\beta x\right\}u(x)=Eu(x) \tag{3.38}$$

with the boundary condition $u(0)=0$ at $x=0$ for some eigenfunction $u(x)\in L^2(0,\infty)$. To see the connection, we first note

$$\frac{\partial}{\partial t}f_1(t,x)=k\left\{\frac{\partial^2}{\partial x^2}-(\alpha+\beta x)\right\}f_1(t,x) \tag{3.39}$$

since $f_1(t,x)\in\mathcal{H}$. We next choose $k=-i$, and observe

$$\lim_{t\to\pm\infty}f_1(t+i\delta,x)=0,$$

for any $\delta>0$. Therefore, if we set

$$u(x)=\int_{-\infty}^{\infty}\mathrm{d}t\,f_1(t+i\delta,x) \tag{3.40}$$

and integrate Eq. (3.39) in t, $u(x)$ satisfies Eq. (3.38) with $E=-\alpha$. Moreover, letting $\delta\to+0$, we calculate

$$u(x)=2\int_0^{\infty}\mathrm{d}t\cos\left\{(\alpha+\beta x)t+\frac{1}{3}\beta^2t^3\right\}, \tag{3.41}$$

which is the Airy's function[10] with $u(x)\in L^2(0,\infty)$ for $\beta>0$. Therefore, if we set $x=0$ with $\alpha=-E$, the boundary condition $u(0)=0$ leads to

$$\int_0^\infty dt \cos\left(\frac{1}{3}\beta^2 t^3 - Et\right) = 0. \tag{3.42}$$

The relevance of this solution to the quarquonium spectra for the S-wave bound states of the three-dimensional confining linear potential can be found in Ref. 11.

Remark 3.9: Another interesting property of the function $f_1(t,x)$ is that it is invariant under the following two-dimensional Abelian subgroup G_0 of G, which consists of all elements of form:

$$\Lambda_0 = \left\{ \begin{pmatrix} 1 & \lambda \\ 0 & 1 \end{pmatrix}, \quad \begin{pmatrix} \mu \\ 0 \end{pmatrix} \right\}. \tag{3.43}$$

Then, it is straightforward to show the validity of

$$U(\Lambda_0) f_1(t,x) = f_1(t,x)$$

so that the G-orbit of $f_1(t,x)$ is the symmetric space G/G_0. Note that under Λ_0, the coordinate transform as a special Galilean transformation of

$$t \to t' = t + \lambda,$$

$$x \to x' = x + (\mu + k^2 \beta \lambda^2) + 2k^2 \beta \lambda t$$

by Eq. (3.25).

Remark 3.10: If we set $\mu = \nu = 0$, then the group G reduces to $SL(2,R)$. Consider now the following time-dependent potential

$$V(t,x) = \alpha + \beta x + \frac{\lambda}{(x - k^2 \beta t^2)^2} \tag{3.44}$$

for a constant λ. Then, the wave function $\psi(t,x)$ satisfying

$$\frac{\partial}{\partial t}\psi(t,x) = k\left\{\frac{\partial^2}{\partial x^2} - V(t,x)\right\}\psi(t,x) \tag{3.45}$$

is still invariant under the $SL(2,R)$ symmetry, since we will have

$$x' - k^2 \beta t'^2 = \frac{1}{at+b}(x - k^2 \beta t^2) \tag{3.46}$$

under Eq. (3.9) with $\mu = \nu = 0$. In sec. V, we will also show that any function $\psi(t,x)$ satisfying Eq. (3.45) is an eigenstate of the Casimir invariant I_2 of the $s\ell(2)$ Lie algebra.

IV. QUADRATIC POTENTIAL

The same method given in the previous sections is also applicable to the case of the quadratic potential

$$\frac{\partial}{\partial t}\psi(t,x) = k\left\{\frac{\partial^2}{\partial x^2} - (\alpha + \omega^2 x^2)\right\}\psi(t,x), \tag{4.1}$$

for real constants α and ω^2. The value of ω^2 could also assume a negative value in what follows. However, in order to avoid the question of the reality constraint for t' and x', we will temporarily suppose that variables t, x, t', and x' as well as other parameters are allowed to assume complex values. We now perform the coordinate transformation

$$t \to t' = \phi(t), \tag{4.2a}$$

$$x \to x' = \xi(t)x + f(t) \tag{4.2b}$$

as before with

$$\psi(t,x) \to \psi'(t,x) = K(t,x)\psi(t',x'), \tag{4.3a}$$

$$K(t,x) = \exp\{A(t) + B(t)x + C(t)x^2\} \tag{4.3b}$$

as in Sec. I. Then Eqs. (1.17) and (1.18) for $n=1$ give differential equations

$$\text{(i)} \quad \xi(t)\ddot{\xi}(t) - 2\dot{\xi}(t)\dot{\xi}(t) = 4k^2\omega^2\xi^2(t)\{\xi^4(t) - 1\}, \tag{4.4a}$$

$$\text{(ii)} \quad \xi(t)\ddot{f}(t) - 2\dot{\xi}(t)\dot{f}(t) = 4k^2\omega^2\xi^5(t)f(t), \tag{4.4b}$$

$$\text{(iii)} \quad \dot{\phi}(t) = \xi^2(t), \tag{4.4c}$$

among many others.

First, the solution of Eq. (4.4a) leads to

$$\xi^2(t) = \pm \frac{\exp(4k\omega t)}{\{b + a\exp(4k\omega t)\}\{d + c\exp(4k\omega t)\}} \tag{4.5}$$

for constants a, b, c, and d satisfying $bc - ad = 1$. At first glance, this appears rather peculiar, since the second-order differential equation, Eq. (4.4a), admits solutions containing three instead of two arbitrary parameters. However, in writing Eq. (4.5), we took advantage of the translation invariance of Eq. (4.4a) under

$$t \to t' = t + \text{ constant},$$

which adds one more parameter in theory. Then, the general solution of Eq. (4.4b) is found to be

$$f(t) = \nu\left[\frac{d + c\exp(4k\omega t)}{b + a\exp(4k\omega t)}\right]^{1/2} - \mu\left[\frac{b + a\exp(4k\omega t)}{d + c\exp(4k\omega t)}\right]^{1/2}, \tag{4.6}$$

for additional constant μ and ν. Therefore, the solution contains five parameters which we specify by

$$\Lambda = \left\{M, \begin{pmatrix}\mu \\ \nu\end{pmatrix}\right\}, \tag{4.7a}$$

$$M = \begin{pmatrix} c & d \\ a & b \end{pmatrix} \quad \text{at} \quad M = 1 \tag{4.7b}$$

just as Eq. (3.3). If we allow complex values for all these parameters, then the present theory remarkably gives the same symmetry group of $SL(2,C)\,\textcircled{S}\,T_2(C)$ also as we will see in the following. However if we restrict ourselves to real values for t, x, t', and x', then we will have the following complications. Because of the square roots operations for $\xi(t)$ in Eq. (4.5) as well as in $f(t)$ of Eq (4.6), x' given by Eq. (4.2b) will not remain real for arbitrary real values of a, b, c, d, μ, and ν. We will discuss the problem later.

Since all functions $\xi(t)$, $f(t)$, etc., depend upon the parameters of Λ, we rewrite them again as $\xi(t|\Lambda)$, $f(t|\Lambda)$, etc. However, the formulas become simpler, if we use the new variable

$$u = \exp(4k\omega t), \tag{4.8a}$$

$$u' = \exp(4k\omega t') \tag{4.8b}$$

instead of t and t'.

We can then rewrite Eq. (4.2) as

$$u' = \frac{cu+d}{au+b}, \quad bc-ad=1, \tag{4.9a}$$

$$x' = \xi(t|\Lambda)x + f(t|\Lambda), \tag{4.9b}$$

where

$$\xi(t|\Lambda) = \left[\frac{u}{(au+b)(cu+d)}\right]^{1/2}, \tag{4.10a}$$

$$f(t|\Lambda) = \nu\left[\frac{cu+d}{au+b}\right]^{1/2} - \mu\left[\frac{au+b}{cu+d}\right]^{1/2}. \tag{4.10b}$$

Calculating now explicit forms of $A(t|\Lambda)$, $B(t|\Lambda)$, and $C(t|\Lambda)$ as in the previous section, we find:

Proposition 4.1: For any $\psi(t,x)$ satisfying Eq. (4.1), the new function given by

$$\psi'(t,x) = K(t,x|\Lambda)\psi(t',x')(=U(\Lambda^{-1})\psi(t,x)) \tag{4.11}$$

is also a solution of the same differential equation, Eq. (4.1). Here, we have set

$$K(t,x|\Lambda) = \exp\{A(t|\Lambda) + B(t|\Lambda)x + C(t|\Lambda)x^2\}, \tag{4.12a}$$

$$A(t|\Lambda) = \frac{1}{4}\log\frac{u}{(au+b)(cu+d)} + \frac{\alpha}{4\omega}\left\{\log\left(\frac{cu+d}{au+b}\right) - \log u\right\} + \frac{\omega}{2}\left\{\nu^2\frac{cu+d}{au+b} - \mu^2\frac{au+b}{cu+d}\right\}, \tag{4.12b}$$

$$B(t|\Lambda) = \omega\left\{\frac{\nu\sqrt{u}}{au+b} + \frac{\mu\sqrt{u}}{cu+d}\right\}, \tag{4.12c}$$

$$C(t|\Lambda) = \frac{\omega}{2}\left\{-1 + \frac{b}{au+b} + \frac{d}{cu+d}\right\}. \tag{4.12d}$$

We introduce the product $\Lambda\circ\Lambda'$ for two Λ and Λ' again by Eq. (3.11), which defines the group $G = SL(2,C)\,\textcircled{S}\,T_2(C)$ for complex Λ and Λ'. We also assume the action of Λ to the coordinate $Z=\{t,x\}$ to be given by Eq. (3.14) so that

$$\Lambda Z = \Lambda\{t,x\} = \{t',x'\}. \tag{4.13}$$

We then discover after some calculations that the exact analog of Proposition 3.2 also holds valid for the present case except for the fact that $\omega(\Lambda,\Lambda')$ there is now replaced by

$$\omega(\Lambda,\Lambda') \to \tilde{\omega}(\Lambda,\Lambda') = \omega\{(\mu a - \nu c)\mu' + (\mu b - \nu a)\nu'\}. \tag{4.14}$$

For the proof of these facts, the identities (3.19) (with $t\to u$) as well as

$$\frac{b}{a''u+b''}\,\frac{a'u+b'}{c'u+d'} = \frac{1}{c'u+d'} - \frac{a}{a''u+b''}, \tag{4.15a}$$

$$\frac{d}{c''u+d''}\,\frac{a'u+b'}{c'u+d'}=\frac{1}{c'u+d'}-\frac{c}{c''u+d''} \tag{4.15b}$$

are useful, although we will not go into detail. However, we do not understand the reason why both cases of linear and quadratic potentials give at least formally the identical final results.

Remark 4.2: In contrast to the case of linear potential, the special transformation Eq. (3.24) of $G=SL(2,R)\,\textcircled{S}\,T_2(R)$ with Eq. (4.9) does not give the Galilean formula (3.25) for the present problem. This is, of course, expected since the classical Newton's formula $m\ddot{x}=F=\lambda x$ (sor some constant λ) is no longer invariant under the Galilean transformation.

So far we have ignored the question of the reality for variables t, x, t', and x'. Let us discuss the problem in some detail in the following. Since both constants k and ω are assumed to be either real or purely imaginary, so will be the product $k\omega$. Suppose first that $k\omega$ is real. Then, $u=\exp(4k\omega t)$ is real and positive for real t. The condition that both x' and t' are real requires that $au+b$ and $cu+d$ be real with $(au+b)(cu+d)>0$ for any $u>0$. This can be possible in general only in a neighborhood of the unit element $E=\left(\begin{smallmatrix}1&0\\0&1\end{smallmatrix}\right)$ of the $SL(2,R)$ matrix M. Moreover, the allowed values for M depend upon the time t. In other words, the symmetry group of the theory is not in general global $SL(2,R)$ group, but is the so-called local group (or group germ). Alternatively we may better consider a subset of $SL(2,R)$ such that all a, b, c, d are non-negative. Then, the reality condition for t' and u' is readily maintained. However, the inverse matrix M^{-1} does not satisfy the requirement, then. In this case, the symmetry is not a group but a global semigroup consisting of all non-negative matrices in $SL(2,R)$, when $k\omega$ is real. Note that μ and ν are chosen to be real in the present case in order to make x' to be real in Eq. (4.9b).

On the other side, suppose now that $k\omega$ is purely imaginary. Then, we have $|u|=|u'|=1$. In that case, instead of the parametrization Eq. (4.7b) for M, we may use the conformal mapping in the complex u plane by

$$u\to u'=e^{2i\theta}\frac{u-\lambda}{1-\lambda^{*}u}, \tag{4.16}$$

for real θ and any complex λ with $|\lambda|\neq=1$. The condition $|u'|=1$ whenever we have $|u|=1$ is automatically guaranteed by Eq. (4.16) for arbitrary complex number λ. In terms of θ and λ, we can express a, b, c, d as

$$\begin{gathered}a=-\frac{\lambda^{*}}{\sqrt{1-|\lambda|^2}}e^{i\theta},\quad b=\frac{1}{\sqrt{1-|\lambda|^2}}e^{-i\theta},\\ c=\frac{1}{\sqrt{1-|\lambda|^2}}e^{i\theta}=b^{*},\quad d=-\frac{\lambda}{\sqrt{1-|\lambda|^2}}e^{-i\theta}=a^{*}\end{gathered} \tag{4.17}$$

for $|\lambda|<1$. This especially gives an identity

$$cu+d=(au+b)^{*}u \tag{4.18}$$

for $|u|=1$. Then, Eq. (4.10a) gives the desired result of the reality constraint of

$$\xi(t|\Lambda)=\frac{1}{|au+b|}>0.$$

If we next rewrite Eq. (4.10b) as

$$f(t|\Lambda)=\nu\left[\frac{(au+b)^{*}u}{au+b}\right]^{1/2}-\mu\left[\frac{(au+b)u^{*}}{(au+b)^{*}}\right]^{1/2} \tag{4.19}$$

for $|u|=1$, then the reality of $f(t|\Lambda)$ can also be maintained as long as we have

$$\mu^* = -\nu. \tag{4.20}$$

We can verify that both Eq. (4.20) and

$$M = \begin{pmatrix} b^*, & a^* \\ a, & b \end{pmatrix}$$

given by Eq. (4.17) remains invariant under the composition law Eq. (3.11). In conclusion, if $k\omega$ is purely imaginary, the symmetry group of the problem is a particular global subgroup of $G = SL(2,C) \circledS T_2(C)$, where we use the parametrization of $SL(2,C)$ and $T_2(C)$ as in Eqs. (4.17) and (4.20). Especially, it contains a group of conformal mappings of transforming the unit circle onto itself in the complex u plane.

Last, we would like to present another example for Theorem 1.3 for the present problem with $V_0(\mathbf{x})=0$. Let us set

$$\mathcal{H}_0 = \left\{ \psi_0(t,x) \left| \left(\frac{\partial}{\partial t} - k \frac{\partial^2}{\partial x^2} \right) \psi_0(t,x) = 0 \right. \right\}, \tag{4.21a}$$

$$\mathcal{H}_1 = \left\{ \psi(t,x) \left| \left(\frac{\partial}{\partial t} - k \frac{\partial^2}{\partial x^2} - k(\alpha + \omega^2 x^2) \right) \psi(t,x) = 0 \right. \right\}. \tag{4.21b}$$

Solving conditions given in Theorem 1.3, we then find:

Proposition 4.2: For any $\psi_0(t,x) \in \mathcal{H}_0$, the function given by

$$\psi(t,x) = K_0(t,x)\psi_0(t',x') \tag{4.22}$$

is an element of $\mathcal{H}$, where

$$t' = -\frac{\sigma^2}{4k\omega} \frac{1}{u+\lambda}, \tag{4.23a}$$

$$x' = \sigma \frac{\sqrt{u}}{u+\lambda} x - \frac{\sigma\tau}{2\omega} \frac{1}{u+\lambda}, \tag{4.23b}$$

with

$$K_0(t,x) = \frac{u^{1/4}}{(\lambda+u)^{1/2}} \exp\{A_0(t) + B_0(t)x + C_0(t)x^2\}, \tag{4.24a}$$

$$A_0(t) = -\frac{\tau^2}{4\omega} \frac{1}{u+\lambda} - k\alpha t, \tag{4.24b}$$

$$B_0(t) = \tau \frac{\sqrt{u}}{u+\lambda}, \tag{4.24c}$$

$$C_0(t) = \frac{\omega(\lambda-u)}{2(u+\lambda)}. \tag{4.24d}$$

Here, σ, λ, τ are arbitrary constants and

$$u = \exp\{4k\omega t\}. \tag{4.25}$$

Remark 4.3: Unfortunately, the variables t' and x' given by Eq. (4.23) can be real only for the case of $k\omega$ being real. For that case, we can construct solutions of Eq. (4.21b) from that of $\psi(t,x)$ satisfying Eq. (3.26b) by combining Eqs. (3.30) and (4.22).

V. LIE ALGEBRAS AND LOCAL SYMMETRY

In the preceding sections, we found that the time-dependent Schrödinger equation for some potentials has global groups as symmetry of the theory. However, much larger local symmetry could emerge, if we consider its Lie algebraic structure as follows.

Let us first set for simplicity

$$K \equiv \frac{\partial}{\partial t} - k\left\{\frac{\partial^2}{\partial x^2} - V(x)\right\} \tag{5.1}$$

and

$$\mathcal{H} = \{\psi(t,x) | K\psi(t,x) = 0\}. \tag{5.2}$$

Consider now, as an example, the symmetry group $G = SL(2,R) \circledS T_2(R)$ of Sec. III for the linear potential. We know that for any $\psi(t,x) \in \mathcal{H}$, we have $U(\Lambda)\psi(t,x) \in \mathcal{H}$ for any $\Lambda \in G$. Since G is a Lie group, we can associate a Lie algebra L by considering infinitesimal Λ's. It is then evident that we have

$$g\psi(t,x) \in \mathcal{H}, \quad g \in L. \tag{5.3}$$

Let $\tilde{U}(L)$ be the universal enveloping algebra of L. Also, we will then have

$$\tilde{U}(L)\psi(t,x) \in \mathcal{H} \tag{5.4}$$

whenever $\psi(t,x)$ is a sufficiently smooth function of t and x. Since K is invariant under the time translation $t \to t' = t + \lambda$ for any constant λ, the Lie algebra L always contain a special element

$$D \equiv \frac{\partial}{\partial t} \in L \tag{5.5}$$

so that this implies the validity of

$$D^n\psi(t,x) \in \mathcal{H} \tag{5.6}$$

for any positive integer n. This can be, of course, more directly verified from $[D^n, K] = 0$. For the case of the linear potential of Sec. III, the Lie algebra L consists now of six elements (instead of five with the additional unit element 1);

$$L = \{L_\pm, L_3, T_1, T_2, 1\}, \tag{5.7}$$

which forms the Abelian-extended Lie algebra of

$$L = s\ell(2) \oplus t(2) \oplus u(1), \tag{5.8}$$

where $u(1)$ is the extra one-dimensional Abelian algebra in conformity with the projective representation nature of $U(\Lambda)$ in Eq. (3.23). Their explicit forms are easily calculated from Eqs. (3.4), (3.5), (3.7), and (3.9) to be given by

$$-L_3 = t\frac{\partial}{\partial t} + \frac{1}{2}(x + 3k^2\beta t^2)\frac{\partial}{\partial x} + k\left(\alpha + \frac{3}{2}\beta x\right)t + \frac{1}{2}k^3\beta^2 t^3 + \frac{1}{4}, \tag{5.9a}$$

$$L_+ = \frac{\partial}{\partial t} + 2k^2\beta t\frac{\partial}{\partial x} + k(\alpha+\beta x) + k^3\beta^2 t^2, \tag{5.9b}$$

$$L_- = t^2\frac{\partial}{\partial t} + (tx + k^2\beta t^3)\frac{\partial}{\partial x} + \frac{1}{2}t + \alpha k t^2 + \frac{1}{4}k^3\beta^2 t^4 + \frac{3}{2}k\beta t^2 x + \frac{1}{4k}x^2, \tag{5.9c}$$

and

$$T_1 = \frac{\partial}{\partial x} + k\beta t, \tag{5.10a}$$

$$T_2 = t\frac{\partial}{\partial x} + \frac{1}{2k}x + \frac{k\beta}{2}t^2. \tag{5.10b}$$

They satisfy commutation relations:

$$[L_3, L_\pm] = \pm L_\pm, \quad [L_+, L_-] = -2L_3, \tag{5.11a}$$

$$[L_3, T_1] = \frac{1}{2}T_1, \quad [L_3, T_2] = -\frac{1}{2}T_2, \tag{5.11b}$$

$$[L_+, T_1] = [L_-, T_2] = 0, \tag{5.11c}$$

$$[L_+, T_2] = T_1, \quad [L_-, T_1] = -T_2, \tag{5.11d}$$

$$[T_1, T_2] = \frac{1}{2k}. \tag{5.11e}$$

Note that $[T_1, T_2] = 1/2k \neq 0$, reflecting the projective representation of Eq. (3.23). We note that T_1 and T_2 play the role of creation and annihilation operators.

Since $W(\Lambda)$ is also a representation of G, we can perform the same analysis to find that the corresponding Lie algebra $\tilde{L}$ consisting of

$$\tilde{L} = \{\tilde{L}_\pm, \tilde{L}_3, \tilde{T}_1, \tilde{T}_2, 1\} \tag{5.12}$$

has the form

$$\begin{gathered} \tilde{L}_3 = L_3 - 1, \quad \tilde{L}_+ = L_+, \quad \tilde{L}_- = L_- + 2t, \\ \tilde{T}_1 = T_1, \quad \tilde{T}_2 = T_2 \end{gathered} \tag{5.13}$$

with the same commutation relation, Eq. (5.11). When we write

$$K_1 = \frac{\partial}{\partial t} - k\left\{\frac{\partial^2}{\partial x^2} - \alpha - \beta x\right\}, \tag{5.14}$$

then Eq. (1.11) becomes

$$\tilde{L}K_1 = K_1 L. \tag{5.15}$$

This especially implies $[L_+, K_1] = [T_1, K_1] = [T_2, K_1] = 0$ and $[L_3, K_1] = K_1$. Moreover, we can easily find that K_1 is rewritten as a element of $\tilde{U}(L)$ as

$$K_1 = L_+ - kT_1^2 \tag{5.16}$$

while the time derivative $D = \partial/\partial t$ is expressed as

$$D = L_+ - 2k^2\beta T_2 - k\alpha.$$

Before going into further details, we note first that the second-order Casimir invariant of the $s\ell(2)$ sub-Lie algebra of L is given by

$$I_2 = L_+L_- - L_3^2 + L_3. \tag{5.17}$$

In contrast, the larger Lie algebra L possesses not the second- but third-order Casimir invariant

$$I_3 = -I_2 + k\{L_3(T_1T_2 + T_2T_1) + L_+T_2T_2 + L_-T_1T_1\}. \tag{5.18}$$

For our particular form of generators given by Eqs. (5.9) and Eq. (5.10), we find that I_3 is purely a constant

$$I_3 = \tfrac{3}{16}, \tag{5.19}$$

while I_2 is rewritten as

$$I_2 = \frac{3}{16} + \frac{1}{4k}(x - k^2\beta t^2)^2 K_1. \tag{5.20}$$

Especially for any function $\psi = \psi(t,x)$ satisfying $K_1\psi = 0$, we have $I_2\psi = \frac{3}{16}\ \psi$. In this connection, two special functions $f_1(t,x)$ and $f_2(t,x)$ given in Eq. (3.27) have the following interesting property. They satisfy

$$L_+ f_1(t,x) = T_1 f_1(t,x) = 0, \quad L_3 f_1(t,x) = -\tfrac{1}{4}\ f_1(t,x), \tag{5.21a}$$

$$L_- f_2(t,x) = T_2 f_2(t,x) = 0, \quad L_3 f_2(t,x) = \tfrac{1}{4}\ f_2(t,x). \tag{5.21b}$$

Therefore, the function $f_1(t,x)$ corresponds to the highest weight state of simultaneous representations of both $s\ell(2)$ and L, while $f_2(t,x)$ plays the role of the lowest weight state of another representation. They are infinite dimensional and irreducible but *not* unitary. Moreover, they satisfy $K_1 f_j(t,x) = 0$ for $j = 1,2$ so that we have

$$I_2 f_j(t,x) = I_3 f_j(t,x) = \tfrac{3}{16}\ f_j(t,x) \quad (j = 1,2). \tag{5.22}$$

Also, in view of Eq. (5.20), the wave function $\psi(t,x)$ satisfying Eqs. (3.44) and (3.45) is the eigenstate of I_2 with

$$I_2\psi(t,x) = \left\{\frac{3}{16} - \frac{\lambda}{4}\right\}\psi(t,x).$$

The same analysis is readily applicable for the quadratic potential of Sec. IV. In this case, the Lie algebras L and $\tilde{L}$ are specified by

$$-L_3 = u\frac{\partial}{\partial u} + \frac{\alpha}{4\omega}, \tag{5.23a}$$

$$L_+ = \frac{\partial}{\partial u} - \frac{1}{2u}x\frac{\partial}{\partial x} + \left(\frac{\alpha}{4\omega} - \frac{1}{4}\right)\frac{1}{u} + \frac{\omega}{2}\ \frac{x^2}{u}, \tag{5.23b}$$

$$L_- = u^2\frac{\partial}{\partial u} + \frac{1}{2}ux\frac{\partial}{\partial x} + \left(\frac{\alpha}{4\omega} + \frac{1}{4}\right)\ u + \frac{\omega}{2}ux^2, \tag{5.23c}$$

$$T_1 = \frac{1}{\sqrt{u}}\ \frac{\partial}{\partial x} - \frac{\omega}{\sqrt{u}}x, \tag{5.23d}$$

$$T_2 = \sqrt{u}\ \frac{\partial}{\partial x} + \omega\sqrt{u}x, \tag{5.23e}$$

with $u = \exp(4k\omega t)$, and

$$\tilde{L}_3 = L_3, \quad \tilde{L}_+ = L_+ - \frac{1}{u}, \quad \tilde{L}_- = L_- + u, \tag{5.24a}$$

$$\tilde{T}_1 = T_1, \quad \tilde{T}_2 = T_2. \tag{5.24b}$$

They satisfy the same commutation relations. Eqs. (5.11a)–(5.11d) while Eq. (5.11e) is now replaced by

$$[T_1, T_2] = 2\omega. \tag{5.25}$$

Writing

$$K_2 = \frac{\partial}{\partial t} - k\left\{\frac{\partial^2}{\partial x^2} - \alpha - \omega^2 x^2\right\}, \tag{5.26}$$

the analogs of Eqs. (5.15), and (5.16), are now given by

$$\tilde{L}K_2 = K_2 L, \tag{5.27a}$$

$$K_2 = -4k\omega L_3 - \frac{k}{2}(T_1T_2 + T_2T_1), \tag{5.27b}$$

$$D = \frac{\partial}{\partial t} = -4k\omega L_3 - k\alpha. \tag{5.27c}$$

Especially, Eqs. (5.24) and (5.27a) lead to

$$[L_3, K_2] = [T_1, K_2] = [T_2, K_2] = 0.$$

For this case, the second-order Casimir invariant I_2 is still given by Eq. (5.17), while Eq. (5.18) for I_3 must now be replaced by

$$I_3 = -I_2 + \frac{1}{4\omega}\{L_3(T_1T_2 + T_2T_1) + L_-T_1T_1 + L_+T_2T_2\}. \tag{5.28}$$

We still have the validity of $I_3 = 3/16$ but Eq. (5.20) is now replaced by

$$I_2 = \frac{3}{16} + \frac{1}{4k}x^2K_2. \tag{5.29}$$

Especially, if $\psi(t,x)$ now satisfies

$$\left\{\frac{\partial}{\partial t}-k\left(\frac{\partial^2}{\partial x^2}-\alpha-\omega^2x^2-\frac{\lambda}{x^2}\right)\right\}\psi(t,x)=0$$

for some constant λ, then Eq. (5.29) now implies

$$I_2\psi(t,x)=\left(\frac{3}{16}-\frac{\lambda}{4}\right)\psi(t,x).$$

There exist relations analogous to Eqs. (5.21). Setting

$$g_1(t,x)=\exp\left\{k(\omega-\alpha)t+\frac{\omega}{2}x^2\right\}, \tag{5.30a}$$

$$g_2(t,x)=\exp\left\{-k(\omega+\alpha)t-\frac{\omega}{2}x^2\right\}, \tag{5.30b}$$

it is easy to verify

$$K_2g_1(t,x)=L_+g_1(t,x)=T_1g_1(t,x)=0,\quad L_3g_1(t,x)=-\tfrac{1}{4}\,g_1(t,x), \tag{5.31a}$$

$$K_2g_2(t,x)=L_-g_2(t,x)=T_2g_2(t,x)=0,\quad L_3g_2(t,x)=\tfrac{1}{4}\,g_2(t,x). \tag{5.31b}$$

Note that $g_2(t,x)$ given by Eq. (5.30b) corresponds to the ground state wave function of the familiar harmonic potential. It is again the lowest weight state of representations of both $s\ell(2)$ and L. Another interesting function is obtained by setting $\tau=\lambda=0$, and $\sigma=1$ with appropriate choice for $\psi_0(t,x)$ in Proposition 4.3. In this way, the function

$$g_3(t,x)=\exp\left\{-k(\alpha+\omega)t-\frac{\omega}{2}x^2-\gamma\frac{x}{\sqrt{u}}-\frac{\gamma^2}{4\omega}\frac{1}{u}\right\} \tag{5.32}$$

for an arbitrary constant γ turns out to be a simultaneous eigenfunction of K_2, T_2, and L_- as in

$$\text{(i)}\quad K_2g_3(t,x)=0, \tag{5.33a}$$

$$\text{(ii)}\quad T_2g_3(t,x)=\gamma g_3(t,x), \tag{5.33b}$$

$$\text{(iii)}\quad L_-g_3(t,x)=\frac{\gamma^2}{4\omega}g_3(t,x). \tag{5.33c}$$

Especially, Eq. (5.33b) implies that $g_3(t,x)$ plays a role of coherent state as in the quantum optics,[12] since T_2 may be regarded as the analog of the annihilation operator.

Nonlinear transforms of momenta and Planck scale limit

A. Chakrabarti[a)]
Centre de Physique Théorique,[b)] *Ecole Polytechnique,*

(Received 28 November 2002; accepted 28 April 2003)

Starting with the generators of the Poincaré group for arbitrary mass (m) and spin (s), a nonunitary transformation is implemented to obtain momenta with an absolute Planck scale limit. In the rest frame (for $m>0$) the transformed energy coincides with the standard one, both being m. As the latter tends to infinity under Lorentz transformations the former tends to a finite upper limit $m\coth(lm)=l^{-1}+O(l)$, where l is the Planck length and the mass-dependent nonleading terms vanish exactly for zero rest mass. The invariant m^2 is conserved for the transformed momenta. The speed of light continues to be the absolute scale for velocities. We study various aspects of the kinematics in which two absolute scales have been introduced in this specific fashion. The precession of polarization and transformed position operators are among them. A deformation of the Poincaré algebra to the $SO(4,1)$ de Sitter one permits the implementation of our transformation in the latter case. A supersymmetric extension of the Poincaré algebra is also studied in this context. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1593225]

I. INTRODUCTION

Possible modifications of special relativity introducing, in addition to the velocity of light, a second invariant scale corresponding to the Planck energy (the inverse of the Planck length) have been studied in numerous recent papers exploring various aspects.[1–11] The titles of these papers (citing other relevant sources) convey some idea of the topics addressed. Among the papers cited above, our work can be compared most directly, concerning both analogies and crucial differences, with the work of Magueijo and Smolin.[4,5] Like them, we introduce the nonlinear constructions via a nonunitary transformation. But (unlike all the foregoing studies) we introduce spin at the outset. To be able to do so adequately, we start with an irreducible representation $[m,s]$ of the Poincaré group of positive rest mass ($m>0$) and an arbitrary integer or half-integer spin s. The momentum generators are thus constrained to satisfy

$$P^{\mu}P_{\mu}=P_0^2-\vec{P}^2=m^2. \tag{1}$$

It will be implicit henceforth that (with a positive square root and ∇_i denoting the derivative with respect to P_i),

$$P_0=\sqrt{\vec{P}^2+m^2},\quad \vec{\nabla}P_0=\frac{\vec{P}}{P_0}. \tag{2}$$

Introducing $(2s+1)\times(2s+1)$ spin matrices $\vec{S}$, satisfying

$$[S_i,S_j]=i\epsilon_{ijk}S_k, \tag{3}$$

a)Electronic mail: chakra@cpht.polytechnique.fr
b)Laboratoire Propre du CNRS UPR A.0014.

the generators of pure rotations ($\vec{J}$) and those of pure Lorentz transformations ($\vec{K}$) can be represented as

$$\vec{J}=-i\vec{P}\times\vec{\nabla}+\vec{S}, \tag{4}$$

$$\vec{K}=-iP_0\vec{\nabla}-\frac{\vec{P}\times\vec{S}}{P_0+m}. \tag{5}$$

Let us briefly note the following points[12] for later use.

(a) The first term of $\vec{K}$ should *not* be symmetrized. The hermiticity of $\vec{K}$ and the relation to Newton–Wigner position operators are discussed in Ref. 12 [from Eq. (2.18) onward].

(b) For $m=0$, the last term of $\vec{K}$ is not well defined only for energy momenta (0,0,0,0), namely, at the tip of the light cone that is never in the same orbit with

$$p^2=0, \quad p_0\neq 0.$$

Hence, excluding massless particles with strictly zero energy, one can consistently use (5) with $m=0$. We will present below results for $m=0$ obtained systematically in this fashion. An explicit unitary transformation to Wigner's construction in terms of the little group E_2 has been presented elsewhere (see the discussion and the references in Ref. 12 from Eq. (2.21) onward). There it is explained how, in spite of the presence of three spin components in (4) and (5), one finally deals with only one conserved helicity component for $m=0$.

(c) The canonical form given by (4) and (5) is valid for any spin. The Pauli–Lubansky 4-vector is obtained by contracting the dual of the tensor ($\vec{J},\vec{K}$) by P_μ, or equivalently as

$$W_\mu=-i[P_\mu,\vec{K}\cdot\vec{J}] \tag{6}$$

$$=(\vec{P}\cdot\vec{J},P_0\vec{J}-\vec{P}\times\vec{K}) \tag{7}$$

$$=(\vec{P}\cdot\vec{S},m\vec{S}+(P_0+m)^{-1}(\vec{P}\cdot\vec{S})\vec{P}). \tag{8}$$

This satisfies

$$W_\mu W^\mu=-m^2\vec{S}^2. \tag{9}$$

The relation, for $s=1/2$, with the the Dirac representation and the Dirac equation, are indicated in Ref. 12 [from Eq. (2.49) onward]. The relevant transformation relating the two representations diagonalizes the Dirac mass operator ($\gamma\cdot p$).

Before introducing the explicit form of the transformation V (to be presented below) let us note the following aspect.

Having explicitly constructed all the transforms,

$$V(P_0,\vec{P},\vec{J},\vec{K})V^{-1}, \tag{10}$$

one can study the set

$$V(\vec{J},\vec{K})V^{-1},(P_0,\vec{P}),$$

or, in a complementary fashion, the set

$$(\vec{J},\vec{K}),V(P_0,\vec{P})V^{-1}.$$

In the latter case one conserves the explicit representation of the Lorentz algebra and associates physical significance with the transformed momenta. We will adopt the latter approach below

[providing, however, complete results for (10)]. This will furnish, in the terminology of Ref. 7, an example of DSR2 theories with bounded energy and momenta. The inverse formulas, giving the standard momenta in terms of the transformed ones, are obtained very simply.

II. THE TRANSFORMATION

Let

$$V=\exp(-lP_0\vec{P}\cdot\vec{\nabla}), \tag{11}$$

where $0<l\ll 1$, and $P_0=\sqrt{\vec{P}^2+m^2}$.

In fact, one may assume that in our chosen units ($c=1$), l is the Planck length, which is, more generally,

$$l_P=\sqrt{(\hbar G/c^3)}. \tag{12}$$

As compared to the corresponding operator,

$$U^{-1}=\exp(-l_P p_0 p^\mu \partial_\mu), \tag{13}$$

of Ref. 4, we have kept only the three space components in the scalar product, but still with the factor P_0 rather than $P=|\vec{P}|$. This is crucial for the remarkable properties obtained below for arbitrary spin.

Implementing, consistently with (2), for any f,

$$[\vec{\nabla},P_0]f=\frac{\vec{P}}{P_0}f,$$

one obtains

$$\vec{\mathsf{P}}\equiv V\vec{P}V^{-1}=\frac{m\vec{P}}{\sinh(lm)P_0+\cosh(lm)m}, \tag{14}$$

$$\mathsf{P}_0\equiv VP_0V^{-1}=m\frac{\cosh(lm)P_0+\sinh(lm)m}{\sinh(lm)P_0+\cosh(lm)m}, \tag{15}$$

satisfying

$$\mathsf{P}_0^2-\vec{\mathsf{P}}^2=P_0^2-\vec{P}^2=m^2, \tag{16}$$

$$V\vec{J}V^{-1}=\vec{J}=-i\vec{P}\times\vec{\nabla}+\vec{S}, \tag{17}$$

$$V\vec{K}V^{-1}=-i\cosh(lm)P_0\vec{\nabla}-i\sinh(lm)(m\vec{\nabla}+m^{-1}\vec{P}(\vec{P}\cdot\vec{\nabla}))-e^{-lm}\frac{\vec{P}\times\vec{S}}{P_0+m}. \tag{18}$$

Note the simplicity of the spin-dependent part on the right of (18). This corresponds to

$$V\frac{\vec{P}}{P_0+m}V^{-1}=e^{-lm}\frac{\vec{P}}{P_0+m}. \tag{19}$$

Hence, squaring each side and using (1), one obtains

$$V\frac{P_0-m}{P_0+m}V^{-1}=e^{-2lm}\frac{P_0-m}{P_0+m}. \tag{20}$$

Thus, one readily obtains (15) and hence also (14). If, without knowing (15) beforehand, one proceeds directly to compute the power series,

$$\mathsf{P}_0 = VP_0V^{-1} = P_0 - l[P_0(\vec{P}\cdot\vec{\nabla}),P_0] + l^2[P_0(\vec{P}\cdot\vec{\nabla})[P_0(\vec{P}\cdot\vec{\nabla}),P_0]] - \cdots, \tag{21}$$

one obtains

$$\mathsf{P}_0 = P_0 - l(P_0^2 - m^2) + l^2 P_0(P_0^2 - m^2) - \cdots. \tag{22}$$

The series is difficult to sum up. On the other hand, developing (15) in powers of l, one easily reproduces (22). One similarly obtains for the modulus of the momentum,

$$\mathsf{P} = P - lPP_0 + \tfrac{1}{2}l^2P(P_0^2 + P^2) - \cdots. \tag{23}$$

It is easy to verify that (14) and (15) can be inverted by simply changing the sign of l. Thus,

$$P_0 = m\frac{\cosh(lm)\mathsf{P}_0 - \sinh(lm)m}{-\sinh(lm)\mathsf{P}_0 + \cosh(lm)m}, \tag{24}$$

and so on. This is consistent with the invariance of $(P_0(\vec{P}\cdot\vec{\nabla}))$ under the transformation.

Let us now consider momentum eigenstates and denote the eigenvalues of P_μ and P_μ by p_μ and p'_μ, respectively. Then

$$p'_0 = m\frac{\coth(lm)p_0 + m}{p_0 + \coth(lm)m}. \tag{25}$$

Hence, since we are considering positive p_0, m, and l,

$$p'_0 < \coth(lm)m.$$

Similarly, for the modulus of the momentum, one obtains

$$p' < \frac{m}{\sinh(lm)}.$$

Thus our transformation, valid for arbitrary spin, indeed leads to an invariant energy scale. This is the crucial property. For

$$p_0 = m, \quad p'_0 = m,$$

and as

$$p_0 \to \infty, \quad p'_0 \to \coth(lm)m,$$

from below. *For all observers, p'_0 remains bounded.* Starting together with p_0 in the rest frame p'_0 lags progressively behind as the former increases to finally encounter the barrier $m\coth(lm)$. In powers of l, one obtains

$$p'_0 < l^{-1} + \tfrac{1}{3}m^2 l + O(l^2), \tag{26}$$

and

$$p' < l^{-1} - \tfrac{1}{6}m^2 l + O(l^2). \tag{27}$$

The modulus of the transformed velocity, quite consistently with our chosen units ($c=1$), has the high-energy limit, for $p_0\to\infty$, given by

$$\frac{p'}{p_0'}\to\frac{1}{\cosh(lm)}=1-\frac{1}{2}l^2m^2<1. \tag{28}$$

The limit 1 is attained exactly for for $m=0$. This will be seen more precisely immediately below.

III. ZERO REST MASS

As explained in (b) following Eq. (5), the essential results for $m=0$ can be obtained (rather than starting again with $m=0$ in V) easily and directly from our previous ones. Thus for $m\to 0$ one obtains from (14) and (15),

$$\vec{\mathsf{P}}=\frac{\vec{P}}{lP_0+1} \tag{29}$$

and

$$\mathsf{P}_0=\frac{P_0}{lP_0+1}, \tag{30}$$

satisfying evidently (like P_0 and $\vec{P}$)

$$\mathsf{P}_0^2-\vec{\mathsf{P}}^2=0.$$

Now, as compared to the inequality following (25), again for all parameters positive,

$$p_0'=\frac{p_0}{lp_0+1}<l^{-1}. \tag{31}$$

As

$$p_0\to\infty,\quad p_0'\to l^{-1},$$

from below. And as compared to (28),

$$\frac{p'}{p_0'}=\frac{p}{p_0}=1. \tag{32}$$

Thus, considering all masses and the system

$$(\vec{J},\vec{K},\mathsf{P}_0,\vec{\mathsf{P}}),$$

one indeed implements *two absolute scales: one for velocity* ($c=1$) *and one for energy*. The leading term for the limiting energy is always l^{-1}. This becomes exact for zero rest mass. For positive mass the exact result is provided by (25).

IV. PRECESSION OF POLARIZATION

Since V commutes with $\vec{S}$ the standard results for precession of polarization are conserved. (See the complete discussion in Ref. 12.) They can, however, be reexpressed in terms of $(\mathsf{P}_0,\vec{\mathsf{P}})$, if so desired. Thus, under an infinitesimal Lorentz transformation of velocity $\tanh\chi\,(\to\chi)$ parallel to the unit vector $\hat{n}$, the change

$$\delta\vec{S}=i[\chi\hat{n}\cdot\vec{K},\vec{S}]=-\chi\frac{(\hat{n}\times\vec{P})\times\vec{S}}{P_0+m}=-\chi e^{lm}\frac{(\hat{n}\times\vec{\mathsf{P}})\times\vec{S}}{\mathsf{P}_0+m}. \tag{33}$$

Thus, the formal expression is altered by a simple overall factor $e^{lm}(=1+O(l))$. In Ref. 12, it is explained how (33) leads to the famous Thomas factor $\frac{1}{2}$. We will not go further into such topics in the present study.

We indicate below very briefly possible generalizations of our study in two different directions.

V. DEFORMATION OF POINCARÉ TO *SO*(4,1) de SITTER ALGEBRA

The Lorentz algebra has two invariants:

$$(\vec{K},\vec{J}),\quad (\vec{K}^2-\vec{J}^2).$$

As pointed out before [see Eqs. (6)–(9)], commuting P_μ with the first one leads to W_μ giving the spin. The commutation of P_μ with the second leads to the homogenous $SO(4,1)$ algebra, where [along with the Lorentz $SO(3,1)$ generators and $\mu=(0,1,2,3)$]

$$L_{\mu 5}=\frac{i}{M}[(\vec{K}^2-\vec{J}^2),P_\mu]+\lambda P_\mu. \tag{34}$$

Here $M=(P^\mu P_\mu)^{1/2}$ is the mass operator and λ is an arbitrary parameter. Starting with an irreducible space $[m,s]$ (with $m>0$, say) one can compute explicitly the actions of $L_{\mu 5}$ on the states using (34). Elsewhere,[13] we have studied (34) in a more general context using, however, the Lorentz basis. Here we only point out that $(VL_{\mu 5}V^{-1})$ is obtained directly from our foregoing results. A detailed study is beyond the scope of this paper.

VI. A SUPERSYMMETRIC EXTENSION

A simple supersymmetric extension[14] permitting a ready implementation of our transformation can be obtained as follows. (Previous sources are cited in Ref. 14.) One starts with two fermionic operators satisfying (for $i=1,2$)

$$[a_i,a_j]_+=0=[a_i^\dagger,a_j^\dagger]_+,\quad [a_i,a_j^\dagger]_+=\delta_{ij}.$$

One defines $Q=(Q_1,Q_2)$ and the adjoint $Q^\dagger$ (a column with two rows) as

$$Q^\dagger=\frac{1}{\sqrt{2(P_0+M)}}[(P_0+M)+\vec{\tau}\cdot\vec{P}]a^\dagger. \tag{35}$$

Then in terms of Pauli matrices,

$$[Q^\dagger,Q]_+=\tau_0 P_0+\vec{\tau}\cdot\vec{P}. \tag{36}$$

This compact notation implies symmetrization of each term of the 2×2 matrix $Q^\dagger Q$. Thus, for example, at the top right one obtains

$$Q_1^\dagger Q_2+Q_2Q_1^\dagger=P_1-iP_2.$$

A Majorana spinor is provided by $(Q_1,Q_2,Q^\dagger{}_2,-Q^\dagger{}_1)$.

Next, one defines

$$\vec{\Sigma}=\tfrac{1}{2}(a\vec{\tau}a^\dagger). \tag{37}$$

Adding the spin operator $\vec{\Sigma}$ to $\vec{S}$, define

$$\vec{J}=-i\vec{P}\times\vec{\nabla}+(\vec{S}+\vec{\Sigma}), \tag{38}$$

$$\vec{K}=-iP_0\vec{\nabla}-\frac{\vec{P}\times(\vec{S}+\vec{\Sigma})}{P_0+m}. \tag{39}$$

Now $(P_\mu,\vec{K},\vec{J})$ continue to satisfy the Poincaré algebra along with

$$[\vec{J},Q^\dagger]=-\tfrac{1}{2}\vec{\tau}Q^\dagger, \tag{40}$$

$$[\vec{K},Q^\dagger]=-\frac{i}{2}\vec{\tau}Q^\dagger. \tag{41}$$

Thus, (36), (40), (41) together complete the supersymmetric extension. Various aspects are studied in Ref. 14, citing other sources. Here we only note that $\vec{\Sigma}$ commutes with V and denoting

$$\tilde{Q}=VQV^{-1},$$

$$\tilde{Q}^\dagger=\frac{1}{\sqrt{2(\mathsf{P}^0+M)}}[(\mathsf{P}_0+M)+\vec{\tau}\cdot\vec{\mathsf{P}}]a^\dagger, \tag{42}$$

and

$$[\tilde{Q}^\dagger,\tilde{Q}]_+=\tau_0\mathsf{P}_0+\vec{\tau}\cdot\vec{\mathsf{P}}. \tag{43}$$

Thus, our transformation can be readily implemented for such an extension. A more detailed study is beyond the scope of this paper.

VII. GRADIENT OPERATORS FOR $\vec{\mathsf{P}}$

One obtains for transforms of $\vec{\nabla}$, consistently with (15) and (18) and with P_0 given by (15),

$$\vec{\xi}=\frac{1}{\mathsf{P}_0}((\cosh(lm)P_0+\sinh(lm)m)\vec{\nabla}+m^{-1}\sinh(lm)\vec{P}(\vec{P}\cdot\vec{\nabla})), \tag{44}$$

where

$$\vec{\xi}\equiv V\vec{\nabla}V^{-1}.$$

Hence, for such ξ_i,

$$[\xi_i,\mathsf{P}_j]=\delta_{ij} \tag{45}$$

and

$$[\xi_i,\xi_j]=0. \tag{46}$$

Substituting for ξ_i,

$$\xi_i'=\xi_i+Vf_iV^{-1},$$

where f_i depends only on the momenta conserves (45) but not necessarily (46) unless

$$(\partial_i f_j - \partial_j f_i) = 0.$$

In particular, starting with the localizing and Hermitian Newton–Wigner position operators [Ref. 12 from Eq. (2.18) onward], namely,

$$\vec{X} = i\vec{\nabla} - \frac{\vec{P}}{2P_0^2}, \tag{47}$$

one obtains

$$V\vec{X}V^{-1} = i\vec{\xi} - \frac{\vec{\mathsf{P}}}{2\mathsf{P}_0^2}. \tag{48}$$

The components continue to satisfy (45) and (46) (with a factor i).

We will not attempt to explore here whether other choices can lead to interesting noncommutative Hopf algebras for the coordinates. Both noncommutative (Ref. 9 and sources cited) and commutative[5] space–times have been proposed in the context of Planck scale limits of momenta. In our formalism, apart from the commutativity of (46), the time t remains a parameter [P_0 being given by (2)].

VIII. CONCLUSION

For all mass and spin we have obtained nonlinear functions of the standard momenta possessing a Planck scale limit. Our construction exhibits that such a property is quite consistent with a fixed velocity of light, time remaining a parameter and commuting position operators corresponding to those for the nonlinear momenta. Even if one deliberately seeks a different formalism violating such properties, a comparison with our formalism will provide a deeper understanding.

Due to the fact that the new momenta are introduced via a relatively simple conjugation, by our V, all relevant properties are obtained fairly easily and systematically. This has permitted a ready passage to de Sitter $SO(4,1)$ and to a supersymmetric extension as well.

Elsewhere[15] we have presented explicit constructions for the generators of the Poincaré group for spacelike momenta and for lightlike momenta with continuous spin. We just mention that they have strong analogies with those introduced here for the timelike case and thus may suggest how our transformation can be adapted to those cases.

We add the following notes.

(1) In this paper we try to clarify further the properties of the transformed momenta. We repeat that in our case equivalence with the standard (untransformed) case would have persisted had one used (10), namely,

$$V(P_0, \vec{P}, \vec{J}, \vec{K})V^{-1}.$$

But implementing, as we choose to do,

$$V(P_0, \vec{P})V^{-1}, \vec{J}, \vec{K},$$

one obtains fundamentally different properties. *Leaving untouched* the realization of the Lorentz algebra and the base space, we attribute direct physical significance to the transformed momenta. One can legitimately explore other, different postulates. Here we have tried to indicate the remarkable consequences of adopting this one, along with our specific transformation.

The simplicity of the inverse transformation [see (24) and related comments] permits quite straightforward derivations of the nonlinear Lorentz transformation properties of the new mo-

menta and the new addition law for velocities. For brevity, we give only one example.

Consider a pure Lorentz transformation along the unit vector $\hat{n}$ and denote $\vec{K}\cdot\hat{n}=K_n$ and so on. Now

$$e^{i\chi K_n}P_0e^{-i\chi K_n}=\cosh\chi P_0+\sinh\chi P_n$$

and

$$e^{i\chi K_n}\mathsf{P}_0e^{-i\chi K_n}=m\,\frac{f_1(\mathsf{P}_0-m\coth(lm))+\coth(lm)\sinh\chi(\sinh(lm)\mathsf{P}_n+m\coth\chi)}{f_2(\mathsf{P}_0-m\coth(lm))+\sinh\chi(\sinh(lm)\mathsf{P}_n+m\coth\chi)},$$

where

$$f_1=(\cosh\chi(\cosh(lm))^2-(\sinh(lm))^2),\quad f_2=\cosh(lm)\sinh(lm)(\cosh\chi-1).$$

It is evident that the eigenvalue $m\coth(lm)$ of P_0 is invariant under Lorentz transformation. Thus the Planck scale limit presented below (25) is encapsulated in the nonlinear Lorentz transformation laws for P_μ. In form and also in content, the two transformation laws exhibited avove are, to say the least, distinguishable.

(2) A paper by Ahluwalia, Kirchbach, and Dadhich (gr-qc/0212128) has been brought to our notice. There also spin has been taken into consideration. In contrast to our canonical generators [(4),(5)] spinor equations are introduced starting with the Dirac equation. We have indicated [below (9)] references to transformations relating spinor and canonical representations.

ACKNOWLEDGMENT

I thank D. V. Ahluwalia for an exchange of information and comments.

(Received 26 March 2002; accepted 24 April 2003)

We show that the Ocneanu algebra of quantum symmetries, for an *ADE* diagram (or for higher Coxeter–Dynkin systems, like the Di Francesco–Zuber system) can be, in most cases, deduced from the structure of the modular *T* matrix in the *A* series. We recover in this way the (known) quantum symmetries of su(2) diagrams and illustrate our method by studying those associated with the three genuine exceptional diagrams of type su(3), namely, $\mathcal{E}_5$, $\mathcal{E}_9$, and $\mathcal{E}_{21}$. This also provides the shortest way to the determination of twisted partition functions in boundary conformal field theory with defect lines. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1592609]

I. INTRODUCTION

This article provides a simple tool for the determination, in most cases, of the algebra of quantum symmetries associated with *ADE* Dynkin diagrams [considered as quantum su(2) objects] or with their generalizations to higher systems [Di Francesco–Zuber diagrams in the case of su(3)].

Although a precise general definition of extended Coxeter–Dynkin systems is still lacking, the known examples always contain a ''principal'' series (the $\mathcal{A}$ series) and a finite number of ''genuine exceptional'' cases.[24] The other diagrams of the system are obtained as orbifolds of the genuine diagrams (exceptional or not) and as twists or conjugates (sometimes both) of the genuine diagrams and of their orbifolds. In the case of su(2) (the usual *ADE* system), we have the principal *A* series, and the two genuine exceptional cases E_6 and E_8; the D_{2n} diagrams are orbifolds of the A_{4n-3} diagrams; and the D_{2n+1} diagrams are orbifolds of the A_{4n-1} diagrams and E_7 is a twist of the D_{10} diagram (itself an orbifold of A_{17}). In the case of su(3) (the Di Francesco–Zuber system, slightly amended by A. Ocneanu in Ref. 25), we have the principal series $\mathcal{A}_k$, and three genuine exceptional diagrams: $\mathcal{E}_5$, $\mathcal{E}_9$, and $\mathcal{E}_{21}$; the others (in particular the other four exceptionals) of the system are obtained from these genuine diagrams by orbifolding, twisting and conjugating.

In some cases, the vector space spanned by the vertices of a given diagram *G* admits ''self-fusion,'' [27,28] i.e., it possesses an associative algebra structure with positive integral structure constants [like A_n, D_{2n}, E_6 and E_8 for the su(2) system]. Sometimes it does not (like D_{2n+1} and E_7). In all cases, this vector space is a module over the associative algebra of the particular diagram *A* of the $\mathcal{A}$ series which has the same Coxeter number (whose definition has to be suitably generalized for the higher systems).

The $\mathcal{A}$ series is always modular: one can define a representation of $\mathrm{SL}(2,\mathbb{Z})$ on the vector space of every diagram of this class (actually this representation factors to a finite group, but we

a)Electronic mail: robert.coquereaux@cpt.univ-mrs.fr
b)Electronic mail: schieber@if.ufrj.br

shall not need this information here). The standard generators of this group are called S and T. The vector space of the chosen diagram comes with a particular basis, where the basis vectors are associated with graph vertices. The operator T is diagonal on the vertices.

Take G to be a diagram and A to be the corresponding member of the $\mathcal{A}$ series. Being a module over the algebra of A, there exist induction-restriction maps between G and A and one can try to define an action of $\mathrm{SL}(2,\mathbb{Z})$ on the vector space of G, in a way that would be compatible with those maps; this is not necessarily possible. In plain terms, suppose that the vertex σ of G appears both in the branching rules (restriction map from A to G) of vertices τ_p and τ_q of A; one could think of defining the value of the modular generator T on σ either as $T(\tau_p)$ or as $T(\tau_q)$, but this is ambiguous, unless these two values are equal. In general, there is only a subset J of the vertices of G for which T can be defined: a vertex σ will belong to this subset whenever T is constant along the vertices of A whose restriction to G contains σ.

Following Ocneanu,[23] to every diagram G (with or without self-fusion) belonging to a Coxeter–Dynkin system, one can associate a bialgebra $\mathcal{B}G$. This bialgebra should be, technically, a weak Hopf algebra—or quantum groupoid—and we have checked this in a few cases, but we are not aware of any general proof (see our comments in the final section). By using a particular scalar product, one can trade the comultiplication for a multiplication and think that $\mathcal{B}G$ is a di-algebra rather than a bialgebra. There are two—usually distinct—block decompositions for this di-algebra. Blocks of the first type are labeled by points of a diagram A (the member of the $\mathcal{A}$ series that has same Coxeter number as G). Blocks of the second type are labeled by points of another diagram that we call $\mathrm{Oc}(G)$. The two sets of orthogonal projectors associated with these two block decompositions can be multiplied with either of these two associative multiplications and this allows one to define associative algebra structures on the vector spaces spanned by the vertices of the two graphs A and $\mathrm{Oc}(G)$. We denote these algebras by the same symbol as the graphs themselves. In the particular case where G is a member of the $\mathcal{A}$ series, these algebras coincide. In all cases, A is an algebra with a single generator and it is commutative. $\mathrm{Oc}(G)$, also called "algebra of quantum symmetries of G," is in general an algebra with two generators (only one if $G=A$) and it is not always commutative.

In the cases where $\mathrm{Oc}(G)$ is commutative, we observe that this algebra of quantum symmetries can be written in terms of a tensor product of appropriate graph algebras, but the tensor product should be taken above some subalgebra determined by the modular properties of the graph G and we refer to Sec. III for a discussion of the several ADE cases. Paradoxically, the simplest cases (besides the A_n) are those where the diagram G is an exceptional diagram equal to E_6 or E_8 (notice that E_7 does not enjoy self-fusion); in those simple cases $\mathrm{Oc}(G)$ is isomorphic with $G \otimes_J G$, where J is the particular subalgebra of the graph algebra of G whose determination (using modular considerations) was sketched previously. The tensor product sign, taken "above J," means that we identify $au \otimes b$ and $a \otimes ub$ whenever $u \in J \subset G$. When $\mathrm{Oc}(G)$ is not commutative, the method is not fully satisfactory, as we shall see.

The structure of our article is as follows. The first section reminds the reader of several useful (but not necessarily widely known) facts about graph algebras and their quantum symmetries. It also precises our notations. The reader already familiar with quantum symmetries of graphs may skip this part. In the second section, we consider the su(2) Coxeter–Dynkin system, i.e., the usual ADE diagrams. For every one of them we simply recover the structure of $\mathrm{Oc}(G)$ by our method (which is not fully satisfactory for D_{2n}, since the algebra of quantum symmetries of the later is non commutative). We give more details on the E_6 case because it is both nice and pedagogical. In the third section, we move to the su(3) Coxeter–Dynkin system. After some generalities on these Di Francesco–Zuber graphs and a short description of the cases associated with diagrams of $\mathcal{A}$ type (which are relatively trivial), we study, in detail, also because it is simple enough to be pedagogical, the quantum symmetries of the diagram $\mathcal{E}_5$ (the David star), which is one of the three genuine exceptional cases and is a module over $\mathcal{A}_5$. The technique being now clear, we list only the results for the other two genuine exceptional diagrams $\mathcal{E}_9$ and $\mathcal{E}_{21}$, i.e., we give their induction-restriction graphs, the values of the modular operator T and, for $\mathcal{E}_5$ and $\mathcal{E}_{21}$, the structure of their Ocneanu graph. To every point of such a graph, one may associate a "toric matrix,"[7,23] or,

equivalently, a twisted partition function in boundary conformal field theory with defect lines;[31] we also give their explicit expressions for the studied su(3) cases, at least those associated with the so-called ambichiral points (to keep the size of this article reasonable). The list of Di Francesco–Zuber graphs being quite long, we stop at this point, but all the other associated Ocneanu graphs should be obtained by proper generalizations of the study made for su(2); the details can, admittedly, be quite intricate, in particular for those graphs for which $\mathrm{Oc}(G)$ is not commutative.

Many topics discussed in the present article are already known to experts. We believe, however, that a systematic discussion of the correspondence between the eigenvalues of the T operators and the determination of quantum symmetries is not available elsewhere. Our explicit results concerning the Ocneanu graphs of several exceptional diagrams of the su(3) system seem also to be new, and, we hope, of interest for the reader.

II. ABOUT COXETER–DYNKIN GRAPH ALGEBRAS AND THEIR QUANTUM SYMMETRIES

A. Generalities

To a diagram G belonging to a (possibly higher) Coxeter–Dynkin system, one can associate[23] a bialgebra $\mathcal{B}(G)$ that we call Ocneanu–Racah–Wigner bialgebra (the precise definition of this bialgebra uses the notion of essential paths on the graph G: see our discussion in the Appendix). According to A. Ocneanu (unpublished), this object, also called ''algebra of double triangles,'' is a semi-simple weak Hopf algebra (or quantum groupoid)—see Refs. 3 and 21 for general properties of quantum groupoids. We shall not use it explicitly in our article and it is enough to say that, as a bialgebra, it possesses two associative algebra structures (say ''composition $\circ$'' and ''convolution $\star$''), for which the underlying vector space can be block diagonalized (i.e., decomposed as a sum of matrix algebras) in two different ways. Diagonalization of the convolution product is encoded by a finite dimensional algebra $\mathrm{Oc}(G)$ called ''algebra of quantum symmetries.'' As a vector space, $\mathrm{Oc}(G)$ contains one linear generator for every single block of $(\mathcal{B}(G),\star)$. As an algebra, it has a unit called $\underline{0}$ and two generators called $\underline{1}_L$ and $\underline{1}_R$, which, when G is a member of an $\mathcal{A}$ series, coincide. Like the graph algebra of G (when it exists), the algebra $\mathrm{Oc}(G)$ comes with a preferred basis. Even when the vector space of G does not admit self-fusion, so that it is only a module over the corresponding $\mathcal{A}$, the associated object $\mathrm{Oc}(G)$ is always both an associative algebra and a bimodule over $\mathcal{A}\otimes\mathcal{A}$. This last structure is encoded by a set of matrices that we call ''toric matrices''; there is one such matrix for every point of the Ocneanu graph. The multiplicative structure of $\mathrm{Oc}(G)$ is fully determined by the two Cayley graphs of multiplication by the generators; the union of these two graphs is called the Ocneanu graph of G and is denoted by the same symbol. In most cases, $\mathrm{Oc}(G)$ is isomorphic with a tensor product—over a particular subalgebra J—of two associative and commutative algebras; we write $\dot{\otimes}\equiv\otimes_J$ this tensor product; in these cases, $\mathrm{Oc}(G)$ is commutative. When it is not commutative [the case of D_{2n} for the su(2) system], one has also to add some matrix algebra component to this tensor product, in order to take the non-commutativity into account (see Ref. 8 for explicit formulas for D_{2n} cases). The two generators of $\mathrm{Oc}(G)$ read $\underline{1}_L=1\dot{\otimes}0$ and $\underline{1}_R=0\dot{\otimes}1$. Their algebraic span are respectively the ''left chiral'' and ''right chiral'' parts. The intersection of chiral subalgebras is called ''ambichiral'' and the vector space spanned by those (preferred) linear generators which belong to none of the chiral parts is called ''the supplementary part.'' All these structures lead to ''nimreps'' (non-negative integer valued matrix representations) of certain algebras.[30]

From the point of view of conformal field theory, we are interested in partition functions on a torus with defect lines. When there are no defects these partition functions are modular invariant; this is usually not so in the presence of defects. In all cases, they are sesquilinear forms with non-negative integer entries defined on the vector space spanned by the characters of an affine Lie algebra $\hat{\mathcal{G}}$. Here we forget this interpretation and replace these characters by vertices of a diagram of type $\mathcal{A}$. Partition functions are therefore square matrices indexed by these vertices. It was recognized more than 7 years ago by A. Ocneanu (published reference is Ref. 23) that ''the'' modular invariant of Cappelli–Itzykson–Zuber,[4,26,33] for a given ADE diagram G, was given by

the toric matrix W_0 associated with the origin $\underline{0}$ of the graph $\mathrm{Oc}(G)$. To see an example of how all this works, the reader may look at Ref. 7, where toric matrices W_x associated with the 12 points x of the graph $\mathrm{Oc}(E_6)$ are calculated. In Ref. 29 it was shown (among other things) that to the other points—other than the origin—of a graph $\mathrm{Oc}(G)$ can be associated partition functions in boundary conformal field theory (BCFT) with one defect line; these functions are not modular invariant. More general toric matrices (or partition functions) $W_{x,y}$, associated to BCFT with two defect lines, were also introduced in the same paper (note: $W_x \equiv W_{x,\underline{0}}$). Fully explicit expressions for the twisted partition functions W_x are given in Ref. 8, for all ADE cases, by using the formalism introduced in Ref. 7. This was done independently of Ref. 31. It should probably be stressed that all these expressions were already obtained (but unpublished) almost 8 years ago by A. Ocneanu himself.

The direct determination of the algebra $\mathrm{Oc}(G)$, with the definition provided by A. Ocneanu, is not an easy task and the associated graphs are only known (published) for the su(2) Coxeter–Dynkin system. One of the purposes of Refs. 7 and 8, besides the calculation of the toric matrices, was actually to give an algebraic construction providing a realization of the *algebra* $\mathrm{Oc}(G)$ in terms of graph algebras associated with appropriated Dynkin diagrams.

In the simple cases (paradoxically, for Dynkin diagrams, besides the A_n themselves, the ''simple'' cases happen to be those where G is an exceptional diagram equal to E_6 or E_8), the algebra of quantum symmetries is isomorphic with $G \otimes_J G$, where J is a particular subalgebra of the algebra of G (we refer to Ref. 8 for a discussion of all ADE cases). The tensor product sign, taken ''above J,'' means that we identify $au \otimes b$ and $a \otimes ub$ whenever $u \in J \subset G$. In the last quoted reference, the Ocneanu *graphs*, determined by Ocneanu himself, had to be taken as an input. This was a weak point in our approach.

For the su(2) Dynkin system, i.e., for ADE diagrams, one purpose of the present article is to show that the structure of $\mathrm{Oc}(G)$, can be, in most cases, determined from the eigenvalues of the modular T matrix in the Hurwitz-Verlinde representation,[1,15,34] associated with the graph algebra of A_n. The method is general but its implementation depends about the type of diagram considered, i.e., whether it is a member of the $\mathcal{A}$ series, a genuine exceptional, or if it is obtained as an orbifold or by twisting. In any case, one has first to select a particular subspace J by using the list of eigenvalues of the modular operator T acting on the vertices belonging to the corresponding $\mathcal{A}$ diagram. In the case of E_6, for instance, the subset J, obtained as explained in the introduction, by using a modular constraint on the induction-restriction rules coming from the A_{11} action, is isomorphic with an A_3 subalgebra of E_6 and the Ocneanu algebra $\mathrm{Oc}(E_6)$ is recognized as $E_6 \dot{\otimes}_{A_3} E_6$. Warning: everywhere in this article, the symbol denoting the diagram also denotes its corresponding associative graph algebra, when it exists; it never refers to the corresponding Lie algebra with the same name (for the higher Coxeter–Dynkin systems, this would not even be an algebra in the usual sense!). The analysis of the D_{2n} cases, where $\mathrm{Oc}(G)$ is not commutative, is more subtle.

For the su(3) system, a direct diagonalization of the convolution law $\star$ of the bialgebra $\mathcal{B}(G)$ was never performed explicitly (or maybe by A. Ocneanu, but this information is not available), and the algebras $\mathrm{Oc}(G)$—or their Cayley graphs—have never been calculated (published) or even properly defined; therefore our method, which can indeed be generalized in a straightforward manner to this more general setting, has a conjectural flavor since we do not compare our results with those that would be obtained by a direct approach. Nevertheless, we have checked, in the case of exceptional graphs of su(3) type, that partition functions (toric matrices) associated with the origin of ''our'' Ocneanu graphs indeed coincide with the modular invariant partition functions calculated by Ref. 13 and that expected sum rules also hold (nontrivial equalities between two sums of squares coming from the diagonalization of the two associative structures for a given bialgebra). We obtain also, as a by product, the list of twisted partition functions corresponding to a given diagram G [there are 24 of them for the exceptional $\mathcal{E}_5$ case of the su(3) system].

B. Useful formulas and notations

For Dynkin diagrams, i.e., the su(2) system, κ is the (dual) Coxeter number of the diagram itself. It can be defined, without any reference to the theory of Lie algebras, from the norm β of the graph (biggest eigenvalue of the adjacency matrix): β is equal to $2\cos(\pi/\kappa)$. Note that $1<\beta<2$ (see also Ref. 14). For Di Francesco–Zuber graphs, i.e., the su(3) system, the norm β is equal to $1+2\cos(2\pi/\kappa)$. Note that $2<\beta<3$. This again defines the integer κ. We call it the "generalized Coxeter number of the graph" or "altitude" (like in Ref. 10). We also define $q=\exp(i\pi/\kappa)$, so that $q^{2\kappa}=1$. Another integer h characterizes the system of diagrams. For Dynkin diagrams, $h=2$, the (dual) Coxeter number of su(2). For Di Francesco–Zuber graphs, $h=3$, the (dual) Coxeter number of su(3).

The level k of a *diagram* is defined by the relation $k=\kappa-h$. Notation for graphs: we keep the standard notation for usual Dynkin diagrams, with subscript referring to the number of vertices, i.e., the rank of the corresponding Lie algebra. However, for consistency with the notation used for higher Coxeter–Dynkin systems, it would be better for this subscript to refer to the level k or to the altitude κ. We may use both notations, but with script capitals in the latter case, for instance (Dynkin diagrams), $\mathcal{A}_{\kappa-2}=A_{\kappa-1}$, $\mathcal{E}_{10}=E_6$, $\mathcal{E}_{16}=E_7$, $\mathcal{E}_{28}=E_8$. In the case of the Di Francesco–Zuber system of graphs, our subscript will always refer to the level. Since $h=3$ for su(3), we have $k=\kappa-3$ for all diagrams of this family. The reader should be warned that this notation is not universally accepted, and some authors may prefer to use the altitude (as an upper index) rather than the level. For instance, the graphs that we call $\mathcal{E}_5$, $\mathcal{E}_9$ and $\mathcal{E}_{21}$ (like in Ref. 25) were called respectively $\mathcal{E}^{(8)}$, $\mathcal{E}_2^{(12)}$ and $\mathcal{E}^{(24)}$ in Ref. 10.

In the case of su(N), there are $N-1$ fundamental representations f, and therefore $N-1$ graphs G^f (see Ref. 10), representing tensor multiplication of irreps by f. Since we shall work only with su(2) or su(3), we need only one graph. In the case of su(2), this is clear. In the case of su(3), this graph is associated with one fundamental irrep (say 3), the other graph associated with its conjugate (say $\overline{3}$) is obtained by reversing all the arrows; adjacency matrices corresponding to the fundamental and to its conjugate are denoted by G and by its transpose G^T.

For a diagram of type su(N), the graph algebra, when it exists, is faithfully represented (regular representation) by $r\times r$ matrices G_a. In all cases, G_0 is the identity matrix and G_1 is the adjacency matrix. We denote by r the number of vertices of the diagram G. The r linear generators σ_a of G, with dual Coxeter number (or altitude) κ, are then represented by r commuting matrices G_a.

In the particular case where G is a member of the A system, the generators will be called τ_i and the corresponding matrices will be called N_i. For a diagram of type A belonging to a given su(N) system, writing down matrices N_0 (identity) and N_1 (adjacency matrix) is immediate, and there are always simple recurrence formulas that allow one to compute the matrices N_i for all vertices of the A system in terms of N_0 and N_1 (thought as the basic representation). These standard recurrence formulas can be obtained, for instance, by making products of Young frames [see later sections for su(2) and su(3)].

The module property (external multiplication) of the vector space associated with a diagram G, of level k and possessing r vertices, with respect to an action of the corresponding algebra $\mathcal{A}_k$ is encoded by a set of s matrices F_i, $i=0,\ldots,s-1$, of dimension $r\times r$, sometimes called "fused graph matrices" (a misleading terminology!): $\tau_i\sigma_a=\Sigma_b(F_i)_{ab}\sigma_b$. The number s of vertices of $\mathcal{A}_k$ depends on the system: for Dynkin diagrams ($\mathcal{A}_k=A_{k+1}$), $s=k+1$; for Di Francesco–Zuber graphs, $s=(k+1)(k+2)/2$. Matrix F_0 is the identity and matrix $F_1=G_1$ is also the adjacency matrix of G. The other F matrices are determined by imposing that they should obey the same recurrence relation as the N matrices; this ensures compatibility with left multiplication by the algebra $\mathcal{A}_k$. The sets of matrices F_i, N_i and G_a of course coincide when G is a diagram of type A. The r essential matrices E_a are rectangular matrices of dimension $s\times r$ defined by setting $(E_a)_{ib}=(F_i)_{ab}$ (the reader should be cautious about the meaning of indices: our indices i or a refer to actual vertices of the graphs but the numbers chosen for labeling rows and columns depend on some arbitrary ordering on these sets of vertices). The particular matrix E_0 is usually

called ''intertwiner,'' in the statistical physics literature; it also describes ''essential paths'' emanating from the origin (we shall not need this notion in the present article). One can check that, for graphs with self-fusion, $E_a = E_0 G_a$.

Vertices of the diagram G should be thought of as an analog of irreducible representations for a subgroup of a group; the irreducible representations of the bigger group are themselves represented by vertices of the graph A. In this analogy, the first column of each matrix F_i describes the branching rule of τ_i with respect to the chosen subgroup (restriction mechanism). In the same way, the columns of the particular essential matrix E_0 describe the induction mechanism: the nonzero matrix elements of the column labeled by σ_b tell us what are those representations τ_i that contain σ_b in their decomposition (for the branching $A \to G$).

Let us recall how we compute the (twisted) partition functions $Z_{x,y}$, at least, in the cases where $\mathrm{Oc}(G) \simeq G \otimes_J G$. Again, we follow the method explained in Ref. 7 and refer to Ref. 8 for a discussion of all the ADE cases, but another formalism for calculating these quantities was described in Ref. 31. The bimodule structure of $\mathrm{Oc}(G)$ with respect to the corresponding $\mathcal{A}_k$ algebra is encoded by matrices $W_{x,y}$ defined as $\tau_i . x . \tau_j = \Sigma_y (W_{x,y})_{ij} . y$. One sets $W_x = W_{x,\underline{0}}$ and obtain the corresponding twisted partition functions as sesquilinear forms $Z_{x,y} = \overline{\chi} W_{x,y} \chi$, or $Z_x = Z_{x,\underline{0}}$. Here χ is a vector in the complex vector space $\mathbb{C}^s$. The modular invariant partition function is $Z_{\underline{0}}$ with $\underline{0} = 0 \dot{\otimes} 0$. The $W_{x,y}$ can be simply obtained from the W_x by working out the multiplication table of $\mathrm{Oc}(G)$ and decomposing the product $x \times y$ on the basis generators [one of us (RC) acknowledges discussions with M. Huerta about this]. Practically, once we have the r rectangular matrices E_a, of dimension $s \times r$ (with $s = \kappa - 1$ for ADE diagrams), we first replace by 0 all the matrix elements of the columns labeled by vertices b that *do not* belong to the subset J of the graph G, call E_a^{red} these ''reduced'' matrices, and obtain, for each point $x = a \dot{\otimes} b$ of the Ocneanu graph $\mathrm{Oc}(G)$ (in some cases, x may be a linear combination of such elements), a ''toric matrix'' $W_x = E_a (E_b^{red})^T$ of size $s \times s$.

The usual partition function on a torus is calculated by identifying the states at the end of a cylinder through the trace operation. One may incorporate the action of an operator X attached to a nontrivial cycle of the cylinder before identifying the two ends. This operator should commute with the Virasoro generators and its effect is basically to twist the boundary conditions. An explicit expression, in the presence of two twists X and Y, was written for such a twisted partition function by Refs. 29 and 31; it involves matrix elements of the modular operator S. Our own determination of the toric matrices (and corresponding twisted partition functions) uses directly the fusion algebra—i.e., the graph algebra of the A_n diagrams. Of course we could, by using the Verlinde formula, express the fusion rule coefficients through the matrix S, but in our approach, the diagrams themselves are taken as primary data and we do not need to use this operator at all, at least for the determination of the $W_{x,y}$.

III. *ADE* DIAGRAMS: THE su(2) SYSTEM

A. Preliminary remarks

ADE Dynkin diagrams are well known. Their norm (highest eigenvalue of the adjacency matrix) is $2\cos(\pi/\kappa) = \beta$. Diagrams $A_{\kappa-1}$ have r points τ_j, $j = 0, \ldots, \kappa - 2$, with $r = \kappa - 1 = k + 1$ (this defines the level k). In the light of McKay correspondance,[20] these diagrams appear as quantum analog of binary polyhedral groups.[6,17,18] For su(2), the recurrence formula for adjacency matrices associated with irreps is very well known: we have $N_0 N_j = N_j$, $N_1 N_j = N_{j-1} + N_{j+1}$, for $1 \leqslant j \leqslant \kappa - 2$. This is the usual multiplication of spin $j/2$ representation by the fundamental (spin $\frac{1}{2}$). For the diagram $A_{\kappa-1}$, we also have a truncation of the spin rule: $N_1 N_{\kappa-2} = N_{\kappa-3}$.

Left action of the algebra $A_{\kappa-1}$ on the vector space of a diagram G is defined by setting $F_0 = G_0 = \mathbf{1}_{r \times r}$, $F_1 = G_1$, and compatiblility with left multiplication in $A_{\kappa-1}$ is ensured by imposing the spin rule $F_1 F_i = F_{i-1} + F_{i+1}$, a relation that determines the F_i's iteratively.

The modular generator T, in the Hurwitz–Verlinde representation, is given by

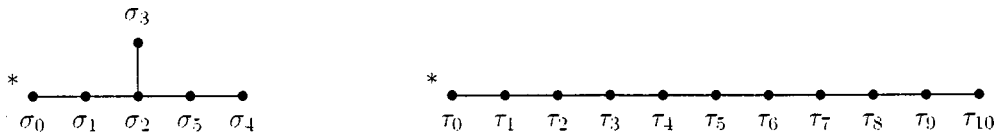

FIG. 1. The E_6 and A_{11} Dynkin diagrams.

$$T_{jj'}=\exp\left[2i\pi\left(\frac{(j+1)^2}{4\kappa}-\frac{1}{8}\right)\right]\delta_{jj'},$$

where j,j' run from 0 to $\kappa-2$.

The value of T on the vertex τ_j of $A_{\kappa-1}$ is therefore determined, up to a global phase, by the quantity $\hat{T}=(j+1)^2 \bmod 4\kappa$, which we will call the "modular exponent" (see also the Appendix). The algebras of quantum symmetries $\mathrm{Oc}(G)$, for diagrams G of type ADE, are already known, and the corresponding Ocneanu graphs can be found, for instance, in Refs. 5, 7, 8, 23, 30, and 31, or also, in the context of the theory of induction of sectors, in Ref. 2. In the present section, the overlap with Ref. 8 is important: in the later reference, an algebraic realization of the algebras $\mathrm{Oc}(G)$ was given, but the primary data was the Ocneanu graph itself, taken from Ref. 23. In the present section, our aim is neither to describe the algebras of quantum symmetries nor their corresponding graphs, since this is known already, but to show how the modular properties of the diagrams (in particular the table of eigenvalues for the operator T), together with the induction-restriction pattern, can be used to recover the known algebras of quantum symmetries. This section also provides a kind of introduction to Sec. IV where the same techniques will be used to determine the structure of $\mathrm{Oc}(G)$ for several diagrams belonging to the su(3) system.

B. First example: The E_6 case

1. Graphs

The vector space of E_6 is both an associative (and commutative) algebra with positive integral structure constants (in other words, it admits self-fusion), and it is a module over A_{11}. This example is fully studied in Ref. 7 (see also Ref. 6); in particular its graph algebra matrices, essential matrices, Ocneanu graph and toric matrices are given there. The E_6 Dynkin diagram and the corresponding A diagram with same norm (i.e., A_{11}) are displayed in Fig. 1.

For trees with one branching point (for instance, E_6, E_7 and E_8 diagrams), we label (one of) the longest branches with increasing integers starting from 0, up to the branching point, then we jump to the extremity of the next (clockwise) branch and so on. This is the ordering consistently chosen in Refs. 7 and 8.

2. Restriction mechanism

We look at E_6 as a module over A_{11}. For this, we define an action of A_{11} on E_6:

$$A_{11}\times E_6\to E_6$$

$$\tau_0.\sigma_i=\sigma_i$$

$$\tau_1.\sigma_i=\sum{}'\ \sigma_j$$

where Σ' runs over the neighbors of σ_i on the diagram E_6.

We have obvious restrictions: $\tau_0\hookrightarrow\sigma_0$, $\tau_1\hookrightarrow\sigma_1$. To obtain the others, we impose the compatibility condition: $(\tau_1)^n.\sigma_i=(\sigma_1)^n.\sigma_i$. We therefore calculate the powers of the fundamentals τ_1 and σ_1 and compare the results:

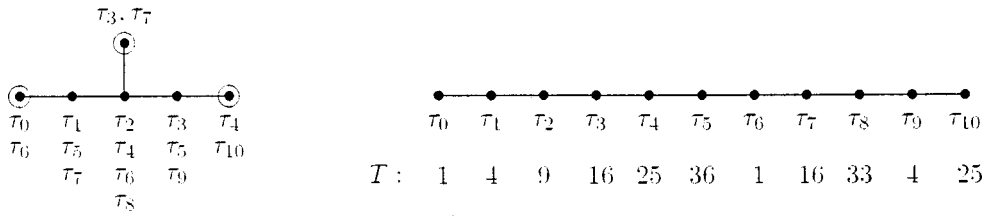

FIG. 2. The $E_6 \hookleftarrow A_{11}$ induction graph and the values of $\hat{T}$ on irreps of A_{11}.

$$(\tau_1)^2 = \tau_0 + \tau_2, \quad (\sigma_1)^2 = \sigma_0 + \sigma_2, \quad \text{so} \quad \tau_2 \hookrightarrow \sigma_2;$$

$$(\tau_1)^3 = 2\tau_1 + \tau_3, \quad (\sigma_1)^3 = 2\sigma_1 + \sigma_3 + \sigma_5, \quad \text{so} \quad \tau_3 \hookrightarrow \sigma_3 + \sigma_5;$$

and so on. In this way, we get the following branching rules $\tau_i \hookrightarrow \oplus E^0_{ij}\sigma_j$ (essential matrix E_0):

$$\tau_0 \hookrightarrow \sigma_0 \quad \tau_1 \hookrightarrow \sigma_1 \quad \tau_2 \hookrightarrow \sigma_2 \quad \tau_3 \hookrightarrow \sigma_3 + \sigma_5$$

$$\tau_4 \hookrightarrow \sigma_2 + \sigma_4 \quad \tau_5 \hookrightarrow \sigma_1 + \sigma_5 \quad \tau_6 \hookrightarrow \sigma_0 + \sigma_2 \quad \tau_7 \hookrightarrow \sigma_1 + \sigma_3$$

$$\tau_8 \hookrightarrow \sigma_2 \quad \tau_9 \hookrightarrow \sigma_5 \quad \tau_{10} \hookrightarrow \sigma_4.$$

The rectangular 11×6 matrix E_0 encodes this result, i.e., the above branching rules give us the lines of this matrix. Notice that this determination of E_0 does not require any calculation involving essential paths (this notion, although extremely nice and useful, is not required at this level).

