The space of state vectors: A hyperfinite approach

J. Almeida[a] and J. Teixeira[b]

(Received 24 July 2003; accepted 29 September 2003)

We present a version of the formalism of Dirac based on nonstandard analysis, allowing us to deal with state vectors and operators using the resources of finite-dimensional linear algebra. The space of state vectors is a nonstandard Hilbert space with hyperfinite dimension, which includes all square-integrable functions, together with vectors representing states of definite position or momentum. Every vector is normalizable, even when its norm is infinite. Observables are represented by Hermitian operators, which are always (hyper)bounded and defined on the whole space. The connection with the standard theory is established by postulating the existence of ''hyper-observables'' and nonstandard states. Each observable in the usual sense appears as a kind of standard-scale approximation of some hyper-observable. We show that the probabilistic predictions are consistent with those of the standard theory. Consistency extends to time evolution, in the sense that if an initial nonstandard state is ''near-standard,'' then the state after a finite time shall be infinitely near the standard state obtained through the Schrödinger equation. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1631394]

I. INTRODUCTION

A. Preliminaries

The essential features of the general formalism of quantum mechanics can be summarized as follows: To a quantum system a complex Hilbert space can be associated such that every physical state of the system is represented by a normalized vector and every observable is represented by a Hermitian operator on the same space. The outcome of a measurement of an observable represented by an operator A upon a state represented by a vector u is necessarily an eigenvalue of A. The probability to obtain a particular eigenvalue a is $|(u|P_a u)|^2$, where P_a is the projection operator onto the subspace spanned by the eigenvectors belonging to the eigenvalue a. Furthermore, the state of the system after the measurement is represented by a vector belonging to the same subspace. (A stronger postulate states that such vector is $P_a u/\|P_a u\|$.)

In order to completely specify the Hilbert space associated with a particular system, it suffices to postulate its Hilbert dimension, since any two Hilbert spaces with the same Hilbert dimension are necessarily isomorphic. To establish the physical meaning of concrete vectors one can proceed along the following lines: A complete set of compatible observables is chosen (see Ref. 6) and the set of all its possible outcomes is identified. A Hilbert basis is then introduced by naming its vectors after those possible outcomes. Thereafter the coordinates of any vector in that basis provide a link to physical reality, through the relation of the corresponding state to the base states. Furthermore, the basis induces a unitary isomorphism from the abstract space to a concrete space, which constitutes a representation of the abstract space: Every vector u admits a unique expression as $u=\Sigma_{i\in I} c_i u_i$, where $(u_i)_{i\in I}$ is the set of base vectors indexed on some set I and $c_i=(u_i|u)$ for every i. The indexed family $(c_i)_{i\in I}$ of coordinates is such that all values c_i are zero except at most at a countable subset of I and that $\Sigma_i|c_i|^2<+\infty$, where the sum extends over all values of $i\in I$ for which $c_i\neq 0$. The set of all families satisfying these conditions constitutes a Hilbert space (when

[a]Electronic mail: jalmeida@math.ist.utl.pt
[b]Electronic mail: jteix@math.ist.utl.pt

the algebraic operations and inner product are defined in the obvious way) for which the mapping $u \mapsto (c_i)_{i \in I}$ is a unitary isomorphism. In this space, any observable belonging to the set that induced the representation is represented by a "multiplication operator:" If the observable has the value a_i in the state u_i, then the corresponding operator A maps $(c_i)_{i \in I}$ to $(a_i c_i)_{i \in I}$.

This general framework requires modification even in such a simple case as the one corresponding to a one-dimensional, nonrelativistic, spinless particle. In this case, the space $L^2(\mathbb{R})$ would appear as a concrete Hilbert space corresponding to the observable "position," due to the probabilistic interpretation of wave functions and the role of the operator of multiplication by the independent variable, together with the experimental fact that the position observable constitutes by itself a complete set. Thus, one is tempted to assume the existence of a Hilbert basis $(\chi_x)_{x \in \mathbb{R}}$ of vectors that would correspond to the states of definite position, in such a way that the wave function φ associated with a vector u satisfies the identity $\varphi(x) = (\chi_x | u)$, at least when φ is an element of $L^2(\mathbb{R})$ representable by a continuous function [for otherwise $\varphi(x)$ is not well-defined]. However, this is clearly impossible, since the space $L^2(\mathbb{R})$ is known to be separable. Moreover, such a family $(\chi_x)_{x \in \mathbb{R}}$ cannot be a Hilbert basis for any Hilbert space extending $L^2(\mathbb{R})$: If $u = \Sigma_{x \in \mathbb{R}} c_x \chi_x$, we would have $(\chi_x | u) = \varphi(x) = c_x$; since $c_x = 0$ except at countable values of x, this would imply that $\varphi = 0$ as an element of $L^2(\mathbb{R})$.

To overcome these difficulties while preserving as much as possible of the original formalism, Dirac assumed the existence of $(\chi_x)_{x \in \mathbb{R}}$ such that vectors could be expressed as integrals rather than sums; this was supported by the fact that wave functions yield probabilities through integral expressions, as well as by the continuous nature of the parameter x. If u is a vector associated with the wave function φ, then $u = \int_{-\infty}^{+\infty} \varphi(x) \chi_x \, dx$, and for every x_0,

$$(\chi_{x_0} | u) = \int_{-\infty}^{+\infty} \varphi(x) (\chi_{x_0} | \chi_x) \, dx = \varphi(x_0) \ . \tag{1}$$

Since the physical meaning of $(\chi_x)_{x \in \mathbb{R}}$ demands that $(\chi_{x_0} | \chi_x) = 0$ whenever $x_0 \neq x$, Dirac attributed an infinite value to $(\chi_{x_0} | \chi_{x_0})$, for otherwise one would obtain $\varphi(x_0) = 0$. Thus the "function" δ such that $\delta(x_0 - x) = (\chi_{x_0} | \chi_x)$ appears as a continuous-case counterpart of the Kronecker symbol.

It is presently understood that formulas with the δ of Dirac can be interpreted rigorously if $L^2(\mathbb{R})$ is embedded in some space of distributions in the sense of Schwartz. However, this and other similar approaches depart considerably from the original formalism, the mathematics of which is essentially basic, finite-dimensional, linear algebra. In fact, the extended space is not endowed with a *bona fide* inner product; in particular, a vector χ_x cannot be multiplied by itself—vectors with "infinite norm" certainly do not have place in a Hilbert space. Nevertheless, the "vector" χ_{x_0}, understood as the distribution $\delta(x - x_0)$ (where x is the variable and x_0 is fixed), behaves like an eigenvector of the operator of multiplication by x belonging to the eigenvalue x_0. On the other hand, even classical functions of interest may not be in $L^2(\mathbb{R})$, as it is the case with the exponentials representing eigenvectors of the momentum operator. Moreover, operators corresponding to observables are often defined on a strict subspace of the Hilbert space. The formulation of von Neumann[14] achieves mathematical rigor at the cost of renouncing the primitive simplicity: It is no longer allowed to say, in general, that the outcome of a measurement must be an eigenvalue of the operator associated to the observable. However, to determine whether an observable A has a value in an interval is to determine whether the observable $f(A)$ has value 1, where f is the characteristic function of the interval. Thus, even within this framework much of the original formalism is present.

B. Nonstandard approach

Whether or not one attributes physical meaning to a state of definite position, for example, the considerations above suggest that it would be desirable to be able to work within the original intuitive framework of Dirac, as it is usually done at an informal level. We propose a nonstandard version of the formalism of Dirac that makes it applicable rigorously, without change of form, even in cases where operators with continuous spectra arise in the standard theory. The space $\mathcal{H}$ associated with a system is now a *complex Hilbert space. (See the Appendix.) The inner product of two vectors is a *complex number, finite or infinite but always well-defined. Every non-null vector is normalizable, even when its norm is infinite. Furthermore, the space $\mathcal{H}$ has *finite dimension, and thus the features of finite-dimensional linear algebra are present, by transfer.

In order to obtain the space $\mathcal{H}$ associated with a particular system, we start from a Hilbert space $\mathcal{H}_0$ assigned to the system by the standard theory according to the formulation of von Neumann. We then define $\mathcal{H}$ as a hyperfinite subspace of the hypercomplex Hilbert space ${}^*\mathcal{H}_0$. Moreover, to each $\varphi \in \mathcal{H}_0$ we shall associate, in a canonical way, a vector $\overline{\varphi} \in \mathcal{H}$. The mapping $\varphi \mapsto \overline{\varphi}$ is linear and one-to-one, and preserves inner products up to infinitesimals. Thus, $\mathcal{H}_0$ is identifiable to a linear subspace, but not to a Hilbert subspace, of $\mathcal{H}$.

For the purpose of assigning a consistent semantics to this ''hyperfinite model,'' we may adopt the point of view that the system can be subjected (in principle) to *physical actions, some of which are associated with *experimental setups of finite or infinite (nonstandard) precision. An *action may correspond to the *measurement of an *observable, yielding *real outcomes. The system is always found in some *state, which influences the way the system responds to any *action, and in turn can be determined by a *measurement of a complete set of *observables.

The hyperfinite formalism relates to these *states and *observables in exactly the same way as the standard formalism: To each *observable β corresponds a Hermitian operator $B:\mathcal{H}\to\mathcal{H}$ such that $(u|Bu)$ is to be interpreted as the expected value of β upon *measurement on the system in the *physical state represented by the normalized vector $u \in \mathcal{H}$. (In particular, any *observable is represented by a * bounded Hermitian operator, defined on the whole space.) Moreover, if $f(\beta)$ denotes the *observable obtained by measuring β and then substituting the outcome b by $f(b)$, where f is an internal *real-valued function defined on the set of all possible outcomes of β, then the operator corresponding to $f(\beta)$ is $f(B)$, defined in the usual way by means of the spectral theorem.

The outcome of a *measurement is necessarily an eigenvalue, standard or nonstandard, of the corresponding operator, and the *state following the *measurement is represented by an eigenvector of the same operator. The *probability of a particular eigenvalue may be infinitesimal, but is always expressed in the usual way. As to the *probability of complex events, it is obtained as a *sum, since the set of possible outcomes is *finite. The integral in the formula of Dirac gives way to a *sum.

Some *states are standard, being identical to the states of the standard theory; a state represented by $\varphi \in \mathcal{H}_0$ shall be represented in the hyperfinite model by the vector $\overline{\varphi} \in \mathcal{H}$. In the same way, some *actions are standard; in particular, some *actions constitute standard measurements of observables (in the usual sense). Observables are represented in the standard theory by self-adjoint operators in $\mathcal{H}_0$, whereas *observables are represented in the hyperfinite theory by Hermitian operators on $\mathcal{H}$. An observable shall be viewed as associated with the standard experimental setups that can be used, in principle, to measure it. Hence an observable is never a special case of *observable, since the *measurement of the latter upon nonstandard *states requires nonstandard setups. Nevertheless, the relation between an observable α and an *observable β may be such that the knowledge of the probabilistic behavior of β provides all the necessary information about the probabilistic behavior of α. We shall see that this kind of relation exists for every observable: To each self-adjoint operator A in $\mathcal{H}_0$ we shall associate, in a canonical way, a Hermitian operator $\widetilde{A}$ on $\mathcal{H}$ such that a *measurement of the *observable corresponding to $\widetilde{A}$ can be viewed as a kind of generalized measurement of the observable corresponding to A.

To accept the idea that the outcome of a physical measurement can be a nonstandard number,

one must recall that the numerical outcome of a measurement is just a mathematical entity that we associate—according to some criterium previously specified—with the physical situation following the measurement. One can produce an example of nonstandard (or imaginary) measurement by choosing some standard measurement and multiplying the real-valued outcome by $1+\varepsilon$ (or by $1+i$, respectively), where ε is some infinitesimal constant. The real question would be whether the ultimate nature of a given observable (like position) is such that it is better described by a nonstandard formalism. (For the position observable, this would imply that the physical space is discrete at an infinitesimal scale of order much larger than the one associated with known quantum phenomena.) As to nonstandard probabilities, recall that a probability is just a number attributed to an event, supposed to convey information that can be confronted with experience through repetition. A probability can be an irrational number, although relative frequencies are necessarily rational numbers. Likewise, one can accept a probability that is a hyper-real number (necessarily between 0 and 1), it being understood that its standard part must be taken before submitting it to experimental verification.

Other approaches to quantum mechanics using nonstandard analysis have been developed before. We mention in particular M. O. Farrukh,[7] who replaces the usual Hilbert space by its nonstandard counterpart. In this fashion the elements of a continuous spectrum are viewed as ''almost'' eigenvalues, in the sense that for λ in that spectrum there exists a vector f such that $Af=\lambda f$ up to an infinitesimal error, where A is the nonstandard counterpart of a classical operator. The essential point of our approach is the use of a smaller, hyperfinite-dimensional, state space, which allows us to represent *all* states by eigenvectors in a strict sense. This is possible because the mathematics of hyperfinite-dimensional Hilbert spaces amounts to linear algebra.

We note also that there has been recent interest in applying hyperfinite methods to quantum physics, namely with regard to Feynman integrals and quantum field theory. See Refs. 11–13, and 18.

II. THE SPACE OF STATE VECTORS

In this section we introduce the state vector space $\mathcal{H}$ corresponding to the case $\mathcal{H}_0=L^2(\mathbb{R})$. The idea behind the construction of $\mathcal{H}$ is that a continuous square-summable function can be approximated by a piecewise-constant function with compact support, which can be obtained by dividing a large enough compact interval into subintervals of equal length and by sampling the function on each subinterval. Moreover, each such approximation lies within a finite-dimensional space. The original function appears as a kind of limit as the length of the subintervals approaches zero. The issue is how to formalize this idea, since no obvious way to define the notion of limit of a sequence of finite-dimensional Hilbert spaces is available. Nonstandard analysis provides an easy way to introduce a *finite-dimensional space including the approximations corresponding to subintervals of infinitesimal length, wherein, furthermore, vectors with infinite norm have a legitimate place. This space is, in essence, the same as the one considered by M. Kinoshita in Refs. 8, and 9, who constructs representations of the usual (standard) distributions as elements of this space of functions.

A. Definition

The construction of $\mathcal{H}$ depends on the choice of some arbitrary infinite *natural number. Henceforth, we consider that a number $w\in{}^*\mathbb{N}\setminus\mathbb{N}$ has been chosen and we denote by J_w the set $\{k\in{}^*\mathbb{N}:k\leqslant 2w^2\}$. For each $k\in J_w\cup\{0\}$ we write $x_k=-w+k/w$. The interval $[-w,w]$ is thus divided into $2w^2$ subintervals of length $1/w$. For each $k\in J_w$, let χ_k be the element of ${}^*\mathcal{H}_0$ defined by

$$\chi_k(x)=\begin{cases} w & \text{for } x_{k-1}<x\leqslant x_k,\\ 0 & \text{otherwise.}\end{cases}$$

Finally, we define $\mathcal{H}$ as the $2w^2$-dimensional subspace of ${}^*\mathcal{H}_0$ spanned by the family $(\chi_k)_{k\in J_w}$. The elements of $\mathcal{H}$ are the internal functions from ${}^*\mathbb{R}$ to ${}^*\mathbb{C}$ that are constant in each interval $(x_{k-1},x_k]$, where $k\in J_w$, and are null outside the interval $(-w,w]$. For every $k,m\in J_w$,

$$(\chi_k|\chi_m)=\int_{-\infty}^{+\infty}\overline{\chi_k(x)}\chi_m(x)\,dx=\delta_{k,m}\int_{x_{k-1}}^{x_k}w^2\,dx=w\,\delta_{k,m}\ .$$

Thus, the family $(\chi_k)_{k\in J_w}$ constitutes an orthogonal basis of $\mathcal{H}$, with $\|\chi_k\|=\sqrt{w}$ for every $k\in J_w$.

For $u\in\mathcal{H}$, let $(u_k)_{k\in J_w}$ be the family of coordinates of u in the basis $((1/w)\,\chi_k)_{k\in J_w}$:

$$u=\frac{1}{w}\sum_{k\in J_w}u_k\chi_k\,.$$

It is readily seen that

$$u_m=u(x_m)=(\chi_m|u)$$

for every $m\in J_w$. Comparison with (1) shows that the function that maps x_k to $u(x_k)$ corresponds to the wave function of the standard theory. In a similar way the vectors χ_k (with $k\in J_w$) correspond to the ill-defined vectors $|x\rangle$ (where $x\in\mathbb{R}$) of the formalism of Dirac. Observe that all points of the real line are identifiable to points of the set $\{x_k:k\in J_w\}$: To $x\in\mathbb{R}$ we associate x_k, where $k=\max\{n\in J_w:n\leqslant w(x+w)\}$. Then $x\approx x_k$, since from $x_k\leqslant x<x_{k+1}$ it follows that $0\leqslant x-x_k<x_{k+1}-x_k=1/w\approx 0$. Therefore the mapping is one-to-one, for if $x\mapsto x_k$ and $y\mapsto x_k$, then $x\approx x_k\approx y$, and $x\approx y$ implies $x=y$.

A vector $u\in\mathcal{H}$ shall be represented, in ket notation, as $|u\rangle$. We shall also write $|x_k\rangle$ instead of $|\chi_k\rangle$.

B. Representation of standard wave functions

We denote by P the projection operator of ${}^*\mathcal{H}_0$ onto $\mathcal{H}$. Let $\varphi\in{}^*\mathcal{H}_0$. Then, for each $k\in J_w$,

$$(\chi_k|P\varphi)=(\chi_k|\varphi)=\int_{-\infty}^{+\infty}\overline{\chi_k(x)}\varphi(x)\,dx=w\int_{x_{k-1}}^{x_k}\varphi\ .$$

Since $1/w$ is the length of $[x_{k-1},x_k]$, the value of $P\varphi$ on any point of $(x_{k-1},x_k]$ equals the average of φ on the same interval. We shall also write $\overline{\varphi}$ instead of $P\varphi$. Thus, $\overline{\varphi}(x_k)=w\int_{x_{k-1}}^{x_k}\varphi$ for every $k\in J_w$.

We shall see that the restriction of P to $\mathcal{H}_0$ is one-to-one, which allows us to identify the linear space $\mathcal{H}_0$ to a subspace of $\mathcal{H}$. Moreover, such identification preserves inner products up to infinitesimals. Actually, we prove a more general result: Every locally summable function can be considered as an element of $\mathcal{H}$.

Proposition 1: Let $\varphi,\psi\in L^1_{\mathrm{loc}}$. If $\overline{\varphi}(x_k)\approx\overline{\psi}(x_k)$ for all finite x_k, then $\varphi=\psi$ almost everywhere.

Proof: By linearity, it suffices to prove the case $\psi=0$. Let φ be a locally summable function such that $\overline{\varphi}(x_k)\approx 0$ for all finite x_k. We shall show that $\int_I\varphi=0$ for every bounded interval I. This implies that $\int_I\varphi=0$ for every measurable set I, whereby we conclude that $\varphi=0$ up to a set of null Lebesgue measure.

Let $a,b\in\mathbb{R}$, with $a<b$. There exist $m,n\in J_w$ such that $a\approx x_n$ and $b\approx x_m$, and x_k is finite when $n\leqslant k\leqslant m$. Let $\varepsilon\in\mathbb{R}^+$. By hypothesis, $|\overline{\varphi}(x_k)|\leqslant\varepsilon$ for all finite x_k. Thus,

$$\left|\int_{x_n}^{x_m}\varphi\right|=\left|\sum_{k=n+1}^{m}\int_{x_{k-1}}^{x_k}\varphi\right|\leqslant\sum_{k=n+1}^{m}\frac{\varepsilon}{w}\leqslant\varepsilon\frac{m-n}{w}.$$

Since ε is arbitrary and $(m-n)/w$ is finite (as the latter value is infinitely close to $b-a$), we obtain $\int_{x_n}^{x_m}\varphi\approx 0$.

On the other hand,

$$\int_a^b \varphi=\int_{x_n}^{x_m}\varphi+\int_a^{x_n}\varphi+\int_{x_m}^b \varphi.$$

The last two summands are also infinitesimal, since $\lim_{y\to x}\int_x^y\varphi=0$ implies $\int_x^y\varphi\approx 0$ for $y\approx x$. Therefore, $\int_a^b\varphi\approx 0$, whence $\int_a^b\varphi=0$. □

In the following, we shall need the lemma below, concerning a property of convergence in $L^2(\mathbb{R})$. Previously, for each $n\in\mathbb{N}$ we define $J_n=\{k\in\mathbb{N}:k\leqslant 2n^2\}$ and $x_{n,k}=-n+k/n$ for $k\in J_n\cup\{0\}$.

Lemma 1: Let $\varphi\in L^2(\mathbb{R})$, and for each $n\in\mathbb{N}$ let φ_n be the element of $L^2(\mathbb{R})$ defined by

$$\varphi_n(x)=\begin{cases} n\int_{x_{n,k-1}}^{x_{n,k}}\varphi & (if\ \ x_{n,k-1}<x\leqslant x_{n,k},\ \ with\ \ k\in J_n),\\ 0 & (otherwise).\end{cases}$$

Then, the sequence $(\varphi_n)_{n\in\mathbb{N}}$ converges in $L^2(\mathbb{R})$ to φ.

Proof: For each $n\in\mathbb{N}$, denote by P_n the projection operator that maps each φ to φ_n. Let $\varphi\in L^2(\mathbb{R})$. Given $\varepsilon\in\mathbb{R}^+$, there exists $\psi\in L^2(\mathbb{R})$ such that $\|\varphi-\psi\|<\varepsilon$ and ψ is continuous and has bounded support. We have

$$\|\varphi-P_n\varphi\|<\|\varphi-\psi\|+\|\psi-P_n\psi\|+\|P_n(\psi-\varphi)\|<2\varepsilon+\|\psi-P_n\psi\|.$$

Hence, it suffices to prove that

$$\lim_{n\to\infty}\|\psi-P_n\psi\|=0,$$

since this implies $\lim_n\|\varphi-P_n\varphi\|\leqslant 2\varepsilon$, whence $P_n\varphi\to\varphi$.

Choose $N\in\mathbb{N}$ such that $[-N,N]$ contains the support of ψ. Then $\|\psi-P_n\psi\|^2=\int_{-N}^N|\psi(t)-(P_n\psi)(t)|^2\,dt$ for every $n\in\mathbb{N}$. Let $n\geqslant N$. For each $k\in J_n$,

$$\int_{x_{n,k-1}}^{x_{n,k}}|\psi(t)-(P_n\psi)(t)|^2\,dt=\int_{x_{n,k-1}}^{x_{n,k}}|\psi(t)|^2\,dt-\frac{1}{n}|a_{k,n}|^2,$$

where $a_{k,n}=n\int_{x_{n,k-1}}^{x_{n,k}}\psi$. Hence,

$$\|\psi-P_n\psi\|^2=\sum_{k=(n-N)n+1}^{n(n+N)}\int_{x_{n,k-1}}^{x_{n,k}}|\psi(t)-(P_n\psi)(t)|^2\,dt=\int_{-N}^{N}|\psi(t)|^2\,dt-\frac{1}{n}\sum_{k=(n-N)n+1}^{n(n+N)}|a_{k,n}|^2.$$

Since ψ is continuous, $\Sigma_{k=(n-N)n+1}^{n(n+N)}|a_{k,n}|^2$ is a Riemann sum of the function $t\mapsto|\psi(t)|^2$, corresponding to the decomposition of $[-N,N]$ in subintervals of length $1/n$. Hence,

$$\lim_{n\to\infty}\frac{1}{n}\sum_{k=(n-N)n+1}^{n(n+N)}|a_{k,n}|^2=\int_{-N}^{N}|\psi(t)|^2\,dt.$$

This completes the proof. □

Lemma 2: For every $f\in L^1(\mathbb{R})$,

$$\int_{\mathbb{R}} f\approx\frac{1}{w}\sum_{k=1}^{2w^2}\overline{f}(x_k).$$

Proof: Let $f \in L^1(\mathbb{R})$. Since $\int_{\mathbb{R}} f = \lim_n \int_{-n}^{n} f$, we have $\int_{\mathbb{R}} f \approx \int_{-w}^{w} f$.
Since

$$\int_{-n}^{n} f = \sum_{k=1}^{2n^2} \int_{x_{n,k-1}}^{x_{n,k}} f$$

for all $n \in \mathbb{N}$, we obtain, by transfer,

$$\int_{-w}^{w} f = \sum_{k=1}^{2w^2} \int_{x_{k-1}}^{x_k} f = \sum_{k=1}^{2w^2} \frac{\overline{f}(x_k)}{w}.$$

□

Proposition 2: For every $\varphi, \psi \in \mathcal{H}_0$,

$$(\varphi|\psi) \approx (\overline{\varphi}|\overline{\psi}) \approx (\varphi|\overline{\psi}) \ .$$

Proof: Let $\varphi, \psi \in \mathcal{H}_0$ and let $(\varphi_n)_{n\in\mathbb{N}}$ and $(\psi_n)_{n\in\mathbb{N}}$ be the sequences associated with φ and ψ as in Lemma 1. Then $\varphi_n \to \varphi$ and $\psi_n \to \psi$ in $\mathcal{H}_0$. By the continuity of the inner product, $(\varphi_n|\psi_n) \to (\varphi|\psi)$, whence $(\varphi|\psi) \approx (\varphi_w|\psi_w)$. Therefore, $(\varphi|\psi) \approx (\overline{\varphi}|\overline{\psi})$, since $\varphi_w = \overline{\varphi}$ and $\psi_w = \overline{\psi}$.

Similarly, $(\varphi|\psi_n) \to (\varphi|\psi)$, whence $(\varphi|\psi) \approx (\varphi|\overline{\psi})$. □

Proposition 3: For every $\varphi \in \mathcal{H}_0$,

$$\varphi \approx \overline{\varphi} \ .$$

Proof: Let $\varphi \in \mathcal{H}_0$. We have

$$\|\varphi - \overline{\varphi}\|^2 = (\varphi|\varphi) - (\varphi|\overline{\varphi}) - (\overline{\varphi}|\varphi) + (\overline{\varphi}|\overline{\varphi}) \approx 0$$

by Proposition 2. □

Corollary: For every $\varphi \in \mathcal{H}_0$,

$$\|\varphi\| \approx \|\overline{\varphi}\|.$$

Proposition 4: Let $\varphi \in \mathcal{H}_0$. *If* φ *is continuous on a neighborhood of* $x \in \mathbb{R}$, *then* $\varphi(x) \approx \overline{\varphi}(x_k)$ *for* $x_k \approx x$.

Proof: For $x_k \approx x$, the interval $[x_{k-1}, x_k]$ is contained in every standard neighborhood of x. Therefore φ is continuous on $[x_{k-1}, x_k]$, whence, by the mean value theorem,

$$\overline{\varphi}(x_k) = w \int_{x_{k-1}}^{x_k} \varphi = \varphi(c) \ ,$$

where $c \in [x_{k-1}, x_k]$. Since $c \approx x$, it follows from the continuity of φ at x that $\varphi(x) \approx \varphi(c)$, and this completes the proof. □

Proposition 5: Let u, v *be vectors of* $\mathcal{H}$ *such that*

$$\langle x_k|u\rangle \approx \langle x_k|v\rangle$$

for all finite x_k. *If* $\|u - v\|$ *is finite, then*

$$\langle \overline{\varphi}|u\rangle \approx \langle \overline{\varphi}|v\rangle$$

for all $\varphi \in \mathcal{H}_0$.

Proof: Let u and v be as in the proposition. We assume without loss of generality that v is the null vector. Let $\varphi \in \mathcal{H}_0$ and let $(\varphi_n)_{n\in\mathbb{N}}$ be the sequence defined as in Lemma 1.

For every $n \in \mathbb{N}$, the estimate

$$|\langle \overline{\varphi_n}|u\rangle| \leqslant \frac{1}{w}\sum_{k=1}^{2w^2} |\overline{\overline{\varphi_n}(x_k)}\langle x_k|u\rangle| \leqslant \frac{\varepsilon}{w}\sum_{k=1}^{2w^2} |\overline{\varphi_n}(x_k)|$$

holds for all $\varepsilon \in \mathbb{R}^+$. Moreover, the value of $(1/w)\,\Sigma_{k=1}^{2w^2}|\overline{\varphi_n}(x_k)|$ is finite, by Lemma 2, since the function φ_n is summable. Therefore,

$$|\langle \overline{\varphi_n}|u\rangle| \approx 0.$$

By the principle of Cauchy (also known as Robinson's sequential lemma; see Ref. 3; see also Ref. 5), this holds for all $n \leqslant \nu$, for some $\nu \in {}^*\mathbb{N}\backslash\mathbb{N}$. Then,

$$|\langle \overline{\varphi}|u\rangle| \leqslant |\langle \overline{\varphi} - \overline{\varphi_\nu}|u\rangle| + |\langle \overline{\varphi_\nu}|u\rangle| \lesssim \|\overline{\varphi} - \overline{\varphi_\nu}\|\,\|u\|.$$

By Lemma 1, $\overline{\varphi} \approx \overline{\varphi_\nu}$, and therefore $\overline{\varphi} \approx \overline{\varphi_\nu}$, by Proposition 3. Since $\|u\|$ is finite, we conclude that $|\langle \overline{\varphi}|u\rangle| \lesssim 0$. □

Remarks:

(1) Proposition 5 extends Proposition 1, in the sense that even when $|u\rangle$ and $|v\rangle$ are not representatives of locally summable functions the hypothesis that they have the same pointwise behavior (up to infinitesimals) ensures that their relationship with the usual wave-functions is also the same (still up to infinitesimals).

(2) The thesis of Proposition 5 may not hold when $\|u-v\|$ is infinite. Consider $|u\rangle = |x_m\rangle$, where $x_m = \nu \in {}^*\mathbb{N}\backslash\mathbb{N}$, with $\nu \leqslant w^{1/4}$. Let φ be the function such that $\varphi(x) = n$ for $n - 1/n^4 \leqslant x \leqslant n$ (for every $n \in \mathbb{N}$) and $\varphi(x) = 0$ otherwise. Then $\varphi \in L^2(\mathbb{R})$ and $\langle x_k|u\rangle = 0$ for all finite x_k, but

$$\langle u|\varphi\rangle = \overline{\varphi}(x_m) = w\int_{\nu - 1/w}^{\nu} \varphi = \varphi(\nu) = \nu \neq 0.$$

III. OPERATORS

A. A position operator

Switching to the bra–ket notation, we define a "position operator" on $\mathcal{H}$ by

$$X_{\mathrm{h}} = \frac{1}{w}\sum_{k=1}^{2w^2} x_k |x_k\rangle\langle x_k|.$$

The operator X_{h} is Hermitian, since the basis $(|x_k\rangle)_{k\in J_w}$ is orthogonal and all coefficients x_k are *real. It can be shown in the usual way that $\{x_k : k \in J_w\}$ is the set of eigenvalues of X_{h} and that the eigenspace corresponding to x_k is spanned by $|x_k\rangle$. We have $\langle x_k|X_{\mathrm{h}}|u\rangle = x_k\langle x_k|u\rangle$ for all $k \in J_w$ and $u \in \mathcal{H}$. (Hence X_{h} is the restriction to $\mathcal{H}$ of the multiplicative operator in ${}^*\mathcal{H}_0$.)

The present example illustrates some of the notions introduced in Sec. I C. Assuming the usual interpretation of $\mathcal{H}_0$, the multiplicative operator X in $\mathcal{H}_0$ corresponds to the position observable α, and X_{h} corresponds to an *observable β. We shall see that α behaves as a kind of standard-scale version of β insofar as probabilities are concerned, assuming that physical states are represented by continuous wave functions.

Proposition 6: Let $f:\mathbb{R}\to\mathbb{R}$ be a bounded function, continuous except at most at a finite set of points. For every $\varphi \in \mathcal{H}_0$, if φ is continuous and belongs to the domain of $f(X)$, then

$$(\varphi|f(X)\varphi) \approx \langle \overline{\varphi}|f(X_{\mathrm{h}})|\overline{\varphi}\rangle.$$

Proof: Let $\psi(x)=f(x)\varphi(x)$ for all $x\in\mathbb{R}$. For finite x_k such that f is continuous at $\mathrm{st}(x_k)$, the function ψ is continuous on a neighborhood of x, where $x=\mathrm{st}(x_k)$. By Proposition 4, $\langle x_k|\overline{\psi}\rangle = \overline{\psi}(x_k)\approx f(x)\varphi(x)$. On the other hand, for the same x_k,

$$\langle x_k|f(X_\mathrm{h})|\overline{\varphi}\rangle = f(x_k)\overline{\varphi}(x_k)\approx f(x)\varphi(x),$$

because $f(x_k)\approx f(x)$, $\overline{\varphi}(x_k)\approx\varphi(x)$, and all these values are finite.

Let S be the set of standard points at which f is not continuous. Let $\varepsilon\in\mathbb{R}^+$, and denote by u_ε the vector of $\mathcal{H}$ such that $\langle x_k|u_\varepsilon\rangle=f(x_k)\overline{\varphi}(x_k)$ if $x_k\in\cup_{x\in S}(x-\varepsilon,x+\varepsilon)$ and such that $\langle x_k|u_\varepsilon\rangle = \overline{\psi}(x_k)$ otherwise. Hence $\langle x_k|u_\varepsilon\rangle\approx\langle x_k|f(X_\mathrm{h})|\overline{\varphi}\rangle$ for all finite x_k. Moreover, $\|u_\varepsilon-f(X_\mathrm{h})\overline{\varphi}\|$ is finite, since

$$\|u_\varepsilon-f(X_\mathrm{h})\overline{\varphi}\|\leqslant\|\overline{\psi}-f(X_\mathrm{h})\overline{\varphi}\|\leqslant\|\overline{\psi}\|+A\|\overline{\varphi}\|,$$

where A is any upper bound of $|f|$. Therefore, $\langle\overline{\varphi}|u_\varepsilon\rangle\approx\langle\overline{\varphi}|f(X_\mathrm{h})|\overline{\varphi}\rangle$, by Proposition 5.

On the other hand,

$$|u_\varepsilon-\overline{\psi}\rangle=\frac{1}{w}\sum_k\ (f(x_k)\overline{\varphi}(x_k)-\overline{\psi}(x_k))|x_k\rangle,$$

where the sum extends only over those values of k such that $x_k\in\cup_{x\in S}(x-\varepsilon,x+\varepsilon)$. Thus,

$$\langle\overline{\varphi}|u_\varepsilon-\overline{\psi}\rangle=\frac{1}{w}\sum_k\ f(x_k)|\overline{\varphi}(x_k)|^2-\frac{1}{w}\sum_k\ \overline{\overline{\varphi}(x_k)}\overline{\psi}(x_k).$$

An upper bound of the former sum is $A(1/w)\,\Sigma_k|\overline{\varphi}(x_k)|^2$, and

$$\frac{1}{w}\sum_k\ |\overline{\varphi}(x_k)|^2\approx\sum_{x\in S}\int_{x-\varepsilon}^{x+\varepsilon}|\varphi(t)|^2\,dt.$$

Similarly,

$$\frac{1}{w}\sum_k\ \overline{\overline{\varphi}(x_k)}\overline{\psi}(x_k)\approx\sum_{x\in S}\int_{x-\varepsilon}^{x+\varepsilon}\overline{\varphi(t)}\psi(t)\,dt.$$

Hence, given $\delta\in\mathbb{R}^+$, there exists $\varepsilon\in\mathbb{R}^+$ such that $|\langle\overline{\varphi}|u_\varepsilon-\overline{\psi}\rangle|<\delta$. For such ε,

$$(\varphi|f(X)\varphi)\approx\langle\overline{\varphi}|\overline{\psi}\rangle\approx\langle\overline{\varphi}|\overline{\psi}-u_\varepsilon\rangle+\langle\overline{\varphi}|u_\varepsilon\rangle\approx\langle\overline{\varphi}|\overline{\psi}-u_\varepsilon\rangle+\langle\overline{\varphi}|f(X_\mathrm{h})|\overline{\varphi}\rangle.$$

Since $|\langle\overline{\varphi}|\overline{\psi}-u_\varepsilon\rangle|<\delta$ and δ is an arbitrary element of $\mathbb{R}^+$, we conclude that $(\varphi|f(X)\varphi)\approx\langle\overline{\varphi}|f(X_\mathrm{h})|\overline{\varphi}\rangle$. □

When f is the characteristic function of a standard interval I, Proposition 6 shows that the probability $\mathrm{prob}_\varphi(\alpha\in I)$ that a measurement of α upon the state represented by φ will yield an outcome in the set I is the standard part of the *probability $^*\mathrm{prob}_{\overline{\varphi}}(\beta\in{}^*I)$ that a *measurement of β upon the same *state will yield an outcome in the interval $^*I$. In other words,

$$\mathrm{prob}_\varphi(\alpha\in I)=\mathrm{st}\,\langle\overline{\varphi}|f(X_\mathrm{h})|\overline{\varphi}\rangle.$$

Other operators can replace X_h in the statement of Proposition 6. For example, if X_h' is defined by the identity $X_\mathrm{h}'|x_k\rangle=(x_k+1/w)|x_k\rangle$, then it is easy to reproduce the proof of Proposition 6. This example shows that there is no such thing as "the position *observable," but there are several *observables that behave at standard scale like the standard position observable, at least as far as only probabilities are concerned.

B. Representation of observables

We shall associate to any self-adjoint operator A in $\mathcal{H}_0$ a Hermitian operator $\tilde{A}$ in $\mathcal{H}$. We must deal first with bounded operators. To each *bounded operator $T:{}^*\mathcal{H}_0\to{}^*\mathcal{H}_0$ we assign the operator $\overline{T}:\mathcal{H}\to\mathcal{H}$ such that

$$\overline{T}u = PTu$$

for every $u\in\mathcal{H}$. When T is self-adjoint, $\overline{T}$ is Hermitian, since $\overline{T}u = PTPu$ for all $u\in\mathcal{H}$.

*Proposition 7: Let T be a *bounded operator on ${}^*\mathcal{H}_0$ with finite norm. For every $\varphi\in\mathcal{H}_0$,*

$$\overline{T}\overline{\varphi}\approx T\overline{\varphi}\approx P(T\varphi).$$

If, moreover, $T\varphi\in\mathcal{H}_0$, then $P(T\varphi)\approx T\varphi$.

Proof: We have $\overline{\varphi}\approx\varphi$, by Proposition 3. Then $T\overline{\varphi}\approx T\varphi$, because T has finite norm. Since P also has finite norm, $\overline{T}\overline{\varphi}=P(T\overline{\varphi})\approx P(T\varphi)$. Finally, $T\varphi\approx P(T\varphi)$ when $T\varphi\in\mathcal{H}_0$, by Proposition 3. □

The conditions of Proposition 7 are satisfied, in particular, when T is a bounded operator on $\mathcal{H}_0$.

When the domain of a self-adjoint operator A is not the whole space $\mathcal{H}_0$, we cannot define $\overline{A}$ as above. However, the spectral theorem for self-adjoint operators in a Hilbert space yields the equality

$$A=\int_{-\infty}^{+\infty}\lambda\, dE_\lambda,$$

where $(E_\lambda)_{\lambda\in\mathbb{R}}$ is the spectral family associated with A. For every $n\in{}^*\mathbb{N}$, the operator

$$A_n=\int_{-n}^{+n}\lambda\, dE_\lambda$$

is a *bounded operator on ${}^*\mathcal{H}_0$. We shall define a Hermitian operator $\tilde{A}:\mathcal{H}\to\mathcal{H}$ by $\tilde{A}=\overline{A_\nu}$, where ν is an element of ${}^*\mathbb{N}\backslash\mathbb{N}$ satisfying the conditions of Proposition 8, below; these conditions ensure that an appropriate relation between the spectral families of A and $\tilde{A}$ can be obtained. When A is bounded, we have $\tilde{A}=\overline{A}$, since $A=A_\nu$ in such case.

Given a *bounded self-adjoint operator T on ${}^*\mathcal{H}_0$, we write $X(T)=\{(u|Tu):u\in{}^*\mathcal{H}_0,\ \|u\|=1\}$, and $\mu(T)=\inf X(T)$, $M(T)=\sup X(T)$. For $u\in\mathcal{H}$ we have $(u|\overline{T}u)=(u|PTu)=(Pu|Tu)=(u|Tu)$. Hence $X(\overline{T})$ is a subset of $X(T)$, and therefore $[\mu(\overline{T}),M(\overline{T})]\subset[\mu(T),M(T)]$. Hence, if f is a *real-valued function continuous on $[\mu(T),M(T)]$, both operators $f(T)$ and $f(\overline{T})$ are well-defined. Moreover, it is known that the norms thereof satisfy the conditions

$$\|f(T)\|\leqslant\sup\{|f(\lambda)|:\lambda\in[\mu(T),M(T)]\},$$

$$\|f(\overline{T})\|\leqslant\sup\{|f(\lambda)|:\lambda\in[\mu(\overline{T}),M(\overline{T})]\}.$$

Therefore, if $f(T)$ has finite norm, then $f(\overline{T})$ also has finite norm.

Proposition 8: There exists $\nu\in{}^*\mathbb{N}\backslash\mathbb{N}$ such that: For every sequence $(T_n)_{n\in\mathbb{N}}$ of bounded self-adjoint operators on $\mathcal{H}_0$ and every sequence $(f_m)_{m\in\mathbb{N}}$ of real-valued functions such that each f_m is continuous on $[\mu(T_n),M(T_n)]$ whenever $n\geqslant m$,

$$f_m(\overline{T_n})\overline{\varphi}\approx f_m(T_n)\varphi,$$

for every $\varphi\in\mathcal{H}_0$ and every $m,n\in{}^*\mathbb{N}$ such that $m\leqslant n\leqslant\nu$.

Proof: Let $(T_n)_{n\in\mathbb{N}}$, $(f_m)_{m\in\mathbb{N}}$ and φ be as in the proposition. Let $n,m\in\mathbb{N}$, with $m\leqslant n$. If u is an element of $\mathcal{H}$ such that $u\approx\varphi$, then $\overline{T_n}u=PT_nu\approx PT_n\varphi$, since the norm of PT_n is finite. By Proposition 3, $PT_n\varphi\approx T_n\varphi$, and thus $\overline{T_n}u\approx T_n\varphi$. This is readily extended to $p(\overline{T_n})u\approx p(T_n)\varphi$, where p is an arbitrary standard polynomial.

Let $\varepsilon\in\mathbb{R}^+$. Choose a standard polynomial p such that $|f_m(\lambda)-p(\lambda)|\leqslant\varepsilon$ for all λ in the interval $[\mu(T_n),M(T_n)]$. Then

$$\|f_m(T_n)\varphi-p(T_n)\varphi\|=\left\|\int_{-\infty}^{+\infty}(f_m(\lambda)-p(\lambda))\,dE_\lambda\varphi\right\|\leqslant\varepsilon\|\varphi\|,$$

where $(E_\lambda)_{\lambda\in\mathbb{R}}$ is the spectral family associated with T_n. Similarly,

$$f_m(\overline{T_n})\overline{\varphi}-p(\overline{T_n})\overline{\varphi}=\sum_i\,(f_m(\lambda_i)-p(\lambda_i))P_i\overline{\varphi},$$

where the sum extends over all eigenvalues λ_i of $\overline{T_n}$ and P_i is the projection operator onto the eigenspace corresponding to λ_i. Taking into account that every λ_i is in the interval $[\mu(T_n),M(T_n)]$, we obtain

$$\|f_m(\overline{T_n})\overline{\varphi}-p(\overline{T_n})\overline{\varphi}\|^2=\sum_i\,|f_m(\lambda_i)-p(\lambda_i)|^2\|P_i\overline{\varphi}\|^2\leqslant\varepsilon^2\|\overline{\varphi}\|^2.$$

Finally,

$$\begin{aligned}\|f_m(\overline{T_n})\overline{\varphi}-f_m(T_n)\varphi\|&\leqslant\|f_m(\overline{T_n})\overline{\varphi}-p(\overline{T_n})\overline{\varphi}\|+\|p(\overline{T_n})\overline{\varphi}-p(T_n)\varphi\|+\|p(T_n)\varphi-f_m(T_n)\varphi\|\\&\leqslant\varepsilon\|\overline{\varphi}\|+\text{infinitesimal}+\varepsilon\|\varphi\|.\end{aligned}$$

Since $\|\overline{\varphi}\|$ and $\|\varphi\|$ are finite, and ε is arbitrary, this proves that

$$f_m(\overline{T_n})\overline{\varphi}\approx f_m(T_n)\varphi.$$

Given sequences $(f_m)_{m\in\mathbb{N}}$ and $(T_n)_{n\in\mathbb{N}}$, and $j\in\mathbb{N}$, $\varphi\in\mathcal{H}_0$, write $\alpha=((f_m)_m,(T_n)_n,\varphi,j)$ and let

$$S_\alpha=\{k\in{}^*\mathbb{N}:k\geqslant j,\forall_{m,n\in{}^*\mathbb{N},m\leqslant n\leqslant k}\,\|f_m(\overline{T_n})\overline{\varphi}-f_m(T_n)\varphi\|<n^{-1}\}.$$

For $k\in\mathbb{N}$, the condition $\|f_m(\overline{T_n})\overline{\varphi}-f_m(T_n)\varphi\|<n^{-1}$ holds for $m\leqslant n\leqslant k$, since $f_m(\overline{T_n})\overline{\varphi}\approx f_m(T_n)\varphi$. Hence, any $k\in\mathbb{N}$ such that $k\geqslant j$ is an element of S_α. Moreover, the family of all sets S_α with α as above has the finite intersection property (see the Appendix)—it suffices to choose for k the greatest value of j. Therefore, by saturation,

$$\bigcap_\alpha S_\alpha\neq\varnothing,$$

and any $\nu\in\cap_\alpha S_\alpha$ satisfies the conditions of the proposition. □

Henceforth we consider that a value ν as given by Proposition 8 has been chosen. For every self-adjoint operator A we define $\widetilde{A}=\overline{A}_\nu$.

Proposition 9: Let A be a self-adjoint bounded operator on $\mathcal{H}_0$. For every real-valued function f continuous on $[\mu(A),M(A)]$,

$$f(A)\varphi\approx f(\overline{A})u$$

for all $\varphi \in \mathcal{H}_0$ and $u \in \mathcal{H}$ such that $u \approx \varphi$.

Proof: Considering the constant sequences determined by A and f, Proposition 8 yields

$$f(A)\varphi \approx f(\overline{A})\overline{\varphi}$$

for every $\varphi \in \mathcal{H}_0$. If $u \approx \varphi$, with $u \in \mathcal{H}$, then $f(\overline{A})\overline{\varphi} \approx f(\overline{A})u$, since

$$\|f(\overline{A})(\overline{\varphi} - u)\| \leqslant \|f(\overline{A})\|\,\|\overline{\varphi} - u\|$$

and the right side above is the product of a finite number by an infinitesimal. □

Proposition 10: Let A be a self-adjoint operator in $\mathcal{H}_0$. For every continuous function $f:\mathbb{R} \to \mathbb{R}$, the condition

$$f(A)\varphi \approx f(\widetilde{A})\overline{\varphi}$$

holds for every $\varphi \in \mathcal{H}_0$ belonging to the domain of $f(A)$.

Proof: Let $(E_\lambda)_{\lambda \in \mathbb{R}}$ be the spectral family associated with A. We have

$$f(A)\varphi = \lim_n \int_{-n}^{+n} f(\lambda)\, dE_\lambda \varphi = \lim_n f(A_n)\varphi \approx f(A_\nu)\varphi.$$

By Proposition 8, making $f_n = f$ for all n,

$$f(A_\nu)\varphi \approx f(\overline{A}_\nu)\overline{\varphi}.$$

Since $\overline{A}_\nu = \widetilde{A}$, this completes the proof. □

The following proposition relates the spectral families associated with A and $\widetilde{A}$. (A related proposition, for bounded operators, is found in Ref. 4.)

Proposition 11: Let A be a self-adjoint operator in $\mathcal{H}_0$, and let $(E_\lambda)_{\lambda \in \mathbb{R}}$ and $(F_\lambda)_{\lambda \in {}^*\mathbb{R}}$ be the spectral families associated with A and $\widetilde{A}$, respectively. Let $a \in \mathbb{R}$. The conditions

$$E_a \varphi \approx F_{a+\varepsilon} u,$$

$$E_{a^-} \varphi \approx F_{a-\varepsilon} u$$

hold for every infinitesimal $\varepsilon \geqslant \nu^{-1}$ and every $\varphi \in \mathcal{H}_0$ and $u \in \mathcal{H}$ such that $u \approx \varphi$.

Proof: Let $a \in \mathbb{R}$. For $m \in {}^*\mathbb{N}$, we denote by $g_{m,a}$ the continuous function defined on ${}^*\mathbb{R}$ such that (i) $g_{m,a}(\lambda) = 1$ for $\lambda \leqslant a + (m+1)^{-1}$, (ii) $g_{m,a}(\lambda) = 0$ for $\lambda \geqslant a + m^{-1}$, and (iii) $g_{m,a}$ drops linearly from 1 to 0 in the interval $[a + (m+1)^{-1}, a + m^{-1}]$. Moreover, for $x \in {}^*\mathbb{R}$ let h_x be the function such that $h_x(\lambda) = 1$ for $\lambda \leqslant x$ and $h_x(\lambda) = 0$ for $\lambda > x$. Then

$$g_{m,a}(\lambda) \leqslant h_{a+\varepsilon}(\lambda) \leqslant g_{m-2,a}(\lambda)$$

for all m, λ, ε such that $m > 2$ and $m^{-1} \leqslant \varepsilon \leqslant (m-1)^{-1}$. For every Hermitian operator B on $\mathcal{H}$, the operational calculus yields

$$\|g_{m-2,a}(B)u - h_{a+\varepsilon}(B)u\| \leqslant \|g_{m-2,a}(B)u - g_{m,a}(B)u\|$$

for all $u \in \mathcal{H}$. Given an infinitesimal $\varepsilon \geqslant \nu^{-1}$, consider the unique $m \in {}^*\mathbb{N}$ such that $m - 1 < \varepsilon^{-1} \leqslant m$. From $\varepsilon \geqslant \nu^{-1}$ it follows that $m \leqslant \nu$. Moreover, $m^{-1} \leqslant \varepsilon < (m-1)^{-1}$. Therefore, we may particularize the inequality above with such m and ε, and $B = \overline{A}_\nu$ and with $u = \overline{\varphi}$, where $\varphi \in \mathcal{H}_0$:

$$\|g_{m-2,a}(\overline{A}_\nu)\overline{\varphi} - h_{a+\varepsilon}(\overline{A}_\nu)\overline{\varphi}\| \leqslant \|g_{m-2,a}(\overline{A}_\nu)\overline{\varphi} - g_{m,a}(\overline{A}_\nu)\overline{\varphi}\|.$$

We now show that the right side of this inequality is infinitesimal. We have $g_{m-2,a}(\overline{A}_\nu)\overline{\varphi}\approx g_{m-2,a}(A_\nu)\varphi$ and $g_{m,a}(\overline{A}_\nu)\overline{\varphi}\approx g_{m,a}(A_\nu)\varphi$, by the definition of ν. We must show that $g_{m-2,a}(A_\nu)\varphi\approx g_{m,a}(A_\nu)\varphi$: For fixed a, the sequence $(g_{n,a})_{n\in\mathbb{N}}$ is a decreasing sequence of non-negative continuous functions that converges pointwise to the function h_a. The operational calculus ensures that

$$\lim_n g_{n,a}(A)\varphi = h_a(A)\varphi$$

for every $\varphi\in\mathcal{H}_0$. Since ε is infinitesimal, m is infinite, and hence

$$g_{m-2,a}(A)\varphi\approx g_{m,a}(A)\varphi\approx h_a(A)\varphi.$$

On the other hand,

$$\begin{aligned} g_{m-2,a}(A)\varphi &= \int_{-\infty}^{a} g_{m-2,a}(\lambda)\, dE_\lambda\varphi \\ &= g_{m-2,a}(A_\nu)\varphi + \int_{-\infty}^{-\nu} dE_\lambda\varphi \\ &= g_{m-2,a}(A_\nu)\varphi + E_{-\nu}\varphi\approx g_{m-2,a}(A_\nu)\varphi. \end{aligned}$$

In a similar way, $g_{m,a}(A)\varphi\approx g_{m,a}(A_\nu)\varphi$. Thus, we have shown that $g_{m-2,a}(\overline{A}_\nu)\overline{\varphi}\approx h_{a+\varepsilon}(\overline{A}_\nu)\overline{\varphi}$. Therefore, taking into account the definition of ν,

$$h_a(A)\varphi\approx g_{m-2,a}(A)\varphi\approx g_{m-2,a}(A_\nu)\varphi\approx g_{m-2,a}(\overline{A}_\nu)\overline{\varphi}\approx h_{a+\varepsilon}(\overline{A}_\nu)\overline{\varphi}.$$

Finally, $h_a(A)\varphi = E_a\varphi$ and $h_{a+\varepsilon}(\overline{A}_\nu)\overline{\varphi} = F_{a+\varepsilon}\overline{\varphi}$; furthermore, if $u\in\mathcal{H}$ is such that $u\approx\varphi$, then $F_{a+\varepsilon}\overline{\varphi}\approx F_{a+\varepsilon}u$, since the norm of the projection operator $F_{a+\varepsilon}$ is finite.

The proof of the second condition in the thesis is similar. For $m\in{}^*\mathbb{N}$, denote by $\gamma_{m,a}$ the continuous function defined on ${}^*\mathbb{R}$ such that (i) $\gamma_{m,a}(\lambda)=1$ for $\lambda\leqslant a-m^{-1}$, (ii) $\gamma_{m,a}(\lambda)=0$ for $\lambda\geqslant a-(m+1)^{-1}$, and (iii) γ_{ma} drops linearly from 1 to 0 in the interval $[a-m^{-1}, a-(m+1)^{-1}]$. For $x\in{}^*\mathbb{R}$, denote by η_x the function such that $\eta_x(\lambda)=1$ for $\lambda<x$ and $\eta_x(\lambda)=0$ for $\lambda\geqslant x$. Proceeding as in the first part of the proof, we obtain

$$\eta_a(A)\varphi\approx\eta_{a-\varepsilon}(\overline{A}_\nu)\overline{\varphi}.$$

We have $\eta_{a-\varepsilon}(\overline{A}_\nu)\overline{\varphi} = F_{a-\varepsilon}\overline{\varphi}$; on the other hand, $\eta_a(x)=h_a(x)-\theta(x)$ for all x, where $\theta(a)=1$ and $\theta(x)=0$ for $x\neq a$. Hence, $\eta_a(A)\varphi = E_a\varphi-\theta(A)\varphi$. A straightforward computation yields $\int_{-\infty}^{+\infty}\theta(\lambda)dE_\lambda = E_{a^+}-E_{a^-}$. Therefore,

$$E_a\varphi - E_{a^+}\varphi + E_{a^-}\varphi\approx F_{a-\varepsilon}\overline{\varphi}.$$

Finally, $E_a\varphi-E_{a^+}\varphi=0$, since the function $\lambda\mapsto E_\lambda$ is necessarily continuous on the right. □

Corollary: Let A be a self-adjoint operator in $\mathcal{H}_0$, and let $(E_\lambda)_{\lambda\in\mathbb{R}}$ and $(F_\lambda)_{\lambda\in{}^*\mathbb{R}}$ be the spectral families associated with A and $\tilde{A}$, respectively. For $a\in\mathbb{R}$, if the function $\lambda\mapsto E_\lambda$ is continuous at a, then $E_a\varphi\approx F_a u$, for every $\varphi\in\mathcal{H}_0$ and every $u\in\mathcal{H}$ such that $u\approx\varphi$.

Proof: We have $E_a\varphi\approx F_{a+\varepsilon}u$ and $E_{a-}\varphi\approx F_{a-\varepsilon}u$ for $\varepsilon\approx 0$ such that $\varepsilon\geqslant\nu^{-1}$. Since $E_{a-}\varphi = E_a\varphi$, it follows that $E_a\varphi\approx F_{a+\varepsilon}u\approx F_{a-\varepsilon}u$. Since

$$\|F_{a+\varepsilon}u - F_{a-\varepsilon}u\|^2 = \|F_{a+\varepsilon}u - F_a u\|^2 + \|F_a u - F_{a-\varepsilon}u\|^2,$$

we obtain $F_{a+\varepsilon}u\approx F_a u$ and $F_a u\approx F_{a-\varepsilon}u$. □

IV. PROBABILITIES AND CONSISTENCY

A. Nonstandard and standard probabilities

A *measurement of an *observable β will yield a *real outcome, finite or infinite. By taking its standard part when the outcome is finite one obtains a standard outcome. For every bounded Borelian subset of $\mathbb{R}$, the event $\mathrm{st}\,\beta \in S$ amounts to $\beta \in \mathrm{Mon}\,S$, where

$$\mathrm{Mon}\,S = \{x \in {}^*\mathbb{R} : \exists_{y \in S}\ y \approx x\}.$$

(The restriction to bounded sets is due to the possibility that the outcome be infinite.) The question that now arises is that of how to attribute a standard probability to the event $\mathrm{st}\,\beta \in S$. Given a *probability measure P on the class $\mathrm{Bor}({}^*\mathbb{R})$ of Borelian subsets of ${}^*\mathbb{R}$, we shall define a finite σ-additive measure pr on the class $\mathrm{Bor}(\mathbb{R})$ of Borelian subsets of $\mathbb{R}$. If P is the *probability measure associated with the *measurement of an *observable β upon a given *state, then $\mathrm{pr}\,S$ can be viewed as the probability that a *measurement of β will yield a finite outcome with standard part in the Borelian set S. It may happen that $\mathrm{pr}\,\mathbb{R} < 1$, as it was to be expected since an infinite outcome of the *measurement of β does not correspond to an outcome in $\mathbb{R}$. We cannot define $\mathrm{pr}\,S$ as $\mathrm{st}\,P(\mathrm{Mon}\,S)$, since $\mathrm{Mon}\,S$ is not in general an internal set. Nevertheless, the mapping $\mathrm{st} \circ P$ can be extended as a standard probability measure P_{L} to the σ-algebra $\mathcal{A}_{\mathrm{L}}$ spanned by $\mathrm{Bor}({}^*\mathbb{R})$ (The measure P_{L} is known as a Loeb measure; see Ref. 16. Note that this construction would remain valid even if P were only *finitely* additive.) We can easily see that $\mathrm{Mon}\,S$ is in $\mathcal{A}_{\mathrm{L}}$ for every S in $\mathrm{Bor}(\mathbb{R})$: If $S = [a,b]$, with $a \leqslant b$, we have

$$\mathrm{Mon}\,S = \bigcap_{n \in \mathbb{N}} {}^*\left[a - \frac{1}{n}, b + \frac{1}{n}\right],$$

whence $\mathrm{Mon}\,S \in \mathcal{A}_{\mathrm{L}}$. Moreover, the mapping Mon is an isomorphism of σ-rings. Hence, $\mathrm{Mon}(\mathrm{Bor}(\mathbb{R}))$ is the smallest σ-ring including every Mon$S$ where S is a compact interval of $\mathbb{R}$. Therefore, $\mathrm{Mon}(\mathrm{Bor}(\mathbb{R}))$ is contained in $\mathcal{A}_{\mathrm{L}}$, since $\mathcal{A}_{\mathrm{L}}$ is a σ-ring including such sets. Thus, we define

$$\mathrm{pr}\,S = P_{\mathrm{L}}(\mathrm{Mon}\,S),$$

for every bounded S in $\mathrm{Bor}(\mathbb{R})$, and we extend pr to $\mathrm{Bor}(\mathbb{R})$ in the canonical way. Due to the properties of P_{L} and Mon, it is clear that pr is a σ-additive measure, with $\mathrm{pr}(\mathbb{R}) \leqslant 1$.

When $S = [a,b]$ with $a \leqslant b$, we have

$$\mathrm{pr}\,S = P_{\mathrm{L}}\left(\bigcap_{n \in \mathbb{N}} {}^*\left[a - \frac{1}{n}, b + \frac{1}{n}\right]\right) = \inf_{n \in \mathbb{N}} P_{\mathrm{L}}^*\left[a - \frac{1}{n}, b + \frac{1}{n}\right] = \inf_{n \in \mathbb{N}} \mathrm{st}\,P^*\left[a - \frac{1}{n}, b + \frac{1}{n}\right]. \quad (2)$$

Since a measure on $\mathrm{Bor}(\mathbb{R})$ is determined by its values on intervals, there can be no other measure satisfying (2). The considerations above are resumed in the following proposition:

*Proposition 12: Let P be a *probability measure on the Borelian subsets of* ${}^*\mathbb{R}$. *There exists a unique positive σ-additive measure* pr *on the Borelian subsets of* $\mathbb{R}$ *such that* $\mathrm{pr}[a,b]$ *is given by Eq. (2) for all* $a,b \in \mathbb{R}$ *with* $a \leqslant b$. *Furthermore,* $\mathrm{pr}\,\mathbb{R} \leqslant 1$.

In the remainder of this section, we consider that α is an observable represented by a self-adjoint operator A in $\mathcal{H}_0$ and that β is an *observable corresponding to $\tilde{A}$. We now see how β can be viewed as a kind of nonstandard ''extension'' of α.

Proposition 10 entails $\langle \overline{\varphi} | \tilde{A} | \overline{\varphi} \rangle \approx (\varphi | A\varphi)$ for every $\varphi \in \mathcal{H}_0$. Moreover, it is readily seen that if $b = \langle \overline{\varphi} | \tilde{A} | \overline{\varphi} \rangle$ and $a = (\varphi | A\varphi)$, then $\langle \overline{\varphi} | (\tilde{A} - b)^2 | \overline{\varphi} \rangle \approx (\varphi | (A-a)^2 \varphi)$. Recalling that $\|\overline{\varphi}\| \approx \|\varphi\|$, we see that on standard states the expected values and uncertainties of α and β are identical up to

infinitesimals. If $\tilde{A}|\overline{\varphi}\rangle = b|\overline{\varphi}\rangle$ with $\varphi \in \mathcal{H}_0$, $\|\varphi\| = 1$ and $b \in {}^*\mathbb{R}$, then b is finite, because $b \approx (\varphi|A\varphi)$. Setting $a = \mathrm{st}(b)$, we obtain $A\varphi \approx b\varphi \approx a\varphi$, whence $A\varphi = a\varphi$. Therefore, a standard state where β has a definite value c (necessarily finite) is also a state where α has the definite value $\mathrm{st}(c)$. (On the other hand, if α has a definite value on a standard state, then β has an ''almost definite'' value, in the sense that the uncertainty of β is infinitesimal.) Thus, α is similar in status to a function of the *observable β; however, the function $c \mapsto \mathrm{st}(c)$ is not internal, and therefore we cannot say that α is a function of β in the strict sense.

The similitude of α to a function of β extends to states on which α has a value in an interval. In fact, given $\varphi \in \mathcal{H}_0$ and $a, b \in \mathbb{R}$ with $a < b$, Proposition 11 ensures that the condition $\varphi = E_b\varphi - E_{a^-}\varphi$ is equivalent to $\overline{\varphi} \approx F_{b+\varepsilon}\overline{\varphi} - F_{a-\varepsilon}\overline{\varphi}$, where $\varepsilon \approx 0$, $\varepsilon \geqslant \nu^{-1}$ and $(E_\lambda)_{\lambda \in \mathbb{R}}$ and $(F_\lambda)_{\lambda \in {}^*\mathbb{R}}$ are the spectral families of A and $\tilde{A}$, respectively. This means that on a standard state represented by φ the observable α is in $[a,b]$ if and only if on the same state (or on a *state represented by $u \approx \varphi$, as it can be easily seen) the *observable β is ''almost'' in ${}^*(a-\varepsilon, b+\varepsilon]$—in the sense that $f(\beta)u \approx u$, where f is the characteristic function of ${}^*(a-\varepsilon, b+\varepsilon]$. In particular, if a *measurement of β ensures that β is in ${}^*(a,b]$ and if the state following the *measurement is standard, then α is in $[a,b]$, which agrees with the interpretation of α as ''standard part of β.'' However, it may happen that such a state is not standard. Suppose now that the initial state is represented by $v \in \mathcal{H}$ and that a *measurement of $f(\beta)$ is performed, with f as above. If $v \approx \psi \in \mathcal{H}_0$, then, assuming the postulate of Lüders, the state following the *measurement is represented by the vector

$$u = F_{b+\varepsilon}v - F_{a-\varepsilon}v \approx F_{b+\varepsilon}\overline{\psi} - F_{a-\varepsilon}\overline{\psi} \approx E_b\psi - E_a\psi.$$

[This presupposes that the *measurement of $f(\beta)$ involves a minimal perturbation, in that it does not constitute a *measurement of any *observable γ such that $f(\beta)$ is function of γ but γ is not function of $f(\beta)$.]

B. Consistency with the standard theory

We shall now deal with the problem of relating the probabilistic behaviors of α and β. Suppose that a *measurement of β is performed upon a standard state, yielding the outcome c. If the state following the *measurement is standard, the *measurement can be considered as a measurement of α yielding the outcome $\mathrm{st}(c)$. When such a state is not standard, it seems natural to assume that the *measurement can still be viewed as a generalized measurement of α, yielding perhaps the outcome ''infinite.'' Insofar as only probabilities are concerned, the meaning of this last statement can be made precise by saying that the probability measure associated with the measurement of α upon a standard state coincides with the measure pr associated (according to Proposition 12) with the *measurement of β upon the same state. The following proposition shows that this is indeed the case.

*Proposition 13: Let A be a self-adjoint operator in $\mathcal{H}_0$ and let $\varphi \in \mathcal{H}_0$, with $\|\varphi\| = 1$. Let P be the *probability measure associated with the operator $\tilde{A}$ and the state represented by $\overline{\varphi}$, and let* pr *be the standard measure associated with P. For all $a, b \in \mathbb{R}$ such that $a < b$,*

$$\mathrm{pr}\,(a,b] = (\varphi|f(A)\varphi),$$

where f is the characteristic function of $(a,b]$.

Proof: Let $(E_\lambda)_{\lambda \in \mathbb{R}}$ and $(F_\lambda)_{\lambda \in {}^*\mathbb{R}}$ be the spectral families associated with A and $\tilde{A}$, respectively. For some $\rho \approx 1$ dependent on φ, we have, for $a \leqslant b$ and $n \in \mathbb{N}$,

$$P^*(a - 1/n, b + 1/n] = \rho \int_{a-1/n}^{b+1/n} d(\overline{\varphi}|F_\lambda\overline{\varphi}) \approx \langle\overline{\varphi}|F_{b+1/n}|\overline{\varphi}\rangle - \langle\overline{\varphi}|F_{a-1/n}|\overline{\varphi}\rangle.$$

By overspill, this holds for some $n \in {}^*\mathbb{N}$ such that $1/n = \varepsilon \geqslant \nu^{-1}$. By Proposition 11,

$$P^*(a-\varepsilon, b+\varepsilon] \approx (\varphi|E_b\varphi) - (\varphi|E_{a^-}\varphi),$$

whence

$$\mathrm{st}\,P^*(a-\varepsilon,b+\varepsilon]=(\varphi|f(A)\varphi)+(\varphi|E_a\varphi)-(\varphi|E_{a^-}\varphi).$$

The special case $a=b$ yields the equality

$$\mathrm{st}\,P^*(a-\varepsilon,b+\varepsilon]=(\varphi|E_a\varphi)-(\varphi|E_{a^-}\varphi).$$

On the other hand, from

$$^*\left[a-\frac{1}{n+1},\,b+\frac{1}{n+1}\right]\subset{}^*\left(a-\frac{1}{n},\,b+\frac{1}{n}\right]\subset{}^*\left[a-\frac{1}{n},\,b+\frac{1}{n}\right]$$

it follows that

$$\mathrm{pr}\,[a,b]=\inf_{n\in\mathbb{N}}\mathrm{st}\,P^*\left(a-\frac{1}{n},\,b+\frac{1}{n}\right]\approx\mathrm{st}P^*(a-\varepsilon,\,b+\varepsilon],$$

where

$$\mathrm{pr}\,[a,b]=(\varphi|f(A)\varphi)+(\varphi|E_a\varphi)-(\varphi|E_{a^-}\varphi).$$

Considering once more the special case $a=b$, we obtain

$$\mathrm{pr}\,\{a\}=(\varphi|E_a\varphi)-(\varphi|E_{a^-}\varphi),$$

and from the equality

$$\mathrm{pr}\,[a,b]=\mathrm{pr}\,(a,b]+\mathrm{pr}\,\{a\}$$

it follows that $\mathrm{pr}\,(a,b]=(\varphi|f(A)\varphi)$. □

When β is *measured upon a nonstandard state it would be meaningless to ask whether the standard measure pr coincides with the probability measure associated with α. Nevertheless, when a state is represented by a vector $u\in\mathcal{H}$ such that $u\approx\varphi$, with $\varphi\in\mathcal{H}_0$, the vector φ is necessarily unique, and it is readily seen that the function pr associated with β and u coincides with the probability measure associated with α and φ.

C. Time evolution

The Schrödinger equation in the hyperfinite model assumes the same form as in the standard theory: Time appears as a continuous parameter; to each value of t corresponds a vector u_t representing the state of the system at time t; time evolution is determined by a Hermitian operator H_h, in such a way that $u_t=e^{-itH_\mathrm{h}}u_0$ for all t. We must show that the predictions of the hyperfinite model regarding time evolution are consistent with those of the standard theory. If at time $t=0$ the system is in a standard state represented by $\varphi_0\in\mathcal{H}_0$, then, according to the standard theory, at time t the system is in a standard state represented by $\varphi_t=e^{-itH}\varphi_0$, where H is a self-adjoint operator in $\mathcal{H}_0$. According to the hyperfinite model, the state is represented by $\overline{\varphi_0}$ at $t=0$ and by $u_t=e^{-itH_\mathrm{h}}\overline{\varphi_0}$ at time t. We consider that $H_\mathrm{h}=\tilde{H}$. Consistency demands that at time t the vector u_t be "equivalent" to φ_t, in the sense that all standard-scale predictions concerning probabilities and further time evolution should be the same regardless of whether the state at time t is represented by u_t or by φ_t. To ensure this it suffices that $u_t\approx\overline{\varphi_t}$: In such a case, the standard probability associated with measurements upon u_t or φ_t are the same (Proposition 13 and subsequent considerations); as to the time evolution after time t, Proposition 14 below shows that it also leads to infinitely near states, since the hypothesis is $u_0\approx\overline{\varphi_0}$ rather than $u_0=\overline{\varphi_0}$.

Proposition 14: Let H be a self-adjoint operator in $\mathcal{H}_0$ and let $u_0\in\mathcal{H}$, $\varphi_0\in\mathcal{H}_0$. If $u_0\approx\varphi_0$, then

$$u_t \approx e^{-itH}\varphi_0$$

for every finite $t \in {}^*\mathbb{R}$, *where* $u_t = e^{-it\tilde{H}}u_0$.

Proof: Set $\varphi_t = e^{-itH}\varphi_0$, $u_t = e^{-it\tilde{H}}u_0$, and $v_t = \varphi_t - u_t$, for all $t \in {}^*\mathbb{R}$. Taking into account that e^{-itH} and $e^{-it\tilde{H}}$ are unitary operators on $\mathcal{H}_0$ and $\mathcal{H}$, respectively, we obtain

$$(v_t|v_t) = (\varphi_0|\varphi_0) + (u_0|u_0) - (e^{-it\tilde{H}}u_0|e^{-itH}\varphi_0) - (e^{-itH}\varphi_0|e^{-it\tilde{H}}u_0).$$

Hence,

$$\frac{d}{dt}(v_t|v_t) = (i\tilde{H}e^{-it\tilde{H}}u_0|e^{-itH}\varphi_0) + (e^{-it\tilde{H}}u_0|iHe^{-itH}\varphi_0) + (iHe^{-itH}\varphi_0|e^{-it\tilde{H}}u_0) + (e^{-itH}\varphi_0|i\tilde{H}e^{-it\tilde{H}}u_0).$$

We have

$$(\tilde{H}e^{-it\tilde{H}}u_0|e^{-itH}\varphi_0) = (P\tilde{H}e^{-it\tilde{H}}u_0|e^{-itH}\varphi_0) = (\tilde{H}e^{-it\tilde{H}}u_0|Pe^{-itH}\varphi_0) = (e^{-it\tilde{H}}u_0|\tilde{H}Pe^{-itH}\varphi_0).$$

Moreover, $(e^{-it\tilde{H}}u_0|He^{-itH}\varphi_0) = (e^{-it\tilde{H}}u_0|PHe^{-itH}\varphi_0)$. Let $\phi = e^{-itH}\varphi_0$. It follows from Propositions 10 and 3 that $\tilde{H}\overline{\phi} \approx H\phi \approx PH\phi$. Thus $\tilde{H}Pe^{-itH}\varphi_0 \approx PHe^{-itH}\varphi_0$, whence

$$(e^{-it\tilde{H}}u_0|\tilde{H}Pe^{-itH}\varphi_0) \approx (e^{-it\tilde{H}}u_0|PHe^{-itH}\varphi_0),$$

since the norm of $e^{-it\tilde{H}}u_0$ is finite. Thus, $(d/dt)(v_t|v_t) \approx 0$ for all $t \in {}^*\mathbb{R}$, whence

$$|(v_\tau|v_\tau) - (v_0|v_0)| = \left| \int_0^\tau \frac{d}{dt}(v_t|v_t)\, dt \right| < \tau\varepsilon$$

for every $\tau \in {}^*\mathbb{R}$ and every $\varepsilon \in \mathbb{R}^+$. For finite τ, this entails $(v_\tau|v_\tau) \approx (v_0|v_0)$. By hypothesis, $(v_0|v_0) \approx 0$. Therefore, for every finite $t \in {}^*\mathbb{R}$,

$$(v_t|v_t) \approx 0,$$

$$v_t \approx 0,$$

$$\varphi_t - u_t \approx 0.$$

This completes the proof. □

It is easy to see that the proof of Proposition 14 depends on the definition of $\tilde{H}$ only through the property $\tilde{H}\overline{\phi} \approx H\phi$ (where $\phi \in \mathcal{H}_0$); thus, the statement of Proposition 14 still holds when $\tilde{H}$ is replaced by any Hermitian operator H satisfying that condition.

V. THE MULTIDIMENSIONAL CASES

Until now we have considered the simple case of $\mathcal{H}_0 = L^2(\mathbb{R})$. It is not difficult to extend the previous results to the Hilbert space associated with a system constituted by a finite number of distinguishable particles.

When $\mathcal{H}_0 = \mathbb{C}^n$, with $n \in \mathbb{N}$, we define $\mathcal{H} = {}^*\mathbb{C}^n$. Thus, we can associate with $\varphi \in \mathcal{H}_0$ the vector $\overline{\varphi} = \varphi \in \mathcal{H}$. Every normalized vector of $\mathcal{H}$ is a finite superposition of standard vectors, with finite coefficients. Moreover, every such vector is near-standard: If $u = \Sigma_{j=1}^n c_j\varphi_j$, with $\varphi_1, \ldots, \varphi_n \in \mathcal{H}_0$ and $c_1, \ldots, c_n$ finite *complex numbers, then it is readily seen that $u \approx \varphi \in \mathcal{H}_0$, where $\varphi = \Sigma_{j=1}^n \mathrm{st}(c_j)\varphi_j$. Hence, the features of $\mathcal{H}$ are essentially the same as those of $\mathcal{H}_0$.

The space $\mathcal{H}_0$ in the general case is a tensor product $\otimes_i \mathcal{H}_i$ of a finite number of Hilbert spaces; moreover, one can assume that each $\mathcal{H}_i$ is either $L^2(\mathbb{R})$ or $\mathbb{C}$. [Recall that, for example, $L^2(\mathbb{R}^2) \cong L^2(\mathbb{R}) \otimes L^2(\mathbb{R})$.]

Denote by $\overline{\mathcal{H}_i}$ the space ${}^*\mathbb{C}$ (if $\mathcal{H}_i = \mathbb{C}$) or the space defined in Sec. II A (if $\mathcal{H}_i = L^2(\mathbb{R})$). For each i, the space $\mathcal{H}_i$ is a subspace of ${}^*\mathcal{H}_i$, and $\overline{\mathcal{H}_i}$ is also a subspace of ${}^*\mathcal{H}_i$. Hence, the tensor product $\otimes_i \overline{\mathcal{H}_i}$ is a subspace of ${}^*\mathcal{H}_0 = \otimes_i {}^*\mathcal{H}_i$, which we denote by $\mathcal{H}$. We consider henceforth the case of a tensor product of only two factors, for ease of notation.

The mapping $\varphi \mapsto \overline{\varphi}$ is defined by $\overline{\varphi} = P\varphi$, where P is the orthogonal projector of ${}^*\mathcal{H}_0$ onto $\mathcal{H}$. We can see that $P = P_1 \otimes P_2$, where each P_i is the orthogonal projector of ${}^*\mathcal{H}_i$ onto $\overline{\mathcal{H}_i}$: Let $\varphi = \varphi_1 \otimes \varphi_2$, with $\varphi_1 \in {}^*\mathcal{H}_1$ and $\varphi_2 \in {}^*\mathcal{H}_2$. Then,

$$\varphi = (\overline{\varphi_1} + \overline{\varphi_1}^{\perp}) \otimes (\overline{\varphi_2} + \overline{\varphi_2}^{\perp}) = (\overline{\varphi_1} \otimes \overline{\varphi_2}) + (\overline{\varphi_1} \otimes \overline{\varphi_2}^{\perp}) + (\overline{\varphi_1}^{\perp} \otimes \overline{\varphi_2}) + (\overline{\varphi_1}^{\perp} \otimes \overline{\varphi_2}^{\perp}).$$

Recalling the definition of inner product on a tensor product of Hilbert spaces,[15] we observe that the first term in the sum above is orthogonal to the other three terms—for example,

$$(\overline{\varphi_1} \otimes \overline{\varphi_2} | \overline{\varphi_1} \otimes \overline{\varphi_2}^{\perp}) = (\overline{\varphi_1} | \overline{\varphi_1})(\overline{\varphi_2} | \overline{\varphi_2}^{\perp}) = (\overline{\varphi_1} | \overline{\varphi_1}) \cdot 0.$$

Therefore, $P\varphi = \overline{\varphi_1} \otimes \overline{\varphi_2}$, and hence $P = P_1 \otimes P_2$.

The identity $\overline{\varphi} = \overline{\varphi_1} \otimes \overline{\varphi_2}$ entails $\overline{\varphi} \approx \varphi$, since $\overline{\varphi_1} \otimes \overline{\varphi_2}$ equals $\varphi_1 \otimes \varphi_2$ plus three infinitesimal terms, which are tensor products of infinitesimals by finite normed vectors. The relation $\overline{\varphi} \approx \varphi$ extends immediately to finite superpositions of vectors of the above form. Let now φ be a general element of $\mathcal{H}_0$. There exists a sequence $(\varphi_n)_{n \in \mathbb{N}}$ of vectors of $\mathcal{H}_0$ such that $\varphi_n \to \varphi$ and $P\varphi_n \approx \varphi_n$. Given $\varepsilon \in \mathbb{R}^+$, we have $\|\varphi - \varphi_n\| < \varepsilon$ for some $n \in \mathbb{N}$. On the other hand,

$$P\varphi - \varphi = P(\varphi - \varphi_n) + (P\varphi_n - \varphi_n) + (\varphi_n - \varphi).$$

Since $\|\varphi - \varphi_n\| < \varepsilon$, $\|P\| = 1$, and $\|P\varphi_n - \varphi_n\| \approx 0$, we obtain $\|P\varphi - \varphi\| \leqslant 3\varepsilon$, whence $P\varphi \approx \varphi$. Thus we see that Proposition 3 holds when $\mathcal{H}_0 = \mathcal{H}_1 \otimes \mathcal{H}_2$. Proposition 2 is a simple consequence thereof. Another obvious consequence is that the mapping $\varphi \mapsto \overline{\varphi}$ is one-to-one.

Given be a self-adjoint operator A on $\mathcal{H}_0 = \mathcal{H}_1 \otimes \mathcal{H}_2$, the definition of Sec. III B still makes sense: For $u \in \overline{\mathcal{H}_1} \otimes \overline{\mathcal{H}_2}$,

$$\tilde{A}u = P \int_{-\nu}^{\nu} \lambda \, dE_\lambda u.$$

Observe that the constant ν introduced in Sec. III B depends on the Hilbert space considered, but we may assume without loss of generality that ν is the same for the spaces $\mathcal{H}_0$, $\mathcal{H}_1$ and $\mathcal{H}_2$. Propositions 7–14 hold in the multidimensional case, as the proofs thereof depend on Propositions 2 and 3.

It remains to see how the operator representing an observable in a given system relates to the operator representing the same observable in a compound system (see Ref. 15): Given a self-adjoint operator A_1 in $\mathcal{H}_1$, consider the self-adjoint operator in $\mathcal{H}_1 \otimes \mathcal{H}_2$ defined by

$$B_1 = \int_{-\infty}^{+\infty} \lambda \, d(E_{1\lambda} \otimes 1),$$

where $(E_{1\lambda})_{\lambda\in\mathbb{R}}$ is the spectral family associated with A_1. (When A_1 is bounded, B_1 is simply the tensor product $A_1\otimes 1$.) We show that $\tilde{B}_1=\tilde{A}_1\otimes 1$; it suffices to prove that $\tilde{B}_1 u=(\tilde{A}_1\otimes 1)u$ for $u=u_1\otimes u_2$ with $u_1\in\overline{\mathcal{H}_1}$ and $u_2\in\overline{\mathcal{H}_2}$: Recalling the linearity and continuity properties of the tensor products of vectors and operators, we have

$$\begin{aligned}\tilde{B}_1 u &= P\int_{-\nu}^{\nu}\lambda\, d(E_{1\lambda}\otimes 1)(u_1\otimes u_2)=\int_{-\nu}^{\nu}\lambda(P_1\otimes P_2)\, d(E_{1\lambda}u_1\otimes u_2)=\int_{-\nu}^{\nu}\lambda\, d(P_1E_{1\lambda}u_1\otimes P_2u_2)\\ &=\int_{-\nu}^{\nu}\lambda\, d(P_1E_{1\lambda}u_1\otimes u_2)=\left(\int_{-\nu}^{\nu}\lambda\, d(P_1E_{1\lambda}u_1)\right)\otimes u_2=P_1\int_{-\nu}^{\nu}\lambda\, dE_{1\lambda}u_1\otimes u_2=\tilde{A}_1u_1\otimes u_2\\ &=(\tilde{A}_1\otimes 1)u.\end{aligned}$$

APPENDIX

We work in a superstructure $\langle V(\mathbb{R}),{}^*V(\mathbb{R}),*\rangle$. Elements of $V(\mathbb{R})$ are called *standard*, and are mapped by $*$ to elements of ${}^*V(\mathbb{R})$. As usual, we omit stars when denoting the images under $*$ of standard functions or binary operations and relations. Elements of standard sets are called *internal*, and noninternal sets in $V({}^*\mathbb{R})$ are called *external*. We recall that the prefix ''hyper'' is used as a substitute for ''$*$.''

A number $x\in{}^*\mathbb{R}$ is said *finite* if there exists $m\in\mathbb{N}$ such that $|x|<m$. Each finite $x\in{}^*\mathbb{R}$ can be uniquely decomposed as $x=r+\varepsilon$, where $r\in\mathbb{R}$ and ε is infinitesimal; r is called the standard part of x and is denoted by $\mathrm{st}(x)$. If $x,y\in{}^*\mathbb{R}$ are such that $x-y$ is infinitesimal, then we say that x is infinitely close to y, and write $x\approx y$. More generally, if x and y are in a *Hilbert space we say that $x\approx y$ when $\|x-y\|\approx 0$. We write $x\lesssim y$ whenever $x<y$ or $x\approx y$.

Recall that a family of sets satisfies the finite intersection property if all finite intersections of elements of the family are nonempty. We assume the superstructure $\langle V(\mathbb{R}),{}^*V(\mathbb{R}),*\rangle$ to be saturated, i.e., given any family $\mathcal{A}$ of internal sets with cardinality less than the cardinality of $V(\mathbb{R})$, if $\mathcal{A}$ has the finite intersection property, then $\cap\mathcal{A}\neq\varnothing$.

Dissipative Schrödinger–Poisson systems

M. Baro,[a] H.-Chr. Kaiser, H. Neidhardt, and J. Rehberg
Weierstrass Institute for Applied Analysis and Stochastics, Mohrenstr. 39, D-10117 Berlin, Germany

(Received 30 May 2003; accepted 18 September 2003)

We deal with a stationary, dissipative Schrödinger–Poisson system which allows for a current flow through an open, spatially one-dimensional quantum system determined by a dissipative Schrödinger operator. This dissipative Schrödinger operator can be regarded as a pseudo-Hamiltonian of the corresponding open quantum system. The (self-adjoint) dilation of the dissipative operator serves as a quasi-Hamiltonian of the system which is used to define physical quantities such as density and current for the open quantum system. The thus defined charge density in its dependence on the electrostatic potential is the nonlinear term in Poisson's equation. We prove that the dissipative Schrödinger–Poisson system always admits a solution and all solutions are included in a ball the radius of which depends only on the data of the problem. © *2004 American Institute of Physics.*
[DOI: 10.1063/1.1628385]

I. INTRODUCTION

Schrödinger–Poisson systems describe, e.g., the nonlinear interaction between an electric field and charged carriers, electrons and holes in a semiconductor device, within this electric field (see, e.g., Refs. 28, 21, 22, and 10). In the form considered in this article a Schrödinger–Poisson system can be regarded as a nonlinear Poisson equation

$$-\nabla\cdot(\epsilon\nabla\varphi)=q(C+\mathcal{N}_+(V_+)-\mathcal{N}_-(V_-)),\quad V_\pm=V_0^\pm\pm q\varphi, \tag{1}$$

where φ denotes the electrostatic potential and $V_0^\pm$ are prescribed potentials, the band edge offsets; ϵ is the position-dependent permittivity tensor; q is the magnitude of the elementary charge; and C is a position-dependent density of fixed charges (ionized dopants). $\mathcal{N}_\pm$ are operators which associate a density of positive and negative charges (electrons and holes) to a potential which essentially is the electrostatic potential. We will regard a system confined to a bounded spatial domain Ω and (1) has to be supplemented by boundary conditions modeling the way the electrical field inside Ω is contacted to its environment (see Refs. 28 and 10).

In the framework of van Roosbroeck's system which describes the motion of electrons and holes within a semiconductor device due to drift and diffusion, the nonlinear Poisson equation (1) has been regarded with Nemytzkii operators $\mathcal{N}_\pm$ of the form

$$\mathcal{N}_\pm(V)(\mathbf{x})=c_\pm(\mathbf{x})\mathfrak{F}\left(\frac{1}{T}(q\phi_\pm(\mathbf{x})\pm V(\mathbf{x}))\right) \tag{2}$$

(see Refs. 28 and 10); Boltzmann's constant is scaled to 1. In this context we assume that the temperature T, the density of states $c_\pm$, and the electrochemical potentials $\phi_\pm$ are given functions and $\mathfrak{F}$ is a statistical distribution function, e.g., the exponential function

$$\mathfrak{F}(\zeta)=\exp(\zeta) \tag{3}$$

[a]Supported by the DFG research center "Mathematics for key technologies" (FZT 86) in Berlin.

or Fermi's integral to the index $\frac{1}{2}$

$$\mathfrak{F}(\zeta)=\frac{2}{\sqrt{\pi}}\int_0^\infty d\xi\,\frac{\sqrt{\xi}}{1+\exp(\xi-\zeta)},\quad \zeta\in\mathbb{R}. \tag{4}$$

With Boltzmann and Fermi–Dirac statistics, (3) and (4), respectively, (1), (2), are an operator equation in a Sobolev space which is determined by the boundary conditions imposed on the electrostatic potential. The nonlinear Poisson operator involved is strongly monotone and boundedly Lipschitz continuous, hence, the nonlinear Poisson equation has a unique solution. Obviously, this result does neither depend on the Nemytzkii structure (2) of the operators $\mathcal{N}_\pm$ nor the special functions (3), (4). If $\mathcal{N}_\pm$ are anti-monotone and boundedly Lipschitz continuous operators, then the nonlinear Poisson equation (1) has a unique solution (see, e.g., Ref. 11, Chap. III.2.1).

Statistical distribution functions like (3), (4) are based upon the assumption that the carriers of charge, electrons, and holes can move freely in all space directions. However, in nanostructured materials (quantum-wells, -wires, and -dots) this model of a three-dimensional electron-hole gas is not adequate any more. Instead the densities of charge carriers have to be directly computed by quantum mechanical expressions from the spectral representation of an appropriate Hamilton operator (see, e.g., Refs. 6, 29, 10, and 23).

Let us first consider the case of closed quantum systems situated in the bounded domain Ω for the system of positively and negatively charged carriers. These systems can be described by one-electron Hamiltonians in effective mass approximation (Ben–Daniel–Duke form) with an effective potential V:

$$H_\pm(V)\psi=-\tfrac{1}{2}\nabla\cdot(m_\pm^{-1}\nabla\psi)+V\psi, \tag{5}$$

where $\mathrm{dom}(H_\pm)$ is a Sobolev space which is determined by self-adjoint (homogeneous) boundary conditions, including mixed ones, on $\partial\Omega$. $m_\pm$ denotes the position-dependent effective mass tensor of holes and electrons, respectively; $\hbar$ is scaled to 1. In general V is a Kohn–Sham potential (see e.g., Refs. 13, 14, and 27 and the references cited there). The collective behavior of holes and electrons is described by density matrices $\varrho_\pm$. In this article we investigate stationary Schrödinger–Poisson systems, i.e., we regard density matrices which are steady states. If there are equilibrium distribution functions $f_\pm$ such that the operators

$$\varrho_\pm(V)=f_\pm(H_\pm(V))$$

are self-adjoint, non-negative, and nuclear, i.e., density matrices for all admissible potentials V, then the densities $\mathcal{N}_\pm(V)$ of positively and negatively charged carriers, respectively, are given by the Radon–Nikodým derivative of the absolutely continuous measures (with respect to the Lebesgue measure)

$$\int_\omega d\mathbf{x}\,\mathcal{N}_\pm(V)(\mathbf{x})=\mathrm{tr}(f_\pm(H_\pm(V))\chi_\omega), \tag{6}$$

respectively, where χ_ω denotes the indicator function of a set $\omega\subset\Omega$. If the functions $f_\pm$ are positive, strictly monotone, and sufficiently rapidly decreasing, then one can prove that the corresponding nonlinear Poisson equation (1) with (6) has a unique solution (see Refs. 5, 24, and 25), even for heterogeneous material compositions and mixed Dirichlet and Neumann boundary conditions for Schrödinger's operator (see Refs. 13 and 14). If the Schrödinger operators (5) include in addition to the electrostatic potential an exchange-correlation potential, then one still obtains the existence of solutions of the corresponding Schrödinger–Poisson system (see Refs. 13 and 14).

Up to this point we have supposed that the systems of positively and negatively charged carriers are in equilibrium, i.e., the corresponding quantum systems on the bounded domain occupied by the device are closed. In order to describe semiconductor devices operating far from equilibrium, we pass to open quantum systems on the bounded device domain (see also Refs. 9, 4,

and 26). In Refs. 13 and 14 we proposed non-self-adjoint boundary conditions for the Schrödinger operators (5) which are induced by a potential flow acting on the spatial boundary of the open quantum system; the spectral theory for the associated non-self-adjoint Schrödinger-type operators has been developed in Ref. 15. For these non-self-adjoint Schrödinger-type operators the notion of carrier density as sketched above is not valid anymore. However, if the boundary conditions are such that the operator becomes dissipative (see Ref. 15), then one can use the dilation theory for dissipative operators to overcome difficulties arising from the non-self-adjointness. Indeed, the dissipative Schrödinger-type operator can be regarded as a pseudo-Hamiltonian (see Ref. 7, Chap. 4.1) and its dilation, i.e., minimal self-adjoint extension, as a quasi-Hamiltonian. The quasi-Hamiltonian describes a closed quantum system containing the original open one, which is, additionally, in some sense minimal. Then steady states, carrier and current densities can be defined with respect to that larger closed system but have in fact the same meaning as above. In particular, the density matrix describes now the collective behavior of electrons and holes in the larger closed system and not only in the open system. Based upon an explicit representation of the dilation (see Ref. 16), we have established the notion of carrier and current density for this kind of non-self-adjoint Schrödinger-type operator in the spatially one-dimensional case (see Ref. 17). We prove in this article that the corresponding stationary dissipative Schrödinger–Poisson system (see Problem 4.4 for the rigorous setup of the problem), i.e., the nonlinear Poisson equation with the charged carrier densities associated with the quasi-Hamiltonian of some dissipative Schrödinger-type operators, always has a solution in the spatially one-dimensional case. However, we do not get uniqueness of solutions.

At first glance the dissipative Schrödinger–Poisson system seems to be an artificial model with little reference to applications in science. This is not so, however, as the following closer look reveals. In Ref. 1 we have investigated the widely used Schrödinger–Poisson system with quantum transmitting boundary conditions (see also Refs. 9 and 4). The quantum transmitting Schrödinger–Poisson system decomposes into dissipative Schrödinger–Poisson systems (see Ref. 1). More precisely, there is a dissipative Schrödinger–Poisson system affiliated to each energy on the continuous scale of the quantum transmitting Schrödinger–Poisson system. Thus the boundary coefficients of the Schrödinger operator depend on the energy, which leads to a family of dissipative Schrödinger-type operators labeled by the energy. The boundary conditions for Schrödinger's operator with respect to which we investigate the Schrödinger–Poisson system in this article serve as a single energy approximation of a corresponding Schrödinger–Poisson system with quantum transmitting boundary conditions (see Ref. 1).

We note that dissipative Schrödinger–Poisson systems also have been considered in a nonstationary setup (see Refs. 12 and 19). In Ref. 2 a dissipative Schrödinger-type operator has been investigated which includes additional terms modeling generation and recombination of particles.

The article is organized as follows: In Sec. II we rigorously define the Schrödinger-type operators (see also Ref. 15), briefly introduce their dilations and generalized eigenfunction expansions (see also Ref. 16), and recall the definition of the carrier density given in Ref. 17. In Sec. III we introduce, following Ref. 13, the (nonlinear) carrier density operator assigning to the potential in a Schrödinger operator the corresponding carrier density. The carrier density operator is continuous; the proof is based upon a relation between the generalized Fourier transform and the Lax–Phillips wave operator. Section IV deals with the rigorous setup of the dissipative Schrödinger–Poisson system, *a priori* estimates, and, finally, the existence of solutions.

II. NOTIONS AND DEFINITIONS

In this section we provide essential notions which are needed in the next sections to investigate the carrier density operator and to give a precise definition of the dissipative Schrödinger–Poisson system and its solution.

A. Notations

The Schrödinger–Poisson system will be regarded on the interval $\Omega=(a,b)$. By L^1 we denote the space of real-valued, Lebesgue integrable functions on the interval $[a,b]$. The space of

real-valued, Lebesgue measurable, and essentially bounded functions on $[a,b]$ will be denoted by L^∞. In order to avoid confusion we denote the space of complex-valued, square integrable functions on the interval $[a,b]$ by $\mathfrak{H}$ and write $(\cdot,\cdot)$ for the scalar product in $\mathfrak{H}$. Furthermore, we denote by $W^{1,2}$ the usual complex Sobolev space $W^{1,2}(a,b)$ and by $C[a,b]$ the space of complex-valued, continuous functions on $[a,b]$.

If $\mathcal{H}_1,\mathcal{H}_2$ are Hilbert spaces, then $\mathfrak{L}_1(\mathcal{H}_1;\mathcal{H}_2)$ denotes the space of nuclear operators from $\mathcal{H}_1$ into $\mathcal{H}_2$ and $\mathfrak{L}_2(\mathcal{H}_1;\mathcal{H}_2)$ denotes the space of Hilbert Schmidt operators, each with its canonic norm. We abbreviate $\mathfrak{L}_1(\mathcal{H};\mathcal{H})=\mathfrak{L}_1(\mathcal{H})$ and $\mathfrak{L}_2(\mathcal{H};\mathcal{H})=\mathfrak{L}_2(\mathcal{H})$. For Banach spaces X and Y, we denote by $\mathfrak{B}(X;Y)$ the space of all linear, continuous operators from X into Y. If $X=Y$, we write $\mathfrak{B}(X)$.

B. Poisson's equation

One ingredient of the Schrödinger–Poisson system is, of course, Poisson's equation which determines the electrostatic potential φ on the interval (a,b):

$$-\frac{d}{dx}\left(\epsilon(x)\frac{d}{dx}\varphi(x)\right)=q(C(x)+u^+(x)-u^-(x)),\quad x\in[a,b], \tag{7}$$

where u^+ and u^- are the densities of holes and electrons, respectively, q is the magnitude of the elementary charge, C is the doping profile of the semiconductor device, and ϵ is the dielectric permittivity. We regard the following mixed boundary conditions for Poisson's equation (7),

$$\begin{aligned}\varphi(x)&=\varphi_\Gamma(x),\quad \text{if } x\in\Gamma,\\ -\epsilon(x)\frac{d}{dx}\varphi(x)&=k(x)(\varphi(x)-\varphi_\Gamma(x)),\quad \text{if } x\in\{a,b\}\backslash\Gamma,\end{aligned} \tag{8}$$

where $\Gamma\subseteq\{a,b\}$. The function φ_Γ, defined on $[a,b]$, represents the boundary values given on Γ and the inhomogeneous boundary conditions of third kind on $\{a,b\}\backslash\Gamma$. The function $k\geqslant 0$ is defined on $\{a,b\}$. These boundary conditions describe the coupling of the semiconductor device to its environment. In particular, the Dirichlet boundary part represents Ohmic (metal) contacts of the semiconductor device (see, e.g., Refs. 28 and 10).

C. Schrödinger-type operators

The densities u^+ and u^- of holes and electrons appearing on the right-hand side of Poisson's equation (7) are determined by density matrices ϱ_+ and ϱ_- on the one hand and the spectral properties of Schrödinger-type operators H_+ and H_- on the other. Following the proposal in Ref. 13 we consider for each species (holes and electrons) a non-self-adjoint Schrödinger-type operator $H(V)$ (we drop here the index "+" and "−") on the Hilbert space $\mathfrak{H}$. It is defined by

$$\mathrm{dom}(H(V))=\left\{ g\in W^{1,2}:\ \begin{array}{l}\dfrac{1}{m}g'\in W^{1,2},\\ \dfrac{1}{2m(a)}g'(a)=-\kappa_a g(a),\\ \dfrac{1}{2m(b)}g'(b)=\kappa_b g(b)\end{array}\right\} \tag{9}$$

and

$$(H(V)g)(x)=(l(g))(x),\quad g\in\mathrm{dom}(H(V)), \tag{10}$$

where

$$(l(g))(x) := -\frac{1}{2}\frac{d}{dx}\frac{1}{m(x)}\frac{d}{dx}g(x) + V(x)g(x) \tag{11}$$

(see Refs. 15 and 16). With respect to the coefficients in (9)–(11) we assume the function m, i.e., the effective mass, is positive and obeys $m, 1/m \in L^\infty$; the boundary coefficients κ_a, κ_b are from the upper half-plane $\mathbb{C}_+ := \{z \in \mathbb{C} : \Im(z) > 0\}$. Furthermore, it is assumed hereafter that the occurring potentials V are from L^∞. We already know the following about the operators $H(V)$.

Proposition 2.1: (See Ref. 15, Sec. 5, in particular Theorem 5.2.) The operator $H(V)$ is maximal dissipative and completely non-self-adjoint. The spectrum of $H(V)$ consists of isolated eigenvalues in the lower half-plane with the only accumulation point at infinity. Since the operator $H(V)$ is completely non-self-adjoint there do not exist real eigenvalues.

In order to prove resolvent estimates for the Schrödinger-type operator $H(V)$ we regard the quadratic form associated with $H(V)$ as a perturbation of a quadratic form which is independent of the potential V and we derive relative bounds with respect to the latter. To this end we introduce the sesquilinear form $\mathfrak{h}_0$,

$$\mathfrak{h}_0[g,f] := \int_a^b dx \left\{ \frac{1}{2m(x)} g'(x)\overline{f'(x)} + g(x)\overline{f(x)} \right\}, \quad f,g \in \mathrm{dom}(\mathfrak{h}_0) = W^{1,2}$$

(see Ref. 15). The form $\mathfrak{h}_0$ is symmetric and non-negative. Since $\mathfrak{h}_0$ is closed there is a unique self-adjoint operator H_0 with the representation

$$\mathfrak{h}_0[g,f] = (H_0 g, f), \quad g \in \mathrm{dom}(H_0), \quad f \in \mathrm{dom}(\mathfrak{h}_0). \tag{12}$$

This operator H_0 can be explicitly described by (9)–(11) specifying $\kappa_a = \kappa_b = 0$ and $V \equiv 1$. Obviously, there is $H_0 \geqslant I$. In order to obtain further properties of the operators $H(V)$ we introduce certain quadratic forms in terms of which $H(V)$ can be understood as a (form) perturbation of H_0. We start with the boundary form $\mathfrak{t}_{\partial\Omega}$ defined by

$$\mathfrak{t}_{\partial\Omega}[g,f] := -\kappa_a g(a)\overline{f(a)} - \kappa_b g(b)\overline{f(b)}, \quad f,g \in \mathrm{dom}(\mathfrak{t}_{\partial\Omega}) = W^{1,2}.$$

Next we define the potential form $\mathfrak{t}_V$,

$$\mathfrak{t}_V[g,f] := \int_a^b dx\, V(x) g(x)\overline{f(x)}, \quad f,g \in \mathrm{dom}(\mathfrak{t}_V) = W^{1,2},$$

and the form sum

$$\mathfrak{t}_{\partial\Omega,V} := \mathfrak{t}_{\partial\Omega} + \mathfrak{t}_V, \quad \mathrm{dom}(\mathfrak{t}_{\partial\Omega,V}) = W^{1,2}.$$

As usual, we will denote the corresponding quadratic forms by the same symbols with a single argument. In the following we will supply relative form estimates for $\mathfrak{t}_{\partial\Omega}$, $\mathfrak{t}_V$, and $\mathfrak{t}_{\partial\Omega,V}$ with respect to $\mathfrak{h}_0$.

Proposition 2.2: (See Ref. 15, Sec. 2, in particular 2.14–18.) The quadratic form $\mathfrak{t}_{\partial\Omega,V}$ is infinitesimally small with respect to $\mathfrak{h}_0$, i.e., there is a constant c such that for each $\delta > 0$

$$|\mathfrak{t}_{\partial\Omega,V}[f]| \leqslant \delta \mathfrak{h}_0[f] + \left(\frac{c}{\delta} + \|V\|_{L^\infty} \right) \|f\|_{\mathfrak{H}}^2. \tag{13}$$

Hence, the quadratic form corresponding to the sesquilinear form $\mathfrak{h}_V$ given by

$$\mathfrak{h}_V[g,f] := \mathfrak{h}_0[g,f] + \mathfrak{t}_{\partial\Omega,V}[g,f] - (g,f) = \mathfrak{h}_0[g,f] + \mathfrak{t}_{\partial\Omega,V-1}[g,f], \quad f,g \in \mathrm{dom}(\mathfrak{h}_V) = W^{1,2},$$

is closed and sectorial. Consequently, there is a (unique) maximal sectorial operator $H(V)$ *such that the representation* $\mathfrak{h}_V[g,f]=(H(V)g,f)$ *is valid for* $g\in\mathrm{dom}(H(V))$ *and* $f\in\mathrm{dom}(\mathfrak{h}_V)$. *In particular, the thus defined operator* $H(V)$ *coincides with the operator given by (9)–(11).*

Remark 2.3: The constant c in (13) can be specified as

$$c:=\frac{(|\kappa_a|+|\kappa_b|)^2\mathfrak{g}_1^4\tilde{m}}{2},\quad \tilde{m}:=\max\{1,\|m\|_{L^\infty}\},\tag{14}$$

where $\mathfrak{g}_1$ *is the Gagliardo–Nirenberg constant, i.e.,*

$$\|\psi\|_{C[a,b]}\leqslant\mathfrak{g}_1\|\psi\|_{W^{1,2}}^{1/2}\|\psi\|_{\mathfrak{H}}^{1/2}\quad\text{for all}\quad\psi\in W^{1,2}.\tag{15}$$

Next we introduce an operator $B_\mu(V)$ in order to give a factorization of the resolvent of $H(V)$ (see Lemma 2.5). For $V\in L^\infty$ and $\mu\geqslant 0$ the sesquilinear form

$$b_\mu(V)[f,g]:=\mathfrak{t}_{\partial\Omega,V-1}[(H_0+\mu)^{-1/2}f,(H_0+\mu)^{-1/2}g],\quad f,g\in\mathrm{dom}(b_\mu(V))=\mathfrak{H},$$

defines a bounded operator $B_\mu(V)$ on $\mathfrak{H}$. For the following considerations the norm of the operator $B_\mu(V)$ is of fundamental interest.

Lemma 2.4: If $V\in L^\infty$ *and* $\mu\geqslant 0$, *then*

$$\|B_\mu(V)\|_{\mathfrak{B}(\mathfrak{H})}\leqslant\delta+\left(\frac{c}{\delta}+1+\|V\|_{L^\infty}\right)\frac{1}{1+\mu}\quad\text{for all}\quad\delta\in(0,1)\tag{16}$$

with c according to (14). In particular, if

$$\mu\geqslant 4c+2+2\|V\|_{L^\infty},\tag{17}$$

then $\|B_\mu(V)\|_{\mathfrak{B}(\mathfrak{H})}<1$ *and*

$$\|(I+B_\mu(V))^{-1}\|_{\mathfrak{B}(\mathfrak{H})}\leqslant\frac{2(\mu+1)}{\mu-1-4c-2\|V\|_{L^\infty}}.\tag{18}$$

Proof: Equation (16) follows from (13). Setting $\delta=\frac{1}{2}$ we get from (16) and (17) that $\|B_\mu(V)\|_{\mathfrak{B}(\mathfrak{H})}<1$. The last assertion follows from (16), (17) and the representation of the resolvent by Neumann's series. □

Lemma 2.5: If $V\in L^\infty$ *and* $\mu\geqslant 4c+2+2\|V\|_{L^\infty}$ *with c given by (14), then*

$$(H(V)+\mu)^{-1}=(H_0+\mu)^{-1/2}(I+B_\mu(V))^{-1}(H_0+\mu)^{-1/2}.\tag{19}$$

Proof: For any $f,g\in W^{1,2}$ and $\mu>0$ one has

$$\mathfrak{h}_V[g,f]+\mu(g,f)=((H_0+\mu)^{1/2}g,(H_0+\mu)^{1/2}f)+\mathfrak{t}_{\partial\Omega,V-1}[g,f],$$

which yields

$$\mathfrak{h}_V[g,f]+\mu(g,f)=((I+B_\mu(V))(H_0+\mu)^{1/2}g,(H_0+\mu)^{1/2}f).$$

From Lemma 2.4 we get $\|B_\mu(V)\|_{\mathfrak{B}(\mathfrak{H})}<1$. Hence, the inverse operator of $I+B_\mu(V)$ exists and is bounded. Therefore, the definition

$$R_\mu(V):=(H_0+\mu)^{-1/2}(I+B_\mu(V))^{-1}(H_0+\mu)^{-1/2}$$

is justified. Since $R_\mu(V)g\in W^{1,2}$ for all $g\in\mathfrak{H}$ we have

$$\mathfrak{h}_V[R_\mu(V)g,f]+\mu(R_\mu(V)g,f)=((H_0+\mu)^{1/2}R_\mu(V)g,(H_0+\mu)^{1/2}f+\mathfrak{t}_{\partial\Omega,V-1}[R_\mu(V)g,f],$$
$$g\in\mathfrak{H},\quad f\in W^{1,2}.$$

Consequently, we obtain

$$\mathfrak{h}_V[R_\mu(V)g,f]+\mu(R_\mu(V)g,f)=((I+B_\mu(V))^{-1}(H_0+\mu)^{-1/2}g,(H_0+\mu)^{1/2}f)$$
$$+(B_\mu(V)(I+B_\mu(V))^{-1}(H_0+\mu)^{-1/2}g,(H_0+\mu)^{1/2}f),$$

which shows that

$$\mathfrak{h}_V[R_\mu(V)g,f]+\mu(R_\mu(V)g,f)=(g,f),\quad g\in\mathfrak{H},\quad f\in W^{1,2}. \tag{20}$$

The relation (20) implies that $R_\mu(V)g\in\mathrm{dom}(H(V))$ and $(H(V)+\mu)R_\mu(V)g=g$ for any $g\in\mathfrak{H}$. Similarly, one proves that $R_\mu(V)(H(V)+\mu)g=g$ for any $g\in\mathrm{dom}(H(V))$. Hence, $(H(V)+\mu)^{-1}=R_\mu(V)$. □

D. Dilations

In the conceptual framework of quantum mechanics, physical quantities, such as the densities of electrons and holes regarded here, are derived from a Hamiltonian, i.e., a self-adjoint operator on some Hilbert space. This procedure cannot be directly applied to open quantum systems. Instead we proceed as follows: first we embed the open quantum system into an appropriate closed one and define physical quantities with respect to the closed system; finally one makes some ''projection'' onto the open (sub-)system (see Remark 2.6). This section deals with the construction of the covering closed system. In Sec. II C we have stated the spectral properties of the (completely non-self-adjoint) pseudo-Hamiltonian $H(V)$. Based upon these results we will now derive a Hamiltonian on an appropriate Hilbert space which serves as a quasi-Hamiltonian for the open quantum system under consideration. Since $H(V)$ is a maximal dissipative operator there is a larger Hilbert space $\mathfrak{K}\supseteq\mathfrak{H}$ and a self-adjoint operator $K(V)$ on $\mathfrak{K}$ such that

$$P_{\mathfrak{H}}^{\mathfrak{K}}(K(V)-z)^{-1}|\mathfrak{H}=(H(V)-z)^{-1},\quad \Im(z)>0, \tag{21}$$

where $P_{\mathfrak{H}}^{\mathfrak{K}}$ denotes the projection from $\mathfrak{K}$ onto $\mathfrak{H}$ (see Ref. 8). The operator $K(V)$ is called a self-adjoint dilation of the maximal dissipative operator $H(V)$. Obviously, from the condition (21) one gets

$$P_{\mathfrak{H}}^{\mathfrak{K}}(K(V)-z)^{-1}|\mathfrak{H}=(H(V)^*-z)^{-1},\quad \Im(z)<0.$$

If the condition

$$\operatorname*{clospan}_{z\in\mathbb{C}\setminus\mathbb{R}}(K(V)-z)^{-1}\mathfrak{H}=\mathfrak{K}$$

is satisfied, then $K(V)$ is called a minimal self-adjoint dilation of $H(V)$. Minimal self-adjoint dilations of maximal dissipative operators are determined up to an isomorphism, that means, all minimal self-adjoint dilations are unitarily equivalent.

A special feature of the spatially one-dimensional case is that the resolvent of the dilation $K(V)$ of $H(V)$ can be described by the characteristic function $\Theta_{H(V)}(z)$ of $H(V)$ (see Ref. 8). The definition of the characteristic function relies on the boundary operators $T(V)(z):\mathfrak{H}\to\mathbb{C}^2$, $z\in\mathrm{res}(H(V))$, and $T_*(V)(z):\mathfrak{H}\to\mathbb{C}^2$, $z\in\mathrm{res}(H(V)^*)$ which we will introduce now. To that end let us define the operator

$$\alpha:\mathfrak{H}\to\mathbb{C}^2,\quad \alpha f=\begin{pmatrix}\alpha_b f(b)\\ -\alpha_a f(a)\end{pmatrix},\quad f\in\mathrm{dom}(\alpha)=C[a,b],$$

where

$$\kappa_a = q_a + \frac{i}{2}\alpha_a^2 \quad \text{and} \quad \kappa_b = q_b + \frac{i}{2}\alpha_b^2, \quad q_a, q_b \in \mathbb{R}, \quad \alpha_a, \alpha_b > 0.$$

Now the boundary operators are given by

$$T(V)(z)f := \alpha(H(V) - z)^{-1}f, \quad T_*(V)(z)f := \alpha(H(V)^* - z)^{-1}f, \quad f \in \mathfrak{H}. \tag{22}$$

The characteristic function $\Theta_{H(V)}$ of the maximal dissipative operator $H(V)$ is a two-by-two matrix-valued function which satisfies the relation

$$\Theta_{H(V)}(z)T(V)(z)f = T_*(V)(z)f, \quad z \in \mathrm{res}(H(V)) \cap \mathrm{res}(H(V)^*), \quad f \in \mathfrak{H}.$$

It is a holomorphic function on $\mathrm{res}(H(V)) \cap \mathrm{res}(H(V)^*)$ and contractive on $\mathbb{C}_- \cup \mathbb{R}$, i.e.,

$$\|\Theta_{H(V)}(z)\|_{\mathfrak{B}(\mathbb{C}^2)} \leqslant 1 \quad \text{for } z \in \mathbb{C}_- \cup \mathbb{R}.$$

The characteristic function of $H(V)$ is given by

$$\Theta_{H(V)}(z) = I_{\mathbb{C}^2} - i\alpha T(V)(\overline{z})^*$$

(see Ref. 16). We now explicitly describe the resolvent of the minimal self-adjoint dilation $K(V)$ of the maximal dissipative operator $H(V)$ (see Ref. 16). The dilation space $\mathfrak{K}$ is given by

$$\mathfrak{K} = \mathcal{D}_- \oplus \mathfrak{H} \oplus \mathcal{D}_+, \tag{23}$$

where $\mathcal{D}_\pm := L^2(\mathbb{R}_\pm, \mathbb{C}^2)$. In accordance with (23) we write $\vec{f} = (f_-, f, f_+) \in \mathfrak{K}$. The resolvent of $K(V)$ is given by

$$(K(V) - z)^{-1}(f_-, f, f_+) = \begin{cases} (g_-, g, g_+) & \text{if } \Im(z) > 0, \\ (h_-, h, h_+) & \text{if } \Im(z) < 0, \end{cases} \tag{24}$$

where

$$g_-(x) = i\int_{-\infty}^{x} dy\, e^{i(x-y)z} f_-(y), \quad x \in \mathbb{R}_-,$$

$$g(x) = ((H(V) - z)^{-1}f)(x) + i\left(T_*(V)(\overline{z})^* \int_{-\infty}^{0} dy\, e^{-iyz} f_-(y)\right)(x), \quad x \in (a,b),$$

$$g_+(x) = i\int_0^x dy\, e^{i(x-y)z} f_+(y) + ie^{izx}(T(V)(z)f)(x) + i\Theta_{H(V)}(\overline{z})^* \int_{-\infty}^{0} dy\, e^{i(x-y)z} f_-(y),$$

$$x \in \mathbb{R}_+,$$

and

$$h_-(x) = -i\int_x^0 dy\, e^{i(x-y)z} f_-(y) - ie^{izx}(T_*(V)(z)f)(x) - i\Theta_{H(V)}(z)\int_0^\infty dy\, e^{i(x-y)z} f_+(y),$$

$$x \in \mathbb{R}_-,$$

$$h(x) = ((H(V)^* - z)^{-1}f)(x) - i\left(T(V)(\overline{z})^* \int_0^\infty dy\, e^{-iyz} f_+(y)\right)(x), \quad x \in (a,b),$$

$$h_+(x) = -i\int_x^\infty dy\, e^{i(x-y)z} f_+(y), \quad x \in \mathbb{R}_+ .$$

The self-adjoint operator $K(V)$ is absolutely continuous and its spectrum coincides with the real axis, i.e., $\mathrm{spec}(K(V)) = \mathbb{R}$. The multiplicity of its spectrum is two. For more details, see Ref. 16.

E. Eigenfunction expansions

We are interested in an explicit expression for the densities of electrons and holes. For a spatially one-dimensional open quantum system with a quantum transmitting boundary[9] the particle density can be expressed in terms of a density matrix, describing the collective behavior of the particles, and of certain generalized eigenfunctions of a Schrödinger operator (see Refs. 4 and 1). An analogous concept is on the agenda of this article (see Sec. II F). In pursuit of this goal we recall the properties of the generalized eigenfunctions of the quasi-Hamiltonian $K(V)$ which has been defined in Sec. II D. The generalized eigenfunctions $\vec{\psi}(V)(\cdot,\lambda,\tau)$, $\lambda \in \mathbb{R}$, $\tau = a, b$, of $K(V)$ are given by (see Ref. 16)

$$\vec{\psi}(V)(x,\lambda,\tau) := \begin{cases} \psi_-(V)(x,\lambda,\tau) := \dfrac{1}{\sqrt{2\pi}} e^{ix\lambda} e_\tau, & x \in \mathbb{R}_- , \\ \psi(V)(x,\lambda,\tau) := \dfrac{1}{\sqrt{2\pi}} ((T_*(V)(\lambda))^* e_\tau)(x), & x \in (a,b), \\ \psi_+(V)(x,\lambda,\tau) := \dfrac{1}{\sqrt{2\pi}} e^{ix\lambda} \Theta_{H(V)}(\lambda)^* e_\tau, & x \in \mathbb{R}_+ , \end{cases}$$

where the argument x has to be interpreted in the sense of (23) and

$$e_b := \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad e_a := \begin{pmatrix} 0 \\ 1 \end{pmatrix}.$$

The generalized eigenfunctions of $K(V)$ are orthogonal (see Ref. 16), and their linear span (modulo the scalar, continuous, compactly supported functions) is dense in $\mathfrak{K}$. We note that the generalized eigenfunctions $\vec{\psi}(V)(\cdot,\lambda,\tau)$ are usually called the incoming eigenfunctions. Using the incoming eigenfunctions one defines a transformation $\Phi(V): \mathfrak{K} \to L^2(\mathbb{R},\mathbb{C}^2)$

$$(\Phi(V)\vec{g})(\lambda) =: \hat{g}(\lambda) = \begin{pmatrix} \hat{g}^b(\lambda) \\ \hat{g}^a(\lambda) \end{pmatrix},$$

where

$$\hat{g}^\tau(\lambda) := \int_{\mathbb{R}_-} dx \langle g_-(x), \psi_-(V)(x,\lambda,\tau)\rangle_{\mathbb{C}^2} + \int_a^b dx\, g(x)\overline{\psi(V)(x,\lambda,\tau)} + \int_{\mathbb{R}_+} dx \langle g_+(x), \psi_+(V)(x,\lambda,\tau)\rangle_{\mathbb{C}^2},$$

and $\vec{g} = (g_-, g, g_+)$, $\tau = a, b$. $\Phi(V)$ is unitary and called the incoming Fourier transformation. The inverse incoming Fourier transformation $\Phi(V)^{-1}$ is given by

$$(\Phi(V)^{-1}\hat{g})(\cdot) = \int_{\mathbb{R}} d\lambda \sum_{\tau=a,b} \vec{\psi}(V)(\cdot,\lambda,\tau)\hat{g}^\tau(\lambda), \quad \hat{g} \in L^2(\mathbb{R},\mathbb{C}^2).$$

We note that

$$\Phi(V)K(V)\Phi(V)^{-1} = M,$$

where M is the multiplication operator by the independent variable λ on $L^2(\mathbb{R},\mathbb{C}^2)$, i.e.,

$$\begin{aligned}(M\hat{g})(\lambda) &:= \lambda\hat{g}(\lambda), \quad \hat{g}\in \mathrm{dom}(M), \quad \lambda\in\mathbb{R},\\ \mathrm{dom}(M) &:= \{\hat{g}\in L^2(\mathbb{R},\mathbb{C}^2): M\hat{g}\in L^2(\mathbb{R},\mathbb{C}^2)\}.\end{aligned} \tag{25}$$

The representation (25) induced by $\Phi(V)$ is called the incoming spectral representation of $K(V)$. Finally, we note that each bounded self-adjoint operator G on $\mathfrak{K}$, which commutes with $K(V)$, corresponds to a measurable function $\hat{G}\in L^\infty(\mathbb{R},\mathfrak{B}(\mathbb{C}^2))$. The multiplication operator on $L^2(\mathbb{R},\mathbb{C}^2)$ generated by $\hat{G}$, which we also denote by $\hat{G}$ and which is defined by

$$\begin{aligned}(\hat{G}\hat{g})(\lambda) &:= \hat{G}(\lambda)\hat{g}(\lambda), \quad \hat{g}\in \mathrm{dom}(\hat{G}), \quad \lambda\in\mathbb{R},\\ \mathrm{dom}(\hat{G}) &:= \{\hat{g}\in L^2(\mathbb{R},\mathbb{C}^2): \hat{G}\hat{g}\in L^2(\mathbb{R},\mathbb{C}^2)\},\end{aligned} \tag{26}$$

is unitarily equivalent to G, which means $\Phi(V)G\Phi(V)^{-1}=\hat{G}$ (see Ref. 3, 4.4.2. Proposition 18). The representation (26) is called the incoming spectral representation of G. The incoming Fourier transform $\Phi(V)$ is related to the Lax–Phillips wave operators (see Ref. 17, Remark 5.2). Since

$$e^{-itK(V)}\mathcal{D}_-\subseteq\mathcal{D}_-, \quad t\leqslant 0,$$

$$e^{-itK(V)}\mathcal{D}_+\subseteq\mathcal{D}_+, \quad t\geqslant 0,$$

as well as

$$\begin{aligned}\bigcap_{t\in\mathbb{R}} e^{-itK(V)}\mathcal{D}_- &= \bigcap_{t\in\mathbb{R}} e^{-itK(V)}\mathcal{D}_+ = \{0\},\\ \overline{\bigcup_{t\in\mathbb{R}} e^{-itK(V)}\mathcal{D}_-} &= \overline{\bigcup_{t\in\mathbb{R}} e^{-itK(V)}\mathcal{D}_+} = \mathfrak{K}\end{aligned} \tag{27}$$

the subspaces $\mathcal{D}_-$ and $\mathcal{D}_+$ are called incoming and outgoing subspaces with respect to $e^{-itK(V)}$ (see Ref. 3, Chap XII or Ref. 20). Further, introducing the Hilbert space $\mathfrak{K}_0$,

$$\mathfrak{K}_0 := L^2(\mathbb{R},\mathbb{C}^2)=\mathcal{D}_-\oplus\mathcal{D}_+\subseteq\mathfrak{K}=\mathcal{D}_-\oplus\mathfrak{H}\oplus\mathcal{D}_+,$$

and the self-adjoint differentiation operator K_0,

$$(K_0 f)(x) = -i\frac{d}{dx}f(x), \quad f\in\mathrm{dom}(K_0)=W^{1,2}(\mathbb{R},\mathbb{C}^2),$$

one easily verifies that $\mathcal{D}_-$ and $\mathcal{D}_+$ are incoming and outgoing subspaces with respect to e^{-itK_0}. The Lax–Phillips wave operators are defined by

$$W_\pm(K(V),K_0;J_\pm) := s-\lim_{t\to\pm\infty} e^{itK(V)}J_\pm e^{-itK_0},$$

with identification operators $J_\pm:\mathfrak{K}_0\to\mathfrak{K}$ given by

$$J_- f := (P^{\mathfrak{K}_0}_{\mathcal{D}_-}f,0,0), \quad f\in\mathfrak{K}_0,$$

$$J_+ f := (0,0,P^{\mathfrak{K}_0}_{\mathcal{D}_+}f), \quad f\in\mathfrak{K}_0,$$

where $P^{\mathfrak{K}_0}_{\mathcal{D}_-}$, $P^{\mathfrak{K}_0}_{\mathcal{D}_+}$ denote the projection from $\mathfrak{K}_0$ onto $\mathcal{D}_-$ and from $\mathfrak{K}_0$ onto $\mathcal{D}_+$, respectively. Since

$$e^{-itK(V)}|\mathcal{D}_- = e^{-itK_0}|\mathcal{D}_-, \quad t \leqslant 0,$$

$$e^{-itK(V)}|\mathcal{D}_+ = e^{-itK_0}|\mathcal{D}_+, \quad t \geqslant 0,$$

the wave operators exist. Using (27) one proves the completeness of the wave operators, i.e., $\mathrm{ran}(W_\pm(K(V),K_0;J_\pm)) = \mathfrak{K}$. For details (see Ref. 3, Chap. XII or Ref. 20). Defining the Fourier operator $\mathcal{F}: L^2(\mathbb{R},\mathbb{C}^2) \to L^2(\mathbb{R},\mathbb{C}^2)$ by

$$(\mathcal{F}f)(\lambda) := \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} dx\, e^{-ix\lambda} f(x), \quad f \in L^2(\mathbb{R},\mathbb{C}^2), \quad \lambda \in \mathbb{R},$$

one gets the representation

$$\Phi(V) = \mathcal{F}W_-(K(V),K_0;J_-)^* \tag{28}$$

(see Ref. 17, Remark 5.2).

F. Carrier densities

Following Ref. 17, we now introduce the particle density and express it in terms of the generalized eigenfunctions (see Sec. II E) of the quasi-Hamiltonian associated with a dissipative open quantum system (see Sec. II D). An operator $\varrho \in \mathfrak{B}(\mathfrak{K})$ is called a density matrix if ϱ is non-negative and self-adjoint. The operator ϱ is a steady state, if ϱ commutes with $K(V)$. Thus any steady-state ϱ is unitarily equivalent to a multiplication operator $\hat{\varrho}$ on the Hilbert space $L^2(\mathbb{R},\mathbb{C}^2)$ induced by a measurable function from the space $L^\infty(\mathbb{R},\mathfrak{B}(\mathbb{C}^2))$; we denote this function by the same symbol $\hat{\varrho}$ as the multiplication operator. In the following we assume that the function $\hat{\varrho}$ is fixed, i.e., the function $\hat{\varrho}$ does not depend on the potential V. This leads to a steady state of the form

$$\varrho(V) = \Phi(V)^{-1}\hat{\varrho}\Phi(V), \tag{29}$$

which depends on V. In order to define the carrier density $u_{\hat{\varrho}}(V)$ one has to introduce the carrier density observable in terms of the generalized eigenfunctions as defined in Sec. II E:

$$D(V)(x,\lambda) := \begin{pmatrix} |\psi(V)(x,\lambda,b)|^2 & \psi(V)(x,\lambda,a)\overline{\psi(V)(x,\lambda,b)} \\ \psi(V)(x,\lambda,b)\overline{\psi(V)(x,\lambda,a)} & |\psi(V)(x,\lambda,a)|^2 \end{pmatrix}.$$

With respect to the carrier density observable $D(V)(x,\lambda)$ one defines the carrier density at $x \in [a,b]$ and at energy $\lambda \in \mathbb{R}$ by

$$u_{\hat{\varrho}}(V)(x,\lambda) := \mathrm{tr}(\hat{\varrho}(\lambda)D(V)(x,\lambda)) \geqslant 0.$$

The carrier density $u_{\hat{\varrho}}(V)$ is given by

$$u_{\hat{\varrho}}(V)(x) = \int_{\mathbb{R}} d\lambda\, u_{\hat{\varrho}}(V)(x,\lambda). \tag{30}$$

If the function $\hat{\varrho}$ satisfies the condition

$$C_{\hat{\varrho}} := \sup_{\lambda \in \mathbb{R}} \sqrt{\lambda^2+1}\,\|\hat{\varrho}(\lambda)\|_{\mathfrak{B}(\mathbb{C}^2)} < \infty, \tag{31}$$

then the definition (30) makes sense for a.e. $x \in [a,b]$. Moreover, in this case $u_{\hat{\varrho}}(V)$ is a *non-negative* and *integrable* function. Furthermore, $P^{\mathfrak{K}}_{\mathfrak{H}}(K(V)-i)^{-1} \in \mathfrak{L}_1(\mathfrak{K})$ and the estimate

$$\|u_{\hat{\varrho}}(V)\|_{L^1}=\mathrm{tr}(\varrho(V)P_{\mathfrak{H}}^{\mathfrak{K}})\leqslant C_{\hat{\varrho}}\|(K(V)-i)^{-1}P_{\mathfrak{H}}^{\mathfrak{K}}\|_{\mathfrak{L}_1(\mathfrak{K})} \tag{32}$$

is valid (see Ref. 17). Let us introduce the operator

$$(M(h)\vec{f})(x):=(0,h(x)f(x),0),\quad \vec{f}=(f_-,f,f_+)\in\mathrm{dom}(M(h))=\mathfrak{K},$$

for functions $h\in L^\infty$. If the condition (31) is satisfied, then

$$\int_a^b dx\, u_{\hat{\varrho}}(V)(x)h(x)=\mathrm{tr}(\varrho(V)M(h)) \tag{33}$$

for any $h\in L^\infty$ (see Ref. 17).

Remark 2.6: In order to express the carrier density via the density matrix, only the action of the density matrix $\varrho(V)$ on multiplication operators on the small Hilbert space $\mathfrak{H}$ is of interest [see (33)]. This is exactly what we have addressed as "projection" onto the open quantum system in the introduction of Sec. II D.

III. THE CARRIER DENSITY OPERATOR: BOUNDEDNESS AND CONTINUITY

As in Refs. 13 and 14 we introduce the (nonlinear) carrier density operator $\mathcal{N}_{\hat{\varrho}}:L^\infty\to L^1$ defined by

$$\mathcal{N}_{\hat{\varrho}}(V):=u_{\hat{\varrho}}(V),\quad V\in\mathrm{dom}(\mathcal{N}_{\hat{\varrho}})=L^\infty, \tag{34}$$

where $u_{\hat{\varrho}}(V)$ is the carrier density defined by (30). The dissipative Schrödinger–Poisson system is essentially a nonlinear Poisson equation (1) with density operators of the form (34) for electrons and holes as nonlinearities on the right-hand side of (1). In Sec. IV we prove the existence of solutions of the dissipative Schrödinger–Poisson system by means of Schauder's fixed point theorem. To that end we need bounds of the carrier density operator and its continuity. Let us first give a bound for the carrier density operator.