Once the adjacency matrix G_1 is known (read it from the graph), and the essential matrix E_0 (or intertwiner) determined, we can use the general formulas given in the Introduction to determine the 6 graph matrices G_a, the 11 matrices F_i and the other essential matrices E_a (six of them, including E_0). Notice that, from the very beginning, we could have proceeded differently, determining first the F_i by using both the equation $F_1 = G_1$ and the su(2) rule of composition of spins (recurrence relation); these matrices, in turn, determine the E_a's (in particular E_0).

3. Induction mechanism

We now look at these previous branching rules, but in the opposite direction: for instance, σ_3 *comes from* τ_3 and τ_7, so we can write $\sigma_3 \hookleftarrow (\tau_3, \tau_7)$. We get the induction correspondence $E_6 \hookleftarrow A_{11}$ displayed in Fig. 2. This is only another way to write the columns of the E_0 matrix. We also plot the values of the modular exponent $\hat{T}$ for the vertices τ_i's of A_{11}.

From the induction graph we have $\sigma_0 \hookleftarrow (\tau_0, \tau_6)$, and we notice that the value of the modular matrix T on τ_0 and τ_6 is the same (also for τ_3 and τ_7, and for τ_4 and τ_{10}). This allows one to assign a fixed value of T to three particular vertices of E_6: $\hat{T}(\sigma_0) = 1$, $\hat{T}(\sigma_3) = 16$ and $\hat{T}(\sigma_4) = 25$. For every other point of the E_6 graph, the value of T that would be inherited from the A_{11} graph by this induction mechanism is not uniquely determined (for instance, in the case of σ_1, the values of $\hat{T}$ obtained from A_{11} would be associated with τ_1, τ_5 and τ_7 but these values are not all equal). These elements $\{\sigma_0, \sigma_4, \sigma_3\}$ span the subalgebra $J = A_3$. This subalgebra is known to admit an invariant supplement in the graph algebra of E_6.

4. Quantum symmetries

The Ocneanu graph of E_6 given in Refs. 7, 8, 23, and 31 is the Cayley graph of multiplication by the two generators of an associative algebra $\mathrm{Oc}(E_6)$ which can be realized (see Refs. 7 and 8) as $E_6 \otimes_{A_3} E_6$. It has $12 = 6 \times \frac{6}{3}$ vertices, three of them being ambichiral, namely $\sigma_0 \dot{\otimes} \sigma_0$, $\sigma_0 \dot{\otimes} \sigma_3$ and $\sigma_0 \dot{\otimes} \sigma_4$. We introduce the symbol $\dot{\otimes}$ to denote $\otimes_{A_3}$ to stress the fact that the tensor product is taken not above the complex numbers but above the subalgebra $J = A_3$. This means that

$a\,u\dot{\otimes}b=a\dot{\otimes}u\,b$ whenever $u\in\{\sigma_0,\sigma_4,\sigma_3\}$ and $a,b\in E_6$. The point that we make, here, is that this subalgebra A_3 is actually *determined* as above, by induction, from the eigenvalues of the T operator.

5. Dimensions of blocks

Diagonalization of the two algebra structures of $\mathcal{B}E_6$ leads to the quadratic sum rule

$$dim(\mathcal{B}E_6)=\sum_{i\in A_{11}} d_i^2=\sum_{x\in Oc(E_6)} d_x^2=2512=(2)^4(157)^1,$$

where $d_i=\Sigma_{a,b\in G}(F_i)_{ab}$ runs in the list (6,10,14,18,20,20,20,18,14,10,6) and where, for $x=a\dot{\otimes}b$, $d_x=\Sigma_{i,j\in A_{11}}(G_a.G_b)_{ij}$ runs in the list (6,8,6,10,14,10,10,14,10,20,28,20). This identity follows directly from the fact that $\mathcal{B}E_6$ can be written in two different ways as a direct sum of matrix algebras ($\mathcal{B}E_6$ is semi-simple for both structures).

We have also the linear sum rule $\Sigma d_i=\Sigma d_x=720=(2)^4(3)^2(5)^1$. Such a linear sum rule also holds "experimentally" in almost all ADE cases (for the D_{2n} cases one has actually to introduce a simple correcting factor, as explained in Ref. 31). In general, there is no reason, for a general bialgebra—even semi-simple for both structures—to give rise to such a linear sum rule. The interpretation of this property is therefore still mysterious. As we shall see in the next part, it also holds for the several examples of diagrams of type su(3) that we have analyzed so far.

There are also quantum sum rules ("mass relations"): define $o(G)\doteq\Sigma_{a\in G}qdim_a^2$, where $qdim_a$ are the quantum dimensions of the vertices a of G [for example, $o(E_6)=4(3+\sqrt{3})$, $o(A_{11})=24(2+\sqrt{3})$, $o(A_3)=(1+(\sqrt{2}))^2=4$]; then, if the diagonalizations of the two algebra structures of $\mathcal{B}(G)$ are described respectively by $\mathcal{A}_k$, for some k, and by $\mathrm{Oc}(G)=G\otimes_J G$ for some J, one can check that $o(\mathrm{Oc}(G))$ defined as $o(G)\times o(G)/o(J)$ is equal to $o(\mathcal{A}_k)$. In the present case, $o(E_6)\times o(E_6)/o(A_3)=o(A_{11})$. This observational fact, properly generalized, holds for all ADE diagrams. Indeed, $o(D_n)=\frac{1}{2}o(A_{2n-3})$ and $o(E8)\times o(E8)/o(J)=o(A_{29})$, where $o(J)=[1]_q^2+([5]_q/[3]_q)^2$ since the quantum dimensions of vertices σ_0 and σ_6 spanning the subspace J of E_8 are respectively equal to the q-numbers $[1]_q$ and $[5]_q/[3]_q$ (here $q=\exp(i\pi/30)$). In the case of E_7, we found that $o(\mathrm{Oc}(E_7))$ defined as $o(D_{10})\times o(D10)/o(J)$, where J is the subalgebra of D_{10}, is equal to $o(A_{17})$. We found also empirically the relation $o(A_{17})=o(E_7)\times o(D_{10})/o(J)$, where $o(J)=[2]_q^2+[4]_q^2+([4]_q/[3]_q)^2$ and where the q-numbers $[2]_q$, $[4]_q$ and $[4]_q/[3]_q$ are the q-dimensions of the vertices σ_1, σ_3 and σ_5 of E_7 [here $q=\exp(i\pi/18)$]. Analogous quantum sum rules hold for the several examples of diagrams of type su(3) that we have analyzed so far. We do not know any general formal proof of these quantum relations.

C. The *ADE* diagrams

We show in this section how all cases relative to the su(2) system can be studied in the same manner.

1. E_6 case

It was studied in the last section.

2. E_8 case

The cases of E_6 and E_8 are very similar. The Dynkin diagram of the A series with same Coxeter number ($\kappa=30$) as E_8 is A_{29}. Like E_6, the vector space of the diagram E_8 admits self-fusion (associative algebra structure with positive integral structure constants). The induction graph $E_8\hookleftarrow A_{29}$ is displayed in Fig. 3.

The value of $\hat{T}$ on irreps $(\tau_0,\tau_1,\tau_2,\ldots,\tau_{28})$ of A_{29} [equal for τ_j to $(j+1)^2$ mod 120] gives

$$(\underline{1},4,9,16,25,36,\underline{\underline{49}},64,81,100,\underline{1},22,\underline{\underline{49}},76,105,16,\underline{\underline{49}},84,\underline{1},40,81,4,\underline{\underline{49}},96,25,76,9,64,\underline{1}).$$

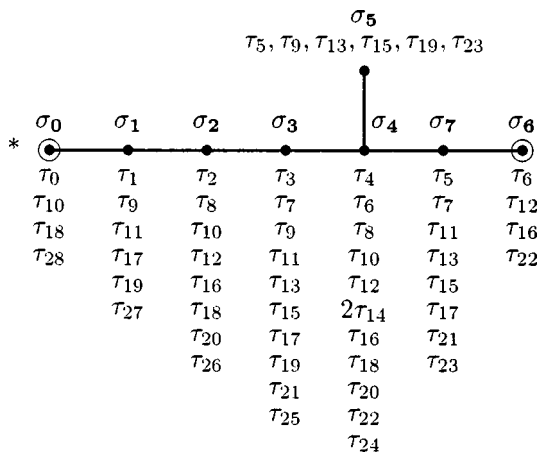

FIG. 3. The $E_8 \hookleftarrow A_{29}$ induction graph.

We see that T has the same value on vertices τ_j that correspond to σ_0 ($\hat{T}=1$). Same comment for σ_6 ($\hat{T}=49$). We therefore take $J=\{\sigma_0,\sigma_6\}$; this generates a subalgebra which is isomorphic with the algebra of the A_2 graph. We have indeed $\mathrm{Oc}(E_8)=E_8 \otimes_{A_2} E_8$ and the Ocneanu graph has $32=8\times\frac{8}{2}$ vertices, two of them being ambichiral, namely, $\sigma_0 \dot{\otimes} \sigma_0$ and $\sigma_0 \dot{\otimes} \sigma_6$. Notice that $\sigma_6 \dot{\otimes} \sigma_6 = \sigma_0 \dot{\otimes} \sigma_0$. Dimensions of blocks can be computed as before (see, for instance, Ref. 8). One writes $dim(\mathcal{B}E_8)=63\,136=(2)^5(1973)^1$ in two different ways as a sum of 29 or 32 squares. The linear sum rule gives $\Sigma d_i = \Sigma d_x = 1240 = (2)^3(5)^1(31)^1$.

3. $A_{\kappa-1}$ cases

The induction-restriction rules from $A_{\kappa-1}$ to itself are of course trivial and the subalgebra J determined by the constancy of T on preimages is equal to the algebra $A_{\kappa-1}$ itself. The algebra $\mathrm{Oc}(A_{\kappa-1})$ equal to $A_{\kappa-1} \otimes_{A_{\kappa-1}} A_{\kappa-1}$ is therefore isomorphic with $A_{\kappa-1}$ itself. The Ocneanu graph coincides with the original Dynkin diagram.

4. D_{2n+1} cases

The Dynkin diagram of the A series with same Coxeter number ($\kappa=4n-2$) as D_{2n+1} is A_{4n-1}. Actually (see Ref. 19). D diagrams are $\mathbb{Z}_2$ orbifolds of A diagrams.

Let's first have a look at the A_7 case. Its Dynkin diagram and the values of $\hat{T}$ on irreps τ_i's are given in Fig. 4.

The algebra of quantum symmetries of A_7, as we saw, is $A_7 \otimes_{A_7} A_7 \simeq A_7$, but there is also another way to quotient the tensor product if we want T to be well defined in the quotient. We see that the values of T are the same ($\hat{T}=4$) for τ_1 and τ_5, so we define therefore a map (twist) $\rho: A_7 \to A_7$ such that

$$\rho(\tau_i)=\tau_i \quad \text{for } i \in \{0,2,3,4,6\} \quad \text{and} \quad \rho(\tau_1)=\tau_5, \quad \rho(\tau_5)=\tau_1.$$

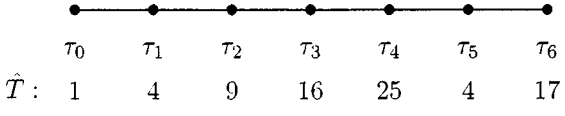

FIG. 4. The A_7 diagram and the values of $\hat{T}$.

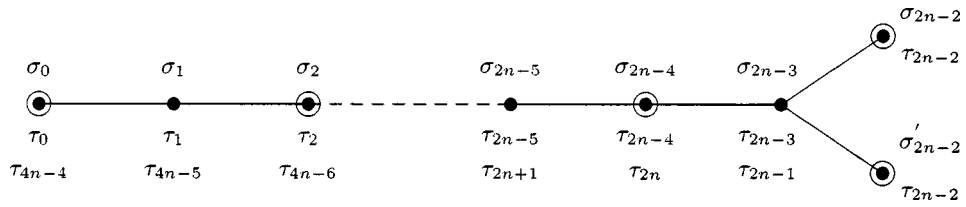

FIG. 5. The $D_{2n} \hookleftarrow A_{4n-3}$ induction graph.

Defining then $\mathrm{Oc}(D_5) = A_7 \otimes_{\rho(A_7)} A_7$ we recover the algebra of quantum symmetry of D_5. This can be generalized for all D_{2n+1} cases. These diagrams do not enjoy self-fusion displayed in Fig. 5.

5. D_{2n} cases

Starting with the D_{2n} diagram and graph algebra, we obtain the induction graph with respect to the corresponding A diagram with the same norm (A_{4n-3}) displayed in Fig. 5.

The value of $\hat{T}$ on the irreps $\{\tau_0, \tau_1, \tau_2, \ldots, \tau_{2n-1}, \tau_{2n}, \tau_{2n+1}, \ldots, \tau_{4n-6}, \tau_{4n-5}, \tau_{4n-4}\}$ of A_{4n-3} gives

$$T(\tau_0) = T(\tau_{4n-4}) \quad T(\tau_2) = T(\tau_{4n-6}) \quad \cdots \quad T(\tau_{2n-4}) = T(\tau_{2n}).$$

These last values are symmetric with respect to the central vertex τ_{2n}.

We can assign a fixed value of T for the irreps $\{\sigma_0, \sigma_2, \ldots, \sigma_{2n-4}, \sigma_{2n-2}, \sigma'_{2n-2}\}$ for D_{2n} (marked with a circle in the induction diagram). They span the subalgebra J. However, we notice immediately that something special happens here: the two ends of the fork (vertices σ_{2n-2} and σ'_{2n-2}) are not distinguished by the values of T. Actually, the determination of the graph matrices G_a for the Dynkin diagram D_{2n} is not as straightforward as for some other cases: looking for an associative algebra determined by this diagram leads to a two-parameter family of solutions, but there is only one solution (up to permutation $G_{2n-2} \leftrightarrow G'_{2n-2}$) that has correct self fusion, i.e., integrality and positivity of structure constants [a similar phenomenon appears, for example, for the $\mathcal{E}_9$ diagram of the su(3) system]. Since T may be defined on any linear combination of these two vertices, it is natural to expect that this arbitrariness is encoded, at the level of the algebra of quantum symmetries, in a "noncommutative geometrical spirit," by an algebra of 2×2 matrices. $\mathrm{Oc}(D_{2n})$ consists indeed of two separate components: the first (usual) is given by $D_{2n}^{trunc} \otimes_{J'} D_{2n}^{trunc}$, where D_{2n}^{trunc} is the vector space corresponding to the subdiagram spanned by $\{\sigma_0, \sigma_1, \sigma_2, \ldots, \sigma_{2n-3}\}$, obtained by removing the fork, and $J' = \{\sigma_0, \sigma_2, \ldots, \sigma_{2n-4}\}$ is the corresponding truncated subset of J. The second component is a noncommutative 2×2 matrix algebra reflecting the indistinguishability of σ_{2n-2} and σ'_{2n-2}. Ambichiral points are associated with the $n+1$ vertices of J (i.e., $n-1$ for the linear branch and 2 for the fork); we expect therefore that the Ocneanu graph of D_{2n} will have $(2n-2)(2n-2)/n - 1 + 4 = 4n$ vertices. We could as well say that the number of "effective" points of J is n, rather than $n+1$ and notice that $4n = 2n \times 2n/n$. This is indeed correct (see Refs. 8, 23, and 31). One way to realize the algebra $\mathrm{Oc}(D_{2n})$ is to write it as a quotient of the semi-direct product, by $\mathbb{Z}_2 = \{-, +\}$ of the tensor square of the graph algebra D_{2n}. The noncommutativity of the multiplication can be seen, for instance, from the fact that $(2 \dot{\otimes} 0, +)(0 \dot{\otimes} 0, -) = (2 \dot{\otimes} 0, -)$, but $(0 \dot{\otimes} 0, -)(2 \dot{\otimes} 0, +) = (2' \dot{\otimes} 0, -)$. The reader may refer to Ref. 8 for another explicit realization of this algebra. In any case, the method followed so far, which is based on the eigenvalues of the T operator, seems to be insufficient to fully determine the Ocneanu graph in that example.

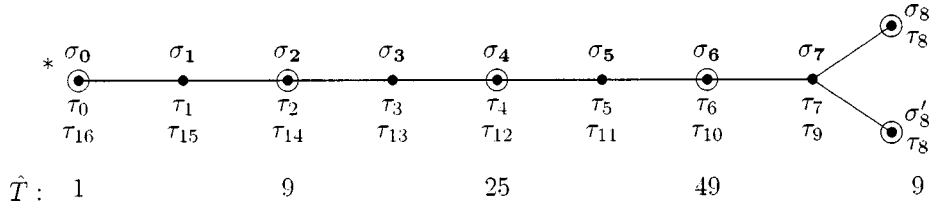

FIG. 6. The $D_{10} \hookleftarrow A_{17}$ induction graph and the values of $\hat{T}$.

6. E_7 case (related to the D_{10} case)

For the D_{10} case, something special happens. The corresponding A diagram with the same norm is A_{17}, the induction graph is displayed in Fig. 6, and the value of T in irreps $\{\tau_0, \tau_1, \ldots, \tau_8, \ldots, \tau_{15}, \tau_{16}\}$ of A_{17} are

$$(1,4,\underline{9},16,25,36,49,64,\underline{9},28,49,0,25,52,\underline{9},40,1).$$

These values are symmetric with respect to the central vertex, as in all A_{4n-3} case. For A_{17}, the value of T on the central vertex (τ_8) is equal to the value of T on other vertices, namely τ_2 and τ_{14}. This gives us another way to define a twist ρ acting on the vertices of D_{10} (this is "the" exceptional twist of the su(2) Coxeter–Dynkin system; existence of this twist is not new, but what we discuss here is its relation with the modular T operator). In other words, we form the tensor product $D_{10} \otimes D_{10}$, but identify $au \otimes b$ with $a \otimes \rho(u) b$ when $u \in \{\sigma_0, \sigma_2, \sigma_4, \sigma_6, \sigma_8, \sigma'_8\}$ and

$$\rho(\sigma_0) = \sigma_0, \quad \rho(\sigma_4) = \sigma_4, \quad \rho(\sigma_8) = \sigma_2,$$

$$\rho(\sigma_2) = \sigma_8, \quad \rho(\sigma_6) = \sigma_6, \quad \rho(\sigma'_8) = \sigma'_8.$$

We obtain the algebra $D_{10} \otimes_\rho D_{10}$ which is isomorphic with the algebra of quantum symmetries of the E_7 diagram. The diagram E_7 does not enjoy self-fusion.

Remark 1. The reader will have noticed that we do not necessarily *start* from a given graph G (for instance, E_7), for which we want to deduce $\mathrm{Oc}(G)$. Rather, we first consider all those graphs G which admit a good algebra structure (self-fusion), i.e., A, D_{2n}, E_6 and E_8; we then determine, for every one of them, the induced pattern of T eigenvalues by looking at the well determined $A \to G$ restriction; finally, we build all the possible quotients of $G \otimes G$ over the subalgebras—and possibly twists—determined by the pattern of T values. For example, if we assume that E_7 is already known to "exist" (as a module over A_{17}), and since it does not admit self-fusion, the only thing that we expect *a priori* is that its algebra of quantum symmetries $\mathrm{Oc}(E_7)$ will be obtained as a quotient of a tensor product of the algebras A_{17} or D_{10}. Therefore, $\mathrm{Oc}(E_7)$ is only the *name* given to $D_{10} \otimes_\rho D_{10}$; the graph E_7 itself can then be recognized as one of the two subsets of vertices of $\mathrm{Oc}(E_7)$ that linearly generates a module over one of the two chiral parts of the Ocneanu graph (each one being isomorphic with the algebra of D_{10}).

Remark 2. As discussed previously, the method that we follow seems to be insufficient to fully determine $\mathrm{Oc}(G)$ when the later is not commutative (cases when a coefficient strictly larger than 1 appears in the corresponding expression of the modular invariant partition function). These is only one example of this kind for the su(2) system (the D_{2n} diagrams), but there are several such examples for the su(3) system.

IV. DI FRANCESCO–ZUBER DIAGRAMS: THE su(3) SYSTEM

A. Preliminary remarks

In the su(2) case, the classification follows an ADE pattern. For su(n), $n \geqslant 2$ cases, there was no at-hand diagrams to start with, but the list of su(3) diagrams ("generalized Coxeter Dynkin diagrams") was obtained in 1989 (with CAF = computer-aided flair) by Di Francesco and Zuber in

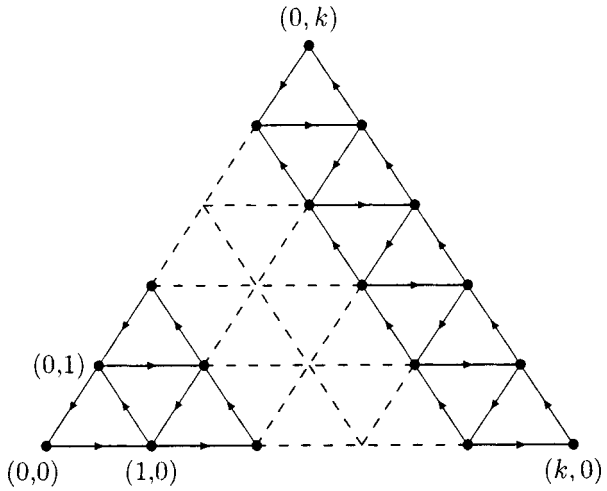

FIG. 7. The $\mathcal{A}_k$ diagram for su(3) with $(k+1)(k+2)/2$ vertices.

Ref. 10; this list was later shown to be complete by A. Ocneanu, during the Bariloche school at the very beginning of 2000 (actually one of their graphs—the one called $\mathcal{E}_3^{(12)}$ in Ref. 10—had to be removed).

Pictures of the graphs belonging to the Coxeter–Dynkin system of su(3) can be found in Refs. 10, 11, and 35–37; we refer to Refs. 25 and 38 or to the school web page *www.univ−mrs.fr/∼coque/Bariloche.html* for the final list. We do not discuss the su(4) system in this article, but these graphs can also be found in the Ocneanu contribution to the same Bariloche school[25] and on the corresponding web pages.

As recalled earlier, this system contains the principal $\mathcal{A}$ series and three genuine exceptional cases: $\mathcal{E}_5$, $\mathcal{E}_9$ and $\mathcal{E}_{21}$. The other diagrams of this system (and in particular the four other exceptional ones) are obtained as twists or as orbifolds of the former list (the ''genuine graphs''), or by using conjugation and twisting on the genuine graphs or on their orbifolds. A member of the $\mathcal{A}$ series (a Weyl alcove) is obtained by truncation of the diagram (Weyl chamber) of tensorization of irreps of su(3) by one of the two—conjugate—fundamentals 3 or $\overline{3}$; for this reason the graphs are oriented (see Fig. 7).

The index refers to the level k of the graph *defined* by $k=\kappa-h=\kappa-3$. Here $h=3$ is the Coxeter number of *the group* SU(3) and κ is the generalized Coxeter number of *the graph* (also called ''altitude'').

We label the vertices j of the $\mathcal{A}_\kappa$ diagram as (λ_1,λ_2), with $\lambda_1,\lambda_2\geqslant 0$ and $\lambda_1+\lambda_2\leqslant k$. Warning: our labels start from 0 and not from 1; many authors follow a different convention. Diagrams $\mathcal{A}_k$ have r points with $r=(k+1)(k+2)/2$.

The action of the modular matrix T on vertices $\tau_j\equiv\tau_{(\lambda_1,\lambda_2)}$ of $\mathcal{A}_k$ is diagonal and given by

$$(T^{(k)})_{\lambda\mu}=e_\kappa[-(\lambda_1+1)^2-(\lambda_1+1).(\lambda_2+1)-(\lambda_2+1)^2+\kappa]\delta_{\lambda\mu},$$

where $\lambda\doteq(\lambda_1,\lambda_2)$, $\mu\doteq(\mu_1,\mu_2)$, $e_\kappa[x]\doteq\exp(-2i\pi x/3\kappa)$, and $\kappa=k+3$. We call ''modular exponent'' the quantity $\hat{T}=-(\lambda_1+1)^2-(\lambda_1+1).(\lambda_2+1)-(\lambda_2+1)^2+\kappa \bmod 3\kappa$.

For su(3), the recurrence formula for adjacency matrices N_i associated with irreps is

$$N_{\lambda,\mu}=0 \qquad \text{if } \lambda<0 \text{ or } \mu<0,$$

$$N_{\lambda,0}=N_{1,0}N_{\lambda-1,0}-N_{\lambda-2,1},$$

$$N_{\lambda,\mu}=N_{1,0}N_{\lambda-1,\mu}-N_{\lambda-1,\mu-1}-N_{\lambda-2,\mu+1} \quad \text{if } \mu\neq 0,$$

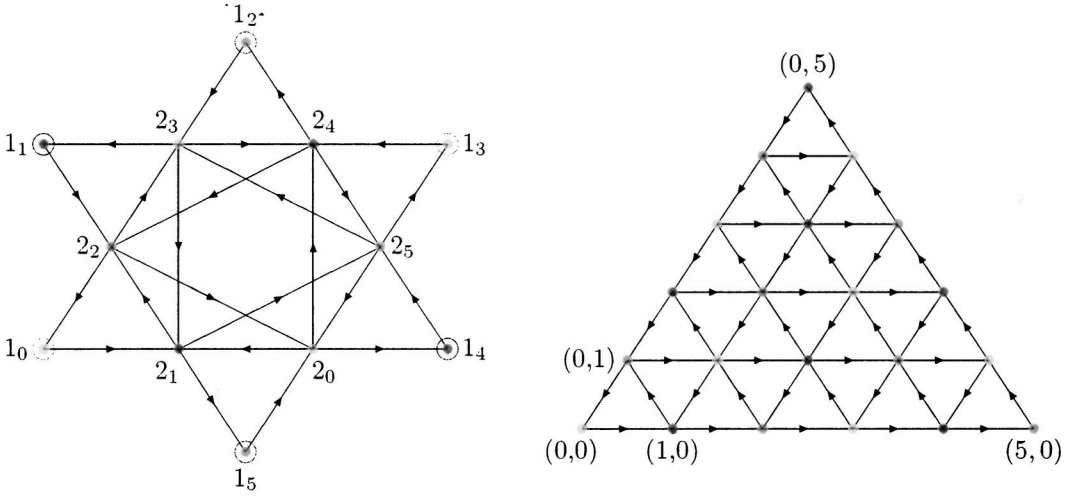

FIG. 8. The $\mathcal{E}_5$ and $\mathcal{A}_5$ generalized Dynkin diagrams.

$$N_{0,\lambda}=N_{\lambda,0}^{T}.$$

Remember that fused adjacency matrices F_i, associated with any graph G of the same level, are determined by the same recurrence relations (but the seed is different: $F_1=G_1$, the adjacency matrix of G).

In some cases the vector space generated by the vertices of a Di Francesco–Zuber graph is an algebra with positive integral structure constants (self-fusion). In all cases it is a module over the algebra of type $\mathcal{A}$ with the same Coxeter number. For an $\mathcal{A}$ graph, the identity element is (0,0); vertices (1,0) and (0,1), corresponding classically to the two representations of dimension 3, are the two complex conjugated generators. As always, a given diagram encodes the multiplication by the generators in the following sense: multiplication of an irrep (λ_1,λ_2) by the left generator (1,0) is given by the sum of the irreps which are connected to (λ_1,λ_2) by an incoming arrow, whereas multiplication by the right generator (0,1) is given by the sum of the irreps which are connected to (λ_1,λ_2) by an outgoing arrow. To label vertices, some readers may prefer Young frames (diagrams) rather than a notation using weights. The correspondance is as follows: (λ_1,λ_2) correspond to Young diagrams $Y(p=\lambda_1+\lambda_2,q=\lambda_2)$ with two rows, p boxes on the first row, and q boxes on the second row. Graphs whose vector space possesses self-fusion have a unit, and one of the two generators is located at the extremity of the (single) oriented edge that leaves the origin (reverse the arrows to get the other generator). Triality, i.e., $\{0,1,2\in\mathbb{Z}/3\mathbb{Z}\}$, is well defined and compatible with internal multiplication (if it exists) or with external multiplication by vertices of the corresponding $\mathcal{A}$ graph; it is represented by different choices of ''colors'' of vertices on the pictures. There is also a conjugacy transformation $\sigma\rightarrow\sigma^c$. At the level of graph matrices, it corresponds to transposition. For $\mathcal{A}$ graphs, it is represented by symmetry with respect to the inner bissectrix of the graph. The adjacency matrix is not symmetric, but it is normal, so that it can always be diagonalized.

In the following we illustrate the construction of the Ocneanu graphs of quantum symmetries, using our method based on the eigenvalues of the T operator, for the three genuine exceptional cases. Going through the whole list of Di Francesco–Zuber graphs would constitute a giant outgrowth of this article. We shall give some more details on the $\mathcal{E}_5$ case than on the two others.

Notice that the genuine diagrams $\mathcal{E}_5,\mathcal{E}_9$ and $\mathcal{E}_{21}$ are the only ones among exceptionals to admit self-fusion; this was first observed in Ref. 9.

B. First example: The $\mathcal{E}_5$ case

The $\mathcal{E}_5$ diagram is illustrated in Fig. 8, together with the corresponding $\mathcal{A}_5$ diagram, with same

norm, equal to $1+\sqrt{2}$, since the altitude is $\kappa=8$. Their respective adjacency matrices G_1 and N_1 are immediately determined (the adjacency matrix given in Ref. 11 is not typed correctly).

The $\mathcal{E}_5$ diagram admits self-fusion; 1_0 is the identity, 2_1 and 2_2 are the left and right generators. The multiplication table of the graph algebra of $\mathcal{E}_5$ reads

$$1_j.1_k=1_{j+k},$$

$$1_j.2_k=2_{j+k},$$

$$2_j.2_k=2_{j+k}+2_{j+k-3}+1_{j+k-3}.$$

This multiplication table allows one to compute easily the 12 square matrices G_a of the graph. The subset 1_i clearly forms a subalgebra of the graph algebra.

1. Restriction mechanism

We define an action of $\mathcal{A}_5$ on $\mathcal{E}_5$ in the same way as for the previous cases (see the discussion for E_6), getting the following restrictions: $(0,0)\hookrightarrow 1_0$, $(1,0)\hookrightarrow 2_1$ and $(0,1)\hookrightarrow 2_2$. For the others points, we compute the powers $(1,0)^\alpha(0,1)^\beta$ of the two fundamentals as well as the powers $(2_1)^\alpha(2_2)^\beta$ and compare them:

$$(1,0)^2=(2,0)+(0,1),\quad (2_1)^2=2_2+2_5+1_5,\quad \text{so}\quad (2,0)\hookrightarrow 1_5+2_5;$$

$$(0,1)^2=(1,0)+(0,2),\quad (2_2)^2=2_1+2_4+1_1,\quad \text{so}\quad (0,2)\hookrightarrow 1_1+2_4;$$

$$(1,0).(0,1)=(0,0)+(1,1),\quad 2_1.2_2=1_0+2_0+2_3,\quad \text{so}\quad (1,1)\hookrightarrow 2_0+2_3;$$

$$(1,0)^3=2(1,1)+(3,0)+(0,0),\quad (2_1)^3=1_0+32_0+22_3+1_3,\quad \text{so}\quad (3,0)\hookrightarrow 2_0+1_3;$$

and so on.

From these restriction rules, we obtain immediately the lines of essential matrix E_0 (intertwiner): it is a rectangular matrix with 12 columns, indexed by vertices of $\mathcal{E}_5$ and 21 rows indexed by vertices of $\mathcal{A}_5$ [i.e., by pairs of integers (λ_1,λ_2) with $\lambda_1+\lambda_2\leqslant 5$ or by Young frames $Y(p,q)$ with $5\geqslant p\geqslant q$].

We could have, as well, calculated directly the 21 fused matrices F_i from G_1 alone by using the su(3) recurrence relations; these matrices, in turn, determine the 12 essential (rectangular) matrices E_a.

2. Induction mechanism

From the branching rules $\mathcal{A}_5\rightarrow\mathcal{E}_5$, we get the following induction rules:

$$1_0\hookleftarrow(0,0),(2,2),\quad 2_1\hookleftarrow(1,0),(2,1),(1,3),(3,2),$$

$$1_1\hookleftarrow(0,2),(3,2),\quad 2_2\hookleftarrow(0,1),(1,2),(3,1),(2,3),$$

$$1_2\hookleftarrow(1,2),(5,0),\quad 2_3\hookleftarrow(1,1),(0,3),(2,2),(4,1),$$

$$1_3\hookleftarrow(3,0),(0,3),\quad 2_4\hookleftarrow(0,2),(2,1),(4,0),(1,3),$$

$$1_4\hookleftarrow(2,1),(0,5),\quad 2_5\hookleftarrow(2,0),(1,2),(3,1),(0,4),$$

$$1_5\hookleftarrow(2,0),(2,3),\quad 2_0\hookleftarrow(1,1),(3,0),(2,2),(1,4).$$

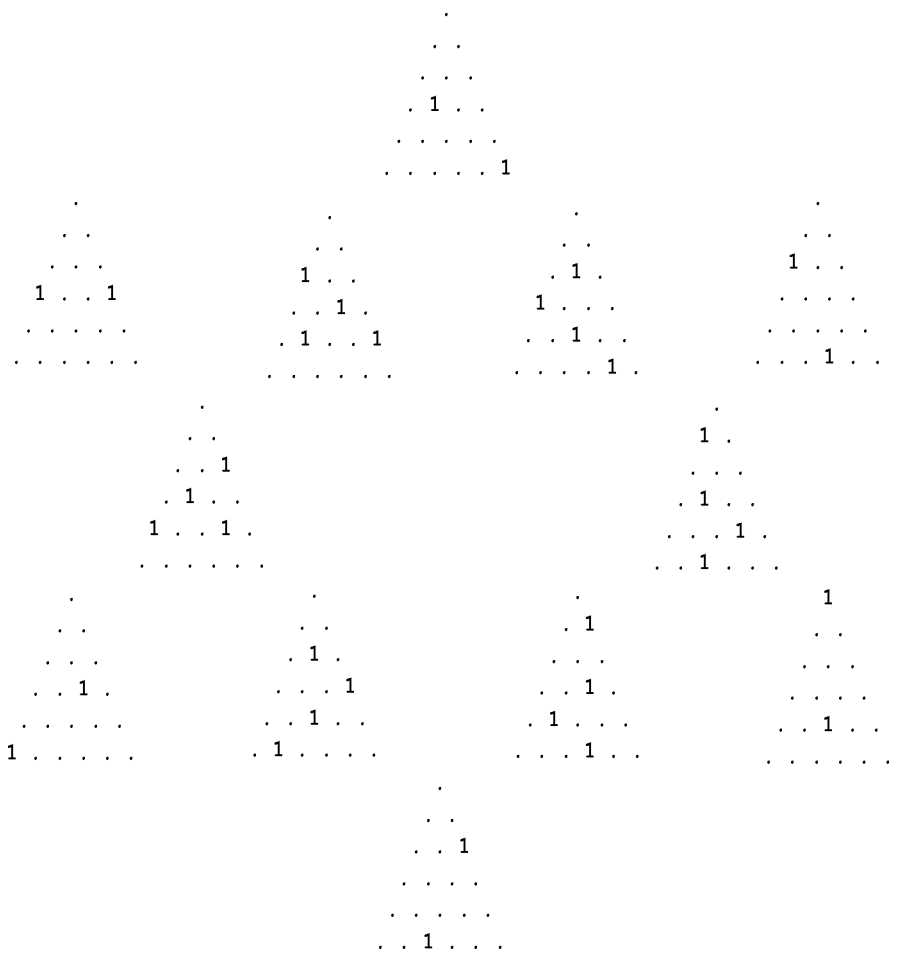

FIG. 9. Matrix E_0 for $\mathcal{E}_5$.

The same information can be gathered from the columns of matrix E_0 (see Fig. 9: each triangle corresponds to a single column). The first rule can be interpreted as a manifestation of the existence of a nontrivial quantum invariant of ''degree'' (2,2).

3. Quantum symmetries

For each 1_i, we can verify that the values of T on the two corresponding (λ_1,λ_2) coming from the induction are the same (see Table I). This allows us to assign a fixed value of T to the 1_i's. We can also verify that we can not do the same for the other vertices 2_i's. We get in this way a characterization of the subalgebra J, spanned by the elements 1_i's.

We therefore expect the algebra of quantum symmetries of $\mathcal{E}_5$ to be $\mathrm{Oc}(\mathcal{E}_5)=\mathcal{E}_5\otimes_J\mathcal{E}_5$. Its dimension is $12.12/6=24$. The left and right subalgebras are respectively spanned by $L=\{a\dot{\otimes}1_0\}$ and $R=\{1_0\dot{\otimes}a\}$, with a equal to 2_j or 1_j. Both left and right chiral subgraphs have 12 points. The ambichiral subalgebra (of dimension 6) is spanned by $A=\{1_j\dot{\otimes}1_0=1_0\dot{\otimes}1_j\}$ and the

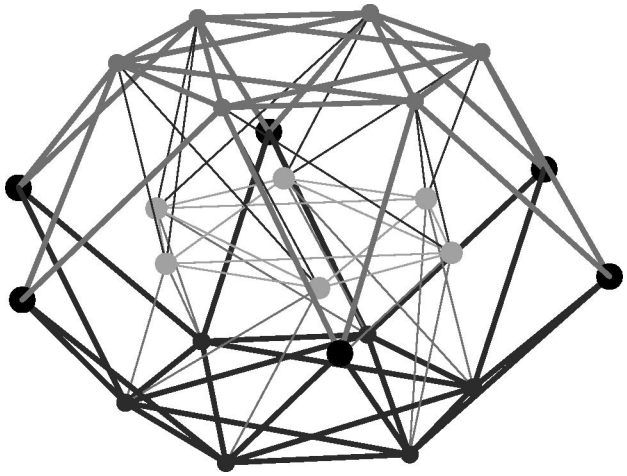

FIG. 10. The $\mathcal{E}_5$ Ocneanu graph.

supplementary subspace (also 6 points) is spanned by $C=\{2_j\dot{\otimes}2_k=2_0\dot{\otimes}2_{j+k}\}$. The Ocneanu graph can be displayed on the (three dimensional) picture (Fig. 10) as two superposed stars kissing each other along the six ambichiral points, with the vertices spanning the supplement displayed ''inside'' the others. As usual, bold lines—of two different colors—refer to the chiral parts and thin lines to the corresponding quotients. This graph is oriented but we have not displayed the orientation of the edges in order not to clutter the picture; the interested reader should do it for himself.

4. Dimensions of blocks

The two multiplicative structures $\circ$ and $\star$ of the bialgebra $\mathcal{BE}_5$ can be diagonalized. Blocks corresponding to the first structure are labeled by the 21 points of the $\mathcal{A}_5$ diagram. Dimension d_i of the block i is obtained by summing the matrix elements of F_i. We order the blocks $i=(\lambda,\mu)$ according to the level, i.e., $(\lambda,\mu)<(\lambda',\mu')$ if $\lambda<\lambda'$ or $\lambda=\lambda'$ and $\mu<\mu'$, and find

$$\{12\},\{24,24\},\{36,48,36\},\{36,60,60,36\},\{24,48,60,48,24\},\{12,24,36,36,24,12\}.$$

Dimension of the bialgebra is obtained by summing the square of these 21 integers d_i: $dim(\mathcal{BE}_5)=29\,376$. Dimension of the vector space of essential paths (graded by the Young frames of $\mathcal{A}_5$) is $\Sigma_i d_i=720$.

Blocks corresponding to the second structure are labeled by the 24 points of the Ocneanu graph $\mathrm{Oc}(\mathcal{E}_5)$. Dimension d_x of the block x is obtained by summing the matrix elements of matrices $S_x=G_aG_b$ when $x=a\dot{\otimes}b$ runs over the points of $\mathrm{Oc}(\mathcal{E}_5)$. One finds the following: the six ambichiral blocks have dimension 12, the six left chiral and the six right chiral blocks which are not ambichiral have dimension 24, the six complementary blocks have dimension 60. Dimension of the bialgebra is also obtained by summing the square of these 24 integers d_x and one finds the same total as before. Notice that writing 29 376 in two different ways as a sum of 21 or 24 squares constitutes, of course, a rather nontrivial check. Notice that we find also $\Sigma_x d_x=720$.

We summarize the discussion as follows:

$$dim(\mathcal{BE}_5)=\sum_{i\in\mathcal{A}_5}d_i^2=\sum_{x\in\mathrm{Oc}(\mathcal{E}_5)}d_x^2=(2)^6(3)^3(17)^1 \quad\text{and}\quad \sum_{i\in\mathcal{A}_5}d_i=\sum_{x\in\mathrm{Oc}(\mathcal{E}_5)}d_x=(2)^4(3)^2(5)^1.$$

5. Toric matrices and twisted partition functions

From the essential matrices E_a, we easily calculate the toric matrices (square matrices of dimension 21) and the corresponding partition functions by the method described earlier. There is one such function for each point of the Ocneanu graph $\mathrm{Oc}(\mathcal{E}_5)$. The one obtained from the identity $1_0 \dot{\otimes} 1_0$ of the graph is the modular-invariant and agrees with the expression of Ref. 13 (there is a global shift of (1,1) due to our conventions):

$$\mathcal{Z}_{\mathcal{E}_5} \doteq \mathcal{Z}_{1_0 \dot{\otimes} 1_0} = |\chi_{(0,0)} + \chi_{(2,2)}|^2 + |\chi_{(0,2)} + \chi_{(3,2)}|^2 + |\chi_{(2,0)} + \chi_{(2,3)}|^2 + |\chi_{(2,1)} + \chi_{(0,5)}|^2 + |\chi_{(3,0)} + \chi_{(0,3)}|^2 + |\chi_{(1,2)} + \chi_{(5,0)}|^2.$$

The others are interpreted as twisted partition functions (one defect line, in the interpretation of Ref. 31). We give only the twisted partition functions associated with ambichiral points $1_0 \dot{\otimes} 1_i$, for $i \in \{1,2,3,4,5\}$:

$$\mathcal{Z}_{1_0 \dot{\otimes} 1_1} = (\chi_{(0,3)} + \chi_{(3,0)}).(\overline{\chi}_{(0,5)} + \overline{\chi}_{(2,1)}) + (\chi_{(2,0)} + \chi_{(2,3)}).(\overline{\chi}_{(0,0)} + \overline{\chi}_{(2,2)}) + (\chi_{(0,5)} + \chi_{(2,1)}).(\overline{\chi}_{(2,0)} + \overline{\chi}_{(2,3)}) + (\chi_{(1,2)} + \chi_{(5,0)}).(\overline{\chi}_{(0,3)} + \overline{\chi}_{(3,0)}) + (\chi_{(0,0)} + \chi_{(2,2)}).(\overline{\chi}_{(0,2)} + \overline{\chi}_{(3,2)}) + (\chi_{(0,2)} + \chi_{(3,2)}).(\overline{\chi}_{(1,2)} + \overline{\chi}_{(5,0)}),$$

$$\mathcal{Z}_{1_0 \dot{\otimes} 1_2} = (\chi_{(1,2)} + \chi_{(5,0)}).(\overline{\chi}_{(0,5)} + \overline{\chi}_{(2,1)}) + (\chi_{(0,5)} + \chi_{(2,1)}).(\overline{\chi}_{(0,0)} + \overline{\chi}_{(2,2)}) + (\chi_{(0,3)} + \chi_{(3,0)}).(\overline{\chi}_{(2,0)} + \overline{\chi}_{(2,3)}) + (\chi_{(0,2)} + \chi_{(3,2)}).(\overline{\chi}_{(0,3)} + \overline{\chi}_{(3,0)}) + (\chi_{(2,0)} + \chi_{(2,3)}).(\overline{\chi}_{(0,2)} + \overline{\chi}_{(3,2)}) + (\chi_{(0,0)} + \chi_{(2,2)}).(\overline{\chi}_{(1,2)} + \overline{\chi}_{(5,0)}),$$

$$\mathcal{Z}_{1_0 \dot{\otimes} 1_3} = (\chi_{(0,2)} + \chi_{(3,2)}).(\overline{\chi}_{(0,5)} + \overline{\chi}_{(2,1)}) + (\chi_{(0,3)} + \chi_{(3,0)}).(\overline{\chi}_{(0,0)} + \overline{\chi}_{(2,2)}) + (\chi_{(1,2)} + \chi_{(5,0)}).(\overline{\chi}_{(2,0)} + \overline{\chi}_{(2,3)}) + (\chi_{(0,0)} + \chi_{(2,2)}).(\overline{\chi}_{(0,3)} + \overline{\chi}_{(3,0)}) + (\chi_{(0,5)} + \chi_{(2,1)}).(\overline{\chi}_{(0,2)} + \overline{\chi}_{(3,2)}) + (\chi_{(2,0)} + \chi_{(2,3)}).(\overline{\chi}_{(1,2)} + \overline{\chi}_{(5,0)}),$$

$$\mathcal{Z}_{1_0 \dot{\otimes} 1_4} = (\chi_{(0,0)} + \chi_{(2,2)}).(\overline{\chi}_{(0,5)} + \overline{\chi}_{(2,1)}) + (\chi_{(1,2)} + \chi_{(5,0)}).(\overline{\chi}_{(0,0)} + \overline{\chi}_{(2,2)}) + (\chi_{(0,2)} + \chi_{(3,2)}).(\overline{\chi}_{(2,0)} + \overline{\chi}_{(2,3)}) + (\chi_{(2,0)} + \chi_{(2,3)}).(\overline{\chi}_{(0,3)} + \overline{\chi}_{(3,0)}) + (\chi_{(0,3)} + \chi_{(3,0)}).(\overline{\chi}_{(0,2)} + \overline{\chi}_{(3,2)}) + (\chi_{(0,5)} + \chi_{(2,1)}).(\overline{\chi}_{(1,2)} + \overline{\chi}_{(5,0)}),$$

$$\mathcal{Z}_{1_0 \dot{\otimes} 1_5} = (\chi_{(2,0)} + \chi_{(2,3)}).(\overline{\chi}_{(0,5)} + \overline{\chi}_{(2,1)}) + (\chi_{(0,2)} + \chi_{(3,2)}).(\overline{\chi}_{(0,0)} + \overline{\chi}_{(2,2)}) + (\chi_{(0,0)} + \chi_{(2,2)}).(\overline{\chi}_{(2,0)} + \overline{\chi}_{(2,3)}) + (\chi_{(0,5)} + \chi_{(2,1)}).(\overline{\chi}_{(0,3)} + \overline{\chi}_{(3,0)}) + (\chi_{(1,2)} + \chi_{(5,0)}).(\overline{\chi}_{(0,2)} + \overline{\chi}_{(3,2)}) + (\chi_{(0,3)} + \chi_{(3,0)}).(\overline{\chi}_{(1,2)} + \overline{\chi}_{(5,0)}).$$

C. Second example: The $\mathcal{E}_9$ case

This diagram is illustrated on Fig. 11 (notice that it would be better drawn three-dimensionally as a small starwars spaceship with two wings and a cockpit, because of the existing symmetries between the two wings, reminiscent of what happens for the D_{2n} Dynkin diagrams).

The corresponding diagram of the A series is $\mathcal{A}_9$. Altitude of both is $\kappa = 9+3 = 12$. Their respective adjacency matrices are immediately read from the graphs. Their number of vertices are 12 and $10 \times \frac{11}{2} = 55$. Restriction and induction is studied as usual, and imposing constancy of the modular operator T singles out the three circled vertices of Fig. 11 as elements of the vector

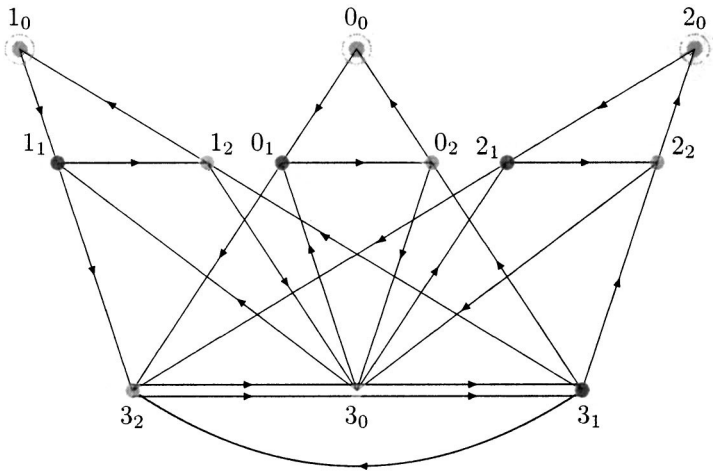

FIG. 11. The $\mathcal{E}_9$ generalized Dynkin diagram.

subspace J that is used to characterize the ambichiral points of the Ocneanu graph. The fused adjacency matrices F_i are obtained from the su(3) recurrence formula; this determines the essential matrices E_a. We give on Fig. 12 the columns of the E_0 matrix indexed by the three special points (these are the ''ambichiral columns'' of the intertwiner E_0); a consistent value of T can be defined for these three points (and these three points only), one finds $\hat{T}=9$ for the vertex 0_0 and $\hat{T}=21$ for 1_0 and 2_0.

Blocks of the bialgebra $\mathcal{BE}_9$, for its first associative law ($\circ$), are labeled by the 55 vertices of $\mathcal{A}_9$ and their dimensions are given on Fig. 13. The total dimension is the sum of corresponding squares: $dim(\mathcal{BE}_9)=\Sigma_i d_i^2=518976=(2)^6(3)^2(17)^1(53)^1$.

Something special happens however for this graph (again reminiscent of a similar situation in the D_{2n} case of Dynkin diagrams): first of all, the diagram itself is not sufficient to determine a unique associative algebra structure, and one has to impose positivity and integrality of the structure constants in order to determine a self-fusion structure (it is unique up to permutation of the two wings). Since the determination of the corresponding graph matrices is not totally straightforward, we give below the two matrices corresponding to the endpoints 1_0 and 2_0. We choose the following order for the vertices: $0_0,1_0,2_0,3_0;0_1,1_1,2_1,3_1;0_2,1_2,2_2,3_2$. We also give the adjacency matrix G_{0_1} whose determination *is* straightforward.

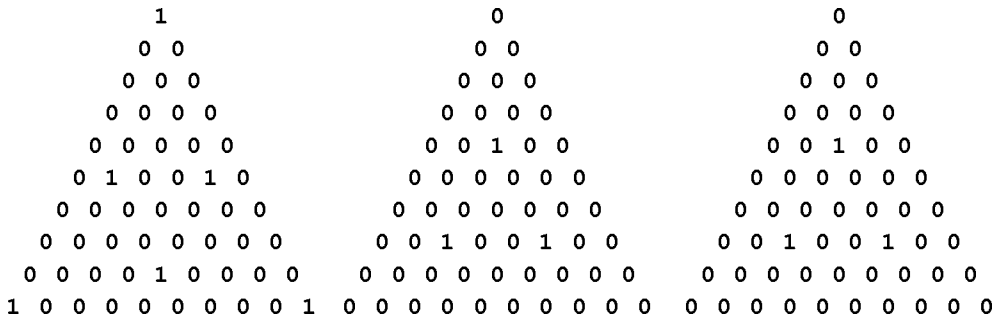

FIG. 12. Induction corresponding to the three upper vertices of $\mathcal{E}_9$.

$$G_{0_1}=\begin{pmatrix}
. & . & . & . & . & . & . & . & 1 & . & . & . \\
. & . & . & . & . & . & . & . & . & 1 & . & . \\
. & . & . & . & . & . & . & . & . & . & 1 & . \\
. & . & . & . & . & . & . & . & 1 & 1 & 1 & 2 \\
1 & . & . & 1 & . & . & . & . & . & . & . & . \\
. & 1 & . & 1 & . & . & . & . & . & . & . & . \\
. & . & 1 & 1 & . & . & . & . & . & . & . & . \\
. & . & . & 2 & . & . & . & . & . & . & . & . \\
. & . & . & . & 1 & . & . & 1 & . & . & . & . \\
. & . & . & . & . & 1 & . & 1 & . & . & . & . \\
. & . & . & . & . & . & 1 & 1 & . & . & . & . \\
. & . & . & . & 1 & 1 & 1 & 1 & . & . & . & .
\end{pmatrix},$$

$$G_{1_0}=\begin{pmatrix}
. & 1 & . & . & . & . & . & . & . & . & . & . \\
. & . & 1 & . & . & . & . & . & . & . & . & . \\
1 & . & . & . & . & . & . & . & . & . & . & . \\
. & . & . & 1 & . & . & . & . & . & . & . & . \\
. & . & . & . & . & 1 & . & . & . & . & . & . \\
. & . & . & . & . & . & 1 & . & . & . & . & . \\
. & . & . & . & 1 & . & . & . & . & . & . & . \\
. & . & . & . & . & . & . & 1 & . & . & . & . \\
. & . & . & . & . & . & . & . & 1 & . & . & . \\
. & . & . & . & . & . & . & . & . & 1 & . & . \\
. & . & . & . & . & . & . & . & 1 & . & . & . \\
. & . & . & . & . & . & . & . & . & . & . & 1
\end{pmatrix},$$

$$G_{2_0}=\begin{pmatrix}
. & . & 1 & . & . & . & . & . & . & . & . & . \\
1 & . & . & . & . & . & . & . & . & . & . & . \\
. & 1 & . & . & . & . & . & . & . & . & . & . \\
. & . & . & 1 & . & . & . & . & . & . & . & . \\
. & . & . & . & . & . & 1 & . & . & . & . & . \\
. & . & . & . & 1 & . & . & . & . & . & . & . \\
. & . & . & . & . & 1 & . & . & . & . & . & . \\
. & . & . & . & . & . & . & 1 & . & . & . & . \\
. & . & . & . & . & . & . & . & . & . & 1 & . \\
. & . & . & . & . & . & . & . & 1 & . & . & . \\
. & . & . & . & . & . & . & . & . & 1 & . & . \\
. & . & . & . & . & . & . & . & . & . & . & 1
\end{pmatrix}.$$

Next, and as expected, the operator T does not distinguish between these two points, and we therefore expect, as in the D_{2n} case of the su(2) system, that the algebra $\mathrm{Oc}(\mathcal{E}_9)$ of quantum symmetries will possess a noncommutative 2×2 matrix component, encoding, in a ''noncommu-

FIG. 13. Dimension of space of blocks (law $\circ$) for $\mathcal{E}_9$.

tative geometrical spirit,'' this indistinguishability. The presence of such a noncommutative piece is also reflected in the presence of a coefficient 2 in the (known) modular invariant partition function. We note, however, that ambichiral points are bound to be, in any case, $0_0\dot{\otimes}0_0$, $1_0\dot{\otimes}0_0=0_0\dot{\otimes}1_0$ and $2_0\dot{\otimes}0_0=0_0\dot{\otimes}2_0$. The corresponding toric matrices W and partition functions $\mathcal{Z}$ are computed as usual. We define the linear combination U and V of characters

$$U=\chi_{(2,2)}+\chi_{(2,5)}+\chi_{(5,2)},$$

$$V=\chi_{(0,0)}+\chi_{(0,9)}+\chi_{(9,0)}+\chi_{(1,4)}+\chi_{(4,1)}+\chi_{(4,4)},$$

and find

$$\mathcal{Z}_{0_0\dot{\otimes}0_0}=2\,U.\overline{U}+V.\overline{V},$$

$$\mathcal{Z}_{1_0\dot{\otimes}0_0}=\mathcal{Z}_{2_0\dot{\otimes}0_0}=U.\overline{V}+V.\overline{U}.$$

The first one is modular invariant and agrees with the expression of Gannon.[13] The other one should be interpreted as a twisted partition function in a BCFT with defect lines.

Unfortunately, in this case, as it was for D_{2n}, the data provided by the eigenvalues of the modular operator T does not seem to be sufficient to determine the full (noncommutative in this case) structure of $\mathrm{Oc}(\mathcal{E}_9)$ or the Ocneanu graph itself, and we decide to stop at this point.

D. Third example: The $\mathcal{E}_{21}$ case

The $\mathcal{E}_{21}$ diagram is illustrated in Fig. 14. The corresponding $\mathcal{A}$ diagram with same norm is $\mathcal{A}_{21}$. The altitude of both is $\kappa=21+3=24$. Their respective adjacency matrices G_1 and N_1 are immediately obtained from the diagrams. The number of vertices of the two diagrams are respectively equal to 24 and $22\times\frac{23}{2}=253$.

1. Restriction and induction mechanism

The easiest method is to determine first the fused matrices F_i by using the recurrence formula for su(3). Essential matrices E_a—and in particular E_0—are then obtained in the usual way from the F_i's. The first column of E_0 gives the quantum invariants; it is displayed on the left array of Fig. 15.

One can check that the values of the modular operator T, calculated for $\mathcal{A}_{21}$, are equal for all nonzero entries of this table. The same property is also true for the column of E_0 associated with the rightmost point of the $\mathcal{E}_{21}$ graph (right array of Fig. 15). However, T, when evaluated on nonzero entries of the 22 other columns of E_0, is not constant. We conclude that the set J

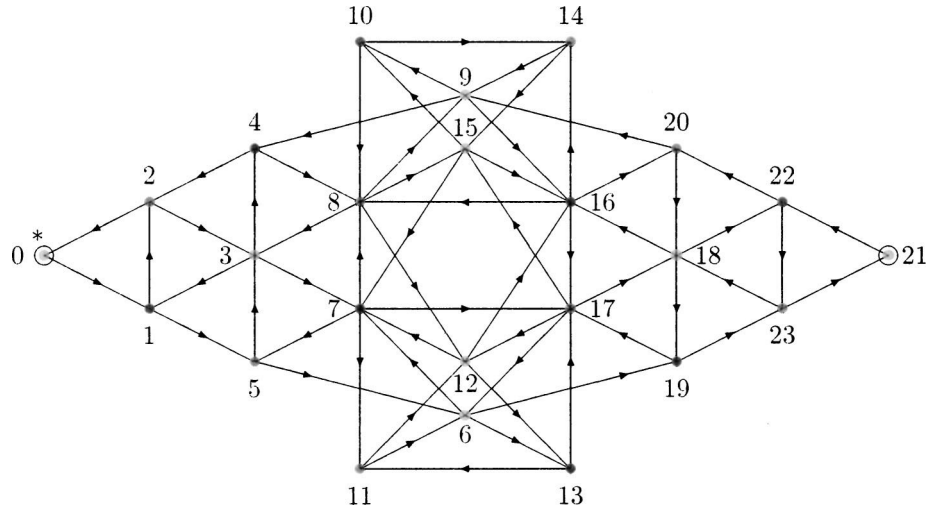

FIG. 14. The $\mathcal{E}_{21}$ generalized Dynkin diagram.

characterizing the ambichiral points of $\mathrm{Oc}(\mathcal{E}_{21})$ is a set with two elements: the two extreme vertices of $\mathcal{E}_{21}$. The values of the modular exponent T obtained for these two points are $\hat{T}=21$ and $\hat{T}=39$.

The dimensions d_j, with $j=(\lambda_1,\lambda_2)$ of the 253 blocks of the bialgebra $\mathcal{BE}_{21}$, for the first law determined by composition of endomorphisms, are obtained by summing matrix elements of matrices F_j. They are displayed in Fig. 16. We obtain $dim(\mathcal{BE}_{21})=\Sigma_j d_j^2=480\,701\,952=(2)^9(3)^4(67)^1(173)^1$, and also $\Sigma_j d_j=288\,576=(2)^6(3)^3(167)^1$.

2. Determination of the graph algebra and of matrices G_a

The determination of graph matrices G_a comes from the graph $\mathcal{E}_{21}$ itself. To ease the calculation, it is worth noticing that graph matrices associated with points symmetric with respect to the horizontal symmetry axis of the graph are transposed. We have, for example, $G_5=G_1.G_1-G_2$ so that $G_4=(G_5)^t=G_2.G_2-G_1$. Their determination is straightforward from vertices 1 to 9. We then use the fact that $G_6.G_{21}=G_9$ to compute the matrix G_{21} associated with the rightmost point of the graph. Multiplying a vertex k by the vertex 21 gives a vertex which is the symmetric of k

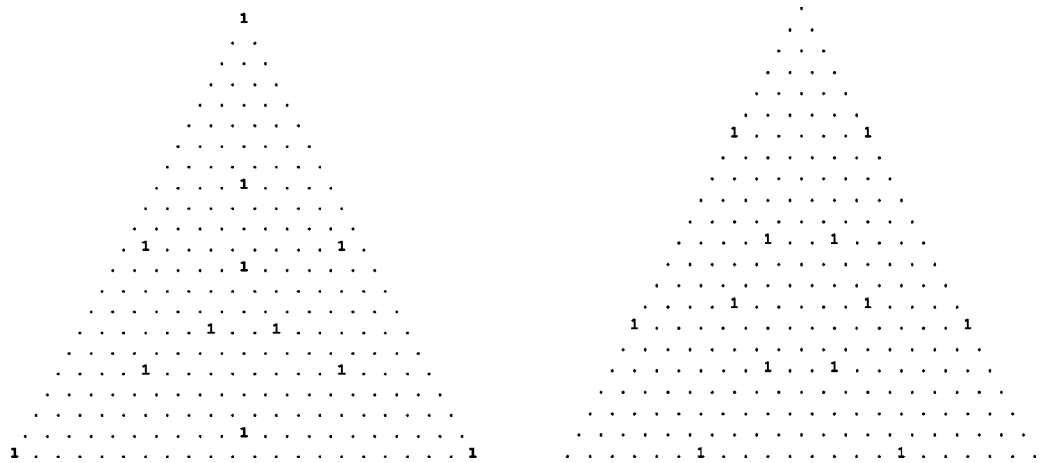

FIG. 15. Induction corresponding to the two extreme points of $\mathcal{E}_{21}$.

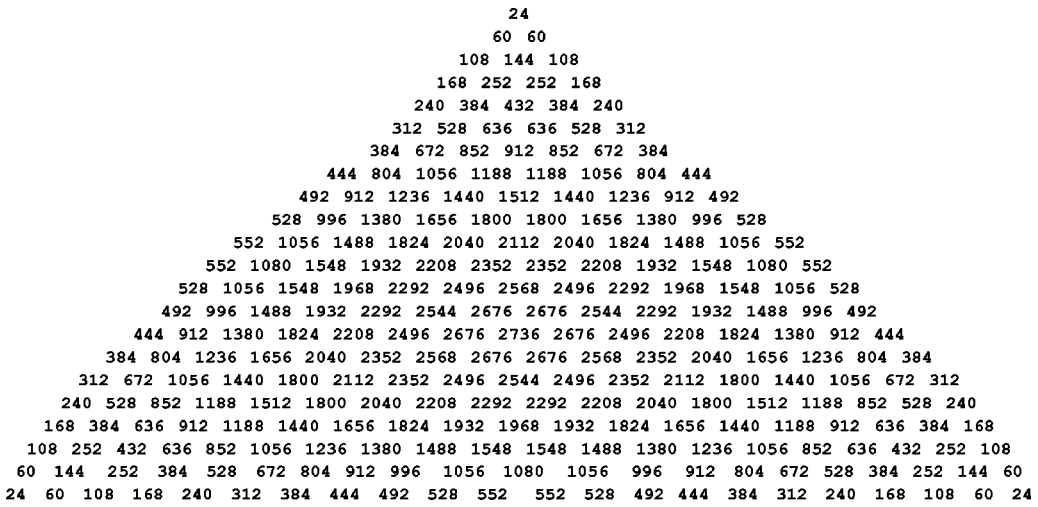

FIG. 16. Dimension of space of blocks (law $\circ$).

with respect to the center of the graph (the center of a star). In graph algebra terms, we get, for example, $G_5.G_{21}=G_{20}$ and $G_8.G_{21}=G_{17}$. It is then easy to compute the matrices associated with all the other vertices of the graph. The most important result, for what follows, is that $G_{21}.G_{21}=G_0$.

3. Quantum symmetries

As already discussed, the subspace J of $\mathcal{E}_{21}$ determining the algebra of quantum symmetries is spanned by 0 and 21; we set $\mathrm{Oc}(\mathcal{E}_{21})=\mathcal{E}_{21}\otimes_J\mathcal{E}_{21}$. This is a commutative algebra. The left and right subalgebras L and R are respectively spanned by $a\dot{\otimes}0$ and by $0\dot{\otimes}a$, where $a=0,1,\ldots,23$. Both left and right chiral subgraphs have 24 points. The ambichiral subalgebra A, of dimension 2 is spanned by $\{0\dot{\otimes}0=21\dot{\otimes}21\}$ and by $\{0\dot{\otimes}21=21\dot{\otimes}0\}$. The supplementary subspace C is spanned by $u\dot{\otimes}a$, where $u\in\{1,2,3,4,5,6,7,8,10,11,12\}$ and a takes all possible values (but neither 0 nor 21). The total number of vertices of the Ocneanu graph is therefore $22+22+2+11\times22=288$, as expected from the naive dimension count $24\times\frac{24}{2}=288$. As usual, blocks corresponding to the second structure of the bialgebra $\mathcal{B}\mathcal{E}_{21}$ are labeled by the 288 points of the Ocneanu graph, and the dimension d_x of the block x is obtained by summing the matrix elements of matrices $S_x=G_aG_b$ when $x=a\dot{\otimes}b$ runs over the points of $\mathrm{Oc}(\mathcal{E}_{21})$. We find (subscript give multiplicities of the blocks)

$$\text{Ambichiral: } (24)_2$$

$$\text{Left (not ambichiral): } (60)_4(108)_4(132)_4(144)_2(168)_2(216)_2(252)_4$$

$$\text{Right (not ambichiral): } (60)_4(108)_4(132)_4(144)_2(168)_2(216)_2(252)_4$$

$$\text{Supplement: } (168)_8(312)_{16}(384)_{16}(420)_8(492)_8(600)_8(636)_8(744)_{32}(804)_8(936)_8(948)_8(996)_8$$

$$(1080)_2(1188)_8(1236)_8(1272)_4(1440)_{16}(1512)_2(1548)_8(1656)_4(1800)_{16}(1932)_8$$

$$(1968)_4(2292)_8(2568)_2(2988)_8(3480)_8$$

The quadratic and linear sum rules read

$$\sum d_x = \sum d_i = 288\,576 = (2)^6(3)^3(167)^1,$$

$$\sum d_x^2 = \sum d_i^2 = 480\,701\,952 = (2)^9(3)^4(67)^1(173)^1.$$

4. Toric matrices and twisted partition functions

We define the linear combination U and V of characters as follows:

$$U = \chi_{(0,0)} + \chi_{(0,21)} + \chi_{(1,10)} + \chi_{(4,4)} + \chi_{(4,13)} + \chi_{(6,6)} + \chi_{(6,9)} + \chi_{(9,6)} + \chi_{(10,1)} + \chi_{(10,10)} + \chi_{(13,4)} + \chi_{(21,0)},$$

$$V = \chi_{(0,6)} + \chi_{(0,15)} + \chi_{(4,7)} + \chi_{(4,10)} + \chi_{(6,0)} + \chi_{(6,15)} + \chi_{(7,4)} + \chi_{(7,10)} + \chi_{(10,4)} + \chi_{(10,7)} + \chi_{(15,0)} + \chi_{(15,6)}.$$

The modular-invariant partition function $\mathcal{Z}_{\mathcal{E}_5}$ (associated with the vertex $0\dot{\otimes}0$) and the one associated with the vertex $0\dot{\otimes}21$, that we call $\mathcal{Z}'_{\mathcal{E}_5}$, are

$$\mathcal{Z}_{\mathcal{E}_5} \doteq \mathcal{Z}_{0\dot{\otimes}0} = U.\overline{U} + V.\overline{V},$$

$$\mathcal{Z}'_{\mathcal{E}_5} \doteq \mathcal{Z}_{0\dot{\otimes}21} = U.\overline{V} + V.\overline{U}.$$

The first one agrees with the expression of Ref. 13, the other, as explained in Sec. II B, should be interpreted as a twisted partition function in a BCFT with one defect line.[29] There are 286 other such functions for the $\mathcal{E}_{21}$ diagram, but these two are the only ones that are ambichiral.

ACKNOWLEDGMENTS

We thank the referee for his careful reading of the manuscript and for his questions and comments. One of us (R.C.) wants to thank the Centro Brasileiro de Pesquisas Físicas (CBPF, Rio de Janeiro), where part of this work was done, for its hospitality. G.S. would like to thank the Conselho Nacional de Desenvolvimento Científico e Tecnológico, CNPq, and the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior, CAPES, Brazilian Research Agencies, for financial support.

APPENDIX A: ABOUT MODULAR INVARIANCE

The expressions for S and T can be taken from the theory of quantum groups $\mathcal{U}_q(\mathcal{G})$ at roots of unity, i.e., when $q = e^{i\pi/\mu\kappa}$. Here μ is half the length of a long root, so it is equal to 1 when the Lie algebra $\mathcal{G}$ is simply laced, which is the case in particular for su(2) and su(3), and κ is an arbitrary positive integer, larger or equal to h, the dual Coxeter number of $\mathcal{G}$. The equation $\kappa = h + k$ defines the "level" k. One should consider a particular category whose objects are the so-called tilting modules of $\mathcal{U}_q(\mathcal{G})$ and whose morphisms are defined up to "negligible morphisms" (see, for instance, Ref. 1); this is a semisimple ribbon and modular category. This implies, in particular, that a (projective) representation of $\mathrm{SL}(2,\mathbb{Z})$ can be defined on the simple objects, thanks to two matrices s and t and a phase ζ which are such that $(st)^3 = \zeta^3 s^2$, $s^2 = C$, $Ct = tC$ and $C^2 = 1$. The matrix C is called "conjugation matrix" and t is the "modular twist." For this category, $\zeta = e^{2i\pi c/24}$ with $c = (\kappa - h)dim(\mathcal{G})/\kappa$. The expression for the t matrix, in the case of an arbitrary Lie algebra $\mathcal{G}$ is $t_{mn} = \delta_{mn} q^{\langle\langle n, n+2\rho\rangle\rangle}$ where ρ is half the sum of positive roots and m, n are elements of the weight lattice of $\mathcal{G}$ characterizing the representation τ_m and τ_n. Here $\langle\langle .,. \rangle\rangle$ is

an invariant bilinear form on $\mathcal{G}$ normalized by $\langle\langle\alpha,\alpha\rangle\rangle=2$ for a short root α. The corresponding general expression for the s matrix is more involved and we do not need it in our article. The same expressions for the modular generators can be obtained from the Kac–Peterson formulas[16] for the modular transformations of characters of the affine Lie algebra $\hat{\mathcal{G}}$, evaluated at the same value $q=e^{i\pi/\mu\kappa}$. Here $k=\kappa-h$ is indeed equal to the usual level.

In the case of su(2), the modular generators S, T, are as follows: $S=s$ and $T=t/\zeta$. The SL(2,$\mathbb{Z}$) relations read then $(ST)^3=S^2=1$, with $s_{mn}=\sqrt{2/\kappa}\sin(\pi(m+1)(n+1)/\kappa)$, for $0\leqslant m,n\leqslant\kappa-2$ and $t_{mn}=e^{(i\pi/2\kappa)\,n(n+2)}\delta_{mn}$. Still for su(2) we have $c=3-6/\kappa$, so that $\zeta=e^{i\pi/4}e^{-i\pi/2\kappa}$ and therefore

$$T_{mn}=\exp\left[2i\pi\left(\frac{(n+1)^2}{4\kappa}-\frac{1}{8}\right)\right]\delta_{mn},$$

which is the expression used in the text. One can explicitly see that the previous SL(2,$\mathbb{Z}$) relations hold. It can be checked, from this expression that, $T^{8\kappa}=1$ when κ is odd and $T^{4\kappa}=1$ when κ is even. This, by itself, is not enough to imply the following property, which is nevertheless true, and was proven more than 100 years ago:[15] the above representation of SL(2,$\mathbb{Z}$) factorizes over the finite group SL(2,$\mathbb{Z}/8\kappa\mathbb{Z}$) when κ is odd, and factorizes over SL(2,$\mathbb{Z}/4\kappa\mathbb{Z}$) when κ is even. So, in particular, $T^{40}=1$ for the A_4 graph ($40=8\times5$), but $T^{48}=1$ for the A_{11} graph ($48=4\times12$). In the text, we use [for su(2)] a "modular exponent" defined by $\hat{T}=(n+1)^2 \bmod 4\kappa$, but it is clear that we could use as well $n(n+2) \bmod 4\kappa$ or any other expression differing by a constant shift.

APPENDIX B: THE GENERAL NOTION OF ESSENTIAL PATHS ON A GRAPH *G* OF TYPE *ADE*

The following definitions are not needed if we only want to count the number of essential paths on a graph. They are necessary if we want to obtain explicit expressions for them. These definitions are adapted from Ref. 23, see also several comments made in Refs. 7 and 6. Call β the norm of the graph G (the biggest eigenvalue of its adjacency matrix $\mathcal{G}$) and D_i the components of the (normalized) Perron Frobenius eigenvector. Call σ_i the vertices of G and, if σ_j is a neighbor of σ_i, call ξ_{ij} the oriented edge from σ_i to σ_j. If G is unoriented (the case for ADE and affine ADE diagrams), each edge should be considered as carrying both orientations. An elementary path can be written either as a finite sequence of consecutive (i.e., neighbors on the graph) vertices, $[\sigma_{a_1}\sigma_{a_2}\sigma_{a_3}\cdots]$, or, better, as a sequence $(\xi(1)\xi(2)\cdots)$ of consecutive edges, with $\xi(1)=\xi_{a_1a_2}=\sigma_{a_1}\sigma_{a_2}$, $\xi(2)=\xi_{a_2a_3}=\sigma_{a_2}\sigma_{a_3}$, etc. Vertices are considered as paths of length 0. The length of the (possibly backtracking) path $(\xi(1)\xi(2)\cdots\xi(p))$ is p. We call $r(\xi_{ij})=\sigma_j$ the range of ξ_{ij}, and $s(\xi_{ij})=\sigma_i$ the source of ξ_{ij}. For all edges $\xi(n+1)=\xi_{ij}$ that appear in an elementary path, we set $\xi(n+1)^{-1}\doteq\xi ji$. For every integer $n>0$, the annihilation operator C_n, acting on the vector space generated by elementary paths of length p, is defined as follows: if $p\leqslant n$, C_n vanishes, whereas if $p\geqslant n+1$, then

$$C_n(\xi(1)\xi(2)\cdots\xi(n)\xi(n+1)\cdots)=\sqrt{\frac{D_{r(\xi(n))}}{D_{s(\xi(n))}}}\,\delta_{\xi(n),\xi(n+1)^{-1}}(\xi(1)\xi(2)\cdots\hat{\xi}(n)\hat{\xi}(n+1)\cdots).$$

Here, the symbol "hat" (like in $\hat{\xi}$) denotes omission. The result is therefore either 0 or a linear combination of paths of length $p-2$. Intuitively, C_n chops the round trip that possibly appears at positions n and $n+1$.

A path is called essential if it belongs to the intersection of the kernels of the anihilators C_n's.

The following is an example of calculation for the E_6 diagram (square brackets enclose q-numbers),

$$C_3(\xi_{01}\xi_{12}\xi_{23}\xi_{32}) = \sqrt{\frac{1}{[2]}}(\xi_{01}\xi_{12}),$$

$$C_3(\xi_{01}\xi_{12}\xi_{25}\xi_{52}) = \sqrt{\frac{[2]}{[3]}}(\xi_{01}\xi_{12}).$$

The following difference of nonessential paths of length 4 starting at σ_0 and ending at σ_2 is an essential path of length 4 on E_6:

$$\sqrt{[2]}(\xi_{01}\xi_{12}\xi_{23}\xi_{32}) - \sqrt{\frac{[3]}{[2]}}(\xi_{01}\xi_{12}\xi_{25}\xi_{52}) = \sqrt{[2]}[0,1,2,3,2] - \sqrt{\frac{[3]}{[2]}}[0,1,2,5,2].$$

Remember the values of the q-numbers: $[2]=\sqrt{2}/(\sqrt{3}-1)$ and $[3]=2/(\sqrt{3}-1)$.

Acting on elementary path of length p, the creating operators $C_n^\dagger$ are defined as follows: if $n>p+1$, $C_n^\dagger$ vanishes and, if $n\leqslant p+1$, then, setting $j=r(\xi(n-1))$,

$$C_n^\dagger(\xi(1)\cdots\xi(n-1)\cdots) = \sum_{d(j,k)=1} \sqrt{\left(\frac{D_k}{D_j}\right)}(\xi(1)\cdots\xi(n-1)\xi_{jk}\xi_{kj}\cdots).$$

The above sum is taken over the neighbors σ_k of σ_j on the graph. Intuitively, this operator adds one (or several) small round trip(s) at position n. The result is therefore either 0 or a linear combination of paths of length $p+2$. For instance, on paths of length zero (i.e., vertices),

$$C_1^\dagger(\sigma_j) = \sum_{d(j,k)=1} \sqrt{\left(\frac{D_k}{D_j}\right)}\xi_{jk}\xi_{kj} = \sum_{d(j,k)=1} \sqrt{\left(\frac{D_k}{D_j}\right)}[\sigma_j\sigma_k\sigma_j].$$

Jones' projectors e_k can be realized (as endomorphisms of Path^p) by

$$e_k \doteq \frac{1}{\beta} C_k^\dagger C_k .$$

The reader can check that all Jones–Temperley–Lieb relations between the e_i are satisfied. Essential paths can also be defined as elements of the intersection of the kernels of the Jones projectors e_i's.

APPENDIX C: THE STRUCTURE OF $\mathcal{BG}$

Paths on G generate a vector space Paths(G) which comes with a grading: paths of homogeneous grade j are associated with Young diagrams of SU(N). In the case of su(2) this grading is just an integer (to be thought of as a length or as a point of a diagram of type $\mathcal{A}$).

What turns out to be most interesting is a particular vector subspace $\mathcal{E}=$EssPaths(G) of Paths whose elements are called "essential paths" (see above definition). This subspace is is itself graded in the same way as Paths.

We then consider the graded algebra of endomorphisms of essential paths

$$\mathcal{BG} = \mathrm{End}_\sharp(\mathrm{EssPaths}) = \bigoplus_{j=0,r-1} \mathrm{End}(\mathrm{EssPaths}^j),$$

which, by definition, is an associative algebra. By using the fact that paths on the chosen diagram can be concatenated, one may define[23] *another* multiplicative associative structure on $\mathcal{BG}$ that we call convolution product (see our comments in the next subsection). This vector space with two algebra structures is called, by A. Ocneanu, the "algebra of double triangles."

Existence of a scalar product allows one to transmute one of the multiplications (for instance, the convolution product) into a co-multiplication and it happens that the coproduct Δ is compatible

with the product [in the sense that we have the homomorphism property $\Delta(uv)=\Delta u\otimes\Delta v$]. $\mathcal{B}G$ is therefore a bialgebra. However, $\mathcal{B}G$ is not a Hopf algebra but a weak Hopf algebra (or quantum groupoid). This statement should be taken with a grain of salt: see our comments in the next appendix. General axioms for weak Hopf algebras are given in Ref. 3. In the present case, the following axiom for Hopf algebras fails to be satisfied: the coproduct of the unit $\Delta\mathbb{1}=\mathbb{1}_1\otimes\mathbb{1}_2$ is not equal to $\mathbb{1}\otimes\mathbb{1}$ (as usual, a summation is understood); several other axioms for Hopf algebras are also modified: the counit is not an homomorphism ($\epsilon(xy)=\epsilon(x\mathbb{1}_1)\epsilon(y\mathbb{1}_2)$) and, if $\Delta^2x=x_1\otimes x_2\otimes x_3$, the compatibility axiom for the antipode is modified as follows $S(x_1)x_2\otimes x_3=\mathbb{1}_1\otimes x\mathbb{1}_2$.

APPENDIX D: REMARKS AND OPEN QUESTIONS

Essential paths for *ADE* diagrams [i.e., the su(2) system] have been defined in several published papers but their analog for higher systems (for instance, the Di Francesco–Zuber diagrams), although reasonably well understood by a few people, have never been described, as far as we know, in the literature.

The general definition of the convolution product of $\mathcal{B}G$, for *ADE* diagrams, was given "explicitly" by A. Ocneanu in Ref. 23 by a rather difficult formula involving several types of generalized quantum $6j$ symbols. It is certainly interesting to know this general formula, but, in our opinion, this expression is not very helpful for a practical investigation of the different cases.

The fact that $\mathcal{B}G$ is a weak Hopf algebra is a claim that belongs to the folklore, but we are not aware of any general reference showing that all the axioms of Ref. 3 are indeed verified in this situation. The authors (together with A. Garcia and R. Trinchero) have, however, checked that it is so in a number of particular cases belonging to the *ADE* series and are working on a general proof.

Another possibility for defining the convolution product of $\mathcal{B}G$ is to make use of the notion of cell systems. This general notion was defined in Ref. 22; it is also described in Ref. 12 and it is used, in a particular context, by Ref. 32. We cannot summarize this theory here. Let us just mention that a cell system involves four graphs (top, bottom, left and right) with matching properties and that, in the present case, the top and bottom graphs are the same *ADE* diagram G. Cells are rectangles with top and bottom edges which are also edges of the given graph(s). Macrocells have top and bottom edges (or "horizontal paths") that coincide with the essential paths on G; their left and right edges are called "vertical paths." To every cell system one can associate "'connections" which are particular maps associating complex numbers with cells or macrocells. These numbers, in turn, can be used to define the structure constants of the algebra we are looking for. For every point of the graph Oc(G) there is an irreducible connection on the cell system (or an irreducible quantum symmetry). Although it seems to provide (at the time of this writing) the shortest road to the explicit construction of the bialgebra $\mathcal{B}G$, this construction is unfortunately not explicitly available in the literature.

Among other results, and in the framework of statistical mechanics, Ref. 31 gives many useful relations between the vertical product of $\mathcal{B}G$ [the product of endomorphisms acting on EssPaths(G)] and its horizontal product (or convolution product). There are indeed several families of numeral constants that appear as structure constants for these two products, or that appear as coefficients of a kind of Fourier transform relating the two. These constants look like generalized quantum $6j$ symbols and obey different types of (mixed) pentagon equations which themselves generalize the quantum group version of the Biedenharn–Elliot identity. As discussed in Ref. 3, any solution of this "big pentagon equation" (involving six different types of generalized $6j$ symbols) determines the structural maps of a weak C^* Hopf algebra. Unfortunately, we do not know a single reference that describes a practical implementation of this general construction (and gives the values of these structure constants) for the bialgebras $\mathcal{B}G$ associated with specific *ADE* diagrams or with their higher generalizations.