Theorem 3.1: *Suppose $V\in L^\infty$. If the spectral representation $\hat{\varrho}$ of a density matrix $\varrho(V)$ [see (29)] obeys (31), then*

$$\begin{aligned}\|\mathcal{N}_{\hat{\varrho}}(V)\|_{L^1}\leqslant C_{\hat{\varrho}}(&8+4\sqrt{2}(b-a)\sqrt{\|m\|_{L^\infty}}\sqrt{8c+5+4\|V\|_{L^\infty}}\\&+8\sqrt{2}\mathfrak{g}_1(\alpha_a^2+\alpha_b^2)^{1/2}\|H_0^{-1/2}\|^{1/2}_{\mathfrak{B}(\mathfrak{H};W^{1,2})}(8c+5+4\|V\|_{L^\infty})^{1/4}),\end{aligned} \tag{35}$$

where c is defined by (14).

Proof: In view of (32) it suffices to estimate $\|(K(V)-i)^{-1}P_{\mathfrak{H}}^{\mathfrak{K}}\|_{\mathfrak{L}_1(\mathfrak{K})}$. Using (24), we obtain the equation

$$(K(V)-i)^{-1}P_{\mathfrak{H}}^{\mathfrak{K}}\vec{f}=(0,(H(V)-i)^{-1}f,ie^{-\bullet}T(V)(i)f_+),$$

where $\vec{f}=(f_-,f,f_+)$. Thus, one can estimate

$$\|(K(V)-i)^{-1}P_{\mathfrak{H}}^{\mathfrak{K}}\|_{\mathfrak{L}_1(\mathfrak{K})}\leqslant\|(H(V)-i)^{-1}\|_{\mathfrak{L}_1(\mathfrak{H})}+\|ie^{-\bullet}T(V)(i)\|_{\mathfrak{L}_1(\mathfrak{H};\mathcal{D}_+)}. \tag{36}$$

We estimate the first addend on the right-hand side. Let μ be a sufficiently large positive number (to be specified later). We write

$$(H(V)-i)^{-1}=(H(V)+\mu)^{-1}(1+(\mu+i)(H(V)-i)^{-1}). \tag{37}$$

Since $H(V)$ is a maximal dissipative operator one has $\|(H(V)-i)^{-1}\|_{\mathfrak{B}(\mathfrak{H})}\leqslant 1$. Thus, (37) implies

$$\|(H(V)-i)^{-1}\|_{\mathfrak{L}_1(\mathfrak{H})}\leqslant(2+\mu)\|(H(V)+\mu)^{-1}\|_{\mathfrak{L}_1(\mathfrak{H})}. \tag{38}$$

Applying the factorization formula (19) one gets

$$\|(H(V)+\mu)^{-1}\|_{\mathfrak{L}_1(\mathfrak{H})}\leqslant\|(H_0+\mu)^{-1/2}\|^2_{\mathfrak{L}_2(\mathfrak{H})}\|(I+B_\mu(V))^{-1}\|_{\mathfrak{B}(\mathfrak{H})}.$$

The first factor of the right-hand side can be estimated (see the Appendix)

$$\|(H_0+\mu)^{-1/2}\|^2_{\mathfrak{L}_2(\mathfrak{H})}\leqslant\frac{1}{1+\mu}+\sqrt{\|m\|_{L^\infty}}\frac{b-a}{\sqrt{2}}\frac{1}{\sqrt{1+\mu}}.$$

Hence,

$$\begin{aligned}\|(H(V)-i)^{-1}\|_{\mathfrak{L}_1(\mathfrak{H})}&\leqslant\left(\frac{2+\mu}{1+\mu}+\sqrt{\|m\|_{L^\infty}}\frac{b-a}{\sqrt{2}}\frac{2+\mu}{\sqrt{1+\mu}}\right)\|(I+B_\mu(V))^{-1}\|_{\mathfrak{B}(\mathfrak{H})}\\&\leqslant(2+\sqrt{2}\sqrt{\|m\|_{L^\infty}}(b-a)\sqrt{1+\mu})\|(I+B_\mu(V))^{-1}\|_{\mathfrak{B}(\mathfrak{H})}.\end{aligned}$$

Setting $\mu=2(4c+2+2\|V\|_{L^\infty})$ and taking into account (18) one gets

$$\|(I+B_\mu(V))^{-1}\|_{\mathfrak{B}(\mathfrak{H})}\leqslant 4,$$

which finally implies

$$\|(H(V)-i)^{-1}\|_{\mathfrak{L}_1(\mathfrak{H})}\leqslant 8+4\sqrt{2}(b-a)\sqrt{\|m\|_{L^\infty}}\sqrt{8c+5+4\|V\|_{L^\infty}}. \tag{39}$$

Now we are going to estimate the second term on the right-hand side of (36). Since $\|e^{-\bullet}\otimes I_{\mathbb{C}^2}\|_{\mathfrak{L}_1(\mathbb{C}^2;\mathcal{D}_+)}=\sqrt{2}$, we get, using Eq. (22), that

$$\|ie^{-\bullet}T(V)(i)\|_{\mathfrak{L}_1(\mathfrak{H};\mathcal{D}_+)}\leqslant\sqrt{2}(\alpha_a^2+\alpha_b^2)^{1/2}\|(H(V)-i)^{-1}\|_{\mathfrak{B}(\mathfrak{H};C[a,b])}.$$

It remains to estimate $\|(H(V)-i)^{-1}\|_{\mathfrak{B}(\mathfrak{H};C[a,b])}$. Taking into account (37) one obtains [analogous to (38)]

$$\|(H(V)-i)^{-1}\|_{\mathfrak{B}(\mathfrak{H};C[a,b])}\leqslant(2+\mu)\|(H(V)+\mu)^{-1}\|_{\mathfrak{B}(\mathfrak{H};C[a,b])}.$$

As in the previous part of the proof we put $\mu=2(4c+2+2\|V\|_{L^\infty})$ and afterwards substitute $(H(V)+\mu)^{-1}$ via the factorization formula (19). This leads to the following estimate:

$$\begin{aligned}\|(H(V)-i)^{-1}\|_{\mathfrak{B}(\mathfrak{H};C[a,b])}&\leqslant(\mu+2)\|(H_0+\mu)^{-1/2}\|_{\mathfrak{B}(\mathfrak{H};C[a,b])}\|(H_0+\mu)^{-1/2}\|_{\mathfrak{B}(\mathfrak{H};C[a,b])}\\&\quad\times\|(I+B_\mu(V))^{-1}\|_{\mathfrak{B}(\mathfrak{H})}\|(H_0+\mu)^{-1/2}\|_{\mathfrak{B}(\mathfrak{H})}.\end{aligned}$$

By $\|(I+B_\mu(V))^{-1}\|_{\mathfrak{B}(\mathfrak{H})}\leqslant 4$ and $\|(H_0+\mu)^{-1/2}\|_{\mathfrak{B}(\mathfrak{H})}\leqslant 1/\sqrt{1+\mu}$ one gets

$$\|(H(V)-i)^{-1}\|_{\mathfrak{B}(\mathfrak{H};C[a,b])}\leqslant 4\frac{2+\mu}{\sqrt{1+\mu}}\|(H_0+\mu)^{-1/2}\|_{\mathfrak{B}(\mathfrak{H};C[a,b])}. \tag{40}$$

We estimate the last factor in this inequality by the Gagliardo–Nirenberg inequality (15). For any $\psi\in\mathfrak{H}$ one has

$$\begin{aligned}\|(H_0+\mu)^{-1/2}\psi\|_{C[a,b]} &\leqslant \mathfrak{g}_1\|(H_0+\mu)^{-1/2}\psi\|_{W^{1,2}}^{1/2}\|(H_0+\mu)^{-1/2}\psi\|_{\mathfrak{H}}^{1/2}\\ &\leqslant \mathfrak{g}_1\|H_0^{-1/2}\|_{\mathfrak{B}(\mathfrak{H};W^{1,2})}^{1/2}\|(H_0+\mu)^{-1/2}\|_{\mathfrak{B}(\mathfrak{H})}^{1/2}\|\psi\|_{\mathfrak{H}}\\ &\leqslant \mathfrak{g}_1\frac{\|H_0^{-1/2}\|_{\mathfrak{B}(\mathfrak{H};W^{1,2})}^{1/2}}{(1+\mu)^{1/4}}\|\psi\|_{\mathfrak{H}}.\end{aligned}$$

This yields

$$\|(H_0+\mu)^{-1/2}\|_{\mathfrak{B}(\mathfrak{H};C[a,b])} \leqslant \mathfrak{g}_1\frac{\|H_0^{-1/2}\|_{\mathfrak{B}(\mathfrak{H};W^{1,2})}^{1/2}}{(1+\mu)^{1/4}}.$$

Together with (40) this gives

$$\|H(V)-i)^{-1}\|_{\mathfrak{B}(\mathfrak{H};C[a,b])} \leqslant 8\,\mathfrak{g}_1\|H_0^{-1/2}\|_{\mathfrak{B}(\mathfrak{H},W^{1,2})}^{1/2}(1+\mu)^{1/4}.$$

Inserting the chosen $\mu=2(4c+2+2\|V\|_{L^\infty})$, we obtain for the second addend on the right-hand side of (36):

$$\|ie^{-\cdot}T(V)(i)\|_{\mathfrak{L}_1(\mathfrak{H};\mathcal{D}_+)} \leqslant 8\sqrt{2}\,\mathfrak{g}_1(\alpha_a^2+\alpha_b^2)^{1/2}\|H_0^{-1/2}\|_{\mathfrak{B}(\mathfrak{H};W^{1,2})}^{1/2}(8c+5+4\|V\|_{L^\infty})^{1/4}.$$

Fitting together (32), (36), (39), and the last estimate completes the proof of (35). □

Remark 3.2: One can prove that the carrier density operator takes its values not only in L^1 but in L^2. Additionally, one can prove estimates similar to (35). These facts are not needed in this article; they become, however, essential if one wants to include recombination effects of electrons and holes into the model.

Our next aim is to verify the continuity of the carrier density operator. To this end we need the continuity of the incoming Fourier transformation in dependence of the potential V.

Lemma 3.3: If V, $V_n \in L^\infty$, $n=1,2,...$, and $V_n \overset{L^\infty}{\to} V$ as $n\to\infty$, then

$$s-\lim_{n\to\infty}\Phi(V_n)=\Phi(V). \tag{41}$$

Proof: The potentials V and V_n define self-adjoint multiplication operators on the Hilbert space $\mathfrak{H}$. We denote these operators by the same symbols and extend them to the dilation space $\mathfrak{K}$ setting

$$\hat{V}=(0,V,0) \quad \text{and} \quad \hat{V}_n=(0,V_n,0), \quad n=1,2,\ldots.$$

Obviously, one has

$$K(V)=K(0)+\hat{V} \quad \text{and} \quad K(V_n)=K(0)+\hat{V}_n,$$

$n=1,2,\ldots$. Hence

$$(K(V_n)-i)^{-1}-(K(V)-i)^{-1}=(K(V_n)-i)^{-1}(\hat{V}-\hat{V}_n)(K(V)-i)^{-1},$$

$n=1,2,\ldots$. Using $(\hat{V}-\hat{V}_n)=(\hat{V}-\hat{V}_n)P_{\mathfrak{H}}^{\mathfrak{K}}$, $n=1,2,...$, we obtain the representation

$$(K(V_n)-i)^{-1}-(K(V)-i)^{-1}=(K(V_n)-i)^{-1}(\hat{V}-\hat{V}_n)P_{\mathfrak{H}}^{\mathfrak{K}}(K(V)-i)^{-1}, \tag{42}$$

$n=1,2,\ldots$. Since $P_{\mathfrak{H}}^{\mathfrak{K}}(K(V)-i)^{-1}$ is a nuclear operator the resolvent difference $(K(V_n)-i)^{-1}-(K(V)-i)^{-1}$ is a nuclear operator, too. By Ref. 18, Theorem X.4.12, the wave operators

$$W_-(K(V_n),K(V))=s-\lim_{t\to-\infty}e^{itK(V_n)}e^{-itK(V)}$$

as well as

$$W_-(K(V),K(V_n))=s-\lim_{t\to-\infty}e^{itK(V)}e^{-itK(V_n)},\quad n=1,2,...,$$

exist and are complete. Note that $W_-(K(V_n),K(V))^*=W_-(K(V),K(V_n))$. Using the chain rule for wave operators (Ref. 3, Theorem III.21) we find the representation

$$W_-(K(V_n),K_0;J_-)=W_-(K(V_n),K(V))W_-(K(V),K_0;J_-)$$

for $n=1,2,...$, which yields

$$W_-(K(V_n),K_0;J_-)^*=W_-(K(V),K_0;J_-)^*W_-(K(V),K(V_n)) \tag{43}$$

for $n=1,2,...$. Furthermore, from (42) one gets the estimate

$$\|(K(V_n)-i)^{-1}-(K(V)-i)^{-1}\|_{\mathfrak{L}_1(\mathfrak{K})}\leqslant\|V-V_n\|_{L^\infty}\|P_{\mathfrak{H}}^{\mathfrak{K}}(K(V)-i)^{-1}\|_{\mathfrak{L}_1(\mathfrak{K})},$$

$n=1,2,...$, which implies

$$\lim_{n\to\infty}\|(K(V_n)-i)^{-1}-(K(V)-i)^{-1}\|_{\mathfrak{L}_1(\mathfrak{K})}=0. \tag{44}$$

Therefore (see also Ref. 18, Remark X.4.17),

$$s-\lim_{n\to\infty}W_-(K(V_n),K(V))=W_-(K(V),K(V))=I_{\mathfrak{K}},$$

which yields

$$w-\lim_{n\to\infty}W_-(K(V_n),K(V))^*=w-\lim_{n\to\infty}W_-(K(V),K(V_n))=I_{\mathfrak{K}}.$$

Since $W_-(K(V),K(V_n))$, $n=1,2,...$, is a sequence of unitary operators we obtain

$$s-\lim_{n\to\infty}W_-(K(V),K(V_n))=I_{\mathfrak{K}}.$$

Finally, from (28) and (43) we get the representation

$$\Phi(V_n)=\Phi(V)W_-(K(V),K(V_n)),\quad n=1,2,....$$

Using $s-\lim_{n\to\infty}W_-(K(V),K(V_n))=I_{\mathfrak{K}}$ we complete the proof. □

Now we can verify the continuity of the carrier density operator.

Theorem 3.4: *Let* $V\in L^\infty$, $V_n\in L^\infty$, $n=1,2,...$. *If* $\hat{\varrho}$ *satisfies the condition (31) and* $V_n\overset{L^\infty}{\to}V$ *as* $n\to\infty$, *then* $u_{\hat{\varrho}}(V_n)\overset{L^1}{\to}u_{\hat{\varrho}}(V)$ *as* $n\to\infty$, *i.e.,*

$$\lim_{n\to\infty}\int_a^b dx\,|u_{\hat{\varrho}}(V_n)(x)-u_{\hat{\varrho}}(V)(x)|=0, \tag{45}$$

i.e., the carrier density operator $\mathcal{N}_{\hat{\varrho}}:L^\infty\to L^1$ *is continuous.*

Proof: By (33) we have the representation

$$\int_a^b dx(u_{\hat{\varrho}}(V_n)(x)-u_{\hat{\varrho}}(V)(x))h(x)=\mathrm{tr}((\varrho(V_n)-\varrho(V))M(h)) \tag{46}$$

for each $h \in L^\infty$ and $n=1,2,\ldots$. Since

$$\mathrm{tr}(\varrho(V)M(h)) = \mathrm{tr}(\varrho(V)(K(V)+i)(K(V)+i)^{-1}M(h)),$$

one gets

$$\begin{aligned}\mathrm{tr}((\varrho(V_n)-\varrho(V))M(h)) &= \mathrm{tr}(\varrho(V_n)(K(V_n)+i)\{(K(V_n)+i)^{-1}-(K(V)+i)^{-1}\}M(h)) \\ &\quad + \mathrm{tr}((\varrho(V_n)(K(V_n)+i)-\varrho(V)(K(V)+i))(K(V)+i)^{-1}M(h))\end{aligned} \tag{47}$$

for $n=1,2,\ldots$. By (31) we have

$$\|\varrho(V_n)(K(V_n)+i)\|_{\mathfrak{B}(\mathfrak{K})} \leqslant C_{\hat{\varrho}}$$

and therefore

$$\begin{aligned}&|\mathrm{tr}(\varrho(V_n)(K(V_n)+i)((K(V_n)+i)^{-1}-(K(V)+i)^{-1})M(h))| \\ &\quad \leqslant C_{\hat{\varrho}}\|(K(V_n)+i)^{-1}-(K(V)+i)^{-1}\|_{\mathfrak{L}_1(\mathfrak{K})}\end{aligned} \tag{48}$$

for $n=1,2,\ldots$. We set

$$\hat{k}(\lambda) := \hat{\varrho}(\lambda)(\lambda+i), \quad \lambda \in \mathbb{R},$$

and identify this matrix-valued function with the multiplication operator $\hat{k}$ induced by $\hat{k}$ on $L^2(\mathbb{R},\mathbb{C}^2)$. In this notation there is

$$\varrho(V_n)(K(V_n)+i) = \Phi(V_n)^{-1}\hat{k}\Phi(V_n), \quad n=1,2,\ldots,$$

$$\varrho(V)(K(V)+i) = \Phi(V)^{-1}\hat{k}\Phi(V).$$

Hence the representation

$$\varrho(V_n)(K(V_n)+i)-\varrho(V)(K(V)+i) = (\Phi(V_n)^{-1}-\Phi(V)^{-1})\hat{k}\Phi(V_n)+\Phi(V)\hat{k}(\Phi(V_n)-\Phi(V)) \tag{49}$$

is valid. From (49) we deduce the estimate

$$\begin{aligned}&|\mathrm{tr}((\varrho(V_n)(K(V_n)+i)-\varrho(V)(K(V)+i))(K(V)+i)^{-1}M(h))| \\ &\quad \leqslant C_{\hat{\varrho}}\|(\Phi(V_n)-\Phi(V))P_{\mathfrak{H}}^{\mathfrak{K}}(K(V)-i)^{-1}\|_{\mathfrak{L}_1(\mathfrak{K};L^2(\mathbb{R},\mathbb{C}^2))}\|h\|_{L^\infty} \\ &\quad + C_{\hat{\varrho}}\|(\Phi(V_n)-\Phi(V))(K(V)+i)^{-1}P_{\mathfrak{H}}^{\mathfrak{K}}\|_{\mathfrak{L}_1(\mathfrak{K};L^2(\mathbb{R},\mathbb{C}^2))}\|h\|_{L^\infty}.\end{aligned} \tag{50}$$

Taking into account (47), (48), and (50) we finally get the estimate

$$\begin{aligned}|\mathrm{tr}((\varrho(V_n)-\varrho(V))M(h))| &\leqslant C_{\hat{\varrho}}(\|(K(V_n)+i)^{-1}-(K(V)+i)^{-1}\|_{\mathfrak{L}_1(\mathfrak{K})} \\ &\quad + \|(\Phi(V_n)-\Phi(V))P_{\mathfrak{H}}^{\mathfrak{K}}(K(V)-i)^{-1}\|_{\mathfrak{L}_1(\mathfrak{K};L^2(\mathbb{R},\mathbb{C}^2))} \\ &\quad + \|(\Phi(V_n)-\Phi(V))(K(V)+i)^{-1}P_{\mathfrak{H}}^{\mathfrak{K}}\|_{\mathfrak{L}_1(\mathfrak{K};L^2(\mathbb{R},\mathbb{C}^2))}\|h\|_{L^\infty}).\end{aligned}$$

Since h is arbitrary we obtain from (46) the estimate

$$\int_a^b dx\,|(u_{\hat{\varrho}}(V_n)(x)-u_{\hat{\varrho}}(V)(x))| \leqslant C_{\hat{\varrho}}(\|(K(V_n)+i)^{-1}-(K(V)+i)^{-1}\|_{\mathfrak{L}_1(\mathfrak{K})}$$
$$+\|(\Phi(V_n)-\Phi(V))P_{\mathfrak{H}}^{\mathfrak{K}}(K(V)-i)^{-1}\|_{\mathfrak{L}_1(\mathfrak{K};L^2(\mathbb{R},\mathbb{C}^2))}$$
$$+\|(\Phi(V_n)-\Phi(V))(K(V)+i)^{-1}P_{\mathfrak{H}}^{\mathfrak{K}}\|_{\mathfrak{L}_1(\mathfrak{K};L^2(\mathbb{R},\mathbb{C}^2))}).$$

According to (44) the first addend on the right-hand side goes to zero as $n\to\infty$. Since $P_{\mathfrak{H}}^{\mathfrak{K}}(K(V)-i)^{-1}$ is a trace class operator, one gets by (41) that the second addend on the right-hand side tends to zero, too. Similarly one proves that the third addend tends to zero. □

IV. THE DISSIPATIVE SCHRÖDINGER–POISSON SYSTEM

In this section we first give a rigorous definition of the dissipative Schrödinger–Poisson system. The solution of the dissipative Schrödinger–Poisson system is defined as a self-consistent solution of the nonlinear Poisson equation (1) with density operators of the form (34) for electrons and holes as nonlinearities on the right-hand side of (1). We show that the existence problem of a solution can be reformulated as a fixed point problem for a certain nonlinear map. Applying Schauder's fixed point theorem we find that a solution always exists. From the technical point of view one has to ensure that this map is continuous and compact and has an invariant bounded and convex set. Let us first introduce some further notations:

Definition 4.1: We denote the real part of $W^{1,2}$ by $W_{\mathbb{R}}^{1,2}$. Let $\Gamma\subset\{a,b\}$ be the (possibly empty) Dirichlet boundary of Poisson's equation. We define

$$W_{\Gamma}^{1,2}:=W_{\mathbb{R}}^{1,2}\cap\{\psi:\psi(\Gamma)\subset\{0\}\}.$$

By $W_{\Gamma}^{-1,2}$ we denote the dual space of $W_{\Gamma}^{1,2}$ and by $\langle\cdot,\cdot\rangle_1$ the dual pairing between $W_{\Gamma}^{1,2}$ and $W_{\Gamma}^{-1,2}$. In the following we denote the embedding operator from L^1 into $W_{\Gamma}^{-1,2}$ by E_1 and its norm by ε_1. Moreover, we denote by E_∞ the dual to E_1, i.e., the embedding operator of $W_{\mathbb{R}}^{1,2}$ into L^∞ the norm of which is also ε_1.

Following Ref. 17 we deal with a dissipative Schrödinger–Poisson system constituted by two dissipative Schrödinger-type operators $H^{\pm}(V_{\pm})$:

$$H^{\pm}(V_{\pm})=-\frac{1}{2}\frac{d}{dx}\frac{1}{m_{\pm}}\frac{d}{dx}+V_{\pm},$$

one for electrons (indexed "$-$") and one for holes (indexed "$+$") and Poisson's equation (7); please note that $\hbar$ is scaled to 1. The dissipative Schrödinger-type operators are determined by the effective masses $m_{\pm}$, the boundary coefficients $\kappa_a^{\pm}$, $\kappa_b^{\pm}$ and the potentials $V_{\pm}$ which are of the form

$$V_{\pm}=V_0^{\pm}\pm q\varphi,$$

where $V_0^{\pm}$ are external potentials representing the band-edge offsets and φ is the electrostatic potential which is determined by Poisson's equation. To formulate Poisson's equation one needs the dielectric permittivity ϵ, the doping profile C, and the functions k and φ_Γ [see (8)].

Assumption 4.2: With respect to the data of the problem we assume the following:

- $(A_1^{\pm})$ *The effective masses $m_{\pm}$ are positive and obey $m_{\pm}$, $1/m_{\pm}\in L^\infty$.*
- $(A_2^{\pm})$ *The boundary coefficients $\kappa_a^{\pm}$, $\kappa_b^{\pm}$ are from the upper half-plane $\mathbb{C}_+$.*
- $(A_3^{\pm})$ *The external potentials $V_0^{\pm}$ belong to L^∞.*
- $(A_4^{\pm})$ *The matrix-valued functions $\hat{\varrho}_{\pm}\in L^\infty(\mathbb{R},\mathfrak{B}(\mathbb{C}^2))$ satisfy (31).*
- (A_5) *The doping profile C belongs to $W_{\Gamma}^{-1,2}$.*
- (A_6) *The dielectric permittivity ϵ is positive and obeys ϵ, $1/\epsilon\in L^\infty$. We set $\widetilde{\epsilon}:=\max\{1,\|1/\epsilon\|_{L^\infty}\}$.*

(A_7) *The set* Γ *is not empty, or at least one of the numbers* $k(x)\geqslant 0$, $x\in\{a,b\}\backslash\Gamma$, *is strictly positive.*

(A_8) *The function* φ_Γ *is from the space* $W^{1,2}_{\mathbb{R}}$.

To each Schrödinger operator $H^{\pm}(V_{\pm})$ corresponds a minimal self-adjoint dilation $K^{\pm}(V_{\pm})$. As in Sec. II F the functions $\hat{\varrho}_{\pm}$ define steady states $\varrho_{\pm}(V_{\pm})$, i.e., non-negative self-adjoint operators which commute with $K^{\pm}(V_{\pm})$. The carrier densities $u^{\pm}_{\hat{\varrho}_{\pm}}(V_{\pm})$ for electrons and holes are defined as in Sec. II F. Notice that the electron density $u^{-}_{\hat{\varrho}_{-}}(V_{-})$ is determined by the electron quantities m_{-}, κ^{-}_{a}, κ^{-}_{b}, and V^{-}_{0}, while the hole density $u^{+}_{\hat{\varrho}_{+}}(V_{+})$ refers to m_{+}, κ^{+}_{a}, κ^{+}_{b}, and V^{+}_{0}. The corresponding carrier density operators are denoted by $\mathcal{N}^{-}_{\hat{\varrho}_{-}}$ and $\mathcal{N}^{+}_{\hat{\varrho}_{+}}$, respectively.

A. Rigorous setup of the problem

First we give a rigorous definition of Poisson's equation and afterwards define what we call a solution of the dissipative Schrödinger–Poisson system.

Definition 4.3: The linear Poisson operator $\mathcal{P}: W^{1,2}_{\mathbb{R}}\to W^{-1,2}_{\Gamma}$ *is defined by*

$$\langle \mathcal{P}v,\varsigma\rangle_1=\int_a^b dx\,\epsilon(x)v'(x)\varsigma'(x)+\sum_{x\in\{a,b\}\backslash\Gamma}k(x)v(x)\varsigma(x),\quad v\in W^{1,2}_{\mathbb{R}},\quad \varsigma\in W^{1,2}_{\Gamma}.$$

The restriction of $\mathcal{P}$ *to the subspace* $W^{1,2}_{\Gamma}$ *will be denoted by* $\mathcal{P}_0$.

We have

$$|\langle \mathcal{P}v,\varsigma\rangle_1|\leqslant\left(\|\epsilon\|_{L^\infty}+\sum_{x\in\{a,b\}\backslash\Gamma}k(x)\varepsilon_1^2\right)\|v\|_{W^{1,2}_{\mathbb{R}}}\|\varsigma\|_{W^{1,2}_{\Gamma}}.$$

Hence $\mathcal{P}$ is continuous. Furthermore, we get

$$\|\varphi\|^2_{W^{1,2}_{\Gamma}}\leqslant(1+\gamma_k)\left(\int_a^b dx\,|\varphi'(x)|^2+\sum_{x\in\{a,b\}\backslash\Gamma}k(x)|\varphi(x)|^2\right),\forall\,\varphi\in W^{1,2}_{\Gamma},\tag{51}$$

with

$$\gamma_k:=\sup_{0\neq\psi\in W^{1,2}_{\Gamma}}\frac{\displaystyle\int_a^b dx\,\psi(x)^2}{\displaystyle\int_a^b dx\,|\psi'(x)|^2+\sum_{x\in\{a,b\}\backslash\Gamma}k(x)|\psi(x)|^2}.$$

Because the case of purely homogeneous Neumann conditions is excluded by (A_7), see Assumption 4.2, the constant γ_k is indeed finite. Thus, (51) implies

$$\|\varphi\|^2_{W^{1,2}_{\Gamma}}\leqslant\tilde{\epsilon}(1+\gamma_k)|\langle\mathcal{P}_0\varphi,\varphi\rangle_1|.$$

Therefore, we get by the Lax–Milgram lemma that the inverse of $\mathcal{P}_0$ exists and its norm does not exceed $\tilde{\epsilon}(1+\gamma_k)$. We now state what is a solution of the dissipative Schrödinger–Poisson system.

Problem 4.4: Let us assume that $u^{\pm}\in L^1$. *We say* $\varphi\in W^{1,2}_{\mathbb{R}}$ *satisfies Poisson's equation (7) if* $\varphi-\varphi_\Gamma\in W^{1,2}_{\Gamma}$ *satisfies*

$$\mathcal{P}_0(\varphi-\varphi_\Gamma)=D+qE_1u^{+}-qE_1u^{-},$$

where $D:=qC-\tilde{\varphi}_\Gamma$ *and* $\tilde{\varphi}_\Gamma$ *is the linear form* $v\mapsto\int_a^b dx\,\epsilon(x)\varphi'_\Gamma(x)v'(x)$, *on* $W^{1,2}_{\Gamma}$. *We say a triple* $(\varphi,u^{+},u^{-})\in W^{1,2}_{\mathbb{R}}\times L^1\times L^1$ *satisfies the dissipative Schrödinger–Poisson system if* φ *satisfies Poisson's equation as well as*

$$u^{+}=u^{+}_{\hat{\varrho}_{+}}(V^{+}_{0}+qE_\infty\varphi)\quad\text{and}\quad u^{-}=u^{-}_{\hat{\varrho}_{-}}(V^{-}_{0}-qE_\infty\varphi).$$

B. Existence of solutions and *a priori* estimates

We now prove that the dissipative Schrödinger–Poisson system always admits a solution and investigate these solutions. Following Ref. 13, we define a mapping the fixed points of which exactly determine the solutions of the dissipative Schrödinger–Poisson system.

By $\mathcal{J}:L^1\times L^1\to W^{1,2}_{\mathbb{R}}$ we denote the map which assigns to $(u^+,u^-)\in L^1\times L^1$ the solution of Poisson's equation. Obviously, the map $\mathcal{J}$ is continuous. Further, we define $\Psi:L^\infty\to W^{1,2}_{\mathbb{R}}$ by

$$\Psi:W\to(\mathcal{N}^+_{\hat{\varrho}_+}(V_0^+ + qW),\mathcal{N}^-_{\hat{\varrho}_-}(V_0^- - qW))\to\mathcal{J}(\mathcal{N}^+_{\hat{\varrho}_+}(V_0^+ + qW),\mathcal{N}^-_{\hat{\varrho}_-}(V_0^- - qW)).$$

Since the map $\mathcal{J}:L^1\times L^1\to W^{1,2}_{\mathbb{R}}$ is continuous and by Proposition 3.4 the maps $\mathcal{N}^\pm:L^\infty\to L^1$ are also continuous, the map $\Psi:L^\infty\to W^{1,2}_{\mathbb{R}}$ is continuous, too. With Ψ we associate the map $\Psi_\infty:L^\infty\to L^\infty$,

$$\Psi_\infty := E_\infty\Psi,$$

which is also continuous. Moreover, since E_∞ is compact, the map Ψ_∞ is also compact.

Lemma 4.5: An element $W\in L^\infty$ is a fixed point of Ψ_∞ if and only if the triple

$$(\Psi(W),u^+,u^-)=(\Psi(W),u^+_{\hat{\varrho}_+}(V_0^+ + qW),u^-_{\hat{\varrho}_-}(V_0^- - qW))$$

satisfies the dissipative Schrödinger–Poisson system.

The proof is obvious. Notice that $E_\infty\Psi(W)=\Psi_\infty(W)=W$ for any fixed point W. To prove the central results of this chapter, we also need the following technical lemma.

Lemma 4.6: Let σ_1, σ_2, σ_3 be three strictly positive numbers and let x_0 be the smallest positive root of the polynomial $p:x\mapsto x^4-\sigma_1x^2-\sigma_2x-\sigma_3$. Then for all $x>x_0$ one has $p(x)>0$. In particular, p does not admit other positive roots.

Proof: It is clear that at least one positive root x_0 exists. Then one has for $x=tx_0$ with $t>1$:

$$\begin{aligned}p(x)&=t^4x_0^4-\sigma_1t^2x_0^2-\sigma_2tx_0-\sigma_3\\&=t^4(\sigma_1x_0^2+\sigma_2x_0+\sigma_3)-\sigma_1t^2x_0^2-\sigma_2tx_0-\sigma_3\\&=\sigma_1t^2(t^2-1)x_0^2+\sigma_2t(t^3-1)x_0+\sigma_3(t^4-1)>0.\end{aligned}$$

This shows that a positive root larger than x_0 does not exist. □

Let $c_\pm$ be the constants defined by (14). We specify σ_1, σ_2, σ_3 to

$$\sigma_1 := 8\sqrt{2}q^{3/2}(b-a)\varepsilon_1^2\tilde{\epsilon}(1+\gamma_k)(C_{\hat{\varrho}_+}\sqrt{\|m_+\|}+C_{\hat{\varrho}_-}\sqrt{\|m_-\|}),\tag{52}$$

$$\sigma_2 := 16q^{5/4}\mathfrak{g}_1\varepsilon_1^2\tilde{\epsilon}(1+\gamma_k)(C_{\hat{\varrho}_+}p_+ + C_{\hat{\varrho}_-}p_-),\tag{53}$$

$$\sigma_3 := \varepsilon_1(\|\varphi_\Gamma\|_{W^{1,2}_{\mathbb{R}}}+\tilde{\epsilon}(1+\gamma_k)(\|D\|_{W^{-1,2}_\Gamma}+q\varepsilon_1(C_{\hat{\varrho}_+}r_+ + C_{\hat{\varrho}_-}r_-))),\tag{54}$$

where $C_{\hat{\varrho}_\pm}$ are according to (31), $c_\pm$ according to (14), and

$$p_\pm := ((\alpha_a^\pm)^2+(\alpha_b^\pm)^2)^{1/2}\|(H_0^\pm)^{-1/2}\|^{1/2}_{\mathfrak{B}(\mathfrak{H},W^{1,2})},\tag{55}$$

$$\begin{aligned}r_\pm :=& 8+4\sqrt{2}(b-a)\sqrt{\|m_\pm\|_{L^\infty}}\sqrt{8c_\pm+5+4\|V_0^\pm\|_{L^\infty}}\\&+8\sqrt{2}\mathfrak{g}_1((\alpha_a^\pm)^2+(\alpha_b^\pm)^2)^{1/2}\|(H_0^\pm)^{-1/2}\|^{1/2}_{\mathfrak{B}(\mathfrak{H};W^{1,2})}(8c_\pm+5+4\|V_0^\pm\|_{L^\infty})^{1/4}.\end{aligned}\tag{56}$$

Theorem 4.7: *The following statements are true:*

(1) The mapping $\Psi_\infty:L^\infty\to L^\infty$ always has a fixed point.

(2) If x_0 is the (unique) positive root of the polynomial $p:x\to x^4-\sigma_1x^2-\sigma_2x-\sigma_3$, then for any fixed point W of Ψ_∞ the inequality

$$\|W\|_{L^\infty}\leqslant x_0^4 \tag{57}$$

holds.

Proof: One has

$$\begin{aligned}\|\mathcal{J}(u^+,u^-)\|_{W^{1,2}_{\mathbb{R}}}&\leqslant\|\varphi_\Gamma\|_{W^{1,2}_{\mathbb{R}}}+\|\mathcal{P}_0^{-1}(D+qu^+-qu^-)\|_{W^{1,2}_\Gamma}\\&\leqslant\|\varphi_\Gamma\|_{W^{1,2}_{\mathbb{R}}}+\tilde{\epsilon}(1+\gamma_k)\|D+qu^+-qu^-\|_{W^{-1,2}_\Gamma}\\&\leqslant\|\varphi_\Gamma\|_{W^{1,2}_{\mathbb{R}}}+\tilde{\epsilon}(1+\gamma_k)(\|D\|_{W^{-1,2}_\Gamma}+q\varepsilon_1(\|u^+\|_{L^1}+\|u^-\|_{L^1})),\end{aligned}$$

which implies

$$\|E_\infty\mathcal{J}(u^+,u^-)\|_{L^\infty}\leqslant\varepsilon_1\|\varphi_\Gamma\|_{W^{1,2}_{\mathbb{R}}}+\varepsilon_1\tilde{\epsilon}(1+\gamma_k)(\|D\|_{W^{-1,2}_\Gamma}+q\varepsilon_1(\|u^+\|_{L^1}+\|u^-\|_{L^1})). \tag{58}$$

Since $u^\pm=\mathcal{N}^\pm_{\hat{\varrho}_\pm}(V_\pm)$ one gets from (35) the estimate

$$\begin{aligned}\|u^\pm\|_{L^1}\leqslant C_{\hat{\varrho}_\pm}&(8+4\sqrt{2}(b-a)\sqrt{\|m_\pm\|_{L^\infty}}\sqrt{8c_\pm+5+4\|V_\pm\|_{L^\infty}}\\&+8\sqrt{2}\mathfrak{g}_1((\alpha_a^\pm)^2+(\alpha_b^\pm)^2)^{1/2}\|(H_0^\pm)^{-1/2}\|^{1/2}_{\mathfrak{B}(\mathfrak{H},W^{1,2})}(8c_\pm+5+4\|V_\pm\|_{L^\infty})^{1/4}).\end{aligned}$$

By $V_\pm=V_0^\pm\pm qW$ we obtain

$$\begin{aligned}\|u^\pm\|_{L^1}\leqslant C_{\hat{\varrho}_\pm}&(8+4\sqrt{2}(b-a)\sqrt{\|m_\pm\|_{L^\infty}}\sqrt{8c_\pm+5+4\|V_0^\pm\|_{L^\infty}+4q\|W\|_{L^\infty}}\\&+8\sqrt{2}\mathfrak{g}_1((\alpha_a^\pm)^2+(\alpha_b^\pm)^2)^{1/2}\|(H_0^\pm)^{-1/2}\|^{1/2}_{\mathfrak{B}(\mathfrak{H},W^{1,2})}(8c_\pm+5+4\|V_0^\pm\|_{L^\infty}+4q\|W\|_{L^\infty})^{1/4}).\end{aligned} \tag{59}$$

Using the estimates

$$\sqrt{8c_\pm+5+4\|V_0^\pm\|_{L^\infty}+4q\|W\|_{L^\infty}}\leqslant\sqrt{8c_\pm+5+4\|V_0^\pm\|_{L^\infty}}+2\sqrt{q\|W\|_{L^\infty}}$$

and

$$(8c_\pm+5+4\|V_0^\pm\|_{L^\infty}+4q\|W\|_{L^\infty})^{1/4}\leqslant(8c_\pm+5+4\|V_0^\pm\|_{L^\infty})^{1/4}+(4q\|W\|_{L^\infty})^{1/4}$$

we get

$$\|u^\pm\|_{L^1}\leqslant\sigma_1^\pm\|W\|^{1/2}_{L^\infty}+\sigma_2^\pm\|W\|^{1/4}_{L^\infty}+\sigma_3^\pm, \tag{60}$$

with

$$\sigma_1^\pm:=8C_{\hat{\varrho}_\pm}(b-a)\sqrt{2q\|m_\pm\|_{L^\infty}},$$

$$\sigma_2^\pm:=16q^{1/4}\mathfrak{g}_1C_{\hat{\varrho}_\pm}p_\pm,$$

$$\sigma_3^\pm:=C_{\hat{\varrho}_\pm}r_\pm,$$

where $p_\pm$ and $r_\pm$ are defined by (55) and (56), respectively. Inserting (60) into (58) we obtain

$$\|E_\infty\mathcal{J}(u^+,u^-)\|_{L^\infty}\leqslant\sigma_1\|W\|^{1/2}_{L^\infty}+\sigma_2\|W\|^{1/4}_{L^\infty}+\sigma_3,$$

where σ_1, σ_2, σ_3 are the constants defined under (52)–(54). Hence we get the estimate

$$\|\Psi_\infty(W)\|_{L^\infty} \leqslant \sigma_1 \|W\|_{L^\infty}^{1/2} + \sigma_2 \|W\|_{L^\infty}^{1/4} + \sigma_3 . \tag{61}$$

If x_0 is the (unique) positive root of the polynomial $x \to x^4 - \sigma_1 x^2 - \sigma_2 x - \sigma_3$ and $\|W\|_{L^\infty} \leqslant x_0^4$, then by (61) one obtains

$$\|\Psi_\infty(W)\|_{L^\infty} \leqslant \sigma_1 (\|W\|_{L^\infty}^{1/4})^2 + \sigma_2 \|W\|_{L^\infty}^{1/4} + \sigma_3 \leqslant \sigma_1 x_0^2 + \sigma_2 x_0 + \sigma_3 = x_0^4.$$

This means, that Ψ_∞ maps the ball $\{W: \|W\|_{L^\infty} \leqslant x_0^4\}$ continuously into itself. Since Ψ_∞ is compact the image of this ball under Ψ_∞ is precompact in L^∞. Thus, by Schauder's fixed point theorem Ψ_∞ must have a fixed point. This proves the first assertion.

Assume that the second assertion is false and a fixed point W satisfying $\|W\|_{L^\infty} > x_0^4$ exists. Then (61) would give

$$(\|W\|_{L^\infty}^{1/4})^4 = \|W\|_{L^\infty} = \|\Psi_\infty(W)\|_{L^\infty} \leqslant \sigma_1 (\|W\|_{L^\infty}^{1/4})^2 + \sigma_2 \|W\|_{L^\infty}^{1/4} + \sigma_3 .$$

On account of $\|W\|_{L^\infty}^{1/4} > x_0$ this is a contradiction to Lemma 4.6. □

Now we can state our main result:

Theorem 4.8: *Under Assumption 4.2 the dissipative Schrödinger–Poisson system (see Problem 4.4) always has a solution and any solution* (φ, u^+, u^-) *of the dissipative Schrödinger–Poisson system satisfies the a priori estimates*

$$\|\varphi\|_{L^\infty} \leqslant x_0^4, \quad \|u^\pm\|_{L^1} \leqslant C_{\hat{\varrho}_\pm} \hat{r}_\pm , \tag{62}$$

where x_0 *is the unique positive root of the polynomial* $x \to x^4 - \sigma_1 x^2 - \sigma_2 x - \sigma_3$ *with coefficients given by (52)–(56) and*

$$\hat{r}_\pm := [8 + 4\sqrt{2}(b-a)\sqrt{\|m_\pm\|_{L^\infty}} \sqrt{8c_\pm + 5 + 4\|V_0^\pm\|_{L^\infty} + 4qx_0^4}$$
$$+ 8\sqrt{2}\mathfrak{g}_1((\alpha_a^\pm)^2 + (\alpha_b^\pm)^2)^{1/2} \|(H_0^\pm)^{-1/2}\|_{\mathfrak{B}(\mathfrak{H}, W^{1,2})}^{1/2} (8c_\pm + 5 + 4\|V_0^\pm\|_{L^\infty} + 4qx_0^4)^{1/4}].$$

Proof: The first assertion follows from Lemma 4.5 and Theorem 4.7. The first inequality of (62) is implied by (57), while the other estimates are obtained from (59) and the first inequality. □

V. CONCLUSION

Let us comment the results.

(i) We have shown (see Theorem 4.8) that the dissipative Schrödinger–Poisson system (see Problem 4.4) *always* has a solution, if the Assumptions 4.2 are satisfied.

(ii) The solutions (φ, u^+, u^-) of a dissipative Schrödinger–Poisson system have bounds which *only* depend on the data $m_\pm$, $\kappa_a^\pm$, $\kappa_b^\pm$, $V_0^\pm$, C, ϵ, φ_Γ, k, and the steady states $\varrho_\pm$. In particular, the bound for the electrostatic potential φ may be directly calculated from the data by Cardano's formula.

(iii) In contrast to self-adjoint Schrödinger–Poisson systems dissipative ones allow in general nontrivial currents $j_{\hat{\varrho}_\pm}^\pm$ which are independent from $x \in [a,b]$ provided the steady states $\varrho_\pm$ are determined by (29) with

$$\int_{\mathbb{R}} d\lambda \, \mathrm{tr}(\hat{\varrho}_\pm(\lambda)) < \infty$$

(see Ref. 17).

(iv) The last fact allows us to couple dissipative Schrödinger–Poisson systems to drift diffusion models acting outside the interval $[a,b]$ via a current continuity condition. In a forthcoming paper we will show how this can be done and we will prove that the coupled system has a solution.

(v) It is an open problem under which conditions the solution, guaranteed by Theorem 4.8, is unique. This situation is similar to that of the stationary Van Roosbroeck system (see Ref. 21, 3.4), or that of the Kohn-Sham equations (see Refs. 13, 14, and 27 and the references cited there).

(vi) The present article solves the dissipative Schrödinger–Poisson system in one spatial dimension; the two- and three-dimensional problems remain open.

(vii) The density matrices $\varrho_\pm$ determine the statistical properties of the quantum system. Therefore, they change from system to system.

APPENDIX: RESOLVENT ESTIMATE FOR H_0

For the operator (12) there is

$$\|(H_0+\mu)^{-1/2}\|^2_{\mathfrak{L}_2(\mathfrak{H})}=\sum_{l=0}^{\infty}\frac{1}{\zeta_l+1+\mu},$$

where the numbers ζ_l are the eigenvalues of the operator H_0-1. Let $\hat{H}_0$ be the self-adjoint operator (12) where m is specified to $m(x)\equiv 1$. Obviously, there is $1/\|m\|_{L^\infty}(\hat{H}_0-1)\leqslant H_0-1$. The eigenvalues of $\hat{H}_0-1$ are given by $\pi^2 l^2/(2(b-a)^2)$, $l=0,1,\ldots$. Thus the minimax principle implies

$$(1/\|m\|_{L^\infty})[\pi^2 l^2/(2(b-a)^2)]\leqslant\zeta_l, =0,1,\ldots.$$

Hence,

$$\|(H_0+\mu)^{-1/2}\|^2_{\mathfrak{L}_2(\mathfrak{H})}\leqslant\sum_{l=0}^{\infty}\frac{1}{(1/\|m\|_{L^\infty})[\pi^2/(2(b-a)^2)]l^2+1+\mu}.$$

For any $l\geqslant 1$ we have

$$\frac{1}{(1/\|m\|_{L^\infty})[4\pi^2/(b-a)^2]l^2+1+\mu}\leqslant\int_{l-1}^{l}\frac{ds}{(1/\|m\|_{L^\infty})[\pi^2/(2(b-a)^2)]s^2+1+\mu}.$$

Thus,

$$\|(H_0+\mu)^{-1/2}\|^2_{\mathfrak{L}_2(\mathfrak{H})}\leqslant\frac{1}{1+\mu}+\sum_{l=1}^{\infty}\int_{l-1}^{l}\frac{ds}{(1/\|m\|_{L^\infty})[\pi^2/(2(b-a)^2)]s^2+1+\mu},$$

which yields

$$\|(H_0+\mu)^{-1/2}\|^2_{\mathfrak{L}_2(\mathfrak{H})}\leqslant\frac{1}{1+\mu}+\sqrt{\|m\|_{L^\infty}}\,\frac{b-a}{\sqrt{2}}\,\frac{1}{\sqrt{1+\mu}}.$$

A polymer expansion for the quantum Heisenberg ferromagnet wave function

Paul Federbush[a)]
Department of Mathematics, University of Michigan, Ann Arbor, Michigan 48109-1109

(Received 17 June 2003; accepted 17 September 2003)

A polymer expansion is given for the quantum Heisenberg ferromagnet wave function. Working on a finite lattice, one is dealing entirely with algebraic identities; there is no question of convergence. The conjecture to be pursued in further work is that effects of large polymers are small. This is relevant to the question of the utility of the expansion and its possible extension to the infinite volume. In themselves the constructions of the present paper are neat and elegant and have surprising simplicity. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1627958]

This paper assumes the fundamentals of the Heisenberg model but is basically self-contained; it arises from the work in Refs. 1 and 2, but these references need not be referred to. We intend to continue the work in the present paper, to obtain bounds on polymer contributions enabling extension to the infinite lattice.

Unpublished preprints (Refs. 1 and 2) are the previous works by the author, directly related to the current paper. Reference 1 is an experimental study of a number of approximations for certain spin expectations. Incidentally, one of the formal constructs studied below was introduced, with some properties there stated without proof, which are in the present paper. This is detailed below. We do hope that the present cluster expansion can be used to justify some of the approximations of Ref. 1; this is a line of theoretical interest for future work. In Ref. 2 there is an alternate construction of a cluster expansion to our present one. Therein there is also proof of convergence in the t small region. Our present construction is much simpler. Whether patent or latent, underlying all our work on the Heisenberg model is the hope that it eventually leads to a proof of the phase transition.

Equation (16) is the representation of the Heisenberg wave function we devote this paper towards developing. It is in the form commonly called a ''polymer expansion'' or ''cluster expansion'' in statistical mechanics nomenclature. At the end of the paper we give a brief physical discussion addressing usual interpretations of such expansions.

We work with a finite rectangular lattice, V, in d-dimensions, $\mathcal{V}$ the set of its vertices. The Hamiltonian is taken as

$$H=-\sum_{i\sim j}\ \frac{1}{2}\ (\boldsymbol{\sigma}_i\cdot\boldsymbol{\sigma}_j-1)=-\sum_{i\sim j}\ (I_{ij}-1), \tag{1}$$

where I_{ij} interchanges the spins at nearest neighbor sites i and j. The Hilbert space $\mathcal{H}$ is constructed from basis elements $\mathbf{i}_{\mathcal{S}}$, basis elements in 1–1 correspondence with subsets $\mathcal{S}$ of $\mathcal{V}$, used for their labeling. In a spin-up spin-down representation

$$\mathbf{i}_{\mathcal{S}}=\bigotimes_{i\in\mathcal{S}}\begin{pmatrix}1\\0\end{pmatrix}_i\bigotimes_{j\notin\mathcal{S}}\begin{pmatrix}0\\1\end{pmatrix}_j. \tag{2}$$

A vector $\mathbf{f}$ in $\mathcal{H}$ may be expanded as

a)Electronic mail: pfed@umich.edu

$$\mathbf{f}=\sum_{\mathcal{S}} f(\mathcal{S})\mathbf{i}_{\mathcal{S}}. \tag{3}$$

For two sets $\mathcal{S}$ and $\mathcal{S}'$ we write $\mathcal{S}\sim\mathcal{S}'$ if $\mathcal{S}'$ is constructed from $\mathcal{S}$ by replacing some single element of $\mathcal{S}$ by one of its nearest neighbors. That is, $\mathcal{S}\sim\mathcal{S}'$ if there is a set $\mathcal{F}$ and elements of $\mathcal{V}$, i and j, so that

$$\begin{aligned}\mathcal{S}&=\mathcal{F}\cup i,\\ \mathcal{S}'&=\mathcal{F}\cup j,\end{aligned} \tag{4}$$

where $i\sim j$ and the unions in (4) are disjoint. If we write

$$\mathbf{f}(t)=e^{-Ht}\mathbf{f}=\sum_{\mathcal{S}} f(\mathcal{S},t)\mathbf{i}_{\mathcal{S}}, \tag{5}$$

it is easy to see that the $f(\mathcal{S},t)$ satisfy the differential equations

$$\frac{\partial}{\partial t}f(\mathcal{S},t)=\sum_{\mathcal{S}'\sim\mathcal{S}}(f(\mathcal{S}',t)-f(\mathcal{S},t)). \tag{6}$$

This is the graph heat equation, corresponding to a graph with vertices the subsets of $\mathcal{V}$, and with an edge connecting vertices $\mathcal{S}_1$ and $\mathcal{S}_2$ if and only if $\mathcal{S}_1\sim\mathcal{S}_2$. Physically, Eq. (6) is the imaginary time Schrödinger equation corresponding to the quantum Heisenberg Hamiltonian given in (1). (In Ref. 1 as in many other places the Heisenberg model has been experimentally studied by solving the coupled differential equations of (6) numerically.)

We now write $\mathcal{H}$ as direct sum

$$\mathcal{H}=\bigoplus_{n=0}^{\#(\mathcal{V})}\mathcal{H}^n, \tag{7}$$

where as indicated n ranges from 0 to $\#(\mathcal{V})$. $\mathcal{H}^n$ is spanned by the basis elements $\mathbf{i}_{\mathcal{S}}$, where $\#(\mathcal{S})=n$. $\mathcal{H}^n$ is the n spin-wave vector of the Hilbert space $\mathcal{H}$. The $\mathcal{H}^n$ are invariant subspaces of H. We write H^n for H restricted to $\mathcal{H}^n$.

We introduce operators $T^{r,s}$, where $T^{r,s}$ is a linear mapping from $\mathcal{H}^r$ to $\mathcal{H}^s$. They are defined as follows:

(1) $T^{r,r}$ is the identity on $\mathcal{H}^r$;
(2) If $s>r$,

$$T^{r,s}=0;$$

(3) If $s<r$ let $\mathbf{g}$ be in $\mathcal{H}^r$,

$$\mathbf{g}=\sum_{\mathcal{S}} g(\mathcal{S})\mathbf{i}_{\mathcal{S}}, \tag{8}$$

where $g(\mathcal{S})$ is nonzero only if $\#(\mathcal{S})=r$. Let

$$\mathbf{h}=T^{r,s}\mathbf{g}=\sum_{\mathcal{S}} h(\mathcal{S})\mathbf{i}_{\mathcal{S}}. \tag{9}$$

Then $h(\mathcal{S})=0$ unless $\#(\mathcal{S})=s$, and

$$h(\mathcal{S}) = \sum_{\mathcal{S}' \supset \mathcal{S}} g(\mathcal{S}') \quad \text{if} \quad \#(\mathcal{S}) = s. \tag{10}$$

We note that if $r > s > k$, then

$$T^{s,k} T^{r,s} = \frac{(r-k)!}{(s-k)!(r-s)!} T^{r,k}. \tag{11}$$

This is easy counting.

A nice result is that $T^{r,s}$ intertwines H^r and H^s. That is

$$T^{r,s} H^r = H^s T^{r,s}, \tag{12}$$

where both sides of (12) are viewed as mappings from $\mathcal{H}^r$ to $\mathcal{H}^s$. This is treated in Appendix A. The formalism of the mappings $T^{r,s}$ was introduced in Sec. II of Ref. 1, without proofs therein. We know of no earlier references to these operators. They may also be studied as a direct consequence of the global rotation invariance of the Heisenberg model, a viewpoint we do not pursue here. From any view, upon familiarlity the $T^{r,s}$ and their properties soon become trivial. A similar more complex parallel theory is given in Ref. 3 for random walks on the permutation group, instead of subspaces of a lattice.

We start presenting the polymer expansion for $\mathbf{f}(t)$ of Eq. (5). We assume $\mathbf{f}(t)$ is normalized so that

$$\sum_{\mathcal{S}} f(\mathcal{S}, t) = 1. \tag{13}$$

We note that if at any time this equation holds, the heat equation, Eq. (6), preserves the identity. We do not consider the possibility that the sum on the left-hand side of (13) be zero, so no such normalization is possible.

We let $\mathcal{P}$ be a partition of $\mathcal{V}$. We write $\mathcal{S}_\alpha < \mathcal{P}$ for a subset $\mathcal{S}_\alpha$ of the partition $\mathcal{P}$. One has

$$S_\alpha \cap S_\beta = \varnothing, \quad \alpha \neq \beta, \tag{14}$$

$$\bigcup_{\alpha \in I^{\mathcal{P}}} \mathcal{S}_\alpha = \mathcal{V}. \tag{15}$$

We will have (summing over all such partitions)

$$\mathbf{f}(t) = \sum_{\mathcal{P}} \bigotimes_{\mathcal{S}\alpha < \mathcal{P}} \mathbf{u}(\mathcal{S}_\alpha, t), \tag{16}$$

where

$$\mathbf{u}(\mathcal{S}_\alpha, t) = \begin{pmatrix} \phi_i(t) \\ 1 - \phi_i(t) \end{pmatrix}_i \tag{17}$$

if $\mathcal{S}_\alpha = \{i\}$.

If $\#(\mathcal{S}_\alpha) = r > 1$,

$$\mathbf{u}(\mathcal{S}_\alpha, t) = u^r(\mathcal{S}_\alpha, t) \bigotimes_{i \in \mathcal{S}\alpha} \begin{pmatrix} 1 \\ -1 \end{pmatrix}_i. \tag{18}$$

We also write

$$u(\mathcal{S},t)=u^r(\mathcal{S},t) \quad \text{if} \quad \#(\mathcal{S})=r \tag{19}$$

and, for the special case $r=1$,

$$u(\mathcal{S},t)=u^1(\mathcal{S},t)=\phi_i(t) \quad \text{if} \quad \mathcal{S}=\{i\}. \tag{20}$$

We write $\mathbf{f}(t)$ as a sum of its different spin-wave number components

$$\mathbf{f}(t)=\sum_{n=0}^{\#(\mathcal{V})} \mathbf{f}_n(t), \tag{21}$$

$$\mathbf{f}_n(t)\in\mathcal{H}^n. \tag{22}$$

We set

$$\mathbf{c}_r(t)=\sum_{n=0}^{\#(\mathcal{V})} T^{n,r}\mathbf{f}_n(t) \tag{23}$$

and

$$\mathbf{c}_r(t)=\sum_{\mathcal{S}} c^r(\mathcal{S},t)\mathbf{i}_{\mathcal{S}}. \tag{24}$$

(Notice that the c^r satisfy the graph heat equation, (6).) Then we find that Eq. (16) is satisfied if the $u(\mathcal{S},t)$ are chosen to satisfy:

$$c^r(\mathcal{S},t)=u^r(\mathcal{S},t)+\sum_{\mathcal{P}} \prod_{\mathcal{S}_\beta<\mathcal{P}} u(\mathcal{S}_\beta,t), \tag{25}$$

where here the $\mathcal{P}$ are all **proper** partitions of $\mathcal{S}$ and $\#(\mathcal{S})=r$. r will range from 1 to $\#(\mathcal{V})$. Equations (16) and (25) are prototype cluster-expansion/polymer-expansion equations. But the form of Eq. (18) is perhaps surprising. Appendix B treats the consistency of the formalism; that there is a unique solution for the u's from (25), and they yield Eq. (16).

We present in bold strokes the conventional ways of thinking about cluster expansions like Eq. (16). In the second term in Eq. (5) as one expands the exponent in powers of H, each I_{ij} that appears represents a ''collision'' and interchanges spins at i and j. We can neglect interchanges when both spins are the same. Then we have a picture where spins ''collide'' and change places. The evolution yields a sequence of collisions and corresponding motions of the spins. This naturally leads to a ''random-walk'' picture of spins moving and colliding. $u^r(\mathcal{S},t)$ is related to a process where the spins at the sites in $\mathcal{S}$ at time t have had a history in which they have all mutually collided, and where spins in no smaller subset of $\mathcal{S}$ has not collided with spins in the complementary portion of $\mathcal{S}$.

Reference 4 is a standard general treatment of cluster expansions, and Ref. 5 a treatment of the random walk picture sketched above. However knowledge of these detailed technical directions will not simplify our derivation above; and further, starting from Refs. 4 and 5, I think it unlikely that many researchers would find our ''simple'' result. However to get the estimates on the u^r needed for applications, these references will be useful.

The proof of convergence in the infinite volume, commonly referred to simply as ''convergence of the cluster expansion,'' depends on obtaining appropriate bounds on the u^r. Convergence in the ''small t'' region was proven in Ref. 2 for a different construction of a cluster expansion. A proof for the ''small t'' region can certainly be greatly simplified over that in Ref. 2. The author believes that the expansion converges also in the ''large t'' region, i.e., for $t>T_0$ for some T_0 (possibly even for all t). This will be difficult to prove. It seems that the proof for large t will depend on incorporating unusual probabilistic estimates, exhibiting probabilistic cancellations in

certain sums involving many terms. One may hope that the compact form of the present construction of the cluster expansion may simplify some details of a proof, still a substantial theoretical challenge.

APPENDIX A: INTERTWINING RESULT

In virtue of Eq. (11) it is enough to show $T^{r,r-1}$ intertwines. We choose to show equivalently that $T^{r,r-1}$ carries a solution of the heat equation into a solution of the heat equation. Let $f(\mathcal{S},t)$ satisfy the heat equation, and be zero unless $\#(\mathcal{S})=r$. We define

$$g(s,t)=\sum_j f(s\cup j,t),\quad \#(s)=r-1. \tag{A1}$$

We wish to show g satisfies the heat equation. Writing the heat equation for f:

$$\frac{\partial f}{\partial t}(s\cup i,t)=\sum_{\mathcal{S}'\sim(s\cup i)}(f(\mathcal{S}',t)-f(s\cup i,t)). \tag{A2}$$

We sum the two sides of (A2) over i,

$$\frac{\partial}{\partial t}g(s,t)=\sum_i\sum_{\mathcal{S}'\sim(s\cup i)}(f(\mathcal{S}',t)-f(s\cup i,t)). \tag{A3}$$

The right-hand side splits into two terms I_1 and I_2,

$$I_1=\sum_i\sum_{s'\sim s}(f(s'\cup i,t)-f(s\cup i,t)) \tag{A4}$$

and

$$I_2=\sum_i\sum_{j\sim i}(f(s\cup j,t)-f(s\cup i,t)). \tag{A5}$$

It is easy to see

$$I_1=\sum_{s'\sim s}(g(s',t)-g(s,t)) \tag{A6}$$

and just a little harder to see

$$I_2=0$$

and the result is proved.

APPENDIX B: IN THREE PARTS

We divide the demonstration of consistency into three parts:

(i) We first note that Eq. (25) has a unique solution for the u^r (these are the unknowns). One solves inductively over r, the rth equation uniquely determining u^r.

(ii) Once the u's are determined from Eq. (25), we substitute them in the right-hand side of Eq. (16) which we call $\mathbf{X}(t)$, so Eq. (16) becomes

$$\mathbf{f}(t)=\mathbf{X}(t). \tag{B1}$$

(Of course we do not know whether (B1) is true, that is what we are trying to show.) We decompose $\mathbf{X}(t)$,

$$\mathbf{X}(t)=\sum_{n=0}^{\#(\mathcal{V})}\mathbf{X}_n(t), \tag{B2}$$

$$\mathbf{X}_n(t)\in\mathcal{H}^n, \tag{B3}$$

and define

$$\mathbf{d}_r(t)=\sum_{n=0}^{\#(\mathcal{V})}T^{n,r}\mathbf{X}_n(t), \tag{B4}$$

$$\mathbf{d}_r(t)=\sum_{\mathcal{S}}d^r(\mathcal{S},t)\mathbf{i}_{\mathcal{S}}. \tag{B5}$$

The result we seek to now show is the following: If $d^r(\mathcal{S},t)=c^r(\mathcal{S},t)$ all $\mathcal{S},r$, then $\mathbf{f}(t)=\mathbf{X}(t)$.

This we also show by induction over r, but in the opposite direction, from $r=\#(\mathcal{V})$ down to $r=0$. At the step $r=r$ we clearly get

$$\mathbf{f}_r(t)=\mathbf{X}_r(t). \tag{B6}$$

(One only needs $T^{r,r}=I$, and $T^{r,s}=0$ if $s>r$.)

(iii) We are left with the task of showing

$$d^r(\mathcal{S},t)=c^r(\mathcal{S},t). \tag{B7}$$

We first do a preliminary investigation.

Let

$$\mathbf{h}(t)=\sum h(\mathcal{S},t)\mathbf{i}_{\mathcal{S}} \tag{B8}$$

$$=\sum_{n=0}^{\#(\mathcal{V})}\mathbf{h}_n(t), \tag{B9}$$

$$\mathbf{h}_n(t)\in\mathcal{H}^n \tag{B10}$$

and define

$$\mathbf{g}_r(t)=\sum_n T^{n,r}\mathbf{h}_n(t) \tag{B11}$$

$$=\sum_{\mathcal{S}}g^r(\mathcal{S},t)\mathbf{i}_{\mathcal{S}}. \tag{B12}$$

We then find the following expression for $g^r(\mathcal{S},t)$:

$$g^r(\mathcal{S},t)=\sum_{\substack{\mathcal{S}'\\ \mathcal{S}'\cap\mathcal{S}=\phi}}h(\mathcal{S}\cup\mathcal{S}',t), \tag{B13}$$

where $\#(\mathcal{S})=r$.

Now when we compute $d^r(\mathcal{S},t)$ using expression (B13) with X replacing h ($\mathbf{X}(t)=\Sigma_{\mathcal{S}}X(\mathcal{S},t)\mathbf{i}_{\mathcal{S}}$), the only terms in the expression for $\mathbf{X}(t)$ from (16) which will contribute are of the form

$$\left(\mathbf{u}^r(\mathcal{S},t)+\sum_{\mathcal{P}}\bigotimes_{\mathcal{S}_\beta<\mathcal{P}}\mathbf{u}(\mathcal{S}_\beta,t)\right)\bigotimes_{i\notin\mathcal{S}}\begin{pmatrix}\phi_i(t)\\ 1-\phi_i(t)\end{pmatrix}_i \tag{B14}$$

using the notation from Eq. (25). That is because the sum over $\mathcal{S}'$ in (B13) may be written as an iterated sum, summing for each vertex not in $\mathcal{S}$, whether the vertex is in $\mathcal{S}'$ or not. This amounts to summing over spin-up and spin-down at that vertex. At vertex k this sum applied to the term in the tensor product

$$\begin{pmatrix} \phi_k(t) \\ 1-\phi_k(t) \end{pmatrix}_k$$

yields 1, and applied to

$$\begin{pmatrix} 1 \\ -1 \end{pmatrix}_k$$

yields 0. We get from the terms in $\mathbf{X}(t)$ in (B14) that

$$d^r(\mathcal{S},t)=c^r(\mathcal{S},t). \tag{B15}$$

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 1 JANUARY 2004

On the Pauli operator for the Aharonov–Bohm effect with two solenoids

V. A. Geyler
Department of Mathematics, Mordovian State University, Bolshevistskaya 68, Saransk 430000, Russia

P. Šťovíček
Department of Mathematics, Faculty of Nuclear Science, Czech Technical University, Trojanova 13, 120 00 Prague, Czech Republic

(Received 23 June 2003; accepted 18 September 2003)

We consider a spin-1/2 charged particle in the plane under the influence of two idealized Aharonov–Bohm fluxes. We show that the Pauli operator as a differential operator is defined by appropriate boundary conditions at the two vortices. Further we explicitly construct a basis in the deficiency subspaces of the symmetric operator obtained by restricting the domain to functions with supports separated from the vortices. This construction makes it possible to apply the Krein's formula to the Pauli operator. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1629395]

I. INTRODUCTION

The goal of the present paper is to provide a more detailed analysis of the Pauli operator describing a spin-1/2 charged particle under the influence of two Aharonov–Bohm (AB) fluxes.[1] We consider the idealized setup when the magnetic fluxes are concentrated along two parallel lines so that the problem effectively reduces to a two-dimensional quantum system living in a perpendicular plane. In what follows we call the intersection points of the fluxes with the plane vortices.

To define the Pauli Hamiltonian with singular fluxes we use the Aharonov–Casher decomposition.[2] It makes it possible to introduce the two diagonal components of the Pauli operator corresponding to spin up and down as the unique self-adjoint operators associated to appropriate quadratic forms. Since the magnetic field vanishes outside of the vortices the two components of the Pauli Hamiltonian as well as the spinless AB Hamiltonian are self-adjoint extensions of the same symmetric operator. In the case of one AB flux all the self-adjoint extensions are known to be defined by appropriate boundary conditions at the vortex.[3,4] Thus our first goal was to distinguish the boundary conditions defining the two components of the Pauli Hamiltonian.

The second goal was to construct a basis in the deficiency subspaces in the two-vortex case. In this case as well the two diagonal components of the Pauli Hamiltonian and the spinless Hamiltonian are self-adjoint extensions of a common symmetric operator. We show that the deficiency indices of this symmetric operator are (4,4). The construction is based on the observation that the coefficients $\psi(x)$ standing at singular terms in the asymptotic expansion in the variable x_0 at a vortex of the Green function $\mathcal{G}_z(x,x_0)$ belong to the deficiency subspace with spectral parameter z. Here we make use of the explicit knowledge of the spinless two-vortex Green function $\mathcal{G}_z(x,x_0)$.[5]

The next and final goal which naturally follows is a construction of the two-vortex Green function for the Pauli Hamiltonian with the aid of the Krein's formula. Even this problem is solved explicitly. Surprisingly many features can be again derived from the asymptotic analysis near a vortex.

The paper is organized as follows. In Sec. II we summarize some basic facts and formulas concerning the spinless AB Hamiltonian with one and two vortices. In Sec. III we introduce the Pauli operator with one and two AB fluxes and derive the boundary conditions at a vortex defining

the spin up and down components of the Pauli Hamiltonian. In Sec. IV we provide a basic asymptotic analysis near a vortex of functions from the deficiency subspaces as well as that of the spinless Green function. In Sec. V we construct a basis in the deficiency subspaces. Section VI is devoted to the application of the Krein's formula to our problem.

II. PRELIMINARIES. THE AB HAMILTONIAN FOR A SPINLESS PARTICLE

The AB Hamiltonian with one vortex and describing a spinless particle, H_0, was introduced in Ref. 1 and studied in a long series of papers by many authors. For example, one can consult Ref. 6 for some mathematical details. It acts in $L^2(\mathbb{R}^2, \mathrm{d}^2x)$ and is nothing but the self-adjoint operator associated to the closure of the positive quadratic form

$$\int_{\mathbb{R}^2}\left(\left|\left(\partial_{x_1}-i\frac{\alpha x_2}{|x|^2}\right)\varphi\right|^2+\left|\left(\partial_{x_2}+i\frac{\alpha x_1}{|x|^2}\right)\varphi\right|^2\right)\mathrm{d}^2x\,, \tag{1}$$

defined on the space of test functions $\mathcal{D}(\mathbb{R}^2\backslash\{0\})$. In other words, H_0 is the Friedrichs extension of the corresponding symmetric operator with the domain $\mathcal{D}(\mathbb{R}^2\backslash\{0\})$. Owing to the gauge equivalence we can assume that $\alpha\in(0,1)$.

We shall use the polar coordinates (r,θ) with the angle $\theta\in(-\pi,\pi)$. This implies a cut along the negative x_1 half-axis. Sometimes it is convenient to apply the unitary operator

$$(U_\alpha\varphi)(r,\theta)=e^{i\alpha\theta}\varphi(r,\theta)$$

and work with the unitarily equivalent operator

$$H=U_\alpha H_0 U_\alpha^{-1}\,.$$

In particular this unitary transformation is useful when constructing the Green function. This means that

$$\mathrm{Dom}(H)=U_\alpha(\mathrm{Dom}(H_0))\,.$$

Formally, as a differential operator,

$$H=-\Delta\,.$$

The domain of H is determined by the boundary conditions at the cut, namely,

$$\psi(r,\pi)=e^{2\pi i\alpha}\psi(r,-\pi),\quad \partial_r\psi(r,\pi)=e^{2\pi i\alpha}\partial_r\psi(r,-\pi)\,. \tag{2}$$

In addition, one should take care about boundary conditions at the vortex. As analyzed in Refs. 3 and 4, the domain of H_0 is characterized by the boundary condition $\varphi(0)=0$. Since $\psi(r,\theta)=\exp(i\alpha\theta)\varphi(r,\theta)$ the same is true for $\mathrm{Dom}(H)$, namely the boundary condition at the vortex reads $\psi(0)=0$.

The generalized eigenfunctions of H,

$$\left\{\frac{1}{\sqrt{2\pi}}J_{|n+\alpha|}(k\,r)\,e^{i(n+\alpha)\theta}\right\}_{k>0,\,n\in\mathbb{Z}},$$

form a complete normalized set,

$$\int_0^\infty J_\nu(k\,x)\,J_\nu(k\,y)\,k\,\mathrm{d}k=\frac{1}{x}\,\delta(x-y)\,.$$

This makes it possible to write down the Green function and the propagator as integrals,

$$\mathcal{G}_z(r,\theta;r_0,\theta_0)=\frac{1}{2\pi}\sum_{n\in\mathbb{Z}} e^{i(n+\alpha)(\theta-\theta_0)}\int_0^\infty \frac{J_{|n+\alpha|}(k\,r)\,J_{|n+\alpha|}(k\,r_0)}{k^2-z}\,k\,\mathrm{d}k \tag{3}$$

and

$$\mathcal{K}_t(r,\theta;r_0,\theta_0)=\frac{1}{2\pi}\sum_{n\in\mathbb{Z}} e^{i(n+\alpha)(\theta-\theta_0)}\int_0^\infty e^{-i\,k^2 t}J_{|n+\alpha|}(k\,r)\,J_{|n+\alpha|}(k\,r_0)\,k\,\mathrm{d}k\,. \tag{4}$$

They are related by the Laplace transform,

$$\mathcal{G}_z(r,\theta;r_0,\theta_0)=\int_0^\infty e^{z\,t}\,\mathcal{K}_{-i\,t}(r,\theta;r_0,\theta_0)\,\mathrm{d}t\,.$$

Starting from (4) one can derive the following formula for the propagator:[5]

$$\mathcal{K}_t(r,\theta;r_0,\theta_0)=\left\{\begin{array}{c}1\\ e^{2\pi i\alpha}\\ e^{-2\pi i\alpha}\end{array}\right\}\frac{1}{4\pi i\,t}\exp\left(-\frac{1}{4i\,t}|x-x_0|^2\right)-\frac{\sin(\pi\alpha)}{\pi}\int_{-\infty}^{\infty}\frac{1}{4\pi i\,t}$$
$$\times\exp\left(-\frac{1}{4i\,t}R(s)^2\right)\frac{e^{-\alpha s+i\alpha(\theta-\theta_0)}}{1+e^{-s+i(\theta-\theta_0)}}\,\mathrm{d}s\,, \tag{5}$$

where

$$|x-x_0|^2=r^2+r_0^2-2r\,r_0\cos(\theta-\theta_0),\quad R(s)^2=r^2+r_0^2+2r\,r_0\cosh(s),$$

and the phase factor in front of the first term depends on whether

$$\theta-\theta_0\in(-\pi,\pi),\ (\pi,2\pi)\ \text{ or }\ (-2\pi,-\pi).$$

The Laplace transformation results in a formula for the Green function,

$$\mathcal{G}_z(r,\theta;r_0,\theta_0)=\left\{\begin{array}{c}1\\ e^{2\pi i\alpha}\\ e^{-2\pi i\alpha}\end{array}\right\}\frac{1}{2\pi}K_0(\sqrt{-z}|x-x_0|)$$
$$-\frac{\sin(\pi\alpha)}{\pi}\int_{-\infty}^{\infty}\frac{1}{2\pi}K_0(\sqrt{-z}\,R(s))\frac{e^{-\alpha s+i\alpha(\theta-\theta_0)}}{1+e^{-s+i(\theta-\theta_0)}}\,\mathrm{d}s\,. \tag{6}$$

The second term on the RHS of (6) can be given still another form with the aid of the identity

$$\int_{-\infty}^{\infty}K_{i\tau}(a)\,K_{-i\tau}(b)\,\frac{e^{\phi\,\tau}}{\sin(\pi(\alpha+i\tau))}\,\mathrm{d}\tau\quad=\int_{-\infty}^{\infty}K_0(\sqrt{a^2+b^2+2\,a\,b\cosh(u)}\,)\,\frac{e^{-\alpha(u-i\,\phi)}}{1+e^{-u+i\,\phi}}\,\mathrm{d}u$$

for $a>0$, $b>0$, $0<\alpha<1$, and $|\phi|<\pi$. This way we get

$$\mathcal{G}_z(r,\theta;r_0,\theta_0)=\frac{1}{2\pi}K_0(\sqrt{-z}|x-x_0|)$$
$$-\frac{\sin(\pi\alpha)}{2\pi^2}\int_{-\infty}^{\infty}K_{i\tau}(\sqrt{-z}\,r)\,K_{-i\tau}(\sqrt{-z}\,r_0)\,\frac{e^{(\theta-\theta_0)\,\tau}}{\sin(\pi(\alpha+i\,\tau))}\,\mathrm{d}\tau \tag{7a}$$

for $\theta-\theta_0\in(-\pi,\pi)$,

$$\mathcal{G}_z(r,\theta;r_0,\theta_0)=e^{2\pi i\alpha}\left(\frac{1}{2\pi}K_0(\sqrt{-z}|x-x_0|)\right.$$
$$\left.-\frac{\sin(\pi\alpha)}{2\pi^2}\int_{-\infty}^{\infty}K_{i\tau}(\sqrt{-z}\,r)\,K_{-i\tau}(\sqrt{-z}\,r_0)\frac{e^{(\theta-\theta_0-2\pi)\tau}}{\sin(\pi(\alpha+i\tau))}\,\mathrm{d}\tau\right) \qquad (7b)$$

for $\theta-\theta_0\in(\pi,2\pi)$, and

$$\mathcal{G}_z(r,\theta;r_0,\theta_0)=e^{-2\pi i\alpha}\left(\frac{1}{2\pi}K_0(\sqrt{-z}|x-x_0|)\right.$$
$$\left.-\frac{\sin(\pi\alpha)}{2\pi^2}\int_{-\infty}^{\infty}K_{i\tau}(\sqrt{-z}\,r)\,K_{-i\tau}(\sqrt{-z}\,r_0)\frac{e^{(\theta-\theta_0+2\pi)\tau}}{\sin(\pi(\alpha+i\tau))}\,\mathrm{d}\tau\right) \qquad (7c)$$

for $\theta-\theta_0\in(-2\pi,-\pi)$.

Despite this threefold description depending on the value of $\theta-\theta_0$ the Green function should be continuous, even real analytic, in its domain of definition if $x\neq x_0$. Checking the limits from the right and left for $\theta-\theta_0=\pm\pi$ one finds that the continuity is guaranteed by the identity

$$\int_{-\infty}^{\infty}K_{i\tau}(a)\,K_{-i\tau}(b)\,\mathrm{d}\tau=\pi K_0(a+b)\quad\text{for } a>0,\ b>0.$$

Let us add a remark on deficiency subspaces. First we recall a general and easy to verify fact. Let A be a self-adjoint extension of a symmetric operator X. Denote by $\mathcal{N}(z)=\mathrm{Ker}(X^*-z)$ the deficiency subspaces, $\mathrm{Im}\,z\neq0$. Then it holds

$$f\in\mathcal{N}(w)\Rightarrow f+(z-w)(A-z)^{-1}f\in\mathcal{N}(z)\,.$$

This can be illustrated on our problem. We choose H [the one-vortex AB Hamiltonian defined by the boundary conditions (2)] for A, and X is a restriction of H obtained by requiring the supports of functions from the domain of X to be separated from the singular point (the origin). The deficiency indices are known to be (2,2). For a basis in $\mathcal{N}(z)$ we can choose the vectors

$$\psi_{-1,z}(r,\theta)=K_{1-\alpha}(\sqrt{-z}\,r)e^{i(\alpha-1)\theta},\quad \psi_{0,z}(r,\theta)=K_{\alpha}(\sqrt{-z}\,r)e^{i\alpha\theta}. \qquad (8)$$

Here $z\in\mathbb{C}\backslash\mathbb{R}_+$, $\mathrm{Re}\,\sqrt{-z}>0$. As shown in Ref. 3 it holds true that

$$\int_0^{\infty}\left(\int_{-\pi}^{\pi}\mathcal{G}_z(r,\theta;r_0,\theta_0)\,\psi_{0,w}(r_0,\theta_0)\,\mathrm{d}\theta_0\right)r_0\,\mathrm{d}r_0$$
$$=\frac{1}{z-w}e^{i\alpha\theta}\left(\left(\frac{\sqrt{-z}}{\sqrt{-w}}\right)^{\alpha}K_{\alpha}(\sqrt{-z}\,r)-K_{\alpha}(\sqrt{-w}\,r)\right),$$

hence

$$\psi_{0,w}+(z-w)(H-z)^{-1}\psi_{0,w}=\left(\frac{\sqrt{-z}}{\sqrt{-w}}\right)^{\alpha}\psi_{0,z}\,. \qquad (9)$$

Similarly,

$$\psi_{-1,w}+(z-w)(H-z)^{-1}\psi_{-1,w}=\left(\frac{\sqrt{-z}}{\sqrt{-w}}\right)^{1-\alpha}\psi_{-1,z}\,. \qquad (10)$$

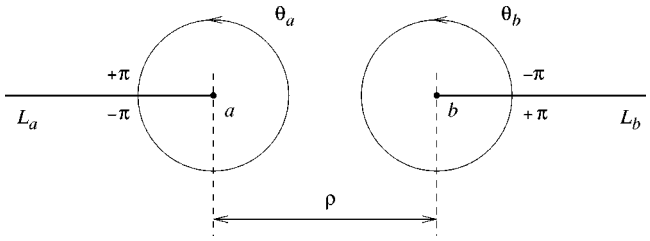

FIG. 1. Geometrical arrangement. Choice of the cuts L_a, L_b and choice of the angle variables θ_a, θ_b.

Let us now focus on the case of two vortices but still considering a spineless particle. The vortices are supposed to be located in the points $a=(0,0)$ and $b=(\rho,0)$, $\rho>0$. Let (r_a,θ_a) be the polar coordinates centered at the point a and (r_b,θ_b) be the polar coordinates centered at the point b. The two-vortex AB Hamiltonian H_0 is the unique self-adjoint operator associated to the quadratic form

$$\int_{\mathbb{R}^2}(|(-i\,\partial_{x_1}-A_1)\varphi|^2+|(-i\,\partial_{x_2}-A_2)\varphi|)^2\,\mathrm{d}^2x\,, \tag{11a}$$

where

$$A=-\alpha\,\mathrm{d}\theta_a-\beta\,\mathrm{d}\theta_b\,. \tag{11b}$$

Again, owing to the gauge equivalence, we can assume that $\alpha,\beta\in(0,1)$.

Also in this case one can pass to a unitarily equivalent formulation. The plane is cut along two half-lines,

$$L_a=(-\infty,0)\times\{0\}\quad\text{and}\quad L_b=(\rho,+\infty)\times\{0\}.$$

The values $\theta_a=\pm\pi$ correspond to the two sides of the cut L_a and similarly for θ_b and L_b. The geometrical arrangement is sketched in Fig. 1. The unitarily equivalent Hamiltonian H is formally equal to $-\Delta$ and is determined by the boundary conditions along the cut,

$$\begin{aligned}&\psi(r_a,\theta_a=\pi)=e^{2\pi i\alpha}\psi(r_a,\theta_a=-\pi),\quad \partial_{r_a}\psi(r_a,\theta_a=\pi)=e^{2\pi i\alpha}\partial_{r_a}\psi(r_a,\theta_a=-\pi)\,,\\&\psi(r_b,\theta_b=\pi)=e^{2\pi i\beta}\psi(r_b,\theta_b=-\pi),\quad \partial_{r_b}\psi(r_b,\theta_b=\pi)=e^{2\pi i\beta}\partial_{r_b}\psi(r_b,\theta_b=-\pi)\,.\end{aligned} \tag{12}$$

In addition, one should impose a boundary condition at the vortex, namely, $\psi(a)=\psi(b)=0$.

A formula for the Green function of the Hamiltonian H is known also in the case of two vortices.[5] For a couple of points $x,x_0\in\mathbb{R}^2\backslash(L_a\cup L_b)$ we set

$$\zeta_a=1\quad\text{or}\quad\zeta_a=e^{2\pi i\alpha}\quad\text{or}\quad\zeta_a=e^{-2\pi i\alpha}$$

depending on whether the segment $\overline{x_0x}$ does not intersect L_a, or $\overline{x_0x}$ intersects L_a and x_0 lies in the lower half-plane, or $\overline{x_0x}$ intersects L_a and x_0 lies in the upper half-plane. Analogously,

$$\zeta_b=1\quad\text{or}\quad\zeta_b=e^{2\pi i\beta}\quad\text{or}\quad\zeta_b=e^{-2\pi i\beta}$$

depending on whether the segment $\overline{x_0x}$ does not intersect L_b, or $\overline{x_0x}$ intersects L_b and x_0 lies in the upper half-plane, or $\overline{x_0x}$ intersects L_b and x_0 lies in the lower half-plane. Furthermore, let us set

$$\zeta_a=e^{i\alpha\eta_a},\quad \zeta_b=e^{i\beta\eta_b},\ \text{where}\quad \eta_a,\eta_b\in\{0,2\pi,-2\pi\}.$$

Remark: Notice that if $\zeta_a \neq 1$ then necessarily $\zeta_b = 1$ and vice versa.

The formula for the Green function reads

$$\begin{aligned}
\mathcal{G}_z(x,x_0) = {} & \zeta_a\zeta_b \frac{1}{2\pi} K_0(\sqrt{-z}|x-x_0|) \\
& - \zeta_a \frac{\sin(\pi\alpha)}{2\pi^2} \int_{-\infty}^{\infty} K_{i\tau}(\sqrt{-z}\, r_a)\, K_{-i\tau}(\sqrt{-z}\, r_{0a}) \frac{e^{(\theta_a-\theta_{0a}-\eta_a)\tau}}{\sin(\pi(\alpha+i\tau))}\,\mathrm{d}\tau \\
& - \zeta_b \frac{\sin(\pi\beta)}{2\pi^2} \int_{-\infty}^{\infty} K_{i\tau}(\sqrt{-z}\, r_b)\, K_{-i\tau}(\sqrt{-z}\, r_{0b}) \frac{e^{(\theta_b-\theta_{0b}-\eta_b)\tau}}{\sin(\pi(\beta+i\tau))}\,\mathrm{d}\tau + \frac{1}{2\pi} \\
& \times \sum_{\gamma,\, n\geqslant 2} (-1)^n \int_{\mathbb{R}^n} K_{i\tau_n}(\sqrt{-z}\, r) K_{i(\tau_{n-1}-\tau_n)}(\sqrt{-z}\,\rho) \\
& \times \cdots \times K_{i(\tau_1-\tau_2)}(\sqrt{-z}\,\rho) K_{-i\tau_1}(\sqrt{-z}\, r_0) \frac{\sin(\pi\sigma_n)\exp(\theta\tau_n)}{\pi\sin(\pi(\sigma_n+i\tau_n))} \\
& \times \frac{\sin(\pi\sigma_{n-1})}{\pi\sin(\pi(\sigma_{n-1}+i\tau_{n-1}))} \times \cdots \times \frac{\sin(\pi\sigma_2)}{\pi\sin(\pi(\sigma_2+i\tau_2))} \frac{\sin(\pi\sigma_1)\exp(-\theta_0\tau_1)}{\pi\sin(\pi(\sigma_1+i\tau_1))}\,\mathrm{d}^n\tau\,.
\end{aligned} \tag{13}$$

Here the sum $\Sigma_{\gamma,\, n\geqslant 2}$ runs over all finite alternating sequences of length at least two, $\gamma = (c_n, c_{n-1}, \ldots, c_1)$, such that for all j, $c_j \in \{a,b\}$ and $c_j \neq c_{j+1}$, and $\sigma_j = \alpha$ (respectively, β) depending on whether $c_j = a$ (respectively, b). In addition, (r,θ) are the polar coordinates of the point x with respect to the center c_n, (r_0,θ_0) are the polar coordinates of the point x_0 with respect to the center c_1 (the dependence on γ is not indicated explicitly).

III. THE PAULI HAMILTONIAN WITH AB FLUXES

According to the Aharonov–Casher ansatz[2] the two diagonal components of the Pauli Hamiltonian with the third component of spin equal to $\pm 1/2$ can be factorized,

$$H^{\pm} = (p-A)^2 \mp B = P_{\pm}^{*} P_{\pm}\,,$$

where

$$P_{\pm} = (p_1 - A_1) \pm i\,(p_2 - A_2).$$

Using the complex coordinate $z = x_1 + i\,x_2$ one can rewrite the Pauli Hamiltonian as follows:

$$H^{+} = 4(-i\,\partial_z - A_z)(-i\,\partial_{\bar z} - A_{\bar z}),$$

$$H^{-} = 4(-i\,\partial_{\bar z} - A_{\bar z})(-i\,\partial_z - A_z).$$

We start our discussion from considering the situation with one vortex. Then

$$A = \frac{\alpha}{r^2}(x_2\,\mathrm{d}x_1 - x_1\,\mathrm{d}x_2) = -\alpha\;\mathrm{d}\theta = \frac{i\,\alpha}{2} e^{-2i\,\theta}\,\mathrm{d}e^{2i\,\theta} = \frac{i\,\alpha}{2}\frac{\bar z}{z}\,\mathrm{d}\frac{z}{\bar z} = \frac{i\,\alpha}{2}\left(\frac{\mathrm{d}z}{z} - \frac{\mathrm{d}\bar z}{\bar z}\right).$$

Hence

$$A_z = \frac{i\,\alpha}{2z}, \quad A_{\bar z} = -\frac{i\,\alpha}{2\bar z},$$

and we can write

$$H^+ = -4\left(\partial_z + \frac{\alpha}{2z}\right)\left(\partial_{\bar z} - \frac{\alpha}{2\bar z}\right), \quad H^- = -4\left(\partial_{\bar z} - \frac{\alpha}{2\bar z}\right)\left(\partial_z + \frac{\alpha}{2z}\right).$$

In fact, these are formal expressions. More precisely, the operators are defined as the unique self-adjoint operators associated, respectively, to the positive quadratic forms

$$\mathfrak{q}_+(\varphi) = 4\int_{\mathbb{R}^2}\left|\left(\partial_{\bar z} - \frac{\alpha}{2\bar z}\right)\varphi\right|^2 \mathrm{d}^2x, \quad \mathfrak{q}_-(\varphi) = 4\int_{\mathbb{R}^2}\left|\left(\partial_z + \frac{\alpha}{2z}\right)\varphi\right|^2 \mathrm{d}^2x, \tag{14}$$

with their natural maximal domains of definition.

Since the magnetic field vanishes on $\mathbb{R}^2\backslash\{0\}$ the operators $H^\pm$ coincide with the spinless AB Hamiltonian H_0 on the domain $\mathcal{D}(\mathbb{R}^2\backslash\{0\})$ ($\mathcal{D}$ is the space of test functions). This means that all three operators H^+, H^-, and H_0 are self-adjoint extensions of the same symmetric operator $\widetilde{X}$. From Refs. 3 and 4 it is known that all self-adjoint extensions can be described by appropriate boundary conditions at the origin. The method used to derive the boundary conditions was inspired by the description of point interactions in the plane given in Ref. 7. Let us also note that analogous boundary conditions have been derived in Ref. 8 for the model with additional homogeneous magnetic field. The Dirac operator has been discussed, for instance, in Ref. 9.

To describe the boundary conditions one introduces four functionals,

$$\Phi_1^{-1}(\varphi) = \lim_{r\downarrow 0} r^{1-\alpha}\frac{1}{2\pi}\int_0^{2\pi}\varphi(r,\theta)\, e^{i\theta}\,\mathrm{d}\theta,$$

$$\Phi_2^{-1}(\varphi) = \lim_{r\downarrow 0} r^{-1+\alpha}\left(\frac{1}{2\pi}\int_0^{2\pi}\varphi(r,\theta)\, e^{i\theta}\,\mathrm{d}\theta - r^{-1+\alpha}\Phi_1^{-1}(\varphi)\right),$$

$$\Phi_1^{0}(\varphi) = \lim_{r\downarrow 0} r^{\alpha}\frac{1}{2\pi}\int_0^{2\pi}\varphi(r,\theta)\,\mathrm{d}\theta,$$

$$\Phi_2^{0}(\varphi) = \lim_{r\downarrow 0} r^{-\alpha}\left(\frac{1}{2\pi}\int_0^{2\pi}\varphi(r,\theta)\,\mathrm{d}\theta - r^{-\alpha}\Phi_1^{0}(\varphi)\right).$$

Each boundary condition is determined by a couple of matrices $A_1, A_2 \in \mathrm{Mat}(2,\mathbb{C})$ fulfilling [the symbol (A_1, A_2) designates a 2×4 matrix]

$$\mathrm{rank}\,(A_1, A_2) = 2, \quad A_1 D^{-1} A_2^* = A_2 D^{-1} A_1^*,$$

where

$$D = \begin{pmatrix} 1-\alpha & 0 \\ 0 & \alpha \end{pmatrix}.$$

The boundary condition takes the form

$$A_1\begin{pmatrix} \Phi_1^{-1}(\varphi) \\ \Phi_1^{0}(\varphi) \end{pmatrix} + A_2\begin{pmatrix} \Phi_2^{-1}(\varphi) \\ \Phi_2^{0}(\varphi) \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}.$$

Two couples of matrices, $\{A_1, A_2\}$ and $\{A_1', A_2'\}$, determine the same boundary condition if and only if there exists a regular matrix $G \in \mathrm{GL}(2,\mathbb{C})$ such that $(A_1', A_2') = G(A_1, A_2)$.

For example, the domain of the spinless AB Hamiltonian H_0 is determined by the boundary conditions at the vortex $\Phi_1^{-1}(\varphi) = \Phi_1^{0}(\varphi) = 0$ and so by the couple of matrices

$$A_1=\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix},\quad A_2=\begin{pmatrix}0 & 0\\ 0 & 0\end{pmatrix}.$$

We wish to derive the boundary conditions for the Hamiltonians H^+ and H^-. According to the well-known construction, the operator A associated to a semibounded quadratic form $\mathfrak{q}$ is determined by the condition

$$\forall f\in\mathrm{Dom}(A)\subset\mathrm{Dom}(\mathfrak{q}),\quad \forall\varphi\in\mathrm{Dom}(\mathfrak{q}),\quad \langle\varphi,Af\rangle=\mathfrak{q}(\varphi,f)\,.$$

This is to say that $f\in\mathrm{Dom}(\mathfrak{q})$ belongs to $\mathrm{Dom}(A)$ if and only if there exists $g\in\mathcal{H}$ such that the equality $\langle\varphi,g\rangle=\mathfrak{q}(\varphi,f)$ holds true for all $\varphi\in\mathrm{Dom}(\mathfrak{q})$. In that case g is unique and $Af=g$. We are going to apply this prescription to the quadratic forms (14). This amounts to integration by parts.

More precisely, the Green formula implies that

$$\int_{\mathbb{R}^2}(\partial_z f)g\,\mathrm{d}^2x=-\int_{\mathbb{R}^2}f(\partial_z g)\,\mathrm{d}^2x-\lim_{a\downarrow 0}\frac{a}{2}\int_0^{2\pi}(fg)(a\cos(\theta),a\sin(\theta))\,e^{-i\theta}\,\mathrm{d}\theta\,.$$

Thus one finds that $f\in\mathrm{Dom}(\tilde{X}^*)$ belongs to $\mathrm{Dom}(H^+)$ if and only if for all $\varphi\in\mathrm{Dom}(\mathfrak{q}_+)$,

$$\lim_{a\downarrow 0}a\int_0^{2\pi}\left(\overline{\varphi}\left(\partial_{\overline{z}}-\frac{\alpha}{2\overline{z}}\right)f\right)(a\cos(\theta),a\sin(\theta))\,e^{-i\theta}\,\mathrm{d}\theta=0,$$

or, when expressing $(z,\overline{z})$ in the polar coordinates,

$$\lim_{a\downarrow 0}\int_0^{2\pi}(\overline{\varphi}(r\,\partial_r+i\,\partial_\theta-\alpha)f)(a\cos(\theta),a\sin(\theta))\,\mathrm{d}\theta=0.$$

Any $f\in\mathrm{Dom}(\tilde{X}^*)$ asymptotically behaves like

$$f=(\Phi_1^{-1}(f)\,r^{-1+\alpha}+\Phi_2^{-1}(f)\,r^{1-\alpha})e^{-i\theta}+(\Phi_1^0(f)\,r^{-\alpha}+\Phi_2^0(f)\,r^{\alpha})+\text{regular part}.$$

Hence

$$(r\,\partial_r+i\,\partial_\theta-\alpha)f\sim 2(1-\alpha)\Phi_2^{-1}(f)\,r^{1-\alpha}e^{-i\theta}-2\alpha\,\Phi_1^0(f)\,r^{-\alpha}+\cdots.$$

Notice that

$$(r\,\partial_r+i\,\partial_\theta-\alpha)r^{-1+\alpha}e^{-i\theta}=(r\,\partial_r+i\,\partial_\theta-\alpha)r^{\alpha}=0$$

and so any function of the form $r^{-1+\alpha}\eta(r)e^{-i\theta}$ or $r^{\alpha}\eta(r)$, with $\eta\in C^\infty(\mathbb{R}_+)$, $\eta(r)\equiv 1$ in a neighborhood of 0 and $\eta(r)\equiv 0$ in a neighborhood of $+\infty$, belongs to $\mathrm{Dom}(\mathfrak{q}_+)$. Therefore a sufficient and necessary condition for f to belong to $\mathrm{Dom}(H^+)$ is

$$\Phi_2^{-1}(f)=\Phi_1^0(f)=0. \tag{15}$$

The corresponding couple of matrices can be chosen as

$$A_1=\begin{pmatrix}0 & 1\\ 0 & 0\end{pmatrix},\quad A_2=\begin{pmatrix}0 & 0\\ 1 & 0\end{pmatrix}.$$

The other component of the Pauli Hamiltonian, H^-, can be treated similarly. One finds that $f\in\mathrm{Dom}(\tilde{X}^*)$ belongs to $\mathrm{Dom}(H^-)$ if and only if for all $\varphi\in\mathrm{Dom}(\mathfrak{q}_-)$,

$$\lim_{a\downarrow 0}\int_0^{2\pi}(\overline{\varphi}(r\,\partial_r - i\,\partial_\theta+\alpha)f)(a\cos(\theta),a\sin(\theta))\,\mathrm{d}\theta=0,$$

which turns out to be equivalent to

$$\Phi_1^{-1}(f)=\Phi_2^0(f)=0. \tag{16}$$

The corresponding couple of matrices can be chosen as

$$A_1=\begin{pmatrix}1 & 0\\ 0 & 0\end{pmatrix},\quad A_2=\begin{pmatrix}0 & 0\\ 0 & 1\end{pmatrix}.$$

The generalization to the case of several vortices is quite straightforward. One simply imposes the above derived boundary conditions at each vortex. Let us consider the case of two vortices. For the sake of simplicity we assume that the vortices are $a=(0,0)$ and $b=(1,0)$. The Pauli Hamiltonian formally reads

$$H^+=-4\left(\partial_z+\frac{1}{2}\left(\frac{\alpha}{z}+\frac{\beta}{z-1}\right)\right)\left(\partial_{\bar z}-\frac{1}{2}\left(\frac{\alpha}{\bar z}+\frac{\beta}{\bar z-1}\right)\right),$$

$$H^-=-4\left(\partial_{\bar z}-\frac{1}{2}\left(\frac{\alpha}{\bar z}+\frac{\beta}{\bar z-1}\right)\right)\left(\partial_z+\frac{1}{2}\left(\frac{\alpha}{z}+\frac{\beta}{z-1}\right)\right).$$

We still assume that $0<\alpha,\beta<1$ (in virtue of the gauge equivalence).

The Pauli Hamiltonian with two vortices is known to have zero modes.[10] They can be computed with the aid of the Aharonov–Casher ansatz since it effectively enables to reduce the second order differential equation to a first order one. Explicit solutions are even known in some essentially more complicated situations (see, for example, Ref. 11). Just for the sake of illustration let us verify that the zero modes actually satisfy the above derived boundary conditions (15) or (16).

If $\alpha+\beta<1$ then the function

$$\varphi(z)=\frac{|z|^\alpha|z-1|^\beta}{z(z-1)}$$

is L^2 integrable and solves

$$\left(\partial_{\bar z}-\frac{1}{2}\left(\frac{\alpha}{\bar z}+\frac{\beta}{\bar z-1}\right)\right)\varphi=0.$$

So it is a zero mode of H^+. It is elementary to compute its asymptotic behavior for $r_a\to 0$,

$$\varphi=r_a^{-1+\alpha}e^{-i\,\theta_a}+\left(1-\frac{\beta}{2}\right)r_a^\alpha-\frac{\beta}{2}r_a^\alpha e^{-2\,i\,\theta_a}+O(r_a^{1+\alpha}).$$

Hence φ obeys (15). The boundary condition at the vortex b is analogous.

Similarly, if $\alpha+\beta>1$ then

$$\varphi(z)=\frac{1}{|z|^\alpha|z-1|^\beta}$$

is a zero mode of H^- and

$$\varphi=-\frac{\beta}{2}r_a^{1-\alpha}e^{-i\,\theta_a}+r_a^{-\alpha}-\frac{\beta}{2}r_a^{1-\alpha}e^{i\,\theta_a}+O(r_a^{2-\alpha}).$$

Hence φ obeys (16).

IV. ASYMPTOTIC BEHAVIOR NEAR A VORTEX

Our first task in this section is the asymptotic analysis of functions from a deficiency subspace. To simplify the discussion we shall use the symbol $O(r^\gamma)$ in a sense somewhat weaker than it is common. The equality $f(r,\theta)=O(r^\gamma)$ for $r\downarrow 0$ will mean that $f(r,\theta)=\Sigma_{n\in\mathbb{Z}} f_n(r)e^{in\theta}$ and for all n it holds $f_n(r)=O(r^\gamma)$.

Lemma 1: Assume that $R>0$, $z\in\mathbb{C}\backslash\mathbb{R}_+$, $0<\alpha<1$ *and* $\varphi\in L^2(B(0,R),\mathrm{d}^2x)$ *satisfies in the weak sense the differential equation*

$$(Y-z)\varphi=0$$

on $B(0,R)\backslash\{0\}$ (*the disk centered at* 0 *with the radius equal to* R) *where* [*using the polar coordinates* (r,θ)]

$$Y=-e^{-i\alpha\theta}\Delta\, e^{i\alpha\theta}=-(\partial_{x_1}+i\alpha\,\partial_{x_1}\theta)^2-(\partial_{x_2}+i\alpha\,\partial_{x_2}\theta)^2=-\left(\frac{\partial^2}{\partial r^2}+\frac{1}{r}\frac{\partial}{\partial r}+\frac{1}{r^2}\left(\frac{\partial}{\partial\theta}+i\alpha\right)^2\right).$$

Then there exist constants c_0, d_0, c_{-1}, d_{-1}, *such that*

$$\varphi(r,\theta)=c_0r^{-\alpha}+d_0r^{\alpha}+(c_{-1}r^{-1+\alpha}+d_{-1}r^{1-\alpha})e^{-i\theta}+O(r^\gamma)\quad\text{for } r\downarrow 0\,, \tag{17}$$

where $\gamma=\min\{2-\alpha,1+\alpha\}$.

Proof: For all $n\in\mathbb{Z}$, $\eta\in\mathcal{D}((0,R))$ (the space of test functions) it holds true that

$$0=\langle(Y-\overline{z})\,\eta(r)\,e^{in\theta},\varphi\rangle=-\left\langle\left(\frac{\partial^2}{\partial r^2}+\frac{1}{r}\frac{\partial}{\partial r}+\overline{z}-\frac{(n+\alpha)^2}{r^2}\right)\eta(r)\,e^{in\theta},\varphi\right\rangle.$$

Hence

$$\varphi(r,\theta)=\sum_{n=-\infty}^{\infty} f_n(r)\,e^{in\theta},$$

where

$$\forall n\in\mathbb{Z},\ \left(\frac{\partial^2}{\partial r^2}+\frac{1}{r}\frac{\partial}{\partial r}+z-\frac{(n+\alpha)^2}{r^2}\right)f_n(r)=0\quad\text{on}\quad(0,R)$$

in the weak sense. This implies that the generalized derivative $\partial_r(r\,\partial_r f_n(r))$ belongs to $L^1_{\mathrm{loc}}((0,R))$ and consequently $f_n\in AC^2((\varepsilon,R))$ for all $0<\varepsilon<R$. Therefore necessarily $f_n(r)$ is a linear combination of the modified Bessel functions,

$$f_n(r)=a_n K_{n+\alpha}(\sqrt{-z}\,r)+b_n I_{|n+\alpha|}(\sqrt{-z}\,r).$$

Let us recall the asymptotic behavior of the Bessel functions. If $0<\nu$ and $\nu\notin\mathbb{N}$ then

$$I_\nu(r)=\frac{1}{\Gamma(\nu+1)}\left(\frac{r}{2}\right)^\nu+O(r^{\nu+2})$$

and

$$K_\nu(r)=\frac{\Gamma(\nu)}{2}\left(\frac{r}{2}\right)^{-\nu}(1+O(r^2))-\frac{\Gamma(1-\nu)}{2\nu}\left(\frac{r}{2}\right)^{\nu}(1+O(r^2)).$$

This implies that $f_n\in L^2((0,R),r\,\mathrm{d}r)$ if and only if either $a_n=0$ or $n\in\{0,-1\}$. This is to say that a_n can be nonzero only for $n=0,-1$. So if $n\neq 0,-1$ then $f_n(r)=O(r^{|n+\alpha|})$. This proves the lemma. □

Let H be the two-vortex spinless AB Hamiltonian defined by boundary conditions (12). The symbol X below stands for the symmetric operator obtained by restricting the domain of H so that functions from $\mathrm{Dom}\,X$ vanish in some neighborhood of the vortices. The deficiency subspaces are denoted by $\mathcal{N}(z)=\mathrm{Ker}(X^*-z)$.

Corollary 2: If $z\in\mathbb{C}\backslash\mathbb{R}_+$ and $\psi\in\mathcal{N}(z)$ then there exist constants $c_{a,0}$, $c_{a,-1}$, $c_{b,0}$, $c_{b,-1}$, such that

$$\psi(x)=c_{a,0}\,r_a^{-\alpha}\,e^{i\,\alpha\,\theta_a}+c_{a,-1}\,r_a^{-1+\alpha}\,e^{i(\alpha-1)\theta_a}+o(1)\quad\text{for } r_a\downarrow 0 \tag{18}$$

and

$$\psi(x)=c_{b,0}\,r_b^{-\beta}\,e^{i\,\beta\,\theta_b}+c_{b,-1}\,r_b^{-1+\beta}\,e^{i(\beta-1)\theta_b}+o(1)\quad\text{for } r_b\downarrow 0. \tag{19}$$

Proof: The property $\psi\in\mathcal{N}(z)$ means that $\psi\in L^2(B(0,R),\mathrm{d}^2x)$, $(-\Delta-z)\psi=0$ on $\mathbb{R}^2\backslash(L_a\cup L_b)$ in the weak sense and ψ satisfies the boundary conditions (12) on $L_a\cup L_b$. Then the function $\exp(-i\,\alpha\,\theta_a)\psi$ obeys the assumptions of Lemma 1 and relation (17) implies (18). Relation (19) can be shown similarly. □

Corollary 3: Assume that $z\in\mathbb{C}\backslash\mathbb{R}_+$, $\psi\in\mathcal{N}(z)$ and $\psi(a)=\psi(b)=0$. Then $\psi\in\mathrm{Dom}(H)$ and hence $\psi=0$.

Proof: We use once more the fact that $\exp(-i\,\alpha\,\theta_a)\psi$ obeys the assumptions of Lemma 1 and hence

$$\exp(-i\,\alpha\,\theta_a)\psi(x)=c_0 r_a^{-\alpha}+d_0 r_a^{\alpha}+(c_{-1}r_a^{-1+\alpha}+d_{-1}r_a^{1-\alpha})e^{-i\,\theta_a}+O(r_a^{\gamma})\quad\text{for } r_a\downarrow 0\,.$$

Since $\psi(a)=0$ it holds $c_{-1}=c_0=0$. Let U be the unitary operator on $L^2(\mathbb{R}^2,\mathrm{d}^2x)$ acting via multiplication by the phase factor $\exp(i\alpha\theta_a+i\beta\theta_b)$. Then $\varphi=\exp(-i\alpha\theta_a-i\beta\theta_b)\psi$ belongs to $\mathrm{Ker}(\tilde{X}^*-z)$ where $\tilde{X}=U^{-1}XU$. The function $\theta_b(x)$ is real analytic in a neighborhood of a and

$$\theta_b(x)=\sin(\theta_a)\,\frac{r_a}{\rho}+O(r_a^2)\quad\text{for } r_a\downarrow 0\,.$$

A straightforward computation gives the asymptotic behavior of φ and one finds that

$$\Phi_1^{-1}(\varphi)=c_{-1},\quad \Phi_2^{-1}(\varphi)=d_{-1}+\frac{\beta c_0}{2\rho},\quad \Phi_1^{0}(\varphi)=c_0,\quad \Phi_2^{0}(\varphi)=d_0-\frac{\beta c_{-1}}{2\rho}.$$

So one finds that the boundary condition $\Phi_1^{-1}(\varphi)=\Phi_1^0(\varphi)=0$ is satisfied at the vortex a. Analogously, the same boundary condition is fulfilled at the vortex b. As recalled in Sec. III, these boundary conditions determine the domain of H_0. Hence $\varphi\in\mathrm{Dom}(H_0)$ and $\psi\in\mathrm{Dom}(H)$. But H is positive, $z\notin\mathbb{R}_+$, and therefore $\mathrm{Dom}(H)\cap\mathcal{N}(z)=\{0\}$. This shows that $\psi=0$. □

Further we are interested in the asymptotic behavior near a vortex of the Green functions (7) and (13). It is easy to see that in the spinless case the Green function vanishes in each vortex. For example, in the case of two vortices it holds true that $\mathcal{G}_z(a,x_0)=0$. This can be derived from (13) with the aid of the relation

$$K_{i\tau}(r)\to\pi\,\delta(\tau)\quad\text{for } r\downarrow 0 \tag{20}$$

and some simple combinatorics. It is also obvious that

$$K_0(\sqrt{-z}|x-x_0|)=K_0(\sqrt{-z}\,r_{0a})+O(r_a)\quad\text{for } r_a\downarrow 0$$

(here $r_{0a}=|a-x_0|$) and

$$K_{i\nu}(\sqrt{-z}\,r_b)=K_{i\nu}(\sqrt{-z}\,\rho)+O(r_a)\quad\text{for } r_a\downarrow 0.$$

To get additional information we shall need an asymptotic formula for the integral

$$\int_{-\infty}^{\infty} K_{i\tau}(\sqrt{-z}\, r_a)\, K_{i(\nu-\tau)}(\sqrt{-z}\,\rho)\, \frac{\sin(\pi\alpha)\exp(\theta_a\tau)}{\pi\sin(\pi(\alpha+i\tau))}\, \mathrm{d}\tau\,. \tag{21}$$

Such an asymptotic analysis can be carried on with the aid of the following lemma.

Lemma 4: Suppose that $r>0$, $|\theta|<\pi$ *and* $0<\alpha<1$. *Then*

$$\int_{-\infty}^{\infty} e^{-r\cosh(s)} \frac{e^{-\alpha(u-s-i\theta)}}{1+e^{-u+s+i\theta}}\,\mathrm{d}s = \frac{\pi}{\sin(\pi\alpha)} - \frac{\Gamma(\alpha)}{1-\alpha}\left(\frac{r}{2}\right)^{1-\alpha} e^{(1-\alpha)(u-i\theta)} - \frac{\Gamma(1-\alpha)}{\alpha}\left(\frac{r}{2}\right)^{\alpha} e^{-\alpha(u-i\theta)} + Z(r,u)\,, \tag{22a}$$

where

$$\forall r\in(0,1), \quad \forall u\in\mathbb{R}, \quad |Z(r,u)|\leqslant Kr\cosh(u) \tag{22b}$$

and K *depends on* θ *and* α *but does not depend on* r *and* u.

Proof: The LHS of (22a) equals

$$\int_{u}^{\infty} e^{-r\cosh(s)} \frac{e^{-(1-\alpha)(s-u+i\theta)}}{1+e^{-s+u-i\theta}}\,\mathrm{d}s + \int_{-u}^{\infty} e^{-r\cosh(s)} \frac{e^{-\alpha(s+u-i\theta)}}{1+e^{-s-u+i\theta}}\,\mathrm{d}s\,. \tag{23}$$

Therefore it suffices to study integrals of the form

$$\int_{u}^{\infty} e^{-r\cosh(s)} \frac{e^{-\gamma(s-u+i\theta)}}{1+e^{-s+u-i\theta}}\,\mathrm{d}s = e^{\gamma(u-i\theta)} \int_{u}^{\infty} e^{-r\cosh(s)-\gamma s}\,\mathrm{d}s - \int_{u}^{\infty} e^{-r\cosh(s)} \frac{e^{-(\gamma+1)(s-u+i\theta)}}{1+e^{-s+u-i\theta}}\,\mathrm{d}s \tag{24}$$

for $0<\gamma<1$. The second integral on the RHS of (24) can be treated easily and one finds that

$$\int_{u}^{\infty} e^{-r\cosh(s)} \frac{e^{-(\gamma+1)(s-u+i\theta)}}{1+e^{-s+u-i\theta}}\,\mathrm{d}s = \frac{e^{-i\gamma\theta}}{\gamma} - \int_{0}^{\infty} \frac{e^{-\gamma(s+i\theta)}}{1+e^{-s-i\theta}}\,\mathrm{d}s + Z_1(r,u)\,,$$

where $Z_1(r,u)$ satisfies estimate (22b). To treat the first integral on the RHS of (24) we note that

$$e^{-r\cosh(s)} = \exp\left(-\frac{r}{2}e^{s}\right) \sum_{k=0}^{\infty} \frac{1}{k!}\left(-\frac{r}{2}\right)^{k} e^{-ks}$$

and therefore

$$\int_{0}^{\infty} e^{-r\cosh(s)-\gamma s}\,\mathrm{d}s = \sum_{k=0}^{\infty} \frac{1}{k!}\, 2^{-\gamma-k} r^{\gamma+k}\, \Gamma\left(-\gamma-k, \frac{r}{2}\right)\left(-\frac{r}{2}\right)^{k} = -\frac{\Gamma(1-\gamma)}{\gamma}\left(\frac{r}{2}\right)^{\gamma} + \frac{1}{\gamma} + \frac{\gamma}{1-\gamma^2}\, r + O(r^2)\,.$$

Furthermore,

$$\int_{u}^{0} e^{-r\cosh(s)-\gamma s}\,\mathrm{d}s = \frac{e^{-\gamma u}-1}{\gamma} + Z_2(r,u)\,,$$

where $Z_2(r,u)$ satisfies estimate (22b). Thus we have derived that

$$\int_u^\infty e^{-r\cosh(s)}\frac{e^{-\gamma(s-u+i\theta)}}{1+e^{-s+u-i\theta}}\,\mathrm{d}s=-\frac{\Gamma(1-\gamma)}{\gamma}\left(\frac{r}{2}\right)^{\gamma}e^{\gamma(u-i\theta)}+\int_0^\infty\frac{e^{-\gamma(s+i\theta)}}{1+e^{-s-i\theta}}\,\mathrm{d}s+Z_3(r,u)\,, \tag{25}$$

where $Z_3(r,u)$ satisfies estimate (22b). To conclude the proof it suffices to apply (25) to both integrals in (23) and to take into account that

$$\int_0^\infty\frac{e^{-(1-\alpha)(s+i\theta)}}{1+e^{-s-i\theta}}\,\mathrm{d}s+\int_0^\infty\frac{e^{-\alpha(s-i\theta)}}{1+e^{-s+i\theta}}\,\mathrm{d}s=\int_{-\infty}^\infty\frac{e^{-\alpha(s-i\theta)}}{1+e^{-s+i\theta}}\,\mathrm{d}s=\frac{\pi}{\sin(\pi\alpha)}$$

for $|\theta|<\pi$. □

Corollary 5: Under the same assumptions as in Lemma 4 it holds true that

$$\begin{aligned}&\int_{-\infty}^\infty K_{i\tau}(\sqrt{-z}\,r)\,K_{i(\nu-\tau)}(\sqrt{-z}\,\rho)\,\frac{\sin(\pi\alpha)\exp(\theta\tau)}{\pi\sin(\pi(\alpha+i\tau))}\,\mathrm{d}\tau\\&\quad=K_{i\nu}(\sqrt{-z}\,\rho)-\frac{\sin(\pi\alpha)}{\pi}\,\frac{\Gamma(\alpha)}{1-\alpha}\left(\frac{\sqrt{-z}\,r}{2}\right)^{1-\alpha}e^{i(\alpha-1)\theta}K_{i\nu-1+\alpha}(\sqrt{-z}\,\rho)\\&\quad\quad-\frac{\sin(\pi\alpha)}{\pi}\,\frac{\Gamma(1-\alpha)}{\alpha}\left(\frac{\sqrt{-z}\,r}{2}\right)^{\alpha}e^{i\alpha\theta}K_{i\nu+\alpha}(\sqrt{-z}\,\rho)+O(r)\end{aligned} \tag{26}$$

for $r\downarrow 0$.

Proof: Using

$$K_{i\tau}(a)=\frac{1}{2}\int_{-\infty}^\infty e^{is\tau-a\cosh(s)}\,\mathrm{d}s\quad\text{for}\quad a>0,\ \ \tau\in\mathbb{R}, \tag{27}$$

and applying the equality

$$\int_{-\infty}^\infty e^{i\tau(u-s)}\frac{\exp(\theta\tau)}{\sin(\pi(\alpha+i\tau))}\,\mathrm{d}\tau=2\,\frac{e^{-\alpha(u-s-i\theta)}}{1+e^{-u+s+i\theta}}$$

we find that (21) equals

$$\frac{\sin(\pi\alpha)}{2\pi}\int_{-\infty}^\infty e^{-\sqrt{-z}\,\rho\cosh(u)-i\nu u}\left(\int_{-\infty}^\infty e^{-\sqrt{-z}\,r\cosh(s)}\frac{e^{-\alpha(u-s-i\theta)}}{1+e^{-u+s+i\theta}}\,\mathrm{d}s\right)\mathrm{d}u\,.$$

Now it suffices to apply (22) to the inner bracket and then to use the integral form (27) in the reversed sense. □

First let us apply (26) to the case of one vortex. In fact, the following observation about the asymptotic expansion of the Green function (7) near the vortex will be crucial for the subsequent analysis. We get either the asymptotic expansion of $\mathcal{G}_z(r,\theta;r_0,\theta_0)$ for $r\downarrow 0$, or, since in general it holds true that

$$\overline{\mathcal{G}_z(r,\theta;r_0,\theta_0)}=\mathcal{G}_z(r_0,\theta_0;r,\theta), \tag{28}$$

the expansion for $r_0\downarrow 0$ as well, namely,

$$\begin{aligned}\mathcal{G}_z(r,\theta;r_0,\theta_0)=&\frac{\sin(\pi\alpha)}{2\pi^2}\,\frac{\Gamma(\alpha)}{1-\alpha}\left(\frac{\sqrt{-z}\,r_0}{2}\right)^{1-\alpha}K_{-1+\alpha}(\sqrt{-z}r)\,e^{i(\alpha-1)(\theta-\theta_0)}\\&+\frac{\sin(\pi\alpha)}{2\pi^2}\,\frac{\Gamma(1-\alpha)}{\alpha}\left(\frac{\sqrt{-z}\,r_0}{2}\right)^{\alpha}K_{\alpha}(\sqrt{-z}r)\,e^{i\alpha(\theta-\theta_0)}+O(r_0)\,.\end{aligned} \tag{29}$$

One observes that the coefficients standing at $r_0^{1-\alpha}e^{-i(\alpha-1)\theta_0}$ and $r_0^{\alpha}e^{-i\alpha\theta_0}$ are, respectively, proportional to

$$K_{-1+\alpha}(\sqrt{-z}\,r)\,e^{i(\alpha-1)\theta} \quad \text{and} \quad K_{\alpha}(\sqrt{-z}\,r)\,e^{i\alpha\theta}.$$

But these functions are nothing but the basis functions in the corresponding deficiency subspace, see (8).

Next we shall consider the case of two vortices. Applying (26) to (13) we get

$$\begin{aligned}\mathcal{G}_z(x,x_0)=&\frac{\sin(\pi\alpha)}{2\pi^2}\,\frac{\Gamma(\alpha)}{1-\alpha}\left(\frac{\sqrt{-z}\,r_a}{2}\right)^{1-\alpha}e^{i(\alpha-1)\theta_a}\mathcal{L}_{\alpha-1}(x_0)\\&+\frac{\sin(\pi\alpha)}{2\pi^2}\,\frac{\Gamma(1-\alpha)}{\alpha}\left(\frac{\sqrt{-z}\,r_a}{2}\right)^{\alpha}e^{i\alpha\theta_a}\,\mathcal{L}_{\alpha}(x_0)+O(r_a)\end{aligned}\tag{30a}$$

for $r_a\downarrow 0$ where

$$\begin{aligned}\mathcal{L}_{\nu}(x_0)=&K_{\nu}(\sqrt{-z}\,r_{0a})\,e^{-i\nu\theta_{0a}}+\sum_{\gamma,\,n\geqslant 2,\,c_n=a}(-1)^{n-1}\int_{\mathbb{R}^{n-1}}K_{i\tau_{n-1}+\nu}(\sqrt{-z}\,\rho)\\&\times K_{i(\tau_{n-2}-\tau_{n-1})}(\sqrt{-z}\,\rho)\times\cdots\times K_{i(\tau_1-\tau_2)}(\sqrt{-z}\,\rho)K_{-i\tau_1}(\sqrt{-z}\,r_0)\\&\times\frac{\sin(\pi\sigma_{n-1})}{\pi\sin(\pi(\sigma_{n-1}+i\tau_{n-1}))}\times\cdots\times\frac{\sin(\pi\sigma_2)}{\pi\sin(\pi(\sigma_2+i\tau_2))}\,\frac{\sin(\pi\sigma_1)\exp(-\theta_0\tau_1)}{\pi\sin(\pi(\sigma_1+i\tau_1))}\,\mathrm{d}^{n-1}\tau\end{aligned}\tag{30b}$$

[and, again, (r_0,θ_0) are the polar coordinates of the point x_0 with respect to the center c_1]. The convergence of the series in (30b) will be discussed later in Sec. V.

V. DEFICIENCY SUBSPACES FOR THE CASE OF TWO VORTICES

In this section we are going to construct a basis in the deficiency subspaces in the two-vortex case. So H designates the two-vortex spinless AB Hamiltonian described by the boundary conditions (12), X is the symmetric operator obtained by restricting the domain of H as described in Sec. IV and $\mathcal{N}(z)=\mathrm{Ker}(X^*-z)$ is a deficiency subspace.

Asymptotic expansion (29) for the one vortex case suggests that also in the two vortex case one may extract from the Green function a basis in the deficiency subspace. From (30) and (28) one derives immediately a candidate for such a basis. It is formed by the functions

$$\psi_{u,\nu,z}(x)=\sum_{n=0}^{\infty}S_n(u,\nu,z;x)\,,\tag{31a}$$

where

$$S_0(u,\nu,z;x)=K_{\nu}(\sqrt{-z}\,r_u)\,e^{i\nu\theta_u},\tag{31b}$$

$$\begin{aligned}S_n(u,\nu,z;x)=&(-1)^n\int_{\mathbb{R}^n}K_{i\tau_n}(\sqrt{-z}\,r_n)\times K_{i(\tau_{n-1}-\tau_n)}(\sqrt{-z}\rho)\\&\times\cdots\times K_{i(\tau_1-\tau_2)}(\sqrt{-z}\rho)K_{-i\tau_1-\nu}(\sqrt{-z}\rho)\\&\times\frac{\sin(\pi\sigma_n)\exp(\theta_n\tau_n)}{\pi\sin(\pi(\sigma_n+i\tau_n))}\,\frac{\sin(\pi\sigma_{n-1})}{\pi\sin(\pi(\sigma_{n-1}+i\tau_{n-1}))}\times\cdots\times\frac{\sin(\pi\sigma_1)}{\pi\sin(\pi(\sigma_1+i\tau_1))}\,\mathrm{d}^n\tau\end{aligned}\tag{31c}$$

for $n \geqslant 1$, the indices are restricted to the range

$$u \in \{a,b\}, \quad \nu \in \{\omega-1,\omega\} \text{ where } \omega=\alpha \text{ if } u=a, \text{ and } \omega=\beta \text{ if } u=b, \tag{31d}$$

and to each $n \in \mathbb{N}$ one relates the unique alternating sequence $(c_n, c_{n-1}, \ldots, c_1)$, $c_j \in \{a,b\}$ and $c_j \neq c_{j+1}$, such that $c_1 \neq u$. Correspondingly, $\sigma_j=\alpha$ if $c_j=a$ and $\sigma_j=\beta$ if $c_j=b$. As usual, $(r_n,\theta_n)=(r_{c_n},\theta_{c_n})$ are the polar coordinates with respect to the center c_n, (r_c,θ_c) are the polar coordinates centered at the point c.

Let us show that the series (31a) actually converges. In the Hilbert space $L^2(\mathbb{R}, \mathrm{d}\tau)$ we introduce the vectors

$$\mathfrak{f}_{u,z}(x;\tau)=K_{i\tau}(\sqrt{-z}\, r_u)\exp(\theta_u \tau)\frac{\sin(\pi\sigma)}{\pi \sin(\pi(\sigma+i\tau))}, \qquad \mathfrak{g}_{\nu,z}(\tau)=K_{-i\tau-\nu}(\sqrt{-z}\,\rho),$$

and the operators $\mathfrak{K}_z$ and $\mathfrak{D}_u$ with the generalized kernels

$$\mathfrak{K}_z(\mu,\omega)=K_{i(\omega-\mu)}(\sqrt{-z}\rho), \qquad \mathfrak{D}_u(\mu,\omega)=\frac{\sin(\pi\sigma)}{\pi\sin(\pi(\sigma+i\mu))}\,\delta(\mu-\omega),$$

where

$$u \in \{a,b\}, \qquad \sigma=\alpha \text{ if } u=a, \text{ and } \sigma=\beta \text{ if } u=b.$$

For $u \in \{a,b\}$ let v be the complementary vortex, i.e., $\{u,v\}=\{a,b\}$. For the sake of brevity we shall use the matrixlike notation in the following paragraph. Thus the transposition will in fact indicate an integration, i.e., $\mathfrak{f}^T\mathfrak{g}=\int_{\mathbb{R}}\mathfrak{f}(\tau)\,\mathfrak{g}(\tau)\,\mathrm{d}\tau$.

We can rewrite the summands in Eq. (31a) using this notation (here $n \geqslant 1$),

$$S_{2n-1}(u,\nu,z;x)=-\mathfrak{f}_{v,z}(x)^T(\mathfrak{K}_z\mathfrak{D}_u\mathfrak{K}_z\mathfrak{D}_v)^{n-1}\mathfrak{g}_{\nu,z},$$

$$S_{2n}(u,\nu,z;x)=\mathfrak{f}_{u,z}(x)^T\mathfrak{K}_z\mathfrak{D}_v(\mathfrak{K}_z\mathfrak{D}_u\mathfrak{K}_z\mathfrak{D}_v)^{n-1}\mathfrak{g}_{\nu,z}.$$

These formulas make it possible to estimate the summands. Note that $\mathfrak{K}_z$ acts as a convolution operator and so it is diagonalized by the Fourier transform. Since

$$\int_{-\infty}^{\infty} e^{i x \tau}K_{i\tau}(a)\,\mathrm{d}\tau=\pi\, e^{-a\cosh(x)},$$

we get

$$\|\mathfrak{K}_z\|=\pi\, e^{-\mathrm{Re}(\sqrt{-z})\rho}.$$

The operator $\mathfrak{D}_u$ is already diagonal. Therefore

$$\|\mathfrak{D}_u\|=\sup_{\mu\in\mathbb{R}}\left|\frac{\sin(\pi\sigma)}{\pi\sin(\pi(\sigma+i\mu))}\right|=\frac{1}{\pi}.$$

Jointly this implies that

$$|S_{2n-1}(u,\nu,z;x)| \leqslant \|\mathfrak{f}_{v,z}(x)\|\|\mathfrak{g}_{\nu,z}\|\, e^{-(2n-2)\,\mathrm{Re}(\sqrt{-z})\,\rho},$$

$$|S_{2n}(u,\nu,z;x)| \leqslant \|\mathfrak{f}_{u,z}(x)\|\|\mathfrak{g}_{\nu,z}\|\, e^{-(2n-1)\,\mathrm{Re}(\sqrt{-z})\,\rho}.$$

The estimates show that the series (31a) converges absolutely at least as fast as a geometric series. Even one can rewrite the formula for $\psi_{u,\nu,z}(x)$ in a compact form, namely,

$$\psi_{u,\nu,z}(x)=K_\nu(\sqrt{-z}\,r_u)e^{i\nu\theta_u}+(\mathfrak{f}_{u,z}(x)^T\mathfrak{K}_z\mathfrak{D}_v-\mathfrak{f}_{v,z}(x)^T)(\mathbb{I}-\mathfrak{K}_z\mathfrak{D}_u\mathfrak{K}_z\mathfrak{D}_v)^{-1}\mathfrak{g}_{\nu,z}. \tag{32}$$

Here the inverse operator $(\mathbb{I}-\mathfrak{K}_z\mathfrak{D}_u\mathfrak{K}_z\mathfrak{D}_v)^{-1}$ exists with the norm estimated from above by $(1-\exp(-2\,\mathrm{Re}(\sqrt{-z})\,\rho))^{-1}$.

Altogether we get four functions: $\psi_{a,\alpha-1,z}$, $\psi_{a,\alpha,z}$, $\psi_{b,\beta-1,z}$, and $\psi_{b,\beta,z}$. Our goal is to show that they actually form a basis in the deficiency subspace. Obviously

$$(\Delta+z)\psi_{u,\nu,z}=0$$

since

$$(\Delta+z)K_\nu(\sqrt{-z}\,r)e^{\pm i\nu\theta}=0 \quad \text{on } \mathbb{R}^2\backslash\{0\}$$

for all $\nu\in\mathbb{C}$, $z\in\mathbb{C}\backslash\mathbb{R}_+$, and therefore all the summands satisfy the equation $(\Delta+z)S_n(u,\nu,z)=0$ in the domain $\mathbb{R}^2\backslash(L_a\cup L_b)$.

Let us verify that $\psi_{u,\nu,z}$ obeys the boundary conditions (12). For the sake of definiteness we shall consider the function $\psi_{a,\nu,z}$, $\nu\in\{\alpha-1,\alpha\}$. First we shall show that

$$e^{-i\alpha\pi}\psi_{a,\nu,z}|_{\theta_a=\pi}-e^{i\alpha\pi}\psi_{a,\nu,z}|_{\theta_a=-\pi}=0. \tag{33}$$

If $n=2m-1$ is odd then $c_n=b$. Moreover, if $\theta_a=\pm\pi$ then $\theta_b=0$ and $r_b=r_a+\rho$. Hence

$$\begin{aligned}
&e^{-i\alpha\pi}S_{2m-1}(a,\nu,z)|_{\theta_a=\pi}-e^{i\alpha\pi}S_{2m-1}(a,\nu,z)|_{\theta_a=-\pi}\\
&\quad=\int_{\mathbb{R}^{2m-1}}K_{i\tau_{2m-1}}(\sqrt{-z}(r_a+\rho))\times\cdots\times K_{i(\tau_1-\tau_2)}(\sqrt{-z}\,\rho)K_{-i\tau_1-\nu}(\sqrt{-z}\,\rho)\\
&\qquad\times\frac{2\,i\sin(\pi\alpha)\sin(\pi\sigma_{2m-1})}{\pi\sin(\pi(\sigma_{2m-1}+i\tau_{2m-1}))}\times\cdots\times\frac{\sin(\pi\sigma_1)}{\pi\sin(\pi(\sigma_1+i\tau_1))}\,\mathrm{d}^{2m-1}\tau.
\end{aligned}$$

If $n=2m$, $m\geqslant 1$, is even then $c_n=a$ and

$$e^{-i\alpha\pi}\exp(\pi\tau_n)-e^{i\alpha\pi}\exp(-\pi\tau_n)=-2\,i\sin(\pi(\sigma_n+i\tau_n))$$

hence

$$\begin{aligned}
&e^{-i\alpha\pi}S_{2m}(a,\nu,z)|_{\theta_a=\pi}-e^{i\alpha\pi}S_{2m}(a,\nu,z)|_{\theta_a=-\pi}\\
&\quad=-\int_{\mathbb{R}^{2m}}K_{i\tau_{2m}}(\sqrt{-z}\,r_a)K_{i(\tau_{2m-1}-\tau_{2m})}(\sqrt{-z}\,\rho)\times\cdots\times K_{-i\tau_1-\nu}(\sqrt{-z}\,\rho)\\
&\qquad\times\frac{2i\sin(\pi\alpha)}{\pi}\,\frac{\sin(\pi\sigma_{2m-1})}{\pi\sin(\pi(\sigma_{2m-1}+i\tau_{2m-1}))}\times\cdots\times\frac{\sin(\pi\sigma_1)}{\pi\sin(\pi(\sigma_1+i\tau_1))}\,\mathrm{d}^{2m}\tau.
\end{aligned}$$

The integration in τ_{2m} can be carried on with the aid of the identity

$$\int_{-\infty}^{\infty}K_{i\tau}(a)\,K_{i(\nu-\tau)}(b)\,\mathrm{d}\tau=\pi\,K_{i\nu}(a+b) \quad \text{for } a>0,\ b>0. \tag{34}$$

This way we get the equality

$$\begin{aligned}
&e^{-i\alpha\pi}S_{2m}(a,\nu,z)|_{\theta_a=\pi}-e^{i\alpha\pi}S_{2m}(a,\nu,z)|_{\theta_a=-\pi}\\
&\quad=-(e^{-i\alpha\pi}S_{2m-1}(a,\nu,z)|_{\theta_a=\pi}-e^{i\alpha\pi}S_{2m-1}(a,\nu,z)|_{\theta_a=-\pi})
\end{aligned}$$

valid for all $m \geqslant 1$. Obviously,

$$e^{-i\alpha\pi} S_0(a,\nu,z)\big|_{\theta_a=\pi} - e^{i\alpha\pi} S_0(a,\nu,z)\big|_{\theta_a=-\pi} = 0.$$

The last two equalities imply (33).

Similarly one can show that

$$e^{-i\beta\pi} \psi_{a,\nu,z}\big|_{\theta_b=\pi} - e^{i\beta\pi} \psi_{a,\nu,z}\big|_{\theta_b=-\pi} = 0. \tag{35}$$

Equality (34) again turns out to be useful but this time when treating the odd summands. With its aid the dimension of the integration domain is reduced by 1 and one obtains the equality

$$\begin{aligned} &e^{-i\beta\pi} S_{2m-1}(a,\nu,z)\big|_{\theta_b=\pi} - e^{i\beta\pi} S_{2m-1}(a,\nu,z)\big|_{\theta_b=-\pi} \\ &\quad = -\left(e^{-i\beta\pi} S_{2m-2}(a,\nu,z)\big|_{\theta_b=\pi} - e^{i\beta\pi} S_{2m-2}(a,\nu,z)\big|_{\theta_b=-\pi}\right) \end{aligned}$$

valid for all $m \geqslant 1$. This shows (35).

Finally we note that the remaining two boundary conditions,

$$e^{-i\alpha\pi} \frac{\partial \psi_{a,\nu,z}}{\partial r_a}\bigg|_{\theta_a=\pi} - e^{i\alpha\pi} \frac{\partial \psi_{a,\nu,z}}{\partial r_a}\bigg|_{\theta_a=-\pi} = 0,$$

$$e^{-i\beta\pi} \frac{\partial \psi_{a,\nu,z}}{\partial r_b}\bigg|_{\theta_b=\pi} - e^{i\beta\pi} \frac{\partial \psi_{a,\nu,z}}{\partial r_b}\bigg|_{\theta_b=-\pi} = 0,$$

can be verified in exactly the same way.

Next we wish to examine the asymptotic behavior of the functions $\psi_{u,\nu,z}$ near the singular points a and b. We shall again focus on the functions $\psi_{a,\nu,z}$, the functions $\psi_{b,\nu,z}$ can be treated similarly. First notice that

$$\psi_{a,\nu,z}(b) = 0. \tag{36}$$

Actually, for the even summands in (31a) the limit $x \to b$ just means setting $r_a = \rho$. To treat the odd summands one applies the limit procedure (20) for $r_b \to 0$ and finds that

$$S_{2m-1}(a,\nu,z;b) = -S_{2m-2}(a,\nu,z;b) \quad \text{for all } m \geqslant 1.$$

This shows (36).

Let us make this result more precise. The even summands in (31a) simply satisfy

$$S_{2m}(a,\nu,z;x) = S_{2m}(a,\nu,z;b) + O(r_b) \quad \text{for } x \to b.$$

Asymptotic behavior of the odd summands can be obtained with the aid of relation (26). We get [here $S_{2m-1}(a,\nu,z;b) = -S_{2m-2}(a,\nu,z;b)$]

$$\begin{aligned} S_{2m-1}(a,\nu,z;x) = S_{2m-1}(a,\nu,z;b) &+ \frac{\sin(\pi\beta)}{\pi} \frac{\Gamma(\beta)}{1-\beta} \left(\frac{\sqrt{-z}\, r_b}{2}\right)^{1-\beta} e^{i(\beta-1)\theta_b} \\ &\times \int_{\mathbb{R}^{2m-2}} K_{i\tau_{2m-2}-1+\beta}(\sqrt{-z}\rho) \times \cdots \times K_{i(\tau_1-\tau_2)}(\sqrt{-z}\,\rho) K_{-i\tau_1-\nu}(\sqrt{-z}\rho) \\ &\times \frac{\sin(\pi\sigma_{2m-2})}{\pi \sin(\pi(\sigma_{2m-2}+i\tau_{2m-2}))} \times \cdots \times \frac{\sin(\pi\sigma_1)}{\pi \sin(\pi(\sigma_1+i\tau_1))}\, \mathrm{d}^{2m-2}\tau \end{aligned}$$

$$+\frac{\sin(\pi\beta)}{\pi}\frac{\Gamma(1-\beta)}{\beta}\left(\frac{\sqrt{-z}\,r_b}{2}\right)^{\beta}e^{i\beta\theta_b}\int_{\mathbb{R}^{2m-2}}K_{i\tau_{2m-2}+\beta}(\sqrt{-z}\,\rho)$$

$$\times\cdots\times K_{i(\tau_1-\tau_2)}(\sqrt{-z}\,\rho)K_{-i\tau_1-\nu}(\sqrt{-z}\rho)\,\frac{\sin(\pi\sigma_{2m-2})}{\pi\sin(\pi(\sigma_{2m-2}+i\tau_{2m-2}))}$$

$$\times\cdots\times\frac{\sin(\pi\sigma_1)}{\pi\sin(\pi(\sigma_1+i\tau_1))}\,\mathrm{d}^{2m-2}\tau+O(r_b)$$

for $x\to b$. Jointly this means that

$$\psi_{a,\nu,z}(x)=\sum_{\mu\in\{\beta-1,\,\beta\}}\frac{\sin(\pi|\mu|)}{\pi}\,\frac{\Gamma(1-|\mu|)}{|\mu|}\left(\frac{\sqrt{-z}\,r_b}{2}\right)^{|\mu|}e^{i\mu\theta_b}\mathcal{S}_{\mu,\nu}(\alpha,\beta;z)+O(r_b)\quad(37)$$

for $x\to b$ where

$$\mathcal{S}_{\omega,\nu}(\alpha,\beta;z)=K_{\omega-\nu}(\sqrt{-z}\rho)+\sum_{m=1}^{\infty}\int_{\mathbb{R}^{2m}}K_{i\tau_{2m}+\omega}(\sqrt{-z}\,\rho)\,K_{i(\tau_{2m-1}-\tau_{2m})}(\sqrt{-z}\,\rho)$$

$$\times\cdots\times K_{i(\tau_1-\tau_2)}(\sqrt{-z}\,\rho)K_{-i\tau_1-\nu}(\sqrt{-z}\,\rho)\,\frac{\sin(\pi\sigma_{2m})}{\pi\sin(\pi(\sigma_{2m}+i\tau_{2m}))}$$

$$\times\cdots\times\frac{\sin(\pi\sigma_1)}{\pi\sin(\pi(\sigma_1+i\tau_1))}\,\mathrm{d}^{2m}\tau\qquad(38)$$

with $(\sigma_{2m},\ldots,\sigma_2,\sigma_1)=(\alpha,\ldots,\alpha,\beta)$.

The function $\psi_{a,\nu,z}$ has a singularity at the point a. Nevertheless it holds true that

$$\sum_{n=1}^{\infty}S_n(a,\nu,z;a)=0.\qquad(39)$$

The verification is similar to that of equality (36). This time it holds true that

$$S_{2m}(a,\nu,z;a)=-S_{2m-1}(a,\nu,z;a)\quad\text{for all } m\geqslant 1.$$

This shows (39). A more precise result can be derived as follows. Note that

$$S_{2m-1}(a,\nu,z;x)=S_{2m-1}(a,\nu,z;a)+O(r_a)\quad\text{for } x\to a.$$

Asymptotic behavior of the even summands can be obtained with the aid of relation (26). We get

$$S_{2m}(a,\nu,z;x)=S_{2m}(a,\nu,z;a)-\frac{\sin(\pi\alpha)}{\pi}\,\frac{\Gamma(\alpha)}{1-\alpha}\left(\frac{\sqrt{-z}\,r_a}{2}\right)^{1-\alpha}e^{i(\alpha-1)\theta_a}$$

$$\times\int_{\mathbb{R}^{2m-1}}K_{i\tau_{2m-1}-1+\alpha}(\sqrt{-z}\,\rho)\times\cdots\times K_{i(\tau_1-\tau_2)}(\sqrt{-z}\,\rho)K_{-i\tau_1-\nu}(\sqrt{-z}\,\rho)$$

$$\times\frac{\sin(\pi\sigma_{2m-1})}{\pi\sin(\pi(\sigma_{2m-1}+i\tau_{2m-1}))}\times\cdots\times\frac{\sin(\pi\sigma_1)}{\pi\sin(\pi(\sigma_1+i\tau_1))}\,\mathrm{d}^{2m-1}\tau$$

$$-\frac{\sin(\pi\alpha)}{\pi}\,\frac{\Gamma(1-\alpha)}{\alpha}\left(\frac{\sqrt{-z}\,r_a}{2}\right)^{\alpha}e^{i\alpha\theta_a}\int_{\mathbb{R}^{2m-1}}K_{i\tau_{2m-1}+\alpha}(\sqrt{-z}\,\rho)$$

$$\times\cdots\times K_{i(\tau_1-\tau_2)}(\sqrt{-z}\,\rho)K_{-i\tau_1-\nu}(\sqrt{-z}\,\rho)\,\frac{\sin(\pi\sigma_{2m-1})}{\pi\sin(\pi(\sigma_{2m-1}+i\tau_{2m-1}))}$$

$$\times\cdots\times\frac{\sin(\pi\sigma_1)}{\pi\sin(\pi(\sigma_1+i\tau_1))}\,\mathrm{d}^{2m-1}\tau+O(r_a)$$

for $x\to a$. The asymptotic behavior of the Macdonald function is given by the formula[12]

$$\begin{aligned}K_\nu(x)&=\frac{\pi}{2\sin(\nu\pi)}\left(\frac{2^\nu}{\Gamma(1-\nu)}x^{-\nu}-\frac{2^{-\nu}}{\Gamma(1+\nu)}x^\nu\right)+O(x^{-\nu+2})\\&=\frac{\Gamma(\nu)}{2}\left(\frac{x}{2}\right)^{-\nu}-\frac{\Gamma(1-\nu)}{2\nu}\left(\frac{x}{2}\right)^{\nu}+O(x^{-\nu+2})\quad\text{for } 0<\nu<1.\end{aligned}$$

Finally we arrive at the expansion

$$\begin{aligned}\psi_{a,\nu,z}(x)=&\frac{\Gamma(|\nu|)}{2}\left(\frac{\sqrt{-z}\,r_a}{2}\right)^{-|\nu|}e^{i\nu\theta_a}\\&-\sum_{\mu\in\{\alpha-1,\alpha\}}\frac{\sin(\pi|\mu|)}{\pi}\,\frac{\Gamma(1-|\mu|)}{|\mu|}\left(\frac{\sqrt{-z}\,r_a}{2}\right)^{|\mu|}e^{i\mu\theta_a}\mathcal{T}_{\mu,\nu}(\alpha,\beta;z)+O(r_a)\end{aligned}\tag{40}$$

for $x\to a$ where

$$\begin{aligned}\mathcal{T}_{\omega,\nu}(\alpha,\beta;z)=&\frac{\pi}{2\sin(\pi\alpha)}\,\delta_{\omega\nu}+\sum_{m=1}^{\infty}\int_{\mathbb{R}^{2m-1}}K_{i\tau_{2m-1}+\omega}(\sqrt{-z}\,\rho)\,K_{i(\tau_{2m-2}-\tau_{2m-1})}(\sqrt{-z}\,\rho)\\&\times\cdots\times K_{i(\tau_1-\tau_2)}(\sqrt{-z}\,\rho)K_{-i\tau_1-\nu}(\sqrt{-z}\,\rho)\,\frac{\sin(\pi\sigma_{2m-1})}{\pi\sin(\pi(\sigma_{2m-1}+i\tau_{2m-1}))}\\&\times\cdots\times\frac{\sin(\pi\sigma_1)}{\pi\sin(\pi(\sigma_1+i\tau_1))}\,\mathrm{d}^{2m-1}\tau\end{aligned}\tag{41}$$

with $(\sigma_{2m-1},\ldots,\sigma_2,\sigma_1)=(\beta,\ldots,\alpha,\beta)$.

Remark: As a consequence one can show that

$$\sum_{n=1}^{\infty}S_n(u,\nu,z;x)=\sum_{n=1}^{\infty}S_n(u,-\nu,z;x).\tag{42}$$

Actually, a short inspection of the above derivation shows that the functions

$$\tilde{\psi}_{u,\nu,z}(x)=\sum_{n=0}^{\infty}S_n(u,-\nu,z;x)$$

also satisfy the boundary conditions (12) and solve the equation $(\Delta+z)\tilde{\psi}_{u,\nu,z}=0$. Therefore the function

$$f(x)=\sum_{n=1}^{\infty}S_n(u,\nu,z;x)-\sum_{n=1}^{\infty}S_n(u,-\nu,z;x)$$

satisfies the boundary conditions (12) as well and solves $(\Delta+z)f=0$. In addition, $f(a)=f(b)=0$. Consequently, $f\in\mathrm{Dom}(H)$ and $(H-z)f=0$. Necessarily $f=0$.

Lemma 6: $\dim\mathcal{N}(z)\leqslant 4$.

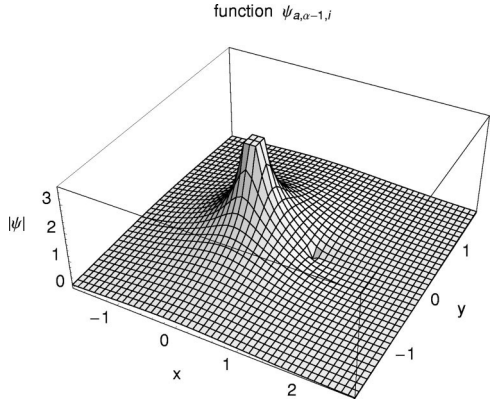

FIG. 2. Function $\psi_{a,\alpha-1,i}$ from the deficiency subspace for the values of parameters $\alpha=1/3$, $\beta=2/3$, $\rho=1$.

Proof: In virtue of Corollary 2, for any five-tuple of functions from $\mathcal{N}(z)$ there exists a nontrivial linear combination of these functions vanishing both at a and b. By Corollary 3, such a linear combination equals 0. □

Proposition 7: $\dim\mathcal{N}(z)=4$.

Proof: Owing to Lemma 6 it suffices to show that $\dim\mathcal{N}(z)\geqslant 4$. But in relation (31) we have constructed four functions $\psi_{a,\alpha-1,z}$, $\psi_{a,\alpha,z}$, $\psi_{b,\beta-1,z}$ and $\psi_{b,\beta,z}$ from the deficiency subspace $\mathcal{N}(z)$. The asymptotic expansions (37) and (40) show that these functions are actually linearly independent. □

We conclude that the functions $\{\psi_{a,\alpha-1,z},\psi_{a,\alpha,z},\psi_{b,\beta-1,z},\psi_{b,\beta,z}\}$ form a basis in $\mathcal{N}(z)$.

Remark: Formula (32) is well suited for numerical computations. To give the reader an idea about the behavior of $\psi_{u,\nu,z}$ we have plotted $|\psi_{a,\alpha-1,i}|$ in Fig. 2 and $|\psi_{b,\beta,i}|$ in Fig. 3, with $\alpha=1/3$, $\beta=2/3$ and $\rho=1$. Note that the former function vanishes in the vortex b while the latter one vanishes in the vortex a.

VI. THE KREIN'S FORMULA

We would like to emphasize once more that we are using two unitarily equivalent formulations. The operators $H^{\pm}$, H_0 are, respectively, associated to the quadratic forms (14) and (11). Let U be the unitary operator in $L^2(\mathbb{R}^2, \mathrm{d}^2x)$ acting as $U\varphi=\exp(i\alpha\theta_a+i\beta\theta_b)\varphi$. The Green function (13) corresponds to the operator $H=UH_0U^{-1}$ defined by the boundary conditions on the cut (12).

Set

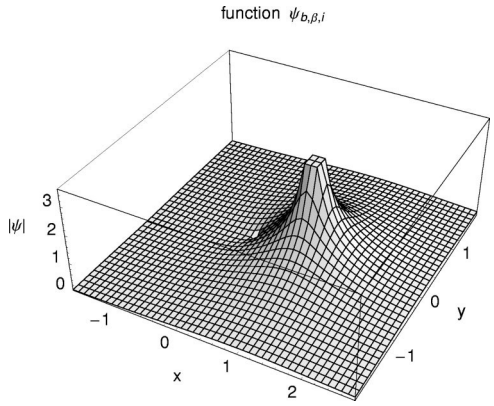

FIG. 3. Function $\psi_{b,\beta,i}$ from the deficiency subspace for the values of parameters $\alpha=1/3$, $\beta=2/3$, $\rho=1$.

$$f_{u,\nu,z}=(\sqrt{-z})^{|\nu|}\psi_{u,\nu,z}\,. \tag{43}$$

Let us enumerate the basis $\{f_{a,\alpha-1,z},f_{a,\alpha,z},f_{b,\beta-1,z},f_{b,\beta,z}\}$ in $\mathcal{N}(z)$ as $\{f_z^1,f_z^2,f_z^3,f_z^4\}$ (in this order). Set $\tilde{f}_z^j=U^{-1}f_z^j$, $R_z=(H_0-z)^{-1}$, $R_z^{\pm}=(H^{\pm}-z)^{-1}$. According to the Krein's formula

$$R_z^{\pm}-R_z=\sum_{j,\,k}\,(M_z^{\pm})^{j,k}\tilde{f}_z^j\langle\tilde{f}_{\bar{z}}^k,\cdot\,\rangle \tag{44}$$

or, in terms of Green functions,

$$\mathcal{G}_z^{\pm}(x,x_0)=\mathcal{G}_z(x,x_0)+\sum_{j,\,k}\,(M_z^{\pm})^{j,k}\,f_z^j(x)\,\overline{f_{\bar{z}}^k(x_0)}\,, \tag{45}$$

where $M_z^{\pm}$ is a holomorphic matrix-valued function defined on $\mathbb{C}\backslash\mathbb{R}$.

An operator-valued function $R_z^{\pm}$ constructed this way will be the resolvent of a self-adjoint operator if and only if it satisfies (Ref. 13, Chap. 5.2)

$$\forall z\in\mathbb{C}\backslash\mathbb{R},\quad (R_z^{\pm})^*=R_{\bar{z}}^{\pm} \tag{46}$$

and (the Hilbert identity)

$$\forall z,w\in\mathbb{C}\backslash\mathbb{R},\quad R_z^{\pm}-R_w^{\pm}=(z-w)R_z^{\pm}R_w^{\pm} \tag{47}$$

[it follows from (44) that $\mathrm{Ker}\,R_z^{\pm}=\{0\}$ for all $z\in\mathbb{C}\backslash\mathbb{R}$]. Let us analyze conditions (46) and (47). It is straightforward to see that (46) is satisfied if and only if

$$M_z^*=M_{\bar{z}}. \tag{48}$$

In equality (52) below we shall show that

$$\forall z,w\in\mathbb{C}\backslash\mathbb{R},\,\forall j,\quad \tilde{f}_w^j+(z-w)R_z\tilde{f}_w^j=\tilde{f}_z^j\,.$$

With the aid of this identity it is just an easy computation to show that (47) is equivalent to the condition

$$\forall z,w\in\mathbb{C}\backslash\mathbb{R},\quad M_z-M_w=(z-w)\,M_zP(\bar{z},w)\,M_w\,, \tag{49}$$

where $P(z,w)$ is the 4×4 matrix of scalar products,

$$P(z,w)^{j,k}=\langle f_z^j,f_w^k\rangle.$$

Equality (49) was presented in Ref. 14 and was applied to problems similar to ours, for example, in Refs. 15 and 3.

According to formula (30) and definition (31) of $\psi_{u,\nu,z}(x)$ we have

$$\begin{aligned}\mathcal{G}_z(x,x_0)=&\frac{\sin(\pi\alpha)}{2\pi^2}\,\frac{\Gamma(\alpha)}{1-\alpha}\left(\frac{\sqrt{-z}\,r_{0a}}{2}\right)^{1-\alpha}e^{-i(\alpha-1)\theta_{0a}}\psi_{a,\alpha-1,z}(x)\\&+\frac{\sin(\pi\alpha)}{2\pi^2}\,\frac{\Gamma(1-\alpha)}{\alpha}\left(\frac{\sqrt{-z}\,r_{0a}}{2}\right)^{\alpha}e^{-i\,\alpha\,\theta_{0a}}\,\psi_{a,\alpha,z}(x)+O(r_{0a})\end{aligned} \tag{50}$$

for $r_{0a}\downarrow0$. Using this asymptotic behavior and the Hilbert identity written in terms of Green functions,

$$(z-w)\int_{\mathbb{R}^2}\mathcal{G}_z(x,y)\,\mathcal{G}_w(y,x_0)\,\mathrm{d}^2y=\mathcal{G}_z(x,x_0)-\mathcal{G}_w(x,x_0)\,,$$

we obtain an equality valid for $u=a$, namely,

$$(z-w)(\sqrt{-w})^{|\nu|}\int_{\mathbb{R}^2}\mathcal{G}_z(x,y)\,\psi_{u,\nu,w}(y)\,\mathrm{d}^2y=(\sqrt{-z})^{|\nu|}\psi_{u,\nu,z}(x)-(\sqrt{-w})^{|\nu|}\psi_{u,\nu,w}(x)\,. \quad (51)$$

This means that

$$\psi_{u,\nu,w}+(z-w)(H-z)^{-1}\psi_{u,\nu,w}=\left(\frac{\sqrt{-z}}{\sqrt{-w}}\right)^{|\nu|}\psi_{u,\nu,z}$$

for $\nu\in\{\alpha-1,\alpha\}$ and $u=a$. The same argument naturally applies also to the vortex $u=b$. Using notation (43) we find that

$$f_{u,\nu,w}+(z-w)(H-z)^{-1}f_{u,\nu,w}=f_{u,\nu,z} \quad (52)$$

holds true for all $w,z\in\mathbb{C}\backslash\mathbb{R}$.

We wish to compute the 4×4 matrix of scalar products $P(z,w)$. Using (28) and applying the asymptotic behavior (50) once more, this time to equality (51), we find that the integral

$$\int_{\mathbb{R}^2}\overline{\psi_{v,\mu,z}(y)}\,\psi_{u,\nu,w}(y)\,\mathrm{d}^2y$$

equals the coefficient standing at

$$\frac{\sin(\pi|\mu|)}{2\pi^2}\,\frac{\Gamma(1-|\mu|)}{|\mu|}\left(\frac{r_v}{2}\right)^{|\mu|}e^{i\,\mu\,\theta_v}$$

when taking the asymptotic expansion of the expression

$$\frac{1}{\overline{z}-w}\left(\frac{1}{(\sqrt{-w})^{|\nu|}}\,\psi_{u,\nu,\overline{z}}(x)-\frac{1}{(\sqrt{-\overline{z}})^{|\nu|}}\,\psi_{u,\nu,w}(x)\right)$$

for $x\to v$, i.e., $r_v\downarrow0$. In virtue of (40) and (37) we get

$$\int_{\mathbb{R}^2}\overline{\psi_{a,\mu,z}(y)}\,\psi_{a,\nu,w}(y)\,\mathrm{d}^2y=-2\pi\frac{1}{\overline{z}-w}\left(\left(\frac{\sqrt{-\overline{z}}}{\sqrt{-w}}\right)^{|\nu|}\mathcal{T}_{\mu,\nu}(\alpha,\beta;\overline{z})-\left(\frac{\sqrt{-w}}{\sqrt{-\overline{z}}}\right)^{|\mu|}\mathcal{T}_{\mu,\nu}(\alpha,\beta;w)\right)$$

and

$$\int_{\mathbb{R}^2}\overline{\psi_{a,\mu,z}(y)}\,\psi_{b,\nu,w}(y)\,\mathrm{d}^2y=2\pi\frac{1}{\overline{z}-w}\left(\left(\frac{\sqrt{-\overline{z}}}{\sqrt{-w}}\right)^{|\nu|}\mathcal{S}_{\nu,\mu}(\alpha,\beta;\overline{z})-\left(\frac{\sqrt{-w}}{\sqrt{-\overline{z}}}\right)^{|\mu|}\mathcal{S}_{\nu,\mu}(\alpha,\beta;w)\right).$$

In particular,

$$\int_{\mathbb{R}^2}|\psi_{a,\nu,z}(x)|^2\,\mathrm{d}^2x=-\frac{2\pi}{\mathrm{Im}(z)}\,\mathrm{Im}\left(\left(\frac{\sqrt{-z}}{\sqrt{-\overline{z}}}\right)^{|\nu|}\mathcal{T}_{\nu,\nu}(\alpha,\beta;z)\right).$$

This means that, when passing to functions $\{f^j_z\}$ instead of $\{\psi_{u,\nu,z}\}$,

$$
\begin{aligned}
&(\overline{z}-w)\,P(z,w)\\
&\quad=-2\pi\begin{pmatrix}
(\sqrt{-\overline{z}})^{2-2\alpha}\mathcal{T}_{\alpha-1,\alpha-1}(\alpha,\beta;\overline{z}) & \sqrt{-\overline{z}}\,\mathcal{T}_{\alpha,\alpha-1}(\alpha,\beta;\overline{z})\\
\sqrt{-\overline{z}}\,\mathcal{T}_{\alpha-1,\alpha}(\alpha,\beta;\overline{z}) & (\sqrt{-\overline{z}})^{2\alpha}\mathcal{T}_{\alpha,\alpha}(\alpha,\beta;\overline{z})\\
-(\sqrt{-\overline{z}})^{2-\alpha-\beta}\mathcal{S}_{\alpha-1,\beta-1}(\beta,\alpha;\overline{z}) & -(\sqrt{-\overline{z}})^{1+\alpha-\beta}\mathcal{S}_{\alpha,\beta-1}(\beta,\alpha;\overline{z})\\
-(\sqrt{-\overline{z}})^{1-\alpha+\beta}\mathcal{S}_{\alpha-1,\beta}(\beta,\alpha;\overline{z}) & -(\sqrt{-\overline{z}})^{\alpha+\beta}\mathcal{S}_{\alpha,\beta}(\beta,\alpha;\overline{z})
\end{pmatrix}\\
&\qquad\begin{pmatrix}
-(\sqrt{-\overline{z}})^{2-\alpha-\beta}\mathcal{S}_{\beta-1,\alpha-1}(\alpha,\beta;\overline{z}) & -(\sqrt{-\overline{z}})^{1-\alpha+\beta}\mathcal{S}_{\beta,\alpha-1}(\alpha,\beta;\overline{z})\\
-(\sqrt{-\overline{z}})^{1+\alpha-\beta}\mathcal{S}_{\beta-1,\alpha}(\alpha,\beta;\overline{z}) & -(\sqrt{-\overline{z}})^{\alpha+\beta}\mathcal{S}_{\beta,\alpha}(\alpha,\beta;\overline{z})\\
(\sqrt{-\overline{z}})^{2-2\beta}\mathcal{T}_{\beta-1,\beta-1}(\beta,\alpha;\overline{z}) & \sqrt{-\overline{z}}\,\mathcal{T}_{\beta,\beta-1}(\beta,\alpha;\overline{z})\\
\sqrt{-\overline{z}}\,\mathcal{T}_{\beta-1,\beta}(\beta,\alpha;\overline{z}) & (\sqrt{-\overline{z}})^{2\beta}\mathcal{T}_{\beta,\beta}(\beta,\alpha;\overline{z})
\end{pmatrix}\\
&\qquad-(\overline{z}\leftrightarrow w)\,. \qquad (53)
\end{aligned}
$$

The Green functions $\mathcal{G}_z^{\pm}(x,x_0)$ should satisfy the corresponding boundary conditions in each variable x, x_0. Let us first consider the case of H^+. Recall that the boundary conditions which determine the domain of H^+ are $\Phi_2^{-1}=\Phi_1^0=0$ [see (15)]. Let us check the asymptotic behavior of $\mathcal{G}_z^{\pm}(x,x_0)$ for $x_0\to a$. Asymptotic behavior of $\mathcal{G}_z(x,x_0)$ is given in (50) and asymptotic behavior of $f_z^j(x_0)$ follows from (40) and (37) jointly with definition (43). The condition $\Phi_1^0=0$ means that the coefficient standing at $(r_{0a}/2)^{-\alpha}\exp(-i\alpha\theta_{0a})$ vanishes. This term occurs only in the asymptotic expansion of $f_z^2(x_0)$ and so

$$\sum_j\,(M_z^+)^{j,2}\,f_z^j(x)=0\,.$$

The set of functions $\{f_z^j\}$ is linearly independent and thus we get a condition on the matrix M_z^+: $(M_z^+)^{j,2}=0$ for all j. Considering the limit $x_0\to b$ one similarly derives the condition $(M_z^+)^{j,4}=0$. In view of (48) one obtains more, namely,

$$(M_z^+)^{j,k}=0\quad\text{whenever } j=2,4\ \text{ or } k=2,4. \qquad (54)$$

Let us denote by $M_z^{+,\mathrm{red}}$ the reduced 2×2 matrix obtained by omitting the vanishing rows and columns, i.e.,

$$M_z^{+,\mathrm{red}}=\begin{pmatrix}(M_z^+)^{1,1} & (M_z^+)^{1,3}\\ (M_z^+)^{3,1} & (M_z^+)^{3,3}\end{pmatrix}.$$

The condition $\Phi_2^{-1}=0$ for $x_0\to a$ means that the coefficient standing at $(r_{0a}/2)^{1-\alpha}\times\exp(-i(\alpha-1)\theta_{0a})$ vanishes. Using (54) we get

$$
\begin{aligned}
&\frac{\sin(\pi\alpha)}{2\pi^2}\,\frac{\Gamma(\alpha)}{1-\alpha}f_z^1(x)+\sum_j\,f_z^j(x)\Bigg(-(M_z^+)^{j,1}\frac{\sin(\pi\alpha)}{\pi}\,\frac{\Gamma(\alpha)}{1-\alpha}(\sqrt{-z})^{2(1-\alpha)}\,\mathcal{T}_{\alpha-1,\alpha-1}(\alpha,\beta;z)\\
&\quad+(M_z^+)^{j,3}\frac{\sin(\pi\alpha)}{\pi}\,\frac{\Gamma(\alpha)}{1-\alpha}(\sqrt{-z})^{2-\alpha-\beta}\,\mathcal{S}_{\alpha-1,\beta-1}(\beta,\alpha;z)\Bigg)=0.
\end{aligned}
$$

This is equivalent to the couple of equations

$$
\begin{aligned}
&\frac{1}{2\pi}-(M_z^+)^{1,1}(\sqrt{-z})^{2(1-\alpha)}\,\mathcal{T}_{\alpha-1,\alpha-1}(\alpha,\beta;z)+(M_z^+)^{1,3}(\sqrt{-z})^{2-\alpha-\beta}\,\mathcal{S}_{\alpha-1,\beta-1}(\beta,\alpha;z)=0,\\
&-(M_z^+)^{3,1}(\sqrt{-z})^{2(1-\alpha)}\,\mathcal{T}_{\alpha-1,\alpha-1}(\alpha,\beta;z)+(M_z^+)^{3,3}(\sqrt{-z})^{2-\alpha-\beta}\,\mathcal{S}_{\alpha-1,\beta-1}(\beta,\alpha;z)=0.
\end{aligned}
$$

Analogously, another two equations are obtained when considering the limit $x_0 \to b$, namely,

$$\frac{1}{2\pi} - (M_z^+)^{3,3}(\sqrt{-z})^{2(1-\beta)}\mathcal{T}_{\beta-1,\beta-1}(\beta,\alpha;z) + (M_z^+)^{3,1}(\sqrt{-z})^{2-\alpha-\beta}\mathcal{S}_{\beta-1,\alpha-1}(\alpha,\beta;z) = 0,$$

$$-(M_z^+)^{1,3}(\sqrt{-z})^{2(1-\beta)}\mathcal{T}_{\beta-1,\beta-1}(\beta,\alpha;z) + (M_z^+)^{1,1}(\sqrt{-z})^{2-\alpha-\beta}\mathcal{S}_{\beta-1,\alpha-1}(\alpha,\beta;z) = 0.$$

The four equations can be jointly rewritten in the matrix form,

$$M_z^{+,\mathrm{red}} = \frac{1}{2\pi}\begin{pmatrix} (\sqrt{-z})^{2-2\alpha}\mathcal{T}_{\alpha-1,\alpha-1}(\alpha,\beta;z) & -(\sqrt{-z})^{2-\alpha-\beta}\mathcal{S}_{\beta-1,\alpha-1}(\alpha,\beta;z) \\ -(\sqrt{-z})^{2-\alpha-\beta}\mathcal{S}_{\alpha-1,\beta-1}(\beta,\alpha;z) & (\sqrt{-z})^{2-2\beta}\mathcal{T}_{\beta-1,\beta-1}(\beta,\alpha;z) \end{pmatrix}^{-1}. \tag{55}$$

It is straightforward to verify that the derived matrix M_z^+ actually obeys conditions (48) and (49). The former one follows from the equalities

$$\overline{\mathcal{T}_{\mu,\nu}(\alpha,\beta;z)} = \mathcal{T}_{\mu,\nu}(\alpha,\beta;\overline{z}), \quad \overline{\mathcal{S}_{\mu,\nu}(\alpha,\beta;z)} = \mathcal{S}_{\mu,\nu}(\alpha,\beta;\overline{z})$$

and

$$\mathcal{T}_{\mu,\nu}(\alpha,\beta;z) = \mathcal{T}_{\nu,\mu}(\alpha,\beta;z), \quad \mathcal{S}_{\mu,\nu}(\alpha,\beta;z) = \mathcal{S}_{\nu,\mu}(\beta,\alpha;z).$$

The latter one follows from the form of $P(z,w)$ given in (53). In fact, (53) and (55) jointly imply

$$(\overline{z}-w)\,P(z,w)^{\mathrm{red}} = (M_w^{+,\mathrm{red}})^{-1} - (M_z^{\pm,\mathrm{red}})^{-1}.$$

The other component of the Pauli operator, H^-, can be treated similarly. The boundary conditions read $\Phi_1^{-1} = \Phi_2^0 = 0$ [see (16)]. The condition $\Phi_1^{-1} = 0$ for $x_0 \to a$ means that the coefficient standing at $(r_{0a}/2)^{-1+\alpha}\exp(-i(\alpha-1)\theta_{0a})$ vanishes. Hence

$$\sum_j (M_z^-)^{j,1} f_z^j(x) = 0\,,$$

or equivalently, $(M_z^-)^{j,1} = 0$. Similarly for $x_0 \to 0$ we derive that $(M_z^-)^{j,3} = 0$, hence

$$(M_z^-)^{j,k} = 0 \quad \text{whenever } j = 1,3 \text{ or } k = 1,3. \tag{56}$$

Set

$$M_z^{-,\mathrm{red}} = \begin{pmatrix} (M_z^-)^{2,2} & (M_z^-)^{2,4} \\ (M_z^-)^{4,2} & (M_z^-)^{4,4} \end{pmatrix}.$$

The condition $\Phi_2^0 = 0$ for $x_0 \to a$ means that the coefficient standing at $(r_{0a}/2)^{\alpha}\exp(-i\alpha\theta_{0a})$ vanishes. Using (56) we get

$$\frac{\sin(\pi\alpha)}{2\pi^2}\frac{\Gamma(1-\alpha)}{\alpha} f_z^2(x) + \sum_j f_z^j(x)\Bigg(-(M_z^+)^{j,2}\frac{\sin(\pi\alpha)}{\pi}\frac{\Gamma(1-\alpha)}{\alpha}(\sqrt{-z})^{2\alpha}\mathcal{T}_{\alpha,\alpha}(\alpha,\beta;z)$$

$$+ (M_z^+)^{j,4}\frac{\sin(\pi\alpha)}{\pi}\frac{\Gamma(1-\alpha)}{\alpha}(\sqrt{-z})^{\alpha+\beta}\mathcal{S}_{\alpha,\beta}(\beta,\alpha;z)\Bigg) = 0.$$

This is equivalent to the couple of equations

$$\frac{1}{2\pi} - (M_z^-)^{2,2}(\sqrt{-z})^{2\alpha}\mathcal{T}_{\alpha,\alpha}(\alpha,\beta;z) + (M_z^-)^{2,4}(\sqrt{-z})^{\alpha+\beta}\mathcal{S}_{\alpha,\beta}(\beta,\alpha;z) = 0,$$

$$-(M_z^-)^{4,2}(\sqrt{-z})^{2\alpha}\mathcal{T}_{\alpha,\alpha}(\alpha,\beta;z)+(M_z^-)^{4,4}(\sqrt{-z})^{\alpha+\beta}\mathcal{S}_{\alpha,\beta}(\beta,\alpha;z)=0.$$

For $x_0\to b$ one derives other two equations,

$$\frac{1}{2\pi}-(M_z^-)^{4,4}(\sqrt{-z})^{2\beta}\mathcal{T}_{\beta,\beta}(\beta,\alpha;z)+(M_z^-)^{4,2}(\sqrt{-z})^{\alpha+\beta}\mathcal{S}_{\beta,\alpha}(\alpha,\beta;z)=0,$$

$$-(M_z^-)^{2,4}(\sqrt{-z})^{2\beta}\mathcal{T}_{\beta,\beta}(\beta,\alpha;z)+(M_z^-)^{2,2}(\sqrt{-z})^{\alpha+\beta}\mathcal{S}_{\beta,\alpha}(\alpha,\beta;z)=0.$$

Jointly the four equations mean that

$$M_z^{-,\mathrm{red}}=\frac{1}{2\pi}\begin{pmatrix}(\sqrt{-z})^{2\alpha}\mathcal{T}_{\alpha,\alpha}(\alpha,\beta;z) & -(\sqrt{-z})^{\alpha+\beta}\mathcal{S}_{\beta,\alpha}(\alpha,\beta;z)\\ -(\sqrt{-z})^{\alpha+\beta}\mathcal{S}_{\alpha,\beta}(\beta,\alpha;z) & (\sqrt{-z})^{2\beta}\mathcal{T}_{\beta,\beta}(\beta,\alpha;z)\end{pmatrix}^{-1}. \tag{57}$$

Let us note that the inverted matrices on the right-hand side of (55) and (57) are actually well defined. This is because the matrices in question depend on z analytically in the domain $\mathbb{C}\backslash\mathbb{R}_+$ and tend exponentially fast to invertible diagonal matrices for $\mathrm{Re}\,\sqrt{-z}\to+\infty$ as one can easily deduce from the discussion of the formula (32) related to the convergence of the series (31a) and from the form of matrix entries (38) and (41).

VII. CONCLUDING REMARKS

Having a formula for the Green function $\mathcal{G}_z^{\pm}(x,x_0)$ it would be, of course, desirable to use it for a more detailed analysis of the Pauli operator, first of all for its spectral analysis. This aim would assume, however, a more detailed analysis of the functions $\mathcal{S}_{\omega,\nu}(\alpha,\beta;z)$ and $\mathcal{T}_{\omega,\nu}(\alpha,\beta;z)$. In particular, it would be important to know what happens in the limit $\mathrm{Re}\,\sqrt{-z}\to 0$, i.e., when z approaches $\lambda\in\mathbb{R}_+$ from the upper or lower half-plane. Recall that both $\mathcal{S}_{\omega,\nu}(\alpha,\beta;z)$ and $\mathcal{T}_{\omega,\nu}(\alpha,\beta;z)$ are expressed as infinite series whose convergence is guaranteed for $\mathrm{Re}\,\sqrt{-z}>0$. Our first attempts in this direction suggest that such an analysis might be rather complex and should be considered as an independent problem in its own right.

Given a completely integrable system, we associate to any connection on a fiber bundle in invariant tori over a parameter manifold the classical and quantum holonomy operator (generalized Berry's phase factor), without any adiabatic approximation. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1627957]

I. INTRODUCTION

At present, holonomy operators in quantum systems attract special attention in connection with quantum computation (see, e.g., Refs. 1–3). They exemplify the non-Abelian generalization of Berry's geometric phase by means of driving a finite level degenerate eigenstate of a Hamiltonian over a parameter manifold. The key point is that a geometric phase depends only on the geometry of a path executed and, therefore, provides a possibility to perform quantum gate operations in an intrinsically fault-tolerant way. The problem lies in separation of a geometric phase factor from the total evolution operator without using an adiabatic assumption. First, holonomy quantum computation implies exact cyclic evolution, but exact adiabatic cyclic evolution almost never exists. Second, an adiabatic condition requires that the evolution time must be long enough.

A nonadiabatic Abelian phase was discovered by Aharonov and Anandan who considered a loop in a projective Hilbert space instead of a parameter space.[4] Non-Abelian generalization of the Aharonov–Anandan phase has been studied under rather particular assumption.[5] Moreover, a non-Abelian Aharonov–Anandan phase fails to be separated from the dynamic one in general. Recently, several schemes using the Aharonov–Anandan phase were proposed for nonadiabatic geometric gates.[6–8]

In a general setting, let us consider a linear (not necessarily finite-dimensional) dynamical system $\partial_t\psi=\hat{S}\psi$ whose linear (time-dependent) dynamic operator $\hat{S}$ falls into the sum

$$\hat{S}=\hat{S}_0+\Delta=\hat{S}_0+\Delta_\alpha\partial_t\xi^\alpha, \tag{1}$$

where $\xi(t)$ is a function of time taking its values in a finite-dimensional smooth real parameter manifold Σ coordinated by (σ^α). Let us assume that (i) the operators $\hat{S}_0(t)$ and $\Delta(t')$ commute for all instants t and t', and (ii) the operator Δ depends on time only through $\xi(t)$. Then the evolution operator $U(t)$ can be represented by the product of time-ordered exponentials

$$U(t)=U_0(t)\circ U_1(t)=T\exp\left[\int_0^t\hat{S}_0dt'\right]\circ T\exp\left[\int_0^t\Delta dt'\right], \tag{2}$$

where the second one is brought into the ordered exponential

[a]Electronic mail: giovanni.giachetta@unicam.it
[b]Electronic mail: luigi.mangiarotti@unicam.it
[c]Electronic mail: sard@grav.phys.msu.su

$$U_1(t)=T\exp\left[\int_0^t \Delta_\alpha(\xi(t'))\partial_t\xi^\alpha(t')dt'\right]=T\exp\left[\int_{\xi[0,t]}\Delta_\alpha(\sigma)d\sigma^\alpha\right] \tag{3}$$

along the curve $\xi[0,t]$ in the parameter manifold Σ. It is a nonadiabatic geometric factor depending only on the trajectory of the parameter function ξ. Accordingly, Δ is a holonomy operator. The geometric factor (3) is well defined if $\Delta_\alpha d\sigma^\alpha$ is an Ehresmann connection on a fiber bundle over a parameter manifold Σ. Then this factor is a displacement operator along an arbitrary curve $\xi[0,t]\subset\Sigma$.

A problem is that the above mentioned commutativity condition (i) is very restrictive. Moreover, it need not be preserved under time-dependent transformations.

For instance, let us consider a Hamiltonian system of dynamic variables (q,p). Written with respect to the initial data coordinates (q_0,p_0), its Hamiltonian $\mathcal{H}(q_0,p_0)$ vanishes. Given these coordinates (q_0,p_0), let one introduce a perturbed Hamiltonian $\mathcal{H}_\xi(q_0,p_0,\xi(t))$ which depends on parameter functions $\xi(t)$ and generates a holonomy operator Δ (1). Then the evolution operator of the perturbed Hamiltonian system reduces to the geometric factor (3). Relative to the original variables (q,p), a Hamiltonian of this perturbed Hamiltonian system is

$$\mathcal{H}'=\mathcal{H}(q,p,t)+\mathcal{H}_\xi(q_0(t,q,p),p_0(t,q,p),\xi(t)).$$

However, the corresponding evolution operator does not fall into the product (2) because a Hamiltonian $\mathcal{H}$ is not a function under time-dependent transformations and, consequently, the Poisson bracket $\{\mathcal{H},\mathcal{H}_\xi\}$ with respect to original variables (q,p) need not vanish.

Nevertheless, basing on this example, we can essentially extend the class of dynamical systems admitting a nonadiabatic geometric phase. We aim to describe dynamical systems where the commutativity condition (i) is not satisfied, but a part of dynamic variables is driven only by a holonomy operator. These are completely integrable Hamiltonian systems.

Let us consider a completely integrable Hamiltonian system (henceforth CIS) of m degrees of freedom around its invariant tori T^m. We show that, being constant under an internal evolution, its action variables are driven only by a perturbation holonomy operator Δ which can be associated to an arbitrary connection on a fiber bundle

$$\Sigma\times T^m\to\Sigma. \tag{4}$$

This holonomy operator is defined with respect to the initial data action-angle coordinates without any adiabatic approximation. Then we return to the original action-angle coordinates. The key point is that both classical evolution of action variables and mean values of quantum action operators relative to original action-angle coordinates are determined in full by the dynamics of initial data action and angle variables.

The plan of the paper is as follows. Section II addresses classical time-dependent CIS. The key point is that any time-dependent CIS of m degrees of freedom is extended to an autonomous CIS of $m+1$ degrees of freedom[9–11] and, as a consequence, can be provided with action-angle variables around a regular instantly compact invariant manifold.[10,11]

In Sec. III, we introduce the holonomy operator in a classical CIS by use of the fact that a generic Hamiltonian of a mechanical system with time-dependent parameters contains a term which is linear both in momenta and the temporal derivative of a parameter function.[12,13] This term comes from a connection on the configuration space of the system fibered over a parameter manifold.

Section IV is devoted to geometric quantization of a CIS with respect to the angle polarization. This polarization leads to the Schrödinger representation of action variables in the separable Hilbert space of smooth complex functions on T^m.[10,14] We show that this quantization both with respect to the original action-angle variables and the initial data action-angle variables is equivalent.

In Sec. V, the classical holonomy operator of Sec. III is quantized with respect to the initial data action-angle variables.

The symbols $\rfloor$ and $\lfloor$ below stand for the left and right interior products of multivector fields and exterior forms, respectively.

Let us recall that, given a fiber bundle $Y\to X$ coordinated by (x^λ,y^i), a connection K on $Y\to X$ is defined by a tangent-valued form

$$K=dx^\lambda\otimes(\partial_\lambda+k^i_\lambda\partial_i)$$

on Y.[15] A connection on a fiber bundle $Y\to X$ is said to be an Ehresmann connection if, given an arbitrary smooth curve $\xi([0,1])\subset X$, there exists its horizontal lift through any point of Y over $\xi(0)$.

Let X be a real axis $\mathbb{R}$ provided with the Cartesian coordinate t possessing transition functions $t'=t+\text{const}$. A connection K on a fiber bundle $Y\to\mathbb{R}$ is uniquely represented by a vector field K on Y such that $K\rfloor dt=1$.[12] This is the case of time-dependent mechanics.

II. CLASSICAL TIME-DEPENDENT CIS

Recall that the configuration space of time-dependent mechanics is a fiber bundle $Q\to\mathbb{R}$ over the time axis $\mathbb{R}$. Let it be equipped with the bundle coordinates (t,q^k), $k=1,\ldots,m$. The corresponding phase space is the vertical cotangent bundle V^*Q of $Q\to\mathbb{R}$ endowed with the induced coordinates (t,q^k,p_k) relative to the holonomic coframes $\{dq^k\}$.[12,16] The cotangent bundle T^*Q of $Q\to\mathbb{R}$ plays a role of the homogeneous phase space of time-dependent mechanics. It is equipped with the induced coordinates (t,q^k,p,p_k) relative to the holonomic coframes $\{dt,dq^k\}$. With respect to these coordinates, the canonical symplectic form and the corresponding Poisson bracket on T^*Q read

$$\Omega=dp\wedge dt+dp_k\wedge dq^k,$$

$$\{f,f'\}_T=\partial_p f\partial_t f'-\partial_t f\partial_p f'+\partial^k f\partial_k f'-\partial_k f\partial^k f',\quad f,f'\in C^\infty(T^*Q).$$

There is the one-dimensional trivial affine bundle

$$\zeta: T^*Q\to V^*Q. \tag{5}$$

As a consequence, the phase space V^*Q of time-dependent mechanics is provided with the canonical Poisson structure

$$\{f,f'\}_V=\partial^k f\partial_k f'-\partial_k f\partial^k f',\quad f,f'\in C^\infty(V^*Q), \tag{6}$$

given by the relations

$$\zeta^*\{f,f'\}_V=\{\zeta^*f,\zeta^*f'\}_T,\quad f,f'\in C^\infty(V^*Q).$$

The corresponding Poisson bivector on V^*Q reads $w_V=\partial_k\wedge\partial^k$.

A Hamiltonian of time-dependent mechanics is defined as a global section

$$h: V^*Q\to T^*Q,\quad p\circ h=-\mathcal{H}(t,q^j,p_j), \tag{7}$$

of the affine bundle ζ (5).[12,16] Given the pull-back form $h^*\Omega$, the relations $\gamma_H\rfloor dt=1$, $\gamma_H\rfloor h^*\Omega=0$ define a unique Hamilton vector field

$$\gamma_H=\partial_t+\partial^k\mathcal{H}\partial_k-\partial_k\mathcal{H}\partial^k \tag{8}$$

on V^*Q and the corresponding Hamilton equations

$$\dot q^k=\partial^k\mathcal{H},\quad \dot p_k=-\partial_k\mathcal{H}. \tag{9}$$

Note that, given a connection $\Gamma=\partial_t+\Gamma_t^i\partial_i$ on $Q\to\mathbb{R}$, any Hamiltonian $\mathcal{H}$ (7) admits the decomposition $\mathcal{H}=p_i\Gamma_t^i+\widetilde{\mathcal{H}}$ where $\widetilde{\mathcal{H}}$ is a function on V^*Q.

An integral of motion of the Hamilton equations (9) is a smooth real function F on V^*Q whose Lie derivative

$$\mathbf{L}_{\gamma_H}F=\gamma_H\rfloor dF=\partial_t F+\{\mathcal{H},F\}_V$$

along the Hamilton vector field γ_H (8) vanishes. A time-dependent Hamiltonian system of m degrees of freedom is a CIS if there exist m independent integrals of motion $\{F_k\}$ in involution with respect to the Poisson bracket $\{,\}_V$ (6). Their Hamiltonian vector fields

$$\vartheta_i=-w_V\rfloor dF_i=\partial^k F_i\partial_k-\partial_k F_i\partial^k$$

and the Hamilton vector field γ_H (8) generate a smooth regular distribution on the phase space V^*Q and the corresponding foliation of V^*Q in invariant manifolds.

One can associate to any time-dependent CIS on V^*Q an autonomous CIS on the homogeneous phase space T^*Q as follows.

Given a Hamiltonian h (7), let us consider an autonomous Hamiltonian system on the symplectic manifold (T^*Q,Ω) with the Hamiltonian

$$\mathbf{H}=\partial_t\rfloor(\Xi-\zeta^*h^*\Xi)=p+\mathcal{H}.$$

Its Hamiltonian vector field

$$\gamma_T=\partial_t-\partial_t\mathcal{H}\partial_p+\partial^k\mathcal{H}\partial_k-\partial_k\mathcal{H}\partial^k \tag{10}$$

is projected onto the Hamilton vector field γ_H (8) on V^*Q so that

$$\zeta^*(\mathbf{L}_{\gamma_H}f)=\{\mathbf{H},\zeta^*f\}_T,\quad f\in C^\infty(V^*Q).$$

An immediate consequence of this relation is the following.

(i) Given a time-dependent CIS $(H;F_k)$ on V^*Q, the Hamiltonian system $\{\mathbf{H},\zeta^*F_k\}$ on T^*Q is a CIS.

(ii) If $M\subset V^*Q$ is an invariant manifold of the time-dependent CIS $\{H;F_k\}$, then $h(M)\subset T^*Q$ is an invariant manifold of the homogeneous CIS $(\mathbf{H},\zeta^*F_k)$.

Hereafter, let the Hamilton vector field γ_H (8) be complete, i.e., the Hamilton equations (9) admit a unique global solution (a trajectory of γ_H) through every point of the phase space V^*Q. The trajectories of γ_H define a trivial bundle $V^*Q\to V_0^*Q$ over the fiber V_0^*Q of $V^*Q\to\mathbb{R}$ at $t=0$. Then any invariant manifold M of $\{H;F_k\}$ is also a trivial bundle $M=\mathbb{R}\times M_0$ over $M_0=M\cap V_0^*Q$.

If M_0 is compact, one can introduce action-angle coordinates around an invariant manifold M by use of the action-angle coordinates around the invariant manifold $h(M)$ of the corresponding autonomous CIS on T^*Q.[10] Namely, $h(M)$ has an open neighborhood which is a trivial bundle

$$U'=V'\times\mathbb{R}\times T^m\to V'\times\mathbb{R}\to V' \tag{11}$$

over a domain $V'\subset\mathbb{R}^{m+1}$ with respect to the action-angle coordinates (I_0,I_i,t,ϕ^i). Herewith, the following holds. (i) $I_0=\mathbf{H}$. (ii) The integrals of motion ζ^*F_k depend only on the action coordinates I_i. (iii) The symplectic form Ω on U' reads

$$\Omega=dI_0\wedge dt+dI_i\wedge d\phi^i.$$

The symplectic annulus U' (11) inherits the fibration structure (5) over the toroidal domain

$$U=V\times\mathbb{R}\times T^m, \quad V\subset\mathbb{R}^m. \tag{12}$$

Coordinated by (I_i,t,ϕ^i) and provided with the Poisson structure (6), the toroidal domain (12) is a phase space of the time-dependent CIS $(H;F_i)$ around its instantly compact invariant manifold M. Since $\mathbf{H}=I_0$, the Hamilton vector field (10) is $\gamma_T=\partial_t$, and so is its projection γ_H (8) onto U. Hence, the above-mentioned action-angle coordinates (I_i,t,ϕ^i) are the initial data coordinates.

These action-angle coordinates are by no means unique. Let $\mathcal{H}$ be an arbitrary smooth function on $\mathbb{R}^m$. Then the canonical transformation

$$I_0'=I_0-\mathcal{H}(I_j), \quad I_i'=I_i, \quad t'=t, \quad \varphi^i=\phi^i+t\partial^i\mathcal{H}(I_j) \tag{13}$$

gives new action-angle coordinates corresponding to a different trivialization of U' (11) [and U (12)]. Accordingly, the Hamilton vector field γ_H takes the form (8), and the Hamilton equations (9) read

$$\dot\varphi^k=\partial^k\mathcal{H}, \quad \dot I_k=0.$$

These are the Hamilton equations of an autonomous CIS with a time-independent Hamiltonian $\mathcal{H}$ on the toroidal domain U (12).

III. CLASSICAL HOLONOMY OPERATORS

The phase space of a Hamiltonian system with time-dependent parameters is a composite fiber bundle $\Pi\to\Sigma\times\mathbb{R}\to\mathbb{R}$, where $\Pi\to\Sigma\times\mathbb{R}$ is a symplectic bundle and $\Sigma\times\mathbb{R}\to\mathbb{R}$ is a parameter bundle whose sections are parameter functions.[12,13,17,18] In the case under consideration, all bundles are trivial and their trivializations hold fixed. Namely, the phase space is the product

$$\Pi=\Sigma\times U=\Sigma\times(V\times\mathbb{R}\times T^m)\to\Sigma\times\mathbb{R}\to\mathbb{R},$$

equipped with the coordinates $(\sigma^\alpha,I_k,t,\phi^k)$. Let us suppose for a time that parameters are also dynamic variables. The phase space of this system is the fiber bundle

$$\Pi'=T^*\Sigma\times U\to\Sigma\times\mathbb{R}\times T^m$$

coordinated by $(\sigma^\alpha,\sigma_\alpha,I_k,t,\phi^k)$. A generic Hamiltonian of such a system is

$$\mathcal{H}_\Sigma=\sigma_\alpha\Sigma_t^\alpha+I_k(\Lambda_t^k+\Lambda_\alpha^k\Sigma_t^\alpha)+\widetilde{\mathcal{H}}(\sigma^\beta,I_j,t,\phi^j), \tag{14}$$

where

$$\partial_t+\Sigma_t^\alpha\partial_\alpha+(\Lambda_t^k+\Lambda_\alpha^k\Sigma_t^\alpha)\partial_k$$

is a composite connection on the fiber bundle $\Sigma\times\mathbb{R}\times T^m\to\mathbb{R}$ generated by a connection $\partial_t+\Sigma_t^\alpha\partial_\alpha$ on the parameter bundle $\Sigma\times\mathbb{R}\to\mathbb{R}$ and a connection

$$\Lambda=dt\otimes(\partial_t+\Lambda_t^k\partial_k)+d\sigma^\alpha\otimes(\partial_\alpha+\Lambda_\alpha^k\partial_k) \tag{15}$$

on $\Sigma\times\mathbb{R}\times T^m\to\Sigma\times\mathbb{R}$.[12,13,18] Then a Hamiltonian system with a fixed parameter function $\sigma^\alpha=\xi^\alpha(t)$ is characterized by the Hamiltonian

$$\mathcal{H}_\xi=I_k[\Lambda_t^k(t,\phi^j)+\Lambda_\alpha^k(\xi^\beta,t,\phi^j)\partial_t\xi^\alpha]+\widetilde{\mathcal{H}}(\xi^\beta,I_j,t,\phi^j) \tag{16}$$

on the pull-back bundle $U=\xi^*\Pi$ (12).

Let (I_k, t, ϕ^k) be the initial data action-angle coordinates of a time-dependent CIS. Its Hamiltonian $\mathcal{H}$ with respect to these coordinates vanishes. Therefore, we can introduce a desired holonomy operator by the appropriate choice of the connection Λ (15). Let us put $\Lambda^k_t = 0$ and assume that coefficients Λ^k_α are independent of time, i.e., the part

$$\Lambda_\Sigma = d\sigma^\alpha \otimes (\partial_\alpha + \Lambda^k_\alpha \partial_k) \tag{17}$$

of the connection Λ (15) is a connection on the fiber bundle (4). Then the Hamiltonian of a perturbed CIS reads

$$\mathcal{H}_\xi = I_k \Lambda^k_\alpha(\xi^\beta, \phi^j)\partial_t \xi^\alpha. \tag{18}$$

Its Hamilton vector field (8) is

$$\gamma_H = \partial_t + \Lambda^i_\alpha \partial_t \xi^\alpha \partial_i - I_k \partial_i \Lambda^k_\alpha \partial_t \xi^\alpha \partial^i. \tag{19}$$

It leads to the Hamilton equations

$$\partial_t \phi^i = \Lambda^i_\alpha(\xi(t), \phi^l)\partial_t \xi^\alpha, \tag{20}$$

$$\partial_t I_i = -I_k \partial_i \Lambda^k_\alpha(\xi(t), \phi^l)\partial_t \xi^\alpha. \tag{21}$$

Note that

$$V^*\Lambda_\Sigma = d\sigma^\alpha \otimes (\partial_\alpha + \Lambda^i_\alpha \partial_i - I_k \partial_i \Lambda^k_\alpha \partial^i) \tag{22}$$

is the lift of the connection Λ_Σ (17) onto the fiber bundle $\Sigma \times (V \times T^m) \to \Sigma$, seen as a subbundle of the vertical cotangent bundle $V^*(\Sigma \times T^m) = \Sigma \times T^*T^m$ of the fiber bundle (4). It follows that any solution $I_i(t)$, $\phi^i(t)$ of the Hamilton equations (20) and (21) [i.e., an integral curve of the Hamilton vector field (19)] is a horizontal lift of the curve $\xi(t) \subset \Sigma$ with respect to the connection $V^*\Lambda_\Sigma$ (22), i.e., $I_i(t) = I_i(\xi(t))$, $\phi^i(t) = \phi^i(\xi(t))$. Thus, the right-hand side of the Hamilton equations (20) and (21) is the holonomy operator

$$\Delta = (\Lambda^i_\alpha \partial_t \xi^\alpha, -I_k \partial_i \Lambda^k_\alpha \partial_t \xi^\alpha) \tag{23}$$

[cf. (1) where $\hat{S}_0 = 0$]. It is not a linear operator, but the substitution of a solution $\phi(\xi(t))$ of the equation (20) into the Hamilton equation (21) results in a linear holonomy operator on the action variables I_i.

Let us show that the holonomy operator (23) is well defined. Since any vector field ϑ on $\mathbb{R} \times T^m$ such that $\vartheta \rfloor dt = 1$ is complete, the Hamilton equation (20) has solutions for any parameter function $\xi(t)$. It follows that any connection Λ_Σ (17) on the fiber bundle (4) is an Ehresmann connection, and so is its lift (22). Therefore, any curve $\xi([0,1]) \subset \Sigma$ can play the role of the parameter function in the holonomy operator Δ (23).

Now, let us return to the original action-angle coordinates (I_k, t, φ^k) by means of the canonical transformation (13). Relative to these coordinates, the perturbed Hamiltonian reads

$$\mathcal{H}' = I_k \Lambda^k_\alpha(\xi(t), \varphi^i - t\partial^i \mathcal{H}(I_j))\partial_t \xi^\alpha(t) + \mathcal{H}(I_j),$$

and the Hamilton equations (20) and (21) take the form

$$\partial_t \varphi^i = \partial^i \mathcal{H}(I_j) + \Lambda^i_\alpha(\xi(t), \varphi^l - t\partial^l \mathcal{H}(I_j))\partial_t \xi^\alpha(t) - tI_k \partial^i \partial^s \mathcal{H}(I_j)\partial_s \Lambda^k_\alpha(\xi(t), \varphi^l - t\partial^l \mathcal{H}(I_j))\partial_t \xi^\alpha(t),$$

$$\partial_t I_i = -I_k \partial_i \Lambda^k_\alpha(\xi(t), \varphi^l - t\partial^l \mathcal{H}(I_j))\partial_t \xi^\alpha(t).$$

Their solution is $I_i(\xi(t))$, $\varphi^i(t)=\phi^i(\xi(t))+t\partial^i\mathcal{H}(I_j(\xi(t)))$ where $I_i(\xi(t))$, $\phi^i(\xi(t))$ is a solution of the Hamilton equations (20) and (21). It is readily observed that the action variables I_k are driven only by the holonomy operator, while the angle variables φ^i have a nongeometric summand.

Let us emphasize that, in the construction of the holonomy operator (23), we did not impose any restriction on the connection Λ_Σ (17). Therefore, any connection on the fiber bundle (4) generates a holonomy operator in a CIS. However, a glance at the expression (23) shows that this operator becomes zero on action variables if all coefficients Λ^k_λ of the connection Λ_Σ (17) are constant, i.e., Λ_Σ is a principal connection on the fiber bundle (4) seen as a principal bundle with the structure group T^m.

IV. QUANTUM CIS

There are different approaches to quantization of CISs.[19] Their geometric quantization was studied at first with respect to the polarization spanned by Hamiltonian vector fields of integrals of motion.[20] For example, the well-known Simms quantization of the harmonic oscillator is of this type. In this approach, the problem is that the associated quantum algebra includes affine functions of angle coordinates which are ill defined. As a consequence, elements of the carrier space of this quantization fail to be smooth, but are tempered distributions. In recent works,[10,14] we have developed a different variant of geometric quantization of CISs by use of the angle polarization spanned by almost-Hamiltonian vector fields ∂^k of angle variables. This quantization is equivalent to geometric quantization of the cotangent bundle T^*T^m of a torus T^m with respect to the vertical polarization. The result is as follows.

Given an autonomous CIS on a symplectic annulus

$$P=V\times T^m, \quad \Omega_P=dI_i\wedge d\varphi^i$$

equipped with the action-angle coordinates (I_i,φ^i), its quantum algebra $\mathcal{A}$ with respect to the above mentioned angle polarization consists of affine functions

$$f=a^k(\varphi^j)I_k+b(\varphi^j)$$

of action coordinates I_k. They are represented by self-adjoint unbounded operators

$$\hat{f}=-ia^k\partial_k-\frac{i}{2}\partial_k a^k-a^k\lambda_k+b \tag{24}$$

in the separable pre-Hilbert space of complex half-forms on T^m. If coordinate transformations of T^m are only translations, this space can be identified with the pre-Hilbert space $\mathbb{C}^\infty(T^m)$ of smooth complex functions on T^m. Different tuples of real numbers $(\lambda_1,\ldots,\lambda_m)$ and $(\lambda'_1,\ldots,\lambda'_m)$ specify inequivalent representations (24), unless $\lambda_k-\lambda'_k\in\mathbb{Z}$ for all $k=1,\ldots,m$. These numbers come from the de Rham cohomology group $H^1(T^m)=\mathbb{R}^m$.

In particular, the action operators (24) read $\hat{I}_k=-i\partial_k-\lambda_k$. They are bounded. By virtue of the multidimensional Fourier theorem, an orthonormal basis for $\mathbb{C}^\infty(T^m)$ consists of functions

$$\psi_{(n_r)}(\varphi)=\exp[in_r\varphi^r], \quad (n_r)=(n_1,\ldots,n_m)\in\mathbb{Z}^m. \tag{25}$$

With respect to this basis, the action operators are brought into countable diagonal matrices

$$\hat{I}_k\psi_{(n_r)}=(n_k-\lambda_k)\psi_{(n_r)}, \tag{26}$$

while functions $a^k(\varphi)$ are decomposed in Fourier series of the functions $\psi_{(n_r)}$, which act on $\mathbb{C}^\infty(T^m)$ by the law

$$\hat{\psi}_{(n_r)}\psi_{(n'_r)}=\psi_{(n_r+n'_r)}. \tag{27}$$

It should be emphasized that $\hat{a}^k\hat{I}_k\neq\widehat{a^kI_k}\neq\widehat{I_ka^k}$.

If a Hamiltonian $\mathcal{H}(I_k)$ of an autonomous CIS is an analytic function on $\mathbb{R}^m$, it is uniquely quantized as a Hermitian element $\hat{\mathcal{H}}(I_k)=\mathcal{H}(\hat{I}_k)$ of the enveloping algebra of $\mathcal{A}$. It is a bounded self-adjoint operator with the countable spectrum

$$\hat{\mathcal{H}}(I_k)\psi_{(n_r)}=E_{(n_r)}\psi_{(n_r)}, \quad E_{(n_r)}=\mathcal{H}(n_k-\lambda_k), \quad n_k\in(n_r). \tag{28}$$

In order to quantize a time-dependent CIS on the Poisson toroidal domain $(U,\{,\}_V)$ (12) equipped with action-angle coordinates (I_i,t,φ^i), one may follow the instantwise geometric quantization of time-dependent mechanics.[21] As a result, we can simply replace functions on T^m with those on $\mathbb{R}\times T^m$.[10] Namely, the corresponding quantum algebra $\mathcal{A}\subset C^\infty(U)$ consists of affine functions

$$f=a^k(t,\varphi^j)I_k+b(t,\varphi^j) \tag{29}$$

of action coordinates I_k represented by the operators (24) in the space

$$E=\mathbb{C}^\infty(\mathbb{R}\times T^m) \tag{30}$$

of smooth complex functions $\psi(t,\varphi)$ on $\mathbb{R}\times T^m$. This space is provided with the structure of the pre-Hilbert $\mathbb{C}^\infty(\mathbb{R})$-module with respect to the nondegenerate $\mathbb{C}^\infty(\mathbb{R})$-bilinear form

$$\langle\psi|\psi'\rangle=\left(\frac{1}{2\pi}\right)^m\int_{T^m}\psi\overline{\psi'}\,d^m\varphi, \quad \psi,\psi'\in\mathbb{C}^\infty(\mathbb{R}\times T^m).$$

Its basis consists of the pull-back onto $\mathbb{R}\times T^m$ of the functions $\psi_{(n_r)}$ in (25).

This quantization of a time-dependent CIS is extended to the associated homogeneous CIS on the symplectic annulus (U',Ω) in (11) by means of the operator $\hat{I}_0=-i\partial_t$ in the pre-Hilbert module E in (30). Accordingly, the homogeneous Hamiltonian $\mathbf{H}$ is quantized as $\hat{\mathbf{H}}=-i\partial_t+\hat{\mathcal{H}}$. The corresponding Schrödinger equation is

$$\hat{\mathbf{H}}\psi=-i\partial_t\psi+\hat{\mathcal{H}}\psi=0, \quad \psi\in E. \tag{31}$$

For instance, the quantum Hamiltonian of the original autonomous CIS is

$$\hat{\mathbf{H}}=-i\partial_t+\mathcal{H}(\hat{I}_j).$$

Its spectrum $\hat{\mathbf{H}}\psi_{(n_r)}=E_{(n_r)}\psi_{(n_r)}$ relative to the basis $\{\psi_{(n_r)}\}$ for E in (30) coincides with that of the autonomous Hamiltonian (28). The Schrödinger equation (31) reads

$$\hat{\mathbf{H}}\psi=-i\partial_t\psi+\mathcal{H}(-i\partial_k-\lambda_k)\psi=0, \quad \psi\in E.$$

Its solutions are the Fourier series

$$\psi=\sum_{(n_r)}B_{(n_r)}\exp[-itE_{(n_r)}]\psi_{(n_r)}, \quad B_{(n_r)}\in\mathbb{C}.$$

Now, let us quantize this CIS with respect to the initial data action-angle coordinates (I_i,ϕ^i). Its quantum algebra $\mathcal{A}_0\subset C^\infty(U)$ consists of affine functions

$$f=a^k(t,\phi^j)I_k+b(t,\phi^j). \tag{32}$$

The canonical transformation (13) provides an isomorphism between Poisson algebras $\mathcal{A}$ and $\mathcal{A}_0$. Functions f in (32) are represented by the operators $\hat{f}$ in (24) in the pre-Hilbert module E_0 of smooth complex functions $\Psi(t,\phi)$ on $\mathbb{R}\times T^m$. Given its basis $\Psi_{(n_r)}(\phi)=\exp[in_r\phi^r]$, the operators $\hat{I}_k$ and $\hat{\psi}_{(n_r)}$ take the form (26) and (27), respectively. The Hamiltonian of a quantum CIS with respect to the initial data variables is $\hat{\mathbf{H}}_0=-i\partial_t$. Then one easily obtains the isometric isomorphism

$$R(\psi_{(n_r)})=\exp[itE_{(n_r)}]\Psi_{(n_r)}, \quad \langle R(\psi)|R(\psi')\rangle=\langle\psi|\psi'\rangle, \tag{33}$$

between the pre-Hilbert modules E and E_0 which provides the equivalence

$$\hat{I}_i=R^{-1}\hat{I}_iR, \quad \hat{\psi}_{(n_r)}=R^{-1}\hat{\Psi}_{(n_r)}R, \quad \hat{\mathbf{H}}=R^{-1}\hat{\mathbf{H}}_0R \tag{34}$$

of the quantizations of a CIS with respect to the original and initial data action-angle variables.

V. QUANTUM HOLONOMY OPERATORS

In view of the isomorphism (34), let us first construct a holonomy operator for a quantum CIS $(\mathcal{A}_0,\hat{\mathbf{H}}_0)$ with respect to the initial data action-angle coordinates. Let us consider the perturbed homogeneous Hamiltonian

$$\mathbf{H}_\xi=\mathbf{H}_0+\mathbf{H}_1=I_0+\partial_t\xi^\alpha(t)\Lambda^k_\alpha(\xi(t),\phi^j)I_k$$

of the classical perturbed system (18). Its perturbation term $\mathbf{H}_1$ is of the form (29) and, therefore, is quantized by the operator

$$\hat{\mathbf{H}}_1=-i\partial_t\xi^\alpha\hat{\Delta}_\alpha=-i\partial_t\xi^\alpha[\Lambda^k_\alpha\partial_k+\tfrac{1}{2}\partial_k(\Lambda^k_\alpha)-i\lambda_k\Lambda^k_\alpha].$$

The quantum Hamiltonian $\hat{\mathbf{H}}_\xi=\hat{\mathbf{H}}_0+\hat{\mathbf{H}}_1$ defines the Schrödinger equation

$$\partial_t\Psi+\partial_t\xi^\alpha[\Lambda^k_\alpha\partial_k+\tfrac{1}{2}\partial_k(\Lambda^k_\alpha)-i\lambda_k\Lambda^k_\alpha]\Psi=0. \tag{35}$$

If a solution exists, it can be written by means of the evolution operator which reduces to the geometric factor U_1 in (3). The latter can be viewed as a displacement operator along the curve $\xi[0,1]\subset\Sigma$ with respect to the connection

$$\hat{\Lambda}_\Sigma=d\sigma^\alpha(\partial_\alpha+\hat{\Delta}_\alpha) \tag{36}$$

in the $\mathbb{C}^\infty(\Sigma)$-module $\mathbb{C}^\infty(\Sigma\times T^m)$ of smooth complex functions on $\Sigma\times T^m$.[13,15,18,22] Let us study the existence of this displacement operator.

Given a connection Λ_Σ in (17), let $\Phi^i(t,\phi)$ denote the flow of the complete vector field $\partial_t+\Lambda^i_\alpha(\xi,\phi)\partial_t\xi^\alpha\partial_i$ on $\mathbb{R}\times T^m$. It is a solution of the Hamilton equation (20) with the initial data ϕ. We need the inverse flow $(\Phi^{-1})^i(t,\phi)$ which obeys the equation

$$\partial_t(\Phi^{-1})^i(t,\phi)=-\partial_t\xi^\alpha\Lambda^i_\alpha(\xi,(\Phi^{-1})^i(t,\phi))=-\partial_t\xi^\alpha\Lambda^k_\alpha(\xi,\phi)\partial_k(\Phi^{-1})^i(t,\phi).$$

Let Ψ_0 be an arbitrary complex half-form Ψ_0 on T^m possessing identical transition functions, and let the same symbol stand for its pull-back onto $\mathbb{R}\times T^m$. Given its pull-back

$$(\Phi^{-1})^*\Psi_0=\det\left(\frac{\partial(\Phi^{-1})^i}{\partial\phi^k}\right)^{1/2}\Psi_0(\Phi^{-1}(t,\phi)), \tag{37}$$

it is readily observed that

$$\Psi = (\Phi^{-1})^* \Psi_0 \exp[i\lambda_k \phi^k]$$

obeys the Schrödinger equation (35) with the initial data Ψ_0. This function is well defined only if all the numbers λ_k equal 0 or $\pm\frac{1}{2}$. Note that, if some numbers λ_k are equal to $\pm\frac{1}{2}$, then $\Psi_0 \exp[i\lambda_k \phi^k]$ is a half-density on T^m whose transition functions equal ± 1, i.e., it is a section of a nontrivial metalinear bundle over T^m.

We thus observe that if λ_k equals 0 or $\pm\frac{1}{2}$, then the displacement operator always exists and $\Delta = i\mathbf{H}_1$ is a holonomy operator. A glance at the action law (27) shows that this operator is infinite-dimensional.

For instance, let Λ_Σ in (17) be the above mentioned principal connection, i.e., $\Lambda^k_\alpha = \text{const}$. Then the Schrödinger equation (35) where $\lambda_k = 0$ takes the form

$$\partial_t \Psi(t, \phi^j) + \partial_t \xi^\alpha(t) \Lambda^k_\alpha \partial_k \Psi(t, \phi^j) = 0.$$

Its solution (37) is

$$\Psi(t, \phi^j) = \Psi_0(\phi^j - (\xi^\alpha(t) - \xi^\alpha(0))\Lambda^j_\alpha).$$

The corresponding evolution operator reduces to Berry's phase multiplier

$$U_1 \Psi_{(n_r)} = \exp[-in_j(\xi^\alpha(t) - \xi^\alpha(0))\Lambda^j_\alpha)]\Psi_{(n_r)}, \quad n_j \in (n_r).$$

It keeps the eigenvectors of the action operators $\hat{I}_i$.

In order to return to the original action-angle variables, one can employ the morphism R in (33). The corresponding Hamiltonian reads $\mathbf{H}' = R^{-1}\mathbf{H}_\xi R$. The key point is that, due to the relation (34), the action operators $\hat{I}_i$ have the same mean values

$$\langle I_k \psi | \psi \rangle = \langle I_k \Psi | \Psi \rangle, \quad \Psi = R(\psi),$$

with respect both to the original and the initial data action-angle variables. Therefore, these mean values are defined only by the holonomy operator.

VI. CONCLUSIONS

We have shown that any CIS around its compact invariant manifold admits a perturbation dependent on parameters by means of a holonomy operator associated to a connection on the fiber bundle (4).

Since action variables are driven only by a holonomy operator, one can use this operator in order to perform a dynamic transition between classical solutions or quantum states of an unperturbed CIS by an appropriate choice of a parameter function ξ. The key point is that this transition can take an arbitrary short time because we are entirely free with time parametrization of ξ and can choose it quickly changing, in contrast with slowly varying parameter functions in adiabatic models. For instance, one can choose ξ a step function; then its time derivative is a δ-function of time. This fact makes nonadiabatic holonomy operators in CISs promising for several applications, including classical and quantum scattering in integrable Hamiltonian systems,[23] quantum control operators,[24,25] and the above mentioned quantum computation. It also looks attractive that quantum holonomy operators in CISs are essentially infinite-dimensional, whereas both the existent quantum control theory and the theory of quantum information and computation[26] involve only finite-dimensional operators.

Weak coherent state path integrals

Lorenz Hartmann

(Received 28 August 2003; accepted 4 September 2003)

Weak coherent states share many properties of the usual coherent states, but do not admit a resolution of unity expressed in terms of a local integral. They arise, e.g., in the case that a group acts on an inadmissible fiducial vector. Motivated by the recent Affine Quantum Gravity Program, the present article studies the path integral representation of the affine weak coherent state matrix elements of the unitary time-evolution operator. Since weak coherent states do not admit a resolution of unity, it is clear that the standard way of constructing a path integral, by time slicing, is predestined to fail. Instead a well-defined path integral with Wiener measure, based on a continuous-time regularization, is used to approach this problem. The dynamics is rigorously established for linear Hamiltonians, and the difficulties presented by more general Hamiltonians are addressed. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1627959]

I. INTRODUCTION

Unlike the standard phase space path integrals constructed by the time slicing method, the path integral with Wiener measure invented by Klauder, Daubechies, and others uses a continuous-time regularization factor.[1–5] This path integral is $\int \exp\{-i\int[qdp+dG(p,q)+h(p,q)dt]\}\, d\mu_W^\nu$, where G is an arbitrary C^1 function and h is the classical Hamiltonian in a sense which will be explained later. The pinned Wiener measure $d\mu_W^\nu$ is defined with the help of the heat kernel $\int d\mu_W^\nu := [\exp\{\nu T\Delta_{\mathrm{LB}}\}](p'',q'',q',p')$. Thus, by way of the Laplace–Beltrami operator Δ_{LB}, a metric is introduced. The formal phase space path integral $\mathcal{N}_\nu \int \exp\{-i\int[q\dot{p}+\dot{G}(p,q)+h(p,q)]dt\}\exp\{-(1/2\nu)\int(d\sigma^2/dt^2)dt\}\mathcal{D}p\mathcal{D}q$ can be given meaning by equating it to the above Wiener measure path integral. Here, $\mathcal{N}_\nu$ is a formal normalization constant, and $d\sigma^2$ is the metric mentioned above. The variables p and q in the well-defined Wiener measure path integral are stochastic variables describing Brownian Bridges. The integral $\int qdp$ has to be interpreted as a stochastic integral. The rule adopted here is the Stratonovich midpoint rule $\int qdp := \lim \Sigma \frac{1}{2}(q_{l+1}+q_l)(p_{l+1}-p_l)$, which guarantees that the ordinary rules of calculus still apply. It was shown, first for the case of a flat and spherical phase space metric,[1] then for a hyperbolic metric,[2] that the limit of diverging diffusion constant ν exists for a wide set of quantum Hamiltonians $\mathcal{H}$, including at least all Hamiltonians polynomial in the basic quantum kinematical operators. The limit is equal to the coherent state matrix element $\langle p''q''|\exp\{-iT\mathcal{H}\}|p'q'\rangle$ of the unitary time-evolution operator and the specific metric determines the coherent states in question: The flat metric is inevitably connected with the coherent states of the Heisenberg–Weyl group (and in the canonical, Cartesian form, it is connected to the canonical coherent states), the spherical metric is associated with the coherent states of the SU(2) group, and the hyperbolic metric leads to the coherent states of the affine group. And with each group comes a set of quantum kinematical operators. Thus, one can say that in these three cases the choice of geometry augmenting the classical phase space manifold determines the quantum kinematical operators uniquely! Furthermore, the classical Hamiltonian that goes with the quantum Hamiltonian $\mathcal{H}$ is given by the lower symbol (other authors call this symbol the upper symbol, since it is involved in an upper bound in the Berezin–Lieb inequalities)

h, implicitly defined by the relation $\mathcal{H}=\int h(p,q)|pq\rangle\langle pq|d\mu(p,q)$. Here, $d\mu(p,q)$ is the left-invariant group measure of the group which defines the coherent states. This measure is normalized such that $h(p,q)\equiv 1$ leads to $\mathcal{H}=\mathbb{1}$, and, thus, provides the usual resolution of unity. Since the Stratonovich rule is used, and since the coherent states merely change labels under canonical (coordinate) transformations, apart from possible phase factors, the path integral $\langle p''q''|\times\exp\{-iT\mathcal{H}\}|p'q'\rangle=\lim_{\nu\to\infty}\int\exp\{-i\int[qdp+dG(p,q)+h(p,q)dt]\}\,d\mu_W^\nu$ is covariant under canonical (coordinate) transformations and the quantization is fully geometric in nature.[3,4] The foregoing has been extended to arbitrary geometries of the phase space.[6]

In an attempt to quantize gravity,[7,8] Klauder was led to consider affine rather than canonical commutation relations for the field operators (the spatial part of the metric and its partner field). In the simplest case of constant fields, the problem reduces to a toy model of just one degree of freedom, namely, the affine coherent states. To be more precise, it includes the affine coherent states, which fulfill a fiducial vector admissibility condition,[2,5,9] but also those states which violate it. These latter states do not resolve unity anymore and, therefore, are called weak coherent states. The Affine Quantum Gravity Program has provided the motivation to raise the question of the existence of path integrals for these weak coherent states.

It is clear that a path integral cannot be constructed with weak coherent states in the standard way, since the resolution of unity is the key to the time-slicing approximation. However, the extension of the well-defined path integral with Wiener measure introduced above to the situation of weak coherent states could still be possible, and this is the goal of the present article. Two different methods to extend the Wiener measure path integral will be introduced: the first is based on the spectral decomposition of certain operators and will therefore be called the ''spectral approach.'' Unfortunately, it is limited to one very special case. The second uses an extra regularization parameter and is consequently called the ''regularizing approach.'' In both cases, the path integral for zero Hamiltonian is studied first, while the dynamics is introduced as a second step.

II. WEAK COHERENT STATE PATH INTEGRALS

A. General definitions

Coherent states are defined by two properties:[10]

(1) *Continuity:* The states $|l\rangle$ are a strongly continuous vector-valued function of the label l.
(2) *Resolution of unity:* There exists a positive measure δl on the label space $\mathfrak{L}$ such that the identity operator $\mathbb{1}$ on $\mathfrak{H}$ can, upon integration over $\mathfrak{L}$, be represented as

$$\mathbb{1}=\int|l\rangle\langle l|\,\delta l.$$

A more general class of states can be obtained by relaxing the second property:
(2′) *Completeness:* The family of vectors $(|l\rangle)$ is total, i.e., the closed linear span of $(|l\rangle)$ is the whole Hilbert space $\mathfrak{H}$.

States which share properties (1) and (2′) have been named Klauder states.[11] They are the disjoint union of the coherent states in the sense above and the weak coherent states, which do not possess a resolution of unity.

B. Affine weak coherent states

The affine group $(M_+,\circ)$ is the set $M_+:=\mathbb{R}^+\times\mathbb{R}$ with the group law $(q,p)\circ(q',p')=(qq',p+q^{-1}p')$ and has two nontrivial, inequivalent, irreducible, unitary representations[2] $U_\pm(p,q)=e^{\pm ipQ}e^{-i\ln qD}$, where the generators $Q>0$ and D obey the affine commutation relation $[Q,D]=iQ$. The uncertainty product of the irreducible, self-adjoint operators Q and D is $\Delta Q\Delta D\geqslant\frac{1}{2}\langle Q\rangle$. Setting $\langle Q\rangle=1$ leads to a one-parameter family of minimum uncertainty states given in x-representation by[5] $\eta_\beta(x)=N_\beta x^{\beta-1/2}e^{-\beta x}$ with normalization $N_\beta=(2\beta)^\beta\Gamma^{-1/2}(2\beta)$. The affine coherent states are defined as $|pq\rangle:=U_+(p,q)|\eta_\beta\rangle$. The group acts on admissible

fiducial vectors, which fulfill[2,5,9] $\langle Q^{-1}\rangle = \int_0^\infty x^{-1} |\eta_\beta(x)|^2 dx < \infty$. Namely, these are the states with $\beta > 1/2$. Weak coherent states, on the other hand, are generated by the same group action on fiducial vectors with $0 < \beta \leqslant 1/2$. For the whole parameter range $0 < \beta$, the overlap reads

$$\langle pq|rs\rangle = (qs)^{-\beta} 2^{2\beta} [(q^{-1}+s^{-1}) + i\beta^{-1}(p-r)]^{-2\beta}.$$

The construction of the affine coherent state path integral with Wiener measure[2] is based on a linear complex polarization condition. For the minimum uncertainty fiducial vectors, $(Q - 1 + i\beta^{-1}D)|\eta_\beta\rangle = 0$ holds. Hence, all functions $\psi(p,q) := \langle pq|\psi\rangle$ are annihilated by the operator $B = -iq^{-1}\partial_p + 1 + \beta^{-1} q \partial_q$. The same is true for the second-order differential operator

$$A := \tfrac{1}{2}\beta B^\dagger B = \tfrac{1}{2}\{-\beta^{-1}\partial_q q^2 \partial_q - \beta q^{-2}\partial_p^2 - 1 + \beta - 2i\beta q^{-1}\partial_p\}$$

which is a non-negative, self-adjoint operator with spectrum

$$\mathrm{spec}(A) = \{(\beta - \tfrac{1}{2})^2 - (\beta - \tfrac{1}{2} - n)^2; n \in \mathbb{N}, n < \beta - \tfrac{1}{2}\} \cup [(\beta - \tfrac{1}{2})^2, \infty).$$

For $\beta > 1/2$, the operator A has a discrete eigenvalue 0 and it follows, for $T > 0$, that $\lim_{\nu\to\infty}[e^{-\nu TA}]\delta(p-p')\delta(q-q')|_{p=p'',q=q''} = [P_0](p'',q'';p',q')$, where the expression on the right-hand side is the kernel of the projection operator onto the ground state. But this kernel is also given by $(2\pi)^{-1}(1 - (1/2\beta))\langle p''q''|p'q'\rangle$. This is the key part of the construction, since the rest follows by the Feynman–Kac–Stratonovich representation of the kernel of $e^{-\nu TA}$, which is $\mathcal{N}_\nu \int e^{-i\int q\dot{p}dt - (1/2\nu)\int[\beta^{-1}q^2\dot{p}^2 + \beta q^{-2}\dot{q}^2]dt}\mathcal{D}p\mathcal{D}q$. As stated in the Introduction, this formal expression makes sense as a Wiener measure path integral, and so finally

$$\langle p''q''|p'q'\rangle = \lim_{\nu\to\infty} 2\pi\left(1 - \frac{1}{2\beta}\right)^{-1} e^{\nu T/2} \int e^{-i\int q\, dp}\, d\mu_W^\nu(p,q),$$

which is a well-defined expression. (The path integral for a nonzero Hamiltonian is constructed in much the same way. The only difference is that νA must be replaced by an operator involving the Hamiltonian h, namely $\nu A + ih$.)

For $0 < \beta \leqslant 1/2$, i.e., in the weak coherent state case, the operator A has only a continuous spectrum, and the limit of diverging diffusion constant of the operator $e^{-\nu TA}$ is zero. Thus, the whole construction outlined above breaks down. To prevent this collapse to a trivial result, two different approaches will be discussed.

C. Spectral approach

The idea in this approach is to determine a ν-dependent rescaling factor, such that the limit of diverging diffusion constant will be nontrivial. This was proposed by Klauder.[5]

1. The general case

Let X be a non-negative self-adjoint operator on a certain Hilbert space and assume zero is in its continuous, but not in its discrete, spectrum. The operator X generates a semigroup $e^{-\nu TX}$, which has a spectral representation $e^{-\nu XT} = \int_0^\infty e^{-\nu\lambda T} d\mathbb{E}(\lambda)$ or $\langle x''|e^{-\nu TX}|x'\rangle = \int_0^\infty e^{-\nu\lambda T} d\langle x''|\mathbb{E}(\lambda)|x'\rangle$.

Since only well-behaved potentials will eventually be of interest, the reasonable assumption is made that the measure $d\langle x''|\mathbb{E}(\lambda)|x'\rangle$ has an absolutely continuous, but no singularly continuous part. Then the spectral family can be written as a (weighted) integral over one-dimensional projection operators $\mathbb{E}(\lambda) = \int_{-\infty}^{\lambda} |E\rangle\langle E|\rho(E)dE$. [For a singularly continuous measure this would not be possible: $\mu_{\mathrm{sc}}(x) = \int_{-\infty}^{x} d\mu_{\mathrm{sc}}(y) \neq \int_{-\infty}^{x} (d\mu_{\mathrm{sc}}/dy)dy = 0$ since $d\mu_{\mathrm{sc}}/dy = 0$ almost everywhere.] If the generalized eigenstates $|E\rangle$ are δ-orthonormalized, then $\rho(E) = 1$.

The matrix element of $e^{-\nu TX}$ can then be written as

$$\langle x''|e^{-\nu TX}|x'\rangle = \int_0^\infty e^{-\nu\lambda T}\psi_\lambda(x'')\psi_\lambda^*(x')\rho(\lambda)d\lambda \tag{1}$$

and the ψ_λ are continuous in λ. Moreover, ρ—being part of the measure—is at least right-continuous. For δ-orthonormalized wave functions, $\rho(\lambda)\equiv 1$.

The goal is to find the rescaling factor which saves Eq. (1) from becoming trivial in the limit of diverging diffusion constant ν. Since, for very large ν, the factor $e^{-\nu T\lambda}$ suppresses everything but the values for very small λ, the behavior of $f_{x',x''}(\lambda) := \psi_\lambda(x'')\psi_\lambda^*(x')\rho(\lambda)$ near $\lambda = 0$ is all that matters. To give an example, assume that $f_{x',x''}(\lambda) \propto \lambda^a$ for small λ. Now, the proper rescaling factor can be determined, and in the example it is

$$\int_0^\infty d\lambda\, \lambda^a e^{-\nu\lambda T} = \frac{\Gamma(a+1)}{(\nu T)^{a+1}}. \tag{2}$$

After rescaling with the inverse one gets $[(\nu T)^{a+1}/\Gamma(a+1)]\,\lambda^a e^{-\nu\lambda T} \overset{\nu\to\infty}{\longrightarrow} \delta(\lambda)$ which represents a δ-function weight on $\lambda = 0$.

The rescaling factor can be computed self-consistently, and the general formula reads

$$\frac{\int_0^\infty e^{-\nu\lambda T}\psi_\lambda(x'')\psi_\lambda^*(x')\rho(\lambda)d\lambda}{\int_0^\infty e^{-\nu\lambda T}\psi_\lambda(0)\psi_\lambda^*(0)\rho(\lambda)d\lambda} \overset{\nu\to\infty}{\rightharpoonup} \frac{\psi_0(x'')\psi_0^*(x')}{\psi_0(0)\psi_0^*(0)}. \tag{3}$$

The numerator of the last expression, $\psi_0(x'')\psi_0^*(x')$, is the kernel of the desired projection operator onto the ground state, and we have assumed that the denominator is nonzero. The convergence is in a distributional sense (denoted by the symbol $\rightharpoonup$). If the functional form of $\psi_0(x'')\psi_0^*(x')$ is known to be continuous, then the convergence is pointwise.

Observe, in the example with $f_{x',x''}(\lambda) = \lambda^a$, one must have $a > -1$, or else the rescaling factor would be identically zero (since the integral would be infinity). But, since the rescaling factor can be determined self-consistently, i.e., by the denominator of Eq. (3), which always exists, there is no hidden ''trap'' to look out for. Moreover, the evaluation of the denominator need not necessarily be at the point $x'' = x' = 0$. It could be at any point $x'' = x' = b$, $b \in \mathbb{R}$, or even $b = \pm\infty$, as long as the function $\psi_\lambda(x)$ is not 0 at b. Whatever gives the easiest result is the preferred choice. And the arbitrariness of this choice is not critical: Assume K to be the reproducing kernel of some reproducing kernel Hilbert space, and let a be a positive constant. Then, aK is just as good a reproducing kernel, since the same class of functions arises, only the inner product has to be redefined.

2. The affine case

The foregoing is now applied to the case of the affine weak coherent states. Unfortunately, A matches the required properties, namely that 0 be in the continuous spectrum, only in the case $\beta = 1/2$! This is true in spite of the fact that $A\langle pq|\psi\rangle = 0$ (for arbitrary $|\psi\rangle$), since an equation $A\psi = \alpha\psi$ need not necessarily imply $\alpha \in \mathrm{spec}(A)$. In fact, the $\psi(p,q) = \langle pq|\psi\rangle$ are not generalized eigenvectors except in the case $\beta = 1/2$.[11] Consequently, the isolating procedure can only be performed for $\beta = 1/2$, and the general theory above ensures the existence of the weak coherent state path integral.

For the case at hand a connection between the operator A and the one-dimensional Morse operator H_{Morse} exists[2] and makes the explicit functional form of the generalized eigenfunctions available. With the aid of these, the rescaling factor can be computed explicitly.

The problem to find the eigenfunctions of the operator A is first reduced to a problem on $L^2(\mathbb{R}^+)$ and then to a problem on $L^2(\mathbb{R})$, leading to the Morse operator,

$$
\begin{aligned}
A\langle U(p,q)\phi|\psi\rangle &= \langle A^* U(p,q)\phi|\psi\rangle \\
&= \tfrac{1}{2}\langle[-\beta^{-1}\partial_q q^2\partial_q - \beta q^{-2}\partial_p^2 - 2i\beta q^{-1}\partial_p + \beta - 1]e^{ipQ}e^{-i\ln qD}\phi|\psi\rangle \\
&= \tfrac{1}{2}\beta^{-1}\langle e^{ipQ}e^{-i\ln qD}\{D^2 + iD + \beta^2 Q^2 - 2\beta^2 Q + \beta^2 - \beta\}(Q^{1/2}\phi')|\psi\rangle \\
&= \tfrac{1}{2}\beta^{-1}\langle e^{ipQ}e^{-i\ln qD}Q^{1/2}\{D^2 + \beta^2 Q^2 - 2\beta^2 Q + (\beta - 1/2)^2\}\phi'|\psi\rangle, \qquad (4)
\end{aligned}
$$

where $\phi = Q^{1/2}\phi'$.

Under the unitary transformation

$$
(\tilde{U}\psi)(x) = e^{x/2}\psi(e^x), \qquad (5)
$$

the operator in braces in the last line of Eq. (4) (called H in Ref. 2) is transformed to the Morse operator,

$$
H_{\text{Morse}} = -\frac{d^2}{dx^2} + \beta^2(e^{2x} - 2e^x) + \left(\beta - \frac{1}{2}\right)^2. \qquad (6)
$$

The eigenfunctions of the Morse operator can be found in Ref. 12, and, for $\beta = 1/2$, they are given in momentum representation (and δ-orthonormalized) by

$$
\psi_\lambda(x) = \left(\frac{\lambda \sinh(2\pi\lambda)}{\pi^2}\right)^{1/2}\Gamma(i\lambda)e^{-x/2}W_{1/2,i\lambda}(e^x), \qquad (7)
$$

where W is a Whittaker function. With a mass $m = 1/2$, one has the relation $E = \lambda^2$ for energy and momentum, and the δ-orthonormalized eigenfunctions in energy representation are

$$
\psi_E(x) = \left(\frac{\sinh(2\pi\sqrt{E})}{2\pi^2}\right)^{1/2}\Gamma(i\sqrt{E})e^{-x/2}W_{1/2,i\sqrt{E}}(e^x). \qquad (8)
$$

Since the Whittaker function $W_{1/2,0}(z) = e^{-z/2}z^{1/2}$, the x-dependence of $\psi_{E=0}(x)$ is $e^{-e^x/2}$. Thus, the rescaling factor can best be determined with the choice $x'' = x' = b = -\infty$ where this function is equal to one. For small E, the function $f_{-\infty,-\infty}(E) = \psi_E(-\infty)\psi_E^*(-\infty)\rho(E) \approx \pi^{-1}E^{-1/2}$ because $\sinh(2\pi\sqrt{E}) \approx 2\pi\sqrt{E}$, $|\Gamma(i\sqrt{E})|^2 \approx 1/E$. Inserting this E-dependence into the general formula ($\rho(E) = 1$ because of δ-orthonormalization), one finds the inverse rescaling factor

$$
\int_0^\infty e^{-\nu TE} f_{-\infty,-\infty}(E)\,dE = (\pi\nu T)^{-1/2}. \qquad (9)
$$

Because of the connection between the ''Morse''-level and the original problem [Eqs. (4) and (5)], this is already the proper rescaling factor for the original problem as well.

The sought-for weak coherent state path integral for $\beta = 1/2$ and vanishing Hamiltonian is thus

$$
\langle p''q''|p'q'\rangle = \lim_{\nu\to\infty} K_\nu \int e^{-i\int q\,dp}\,d\mu_W^\nu \qquad (10)
$$

with rescaling factor $K_\nu = (\pi\nu T)^{1/2}$.

D. Introducing dynamics

Since the only case in which the spectral approach worked was $\beta = 1/2$, this value is assumed throughout the remainder of this subsection. Dynamics are introduced by the quantum Hamiltonian $\mathcal{H}$, which is a function of the basic kinematical operators Q and D. The goal is to represent the propagator $\langle p''q''|\exp\{-iT\mathcal{H}\}|p'q'\rangle$ as a (weak coherent state) path integral. The expression

$$\langle p''q''|e^{-iT\mathcal{H}}|p'q'\rangle = \lim_{\nu\to\infty} K_\nu \mathcal{N}_\nu \int e^{-i\int[q\dot{p}+h_w(p,q)]dt} e^{-(1/2\nu)\int[\beta^{-1}q^2\dot{p}^2+\beta q^{-2}\dot{q}^2]dt} \mathcal{D}p\mathcal{D}q$$

$$= \lim_{\nu\to\infty} K_\nu \int e^{-i\int[q\,dp+h_w(p,q)dt]}\, d\mu_W^\nu \tag{11}$$

was proposed[5] as the path integral for a class of Hamiltonians which contains at least all Hamiltonians polynomial in Q and D. The new symbol $h_w(p,q)$, interpreted as the classical Hamiltonian associated with the quantum Hamiltonian, is implicitly given by

$$\langle p''q''|\mathcal{H}|p'q'\rangle = \lim_{\nu\to\infty} K_\nu \int e^{-i\int q\,dp}\left[T^{-1}\int h_w(p,q)dt\right] d\mu_W^\nu \tag{12}$$

and will be called the weak symbol.

The whole conjecture is based on the observation that, for a linear Hamiltonian $RQ+SD$, the propagator can be reduced to a mere overlap:[5,11]

$$\langle p''q''|e^{-i(RQ+SD)T}|p'q'\rangle = \langle p''e^{ST}+R/S\cdot(e^{ST}-1), q''e^{-ST}|p'q'\rangle. \tag{13}$$

Consequently, the problem is already solved for a linear Hamiltonian, and what remains is to determine the weak symbol associated with $\mathcal{H}=RQ+SD$. According to Eq. (10) the path integral for this Hamiltonian is

$$\lim_{\nu\to\infty} K_\nu \int_{p',q'}^{p''e^{ST}+R/S\cdot(e^{ST}-1), q''e^{-ST}} e^{-i\int q\,dp}\, d\mu_W^\nu. \tag{14}$$

Since this is a well-defined functional integral, one can change integration variables

$$p(t)\to p(t)e^{St}+R/S(e^{St}-1),$$

$$q(t)\to q(t)e^{-St},$$

and obtain $\exp\{-i\int(qe^{-St}d[pe^{St}+R/S(e^{St}-1)]\}=\exp\{-i\int[q\,dp+(Rq+Spq)dt]\}$ as the new integrand. The new measure is [$(\cdots)^{\cdot}$ means the time derivative of the expression in parentheses]

$$d\tilde{\mu}_W^\nu = \mathcal{N}_\nu \exp\left\{-\frac{1}{2\nu}\int\left[\beta^{-1}(qe^{-St})^2\left(pe^{St}+\frac{R}{S}(e^{St}-1)\right)^{\cdot 2}+\beta(qe^{-St})^{-2}(qe^{-St})^{\cdot 2}\right]dt\right\}$$
$$\times\mathcal{D}\left[pe^{St}+\frac{R}{S}(e^{St}-1)\right]\mathcal{D}(qe^{-St}).$$

But, since the measure is actually

$$\mathcal{D}\left[pe^{St}+\frac{R}{S}(e^{St}-1)\right] = \lim_{\epsilon\to 0}\prod_{k=1}^{N} d\left[p(t)e^{St}|_{t=k\epsilon}+\frac{R}{S}(e^{St}-1)|_{t=k\epsilon}\right]$$

$$= \lim_{\epsilon\to 0}\prod_{k=1}^{N}\left[dp(t)e^{St}|_{t=k\epsilon}+(pSe^{St}+\mathrm{Re}^{St})dt|_{t=k\epsilon}\right]$$

$$= \lim_{\epsilon\to 0}\prod_{k=1}^{N}\left[dp_k e^{Sk\epsilon}+(p_k Se^{Sk\epsilon}+\mathrm{Re}^{Sk\epsilon})\epsilon\right] = \lim_{\epsilon\to 0}\prod_{k=1}^{N} dp_k e^{Sk\epsilon} = \mathcal{D}p\prod_t e^{St},$$

and analogous $\mathcal{D}(qe^{-St})=\mathcal{D}q\Pi_t e^{-St}$, the new measure can be expressed in terms of the old one as

$$d\tilde{\mu}_W^\nu = e^{-(1/2\nu)\int[\beta^{-1}q^2((Sp+R)^2+2(Sp+R)\dot{p})+\beta q^{-2}(S^2q^2-2Sq\dot{q})]dt}\, d\mu_W^\nu$$
$$= e^{-(1/2\nu)\int[\beta^{-1}q^2((Sp+R)^2dt+2(Sp+R)dp)+\beta q^{-2}(S^2q^2dt-2Sqdq)]}\, d\mu_W^\nu.$$

The first equality is again formal and gains meaning by the second line, where the stochastic integrals are understood in the Stratonovich sense, as usual. The change of variables has introduced additional terms in the exponent of the formal expression, which are at most linear in $\dot{p}$ or $\dot{q}$, respectively. These terms are not critical since, in the limit of diverging diffusion constant ν, they will vanish. This means that the total change of the measure disappears in the limit. Thus, one can write the path integral with the old measure $d\mu_W^\nu$ instead of with the new $d\tilde{\mu}_W^\nu$:

$$\langle p''q''|e^{-i(RQ+SD)T}|p'q'\rangle = \lim_{\nu\to\infty} K_\nu \int_{p',q'}^{p'',q''} e^{-i\int[q\,dp+(Rq+Spq)dt]}\, d\mu_W^\nu. \tag{15}$$

Now, the weak symbol can be read off:

$$h_w(p,q)=Rq+Spq. \tag{16}$$

The generalization to other Hamiltonians is based on the linearity, completeness, and irreducibility of the basic operators Q and D by virtue of which $\lim_{J\to\infty}\Sigma_{j=1}^J \alpha_j e^{-i(R_jQ+S_jD)}$ weakly converges to any (bounded) operator such as $e^{-i\mathcal{H}T}$. Thus,

$$\langle p''q''|e^{-i\mathcal{H}T}|p'q'\rangle = \lim_{J\to\infty}\langle p''q''|\sum_{j=1}^J \alpha_j e^{-i(R_jQ+S_jD)}|p'q'\rangle$$
$$= \lim_{J\to\infty}\lim_{\nu\to\infty} K_\nu \int e^{-i\int q\,dp}\left[\sum_{j=1}^J \alpha_j e^{-i\int(R_jq+S_jpq)dt}\right] d\mu_W^\nu \tag{17}$$

and the question, on which the next steps depend, is: Can the two limits be interchanged? In spite of some effort this question is not yet answered. Assuming that they can, however, one obtains

$$\langle p''q''|e^{-i\mathcal{H}T}|p'q'\rangle = \lim_{\nu\to\infty} K_\nu \int e^{-i\int q\,dp}\left[\lim_{J\to\infty}\sum_{j=1}^J \alpha_j e^{-i\int(R_jq+S_jpq)dt}\right] d\mu_W^\nu. \tag{18}$$

The expression $[\lim_{J\to\infty}\Sigma_{j=1}^J \alpha_j e^{-i\int(R_jq+S_jpq)dt}]=:F[\int qdt,\int pqdt]$ is, unfortunately, not of the form $e^{-i\int h_w(p,q)dt}$ for a general, local Hamiltonian h_w, e.g., $e^{-i\int q^2dt}$ with Hamiltonian q^2. To produce local Hamiltonians, one would need distributions $R(t)$ and $S(t)$ instead of the constants R and S. Then, taking, e.g., $R(t)=\delta(t-\tau)$, one gets a local expression $q(\tau)$ and, by forming functions thereof, local Hamiltonians. This was proposed in Ref. 5. However, the construction of distributions from piecewise constant functions would require yet another limiting process, and, again, the interchangeability of the limits is questionable.

In the case of a linear Hamiltonian, the weak symbol was shown to be $h_w(p,q)=Rq+Spq$. This is exactly what one would expect since the connection of the basic operators Q and D to classical variables is, according to the weak correspondence principle, q and pq, respectively. But, the correspondence for a more general Hamiltonian is not immediately clear and remains to be determined.

E. Regularizing approach

The idea for this second approach is the introduction of an additional regularization factor which will reintroduce a discrete ground state with eigenvalue zero. Then, the construction of the path integral moves along the same lines as in the coherent state case ($\beta>1/2$). The limit to remove the regularization is taken as the last step.

For large q, the overlap $\langle pq|p'q'\rangle$ is proportional to $q^{-\beta}$. Because $0<\beta\leqslant 1/2$, a regularization factor which is effective at infinity is required to produce Hilbert space vectors again. Since, for $0<\beta\leqslant 1/4$, $\int_{-\infty}^{\infty}(c^2+p^2)^{-2\beta}dp=\infty$ (where c is a constant), one must in this case regularize in p, too. For $1<4\beta<2$ this is not required. A regularization in p will make a regularization in q (for small q) necessary as well.[11]

Case 1/4<β⩽1/2: Let

$$\langle pq|rs\rangle_\varepsilon := N_\varepsilon \langle pq|rs\rangle e^{-(q+s)\varepsilon} \tag{19}$$

be a normalized vector in $L^2(M_+)$ with normalization constant N_ε. The extra factor $e^{-(q+s)\varepsilon}$ goes to one in the limit $\varepsilon\to 0$. For arbitrary $x\in\mathbb{R}$, $y\in\mathbb{R}^+$, the overlap $\langle xy|xy\rangle_\varepsilon$ equals $N_\varepsilon e^{-2y\varepsilon}$. Hence, one can write $\langle pq|rs\rangle=\lim_{\varepsilon\to 0}\langle xy|xy\rangle_\varepsilon^{-1}\langle pq|rs\rangle_\varepsilon$ in a self-consistent way without explicitly referring to the normalization constant. The following notation is used:

$$\langle xy|xy\rangle_\varepsilon =: c_{\beta,\varepsilon}\,.$$

The new operator B_ε, which annihilates the modified kernel, is derived by exploiting analyticity: $[(q^{-1}+s^{-1})+i\beta^{-1}(p-r)]^{-2\beta}=:Y$ is analytic, so $\partial_{(q^{-1}-i\beta^{-1}p)}Y=\frac{1}{2}(-q^2\partial_q+i\beta\partial_p)Y=0$. Write Y as $e^{(q+s)\varepsilon}(qs)^\beta\langle pq|rs\rangle_\varepsilon$, and move $e^{q\varepsilon}(qs)^\beta$ to the left of this operator. Then, $e^{q\varepsilon}(qs)^\beta$ can be canceled since the expression is everywhere nonzero. The result is the new operator

$$B_\varepsilon=(\beta^{-1}q\partial_q+\beta^{-1}q\varepsilon+1-iq^{-1}\partial_p)$$

for which $B_\varepsilon\langle pq|rs\rangle_\varepsilon=0$. Define $A_\varepsilon:=\frac{1}{2}\beta B_\varepsilon^\dagger B_\varepsilon$, then

$$\begin{aligned}A_\varepsilon&=\tfrac{1}{2}\beta(-iq^{-1}\partial_p+1-\beta^{-1}\partial_q q+\beta^{-1}q\varepsilon)(-iq^{-1}\partial_p+1+\beta^{-1}q\partial_q+\beta^{-1}q\varepsilon)\\&=\tfrac{1}{2}\{\beta[-iq^{-1}\partial_p+1+\beta^{-1}q\varepsilon]^2-\beta^{-1}\partial_q q^2\partial_q-1-2\beta^{-1}q\varepsilon\}.\end{aligned} \tag{20}$$

A_ε can be shown to be essentially self-adjoint since the deficiency index equation $[(A_\varepsilon^\dagger\pm i)\psi](p,q)=0$ has no solution.[11] In a slight abuse of notation the closure of this operator will be denoted by A_ε as well. It is a self-adjoint, non-negative operator with zero in its discrete spectrum.

The Feynman–Kac–Stratonovich representation of the kernel of the operator $e^{-\nu TA_\varepsilon}$ is (see Appendix for the derivation)

$$e^{-\nu A_\varepsilon T}\delta(p-p')\,\delta(q-q')|_{p=p'',q=q''}=e^{\nu T/2}\int e^{-i\int(q+\beta^{-1}q^2\varepsilon)dp+\nu\int\beta^{-1}q\varepsilon dt}\,d\mu_W^\nu$$

and it follows that

$$\langle p''q''|p'q'\rangle=\lim_{\varepsilon\to 0}c_{\beta,\varepsilon}^{-1}\langle p''q''|p'q'\rangle_\varepsilon=\lim_{\varepsilon\to 0}\lim_{\nu\to\infty}c_{\beta,\varepsilon}^{-1}e^{\nu T/2}\int e^{-i\int(q+\beta^{-1}q^2\varepsilon)dp+\nu\int\beta^{-1}q\varepsilon dt}\,d\mu_W^\nu. \tag{21}$$

The stochastic processes involved are still Brownian bridges, and, when the stochastic integrals are interpreted in the Stratonovich sense, canonical (coordinate) transformations can be made in the same way as before. Thus, the geometric nature of the quantization is preserved.

Case $0<\beta\leqslant 1/4$: For a parameter $\beta\leqslant 1/4$, a regularization for large q is not enough. It turns out that an additional p-regularization will even make a regularization for small q necessary (otherwise the overlap would be square integrable, but not in the domain of A_ε).

In the present case, let

$$\langle pq|rs\rangle_\varepsilon := N_\varepsilon \langle pq|rs\rangle e^{-(q+s)\varepsilon-(q^{-1}+s^{-1})\varepsilon-(p^2+r^2)\varepsilon}, \tag{22}$$

where $\langle pq|rs\rangle=(qs)^{-\beta}2^{2\beta}[(q^{-1}+s^{-1})+i\beta^{-1}(p-r)]^{-2\beta}$ is the (weak coherent state) overlap which is analytic in the complex variable $z:=q^{-1}+i\beta^{-1}p$, apart from the factor $(qs)^{-\beta}$. One can write the analytic part (previously called Y) as $e^{(q+s)\varepsilon+(q^{-1}+s^{-1})\varepsilon+(p^2+q^2)\varepsilon}(qs)^{\beta}\langle pq|rs\rangle_\varepsilon$, and let the differential operator $\partial_{q^{-1}-i\beta^{-1}p}=\frac{1}{2}(-q^2\partial_q+i\beta\partial_p)$ act on this expression. Using $\partial_{z^*}f=0$ (valid for an analytic function), this results in the new operator

$$B_\varepsilon=\beta^{-1}q\partial_q+1+\beta^{-1}q\varepsilon+\beta^{-1}q^{-1}\varepsilon-2ipq^{-1}\varepsilon-iq^{-1}\partial_p$$

for which $B_\varepsilon\langle pq|rs\rangle_\varepsilon=0$. As before, define $A_\varepsilon:=\frac{1}{2}\beta B_\varepsilon^\dagger B_\varepsilon$, then

$$\begin{aligned}A_\varepsilon=\tfrac{1}{2}\{&\beta(-iq^{-1}\partial_p+1+\beta^{-1}q\varepsilon\beta^{-1}q^{-1}\varepsilon)^2-2\beta q^{-2}\varepsilon+4ip\partial_q\varepsilon\\&+4\beta p^2q^{-2}\varepsilon^2-\beta^{-1}\partial_q q^2\partial_q-1-2\beta^{-1}q\varepsilon\}.\end{aligned} \tag{23}$$

Instead of trying to solve the deficiency index equation for the "new" A_ε, one can avoid the question about self-adjointness altogether.

Assume A_ε is not self-adjoint. The (sesquilinear) form $s_\varepsilon(x,y):=\langle x|A_\varepsilon y\rangle$ generated by A_ε is closable since A_ε is symmetric and bounded below.[13] There is a bijection between the set of all (densely defined) closed, below-bounded forms and the set of all self-adjoint, below-bounded operators. Let $\overline{s_\varepsilon}$ be the closure of the form generated by A_ε and $A_{\overline{s_\varepsilon}}$ be the self-adjoint operator associated with $\overline{s_\varepsilon}$. Then, $A_{\overline{s_\varepsilon}}$ preserves the lower bound and is called the Friedrichs' extension of the operator A_ε. [It is the unique extension fulfilling $D(A_{\overline{s_\varepsilon}})\subset D(\overline{s_\varepsilon})$.[13]]

In a slight abuse of notation $A_{\overline{s_\varepsilon}}$ will be written as A_ε. So from now on, A_ε denotes the Friedrichs' extension (which is trivial in the case that A_ε is already self-adjoint). Then it is clear that A_ε is non-negative.

The Feynman–Kac–Stratonovich representation of the kernel of the operator $\exp\{-\nu TA_\varepsilon\}$ is derived in much the same way as before (see Appendix)

$$e^{\nu T/2}e^{-i\beta^{-1}\varepsilon(p''-p')}\int e^{-i\int[(q+\beta^{-1}q^2\varepsilon)\,dp-2\beta pq^{-2}\varepsilon\,dq]+\nu\int[\beta q^{-2}\varepsilon+\beta^{-1}q\varepsilon]dt}\,d\mu_W^\nu.$$

Partial integration, i.e., $2\beta\varepsilon\int pq^{-2}dq=-2\beta\varepsilon\int pd(q^{-1})=-2\beta\varepsilon pq^{-1}\big|_{(p',q')}^{(p'',q'')}+2\beta\varepsilon\int q^{-1}dp$, leads to

$$e^{\nu T/2}e^{-i\beta^{-1}\varepsilon(p''-p')-2i\beta\varepsilon(p''q''^{-1}-p'q'^{-1})}\int e^{-i\int(q+\beta^{-1}q^2\varepsilon-2\beta q^{-1}\varepsilon)dp+\nu\int[\beta q^{-2}\varepsilon+\beta^{-1}q\varepsilon]dt}\,d\mu_W^\nu. \tag{24}$$

The phase factors in Eq. (24) are ν-independent, so they come outside of the ν-limit, where the ε-limit renders them unity. Finally, one gets

$$\begin{aligned}\langle p''q''|p'q'\rangle&=\lim_{\varepsilon\to 0}\lim_{\nu\to\infty}c_{\beta,\varepsilon}^{-1}\langle p''q''|p'q'\rangle_\varepsilon\\&:=\lim_{\varepsilon\to 0}\lim_{\nu\to\infty}c_{\beta,\varepsilon}^{-1}e^{\nu T/2}\int e^{-i\int(q+\beta^{-1}q^2\varepsilon-2\beta q^{-1}\varepsilon)dp+\nu\int[\beta q^{-2}\varepsilon+\beta^{-1}q\varepsilon]dt}\,d\mu_W^\nu.\end{aligned} \tag{25}$$

This is the path integral representation for $0<\beta\leqslant 1/4$.

F. Introducing dynamics

Dynamics is introduced in the same way as for the spectral approach. For a linear Hamiltonian $\mathcal{H}=RQ+SD$, the problem is already solved as it reduces to an overlap with modified ending points. What remains to do is to write down the path integral. This is straightforward since everything stated previously concerning the measure, etc., remains valid and the formula for $1/4<\beta\leqslant 1/2$ is

$$\begin{aligned}\langle p''q''|e^{-i(RQ+SD)T}|p'q'\rangle &= \left\langle p''e^{ST}+\frac{R}{S}(e^{ST}-1), q''e^{-ST}\middle| p'q'\right\rangle \\ &= \lim_{\varepsilon\to 0}\lim_{\nu\to\infty} c_{\beta,\varepsilon}^{-1} e^{\nu T/2}\int_{p',q'}^{p''e^{ST}+(R/S)(e^{ST}-1),q''e^{-ST}} \\ &\quad\times\exp\left\{-i\int (q+\beta^{-1}q^2\varepsilon)dp+\nu\int \beta^{-1}q\varepsilon dt\right\} d\mu_W^\nu, \\ &= \lim_{\varepsilon\to 0}\lim_{\nu\to\infty} c_{\beta,\varepsilon}^{-1} e^{\nu T/2}\int_{p',q'}^{p'',q''} \exp\left\{-i\int (qe^{-St}+\beta^{-1}q^2e^{-2St}\varepsilon)\right. \\ &\quad\left.\times d\left[pe^{St}+\frac{R}{S}(e^{St}-1)\right]+\nu\int \beta^{-1}qe^{-St}\varepsilon dt\right\} d\mu_W^\nu \\ &= \lim_{\varepsilon\to 0}\lim_{\nu\to\infty} c_{\beta,\varepsilon}^{-1} e^{\nu T/2}\int_{p',q'}^{p'',q''} \exp\left\{-i\left[\int (q+\beta^{-1}q^2e^{-St}\varepsilon)dp\right.\right. \\ &\quad\left.+\int (q+\beta^{-1}q^2e^{-St}\varepsilon)(Sp+R)dt\right] \\ &\quad\left.+\nu\int \beta^{-1}qe^{-St}\varepsilon dt\right\} d\mu_W^\nu. \end{aligned} \tag{26}$$

Introducing the new variable $q_\varepsilon := q+\beta^{-1}q^2e^{-St}\varepsilon$, and the new measure $d\mu_W^{\nu,\varepsilon} := \exp\{\nu\int\beta^{-1}qe^{-St}\varepsilon dt\}\, d\mu_W^\nu$, the complexity of the final expression can be hidden. The new measure is equivalent to the old Wiener measure because the factor $\exp\{\nu\int\beta^{-1}qe^{-St}\varepsilon dt\}$ serves as a Radon–Nykodym derivative. Then, the formula resembles the path integral for coherent states and reads

$$\lim_{\varepsilon\to 0}\lim_{\nu\to\infty} c_{\beta,\varepsilon}^{-1} e^{\nu T/2}\int_{p',q'}^{p'',q''} e^{-i[\int q_\varepsilon dp+(Spq_\varepsilon+Rq_\varepsilon)dt]}\, d\mu_W^{\nu,\varepsilon}. \tag{27}$$

The ε-modified Hamiltonian is given by the weak modified symbol $h_{w,\varepsilon} := Rq_\varepsilon+Spq_\varepsilon$.

The same procedure for $0<\beta\leqslant 1/4$ leads to

$$\begin{aligned}\langle p''q''|e^{-i(RQ+SD)T}|p'q'\rangle &= \lim_{\varepsilon\to 0}\lim_{\nu\to\infty} c_{\beta,\varepsilon}^{-1} e^{\nu T/2}\int_{p',q'}^{p'',q''} \exp\left\{-i\left[\int (q+\beta^{-1}q^2e^{-St}\varepsilon\right.\right. \\ &\quad\left.-2\beta q^{-1}e^{2St}\varepsilon)dp+\int (q+\beta^{-1}q^2e^{-St}\varepsilon-2\beta q^{-1}e^{2St}\varepsilon)(Sp+R)dt\right] \\ &\quad\left.+\nu\int (\beta^{-1}qe^{-St}\varepsilon+\beta q^{-2}e^{2St}\varepsilon)dt\right\} d\mu_W^\nu \\ &= \lim_{\varepsilon\to 0}\lim_{\nu\to\infty} c_{\beta,\varepsilon}^{-1} e^{\nu T/2}\int_{p',q'}^{p'',q''} \exp\left\{-i\left[\int \tilde{q}_\varepsilon dp+\int (Sp\tilde{q}_\varepsilon\right.\right. \\ &\quad\left.\left.+R\tilde{q}_\varepsilon)dt\right]\right\} d\tilde{\mu}_W^{\nu,\varepsilon}. \end{aligned} \tag{28}$$

Here, the variable $\tilde{q}_\varepsilon := (q+\beta^{-1}q^2e^{-St}\varepsilon - 2\beta q^{-1}e^{2St}\varepsilon)$ and the Radon–Nykodym measure $d\tilde{\mu}_W^{\nu,\varepsilon} := \exp\{\nu\int(\beta^{-1}qe^{-St}\varepsilon+\beta q^{-2}e^{2St}\varepsilon)dt\}\, d\mu_W^\nu$ were used. The weak modified symbol is now $h_{w,\varepsilon} = R\tilde{q}_\varepsilon + Sp\tilde{q}_\varepsilon$.

The problem of how this can be extended to, say, all polynomial Hamiltonians was already discussed in the spectral approach. Here, on the other hand, there could be a second possibility to proceed. With the discrete ground state artifically reintroduced, it seems possible to construct the path integral in essentially the same way as for zero Hamiltonian. The operator νA_ε has to be replaced by $\nu A_\varepsilon + ih_{w,\varepsilon}$, and the conditions required for the construction will imply restrictions for the functions $h_{w,\varepsilon}$ (see Ref. 2 for a guideline to the proof). Observe, that this weak modified symbol does not necessarily have to be the same as the one mentioned in the previous parts of the subsection.

APPENDIX: FEYNMAN–KAC–STRATONOVICH REPRESENTATION OF THE OPERATOR A_ε

The case $1/4 < \beta \leqslant 1/2$

The Feynman–Kac–Stratonovich representation of the kernel of the operator $\exp\{-\nu TA_\varepsilon\}$ is derived in the following way:

$$
\begin{aligned}
&\exp\{-\nu TA_\varepsilon\}\delta(p-p')\delta(q-q')\big|_{p=p'',q=q''} \\
&\quad = \exp\{-\tfrac{1}{2}\nu T[\beta(-iq^{-1}\partial_p+1+\beta^{-1}q\varepsilon)^2-\beta^{-1}\partial_q q^2\partial_q-1-2\beta^{-1}q\varepsilon]\} \\
&\qquad \times \int e^{ix(p-p')-ik(q-q')}\frac{dxdk}{(2\pi)^2}\bigg|_{p=p'',q=q''} \\
&\quad = e^{\nu T/2}\lim_{N\to\infty}[\exp\{-\tfrac{1}{2}\nu\delta[\beta(-iq^{-1}\partial_p+1+\beta^{-1}q\varepsilon)^2-2\beta^{-1}q\varepsilon]\} \\
&\qquad \times \exp\{-\tfrac{1}{2}\nu\delta(-\beta^{-1}\partial_q q^2\partial_q)\}]^N \int e^{ix(p-p')-ik(q-q')}\frac{dxdk}{(2\pi)^2}\bigg|_{p=p'',q=q''} \\
&\quad = \lim_{N\to\infty} e^{\nu T/2}\int \exp\Big\{i\sum x_{l+1/2}(p_{l+1}-p_l)-ik_{l+1/2}(q_{l+1}-q_l)\Big\} \\
&\qquad \times \exp\Big\{-\frac{1}{2}\nu\delta\sum[\beta(q_l^{-1}x_{l+1/2}+1+\beta^{-1}q_l\varepsilon)^2-2\beta^{-1}q_l\varepsilon]\Big\} \\
&\qquad \times \exp\Big\{-\frac{1}{2}\nu\delta\sum\beta^{-1}k_{l+1/2}^2q_l^2\Big\}\prod_{l=0}^{N}\frac{dk_{l+1/2}dx_{l+1/2}}{(2\pi)^2}\prod_{l=1}^{N}dp_ldq_l \\
&\quad =: e^{\nu T/2}\mathcal{N}\int \exp\Big\{i\int(x\dot{p}-k\dot{q})dt\Big\} \\
&\qquad \times \exp\Big\{-\frac{1}{2}\nu\int\{\beta(q^{-1}x+1+\beta^{-1}q\varepsilon)^2-2\beta^{-1}q\varepsilon+\beta^{-1}k^2q^2\}dt\Big\}\mathcal{D}x\mathcal{D}k\mathcal{D}p\mathcal{D}q \\
&\quad = e^{\nu T/2}\mathcal{N}\int \exp\Big\{i\int[(x-q-\beta^{-1}q^2\varepsilon)\dot{p}-k\dot{q}]\Big\}
\end{aligned}
$$

$$\times\exp\left\{-\frac{1}{2}\nu\int(\beta q^{-2}x^2-2\beta^{-1}q\varepsilon+\beta^{-1}k^2q^2)dt\right\}\mathcal{D}x\mathcal{D}k\mathcal{D}p\mathcal{D}q$$

$$=e^{\nu T/2}\mathcal{N}\int\exp\left\{-i\int(q+\beta^{-1}q^2\varepsilon)\dot{p}dt\right\}\exp\left\{\frac{1}{2}\nu\int 2\beta^{-1}q\varepsilon dt\right\}$$

$$\times\exp\left\{-\frac{1}{2\nu}\int[\beta^{-1}q^2\dot{p}^2+\beta q^{-2}\dot{q}^2]dt\right\}\mathcal{D}p\mathcal{D}q$$

with $N=T/\delta$. The Lie–Trotter product formula was used to go from the second to the third equality. The indices $l+1/2$ and l serve to emphasize that the temporal lattice points must not coincide for x,p or q,k, respectively. (This would violate the Heisenberg uncertainty principle.) For the endpoints, the definitions $p_0:=p'$, $p_{N+1}:=p''$, $q_0:=q'$ and $q_{N+1}:=q''$ were made. Note that $\exp\{-\frac{1}{2}\nu\delta(-\beta^{-1}\partial_q q^2\partial_q)\}\exp\{-ik(q-q')\}\approx\exp\{-\frac{1}{2}\nu\delta\beta^{-1}k^2q^2\}\exp\{-ik(q-q')\}$ only to first order in δ, but that is good enough for the path integral. In the second to last line, x was substituted by $x-q-\beta^{-1}q^2\varepsilon$, and the x- and p-integrations were carried out.