Graphs Oc(G), encoding the structure of the algebra of quantum symmetries of the diagram G, have been "conceptually" defined by A. Ocneanu in terms of the block structure of $\mathcal{B}G$ for its convolution product, but it is interesting to notice that, to our knowledge, they were never obtained

in this way. Clearly, it would be interesting to do so. We repeat that our modest purpose, in the present article, was to observe that known Ocneanu graphs (or algebras), in the ADE cases, could be recovered, in most cases, from the modular properties of the T matrix; we then used this observation to study several cases belonging to the su(3) system. The problem of deducing Ocneanu graphs from the explicit structure of the bialgebra $\mathcal{B}G$, in the different cases, is a much more difficult and interesting program that it would be nice to investigate.

Here comes a short list of open questions that, we hope, may trigger the interest of the reader:

(i) Give a simple definition—valid in all cases—of the convolution product of $\mathcal{B}G$.
(ii) Show that this bialgebra is indeed a weak Hopf algebra in all cases.
(iii) Is it possible to find a kind of multiplication on EssPaths(G) that would allow one to construct $\mathcal{B}G$ in a functorial (and simple) way?
(iv) Determine explicitly the graphs Oc(G) directly from the study of the corresponding bialgebra $\mathcal{B}G$.
(v) Find a simple algorithm allowing one to calculate all irreducible connections on cell systems (i.e., the values of cells) in all ADE or generalized ADE cases.
(vi) Precise the relation (if any) between the generalized Coxeter–Dynkin systems and the finite subgroups of Lie groups.
(vii) What is the interpretation of all these contructions in terms of the finite dimensional Hopf quotients of $U_q(\mathrm{SL2})$ at roots of unity?
(viii) Can one, in some sense, ''supersymmetrize'' these constructions?
(ix) What is the origin of the linear sum rules?
(x) What is the origin of the quantum sum rules?
(xi) As we know, toric matrices (twisted or not) described in the text can be interpreted as partition functions (with or without defect lines) on a torus, at the critical point, for affine models (WZW models). Clearly this framework can be generalized in several directions: one may consider more general correlation functions, replace affine models by (generalized) minimal models, and replace the torus by higher genus surfaces.
(xii) We know explicitly how to generalize the ADE diagrams in the cases of su(3) and su(4) and a definition of what are the ''generalized Coxeter-Dynkin systems'' was briefly mentionned in Ref. 24 but a detailed description of this notion is clearly needed.
(xiii) What kind of algebraic structures (generalizing the notion of Lie algebras) can one associate with a diagram belonging to such a generalized system?

(Received 4 February 2003; accepted 24 April 2003)

In this paper we present a covariant quantization of the ''massive'' spin-2 field on de Sitter (dS) space. By ''massive'' we mean a field which carries a specific principal series representation of the dS group. The work is in the direct continuation of previous ones concerning the scalar, the spinor, and the vector cases. The quantization procedure, independent of the choice of the coordinate system, is based on the Wightman-Gärding axiomatic and on analyticity requirements for the two-point function in the complexified pseudo-Riemanian manifold. Such a construction is necessary in view of preparing and comparing with the dS conformal spin-2 massless case (dS linear quantum gravity) which will be considered in a forthcoming paper and for which specific quantization methods are needed. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1599055]

I. INTRODUCTION

As recent observational data clearly favors a positive acceleration of the present universe, the de Sitter (dS) model represents an appealing first approximation of the background space–time. In two previous papers,[1,2] quantizations of ''massive'' spinor fields and vector fields on the dS space have been considered. The spin-2 case is of great importance since the massless tensor field (spin-2) is among the central objects in quantum cosmology and quantum gravity on dS space (dS linear quantum gravity). It has been found that the corresponding propagator (in the usual linear approximation for gravitational field) exhibits a pathological behavior for large separated points (infrared divergence).[3–5]

On one hand, this behavior may originate from the gauge invariance of the field equation and so should have no physical consequences. Antoniadis, Iliopoulos and Tomaras[6] have shown that the large-distance pathological behavior of the graviton propagator on dS background does not manifest itself in the quadratic part of the effective action in the one-loop approximation. This means the pathological behavior of the graviton propagator may be gauge dependent and so should not appear in an effective way as a physical quantity.

On the other hand, some authors argue that infrared divergence could be exploited in order to create instability of dS space.[7,8] Tsamis and Woodard have considered the field operator for linear gravity in dS space along the latter line in terms of flat coordinates, which cover only one-half of the dS hyperboloid.[9] Hence they have found a quantum field which breaks dS invariance, and they have examined the resulting possibility of quantum instability.

Nevertheless, a fully covariant quantization of the linear gravitational field without infrared divergence in dS space–time may reveal to be of extreme importance for further developments. It

[a]Electronic mail: garidi@ccr.jussieu.fr
[b]Electronic mail: gazeau@ccr.jussieu.fr
[c]Electronic mail: takook@ccr.jussieu.fr

will be considered in a forthcoming paper.[10] Such a quantization requires preliminary covariant quantizations of the minimally coupled scalar field and the "massive" spin-2 field respectively.

Recently, de Vega *et al.*[11] have shown that, in flat coordinates (not global) on de Sitter space–time, the infrared divergence does not appear in the "massless" minimally coupled scalar field. The question of the covariant minimally coupled scalar field has been completely answered in Ref. 12 after introducing a specific Krein QFT. We have shown that the effect of that quantization, without changing the physical content of the theory, appears as an automatic renormalization of the ultraviolet divergence in the stress tensor and of the infrared divergence in the two-point function.[13] By using this method for linear gravity (the traceless rank-2 "massless" tensor field) the two-point function is free of any infrared divergence.[14] This result has been also obtained by Refs. 15–17.

Here, we present a fully covariant quantization of the "massive" spin-2 field. Our method is based on a rigorous group-theoretical approach combined with a suitable adaptation of the Wightman–Gärding axiomatic, which is carried out in terms of coordinate independent dS waves. The whole procedure originated by Ref. 18 is based on analyticity requirements in the complexified pseudo-Riemanian manifold. The SO(1,N) unitary irreducible representations (UIRs) acting on symmetric, traceless and divergence-free tensor eigenfunctions of the Laplace–Beltrami operator have been investigated in Ref. 19. Previous studies of the "massive" spin-2 field have been carried out in Ref. 20 with a specific choice of coordinates (flat coordinates) covering only one-half of the dS hyperboloid, and in Ref. 21 where the forbidden mass range for spin-2 fields has been clarified, and the null-mass limit considered. The mentioned forbidden mass range is closely related to a novel gauge invariance occurring for a specific representation of the dS group. This phenomena has first been observed in Refs. 22 and 23 in the general framework of constant curvature spaces. Recently, various aspects of higher spin physics have been considered in a series of papers by S. Deser and A. Waldron. Among these, a stability analysis of the massive spin-2 field[24] is given as well as detailed discussions about the richness of the plane defined by the mass parameter and the cosmological constant.[25–27] It is notably shown how this plane is divided by partially massless lines in various regions with different properties (null propagation, stability,...). The null-mass limit has also been analyzed in Ref. 28 and a consistent theory for a massive spin-2 field in a general gravitational background has been presented in Refs. 29 and 30. Pioneering works concerning propagators in a general curved background are due to A. Lichnerowicz (see, for instance, Ref. 31).

In Sec. II, we describe the dS tensor field equation as an eigenvalue equation of the SO(1,4) Casimir operators. The notations and the two independent Casimir operators are introduced. It will be convenient to use ambient space notations in order to express the spin-2 field equation in terms of the coordinate independent Casimir operators. The latter carry the group-theoretical content of the theory and it will be reminded how they enable us to classify the dS group UIR[32,33] according to two parameters p and q which behave like a spin (s) and a mass (m) in the Minkowskian limit, depending on the nature of the involved group representation.

Section III is devoted to the field equation and its solutions. The dS tensor modes are written in terms of a scalar field ϕ and a generalized polarization tensor $\mathcal{E}$,

$$\mathsf{K}_{\alpha\beta}(x)=\mathcal{E}_{\alpha\beta}(x,\xi)\,\phi(x).$$

As for spinor and vector fields, the tensor $\mathcal{E}(x,\xi)$ is a space–time function in dS space–time. There is a certain extent of arbitrariness in the choice of this tensor and we fix it in such a way that, in the limit $H=0$, one obtains the polarization tensor in Minkowski space–time.

In Sec. IV we derive the Wightman two-point function $\mathcal{W}_{\alpha\beta\alpha'\beta'}(x,x')$. This function fulfills the conditions of (a) positiveness, (b) locality, (c) covariance, (d) normal analyticity, (e) transversality, (f) divergencelessness and (g) permutational index symmetries. The four conditions (c), (e), (f), and (g) allow one to associate this field with a spin-2 unitary irreducible representation of the dS group. The positivity condition permits us to construct a Hilbert space structure. The locality is related to the causality principle, which is a well defined concept in dS space. The normal analy-

ticity allows one to view $\mathcal{W}_{\alpha\beta\alpha'\beta'}(x,x')$ as the boundary value of an analytic two-point function $W_{\alpha\beta\alpha'\beta'}(z,z')$ from the tube domains. The analytic kernel $W_{\alpha\beta\alpha'\beta'}(z,z')$ is defined in terms of dS waves in their tubular domains. Then, the Hilbert space structure is made explicit and the field operator $\mathcal{K}(f)$ is derived. We also give a coordinate-independent formula for the unsmeared field operator $\mathcal{K}(x)$. Brief conclusion and outlook are given in Sec. V. It is in particular asserted that the extension of our approach to ''massless'' tensor field (gravitational field in a dS background in the linear approximation) requires an indecomposable representation of the dS group in view of the construction of the corresponding covariant quantum field. Finally, we have detailed the classification of the unitary irreducible representation of $SO_0(1,4)$ in Appendix A. In Appendix B we relate our construction to the maximally symmetric bitensors introduced in Ref. 34. In Appendixes C and D we respectively present the ''massive'' vector and tensor two-point functions.

II. FIELD EQUATIONS ON de SITTER SPACE

A. Ambient space notations and Casimir operators

The de Sitter space is a solution of the cosmological Einstein equation with positive cosmological constant Λ. It is conveniently described as a hyperboloid embedded in a five-dimensional Minkowski space

$$X_H=\left\{x\in\mathbb{R}^5; x^2=\eta_{\alpha\beta}x^\alpha x^\beta=-H^{-2}=-\frac{3}{\Lambda}\right\},\quad \alpha,\beta=0,1,2,3,4, \tag{2.1}$$

where $\eta_{\alpha\beta}=\mathrm{diag}(1,-1,-1,-1,-1)$. The de Sitter metrics reads

$$ds^2=\eta_{\alpha\beta}dx^\alpha dx^\beta=g^{dS}_{\mu\nu}dX^\mu dX^\nu,\quad \mu=0,1,2,3,$$

where the X^μ's are four space–time intrinsic coordinates of the dS hyperboloid.

An immediate realization of field space is made of a second-rank intrinsic tensor field $h_{\mu\nu}$ satisfying the conditions of divergenceless, tracelessness, and index permutational symmetry respectively:

$$\nabla\cdot h(X)=0,\quad h^\mu_\mu(X)=0,\quad h_{\mu\nu}=h_{\nu\mu}. \tag{2.2}$$

The wave equation for such fields propagating in de Sitter space can be written as[20]

$$(\Box_H+2H^2+m_H^2)h_{\mu\nu}(X)=0, \tag{2.3}$$

where $\Box_H=\nabla_\mu\nabla^\mu$ is the d'Alembertian operator.

Let us now adopt ambient space notations (for details, see Ref. 35), namely, $\mathcal{K}_{\alpha\beta}(x)$ for the field. With these notations, the relationship with unitary irreducible representations of the dS group becomes straightforward because the Casimir operators are easy to identify. The tensor field $\mathcal{K}_{\alpha\beta}(x)$ has to be viewed as a homogeneous function of the $\mathbb{R}^5$-variables x^α with homogeneous degree λ and thus satisfies

$$x^\alpha\frac{\partial}{\partial x^\alpha}\mathcal{K}_{\gamma\beta}(x)=x\cdot\partial\mathcal{K}_{\gamma\beta}(x)=\lambda\,\mathcal{K}_{\gamma\beta}(x). \tag{2.4}$$

The direction of $\mathcal{K}_{\alpha\beta}(x)$ lies in the de Sitter space if we require the condition of transversality[36]

$$x\cdot\mathcal{K}(x)=0. \tag{2.5}$$

With these notations, the conditions (2.2) read as

$$\overline{\partial}\cdot\mathcal{K}=0,\quad \mathcal{K}^\alpha_\alpha=\mathcal{K}'=0,\quad \mathcal{K}_{\alpha\beta}=\mathcal{K}_{\beta\alpha}, \tag{2.6}$$

where $\overline{\partial}$ is the tangential (or transverse) derivative on dS space,

$$\overline{\partial}_\alpha = \theta_{\alpha\beta}\partial^\beta = \partial_\alpha + H^2 x_\alpha x\cdot\partial, \quad \text{with} \quad x\cdot\overline{\partial}=0. \tag{2.7}$$

The tensor with components $\theta_{\alpha\beta}=\eta_{\alpha\beta}+H^2x_\alpha x_\beta$ is the so-called transverse projector.

In order to express Eq. (2.3) in terms of the ambient coordinates, we use the fact that the "intrinsic" field $h_{\mu\nu}(X)$ is locally determined by the transverse tensor field $\mathcal{K}_{\alpha\beta}(x)$ through

$$h_{\mu\nu}(X)=\frac{\partial x^\alpha}{\partial X^\mu}\frac{\partial x^\beta}{\partial X^\nu}\mathcal{K}_{\alpha\beta}(x(X)). \tag{2.8}$$

For instance, it is easily shown that the metric $\eta_{\mu\nu}$ corresponds to the transverse projector $\theta_{\alpha\beta}$. Covariant derivatives acting on a l-rank tensor are transformed according to

$$\nabla_\mu\nabla_\nu\cdots\nabla_\rho h_{\lambda_1\cdots\lambda_l}=\frac{\partial x^\alpha}{\partial X^\mu}\frac{\partial x^\beta}{\partial X^\nu}\cdots\frac{\partial x^\gamma}{\partial X^\rho}\frac{\partial x^{\eta_1}}{\partial X^{\lambda_1}}\cdots\frac{\partial x^{\eta_l}}{\partial X^{\lambda_l}}\mathrm{Trpr}\overline{\partial}_\alpha\mathrm{Trpr}\overline{\partial}_\beta\cdots\mathrm{Trpr}\overline{\partial}_\gamma\mathcal{K}_{\eta_1..\eta_l}, \tag{2.9}$$

where the transverse projection defined by

$$(\mathrm{Trpr}\,\mathcal{K})_{\lambda_1\cdots\lambda_l}\equiv\theta^{\eta_1}_{\lambda_1}\cdots\theta^{\eta_l}_{\lambda_l}\mathcal{K}_{\eta_1..\eta_l}$$

guarantees the transversality in each index. Applying this procedure to a transverse second rank, symmetric tensor field, leads to

$$\begin{aligned}\nabla_\mu\nabla_\nu h_{\rho\lambda}&=\frac{\partial x^\alpha}{\partial X^\mu}\frac{\partial x^\beta}{\partial X^\nu}\frac{\partial x^\gamma}{\partial X^\rho}\frac{\partial x^\eta}{\partial X^\lambda}\mathrm{Trpr}\overline{\partial}_\alpha\mathrm{Trpr}\overline{\partial}_\beta\mathcal{K}_{\gamma\eta}\\&=\frac{\partial x^\alpha}{\partial X^\mu}\frac{\partial x^\beta}{\partial X^\nu}\frac{\partial x^\gamma}{\partial X^\rho}\frac{\partial x^\eta}{\partial X^\lambda}(\overline{\partial}_\alpha\overline{\partial}_\beta\mathcal{K}_{\gamma\eta}-H^2\theta_{\alpha\gamma}\mathcal{K}_{\beta\eta}-H^2\theta_{\alpha\eta}\mathcal{K}_{\beta\gamma}).\end{aligned} \tag{2.10}$$

The kinematical group of the de Sitter space is the ten-parameter group $SO_0(1,4)$ [connected component of the identity in SO(1,4)], which is one of the two possible deformations of the Poincaré group. There are two Casimir operators

$$Q_2^{(1)}=-\tfrac{1}{2}L_{\alpha\beta}L^{\alpha\beta}, \quad Q_2^{(2)}=-W_\alpha W^\alpha, \tag{2.11}$$

where

$$W_\alpha=-\tfrac{1}{8}\epsilon_{\alpha\beta\gamma\delta\eta}L^{\beta\gamma}L^{\delta\eta}, \quad \text{with ten infinitesimal generators} \quad L_{\alpha\beta}=M_{\alpha\beta}+S_{\alpha\beta}. \tag{2.12}$$

The subscript 2 in $Q_2^{(1)}$, $Q_2^{(2)}$ reminds that the carrier space is constituted by second rank tensors. The orbital part $M_{\alpha\beta}$ and the action of the spinorial part $S_{\alpha\beta}$ on a tensor field $\mathcal{K}$ defined on the ambient space read respectively[37]

$$\begin{aligned}M_{\alpha\beta}&=-i(x_\alpha\partial_\beta-x_\beta\partial_\alpha),\\S_{\alpha\beta}\mathcal{K}_{\gamma\delta}&=-i(\eta_{\alpha\gamma}\mathcal{K}_{\beta\delta}-\eta_{\beta\gamma}\mathcal{K}_{\alpha\delta}+\eta_{\alpha\delta}\mathcal{K}_{\beta\gamma}-\eta_{\beta\delta}\mathcal{K}_{\alpha\gamma}).\end{aligned} \tag{2.13}$$

The symbol $\epsilon_{\alpha\beta\gamma\delta\eta}$ holds for the usual antisymmetrical tensor. The action of the Casimir operator $Q_2^{(1)}$ on $\mathcal{K}$ can be written in the more explicit form

$$Q_2^{(1)}\mathcal{K}(x)=(Q_0^{(1)}-6)\mathcal{K}(x)+2\,\eta\mathcal{K}'+2\mathcal{S}x\partial\cdot\mathcal{K}(x)-2\mathcal{S}\partial x\cdot\mathcal{K}(x), \tag{2.14}$$

In the latter, $Q_0^{(1)}=-\frac{1}{2}M_{\alpha\beta}M^{\alpha\beta}$, and the vector symmetrizer $\mathcal{S}$ is defined for two vectors ξ_α and ω_β by $\mathcal{S}(\xi_\alpha\omega_\beta)=\xi_\alpha\omega_\beta+\xi_\beta\omega_\alpha$.

We are now in position to express the wave equation (2.3) by using the Casimir operators. This can be done with the help of Eq. (2.10) since $Q_0^{(1)}=-H^{-2}(\overline{\partial})^2$. The d'Alembertian operator becomes

$$\Box_H h_{\mu\nu}=\nabla^\lambda\nabla_\lambda h_{\mu\nu}=-\frac{\partial x^\alpha}{\partial X^\mu}\frac{\partial x^\beta}{\partial X^\nu}[Q_0^{(1)}H^2+2H^2]\mathcal{K}_{\alpha\beta}\quad, \tag{2.15}$$

and the wave equation (2.3) is rewritten as

$$(Q_0^{(1)}-H^{-2}m_H^2)\mathcal{K}_{\alpha\beta}(x)=0. \tag{2.16}$$

Finally, using formula (2.14) for the tensor field $\mathcal{K}_{\alpha\beta}(x)$ which satisfies the conditions (2.6), the field equation becomes

$$(Q_2^{(1)}-(m_H^2H^{-2}-6))\mathcal{K}_{\alpha\beta}(x)=0. \tag{2.17}$$

As expected, this formulation of the field equation has now a clear group-theoretical content. In fact, using the representation classification given by the eigenvalues of the Casimir operator, we will be able to identify the involved field. At this point let us clarify what we mean by ''massive'' spin-2 de Sitter field. Inasmuch as mass and spin are well-defined Poincaré concepts, we will consider exclusively the de Sitter elementary systems (in the Wigner sense) associated to a UIR of $SO_0(1,4)$ that admit a nonambiguous massive spin-2 UIR of the Poincaré group at the $H=0$ contraction limit. This contraction is performed with respect to the subgroup $SO_0(1,3)$ which is identified as the Lorentz subgroup in both relativities, and the concerned de Sitter representations are precisely those ones which are induced by the *minimal parabolic*[38] subgroup $SO(3)\times SO(1,1)\times$ (a certain nilpotent subgroup), where SO(3) is the space rotation subgroup of the Lorentz subgroup in both cases. This fully clarifies the concept of spin in de Sitter since it is issued from the *same* SO(3).

B. "Massive" spin-2 unitary representation of the de Sitter group $SO_0(1,4)$

The operator $Q_2^{(1)}$ commutes with the action of the group generators and, as a consequence, it is constant in each unitary irreducible representation (UIR). Thus the eigenvalues of $Q_2^{(1)}$ can be used to classify the UIR's, i.e.,

$$(Q_2^{(1)}-\langle Q_2^{(1)}\rangle)\mathcal{K}(x)=0. \tag{2.18}$$

Following Dixmier[32] we get a classification scheme using a pair (p,q) of parameters involved in the following possible spectral values of the Casimir operators:

$$Q^{(1)}=(-p(p+1)-(q+1)(q-2))I_d,\quad Q^{(2)}=(-p(p+1)q(q-1))I_d. \tag{2.19}$$

Three types of scalar, tensorial or spinorial UIR are distinguished for $SO_0(1,4)$ according to the range of values of the parameters q and p,[32,33] namely, the principal, the complementary and the discrete series. In the following, we shall restrict the list to the unitary representations which have a Minkowskian physical spin-2 interpretation in the limit $H=0$ (for the general situation see Ref. 39 and Appendix A). The flat limit tells us that for the principal and the complementary series it is the value of p which has a spin meaning, and that, in the case of the discrete series, the only representations which have a physically meaningful Minkowskian counterpart are those with $p=q$ (details about the mathematics of the group contraction and the physical principles underlying the relationship between de Sitter and Poincaré groups can be found in Refs. 40 and 41, respectively). The spin-2 tensor representations relevant to the present work are the following:

(i) The UIR's $U^{2,\nu}$ in the principal series where $p=s=2$ and $q=\frac{1}{2}+i\nu$ correspond to the Casimir spectral values:

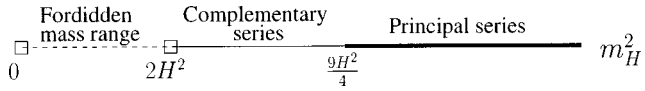

FIG. 1. Mass range and spin-2 $SO_0(1,4)$ unitary irreducible representations.

$$\langle Q_2^{(1)} \rangle = \nu^2 - \tfrac{15}{4}, \tag{2.20}$$

with parameter $\nu \in \mathbb{R}$ (note that $U^{2,\nu}$ and $U^{2,-\nu}$ are equivalent).

(ii) The UIR's $V^{2,q}$ in the complementary series where $p=s=2$ and $q-q^2=\mu$ correspond to

$$\langle Q_2^{(1)} \rangle = q - q^2 - 4 \equiv \mu - 4, \quad 0 < \mu < \tfrac{1}{4}. \tag{2.21}$$

(iii) The UIR's $\Pi^{\pm}_{2,2}$ in the discrete series where $q=p=s=2$ correspond to

$$\langle Q_2^{(1)} \rangle = -6. \tag{2.22}$$

The spin-2 "massless" field in de Sitter space corresponds to the latter case in which the sign $\pm$ in $\Pi^{\pm}_{2,2}$ stands for the helicity. A forthcoming paper will be entirely devoted to this specific field.

Equation (2.17) leads to $H^2(\langle Q_2^{(1)} \rangle + 6) = m_H^2$ which enables us to write the respective "mass" relations for the three types of UIR previously described:

$$m_H^2 = \begin{cases} m_p^2 = H^2(\nu^2 + \frac{9}{4}), & \nu \geqslant 0 \quad \text{(for the principal series)}, \\ m_c^2 = H^2(\mu + 2), & 0 < \mu < \frac{1}{4} \quad \text{(for the complementary series)}, \\ m_d^2 = 0 \quad \text{(for the discrete series)}. \end{cases} \tag{2.23}$$

The spin-2 "mass" range is represented in Fig. 1. The forbidden mass range phenomenon has been discussed by Higuchi in Ref. 21 and largely developed by S. Deser and A. Waldron in Refs. 25–27. It has in particular been shown that for (A)dS space times and for fields with $s>1$, the plane (m_H^2, Λ) is divided in different phases which correspond to unitary or nonunitary regions. These regions are separated "by lines of novel partially massless gauge theories" which correspond to specific representations of the involved group. In the case of the dS group and the spin-2 field, theses lines are given by the values $m_H^2 = 2\Lambda/3 = 2H^2$ and $m_H^2 = 0$. They belong to the discrete series of unitary irreducible representations with the values $p=2$ with $q=1$ $(m_H^2 = 2H^2)$ or $q=2$ $(m_H^2 = 0)$. They are represented by the symbol $\square$ in Fig. 1. Both cases are characterized by a certain gauge invariance which allows us to reduce the degrees of freedom of the corresponding fields. One gets two helicities in the case $m_H^2 = 0$ and four degrees of freedom for the field with $m_H^2 = 2H^2$.

As it is explained above, the case $m_H^2 = 0$ with $p=q=2$ corresponding to the spin-2 linearized gravity admits a Minkowskian interpretation in the flat limit. On the other hand, we do not consider the values of m_H in the range of the complementary series and the discrete series case $m_H^2 = 2H^2$ as acceptable values of a "mass." This is because neither the complementary series with $p=2$ nor the discrete series with $p \neq q$ are linked to any physical representation in the Poincaré flat limit sense. The crucial points are for the complementary series that m_c^2 (unlike m_p^2!) is confined between the values 0 and $\frac{1}{4}$ and therefore simply vanishes in the limit $H=0$ and for the discrete series that in the case $p \neq q$ p and q lose their spin meaning. On the contrary, for the principal series, the contraction limit has to be understood through the constraint $m = H\nu$. The quantity m_H, supposed to depend on H, goes to the Minkowskian mass m when the curvature goes to zero. In short, we only consider as "massive" tensor fields those ones for which the values assumed by the parameter m_H are in the range m_p which corresponds to the principal series of representations. Equation (2.17) then gives

$$(\Box_H + 2H^2 + m_p^2)\mathcal{K}_{\alpha\beta}(x) = 0. \tag{2.24}$$

In order to be more precise, let us recall at this point the physical content of the principal series representation from the point of view of a Minkowskian observer (at the limit $H=0$). The principal series UIR $U^{2,\nu}$, $\nu \geqslant 0$, contracts toward the tensor massive Poincaré UIR's $P^<(m,2)$ and $P^>(m,2)$ with negative and positive energies, respectively. Actually, the group representation contraction procedure is not unique and it has been shown that the principal series UIR can contract either toward the direct sum of the two tensor massive Poincaré UIRs,[42]

$$U^{2,\nu} \frac{H\to 0, \nu\to\infty}{H\nu = m} \to P^<(m,2) \oplus P^>(m,2), \tag{2.25}$$

or simply[43]

$$U^{2,\nu} \frac{H\to 0, \nu\to\infty}{H\nu = m} \to P^>(m,2) \quad \text{or} \quad U^{2,-\nu} \frac{H\to 0, \nu\to\infty}{H\nu = m} \to P^<(m,2). \tag{2.26}$$

In contrast, in the massless spin-2 case, only the two aforementioned representations $\Pi^{\pm}_{2,2}$, in the discrete series with $p=q=2$, have a Minkowskian interpretation. The representation $\Pi^{+}_{2,2}$ has a unique extension to a direct sum of two UIRs $C(3;2,0)$ and $C(-3;2,0)$ of the conformal group $SO_0(2,4)$ with positive and negative energies, respectively.[39,44] The latter restricts to the tensor massless Poincaré UIRs $P^>(0,2)$ and $P^<(0,2)$ with positive and negative energies, respectively. The following diagrams illustrate these connections:

$$\begin{array}{ccccccc} & & \mathcal{C}(3,2,0) & & \mathcal{C}(3,2,0) & \hookleftarrow & \mathcal{P}^>(0,2) \\ \Pi^{+}_{2,2} & \hookrightarrow & \oplus & \overset{H=0}{\to} & \oplus & & \oplus \\ & & \mathcal{C}(-3,2,0) & & \mathcal{C}(-3,2,0) & \hookleftarrow & \mathcal{P}^<(0,2), \end{array} \tag{2.27}$$

$$\begin{array}{ccccccc} & & \mathcal{C}(3,0,2) & & \mathcal{C}(3,0,2) & \hookleftarrow & \mathcal{P}^>(0,-2) \\ \Pi^{-}_{2,2} & \hookrightarrow & \oplus & \overset{H=0}{\to} & \oplus & & \oplus \\ & & \mathcal{C}(-3,0,2) & & \mathcal{C}(-3,0,2) & \hookleftarrow & \mathcal{P}^<(0,-2), \end{array} \tag{2.28}$$

where the arrows $\hookrightarrow$ designate unique extension, and $\mathcal{P}^{\gtrless}(0,2)$ [resp. $\mathcal{P}^{\gtrless}(0,-2)$] are the massless Poincaré UIRs with positive and negative energies and positive (resp. negative) helicity.

III. de SITTER TENSOR WAVES

A. Field equation solution

Our aim is now to solve the "massive" spin-2 wave equation for the dS mode $\mathsf{K}(x)$

$$(Q_2^{(1)} - \langle Q_2^{(1)} \rangle)\mathsf{K}(x) = 0 \quad \text{with} \quad \langle Q_2^{(1)} \rangle = \nu^2 - \tfrac{15}{4}. \tag{3.1}$$

In ambient space notations, the most general transverse, symmetric field $\mathsf{K}_{\alpha\beta}(x)$ can be written in terms of two vector fields K, K_g and a scalar field ϕ through the following recurrence formula:[37]

$$\mathsf{K} = \theta\phi + \mathcal{S}\overline{Z}_1 K + D_2 K_g, \tag{3.2}$$

with K satisfying the conditions (2.6). The symbol Z_1 denotes a constant vector and $\overline{Z}_{1\alpha} = \theta_{\alpha\beta} Z_1^{\beta}$, $x \cdot \overline{Z}_1 = 0$. The operator D_2 is the generalized gradient $D_2 K = H^{-2}\mathcal{S}(\overline{\partial} - H^2 x)K$ which makes a symmetric transverse tensor field from the transverse vector K. The algebraic machinery

valid for describing fields in anti-de Sitter space can be easily transferred *mutatis mutendis* to dS space formalism by the substitutions (see, for instance, Refs. 35, 37, and 45):

$$Q_s^{AdS} \to -Q_s^{dS}, \qquad (H^2)^{AdS} \to -(H^2)^{dS}.$$

Reference 45 provides the following useful relations:

$$\begin{gathered} Q_2\theta\phi = \theta Q_0\phi, \quad Q_2 D_2 K_g = D_2 Q_1 K_g, \\ Q_2 \mathcal{S}\overline{Z}_1 K = \mathcal{S}\overline{Z}_1 (Q_1 - 4)K - 2H^2 D_2 (x\cdot Z_1)K + 4\theta(Z_1\cdot K). \end{gathered} \tag{3.3}$$

Defining the generalized divergence $\partial_2\cdot \mathsf{K} = \partial\cdot\mathsf{K} - H^2 x\mathsf{K}' - \frac{1}{2}\overline{\partial}\mathsf{K}'$ and $D_1 = H^{-2}\overline{\partial}$, one also has

$$\begin{gathered} \partial_2\cdot\theta\phi = -H^2 D_1\phi, \quad \partial_2\cdot D_2 K_g = -(Q_1+6)K_g, \\ \partial_2\cdot\mathcal{S}\overline{Z}_1 K = \overline{Z}_1\partial\cdot K - H^2 D_1(Z_1\cdot K) - H^2 x(Z_1\cdot K) + Z_1\cdot\overline{\partial}K + 5H^2(Z_1\cdot x)K. \end{gathered} \tag{3.4}$$

Putting $\mathsf{K}_{\alpha\beta}(x)$ given by (3.2) into (3.1) and from the linear independence of the terms in (3.2) one gets

$$(Q_1 - \langle Q_1^{(1)}\rangle)K = 0 \quad \text{with} \quad \langle Q_1^{(1)}\rangle = \langle Q_2^{(1)}\rangle + 4\ , \tag{3.5}$$

$$(Q_0 - \langle Q_2^{(1)}\rangle)\phi = -4(Z_1\cdot K)\ , \tag{3.6}$$

$$(Q_1 - \langle Q_2^{(1)}\rangle)K_g = 2H^2(x\cdot Z_1)K\ . \tag{3.7}$$

Note that in these formulas, $\langle Q_s^{(1)}\rangle$ corresponds to the principal series of representation with spin s and that K is chosen to be divergenceless. Using the equations (3.4), the divergenceless condition combined with Eq. (3.7) leads to

$$K_g = \frac{1}{\langle Q_0^{(1)}\rangle}[-H^2 D_1(\phi + Z_1\cdot K) + Z_1\cdot\overline{\partial}K - H^2 x Z_1\cdot K + 3H^2 x\cdot Z_1 K], \tag{3.8}$$

where $\langle Q_0^{(1)}\rangle = \langle Q_2^{(1)}\rangle + 6$. Finally, the traceless condition which yields

$$\overline{\partial}\cdot K_g = -2H^2\phi - H^2 Z_1\cdot K, \tag{3.9}$$

compared to the divergence of Eq. (3.8) allows us to express ϕ in terms of K:

$$\phi = -\tfrac{2}{3}(Z_1\cdot K). \tag{3.10}$$

Thus, the fields K and ϕ are respectively "massive" vector field (e.g., transforming under the vector UIR $U^{1,\nu}$ of the principal series)[1] and "massive" scalar field (e.g., transforming under the scalar UIR $U^{0,\nu}$ of the principal series):[18]

$$(Q_1 - \langle Q_1^{(1)}\rangle)K = 0 \quad \text{and} \quad (Q_0 - \langle Q_0^{(1)}\rangle)\phi = 0. \tag{3.11}$$

Note that the equations for K and ϕ are compatible with the relation $\phi = -\frac{2}{3}Z_1\cdot K$. The equations (3.8) and (3.10) show that the massive vector K determines completely the tensor field K which can now be written

$$\mathsf{K}(x) = \left(-\frac{2}{3}\theta Z_1\cdot + \mathcal{S}\overline{Z}_1 + \frac{1}{\langle Q_0^{(1)}\rangle} D_2\left[Z_1\cdot\overline{\partial} - H^2 x Z_1\cdot + 3H^2 x\cdot Z_1 - \frac{1}{3}H^2 D_1 Z_1\cdot \right]\right) K. \tag{3.12}$$

As explained in Ref. 1 the solutions to Eq. (3.5) are defined on connected open subsets of X_H such that $x\cdot\xi\neq 0$, where $\xi\in\mathbb{R}^5$ lies on the null cone $\mathcal{C}=\{\xi\in\mathbb{R}^5;\quad \xi^2=0\}$. They are homogeneous with degree $-\frac{3}{2}\mp i\nu$ on $\mathcal{C}$ and thus are entirely determined by specifying their values on a well chosen curve (the orbital basis) γ of $\mathcal{C}$. They can be written[1] as a product of a generalized polarization vector $\mathcal{E}_\alpha(x,\xi,Z_2)$ with the so-called[46] (scalar) dS waves $(Hx\cdot\xi)^\sigma$ where $\sigma=-\frac{3}{2}-i\nu\in\mathbb{C}$. The dS wave equations solutions, as functions on de Sitter space, are only locally defined since they are singular on specific lower dimensional subsets of X_H and multivalued on dS space–time. The physical relevance of such waves can be questioned of course, because of their singular behavior and multivaluedness; however their mathematical existence and properties are rigorously justified within the framework of distribution theory.[46,47] Moreover physical de Sitter entities like square integrable states can be built as superpositions of such waves exactly like wave packets are built by superposition of non-square-integrable plane waves in Minkowskian or Galilean quantum mechanics.

The solutions to Eq. (3.5) read

$$K_\alpha(x)=\left(\frac{\sigma}{\sigma+1}\right)\mathcal{E}_\alpha(x,\xi,Z_2)(Hx\cdot\xi)^\sigma,\quad \text{with}\quad \sigma=-\frac{3}{2}-i\nu, \tag{3.13}$$

where Z_2 is another constant vector. Note that contrary to the Minkowskian case, the polarization tensor is a function of space–time. The simplest form of $\mathcal{E}_\alpha(x,\xi,Z_2)$ compatible with the Minkowski polarization vector in the flat limit (see Ref. 1) is obtained through the choice $\xi\cdot Z_2=0$ and reads

$$\mathcal{E}(x,\xi,Z_2)=\left(\overline{Z_2^\lambda}-\frac{Z_2^\lambda\cdot x}{x\cdot\xi}\overline{\xi}\right)\quad \text{with}\quad \mathcal{E}^\lambda(x,\xi,Z_2)\cdot\overline{\xi}=Z_2^\lambda\cdot\xi=0\,. \tag{3.14}$$

It is easy to see (flat limit) that the three Minkowski polarization four-vectors ϵ_μ^λ with $\mu=0,1,2,3$ are linked to Z_2^λ by

$$\lim_{H\to 0}\mathcal{E}_\alpha^\lambda(x,\xi,Z_2)=Z_{2\mu}^\lambda-\frac{Z_{24}^\lambda}{\xi_4}\xi_\mu\equiv\epsilon_\mu^\lambda\,. \tag{3.15}$$

We demand that the Minkowski polarization vectors satisfy the usual relations

$$\epsilon^\lambda\cdot k=0,\quad \epsilon^\lambda\cdot\epsilon^{\lambda'}=\eta^{\lambda\lambda'},\quad \sum_{\lambda=1}^{3}\epsilon_\mu^\lambda(k)\,\epsilon_\nu^\lambda(k)=-\left(\eta_{\mu\nu}-\frac{k_\mu k_\nu}{m^2}\right)\equiv\Pi_{\mu\nu}(k), \tag{3.16}$$

which is achieved if the Z_2^λ's are such that

$$Z_2^\lambda\cdot\xi=0,\quad Z_2^\lambda\cdot Z_2^{\lambda'}=\eta^{\lambda\lambda'},\quad \sum_{\lambda=1}^{3}Z_{2\alpha}^\lambda Z_{2\beta}^\lambda=-\eta_{\alpha\beta}\quad\text{and}\quad \sum_{\lambda=1}^{3}Z_{24}^\lambda Z_{2\mu}^\lambda=0\ \ \forall\ \ \mu\,. \tag{3.17}$$

These conditions are easily derived by working with a well adapted (to the flat limit) orbital basis. This basis, characterized by the values ± 1 of the component ξ_4, will be discussed later on. A remarkable feature connected with the use of ambient space notations is that with Eq. (3.17) one shows that the properties of the dS polarization vector are very similar to the Minkowskian case:

$$\begin{aligned}&\sum_{\lambda=1}^{3}\mathcal{E}_\alpha^\lambda(x,\xi,Z_2)\,\mathcal{E}_\beta^\lambda(x,\xi,Z_2)=-\left(\theta_{\alpha\beta}-\frac{\overline{\xi}_\alpha\overline{\xi}_\beta}{(Hx\cdot\xi)^2}\right)\equiv\Pi_{\alpha\beta}(x,\xi)\,,\\ &\mathcal{E}^\lambda(x,\xi,Z_2)\cdot\mathcal{E}^{\lambda'}(x,\xi,Z_2)=Z_2^\lambda\cdot\mathcal{E}^{\lambda'}(x,\xi,Z_2)=\mathcal{E}^\lambda(x,\xi,Z_2)\cdot\mathcal{E}^{\lambda'}(x',\xi,Z_2)=\eta^{\lambda\lambda'}\,.\end{aligned} \tag{3.18}$$

The last equality involves different space–time points x,x' and will be useful on the level of the two-point function. It follows from Eq. (3.12) that the two spin-2 families of solutions to Eq. (3.1) read

$$\mathsf{K}(x)=\theta\phi+\mathcal{S}\overline{Z_1}K+D_2K_g\equiv\mathcal{D}(x,\partial,Z_1,Z_2)(Hx\cdot\xi)^{-(3/2)\mp i\nu},$$

where the operator $\mathcal{D}(x,\partial,Z_1,Z_2)$ is given by

$$\left(\frac{\sigma}{\sigma+1}\right)\left(-\frac{2}{3}\theta Z_1\cdot+\mathcal{S}\overline{Z_1}+\frac{1}{\langle Q_0^{(1)}\rangle}D_2\left[Z_1\cdot\overline{\partial}-H^2xZ_1\cdot+3H^2x\cdot Z_1-\frac{1}{3}H^2D_1Z_1\cdot\right]\right)\mathcal{E}(x,\xi,Z_2). \tag{3.19}$$

These spin-2 solutions can be brought into the form

$$\mathsf{K}_{\alpha\beta}(x)=a_\nu\mathcal{E}_{\alpha\beta}(x,\xi,Z_1,Z_2)(Hx\cdot\xi)^\sigma \quad\text{and}\quad \mathsf{K}^*_{\alpha\beta}(x) \quad\text{with}\quad a_\nu=c_\nu\left(\frac{2(\sigma-1)}{\sigma+1}\right), \tag{3.20}$$

where the $\mathcal{E}_{\alpha\beta}$'s are the generalized polarization tensor components, c_ν is a normalization constant and where we have again omitted the superscript λ. Because of the conditions $\mathsf{K}_{\alpha\beta}=\mathsf{K}_{\beta\alpha}$, $\partial\cdot\mathsf{K}=0$, and $x\cdot\mathsf{K}=0$, the 25 components $\mathcal{E}_{\alpha\beta}$ reduce to 5 independent components which correspond precisely to the $2s+1=5$ degrees of freedom of a spin-2 field.

The arbitrariness due to the introduction of the constant vectors Z_1,Z_2 in our solution has partly been removed in (3.17) by comparison with the Minkowski polarization vector one eventually reaches by going to the flat limit [see (3.15)]. We now apply the same procedure in order to fix the value of Z_1, that is we investigate the behavior of Eq. (3.19) in the $H=0$ limit. More precisely, we show that $\mathcal{E}_{\alpha\beta}(x,\xi,Z_1,Z_2)$ contracts toward the usual Minkowski tensor polarization and takes a simple form if Z_1 is chosen to be equal to Z_2 and denoted by Z in the following. It is a matter of simple calculation to get the de Sitter polarization tensor starting with formula (3.19):

$$\mathcal{E}_{\alpha\beta}(x,\xi,Z)\equiv\mathcal{E}^{\lambda\lambda'}_{\alpha\beta}(x,\xi)=\frac{1}{2}\left[\mathcal{S}\mathcal{E}^\lambda_\alpha(x,\xi)\mathcal{E}^{\lambda'}_\beta(x,\xi)-\frac{2}{3}\left(\theta_{\alpha\beta}-\frac{\overline{\xi}_\alpha\overline{\xi}_\beta}{(Hx\cdot\xi)^2}\right)\mathcal{E}^\lambda(x,\xi)\cdot\mathcal{E}^{\lambda'}(x,\xi)\right], \tag{3.21}$$

where $\mathcal{E}^\lambda(x,\xi)=\mathcal{E}^\lambda(x,\xi,Z_2)$. In view of (3.18) one obtains

$$\mathcal{E}^{\lambda\lambda'}_{\alpha\beta}(x,\xi)=\frac{1}{2}\left[\mathcal{S}\mathcal{E}^\lambda_\alpha(x,\xi)\mathcal{E}^{\lambda'}_\beta(x,\xi)+\frac{2}{3}\eta^{\lambda\lambda'}\sum_\rho\mathcal{E}^\rho_\alpha(x,\xi)\mathcal{E}^\rho_\beta(x,\xi)\right]. \tag{3.22}$$

It is easy to check that the tensor polarization (3.22) satisfies the properties $\eta^{\alpha\beta}\mathcal{E}_{\alpha\beta}(x,\xi,Z)=0$ (tracelessness), $\overline{\xi}\cdot\mathcal{E}_{\alpha\beta}(x,\xi,Z)=0$ and the relation

$$\mathcal{E}^{\lambda\lambda'}(x,\xi)\cdot\cdot\,\mathcal{E}^{\lambda''\lambda'''}(x,\xi)=\mathcal{E}^{\lambda\lambda'}(x',\xi)\cdot\cdot\,\mathcal{E}^{\lambda''\lambda'''}(x,\xi)=[\eta^{\lambda\lambda''}\eta^{\lambda'\lambda'''}+\eta^{\lambda\lambda'}\eta^{\lambda''\lambda'''}]. \tag{3.23}$$

The dS tensor waves $\mathsf{K}_{\alpha\beta}(x)$ are homogeneous with degree σ on the null cone $\mathcal{C}$ and on the dS submanifold X_H characterized by $x\cdot x=-H^{-2}$ with H being constant. This is due to

$$\mathcal{E}^\lambda(x,a\xi)=\mathcal{E}^\lambda(x,\xi) \quad\text{and}\quad \mathcal{E}^\lambda(ax,\xi)=\mathcal{E}^\lambda(x,\xi),$$

which is obvious from the definition of $\mathcal{E}^\lambda(x,\xi)$

$$\mathcal{E}^\lambda(x,\xi)=\left(\overline{Z^\lambda}-\frac{Z^\lambda\cdot x}{\xi\cdot x}\overline{\xi}\right)=\left(Z^\lambda-\frac{Z^\lambda\cdot x}{\xi\cdot x}\xi\right). \tag{3.24}$$

Note that as a function of $\mathbb{R}^5$, the wave $\mathsf{K}_{\alpha\beta}(x)$ is homogeneous with degree zero $[H(x)=-1/\sqrt{-x\cdot x}]$.

B. Flat limit and analytic tensor wave

It order to compute the flat limit of the polarization tensor, it is useful to precise the notion of orbital basis γ for the future null cone $\mathcal{C}^+=\{\xi\in\mathcal{C};\ \ \xi^0>0\}$.[46] Let us choose a unit vector e in $\mathbb{R}^5$ and let H_e be its stabilizer subgroup in $SO_0(1,4)$. Then two types of orbits are interesting in the present context.

(i) The spherical type γ_0 corresponds to $e\in V^+\equiv\{x\in\mathbb{R}^5;\quad x^0>\sqrt{\|\vec{x}\|^2+(x^4)^2}\}$, and is an orbit of $H_e\approx \mathrm{SO}(4)$,

$$\gamma_0=\{\xi;e\cdot\xi=a>0\}\cap\mathcal{C}^+\quad .$$

(ii) The hyperbolic type γ_4 corresponds to $e^2=-1$. It is divided into two hyperboloid sheets, both being orbits of $H_e\approx \mathrm{SO}_0(1,3)$.

The most suitable parametrization when one has in view the link with massive Poincaré UIRs is to work with the orbital basis of the second type,

$$\gamma_4=\{\xi\in C^+,\xi^{(4)}=1\}\cup\{\xi\in C^+,\xi^{(4)}=-1\},$$

with the null vector ξ given in terms of the four-momentum $(k^0,\vec{k})$ of a Minkowskian particle of mass m:

$$\xi_\pm=\left(\frac{k^0}{mc}=\sqrt{\frac{\vec{k}^2}{m^2c^2}+1},\frac{\vec{k}}{mc},\pm 1\right). \tag{3.25}$$

An appropriate choice of global coordinates is given by

$$\begin{aligned} x^0&=H^{-1}\sinh(HX^0)\,,\\ \vec{x}&=(H\|\vec{X}\|)^{-1}\vec{X}\cosh(HX^0)\sin(H\|\vec{X}\|)\,,\\ x^4&=H^{-1}\cosh(HX^0)\cos(H\|\vec{X}\|)\,, \end{aligned} \tag{3.26}$$

where the dS point is expressed in terms of the Minkowskian variables $X=(X_0=ct,\vec{X})$ measured in units of the dS radius H^{-1}.

The Minkowskian limit of the dS waves at point x can be written as[18]

$$\begin{aligned} &\lim_{H\to 0}(Hx\cdot\xi_-)^\sigma=\exp[-ik\cdot X]\quad\ \ (\text{positive energy}),\\ &\lim_{H\to 0}e^{-i\pi\sigma}(Hx\cdot\xi_+)^\sigma=\exp[ik\cdot X]\quad\ \ (\text{negative energy}). \end{aligned} \tag{3.27}$$

Since the contraction is done with respect to the Lorentz subgroup $\mathrm{SO}_0(1,3)$ [γ_4 is invariant under $\mathrm{SO}_0(1,3)$] the equations (3.27) indicate that with the orbital basis γ_4, dS waves can contract toward the sum of two solutions with opposite energies (see Ref. 43).

The polarization tensor limit is easily obtained with the help of

$$\lim_{H\to 0}H^2\sigma^2=-m^2,\quad \lim_{H\to 0}\mathcal{E}^\lambda_\alpha(x,\xi)=\epsilon^\lambda_\mu(k)\,,\quad \lim_{H\to 0}\theta_{\alpha\beta}=\eta_{\mu\nu}\,,\quad \lim_{H\to 0}\overline{\xi}_\alpha=\frac{k_\mu}{m}\forall\,\xi\in\gamma_4.$$

Finally, one recovers the Minkowskian massive spin-2 polarization tensor:[48]

$$\lim_{H\to 0}\mathcal{E}^{\lambda\lambda'}_{\alpha\beta}(x,\xi)=\epsilon^{\lambda\lambda'}_{\mu\nu}(k)=\frac{1}{2}\mathcal{S}\epsilon^\lambda_\mu(k)\epsilon^{\lambda'}_\nu(k)+\frac{1}{3}\eta^{\lambda\lambda'}\sum_\lambda\ \epsilon^\lambda_\mu(k)\epsilon^\lambda_\nu(k)\,,$$

which satisfies $\eta^{\mu\nu}\epsilon_{\mu\nu}^{\lambda\lambda'}(k)=k^{\mu}\epsilon_{\mu\nu}^{\lambda\lambda'}(k)=0$ and

$$\sum_{\lambda\lambda'}\epsilon_{\mu\nu}^{\lambda\lambda'}(k)\epsilon_{\rho\pi}^{\lambda\lambda'}(k)=\frac{1}{2}[\Pi_{\mu\rho}(k)\Pi_{\nu\pi}(k)+\Pi_{\nu\rho}(k)\Pi_{\mu\pi}(k)]-\frac{1}{3}[\Pi_{\mu\nu}(k)\Pi_{\rho\pi}(k)]. \quad (3.28)$$

Hence, we have shown that in the limit $H=0$, $(Hx\cdot\xi)^{\sigma}$ and $\mathcal{E}_{\alpha\beta}(x,\xi,Z)$ behave like the plane wave $e^{ik\cdot X}$ and the polarization tensor in Minkowski space–time, respectively.

Although the "massive" field equation solutions $\mathsf{K}_{\alpha\beta}(x)$ and $\mathsf{K}^{*}_{\alpha\beta}(x)$ are complex conjugated, they cannot be associated with the positive and negative energies respectively as in the Minkowskian situation. Actually, despite the fact that the solutions are globally defined (in a distributional sense) in dS space, the concept of energy is not (absence of global timelike killing vector field). As a result, concepts like "particle" and "antiparticle" are rather unclear and the differences between these two solutions is not really explained or understood. In terms of group representation these two solutions are equivalent, because the two representations $U^{2,\nu}$ and $U^{2,-\nu}$ are. Note that the minimally coupled scalar field requires both sets of solutions in order to achieve a covariant quantization.[12] This will certainly also be the case for the spin-2 massless field in dS space since it is constructed from a minimally coupled scalar field as it will be shown in Ref. 10.

In the present case, the "massive" free field covariant quantization can be constructed from the positive norm states alone since $\mathsf{K}_{\alpha\beta}(x)$ transforms under the group action in a closed way:

$$\begin{aligned}(U(g)\,\mathsf{K})_{\alpha\beta}(x)&=g_{\alpha}^{\gamma}g_{\beta}^{\delta}\mathsf{K}_{\gamma\delta}(g^{-1}x)\\&=g_{\alpha}^{\gamma}g_{\beta}^{\delta}\,a_{\nu}\mathcal{E}_{\gamma\delta}(g^{-1}x,\xi,Z)(Hg^{-1}x\cdot\xi)^{\sigma}\\&=a_{\nu}\mathcal{E}_{\alpha\beta}(x,g\xi,gZ)(Hx\cdot g\xi)^{\sigma}.\end{aligned} \quad (3.29)$$

This is easily proved since the vector polarization satisfies

$$\mathcal{E}_{\alpha}(g^{-1}x,\xi,Z)=\left(Z_{\alpha}-\frac{g^{-1}x\cdot Z}{g^{-1}x\cdot\xi}\xi_{\alpha}\right)=\left(Z_{\alpha}-\frac{x\cdot gZ}{x\cdot g\xi}\xi_{\alpha}\right)=(g^{-1})_{\alpha}^{\delta}\mathcal{E}_{\delta}(x,g\xi,gZ). \quad (3.30)$$

We have mentioned that the dS waves solutions, as functions on de Sitter space, are only locally defined since they are singular on specific lower dimensional subsets of X_H and multivalued on dS space–time. In order to get a global definition, they have to be viewed as distributions[47] which are boundary values of analytic continuations of the solutions to tubular domains in the complexified de Sitter space $X_H^{(c)}$. The latter is defined as follows:

$$\begin{aligned}X_H^{(c)}&=\{z=x+iy\in\mathbb{C}^5;\ \ \eta_{\alpha\beta}z^{\alpha}z^{\beta}=(z^0)^2-\vec{z}\cdot\vec{z}-(z^4)^2=-H^{-2}\}\\&=\{(x,y)\in\mathbb{R}^5\times\mathbb{R}^5;\ \ x^2-y^2=-H^{-2},\ \ x\cdot y=0\}.\end{aligned}$$

For an univalued determination, we must introduce the forward and backward tubes of $X_H^{(c)}$. First of all, let $T^{\pm}=\mathbb{R}^5-iV^{\pm}$ be the forward and backward tubes in $\mathbb{C}^5$. The domain V^{+} (resp. V^{-}) stems from the causal structure on X_H:

$$V^{\pm}=\{x\in\mathbb{R}^5;\quad x^0\gtrless\sqrt{\|\vec{x}\|^2+(x^4)^2}\}. \quad (3.31)$$

We then introduce their respective intersections with $X_H^{(c)}$,

$$\mathcal{T}^{\pm}=T^{\pm}\cap X_H^{(c)}, \quad (3.32)$$

which are the tubes of $X_H^{(c)}$. Finally, we define the "tuboid" above $X_H^{(c)}\times X_H^{(c)}$ by

$$\mathcal{T}_{12}=\{(z,z');\quad z\in\mathcal{T}^{+},z'\in\mathcal{T}^{-}\}. \quad (3.33)$$

Details are given in Ref. 46. When z varies in $\mathcal{T}^+$ (or $\mathcal{T}^-$) and ξ lies in the positive cone $\mathcal{C}^+$ the wave solutions are globally defined because the imaginary part of $(z\cdot\xi)$ has a fixed sign and $z\cdot\xi\neq 0$.

We define the de Sitter tensor wave $\mathsf{K}_{\alpha\beta}(x)$ as the boundary value of the analytic continuation to the future tube of Eq. (3.20). Hence, for $z\in\mathcal{T}^+$ and $\xi\in\mathcal{C}^+$ one gets the two solutions

$$\mathsf{K}_{\alpha\beta}(z)=a_\nu\,\mathcal{E}^{\lambda\lambda'}_{\alpha\beta}(z,\xi)(Hz\cdot\xi)^\sigma \quad \text{and} \quad \mathsf{K}^*_{\alpha\beta}(z^*)=a^*_\nu\,\mathcal{E}^{*\lambda\lambda'}_{\alpha\beta}(z^*,\xi)(Hz\cdot\xi)^{\sigma^*}. \tag{3.34}$$

IV. TWO-POINT FUNCTION AND QUANTUM FIELD

A. The two-point function

As explained in Ref. 46, the dS axiomatic field theory is based on the Wightman two-point double tensor-valued function

$$\mathcal{W}_{\alpha\beta\alpha'\beta'}(x,x') \quad \alpha',\beta'=0,1,...,4. \tag{4.1}$$

Indeed, this kernel entirely encodes the theory of the generalized free fields on dS space–time X_H, at least for the massive case. For this, it has to satisfy the following requirements:

(a) **Positiveness:** For any test function $f_{\alpha\beta}\in\mathcal{D}(X_H)$, we have

$$\int_{X_H\times X_H} f^{*\alpha\beta}(x)\mathcal{W}_{\alpha\beta\alpha'\beta'}(x,x')f^{\alpha'\beta'}(x')d\sigma(x)d\sigma(x')\geqslant 0, \tag{4.2}$$

where $d\sigma(x)$ denotes the dS-invariant measure on X_H.[46] $\mathcal{D}(X_H)$ is the space of functions C^∞ with compact support in X_H.

(b) **Locality:** For every spacelike separated pair (x,x'), i.e., $x\cdot x'>-H^{-2}$,

$$\mathcal{W}_{\alpha\beta\alpha'\beta'}(x,x')=\mathcal{W}_{\alpha'\beta'\alpha\beta}(x',x). \tag{4.3}$$

(c) **Covariance:**

$$(g^{-1})^\gamma_\alpha(g^{-1})^\delta_\beta\mathcal{W}_{\gamma\delta\gamma'\delta'}(gx,gx')g^{\gamma'}_{\alpha'}g^{\delta'}_{\beta'}=\mathcal{W}_{\alpha\beta\alpha'\beta'}(x,x'), \tag{4.4}$$

for all $g\in \mathrm{SO}_0(1,4)$.

(d) **Index symmetrizer:**

$$\mathcal{W}_{\alpha\beta\alpha'\beta'}(x,x')=\mathcal{W}_{\alpha\beta\beta'\alpha'}(x,x')=\mathcal{W}_{\beta\alpha\alpha'\beta'}(x,x'). \tag{4.5}$$

(e) **Transversality:**

$$x^\alpha\mathcal{W}_{\alpha\beta\alpha'\beta'}(x,x')=0=x'^{\alpha'}\mathcal{W}_{\alpha\beta\alpha'\beta'}(x,x'). \tag{4.6}$$

(f) **Divergencelessness:**

$$\partial^\alpha_x\mathcal{W}_{\alpha\beta\alpha'\beta'}(x,x')=0=\partial^{\alpha'}_{x'}\mathcal{W}_{\alpha\beta\alpha'\beta'}(x,x'). \tag{4.7}$$

(g) **Normal analyticity:** $\mathcal{W}_{\alpha\beta\alpha'\beta'}(x,x')$ is the boundary value (bv) in the distributional sense of an analytic function $W_{\alpha\beta\alpha'\beta'}(z,z')$.

Concerning the last requirement, $W_{\alpha\beta\alpha'\beta'}(z,z')$ is actually maximally analytic, i.e., can be analytically continued to the ''cut domain''

$$\Delta=\{(z,z')\in X_H^{(c)}\times X_H^{(c)}:(z-z')^2<0\}.$$

The Wightman two-point function $\mathcal{W}_{\alpha\beta\alpha'\beta'}(x,x')$ is the boundary value of $W_{\alpha\beta\alpha'\beta'}(z,z')$ from $\mathcal{T}_{12}$ and the "permuted Wightman function" $\mathcal{W}_{\alpha'\beta'\alpha\beta}(x',x)$ is the boundary value of $W_{\alpha\beta\alpha'\beta'}(z,z')$ from the domain

$$\mathcal{T}_{21}=\{(z,z');\quad z\in\mathcal{T}^-,z'\in\mathcal{T}^+\}.$$

Once these properties are satisfied, the reconstruction theorem[49] allows us to recover the corresponding quantum field theory. Our present task is therefore to find a doubled tensor valued analytic function of the variable (z,z') satisfying the properties (a)–(g). Following Ref. 46 (in which the construction has been done for the scalar case), the analytic two-point function $W_{\alpha\beta\alpha'\beta'}(z,z')\equiv W^{\nu}_{\alpha\beta\alpha'\beta'}(z,z')$ is obtained from the dS tensor waves (3.34). The parameter ν refers to the principal series. The two-point function is given in terms of the following class of integral representations,

$$W^{\nu}_{\alpha\beta\alpha'\beta'}(z,z')=|a_\nu|^2\int_\gamma (Hz\cdot\xi)^\sigma (Hz'\cdot\xi)^{\sigma^*}\sum_{\lambda\lambda'}\mathcal{E}^{\lambda\lambda'}_{\alpha\beta}(z,\xi)\,\mathcal{E}^{*\lambda\lambda'}_{\alpha'\beta'}(z'^*,\xi)\,d\sigma_\gamma(\xi),\quad (4.8)$$

where $d\sigma_\gamma(\xi)$ is the natural $\mathcal{C}^+$ invariant measure on γ, induced from the $\mathbb{R}^5$ Lebesgue measure,[46] and the normalization constant a_ν is fixed by local Hadamard condition. The latter selects a unique vacuum state for quantum tensor fields which satisfies the dS field equation. In order to check whether conditions (a)–(g) are satisfied by Eq. (4.8), let us first rewrite the two-point function in a more explicit way. This will be done by using the scalar and the vector "massive" analytic two-point functions $W^\nu_0(z,z')$, $W^\nu_1(z,z')$ (where $\mathcal{Z}=-H^2z\cdot z'$). The latter satisfy the complex versions of the Casimir equations:

$$(Q_1-\langle Q_1^{(1)}\rangle)W^\nu_1(z,z')=0\ \text{ and }\ (Q_0-\langle Q_0^{(1)}\rangle)W^\nu_0(z,z')=0\,.\quad (4.9)$$

In Appendix C and in Ref. 1 it is shown how $W^\nu_1(z,z')$ can be written in terms of the scalar analytic two-point function:

$$W^\nu_1(z,z')=\frac{\langle Q_0\rangle}{\langle Q_1\rangle}\left(-\theta_\alpha\cdot\theta'_{\alpha'}+\frac{H^2\sigma(\theta\cdot z')D'_1}{\langle Q_0\rangle}+\frac{H^2\sigma^*(\theta'\cdot z)D_1}{\langle Q_0\rangle}+\frac{H^2\mathcal{Z}D_1D'_1}{\langle Q_0\rangle}\right)W^\nu_0(z,z').\quad (4.10)$$

The Wightman scalar two-point function $\mathcal{W}^\nu_0(x,x')$ is given by[46]

$$\mathcal{W}^\nu_0(x,x')=\mathrm{bv}\ \ W_0(z,z')\quad\text{with}\quad W^\nu_0(z,z')=c^2_\nu\int_\gamma (Hz\cdot\xi)^\sigma(Hz'\cdot\xi)^{\sigma^*}\,d\sigma_\gamma(\xi)\,.\quad (4.11)$$

The normalization constant c^2_ν is determined by imposing the Hadamard condition on the two-point function. This has been done in Ref. 46 where the scalar two-point function has been rewritten in terms of the generalized Legendre function for well chosen spacelike separated points z and z'. It has been established that $W_0(z,z')=C_\nu P^{(5)}_\sigma(-\mathcal{Z})$ with $C_\nu=2\pi^2e^{-\pi\nu}c^2_\nu$ and

$$c^2_\nu=\frac{H^2e^{\pi\nu}\Gamma(-\sigma)\Gamma(-\sigma^*)}{2^5\pi^4m^2}.\quad (4.12)$$

This normalization corresponds to the Euclidean vacuum[46] and $P^{(5)}_\sigma(\mathcal{Z})$ is the generalized Legendre function of the first kind. There are several reasons which explain the appearance of $W^\nu_0(z,z')$ and $W^\nu_1(z,z')$. First of all, both correspond to the commonly used two-point functions (see, for instance, Ref. 34) as it is checked in Appendix C. Moreover, since the vector two-point function, is written in terms of the scalar two-point function it exhibits the two building blocks of the tensor expression which are well known and simple to manipulate. As a matter of fact, the flat limit is very easy to compute in this framework.

We have seen that the spin-2 analytic two-point function (4.8) is obtained from the tensor waves (3.34). Let us cast the latter into the more suitable form

$$\mathcal{K}(z)=\frac{a_\nu}{2}\left[\mathcal{S}\mathcal{E}^{\lambda}(z,\xi)\mathcal{E}^{\lambda'}(z,\xi)-\frac{2\sigma g^{\lambda\lambda'}}{3(\sigma-1)}\left(\theta-\frac{H^2D_2D_1}{2\sigma^2}\right)\right](Hz\cdot\xi)^{\sigma} \tag{4.13}$$

by using the property

$$\sum_{\lambda}\mathcal{E}^{\lambda}(z,\xi)\,\mathcal{E}^{\lambda}(z,\xi)(Hz\cdot\xi)^{\sigma}=-\left(\theta-\frac{\overline{\xi\xi}}{(Hz\cdot\xi)^2}\right)(Hz\cdot\xi)^{\sigma}=-\frac{\sigma}{\sigma-1}\left[\theta-\frac{H^2D_2D_1}{2\sigma^2}\right](Hz\cdot\xi)^{\sigma}. \tag{4.14}$$

We then simply develop the two-point function and obtain

$$\begin{aligned}W^{\nu}(z,z')=\frac{|a_\nu|^2}{4}\int_{\gamma}\mathcal{S}\mathcal{S}'&\left(\sum_{\lambda}\mathcal{E}^{\lambda}(z,\xi)\,\mathcal{E}^{*\lambda}(z'^{*},\xi)\right)\left(\sum_{\lambda'}\mathcal{E}^{\lambda'}(z,\xi)\,\mathcal{E}^{*\lambda'}(z'^{*},\xi)\right)\\&\times(Hz\cdot\xi)^{\sigma}(Hz'\cdot\xi)^{\sigma^*}\,d\sigma_{\gamma}(\xi)-\frac{4}{3}\frac{\langle Q_0\rangle}{\langle Q_1\rangle}\left[\theta-\frac{H^2D_2D_1}{2\sigma^2}\right]\left[\theta'-\frac{H^2D_2'D_1'}{2\sigma^{*2}}\right]\\&\times c_\nu^2\int_{\gamma}(Hz\cdot\xi)^{\sigma}(Hz'\cdot\xi)^{\sigma^*}\,d\sigma_{\gamma}(\xi).\end{aligned} \tag{4.15}$$

From the property

$$\sum_{\lambda}\mathcal{E}^{\lambda}(z)\mathcal{E}^{*\lambda}(z'^{*})=\left[-\theta\cdot\theta'+\frac{(\theta\cdot z')\overline{\xi'}}{z'\cdot\xi}+\frac{(\theta'\cdot z)\overline{\xi}}{z\cdot\xi}+\frac{\mathcal{Z}\,\overline{\xi\xi'}}{H^2z\cdot\xi z'\cdot\xi}\right], \tag{4.16}$$

and the relation $H^2D_2K(x)=(\sigma-1)\,\mathcal{S}\overline{\xi}K(x)/(z\cdot\xi)$, it is clear that the analytic two-point function can be written in the general form:

$$W^{\nu}(z,z')=M(z,z')\,W_1^{\nu}(z,z')+N(z,z')\,W_0^{\nu}(z,z'). \tag{4.17}$$

The differential operators $M(z,z')$ and $N(z,z')$ are given by

$$\begin{aligned}M(z,z')&=\frac{\langle Q_0\rangle+4}{\langle Q_0\rangle}\left[-\mathcal{S}\mathcal{S}'\,\theta\cdot\theta'+\frac{H^2\mathcal{S}(\theta\cdot z')D_2'}{\sigma^*-1}+\frac{H^2\mathcal{S}'(\theta'\cdot z)D_2}{\sigma-1}+\frac{\mathcal{Z}H^2D_2D_2'}{(\sigma-1)(\sigma^*-1)}\right],\\N(z,z')&=\frac{4}{3}\frac{\langle Q_0\rangle}{\langle Q_1\rangle}\left[\theta-\frac{H^2D_2D_1}{2\sigma^2}\right]\left[\theta'-\frac{H^2D_2'D_1'}{2\sigma^{*2}}\right].\end{aligned} \tag{4.18}$$

Eventually, the analytic tensor two-point function is given in terms of the scalar analytic two-point function by

$$W^{\nu}_{\alpha\beta\alpha'\beta'}(z,z')=D(z,z')W_0^{\nu}(z,z'),$$

with $D(z,z')$ a differential operator discussed in Appendix D. The boundary value of $W^{\nu}(z,z')$ gives the following integral representation for the Wightman two-point function:

$$\mathcal{W}(x,x')=|a_\nu|^2\sum_{\lambda\lambda'}\int_{\gamma}d\sigma_{\gamma}(\xi)\mathcal{E}^{\lambda\lambda'}(x,\xi)\mathcal{E}^{*\lambda\lambda'}(x',\xi)\,\mathrm{bv}(Hz\cdot\xi)^{\sigma}(Hz'\cdot\xi)^{\sigma^*}, \tag{4.19}$$

with

$$\mathrm{bv}(Hz\cdot\xi)^{\sigma}(Hz'\cdot\xi)^{\sigma^*}=|Hx\cdot\xi|^{\sigma}|Hx'\cdot\xi|^{\sigma^*}[\,\theta(Hx\cdot\xi)+\theta(-Hx\cdot\xi)\,e^{-i\pi\sigma}]$$
$$\times[\,\theta(Hx'\cdot\xi)+\theta(-Hx'\cdot\xi)\,e^{+i\pi\sigma^*}]. \tag{4.20}$$

This relation defines the two-point function in terms of global waves on the real hyperboloid X_H.

Let us now check if this kernel fulfills the conditions (a)–(g) required in order to get a Wightman two-point function. We recall that the existence of the latter which is requested by dS axiomatic field theory.

(i) The positiveness property follows from the relation

$$\int_{X_H\times X_H} f^{*\alpha\beta}(x)\mathcal{W}_{\alpha\beta\alpha'\beta'}(x,x')f^{\alpha'\beta'}(x')d\sigma(x)d\sigma(x')=|a_\nu|^2\int_\gamma d\sigma_\gamma(\xi)\sum_{\lambda\lambda'} g^{*\lambda\lambda'}(\xi)\,g^{\lambda\lambda'}(\xi)\,, \tag{4.21}$$

where

$$g^{\lambda\lambda'}(\xi)=\int_{X_H} d\sigma(x)f^{\alpha\beta}(x)\mathcal{E}^{*\lambda\lambda'}_{\alpha\beta}(x,\xi)[\,\theta(Hx\cdot\xi)+\theta(-Hx\cdot\xi)\,e^{+i\pi\sigma^*}]|Hx\cdot\xi|^{\sigma^*}\,. \tag{4.22}$$

The hermiticity property is obtained by considering boundary values of the following identity,

$$W_{\alpha\beta\alpha'\beta'}(z,z')=W^*_{\alpha'\beta'\alpha\beta}(z'^*,z^*), \tag{4.23}$$

which is easily checked on Eq. (4.8).

(ii) In order to prove the locality condition, we use the hermiticity condition and the following relation:

$$W^*_{\alpha'\beta'\alpha\beta}(z'^*,z^*)=W_{\alpha'\beta'\alpha\beta}(z',z).$$

This easily follows from the form of the two-point function for spacelike separated points given in Appendix D:

$$W^{\nu}(z,z')=C_\nu D(z,z')P^{(5)}_{\sigma}(-\mathcal{Z}) \quad \text{with} \quad D^*(z^*,z'^*)=D(z,z'),$$

and from the relation[50]

$$P^{(5)}_{\sigma}(-\mathcal{Z})=P^{(5)}_{\sigma^*}(-\mathcal{Z}).$$

One finally gets

$$W_{\alpha\beta\alpha'\beta'}(z,z')=W^*_{\alpha'\beta'\alpha\beta}(z'^*,z^*)=W_{\alpha'\beta'\alpha\beta}(z',z).$$

It should be noticed that the spacelike separated pair (x,x') lies in the same orbit of the complex dS group as the pairs (z,z') and (z'^*,z^*). Therefore the locality condition $\mathcal{W}_{\alpha\beta\alpha'\beta'}(x,x')=\mathcal{W}_{\alpha'\beta'\alpha\beta}(x',x)$ holds.

(iii) The group action on the dS modes (3.29) and the independence of the integral (4.8) with respect to the selected orbital basis entail the covariance property

$$(g^{-1})^{\gamma}_{\alpha}(g^{-1})^{\delta}_{\beta}\mathcal{W}_{\gamma\delta\gamma'\delta'}(gx,gx')g^{\gamma'}_{\alpha'}g^{\delta'}_{\beta'}=\mathcal{W}_{\alpha\beta\alpha'\beta'}(x,x'). \tag{4.24}$$

(iv) The symmetry with respect to the indices α, β and α', β' and the transversality with respect to x and x' are guaranteed by construction. So is the divergencelessness condition.

(v) The analyticity properties of the tensor Wightman two-point function follow from the expression of the dS tensor waves (3.34).

Remark: A massive spin-2 two-point function had already been proposed in Ref. 20. Although the approach we have used here is very different (in Ref. 20 the coordinates are nonglobal, the modes have a spin-0 and spin-2 content,...), it has been possible to check that our vector two-point function is in agreement with the one presented in Ref. 20. This is of importance since it confirms for tensor fields the validity of the integral representation method (4.8) originated in Ref. 46 for the scalar case. However, explicit comparison for the spin-2 case would be a rather tedious task given the differences between both formalisms and the involved expression of the spin-2 two-point function given in Ref. 20. It seems that one can at least say that the ambient space formalism presents the advantage of simplicity. This is again verified by performing the flat limit as it is seen in the next paragraph and this was already the case when the unitary irreducible representations had to be identified in Sec. II.

B. The flat limit

The flat limit is straightforward to compute with the help of the orbital basis γ_4. The measure $d\sigma_{\gamma_4}(\xi)$ is chosen to be m^2 times the natural one induced from the $\mathbb{R}^5$ Lebesgue measure. This yields $d\sigma_{\gamma_4}(\xi)=d^3\vec{k}/k_0$ and the constant $|a_\nu|^2$ reads

$$|a_\nu|^2=4\,\frac{\langle Q_0\rangle+4}{\langle Q_1\rangle}\left[\frac{H^2e^{\pi\nu}\Gamma(-\sigma)\Gamma(-\sigma^*)}{2^5\pi^4m^2}\right]=4\,\frac{\langle Q_0\rangle+4}{\langle Q_1\rangle}\left[\frac{H^2\nu^2+H^2/4}{2^4\pi^3m^2}\right]. \tag{4.25}$$

One finds the massive spin-2 Minkowski two-point function:

$$\lim_{H\to 0}\frac{1}{4}\mathcal{W}^\nu(x,x')=\frac{1}{2(2\pi)^3}\int\sum_{\lambda\lambda'}\epsilon^{\lambda\lambda'}(k)\epsilon^{\lambda\lambda'}(k)\exp(-ik(x-x'))d^3\vec{k}/k_0\,, \tag{4.26}$$

where the factor 1/4 is due to our definition of the operators $\mathcal{S}$ and $\mathcal{S}'$. This limit can also be computed (more explicitly) starting with Formula (4.17). The flat limit for the scalar and vector two-point functions have been computed in Refs. 1 and 46, one obtains:

$$\lim_{H\to 0}\mathcal{W}_0^\nu(x,x')=\mathcal{W}^P(X,X'),\quad \lim_{H\to 0}\mathcal{W}_1(x,x')=-\left[\eta_{\mu\nu}+\frac{1}{m^2}\frac{\partial}{\partial X^\mu\partial X^\nu}\right]\mathcal{W}^P(X,X')\equiv\mathcal{W}^P_{\mu\nu}(X,X')\,, \tag{4.27}$$

where $\mathcal{W}^P(X,X')$ and $\mathcal{W}^P_{\mu\nu}(X,X')$ are the scalar and vector massive Minkowskian two-point functions respectively. Under the constraint $H\nu=m$, which implies

$$\lim_{H\to 0}H^2\langle Q_s\rangle=m^2\quad\text{and}\quad\lim_{H\to 0}H^2\sigma^2=-m^2\,, \tag{4.28}$$

one finally gets the massive spin-2 Minkowski two-point function (see, for instance, Ref. 19)

$$\begin{aligned}\lim_{H\to 0}\frac{1}{4}\mathcal{W}(x,x')=&+\frac{1}{3}\left[\eta_{\mu\nu}+\frac{1}{m^2}\frac{\partial}{\partial X^\mu\partial X^\nu}\right]\mathcal{W}^P_{\mu'\nu'}(X,X')\\&-\frac{1}{2}\mathcal{S}\left[\eta_{\mu\nu'}+\frac{1}{m^2}\frac{\partial}{\partial X^\mu\partial X^{\nu'}}\right]\mathcal{W}^P_{\mu'\nu}(X,X')\,.\end{aligned} \tag{4.29}$$

C. The quantum field

The explicit knowledge of $\mathcal{W}^\nu(x,x')$ allows us to make the QF formalism work. The tensor field $\mathcal{K}(x)$ is expected to be an operator-valued distributions on X_H acting on a Hilbert space $\mathcal{H}$. In terms of Hilbert space and field operator, the properties of the Wightman two-point functions are equivalent to the following conditions:[49]

(1) **Existence of an unitary irreducible representation of the dS group**

$$U=U^{2,\nu}, \quad (\text{and possibly} \quad V^{2,q}).$$

(2) **Existence of at least one "vacuum state"** Ω, cyclic for the polynomial algebra of field operators and invariant under the above representation of the dS group.

(3) **Existence of a Hilbert space** $\mathcal{H}$ with positive definite metric that can be described as the Hilbertian sum

$$\mathcal{H}=\mathcal{H}_0\oplus[\oplus_{n=1}^{\infty}\mathcal{SH}_1^{\otimes n}],$$

where $\mathcal{H}_0=\{\lambda\Omega, \quad \lambda\in\mathbb{C}\}$.

(4) **Covariance** of the field operators under the representation U,

$$U(g)\mathcal{K}_{\alpha\beta}(x)U(g^{-1})=g_{\alpha}^{\gamma}g_{\beta}^{\delta}\mathcal{K}_{\gamma\delta}(gx).$$

(5) **Locality** for every spacelike separated pair (x,x')

$$[\mathcal{K}_{\alpha\beta}(x),\mathcal{K}_{\alpha'\beta'}(x')]=0.$$

(6) **KMS condition or geodesic spectral condition**[46] which means the vacuum is defined as a physical state with the temperature $T=H/2\pi$.

(7) **Transversality**

$$x\cdot\mathcal{K}(x)=0.$$

(8) **Divergencelessness**

$$\partial\cdot\mathcal{K}(x)=0.$$

(9) **Index symmetrizer**

$$\mathcal{K}_{\alpha\beta}=\mathcal{K}_{\beta\alpha}.$$

Given the two-point function, one can realize the Hilbert space as functions on X_H as follows. For any test function $f_{\alpha\beta}\in\mathcal{D}(X_H)$, we define the vector valued distribution taking values in the space generated by the modes $\mathsf{K}_{\alpha\beta}(x,\xi)\equiv \mathrm{bv}\,\mathsf{K}_{\alpha\beta}(z,\xi)$ by

$$x\to p_{\alpha\beta}(f)(x)=\int_{X_H}\mathcal{W}_{\alpha\beta\alpha'\beta'}(x,x')f^{\alpha'\beta'}(x')d\sigma(x')=\sum_{\lambda\lambda'}\int_{\gamma}d\sigma_{\gamma}(\xi)\mathsf{K}_{\xi}^{\lambda\lambda'}(f)\,\mathsf{K}_{\alpha\beta}^{\lambda\lambda'}(x,\xi), \tag{4.30}$$

where $\mathsf{K}_{\xi}^{\lambda\lambda'}(f)$ is the smeared form of the modes:

$$\mathsf{K}_{\xi}^{\lambda\lambda'}(f)=\int_{X_H}\mathsf{K}_{\alpha\beta}^{*\lambda\lambda'}(x,\xi)f^{\alpha\beta}(x)d\sigma(x). \tag{4.31}$$

The space generated by the $p(f)$'s is equipped with the positive invariant inner product

$$\langle p(f),p(g)\rangle=\int_{X_H\times X_H}f^{*\alpha\beta}(x)\mathcal{W}_{\alpha\beta\alpha'\beta'}(x,x')g^{\alpha'\beta'}(x')d\sigma(x')d\sigma(x). \tag{4.32}$$

As usual, the field is defined by the operator valued distribution

$$\mathcal{K}(f)=a(p(f))+a^{\dagger}(p(f)), \tag{4.33}$$

where the operators $a(\mathsf{K}^{\lambda\lambda'}(\xi))\equiv a^{\lambda\lambda'}(\xi)$ and $a^{\dagger}(\mathsf{K}^{\lambda\lambda'}(\xi))\equiv a^{\dagger\lambda\lambda'}(\xi)$ are respectively antilinear and linear in their arguments. One gets

$$\mathcal{K}(f)=\sum_{\lambda\lambda'}\int_{\gamma}d\sigma_{\gamma}(\xi)[\mathsf{K}_{\xi}^{*\lambda\lambda'}(f)\,a^{\lambda\lambda'}(\xi)+\mathsf{K}_{\xi}^{\lambda\lambda'}(f)\,a^{\dagger\lambda\lambda'}(\xi)]. \tag{4.34}$$

The unsmeared operator reads

$$\mathcal{K}_{\alpha\beta}(x)=\sum_{\lambda\lambda'}\int_{\gamma}d\sigma_{\gamma}(\xi)[\mathsf{K}_{\alpha\beta}^{\lambda\lambda'}(x,\xi)\,a^{\lambda\lambda'}(\xi)+\mathsf{K}_{\alpha\beta}^{*\lambda\lambda'}(x,\xi)\,a^{\dagger\lambda\lambda'}(\xi)], \tag{4.35}$$

where $a^{\lambda\lambda'}(\xi)$ satisfies the canonical commutation relations (ccr) and is defined by

$$a^{\lambda\lambda'}(\xi)|\Omega>=0.$$

The measure satisfies $d\sigma_{\gamma}(l\xi)=l^{3}d\sigma_{\gamma}(\xi)$ and $\mathsf{K}_{\alpha\beta}^{\lambda\lambda'}(x,l\xi)=l^{\sigma}\mathsf{K}_{\alpha\beta}^{\lambda\lambda'}(x,\xi)$ yields the homogeneity condition

$$a^{\lambda\lambda'}(l\xi)\equiv a(\mathsf{K}^{\lambda\lambda'}(l\xi))=a(l^{\sigma}\mathsf{K}^{\lambda\lambda'}(\xi))=l^{\sigma*}a^{\lambda\lambda'}(\xi).$$

The integral representation (4.35) is independent of the orbital basis γ as explained in Ref. 46. For the hyperbolic type submanifold γ_4 the measure is $d\sigma_{\gamma_4}(\xi)=d^{3}\vec{\xi}/\xi_0$ and the ccr are represented by

$$[a^{\lambda\lambda'}(\xi),a^{\dagger\lambda''\lambda'''}(\xi')]=[\eta^{\lambda\lambda''}\eta^{\lambda'\lambda'''}+\eta^{\lambda\lambda'}\eta^{\lambda''\lambda'''}]\xi^{0}\delta^{3}(\vec{\xi}-\vec{\xi}'). \tag{4.36}$$

The field commutation relations are

$$[\mathcal{K}_{\alpha\beta}(x),\mathcal{K}_{\alpha'\beta'}(x')]=2i\,\mathrm{Im}\langle p_{\alpha\beta}(x),p_{\alpha'\beta'}(x')\rangle=2i\,\mathrm{Im}\mathcal{W}_{\alpha\beta\alpha'\beta'}(x,x'). \tag{4.37}$$

V. CONCLUSION

In this article we have considered the ''massive'' spin-2 tensor field that is associated to the principal series of the dS group $\mathrm{SO}_0(1,4)$ with $\langle Q_{\nu}\rangle=\nu^{2}-\frac{15}{4}\geqslant 0$, and corresponding to the nonzero ''mass'' $m_p^{2}=H^{2}(\nu^{2}+\frac{9}{4})$. In our view, the use of the ''mass'' concept is more forced by tradition than relevant to our analysis. The use of ambient space formalism endowed the de Sitter physics with a Minkowskian-type appearance. The main differences hold in the space time dependence of the de Sitter polarization tensor. This formalism yields simple expressions and makes de Sitter QFT look almost like standard QFT in flat space–time.