The case $0<\beta\leqslant 1/4$

The Feynman–Kac–Stratonovich representation of the kernel of the operator $\exp\{-\nu TA_\varepsilon\}$ is derived in much the same way as before, and, with the same conventions for notation, it reads

$$\exp\{-\nu TA_\varepsilon\}\delta(p-p')\delta(q-q')\big|_{p=p'',q=q''}$$

$$=\exp\{-\nu T/2[\beta(-iq^{-1}\partial_p+1+\beta^{-1}q\varepsilon+\beta^{-1}q^{-1}\varepsilon)^2-2\beta q^{-2}\varepsilon+4ip\partial_q\varepsilon+4\beta p^2q^{-2}\varepsilon^2$$

$$-\beta^{-1}\partial_q q^2\partial_q-1-2\beta^{-1}q\varepsilon]\}\int\exp\{ix(p-p')-ik(q-q')\}\frac{dxdk}{(2\pi)^2}\bigg|_{p=p'',q=q''}$$

$$=e^{\nu T/2}\lim_{N\to\infty}[\exp\{-\nu\delta/2[\beta(-iq^{-1}\partial_p+1+\beta^{-1}q\varepsilon+\beta^{-1}q^{-1}\varepsilon)^2-2\beta q^{-2}\varepsilon-2\beta^{-1}q\varepsilon]\}$$

$$\times\exp\{-\nu\delta/2(-\beta^{-1}\partial_q q^2\partial_q)\}\exp\{-\nu\delta/2\cdot 4ip\partial_q\varepsilon\}\exp\{-\nu\delta/2\cdot 4\beta p^2q^{-2}\varepsilon^2\}]^N$$

$$\times\int\exp\{ix(p-p')-ik(q-q')\}\frac{dxdk}{(2\pi)^2}\bigg|_{p=p'',q=q''}$$

$$=\lim_{N\to\infty}e^{\nu T/2}\int\exp\left\{i\sum x_{l+1/2}(p_{l+1}-p_l)-ik_{l+1/2}(q_{l+1}-q_l)\right\}$$

$$\times\exp\left\{-\nu\delta/2\sum[\beta(q_l^{-1}x_{l+1/2}+1+\beta^{-1}q_l\varepsilon+\beta^{-1}q_l^{-1}\varepsilon)^2-2\beta q_l^{-2}\varepsilon-2\beta^{-1}q_l\varepsilon]\right\}$$

$$\times\exp\left\{-\nu\delta/2\sum\beta^{-1}k_{l+1/2}^2q_l^2\right\}\exp\left\{-\nu\delta/2\sum 4ip_l(-ik_{l+1/2})\varepsilon\right\}$$

$$\times\exp\left\{-\nu\delta/2\sum 4\beta p_l^2q_l^{-2}\varepsilon^2\right\}\prod_{l=0}^{N}\frac{dk_{l+1/2}dx_{l+1/2}}{(2\pi)^2}\prod_{l=1}^{N}dp_ldq_l$$

$$=:e^{\nu T/2}\mathcal{N}\int\exp\left\{i\int(x\dot{p}-k\dot{q})dt\right\}$$

$$\times\exp\left\{-\nu/2\int\{\beta(q^{-1}x+1+\beta^{-1}q\varepsilon+\beta^{-1}q^{-1}\varepsilon)^2-2\beta q^{-2}\varepsilon\right.$$

$$\left.-2\beta^{-1}q\varepsilon+\beta^{-1}k^2q^2+4pk\varepsilon+4\beta p^2q^{-2}\varepsilon^2\}dt\right\}\mathcal{D}x\mathcal{D}k\mathcal{D}p\mathcal{D}q$$

$$
\begin{aligned}
&= e^{\nu T/2}\mathcal{N}\int \exp\left\{ i\int [(x-q-\beta^{-1}q^2\varepsilon-\beta^{-1}\varepsilon)\dot{p}-k\dot{q}]dt\right\}\\
&\quad\times\exp\left\{-\nu/2\int (\beta q^{-2}x^2-2\beta q^{-2}\varepsilon-2\beta^{-1}q\varepsilon+\beta^{-1}k^2q^2+4pk\varepsilon\right.\\
&\quad\left.+4\beta p^2q^{-2}\varepsilon^2)dt\right\}\mathcal{D}x\mathcal{D}k\mathcal{D}p\mathcal{D}q\\
&= e^{\nu T/2}\mathcal{N}\int \exp\left\{-i\int (q+\beta^{-1}\varepsilon+\beta^{-1}q^2\varepsilon)\dot{p}dt+i\int 2\beta pq^{-2}\varepsilon\dot{q}dt\right\}\\
&\quad\times\exp\left\{\nu/2\int (2\beta^{-1}q\varepsilon+2\beta q^{-2}\varepsilon)dt\right\}\\
&\quad\times\exp\left\{-1/(2\nu)\int [\beta^{-1}q^2\dot{p}^2+\beta q^{-2}\dot{q}^2]dt\right\}\mathcal{D}p\mathcal{D}q.
\end{aligned}

Expansions about free-fermion models

Saibal Mitra[a)]
Instituut voor Theoretische Fysica, Universiteit van Amsterdam, 1018 XE Amsterdam, The Netherlands

(Received 2 July 2003; accepted 15 September 2003)

A simple technique for expanding the free energy of general six-vertex models about free-fermion points is introduced. This technique is used to verify a Coulomb gas prediction about the behavior of the leading singularity in the free energy of the staggered F-model at zero staggered field. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1626270]

I. DEFINITION OF THE STAGGERED F-MODEL

The staggered F-model is a special case of the six-vertex model. The six-vertex model can be defined as follows: place arrows on the edges of a square lattice so that there are two arrows pointing into each vertex. Six types of vertices can arise (hence the name of the model). These vertices are shown in Fig. 1. By giving each vertex type an (position-dependent) energy the model is defined. These models were first introduced to study (anti-)ferroelectric systems. Later it was shown that six-vertex models can be mapped to solid-on-solid models.[4] Only a few of these models can be solved exactly. These include the free-fermion models[5,14] and models that can be solved using the Bethe ansatz.[3,8–10,2] To define the staggered F-model, we divide the lattice into two sublattices A and B, such that the nearest neighbor of an A vertex is a B vertex. The vertex energies are chosen as indicated in Fig. 1. When the staggered field (s) vanishes the model reduces to the F-model, which has been solved by Lieb.[9] At zero staggered field the model is critical. In this case the groundstate is twofold degenerate consisting of vertices of type 5 on sublattice A and vertices of type 6 on sublattice B, or vice versa. For $\beta\epsilon>0$ a nonzero staggered field lifts this degeneracy, and forces the model into an ordered state.[13]

II. COULOMB GAS RESULTS

By assuming that the F-model renormalizes to the Gaussian model, it is possible to find the behavior of the staggered F-model in infinitesimal staggered fields.[11] It is found that the leading singularity in the free energy is

$$F_s(\beta\epsilon,\beta s)\approx(\beta s)^{2/(2-\pi/4j(\beta\epsilon))}, \tag{1}$$

where

$$j(\beta\epsilon)=\tfrac{1}{2}\arccos(1-\tfrac{1}{2}\exp(2\beta\epsilon)). \tag{2}$$

At the point $\beta\epsilon=\frac{1}{2}\ln(2-\sqrt{2})\approx-0.2674$ the exponent becomes infinite. Below this point a finite staggered field is necessary to force the model to an ordered state. In this case the transition to the ordered state happens via a Kosterlitz–Thouless (KT) transition. The existence of a line of KT transitions intersecting the point ($\beta\epsilon=\frac{1}{2}\ln(2-\sqrt{2})$, $\beta s=0$) has been verified by combining the results of transfer matrix studies with scaling arguments.[11]

In this article we will verify (1) by expanding around Baxter's exact solution on the line $\beta\epsilon=\frac{1}{2}\ln 2$.

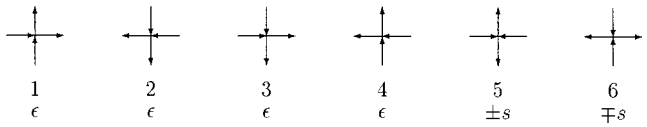

FIG. 1. The six vertices and their energies. The upper and lower signs respectively correspond to sublattices A and B.

III. BAXTER'S SOLUTION OF THE STAGGERED F-MODEL

Baxter has solved the staggered F-model at $\beta\epsilon=\frac{1}{2}\ln(2)$.[1] Later it was found that this solution could be generalized to other models if a certain condition involving the vertex weights is met. This condition is called the free-fermion condition because for eight-vertex models satisfying this condition the problem leads to a problem of noninteracting fermions in the S-matrix formulation. Let w_i be the vertex weight for a vertex of type i (see Fig. 1). Then the free-fermion condition for six-vertex models is

$$w_1w_2+w_3w_4-w_5w_6=0. \tag{3}$$

The weights w_i may be chosen inhomogeneous. We now proceed by presenting Baxter's solution of the staggered F-model.

Divide the lattice into two sublattices A and B. Choose the vertex energies as indicated in Fig. 1. Consider the ground state in which all A vertices are vertices of type 6, and all B vertices are of type 5. Any state can now be represented by drawing lines on the lattice where the arrows point oppositely to the ground state configuration. In terms of these lines the six vertices are represented by vertices with either no lines, two lines at right angles, or four lines. The energies of these vertices are respectively $-s$, ϵ and s. The next step is to replace the original lattice by a decorated lattice by replacing each original vertex by a "city" of four internally connected points (see Fig. 2).

The lines on the original lattice are regarded as dimers on the external edges of the decorated lattice. For any configuration on the original lattice, it is possible to place dimers on the internal edges of the decorated lattice, so that the lattice becomes completely covered. Now associate to each dimer a weight as indicated in Fig. 2. Demanding that the closed-packed dimer problem formulated on the decorated lattice is equivalent to our original problem yields

$$C=\exp(-\tfrac{1}{2}\beta s), \tag{4}$$

$$u=\tfrac{1}{2}\sqrt{2}\exp(\tfrac{1}{2}\beta s), \tag{5}$$

$$\beta\epsilon=\tfrac{1}{2}\ln(2). \tag{6}$$

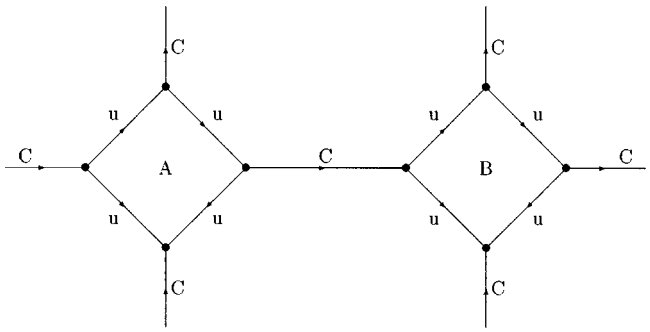

FIG. 2. The "cities" on the decorated lattice. A and B refer to the two sublattices. The meaning of the orientations on the edges is explained in the text.

To solve the close-packed dimer problem, we use the Pfaffian method.[6,7,12] This method expresses the partition function Z for a closed packed dimer model on an N by M planar lattice:

$$Z^2 = \det R. \tag{7}$$

Here R is an $N\times M$ by $N\times M$ antisymmetric matrix, defined as follows. Enumerate all the $N\times M$ vertices on the decorated lattice. If vertex i is not connected to vertex j via an edge, $R_{i,j}=0$, else $R_{i,j}=\pm$ fugacity of dimer at edge connecting i to j. The way the signs have to be chosen is explained in Ref. 7 These signs define an orientation of the edges. Positive $R_{i,j}$ is indicated by an arrow pointing from i to j.

To set up a perturbation theory about $\beta\epsilon=\frac{1}{2}\ln(2)$, we also need the inverse of R. Both the determinant and the inverse of R are easily calculated by performing a similarity transformation (see Ref. 1 for details). The determinant yields the following expression for the reduced free energy per vertex (i.e., the free energy times $-\beta$), denoted as F_{Baxter}, for an infinite by infinite lattice:

$$F_{\text{Baxter}} = \lim_{N,M\to\infty}\frac{1}{2NM}\ln\det R = \frac{1}{8\pi^2}\int_0^{2\pi}\int_0^{2\pi}\ln[2\cosh(2\beta s)+2\cos(\theta_1)\cos(\theta_2)]d\theta_1 d\theta_2. \tag{8}$$

IV. PERTURBATION THEORY

We now proceed with the derivation of a perturbation theory about the free-fermion line of a six-vertex model. The Hamiltonian of a general six-vertex model can be defined as follows. One assigns an energy $e(p,i)$ to a vertex in state p (see Fig. 1) and position i. The configuration of the lattice can be specified by a function c which maps a position of a vertex to a number, 1,...,6, which is to be interpreted as the state of the vertex at that position. The reduced Hamiltonian (H) is defined to be the functional that assigns to each state c its energy times $-\beta$. We can thus write

$$H(c) = -\beta\sum_i e(c(i),i). \tag{9}$$

For H a Hamiltonian of a general six-vertex model and H_0 a Hamiltonian of a free-fermion model, a perturbation V can be defined so that we have

$$H = H_0 + V. \tag{10}$$

The partition function Z can be written as

$$Z = \sum_c \exp(H_0(c)+V(c)) = Z_0\langle\exp(V)\rangle. \tag{11}$$

Here Z_0 is the partition function of the free-fermion model. The reduced free energy can be expressed as

$$F = F_0 + \ln\langle\exp(V)\rangle = F_0 + \langle V\rangle + \tfrac{1}{2}\langle(V-\langle V\rangle)^2\rangle + \cdots. \tag{12}$$

Here F_0 is the reduced free energy of the free-fermion model. Now write $V=\Sigma_i V_i$ with $V_i(c(i))$ a perturbation of the vertex energy times $-\beta$ at position i. Equation (12) can be rewritten as

$$F = F_0 + \sum_i \langle V_i\rangle + \frac{1}{2}\sum_{ij}[\langle V_i V_j\rangle - \langle V_i\rangle\langle V_j\rangle] + \cdots. \tag{13}$$

To compute a free-fermion average $\langle V_{i_1}V_{i_2}\cdots V_{i_n}\rangle$, we can proceed as follows: Introduce a constraint in the free-fermion model by requiring the vertices at the positions $i_1\cdots i_n$ to be in the states $x_1\cdots x_n$. The partition function of this model is denoted by $Z_{i_1\cdots i_n}(x_1\cdots x_n)$. We can then write

$$\langle V_{i_1}V_{i_2}\cdots V_{i_n}\rangle=\sum_{x_1\cdots x_n}\frac{Z_{i_1\cdots i_n}(x_1\cdots x_n)V(x_1)\cdots V(x_n)}{Z_0}. \tag{14}$$

It now remains to calculate $Z_{i_1\cdots i_n}(x_1\cdots x_n)$. It is convenient to reformulate this problem as follows: Denote the state of an arrow located at the edge j by s_j. Put $s_j=1$ if the arrow points oppositely to the ground state configuration and $s_j=0$ otherwise. Define a constrained free-fermion model by requiring the arrow at the edge j_r to be in state s_{j_r} for $1\leqslant r\leqslant m$. We then want to evaluate the partition function of this model, which we denote as $Z^{\mathrm{cons}}(s_{j_1}\cdots s_{j_m})$. The idea is to perturb the weights of the dimers on the edges j_r infinitesimally. We redefine the weight of the dimer on the edge j_r by multiplying it by $(1+\epsilon_r)$. The partition function of the redefined free-fermion model $(Z(\epsilon_1\cdots\epsilon_m))$ can be written in terms of the constrained partition functions as

$$\begin{aligned}Z(\epsilon_1\cdots\epsilon_m)&=\sum_{\{s\}}Z^{\mathrm{cons}}(s_{j_1}\cdots s_{j_m})\prod_{k=1}^{m}(1+s_{j_k}\epsilon_k)\\&=Z_0+\sum_k Z^{\mathrm{cons}}(s_{j_k}=1)\epsilon_k+\sum_{k<l}Z^{\mathrm{cons}}(s_{j_k}=1,s_{j_l}=1)\epsilon_k\epsilon_l+\cdots.\end{aligned} \tag{15}$$

$Z(\epsilon_1\cdots\epsilon_m)$ can be calculated using (7), by making the necessary changes to R. We can write

$$R=R_0+\sum_{k=1}^{m}\epsilon_k R_{(k)}. \tag{16}$$

Here R_0 is the original unperturbed matrix; $R_{(k)}$ is defined as follows:

$$R_{(k),ij}=R_{0,ij}$$

if i and j are connected by j_k, and

$$R_{(k),ij}=0$$

if i and j are not connected by j_k.

Note that the $R_{(k)}$ have only two nonzero matrix elements. Inserting (16) in (7) and expanding gives

$$\begin{aligned}Z(\epsilon_1\cdots\epsilon_m)&=\sqrt{\det R}\\&=\sqrt{\det R_0}\exp\left(\frac{1}{2}\mathrm{Tr}\ln\left[1+\sum_k\epsilon_k R_0^{-1}R_{(k)}\right]\right)\\&=\sqrt{\det R_0}\left[1+\frac{1}{2}\sum_k\epsilon_k\mathrm{Tr}(R_0^{-1}R_{(k)})+\frac{1}{4}\sum_{k,l}\epsilon_k\epsilon_l\left[\frac{1}{2}\mathrm{Tr}(R_0^{-1}R_{(k)})\mathrm{Tr}(R_0^{-1}R_{(l)})\right.\right.\\&\quad\left.\left.-\mathrm{Tr}(R_0^{-1}R_{(k)}R_0^{-1}R_{(l)})\right]+\cdots\right].\end{aligned} \tag{17}$$

Using (17) and (15) we can directly read off the constrained partition functions if all the constrained arrows point oppositely to the ground state configuration. To calculate a general con-

strained partition function one can apply the principle of inclusion and exclusion, e.g., consider the evaluation of $Z(s_1,s_2,s_3,s_4,s_5)$, with $s_1=s_2=1$ and $s_3=s_4=s_5=0$. Put $t_3=t_4=t_5=1$. According to the principle of incusion and exclusion, we can write

$$Z(s_1,s_2,s_3,s_4,s_5)=Z(s_1,s_2)-[Z(s_1,s_2,t_3)+Z(s_1,s_2,t_4)+Z(s_1,s_2,t_5)]+Z(s_1,s_2,t_3,t_4)+Z(s_1,s_2,t_3,t_5)+Z(s_1,s_2,t_4,t_5)-Z(s_1,s_2,t_3,t_4,t_5). \tag{18}$$

V. FIRST ORDER COMPUTATION FOR THE STAGGERED F-MODEL

For the staggered F-model the expansion can be simplified. The vertex in the ground state at a particular point will be referred to as an a-vertex. A b-vertex is obtained by reversing the arrows of an a-vertex. An a-vertex (b-vertex) is thus of type 5 or 6 and has an energy of $-s$ (s). The constrained partition function corresponding to the model with one vertex constrained to be an a-vertex (b-vertex) is denoted as Z_a (Z_b). Note that under the transformation $s\rightarrow -s$ the role of vertices a and b are interchanged. We thus have

$$Z_a(\beta s)=Z_b(-\beta s). \tag{19}$$

If we put $\beta\epsilon=\frac{1}{2}\ln(2)+U$, we have, according to (13) and (14), to first order in U

$$F=F_0-\frac{Z_0-Z_a-Z_b}{Z_0}U+O(U^2). \tag{20}$$

Here F is the reduced free energy per vertex of the staggered F-model, and $F_0=F_{\text{Baxter}}$ in (8). To calculate Z_b we only have to constrain two opposing arrows of one vertex to point oppositely to an a-vertex. Using the formalism of the previous section, we have obtained

$$\frac{Z_b}{Z_0}=\frac{1}{64\pi^4}\left[\int_0^{2\pi}\int_0^{2\pi}d\theta_1 d\theta_2\frac{\exp(-2\beta s)+\cos(\theta_1)\cos(\theta_2)}{\cosh(2\beta s)+\cos(\theta_1)\cos(\theta_2)}\right]^2. \tag{21}$$

Using this, the first order expansion of the free energy can be written as

$$F=F_0+\frac{1}{2}\left[\left(\frac{\partial F_0}{\partial\beta s}\right)^2-1\right]U+\cdots. \tag{22}$$

VI. SINGULAR BEHAVIOR IN THE VICINITY OF THE FREE-FERMION LINE

We will now verify the Coulomb gas result (see Sec. II):

$$F_s\sim(\beta s)^{2/(2-\pi/4j(\beta\epsilon))} \tag{23}$$

where

$$j(\beta\epsilon)=\tfrac{1}{2}\arccos(1-\tfrac{1}{2}\exp(2\beta\epsilon)), \tag{24}$$

to first order about the free-fermion line. Putting

$$\beta\epsilon=\tfrac{1}{2}\ln(2)+U, \tag{25}$$

and expanding in powers of U yields

$$F_s = A(U)(\beta s)^2\left[-\frac{8}{\pi}(U+O(U^2))\ln(\beta s) + \frac{32}{\pi^2}(U^2+O(U^3))\ln^2|\beta s| + \cdots \right], \tag{26}$$

where the amplitude $A(U)$ is a meromorphic function. If we compare this with the nonanalytical behavior at $U=0$ [see (A11) in the Appendix], we find

$$A(U) = \frac{1}{4U} + O(1). \tag{27}$$

It then follows that the amplitude of the term $(\beta s)^2\ln^2|\beta s|$ is $(8/\pi^2)(U+O(U^2))$. It is now a simple matter to verify this using (22) and (A11). From (A11) and (22) it follows that the order U contribution to the singular part of the reduced free energy, $F_{1,s}(\beta s)$, can be written as

$$F_{1,s}(\beta s) = [B_1(\beta s)\ln|\beta s| + B_2(\beta s)\ln^2|\beta s|]U \tag{28}$$

with B_1 and B_2 regular functions of βs. Inserting (A11) in (22) gives

$$B_2(\beta s) = \frac{8}{\pi^2}\left[(\beta s)^2 - \frac{2}{3}(\beta s)^4 + \frac{79}{90}(\beta s)^6 + \cdots \right]. \tag{29}$$

We have thus verified (24) to first order in U.

VII. CONCLUSIONS AND OUTLOOK

We have presented a simple technique for expanding the free energy of six-vertex models about free-fermion points. Applying this technique to the staggered F-model has enabled us to verify a Coulomb gas prediction about the singular part of the free energy of this model. It would be interesting to perform such computations to higher order in the free-fermion expansion. It is possible that such an undertaking might lead to proofs of certain Coulomb gas results.

APPENDIX: SINGULAR PART OF THE FREE ENERGY

In this appendix we calculate the singular part of the free energy of the staggered F-model at $\beta s = 0$ on the free-fermion line. Expanding the logarithm in (8) yields

$$\begin{aligned} F_{\text{Baxter}}(\beta s) &= -\frac{1}{8\pi^2}\int_{-\pi}^{\pi}\int_{-\pi}^{\pi} d\theta_1 d\theta_2 \sum_{n=1}^{\infty} \frac{\cos^n(\theta_1)\cos^n(\theta_2)}{n\cosh^n(2\beta s)} \\ &= -\frac{1}{2}\sum_{n=1}^{\infty} \frac{1}{2n\cosh^{2n}(2\beta s)}\left[\frac{(2n)!}{4^n n!^2}\right]^2. \end{aligned} \tag{A1}$$

Using the asymptotic expansion

$$n! = n^n \exp(-n)\sqrt{2\pi n}\exp\left(\sum_{k=1}^{\infty} \frac{B_{2k}}{2k(2k-1)}\frac{1}{n^{2k-1}} \right), \tag{A2}$$

where the B_r are the Bernoulli numbers, we find

$$F_{\text{Baxter}}(\beta s) = -\frac{1}{4\pi}\sum_{n=1}^{\infty} \frac{1}{n^2\cosh^{2n}(2\beta s)}\left[1 - \frac{1}{4n} + \frac{1}{32n^2} + \frac{1}{128n^3} + \cdots \right]. \tag{A3}$$

We can find the nonanalytical part of the function $\Sigma_{n=1}^{\infty} 1/n^p \cosh^{2n}(2\beta s)$ as follows: Put $t = \ln(\cosh^2(2\beta s))$. We then have to find the nonanalytical part of the function $U_p(t)$ with

$$U_p(t)=\sum_{n=1}^{\infty}\frac{\exp(-nt)}{n^p} \tag{A4}$$

at $t=0$ for $p\geqslant 2$. From (A4) it follows that

$$\frac{dU_{p+1}}{dt}=-U_p. \tag{A5}$$

We denote the nonanalytical part of U_p by $\tilde{U}_p$. It then follows from (A5) that

$$\frac{d\tilde{U}_{p+1}}{dt}=-\tilde{U}_p. \tag{A6}$$

For $p=1$ the sum in (A4) is easily evaluated:

$$U_1(t)=-\ln(1-\exp(-t)), \tag{A7}$$

and we see that $\tilde{U}_1(t)$ is given by

$$\tilde{U}_1(t)=-\ln(t). \tag{A8}$$

From (A8) and (A6) it then follows that

$$\tilde{U}_p(t)=(-1)^p\frac{t^{p-1}}{(p-1)!}\ln(t). \tag{A9}$$

Inserting this in (A3) gives

$$F_s(\beta s)=-\frac{1}{4\pi}\left(t+\frac{t^2}{8}+\frac{t^3}{192}-\frac{t^4}{3072}+\cdots\right)\ln(t), \tag{A10}$$

where $F_s(\beta s)$ is the singular part of the free energy and $t=2\ln(\cosh(2\beta s))$. Expanding (A10) in powers of βs gives

$$F_s(\beta s)=-\frac{2}{\pi}\left[(\beta s)^2-\frac{1}{6}(\beta s)^4+\frac{23}{180}(\beta s)^6-\frac{593}{5040}(\beta s)^8+\cdots\right]\ln|\beta s|. \tag{A11}$$

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 1 JANUARY 2004

Quantum study of the spin inversion

P. Moretti,[a] M. Lantieri, and L. Cianchi
Istituto di Fisica Applicata "N. Carrara," CNR, via Panciatichi 64, 50127 Firenze, Italy

(Received 15 July 2003; accepted 2 October 2003)

Spin motion is studied by means of the direct use of the Schrödinger equation. The solution is found in terms of Lommel's polynomials. An expression of the tunneling splitting is obtained, in good agreement with the results coming from other calculations. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1630704]

I. INTRODUCTION

In quantum mechanics the direct solution of a problem by means of the Schrödinger equation can be often applied in a lot of different physical situations. For instance, the results concerning the double harmonic oscillator can be suitably used in the study of transitions in a general two-state system;[1] the wave functions of a particle in a constant force field are useful when, dealing with the Wentzel–Kramers–Brillouin (WKB) method, a turning point is crossed;[2] and so on. On the ground of these considerations, we think it advisable to present here the study of a kind of spin motion using directly the Schrödinger equation. An entire spin S in a static magnetic field is considered, performing transitions between neighboring states. The solution turns out to be expressed in terms of Lommel's polynomials, and an application to a practical case is discussed.

II. MOTION EQUATION FOR THE SPIN

The Hamiltonian has the form: $H=H_0+V$, where H_0 is a static Hamiltonian (e.g., a magnetic field) and V is the term responsible for the transitions between spin states.

Starting from the discrete set of the N $(N=2S+1)$ spin eigenstates $|n\rangle$ of H_0 with energies E_n, we can write the wave function as

$$\psi(t)=\sum_{n=1}^{N} a_n(t)|n\rangle\exp(-iE_nt/\hbar). \tag{1}$$

From the Schrödinger equation, the coefficients $a_n(t)$ result:

$$i\hbar\dot{a}_n(t)=\sum_{l=1}^{N} a_l(t)V_{nl}\exp(i\omega_{nl}t), \tag{2}$$

with $V_{nl}=\langle n|V|l\rangle$ and $\omega_{nl}=(E_n-E_l)/\hbar$. Some simplifications are in order. First, we can assume that V connects only neighboring states, and does not have diagonal elements; moreover, $|\omega_{n,n\pm1}|=\omega$, independent of n, and $V^*_{n,n+1}=V_{n,n-1}=k$. Consequently, system (2) becomes

$$i\hbar\dot{a}_n(t)-k^*a_{n+1}(t)e^{-i\omega t}-ka_{n-1}(t)e^{i\omega t}=0, \tag{3}$$

with the obvious boundary conditions

$$i\hbar\dot{a}_1(t)-k^*a_2(t)e^{-i\omega t}=0, \tag{4a}$$

$$i\hbar\dot{a}_N(t)-ka_{N-1}(t)e^{i\omega t}=0. \tag{4b}$$

[a]Electronic mail: p.moretti@ifac.cnr.it

The initial conditions of interest are

$$a_1(0)=1, \tag{5a}$$

$$a_n(0)=0, \quad n=2,3,\ldots N, \tag{5b}$$

which correspond to the spin up (or down).

The substitution

$$b_n(t)=a_n(t)\mathrm{e}^{-in\omega t}, \tag{6}$$

leads to

$$i\hbar[\dot{b}_n(t)+in\omega b_n(t)]-k^*b_{n+1}(t)-kb_{n-1}(t)=0, \tag{7}$$

and to the following boundary and initial conditions, respectively,

$$i\hbar[\dot{b}_1(t)+i\omega b_1(t)]-k^*b_2(t)=0, \tag{8a}$$

$$i\hbar[\dot{b}_m(t)+im\omega b_m(t)]-kb_{m-1}(t)=0 \tag{8b}$$

$$b_1(0)=1, \tag{9a}$$

$$b_n(0)=0, \quad n=2,3,\ldots,m. \tag{9b}$$

After the Laplace transform $[b_n(p)=\int_0^\infty \mathrm{d}t b_n(t)\exp(-pt)]$, introducing the further simplification $k=k^*>0$ and with the following substitutions:

$$\rho=\hbar\omega/k, \quad \tau=\omega^{-1}, \tag{10}$$

we obtain the recursive equation

$$b_{n+1}(p)=\rho(i\tau p-n)b_n(p)-b_{n-1}(p), \tag{11}$$

where conditions (8) and (9) become

$$\rho(i\tau p-1)b_1(p)-b_2(p)=i\rho\tau, \tag{12a}$$

$$\rho(i\tau p-N)b_N(p)-b_{N-1}(p)=0. \tag{12b}$$

At this point, let us recall that the Bessel functions[3] $\mathcal{Z}_\nu(z)$ (with $\mathcal{Z}=J,Y$) satisfy a recurrence relation similar to (11). In the original definition, ν and z are independent quantities, but this does not prevent $\nu=\nu(z)$, provided that derivatives with respect to z are not performed. In particular, if $\nu=\nu(z)$, these functions are not the solution to Bessel's differential equation, and all the properties obtained using this fact are lost. By rewriting this recurrence relation as

$$\mathcal{Z}_{\nu+1}(z)=\frac{2\nu}{z}\mathcal{Z}_\nu(z)-\mathcal{Z}_{\nu-1}(z), \tag{13}$$

it has the form (11) by making the following identification

$$b_n(p)=\mathcal{Z}_{i\tau p-n}(2/\rho), \tag{14}$$

where

$$z=2/\rho, \quad \nu(z)=i\tau p-n. \tag{15}$$

So, with the substitution

$$J_\nu(z)=J_{i\tau p-n}(2/\rho)=J(p,n), \tag{16a}$$

$$Y_\nu(z)=Y_{i\tau p-n}(2/\rho)=Y(p,n), \tag{16b}$$

the general solution of (11) can be written as

$$b_n(p)=A(p)J(p,n)+B(p)Y(p,n), \tag{17}$$

where A and B are found by using (12). By applying the relation (13) and introducing the quantity

$$\Delta(p,N)=J(p,0)Y(p,N+1)-Y(p,0)J(p,N+1), \tag{18}$$

we obtain

$$b_n(p)=i\rho\tau[J(p,n)Y(p,N+1)-Y(p,n)J(p,N+1)]\Delta^{-1}(p,N)=\frac{i\hbar}{k}B_n(p). \tag{19}$$

This expression can be simplified. It is obvious that the recurrence formula (13) may be used to express $\mathcal{Z}_{\mu+n}$ linearly in terms of $\mathcal{Z}_\mu$ and $\mathcal{Z}_{\mu-1}$; the coefficients in this linear relation are polynomials in $1/z$, known as Lommel's polynomials[3] and indicated as $R_{n,\mu}(z)$. In our case $(-\mu=i\tau p)$

$$\mathcal{Z}_{-\mu-n}(z)=(-1)^n[\mathcal{Z}_{-\mu}(z)R_{n,\mu}(z)+\mathcal{Z}_{-\mu+1}(z)R_{n-1,\mu+1}(z)]. \tag{20}$$

By introducing (20) into (19), it follows that

$$B_n(p,z)=(-1)^n\frac{R_{n,\mu}(z)R_{N,\mu+1}(z)-R_{n-1,\mu+1}(z)R_{N+1,\mu}(z)}{R_{0,\mu}(z)R_{N,\mu+1}(z)-R_{-1,\mu+1}(z)R_{N+1,\mu}(z)}. \tag{21}$$

By taking into account the relations[3]

$$R_{0,\mu}=1, \quad R_{-1,\mu}=0 \tag{22}$$

and

$$R_{n,\mu}(z)R_{N,\mu+1}(z)-R_{n-1,\mu+1}(z)R_{N+1,\mu}(z)=R_{N-n,\mu+n+1}(z), \tag{23}$$

this noteworthy result is obtained

$$B_n(p,z)=(-1)^n\frac{R_{N-n,\mu+n+1}(z)}{R_{N,\mu+1}(z)}. \tag{24}$$

If $n=N$, corresponding to the spin inversion, we have

$$B_N(p,z)=(-1)^N[R_{N,\mu+1}(z)]^{-1}. \tag{25}$$

From the explicit expression of Lommel's polynomials [see (27)], it is easy to see that $R_{N,\mu+1}$ is a polynomial of degree N in p, which has exactly N complex zeros p_s.

Heaviside's expansion theorem[4] gives, therefore,

$$b_n(t)=\frac{i\hbar}{k}(-1)^n\sum_{s=1}^{N}\left[\frac{R_{N-n,-ip/\omega+n+1}\big|_{p=p_s}}{R'_{N,-ip/\omega+1}\big|_{p=p_s}}\right]e^{p_s t}, \tag{26}$$

where, obviously, the $'$ denotes the derivative with respect to p.

It is now interesting to study the behavior of $b_n(p)$ when $\omega\to 0$ (remember that $\mu=-ip/\omega$, $z=2k/\hbar\omega$). By using the explicit expression of Lommel's polynomials to express $R_{N-n,\mu+n+1}(z)$,[3]

$$R_{N-n,\mu+n+1}(z)=\sum_{l=0}^{\leqslant (N-n)/2}\frac{(-1)^l(N-n-l)!\Gamma(\mu+N-l+1)}{l!(N-n-2l)!\Gamma(\mu+n+l+1)}\left(\frac{1}{2}z\right)^{-N+n+2l}, \tag{27}$$

and by observing that

$$\frac{\Gamma(\mu+N-l+1)}{\Gamma(\mu+n+l+1)}\left(\frac{1}{2}z\right)^{-N+n+2l}=\left(-\frac{i\hbar}{k}p\right)^{N-n-2l}\left[1+\frac{i\omega}{p}(N-l)\right]\times\left[1+\frac{i\omega}{p}(N-l-1)\right]\cdots\left[1+\frac{i\omega}{p}(N+l+1)\right], \tag{28}$$

in the limit $\omega\to 0$ we finally obtain

$$R_{N-n,-ip/\omega+n+1}\big|_{\omega\to 0}=\sum_{l=0}^{\leqslant (N-n)/2}\frac{(-1)^l(N-n-l)!}{l!(N-n-2l)!}\left(-\frac{i\hbar}{k}p\right)^{N-n-2l}. \tag{29}$$

This finite sum is simply the Chebyshev polynomial of the second kind $U_{N-n}(\xi)$, $\xi=-i\hbar p/2k$.[4] By posing $\xi=\cos\theta$

$$R_{N-n,-ip/\omega+n+1}\big|_{\omega\to 0}=U_{N-n}(\cos\theta)=\frac{\sin(N-n+1)\theta}{\sin\theta}, \tag{30}$$

so that (19) can be written

$$b_n(p)\big|_{\omega\to 0}=\frac{i\hbar}{k}(-1)^n\frac{\sin(N-n+1)\theta}{\sin(N+1)\theta}. \tag{31}$$

Since the distinct zeros of the denominator are

$$p_s=\frac{2ik}{\hbar}\cos\frac{s\pi}{N+1},\quad s=0,1,\ldots N, \tag{32}$$

Heaviside's expansion applied to (31) gives, in the limit $\omega\to 0$ and after straightforward calculation

$$b_n(t)=-2\frac{(-1)^n}{N+1}\sum_{s=1}^{N}\sin\frac{s\pi}{N+1}\sin\frac{ns\pi}{N+1}\exp\left(\frac{2ik}{\hbar}t\cos\frac{s\pi}{N+1}\right). \tag{33}$$

This result can be obtained in a simple way by using the difference Eqs. (11) and (12) directly with $\omega=0$, which can now be solved using the standard method.

Although p_s's cannot be explicitly calculated for $\omega\neq 0$, an expression for small values of ω can be found. By approximating the square brackets in (28) with exponentials and performing the sum in the exponent, it follows that

$$\frac{\Gamma(\mu+N-l+1)}{\Gamma(\mu+n+l+1)}\left(\frac{1}{2}z\right)^{-N+n+2l}\approx\left[-\frac{i\hbar}{k}p\exp\left(\frac{i\omega(N+n+1)}{2p}\right)\right]^{N-n-2l}. \tag{34}$$

Thus, (27) becomes

$$R_{N-n,-ip/\omega+n+1} \approx \sum_{l=0}^{\leqslant (N-n)/2} \frac{(-1)^l (N-n-l)!}{l!(N-n-2l)!} \left[-\frac{i\hbar}{k} p \exp\left(\frac{i\omega(N+n+1)}{2p} \right) \right]^{N-n-2l}. \quad (35)$$

Proceeding as before, we pose

$$\xi = -\frac{i\hbar}{k} p \exp\left(\frac{i\omega(N+n+1)}{2p} \right) = \cos\theta,$$

giving (to the first order in ω)

$$p_s \approx i\left[\alpha \cos\frac{s\pi}{N+1} - \frac{\omega}{2}(N+1) \right], \quad (36)$$

where $\alpha = 2k/\hbar$. By performing the same standard calculation as before to obtain the Laplace transform of (31), in spite of the more complicated relation connecting p and θ, it turns out that the p-derivative of $\sin(N+1)\theta$ retains its old form. Therefore, the coefficient b_n is again given by (33) within a phase factor only; thus, if ω is not too large, it is nearly insensitive to its variation.

III. CALCULATION OF THE INVERSION TIME

The first maximum $t = \overline{t}$ of b_n as a function of time indicates when the system, in the state $|1\rangle$ for $t = 0$, first "goes" into the state $|n\rangle$. A study of the function (33) is, therefore, in order. It is easy to show that, for large values of N, the sum can be written as an integral, provided that $n \ll N$ and $\alpha t \ll N$:

$$b_n(t) \simeq (-1)^n \frac{1}{\pi} \int_0^\pi d\xi [\cos(n+1)\xi - \cos(n-1)\xi] e^{i\alpha t \cos\xi} \quad (37)$$

and

$$b_n(t) \simeq (i)^{-n+1} \frac{2n}{\alpha t} J_n(\alpha t) \quad (38)$$

is obtained as a final form, where J_n is the Bessel function of the first kind, of order n.[4] The first maximum of $b_n(t)$ obviously corresponds to the first zero of $d/dt[J_n(\alpha t)/\alpha t]$. Thus, by indicating $\alpha t \equiv \tau$, we must solve the following equation:

$$\frac{dJ_n(\tau)}{d\tau} - \frac{J_n(\tau)}{\tau} = 0. \quad (39)$$

Since the first zero of $dJ_n(\alpha t)/dt$ is found to be a good first approximation of the solution $\overline{\tau}$ of (39), this solution can be found by using a Taylor expansion. A straightforward calculation leads to the result

$$\overline{\tau} \simeq n + 0.8n^{1/3} - 0.55n^{-1/3}. \quad (40)$$

This solution was obtained from the "continuous" form (38) of $b_n(t)$, but it also works very well for the true form (33) when $n = N$, $\alpha t \leqslant N$.

The result that $\overline{\tau} \sim n$ can be found in a more intuitive way by observing that $b_n(t)$ has the form of a standing wave given by the sum of a progressive wave packet and a regressive one. By retaining only the progressive component for $t > 0$ and performing the standard analysis,[5] $b_n(t)$ takes the form

$$b_n(t) \propto \int_{-\pi/2}^{\pi/2} d\xi A(\xi) e^{i(n-\alpha t)\xi}, \tag{41}$$

that is, the maximum of the packet travels with the group velocity $v_g = \alpha$; "position" n is reached at the time $\bar{t} = n/\alpha$.

We could approach the same result directly by using the sum (33). A constructive interference is obtained only in the neighborhood of the values of s where the phase is stationary, and a short calculation immediately gives the leading term of (40).

IV. AN EXAMPLE: Fe8 CLUSTER

We were interested in applying the result expressed in Eq. (40) ($\bar{\tau} \sim n$) to a cluster with 8 Fe^{+3}.[6] We deal with spin dynamics only at very low temperatures, where the tunnel effect consists essentially (or, better, exclusively) of coherent jumps between the two spin states of the ground doublet (which, for this cluster, corresponds to $S = 10$).

The main terms of the spin Hamiltonian for the ground state are

$$H_s = DS_z^2 + \frac{\varepsilon}{2}(S_+^2 + S_-^2) + H_{h.o.}, \tag{42}$$

where $H_{h.o.}$ indicates fourth-order terms in the spin components. See Ref. 6 for further details. In this case, by diagonalizing H_s in the space of the ground spin state $|10,M\rangle$, we have six quasi-degenerate lowest doublets from $M = \pm 10$ to $M = \pm 5$, corresponding merely to the axial term of H_s, and a strong mixing of the nine highest singlets with $\langle M \rangle = 0$, due to the transverse term of H_s.

In order to evaluate the quantum tunneling frequencies ω_M (i.e., for a given M, the frequencies of the coherent $M \leftrightarrow -M$ jumps) as functions of M and $\varepsilon/|D|$, it is useful to apply the Brillouin–Wigner perturbation theory. As shown in Ref. 6, the following expression for ω_M is obtained:

$$\omega_M = F(M)\left(\frac{\varepsilon}{2|D|}\right)^M \frac{|D|}{\hbar}, \tag{43}$$

where $F(M)$ is independent of ε and $|D|$, and is calculated by means of the perturbation theory (for the inversion $-10 \leftrightarrow 10$ $F(M) \simeq 1.09 \times 10^5$).

The frequency ω_M can be calculated also by means of the theory explained in the previous section, since the two states corresponding to the spin inversion ($M = \pm 10$) are quasi-degenerate and it is possible to pass from one to another only by means of the matrix element between neighboring states. On the other hand, we have seen that the coefficient b_n shows only little dependence on the energy differences. Therefore, by comparing (43) with the relation (40):

$$\Delta_{M,-M} = \hbar \omega_M = \frac{2\pi\hbar}{\bar{t}} \simeq \frac{4\pi k}{2M+1}, \tag{44}$$

where $k \equiv V_{M,M-1} = \varepsilon$, we finally obtain

$$\frac{\varepsilon}{D} = \left[4\pi\left(\frac{2^M}{2M+1}\right)\frac{1}{F(M)}\right]^{1/M-1}. \tag{45}$$

In our case, the inversion $-10 \leftrightarrow 10$ takes place by means of six jumps ($M = 6$) between the quasi-degenerate doublets with $M = \pm 10, \pm 8, \pm 6$ and the mixing of the highest singlets with

$\langle M\rangle = 0$ by running across the path: $10 \leftrightarrow 8 \leftrightarrow 6 \leftrightarrow \langle M\rangle = 0 \leftrightarrow -6 \leftrightarrow -8 \leftrightarrow -10$. In solving Eq. (45) with $M = 6$ and $F(M) \simeq 1.09 \times 10^5$, we obtain $\varepsilon/D \sim 0.25$, which can be considered to be in good agreement with the experimental result of 0.16.

(Received 2 May 2003; accepted 4 October 2003)

We consider the problem of setting up the Wigner distribution for states of a quantum system whose configuration space is a Lie group. The basic properties of Wigner distributions in the familiar Cartesian case are systematically generalized to accommodate new features which arise when the configuration space changes from n-dimensional Euclidean space $\mathcal{R}^n$ to a Lie group G. The notion of canonical momentum is carefully analyzed, and the meanings of marginal probability distributions and their recovery from the Wigner distribution are clarified. For the case of compact G an explicit definition of the Wigner distribution is proposed, possessing all the required properties. Geodesic curves in G which help introduce a notion of the midpoint of two group elements play a central role in the construction. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1631393]

I. INTRODUCTION

The method of Wigner distributions[1] as a description of states of quantum mechanical systems appeared in 1932, quite early in the history of quantum mechanics. For systems whose kinematics is based upon a set of Heisenberg canonical commutation relations, it gives a way of describing both pure and mixed states in a classical phase space setting, at the level of density operators. Thus it must be sharply distinguished in mathematical structure from the Hilbert space state vector or wave function description of states, which highlights the superposition principle of quantum mechanics. In the Wigner distribution language, this principle is not obvious or manifest, but is somewhat hidden in the formalism. On the other hand, the formation of convex classical statistical mixtures of general states to generate new states becomes much more obvious. Somewhat later it was appreciated that the Wigner distribution way of describing quantum mechanical states is dual to, or is naturally accompanied by, the Weyl ordering rule[2]—a convention by which one can set up a one-to-one correspondence between operators in quantum theory (in the case of the Heisenberg commutation relations) and c-number dynamical phase space variables for the comparison classical system. Thus expectation values for general quantum dynamical variables in general quantum states can be faithfully expressed in the full operator-state vector language, or equally well in

a completely c-number classical phase space language. In this general scheme, the group $\mathrm{Sp}(2n,R)$ of linear canonical transformations for n Cartesian degrees of freedom, and the related two-fold covering group $\mathrm{Mp}(2n)$, play prominent roles.[3]

An important property of the Wigner distribution for a general quantum state is that while it is a real function on the classical phase space, it is not always pointwise non-negative. Therefore it is usually called a quasi probability distribution, and cannot be interpreted as a phase space probability density in the sense of classical statistical mechanics. However, the Wigner distribution does have the attractive property that the marginal distributions, obtained by integrating away either the momentum or the position variables, do reproduce the correct non-negative position space and momentum space probability distributions respectively as specified by quantum mechanics. This recovery or reproducibility of correct marginal distributions is of course maintained even after unitary action by any $\mathrm{Mp}(2n)$ element.

There have been several attempts[4–15] over the years to generalize the method of Wigner distributions to handle quantum mechanical situations where the basic kinematics is defined, not by Heisenberg-type canonical commutation relations, but by some Lie group which acts as the covariance group of the system of interest. (As will become clear in the sequel, the traditional case is also governed by a group, namely the Abelian group $\mathcal{R}^n$ of translations in n-dimensional Euclidean space.) A commonly studied group is SU(2), in the context of spin systems as well as two-level atoms. One of the important early efforts at providing a general group theoretical setting for the Wigner distribution is due to Stratonovich.[16] In this context we should also mention the comprehensive monograph of Dubin *et al.*[17] It seems to us, however, that in most of these attempts the requirement that certain marginal probability distributions be recovered in a natural way from the Wigner distribution corresponding to a general quantum state, which as mentioned above is an important feature of the usual Cartesian case, is not discussed in a satisfactory manner; in some of these works this important aspect is not considered at all.

The aim of the present paper is to develop from first principles the basic features of quantum kinematics for a system whose configuration space is a general non-Abelian Lie group G rather than a Cartesian space $\mathcal{R}^n$, and then set up a corresponding Wigner distribution formalism which respects the requirement that natural marginal probability distributions are reproduced in a simple manner. This involves several extensions or modifications of the familiar formalism in the Cartesian case. The role of Schrödinger wave functions is of course now played by complex square integrable functions on G, and after normalization each such wave function determines a probability distribution over G. The meaning and definition of canonical momentum variables, and determination of the momentum space probability distribution for a given state, are however nontrivial questions in which the many structural features associated with G play important roles. In particular for a non-Abelian G canonical momenta in quantum theory become noncommuting operators, leading to deep changes in the meaning of momentum eigenstates, momentum eigenvalues and momentum space, etc. It is here that the unitary representation theory of G plays an important role. We show that all these features can be properly taken into account, and a fully satisfactory Wigner distribution can be set up as a function of carefully chosen arguments. This turns out to have simple transformation properties under G action and also to reproduce the marginal position and momentum space probability distributions properly.

It needs to be emphasised that our interest in developing a Wigner distribution formalism for systems whose configuration space is a non-Abelian group is not purely academic. In fact, there are many familiar systems which fall in this category. A general rigid body which has the group SO(3) as its configuration space is a case in point. Another well studied example in this category is the relativistic spherical top[18] whose configuration space is the noncompact group SO(3,1).

The material of this paper is arranged as follows. In Sec. II we recall the main definitions and properties of Wigner distributions in the Cartesian situation. We emphasize several familiar features in this case: the possibility of use of the classical phase space as the domain of definition of Wigner distributions; the roles of the groups $\mathrm{Sp}(2n,R)$ and $\mathrm{Mp}(2n)$; the reality but in general loss of pointwise positivity of Wigner distributions; and the recovery of the coordinate space and momentum space probability distributions for a given state by integrating over half the arguments

of the Wigner distribution. Section III describes briefly the properties of Wigner distributions in the angle-angular momentum case.[19] This brings out some new features, namely, loss of the classical phase space as the domain of definition of Wigner distributions, and absence of replacements for the groups $\mathrm{Sp}(2n,R)$ and $\mathrm{Mp}(2n)$, which indicate the type of changes we should expect in the case of a general Lie group. Section IV analyzes in some detail the classical phase space that goes with a non-Abelian Lie group G as configuration space. Both global intrinsic and local coordinate based descriptions are given, and the associated classical Poisson bracket relations are developed and described in several ways. In particular a careful analysis of the concept of classical canonical momenta in this case is provided. The transition to quantum mechanics, based on Schrödinger wave functions over G, is then outlined. It is emphasised that a naive generalization of the usual canonical Heisenberg commutation relations is not possible, and all the concepts of position operators, momentum operators and their commutation relations have to be treated with care. A brief Sec. V indicates the kinds of new features we may expect to appear, based on the results and discussions of Sec. III and IV. In Sec. VI we pose the main problem of defining Wigner distributions in a suitable way, with suitable choice of arguments, subject to the main requirements already mentioned above: reasonable transformation laws under G action, recovery of marginal probability distributions, and capturing the full information contained in a general pure or mixed quantum state. We propose a solution to this problem, possessing all the desired properties. We find that our solution uses in an essential and interesting manner the concept and properties of geodesics in G leading to the notion of a midpoint of two group elements, a key ingredient in our construction. For definiteness we confine ourselves to the case of compact G. Section VII shows how the known results of Secs. II and III, for Cartesian quantum mechanics and for the angle angular-momentum pair, are easily recovered from the general case. They correspond actually to the choices $G=\mathcal{R}^n$ and $G=\mathrm{SO}(2)$, which are both Abelian and, respectively, noncompact and compact. The case of $G=\mathrm{SU}(2)$ is then briefly considered, giving adequate background details so that the structure of the Wigner distribution can be easily appreciated. Some of the important differences compared to the Cartesian case, as well as to earlier approaches, are mentioned. Section VIII contains some concluding remarks. We have included two appendices. Appendix A recollects basic results from the theory of the regular representation of G in the compact case, based essentially on the Peter–Weyl theorem. In addition certain useful operator structures are set up, which help us understand better the construction of Wigner distributions in Sec. VI. Appendix B discusses the question of completeness of the information content in the Wigner distribution set up in Sec. VI, and generalizations of the Weyl exponential operators to the non-Abelian Lie group case.

II. THE WIGNER DISTRIBUTION IN THE CARTESIAN CASE

It is useful to recall briefly the usual definition and the basic properties of the Wigner distribution in the case of Cartesian quantum mechanics, and to highlight those important features which are likely to need generalization when we later take up the treatment of quantum mechanics on a general Lie group.

We consider a quantum system whose kinematics is based on $2n$ Hermitian irreducible Cartesian position and momentum operators $\hat{q}_r,\hat{p}_r, r=1,2,\ldots,n$, obeying the standard Heisenberg commutation relations

$$[\hat{q}_r,\hat{p}_s]=i\hbar\,\delta_{rs}, \quad [\hat{q}_r,\hat{q}_s]=[\hat{p}_r,\hat{p}_s]=0, \quad r,s=1,2,\ldots,n. \tag{2.1}$$

It is useful to express these relations more compactly by defining a $2n$-dimensional column vector with Hermitian operator entries,

$$\hat{\xi}=(\hat{\xi}_a)=(\hat{q}_1\ldots\hat{q}_n \quad \hat{p}_1\ldots\hat{p}_n)^T, \quad a=1,2,\ldots,2n, \tag{2.2}$$

and a real antisymmetric nondegenerate $2n$ dimensional symplectic metric matrix β as

$$\beta=\begin{pmatrix} 0_{n\times n} & 1_{n\times n} \\ -1_{n\times n} & 0_{n\times n} \end{pmatrix}. \tag{2.3}$$

Then Eq. (2.1) can be written as

$$[\hat{\xi}_a,\hat{\xi}_b]=i\hbar\beta_{ab}. \tag{2.4}$$

These commutation relations and the Hermiticity properties are preserved when we subject the operators $\hat{\xi}_a$ to a real linear transformation by any matrix of the symplectic group $\mathrm{Sp}(2n,R)$:

$$\mathrm{Sp}(2n,R)=\{S=2n\times 2n \quad \text{real matrix} \quad |S\beta S^T=\beta\}, \tag{2.5a}$$

$$S \in \mathrm{Sp}(2n,R): \quad \hat{\xi}_a\to\hat{\xi}'_a=S_{ab}\hat{\xi}_b,$$

$$[\hat{\xi}'_a,\hat{\xi}'_b]=i\hbar\beta_{ab}. \tag{2.5b}$$

On account of the Stone–von Neumann theorem, such linear transformations must be unitarily induced; i.e., for each $S \in \mathrm{Sp}(2n,R)$, there exists a unitary operator $\overline{\mathrm{U}}(S)$, determined up to a phase, such that

$$\hat{\xi}'_a=S_{ab}\hat{\xi}_b=\overline{\mathrm{U}}(S)^{-1}\hat{\xi}_a\overline{\mathrm{U}}(S). \tag{2.6}$$

These unitary operators give a unitary representation of $\mathrm{Sp}(2n,R)$ up to phases which cannot be totally eliminated, but can at best be reduced to a sign ambiguity:

$$S',S \in \mathrm{Sp}(2n,R):\overline{\mathrm{U}}(S')\overline{\mathrm{U}}(S)=\pm\overline{\mathrm{U}}(S'S). \tag{2.7}$$

This situation may be expressed by the statement that one is actually dealing here with a true representation of the group $\mathrm{Mp}(2n)$ which is a double cover of $\mathrm{Sp}(2n,R)$. These objects will be seen to play important roles in the theory of Wigner distributions in the present case.

Vectors in the Hilbert space $\mathcal{H}$ on which the $\hat{\xi}_a$ are irreducibly represented may be described by their Schrödinger wave functions in the usual manner,

$$|\psi\rangle\in\mathcal{H}:\psi(\underline{q})=\langle\underline{q}|\psi\rangle,$$

$$\langle\underline{q}'|\underline{q}\rangle=\delta^{(n)}(\underline{q}'-\underline{q}), \tag{2.8}$$

$$\langle\psi|\psi\rangle=\|\psi\|^2=\int_{\mathcal{R}^n}\mathrm{d}^n q\,|\psi(\underline{q})|^2.$$

The (ideal) kets $|\underline{q}\rangle$ are simultaneous eigenvectors of the n commuting position operators $\hat{q}_r, r=1,\ldots,n$. Alternatively we may describe them by their momentum space wave functions $\tilde{\psi}(\underline{p})$ by taking the overlap with simultaneous eigenvectors of the commuting momentum operators $\hat{p}_r, r=1,\ldots,n$:

$$\tilde{\psi}(\underline{p})=\langle\underline{p}|\psi\rangle=\int_{\mathcal{R}^n}\frac{\mathrm{d}^n q}{(2\pi\hbar)^{n/2}}\psi(\underline{q})\exp(-i\ \underline{p}\cdot\underline{q}/\hbar),$$

$$\langle\underline{q}|\underline{p}\rangle=(2\pi\hbar)^{-n/2}\exp(i\ \underline{q}\cdot\underline{p}/\hbar), \tag{2.9}$$

$$\langle\psi|\psi\rangle=\int_{\mathcal{R}^n}\mathrm{d}^n p\,|\tilde{\psi}(\underline{p})|^2.$$

Given a pure state $|\psi\rangle$ of the above quantum system, the corresponding Wigner distribution is a function $W(\underline{q},\underline{p})$ of $2n$ classical real variables, i.e., a function on $\mathcal{R}^{2n}$. In analogy with Eq. (2.2) we assemble the arguments $q_1\cdots q_n \;\; p_1\cdots p_n$ into a real $2n$-component column vector $\xi=(\xi_a)=(q_1\cdots q_n \;\; p_1\cdots p_n)^T$, and then $W(\xi)$ is defined by a partial Fourier transformation:

$$W(\xi)=(2\pi\hbar)^{-n}\int_{\mathcal{R}^n}\mathrm{d}^n q'\;\psi(\underline{q}-\tfrac{1}{2}\underline{q}')\,\psi(\underline{q}+\tfrac{1}{2}\underline{q}')^*\exp(i\;\;\underline{p}\cdot\underline{q}'/\hbar). \tag{2.10}$$

Here the dependence of $W(\xi)$ on ψ is left implicit. For a general mixed state we define $W(\xi)$ through the configuration space matrix elements of the density operator $\hat{\rho}$,

$$W(\xi)=(2\pi\hbar)^{-n}\int_{\mathcal{R}^n}\mathrm{d}^n q'\langle\underline{q}-\tfrac{1}{2}\underline{q}'|\hat{\rho}|\underline{q}+\tfrac{1}{2}\underline{q}'\rangle\exp(i\;\;\underline{p}\cdot\underline{q}'/\hbar), \tag{2.11}$$

once again leaving the dependence on $\hat{\rho}$ implicit. It is clear by construction that $W(\xi)$ is a real phase space function. The recovery of the proper non-negative marginal probability distributions is demonstrated by

$$\begin{aligned}\int_{\mathcal{R}^n}\mathrm{d}^n p\;W(\xi)&=|\psi(\underline{q})|^2,\\ \int_{\mathcal{R}^n}\mathrm{d}^n q\;W(\xi)&=|\tilde{\psi}(\underline{p})|^2.\end{aligned} \tag{2.12}$$

On the other hand, if $W(\xi)$ and $W'(\xi)$ correspond, respectively, to $\hat{\rho}$ and $\hat{\rho}'$, it is easily shown that

$$\mathrm{Tr}(\hat{\rho}'\hat{\rho})=(2\pi\hbar)^{-n}\int_{\mathcal{R}^{2n}}\mathrm{d}^{2n}\xi\;W'(\xi)W(\xi)\geqslant 0. \tag{2.13}$$

But since it is easy to construct cases where the trace on the left-hand side actually vanishes, we can expect that in general $W(\xi)$ becomes negative in some regions of $\mathcal{R}^{2n}$. Indeed, the simplest explicit example showing this is the expression for the Wigner function for the first excited state of the harmonic oscillator in one dimension. Taking $n=1$ and setting $\hbar=1$ for simplicity, we have

$$\psi(q)=\frac{\sqrt{2}}{\pi^{1/4}}q\;\;e^{-q^2/2}\rightarrow W(\xi)=\frac{2}{\pi}\left(q^2+p^2-\frac{1}{2}\right)\;\;e^{-q^2-p^2}. \tag{2.14}$$

In this context it is interesting to recall the following two results (again in one dimension) as indicative of the characteristic features of Wigner distributions.

(i) *Hudson:*[20] For a pure state $\psi(q)$ the Wigner function is pointwise non-negative if and only if $\psi(q)$ [and hence $W(\xi)$ as well] is a (complex) Gaussian.

(ii) *Folland-Sitaram:*[21] If $W(\xi)$ has compact support in $\mathcal{R}^2$, it must vanish identically.

Under the unitary action of $\mathrm{Mp}(2n)$ on $\hat{\rho}$, $W(\xi)$ experiences a simple point transformation

$$\hat{\rho}'=\overline{\mathrm{U}}(S)\hat{\rho}\overline{\mathrm{U}}(S)^{-1}\Leftrightarrow W'(\xi)=W(S^{-1}\xi),\;S\in\mathrm{Sp}(2n,R). \tag{2.15}$$

Thus we have covariance under the group $\mathrm{Sp}(2n,R)$ which is the maximal linear homogeneous group mixing q's and p's. This combined with the results of Eq. (2.12) shows that we recover the correct marginal probability distributions by integrating over half the variables in $W(\xi)$ even after action by any $\mathrm{Sp}(2n,R)$ transformation.

The sense in which the definitions (2.10) and (2.11) of the Wigner distribution are dual to the Weyl ordering rule is as follows. The latter rule associates with each elementary classical exponential a corresponding elementary operator exponential,

$$\exp(i\ \underline{\lambda}\cdot\underline{q}-i\ \underline{\mu}\cdot\underline{p})\rightarrow\exp(i\ \underline{\lambda}\cdot\underline{\hat{q}}-i\ \underline{\mu}\cdot\underline{\hat{p}}), \tag{2.16}$$

where $\underline{\lambda}$ and $\underline{\mu}$ are arbitrary real vectors in $\mathcal{R}^n$; and this is then extended by linearity and Fourier transformation to general classical functions, say

$$f(\underline{q},\underline{p})\equiv f(\xi)\rightarrow\hat{F}. \tag{2.17}$$

Then the dual relationship is expressed by the equality of two ways of computing quantum expectation values,

$$\begin{aligned}\mathrm{Tr}(\hat{\rho}\exp(i\ \underline{\lambda}\cdot\underline{\hat{q}}-i\ \underline{\mu}\cdot\underline{\hat{p}}))&=(2\pi\hbar)^{-n}\int_{\mathcal{R}^{2n}}\mathrm{d}^{2n}\xi\,W(\xi)\exp(i\ \underline{\lambda}\cdot\underline{q}-i\ \underline{\mu}\cdot\underline{p}),\\ \mathrm{Tr}(\hat{\rho}\hat{F})&=(2\pi\hbar)^{-n}\int_{\mathcal{R}^{2n}}\mathrm{d}^{2n}\xi W(\xi)f(\xi).\end{aligned} \tag{2.18}$$

The definition (2.10) gives $W(\xi)$ for a given pure state $\psi(\underline{q})$. By polarization we can obtain a sesquilinear expression: for any two pure states ψ, φ we can set up a (generally complex) Wigner distribution

$$W_{\psi,\varphi}(\xi)=(2\pi\hbar)^{-n}\int_{\mathcal{R}^n}\mathrm{d}^n q'\ \psi(\underline{q}-\tfrac{1}{2}\underline{q}')\varphi(\underline{q}+\tfrac{1}{2}\underline{q}')^*\exp(i\ \underline{p}\cdot\underline{q}'/\hbar), \tag{2.19}$$

linear in ψ and antilinear in φ. Under complex conjugation we have

$$W_{\psi,\varphi}(\xi)^*=W_{\varphi,\psi}(\xi), \tag{2.20}$$

and both the formula (2.13) and the $\mathrm{Mp}(2n)$ covariance law (2.15) can be easily extended for such objects. For some purposes such expressions may be useful, but we do not make much use of them.

While all of the foregoing is quite familiar, it is useful to make the following additional remarks. It is characteristic of the Heisenberg commutation relations (2.1) that even after quantization, i.e., within quantum mechanics, the possible (sets of simultaneous) eigenvalues of the (commuting) momenta $\hat{p}_r$ by themselves do not suffer any quantization. Thus a general set of eigenvalues $p_r, r=1,\ldots,n$ for $\hat{p}_r$ determines a general point in $\mathcal{R}^n$, just as the eigenvalues q_r of the position operators $\hat{q}_r$ do. It is ultimately this that allows us to describe quantum states for such systems via Wigner distributions over the classical phase space $T^*\mathcal{R}^n\simeq\mathcal{R}^{2n}$, a general point $(\underline{q},\underline{p})$ of which is made up of (nonsimultaneous) eigenvalue sets $\underline{q},\underline{p}$ for the (noncommuting) operator sets $\hat{q}_r,\hat{p}_r$. The appearance and use of the classical phase space here is not as a result of taking the classical or semiclassical limit of the quantum theory, but is a way of expressing the exact content of the quantum theory in a fully c-number language. The role and relevance of the groups $\mathrm{Sp}(2n,R),\mathrm{Mp}(2n)$ in Cartesian quantum mechanics can really be traced back to these facts; it makes sense to form canonical linear combinations of Cartesian $\hat{q}$'s and $\hat{p}$'s. The importance of these remarks is seen from a comparison with the case of an angle-angular momentum pair,[19] and the proper way to set up Wigner distributions in that case. We recall this briefly in the next section, emphasizing the differences compared to the Cartesian situation.

III. THE WIGNER DISTRIBUTION IN THE ANGLE-ANGULAR MOMENTUM CASE

For a classical angle variable $\theta\in(-\pi,\pi)$, the configuration space Q is the circle S^1; so at the classical level the phase space or cotangent bundle is the cylinder $T^*S^1\simeq S^1\times\mathcal{R}$. This contains, in addition to the coordinate θ, a generalized momentum, p_θ say, which can be any real number: $p_\theta\in\mathcal{R}$. Now in the quantum situation we have an angle operator $\hat{\theta}$ with eigenvalues $\theta\in(-\pi,\pi)$, and a conjugate angular momentum operator $\hat{M}$ whose eigenvalues are quantized and

are $m=0,\pm 1,\pm 2,...$, i.e., $m\in\mathcal{Z}$ and *not* $m\in\mathcal{R}$. It is unnatural in this case to write down a commutation relation between $\hat{\theta}$ and $\hat{M}$; rather their mutual relationship is best expressed through these eigenvalue and eigenvector statements,

$$\hat{\theta}|\theta\rangle=\theta|\theta\rangle,\quad \theta\in(-\pi,\pi),$$

$$\langle\theta'|\theta\rangle=\delta(\theta'-\theta), \tag{3.1a}$$

$$\hat{M}|m\rangle=m\hbar|m\rangle,\quad m\in\mathcal{Z},$$

$$\langle m'|m\rangle=\delta_{m'm}, \tag{3.1b}$$

$$\langle\theta|m\rangle=(2\pi)^{-1/2}\exp(im\theta), \tag{3.1c}$$

$$\int_{-\pi}^{\pi}\mathrm{d}\theta|\theta\rangle\langle\theta|=\sum_{m\in\mathcal{Z}}|m\rangle\langle m|=1. \tag{3.1d}$$

The Hilbert space $\mathcal{H}$ relevant here is $L^2(-\pi,\pi)\simeq\ell^2$. Now we define the bounded unitary exponentials (Weyl exponentials)

$$U(n)=\exp(in\hat{\theta}),\quad n\in\mathcal{Z},$$
$$V(\tau)=\exp(-i\tau\hat{M}),\quad \tau\in(-\pi,\pi). \tag{3.2}$$

[We do not need to define the more general $U(\sigma),V(\tau)$ for $\sigma,\tau\in\mathcal{R}$.] In contrast to the Cartesian case where both $\hat{q}$ and $\hat{p}$ are unbounded, here only $\hat{M}$ is unbounded. Then, for a given pure state $|\psi\rangle\in\ \mathcal{H}$ with wave function $\psi(\theta)=\langle\theta|\psi\rangle$, the Wigner distribution is a real function $W(\theta,m)$ of an angle θ and an integer m defined as follows:

$$W(\theta,m)=\frac{1}{2\pi}\int_{-\pi}^{\pi}\mathrm{d}\tau\,\psi(\theta+\tau/2)\psi(\theta-\tau/2)^*\ \ e^{-im\tau}, \tag{3.3}$$

the arguments of ψ and ψ^* always being in the range $(-\pi,\pi)$ via shifts of amounts $\pm 2\pi$. We note that the pair (θ,m) is not a point in the classical phase space T^*S^1, just because the ''momentum'' eigenvalue m is quantized. The definition (3.3) reproduces the marginals correctly,

$$\int_{-\pi}^{\pi}\mathrm{d}\theta\,W(\theta,m)=|\langle m|\psi\rangle|^2,$$
$$\sum_{m\in\mathcal{Z}}W(\theta,m)=|\langle\theta|\psi\rangle|^2. \tag{3.4}$$

There is an accompanying dual Weyl operator correspondence as well: it takes elementary classical exponentials on $S^1\times\mathcal{Z}$ into specific products of the U's and V's of Eq. (3.2):

$$\exp(in\theta-i\tau m)\to U(n)V(\tau)e^{-in\tau/2}=V(\tau)U(n)e^{in\tau/2},$$
$$n\in\mathcal{Z},\quad \tau\in(-\pi,\pi), \tag{3.5a}$$

$$\langle\psi|U(n)V(\tau)e^{-in\tau/2}|\psi\rangle=\int_{-\pi}^{\pi}\mathrm{d}\theta\sum_{m\in\mathcal{Z}}W(\theta,m)e^{i(n\theta-\tau m)}. \tag{3.5b}$$

[The operator exponentials in (3.5a) cannot be combined into single exponentials.] It is the case that the operators $U(n)V(\tau)e^{-in\tau/2}$ for all $n\in\mathcal{Z}$ and $\tau\in(-\pi,\pi)$ do form a complete (trace orthonormal) basis for all operators on $\mathcal{H}$; and what the Weyl rule here does is to place any operator $\hat{F}$ on $\mathcal{H}$ in correspondence with a classical function $f(\theta,m)$ on $S^1\times\mathcal{Z}$, not on $T^*S^1\simeq S^1\times\mathcal{R}$.

One appreciates that here a certain amount of quantization is already incorporated into the classical phase space structure, before the Wigner distribution can be defined in a reasonable way. There is also no room for the groups $\mathrm{Sp}(2,R)$ and $\mathrm{Mp}(2)$. These characteristic differences compared to the Cartesian case will get magnified in the case of a general Lie group.

The replacements for Eqs. (2.11) and (2.13) of the Cartesian case turn out to be as follows:

$$W(\theta,m)=\frac{1}{2\pi}\int_{-\pi}^{\pi}d\tau\langle\theta+\tau/2|\hat{\rho}|\theta-\tau/2\rangle e^{-im\tau},$$
$$\mathrm{Tr}(\hat{\rho}'\hat{\rho})=\sum_{m\in\mathcal{Z}}\int_{-\pi}^{\pi}\mathrm{d}\theta\,W'(\theta,m)W(\theta,m). \tag{3.6}$$

Thus from the latter we can see again that in general $W(\theta,m)$, though real, can become negative for some arguments.

In concluding this section, we mention one interesting case which has no Cartesian analogue. Since $\hat{M}$ has a discrete spectrum, its eigenvectors are normalizable, and in that case we find

$$|\psi\rangle=|m_0\rangle:W(\theta,m)=\frac{1}{2\pi}\delta_{m,m_0}. \tag{3.7}$$

Clearly both of Eqs. (3.4) are satisfied.

IV. CLASSICAL AND QUANTUM MECHANICS ON PHASE SPACE OF A LIE GROUP

As a preliminary step towards setting up the Wigner distribution formalism for quantum systems with kinematics based on a general Lie group, we first briefly recall the important features of the corresponding classical situation.[22]

Let G be a connected Lie group of dimension n, and let us regard it as the configuration space Q of a classical dynamical system. Then the generalized coordinate for the system is a variable element $g\in G$. The corresponding phase space T^*Q is the cotangent bundle T^*G. We can describe T^*G in intrinsic purely geometric terms, which has the advantage of being globally well defined. However from the point of view of facilitating practical calculations in any particular case, and so as to avoid being too cryptic, it is also useful to develop local coordinate based descriptions of T^*G. We outline the former first, and then turn to the latter.

Intrinsic descriptions of T^*G: As is well known, every Lie group is a parallelizable differentiable manifold. Therefore, if we denote the Lie algebra of G by $\underline{G}$, and the dual to $\underline{G}$ by $\underline{G}^*$, it turns out that T^*G is essentially the Cartesian product $G\times\underline{G}^*$. This equivalence can be established in two equally good ways, neither of which is preferred. For definiteness we identify $\underline{G}$ and $\underline{G}^*$ as the tangent and cotangent spaces to G at the identity e,

$$\underline{G}=T_eG,\quad \underline{G}^*=T_e^*G. \tag{4.1}$$

The Lie group G automatically brings with it the set of left translations L_g and the set of right translations R_g. These are mutually commuting realizations of G by mappings of G onto itself. Their definitions and main properties are

$$L_g:g'\in G\to gg'\in G,$$

$$L_{g_1}\circ L_{g_2}=L_{g_1g_2};$$

$$R_g: g'\in G\to g'g^{-1}\in G, \tag{4.2}$$

$$R_{g_1}\circ R_{g_2}=R_{g_1g_2};$$

$$L_{g_1}\circ R_{g_2}=R_{g_2}\circ L_{g_1}.$$

The corresponding tangent maps and pull backs act as nonsingular linear transformations on the tangent and cotangent spaces respectively at general points of G, according to the following scheme:

$$(L_g)_*: T_{g'}G\to T_{gg'}G,$$
$$(R_g)_*: T_{g'}G\to T_{g'g^{-1}}G, \tag{4.3a}$$

$$L_g^*: T_{g'}^*G\to T_{g^{-1}g'}^*G,$$
$$R_g^*: T_{g'}^*G\to T_{g'g}^*G. \tag{4.3b}$$

Now introduce dual bases $\{e_r\},\{e^r\}, r=1,2,\ldots,n$ for T_eG, T_e^*G,

$$\underline{G}=T_eG=\mathrm{Sp}\{e_r\},\quad \underline{G}^*=T_e^*G=\mathrm{Sp}\{e^r\},$$
$$\langle e^r,e_s\rangle=\delta_s^r,\quad r,s=1,2,\ldots,n. \tag{4.4}$$

By applying the tangent maps to $\{e_r\}$ at e, we obtain two sets of bases at each T_gG, in fact two bases for general vector fields on G,

$$X_r(g)=(R_{g^{-1}})_*(e_r),$$

$$\tilde{X}_r(g)=(L_g)_*(-e_r), \tag{4.5}$$

$$T_gG=\mathrm{Sp}\{X_r(g)\}=\mathrm{Sp}\{\tilde{X}_r(g)\}.$$

[The negative sign in the second line is to secure common commutation relations in Eq. (4.6) below.] The vector fields $\{X_r\}$ are right invariant and are the generators of the left translations L_g, while the vector fields $\{\tilde{X}_r\}$ are left invariant and generate the right translations R_g. Each set obeys the commutation relations (commutators among vector fields!) characterizing the Lie algebra $\underline{G}$ of G and involving structure constants f_{rs}^t,

$$[X_r,X_s]=f_{rs}{}^tX_t,$$

$$[\tilde{X}_r,\tilde{X}_s]=f_{rs}{}^t\tilde{X}_t, \tag{4.6}$$

$$[X_r,\tilde{X}_s]=0.$$

We naturally have two dual bases for the cotangent spaces T_g^*G:

$$T_g^*G=\mathrm{Sp}\{\theta^r(g)\}=\mathrm{Sp}\{\tilde{\theta}^r(g)\},$$

$$\langle\theta^r(g),X_s(g)\rangle=\langle\tilde{\theta}^r(g),\tilde{X}_s(g)\rangle=\delta_s^r,$$

$$\theta^r(g)=R_g^*(e^r),$$

$$\tilde{\theta}^r(g)=L_{g^{-1}}^*(-e^r). \tag{4.7}$$

In terms of these forms, the commutation relations (4.6) appear as the Maurer–Cartan relations:

$$\begin{aligned} &\mathrm{d}\theta^r+\tfrac{1}{2}f_{st}{}^r\theta^s\wedge\theta^t=0,\\ &\mathrm{d}\tilde{\theta}^r+\tfrac{1}{2}f_{st}{}^r\tilde{\theta}^s\wedge\tilde{\theta}^t=0. \end{aligned} \tag{4.8}$$

At each $g \in G$ the two sets of objects are related by the $n\times n$ matrices $\mathcal{D}(g)=(\mathcal{D}_s^r(g))$ of the adjoint representation of G (superscript=row, subscript=column index):

$$\begin{aligned} \tilde{X}_r(g)&=-\mathcal{D}_r^s(g)X_s(g),\\ \theta^r(g)&=-\mathcal{D}_s^r(g)\tilde{\theta}^s(g). \end{aligned} \tag{4.9}$$

The important point is that all these maps, objects and relationships are globally well defined.

With this geometric preparation, we can easily see in two ways why the phase space T^*G is essentially the product $G\times\underline{G}^*$. A general point in T^*G is a pair (g,ω) where $g\in G$ and $\omega \in T_g^*G$. But we can expand ω in either of the two bases $\{\theta^r(g)\},\{\tilde{\theta}^r(g)\}$ for T_g^*G, and use the expansion coefficients to synthesize elements in $T_e^*G=\underline{G}^*$,

$$\omega=\omega_r\theta^r(g)=R_g^*(\omega_r e^r)\in T_g^*G\Leftrightarrow\omega_0=\omega_r e^r\in\underline{G}^*, \tag{4.10a}$$

$$\omega=-\tilde{\omega}_r\tilde{\theta}^r(g)=L_{g^{-1}}^*(\tilde{\omega}_r e^r)\in T_g^*G\Leftrightarrow\tilde{\omega}_0=\tilde{\omega}_r e^r\in\underline{G}^*. \tag{4.10b}$$

Each of these ways of setting up correspondences gives a globally well-defined method of identifying T^*G with $G\times\underline{G}^*$. For given $\omega\in T_g^*G$, ω_0 and $\tilde{\omega}_0$ are related by the coadjoint representation of G, since

$$\tilde{\omega}_r=\mathcal{D}_r^s(g)\omega_s. \tag{4.11}$$

The above development displays the structure of the classical phase space T^*G in an intrinsic and globally well-defined manner; in particular it brings out the fact that as a bundle over the base G, T^*G is trivial. (In contrast, for example, T^*S^2 is nontrivial). Now, as stated earlier, we link up to local coordinate based descriptions more suited to practical computations and statements of Poisson bracket relations.

Local coordinate descriptions of T^*G: In general the elements of a Lie group G cannot be described with the help of coordinates in a globally smooth manner. In particular this is so if G is compact. One has to work with charts or locally defined coordinates, with well-defined transition rules in overlaps, etc. For simplicity we will work within a single chart over some open neighborhood of the identity; the setting up of a suitable notation to handle a collection of charts is in principle quite straightforward but is omitted.

Let the element $g\in G$ be labeled by n real independent continuous coordinates $q^r, r=1,2,\ldots,n$; as a convention we set $q^r=0$ at e. These q's are numerical generalized coordinates; especially in case G is compact, each of them is expected to be an angle type variable. To the set of coordinates q^r corresponds the element $g(q)\in G$. We identify the basis elements e_r, e^r for T_eG and T_e^*G, Eq. (4.4), as

$$e_r=\left(\frac{\partial}{\partial q^r}\right)_0, \quad e^r=(\mathrm{d}q^r)_0. \tag{4.12}$$

For practical convenience it is often useful to work with some faithful matrix representation of G. This has nothing to do with quantization per se, but is just a convenient way of handling G less abstractly than otherwise. In this sense let $A(q)$ be some faithful matrix representation of G; we identify its generator matrices and commutation relations by

$$\begin{aligned} A(\delta q) &\simeq 1 - i\,\delta q^r T_r, \\ [T_r, T_s] &= i f_{rs}{}^t T_t. \end{aligned} \tag{4.13}$$

The product of two elements $A(q'), A(q)$ is written as

$$A(q')A(q) = A(f(q';q)), \tag{4.14}$$

where the n functions $f^r(q';q)$ of $2n$ real arguments each express the composition law in G. Certain important auxiliary functions play an important role; their definitions and some properties are summarized here,

$$\begin{aligned} \eta_s^r(q) &= \left(\frac{\partial f^r}{\partial q'^s}(q';q) \right)_{q'=0}, \\ \tilde{\eta}_s^r(q) &= \left(\frac{\partial f^r}{\partial q'^s}(q;q') \right)_{q'=0}, \end{aligned} \tag{4.15a}$$

$$\begin{aligned} (\xi_s^r(q)) &= (\eta_s^r(q))^{-1}, \\ (\tilde{\xi}_s^r(q)) &= (\tilde{\eta}_s^r(q))^{-1}, \end{aligned} \tag{4.15b}$$

$$\begin{aligned} f(\delta q; q) &\simeq q + \eta(q)\,\delta q, \\ f(q; \delta q) &\simeq q + \tilde{\eta}(q)\,\delta q, \end{aligned} \tag{4.15c}$$

$$\begin{aligned} \eta_s^r(q) \frac{\partial A(q)}{\partial q^r} &= -i T_s A(q), \\ \tilde{\eta}_s^r(q) \frac{\partial A(q)}{\partial q^r} &= -i A(q) T_s. \end{aligned} \tag{4.15d}$$

[For matrix operations here, superscripts (subscripts) are row (column) indices.] The vector fields and one forms in Eqs. (4.5) and (4.7) have the following local expressions:

$$\begin{aligned} X_r &= \eta_r^s(q) \frac{\partial}{\partial q^s}, \quad \tilde{X}_r = -\tilde{\eta}_r^s(q) \frac{\partial}{\partial q^s}, \\ \theta^r &= \xi_s^r(q)\,\mathrm{d}q^s, \quad \tilde{\theta}^r = -\tilde{\xi}_s^r(q)\,\mathrm{d}q^s, \end{aligned} \tag{4.16}$$

and the adjoint representation matrices $\mathcal{D}(g)$ are given by the product

$$\mathcal{D}(g(q)) = \xi(q)\,\tilde{\eta}(q). \tag{4.17}$$

In the sense of classical canonical mechanics when we go to T^*G we have (local) canonically conjugate momentum variables $p_r, r = 1,2,\ldots,n$; and the basic classical Poisson bracket (PB) relations are

$$\{q^r, p_s\} = \delta_s^r, \quad \{q^r, q^s\} = \{p_r, p_s\} = 0. \tag{4.18}$$

As for the ranges of these variables, while the structure of G determines the nature of the q^r, it is generally assumed that each p_r ranges independently over the entire real line $\mathcal{R}$. In other words, $T^*_g G \simeq \mathcal{R}^n$ at each $g \in G$.

While both the coordinates q^r and the momenta p_r have so far a local character, it is possible to replace the latter by certain q-dependent linear combinations which are then globally well defined. They express the structure of the phase space T^*G in a much more natural way. We get a clue to their definitions by noticing, upon combining the PB relations

$$\{A(q), p_r\} = \frac{\partial A(q)}{\partial q^r} \tag{4.19}$$

with Eq. (4.15d), that

$$\begin{aligned} \{A(q), \eta^r_s(q) p_r\} &= -iT_s A(q), \\ \{A(q), -\tilde{\eta}^r_s(q) p_r\} &= iA(q) T_s . \end{aligned} \tag{4.20}$$

These relations lead us to define generalized canonical momentum like variables $J_r, \tilde{J}_r$ as follows:

$$J_r = \eta^s_r(q) p_s , \quad \tilde{J}_r = -\tilde{\eta}^s_r(q) p_s . \tag{4.21}$$

The connection between the two sets is

$$\tilde{J}_r = -\mathcal{D}^s_r(g(q)) J_s , \tag{4.22}$$

and, consistent with Eqs. (4.13) and (4.15d), their PB relations are

$$\begin{aligned} \{J_r, J_s\} &= f_{rs}{}^t J_t , \\ \{\tilde{J}_r, \tilde{J}_s\} &= f_{rs}{}^t \tilde{J}_t , \\ \{J_r, \tilde{J}_s\} &= 0. \end{aligned} \tag{4.23}$$

The complete coordinate-based description of the basic PB relations obtaining on T^*G can now be given in many equally good ways, and we list all of them (allowing for some repetition):

$$\{q^r, q^s\} = 0, \tag{4.24a}$$

$$\begin{aligned} \{q^r, J_s\} &= \eta^r_s(q), \\ \{q^r, \tilde{J}_s\} &= -\tilde{\eta}^r_s(q), \\ \{A(q), J_r\} &= -iT_r A(q), \\ \{A(q), \tilde{J}_r\} &= iA(q) T_r , \end{aligned} \tag{4.24b}$$

$$\begin{aligned} \{J_r, J_s\} &= f_{rs}{}^t J_t , \\ \{J_r, \tilde{J}_s\} &= 0, \\ \{\tilde{J}_r, \tilde{J}_s\} &= f_{rs}{}^t \tilde{J}_t . \end{aligned} \tag{4.24c}$$

It is thus best to view the set of J_r (or $\tilde{J}_r$) as the covariant momentum canonically conjugate to the group element $g \in G$ as a generalized coordinate.

At this point, in the present framework, we recognize that the Lie group underlying the kinematic structure of Cartesian quantum mechanics for n degrees of freedom, expressed by the Heisenberg commutation relations (2.1) and (2.3), is the Abelian translation group $G=\mathcal{R}^n$ in n real dimensions. In this case, the coordinates $q^r, r=1,2,\ldots,n$ denoting an element of $\mathcal{R}^n$ are globally well defined, and $T^*G=T^*\mathcal{R}^n\simeq\mathcal{R}^{2n}$, corresponding to the Cartesian phase space q's and p's. Due to the group being Abelian, the structure constants vanish; the $n\times n$ matrices $\eta(q),\xi(q),\tilde{\eta}(q),\tilde{\xi}(q)$ of Eq. (4.15a) and (4.15b) all reduce to the identity matrix; the momenta J_r and $\tilde{J}_r$ essentially coincide as $J_r=-\tilde{J}_r=p_r$; and the PB relations (4.24) reduce to the familiar classical forms for which the Heisenberg relations (2.1) are the quantized version. We have no difficulty in principle in postulating quantum kinematics through these commutation relations.

However the angle-angular momentum case briefly described in Sec. III corresponds to the group $G=\mathrm{U}(1)\simeq\mathrm{SO}(2)$ which is of course also Abelian. But one immediately sees new features emerging. For instance, the angle variable θ is not a globally well-defined coordinate over G. It is also not very satisfactory, due to operator domain problems, to postulate simple minded Heisenberg-type commutation relations between $\hat{\theta}$ and its canonical conjugate $\hat{M}$ in the quantum case. This is over and above the fact that now $\hat{M}$ is quantized. Thus in the $G=\mathrm{SO}(2)$ case, it is better to base the treatment on the set of relations for operators, eigenvalues, and eigenvectors collected in Eqs. (3.1).

Turning to a general Lie group G where the classical PB structure on T^*G is conveyed by any of the forms given in Eqs. (4.24), it should be evident that we should not base the quantum kinematics on a naive set of commutation relations for operator forms of the group coordinates q^r and the momenta $J_r,\tilde{J}_r$. Rather, while the latter can be satisfactorily handled (and this just involves the representation theory of G), the treatment of the abstract group element g as a coordinate operator after quantization has to be handled somewhat differently.

Quantum kinematics for the Lie group case: We now motivate the forms of the replacements for the Heisenberg canonical commutation relations (2.1) and (2.4) when we consider a quantum system whose configuration space Q is a Lie group G. Just as we identified $G=\mathcal{R}^n$ for n-dimensional Cartesian quantum mechanics, where we know that the Schrödinger wave functions are complex valued square integrable functions on $\mathcal{R}^n$, we should now expect that the Schrödinger wave functions should be complex valued square integrable (in a suitable sense) functions on G. The question now is: with what algebraic operator relations do we replace the earlier canonical $\hat{q}-\hat{p}$ commutation relations?

If we try to avoid the use of (local) coordinates for group elements, in the interests of being as intrinsic as possible, we might be tempted to imagine the following: upon quantization, the classical generalized coordinate $g\in G$ is replaced by an ''operator $\hat{g}$'' for which the possible ''eigenvalues'' are the classical abstract group elements. However this seems excessively formal. A more reasonable strategy would be to first set up a classical commutative algebra $\mathcal{A}$, say, of all smooth, i.e., $\mathcal{C}^\infty$, real valued functions $f(g)$ on G,

$$\begin{gathered} g \in G\to f(g) \in \mathcal{R}: f \in \mathcal{A}, \\ f_1,f_2 \in \mathcal{A}\Rightarrow c_1f_1+c_2f_2, f_1f_2 \in \mathcal{A}. \end{gathered} \tag{4.25}$$

Here the c's are real numbers, and the above choice of functions $f\in\mathcal{A}$ captures the differentiable manifold structure of G. The left and right translations L_g,R_g of Eq. (4.2) now act on $\mathcal{A}$ as follows:

$$\begin{gathered} \text{Left action,} \quad g'\in G: f(g)\to f(g'^{-1}g), \\ \text{Right action,} \quad g'\in G: f(g)\to f(gg'). \end{gathered} \tag{4.26}$$

Upon quantization we ask for an Abelian operator algebra $\hat{\mathcal{A}}$, say, consisting of Hermitian operators such that in a natural way we ensure

$$f \in \mathcal{A} \to \hat{f} \in \hat{\mathcal{A}},$$

$$f_1, f_2 \in \mathcal{A} \Rightarrow c_1 f_1 + c_2 f_2 \to c_1 \hat{f}_1 + c_2 \hat{f}_2, \tag{4.27}$$

$$f_1 f_2 \to \hat{f}_1 \hat{f}_2 .$$

This is the replacement for the $\hat{q}-\hat{q}$ part of the canonical relations (2.1), and is the quantized version of the PB relations $\{q^r, q^s\} = 0$ in Eq. (4.24a), in a globally well-defined form.

Turning to the quantization of the remaining PB relations in Eqs. (4.24b) and (4.24c), we can work either with finite group elements or with infinitesimal generators. In the former, we ask for unitary operator families $V(g), \tilde{V}(g)$ realizing the left and right translation groups on G, and producing on $\hat{\mathcal{A}}$ the effects implied by Eq. (4.26),

$$f(g) \in \mathcal{A} \to \hat{f} \in \hat{\mathcal{A}} \Rightarrow$$

$$f(g'^{-1} g) \to V(g') \hat{f} V(g')^{-1}, \tag{4.28a}$$

$$f(gg') \to \tilde{V}(g') \hat{f} \tilde{V}(g')^{-1}, \quad g' \in G,$$

$$V(g_1) V(g_2) = V(g_1 g_2),$$

$$\tilde{V}(g_1) \tilde{V}(g_2) = \tilde{V}(g_1 g_2), \tag{4.28b}$$

$$V(g_1) \tilde{V}(g_2) = \tilde{V}(g_2) V(g_1). \tag{4.28c}$$

The operator relations (4.28a) are the quantized and finite forms of the PB relations in (4.24b) involving $\{q^r$ or $A(q)$, J_s or $\tilde{J}_s\}$; while the operator relations (4.28b) and (4.28c) are the integrated forms of the result of quantizing the PB relations (4.24c) keeping track of course of the global connectivity properties of G. The latter can also be expressed at the generator level. If the generators of $V(g), \tilde{V}(g)$ are $\hat{J}_r, \hat{\tilde{J}}_r$, respectively, we require them to be Hermitian and to obey

$$[\hat{J}_r, \hat{J}_s] = i f_{rs}{}^t \hat{J}_t,$$

$$[\hat{\tilde{J}}_r, \hat{\tilde{J}}_s] = i f_{rs}{}^t \hat{\tilde{J}}_t,$$

$$[\hat{J}_r, \hat{\tilde{J}}_s] = 0, \tag{4.29}$$

$$\hat{\tilde{J}}_r = -\mathcal{D}_r^s(g) \hat{J}_s .$$

In comparison to the canonical commutation relations (2.1), we see that Eq. (4.28a) correspond to the $\hat{q}-\hat{p}$ part, and Eqs. (4.28b), (4.28c), and (4.29) correspond to the $\hat{p}-\hat{p}$ part, respectively. Thus the complete set of algebraic relations expressing quantum kinematics for quantum mechanics on a Lie group as configuration space are Eqs. (4.27), (4.28a)–(4.28c), (4.29). These have to be realized irreducibly on a suitable Hilbert space.

A clarifying remark may be made at this point. If we were looking only for a unitary representation (UR) or unitary irreducible representation (UIR) of G, the only commutation relations to be satisfied would be those among the Hermitian generators, $\hat{J}_r$ say, of such a UR or UIR. But these comprise only a part—the $\hat{p}-\hat{p}$ part—of the complete set of algebraic relations developed above; and do not include the operators in $\hat{\mathcal{A}}$ which represent smooth functions on G and which capture the notion of position operator in this case. Conversely, a single UIR of G on some Hilbert space, over which the $\hat{J}_r$ act irreducibly, is here the analogue of a single simultaneous (ideal)

eigenvector of all the (commuting) momenta $\hat{p}_r$. The latter is always one dimensional because $\mathcal{R}^n$ is Abelian—there is just one (ideal) eigenvector $|\underline{p}\rangle$ of the $\hat{p}_r$ for given eigenvalues p_r. With a general non-Abelian Lie group G, the analogue of a ''momentum eigenstate'' is a (finite or infinite dimensional) UIR of G.

A natural representation of all the algebraic relations imposed above is via the regular representation of G. We will hereafter always assume that there is a unique (up to a factor) left and right translation invariant volume element $\mathrm{d}g$ on G, the Haar measure, which in the compact case will be normalized so that G has total volume unity,

$$f \in \mathcal{A}: \int_G \mathrm{d}g\, f(g) = \int_G \mathrm{d}g\, f(g'^{-1}g) = \int_G \mathrm{d}g\, f(gg'),$$
$$\int_G \mathrm{d}g = 1 \quad \text{if} \quad G \quad \text{compact.} \tag{4.30}$$

In local coordinates q^r for G, apart from a normalization factor, this volume element involves the determinants of the matrices $\xi(q)$, $\tilde{\xi}(q)$ defined in (4.15b),

$$\mathrm{d}g = \det(\xi(q))\mathrm{d}^n q = \det(\tilde{\xi}(q))\mathrm{d}^n q. \tag{4.31}$$

Then the Hilbert space $\mathcal{H} = L^2(G)$ is defined, in the ''Schrödinger representation,'' as

$$\mathcal{H} = \left\{ \psi(g) \in \mathcal{C} | \|\psi\|^2 = \int_G \mathrm{d}g\, |\psi(g)|^2 < \infty \right\}. \tag{4.32}$$

On this space the required operators $\hat{f} \in \hat{\mathcal{A}}, V(g'), \tilde{V}(g')$ are easily defined,

$$f(g) \in \mathcal{A} \to \hat{f} \in \hat{\mathcal{A}}: \quad (\hat{f}\psi)(g) = f(g)\psi(g),$$
$$(V(g')\psi)(g) = \psi(g'^{-1}g), \tag{4.33}$$
$$(\tilde{V}(g')\psi)(g) = \psi(gg').$$

This is indeed an irreducible representation of the complete algebraic system as is shown in Appendix A.

In local coordinates if we write $\psi(g)$ as $\psi(q)$, the generators $\hat{J}_r, \hat{\tilde{J}}_r$ are immediately obtained as

$$\hat{J}_r = -i\eta_r^s(q)\frac{\partial}{\partial q^s},$$
$$\hat{\tilde{J}}_r = i\tilde{\eta}_r^s(q)\frac{\partial}{\partial q^s}, \tag{4.34}$$
$$V(\delta q) \simeq 1 - i\delta q^r \hat{J}_r, \quad \tilde{V}(\delta q) \simeq 1 - i\delta q^r \hat{\tilde{J}}_r.$$

Thus these generators are essentially the vector fields $X_r, \tilde{X}_r$ defined earlier in Eqs. (4.5) and (4.16), but now interpreted as Hermitian operators on $L^2(G)$.

It is for the elements $|\psi\rangle$ in the Hilbert space $\mathcal{H}$ of Eq. (4.32) that we wish to set up a Wigner distribution formalism with natural properties.

V. NEW FEATURES TO BE ACCOMMODATED

For Cartesian quantum mechanics we have the well-known Stone–von Neumann theorem which states that up to unitary equivalence there is only one irreducible representation of Hermitian operators $\hat{q}_r, \hat{p}_r$ obeying the Heisenberg relations (2.1). This irreducible representation is of course describable in many ways—position representation with $\hat{q}_r$ diagonal; momentum representation with $\hat{p}_r$ diagonal; Fock basis; coherent states, etc. When $\mathcal{R}^n$ here is replaced by a general Lie group G, we have already appreciated that the basic building block for the quantum theory is *not* a UIR of G, but an irreducible representation of the entire algebraic system consisting of $\hat{\mathcal{A}}, V(\cdot)$ and $\tilde{V}(\cdot)$. A single UIR of G is too small to support the action of a group element as a generalized coordinate. To achieve this many UIR's of G have to be put together in a careful manner.

As for UIR's of G, we recall several familiar facts. If G is compact, every UIR is finite dimensional. If G is noncompact simple, then every nontrivial UIR is infinite dimensional; every finite-dimensional representation is nonunitary; and in addition there are infinite dimensional nonunitary representations.

We will for the most part and for definiteness consider the case of a compact simple Lie group G. A natural irreducible representation of the entire algebraic structure we are interested in is given, as we have seen, by the regular representation. The main features and auxiliary operators associated with it, and some notations, are given in Appendix A.

In passing we mention the fact that while for compact G every UIR is seen in the regular representation, in the noncompact case there are UIR's (the exceptional series) not contained in the regular representation.

One last general comment is important before proceeding. As we have seen in general the momenta of our problem are noncommuting operators. This is a genuine new feature absent in Cartesian quantum mechanics, and it has significant consequences. We have seen hints of this in the angle-angular momentum case in Sec. III, even though there was only one momentum $\hat{M}$ involved. For general G, the momenta $\hat{J}_r, \hat{\tilde{J}}_r$ cannot all be simultaneously diagonal and their spectra undergo quantization. Therefore the space of arguments of the Wigner distribution has to be carefully chosen; it is definitely not a function on the classical phase space T^*G in general. By the same token, there are in general no analogues to the groups $\mathrm{Sp}(2n,R), \mathrm{Mp}(2n)$ which are so important in the Cartesian case.

VI. THE WIGNER DISTRIBUTION IN THE REGULAR REPRESENTATION

Let $|\psi\rangle \in \mathcal{H} = L^2(G)$ be a normalized state vector. The corresponding ''position space'' probability density is a probability distribution on the group G given by [cf. Eq. (A5)],

$$|\psi(g)|^2 = |\langle g|\psi\rangle|^2. \tag{6.1}$$

The complementary ''momentum space'' probability distribution is (assuming G to be compact) a discrete set of probabilities indexed by the quantum numbers JMN and given by [cf. Eq. (A14)]

$$|\psi_{JMN}|^2 = |\langle JMN|\psi\rangle|^2. \tag{6.2}$$

The common normalization states that

$$\|\psi\|^2 = \int_G \mathrm{d}g\, |\psi(g)|^2 = \sum_{JMN} |\psi_{JMN}|^2 = 1. \tag{6.3}$$

At first glance we might suppose that, given $|\psi\rangle$, the corresponding Wigner distribution $W(\cdots)$ should be a real function with g and JMN (coordinates and quantized momenta) as arguments, bilinear in ψ (more precisely involving one ψ factor and one ψ^* factor), such that integration over g yields $|\psi_{JMN}|^2$ while summation over JMN yields $|\psi(g)|^2$. This would be a natural way in

which the marginals (6.1) and (6.2) are reproduced. However, we should also require covariance under both (left and right) actions by G on ψ: the choice of the arguments in $W(\cdots)$ should allow for a natural linear transformation law under each of the changes $\psi(g)\to\psi(g_1^{-1}g)$ and $\psi(g)\to\psi(gg_2)$ in ψ. Now the momentum space amplitudes ψ_{JMN} of ψ transform linearly as follows [cf. Eq. (A14)]:

$$
\begin{aligned}
&|\psi'\rangle = V(g_1)|\psi\rangle, \quad \psi'(g) = \psi(g_1^{-1}g),\\
&\psi'_{JMN} = \sum_{M'} \mathcal{D}^J_{MM'}(g_1)^* \psi_{JM'N},\\
&|\psi''\rangle = \tilde{V}(g_2)|\psi\rangle, \quad \psi''(g) = \psi(gg_2),\\
&\psi''_{JMN} = \sum_{N'} \mathcal{D}^J_{N'N}(g_2^{-1})^* \psi_{JMN'}.
\end{aligned}
\tag{6.4}
$$

Thus in each case there is a linear mixing of the components ψ_{JMN} for fixed J at the ψ level. Remembering that $W(\cdots)$ should involve the bilinear expressions $\psi\psi^*$, a little reflection shows that it would be too narrow to imagine that the Wigner distribution should be some real function $W(g;JMN)$: there would be too few momentum space arguments to support the changes (6.4) in ψ in a reasonable manner.

There is another way in which this situation could be described. As we have already pointed out in Sec. V, an essential new feature is that now the analogue of the single momentum eigenket $|\underline{p}\rangle$ in Cartesian quantum mechanics is a multidimensional object, an entire UIR of G; actually in the regular representation even more since both $\hat{J}$'s and $\hat{\tilde{J}}$'s have to be represented. In this sense, with a general Lie group G different from $\mathcal{R}^n$, there is a genuine asymmetry between positions and momenta. While the analogue of position eigenstate remains one dimensional, $|\underline{q}\rangle$ being replaced by $|g\rangle$, the momentum operators constitute the noncommutative algebra of $\hat{J}$'s and $\hat{\tilde{J}}$'s, leading to the quantum numbers JMN where only J remains fixed. (Incidentally the first part of this statement is not in conflict with the fact that G itself may be non-Abelian. In local coordinates q^r for G, the ideal ket $|g\rangle$ may be written as $|\underline{q}\rangle$, and all the q's are simultaneously diagonal.) Out of all the momentum operators, a complete commuting set consists of the (shared) Casimir operators formed out of the $\hat{J}$'s, and separately out of the $\hat{\tilde{J}}$'s, accounting for J in the set JMN; a maximal commuting subset of the $\hat{J}$'s, supplying some of the labels in M; a similar maximal commuting subset of the $\hat{\tilde{J}}$'s supplying the analogous labels in N; and further nonlinear mutually commuting expressions in $\hat{J}$'s (respectively, $\hat{\tilde{J}}$'s) to account for the remaining labels in M (respectively, N). The main point is that in the process of obtaining the marginal distribution (6.2) upon integrating the Wigner distribution with respect to its argument g, we should expect at first to get something like a density matrix within the Jth subspace of momentum labels, and then upon going to the diagonal elements recover the probabilities $|\psi_{JMN}|^2$. The transformation laws (6.4) can already be written in a matrix form (at the level of ψ, not of the density matrix) thus,

$$
\psi^{(J)} = (\psi_{JMN}) : |\psi\rangle \to V(g_1)\tilde{V}(g_2)|\psi\rangle \Rightarrow \psi^{(J)} \to \mathcal{D}^J(g_1)^* \psi^{(J)} \mathcal{D}^J(g_2^{-1})^*. \tag{6.5}
$$

Since the individual probabilities $|\psi_{JMN}|^2$ do not transform linearly among themselves under such G actions, but do bring in off-diagonal quantities, the structure of the Wigner distribution will inevitably reflect this fact.

Based on these considerations we now list the basic desired properties for the Wigner distribution $W(\cdots)$ associated with a given normalized $|\psi\rangle \in \mathcal{H}$ (for simplicity the dependence of the former on the latter is left implicit) initially as

$$\psi(g)\in\mathcal{H}\rightarrow W(g;JMN\quad M'N'),$$
$$W(g;JMN\quad M'N')^*=W(g;JM'N'\quad MN), \tag{6.6a}$$

$$\int_G \mathrm{d}g\, W(g;JMN\quad MN)=|\psi_{JMN}|^2, \tag{6.6b}$$
$$\sum_{JMN} W(g;JMN\quad MN)=|\psi(g)|^2,$$

$$\psi'(g)=\psi(g_1^{-1}g)\rightarrow W'(g;JMN\quad M'N')$$
$$=\sum_{M_1M_1'}\mathcal{D}^J_{MM_1}(g_1)D^J_{M'M_1'}(g_1)^*W(g_1^{-1}g;JM_1N\quad M_1'N'), \tag{6.6c}$$

$$\psi''(g)=\psi(gg_2)\rightarrow W''(g;JMN\quad M'N')$$
$$=\sum_{N_1N_1'} W(gg_2;JMN_1M'N_1')\mathcal{D}^J_{N_1N}(g_2^{-1})\mathcal{D}^J_{N_1'N'}(g_2^{-1})^*. \tag{6.6d}$$

One can see that the covariance conditions (6.6c) and (6.6d) are compatible with the transformation laws (6.4) for ψ_{JMN} and the requirement (6.6b) for reproduction of the marginals. Actually one has little option but to extend the requirement in the first of Eq. (6.6b) to read

$$\int_G \mathrm{d}g\, W(g;JMN\quad M'N')=\psi^*_{JMN}\quad\psi_{JM'N'}. \tag{6.7}$$

Upon then setting $M'=M,N'=N$ here one recovers the true probabilities $|\psi_{JMN}|^2$. To all of the above we add a natural condition that W be of the general structure $\psi\psi^*$.

We now propose the following form for the Wigner distribution:

$$W(g;JMNM'N')=N_J\int_G \mathrm{d}g'\int_G \mathrm{d}g''\,\delta(g^{-1}s(g',g''))\mathcal{D}^J_{MN}(g')\psi(g')^*\mathcal{D}^J_{M'N'}(g'')^*\psi(g''). \tag{6.8}$$

This involves a group element $s(g',g'')\in G$ depending on two arguments also drawn from G, which must have suitable covariance and other properties. The set of conditions (6.6a)–(6.6d), and (6.7) now translates into a set of requirements on this function $s:G\times G\rightarrow G$ which are

$$g',g''\in G\rightarrow s(g',g'')\in G,$$
$$s(g',g'')=s(g'',g'),$$
$$s(g',g')=g', \tag{6.9}$$
$$s(g_1g'g_2^{-1},g_1g''g_2^{-1})=g_1s(g',g'')g_2^{-1}.$$

Any choice of a function $s(g',g'')$ obeying these conditions leads to an acceptable definition of a Wigner distribution for quantum mechanics on a (compact) Lie group G.

The second and third lines of Eq. (6.9) suggest that we view $s(g',g'')$ as a kind of symmetric square root of the product of two (generally noncommuting) group elements $g',g''\in G$. The covariance conditions in the last line help us simplify the problem to the choice of a suitable function $s_0(g')$ of a single argument drawn from G, obeying conditions that ensure (6.9),

$$
\begin{aligned}
s(e,g)&=s_0(g),\\
s(g',g'')&=g's_0(g'^{-1}g''),\\
s_0(e)&=e,\\
s_0(g^{-1})&=g^{-1}s_0(g),\\
s_0(g'gg'^{-1})&=g's_0(g)g'^{-1}.
\end{aligned}
\tag{6.10}
$$

It is a consequence of these conditions on $s_0(g)$ that

$$
s_0(g)g=gs_0(g). \tag{6.11}
$$

We now present a solution to the above problem in the case of a compact simple Lie group G. Any such group carries a unique Riemannian metric defined in terms of the structure constants, and possessing left and right translation invariances. We shall content ourselves with a local coordinate description and use the notations of Eqs. (4.12)–(4.17). Admitting the over use of the letter g, at the identity the metric tensor has components

$$
g_{rs}(0)=-f_{ru}{}^{v}f_{sv}{}^{u}, \tag{6.12}
$$

the negative sign ensuring that the matrix $(g_{rs}(0))$ is positive definite. This tensor is checked to be invariant under the action by the adjoint representation

$$
\mathcal{D}^{u}_{r}(g)\mathcal{D}^{v}_{s}(g)g_{uv}(0)=g_{rs}(0). \tag{6.13}
$$

At a general point $g(q)\in G$ we obtain $g_{rs}(q)$ by shifting $g_{rs}(0)$ as a tensor to $g(q)$ using either left or right translation; on account of (6.13) the two results are the same and we find

$$
g_{rs}(q)=\xi^{u}{}_{r}(q)\xi^{v}{}_{s}(q)g_{uv}(0)=\tilde{\xi}^{u}{}_{r}(q)\tilde{\xi}^{v}{}_{s}(q)g_{uv}(0). \tag{6.14}
$$

Geodesics in G are curves of minimum length with respect to the above Riemannian metric. As is well known, both left and right translations, L_g and R_g, applied pointwise map geodesics onto geodesics. Thus if $g(q(\sigma))\in G$ is a solution to the variational problem

$$
\delta\int_{\sigma_1}^{\sigma_2}\mathrm{d}\sigma\left(g_{rs}(q(\sigma))\frac{\mathrm{d}q^{r}(\sigma)}{\mathrm{d}\sigma}\frac{\mathrm{d}q^{s}(\sigma)}{\mathrm{d}\sigma}\right)^{1/2}=0, \tag{6.15}
$$

where we assume an affine parametrization is chosen so that

$$
g_{rs}(q(\sigma))\frac{\mathrm{d}q^{r}(\sigma)}{\mathrm{d}\sigma}\frac{\mathrm{d}q^{s}(\sigma)}{\mathrm{d}\sigma}=\text{const}, \tag{6.16}
$$

then both $L_{g_1}g(q(\sigma))$ and $R_{g_2}g(q(\sigma))$ are solutions to the same variational problem.

We now use geodesics in G to construct the function $s_0(g)$. It is a fact that for almost all $g\in G$ (i.e., except for a set of measure zero), there is a unique geodesic [minimizing the functional appearing in Eq. (6.15)] running from the identity e to g. We assume the affine parametrization is normalized so that the geodesic passes through e at $\sigma=0$ and through g at $\sigma=1$,

$$
g\in G: g(q(0))=e,\quad g(q(1))=g. \tag{6.17}
$$

We then take $s_0(g)$ to be the half-way point reached at $\sigma=1/2$,

$$
s_0(g)=g(q(1/2)). \tag{6.18}
$$

It is a matter of easy verification that all the conditions (6.10) are indeed obeyed: one has to exploit the natural covariance and other properties of general geodesics. With this we have solved the problem of defining Wigner distributions for quantum mechanics on a (compact) Lie group, possessing all the properties listed in Eqs. (6.6a)–(6.6d), and (6.7). The fact that $s_0(g)$ is defined everywhere except possibly on a set of vanishing measure causes no problems in carrying out integrations over G, or in recovering the marginals.

It may be pointed out that for a general pair of elements $g',g'' \in G$ (except in cases amounting to a set of vanishing measure) there is a unique geodesic running from g' to g'', normalized so that the affine parameter has values $\sigma=0$ and $\sigma=1$ at start and at finish. This geodesic is the result of applying $L_{g'}$ to the geodesic from e to $g'^{-1}g''$, or equally well of applying $R_{g'^{-1}}$ to the one from e to $g''g'^{-1}$. In either view, $s(g',g'')$ is the midpoint of this geodesic, reached at $\sigma=1/2$. Moreover, geodesics passing through the identity e are one-parameter subgroups in G. If we define $s_0(g)$ in Eq. (6.18) to be the square root of the element g, we can write the general quantity $s(g',g'')$ in these suggestive ways,

$$s(g',g'')=g'(g'^{-1}g'')^{1/2}=g''(g''^{-1}g')^{1/2}=(g''g'^{-1})^{1/2}g'=(g'g''^{-1})^{1/2}g''. \tag{6.19}$$

The definition (6.8) of the Wigner distribution associated with a pure state $\psi(g)$ generalizes to a mixed state with density operator $\hat{\rho}$,

$$W(g;JMN\ \ M'N')=N_J\int_G dg'\int_G dg''\,\delta(g^{-1}s(g',g''))\langle g''|\hat{\rho}|g'\rangle \mathcal{D}^J_{MN}(g')\ \ \mathcal{D}^J_{M'N'}(g'')^*,$$

$$\int dg\, W(g;JMN\ \ M'N')=\langle JM'N'|\hat{\rho}|JMN\rangle, \tag{6.20}$$

$$\sum_{JMN} W(g;JMN\ \ MN)=\langle g|\hat{\rho}|g\rangle.$$

We now verify that $W(g;JMN\ \ M'N')$ is a faithful representation of $\hat{\rho}$ in the sense that it contains complete information concerning $\hat{\rho}$. This will be shown by developing analogues to the previous Eqs. (2.13) and (3.6); in fact we will find two separate analogues.

The Wigner distribution in Eq. (6.20) transforms according to Eqs. (6.6c) and (6.6d) under independent left and right translations. By setting $N=N'$ and then summing over N, we obtain, using (A9), a slightly simpler function, $\tilde{W}$ say, corresponding to the density operator $\hat{\rho}$,

$$\tilde{W}(g;JMM')=\sum_N W(g;JMN\ \ M'N)$$

$$=N_J\int_G dg'\int_G dg''\,\delta(g^{-1}s(g',g''))\langle g''|\hat{\rho}|g'\rangle \mathcal{D}^J_{MM'}(g'g''^{-1})\ \ . \tag{6.21}$$

This auxiliary function is invariant under right translations except for a change of argument $g \to gg_2$, while under left translations it transforms in a manner similar to Eq. (6.6d). Now consider two density operators $\hat{\rho}_1$ and $\hat{\rho}_2$, with associated functions $\tilde{W}_1$ and $\tilde{W}_2$. It can then be shown that we can obtain $\mathrm{Tr}(\hat{\rho}_1\hat{\rho}_2)$ from $\tilde{W}_1$ and $\tilde{W}_2$ by summing over all the arguments,

$$\sum_{JMM'} N_J^{-1}\int dg\, \tilde{W}_1(g;JMM')\tilde{W}_2(g;JM'M)=\mathrm{Tr}(\hat{\rho}_1\hat{\rho}_2). \tag{6.22}$$

The proof is presented in Appendix B. Since any density operator $\hat{\rho}_1$ is fully determined by the traces of its products with all other density operators $\hat{\rho}_2$, we can see that even the simpler function $\tilde{W}(g;JMM')$ fully characterizes $\hat{\rho}$.

Obviously another analogue to Eqs. (2.13) and (3.6) can be obtained by interchanging the roles of left and right translations in the above. If in place of (6.21) we define

$$\tilde{\tilde{W}}(g;JNN')=\sum_M W(g;JMN\ \ MN')$$
$$=N_J\int_G dg'\int_G dg''\,\delta(g^{-1}s(g',g''))\langle g''|\hat{\rho}|g'\rangle\mathcal{D}^J_{N'N}(g''^{-1}g'), \tag{6.23}$$

then for two density operators $\hat{\rho}_1$, $\hat{\rho}_2$ we have

$$\sum_{JNN'} N_J^{-1}\int dg\ \tilde{\tilde{W}}_1(g;JNN')\tilde{\tilde{W}}_2(g;JN'N)=\mathrm{Tr}(\hat{\rho}_1\hat{\rho}_2). \tag{6.24}$$

The conclusion we can draw, in interesting contrast to the Cartesian and Abelian cases, is this. In order to be able to recover the marginal probability distributions $\langle g|\hat{\rho}|g\rangle$, $\langle JMN|\hat{\rho}|JMN\rangle$ in natural ways and also to have simple transformation behaviors under both left and right translations on G, we need to define the Wigner distribution as in Eqs. (6.8) and (6.20) with independent arguments $g\ J\ M\ N\ M'\ N'$. However, this object captures information contained in $\hat{\rho}$ in an over complete manner, since $\hat{\rho}$ is in fact completely determined in principle already by $\tilde{W}(g;JMM')$ [or $\tilde{\tilde{W}}(g;JNN')$]. All this is traceable to the fact that for non-Abelian G, the UIR's are in general multidimensional, so the concept of momentum eigenstate is also a multidimensional set of vectors.

VII. RECOVERY OF THE CARTESIAN AND ANGLE-ANGULAR MOMENTUM CASES, AND THE SU(2) CASE

We now indicate briefly how the known earlier results of Secs. II and III can be immediately recovered from the definitions of the preceding section. The expression (6.8) for the Wigner distribution $W(g;\ JMNM'N')$ uses the function $s(g',g'')$ depending symmetrically on the group elements g',g'', and is itself a group element obeying the conditions in (6.9). For the case of a compact simple Lie group G with nontrivial Cartan–Killing metric and associated geodesics, we have found a solution for $s(g',g'')$ in terms of the mid point rule. If however G is Abelian we can directly give an elementary solution for $s(g',g'')$ not using the geodesic construction at all.

For Cartesian quantum mechanics we have $G=\mathcal{R}^n$, which is Abelian. Consequently each UIR of G is one-dimensional and corresponds to a definite numerical momentum vector

$$\underline{q}\in G\rightarrow e^{i\underline{q}\cdot\underline{p}/\hbar},\underline{p}\in\mathcal{R}^n. \tag{7.1}$$

We can regard the continuous vector $\underline{p}\in\mathcal{R}^n$ (actually dual to G, the space of characters) as the analogue of the label J of the preceding section, and as each UIR is one dimensional there is no need and no room for the labels $M\ N\ M'\ N'$. If we present the usual definition (2.11) in the form

$$W(\underline{q},\underline{p})=(2\pi\hbar)^{-n}\int_{\mathcal{R}^n}d^nq'\int_{\mathcal{R}^n}d^nq''\,\delta^{(n)}(\underline{q}-\underline{s}(\underline{q}',\underline{q}''))\langle\underline{q}''|\hat{\rho}|\underline{q}'\rangle$$
$$\times\exp(i\underline{q}'\cdot\underline{p}/\hbar)\exp(-i\underline{q}''\cdot\underline{p}/\hbar),$$
$$\underline{s}(\underline{q}',\underline{q}'')=\tfrac{1}{2}(\underline{q}'+\underline{q}''), \tag{7.2}$$

we see that all the conditions (6.9) are indeed obeyed and this familiar case is seen to be a special case of our general construction.

The key point is that our construction of the Wigner distribution only depends on finding the group element $s(g',g'')$. We may use the geodesic construction if it is available, but can use any other method if a metric on G and geodesics are not available.

Turning to the compact case $G=\mathrm{SO}(2)$, this is again Abelian, so each UIR is one dimensional,

$$\theta\in G\to e^{im\theta},\quad m=0,\pm1,\pm2,\ldots. \tag{7.3}$$

We can now write the Wigner distribution (3.6) as

$$W(\theta,m)=\frac{1}{2\pi}\int_{-\pi}^{\pi}\mathrm{d}\theta'\int_{-\pi}^{\pi}\mathrm{d}\theta''\,\delta(\theta-s(\theta',\theta''))\langle\theta''|\hat{\rho}|\theta'\rangle\exp(im\theta')\exp(-im\theta'')\quad,$$

$$s(\theta',\theta'')=\tfrac{1}{2}(\theta'+\theta'')\mod 2\pi, \tag{7.4}$$

and again see that it falls into our general pattern.

Finally we present briefly the structure and some significant features of Wigner functions in the case $G=\mathrm{SU}(2)$, in a sense the simplest yet archetypal compact non-Abelian Lie group. Here the method of geodesics is essential for the construction. We recall very rapidly the basic definitions and notations concerning SU(2), emphasizing the four-dimensional geometric aspects available in this case

The defining representation of SU(2) is via 2×2 unitary unimodular matrices, which leads immediately to the identification of the group manifold with S^3, the real unit sphere in four-dimensional Euclidean space $\mathcal{R}^4$. We shall exploit this way of picturing SU(2). We denote group elements in the abstract by $a,b,a',b',\ldots$, these symbols also standing for points on S^3:

$$\begin{gathered}a=(a_\mu)\in S^3,\quad \mu=0,1,2,3,\\ a_\mu a_\mu=a_0^2+\underline{a}\cdot\underline{a}=1.\end{gathered} \tag{7.5}$$

The spatial part (a_1,a_2,a_3) of (a_μ) is denoted by $\underline{a}$. Inverses and products of group elements are denoted by a^{-1},ab, respectively. (The group element ab is to be carefully distinguished from the four vector inner product $a\cdot b$ which is a real number.) Then in the defining representation the matrix corresponding to $a\in\mathrm{SU}(2)$ is

$$\begin{gathered}u(a)=a_0\cdot I-i\ \ \underline{a}\cdot\underline{\sigma}=\begin{pmatrix}\lambda & \mu\\ -\mu^* & \lambda^*\end{pmatrix},\\ \lambda=a_0-ia_3,\quad \mu=-(a_2+ia_1).\end{gathered} \tag{7.6}$$

Here $\underline{\sigma}=(\sigma_1,\sigma_2,\sigma_3)$ are the Pauli matrices. The inverse arises by reversing the sign of $\underline{a}$,

$$u(a)^{-1}=u(a^{-1})=u(a_0,-\underline{a})=a_0\cdot I+i\underline{a}\cdot\underline{\sigma}. \tag{7.7}$$

The group multiplication law is subsumed in the description of left and right translations, each of which is realized by elements of SO(4):

$$u(a)u(b)=u(ab)=u(L(a)b),$$

$$L(a)=\begin{pmatrix}a_0 & -a_1 & -a_2 & -a_3\\ a_1 & a_0 & -a_3 & a_2\\ a_2 & a_3 & a_0 & -a_1\\ a_3 & -a_2 & a_1 & a_0\end{pmatrix}\in\mathrm{SO}(4), \tag{7.8a}$$

$$u(b)u(a^{-1})=u(ba^{-1})=u(R(a)b),$$

$$R(a)=\begin{pmatrix} a_0 & a_1 & a_2 & a_3 \\ -a_1 & a_0 & -a_3 & a_2 \\ -a_2 & a_3 & a_0 & -a_1 \\ -a_3 & -a_2 & a_1 & a_0 \end{pmatrix} \in \mathrm{SO}(4); \tag{7.8b}$$

$$L(a)L(b)=L(ab), \quad R(a)R(b)=R(ab),$$

$$L(a)R(b)=R(b)L(a). \tag{7.8c}$$

Each of these mutually commuting sets $\{L(a)\},\{R(a)\}$ faithfully represents SU(2) via SO(4) matrices. The only common elements correspond to $a=(\pm 1,\underline{0})$ leading to the two matrices $Z_2=\{\pm I\}$ within SO(4). This leads to the familiar statement

$$\mathrm{SO}(4)=\mathrm{SU}(2)\times\mathrm{SU}(2)/Z_2. \tag{7.9}$$

We mention these details since the general covariance requirements in Eqs. (6.6c) and (6.6d) require them.

The relation to the Euler angles parametrization is given by

$$u(a)=e^{-(i/2)\,\alpha\sigma_3}e^{-(i/2)\,\beta\sigma_2}e^{-(i/2)\,\gamma\sigma_3},$$

$$a_0-ia_3=\cos\beta/2\;\; e^{-i(\alpha+\gamma)/2},$$

$$a_2+ia_1=\sin\beta/2\;\; e^{i(\gamma-\alpha)/2}, \tag{7.10}$$

$$0\leqslant\alpha\leqslant 2\pi, \quad 0\leqslant\beta\leqslant\pi, \quad 0\leqslant\gamma\leqslant 4\pi.$$

We can regard α, β, γ as angular coordinates over S^3, though because of the occurrence of half angles they are not quite the natural generalization of spherical polar angles from S^2 to S^3. The invariant line element $(\mathrm{d}s)^2$ on S^3, the invariant normalized volume element $\mathrm{d}a$ on SU(2), and the element of solid angle $\mathrm{d}\Omega(a)$ on S^3 can all be easily worked out,

$$\begin{aligned}(\mathrm{d}s)^2=\mathrm{d}a_\mu\,\mathrm{d}a_\mu&=|\mathrm{d}(a_0-ia_3)|^2+|\mathrm{d}(a_2+ia_1)|^2\\&=\tfrac{1}{4}((\mathrm{d}\alpha)^2+(\mathrm{d}\beta)^2+(\mathrm{d}\gamma)^2+2\cos\beta\;\;\mathrm{d}\alpha\;\;\mathrm{d}\gamma),\end{aligned} \tag{7.11a}$$

$$\mathrm{d}a=\frac{1}{2\pi^2}\mathrm{d}\Omega(a)=\frac{1}{16\pi^2}\mathrm{d}\alpha\sin\beta\,\mathrm{d}\beta\,\mathrm{d}\gamma. \tag{7.11b}$$

It is clear that the above line element on S^3 is the one induced from the Euclidean line element in $\mathcal{R}^4$, hence the corresponding geodesics are great circle arcs. Such arcs are carried into one another by both left and right SU(2) translations—the SO(4) invariance of $(\mathrm{d}s)^2$ along with Eq. (7.9) make this obvious. Therefore, if a,b are any two points of S^3 [any two elements of SU(2)] which are not diagonally opposite one another $[u(a)\neq -u(b)]$, the (shorter) geodesic connecting them is the affinely parametrized curve

$$a(\theta)=a\cos\theta+(b-a\;\;a\cdot b)\sin\theta/\sqrt{1-(a\cdot b)^2},$$

$$0\leqslant\theta\leqslant\theta_0=\cos^{-1}(a\cdot b)\in[0,\pi). \tag{7.12}$$

Along this geodesic we have $(\mathrm{d}s)^2=(\mathrm{d}\theta)^2$, and the midpoint is given by

$$a\left(\frac{\theta_0}{2}\right)=(a+b)/\sqrt{2(1+a\cdot b)} \tag{7.13}$$

which is geometrically obvious.

The Dirac delta function accompanying the volume element da on SU(2) may be written as $\delta(a,b)$ involving two group elements, or in a more compact form as $\delta(a^{-1}b)$. Its properties are summarized by

$$\int_{\mathrm{SU}(2)} \mathrm{d}b\ \delta(a,b)\quad f(b)\equiv \int_{S^3}\frac{\mathrm{d}\Omega(b)}{2\pi^2}\,\delta(a,b)\quad f(b)=f(a),$$

i.e.,

$$\int_{S^3}\ \mathrm{d}\Omega(b)\quad \delta(a,b)\quad f(b)=2\pi^2 f(a) \tag{7.14}$$

for suitable test functions $f(b)$. We can equally well regard $\delta(a,b)$ as a delta function on SU(2) or on S^3. In terms of Euler angles we have

$$\begin{gathered} a\to(\alpha,\beta,\gamma),\quad b\to(\alpha',\beta',\gamma'),\\ \delta(a,b)=16\pi^2\delta(\alpha'-\alpha)\,\delta(\beta'-\beta)\,\delta(\gamma'-\gamma)/\sin\beta. \end{gathered} \tag{7.15}$$

The last item in this resume concerns the matrices $D^j_{mm'}(a)$ representing SU(2) elements in the various UIR's. The ranges of the UIR label j and magnetic quantum numbers m,m' are, as usual, $j=0,1/2,1,3/2,\ldots,\ \ m,m'=j,j-1,\ldots,-j$. Then with canonical basis vectors $|jm\rangle$ in the jth UIR and Hermitian generators J_1,J_2,J_3 we have from the quantum theory of angular momentum,[23]

$$D^j_{mm'}(a)=\langle jm|e^{-i\alpha J_3}e^{-i\beta J_2}e^{-i\gamma J_3}|jm'\rangle=e^{-im\alpha-im'\gamma}d^j_{mm'}(\beta),$$

$$\begin{aligned} d^j_{mm'}(\beta)&=\langle jm|e^{-i\beta J_2}|jm'\rangle\\ &=\sqrt{\frac{(j+m')!(j-m')!}{(j+m)!(j-m)!}}\left(\sin\frac{\beta}{2}\right)^{m'-m}\left(\cos\frac{\beta}{2}\right)^{m'+m}P^{(m'-m,m'+m)}_{j-m'}(\cos\beta), \end{aligned} \tag{7.16}$$

where the P's are the Jacobi polynomials. The orthogonality and completeness properties of these D-functions are

$$\begin{gathered} \int_{\mathrm{SU}(2)}\mathrm{d}a\ D^j_{mm'}(a)^*D^{j'}_{m''m'''}(a)=(2j+1)^{-1}\quad \delta_{jj'}\delta_{mm''}\delta_{m'm'''},\\ \sum_{j=0,1/2,1,\ldots}\ \sum_{m,m'=-j}^{j}(2j+1)D^j_{mm'}(a)\quad D^j_{mm'}(b)^*=\delta(a,b)=\delta(a^{-1}b). \end{gathered} \tag{7.17}$$

With these details in place we can proceed to the definition of the Wigner distribution. The Hilbert space of Schrödinger wave functions is

$$\mathcal{H}=L^2(\mathrm{SU}(2))=\left\{\psi(a)\in C\,\middle|\, a\in\mathrm{SU}(2),\|\psi\|^2=\int_{\mathrm{SU}(2)}\ \mathrm{d}a\ \ |\psi(a)|^2<\infty\right\}. \tag{7.18}$$

Given $\psi\in\mathcal{H}$, the corresponding Wigner distribution is obtained by specializing Eqs. (6.8), (6.10), and (6.18) to this case and using Eq. (7.13) above,

$$W(a;jmn\ \ m'n') = \frac{(2j+1)}{4\pi^4}\int_{S^3} d\Omega(a')\int_{S^3} d\Omega(a'')\ \ \delta\left(a, \frac{a'+a''}{\sqrt{2(1+a'\cdot a'')}}\right)$$
$$\times D^j_{mn}(a')\psi(a')^*\ \ D^j_{m'n'}(a'')^*\ \ \psi(a''). \tag{7.19}$$

The occurrence of the midpoint of the geodesic from a' to a'' within the delta function is to be noted. We see immediately that the marginals are properly reproduced,

$$\int da\ W(a;jmn\ \ m'n') = \psi_{jm'n'}\psi^*_{jmn},$$

$$\psi_{jmn} = \frac{\sqrt{2j+1}}{2\pi^2}\int d\Omega(a)\ \ D^j_{mn}(a)^*\ \ \psi(a), \tag{7.20a}$$

$$\sum_{jmn} W(a;jmn\ \ mn) = |\psi(a)|^2. \tag{7.20b}$$

Since the integrations involved in Eq. (7.19) are nontrivial, we limit ourselves to pointing out some qualitative features of the SU(2) Wigner distribution (7.19) which distinguish it from the Cartesian case as well as from earlier treatments of this problem.

(a) The appearance of all the arguments $a\ \ jmn\ \ m'n'$ in the Wigner distribution is essential to be able to satisfy the covariance laws (6.6c) and (6.6d) under independent left and right SU(2) translations, and to reproduce the configuration space and momentum space marginal probability distributions as in Eq. (7.20). In this respect the situation is markedly different from earlier approaches to the SU(2) Wigner distribution problem,[4] where attention was limited to states within some fixed (finite dimensional) UIR of SU(2) and the density matrix was expanded in the complete set of unit tensor operators within that UIR.

(b) If we consider as an idealized limit the case of $\psi(a)$ becoming a position eigenstate, the Wigner distribution simplifies as follows:

$$\psi(a) \to \delta(a, a^{(0)}),$$
$$W(a;jmn\ \ m'n') = \frac{(2j+1)}{4\pi^4}\delta(a,a^{(0)})\ \ D^j_{mn}(a^{(0)})\ \ D^j_{m'n'}(a^{(0)})^*. \tag{7.21}$$

This retains a dependence on the momentum variables $jmn\ \ m'n'$. This is in contrast to the (one-dimensional) Cartesian case where from Eq. (2.10) we find

$$\psi(q) \to \delta(q-q_0), \quad W(q,p) = \frac{1}{h}\delta(q-q_0), \tag{7.22}$$

showing no p dependence.

(c) Similarly if we consider $\psi(a)$ to be a (normalized) linear combination of $D^{j_0}_{m_0 n_0}(a)$ over $m_0\ \ n_0$ for some fixed j_0, the Wigner distribution has a nontrivial dependence on all its arguments, and *in particular is generally nonvanishing for* $j \neq j_0$. In the Cartesian case, in contrast, we have, similar to Eq. (7.22),

$$\psi(q) \to \frac{1}{h^{1/2}} e^{ip_0 q}, \quad W(q,p) = \frac{1}{h}\delta(p-p_0), \tag{7.23}$$

concentrated at $p = p_0$ and independent of q.

All these features can be attributed to the non-Abelian nature of SU(2).

VIII. CONCLUDING REMARKS

We have discussed the problem of setting up Wigner distributions for the states of a quantum system whose configuration space is a general non-Abelian Lie group G, and have given a complete solution for the case that G is compact. Many new features compared to the familiar Abelian case where $G=\mathcal{R}^n$ have appeared. For emphasis we repeat some of them here: while the classical phase space T^*G associated to G already brings in interesting structural aspects, in the quantum case the Wigner distribution is not a function defined on the classical T^*G. Instead it is a function of a classical unquantized group element $g\in G$ playing the role of coordinate variable, and quantized momenta consisting of labels $J\ M\ NM'\ N'$ associated with all the UIR's of G. The analogues of the familiar Heisenberg canonical commutation relations are now much more intricate, and the ideas of momentum eigenstates and momentum eigenvalues have to be understood with some care. While the distribution $W(g;\ JMN\ M'N')$ associated with a given $\hat{\rho}$ transforms nicely under left and right group actions, and reproduces the marginal probability distributions satisfactorily, it describes $\hat{\rho}$ in an over complete manner.

The points of view of the present work suggest that we also consider quantum systems whose covariance group is a given Lie group G, even if G is not the configuration space. These arise naturally if the configuration space is a coset space G/H, where H is some Lie subgroup of G. In that case there is only one (say left) action of G on G/H, rather than two independent mutually commuting actions. Action by G remains significant, and we would like to set up Wigner distributions for wave functions belonging to $L^2(G/H)$. Such UR's of G are typically much smaller than the regular representation.

Going beyond coset space representations, we have yet other physically interesting cases typified for example by the Schwinger oscillator representation of SU(2). Similar constructions are easily made for SU(3), etc.[24] These are not representations on spaces $L^2(G/H)$ for any choice of H; yet because of their use in various physical problems it is worthwhile to be able to set up Wigner distributions for them too.

We intend to examine some of these problems elsewhere.

APPENDIX A: THE REGULAR REPRESENTATION AND ASSOCIATED STRUCTURES

We assemble here some familiar facts concerning the regular representation of a compact Lie group, to settle notations and as preparation for setting up further operator structures. We know that the Lie group G under consideration possesses a left and right translation and inversion invariant volume element, $\mathrm{d}g$ say, so that the integral of a (complex valued) function $f(g)$ over G has the properties

$$\int_G \mathrm{d}g\, f(g)=\int_G \mathrm{d}g\quad (f(g^{-1})\quad \text{or}\quad f(g'g)\quad \text{or}\quad f(gg')), \tag{A1}$$

where g' is any fixed element in G. For the compact case we normalize $\mathrm{d}g$ so that

$$\int_G \mathrm{d}g=1. \tag{A2}$$

With such a measure the carrier space for the unitary regular representation of G is the Hilbert space $\mathcal{H}=L^2(G)$ defined as in Eq. (4.32),

$$\mathcal{H}=\left\{\psi(g)\in\mathcal{C}\,\middle|\,\|\psi\|^2=\int_G \mathrm{d}g\,|\psi(g)|^2<\infty\right\}. \tag{A3}$$

A Dirac delta function can be defined with suitable invariance properties,

$$\int_G \mathrm{d}g\, f(g) \quad \delta(g) = \int_G \mathrm{d}g\, f(g) \quad \delta(g^{-1}) = f(e),$$
$$\int_G \mathrm{d}g\, f(g) \quad \delta(gg'^{-1} \quad \text{or} \quad g^{-1}g' \quad \text{or} \quad g'^{-1}g \quad \text{or} \quad g'g^{-1}) = f(g'). \tag{A4}$$

We can introduce a convenient set of ideal basis vectors for $\mathcal{H}$ such that the wave function $\psi(g)$ is the overlap of $|\psi\rangle$ with one of these,

$$\psi(g) = \langle g|\psi\rangle,$$
$$\langle g'|g\rangle = \delta(g'g^{-1}),$$
$$\int_G \mathrm{d}g|g\rangle\langle g| = 1 \text{ on } \mathcal{H}. \tag{A5}$$

The group G can be unitarily represented on $\mathcal{H}$ in two mutually commuting ways, by left or by right translations. We denote the corresponding operators by $V(g), \tilde{V}(g)$ and define them by

$$V(g')|g\rangle = |g'g\rangle,$$
$$\tilde{V}(g')|g\rangle = |gg'^{-1}\rangle. \tag{A6}$$

Both of them are unitary and obey the composition and commutation relations

$$V(g_2)V(g_1) = V(g_2g_1),$$
$$\tilde{V}(g_2)\tilde{V}(g_1) = \tilde{V}(g_2g_1), \tag{A7}$$
$$V(g_1)\tilde{V}(g_2) = \tilde{V}(g_2)V(g_1).$$

On wave functions the effects are as given in Eq. (4.33),

$$(V(g')\psi)(g) = \psi(g'^{-1}g),$$
$$(\tilde{V}(g')\psi)(g) = \psi(gg'). \tag{A8}$$

These are infinite dimensional reducible UR's of G; and in the compact case, according to the Peter–Weyl theorem, each of them contains every UIR of G as often as its dimension. Motivated by the notations in the case of SU(2), we shall use symbols $J, J', J_1, J_2, \ldots$ to label the various UIR's of G (some of which may not be faithful); so in fact J stands for several independent discrete or quantized labels, as many as the rank of G. Within the Jth UIR, in some chosen orthonormal basis, we label rows and columns by indices $M, N, M'N', \ldots$. Once again each of these stands for a collection of discrete labels: for instance the eigenvalues of as many commuting generators as the rank of G, plus further eigenvalues of chosen commuting nonlinear polynomials in the generators. In the Jth UIR, we write $\mathcal{D}^J_{MN}(g)$ for the unitary representation matrices. These obey composition, orthogonality and completeness relations:

$$\sum_{M'} \mathcal{D}^J_{MM'}(g')\mathcal{D}^J_{M'N}(g) = \mathcal{D}^J_{MN}(g'g), \tag{A9}$$

$$\int_G \mathrm{d}g\, \mathcal{D}^{J'}_{M'N'}(g)^* \mathcal{D}^J_{MN}(g) = \delta_{J'J}\delta_{M'M}\delta_{N'N}/N_J, \tag{A10}$$

$$\sum_{JMN} N_J \mathcal{D}^J_{MN}(g)\mathcal{D}^J_{MN}(g')^* = \delta(g^{-1}g'). \tag{A11}$$

Here N_J is the dimension of the Jth UIR. With the help of these matrices we can introduce another orthonormal basis for $\mathcal{H}$ which explicitly accomplishes the simultaneous reduction of both UR's $V(\cdot), \tilde{V}(\cdot)$ into irreducibles. These basis vectors and their main properties are

$$\begin{gathered} |JMN\rangle = N_J^{1/2} \int_G \mathrm{d}g\, \mathcal{D}^J_{MN}(g)|g\rangle, \\ \langle g|JMN\rangle = N_J^{1/2}\mathcal{D}^J_{MN}(g), \\ \langle J'M'N'|JMN\rangle = \delta_{J'J}\delta_{M'M}\delta_{N'N}, \\ \sum_{JMN} |JMN\rangle\langle JMN| = 1 \ \text{ on } \ \mathcal{H}. \end{gathered} \tag{A12}$$

Under action by $V(\cdot), \tilde{V}(\cdot)$ they transform among themselves conserving J,

$$\begin{aligned} V(g)|JMN\rangle &= \sum_{M'} \mathcal{D}^J_{MM'}(g^{-1})|JM'N\rangle, \\ \tilde{V}(g)|JMN\rangle &= \sum_{N'} \mathcal{D}^J_{N'N}(g)|JMN'\rangle. \end{aligned} \tag{A13}$$

Therefore in $|JMN\rangle$ the index N counts the multiplicity of occurrence of the Jth UIR in the reduction of $V(\cdot)$, and the index M performs a similar function in the reduction of $\tilde{V}(\cdot)$. A general $|\psi\rangle$ can be expanded in either basis and we have

$$\begin{gathered} |\psi\rangle = \int_G \mathrm{d}g\ \psi(g)|g\rangle = \sum_{JMN} \psi_{JMN}|JMN\rangle, \\ \psi_{JMN} = \langle JMN|\psi\rangle = N_J^{1/2}\int_G \mathrm{d}g\, \mathcal{D}^J_{MN}(g)^*\psi(g), \\ \|\psi\|^2 = \int_G \mathrm{d}g\ \ |\psi(g)|^2 = \sum_{JMN} |\psi_{JMN}|^2. \end{gathered} \tag{A14}$$

Towards getting projections onto individual vectors $|JMN\rangle$ we set up the Fourier components of $V(\cdot)$ and $\tilde{V}(\cdot)$ as follows:

$$\begin{aligned} P_{JMN} &= N_J \int_G \mathrm{d}g\, \mathcal{D}^J_{MN}(g)V(g), \\ \tilde{P}_{JMN} &= N_J \int_G \mathrm{d}g\, \mathcal{D}^J_{MN}(g^{-1})\tilde{V}(g). \end{aligned} \tag{A15}$$

With respect to Hermitian conjugation the indices get interchanged,

$$P^\dagger_{JMN} = P_{JNM}, \quad \tilde{P}^\dagger_{JMN} = \tilde{P}_{JNM}, \tag{A16}$$

and their composition and multiplication laws are

$$P_{J'M'N'}P_{JMN}=\delta_{J'J}\delta_{N'M}P_{JM'N},$$

$$\tilde{P}_{J'M'N'}\tilde{P}_{JMN}=\delta_{J'J}\delta_{M'N}\tilde{P}_{JMN'}, \tag{A17}$$

$$P_{JMN}\tilde{P}_{J'M'N'}=\tilde{P}_{J'M'N'}P_{JMN}.$$

Their actions on the two complementary bases for $\mathcal{H}$ are immediate,

$$P_{J'M'N'}|JMN\rangle=\delta_{J'J}\delta_{N'M}|JM'N\rangle,$$

$$\tilde{P}_{J'M'N'}|JMN\rangle=\delta_{J'J}\delta_{M'N}|JMN'\rangle,$$

$$P_{JMN}|g\rangle=N_J^{1/2}\sum_{N'}\mathcal{D}^J_{N'N}(g^{-1})|JMN'\rangle, \tag{A18}$$

$$\tilde{P}_{JMN}|g\rangle=N_J^{1/2}\sum_{M'}\mathcal{D}^J_{MM'}(g^{-1})|JM'N\rangle.$$

Therefore the projections onto $|JMN\rangle$ are

$$|JMN\rangle\langle JMN|=P_{JMM}\tilde{P}_{JNN}, \tag{A19}$$

and we have the completeness identities

$$\sum_M P_{JMM}=\sum_M \tilde{P}_{JMM},$$

$$\sum_{JM} P_{JMM}=\sum_{JM}\tilde{P}_{JMM}=1 \text{ on } \mathcal{H}. \tag{A20}$$

Now we proceed to a construction of certain operators directly relevant to the Wigner distribution problem. Here we will be guided by analogy to what is done for the (one degree of freedom) $\hat{q}-\hat{p}$ pair and the $\hat{\theta}-\hat{M}$ pair, as recounted in Secs. II and III. In these cases we know that the unitary Weyl exponentials $U(\sigma)=\exp(i\sigma\hat{q})$, $V(\tau)=\exp(-i\tau\hat{p})$ and $U(n)=\exp(in\hat{\theta})$, $V(\tau)=\exp(-i\tau\hat{M})$ play important roles. It is seen that it is natural here to regard $\sigma(n)$ as a typical eigenvalue of $\hat{p}(\hat{M})$ and τ[in $\mathcal{R}$ or in $(-\pi,\pi)$] as a typical eigenvalue of $\hat{q}(\hat{\theta})$. Now the operator $V(\tau)$ has been generalized in the Lie group situation to the *two* families $V(g),\tilde{V}(g)$. These are indeed exponentials of the "momentum operators:" if the group element g is expressed as the exponential of an element in $\underline{G}$, then $V(g)$ and $\tilde{V}(g)$ are corresponding exponentials in their generators (4.34) obeying (4.29):

$$g=\exp(\tau^r\ e_r):V(g)=\exp(-i\ \tau^r\hat{J}_r),$$

$$\tilde{V}(g)=\exp(-i\ \tau^r\hat{\tilde{J}}_r). \tag{A21}$$

With τ^r as coordinates for g, these are precisely exponentials in momenta. To generalize $U(\sigma),U(n)$ we recall on the other hand that now a typical "momentum eigenvalue" is the collection of quantum numbers JMN associated with a subspace of $\mathcal{H}$ supporting a UIR of the $\hat{J}_r,\hat{\tilde{J}}_r$. This suggests that the generalization of $U(\sigma),U(n)$ must be an operator diagonal in the "coordinate" or $|g\rangle$ basis, and labeled by JMN: it must be a function of the coordinates alone. Based on this reasoning, we define operators U_{JMN} by

$$U_{JMN}|g\rangle = \mathcal{D}^J_{MN}(g)|g\rangle,$$
$$\langle g|U_{JMN} = \mathcal{D}^J_{MN}(g)\langle g|. \tag{A22}$$

Their adjoints are also diagonal in this basis,

$$U^\dagger_{JMN}|g\rangle = \mathcal{D}^J_{MN}(g)^*|g\rangle,$$
$$\langle g|U^\dagger_{JMN} = \mathcal{D}^J_{MN}(g)^*\langle g|, \tag{A23}$$

and unitarity is expressed in a matrix sense,

$$\sum_M U^\dagger_{JMN}U_{JMN'} = \sum_M U^\dagger_{JNM}U_{JN'M} = \delta_{N'N}\cdot 1 \quad \text{on} \quad \mathcal{H}. \tag{A24}$$

Being simultaneously diagonal, the commutators vanish,

$$[U_{JMN}, U_{J'M'N'}] = [U_{JMN}, U^\dagger_{J'M'N'}] = 0. \tag{A25}$$

Completeness of the $\mathcal{D}$-functions $\mathcal{D}^J_{MN}(g)$ as expressed in Eq. (A11) now means that the operators $\{U_{JMN}\}$ form a (linear) basis for the commutative algebra $\hat{\mathcal{A}}$. In fact the map (4.27) from the classical algebra $\mathcal{A}$ to the quantized $\hat{\mathcal{A}}$ can be made explicit,

$$f \in \mathcal{A}: f(g) = \sum_{JMN} f_{JMN}\mathcal{D}^J_{MN}(g) \rightarrow$$
$$\hat{f} = \sum_{JMN} f_{JMN}U_{JMN} \in \hat{\mathcal{A}}. \tag{A26}$$

The relations connecting $\{U_{JMN}\}$ to $V(\cdot), \tilde{V}(\cdot)$ are easily worked out,

$$V(g)U_{JMN}V(g)^{-1} = \sum_{M'} \mathcal{D}^J_{MM'}(g^{-1})U_{JM'N},$$
$$\tilde{V}(g)U_{JMN}\tilde{V}(g)^{-1} = \sum_{N'} \mathcal{D}^J_{N'N}(g)U_{JMN'}. \tag{A27}$$

What remains are expressions for the product of two U's, and the action of a U on $|JMN\rangle$. For both these, the Clebsch–Gordan coefficients for G have to be brought in.

Let the reduction of the direct product of the Jth and J'th UIR's of G contain various UIR's J'' with various multiplicities. This means that we have a family of Clebsch–Gordan coefficients carrying three sets of $J-M$ labels and in addition a multiplicity index λ, say; and they obey two sets of unitarity conditions,

$$\sum_{M,M'} C^{JJ'J''\lambda *}_{MM'M''}C^{JJ'J'''\lambda'}_{MM'M'''} = \delta_{J''J'''}\delta_{\lambda\lambda'}\delta_{M''M'''},$$
$$\sum_{J''\lambda M''} C^{JJ'J''\lambda *}_{MM'M''}C^{JJ'J''\lambda}_{NN'M''} = \delta_{MN}\delta_{M'N'}. \tag{A28}$$

Using these coefficients the product of two $\mathcal{D}$-functions decomposes into a sum

$$\mathcal{D}^{J}_{MN}(g)\mathcal{D}^{J'}_{M'N'}(g)=\sum_{J''\lambda M''N''} C^{JJ'J''\lambda *}_{MM'M''}C^{JJ'J''\lambda}_{NN'N''}\mathcal{D}^{J''}_{M''N''}(g). \tag{A29}$$

In all these relations the multiplicity index λ accompanying the ''final'' UIR J'' runs over as many values as the number of times J'' occurs in the product of J and J'; and at each stage we have manifest unitary invariance under changes in the choice of λ's. Combining Eq. (A29) in turn with Eqs. (A12) and (A22) we immediately get the results for the products of two U_{JMN}'s and the action of a U_{JMN} on a state $|J'M'N'\rangle$,

$$U_{JMN}U_{J'M'N'}=\sum_{J''\lambda M''N''} C^{JJ'J''\lambda *}_{MM'M''}C^{JJ'J''\lambda}_{NN'N''}U_{J''M''N''},$$

$$U_{JMN}|J'M'N'\rangle=\sum_{J''\lambda M''N''} \sqrt{\frac{N_{J'}}{N_{J''}}}C^{JJ'J''\lambda *}_{MM'M''}C^{JJ'J''\lambda}_{NN'N''}|J''M''N''\rangle. \tag{A30}$$

The unitary invariance with respect to λ is manifest.

Thus we have expressions (A6) and (A22) for the actions of $U,\ldots,V(\cdot),\tilde{V}(\cdot)$ on $|g\rangle$, and expressions (A30) and (A13) for their actions on $|JMN\rangle$.

Last we consider the question of setting up in a natural way a complete trace orthonormal set of operators on $\mathcal{H}=L^2(G)$, involving the U's, V's, and $\tilde{V}$'s in a ''symmetrical'' manner. In the Cartesian case the phase space displacement operators

$$e^{i(\sigma\hat{q}-\tau\hat{p})}=e^{i\sigma\hat{q}}e^{-i\tau\hat{p}}e^{-i\sigma\tau/2}=e^{-i\tau\hat{p}}e^{i\sigma\hat{q}}e^{i\sigma\tau/2} \tag{A31}$$

give us such a system, and they are basic to the Weyl correspondence. Already in the $\hat{\theta}-\hat{M}$ case we know from Eqs. (3.5a) and (3.5b) that we have to work with the operators

$$e^{in\hat{\theta}}e^{-i\tau\hat{M}}e^{-in\tau/2}=e^{-i\tau\hat{M}}e^{in\hat{\theta}}e^{in\tau/2}, \tag{A32}$$

which are again complete and trace orthonormal, but we can no longer write these as single exponentials. In the case of general G, this latter trend continues. Generalizing from the known examples, we now define a family of operators labeled by $g\in G$ together with JMN, as follows:

$$\hat{\mathcal{D}}(g;JMN)=V(g)U_{JMN}=\sum_{M'}\mathcal{D}^{J}_{MM'}(g^{-1})U_{JM'N}V(g). \tag{A33}$$

It is easy to show trace orthogonality, using Eqs. (A6) and (A22),

$$\begin{aligned}\mathrm{Tr}(\hat{\mathcal{D}}(g';J'M'N')^{\dagger}\hat{\mathcal{D}}(g;JMN))&=\int_G dg''\langle g''|U^{\dagger}_{J'M'N'}V(g')^{-1}V(g)U_{JMN}|g''\rangle\\&=\int_G dg''\,\mathcal{D}^{J'}_{M'N'}(g'')^{*}\mathcal{D}^{J}_{MN}(g'')\langle g''|V(g'^{-1}g)|g''\rangle\\&=\delta(g'^{-1}g)\,\delta_{J'J}\delta_{M'M}\delta_{N'N}/N_J.\end{aligned} \tag{A34}$$

As for completeness we begin with

$$\hat{\mathcal{D}}(g;JMN)|g'\rangle=\mathcal{D}^{J}_{MN}(g')|gg'\rangle, \tag{A35}$$

multiply both sides by $N_J\mathcal{D}^{J}_{MN}(g'')^{*}$, sum on JMN and use Eq. (A11) to get

$$\sum_{JMN} N_J \mathcal{D}^J_{MN}(g'')^* \hat{\mathcal{D}}(g;JMN)|g'\rangle = \delta(g''^{-1}g')|gg'\rangle = |gg''\rangle\langle g''|g'\rangle. \tag{A36}$$

Peeling off $|g'\rangle$ and then replacing gg'' by g' we get

$$|g'\rangle\langle g''| = \sum_{JMN} N_J \mathcal{D}^J_{MN}(g'')^* \hat{\mathcal{D}}(g'g''^{-1};JMN). \tag{A37}$$

This shows, albeit in a somewhat formal manner, that any operator on $\mathcal{H}$ can be linearly expanded in the set $\hat{\mathcal{D}}(g;JMN)$. If in Eq. (A33) we use $\tilde{V}(\cdot)$ in place of $V(\cdot)$ we get the alternative results,

$$\hat{\tilde{\mathcal{D}}}(g;JMN) = \tilde{V}(g)U_{JMN} = \sum_{N'} \mathcal{D}^J_{N'N}(g)U_{JMN'}\tilde{V}(g), \tag{A38}$$

$$\mathrm{Tr}(\hat{\tilde{\mathcal{D}}}(g';J'M'N')^\dagger \hat{\tilde{\mathcal{D}}}(g;JMN)) = \delta(g'^{-1}g) \quad \delta_{J'J}\delta_{M'M}\delta_{N'N}/N_J, \tag{A39}$$

$$|g'\rangle\langle g''| = \sum_{JMN} N_J \mathcal{D}^J_{MN}(g'')^* \hat{\tilde{\mathcal{D}}}(g''g'^{-1};JMN). \tag{A40}$$

One can ask whether similar completeness statements can be developed for outer products of vectors of the form $|JMN\rangle\langle J'M'N'|$. This is indeed possible, but the expressions are somewhat unwieldy and involve the Clebsch–Gordan coefficients explicity, so we omit them.

The results (A38)–(A40) prove that the representation of $\hat{\mathcal{A}}, V(\cdot)$ and $\tilde{V}(\cdot)$ on $\mathcal{H}=L^2(G)$ is irreducible, since any operator on $\mathcal{H}$ is expressible as a linear combination of the operators $\hat{\mathcal{D}}(g;JMN)$ [or $\hat{\tilde{\mathcal{D}}}(g;JMN)$].

APPENDIX B

Here we briefly outline the proofs for Eqs. (6.22) and (6.24) and also derive some useful relations similar in form to those known in the Cartesian and angle-angular momentum cases.

To prove (6.22), consider its left-hand side (LHS):

$$\sum_{JMM'} N_J^{-1} \int \mathrm{d}g \tilde{W}_1(g;JMM')\tilde{W}_2(g;JM'M). \tag{B1}$$

On substituting for $\tilde{W}$ using (6.21) and carrying out the summation over JMM' using (A11), this expression becomes

$$\int \mathrm{d}g \int \mathrm{d}g'_1 \int \mathrm{d}g''_1 \int \mathrm{d}g'_2 \int \mathrm{d}g''_2 \langle g''_1|\hat{\rho}_1|g'_1\rangle \times \langle g''_2|\hat{\rho}_2|g'_2\rangle \delta(g^{-1}s(g'_1,g''_1)) \quad \delta(g^{-1}s(g'_2,g''_2)) \quad \delta(g''_1 g'^{-1}_1 g''_2 g'^{-1}_2). \tag{B2}$$

Using the fact that $\delta(gg') = \delta(g'g)$, the third delta function in the integrand can be written as $\delta(g'^{-1}_1 g''_2 g'^{-1}_2 g''_1)$ or as $\delta((g''^{-1}_2 g'_1)^{-1} g'^{-1}_2 g''_1)$ which in turn implies that the integral vanishes unless $g''_1 = g'_2 \cdot h; g'_1 = g''_2 \cdot h$, $h \in G$. This, together with the other two delta functions implies that $h=e$. The three delta functions above are therefore equivalent to $\delta(g^{-1}s(g'_1,g''_1))\ \delta(g'^{-1}_1 g''_2)\ \delta(g''^{-1}_1 g'_2)$. On carrying out the integrals in (B2) with the help of these delta functions one obtains the right-hand side (RHS) of (6.22).

A similar line of argument can be used to establish the relation (6.24). Next we show that, in analogy with the Cartesian and angle-angular momentum cases, the Wigner distribution in (6.20) corresponding to a density operator $\hat{\rho}$ can be written in the following compact form:

$$W(g;JMN\ \ M'N')=\mathrm{Tr}[\hat{\rho}\hat{W}(g;JMNM'N')], \tag{B3}$$

where the Wigner operator $\hat{W}(g;JMNM'N')$ can be expressed in terms of operators related to $\hat{\mathcal{D}}(g;JMN)$ as follows:

$$\hat{W}(g;JMNM'N')=N_J\hat{\mathcal{D}}_1(g;JMN)\ \ \Delta\ \ \hat{\mathcal{D}}_1^{\dagger}(g;JM'N'). \tag{B4}$$

Here

$$\hat{\mathcal{D}}_1(g;JMN)=U_{JMN}V(g) \tag{B5}$$

$$=\sum_{M'}\ \mathcal{D}^J_{MM'}(g)\hat{\mathcal{D}}(g;JM'N), \tag{B6}$$

$$\Delta=\int \mathrm{d}g\sum_{JMN}\ N_J\mathcal{D}^J_{MN}(e)^*\hat{\mathcal{D}}_0(g;JMN), \tag{B7}$$

$$\hat{\mathcal{D}}_0(g;JMN)=\sum_{M'}\ \mathcal{D}^J_{MM'}(s_0(g))\hat{\mathcal{D}}(g;JM'N) \tag{B8}$$

$$=\sum_{M'}\ \mathcal{D}^J_{MM'}(s_0(g^{-1}))\hat{\mathcal{D}}_1(g;JM'N). \tag{B9}$$

Note that the operator $\hat{\mathcal{D}}_0(g;JMN)$ introduced here can be regarded as the analogue of $e^{ip\hat{q}-iq\hat{p}}$ $\equiv e^{-iq\hat{p}}e^{ip\hat{q}}e^{ipq/2}$ or of $e^{-i\tau\hat{M}}e^{in\hat{\theta}}e^{in\tau/2}$ in the angle-angular momentum case.

To show (B3), we note that the RHS of (B3) can be written as

$$\mathrm{Tr}[\hat{\rho}\hat{W}(g;JMNM'N')]=\int \mathrm{d}g_1\int \mathrm{d}g_2\langle g_2|\hat{\rho}|g_1\rangle\langle g_1|\hat{W}(g;JMNM'N')|g_2\rangle. \tag{B10}$$

Now

$$\langle g_1|\hat{W}(g;JMNM'N')|g_2\rangle=N_J\int \mathrm{d}g_3\int \mathrm{d}g_4\langle g_1|\hat{\mathcal{D}}_1(g;JMN)|g_3\rangle\langle g_3|\Delta|g_4\rangle$$
$$\times\langle g_4|\hat{\mathcal{D}}_1(g;JMN)|g_2\rangle, \tag{B11}$$

and from the definitions (B5)–(B9) of the operators that occur here it can easily be shown that

$$\langle g_1|\hat{\mathcal{D}}_1(g;JMN)|g_2\rangle=\mathcal{D}^J_{MN}(g_1)\,\delta(g_1(gg_2)^{-1}), \tag{B12}$$

$$\langle g_1|\hat{\mathcal{D}}_0(g;JMN)|g_2\rangle=\mathcal{D}^J_{MN}(s(g_1,g_2))\,\delta(g_1(gg_2)^{-1}), \tag{B13}$$

$$\langle g_1|\Delta|g_2\rangle=\int \mathrm{d}g\sum_{JMN}\ N_J\mathcal{D}^J_{MN}(e)^*\langle g_1|\hat{\mathcal{D}}_0(g;JMN)|g_2\rangle$$

$$=\int \mathrm{d}g\sum_{JMN}\ N_J\mathcal{D}^J_{MN}(e)^*\mathcal{D}^J_{MN}(s(g_1,g_2))\,\delta(g_1(gg_2)^{-1})$$

$$=\delta(s(g_1,g_2)). \tag{B14}$$

Using these in (B11) one obtains

$$\langle g_1|\hat{W}(g;JMN,M'N')|g_2\rangle = N_J \delta(g^{-1}s(g_1,g_2))\mathcal{D}^J_{MN}(g_1)\mathcal{D}^J_{M'N'}(g_2)^*, \tag{B15}$$

which when substituted in (B10) yields (B3).

On setting $N=N'$ $(M=M')$ in (B3) and summing over N (M) we obtain the following formulas for the simpler Wigner distributions in terms of simpler Wigner operators:

$$\tilde{W}(g;JMM') = \mathrm{Tr}[\hat{\rho} \quad \hat{\tilde{W}}(g;JMM'), \tag{B16}$$

$$\tilde{\tilde{W}}(g;JNN') = \mathrm{Tr}[\rho \quad \hat{\tilde{W}}(g;JNN')], \tag{B17}$$

where

$$\hat{\tilde{W}}(g;JMM') = \sum_N \hat{W}(g;JMNM'N), \tag{B18}$$

$$\hat{\tilde{W}}(g;JNN') = \sum_M \hat{W}(g;JMNMN'). \tag{B19}$$

The relations (B16) and (B17) can be inverted with the help of (6.22) and (6.24), respectively, to obtain

$$\hat{\rho} = \int \mathrm{d}g \sum_{JMM'} \frac{1}{N_J} \tilde{W}(g;JMM')\hat{\tilde{W}}(g;JM'M), \tag{B20}$$

$$\hat{\rho} = \int \mathrm{d}g \sum_{JNN'} \frac{1}{N_J} \tilde{\tilde{W}}(g;JNN')\hat{\tilde{\tilde{W}}}(g;JN'N). \tag{B21}$$

This can be seen as follows. Setting $\hat{\rho}_1 \equiv \hat{\rho}$ and $\hat{\rho}_2 = |g_2\rangle\langle g_1|$ in (6.22) and using (B16) for the second Wigner distribution one obtains

$$\langle g_1|\hat{\rho}|g_2\rangle = \int \mathrm{d}g \sum_{JMM'} \frac{1}{N_J} \tilde{W}(g;JMM')\langle g_1|\hat{\tilde{W}}(g;JM'M)|g_2\rangle, \tag{B22}$$

which on peeling off $\langle g_1|$ and $|g_2\rangle$ gives (B20). Equation (B21) can be derived in a similar fashion.

(Received 29 August 2003; accepted 8 September 2003)

Lattice ϕ_2^4-quantum field models with different lattice cutoffs in the free and interacting parts are constructed and their continuum limits are studied. A comparision with previously constructed continuum limits is given, in the spirit of a discussion on how limit models depend on chosen regularizations. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1626807]

I. INTRODUCTION

The usual (continuum) ϕ_d^4-quantum field theory[1,2] is heuristically described by the following probability measure:

$$N_{\lambda_1,\lambda_2,\lambda_3}^{-1}\prod_{x\in R^d} d\phi(x)\exp\left(-\int_{R^d}(\lambda_1|\nabla\phi(x)|^2+\lambda_2\phi^2(x)+\lambda_3\phi^4(x))dx\right), \tag{1.1}$$

where $N_{\lambda_1,\lambda_2,\lambda_3}$ is the normalization constant, λ_1, λ_2, and λ_3 are real strictly positive coupling constants, and ϕ is the real-valued field. There have been many approaches to the problem of giving a meaning to the above heuristic measure for $d=2$ and $d=3$ (see Refs. 3–15 and references therein). The lattice approximation is an important tool in constructing and studying the continuum ϕ_d^4 field, Let us set $aZ^d=\{ax: x\in Z^d\}$, $a>0$. Heuristically, the quantities $\int|\nabla\phi(x)|^2dx$, $\int\phi^2(x)dx$, and $\int\phi^4(x)dx$ can be approximated, respectively, by $a^{d-2}\Sigma_{|x-y|=a;x,y\in aZ^d}(\phi_x-\phi_y)^2$, $a^d\Sigma_{x\in aZ^d}\phi_x^2$, and $a^d\Sigma_{x\in aZ^d}\phi_x^4$, as a tends to zero. Thus heuristically (1.1) can be approximated by the following heuristic probability measure:

$$N_a^{-1}\prod_{x\in aZ^d} d\phi_x \times\exp\left(2\lambda_1 a^{d-2}\sum_{|x-y|=a;x,y\in aZ^d}\phi_x\phi_y-(\lambda_2 a^d+4d\lambda_1 a^{d-2})\sum_{x\in aZ^d}\phi_x^2-\lambda_3 a^d\sum_{x\in aZ^d}\phi_x^4\right), \tag{1.2}$$

*Deceased.

where N_a is the normalization constant. (1.2) is still just a heuristic expression, because of the sums over the infinite set aZ^d, but it is indeed not hard to give a rigorous sense to (1.2) (see Refs. 3, 5, 11, and 12 and references therein). By using a natural embedding of aZ^d in R^d, the so obtained probability measure μ_a can be realized on the distribution space $\mathcal{S}'(R^d)$.[11] We call this the lattice ϕ_2^4-field measure. From μ_a by deriving suitable bounds on its moments and choosing subsequences if necessary one gets limit measures for $d=1,2,3$, by weak convergence (in the sense of moments of probability measures). These are then the continuum ϕ_d^4-field measures, realized as probability measures on $\mathcal{S}'(R^d)$, $d=1,2,3$. For suitable choices of λ_1, λ_2, and λ_3 one has indeeed even weak convergence of μ_a to a unique probability measure μ, as $a\downarrow 0$ (Refs. 5, 11, and 13) for a "simplicial approximation approach" to the continuum limit.

In this paper we consider a new lattice approximation to (1.1). For this we choose a "new cutoff" $a'=a'(a)>0$ satisfying $\lim_{a\to 0^+} a'(a)=0$. For convenience we assume $a'\geqslant a>0$ so that $a'Z^d\subset aZ^d$. Heuristically, the quantity $\int \phi^4(x)dx$ can also be approximated by $a'^d\Sigma_{x\in a'Z^d}\phi_x^4$ as a tends to zero. Thus the heuristic measure (1.1) can also be approximated by the following heuristic probability measure:

$$N_{a,a'}^{-1}\prod_{x\in aZ^d} d\phi_x \times\exp\left(2\lambda_1 a^{d-2}\sum_{|x-y|=a;x,y\in aZ^d}\phi_x\phi_y-(\lambda_2 a^d+4d\lambda_1 a^{d-2})\sum_{x\in aZ^d}\phi_x^2-\lambda_3 a'^d\sum_{x\in a'Z^d}\phi_x^4\right), \tag{1.3}$$

where $N_{a,a'}$ is the normalization constant. We denote the latter heuristic probability measure by $\nu_{a,a'}$ and call it, for simplicity, "the new lattice ϕ_2^4-fields model." This measure can be thought as describing a lattice ϕ^4-field theory with different lattice cutoffs in the free and interacting parts. Similarly as for (1.2) one can give a rigorous sense to (1.3). The basic question discussed in this paper is to what extent the continuuum limit depends on the chosen regularization a,a'. Since $a'\geqslant a$, the interaction part appears only on a subset $a'Z^d$ of the lattice points aZ^d. It is however also present in the normalization term $N_{a,a'}$, so that we can expect that the procedure of choosing $a'\neq a$ might enhance the singular behavior of moments at coinciding points, with respect to the case $a'=a$. It is natural to think that the continuum limit, without additional counterterms, only exists for a suitable dependence of a' on a. In fact we will prove in Theorem 2.1 that if $\limsup_{a\to 0^+} a'|\log a|^{5/4}<+\infty$ and the coupling λ is weak, then the continuum limit of the lattice ϕ_2^4 given by (1.3) exists and the probability measure associated to the distribution-valued field satisfies all the Osterwalder–Schrader axioms of the Euclidean quantum field, except possibily the rotation invariance. For such a result we follow the approach in Ref. 5. First we will construct an action in the finite volume Λ as a finite-difference approximation to the continuum action. Then we will define a renormalized total action in bounded lattice regions $L=aZ^d\cap\Lambda$ and $L'=a'Z^d\cap\Lambda$ with Dirichlet boundary conditions. The bare mass m will be expressed in terms of counterterms depending on both a and a', as a perturbation of the mass m_0, corresponding to the mass for the free lattice field model. By the second Griffiths inequality we will extend this action to the whole lattices aZ^d and $a'Z^d$. By the Schwinger–Dyson field equation we will express the interacting 2-points function, i.e., the interacting propagator, in terms of the interacting 4-point function, and by skeleton inequalities we will estimate the latter 4-point function from above and from below by the 2-point function, so that we will get upper and lower bounds for the 2-point function in terms of itself. Since we will prove that the 2-point function is continuous with respect to λ, and hence for a weak coupling it is close to the free propagator, we will get a uniform estimate with respect to the variables a and a' of the 2-point function. Further we will estimate the $2n$-point function from above and from below by the 2-point function, and hence by the free propagator. Therefore we will prove that its limit is nontrivial and that the distribution associated with the continuum field is uniquely determined by its moments.

In the Appendix the proof of the existence of the continuum limit is extended from the case of the above condition $\limsup_{a\to 0^+} a'|\log a|^{5/4}<+\infty$ to the one where $\limsup_{a\to 0^+} a'|\log a|^{7/6}<+\infty$. For this proof general skeleton inequalities are used. It is also remarked that our method might be further extended so that we might prove the existence of the continuum limit under the more general condition $\limsup_{a\to 0^+} a'|\log a|^{1+\epsilon}<+\infty$, with $\epsilon>0$ (in this case new counterterms are required which might modify the continuum limit).

Another basic result of the paper is stated in Theorem 2.2. It says roughly that in the presence of a space cutoff and under the assumption that $a'|\log a|^2$ stays bounded (a situation where no new counterterm is needed, as compared to the usual lattice model) the new constructed continuum ϕ_2^4 model coincides with the old one. This result also implies that for models with space cutoff in the interaction performing first the infinite volume limit $\Lambda\uparrow R^2$ and then the continuum limit leads to the same result as taking the limits in the opposite order. The proof uses the properties of Wick powers and estimates on the n-point functions of the relevant measures, in order to prove that they have the same asymptotic behavior (such measures being uniquely determined by their moments), one gets the result. We also discuss the question whether in general $\nu_{a,a'}$ and $\nu_{a,a}$ might have the same limit points. We give motivations for this not to be the case in general (this is in analogy with the situation in the discrete Edward model in two dimensions[16]).

The paper is organized as follows. In Sec. II we will give a rigorous definition of the new lattice ϕ_2^4-field model given by the measure $\nu_{a,a'}$. We also state the main results of this paper. In Sec. III we will first state some skeleton inequalities for the new lattice ϕ_2^4-field model and then derive some estimates of the corresponding two point functions. In Sec. IV we will use the Schwinger–Dyson field equation and some skeleton inequalities to derive uniform bounds on two point functions. In Sec. V we will first derive some bounds on the $2n$-point functions and then construct the new ϕ_2^4 fields by approximating from the corresponding $2n$-point functions associated with the new lattice ϕ_2^4-field measure $\nu_{a,a'}$. In Secs. VI and VII we will prove that $\{\nu_{a,a'}\}$ is weakly convergent to the *original* continuum ϕ_2^4 field [described heuristically by (1.1), constructed, e.g., in Refs. 2, 8, and 11] if $\limsup_{a\to 0^+} a'|\log a|^2<\infty$. In Sec. VIII we will discuss some properties of the continuum ϕ_2^4 field in the case where $\lim_{a\to 0^+} a'|\log a|^2=\infty$ and propose some open problems which further illustrate the interest to study the new lattice approximation of ϕ_2^4 fields given in the present paper. In the Appendix we will derive a correlation inequality up to the third order in the coupling constant λ and apply it to prove the convergence of scaled moment functions for an interaction with a suitable mass counterterms to the moment functions of a limit probability measure, in the case where $\lim_{a\to 0^+} a'|\log a|^{7/6}<\infty$.

II. MODELS AND MAIN RESULTS

To construct our new ϕ_2^4-field models, we first construct ϕ_2^4 models in a bounded lattice region, with different lattice cutoffs a and a' in the free, respectively, interacting parts. We then use the strategy of Ref. 5, applying the second Griffiths inequality[11,17] to take the "infinite-volume" limit, and then pass to the continuum limit as the lattice spacings a,a' go to zero. We note, however, that in many previous references, the continuum limit of the lattice ϕ_2^4 fields was taken before performing the infinite-volume limit.[8,11] In case λ_3 is small, we show that under some assumptions on the terms $a,a'\to 0$ the continuum ϕ_2^4 fields constructed by the above two approaches coincide. For convenience we will call the continuum ϕ_2^4 field, obtained by one of the above approaches, the original continuum ϕ_2^4 field (in the infinite-volume case, i.e., without a spatial cutoff). We remark that the approach given in Ref. 5 is also suitable for the construction of the continuum ϕ_2^4 field with spatial cutoffs.

Let Λ be a given regular bounded region in R^2 (for its definition, the reader is refered to Ref. 11, p. 267) and set

$$L=aZ^2\cap\Lambda\subset R^2,\quad L'=a'Z^2\cap\Lambda\subset R^2,$$

where $a'=a'(a)$ is assumed to satisfy the assumptions given in Sec. I, so that in particular $L'\subset L$. Let $g\geqslant 0$ be a given function in R^2 which is bounded and Borel measurable. Define an action in the finite volume $L\subset Z^2$ with Dirichlet boundary condition

$$S_{\Lambda,D}(\phi)=\frac{1}{2}\sum_{\langle xy\rangle;x,y\in L}(\phi_x-\phi_y)^2+\frac{1}{2}m^2a^2\sum_{x\in L}\phi_x^2+\frac{\lambda}{4}a'^2\sum_{x\in L'}g(x)\phi_x^4, \tag{2.1}$$

where $\langle xy\rangle$ represents the set $\{(x,y):\ |x-y|=a;\ x,y\in aZ^2\}$. Then the probability measure

$$Z_{\Lambda,D}^{-1}\prod_{x\in L}e^{-S_{\Lambda,D}(\phi)}d\phi_x \tag{2.2}$$

is well defined, where $Z_{\Lambda,D}$ is the normalization constant. Heuristically, the lattice action $S_{\Lambda,D}(\phi)$ is a finite-difference approximation to the continuum action,

$$S_{\Lambda,C}(\phi)=\int_\Lambda\left\{\frac{1}{2}[\nabla\phi(x)]^2+\frac{1}{2}m^2\phi(x)^2+\frac{\lambda}{4}g(x)\phi(x)^4\right\}dx,$$

and the probability measure (2.2) can be thought of as a finite-difference approximation to a measure on continuum fields which is heuristically given by

$$Z_{\Lambda,C}^{-1}e^{-S_{\Lambda,C}(\phi)}\prod_{x\in\Lambda}d\phi(x).$$

Let G_a be the probability measure for the free lattice field model of mass m_0 on aZ^2 [i.e., $\lambda=0$, $m^2=m_0^2$ and $L=aZ^2$ in (2.1) and (2.2)] and let $\langle\cdot\rangle_{G_a}$ denote the expectation with respect to G_a. Let

$$C^{(a)}(x-y)=\langle\phi_x\phi_y\rangle_{G_a}.$$

G_a is thus the (lattice) Gaussian measure with mean zero and covariance $C^{(a)}$. It is easy to show that[8,11]

$$C^{(a)}(x-y)=(2\pi)^{-2}\int_{[-\pi/a,\pi/a]^2}\left[m_0^2+2a^{-2}\sum_{j=1}^{2}(1-\cos ak_j)\right]^{-1}e^{ik(x-y)}dk_1dk_2,$$

where $k=(k_1,k_2)$. Let

$$G_{a,L}=N_{a,L}^{-1}\exp\left(-\frac{1}{2}\sum_{\langle xy\rangle;x,y\in L}(\phi_x-\phi_y)^2-\frac{1}{2}m_0^2a^2\sum_{x\in L}\phi_x^2\right)\prod_{x\in L}d\phi_x,$$

where $N_{a,L}$ is the normalization constant. Let

$$C_L^{(a)}(x,y)=\langle\phi_x\phi_y\rangle_{G_{a,L}}.$$

By Ref. 11, Chap. VIII, we know that

$$C^{(a)}(x-y)=\lim_{L\to aZ^2}C_L^{(a)}(x,y).$$

One can also check that $C^{(a)}(x-y)$ is bounded by $c|\log|x-y||$ for $a\leqslant|x-y|\leqslant 1$, and $C^{(a)}(0)$ behaves like $c|\log a|$ for some constant $c\in(0,\infty)$, as a tends to zero.[18] We now introduce the counterterms which are necessary to define rigorously (1.1). Let $\delta m_1^2=-3\lambda C^{(a)}(0)$ and set

$$\delta m_2^2 = \begin{cases} 6\lambda^2 a'^2 C^{(a)}(0)^3, & \limsup_{a\to 0^+} a'|\log a|^{3/2} \in (0,\infty], \\ 0, & \text{otherwise.} \end{cases}$$

It is clear that $\limsup_{a\to 0^+} \delta m_2^2 = +\infty$ if $\limsup_{a\to 0^+} a'|\log a|^{3/2} = +\infty$. We define the normalized action S_L in the bounded region L with Dirichlet boundary condition by setting

$$S_L(\phi) = \frac{1}{2} \sum_{\langle xy\rangle; x,y\in L} (\phi_x - \phi_y)^2 + \frac{1}{2} m_0^2 a^2 \sum_{x\in L} \phi_x^2 + \frac{1}{2} \delta m_1^2 a'^2 \sum_{x\in L'} g(x)\phi_x^2 + \frac{1}{2} \delta m_2^2 a'^2 \sum_{x\in L'} g(x)^2 \phi_x^2 + \frac{\lambda}{4} a'^2 \sum_{x\in L'} g(x)\phi_x^4 .$$

The expectation $\langle\cdot\rangle_L$ is defined, for any real measurable function F on R for which the right-hand side (RHS) is finite, by

$$\langle F\rangle_L = Z_L^{-1} \int \prod_{x\in L} e^{-S_L(\phi)} F(\phi)\, d\phi_x ,$$

where Z_L^{-1} is the normalization constant. If we set

$$V_{L'} = \frac{\lambda}{4} \int_{L'}' g(x)\phi_x^4 dx + \frac{1}{2} \delta m_1^2 \int_{L'}' g(x)\phi_x^2 dx + \frac{1}{2} \delta m_2^2 \int_{L'}' g(x)^2 \phi_x^2 dx,$$

then we have

$$\langle F\rangle_L = \frac{\langle F e^{-V_{L'}}\rangle_{G_{a,L}}}{\langle e^{-V_{L'}}\rangle_{G_{a,L}}}.$$

If $F(\phi)$ is a polynomial in $\{\phi_x,\ x\in L\}$ with positive coefficients and $\tilde{L}\subset aZ^2$ is a lattice containing L, then we know by the second Griffiths inequality[11,17] that

$$\langle F\rangle_L \leqslant \langle F\rangle_{\tilde{L}} .$$

Moreover, $\langle F\rangle_L$ is bounded uniformly in $L\subset aZ^2$. Thus we can define the limit

$$\langle F\rangle^{(a)} = \lim_{L\to aZ^2} \langle F\rangle_L .$$

For convenience we let the integral $\int_L dx$ denote the lattice sum on L with weight a^2 and the integral $\int_{L'}' dx$ denote the lattice sum on L' with weight a'^2. For short we denote $\int_{aZ^2} dx$ and $\int_{a'Z^2} dx$, respectively, by $\int dx$ and $\int' dx$, and write shortly V for $V_{a'Z^2}$. The expectation $\langle F\rangle := \langle F e^{-V}\rangle_{G_a} / \langle e^{-V}\rangle_{G_a}$ is then equal to $\langle F\rangle^{(a)}$. The $2n$-point function $S(x_1,\ldots,x_{2n}) := S^{(a,a')}(x_1,\ldots,x_{2n})$ is defined by

$$S^{(a,a')}(x_1,\ldots,x_{2n}) = \frac{\langle \phi_{x_1}\cdots\phi_{x_{2n}} e^{-V}\rangle_{G_a}}{\langle e^{-V}\rangle_{G_a}}. \tag{2.3}$$

We will call $S^{(a,a')}(x_1,\ldots,x_{2n})$ the $2n$-point function corresponding to (the spatial cutoff) g.

As in Ref. 5, (5.6), one can derive the following field equation for the 2-point function:

$$S(x,y)=C^{(a)}(x-y)-\delta m_1^2\int' dz g(z)C^{(a)}(x-z)S(z,y)$$
$$-\delta m_2^2\int' dz g(z)^2 C^{(a)}(x-z)S(z,y)-\lambda\int' dz C^{(a)}(x-z)g(z)\langle\phi_z^3\phi_y\rangle. \quad (2.4)$$

We remark that in the case of infinite volume [i.e., $g(x)=1,\forall x\in R^2$] we have $S(x,y)=S(0,y-x)$, and so in this case $S(x,y)$ can be denoted by $S(x-y)$.

Before stating the main theorems, let us first recall some basic results about the original ϕ_2^4 field $\nu_{\lambda,g}$ with spatial cutoff g. For simplicity we shall also denote $\nu_{\lambda,g}$ shortly by ν_λ. Let $g\in C_0(R^2)$ be a given function and μ_0 be the Gaussian measure, "free field measure," on $\mathcal{S}'(R^2)$ with covariance

$$\langle\phi(f_1)\phi(f_2)\rangle_{\mu_0}=\langle f_1,(-\Delta+m_0^2)^{-1}f_2\rangle.$$

Let :: denote the Wick power with respect to μ_0 and set $U(g)=\int_{R^2}g(x):\phi(x)^4:dx$ (for its definition, the reader is referred to Ref. 11). Then the original ϕ_2^4 field $\nu_{\lambda,g}$ with spatial cutoff $g\geqslant 0$ is given by

$$d\nu_{\lambda,g}=\left(\int \exp(-\lambda U(g))d\mu_0\right)^{-1}\exp(-\lambda U(g))d\mu_0.$$

This is a well-defined probability measure on $\mathcal{S}'(R^2)$ absolutely continuous with respect to μ_0 (Refs. 11 and 19).

The main results in this paper are as follows.

Theorem 2.1: Let $g\geqslant 0$ be a given bounded continuous function. Then there exists $\lambda_0>0$ so that for all $\lambda\leqslant\lambda_0$ there are sequences $\{a_n\}_{n\geqslant 1}$, $\{a_n'\}_{n\geqslant 1}$ with $\lim_{n\to\infty}a_n=0$ and $\lim_{n\to\infty}a_n'|\log a_n|^{5/4}<\infty$, and $\{g_n\}_{n\geqslant 1}\subset C_0(R^2)$ with $\lim_{n\to\infty}g_n(x)=g(x)$, $x\in R^2$, such that for any given $f_1,\ldots,f_{2m}\in\mathcal{S}(R^2)$ and $m\geqslant 1$ the following limit exists:

$$S(f_1,\ldots,f_{2m})=:\lim_{n\to\infty}\sum_{x_1,\ldots,x_{2m}\in a_nZ^2}S^{(a_n,a_n')}(x_1,\ldots,x_{2m})\prod_{i=1}^{2m}a_n^2f_i(x_i),$$

where $S^{(a_n,a_n')}(x_1,\ldots,x_{2m})$ is the $2m$-point function corresponding to the function g_n, defined by (2.3). Moreover, there is a probability measure $\mu_{\lambda,g}$ on $\mathcal{S}'(R^2)$ satisfying

$$\int_{\mathcal{S}'(R^2)}\phi(f_1)\cdots\phi(f_{2m})\mu_{\lambda,g}(d\phi)=S(f_1,\ldots,f_{2m}),\quad f_1,\ldots,f_{2m}\in\mathcal{S}(R^2),\ m\geqslant 1.$$

Remark: If $g(x)=1$, $\forall x\in R^2$, then $\mu_{\lambda,g}$ given in the above theorem is a continuum ϕ_2^4-quantum field in the infinite-volume case (i.e., without a spatial cutoff). If $g(\geqslant 0)\in C_0(R^2)$, then $\mu_{\lambda,g}$ given in the above theorem is a continuum ϕ_2^4-quantum field with spatial cutoff g. For simplicity we shall also denote $\mu_{\lambda,g}$ shortly by μ_λ.

If $\limsup_{a\to 0^+}a'|\log a|^{1+\epsilon}<\infty$ for some $\epsilon\in(0,1/4)$, then with an analogous procedure it should be possible to define new counterterms and prove the existence of the continuum limit of the new lattice ϕ_2^4 fields (by subsequences) with these new counterterms. In the Appendix we will discuss the case $\lim_{a\to 0^+}a'|\log a|^{7/6}<\infty$.

Remark: Our construction of a continuum limit for a lattice model yields models satisfying all Euclidean axioms,[20–23] except possibly for the axiom of rotation invariance (this is a problem common to all constructions of Euclidean quantum field models starting from lattices). In case the limit can be identified with some models constructed in other ways, the rotation invariant can be verified; see below.

The next theorem tells us that the continuum ϕ_2^4 field $\mu_{\lambda,g}$ in many cases coincides with the original ϕ_2^4 field $\nu_{\lambda,g}$.

Theorem 2.2: Assume that $g \in C_0^1(R^2)$ is non-negative, $\int_{R^2} g_x^2 dx$ is strictly positive, and $\lambda > 0$ is sufficient small. If $\lim_{n\to\infty} a_n' |\log a_n|^2 = A \in [0,\infty)$, then the measure $\mu_{\lambda,g}$ given in Theorem 2.1 coincides with the original ϕ_2^4 field measure $\nu_{\lambda,g}$.

Remark: The measure $\mu_{\lambda,g}$ in the case where $\lim_{a\to 0^+} a' |\log a|^2 = +\infty$ constructed in Theorem 1.1 is believed to be different from the measure $\nu_{\lambda,g}$ for $\lambda > 0$ [see the discussions (iii) and (v) given in Sec. VIII below]. The proof of Theorem 2.2 for $A = 0$ is much easier than the one for $A > 0$. We will prove Theorem 2.2 for $A = 0$ and $A > 0$ in Secs. VI and VII, respectively.

III. SKELETON INEQUALITIES

In this section we first give some correlation inequalities and then use these inequalities to derive some estimates of the 2-point function $S(x-y)$. In Sec. VII below we will give a more precise correlation inequality for the four point function. As in Refs. 14 and 24–26 we consider a model of one-component classical spins on a finite lattice Λ whose partition function is defined by

$$Z = \int e^{(\phi, J\phi)/2} \prod_{j\in\Lambda} g(j)(\phi_j^2) d\phi_j,$$

where $J = (J_{ij})$ is a symmetric matrix, i.e., $J_{ij} = J_{ji}$, $i,j \in \Lambda$, $\phi_j \in R$, $(\phi, J\phi) = \Sigma_{i,j\in\Lambda} J_{ij}\phi_i\phi_j$. We only consider the ferromagnetic case $J_{ij} \geqslant 0$, $\forall i,j$, and set

$$g(j)(\phi^2) = \exp\left(-\frac{\lambda_j}{4!}\phi^4 - \frac{B_j}{2}\phi^2 \right),$$

for some constants $\lambda_j \in R_+$, $B_j > 0$.

Let

$$\langle \phi_{x_1} \cdots \phi_{x_n} \rangle = Z^{-1} \int \phi_{x_1} \cdots \phi_{x_n} e^{(\phi, J\phi)/2} \prod_j g(j)(\phi_j^2) d\phi_j,$$

$x_i \in \Lambda$, $i = 1, \ldots, n$ (from now on we indicate sums and products over Λ simply by Σ_j, respectively, Π_j).

Set

$$U_4(x_1,x_2,x_3,x_4) = \langle \phi_{x_1}\phi_{x_2}\phi_{x_3}\phi_{x_4} \rangle - \langle \phi_{x_1}\phi_{x_2} \rangle \langle \phi_{x_3}\phi_{x_4} \rangle - \langle \phi_{x_1}\phi_{x_3} \rangle \langle \phi_{x_2}\phi_{x_4} \rangle - \langle \phi_{x_1}\phi_{x_4} \rangle \times \langle \phi_{x_2}\phi_{x_3} \rangle.$$

For the special case where the constants λ_j and B_j are independent of the site j, Brydges *et al.*[24] already derived some inequalities for $U_4(x_1,x_2,x_3,x_4)$ in terms of the 2-point functions. The proof of these skeleton inequalities is based on the random walk representation of the correlation functions.[3,26–28] As remarked in Ref. 24, p. 123, the arguments given in Ref. 24 are still suitable for the general cases where λ_j and B_j depend on the site j. Also instead of U_4 one can consider U_n for general n, but for simplicity we will only give the inequalities for U_4. In fact we can use the arguments given in Ref. 24 to derive the following correlation inequalities:

$$U_4(x_1,x_2,x_3,x_4) \leqslant 0, \tag{3.1}$$

$$U_4(x_1,x_2,x_3,x_4) \geqslant -\sum_z \lambda_z \langle \phi_{x_1}\phi_z \rangle \langle \phi_{x_2}\phi_z \rangle \langle \phi_{x_3}\phi_z \rangle \langle \phi_{x_4}\phi_z \rangle, \tag{3.2}$$

$$U_4(x_1,x_2,x_3,x_4)\leqslant -\sum_z \lambda_z\langle\phi_{x_1}\phi_z\rangle\langle\phi_{x_2}\phi_z\rangle\langle\phi_{x_3}\phi_z\rangle\langle\phi_{x_4}\phi_z\rangle+\frac{1}{2}\sum_{j,k}\lambda_j\lambda_k\langle\phi_{x_1}\phi_j\rangle\langle\phi_{x_2}\phi_j\rangle$$
$$\times\langle\phi_j\phi_k\rangle^2\langle\phi_{x_3}\phi_k\rangle\langle\phi_{x_4}\phi_k\rangle+\frac{1}{2}\sum_{j,k}\lambda_j\lambda_k\langle\phi_{x_1}\phi_j\rangle\langle\phi_{x_3}\phi_j\rangle\langle\phi_j\phi_k\rangle^2\langle\phi_{x_2}\phi_k\rangle$$
$$\times\langle\phi_{x_4}\phi_k\rangle+\frac{1}{2}\sum_{j,k}\lambda_j\lambda_k\langle\phi_{x_1}\phi_j\rangle\langle\phi_{x_4}\phi_j\rangle\langle\phi_j\phi_k\rangle^2\langle\phi_{x_2}\phi_k\rangle\langle\phi_{x_3}\phi_k\rangle. \quad (3.3)$$

The inequality (3.1), which is usually called the Lebowitz inequality, was first obtained by Lebowitz.[29] A further correlation inequality up to the third order will be given in the Appendix. The inequalities (3.1), (3.2), and (3.3) hold first for the finite lattice Λ. However, as in Sec. II we can use DLR equations and Griffiths' first and second inequalities to show that (3.1), (3.2), and (3.3) also hold with Λ replaced by aZ^2, for any $a>0$. In particular, (3.1), (3.2), and (3.3) can be used to discuss the models introduced in Sec. II. For this purpose we set

$$\lambda_j=\begin{cases}0, & j\in aZ^2\backslash a'Z^2,\\ 6\lambda g(j), & j\in a'Z^2,\end{cases}$$

where $g\geqslant 0$ is a given bounded Borel measurable function. By (3.1), (3.2), and (3.3) we can get the following estimates of $S(x,y)$, $x,y\in L$, from Eq. (2.4):

$$S(x,y)\geqslant C(x-y)-\delta m_1^2\int' dzC(x-z)g(z)S(z,y)$$
$$-\delta m_2^2\int' dzg(z)^2C(x-z)S(z,y)-3\lambda\int' dzC(x-z)g(z)\langle\phi_z^2\rangle\langle\phi_z\phi_y\rangle, \quad (3.4)$$

$$S(x,y)\leqslant C(x-y)-\delta m_1^2\int' dzC(x-z)g(z)S(z,y)-\delta m_2^2\int' dzg(z)^2C(x-z)S(z,y)$$
$$-3\lambda\int' dzC(x-z)g(z)\langle\phi_z^2\rangle\langle\phi_z\phi_y\rangle$$
$$+6\lambda^2\int' dzC(x-z)g(z)\int' dz_1g(z_1)\langle\phi_z\phi_{z_1}\rangle^3\langle\phi_{z_1}\phi_y\rangle, \quad (3.5)$$

$$S(x,y)\geqslant C(x-y)-\delta m_1^2\int' dzC(x-z)g(z)S(z,y)-\delta m_2^2\int' dzg_z^2C(x-z)S(z,y)$$
$$-3\lambda\int' dzC(x-z)g(z)\langle\phi_z^2\rangle\langle\phi_z\phi_y\rangle+6\lambda^2\int' dzC(x-z)g(z)\int' dz_1g(z_1)$$
$$\times\langle\phi_z\phi_{z_1}\rangle^3\langle\phi_{z_1}\phi_y\rangle,-54\lambda^3\int' dzC(x-z)g(z)\int' dz_1\int' dz_2g(z_1)g(z_2)$$
$$\times\langle\phi_z\phi_{z_1}\rangle^2\langle\phi_{z_1}\phi_{z_2}\rangle^2\langle\phi_z\phi_{z_2}\rangle\langle\phi_{z_2}\phi_y\rangle, \quad (3.6)$$

where $S(x,y)$ was defined in Sec. II and $C(x-y)=C^{(a)}(x-y)$.

Some Gaussian inequalities[19] will also be useful in the present paper. By means of the random walk representation,[19] Th. 7, and Ref. 24 one can also derive the following relation:

$$S(x_1,\ldots,x_{2n}) \leqslant \sum_{i=2}^{2n} S(x_1,x_i)S(x_2,\ldots,x_{i-1},x_{i+1},\ldots,x_{2n}), \tag{3.7}$$

for any $x_i \in L$, $i=1,\ldots,2n$.

IV. RECURSIVE ESTIMATES FOR THE 2-POINT FUNCTION

Without loss of generality, in this section we assume that the bare mass m_0 is equal to 1. In fact, if $m_0 \neq 1$ [but $m_0 \in (0,\infty)$] and if some statements given before Proposition 4.2 are changed accordingly, then the discussions given in this section are still suitable for the case of general m_0. For convenience, in this section we assume that g is a given function from aZ^2 to R such that

$$0 \leqslant g(x) \leqslant 1, \quad \forall x \in aZ^2.$$

As in Ref. 5 we introduce the notation

$$|||f||| = \|f\|_1 + \|f\|_\infty = a^2 \sum_{x \in aZ^2} |f(x)| + \sup_{x \in aZ^2} |f(x)|.$$

We also introduce the exponentially weighted L^p norms

$$\|f\|_{p,\alpha} = \left(\int_{R^2} |\cosh(\alpha x_1) f(x)|^p dx \right)^{1/p}, \quad |||f|||_\alpha = \|f\|_{1,\alpha} + \|f\|_{\infty,\alpha},$$

where $x=(x_1,x_2)$. Let

$$E^{(a,a')}(x,y) = S^{(a,a')}(x,y) - C^{(a)}(x-y),$$

where $S^{(a,a')}(x,y)$ and $C^{(a)}(x-y)$ were defined in Sec. II. We will only consider the case where both conditions

$$\limsup_{a \to 0^+} a' |\log a|^{5/4} < \infty, \quad \liminf_{a \to 0^+} a' |\log a|^{3/2} = \infty$$

are satisfied. The discussion for the other relevant case (i.e., where $\limsup_{a\to 0^+} a'|\log a|^{3/2} = 0$) is easier [the case where $\limsup_{a\to 0^+} a'|\log a|^{3/2} \in (0,\infty)$ is trivial].

In this section we denote $C^{(a)}(x-y)$ and $S^{(a,a')}(x,y)$, respectively, by $C(x-y)$ and $S(x,y)$. One of the main results in this section is as follows.

Proposition 4.1: Assume $\limsup_{a\to 0^+} a'|\log a|^{5/4} < \infty$. Then there exist polynomials P_i, Q_i, $1 \leqslant i \leqslant 3$, with positive coefficients, independent of a, except for the constant term of Q_2, such that

$$\sup_x |||E_x^{(a,a')}||| \leqslant \sum_{i=1}^{3} \lambda^i P_i(\sup_x |||E_x^{(a,a')}|||), \tag{4.1}$$

$$\sup_x \left\| E_x^{(a,a')} - 6\lambda^2 \int dz C(x-z) g(z) \int dz_1 g(z_1) C(z-z_1)^3 C(z_1-y) \right\|$$

$$\leqslant \sum_{i=1}^{3} \lambda^i Q_i(\sup_x |||E_x^{(a,a')}|||), \tag{4.2}$$

for all $a,a' \in (0,1)$, where $E_x^{(a,a')}(y)=E^{(a,a')}(x,y)$. Moreover, the polynomials P_1 and Q_1 have zero constant term, and Q_2 has a constant term which goes to zero as $a\to 0^+$.

Proof: For short we denote $E^{(a,a')}$ and $E_x^{(a,a')}$, respectively, by E and E_x. Let $C_x*S(y)=\int' dz C_x(z)S(z,y)$, where $C_x(y)=C(x-y)$. It is easy to show by Young's inequality that

$$\|C_x*E\|_1 \leqslant \int' dz C_x(z) \sup_z \|E_z\|_1 \leqslant O(1)\sup_z \|E_z\|_1, \quad \|C_x*E\|_\infty \leqslant O(1)\sup_z \|E_z\|_\infty,$$

which implies that

$$|||C_x*S||| \leqslant |||C_x*C||| + |||C_x*E||| \leqslant O(1)(1+\sup_z |||E_z|||).$$

By (3.5) and (3.6) we know that the term of order λ in the expression $S(x,y)-C(x-y)$ can be bounded by

$$\sup_x \|E_x\|_\infty \cdot |||C_x*S||| \leqslant O(1)\sup_x |||E_x||| \cdot (1+\sup_x |||E_x|||).$$

To consider the term of order λ^2 in the expression $S(x,y)-C(x-y)$, we set

$$f_1(x,y)=6\lambda^2 a'^2 \int' dz C(x-z)g(z)^2 \langle \phi_z \phi_y \rangle \langle \phi_z^2 \rangle^3,$$

$$f_2(x,y)=6\lambda^2 a'^2 \int' dz C(x-z)g(z) \sum_{z_1 \in a'Z^2 \setminus \{z\}} g(z_1)\langle \phi_z \phi_{z_1} \rangle^3 \langle \phi_{z_1} \phi_y \rangle.$$

From the assumption $\limsup_{a\to 0^+} a'|\log a|^{5/4}<\infty$ we can see that $\limsup_{a\to 0^+} a' C^{(a)}(0)=0$ and so $\{a'C^{(a)}(0)\}$ is bounded for all $a\in(0,1)$. For any fixed $x \in aZ^2$, by Young's and Hölder's inequalities we have

$$\begin{aligned}
&\left\| f_1(x,\cdot) - \delta m_2^2 \int' dz C(x-z)g(z)^2 \langle \phi_z \phi_\cdot \rangle \right\| \\
&\quad \leqslant \sup_z \| \delta m_2^2 - 6\lambda^2 a'^2 \langle \phi_z^2 \rangle^3 \|_\infty \cdot |||C_x*S||| \\
&\quad \leqslant 6\lambda^2 \sup_z \|E_z\|_\infty a'^2 [C^2(0)+C(0)\langle \phi_z^2 \rangle + \langle \phi_z^2 \rangle^2] \cdot |||C_x*S||| \\
&\quad \leqslant O(1)\lambda^2 \sup_z [a'^2 C^2(0) + a'^2 \|E_z\|_\infty^2] \|E_z\|_\infty (1+\sup_z |||E_z|||) \\
&\quad \leqslant c\lambda^2 \sup_{z\in aZ^2} |||E_z||| (1+\sup_{z\in aZ^2} |||E_z|||^3),
\end{aligned} \tag{4.3}$$

where the constant $c\in(0,\infty)$ is independent of $x\in aZ^2$. It is clear that this constant c can be chosen to satisfy $\lim_{a\to 0^+} c=0$.

Let $f_{2,x}(y)=f_2(x,y)$. Since $\limsup_{a\to 0^+} a'|\log a|^{5/4}<\infty$ and $C(x-y)$ behaves like $c|\log|x-y||$ as $|x-y|$ goes to zero, we can easily show that

$$\begin{aligned}
\sup_{x\in aZ^2} |||f_{2,x}||| &\leqslant 6\lambda^2 \sup_{x\in aZ^2} \left\| \int' dz C(x-z) a'^2 \sum_{z_1 \in a'Z^2 \setminus \{z\}} S(z,z_1)^3 S(z_1,y) \right\| \\
&\leqslant O(1)\lambda^2 (1+\sup_{z\in aZ^2} |||E_z|||^4).
\end{aligned}$$

Finally we consider the term of order λ^3 on the right-hand side of (3.6). We denote this term by $f_{3,x}(y)$. We remark that $f_{3,x}$ is the summation of the function $C(x-z)g(z)g(z_1)g(z_2)\times\langle\phi_z\phi_{z_1}\rangle^2\langle\phi_{z_1}\phi_{z_2}\rangle^2\langle\phi_z\phi_{z_2}\rangle\langle\phi_{z_2}\phi_y\rangle$ on the set $\{(z,z_1,z_2)\colon z,z_1,z_2\in a'Z^2\}$. Then this summation can be decomposed as

$$\sum_{z=z_1=z_2\in a'Z^2}+\sum_{z=z_1,z_2\neq z}+\sum_{z=z_2,z_1\neq z}+\sum_{z_1=z_2\neq z}+\sum_{z_2\neq z_1,z_2\neq z,z_1\neq z}.$$

Using this expression we get

$$\begin{aligned}\|f_{3,x}\|_\infty\leqslant 54\lambda^3&\left\|\int' dzC(x-z)a'^4\langle\phi_z^2\rangle^5\langle\phi_z\phi_y\rangle\right\|_\infty\\&+54\lambda^3\left\|\int' dzC(x-z)a'^2\langle\phi_z^2\rangle^2\sum_{z_2\neq z}\langle\phi_z\phi_{z_2}\rangle^3\langle\phi_{z_2}\phi_y\rangle\right\|_\infty\\&+54\lambda^3\left\|\int' dzC(x-z)a'^2\langle\phi_z^2\rangle\sum_{z_1\neq z}\langle\phi_z\phi_{z_1}\rangle^4\langle\phi_z\phi_y\rangle\right\|_\infty\\&+54\lambda^3\left\|\int' dzC(x-z)a'^2\sum_{z_2\neq z}\langle\phi_{z_2}^2\rangle^2\langle\phi_z\phi_{z_2}\rangle^3\langle\phi_{z_2}\phi_y\rangle\right\|_\infty\\&+54\lambda^3\left\|\int' dzC(x-z)\sum_{z_1\neq z,z_2\neq z,z_1\neq z_2}\langle\phi_z\phi_{z_1}\rangle^2\langle\phi_{z_1}\phi_{z_2}\rangle^2\langle\phi_z\phi_{z_2}\rangle\langle\phi_{z_2}\phi_y\rangle\right\|_\infty.\end{aligned}$$

Using the assumption $\limsup_{a\to 0^+}a'|\log a|^{5/4}<\infty$ and the above estimate we show that

$$\sup_{x\in aZ^2}\|f_{3,x}\|_\infty\leqslant O(1)(1+\sup_{x\in aZ^2}\|E_x\|_\infty^6).$$

By a similar argument as above we obtain

$$\sup_{x\in aZ^2}\|f_{3,x}\|_1\leqslant O(1)(1+\sup_{x\in aZ^2}\|E_x\|_1^6).$$

Therefore,

$$\sup_{x\in aZ^2}|\|f_{3,x}\||\leqslant O(1)(1+\sup_{x\in aZ^2}|\|E_x\||^6),$$

which proves (4.1).

If $\limsup_{a\to 0^+}a'|\log a|^{5/4}<\infty$, then we see that there exists $\epsilon(a)\in(0,\infty)$ with $\lim_{a\to 0^+}\epsilon(a)=0$ such that

$$\left|\left\|\int' dzC(x-z)g(z)a'^2\sum_{z_1\in a'Z^2\setminus\{z\}}g(z_1)C(z-z_1)^3C(z_1-y)-\int dzC(x-z)g(z)\int dz_1g(z_1)C(z-z_1)^3C(z_1-y)\right\|\right|\leqslant\epsilon(a).$$

Using this estimate we derive the inequality

$$\begin{aligned}
&\left\|\left\| \int' dzC(x-z)g(z)a'^2 \sum_{z_1\in a'Z^2\setminus\{z\}} g(z_1)\langle\phi_z\phi_{z_1}\rangle^3\langle\phi_{z_1}\phi_y\rangle \right.\right.\\
&\qquad \left.\left. - \int dzC(x-z)g(z)\int dz_1 g(z_1)C(z-z_1)^3C(z_1-y)\right\|\right|\\
&\leqslant \left\|\left\| \int' dzC(x-z)g(z)a'^2 \sum_{z_1\in a'Z^2\setminus\{;z\}} g(z_1)\langle\phi_z\phi_{z_1}\rangle^3\langle\phi_{z_1}\phi_y\rangle \right.\right.\\
&\qquad \left.\left. - \int' dzC(x-z)g(z)a'^2 \sum_{z_1\in a'Z^2\setminus\{z\}} g(z_1)C(z-z_1)^3C(z_1-y)\right\|\right|\\
&\qquad + \left\|\left\| \int' dzC(x-z)g(z)a'^2 \sum_{z_1\in a'Z^2\setminus\{z\}} g(z_1)C(z-z_1)^3C(z_1-y) \right.\right.\\
&\qquad \left.\left. - \int dzC(x-z)g(z)\int dz_1 g(z_1)C(z-z_1)^3C(z_1-y)\right\|\right|\\
&\leqslant \epsilon(a) + C\lambda(1+\sup_{x\in aZ^2}|||E_x|||^4).
\end{aligned}$$

Thus, by (4.3) we know that

$$\begin{aligned}
&\left\|\left\| f_1(x,y)+f_2(x,y)-6\lambda^2\int dzC(x-z)g(z)\int dz_1 g(z_1)C(z-z_1)^3C(z_1-y)\right\|\right|\\
&\qquad \leqslant [\epsilon(a)+C\sup_{x\in aZ^2}|||E_x|||(1+\sup_{x\in aZ^2}|||E_x|||^3)]\lambda^2 + C\lambda^3(1+\sup_{x\in aZ^2}|||E_x|||^4), \qquad (4.4)
\end{aligned}$$

where the constant $C\in(0,\infty)$ is independent of $x\in aZ^2$. On the other hand, using the assumption $\limsup_{a\to 0^+} a'|\log a|^{5/4}<\infty$ we prove that

$$|||f_{3,x}|||\leqslant C\lambda^3(1+\sup_{x\in aZ^2}|||E_x|||^6).$$

Combining this with (4.4) we can get the desired result (4.2). The proof of Proposition 4.1 is then complete. ■

To state the next result, we let $m_0^{(a)}>0$ be the unique solution of

$$1+2a^{-2}(1-\cosh(am_0^{(a)}))=0.$$

By a Paley–Wiener theorem,[30] $C^{(a)}(x)$ decays roughly as $\exp(-m_0^{(a)}|x_1|)$ in the x_1 direction. One can show that $m_0^{(a)}<m_0=1$ for $a\in(0,1)$ and $\lim_{a\to 0^+} m_0^{(a)}=m_0=1$.

The other result in this section is as follows.

Proposition 4.2: Let $\delta\in(0,1)$ be given. There are polynomials P_i, Q_i for $1\leqslant i\leqslant 3$ with positive coefficients, independent of a, except for the constant term of Q_2, such that

$$\begin{aligned}
\sup_x|||E_x^{(a,a')}|||_\alpha &\leqslant \sum_{i=1}^3 \lambda^i P_i(\sup_x|||E_x^{(a,a')}|||_\alpha)\\
&\quad \times \sup_x\left\|\left\| E_x^{(a,a')} - 6\lambda^2\int dzC(x-z)g(z)\int dz_1 g(z_1)C(z-z_1)^3C(z_1-y)\right\|\right|\\
&\leqslant \sum_{i=1}^3 \lambda^i Q_i(\sup_x|||E_x^{(a,a')}|||_\alpha) \qquad (4.5)
\end{aligned}$$

for all $a,a' \in (0,1)$ and $\alpha \in (0,(1-\delta)m_0^{(a)})$, where the polynomials P_1 and Q_1 have zero constant term, and Q_2 has a constant term which goes to zero as $a \to 0^+$.

Some technical points in the proof of Proposition 4.2 were mentioned in the proof of Ref. 5, Theorem 7.2. The detailed proof of Proposition 4.2 is quite similar to that of above Proposition 4.1, hence it is omitted.

V. CONTINUUM LIMIT

In this section we always assume $\limsup_{a\to 0^+} a'|\log a|^{5/4} < \infty$. The main aim of this section is to complete the proof of Theorem 2.1. Let us first introduce a notation. In Sec. II we already introduced the counterterms δm_1^2 and δm_2^2, and defined a quantity $V_{L'}$ by means of δm_1^2 and δm_2^2. By means of this $V_{L'}$ we defined in Sec. II a lattice field on aZ^2 whose covariance function (i.e., 2-point function) is $S^{(a,a')}(x,y)$. Now we replace δm_1^2 and δm_2^2, respectively, by the real-valued variables ϵ_1 and ϵ_2. We can then construct a corresponding lattice field on aZ^2 and we shall denote the covariance function of this new lattice field by $S^{(\lambda,\epsilon_1,\epsilon_2)}(x,y)$.

We will first use Propositions 4.1 and 4.2 to derive some estimates on $S^{(a,a')}(x,y)$. To this end, as in Ref. 5 we need to prove the continuity of $S^{(a,a')}(x,y)$ with respect to $\lambda > 0$. Since δm_1^2 and δm_2^2 are continuous with respect to $\lambda > 0$, it suffices to prove the continuity of $S^{(\lambda,\epsilon_1,\epsilon_2)}(x,y)$ with respect to $(\lambda,\epsilon_1,\epsilon_2)$. Let

$$\mathcal{B} = \{(\lambda,\epsilon_1,\epsilon_2):\ \lambda > 0, \epsilon_1,\epsilon_2 \in R\} \cup \{(\lambda,\epsilon_1,\epsilon_2):\ \lambda = 0, \epsilon_1,\epsilon_2 > 0\}.$$

We first state two lemmas.

Lemma 5.1: Let the lattice spacing $a \in (0,1)$ and the function $g(\geqslant 0) \in C_0(R^2)$ be given. Then the following statements are true.

(i) The set

$$\mathcal{B}_0 = \{(\lambda,\epsilon_1,\epsilon_2) \in \mathcal{B}:\ \sup_{x\in aZ^2} \|S^{(\lambda,\epsilon_1,\epsilon_2)}(x,\cdot)\|_1 < \infty\}$$

is a nonempty, connected, and open subset of $\mathcal{B}$.

(ii) The map $(\lambda,\epsilon_1,\epsilon_2) \to \sup_{x\in aZ^2} \|S^{(\lambda,\epsilon_1,\epsilon_2)}(x,\cdot)\|_1$ is continuous from $\mathcal{B}$ to $[0,+\infty]$, and also continuous from $\mathcal{B}_0$ to $[0,\infty)$.

Since we already assumed in Lemma 5.1 that the function $g \geqslant 0$ has a compact support (i.e., that we are in the finite-volume case), this lemma can easily be proven (see the proof of Ref. 5, Proposition 5.1). For the infinite-volume case, the corresponding result was proven in Ref. 26, Proposition 5.1. In that case, the 2-point function $S^{(\lambda,\epsilon_1,\epsilon_2)}(x,y)$ only depends on $x-y$ (since it is translation invariant).

Similarly, we have the following result.

Lemma 5.2: Let the lattice spacing $a \in (0,1)$ and the function $g(\geqslant 0) \in C_0(R^2)$ be given. Then, for each $\alpha \geqslant 0$, the following statements are true.

(i) The set

$$\mathcal{B}_\alpha = \{(\lambda,\epsilon_1,\epsilon_2) \in \mathcal{B}:\ \sup_{x\in aZ^2} \|S^{(\lambda,\epsilon_1,\epsilon_2)}(x,\cdot)\|_{1,\alpha} < \infty\}$$

is a nonempty, connected and open subset of $\mathcal{B}$.

(ii) The map $(\lambda,\epsilon_1,\epsilon_2) \to \sup_{x\in aZ^2} \|S^{(\lambda,\epsilon_1,\epsilon_2)}(x,\cdot)\|_{1,\alpha}$ is continuous from $\mathcal{B}$ to $[0,\infty]$ and also continuous from $\mathcal{B}_\alpha$ to $[0,\infty)$.

Some technical points in the proof of Lemma 5.2 were already mentioned in the proof of Ref. 5, Proposition 7.1, so we will also omit the proof of Lemma 5.2.

For short, in this section we shall denote $C^{(a)}(x-y)$ and $S^{(a,a')}(x,y)$, respectively, by $C(x-y)$ and $S(x,y)$.

By Lemma 5.1 and Lemma 5.2 we know that $\sup_{x\in aZ^2}|||E_x|||$ and $\sup_{x\in aZ^2}|||E_x|||_\alpha$ are continuous with respect to $\lambda>0$ if $a\in(0,1)$ and $g(\geqslant 0)\in C_0(R^2)$ are fixed. Using these continuity properties together with Proposition 4.1 and Proposition 4.2 we can easily prove the following results (for their proofs, the reader is referred, respectively, to the proofs of Ref. 5, Theorem 6.1 and Theorem 7.2).

Proposition 5.3: There exist universal constants $\lambda_0>0$, $c_1,c_2\in(0,\infty)$ such that, for $0\leqslant\lambda\leqslant\lambda_0$,

$$\sup_{x\in aZ^2}|||S(x,\cdot)-C(x-\cdot)|||\leqslant c_1\lambda^2,$$

$$\sup_{x\in aZ^2}\left|\left|\left|S(x,\cdot)-C(x-\cdot)-6\lambda^2\int dzC(x-z)g(z)\int dz_1g(z_1)C(z-z_1)^3C(z_1-\cdot)\right|\right|\right|\leqslant c_2\lambda^3+\epsilon(a)\lambda^2,$$

where $\epsilon(a)>0$ satisfies $\lim_{a\to 0^+}\epsilon(a)=0$, and $g\in C_0(R^2)$ satisfies $0\leqslant g\leqslant 1$.

Proposition 5.4: Let $\delta\in(0,1)$ be given. There exist universal constants $\lambda_0>0$, $c_1,c_2\in(0,\infty)$ such that, for $0\leqslant\lambda\leqslant\lambda_0$ and $\alpha\in(0,(1-\delta)m_0^{(a)}]$,

$$\sup_{x\in aZ^2}|||S(x,\cdot)-C(x-\cdot)|||_\alpha\leqslant c_1\lambda^2,$$

$$\sup_{x\in aZ^2}\left|\left|\left|S(x,\cdot)-C(x-\cdot)-6\lambda^2\int dzC(x-z)g(z)\int dz_1g(z_1)C(z-z_1)^3C(z_1-\cdot)\right|\right|\right|_\alpha\leqslant c_2\lambda^3+\epsilon(a)\lambda^2,$$

where $\epsilon(a)>0$ satisfies $\lim_{a\to 0^+}\epsilon(a)=0$, and $g\in C_0(R^2)$ satisfies $0\leqslant g\leqslant 1$.

Remark: We remark that the polynomials P_i,Q_i for $1\leqslant i\leqslant 3$ given in Proposition 4.1 and Proposition 4.2 do not depend on the choice of g with $g\in C_0(R^2)$ and $0\leqslant g\leqslant 1$. Hence, the constants λ_0, c_1, and c_2 given in Proposition 5.3 and Proposition 5.4 do not depend on the choice of g, if $g\in C_0(R^2)$ and $0\leqslant g\leqslant 1$.

Having these propositions, we can now prove Theorem 2.1.

Proof of Theorem 2.1: By Proposition 5.4 we know that for $\alpha<m_0=1$ there are $c(\alpha)<\infty$ and $\lambda_\alpha>0$ such that

$$\sup_{x\in aZ^2}|||S(x,\cdot)-C(x-\cdot)|||_\alpha\leqslant c(\alpha)\lambda,\qquad 0\leqslant\lambda\leqslant\lambda_\alpha,$$

if $g\in C_0(R^2)$ and $0\leqslant g\leqslant 1$, where $S(x,y)$ is the 2-point function corresponding to the function g, which was defined in Sec. II. Thus, $S(x,y)$ behaves like $C(x-y)$ for $|x-y|\to 0$. By the Gaussian inequality (3.7) we know that (for S defined in Sec. II, with the given g)

$$S(x_1,\ldots,x_{2m})\leqslant\sum_{\pi\in Q_{2m}}\prod_{i=1}^{m}S(x_{\pi(2i-1)},x_{\pi(2i)}),$$

with Q_{2m} the set of all pair partitions of $\{1,2,\ldots,2m\}$. By the bound

$$|S(x,y)|\leqslant K\ C(y-x)$$

for some constant $K\in(0,\infty)$ and for all x,y, we have thus

$$S(x_1,\ldots,x_{2m})\leqslant\sum_{\pi\in Q_{2m}}\prod_{i=1}^{m}K^m\ C(x_{\pi(2i)}-x_{\pi(2i-1)}).$$

By applying the inequality for the function $C(y-x)$, cited in Sec. II, we obtain

$$C(y-x)\leqslant c\ |\log|y-x||,$$

where c is a positive constant. Finally we get

$$S(x_1,\ldots,x_{2m})\leqslant \sum_{\pi\in Q_{2m}}\prod_{i=1}^{m} C\ \ K^m\ \ |\log|x_{\pi(2i)}-x_{\pi(2i-1)}||. \tag{5.1}$$

For any given continuous function g with $0\leqslant g\leqslant 1$, we can find a series $\{g_n\}_{n\geqslant 1}\subset C_0(R^2)$ with $0\leqslant g_n\leqslant 1$ such that g_n increases to g as n increases to ∞. By Eq. (5.1) we can find sequences $\{a_n\}_{n\geqslant 1}$, $\{a_n'\}_{n\geqslant 1}$ with $\lim_{n\to\infty} a_n'|\log a_n|^{5/4}<\infty$ and $\{g_{k_n}\}_{n\geqslant 1}$ with $\lim_{n\to\infty} g_{k_n}(x)=g(x)$, such that the limit

$$\lim_{n\to\infty}\sum_{x_1,\ldots,x_{2m}\in a_nZ^2} S^{(a_n,a_n')}(x_1,\ldots,x_{2m})\prod_{i=1}^{2m} a_n^2 f_i(x_i) \tag{5.2}$$

exists for all $f_1,\ldots,f_{2m}\in\mathcal{S}(R^2)$ and $m\geqslant 1$, where $S^{(a_n,a_n')}(x_1,\ldots,x_{2m})$ is the $2m$-point function corresponding to the function g_{k_n} (of compact supports). We denote the limit (5.2) by $S(f_1,\ldots,f_{2m})$. On the other hand, by the second Griffiths inequality one gets that [see Ref. 5, (8.3)]

$$S^{(a,a')}(x_1,\ldots,x_{2m})\geqslant \frac{1}{(2m-1)!!}\sum_{\pi\in Q_{2m}}\prod_{i=1}^{m} S^{(a,a')}(x_{\pi(2i-1)},x_{\pi(2i)}).$$

This fact tells us that the continuum limits for $S^{(a,a')}(x_1,\ldots,x_{2m})$ are not identically zero. Thus, by (5.1) and Ref. 31, Theorem 1.1, we know that there is a probability measure uniquely determined by its moments μ_λ on $\mathcal{S}'(R^2)$ such that

$$\int_{\mathcal{S}'(R^2)}\phi(f_1)\cdots\phi(f_{2m})\mu_\lambda(d\phi)=S(f_1,\ldots,f_{2m}),\quad f_1,\ldots,f_{2m}\in\mathcal{S}(R^2),\ \ m\geqslant 1.$$

This then completes the proof of Theorem 2.1. ■

VI. PROOF OF THEOREM 2.2 FOR $A=0$

Let us first introduce some notations. As in Ref. 31, let (,) and $\|\ \|$ denote the inner product and the norm in $L^2(R^2)$, respectively, and H_n be the Hermite polynomial of order n. For $n\geqslant 0$, the Hermite function of order n is given by

$$h_n(x)=c_nH_n(x)\exp\left(-\frac{x^2}{2}\right),\quad x\in R,$$

where c_n is a constant for which $\|h_n\|=1$. Then $\{h_n\}_{n\geqslant 0}$ is an orthonomal base in $L^2(R^2)$. For $\beta=(\beta_1,\beta_2)$ with $\beta_1,\beta_2\geqslant 0$, the function $h_\beta\colon R^2\to R$ is defined by

$$h_\beta(x_1,x_2)=h_{\beta_1}(x_1)h_{\beta_2}(x_2).$$

Then $\{h_\beta,\ \beta\geqslant 0\}$ is an orthonormal base in $L^2(R^2)$. The m-norm $\|\cdot\|_m$ in $\mathcal{S}(R^2)$ is defined by

$$\|f\|_m^2=\sum_\beta\ (f,h_\beta)^2(2(\beta_1+\beta_2)+2)^m,\quad f\in\mathcal{S}(R^2),\ \ m\geqslant 0,$$

with $\beta=(\beta_1,\beta_2)$. Let $\Phi_m=\{f\in\mathcal{S}(R^2):\ \|f\|_m<\infty\}$. The $(-m)$-norm $\|\cdot\|_{-m}$ in $\mathcal{S}'(R^2)$ is defined by

$$\|\phi\|_{-m}^2=\sum_{\beta}\ \phi^2(h_\beta)(2(\beta_1+\beta_2)+2)^{-m},\quad \phi\in\mathcal{S}'(R^2).$$

One checks easily that

$$\|\phi\|_{-m}=\sup\{|\phi(f)|:\ f\in\mathcal{S}(R^2),\ \|f\|_m\leqslant 1\}.$$

Let Φ_m' denote the dual space of Φ_m.

In this section we let $g\geqslant 0$ be a given function in $C_0^1(R^2)$ such that $\int_{R^2}|g(x)|dx>0$. The main aim of this section is to complete the proof of Theorem 2.2 in the case where $A=0$. In other words, we will prove that μ_λ for small $\lambda>0$ is equal to the original continuum ϕ_2^4 field ν_λ if $\lim_{a\to 0^+}a'|\log a|^2=0$. For this purpose we first prove a weak convergence (see Lemma 6.1 below).

As in Sec. II, we let μ_0 be the Gaussian measure on $\mathcal{S}'(R^2)$ with the covariance $C=(-\Delta+m_0^2)^{-1}$. We define the function $f_{x,a}(\cdot)$ whose Fourier transform is

$$\hat{f}_{x,a}(k)=\begin{cases}(2\pi)^{-1}e^{-ikx}\mu_a(k)^{-1}\mu(k), & \text{if } |k_i|\leqslant\pi/a,\\ 0, & \text{otherwise,}\end{cases}$$

where $\mu^{-1}(k)=(|k|^2+m_0^2)^{-1}$ and $\mu_a^{-1}(k)=(m_0^2+2a^{-2}\Sigma_{j=1}^2(1-\cos(ak_j)))^{-1}$. It is easy to check that (see Ref. 11, Sec. VIII.1)

$$\langle\phi(f_{x,a})\phi(f_{y,a})\rangle_{\mu_0}=\langle\phi_x\phi_y\rangle_{G_a}.$$

Thus we can realize the Gaussian field ϕ_x on aZ^2 by $\phi_x=\phi(f_{x,a})$, which is well defined on $\mathcal{S}'(R^2)$.

For $\lambda>0$ we set

$$d\mu_{a,a',\lambda}=N_{a,a',\lambda}^{-1}\exp\left(-\frac{\lambda}{4}\int'g(x):\phi_x^4:dx\right)dG_a,$$

where $N_{a,a',\lambda}$ is the normalization constant such that $\mu_{a,a',\lambda}$ is a probability measure. The lattice field $\mu_{a,a',\lambda}$ on aZ^2 can be thought of as a field on $\mathcal{S}'(R^2)$:

$$d\mu_{a,a',\lambda}=N_{a,a',\lambda}^{-1}\exp\left(-\frac{\lambda}{4}\int'g(x):\phi^4(f_{x,a}):dx\right)d\mu_0.$$

It is easy to show that

$$S^{(a,a')}(x_1,\ldots,x_{2n})=\langle\phi(f_{x_1,a})\cdots\phi(f_{x_{2n},a})\rangle_{\mu_{a,a',\lambda}}.$$

Assume that $\lambda>0$ is sufficient small. By Theorem 2.1 we know that there are subsequences $\{a_n\}$ and $\{a_n'\}$ with $\lim_{n\to\infty}a_n'|\log a_n|^{5/4}<\infty$ [here we already assumed $g\in C_0^1(R^2)$] such that

$$S_n(q_1,\ldots,q_{2m}):=a^{4m}\sum_{x_1,\ldots,x_{2m}\in aZ^2}q_1(x_1)\cdots q_{2m}(x_{2m})S^{(a_n,a_n')}(x_1,\ldots,x_{2m})$$

is convergent as $n\to\infty$, where $q_1,\ldots,q_{2m}\in\mathcal{S}(R^2)$ for $m\geqslant 1$. It is clear that $\mu_{a_n,a_n',\lambda}$ can be thought of as a probability measure on $\mathcal{S}'(R^2)$.

The correlation function $\langle \phi(q_1)\cdots\phi(q_{2m})\rangle_{\mu_{a_n,a_n',\lambda}}$ is well defined, but it is not equal to $S_n(q_1,\ldots,q_{2m})$. Let us first prove a lemma.

Lemma 6.1: Assume $\lim_{n\to\infty} a_n'|\log a_n|^{5/4}<\infty$. For sufficiently small $\lambda>0$, $\{\mu_{a_n,a_n',\lambda}\}$ is weakly convergent to μ_λ as $n\to\infty$.

Proof: From the proof of Theorem 2.1 we see that

$$\lim_{n\to\infty} S_n(q_1,\ldots,q_{2m})=\langle \phi(q_1)\cdots\phi(q_{2m})\rangle_{\mu_\lambda}.$$

Thus it suffices to prove that $S_n(q_1,\ldots,q_{2m})$ and $\langle \phi(q_1)\cdots\phi(q_{2m})\rangle_{\mu_{a_n,a_n',\lambda}}$ have the same asymptotic behavior.

By Ref. 11, Theorem VIII.5 (a), p. 263, we know that

$$\langle(\phi(q_i)-\phi_a(q_i))^2\rangle_{\mu_0}\leqslant ca^2$$

for some constant $c\in(0,\infty)$, where $\phi_a(q_i)=a^2\Sigma_{x\in aZ^2}q_i(x)\phi(f_{x,a})$. Using the hypercontractivity (see Ref. 11, Theorem I.22, p. 38) we show that

$$\langle|\phi(q_i)-\phi_a(q_i)|^p\rangle_{\mu_0}^{1/p}\leqslant(p-1)^{1/2}\langle(\phi(q_i)-\phi_a(q_i))^2\rangle_{\mu_0}^{1/2}\leqslant c(p-1)^{1/2}a \tag{6.1}$$

for some constant $c\in(0,\infty)$. It is easy to show that

$$S_n(q_1,\ldots,q_{2m})=\langle \phi_a(q_1)\cdots\phi_a(q_{2m})\rangle_{\mu_{a_n,a_n',\lambda}}.$$

By the Hölder inequality we have

$$\begin{aligned}&|S_n(q_1,\ldots,q_{2m})-\langle \phi(q_1)\cdots\phi(q_{2m})\rangle_{\mu_{a_n,a_n',\lambda}}|\\&\quad\leqslant N_{a_n,a_n',\lambda}^{-1}\left\langle \exp\left(-\frac{p}{p-1}\frac{\lambda}{4}\int' g(x):\phi^4(f_{x,a_n}):dx\right)\right\rangle_{\mu_0}^{1-1/p}\\&\qquad\times\langle|\phi_a(q_1)\cdots\phi_a(q_{2m})-\phi(q_1)\cdots\phi(q_{2m})|^p\rangle_{\mu_0}^{1/p}.\end{aligned}\tag{6.2}$$

We now choose $p=a^{-1/2m}$. It is not difficult to show that there exists a constant $M<\infty$ such that $-\int' g(x):\phi^4(f_{x,a_n}):dx\leqslant M|\log a|^2$. Thus

$$\begin{aligned}\left\langle \exp\left(-\frac{p}{p-1}\frac{\lambda}{4}\int' g(x):\phi^4(f_{x,a_n}):dx\right)\right\rangle_{\mu_0}^{1-1/p}&\leqslant c\left\langle \exp\left(-\frac{\lambda}{4}\int' g(x):\phi^4(f_{x,a_n}):dx\right)\right\rangle_{\mu_0}\\&=cN_{a_n,a_n',\lambda}.\end{aligned}$$

Therefore, the left-hand side of (6.2) is less than

$$c\langle|\phi_a(q_1)\cdots\phi_a(q_{2m})-\phi(q_1)\cdots\phi(q_{2m})|^p\rangle_{\mu_0}^{1-1/p},$$

which by (6.1) goes to zero as $a\to0^+$. This then proves that $\langle \phi(q_1)\cdots\phi(q_{2m})\rangle_{\mu_{a_n,a_n',\lambda}}$ and $S_n(q_1,\ldots,q_{2m})$ have the same asymptotic behavior for $a\to0^+$. By Proposition 5.3 we know that for any given $f\in\mathcal{S}(R^2)$ there are constants $c,c'\in(0,\infty)$ such that

$$\int_{\mathcal{S}'(R^2)} |\phi(f)|\mu_\lambda(d\phi) \leqslant \limsup_{n\to\infty} a_n^4 \sum_{x_1,x_2\in a_n Z^2} f(x_1)f(x_2)S^{(a_n,a_n')}(x_1,x_2)$$

$$\leqslant c \limsup_{n\to\infty} a_n^4 \sum_{x_1,x_2\in a_n Z^2} f(x_1)f(x_2)C^{(a_n)}(x_2-x_1) \leqslant c'. \tag{6.3}$$

Using this we show following, e.g., Ref. 31, Proposition 3.7, that there are $n_0 \geqslant 1$ and $c\in(0,\infty)$ such that, for all $f\in\mathcal{S}(R^2)$,

$$\left| \int |\phi(f)|^p \mu_\lambda(d\phi) \right|^{1/p} \leqslant c\|f\|_{n_0},$$

and there exists $n_1 > n_0$ such that

$$\mu_\lambda(\Phi'_{n_1}) = 1.$$

By (6.3) and Ref. 31, Theorem 2.1, we then know that $\mu_{a_n,a_n',\lambda}$ is weakly convergent to μ_λ for sufficiently small $\lambda>0$, where μ_λ was constructed in Theorem 2.1. ■

We now prove that μ_λ coincides with ν_λ if $\lim_{a\to 0^+} a'|\log a|^2 = 0$. For this purpose we first prove a lemma.

Lemma 6.2: If $\lim_{a\to 0^+} a'|\log a|^2 < \infty$, then there are constants $C, \lambda_1 \in (0,\infty)$ such that

$$\left\langle \exp\left(-\lambda/4 \int' dx g(x) {:}\phi_x^4{:} \right) \right\rangle_{G_a} \leqslant C, \quad \forall a\in(0,1), \lambda\in[0,\lambda_1), \tag{6.4}$$

where $\int' dx$ was defined in Sec. II.

Proof: Let

$$\xi_1 = \int' dx g(x) {:}\phi_x^4{:}, \quad \xi_2 = \int dx g(x) {:}\phi_x^4{:},$$

where $\int dx$ was also defined in Sec. II. For $s\in[0,1]$ and $\lambda>0$, we define a new probability measure $G(s,\lambda)$ by

$$\langle\cdot\rangle_{G(s,\lambda)} = \frac{\left\langle \cdot \exp\left(-\frac{s\lambda}{4}\xi_1 - \frac{(1-s)\lambda}{4}\xi_2 \right) \right\rangle_{G_a}}{\left\langle \exp\left(-\frac{s\lambda}{4}\xi_1 - \frac{(1-s)\lambda}{4}\xi_2 \right) \right\rangle_{G_a}}.$$

As in the proof of Proposition 5.3 we can easily show that there is a constant $\lambda_2>0$ such that

$$|\langle\phi_x\phi_y\rangle_{G(s,\lambda)} - C^{(a)}(x,y)| \leqslant O(1)\lambda, \quad \lambda\in[0,\lambda_2),$$

for any $x,y\in aZ^2$ and $s\in[0,1]$. By the skeleton inequalities given in Sec. III [see, e.g., (3.1) and (3.2)], we know that

$$\langle\phi_x^4\rangle_{G(s,\lambda)} \leqslant 3\langle\phi_x^2\rangle^2_{G(s,\lambda)},$$

$$\langle\phi_x^4\rangle_{G(s,\lambda)} \geqslant 3\langle\phi_x^2\rangle^2_{G(s,\lambda)} - 6s\lambda \int dj g(j) \langle\phi_x\phi_j\rangle^4_{G(s,\lambda)} - 6(1-s)\lambda \int' dj g(j) \langle\phi_x\phi_j\rangle^4_{G(s,\lambda)}. \tag{6.5}$$

We remark that

$$:\phi_x^4:=\phi_x^4-6\langle\phi_x^2\rangle_{G_a}\phi_x^2+3\langle\phi_x^2\rangle_{G_a}^2.$$

Hence, there are constants $c_1,c_2,c_3\in(0,\infty)$ such that

$$\begin{aligned}\langle:\phi_x^4:\rangle_{G(s,\lambda)}&\leqslant 3\langle\phi_x^2\rangle_{G(s,\lambda)}^2-6\langle\phi_x^2\rangle_{G_a}\langle\phi_x^2\rangle_{G(s,\lambda)}+3\langle\phi_x^2\rangle_{G_a}^2\\&\leqslant 3(\langle\phi_x^2\rangle_{G(s,\lambda)}-C^{(a)}(x,x))^2\\&\leqslant c_1\lambda^2,\quad s\in[0,1],\end{aligned}$$

$$\begin{aligned}\langle:\phi_x^4:\rangle_{G(s,\lambda)}&\geqslant 3(\langle\phi_x^2\rangle_{G(s,\lambda)}-C^{(a)}(x,x))^2-O(1)\lambda\int djg(j)C^{(a)}(x,j)^4\\&\quad-O(1)\lambda\int' djg(j)C^{(a)}(x,j)^4\geqslant c_2\lambda^2-c_3\lambda,\qquad s\in[0,1],\end{aligned}$$

if $\lambda\in[0,\lambda_2)$. It follows that there is a constant $c_4\in(0,\infty)$ such that

$$\left|\left\langle\int' dxg(x):\phi_x^4:-\int dxg(x):\phi_x^4:\right\rangle_{G(s,\lambda)}\right|\leqslant c_4\lambda,\quad\forall s\in[0,1],\lambda\in[0,\lambda_2).$$

Therefore, if $\lambda\in[0,\lambda_2)$,

$$\begin{aligned}\left|\left\langle\exp\left(-\frac{\lambda}{4}\xi_1\right)\right\rangle_{G_a}-\left\langle\exp\left(-\frac{\lambda}{4}\xi_2\right)\right\rangle_{G_a}\right|&=\frac{\lambda}{4}\left|\int_0^1(\xi_2-\xi_1)\exp\left(-\frac{s\lambda}{4}\xi_1-\frac{(1-s)\lambda}{4}\xi_2\right)ds\right|\\&\leqslant\frac{c_4\lambda^2}{4}\int_0^1\left\langle\exp\left(\frac{s\lambda}{4}\xi_1-\frac{(1-s)\lambda}{4}\xi_2\right)\right\rangle_{G_a}ds\\&\leqslant\frac{c_4\lambda^2}{4}\left\langle\exp\left(-\frac{\lambda}{4}\xi_1\right)\right\rangle_{G_a}\left\langle\exp\left(-\frac{\lambda}{4}\xi_2\right)\right\rangle_{G_a}\\&\quad\text{(by Hölder's inequality).}\end{aligned}\tag{6.6}$$

On the other hand, it follows from Ref. 11, Theorem VIII.5, p. 263, that there is a constant $c_5\in(0,\infty)$ such that

$$\left\langle\exp\left(-\frac{\lambda}{4}\xi_2\right)\right\rangle_{G_a}\leqslant c_5,\quad\forall\lambda\in[0,\lambda_2).\tag{6.7}$$

Thus, by (6.5) we can easily show that (6.4) is true. The proof of Lemma 6.2 is then complete.■

If $\lim_{a\to0^+}a'|\log a|^2=0$, by (7.1) below we can easily show that there is a constant $c_6\in(0,\infty)$ such that

$$\left\langle\left(\int' dxg(x):\phi^4(f_{x,a}):-\int dxg(x):\phi^4(f_{x,a}):\right)^2\right\rangle_{\mu_0}=\langle(\xi_1-\xi_2)^2\rangle_{G_a}\leqslant c_6(a'^2|\log a|^4+a')\tag{6.8}$$

goes to zero as $a\to0^+$. Thus, by (6.4) and (6.6) we know that $\mu_{a,a',\lambda}$ and $\mu_{a,a,\lambda}$ have the same asymptotic behavior as $a\to0^+$, if $\lim_{a\to0^+}a'|\log a|^2=0$, which proves Theorem 2.2 for $A=0$.■

Remark: We guess that the left-hand side of (6.4) is also bounded on $a\in(0,1)$ if $\limsup_{a\to0^+}a'|\log a|^2<\infty$. This assertion can probably be proven by using the approach exploited in Ref. 6 or 9, where a continuum ϕ_3^4 field was constructed.

VII. PROOF OF THEOREM 2.2 FOR $A>0$

Let us first recall some properties of Wick powers (see Ref. 11, Sec. I.1). If ϕ_x is a Gaussian random variable (under the Gaussian measure G), then

$$:\exp(t\phi_x):=\exp(t\phi_x-\tfrac{1}{2}t^2\langle\phi_x^2\rangle_G),$$

which implies

$$\prod_{i=1}^{n}:\exp(t_i\phi_{x_i}):=\exp\left(\sum_{i=1}^{n}t_i\phi_{x_i}\right)\exp\left(-\frac{1}{2}\sum_{i=1}^{n}t_i^2\langle\phi_{x_i}^2\rangle_G\right)$$
$$=:\exp\left(\sum_{i=1}^{n}t_i\phi_{x_i}\right):\exp\left(\sum_{1\leqslant i<j\leqslant n}t_it_j\langle\phi_{x_i}\phi_{x_j}\rangle_G\right).$$

We remark that $\exp(\Sigma_{1\leqslant i<j\leqslant n}t_it_j\langle\phi_{x_i}\phi_{x_j}\rangle_G)$ is not random and

$$\left\langle:\exp\left(\sum_{i=1}^{n}t_i\phi_{x_i}\right):\right\rangle_G=1.$$

Therefore,

$$\left\langle\prod_{i=1}^{n}:\exp(t_i\phi_{x_i}):\right\rangle_G=\exp\left(\sum_{1\leqslant i<j\leqslant n}t_it_j\langle\phi_{x_i}\phi_{x_j}\rangle_G\right).\tag{7.1}$$

In this section we also let $g\geqslant 0$ be a given function in $C_0^1(R^2)$ such that $\int_{R^2}|g(x)|dx>0$. We always assume in this section that $\lim_{a\to 0^+}a'|\log a|^2\in(0,\infty)$. The main aim of this section is to prove Theorem 2.2 for $A>0$. Many combinatorial results will be used in the following discussions.

We set

$$\xi_1=\int'dxg(x):\phi_x^4:=\int'dxg(x):\phi^4(f_{x,a}):,$$

$$\xi_2=\int dxg(x):\phi_x^4:=\int dxg(x):\phi^4(f_{x,a}):.$$

Let

$$\sigma=4!\int_{R^2}g(x)^2dx\lim_{a\to 0^+}a'^2C^{(a)}(0)^4,$$

where $C^{(a)}(x-y)$ was defined in Sec. II. Let η be a random variable with the normal distribution $N(0,\sigma)$ and P be a probability measure under which η is independent of $U(g)$ and $\{\phi(f),\ f\in\mathcal{S}(R^2)\}$, where $U(g)$ was defined in Sec. II.

The following proposition will play a key role in the proof of Theorem 2.2 for $A>0$.

Proposition 7.1: (i) For any $x\in R$ we have

$$\lim_{a\to 0^+}G_a(\xi_1\leqslant x)=P(U(g)+\eta\leqslant x).$$

(ii) Assume that $\lambda>0$ is sufficient small. For any $f_1,\ldots,f_m\in\mathcal{S}(R^2)$ we have

$$\lim_{a\to 0^+}\langle \phi(f_1)\cdots\phi(f_m)e^{(-\lambda/4)\,\xi_1}\rangle_{\mu_0}=\langle \phi(f_1)\cdots\phi(f_m)e^{(-\lambda/4)[U(g)+\eta]}\rangle_P,$$

where $\langle\cdot\rangle_P$ denotes the expectation with respect to P.

It is easy to show that

$$\lim_{a\to 0^+} a^{2m}\sum_{x_1,\ldots,x_{2m}\in aZ^2} f_1(x_1)\cdots f_m(x_m)\langle \phi_{x_1}\cdots\phi_{x_m}\xi_2^k\rangle_{G_a}=\langle \phi(f_1)\cdots\phi(f_m)U(g)^k\rangle_{\mu_0}.$$

Therefore

$$\lim_{a\to 0^+}\langle(\xi_2+\eta)^k\rangle_P=\sum_{i=0}^{k}\binom{i}{k}\langle U(g)^i\rangle_P\langle\eta^{k-i}\rangle_P,$$

$$\lim_{a\to 0^+} a^{2m}\sum_{x_1,\ldots,x_m\in aZ^2} f_1(x_1)\cdots f_m(x_m)\langle \phi(f_{x_1,a})\cdots\phi(f_{x_m,a})(\xi_2+\eta)^k\rangle_P$$
$$=\langle \phi(f_1)\cdots\phi(f_m)(U(g)+\eta)^k\rangle_P,$$

where $\binom{i}{k}=[k(k-1)\cdots(k-i+1)]/i!$. Thus, by Lemma 6.2 we can see that Proposition 7.1 is a consequence of the following relations:

$$\lim_{a\to 0^+}(\langle\xi_1^k\rangle_{G_a}-\langle(\xi_2+\eta)^k\rangle_P)=0, \tag{7.2}$$

$$\lim_{a\to 0^+}(\langle \phi_{x_1}\cdots\phi_{x_m}\xi_1^k\rangle_{G_a}-\langle \phi_{x_1}\cdots\phi_{x_m}(\xi_2+\eta)^k\rangle_P)=0 \tag{7.3}$$

for all $k\geqslant 0$, where $x_1,\ldots,x_m\in aZ^2$ with $\#\{x_1,\ldots,x_m\}=m$. We prove only (7.2) in detail; (7.3) can be proven by a similar argument.

To prove (7.2) we need to compute the quantity $\langle\xi_1^k\rangle_{G_a}$. We remark that

$$\langle\xi_1^k\rangle_{G_a}=a'^{2k}\sum_{x_1,\ldots,x_k\in a'Z^2} g(x_1)\cdots g(x_k)\langle:\phi_{x_1}^4:\cdots:\phi_{x_k}^4:\rangle_{G_a}.$$

Thus, it suffices to compute $\langle:\phi_{x_1}^4:\cdots:\phi_{x_k}^4:\rangle_{G_a}$. For this purpose we now compare the terms with the coefficient $\Pi_{i=1}^k t_i^4$ on both sides of (7.1). In general, the term with the coefficient $\Pi_{i=1}^k t_i^4$ on the right-hand side of (7.1) can be expressed as a sum of some quantities of the following form

$$q_{a,a'}(x_1,\ldots,x_k):=\mathcal{C}_k\prod_{j=2}^{k}\langle \phi_{x_1}\phi_{x_j}\rangle_{G_a}^{l_{1,j}}\prod_{j=3}^{k}\langle \phi_{x_2}\phi_{x_j}\rangle_{G_a}^{l_{2,j}}\cdots\prod_{j=k-1}^{k}\langle \phi_{x_{k-2}}\phi_{x_j}\rangle_{G_a}^{l_{k-2,j}}\langle \phi_{x_{k-1}}\phi_{x_k}\rangle_{G_a}^{l_{k-1,k}},$$

where $\mathcal{C}_k$ is just the coefficient, $l_{i,j}\in\{0,1,2,3,4\}$, $\Sigma_{j=2}^k l_{1,j}=4$, and

$$\sum_{j=1}^{i-1} l_{j,i}+\sum_{j=i+1}^{k} l_{i,j}=4,\quad i=2,\ldots,k-1.$$

We remark that there is a one-to-one correspondence between the quantity $q_{a,a'}$ and the set of $l_{i,j}$. For convenience we will use the set of $l_{i,j}$ to represent the quantity $q_{a,a'}$.

Let

$$Q_{a,a'}(x_1,\ldots,x_k)=\sum_{l_{i,j}<4} q_{a,a'}(x_1,\ldots,x_k),$$

where the sum is taken over all $l_{i,j}$ with $l_{i,j}\in\{0,1,2,3\}$. If there is no such $l_{i,j}$, then we set $Q_{a,a'}(x_1,\ldots,x_k)=0$. Let

$$Q_k=\lim_{a\to 0^+} a^{2k}\sum_{x_1,\ldots,x_k\in aZ^2} g(x_1)\cdots g(x_k)Q_{a,a}(x_1,\ldots,x_k).$$

It is easy to prove that the latter limit indeed exists and is equal to

$$\lim_{a\to 0^+} a'^{2k}\sum_{x_1,\ldots,x_k\in a'Z^2} g(x_1)\cdots g(x_k)Q_{a,a'}(x_1,\ldots,x_k).$$

Let us first prove a lemma.

Lemma 7.2: For any $k\geqslant 2$ we have

$$\lim_{a\to 0^+}\langle\xi_2^k\rangle_{G_a}=\langle U(g)^k\rangle_{\mu_0}=\sum_{m=0}^{[k/2]}\binom{2m}{k}(2m-1)!!\langle U(g)^2\rangle_{\mu_0}^m Q_{k-2m},$$

where $(2m-1)!!=(2m-1)\cdots 3\times 1$.

Proof: The first equality is easy to prove. We only prove the second equality. As explained before, we use the set $\{l_{i,j}\}$ to represent the quantity $q_{a,a'}(x_1,\ldots,x_k)$. Let $m=\#\{(i,j):\ l_{i,j}=4\}$ and

$$F_m(a,a')=\sum_{\#\{(i,j):l_{i,j}=4\}=m} a'^{2k}\sum_{x_1,\ldots,x_k\in a'Z^2} g(x_1)\cdots g(x_k)q_{a,a'}(x_1,\ldots,x_k).$$

Then, $\langle\xi_2^k\rangle_{G_a}$ is equal to

$$a^{2k}\sum_{x_1,\ldots,x_k\in aZ^2} g(x_1)\cdots g(x_k)\langle:\phi_{x_1}^4:\cdots:\phi_{x_k}^4:\rangle_{G_a}=\sum_{m=0}^{[k/2]}F_m(a,a).$$

We already know that

$$\lim_{a\to 0^+}F_0(a,a)=\lim_{a\to 0^+}a^{2k}\sum_{x_1,\ldots,x_k\in aZ^2} g(x_1)\cdots g(x_k)Q_{a,a}(x_1,\ldots,x_k)=Q_k.$$

We now consider $F_m(a,a)$ for $m\in[1,[k/2]]$. For $m\in[1,[k/2]]$ we can choose a subset $\{i_1,i_2,\ldots,i_{2m-1},i_{2m}\}$ from the set $\{1,2,\ldots,k\}$ such that $l_{s,t}=4$, if $s<t\in\{i_1,\ldots,i_{2m}\}$. It is clear that there are $\binom{2m}{k}$ choices of such subsets. For such a fixed subset $\{i_1,i_2,\ldots,i_{2m-1},i_{2m}\}$ we can construct m pairs $(j_1,j_2),\ldots,(j_{2m-1},j_{2m})$ with $\{j_1,\ldots,j_{2m}\}=\{i_1,\ldots,i_{2m}\}$. It is clear that there are $(2m-1)!!$ choices of such pairs. Moreover, by (7.1) we easily prove that

$$\begin{aligned}&\lim_{a\to 0^+}a^4\sum_{x_1,x_2\in aZ^2} g(x_1)g(x_2)\langle:\phi_{x_1}^4::\phi_{x_2}^4:\rangle_{G_a}\\&\quad=\lim_{a\to 0^+}4!a^4\sum_{x_1,x_2\in aZ^2} g(x_1)g(x_2)\langle\phi_{x_1}\phi_{x_2}\rangle_{G_a}^4\\&\quad=\langle U(g)^2\rangle_{\mu_0}.\end{aligned}$$

From the above discussions we see that $\lim_{a\to 0^+}\langle\xi_2^k\rangle_{G_a}$ is equal to

$$\lim_{a\to 0^+}\sum_{m=0}^{[k/2]}\binom{2m}{k}\sum_{l_{j_1,j_2}=\cdots=l_{j_{2m-1},j_{2m}}=4} a^{4m}(4!)^m \sum_{x_{j_1},\ldots,x_{j_{2m}}\in aZ^2} g(x_{j_1})\cdots g(x_{j_{2m}})\langle \phi_{x_{j_1}}\phi_{x_{j_2}}\rangle_{G_a}^4\cdots$$

$$\times\langle \phi_{x_{j_{2m-1}}}\phi_{x_{j_{2m}}}\rangle_{G_a}^4 a^{2k-4m}\sum_{x_{t_1},\ldots,x_{t_{k-2m}}\in aZ^2} g(x_{t_1})\cdots g(x_{t_{k-2m}})Q_{a,a}(x_{t_1},\ldots,x_{t_{k-2m}})$$

$$=\sum_{m=0}^{[k/2]}\binom{2m}{k}(2m-1)!!\langle U(g)^2\rangle_{\mu_0}^m Q_{k-2m},$$

where $\{t_1,\ldots,t_{k-2m}\}=\{1,2,\ldots,k\}\backslash\{j_1,j_2,\ldots,j_{2m}\}$. This then completes the proof of Lemma 7.2.■

We now turn to the proof of (7.2). It is clear that (7.2) holds for $k=0$ and 1. Let us first prove (7.2) for $k=2$. By (7.1) we know that $\langle :\phi_x^4::\phi_y^4:\rangle_{G_a}=4!C^{(a)}(x-y)^4$. Hence

$$\langle \xi_1^2\rangle_{G_a}=a'^4\sum_{x,y\in a'Z^2} g(x)g(y)\langle :\phi_x^4::\phi_y^4:\rangle_{G_a}$$

$$=4!a'^4\sum_{x,y\in a'Z^2} g(x)g(y)C^{(a)}(x-y)^4$$

$$=4!a'^2C^{(a)}(0)^4a'^2\sum_{x\in a'Z^2} g(x)^2+4!a'^4\sum_{x,y\in a'Z^2,x\neq y} g(x)g(y)C^{(a)}(x-y)^4.$$

Since $\lim_{a\to 0^+} a'|\log a|^2\in(0,\infty)$, it is easy to show that

$$\lim_{a\to 0^+} 4!a'^4\sum_{x,y\in a'Z^2,x\neq y} g(x)g(y)C^{(a)}(x-y)^4$$

$$=\lim_{a\to 0^+} 4!a^4\sum_{x,y\in aZ^2} g(x)g(y)C^{(a)}(x-y)^4$$

$$=\langle U(g)^2\rangle_{\mu_0}.$$

In other words, we have

$$\lim_{a\to 0^+}\left(4!a'^4\sum_{x,y\in a'Z^2,x\neq y} g(x)g(y)C^{(a)}(x-y)^4-\langle \xi_2^2\rangle_{G_a}\right)=0.$$

Moreover,

$$\lim_{a\to 0^+} 4!a'^2C^{(a)}(0)^4a'^2\sum_{x\in a'Z^2} g(x)^2=\langle \eta^2\rangle_P=\sigma.$$

Therefore,

$$\lim_{a\to 0^+}(\langle \xi_1^2\rangle_{G_a}-\langle \eta^2\rangle_P-\langle \xi_2^2\rangle_{G_a})=0,$$

which implies (7.2) for $k=2$, since $\langle(\eta+\xi_2)^2\rangle_P=\langle \eta^2\rangle_P+\langle \xi_2^2\rangle_{G_a}$.

We now prove (7.2) for the general case. From the proof of Lemma 7.2 we see that

$$\langle \xi_1^k \rangle_{G_a} = \sum_{m=0}^{[k/2]} F_m(a,a')$$

$$= \sum_{m=0}^{[k/2]} \binom{2m}{k} \sum_{l_{j_1,j_2}=\cdots=l_{j_{2m-1},j_{2m}}=4} a'^{4m} (4!)^m \sum_{x_{j_1},\ldots,x_{j_{2m}} \in a'Z^2} g(x_{j_1}) \cdots g(x_{j_{2m}})$$

$$\times \langle \phi_{x_{j_1}} \phi_{x_{j_2}} \rangle_{G_a}^4 \cdots \langle \phi_{x_{j_{2m-1}}} \phi_{x_{j_{2m}}} \rangle_{G_a}^4 a'^{2k-4m}$$

$$\times \sum_{x_{t_1},\ldots,x_{t_{k-2m}} \in a'Z^2} g(x_{t_1}) \cdots g(x_{t_{k-2m}}) Q_{a,a'}(x_{t_1},\ldots,x_{t_{k-2m}}).$$

From the proof of (7.2) for $k=2$ we also see that

$$\lim_{a \to 0^+} 4! a'^4 \sum_{x_{j_{2i-1}}, x_{j_{2i}} \in a'Z^2} g(x_{j_{2i-1}}) g(x_{j_{2i}}) \langle \phi_{x_{j_{2i-1}}} \phi_{x_{j_{2i}}} \rangle_{G_a}^4 = \langle \eta^2 \rangle_P + \langle U(g)^2 \rangle_{\mu_0}.$$

Using this we easily show that

$$\lim_{a \to 0^+} (4!)^m a'^{4m} \sum_{x_{j_1},\ldots,x_{j_{2m}} \in a'Z^2} g(x_{j_1}) \cdots g(x_{j_{2m}}) \langle \phi_{x_{j_1}} \phi_{x_{j_2}} \rangle_{G_a}^4 \cdots \langle \phi_{x_{j_{2m-1}}} \phi_{x_{j_{2m}}} \rangle_{G_a}^4$$

$$= \sum_{l=0}^{m} \binom{l}{m} \langle \eta^2 \rangle_P^l \langle U(g)^2 \rangle_{\mu_0}^{m-l}.$$

It is clear that

$$\lim_{a \to 0^+} a'^{2k-4m} \sum_{x_{t_1}\ldots,x_{t_{k-2m}} \in a'Z^2} g(x_{t_1}) \cdots g(x_{t_{k-2m}}) Q_{a,a'}(x_{t_1},\ldots,x_{t_{k-2m}}) = Q_{k-2m}.$$

It follows, inserting this result in above expression for $\langle \xi_1^k \rangle_{G_a}$,

$$\lim_{a \to 0^+} \langle \xi_1^k \rangle_{G_a} = \sum_{m=0}^{[k/2]} \binom{2m}{k} (2m-1)!! \sum_{l=0}^{m} \binom{l}{m} \langle \eta^2 \rangle_P^l \langle U(g)^2 \rangle_{\mu_0}^{m-l} Q_{k-2m}. \tag{7.4}$$

By computation we know that the right-hand side of (7.4) is equal to

$$\sum_{l=0}^{[k/2]} \sum_{m=l}^{[k/2]} \binom{l}{m} \binom{2m}{k} (2m-1)!! \langle \eta^2 \rangle_P^l \langle U(g)^2 \rangle_{\mu_0}^{m-l} Q_{k-2m}$$

$$= \sum_{l=0}^{[k/2]} \binom{2l}{k} (2l-1)!! \langle \eta^2 \rangle_P^l \sum_{m=l}^{[k/2]} \frac{(k-2l)\cdots(k-2m+1)}{2^{m-l}(m-l)!} \langle U(g)^2 \rangle_{\mu_0}^{m-l} Q_{k-2m}$$

$$= \sum_{l=0}^{[k/2]} \binom{2l}{k} (2l-1)!! \langle \eta^2 \rangle_P^l \sum_{m=0}^{[(k-2l)/2]} \binom{2m}{k-2l} (2m-1)!! \langle U(g)^2 \rangle_{\mu_0}^{m} Q_{k-2l-2m},$$

which is equal by Lemma 7.2 to

$$\sum_{l=0}^{[k/2]} \binom{2l}{k} (2l-1)!! \langle \eta^2 \rangle_P^l \langle U(g)^{k-2l} \rangle_{\mu_0} = \langle [\eta + U(g)]^k \rangle_P.$$

This then completes the proof of (7.2), since $\lim_{a\to 0^+}\langle(\eta+\xi_2)^k\rangle_P=\langle[\eta+U(g)]^k\rangle_P$. Thus we also have completed the proof of Proposition 7.1. ■

Proof of Theorem 2.2 for A>0: By Lemma 6.1 and Lemma 6.2 we easily show that if $\lambda>0$ is sufficient small,

$$\lim_{a\to 0^+}\left\langle \exp\left(-\frac{\lambda}{4}\xi_1\right)\right\rangle_{G_a}=\left\langle \exp\left(-\frac{\lambda}{4}[U(g)+\eta]\right)\right\rangle_P$$

$$=\left\langle \exp\left(-\frac{\lambda}{4}U(g)\right)\right\rangle_{\mu_0}\left\langle \exp\left(-\frac{\lambda}{4}\eta\right)\right\rangle_P,$$

$$\lim_{a\to 0^+}\left\langle \phi(f_1)\cdots\phi(f_m)\exp\left(-\frac{\lambda}{4}\xi_1\right)\right\rangle_{G_a}=\left\langle \phi(f_1)\cdots\phi(f_m)\exp\left(-\frac{\lambda}{4}[U(g)+\eta]\right)\right\rangle_P$$

$$=\left\langle \phi(f_1)\cdots\phi(f_m)\exp\left(-\frac{\lambda}{4}U(g)\right)\right\rangle_{\mu_0}\left\langle \exp\left(-\frac{\lambda}{4}\eta\right)\right\rangle_P.$$

Therefore, if $\lambda>0$ is sufficiently small, we have

$$\lim_{a\to 0^+}\langle\phi(f_1)\cdots\phi(f_m)\rangle_{\mu_{a,a',\lambda}}=\langle\phi(f_1)\cdots\phi(f_m)\rangle_{\nu_{\lambda,g}}.$$

Since the original continuum ϕ_2^4-quantum field measure $\nu_{\lambda,g}$ is uniquely determined by its moment functions,[31] we have actually proved $\mu_{\lambda.g}=\nu_{\lambda,g}$, if $\lambda>0$ is sufficient small. This ends the proof of Theorem 2.2 for $A>0$. ■

VIII. SOME REMARKS AND OPEN PROBLEMS

In this section we give some remarks on the new lattice approximation of the continuum ϕ_2^4-quantum field. In the following we always assume that $g\in C_0^1(R^2)$ is given such that, $g\geqslant 0$, $\int_{R^2}g(x)dx>0$.