The group theoretical point of view allows a systematic and complete study of the spin-2 field theory and legitimizes the restriction of ''massive'' fields to those which carry principal series representations. Indeed, in the case of the complementary series ($\langle Q_{\mu}\rangle=\mu-4,\quad 0<\mu<\frac{1}{4}$), although the associated ''mass'' $m_c^{2}=H^{2}(\mu+2),\quad 0<\mu<\frac{1}{4}$ is strictly positive, the physical meaning of their carrier fields remains unclear since the $H=0$ limits of these representations in the complementary series do not correspond to any physical representation of the Poincaré group.

Since m_p^{2} and m_c^{2} are strictly nonzero, ''massless'' spin-2 fields must belong to the discrete series among which only $\Pi_{s,s}^{\pm}$ have a physically meaningful Poincaré limit. Now since the associated ''mass'' is $m_d^{2}=H^{2}\{6-2(s^{2}-1)\},\quad s\geqslant 2$, and is expected to be real, the only possible value of s is 2 with $m_d^{2}=0$. Hence $\Pi_{2,2}^{\pm}$ correspond precisely to ''massless'' tensor fields (linear quantum gravity in dS space) in perfect agreement with the fact that, on one hand, these representations have nonambiguous extensions to the conformal group SO(4,2) and, on the other hand, the latter are precisely the unique extensions of the massless Poincaré group representations with helicity ± 2. In this case ν should be replaced by $\pm 3i/2$ in the formulas of the present article.[14] The projection operator $\mathcal{D}$ [Eq. (3.19) on the classical level] and the normalization constant c_{ν}^{2}

[Eq. (4.12) on the quantum level] then become singular. This singularity is actually due to the divergencelessness condition needed to associate the tensor field with a specific UIR of the dS group. To solve this problem, the divergencelessness condition must be dropped. Then the field equation becomes gauge invariant, i.e., $\mathcal{K}^{gt}=\mathcal{K}+D_2\Lambda_g$ is a solution of the field equation for any vector field Λ_g as far as $\mathcal{K}$ is. As a result, the general solutions transform under indecomposable representations of the dS group. By fixing the gauge, the field can eventually be quantized.

A second type of singularity appears. It is due to the zero mode problem of the Laplace–Beltrami operator on dS space inherited from the minimally coupled scalar field.[12] Accordingly, we feel that a Krein space quantization along the lines presented in Ref. 12 can be successfully carried out in the spin-2 massless case in dS space. This situation will be considered in a forthcoming paper.[10]

APPENDIX A: CLASSIFICATION OF THE UNITARY IRREDUCIBLE REPRESENTATIONS OF THE de SITTER GROUP $SO_0(1,4)$

Unitary irreducible representations (UIRs) of $SO_0(1,4)$ are characterized by the eigenvalues of the two Casimir operators $Q^{(1)}$ and $Q^{(2)}$ introduced in Sec. II. In fact the UIRs may be labeled by a pair of parameters $\Delta=(p,q)$ with $2p\in\mathbb{N}$ and $q\in\mathbb{C}$, in terms of which the eigenvalues of $Q^{(1)}$ and $Q^{(2)}$ are expressed as follows:[2,32,33]

$$Q^{(1)}=[-p(p+1)-(q+1)(q-2)]\mathbf{Id},\quad Q^{(2)}=[-p(p+1)q(q-1)]\mathbf{Id}.$$

According to the possible values for p and q, three series of inequivalent representations may be distinguished: the principal, complementary and discrete series. We write s when p or q have spin meaning.

(1) Principal series representations $U_{s,\nu}$, also called "massive" representations: $\Delta=(s,\frac{1}{2}+i\nu)$ with

$$s=0,1,2,\ldots\quad\text{and}\quad\nu\geqslant 0\quad\text{or}\quad s=\tfrac{1}{2},\tfrac{3}{2},\ldots\quad\text{and}\quad\nu>0.$$

The operators $Q^{(1)}$ and $Q^{(2)}$ take respectively the following forms:

$$Q^{(1)}=[(\tfrac{9}{4}+\nu^2)-s(s+1)]\,\mathbf{Id},\quad Q^{(2)}=[(\tfrac{1}{4}+\nu^2)s(s+1)]\,\mathbf{Id}.$$

They are called the massive representations of the dS group because they contract toward the massive spin s representations of the Poincaré group.

(2) Complementary series representations $V_{s,\nu}$: $\Delta=(s,\frac{1}{2}+\nu)$ with

$$s=0\quad\text{and}\quad\nu\in\mathbb{R}\ ,\ 0<|\nu|<\tfrac{3}{2}\quad\text{or}\quad s=1,2,3,\ldots\quad\text{and}\quad\nu\in\mathbb{R}\ ,0<|\nu|<\tfrac{1}{2}.$$

The operators $Q^{(1)}$ and $Q^{(2)}$ take the forms

$$Q^{(1)}=[(\tfrac{9}{4}-\nu^2)-s(s+1)]\,\mathbf{Id},\quad Q^{(2)}=[(\tfrac{1}{4}-\nu^2)s(s+1)]\,\mathbf{Id}.$$

Here, the only physical representation in the sense of the Poincaré limit is the scalar case corresponding to $\Delta=(0,1)$ and also called the conformally coupled massless case.

(3) Discrete series $\Pi_{p,0}$ and $\Pi^{\pm}_{p,q}$: $\Delta=(p,q)$ with

$$p=1,2,3,\ldots\quad\text{and}\quad q=0\quad\text{or}\quad p=\tfrac{1}{2},1,\tfrac{3}{2},2,\ldots\quad\text{and}\quad q=p,p-1,\ldots,1\ \text{or}\ \tfrac{1}{2}.$$

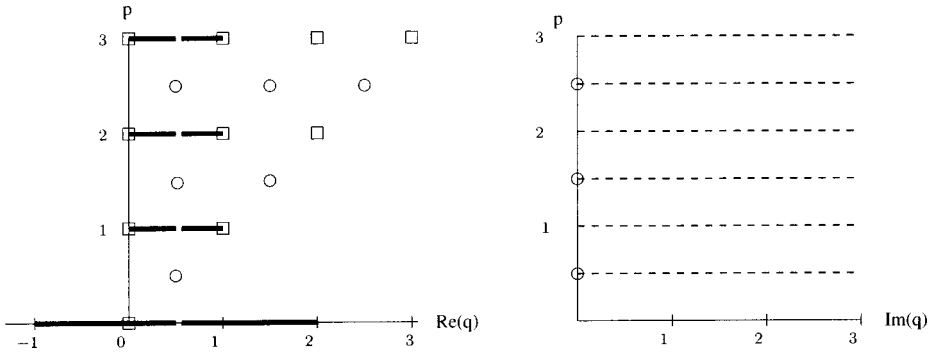

FIG. 2. $SO_0(1,4)$ unitary irreducible representation diagrams.

In this case, the only physical representations in the sense of Poincaré limit are those with $p=q=s$. They are called the massless representations of the dS group.

Note that the substitution $q\rightarrow(1-q)$ does not alter the eigenvalues; the representations with labels $\Delta=(p,q)$ and $\Delta=(p,1-q)$ can be shown to be equivalent. Finally, we have pictured some of these representations in terms of p and q in Fig. 2. The symbols ○ and □ stand for the discrete series with semi-integer and integer values of p, respectively. The complementary series is represented in the same frame by bold lines. The principal series is represented in the $\mathrm{Re}\,(q)=\frac{1}{2}$ plane by dashed lines. We have represented the three discrete series of representation with values $p=\frac{1}{2},\frac{3}{2},\frac{5}{2}$, $\mathrm{Re}\,(q)=\frac{1}{2}$ and $\mathrm{Im}\,(q)=0$ with the principal series in order to show how these two diagrams fit together.

APPENDIX B: MAXIMALLY SYMMETRIC BITENSORS IN AMBIENT SPACE

Following Allen and Jacobson in Ref. 34 we will write the two-point functions in de Sitter space (maximally symmetric) in terms of bitensors. These are functions of two points (x,x') which behave like tensors under coordinate transformations at either point. The bitensors are called maximally symmetric if they respect the de Sitter invariance.

As shown in Ref. 34, any maximally symmetric bitensor can be expressed as a sum of products of three basic tensors. The coefficients in this expansion are functions of the geodesic distance $\mu(x,x')$, that is the distance along the geodesic connecting the points x and x' [note that $\mu(x,x')$ can be defined by unique analytic extension also when no geodesic connects x and x']. In this sense, these fundamental tensors form a complete set. They can be obtained by differentiating the geodesic distance:

$$n_a=\nabla_a\mu(x,x'),\quad n_{a'}=\nabla_{a'}\mu(x,x'),$$

and the parallel propagator

$$g_{ab'}=-c^{-1}(\mathcal{Z})\nabla_a n_{b'}+n_a n_{b'}.$$

The geodesic distance is implicitly defined[46] for $\mathcal{Z}=-H^2x\cdot x'$ by

$$\mathcal{Z}=\cosh(\mu H)\quad \text{for } x \text{ and } y \text{ timelike separated,}$$

$$\mathcal{Z}=\cos(\mu H)\quad \text{for } x \text{ and } y \text{ spacelike separated such that } |x\cdot x'|<H^{-2}.$$

The basic bitensors in ambient space notations are found through

$$\overline{\partial}_\alpha\mu(x,x'),\quad \overline{\partial}'_{\beta'}\mu(x,x'),\quad \overline{\partial}_\alpha\overline{\partial}'_{\beta'}\mu(x,x'),$$

restricted to the hyperboloid by

$$T_{ab'}(x,x')=\frac{\partial x^{\alpha}}{\partial X^{a}}\frac{\partial x'^{\beta'}}{\partial X'^{b'}}T_{\alpha\beta'}\quad .$$

For $\mathcal{Z}=\cos(\mu H)$, one finds

$$n_a=\frac{\partial x^{\alpha}}{\partial X^{a}}\overline{\partial}_{\alpha}\mu(x,x')=\frac{\partial x^{\alpha}}{\partial X^{a}}\ \frac{H(\theta_{\alpha}\cdot x')}{\sqrt{1-\mathcal{Z}^2}},\quad n_b=\frac{\partial x'^{\beta'}}{\partial X'^{b'}}\overline{\partial}'_{\beta'}\mu(x,x')=\frac{\partial x'^{\beta'}}{\partial X'^{b'}}\ \frac{H(\theta'_{\beta'}\cdot x)}{\sqrt{1-\mathcal{Z}^2}},$$

and

$$\nabla_a n_{b'}=\frac{\partial x^{\alpha}}{\partial X^{a}}\frac{\partial x'^{\beta'}}{\partial X'^{b'}}\theta^{\sigma}_{\alpha}\theta'^{\gamma'}_{\beta'}\overline{\partial}_{\sigma}\overline{\partial}'_{\gamma'}\mu(x,x')=c(\mathcal{Z})\left[\mathcal{Z}n_a n_{b'}-\frac{\partial x^{\alpha}}{\partial X^{a}}\frac{\partial x'^{\beta'}}{\partial X'^{b'}}\theta_{\alpha}\cdot\theta'_{\beta'}\right],$$

with $c(\mathcal{Z})=-H/\sqrt{1-\mathcal{Z}^2}$. For $\mathcal{Z}=\cosh(\mu H)$, n_a, $n_{b'}$ are multiplied by i and $c(\mathcal{Z})$ becomes $-iH/\sqrt{1-\mathcal{Z}^2}$. In both cases we have

$$\frac{\partial x^{\alpha}}{\partial X^{a}}\frac{\partial x'^{\beta'}}{\partial X'^{b'}}\theta_{\alpha}\cdot\theta'_{\beta'}=g_{ab'}+(\mathcal{Z}-1)n_a n_{b'}.$$

APPENDIX C: "MASSIVE" VECTOR TWO-POINT FUNCTION

Given the important role played by the "massive" vector Wightman two-point function in the construction of the spin-2 two-point function we briefly present here a derivation of it (for details see Ref. 1). In addition we compare our two-point function with the one given in Ref. 34. We consider the "massive" vector Wightman two-point function which corresponds to the principal series of representation of $SO_0(1,4)$ and satisfies

$$(Q_1-\langle Q_1\rangle)\mathcal{W}^{\nu}_{1\alpha\beta'}(x,x')=0,\quad \text{where}\quad \langle Q_1\rangle=\nu^2+\tfrac{1}{4}\quad \text{with}\quad \nu\in\mathbb{R}.$$

This bivector is obtained as the boundary value of the analytic bivector two-point function obtained with the modes (3.13):

$$W^{\nu}_{1\alpha\beta'}(z,z')=c_{\nu}^2\frac{\langle Q_1\rangle}{\langle Q_0\rangle}\int_{\gamma}\sum_{\lambda}\mathcal{E}^{\lambda}_{\alpha}(z,\xi)\,\mathcal{E}^{*\lambda}_{\beta'}(z'^{*},\xi)(Hz\cdot\xi)^{\sigma}(Hz'\cdot\xi)^{\sigma^*}\,d\sigma_{\gamma}(\xi).$$

With the help of Eq. (4.16) and the relation $H^2D_1(Hz\cdot\xi)^{\sigma}=\sigma\overline{\xi}(Hz\cdot\xi)^{\sigma}/(z\cdot\xi)$ it is easy to expand the transverse bivector in terms of the analytic scalar two-point function $W_0(z,z')$:

$$W^{\nu}_{1}(z,z')=\frac{\langle Q_0\rangle}{\langle Q_1\rangle}\left(-\theta_{\alpha}\cdot\theta'_{\alpha'}+\frac{H^2\sigma(\theta\cdot z')D'_1}{\langle Q_0\rangle}+\frac{H^2\sigma^*(\theta'\cdot z)D_1}{\langle Q_0\rangle}+\frac{H^2\mathcal{Z}D_1D'_1}{\langle Q_0\rangle}\right)W^{\nu}_{0}(z,z').$$

The analytic "massive " scalar two-point function is

$$W^{\nu}_{0}(z,z')=c_{\nu}^2\int_{\gamma}(Hz\cdot\xi)^{\sigma}(Hz'\cdot\xi)^{\sigma^*}\,d\sigma_{\gamma}(\xi)\quad \text{with}\quad c_{\nu}^2=H^2e^{+\pi\nu}\Gamma(-\sigma)\Gamma(-\sigma^*)/(2^5\pi^4m^2),$$

which satisfies

$$(Q_0-\langle Q_0\rangle)W^{\nu}_{0}(z,z')=0,\quad \text{where}\quad \langle Q_0\rangle=\nu^2+\tfrac{9}{4}\quad \text{with}\quad \nu\in\mathbb{R}.$$

The choice of normalization corresponds to the Euclidean vacuum and $W_0(z,z')$ can be written as a hypergeometric function (see Ref. 46):

$$W_0^{\nu}(z,z')=C_{\nu}\ {}_2F_1\left(-\sigma,-\sigma^*;2;\frac{1+\mathcal{Z}}{2}\right)=C_{\nu}P_{\sigma}^{5}(-\mathcal{Z}) \qquad \text{with} \quad C_{\nu}=\frac{H^2\Gamma(-\sigma)\ \ \Gamma(-\sigma^*)}{2^4\pi^2m^2}.$$

In order to show that our vector two-point function is the same two-point function as the one given by Allen and Jacobson in Ref. 34, we develop $W_1^{\nu}(z,z')$ using essentially $\bar{\partial}_{\alpha}\phi(\mathcal{Z})=-(\theta_{\alpha}\cdot z')H^2\,(d/d\mathcal{Z})\,\phi(\mathcal{Z})$. One finds

$$\mathcal{W}_{1\alpha\beta'}^{\nu}(x,x')=\mathrm{bv}\,W_1^{\nu}(z,z')=\theta_{\alpha}\cdot\theta'_{\beta'}U(\mathcal{Z})+H^2\frac{(\theta'_{\beta'}\cdot z)(\theta_{\alpha}\cdot z')}{1-\mathcal{Z}^2}V(\mathcal{Z}),$$

with

$$U(\mathcal{Z})=-\frac{1}{\langle Q_1\rangle}\left[Q_0+\mathcal{Z}\frac{d}{d\mathcal{Z}}\ \right]W_0^{\nu}(z,z')\ \ ,\quad V(\mathcal{Z})=\frac{1}{\langle Q_1\rangle}\left[3\frac{d}{d\mathcal{Z}}+\mathcal{Z}^2\frac{d}{d\mathcal{Z}}+\mathcal{Z}Q_0\right]W_0^{\nu}(z,z'),$$

where

$$Q_0=(1-\mathcal{Z}^2)\frac{d^2}{d\mathcal{Z}^2}-4\mathcal{Z}\frac{d}{d\mathcal{Z}}$$

is the second order differential operator deduced from the Casimir operator expressed with the variable $\mathcal{Z}$ in place of (z,z'). The functions $U(\mathcal{Z})$ and $V(\mathcal{Z})$ satisfy the property

$$\mathcal{Z}U(\mathcal{Z})+V(\mathcal{Z})=\frac{3}{\langle Q_1\rangle}\frac{d}{d\mathcal{Z}}W_0^{\nu}(z,z')\equiv\Lambda(\mathcal{Z}),$$

with

$$\Lambda(\mathcal{Z})=3H^2\frac{\Gamma(1-\sigma)\ \ \Gamma(1-\sigma^*)}{2^6\langle Q_1\rangle\pi^2m^2}\,{}_2F_1\left(1-\sigma,1-\sigma^*;3;\frac{1+\mathcal{Z}}{2}\right),$$

which is the solution of the equation

$$\left[Q_0-2\mathcal{Z}\frac{d}{d\mathcal{Z}}-6-\langle Q_1\rangle\right]\Lambda(\mathcal{Z})=0.$$

Finally, let us write the intrinsic expression of the two-point function $\mathcal{W}_1^{\nu}(x,x')$ obtained as the boundary value of $W_1^{\nu}(z,z')$. The intrinsic expression is

$$Q_{ab'}\equiv\frac{\partial x^{\alpha}}{\partial X^a}\frac{\partial x'^{\beta'}}{\partial X'^{b'}}\ \ \mathcal{W}_{1\alpha\beta'}^{\nu}(x,x').$$

Since

$$\frac{\partial x^{\alpha}}{\partial X^a}\frac{\partial x'^{\beta'}}{\partial X'^{b'}}\theta_{\alpha}\cdot\theta'_{\beta'}=g_{ab'}+(\mathcal{Z}-1)n_an_{b'}\,,\quad \frac{\partial x^{\alpha}}{\partial X^a}\frac{\partial x'^{\beta'}}{\partial X'^{b'}}\ \ \frac{H^2(\theta'_{\beta'}\cdot x)(\theta_{\alpha}\cdot x')}{1-\mathcal{Z}^2}=n_an_{b'}\,,$$

one gets

$$Q_{ab}=g_{ab'}U(\mathcal{Z})+n_a\,n_{b'}(\Lambda(\mathcal{Z})-U(\mathcal{Z})),$$

and in the case of $SO_0(4,1)$:

$$Q_{ab} = -g_{ab'}U(\mathcal{Z}) - n_a n_{b'}(U(\mathcal{Z}) - \Lambda(\mathcal{Z})).$$

This is the expression given by Allen and Jacobson in Refs. 20 and 34.

APPENDIX D: ANOTHER EXPRESSION FOR THE SPIN-2 TWO-POINT FUNCTION

We present another form of the spin-2 two-point function, which is useful for the proof of the locality condition. We begin with the term $M(z,z')W_1^\nu(z,z')$:

$$\frac{\langle Q_0\rangle + 4}{\langle Q_0\rangle}\left[-\mathcal{S}\mathcal{S}'\,\theta\cdot\theta' + \frac{H^2\mathcal{S}(\theta\cdot z')D_2'}{\sigma^*-1} + \frac{H^2\mathcal{S}'(\theta'\cdot z)D_2}{\sigma-1} + \frac{\mathcal{Z}H^2D_2D_2'}{(\sigma-1)(\sigma^*-1)}\right]W_1^\nu(z,z').$$

We rewrite this equation using the relations

$$H^2\mathcal{S}(\theta\cdot z')D_2'W_1^\nu = -\mathcal{S}\mathcal{S}'\,\theta\cdot\theta' W_1^\nu + 2\,\theta'\mathcal{S}\theta\cdot W_1^\nu + \tfrac{1}{2}D_2D_2'W_2,$$

$$H^2\mathcal{S}'(\theta'\cdot z)D_2W_1^\nu = -\mathcal{S}\mathcal{S}'\,\theta\cdot\theta' W_1^\nu + 2\,\theta\mathcal{S}'\,\theta'\cdot W_1^\nu + \tfrac{1}{2}D_2D_2'W_2,$$

$$H^2\mathcal{Z}D_2D_2'W_1^\nu = -\mathcal{S}\mathcal{S}'\,\theta\cdot\theta' W_1^\nu + 2\,\theta\mathcal{S}'\,\theta'\cdot W_1^\nu + 2\,\theta'\mathcal{S}\theta\cdot W_1^\nu + D_2D_2'(W_2 + H^2\mathcal{Z}W_1^\nu),$$

where $D_2D_2'W_2 = 2H^2D_2\mathcal{S}'(\theta'\cdot z)W_1 - 4\,\theta\mathcal{S}'\,\theta'\cdot W_1$. This is obtained by simple calculation of

$$(Q_2 - \langle Q_2\rangle)(\mathcal{S}\mathcal{S}'\,\theta\cdot\theta' W_1^\nu + D_2D_2'W_3) = 0,$$

with the help of Eq. (3.3) and where we have written $W_2 = (Q_1 - \langle Q_2\rangle)W_3$. One gets

$$M(z,z')W_1^\nu(z,z') = -\mathcal{S}\mathcal{S}'\,\theta\cdot\theta' W_1^\nu + \frac{2\,\theta\sigma^*\mathcal{S}'\,\theta'\cdot W_1^\nu}{\langle Q_0\rangle} + \frac{2\,\theta'\sigma\mathcal{S}\theta\cdot W_1^\nu}{\langle Q_0\rangle} + D_2D_2'\left(\frac{H^2\mathcal{Z}W_1^\nu}{\langle Q_0\rangle} - \frac{3W_2}{2\langle Q_0\rangle}\right).$$

Now, given that

$$\mathcal{S}\theta\cdot W_1^\nu = \frac{2}{3}\left[\theta + \frac{H^2D_2D_1}{2\langle Q_0\rangle}\right](W_1^\nu)' \quad \text{and} \quad \mathcal{S}'\,\theta'\cdot W_1^\nu = \frac{2}{3}\left[\theta' + \frac{H^2D_2'D_1'}{2\langle Q_0\rangle}\right](W_1^\nu)',$$

where $(W_1^\nu)'$ is the trace of the vector two-point function given by

$$(W_1^\nu)' = \eta\cdot\cdot\, W_1^\nu = 3U(\mathcal{Z}) + \mathcal{Z}\Lambda(\mathcal{Z}) = -3\frac{\langle Q_0\rangle}{\langle Q_1\rangle}W_0^\nu(z,z'),$$

we find the following form for the spin-2 two-point function:

$$\begin{aligned} W^\nu(z,z') &= M(z,z')W_1^\nu(z,z') + N(z,z')W_0^\nu(z,z') \\ &= q[\,\theta\theta'(W_1^\nu)' - \tfrac{3}{2}\,\theta\mathcal{S}'\,\theta'\cdot W_1^\nu - \tfrac{3}{2}\,\theta'\mathcal{S}\theta\cdot W_1^\nu] - \mathcal{S}\mathcal{S}'\,\theta\cdot\theta' W_1^\nu + D_2D_2'W_4, \end{aligned}$$

where $q = -\frac{4}{9}(\langle Q_0\rangle - 9)/\langle Q_0\rangle$ and

$$D_2D_2'W_4 = \frac{6\,\theta\mathcal{S}'\,\theta'\cdot W_1^\nu}{\langle Q_0\rangle} - \frac{3H^2D_2\mathcal{S}'(\theta'\cdot z)W_1^\nu}{\langle Q_0\rangle} + D_2D_2'\left(\frac{H^2\mathcal{Z}W_1^\nu}{\langle Q_0\rangle} + \frac{H^4D_1D_1'(W_1^\nu)'}{9\langle Q_0\rangle^2}\right).$$

The two-point function can be rewritten as

$$W^{\nu}(z,z')=D(z,z')W_0^{\nu}(z,z'),$$

where the differential operator $D(z,z')$ obviously satisfies $D^*(z^*,z'^*)=D(z,z')$. This property serves to prove the locality condition.

(Received 9 January 2003; accepted 22 April 2003)

The Epstein–Glaser type T-subtraction introduced by one of the authors in a previous paper is extended to the Lorentz invariant framework. The advantage of using our subtraction instead of the Epstein and Glaser standard W-subtraction method is especially important when working in Minkowski space, as then the counterterms necessary to keep Lorentz invariance are simplified. We show how T-renormalization of primitive diagrams in the Lorentz invariant framework directly relates to causal Riesz distributions. A covariant subtraction rule in momentum space is found, sharply improving upon the BPHZL method for massless theories. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1597420]

I. INTRODUCTION

According to the spirit of Epstein–Glaser theory,[1] the physical process of renormalization is mathematically expressed as an extension of functionals, v.gr. (convolutions of) powers of Feynman propagators, to well defined distributions. This paper is a continuation of Ref. 2 by the second named author, in which an extension on configuration space was presented. By modifying the use of, and relaxing the conditions on, the infrared regulators w introduced by Epstein and Glaser, very useful results on the distributions at the crossroads of mathematics and quantum field theory have been obtained; the relationship of this improved Epstein–Glaser subtraction, dubbed ''T-renormalization,'' with Hadamard regularization, the minimal subtraction scheme in analytical regularization, and differential renormalization, has been treated there at length. Hereinafter that paper[2] will be denoted by Paper I.

The discussion in Paper I took place in the Euclidean framework introduced by Stora[3] in the realm of the Epstein–Glaser construction. We tackle in this paper the problem of going to the ''physical world'' with its symmetry group of transformations, namely the Minkowski space and the Lorentz group, respectively.

The Lorentz covariance properties of extensions for powers of propagators are deeply related to the S-matrix covariance. Prima facie, Epstein–Glaser procedures are not covariant. A proof of existence of covariant time ordered products was first given in Ref. 1, working on momentum space. About 10 years later, the problem was translated into a group cohomological question on configuration space by Popineau and Stora in Ref. 4—another work which has remained at the status of preprint. The latter analysis is available in textbook form.[5] In relatively recent (also apparently unpublished) preprints,[6,7] explicit computations for ''counterterms'' re-establishing Lorentz invariance of the extensions have been performed.

A perfectly covariant method for the extension of distributions employed in quantum field theory exists, although it is rarely used: the ''analytical regularization'' method[8] of Bollini, Giam-

b)Unité Propre de Recherche 7061, et FRUMAM/Fédération de Recherche 2291.

biagi, and Gonzales Domínguez. It leads to quantum versions of the Riesz distributions of classical field theory.[9–11]

In this paper we extend T-renormalization of primitive diagrams to the Lorentz-invariant framework, and show that it generalizes directly the causal or quantum Riesz distributions.

The proof that all difficulties in renormalization theory can be overcome through exclusive use of the T operation is work in progress; the third paper of the series[12]—from now on denoted Paper III—deals with renormalization of nonprimitive diagrams and the Hopf algebra of Feynman graphs.[13–15] It is of course not claimed that the simplicity of the class of extensions envisaged in this work guarantees that it is the physically relevant one in all circumstances; as a rule, the latter will be singled out by appropriate renormalization prescriptions.

We do not suppose the reader to be familiar with causal Riesz distributions. Thus we turn to them in Sec. III, after recalling the main properties of our ''natural'' extension method in Sec. II. The covariance properties of T-renormalization are then addressed in Sec. IV. To fix ideas, we mainly consider in Sec. V the basic primitively divergent graphs in massless φ_4^4 theory, and demonstrate by way of example the link to analytical regularization and causal Riesz distributions. Section VI shows how T-renormalization improves upon the BPHZL formalism. We conclude with a brief discussion and outlook.

II. MAIN FEATURES OF *T*-RENORMALIZATION

Let us begin by fixing some conventions. The scalar functionals we shall be dealing with (coming from the Wick theorem) are to be extended to the main diagonal of $\mathbb{R}^{4(n+1)}$. The latter can be regarded as the origin in $\mathbb{R}^{4n}$ thanks to translation invariance, allowing to set $x_{n+1}=0$, for instance.

For fixed $j\in\{1,\ldots,n\}$, to each four coordinate x_j (a point in $\mathbb{R}^4$) let $\alpha^j=(\alpha_0^j,\alpha_1^j,\alpha_2^j,\alpha_3^j)$ be a quadri-index, where α_μ^j is a non-negative integer for each j and each Lorentz index μ. One has, according to Schwartz's notation,[16] $\alpha^j!=\alpha_0^j!\,\alpha_1^j!\,\alpha_2^j!\,\alpha_3^j!$ and $|\alpha^j|=\alpha_0^j+\alpha_1^j+\alpha_2^j+\alpha_3^j$, as well as

$$x_j^{\alpha^j}:=\prod_{\mu=0}^{3}(x_j^\mu)^{\alpha_\mu^j},\quad \partial_{\alpha^j}:=\left(\frac{\partial}{\partial x_j}\right)^{\alpha^j}=\prod_{\mu=0}^{3}\left(\frac{\partial}{\partial x_j^\mu}\right)^{\alpha_\mu^j}=:\prod_{\mu=0}^{3}(\partial_\mu^j)^{\alpha_\mu^j}.$$

We also use a multiquadri-index $\alpha=(\alpha_\mu^j)$ notation: $\alpha!=\alpha^1!\,\alpha^2!\cdots\alpha^n!$ and $|\alpha|=|\alpha^1|+|\alpha^2|+\cdots+|\alpha^n|$, as well as

$$x^\alpha:=\prod_{j=1}^{n}x_j^{\alpha^j},\quad \partial_\alpha:=\prod_{j=1}^{n}\partial_{\alpha^j}.$$

We assume that the reader is familiar with the basic concepts of distribution theory. In this paper, operators (Fourier transforms, actions of the Lorentz group, subtractions, ...) are defined on distributions always by transposition (or adjoint mapping), and we denote them by the *same* letter denoting the original action on test functions.

Consider scalar functionals $f(x_j)$ defined on $M_4^{n+1}\setminus D_{n+1}$, where $D_{n+1}:=\{x_1=\cdots=x_{n+1}\}$ is the full diagonal; thus we assume that the diagram is primitive or that Bogoliubov's[17] disentangling operation $\overline{R}$ corresponding to all subgraphs (see Paper III) has been performed. Those will be considered as functionals of the difference variables in $\mathbb{R}^{4n}\setminus\{0\}$. A tempered distribution $\tilde{f}\in\mathcal{S}'(\mathbb{R}^{4n})$ is an *extension* or *renormalization* of f if

$$\tilde{f}[\phi]\equiv\langle\tilde{f},\phi\rangle=\int_{\mathbb{R}^{4n}}f(x)\,\phi(x)\,\mathrm{d}^{4n}x$$

holds whenever ϕ belongs to $\mathcal{S}(\mathbb{R}^{4n}\setminus\{0\})$. In QFT one considers a generalized homogeneity degree, the *scaling degree*.[18] The scaling degree σ of a scalar distribution f at the origin of $\mathbb{R}^d$ is defined to be

$$\sigma(f)=\inf\{\, s:\lim_{\lambda\to 0}\lambda^s f(\lambda x)=0\,\}\quad \text{for } f\in\mathcal{S}'(\mathbb{R}^{4n}),$$

where the limit is taken in the sense of distributions. Essentially this means that $f(x)=O(|x|^{-\sigma(f)})$ as $x\to 0$ in the Cesàro or distributional average sense.[19]

Let then $\sigma(f)=a$, with a an integer, and $k=a-4n\geqslant 0$. Then, $f\notin L^1_{\mathrm{loc}}(\mathbb{R}^{4n})$. The simplest way to get an extension of f would appear to be standard Taylor series surgery: throw away the k-jet $j_0^k\phi$ of ϕ at the origin, and define $\tilde{f}$ by transposition:

$$\langle\tilde{f},\phi\rangle=\langle R_0^k f,\phi\rangle:=\langle f,R_0^k\phi\rangle,$$

where $R_0^k\phi:=\phi-j_0^k\phi$ is the Taylor remainder. Using Lagrange's integral formula for R_0^k, and exchanging integrations, one appears to obtain an explicit integral formula for $R_0^k f$:

$$R_0^k f(x)\equiv T_1 f(x):=(-)^{k+1}(k+1)\sum_{|\beta|=k+1}\partial_\beta\left[\frac{x^\beta}{\beta!}\int_0^1 dt\,\frac{(1-t)^k}{t^{k+4n+1}}f\left(\frac{x}{t}\right)\right]. \tag{1}$$

The trouble with (1) is that the remainder $R_0^k\phi$ is not a test function and therefore, unless the infrared behavior of f is good, we can end up with an undefined integral. Actually, for the needs of theories with only massive fields, formula (1) is largely sufficient. However in theories with massless particles, f is typically an homogeneous function with an algebraic singularity, the infrared behavior is pretty bad, and $-4n$ is also the critical degree. A way to avoid the problem is to *weigh* the Taylor subtraction. Epstein and Glaser[1] introduced infrared regulators w with the properties $w(0)=1$ and $w^{(\alpha)}(0)=0$ for $0<|\alpha|\leqslant k$, as well as projector maps $\phi\mapsto W_w\phi$ on $\mathcal{S}(\mathbb{R}^d)$ given by

$$W_w\phi(x):=\phi(x)-w(x)j_0^k\phi(x). \tag{2}$$

There is a considerable amount of overkill in (2). We argued in Paper I that one can, and should, weigh only the *last* term of the Taylor expansion. This leads to the definition used in this paper, at variance with Epstein and Glaser:

$$T_w\phi(x):=\phi(x)-j_0^{k-1}(\phi)(x)-w(x)\sum_{|\alpha|=k}\frac{x^\alpha}{\alpha!}\phi^{(\alpha)}(0). \tag{3}$$

Just $w(0)=1$ is now required in principle for the weight function. T_w is also a projector. To obtain an integral formula for it, start from

$$T_w\phi=(1-w)R_0^{k-1}\phi+wR_0^k\phi.$$

By transposition, using (1), we derive

$$\begin{aligned}T_w f(x)=&(-)^k k\sum_{|\alpha|=k}\partial_\alpha\left[\frac{x^\alpha}{\alpha!}\int_0^1 dt\,\frac{(1-t)^{k-1}}{t^{k+d}}f\left(\frac{x}{t}\right)\left(1-w\left(\frac{x}{t}\right)\right)\right]\\&+(-)^{k+1}(k+1)\sum_{|\beta|=k+1}\partial_\beta\left[\frac{x^\beta}{\beta!}\int_0^1 dt\,\frac{(1-t)^k}{t^{k+d+1}}f\left(\frac{x}{t}\right)w\left(\frac{x}{t}\right)\right].\end{aligned} \tag{4}$$

Consider the functional variation of the renormalized amplitudes with respect to w. One has

$$\left\langle\frac{\delta}{\delta w}T_w f,\psi\right\rangle:=\frac{d}{d\lambda}T_{w+\lambda\psi}f\Big|_{\lambda=0}.$$

Equation (3) yields

$$\frac{\delta}{\delta w} T_w f[\cdot] = (-)^{k+1} \sum_{|\alpha|=k} f[x^\alpha \cdot] \frac{\partial_\alpha \delta}{\alpha!}, \tag{5}$$

independently of w. The combination $(-)^{|\alpha|}/\alpha!\ \partial_\alpha \delta$ is rebaptized δ_α. A central fact of renormalization theory, under its distributional guise, is that there is no unique way to construct the renormalized amplitudes, the inherent ambiguity being represented by the undetermined coefficients of the δ and its derivatives, describing how the chosen extension acts on the (finite codimension) space of test functions which do *not* vanish to some order in a neighborhood of 0. There is, however, a more natural way—in which the ambiguity is reduced to terms in the higher-order derivatives of δ, as seen in (5), exclusively. This is guaranteed by our choice of T_w.

A word on the space of infrared regulators w is in order. In Paper I it was shown that, for the extension of homogeneous f of the kind found in massless field models, any element of the space $\mathcal{K}'$ (dual of the Grossmann–Loupias–Stein function space) of distributions rapidly decreasing in the Cesàro sense,[20] taking the value 1 at zero, qualifies as a weight "function." The space $\mathcal{K}'$ is a kind of distributional analogue of the Schwartz space $\mathcal{S}$. Elements of $\mathcal{K}'$ have moments of all orders. In particular, exponential functions e^{iqx} do qualify; this was realized by Prange, at the heuristical level.[21] See the consequences in Sec. VI. The usefulness of $\mathcal{K}'$ has appeared by now in many different contexts.[22] The regulator $w(\mu x) = H(1-\mu|x|)$ of Paper I, with H the Heaviside function, will be mainly used here. Call T_μ the corresponding renormalization.

The results just summarized go a long way to justify the conjecture (made by Connes and independently by Estrada) that Hadamard's finite part theory is in principle enough to deal with quantum field theory divergences. At least in the Euclidean context. When going from there to the physical signature for the space–time, both the ultraviolet and the infrared problems immediately turn nastier, in a tangled sort of way. For the first, since the singular support of the Feynman propagator lies on the whole light cone, it would appear that we have to worry about singularities supported on the entire cone, and not just at the origin. For the second, it is easy to see that if we approach infinity in directions parallel to the light cone, the Feynman propagator decays as $1/|x|$ and not "naïvely" anymore as $1/|x|^2$.

Both kinds of trouble are a bit less ferocious than they seem. There are techniques for dealing with the worsened infrared problem, conjuring at need combinations of diagrams.[23] Microlocal analysis (Ref. 24, Sec. 8.2) can be invoked[25] to argue that the ultraviolet troubles remain concentrated at the origin, just as in the Euclidean case. In the next section, we show the same for the square and the cube of the Feynman propagator (i.e., the basic four-point and two-point divergent graphs in the φ_4^4 model), by a direct calculation.

Whereas T_1 of (1) ostensibly preserves the Lorentz covariance properties of f, the operator T_w of (4) in general does not. Our main task is to fix this problem.

III. CAUSAL RIESZ DISTRIBUTIONS

Riesz's method consists in generalizing to the Lorentz-invariant context the well-known holomorphic family of distributions on $\mathbb{R}$,

$$\Phi^\lambda(x) := \frac{x_+^{\lambda-1}}{\Gamma(\lambda)}$$

for complex λ, which have the properties

$$\Phi^\lambda * \Phi^\mu = \Phi^{\lambda+\mu}, \quad \frac{d\Phi^\lambda}{dx} = \Phi^{\lambda-1}, \quad \Phi^0(x) = \delta(x),$$

where $*$ denotes convolution of distributions. In fact, Riesz only dealt with the (advanced and) retarded propagators. He was able to show that the holomorphic family of distributions G_{ret}^λ defined on $\mathbb{R}^4$ as follows:

$$G^{\lambda}_{\mathrm{ret}}(x)=C_{\lambda}\,x_{+}^{2(\lambda-2)},$$

with x_{+}^{2} equal to $t^2-|\vec{x}|^2=t^2-r^2$ on the forward light cone and to 0 anywhere else, and

$$C_{\lambda}=\frac{1}{2^{2\lambda-1}\pi\,\Gamma(\lambda)\Gamma(\lambda-1)},$$

fulfills

$$G^{\lambda}_{\mathrm{ret}}*G^{\mu}_{\mathrm{ret}}=G^{\lambda+\mu}_{\mathrm{ret}},\quad \Box G^{\lambda}_{\mathrm{ret}}=G^{\lambda-1}_{\mathrm{ret}},\quad G^{0}_{\mathrm{ret}}=\delta.$$

In particular, $x_{+}^{2(\lambda-2)}$ is at once seen to have (generally double) poles with residues concentrated at the origin as the only singularities. The $G^{\lambda}_{\mathrm{ret}}$ constitute a set of convolution inverse powers of the d'Alembertian, verifying $\Box^{\lambda}G^{\lambda}_{\mathrm{ret}}=\delta(x)$.

In quantum field theory, as stressed in Ref. 8, the relevant set of inverse powers is related to the Feynman propagator

$$D_F(x)=\frac{-i}{4\pi^2(t^2-r^2-i\epsilon)}.$$

We therefore focus on $(t^2-r^2\pm i\epsilon)^{\alpha-2}$, with poles at $\alpha=0,-1,\ldots$, with the aim of studying the renormalization by analytic regularization in the variable α of the functionals $(t^2-r^2\pm i\epsilon)^{-2}$, $(t^2-r^2\pm i\epsilon)^{-3}$, and so on, ill-defined as distributions. For a start, we need to compute the residues at the poles.

It is instructive and convenient for the purpose of looking at the spirit of analytic regularization at the Euclidean $\mathbb{R}^4$ first, in a somewhat unconventional manner. Consider $\rho^2:=|x|^2=t^2+r^2$. The singularities of ρ^{α} are well known (see Paper I): simple poles in the regularizing variable α at $-4-2k$, for $k=0,1,\ldots$, with residues

$$\operatorname*{Res}_{\alpha=-4-2k}\rho^{\alpha}=\frac{\Omega_4\,\Delta^k\delta}{2^k k!\;4.6.8\cdots(2+2k)},\tag{6}$$

the denominator in the case $k=0$ being 1; here $\Omega_4=2\pi^2$ is the area of the sphere in dimension 4, and Δ the Laplacian in dimension 4. It is possible, and usually done, to define a holomorphic family of distributions that encodes the pole structure of ρ^{α} in the same way that Φ^{λ} encodes that of x_{+}^{λ}. However, we consider instead the following *meromorphic* family:

$$G^{\alpha}_{\mathrm{eucl}}(x)=C_{\alpha}\,\rho^{2(\alpha-2)},$$

with

$$C_{\alpha}=\frac{e^{-i\pi\alpha}\Gamma(2-\alpha)}{4^{\alpha}\pi^2\Gamma(\alpha)}.$$

Notice that G^{1}_{eucl} is the Green function for the Laplace equation on $\mathbb{R}^4$; that $\Delta G^{\alpha}_{\mathrm{eucl}}=G^{\alpha-1}_{\mathrm{eucl}}$, which is quickly seen from $\Delta\rho^{\mu}=\mu(\mu+2)\rho^{\mu-2}$; and that $G^{-m}_{\mathrm{eucl}}(x)=\Delta^m\delta(x)$; the latter of course is just another way of writing (6).

It is also true that $G^{\alpha}_{\mathrm{eucl}}*G^{\beta}_{\mathrm{eucl}}=G^{\alpha+\beta}_{\mathrm{eucl}}$. For that, define the Fourier transforms on test functions by

$$F[\phi](p)\equiv\hat{\phi}(p):=\int\frac{\mathrm{d}^4x}{(2\pi)^2}\,e^{-ipx}\phi(x),\quad F^{-1}[\phi](p)\equiv\check{\phi}(p):=\int\frac{\mathrm{d}^4x}{(2\pi)^2}\,e^{ipx}\phi(x),$$

and on distributions by transposition. Then $Ff\,Fg=(2\pi)^{-2}F(f*g)$ for convolvable distributions. It turns out (Ref. 26, Theorem 5.9) that

$$\hat{G}^{\alpha}_{\mathrm{eucl}}(p)=(2\pi)^{-2}e^{-i\pi\alpha}|p|^{-2\alpha}, \tag{7}$$

a most interesting duality. From this the convolution identity follows.

Now we obtain the poles of $(x^2\pm i\epsilon)^{\alpha}$ from the poles of $\rho^{2\alpha}$. We follow Gelfand and Shilov (Ref. 27, Chap. III, Secs. 2.3 and 2.4) in this. Consider the quadratic forms $g_{\pm}(x):=\pm i\rho^2$. Then $g^{\alpha}_{\pm}=e^{\pm i\pi\alpha/2}\rho^{2\alpha}$. Rewrite equation (6) as

$$\operatorname*{Res}_{\alpha=-2-l} g^{\alpha}_{\pm}=\frac{-\pi^2\,\Delta^{l}_{g_{\pm}}\delta}{4^l l!(l+1)!\sqrt{(\mp i)^4\det g_{\pm}}},$$

with $\Delta_{g_{\pm}}$ the Laplacian canonically associated to $g_{\pm}$, which is $\mp i\Delta$ on this occasion. To be precise, if $\tilde{g}^{ij}$ is the inverse matrix of the quadratic form g, then

$$\Delta_g:=\sum_{i,j}\tilde{g}^{ij}\,\partial_i\,\partial_j\,.$$

For the forms $g(x)=t^2-r^2\pm i\epsilon(t^2+r^2)$, we find then by analytic continuation:

$$\operatorname*{Res}_{\alpha=-2-l}(x^2\pm i\epsilon)^{\alpha}=\frac{\pm i\pi^2\,\Box^l\delta}{4^l l!(l+1)!}.$$

(This analytic continuation is not to be confused with the one involved in the definition of the G^{α} for α complex.)

The information on the singularity structure of $(x^2\pm i\epsilon)^{\alpha}$—and of its Fourier transform—can now be codified in *causal Riesz distributions* $G^{\alpha}_{\pm}$. To wit, we define

$$G^{\alpha}_{\pm}(x):=\frac{\mp ie^{\mp i\pi\alpha}\Gamma(2-\alpha)}{4^{\alpha}\pi^2\Gamma(\alpha)}(t^2-r^2\pm i\epsilon)^{\alpha-2}, \tag{8}$$

and, sure enough,

$$G^{1}_{-}(x)=D_F(x),\quad G^{-l}_{\pm}(x)=\Box^l\delta(x)$$

for $l\geqslant 0$. Also, $\Box G^{\alpha}_{\pm}(x)=G^{\alpha-1}_{\pm}(x)$, just as for the ordinary Riesz distributions. This is clear from

$$\Box(t^2-r^2\pm i\epsilon)^{\alpha-2}=4(\alpha-1)(\alpha-2)(t^2-r^2\pm i\epsilon)^{\alpha-3}$$

valid for $1<\Re\alpha<2$, and then analytically extended. It follows that $\Box^l f=G^{-l}_{\pm}*f$ for appropriately convolvable f; and $\Box^{\alpha}$ for complex α can be defined by $\Box^{\alpha}f=G^{-\alpha}_{\pm}*f$.

We can perform the (covariant, if one wishes) Fourier transforms by the same method of analytic prolongation from the Fourier transforms of the $r^{2\alpha}$. The result is

$$\hat{G}^{\alpha}_{\pm}(p)=(2\pi)^{-2}e^{\mp i\pi\alpha}(p^2\mp i\epsilon)^{-\alpha}, \tag{9}$$

where $p^2=E^2-|\vec{p}|^2$. For instance,

$$\hat{G}^{0}_{-}(p)=1/4\pi^2,\quad \hat{G}^{1}_{-}(p)=\hat{D}_F(p)=\frac{-1}{4\pi^2(p^2+i\epsilon)},$$

as expected.[17] There is still an interesting duality at work here. Moreover,

$$G_{\pm}^{\alpha} * G_{\pm}^{\beta} = G_{\pm}^{\alpha+\beta}.$$

In summary, thanks to (rigorous) "Wick rotation," the structure of the causal Riesz distributions $G_{\pm}^{\alpha}$ is remarkably simpler than the structure of the retarded Riesz distributions $G_{\mathrm{ret}}^{\alpha}$. It largely parallels the positive signature case, vindicating Schwinger's contention on the "Euclidean" character of quantum field theory.[28]

We turn finally to the renormalization of the functionals $(t^2-r^2-i\epsilon)^{-l}$ with $l \geqslant 2$ from G_{-}^{α}. We may define the extension $[(t^2-r^2-i\epsilon)^{-2}]_{\mathrm{AR}}$, as a distribution, to be the second term on the right-hand side of the expansion

$$(t^2-r^2-i\epsilon)^{\kappa-2} =: \frac{-i\pi^2\delta(x)}{\kappa} + [(t^2-r^2-i\epsilon)^{-2}]_{\mathrm{AR}} + O(\kappa).$$

That is to say,

$$[(t^2-r^2-i\epsilon)^{-2}]_{\mathrm{AR}} = \lim_{\kappa\to 0} \frac{d}{d\kappa}[\kappa(t^2-r^2-i\epsilon)^{\kappa-2}].$$

Analogously,

$$(t^2-r^2-i\epsilon)^{\kappa-3} =: \frac{-i\pi^2\Box\delta(x)}{8\kappa} + [(t^2-r^2-i\epsilon)^{-3}]_{\mathrm{AR}} + O(\kappa), \tag{10}$$

as $\kappa\to 0$ defines $[(t^2-r^2-i\epsilon)^{-3}]_{\mathrm{AR}}$, and so on.

IV. LORENTZ COVARIANCE OF THE *T*-RENORMALIZATION

The action of an element Λ of the Lorentz group on $\mathbb{R}^{4n}$ is given by the tensorial representation

$$\Lambda^{\otimes n} x := (\Lambda x_1, \ldots, \Lambda x_n),$$

to be denoted Λ as well, according to custom. The action of the Lorentz group on functionals is defined by

$$\langle \Lambda f(x), \phi(x)\rangle \equiv \langle f(\Lambda x), \phi(x)\rangle := \langle f(x), \Lambda\phi(x)\rangle, \quad \text{with } \Lambda\phi(x) := \phi(\Lambda^{-1}x).$$

It follows that $\langle \Lambda f(x), \Lambda^{-1}\phi(x)\rangle = \langle f(x), \phi(x)\rangle$.

A Lorentz invariant functional fulfills

$$f(\Lambda x) = f(x). \tag{11}$$

[More generally, in the nonscalar case, f would have tensorial and/or spinorial character and one would have a covariant transformation

$$f(\Lambda x) = [D(\Lambda)f](x)$$

with $D(\Lambda)$ a finite dimensional representation of SL(2, $\mathbb{C}$)—making no notational distinction between belonging to the Lorentz group and to its cover—acting on functionals in the obvious way.]

Derivatives will transform according to the (tensor powers of the) contragredient representation: one has

$$x^{\alpha}\,\partial_{\alpha}(\Lambda\phi) = x^{\alpha}\,\partial_{\alpha}(\phi\circ\Lambda^{-1}) = x^{\alpha}[\Lambda^{-1}]^{\beta}{}_{\alpha}(\partial_{\beta}\phi)\circ\Lambda^{-1} = (\Lambda x)^{\beta}(\partial_{\beta}\phi)\circ\Lambda^{-1}.$$

In particular,

$$x^\alpha \partial_\alpha(\Lambda\phi)(0)=[\Lambda^{-1}x]^\beta \partial_\beta\phi(0), \tag{12}$$

that is to say $R_0^k\Lambda=\Lambda R_0^k$, and

$$\delta_\alpha(\Lambda x)=[\Lambda^{-1}x]_\alpha^\beta \delta_\beta(x). \tag{13}$$

Suppose that f is Lorentz invariant and a particular extension $T_w f$ to the whole of $\mathbb{R}^{4n}$ has been constructed, according to our scheme. *All* the extensions of f are given by

$$T_w f+\sum_{|\alpha|\leqslant k} a^\alpha \delta_\alpha, \tag{14}$$

with $\binom{4n+k}{k}$ coefficients a^α. Our goal is to show that a Lorentz invariant extension $T_w^{\mathrm{cov}} f$ can be obtained within the class of T extensions, advocated in this series of papers. Namely,

$$T_w^{\mathrm{cov}} f(\Lambda x)=T_w^{\mathrm{cov}} f(x),$$

with

$$T_w^{\mathrm{cov}} f=T_w f+\sum_{|\alpha|=k} a^\alpha \delta_\alpha, \tag{15}$$

for at most $\binom{4n-1+k}{k}$ coefficients a^α; so that the ambiguity (14) in all the smaller orders drops out.

By a theorem of Gårding and Lions,[29] the difference between two covariant extensions must be of the form $P(\Box)\delta$, where $P(\Box)$ is a polynomial in $\Box$; in our case, a monomial.

The proof is by direct computation; since $\Lambda f=f$, we get

$$\begin{aligned}
\langle\Lambda(T_w f)-T_w f,\phi\rangle &=\langle T_w f,\Lambda\phi\rangle-\langle T_w f,\phi\rangle\\
&=\langle f,T_w\Lambda\phi\rangle-\langle f,T_w\phi\rangle\\
&=\langle f,(1-w)R_0^{k-1}\Lambda\phi+wR_0^k\Lambda\phi\rangle-\langle f,(1-w)R_0^{k-1}\phi+wR_0^k\phi\rangle\\
&\overset{(12)}{=}\langle f,(1-w)\Lambda R_0^{k-1}\phi+w\Lambda R_0^k\phi\rangle-\langle f,(1-w)R_0^{k-1}\phi+wR_0^k\phi\rangle\\
&=\langle\Lambda f,(1-\Lambda^{-1}w)R_0^{k-1}\phi+\Lambda^{-1}wR_0^k\phi\rangle-\langle f,(1-w)R_0^{k-1}\phi+wR_0^k\phi\rangle\\
&\overset{(11)}{=}\langle f,(1-\Lambda^{-1}w)R_0^{k-1}\phi+\Lambda^{-1}wR_0^k\phi\rangle-\langle f,(1-w)R_0^{k-1}\phi+wR_0^k\phi\rangle\\
&=\langle f,(w-\Lambda^{-1}w)(R_0^{k-1}\phi-R_0^k\phi)\rangle=\sum_{|\alpha|=k}\langle f,(w-\Lambda^{-1}w)x^\alpha\rangle\frac{\partial_\alpha\phi(0)}{\alpha!}.
\end{aligned}$$

The integral $\langle f,(w-\Lambda^{-1}w)x^\alpha\rangle$ exists under the hypothesis we have made.

This shows that

$$\Lambda(T_w f)-T_w f=\sum_{|\alpha|=k} b^\alpha(\Lambda)\delta_\alpha,$$

with coefficients

$$b^\alpha(\Lambda)=(-)^k\langle f,(w-\Lambda^{-1}w)x^\alpha\rangle,$$

with $|\alpha|=k$. One also has

$$\sum_{|\alpha|=k} b^{\alpha}(\Lambda)\,\delta_{\alpha}=k\sum_{|\alpha|=k}\partial^{\alpha}\left[\frac{x^{\alpha}}{\alpha!}\int_0^1 \mathrm{d}t\,\frac{(1-t)^{k-1}}{t^{k+4n}}f\left(\frac{x}{t}\right)\left(w\left(\frac{x}{t}\right)-w\left(\frac{\Lambda x}{t}\right)\right)\right]$$
$$+(k+1)\sum_{|\beta|=k+1}\partial^{\beta}\left[\frac{x^{\beta}}{\beta!}\int_0^1 \mathrm{d}t\,\frac{(1-t)^{k}}{t^{k+4n+1}}f\left(\frac{x}{t}\right)\left(w\left(\frac{\Lambda x}{t}\right)-w\left(\frac{x}{t}\right)\right)\right].$$

The rest of the proof just follows the steps of the cohomological argument in Ref. 4: applying two Lorentz transformations, on use of (13)—and omitting indices—one obtains

$$b(\Lambda_1\Lambda_2)=\Lambda_2^{-1}b(\Lambda_1)+b(\Lambda_2), \tag{16}$$

where Λ_2^{-1} denotes the tensor antirepresentation. A solution for this equation is given by

$$b(\Lambda)=(1-\Lambda^{-1})a \tag{17}$$

with $a\in\mathbb{R}^{4k}$ independent of Λ. Actually (16) is a group 1-cocycle equation, for SL(2, $\mathbb{C}$), with values in the space carrying the contragredient representation, and because of the vanishing of the the first cohomology group $H^1(\mathrm{SL}(2,\mathbb{C});\mathbb{R}^{4k})$[30] its only solutions are of the trivial form (17).

Now, we conclude that, if a satisfies (17), then, in view of (13), formula (15) gives indeed a Lorentz invariant renormalization of f.

For logarithmic divergences, $b=0$, and, as $[\Lambda^{-1}]^{\otimes 0}=1$, one can take a arbitrary (this is *a priori* obvious in view of the Lorentz invariance of δ). The choice $a=0$ commends itself.

For higher order divergences, in principle one solves (17) for a and plugs the (in general nonunique) solution in (15). However, following a suggestion in Ref. 25, a wiser course can be devised. For simplicity, we take $n=1$ from now on. Then we can assume that f depends only on x^2.[31] It will be seen that only the symmetric part of the Lorentz content of a^{α} counts. Consider $\sigma(f)=6$, i.e., $k=2$, a quadratic divergence. We revert to a Lorentz quadri-index notation: $|\alpha|=2$, $\alpha\leftrightarrow(\mu_1\mu_2)$. It is found[6] that the totally symmetric part

$$a^{(\mu_1\mu_2)}=-\tfrac{1}{4}\langle f,(x^{\mu_1}x^{\mu_2}x^{\rho}\partial_{\rho}-x^2x^{(\mu_1}\partial^{\mu_2)})w\rangle,$$

is a possible choice for a; this choice is canonical in that $a^{\mu}_{\mu}=0$. Integrating by parts the previous expression, on account of $\partial_{\mu}f=2x_{\mu}f'$, we obtain

$$a^{(\mu_1\mu_2)}=\langle f,(x^{\mu_1}x^{\mu_2}-\tfrac{1}{4}x^2g^{\mu_1\mu_2})w\rangle.$$

In (15) with use of (3) we see cancellation of the first term on the right-hand side of this equation, and finally the canonical expression

$$\langle T_w^{\mathrm{cov}}f(x),\phi(x)\rangle=\left\langle f(x),\phi(x)-\phi(0)-w(x)\frac{\Box\phi(0)}{8}x^2\right\rangle,$$

emerges for the Lorentz-invariant distribution extending a quadratically divergent Lorentz-invariant functional f. This formula supplants the case $k=2$ of (3) in practice.

More generally, from the formulas in Ref. 6, we can derive, for $\sigma(f)=2m+4$ or $2m+5$:

$$\langle T_w^{\mathrm{cov}}f(x),\phi(x)\rangle=\left\langle f(x),\phi(x)-\phi(0)-\frac{\Box\phi(0)}{8}x^2-\cdots-w(x)\xi_m x^{2m}\right\rangle, \tag{18}$$

where

$$\xi_m:=\frac{2(2m-1)!!}{(2m+2)!!(2m)!}.$$

Concentrate now in T_μ^{cov}. In Sec. IV B of Paper I we proved that the Euclidean $\langle[\rho^{-4-2m}]_{\mathrm{AR}},\phi(x)\rangle$ is given by

$$\left\langle \rho^{-4-2m},\phi(x)-\phi(0)-\frac{\Delta\phi(0)}{8}\rho^2-\cdots-H(1-\rho)\xi_m\Delta^m\phi(0)\rho^{2m}\right\rangle.$$

This expression Wick-rotates into $\langle[(x^2\pm i\epsilon)^{-2-m}]_{\mathrm{AR}},\phi(x)\rangle$, which therefore is given by

$$\left\langle (x^2\pm i\epsilon)^{-2-m},\phi(x)-\phi(0)-\frac{\Box\phi(0)}{8}x^2-\cdots-H(1-\rho)\xi_m\Box^m\phi(0)(x^2)^m\right\rangle.$$

The conclusion is that $[(x^2\pm i\epsilon)^{-2-m}]_{\mathrm{AR}}=T^{\mathrm{cov}}_{\mu=1}(x^2\pm i\epsilon)^{-2-m}$. For negative powers of the Feynman propagator, the Bollini, Giambiagi, and Gonzales Domínguez analytic regularization and our canonical covariant renormalization using the *improved* subtraction $T_{\mu=1}$ give one and the same result.

This coincidence is extended to T_μ for all values of μ by introduction of a 't Hooft factor in the definition of $[(x^2\pm i\epsilon)^{-2-m}]_{\mathrm{AR}}$. The procedure will be clear from the examples in the next section.

V. COMPUTING EXAMPLES

The singularities of the powers of D_F are concentrated at the origin, so that the improved method of Epstein and Glaser is directly applicable here. Consider first the T_μ renormalization of $(t^2-r^2-i\epsilon)^{-2}$, corresponding to the "fish" diagram in the φ_4^4 model. We use the notations $[f]_{\mathrm{R}}:=[f]_{\mathrm{R},\mu}:=T_\mu^{\mathrm{cov}}f$. From (4) we obtain, in full analogy with the Euclidean case (see Sec. III of Paper I):

$$[(x^2-i\epsilon)^{-2}]_{\mathrm{R},\mu}=\tfrac{1}{2}\partial_\nu\left[x^\nu\frac{\log\mu^2(x^2-i\epsilon)}{(x^2-i\epsilon)^2}\right].$$

This is the very same result coming from analytical regularization: just check

$$\mu^{2\kappa}(x^2-i\epsilon)^{\kappa-2}=\frac{\mu^{2\kappa}}{2\kappa}\partial_\nu[x^\nu(x^2-i\epsilon)^{\kappa-2}],$$

and expand in κ the right-hand side. In conclusion,

$$[(t^2-r^2-i\epsilon)^{-2}]_{\mathrm{R},\mu}=[(t^2-r^2-i\epsilon)^{-2}]_{\mathrm{AR},\mu},$$

or $[(D_F)^2]_{\mathrm{R}}=[(D_F)^2]_{\mathrm{AR}}$, with this generalized definition of $[\,\cdot\,]_{\mathrm{AR}}$.

Consider now the "sunset" diagram in the same model. Have another look at Sec. III of Paper I; one obtains

$$[(x^2-i\epsilon)^{-3}]_{\mathrm{R},\mu}=3\sum_{|\beta|=3}\partial_\beta\left[\frac{x^\beta}{\beta!}\frac{\log(\mu^2(x^2-i\epsilon))}{(x^2-i\epsilon)^3}\right]-\frac{3i\pi^2}{8}\Box\delta(x).$$

Analogously, one checks by a longer but straightforward calculation,

$$\mu^{2\kappa}(x^2-i\epsilon)^{\kappa-3}=\frac{3\mu^{2\kappa}}{2\kappa(1-3\kappa+2\kappa^2)}\sum_{|\beta|=3}\partial_\beta\left(\frac{x^\beta(x^2-i\epsilon)^{\kappa-3}}{\beta!}\right).$$

It is clear from (10) that

$$3\,\partial_\beta\left(\frac{x^\beta(x^2-i\epsilon)^{\kappa-3}}{\beta!}\right)=-\frac{i\pi^2}{4}\Box\delta(x),$$

from which

$$\mu^{2\kappa}(x^2-i\epsilon)^{\kappa-3}=\frac{-i\pi^2\Box\delta(x)}{8\kappa}+[(x^2-i\epsilon)^{-3}]_{\mathrm{R},\mu}+O(\kappa).$$

Therefore $[(D_F)^3]_{\mathrm{R}}=[(D_F)^3]_{\mathrm{AR}}$.

For higher order powers of G_F similar arguments show that

$$[(D_F)^l]_{\mathrm{R}}=[(D_F)^l]_{\mathrm{AR}}$$

is true generally for $l\geqslant 2$.

Powers of the massive propagator D_F^m are renormalizable in our standard way, by use of (1), now applicable, and automatically Lorentz-covariance preserving. The scaling degree of the (powers of) propagators is the same in the massive and in the massless cases. One routinely finds, for instance,

$$[(D_F^m)^2]_{\mathrm{R}}(x)=-\frac{m^2}{32\pi^4}\partial_\mu x^\mu\left(\frac{K_1^2(m\sqrt{-x^2+i\epsilon})-K_0(m\sqrt{-x^2+i\epsilon})K_2(m\sqrt{-x^2+i\epsilon})}{-x^2+i\epsilon}\right).$$

VI. BPHZ RENORMALIZATION REVISITED

It is well known that for zero-mass models, the basic BPHZ scheme runs into trouble. This is due to the failure of $\partial^\mu\hat{f}(0)$ to exist for $|\mu|=k$, on account of the infrared problem. Now, one can try subtraction at some suitable external momentum $q\neq 0$, providing a mass scale. It is patent that this last subtraction will introduce in the Minkowskian context a noncovariance. This prompted Lowenstein and Zimmermann to introduce their ''soft mass insertions;'' [32] but that BPHZL method is quite awkward in practice.

A far simpler solution to the problem is now available to us. It comes from the observation in Paper I that the BPHZ method is ancillary to the Epstein and Glaser: from the definitions

$$\langle F[R_0^k f],F^{-1}[\phi]\rangle=\langle F[f],F^{-1}[R_0^k\phi]\rangle. \tag{19}$$

An expression such as $F[f]$ is *not a priori* meaningless: it is a well-defined functional on the linear subspace of Schwartz functions ϕ whose first moments $\int p^\alpha\phi(p)\,\mathrm{d}^d p$ up to order $k+1$ happen to vanish: this is the Fourier counterpart of the space of distributions on configuration space acting on Schwartz test functions vanishing up to order $k+1$ at the origin.

Now, one has

$$(x^\mu\phi)\check{}\,(p)=(-i)^{|\mu|}\,\partial^\mu\check{\phi}(p),$$

where μ denotes a multi-index; so that, in particular,

$$(x^\mu)\check{}\,(p)=(-i)^{|\mu|}(2\pi)^{d/2}\,\partial^\mu\delta(p).$$

Also,

$$\partial_\mu\phi(0)=(-i)^{|\mu|}(2\pi)^{-d/2}\langle p^\mu,\check{\phi}\rangle.$$

From this, with an integration by parts in the right-hand side of (19), we conclude

$$\langle F[R_0^k f],F^{-1}[\phi]\rangle=\langle R_0^k F[f],F^{-1}[\phi]\rangle;$$

that is to say, F and R_0^k *commute*. Thus the BPHZ subtraction rule in momentum space is equivalent to (1).

Now use (18) instead of (1), with employment of $w(x)=\exp(-iqx)$, with $q\neq 0$, which, as discussed earlier, is a perfectly good infrared regulator. From that follows the simple, obviously covariant, rule:

$$T_q^{\mathrm{cov}} f(p) = f(p) - \frac{\Box f(0) p^2}{8} - \cdots - \xi_m \Box^m f(q)\,(p^2)^m$$

for a Feynman amplitude f in momentum space. Note $\Box^m T_q^{\mathrm{cov}} f(q)=0$. The difference between two of these recipes is, as it should be, a Lorentz-invariant polynomial in p, of degree the divergence index.

VII. OUTLOOK

The ''missing link'' between the Epstein–Glaser subtraction method and the literature on prolongation of distributions found in Paper I has here been extended to the Minkowskian context. Before rendering in the language of T renormalization the full complexity of the construction of time-ordered products, and the main result of perturbative renormalization theory, one needs to handle the combinatorial aspects of diagrams with subdivergences. This we do in the next paper of the series (Paper III), using a variant of the Connes–Kreimer Hopf algebraic paradigm.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 9 SEPTEMBER 2003

Dynamical structure of irregular constrained systems

Olivera Mišković[a] and Jorge Zanelli
Centro de Estudios Científicos (CECS), Casilla 1469, Valdivia, Chile

(Received 5 February 2003; accepted 2 May 2003)

Hamiltonian systems with functionally dependent constraints (irregular systems), for which the standard Dirac procedure is not directly applicable, are discussed. They are classified according to their behavior in the vicinity of the constraint surface into two fundamental types. If the irregular constraints are multilinear (type I), then it is possible to regularize the system so that the Hamiltonian and Lagrangian descriptions are equivalent. When the constraints are power of a linear function (type II), regularization is not always possible and the Hamiltonian and Lagrangian descriptions may be dynamically inequivalent. It is shown that the inequivalence between the two formalisms can occur if the kinetic energy is an indefinite quadratic form in the velocities. It is also shown that a system of type I can evolve in time from a regular configuration into an irregular one, without any catastrophic changes. Irregularities have important consequences in the linearized approximation to nonlinear theories, as well as for the quantization of such systems. The relevance of these problems to Chern–Simons theories in higher dimensions is discussed. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1601299]

I. INTRODUCTION

Dirac's Hamiltonian analysis provides a systematic method for finding the gauge symmetries and the physical degrees of freedom of constrained systems like gauge theories and gravity.[1] Constraints arise through conditions of the form

$$\phi^r(z)\approx 0 \quad (r=1,\ldots,R), \tag{1}$$

where z are local coordinates in phase space Γ. In the most common cases of physical interest the ϕ's are functionally independent; these are the regular constrained systems. There are some exceptional cases in which functional independence is violated. In these *irregular systems* it is not always clear how to identify symmetries and true degrees of freedom. Moreover, the Hamiltonian and Lagrangian descriptions may not be equivalent in irregular systems.

Irregular systems are not necessarily intractable nor exotic. A common example is a relativistic massless particle ($p^\mu p_\mu=0$), which is irregular at the origin of momentum space ($p^\mu=0$). There are other physical circumstances in which regularity is violated, and not only for isolated states but on large portions of phase space where the system evolves. This is the case in Chern–Simons (CS) theories for dimensions $D\geqslant 5$ where, for some initial configurations, regularity can fail at all times and one is forced to live with this problem.

A CS Lagrangian describes a gauge theory for a certain Lie group G in a space–time of odd dimension. The construction is naturally invariant under diffeomorphisms and provides a nonstandard but otherwise acceptable description of gravity as a gauge theory.[2–5] Furthermore, CS theories are highly nonlinear, possess propagating degrees of freedom,[6] and have a very rich phase space structure with many different sectors, some of which describe irregular systems.[7]

In five-dimensional CS supergravity, it was observed that the linearized action around a certain anti–de Sitter background seems to have *one more degree of freedom* than the fully

nonlinear system.[8] This paradoxical behavior can be seen to arise from a violation of the regularity conditions among the symmetry generators of the theory in the region of phase space defined by the selected background.

Here we address different scenarios in which regularity conditions can be violated, how such systems can be handled in some cases, and why linearization may fail to approximate a nonlinear system faithfully. It is found that there are two main types of irregular constraints, multilinear (type I) and nonlinear (type II). The constraints of the first type can always be regularized, while type II constraints (of the form f^k, where f has a simple zero and $k>1$) can be regularized only if f is a second class function.

Constraints satisfying regularity conditions are sometimes referred to as *effective* constraints.[9] The issue of regularity (*effectiveness*) and its relevance for the equivalence between the Lagrangian and Hamiltonian formalisms has also been discussed in Refs. 10 and 11.

II. REGULARITY CONDITIONS

Consider a dynamical system in a phase space Γ with local coordinates $z^i \equiv (q,p)$ $(i=1,\ldots,2n)$. Conditions (1) define the constraint surface

$$\Sigma = \{\overline{z} \in \Gamma \,|\, \phi^r(\overline{z}) = 0 \;\; (r=1,\ldots,R)(R \leqslant 2n)\}. \tag{2}$$

Dirac's procedure guarantees that the system remains on the constraint surface during its evolution (for reviews, see Refs. 1,12–16). Choosing different coordinates on Γ may lead to different forms for the constraint functions whose functional independence is not obvious. The *regularity conditions* were designed by Dirac to test this.[17]

Regularity conditions (RCs): The constraints $\phi^r \approx 0$ are regular if and only if their small variations $\delta\phi^r$ evaluated on Σ define R linearly independent functions of δz^i.

To first order in δz^i, the variations of the constraints have the form

$$\delta\phi^r = J^r_i \delta z^i \quad (r=1,\ldots,R), \tag{3}$$

where $J^r_i \equiv \partial\phi^r/\partial z^i\,|_\Sigma$ is the Jacobian evaluated on the constraint surface. An equivalent definition of the RCs is:[13] *The set of constraints $\phi^r \approx 0$ is regular if and only if the Jacobian $J^r_i = \partial\phi^r/\partial z^i\,|_\Sigma$ has maximal rank, $\mathfrak{R}(\mathbf{J}) = R$.*

A simple classical mechanical example of functionally *dependent* constraints occurs in a two-dimensional phase space with coordinates (q,p) and constraints $\phi^1 \equiv q \approx 0$ and $\phi^2 \equiv pq \approx 0$. In this case, $\mathbf{J} = \left[\begin{smallmatrix} 1 & p \\ 0 & q \end{smallmatrix}\right]_{q=0}$ and $\mathfrak{R}(\mathbf{J}) = 1$.

A system of just one constraint can also fail the test of regularity. Consider, for example, the constraint $\phi = q^2 \approx 0$ in a two-dimensional phase space. In this case, $\mathbf{J} = (2q,0)_{q^2=0} = 0$ and $\mathfrak{R}(\mathbf{J}) = 0$. The same problem occurs with the constraint $q^k \approx 0$, for $k>1$, which has a zero of kth order on the constraint surface. This example illustrates that one *constraint* may be dependent on itself, while one *function* is, by definition, always functionally independent.

Equivalence: Different sets of constraints are said to be equivalent if they define the same constraint surface.

Note that this definition refers to the locus of constraints, not to equivalence of the resulting dynamics. Since the surface Σ is defined by the zeros of the constraints, while the regularity conditions depend on their derivatives, it is possible to replace a set of irregular ϕ's by an *equivalent* set of *regular* constraints $\tilde{\phi}$.

In the classification of irregular systems, two questions present themselves: what is the *nature* of the constraints that give rise to irregularity, and *where* the irregularities can occur. These issues are addressed in the following sections. A third question is whether a system can evolve from an initial state in which regularity holds, into an irregular configuration. This will be discussed in the last section.

A. Basic types of irregular constraints

Irregular constraints can be classified according to their behavior in the vicinity of the surface Σ. For example, linearly dependent constraints have Jacobian with constant rank R' throughout Σ, and

$$\phi^r \equiv J_i^r(\overline{z})(z^i - \overline{z}^i) \approx 0, \quad \mathfrak{R}(\mathbf{J}) = R' < R. \tag{4}$$

These constraints are regular systems in disguise simply because $R - R'$ constraints are redundant and should be discarded. The subset with R' linearly independent constraints gives the correct description. For example, the linearly dependent constraints $\phi^1 = z$ and $\phi^2 = 2z$ are clearly in this category. Apart from this trivial case, two main types of truly irregular constraints, which do not possess a linear approximation in the vicinity of some points of Σ, can be distinguished.

Type I. Multilinear constraints: Consider the constraint

$$\phi \equiv \prod_{i=1}^{M} f_i(z) \approx 0, \tag{5}$$

where the functions f_i have simple zeros. Each factor defines a surface of codimension 1,

$$\Sigma_i \equiv \{\overline{z} \in \Gamma \,|\, f_i(\overline{z}) = 0\}, \tag{6}$$

and Σ is the collection of all surfaces, $\Sigma = \cup \Sigma_i$. The rank of Jacobian of ϕ is reduced at intersections

$$\Sigma_{ij} \equiv \Sigma_i \cap \Sigma_j . \tag{7}$$

Thus, the RCs hold everywhere on Σ, except at the intersections Σ_{ij}, where ϕ has zeros of higher order. Note that the intersections (7) also include the points where more than two Σ's overlap.

Type II. Nonlinear constraints: Consider the constraint of the form

$$\phi \equiv [f(z)]^k \approx 0 \quad (k > 1), \tag{8}$$

where the function $f(z)$ has a simple zero. This constraint has a zero order k in the vicinity of Σ, its Jacobian vanishes on the constraint surface and, therefore, the RCs fail (here we assume $k > 1$ in order to avoid infinite values for $\partial\phi/\partial z^i$ on Σ). It could seem harmless to replace ϕ by the equivalent regular constraint $f(z) \approx 0$, but it turns out that this may change the dynamics of original system, as we show below.

Types I and II are the two fundamental generic classes of irregular constraints. In general, there can be combinations of them occurring simultaneously near a constraint surface, as in constraints of the form $\phi = [f_1(z)]^2 f_2(z) \approx 0$, etc.

B. Classification of constraint surfaces

The previous classification refers to the way in which ϕ approaches zero. Now we will discuss *where* regularity can be violated. The rank of the Jacobian $\partial\phi^r/\partial z^i$ need not be constant throughout Σ: suppose one eigenvalue of the Jacobian vanishes on a submanifold $\Sigma_0 \subset \Sigma$. On Σ_0 regularity is violated, while it still holds on the rest of Σ. Thus, barring accidental degeneracies such as linearly dependent constraints, one of these three situation may present themselves.

(A) *The RCs are satisfied everywhere on the constraint surface:* $\mathbf{J}$ has maximal rank throughout Σ (regular systems).

(B) *The RCs fail everywhere on the constraint surface:* $\mathbf{J}$ has constant rank $R' < R$ on Σ.

(C) *The RCs fail on* Σ_0: $\mathfrak{R}(\mathbf{J})|_{\Sigma_0} = R' < R$, while $\mathfrak{R}(\mathbf{J}) = R$ elsewhere on Σ.

In the last case, the constraint surface can be decomposed into two nonoverlapping sets Σ_0 and Σ_R. Then, the rank of the Jacobian jumps from $\mathfrak{R}(\mathbf{J})=R$ on Σ_R, to $\mathfrak{R}(\mathbf{J})=R'$ on Σ_0. Although the functions ϕ^r are continuous and differentiable, this is not sufficient for regularity. Irregular cases are illustrated by the following examples.

In a $(2+N)$-dimensional phase space $(q,p,z^1,\ldots,z^N)$, the constraints $\phi^1\equiv q-p\approx 0$ and $\phi^2\equiv qp\approx 0$ are irregular on the whole constraint surface $\{(0,0,z^1,\ldots,z^N)\}$, where the Jacobian has rank $\mathfrak{R}(\mathbf{J})=1$. Note that these constraints are always irregular, although the functions $q+p$ and qp are functionally independent everywhere except for $q=p$, which happens to be the case at the constraint surface.

An example having both regular and irregular sectors is a massless relativistic particle in Minkowski space with phase space (q^μ,p_ν). The constraint $\phi\equiv p^\mu p_\mu\approx 0$ has Jacobian $\mathbf{J}=(0,2p^\mu)_{\phi=0}$, and its rank is one everywhere, except at the apex of the cone, $p^\mu=0$, where the light cone is not differentiable and the Jacobian has rank zero.

The lack of regularity, however, is not necessarily due to the absence of a well-defined smooth tangent space for Σ. Consider, for example, the multilinear constraint

$$\phi(x,y,z)=(x-1)(x^2+y^2-1)\approx 0. \tag{9}$$

Here the constraint surface Σ is composed of two submanifolds: the plane $\Pi=\{(x,y,z)|x-1\approx 0\}$, and the cylinder $C=\{(x,y,z)|x^2+y^2-1\approx 0\}$, which are tangent to each other along the line $L=\{(x,y,z)|x=1,y=0,z\in\mathbb{R}\}$. The Jacobian on Σ is

$$\mathbf{J}=(3x^2+y^2-2x-1,2y(x-1),0)_{\phi=0} \tag{10}$$

and its rank is 1 everywhere, except on L, where it is zero. The constraint ϕ is irregular on this line. However, the tangent vectors to Σ are well defined there. The irregularity arises because ϕ is a multilinear constraint of the type described by (5) and has two simple zeros overlapping on L. The equivalent set of regular constraints on L is $\{\phi_\Pi=x-1\approx 0,\phi_C=x^2+y^2-1\approx 0\}$, as we will see below.

III. TREATMENT OF IRREGULAR SYSTEMS

In what follows regular systems and linearly dependent constraints will not be discussed. They are either treated in standard texts, or they can be trivially reduced to the regular case.

A. Multilinear constraints

Consider a system of type I, as in Eq. (5). In the vicinity of an irregular point where only two surfaces (6) intersect, say Σ_1 and Σ_2, the constraint $\phi\approx 0$ is equivalently described by the set of regular constraints

$$f_1\approx 0,\quad f_2\approx 0. \tag{11}$$

This replacement generically changes the Lagrangian of the system, and the orbits, as well. Suppose the original canonical Lagrangian is

$$L(q,u)=p_i\dot{q}^i-H(q,p)-u\phi(q,p), \tag{12}$$

where H is the Hamiltonian containing all regular constraints. Replacing ϕ by (11), gives rise to an effective Lagrangian

$$L_{12}(q,v)=p_i\dot{q}^i-H(q,p)-v^1f_1(q,p)-v^2f_2(q,p) \tag{13}$$

defined on Σ_{12}. Thus, instead of the *irregular* Lagrangian (12) defined on the whole Σ, there is a collection of *regularized* effective Lagrangians defined in the neighborhood of the different intersections of Σ_i's. For each of these regularized Lagrangians, the Dirac procedure can be carried out to the end.

Let us illustrate this with the example of a Lagrangian in a $(2+N)$-dimensional configuration space $(x,y,q^1,\ldots,q^N)$,

$$L=\frac{1}{2}\sum_{k=1}^{N}(\dot{q}^k)^2+\frac{1}{2}(\dot{x}^2+\dot{y}^2)-\lambda xy. \tag{14}$$

This Lagrangian describes a free particle moving on the set

$$\{(x,y,q^k)\in\mathbb{R}^{N+2}|xy=0\}\subset\mathbb{R}^{N+2}, \tag{15}$$

which is the union of two $(N+1)$-dimensional planes where x and y vanish, respectively. The constraint surface defined by $xy=0$ can be divided into the following sets:

$$\begin{aligned}\Sigma_1&=\{(x,0,q^k;p_x,p_y,p_k)|x\neq 0\},\\ \Sigma_2&=\{(0,y,q^k;p_x,p_y,p_k)|y\neq 0\},\\ \Sigma_{12}&=\{(0,0,q^k;p_x,p_y,p_k)\}.\end{aligned} \tag{16}$$

The constraint is regular on $\Sigma_1\cup\Sigma_2$, while on Σ_{12} it is irregular and can be exchanged by $\{\phi_1=x\approx 0,\ \phi_2=y\approx 0\}$. The corresponding regularized Lagrangians are

$$\begin{aligned}L_1&=\frac{1}{2}\sum_{k=1}^{N}(\dot{q}^k)^2+\frac{1}{2}\dot{x}^2,\\ L_2&=\frac{1}{2}\sum_{k=1}^{N}(\dot{q}^k)^2+\frac{1}{2}\dot{y}^2,\\ L_{12}&=\frac{1}{2}\sum_{k=1}^{N}(\dot{q}^k)^2,\end{aligned} \tag{17}$$

and the Lagrange multipliers have dropped out, so the regularized Lagrangians describe physical degrees of freedom only—as expected.