(i) *Coincidence with the original field.* Assume $\lim_{a\to 0^+}a'|\log a|^2<\infty$. In this case, we believe that $\mu_{\lambda,g}$ as given in Theorem 2.1 is well defined also for *all* $\lambda\geqslant 0$ (without the restriction $0\leqslant\lambda\leqslant\lambda_0$). If one could prove this, then from the proof of Theorem 2.2 we would have that the measure $\mu_{\lambda,g}$ with $\lambda\in[0,\infty)$ also coincides with the original ϕ_2^4-field measure with cutoff g, $\nu_{\lambda,g}$, for all λ,g. Unfortunately, we are not yet able to prove the former assertion on $\mu_{\lambda,g}$. The main difficulty is that we are not able to prove the boundedness of the sequence $\{\langle e^{-\lambda V_{a_n'Z^2}}\rangle_{G_{a_n}}\}_{n\geqslant 1}$ for all $\lambda\geqslant 0$ (we have only a control for $0\leqslant\lambda\leqslant\lambda_0$).

(ii) *A general existence result.* In Theorem 2.1 we already constructed a continuum ϕ_2^4-quantum field $\mu_{\lambda,g}$ if $\lim_{a\to 0^+}a'|\log a|^{5/4}<\infty$. From the discussion given in the Appendix we can see that we can also construct a continuum ϕ_2^4-quantum field $\mu_{\lambda,g}$ if $\lim_{a\to 0^+}a'|\log a|^{7/6}<\infty$. In general, if there is $\epsilon\in(0,\frac{1}{4})$ such that $\lim_{a\to 0^+}a'|\log a|^{1+\epsilon}<\infty$, then with similar techniques it should be possible to show that we could use the general skeleton inequalities given in Ref. 25 to define lattice ϕ_2^4 fields with new counterterms and then construct a (nontrivial) continuum ϕ_2^4-quantum field $\mu_{\lambda,g}$ by approximation from these lattice ϕ_2^4 fields with the new counterterms. Since the main idea for constructing the new continuum ϕ_2^4 field has been already explained in the proof of Theorem 2.1, we are not going to state and prove the general existence theorem.

(iii) *Singularity with respect to the Gaussian measure.* Consider the case

$$\lim_{a\to 0^+}a'|\log a|^2=\infty \qquad \lim_{a\to 0^+}a'|\log a|^{1+\epsilon}<\infty$$

for some $\epsilon \in (0,\frac{1}{4})$. The original ϕ_2^4-field measure with spatial cutoff g (i.e., the measure $\nu_{\lambda,g}$ given before Theorem 2.1) is absolutely continuous with respect to the Gaussian measure μ_0. It is easy to show that $\langle (\int' dx g(x):\phi_x^4:)^2 \rangle_{G_a}$ goes to infinity as $a \to 0^+$, if $\lim_{a\to 0^+} a'|\log a|^2 = \infty$. In another paper[18] we have proved that $\int' dx g(x):\phi_x^4:$ satisfies the central limit theorem as $a \to 0^+$, if $\lim_{a\to 0^+} a'|\log a|^2 = \infty$. In other words, we proved in Ref. 18 that there is a constant $c \in (0,\infty)$ such that

$$\lim_{a\to 0^+} G_a\left(c(a'|\log a|^2)^{-1} \int' dx g(x):\phi_x^4: \leqslant y \right) = (2\pi)^{-1/2} \int_{-\infty}^{y} e^{-|z|^2/2} dz, \quad \forall y \in R.$$

Using this fact one might try to prove that there are Borel measurable sets D_n, $n \geqslant 1$ such that

$$\lim_{n\to\infty} \mu_0(D_n) = 0, \qquad \liminf_{n\to\infty} \mu_{\lambda,g}(D_n) > 0.$$

It then would follow that the new measure $\mu_{\lambda,g}$ (constructed for $\lambda > 0$ sufficiently small) is not absolutely continuous with respect to the Gaussian measure μ_0 if $\lim_{a\to 0^+} a'|\log a|^2 = \infty$ and $\lim_{a\to 0^+} a'|\log a|^{1+\epsilon} < \infty$.

(iv) *Quasi-invariance*. Assume $\lim_{a\to 0^+} a'|\log a|^2 = \infty$ and $\lim_{a\to 0^+} a'|\log a|^{3/2} < \infty$. In this case, we believe that the new measure $\mu_{\lambda,g}$ is k quasi-invariant for a linear subset of k in $\mathcal{S}(R^2)$ (for the definition of k quasi-invariance the reader is referred to Ref. 11, 32–34, or 35; the corresponding property in the standard ϕ_2^4 model was discussed, e.g., in Refs. 35–37). In this case it should be possible to use the approach by Dirichlet forms,[35,36] as a tool, to study the stochastic quantization of the field measure $\mu_{\lambda,g}$ (similarly as it was done in Refs. 35 and 36 for the original ϕ_2^4-field measure and in Ref. 38 for the three-dimensional polymer measure).

(v) *No quasi-invariance*. Assume $\lim_{a\to 0^+} a'|\log a|^{3/2} = \infty$ and $\lim_{a\to 0^+} a'|\log a|^{1+\epsilon} < \infty$ for some $\epsilon \in (0,1/2)$. In this case we believe that $\mu_{\lambda,g}$ with small $\lambda > 0$ is not quasi-invariant for any $k \in \mathcal{S}(R^2)$. We remark that the original continuum ϕ_2^4 field is k quasi-invariant for some $k \in \mathcal{S}(R^2)$.[11,32] Thus in particular $\mu_{\lambda,g}$ would be different from the original ϕ_2^4 field measure $\nu_{\lambda,g}$. The original continuum ϕ_3^4-field measure with spatial cutoff is believed to be not k quasi-invariant and also singular with respect to the Gaussian measure μ_0 on $\mathcal{S}'(R^3)$ (cf. Ref. 39 for partial results). In this sense, the new field $\mu_{\lambda,g}$ in the present case might behave like the original ϕ_3^4-field measure.

(vi) *No Borel summability*. Assume as in (v) $\lim_{a\to 0^+} a'|\log a|^{3/2} = \infty$ and $\lim_{a\to 0^+} a'|\log a|^{1+\epsilon} < \infty$ for some $\epsilon \in (0,1/2)$. If the conjecture we made in (v) holds, we have that $\mu_{\lambda,g}$ is different from $\nu_{\lambda,g}$. In this case we expect that the expansion in powers of λ of the n-point functions of $\mu_{\lambda,g}$ is not Borel summable (whereas it is for those of the standard $\nu_{\lambda,g}$ (Ref. 40).

(vii) *Triviality*. Assume $\lim_{a\to 0^+} a'|\log a| < \infty$ and $\lim_{a\to 0^+} a'|\log a|^2 = \infty$. In this case, we believe that any lattice ϕ_2^4-field model measure with or without counterterms is weakly convergent to a Gaussian field measure (if the limit exists). This conjecture is based on an intersection (restricted to the subset $m_n Z^2$, with $m_n \in N$) property of independent random walks in Z^2. Let $\{X_n\}$ and $\{Y_n\}$ be two independent simple random walks in Z^2 with probability measure P'. Assume that $X_0 = x_n$, $Y_0 = y_n$ and $|x_n - y_n| \geqslant O(1)n^{1/2}$. Then we can easily prove that $\lim_{n\to\infty} P'$ (there are $k \geqslant 1$ and $l \geqslant 1$ such that $X_k = Y_l \in m_n Z^2) = 0$, if $\lim_{n\to\infty} m_n^2 n^{-1} (\log n)^2 = \infty$ (cf. Ref. 41, Theorem 1.3 and Lemma 4.5). It seems possible to prove the above conjecture by using the approach given in Ref. 1 or 42, where the lattice ϕ_d^4 fields for $d \geqslant 5$ with the same cutoff in the free and interacting parts were proved to be weakly convergent to the Gaussian field (if the limit exists).

(viii) *Convergence without subsequences*. Following Ref. 5, one can show that all Osterwalder–Schrader axioms, except perhaps for rotation invariance, are satisfied for the new ϕ_2^4 fields in the infinite-volume limit defined by Theorem 2.1. The continuum ϕ_2^4 and ϕ_3^4 fields are also constructed in Ref. 5 as subsequence limits of some lattice field theories. It is believed that

these fields given in Ref. 5 are also continuum limits of the corresponding lattice theories without involving subsequences. In Ref. 5, Sec. 9, Eq. (2), a way was suggested to prove that the above assertion is correct. According to this suggestion one has to formulate the ϕ_d^4 fields on two different lattices (with different lattice meshes a_1, a_1' and a_2, a_2', respectively) as a field on one lattice and then try to interpolate between the two fields in two stages [i.e., try to estimate the differences given by Ref. 5, Eq. (9.4)]. From Theorem 2.1 given above, however, we can see that each difference given in Ref. 5, Eq. (9.4), is not always convergent to zero as $a_i, i=1,2$, go to zero, although the summation of the two differences given in Ref. 5, Eq. (9.4), is believed to be convergent to zero. to It would also be very interesting to prove the existence of the continuum limit of $\nu_{a,a'}$ as $a, a' \to 0^+$ without involving subsequences.

Finally, we remark that one can also use the approach given in Ref. 5 to discuss the new convergent lattice approximation for the ϕ_3^4-quantum field.

Note added. A first version of this paper was prepared in 1995. Due to the untimely departure of Xian Yin Zhou, the revised version had to be completed by the two first named authors, without the essential precious help of Xian Yin. These authors deeply mourn the departure of their friend, whose work and inspiration were at the basis of the whole present paper.

Note added in proof. An earlier version of the present paper, with the title ''A new convergent lattice approximation for the ϕ_2^4-quantum field'' has appeared in ''Collection Papers of Zhou Xianyin,'' Beijing Normal University, Press, Beijing (Vol. II, pp. 778–810), 2002.

ACKNOWLEDGMENTS

We thank Professor Michael Röckner for very instructive and stimulating discussions, in particular for underlying the relevance of Ref. 31 and for useful comments concerning Sec. VIII. The financial support of SFB 611 in Bielefeld and the DFG research project for X.Y.Z. is gratefully acknowledged.

APPENDIX

In this appendix, we give an estimate of U_4 (see Sec. III) up to the third order in the coupling constant λ. As in Ref. 24, Sec. 3, we write U_4 with the help of a function $F(x_1,x_2|x_3,x_4)$ in the form

$$U_4(x_1,x_2,x_3,x_4)=F(x_1,x_2|x_3,x_4)+F(x_1,x_3|x_2,x_4)+F(x_1,x_4|x_2,x_3).$$

Let

$$I_{k_1,k_2,k_3}(x_1,x_2)=\sum_{i_1,i_2,i_3}\langle\phi_{x_1}\phi_{k_{i_1}}\rangle\langle\phi_{k_{i_1}}\phi_{k_{i_2}}\rangle\langle\phi_{k_{i_2}}\phi_{k_{i_3}}\rangle\langle\phi_{k_{i_3}}\phi_{x_2}\rangle,$$

where the sum is taken over all the permutations (i_1,i_2,i_3) of the set $\{1,2,3\}$. Using the random walk representation we can show that there is $I(x_1,x_2|x_3,x_4)$ such that

$$F(x_1,x_2|x_3,x_4)\geqslant\lambda c_1(\vec{x})+\lambda^2 c_2(\vec{x})+\lambda^3 c_3(\vec{x})+\lambda^5 I(x_1,x_2|x_3,x_4),$$

with $\vec{x}=(x_1,x_2,x_3,x_4)$, $I(x_1,x_2|x_3,x_4)$ does not depend on λ, and

$$c_1(\vec{x}) \equiv -6 \int' djg(j) \langle \phi_{x_1} \phi_j \rangle \langle \phi_{x_2} \phi_j \rangle \langle \phi_{x_3} \phi_j \rangle \langle \phi_{x_4} \phi_j \rangle,$$

$$\begin{aligned} c_2(\vec{x}) \equiv & 18 \int' djg(j) \int' dkg(k) \langle \phi_{x_1} \phi_j \rangle \langle \phi_{x_2} \phi_j \rangle \langle \phi_{x_3} \phi_k \rangle \langle \phi_{x_4} \phi_k \rangle \langle \phi_j \phi_k \rangle^2 \\ & + 18 \int' djg(j) \int' dkg(k) \langle \phi_{x_3} \phi_j \rangle \langle \phi_{x_4} \phi_k \rangle \langle \phi_j \phi_k \rangle^2 (\langle \phi_{x_1} \phi_j \rangle \langle \phi_k \phi_{x_2} \rangle \\ & + \langle \phi_{x_1} \phi_k \rangle \langle \phi_j \phi_{x_2} \rangle), \end{aligned}$$

$$\begin{aligned} c_3(\vec{x}) \equiv & -8 \int' djg(j) \langle \phi_{x_3} \phi_j \rangle \langle \phi_{x_4} \phi_j \rangle \int' dk_1 g(k_1) \int' dk_2 g(k_2) \langle \phi_{x_1} \phi_{k_1} \rangle \langle \phi_{k_1} \phi_{k_2} \rangle^2 \langle \phi_{k_2} \phi_j \rangle \\ & \times \langle \phi_j \phi_{k_1} \rangle \langle \phi_{k_1} \phi_{x_2} \rangle - 12 \int' djg(j) \langle \phi_{x_3} \phi_j \rangle \langle \phi_{x_4} \phi_j \rangle \int' dk_1 g(k_1) \int' dk_2 g(k_2) \langle \phi_{x_1} \phi_{k_1} \rangle \\ & \times \langle \phi_{k_1} \phi_j \rangle \langle \phi_j \phi_{k_2} \rangle \langle \phi_{k_1} \phi_{k_2} \rangle^2 \langle \phi_{k_2} \phi_{x_2} \rangle - 8 \int' djg(j) \langle \phi_{x_3} \phi_j \rangle \\ & \times \langle \phi_{x_4} \phi_j \rangle \int' dk_1 g(k_1) \int' dk_2 g(k_2) \langle \phi_j \phi_{k_1} \rangle \langle \phi_{x_2} \phi_{k_2} \rangle \langle \phi_{k_1} \phi_{k_2} \rangle^2 (\langle \phi_{x_1} \phi_{k_1} \rangle^2 \langle \phi_{k_2} \phi_j \rangle \\ & + \langle \phi_{x_1} \phi_{k_2} \rangle \langle \phi_{k_1} \phi_j \rangle) - 12 \int' djg(j) \int' dk_1 g(k_1) \int' dk_2 g(k_2) \langle \phi_{x_1} \phi_{k_1} \rangle \langle \phi_{k_1} \phi_j \rangle^2 \langle \phi_{k_1} \phi_{x_2} \rangle \\ & \times \langle \phi_{x_3} \phi_{k_2} \rangle \langle \phi_{x_4} \phi_{k_2} \rangle \langle \phi_j \phi_{k_2} \rangle^2 - 8 \int' djg(j) \int' dkg(k) \langle \phi_{x_3} \phi_j \rangle \langle \phi_{x_4} \phi_k \rangle \langle \phi_j \phi_k \rangle \\ & \times \Big[\langle \phi_k \phi_{x_2} \rangle \int' dlg(l) \langle \phi_{x_1} \phi_l \rangle \langle \phi_k \phi_l \rangle \langle \phi_j \phi_l \rangle^2 + \langle \phi_j \phi_{x_2} \rangle \int' dl \;\; g(l) (\langle \phi_{x_1} \phi_l \rangle \langle \phi_j \phi_l \rangle \\ & \times \langle \phi_k \phi_l \rangle^2) + \int' dlg(l) \langle \phi_k \phi_l \rangle \langle \phi_l \phi_{x_2} \rangle \langle \phi_l \phi_j \rangle (\langle \phi_{x_1} \phi_l \rangle \langle \phi_j \phi_k \rangle + \langle \phi_{x_1} \phi_j \rangle \langle \phi_l \phi_k \rangle) \\ & + \int' dlg(l) \langle \phi_j \phi_l \rangle \langle \phi_l \phi_{x_2} \rangle \langle \phi_l \phi_k \rangle (\langle \phi_{x_1} \phi_l \rangle \langle \phi_j \phi_k \rangle + \langle \phi_{x_1} \phi_k \rangle \langle \phi_l \phi_j \rangle) \Big] - 36 \int' djg(j) \\ & \times \langle \phi_{x_1} \phi_j \rangle \langle \phi_j \phi_{x_2} \rangle \int' dk_1 g(k_1) \int' dk_2 g(k_2) \langle \phi_{x_3} \phi_{k_1} \rangle \langle \phi_j \phi_{k_1} \rangle \\ & \times \langle \phi_{k_1} \phi_{k_2} \rangle^2 \langle \phi_{x_4} \phi_{k_2} \rangle^2 \langle \phi_{x_4} \phi_{k_2} \rangle \langle \phi_j \phi_{k_2} \rangle - 18 \int' djg(j) \langle \phi_{x_1} \phi_j \rangle \\ & \times \langle \phi_j \phi_{x_2} \rangle \int' dk_1 g(k_1) \int' dk_2 g(k_2) \langle \phi_{x_3} \phi_{k_1} \rangle \langle \phi_{x_4} \phi_{k_1} \rangle \langle \phi_{k_1} \phi_{k_2} \rangle^2 \langle \phi_j \phi_{k_2} \rangle^2 \\ & - \frac{8}{3} \int' djg(j) \int' dk_1 g(k_1) \int' dk_2 g(k_2) \langle \phi_{x_3} \phi_{k_1} \rangle \langle \phi_j \phi_{k_1} \rangle \langle \phi_{x_4} \phi_{k_2} \rangle \langle \phi_j \phi_{k_2} \rangle \\ & \times I_{j,k_1,k_2}(x_1, x_2) - 6 \int' djg(j) \int' dk_1 g(k_1) \int' dk_2 g(k_2) \langle \phi_{x_4} \phi_{k_1} \rangle \langle \phi_j \phi_{k_1} \rangle^2 \langle \phi_{x_3} \phi_{k_2} \rangle \\ & \times \langle \phi_{k_1} \phi_{k_2} \rangle \langle \phi_j \phi_{k_2} \rangle (\langle \phi_{k_2} \phi_{x_2} \rangle \langle \phi_{x_1} \phi_j \rangle + \langle \phi_j \phi_{x_2} \rangle \langle \phi_{x_1} \phi_{k_2} \rangle) \\ & - 6 \int' djg(j) \int' dk_1 g(k_1) \int' dk_2 g(k_2) \langle \phi_{x_3} \phi_{k_1} \rangle \langle \phi_j \phi_{k_1} \rangle^2 \langle \phi_{x_4} \phi_{k_2} \rangle \langle \phi_{k_1} \phi_{k_2} \rangle \langle \phi_j \phi_{k_2} \rangle \end{aligned}$$

$$\times(\langle\phi_{k_2}\phi_{x_2}\rangle\langle\phi_{x_1}\phi_j\rangle+\langle\phi_j\phi_{x_2}\rangle\langle\phi_{x_1}\phi_{k_2}\rangle)-12\int' djg(j)\int' dk_1 g(k_1)\int' dk_2 g(k_2)$$

$$\times\langle\phi_{x_3}\phi_{k_1}\rangle\langle\phi_{x_4}\phi_{k_1}\rangle\langle\phi_j\phi_{k_1}\rangle\langle\phi_j\phi_{k_2}\rangle^2\langle\phi_{k_1}\phi_{k_2}\rangle(\langle\phi_{k_2}\phi_{x_2}\rangle\langle\phi_{x_1}\phi_j\rangle+\langle\phi_j\phi_{x_2}\rangle\langle\phi_{x_1}\phi_{k_2}\rangle)$$

$$-36\int' djg(j)\int' dk_1 g(k_1)\int' dk_2 g(k_2)\langle\phi_{x_4}\phi_j\rangle\langle\phi_{x_3}\phi_{k_2}\rangle\langle\phi_j\phi_{k_2}\rangle\langle\phi_{k_1}\phi_{k_2}\rangle^2\langle\phi_j\phi_{k_1}\rangle$$

$$\times(\langle\phi_{k_1}\phi_{x_2}\rangle\langle\phi_{x_1}\phi_j\rangle+\langle\phi_j\phi_{x_2}\rangle\langle\phi_{x_1}\phi_{k_1}\rangle)-36\int' djg(j)\int' dk_1 g(k_1)\int' dk_2 g(k_2)$$

$$\times\langle\phi_{x_3}\phi_j\rangle\langle\phi_{x_4}\phi_{k_2}\rangle\langle\phi_j\phi_{k_2}\rangle\langle\phi_{k_1}\phi_{k_2}\rangle^2\times\langle\phi_j\phi_{k_1}\rangle(\langle\phi_{k_1}\phi_{x_2}\rangle\langle\phi_{x_1}\phi_j\rangle+\langle\phi_j\phi_{x_2}\rangle$$

$$\times\langle\phi_{x_1}\phi_{k_1}\rangle)-24\int' djg(j)\int' dk_1 g(k_1)\int' dk_2 g(k_2)\langle\phi_{x_3}\phi_j\rangle\langle\phi_{x_4}\phi_{k_1}\rangle\langle\phi_j\phi_{k_2}\rangle$$

$$\times\langle\phi_{k_1}\phi_{k_2}\rangle I_{j,k_1,k_2}(x_1,x_2)-24\int' djg(j)\int' dk_1 g(k_1)\int' dk_2 g(k_2)\langle\phi_{x_4}\phi_j\rangle\langle\phi_{x_3}\phi_{k_1}\rangle$$

$$\times\langle\phi_j\phi_{k_2}\rangle\langle\phi_{k_1}\phi_{k_2}\rangle I_{j,k_1,k_2}(x_1,x_2). \tag{A1}$$

Define

$$\delta m_2^3=-54\lambda^3 a'^4 C^{(a)}(0)^5$$

and

$$\overline{V}=\frac{\lambda}{4}\int' g(x)\phi_x^4 dx+\frac{1}{2}\delta m_1^2\int' g(x)\phi_x^2 dx+\frac{1}{2}\delta m_2^2\int' g(x)^2\phi_x^2 dx+\frac{1}{2}\delta m_3^2\int' g(x)^3\phi_x^2 dx,$$

$$\overline{S}^{(a,a')}(x_1,\ldots,x_{2n})=\frac{\langle\phi_{x_1}\cdots\phi_{x_{2n}}e^{-\overline{V}}\rangle_{G_a}}{\langle e^{-\overline{V}}\rangle_{G_a}}.$$

Then, proceeding as in the proof of Theorem 2.1 we can use (A1) to prove that there are sequences $\{a_n\}$, $\{a_n'\}$ with $\lim_{n\to\infty}a_n=0$ and $\lim_{n\to\infty}a_n'|\log a_n|^{7/6}<\infty$, and $\{g_n\}\subset C_0(R^2)$ with $\lim_{n\to\infty}g_n(x)=g(x)$, such that for any given $f_1,\ldots,f_{2m}\in\mathcal{S}(R^2)$ and $m\geqslant 1$ the following limit exists:

$$\overline{S}(f_1,\ldots,f_{2m})=:\lim_{n\to\infty}\sum_{x_1,\ldots,x_{2m}\in a_nZ^2}\overline{S}^{(a_n,a_n')}(x_1,\ldots,x_{2m})\prod_{i=1}^{2m}a_n^2 f_i(x_i).$$

Moreover, there is a probability measure $\overline{\mu}_{\lambda,g}$ on $\mathcal{S}'(R^2)$ satisfying

$$\int_{\mathcal{S}'(R^2)}\phi(f_1)\cdots\phi(f_{2m})\overline{\mu}_{\lambda,g}(d\phi)=\overline{S}(f_1,\ldots,f_{2m}),\qquad f_1,\ldots,f_{2m}\in\mathcal{S}(R^2),\ \ m\geqslant 1.$$

(Received 29 July 2003; accepted 19 September 2003)

We first discuss the approach of effective field theory in a d-dimensional Euclidean space. We consider a model with two interacting scalar fields ($\mathcal{L}_{\rm int}(\varphi_1,\varphi_2) = (\lambda_2/2)(\varphi_1\varphi_2)^2$) with masses m_1 and m_2. Assuming $m_2 \gg m_1$ we show that there is a decoupling in the effective theory describing the dynamic of the light mass field. Furthermore, we consider the presence of two parallel hyperplanes which break translational symmetry, with a natural cutoff satisfying $m_2 \gg \Lambda > m_1$. Then imposing Dirichlet and also Neumann boundary conditions, we study the perturbative renormalization of the effective theory ($\lambda\varphi^4$) in a region bounded by the two parallel hyperplanes in the one-loop approximation. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1629138]

I. INTRODUCTION

The quantum field theory of a self-interacting scalar field has long served as a laboratory for developing methods of analysis that can be applied to theories of more direct physical interest. In this paper we consider a theory with a light mass field $\varphi_1(x)$, and a heavy mass field $\varphi_2(x)$ with masses m_1 and m_2, respectively. Our purpose is to investigate first the effective theory associated with these two interacting scalar fields defined in a d-dimensional Euclidean space. After the construction of an effective theory for the light field, we show that, in some limit, there is a decoupling between the light and heavy mass fields as stated by the Appelquist–Carazzone theorem.[1] Additionally, we impose boundary conditions on the resulting theory in order to study finite-size effects and the renormalization program in systems where translational symmetry is broken. The interest in the study of quantum fields in the presence of boundaries appears after the problem investigated by Casimir more than 50 years ago.[2] Complete reviews of this effect can be found in Refs. 3–5.

In 1948, Casimir showed that neutral perfectly conducting parallel plates in vacuum attract each other. The effect can be interpreted as follows: the presence of metallic plates changes the vacuum fluctuations of a quantized electromagnetic field. Consequently, the zero-point energy of the electromagnetic field becomes a measurable quantity. In the absence of any classical background, the renormalized vacuum expectation value of the Hamiltonian operator can be correctly defined by the Wick-ordered product. The main support for this procedure comes from the proof that for a relativistic field theory, the vacuum expectation value of the stress-energy tensor should vanish. This fact is necessary to ensure that the realization of the Poincaré generators in terms of the fields of the theory satisfy the correct commutation relations.[6] On the other hand, where external fields or macroscopic structures are present in the domain where the field is defined, more elaborated methods must be used to find the renormalized vacuum energy of the quantized field to

avoid undesirable divergences. A cutoff regularization that identifies the divergent contributions to the vacuum energy, or any regularization procedure, followed by a renormalization, is mandatory. The fundamental idea of the Casimir renormalization procedure is the following: although the zero-point energy of a system with infinite degrees of freedom is formally divergent, the difference between the zero-point energies of two different physical configurations, in some situations, can be shown to be finite.

In quantum electrodynamics there is a standard argument used to support the implementation of a regularization procedure followed by renormalization. Both procedures are necessary to obtain the renormalized vacuum expectation value of the stress-energy tensor associated with the Maxwell field in the presence of boundaries. At high frequencies no real material is a perfect conductor and a wavelength cutoff corresponding to the finite plasma frequency must be included in the model. High energy modes are insensitive to the boundaries and only the low energy modes are affected by them. Consequently, in the study of quantum electrodynamics in the presence of conducting boundaries, starting from the generating functional for the n-point correlation functions, one may integrate out all the Fourier modes associated with the Dirac field and obtain an effective theory for the Maxwell field.

We are investigating a theory describing two massive interacting scalar fields in a d-dimensional Euclidean space. Assuming different mass scales, we are obtaining the effective action for the light mass field. One could, theoretically, envision a theory with two massive fields with different mass scales on which the mass of the heavy field is much smaller than the natural cutoff of the boundary, Λ. In this paper we are not interested in discussing this situation.

It is important to keep in mind that in order to construct an effective action that gives a good description of the physics of the light mass field in the presence of the boundaries, the Fourier modes associated with both fields with wavelength smaller than Λ^{-1} must be integrated out (note that we are always assuming a sharp cutoff). Since dealing with functional integrals with cutoffs in general models is quite complicated, we will limit ourselves to a heavy mass field without a self-interacting term in the action. We are studying finite size effects for the light mass field in three steps. First, we integrate over the modes of the heavy mass field, obtaining an effective action for the light mass field. Second, we are taking the limit in which the decoupling theorem is valid ($m_2 \to \infty$), with regard to the effective action as the fundamental action and we are assuming boundary conditions over the remaining light field. Finally, combining different analytic regularization procedures, followed by a renormalization, one is able to eliminate the usual bulk and also the additional surface divergences that appear in the theory. The final result of our procedure is that we have the effect of the compactification of one dimension, breaking the translational invariance of the original theory. In this situation we have an effective field theory of the light mass field, with finite size effects. Due to our choice (two-parallel hyperplates), the region outside the boundaries is the union of two simply connected domains. The renormalization of the interacting field theory in such a region must be carried out along the same lines as for the interior region. For simplicity we are considering only the interior region.

There are many papers in the literature discussing quantum field theory in the presence of boundaries or of macroscopic structures. The radiative corrections to the renormalized energy density associated with the Maxwell field, in the presence of perfectly conducting plates, assuming no boundary conditions for the Dirac field, was performed by Bordag *et al.*[7] Temperature corrections for this model were analyzed by Robaschik *et al.*[8] Bordag *et al.*[9] also studied the leading radiative correction to the renormalized energy, assuming that the parallel plates are represented by delta function potentials. Using the approach of effective field theory, the radiative correction to the Casimir effect integrating out the fermionic degrees of freedom was examined by Kong and Ravndal and Ravndal and Thomassen.[10] A different approach was used by Falomir *et al.*[11] These authors used a sharp cutoff to study scalar fields in the presence of a spherical shell. They assume that the boundary is transparent to the heavy modes while for the soft modes they assumed Dirichlet boundary conditions. Actor[12] studied two interacting scalar fields in the presence of macroscopic boundaries assuming that only one of the fields satisfies classical boundary conditions. Using the generalized zeta function method[13] the one-loop effective action was presented.

More recently, Melnikov[14] investigated the low-energy effective action in a model with two scalar fields and also in quantum electrodynamics. Our treatment is very similar to that of Melnikov's in the study of the low-energy effective action for a theory with two interacting scalar fields.

It is important to point out that the combination of effective field theory and finite size effects can produce unexpected new phenomena. A well-known example of this situation is the Scharnhorst effect.[15] Studying quantum electrodynamics between perfectly conducting plates, Scharnhorst concluded that the speed of light normal to the plates exceeds light speed in vacuum. Nevertheless, parallel to the plates, light travels as in unbounded space, i.e., with its vacuum speed. Further calculations by Barton[16] and also by Barton and Scharnhorst[17] confirmed the original result. The Scharnhorst effect is a consequence of the use of the Euler–Heisenberg Lagrangian density[18,19] in the presence of the plates. The central feature of this effective Lagrangian is a derivative expansion of the photon effective action obtained by integrating out the fermionic field in the Maxwell–Dirac action. For an interesting discussion concerning the velocity of propagation of signals in different effective field theory models, see Ref. 20.

Finite size effects that do not break translational invariance in quantum field theory also have been extensively studied in the literature.[21,22] For translationally invariant systems, we can change from coordinate space to momentum space representation. The latter is a more convenient framework to analyze the divergences of the n-point Schwinger functions, on which translational invariance is realized through conservation conditions. For systems where the translational invariance has been partially broken (so there is still translational invariance along certain directions) a more convenient representation for the n-point Schwinger functions is a mixed momentum-coordinate representation. Important references discussing the renormalization program in the presence of boundaries are the Symanzik[23] and also Diehl and Dietrich[24] papers.

In this paper we are studying the one-loop renormalization program in the presence of surfaces where a self-interacting scalar field satisfies boundary conditions. We are interested in investigating a very simple model where we can construct an effective field theory for the light mass field on which the decoupling theorem holds. Furthermore, we consider a self-interacting field theory in the presence of boundaries. We will consider a Casimir-type configuration where one of the coordinates, z, lies in the interval $[0,L]$ imposing Dirichlet–Dirichlet boundary conditions. For the sake of completeness we will also study the Neumann–Neumann boundary conditions.

The organization of the paper is as follows: in Sec. II we introduce a simple model of two Euclidean interacting scalar fields. By integrating out the heavy mass field in the functional integral, we are able to build the effective action for the light mass field. In Sec. III we discuss a scalar field theory with finite size effects assuming boundary conditions over hypersurfaces. We thus build the two-point and four-point functions, both for Dirichlet–Dirichlet and Neumann–Neumann boundary conditions. In Sec. IV we discuss the surface divergences of the one-loop two-point and also four-point function. In Sec. V we discuss the global approach, used to define the Casimir energy associated with a field in the presence of boundaries with well defined geometric shapes. Finally, Sec. VI contains our conclusions. In this paper we are using $\hbar = c = 1$.

II. THE EUCLIDEAN FUNCTIONAL INTEGRAL AND THE EFFECTIVE ACTION

The goal of this section is to study a very simple model of two interacting scalar fields defined in a d-dimensional Euclidean space. After the construction of an effective action,[25–28] the decoupling theorem holds. This can be done imposing the infinite mass limit for the heavy field. For this purpose we start from a model with two different mass scales. We consider two real interacting massive scalar fields $\varphi_1(x)$ and $\varphi_2(x)$ with masses m_1 and m_2, respectively, and regard field $\varphi_2(x)$ as the heavy field $(m_2 \gg m_1)$. For this theory, we will rederive the Euclidean version for the Appelquist–Carazzone theorem. For a particular self-interacting $\varphi_1(x)$ part, in the limit $m_2 \to \infty$, there is a decoupling in the effective theory. The only effects of the heavy field $\varphi_2(x)$ are a modification of the value of the renormalized mass and the coupling constant of the light field $\varphi_1(x)$.

The Schwinger functional (the generating functional of the n-point Schwinger functions) associated with two massive real fields in a d-dimensional Euclidean space given by

$$Z[j_1,j_2]=\mathcal{N}\int [d\varphi_1][d\varphi_2]\, e^{-S[\varphi_1,\varphi_2]+(\text{source terms})}, \tag{1}$$

where $[d\varphi_1][d\varphi_2]=\Pi_{x\in R^d} d\varphi_1(x)d\varphi_2(x)$ is an appropriate measure, $S[\varphi_1,\varphi_2]$ is the classical action associated with the Euclidean fields, and in the generating functional, $\mathcal{N}$ is a normalization. As usual, the n-point Schwinger functions of the theory can be obtained by functional differentiation with respect to the external sources $j_1(x)$ and $j_2(x)$. Since in this section our interest is in constructing the effective theory for the light field, the introduction of the external sources in the functional integral is not important for our discussion. We consider the theory described by the following Lagrangian density with two real scalar fields

$$\mathcal{L}(\varphi_1,\varphi_2)=\mathcal{L}_0(\varphi_1,\varphi_2)+\mathcal{L}_{int}(\varphi_1,\varphi_2), \tag{2}$$

where the free part of the Lagrangian density is given by

$$\mathcal{L}_0(\varphi_1,\varphi_2)=\tfrac{1}{2}(\partial_\mu\varphi_1)^2+\tfrac{1}{2}m_1^2\varphi_1^2+\tfrac{1}{2}(\partial_\mu\varphi_2)^2+\tfrac{1}{2}m_2^2\varphi_2^2, \tag{3}$$

and the interacting part is given by

$$\mathcal{L}_{\text{int}}(\varphi_1,\varphi_2)=V(\varphi_1)+\frac{\lambda_2}{2}(\varphi_1\varphi_2)^2. \tag{4}$$

Note that the precise form of $V(\varphi_1)$ is not important for the construction of the effective action. As we will see later in this section, the form of the $V(\varphi_1)$ is important to implement the Appelquist–Carazzone decoupling theorem.

The action of the model is given by

$$S[\varphi_1,\varphi_2]=\int d^dx\, \mathcal{L}(\varphi_1(x),\varphi_2(x)), \tag{5}$$

and using Eq. (3) and Eq. (4) can be conveniently split up as

$$S[\varphi_1,\varphi_2]=S[\varphi_1(x)]+S_{\varphi_2}[\varphi_1(x),\varphi_2(x)], \tag{6}$$

$S[\varphi_1(x)]$ being the $\varphi_2(x)$-independent part of it. In order to obtain a derivative expansion of the effective action $\Gamma_{\text{eff}}[\varphi_1]$, we have to assume $m_2\gg m_1$. The operators $(-\Delta+m_1^2)^{-1}$ and $(-\Delta+m_2^2)^{-1}$ must be used to define the free two-point Schwinger functions of the fields $\varphi_1(x)$ and $\varphi_2(x)$. As usual, Δ is the Laplacian operator in $\mathcal{R}^d$. The free two-point Schwinger functions of both fields can be represented by

$$G(x-y;m_i)=\langle x|(-\Delta+m_i^2)^{-1}|y\rangle,\ i=1,2 \tag{7}$$

and they satisfy

$$(-\Delta+m_i^2)G(x-y;m_i)=\delta^d(x-y). \tag{8}$$

To obtain an effective action for the light mass field of the theory, we integrate out the heavy field $\varphi_2(x)$ in the functional integral. The effective action of the light mass field $\Gamma_{\text{eff}}[\varphi_1]$ is defined by

$$e^{-\Gamma_{\text{eff}}[\varphi_1]}=\int [d\varphi_2]\, e^{-S[\varphi_1,\varphi_2]}. \tag{9}$$

Using Eq. (6) it is possible to write Eq. (9) as

$$e^{-\Gamma_{\text{eff}}[\varphi_1]} = e^{-S[\varphi_1]} \int [d\varphi_2]\, e^{-S_{\varphi_2}[\varphi_1,\varphi_2]}. \tag{10}$$

The first step in our calculation is straightforward, since $S_{\varphi_2}[\varphi_1,\varphi_2]$ is given by

$$S_{\varphi_2}[\varphi_1,\varphi_2] = \int d^dx \left(\varphi_2(-\Delta + m_2^2)\varphi_2 + \frac{\lambda_2}{2}(\varphi_1\varphi_2)^2 \right). \tag{11}$$

Using Eq. (11) the functional integral appearing in Eq. (10) can be performed by means of Gaussian integrations, yielding

$$e^{-\Gamma_{\text{eff}}[\varphi_1]} = e^{-S[\varphi_1]} (\det O)^{-(1/2)}, \tag{12}$$

where we have

$$O(x,y;m_2) = \langle x|O|y\rangle = (-\Delta_x + m_2^2 + \lambda_2\varphi_1^2(x))\,\delta^d(x-y). \tag{13}$$

Consequently, the effective action for the light mass field $\varphi_1(x)$ is given by

$$\Gamma_{\text{eff}}[\varphi_1] = S[\varphi_1] + \tfrac{1}{2}\operatorname{tr}\ln O. \tag{14}$$

Dropping a term that contributes trivially to the effective action $\Gamma_{\text{eff}}[\varphi_1]$, we get

$$\Gamma_{\text{eff}}[\varphi_1] = S[\varphi_1] + \tfrac{1}{2}\operatorname{tr}\ln(1 + \lambda_2(-\Delta_x + m_2^2)^{-1}\varphi_1^2). \tag{15}$$

There are many ways to evaluate the Fredholm determinant, defined by the above equation. Using a series expansion, it is possible to rewrite Eq. (15) as

$$\Gamma_{\text{eff}}[\varphi_1] = S[\varphi_1] - \frac{1}{2}\sum_{k=1}^{\infty} \frac{(-1)^k}{k} \operatorname{tr}(\lambda_2(-\Delta_x + m_2^2)^{-1}\varphi_1^2)^k, \tag{16}$$

or, in a more compact notation,

$$\Gamma_{\text{eff}}[\varphi_1] = S[\varphi_1] + \sum_{k=1}^{\infty} \Gamma^{(k)}[\varphi_1], \tag{17}$$

where each term of the series $\Gamma^{(k)}[\varphi_1]$ is given by Eq. (16). Let us study the first nontrivial contribution of this series, namely, the term $k=1$ which corresponds to a one-loop diagram. It is explicitly given by

$$\Gamma^{(1)}[\varphi_1] = \frac{\lambda_2}{2} \int d^dx\, G(x-x;m_2)\, \varphi_1^2(x). \tag{18}$$

Using the Fourier representation of the two-point Schwinger function associated with the heavy mass field $\varphi_2(x)$, and defining a new coupling constant $\sigma = \lambda_2\mu^{4-d}$, where μ is the usual dimensional parameter that appears in the dimensional regularization procedure, we readily obtain

$$\Gamma^{(1)}[\varphi_1] = \frac{\sigma}{2(2\sqrt{\pi})^d} \Gamma\left(1 - \frac{d}{2}\right) (m_2)^{d-2} \int d^dx \quad \varphi_1^2(x). \tag{19}$$

Now, the Gamma function $\Gamma(z)$ is a meromorphic function of the complex variable z with simple poles at the points $z=0,-1,-2,\ldots$. In the neighborhood of any of its poles $z=-n$, for $n=0,1,2,\ldots$, $\Gamma(z)$ has a representation given by

$$\Gamma(z)=\frac{(-1)^n}{n!}\frac{1}{(z+n)}+\Omega(z+n), \tag{20}$$

where $\Omega(z+n)$ stands for the regular part of the analytic extension of $\Gamma(z)$. Note that for odd dimensions $\Gamma^{(1)}[\varphi_1]$ is completely regular while in even dimensions ($d=2\ell$ $\ell=1,2,\ldots$) there are singularities in the dimensional regularized quantity. By using the standard dimensional regularization prescription $d=2\ell-\epsilon$ and since Eq. (19) is quadratic in the field $\varphi_1(x)$, the divergence can be absorbed in the renormalized mass of the $\varphi_1(x)$ field. Consequently, we define the renormalized mass for the light field as

$$m_{1R}^2=m_1^2-\frac{\sigma m_2^{d-2}}{(4\pi)^{d/2}}\left[\frac{(-1)^{(d/2)-1}}{\left(\frac{d}{2}-1\right)!}\frac{2}{\epsilon}+\Omega\left(\frac{\epsilon}{2}\right)\right]. \tag{21}$$

Note that for odd-dimensional cases there are no poles. We have thus shown that at the one-loop approximation, the first correction to the effective action given by $\Gamma^{(1)}[\varphi]$ that we obtain integrating out the heavy mass field $\varphi_2(x)$ is just a modification of the value of the renormalized mass associated with the light field.

We will now show that the second correction to the effective action given by $\Gamma^{(2)}[\varphi_1]$ only modifies the value of the coupling constant of the field $\varphi_1(x)$. To this end, let us study the second term of the series in Eq. (17). It corresponds to a one-loop diagram and is actually given by

$$\Gamma^{(2)}[\varphi_1]=-\frac{\sigma^2}{4}\int d^dx\int d^dy\, G(y-x;m_2)G(x-y;m_2)\varphi_1^2(x)\varphi_1^2(y), \tag{22}$$

which, upon substitution of the free two-point Schwinger function associated with the $\varphi_2(x)$ heavy field and the introduction of $I(p^2,m_2^2)$ as

$$I(p^2,m_2^2)=\frac{1}{(2\pi)^d}\int d^dq\,\frac{m_2^{4-d}}{(q^2+m_2^2)((p+q)^2+m_2^2)}, \tag{23}$$

can be written as

$$\Gamma^{(2)}[\varphi_1]=-\frac{\sigma^2}{4(2\pi)^d}\int d^dx\int d^dy\,\varphi_1^2(x)\varphi_1^2(y)\int d^dp\,e^{-ip(y-x)}m_2^{d-4}I(p^2,m_2^2). \tag{24}$$

In the regularization and renormalization procedure we have to eliminate the poles and their residues adding counterterms in the Lagrangian density. To this end, let us study the quantity $I(p^2,m_2^2)$. Using the Feynman parametrization,[29] it is possible to write $I(p^2,m_2^2)$ as

$$I(p^2,m_2^2)=N_d\left(-\frac{1}{\epsilon}+O(\epsilon)\right)\left(1-\frac{d}{2}\right)\int_0^1 dt\left(\frac{p^2}{m_2^2}t(1-t)+1\right)^{(d/2)-2}, \tag{25}$$

where N_d is the area of the sphere $S_{d-1}/(2\pi)^d$. The expression given by Eq. (25) contains a power of a binomial. In a d-dimensional Euclidean space, when d is even, the power is an integer and the use of Newton's binomial theorem gives us a direct way of evaluating $I(p^2,m_2^2)$. When d is odd, the expansion of $(1+(p^2/m_2^2)\,t(1-t))^{(d/2)-2}$ yields an infinite power series. Since we are using dimensional regularization we have an infinite power series. Note that the generalization of

the binomial series is valid for any complex exponent p. In other words, we have an everywhere convergent power series in p, hence a continuous function on p in the complex plane.[30] If we define

$$C_r^0=1, \quad C_r^1=\frac{r}{1!}, \quad C_r^2=\frac{r(r-1)}{2!}, \cdots \tag{26}$$

until

$$C_r^k=\frac{r(r-1)\cdots(r-k+1)}{k!}, \tag{27}$$

where $r=(d/2)-2$, it is possible to write $I(p^2,m_2^2)$ as

$$I(p^2,m_2^2)=\left(1-\frac{d}{2}\right)N_d\left(-\frac{1}{\epsilon}+O(\epsilon)\right)\sum_{k=0}^{\infty} C_{(d/2)-2}^k \frac{p^{2k}}{m_2^{2k}}\int_0^1 dt(t(1-t))^k. \tag{28}$$

Let us use Euler's integral of first kind $B(\alpha,\beta)$ given by[31]

$$B(\alpha,\beta)=\int_0^1 dx\, x^{\alpha-1}(1-x)^{\beta-1}=\frac{\Gamma(\alpha)\Gamma(\beta)}{\Gamma(\alpha+\beta)}, \ \mathrm{Re}\,\alpha>0, \mathrm{Re}\,\beta>0. \tag{29}$$

Substituting Eq. (28) and Eq. (29) in Eq. (24), we find that the second term of the series that represents the effective action, $\Gamma^{(2)}[\varphi_1]$, can be written as

$$\Gamma^{(2)}[\varphi_1]=-\frac{\sigma^2}{4(2\pi)^d}\int d^dx \int d^dy\, \varphi_1^2(x)\varphi_1^2(y)\int d^dp\ e^{-ip(y-x)}m_2^{d-4}\left(1-\frac{d}{2}\right)$$
$$\times N_d\left(-\frac{1}{\epsilon}+O(\epsilon)\right)\sum_{k=0}^{\infty} C_{(d/2)-2}^k \frac{p^{2k}}{m_2^{2k}}B(k+1,k+1). \tag{30}$$

If we choose the self-interacting part of the field $\varphi_1(x)$ to be $\lambda_1\varphi_1^4(x)$, it is possible to define the renormalized coupling constant λ_R subtracting the polar part. Consequently, the effective action for the $\varphi_1(x)$ field is given by

$$\Gamma_{\mathrm{eff}}[\varphi_1]=\frac{1}{2}\int d^dx\ \ \varphi_1(x)(-\Delta+m_1^2)\varphi_1(x)+\lambda_R\int d^dx\ \ \varphi_1^4(x)+\frac{\sigma^2}{4!(4\pi)^2m_2^2}$$
$$\times\int d^dx\ \ \varphi_1^2(x)(-\Delta+m_1^2)\varphi_1^2(x)+O\left(\frac{\Delta}{m_2^2}\right)^2. \tag{31}$$

Note that the terms $k=3,4,...$ are not divergent (in a four-dimensional theory) and although they contribute to the effective action, in the limit $m_2\to\infty$, the heavy mass field $\varphi_2(x)$ decouples from the light mass field $\varphi_1(x)$. The effect of the heavy mass field appears only modifying the values of the renormalized mass m_{1R} and the coupling constant λ_R. We showed that the Euclidean version of the Appelquist–Carazzone decoupling theorem works in this specific model. Another well known example where the decoupling theorem can be used is in quantum electrodynamics, where for energies much lower than the electron mass it is possible to construct a derivative expansion of the Maxwell field effective action integrating out the Dirac field. This is an expected result, since we known that the Appelquist–Carazzone theorem is valid for renormalizable theories without spontaneous symmmetry breaking or chiral fermions. The above discussion justifies the approach used by some authors that have been using the Euler–Heisenberg Lagrangian density to investigate the radiative correction to the Casimir effect,[10] although these radiative corrections

are of no phenomenological significance as pointed out by Melnikov.[14] For a careful discussion of effective Lagrangians in quantum electrodynamics and finite temperature field theory, see Refs. 32 and 33, respectively.

In the next section we will study the massive $(\lambda\varphi^4)_d$ theory in the presence of two parallel hyperplanes. Consequently, going back to the Schwinger functional, we are assuming that the functional integral must be taken over the space of the functions that vanish on the boundaries. One way to implement this is to introduce delta functions in the functional integral. This is equivalent to evaluate the functional integral over a space of functions that satisfy the boundary conditions. This is the procedure that we are adopting. It is clear that this procedure will introduce additional surface divergences that can be eliminated by surface counterterms. In the end, we have the effective model for the light mass field that satisfies boundary conditions over some surfaces.

III. FINITE SIZE EFFECTS AND THE TWO AND FOUR-POINT SCHWINGER FUNCTIONS IN THE ONE-LOOP APPROXIMATION

In the last section, we studied a very simple model of two massive scalar fields where the decoupling theorem holds after the construction of an effective theory of the light mass field. We have shown that in our model of two massive interacting scalar fields, the heavy modes associated with the $\varphi_2(x)$ field completely decouple from the light ones associated with the light mass field $\varphi_1(x)$ in the limit $m_2\to\infty$. In the case of a $\lambda_1\varphi_1^4(x)$ self-interacting part, the only effect of the heavy mass field is a modification of the mass m_1 and of the coupling constant of the light mass field. We are reducing the problem in this manner since we are able to concentrate in such a one field theory, i.e., we will consider a $\lambda_1\varphi^4(x)$ self-interacting model. We will consider that the field $\varphi(x)$ depends on $d-1$ unbounded coordinates that we call $\mathbf{r}$, and one bounded coordinate which we will refer to as z that will be assumed to lie in the interval $[0,L]$. If we exclude the possibility of periodic or antiperiodic boundary conditions, this choice obviously breaks the full translational invariance because we have to assume boundary conditions on the hyperplanes $z=0$ and $z=L$.

To write the full renormalized action for the theory with boundaries we need two regulators: the first one is the usual ϵ that is introduced in the dimensional regularization procedure and the second one, that we call η, represents the distance to a boundary. According to this the full renormalized action must be given by[24]

$$S(\varphi)=\int_0^L dz\int d^{d-1}r\left(\frac{A(\epsilon)}{2}(\partial_\mu\varphi)^2+\frac{B(\epsilon)}{2}\varphi^2+\frac{C(\epsilon)}{4!}\varphi^4\right)+\int d^{d-1}r(c_1(\eta)\varphi^2(\mathbf{r},0)$$

$$+c_2(\eta)\varphi^2(\mathbf{r},L))+\int d^{d-1}r(c_3(\eta)\varphi^4(\mathbf{r},0)+c_4(\eta)\varphi^4(\mathbf{r},L)), \tag{32}$$

where $A(\epsilon)$, $B(\epsilon)$, and $C(\epsilon)$ are the usual coefficients for the bulk counterterms and the coefficients $c_i(\eta)$ $i=1,...,4$, which depend on the boundary conditions for the field, are the coefficients for the surface counterterms. As usual all of these coefficients must be calculated order by order in perturbation theory. We are considering two different possibilities for the boundary conditions, namely Dirichlet–Dirichlet (DD) and Neumann–Neumann (NN) boundary conditions. These boundary conditions are given, respectively, by

$$\varphi(\mathbf{r},z)\big|_{z=0}=\varphi(\mathbf{r},z)\big|_{z=L}=0, \tag{33}$$

and

$$\frac{\partial}{\partial z}\varphi(\mathbf{r},z)\bigg|_{z=0}=\frac{\partial}{\partial z}\varphi(\mathbf{r},z)\bigg|_{z=L}=0. \tag{34}$$

The system we are interested in is invariant only under translations along the direction parallel to the plates. This implies that what is conserved is not the full momentum but the $(d-1)$ dimen-

sional parallel momentum **p**. For such conditions, a more convenient representation of the n-point Schwinger functions is a mixed $(\mathbf{p},z)$ representation. A Euclidean scalar field $\varphi(x)$ satisfying certain homogeneous boundary conditions on $z=0$ and L can be expanded in Fourier series as

$$\varphi(\mathbf{r},z)=\frac{1}{(2\pi)^{(d-1)/2}}\sum_n u_n(z)\int d^{d-1}p\ \phi_n(\mathbf{p})\,e^{i\mathbf{p}.\mathbf{r}}, \tag{35}$$

where **p** is the continuum parallel momentum, and $u_n(z)$ stands for the eigenfunctions of the operator $-(d^2/dz^2)$,

$$-\frac{d}{dz^2}u_n(z)=k_n^2u_n(z), \tag{36}$$

where $k_n=n\pi/L$, $n=1,2,...$ for DD b.c., and $n=0,1,2,...$ for NN boundary conditions, respectively. The main difference between the boundary conditions is the presence of the zero mode. The free two-point Schwinger function of the theory $G_0^{(2)}(\mathbf{r},z,\mathbf{r}',z')$ can be expressed as

$$G_0^{(2)}(\mathbf{r},z,\mathbf{r}',z')=\frac{1}{(2\pi)^{d-1}}\sum_n u_n(z)u_n^*(z')\int d^{d-1}p\,\frac{e^{i\mathbf{p}.(\mathbf{r}-\mathbf{r}')}}{(\mathbf{p}+k_n^2+m^2)}. \tag{37}$$

Note that we have changed the notation in this section as follows: $m_1\to m$ and also $G(x,x';m_1)\to G_0(x,x')$. It is useful to define also $\boldsymbol{\rho}=\mathbf{r}-\mathbf{r}'$. When considering DD boundary conditions, one finds that the free two-point Schwinger function is explicitly given by

$$G_0^{(2)}(\boldsymbol{\rho},z,z')=\frac{2}{L}\sum_{n=1}^{\infty}\sin\left(\frac{n\pi z}{L}\right)\sin\left(\frac{n\pi z'}{L}\right)I_n(L,m,d,\boldsymbol{\rho}), \tag{38}$$

where

$$I_n(L,m,d,\boldsymbol{\rho})=\frac{1}{(2\pi)^{d-1}}\int d^{d-1}p\,\frac{e^{i\mathbf{p}.\boldsymbol{\rho}}}{\left(\mathbf{p}^2+\left(\frac{n\pi}{L}\right)^2+m^2\right)}. \tag{39}$$

It is clear that the family of $I_n(L,m,d,\boldsymbol{\rho})$ functions can be thought of as the free propagators of a tower of massive scalar fields in $(d-1)$ dimensions, the effective mass of each mode being given by $M_n^2=m^2+(n\pi/L)^2$. This is to be expected since our theory has been formulated in a compactified space. From an even simpler point of view, $I_n(L,m,d,\boldsymbol{\rho})$ is nothing but the Fourier transform of a "spherically" $(\mathrm{SO}(d-1))$ symmetric function of the parallel momentum **p**.

We begin the study of the interacting theory by building the one-loop correction $(G_1^{(2)}(\lambda_1,x,x'))$ to the bare two-point Schwinger function $G_0^{(2)}(x,x')$, for both the DD and NN boundary conditions. Using the Feynman rules we have

$$G_1^{(2)}(\lambda_1,\mathbf{r}_1,z_1,\mathbf{r}_2,z_2)=\frac{\lambda_1}{2}\int d^{d-1}r\int_0^L dz\ G_0^{(2)}(\mathbf{r}_1-\mathbf{r},z_1,z)G_0^{(2)}(\mathbf{0},z)G_0^{(2)}(\mathbf{r}-\mathbf{r}_2,z,z_2). \tag{40}$$

Here we point out that even though the functions $G_0^{(2)}(\mathbf{r}_1-\mathbf{r}_2,z_1,z_2)$ and $G_0^{(2)}(\mathbf{r}_2-\mathbf{r}_3,z_2,z_3)$ are singular at coincident points $(\mathbf{r}_1=\mathbf{r}_2,\ z_1=z_2)$ and $(\mathbf{r}_2=\mathbf{r}_3,\ z_2=z_3)$, the singularities are integrable for points outside the plates. Using the notation $G_0^{(2)}(\mathbf{0},z)=T_{\mathrm{DD}}(L,m,d,z)$, a straightforward substitution yields the order λ_1 correction to the bare two-point Schwinger function in the one-loop approximation for the case of Dirichlet boundary conditions:

$$G_1^{(2)}(\lambda_1,\mathbf{r}_1-\mathbf{r}_2,z_1,z_2)=\frac{2\lambda_1}{(2\pi)^{d-1}L^2}\int_0^L dz\sum_{n,n'=1}^{\infty}\sin\left(\frac{n\pi z_1}{L}\right)\sin\left(\frac{n\pi z}{L}\right)\sin\left(\frac{n'\pi z}{L}\right)\sin\left(\frac{n'\pi z_2}{L}\right)$$
$$\times\int d^{d-1}p\,\frac{e^{i\mathbf{p}(\mathbf{r}_1-\mathbf{r}_2)}}{\left(\mathbf{p}^2+\left(\frac{n\pi}{L}\right)^2+m^2\right)\left(\mathbf{p}^2+\left(\frac{n'\pi}{L}\right)^2+m^2\right)}T_{\mathrm{DD}}(L,m,d,z). \tag{41}$$

Note that since we use dimensional regularization techniques, we have introduced a dimensional parameter μ, defining a dimensionless coupling constant $\lambda=\lambda_1\mu^{4-d}$. The expression for the amputated one-loop two-point function $T_{\mathrm{DD}}(L,m,d,z)$ is given by

$$T_{\mathrm{DD}}(L,m,d,z)=\frac{2}{(2\pi)^{d-1}L}\sum_{n=1}^{\infty}\sin^2\left(\frac{n\pi z}{L}\right)\int d^{d-1}p\,\frac{1}{\left(\mathbf{p}^2+\left(\frac{n\pi}{L}\right)^2+m^2\right)}. \tag{42}$$

In the case of Neumann–Neumann boundary conditions the expression for the amputated one-loop two-point function can also be found following the same procedure, and it is given by

$$T_{\mathrm{NN}}(L,m,d,z)=\frac{1}{(2\pi)^{d-1}L}\int d^{d-1}k\,\frac{1}{(\mathbf{k}^2+m^2)}$$
$$+\frac{2}{(2\pi)^{d-1}L}\sum_{n=1}^{\infty}\cos^2\left(\frac{n\pi z}{L}\right)\int d^{d-1}p\,\frac{1}{\left(\mathbf{p}^2+\left(\frac{n\pi}{L}\right)^2+m^2\right)}. \tag{43}$$

Both $T_{\mathrm{DD}}(L,m,d,z)$ and $T_{\mathrm{NN}}(L,m,d,z)$ diverge in their continuum momenta integrals and also in the discrete mode summation. Using the Feynman rules, $G_2^{(4)}(\lambda,x_1,x_2,x_3,x_4)$, i.e., the $O(\lambda^2)$ correction to the bare one-loop four-point Schwinger function, is given by

$$G_2^{(4)}(\lambda,\mathbf{r}_1,z_1,\mathbf{r}_2,z_2,\mathbf{r}_3,z_3,\mathbf{r}_4,z_4)=\frac{\lambda^2}{2}\int d^{d-1}r\int d^{d-1}r'\int_0^L dz\int_0^L dz'\;\; G_0^{(2)}(\mathbf{r}_1-\mathbf{r},z_1,z)$$
$$\times G_0^{(2)}(\mathbf{r}_2-\mathbf{r},z_2,z)(G_0^{(2)}(\mathbf{r}-\mathbf{r}',z,z'))^2$$
$$\times G_0^{(2)}(\mathbf{r}'-\mathbf{r}_3,z',z_3)G_0^{(2)}(\mathbf{r}'-\mathbf{r}_4,z',z_4). \tag{44}$$

Again, all G_0's are singular at coincident points, but the singularities are integrable for points outside the plates, except for $G_0^{(2)}(\mathbf{r}-\mathbf{r}',z,z')$.

In the next section we will begin the renormalization program for the massless one-loop two-point Schwinger functions for the case of Dirichlet–Dirichlet boundary condition. The two-point Schwinger function for the case of Dirichlet–Dirichlet boundary conditions is IR finite for $m=0$. The study of the complementary set of boundary conditions, namely, NN boundary conditions, can be performed along the same lines. When the field satisfies NN boundary conditions, infrared divergences appear and such divergences come from the zero mode contribution. For the case of NN we must have a finite Euclidean volume to regularize the theory in the infrared. Another possible solution to the problem of the infrared divergences in the case of Neumann–Neumann boundary condition is to perform a resummation of the daisy diagrams.[34–37] This procedure is standard in the study of scalar models where the translational invariance is maintained, as for example finite temperature field theory. For systems where the translational invariance is broken, the problem of how to carry out the resummation program still remains open.

IV. THE REGULARIZED ONE-LOOP TWO AND FOUR-POINT SCHWINGER FUNCTIONS

In this section we would like to discuss how to implement the one-loop renormalization program in finite size systems where flat surfaces break the translational invariance. Thus, the aim of this section is first to analyze the structure of the divergences associated with the one-loop two and four-point functions for the case of Dirichlet–Dirichlet boundary conditions.

The amputated one-loop two-point Schwinger function $T_{\mathrm{DD}}(L,m,d,z)$ can be decomposed in a translational invariant part and another one that breaks the translational invariance. Indeed, using algebraic identities as in Refs. 31 and 38, one gets

$$T_{\mathrm{DD}}(L,m,d,z)=f_1(L,m,d)-f_2(L,m,d,z), \tag{45}$$

where the functions $f_1(L,m,d)$ and $f_2(L,m,d,z)$ are given, respectively, by

$$f_1(L,m,d)=\frac{1}{2(2\pi)^{d-1}L}\sum_{n=-\infty}^{\infty}\int d^{d-1}p\,\frac{1}{\left(\mathbf{p}^2+\left(\frac{n\pi}{L}\right)^2+m^2\right)} \tag{46}$$

and

$$f_2(L,m,d,z)=\frac{1}{2(2\pi)^{d-1}}\int d^{d-1}p\,\frac{1}{\sqrt{\mathbf{p}^2+m^2}}\,\frac{\cosh((L-2z)\sqrt{\mathbf{p}^2+m^2})}{\sinh(L\sqrt{\mathbf{p}^2+m^2})}. \tag{47}$$

The amputated one-loop two-point Schwinger function for the Neumann–Neumann boundary conditions, $T_{\mathrm{NN}}(L,m,d,z)$, can be similarly split up as

$$T_{\mathrm{NN}}(L,m,d,z)=f_1(L,m,d)+f_2(L,m,d,z). \tag{48}$$

The above decompositions of $T_{\mathrm{DD}}(L,m,d,z)$ and $T_{\mathrm{NN}}(L,m,d,z)$ have the same functional form. Some divergences come purely from the bulk, while others depend on the distance to the boundaries. Indeed, since $f_1(L,m,d)$ does not depend on z, it contains only bulk divergences. These divergences occur not only in the discrete sums but also in the momentum integrations. After the identification: $\beta\equiv 2L$, the term $f_1(L,m,d)$ is formally proportional to the amputated one-loop two-point function of the theory assuming that the system is in thermal equilibrium with a reservoir at temperature β^{-1}. To deal with the divergences of $f_1(L,m,d)$, or equivalently, the one-loop two-point Schwinger functions at finite temperature we have to do frequency sums and $(d-1)$ dimensional integrals for the continuum momenta. One way to perform the integrals with Matsubara sums is to analytically extend away from the discrete complex energies down to real axis with the replacement of the energy sums by contour integrals.[39,40] Another way is to use dimensional regularization and afterwards to analytically extend the modified Epstein zeta function which appears after dimensional regularization. Direct use of dimensional regularization identities and the analytic extension of the modified Epstein zeta function in the sum given by Eq. (46) which defines $f_1(L,m,d)$, gives us a polar part (size independent) plus a size-dependent analytic correction. The mass counterterm (the principal part of the Laurent series of the analytic regularized quantity) generated by $f_1(L,m,d)$ is size independent, in the same way that the finite temperature field theory has no temperature dependent counterterm. Observe that the nontranslational invariant part of the amputated one-loop two-point Schwinger function expressed by $T_{\mathrm{DD}}(L,m,d,z)$ and $T_{\mathrm{NN}}(L,m,d,z)$ has the same z dependence in modulus but with opposite signs.

We have shown that the $T_{\mathrm{DD}}(L,m,d,z)$ and $T_{\mathrm{NN}}(L,m,d,z)$ can be split into two functions $f_1(L,m,d)$ and $f_2(L,m,d,z)$ and since as we have just discussed the behavior of $f_1(L,m,d)$, we can now turn our attention to the study of the divergences contained in $f_2(L,m,d,z)$. We begin by an angular integration ($d^{d-1}p=p^{d-2}dp\,d\Omega_{d-1}$ and $\int d\Omega_d=[2\pi^{(d/2)}]/[\Gamma d/2]$) that leads to an alternative expression for the nontranslational invariant part $f_2(L,m,d,z)$, namely,

$$f_2(L,m,d,z)=\frac{1}{2}h(d)\int_0^\infty dp\,\frac{p^{d-2}}{\sqrt{p^2+m^2}}\,\frac{\cosh((L-2z)\sqrt{p^2+m^2})}{\sinh(L\sqrt{p^2+m^2})}. \tag{49}$$

Using the change of variables $s=\sqrt{p^2+m^2}$ in the above expression yields the following formula for $f_2(L,m,d,z)$:

$$f_2(L,m,d,z)=\frac{1}{2}h(d)\int_m^\infty ds(s^2-m^2)^{(d-3)/2}\cosh((L-2z)s)(\sinh Ls)^{-1}, \tag{50}$$

where $h(d)$ is an analytic function of d given by

$$h(d)=\frac{1}{2(2\sqrt{\pi})^{d-1}}\,\frac{1}{\Gamma\left(\frac{d-1}{2}\right)}.$$

We now start studying the massless case following Fosco and Svaiter.[41] In fact, we are particularly interested in examining the limits ($z\to 0^+$ and $z\to L^-$) which obviously contain the information about the effects of the boundaries. In order to fulfill this goal we introduce two new variables $x=Ls$ and $q=zs$, in terms of which we can write $f_2(L,m,d,z)|_{m=0}$ as

$$f_2(L,m,d,z)|_{m=0}=\frac{h(d)}{2L^{d-2}}\int_0^\infty dx\,x^{d-3}(\coth x-1)\cosh\left(\frac{2zx}{L}\right)+\frac{h(d)}{2z^{d-2}}\int_0^\infty dq\,q^{d-3}e^{-2q}. \tag{51}$$

The second term of Eq. (51) gives us the well known result that for a massless scalar field in $d=4$ the one-loop vacuum fluctuations diverge as $1/z^2$ if we approach the boundary at $z=0$.[42] The other term of Eq. (51) should behave as $1/(L-z)^{d-2}$. To see this let us investigate the behavior of the first integral of $f_2(L,m,d,z)|_{m=0}$ near the boundary at $z=L$. In order to do this, we make use of two formulas involving the definition for the Gamma function, and also another well known integral representation for the product of the Gamma function times the Hurwitz zeta function given by

$$\int_0^\infty dx\,x^{\mu-1}e^{-\beta x}(\coth x-1)=2^{1-\mu}\Gamma(\mu)\zeta\left(\mu,\frac{\beta}{2}+1\right)\quad \mathrm{Re}(\beta)>0,\ \mathrm{Re}(\mu)>1, \tag{52}$$

where $\zeta(z,a)$ is the Hurwitz zeta function defined by[31]

$$\zeta(z,a)=\sum_{n=0}^{\infty}\frac{1}{(n+a)^z},\quad \mathrm{Re}(z)>1,\quad a\neq 0,-1,-2,\ldots. \tag{53}$$

From the definition of the Gamma function and using Eq. (52) in Eq. (51) we may write the following closed expression:

$$f_2(L,m,d,z)|_{m=0}=\frac{h(d)}{2L^{d-2}}\left[2^{2-d}\Gamma(d-2)\left(\zeta\left(d-2,\frac{z}{L}+1\right)+\zeta\left(d-2,-\frac{z}{L}+1\right)\right)\right]$$
$$+\frac{1}{(2z)^{d-2}}h(d)\Gamma(d-2). \tag{54}$$

From this last expression and using the definition of the Hurwitz zeta function given by Eq. (53) it is evident that the regularized $f_2(L,m,d,z)|_{m=0}$ has two poles of order $(d-2)$, one at $z=0$ and another at $z=L$.

To study the massive case, from the expression given by Eq. (50) it is possible to write $f_2(L,m,d,z)$ in a more convenient way by

$$f_2(L,m,d,z)=f_{21}(L,m,d,z)+f_{22}(L,m,d,z), \tag{55}$$

where $f_{21}(L,m,d,z)$ and $f_{22}(L,m,d,z)$ are

$$f_{21}(L,m,d,z)=\frac{1}{2}h(d)\int_m^\infty ds(s^2-m^2)^{(d-3)/2}e^{-2zs}, \tag{56}$$

and

$$f_{22}(L,m,d,z)=\frac{1}{2}h(d)\int_m^\infty ds(s^2-m^2)^{(d-3)/2}(\coth Ls-1)\cosh 2zs. \tag{57}$$

Using an integral representation of the Bessel function of third kind (Macdonald's function) it is possible to find the following closed expression for $f_{12}(L,m,d,z)$:

$$f_{21}(L,m,d,z)=\frac{1}{2}\frac{1}{(2\sqrt{\pi})^{d-1}}\left(\frac{m}{z}\right)^{(d-2)/2}K_{(d-2)/2}(2mz). \tag{58}$$

For small z and finite m we have the asymptotic formula $K_\nu(z)\approx 2^{\nu-1}\Gamma(\nu)z^{-\nu}$, which means that for $z\to 0^+$, the function $f_{21}(L,m,d,z)$ diverges as $1/z^{d-2}$. To calculate $f_{22}(L,m,d,z)$ we will use the same method that we used in Sec. II. Making use of the generalized binomial formula,

$$\left(1-\frac{m^2}{s^2}\right)^{(d-3)/2}=\sum_{k=0}^{\infty}(-1)^k C^k_{(d-3)/2}\left(\frac{m}{s}\right)^{2k}, \tag{59}$$

and introducing a new variable $u=Ls$, we obtain

$$f_{22}(L,m,d,z)=\frac{h(d)}{2L^{d-2}}\sum_{k=0}^{\infty}(-1)^k C^k_{(d-3)/2}(Lm)^{2k}\int_{Lm}^\infty du\,u^{d-3-2k}(\coth u-1)\cosh\left(\frac{2zu}{L}\right). \tag{60}$$

Our next step is to show that this result can be expressed in terms of the Hurwitz zeta function. Let split $f_{22}(L,m,z,d)$ as a sum of two terms

$$f_{22}(L,m,d,z)=f^<_{22}(L,m,z,d)+f^>_{22}(L,m,z,d), \tag{61}$$

where

$$f^<_{22}(L,m,z,d)=-\frac{1}{4L^{d-2}}\sum_{k=0}^{k<(d-3)/2}C^{(1)}(d,k)(Lm)^{2k}\int_{Lm}^\infty du\,u^{d-3-2k}(\coth u-1)\cosh\left(\frac{2uz}{L}\right), \tag{62}$$

and

$$f^>_{22}(L,m,z,d)=-\frac{1}{4L^{d-2}}\sum_{k\geqslant (d-3)/2}^{\infty}C^{(1)}(d,k)(Lm)^{2k}\int_{Lm}^\infty du\,u^{d-3-2k}(\coth u-1)\cosh\left(\frac{2uz}{L}\right). \tag{63}$$

Here we have introduced $C^{(1)}(d,k)=(-1)^k C^k_{(d-3)/2}h(d)$ and also $C^{(2)}(d,k)\equiv[\Gamma(d-2-2k)/2^{d-3-2k}]\,C^{(1)}(d,k)$. Thus it is possible to write Eq. (62) in the following way:

$$f_{22}^{<}(L,m,z,d)=-\frac{1}{4L^{d-2}}\sum_{k=0}^{k<(d-3)/2}C^{(2)}(d,k)(Lm)^{2k}\left(\zeta\left(d-2-2k,-\frac{z}{L}+1\right)+\zeta\left(d-2-2k,\frac{z}{L}+1\right)\right)+\frac{1}{4L^{d-2}}\sum_{k=0}^{k<(d-3)/2}C^{(1)}(d,k)(Lm)^{2k}\times\int_0^{Lm}du\,u^{d-3-2k}(\coth u-1)\cosh\left(\frac{2uz}{L}\right),\tag{64}$$

where the singularities of $f_{22}^{<}(L,m,z,d)$ appear at $z\to L$. Turning our attention to $f_{22}^{>}(L,m,z,d)$, it is clear that in the expression above we see that the surface divergences are the same as we studied before in the massless case.

We now turn our attention back to the four-point Schwinger function in the one-loop approximation. Introducing new variables as $u_{\pm}\equiv z\pm z'$, the two-point Schwinger function in the tree-level can be split into

$$G_0^{(2)}(\boldsymbol{\rho},z,z')=G_{+}^{(2)}(\boldsymbol{\rho},u_{+})+G_{-}^{(2)}(\boldsymbol{\rho},u_{-}),\tag{65}$$

where making use of the definition of $I_n(L,m,d,\boldsymbol{\rho})$ given by Eq. (39) we have

$$G_{\pm}^{(2)}(\boldsymbol{\rho},u_{\pm})=\mp\frac{1}{L}\sum_{n=1}^{\infty}\cos\left(\frac{n\pi u_{\pm}}{L}\right)I_n(L,m,d,\boldsymbol{\rho}).\tag{66}$$

Before we continue, let us present an explicit formula of the free two-point Schwinger function in terms of Bessel functions. Defining an analytic function $g(d)$ by

$$g(d)=\frac{1}{\sqrt{\pi}(2\pi)^{(d-1)/2}}\frac{\Gamma\left(\frac{d-2}{2}\right)}{\Gamma\left(\frac{d-3}{2}\right)},\tag{67}$$

it is possible to show that we can write $G_{\pm}^{(2)}(\rho,u_{\pm})$ as

$$G_{\pm}^{(2)}(\rho,u_{\pm})=\mp\frac{g(d)}{\rho^{(d-3)/2}L}\sum_{n=1}^{\infty}\cos\left(\frac{n\pi u_{\pm}}{L}\right)\left(\left(\frac{n\pi}{L}\right)^2+m^2\right)^{(d-3)/4}K_{(d-3)/2}\left(\rho\left(m^2+\left(\frac{n\pi}{L}\right)^2\right)^{1/2}\right).\tag{68}$$

Using Eq. (65) and the above formula we obtain the explicit expression for the two-point Schwinger function in a generic d-dimensional Euclidean space confined between two flat parallel hyperplanes where we assume Dirichlet–Dirichlet boundary conditions. It is hard to use the above expressions for $G_{\pm}^{(2)}(\rho,u_{\pm})$ to investigate the analytic structure of the four-point function given by Eq. (44) $G_2^{(4)}(\lambda,\mathbf{r}_1,z_1,\mathbf{r}_2,z_2,\mathbf{r}_3,z_3,\mathbf{r}_4,z_4)$, for both the bulk and near the boundaries. Nevertheless from Eqs. (38) and (39) it is clear that the divergences of the four-point function in the one-loop approximation appear at coincident points and, therefore, the singular behavior is encoded in the polar part of $M(\lambda,L,m,d)$ given by

$$M(\lambda,L,m,d)=\lambda^2\int d^{d-1}r\int d^{d-1}r'\int_0^L dz\int_0^L dz'F(\mathbf{r},\mathbf{r}',z,z')(G_0^{(2)}(\mathbf{r}-\mathbf{r}',z,z'))^2,\tag{69}$$

where $F(\mathbf{r},\mathbf{r}',z,z')$ is a regular function. Exactly as in the one-loop two point function, the above equation has two kinds of singularities: those coming from the bulk and those arising from the

behavior near the surface. As before, the behavior in the bulk is that of thermal field theory. Consequently we will only discuss the singularities that arise from the boundaries. This can be done by studying the polar part of $\tilde{M}(\lambda,L,m,d)$ given by

$$\tilde{M}(\lambda,L,m,d)=\frac{\lambda^2}{2}\int_0^L dz\int_0^L dz'\,\mathcal{F}(z,z')(G_0^{(2)}(\mathbf{0},z,z'))^2, \tag{70}$$

where $\mathcal{F}(z,z')$ is a regular function. Now, we recall that the form of $G_{\pm}^{(2)}(\rho,u_{\pm})|_{\rho=0}$ is given by

$$G_{\pm}^{(2)}(\rho,u_{\pm})|_{\rho=0}=\mp\frac{1}{(2\pi)^{d-1}L}\sum_{n=1}^{\infty}\cos\left(\frac{n\pi u_{\pm}}{L}\right)\int d^{d-1}p\,\frac{1}{\left(\mathbf{p}^2+m^2+\left(\frac{n\pi}{L}\right)^2\right)}, \tag{71}$$

from which one can show that the free correlation function is given by

$$G_0^{(2)}(\rho,z,z')|_{\rho=0}=f_2\left(L,m,d,\frac{u_-}{2}\right)-f_2\left(L,m,d,\frac{u_+}{2}\right). \tag{72}$$

For the sake of simplicity we will discuss only the massless case, since the singularities of the massive case have the same structure as the massless one. The function $f_2(L,m,d,u_+/2)$ is nonsingular in the bulk, i.e., in the interior of the interval $[0,L]$, while $f_2(L,m,d,u_-/2)$ has a singularity along the line $z=z'$. Indeed, closer inspection shows that for $0\leqslant z,z'\leqslant L$ the only singularities are those at $u_+=0$, $u_+=2L$ and also $u_-=0$. The former two are genuinely boundary singularities (the two conditions imply $z,z'\to 0$ or $z,z'\to L$), while the one coming from $z=z'$ in the whole domain is just the standard bulk singularity. One finds that the counterterms for $\tilde{M}$ are given by

$$-\text{pole}\int_0^L dz\int_0^L dz'\left[\frac{C_1}{(z+z')^{d-2}}+\frac{C_2}{(2L-z-z')^{d-2}}+\frac{C_3}{(z-z')^{d-2}}+\cdots\right]^2, \tag{73}$$

where $C_i, i=1,...,3$ are regular functions that do not depend on z nor on z'. From this discussion it is clear that in order to render the field theory finite, we must introduce surface terms in the action. This is a general statement. For any fields that satisfy boundary condition that breaks the translational invariance, in addition to the usual bulk counterterms, it is sufficient to introduce surface counterterms in the action to render the theory finite.

V. BOUNDARY EFFECTS AND RENORMALIZATION

In the last section we presented the one-loop renormalization of the $\lambda\varphi^4$ model, and also considered that the field $\varphi(x)$ depends on $d-1$ unbounded coordinates that we call $\mathbf{r}$ and one bounded coordinate defined in the interval $[0,L]$. The boundary conditions on the hyperplanes $z=0$ and $z=L$ are the usual Dirichlet–Dirichlet and also Neumann–Neumann boundary conditions.

In this section we would like to discuss briefly the global approach, used to define the Casimir energy associated with any field in the presence of surfaces with well defined geometric shape. For a updated discussion of the problem, see Ref. 43. The crucial conceptual question is the meaning of the renormalized vacuum energy associated with any field in the presence of any macroscopic structure that divides the space into the internal and the external region. It is important to keep separate different situations. In the case of the parallel plates, the region outside the plates is the union of two simply connected domains and both have the same geometry of the internal region. In this situation the Casimir renormalization procedure is well defined and the renormalized vacuum energy is unambiguously defined. In the case of the spherical or a cylindrical shell, the contribution of the exterior modes are not cancelled out in the Casimir renormalization procedure.

It is not difficult to understand the origin of the problem, which has been extensively discussed in the literature. If we are assuming perfectly reflecting boundaries, by the Weyl theorem we know that the asymptoptic distribution of eigenvalues of some elliptic differential operator is related with the geometric invariants associated with the surface where the field satisfy some boundary condition.[44,45] Consequently, in the regularized energy, we have divergent terms proportional to the volume, area, etc. In the Casimir definition of the renormalized vacuum energy, it is not possible to cancel the area contribution for a generic surface. The generalization of the Weyl's expansion can be done investigating the trace of the heat kernel on a specified manifold with boundary. We conclude that the assumption of perfect conducting static boundaries with a generic shape introduces new problems to define the renormalized vacuum energy of a quantum system in the presence of these macroscopic objects.[46–49] If someone insists in the assumption of perfect conducting boundaries there are different ways to solve the problem of infinite energy associated with the field in the presence of this configuration. One is to introduce counterterms concentrated on the boundaries, as discussed by the authors that use the generalized zeta function method.[50] A different approach is to smooth out the plate surface by a classical potential.[51,52] It is clear that the introduction of a classical potential $V(x)$ does not solve the problem of surface counterterms since in this situation we have to renormalize the potential. A very simple situation is the case of a background field where to compute the effective action we have to evaluate the following Fredholm determinant, where we are assuming that the positive potential is a large quantity

$$D(V)=\det(-\Delta+m^2+V(x))(-\Delta+m^2)^{-1}. \tag{74}$$

For sufficient regular but large $V(x)$, it is possible to show that for $d=4$ a counterterm quadratic in V is required in order to eliminate the divergences of the model.[53] Thus the introduction of a classical potential $V(x)$, in trying to improve the unphysical boundary condition, does not solve the problem of surface counterterms since in this situation we have to renormalize the potential. Instead of smoothing plate surfaces, an alternative approach to avoid surface divergences, discussed by Kennedy *et al.*,[50] is to treat the boundary as a quantum mechanical object. This approach was developed recently by Ford and Svaiter[54] to produce finite values for the renormalized $\langle\varphi^2(x)\rangle$ and other quantities that diverge as one approaches the classical boundary. We would like to stress that there will not be any surface divergences in a more exact treatment; however, one can still make the case that surface counterterms are a useful phenomenological approach for dealing with the apparent surface divergences without going into the complexity of the more exact approach.

VI. CONCLUSIONS

In this paper we discussed the approach of effective theory to perform calculations in field theory in the presence of macroscopic structures. We first assumed the theory of two interacting massive scalar fields $\varphi_1(x)$ and $\varphi_2(x)$ with masses m_1 and m_2 satisfying the condition $m_2 \gg m_1$. Integrating out the modes of the field $\varphi_2(x)$ we obtained an effective action for the $\varphi_1(x)$ field. In the limit $m_2\to\infty$ the field $\varphi_2(x)$ decouples from $\varphi_1(x)$, the only effect of $\varphi_2(x)$ being modifying both the value of the renormalized mass m_1 and the coupling constant of the light field φ_1. Thus we considered the $(\lambda/4!)\,\varphi_1^4$ model on a d-dimensional Euclidean space, where all but one of the coordinates are unbounded. Translation invariance along the bounded coordinate, z, which lies in the interval $[0,L]$, is broken because of the boundary conditions (BC's) chosen for the hyperplanes $z=0$ and $z=L$. Two different possibilities for these BC's boundary conditions are considered: DD and NN, where D denotes Dirichlet and N denotes Neumann. The renormalization procedure up to one-loop order was implemented. The main result of our investigations is that in the presence of boundaries where the field satisfies some boundary condition, the augmented action with surface counterterms can deal with the surface divergences that appear in the one-loop Feynman diagrams.

There are several directions for future research in field theory in the presence of surfaces, out of which we would like to emphasize two. The first one is to implement the renormalization

program beyond the one-loop approximation, where overlapping divergences emerge. The second one is related to the infrared divergences. As we discussed, one way to deal with the infrared divergences in the case of Neumann–Neumann boundary condition is to perform a resummation of the daisy diagrams. Although this procedure is standard in the study of scalar models at finite temperature, for systems where translational invariance is broken, the resummation program is still an open problem. Both subjects are under investigation by the authors.

Free field dynamics in the generalized AdS (super)space

V. E. Didenko[a] and M. A. Vasiliev[b]
I.E.Tamm Department of Theoretical Physics, Lebedev Physical Institute, Leninsky prospect 53, 119991, Moscow, Russia

(Received 2 June 2003; accepted 26 September 2003)

Pure gauge representation for general vacuum background fields (Cartan forms) in the generalized AdS superspace identified with $\mathrm{OSp}(L,M)$ is found. This allows us to formulate dynamics of free massless fields in the generalized AdS space–time and to find their (generalized) conformal and higher spin field transformation laws. Generic solution of the field equations is also constructed explicitly. The results are obtained with the aid of the star product realization of ortosymplectic superalgebras. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1633022]

I. INTRODUCTION

In the recent papers[1,2] it was shown that infinite multiplets of massless higher spins in $4d$ flat Minkowski space–time admit description in terms of 10-dimensional space–time $\mathcal{M}_4$ with real symmetric bispinor matrix coordinates $X^{\alpha\beta}=X^{\beta\alpha}$ $(\alpha,\beta=1,\ldots,4)$. A single scalar field $c(X)$ in $\mathcal{M}_4$ describes massless fields of all integer spins in $4d$ Minkowski space–time upon imposing field equations found in Ref. 1. Half-integer spin massless fields are described analogously by a spinor field $c_\alpha(X)$. That massless fields of all spins have to admit some formulation in $\mathcal{M}_4$ was argued by Fronsdal in the pioneering paper[3] where it was also stressed that such infinite sets of massless fields have to form representations of the extension of the $4d$ conformal group su(2,2) to $\mathrm{sp}(8|R)$. Then in Ref. 4 it was found that world-line particle models based on sp(8) give rise to massless higher spin excitations of all spins. The explicit realization of the sp(8) symmetry by local transformations was given in Ref. 1 as well as the generalization of the proposed sp(8) covariant dynamical equations to $\mathcal{M}_M$ with arbitrary even M.

Properties of the $\mathrm{Sp}(2M)$ invariant space–time $\mathcal{M}_M$ were analyzed in Ref. 2. It was shown that the classical solutions of the field equations define a causal structure and give rise to correct quantization in a positive definite Hilbert space. Usual d-dimensional Minkowski space–time appears as a subspace of the generalized space–time. The analysis of Refs. 1 and 2 was performed for the case of flat space–time although the formalism as a whole works in any (generalized) conformally flat background. In particular it is interesting to extend this analysis to the generalized anti-de Sitter space–time which was argued in Ref. 1 to be the group manifold $\mathrm{Sp}(M)$ (M is even) having $\mathrm{Sp}(M)\times\mathrm{Sp}(M)\subset\mathrm{Sp}(2M)$ as the group of motions realized by left and right group actions on itself. Since the analysis of $\mathrm{Sp}(2M)$ invariant higher spin systems is most naturally performed in terms of star product algebras, for its extension to the generalized AdS space–time it is necessary to built star-product realizations of left invariant Cartan forms (i.e., flat connections) on $\mathrm{Sp}(M)$. This is the primary goal of this paper. Obtained results will allow us to present explicit formulas for symmetries and solutions of the massless field equations in the generalized AdS space–time. The analogous construction will also be given for the supersymmetric case associated with $\mathrm{OSp}(L,M)$.

Let us note that since the star-product formalism we apply leads to compact expressions for $\mathrm{OSp}(L,M)$ Cartan superforms, apart from the higher spin problem, the results obtained in this paper may have applications to other problems where left-invariant forms of $\mathrm{OSp}(L,M)$ appear. For example, in Ref. 5 it was shown how $\mathrm{OSp}(1,M)$ Cartan forms can be used to construct

[a]Electronic mail: didenko@lpi.ru
[b]Electronic mail: vasiliev@lpi.ru

twistorlike actions for superparticles and possible applications to superbranes were discussed while in Ref. 6 a toy model of M theory based on osp(1,64) was suggested.

A. Generalized conformal symmetry

The generators L_{mn}, P_m, K_m, D of the conformal algebra o(d,2) satisfy the following commutation relations:

$$\begin{gathered}[L_{ab}, L_{cd}] = \eta_{ac} L_{bd} - \eta_{bc} L_{ad} + \eta_{ad} L_{cb} - \eta_{bd} L_{ca}, \\ [L_{ab}, P_c] = \eta_{ac} P_b - \eta_{bc} P_a, \quad [L_{ab}, K_c] = \eta_{ac} K_b - \eta_{bc} K_a, \\ [L_{ab}, D] = [P_a, P_b] = [K_a, K_b] = 0, \\ [P_a, K_b] = 2(\eta_{ab} D + L_{ab}), \quad [P_a, D] = P_a, \quad [K_a, D] = -K_a,\end{gathered} \tag{1.1}$$

$m,n = 0,\ldots,d-1$, $\eta_{mn} = \mathrm{diag}(1,-1,\ldots,-1)$. The conformal algebra can be realized by the vector fields

$$\begin{gathered}L_{ab} = \eta_{ac} x^c \frac{\partial}{\partial x^b} - \eta_{bc} x^c \frac{\partial}{\partial x^a}, \\ P_a = \frac{\partial}{\partial x^a}, \quad D = x^a \frac{\partial}{\partial x^a}, \\ K_a = 2\,\eta_{ac} x^c x^b \frac{\partial}{\partial x^b} - \eta_{bc} x^b x^c \frac{\partial}{\partial x^a}.\end{gathered} \tag{1.2}$$

The Poincare subalgebra is spanned by L_{mn} and P_m. K_m and D are the generators of special conformal transformations and dilatations, respectively. To embed the AdS_d algebra o($d-1$,2) into the d-dimensional conformal algebra o(d,2) one identifies the AdS_d translations with the mixture of translations and special conformal transformations in the conformal algebra

$$P^a_{\mathrm{AdS}_d} = P^a - \lambda^2 K^a. \tag{1.3}$$

The generators $P^a_{\mathrm{AdS}_d}$ and L_{ab} form the AdS_d subalgebra o($d-1$,2)$\subset$o(d,2). This embedding breaks down the manifest o(1,1) dilatation covariance because it mixes the operators P^a and K^a, which have different dimensions. λ is the dimensionful Wigner–Inönu contraction parameter to be identified with the inverse AdS_d radius.

The sp($2M$) algebra admits analogous description in terms of the generators $L_\alpha{}^\beta, P_{\alpha\beta}, K^{\alpha\beta}$, and D, where indices $\alpha,\beta,\ldots$ range from 1 to M and $L_\alpha{}^\beta$ is traceless. The commutation relations are

$$[K^{\alpha\beta}, K^{\gamma\delta}] = 0, \quad [P_{\alpha\beta}, P_{\gamma\delta}] = 0, \tag{1.4}$$

$$[D, P_{\alpha\beta}] = -P_{\alpha\beta}, \quad [D, K^{\alpha\beta}] = K^{\alpha\beta}, \quad [D, L_\alpha{}^\beta] = 0, \tag{1.5}$$

$$[L_\alpha{}^\beta, P_{\gamma\delta}] = -\delta_\gamma{}^\beta P_{\alpha\delta} - \delta_\delta{}^\beta P_{\alpha\gamma} + \frac{2}{M}\delta_\alpha{}^\beta P_{\gamma\delta}, \tag{1.6}$$

$$[L_\alpha{}^\beta, K^{\gamma\delta}] = \delta_\alpha{}^\gamma K^{\beta\delta} + \delta_\alpha{}^\delta K^{\beta\gamma} - \frac{2}{M}\delta_\alpha{}^\beta K^{\gamma\delta}, \tag{1.7}$$

$$[P_{\alpha\beta},K^{\gamma\delta}]=L_\alpha{}^\delta\delta_\beta{}^\gamma+L_\beta{}^\delta\delta_\alpha{}^\gamma+L_\alpha{}^\gamma\delta_\beta{}^\delta+L_\beta{}^\gamma\delta_\alpha{}^\delta+\frac{4}{M}D(\delta_\alpha{}^\delta\delta_\beta{}^\gamma+\delta_\beta{}^\delta\delta_\alpha{}^\gamma)\,, \tag{1.8}$$

$$[L_\alpha{}^\beta,L_\gamma{}^\delta]=\delta_\alpha{}^\delta L_\gamma{}^\beta-\delta_\gamma{}^\beta L_\alpha{}^\delta\,. \tag{1.9}$$

Note that the generalized Lorentz subalgebra generated by $L_\alpha{}^\beta$ is sl_M. Analogously to the usual conformal algebra, generalized translations generated by $P_{\alpha\beta}$ form Abelian subalgebra of $\mathrm{sp}(2M)$. Generalized special conformal transformations generate a dual Abelian subalgebra. Let us note that as shown in Ref. 2 $\mathrm{sp}(2M)$ contains conformal algebra $\mathrm{o}(d,2)$ which acts in the usual d-dimensional Minkowski space as subalgebra. In the higher spin field-theoretical models, which contain infinite towers of fields, $\mathrm{o}(d,2)$ acts individualy on every massless field while the generators in $\mathrm{sp}(2M)/\mathrm{o}(d,2)$ mix different massless fields. We therefore will call $\mathrm{sp}(2M)$ as generalized conformal algebra.

The commutation relations (1.4)–(1.9) can be realized by the vector fields

$$P_{\alpha\beta}=\frac{\partial}{\partial X^{\alpha\beta}}\,,\quad K^{\alpha\beta}=4X^{\alpha\gamma}X^{\beta\eta}\frac{\partial}{\partial X^{\gamma\eta}}\,, \tag{1.10}$$

$$L_\alpha{}^\beta=2X^{\beta\gamma}\frac{\partial}{\partial X^{\alpha\gamma}}-\frac{2}{M}\delta_\alpha{}^\beta X^{\beta\gamma}\frac{\partial}{\partial X^{\beta\gamma}}\,,\quad D=X^{\beta\gamma}\frac{\partial}{\partial X^{\beta\gamma}}\,, \tag{1.11}$$

where $X^{\alpha\beta}=X^{\beta\alpha}$ are coordinates of $\mathcal{M}_M$.

The simplest way to see that the commutation relations (1.4)–(1.9) are indeed of $\mathrm{sp}(2M)$ is to use its oscillator realization.[7] Actually, let $\hat a_\alpha$ and $\hat b^\alpha$ be oscillators with the commutation relations

$$[\hat a_\alpha,\hat b^\beta]=\delta_\alpha{}^\beta\,,\quad [\hat a_\alpha,\hat a_\beta]=0\,,\quad [\hat b^\alpha,\hat b^\beta]=0\,. \tag{1.12}$$

The generators of $\mathrm{sp}(2M)$ are spanned by the bilinears

$$\hat T_\alpha{}^\beta=\tfrac{1}{2}\{\hat a_\alpha,\hat b^\beta\}\,,\quad \hat P_{\alpha\beta}=\hat a_\alpha\hat a_\beta\,,\quad \hat K^{\alpha\beta}=\hat b^\alpha\hat b^\beta\,. \tag{1.13}$$

Instead of working in terms of operators it is convenient to use the star-product operation in the algebra of polynomials of commuting variables a_α and b^α,

$$(f\star g)(a,b)=\frac{1}{\pi^{2M}}\int f(a+u,b+t)g(a+s,b+v)e^{2(s_\alpha t^\alpha-u_\alpha v^\alpha)}\,\mathrm{d}^Mu\,\mathrm{d}^Mt\,\mathrm{d}^Ms\,\mathrm{d}^Mv\,. \tag{1.14}$$

The star-product defined this way, often called Moyal product, describes the product of symmetrized (i.e., Weyl ordered) polynomials of oscillators in terms of symbols of operators. The integral is normalized in such a way that

$$\frac{1}{\pi^{2M}}\int e^{2(s_\alpha t^\alpha-u_\alpha v^\alpha)}\,\mathrm{d}^Mu\,\mathrm{d}^Mt\,\mathrm{d}^Ms\,\mathrm{d}^Mv=1\,, \tag{1.15}$$

so that 1 is the unit element of the algebra. Equation (1.14) defines the associative algebra with the defining relations

$$[a_\alpha,b^\beta]_\star=\delta_\alpha{}^\beta\,,\quad [a_\alpha,a_\beta]_\star=0\,,\quad [b^\alpha,b^\beta]_\star=0 \tag{1.16}$$

($[a,b]_\star=a\star b-b\star a$). The star-product realization of the generators of $\mathrm{sp}(2M)$ is

$$T_\alpha{}^\beta=a_\alpha b^\beta\,,\quad P_{\alpha\beta}=a_\alpha a_\beta\,,\quad K^{\alpha\beta}=b^\alpha b^\beta\,, \tag{1.17}$$

where the gl(M) generator $T_\alpha{}^\beta$ decomposes into the sl(M) "Lorentz" and o(1,1) "dilatation" generators

$$L_\alpha{}^\beta = a_\alpha b^\beta - \frac{1}{M}\delta_\alpha{}^\beta a_\gamma b^\gamma, \quad D = \tfrac{1}{2} a_\alpha b^\alpha . \tag{1.18}$$

The bilinears of oscillators fulfil the commutation relations (1.4)–(1.9).

The embedding of the generalized AdS subalgebra into the conformal algebra sp($2M$) is achieved by identification of the (generalized) AdS translations with the mixture of translations and special conformal transformations $P^{\mathrm{AdS}}_{\alpha\beta} = P_{\alpha\beta} + \lambda^2 \eta_{\alpha\beta\gamma\delta} K^{\gamma\delta}$ with some bilinear form $\eta_{\alpha\beta\gamma\delta}$. (Note that keeping the same number of translation generators we keep dimension of the generalized space–time intact.) As argued in Ref. 1, $\eta_{\alpha\beta\gamma\delta}$ has to have the factorized form: $\eta_{\alpha\beta\gamma\delta} = V_{\alpha\gamma} V_{\beta\delta}$, where $V_{\alpha\beta}$ is some nondegenerate antisymmetric form (thus requiring M to be even). In what follows the form $V_{\alpha\beta}$ will be used to raise and lower indices according to the rule

$$A_\alpha = V_{\beta\alpha} A^\beta, \quad A^\alpha = V^{\alpha\beta} A_\beta, \quad V_{\alpha\beta} V^{\alpha\gamma} = \delta_\beta{}^\gamma . \tag{1.19}$$

Thus, the generalized AdS translations have the form

$$P^{\mathrm{AdS}}_{\alpha\beta} = P_{\alpha\beta} + \lambda^2 V_{\alpha\gamma} V_{\beta\delta} K^{\gamma\delta} = P_{\alpha\beta} + \lambda^2 K_{\alpha\beta} . \tag{1.20}$$

The commutation relations of $P^{\mathrm{AdS}}_{\alpha\beta}$ have the form

$$[P^{\mathrm{AdS}}_{\alpha\beta}, P^{\mathrm{AdS}}_{\gamma\delta}] = 2\lambda^2 (V_{\beta\gamma} L^{\mathrm{AdS}}_{\alpha\delta} + V_{\beta\delta} L^{\mathrm{AdS}}_{\alpha\gamma} + V_{\alpha\gamma} L^{\mathrm{AdS}}_{\beta\delta} + V_{\alpha\delta} L^{\mathrm{AdS}}_{\beta\gamma}) , \tag{1.21}$$

where $L^{\mathrm{AdS}}_{\alpha\beta} = L^{\mathrm{AdS}}_{\beta\alpha}$ are generators of the sp(M) subalgebra of gl_M which leaves invariant the symplectic form $V_{\alpha\beta}$. The full generalized AdS subalgebra is $\mathrm{sp}(M) \oplus \mathrm{sp}(M) \subset \mathrm{sp}(2M)$. Its Lorentz subalgebra $\mathrm{sp}^l(M)$ identifies with the diagonal sp(M) while AdS translations span $\mathrm{sp}(M) \oplus \mathrm{sp}(M)/\mathrm{sp}^l(M)$. Note that the generalized dS algebra obtained from (1.20) by virtue of the sign change $\lambda^2 \to -\lambda^2$ is $\mathrm{Sp}(M,C)^R$.

B. Fock space and Sp($2M$) covariant equations

The sp($2M$) invariant equations of all massless fields in three and four dimensions are naturally described[8,1] in terms of sections of the Fock fiber bundle over $\mathcal{M}_M$. In other words, consider functions on $\mathcal{M}_M$ taking values in the Fock module F,

$$|\Phi(b|X)\rangle = C(b|X) \star |0\rangle\langle 0| , \tag{1.22}$$

where $C(b|X)$ is some "generating function,"

$$C(b|X) = \sum_{m=0}^{\infty} \frac{1}{m!} c_{\beta_1 \cdots \beta_m}(X) b^{\beta_1} \cdots b^{\beta_m}, \tag{1.23}$$

and $|0\rangle\langle 0|$ is the Fock vacuum defined by the relations

$$a_\alpha \star |0\rangle\langle 0| = 0 , \quad |0\rangle\langle 0| \star b^\alpha = 0 . \tag{1.24}$$

$|0\rangle\langle 0|$ can be realized as an element of the star-product algebra

$$|0\rangle\langle 0| = e^{-2 a_\alpha b^\alpha} . \tag{1.25}$$

Note that the Fock vacuum is the space–time constant projector

$$d|0\rangle\langle 0| = 0 , \quad |0\rangle\langle 0| \star |0\rangle\langle 0| = |0\rangle\langle 0| , \tag{1.26}$$

where d is de Rahm differential

$$d=\mathrm{d}X^{\alpha\beta}\frac{\partial}{\partial X^{\alpha\beta}},\quad d^2=0. \tag{1.27}$$

As shown in Ref. 1 the relevant flat space $\mathrm{Sp}(2M)$ covariant equation can be formulated in the form

$$d|\Phi(b|X)\rangle - w_0\star|\Phi(b|X)\rangle=0\,, \tag{1.28}$$

where

$$w_0=\tfrac{1}{2}\mathrm{d}X^{\alpha\beta}a_\alpha a_\beta\,. \tag{1.29}$$

That the equation (1.28) does indeed describe all conformal field equations in $d=3$ and $d=4$ was shown in Refs. 8 and 1 for the cases of $M=2$ and $M=4$, respectively. In this paper we will consider the general case of any even M. It is worth to mention that the cases of $M=8$, $M=16$, and $M=32$ were argued in Ref. 2 to correspond to conformal systems in $d=6$, $d=10$, and $d=11$, respectively.

The Fock fiber bundle realization of the higher spin equations guarantees generalized conformal symmetry of the system along with its infinite-dimensional higher spin extension. Actually, let w_0 be some one-form, taking values in the higher spin algebra identified with the star product algebra (i.e., the algebra of regular functions of oscillators acting on the Fock module F)

$$w_0(X)=\sum_{m,n=0}^{\infty}\frac{1}{m!n!}w_{0\,\beta_1\cdots\beta_m}{}^{\alpha_1\cdots\alpha_n}(X)a_{\alpha_1}\cdots a_{\alpha_n}b^{\beta_1}\cdots b^{\beta_m}\,, \tag{1.30}$$

which satisfies the zero-curvature condition

$$\mathrm{d}w_0=w_0\star\wedge w_0\,. \tag{1.31}$$

The equations (1.28), (1.31) are invariant under the gauge transformations

$$\delta w_0=\mathrm{d}\epsilon-[w_0,\epsilon]_\star\,, \tag{1.32}$$

$$\delta|\Phi(b|X)\rangle=\epsilon\star|\Phi(b|X)\rangle\,, \tag{1.33}$$

where $\epsilon(a,b|X)$ is an arbitrary infinitesimal gauge parameter. Any fixed vacuum solution w_0 of the equation (1.31) breaks the local higher spin symmetry to its stability subalgebra with the infinitesimal parameters $\epsilon_0(a,b|X)$ satisfying the equation

$$\mathrm{d}\epsilon_0-[w_0,\epsilon_0]_\star=0. \tag{1.34}$$

Consistency of this equation is guaranteed by (1.31). As a result, (1.34) admits locally a pure gauge solution

$$w_0(X)=-g^{-1}(X)\star\mathrm{d}g(X)\,, \tag{1.35}$$

where $g(a,b|X)$ is some invertible element of the star-product algebra. The global symmetry parameters satisfying (1.34) then have the form

$$\epsilon_0(X)=g^{-1}(X)\star\xi\star g(X)\,, \tag{1.36}$$

where an arbitrary X-independent element $\xi=\xi(a,b)$ of the star-product algebra describes parameters of the global higher spin symmetry which acts on the solutions of the equation (1.28) (for any given w_0). In particular, the $\mathrm{sp}(2M)$ subalgebra spanned by bilinears of oscillators is thus shown to be a symmetry of the equation (1.28). (See Ref. 9.)

Analogously one solves the equation (1.28) in the form

$$|\Phi(b|X)\rangle = g^{-1}\star|\Phi(b|X_0)\rangle\,, \tag{1.37}$$

where $|\Phi(b|X_0)\rangle$ plays a role of initial data. The meaning of this formula is that the Fock module $|\Phi(b|X_0)\rangle$ parametrizes all combinations of the derivatives of the dynamical fields at $X=X_0$ which are allowed to be nonzero by the field equations. The formula (1.37) plays a role of the covariantized Taylor expansion reconstructing generic solution in terms of its derivatives at $X=X_0$. Note that the Fock module F is not unitary because it decomposes into an infinite sum of finite-dimensional (tensor) representations of the generalized noncompact Lorentz algebra $\mathrm{sl}_M(\mathbf{R})$. Nevertheless, the fact that initial data of the problem are formulated in terms of the Fock module F is closely related to the fact (see, e.g., Refs. 3 and 4) that the collection of unitary massless representations corresponding to this dynamical system in $d=4$ is described by the unitary Fock module U known as singleton representation of sp(8). (It is also well known that unitary representations of the $4d$ conformal algebra associated with massless fields admit Fock realization in terms of appropriate oscillators.[10]) As shown in Refs. 8 and 1, the modules U and F are related by some Bogolyubov transform.

The formulas (1.35), (1.37) will play the key role in our analysis. They allow one to solve the equations of motion explicitly provided that the gauge function $g(X)$ is found that corresponds to a chosen zero-curvature connection w_0. This program for the flat connection (1.29) was accomplished in Ref. 1. In this paper we will find a family of such gauge functions $g(X)$ that all nonvanishing components of w_0 take values in the AdS subalgebra $\mathrm{osp}(L|M)\oplus\mathrm{osp}(L|M)$ of $\mathrm{osp}(2L|2M)$.

II. Sp(M) AND STAR PRODUCT

As argued in Ref. 1, the generalized AdS space is identified with $\mathrm{Sp}(M)$. Let us note that the generalized conformal group $\mathrm{Sp}(2M)$ does not act globally on $\mathrm{Sp}(M)$ analogously to the usual conformal group acting in the Minkowski space–time by Möbius transformations which have singularities. Recall that usual Minkowski space–time is the big cell of the compactified Minkowski space. Analogously, the generalized Minkowski space–time is the big cell in the compactified generalized space–time $\mathcal{M}_M$. The universal covering space of $\mathrm{Sp}(M)$ can be thought of as a sort of deformation of the generalized Minkowski space–time being the big cell of $\mathcal{M}_M$.

The group $\mathrm{Sp}(M)$ is realized by the $M\times M$ matrices $U_\alpha{}^\beta$ satisfying

$$U_\alpha{}^\beta U_\gamma{}^\delta V^{\alpha\gamma} = V^{\beta\delta}\,, \tag{2.1}$$

where $V^{\alpha\beta}$ is some nondegenerate antisymmetric form $V^{\alpha\beta}=-V^{\beta\alpha}$ (M is even). The manifold $\mathrm{Sp}(M)$ is $[M(M+1)/2]$ dimensional. It can be described by local coordinates $X^{\alpha\beta}=X^{\beta\alpha}$. The simplest parametrization is

$$U_\alpha{}^\beta = (\exp(\lambda X))_\alpha{}^\beta, \tag{2.2}$$

where λ is inverse "radius" of $\mathrm{Sp}(M)$ introduced to compensate the space dimensionality of $X^{\alpha\beta}$. Note that a particular value of $\lambda\neq 0$ is irrelevant unless there are some other dimensional parameters in the theory (e.g., the gravitational constant). The exponential in (2.2) is matrix exponential of

$$X_\alpha{}^\beta = V_{\gamma\alpha}X^{\gamma\beta}\,. \tag{2.3}$$

It is elementary to see that the parametrization (2.2) solves the group equation (2.1). The exponential parametrization (2.2) provides the universal covering space[11] of $\mathrm{Sp}(M)$ [metaplectic group $\mathrm{Mp}(M)$] topologically equivalent to $R^{[M(M+1)/2]}$, the big cell of $\mathcal{M}_M$.

$\mathrm{Sp}(M)$ is invariant under the action of $\mathrm{Sp}(M)\times\mathrm{Sp}(M)$ generated by left and right actions of $\mathrm{Sp}(M)$ on itself. Using the oscillator realization of $\mathrm{sp}(M)\oplus\mathrm{sp}(M)\subset\mathrm{sp}(2M)$ we can set

$$w_0(X)=\omega_{\alpha\beta}(X)a^\alpha b^\beta+h_{\alpha\beta}(X)(a^\alpha a^\beta+\lambda^2 b^\alpha b^\beta)\,, \tag{2.4}$$

where the "Lorentz connection" $\omega_{\alpha\beta}(X)$ and the "frame" $h_{\alpha\beta}(X)$ have the form

$$\omega_{\alpha\beta}=-\tfrac{1}{2}(\mathrm{d}(U^{-1})_\alpha{}^\gamma U_{\gamma\beta}+\mathrm{d}U_\alpha{}^\gamma(U^{-1})_{\gamma\beta})\,, \tag{2.5}$$

$$h_{\alpha\beta}=\frac{1}{4\lambda}(\mathrm{d}U_\alpha{}^\gamma(U^{-1})_{\gamma\beta}-\mathrm{d}(U^{-1})_\alpha{}^\gamma U_{\gamma\beta})\,, \tag{2.6}$$

which guarantees that w_0 satisfies (1.31). In the exponential parametrization (2.2) one gets

$$\omega^{\alpha\beta}=\frac{\lambda}{2}\mathrm{d}X_{\mu\nu}\left(\int_0^1\exp(\lambda Xt)^{\mu\beta}\exp(\lambda Xt)^{\nu\alpha}\,\mathrm{d}t-\int_{-1}^0\exp(\lambda Xt)^{\mu\beta}\exp(\lambda Xt)^{\nu\alpha}\,\mathrm{d}t\right), \tag{2.7}$$

$$h^{\alpha\beta}=\frac{1}{4}\mathrm{d}X_{\mu\nu}\int_{-1}^1\exp(\lambda Xt)^{\mu\beta}\exp(\lambda Xt)^{\nu\alpha}\,\mathrm{d}t\,, \tag{2.8}$$

where we used the identity $\delta e^A=\int_0^1 e^{At}\delta A e^{A(1-t)}\,\mathrm{d}t$ valid for an arbitrary matrix A. As expected, in the flat limit $\lambda\to 0$ one recovers (1.29).

Let us now present the star-product pure gauge form (1.35) of the connection (2.4)–(2.6). The final result is

$$g=\frac{1}{\det\left\|\mathrm{ch}\dfrac{\lambda X}{2}\right\|}\exp\left(-\frac{1}{\lambda}\left(\mathrm{th}\frac{\lambda X}{2}\right)^{\alpha\beta}(a_\alpha a_\beta+\lambda^2 b_\alpha b_\beta)\right), \tag{2.9}$$

$$g^{-1}=\frac{1}{\det\left\|\mathrm{ch}\dfrac{\lambda X}{2}\right\|}\exp\left(\frac{1}{\lambda}\left(\mathrm{th}\frac{\lambda X}{2}\right)^{\alpha\beta}(a_\alpha a_\beta+\lambda^2 b_\alpha b_\beta)\right). \tag{2.10}$$

This formula is derived as follows. Let $\mathrm{sp}(M)$ be realized in terms of bilinears of oscillators α_α satisfying the commutation relations

$$[\alpha_\alpha,\alpha_\beta]_*=2V_{\alpha\beta}\,, \tag{2.11}$$

with the star product,

$$(f*g)(\alpha)=\frac{1}{\pi^M}\int f(\alpha+u)g(\alpha+v)e^{-u_\alpha v^\alpha}\,\mathrm{d}^M u\,\mathrm{d}^M v\,. \tag{2.12}$$

Consider star-product algebra elements g_1 and g_2 of the form

$$g_1=r_1 e^{1/2\,f_1^{\alpha\beta}\alpha_\alpha\alpha_\beta},\quad g_2=r_2 e^{1/2\,f_2^{\alpha\beta}\alpha_\alpha\alpha_\beta} \tag{2.13}$$

with some α-independent r_1, r_2, $f_1^{\alpha\beta}$, and $f_2^{\alpha\beta}$. Elementary evaluation of the Gaussian integrals shows that

$$g_{1,2}=g_1*g_2=r_{1,2}e^{1/2(f_1\circ f_2)^{\alpha\beta}\alpha_\alpha\alpha_\beta}\,, \tag{2.14}$$

where

$$r_{1,2}=\frac{r_1 r_2}{\sqrt{\det\|f_1 f_2+1\|}} \tag{2.15}$$

and

$$f_1\circ f_2=\frac{1}{1+f_2 f_1}(1+f_2)-\frac{1}{1+f_1 f_2}(1-f_1) \tag{2.16}$$

[with the usual matrix multiplication on the right-hand side, $AB\to A_\alpha{}^\gamma B_\gamma{}^\beta$, $(1/A)\,B \to (A^{-1})_\alpha{}^\gamma B_\gamma{}^\beta$]. Let us look for a map

$$g(U)=r(U)e^{1/2\, f^{\alpha\beta}(U)\alpha_\alpha\alpha_\beta} \tag{2.17}$$

of $\mathrm{Sp}(M)$ into the star-product algebra, such that

$$g(U_1)*g(U_2)=g(U_1U_2)=r(U_1U_2)e^{1/2\, f^{\alpha\beta}(U_1U_2)\alpha_\alpha\alpha_\beta}. \tag{2.18}$$

Equivalently, one can use the inverse map $U(f)$ requiring

$$U(f_1)U(f_2)=U(f_1\circ f_2). \tag{2.19}$$

As shown in the Appendix, the multiplication law (2.16) requires

$$U^{\alpha\beta}(f)=\left(\frac{1+f}{1-f}\right)^{\alpha\beta}. \tag{2.20}$$

The inverse formula is analogous

$$f^{\alpha\beta}(U)=\left(\frac{U-1}{1+U}\right)^{\alpha\beta}. \tag{2.21}$$

The normalization factor is

$$r(U)=\frac{2^{M/2}}{\sqrt{\det\|U+1\|}}. \tag{2.22}$$

To derive (2.9) it remains to use (2.2) and to observe that the two $\mathrm{sp}(M)$ subalgebras of $\mathrm{sp}(2M)$ are generated by the two mutually commuting sets of oscillators

$$\alpha^\pm_\alpha=\frac{a_\alpha}{\sqrt{\lambda}}\pm\sqrt{\lambda}V_{\beta\alpha}b^\beta=\frac{1}{\sqrt{\lambda}}(a_\alpha\pm\lambda b_\alpha), \tag{2.23}$$

satisfying the commutation relations

$$[\alpha^\pm_\alpha,\alpha^\pm_\beta]_*=\pm 2V_{\alpha\beta}. \tag{2.24}$$

The map (2.20) has a number of interesting properties. In particular,

$$U^{-1}(f)=U(-f), \tag{2.25}$$

$$U(f)=-U^{-1}(-f^{-1}). \tag{2.26}$$

The property (2.25) is a consequence of the elementary fact (see, e.g., Ref. 12) that the star product (2.12) admits an antiautomorphism $\rho(g(\alpha))=g(i\alpha)$, i.e., $\rho(g_1)*\rho(g_2)=\rho(g_2*g_1)$. From (2.17) it follows that $\rho(U(f))=U(-f)$. The natural group antiautomorphism is $\rho(U)=U^{-1}$. The formula (2.25) identifies the antiautomorphism ρ in the star-product algebra with that of the group $\mathrm{Sp}(M)$.

The formula (2.26) is more interesting. It does not have a global interpretation within $\mathrm{Sp}(M)$ being singular at degenerate $f^{\alpha\beta}$ (in particular for $f^{\alpha\beta}=0$ and, therefore, $U=I$). However, these maps are expected to have global meaning in $\mathcal{M}_M$ where one can define inversion by analogy with the flat case considered in Ref. 2,

$$I(f)=-f^{-1}, \quad I(U)=-U^{-1}. \tag{2.27}$$

The formula (2.26) implies that these two definitions are consistent with each other. Note that inversion defined this way maps unit element of $\mathrm{Sp}(M)$ to the central element $-I$ which does not belong to the connected component of unity $\mathrm{PSp}(M)\subset\mathrm{Sp}(M)$.

III. ARBITRARY COORDINATES

The gauge function (2.9) corresponds to the exponential realization of $\mathrm{Sp}(M)$, thus yielding global coordinates which cover the metaplectic group $\mathrm{Mp}(M)$. Our formalism allows one to write down explicit form of vacuum gauge connections (Cartan forms) in arbitrary coordinates, however. Indeed, let us consider a gauge function of the form

$$\begin{aligned} g&=\sqrt{\det\|1-\lambda^2 f^2(X)\|}\,\exp(-f(X)^{\alpha\beta}(a_\alpha a_\beta+\lambda^2 b_\alpha b_\beta))\,,\\ g^{-1}&=\sqrt{\det\|1-\lambda^2 f^2(X)\|}\,\exp(f(X)^{\alpha\beta}(a_\alpha a_\beta+\lambda^2 b_\alpha b_\beta))\,, \end{aligned} \tag{3.1}$$

where $f^{\alpha\beta}(X)=f^{\beta\alpha}(X)$ is an arbitrary function of matrix coordinates $X^{\alpha\beta}$. The zero-curvature connection (1.35) can be written in the form

$$w_0=-g(-f)\star\left(\mathrm{d}X^{\alpha\beta}\frac{\partial f_1^{\gamma\lambda}}{\partial X^{\alpha\beta}}\frac{\partial}{\partial f_1^{\gamma\lambda}}g(f_1)\right)\Bigg|_{f_1=f}. \tag{3.2}$$

Direct computation leads to the expressions for the ''Lorentz connection'' and ''frame''

$$h^{\alpha\beta}=\mathrm{d}X^{\rho\sigma}\left(\frac{1}{1-\lambda^2 f^2}\right)^{\alpha\gamma}\left(\frac{\partial f_\gamma{}^\lambda}{\partial X^{\rho\sigma}}-\lambda^2 f_\gamma{}^\mu\frac{\partial f_\mu{}^\nu}{\partial X^{\rho\sigma}}f_\nu{}^\lambda\right)\left(\frac{1}{1-\lambda^2 f^2}\right)_\lambda^\beta, \tag{3.3}$$

$$\omega^{\alpha\beta}=2\lambda^2\,\mathrm{d}X^{\rho\sigma}\left(\frac{1}{1-\lambda^2 f^2}\right)^{\alpha\gamma}\left(\frac{\partial f_\gamma{}^\mu}{\partial X^{\rho\sigma}}f_\mu{}^\lambda-f_\gamma{}^\mu\frac{\partial f_\mu{}^\lambda}{\partial X^{\rho\sigma}}\right)\left(\frac{1}{1-\lambda^2 f^2}\right)_\lambda^\beta. \tag{3.4}$$

Note that from these formulas it follows that

$$\omega^{\alpha\beta}=2h^{\alpha\gamma}f_\gamma{}^\beta-2\,f^{\alpha\gamma}h_\gamma{}^\beta+\lambda^2 f^{\alpha\gamma}\omega_\gamma{}^\lambda f_\lambda{}^\beta. \tag{3.5}$$

An arbitrary function $f^{\alpha\beta}(X)$ parametrizes various coordinate choices in $\mathrm{Sp}(M)$. A relationship with the coordinates of the exponential parametrization obviously is

$$f(\tilde{X})=\frac{1}{\lambda}\mathrm{th}\frac{\lambda X}{2}, \tag{3.6}$$

which implies locally

$$\mathrm{sh}\frac{\lambda X}{2}=\frac{\lambda f(\widetilde{X})}{\sqrt{1-\lambda^2 f^2(\widetilde{X})}},\quad \mathrm{ch}\frac{\lambda X}{2}=\frac{1}{\sqrt{1-\lambda^2 f^2(\widetilde{X})}}. \tag{3.7}$$

The formulas (3.3) and (3.4) thus provide a representation for Cartan forms in arbitrary coordinates associated with one or another function $f^{\alpha\beta}(X)$. Consider now a few particular examples. Let $f^{\alpha\beta}(X)$ be of the form

$$f^{\alpha\beta}(X)=\phi(\det\|X\|)X^{\alpha\beta}. \tag{3.8}$$

The corresponding connections are

$$h^{\alpha\beta}=\phi\cdot\left(\frac{1}{1-\lambda^2\phi^2X^2}\right)^{\alpha\gamma}(\mathrm{d}X_\gamma{}^\lambda-\lambda^2\phi^2X_\gamma{}^\mu\,\mathrm{d}X_\mu{}^\nu X_\nu{}^\lambda)\left(\frac{1}{1-\lambda^2\phi^2X^2}\right)_\lambda^\beta$$
$$+\widetilde{\phi}\cdot\mathrm{d}X^{\rho\sigma}(X^{-1})_{\rho\sigma}\left(\frac{X}{1-\lambda^2\phi^2X^2}\right)^{\alpha\beta}, \tag{3.9}$$

$$\omega^{\alpha\beta}=2\lambda^2\phi^2\cdot\left(\frac{1}{1-\lambda^2\phi^2X^2}\right)^{\alpha\gamma}(\mathrm{d}X_\gamma{}^\mu X_\mu{}^\lambda-X_\gamma{}^\mu\,\mathrm{d}X_\mu{}^\lambda)\left(\frac{1}{1-\lambda^2\phi^2X^2}\right)_\lambda^\beta, \tag{3.10}$$

where

$$\widetilde{\phi}=\frac{\partial\phi}{\partial\ln\det\|X\|}. \tag{3.11}$$

Another useful example results from

$$f^{\pm}_{\alpha\beta}(X)=\left(\frac{X}{1\mp\sqrt{1-\lambda^2X^2}}\right)_{\alpha\beta}. \tag{3.12}$$

The corresponding gauge function is

$$g^{\pm}=\det\left\|\frac{1+\lambda X\pm\sqrt{1-\lambda^2X^2}}{\lambda X}\right\|\exp\left(-\left(\frac{X}{1\mp\sqrt{1-\lambda^2X^2}}\right)^{\alpha\beta}(a_\alpha a_\beta+\lambda^2b_\alpha b_\beta)\right). \tag{3.13}$$

In these ''stereographic'' coordinates the ''frame'' gets the following simple form:

$$h^{\alpha\beta}=\frac{1}{2}\left(\frac{1}{\sqrt{1-\lambda^2X^2}}\right)^{\alpha\gamma}\mathrm{d}X_\gamma{}^\lambda\left(\frac{1}{\sqrt{1-\lambda^2X^2}}\right)_\lambda^\beta. \tag{3.14}$$

Let us now compare this formula with those obtained in Refs. 8 and 9 to describe massless fields in $\mathrm{AdS}_3(M=2)$ and $\mathrm{AdS}_4(M=4)$.

Let us first consider the case $M=2$. Using, for example, g^+, from (3.13) one obtains

$$g=\frac{2\sqrt{z}}{1+\sqrt{z}}\exp\left(-\frac{1}{1+\sqrt{z}}x^{\alpha\beta}(a_\alpha a_\beta+\lambda^2b_\alpha b_\beta)\right), \tag{3.15}$$

$$g^{-1}=\frac{2\sqrt{z}}{1+\sqrt{z}}\exp\left(\frac{1}{1+\sqrt{z}}x^{\alpha\beta}(a_\alpha a_\beta+\lambda^2b_\alpha b_\beta)\right), \tag{3.16}$$

where $z=1+\frac{1}{2}\lambda^2x_{\alpha\beta}x^{\alpha\beta}$. The ''frame'' and the ''Lorentz connection'' are

$$h_{\alpha\beta}=\frac{1}{2z}\mathrm{d}x_{\alpha\beta}\,,\quad \omega_{\alpha\beta}=\frac{1}{2z}(\mathrm{d}x_{\alpha}{}^{\gamma}x_{\gamma\beta}+\mathrm{d}x_{\beta}{}^{\gamma}x_{\gamma\alpha}). \tag{3.17}$$

To derive this result, which reproduces that of Ref. 8, we used a simple fact that, when $M=2$, any antisymmetric matrix is proportional to $V_{\alpha\beta}$ and, therefore, any polynomial of matrix coordinates $P(x)^{\alpha\beta}$ decomposes into a combination of its symmetric part $P_S(x_{\mu\nu}x^{\mu\nu})x^{\alpha\beta}$ and antisymmetric part $P_A(x_{\mu\nu}x^{\mu\nu})V^{\alpha\beta}$. From (3.17) it follows that the metric tensor is

$$g_{mn}=\tfrac{1}{2}h_{\alpha\beta,n}h^{\alpha\beta}{}_{,m}=\frac{1}{4}\,\frac{\eta_{mn}}{(1+\lambda^2x_kx^k)^2}\,, \tag{3.18}$$

where

$$x_n=\sigma_n{}^{\alpha\beta}x_{\alpha\beta}\,,\quad x_{\alpha\beta}=\tfrac{1}{2}\sigma_{\alpha\beta}{}^{n}x_n\,, \tag{3.19}$$

and $\sigma_n{}^{\alpha\beta}$ is a set of basis symmetric real matrices normalized to satisfy

$$\sigma_n{}^{\alpha\beta}\sigma_{m\alpha\beta}=2\,\eta_{mn}\,, \tag{3.20}$$

where η_{mn} is the flat Minkowski metric.

To consider the $4d$ case we embed AdS_4 space–time into $\mathcal{M}_4$ as follows:

$$X^{\alpha\beta}=\begin{pmatrix}\mathbf{0} & x^{\bar\alpha\dot\beta}\\ x^{\beta\bar\alpha} & \mathbf{0}\end{pmatrix}, \tag{3.21}$$

where $\bar\alpha,\bar\beta=1,2$, $\dot\alpha,\dot\beta=3,4$, and $x^{\bar\alpha\dot\beta}$ are local AdS_4 coordinates which can be expressed via the vector coordinates x^n $(n=0,\ldots,3)$ with the aid of Pauli matrices $\sigma_n{}^{\bar\alpha\dot\beta}=(I,\sigma_1{}^{\bar\alpha\dot\beta},\ldots,\sigma_3{}^{\bar\alpha\dot\beta})$ as

$$x^n=\sigma^n{}_{\bar\alpha\beta}x^{\bar\alpha\dot\beta}\,,\quad x^{\bar\alpha\dot\beta}=\tfrac{1}{2}x_n\sigma^{n\bar\alpha\dot\beta}\,,\quad \sigma_{n\,\dot\alpha\bar\beta}\sigma_m{}^{\bar\alpha\dot\beta}=2\,\eta_{mn}\,. \tag{3.22}$$

The gauge function and gravitational fields resulting from (3.13) and (3.14) are

$$g=\left(\frac{2\sqrt{z}}{1+\sqrt{z}}\right)^2\exp\left(-\frac{1}{1+\sqrt{z}}x^{\bar\alpha\dot\beta}(a_{\bar\alpha}a_{\dot\beta}+\lambda^2b_{\bar\alpha}b_{\dot\beta})\right), \tag{3.23}$$

$$h_{\bar\alpha\dot\beta}=\frac{1}{2z}\mathrm{d}x_{\bar\alpha\dot\beta}, \tag{3.24}$$

$$\omega_{\bar\alpha\bar\beta}=\frac{1}{2z}(\mathrm{d}x_{\bar\alpha}{}^{\dot\gamma}x_{\bar\beta\dot\gamma}+\mathrm{d}x_{\bar\beta}{}^{\dot\gamma}x_{\bar\alpha\dot\gamma})\,,\quad \bar\omega_{\dot\alpha\dot\beta}=\frac{1}{2z}(\mathrm{d}x^{\bar\gamma}{}_{\dot\alpha}x_{\bar\gamma\dot\beta}+\mathrm{d}x^{\bar\gamma}{}_{\dot\beta}x_{\bar\gamma\dot\alpha}), \tag{3.25}$$

where $z=1+\frac{1}{2}\lambda^2x_{\bar\alpha\dot\beta}x^{\bar\alpha\dot\beta}=1+\lambda^2x_nx^n$. These AdS_4 gravitational fields coincide with those found in Ref. 9.

IV. SYMMETRIES

Having fixed some vacuum solution w_0 of (1.31), the local higher spin symmetry is broken down to the global one with the parameter $\epsilon_0(a,b|X)$ satisfying (1.34). Once the vacuum solution w_0 is fixed in the pure gauge form (1.35) with some gauge function g, it is easy to find the gauge parameter $\epsilon_0(a,b|X)$ of the leftover global symmetry. Indeed let the generating parameter $\xi(a,b;\mu,\eta)$ in (1.36) be of the form

$$\xi=\xi_0\exp(a_\alpha\mu^\alpha-b^\alpha\eta_\alpha)\,, \tag{4.1}$$

where ξ_0 is an infinitesimal constant while μ^α and η_α are constant parameters. An arbitrary symmetry with star-product polynomial parameters can be obtained via differentiation of ξ with respect to μ^α and η_α. Substitution of (2.9) into (1.36) gives

$$\epsilon_0(a,b;\mu,\eta|X)=g^{-1}\star\xi\star g=\xi_0\exp(a_\alpha\hat{\mu}^\alpha-b^\alpha\hat{\eta}_\alpha)\,, \tag{4.2}$$

where

$$\hat{\mu}^\alpha=\mathrm{ch}(\lambda X)^{\alpha\beta}\mu_\beta-\frac{\mathrm{sh}(\lambda X)^{\alpha\beta}}{\lambda}\eta_\beta\,,\quad \hat{\eta}^\alpha=\mathrm{ch}(\lambda X)^{\alpha\beta}\eta_\beta-\lambda\cdot\mathrm{sh}(\lambda X)^{\alpha\beta}\mu_\beta\,. \tag{4.3}$$

According to (3.7), in the arbitrary coordinates associated with the function $f^{\alpha\beta}(X)$ of Sec. III, we have

$$\hat{\mu}_\alpha=\left(\frac{1+\lambda^2f^2(X)}{1-\lambda^2f^2(X)}\right)_\alpha^{\ \beta}\mu_\beta-\left(\frac{2\,f(X)}{1-\lambda^2f^2(X)}\right)_\alpha^{\ \beta}\eta_\beta\,, \tag{4.4}$$

$$\hat{\eta}_\alpha=\left(\frac{1+\lambda^2f^2(X)}{1-\lambda^2f^2(X)}\right)_\alpha^{\ \beta}\eta_\beta-\lambda^2\left(\frac{2\,f(X)}{1-\lambda^2f^2(X)}\right)_\alpha^{\ \beta}\mu_\beta\,. \tag{4.5}$$

The global symmetry transformation of the higher spin generating function

$$\delta|\Phi(b|X)\rangle\equiv\epsilon_0\star|\Phi(b|X)\rangle=\xi_0\exp(-\hat{\eta}_\alpha b^\alpha+\tfrac{1}{2}\hat{\eta}^\alpha\hat{\mu}_\alpha)\cdot C(b+\hat{\mu}|X)\star|0\rangle\langle 0| \tag{4.6}$$

implies

$$\delta C(b|X)=\xi_0C(b+\hat{\mu}|X)\exp(\tfrac{1}{2}\hat{\eta}^\alpha\hat{\mu}_\alpha-b^\alpha\hat{\eta}_\alpha)\,. \tag{4.7}$$

The dynamical fields are associated with the scalar $c(X)=C(0|X)$ and vector $c_\alpha(X)=(\partial/\partial b^\alpha)\,C(b|X)|_{b=0}$ in the expansion (1.23). [All other fields in $C(b|X)$ are expressed via derivatives of the dynamical fields.[1]] Their transformation laws are

$$\delta c(X)=\xi_0C(\hat{\mu}|X)\exp(\tfrac{1}{2}\hat{\eta}^\alpha\hat{\mu}_\alpha)\,, \tag{4.8}$$

$$\delta c_\alpha(X)=\xi_0\left(\frac{\partial}{\partial b^\alpha}C(b+\hat{\mu}|X)\bigg|_{b=0}-\hat{\eta}_\alpha C(\hat{\mu}|X)\right)\exp\left(\frac{1}{2}\,\hat{\eta}^\alpha\hat{\mu}_\alpha\right)\,. \tag{4.9}$$

Differentiating over the parameters μ^α and η_α and setting them then equal to zero one obtains explicit expressions for the higher spin symmetry transformations associated with any symmetry parameters $\epsilon_0(a,b|X)$ polynomial in the oscillators a and b. In particular, the transformation law with the parameters bilinear in the oscillators reproduces the $\mathrm{Sp}(2M)$ generalized conformal transformations in the generalized AdS space–time $\mathrm{Sp}(M)$.

V. LIGHTLIKE SOLUTIONS

Once the gauge function g is known one solves the system of free field equation (1.28) for all massless fields via (1.37). Let us consider basis lightlike solutions generated by the initial data of the form

$$C(b|0)=C_0\exp(\kappa_\alpha b^\alpha)\,, \tag{5.1}$$

where C_0 is an arbitrary constant and κ^α is some space–time constant spinor. According to (1.22) the Fock representation of the initial data has the form

$$|\Phi(b|0)\rangle = C_0 \exp(\kappa_\alpha b^\alpha) \star |0\rangle\langle 0|. \tag{5.2}$$

So the dynamical problem is solved by

$$|\Phi(b|X)\rangle = g^{-1}(X) \star |\Phi(b|0)\rangle = \frac{C_0}{\det\left\| \mathrm{ch}\dfrac{\lambda X}{2}\right\|} e^{(1/\lambda)[\mathrm{th}\,(\lambda X/2)]^{\alpha\beta}(a_\alpha a_\beta + \lambda^2 b_\alpha b_\beta)} \star e^{\kappa_\alpha b^\alpha} \star e^{-2a_\alpha b^\alpha}. \tag{5.3}$$

Elementary evaluation of Gaussian integrals gives the following result:

$$C(b|X) = \frac{C_0}{\sqrt{\det\|\mathrm{ch}\,\lambda X\|}} \exp(t^{\alpha\beta}(\lambda^2 b_\alpha b_\beta + \kappa_\alpha \kappa_\beta) + p_\beta{}^\alpha \kappa_\alpha b^\beta), \tag{5.4}$$

where we use notations

$$t_\alpha{}^\beta = \left(\frac{\mathrm{th}(\lambda X)}{2\lambda}\right)_\alpha^\beta, \quad p_\alpha{}^\beta = (\mathrm{ch}^{-1}(\lambda X))_\alpha{}^\beta, \tag{5.5}$$

equivalent by virtue of (3.7) to

$$t_\alpha{}^\beta = \left(\frac{f(X)}{1+\lambda^2 f^2(X)}\right)_\alpha^\beta, \quad p_\alpha{}^\beta = \left(\frac{1-\lambda^2 f^2(X)}{1+\lambda^2 f^2(X)}\right)_\alpha^\beta. \tag{5.6}$$

Let us stress that, according to Refs. 1 and 2, for the particular case of $M=4$ the obtained expressions describe solutions of massless equations for all spins in AdS_4, constructed in Ref. 9. Using (3.23), these solutions take the form

$$C(b|x) = z \exp\left(\frac{x^{\dot\alpha\dot\beta}}{2}(\kappa_{\dot\alpha}\kappa_{\dot\beta} + \lambda^2 b_{\dot\alpha} b_{\dot\beta}) + \sqrt{z}\kappa_\alpha b^\alpha\right). \tag{5.7}$$

For the case of $M=2$ we get solutions of the AdS_3 massless equations discussed in Ref. 8 of the form

$$C(b|x) = \sqrt{z} \exp\left(\frac{x^{\alpha\beta}}{2}(\kappa_\alpha \kappa_\beta + \lambda^2 b_\alpha b_\beta) + \sqrt{z}\kappa_\alpha b^\alpha\right). \tag{5.8}$$

Here we make use of the gauge function (3.15).

For the dynamical fields we obtain

$$c(X) = C_0 \sqrt{\det\left\|\frac{1-\lambda^2 f^2(X)}{1+\lambda^2 f^2(X)}\right\|} \exp(t^{\alpha\beta}\kappa_\alpha\kappa_\beta), \tag{5.9}$$

$$c_\alpha(X) = C_0 \sqrt{\det\left\|\frac{1-\lambda^2 f^2(X)}{1+\lambda^2 f^2(X)}\right\|} p_\alpha{}^\beta \kappa_\beta \exp(t^{\alpha\beta}\kappa_\alpha\kappa_\beta). \tag{5.10}$$

Substitution of ϵ_0 into (1.33) gives the global higher spin symmetry transformation of the solution (5.3),

$$\delta C(b|X)=C_0\xi_0\sqrt{\det\left\|\frac{1-\lambda^2 f^2(X)}{1+\lambda^2 f^2(X)}\right\|}$$
$$\times\exp\left(t^{\alpha\beta}\lambda^2(b_\alpha+\hat\mu_\alpha)(b_\beta+\hat\mu_\beta)+t^{\alpha\beta}\kappa_\alpha\kappa_\beta+p_\beta{}^\alpha\kappa_\alpha(b^\beta+\hat\mu^\beta)-\hat\eta_\alpha\left(b^\alpha+\frac{1}{2}\hat\mu^\alpha\right)\right). \tag{5.11}$$

The flat limit $\lambda\to 0$ gives

$$\delta C(b|X)=C_0\xi_0\exp(\tfrac{1}{2}X^{\alpha\beta}(\kappa_\alpha\kappa_\beta-2\kappa_\alpha\eta_\beta+\eta_\alpha\eta_\beta)+b^\alpha(\kappa_\alpha-\eta_\alpha)+\kappa_\alpha\mu^\alpha+\tfrac{1}{2}\mu_\alpha\eta^\alpha). \tag{5.12}$$

For the dynamical fields we get the plane wave solutions

$$c^{\text{plane}}(X)=C_0 e^{1/2\,X_{\alpha\beta}\kappa^\alpha\kappa^\beta},\quad c^{\text{plane}}_\alpha(X)=C_0\kappa_\alpha e^{1/2\,X_{\alpha\beta}\kappa^\alpha\kappa^\beta}, \tag{5.13}$$

with the twistorial "wave vector" $K_{\alpha\beta}=\frac{1}{2}\kappa_\alpha\kappa_\beta$.

The solution deformed to the AdS case is not strictly speaking plane wave. However it is "conformally plane wave" in the sense that it has still leftover generalized conformal invariances identified with such global symmetry transformations that

$$\delta_{\epsilon_0}|\Phi(b|X)\rangle=0\,. \tag{5.14}$$

It is easy to see using (4.2) that this condition is solved by any parameter of the form

$$\xi=f(a,b)\star(\rho^\alpha a_\alpha)\,, \tag{5.15}$$

where ρ is an arbitrary parameter such that $\rho^\alpha\kappa_\alpha=0$ and $f(a,b)$ is an arbitrary function. Indeed, according to (1.37),

$$\delta_{\epsilon_0}|\Phi(b|X)\rangle=g^{-1}\star\xi\star C(b|0)\star|0\rangle\langle 0|=g^{-1}\star f\star(\rho^\alpha a_\alpha)\star e^{\kappa_\alpha b^\alpha}\star|0\rangle\langle 0|=0\,. \tag{5.16}$$

VI. SUPEREXTENSION

The star-product formalism we use admits a straightforward generalization to the supersymmetric case associated with $\mathrm{OSp}(L|2M)$ where L is an arbitrary integer. To describe $\mathrm{osp}(L|2M)$ superalgebra let us introduce the Clifford elements ψ_i $(i=1,\dots,L)$ satisfying the anticommutation relations

$$\{\psi_i,\psi_j\}_*=\eta_{ij}\,, \tag{6.1}$$

where $\eta_{ij}=\eta_{ji}$ is some nondegenerate symmetric form. The Clifford star product in (6.1) is defined (see, e.g., Ref. 12) according to

$$(f*g)(\psi)=\frac{1}{2^L}\int f(\psi+\phi)g(\psi+\chi)e^{-2\chi^i\phi_i}\,\mathrm{d}^L\phi\,\mathrm{d}^L\chi\,, \tag{6.2}$$

where χ_i and ϕ_i are anticommuting variables. The supercharges

$$Q_{i\alpha}=a_\alpha\psi_i\,,\quad S_i^\alpha=b^\alpha\psi_i\,, \tag{6.3}$$

satisfy

$$\{Q_{i\alpha},Q_{i\beta}\}_*=\eta_{ij}P_{\alpha\beta}\,,\quad \{S_i^\alpha,S_j^\beta\}_*=\eta_{ij}K^{\alpha\beta}\,. \tag{6.4}$$

Let the Grassmann odd coordinates $\theta^{i\alpha}$ be associated with the Q-supergenerators. It is convenient to require the differential $d\theta^{i\alpha}$ to anticommute to $dX^{\alpha\beta}$ and $\theta^{i\alpha}$.

It is easy to see[1] that the gauge function

$$g = e^{-X^{\alpha\beta} a_\alpha a_\beta - \theta^{i\alpha} a_\alpha \psi_i} \tag{6.5}$$

reproduces the flat superspace vacuum one-form

$$w_0 = (\mathrm{d}X^{\alpha\beta} + \tfrac{1}{2}\mathrm{d}\theta^{i\alpha}\,\theta_i^{\beta}) P_{\alpha\beta} + \mathrm{d}\theta^{i\alpha} Q_{i\alpha}\,. \tag{6.6}$$

The left Fock module $|\Phi(b,\psi^+|X,\theta)\rangle$ satisfies the osp$(L|2M)$ supersymmetric equation

$$(d - w_0) \star |\Phi(b,\psi^+|X,\theta)\rangle = 0\,, \tag{6.7}$$

where the supersymmetric Fock vacuum $|0\rangle\langle 0|$ in addition to (1.26) is annihilated by the $\frac{1}{2}L$ (in case of even L) or $\frac{1}{2}(L-1)$ (in case of odd L) annihilation Clifford elements ψ^- and, when L is odd, it is an eigenvector of the central element $\Psi^L = \psi_1, \ldots, \psi_L$,

$$\Psi^L \star |0\rangle\langle 0| = \pm |0\rangle\langle 0|\,.$$

Let us now consider free field dynamics in the generalized AdS superspace. The corresponding supersymmetry algebra is osp$(L,M) \oplus$ osp(L,M) while the superspace is osp(L,M). To describe background fields (i.e., Cartan forms) in such a space we follow the same procedure as for Sp(M).

The OSp$(L|M)$ supergroup is realized by $(M+L)\times(M+L)$ matrices $U_A{}^B$, where $A = (\alpha, i)(\alpha = 1, \ldots, M,\ i = 1, \ldots, L)$, satisfying the group condition

$$U_A{}^B U_C{}^D \Omega^{AC} = \Omega^{BD}\,, \tag{6.8}$$

where $\Omega^{AB} = -(-1)^{\pi_A \pi_B} \Omega^{BA}$ and

$$\pi_A = \begin{cases} 1\,, & A = i, \\ 0\,, & A = \alpha. \end{cases}$$

It can be described by the local supercoordinates $X^{AB} = (-1)^{\pi_A \pi_B} X^{BA}$ with the aid of the exponential parametrization

$$U_A{}^B = \exp(\lambda X)_A{}^B\,. \tag{6.9}$$

Let us introduce the superoscillators a_A, b^A satisfying the (anti)commutation relations

$$a_A \star b^B - (-1)^{\pi_A \pi_B} b^B \star a_A = \delta_A{}^B\,, \tag{6.10}$$

with respect to the star product,

$$(f \star g)(a,b|X) = \frac{1}{2^{2L}\pi^M} \int f(a+u, b+t) g(a+s, b+v) e^{2(t^A s_A - v^A u_A)}\, \mathrm{d}u\, \mathrm{d}t\, \mathrm{d}s\, \mathrm{d}v\,, \tag{6.11}$$

where the statistics of the integration variables is defined according to

$$u_A u_B = (-1)^{\pi_A \pi_B} u_B u_A\,.$$

The integration measure is chosen so that 1 is the unit element of the star-product algebra (6.11).

Using the oscillator realization of osp$(L|M) \oplus$ osp$(L|M) \subset$ osp$(2L|2M)$ we can set

$$w_0 = \omega^{AB} a_B b_A + h^{AB} (a_B a_A + \lambda^2 b_B b_A)\,. \tag{6.12}$$

The analysis analogous to that of Sec. II shows that the gauge function

$$g=\sqrt{s\ \det\|1-\lambda^2 f^2(X)\|}\ \exp(-f^{AB}(X)(a_B a_A+\lambda^2 b_B b_A)) \tag{6.13}$$

provides the ''Lorentz connection'' ω_{AB} and the ''frame'' h_{AB} of the form

$$\omega_{AB}=\tfrac{1}{2}(\mathrm{d}U_A{}^C(U^{-1})_{CB}+\mathrm{d}(U^{-1})_A{}^C U_{CB})\,, \tag{6.14}$$

$$h_{AB}=\frac{1}{4\lambda}(\mathrm{d}U_A{}^C(U^{-1})_{CB}-\mathrm{d}(U^{-1})_A{}^C U_{CB})\,, \tag{6.15}$$

where

$$U_A{}^B=\left(\frac{1+\lambda f(X)}{1-\lambda f(X)}\right)_A^B. \tag{6.16}$$

The relationship between h_{AB} and ω_{AB} is analogous to (3.5),

$$\omega_{AB}=2h_A{}^C f_{CB}-2\,f_A{}^C h_{CB}+\lambda^2 f_A{}^C\omega_C{}^D f_{DB}\,. \tag{6.17}$$

Here is the list of the gauge functions and corresponding Cartan forms in different coordinates.

(1) The exponential parametrization (6.9),

$$g=\frac{1}{s\ \det\left\|\mathrm{ch}\dfrac{\lambda X}{2}\right\|}\exp\left(-\left(\mathrm{th}\frac{\lambda X}{2}\right)^{AB}(a_B a_A+\lambda^2 b_B b_A)\right), \tag{6.18}$$

$$\omega_{AB}=\frac{\lambda}{2}\left(\int_0^1 \exp(\lambda X t)_A{}^C\,\mathrm{d}X_C{}^D\exp(\lambda X t)_{DB}\,\mathrm{d}t-\int_{-1}^0 \exp(\lambda X t)_A{}^C\,\mathrm{d}X_C{}^D\exp(\lambda X t)_{DB}\,\mathrm{d}t\right), \tag{6.19}$$

$$h_{AB}=\frac{1}{4}\int_{-1}^1 \exp(\lambda X t)_A{}^C\,\mathrm{d}X_C{}^D\exp(\lambda X t)_{DB}\,\mathrm{d}t. \tag{6.20}$$

(2) $f^{AB}=\phi(s\ \det\|X\|)X^{AB}$,

$$g=\sqrt{s\ \det\|1-\lambda^2\phi^2\cdot X^2\|}\ \exp(-\phi X^{AB}(a_B a_A+\lambda^2 b_B b_A))\,, \tag{6.21}$$

$$\begin{aligned}h_{AB}=&\,\phi\cdot\left(\frac{1}{1-\lambda^2\phi^2X^2}\right)_A^C(\mathrm{d}X_C{}^D-\lambda^2\phi^2X_C{}^M\,\mathrm{d}X_M{}^N X_N{}^D)\left(\frac{1}{1-\lambda^2\phi^2X^2}\right)_{DB}\\&-\tilde{\phi}\cdot\left(\frac{X}{1-\lambda^2\phi^2X^2}\right)_{AB}(X^{-1})_M{}^N\,\mathrm{d}X_N{}^M\,,\end{aligned}$$

$$\omega_{AB}=2\lambda^2\phi^2\cdot\left(\frac{1}{1-\lambda^2\phi^2X^2}\right)_A^C(\mathrm{d}X_C{}^M X_M{}^D-X_C{}^M\,\mathrm{d}X_M{}^D)\left(\frac{1}{1-\lambda^2\phi^2X^2}\right)_{DB}, \tag{6.22}$$

where

$$\tilde{\phi}=\frac{\partial\phi}{\partial\ln s\ \det\|X\|}\,. \tag{6.23}$$

(3) The ''stereographic'' coordinates $f^{AB}(X)=(X/(1\mp\sqrt{1-\lambda^2X^2}))^{AB}$,

$$g^{\pm}=\sqrt{s\,\det\|1-\lambda^2 f^2(X)\|}\,\exp\left(-\left(\frac{X}{1\mp\sqrt{1-\lambda^2X^2}}\right)^{AB}(a_Ba_A+\lambda^2b_Bb_A)\right), \tag{6.24}$$

$$h_{AB}=\frac{1}{2}\left(\frac{1}{\sqrt{1-\lambda^2X^2}}\right)_A^C \mathrm{d}X_C{}^D\left(\frac{1}{\sqrt{1-\lambda^2X^2}}\right)_{DB}. \tag{6.25}$$

In the supersymmetric case, the global higher spin symmetry transformation law for the generating function $C(b|X)$ with respect to infinitesimal parameter,

$$\xi=\xi_0\exp(\mu^Aa_A-b^A\eta_A)$$

is analogous to (4.7),

$$\delta C(b|X)=C(b+\hat{\mu}|X)\exp(-(b^A+\tfrac{1}{2}\hat{\mu}^A)\,\hat{\eta}_A), \tag{6.26}$$

where

$$\hat{\mu}^A=\mathrm{ch}(\lambda X)^{AB}\mu_B-\frac{\mathrm{sh}(\lambda X)^{AB}}{\lambda}\eta_B,\quad \hat{\eta}^A=\mathrm{ch}(\lambda X)^{AB}\eta_B-\lambda\cdot\mathrm{sh}(\lambda X)^{AB}\mu_B. \tag{6.27}$$

It is straightforward to extend the rest of the analysis to the dynamics in the generalized superspace. Also, having found left invariant forms it is elementary to write down world-line particle actions (see, e.g., Refs. 4, 5, and 1 for more details and references). The form of the world-line particle Lagrangian suggested in Ref. 1 is

$$L=\dot{X}^{AB}w_{0AB}(a,b|X)+a_A\dot{b}^A, \tag{6.28}$$

where $\mathrm{d}X^{AB}w_{0AB}(a,b|X)=w_0(a,b|X)$ is the vacuum one-form satisfying the zero-curvature equation (1.31) and dot denotes the derivative with respect to the world-line parameter. Applying the Stokes theorem and using (1.31) the particle action (6.28) can be rewritten in the string form as an integral over a two-dimensional surface bounded by a particle trajectory and parametrized by σ^l,

$$S=\int_{\Sigma^2}\left(w_0(a,b|X)\star\wedge w_0(a,b|X)+\mathrm{d}a_A\wedge\mathrm{d}b^A+\left(\mathrm{d}a_A\frac{\partial}{\partial a_A}+\mathrm{d}b^A\frac{\partial}{\partial b^A}\right)\wedge w_0(a,b|X)\right), \tag{6.29}$$

where the pullback is defined as usual

$$w_0(a,b|X)=\mathrm{d}\sigma^l\frac{\partial X^{AB}}{\partial\sigma^l}w_{0AB}(a,b|X),\quad \mathrm{d}a_A=\mathrm{d}\sigma^l\frac{\partial a_A}{\partial\sigma^l},\quad \mathrm{d}b^A=\mathrm{d}\sigma^l\frac{\partial b^A}{\partial\sigma^l}. \tag{6.30}$$

The problem of calculating Cartan superforms in $\mathrm{osp}(1|2M)$ superspace was considered in Ref. 5 where a particular parametrization was found with bosonic Cartan forms being at most bilinear in fermionic coordinates. Note that the star-product algebra formalism simplifies some of the computational problems being reduced to evaluation of elementary Gaussian integrals. (See Ref. 13.)

VII. CONCLUSIONS

It is demonstrated how the star-product algebra formalism can be applied to the calculation of the vacuum of fields of the generalized AdS space associated with $\mathrm{sp}(M)\oplus\mathrm{sp}(M)$ subalgebra of the recently proposed in Ref. 2 generalized conformal symmetry $\mathrm{Sp}(2M)$. The method is universal working equally well for the supersymmetric case of $\mathrm{OSp}(L,M)$ with any M and L. The formalism of star-product algebra is shown to be very efficient for solving free field equations in

nontrivial (generalized conformally flat) geometries in $\mathcal{M}_M$ and calculating Cartan forms in arbitrary coordinates. Hopefully it may have applications to formulations of world-line (super)particle dynamics as well as (super)string actions in M theory backgrounds.

APPENDIX

Let us prove that the formula

$$g(U)=\frac{2^{M/2}}{\sqrt{\det\|U+1\|}}\exp\left(\frac{1}{2}\left(\frac{U-1}{U+1}\right)^{\alpha\beta}\alpha_\alpha\alpha_\beta\right) \tag{A1}$$

respects the group multiplication law of $\mathrm{Sp}(M)$, i.e., that the formula (2.20) solves the equation (2.19). Let us look for $U(f)$ in the form

$$U(f)=\sum_{n=0}^{\infty} a_n f^n, \tag{A2}$$

where a_n are some coefficients. Hence $U(f_1)U(f_2)=\Sigma_{m,n=0}^{\infty}a_m a_n f_1^m f_2^n$. Since this expression contains all f_1 on the left-hand side, and f_2 on the right-hand, we have to find such a function $U(f)$ that $U(f_1\circ f_2)$ contains f_1 and f_2 in the correct order. We have

$$U(f_1\circ f_2)=\sum_{m=0}^{\infty} a_m\left\{\sum_{n=0}^{\infty} a_n(-1)^n((f_1f_2)^n(1+f_1)-(f_2f_1)^n(1+f_2))\right\}^m. \tag{A3}$$

All terms of wrong order must vanish. The analysis of a few first terms of $U(f_1\circ f_2)$ gives a hint that the coefficients are $a_n=\{a_0,a,a,a,\dots\}$, i.e.,

$$U(f)=a_0-a+\frac{a}{1-f}. \tag{A4}$$

The substitution of $U(f)$ into the equation $U^2(f)=U(f\circ f)$ fixes $a_0=1,a=2$ so that

$$U(f)=\frac{1+f}{1-f}. \tag{A5}$$

To prove that the obtained solution satisfies the equation (2.19) one has to check the identity

$$(1+f_1\circ f_2)\frac{1-f_2}{1+f_2}=(1-f_1\circ f_2)\frac{1+f_1}{1-f_1} \tag{A6}$$

equivalent to the relation

$$\begin{aligned}&\left\{1+\sum_{n=0}^{\infty}(-1)^n((f_2f_1)^n(1+f_2)-(f_1f_2)^n(1-f_1))\right\}\left(1+2\sum_{m=1}^{\infty}(-1)^m f_2^m\right)\\&\quad=\left\{1-\sum_{n=0}^{\infty}(-1)^n((f_2f_1)^n(1+f_2)-(f_1f_2)^n(1-f_1))\right\}\left(1+2\sum_{m=1}^{\infty}f_1^m\right),\end{aligned} \tag{A7}$$

which is elementary to check.

The normalization factor solves the equation

$$\frac{r(U_1)r(U_2)}{\sqrt{\det\|f_1 f_2+1\|}}=r(U_1U_2)\,, \tag{A8}$$

which is obviously true after the substitution (2.20),

$$\frac{2^{M/2}}{\sqrt{\det\|U_1+1\|}}\cdot\frac{2^{M/2}}{\sqrt{\det\|U_2+1\|}}\cdot\frac{1}{\sqrt{\det\left\|\dfrac{U_1-1}{U_1+1}\,\dfrac{U_2-1}{U_2+1}+1\right\|}}=\frac{2^{M/2}}{\sqrt{\det\|U_1U_2+1\|}}\,. \tag{A9}$$

This completes the proof of Eq. (2.20). The proof for the supersymmetric case is analogous.

String theory extensions of Einstein–Maxwell fields: The stationary case

Alfredo Herrera-Aguilar[a] and Oleg V. Kechkin[b]
Instituto de Física y Matemáticas, Universidad Michoacana de San Nicolás de Hidalgo, Edificio C–3, Ciudad Universitaria, CP 58040. Morelia, Mich., México

(Received 3 October 2003; accepted 10 October 2003)

We present a new approach for generating solutions in heterotic string theory compactified down to three dimensions on a torus with $d+n>2$, where d and n stand for the number of compactified space–time dimensions and Abelian gauge fields, respectively. It is shown that in the case when $d=2k+1$, and n is arbitrary, one can apply a solution-generating procedure which consists of mapping seed solutions of the stationary Einstein theory with k Maxwell fields to the heterotic string realm by using pure field redefinitions. A novel feature of this method is that it is precisely the electromagnetic sector of the stationary electrovacuum that mainly gives rise to a nontrivial multidimensional metric. This approach leads to classes of solutions which are invariant with respect to the total group of three-dimensional charging symmetries of the heterotic string theory, i.e., to all *finite* transformations which generate charged solutions from neutral ones and preserve the asymptotics of the starting field configurations. As an application of the presented approach we generate a particular extension of the stationary Einstein–multi-Maxwell theory obtained on the basis of the Kerr–multi-Newman–NUT special class of solutions and establish the conditions under which the resulting multi-dimensional metric of the heterotic string theory is asymptotically flat. [DOI: 10.1063/1.1631080]

I. INTRODUCTION

Symmetry based approaches used for the construction of solutions in the framework of effective field (low-energy) limits of string theories play an important role.[1–3] In this article we develop a new approach which allows one to extend the solution space of the stationary Einstein–multi-Maxwell (EmM) theory to the realm of heterotic string theory compactified down to three spatial dimensions on a torus. Namely, we show that a new charging symmetry invariant subspace of solutions of heterotic string theories (with $d=2k+1$ toroidally compactified space–time dimensions and arbitrary number n of original Abelian vector fields) can be generated from the solution spectrum of the stationary Einstein theory with k Maxwell fields by making use of pure field redefinitions. In particular, for the critical cases of heterotic ($d=7$) and bosonic ($d=23$) string theories one must start from the EmM theory with $k=3$ and $k=11$ Maxwell fields, respectively. Thus, the nontrivial multidimensional gravitational sector (the metric) of the heterotic string theory is mainly generated from the electromagnetic sector of the stationary EmM theory, an interesting fact that establishes a relationship between gravity and matter fields.

The toroidal compactification of heterotic string theory with arbitrary values of d and n was performed in Refs. 4 and 5, whereas the special case when the resulting theory is three-dimensional was originally studied in Refs. 6 and 7. There, the corresponding symmetric space model was identified and an explicit representation in terms of a null-curvature matrix was given (see Ref. 8 for such models and their classification). In this article we exploit the general formal-

[a]Electronic mail: herrera@itzel.ifm.umich.mx
[b]Author on leave from Institute of Nuclear Physics of M.V. Lomonosov Moscow State University, Vorob'jovy Gory, 119899 Moscow, Russia. Electronic mail: kechkin@ginette.ifm.umich.mx, kechkin@depni.npi.msu.su

ism developed in Refs. 9–11 as a natural matrix generalization of the stationary Einstein–Maxwell (EM) theory written down in terms of potentials which are closely related to the Ernst ones (see Refs. 12–14). In the framework of this formalism, the subgroup of charging symmetry transformations (all finite transformations which generate charged solutions from neutral ones and preserve the asymptotic characteristics of the seed field configurations[15]) acts as a linear and homogeneous map; this fact allows one to work with the solution spectrum of the theory in a transparently charging symmetry invariant form. In particular, all the results of this article are automatically invariant with respect to the action of the total three-dimensional subgroup of charging symmetries $\mathrm{SO}(2,d-1)\times\mathrm{SO}(2,d-1+n)$ of the heterotic string theory compactified on a torus.[10]

In this article we continue our investigation on string theory extensions of EM fields. In a previous work[16] we have studied two theories with $d+n=2$; here we deal with theories with $d+n>2$. Such a split of the effective theories which arise upon toroidal compactification with arbitrary parameters d and n, in the framework of the low-energy limit of heterotic string theory, follows from the study of the general Israel–Wilson–Perjés (IWP) class of solutions of this theory performed in Ref. 11. The new formalism allows one to construct, in particular, a continuous generalization of the extremal IWP families of solutions in the corresponding string theories to the field of nonextremal ones. In Ref. 16 it was shown that the *static* EM theory plays the role of starting system for two theories with $d+n=2$; in this article we show that for the theories with $d+n>2$ such starting systems can be related to the *stationary* EmM theory and illustrate the developed general approach by considering an extension of the Kerr–multi-Newman–NUT solution to the realm of heterotic string theory.

II. NEW FORMALISM FOR 3D HETEROTIC STRING THEORY

In this section we review the necessary elements of the new formalism developed in Ref. 11 for the D-dimensional $(D=d+3)$ heterotic string theory with n Abelian gauge fields.

We start with the action for the bosonic sector of the low-energy heterotic string theory at tree level:[1,2]

$$\mathcal{S}_D=\int d^DX|\det G_{MN}|^{1/2}e^{-\Phi}\left(R_D+\Phi_{,M}\Phi^{,M}-\frac{1}{12}H_{MNK}H^{MNK}-\frac{1}{4}F^I_{MN}F^{I\,MN}\right), \tag{2.1}$$

where $H_{MNK}=\partial_M B_{NK}-\frac{1}{2}A^I_M F^I_{NK}+\text{cyclic}\{M,N,K\}$ and $F^I_{MN}=\partial_M A^I_N-\partial_N A^I_M$ $(M=1,\ldots,D)$. Here X^M is the Mth coordinate of the physical space–time of signature $(-,+,\ldots,+)$, G_{MN} is the metric, whereas Φ, B_{MN} and A^I_M $(I=1,\ldots,n)$ are the dilaton, Kalb-Ramond and Abelian gauge fields, respectively. In order to determine the resulting theory after the toroidal compactification on T^d down to three dimensions, let us set $D=d+3$, $X^m=(Y^m,x^\mu)$ with the extra-dimensional coordinates $Y^M=X^m$ $(m=1,\ldots,d)$ and the dynamical ones $x^\mu=X^{d+\mu}$ $(\mu=1,2,3)$. In Ref. 11 it was shown that, after the toroidal compactification of the first d dimensions Y^m, the resulting theory can be expressed in terms of the pair of field variables $(\mathcal{Z},h_{\mu\nu})$ which describes three-dimensional gravity, with metric $h_{\mu\nu}=h_{\mu\nu}(x^\lambda)$, coupled to a matter sector parametrized by the $(d+1)\times(d+1+n)$-matrix field variable $\mathcal{Z}=\mathcal{Z}(x^\lambda)$; its effective dynamics is given by the action

$$\mathcal{S}_3=\int d^3x h^{1/2}(-R_3+L_3), \tag{2.2}$$

where $R_3=R_3(h_{\mu\nu})$ is the curvature scalar for the line element $ds_3^2=h_{\mu\nu}dx^\mu dx^\nu$ and the matter sector of the theory reads

$$L_3=\mathrm{Tr}\,[\nabla\mathcal{Z}(\Xi-\mathcal{Z}^T\Sigma\mathcal{Z})^{-1}\nabla\mathcal{Z}^T(\Sigma-\mathcal{Z}\Xi\mathcal{Z}^T)^{-1}], \tag{2.3}$$

where $\Sigma=\mathrm{diag}(-1,-1;1,\ldots,1)$ is a $(d+1)\times(d+1)$-matrix and $\Xi=\mathrm{diag}(-1,-1;1,\ldots,1)$ is a $(d+1+n)\times(d+1+n)$-matrix.

This σ-model representation of the theory is the most compact one because of the dimensions of the matrix variable $\mathcal{Z}$. In order to come back to the original field components of the heterotic string theory from this σ-model description, it is convenient to introduce three doublets of potentials $(\mathcal{M}_\alpha,\vec{\Omega}_\alpha)$ $(\alpha=1,2,3)$ which are constructed on the basis of the field variables $(\mathcal{Z}, h_{\mu\nu})$ according to the following equations:

$$\mathcal{M}_1=\mathcal{H}^{-1},\quad \nabla\times\vec{\Omega}_1=\vec{J},$$

$$\mathcal{M}_2=\mathcal{H}^{-1}\mathcal{Z},\quad \nabla\times\vec{\Omega}_2=\mathcal{H}^{-1}\nabla\mathcal{Z}-\vec{J}\mathcal{Z}, \tag{2.4}$$

$$\mathcal{M}_3=\mathcal{Z}^T\mathcal{H}^{-1}\mathcal{Z},\quad \nabla\times\vec{\Omega}_3=\nabla\mathcal{Z}^T\mathcal{H}^{-1}\mathcal{Z}-\mathcal{Z}^T\mathcal{H}^{-1}\nabla\mathcal{Z}+\mathcal{Z}^T\vec{J}\mathcal{Z},$$

where $\mathcal{H}=\Sigma-\mathcal{Z}\Xi\mathcal{Z}^T$ and $\vec{J}=\mathcal{H}^{-1}(\mathcal{Z}\Xi\nabla\mathcal{Z}^T-\nabla\mathcal{Z}\Xi\mathcal{Z}^T)\mathcal{H}^{-1}$. In Eq. (2.4) the scalars $\mathcal{M}_\alpha$ are off-shell defined magnitudes, whereas the vectors $\vec{\Omega}_\alpha$ are defined on-shell. The scalar and vector potentials that conform each doublet have the same matrix dimensionality; let us represent them in the following block form:

$$\begin{pmatrix} 1\times1 & 1\times d\\ d\times1 & d\times d\end{pmatrix},\quad \begin{pmatrix} 1\times1 & 1\times d & 1\times n\\ d\times1 & d\times d & d\times n\end{pmatrix},\quad \begin{pmatrix} 1\times1 & 1\times d & 1\times n\\ d\times1 & d\times d & d\times n\\ n\times1 & n\times d & n\times n\end{pmatrix}, \tag{2.5}$$

for $\alpha=1,2,3$, respectively, where, for example, the ''13'' block components of the potentials $\mathcal{M}_2$ and $\vec{\Omega}_2$ are $1\times n$ matrices, the ''32'' block components of the potentials $\mathcal{M}_3$ and $\vec{\Omega}_3$ are $n\times d$ matrices, etc. Afterwards let us define the set of magnitudes which are directly involved in the solution-generating procedure that will be exposed in Sec. III; these include the following scalar matrix fields,

$$S_\alpha=U_\alpha+S_0^{-1}W_1^TW_\alpha, \tag{2.6}$$

where

$$\begin{aligned}
S_0&=-\mathcal{M}_{1,11}+2\mathcal{M}_{2,11}-\mathcal{M}_{3,11},\\
U_1&=G_0\mathcal{M}_{1,22}G_0+G_0\mathcal{M}_{2,22}+(\mathcal{M}_{2,22})^TG_0+\mathcal{M}_{3,22},\\
U_2&=G_0\mathcal{M}_{1,22}-G_0\mathcal{M}_{2,22}G_0+(\mathcal{M}_{2,22})^T-\mathcal{M}_{3,22}G_0,\\
U_3&=\sqrt{2}(G_0\mathcal{M}_{2,23}+\mathcal{M}_{3,23}),\\
W_1&=-\mathcal{M}_{1,12}G_0-\mathcal{M}_{2,12}+(\mathcal{M}_{2,21})^TG_0+\mathcal{M}_{3,12},\\
W_2&=\mathcal{M}_{1,12}-\mathcal{M}_{2,12}G_0+(\mathcal{M}_{2,21})^T-\mathcal{M}_{3,12}G_0,\\
W_3&=\sqrt{2}(\mathcal{M}_{2,13}+\mathcal{M}_{3,13}),
\end{aligned} \tag{2.7}$$

where $G_0=\mathrm{diag}(-1;1,\ldots,1)$ is a $d\times d$-matrix, and the matrix vector fields

$$\begin{aligned}
\vec{V}_1&=[-\vec{\Omega}_{1,12}G_0+\vec{\Omega}_{2,12}+(\vec{\Omega}_{2,21})^TG_0+\vec{\Omega}_{3,12}]^T,\\
\vec{V}_2&=[-\vec{\Omega}_{1,12}-\vec{\Omega}_{2,12}G_0+(\vec{\Omega}_{2,21})^T-\vec{\Omega}_{3,12}G_0]^T,
\end{aligned} \tag{2.8}$$

$$\vec{V}_3=\sqrt{2}(\vec{\Omega}_{2,13}+\vec{\Omega}_{3,13})^T.$$

In the language of these matrix variables the heterotic string theory fields read

$$ds_D^2=ds_{d+3}^2=(dY+V_{1\mu}dx^\mu)^T S_1^{-1}(dY+V_{1\nu}dx^\nu)+S_0 ds_3^2,$$

$$e^\Phi=|S_0\det S_1|^{1/2},$$

$$B_{mk}=\tfrac{1}{2}(S_1^{-1}S_2-S_2^T S_1^{-1})_{mk},$$

$$B_{m\,d+\nu}=\{V_{2\nu}+\tfrac{1}{2}(S_1^{-1}S_2-S_2^T S_1^{-1})V_{1\nu}-S_1^{-1}S_3 V_{3\nu}\}_m, \tag{2.9}$$

$$B_{d+\mu\,d+\nu}=\tfrac{1}{2}[V_{1\mu}^T(S_1^{-1}S_2-S_2^T S_1^{-1})V_{1\nu}+V_{1\mu}^T V_{2\nu}-V_{1\nu}^T V_{2\mu}],$$

$$A_m^I=(S_1^{-1}S_3)_{mI},$$

$$A_{d+\mu}^I=(-V_{3\mu}+S_3^T S_1^{-1}V_{1\mu})_I.$$

From Eq. (2.9) it follows that, apart from the magnitudes S_0, S_α and $\vec{V}_\alpha$, we also must compute $\det S_1$ and S_1^{-1} in order to obtain explicit expressions for the field components of the heterotic string theory (2.1). Therefore, after some algebraic calculations it can be proved that

$$\begin{aligned}\det S_1&=(1+S_0 W_1 U_1^{-1}W_1^T)\det U_1,\\ S_1^{-1}&=U_1^{-1}-\frac{S_0^{-1}U_1^{-1}W_1^T W_1 U_1^{-1}}{1+S_0^{-1}W_1 U_1^{-1}W_1^T}.\end{aligned} \tag{2.10}$$

Finally, let us point out that the magnitudes S_0, U_α, W_α and $\vec{V}_\alpha$ can be used to explicitly write down any solution of the theory under consideration. As it was indicated above, these magnitudes are directly involved in the solution-generating technique that will be developed in the next section, and in Sec. IV we shall calculate them in order to obtain a concrete extension of the stationary EmM theory to the realm of the low-energy heterotic string theory.

At the end of this section let us notice that the transformation

$$\mathcal{Z}\to\mathcal{C}_1\mathcal{Z}\mathcal{C}_2, \tag{2.11}$$

where $\mathcal{C}_1$ and $\mathcal{C}_2$ obey the orthogonal group conditions

$$\mathcal{C}_1^T\Sigma\mathcal{C}_1=\Sigma \quad \text{and} \quad \mathcal{C}_2^T\Xi\mathcal{C}_2=\Xi, \tag{2.12}$$

is a transparent symmetry of the Lagrangian (2.3) since it remains invariant under such a transformation. In Refs. 10 and 11 it was shown that this symmetry transformation coincides with the total group of three-dimensional charging symmetries $\mathrm{SO}(2,d-1)\times\mathrm{SO}(2,d-1+n)$. As it was mentioned before, the above reviewed formalism, based on the use of the matrix potential $\mathcal{Z}$, constitutes a *sigma*-model representation of the theory (2.3) with the lowest possible matrix dimension and is, in fact, a $\mathrm{O}(d+1,d+n+1)/\mathrm{O}[(d+1)\times(d+n+1)]$ symmetric space model of dimension $(d+1)(d+n+1)$ according to the classification of (Ref. 8). From Eq. (2.11) it also follows that the general transformation of the charging symmetry subgroup of the theory acts as a linear and homogeneous map, a fact that was just discussed in the Introduction. Since this symmetry subgroup preserves the asymptotic properties of the seed solutions when one applies a solution-generating procedure, this formalism is especially convenient for the study of asymptotically flat solutions of heterotic string theory toroidally compactified down to three dimensions because all the results can be obtained in a transparent charging symmetry invariant form.

III. STRING THEORIES FROM STATIONARY EINSTEIN–MULTI-MAXWELL SYSTEM

In this section we show how to map solutions of the stationary Einstein theory with k Maxwell fields into solutions to the three-dimensional heterotic string theory with $d=2k+1$ toroidally compactified space–time dimensions and arbitrary number n of Abelian gauge fields.

First of all, let us formulate the main idea of our approach; it is related to the heterotic string/Einstein–Maxwell theory correspondence and the explicit form of the IWP class of solutions in both of these theories.[11] In order to achieve this aim, let us represent the stationary EM theory in a very similar form to the three-dimensional effective field theory of the heterotic string represented by Eq. (2.3). Namely, it is well known that the effective three-dimensional Lagrangian of the stationary EM theory reads

$$L_3=L_{EM}=\frac{1}{2f^2}|\nabla E-\overline{F}\nabla F|^2-\frac{1}{f}|\nabla F|^2, \tag{3.1}$$

where $f=\frac{1}{2}(E+\overline{E}-|F|^2)$, and E and F are the conventional Ernst potentials. Let us introduce the 1×2 matrix potential

$$z=(z_1\ z_2) \tag{3.2}$$

with

$$z_1=\frac{1-E}{1+E},\quad z_2=\frac{\sqrt{2}F}{1+E}. \tag{3.3}$$

Then

$$L_{EM}=2\,\frac{\nabla z(\sigma_3-z^\dagger z)^{-1}\nabla z^\dagger}{1-z\sigma_3 z^\dagger}, \tag{3.4}$$

where $\sigma_3=\mathrm{diag}(1\ -1)$. By comparing Eqs. (2.3) and (3.4) it follows that the correspondence

$$\mathcal{Z}\leftrightarrow z,\quad \Xi\leftrightarrow\sigma_3,\quad \Sigma\leftrightarrow 1, \tag{3.5}$$

together with the interchange of operations $T\leftrightarrow\dagger$, relates three-dimensional heterotic string and stationary EM theories; the factor "2" in (3.4) can be understood as a consequence of the exact matrix representation of complex magnitudes (see below and Ref. 11 as well for details). It turns out that the IWP class of solutions of the EM theory[17] can be rewritten in terms of the z-potential as $z=\lambda q$, where $\lambda=\lambda(x^\mu)$ is a complex harmonic function ($\nabla^2\lambda=0$), q is a 1×2-matrix constant parameter and when the parameter $\kappa=q\sigma_3 q^\dagger$ vanishes; in this case, the corresponding three-dimensional metric $h_{\mu\nu}$ is flat. It is clear that, in view of the correspondence (3.5), the IWP class of solutions of the heterotic string theory arises in the framework of the ansatz

$$\mathcal{Z}=\Lambda\mathcal{Q}, \tag{3.6}$$

where $\Lambda=\Lambda(x^\mu)$ is a real harmonic $(d+1\times 2)$-matrix function and $\mathcal{Q}$ is a constant $(2\times d+n+1)$-matrix parameter. In Ref. 11 it was shown that this fact actually takes place if the parameter

$$\kappa=\mathcal{Q}\Xi\,\mathcal{Q}^T \tag{3.7}$$

vanishes and the three-metric $h_{\mu\nu}$ is flat again, in complete accordance with the correspondence (3.5). There, it also was shown that the restriction $\kappa=0$ completely fixes the dimensionality of the matrices Λ and $\mathcal{Q}$: for two theories with $d+n=2$, such matrices have dimensions $(d+1)\times 1$ and 1×3, respectively, whereas for the theories with $d+n>2$ the dimensions are $(d+1)\times 2$ and $2\times(d+n+1)$, respectively, as it was pointed out above.

A crucial point in our approach consists of removing the $\kappa=0$ restriction in order to consider the generalization of the IWP class of solutions of heterotic string theory to the subspace of the nonextremal solutions. This means that we shall preserve the form of the ansatz (3.6) and the dimensions of the matrices Λ and $\mathcal{Q}$, but we shall allow arbitrary values of the parameter κ defined by Eq. (3.7). Such a procedure can be applied in a very natural way in the framework of the stationary EM theory, where it defines, for instance, a continuous extension of the extremal Kerr–multi-Newman–NUT solution to the corresponding nonextremal one.[14] Such an extension is really interesting from the point of view of physical applications since the example given above concerns black hole physics in EM theory.[18] In view of the correspondence (3.5) the same motivation for the study of the ansatz (3.6) with $\kappa\neq 0$ must be valid for the low-energy heterotic string theory; thus, the study of such an ansatz is also interesting since it is related to black hole physics in the framework of string theory.[3,19]

In this article we consider string theories with $d+n>2$, when κ is a symmetric 2×2-matrix. By straightforwardly substituting the ansatz (3.6) into the equations of motion derived from Eqs. (2.2) and (2.3), one obtains

$$\begin{aligned}&\nabla^2\Lambda+2\nabla\Lambda\kappa\Lambda^T(\Sigma-\Lambda\kappa\Lambda^T)^{-1}\nabla\Lambda=0,\\ &R_{3\ \mu\nu}=Tr[\Lambda_{,(\mu}\kappa(1-\Lambda^T\Sigma\Lambda\kappa)^{-1}\Lambda^T_{,\nu)}(\Sigma-\Lambda\kappa\Lambda^T)^{-1}].\end{aligned}\tag{3.8}$$

It is obvious that in the case $\kappa=0$ we recover the extremal case studied in Ref. 11, whereas for $\kappa\neq 0$ we have the above mentioned continuous extension of the formalism to the nonextremal case. Below we study the situation when κ is nonzero and, moreover, nondegenerate matrix with signature $\tilde{\Sigma}=\mathrm{diag}(-1,-1)$. The reason for considering such a particularization of the ansatz (3.6) is that, in this case, the effective system defined by Eqs. (3.8) corresponds to some new heterotic string theory by itself. Actually, Eqs. (3.8) are the equations of motion for the action (2.2) with the matter Lagrangian (2.3) replaced by

$$\tilde{\mathcal{L}}_3=Tr[\nabla\Lambda\kappa(1-\Lambda^T\Sigma\Lambda\kappa)^{-1}\nabla\Lambda^T(\Sigma-\Lambda\kappa\Lambda^T)^{-1}].\tag{3.9}$$

Then, as an algebraic fact it follows that there exists a nondegenerate matrix K such that

$$\kappa=K\tilde{\Sigma}K^T.\tag{3.10}$$

Let us introduce the new matrix potential

$$\tilde{\mathcal{Z}}=K^T\Lambda^T\tag{3.11}$$

and set $\tilde{\Xi}=\Sigma$. We claim that it is possible to rewrite the effective Lagrangian $\tilde{\mathcal{L}}_3$ (3.9) in terms of $\tilde{\mathcal{Z}}$, $\tilde{\Sigma}$ and $\tilde{\Xi}$; the resulting Lagrangian exactly coincides with the relation (2.3) up to the tilde. Thus, the effective system (3.9) is nothing else than the heterotic string theory with $\tilde{d}=1$ compactified dimensions and $\tilde{n}=d-1$ Abelian gauge fields. From Eqs. (3.6) and (3.11) it follows that

$$\mathcal{Z}=\tilde{\mathcal{Z}}^TT,\tag{3.12}$$

where $T=K^{-1}\mathcal{Q}$. Equation (3.12) maps the space of solutions of the theory in terms of $\tilde{\mathcal{Z}}$ into that of the theory in terms of the potential $\mathcal{Z}$, so that the matrix T plays the role of a symmetry operator. Let us now calculate the general explicit form of such symmetry operator using Eqs. (3.6) and (3.10). Without loss of generality (see Ref. 11 for details), the matrix $\mathcal{Q}$ can be parametrized in the form

$$\mathcal{Q}=\begin{pmatrix}1 & 0 & n_1^T\\ 0 & 1 & n_2^T\end{pmatrix},\tag{3.13}$$

where n_a $(a=1,2)$ are two $(d+n-1)\times 1$ columns. Thus, the extremal case corresponds to the restriction $n_a^T n_b=\delta_{ab}$, i.e., it is realized by the unit orthogonal columns n_a. Our generalization of the extremal ansatz corresponds, in this geometric language, to the case of columns with arbitrary length and arbitrary angle between them, which is compatible with the signature $\tilde{\Sigma}$ of the matrix κ.

Now we are able to compute the matrix κ and to determine the quantity K using, for example, the orthogonalization procedure of the theory of quadratic forms. A special solution reads

$$K=\begin{pmatrix} \sqrt{1-n_1^T n_1} & 0 \\ -\dfrac{n_1^T n_2}{\sqrt{1-n_1^T n_1}} & \sqrt{\dfrac{1-n_1^T n_1-n_2^T n_2+(n_1^T n_1)(n_2^T n_2)-(n_1^T n_2)^2}{1-n_1^T n_1}} \end{pmatrix}. \tag{3.14}$$

In order to obtain a general solution K to the quadratic equation (3.10) one must generalize the special solution (3.14) through the map $K\to K\mathcal{C}$ where $\mathcal{C}^T\tilde{\Sigma}\mathcal{C}=\tilde{\Sigma}$, i.e., $\mathcal{C}\in O(2)$. However, this map is effectively equivalent to the transformation $\tilde{\mathcal{Z}}\to(\mathcal{C}^T)^{-1}\tilde{\mathcal{Z}}$ as it follows from Eq. (3.12). It is clear that $(\mathcal{C}^T)^{-1}$ is nothing more than an alternative notation for the "left" matrix $\mathcal{C}_1$ of the charging symmetry transformation (2.11), thus, it can be omitted when considering charging symmetry invariant classes of solutions represented by $\tilde{\mathcal{Z}}$. Thus, without loss of generality one can take $\mathcal{Q}$ and K in the form given by Eqs. (3.13) and (3.14) when constructing a symmetry operator according to Eq. (3.12). It is worth noticing that the definition of K is consistent with the assumed signature of κ.

Now let us consider a special situation with $d=2k+1$, when the potential $\tilde{\mathcal{Z}}$ can be split into $k+1$ different 2×2-matrix blocks:

$$\tilde{\mathcal{Z}}=(\tilde{\mathcal{Z}}_1,\ \tilde{\mathcal{Z}}_2,\ \ldots,\ \tilde{\mathcal{Z}}_{k+1}). \tag{3.15}$$

Let us consider a consistent ansatz with

$$\tilde{\mathcal{Z}}_{\mathcal{P}}=\begin{pmatrix} z'_{\mathcal{P}} & -z''_{\mathcal{P}} \\ z''_{\mathcal{P}} & z'_{\mathcal{P}} \end{pmatrix}, \tag{3.16}$$

where $\mathcal{P}=1,2,\ldots,k+1$. Let us introduce $k+1$ complex functions $z_{\mathcal{P}}=z'_{\mathcal{P}}+iz''_{\mathcal{P}}$. Our statement is that the heterotic string theory field equations corresponding to the special subsystem (3.15) and (3.16) can be derived from the effective Lagrangian

$$L_3=L_{EmM}=2\,\frac{\nabla\tilde{z}(\tilde{\sigma}_3-\tilde{z}^{\dagger}\tilde{z})^{-1}\nabla\tilde{z}^{\dagger}}{1-\tilde{z}\tilde{\sigma}_3\tilde{z}^{\dagger}}, \tag{3.17}$$

where $\tilde{z}=(\tilde{z}_1,\tilde{z}_2,\ \ldots,\ \tilde{z}_{k+1})$ and $\tilde{\sigma}_3=\mathrm{diag}(1,-1,-1,\ldots,-1)$. It is clear that in the case $k=1$ one recovers Eq. (3.4), i.e., one deals with the stationary EM theory. It is natural to suppose that in the case of arbitrary k one obtains the stationary Einstein theory with k Maxwell fields. In order to verify this statement it is convenient to introduce new variables [compare to Eq. (3.3)]

$$E=\frac{1-\tilde{z}_1}{1+\tilde{z}_1},\quad F_p=\frac{\sqrt{2}\tilde{z}_{p+1}}{1+\tilde{z}_1}, \tag{3.18}$$

where $p=1,2,\ldots,k$. In terms of these variables the effective Lagrangian adopts the form

$$L_{EmM}=\frac{1}{2f^2}|\nabla E-\overline{F}_p\nabla F_p|^2-\frac{1}{f}|\nabla F_p|^2, \tag{3.19}$$

where $f=\frac{1}{2}(E+\overline{E}-F_p\overline{F}_p)$, thus, the potentials E and F_p can be interpreted as the conventional Ernst potentials of the classical four-dimensional Einstein theory with k Maxwell fields in the stationary case.

The theory (3.17) can be studied in a form which is very close to that of the heterotic string theory (see Sec. II) by using the correspondence (3.5) modified to the case of k Maxwell fields, i.e., by making the following replacement:

$$z\to\tilde{z},\quad \sigma_3\to\tilde{\sigma}_3 \tag{3.20}$$

[see Eqs. (3.4) and (3.7)]. Namely, it is convenient to introduce the doublets $(\tilde{m}_\alpha,\tilde{\vec{\omega}}_\alpha)$ with

$$\tilde{m}_1=\tilde{h}^{-1},\quad \nabla\times\tilde{\vec{\omega}}_1=\tilde{\vec{j}},$$

$$\tilde{m}_2=\tilde{h}^{-1}\tilde{z},\quad \nabla\times\tilde{\vec{\omega}}_2=\tilde{h}^{-1}\nabla\tilde{z}-\tilde{\vec{j}}\tilde{z}, \tag{3.21}$$

$$\tilde{m}_3=\tilde{h}^{-1}\tilde{z}^\dagger\tilde{z},\quad \nabla\times\tilde{\vec{\omega}}_3=\tilde{h}^{-1}(\nabla\tilde{z}^\dagger\tilde{z}-\tilde{z}^\dagger\nabla\tilde{z})+\tilde{\vec{j}}\tilde{z}^\dagger\tilde{z},$$

where $\tilde{h}=-(1-\tilde{z}\tilde{\sigma}_3\tilde{z}^\dagger)$ and $\tilde{\vec{j}}=-\tilde{h}^{-2}(\tilde{z}\tilde{\sigma}_3\nabla\tilde{z}^\dagger-\nabla\tilde{z}\tilde{\sigma}_3\tilde{z}^\dagger)$ [compare with Eq. (2.4)]. It is clear that the doublet $(\tilde{m}_1,\tilde{\vec{\omega}}_1)$ consists of complex functions, whereas the doublets $(\tilde{m}_2,\tilde{\vec{\omega}}_2)$ and $(\tilde{m}_3,\tilde{\vec{\omega}}_3)$ consist of $1\times(k+1)$– and $(k+1)\times(k+1)$-matrices, respectively. From Eqs. (3.15) and (3.16) we extract a rule for reconstructing the heterotic string theory described by the potential $\tilde{\mathcal{Z}}$ of dimension $2\times[2(k+1)]$. Further, from Eqs. (3.12)–(3.14) one obtains the explicit form of the symmetry map $\tilde{\mathcal{Z}}\to\mathcal{Z}$. It is interesting that this map is nonholomorphic due to the transposition of $\tilde{\mathcal{Z}}$ in Eq. (3.12), which is equivalent to the Hermitian conjugation of $\tilde{z}$ in view of the correspondence (3.20) discussed above.

Thus, a symmetry transformation that maps the space of solutions of the stationary Einstein theory with k Maxwell fields into the corresponding subspace of solutions of the heterotic string with $d=2k+1$ toroidally compactified dimensions and n arbitrary Abelian gauge fields is established by the following procedure:

(i) First of all, one must calculate in explicit form three doublets of potentials $(\tilde{m}_\alpha,\tilde{\vec{\omega}}_\alpha)$ for the stationary EmM theory.

(ii) After that one must rewrite them in the form $(\tilde{M}_\alpha,\tilde{\vec{\Omega}}_\alpha)$ using the exact matrix representation of complex magnitudes. [Equations (3.15) and (3.16) give, in fact, an example of such a representation of the complex potential $\tilde{z}$ in terms of the real potential $\tilde{\mathcal{Z}}$.]

(iii) The next step consists of calculating the matrix potentials $(\mathcal{M}_\alpha,\vec{\Omega}_\alpha)$ for the heterotic string theory which is an image of the EmM system according to the map (3.12).

(iv) Afterwards, one must obtain the explicit form of the magnitudes S_0, W_α, U_α and $\vec{V}_\alpha$, using the found potentials $(\mathcal{M}_\alpha,\vec{\Omega}_\alpha)$.

(v) Finally, by using (2.9) one gets explicit expressions for the original field variables of heterotic string theory.

At the end of this section let us compute the doublets $(\mathcal{M}_\alpha,\vec{\Omega}_\alpha)$. By making use of Eqs. (2.4) and (3.12), after some algebraic calculations, one obtains

$$\mathcal{M}_1=\Sigma+\Sigma\tilde{\mathcal{M}}_3\Sigma,\quad \vec{\Omega}_1=-\Sigma\tilde{\vec{\Omega}}_3\Sigma,$$

$$\mathcal{M}_2=-\Sigma\tilde{\mathcal{M}}_2^TT,\quad \vec{\Omega}_2=-\Sigma\tilde{\vec{\Omega}}_2^TT, \tag{3.22}$$

$$\mathcal{M}_3=T^T(\tilde{\mathcal{M}}_1+1)T,\quad \vec{\Omega}_3=-T^T\tilde{\vec{\Omega}}_1T.$$

In the next section we shall exploit these formulas in order to construct a subspace of solutions for the heterotic string theory with $d=2k+1$ and arbitrary n starting from the stationary Einstein theory with k Maxwell fields.

IV. SOLUTIONS VIA KERR–MULTI-NEWMAN–NUT FAMILY

In order to calculate the potentials S_0, W_α, U_α and $\vec{V}_\alpha$ for the heterotic string fields, which correspond to the EmM ones, according to the scheme developed in the previous section, let us parametrize the potential $\tilde{\mathcal{Z}}$ and the symmetry operator T in the appropriate form. For $\tilde{\mathcal{Z}}$ is convenient to set

$$\tilde{\mathcal{Z}}=(\tilde{\mathcal{Z}}_I\ \tilde{\mathcal{Z}}_{II}), \tag{4.1}$$

where $\tilde{\mathcal{Z}}_I$ is a 2×1-column and $\tilde{\mathcal{Z}}_{II}$ is a $2\times(2k+1)$-matrix that read

$$\tilde{\mathcal{Z}}_I=\begin{pmatrix}\tilde{z}'_1\\ \tilde{z}''_1\end{pmatrix},\quad \tilde{\mathcal{Z}}_{II}=\begin{pmatrix}-\tilde{z}''_1 & \tilde{z}'_{1+p} & -\tilde{z}''_{1+p}\\ \tilde{z}'_1 & \tilde{z}''_{1+p} & \tilde{z}'_{1+p}\end{pmatrix}. \tag{4.2}$$

Therefore, for T we choose the following segmentation,

$$T=(T_I\ T_{II}\ T_{III}), \tag{4.3}$$

where T_I is a 2×1-column, T_{II} is a $2\times(2k+1)$-matrix, and T_{III} is a $2\times n$-matrix, i.e.,

$$\begin{gathered}T_I=\mathcal{K}^{-1}\mathcal{Q}_I,\quad \tilde{\mathcal{Q}}_I=\begin{pmatrix}1\\0\end{pmatrix},\\ T_{II}=\mathcal{K}^{-1}\mathcal{Q}_{II},\quad Q_{II}=\begin{pmatrix}0 & r_1^T\\ 1 & r_2^T\end{pmatrix},\\ T_{III}=\mathcal{K}^{-1}\mathcal{Q}_{III},\quad \tilde{\mathcal{Q}}_{III}=\begin{pmatrix}l_1^T\\ l_2^T\end{pmatrix},\end{gathered} \tag{4.4}$$

where we have naturally decomposed $n_a^T=(r_a^T\ l_a^T)$ into the rows r_a^T and l_a^T of dimension $1\times 2k$ and $1\times n$, respectively. It is worth noticing that the block representation (4.1) and (4.3) of the magnitudes $\tilde{\mathcal{Z}}$ and T is directly related to the number of compactified dimensions and Abelian vector fields ($2k+1$ and n, respectively) and, thus, is actually fruitful for the application of Eqs (2.9). Thus, after some algebraic computations, Eqs. (2.7) yield the following expression for the scalar S_0:

$$S_0=1-T_I^TT_I-\tilde{h}^{-1}(\tilde{\mathcal{Z}}_I-T_I)^T(\tilde{\mathcal{Z}}_I-T_I), \tag{4.5}$$

whereas for the columns W_α one obtains

$$\begin{gathered}W_1=T_I^TT_{II}+\tilde{h}^{-1}(\tilde{\mathcal{Z}}_I-T_I)^T(\tilde{\mathcal{Z}}_{II}-T_{II}),\\ W_2=-[T_I^TT_{II}+\tilde{h}^{-1}(\tilde{\mathcal{Z}}_I+T_I)^T(\tilde{\mathcal{Z}}_{II}+T_{II})]G_0,\\ W_3=\sqrt{2}[T_I+\tilde{h}^{-1}(\tilde{\mathcal{Z}}_I+T_I)]^TT_{III};\end{gathered} \tag{4.6}$$

finally, for the matrix potentials U_α one gets

$$U_1 = G_0 + T_{II}^T T_{II} + \tilde{h}^{-1}(\tilde{\mathcal{Z}}_{II} - T_{II})^T(\tilde{\mathcal{Z}}_{II} - T_{II}),$$

$$U_2 = -[T_{II}^T T_{II} - \tilde{h}^{-1}(\tilde{\mathcal{Z}}_{II} - T_{II})^T(\tilde{\mathcal{Z}}_{II} + T_{II})]G_0, \tag{4.7}$$

$$U_3 = \sqrt{2}[T_{II} - \tilde{h}^{-1}(\tilde{\mathcal{Z}}_{II} - T_{II})]^T T_{III}.$$

On the other hand, the vector matrices $\tilde{\tilde{\Omega}}_\alpha$ possess the following parametrization,

$$\tilde{\tilde{\Omega}}_1 = \vec{\omega}\epsilon, \quad \tilde{\tilde{\Omega}}_2 = (\tilde{\tilde{\Omega}}_{2,I}\ \tilde{\tilde{\Omega}}_{2,II}), \quad \tilde{\tilde{\Omega}}_3 = \begin{pmatrix} 0 & \tilde{\tilde{\Omega}}_{3,I\ II} \\ \tilde{\tilde{\Omega}}_{3,II\ I} & \tilde{\tilde{\Omega}}_{3,II\ II} \end{pmatrix}, \tag{4.8}$$

where $\vec{\omega} = \tilde{\tilde{\omega}}_1''$ (the magnitude $\tilde{\tilde{\omega}}_1$ is purely imaginary, i.e., $\tilde{\tilde{\omega}}_1' = 0$), ϵ is the antisymmetric 2×2-matrix with $\epsilon_{12} = -1$, the block components of $\tilde{\tilde{\Omega}}_2$ read

$$\tilde{\tilde{\Omega}}_{2,I} = \begin{pmatrix} \tilde{\tilde{\omega}}_{2,1}' \\ \tilde{\tilde{\omega}}_{2,1}'' \end{pmatrix}, \quad \tilde{\tilde{\Omega}}_{2,II} = \begin{pmatrix} -\tilde{\tilde{\omega}}_{2,1}'' & \tilde{\tilde{\omega}}_{2,1+p}' & -\tilde{\tilde{\omega}}_{2,1+p}'' \\ \tilde{\tilde{\omega}}_{2,1}' & \tilde{\tilde{\omega}}_{2,1+p}'' & \tilde{\tilde{\omega}}_{2,1+p}' \end{pmatrix}, \tag{4.9}$$

whereas $\tilde{\tilde{\Omega}}_{3,II\ I} = -\tilde{\tilde{\Omega}}_{3,I\ II}^T$, $\tilde{\tilde{\Omega}}_{3,II\ II} = -\tilde{\tilde{\Omega}}_{3,II\ II}^T$ ($\tilde{\tilde{\Omega}}_3 = -\tilde{\tilde{\Omega}}_3^T$) and

$$\tilde{\tilde{\Omega}}_{3,I\ II} = (-\tilde{\tilde{\omega}}_{3,1\ 1}''\ \ \tilde{\tilde{\omega}}_{3,1\ 1+p}'\ \ -\tilde{\tilde{\omega}}_{3,1\ 1+p}''). \tag{4.10}$$

Note that, in view of Eqs. (2.11) and (3.22), only the magnitudes $\tilde{\tilde{\omega}}$, $\tilde{\tilde{\Omega}}_{2,I}$, $\tilde{\tilde{\Omega}}_{2,II}$ and $\tilde{\tilde{\Omega}}_{3,I\ II}$ are necessary for the explicit construction of the potential $\vec{V}_\alpha$. Finally, the explicit expressions for these vectors read

$$\vec{V}_1 = \tilde{\tilde{\omega}} T_{II}^T \epsilon T_I - \tilde{\tilde{\Omega}}_{2,II}^T T_I + T_{II}^T \tilde{\tilde{\Omega}}_{2,I} - \tilde{\tilde{\Omega}}_{3,I\ II}^T,$$

$$\vec{V}_2 = -\mathcal{G}_0(\tilde{\tilde{\omega}} T_{II}^T \epsilon T_I + \tilde{\tilde{\Omega}}_{2,II}^T T_I + T_{II}^T \tilde{\tilde{\Omega}}_{2,I} + \tilde{\tilde{\Omega}}_{3,I\ II}^T), \tag{4.11}$$

$$\vec{V}_3 = \sqrt{2}(\tilde{\tilde{\omega}}\epsilon T_I + \tilde{\tilde{\Omega}}_{2,I})^T T_{III}.$$

At this stage some remarks are in order: Eqs. (4.5), (4.7), and (4.11) also possess another parametrization which is based on the identities $\mathcal{K}\mathcal{K}^T = -\kappa$ and $\mathcal{K}\epsilon\mathcal{K}^T = \sqrt{\det \kappa}\epsilon$. In both representations the potentials S_0, W_α, U_α and $\vec{V}_\alpha$ become trivial ($S_0 = 1$, $U_1 = G_0$ and other fields vanish) for a starting EmM solution corresponding to $\tilde{\mathcal{Z}} = 0$. This fact reflects the underlying property of the primordial symmetry map (3.12) in the language of the potentials which define the components of the physical fields of string theory. As a last remark let us point out that the appearance of the $(2k+1)\times(2k+1)$-matrix $G_0 = \mathrm{diag}(-1,1,1,\ldots,1)$, which describes the flat metric corresponding to extra dimensions, in Eq. (4.7) is very natural.

As a matter of fact, our solution-generating procedure, based on the use of Eq. (3.12) and the special choice of the starting matrix potential $\tilde{\mathcal{Z}}$ in an EmM form [see Eqs. (4.1) and (4.2)], breaks the complex structure of the starting theory. Actually, in the general case, the $2\times[2(k+1)+n]$-dimensional symmetry operator T does not represent any complex magnitude t of dimension $1\times(k+1+n/2)$. In particular, the number of Abelian gauge fields n can be odd. However, if n is even, i.e., $n = 2J$, and also $r_{2,2p} = r_{1,2p-1} \equiv r_p'$, $r_{2,2p-1} = -r_{1,2p} \equiv r_p''$, $l_{2,2j} = l_{1,2j-1} \equiv l_j'$, $l_{2,2j-1} = -l_{1,2j} \equiv l_j''$ ($p = 1,2,\ldots,k; j = 1,2,\ldots,J$), then

$$T=\frac{1}{\sqrt{1-\mathcal{N}^2}}\begin{pmatrix}1 & 0 & r'_p & -r''_p & l'_j & -l''_j\\ 0 & 1 & r''_p & r'_p & l''_j & l'_j\end{pmatrix}, \tag{4.12}$$

where $\mathcal{N}^2=n_1^T n_1=n_2^T n_2$. In this special case, vectors n_1 and n_2 have the same length and are mutually orthogonal $(n_1^T n_2=0)$. Therefore, from Eq. (4.12) it immediately follows that the operator T is a real matrix representation of the complex $1\times(k+1+J)$ row $t=|1-\mathcal{N}^2|^{-1/2}(1\ r_p\ l_j)$ where $r_p=r'_p+ir''_p$ and $l_j=l'_j+il''_j$. Notice that in the special case under consideration it is possible to express Eq. (3.22) in a complex form by substituting $\mathcal{M}_\alpha\to m_\alpha$, $\tilde{\mathcal{M}}_\alpha\to\tilde{m}_\alpha$, $T\to t$ and $\Sigma\to\tilde{\sigma}_3$. Thus, in this special case it is possible to keep pure complex notations.

As an example of a concrete class of solutions of the EmM theory one can consider the solution which arises in the framework of the ansatz

$$\tilde{z}=\lambda\tilde{q}, \tag{4.13}$$

where λ is a complex function and $\tilde{q}$ is a $1\times(k+1)$ constant complex row. The corresponding effective system is related to the Lagrangian

$$L_3=2\tilde{\kappa}\frac{|\nabla\lambda|^2}{(1-\tilde{\kappa}|\lambda|^2)}, \tag{4.14}$$

in the case of $\tilde{\kappa}\neq 0$, where

$$\tilde{\kappa}=\tilde{q}\tilde{\sigma}_3\tilde{q}^\dagger. \tag{4.15}$$

When $\tilde{\kappa}=0$ one obtains a decoupled three-dimensional flat space and a harmonic field λ. The parameter $\tilde{\kappa}$ plays the role of a coupling constant between three-dimensional gravity and the complex scalar field λ. We claim that the following concrete choice of the scalar field and the three metric

$$\begin{gathered}\lambda=\frac{1}{R-ia\cos\theta},\\ ds_3^2=\Delta\left(\frac{dR^2}{R^2+a^2-\tilde{\kappa}}+d\theta^2\right)+(R^2+a^2-\tilde{\kappa})\sin^2\theta d\varphi^2,\end{gathered} \tag{4.16}$$

where $\Delta=R^2+a^2\cos^2\theta-\tilde{\kappa}$ and a is a constant, gives a solution of the corresponding equations of motion. Note that in Eq. (4.16) the value of the parameter $\tilde{\kappa}$ is arbitrary. In what follows, this concrete class of solutions will be considered as the typical starting one in the framework of the developed solution-generating scheme.

To start with, we need explicit expressions for the magnitudes $\tilde{m}_\alpha$ and $\tilde{\tilde{\omega}}_\alpha$. For the scalar sector one immediately gets

$$\begin{gathered}\tilde{m}_1=-\left(1+\frac{\tilde{\kappa}}{\Delta}\right),\\ \tilde{m}_2=-\tilde{q}\frac{R+ia\cos\theta}{\Delta},\\ \tilde{m}_3=-\tilde{q}^\dagger\tilde{q}\frac{1}{\Delta},\end{gathered} \tag{4.17}$$

whereas for the vector one, after the corresponding integration, one finds that

$$\tilde{\vec{\omega}}_{1\,\varphi}=-i\frac{a\tilde{\kappa}\sin^2\theta}{\Delta},$$

$$\tilde{\vec{\omega}}_{2\,\varphi}=\tilde{q}\left(-\cos\theta+ia\sin^2\theta\frac{R+ia\cos\theta}{\Delta}\right), \tag{4.18}$$

$$\tilde{\vec{\omega}}_{3\,\varphi}=-i\tilde{q}\dagger\tilde{q}\frac{a\sin^2\theta}{\Delta},$$

and other vector components vanish. These relations define the extension of the solution (4.16) to the realm of the heterotic string theory according to the relations (2.6)–(2.8), (4.5)–(4.7), and (4.11). Let us discuss both, the starting EmM family of solutions and the resulting heterotic string theory fields.

First of all, let us compute the Ernst potentials (3.18) corresponding to the solution (4.16):

$$\mathcal{E}=1-\frac{2(M+iN)}{r+i(N-a\cos\theta)},$$

$$\mathcal{F}_p=\sqrt{2}\,\frac{(e_p+ig_p)}{r+i(N-a\cos\theta)}, \tag{4.19}$$

where

$$\tilde{q}_1=M+iN,\quad \tilde{q}_{1+p}=e_p+ig_p, \tag{4.20}$$

and $r=R+M$ and $\tilde{\kappa}=-M^2-N^2+\Sigma_p(e_p^2+g_p^2)$. It is clear that our starting solution is precisely the Kerr–multi-Newman family of solutions with nontrivial NUT parameter. Thus, (r,θ,φ) stand for conventional oblate spheroidal coordinates, whereas the parameters M, N, e_p and g_p are the mass, NUT, electric and magnetic charges, respectively. Another interesting issue concerns the asymptotical flatness of the resulting multidimensional field configuration in the framework of our solution-generating method in the general case. It turns out that the generating field configurations contain the so-called ''Dirac strings'' and are not asymptotically flat, i.e., they contain a term which is proportional to $\cos\theta$ at spatial infinity $(R\to\infty)$. The same situation takes place for the starting four-dimensional metric of the EmM theory: the corresponding term is proportional to the NUT parameter and it vanishes if $N=0$. Thus, in the starting solution this Dirac string peculiarity is removable. From Eqs. (4.11) and (4.18) it follows that the Dirac string for the metric (i.e., for the magnitude $\vec{V}_1$) is absent if one imposes the restriction

$$\tilde{\mathcal{Q}}_I^T T_{II}=T_I^T\tilde{\mathcal{Q}}_{II} \tag{4.21}$$

on the starting charge configuration and the operator of the symmetry transformation. Here $\tilde{\mathcal{Q}}_I$ and $\tilde{\mathcal{Q}}_{II}$ are, respectively, 2×1 and $2\times(2k+1)$ block components of the charge matrix $\tilde{\mathcal{Q}}=(\tilde{\mathcal{Q}}_I\ \tilde{\mathcal{Q}}_{II})$ which realizes a real matrix representation of the complex charge parameter $\tilde{q}$. Notice that all the relations which involve the matrix $\tilde{\mathcal{Q}}$ can be obtained from the relations for $\tilde{\mathcal{Z}}$ by replacing $z_{\mathcal{P}}\to q_{\mathcal{P}}$ in $\tilde{\mathcal{Z}}$; notice that we have used a decomposition of $\tilde{\mathcal{Q}}$ similar to that of Eqs. (4.1) and (4.2).

It is possible to solve the algebraic restriction (4.21) for the general case. However, for the special case (4.12), when the symmetry operator can be represented in complex form, this can be done in an easy and elegant way. Actually, a simple algebraic analysis shows that in this case Eq. (4.21) leads to $N=0$ and the relations

$$e_p=r'_pM,\quad g_p=r''_pM, \tag{4.22}$$

i.e., to the NUT-less starting solution and to hard relations between the electromagnetic charges and the nonelectromagnetic sector of the symmetry operator T. In this special case, up to construction, the resulting metric is asymptotically flat at spatial infinity. Notice that the resulting matter fields of heterotic string theory also contain Dirac strings. In order to remove them one must impose the corresponding restrictions on the magnitudes $\vec{V}_2$ and $\vec{V}_3$ (to eliminate, in turn, the terms proportional to $\cos\theta$). Here we will not discuss these pure algebraic topics; thus, our final solutions will include, for instance, magnetically charged field configurations.

At the end of this section let us note that our solution-generating procedure, based on Eq. (3.12), maps the full EmM theory into the pure bosonic string theory sector in the case $l_a \equiv 0$. Actually, this last restriction can be imposed independently of our generation scheme. This fact is also reflected in the number of compactified space–time dimensions, which is equal to $2k+1$, where k is precisely the number of starting Maxwell fields. Thus, a surprising fact is that the Abelian gauge field sector of heterotic string theory is not related to the Maxwell sector of the starting EmM theory: all the string theory gauge fields depend only on the structure of the symmetry operator T. Namely, one obtains n Abelian vector fields $U(1)$ if one chooses the parameter l_a of height n.

V. CONCLUSION AND DISCUSSION

The main result of this article is the presentation of a new and explicit scheme of generation of heterotic string theory solutions from stationary fields of the EmM theory. Namely, one can start with an arbitrary stationary solution of Einstein theory coupled to k Maxwell fields and obtain a solution of heterotic string theory with n Abelian gauge fields which lives in $2(k+2)$ dimensions by making use of the procedure developed in this article. It is worth noticing that our symmetry approach is based on pure algebraic calculations only as far as all the potentials of the starting EmM theory have been already computed.

Let us make two remarks concerning the properties of the underlying symmetry map (3.12) [or (4.5)–(4.7) and (4.11) in an equivalent and physically meaningful form]. First of all, it is interesting to notice that for the case $k=3$, the resulting heterotic string theory becomes ten-dimensional. However, the complete theory with $k=3$ (we refer to a theory with arbitrary potential $\tilde{\mathcal{Z}}$ of dimension 2×8, not to the Einstein theory with three Maxwell fields) corresponds to the bosonic sector of $N=4$ supergravity in four dimensions. Thus, when $n=16$, our procedure relates $N=D=4$ and $N=1$, $D=10$ supergravities in a transparent form. Keeping this in mind, it will be interesting to study the problem of supersymmetric, and therefore BPS saturated, solutions in the framework of the established correspondence. Namely, a question that naturally arises is whether or not supersymmetric solutions of the four-dimensional theory map into supersymmetric solutions of the ten-dimensional one. If they do so, how many supersymmetries will preserve under this correspondence? Notice that some classes of four-dimensional supersymmetric solutions have been extensively studied during last several years (see, for instance, Refs. 20 and 19); some special classes of ten-dimensional supersymmetric solutions have also been obtained (see Refs. 21 and 3) and the topic is still under active investigation now.

Our second remark is related to the level of generality of the map (3.12). We consider this issue in the framework of asymptotically flat field configurations in the three-dimensional sense. Namely, we consider that the fields which are encoded in the potential $\mathcal{Z}$ vanish at spatial infinity. In this sense our map (3.12) is complete with respect to the total group of three-dimensional charging symmetries, i.e., to the transformations that preserve the asymptotical triviality of the matrix potential $\mathcal{Z}$. Thus, if in Eq. (3.12) the potential $\tilde{\mathcal{Z}}$ and the symmetry operator T have the most general form, our procedure is nongeneralizable by making use of hidden symmetries that act in the subspace of three-dimensional asymptotically flat field solutions. However, if one starts with the potential $\tilde{\mathcal{Z}}$ and the symmetry operator T given in the matrix representation which corresponds to the complex $\tilde{z}$ and t, one partially loses the charging symmetry self-invariance of the resulting solutions of the heterotic string theory. In fact, one loses the part of the total charging symmetry group of the heterotic string theory which breaks the special (complex) structure of the matrix

potential $\tilde{\mathcal{Z}}$ and the symmetry operator T given by Eqs. (4.2) and (4.12). This lost symmetry sector is evidently nontrivial and can be used for the further generalization of the solutions obtained in the framework of the pure complex generating scheme developed at the end of the previous section.

In this article we have constructed as well the string theory extension of the Kerr–multi-Newman solution of the EmM theory. This extension was presented as some simple and natural application of the developed general formalism. It was also shown how to remove all the Dirac string peculiarities from the resulting multi-dimensional metric field, so that the resulting space-time of the heterotic string theory is asymptotically flat. Note that the constructed family of solutions constitutes the first example of extension of the Kerr-multi-Newman solution to the realm of the heterotic string theory. The obtained class of solutions is really interesting from the point of view of black hole physics and can be studied in detail in a conventional manner.[3,18,19]

Holography and SL(2,$\mathbb{R}$) symmetry in 2D Rindler space–time

Valter Moretti[a] and Nicola Pinamonti[b]
Department of Mathematics, Faculty of Science, University of Trento, via Sommarive 14, I-38050 Povo (TN), Italy

(Received 25 July 2003; accepted 11 September 2003)

It is shown that it is possible to define quantum field theory of a massless scalar free field on the Killing horizon of a 2D Rindler space–time. Free quantum field theory on the horizon enjoys diffeomorphism invariance and turns out to be unitarily and algebraically equivalent to the analogous theory of a scalar field propagating inside Rindler space–time, no matter the value of the mass of the field in the bulk. More precisely, there exists a unitary transformation that realizes the bulk-boundary correspondence upon an appropriate choice for Fock representation spaces. Second, the found correspondence is a subcase of an analogous algebraic correspondence described by injective $*$-homomorphisms of the abstract algebras of observables generated by abstract quantum free-field operators. These field operators are smeared with suitable test functions in the bulk and exact one-forms on the horizon. In this sense the correspondence is independent from the chosen vacua. It is proven that, under that correspondence, the ''hidden'' SL(2,$\mathbb{R}$) quantum symmetry found in a previous work gets a clear geometric meaning, it being associated with a group of diffeomorphisms of the horizon itself. © *2004 American Institute of Physics.*

I. INTRODUCTION

This article deals with some holographic properties of quantum field theory (QFT) in a manifold that admits a (Killing) horizon. The holographic correspondence holds between QFT in the manifold and QFT suitably defined on the horizon itself. It is shown that these holographic properties enjoy a nice interplay with the hidden SL(2,$\mathbb{R}$) symmetry found in Ref. 1.

In the context of the problem of the microscopic origin of black-hole entropy, holographic principle[2–4] arose by the idea that gravity near the horizon should be described by a low dimensional theory with a higher dimensional group of symmetry. On the other hand, in a very famous paper, Brown and Henneaux[5] described the entropy of an asymptotically AdS_3 black hole in terms of diffeomorphisms preserving the space–time structure at spatial infinity. After that, the correspondence between quantum field theories of different dimensions was conjectured by Maldacena in his celebrated work about AdS/Cft correspondence.[6] Using the machinery of string theory, he argued that there is a correspondence between quantum field theory in an asymptotically AdS, $d+1$-dimensional space–time—the ''bulk''—and a conformal theory in a d-dimensional manifold—the (conformal) ''boundary'' at spacelike infinity. Afterwards, Witten[7] described the above correspondence in terms of relations of observables of the two theories. See also Ref. 8 for further details. The correspondence in the two dimensional case was studied in Ref. 9. Results that arose from those works were proven rigorously by Rehren for local quantum fields in an AdS background, establishing the existence of a correspondence between bulk observables and boundary observables (usually called algebraic holography) without employing string technology.[10,11] Finally, Strominger[12] proposed to enlarge the found results by showing that there is an analogous

correspondence between dS space and a possible conformal field theory on its timelike boundary. In another work,[13] making use of the optical metric, the near horizon limit of a massless theory in Schwarzschild-like space–time has been intepreted as a theory in an asymptotic AdS space–time, giving rise to holographic properties.

A crucial point to explain the holographic correspondence in Rehren's version is that, in AdS_{d+1} space, the conformal group which acts in d dimensions can be realized as the group of the isometries of the AdS_{d+1} bulk. In this way, from a pure geometric point of view, the nature of the bulk-boundary correspondence has a straightforward explanation. This is not the case of manifolds with bifurcate Killing horizon such as Kruskal and Minkowski space–times. In Schwarzschild space–time embedded in Kruskal manifold, the proper boundary relevant to state holographic theorems (dropping the boundary at infinity) seems to be made of the event horizon of the black hole. Obviously a first and intriguing problem is the definition of a quantum field theory on a manifold—as an (event or Killing) horizon—whose metric is degenerate. This problem is considered in this article among other related issues. To approach the general issue in the simplest version, we notice that two-dimensional Rindler space–time embedded in Minkowski space–time approximates the nontrivial part of the space–time structure near a bifurcate horizon as that of a Schwartzschild black hole embedded in Kruskal space–time. The remaining transverse manifold is not so relevant in several interesting quantum effects as Hawking's radiation and it seems that it can be dropped in the simplest approximation. In that context, we have argued in a recent work[1] that free quantum field theory in two-dimensional Rindler space presents a ''hidden'' SL(2,$\mathbb{R}$) symmetry. In other words the theory turns out to be invariant under a unitary representation of SL(2,$\mathbb{R}$) but such a quantum symmetry cannot be induced by the geometric background which enjoys a different group of isometries. SL(2,$\mathbb{R}$) is the group of symmetry of the zero-dimensional conformal field theory in the sense of Ref. 14, so, as for the case of AdS space–time, it suggests the existence of a possible correspondence between quantum field theory in Rindler space and a conformal field theory defined on its (Killing) horizon. In fact, as it is shown within this work, the found hidden symmetry becomes manifest when one examines, after an appropriate definition, quantum field theory on the (Killing) horizon. That theory enjoys diffeomorphism invariance and the SL(2,$\mathbb{R}$) symmetry represents, in the quantum context, the geometric invariance of the theory under a little group of diffeomorphisms of the horizon. (We stress that invariance under isometries makes no sense since the metric is degenerate.) We address in Sec. II technical details concerning the structure of quantum field theory on the horizon that, in a sense, is the limit of the bulk theory toward the horizon. We only say here that, generalizing the symplectic approach valid in the bulk, the theory can be built up by defining a suitable quantum field operator smeared with exact one-forms, which are defined on the horizon, to assure the invariance under diffeomorphisms; moreover the causal propagator (which involves bosonic commutation rules) is naturally defined in spite of the absence, shared with other holographic approaches in other contexts, of any natural evolution equation. The appearance of a manifest quantum SL(2,$\mathbb{R}$) symmetry on the horizon is only a part of the results established in this article. In fact, the manifest SL(2,$\mathbb{R}$) symmetry on the horizon is nothing but a simple result which follows from a holographic boundary-bulk correspondence established in this article for 2D Rindler space–time either in terms of unitary equivalences or in terms of $*$-algebra homomorphisms of free field observables. This operator algebra has a clear geometric interpretation in terms of vector fields defined on the horizon and generating the group of (orientation preserving) diffeomorphisms of the horizon itself. Some overlap with our results could be present in the literature. Guido, Longo, Roberts, and Verch[15] discussed from a general point of view SL(2,$\mathbb{R}$) covariant local QFT defined on a bifurcate Killing horizon and obtained by restriction on the horizon of the net of local (Von Neumann) observables (referred to a Hadamard state with respect to the Killing field) given in the manifold. Along a similar theme, Schroer and Wiesbrock[16] have studied the relationship between QFTs on horizons and QFTs on the ambient space–time. They even use the term ''hidden symmetry'' in a sense similar to we do here and in Ref. 1. In related follow-up works by Schroer[17] and Schroer and Fassarella,[18] the relation to holography and diffeomorphism covariance is also discussed.

This work is organized as follows: the next section is devoted to review and briefly improves

a few results established in Ref. 1, also giving rigorous proofs, concerning hidden $\mathrm{SL}(2,\mathbb{R})$ symmetry for a free quantum scalar field propagating in 2D Rindler space–time. In the third section we present the main achievement of this work: We build up a quantum field theory for a massless scalar field on the horizon which, in a sense, is the limit toward the horizon of the analogous theory developed for a (also massive) field propagating in the bulk. Moreover, we show that any free quantum field theories in the bulk and on the horizon are unitarily and algebraically equivalent (no matter the value of the mass). In other words, there exists a unitary transformation that realizes the bulk-boundary correspondence upon an appropriate choice for Fock representation spaces. In particular, the vacuum expectation values of observables of the free-field theory are invariant under the unitary equivalence. Actually, as we said, the found correspondence is valid in an algebraic sense too, i.e., it is described by injective $*$-homomorphisms of the abstract algebras of observables constructed by products of free-field operators smeared by suitable test functions/one-forms. In this sense the correspondence is independent from the chosen vacua. In the fourth section we show that, as we expected, hidden $\mathrm{SL}(2,\mathbb{R})$ invariance found in Ref. 1 becomes manifast on the horizon. In a forthcoming work[19] we show that the found manifest $\mathrm{SL}(2,\mathbb{R})$ unitary representation defined for the horizon QFT can be extended into a full positive-energy unitary Virasoro algebra representation with nonvanishing central charge which represents the Lie algebra of vector fields on the (compactified) Killing horizon. In the last section we make some remarks and comments on the extension of our result to more complicated space–times containing a bifurcate Killing horizon.

II. HIDDEN $\mathrm{SL}(2,\mathbb{R})$ SYMMETRY NEAR A BIFURCATE KILLING HORIZON

A. Rindler space

In Ref. 1 we have proven that quantum mechanics in a 2D space–time which approximates the space–time near a bifurcate Killing horizon enjoys *hidden* $\mathrm{SL}(2,\mathbb{R})$ invariance. This has been done by using and technically improving some general results on $\mathrm{SL}(2,\mathbb{R})$ invariance in quantum mechanics.[14] Let us review part of the results achieved in Ref. 1 from the point of view of quantum field theory in curved space–time (essentially in the formulation presented in Refs. 20 and 21 but using $*$-algebras instead of C^*-algebras).

Remark: We illustrate the construction of quantum field theory in the considered background in some detail because the general framework will be useful later in developing quantum field theory on a horizon and holography.

Consider a Schwarzschild-like metric

$$-A(r)dt\otimes dt+A^{-1}(r)dr\otimes dr+r^2d\Sigma^2, \tag{1}$$

where Σ denotes angular coordinates. Let $R>0$ denote the radius of the black hole. As the horizon is bifurcate, $A'(R)/2\neq 0$ and we can use the following approximation in the limit $r\to R$,

$$-\kappa^2y^2dt\otimes dt+dy\otimes dy+R^2d\Sigma^2, \tag{2}$$

where $\kappa=A'(R)/2$ and $r=R+A'(R)y^2/4$. Dropping the angular part $R^2d\Sigma$, the metric becomes that of the space–time called *(right) Rindler wedge* $\mathbf{R}$ which is part of Minkowski space–time:

$$g_{\mathbf{R}}:=-\kappa^2y^2dt\otimes dt+dy\otimes dy, \tag{3}$$

with global coordinates $t\in(-\infty,+\infty)$, $y\in(0,+\infty)$. That space–time is static[22] with respect to the timelike Killing vector ∂_t and spacelike surfaces at constant t. Later we shall make use of *Rindler light coordinates* $u,v\in\mathbb{R}$ which cover $\mathbf{R}$ and satisfy

$$u:=t-\frac{\log(\kappa y)}{\kappa}\quad,\quad v:=t+\frac{\log(\kappa y)}{\kappa}\quad,\quad \text{where}\quad t\in\mathbb{R}\ ,y\in(0,+\infty). \tag{4}$$

B. One-particle Hilbert space

As **R** is globally hyperbolic,[22] in particular t-constant surfaces are Cauchy surfaces, quantum field theory can be implemented without difficulties.[21] There is no guarantee for the validity of the approach to quantum field theory for static space–times based on the quadratic form induced by the stress energy tensor presented in Ref. 21 since $-g_{\mathbf{R}}(\partial_t,\partial_t)$ has no positive lower bound. However, we build up quantum field theory of a real scalar field ϕ with mass $m\geqslant 0$ propagating in **R** by following a more direct stationary-mode-decomposition approach. In fact, *a posteriori* it is possible to show that our procedure produces the same quantization as that in Ref. 21. The Klein–Gordon equation reads

$$-\partial_t^2\phi+\kappa^2(y\partial_y y\partial_y-y^2m^2)\phi=0. \tag{5}$$

If $m>0$, $\mathcal{S}$ denotes the vector space of *real wave functions*, i.e., C^∞ real solutions ψ which have Cauchy data with compact support on a Cauchy surface. If $m=0$, (5) reduces to

$$(\partial_t+\kappa y\partial_y)(-\partial_t+\kappa y\partial_y)\phi \quad (=(-\partial_t+\kappa y\partial_y)(\partial_t+\kappa y\partial_y)\phi)=0 \tag{6}$$

and the space of real wave functions we want to consider is defined as $\mathcal{S}:=\mathcal{S}_{\text{out}}+\mathcal{S}_{\text{in}}$ where $\mathcal{S}_{\text{out}}$ and $\mathcal{S}_{\text{in}}$ are, respectively, the space of real C^∞ solutions of $(\partial_t+\kappa y\partial_y)\psi=0$ and $(-\partial_t+\kappa y\partial_y)\psi=0$ with compactly supported Cauchy data. The compactness requirement does not depend on the Cauchy surface.[21] There are solutions of (5) with $m=0$ which do not belong to $\mathcal{S}$ in spite of having compactly supported Cauchy data. [*With the notation used in (7), it is sufficient to fix compact-support Cauchy data* $\psi, n^\mu\partial_\mu\psi$ *on a* t*-constant Cauchy surface* Λ *such that* $\int_\Lambda \partial_\mu\psi\, n^\mu d\sigma\neq 0$.] Define in $\mathcal{S}\times\mathcal{S}$ the following *symplectic form*,[21] which does not depend on the used spacelike Cauchy surface Λ with induced measure $d\sigma$ and unit normal vector n pointing toward the future:

$$\Omega(\psi,\psi'):=\int_\Lambda(\psi'\nabla^\mu\psi-\psi\nabla^\mu\psi')n_\mu\, d\sigma. \tag{7}$$

The definition is well-behaved for a pair of complex-valued wave functions, too, and also if one of these has no compactly supported Cauchy data. Equipped with these tools we can define the one-particle Hilbert space $\mathcal{H}$ associated with the Killing field ∂_t. To this end, consider the two classes of $C^\infty(\mathbf{R};\mathbb{C})$, ∂_t-stationary solutions of (5) where K_a is the usual Bessel–McDonald function:

$$\Phi_E(t,y):=\sqrt{\frac{2E\sinh(\pi E/\kappa)}{\pi^2\kappa}}K_{iE/\kappa}(my)\frac{e^{-iEt}}{\sqrt{2E}} \quad \text{with } E\in\mathbb{R}^+, \qquad \text{if } m>0, \tag{8}$$

$$\Phi_E^{\text{(in)}\atop\text{(out)}}(t,y):=\frac{e^{-iE(t\pm\kappa^{-1}\ln(\kappa y))}}{\sqrt{4\pi E}} \quad \text{with } E\in\mathbb{R}^+, \qquad \text{if } m=0, \tag{9}$$

where $\mathbb{R}^+:=[0,+\infty)$. Modes $\Phi_E^{(\text{in})}$ are associated with particles crossing the future horizon at $t\to+\infty$, modes $\Phi_E^{(\text{out})}$ are associated with particles crossing the past horizon at $t\to-\infty$.

We have a pair of propositions whose proof is straightforward by using properties of K_{ia}, Fourier transform and Lebedev transform.[23]

Proposition 2.1 (completeness of modes): If $m>0$ *and* $\psi\in\mathcal{S}$, *the function on* $\mathbb{R}^+$,

$$E\mapsto\tilde{\psi}_+(E):=-i\Omega(\overline{\Phi_E},\psi), \tag{10}$$

satisfies $\tilde{\psi}_+(E)=\sqrt{E}g(E)$, *and* $\overline{\tilde{\psi}_+(E)}=-\sqrt{E}g(-E)$, *for some* $g\in\mathsf{S}(\mathbb{R};\mathbb{C})$ *(space of complex-valuated Schwartz' functions on the whole* $\mathbb{R}$*). Moreover,*

$$\psi(t,y)=\int_0^{+\infty}\Phi_E(t,y)\tilde{\psi}_+(E)\,dE+\int_0^{+\infty}\overline{\Phi_E(t,y)\tilde{\psi}_+(E)}\,dE \qquad \text{for } (t,y)\in\mathbb{R}\times(0,+\infty). \tag{11}$$

If $m=0$ *and* $\psi\in\mathcal{S}$, *the functions on* $\mathbb{R}^+$ *with* $\alpha=in,\ out$,

$$E\mapsto\tilde{\psi}_+^{(\alpha)}(E):=-i\Omega(\overline{\Phi_E^{(\alpha)}},\psi), \tag{12}$$

satisfy $\tilde{\psi}_+^{(\alpha)}(E)=\sqrt{E}g^{(\alpha)}(E)$, $\overline{\tilde{\psi}_+^{(\alpha)}(E)}=\sqrt{E}g^{(\alpha)}(-E)$, *where* $g^{(\alpha)}\in\mathsf{S}(\mathbb{R};\mathbb{C})$. *Moreover, for* $(t,y)\in\mathbb{R}\times(0,+\infty)$

$$\psi(t,y)=\int_0^{+\infty}\sum_\alpha\Phi_E^{(\alpha)}(t,y)\tilde{\psi}_+^{(\alpha)}(E)\,dE+\int_0^{+\infty}\sum_\alpha\overline{\Phi_E^{(\alpha)}(t,y)\tilde{\psi}_+^{(\alpha)}(E)}\,dE. \tag{13}$$

Proposition 2.2 (associated Hilbert spaces): If $\psi\in\mathcal{S}$, *define the one-to-one associated positive-frequency wave function for* $m>0$ *and* $m=0$, *respectively, as*

$$\psi_+(t,y):=\int_0^{+\infty}\Phi_E(t,y)\tilde{\psi}_+(E)\,dE\ ,\ \psi_+(t,y):=\int_0^{+\infty}\sum_\alpha\Phi_E^{(\alpha)}(t,y)\tilde{\psi}_+^{(\alpha)}(E)\,dE. \tag{14}$$

With that definition, for $\psi_1,\psi_2\in\mathcal{S}$ *it results that* $\Omega(\psi_{1+},\psi_{2+})=0$, *whereas*

$$\langle\psi_{1+},\psi_{2+}\rangle:=-i\Omega(\overline{\psi_{1+}},\psi_{2+}) \tag{15}$$

is well-defined (at least on t-constant surfaces). Notice that, at least for $m=0$, *positive/negative frequency wave functions cannot have Cauchy data with compact support due to known analiticity properties of Fourier transform. Moreover, for* $m>0$ *and* $m=0$, *respectively,*

$$\langle\psi_{1+},\psi_{2+}\rangle=\int_0^{+\infty}\overline{\tilde{\psi}_{1+}(E)}\tilde{\psi}_{2+}(E)\,dE\ ,\ \langle\psi_{1+},\psi_{2+}\rangle=\int_0^{+\infty}\sum_\alpha\overline{\tilde{\psi}_{1+}^{(\alpha)}(E)}\tilde{\psi}_{2+}^{(\alpha)}(E)\,dE. \tag{16}$$

The one-particle Hilbert *space* $\mathcal{H}$ *is defined as the Hilbert completion of the space of finite complex linear combinations of functions* ψ_+, $\psi\in\mathcal{S}$, *equipped with the extension of the scalar product (15) to complex linear combinations of arguments. It results that* $\mathcal{H}\cong L^2(\mathbb{R}^+,dE)$ *if* $m>0$ *or, if* $m=0$, $\mathcal{H}\cong\mathcal{H}_{(\mathrm{in})}\oplus\mathcal{H}_{(\mathrm{out})}$ *with* $\mathcal{H}_{(\alpha)}\cong L^2(\mathbb{R}^+,dE)$, $\alpha=in,out$.

C. Quantum field operators: Symplectic approach

As usual, the whole quantum field is represented in the symmetrized Fock space $\mathfrak{F}(\mathcal{H})$—that is $\cong\mathfrak{F}(\mathcal{H}_{(\mathrm{in})})\otimes\mathfrak{F}(\mathcal{H}_{(\mathrm{out})})$ in the massless case—and referred to a vacuum state $\Psi_{\mathbf{R}}$—namely, $\Psi_{\mathbf{R}}^{(\mathrm{in})}\otimes\Psi_{\mathbf{R}}^{(\mathrm{out})}$ in the massless case—called the *Rindler vacuum state*. $\Psi_{\mathbf{R}}$ does not belong to the Hilbert space of Minkowski particles in the sense that quantum field theory in Rindler space and the Minkowski one are not unitarily equivalent.[21] The *quantum field* $\Omega(\ \cdot\ ,\hat{\phi})$ associated with the real scalar field ϕ in (5) is the linear map[21]

$$\mathcal{S}\ni\psi\mapsto\Omega(\psi,\hat{\phi}):=ia(\overline{\psi_+})-ia^\dagger(\psi_+), \tag{17}$$

where $\psi\in\mathcal{S}$ and $a(\overline{\psi_+})$ and $a^\dagger(\psi_+)$, respectively, denote the annihilation [the conjugation being used just to the get a linear map $\psi_+\mapsto a(\overline{\psi_+})$] and construction operators associated with the one-particle state ψ_+. The right-hand side of (17) is an essentially self-adjoint operator defined in the dense invariant subspace $\mathfrak{F}_0\subset\mathfrak{F}(\mathcal{H})$ spanned by all states containing a finite arbitrarily large number of particles with states given by positive-frequency wave functions. Equation (17) is formally equivalent via (11) to the nonrigorous but popular definition

$$\hat{\phi}(x)\text{“}=\text{”}\int_0^{+\infty}\Phi_E(x)a_E+\overline{\Phi_E(x)}a_E^\dagger\,dE. \tag{18}$$

The given procedure can be generalized to any Klein–Gordon scalar field propagating in a (not necessarily static) globally hyperbolic space–time provided a suitable vacuum state is given.[21] Let $\mathcal{D}(\mathbf{R})$ denote the space of real compactly supported smooth functions in $\mathbf{R}$, in the massless case these functions being also assumed to have zero integral on the Rindler space, and $J(A)$ the union of the *causal past* and *causal future* of a set $A\subset\mathbf{R}$. As $\mathbf{R}$ is globally hyperbolic, there is a uniquely determined *causal propagator* $E:\mathcal{D}(\mathbf{R})\to\mathcal{S}$ of the Klein–Gordon operator K of the field ϕ.[21] E enjoys the following properties. It is linear and surjective, $\mathrm{supp}(Ef)\subset J(\mathrm{supp}f)$, $Ef=0$ only if $f=Kg$ for some $g\in\mathcal{D}(\mathbf{R})$ and E satisfies for all $\psi\in\mathcal{S}$, $f,h\in\mathcal{D}(\mathbf{R})$,

$$\int_{\mathbf{R}}\psi f\,d\mu_g=\Omega(Ef,\psi)\quad\text{and}\quad\int_{\mathbf{R}}h(x)(Ef)(x)\,d\mu_g(x)=\Omega(Ef,Eh), \tag{19}$$

μ_g being the measure induced by the metric in $\mathbf{R}$. Equation (19) suggests to define[21] a quantum-field operator *smeared with functions* f of $\mathcal{D}(\mathbf{R})$ as the linear map

$$f\mapsto\hat{\phi}(f):=\Omega(Ef,\hat{\phi}). \tag{20}$$

It is possible to smear the field operator by means of compactly supported complex-valued functions, whose space will be denoted by $\mathcal{D}(\mathbf{R};\mathbb{C})$, simply by defining $\hat{\phi}(f+ih):=\hat{\phi}(f)+i\hat{\phi}(h)$ when $f,h\in\mathcal{D}(\mathbf{R})$. Equation (20) entails[21]

$$[\hat{\phi}(f),\hat{\phi}(h)]=-iE(f,h):=-i\int_{\mathbf{R}}h(x)(Ef)(x)\,d\mu_g(x), \tag{21}$$

that is the rigorous version of the formal identity $[\hat{\phi}(x),\hat{\phi}(x')]=-iE(x,x')$. As a further result[21] $[\hat{\phi}(f),\hat{\phi}(g)]=0$ if the supports of f and g are *spatially separated*, that is, $\mathrm{supp}f\not\subset J(\mathrm{supp}g)$ [which is equivalent to $\mathrm{supp}g\not\subset J(\mathrm{supp}f)$].

All that we said holds for $m\geqslant 0$. Let us specialize to the massless case giving further details. In Rindler light coordinates (4) the decomposition $\mathcal{S}=\mathcal{S}_{\mathrm{in}}+\mathcal{S}_{\mathrm{out}}$ (see Sec. II B) reads, if $\psi\in\mathcal{S}$, $\psi(u,v)=\psi(v)+\psi'(u)$ where $\psi\in\mathcal{S}_{\mathrm{in}}$ and $\psi'\in\mathcal{S}_{\mathrm{out}}$ are compactly supported. Trivial consequences are that ψ vanishes on the past horizon $v\to-\infty$, and ψ' vanishes on the future horizon $u\to+\infty$ (see Sec. III A) and $\Omega(\psi,\psi')=0$. In the considered case

$$E=E_{\mathrm{in}}+E_{\mathrm{out}}, \tag{22}$$

where, in terms of bi-distributions interpreted as in (21),

$$E_{\mathrm{in}}((u',v'),(u,v))=\tfrac{1}{4}\,\mathrm{sign}(v-v')\quad\text{whereas}\quad E_{\mathrm{out}}((u',v'),(u,v))=\tfrac{1}{4}\,\mathrm{sign}(u-u'). \tag{23}$$

The maps $f\mapsto E_{\mathrm{in/out}}f$ from $\mathcal{D}(\mathbf{R})$ to, respectively, $\mathcal{S}_{\mathrm{in/out}}$ are surjective and $E_{\mathrm{in/out}}f=0$ if and only if, respectively, $\gamma f=\partial_u g$ or $\gamma f=\partial_v g$ for some compactly-supported function g and $\gamma\,du\,dv=d\mu_g$.

In the Fock space associated with Rindler vacuum $\Psi_{\mathbf{R}}$, we have the natural decomposition

$$\hat{\phi}(f)=\hat{\phi}_{\mathrm{in}}(f)+\hat{\phi}_{\mathrm{out}}(f)\quad\text{with}\quad\hat{\phi}_{\mathrm{in/out}}(f):=\Omega(E_{\mathrm{in/out}}f,\hat{\phi}) \tag{24}$$

and the two kinds of field operators commute, i.e., $[\hat{\phi}_{\mathrm{in}}(f),\hat{\phi}_{\mathrm{out}}(g)]=i\Omega(E_{\mathrm{in}}f,E_{\mathrm{out}}g)=0$.

D. SL(2,$\mathbb{R}$) symmetry

If $m>0$ and thus $\mathcal{H}\cong L^2(\mathbb{R}^+,dE)$, the *one-particle (Rindler) Hamiltonian* H is the self-adjoint operator

$$(Hf)(E) := Ef(E) \quad \text{with domain} \quad \mathcal{D}(H) = \left\{ f \in L^2(\mathbb{R}^+, dE) \;\middle|\; \int_0^{+\infty} E^2 |f(E)|^2 dE < +\infty \right\}. \tag{25}$$

If $m=0$ and thus $\mathcal{H} \cong L^2(\mathbb{R}^+, dE) \oplus L^2(\mathbb{R}^+, dE) \cong \mathbb{C}^2 \otimes L^2(\mathbb{R}^+, dE)$, the Hamiltonian H reads $I \otimes H'$, H' being the operator defined on the right-hand side of (25) referred to $L^2(\mathbb{R}^+, dE)$ and *the identity operator I being referred to* $\mathbb{C}^2$.

In Ref. 1 it was argued that the one-particle system enjoys invariance under a unitary representation of $\mathrm{SL}(2,\mathbb{R})$ as a consequence of the form of the spectrum of H which is $\sigma(H) = [0, +\infty)$ with no degeneracy for $m \neq 0$ and double degeneracy if $m=0$. Let us state and prove rigorously some of the statements of Ref. 1 in a form which is relevant for the remaining part of this work. First of all, one has to fix a real constant $\beta > 0$,[1] with the physical dimensions $energy^{-1}$, that is necessary for dimensional reasons in defining the relevant domain of operators as it will be clear from the proof of Theorem 2.1. *We assume to use the same value of β throughout this work*. Fix reals $k, m > 0$ and define the dense subspace $\mathcal{D}_k \subset \mathcal{H} \cong L^2(\mathbb{R}^+, dE)$ spanned by vectors:

$$Z_n^{(k)}(E) := \sqrt{\frac{\Gamma(n-k+1)}{E\,\Gamma(n+k)}}\, e^{-\beta E} (2\beta E)^k \mathsf{L}_{n-k}^{(2k-1)}(2\beta E), \qquad n = k, k+1, \ldots, \tag{26}$$

where $\mathsf{L}_p^{(\alpha)}$ are modified Laguerre's polynomials.[24] Notice that $\mathcal{D}_k \subset \mathcal{D}(H)$. Moreover, $\mathcal{D}_k$ is invariant under the linearly independent symmetric operators defined on $\mathcal{D}_k$:

$$H_0 := H \restriction_{\mathcal{D}_k}, \qquad D := -i\left(\frac{1}{2} + E\frac{d}{dE}\right), \qquad C := -\frac{d}{dE} E \frac{d}{dE} + \frac{(k-\frac{1}{2})^2}{E}, \tag{27}$$

which enjoy the commutation relations of the Lie algebra of $\mathrm{SL}(2,\mathbb{R})$, $\mathrm{sl}(2,\mathbb{R})$,

$$[iH_0, iD] = -iH_0, \quad [iC, iD] = iC, \quad [iH_0, iC] = -2iD. \tag{28}$$

iH_0, iC, iD are operatorial realizations of the basis elements of $\mathrm{sl}(2,\mathbb{R})$

$$h = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}, \quad c = \begin{bmatrix} 0 & 0 \\ -1 & 0 \end{bmatrix}, \quad d = \frac{1}{2}\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}. \tag{29}$$

As a consequence, one expects that operators in (27) generate a strongly continuous unitary representation of $\mathrm{SL}(2,\mathbb{R})$. A complete treatment of the representations of $\mathrm{SL}(2,\mathbb{R})$ can be found in Ref. 25–27. Let $\mathcal{L}$ indicate the space of finite real linear combinations of operators in (27), let $\rho: \mathrm{sl}(2,\mathbb{R}) \to i\mathcal{L}$ be the unique Lie algebra isomorphism with $\rho(h) = iH_0$, $\rho(c) = iC$, $\rho(d) = iD$, and let $\widetilde{\mathrm{SL}}(2,\mathbb{R})$ denote the universal covering of $\mathrm{SL}(2,\mathbb{R})$.

Theorem 2.1: *The operators of $\mathcal{L}$ are essentially self-adjoint, $\overline{H_0} = H$ in particular, and we have the following.*

(a) $\mathcal{H}$ is irreducible under the unique unitary strongly continuous representation of $\widetilde{\mathrm{SL}}(2,\mathbb{R})$, $g \mapsto U_g : \mathcal{H} \to \mathcal{H}$ such that $U(\exp(tx)) = e^{it\overline{\rho(x)}}$ for all $x \in sl(2,\mathbb{R})$, $t \in \mathbb{R}$. If (and only if) $k \in \{\frac{1}{2}, 1, \frac{3}{2}, \ldots\}$, U is a representation of $\mathrm{SL}(2,\mathbb{R})$ and it is faithful only if $k = 1/2$. U does not depend on $\beta > 0$.

(b) $\{U_g\}_{g \in \widetilde{\mathrm{SL}}(2,\mathbb{R})}$ is a group of symmetries *of the quantum system, that is, for every $t \in \mathbb{R}$ and $g \in \widetilde{\mathrm{SL}}(2,\mathbb{R})$, there is $g(t) \in \widetilde{\mathrm{SL}}(2,\mathbb{R})$ such that*

$$e^{itH}\, U_g\, A\, U_g^\dagger\, e^{-itH} = U_{g(t)}\, e^{itH}\, A\, e^{-itH}\, U_{g(t)}^\dagger, \tag{30}$$

for every observable (i.e., self-adjoint operator) A. If $g = \exp(uh + vc + wd)$, with $u, v, w \in \mathbb{R}$,

$$g(t)=\exp((u+tw+t^2v)h+(w+2tv)d+vc). \tag{31}$$

(c) For every $t\in\mathbb{R}$, consider the linearly independent elements of $\mathcal{L}$

$$H_0(t):=H_0,\quad D(t):=D+tH,\qquad C(t):=C+2tD+t^2H. \tag{32}$$

The time-dependent observables generated by those operators are constants of motion, i.e.,

$$e^{itH}\,\overline{uH_0(t)+vC(t)+wD(t)}\;e^{-itH}=\overline{uH_0+vC+wD}\,,\quad \text{for every}\quad t,u,v,w\in\mathbb{R}. \tag{33}$$

Proof: (a) $\{Z_n^{(k)}\}_{n=k,k+1,\ldots}$ (26) is a Hilbert base of eigenvectors of the operator $K=\frac{1}{2}(\beta H_0+\beta^{-1}C)$.[1] Moreover, $X=\beta^2H_0^2+\beta^{-2}C^2+2D^2$ is essentially self-adjoint in $\mathcal{D}_k$ because $\{Z_n^{(k)}\}_{n=k,k+1,\ldots}$ are analytic vectors for X since $X=4K^2+cI$ from (28) where $c\in\mathbb{R}$. Since X is essentially self-adjoint, general results due to Nelson (Theorem 5.2, Corollary 9.1, Lemma 9.1 and Lemma 5.1 in Ref. 28) imply that the operators in $i\mathcal{L}$ are essentially self-adjoint on $\mathcal{D}_k$, moreover, they imply the existence and uniqueness of a unitary representation on $\mathcal{H}$ of the unique simply connected group with Lie algebra given by the space generated by $\beta h,\beta^{-1}c,2d$ [that is $\widetilde{\mathrm{SL}}(2,\mathbb{R})$] such that $d/dt\,|_{t=0}U(\exp(tx))=i\overline{\rho(x)}$ for all $x\in\mathrm{sl}(2,\mathbb{R})$. The derivative on the left-hand side is evaluated in the strong operator topology sense on a suitable subspace G (Gårding space[28]) and gives a restriction of the Stone generator of the strongly continuous unitary one-parameter subgroup $\mathbb{R}\ni t\mapsto U(\exp(tx))$. As G contains a dense set of analytical vectors for the elements of $\mathcal{L}$,[28] $-i\,d/dt\,|_{t=0}U(\exp(tx))$ is essentially self-adjoint and thus its closure coincides with the usual Stone generator and $U(\exp(tx))=e^{it\overline{\rho(x)}}$. As $\mathcal{D}_k\subset\mathcal{D}(H)$, the unique self-adjoint extension of H_0, $\overline{H_0}$ must coincide with H itself. Suppose that P is the orthogonal projector onto an invariant subspace for each U_g. P must commute with e^{itK} in particular. Using Stone′s theorem and the fact that the spectrum of K is not degenerate, one has that (in strong operator topology sense) $P=\Sigma_{i\in M}Z_n^{(k)}\langle Z_n^{(k)},\cdot\,\rangle$ where $M\subset\mathbb{N}$. Similarly, P must commute with every element of $\mathcal{L}+i\mathcal{L}$, $A_\pm:=\mp iD+\frac{1}{2}(\beta H_0-\beta^{-1}C)$ in particular. Using the fact that, for every $m,n\in\mathbb{N}$ with $m>0$, $Z_{n+1}^{(k)}=c_nA_+Z_n^{(k)}$ and $Z_{m-1}^{(k)}=c_mA_-Z_m^{(k)}$ for some reals $c_n,c_m>0$,[1] one proves that $M=\mathbb{N}$, that is $P=I$ and so the representation is irreducible. The proof of the fact that the representation of $\widetilde{\mathrm{SL}}(2,\mathbb{R})$ reduces to a representation of $\mathrm{SL}(2,\mathbb{R})$ iff $k\in\{\frac{1}{2},1,\frac{3}{2},\ldots\}$ and that the representation is faithful only for $k=\frac{1}{2}$ is based on the representation of the subgroup $\{\exp t(h+c)\}_{t\in\mathbb{R}}\subset\widetilde{\mathrm{SL}}(2,\mathbb{R})$, which is isomorphic to SO(2) and is responsible for the fact that $\widetilde{\mathrm{SL}}(2,\mathbb{R})$ is multiply connected. The proof has been sketched in Sec. 6.2 and footnote 4 in Ref. 1. The self-adjoint extensions of the elements in $\mathcal{L}$ do not depend on the value of $\beta>0$ — and thus it happens for the representation U itself since every $g\in\widetilde{\mathrm{SL}}(2,\mathbb{R})$ is the finite product of elements of some one-parameter subgroups because, if $\beta'\neq\beta$, there is a subspace $\mathcal{D}$ containing, with obvious notation, both $\mathcal{D}_k^{(\beta)}$ and $\mathcal{D}_k^{(\beta')}$ where each element of $\mathcal{L}$ (which is essentially self-adjoint on both $\mathcal{D}_k^{(\beta)}$ and $\mathcal{D}_k^{(\beta')}$) determines the same symmetric extension no matter if one starts with $\mathcal{D}_k^{(\beta)}$ or $\mathcal{D}_k^{(\beta')}$. That extension is essentially self-adjoint since $\mathcal{D}_k^{(\beta)}$ is a dense set of analytic vectors in $\mathcal{D}$. To prove (b) and (c) notice that $e^{itH}=U(\exp(th))$. So, if $g\in\widetilde{\mathrm{SL}}(2,\mathbb{R})$, $g(t):=\exp(th)g(\exp(th))^{-1}$ fulfills (30) by application of the representation U. Define $h(t):=\rho^{-1}(H_0(t))$, $c(t):=\rho^{-1}(C(t))$, $d(t):=\rho^{-1}(D(t))$. These matrices satisfy the commutation rules (28) for every t. Using (28) and uniqueness theorems for matrix-valued differential equations one gets, for $s,t,u,v,w\in\mathbb{R}$,

$$\exp\{th\}\exp\{s(uh(t)+vc(t)+wd(t))\}(\exp\{th\})^{-1}=\exp\{s(uh+vc+wd)\},$$

which is (31) if $s=1$. Applying U on both sides one gets $\exp(itH)\exp[is\,\overline{uH_0(t)+vC(t)+wD(t)}\,\exp(-itH)=\exp(is\,\overline{uH_0+vC+wD})$, which is equivalent to $\exp[is\exp\{itH\}uH_0(t)+vC(t)+wD(t)\exp\{-itH\}]=\exp(is\,uH_0+vC+wD)$. Stone's theorem entails (33) by strongly differentiating both sides in s. □

The generalization to the case $m=0$ is trivial: The theorem holds true separately in each space $L^2(\mathbb{R}^+,dE)$ of $\mathcal{H}\cong L^2(\mathbb{R}^+,dE)\oplus L^2(\mathbb{R}^+,dE)$.

Remarks: (1) From now on we assume to work in the *Heisenberg representation*. Within this picture, by (33), H, $\overline{C}$, $\overline{D}$ coincide with the Heisenberg evolution of, respectively, $\overline{H_0(t)}$, $\overline{C(t)}$, $\overline{D(t)}$ at time t. Moreover, in this picture, $e^{-i\tau H}\psi_+$ must not be seen as the time evolution (at time τ) of the state ψ_+ (given at time 0), but it must be considered as a different state altogether. This turns out to be in accordance with the relationship between states and wave functions (see Sec. II E): ψ and $\alpha_{-\tau}^{(\partial_t)}(\psi)$ are two different wave functions. This point of view will be useful shortly in a context where time evolution makes no sense at all.

(2) The found $\mathrm{SL}(2,\mathbb{R})$ symmetry is only due to the shape of the spectrum of $\sigma(H)$ which is $[0,+\infty)$. The absence of degeneracy implies that the representation is irreducible. From a physical point of view, invariance under the conformal group $\mathrm{SL}(2,\mathbb{R})$ could look very unexpected if $m>0$ since the theory admits the scale m. However, that scale does not affect the spectrum of H. In physical terms this is due to the gravitational energy which is encompassed by H itself since the Rindler frame represents the space–time experienced by an accelerated observer.

(3) It is clear that the found $\mathrm{SL}(2,\mathbb{R})$ symmetry can straightforwardly be extended to the free-field quantization by defining multi-particle operators generated by H,C,D.

(4) Generators iH_0, iD, *differently* from iH_0 and iC, define a basis of the Lie algebra of a subgroup of $\mathrm{SL}(2,\mathbb{R})$, $\mathrm{SL}_+^{\triangle}(2,\mathbb{R})$, made of real 2×2 upper triangular matrices with unitary determinant and positive trace. Equation (30) holds for U_g, $g\in \mathrm{SL}_+^{\triangle}(2,\mathbb{R})$, giving rise to another smaller symmetry of the system. The subgroup generated by iH_0 trivially enjoys the same fact.

E. Hidden and manifest symmetries

A differentiable group of *geometric* symmetries of a classical Klein–Gordon field in $\mathbf{R}$ (however, everything we say can be extended to any globally hyperbolic space–time along the procedures presented in Ref. 21) is defined as follows. Take a differentiable, locally bijective, representation, $G\ni g\mapsto d_g$, of a connected Lie group, G, where $d_g:\mathbf{R}\to\mathbf{R}$ are isometries. The representation automatically induces a group of transformations $\{\alpha_g\}_{g\in G}$ of scalar fields $f:\mathbf{R}\to\mathbb{R}$ (or $\mathbb{C}$), with $(\alpha_g(f))(x):=f(d_{g^{-1}}(x))$. As d_g are (orientation-preserving) isometries, α_g define *geometric symmetries* of the field in the sense that they transform elements of $\mathcal{S}$ into elements of $\mathcal{S}$ not affecting the symplectic form. If quantization is implemented, solutions of the equation of motion in $\mathcal{S}$ are associated with one-particle quantum states through the decompositions (11) and (13). Consider a group of quantum symmetries in the sense of (30), described by a strongly continuous representation of a Lie group G in terms of unitary operators $\{U_g\}_{g\in G}$. In this picture, the one-parameter unitary group generated by the Hamiltonian is assumed to be a subgroup of $\{U_g\}_{g\in G}$. If the symmetry "does not depend on time," i.e., $g(t)=g$ in (30), that assumption can be dropped or, equivalently, the subgroup generated by the Hamiltonian can be considered in the center of $\{U_g\}_{g\in G}$ (i.e., it commutes with the other elements of the group). If $\{U_g\}_{g\in G}$ is related, by means of (11), (13), and (14), to a group of geometric symmetries $\{\alpha_g\}_{g\in G}$, that is $\widetilde{(\alpha_g(\psi))}_+ = U_g\tilde{\psi}_+$ for all $g\in G$ and $\psi\in\mathcal{S}$, we say that the symmetry is *manifest*. Otherwise we say that the symmetry is *hidden*. In Rindler space, the quantum symmetry group $\{e^{i\tau H}\}_{\tau\in\mathbb{R}}$ gives rise to manifest symmetry because it is associated with the geometric group of symmetries $\{\alpha_\tau\}_{\tau\in\mathbb{R}}$, induced by the one-parameter group of isometries generated by the Killing vector ∂_t. The situation changes dramatically if considering the whole $\widetilde{\mathrm{SL}}(2,\mathbb{R})$ symmetry. The space of Killing fields of $\mathbf{R}$ has a basis $\partial_t,\partial_X,\partial_T$ with $\{\partial_T,\partial_X\}=0$, $\{\partial_T,\partial_t\}=\partial_X$ and $\{\partial_X,\partial_t\}=\partial_T$. ($X$ and T are the spatial and temporal coordinates of a Minkowski frame with $\partial_t=X\partial_T+T\partial_X$.) It is trivially proven that no Killing field $a\partial_t+b\partial_X+c\partial_T$ enjoys, with respect to ∂_t, the commutation rule that D enjoys with respect to H_0 in (28) so that no Killing field corresponding to C makes sense. Summarizing, $\mathbf{R}$ cannot support isometry representations of $\mathrm{SL}(2,\mathbb{R})$ [or $\widetilde{\mathrm{SL}}(2,\mathbb{R})$] or the subgroup $\mathrm{SL}_+^{\triangle}(2,\mathbb{R})$ generated by H_0,D. Hence the whole $\mathrm{SL}(2,\mathbb{R})$ symmetry and that associated with D are *hidden*.

III. CONFORMAL FIELD ON THE HORIZON

A. Restriction to horizons

In Ref. 1, a similar analysis is performed for $\mathbf{AdS}_2$ space–time since the spectrum of the Hamiltonian of a particle has the same structure as that in Rindler space. However, as a remarkable difference, SL(2,$\mathbb{R}$) is a *manifest* symmetry of a quantum particle moving in $\mathbf{AdS}_2$ because SL(2,$\mathbb{R}$) admits a representation in terms of $\mathbf{AdS}_2$ isometries.

Coming back to Rindler space viewed as a (open) submanifold of Minkowski space–time, a natural question arises: "*Regardless the found* SL(2,$\mathbb{R}$) *symmetry is hidden, does it become manifest if one considers quantum field theory in an appropriate subregion of* $\mathbf{R}\cup\partial\mathbf{R}$?"

We shall see that investigation on this natural question has several implications with holography because it naturally leads to the formulation of a quantum field theory on the horizon which is algebraically and unitarily related with that formulated in the bulk, but also it suggests that the symmetry of the theory is greater than SL(2,$\mathbb{R}$), it being described by a *Virasoro algebra*. It is clear from Sec. II E that the only region which could give a positive answer to the question is the boundary $\partial\mathbf{R}$ of the Rindler wedge, i.e., a *bifurcate Killing horizon* made of three disjoint parts $\mathbf{F}\cup\mathbf{P}\cup\mathbf{S}$. **S** (a point in our 2D case) is the spacelike submanifold of Minkowski space–time where the limit of the Killing field ∂_t vanishes whereas the lightlike submanifold of Minkowski space–time **F** and **P** (the former in the causal future of the latter) are the *future* and the *past* horizons, respectively, where the limit of ∂_t becomes lightlike but does *not* vanish. Since the induced metric on $\mathbf{F}\cup\mathbf{P}$ is degenerate, the diffeomorphisms of $\mathbf{F}\cup\mathbf{P}$ can be viewed as isometries and the question about a possible *manifest* SL(2,$\mathbb{R}$) symmetry on the horizon must be interpreted in that sense: The unitary representation has to be associated with a group of diffeomorphisms induced by a Lie algebra of vector fields defined on the horizon.

To go on, let us investigate the limit of wave functions when the horizon is approached by Rindler-time evolution. To this end, consider the Rindler light coordinates (4). **F** is represented by $u\to+\infty$, $v\in\mathbb{R}$, whereas **P** is given by $v\to-\infty$, $u\in\mathbb{R}$. Coordinates u,v actually cover the Rindler space only, but, separately, the limit of v is well defined on the lightlike submanifold **F** and the limit of u is well defined on the submanifold **P** and they define well-behaved global coordinate frames on these submanifolds. [*It holds in the* 2D *case. For greater dimension,* v (*resp.,* u) *together with other "transverse" coordinates defines global coordinates on* **F** (*resp.,* **P**) *as well.*] This can be proven by passing to Minkowski light coordinates $U:=T-X, V:=T+X$ which satisfy $V=e^{\kappa v}$, $U=e^{-\kappa u}$ in **R**. So, from now v and u are also interpreted as coordinates on **F** and **P**, respectively. We have the following remarkable technical result (where, if $a\in\mathbb{C}$, "$a+$c.c." means "a $+complex\ conjugation\ of\ a$").

Proposition 3.1: Take $\psi\in\mathcal{S}$, *with associated (Rindler) positive frequency parts* $\tilde{\psi}_+$ *or* $\tilde{\psi}_+^{(\alpha)}$ *as in (11) and (13) and consider the evolution of* ψ *in the whole Minkowski space–time. In coordinate* $v\in\mathbb{R}$, *the restriction of* ψ *to* **F** *reads, respectively, for* $m>0$ *and* $m=0$,

$$\psi(v)=\int_{\mathbb{R}^+}\frac{e^{-iEv}}{\sqrt{4\pi E}}N_{m,\kappa}(E)\,\tilde{\psi}_+(E)\;dE+\text{c.c.},\quad \psi(v)=\int_{\mathbb{R}^+}\frac{e^{-iEv}}{\sqrt{4\pi E}}\,\tilde{\psi}_+^{(\text{in})}(E)\;dE+\text{c.c.}\tag{34}$$

In coordinate $u\in\mathbb{R}$, *the restriction of* ψ *to* **P** *reads, respectively, for* $m>0$ *and* $m=0$,

$$\psi(u)=\int_{\mathbb{R}^+}\frac{e^{-iEu}}{\sqrt{4\pi E}}\overline{N_{m,\kappa}(E)}\,\tilde{\psi}_+(E)\;dE+\text{c.c.},\quad \psi(u)=\int_{\mathbb{R}^+}\frac{e^{-iEu}}{\sqrt{4\pi E}}\,\tilde{\psi}_+^{(\text{out})}(E)\;dE+\text{c.c.}\tag{35}$$

The function $N_{m,\kappa}$ [*that is restricted to* $\mathbb{R}^+$ *in (34) and (35)*] *can be defined on the whole* $\mathbb{R}$ *as*

$$N_{m,\kappa}(E):=e^{-i\,(E/\kappa)\log(m/2\kappa)}\;\text{sign}(E)\;\Gamma\left(\frac{iE}{\kappa}\right)\sqrt{\frac{E}{\kappa\pi}\sinh\frac{\pi E}{\kappa}}\,.\tag{36}$$

It belongs to $C^\infty(\mathbb{R})$ *and satisfies* $|N_{m,\kappa}(E)|=1$ *and* $\overline{N_{m,\kappa}(E)}=-N_{m,\kappa}(-E)$ *for all* $E\in\mathbb{R}$.