The corresponding regularized Hamiltonians are

$$\begin{aligned}H_1&=\frac{1}{2}\sum_{k=1}^{N}p_k^2+\frac{1}{2}p_x^2,\\ H_2&=\frac{1}{2}\sum_{k=1}^{N}p_k^2+\frac{1}{2}p_y^2,\\ H_{12}&=\frac{1}{2}\sum_{k=1}^{N}p_k^2,\end{aligned} \tag{18}$$

which are defined in the corresponding reduced manifolds of phase space (obtained after completing the Dirac procedure):

$$\tilde{\Sigma}_1=\{(x,0,q^k;p_x,0,p_k)|x\neq 0\},$$

$$\tilde{\Sigma}_2=\{(0,y,q^k;0,p_y,p_k)|y\neq 0\}, \tag{19}$$

$$\tilde{\Sigma}_{12}=\{(0,0,q^k;0,0,p_k)\}.$$

It is straightforward to generalize the proposed treatment when more than two surfaces Σ_i overlap.

Evolution of a multilinearly constrained system: Since in the presence of a multilinear constraint there are regions of the phase space where the Jacobian has different rank, a question arises about the evolution of this system. Can the system evolve from a generic configuration in a region of maximal rank, reaching a configuration of lower rank in finite time? In the case that that were possible, what happens with the system afterwards? (This problem should not be confused with the issues arising in degenerate systems.[18–20])

To answer this question let us consider the simple example discussed above (14), for $N=1$,

$$L=\tfrac{1}{2}(\dot{x}^2+\dot{y}^2+\dot{z}^2)-\lambda xy. \tag{20}$$

In the regions Σ_1 and Σ_2 [see Eqs. (16)], the rank is maximal and the free particle can move freely along the x- or y-axis, respectively.

Suppose that the initial state is

$$x(0)=a>0, \quad y(0)=0, \quad z(0)=0, \quad \dot{x}(0)=-v<0, \quad \dot{y}(0)=0, \quad \dot{z}(0)=0, \tag{21}$$

so that the particle is moving on Σ_1, with finite speed along the x-axis towards $x=0$ on Σ_{12}. The evolution is given by $\overline{x}(t)=a-vt$, $\overline{y}(t)=0$, $\overline{z}(t)=0$ and the particle clearly reaches $x=0$ in a finite time ($T=a/v$). What happens then? According to the evolution equation, for $x<0$ the trajectory takes the form $\overline{x}(t)=a'-v't$, $\overline{y}(t)=0$, $\overline{z}(t)=0$, however the action would be infinite unless $a=a'$ and $v=v'$. Therefore, the particle continues unperturbed past beyond the point where the RCs fail. So, the irregular surface is not only reachable in a finite time, but it is crossed without any observable effect on the trajectory.

From the point of view of the trajectory in phase space, it is clear that the initial state $(a,0,0;-v,0,0)$ lies on the surface $\tilde{\Sigma}_1$, and at $t=T$ the system reaches the point $(0,0,0;-v,0,0)$, which *does not lie on* the surface $\tilde{\Sigma}_{12}=\{(0,0,z;0,0,p_z)\}$.

While it is true that at $t=T$ the Jacobian changes rank, it would be incorrect to conclude that the evolution suffers a jump since the dynamical equations are perfectly valid there. In order to have significant change in dynamics, the Jacobian should change its rank in an open set.

B. Nonlinear constraints

Let us now turn to the case of irregular systems of type II. As we will show, it is possible to replace a nonlinear irregular constraint by an equivalent linear one without changing the dynamical contents of the theory, provided the linear constraint is second class. Otherwise, the resulting Hamiltonian dynamics will be, in general, inequivalent to that of the original Lagrangian system.

In order to illustrate this point, consider a system given by the Lagrangian

$$L(q,u)=\tfrac{1}{2}\gamma_{ij}\dot{q}^i\dot{q}^j-u[f(q)]^k, \tag{22}$$

where $k>1$ and

$$f(q)\equiv c_i q^i \neq 0, \quad i=1,\ldots,N. \tag{23}$$

Here we assume the metric γ_{ij} to be constant and invertible, and the coefficients c_i are also constant. The Euler–Lagrange equations describe a free particle in an N-dimensional space, with time evolution $\overline{q^i}(t)=v_0^i t+q_0^i$, where $u(t)$ is a Lagrange multiplier. This solution is determined by $2N$ initial conditions, $q^i(0)=q_0^i$ and $\dot{q}^i(0)=v_0^i$ subject to the constraints $c_i q_0^i=0$ and $c_i v_0^i=0$. Thus, the system possesses $N-1$ physical degrees of freedom.

In the Hamiltonian approach this system has a primary constraint $\pi\equiv \partial L_2/\partial \dot{u}\approx 0$ whose preservation in time leads to the secondary constraint

$$\phi\equiv[f(q)]^k\approx 0. \tag{24}$$

According to (8), this is a nonlinear constraint and there are no further constraints. As a consequence, the system has only two first class constraints $\{\pi\approx 0,\ f^k\approx 0\}$, and $N-1$ degrees of freedom, as found in the Lagrangian approach.

On the other hand, if one chooses instead of (24), the equivalent linear constraint

$$f(q)=c_i q^i\approx 0, \tag{25}$$

then its time evolution yields a *new* constraint,

$$\chi(p)\equiv \gamma^{ij}c_i p_j\approx 0. \tag{26}$$

Now, since

$$\{f,\chi\}=\gamma^{ij}c_i c_j\equiv\|c\|^2, \tag{27}$$

two cases can be distinguished.

(1) If $\|c\|=0$, there are three first class constraints, $\pi\approx 0$, $f\approx 0$, and $\chi\approx 0$, which means that the system has $N-2$ physical degrees of freedom. In this case, substitution of (24) by the equivalent linear constraint (25), yields a *dynamically inequivalent* system.
(2) If $\|c\|\neq 0$, then $f\approx 0$ and $\chi\approx 0$ are second class, while $\pi\approx 0$ is first class, which leaves $N-1$ physical degrees of freedom and the substitution does not change the dynamics of the system.

Thus, if $f^k\approx 0$ is irregular, replacing it by the regular constraint $f\approx 0$ changes the dynamics if f is a first class function, but it gives the correct result if it is a second class function.

Note that in the Lagrangian description there is no room to distinguish first and second class constraints, so it would seem like the value of $\|c\|$ did not matter. However, the inequivalence of the substitution can be understood in the Lagrangian analysis as well. Suppose that it were permissible to exchange the constraint $f^k\approx 0$ by $f\approx 0$ in the Lagrangian. Then, instead of (22), one would have

$$\tilde{L}(q,u)=\tfrac{1}{2}\gamma_{ij}\dot{q}^i\dot{q}^j-uf(q). \tag{28}$$

It can be easily checked that (28) yields $N-2$ degrees of freedom when $\|c\|=0$, and $N-1$ degrees of freedom when $\|c\|\neq 0$, which agrees with the results obtained in the Hamiltonian analysis. Note that the substitution of f^k by f modifies the dynamics only if $\gamma^{ij}c_i c_j=0$, but this can happen nontrivially only if the metric γ_{ij} is not positive definite.

In general, a nonlinear irregular constraint $\phi\approx 0$ has a multiple zero on the constraint surface Σ, which means that its gradient vanishes on Σ as well. An immediate consequence of $(\partial\phi/\partial z^i)\approx 0$, is that ϕ commutes with all *finite* functions on Γ,

$$\{\phi,F(z)\}\approx 0. \tag{29}$$

As a consequence, $\phi \approx 0$ is first class and is always preserved in time,

$$\dot{\phi} \approx 0. \tag{30}$$

On the other hand, a nonlinear constraint cannot be viewed as a symmetry generator simply because it does not generate any transformation,

$$\delta_\varepsilon z^i = \{z^i, \varepsilon \phi\} \approx 0. \tag{31}$$

Consistently with this, ϕ cannot be gauge-fixed, as there is no finite function $\mathcal{P}$ on Γ such that

$$\{\phi, \mathcal{P}\} \neq 0. \tag{32}$$

In this sense, a nonlinear first class constraint that cannot be gauge-fixed, cancels only half a degree of freedom. The other half degree of freedom cannot be cancelled because the gauge-fixing function does not exist and, in particular, it cannot appear in the Hamiltonian. Although the features (29)–(32) allow counting the degrees of freedom in a theory, these systems are pathological and their physical relevance is questionable since their Lagrangians cannot be regularized.

When a nonlinear constraint $\phi \approx 0$ can be exchanged by a regular one, the Lagrangian is regularized as in the case of multilinear constraints. For example, the system (22) with $\|c\| \neq 0$ has Hamiltonian

$$H = \tfrac{1}{2}\gamma^{ij} p_i p_j + \lambda \pi + u f(q), \tag{33}$$

where $f = c_i q^i$ will turn out to be a second class constraint. The corresponding regularized Lagrangian is

$$L_{\text{reg}} = \tfrac{1}{2}\gamma_{ij}\dot{q}^i \dot{q}^j - u f(q), \tag{34}$$

which coincides with $\tilde{L}$, Eq. (28), as expected.

In Refs. 10 and 11 irregular systems of the type II were discussed. It was pointed out that there was a possible loss of dynamical information in some cases. From our point of view, it is clear that this would occur when f is a first class function.

IV. LINEARIZATION OF IRREGULAR SYSTEMS

It has been observed in five-dimensional Chern–Simons theory, that the effective action for the linearized perturbations of the system around certain backgrounds seems to have more degrees of freedom than the fully nonlinear theory.[8] This is puzzling since the heuristic picture is that the degrees of freedom of a system correspond to the small perturbations around a local minimum of the action, and therefore the number of degrees of freedom should not change when the linearized approximation is used.

In view of the discussion in the preceding section, it is clear that a possible solution of the puzzle lies in the fact that substituting a nonlinear constraint by a linear one may change the dynamical features of the theory. But the problem with linear approximations is more serious: the linearized approximation retains only up to quadratic and bilinear terms in the Lagrangian, which give linear equations for the perturbations. Thus, irregular constraints in the vicinity of the constraint surface are erased in the linearized action. The smaller number of constraints in the effective theory can lead to the wrong conclusion that the effective system possess more degrees of freedom than the unperturbed theory. The lesson to be learned is that the linear approximation is not valid in the part of the phase space where the RCs fail.

This is illustrated by the same example discussed earlier (22). One can choose as a background the solution $(\overline{q}^1, \ldots, \overline{q}^N, \overline{u})$, where $\overline{q}^i(t) = q_0^i + v_0^i t$ satisfies the constraint

$$c_i \overline{q}^i = 0, \tag{35}$$

and $\overline{u}(t)$ is an arbitrarily given function. This describes a free particle moving in the $(N-1)$-dimensional plane defined by (35). The linearized effective Lagrangian, to second order in the small perturbations $s^i=q^i-\overline{q}^i(t)$ and $w=u-\overline{u}(t)$, has the form

$$L_{\text{eff}}(s,w)=\tfrac{1}{2}\gamma_{ij}(v_0^i+\dot{s}^i)(v_0^j+\dot{s}^j)-\overline{u}(c_is^i)^2, \tag{36}$$

and the equations of motion are

$$\ddot{s}^i+\Gamma^i_j(t)\,s^j=0, \quad i=1,\ldots,N, \tag{37}$$

where $\Gamma^i_j\equiv 2\overline{u}\,\gamma^{ik}c_kc_j$ is the eigenfrequency matrix. Since $\overline{u}$ is not a dynamical variable, it is not varied and the nonlinear constraint $(c_is^i)^2=0$ is absent from the linearized equations. The system described by (37) possesses N physical degrees of freedom, that is, one degree of freedom more than the original nonlinear theory (22).

The only indication that one of these degrees of freedom has a nonphysical origin is the following: If $\|c\|\neq 0$, splitting the components of s^i along c_i and orthogonal to c_i as

$$s^i(t)\equiv s(t)\,\gamma^{ij}c_j+s^i_\perp(t), \tag{38}$$

gives rise to the projected equations

$$\ddot{s}^i_\perp=0, \tag{39}$$

$$\ddot{s}+2\overline{u}(t)\|c\|^2s=0. \tag{40}$$

The $N-1$ components of $s^i_\perp(t)$ obey a deterministic second order equation, whereas $s(t)$ satisfies an equation which depends on an indeterminate arbitrary function $\overline{u}(t)$. The dependence of $s=\overline{s}(t,\overline{u}(t))$ on the background Lagrange multiplier $\overline{u}$ is an indication that s is a nonphysical degree of freedom, since u was an arbitrary function to begin with. This is not manifest in Eq. (40), where $\overline{u}$ is a fixed function and, from a naive point of view, $s(t)$ is determined by the same equation, regardless of the physically obscure origin of the function $\overline{u}$. It is this naive analysis that leads to the wrong conclusion indicated above.

Let us emphasize that a linearized theory may be consistent by itself, but it is not necessarily a faithful approximation of a nonlinear theory.

One way to avoid the inconsistencies between the original theory and the linearized one would be to first regularize the constraints (if possible) and then linearize the corresponding regular Lagrangian.

V. CHERN–SIMONS THEORIES

Hamiltonian structure of CS theories has been studied in Ref. 6. The phase space of a CS theory in $D=2n+1$ space–time dimensions, invariant under N-parameter gauge group, is defined by canonically conjugate pairs of fields $(A^a_i(x,t),\pi^i_a(x',t))$, where $a=1,\ldots,N$ and x^i $(i=1,\ldots,2n)$ are the local coordinates on a spatial section. The CS Hamiltonian density is given by

$$\mathcal{H}=A^a_0\,\tilde{G}_a+u^a_i\phi^i_a, \tag{41}$$

where $u^a_i(x,t)$ and $A^a_0(x,t)$ are Lagrange multipliers for the constraints

$$\phi^i_a\equiv\pi^i_a-\mathcal{L}^{\,i}_a(A^b_j)\approx 0, \tag{42}$$

$$G_a=g_{aa_1\cdots a_n}F^{a_1}\wedge\cdots\wedge F^{a_n}\approx 0. \tag{43}$$

Here $G_a\equiv \mathrm{d}^{2n}x\,\tilde{G}_a$, g is a symmetric tensor of rank $n+1$, invariant under action of a gauge group, and $F=\mathrm{d}A+A\wedge A$ is the curvature two-form associated to the gauge field one-form A.

Constraints ϕ_a^i are regular because they are linear in momenta. Thus, the regularity of CS theories is determined by momentum-independent constraints G_a. Their small variations, $\delta G_a = \mathbf{J}_{ab} D \delta A^b$, evaluated at $G_a = 0$, give the $(2n-2)$-form $\mathbf{J}_{ab}$, which can be identified as the Jacobian,

$$\mathbf{J}_{ab} \equiv n\, g_{aba_2\cdots a_n} F^{a_2} \wedge \cdots \wedge F^{a_n}. \tag{44}$$

According to Dirac's definition, sufficient and necessary condition for G_a to be regular is

$$\mathfrak{R}(\mathbf{J}_{ab}) = N. \tag{45}$$

Since $\mathbf{J}_{ab}$ is field dependent, its rank may change in space. In particular, for a pure gauge configuration $F=0$, and $\mathbf{J}_{ab}$ has rank zero. For other configurations, the rank of Jacobian can range from zero to N, and the irregularities are always of multilinear type because in the expression (43) the phase space coordinates A_i^a occur only linearly.

In general, a non-Abelian CS theory for $D \geqslant 5$ possesses a nonvanishing number of physical degrees of freedom[6]

$$f_{2n+1}(N) = nN - n - N \quad (N \geqslant 2) \tag{46}$$

in regular and *generic* cases.[20] Therefore, in CS theories, the study of dynamics requires not only the analysis of regularity, but also of genericity. In spite of the fact that both conditions are expressed in terms of the same matrix Ω_{ab}^{ij}, they are independent. For example, the extreme case of $F=0$ is both irregular and degenerate, but there are examples in CS supergravity which are generic and irregular.[8] The opposite case occurs in a five-dimensional CS theory based on $G_1 \times G_2$ for particular choice of invariant tensor. In this case, there exist configurations which are regular but degenerate. Take the group indices as $a=(r,\alpha)$ corresponding to G_1 and G_2, respectively, and invariant tensor as $g_{rs1} = g_{rs}$ and $g_{\alpha\beta\bar{1}} = g_{\alpha\beta}$ (both invertible). Then the configuration $F^a = (f^1\, \mathrm{d}x^1 \wedge \mathrm{d}x^2, h^{\bar{1}}\, \mathrm{d}x^3 \wedge \mathrm{d}x^4)$ is regular and degenerate. Indeed, $\mathbf{J}_{ab} = \begin{pmatrix} g_{rs} f^1 & 0 \\ 0 & g_{\alpha\beta} h^{\bar{1}} \end{pmatrix}$ is regular, while Ω_{ab}^{ij} with nonvanishing components $\Omega_{rs}^{34} = g_{rs} f^1$ and $\Omega_{\alpha\beta}^{12} = g_{\alpha\beta} h^{\bar{1}}$ has $2N$ zero modes and is therefore degenerate.

As a consequence of existence of both regularity and genericity issues, the regularization problem is much more delicate in CS theories.

VI. COMMENTS

A. Dirac conjecture

Dirac conjectured that *all* first class constraints generate gauge symmetries.[17] It was shown that Dirac's conjecture is not true for first class constraints of the form f^k $(k>1)$, and following from $\dot{f} \approx 0$.[14,15] Therefore, for systems with nonlinear constraints, the conjecture does not work and they generically provide counterexamples of it.[13,21,22]

From the point of view of irregular systems, it is clear that Dirac's conjecture fails for nonlinear constraints because they do not generate any local transformation, cf. Eq. (31). In Refs. 10 and 11 it was observed that Dirac's conjecture may not hold in the presence of irregular constraints of type II.

In the case of multilinear constraints, however, Dirac's conjecture holds. The fact that at irregular points the constraints do not generate any transformation only means that these are fixed points of the gauge transformation.

B. Quantization

Although, in view of the above discussion, it is possible to deal systematically with classical theories containing irregular constraints, there may be severe problems in their quantum description. Consider a path integral of the form

$$Z \sim \int [\mathrm{d}q][\mathrm{d}p][\mathrm{d}u] \exp i[p\dot{q} - H(q,p) - u\phi(q,p)], \tag{47}$$

where $\phi = [f(q,p)]^k$ is a nonlinear constraint. Integration on u yields to $\delta(f^k)$, which is not well defined for a zero of order $k>1$, making the quantum theory ill defined. Only if the nonlinear constraint could be exchanged by the regular one, $f(q,p)\approx 0$, the quantum theory could be saved. An example of this occurs in the standard approach for QED, where it is usual practice to introduce the nonlinear gauge fixing term $u(\partial_i A^i)^2$ in order to fix the primary constraint $\pi^0 \equiv (\delta I_{ED}/\delta \dot{A}_0) \approx 0$. Since the gauge condition $f(A) = \partial_i A^i(x) \approx 0$ is a second class constraint, its substitution by a regular constraint does not change its dynamical structure.

VII. SUMMARY

We have discussed the dynamics and evolution of a system possessing constraints which may violate the regularity conditions (functional independence) on some subsets of the constraint surface Σ. These so-called irregular systems are seen to arise generically because of nonlinearities in the constraints and can be classified into two families: multilinear (type I) and nonlinear (type II).

Type I constraints are of the form $\phi = \Pi f_i(z)$, where f_i possess simple zeros. These constraints violate the regularity conditions (RCs) on sets of measure zero on the constraint surface Σ.

Type I constraints can be exchanged by equivalent constraints which are regular giving an equivalent dynamical system.

Type II constraints are of the form $\phi = f^k$ $(k>1)$ where f has a simple zero. They violate the RCs on sets of nonzero measure on Σ.

A type II constraint can be replaced by an equivalent linear one only if the latter is second class; if the equivalent linear constraint is first class, substituting it for the original constraint would change the system.

In general, the orbits can cross the configurations where the RCs are violated without any catastrophic effect for the system. If the symplectic form degenerates at the irregular points, additional analysis is required.

The naive linearized approximation of an irregular constrained system generically changes it by erasing the irregular constraints. In order to study the perturbations around a classical orbit in an irregular system, it would be necessary to first regularize it (if possible) and only then do the linearized approximation.

Chern–Simons theories possess irregular and regular sectors. This problem is independent of the presence of degeneracies in the symplectic form, making the regularization problem much more complex.

ACKNOWLEDGMENTS

We are grateful to Milutin Blagojević, Marc Henneaux, and Claudio Teitelboim for enlightening and helpful comments, and specially to Ricardo Troncoso for many useful discussions, insights, and friendly criticisms. We would also like to thank Josep María Pons and Antonio García-Zenteno for bringing their work to our attention and for indicating its relevance to ours. [18] These questions have a similar ring to those presented in the case of a degenerate dynamical system, in which the symplectic matrix changes its rank (Ref. 19): Is it possible for a system in a generic initial configuration, to reach (in a finite time) a configuration where the symplectic form has lower rank? That problem is unrelated to the one discussed here and can be treated independently. In the present case it is the functional independence of the constraints that fails; in the degenerate dynamical systems it is the symplectic structure that breaks down.

[20] A configuration is called generic if the symplectic form Ω is invertible. Otherwise, it is called degenerate. In the case of CS theories, the symplectic form is given by $\mathrm{d}^{2n}x\,\Omega^{ij}_{ab}\equiv \mathrm{d}x^i\wedge \mathrm{d}x^j\wedge J_{ab}$. In these theories, the generic configurations are those for which (i) the $2n$ independent vectors $(\mathbf{V}_i)^a_j=F^a_{ij}$ are the only zero modes of Ω^{ij}_{ab}, and (ii) the rank of Ω^{ij}_{ab} is largest, $\mathfrak{R}(\Omega^{ij}_{ab})=2nN-2n$.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 9 SEPTEMBER 2003

Detecting ill posed boundary conditions in general relativity

Gioel Calabrese and Olivier Sarbach

(Received 18 March 2003; accepted 5 May 2003)

A persistent challenge in numerical relativity is the correct specification of boundary conditions. In this work we consider a many-parameter family of symmetric hyperbolic initial-boundary value formulations for the linearized Einstein equations and analyze its well posedness using the Laplace–Fourier technique. By using this technique ill posed modes can be detected and thus a necessary condition for well posedness is provided. We focus on the following types of boundary conditions: (*i*) boundary conditions that have been shown to preserve the constraints, (*ii*) boundary conditions that result from setting the ingoing constraint characteristic fields to zero, and (*iii*) boundary conditions that result from considering the projection of Einstein's equations along the normal to the boundary surface. While we show that in case (*i*) there are no ill posed modes, our analysis reveals that, unless the parameters in the formulation are chosen with care, there exist ill posed constraint violating modes in the remaining cases. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1599056]

I. INTRODUCTION

Obtaining a long time convergent numerical simulation of a binary black hole space–time in domains with artificial boundaries continues to be a challenge in numerical relativity and one which has recently received a substantial amount of attention, notably in the case of hyperbolic formulations (see Refs. 1 and 2 for reviews). The challenge remains in part because of the difficulty in specifying boundary conditions. It has been recognized[3–12] that the boundary conditions have to satisfy two important requirements. First, they have to preserve the constraints. By this we mean that they must guarantee that if the constraints are satisfied initially they are also satisfied at later times. We refer to boundary conditions that satisfy this property as constraint preserving boundary conditions (CPBCs). Second, the boundary conditions have to be such that the resulting initial-boundary value problem (IBVP) is well posed. This means that given initial and boundary data a unique solution exists and that at each fixed time the solution depends continuously on the data. Well posedness is a necessary condition for the construction of consistent and stable finite difference schemes.[13,14]

When the evolution equations are in symmetric hyperbolic form one usually specifies maximal dissipative boundary conditions.[15] Under certain technical assumptions, these conditions guarantee that the resulting IBVP is well posed.[16,17] Using maximal dissipative boundary conditions, Friedrich and Nagy[3] were able to find well posed CPBCs for a particular formulation of the full nonlinear vacuum equations. However, most of the hyperbolic formulations used in numerical relativity are based on evolution equations that use a different set of variables than in Ref. 3. For these formulations, the derivation of well posed CPBCs seems to be more difficult. Part of the problem stems from the fact that CPBCs result in a set of partial differential equations that must hold at the boundary surface, and it is not always possible to cast these equations into the form of maximal dissipative boundary conditions. This is probably the reason why current well posed CPBCs for formulations other than that used in Ref. 3 are either limited to homogeneous boundary data[9] or to linearizations around a Minkowski background.[7–9] Even in those cases, the CPBCs obtained so far might be too restrictive in the sense that they do not allow the specification of the

physical quantities at the boundary with the freedom one would like to have. For example, the well posed boundary conditions obtained in Ref. 7 involve a coupling between the in- and outgoing variables and, likely, this coupling will introduce reflections at the boundary. Therefore, more general techniques are desirable in order to show well posedness for more generic CPBCs.

In this article, we use the Laplace–Fourier technique to analyze boundary conditions in linearized general relativity. This technique is very useful when the evolution equations are linear and have constant coefficients since it can be applied to boundary conditions that are more general than the maximal dissipative ones. Specifically, it can be applied to boundary conditions which have the form of differential equations at the boundary. Furthermore, the method is capable of detecting the presence of ill posed modes analytically. Ill posed modes are solutions to the IBVP that grow exponentially in time with an exponential factor that can be arbitrarily large, and their existence makes it impossible for the solution to depend continuously on the data. The Laplace–Fourier technique therefore provides us with a necessary condition for well posedness. However, it should be emphasized that the absence of ill posed modes (as defined in this article) does not automatically guarantee well posedness. Although more complicated in this case, results for the variable coefficient case are available by freezing the coefficients at the boundary (see Refs. 18 and 19).

This article is organized as follows: The conditions under which the specification of nonmaximal dissipative boundary conditions for symmetric hyperbolic systems with constant coefficients yields ill posed modes are reviewed in Sec. II. In Sec. III we discuss the boundary conditions that have been considered for the generalized Einstein–Christoffel formulation of Einstein's equations[20,21] when linearized around flat space–time. The generalized Einstein–Christoffel system is a family of symmetric hyperbolic formulations that is parametrized by a constant η. The boundary conditions we are considering are (i) the CPBCs that were considered in Ref. 7 and that are based on solving a closed evolution system at the boundary and on maximal dissipative boundary conditions, (ii) boundary conditions that are obtained by setting the ingoing constraint characteristic fields to zero, and (iii) boundary conditions that are obtained by considering the projection of Einstein's equations along the normal to the boundary surface, as recently proposed by Frittelli and Gomez.[10,11] In Sec. IV we apply the techniques discussed in Sec. II and show that the cases (ii) and (iii) suffer from the presence of ill posed modes unless the parameter η in the generalized Einstein–Christoffel formulation lies in a specific range. We also show that there are no ill posed modes in case (i) which is consistent with the well posedness estimates derived in Ref. 7. In Sec. V we show that the ill posed modes we have found in cases (ii) and (iii) do, in fact, all violate the constraints. This means that the evolution system for the constraint variables is ill posed in those cases. Since this system is always strongly hyperbolic and since our boundary conditions are constructed from specifying maximal dissipative conditions for this system, this also illustrates that maximal dissipative boundary conditions do not necessarily yield a well posed formulation if the evolution equations are strongly hyperbolic (but not symmetrizable). In particular, our calculations show that the boundary conditions that are constructed following schemes (ii) and (iii) do not necessarily lead to CPBCs and that one should always check the evolution system for the constraint variables. Our results and their implications on deriving well posed CPBCs are discussed in Sec. VI. A similar analysis for the Frittelli–Reula[22] system has been undertaken by Stewart.[4]

II. DETECTING ILL POSED MODES

In this section, we review the techniques that can reveal the presence of ill posed modes. They are based on a Laplace transformation in time and on a Fourier transformation in the spatial directions that are tangential to the boundaries and are described in more detail in Refs. 13 and 23. For simplicity, we restrict the following discussion to the 2D case; the generalization to 3D is straightforward.

Consider a 2D first order in time and space linear evolution equation of the form

$$\partial_t u = A\partial_x u + B\partial_y u, \tag{1}$$

where $u=u(t,x,y)$ is a vector-valued function and the matrices A and B are constant and symmetric. We consider solutions to Eq. (1) on the domain $t>0$, $x>0$, $-\pi<y<+\pi$ with initial data

$$u(0,x,y)=f(x,y) \tag{2}$$

and boundary conditions at $x=0$ of the form

$$L(\partial_t,\partial_y)u(t,0,y)=g(t,y), \tag{3}$$

where L is a linear operator with constant coefficients that only involves derivatives which are tangential to the boundary. For technical reasons, we assume that $L(\partial_t,\partial_y)$ is homogeneous in the sense that $L(\mu\partial_t,\mu\partial_y)=\mu L(\partial_t,\partial_y)$ for all positive μ. We also assume periodic boundary conditions in the y-direction (similar conclusions hold for the case $-\infty<y<+\infty$).

The IBVP (1)–(3) is said to be well posed,[24] if given smooth square integrable data f, g, there exists a unique smooth solution. Furthermore, there are constants C, a such that

$$\|u(t,.)\|^2\leqslant Ce^{at}\left[\|f\|^2+\int_0^t\|g(\tau,.)\|^2d\tau\right], \tag{4}$$

for all $t>0$ and all square integrable data f and g. Here, $\|u(t,.)\|$ denotes the L^2 norm of u defined by $\|u(t,.)\|^2=\int_{x>0}|u(t,x,y)|^2dxdy$ and, similarly, $\|f\|^2=\int_{x>0}|f(x,y)|^2dxdy$ and $\|g(\tau,.)\|^2=\int|g(\tau,y)|^2dy$. The estimate (4) implies that for each fixed t, the solution depends continuously on the data f and g.

A first step in checking if a given initial-boundary formulation satisfies a well posedness inequality of the type (4) is to look for solutions of the problem with homogeneous data ($g=0$) which are of the form

$$u(t,x,y)=e^{st+i\omega y}\tilde{u}(x), \tag{5}$$

where ω is an integer, s is complex with $\mathrm{Re}(s)>0$ and $\tilde{u}(x)$ is a smooth function that lies in $L^2(0,\infty)$. If such a solution exists, the problem cannot be well posed. In order to see this we notice that the functions

$$u_m(t,x,y)=e^{m(st+i\omega y)}\tilde{u}(mx), \tag{6}$$

where $m=1,2,3,\ldots$ can be arbitrarily large, are also solutions and since $\|u_m(t,.)\|/\|u_m(0,.)\|=\exp(m\,\mathrm{Re}(s)t)$ the estimate (4) cannot hold with constants C and a that are independent of the initial data. Therefore, an obvious check for well posedness is to see whether or not Eqs. (1) and (3) admit nontrivial solutions of the form (5) with homogeneous boundary data.

Using expression (5) in Eqs. (1) and (3), we obtain (for $g=0$)

$$s\tilde{u}=A\partial_x\tilde{u}+i\omega B\tilde{u}, \tag{7}$$

$$L(s,i\omega)\tilde{u}(0)=0. \tag{8}$$

These equations form a system of ordinary differential equations and can be solved analytically. In order to do so, we first bring A to diagonal form through an orthonormal transformation. Thus, the matrix B is still symmetric and we can write

$$A=\begin{pmatrix}0 & 0\\ 0 & A_1\end{pmatrix},$$

where $A_1=\mathrm{diag}(\lambda_1,\ldots,\lambda_p,\lambda_{p+1},\ldots,\lambda_{p+q})$ with $\lambda_1,\ldots\lambda_p$ real and negative and $\lambda_{p+1},\ldots,\lambda_{p+q}$ real and positive. Here, p and q are the number of in- and outgoing modes, respectively. Accordingly, we write

$$B=\begin{pmatrix} B_{00} & B_{01} \\ B_{10} & B_{11} \end{pmatrix}, \quad L=(L_0,L_1), \quad \tilde{u}=\begin{pmatrix} \tilde{u}_0 \\ \tilde{u}_1 \end{pmatrix}.$$

Now the zero components of Eq. (7) yield the following algebraic relation between $\tilde{u}_0$ and $\tilde{u}_1$:

$$S_{00}\tilde{u}_0=-S_{01}\tilde{u}_1, \tag{9}$$

where we have introduced the matrix $S=S(s,\omega)=sI-i\omega B$. Since the matrix B is symmetric, the matrix $S_{00}=sI-i\omega B_{00}$ is invertible for all $\mathrm{Re}(s)>0$ and all integer ω, and we can express $\tilde{u}_0$ in terms of $\tilde{u}_1$:

$$\tilde{u}_0=-S_{00}^{-1}S_{01}\tilde{u}_1. \tag{10}$$

Inserting this into the remaining equations of the system (7) and (8), we obtain the reduced problem

$$\partial_x\tilde{u}_1=M(s,\omega)\tilde{u}_1, \tag{11}$$

$$\tilde{L}\tilde{u}_1=0, \tag{12}$$

where

$$M(s,\omega)=A_1^{-1}(S_{11}(s,\omega)-S_{10}S_{00}^{-1}S_{01}(s,\omega)),$$

$$\tilde{L}(s,\omega)=L_1-L_0S_{00}^{-1}S_{01}.$$

One can show[19] that for $\mathrm{Re}(s)>0$ the matrix $M(s,\omega)$ has exactly p eigenvalues with negative real parts and exactly q eigenvalues with positive real parts (the eigenvalues are counted according to their algebraic multiplicity).

The eigenvalues of M that have positive real part lead to exponential growth in x. Since the solution $\tilde{u}$ has to be in $L^2(0,\infty)$, the integration constants have to be chosen such that there is no such growth in x. In order to achieve this, we choose, for each (s,ω), a unitary matrix $U=U(s,\omega)$ that brings $M(s,\omega)$ in upper triangular form:

$$U(s,\omega)^{-1}M(s,\omega)U(s,\omega)=\begin{pmatrix} M_-(s,\omega) & M_0(s,\omega) \\ 0 & M_+(s,\omega) \end{pmatrix}. \tag{13}$$

Here, M_- (M_+) is an upper triangular matrix whose eigenvalues have negative (positive) real parts. If we introduce the new variable $v(x)=U(s,\omega)^{-1}\tilde{u}_1(x)$, system (11) and (12) becomes

$$\partial_x v_-(x)=M_-(s,\omega)v_-(x)+M_0(s,\omega)v_+(x),$$

$$\partial_x v_+(x)=M_+(s,\omega)v_+(x),$$

$$L_-v_-(0)+L_+v_+(0)=0,$$

where $(L_-,L_+)=\tilde{L}U$. It follows that v_+ must vanish for v to be in $L^2(0,\infty)$. This implies that $v_-(x)=\exp(M_-x)\sigma_-$ where σ_- has to satisfy the boundary condition $L_-\sigma_-=0$. We conclude that the system (7) and (8) has only the trivial solution if and only if the determinant condition[25]

$$\det L_-(s,\omega)\neq 0, \quad \mathrm{Re}(s)>0, \tag{14}$$

is satisfied. (In particular, L_- must be a square matrix of dimension p. This means that we need exactly as many independent boundary conditions as there are ingoing modes.) If the determinant condition is violated at some point $(s,\omega)=(s_0,\omega_0)$, it is also violated for $(s,\omega)=m(s_0,\omega_0)$ with

$m=1,2,3,\ldots$ and the initial-boundary formulation admits solutions of the form (5) that grow exponentially in time where the exponential factor s can have arbitrarily large real part.

In Sec. IV we will discuss the determinant condition for the case of the linearized Einstein equations with boundaries.

III. BOUNDARY CONDITIONS FOR THE LINEARIZED EINSTEIN–CHRISTOFFEL SYSTEM

In this section we discuss boundary conditions for a linearization of the generalized Einstein–Christoffel vacuum equations.[20] This formulation has the attractive feature that when linearized around flat space–time written in Minkowski coordinates it simply reduces to a set of six wave equations, written in first order form:

$$\partial_t K_{ij} = -\delta^{kl}\partial_k f_{lij}, \tag{15}$$

$$\partial_t f_{kij} = -\partial_k K_{ij}. \tag{16}$$

Here, K_{ij} denotes the linearized extrinsic curvature and the symbols f_{kij} represent linear combinations of the linearized Christoffel symbols Γ_{kij}:

$$f_{kij} = \Gamma_{(ij)k} + \delta^{rs}\left(\delta_{ki}\Gamma_{[sj]r} + \delta_{kj}\Gamma_{[si]r} + \frac{\eta-4}{2\eta}\delta_{ij}\Gamma_{[sk]r}\right). \tag{17}$$

The value of η (which has to be different from zero) parametrizes the family of formulations. The particular case with $\eta=4$ corresponds to the original Einstein–Christoffel system derived by Anderson and York.[21] We set the shift to zero, and the lapse is linearized in such a way that it satisfies the densitized lapse gauge condition $\alpha=\sqrt{g}$ up to second order corrections, where g denotes the determinant of the three metric. A solution to the system (15) and (16) is a solution to the linearized Einstein equations if and only if the constraints are satisfied. In terms of the constraint variables

$$C = \frac{\eta}{4}\delta^{rs}\partial_r v_s, \tag{18}$$

$$C_j = \delta^{rs}(\partial_r K_{sj} - \partial_j K_{rs}), \tag{19}$$

$$C_{lkij} = 2\partial_{[l}f_{k]ij} + \eta\,\partial_{[l}\delta_{k](i}v_{j)} + \frac{\eta-4}{4}\delta_{ij}\partial_{[l}v_{k]}, \tag{20}$$

where $v_k = \delta^{ij}(f_{kij} - f_{ijk})$, the constraints are given by $C=0$, $C_j=0$, $C_{lkij}=0$.

We consider the evolution system (15) and (16) on the domain $t>0$, $x>0$, $-\pi<y, z, <+\pi$ and introduce the characteristic variables in the x direction,[26]

$$u^{(-)}_{ij} = \frac{1}{\sqrt{2}}(K_{ij} + f_{xij}), \tag{21}$$

$$u^{(+)}_{ij} = \frac{1}{\sqrt{2}}(K_{ij} - f_{xij}), \tag{22}$$

$$u^{(0)}_{Aij} = f_{Aij}\ . \tag{23}$$

Here and in the following, capital Latin indices stand for the tangential directions y and z. When written in terms of these variables the evolution equations (15) and (16) take the form

$$\partial_t u_{ij}^{(-)} = -\partial_x u_{ij}^{(-)} - \frac{1}{\sqrt{2}} \delta^{AB} \partial_A u_{Bij}^{(0)}, \tag{24}$$

$$\partial_t u_{ij}^{(+)} = +\partial_x u_{ij}^{(+)} - \frac{1}{\sqrt{2}} \delta^{AB} \partial_A u_{Bij}^{(0)}, \tag{25}$$

$$\partial_t u_{Aij}^{(0)} = -\frac{1}{\sqrt{2}} \partial_A (u_{ij}^{(-)} + u_{ij}^{(+)}), \tag{26}$$

and we see that the matrix A in Eq. (1) is diagonal.

For the constraints to be satisfied everywhere, when boundaries are present, one has to ensure that they are satisfied initially and that no constraint violating mode enters the domain. In order to ensure this, we follow the analysis in Ref. 7 and first consider the evolution of the constraint variables with respect to the flux defined by the main evolution equations (15) and (16). One can show[7] that the traceless part of C_{lkij} is constant in time, while the remaining constraints propagate according to

$$\partial_t C = \frac{\eta}{4} \delta^{ij} \partial_i C_j, \tag{27}$$

$$\partial_t C_j = \frac{4-2\eta}{\eta} \partial_j C - \delta^{rs} \partial_r T_{sj}, \tag{28}$$

$$\partial_t T_{ij} = -\partial_i C_j + \left(1 - \frac{3\eta}{4}\right) \partial_j C_i + \frac{\eta}{4} \delta_{ij} \delta^{rs} \partial_r C_s, \tag{29}$$

$$\partial_t V_{ij} = \left(\frac{7\eta}{4} - 3\right) \partial_{[i} C_{j]}, \tag{30}$$

where $T_{ij} = \delta^{rs}(C_{rijs} + C_{ijrs})$, and $V_{ij} = \delta^{rs} C_{ijrs}$. Introducing $\kappa = 1 - 3\eta/4$ and the variables

$$C_{ij} = T_{ij} + \frac{2\eta - 4}{\eta} \delta_{ij} C = \delta^{rs}(\partial_r f_{ijs} - \partial_j f_{irs}) + \kappa \partial_j v_i - \kappa \delta_{ij} \delta^{rs} \partial_r v_s, \tag{31}$$

the characteristic fields can be written as[27]

$$V_j^{(-)} = \frac{1}{\sqrt{2}}(C_j + C_{xj}), \tag{32}$$

$$V_j^{(+)} = \frac{1}{\sqrt{2}}(C_j - C_{xj}), \tag{33}$$

$$V_{Aj}^{(0)} = C_{Aj} + \kappa(\delta_{xj} C_{xA} - \delta_{Aj} C_{xx}), \tag{34}$$

$$\tilde{V}_{ij}^{(0)} = -\frac{7\kappa + 2}{3} C_{[ij]} + (\kappa + 1) V_{ij}. \tag{35}$$

If the system (27)–(30) is symmetric (or symmetrizable) hyperbolic, one can guarantee that if the constraints are satisfied initially and if homogeneous maximal dissipative boundary conditions are given, the constraints will be satisfied everywhere. Therefore, we consider boundary conditions at $x = 0$ which are of the form

$$V_x^{(-)} - a V_x^{(+)} = 0, \quad V_A^{(-)} - b V_A^{(+)} = 0, \tag{36}$$

$$u_{xx}^{(-)} - c\, u_{xx}^{(+)} = g_{xx}, \quad \hat{u}_{AB}^{(-)} - d\, \hat{u}_{AB}^{(+)} = \hat{g}_{AB}, \tag{37}$$

where the magnitudes of a, b, c and d are smaller or equal to 1 and $\hat{u}_{AB}^{(\mp)} = u_{AB}^{(\mp)} - \frac{1}{2}\delta_{AB}\delta^{CD}u_{CD}^{(\mp)}$ denotes the traceless part of $u_{AB}^{(\mp)}$. In order to express the conditions (36) in terms of the main variables K_{ij}, f_{kij}, we use the definition of the constraint variables, Eqs. (18), (19), and (31), and the evolution equations (15) and (16) in order to trade x-derivatives by time and tangential derivatives:

$$V_x^{(\mp)} = \delta^{AB}\left[\pm \partial_t u_{AB}^{(\mp)} + \partial_A u_{xB}^{(\mp)} \pm \frac{\delta^{CD}}{\sqrt{2}}\partial_C u_{DAB}^{(0)} \pm \frac{\kappa}{2}\partial_A(\sqrt{2}\,\delta^{CD}u_{CDB}^{(0)} - \sqrt{2}\,\delta^{ij}u_{Bij}^{(0)} + u_{xB}^{(-)} - u_{xB}^{(+)})\right],$$

$$V_A^{(\mp)} = \mp \partial_t u_{xA}^{(\mp)} + \delta^{CD}\partial_C u_{AD}^{(\mp)} - \delta^{ij}\partial_A u_{ij}^{(\mp)} \mp \frac{\delta^{CD}}{\sqrt{2}}\partial_C u_{DxA}^{(0)} \mp \frac{\kappa}{2}\delta^{CD}\partial_A(\sqrt{2}u_{CDx}^{(0)} - u_{CD}^{(-)} + u_{CD}^{(+)}).$$

It follows from the energy estimates derived in Ref. 7 that when $0 < \eta < 2$ the conditions (36) guarantee that the constraints are satisfied everywhere if they are satisfied initially. In the following, we will also consider other values of η and show that one might have ill posed modes if the parameter η lies outside the interval (0, 2). Notice that the conditions (36) do not involve derivatives normal to the boundary (∂_x). They can be interpreted as evolution equations for the variables $\delta^{AB}(u_{AB}^{(-)} + a u_{AB}^{(+)})$ and $u_{xA}^{(-)} + b u_{xA}^{(+)}$ at the boundary. The functions g_{xx} and $\hat{g}_{AB}$ are data that can be given freely for a combination of the in- and outgoing gauge and physical variables, respectively.[7]

In the next section, we will analyze the following choices of parameters:

(1) $a = -1$, $b = 1$, $c = d = 1$:
This corresponds to the Neumann boundary conditions that we have discussed in Ref. 7. In this case the boundary conditions can be recast in a closed evolution system at the boundary. Its solutions provide boundary data for the main evolution system in the form of maximal dissipative boundary conditions. When $0 < \eta < 2$ one can derive well posedness estimates for the resulting IBVP and the boundary conditions can indeed be called CPBCs.

(2) $a = 1$, $b = -1$, $c = d = -1$:
This corresponds to the Dirichlet conditions specified in Ref. 7. They can also be recast in a closed evolution system at the boundary, and for $0 < \eta < 2$ one has a well-posed IBVP with CPBCs.

(3) $a = 0$, $b = 0$:
This corresponds to setting the ingoing constraint variables to zero and might be the most obvious choice for obtaining CPBCs. However, we will show in the next section that the resulting IBVP possesses ill posed modes unless the parameter η is chosen appropriately.

(4) $a = 0$, $b = 1$:
These are the conditions that one obtains after linearizing the boundary conditions that were recently proposed in Ref. 11. There, the Einstein–Christoffel formulation ($\eta = 4$) is considered and the boundary conditions (36) are obtained by projecting Einstein's equations along the normal to the boundary rather than by analyzing the evolution of the constraints. In fact, one can show that setting G_{xA} to zero and rewriting[28] the resulting equations in terms of the variables K_{ij} and f_{kij} is equivalent to the second equation in (36) with $b = 1$, while setting G_{xx} (G_{tx}) to zero is equivalent to the first equation in (36) with $a = 1$ ($a = -1$). In Ref. 11, the authors propose to set the linear combination $G_{xx} - G_{tx}$ to zero which would correspond to using $a = 0$ in (36). In the next section, we show that the resulting boundary conditions yield an ill posed formulation if the parameter η is not chosen appropriately.

IV. LAPLACE–FOURIER ANALYSIS

Following the analysis described in Sec. II, we look for solutions to Eqs. (15), (16), (36), and (37) with homogeneous boundary data ($g_{xx}=0$, $\hat{g}_{AB}=0$) and which are of the form

$$u_{ij}^{(\mp)}(t,x,y,z)=e^{st+i\omega_y y+i\omega_z z}\tilde{u}_{ij}^{(\mp)}(x), \tag{38}$$

$$u_{Aij}^{(0)}(t,x,y,z)=e^{st+i\omega_y y+i\omega_z z}\tilde{u}_{Aij}^{(0)}(x), \tag{39}$$

where s is a complex number with positive real part and ω_y and ω_z are integers. For the solution to be square integrable, we require the functions $\tilde{u}_{ij}^{(\mp)}(x)$ and $\tilde{u}_{Aij}^{(0)}(x)$ to be in $L^2(0,\infty)$. From Eqs. (38), (39), and (26) we obtain an algebraic condition

$$s\tilde{u}_{Aij}^{(0)}=-\frac{i}{\sqrt{2}}\omega_A(\tilde{u}_{ij}^{(-)}+\tilde{u}_{ij}^{(+)}) \tag{40}$$

that can be used to eliminate the variable $\tilde{u}_{Aij}^{(0)}$ from the remaining equations. Inserting Eqs. (38)–(40) into Eqs. (24) and (25) yields the ordinary differential equation

$$\partial_x\begin{pmatrix}\tilde{u}_{ij}^{(-)}\\ \tilde{u}_{ij}^{(+)}\end{pmatrix}=M(s,\underline{\omega})\begin{pmatrix}\tilde{u}_{ij}^{(-)}\\ \tilde{u}_{ij}^{(+)}\end{pmatrix}, \tag{41}$$

where

$$M(s,\underline{\omega})=\begin{pmatrix}-s-\dfrac{\underline{\omega}^2}{2s} & -\dfrac{\underline{\omega}^2}{2s}\\ \dfrac{\underline{\omega}^2}{2s} & s+\dfrac{\underline{\omega}^2}{2s}\end{pmatrix} \tag{42}$$

and $\underline{\omega}=(\omega_y,\omega_z)$. The matrix $M(s,\underline{\omega})$ has the eigenvalues $\pm\sqrt{s^2+\underline{\omega}^2}$.

We first look at the case $\underline{\omega}=0$, which corresponds to solutions that have trivial y and z dependence. For those, the matrix $M(s,\underline{\omega})$ is diagonal and since $\mathrm{Re}(s)>0$ we see that we must have $\tilde{u}_{ij}^{(+)}=0$ for the solution to be in L^2. The boundary conditions (36) and (37) yield

$$\tilde{u}_{xx}^{(-)}(0)=0,\ \ \hat{\tilde{u}}_{AB}^{(-)}(0)=0,\ \ s\delta^{AB}\tilde{u}_{AB}^{(-)}(0)=0,\ \ s\tilde{u}_{xA}^{(-)}(0)=0, \tag{43}$$

therefore we have only the trivial solution. There are no ill posed modes with trivial dependence on the variables that are tangential to the boundary. We show now that the situation becomes rather more complicated when one considers modes that have a nontrivial tangential dependence.

Assume that $\underline{\omega}\neq 0$. Following the analysis of Sec. II we introduce a unitary matrix $U=U(s,\underline{\omega})$ that brings the matrix $M(s,\underline{\omega})$ into upper triangular form. To lighten the notation we introduce the quantities $\zeta=s/|\underline{\omega}|$, $\lambda=\sqrt{1+\zeta^2}$, $\psi(\zeta)=(\lambda-\zeta)^2$ and $N=1+|\psi(\zeta)|^2$. One can then verify that the matrix (a star denotes complex conjugation)

$$U(\zeta)=N^{-1/2}\begin{pmatrix}-\dfrac{|\zeta|}{\zeta} & \dfrac{|\zeta|}{\zeta^*}\psi^*\\ \dfrac{|\zeta|}{\zeta}\psi & \dfrac{|\zeta|}{\zeta^*}\end{pmatrix} \tag{44}$$

is unitary and satisfies

$$U(\zeta)^{-1}MU(\zeta)=|\underline{\omega}|\begin{pmatrix}-\lambda & M_0(\zeta)\\ 0 & \lambda\end{pmatrix},\quad M_0(\zeta)=\frac{1+\psi^*(2+4\zeta^2+\psi^*)}{2\zeta^*N}, \tag{45}$$

where in λ the branch is chosen such that for $\mathrm{Re}(\zeta)>0$, $\mathrm{Re}(\lambda)>0$. In terms of the new variables $(v_{ij}^{(-)},v_{ij}^{(+)})^T=U^{-1}(\tilde{u}_{ij}^{(-)},\tilde{u}_{ij}^{(+)})^T$ Eq. (41) yields

$$|\underline{\omega}|^{-1}\partial_x v_{ij}^{(-)}=-\lambda v_{ij}^{(-)}+M_0(\zeta)v_{ij}^{(+)}, \tag{46}$$

$$|\underline{\omega}|^{-1}\partial_x v_{ij}^{(+)}=\lambda v_{ij}^{(+)}. \tag{47}$$

For the solution to be in L^2, we must have $v_{ij}^{(+)}=0$. This implies that $v_{ij}^{(-)}=e^{-\lambda|\underline{\omega}|x}\sigma_{ij}$, where σ_{ij} are constants which describe the value that $v_{ij}^{(-)}$ takes at the boundary. Using the matrix $U(\zeta)$ we can express the $\tilde{u}$ variables at the boundary as

$$\tilde{u}_{ij}^{(-)}(0)=-N^{-1/2}\frac{|\zeta|}{\zeta}\sigma_{ij}, \tag{48}$$

$$\tilde{u}_{ij}^{(+)}(0)=N^{-1/2}\frac{|\zeta|}{\zeta}\psi(\zeta)\sigma_{ij}, \tag{49}$$

$$\tilde{u}_{Aij}^{(0)}(0)=\frac{i}{\sqrt{2}}\frac{\hat{\omega}_A}{\zeta}N^{-1/2}\frac{|\zeta|}{\zeta}(1-\psi(\zeta))\sigma_{ij}, \tag{50}$$

where $\hat{\omega}_A=\omega_A/|\underline{\omega}|$.

Using Eqs. (38), (48), and (49) in the boundary condition (37), we find that

$$(1+c\psi(\zeta))\sigma_{xx}=0,\ \ (1+d\psi(\zeta))\hat{\sigma}_{AB}=0, \tag{51}$$

where $\hat{\sigma}_{AB}$ denotes the tracefree part of σ_{AB}. Since the function $\psi(\zeta)$ maps the half plane $\mathrm{Re}(\zeta)>0$ to the interior of the unit circle and since $|c|\leqslant 1$, $|d|\leqslant 1$, it follows that $\sigma_{xx}=0$ and $\hat{\sigma}_{AB}=0$.

Next, we insert all of this into the boundary conditions (36). The result is more conveniently expressed if one introduces a normalized vector $\hat{\xi}_A$ that is orthogonal to $\hat{\omega}_A$ and considers the components $\sigma_{x\omega}=\delta^{AB}\sigma_{xA}\hat{\omega}_B$ and $\sigma_{x\xi}=\delta^{AB}\sigma_{xA}\hat{\xi}_B$. The projection of the second equation in (36) along $\hat{\xi}$ implies that $\sigma_{x\xi}$ must vanish, while the remaining equations in (36) imply that $\sigma\equiv\delta^{AB}\sigma_{AB}$ and $\sigma_{x\omega}$ must satisfy the following 2×2 system:

$$\begin{gathered}L_-(\zeta)\begin{pmatrix}\sigma\\ \sigma_{x\omega}\end{pmatrix}=0,\\ L_-(\zeta)=\begin{pmatrix}2\lambda(1+a\psi)-\kappa(1+a)(\lambda-\zeta) & 2i(1+a\psi)+i\kappa(1+a)(1+\psi)\\ i(1+b\psi)-i\kappa(1+b)(1+\psi) & 2\lambda(1+b\psi)+2\kappa(1+b)(\lambda-\zeta)\end{pmatrix}.\end{gathered} \tag{52}$$

The determinant of $L_-(\zeta)$ is given by

$$\det L_-(\zeta)=(6+4\zeta^2)[(1+a\psi(\zeta))(1+b\psi(\zeta))-\kappa^2(1+a)(1+b)\psi(\zeta)]. \tag{53}$$

Clearly, the first factor cannot be zero since $\mathrm{Re}(\zeta)>0$. Therefore, $\det L_-(\zeta)$ can only vanish if the term inside the square brackets does.

We now focus on the different cases discussed in the previous section:

(1) $a=-1$, $b=1$, $c=d=1$:
In this case, the second term inside the square brackets vanishes and the first term is never zero since $|\psi(\zeta)|<1$. Therefore, the resulting formulation possesses no ill posed modes. Of course, when $0<\eta<2$ this is consistent with our calculation in Ref. 7 where the estimates we have derived exclude the presence of ill posed modes.

(2) $a=1$, $b=-1$, $c=d=-1$:
The result is the same as in the previous case.
(3) $a=0$, $b=0$:
In this case, the terms inside the square brackets simplify to $1-\kappa^2\psi(\zeta)$. A small calculation reveals that this can only be zero if $\zeta=(\kappa^2-1)/2|\kappa|$ and $\kappa\neq 0$. Therefore, $\det L_-(\zeta)$ has a zero with $\mathrm{Re}(\zeta)>0$ if and only if $\kappa^2>1$. This is equivalent to $\eta<0$ or $\eta>\frac{8}{3}$. Therefore, setting the ingoing constraint variables to zero in the family of generalized Einstein–Christoffel systems does indeed yield ill posed boundary conditions if the parameter η lies outside the interval [0, 8/3].
(4) $a=0$, $b=1$:
Here the terms inside the square brackets reduce to $1+(1-2\kappa^2)\psi(\zeta)$. Since the function ψ maps the positive real axis onto the open interval (0, 1) it follows that this expression never vanishes if and only if $\kappa^2\leqslant 1$. In particular, one has ill posed modes when $\eta=4$ and the boundary conditions that were proposed in Ref. 11 yield, at least when linearized around flat space–time, an ill posed initial-boundary formulation. On the other hand, if at the boundary one considers the equations $G_{xy}=G_{xz}=0$ and the equation $G_{xt}=0$ instead of the combination $G_{xx}-G_{xt}=0$, one has $a=-1$ and the resulting formulation does not in fact suffer from possessing ill posed modes.

V. VIOLATIONS OF THE CONSTRAINTS

In this section, we show that the ill posed modes we have found in the previous section violate the constraints. In order to see this, we use these ill posed modes to compute the constraint variables C_j. From $K_{ij}=(u_{ij}^{(-)}+u_{ij}^{(+)})/\sqrt{2}$, Eqs. (19), (48), and (49), and $\sigma_{xx}=0$, $\hat{\sigma}_{AB}=0$, we have

$$C_x=-\frac{|\underline{\omega}|}{\sqrt{2N}}\frac{|\zeta|}{\zeta}(1-\psi(\zeta))(\lambda\sigma+i\sigma_{x\omega})\exp[|\underline{\omega}|(\zeta t-\lambda x+i\hat{\omega}_A x^A)], \tag{54}$$

$$\omega^A C_A=\frac{|\underline{\omega}|}{\sqrt{8N}}\frac{|\zeta|}{\zeta}(1-\psi(\zeta))(i\sigma+2\lambda\sigma_{x\omega})\exp[|\underline{\omega}|(\zeta t-\lambda x+i\hat{\omega}_A x^A)], \tag{55}$$

where $(\sigma,\sigma_{x\omega})$ is a nontrivial solution to Eq. (52). Since $|\psi(\zeta)|<1$ for $\mathrm{Re}(\zeta)>0$, and since

$$\det\begin{pmatrix}\lambda & i\\ i & 2\lambda\end{pmatrix}=3+2\zeta^2\neq 0, \tag{56}$$

we see that the variables C_x and $\omega^A C_A$ cannot simultaneously vanish. Therefore, all the ill posed modes we have found are *constraint violating* modes. This means that under generic small perturbations of the initial data these modes will be excited and the constraint variables will grow exponentially with an exponential factor that can be arbitrarily large. In this sense, the boundary conditions that lead to ill posed modes do *not* preserve the constraints. We point out that the constraint variables constructed from any solution of the main evolution system (15) and (16) with boundary conditions (36) and (37) provide a solution of the evolution of the constraint variables, Eqs. (27)–(30) with boundary conditions (36). Since we have shown that the constraint variables constructed from ill posed modes are ill posed modes themselves [see Eqs. (54) and (55)], the IBVP for the constraint variables cannot be well posed. This emphasizes the importance of looking at the evolution system for the constraints and checking its well posedness when deriving CPBCs for Einstein's equations.

We conclude this section with two remarks. First, one can check that the evolution system for the constraint variables, Eqs. (27)–(30), is strongly hyperbolic for any nonvanishing value of the parameter η. On the other hand, our analysis above shows the existence of ill posed modes when η lies outside of the interval $[0,\frac{8}{3}]$ and the coupling constants a and b are chosen as in cases (3)

and (4) of the previous section. This illustrates that applying maximal dissipative boundary conditions to evolution systems that are strongly hyperbolic (but not symmetrizable) does not necessarily yield a well posed problem.

The second remark concerns the choice $a=b=-1$ for the coupling constants in Eq. (36). In this case it follows that the determinant condition is always satisfied, regardless of the value for the parameter η. In fact, one can show that the resulting boundary conditions are constraint preserving: The evolution equations imply that the constraint variable C_j satisfies the wave equation:

$$\partial_t^2 C_j = \delta^{rs}\partial_r\partial_s C_j. \tag{57}$$

On the other hand, the choice $a=b=-1$ corresponds to imposing the momentum constraint at the boundary. Since C_j satisfies the wave equation, this implies that $C_j=0$ everywhere, if C_j is satisfied initially. It then follows from Eqs. (27), (29), and (30) that the remaining constraints are also satisfied if they are satisfied initially. This explains why one has CPBCs for all $\eta\neq 0$ when $a=b=-1$. However, the above argumentation is expected to break down when one considers the nonlinear regime since in this case lower order terms might prevent one from obtaining a closed system for C_j alone. In this case, one has to rely on the symmetrizer for the system (27)–(30) which was constructed in Ref. 7, and one might not be able to show that the constraints propagate when η lies outside the interval $[0, 2)$, even when $a=b=-1$.

VI. CONCLUSIONS

We have analyzed ill posed modes in the family of the generalized Einstein–Christoffel formulation of Einstein's equations with boundaries. We considered boundary conditions which result from coupling the ingoing characteristic constraint variables to the outgoing ones. Specifically, the cases we have studied include the boundary conditions we have obtained in Ref. 7 and the boundary conditions that originate from considering the projection of Einstein's equations along the normal to the boundary. When linear fluctuations around Minkowski space are considered, we have shown that the formulation is subject to constraint violating ill posed modes unless the parameters in the equations and the coupling between the in- and outgoing constraint variables are chosen carefully. In fact, it is not difficult to show that if the coupling constants a and b are real and satisfy $-1<a\leqslant 1$ and $-1<b\leqslant 1$ there are always ill posed modes as long as the parameter η lies outside the interval $[0,\frac{8}{3}]$. In particular, this is the case when the ingoing constraint variables are set to zero. Furthermore, there are ill posed modes for the boundary conditions that were obtained in Ref. 11 when applied to the linearized Einstein–Christoffel system ($\eta=4$). However, our analysis also reveals that these ill posed modes could easily be avoided by imposing a different linear combination of Einstein's equations at the boundary or by changing the parameter η such that it lies in the interval $0<\eta\leqslant\frac{8}{3}$. In any case, our analysis highlights the importance of studying the evolution system for the constraint variables and ensuring its well posedness since all the ill posed modes we have found are constraint violating. In particular, the formulations we have studied in this article show that even though the main evolution system is symmetric hyperbolic, the evolution equations for the constraint variables is not necessarily symmetrizable. For the cases in which the propagation of the constraints is described by a system that is strongly hyperbolic (but not symmetrizable) we have shown that specifying maximal dissipative boundary conditions can lead to an ill posed system.

It is interesting to note that all the ill posed modes that appear have a nontrivial dependence in the spatial directions that are tangential to the boundary surface. Therefore, such modes would not be present in the one-dimensional case. This might explain why the numerical simulations in Ref. 6, where the Einstein–Christoffel system ($\eta=4$) was evolved using boundary conditions obtained by setting the ingoing constraints to zero, did not show any ill posed modes.

The simple analytic method we have used in this article, which is based on the determinant condition (14), should be used to test the well posedness of the boundary conditions before numerically evolving any evolution system since the presence of ill posed modes would detrimen-

tally affect numerical stability. However, we also stress that more work is required to derive sufficient conditions for well posedness for the choices of parameters when the determinant condition is satisfied. In particular, it would be worthwhile to analyze CPBCs where the incoming physical variables can be freely specified.

[24] When discussing initial-boundary value problems one sometimes demands a slightly stronger estimate that also bounds the norm of the solution at the boundary surface. For the purpose of the present article, it is sufficient to consider the weaker estimate (4) since we will show that when the determinant condition is violated, the inequality (4) cannot hold for all initial data.
[25] This condition is weaker than the uniform Kreiss condition[18] that requires that $|\det L_-|$ must be bounded away from zero. The reason why here we do not require the uniform Kreiss condition is that it might be too strong for the case of CPBCs in general relativity. As we will see in Sec. IV the well posed CPBCs that were derived in Ref. 7 do not satisfy the uniform Kreiss condition.
[26] Notice that the characteristic variables defined here are related with the ones $v_{ij}^{(\pm)}$ defined in Ref. 7 according to $u_{ij}^{(\pm)} = v_{ij}^{(\mp)}/\sqrt{2}$.
[27] For $\eta=2$ or $\eta=\frac{8}{3}$ these fields are not complete. When $\eta=2$ it follows that C_{ij} is traceless and as a consequence, $\delta^{AB}V_{AB}^{(0)}=0$. But in this case one has the additional field $2C+C_{xx}$ that propagates with zero speed. When $\eta=\frac{8}{3}$, $\tilde{V}_{ij}=0$ can be replaced by the fields V_{AB} and $6V_{xA}+5C_{xA}$.
[28] Actually this procedure is not unique since there is an ambiguity when first derivatives of the variables K_{ij} and f_{kij} are substituted for second derivatives of the three-metric. This ambiguity stems from the fact that one can always change the resulting expression by using the constraints $C_{lkij}=0$. For definiteness, we take the choice that leads to the same boundary conditions as in Ref. 7.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 9 SEPTEMBER 2003

Dynamical system approach to FRW models in higher-order gravity theories

John Miritzis[a)]
Department of Marine Sciences, University of the Aegean, Sapfous 5, Mytilene 81100, Greece

(Received 18 March 2003; accepted 30 April 2003)

We study the late time evolution of positively curved FRW models with a scalar field which arises in the conformal frame of the $R+\alpha R^2$ theory. The resulted three-dimensional dynamical system has two equilibrium solutions corresponding to a de Sitter space and an ever expanding closed universe. We analyze the structure of the first equilibrium with the methods of the center manifold theory and, for the second equilibrium, we apply the normal form theory to obtain a simplified system, which we analyze with special phase plane methods. It is shown that an initially expanding closed FRW space–time avoids recollapse. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1602161]

I. INTRODUCTION

A central question in relativistic cosmology is that of deciding about the past and future asymptotic states of cosmological models.[1] However, general relativity leads to singularities in the space–times of all known cosmological models with ordinary matter. Higher order curvature corrections in the gravitational action may rectify the problem and lead to cosmological models free from such pathologies, at the cost of diverging from a FRW behavior at late times.[2] There is a resurgence of interest in such theories which naturally arise in string-theoretic considerations (cf. brane models with Gauss–Bonett terms[3–6]). An interesting feature of higher order theories is that inflation emerges in these theories in a most direct way. In one of the first inflationary models, proposed in 1980 by Starobinsky,[7] inflation is due to the R^2 correction term in a gravitational Lagrangian $L=R+\alpha R^2$ where α is a constant. The dynamics of higher order cosmologies is closely related to scalar-field cosmologies in general relativity because of their conformal equivalence.[8,9] There are certain limitations to this procedure related to the issue of physical reality of the two metrics involved[10] and to the fact that the conformal transformation may fail to be regular at all points of the space–time. Nevertheless, it is practically useful and investigations in the conformal frame have given some interesting results, e.g., the cosmic no-hair theorem in quadratic cosmologies.[11,12]

Most of the studies of scalar-field cosmologies with the dynamical systems methods are restricted to FRW models (see, for example, Refs. 13 and 14, and references therein), although there are important investigations in spatially homogeneous Bianchi cosmologies with an exponential potential.[15] In particular, for flat FRW models with a scalar field there are some general results which do not rely on the particular properties of the potential.[16,17] However, the situation is more delicate for positively curved FRW models with a scalar field having a potential with a zero local minimum. The main problem which confronts us is the following: Can a closed universe filled with ordinary matter and a scalar field avoid recollapse?

In this article we investigate the evolution of positively curved FRW models with a scalar field having the potential which arises in the conformal frame of the $R+\alpha R^2$ theory in vacuum.[8,11] The motivation for this choice is presented in Sec. III. The dimension of the dynamical systems involved in such models is greater than two and the usual methods of phase plane analysis cannot

[a)]Electronic mail: john@env.aegean.gr

be applied. In particular, for nonhyperbolic equilibrium points the linearization theorem does not yield any information about the stability of the equilibria and, therefore, more powerful methods are needed. The center manifold theorem shows that the qualitative behavior in a neighborhood of a nonhyperbolic equilibrium point **q** is determined by its behavior on the center manifold near **q**. Since the dimension of the center manifold is generally smaller than the dimension of the dynamical system, this greatly simplifies the problem. The other general method for simplifying the dynamical system is the normal form theory, which consists in a nonlinear coordinate transformation that allows us to simplify the nonlinear part of the system. Both methods are used in Secs. III and IV, respectively.

The plan of the article is as follows. In the next section we write down the field equations assuming an arbitrary potential, as a constrained four-dimensional dynamical system. In Sec. III, we use the constraint equation to reduce the dimension of the system to three and after a suitable change of variables we find the equilibrium points of the system and discuss the physical meaning of these particular solutions. In particular we show using the methods of the center manifold theory that the equilibrium corresponding to the de Sitter solution is asymptotically unstable. In Sec. IV we find the so-called normal form of the dynamical system, which greatly simplifies the problem, since two of the equations decouple. We study the qualitative behavior of the resulted two-dimensional system and analyze the late time evolution of the model. We show that an initially expanding universe avoids recollapse. In Sec. V we apply the same techniques to flat FRW spaces filled with a barotropic fluid in the conformal frame of the $R+\alpha R^2$ theory and study the detailed evolution of the models.

II. SCALAR-FIELD COSMOLOGIES

In general relativity the evolution of FRW models with a scalar field (ordinary matter is described by a perfect fluid with energy density ρ and pressure p) are governed by the Friedmann equation,

$$\left(\frac{\dot{a}}{a}\right)^2+\frac{k}{a^2}=\frac{1}{3}\left(\rho+\frac{1}{2}\dot{\phi}^2+V(\phi)\right), \tag{1}$$

the Raychaudhuri equation,

$$\frac{\ddot{a}}{a}=-\frac{1}{6}(\rho+3p+2\dot{\phi}^2-2V), \tag{2}$$

the equation of motion of the scalar field,

$$\ddot{\phi}+3\frac{\dot{a}}{a}\dot{\phi}+V'(\phi)=0, \tag{3}$$

and the conservation equation,

$$\dot{\rho}+3(\rho+p)\frac{\dot{a}}{a}=0. \tag{4}$$

We adopt the metric and curvature conventions of Ref. 1. Here, $a(t)$ is the scale factor, an overdot denotes differentiation with respect to time t and units have been chosen so that $c=1=8\pi G$.

From Eqs. (1)–(4) we see that the state $(a,\dot{a},\rho,\phi,\dot{\phi})\in\mathbb{R}^5$ of the system lies on the hypersurface defined by the constraint, (1), and the remaining field equations can be written as a five-dimensional dynamical system. In vacuum, $\rho=0$, the dimension of the dynamical system reduces to four.

In the literature of scalar-field cosmologies the exponential potential function, viz., $V(\phi)=V_0e^{-\lambda\phi}$, is the most popular not only because of the variety of alternative theories of gravity

which predict exponential potentials, but also due to the fact that this potential has the nice property that $V' \propto V$, which allows the introduction of normalized variables according to the formalism of Wainwright *et al.*[1] In flat $k=0$ FRW models, for example, with a scalar field having an exponential potential, introducing the variables $x \sim \dot{\phi}/H$, $y \sim \sqrt{V}/H$ and the time coordinate $\tau = \ln(a/a_0)$ enables the evolution equations to be written as a two-dimensional dynamical system (cf. Ref. 18) and in more general homogeneous cosmologies associated with a scalar field, the dimension of the dynamical system reduces by one if the potential function is exponential.

If we set $\dot{\phi}=y$, $\dot{a}/a=H$, the evolution equations (2)–(4) in vacuum become

$$\begin{aligned} \dot{a} &= Ha, \\ \dot{\phi} &= y, \\ \dot{y} &= -3Hy - V'(\phi), \\ \dot{H} &= -\tfrac{1}{2}y^2 + k/a^2, \end{aligned} \tag{5}$$

subject to the constraint

$$3H^2 + 3k/a^2 = \tfrac{1}{2}y^2 + V(\phi). \tag{6}$$

Therefore, the phase space of the dynamical system (5) is the set

$$\{(a,\phi,y,H) \in \mathbb{R}^4 : 3H^2 + 3k/a^2 = \tfrac{1}{2}y^2 + V(\phi)\}.$$

III. CURVED FRW IN $R+\alpha R^2$ THEORY: EQUILIBRIA

In the remainder of the article we assume that the potential function of the scalar field is

$$V(\phi) = V_\infty (1 - e^{-\sqrt{2/3}\phi})^2, \tag{7}$$

which arises in the conformal frame of the $R+\alpha R^2$ theory.[8,11] This potential has a long and flat plateau. For large values of ϕ, the potential, V, is almost constant, $V_\infty = \lim_{\phi \to +\infty} V(\phi)$, thus V has the general properties for inflation to commence. In Ref. 12 it was proved a cosmic no-hair theorem, i.e., Bianchi models with ordinary matter satisfying the strong energy condition and a scalar field with potential (7), asymptotically isotopize. According to this picture, the universe started in a homogeneous state and during inflation it had enough time to isotropize.

In order to reduce the dimension of the dynamical system (5) we use the constraint (6) to eliminate a. The evolution equations become

$$\begin{aligned} \dot{\phi} &= y, \\ \dot{y} &= -3Hy - V'(\phi), \\ \dot{H} &= -H^2 - \tfrac{1}{3}y^2 + \tfrac{1}{3}V(\phi). \end{aligned} \tag{8}$$

Linearization of (8) near the equilibrium point (0,0,0) shows that the Jacobian matrix at that point has one zero and two purely imaginary eigenvalues. Consequently the Hartman–Grobman theorem does not apply. Therefore, we cannot draw any conclusions about the stability of the equilibrium from an examination of the Jacobian.

We simplify the system by rescaling the variables by the equations

$$\phi \to \sqrt{\tfrac{2}{3}}\phi,$$

$$y \to \sqrt{4V_\infty/3}\, y,$$

$$H \to \frac{\sqrt{2V_\infty}}{3} H,$$

$$t \to \frac{1}{\sqrt{2V_\infty}} t.$$

In order to take account of the equilibrium point corresponding to the point at ''infinity'' and to remove the transcendental functions, it is convenient to introduce the variable u defined by

$$u := e^{-\phi}, \tag{9}$$

to obtain finally

$$\begin{aligned} \dot{u} &= -uy, \\ \dot{y} &= -Hy - u(1-u), \\ \dot{H} &= -\tfrac{1}{3}H^2 - \tfrac{2}{3}y^2 + \tfrac{1}{2}(1-u)^2. \end{aligned} \tag{10}$$

Note that under the transformation (9), the resulted three-dimensional dynamical system (10) is quadratic. In view of (6) we have $3H^2 - \frac{1}{2}y^2 - V(\phi) > 0$, hence, the phase space of the system (10) is the set

$$\Sigma := \{(u,y,H) \in \mathbb{R}^3 : H^2 - y^2 - \tfrac{3}{2}(1-u)^2 > 0\}. \tag{11}$$

The equilibrium points of (10) are

A: $(u=1, y=0, H=0)$. This corresponds to the limiting state of an ever-expanding universe with $H \to 0$ while the scalar field approaches the minimum of the potential and the scale factor goes to infinity. Equality in (11) which arises from the flat, $k=0$, case defines a set on the boundary of Σ. We conclude that the point A, which corresponds to the Minkowski solution, is located on this boundary. The detailed structure of this equilibrium will be analyzed in the next section.

B: $(u=0, y=\pm\sqrt{3}/2, H=0)$. These lie outside of the phase space and, therefore, are unphysical.

C: $(u=0, y=0, H=\pm\sqrt{\frac{3}{2}})$. In the next section we show that only the point with the $+$ sign can be approached by a trajectory starting with a $H>0$. It corresponds to the de Sitter universe with a cosmological constant equal to $\sqrt{V_\infty}$. Regarding the stability of this equilibrium, it is easy to see that the Jacobian matrix of (10) at $\mathbf{q}=(0,0,\sqrt{\frac{3}{2}})$ has one zero and two negative eigenvalues. The center manifold theorem implies that there exists a local two-dimensional stable manifold through $\mathbf{q}$ (see, for example, Ref. 19). That means that all trajectories asymptotically approaching $\mathbf{q}$ as $t \to \infty$ lie on a two-dimensional invariant manifold. Since $\mathbf{q}$ is a nonhyperbolic fixed point, the topology of the flow near $\mathbf{q}$ is nontrivial and is characterized by a one-dimensional local center manifold intersecting $\mathbf{q}$. In the Appendix we prove the following result.

Proposition 1: The equilibrium point $\mathbf{q}=(0,0,\sqrt{\frac{3}{2}})$ *of* (10) *is locally asymptotically unstable.*

IV. LATE TIME EVOLUTION

It is easy to see that at the equilibrium point, $(u=1, y=0, H=0)$, the eigenvalues of the Jacobian of (10) are $\pm i, 0$ and, therefore, we cannot infer about the stability of the equilibrium. Nevertheless, it is the most interesting case, because in all other equilibria the scalar field reaches the flat plateau, which is impossible if we restrict ourselves to initial values of H smaller than

$\sqrt{V_\infty}$. The study of the qualitative behavior of a dynamical system near a nonhyperbolic equilibrium point is difficult even in two dimensions. We find the so-called normal form (cf. Ref. 19 for a brief introduction) of the system (10) near the equilibrium point $(u=1, y=0, H=0)$. The idea of the normal form theory is the following: Given a dynamical system with equilibrium point at the origin, $\dot{\mathbf{x}}=A\mathbf{x}+\mathbf{f}(\mathbf{x})$, where A is the Jordan form of the linear part and $\mathbf{f}(\mathbf{0})=\mathbf{0}$, perform a nonlinear transformation $\mathbf{x}\to\mathbf{x}+\mathbf{h}(\mathbf{x})$, where $\mathbf{h}(\mathbf{x})=O(|\mathbf{x}|^2)$ as $|\mathbf{x}|\to 0$, such that the system becomes "as simple as possible."

To write the system in a form suitable for the application of the normal form theory, we shift the fixed point to (0,0,0) by setting $x=u-1$ and the system becomes

$$\dot{x}=-y-xy,$$

$$\dot{y}=x+x^2-Hy, \tag{12}$$

$$\dot{H}=\tfrac{1}{2}x^2-\tfrac{2}{3}y^2-\tfrac{1}{3}H^2.$$

We now perform the nonlinear transformation

$$x\to x-y^2+\tfrac{1}{4}Hy,$$

$$y\to y+xy+\tfrac{1}{4}Hx,$$

$$H\to H+\tfrac{7}{12}xy,$$

and keeping only terms up to second order we obtain the system

$$\dot{x}=-y-\tfrac{1}{2}Hx,$$

$$\dot{y}=x-\tfrac{1}{2}Hy, \tag{13}$$

$$\dot{H}=-\tfrac{1}{12}(x^2+y^2)-\tfrac{1}{3}H^2.$$

Note that the results are valid only near the origin.

Passing to cylindrical coordinates $(x=r\cos\theta, y=r\sin\theta, H=H)$, we have

$$\dot{r}=-\tfrac{1}{2}rH,$$

$$\dot{\theta}=1, \tag{14}$$

$$\dot{H}=-\tfrac{1}{12}r^2-\tfrac{1}{3}H^2 \quad .$$

We note that the θ dependence of the vector field has been eliminated, so that we can study the system on the $r-H$ plane. The equation $\dot{\theta}=1$ means that the trajectory in the $x-y$ plane spirals with angular velocity 1. It is convenient to rescale the variables by

$$r\to 6r, \quad H\to 3H, \tag{15}$$

so that the projection of (14) on the $r-H$ plane is

$$\dot{r}=-\tfrac{3}{2}rH,$$

$$\dot{H}=-r^2-H^2 \quad . \tag{16}$$

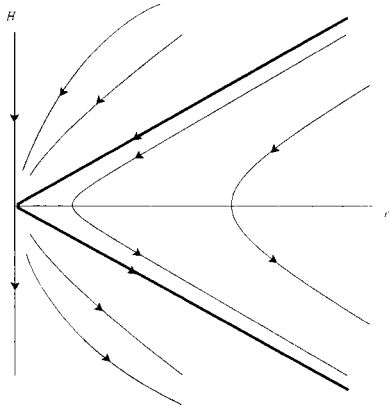

FIG. 1. The phase portrait of (16). The invariant trajectories $H=\pm\sqrt{2}r$ are shown with thicker lines. For expanding models only trajectories above the line $H=\sqrt{6}r$ belong to the phase space of the system.

This system belongs to a family of systems studied in 1974 by Takens.[20]

It is easy to obtain the phase portrait of (16) via numerical integration. However, we can analyze the qualitative behavior of the trajectories using theoretical arguments. First, (16) is invariant under the transformation $t\to -t$, $H\to -H$ (which implies that all trajectories are symmetric with respect to the r axis) and the line $r=0$ is invariant. Second, the system (16) has invariant lines $H=cr$. To see this, write

$$\frac{dH}{dr}=c=\frac{-r^2-c^2r^2}{-\frac{3}{2}cr^2}=\frac{-1-c^2}{-\frac{3}{2}c}\Rightarrow c=\pm\sqrt{2}. \tag{17}$$

Taking the dot product of the vector field $(-\frac{3}{2}rH,-r^2-H^2)^T$ with the radial vector $(r,H)^T$ along the line $H=cr$ we find that it is negative for $H>0$ and positive for $H<0$. Therefore, the direction of the flow along $H=cr$ in the first quadrant is towards the origin and goes away from the origin in the second quadrant. Note that H is always decreasing along the orbits while r is decreasing in the first quadrant. Since no trajectory can cross the line $H=cr$, all trajectories starting above this line approach the origin asymptotically. On any orbit starting in the first quadrant below the line $H=cr$, H becomes zero at some time and the trajectory vertically crosses the r-axis. Once the trajectory enters the second quadrant, r increases and H decreases. The phase portrait is shown in Fig. 1.

At first sight, it seems probable that an initially expanding universe may recollapse. However, the phase space of the dynamical system (16) is not the whole $r-H$ plane, because of the constraint (11), which in terms of the variables (15) becomes

$$H^2>6r^2. \tag{18}$$

Therefore, for an expanding universe we should consider only trajectories starting above the line $H=\sqrt{6}r$ and according to the previous discussion all these trajectories asymptotically approach the origin.

We now turn to the relation of the dynamics in the $r-H$ plane to the full three-dimensional system (14), or the equivalent (13) in Cartesian coordinates. Any trajectory spirals clockwise in the $x-y$ plane while both H and x^2+y^2 are decreasing. In physical terms this means that the scalar field oscillates around the minimum of the potential with a decreasing amplitude, H is always decreasing and, in view of (6), the curvature decreases. A typical trajectory of (13) is shown in Fig. 2.

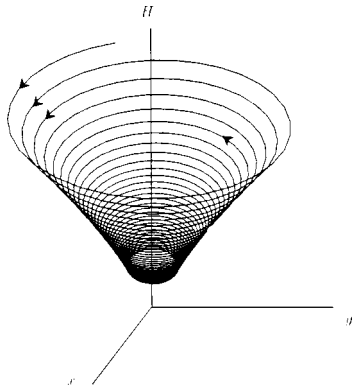

FIG. 2. Trajectories of the full three-dimensional system spiral approaching the origin.

V. COMMENT ON FLAT FRW MODELS

Consider a flat FRW model containing a barotropic fluid with an equation of state $p=(\gamma-1)\rho$, where $0\leqslant\gamma\leqslant 2$, and a scalar field having the potential (7). Then the system (2)–(4) reduces again to a four-dimensional dynamical system, namely,

$$\begin{aligned}\dot{\phi}&=y,\\ \dot{y}&=-3Hy-V'(\phi),\\ \dot{\rho}&=-3\gamma\rho H,\\ \dot{H}&=-\frac{1}{2}y^2-\frac{\gamma}{2}\rho,\end{aligned}\tag{19}$$

subject to the constraint

$$3H^2=\rho+\tfrac{1}{2}y^2+V(\phi).\tag{20}$$

In contrast to (5d), the fourth of (19) implies that H is always decreasing. If we use the constraint (20) to eliminate ρ, the evolution equations become

$$\begin{aligned}\dot{\phi}&=y,\\ \dot{y}&=-3Hy-V'(\phi),\\ \dot{H}&=-\frac{3\gamma}{2}H^2-\frac{2-\gamma}{4}y^2+\frac{\gamma}{2}V(\phi).\end{aligned}\tag{21}$$

We see that the structure of (21) describing a flat FRW model with a perfect fluid and a scalar field, apart from being parameter dependent, has a striking similarity to the dynamical system (8) for the vacuum positively curved FRW with a scalar field. Proceeding as in Sec. IV, we end up with the following system in cylindrical coordinates:

$$\begin{aligned}\dot{r}&=-\tfrac{1}{2}rH,\\ \dot{\theta}&=1,\end{aligned}\tag{22}$$

$$\dot{H}=\frac{5\gamma-4}{8}r^2-\frac{\gamma}{2}H^2 \quad .$$

Although the system (22) depends only on one parameter, it is convenient to rescale the variables by

$$r\to\lambda r, \quad H\to\mu H \tag{23}$$

with

$$\mu=\frac{2}{\gamma}, \quad \lambda=\sqrt{\left|\frac{16}{\gamma(5\gamma-4)}\right|},$$

so that the projection of (22) on the $r-H$ plane is

$$\begin{aligned}\dot{r}&=-\frac{1}{\gamma}rH,\\ \dot{H}&=br^2-H^2 \quad ,\end{aligned} \tag{24}$$

where

$$b=+1 \text{ for } \gamma>\tfrac{4}{5}, \quad b=-1 \text{ for } \gamma<\tfrac{4}{5}.$$

Note that (24) has a first integral, viz.,

$$I(r,H)=-\frac{1}{2\gamma}r^{-2\gamma}\left(\frac{br^2}{1-1/\gamma}-H^2\right). \tag{25}$$

In fact, it is straightforward to verify that $(\partial I/\partial r)\dot{r}+(\partial I/\partial H)\dot{H}=0$ along the solution curves of (24). The level curves of I are the trajectories of the system.

Invariant lines $H=cr$ exist for certain values of the parameter γ. We find [cf. (17)]

$$c=\pm\sqrt{\frac{b}{1-1/\gamma}}.$$

Case I. For $b=+1$, invariant lines exist if $\gamma>1$. We find that the direction of the flow along $H=cr$ in the first quadrant is towards the origin and goes away from the origin in the second quadrant. Note that in the first quadrant r is decreasing along the orbits and that $\dot{H}$ vanishes along the line $H=r$, which lies below the invariant line $H=cr$. It can be shown that in the first quadrant a level curve of $I(r,H)$ may intersect the line $H=r$ only once [it is sufficient to consider the level curve passing through an arbitrary point $(r_1,0)$ and compute the r coordinate at the intersection with the line $H=r$]. We conclude that once a trajectory crosses the line $H=r$, it is trapped between the lines $H=r$ and $H=cr$ and, since $\dot{r}<0$, it approaches the origin asymptotically.

Case II. $b=+1$ and $\frac{4}{5}<\gamma<1$. There are no invariant lines. Similar arguments as in case I yield the phase portrait shown in Fig. 3.

Case III. $\gamma<\frac{4}{5}$ $(\Rightarrow b=-1)$. The analysis is exactly the same as in Sec. IV.

In all cases we must remember that the phase space of the dynamical system (24) is not the whole $r-H$ plane, because of the constraint (11), which in terms of the variables (23) reads

$$H^2>\frac{6\gamma}{|5\gamma-4|}r^2. \tag{26}$$

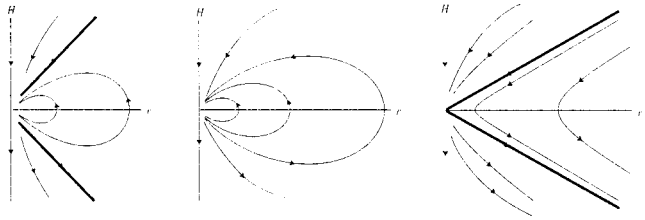

FIG. 3. The phase portrait of (24) for $1<\gamma<2$, $\frac{4}{5}<\gamma<1$, and $0<\gamma<\frac{4}{5}$, respectively.

Therefore, for an expanding universe, we should consider only trajectories starting above the line $H=\sqrt{6\gamma/|5\gamma-4|}r$, which in case III lies always above the line $H=cr$ and, according to the previous discussion, all these trajectories asymptotically approach the origin.

We conclude that, in the conformal frame of the $R+aR^2$ theory, an initially expanding flat universe with a barotropic fluid as matter source remains ever-expanding and eventually the quadratic curvature corrections become negligible. This result, established by stability analysis, is in accordance with the general properties of all flat FRW models with a scalar field having a potential with a unique zero minimum.[17]

VI. DISCUSSION

We have analyzed the qualitative behavior of a positively curved FRW model containing a scalar field with the potential (7). This model is conformally equivalent to the positively curved FRW space–time in the simplest higher order gravity theory, namely the $R+\alpha R^2$ theory. We have shown that an initially expanding closed universe avoids recollapse provided that the initial value of H is less than $\sqrt{V_\infty}$. This result should be compared to a counterexample of the closed universe recollapse conjecture (cf. Ref. 21, where it is shown that initially expanding vacuum diagonal Bianchi IX models in purely quadratic gravity are ever-expanding). It should be of interest to investigate if a closed FRW universe filled with ordinary matter satisfying the usual energy conditions and a scalar field with the potential (7) can avoid recollapse. This is equivalent to the analysis of the qualitative behavior of the full five-dimensional system (2)–(4). A partial answer to this question for an arbitrary non-negative potential having a unique minimum $V(0)=0$ is given in Ref. 17.

ACKNOWLEDGMENTS

I thank P. G. L. Leach and S. Cotsakis for fruitful discussions during the preparation of this work. I wish to thank an anonymous referee for useful suggestions, especially for pointing out to me the remarks regarding the equilibrium A after Eq. (11).

APPENDIX: PROOF OF PROPOSITION 1

In order to determine the local center manifold of (10) at $\mathbf{q}$, we have to transform the system into a form suitable for the application of the center manifold theorem. The procedure is fairly systematic and will be accomplished in the following steps.

(1) The Jacobian of (10) at $\mathbf{q}=(0,0,\sqrt{\frac{3}{2}})$ has eigenvalues 0, $-\sqrt{\frac{2}{3}}$ and $-\sqrt{\frac{3}{2}}$ with corresponding eigenvectors $(-\sqrt{\frac{2}{3}},\frac{2}{3},1)^T$, $(0,0,1)^T$ and $(0,1,0)^T$. Let T be the matrix having as columns these eigenvectors. We shift the fixed point to (0,0,0) by setting $\tilde{H}=H-\sqrt{\frac{3}{2}}$ and write (10) in vector notation as

$$\dot{\mathbf{z}}=A\mathbf{z}+\mathbf{F}(\mathbf{z}), \tag{A1}$$

where A is the linear part of the vector field and $\mathbf{F}(\mathbf{0})=\mathbf{0}$.

(2) Using the matrix T which transforms the linear part of the vector field into Jordan canonical form, we define new variables, $(x,y_1,y_2)\equiv\mathbf{x}$, by the equations

$$u=-\sqrt{\tfrac{2}{3}}x,$$

$$y=\tfrac{2}{3}x+y_2,$$

$$\tilde{H}=x+y_1,$$

or in vector notation $\mathbf{z}=T\mathbf{x}$, so that (A1) becomes

$$\dot{\mathbf{x}}=T^{-1}AT\mathbf{x}+T^{-1}\mathbf{F}(T\mathbf{x}).$$

Denoting the canonical form of A by B we finally obtain the system

$$\dot{\mathbf{x}}=B\mathbf{x}+\mathbf{f}(\mathbf{x}), \tag{A2}$$

where $\mathbf{f}(\mathbf{x})\coloneqq T^{-1}\mathbf{F}(T\mathbf{x})$. In components system (A2) is

$$\begin{pmatrix}\dot{x}\\ \dot{y}_1\\ \dot{y}_2\end{pmatrix}=\begin{pmatrix}0 & 0 & 0\\ 0 & -\sqrt{\frac{2}{3}} & 0\\ 0 & 0 & -\sqrt{\frac{3}{2}}\end{pmatrix}\begin{pmatrix}x\\ y_1\\ y_2\end{pmatrix}+\begin{pmatrix}-\frac{2}{3}x^2-xy_2\\ \frac{10}{27}x^2-\frac{1}{3}y_1^2-\frac{2}{3}y_2^2-\frac{2}{3}xy_1+\frac{1}{9}xy_2\\ \frac{4}{9}x^2-\frac{2}{3}xy_1-\frac{1}{3}xy_2-y_1y_2\end{pmatrix}. \tag{A3}$$

(3) The system (A3) is written in diagonal form

$$\begin{aligned}\dot{x}&=Cx+f(x,\mathbf{y}),\\ \dot{\mathbf{y}}&=P\mathbf{y}+\mathbf{g}(x,\mathbf{y}),\end{aligned} \tag{A4}$$

where $(x,\mathbf{y})\in\mathbb{R}\times\mathbb{R}^2$, C is the zero 1×1 matrix, P is a square matrix with negative eigenvalues and $f,\mathbf{g}$ vanish at $\mathbf{0}$ and have vanishing derivatives at $\mathbf{0}$. The center manifold theorem asserts that there exists a one-dimensional invariant local center manifold $W^c(\mathbf{0})$ of (A4) tangent to the center subspace (the $\mathbf{y}=\mathbf{0}$ space) at $\mathbf{0}$. Moreover, $W^c(\mathbf{0})$ can be represented as

$$W^c(\mathbf{0})=\{(x,\mathbf{y})\in\mathbb{R}\times\mathbb{R}^2:\mathbf{y}=\mathbf{h}(x),\ \ |x|<\delta\};\qquad \mathbf{h}(0)=0,\ D\mathbf{h}(0)=\mathbf{0},$$

for δ sufficiently small (cf. Ref. 19, p. 155). The restriction of (A4) to the center manifold is

$$\dot{x}=Cx+f(x,\mathbf{h}(x)). \tag{A5}$$

According to Theorem 3.2.2 in Ref. 22, if the origin $x=0$ of (A5) is stable (resp. unstable), then the origin of (A4) is also stable (resp. unstable). Therefore, we have to find the local center manifold, i.e., the problem reduces to the computation of $\mathbf{h}(x)$.

(4) Substituting $\mathbf{y}=\mathbf{h}(x)$ in the second component of (A4) and using the chain rule, $\dot{\mathbf{y}}=D\mathbf{h}(x)\dot{x}$, one can show that the function $\mathbf{h}(x)$ that defines the local center manifold satisfies

$$D\mathbf{h}(x)[Cx+f(x,\mathbf{h}(x))]-P\mathbf{h}(x)-\mathbf{g}(x,\mathbf{h}(x))=0. \tag{A6}$$

This condition allows for an approximation of $\mathbf{h}(x)$ by a Taylor series at $x=0$. Since $\mathbf{h}(0)=0$, $D\mathbf{h}(0)=\mathbf{0}$, it is obvious that $\mathbf{h}(x)$ commences with quadratic terms. We substitute

$$\mathbf{h}(x)\coloneqq\begin{pmatrix}h_1(x)\\ h_2(x)\end{pmatrix}=\begin{pmatrix}a_1x^2+a_2x^3+O(x^4)\\ b_1x^2+b_2x^3+O(x^4)\end{pmatrix}$$

into (A6) and set the coefficients of like powers of x equal to zero to find the unknowns $a_1, b_1, \ldots$.

(5) Since y_1 is absent from the first of (A3), we give only the result for $h_2(x)$. We find $b_1 = \frac{4}{9}\sqrt{\frac{2}{3}}$, $b_2 = \frac{4}{81}$. Therefore, (A5) yields

$$\dot{x} = -\tfrac{2}{3}x^2 - \tfrac{4}{9}\sqrt{\tfrac{2}{3}}x^3 - \tfrac{4}{81}x^4 + O(x^5). \tag{A7}$$

It is obvious that the origin $x=0$ of (A7) is asymptotically unstable (saddle point). The theorem mentioned after (A5) implies that the origin $\mathbf{x}=\mathbf{0}$ of the full three-dimensional system is unstable. This completes the proof.

This paper extends the generalized variational principle of Herglotz to one with several independent variables and derives the corresponding generalized Euler–Lagrange equations. The extended principle contains the classical variational principle with several independent variables and the variational principle of Herglotz as special cases. A first Noether-type theorem is proven for the new variational principle, which gives the conserved quantities corresponding to symmetries of the associated functional. This theorem contains the classical first Noether theorem as a special case. As examples for applications we calculate a conserved quantity for the damped nonlinear Klein–Gordon equation and we show that the equations which describe the propagation of electromagnetic fields in a conductive medium can be derived from the generalized variational principle of Herglotz (but not from a classical variational principle). © *2003 American Institute of Physics.*

I. INTRODUCTION

The generalized variational principle, proposed by Herglotz,[1,2] defines the functional whose extrema are sought by a differential equation rather than by an integral. It contains as a special case the classical variational principle with one independent variable.

The Herglotz principle gives a variational description of nonconservative as well as conservative processes involving one independent variable. The solutions of the equations providing the extrema of the functional determine a one-parameter group of contact transformations. See Guenther *et al.*[3] From the paper of Furta[4] we see that there is a close link between the Herglotz variational principle and control and optimal control theories. Through contact transformations the Herglotz principle is also related to thermodynamics. See Mrugala.[5] Georgieva *et al.*[6] prove a Noether-type theorem which yields conservation laws corresponding to the symmetries of the functional defined by the Herglotz variational principle.

In this paper we extend the generalized variational principle of Herglotz to one with several independent variables. This new variational principle can give a variational description of nonconservative processes involving physical fields. It reduces to the Herglotz generalized variational principle when only one independent variable, the time-variable, is present. It also reduces to the classical variational principle with several independent variables. Thus, it contains both the Herglotz's variational principle and the classical variational principle with several independent variables as special cases. One valuable characteristic of the new variational principle is that it gives a variational description of nonconservative processes even when the *Lagrangian is not an explicit*

function of time, which is not possible with the classical variational principle. This is shown in Sec. VII.

The classical first Noether theorem applies only to functionals defined by integrals, see Noether.[7,8] Thus, a need arises for a Noether-type theorem which does apply to functionals defined by differential or integro-differential equations. In this paper we formulate and prove a first Noether-type theorem for the generalized variational principle with several independent variables, i.e., when the functional is defined by an integro-differential equation. One of its corollaries provides an explicit procedure for finding the conserved quantities corresponding to symmetries of this functional.

A criterion for a transformation to be a symmetry of the functional defined by the generalized variational principle with several independent variables is proven. This criterion contains as a special case the criterion for a transformation to be a symmetry of a variational integral due to Lie.

Six corollaries of the first Noether-type theorem are proven. Five of them provide conserved quantities in systems described by the generalized Euler–Lagrange equations with several independent variables. The significance of the first Noether-type theorem in the several independent variables case is further demonstrated by applying it to the equations describing the propagation of electromagnetic fields in conductive media and to the damped nonlinear Klein–Gordon equation.

II. THE GENERALIZED VARIATIONAL PRINCIPLE WITH SEVERAL INDEPENDENT VARIABLES

In the variational principle of Herglotz the functional $z=z[x;s]$ of $x\equiv(x^1,\ldots,x^n)$ is defined by a differential equation of the form

$$\frac{\mathrm{d}z}{\mathrm{d}t}=L(t,x,\dot{x},z), \quad 0\leqslant t\leqslant s,$$

where t is the only independent variable and $\dot{x}=\mathrm{d}x/\mathrm{d}t$. Herglotz showed that the value of this functional is an extremum when its argument functions $x^k(t)$ are solutions of the generalized Euler–Lagrange equations

$$\frac{\partial L}{\partial x^k}-\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L}{\partial \dot{x}^k}+\frac{\partial L}{\partial z}\frac{\partial L}{\partial \dot{x}^k}=0, \quad k=1,\ldots,n.$$

In this section we generalize the Herglotz variational principle to one involving several independent variables.

For the remainder of this paper, the independent variables will be the time variable t and the spatial coordinates $x\equiv(x^1,\ldots,x^n)$. The argument function of the functional $z[u;s]$ defined by the new variational principle will be $u=u(t,x)=(u^1(t,x),\ldots,u^m(t,x))$. The standard abbreviations $u^i_t=\partial u^i/\partial t$ and $u^i_{x^k}=\partial u^i/\partial x^k$ will be used. The summation convention is assumed for the entire paper.

The generalized variational principle with several independent variables is as follows:

Let the functional $z=z[u;s]$ of $u=u(t,x)$ be given by an integro-differential equation of the form

$$\frac{\mathrm{d}z}{\mathrm{d}t}=\int_\Omega \mathcal{L}(t,x,u,u_t,u_x,z)\,\mathrm{d}^n x, \quad 0\leqslant t\leqslant s, \tag{2.1}$$

where $x\equiv(x^1,\ldots,x^n)$, $\mathrm{d}^n x\equiv \mathrm{d}x^1\cdots\mathrm{d}x^n$, $u\equiv(u^1,\ldots,u^m)$, $u_x\equiv(u^1_x,\ldots,u^m_x)$, $u_t\equiv(u^1_t,\ldots,u^m_t)$, and $u^i_x\equiv(u^i_{x^1},\ldots,u^i_{x^n})$, $i=1,\ldots,m$, and where the function $\mathcal{L}$ is at least twice differentiable with respect to u_x, u_t and once differentiable with respect to t,x,z. Let $\eta\equiv(\eta^1(t,x),\ldots,\eta^m(t,x))$ have continuous first derivatives and otherwise be arbitrary except for the boundary conditions:

$$\eta(0,x)=\eta(s,x)=0,$$

$$\eta(t,x)=0 \qquad \text{for} \quad x\in\partial\Omega, \quad 0\leqslant t\leqslant s,$$

where $\partial\Omega$ is the boundary of Ω. Then, the value of the functional $z[u;s]$ is an extremum for functions u which satisfy the condition

$$\frac{\mathrm{d}}{\mathrm{d}\varepsilon} z[u+\varepsilon\,\eta;s]\big|_{\varepsilon=0}=0. \tag{2.2}$$

The function $\mathcal{L}$ will be called, just as in the classical case, the *Lagrangian density*. It should be observed that when a variation $\varepsilon\,\eta$ is applied to u the equation (2.1), defining the functional z, must be solved with the same fixed initial condition $z(0)$ at $t=0$ and the solution evaluated at the same fixed final time $t=s$ for all varied argument functions $u+\varepsilon\,\eta$.

III. GENERALIZED EULER–LAGRANGE EQUATIONS WITH SEVERAL INDEPENDENT VARIABLES

In this section we derive the equations which provide the extrema of the functional $z[u;s]$ defined by the integro-differential equation (2.1). Because of the obvious correspondence with the classical case, we call these equations the *generalized Euler–Lagrange equations with several independent variables*.

Theorem 3.1.: *Every function $u\equiv(u^1,\ldots,u^m)$, for which the functional z defined by the integro-differential equation (2.1) has an extremum, is a solution of*

$$\frac{\partial\mathcal{L}}{\partial u^i}-\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial\mathcal{L}}{\partial u^i_t}-\frac{\mathrm{d}}{\mathrm{d}x^k}\frac{\partial\mathcal{L}}{\partial u^i_{x^k}}+\frac{\partial\mathcal{L}}{\partial u^i_t}\int_\Omega\frac{\partial\mathcal{L}}{\partial z}\,\mathrm{d}x=0\,, \quad i=1,\ldots,m. \tag{3.1}$$

Proof: We will show that equations (3.1) are a consequence of condition (2.2). For this purpose let $\varepsilon\,\eta$ be the variation of the argument of the functional z and denote by $\zeta=\zeta(t)$ the quantity

$$\zeta(t)=\frac{\mathrm{d}}{\mathrm{d}\varepsilon} z[u+\varepsilon\,\eta;t]\big|_{\varepsilon=0}. \tag{3.2}$$

To find the differential equation for ζ we apply the variation $\varepsilon\,\eta$ to the argument function in the defining equation (2.1), i.e.,

$$\frac{\mathrm{d}}{\mathrm{d}t} z[u+\varepsilon\,\eta;t]=\int_\Omega\mathcal{L}(t,x,u+\varepsilon\,\eta,u_t+\varepsilon\,\eta_t,u_x+\varepsilon\,\eta_x,z)\,\mathrm{d}^n x \tag{3.3}$$

and differentiate the result with respect to ε. Then, we set $\varepsilon=0$ to obtain

$$\frac{\mathrm{d}\zeta}{\mathrm{d}t}=\int_\Omega\left(\frac{\partial\mathcal{L}}{\partial u^i}\,\eta^i+\frac{\partial\mathcal{L}}{\partial u^i_t}\,\eta^i_t+\frac{\partial\mathcal{L}}{\partial u^i_{x^k}}\,\eta^i_{x^k}\right)\mathrm{d}^n x+\zeta\int_\Omega\frac{\partial\mathcal{L}}{\partial z}\,\mathrm{d}^n x, \quad i=1,\ldots,m, \tag{3.4}$$

where in the last term we have used the fact that ζ does not depend on x. For convenience we denote by $A(t)$ and $B(t)$ the quantities

$$A(t)=\int_\Omega\left(\frac{\partial\mathcal{L}}{\partial u^i}\,\eta^i+\frac{\partial\mathcal{L}}{\partial u^i_t}\,\eta^i_t+\frac{\partial\mathcal{L}}{\partial u^i_{x^k}}\,\eta^i_{x^k}\right)\mathrm{d}^n x, \quad B(t)=\int_\Omega\frac{\partial\mathcal{L}}{\partial z}\,\mathrm{d}^n x.$$

With this notation Eq. (3.4) becomes

$$\frac{\mathrm{d}\zeta(t)}{\mathrm{d}t}=A(t)+B(t)\,\zeta(t)$$

which is the sought equation for $\zeta(t)$. Its solution $\zeta(s)$, evaluated at the end of the time interval $t=s$, is the variation of $z[u;s]$ and is given by

$$\exp\left(-\int_0^s B(\theta)\,\mathrm{d}\theta\right)\zeta(s)=\int_0^s \exp\left(-\int_0^t B(\theta)\,\mathrm{d}\theta\right)A(t)\,\mathrm{d}t \tag{3.5}$$

since $\zeta(0)=0$. We are interested in those functions u which leave the functional $z[u;s]$ stationary, i.e., those for which the variation $\zeta(s)$ is identically zero. Hence, (3.5) becomes

$$\int_0^s \exp\left(-\int_0^t B(\theta)\,\mathrm{d}\theta\right)A(t)\,\mathrm{d}t=0. \tag{3.6}$$

Inserting expressions $A(t)$ and $B(t)$ into (3.6), denoting the exponential function by

$$E(t)\equiv\exp\left(-\int_0^t B(\theta)\,\mathrm{d}\theta\right)$$

and integrating by parts the terms containing $\eta^i_{x^k}$ produces the equation

$$\int_0^s E(t)\int_\Omega\left(\frac{\partial\mathcal{L}}{\partial u^i}\eta^i+\frac{\partial\mathcal{L}}{\partial u^i_t}\eta^i_t+\frac{\mathrm{d}}{\mathrm{d}x^k}\left(\frac{\partial\mathcal{L}}{\partial u^i_{x^k}}\eta^i\right)-\eta^i\frac{\mathrm{d}}{\mathrm{d}x^k}\frac{\partial\mathcal{L}}{\partial u^i_{x^k}}\right)\mathrm{d}^nx\,\mathrm{d}t=0. \tag{3.7}$$

By Gauss' theorem the space integral of the third term in (3.7)

$$\int_\Omega\frac{\mathrm{d}}{\mathrm{d}x^k}\left(\frac{\partial\mathcal{L}}{\partial u^i_{x^k}}\eta^i\right)\mathrm{d}^nx=\int_{\partial\Omega}\eta^i\frac{\partial\mathcal{L}}{\partial u^i_{x^k}}\mathrm{d}a_k=0$$

vanishes because $\eta=0$ on $\partial\Omega$, by definition. Here, $\mathrm{d}a_k$ stands for the k-component of the surface element $\mathrm{d}a=(\mathrm{d}a_1,\ldots,\mathrm{d}a_n)$ of $\partial\Omega$. Next, we integrate by parts (with respect to t) the terms involving η^i_t in (3.7) to obtain

$$\int_0^s E(t)\int_\Omega\left(\frac{\partial\mathcal{L}}{\partial u^i}-\frac{\mathrm{d}}{\mathrm{d}x^k}\frac{\partial\mathcal{L}}{\partial u^i_{x^k}}\right)\eta^i\,\mathrm{d}^nx\,\mathrm{d}t-\int_\Omega\int_0^s\eta^i\frac{\mathrm{d}}{\mathrm{d}t}\left(E(t)\frac{\partial\mathcal{L}}{\partial u^i_t}\right)\mathrm{d}t\,\mathrm{d}^nx=0$$

because $\eta(0,x)=0$ and $\eta(s,x)=0$, by definition. Finally, expanding the second integrand in the last equation and collecting terms, we get

$$\int_0^s\int_\Omega E(t)\left(\frac{\partial\mathcal{L}}{\partial u^i}-\frac{\mathrm{d}}{\mathrm{d}x^k}\frac{\partial\mathcal{L}}{\partial u^i_{x^k}}-\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial\mathcal{L}}{\partial u^i_t}+\frac{\partial\mathcal{L}}{\partial u^i_t}\int_\Omega\frac{\partial\mathcal{L}}{\partial z}\mathrm{d}^nx\right)\eta^i\,\mathrm{d}^nx\,\mathrm{d}t=0\,.$$

Taking in consideration that η is arbitrary and that $E(t)>0$ for all t, we obtain equation (3.1), which concludes the proof. □

It is important to observe that the generalized Euler–Lagrange equations (3.1) reduce to the classical Euler–Lagrange equations when $\mathcal{L}$ does not depend on z, i.e., when the functional z defined by the integro-differential equation (2.1) reduces to the classical definition of a functional by an integral. Also, Eqs. (3.1) reduce to the generalized Euler–Lagrange equations for the generalized variational principle of Herglotz when t is the only independent variable involved.

IV. INFINITESIMAL CRITERION FOR INVARIANCE

In this section we give an infinitesimal criterion for the invariance of the functional z defined by Eq. (2.1) under the action of a one-parameter group of transformations of the independent variables t, $x\equiv(x^1,\ldots,x^n)$ and the dependent variables $u\equiv(u^1,\ldots,u^m)$, i.e.,

$$\overline{t}=\phi(t,x,u;\varepsilon),$$

$$\overline{x^k}=\varphi^k(t,x,u;\varepsilon),\quad k=1,\ldots,n, \tag{4.1}$$

$$\overline{u^i}=\psi^i(t,x,u;\varepsilon),\quad i=1,\ldots,m\,.$$

To find the transformed functions $\overline{u^i}=\overline{u^i}(\overline{t},\overline{x};\varepsilon)$ of the functions $u^i=u^i(t,x)$ we insert the latter into ϕ and φ^k of (4.1) to get a system of $n+1$ equations with $n+1$ unknowns $t,x^1,\ldots,x^n$ and a parameter ε. We invert this system to obtain t and $x^1,\ldots,x^n$ as functions of $\overline{t}$ and $\overline{x^1},\ldots,\overline{x^n}$. These we substitute into the last m equations of (4.1) to get $\overline{u^i}$ as a function of $\overline{t}$ and $\overline{x^1},\ldots,\overline{x^n}$ and ε, which we denote by $\overline{u^i}=\overline{u^i}(\overline{t},\overline{x};\varepsilon)$.

Definition 4.1: The transformed functional $\overline{z}$ of a functional z defined by (2.1), is the solution of the transformed integro-differential equation

$$\frac{\mathrm{d}\overline{z}}{\mathrm{d}\overline{t}}=\int_{\overline{\Omega}}\mathcal{L}(\overline{t},\overline{x},\overline{u}(\overline{t},\overline{x}),\overline{u_t},\overline{u_x},\overline{z})\,\mathrm{d}^n\overline{x}, \tag{4.2}$$

where $\overline{\Omega}$ is the transformed domain of the domain Ω.

Observation: The most general one-parameter group of transformations of the independent and dependent variables admitted by equation (2.1) is

$$\overline{t}=\phi(t;\varepsilon),$$

$$\overline{x^k}=\varphi^k(t,x,u;\varepsilon),\quad k=1,\ldots,n, \tag{4.3}$$

$$\overline{u^i}=\psi^i(t,x,u;\varepsilon),\quad i=1,\ldots,m.$$

Proof: For a given $u=u(x,t)$ the solution z of the nontransformed equation (2.1) and it's derivative $\mathrm{d}z/\mathrm{d}t$ are functions of t only. Assume that we transform (2.1) with (4.1) where ϕ *does* depend on either x or u or both. Then, from the transformed equation (4.2) follows that $\mathrm{d}\overline{z}/\mathrm{d}\overline{t}$, and hence $\overline{z}$, are functions of $\overline{t}$ only. On the other hand, if we apply the transformation (4.1) directly to the solution z the result will depend on x. Clearly, this is a contradiction. To avoid it, we must restrict the transformation of the t-variable as shown in (4.3). □

Definition 4.2: Let Φ, Ω, and Ψ^i be the sets on which t, x, and $u^i(t,x)$ vary. A local group of transformations G acting on the independent and dependent variables is a *symmetry group* of the functional z defined by the integro-differential equation (2.1) if whenever D is a subdomain with closure $D^{cl}\subset\Omega$ and $u^i=u^i(t,x)$ are functions defined over $\Phi\times D$ whose graphs lie in $\Phi\times\Omega\times\Psi^i$ with continuous second partial derivatives, and $g\in G$ is such that

$$\overline{u^i}=\overline{u^i}(\overline{t},\overline{x})=g\circ u^i(t,x),\quad i=1,\ldots,m$$

are single valued functions defined over $\overline{\Phi}\times\overline{D}\subset\Phi\times\Omega$, then the functional defined by the transformed integro-differential equation

$$\frac{\mathrm{d}\overline{z}}{\mathrm{d}\overline{t}}=\int_{\overline{D}}\mathcal{L}(\overline{t},\overline{x},\overline{u}(\overline{t},\overline{x}),\overline{u_t},\overline{u_x},\overline{z})\,\mathrm{d}^n\overline{x} \tag{4.4}$$

is equal to the functional defined by the original integro-differential equation

$$\frac{\mathrm{d}z}{\mathrm{d}t}=\int_D\mathcal{L}(t,x,u(t,x),u_t,u_x,z)\,\mathrm{d}^nx \tag{4.5}$$

for all t. Here $\overline{D}$ denotes the transformed D under G.

Proposition 4.3: The one-parameter group of transformations G in (4.3) is a symmetry group of the functional defined by the integro-differential equation (2.1) if and only if

$$\frac{\mathrm{d}\tau}{\mathrm{d}t}\mathcal{L}+\left.\frac{\mathrm{d}\overline{t}}{\mathrm{d}t}\right|_{\varepsilon=0}(\,\mathrm{pr}^{(1)}v(\,\mathcal{L})+\,\mathcal{L}\,\mathrm{Div}\,\xi)=0 \tag{4.6}$$

for all t,x,u,u_t, and u_x in the domain of definition, where

$$v=\tau(t)\frac{\partial}{\partial t}+\,\xi^k(t,x,u)\frac{\partial}{\partial x^k}+\,\eta^i(t,x,u)\frac{\partial}{\partial u^i} \tag{4.7}$$

is the infinitesimal generator of the group G, $\mathrm{Div}\,\xi$ denotes the total divergence of the n-tuple $\xi\equiv(\xi^1,\ldots,\xi^n)$, and $\mathrm{pr}^{(1)}v$ is the first prolongation of v.

Proof: The functions τ, ξ^k, and η^i in (4.7) are

$$\tau\equiv\left.\frac{\mathrm{d}\phi}{\mathrm{d}\varepsilon}\right|_{\varepsilon=0},\quad \xi^k\equiv\left.\frac{\mathrm{d}\varphi^k}{\mathrm{d}\varepsilon}\right|_{\varepsilon=0},\quad k=1,\ldots,n,\quad \eta^i\equiv\left.\frac{\mathrm{d}\psi^i}{\mathrm{d}\varepsilon}\right|_{\varepsilon=0},\quad i=1,\ldots,m.$$

For each $g\in G$ the group transformation $(\overline{t},\overline{x},\overline{u})=g\circ(t,x,u)$ can be regarded as a change of variables, so that we can rewrite the transformed equation (4.4) as

$$\frac{\mathrm{d}\overline{z}}{\mathrm{d}t}=\frac{\mathrm{d}\overline{t}}{\mathrm{d}t}\int_D\mathcal{L}(\overline{t},\overline{x},\mathrm{pr}^{(1)}(g\circ u)(\overline{t},\overline{x}),\overline{z})\,\det J_g(t,x,\mathrm{pr}^{(1)}u(t,x))\,\mathrm{d}^nx, \tag{4.8}$$

where the Jacobi matrix has the entries

$$J_g^{kj}(t,x,u^{(1)})=\frac{\mathrm{d}}{\mathrm{d}x^k}\varphi_g^j(t,x,u^{(1)}),$$

and $u^{(1)}=(u,u_t,u_x)$. If G is a symmetry group of the functional z defined by (2.1), then the functional z defined by (4.5) is identical with the functional $\overline{z}$ defined by (4.8). Hence

$$\frac{\mathrm{d}\overline{t}}{\mathrm{d}t}\int_D\mathcal{L}(\overline{t},\overline{x},\mathrm{pr}^{(1)}(g\circ u)(\overline{t},\overline{x}),\overline{z})\,\det J_g(t,x,\mathrm{pr}^{(1)}u(t,x))\,\mathrm{d}^nx=\int_D\mathcal{L}(t,x,u(t,x),u_t,u_x,z)\,\mathrm{d}^nx$$

holds for all subdomains D of Ω, all functions u^i and all t in the domain of definition. Since $\overline{t}=\phi(t;\varepsilon)$ does not depend on $x^1,\ldots,x^n$, the arbitrariness of D implies that

$$\frac{\mathrm{d}\overline{t}}{\mathrm{d}t}\mathcal{L}(\overline{t},\overline{x},\mathrm{pr}^{(1)}(g\circ u)(\overline{t},\overline{x}),\overline{z})\,\det J_g(t,x,\mathrm{pr}^{(1)}u(t,x))=\mathcal{L}(t,x,u(t,x),u_t,u_x,z) \tag{4.9}$$

holds for all t,x,u,u_t,u_x in the domain of definition. The infinitesimal version of (4.9) is obtained by setting $g=g_\varepsilon=\exp(\varepsilon v)$ and differentiating with respect to ε which produces

$$\left(\frac{\mathrm{d}\tau}{\mathrm{d}t}\mathcal{L}+\frac{\mathrm{d}\overline{t}}{\mathrm{d}t}(\,\mathrm{pr}^{(1)}v\,(\mathcal{L})+\,\mathcal{L}\,\mathrm{Div}\,\xi)\right)\det J_{g_\varepsilon}=0, \tag{4.10}$$

the expression in parentheses being evaluated at $(\overline{t},\overline{x},\overline{u}_\varepsilon^{(1)})$. In particular, when $\varepsilon=0$, g_ε is the identity map and we obtain (4.6). Conversely, if (4.6) holds for all (t,x,u,u_t,u_x) in the domain of definition, then (4.10) holds for ε sufficiently small. The left-hand side of (4.10) is just the derivative of the left-hand side of (4.9) with respect to ε. Thus, integrating from 0 to ε we get (4.9)

for g sufficiently near the identity. The usual connectivity arguments complete the proof for all $g \in G$. □

We observe that the infinitesimal criterion which the above proposition provides reduces to the infinitesimal criterion for the invariance of the classical variational integral under a group of transformations, when the generalized variational principle with several independent variables reduces to the classical variational principle.

V. FIRST NOETHER-TYPE THEOREM FOR THE GENERALIZED VARIATIONAL PRINCIPLE WITH SEVERAL INDEPENDENT VARIABLES

In this section we formulate and prove a theorem which provides an identity corresponding to each symmetry of the functional z defined by the integro-differential equation (2.1). We call it a first Noether-type theorem for the generalized variational principle with several independent variables because this theorem contains as a special case the classical first Noether theorem.

As corollaries to this theorem we show that there is a correspondence between the symmetries of the functional z defined by Eq. (2.1) and conserved quantities of the corresponding generalized Euler–Lagrange equations.

Theorem 5.1: *Let (4.3) be a given symmetry group with infinitesimal generator*

$$v = \tau(t)\frac{\partial}{\partial t} + \xi^k(t,x,u)\frac{\partial}{\partial x^k} + \eta^i(t,x,u)\frac{\partial}{\partial u^i}, \quad k=1,\ldots,n, \quad i=1,\ldots,m. \tag{5.1}$$

of the functional $z[u;s]$ defined by (2.1). Then the identity

$$\int_D \left(\frac{\mathrm{d}}{\mathrm{d}t}\left(E\left((\tau u_t^i + \xi^j u_{xj}^i - \eta^i)\frac{\partial \mathcal{L}}{\partial u_t^i} - \tau\mathcal{L}\right)\right) + \frac{\mathrm{d}}{\mathrm{d}x^k}\left(E\left((\tau u_t^i + \xi^j u_{xj}^i - \eta^i)\frac{\partial \mathcal{L}}{\partial u_{x^k}^i} - \xi^k\mathcal{L}\right)\right)\right) \mathrm{d}^n x = 0 \tag{5.2}$$

holds on solutions of the generalized Euler–Lagrange equations (3.1). Here D is any subdomain of Ω, including Ω itself, whose closure $D^{cl} \subset \Omega^{cl}$ and $E = E(t)$ is

$$E = \exp\left(-\int_0^t \int_D \frac{\partial \mathcal{L}}{\partial z}\mathrm{d}^n x\, d\theta\right). \tag{5.3}$$

Proof: We write the integro-differential equation (2.1) for any subdomain D of Ω and apply the transformation (5.1) to it, i.e.,

$$\frac{\mathrm{d}\overline{z}}{\mathrm{d}\overline{t}} = \int_{\overline{D}} \mathcal{L}(\overline{t},\overline{x},\overline{u}(\overline{t},\overline{x}),\overline{u_t},\overline{u_x},\overline{z})\,\mathrm{d}^n\overline{x}, \quad \phi(0;\varepsilon) \leqslant \overline{t} \leqslant \phi(s;\varepsilon). \tag{5.4}$$

Here $\mathrm{d}^n\overline{x} = \mathrm{d}\overline{x^1}\cdots\mathrm{d}\overline{x^n}$ and $\overline{D} = \overline{D}(\overline{t},\overline{u},\varepsilon)$ denotes the result of transforming D with (5.1) which, in general, depends on $\overline{t}$, $\overline{u}$, and ε. Now we change the independent variables $\overline{t}$ and $\overline{x^k}$ in (5.4) (but not the dependent variables) back to the original independent variables t and x^k. The resulting equation is

$$\frac{\mathrm{d}\overline{z}}{\mathrm{d}t} = \frac{\mathrm{d}\overline{t}}{\mathrm{d}t}\int_D \mathcal{L}(\overline{t},\overline{x},\overline{u}(\overline{t},\overline{x}),\overline{u_t},\overline{u_x},\overline{z})\det\left(\frac{\partial\overline{x}}{\partial x}\right)\mathrm{d}^n x, \quad 0 \leqslant t \leqslant s, \tag{5.5}$$

where $\partial\overline{x}/\partial x$ stands for the Jacobian matrix of the transformation of the x variables. Differentiating equation (5.5) with respect to ε,

$$\frac{\mathrm{d}}{\mathrm{d}t}\frac{\mathrm{d}\overline{z}}{\mathrm{d}\varepsilon} = \frac{\mathrm{d}\overline{t}}{\mathrm{d}t}\int_D \left(\frac{\mathrm{d}\mathcal{L}}{\mathrm{d}\varepsilon}\det\left(\frac{\partial\overline{x}}{\partial x}\right) + \mathcal{L}\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\det\left(\frac{\partial\overline{x}}{\partial x}\right)\right)\mathrm{d}^n x + \frac{\mathrm{d}}{\mathrm{d}\varepsilon}\frac{\mathrm{d}\overline{t}}{\mathrm{d}t}\int_D \mathcal{L}\det\left(\frac{\partial\overline{x}}{\partial x}\right)\mathrm{d}^n x, \tag{5.6}$$

and observing that

$$\left.\frac{\mathrm{d}\overline{t}}{\mathrm{d}t}\right|_{\varepsilon=0}=1,\quad \det\left(\left.\frac{\partial\overline{x}}{\partial x}\right)\right|_{\varepsilon=0}=1,\quad \left.\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\frac{\mathrm{d}\overline{t}}{\mathrm{d}t}\right|_{\varepsilon=0}=\frac{\mathrm{d}\tau}{\mathrm{d}t}$$

produces

$$\frac{\mathrm{d}\zeta}{\mathrm{d}t}=\int_D\left.\frac{\mathrm{d}\mathcal{L}}{\mathrm{d}\varepsilon}\right|_{\varepsilon=0}\mathrm{d}^nx+\int_D\mathcal{L}\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\det\left(\left.\frac{\partial\overline{x}}{\partial x}\right)\right|_{\varepsilon=0}\mathrm{d}^nx+\frac{\mathrm{d}\tau}{\mathrm{d}t}\int_D\mathcal{L}\,\mathrm{d}^nx, \tag{5.7}$$

where, by definition, the variation $\zeta=\zeta(t)$ of $\overline{z}$ is

$$\zeta(t)\equiv\left.\frac{\mathrm{d}\overline{z}}{\mathrm{d}\varepsilon}\right|_{\varepsilon=0}.$$

Now, we need to express the first and the second integrands in (5.7) in terms of known functions. The calculations are lengthy and are given in the Appendix. When the results

$$\left.\frac{\mathrm{d}\mathcal{L}}{\mathrm{d}\varepsilon}\right|_{\varepsilon=0}=\frac{\partial\mathcal{L}}{\partial t}\tau+\frac{\partial\mathcal{L}}{\partial x^k}\xi^k+\frac{\partial\mathcal{L}}{\partial u^i}\eta^i+\frac{\partial\mathcal{L}}{\partial u^i_t}\left(\frac{\mathrm{d}\eta^i}{\mathrm{d}t}-u^i_t\frac{\mathrm{d}\tau}{\mathrm{d}t}-u^i_{x^k}\frac{\mathrm{d}\xi^k}{\mathrm{d}t}\right)+\frac{\partial\mathcal{L}}{\partial u^i_{x^k}}\left(\frac{\mathrm{d}\eta^i}{\mathrm{d}x^k}-u^i_{x^j}\frac{\mathrm{d}\xi^j}{\mathrm{d}x^k}\right)+\frac{\partial\mathcal{L}}{\partial z}\zeta, \tag{5.8}$$

$$\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\det\left(\left.\frac{\partial\overline{x}}{\partial x}\right)\right|_{\varepsilon=0}=\frac{\mathrm{d}\xi^k}{\mathrm{d}x^k} \tag{5.9}$$

are inserted into (5.7) we obtain the equation for the variation $\zeta(t)$, namely,

$$\begin{aligned}\frac{\mathrm{d}\zeta(t)}{\mathrm{d}t}=\int_D\Bigg(&\frac{\partial\mathcal{L}}{\partial t}\tau+\frac{\partial\mathcal{L}}{\partial x^k}\xi^k+\frac{\partial\mathcal{L}}{\partial u^i}\eta^i+\frac{\partial\mathcal{L}}{\partial u^i_t}\left(\frac{\mathrm{d}\eta^i}{\mathrm{d}t}-u^i_t\frac{\mathrm{d}\tau}{\mathrm{d}t}-u^i_{x^k}\frac{\mathrm{d}\xi^k}{\mathrm{d}t}\right)\\&+\frac{\partial\mathcal{L}}{\partial u^i_{x^k}}\left(\frac{\mathrm{d}\eta^i}{\mathrm{d}x^k}-u^i_{x^j}\frac{\mathrm{d}\xi^j}{\mathrm{d}x^k}\right)+\mathcal{L}\frac{\mathrm{d}\xi^j}{\mathrm{d}x^j}\Bigg)\mathrm{d}^nx+\frac{\mathrm{d}\tau}{\mathrm{d}t}\int_D\mathcal{L}\,\mathrm{d}^nx+\zeta(t)\int_D\frac{\partial\mathcal{L}}{\partial z}\mathrm{d}^nx.\end{aligned} \tag{5.10}$$

Its solution $\zeta(s)$, evaluated at $t=s$, is given by

$$\begin{aligned}E(s)\,\zeta(s)-\zeta(0)=\int_0^s\int_D E(t)\Bigg(&\frac{\partial\mathcal{L}}{\partial t}\tau+\frac{\partial\mathcal{L}}{\partial x^k}\xi^k+\frac{\partial\mathcal{L}}{\partial u^i}\eta^i+\frac{\partial\mathcal{L}}{\partial u^i_t}\left(\frac{\mathrm{d}\eta^i}{\mathrm{d}t}-u^i_t\frac{\mathrm{d}\tau}{\mathrm{d}t}-u^i_{x^k}\frac{\mathrm{d}\xi^k}{\mathrm{d}t}\right)\\&+\frac{\partial\mathcal{L}}{\partial u^i_{x^k}}\left(\frac{\mathrm{d}\eta^i}{\mathrm{d}x^k}-u^i_{x^j}\frac{\mathrm{d}\xi^j}{\mathrm{d}x^k}\right)+\mathcal{L}\left(\frac{\mathrm{d}\xi^j}{\mathrm{d}x^j}+\frac{\mathrm{d}\tau}{\mathrm{d}t}\right)\Bigg)\mathrm{d}^nx\,\mathrm{d}t,\end{aligned} \tag{5.11}$$

where $E(t)$ is the expression (5.3) and s is the value of t at which the solution $z(t)$ of Eq. (2.1) was evaluated in order to obtain the functional $z[u;s]$. By definition, $\zeta(0)=0$. By hypothesis, the transformation group (4.3) leaves the functional $\overline{z}$ invariant, so $\zeta(s)=0$. Thus, (5.11) becomes

$$\begin{aligned}\int_0^s\int_D E\Bigg(&\frac{\partial\mathcal{L}}{\partial t}\tau+\frac{\partial\mathcal{L}}{\partial x^k}\xi^k+\frac{\partial\mathcal{L}}{\partial u^i}\eta^i+\frac{\partial\mathcal{L}}{\partial u^i_t}\left(\frac{\mathrm{d}\eta^i}{\mathrm{d}t}-u^i_t\frac{\mathrm{d}\tau}{\mathrm{d}t}-u^i_{x^k}\frac{\mathrm{d}\xi^k}{\mathrm{d}t}\right)\\&+\frac{\partial\mathcal{L}}{\partial u^i_{x^k}}\left(\frac{\mathrm{d}\eta^i}{\mathrm{d}x^k}-u^i_{x^j}\frac{\mathrm{d}\xi^j}{\mathrm{d}x^k}\right)+\mathcal{L}\left(\frac{\mathrm{d}\xi^j}{\mathrm{d}x^j}+\frac{\mathrm{d}\tau}{\mathrm{d}t}\right)\Bigg)\mathrm{d}^nx\,\mathrm{d}t=0.\end{aligned} \tag{5.12}$$

Next we form total derivatives with respect to t and x^k in the integrand I of (5.12). A tedious but straightforward calculation yields

$$I=-\frac{\mathrm{d}}{\mathrm{d}t}\left(E\left((\tau u_t^i+\xi^j u_{xj}^i-\eta^i)\frac{\partial\mathcal{L}}{\partial u_t^i}-\tau\mathcal{L}\right)\right)-\frac{\mathrm{d}}{\mathrm{d}x^k}\left(E\left((\tau u_t^i+\xi^j u_{xj}^i-\eta^i)\frac{\partial\mathcal{L}}{\partial u_{x^k}^i}-\xi^k\mathcal{L}\right)\right)$$
$$-E(\tau u_t^i+\xi^j u_{xj}^i-\eta^i)\left(\frac{\partial\mathcal{L}}{\partial u^i}-\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial\mathcal{L}}{\partial u_t^i}-\frac{\mathrm{d}}{\mathrm{d}x^k}\frac{\partial\mathcal{L}}{\partial u_{x^k}^i}+\frac{\partial\mathcal{L}}{\partial u_t^i}\int_D\frac{\partial\mathcal{L}}{\partial z}\mathrm{d}^nx\right)$$
$$+\tau E\left(\mathcal{L}\int_D\frac{\partial\mathcal{L}}{\partial z}\mathrm{d}^nx-\frac{\partial\mathcal{L}}{\partial z}\int_D\mathcal{L}\,\mathrm{d}^nx\right). \tag{5.13}$$

We evaluate the above expression on a solution of the generalized Euler–Lagrange equation (3.1) (hence the third term becomes zero) and insert it into (5.12). Then, recognizing that the space-integral of the last term in (5.13) vanishes, i.e.,

$$\int_D\left(\mathcal{L}\int_D\frac{\partial\mathcal{L}}{\partial z}\mathrm{d}^nx-\frac{\partial\mathcal{L}}{\partial z}\int_D\mathcal{L}\,\mathrm{d}^nx\right)\mathrm{d}^nx'=\int_D\mathcal{L}\,\mathrm{d}^nx'\int_D\frac{\partial\mathcal{L}}{\partial z}\mathrm{d}^nx-\int_D\frac{\partial\mathcal{L}}{\partial z}\mathrm{d}^nx'\int_D\mathcal{L}\,\mathrm{d}^nx=0$$

and that the limit s of the time integral is arbitrary, we obtain

$$\int_D\left(\frac{\mathrm{d}}{\mathrm{d}t}\left(E\left((\tau u_t^i+\xi^j u_{xj}^i-\eta^i)\frac{\partial\mathcal{L}}{\partial u_t^i}-\tau\mathcal{L}\right)\right)+\frac{\mathrm{d}}{\mathrm{d}x^k}\left(E\left((\tau u_t^i+\xi^j u_{xj}^i-\eta^i)\frac{\partial\mathcal{L}}{\partial u_{x^k}^i}-\xi^k\mathcal{L}\right)\right)\right)\mathrm{d}^nx=0,$$

which concludes the proof. □

Corollary 5.2: Theorem 5.1 reduces to the classical first Noether theorem when the generalized variational principle with several independent variables reduces to the classical variational principle.

Proof: The generalized variational principle with several independent variables reduces to the classical variational principle if the Lagrangian density $\mathcal{L}$, in the defining equation (2.1), does not depend on z. This is so because, then, the functional $z[u;s]$ becomes a space–time integral of $\mathcal{L}$, i.e.,

$$z[u;s]=\int_0^s\int_\Omega\mathcal{L}(t,x,u,u_t,u_x)\,\mathrm{d}^nx\,\mathrm{d}t \tag{5.14}$$

and the generalized Euler–Lagrange equation (3.1) becomes the classical Euler–Lagrange equation. On the other hand, when $\mathcal{L}$ does not depend on z the integrand in (5.2) is independent of D since, in this case, $E=1$ as seen from (5.3). Then, the arbitrariness of D in the identity (5.2) implies that the integrand is identically zero and we obtain the conservation law

$$\frac{\mathrm{d}}{\mathrm{d}t}\left((\tau u_t^i+\xi^j u_{xj}^i-\eta^i)\frac{\partial\mathcal{L}}{\partial u_t^i}-\tau\mathcal{L}\right)+\frac{\mathrm{d}}{\mathrm{d}x^k}\left((\tau u_t^i+\xi^j u_{xj}^i-\eta^i)\frac{\partial\mathcal{L}}{\partial u_{x^k}^i}-\xi^k\mathcal{L}\right)=0, \tag{5.15}$$

which holds on solutions of the classical Euler–Lagrange equations. This is precisely the conservation law of the classical first Noether theorem. □

VI. CONSERVED QUANTITIES IN DISSIPATIVE AND GENERATIVE SYSTEMS WITH SEVERAL INDEPENDENT VARIABLES

Systems described by the generalized Euler–Lagrange equations

$$\frac{\partial\mathcal{L}}{\partial u^i}-\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial\mathcal{L}}{\partial u_t^i}-\frac{\mathrm{d}}{\mathrm{d}x^k}\frac{\partial\mathcal{L}}{\partial u_{x^k}^i}+\frac{\partial\mathcal{L}}{\partial u_t^i}\int_\Omega\frac{\partial\mathcal{L}}{\partial z}\mathrm{d}^nx=0,\quad i=1,\ldots,m \tag{6.1}$$

are in general not conservative. In this section we show how Theorem 5.1 can be used to find conserved quantities in such systems. To carry out this procedure, we must find the symmetries of

the functional $z[u,s]$ defined by Eq. (2.1). Each one-parameter symmetry provides one conserved quantity. To test whether a one-parameter group of transformations of the independent and dependent variables is a symmetry group of the functional z we use the infinitesimal criterion which Proposition 4.3 provides.

Theorem 6.1: *Let (4.3) be a symmetry group, with infinitesimal generator (4.7), of the functional z defined by (2.1). If the equations*

$$(\tau u_t^i+\xi^j u_{x^j}^i-\eta^i)\frac{\partial \mathcal{L}}{\partial u_{x^k}^i}-\xi^k\mathcal{L}=0, \quad k=1,\ldots,n, \quad i=1,\ldots,m$$

hold on the boundary $\partial\Omega$ of Ω, then the quantity

$$E(t)\int_\Omega\left((\tau u_t^i+\xi^j u_{x^j}^i-\eta^i)\frac{\partial \mathcal{L}}{\partial u_t^i}-\tau\mathcal{L}\right)\mathrm{d}^n x=\text{const} \tag{6.2}$$

is conserved on solutions of the generalized Euler–Lagrange equations (6.1), where

$$E(t)\equiv\exp\left(-\int_0^t\int_\Omega\frac{\partial \mathcal{L}}{\partial z}\mathrm{d}^n x\,\mathrm{d}\theta\right). \tag{6.3}$$

Proof: From Gauss divergence theorem and the hypothesis of the theorem follows that the second term in the identity (5.2) of Theorem 5.1 is zero, that is

$$\int_\Omega\frac{\mathrm{d}}{\mathrm{d}x^k}\left(E\left((\tau u_t^i+\xi^j u_{x^j}^i-\eta^i)\frac{\partial \mathcal{L}}{\partial u_{x^k}^i}-\xi^k\mathcal{L}\right)\right)\mathrm{d}^n x=0.$$

Hence, identity (5.2) becomes

$$\frac{\mathrm{d}}{\mathrm{d}t}\int_\Omega E\left((\tau u_t^i+\xi^j u_{x^j}^i-\eta^i)\frac{\partial \mathcal{L}}{\partial u_t^i}-\tau\mathcal{L}\right)\mathrm{d}^n x=0,$$

which is the statement of the theorem. □

The following corollary is an important special case of Theorem 6.1.

Corollary 6.2: Let (4.3) be a symmetry group, with infinitesimal generator (5.1), of the functional z defined by (2.1) with $\Omega=\mathbb{R}^n$. If

$$\left|\int_{\mathbb{R}^n}\mathcal{L}(t,x,u(t,x),u_t,u_x,z)\,\mathrm{d}^n x\right|<\infty \tag{6.4}$$

over the entire time domain, then the quantity

$$E(t)\int_{\mathbb{R}^n}\left((\tau u_t^i+\xi^j u_{x^j}^i-\eta^i)\frac{\partial \mathcal{L}}{\partial u_t^i}-\tau\mathcal{L}\right)\mathrm{d}^n x=\text{const} \tag{6.5}$$

is conserved on solutions of the generalized Euler–Lagrange equations (6.1), where

$$E(t)\equiv\exp\left(-\int_0^t\int_{\mathbb{R}^n}\frac{\partial \mathcal{L}}{\partial z}\mathrm{d}^n x\,d\theta\right). \tag{6.6}$$

Proof: The requirement (6.4) implies that $\lim_{|x|\to\infty}\mathcal{L}=0$. Then $\partial\mathcal{L}/\partial u_{x^k}^i$, $k=1,\ldots,n$, $i=1,\ldots,m$ are also zero at infinity. Thus, the hypotheses of Theorem 6.1 are satisfied and (6.5) follows from (6.2). □

VII. SOME APPLICATIONS

The generalized variational principle with several independent variables gives a variational description of nonconservative as well as conservative processes involving physical fields. The next three corollaries give conserved quantities which correspond in the classical case to the total energy, linear momentum, and angular momentum of the field $u(t,x)=(u^1(t,x),\ldots,u^m(t,x))$ defined on $\mathbb{R}^n$. See Goldstein,[9] Chap. 12.

Corollary 7.1: Let the condition (6.4) hold and let the functional z, defined by the equation (2.1), be invariant with respect to translations in time. Then the quantity

$$E(t)\int_{\mathbb{R}^n}\left(u_t^i\frac{\partial\mathcal{L}}{\partial u_t^i}-\mathcal{L}\right)\mathrm{d}^n x=\text{const},\quad i=1,\ldots,m \tag{7.1}$$

with $E(t)$ given by (6.6), is conserved on solutions of the generalized Euler–Lagrange equations (6.1).

Proof: Time-translations are the transformations

$$\overline{t}=t+\varepsilon,\quad \overline{x^k}=x^k,\quad k=1,\ldots,n,\quad \overline{u}=u$$

from which we have

$$\tau=\left.\frac{\mathrm{d}\overline{t}}{\mathrm{d}\varepsilon}\right|_{\varepsilon=0}=1,\quad \xi^k=0,\quad k=1,\ldots,n,\quad \eta=0.$$

Inserting these into (6.5) produces (7.1). □

If, following the classical field theory, we interpret the expression

$$\mathcal{E}=u_t^i\frac{\partial\mathcal{L}}{\partial u_t^i}-\mathcal{L} \tag{7.2}$$

as the energy density of the field $u(t,x)$, then (7.1) states that the total field energy changes in time proportional to $1/E(t)$.

Corollary 7.2: Let the condition (6.4) hold and let the functional z, defined by the equation (2.1), be invariant with respect to space translations along the x^k coordinate. Then the quantity

$$E(t)\int_{\mathbb{R}^n}\frac{\partial u^i}{\partial x^k}\frac{\partial\mathcal{L}}{\partial u_t^i}\mathrm{d}^n x=\text{const} \tag{7.3}$$

with $E(t)$ given by (6.6), is conserved on solutions of the generalized Euler–Lagrange equations (6.1).

Proof: Space translations along the x^k coordinate are the transformations

$$\overline{t}=t,\quad \overline{x^k}=x^k+\varepsilon,\quad \overline{x^j}=x^j\quad \text{for } j\neq k,\quad \overline{u}=u,\quad j=1,\ldots,n$$

from which we get

$$\xi^k=\left.\frac{\mathrm{d}\overline{x^k}}{\mathrm{d}\varepsilon}\right|_{\varepsilon=0}=1,\quad \xi^j=0\quad \text{for } j\neq k,\quad \tau=\eta=0.$$

Then, (7.3) follows from (6.5). □

If, following the classical field theory, we interpret the expression

$$\mathcal{P}_k=-\frac{\partial u^i}{\partial x^k}\frac{\partial\mathcal{L}}{\partial u_t^i},\quad i=1,\ldots,m \tag{7.4}$$

as the k component of the linear momentum density, then (7.3) states that the kth component of the field's total linear momentum changes in time proportional to $1/E(t)$.

Corollary 7.3: Let the condition (6.4) hold and let the functional z, defined by the equation (2.1), be invariant with respect to rotations in the ij-coordinate plane. Then the quantity

$$E(t)\int_{\mathbb{R}^n}\left(x^j\frac{\partial u^l}{\partial x^i}-x^i\frac{\partial u^l}{\partial x^j}\right)\frac{\partial \mathcal{L}}{\partial u^l_t}\,\mathrm{d}^n x=\text{const} \tag{7.5}$$

with $E(t)$ given by (6.6), is conserved on solutions of the generalized Euler–Lagrange equations (6.1).

Proof: The rotations in the ij plane are the transformations

$$\overline{x}^i=x^i\cos\varepsilon+x^j\sin\varepsilon,\quad \overline{x}^j=-x^i\sin\varepsilon+x^j\cos\varepsilon,\quad \overline{x}^k=x^k\quad \text{for}\ \ k\neq i,j$$

from which we obtain

$$\xi^i=\left.\frac{\mathrm{d}\overline{x}^i}{\mathrm{d}\varepsilon}\right|_{\varepsilon=0}=x^j,\quad \xi^j=\left.\frac{\mathrm{d}\overline{x}^j}{\mathrm{d}\varepsilon}\right|_{\varepsilon=0}=-x^i,\quad \xi^k=0\quad \text{for}\ \ k\neq i,j,\quad \tau=\eta=0.$$

Inserting these into (6.5) of Corollary 6.2 produces (7.5). □

If, following the classical field theory, we interpret the expression

$$\mathcal{M}_{ij}=\left(x^j\frac{\partial u^l}{\partial x^i}-x^i\frac{\partial u^l}{\partial x^j}\right)\frac{\partial \mathcal{L}}{\partial u^l_t}=x^i\mathcal{P}_j-x^j\mathcal{P}_i \tag{7.6}$$

as the ij component of the angular momentum density of the field $u(t,x)$, then (7.5) states that the ij component of the field's total angular momentum changes in time proportionally to $1/E(t)$.

An observation: Let $\mathcal{F}=\mathcal{F}(u,u_x,u_t,x,t)$ be any real-valued function which is, at least, twice differentiable with respect to u, u_x, u_t and once differentiable with respect to x, t. Then, all equations, linear and nonlinear, of the form

$$\frac{\partial \mathcal{F}}{\partial u^i}-\frac{\mathrm{d}}{\mathrm{d}x^k}\frac{\partial \mathcal{F}}{\partial u^i_{x^k}}-\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial \mathcal{F}}{\partial u^i_t}+a\frac{\partial \mathcal{F}}{\partial u^i_t}=0\,,\quad i=1,\ldots,m \tag{7.7}$$

are generalized Euler–Lagrange equations (3.1) derivable from the generalized variational principle with Lagrangian density

$$\mathcal{L}=\mathcal{F}+\alpha\, z,$$

where $\alpha=\alpha(x,t)$ and

$$a(t)=\int_\Omega \alpha(x,t)\,\mathrm{d}^n x.$$

Hence, we can apply the Noether-type theorems to any equation of the form (7.7). It should be noticed that due to the presence of the term $a\,\partial\mathcal{F}/\partial u^i_t$ these equations describe generative or dissipative processes and cannot be derived from the classical variational principle.

Here, we give two illustrative examples of equations from the family (7.7). The first is the set of equations which describe the propagation of electromagnetic fields in a conductive medium,

$$c^2\,\nabla^2\mathbf{E}-\frac{\partial^2\mathbf{E}}{\partial t^2}-\frac{\sigma}{\varepsilon}\frac{\partial\mathbf{E}}{\partial t}=0, \tag{7.8}$$

where $\mathbf{E}=(E^1,E^2,E^3)$ is the electric field vector, c is the velocity of the electromagnetic waves, σ is the electrical conductivity, and ε is the dielectric constant of the medium. Exactly the same equation holds for the magnetic field vector $\mathbf{B}=(B^1,B^2,B^3)$. These equations are a direct consequence of the Maxwell's equations in conjunction with the medium's property equations $\mathbf{J}=\sigma\mathbf{E}$ and $\rho=0$, where $\mathbf{J}=(J^1,J^2,J^3)$ is the current density and ρ is the charge density.

One can easily verify that Eq. (7.8) belongs to the family (7.7) by inserting

$$\mathcal{L}=c^2\frac{\partial E^i}{\partial x^j}\frac{\partial E^i}{\partial x^j}-\frac{\partial E^i}{\partial t}\frac{\partial E^i}{\partial t}+\alpha(x)\,z, \quad i,j=1,2,3 \tag{7.9}$$

into the generalized Euler–Lagrange equations (3.1) and setting

$$\frac{\sigma}{\varepsilon}=\int_\Omega \alpha(x)\,\mathrm{d}^3x=\text{const.}$$

Thus, the Noether-type theorem can be applied and, with the appropriate boundary conditions and function $\alpha(x)$, we obtain the conserved quantities of the Corollaries 7.1, 7.2, and 7.3.

As a second example consider the equation

$$\nabla^2 u-\frac{1}{v^2}\frac{\partial^2 u}{\partial t^2}+G(uu^*)\,u=0 \tag{7.10}$$

describing the real or complex field $u=u(x,t)$, where u^* denotes the complex conjugate of u, G is a differentiable function and v is a constant. This equation is known as the nonlinear Klein–Gordon equation. Its linear version, with $G=\text{const}$ plays an important role in relativistic field theories. The one-dimensional version of (7.10) with real u and $G(u^2)u=\sin u$ is the sine-Gordon equation. The field equations of the form (7.10) can be derived from the Lagrangian density

$$\mathcal{L}(u,u_t,\nabla u)=\nabla u\cdot\nabla u^*-\frac{1}{v^2}\frac{\partial u}{\partial t}\frac{\partial u^*}{\partial t}-F(uu^*), \tag{7.11}$$

where

$$\frac{\mathrm{d}F(\rho)}{\mathrm{d}\rho}=G(\rho) \quad \text{and} \quad F(0)=0.$$

We consider as physically meaningful only those solutions of (7.10) which are free of singularities and for which

$$\left|\int_\Omega \mathcal{L}(t,x,u,u_t,u_x)\,\mathrm{d}x\right|<\infty$$

holds over the entire time domain. The processes described with an equation of the form (7.10) are conservative since the Lagrangian (7.11) does not explicitly depend on time.

One is also interested in nonconservative processes involving fields. The simplest modification of (7.10) which makes it suitable to describe nonconservative processes is to include in it a term proportional to the time derivative of the field. Thus, a physically meaningful nonconservative version of (7.10) is

$$\nabla^2 u-\frac{1}{v^2}\frac{\partial^2 u}{\partial t^2}+k\frac{\partial u}{\partial t}+G(uu^*)\,u=0, \tag{7.12}$$

where k is a constant. With $k>0$ the process described by (7.12) is generative, and with $k<0$ it is dissipative. When u is a real field, equations of the form (7.12) belong to the family (7.7) and can be derived via the present generalized variational principle from the Lagrangian density

$$\mathcal{L}=\nabla u\cdot\nabla u-\frac{1}{v^2}\left(\frac{\partial u}{\partial t}\right)^2-F(u^2)+\alpha(x)\,z, \tag{7.13}$$

where $\partial F(\rho)/\partial\rho=G(\rho)$, and $\alpha=\alpha(x)$ is a given function of the coordinates $x=(x^1,\ldots,x^n)$ which satisfies the condition

$$\left|\int_\Omega \alpha(x)\,\mathrm{d}^n x\right|<\infty.$$

Indeed, inserting the Lagrangian (7.13) into the generalized Euler–Lagrange equations (3.1),

$$\frac{\partial\mathcal{L}}{\partial u}-\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial\mathcal{L}}{\partial u_t}-\frac{\mathrm{d}}{\mathrm{d}x^k}\frac{\partial\mathcal{L}}{\partial u_{x^k}}+\frac{\partial\mathcal{L}}{\partial u_t}\int_\Omega\frac{\partial\mathcal{L}}{\partial z}\mathrm{d}^n x$$
$$=-2u\frac{\partial F}{\partial(u^2)}+\frac{2}{v^2}\frac{\partial^2 u}{\partial t^2}-2\nabla^2 u-\frac{2}{v^2}\frac{\partial u}{\partial t}\int_\Omega\alpha(x)\,\mathrm{d}^n x=0,$$

we see that the last expression is the same as (7.12) with

$$k=\frac{1}{v^2}\int_\Omega\alpha(x)\,\mathrm{d}^n x=\text{const}. \tag{7.14}$$

Consequently, we may apply the first Noether-type theorem 5.1 to obtain conserved quantities. In particular, observing that the Lagrangian (7.13) is invariant under translations in time we may apply Corollary 7.1 to obtain the conserved quantity

$$\exp(-kv^2t)\int_\Omega\left(\frac{1}{v^2}\left(\frac{\partial u}{\partial t}\right)^2+\nabla u\cdot\nabla u-F(u^2)+\alpha(x)\,z\right)\mathrm{d}x=\text{const}, \tag{7.15}$$

where z is the solution of the defining equation (2.1). In accordance with the conservative case, we can interpreted the quantity

$$\frac{\partial\mathcal{L}}{\partial u_t}u_t-\mathcal{L}=-\frac{1}{v^2}\left(\frac{\partial u}{\partial t}\right)^2-\nabla u\cdot\nabla u+F(u^2)-\alpha(x)\,z$$

as the energy density of the field $u(t,x)$. Then Eq. (7.15) states that the total field energy exponentially increases when $k>0$ and decreases when $k<0$.[10–20]

APPENDIX

Derivation of the relation (5.8): We differentiate the transformed Lagrangian density $\mathcal{L}(\overline{t},\overline{x},\overline{u},\overline{u_t},\overline{u_x},\overline{z})$ in Eq. (5.5) with respect to ε and set $\varepsilon=0$,

$$\left.\frac{\mathrm{d}\mathcal{L}}{\mathrm{d}\varepsilon}\right|_{\varepsilon=0}=\left.\left(\frac{\partial\mathcal{L}}{\partial\overline{t}}\frac{\mathrm{d}\phi}{\mathrm{d}\varepsilon}+\frac{\partial\mathcal{L}}{\partial\overline{x}^k}\frac{\mathrm{d}\varphi^k}{\mathrm{d}\varepsilon}+\frac{\partial\mathcal{L}}{\partial\overline{u}^i}\frac{\mathrm{d}\psi^i}{\mathrm{d}\varepsilon}+\frac{\partial\mathcal{L}}{\partial\overline{u}^i_t}\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\frac{\partial\overline{u}^i}{\partial\overline{t}}+\frac{\partial\mathcal{L}}{\partial\overline{u}^i_{\overline{x}^k}}\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\frac{\partial\overline{u}^i}{\partial\overline{x}^k}+\frac{\partial\mathcal{L}}{\partial\overline{z}}\frac{\mathrm{d}\overline{z}}{\mathrm{d}\varepsilon}\right)\right|_{\varepsilon=0},$$

which when written with ζ and the infinitesimal generators of the group becomes

$$\left.\frac{\mathrm{d}\mathcal{L}}{\mathrm{d}\varepsilon}\right|_{\varepsilon=0}=\frac{\partial\mathcal{L}}{\partial t}\tau+\frac{\partial\mathcal{L}}{\partial x^k}\xi^k+\frac{\partial\mathcal{L}}{\partial u^i}\eta^i+\frac{\partial\mathcal{L}}{\partial u^i_t}\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\left(\frac{\partial\overline{u}^i}{\partial\overline{t}}\right)\Bigg|_{\varepsilon=0}+\frac{\partial\mathcal{L}}{\partial u^i_{x^k}}\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\left(\frac{\partial\overline{u}^i}{\partial\overline{x}^k}\right)\Bigg|_{\varepsilon=0}+\frac{\partial\mathcal{L}}{\partial z}\zeta. \quad \text{(A1)}$$

To calculate

$$\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\left(\frac{\partial\overline{u}^i}{\partial\overline{t}}\right)\Bigg|_{\varepsilon=0}$$

differentiate the equation $\overline{u}^i(\overline{t},\overline{x};\varepsilon)=\psi^i(t,x,u;\varepsilon)=\overline{u}^i(t,x,u;\varepsilon)$ with respect to t,

$$\frac{\partial\overline{u}^i}{\partial\overline{t}}\frac{\mathrm{d}\overline{t}}{\mathrm{d}t}+\frac{\partial\overline{u}^i}{\partial\overline{x}^k}\left(\frac{\partial\overline{x}^k}{\partial t}+\frac{\partial\overline{x}^k}{\partial u^j}u^j_t\right)=\frac{\partial\overline{u}^i}{\partial t}+\frac{\partial\overline{u}^i}{\partial u^j}u^j_t. \quad \text{(A2)}$$

Set $\varepsilon=0$ and take into account the identities

$$\left.\frac{\partial\overline{u}^i}{\partial t}\right|_{\varepsilon=0}=0,\quad \left.\frac{\partial\overline{u}^i}{\partial u^j}\right|_{\varepsilon=0}=\delta^i_j,\quad \left.\frac{\partial\overline{t}}{\partial t}\right|_{\varepsilon=0}=1,\quad \left.\frac{\partial\overline{x}^k}{\partial t}\right|_{\varepsilon=0}=0,\quad \left.\frac{\partial\overline{x}^k}{\partial u^j}\right|_{\varepsilon=0}=0.$$

Substitute these in (A2) and solve the resulting equation for $\overline{u}^i_{\overline{t}}|_{\varepsilon=0}$ to find

$$\overline{u}^i_{\overline{t}}|_{\varepsilon=0}=u^i_t. \quad \text{(A3)}$$

Differentiate the equation $\overline{u}^i(\overline{t},\overline{x};\varepsilon)=\psi^i(t,x,u;\varepsilon)\equiv\overline{u}^i(t,x,u;\varepsilon)$ with respect to x^k,

$$\frac{\partial\overline{u}^i}{\partial\overline{x}^k}\left(\frac{\partial\overline{x}^k}{\partial x^k}+\frac{\partial\overline{x}^k}{\partial u^j}u^j_{x^k}\right)=\frac{\partial\overline{u}^i}{\partial x^k}+\frac{\partial\overline{u}^i}{\partial u^j}u^j_{x^k}. \quad \text{(A4)}$$

Set $\varepsilon=0$ and substitute the identities

$$\left.\frac{\partial\overline{u}^i}{\partial x^k}\right|_{\varepsilon=0}=0,\quad \left.\frac{\partial\overline{u}^i}{\partial u^j}\right|_{\varepsilon=0}=\delta^i_j,\quad \left.\frac{\partial\overline{x}^k}{\partial x^k}\right|_{\varepsilon=0}=\delta^l_k,\quad \left.\frac{\partial\overline{x}^k}{\partial u^j}\right|_{\varepsilon=0}=0$$

in (A4). Then solve the resulting equation for $\overline{u}^i_{\overline{x}^k}|_{\varepsilon=0}$ to obtain

$$\overline{u}^i_{\overline{x}^k}|_{\varepsilon=0}=u^i_{x^k}. \quad \text{(A5)}$$

Differentiate (A2) with respect to ε to get

$$\begin{aligned}\overline{u}^i_{\overline{t}}\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\frac{\mathrm{d}\overline{t}}{\mathrm{d}t}+\frac{\mathrm{d}\overline{t}}{\mathrm{d}t}\frac{\mathrm{d}\overline{u}^i_{\overline{t}}}{\mathrm{d}\varepsilon}+\overline{u}^i_{\overline{x}^k}\left(\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\frac{\partial\overline{x}^k}{\partial t}+\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\left(\frac{\partial\overline{x}^k}{\partial u^j}\right)u^j_t\right)+\left(\frac{\partial\overline{x}^k}{\partial t}+\frac{\partial\overline{x}^k}{\partial u^j}u^j_t\right)\frac{\mathrm{d}\overline{u}^i_{\overline{x}^k}}{\mathrm{d}\varepsilon}\\ =\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\left(\frac{\partial\overline{u}^i}{\partial t}+\frac{\partial\overline{u}^i}{\partial u^j}u^j_t\right).\end{aligned} \quad \text{(A6)}$$

Set $\varepsilon=0$ in (A6) and substitute (A3) and (A5) in it. Then take into account the identities

$$\left.\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\frac{\partial\overline{u}^i}{\partial t}\right|_{\varepsilon=0}=\frac{\partial\eta^i}{\partial t},\quad \left.\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\frac{\partial\overline{u}^i}{\partial u^j}\right|_{\varepsilon=0}=\frac{\partial\eta^i}{\partial u^j},\quad \left.\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\frac{\partial\overline{t}}{\partial t}\right|_{\varepsilon=0}=\frac{\partial\tau}{\partial t},\quad \left.\frac{\partial\overline{t}}{\partial t}\right|_{\varepsilon=0}=1,$$

$$\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\frac{\partial\overline{x}^k}{\partial t}\bigg|_{\varepsilon=0}=\frac{\partial\xi^k}{\partial t},\quad \frac{\mathrm{d}}{\mathrm{d}\varepsilon}\frac{\partial\overline{x}^k}{\partial u^j}\bigg|_{\varepsilon=0}=\frac{\partial\xi^k}{\partial u^j},\quad \frac{\partial\overline{x}^k}{\partial t}\bigg|_{\varepsilon=0}=0,\quad \frac{\partial\overline{x}^k}{\partial u^j}\bigg|_{\varepsilon=0}=0.$$

Consequently, Eq. (A6) becomes

$$\frac{\partial\eta^i}{\partial t}+\frac{\partial\eta^i}{\partial u^j}u_t^j=u_t^i\frac{\partial\tau}{\partial t}+\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\overline{u}_{\overline{t}}^i\bigg|_{\varepsilon=0}+u_{x^k}^i\left(\frac{\partial\xi^k}{\partial t}+\frac{\partial\xi^k}{\partial u^j}u_t^j\right) \tag{A7}$$

from which we obtain

$$\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\overline{u}_{\overline{t}}^i\bigg|_{\varepsilon=0}=\frac{\mathrm{d}\eta^i}{\mathrm{d}t}-u_t^i\frac{\mathrm{d}\tau}{\mathrm{d}t}-u_{x^k}^i\frac{\mathrm{d}\xi^k}{\mathrm{d}t}. \tag{A8}$$

We must now calculate

$$\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\left(\frac{\partial\overline{u}^i}{\partial\overline{x}^k}\right)\bigg|_{\varepsilon=0},$$

which appears in (A1). For this purpose differentiate (A4) with respect to ε,

$$\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\frac{\partial\overline{u}^i}{\partial x^k}+\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\frac{\partial\overline{u}^i}{\partial u^j}u_{x^k}^j=\frac{\mathrm{d}}{\mathrm{d}\varepsilon}(\overline{u}_{\overline{x}^l}^i)\left(\frac{\partial\overline{x}^l}{\partial x^k}+\frac{\partial\overline{x}^l}{\partial u^j}u_{x^k}^j\right)+\overline{u}_{\overline{x}^l}^i\left(\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\frac{\partial\overline{x}^l}{\partial x^k}+u_{x^k}^j\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\frac{\partial\overline{x}^l}{\partial u^j}\right). \tag{A9}$$

Set $\varepsilon=0$ in (A9), substitute (A3) and (A5) into (A9) and observe that

$$\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\frac{\partial\overline{u}^i}{\partial x^k}\bigg|_{\varepsilon=0}=\frac{\partial\eta^i}{\partial x^k},\quad \frac{\mathrm{d}}{\mathrm{d}\varepsilon}\frac{\partial\overline{u}^i}{\partial u^j}\bigg|_{\varepsilon=0}=\frac{\partial\eta^i}{\partial u^j},\quad \frac{\partial\overline{x}^l}{\partial x^k}\bigg|_{\varepsilon=0}=\delta_k^l,$$

$$\frac{\partial\overline{x}^l}{\partial u^j}\bigg|_{\varepsilon=0}=0,\quad \frac{\mathrm{d}}{\mathrm{d}\varepsilon}\frac{\partial\overline{x}^l}{\partial x^k}\bigg|_{\varepsilon=0}=\frac{\partial\xi^l}{\partial x^k},\quad \frac{\mathrm{d}}{\mathrm{d}\varepsilon}\frac{\partial\overline{x}^l}{\partial u^j}\bigg|_{\varepsilon=0}=\frac{\partial\xi^l}{\partial u^j}.$$

Then (A9) becomes

$$\frac{\partial\eta^i}{\partial x^k}+\frac{\partial\eta^i}{\partial u^j}u_{x^k}^j=\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\overline{u}_{\overline{x}^l}^i\bigg|_{\varepsilon=0}\delta_k^l+u_{x^l}^i\left(\frac{\partial\xi^l}{\partial x^k}+\frac{\partial\xi^l}{\partial u^j}u_{x^k}^j\right), \tag{A10}$$

from which we get

$$\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\overline{u}_{\overline{x}^k}^i\bigg|_{\varepsilon=0}=\frac{\mathrm{d}\eta^i}{\mathrm{d}x^k}-u_{x^l}^i\frac{\mathrm{d}\xi^l}{\mathrm{d}x^k}. \tag{A11}$$

Substituting (A8) and (A11) into (A1) produces the relation (5.8),

$$\frac{\mathrm{d}\mathcal{L}}{\mathrm{d}\varepsilon}\bigg|_{\varepsilon=0}=\frac{\partial\mathcal{L}}{\partial t}\tau+\frac{\partial\mathcal{L}}{\partial x^k}\xi^k+\frac{\partial\mathcal{L}}{\partial u^i}\eta^i+\frac{\partial\mathcal{L}}{\partial u_t^i}\left(\frac{\mathrm{d}\eta^i}{\mathrm{d}t}-u_t^i\frac{\mathrm{d}\tau}{\mathrm{d}t}-u_{x^k}^i\frac{\mathrm{d}\xi^k}{\mathrm{d}t}\right)+\frac{\partial\mathcal{L}}{\partial u_{x^k}^i}\left(\frac{\mathrm{d}\eta^i}{\mathrm{d}x^k}-u_{x^l}^i\frac{\mathrm{d}\xi^l}{\mathrm{d}x^k}\right)+\frac{\partial\mathcal{L}}{\partial z}\zeta.$$

Derivation of the relation (5.9): We use the formula for the derivative of a determinant, according to which

$$\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\det\left(\frac{\partial\overline{x}}{\partial x}\right)=A_k^j\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\left(\frac{\partial\overline{x}^k}{\partial x^j}\right), \tag{A12}$$

where A_k^j is the cofactor of the determinant's entry $\partial\overline{x}^k/\partial x^j$. Next,

$$\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\left(\frac{\partial\overline{x}^k}{\partial x^j}\right)=\frac{\partial}{\partial x^j}\frac{\mathrm{d}\overline{x}^k}{\mathrm{d}\varepsilon}=\frac{\partial^2\overline{x}^k}{\partial x^j\,\partial\varepsilon}+\frac{\partial^2\overline{x}^k}{\partial u^i\,\partial\varepsilon}\frac{\partial u^i}{\partial x^j},$$

because $\overline{x}^k=\overline{x}^k(t,x,u(t,x);\varepsilon)$. Hence (A12) becomes

$$\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\det\left(\frac{\partial\overline{x}}{\partial x}\right)=A_k^j\left(\frac{\partial^2\overline{x}^k}{\partial x^j\,\partial\varepsilon}+\frac{\partial^2\overline{x}^k}{\partial u^i\,\partial\varepsilon}\frac{\partial u^i}{\partial x^j}\right).$$

Setting $\varepsilon=0$ in the above expression and observing that $A_k^j|_{\varepsilon=0}=\delta_k^j$ is a cofactor of the identity matrix, we get the relation (5.9),

$$\frac{\mathrm{d}}{\mathrm{d}\varepsilon}\det\left(\frac{\partial\overline{x}}{\partial x}\right)\Bigg|_{\varepsilon=0}=\left(\frac{\partial\xi^k}{\partial x^j}+\frac{\partial\xi^k}{\partial u^i}\frac{\partial u^i}{\partial x^j}\right)\delta_k^j=\frac{\mathrm{d}\xi^k}{\mathrm{d}x^j}\,\delta_k^j=\frac{\mathrm{d}\xi^k}{\mathrm{d}x^k}.$$

(Received 25 February 2003; accepted 31 March 2003)

On the basis of the equivalence between the AKNS hierarchy and the cKP hierarchy with the constraint $k=1$, we point out that there exist two choices to keep the form of the Lax operator when we perform the gauge transformation for the AKNS hierarchy, which results in two classes of functions to trigger the gauge transformation. For the second choice, two theorems for two types of gauge transformation are established. Several new and more general forms of tau-functions for the AKNS hierarchy are obtained by means of gauge transformations of both types. The union of the two choices leads to new forms of τ-functions. We generate the AKNS hierarchy from the "free" Lax operator $L^{(0)}=\partial$ via a chain of gauge transformations. © *2003 American Institute of Physics.*

I. INTRODUCTION

The AKNS hierarchy and its generalizations[1,2] are very important and basic in the theory of PDEs. They yields the generalized nonlinear Schrödinger equation (including nonlinear Schrödinger equation and the derivative Schrödinger equation), the KdV equation, the mKdV equation, the sine-Gordon equation, the sinh-Gordon equation, the Harry–Dym equation, etc. This hierarchy is also equivalent to the constrained KP hierarchy (cKP) with constraint $k=1$.[3–5] Explicitly, the AKNS hierarchy can be expressed as

$$\frac{\partial L^{(0)}}{\partial t_k}=[B_k^{(0)},L^{(0)}] \tag{1.1}$$

by means of a pseudodifferential operator having the following form:

$$L^{(0)}=\partial+\phi^{(0)}\circ\partial^{-1}\circ\psi^{(0)},\quad B_k^{(0)}\equiv(L^{(0)})_+^k. \tag{1.2}$$

Here A_+, respectively, A_- denote the differential, respectively, integral part of the pseudodifferential operator $A=A_++A_-$. For $L^{(0)}$, $L_+^{(0)}=\partial$, $L_-^{(0)}=\phi^{(0)}\circ\partial^{-1}\circ\psi^{(0)}$, where $\phi^{(0)}$ and $\psi^{(0)}$ in $L^{(0)}$ are the solutions of the equations

$$\frac{\partial\phi^{(0)}}{\partial t_k}=B_k^{(0)}\cdot\phi^{(0)},\quad \frac{\partial\psi^{(0)}}{\partial t_k}=-B_k^{*(0)}\cdot\psi^{(0)}. \tag{1.3}$$

Here the symbol "$\circ$" denotes product of operators and the symbol "$\cdot$" indicates that the operator acts the function just following. For example, $\partial^2\circ f=f_{xx}+2f_x\circ\partial+f\circ\partial^2$ is a sum of operators; $\partial^{-1}\circ f=f\circ\partial^{-1}-f_x\circ\partial^{-2}+f_{xx}\circ\partial^{-2}+\cdots$ is also an operator. But $\partial^2\cdot f=f_{xx}$ is a function; $\partial^{-1}\cdot f=\int f\,dx$ is a function. Of course, $f\circ\partial=f\cdot\partial, f\circ g=f\cdot g$; the functions f and g can be regarded as the zeroth order operators. The symbol * indicates the operation of conjugation; $(A\circ B)^*=B^*$

$\circ A^*, \partial^* = -\partial, f^*(x) = f(x), (f \circ \partial^{-1} \circ g)^* = -g \circ \partial^{-1} \circ f$ (here A, B are differential operators, f, g are functions). It can be shown that (1.3) are consistent with (1.1). For simplicity, we adopt the notation of Ref. 6. The solutions of (1.3), $\phi^{(0)}$, respectively, $\psi^{(0)}$ are called the ''eigenfunction,'' respectively, the ''adjoint eigenfunction'' of the AKNS hierarchy. For example, the first two flows of the AKNS hierarchy $(t_1 = x)$ are

$$\phi^{(0)}_{t_2} = \phi^{(0)}_{xx} + 2(\phi^{(0)})^2 \psi^{(0)}, \quad \psi^{(0)}_{t_2} = -\psi^{(0)}_{xx} - 2\phi^{(0)}(\psi^{(0)})^2, \tag{1.4}$$

and

$$\phi^{(0)}_{t_3} = \phi^{(0)}_{xxx} + 6\phi^{(0)}\psi^{(0)}\phi^{(0)}_x, \quad \psi^{(0)}_{t_3} = \psi^{(0)}_{xxx} + 6\phi^{(0)}\psi^{(0)}\psi^{(0)}_x. \tag{1.5}$$

The Baker–Akhiezer (BA) function $\chi^{(0)}(\lambda, x)$ is defined by the equation

$$L^{(0)} \cdot \chi^{(0)}(\lambda, x) = \lambda \cdot \chi^{(0)}(\lambda, x), \quad \frac{\partial \chi^{(0)}(\lambda, x)}{\partial t_k} = B^{(0)}_k \cdot \chi^{(0)}(\lambda, x). \tag{1.6}$$

The adjoint BA function $\mu^{(0)}(\lambda, x)$ is defined by the equation

$$L^{*(0)} \mu^{(0)}(\lambda, x) = \lambda \cdot \mu^{(0)}(\lambda, x), \quad \frac{\partial \mu^{(0)}(\lambda, x)}{\partial t_k} = -B^{*(0)}_k \cdot \mu^{(0)}(\lambda, x). \tag{1.7}$$

On the other hand, we can rewrite $L^{(0)}$ as

$$L^{(0)} = \partial + u^{(0)}_2 \circ \partial^{-1} + u^{(0)}_3 \circ \partial^{-2} + u^{(0)}_4 \circ \partial^{-3} + \cdots, \tag{1.8}$$

so that the coordinates $u^{(0)}_2, u^{(0)}_3, u^{(0)}_4, \ldots$ are expressed uniquely by the dynamical variables $\phi^{(0)}, \psi^{(0)}$ and their derivatives

$$u^{(0)}_2 = \phi^{(0)} \cdot \psi^{(0)}, \quad u^{(0)}_3 = -\phi^{(0)} \cdot \psi^{(0)}_x, \quad u^{(0)}_4 = \phi^{(0)} \cdot \psi^{(0)}_{xx}, \quad \ldots. \tag{1.9}$$

It is easy to find via $u = u_2, t_1 = x, t_2 = y, t_3 = t$ the KP equation

$$(4u_t - 12uu_x - u_{xxx})_x - 3u_{yy} = 0. \tag{1.10}$$

From Sato's KP theory (see, for example, Refs. 7 and 8), the set $\{u^{(0)}_i\}$ can be generated by the τ-function $\tau^{(0)}$,

$$u^{(0)}_2 = \frac{\partial^2 \ln \tau^{(0)}}{\partial x^2}, \tag{1.11}$$

$$u^{(0)}_3 = \tfrac{1}{2}(\partial_x \partial_{t_2} - \partial_x^2) \cdot \ln \tau^{(0)}, \tag{1.12}$$

etc. Through (1.11) and (1.12), $\{\phi^{(0)}, \psi^{(0)}\}$ can be expressed by the same $\tau^{(0)}$, which provides an alternative to representing the solution to the AKNS hierarchy via its corresponding τ-function.

Recently several peoples have been devoted to solving the cKP hierarchy by gauge transformations.[6,9–18] Two types of gauge transformation operators

$$\text{Type } \mathbf{I}: \quad T_D(\chi) = \chi \circ \partial \circ \chi^{-1},$$

$$\text{Type } \mathbf{II}: \quad T_I(\mu) = \mu^{-1} \circ \partial^{-1} \circ \mu,$$

for the KP hierarchy were proposed first by Ref. 19; they were then shown to be also able to deal with the cKP hierarchy.[6,9–12,18] Here χ and μ are the ''eigenfunction'' and the ''adjoint eigenfunction'' of the KP hierarchy, respectively. On the other hand, there are two classes of functions (we

call them the generating functions of the gauge transformation, denoted shortly by GFGT) appropriate to produce the above-mentioned transformations. The first is the BA function,[9] the other is the ''eigenfunction'' (or the ''adjoint-eigenfunction'').[6,10–12,18] However, the discussion for the two types of gauge transformations with the two classes of GFGT is neither complete nor systematic. In addition, the transformed function $\tau^{(n)}$ of Ref. 6 does not hold for the cKP with $k=1$ and one component (i.e., in the AKNS case). So we provide a unified frame to deal with the AKNS hierarchy and we discuss some explicit solutions of the KP equation as examples.

The organization of the present paper is as follows. In Sec. II, we deduce the transformed Lax operator $L^{(1)}$ from the $L^{(0)}$ in (1.2) under the gauge transformations of Type **I** and Type **II**. In this process, we point out that there are two choices of gauge transformation for the AKNS hierarchy in order to keep the form of the Lax operator, which results in two classes of GFGT. Particularly, the second choice for Type **I** and Type **II** is discussed in detail, respectively. Then, in Sec. III, we study the successive applications of the gauge transformation with the second choice. This is followed by the Sec. IV, which treats the union of the two choices in one chain of gauge transformations. The generation of the AKNS hierarchy from the ''free'' Lax operator $L^{(0)}=\partial$ is the main content of the Sec. V. The last Sec. VI contents some concluding remarks.

Before ending this section, let us list some identities, which are used repeatedly in the following sections:

$$\partial\circ f = f\circ\partial + f_x, \tag{1.13}$$

$$\partial^{-1}\circ f = f\circ\partial^{-1} - \partial^{-1}\circ f_x\circ\partial^{-1}, \tag{1.14}$$

$$T_I(\chi) = -(T_D^{-1}(\chi))^* = -(T_D^*(\chi))^{-1}, \tag{1.15}$$

$$T_D(\mu) = -(T_I^{-1}(\mu))^* = -(T_I^*(\mu))^{-1}, \tag{1.16}$$

$$(T_D(\chi)\circ A_-\circ T_D^{-1}(\chi))_+ = 0. \tag{1.17}$$

In addition, because the τ-function can be only determined up to a constant factor, we always omit the global minus of τ-function for AKNS hierarchy in this paper.

II. TWO CHOICES OF GAUGE TRANSFORMATION FOR THE AKNS HIERARCHY

Let us begin with a brief summary about the gauge transformation for the AKNS hierarchy. Suppose T is a pseudodifferential operator, and

$$L^{(1)} = T\circ L^{(0)}\circ T^{-1}, \quad B_n^{(1)} \equiv (L^{(1)})_+^n, \tag{2.1}$$

so that

$$\frac{\partial}{\partial t_n}L^{(1)} = [B_n^{(1)}, L^{(1)}] \tag{2.2}$$

still holds for the transformed Lax operator $L^{(1)}$; then T is called a gauge transformation operator. According to the definition of gauge transformation, we have

Lemma 2.1: The operator T is a gauge transformation operator, if

$$(T\circ B_n^{(0)}\circ T^{-1})_+ = T\circ B_n^{(0)}\circ T^{-1} + \frac{\partial T}{\partial t_n}\circ T^{-1}, \tag{2.3}$$

or

$$(T\circ B_n^{(0)}\circ T^{-1})_- = -\frac{\partial T}{\partial t_n}\circ T^{-1}. \tag{2.4}$$

Proof: By using (2.1) we have

$$\frac{\partial L^{(1)}}{\partial t_n}=\frac{\partial T}{\partial t_n}\circ T^{-1}\circ T\circ L^{(0)}\circ T^{-1}+T\circ B_n^{(0)}\circ T^{-1}\circ T\circ L^{(0)}\circ T^{-1}-T\circ L^{(0)}$$
$$\circ T^{-1}\circ T\circ B_n^{(0)}\circ T^{-1}-T\circ L^{(0)}\circ T^{-1}\circ\frac{\partial T}{\partial t_n}\circ T^{-1},$$
$$[B_n^{(1)},L^{(1)}]=B_n^{(1)}\circ T\circ L^{(0)}\circ T^{-1}-T\circ L^{(0)}\circ T^{-1}\circ B_n^{(1)}.$$

Taking these back into (2.2), one gets

$$B_n^{(1)}=T\circ B_n^{(0)}\circ T^{-1}+\frac{\partial T}{\partial t_n}\circ T^{-1}.$$

On the other hand, we have

$$B_n^{(1)}\equiv(L^{(1)})_+^n=(T\circ B_n^{(0)}\circ T^{-1})_+.$$

from the definition of the gauge transformation. The lemma is then proved by comparing the two expressions of $B_n^{(1)}$. □

This is concordant with the statement of Refs. 6 and 19, where it is given in the contest of the Zakharov–Shabat (ZS) equation. Our proof is independent of the concrete form of the Lax operator $L^{(0)}$, so it also hold for the generalized KP hierarchy.[14,20] In order to prove the existence of the two types of gauge transformation, we need to discuss first the following lemma.

Lemma 2.2: (Ref. 21) *Let f be a well defined function, A a pseudodifferential operator; then*

$$(1)\quad (f\circ\partial\circ f^{-1}\circ A\circ f\circ\partial^{-1}\circ f^{-1})_+=f\circ\partial\circ f^{-1}\circ A_+\circ f\circ\partial^{-1}\circ f^{-1}-f^{-1}$$
$$\circ[\partial_x(f^{-1}\cdot(A_+\cdot f))]\circ\partial^{-1}\circ f^{-1}. \tag{2.5}$$

$$(2)\quad (f^{-1}\circ\partial^{-1}\circ f\circ A\circ f^{-1}\circ\partial\circ f)_-=f^{-1}\circ\partial^{-1}\circ f\circ A_-\circ f^{-1}\circ\partial\circ f-f^{-1}$$
$$\circ\partial^{-1}\circ f\circ\partial_x(f^{-1}\cdot(A_+^*\cdot f)). \tag{2.6}$$

Theorem 2.1: *(Ref. 6) For the AKNS hierarchy, there exist two types of gauge transformation operators:*

$$\text{Type I:}\quad T_D(\chi)=\chi\circ\partial\circ\chi^{-1}, \tag{2.7}$$

$$\text{Type II:}\quad T_I(\mu)=\mu^{-1}\circ\partial^{-1}\circ\mu. \tag{2.8}$$

Here χ and μ are the eigenfunction and the adjoint eigenfunction of the Lax operator $L^{(0)}$ in (1.2), respectively.

Proof: First, for the Type **I** case [see (2.7)],

$$\begin{aligned}B_n^{(1)}\equiv(L^{(1)})_+^n&=(T_D\circ(L^{(0)})^n\circ T_D^{-1})_+\\&=T_D\circ(L^{(0)})_+^n\circ T_D^{-1}-\chi\cdot\partial_x(\chi^{-1}\cdot((L^{(0)})_+^n\cdot\chi)))\circ\partial^{-1}\circ\chi^{-1}\\&=T_D\circ B_n^{(0)}\circ T_D^{-1}-\chi\cdot\partial_x(\chi^{-1}\cdot(B_n^{(0)}\cdot\chi))\circ\partial^{-1}\circ\chi^{-1}\\&=T_D\circ B_n^{(0)}\circ T_D^{-1}-\left(\chi\circ\partial\circ\frac{\chi_{t_n}}{\chi}\circ\partial^{-1}\circ\chi^{-1}-\chi\circ\frac{\chi_{t_n}}{\chi}\circ\partial\circ\partial^{-1}\circ\chi^{-1}\right)\end{aligned}$$

$$=T_D\circ B_n^{(0)}\circ T_D^{-1}+\frac{\chi_{t_n}}{\chi}-\chi\circ\partial\circ\frac{\chi_{t_n}}{\chi}\circ\partial^{-1}\circ\chi^{-1}.$$

Here the relations (2.5), $B_n^{(0)}=(L^{(0)})_+^n$, $\chi_{t_n}=B_n^{(0)}\cdot\chi$ and (1.13) have been used. On the other hand,

$$\begin{aligned}\frac{\partial T_D}{\partial t_n}\circ T_D^{-1}&=(\chi\circ\partial\circ\chi^{-1})_{t_n}\circ T_D^{-1}\\&=\chi_{t_n}\circ\partial\circ\chi^{-1}\circ\chi\circ\partial^{-1}\circ\chi^{-1}-\chi\circ\partial\circ\frac{\chi_{t_n}}{\chi^2}\circ\chi\circ\partial^{-1}\circ\chi^{-1}\\&=\frac{\chi_{t_n}}{\chi}-\chi\circ\partial\circ\frac{\chi_{t_n}}{\chi}\circ\partial^{-1}\circ\chi^{-1}.\end{aligned}$$

Hence

$$B_n^{(1)}\equiv(L^{(1)})_+^n=T_D\circ B_n^{(0)}\circ T_D^{-1}+\frac{\partial T_D}{\partial t_n}\circ T_D^{-1},$$

and this indicates that $T_D(\chi)$ is indeed a gauge transformation operator via Lemma 2.1. Second, we want to prove that the equation (2.4) hold for Type **II** case [see (2.8)],

$$\begin{aligned}(T_I\circ B_n^{(0)}\circ T_I^{-1})_-&=(\mu^{-1}\circ\partial^{-1}\circ\mu\circ B_n^{(0)}\circ\mu^{-1}\circ\partial\circ\mu)_-\\&=\mu^{-1}\circ\partial^{-1}\circ\mu\circ(B_n^{(0)})_-\circ\mu^{-1}\circ\partial\circ\mu-\mu^{-1}\circ\partial^{-1}\circ\mu\circ\partial_x(\mu^{-1}\cdot((B^{*(0)}_n)_+\cdot\mu))\\&=\mu^{-1}\circ\partial^{-1}\circ\mu\circ\partial_x(\mu^{-1}\cdot\mu_{t_n}).\end{aligned}$$

In the above destination, the relations (2.6), $(B_n^{(0)})_-=0$, $\mu_{t_n}=-B_n^{*(0)}\cdot\mu$ have been used. Moreover, with the help of (1.14), we have

$$\begin{aligned}-\frac{\partial T_I}{\partial t_n}\circ T_I^{-1}&=-\frac{\partial}{\partial t_n}((\mu^{-1}\circ\partial^{-1}\circ\mu))\circ\mu^{-1}\circ\partial\circ\mu\\&=\frac{\mu_{t_n}}{\mu^2}\circ\partial^{-1}\circ\mu\circ\mu^{-1}\circ\partial\circ\mu-\mu^{-1}\circ\partial^{-1}\circ\mu_{t_n}\circ\mu^{-1}\circ\partial\circ\mu\\&=\frac{\mu_{t_n}}{\mu}-\mu^{-1}(\mu_{t_n}\circ\mu^{-1}\circ\partial^{-1}-\partial^{-1}\circ(\mu_{t_n}\cdot\mu^{-1})_x\circ\partial^{-1})\circ\partial\circ\mu\\&=\frac{\mu_{t_n}}{\mu}-\frac{\mu_{t_n}}{\mu}+\mu^{-1}\circ\partial^{-1}\circ\partial_x(\mu_{t_n}\circ\mu^{-1})\circ\mu\\&=\mu^{-1}\circ\partial^{-1}\circ\mu\circ\partial_x(\mu_{t_n}\circ\mu^{-1}).\end{aligned}$$

The above two equations show that $T_I(\mu)$ satisfies (2.4), so $T_I(\mu)$ is also a gauge transformation operator according to Lemma 2.1. □

Although the gauge transformation operators in Theorem 2.1 guarantee the validity of the Lax equation, it is not enough to ensure that the $\phi^{(0)}$ and $\psi^{(0)}$ are transformed to be the new solutions of the AKNS hierarchy. To this end, the gauge transformation operators, must be moreover re-

quired to keep the form of Lax operator. Let us now introduce n BA functions $\{\chi_i^{(0)}=\chi(\lambda_i,x), i=1,2,\ldots,n\}$ and n adjoint BA functions $\{\mu_i^{(0)}=\mu(\lambda_i,x), i=1,2,\ldots,n\}$, besides the "eigenfunction" $\phi^{(0)}$ and the "adjoint eigenfunction" $\psi^{(0)}$ of $L^{(0)}$.

Lemma 2.3: Via the gauge transformation of Type **I** *[see (2.7)], $L^{(0)}$ becomes $L^{(1)}$, which is given by*

$$\begin{aligned} L^{(1)} &= \partial+\chi\cdot(\ln\chi)_{xx}\circ\partial^{-1}\circ\chi^{-1}+\chi\cdot\left(\chi^{-1}\cdot\phi^{(0)}\cdot\int\psi^{(0)}\cdot\chi\right)_x\circ\partial^{-1}\circ\chi^{-1}-\chi \\ &\quad\cdot(\chi^{-1}\cdot\phi^{(0)})_x\circ\partial^{-1}\circ\left(\int\psi^{(0)}\cdot\chi\right)\circ\chi^{-1} \\ &= \partial+\phi_0^{(1)}\circ\partial^{-1}\circ\psi_0^{(1)}+\widetilde{\phi^{(1)}}\circ\partial^{-1}\circ\widetilde{\phi^{(1)}}, \end{aligned} \tag{2.9}$$

$$\phi_0^{(1)}=\chi\cdot(\ln\chi)_{xx}+\chi\cdot\left(\chi^{-1}\cdot\psi^{(0)}\cdot\left(\int\phi^{(0)}\cdot\chi\right)\right)_x=(T_D(\chi)\circ L^{(0)})\cdot\chi, \tag{2.10}$$

$$\psi_0^{(1)}=\chi^{-1}, \tag{2.11}$$

$$\widetilde{\phi^{(1)}}=\chi\cdot(\chi^{-1}\cdot\phi^{(1)})_x=T_D(\chi)\cdot\phi^{(0)}, \tag{2.12}$$

$$\widetilde{\phi^{(0)}}=-\chi^{-1}\cdot\left(\int\psi^{(0)}\cdot\chi\right)=-T_I(\chi)\cdot\psi^{(0)}. \tag{2.13}$$

Proof: The transformed Lax operator $L^{(1)}=T_D(\chi)\circ L^{(0)}\circ(T_D(\chi))^{-1}$ can be written in two parts. (a) The first part is

$$\begin{aligned} L_A &= T_D(\chi)\circ\partial\circ(T_D(\chi))^{-1} \\ &= \left(\partial-\frac{\chi_x}{\chi}\right)\circ\partial\circ\chi\circ\partial^{-1}\circ\chi^{-1} \\ &= \partial^2\circ\chi\circ\partial^{-1}\circ\chi^{-1}-\frac{\chi_x}{\chi}\circ\partial\circ\chi\circ\partial^{-1}\circ\chi^{-1} \\ &= (\chi_{xx}+2\chi_x\circ\partial+\chi\circ\partial^2)\circ\partial^{-1}\circ\chi^{-1}-\frac{\chi_x}{\chi}\circ(\chi_x+\chi\circ\partial)\circ\partial^{-1}\circ\chi^{-1} \\ &= (\chi_{xx}+2\chi_x\circ\partial)\circ\partial^{-1}\circ\chi^{-1}+\chi\circ\partial\circ\chi^{-1}-\frac{\chi_x^2}{\chi}\circ\partial^{-1}\circ\chi^{-1}-\chi_x\cdot\chi^{-1} \\ &= \partial+\left(\chi_{xx}+2\chi_x\circ\partial-\frac{\chi_x^2}{\chi}\right)\circ\partial^{-1}\circ\chi^{-1}-2\frac{\chi_x}{\chi} \\ &= \partial+\left(\chi_{xx}-\frac{\chi_x^2}{\chi}\right)\circ\partial^{-1}\circ\chi^{-1} \\ &= \partial+\chi\cdot(\ln\chi)_{xx}\circ\partial^{-1}\circ\chi^{-1}. \end{aligned}$$

In above destination, the relation (1.13) is used repeatedly. (b) The second part, L_B, comes from

$$
\begin{aligned}
L_B &= T_D(\chi)\circ\phi^{(0)}\circ\partial^{-1}\circ\psi^{(0)}\circ(T_D(\chi))^{-1}\\
&= \chi\circ\partial\circ\chi^{-1}\circ\phi^{(0)}\circ\partial^{-1}\circ\psi^{(0)}\circ\chi\circ\partial^{-1}\circ\chi^{-1}\\
&= \chi\circ\partial\circ\chi^{-1}\circ\phi^{(0)}\circ\left(\left(\int\psi^{(0)}\cdot\chi\right)\circ\partial^{-1}-\partial^{-1}\circ\left(\int\psi^{(0)}\cdot\chi\right)\right)\circ\chi^{-1}\\
&= \chi\cdot\left(\chi^{-1}\cdot\phi^{(0)}\cdot\left(\int\psi^{(0)}\cdot\chi\right)\right)_x\circ\partial^{-1}\circ\chi^{-1}+\chi\cdot\chi^{-1}\cdot\phi^{(0)}\cdot 1\cdot\left(\int\psi^{(0)}\cdot\chi\right)\cdot\chi^{-1}\\
&\quad -\chi\cdot(\chi^{-1}\phi^{(0)})_x\circ\partial^{-1}\circ\left(\int\psi^{(0)}\cdot\chi\right)\circ\chi^{-1}-\chi\cdot\chi^{-1}\phi^{(0)}\cdot 1\cdot\left(\int\psi^{(0)}\cdot\chi\right)\circ\chi^{-1}\\
&= \chi\cdot\left(\chi^{-1}\cdot\phi^{(0)}\cdot\left(\int\psi^{(0)}\cdot\chi\right)\right)_x\circ\partial^{-1}\circ\chi^{-1}-\chi\cdot(\chi^{-1}\phi^{(0)})_x\circ\partial^{-1}\circ\left(\int\psi^{(0)}\cdot\chi\right)\circ\chi^{-1},
\end{aligned}
$$

with the help of (1.13) and (1.14). From (a) and (b), $L^{(1)}$ in (2.9) is obtained. Then

$$
\begin{aligned}
\phi_0^{(1)} &= \chi\cdot(\ln\chi)_{xx}+\chi\cdot\left(\chi^{-1}\cdot\phi^{(0)}\cdot\left(\int\psi^{(0)}\cdot\chi\right)\right)_x\\
&= \chi\cdot\left[(\ln\chi)_x+\chi^{-1}\cdot\phi^{(0)}\cdot\left(\int\psi^{(0)}\cdot\chi\right)\right]_x\\
&= \chi\cdot\left[\frac{1}{\chi}\left(\chi_x+\phi^{(0)}\cdot\left(\int\psi^{(0)}\cdot\chi\right)\right)\right]_x\\
&= \chi\cdot\left[\frac{L^{(0)}\cdot\chi}{\chi}\right]_x=(T_D(\chi)\circ L^{(0)})\cdot\chi.
\end{aligned}
$$

It is easy to deduce the other equations Lemma 2.3.

This lemma shows that, there are two choices to keep the form of $L^{(1)}$: the first choice is characterized by the formula $\widetilde{\phi^{(1)}}\circ\partial^{-1}\circ\widetilde{\phi^{(1)}}=0$; the second choice by the formula $\psi_0^{(1)}\circ\partial^{-1}\circ\psi_0^{(1)}=0$. So we have the following.

Theorem 2.2: *(A) The GFGT of the first choice is the "eigenfunction" of* $L^{(0)}$*, i.e.,* $\chi=\phi^{(0)}$*, which results in* $T_D(\phi^{(0)})=\phi^{(0)}\circ\partial\circ(\phi^{(0)})^{-1}$*, then*

$$
\phi^{(1)}=\phi^{(0)}\cdot((\ln\phi^{(0)})_{xx}+\phi^{(0)}\cdot\psi^{(0)})=(T_D(\phi^{(0)})\circ L^{(0)})\cdot\phi^{(0)},\quad \frac{\partial\phi^{(1)}}{\partial t_n}=B_n^{(1)}\cdot\phi^{(1)}, \tag{2.14}
$$

$$
\psi^{(1)}=(\phi^{(0)})^{-1},\quad \frac{\partial\psi^{(1)}}{\partial t_n}=-B_n^{*(1)}\cdot\psi^{(1)}. \tag{2.15}
$$

Moreover, from $\{\chi_i^{(0)},\mu_i^{(0)},i=1,2,\ldots,n\}$*, if we define*

$$
\chi_i^{(1)}=T_D(\phi^{(0)})\cdot\chi_i^{(0)}=\phi^{(0)}\circ\partial\circ(\phi^{(0)})^{-1}\cdot\chi_i^{(0)}, \tag{2.16}
$$

$$
\mu_i^{(1)}=-T_I(\phi^{(0)})\cdot\mu_i^{(0)}=-(\phi^{(0)})^{-1}\circ\partial^{-1}\circ\phi^{(0)}\cdot\mu_i^{(0)}, \tag{2.17}
$$

then $\{\chi_i^{(1)},\mu_i^{(1)}\}$ *statisfy*

$$
\frac{\partial\chi_i^{(1)}}{\partial t_n}=B_n^{(1)}\cdot\chi_i^{(1)},\quad L^{(1)}\cdot\chi_i^{(1)}=\lambda_i\cdot\chi_i^{(1)}, \tag{2.18}
$$

$$\frac{\partial \mu_i^{(1)}}{\partial t_n} = -B_n^{*(1)} \cdot \mu_i^{(1)}, \quad L^{*(1)} \mu_i^{(1)} = \lambda_i \cdot \mu_i^{(1)}. \tag{2.19}$$

The transformed τ-function $\tau^{(1)}$ related to $L^{(1)}$ reads

$$\tau^{(1)} = \phi^{(0)} \cdot \tau^{(0)}, \tag{2.20}$$

where $\tau^{(0)}$ is the τ-function of $L^{(0)}$. (B) For the second choice, the corresponding $GFGT$ is one of the BA functions, for example, $\chi = \chi_k^{(0)}$, then $T_D(\chi_k^{(0)}) = \chi_k^{(0)} \circ \partial \circ (\chi_k^{(0)})^{-1}$,

$$\phi^{(1)} = T_D(\chi_k^{(0)}) \cdot \phi^{(0)} = \chi_k^{(0)} \circ \partial \circ (\chi_k^{(0)})^{-1} \cdot \phi^{(0)}, \quad \frac{\partial \phi^{(1)}}{\partial t_n} = B_n^{(1)} \cdot \phi^{(1)}, \tag{2.21}$$

$$\psi^{(1)} = -T_I(\chi_k^{(0)}) \cdot \psi^{(0)} = -(\chi_k^{(0)})^{-1} \circ \partial^{-1} \circ \chi_k^{(0)} \cdot \psi^{(0)}, \quad \frac{\partial \psi^{(1)}}{\partial t_n} = -B_n^{*(1)} \cdot \psi^{(1)}. \tag{2.22}$$

From $\{\chi_l^{(0)}, \mu_l^{(0)}, l = 1,2,\ldots,n, l \neq k,\}$, if we define

$$\chi_l^{(1)} = T_D(\chi_k^{(0)}) \cdot \chi_l^{(0)} = \chi_k^{(0)} \circ \partial \circ (\chi_k^{(0)})^{-1} \cdot \chi_l^{(0)}, \quad \chi_k^{(1)} = 0, \tag{2.23}$$

$$\mu_l^{(1)} = -T_I(\chi_k^{(0)}) \cdot \mu_l^{(0)} = -(\chi_k^{(0)})^{-1} \circ \partial^{-1} \circ \chi_k^{(0)} \cdot \mu_l^{(0)}, \quad \mu_k^{(1)} = -T_I(\chi_k^{(0)}) \cdot \mu_k^{(0)} \neq 0, \tag{2.24}$$

then the $\{\chi_l^{(1)}, \mu_l^{(1)}\}$ satisfy

$$\frac{\partial \chi_l^{(1)}}{\partial t_n} = B_n^{(1)} \cdot \chi_l^{(1)}, \quad L^{(1)} \cdot \chi_l^{(1)} = \lambda_l \cdot \chi_l^{(1)}, \tag{2.25}$$

$$\frac{\partial \mu_l^{(1)}}{\partial t_n} = -B_n^{*(1)} \cdot \mu_l^{(1)}, \quad L^{*(1)} \mu_l^{(1)} = \lambda_l \cdot \mu_l^{(1)}. \tag{2.26}$$

The transformed τ-function $\tau^{(1)}$ of $L^{(1)}$ is

$$\tau^{(1)} = \chi_k^{(0)} \cdot \tau^{(0)}, \tag{2.27}$$

in which $\tau^{(0)}$ is the τ-function of $L^{(0)}$.

Furthermore, for the gauge transformation of Type **II** $T_I(\mu) = \mu^{-1} \circ \partial^{-1} \circ \mu$, see (2.8), the transformed Lax operator is given by the following.

Lemma 2.4:

$$\begin{aligned} L^{(1)} &= T_I(\mu) \circ L^{(0)} \circ T_I^{-1}(\mu) \\ &= \partial + \mu^{-1} \circ \partial^{-1} \circ (\mu_x \cdot \mu^{-1})_x \circ \mu + \mu^{-1} \circ \partial^{-1} \\ &\quad \circ \left(\left(\int \mu \cdot \phi^{(0)} \right) \cdot \psi^{(0)} \cdot \mu^{-1} \right)_x \circ \mu - \mu^{-1} \cdot \left(\int \mu \cdot \phi^{(0)} \right) \circ \partial^{-1} \circ (\psi^{(0)} \cdot \mu^{-1})_x \circ \mu \\ &= \partial + \phi_0^{(1)} \circ \partial^{-1} \circ \psi_0^{(1)} + \widetilde{\phi^{(1)}} \circ \partial^{-1} \circ \widetilde{\phi^{(1)}}, \end{aligned} \tag{2.28}$$

in which

$$\psi_0^{(1)} = \mu^{-1}, \tag{2.29}$$

$$\psi_0^{(1)} = (\mu_x \cdot \mu^{-1})_x \cdot \mu + \left(\left(\int \mu \cdot \phi^{(0)} \right) \cdot \psi^{(0)} \cdot \mu^{-1} \right)_x \cdot \mu, \tag{2.30}$$

$$\widetilde{\phi^{(1)}}=T_I(\mu)\cdot\psi^{(0)}=\frac{1}{\mu}\cdot\int\mu\cdot\phi^{(0)}, \tag{2.31}$$

$$\widetilde{\phi^{(1)}}=-T_D(\mu)\cdot\phi^{(0)}=-\mu\cdot\left(\frac{\phi^{(0)}}{\mu}\right)_x. \tag{2.32}$$

Proof: As in Lemma 2.3, it is convenient to express the transformed Lax operator in two parts.
(a) The first part needs

$$\begin{aligned}
L_A&=T_I(\mu)\circ\partial\circ(T_I(\mu))^{-1}\\
&=\mu^{-1}\circ\partial^{-1}\circ\mu\circ\partial\circ\mu^{-1}\circ\partial\circ\mu\\
&=\mu^{-1}\circ(\mu\circ\partial^{-1}-\partial^{-1}\circ\mu_x\circ\partial^{-1})\circ\partial\circ\mu^{-1}\circ\partial\circ\mu\\
&=\mu^{-1}\circ\partial\circ\mu-\mu^{-1}\circ\partial^{-1}\circ\mu_x\circ 1\circ\mu^{-1}\circ\partial\circ\mu\\
&=\partial+\mu^{-1}\cdot\mu_x-\mu^{-1}((\mu_x\cdot\mu^{-1})\circ\partial^{-1}-\partial^{-1}\circ(\mu_x\cdot\mu^{-1})_x\circ\partial^{-1})\circ\partial\circ\mu\\
&=\partial+\mu^{-1}\cdot\mu_x-\mu^{-1}\cdot(\mu_x\cdot\mu^{-1})\circ\partial^{-1}\circ\partial\circ\mu+\mu^{-1}\circ\partial^{-1}\circ(\mu_x\cdot\mu^{-1})_x\circ\partial^{-1}\circ\partial\circ\mu\\
&=\partial+\mu^{-1}\cdot\mu_x-\mu_x\cdot\mu^{-1}+\mu^{-1}\circ\partial^{-1}\circ(\mu_x\cdot\mu^{-1})_x\circ\partial^{-1}\circ\partial\circ\mu\\
&=\partial+\mu^{-1}\circ\partial^{-1}\circ(\mu_x\cdot\mu^{-1})_x\circ\mu.
\end{aligned}$$

Obviously, we used the relation (1.14) repeatedly.

(b) With the same method of (a), on direct computation the second part become

$$\begin{aligned}
L_B&=T_I(\mu)\circ\phi^{(0)}\circ\partial^{-1}\circ\psi^{(0)}\circ(T_I(\mu))^{-1}\\
&=\mu^{-1}\circ\partial^{-1}\circ\mu\circ\phi^{(0)}\circ\partial^{-1}\circ\psi^{(0)}\circ\mu^{-1}\circ\partial\circ\mu\\
&=\mu^{-1}\circ\left(\left(\int\mu\cdot\phi^{(0)}\right)\circ\partial^{-1}-\partial^{-1}\circ\left(\int\mu\cdot\phi^{(0)}\right)\right)\circ\psi^{(0)}\circ\mu^{-1}\circ\partial\circ\mu\\
&=\mu^{-1}\circ\left(\int\mu\cdot\phi^{(0)}\right)\circ\partial^{-1}\circ\psi^{(0)}\circ\mu^{-1}\circ\partial\circ\mu-\mu^{-1}\circ\partial^{-1}\circ\left(\int\mu\cdot\phi^{(0)}\right)\circ\psi^{(0)}\circ\mu^{-1}\circ\partial\circ\mu\\
&=\mu^{-1}\circ\left(\int\mu\cdot\phi^{(0)}\right)\circ((\psi^{(0)}\cdot\mu^{-1})\circ\partial^{-1}-\partial^{-1}\circ(\psi^{(0)}\cdot\mu^{-1})\circ\partial^{-1})\circ\partial\circ\mu\\
&\quad-\mu^{-1}\circ\left(\left(\left(\int\mu\cdot\phi^{(0)}\right)\cdot\psi^{(0)}\cdot\mu^{-1}\right)\circ\partial^{-1}-\partial^{-1}\circ\left(\left(\int\mu\cdot\phi^{(0)}\right)\cdot\psi^{(0)}\cdot\mu^{-1}\right)_x\circ\partial^{-1}\right)\circ\partial\circ\mu\\
&=\mu^{-1}\circ\left(\int\mu\cdot\phi^{(0)}\right)\circ\psi^{(0)}\circ\mu^{-1}\circ\partial^{-1}\circ\partial\circ\mu-\mu^{-1}\circ\left(\int\mu\cdot\phi^{(0)}\right)\circ\partial^{-1}\circ(\psi^{(0)}\cdot\mu^{-1})_x\\
&\quad\circ\partial^{-1}\circ\partial\circ\mu-\mu^{-1}\circ\left(\int\mu\cdot\phi^{(0)}\right)\circ\psi^{(0)}\circ\mu^{-1}\circ\partial^{-1}\circ\partial\circ\mu\\
&\quad+\mu^{-1}\circ\partial^{-1}\circ\left(\left(\int\mu\cdot\phi^{(0)}\right)\cdot\psi^{(0)}\cdot\mu^{-1}\right)_x\circ\partial^{-1}\circ\partial\circ\mu\\
&=-\mu^{-1}\circ\left(\int\mu\cdot\phi^{(0)}\right)\circ\partial^{-1}\circ(\psi^{(0)}\cdot\mu^{-1})_x\circ\mu+\mu^{-1}\circ\partial^{-1}\circ\left(\left(\int\mu\cdot\phi^{(0)}\right)\cdot\psi^{(0)}\cdot\mu^{-1}\right)_x\circ\mu.
\end{aligned}$$

The sum of L_A and L_B provides $L^{(1)}$. In view of its use in the following section, we rewrite $\psi_0^{(1)}$ as

$$\psi_0^{(1)}=(\mu_x\cdot\mu^{-1})_x\cdot\mu+\left(\left(\int\mu\cdot\phi^{(0)}\right)\cdot\psi^{(0)}\cdot\mu^{-1}\right)_x\cdot\mu,$$

$$=-\mu\cdot\left(-\frac{\mu_x}{\mu}-\frac{1}{\mu}\cdot\psi^{(0)}\cdot\left(\int\mu\cdot\phi^{(0)}\right)\right)_x$$

$$=-\mu\cdot\left(\frac{-\mu_x-\psi^{(0)}\cdot(\int\mu\cdot\phi^{(0)})}{\mu}\right)_x=-\mu\cdot\left(\frac{L^{*(0)}\mu}{\mu}\right)_x.$$

$$=-(T_D(\mu)\circ L^{*(0)})\cdot\mu.$$

□

Lemma 2.4 indicates that there are two choices of gauge transformation in order to keep the form of Lax operator. The first choice is $\widetilde{\phi^{(1)}}\circ\partial^{-1}\circ\widetilde{\phi^{(1)}}=0$. The second choice is $\psi^{(1)}\circ\partial^{-1}\circ\psi^{(1)}=0$. Then we have

Theorem 2.3: *(A) Under the gauge transformation with the first choice, characterized by the relation* $\widetilde{\phi^{(1)}}\circ\partial^{-1}\circ\widetilde{\phi^{(1)}}=0$, *the corresponding GFGT is the "adjoint eigenfunction" (of the first class), i.e.,* $\mu=\psi^{(1)}$. *Then* $T_I(\psi^{(1)})=(\psi^{(0)})^{-1}\circ\partial^{-1}\circ\psi^{(0)}$,

$$\psi^{(1)}=(\psi^{(0)})^{-1},\quad \frac{\partial\phi^{(1)}}{\partial t_n}=B_n^{(1)}\cdot\phi^{(1)}, \tag{2.33}$$

$$\psi^{(1)}=\psi^{(0)}\cdot((\ln\psi^{(0)})_{xx}+\psi^{(0)}\cdot\phi^{(0)})=-(T_D(\psi^{(0)})\circ L^{*(0)})\cdot\psi^{(0)}, \tag{2.34}$$

$$\frac{\partial\psi^{(1)}}{\partial t_n}=-B_n^{*(1)}\cdot\psi^{(1)}. \tag{2.35}$$

From $\{\chi_i^{(0)},\mu_i^{(0)},i=1,2,\ldots,n\}$, *if we define*

$$\chi_i^{(1)}=T_I(\psi^{(0)})\cdot\chi_i^{(0)}=\frac{1}{\psi^{(0)}}\cdot\int\psi^{(0)}\cdot\chi_i^{(0)}, \tag{2.36}$$

$$\mu_i^{(1)}=-T_D(\psi^{(0)})\cdot\mu_i^{(0)}=-\psi^{(0)}\cdot\left(\frac{\mu_i^{(0)}}{\psi^{(0)}}\right)_x, \tag{2.37}$$

then $\{\chi_i^{(1)},\mu_i^{(1)}\}$ *satisfy*

$$\frac{\partial\chi_i^{(1)}}{\partial t_n}=B_n^{(1)}\cdot\chi_i^{(1)},\quad L^{(1)}\cdot\chi_i^{(1)}=\lambda_i\cdot\chi_i^{(1)}, \tag{2.38}$$

$$\frac{\partial\mu_i^{(1)}}{\partial t_n}=-B_n^{*(1)}\cdot\mu_i^{(1)},\quad L^{*(1)}\mu_i^{(1)}=\lambda_i\cdot\mu_i^{(1)}. \tag{2.39}$$

The transformed τ*-function* $\tau^{(1)}$ *of* $L^{(1)}$ *becomes*

$$\tau^{(1)}=\psi^{(0)}\cdot\tau^{(0)}, \tag{2.40}$$

where $\tau^{(0)}$ *is the* τ*-function of* $L^{(0)}$.

(B) For the gauge transformation with the second choice, characterized by the relation $\phi^{(1)}\circ\partial^{-1}\circ\psi^{(1)}=0$, *the corresponding GFGT is the adjoint-BA function (of the second class). For example, if* $\mu=\mu_k^{(0)}$, *then* $T_I((\mu_k^{(0)})=(\mu_k^{(0)})^{-1}\circ\partial^{-1}\circ\mu_k^{(0)})$,

$$\phi^{(1)}=T_I(\mu_k^{(0)})\cdot\phi^{(0)}=(\mu_k^{(0)})^{-1}\cdot\left(\int \mu_k^{(0)}\cdot\phi^{(0)}\right),\quad \frac{\partial\phi^{(1)}}{\partial t_n}=B_n^{(1)}\cdot\phi^{(1)}, \tag{2.41}$$

$$\psi^{(1)}=-T_D(\mu_k^{(0)})\cdot\psi^{(0)}=-\mu_k^{(0)}\cdot\left(\frac{\psi^{(0)}}{\mu_k^{(0)}}\right)_x,\quad \frac{\partial\psi^{(1)}}{\partial t_n}=-B_n^{*(1)}\psi^{(1)}. \tag{2.42}$$

Let $l\neq k$, *for* $\{\chi_l^{(0)},\mu_l^{(0)},l=1,2,\ldots,n\}$, *we can then define*

$$\chi_l^{(1)}=T_I(\mu_k^{(0)})\cdot\chi_l^{(0)}=\frac{1}{\mu_k^{(0)}}\cdot\left(\int \mu_k^{(0)}\cdot\chi_l^{(0)}\right),\quad \chi_k^{(1)}=\frac{1}{\mu_k^{(0)}}\cdot\left(\int \mu_k^{(0)}\cdot\chi_k^{(0)}\right)\neq 0, \tag{2.43}$$

$$\mu_l^{(1)}=-T_D(\mu_k^{(0)})\cdot\mu_l^{(0)}=-\mu_k^{(0)}\cdot\left(\frac{\mu_l^{(0)}}{\mu_k^{(0)}}\right)_x,\quad \mu_k^{(1)}=0, \tag{2.44}$$

and then $\{\chi_l^{(1)},\mu_l^{(1)}\}$ *satisfy*

$$\frac{\partial\chi_l^{(1)}}{\partial t_n}=B_n^{(1)}\cdot\chi_l^{(1)},\quad L^{(1)}\cdot\chi_l^{(1)}=\lambda_l\cdot\chi_l^{(1)}, \tag{2.45}$$

$$\frac{\partial\mu_l^{(1)}}{\partial t_n}=-B_n^{*(1)}\mu_l^{(1)},\quad L^{*(1)}\mu_l^{(1)}=\lambda_l\cdot\mu_l^{(1)}. \tag{2.46}$$

The transformed τ*-function* $\tau^{(1)}$ *corresponding to the* $L^{(1)}$ *is*

$$\tau^{(1)}=\mu_k^{(0)}\cdot\tau^{(0)}, \tag{2.47}$$

where $\tau^{(0)}$ *is the* τ *function of* $L^{(0)}$.

Remark 2.1: There is a main difference between the results of Refs. 6, 10–12 and this paper. Their GFGT (i.e., of the first class) can come only from the integral part of $L^{(0)}$, but ours (i.e., of the second class) can come only from the outside of $L^{(0)}$, which implies that the second class of GFGT (which is a BA function of $L^{(0)}$) can't come from $L^{(0)}$. So there exist an essential difference between the two choices, Theorem 2.2 and Theorem 2.3 can not be on obtained results of the Refs. 6, 10–12, although it has a similar form to those results. But let us note that Theorem 2.2 agrees with Ref. 9, which is obtained from the matrix hierarchy.

Remark 2.2: Theorem 2.2 and Theorem 2.3 can be the generalized to the case of the general cKP hierarchy.

Remark 2.3: One can find from Theorem 2.2 and Theorem 2.3 that all the gauge transformations keep the eigenvalue equation of the *BA* functions and the adjoint BA functions $\{\chi_l^{(0)},\mu_l^{(0)},l=1,2,\ldots,n\}$. This observation indicates that we can make gauge transformations with the union of the two choices. This union will be discussed in Sec. IV.

III. SUCCESSIVE APPLICATION OF GAUGE TRANSFORMATIONS WITH THE SECOND CHOICE FOR THE AKNS HIERARCHY

In Refs. 6, 10–12, the gauge transformation with the first choice has been studied clearly and completely. So we will not consider this case in the following. Our main aim is to analyze the successive applications of the gauge transformations with the second choice. To simplify our presentation, we introduce the following notations for the Wronskian $W_n=W_n(\chi_1^{(0)},\chi_2^{(0)},\chi_3^{(0)},\ldots,\chi_n^{(0)})$, and the generalized Wronskian determinant:[22]

$$IW_{k,n}\equiv IW_{k,n}(\mu_k^{(0)},\mu_{k-1}^{(0)},\ldots,\mu_1^{(0)};\chi_1^{(0)},\chi_2^{(0)},\ldots,\chi_n^{(0)})$$

$$=\begin{vmatrix} \int \mu_k^{(0)}\cdot\chi_1^{(0)} & \int \mu_k^{(0)}\cdot\chi_2^{(0)} & \int \mu_k^{(0)}\cdot\chi_3^{(0)} & \cdots & \int \mu_k^{(0)}\cdot\chi_n^{(0)} \\ \int \mu_{k-1}^{(0)}\cdot\chi_1^{(0)} & \int \mu_{k-1}^{(0)}\cdot\chi_2^{(0)} & \int \mu_{k-1}^{(0)}\cdot\chi_3^{(0)} & \cdots & \int \mu_{k-1}^{(0)}\cdot\chi_n^{(0)} \\ \vdots & \vdots & \vdots & \cdots & \vdots \\ \int \mu_1^{(0)}\cdot\chi_1^{(0)} & \int \mu_1^{(0)}\cdot\chi_2^{(0)} & \int \mu_1^{(0)}\cdot\chi_3^{(0)} & \cdots & \int \mu_1^{(0)}\cdot\chi_n^{(0)} \\ \chi_1^{(0)} & \chi_2^{(0)} & \chi_3^{(0)} & \cdots & \chi_n^{(0)} \\ \chi_{1,x}^{(0)} & \chi_{2,x}^{(0)} & \chi_{3,x}^{(0)} & \cdots & \chi_{n,x}^{(0)} \\ \vdots & \vdots & \vdots & \cdots & \vdots \\ (\chi_1^{(0)})^{(n-k-1)} & (\chi_2^{(0)})^{(n-k-1)} & (\chi_3^{(0)})^{(n-k-1)} & \cdots & (\chi_n^{(0)})^{(n-k-1)} \end{vmatrix}, \tag{3.1}$$

$$IW_{0,n}\equiv W_n(\chi_1^{(0)},\chi_2^{(0)},\chi_3^{(0)},\ldots,\chi_n^{(0)}). \tag{3.2}$$

$$\widehat{IW}_{k,n}\equiv\widehat{IW}_{k,n}(\chi_k^{(0)},\chi_{k-1}^{(0)},\ldots,\chi_1^{(0)};\mu_1^{(0)},\ldots,\mu_n^{(0)})$$

$$=\begin{vmatrix} \int \chi_k^{(0)}\cdot\mu_1^{(0)} & \int \chi_k^{(0)}\cdot\mu_2^{(0)} & \int \chi_k^{(0)}\cdot\mu_3^{(0)} & \cdots & \int \chi_k^{(0)}\cdot\mu_n^{(0)} \\ \int \chi_{k-1}^{(0)}\cdot\mu_1^{(0)} & \int \chi_{k-1}^{(0)}\cdot\mu_2^{(0)} & \int \chi_{k-1}^{(0)}\cdot\mu_3^{(0)} & \cdots & \int \chi_{k-1}^{(0)}\cdot\mu_n^{(0)} \\ \vdots & \vdots & \vdots & \cdots & \vdots \\ \int \chi_1^{(0)}\cdot\mu_1^{(0)} & \int \chi_1^{(0)}\cdot\mu_2^{(0)} & \int \chi_1^{(0)}\cdot\mu_3^{(0)} & \cdots & \int \chi_1^{(0)}\cdot\mu_n^{(0)} \\ \mu_1^{(0)} & \mu_2^{(0)} & \mu_3^{(0)} & \cdots & \mu_n^{(0)} \\ \mu_{1,x}^{(0)} & \mu_{2,x}^{(0)} & \mu_{3,x}^{(0)} & \cdots & \mu_{n,x}^{(0)} \\ \vdots & \vdots & \vdots & \cdots & \vdots \\ (\mu_1^{(0)})^{(n-k-1)} & (\mu_2^{(0)})^{(n-k-1)} & (\mu_3^{(0)})^{(n-k-1)} & \cdots & (\mu_n^{(0)})^{(n-k-1)} \end{vmatrix}, \tag{3.3}$$

$$\widehat{IW}_{0,n}\equiv W_n(\mu_1^{(0)},\mu_2^{(0)},\mu_3^{(0)},\ldots,\mu_n^{(0)}). \tag{3.4}$$

Here, $(f_i^{(0)})^{(k)}=\partial^k f_i^{(0)}/\partial x^n$, $\int f=\int f\,\mathrm{d}x$ with the integration constant sets to zero.

Now let us discuss several interesting chains of gauge transformations through the following n-step gauge transformations. We first consider the successive application of T_D in the ith channel (we adopt the notation of Ref. 6). For the chain of gauge transformations, we have the following:

$$L^{(0)}\xrightarrow{T_D^{(1)}(\chi_i^{(0)})}L^{(1)}\xrightarrow{T_I^{(2)}(\mu_i^{(1)})}L^{(2)}\xrightarrow{T_D^{(3)}(\chi_i^{(2)})}L^{(3)}\xrightarrow{T_I^{(4)}(\mu_i^{(3)})}\cdots\to\cdots, \tag{3.5}$$

we have the following.

Lemma 3.1: Let $\chi_i^{(0)}\neq 0,\mu_i^{(0)}\neq 0$, *then*

$$\chi_i^{(1)}=T_D^{(1)}(\chi_i^{(0)})\cdot\chi_i^{(0)}=0,\quad \mu_i^{(1)}=-T_I^{(1)}(\chi_i^{(0)})\cdot\mu_i^{(0)}=-\frac{1}{\chi_i^{(0)}}\int\chi_i^{(0)}\mu_i^{(0)},$$

$$\chi_i^{(2)}=\frac{1}{\mu_i^{(1)}},\quad \mu_i^{(2)}=0,$$

$$\chi_i^{(3)}=0,\quad \mu_i^{(3)}=\frac{1}{\chi_i^{(2)}}=\mu_i^{(1)},$$

$$\chi_i^{(4)}=\frac{1}{\mu_i^{(3)}}=\frac{1}{\mu_i^{(1)}},\quad \mu_i^{(4)}=0,$$

$$\vdots\vdots$$

$$\chi_i^{(2k+1)}=0,\quad \mu_i^{(2k+1)}=\mu_i^{(1)};\quad k\geqslant 1,$$

$$\chi_i^{(2k+2)}=\frac{1}{\mu_i^{(1)}},\quad \mu_i^{(2k+2)}=0,\quad k\geqslant 0. \tag{3.6}$$

Lemma 3.2: Let $\chi_i^{(0)}\neq 0,\mu_i^{(0)}\neq 0$, *then*

$$T_I^{(2)}(\mu_i^{(1)})\circ T_D^{(1)}(\chi_i^{(0)})=1-\frac{\chi_i^{(0)}}{\int \chi_i^{(0)}\cdot\mu_i^{(0)}}\circ\partial^{-1}\circ\mu_i^{(0)}\neq I, \tag{3.7}$$

and

$$T_I^{(2k)}(\mu_i^{(2k-1)})\circ T_D^{(2k-1)}(\chi_i^{(2k-2)})=I\quad (k\geqslant 2), \tag{3.8}$$

$$T_D^{(2k-1)}(\chi_i^{(2k-2)})\circ T_I^{(2k-2)}(\mu_i^{(2k-3)})=I\quad (\geqslant 2). \tag{3.9}$$

Proof:

$$\begin{aligned}T_I^{(2)}(\mu_i^{(1)})\circ T_D^{(1)}(\chi_i^{(0)})&=(\mu_i^{(1)})^{-1}\circ\partial^{-1}\circ\mu_i^{(1)}\circ\chi_i^{(0)}\circ\partial\circ(\chi_i^{(0)})^{-1}\\&=-(\mu_i^{(1)})^{-1}\circ\partial^{-1}\circ\left(\int\mu_i^{(0)}\cdot\chi_i^{(0)}\right)\circ\partial\circ(\chi_i^{(0)})^{-1}\\&=(\mu_i^{(1)})^{-1}\circ\left[\left(-\int\mu_i^{(0)}\cdot\chi_i^{(0)}\right)\circ\partial^{-1}+\partial^{-1}\circ(\mu_i^{(0)}\cdot\chi_i^{(0)})\circ\partial^{-1}\right]\circ\partial\circ(\chi_i^{(0)})^{-1}\\&=1+\frac{1}{\mu_i^{(1)}}\circ\partial^{-1}\circ\mu_i^{(0)}=1-\frac{\chi_i^{(0)}}{\int\chi_i^{(0)}\cdot\mu_i^{(0)}}\circ\partial^{-1}\circ\mu_i^{(0)}\neq I.\end{aligned}$$

Using Lemma 3.1, the left-hand side of (3.8) and (3.9) can be written explicitly as

$$\begin{aligned}T_I^{(2k)}(\mu_i^{(2k-1)})\circ T_D^{(2k-1)}(\chi_i^{(2k-2)})&=(\mu_i^{(2k-1)})^{-1}\circ\partial^{-1}\circ\mu_i^{(2k-1)}\circ\chi_i^{(2k-2)}\circ\partial\circ(\chi_i^{(2k-2)})^{-1}\\&=(\mu_i^{(2k-1)})^{-1}\circ\partial^{-1}\circ 1\circ\partial\circ(\chi_i^{(2k-2)})^{-1}=I\end{aligned}$$

and

$$\begin{aligned}T_D^{(2k-1)}(\mu_i^{(2k-2)})\circ T_I^{(2k-2)}(\chi_i^{(2k-3)})&=\chi_i^{(2k-2)}\circ\partial\circ(\chi_i^{(2k-2)})^{-1}\circ(\mu_i^{(2k-3)})^{-1}\circ\partial^{-1}\circ\mu_i^{(2k-3)}\\&=\chi_i^{(2k-2)}\circ\partial\circ 1\circ\partial^{-1}\circ\mu_i^{(2k-3)}=I.\end{aligned}$$

□

Theorem 3.1:

$$\tau^{(2k)}=\tau^{(2k-2)}=\cdots=\tau^{(2)}=-\left(\int \chi_i^{(0)}\cdot\mu_i^{(0)}\right)\cdot\tau^{(0)}, \tag{3.10}$$

$$\tau^{(2k-1)}=\tau^{(2k-3)}=\cdots=\tau^{(1)}=\chi_i^{(0)}\cdot\tau^{(0)}. \tag{3.11}$$

Proof: From Theorem 2.2 and Theorem 2.3, the tau-function of $L^{(2k)}$ is $\tau^{(2k)}=\mu_i^{(2k-1)}\cdot\tau^{(2k-1)}$. Then, according to Lemma 3.1,

$$\begin{aligned}\tau^{(2k)}&=\mu_i^{(2k-1)}\cdot\tau^{(2k-1)}=\mu_i^{(2k-1)}\cdot\chi_i^{(2k-2)}\tau^{(2k-2)}=\tau^{(2k-2)}=\mu_i^{(2k-3)}\cdot\chi_i^{(2k-4)}\tau^{(2k-4)}=\tau^{(2k-4)}\\ &\vdots\\ &=\tau^{(2)}=\mu_i^{(1)}\cdot\chi_i^{(0)}\cdot\tau^{(0)}=-\left(\int\chi_i^{(0)}\cdot\mu_i^{(0)}\right)\tau^{(0)}.\end{aligned}$$

And (3.11) is obtained by a similar way. □

Remark 3.1: The property of the tau-function in the above theorem is different from the case of the first choice.[6] For the first choice, if we construct one chain of gauge transformations such as (3.5), obviously we can only obtain two tau-functions: $\tau^{(2k)}=\cdots=\tau^{(2)}=\tau^{(0)}, \tau^{(2k-1)}=\cdots=\tau^{(1)}$. In particular, the alternative application of Type **I** and Type **II** can be obtained via the single channel. Meanwhile, this novel property of the τ-function results in the periodical transformation with respect to the number of steps in the chain of gauge transformations, when we consider the multichannel (mixed) case (see below).

We now consider another chain of gauge transformations in the ith channel, in which the first step is a gauge transformation of Type **II**,

$$L^{(0)}\xrightarrow{T_I^{(1)}(\mu_i^{(0)})}L^{(1)}\xrightarrow{T_D^{(2)}(\chi_i^{(1)})}L^{(2)}\xrightarrow{T_I^{(3)}(\mu_i^{(2)})}L^{(3)}\xrightarrow{T_D^{(4)}(\chi_i^{(3)})}\cdots\rightarrow\cdots. \tag{3.12}$$

For this chain of gauge transformations, we have the following.

Lemma 3.3: Let $\chi_i^{(0)}\neq 0, \mu_i^{(0)}\neq 0$, *then*

$$\chi_i^{(1)}=\frac{1}{\mu_i^{(0)}}\circ\partial^{-1}\circ\mu_i^{(1)}\cdot\chi_i^{(0)}=\frac{1}{\mu_i^{(0)}}\cdot\int(\mu_i^{(0)}\cdot\chi_i^{(0)}),\quad \mu_i^{(1)}=0,$$

$$\chi_i^{(2)}=0,\quad \mu_i^{(2)}=\frac{1}{\chi_i^{(1)}},$$

$$\chi_i^{(3)}=\frac{1}{\mu_i^{(2)}}=\chi_i^{(1)},\quad \mu_i^{(3)}=0,$$

$$\chi_i^{(4)}=0,\quad \mu_i^{(4)}=\frac{1}{\chi_i^{(3)}}=\frac{1}{\chi_i^{(1)}},$$

$$\vdots\qquad\vdots$$

$$\chi_i^{(2k)}=0,\quad \mu_i^{(2k)}=\frac{1}{\chi_i^{(2k-1)}}=\frac{1}{\chi_i^{(1)}},\quad k\geqslant 1,$$

$$\chi_i^{(2k+1)}=\frac{1}{\mu_i^{(2k)}}=\chi_i^{(1)},\quad \mu_i^{(2k+1)}=0,\quad k\geqslant 0. \tag{3.13}$$

Lemma 3.4: Let $\chi_i^{(0)} \neq 0, \mu_i^{(0)} \neq 0$, *then*

$$T_D^{(2)}(\chi_i^{(1)}) \circ T_I^{(1)}(\mu_i^{(0)}) = 1 - \frac{\chi_i^{(0)}}{\int \chi_i^{(0)} \cdot \mu_i^{(0)}} \circ \partial^{-1} \circ \mu_i^{(0)} \neq I \tag{3.14}$$

and

$$T_D^{(2k)}(\chi_i^{(2k-1)}) \circ T_I^{(2k-1)}(\mu_i^{(2k-2)}) = I \quad (k \geqslant 2), \tag{3.15}$$

$$T_I^{(2k-1)}(\mu_i^{(2k-2)}) \circ T_D^{(2k-2)}(\chi_i^{(2k-3)}) = I \quad (k \geqslant 2). \tag{3.16}$$

Proof:

$$\begin{aligned} T_D^{(2)}(\chi_i^{(1)}) \circ T_I^{(1)}(\mu_i^{(0)}) &= \chi_i^{(1)} \circ \partial \circ (\chi_i^{(1)})^{-1} \circ (\mu_i^{(0)})^{-1} \circ \partial^{-1} \circ \mu_i^{(0)} \\ &= \chi_i^{(1)} \circ \partial \circ \frac{1}{\int \mu_i^{(0)} \cdot \chi_i^{(0)}} \circ \partial^{-1} \circ \mu_i^{(0)} \\ &= \chi_i^{(1)} \circ \left(\frac{\partial}{\int \mu_i^{(0)} \cdot \chi_i^{(0)}} + \left(\frac{1}{\int \mu_i^{(0)} \cdot \chi_i^{(0)}} \right)_x \right) \circ \partial^{-1} \circ \mu_i^{(0)} \\ &= \frac{\int \mu_i^{(0)} \cdot \chi_i^{(0)}}{\mu_i^{(0)}} \circ \left(- \frac{\mu_i^{(0)} \cdot \chi_i^{(0)}}{(\int \mu_i^{(0)} \cdot \chi_i^{(0)})^2} + \frac{1}{\int \mu_i^{(0)} \cdot \chi_i^{(0)}} \circ \partial \right) \circ \partial^{-1} \circ \mu_i^{(0)} \\ &= 1 - \frac{\chi_i^{(0)}}{\int \mu_i^{(0)} \cdot \chi_i^{(0)}} \circ \partial^{-1} \circ \mu_i^{(0)} \neq = I. \end{aligned}$$

Using Lemma 3.3, then

$$\begin{aligned} T_D^{(2k)}(\chi_i^{(2k-1)}) \circ T_I^{(2k-1)}(\mu_i^{(2k-2)}) &= \chi_i^{(2k-1)} \circ \partial \circ (\chi_i^{(2k-1)})^{-1} \circ (\mu_i^{(2k-2)})^{-1} \circ \partial^{-1} \circ \mu_i^{(2k-2)} \\ &= \chi_i^{(2k-1)} \circ \partial \circ 1 \circ \partial^{-1} \circ \mu_i^{(2k-2)} = I \end{aligned}$$

and

$$\begin{aligned} T_I^{(2k-1)}(\mu_i^{(2k-2)}) \circ T_I^{(2k-2)}(\chi_i^{(2k-3)}) &= (\mu_i^{(2k-2)})^{-1} \circ \partial^{-1} \circ \mu_i^{(2k-2)} \circ \chi_i^{(2k-3)} \circ \partial \circ (\chi_i^{(2k-3)})^{-1} \\ &= \mu_i^{(2k-2)} \circ \partial^{-1} \circ 1 \circ \partial \circ (\chi_i^{(2k-3)})^{-1} = I. \end{aligned}$$

□

Theorem 3.2:

$$\tau^{(2k)} = \tau^{(2k-2)} = \cdots = \tau^{(2)} = \left(\int \chi_i^{(0)} \cdot \mu_i^{(0)} \right) \cdot \tau^{(0)}, \tag{3.17}$$

$$\tau^{(2k-1)} = \tau^{(2k-3)} = \cdots = \tau^{(1)} = \mu_i^{(0)} \cdot \tau^{(0)}. \tag{3.18}$$

Proof: Lemma 3.4 shows that $\tau^{(2k)} = \tau^{(2k-2)} = \cdots = \tau^{(2)}, \tau^{(2k-1)} = \tau^{(2k-3)} = \cdots = \tau^{(1)}$. From Theorem 2.2 and Theorem 2.3, we have $\tau^{(1)} = \mu_i^{(0)} \cdot \tau^{(0)}$ and $\tau^{(2)} = (\int \chi_i^{(0)} \cdot \mu_i^{(0)}) \cdot \tau^{(0)}$. □

In order ot obtain the explicit form of $\phi^{(n)}, \psi^{(n)}, \tau^{(n)}$ after a n-step gauge transformation, we give the determinant representation of the gauge transformation operators.

Lemma 3.5: (Ref. 22) *For* $n > k$, *there are two gauge transformation operators*

$$T_{n+k}=T_I^{(n+k)}(\mu_k^{(n+k-1)})\circ T_I^{(n+k-1)}(\mu_{k-1}^{(n+k-2)})\cdots T_I^{(n+1)}(\mu_1^{(n)})\circ T_D^{(n)}(\chi_n^{(n-1)})$$
$$\circ T_D^{(n-1)}(\chi_{n-1}^{(n-2)})\cdots T_D^{(1)}(\chi_1^{(0)})$$
$$=\frac{1}{IW_{k,n}}\cdot\begin{vmatrix} \int \chi_1^{(0)}\cdot\mu_k^{(0)} & \int \chi_2^{(0)}\cdot\mu_k^{(0)} & \cdots & \int \chi_n^{(0)}\cdot\mu_k^{(0)} & \partial^{-1}\circ\mu_k^{(0)} \\ \int \chi_1^{(0)}\cdot\mu_{k-1}^{(0)} & \int \chi_2^{(0)}\cdot\mu_{k-1}^{(0)} & \cdots & \int \chi_n^{(0)}\cdot\mu_{k-1}^{(0)} & \partial^{-1}\circ\mu_{k-1}^{(0)} \\ \vdots & \vdots & \cdots & \vdots & \vdots \\ \int \chi_1^{(0)}\cdot\mu_1^{(0)} & \int \chi_2^{(0)}\cdot\mu_1^{(0)} & \cdots & \int \chi_n^{(0)}\cdot\mu_1^{(0)} & \partial^{-1}\circ\mu_1^{(0)} \\ \chi_1^{(0)} & \chi_2^{(0)} & \cdots & \chi_n^{(0)} & 1 \\ \chi_{1,x}^{(0)} & \chi_{2,x}^{(0)} & \cdots & \chi_{n,x}^{(0)} & \partial \\ \vdots & \vdots & \cdots & \vdots & \vdots \\ (\chi_1^{(0)})^{(n-k)} & (\chi_2^{(0)})^{(n-k)} & \cdots & (\chi_n^{(0)})^{(n-k)} & \partial^{n-k} \end{vmatrix}, \quad (3.19)$$

and

$$T_{n+k}^{-1}=\begin{vmatrix} \chi_1^{(0)}\circ\partial^{-1} & \int \mu_k^{(0)}\cdot\chi_1^{(0)} & \cdots & \int \mu_1^{(0)}\cdot\chi_1^{(0)} & \chi_1^{(0)} & \chi_{1,x}^{(0)} & \cdots & (\chi_1^{(0)})^{(n-k-2)} \\ \chi_2^{(0)}\circ\partial^{-1} & \int \mu_k^{(0)}\cdot\chi_2^{(0)} & \cdots & \int \mu_1^{(0)}\cdot\chi_2^{(0)} & \chi_2^{(0)} & \chi_{2,x}^{(0)} & \cdots & (\chi_2^{(0)})^{(n-k-2)} \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ \chi_{n-1}^{(0)}\circ\partial^{-1} & \int \mu_k^{(0)}\cdot\chi_{n-1}^{(0)} & \cdots & \int \mu_1^{(0)}\cdot\chi_{n-1}^{(0)} & \chi_{n-1}^{(0)} & \chi_{n-1,x}^{(0)} & \cdots & (\chi_{n-1}^{(0)})^{(n-k-2)} \\ \chi_n^{(0)}\circ\partial^{-1} & \int \mu_k^{(0)}\cdot\chi_n^{(0)} & \cdots & \int \mu_1^{(0)}\cdot\chi_n^{(0)} & \chi_n^{(0)} & \chi_{n,x}^{(0)} & \cdots & (\chi_n^{(0)})^{(n-k-2)} \end{vmatrix}$$
$$\cdot\frac{(-1)^{n-1}}{IW_{k,n}}. \quad (3.20)$$

Let us to discuss the multichannel (pure) case. For the chain of gauge transformations,

$$L^{(0)}\xrightarrow{T_D^{(1)}(\chi_1^{(0)})}L^{(1)}\xrightarrow{T_D^{(2)}(\chi_2^{(1)})}L^{(2)}\xrightarrow{T_D^{(3)}(\chi_3^{(2)})}L^{(3)}\xrightarrow{T_D^{(4)}(\chi_4^{(3)})}\cdots\to\cdots L^{(n-1)}\xrightarrow{T_D^{(n)}(\chi_n^{(n-1)})}L^{(n)}, \quad (3.21)$$

we have

Theorem 3.3:

$$\phi^{(n)}=T_D^{(n)}(\chi_n^{(n-1)})\circ T_D^{(n-1)}(\chi_{n-1}^{(n-2)})\cdots\circ T_D^{(2)}(\chi_2^{(1)})\circ T_D^{(1)}(\chi_1^{(0)})\cdot\phi^{(0)}$$
$$=\frac{W_{n+1}(\chi_1^{(0)},\chi_2^{(0)},\ldots,\chi_n^{(0)},\phi^{(0)})}{W_n(\chi_1^{(0)},\chi_2^{(0)},\ldots,\chi_n^{(0)})}, \quad (3.22)$$

$$\psi^{(n)}=-T_I^{(n)}(\chi_n^{(n-1)})\cdot\psi^{(n-1)}$$
$$=(-1)^n T_I^{(n)}(\chi_n^{(n-1)})\circ T_I^{(n-1)}(\chi_{n-1}^{(n-2)})\cdots T_I^{(2)}(\chi_2^{(1)})\circ T_I^{(1)}(\chi_1^{(0)})\cdot\psi^{(0)}$$
$$=(-1)^n\frac{IW_{1,n}(\psi^{(0)};\chi_1^{(0)},\chi_2^{(0)},\ldots,\chi_n^{(0)})}{W_n}, \quad (3.23)$$

$$\tau^{(n)}=W_n(\chi_1^{(0)},\chi_2^{(0)},\ldots,\chi_n^{(0)})\cdot\tau^{(0)}, \tag{3.24}$$

$$\chi_i^{(j)}=\begin{cases}0, & n\geqslant j\geqslant i,\\ \dfrac{W_{j+1}(\chi_1^{(0)},\chi_2^{(0)},\ldots,\chi_j^{(0)},\chi_i^{(0)})}{W_j(\chi_1^{(0)},\chi_2^{(0)},\ldots,\chi_j^{(0)})}, & j<i\leqslant n,\end{cases} \tag{3.25}$$

$$\begin{aligned}\mu_i^{(n)}&=-T_I^{(n)}(\chi_n^{(n-1)})\cdot\mu_i^{(n-1)}\\&=(-1)^nT_I^{(n)}(\chi_n^{(n-1)})\circ T_I^{(n-1)}(\chi_{n-1}^{(n-2)})\cdots T_I^{(2)}(\chi_2^{(1)})\circ T_I^{(1)}(\chi_1^{(0)})\cdot\mu_i^{(0)}\\&=(-1)^n\frac{IW_{1,n}(\mu_i^{(0)};\chi_1^{(0)},\chi_2^{(0)},\ldots,\chi_n^{(0)})}{W_n}.\end{aligned} \tag{3.26}$$

Proof: This can be obtained by direct calculation with the help of successive applications of Theorem 2.2, and by using Lemma 3.5. □

Similarly, for the gauge transformation of Type **II**, the following chain of gauge transformations:

$$L^{(0)}\xrightarrow{T_I^{(1)}(\mu_1^{(0)})}L^{(1)}\xrightarrow{T_I^{(2)}(\mu_2^{(1)})}L^{(2)}\xrightarrow{T_I^{(3)}(\mu_3^{(2)})}L^{(3)}\xrightarrow{T_I^{(4)}(\mu_4^{(3)})}\cdots\rightarrow L^{(n-1)}\xrightarrow{T_I^{(n)}(\mu_n^{(n-1)})} \tag{3.27}$$

implies the following.

Theorem 3.4:

$$\begin{aligned}\phi^{(n)}&=T_I^{(n)}(\mu_n^{(n-1)})\circ T_I^{(n-1)}(\mu_{n-1}^{(n-2)})\cdots T_I^{(2)}(\mu_2^{(1)})\circ T_I^{(1)}(\mu_1^{(0)})\cdot\phi^{(0)},\\&=\frac{IW_{1,n}(\phi^{(0)};\mu_1^{(0)},\mu_2^{(0)},\ldots,\mu_n^{(0)})}{W_n(\mu_1^{(0)},\mu_2^{(0)},\ldots,\mu_n^{(0)})},\end{aligned} \tag{3.28}$$

$$\begin{aligned}\psi^{(n)}&=(-1)^nT_D^{(n)}(\mu_n^{(n-1)})\circ T_D^{(n-1)}(\mu_{n-1}^{(n-2)})\cdots T_D^{(2)}(\mu_2^{(1)})\circ T_D^{(1)}(\mu_1^{(0)})\cdot\psi^{(0)}\\&=(-1)^n\frac{W_{n+1}(\mu_1^{(0)},\mu_2^{(0)},\ldots,\mu_n^{(0)},\psi^{(0)})}{W_n(\mu_1^{(0)},\mu_2^{(0)},\ldots,\mu_n^{(0)})},\end{aligned} \tag{3.29}$$

$$\tau^{(n)}=W_n(\mu_n^{(0)},\mu_{n-1}^{(0)},\ldots\mu_2^{(0)},\mu_1^{(0)})\cdot\tau^{(0)}, \tag{3.30}$$

$$\begin{aligned}\chi_i^{(n)}=T_I^{(n)}(\mu_n^{(n-1)})\cdot\chi_i^{(n-1)}&=T_I^{(n)}(\mu_n^{(n-1)})\circ T_I^{(n-1)}(\mu_{n-1}^{(n-2)})\cdots T_I^{(2)}(\mu_2^{(1)})\circ T_I^{(1)}(\mu_1^{(0)})\cdot\chi_i^{(0)},\\&=\frac{IW_{1,n}(\chi_i^{(0)};\mu_1^{(0)},\mu_2^{(0)},\ldots,\mu_n^{(0)})}{W_n(\mu_1^{(0)},\mu_2^{(0)},\ldots,\mu_n^{(0)})}\end{aligned} \tag{3.31}$$

$$\mu_i^{(j)}=\begin{cases}0, & n\geqslant j\geqslant i,\\ (-1)^j\cdot\dfrac{W_{j+1}(\mu_1^{(0)},\mu_2^{(0)},\ldots,\mu_j^{(0)},\mu_i^{(0)})}{W_j(\mu_1^{(0)},\mu_2^{(0)},\ldots,\mu_j^{(0)})}, & j<i\leqslant n.\end{cases} \tag{3.32}$$

Remark 3.2: This formula, (3.22), is the same as the result of Ref. 21, and (3.24) also equals with those result [although Ref. 21 does not include the explicit form as (3.24)]. Because the GFGT will be lost after the gauge transformation, cannot do the $(n+1)$th step of gauge transformation in the multichannel (pure) case according to (3.21) and (3.27) if we only use n BA functions or n adjoint BA functions.

Finally, we would like to discuss the more complicated case: the multichannel (mixed). First of all, there is an important lemma exactly similar to the result of Ref. 6 [see (67) and (68) there].

Lemma 3.6: Suppose the BA function $\chi_i^{(k-1)}$ and the adjoint BA function $\mu_j^{(k-1)}$ of $L^{(k-1)}$ lied in a chain of gauge transformations, and $\chi_i^{(k-1)} \neq 0, \mu_i^{(k-1)} \neq 0, i \neq j$. For the two chains,

$$(A): L^{(k-1)} \xrightarrow{T_D(\chi_i^{(k-1)})} L^{(k)} \xrightarrow{T_I(\mu_j^{(k)})} L^{(k+1)}, \tag{3.33}$$

$$(B): L^{(k-1)} \xrightarrow{T_I(\mu_j^{(k-1)})} L^{(k)} \xrightarrow{T_D(\chi_i^{(k)})} L^{(k+1)}, \tag{3.34}$$

we have

$$T_I(\mu_j^{(k)}) \circ T_D(\chi_i^{(k-1)}) = T_D(\chi_i^{(k)}) \circ T_I(\mu_j^{(k-1)}) = 1 - \frac{\chi_i^{(k-1)}}{\int \mu_j^{(k-1)} \cdot \chi_i^{(k-1)}} \circ \partial^{-1} \circ \mu_j^{(k-1)}. \tag{3.35}$$

Meanwhile, the $\tau_A^{(k+1)}$ is generated by A and $\tau_B^{(k+1)}$ is generated by B, which are of the form

$$\tau_A^{(k+1)} = -\left(\int \chi_i^{(k-1)} \cdot \mu_j^{(k-1)} \right) \cdot \tau^{(k-1)}, \tag{3.36}$$

$$\tau_B^{(k+1)} = \left(\int \chi_i^{(k-1)} \cdot \mu_j^{(k-1)} \right) \cdot \tau^{(k-1)}, \tag{3.37}$$

and $\tau_A^{(k+1)}$ is equivalent to $\tau_B^{(k+1)}$.

Proof: Formula (3.35) is proved in a similar way to (3.7) and (3.14). $\tau_A^{(k+1)}$ and $\tau_B^{(n+k)}$ are obtained by successive applications of Theorem 2.2 and Theorem 2.3 with two steps. □

This lemma is very important to study the τ-function generated by gauge transformations in the multichannel (mixed) case. The $\tau^{(n+k)}$ is determined uniquely up to an unimportant minus sign. It leads us to neglect the order of the channel adopted in one chain of gauge transformations. However, in order to understand and calculate easily the transformation of the τ-function, we still discuss firstly the chain of gauge transformations with a fixed ordering of the channels. For the chain of gauge transformations with $n \geqslant k > 1$,

$$\begin{aligned} L^{(0)} &\xrightarrow{T_D^{(1)}(\chi_1^{(0)})} L^{(1)} \xrightarrow{T_D^{(2)}(\chi_2^{(1)})} L^{(2)} \xrightarrow{T_D^{(3)}(\chi_3^{(2)})} L^{(3)} \cdots \\ &\to L^{(n-1)} \xrightarrow{T_D^{(n)}(\chi_n^{(n-1)})} L^{(n)} \xrightarrow{T_I^{(n+1)}(\mu_1^{(n)})} L^{(n+1)} \xrightarrow{T_I^{(n+2)}(\mu_2^{(n+1)})} L^{(n+2)} \cdots \\ &\to L^{(n+k-1)} \xrightarrow{T_I^{(n+k)}(\mu_k^{(n+k-1)})} L^{(n+k)}, \end{aligned} \tag{3.38}$$

we want to obtain the $\phi^{(n+k)}, \psi^{(n+k)}, \tau^{(n+k)}$ of $L^{(n+k)}$ transformed from the $L^{(0)}$ by the above chain of gauge transformations.

Theorem 3.5:

$$\begin{aligned} \phi^{(n+k)} &= T_I^{(n+k)}(\mu_k^{(n+k-1)}) \circ T_I^{(n+k-1)}(\mu_{k-1}^{(n+k-2)}) \cdots T_I^{(n+1)}(\mu_1^{(n)}) \circ T_D^{(n)}(\chi_n^{(n-1)}) \\ &\circ T_D^{(n-1)}(\chi_{n-1}^{(n-2)}) \cdots T_D^{(1)}(\chi_1^{(0)}) \cdot \phi^{(0)} = \frac{IW_{k,n+1}(\mu_k^{(0)}, \ldots, \mu_1^{(0)}; \chi_1^{(0)}, \ldots, \chi_n^{(0)}, \phi^{(0)})}{IW_{k,n}}, \end{aligned} \tag{3.39}$$

$$\psi^{(n+k)} = (T_{n+k}^{-1})^* \cdot \psi^{(0)} = (-1)^n \frac{IW_{k+1,n}(\psi^{(0)}, \mu_k^{(0)}, \mu_{k-1}^{(0)}, \ldots, \mu_1^{(0)}; \chi_1^{(0)}, \ldots, \chi_n^{(0)})}{IW_{k,n}}, \tag{3.40}$$

$$\tau^{(n+k)}=IW_{k,n}\cdot\tau^{(0)}, \tag{3.41}$$

Proof: $\phi^{(n+k)}=T_{n+k}\cdot\phi^{(0)}$ is obtained by the successive applications of Theorem 2.2, Theorem 2.3, then taking the expression of T_{n+k} into it yields the explicit form of $\psi^{(n+k)}$ as a determinant. Meanwhile, using Theorem 2.2, Theorem 2.3 and the definition of operation of conjugation, we have

$$\begin{aligned}\psi^{(n+k)}&=(-1)^{n+k}T_D^{(n+k)}(\mu_k^{(n+k-1)})\circ T_D^{(n+k-1)}(\mu_{k-1}^{(n+k-2)})\cdots T_D^{(n+1)}(\mu_k^{(n+k-1)})T_I^{(n)}(\chi_n^{(n-1)})\\&\quad\circ T_I^{(n)}(\chi_{n-1}^{(n-2)})\cdots T_I^{(n)}(\chi_1^{(0)})\cdot\psi^{(0)}=(T_{n+k}^{-1})^*\cdot\psi^{(0)}.\end{aligned}$$

The formal determinantal expression of $\psi^{(n+k)}$ follows from the above lemma. Theorem 2.2 and Theorem 2.3 imply

$$\tau^{(n+k)}=\mu_k^{(n+k-1)}\cdot\mu_{k-1}^{(n+k-2)}\cdots\mu_1^{(n)}\cdot\tau^{(n)},$$

in which $\mu_i^{(j)}$ given by

$$\begin{aligned}\mu_i^{(n+j)}&=(T_{n+j}^{-1})^*\cdot\mu_i^{(0)}\\&=\begin{cases}0, & j\geqslant i\\ (-1)^n\dfrac{IW_{j+1,n}(\mu_i^{(0)},\mu_j^{(0)},\mu_{j-1}^{(0)},\ldots,\mu_1^{(0)};\chi_1^{(0)},\ldots,\chi_n^{(0)})}{IW_{j,n}(\mu_j^{(0)},\mu_{j-1}^{(0)},\ldots,\mu_1^{(0)};\chi_1^{(0)},\ldots,\chi_n^{(0)})}, & k\geqslant i>j\geqslant 1.\end{cases}\end{aligned}$$

Specially, the $\mu_i^{(n)}$ and the $\tau^{(n)}$ are given by Theorem 3.3. So taking these expressions back into $\tau^{(n+k)}$ finishes the proof of theorem. □

Moreover, for

$$\begin{aligned}&L^{(0)}\xrightarrow{T_I^{(1)}(\mu_1^{(0)})}L^{(1)}\xrightarrow{T_I^{(2)}(\mu_2^{(1)})}L^{(2)}\xrightarrow{T_I^{(3)}(\mu_3^{(2)})}L^{(3)}\cdots\\&\to L^{(n-1)}\xrightarrow{T_I^{(n)}(\mu_n^{(n-1)})}L^{(n)}\xrightarrow{T_D^{(n+1)}(\chi_1^{(n)})}L^{(n+1)}\xrightarrow{T_D^{(n+2)}(\chi_2^{(n+1)})}L^{(n+2)}\cdots L^{(n+k-1)}\xrightarrow{T_D^{(n+k)}(\chi_k^{(n+k-1)})}L^{(n+k)},\end{aligned} \tag{3.42}$$

the $\phi^{(n+k)}$, $\psi^{(n+k)}$, $\tau^{(n+k)}$ are written as follows.

Theorem 3.6:

$$\phi^{(n+k)}=(-1)^k\frac{\widehat{IW}_{k+1,n}(\phi^{(0)},\chi_k^{(0)},\chi_{k-1}^{(0)},\ldots,\chi_1^{(0)};\mu_1^{(0)},\ldots,\mu_n^{(0)})}{\widehat{IW}_{k,n}}, \tag{3.43}$$

$$\begin{aligned}\psi^{(n+k)}&=(-)^{n+k}T_I^{(n+k)}(\chi_k^{(n+k-1)})\circ T_I^{(n+k-1)}(\chi_{k-1}^{(n+k-2)})\cdots T_I^{(n+1)}(\chi_1^{(n)})\circ T_D^{(n)}(\mu_n^{(n-1)})\\&\quad\circ T_D^{(n-1)}(\mu_{n-1}^{(n-2)})\cdots T_D^{(1)}(\mu_1^{(0)})\cdot\psi^{(0)}\\&=(-1)^{n+k}\frac{IW_{k,n+1}(\chi_k^{(0)},\ldots,\chi_1^{(0)};\mu_1^{(0)},\ldots,\mu_n^{(0)},\psi^{(0)})}{\widehat{IW}_{k,n}},\end{aligned} \tag{3.44}$$

$$\tau^{(n+k)}=\widehat{IW}_{k,n}\tau^{(0)}. \tag{3.45}$$

Proof: Its proof is similar to way of Theorem 3.5, hence we omit it.

Theorem 3.7: *For the following chain of gauge transformations with* $k<n$,

$$
\begin{aligned}
&L^{(0)} \xrightarrow{T_D^{(1)}(\chi_1^{(0)})} L^{(1)} \xrightarrow{T_D^{(2)}(\chi_2^{(1)})} L^{(2)} \xrightarrow{T_D^{(3)}(\chi_3^{(2)})} L^{(3)}\cdots\\
&\to L^{(n-1)} \xrightarrow{T_D^{(n)}(\chi_n^{(n-1)})} L^{(n)} \xrightarrow{T_I^{(n+1)}(\mu_1^{(n)})} L^{(n+1)} \xrightarrow{T_I^{(n+2)}(\mu_2^{(n+1)})} L^{(n+2)}\cdots\\
&\to L^{(2n-1)} \xrightarrow{T_I^{(2n)}(\mu_n^{(2n-1)})} L^{(2n)} \xrightarrow{T_D^{(2n+1)}(\chi_1^{(2n)})} L^{(2n+1)} \xrightarrow{T_D^{(2n+2)}(\chi_2^{(2n+1)})} L^{(2n+2)}\cdots\\
&\to L^{(3n-1)} \xrightarrow{T_D^{(2n)}(\chi_n^{(3n-1)})} L^{(3n)} \xrightarrow{T_I^{(3n+1)}(\mu_1^{(3n)})} L^{(3n+1)} \xrightarrow{T_I^{(3n+2)}(\mu_2^{(3n+1)})} L^{(3n+2)}\cdots\\
&\to L^{(4n-1)} \xrightarrow{T_I^{(4n)}(\mu_n^{(4n-1)})} L^{(4n)} \xrightarrow{T_D^{(4n+1)}(\chi_1^{(4n)})} \cdots,
\end{aligned}
\tag{3.46}
$$

the final form of $\tau^{(mn+k)}$ $(m=0,1,2,\ldots;\ k=0,1,2,\ldots,n-1)$ *for* $L^{(mn+k)}$ *is*

$$
\tau^{(mn+k)}=\begin{cases}
\tau^{(k)}=W_k(\chi_1^{(0)},\cdots,\chi_k^{(0)})\cdot\tau^{(0)}, & \text{if } m=0.\\
\tau^{(n+k)}=IW_{k,n}\cdot\tau^{(0)}, & \text{if } m \text{ is odd.}\\
\tau^{(2n+k)}=IW_{n-k,n}(\mu_n^{(0)},\cdots,\mu_{k+1}^{(0)};\chi_1^{(0)},\cdots,\chi_n^{(0)})\cdot\tau^{(0)}, & \text{if } m \text{ is even.}
\end{cases}
\tag{3.47}
$$

Proof: First of all, Lemma 3.2, Lemma 3.4, and Lemma 3.6 imply directly

$$
\tau^{(mn+k)}=\begin{cases}
\tau^{(n+k)}, & \text{if } m \text{ is odd}\\
\tau^{(2n+k)}, & \text{if } m \text{ is even.}
\end{cases}
$$

On the other hand, $\tau^{(k)}$ is given by Theorem 3.3, and $\tau^{(n+k)}$ is given by Theorem 3.5. In fact, according to Lemma 3.2, Lemma 3.4, and Lemma 3.6, $\tau^{(2n+k)}$ is equivalent to τ-function obtained by the following chain:

$$
\begin{aligned}
&L^{(0)} \xrightarrow{T_D^{(1)}(\chi_1^{(0)})} L^{(1)} \xrightarrow{T_D^{(2)}(\chi_2^{(1)})} L^{(2)} \xrightarrow{T_D^{(3)}(\chi_3^{(2)})} L^{(3)}\cdots\\
&\to L^{(n-1)} \xrightarrow{T_D^{(n)}(\chi_n^{(n-1)})} L^{(n)} \xrightarrow{T_I^{(n+1)}(\mu_{k+1}^{(n)})} L^{(n+1)} \xrightarrow{T_I^{(n+2)}(\mu_{k+2}^{(n+1)})} L^{(n+2)}\cdots\\
&\to L^{(n+n-k-1)} \xrightarrow{T_I^{(n+n-k)}(\mu_n^{(n+n-k-1)})} L^{(n+n-k)}.
\end{aligned}
$$

So Theorem 3.5 yields $\tau^{(n+n-k)}$ with a corresponding modification of the GFGTs. □

Moreover,

Theorem 3.8: *For the chain of gauge transformations*

$$
\begin{aligned}
&L^{(0)} \xrightarrow{T_I^{(1)}(\mu_1^{(0)})} L^{(1)} \xrightarrow{T_I^{(2)}(\mu_2^{(1)})} L^{(2)} \xrightarrow{T_I^{(3)}(\mu_3^{(2)})} L^{(3)}\cdots\\
&\to L^{(n-1)} \xrightarrow{T_I^{(n)}(\mu_n^{(n-1)})} L^{(n)} \xrightarrow{T_D^{(n+1)}(\chi_1^{(n)})} L^{(n+1)} \xrightarrow{T_D^{(n+2)}(\chi_2^{(n+1)})} L^{(n+2)}\cdots\\
&\to L^{(2n-1)} \xrightarrow{T_D^{(2n)}(\chi_n^{(2n-1)})} L^{(2n)} \xrightarrow{T_I^{(2n+1)}(\mu_1^{(2n)})} L^{(2n+1)} \xrightarrow{T_I^{(2n+2)}(\mu_2^{(2n+1)})} L^{(2n+2)}\cdots\\
&\to L^{(3n-1)} \xrightarrow{T_I^{(2n)}(\mu_n^{(3n-1)})} L^{(3n)} \xrightarrow{T_D^{(3n+1)}(\chi_1^{(3n)})} L^{(3n+1)} \xrightarrow{T_D^{(3n+2)}(\chi_2^{(3n+1)})} L^{(3n+2)}\cdots
\end{aligned}
$$

$$\rightarrow L^{(4n-1)} \xrightarrow{T_D^{(4n)}(\chi_n^{(4n-1)})} L^{(4n)} \xrightarrow{T_I^{(4n+1)}(\mu_1^{(4n)})} \cdots, \tag{3.48}$$

the final form of $\tau^{(mn+k)}$ $(m=0,1,2,\ldots;\ k=0,1,2,\ldots,n-1)$ *for* $L^{(mn+k)}$ *is*

$$\tau^{(mn+k)}=\begin{cases}\tau^{(k)}=W_k(\mu_1^{(0)},\ldots,\mu_k^{(0)})\cdot\tau^{(0)}, & \text{if } m=0\\ \tau^{(n+k)}=\widehat{IW}_{k,n}\cdot\tau^{(0)}, & \text{if } m \text{ is odd}\\ \tau^{(2n+k)}=\widehat{IW}_{n-k,n}(\chi_n^{(0)},\cdots,\chi_{k+1}^{(0)};\mu_1^{(0)},\ldots,\mu_n^{(0)})\cdot\tau^{(0)}, & \text{if } m \text{ is even.}\end{cases} \tag{3.49}$$

Proof: The proof of this theorem is similar to way of Theorem 3.8. □

IV. THE UNION OF THE TWO CHOICES OF GAUGE TRANSFORMATIONS

In the previous part of this paper, all chains of gauge transformations include only one choice. It is natural to explore the case of the union of two choices. To our knowledge, this has not been done so far in literature. We consider the following four chains. For the chain with $k<n$,

$$\begin{aligned}&L^{(0)} \xrightarrow{T_D^{(1)}(\phi^{(0)})} L^{(1)} \xrightarrow{T_D^{(2)}(\phi^{(1)})} L^{(2)} \xrightarrow{T_D^{(3)}(\phi^{(2)})} L^{(3)}\cdots\\ &\rightarrow L^{(n-1)} \xrightarrow{T_D^{(n)}(\phi^{(n-1)})} L^{(n)} \xrightarrow{T_D^{(n+1)}(\chi_1^{(n)})} L^{(n+1)} \xrightarrow{T_D^{(n+2)}(\chi_2^{(n+1)})} L^{(n+2)}\cdots\\ &\rightarrow L^{(n+k-1)} \xrightarrow{T_D^{(n+k)}(\chi_k^{(n+k-1)})} L^{(n+k)},\end{aligned} \tag{4.1}$$

we have the following.

Theorem 4.1:

$$\phi^{(n)}=\frac{W_{n+1}(\phi^{(0)},\eta^{(1)},\ldots,\eta^{(n-1)},\eta^{(n)})}{W_n(\phi^{(0)},\eta^{(1)},\ldots,\eta^{(n-1)})}, \tag{4.2}$$

$$\psi^{(n)}=(\phi^{(n-1)})^{-1}, \tag{4.3}$$

$$\phi^{(n+k)}=\frac{W_{n+k+1}(\phi^{(0)},\eta^{(1)},\ldots,\eta^{(n-1)},\chi_1^{(0)},\chi_2^{(0)},\ldots,\chi_k^{(0)},\eta^{(n)})}{W_{n+k}(\phi^{(0)},\eta^{(1)},\ldots,\eta^{(n-1)},\chi_1^{(0)},\chi_2^{(0)},\ldots,\chi_k^{(0)})}, \tag{4.4}$$

$$\begin{aligned}\psi^{(n+k)}&=(-1)^k T_I^{(n+k)}(\chi_k^{(n+k-1)})\circ T_I^{(n+k-1)}(\chi_{k-1}^{(n+k-2)})\cdots T_I^{(n+2)}(\chi_2^{(n+1)})\circ T_I^{(n+1)}(\chi_1^{(n)})\cdot\psi^{(n)},\\ &=(-1)^k\frac{IW_{1,k}(\psi^{(n)};\chi_1^{(n)},\ldots,\chi_k^{(n)})}{W_k(\chi_1^{(n)},\ldots,\chi_k^{(n)})},\end{aligned} \tag{4.5}$$

$$\chi_i^{(n+j)}=\begin{cases}0, & k\geqslant j\geqslant i,\\ \dfrac{W_{n+j+1}(\phi^{(0)},\eta^{(1)},\ldots,\eta^{(n-1)},\chi_1^{(0)},\chi_2^{(0)},\ldots,\chi_j^{(0)},\chi_i^{(0)})}{W_{n+j}(\phi^{(0)},\eta^{(1)},\ldots,\eta^{(n-1)},\chi_1^{(0)},\chi_2^{(0)},\ldots,\chi_j^{(0)})}, & j<i\leqslant k,\end{cases} \tag{4.6}$$

$$\begin{aligned}\mu_i^{(n+j)}&=(-1)^{n+j}T_I^{(n+j)}(\chi_j^{(n+j-1)})\circ T_I^{(n+j-1)}(\chi_{j-1}^{(n+j-2)})\cdots T_I^{(n+1)}(\chi_1^{(n)})\circ T_I^{(n)}(\phi^{(n-1)})\\ &\quad\circ T_I^{(n-1)}(\phi^{(n-2)})\cdots T_I^{(1)}(\phi^{(0)})\cdot\mu_i^{(0)}\\ &=(-1)^{n+j}\frac{IW_{1,n+j}(\mu_i^{(0)};\phi^{(0)},\eta^{(1)},\ldots,\eta^{(n-1)},\chi_1^{(0)},\ldots,\chi_j^{(0)})}{W_{n+j}(\phi^{(0)},\eta^{(1)},\ldots,\eta^{(n-1)},\chi_1^{(0)},\ldots,\chi_j^{(0)})},\end{aligned} \tag{4.7}$$

$$\tau^{(n+k)}=W_{n+k}(\phi^{(0)},\eta^{(1)},\eta^{(2)},\ldots,\eta^{(n-1)},\chi_1^{(0)},\chi_2^{(0)},\ldots,\chi_k^{(0)})\tau^{(0)}. \tag{4.8}$$

Here $\eta^{(k)}=(L^{(0)})^k\cdot\phi^{(0)}$.

Proof: This is a straightforward calculation via the repeated use of Theorem 2.2 and Lemma 3.5. We only point that, in the above chain, the first n steps are gauge transformations of Type **I** with the first choice, while the latter **k** steps use the second choice. □

The second chain is

$$\begin{aligned}
&L^{(0)}\xrightarrow{T_D^{(1)}(\phi^{(0)})}L^{(1)}\xrightarrow{T_D^{(2)}(\phi^{(1)})}L^{(2)}\xrightarrow{T_D^{(3)}(\phi^{(2)})}L^{(3)}\cdots\\
&\to L^{(n-1)}\xrightarrow{T_D^{(n)}(\phi^{(n-1)})}L^{(n)}\xrightarrow{T_I^{(n+1)}(\mu_1^{(n)})}L^{(n+1)}\xrightarrow{T_I^{(n+2)}(\mu_2^{(n+1)})}L^{(n+2)}\cdots\\
&\to L^{(n+k-1)}\xrightarrow{T_I^{(n+k)}(\mu_k^{(n+k-1)})}L^{(n+k)}.
\end{aligned} \tag{4.9}$$

If $k<n$, we have

Theorem 4.2:

$$\phi^{(n+k)}=\frac{IW_{k,n+1}(\mu_k^{(0)},\ldots,\mu_1^{(0)};\phi^{(0)},\eta^{(1)},\ldots,\eta^{(n-1)},\eta^{(n)})}{IW_{k,n}(\mu_k^{(0)},\ldots,\mu_1^{(0)};\phi^{(0)},\eta^{(1)},\ldots,\eta^{(n-1)})}, \tag{4.10}$$

$$\psi^{(n+k)}=(-1)^k\frac{W_{k+1}(\mu_1^{(n)},\ldots,\mu_k^{(n)},\psi^{(n)})}{W_k(\mu_1^{(n)},\ldots,\mu_k^{(n)})}, \tag{4.11}$$

$$\chi_i^{(n+k)}=\frac{IW_{k,n+1}(\mu_k^{(0)},\ldots,\mu_1^{(0)};\phi^{(0)},\eta^{(1)},\ldots,\eta^{(n-1)},\chi_i^{(0)})}{IW_{k,n}(\mu_k^{(0)},\ldots,\mu_1^{(0)};\phi^{(0)},\eta^{(1)},\ldots,\eta^{(n-1)})}, \tag{4.12}$$

$$\mu_i^{(n+k)}=(-1)^n\frac{IW_{k+1,n}(\mu_i^{(0)},\mu_k^{(0)},\ldots,\mu_1^{(0)};\phi^{(0)},\eta^{(1)},\ldots,\eta^{(n-1)})}{IW_{k,n}(\mu_k^{(0)},\ldots,\mu_1^{(0)};\phi^{(0)},\eta^{(1)},\ldots,\eta^{(n-1)})}, \tag{4.13}$$

$$\tau^{(n+k)}=IW_{k,n}(\mu_k^{(0)},\ldots,\mu_1^{(0)};\phi^{(0)},\eta^{(1)},\ldots,\eta^{(n-1)})\tau^{(0)}. \tag{4.14}$$

Here $\psi^{(n)}$, $\mu_i^{(n)}$ and $\eta^{(n)}$ are given by Theorem 4.1.

We also like to consider the analogous treatment for the Type **II** case. For the chain with $k<n$,

$$\begin{aligned}
&L^{(0)}\xrightarrow{T_I^{(1)}(\psi^{(0)})}L^{(1)}\xrightarrow{T_I^{(2)}(\psi^{(1)})}L^{(2)}\xrightarrow{T_I^{(3)}(\psi^{(2)})}L^{(3)}\cdots\\
&\to L^{(n-1)}\xrightarrow{T_I^{(m)}(\psi^{(n-1)})}L^{(n)}\xrightarrow{T_I^{(n+1)}(\mu_1^{(n)})}L^{(n+1)}\xrightarrow{T_I^{(n+2)}(\mu_2^{(n+1)})}L^{(n+2)}\cdots\\
&\to L^{(n+k-1)}\xrightarrow{T_I^{(n+k)}(\mu_k^{(n+k-1)})}L^{(n+k)},
\end{aligned} \tag{4.15}$$

we have the following.

Theorem 4.3:

$$\phi^{(n)}=(\psi^{(n-1)})^{-1}, \tag{4.16}$$

$$\psi^{(n)}=(-1)^n\frac{W_{n+1}(\psi^{(0)},\xi^{(1)},\ldots,\xi^{(n-1)},\xi^{(n)})}{W_n(\psi^{(0)},\xi^{(1)},\ldots,\xi^{(n-1)})}, \tag{4.17}$$

$$\phi^{(n+k)}=T_I^{(n+k)}(\mu_k^{(n+k-1)})\circ T_I^{(n+k-1)}(\mu_{k-1}^{(n+k-2)})\cdots T_I^{(n+2)}(\mu_2^{(n+1)})\circ T_I^{(n+1)}(\mu_1^{(n)})\cdot\phi^{(n)},$$
$$=\frac{IW_{1,k}(\phi^{(n)};\mu_1^{(n)},\ldots,\mu_k^{(n)})}{W_k(\mu_1^{(n)},\ldots,\mu_k^{(n)})}, \tag{4.18}$$

$$\psi^{(n+k)}=(-)^{n+k}\frac{W_{n+k+1}(\psi^{(0)},\xi^{(1)},\ldots,\xi^{(n-1)},\mu_1^{(0)},\mu_2^{(0)},\ldots,\mu_k^{(0)},\xi^{(n)})}{W_{n+k}(\psi^{(0)},\xi^{(1)},\ldots,\xi^{(n-1)},\mu_1^{(0)},\mu_2^{(0)},\ldots,\mu_k^{(0)})}, \tag{4.19}$$

$$\chi_i^{(n+j)}=T_I^{(n+j)}(\mu_j^{(n+j-1)})\circ T_I^{(n+j-1)}(\mu_{j-1}^{(n+j-2)})\cdots T_I^{(n+1)}(\mu_1^{(n)})\circ T_I^{(n)}(\psi^{(n-1)})$$
$$\circ T_I^{(n-1)}(\psi^{(n-2)})\cdots T_I^{(1)}(\psi^{(0)})\cdot\chi_i^{(0)}=\frac{IW_{1,n+j}(\chi_i^{(0)};\psi^{(0)},\xi^{(1)},\ldots,\xi^{(n-1)},\mu_1^{(0)},\ldots,\mu_j^{(0)})}{W_{n+j}(\psi^{(0)},\xi^{(1)},\ldots,\xi^{(n-1)},\mu_1^{(0)},\ldots,\mu_j^{(0)})}, \tag{4.20}$$

$$\mu_i^{(n+j)}=\begin{cases}0, & k\geqslant j\geqslant i,\\ (-1)^{n+j}\dfrac{W_{n+j+1}(\psi^{(0)},\xi^{(1)},\ldots,\xi^{(n-1)},\mu_1^{(0)},\mu_2^{(0)},\ldots,\mu_j^{(0)},\mu_i^{(0)})}{W_{n+j}(\psi^{(0)},\xi^{(1)},\ldots,\xi^{(n-1)},\mu_1^{(0)},\mu_2^{(0)},\ldots,\mu_j^{(0)})}, & j<i\leqslant k,\end{cases} \tag{4.21}$$

$$\tau^{(n+k)}=W_{n+k}(\psi^{(0)},\xi^{(1)},\xi^{(2)},\ldots,\xi^{(n-1)},\mu_1^{(0)},\mu_2^{(0)},\ldots,\mu_k^{(0)})\tau^{(0)}. \tag{4.22}$$

Here $\xi^{(k)}=(L^{*(0)})^k\cdot\psi^{(0)}$.

Proof: This is obtained by a straightforward calculation via the repeated use of Theorem 2.3 and Lemma 3.5. We only point that, in the above chain, the first m steps are gauge transformations of Type **II** with the first choice, while in the latter k steps with second choice is used. □

The fourth chain is

$$L^{(0)}\xrightarrow{T_I^{(1)}(\psi^{(0)})}L^{(1)}\xrightarrow{T_I^{(2)}(\psi^{(1)})}L^{(2)}\xrightarrow{T_I^{(3)}(\psi^{(2)})}L^{(3)}\cdots$$
$$\to L^{(n-1)}\xrightarrow{T_I^{(m)}(\psi^{(n-1)})}L^{(n)}\xrightarrow{T_D^{(n+1)}(\chi_1^{(n)})}L^{(n+1)}\xrightarrow{T_D^{(n+2)}(\chi_2^{(n+1)})}L^{(n+2)}\cdots$$
$$\to L^{(n+k-1)}\xrightarrow{T_D^{(n+k)}(\chi_k^{(n+k-1)})}L^{(n+k)}. \tag{4.23}$$

We then have the following.

Theorem 4.4:

$$\phi^{(n+k)}=\frac{W_{k+1}(\chi_1^{(n)},\ldots,\chi_k^{(n)},\phi^{(n)})}{W_k(\chi_1^{(n)},\ldots,\chi_k^{(n)})}, \tag{4.24}$$

$$\psi^{(n+k)}=(-1)^{n+k}\frac{\widehat{IW}_{k,n+1}(\chi_k^{(0)},\ldots,\chi_1^{(0)};\psi^{(0)},\xi^{(1)},\ldots,\xi^{(n-1)},\xi^{(n)})}{\widehat{IW}_{k,n}(\chi_k^{(0)},\ldots,\chi_1^{(0)};\psi^{(0)},\xi^{(1)},\ldots,\xi^{(n-1)})}, \tag{4.25}$$

$$\chi_i^{(n+k)}=(-1)^k\frac{\widehat{IW}_{k+1,n}(\chi_i^{(0)},\chi_k^{(0)},\ldots,\chi_1^{(0)};\psi^{(0)},\xi^{(1)},\ldots,\xi^{(n-1)})}{\widehat{IW}_{k,n}(\chi_k^{(0)},\ldots,\chi_1^{(0)};\psi^{(0)},\xi^{(1)},\ldots,\xi^{(n-1)})}, \tag{4.26}$$

$$\mu_i^{(n+k)}=(-1)^{n+k}\frac{\widehat{IW}_{k,n+1}(\chi_k^{(0)},\ldots,\chi_1^{(0)};\psi^{(0)},\xi^{(1)},\ldots,\xi^{(n-1)},\mu_i^{(0)})}{\widehat{IW}_{k,n}(\chi_k^{(0)},\ldots,\chi_1^{(0)};\psi^{(0)},\xi^{(1)},\ldots,\xi^{(n-1)})}, \tag{4.27}$$

$$\tau^{(n+k)}=\widehat{IW}_{k,n}(\chi_k^{(0)},\ldots,\chi_1^{(0)};\psi^{(0)},\xi^{(1)},\ldots,\xi^{(n-1)})\tau^{(0)}. \tag{4.28}$$

Here, $\xi^{(k)}$, $\chi_i^{(n)}$ and $\phi^{(n)}$ are given by Theorem 4.3.

Remark 4.1: The main characteristic of the τ-functions, $\phi^{(n+k)}$ and $\psi^{(n+k)}$, in the four chains mentioned above is that there are ''eigenfunctions'' and BA functions of $L^{(0)}$ in their Wronskians or the generalized Wronskians at the same time.

V. GENERATION OF THE AKNS HIERARCHY FROM THE "FREE" LAX OPERATOR $L^{(0)}=\partial$

In Refs. 10–12, Aratyn *et al.* have performed the following gauge transformation with the first choice,

$$T_D^{(1)}(\phi^{(0)})=\phi^{(0)}\circ\partial\circ(\phi^{(0)})^{-1}, \tag{5.1}$$

$$L^{(1)}=T_D^{(0)}(\phi^{(0)})\circ\partial\circ(T_D^{(0)}(\phi^{(0)}))^{-1}=\partial+\phi^{(0)}\cdot(\ln\phi^{(0)})_{xx}\circ\partial^{-1}\circ(\phi^{(0)})^{-1}, \tag{5.2}$$

where $\phi^{(0)}$ is an ''eigenfunction'' of $L^{(0)}=\partial$, i.e., it satisfies

$$\frac{\partial\phi^{(0)}}{\partial t_n}=(L^{(0)})_+^n\cdot\phi^{(0)}=\partial^n\cdot\phi^{(0)}. \tag{5.3}$$

They showed

Theorem 5.1: *(Refs. 10–12) For the successive k-step gauge transformations,*

$$L^{(0)}\xrightarrow{T_D^{(1)}(\phi^{(0)})}L^{(1)}\xrightarrow{T_D^{(2)}(\phi^{(1)})}L^{(2)}\xrightarrow{T_D^{(3)}(\phi^{(2)})}L^{(3)}\xrightarrow{T_D^{(4)}(\phi^{(3)})}\cdots\to\cdots, \tag{5.4}$$

starting with the initial "free" Lax operator $L^{(0)}=\partial$,

$$L^{(n)}=T_D^{(n)}(\phi^{(n-1)})\circ\partial\circ(T_D^{(n)}(\phi^{(n-1)}))^{-1}=\partial+\phi^{(n)}\circ\partial^{-1}\circ\psi^{(n)}, \tag{5.5}$$

where

$$\phi^{(n)}=\frac{W_{n+1}\left(\phi^{(0)},\phi_x^{(0)},\phi_{xx}^{(0)},\ldots,\frac{\partial^{n-1}\phi^{(0)}}{\partial x^{n-1}},\frac{\partial^n\phi^{(0)}}{\partial x^n}\right)}{W_n\left(\phi^{(0)},\phi_x^{(0)},\phi_{xx}^{(0)},\ldots,\frac{\partial^{n-1}\phi^{(0)}}{\partial x^{n-1}}\right)}, \tag{5.6}$$

$$\psi^{(n)}=(\phi^{(n-1)})^{-1}, \tag{5.7}$$

$$\tau^{(n)}=W_n\left(\phi^{(0)},\phi_x^{(0)},\phi_{xx}^{(0)},\ldots,\frac{\partial^{n-1}\phi^{(0)}}{\partial x^{n-1}}\right),\quad \tau^{(0)}=1. \tag{5.8}$$

Proof: See Refs. 10–12. In fact, this result is the corollary of Theorem 4.1 in the case $\eta^{(i)}=\partial^i\phi^{(0)}/\partial x^i, i=1,2,\ldots,n$. □

This theorem indicates that one can construct the AKNS hierarchy from the ''free'' Lax operator $L^{(0)}=\partial$. And it is also suggested formula in the following.

Theorem 5.2: *Let* $L^{(0)}=\partial$*; for the chain of n-step gauge transformations with the operator of Type* **II**,

$$L^{(0)} \xrightarrow{T_I^{(1)}(\psi^{(0)})} L^{(1)} \xrightarrow{T_I^{(2)}(\psi^{(1)})} L^{(2)} \xrightarrow{T_I^{(3)}(\psi^{(2)})} L^{(3)} \xrightarrow{T_I^{(4)}(\psi^{(3)})} \cdots \to \cdots, \tag{5.9}$$

we obtain

$$L^{(n)} = T_D^{(n)}(\phi^{(n-1)}) \circ \partial \circ (T_D^{(n)}(\phi^{(n-1)}))^{-1} = \partial + \phi^{(n)} \circ \partial^{-1} \circ \psi^{(n)}, \tag{5.10}$$

where

$$\phi^{(n)} = (\psi^{(n-1)})^{-1}, \tag{5.11}$$

$$\psi^{(n)} = \frac{W_{n+1}\left(\psi^{(0)}, \psi_x^{(0)}, \psi_{xx}^{(0)}, \ldots, \frac{\partial^{n-1}\psi^{(0)}}{\partial x^{n-1}}, \frac{\partial^n \psi^{(0)}}{\partial x^n}\right)}{W_n\left(\psi^{(0)}, \psi_x^{(0)}, \psi_{xx}^{(0)}, \ldots, \frac{\partial^{n-1}\psi^{(0)}}{\partial x^{n-1}}\right)}, \tag{5.12}$$

$$\tau^{(n)} = W_n\left(\psi^{(0)}, \psi_x^{(0)}, \psi_{xx}^{(0)}, \ldots, \frac{\partial^{n-1}\psi^{(0)}}{\partial x^{n-1}}\right), \quad \tau^{(0)} = 1. \tag{5.13}$$

Here $\psi^{(0)}$ is the "adjoint eigenfunction" of $L^{(0)} = \partial$.

Proof: One states by noting that

$$L^{(0)} = \partial \equiv \partial + \phi^{(0)} \circ \partial^{-1} \circ \psi^{(0)}\big|_{\phi^{(0)}=0}.$$

So we can regard $\psi^{(0)}$ as the "adjoint eigenfunction" of $L^{(0)}$, i.e.,

$$\frac{\partial \psi^{(0)}}{\partial t_n} = -(L^{*(0)})_+^n \cdot \psi^{(0)}, \quad \psi_{t_n}^{(0)} = (-1)^{n+1}\partial^n \cdot \psi^{(0)}.$$

Using the gauge transformation with the first choice in Theorem 2.3 (or see Ref. 6), we have

$$T_I^{(1)}(\psi^{(0)}) = (\psi^{(0)})^{-1} \circ \partial^{-1} \circ \psi^{(0)},$$

$$L^{(1)} = T_I^{(1)}(\psi^{(0)}) \circ L^{(0)} \circ (T_I^{(1)}(\psi^{(0)}))^{-1} = T_I^{(1)}(\psi^{(0)}) \circ \partial \circ (T_I^{(1)}(\psi^{(0)}))^{-1} = \partial + \psi^{(1)} \circ \partial^{-1} \circ \psi^{(1)},$$

$$\phi^{(1)} = (\psi^{(0)})^{-1},$$

$$\psi^{(1)} = -T_D^{(1)}(\psi^{(0)}) \cdot (L^{*(0)}\psi^{(0)}) = \frac{W_2(\psi^{(0)}, \psi_x^{(0)})}{W_1(\psi^{(0)})}.$$

Then using the property of the Wronskian, and applying successively T_I with the first choice, this theorem is proven. □

The two chains of gauge transformations mentioned in above refer to single-channel (pure) case. There is no multichannel possibility in the present case (i.e., with the first choice), hence we only need to discuss the single-channel (mixed) case.

Theorem 5.3: *Let one chain of n-step gauge transformations start with $L^{(0)} = \partial$, the let p of them be of Type* **I**, *q of them of Type* **II**, *$W_0 = 1$.*

(A) If the first step is of Type **I**, *$\phi^{(0)} \neq 0$, $\psi^{(0)} = 0$, then*

$$\tau^{(n)} = W_{p-q}\left(\phi^{(0)}, \phi_x^{(0)}, \phi_{xx}^{(0)}, \ldots, \frac{\partial^{p-q}\phi^{(0)}}{\partial x^{p-q}}\right) \tag{5.14}$$

in which $p \geqslant q$.

(B) If the first step is of Type **II**, *$\psi^{(0)} \neq 0$, $\phi^{(0)} = 0$, then*

$$\tau^{(n)}=W_{q-p}\left(\psi^{(0)},\psi_x^{(0)},\psi_{xx}^{(0)},\ldots,\frac{\partial^{q-p}\psi^{(0)}}{\partial x^{q-p}}\right) \tag{5.15}$$

in which $q\geqslant p$.

Proof: There is an obvious identity

$$T_I^{(k+1)}(\psi^{(k+1)})\circ T_D^{(k)}(\phi^{(k)})=T_D^{(k+1)}(\phi^{(k+1)})\circ T_I^{(k)}(\psi^{(k)})=I,$$

which is similar to the equation (61) of Ref. 6. Using this identity and the Theorem 5.1 and Theorem 5.2, theorem is proved. □

Since the AKNS hierarchy can be produced from $L^{(0)}=\partial$ with the first choice, we would like to introduce an analogous procedure for the chain of gauge transformations with the second choice, i.e.,

$$L^{(0)}\xrightarrow{T_D^{(1)}(\chi_1^{(0)})}L^{(1)}\xrightarrow{T_D^{(2)}(\chi_2^{(1)})}L^{(2)}\xrightarrow{T_D^{(3)}(\chi_3^{(2)})}L^{(3)}\xrightarrow{T_D^{(4)}(\chi_4^{(3)})}\cdots\rightarrow\cdots,$$

$$L^{(0)}\xrightarrow{T_I^{(1)}(\mu_1^{(0)})}L^{(1)}\xrightarrow{T_I^{(2)}(\mu_2^{(1)})}L^{(2)}\xrightarrow{T_I^{(3)}(\mu_3^{(2)})}L^{(3)}\xrightarrow{T_I^{(4)}(\mu_4^{(3)})}\cdots\rightarrow\cdots.$$

Unfortunately, these two chains of gauge transformations cannot produce the AKNS hierarchy, because they keep $L^{(k)}=\partial$. However, the union of the two choices is very interesting. Each of the theorems given in the preceding section can supply an explicit approach to generate the AKNS hierarchy from "free" Lax operator $L^{(0)}=\partial$. To save space, we only discuss the gauge transformation chain (4.9) with $L^{(0)}=\partial=\partial+\phi^{(0)}\cdot\partial^{-1}\cdot\psi^{(0)}|_{\psi^{(0)}=0}$, which leads to the following theorem.

Theorem 5.4:

$$\chi_i^{(n)}=\frac{W_{n+1}(\phi^{(0)},\phi_x^{(0)},\phi_{xx}^{(0)},\ldots,(\phi^{(0)})^{(n-1)},\chi_i^{(0)})}{W_n(\phi^{(0)},\phi_x^{(0)},\phi_{xx}^{(0)},\ldots,(\phi^{(0)})^{(n-1)})}, \tag{5.16}$$

$$\mu_i^{(n)}=(-1)^n\frac{IW_{1,n}(\mu_i^{(0)};\phi^{(0)},\phi_x^{(0)},\phi_{xx}^{(0)},\ldots,(\phi^{(0)})^{(n-1)})}{W_n(\phi^{(0)},\phi_x^{(0)},\phi_{xx}^{(0)},\ldots,(\phi^{(0)})^{(n-1)})}, \tag{5.17}$$

$$\phi^{(n+k)}=\frac{IW_{k,n+1}(\mu_k^{(0)},\ldots,\mu_1^{(0)};\phi^{(0)},\phi_x^{(0)},\phi_{xx}^{(0)},\ldots,(\phi^{(0)})^{(n-1)},(\phi^{(0)})^{(n)})}{IW_{k,n}(\mu_k^{(0)},\ldots,\mu_1^{(0)};\phi^{(0)},\phi_x^{(0)},\phi_{xx}^{(0)},\ldots,(\phi^{(0)})^{(n-1)})}, \tag{5.18}$$

$$\psi^{(n+k)}=(-1)^k\frac{W_{k+1}(\mu_1^{(n)},\ldots,\mu_k^{(n)},\psi^{(n)})}{W_k(\mu_1^{(n)},\ldots,\mu_k^{(n)})}, \tag{5.19}$$

$$\chi_i^{(n+k)}=\frac{IW_{k,n+1}(\mu_k^{(0)},\ldots,\mu_1^{(0)};\phi^{(0)},\phi_x^{(0)},\phi_{xx}^{(0)},\ldots,(\phi^{(0)})^{(n-1)},\chi_i^{(0)})}{IW_{k,n}(\mu_k^{(0)},\ldots,\mu_1^{(0)};\phi^{(0)},\phi_x^{(0)},\phi_{xx}^{(0)},\ldots,(\phi^{(0)})^{(n-1)})}, \tag{5.20}$$

$$\mu_i^{(n+k)}=(-1)^n\frac{IW_{k+1,n}(\mu_i^{(0)},\mu_k^{(0)},\ldots,\mu_1^{(0)};\phi^{(0)},\phi_x^{(0)},\phi_{xx}^{(0)},\ldots,(\phi^{(0)})^{(n-1)})}{IW_{k,n}(\mu_k^{(0)},\ldots,\mu_1^{(0)};\phi^{(0)},\phi_x^{(0)},\phi_{xx}^{(0)},\ldots,(\phi^{(0)})^{(n-1)})}, \tag{5.21}$$

$$\tau^{(n+k)}=IW_{k,n}(\mu_k^{(0)},\ldots,\mu_1^{(0)};\phi^{(0)},\phi_x^{(0)},\phi_{xx}^{(0)},\ldots,(\phi^{(0)})^{(n-1)}). \tag{5.22}$$

Here $\phi^{(0)}$ is the eigenfunction of $L^{(0)}=\partial$, hence it satisfies $\partial\phi^{(0)}/\partial t_n=(L^{(0)})_+^n\cdot\phi^{(0)}=\partial^n\cdot\phi^{(0)}$; and $\partial\mu_i^{(0)}/\partial t_n=-(L^{(0)*})_+^n\mu_i^{(0)}=(-1)^{n+1}\partial^n\cdot\mu_i^{(0)}$, $(L^{(0)})^*\cdot\mu_i^{(0)}=-\partial\mu_i^{(0)}=\lambda_i\mu_i^{(0)}$. $\psi^{(n)}$ and $\phi^{(n)}$ are given by Theorem 5.1.

Now we consider some concrete examples of Theorem 5.4 with $n=2,k=1$. Let $\lambda_i(i=1,2,\ldots,5)$ and η_1 be constants, $\theta_i=\lambda_i t_1+\lambda_i^2 t_2+\lambda_i^3 t_3$, $\hat{\theta}_1=-\eta_1 t_1-\eta_1^2 t_2-\eta_1^3 t_3$.

(1) Let

$$\phi^{(0)}=e^{\theta_1}+e^{\theta_2}+e^{\theta_3},\quad \psi^{(0)}=0,\quad \mu_1^{(0)}=e^{\hat{\theta}_1}.$$

Then Theorem 5.4 yields

$$\phi^{(2+1)}=\frac{e^{\theta_1+\theta_2+\theta_3}(\lambda_1-\lambda_2)^2(\lambda_1-\lambda_3)^2(\lambda_2-\lambda_3)^2}{e^{\theta_1+\theta_3}(-\eta_1+\lambda_2)(\lambda_1-\lambda_3)^2+e^{\theta_2+\theta_3}(-\eta_1+\lambda_1)(\lambda_2-\lambda_3)^2+e^{\theta_1+\theta_2}(-\eta_1+\lambda_3)(\lambda_1-\lambda_2)^2},\tag{5.23}$$

$$\psi^{(2+1)}=\frac{e^{\theta_3}(-\eta_1+\lambda_1)(-\eta_1+\lambda_2)+e^{\theta_2}(-\eta_1+\lambda_1)(-\eta_1+\lambda_3)+e^{\theta_1}(-\eta_1+\lambda_2)(-\eta_1+\lambda_3)}{e^{\theta_1+\theta_3}(-\eta_1+\lambda_2)(\lambda_1-\lambda_3)^2+e^{\theta_2+\theta_3}(-\eta_1+\lambda_1)(\lambda_2-\lambda_3)^2+e^{\theta_1+\theta_2}(-\eta_1+\lambda_3)(\lambda_1-\lambda_2)^2},\tag{5.24}$$

$$\tau^{(2+1)}=e^{\hat{\theta}_1}\frac{e^{\theta_1+\theta_3}(\eta_1-\lambda_2)(\lambda_1-\lambda_3)^2+e^{\theta_2+\theta_3}(\eta_1-\lambda_1)(\lambda_2-\lambda_3)^2+e^{\theta_1+\theta_2}(\eta_1-\lambda_3)(\lambda_1-\lambda_2)^2}{(\eta_1-\lambda_1)(\eta_1-\lambda_2)(\eta_1-\lambda_3)}.\tag{5.25}$$

$\phi^{(2+1)}$ and $\psi^{(2+1)}$ satisfy equations (1.4) and (1.5). Furthermore, a solution of the KP equation (1.10) is given by $u=\phi^{(2+1)}\psi^{(2+1)}$ or (1.11). In Figs. 1(a)–1(c), $-\phi^{(2+1)},\psi^{(2+1)},u$, respectively, are plotted.

(2) Let

$$\phi^{(0)}=e^{\theta_1}+e^{\theta_2+\theta_3}+e^{\theta_4},\quad \psi^{(0)}=0,\quad \mu_1^{(0)}=e^{\hat{\theta}_1}.$$

With the help of the *MATHEMATICA*, we got

$$\begin{aligned}\phi^{(2+1)}=&\Bigg\{(e^{\theta_1}\lambda_1^3+e^{\theta_2}\lambda_2^3+e^{\theta_3}\lambda_3^3+e^{\theta_4}\lambda_4^3)\Bigg[(e^{\theta_1}\lambda_1+e^{\theta_2}\lambda_2+e^{\theta_3}\lambda_3+e^{\theta_4}\lambda_4)\Bigg(\frac{e^{\theta_1}}{-\eta_1+\lambda_1}\\&+\frac{e^{\theta_2}}{-\eta_1+\lambda_2}+\frac{e^{\theta_3}}{-\eta_1+\lambda_3}+\frac{e^{\theta_4}}{-\eta_1+\lambda_4}\Bigg)-(e^{\theta_1}+e^{\theta_2}+e^{\theta_3}+e^{\theta_4})\Bigg(\frac{e^{\theta_1}}{-\eta_1+\lambda_1}\lambda_1\\&+\frac{e^{\theta_2}}{-\eta_1+\lambda_2}\lambda_2+\frac{e^{\theta_3}}{-\eta_1+\lambda_3}\lambda_3+\frac{e^{\theta_4}}{-\eta_1+\lambda_4}\lambda_4\Bigg)\Bigg]-(e^{\theta_1}\lambda_1^2+e^{\theta_2}\lambda_2^2+e^{\theta_3}\lambda_3^2+e^{\theta_4}\lambda_4^2)\\&\times\Bigg[(e^{\theta_1}\lambda_1^2+e^{\theta_2}\lambda_2^2+e^{\theta_3}\lambda_3^2+e^{\theta_4}\lambda_4^2)\Bigg(\frac{e^{\theta_1}}{-\eta_1+\lambda_1}+\frac{e^{\theta_2}}{-\eta_1+\lambda_2}+\frac{e^{\theta_3}}{-\eta_1+\lambda_3}+\frac{e^{\theta_4}}{-\eta_1+\lambda_4}\Bigg)\\&-(e^{\theta_1}+e^{\theta_2}+e^{\theta_3}+e^{\theta_4})\Bigg(\frac{e^{\theta_1}}{-\eta_1+\lambda_1}\lambda_1^2+\frac{e^{\theta_2}}{-\eta_1+\lambda_2}\lambda_2^2+\frac{e^{\theta_3}}{-\eta_1+\lambda_3}\lambda_3^2+\frac{e^{\theta_4}}{-\eta_1+\lambda_4}\lambda_4^2\Bigg)\Bigg]\\&+(e^{\theta_1}\lambda_1+e^{\theta_2}\lambda_2+e^{\theta_3}\lambda_3+e^{\theta_4}\lambda_4)\Bigg[(e^{\theta_1}\lambda_1^2+e^{\theta_2}\lambda_2^2+e^{\theta_3}\lambda_3^2+e^{\theta_4}\lambda_4^2)\Bigg(\frac{e^{\theta_1}}{-\eta_1+\lambda_1}\lambda_1\\&+\frac{e^{\theta_2}}{-\eta_1+\lambda_2}\lambda_2+\frac{e^{\theta_3}}{-\eta_1+\lambda_3}\lambda_3+\frac{e^{\theta_4}}{-\eta_1+\lambda_4}\lambda_4\Bigg)-(e^{\theta_1}\lambda_1+e^{\theta_2}\lambda_2+e^{\theta_3}\lambda_3+e^{\theta_4}\lambda_4)\\&\times\Bigg(\frac{e^{\theta_1}}{-\eta_1+\lambda_1}\lambda_1^2+\frac{e^{\theta_2}}{-\eta_1+\lambda_2}\lambda_2^2+\frac{e^{\theta_3}}{-\eta_1+\lambda_3}\lambda_3^2+\frac{e^{\theta_4}}{-\eta_1+\lambda_4}\lambda_4^2\Bigg)\Bigg]\Bigg\}\Bigg\{\frac{e^{\theta_1+\theta_2}(\lambda_1-\lambda_2)^2}{(\eta_1-\lambda_1)(\eta_1-\lambda_2)}\end{aligned}$$

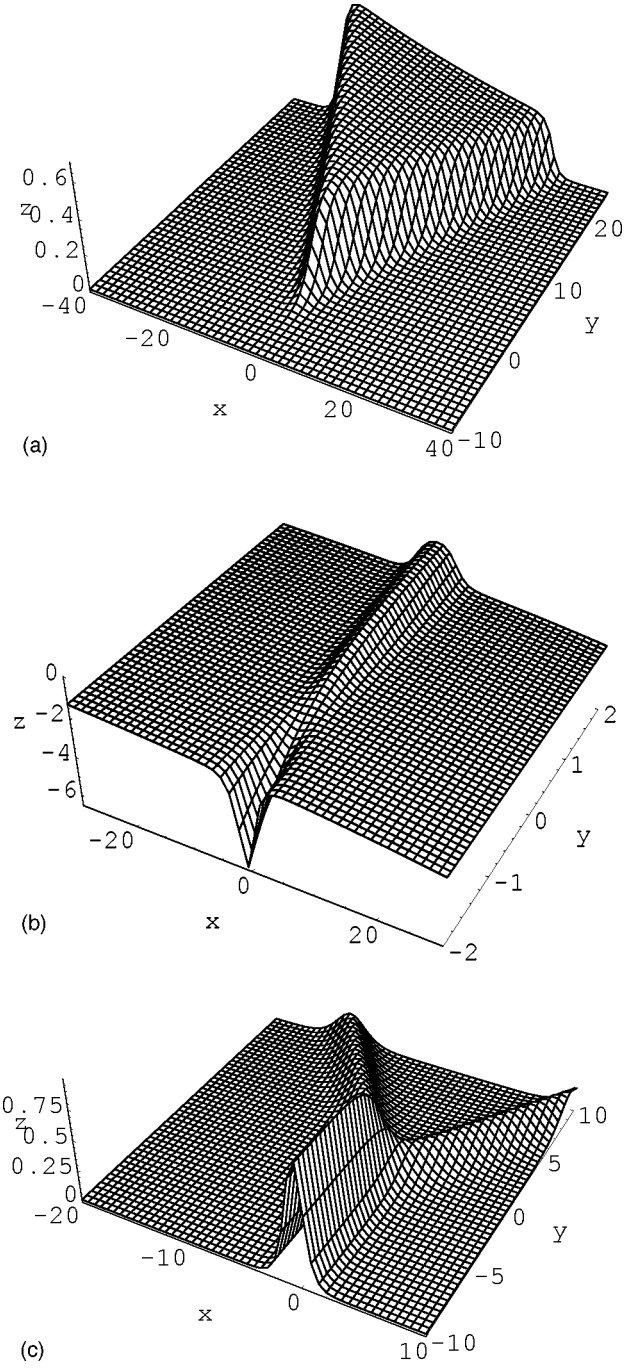

FIG. 1. Parameters in (a)–(c) are $t=0$, $\lambda_1=-1$, $\lambda_2=-0.015$, $\lambda_3=1$, $\eta_1=2$. &-\lambda_4)(e^{\theta_1+\theta_2}(\lambda_1-\lambda_2)^2+e^{\theta_1+\theta_3}(\lambda_1-\lambda_3)^2+e^{\theta_1+\theta_4}(\lambda_1-\lambda_4)^2+e^{\theta_2+\theta_3}(\lambda_2-\lambda_3)^2\\
&+e^{\theta_2+\theta_4}(\lambda_2-\lambda_4)^2+e^{\theta_3+\theta_4}(\lambda_3-\lambda_4)^2)\Big(\frac{e^{\theta_1+\theta_2}(\lambda_1-\lambda_2)^2}{(\eta_1-\lambda_1)(\eta_1-\lambda_2)}+\frac{e^{\theta_1+\theta_3}(\lambda_1-\lambda_3)^2}{(\eta_1-\lambda_1)(\eta_1-\lambda_3)}\\
&+\frac{e^{\theta_2+\theta_3}(\lambda_2-\lambda_3)^2}{(\eta_1-\lambda_2)(\eta_1-\lambda_3)}+\frac{e^{\theta_1+\theta_4}(\lambda_1-\lambda_4)^2}{(\eta_1-\lambda_1)(\eta_1-\lambda_4)}+\frac{e^{\theta_2+\theta_4}(\lambda_2-\lambda_4)^2}{(\eta_1-\lambda_2)(\eta_1-\lambda_4)}\\
&+\frac{e^{\theta_3+\theta_4}(\lambda_3-\lambda_4)^2}{(\eta_1-\lambda_3)(\eta_1-\lambda_4)}\Big)\Big\},
\end{aligned}
\tag{5.27}
$$

$$
\begin{aligned}
\tau^{(2+1)}=e^{\hat{\theta}_1}\Big[&\frac{e^{\theta_1+\theta_2}(\lambda_1-\lambda_2)^2}{(\eta_1-\lambda_1)(\eta_1-\lambda_2)}+\frac{e^{\theta_1+\theta_3}(\lambda_1-\lambda_3)^2}{(\eta_1-\lambda_1)(\eta_1-\lambda_3)}+\frac{e^{\theta_2+\theta_3}(\lambda_2-\lambda_3)^2}{(\eta_1-\lambda_2)(\eta_1-\lambda_3)}\\
&+\frac{e^{\theta_1+\theta_4}(\lambda_1-\lambda_4)^2}{(\eta_1-\lambda_1)(\eta_1-\lambda_4)}+\frac{e^{\theta_2+\theta_4}(\lambda_2-\lambda_4)^2}{(\eta_1-\lambda_2)(\eta_1-\lambda_4)}+\frac{e^{\theta_3+\theta_4}(\lambda_3-\lambda_4)^2}{(\eta_1-\lambda_3)(\eta_1-\lambda_4)}\Big].
\end{aligned}
\tag{5.28}
$$

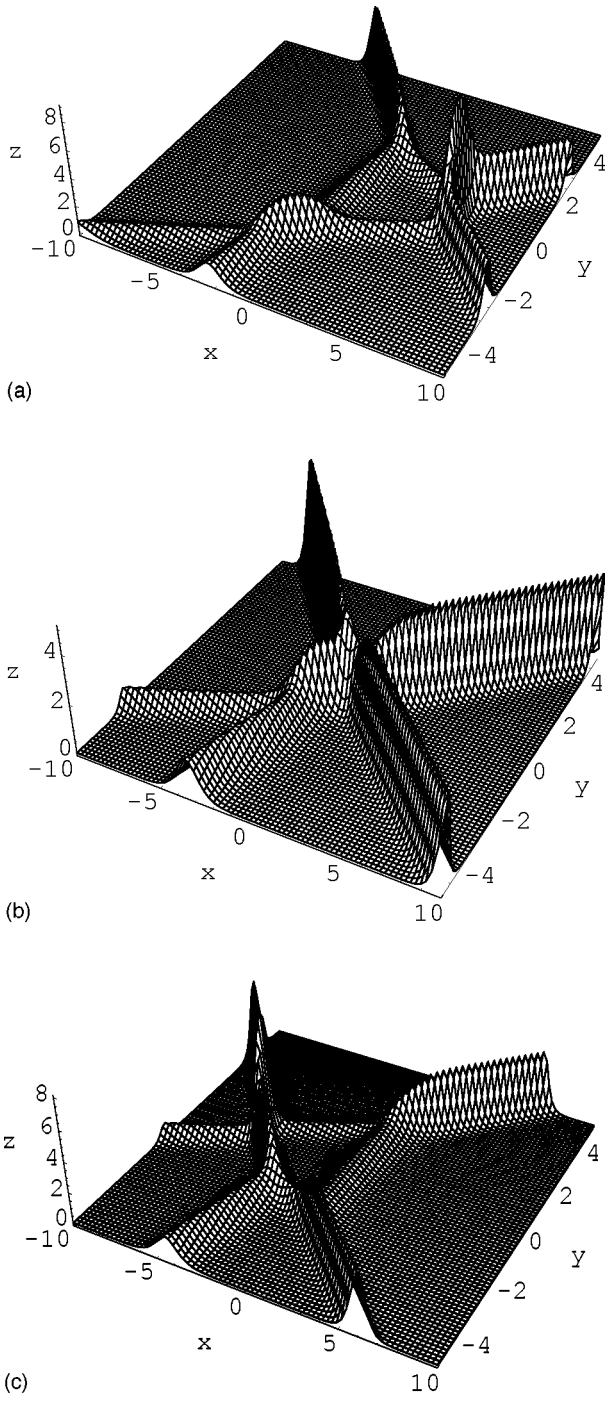

FIG. 4. Solution $u=\phi^{(2+1)}\psi^{(2+1)}$ to the KP equation (1.10) with parameters $\lambda_1=-1$, $\lambda_2=-1.5$, $\lambda_3=1$, $\lambda_4=3$, $\lambda_5=-3$, $\eta_1=-4$. (a) $t=-0.6$; (b) $t=0$; (c) $t=0.6$.

The graphs of $-\phi^{(2+1)},\psi^{(2+1)},u$ are plotted in Figs. 2(a)–2(c) for this case. Additionally, we also give in Fig. 2(d) another graph of u with a different parameter.

(3) Take

$$\phi^{(0)}=e^{\theta_1}+e^{\theta_2}+^{\theta_3}+e^{\theta_4}+e^{\theta_5},\quad \psi^{(0)}=0,\quad \mu_1^{(0)}=e^{\hat{\theta}_1}.$$

We give the graphs [Figs. 3(a)–3(c)] of $-\phi^{(2+1)}, \psi^{(2+1)}, u$, and in Fig. 3(d) the graph of u for a different parameter. Specifically, in order to explore approximately the evolution of the solution of KP equation, we also display in Figs. 4(a)–4(c) u at $t_3 = -0.6, 0, 0.6$.

VI. CONCLUSION AND DISCUSSION

In this paper we point out that there exist two choices that keep the form of the Lax operator when we perform gauge transformations for the AKNS hierarchy, which naturally leads to two classes of GFGT—eigenfunction and BA function of $L^{(0)}$. The second choice automatically implies that the GFGT χ must come from outside of $L^{(0)}$, in contrast to the first choice.[6,10–12] On the basis of these facts, we obtain Theorem 2.2 and Theorem 2.3 about the two choices of Type **I** and Type **II**, respectively. We study systematically the successive application of gauge transformation with the second choice for the AKNS hierarchy. The union of the two choices is also discussed, which results in a new τ-function. Finally, starting with the ''free'' Lax operator $L^{(0)} = \partial$, the AKNS hierarchy has been constructed via gauge transformation, and its several τ-functions are obtained. Our results also show that the generalized Wronskian of the τ function of the AKNS can not be of the binary type if $k > 1$, the latter is defined by Ref. 6 Obviously, $\tau^{(n+k)}$ is still of binary type when $k = 1$.

Finally we would like to re-emphasize that the functions in the elements of the Wronskian of the τ-functions presented in this paper (with the second choice) are different from those in the previous literature.[6,10–12] So the final τ-function are as well essentially different. The figures in Fig. 1 are similar to the results of Ref. 23, which are obtained from the Wronskian solution of the KP hierarchy. The relation between the gauge transformation given here and the known Darboux transformation[24] for the AKNS hierarchy is an interesting question, the discussion of which is left for future publications. Moreover, it will be interesting to consider the analogue of our results for the matrix constrained KP hierarchy, see Ref. 9. For chains of gauge transformations including two choices, there also exist other more complicated cases that shall have to be discussed. Finally, we also would like to generalize our results to the supersymmetric KP and cKP hierarchy.[25–27]

(Received 5 May 2003; accepted 8 May 2003)

A systematic investigation of integrable differential–difference equations with two independent variables admitting multi-Hamiltonian structure is presented. Considering the Volterra (VL), Toda (TL), Relativistic Toda (RT), Belov–Chaltikian (BC) and Blaszak–Marciniak both three (BM3) and four (BM4) coupled lattice equations it is shown that they admit a sequence of operators out of which only three are Hamiltonian ones and so they are tri-Hamiltonian systems only. It is observed that the constructed third operator for VL and BC lattice equations is Hamiltonian only if the field variable is periodic with even period. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1601300]

I. INTRODUCTION

The study of discrete nonlinear systems governed by both ordinary and partial differential–difference and pure difference equations including lattice equations has aroused increasing interest in the last few years particularly from the point of view of complete integrability. It is well known that the completely integrable nonlinear partial differential equations (PDEs) admitting solitons possess a variety of mathematical structures such as Lax representation, Painlevé property, a sequence of generalized symmetries and conservation laws, master symmetries, multi-Hamiltonians, etc.[1–11]

The discovery of solitons started with an investigation of the solution of nonlinear PDEs and the soliton solution could be explained by the existence of conservation laws. It is known that every conservation law of a PDE comes from a corresponding symmetry property. This basic principle constitutes the first fundamental result in the study of classical or quantum mechanical systems with prescribed groups of symmetries. In a classic work, Emmy Noether has devised a procedure to derive conservation laws and explicitly shown that there exists a one to one correspondence between symmetry groups and conservation laws for the Euler Lagrange equations. This resulted in the search for hidden symmetries called generalized symmetries, which are groups whose infinitesimal generators depend not only on the independent and dependent variables of the PDEs but also on the derivatives of the dependent variables.

Considering nonlinear evolution equations with $(1+1)$ dimensions, Olver[12] has shown remarkably that, how a sequence of generalized symmetries can be derived recursively through an operator known as recursion operator, if one nontrivial generalized symmetry is known. In late 1980s Shabat[13] and his school using the basic principles have classified a complete list of nonlinear evolution equations with $(1+1)$ dimension demanding that under what conditions the given equation admits a sequence of generalized symmetries and conservation laws. The possession of a sequence of generalized and conservation laws is characterizing property of integrable nonlinear PDEs.[3] Also the existence of generalized symmetries often helps to derive other integrability properties: recursion operator, hereditary operator, bi-Hamiltonian formulation, etc., of nonlinear PDEs. This fact has been verified for a large number of nonlinear evolution equations with $(1+1)$ and $(2+1)$ dimensions possessing solitons by different researchers during the past few decades. Recent development in discrete nonlinear systems reveals that the above-mentioned results appear to hold for nonlinear PDDEs with two independent variables ($t \in \mathbb{R}$, $n \in \mathbb{Z}$) as well.[14–22] Given a PDDE with two independent variables we have shown that how to construct (i)

a sequence of generalized symmetries and conserved densities[17] and (ii) a factorizable recursion operator using its generalized symmetries.[21] As illustrations, in Ref. 21 we have considered BC, BM3, and RT lattice equations and derived factorizable recursion operators using their generalized symmetries and shown explicitly that they are bi-Hamiltonian systems. It is known that VL, TL, and BM4 lattice equations are bi-Hamiltonian systems.[18,20] In this paper, we wish to investigate whether RT, VL, TL, BC, BM3, and BM4 lattice equations, respectively, governed by

$$v_{nt}=v_n(u_{n-1}-u_n), \quad u_{nt}=u_n(u_{n-1}-u_{n+1}+v_n-v_{n+1}), \tag{1}$$

$$u_{nt}=u_n(u_{n+1}-u_{n-1}), \tag{2}$$

$$u_{nt}=v_{n+1}-v_n, \quad v_{nt}=v_n(u_n-u_{n-1}), \tag{3}$$

$$u_{nt}=u_n(u_{n+1}-u_{n-1})+v_{n-1}-v_n, \quad v_{nt}=v_n(u_{n+2}-u_{n-1}), \tag{4}$$

$$u_{nt}=w_{n+1}-w_{n-1}, \quad v_{nt}=u_{n-1}w_{n-1}-u_nw_n, \quad w_{nt}=w_n(v_n-v_{n+1}), \tag{5}$$

$$u_{nt}=u_n(v_n-v_{n-1}), \quad v_{nt}=w_nu_{n+1}-w_{n-1}u_n, \quad w_{nt}=q_nu_{n+2}-u_nq_{n-1}, \quad q_{nt}=u_{n+3}-u_n, \tag{6}$$

where

$$u_{nt}=\frac{du_n}{dt}, \quad v_{nt}=\frac{dv_n}{dt}, \quad w_{nt}=\frac{dw_n}{dt}, \quad q_{nt}=\frac{dq_n}{dt},$$

$$u_n=u(n,t), \quad v_n=v(n,t), \quad w_n=w(n,t), \quad q_n=q(n,t),$$

t is a continuous variable and n is a discrete variable, admit multi-Hamiltonian structures or not and show explicitly that they are tri-Hamiltonian systems only.

The plan of the article is as follows: In Sec. II, we briefly outline the basic notations and definitions required for this paper. In Sec. III, we explain how to construct a sequence of operators $\{H_3,H_4,\ldots\}$ for an integrable nonlinear PDDE if it admits two distinct and invertible Hamiltonian operators H_1 and H_2. Also for each of the above lattice Eqs. (1)–(6) we construct a sequence of operators and show that only three of them are Hamiltonian ones. In Sec. IV, we give brief details of our results.

II. PRELIMINARIES AND BASIC RESULTS

We recall the following notations and definitions which are required for further discussion. Consider, a first order PDDE with two independent variables (one-continuous, one-discrete) of the form

$$\frac{\partial \mathbf{U}_n}{\partial t}=\mathbf{U}_{nt}=\mathbf{F}(\ldots,\mathbf{U}_{n-1},\mathbf{U}_n,\mathbf{U}_{n+1},\ldots), \tag{7}$$

where $\mathbf{U}_n=\mathbf{U}(n,t)$ and $\mathbf{F}(\cdots)$ are vector quantities with same number of components, say m. The vector function $\mathbf{F}$ is assumed to be a polynomial in the dependent variable and their shifts. There is no restriction on the level of shifts or the degree of nonlinearity. Define the shift operators E and E^{-1} by

$$E\mathbf{U}_n=\mathbf{U}_{n+1}, \quad E^{-1}\mathbf{U}_n=\mathbf{U}_{n-1}.$$

Let Δ and Δ^+ being the difference operators are defined by

$$\Delta\mathbf{U}_n=(E-1)\mathbf{U}_n, \quad \Delta^+\mathbf{U}_n=(E^{-1}-1)\mathbf{U}_n.$$

We then define the linear operator $(E-E^{-1})^{-1}=(\Delta-\Delta^{+})^{-1}$, $(E-1)^{-1}=\Delta^{-1}$, and $(E^{-1}-1)^{-1}=(\Delta^{+})^{-1}$ by

$$(\Delta-\Delta^{+})^{-1}\mathbf{U}_n=\frac{1}{2}\left[\sum_{k=-\infty}^{-1}\mathbf{U}_{n+1+2k}-\sum_{k=1}^{\infty}\mathbf{U}_{n-1+2k}\right],$$

$$\Delta^{-1}\mathbf{U}_n=\frac{1}{2}\left[\sum_{k=-\infty}^{-1}[\mathbf{U}_{n+1+2k}+\mathbf{U}_{n+2k}]-\sum_{k=1}^{\infty}[\mathbf{U}_{n-1+2k}+\mathbf{U}_{n-2+2k}]\right],$$

$$(\Delta^{+})^{-1}\mathbf{U}_n=-\frac{1}{2}\left[\sum_{k=-\infty}^{-1}[\mathbf{U}_{n+2+2k}+\mathbf{U}_{n+1+2k}]-\sum_{k=1}^{\infty}[\mathbf{U}_{n+2k}+\mathbf{U}_{n-1+2k}]\right].$$

Note that $(\Delta-\Delta^{+})^{-1}((\Delta-\Delta^{+})^{-1})^{-1}=((\Delta-\Delta^{+})^{-1})^{-1}(\Delta-\Delta^{+})^{-1}=1$. Let $H:\mathcal{L}^q\to\mathcal{L}^q$ be a linear operator and V_H be a formal evolutionary vector field with characteristic is the q-tuple,

$$(H\theta)_\alpha=\sum_{\beta=1}^{q}H_{\alpha\beta}\theta^{\beta}$$

of vertical univector. Then the prolongation of the vector field is given by

$$PrV_{H\theta}=\sum_{\alpha,J}E^{J}\left(\sum_{\beta}H_{\alpha\beta}\theta^{\beta}\right)\frac{\partial}{\partial E^{J}\mathbf{U}^{\alpha}}.$$

Definition 2.1: A linear operator H_1 of Eq. (7) is said to be a Hamiltonian operator if it is skew symmetric and satisfies Jacobi identity.[4]

Definition 2.2: Equation (7) is said to be a bi-Hamiltonian and tri-Hamiltonian system, if it can be written as

$$\mathbf{U}_{nt}=H_2\frac{\delta\mathcal{H}_0}{\delta\mathbf{U}_n}=H_1\frac{\delta\mathcal{H}_1}{\delta\mathbf{U}_n},\tag{8a}$$

and

$$\mathbf{U}_{nt}=H_3\frac{\delta\mathcal{H}_0}{\delta\mathbf{U}_n}=H_2\frac{\delta\mathcal{H}_1}{\delta\mathbf{U}_n}=H_1\frac{\delta\mathcal{H}_2}{\delta\mathbf{U}_n},\tag{8b}$$

where H_1, H_2, and H_3 are Hamiltonian operators while $\mathcal{H}_0[\mathbf{U}_n]$, $\mathcal{H}_1[\mathbf{U}_n]$, and $\mathcal{H}_2[\mathbf{U}_n]$ are appropriate Hamiltonian functionals.

Definition 2.3: An operator valued function $\mathcal{R}$ is said to be a recursion operator of Eq. (7) if it satisfies

$$\tilde{G}(n)=\mathcal{R}G(n),\tag{9}$$

where $\mathbf{G}(n)=(G_1(n),G_2(n),\ldots,G_m(n))$ and $\tilde{\mathbf{G}}(n)=(\tilde{G}_1(n),\tilde{G}_2(n),\ldots,\tilde{G}_m(n))$ are generalized symmetries of Eq. (7). In other words, $\mathcal{R}$ maps symmetries to new symmetries.

A. Construction of the second operator H_2

Let us assume that the given PDDE (7) can be written as

$$\mathbf{U}_{nt}=H_1\frac{\delta\mathcal{H}_0}{\delta\mathbf{U}_n},\tag{10}$$

where H_1 is an $(m\times m)$ invertible matrix Hamiltonian operator which can be expressed in terms of the difference operators of the dependent variables while $\mathcal{H}_0$ is the associated $(1\times m)$ matrix Hamiltonian functional. We further assume that the entries $(H_{ij}^{(1)})$, $(\mathcal{H}_{1j}^{(0)})$, $(\mathcal{H}_{1j}^{(1)})$ of the Hamiltonian operator H_1, the Hamiltonian functionals $\mathcal{H}_0$ and $\mathcal{H}_1$, respectively, having ranks p_{ij}, r_{1j}, and s_{1j}, $i,j=1,2,\ldots,m$ which may be integers or rational numbers.

The second operator H_2, if exists, for Eq. (7) satisfying the relation

$$H_2\frac{\delta\mathcal{H}_0}{\delta\mathbf{U}_n}=H_1\frac{\delta\mathcal{H}_1}{\delta\mathbf{U}_n} \tag{11}$$

can be constructed in the following way. Let H_2 be a $(m\times m)$ invertible matrix operator of the form

$$H_2=\begin{bmatrix} H_{11}^{(2)} & H_{12}^{(2)} & \ldots & H_{1\mathrm{m}}^{(2)} \\ H_{21}^{(2)} & H_{22}^{(2)} & \ldots & H_{2\mathrm{m}}^{(2)} \\ \vdots & & \vdots & \\ H_{\mathrm{m}1}^{(2)} & H_{\mathrm{m}2}^{(2)} & \ldots & H_{\mathrm{mm}}^{(2)} \end{bmatrix}.$$

Then the rank of the entries $(H_{ij}^{(2)})$ of H_2 must satisfy the following relations:

$$\begin{aligned} &\mathrm{rank}\ \ H_{11}^{(1)}+\mathrm{rank}\frac{\delta\mathcal{H}_1}{\delta U_1}+\cdots+\mathrm{rank}\ \ H_{1\mathrm{m}}^{(1)}+\mathrm{rank}\frac{\delta\mathcal{H}_1}{\delta U_m} \\ &\quad=\mathrm{rank}\ \ H_{11}^{(2)}+\mathrm{rank}\frac{\delta\mathcal{H}_0}{\delta U_1}+\cdots+\mathrm{rank}\ \ H_{1\mathrm{m}}^{(2)}+\mathrm{rank}\frac{\delta\mathcal{H}_0}{\delta U_m}, \\ &\vdots \\ &\mathrm{rank}\ \ H_{\mathrm{m}1}^{(1)}+\mathrm{rank}\frac{\delta\mathcal{H}_1}{\delta U_1}+\cdots+\mathrm{rank}\ \ H_{\mathrm{mm}}^{(1)}+\mathrm{rank}\frac{\delta\mathcal{H}_1}{\delta U_m} \\ &\quad=\mathrm{rank}\ \ H_{\mathrm{m}1}^{(2)}+\mathrm{rank}\frac{\delta\mathcal{H}_0}{\delta U_1}+\cdots+\mathrm{rank}\ \ H_{\mathrm{mm}}^{(2)}+\mathrm{rank}\frac{\delta\mathcal{H}_0}{\delta U_m}. \end{aligned}$$

Accordingly, we choose the entries $(H_{ij}^{(2)})$ of the matrix operator H_2 written in terms of the difference and inverse difference operators of the dependent variables and their inverse. Substituting the operator H_2 in Eq. (11) and then solving yields the explicit form of the operator H_2 with the required ranks.

If the constructed operator H_2 for Eq. (7) is also a Hamiltonian operator, then the recursion operator $\mathcal{R}$ usually can be written as

$$\mathcal{R}=H_2H_1^{-1}.$$

B. Application

We consider the VL lattice equation (2) which can be written as

$$u_{nt}=H_1\frac{\delta\mathcal{H}_1}{\delta u_n}=u_n(E-E^{-1})u_n, \tag{12}$$

where the Hamiltonian operator $H_1=u_n(E-E^{-1})u_n$, while the Hamiltonian functional $\mathcal{H}_1$ takes the form $\mathcal{H}_1=\Sigma_n u_n$. Obviously the rank of the right-hand side of Eq. (12) is 2. We know that the

Hamiltonian functional of VL lattice Eq. (2) is $\mathcal{H}_0=\Sigma_n \log u_n$ and so rank of $\delta\mathcal{H}_0/\delta u_n=-1$. Then the left-hand side of Eq. (11) demands that the rank of H_2 must be equal to 3 and so we consider H_2 having the form[21]

$$H_2=au_n^2Eu_n+bu_nEu_n^2+cu_nEu_nEu_n+a_1u_n^2E^{-1}u_n+b_1u_nE^{-1}u_n^2+c_1u_nE^{-1}u_nE^{-1}u_n+\mathrm{d}_1u_n^3,$$

where a, b, c, a_1, b_1, c_1, and d_1 are arbitrary constants to be determined. Substituting the Hamiltonian operator H_1, Hamiltonian functionals $\mathcal{H}_0$ and $\mathcal{H}_1$ along with the operator H_2 in Eq. (11), we find that the consistency condition holds only for the following parametric restrictions:

$$a=b=c=-a_1=-b_1=-c_1=1$$

and so the operator H_2 becomes

$$H_2=u_n(Eu_n+u_nE+Eu_nE-E^{-1}u_n-u_nE^{-1}u_n-u_nE^{-1})u_n. \tag{13}$$

It is straightforward to check that the skew symmetric operator H_2 is Hamiltonian (see Sec. III). Thus the recursion operator $\mathcal{R}=H_2H_1^{-1}$ for the VL lattice equation (2) is

$$\mathcal{R}=u_n[u_nE-u_nE^{-1}+Eu_n+Eu_nE-E^{-1}u_n-E^{-1}u_nE^{-1}](E-E^{-1})^{-1}\frac{1}{u_n}. \tag{14}$$

It is appropriate to mention here that there exists a link between Lax operators and some of the integrability properties of the nonlinear PDEs (see Ref. 3) and PDDEs.[23,24]

III. TRI-HAMILTONIAN SYSTEM

It is known that if an integrable partial differential–difference equation with two independent variables admit two invertible Hamiltonian operators H_1 and H_2, then it is possible to construct a sequence of operators H_n satisfying the relation

$$H_n=\mathcal{R}^{n-2}H_2, \quad n\geqslant 3, \tag{15}$$

where $\mathcal{R}=H_2H_1^{-1}$ is a recursion operator. It is appropriate to mention here that the constructed operators $H_n, n\geqslant 3$ need not be Hamiltonian, in general. We show below that the integrable lattice Eqs. (1)–(6) possessing bi-Hamiltonian structure admits a sequence of operators $H_n, n\geqslant 3$ out of which the operator H_3 alone Hamiltonian and the remaining operators $H_n, n\geqslant 4$ are non-Hamiltonian ones. For clarity of presentation, we furnish below the computational details of the RT and VL equations and for the remaining lattice equations only brief details are given.

A. RT lattice equation

1. Construction of a sequence of operators

In Ref. 21 we have shown that the RT lattice equation (1) can be written as

$$\begin{bmatrix} v_t \\ u_t \end{bmatrix}=H_2\begin{bmatrix} \dfrac{\delta\mathcal{H}_0}{\delta u} \\ \dfrac{\delta\mathcal{H}_0}{\delta v} \end{bmatrix}=H_1\begin{bmatrix} \dfrac{\delta\mathcal{H}_1}{\delta u} \\ \dfrac{\delta\mathcal{H}_1}{\delta v} \end{bmatrix} \tag{16}$$

associated with the Hamiltonian functionals, $\mathcal{H}_0(u,v)=-\Sigma_n[u+v]$ and $\mathcal{H}_1(u,v)=\Sigma_n\left[\frac{1}{2}(u^2+v^2)+uv+\overline{v}\,u+u\,\overline{u}\right]$, where $u=u_n$, $v=v_n$, $\overline{u}=u_{n+1}$, $\overline{v}=v_{n+1}$. Here the Hamiltonian operators H_1 and H_2 take the form

$$H_1=\begin{bmatrix} uE-E^{-1}u & -(1-E^{-1})u \\ -u(E-1) & 0 \end{bmatrix}, \tag{17a}$$

$$H_2=\begin{bmatrix} 0 & v(E^{-1}-1)u \\ u(E-1)v & u(E-E^{-1})u \end{bmatrix} \tag{17b}$$

and so the recursion operator $\mathcal{R}$ becomes

$$\mathcal{R}=\begin{bmatrix} v & v+v(1-E^{-1})u(E-1)^{-1}\dfrac{1}{u} \\ u(1+E) & u(1+E)+u(E-1)v(E-1)^{-1}\dfrac{1}{u}+u(E-E^{-1})u(E-1)^{-1}\dfrac{1}{u} \end{bmatrix}. \tag{18}$$

Making use of the Hamiltonian operators H_1 and H_2 in Eq. (15) we construct a sequence of operators $(H_n, n\geqslant 3)$:

$$H_3=\begin{bmatrix} v(E^{-1}u-uE)v & v(-v-u-uE+E^{-1}u \\ & \quad +vE^{-1}+E^{-1}uE^{-1})u \\ u(v+u+E^{-1}u-uE-Ev-EuE)v & u(-Eu+uE^{-1}-uE+E^{-1}u \\ & \quad -2Ev+2vE^{-1}-EuE+E^{-1}uE^{-1})u \end{bmatrix}, \tag{19}$$

$$H_4=\mathcal{R}^2H_2=\begin{bmatrix} H_{11}^{(4)} & H_{12}^{(4)} \\ H_{21}^{(4)} & H_{22}^{(4)} \end{bmatrix}, \tag{20}$$

where

$$\begin{aligned} H_{11}^{(4)}&=v^2(E^{-1}u-uE)v+vu(v+u+E^{-1}u-uE-Ev-EuE)v \\ &\quad +v(1-E^{-1})u(E-1)^{-1}(v+u+E^{-1}u-uE-Ev-EuE)v, \end{aligned}$$

$$\begin{aligned} H_{12}^{(4)}&=v^2(-v-u-uE+E^{-1}u+vE^{-1}+E^{-1}uE^{-1})u+vu(-Eu+uE^{-1}-uE+E^{-1}u-2Ev \\ &\quad +2vE^{-1}-EuE+E^{-1}uE^{-1})u+v(1-E^{-1})u(E-1)^{-1}(-Eu+uE^{-1}-uE+E^{-1}u-2Ev \\ &\quad +2vE^{-1}-EuE+E^{-1}uE^{-1})u, \end{aligned} \tag{20a}$$

$$\begin{aligned} H_{21}^{(4)}&=u(1+E)v(E^{-1}u-uE)v+u(1+E)u(v+u+E^{-1}u-uE-Ev-EuE)v \\ &\quad +u(E-1)v(E-1)^{-1}(v+u+E^{-1}u-uE-Ev-EuE)v \\ &\quad +u(E-E^{-1})u(E-1)^{-1}(v+u+E^{-1}u-uE-Ev-EuE)v, \end{aligned}$$

$$\begin{aligned} H_{22}^{(4)}&=u(1+E)v(-v-u-uE+E^{-1}u+vE^{-1}+E^{-1}uE^{-1})u+u(1+E)u(-Eu+uE^{-1}-uE \\ &\quad +E^{-1}u-2Ev+2vE^{-1}-EuE+E^{-1}uE^{-1})u+u(E-1)v(E-1)^{-1}(-Eu+uE^{-1}-uE \\ &\quad +E^{-1}u-2Ev+2vE^{-1}-EuE+E^{-1}uE^{-1})u+u(E-E^{-1})u(E-1)^{-1}(-Eu+uE^{-1} \\ &\quad -uE+E^{-1}u-2Ev+2vE^{-1}-EuE+E^{-1}uE^{-1})u, \end{aligned} \tag{20b}$$

and so on. Since the entries of the remaining operators $H_n, n\geqslant 5$ involves lengthy expressions we refrain from presenting their explicit form.

2. Tri-Hamiltonian structure

For completeness we briefly present the computational details of the operators H_1 and H_2 as Hamiltonian ones. In order to prove that the skew symmetric operators H_1 and H_2 are Hamil-

tonian it remains to prove that they satisfy the Jacobi identity. Let us first consider the skew symmetric operator H_1. It is appropriate to mention the following theorem for a system of nonlinear partial differential equations $\partial \mathbf{u}/\partial t = K(\mathbf{u})$ due to Olver.[4]

Theorem: Let $\mathcal{D}$ be a skew-adjoint $q \times q$ matrix differential operator of the system of partial differential equations, $\partial \mathbf{u}/\partial t = K(\mathbf{u})$ and $\Theta = \frac{1}{2}\int\{\Theta \wedge \mathcal{D}\Theta\}\mathrm{d}x$, the corresponding functional bi-vector. Then $\mathcal{D}$ is Hamiltonian if and only if

$$PrV_{\mathcal{D}\theta}(\Theta) = 0. \tag{21}$$