Proof: As $t=0$ is part of a Cauchy surface in Minkowski space–time, ψ can uniquely be extended into a smooth solution of the Klein–Gordon equation in Minkowski space–time. Therefore it makes sense to consider its restriction to **P** or **F**. As ψ is smooth, those restrictions can be computed by taking the limit of the function represented in light Rindler coordinates. First consider the case $m=0$ and $u\to\infty$. One has $\Phi_E^{(\mathrm{out})}(t(u,v),y(u,v))=e^{-iEu}/\sqrt{4\pi E}$ and $\Phi_E^{(\mathrm{in})}(t(u,v),y(u,v))=e^{-iEv}/\sqrt{4\pi E}$. Insert these functions in (13) and extend each integration on the whole $\mathbb{R}$ axis by defining $\widetilde{\psi}_+^{(\alpha)}(E)=0$ for $E\leqslant 0$. Using the properties of $\widetilde{\psi}_+^{(\alpha)}$ stated in Proposition 2.1 before (13) one sees that $\psi(u,v)$ can be decomposed as a sum of two functions (one in the variable u and the other in the variable v) which are the real part of the Fourier transform of a couple of $L^1(\mathbb{R})$ functions. Taking the limit $u\to+\infty$ the function containing only modes *out* vanishes as a consequence of Riemann–Lebesgue lemma and (34) with $m=0$ arises. The case $m=0$ and $v\to-\infty$ is strongly analogous. The case $m>0$ is based on the following expansion[24] at $x\to 0$ with ω fixed in $\mathbb{R}$:

$$K_{i\omega}(x)=\frac{i\pi e^{\pi\omega/2}}{2}\left(\frac{ix}{2}\right)^{i\omega}\frac{1+O_\omega(x^2)}{\Gamma(1+i\omega)\sinh(\pi\omega)}-\frac{i\pi e^{-\pi\omega/2}}{2}\left(\frac{ix}{2}\right)^{-i\omega}\frac{1+O'_\omega(x^2)}{\Gamma(1-i\omega)\sinh(\pi\omega)}\,, \tag{37}$$

where, for ω fixed, $|O_\omega(x^2)|\leqslant C_\omega|x|^2$ and $|O'_\omega(x^2)|\leqslant C'_\omega|x|^2$ for some real finite C_ω, C'_ω, whereas for x fixed in $\mathbb{R}$, $\omega\mapsto|O_\omega(x^2)|$ and $\omega\mapsto|O'_\omega(x^2)|$ are bounded. Inserting the expansion above in the expression (8) and taking the limit as $u\to\infty$ in (11), Riemann–Lebesgue's lemma together with some trivial properties of Γ function[24] produces (34) for $m>0$. The function (36) is nothing but $\mathrm{sign}(E)\ \exp[-iE(\log(m/2\kappa))/\kappa]\Gamma(iE/\kappa)|\Gamma(iE/\kappa)|^{-1}$ (Ref. 24) and so $|N_{m,\kappa}(E)|=1$ for $E\neq 0$ is trivially true. $\Gamma(ix)$ is smooth along the real axis with a simple pole in $x=0$ that is canceled out by the zero of $\mathrm{sign}(x)\sqrt{x\sinh x}$ that is smooth in the whole $\mathbb{R}$. Thus $N_{m,\kappa}\in C^\infty((-\infty,+\infty))$. $|N_{m,\kappa}(E)|=1$ for $E=0$ is trivially valid by continuity. $\overline{N_{m,\kappa}(E)}=-N_{m,\kappa}(-E)$ is a straightforward consequence of $\overline{\Gamma(ix)}=\Gamma(-ix)$ for $x\in\mathbb{R}$. The case $v\to-\infty$ can be proven similarly. □

From a pure mathematical point of view perhaps straightforwardly extending known results (see Chap. 5 of Ref. 21), Proposition 3.1 shows that a solution in $\mathcal{S}$ of the massive Klein–Gordon equation in 2D Rindler space is completely determined by its values on *either* the future *or* the past horizon, whereas, in the massless case, a solution $\mathcal{S}$ is completely determined by its values on *both* the future *and* the past horizon.

As $|N_{m,\kappa}(E)|=1$ we can write $N_{m,\kappa}(E)=\exp[i\rho_{m,\kappa}(E)]$ where the phase $\rho_{m,\kappa}(E)$ is real-valued. The restriction of ψ to the horizon **F** (the other case is analogous) depends from the mass of the field through the phase $\rho_{m,\kappa}$ only. As a trivial result we see that two (free scalar QFT) theories in **R** with different strictly positive masses $m\neq m'$ and Rindler vacua $\Psi_m,\Psi_{m'}$ turn out to be unitarily equivalent. This is due to the unitary operator $U:\mathfrak{F}(\mathcal{H}_m)\to\mathfrak{F}(\mathcal{H}_{m'})$ naturally defined by the requirement $U\Psi_m=\Psi_{m'}$ and induced by the scalar-product-preserving map between positive frequency wave functions,

$$\psi_+\mapsto\psi'_+\quad,\quad\text{with}\quad \psi'_+(E):=\exp[+i(\rho_{m,\kappa}(E)-\rho_{m',\kappa}(E))]\psi_+(E)\qquad\text{for all}\quad E\geqslant 0,$$

where $\psi_+\in\mathcal{H}_m$ and $\psi'_+\in\mathcal{H}_{m'}$. Similarly, each theory is unitarily equivalent to the massless theory built up using only *in* modes. Avoiding any choice for the mass, one is naturally lead to consider the class of the "fields defined on the horizon,"

$$\psi(v)=\int_{\mathbb{R}^+}\frac{e^{-iEv}}{\sqrt{4\pi E}}\widetilde{\psi}_+(E)\ dE+\int_{\mathbb{R}^+}\frac{e^{+iEv}}{\sqrt{4\pi E}}\overline{\widetilde{\psi}_+(E)}\ dE, \tag{38}$$

as the object which makes possibles all those crossed unitary identifications and exists independently from the quantum fields defined in the bulk **R** with their own masses. We want to try to consider this object as a *quantum* field in a sense we go to specify.

B. Local quantum field theory on F and P

Following the procedure presented in Secs. II B and C we want to show that it is possible to define a local quantum field theory on **F** which matches with that defined in the bulk. (That idea is not new in the literature and it has been used in important works such as Ref. 29). First of all define the space of ''wave functions'' $\mathcal{S}(\mathbf{F})$. A suitable definition, which will be useful later, is the following: $\mathcal{S}(\mathbf{F})$ is the space $\mathsf{S}(\mathbb{R};\mathbb{R})$ of the real-valued Schwartz' functions on $\mathbb{R}$ where $\mathbb{R}$ is identified with **F** itself by means of the coordinate v. Actually the name ''wave function'' is not appropriate because there is no wave equation to fulfill in our context. As a consequence the correct point of view to interpret the formalism is the Heisenberg's picture. $\mathcal{S}(\mathbf{F})$ has a natural nondegenerate symplectic form which is *invariant under the diffeomorphisms of* **F** *which preserve its orientation*:

$$\Omega_{\mathbf{F}}(\varphi,\varphi') := \int_{\mathbf{F}} \varphi' d\varphi - \varphi d\varphi'. \tag{39}$$

To define the one-particle Hilbert space, consider the modes

$$F_E(v) := \frac{e^{-iEv}}{\sqrt{4\pi E}} \quad \text{with } E \in \mathbb{R}^+. \tag{40}$$

Analogous definitions can be given with analogous notations for the past horizon **P** using modes as in (40) with $-iEv$ replaced for $-iEu$. The following pair of propositions can be simply proven using Fourier transform theory for Schwartz' functions.

Proposition 3.2 (completeness of modes): If φ *belongs to* $\mathcal{S}(\mathbf{F})$*, the function*

$$\mathbb{R}^+ \ni E \mapsto \tilde{\varphi}_+(E) := -i\Omega_{\mathbf{F}}(\overline{F_E},\phi) \tag{41}$$

satisfies $\tilde{\varphi}_+(E) = \sqrt{E}g(E)$, $\overline{\tilde{\varphi}_+(E)} = \sqrt{E}g(-E)$, *where* $g \in \mathsf{S}(\mathbb{R},\mathbb{R})$. *Moreover, for* $v \in \mathbb{R}$ *(38),*

$$\varphi(v) = \int_0^{+\infty} F_E(v)\tilde{\varphi}_+(E)\, dE + \int_0^{+\infty} \overline{F_E(v)\tilde{\varphi}_+(E)}\, dE. \tag{42}$$

Similar results hold replacing **F** *for* **P** *everywhere*.

Proposition 3.3 (associated Hilbert spaces): If φ *belongs to either* $\mathcal{S}(\mathbf{F})$*, define the one-to-one associated* positive-frequency wave function

$$\varphi_+(v) := \int_0^{+\infty} F_E(v)\tilde{\varphi}_+(E)\, dE. \tag{43}$$

With that definition and for φ_1, φ_2 *in* $\mathcal{S}(\mathbf{F})$*, it results that* $\Omega_{\mathbf{F}}(\varphi_{1+},\varphi_{2+}) = 0$ *whereas*

$$\langle \varphi_{1+},\varphi_{2+}\rangle_{\mathbf{F}} := -i\Omega_{\mathbf{F}}(\overline{\varphi_{1+}},\varphi_{2+}), \tag{44}$$

is well-defined and

$$\langle \varphi_{1+},\varphi_{2+}\rangle_{\mathbf{F}} = \int_0^{+\infty} \overline{\tilde{\varphi}_{1+}(E)}\tilde{\varphi}_{2+}(E)\, dE. \tag{45}$$

The one-particle Hilbert space $\mathcal{H}_{\mathbf{F}}$ *is defined as the Hilbert completion of the space of finite complex linear combinations of functions* φ_+, *for all* φ *in* $\mathcal{S}(\mathbf{F})$, *equipped with the extension of the scalar product (44) to complex linear combinations of arguments. It results that* $\mathcal{H}_{\mathbf{F}} \cong L^2(\mathbb{R}^+, dE)$. *Similar results and definitions hold replacing* **F** *for* **P** *everywhere.*

Definition 3.1 (quantum field operators on horizons): Consider the symmetrized Fock space $\mathfrak{F}_{\mathbf{F}}(\mathcal{H}_{\mathbf{F}})$ *with vacuum state* $\Psi_{\mathbf{F}}$ *and scalar product* $\langle\ ,\rangle_{\mathbf{F}}$. *The quantum field operator on* **F**, $\Omega_{\mathbf{F}}(\ .\ , \hat{\phi}_{\mathbf{F}})$, *is the symmetric-operator-valued function*

$$\varphi \mapsto \Omega(\varphi, \hat{\phi}_{\mathbf{F}}) := i a_{\mathbf{F}}(\overline{\varphi_+}) - i a^\dagger_{\mathbf{F}}(\varphi_+), \tag{46}$$

where $\varphi \in \mathcal{S}(\mathbf{F})$. *Here* $a_{\mathbf{F}}(\overline{\varphi_+})$ *and* $a^\dagger_{\mathbf{F}}(\varphi_+)$, *respectively, denote the annihilation and construction operators associated with the one-particle state* φ_+ *which are defined in the dense invariant subspace* $\mathfrak{F}_{0\mathbf{F}}$ *spanned by all states containing a finite, arbitrarily large, number of particles with states given by positive-frequency wave functions. An analogous definition is given replacing* **F** *for* **P** *everywhere.*

Operators $\Omega_{\mathbf{F}}(\varphi, \hat{\phi}_{\mathbf{F}})$ and $\Omega_{\mathbf{P}}(\varphi, \hat{\phi}_{\mathbf{P}})$ are essentially self-adjoint on $\mathfrak{F}_{0\mathbf{F}}$ and $\mathfrak{F}_{0\mathbf{P}}$, respectively, since their elements are analytic vectors.

We want to define an analogous procedure to that in the bulk [see (20)] for smearing field operators by means of ''functions'' instead of ''wave functions.'' The issue is however relevant because it permits us to introduce the analog $E_{\mathbf{F}}$ of the causal propagator E in spite of having no equation of motion in **F**. The idea is that something like (19) should work also in our context. A clear difficulty is that there is no diffeomorphism invariant measure which can be used in the analog of (19) in place of $d\mu_g$. On the other hand, integration of k-forms is diffeomorphism invariant on (oriented manifolds). Therefore, we aspect that the space of ''functions'' used to smear quantum fields should properly be a space of one-forms rather than functions. To go on, we notice that *a posteriori* $E_{\mathbf{F}}$ has to fulfill something like $[\hat{\phi}_{\mathbf{F}}(v), \hat{\phi}_{\mathbf{F}}(v')] = -iE_{\mathbf{F}}(v, v')$. By a formal but straightforward computation which uses $[a_E, a^\dagger_{E'}] = \delta(E - E')$ and the analog of (18) with Φ_E replaced for F_E, one finds that $i[\hat{\phi}_{\mathbf{F}}(v), \hat{\phi}_{\mathbf{F}}(v')] = \frac{1}{4}\text{sign}\,(v - v')$. This v-parametrized distribution actually defines a well-behaved transformation from the space of exact (smooth) one-forms in **F** with compact support to the space of smooth functions on **F**. As the functions $f \in \mathcal{S}(\mathbf{F})$ vanish (with all of their derivatives) as $v \to \infty$, if $\eta = df$,

$$\int_{v' \in \mathbb{R}} \text{sign}\,(v - v')\,\eta(v') = f(v) - (-f(v)) = 2\,f(v).$$

In the following, $\mathcal{D}(\mathbf{F})$ is the real space of the one-forms $\eta = d\varphi$ such that $\varphi \in \mathcal{S}(\mathbf{F})$.

Definition 3.2 (causal propagator and associated quantum field on horizons): With the given notations, the causal propagator *in* **F** *is the mapping* $E_{\mathbf{F}} : \mathcal{D}(\mathbf{F}) \to \mathcal{S}(\mathbf{F})$ *with*

$$(E_{\mathbf{F}}\eta)(v) := \frac{1}{4}\int_{v' \in \mathbb{R}} \text{sign}\,(v - v')\,\eta(v'), \tag{47}$$

and the quantum-field operator on **F** smeared with forms η of $\mathcal{D}(\mathbf{F})$ *is the mapping*

$$\eta \mapsto \hat{\phi}_{\mathbf{F}}(\eta) := \Omega_{\mathbf{F}}(E_{\mathbf{F}}\eta, \hat{\phi}_{\mathbf{F}}). \tag{48}$$

Analogous definitions are given replacing **F** *for* **P** *and* v *for* u *everywhere.*

The given definitions are good generalizations of the analogous tools in the usual quantum field theory [see (19) and (21) in particular] as stated in the following pair of propositions whose proof is trivial. The second item in Proposition 3.5 shows that the theory enjoys *locality* in a suitable way

Proposition 3.4: If $\varphi \in \mathcal{S}(\mathbf{F})$, $\omega = 2d\varphi$ *is the unique element of* $\mathcal{D}(\mathbf{F})$ *such that* $\varphi = E_{\mathbf{F}}(\omega)$. *Moreover, if* $\eta, \omega \in \mathcal{D}(\mathbf{F})$,

$$\int_{\mathbf{F}} \varphi\,\eta = \Omega_{\mathbf{F}}(E_{\mathbf{F}}\eta,\varphi) \quad \text{and} \quad \int_{\mathbf{F}} (E_{\mathbf{F}}\omega)\,\eta = \Omega_{\mathbf{F}}(E_{\mathbf{F}}\eta, E_{\mathbf{F}}\omega)\ . \tag{49}$$

An analogous result holds replacing **F** *for* **P** *everywhere.*

Proposition 3.5: If $\varphi \in \mathcal{S}(\mathbf{F})$ *and* $\eta,\omega \in \mathcal{D}(\mathbf{F})$,

$$[\hat{\phi}_{\mathbf{F}}(\eta), \hat{\phi}_{\mathbf{F}}(\omega)] = -iE(\eta,\omega) := -i\int_{\mathbf{F}} (E_{\mathbf{F}}\eta)\,\omega. \tag{50}$$

In particular, the following locality property holds true:

$$[\hat{\phi}_{\mathbf{F}}(\eta), \hat{\phi}_{\mathbf{F}}(\omega)] = 0 \qquad \text{if } \mathrm{supp}\,\eta \cap \mathrm{supp}\,\omega = \varnothing.$$

An analogous result holds replacing **F** *for* **P** *everywhere.*

C. The algebraic approach

To state holographic theorems it is necessary to reformulate quantum field theory in an algebraic approach either in the bulk and on the horizon. In globally hyperbolic space–times, linear QFT can be formulated independently from a preferred vacuum state and Fock representation. It is worthwhile stressing that[21] physics implies the existence of meaningful quantum states which cannot be represented in the same Hilbert (Fock) representation of the algebra of observables. In this sense the algebraic approach is more fundamental than the usual Fock approach in QFT in curved space–time. Let us summarize the procedure in **R** which, at least for $m>0$, could be replaced by any globally hyperbolic space–time. The basic tool is an abstract $*$-algebra, $\mathcal{A}_{\mathbf{R}}$, made of the linear combinations of products of formal field operators $\phi(f), \phi(f)^*$ ($f \in \mathcal{D}(\mathbf{R};\mathbb{C})$) and the unit I, which enjoy the same properties of operators $\hat{\phi}(f), \hat{\phi}(f)^\dagger$ (and the identity operator I). From a physical point of view, the Hermitian elements of $\mathcal{A}_{\mathbf{R}}$ represent the *local observables* of the free-field theory. For $m>0$, the required properties are

(1) $\phi(f)^* = \phi(\overline{f})$ for all $f \in \mathcal{D}(\mathbf{R};\mathbb{C})$,
(2) $\phi(af+bg) = a\phi(f) + b\phi(g)$ for all $f,g \in \mathcal{D}(\mathbf{R};\mathbb{C})$, $a,b \in \mathbb{C}$,
(3) $[\phi(f),\phi(g)] = -iE(f,g)I$ for all $f,g \in \mathcal{D}(\mathbf{R};\mathbb{C})$, and
(4) $\phi(f) = 0$ if (and only if) $f = Kh$ for some compactly-supported smooth function h.

$\mathcal{A}_{\mathbf{R}}$ is rigorously realized as follows. Consider the complex unital algebra $\mathcal{A}_{0\mathbf{R}}$, freely generated by the unit I, and abstract objects $\phi(f)$ and $\phi(f)^*$ for all $f \in \mathcal{D}(\mathbf{R};\mathbb{C})$. The involution * on $\mathcal{A}_{0\mathbf{R}}$ is the unique antilinear involutive function $^*{}_{:\mathcal{A}_{0\mathbf{R}} \to \mathcal{A}_{0\mathbf{R}}}$ such that $I^* = I$, $(\phi(f))^* = \phi(f)^*$. Let $\mathcal{J} \subset \mathcal{A}_{\mathbf{R}}$ be the double-side ideal whose elements are linear combinations of products containing at least one of the following factors $\phi(f)^* - \phi(\overline{f})$, $\phi(af+bg) - a\phi(f) - b\phi(g)$, $[\phi(f),\phi(g)] + iE(f,g)I$, and $\phi(Kg)$ for $f,g \in \mathcal{D}(\mathbf{R};\mathbb{C})$, $a,b \in \mathbb{C}$. $\mathcal{A}_{\mathbf{R}}$ is defined as the space of equivalence classes with respect to the equivalence relation in $\mathcal{A}_{0\mathbf{R}}$, $A \sim B$ iff $A - B \in \mathcal{J}$ and $\mathcal{A}_{\mathbf{R}}$ is equipped with the $*$-structure induced by $\mathcal{A}_{0\mathbf{R}}$ through $\sim$. If, with little misuse of notation, $\phi(f)$ and I, respectively, denote the classes $[\phi(f)]$ and $[I] \in \mathcal{A}_{\mathbf{R}}$, the properties (1)–(4) are fulfilled.

If $m=0$, there are two relevant algebras $\mathcal{A}_{\mathbf{R}}^{(in)}$ and $\mathcal{A}_{\mathbf{R}}^{(out)}$. $\mathcal{A}_{\mathbf{R}}^{(in)}$ is the unital $*$-algebra generated by I, $\phi_{\mathrm{in}}(f)$ and $\phi_{\mathrm{in}}(f)^*$ for every $f \in \mathcal{D}(\mathbf{R},\mathbb{C})$ whereas $\mathcal{A}_{\mathbf{R}}^{(out)}$ is the unital $*$-algebra generated by I, $\phi_{\mathrm{out}}(f)$ and $\phi_{\mathrm{out}}(f)^*$ for every $f \in \mathcal{D}(\mathbf{R},\mathbb{C})$. By definition these algebras satisfy the constraints (1)–(4) with the difference that, in (3), E must be replaced for E_{in} or E_{out}, respectively, and, in (4), K must be replaced by $\gamma^{-1}\partial_u$ or $\gamma^{-1}\partial_v$, respectively. The rigorous definitions can be given similarly to the case $m>0$, by starting from freely generated algebras and passing to quotient algebras. We recall that if $\mathcal{A}$, $\mathcal{B}$ are $*$-algebras with field $\mathbb{C}$ and units $I_{\mathcal{A}}$, $I_{\mathcal{B}}$, $\mathcal{A}\otimes\mathcal{B}$ denotes (see p. 143 of Ref. 30) the $*$-algebra whose associated vector-space structure is the tensor product $\mathcal{A}\otimes\mathcal{B}$, the unit is $I := I_{\mathcal{A}} \otimes I_{\mathcal{B}}$, and the involution and the algebra product are, respectively, given by $(\Sigma_k A_k \otimes B_k)^* := \Sigma_k A_k^* \otimes B_k^*$ and $(\Sigma_k A_k \otimes B_k)(\Sigma_i A_i' \otimes B_i') := \Sigma_{ki} A_k A_i' \otimes B_k B_i'$

$\otimes B_k B_i'$ with obvious notation. Assuming (24) as the definition of $\phi(f)$, the whole field algebra $\mathcal{A}_{\mathbf{R}}$ is *defined* as $\mathcal{A}_{\mathbf{R}} := \mathcal{A}_{\mathbf{R}}^{(in)} \otimes \mathcal{A}_{\mathbf{R}}^{(out)}$. That unital $*$-algebra satisfies (1)–(4).

An *algebraic state* on a $*$-algebra $\mathcal{A}$ with unit I is a linear map $\mu : \mathcal{A} \to \mathbb{C}$ that is normalized [i.e., $\mu(I) = 1$] and positive [i.e., $\mu(A^*A) \geqslant 0$ for $A \in \mathcal{A}$]. The celebrated GNS theorem (e.g., see Ref. 21) states that for every algebraic state μ on $\mathcal{A}$ there is a triple $(\mathfrak{H}_\mu, \Pi_\mu, \Omega_\mu)$ such that the following facts hold. $\mathfrak{H}_\mu$ is a Hilbert space, and Π_μ is a $*$-algebra representation of $\mathcal{A}$ in terms of operators on $\mathfrak{H}_\mu$ which are defined on a dense invariant subspace $\mathfrak{D}_\mu \subset \mathfrak{H}_\mu$ and such that $\Pi_\mu(A^*) = (\Pi_\mu(A))^\dagger \restriction_{\mathfrak{D}_\mu}$. Finally $\mathfrak{D}_\mu$ is spanned by all the vectors $\Pi_\mu(A)\Omega_\mu$, $A \in \mathcal{A}$, and $\mu(A) = \langle \Omega_\mu, \Pi_\mu(A)\Omega_\mu \rangle$ for all $A \in \mathcal{A}$, $\langle\ ,\ \rangle$ denoting the scalar product in $\mathfrak{H}_\mu$. If $(\mathfrak{H}_\mu', \Pi_\mu', \Omega_\mu')$ is another similar triple associated with the same μ, there is a unitary operator $U : \mathfrak{H}_\mu \to \mathfrak{H}_\mu'$ such that $\Omega_\mu' = U\Omega_\mu$ and $\Pi_\mu' = U\Pi_\mu$. If $\mathcal{A} = \mathcal{A}_{\mathbf{F}}$, by direct inspection one finds that quantum field theory in $\mathbf{R}$ in the Fock space $\mathfrak{F}(\mathcal{H})$ with $\Psi_{\mathbf{R}}$ as vacuum state coincides with that in a GNS representation of $\mathcal{A}_{\mathbf{R}}$ associated with the (*quasifree*[21]) algebraic state $\mu_{\mathbf{R}}$ completely determined by $\mu_{\mathbf{R}}(\phi(f)\phi(g)) := \langle \Psi_{\mathbf{R}}, \hat{\phi}(f)\hat{\phi}(g)\Psi_{\mathbf{R}} \rangle$ via Wick expansion of symmetrized n-point functions. Moreover, it results in $\mathfrak{D}_\mu = \mathfrak{F}_0$.

All the procedure can be used to give an algebraic approach for QFT on $\mathbf{F}$ (or $\mathbf{P}$): Define $\mathcal{D}(\mathbf{F};\mathbb{C}) := \mathcal{D}(\mathbf{F}) + i\mathcal{D}(\mathbf{F})$ and define $\hat{\phi}_{\mathbf{F}}(\omega + i\eta) := \hat{\phi}_{\mathbf{F}}(\omega) + i\hat{\phi}_{\mathbf{F}}(\eta)$ when $\omega, \eta \in \mathcal{D}(\mathbf{F})$. Finally, consider the abstract $*$-algebra $\mathcal{A}_{\mathbf{F}}$ with unit I, generated by I, $\phi_{\mathbf{F}}(\omega)$, $\phi_{\mathbf{F}}(\omega)^*$ for all $\omega \in \mathcal{D}(\mathbf{F};\mathbb{C})$, such that, for all $a, b \in \mathbb{C}$ and $\omega, \eta \in \mathcal{D}(\mathbf{F};\mathbb{C})$,

(1) $\phi_{\mathbf{F}}(\omega)^* = \phi_{\mathbf{F}}(\overline{\omega})$,
(2) $\phi_{\mathbf{F}}(a\omega + b\eta) = a\phi_{\mathbf{F}}(\omega) + b\phi_{\mathbf{F}}(\eta)$, and
(3) $[\phi_{\mathbf{F}}(\omega), \phi_{\mathbf{F}}(\eta)] = -iE_{\mathbf{F}}(\omega, \eta)I$.

(The rigorous definition is given in terms of quotient algebras as usual.) From a physical point of view the (Hermitian) elements of $\mathcal{A}_{\mathbf{F}}$ represent the *(quasi) local observables* of the free-field theory on the future horizon. By direct inspection one finds that quantum field theory in $\mathbf{F}$ in the Fock space referred to the vacuum state $\Psi_{\mathbf{F}}$ and coincides with that in a GNS representation of $*$-algebra $\mathcal{A}_{\mathbf{F}}$ associated with the (quasi-free) algebraic state $\mu_{\mathbf{F}}$ completely determined, via Wick expansion, by $\mu_{\mathbf{F}}(\phi_{\mathbf{F}}(\eta)\phi_{\mathbf{F}}(\omega)) := \langle \Psi_{\mathbf{F}}, \hat{\phi}_{\mathbf{F}}(\eta)\hat{\phi}_{\mathbf{F}}(\omega)\Psi_{\mathbf{F}} \rangle_{\mathbf{F}}$ and $\mathfrak{D}_\mu = \mathfrak{F}_{0\mathbf{F}}$.

Everything can be similarly stated for quantum field theory on $\mathbf{P}$ with trivial changes in notation.

D. Two holographic theorems

Here we prove two *holographic* theorems for the observables of free fields, one in the algebraic approach and the latter in the Hilbert space formulation under the choice of suitable vacuum states. The former theorem says that, in the massive case, there is a one-to-one transformation from the algebra of the fields in the bulk $\mathcal{A}_{\mathbf{R}}$—that is, the local observables of the free field in the bulk—to a subalgebra of fields on the future horizon $\mathcal{A}_{\mathbf{F}}$—that is, the observables of the free field in the future horizon. The mapping preserves the structure of the $*$-algebra and thus the two classes of observables can be identified completely no matter the value of the mass of the field in the bulk and the fact that there is no mass associated with the field on the horizon. Remarkably, this identification does not require any choice for reference vacuum states since it is given at a pure algebraic level. To build up the said mapping, take any compactly supported function f in the bulk, consider the generated wave function $\psi_f = E(f)$ (that is assumed to be defined in the whole Minkowski space), restrict ψ_f on $\mathbf{F}$ obtaining a horizon wave function φ_f and associate with that function the unique form ω_f with $\varphi_f = E_{\mathbf{F}}\omega_f$. Finally, define $\chi_{\mathbf{F}}(\phi(f)) := \phi_{\mathbf{F}}(\omega_f)$. The next step is to extend $\chi_{\mathbf{F}}$ to the whole algebra $\mathcal{A}_{\mathbf{R}}$ by requiring that the $*$-algebra structure is preserved, that is, I is mapped in I, $\phi(f)^*$ is mapped into $\chi_{\mathbf{F}}(\phi(f))^*$, products of fields $\phi(f)\phi(g)$ are mapped into $\chi_{\mathbf{F}}(\phi(f))\chi_{\mathbf{F}}(\phi(g))$ and so on. In the massless case, the procedure is similar but one has to consider also the past evolution of wave functions toward the past horizon $\mathbf{P}$. The theorem says

that the required extensions into algebra homomorphisms actually exists, are uniquely determined and are injective so that the observable algebra in the bulk can be seen as a observable subalgebra on the horizon.

Theorem 3.1 (algebraic holography): *In a 2D Rindler space* $\mathbf{R}$ *viewed as immersed in a corresponding 2D Minkowski space–time, consider quantum field theory of a scalar field with mass* $m \geqslant 0$ *satisfying Klein–Gordon equation (5). Consider the algebra* $\mathcal{A}_{\mathbf{R}}$ *(including* $\mathcal{A}_{\mathbf{R}}^{(out)}$, $\mathcal{A}_{\mathbf{R}}^{(in)}$ *if* $m=0$*) of local observables in the bulk and the algebras* $\mathcal{A}_{\mathbf{F}}$ *and* $\mathcal{A}_{\mathbf{P}}$ *of the observables on the horizons* $\mathbf{F}$ *and* $\mathbf{P}$*. The following statements hold.*

(a) If $m>0$*, there is a unital-*-algebra homomorphism* $\chi_{\mathbf{F}}:\mathcal{A}_{\mathbf{R}}\to\mathcal{A}_{\mathbf{F}}$ *uniquely determined by*

$$\chi_{\mathbf{F}}:\phi(f)\mapsto\phi_{\mathbf{F}}(\omega_f) \quad with\ \omega_f:=2d((Ef)\restriction_{\mathbf{F}}) \quad for\ all\ f\in\mathcal{D}(\mathbf{R}), \tag{51}$$

$(Ef)\restriction_{\mathbf{F}}$ *denoting the limit of* $E(f)$ *on* $\mathbf{F}$*.* $\chi_{\mathbf{F}}$ *turns out to be injective.*

An analogous statement holds replacing $\mathbf{F}$ *for* $\mathbf{P}$*.*

(b) If $m=0$*, there are two unital-*-algebra homomorphisms* $\pi_{\mathbf{P}}:\mathcal{A}_{\mathbf{R}}^{(out)}\to\mathcal{A}_{\mathbf{P}}$ *and* $\pi_{\mathbf{F}}:\mathcal{A}_{\mathbf{R}}^{(in)}\to\mathcal{A}_{\mathbf{F}}$ *uniquely determined by*

$$\pi_{\mathbf{F}}:\phi_{in}(f)\mapsto\phi_{\mathbf{F}}(\eta_f) \quad with\ \omega_f:=2d(E(f)\restriction_{\mathbf{F}}) \ for\ all\ f\in\mathcal{D}(\mathbf{R}), \tag{52}$$

$$\pi_{\mathbf{P}}:\phi_{out}(f)\mapsto\phi_{\mathbf{P}}(\omega_f) \quad with\ \eta_f:=2d(E(f)\restriction_{\mathbf{P}}) \ for\ all\ f\in\mathcal{D}(\mathbf{R}). \tag{53}$$

$\pi_{\mathbf{F}}$ *and* $\pi_{\mathbf{P}}$ *turn out to be injective.*

(c) $\pi_{\mathbf{F}}(\mathcal{A}_{\mathbf{R}}^{(in)})\subset\mathcal{A}_{\mathbf{F}}$ *is the subalgebra generated by* I *and abstracts field operators smeared by the elements of* $\mathcal{D}(\mathbf{F},\mathbb{C})$ *with compact support. The analogous statement holds for* $\pi_{\mathbf{P}}(\mathcal{A}_{\mathbf{R}}^{(out)})$.

Proof: (a) The uniqueness of the homomorphism is trivially proven by noticing that the elements of $\mathcal{A}_{\mathbf{R}}$ are of the form $A=aI+\Sigma_k b_k\phi(f_k)+\Sigma_h c_h\phi(g_h)^*+\Sigma_{ls}d_{ls}\phi(h_l)\phi(p_s)+\cdots$ where the overall summation as well as every partial summation is finite. As $\chi_{\mathbf{F}}$ is a homomorphism, $\chi_{\mathbf{F}}(A)=aI+\Sigma_k b_k\chi_{\mathbf{F}}(\phi(f_k))+\Sigma_h c_h\chi_{\mathbf{F}}(\phi(g_h))^*+\Sigma_{ls}d_{ls}\chi_{\mathbf{F}}(\phi(h_l))\chi_{\mathbf{F}}(\phi(p_s))+\cdots$. Moreover, $\chi_{\mathbf{F}}(\phi(h))=\chi_{\mathbf{F}}(\phi(\mathrm{Re}\,h))+i\chi_{\mathbf{F}}(\phi(\mathrm{Im}\,h))$ and thus the values $\chi_{\mathbf{F}}(\phi(f))$ with h real determine the homomorphism provided it exists. Let us prove the existence of the homomorphism. Take $f\in\mathcal{D}(\mathbf{R})$ and consider $\psi_f=Ef$ and the associated function $\tilde{\psi}_{f_+}=\tilde{\psi}_{f_+}(E)$. It holds $\tilde{\psi}_{f_+}(E)=\sqrt{E}f(E)$ with $f\in\mathsf{S}(\mathbb{R},\mathbb{C})$ such that $\overline{f(E)}=-f(-E)$ as stated in Proposition 2.1 and $N_{m,\kappa}\in C^\infty(\mathbb{R})$ [with $|N_{m,\kappa}(E)|=1$] and $\overline{N_{m,\kappa}(E)}=-N_{m,\kappa}(-E)$ as stated in Proposition 3.1. As a consequence $N_{m,\kappa}(E)\tilde{\psi}_+(E)=\sqrt{E}h(E)$ where $\overline{h(E)}=h(-E)$ and $h\in\mathsf{S}(\mathbb{R},\mathbb{C})$. Passing to the function $v\mapsto\psi_f(v)$ in Proposition 3.1 and using these results one gets

$$\psi_f(v)=\mathrm{const}\times\int_0^{+\infty}e^{-iEv}h(E)dE+\mathrm{c.c.}=\mathrm{const}\times\int_{-\infty}^{+\infty}e^{-iEv}h(E)dE.$$

As h belongs to Schwartz' space, ψ_f belongs to the same space because the Fourier transform preserves Schwartz' space. Moreover, ψ_f is real since $h(E)=\overline{h(-E)}$. We have found that $\psi_f\in\mathcal{S}(\mathbf{F})$ and thus $\omega_f:=2d\psi_f=2d[(Ef)\restriction_{\mathbf{F}}]$ is an element of $\mathcal{D}(\mathbf{F})$. Using $f\in\mathcal{D}(\mathbf{R},\mathbb{C})$, the result is preserved trivially by the linear decomposition in the real and imaginary parts. Assume once again that $f\in\mathcal{D}(\mathbf{R})$. Notice that ω_f contains the same information as ψ_f because $\psi_f(v)=2\int_{-\infty}^{v}\omega_f$. In turn ψ_f determines the function $\tilde{\psi}_{f_+}$ which determines Ef. As we said in Sec. II C, Ef determines f up to a term Kh with $h\in\mathcal{D}(\mathbf{R})$. We conclude that $\omega_f=\omega_g$ if and only if $f=g+Kh$ with $h\in\mathcal{D}(\mathbf{R})$. The same result arises for functions $f,g\in\mathcal{D}(\mathbf{R},\mathbb{C})$ by linearity and from the fact that E transforms real functions into real functions. We have found that there is a well-defined linear map $\mathcal{D}(\mathbf{R},\mathbb{C})\ni f\mapsto\omega_f\in\mathcal{D}(\mathbf{F},\mathbb{C})$ that transforms real functions in real forms and such that $\omega_f=\omega_g$ if and only if $f=g+Kh$. Now we define $\chi_{0\mathbf{F}}(\phi(f))=\phi_{\mathbf{F}}(\omega_f)$ and $\chi_{\mathbf{F}}(I)=I$ and $\chi_{\mathbf{F}}(\phi(f)^*)=\phi_{\mathbf{F}}(\omega_f)^*$. That map extends straightforwardly from the $*$-algebra $\mathcal{A}_{0\mathbf{R}}$ freely generated by I, $\phi(f)$, $\phi(f)^*$ (with involution uniquely determined as said in Sec. II D) to the analogous free $*$-algebra on $\mathbf{F}$ giving rise to a $*$-algebra homomorphism $\chi_{0\mathbf{F}}$. However, it is not injective since it

results in $\chi_{0\mathbf{F}}(\phi(f))=\chi_{0\mathbf{F}}(\phi(g))$ whenever $f=g+Kh$, and, more generally, injectivity failure arises for any pair of elements of the algebra which are different from each other because of the presence of factors $\phi(f)$ and $\phi(g)$ with $f-g=Kh$. The injectivity is, however, restored if we take the quotient $*$-algebra $\mathcal{A}_{1\mathbf{R}}$ in $\mathcal{A}_{0\mathbf{R}}$ with respect to the both-side ideal containing linear combinations of products with at least one factor $\phi(Kf)$ or $\phi(Kf)^*$ for any $f\in\mathcal{D}(\mathbf{F},\mathbb{C})$ and redefine the injective map $\chi_{1\mathbf{F}}:\mathcal{A}_{1\mathbf{R}}\to\mathcal{A}_{0\mathbf{F}}$ as the map induced by $\chi_{0\mathbf{F}}$ through the canonical projection of $\mathcal{A}_{0\mathbf{R}}$ onto $\mathcal{A}_{1\mathbf{R}}$. By construction $\chi_{1\mathbf{F}}$ is an injective $*$-algebra isomorphism. In this context and from now on, it is convenient to think of the objects $\phi(f)$ as smeared by the equivalence class $[f]$ rather than f itself, where $[f]$ belongs to the complex vector space obtained by taking the quotient of $\mathcal{D}(\mathbf{R},\mathbb{C})$ with respect to the subspace $K\mathcal{D}(\mathbf{R},\mathbb{C})$. The map $[f]\mapsto\omega_f$ is a well-defined injective vector space isomorphism that preserves the complex conjugation. To conclude we have to extract the algebras $\mathcal{A}_{\mathbf{R}}$ and $\mathcal{A}_{\mathbf{F}}$ by the procedure outlined in Sec. II D, based on the projection on suitable quotient spaces, and prove that the $*$-homeomorphism $\chi_{1\mathbf{F}}$ induces a $*$-homeomorphism $\chi_{\mathbf{F}}:\mathcal{A}_{\mathbf{R}}\to\mathcal{A}_{\mathbf{F}}$. To this end we have to consider the double-side ideal $\mathcal{J}\subset\mathcal{A}_{1\mathbf{R}}$ whose elements are linear combinations of products containing at least one of the following factors: $\phi(f)^*-\phi(\overline{f})$, $\phi(af+bg)-a\phi(f)-b\phi(g)$, $[\phi(f),\phi(g)]+iE(f,g)I$, for $f,g\in\mathcal{D}(\mathbf{R};\mathbb{C})$, $a,b\in\mathbb{C}$. $\mathcal{A}_{\mathbf{R}}$ is defined as the space of equivalence classes with respect to the equivalence relation in $\mathcal{A}_{1\mathbf{R}}$, $A\sim_{\mathcal{J}}B$ iff $A-B\in\mathcal{J}$ and $\mathcal{A}_{\mathbf{R}}$ is equipped with the $*$-algebra structure induced by $\mathcal{A}_{1\mathbf{R}}$ through the canonical projection. The analogous procedure must be used for $\mathcal{A}_{1\mathbf{F}}$ with respect to an analogous ideal $\mathcal{J}_{\mathbf{F}}\subset\mathcal{A}_{1\mathbf{F}}$ in order to produce $\mathcal{A}_{\mathbf{F}}$. Then the injective $*$-homomorphism $\chi_{1\mathbf{F}}$ induces an injective $*$-homomorphism $\chi_{\mathbf{F}}:\mathcal{A}_{\mathbf{R}}\to\mathcal{A}_{\mathbf{F}}$ if the equivalence relations induced by $\mathcal{J}$ and $\mathcal{J}_{\mathbf{F}}$ are preserved by $\chi_{1\mathbf{F}}$ itself, i.e., $A\sim_{\mathcal{J}}B$ if and only if $\chi_{1\mathbf{F}}(A)\sim_{\mathcal{J}_{\mathbf{F}}}\chi_{1\mathbf{F}}(B)$. We leave the simple but tedious proof of this fact to the reader, proving the only nontrivial point which concerns factors $[\phi(f),\phi(g)]+iE(f,g)I$. It is simply found that, among other trivially fulfilled conditions, the preservation of the equivalence relation arises if $\chi_{1\mathbf{F}}([\phi(f),\phi(g)]+iE(f,g)I)=[\phi_{\mathbf{F}}(\omega_f),\phi_{\mathbf{F}}(\omega_g)]+iE_{\mathbf{F}}(\omega_f,\omega_g)I$, which is equivalent to $E(f,g)=E_{\mathbf{F}}(\omega_f,\omega_g)$. (Notice that, by the known properties of the causal propagator, both sides are invariant under the addition of a term Kh to f or g.) $E(f,g)=E_{\mathbf{F}}(\omega_f,\omega_g)$ is equivalent to, with obvious notations, $\Omega(\psi_f,\psi_g)=\Omega_{\mathbf{F}}(\varphi_f,\varphi_g)$. It is sufficient to prove that identity for real f,g. By Propositions 2.2 and 3.3 one finds $-i\Omega(\psi_f,\psi_g)=\langle\psi_{f+},\psi_{g+}\rangle-\overline{\langle\psi_{f+},\psi_{g+}\rangle}$ and $-i\Omega_{\mathbf{F}}(\varphi_f,\varphi_g)=\langle\varphi_{f+},\varphi_{g+}\rangle_{\mathbf{F}}-\overline{\langle\varphi_{f+},\varphi_{g+}\rangle_{\mathbf{F}}}$. Passing in energy representation, where the scalar product is simply that of $L^2(\mathbb{R}^+,dE)$ in both spaces, ψ_{f+} and ψ_{g+} are represented by some $E\mapsto\tilde{\psi}_{f+}(E)$ and $E\mapsto\tilde{\psi}_{g+}(E)$, respectively, whereas, by Proposition 3.1, φ_{f+} and φ_{g+} are represented by $E\mapsto N_{m,\kappa}(E)\tilde{\psi}_{f+}(E)$ and $E\mapsto N_{m,\kappa}(E)\tilde{\psi}_{g+}(E)$, respectively. Since $|N_{m,\kappa}(E)|=1$, it results that $\langle\psi_{f+},\psi_{g+}\rangle=\langle\varphi_{f+},\varphi_{g+}\rangle_{\mathbf{F}}$ that entails $\Omega(\psi_f,\psi_g)=\Omega_{\mathbf{F}}(\varphi_f,\varphi_g)$ and concludes the proof. (b) Following a proof very similar to that as in the case (b) (but simpler since the phases $N_{m,\kappa}$ disappear when one uses Proposition 3.1) one sees that $\mathcal{A}_{\mathbf{R}}^{(\mathrm{in})}$ is isomorphic to $\mathcal{A}_{\mathbf{F}}$ under the unique extension, into an injective $*$-algebra-with-unit homomorphism, of the map $\pi_{\mathbf{F}}:\phi_{\mathrm{in}}(f)\mapsto\phi_{\mathbf{F}}(\omega_f)$ with $\omega_f:=2d(E_{\mathrm{in}}(f))$ and this is equivalent to the thesis because $E_{\mathrm{in}}f=E(f)\restriction_{\mathbf{F}}$ since $E_{\mathrm{out}}(f)\restriction_{\mathbf{F}}=0$ and $E_{\mathrm{in}}(f)\restriction_{\mathbf{F}}=E_{\mathrm{in}}f$, for smooth compactly supported f defined in $\mathbf{R}$ (these facts are consequences of Proposition 3.1). The case of $\mathcal{A}_{\mathbf{R}}^{(\mathrm{out})}$ is strongly analogous. (c) Consider the case of $\pi_{\mathbf{F}}$, the other being analogous. If f is smooth and compactly supported in $\mathbf{R}$, $E_{\mathrm{in}}f$ is a compactly supported function of v and thus $\omega_f=2d(E(f)\restriction_{\mathbf{F}})=2d(E_{\mathrm{in}}f)$ is compactly supported on $\mathbf{F}$. Conversely, if $\omega=d\varphi\in\mathcal{D}(\mathbf{F},\mathbb{C})$ is compactly supported on $\mathbf{F}$, φ must be compactly supported and $f(u,v):=2\gamma^{-1}(u,v)\varphi(u)h(u)$ is smooth, compactly supported in $\mathbf{R}$ for every smooth compactly supported function $h:\mathbb{R}\to\mathbb{R}$ and $\omega=2d(E_{\mathrm{in}}(f))$ if $\int_{\mathbb{R}}h(u)du=1$. □

Remarks: (1) We stress that QFT on the horizon is the same no matter the value of the mass of the field in the bulk: Different choices of the mass determine different injective $*$-algebra homomorphisms from the algebra in the bulk to the *same* algebra of observables on the horizon. (2) There are strong differences between the cases $m>0$ and $m=0$. If f is compactly supported in the bulk, the horizon restriction of Ef is compactly supported if $m=0$ but that is not the case when $m>0$. For that reason we have defined $\mathcal{S}(\mathbf{F})$ [and $\mathcal{D}(\mathbf{F})$] as a space of rapidly decreasing functions

(one-forms) rather than a space of compactly supported functions (one-forms). Moreover, if $m>0$, $\mathcal{A}_{\mathbf{R}}$ is isomorphic to a subalgebra of $\mathcal{A}_{\mathbf{F}}$ (or equivalently $\mathcal{A}_{\mathbf{P}}$). Conversely, if $m=0$, $\mathcal{A}_{\mathbf{R}}$ $(=\mathcal{A}_{\mathbf{R}}^{(\mathrm{in})}\otimes\mathcal{A}_{\mathbf{R}}^{(\mathrm{out})})$ is isomorphic to a subalgebra of $\mathcal{A}_{\mathbf{F}}\otimes\mathcal{A}_{\mathbf{P}}$ by means of the injective unital-$*$-algebra homomorphism $\pi_{\mathbf{P}}\otimes\pi_{\mathbf{F}}:\mathcal{A}_{\mathbf{R}}\to\mathcal{A}_{\mathbf{P}}\otimes\mathcal{A}_{\mathbf{F}}$.

(3) The existence of the $*$-homomorphisms $\chi_{\mathbf{F}}$ and $\pi_{\mathbf{F/P}}$ implies that, for all $f,g\in\mathcal{D}(\mathbf{F},\mathbb{C})$ or $\mathcal{D}(\mathbf{F},\mathbb{C})$ and, respectively, for $m>0$ or $m=0$,

$$[\phi(f),\phi(g)]=[\phi_{\mathbf{F}}(\omega_f),\phi_{\mathbf{F}}(\omega_g)] \quad \text{or} \quad [\phi_{\mathrm{in/out}}(f),\phi_{\mathrm{in/out}}(g)]=[\phi_{\mathbf{F/P}}(\omega_f),\phi_{\mathbf{F/P}}(\omega_g)]. \tag{54}$$

As a consequence, the *causal propagator and the symplectic forms are preserved, too*.

The second theorem concerns the unitary implementation of the $*$-homomorphism given in Theorem 3.1. This theorem states that, if one realizes the algebras of observables $\mathcal{A}_{\mathbf{R}}$ and $\mathcal{A}_{\mathbf{P}}$, $\mathcal{A}_{\mathbf{F}}$ in terms of proper field operators in the Fock spaces constructed over, respectively, the Rindler vacuum $\Psi_{\mathbf{R}}$ and $\Psi_{\mathbf{P}}$, $\Psi_{\mathbf{F}}$, then the injective homomorphisms presented in Theorem 3.1 are implemented by unitary operators which preserve the vacuum states. In other words, *with the said choice of the vacuum states and Fock representation of the algebras of observables*, the theory in the bulk and that on the horizon are *unitarily equivalent*. As an immediate consequence, it arises that the *vacuum expectation values* are preserved passing from the theory in the bulk **R** to the theory on the horizon **F** (or **P**).

Theorem 3.2. (unitary holography): *In the same hypotheses as in Theorem 3.1, consider the realization of the algebra of the local observables of the bulk $\mathcal{A}_{\mathbf{R}}$, in the Fock space $\mathfrak{F}(\mathcal{H})$ with Rindler vacuum $\Psi_{\mathbf{R}}$ $(=\Psi_{\mathbf{R}}^{(\mathrm{out})}\otimes\Psi_{\mathbf{R}}^{(\mathrm{in})}$ if $m=0)$, and the realizations of the algebras of observables of the horizons $\mathcal{A}_{\mathbf{P}}$, $\mathcal{A}_{\mathbf{F}}$ in the Fock spaces $\mathfrak{F}(\mathcal{H}_{\mathbf{P}})$, $\mathfrak{F}(\mathcal{H}_{\mathbf{F}})$ of Definition 3.1 with horizon vacua $\Psi_{\mathbf{P}},gW_{\mathbf{F}}$. With these realizations, the homomorphisms $\chi_{\mathbf{P/F}}$ and $\pi_{\mathbf{P/F}}$ can be implemented by unitary transformations which preserve the vacuum states. More precisely, we have the following.*

(a) If $m>0$, the map that associates a positive frequency wave function ψ_+ in Rindler space with the element of $\mathcal{H}_{\mathbf{F}}\cong L^2(\mathbb{R}^+,dE)$, $\phi:E\mapsto M_{m,\kappa}(E)\tilde{\psi}_+(E)$ extends into the unitary operator $U_{\mathbf{F}}:\mathfrak{F}(\mathcal{H})\to\mathfrak{F}(\mathcal{H}_{\mathbf{F}})$ such that

$$U_{\mathbf{F}}\Psi_{\mathbf{R}}=\Psi_{\mathbf{F}}, \tag{55}$$

$$\chi_{\mathbf{F}}(\hat{A})=U_{\mathbf{F}}\hat{A}U_{\mathbf{F}}^{-1} \quad \textit{for all } \hat{A}\in\mathcal{A}_{\mathbf{R}}. \tag{56}$$

The analogous statement holds replacing **F** *for* **P**.

(b) If $m=0$, the maps which associate positive frequency wave functions $\psi_+^{(\mathrm{in})}$ and $\psi_+^{(\mathrm{out})}$ in Rindler space with respective elements of $\mathcal{H}_{\mathbf{F}}\cong L^2(\mathbb{R}^+,dE)$ and $\mathcal{H}_{\mathbf{P}}\cong L^2(\mathbb{R}^+,dE)$, $\phi^{(\mathrm{in})}:E\mapsto\tilde{\psi}_+^{(\mathrm{in})}(E)$ and $\phi^{(\mathrm{out})}:E\mapsto\tilde{\psi}_+^{(\mathrm{out})}(E)$, extend into unitary operators $V_{\mathbf{F}}:\mathfrak{F}(\mathcal{H}_{(\mathrm{in})})\to\mathfrak{F}(\mathcal{H}_{\mathbf{F}})$ and $V_{\mathbf{P}}:\mathfrak{F}(\mathcal{H}_{(\mathrm{out})})\to\mathfrak{F}(\mathcal{H}_{\mathbf{P}})$, such that

$$V_{\mathbf{F}}\Psi_{\mathbf{R}}^{(\mathrm{in})}=\Psi_{\mathbf{F}}\ , \qquad V_{\mathbf{P}}\Psi_{\mathbf{R}}^{(\mathrm{out})}=\Psi_{\mathbf{P}}, \tag{57}$$

$$\pi_{\mathbf{F}}(\hat{A})=V_{\mathbf{F}}\ \hat{A}\ V_{\mathbf{F}}^{-1} \quad \textit{for all } \hat{A}\in\mathcal{A}_{\mathbf{R}}^{(\mathrm{in})}, \tag{58}$$

$$\pi_{\mathbf{P}}(\hat{A})=V_{\mathbf{P}}\ \hat{A}\ V_{\mathbf{P}}^{-1} \quad \textit{for all } \hat{A}\in\mathcal{A}_{\mathbf{R}}^{(\mathrm{out})}. \tag{59}$$

Proof: (a) We consider the case of **F**, the case of **P** being similar. Under the identifications $\mathcal{H}\cong L^2(\mathbb{R}^+,dE)$ (Proposition 2.2) and $\mathcal{H}_{\mathbf{F}}\cong L^2(\mathbb{R}^+,dE)$ (Proposition 3.3), consider the map $V:\mathcal{H}\ni\psi\mapsto\phi\in\mathcal{H}_{\mathbf{F}}$ where we have defined $\phi(E):=N_{m,\kappa}(E)\psi(E)$ for all $\psi\in\mathcal{H}$. V is a unitary transformation by construction since $N_{m,\kappa}$ is a smooth function with $|N_{m,\kappa}(E)|=1$ for all E as stated in Proposition 3.1. That unitary transformation can be extended into a unitary transformation $U_{\mathbf{F}}:\mathfrak{F}(\mathcal{H})\to\mathfrak{F}(\mathcal{H}_{\mathbf{F}})$ by defining $U_{\mathbf{F}}\Psi_{\mathbf{R}}:=\Psi_{\mathbf{F}}$ and $U_{\mathbf{F}}\restriction_{\mathcal{H}_s^{\otimes n}}:=U_1\otimes\cdots\otimes U_n$ for all $n=1,2,3,\ldots$, where $\mathcal{H}_s^{\otimes n}$ indicates the symmetrized tensor product of n copies of $\mathcal{H}$ and $U_k=V$ for

$k=1,2,\ldots,n$. $U_{\mathbf{F}}$ preserves the vacuum states by construction and induces a unital-$*$-algebra homomorphism $\rho:\mathcal{A}_{\mathbf{R}}\to\mathcal{A}_{\mathbf{F}}$ such that $\rho(A)=U_{\mathbf{F}}AU_{\mathbf{F}}^{-1}$ for every $A\in\mathcal{A}_{\mathbf{R}}$. To conclude the proof, by the uniqueness of $\chi_{\mathbf{F}}$ proven in Theorem 3.1, it is sufficient to show that $\rho(\hat{\phi}(f))=\chi_{\mathbf{F}}(\hat{\phi}(f))$ for every $f\in\mathcal{D}(\mathbf{R})$. To this end, take $f\in\mathcal{D}(\mathbf{R})$ and consider the positive-frequency part of $\psi:=Ef$, ψ_+. The construction used to define $U_{\mathbf{F}}$ implies that $U_{\mathbf{F}}a^\dagger(\psi_+)U_{\mathbf{F}}^{-1}=a^\dagger_{\mathbf{F}}(V\psi_+)$ and $U_{\mathbf{F}}a(\overline{\psi_+})U_{\mathbf{F}}^{-1}=a_{\mathbf{F}}(\overline{V\psi_+})$ and thus, by Definitions 3.1 and 3.2, $U_{\mathbf{F}}\hat{\phi}(f)U_{\mathbf{F}}^{-1}=\hat{\phi}_{\mathbf{F}}(\omega_f)$ where $\omega_f=2d\varphi_f$ with $\varphi_f(v)=\int_{\mathbb{R}^+}(e^{-iEv}/\sqrt{4\pi E})\,N_{m,\kappa}(E)\,\tilde{\psi}_+(E)\,dE+\text{c.c.}$. By (a) of Proposition 3.1, $\varphi_f=(Ef)\restriction_{\mathbf{F}}$ and thus it holds $\rho(\hat{\phi}(f))=U_{\mathbf{F}}\hat{\phi}(f)U_{\mathbf{F}}^{-1}=\chi_{\mathbf{F}}(\hat{\phi}(f))$, which concludes the proof. (b) The proof is strongly analogous to that in the massive case with obvious changes. □

Remark: Once again, the crucial difference between the massive and the massless case is that the Hilbert space of the bulk field is isomorphic to either the Fock spaces $\mathfrak{F}(\mathcal{H}_{\mathbf{F}})$ and $\mathfrak{F}(\mathcal{H}_{\mathbf{P}})$ if $m>0$, whereas it is isomorphic to $\mathfrak{F}(\mathcal{H}_{\mathbf{F}})\otimes\mathfrak{F}(\mathcal{H}_{\mathbf{P}})$ if $m=0$. In the latter case the unitary transformation $V_{\mathbf{F}}\otimes V_{\mathbf{P}}:\mathfrak{F}(\mathcal{H})\to\mathfrak{F}(\mathcal{H}_{\mathbf{F}})\otimes\mathfrak{F}(\mathcal{H}_{\mathbf{P}})$ satisfies $(V_{\mathbf{F}}\otimes V_{\mathbf{P}})\Psi_{\mathbf{R}}=\Psi_{\mathbf{P}}\otimes\Psi_{\mathbf{F}}$ and $(\pi_{\mathbf{F}}\otimes\pi_{\mathbf{P}})(\hat{B})=(V_{\mathbf{F}}\otimes V_{\mathbf{P}})\,\hat{B}\,(V_{\mathbf{F}}^{-1}\otimes V_{\mathbf{P}}^{-1})$ for all $\hat{B}\in\mathcal{A}_{\mathbf{R}}$.

IV. HORIZON MANIFEST SYMMETRY

A. SL(2,$\mathbb{R}$) unitary representations on the horizon

Consider QFT on the future horizon $\mathbf{F}$ in the Fock representation of the algebra $\mathcal{A}_{\mathbf{F}}$ referred to the vacuum state $\Psi_{\mathbf{F}}$. The one-particle space $\mathcal{H}_{\mathbf{F}}$ is isomorphic to $L^2(\mathbb{R}^+,dE)$. An irreducible unitary representation $\widetilde{SL}(2,\mathbb{R})$, $g\mapsto U_{\mathbf{F}}^{(\mathbf{F})}(g)$, generated by the operators (27), $\overline{H_{\mathbf{F}0}}$, $\overline{C_{\mathbf{F}}}$ and $\overline{D_{\mathbf{F}}}$, with

$$H_{\mathbf{F}0}:=E,\qquad D_{\mathbf{F}}:=-i\left(\frac{1}{2}+E\frac{d}{dE}\right),\qquad C_{\mathbf{F}}:=-\frac{d}{dE}E\frac{d}{dE}+\frac{\left(k-\frac{1}{2}\right)^2}{E},\tag{60}$$

can uniquely be defined in $\mathcal{H}_{\mathbf{F}}$ as proven in Theorem 2.1. The operators (60) are defined on the dense invariant subspace $\mathcal{D}_k^{(\mathbf{F})}\subset L^2(\mathbb{R}^+,dE)\cong\mathcal{H}_{\mathbf{F}}$ which has the same definition as $\mathcal{D}_k$. If $m>0$, that representation induces an analogous representation in the one-bulk-particle space $\mathcal{H}$ through unitary holography. That is $SL(2,\mathbb{R})\ni g\mapsto U_g^{(\mathbf{F})}:=U_{\mathbf{F}}^{-1}U_gU_{\mathbf{F}}$ whose generators are $U_{\mathbf{F}}^{-1}\overline{H_{\mathbf{F}0}}U_{\mathbf{F}}$, $U_{\mathbf{F}}^{-1}\overline{D_{\mathbf{F}}}U_{\mathbf{F}}$ and $U_{\mathbf{F}}^{-1}\overline{C_{\mathbf{F}}}U_{\mathbf{F}}$. We stress that $g\mapsto U_g$ does *not* coincide with the analogous representation given in Theorem 2.1, but it is unitarily equivalent to that and thus (a) of Theorem 2.1 can be restated with trivial changes. Moreover (see below), $U_{\mathbf{F}}^{-1}\overline{H_{\mathbf{F}0}}U_{\mathbf{F}}$ still coincides with the Hamiltonian H of the bulk theory. As a consequence, also the analogs of points (b) and (c) in Theorem 2.1 can be restated for the representation $g\mapsto U_g^{\mathbf{F}}$ which, in turn, defines a $\widetilde{\mathrm{SL}}(2,\mathbb{R})$-*symmetry* of the system in the bulk by unitary holography. We are interested in *that* $\widetilde{\mathrm{SL}}(2,\mathbb{R})$-*symmetry* which is induced by the $\widetilde{\mathrm{SL}}(2,\mathbb{R})$ unitary representation on the horizon QFT via (unitary) holography no matter the mass of the field in the bulk. We stress that this $\widetilde{\mathrm{SL}}(2,\mathbb{R})$-symmetry is *hidden* in the bulk because the same argument used in Sec. II E applies to this case, too; however, it could be manifest, in the sense of Sec. II E, when examined on the horizon. That is the issue we want to discuss in the following.

Everything we have said for $\mathbf{F}$ can be restated for $\mathbf{P}$ with obvious changes. If $m=0$ and using (b) of Theorem 3.2, everything we said above concerning the representations of $\widetilde{\mathrm{SL}}(2,\mathbb{R})$ in $\mathcal{H}_{\mathbf{F}}$ and those induced on $\mathcal{H}$ by means of $U_{\mathbf{F}}$ can be restated concerning the triples $\mathcal{H}_{\mathbf{F}}$, $\mathcal{H}_{(\mathrm{in})}$, $V_{\mathbf{F}}$ and $\mathcal{H}_{\mathbf{P}}$, $\mathcal{H}_{(\mathrm{out})}$, $V_{\mathbf{P}}$ separately. Moreover, by the comment after Theorem 3.2, one sees that a pair of $\mathrm{SL}(2,\mathbb{R})$ representations in $\mathcal{H}_{\mathbf{F}}$ and $\mathcal{H}_{\mathbf{P}}$ naturally induces a *reducible* $\mathrm{SL}(2,\mathbb{R})$ on $\mathcal{H}$ by means of $V_{\mathbf{F}}\otimes V_{\mathbf{P}}$.

B. Horizon analysis of the bulk symmetry associated with $H_{\mathbf{F}0}$

Let us focus attention on the first generator $H_{\mathbf{F}0}$ in the case $m>0$. Concerning QFT on $\mathbf{P}$ and the case $m=0$, there are completely analogous results. From now on we use the following conventions referring to a representation of an algebra of observables $\mathcal{A}$ in a symmetrized Fock space $\mathfrak{F}(\mathcal{H})$. If X is a self-adjoint operator in the one-particle Hilbert space $\mathcal{H}$ and $\hat{A}\in\mathcal{A}$, $\hat{A}_\tau^{(X)} := e^{i\tau\mathbf{X}}\hat{A}e^{-i\tau\mathbf{X}}$, where $\mathbf{X}:=0\oplus X\oplus(X\otimes I+I\otimes X)\oplus\cdots$ is the operator naturally associated with X in the Fock space $\mathfrak{F}(\mathcal{H})=\mathbb{C}\oplus\mathcal{H}\oplus(\mathcal{H}\otimes\mathcal{H})_s\oplus\cdots$. In other words, $\hat{A}_\tau^{(X)}$ is the *Heisenberg evolution* of $\hat{A}$ at time τ with respect to the noninteracting multiparticle Hamiltonian $\mathbf{X}$ induced by the one-particle Hamiltonian X. We have the following theorems.

Theorem 4.1: *Unitary holography associates the self-adjoint operator* $\overline{H_{\mathbf{F}0}}$ *with the one-particle Hamiltonian in the bulk H (25), i.e.,*

$$U_{\mathbf{F}}^{-1}\overline{H_{\mathbf{F}0}}U_{\mathbf{F}}=H. \tag{61}$$

Defining $H_{\mathbf{F}}:=\overline{H_{\mathbf{F}0}}$, *the following further statements hold.*

(a) Referring to Fock representations of algebras of observables $\mathcal{A}_{\mathbf{R}}$ *and* $\mathcal{A}_{\mathbf{F}}$ *on vacuum states* $\Psi_{\mathbf{R}}$ *and* $\Psi_{\mathbf{F}}$, *Heisenberg-like evolution is preserved by unitary holography:*

$$U_{\mathbf{F}}\hat{A}_\tau^{(H)}U_{\mathbf{F}}^{-1}=(U_{\mathbf{F}}\hat{A}U_{\mathbf{F}}^{-1})_\tau^{(H_{\mathbf{F}})}. \tag{62}$$

(b) $\{e^{i\tau H_{\mathbf{F}}}\}_{\tau\in\mathbb{R}}$ *induces, via (42), a group of transformations* $\{\alpha_\tau^{(\partial_v)}\}_{\tau\in\mathbb{R}}$ *of horizon wave functions* φ *such that*

$$(\alpha_\tau^{(\partial_v)}(\varphi))(v):=\varphi(v-\tau)\quad \text{for all } \varphi\in\mathcal{S}(\mathbf{F}) \text{ and } v\in\mathbb{R}. \tag{63}$$

That is the same group of transformations of functions induced by the group of diffeomorphisms of $\mathbf{F}$ *generated by the vector field* ∂_v.

(c) If $\{\alpha_\tau^{(\partial_t)}\}_{\tau\in\mathbb{R}}$ *denotes the one-parameter group of Rindler-time displacements of Rindler wave functions (see Sec. II D),*

$$\alpha_\tau^{(\partial_v)}(\psi\restriction_{\mathbf{F}})=(\alpha_\tau^{(\partial_t)}(\psi))\restriction_{\mathbf{F}}\quad \text{for all } \psi\in\mathcal{S}. \tag{64}$$

Proof: Consider the self-adjoint operator on $\mathcal{H}_{\mathbf{F}}\cong L^2(\mathbb{R}^+,dE)$:

$$(H_{\mathbf{F}}f)(E):=Ef(E)\quad \text{for}\quad f\in\mathcal{D}(H_{\mathbf{F}})=\left\{h\in L^2(\mathbb{R}^+,dE)\;\middle|\;\int_0^{+\infty}E^2|h(E)|^2dE<+\infty\right\}. \tag{65}$$

Since $\mathcal{D}_k^{(\mathbf{F})}\subset\mathcal{D}(H_{\mathbf{F}})$ and $H_{\mathbf{F}0}=H$ in $\mathcal{D}_k^{(\mathbf{F})}$ where $H_{\mathbf{F}0}$ is essentially self-adjoint, it must hold $H_{\mathbf{F}}=\overline{H_{\mathbf{F}0}}$. The definition of $U_{\mathbf{F}}$ (its restriction to $\mathcal{H}$ is sufficient) given in (a) in Theorem 3.2, (25) and (65) entail (61). (a) is an immediate consequence of (61). (b) By Proposition 3.2 and (42), $\varphi\in\mathcal{S}(\mathbf{F})$ is the Fourier (anti)transform of a Schwartz' function f with $\tilde{\varphi}_+(E)=\sqrt{E}f(E)$ if $E\geqslant 0$ and the application of $e^{i\tau H_{\mathbf{F}}}$ on $\tilde{\varphi}_+$ changes f into $\mathbb{R}\ni E\mapsto e^{iE\tau}f(E)$ which still is a Schwartz' function. Hence, $\alpha_\tau^{(\partial_t)}(\varphi)$ is constructed by (1) Fourier transforming φ into f, (2) replacing $f(E)$ by $e^{iE\tau}f(E)$ and (3) transforming back that function into $\alpha_\tau^{(\partial_t)}(\varphi)$ via Fourier transformation. By direct inspection one finds $(\alpha_\tau^{(\partial_t)}(\varphi))(v)=\varphi(v-\tau)$ trivially. (c) In $\mathcal{H}\cong L^2(\mathbb{R}^+,dE)$ and $\mathcal{H}_{\mathbf{F}}\cong L^2(\mathbb{R}^+,dE)$, (61) states that both $e^{i\tau H}$ and $e^{i\tau H_{\mathbf{F}}}$ are represented by the same multiplicative operator $e^{i\tau E}$ in the respective spaces. Then (14) and (34) imply (64). □

Remark: Since the one-parameter unitary group generated by $H_{\mathbf{F}}$ turns out to be associated with a vector field of $\mathbf{F}$, ∂_v, which induces a group of (orientation-preserving) diffeomorphisms, the bulk-symmetry generated by $H_{\mathbf{F}}$ via unitary holography is *manifest* also on the horizon.

The machinery can be implemented at algebraic level. To this end, using the relation (see Proposition 3.4) $\omega=2dE_{\mathbf{F}}\omega$, define the one-parameter group of transformations of forms ω

$\in \mathcal{D}(\mathbf{F})$ $\{\beta_\tau^{(\partial_v)}\}_{\tau\in\mathbb{R}}$, where $(\beta_\tau^{(\partial_v)}(\omega))(v) := 2d(\alpha_\tau^{(\partial_v)}(E_{\mathbf{F}}\omega))$. Finally, define the action of $\beta_\tau^{(\partial_v)}$ on quantum fields as $\gamma_\tau^{(\partial_v)}(\phi_{\mathbf{F}}(\omega)) := \phi_{\mathbf{F}}(\beta_{-\tau}^{(\partial_v)}(\omega))$, for $\omega \in \mathcal{D}(\mathbf{F},\mathbb{C})$. One has the following result.

Theorem 4.2: *The transformations $\gamma_\tau^{(\partial_v)}$, $\tau\in\mathbb{R}$, uniquely extended into a group of automorphisms of $\mathcal{A}_{\mathbf{F}}$, $\{\gamma_\tau^{(\partial_v)}\}_{\tau\in\mathbb{R}}$ such that*

(a) if $\{\gamma_\tau^{(\partial_t)}\}_{\tau\in\mathbb{R}}$ denotes the analogous group of automorphisms of the bulk algebra $\mathcal{A}_{\mathbf{R}}$ generated by Rindler time-displacements,

$$(\chi_{\mathbf{F}}\circ\gamma_\tau^{(\partial_t)})(A) = (\gamma_\tau^{(\partial_v)}\circ\chi_{\mathbf{F}})(A) \quad \text{for all} \quad A\in\mathcal{A}_{\mathbf{F}} \quad \text{and} \quad \tau\in\mathbb{R}. \tag{66}$$

(b) In the Fock space realization of $\mathcal{A}_{\mathbf{F}}$ referred to $\Psi_{\mathbf{F}}$,

$$(\hat{B})_\tau^{(H_{\mathbf{F}})} = \gamma_\tau^{(\partial_v)}(\hat{B}) \quad \text{for all} \quad \hat{B}\in\mathcal{A}_{\mathbf{F}} \quad \text{and} \quad \tau\in\mathbb{R}. \tag{67}$$

Sketch of proof: $\alpha_\tau^{(\partial_v)}(E_{\mathbf{F}}\omega) = E_{\mathbf{F}}\beta_\tau^{(\partial_v)}(\omega)$, the preservation of the symplectic form under the action of $\alpha_\tau^{(\partial_v)}$ and Proposition 3.4 entail $E_{\mathbf{F}}(\beta_\tau^{(\partial_v)}(\omega),\beta_\tau^{(\partial_v)}(\omega')) = E_{\mathbf{F}}(\omega,\omega')$. This property trivially extended to complex valued forms. $\gamma_\tau^{(\partial_v)}$ must be extended on the whole algebra $\mathcal{A}_{\mathbf{F}}$ requiring the preservation of the unital $*$-algebra structure. The proof of the existence of such an extension is based on the preservation of the causal propagator established above. If $A=\phi(f)$, (66) is an immediate consequence of (64) and the definition of $\chi_{\mathbf{F}}$ in Theorem 3.2. Then (66) extends to the whole algebra since $\gamma_\tau^{(\partial_v)}$, $\gamma_\tau^{(\partial_t)}$ and $\chi_{\mathbf{F}}$ are homomorphisms. Equation (67) is an immediate consequence of the fact that $\gamma_\tau^{(\partial_v)}(\hat{\phi}_{\mathbf{F}}(\omega))$ is the Heisenberg-like evolution of $\hat{\phi}_{\mathbf{F}}(\omega)$ induced by the "Hamiltonian" $H_{\mathbf{F}}$ and evaluated at "time" τ. □

C. Horizon analysis of the bulk symmetry associated with $D_{\mathbf{F}}$

Let us examine the properties of the unitary one-parameter group, $\{e^{i\,\overline{\mu D_{\mathbf{F}}}}\}_{\mu\in\mathbb{R}}$.

Theorem 4.3: *The unitary one-parameter group, $\{e^{i\,\overline{\mu D_{\mathbf{F}}}}\}_{\mu\in\mathbb{R}}$ enjoys the following properties.*
(a) If $\tilde{\varphi}\in L^2(\mathbb{R}^+,dE)\cong\mathcal{H}_{\mathbf{F}}$, *for all* $\mu\in\mathbb{R}$ and $E\in\mathbb{R}^+$,

$$(e^{i\mu\,\overline{D_{\mathbf{F}}}}\tilde{\varphi})(E) = e^{\mu/2}\tilde{\varphi}(e^{\mu}E). \tag{68}$$

(b) By means of (42), $\{e^{i\,\overline{\mu D_{\mathbf{F}}}}\}_{\mu\in\mathbb{R}}$ induces a group $\{\alpha_\mu^{(v\partial_v)}\}_{\mu\in\mathbb{R}}$ of transformations of horizon wave functions φ with

$$(\alpha_\mu^{(v\partial_v)}(\varphi))(v) := \varphi(e^{-\mu}v) \tag{69}$$

for all $\varphi\in\mathcal{S}(\mathbf{F})$ and $\mu\in\mathbb{R}$. $\{\alpha_\mu^{(v\partial_v)}\}_{\mu\in\mathbb{R}}$ is the same group of transformations of functions associated with the group of diffeomorphisms of $\mathbf{F}$ induced by the vector field $v\partial_v$.

Sketch of proof: (a) Consider the one-parameter group of unitary operators $\{V_\mu\}_{\mu\in\mathbb{R}}$ with $V_\mu(\tilde{\varphi})(E) = e^{\mu/2}\tilde{\varphi}(e^{\mu}E)$, for $\tilde{\varphi}\in L^2(\mathbb{R}^+,dE)$. For every $f\in\mathcal{D}_k^{(\mathbf{F})}$, $\langle f, V_\mu\tilde{\varphi}\rangle = \langle V_{-\mu}f,\tilde{\varphi}\rangle$. On the other hand, using the definition of Schwartz space and Lebesgue's dominated-convergence theorem, it is simply proven that $V_{-\mu}f\to f$ as $\mu\to 0$ and so $\langle f,V_\mu\tilde{\varphi}\rangle\to\langle f,\tilde{\varphi}\rangle$ as $\mu\to 0$ for every $f\in\mathcal{D}_k^{(\mathbf{F})}$ which is dense in $L^2(\mathbb{R}^+,dE)$. As a consequence $\{V_\mu\}_{\mu\in\mathbb{R}}$ is weakly continuous, and thus strongly continuous it being made of unitary operators, and Stone's theorem can be used. With a similar procedure (also using Lagrange's theorem to estimate an incremental ratio) one gets that, if $\tilde{\varphi}\in\mathcal{D}_k^{(\mathbf{F})}$ and interpreting the derivative in the topology of $L^2(\mathbb{R}^+,dE)$, $d/d\mu\,|_{\mu=0}(V_\mu\tilde{\varphi})$ can be computed pointwisely. A straightforward calculation of the pointwise derivative gives $d/d\mu\,|_{\mu=0}(V_\mu\tilde{\varphi}) = i(D_{\mathbf{F}})\tilde{\varphi}$. Stone's theorem implies that generator G of $V_\mu = e^{i\mu G}$ is well-defined on $\mathcal{D}_k^{(\mathbf{F})}$ and coincides with $D_{\mathbf{F}}$ therein. Since $D_{\mathbf{F}}$ is essentially self-adjoint on that domain it must be $G=\overline{D_{\mathbf{F}}}$ and this proves (a). (b) Take $\varphi\in\mathcal{S}(\mathbf{F})$, use the decomposition (42) as in the proof of Theorem 4.1, and transform $\tilde{\varphi}_+\in L^2(\mathbb{R},dE)$ under the action of $e^{i\,\overline{\mu D_{\mathbf{F}}}}$ taking (68) into account.

With a trivial change of variables in the decomposition (42) one sees that, if φ belongs to Schwartz' space, the obtained transformed wave function is just $\varphi(e^{-\mu}v)$ which still is in $\mathcal{S}(\mathbf{F})$.□

Remark: Since the one-parameter unitary group generated by $D_{\mathbf{F}}$ turns out to be associated with the vector field of $\mathbf{F}$, $v\partial_v$, which induces a group of (orientation-preserving) diffeomorphisms, the bulk-symmetry generated by $D_{\mathbf{F}}$ via unitary holography is *manifest* on the horizon.

Once again the machinery can be implemented at algebraic level. We consider the group associated with $v\partial_v$ only. Define the one-parameter group of transformations of forms $\omega \in \mathcal{D}(\mathbf{F})$, $\{\beta_\tau^{(v\partial_v)}\}_{\tau\in\mathbb{R}}$, with $(\beta_\tau^{(v\partial_v)}(\omega))(v) := 2d(\alpha_\tau^{(v\partial_v)}(E_{\mathbf{F}}\omega))$. Finally, extend the action of $\beta_\tau^{(v\partial_v)}$ on quantum fields as $\gamma_\tau^{(v\partial_v)}(\phi_{\mathbf{F}}(\omega)) := \phi_{\mathbf{F}}(\beta_{-\tau}^{(v\partial_v)}(\omega))$, for $\omega\in\mathcal{D}(\mathbf{F},\mathbb{C})$. The following result, whose proof is essentially the same as that of the relevant part of Theorem 4.2, holds.

Theorem 4.4: *Transformations $\gamma_\tau^{(v\partial_v)}$ uniquely extended into a one-parameter group of automorphisms of $\mathcal{A}_{\mathbf{F}}$, $\{\gamma_\tau^{(v\partial_v)}\}_{\tau\in\mathbb{R}}$ such that in the Fock space realization of $\mathcal{A}_{\mathbf{F}}$ referred to $\Psi_{\mathbf{F}}$,*

$$(\hat{B})_\tau^{(\overline{D_{\mathbf{F}}})} = \gamma_\tau^{(v\partial_v)}(\hat{B}) \quad \textit{for all} \quad \hat{B}\in\mathcal{A}_{\mathbf{F}} \quad \textit{and} \quad \tau\in\mathbb{R}. \tag{70}$$

D. Horizon analysis of the unitary group generated by $C_{\mathbf{F}}$

The analysis of the action of the group generated by $C_{\mathbf{F}}$ is much more complicated than the other considered cases. The point is the following. A necessary condition to associate with a transformed state $e^{i\overline{tC_{\mathbf{F}}}}\psi$ ($\psi\in\mathcal{H}_{\mathbf{F}}$) a wave function of $\mathcal{S}(\mathbf{F})$ by (43) (with $\tilde{\varphi}_+ = e^{i\overline{tC_{\mathbf{F}}}}\psi$ and taking the real part of the right-hand side) is that $e^{i\overline{tC_{\mathbf{F}}}}\psi$ belong to the domain of $H_{\mathbf{F}}^{-1/2}$. Indeed in the general case (43) must be interpreted as the Fourier–Plancherel transform of the $L^2(\mathbb{R},dE)$ function given by 0 if $E<0$ and $((4\pi H_{\mathbf{F}})^{-1/2}e^{i\overline{tC_{\mathbf{F}}}}\psi)(E)$ if $E\geqslant 0$. Notice that this is the unique unitary extension of the Fourier transform defined on $L^2(\mathbb{R},dE)$. That requirement is, in fact, fulfilled concerning $e^{i\overline{uH_{\mathbf{F}}+vD_{\mathbf{F}}}}\psi$ if $\psi\in\mathcal{S}(\mathbf{F})$ because $e^{i\overline{uH_{\mathbf{F}}+vD_{\mathbf{F}}}}\psi\in\mathcal{S}(\mathbf{F})$ and so the usual Fourier transformation is sufficient to interpret the formalism. Concerning $C_{\mathbf{F}}$ the situation needs a careful treatment and the space $\mathcal{S}(\mathbf{F})$ must, in fact, be changed in order to assure that $e^{i\overline{tC_{\mathbf{F}}}}\psi$ belongs to the domain of $H_{\mathbf{F}}^{-1/2}$. There are several possibilities to do it at least in the case $k=1$ in the definition of $C_{\mathbf{F}}$. To go on we need some preliminary results. If $k=1$, focus attention on the operator analogous to K in the proof of Theorem 2.1, $K_{\mathbf{F}} := (\frac{1}{2})(\beta H_{\mathbf{F}0} + \beta^{-1}C_{\mathbf{F}})$. It is known[1] that $\sigma(\overline{K_{\mathbf{F}}}) = \{1,2,\ldots\}$ (no matter the value of $\beta>0$) with corresponding eigenvectors $Z_1^{(1)}, Z_2^{(1)},\ldots$ (which do depend on β) given in (26). Thus defining $\Theta := e^{i\pi\overline{K_{\mathbf{F}}}}$ one also gets $\Theta = \Theta^\dagger = \Theta^{-1}$. $\{\Theta, I\}$ is the image under $U^{\mathbf{F}}$ of the discrete subgroup $\{\vartheta, \vartheta^2 = -I, \vartheta^3 = -\vartheta, \vartheta^4 = I\} \subset \mathrm{SL}(2,\mathbb{R})$ with

$$\vartheta = \begin{bmatrix} 0 & \beta \\ -\beta^{-1} & 0 \end{bmatrix} = e^{\pi(\beta h + \beta^{-1}c)/2}\,. \tag{71}$$

Proposition 4.1: Fix $k=1$ in the definition (60) so that the representation of $\widetilde{\mathrm{SL}}(2,\mathbb{R})$ is in fact a representation of $\mathrm{SL}(2,\mathbb{R})$. For every $\beta>0$,

$$\Theta\ \beta H_{\mathbf{F}}\ \Theta = \frac{1}{\beta}\overline{C_{\mathbf{F}}} \quad , \quad \Theta\ \overline{D_{\mathbf{F}}}\ \Theta = -\overline{D_{\mathbf{F}}}\,, \tag{72}$$

$-\Theta$ is nothing but the J_1-Hankel unitary transform:

$$(-\Theta\psi)(E) := \beta \lim_{M\to+\infty} \int_0^M J_1(\beta\sqrt{4EE'})\psi(E')dE', \quad \textit{for all} \quad \psi\in L^2(\mathbb{R}^+,dE), \tag{73}$$

where the limit is computed in the norm of $L^2(\mathbb{R}^+,dE)$ and coincides with the L^1 integral over $\mathbb{R}^+$ if $E\mapsto E^{-1/4}\psi(E)$ belongs to $L^1(\mathbb{R}^+,dE)$ and $E\mapsto\sqrt{E}\psi(E)$ belongs to $L^1([0,1],dE)$.

Sketch of proof: By Stone's theorem, identities in (72) are equivalent to analog identities with self-adjoint operators $H_{\mathbf{F}}$, $\overline{C_{\mathbf{F}}}$ and $\overline{D_{\mathbf{F}}}$ replaced by the respectively generated one-parameter uni-

tary groups. In that form, the thesis can be proven, first for the corresponding one-parameter groups in SL(2,$\mathbb{R}$), using simple analytic procedures based on the uniqueness theorem of the matrix-valued solutions of differential equations, and then the result can be extended to unitary operators using the representation introduced in Theorem 2.1. The second part arises straightforwardly from Chap. 9 in Ref. 31 with trivial adaptations of the definitions. □

Proposition 4.2: Take $\varphi \in \mathcal{S}(\mathbf{F})$ *using notation as in (42), define* $\widetilde{\varphi}_{\beta+} := \Theta\widetilde{\varphi}_+$ *and*

$$\varphi_\beta(v) = \varphi\left(-\frac{\beta^2}{v}\right) - \varphi(0) \quad \text{for all} \quad v \in \mathbf{F}. \tag{74}$$

(a) $\varphi \mapsto \varphi_\beta$ *is the transformation induced by* Θ *on wave functions, i.e., (42) holds by replacing* φ *for* φ_β *and* $\widetilde{\varphi}_+$ *for* $\widetilde{\varphi}_{\beta+}$.

(b) If $X := (\beta/2)\,\partial_v + (1/2\beta)\,v^2\partial_v$ *and* $\alpha^{(X)}_\epsilon(\varphi)$ *denotes the natural action of the local one-parameter group of diffeomorphisms generated by X on* φ, *the first term in the right-hand side of (74) is*

$$\lim_{\epsilon\to\pi}(\alpha^{(X)}_\epsilon(\varphi))(v)\,, \quad \text{for all} \quad v \in \mathbf{F}. \tag{75}$$

Sketch of proof: By hypotheses $\widetilde{\varphi}_+$ satisfies the conditions which enables us to represent $\Theta\widetilde{\varphi}_+$ as in (73). In that case, by the expansion of $J_1(x)$ at $x=0$, one sees that the L^2, and continuous on $(0,+\infty)$, function $E \mapsto (\Theta\widetilde{\varphi}_+)(E)$ is $O(E^{1/2})$ as $E \to 0^+$ and thus it belongs to the domain of $H_{\mathbf{F}}^{-1/2}$. Using Fubini–Tonelli's and dominated convergence theorems we have that $\varphi_\beta(v)$ reads (where the limit in the left-hand side is in the L^2-convergence sense)

$$\lim_{\epsilon\to 0^+}\int_0^\infty e^{-iE(v-i\epsilon)}\frac{(\Theta\widetilde{\varphi}_+)(E)}{\sqrt{4\pi E}}dE = -\beta\int_0^\infty \lim_{\epsilon\to 0^+}\left(\int_0^\infty e^{-iE(v-i\epsilon)}\frac{J_1(\beta\sqrt{4EE'})}{\sqrt{4\pi E}}dE\right)\widetilde{\varphi}_+(E')dE'.$$

The limit on the right-hand side can explicitly be computed by using known results,[24] obtaining that it is $(e^{iE'\beta^2/v}-1)/\sqrt{4\pi E'}$. This result produces $\varphi_\beta(v) = \varphi(-\beta^2/v) - \varphi(0)$. Concerning the second statement, it is simply proven that, for $\epsilon \in (-\pi,\pi)$,

$$(\alpha^{(X)}_\epsilon(\varphi))(v) = \varphi\left(\frac{-\beta^2\tan(\epsilon/2)+\beta v}{\beta + v\tan(\epsilon/2)}\right).$$

With our hypotheses for φ, the limit as $\epsilon \to \pi$ is well defined for every $v \in \mathbb{R}$ and proves the statemet in (b). □

By direct inspection and using (74) one sees that, if $\varphi \in \mathcal{S}(\mathbf{F})$, usually $\varphi_\beta \notin \mathcal{S}(\mathbf{F})$, but $\varphi_\beta \in \mathsf{W}_\infty(\mathbb{R})$ in any case, the latter being the Sobolev space of the C^∞ complex-valued functions which are $L^2(\mathbb{R},dv)$ with all of derivatives of every order.

Now, using (72), the geometric action of $e^{i\lambda\,\overline{C_{\mathbf{F}}}} = \Theta e^{i\lambda\beta^2 H_{\mathbf{F}}}\Theta$ can easily be computed for wave functions φ of $\mathcal{S}(\mathbf{F})$ such that $\varphi(0)=0$ and $v \mapsto \varphi(-1/v)$ still belongs to $\mathcal{S}(\mathbf{F})$. Take such a φ, extract $\widetilde{\varphi}_+$ and apply Θ. The resulting wave function is an element of $\mathcal{S}(\mathbf{F})$ by Proposition 4.2. The application of the one-parameter group generated by $\beta^2 H_{\mathbf{F}}$, $e^{i\lambda\beta^2 H_{\mathbf{F}}}$, gives rise to wave functions (see Theorem 4.1) $v \mapsto \varphi(-\beta^2/(v-\beta^2\lambda))$ which still belongs to $\mathcal{S}(\mathbf{F})$. Finally, since it is possible, apply Θ once again. All that procedure is equivalent to applying the group $e^{i\lambda\,\overline{C_{\mathbf{F}}}} = \Theta e^{i\lambda\beta^2 H_{\mathbf{F}}}\Theta$, on the initial $\widetilde{\varphi}_+$. By this way one gets that the following theorem.

Theorem 4.5: *Consider the horizon wave functions* $\varphi \in \mathcal{S}(\mathbf{F})$ *such that* $\varphi(0)=0$ *and* $v \mapsto \varphi(-1/v)$ *still belongs to* $\mathcal{S}(\mathbf{F})$. *The unitary group,* $\{e^{i\lambda\,\overline{C_{\mathbf{F}}}}\}_{\lambda\in\mathbb{R}}$ *induces a class* $\{\alpha^{(v^2\partial_v)}_\lambda\}_{\lambda\in\mathbb{R}}$ *of transformations of the said wave functions by means of (42), with*

$$(\alpha^{(v^2\partial_v)}_\lambda(\varphi))(v) := \varphi\left(\frac{v}{1+\lambda v}\right) - \varphi\left(\frac{1}{\lambda}\right), \quad \text{for all} \quad \lambda \in \mathbb{R}. \tag{76}$$

The transformation of wave functions defined by the first term on the right-hand side of (76) is that generated by the local *group of diffeomorphisms of* $\mathbf{F}$ *associated with the field* $v^2\partial_v$.

Remarks: (1) In our hypotheses, $\alpha_\lambda^{(v^2\partial_v)}(\varphi)\in \mathsf{W}_\infty(\mathbb{R})$, but in general $\alpha_\lambda^{(v^2\partial_v)}(\varphi)\notin \mathcal{S}(\mathbf{F})$ so that the class of transformations does not define a group of transformations of wave functions in $\mathcal{S}(\mathbf{F})$. It is worthwhile stressing that these transformations define a group when working on the space $\mathcal{E}_\mathbf{F}$ of complex wave functions $\psi=\psi(v)$ whose positive-frequency and negative-frequency parts of Fourier transform are linear combinations of functions $E\mapsto Z_n^{(1)}(|E|)/\sqrt{4\pi|E|}$. In fact $\mathcal{E}_\mathbf{F}$ is invariant under (76). On the other hand, $\mathcal{E}_\mathbf{F}\cap(\mathcal{S}(\mathbf{F})+i\mathcal{S}(\mathbf{F}))=\varnothing$.

(2) The integral curves of the field $v^2\partial_v$, $v(t)=v(0)/(1-tv(0))$, have domain which *depends on the initial condition*: That is, $\mathbb{R}\backslash\{1/v(0)\}$, and $v(t)$ diverges if t approaches the singular point [barring the initial condition $v(0)=0$ that produces a constant orbit]. Thus the one-parameter group of (orientation-preserving) diffeomorphisms generated by $v^2\partial_v$ is only *local*. However, as the functions in $\mathcal{S}(\mathbf{F})$ vanish at infinity with all their derivatives, the singular point of the domain is harmless in (76).

(3) It makes sense to extend the definition of symplectically smeared field operator when $\varphi\in \mathsf{W}_\infty(\mathbb{R})$ by means of Definition 3.1. Indeed the Fourier–Plancherel transform of φ, f satisfies $\int_{\mathbb{R}^+}(1+|E|^k)^2|f(E)|^2dE<\infty$, for $k=0,1,2,\ldots$, and so $\mathbb{R}^+\ni E\to\tilde{\varphi}_+(E):=\sqrt{4\pi E}f(E)$ is a one-particle quantum state of $L^2(\mathbb{R}^+,dE)$. With the same hypotheses $E_\mathbf{F}d\varphi$ is well-defined, in particular $d^k\varphi(v)/dv^k\to 0$ as $v\to\pm\infty$ for $k=0,1,2,\ldots$: by elementary calculus and Cauchy–Schwartz inequality, every $d^k\varphi(v)/dv^k$ is uniformly continuous. If $d^k\varphi(v)/dv^k\not\to 0$ as $v\to\pm\infty$ for some k, there are $\epsilon>0$ and a sequence of intervals I_n with $\int_{I_n}dv=l>0$ and $|d^k\varphi(v)/dv^k\restriction_{I_n}|>\epsilon$. Thus $\int_\mathbb{R}|d^k\varphi(v)/dv^k|^2dv=\infty$ which is impossible. Moreover, $E_\mathbf{F}d\varphi$ enjoys the relevant properties stated in Proposition 3.4 and 3.5. Then enlarging $\mathcal{D}(\mathbf{F},\mathbb{C})$ to include elements $\omega=d\varphi$ where φ is real and belongs to $\mathsf{W}_\infty(\mathbb{R})$, one can define $\hat{\phi}(\omega)$ as in Definition 3.2, not affecting the relevant properties stated in Proposition 3.4 and 3.5. By this way, the algebraic approach can be implemented in terms of formal quantum fields smeared by functions of $\mathsf{W}_\infty(\mathbb{R})$.

The action of the one-group generated by $C_\mathbf{F}$ can be implemented at algebraic level. If $\omega\in\mathcal{D}(\mathbf{F})$ [without the enlargement said in the remark (3) above], one can define $(\beta_\tau^{(v^2\partial_v)}(\omega)):=2d(\alpha_\tau^{(v^2\partial_v)}(E_\mathbf{F}\omega))$. By direct inspection one sees that each $\alpha_\tau^{(v^2\partial_v)}$ preserves the symplectic form $\Omega_\mathbf{F}$ and each $\beta_\tau^{(v^2\partial_v)}$ preserves the causal propagator $E_\mathbf{F}$. Notice that these results are not evident *a priori* since the action of $\alpha_\tau^{(v^2\partial_v)}$ (76) is not that canonically induced by a vector field. Finally, extend the action of $\beta_\tau^{(v^2\partial_v)}$ on quantum fields as $\gamma_\tau^{(v^2\partial_v)}(\phi_\mathbf{F}(\omega)):=\phi_\mathbf{F}(\beta_{-\tau}^{(v\partial_v)}(\omega))$, for $\omega\in\mathcal{D}(\mathbf{F},\mathbb{C})$. The following result, whose proof is essentially the same as that of the relevant part of Theorem 4.2, holds.

Theorem 4.6: *Transformations* $\gamma_\tau^{(v^2\partial_v)}$ *uniquely extended into a one-parameter class of automorphisms of* $\mathcal{A}_\mathbf{F}$, $\{\gamma_\tau^{(v^2\partial_v)}\}_{\tau\in\mathbb{R}}$ *such that in the Fock space realization of* $\mathcal{A}_\mathbf{F}$ *referred to* $\Psi_\mathbf{F}$,

$$(\hat{B})_\tau^{(\overline{C_\mathbf{F}})}=\gamma_\tau^{(v^2\partial_v)}(\hat{B})\quad \textit{for all}\quad \hat{B}\in\mathcal{A}_\mathbf{F}\ \textit{and}\ \tau\in\mathbb{R}. \tag{77}$$

E. The full SL(2,$\mathbb{R}$) action

To conclude we show the general action of $\{U_g^{(\mathbf{F})}\}_{g\in \mathrm{SL}(2,\mathbb{R})}$ on horizon wave functions. With a strightforward generalization of the notion of manifest symmetry due to the appearance of the addend on the right-hand side of (79) below, the symmetry associated with the whole group SL(2,$\mathbb{R}$) can be considered as *manifest*. We leave possible comments on the field algebra extension to the reader. Remind that $\vartheta:=e^{\pi(\beta h+\beta^{-1}c)/2}\in\mathrm{SL}(2,\mathbb{R})$ and consider

$$A=\begin{bmatrix} a & b\\ c & d\end{bmatrix}\in\mathrm{SL}(2,\mathbb{R}). \tag{78}$$

Referring to (71) and generators (29), only one of the following facts holds for suitable λ,μ,τ uniquely determined by a,b,c,d in the examined cases: If $a>0$, $A=e^{\lambda c}e^{\mu d}e^{\tau h}$ or, if $a<0$, $A=\vartheta e^{\lambda c}e^{\mu d}e^{\tau h}$, or, if $a=0$ and $b>0$, $A=\vartheta e^{\mu d}e^{\tau h}$, or, if $a=0$ and $b<0$, $A=\vartheta^3 e^{\mu d}e^{\tau h}$. Using these decompositions, part of Theorems 4.1, 4.3, and 4.5, and Proposition 4.2, the following final theorem can simply be proven.

Theorem 4.7: *Take $\varphi\in\mathcal{S}(\mathbf{F})$ such that $\varphi(0)=0$ and $v\mapsto\varphi(-1/v)$ still belongs to $\mathcal{S}(\mathbf{F})$. If $A\in \mathrm{SL}(2,\mathbb{R})$ has the form (78), let $\alpha^{(A)}(\varphi)$ denote the right-hand side of (42) with $\tilde{\varphi}_+$ replaced for $U_A^{(\mathbf{F})}\tilde{\varphi}_+$ where $\tilde{\varphi}_+$ is defined as in* (41). *For $v\in\mathbb{R}$ it holds*

$$(\alpha^{(A)}(\varphi))(v)=\varphi\left(\frac{dv-b}{a-cv}\right)-\varphi\left(-\frac{d}{c}\right). \tag{79}$$

The second term on the right-hand side disappears if either $d=0$ or $c=0$. Finally, the transformation of wave functions defined by the first term on the right-hand side of (79) is that generated by the local group of diffeomorphisms of **F** *generated by the basis of fields $\partial_v, v\partial_v, v^2\partial_v$.*

Remark: From a pure geometric point of view, the $\mathrm{SL}(2,\mathbb{R})$ symmetry is associated to the Lie algebra of fields ∂_v, $v\partial_v$, $v^2\partial_v$. This suggests to focus on the set of fields defined on **F**, $\{\mathcal{L}_n\}_{n\in\mathbb{Z}}$ with

$$\mathcal{L}_n := -v^{n+1}\partial_v, \qquad n\in\mathbb{Z}. \tag{80}$$

By direct inspection one gets that, if $\{\,,\}$ denotes the Lie bracket of vector fields,

$$\{\mathcal{L}_n,\mathcal{L}_m\}=(n-m)\ \mathcal{L}_{n+m}, \tag{81}$$

that is, the generators $\mathcal{L}_n$ span a Virasoro algebra without central charge. We remark that, in fact, the fields $\mathcal{L}_n$ with $n<0$ are not smooth since a singularity arises at $v=0$. It is anyway interesting to investigate the issue of the quantum representation of that Lie algebra in terms of one-particle operators of a quantum field defined on the horizon perhaps in the whole Fock space. At quantum level a central charge could appear. This is just the main goal of the subsequent paper.[19] In that paper we show that, in fact, a suitable and natural enlargement in the Fock space of the hidden $\mathrm{SL}(2,\mathbb{R})$ symmetry gives rise to a positive-energy unitary Virasoro algebra representation. That representation has quantum central charge $c=1$. The Virasoro algebra of operators gets a manifest geometrical meaning if referring to the holographically associated QFT on the event horizon: It is nothing but a representation of the algebra of vector fields defined on the event horizon equipped with a point at infinity. All that happens provided the Virasoro ground energy $h:=\mu^2/2$ vanishes and, in that case, the Rindler Hamiltonian is associated with a certain Virasoro generator. It seems that for $h=\frac{1}{2}$ the ground state of the generator K corresponds to a thermal state when examined in the Rindler wedge with respect to the Rindler evolution. Moreover, that state has inverse temperature equal to $1/(2\beta)$. Finally, under Wick rotation in Rindler time, the pair of QF theories which are built up on the future and past horizon defines a proper two-dimensional conformal quantum field theory on a cylinder.

V. DISCUSSION, OVERVIEW AND OPEN PROBLEMS

In this article we have rigorously proven that it is possible to define a diffeomorphism invariant local quantum field theory for a massless free scalar field defined on the Killing horizon of a Rindler space–time. Actually all of the procedure could be implemented in a manifold diffeomorphic to $\mathbb{R}$ without fixing any metric structure. The diffeomorphism invariance is a consequence of the fact that the field operators and the symplectic form act on exact one-forms instead of smooth smearing functions and thus they do not need a metric invariant measure. Moreover, when the theory is realized on the (future and/or past) Killing horizon in Rindler space–time, there is a natural injective $*$-algebra homomorphism from any quantum field theory of a (generally massive)

scalar field propagating in the bulk. This holographic identification can be implemented in terms of unitary equivalences if the algebras of the fields are represented in suitable Fock spaces. In this case the vacuum state in the bulk is that associated to Rindler quantization. In an approximated picture where Rindler space corresponds to the space–time near the horizon of a Schwarzschild black hole, Rindler particles are just the Poincaré-invariant particles we experience everyday. Conversely, if the Rindler background is taken seriously as part of the actual space–time (Minkowski space–time) without approximation, the Rindler vacuum has to be thought of as the vacuum state of an accelerated observer in Minkowski space–time and Rindler particles have nothing to do with ordinary Poincaré invariant particles. Actually a problem arises from a pure physical point of view and it deserves further investigation in relation with the *unitary* holographic theorem where vacuum states play a relevant role. Indeed, the Rindler vacuum as well as the Boulware vacuum in the Schwarzschild manifold are states which cannot be defined in the natural extension of the manifold (respectively, Minkowski space–time and Kruskal space–time). Essentially speaking, this is due to the behavior of n-point functions on the Killing horizon which is not Hadamard. In this context it would be interesting to investigate the holographic meaning of the Hadamard states (Minkowski vacuum and Hartle-Hawking state) also to make contact with results found in Refs. 15–18 where the net of Von Neumann algebras are defined with respect to Hadamard states.

Another achieved result in this work is that the hidden SL(2,$\mathbb{R}$) symmetry of the bulk theory corresponds to an analogous symmetry for the horizon theory and this horizon symmetry has a clear geometric interpretation in terms of invariance under diffeomorphisms. However, it is possible to show that this symmetry can be enlarged to include a full Virasoro algebra which represents, in the Hilbert space of the system, the algebra of generators of one-parameter groups of local diffeomorphisms of the horizon. That is the subject of another work.[19]

All the work has been developed in the case of a two-dimensional space–time. Nevertheless, we expect that the result obtained for this simple case can be generalized to encompass some four-dimensional cases. Considering a four-dimensional Schwartzschild black hole manifold within the near horizon approximation, angular degrees of freedom are embodied in the solutions of Klein–Gordon equation by multiplication of a two-dimensional solution and a spherical harmonic $Y^l_m(\theta,\phi)$. All field states are elements of an appropriate tensor product of Hilbert spaces. For instance, in the massive case, the final space is the direct sum of spaces $\mathbb{C}^{2l+1}\otimes L^2(\mathbb{R}^+,dE)$ with $l=0,1,\ldots$. (The "square angular momentum" eigenvalue l defines an effective mass of the field when considered at fixed value of l. In this way the massless theory behaves as the massive one when $l\neq 0$.) With simple adaptations [e.g., the appropriate causal propagator on $\mathbf{F}$ reads

$$E_{\mathbf{F}}(x,x')=(\tfrac{1}{4})\text{sign }(v-v')\,\delta(\theta-\theta')\,\delta(\phi-\phi')\sqrt{g_{\,S^2}(\theta,\phi)}$$

and the horizon field operator $\hat{\phi}_{\mathbf{F}}$ has to be smeared with 3-forms as $df(v,\theta,\phi)\wedge d\theta\wedge d\phi$] all the results found in this article can be restated for that apparently more general case. The same conclusion can be achieved when considering a four-dimensional Rindler space–time.

Some comments can be supplied for the case of the exact Schwartzschild space–time dropping the near-horixon approximation in spite of the absence of exact solutions of the Klein–Gordon equation. By the analysis of the effective potential—which depends on the angular momentum—of either a massive or massless particle propagating in the external region of the black hole space–time, one sees that the energy spectrum is $\sigma(H)=[0,+\infty)$ once again for any values of the angular momentum. If the particle is massive, no degeneracy affects a value E of the energy if the mass is greater than E; otherwise twice the degeneracy arises. That is the only possible case for a massless particle. Therefore, we expect that our results, with appropriate adaptations, may hold for the massless case but they could need some substantial change dealing with the massive case.

Another interesting topic that deserves investigation is if, and how, the holographic procedure can be extended in order to encompass a larger algebra of fields containing Wick monomials "ϕ^n" which naturally arise dealing with perturbative interacting quantum field theory.

Virasoro algebra with central charge $c=1$ on the horizon of a two-dimensional-Rindler space–time

Valter Moretti[a] and Nicola Pinamonti[b]
Department of Mathematics, Faculty of Science, University of Trento, via Sommarive 14, I-38050 Povo (TN), Italy

(Received 14 July 2003; accepted 29 September 2003)

Using the holographic machinery built up in a previous work, we show that the hidden $SL(2,\mathbb{R})$ symmetry of a scalar quantum field propagating in a Rindler space–time admits an enlargement in terms of a unitary positive-energy representation of Virasoro algebra defined in the Fock representation. That representation has central charge $c=1$. The Virasoro algebra of operators gets a manifest geometrical meaning if referring to the holographically associated quantum field theory on the horizon: It is nothing but a representation of the algebra of vector fields defined on the horizon equipped with a point at infinity. All that happens provided the Virasoro ground energy $h:=\mu^2/2$ vanishes and, in that case, the Rindler Hamiltonian is associated with a certain Virasoro generator. If a suitable regularization procedure is employed, for $h=1/2$, the ground state of that generator seems to correspond to a thermal state when examined in the Rindler wedge, taking the expectation value with respect to Rindler time. Finally, under Wick rotation in Rindler time, the pair of quantum field theories which are built up on the future and past horizon defines a proper two-dimensional conformal quantum field theory on a cylinder. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1629396]

I. INTRODUCTION AND SUMMARY OF PREVIOUSLY OBTAINED RESULTS

A number of papers have been concerned with the issue of the statistical origin of black-hole entropy. The holographic principle[1–3] arose from the idea that gravity near the horizon should be described by a low dimensional theory with a higher dimensional group of symmetry. Maldacena and Witten[4,5] showed that there is a correspondence between quantum field theory (QFT) in an asymptotically AdS space–time, the ''bulk,'' and a conformal theory on its ''boundary'' at space–like infinity. Rehren proved rigorously some holographic results for local quantum fields in an AdS background, establishing a correspondence between bulk observables and boundary observables without employing string machinery.[6,7] Dealing with QFT in two-dimensional (2D)-Rindler space–time, we have proved in a recent work[8] that it is possible to define a free quantum theory on the horizon of a two-dimensional Rindler space. That theory enjoys holographic interplay with the analogous theory defined in the bulk. More precisely, there are two holographic theorems. The former shows that there is a $*$-algebra injective homomorphism from the algebra of the bulk observables associated with the Rindler free field to the algebra of the horizon observables associated with the horizon free field. The latter identifies the observables of the theories from the point of view of unitary equivalences whenever the theory is represented in suitable Fock spaces

[a]Also at I.N.d.A.M., Istituto Nazionale di Alta Matematica ''F.Severi,'' unità locale di Trento and I.N.F.N., Istituto Nazionale di Fisica Nucleare, Gruppo Collegato di Trento; electronic mail: moretti@science.unitn.it

(in that case also the vacuum states are in correspondence through the unitary operator which realizes holography). An interesting consequence is that the ''hidden'' $SL(2,\mathbb{R})$ symmetry of free quantum field theory in the bulk found in Ref. 9 becomes manifest when transposed on the Killing horizon by means of unitary holography. In fact, due to the spectrum of the Hamiltonian operator, QFT theory in the bulk turns out to be invariant under a unitary representation of $SL(2,\mathbb{R})$ but such a quantum symmetry cannot be induced by the geometric background because the isometries of Rindler space have a Lie algebra different from that of $SL(2,\mathbb{R})$.[9] Nevertheless, the unitary representation of $SL(2,\mathbb{R})$ realizes that bulk symmetry becomes manifest, i.e., it reveals a clear geometric meaning, if it is examined on the horizon by means of the holographic machinery. All that is summarized later in this section in some detail.

Overlap with ideas and results of Ref. 8 is present in the literature, especially due to Schroer,[10] Schroer and Wiesbrock,[11] and Schroer and Fassarella.[12] In those papers an approach to holography similar to ours is implemented in the framework of LightFront Holography developed at an algebraic level using nets of local observable algebras. From a very elementary point of view, a relevant difference with our machinery is the fact that the quantization of the bulk field used by Schroer and collaborators is that referred to as Minkowski vacuum and Minkowski time instead of Rindler vacuum and time. From a pure physical point of view, perhaps, the quantization with respect to the Rindler frame is more interesting if one tries to use our machinery as a starting point to investigate quantum field theory (QFT) near the bifurcate Killing horizon of a black hole: Rindler quantization corresponds to quantization in a reference frame that gives rise to Minkowski coordinates far from the black hole and the associated particles should be those things are made of. However the interplay of Schroer and collaborators' ideas and achievements and procedures and results presented in our paper deserves further investigation. Another relevant paper which merits particular quotation is that by Guido, Longo, Roberts, and Verch.[13] Overlap with some results arising from our approach is present in Sec. 4 of Ref. 13. In that section, in the very general context of QFT in curved space–time in terms of nets of local C^* algebras (and Von Neumann representations) and making use of very general theorems by Wiesbrock on local quantum field theory defined on $\mathbb{S}^1$ and covariant with respect to $PSL(2,\mathbb{R}) := SL(2,\mathbb{R})/\pm I$, the existence of a local quantum field theory (covariant with respect to $PSL(2,\mathbb{R})/\pm I$) defined on the bifurcate Killing horizon is proven. This is done by considering a net of Von Neumann algebras in the representation of a state which is, in restriction to the subnet of observables which are localized at the horizon, a KMS state at Hawking temperature for the Killing flow.

In Ref. 8 we found some clues for the existence of a whole unitary representation of Virasoro algebra which extends the $SL(2,\mathbb{R})$ unitary representation on the horizon. In this paper we prove the very existence of a full unitary representation of Virasoro algebra with central charge $c=1$ for quantum field theory defined on the horizon. That fact is interesting for several reasons in relation to the problem of the statistical interpretation of black hole entropy. In fact, there are several attempts to give a statistical explanation to black hole entropy by counting microstates in terms of the degeneracy of an eigenspace of a certain Virasoro generator in a suitable irreducible unitary representation of Virasoro algebra.[14,15] This is done by means of the so-called ''Cardy's formula.'' These approaches are, in fact, based on the existence of a Virasoro algebra (with central charge $c\neq 0$) in terms of generators of diffeomorphisms of the black hole manifolds considering the horizon as a boundary. The algebra of the associated generators in the Hamiltonian ADM formulation of gravity gets a nonvanishing central charge. Under the supposition that a quantum version of that Virasoro representation exists, that the value of central charge is not affected by the quantization procedure and that the actual value of the black hole mass is an eigenvalue of the Virasoro generator L_0, it is possible to compute the degeneracy of that eigenspace by means of Cardy's formula because of the presence of a central charge. The logarithm of the degeneracy gives the very black-hole entropy law barring logarithmic corrections.

The main problem of all of those approaches is that the Virasoro algebra representation with nonvanishing central charge is proven to exist at classical level only in the Hamiltonian formulation. All derivations of black hole entropy by that way are based on the found classical formulas

and on the supposition that there is a quantum version of the found Hamiltonian structure (in order to use Cardy's formula).

To make contact with the content of this paper where a quantum scalar field propagating in a 2D-Rindler space is considered, we notice that in the above-outlined approaches, the only near-horizon structure is sufficient to use the Virasoro–Cardy machinery.[15,14,16] Moreover, for a Schwarzschild black-hole manifold, the relevant algebra of diffeomorphisms is that of diffeomorphisms in the plane r,t which preserve the horizon structure. Hence it seems that 2D-Rindler models are relevant to this context. On the other hand, a scalar field arises naturally in these 2D-Rindler space approaches by dimensional reduction[16] from the gravitational theory in four dimensions (4D) in the presence of spherical symmetry. That field supports information of part of the 4D-dimensional gravity in the 2D model. Concerning the problem of the existence of a Virasoro representation at quantum level we stress that, in this paper, we prove that a very positive-energy unitary representation of Virasoro algebra does exist at quantum level for the quantum field defined on the horizon. That algebra of operators can be defined also for the scalar field propagating in the bulk via unitary holography.

In fact, Sec. II of this paper is devoted to showing that the bulk hidden $SL(2,\mathbb{R})$ symmetry admits an enlargement in terms of a unitary representation of Virasoro algebra with central charge $c=1$ defined in Fock representation. The Virasoro algebra of operators gets a manifest geometrical meaning if referring to the holographically associated QFT on the horizon: It gives rise to a unitary representation of a group of automorphisms of the $*$-algebra generated by field operators. This representation is induced by a group of diffeomorphisms of the horizon compactified by adding a point at infinity. Moreover, a subrepresentation which is generated by three certain Virasoro generators reduces to the $SL(2,\mathbb{R})$ representation previously found. Under Wick rotation with respect to Rindler time, the pair of QF theories which are built up on the future and past horizon defines a proper two-dimensional conformal quantum field theory. That CFT can be realized on the Riemann surface given by a two-dimensional cylinder. In Sec. III we see that, with a suitable choice of the weight of the found Virasoro algebra of operators, a certain generator which generalizes Rindler Hamiltonian, admits a ground state Ψ which seems to enjoy thermodynamic properties: When that state is examined in the bulk via holography, and a suitable regularized mean is computed with respect to Rindler-time evolution, Ψ reveals itself as a thermal state whose inverse temperature is 2β, β being the parameter initially used to build up the unitary $SL(2,\mathbb{R})$ representation in the bulk.

We summarize part of the content of Ref. 8 relevant to this work within the following five steps.

[a] Consider the globally hyperbolic space–time **R** called the two-dimensional *Rindler wedge* with metric $ds^2_{\mathbf{R}}=-\kappa^2y^2dt^2+dy^2$, which can be obtained by a suitable near horizon approximation of a general Schwarzschild-like metric also dropping the angular coordinates,[8] above $t\in\mathbb{R}$, $y\in(0,+\infty)$ are global coordinates. A free Klein–Gordon (KG) scalar field ϕ in **R** satisfies the equation of motion $-\partial_t^2\phi+\kappa^2(y\partial_y y\partial_y-y^2m^2)\phi=0$. In Rindler quantization, the one-particle Hilbert space $\mathcal{H}$ consists of the space of complex linear combinations of the positive frequency parts of smooth real solutions ψ of the KG equation with compact Cauchy data. The natural *symplectic form* on that space is $\Omega(\psi,\psi'):=\int_\Lambda(\psi'\nabla^\mu\psi-\psi\nabla^\mu\psi')n_\mu d\sigma$, Λ being any Cauchy surface, $d\sigma$ the induced measure, and n a unit future-oriented normal vector. Every ψ decomposes into ∂_t-stationary modes as

$$\psi(t,y)=\psi_+(t,y)+\text{c.c.}=\int_0^{+\infty}e^{-iEt}\sum_\alpha\Phi_E^{(\alpha)}(y)\,\tilde{\psi}_+^{(\alpha)}(E)\,dE+\text{c.c.} \tag{1}$$

The index α distinguishes between two cases: if $m>0$ there is a single mode $\Phi_E^{(\alpha)}=\Phi_E$. If $m=0$ there are two values of α, corresponding to *ingoing* and *outgoing* modes, $\Phi_E^{(\text{in})/(\text{out})}=e^{\mp iE\ln(\kappa y)/\kappa}/\sqrt{4\pi E}$. In that case both ingoing and outgoing components in (1) must have Cauchy compact support. The one-particle Hilbert space of wave functions is obtained by taking the

completion of the space of complex linear combinations of positive frequency wave functions (obtained from Cauchy support compactly real wave functions) with respect to the Hermitian scalar product $-i\Omega(\overline{\psi'_+},\psi_+)$. ∂_t evolution of a wave function ψ is equivalent to the action of the one-parameter subgroup generated by a Hamiltonian H on the associated $\psi_+ \in \mathcal{H}$. $\sigma(H)=[0, +\infty)$ for $m \geqslant 0$. If $m>0$ there is no energy degeneration and the one-particle Hilbert space $\mathcal{H}$ is isomorphic to $L^2(\mathbb{R}^+,\mathrm{d}E)$ via spectral decomposition of H. In the other case ($m=0$), twofold degeneracy implies that $\mathcal{H}\cong L^2(\mathbb{R}^+,\mathrm{d}E)\oplus L^2(\mathbb{R}^+,\mathrm{d}E)$. Let us pass to the bosonic Fock space, $\mathfrak{F}(\mathcal{H})$, associated with $\mathcal{H}$. The *quantum field* $\Omega(\,\cdot\,,\hat{\phi})$ of our theory is the map

$$\psi \mapsto \Omega(\psi,\hat{\phi}) := ia(\overline{\psi_+}) - ia^\dagger(\psi_+)\ , \tag{2}$$

where ψ is any real compactly supported wave function and $a(\overline{\psi_+})$ and $a^\dagger(\psi_+)$, respectively, denote the annihilation and construction operator associated with the one-particle states $\overline{\psi_+}$ and ψ_+, defined in $\mathfrak{F}(\mathcal{H})$ and referred to the Rindler vacuum $|0\rangle$ (that is $|0\rangle_{\mathrm{in}}\otimes|0\rangle_{\mathrm{out}}$ if $m=0$). $\Omega(\psi,\hat{\phi})$ is essentially self-adjoint in the dense invariant subspace spanned by all states containing a finite arbitrarily large number of particles with states given by positive-frequency wave functions. Every wave function ψ in (1) can be obtained as $\psi=E(f)$ where f is an associated compactly supported smooth function in $\mathbf{R}$ and E is the *causal propagator* (the "advanced-minus-retarded" two point function) of Klein–Gordon operator. Moreover

$$\int_{\mathbf{R}} \psi f \,\mathrm{d}\mu_g = \Omega(Ef,\psi), \quad \int_{\mathbf{R}} h(x)(Ef)(x)\,\mathrm{d}\mu_g(x) = \Omega(Ef,Eh)\ , \tag{3}$$

μ_g being the measure induced by the metric in $\mathbf{R}$. Equation (3) suggests defining[18] a quantum-field operator smeared with compactly supported complex-valued functions f, as the linear map

$$f \mapsto \hat{\phi}(f) := \Omega(Ef,\hat{\phi})\ , \tag{4}$$

which is formally equivalent to the nonrigorous but popular definition

$$\hat{\phi}(t,y) = \int_0^\infty \sum_\alpha \ e^{-iEt}\Phi_E^{(\alpha)}(y)a_{E\alpha} + e^{iEt}\overline{\Phi_E^{(\alpha)}(y)}a^\dagger_{E\alpha}\mathrm{d}E\ . \tag{5}$$

The rigorous version of the formal identity $[\hat{\phi}(x),\hat{\phi}(x')]=-iE(x,x')$ is

$$[\hat{\phi}(f),\hat{\phi}(h)] = -iE(f,h) := -i\int_{\mathbf{R}} h(x)(Ef)(x)\,\mathrm{d}\mu_g(x)\ . \tag{6}$$

[b] In Refs. 9 and 8 we have established that, if $m>0$, $\mathcal{H}$ is irreducible under a (uniquely determined) strongly continuous unitary representation of $SL(2,\mathbb{R})$ whose Lie algebra is given by the (uniquely determined) self-adjoint extension of the real linear combinations of operators H_0, D, C:

$$H_0 := E\ , \quad D := -i\left(\frac{1}{2}+E\frac{\mathrm{d}}{\mathrm{d}E}\right)\ , \quad C := -\frac{\mathrm{d}}{\mathrm{d}E}E\frac{\mathrm{d}}{\mathrm{d}E} + \frac{\left(k-\frac{1}{2}\right)^2}{E}\ . \tag{7}$$

k can arbitrarily be fixed in $\{1/2, 1, 3/2,...\}$. iH_0, iC, iD enjoy the commutation relations of the Lie algebra of $SL(2,\mathbb{R})$ in a suitable dense and invariant domain $\mathcal{D}_k$ where they, and their real linear combinations, are essentially self-adjoint[8] and $\overline{H_0}=H$. $\mathcal{D}_k$ is the subspace spanned by the eigenvectors of the operator

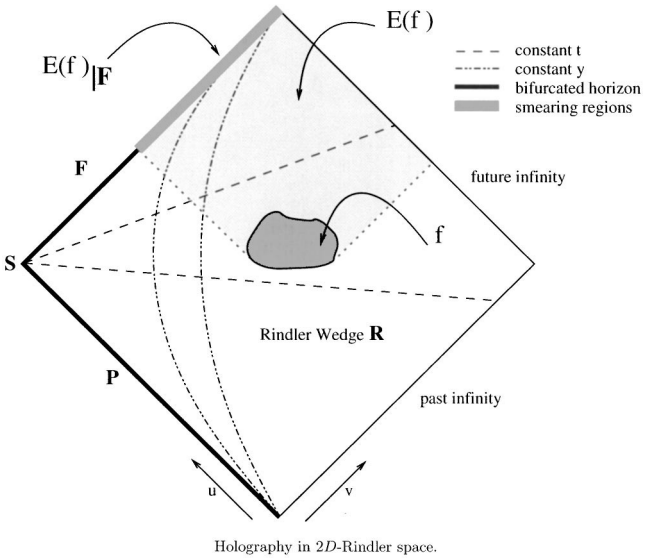

FIG. 1. Holography in 2D-Rindler space.

$$K_\beta := \frac{1}{2}\left(\beta H_0 + \frac{1}{\beta} C\right), \tag{8}$$

β being a constant with the dimensions of an inverse energy. The unitary representation does not depend on the value of β. The spectrum of the self-adjoint operator $\overline{K_\beta}$ (initially defined on $\mathcal{D}_k$) is a pure point spectrum without degeneracy, it does not depend on β itself and is $\sigma(K_\beta) = \{\lambda_n \mid \lambda_n = n,\ \ n = k, k+1, k+2, \ldots\}$. If $\mathrm{L}_p^{(\alpha)}$ are modified Laguerre's polynomials,[17] the associated normalized eigenvectors (which are the same as those of K_β) are

$$Z_n^{(k)}(E) := \eta_n \sqrt{\frac{\Gamma(n-k+1)}{E\,\Gamma(n+k)}}\, e^{-\beta E} (2\beta E)^k \mathrm{L}_{n-k}^{(2k-1)}(2\beta E), \quad n = k, k+1, \ldots, \tag{9}$$

η_n being a pure phase which can be arbitrarily fixed (in Refs. 9 and 8 we used $\eta_n = 1$). As noticed in Ref. 9, if β is interpreted as an inverse temperature, the exponential $e^{-\beta E}$ suggests an interpretation in terms of a canonical ensemble of the energetic content of these states. In this paper we examine in depth this possibility finding out very interesting results.

If $m = 0$ and so $\mathcal{H} \cong L^2(\mathbb{R}^+, \mathrm{d}E) \oplus L^2(\mathbb{R}^+, \mathrm{d}E)$, an analogue representation exists in each space $L^2(\mathbb{R}^+, \mathrm{d}E)$. Making use of the Heisenberg representation it is simply proven that the algebra generated by $H, \overline{D}, \overline{C}$, with depending-on-time coefficients, is made of constant of motions.[8] Thus $SL(2,\mathbb{R})$ is a *symmetry* of the one-particle system. That can straightforwardly be extended to the free quantum field in Fock space. The crucial point is that the found symmetry is *hidden*: It cannot be induced by the background geometry since the Killing fields of Rindler space–time enjoy a different Lie algebra from that of H_0, D, C and no representation of $SL(2,\mathbb{R})$ exists in terms of isometries of **R** (see Ref. 8 for definitions and details). The picture changes dramatically when the found $SL(2,\mathbb{R})$ symmetry is examined on the horizon as noted in [e] below.

[c] The space **R** is naturally embedded in a Minkowski space–time which contains the horizon associated with the Rindler metric. Rindler *light coordinates* $u = t - \log(\kappa y)/\kappa$, $v = t + \log(\kappa y)/\kappa$ (where $u, v \in \mathbb{R}$) cover the (open) Rindler space **R**. Separately, v is well defined on the *future horizon* **F**, $u \to +\infty$, and u is well defined on the *past horizon* **P**, $v \to -\infty$ (see Fig. 1). A wave function in (1) admits well-defined limits toward the future horizon $u \to +\infty$:

$$\psi(v)=\int \frac{e^{-iEv}}{\sqrt{4\pi E}} e^{i\rho_{m,\kappa}(E)}\widetilde{\psi}_+(E)\ \mathrm{d}E+\mathrm{c.c.}, \tag{10}$$

$e^{i\rho_{m,\kappa}(E)}$ being a pure phase.[8] In coordinate $u\in\mathbb{R}$, the restriction of ψ to $\mathbf{P}$ is similar with v replaced for u and $\rho_{m,\kappa}(E)$ replaced by $-\rho_{m,\kappa}(E)$. If $m=0$ restrictions to $\mathbf{F}$ and $\mathbf{P}$ are similar to (10) with the difference that $e^{i\rho_{m,\kappa}(E)}$ is replaced by 1, only ingoing components survive in the limit toward $\mathbf{F}$ and only outgoing components survive in the limit toward $\mathbf{F}$ (v must be replaced for u in that case). Discarding the phase it is possible to consider the following real "*wave function on the (future) horizon* $\mathbf{F}$":

$$\varphi(v)=\int_{\mathbb{R}^+}\frac{e^{-iEv}}{\sqrt{4\pi E}}\widetilde{\varphi}_+(E)\ \mathrm{d}E+\int_{\mathbb{R}^+}\frac{e^{+iEv}}{\sqrt{4\pi E}}\overline{\widetilde{\varphi}_+(E)}\ \mathrm{d}E, \tag{11}$$

where φ *is any real function in Schwartz' space on* $\mathbb{R}\equiv\mathbf{F}$, as the basic object in defining a quantum field theory on the future horizon. The same is doable concerning $\mathbf{P}$. The space of horizon wave functions can be equipped with a diffeomorphism invariant symplectic form $\Omega_{\mathbf{F}}(\varphi,\varphi')\coloneqq\int_{\mathbf{F}}\varphi'\mathrm{d}\varphi-\varphi\mathrm{d}\varphi'$. A suitable causal propagator can also be defined $E_{\mathbf{F}}(v,v')=(1/4)\mathrm{sign}(v-v')$ and used as noted in the following. First of all define the Hermitian scalar product $\langle\varphi'_+,\varphi_+\rangle_{\mathbf{F}}\coloneqq -i\Omega_{\mathbf{F}}(\overline{\varphi'_+},\varphi_+)$. The one-particle Hilbert space $\mathcal{H}_{\mathbf{F}}$ is the completion with respect to that scalar product of the space of complex combinations of positive frequency parts $\widetilde{\varphi}_+(E)$, of horizon wave functions φ. As $\langle\varphi'_+,\varphi_+\rangle_{\mathbf{F}}=\int_{\mathbb{R}^+}\overline{\widetilde{\varphi}'_+(E)}\widetilde{\varphi}_+(E)\mathrm{d}E$, $\mathcal{H}_{\mathbf{F}}$ turns out to be isomorphic to $L^2(\mathbb{R}^+,\mathrm{d}E)$ once again. The field operator is defined in the symmetrized Fock space $\mathfrak{F}(\mathcal{H}_{\mathbf{F}})$, with vacuum state $|0\rangle_{\mathbf{F}}$, with rigorous symplectic definition given by

$$\varphi\mapsto\Omega_{\mathbf{F}}(\varphi,\hat{\phi}_F)\coloneqq ia(\overline{\varphi_+})-ia^\dagger(\varphi_+)\ , \tag{12}$$

where φ is any horizon wave function in the above-specified space. With these definitions, in spite of the absence of any equation of motion the essential features of free quantum field theory are preserved by that definition.[8] Degeneracy of the metric on the horizon prevents one from smearing field operators by functions due to the ill-definiteness of the induced volume measure. However, employing the symplectic approach,[18] a well-defined smearing procedure is that of field operators and exact one-forms $\eta=df$ where $f=f(v)$, $v\in\mathbb{R}\equiv\mathbf{F}$, is any real function in Schwartz's space. More precisely, $\eta(v)\mapsto E_{\mathbf{F}}(\eta)=\frac{1}{4}\int_{\mathbb{R}}\mathrm{sign}(v-v')\,\eta(v')=\psi_\eta(v)$ defines a one-to-one correspondence between exact one-forms and horizon wave functions of the form (11) and $\eta=2d\psi_\eta$. Thus, if $\eta=\mathrm{d}\varphi$ with $\varphi=\varphi(v)$ in Schwartz' space, one can define

$$\eta\mapsto\hat{\phi}_{\mathbf{F}}(\eta)\coloneqq\Omega_{\mathbf{F}}(E_{\mathbf{F}}\eta,\hat{\phi}_{\mathbf{F}})\ , \tag{13}$$

which is the rigorous meaning of

$$\hat{\phi}_{\mathbf{F}}(\eta)=\int_0^\infty\frac{\mathrm{d}E}{\sqrt{4\pi E}}\left(\int_{\mathbb{R}}e^{-iEv}\,\eta(v)\right)a_E+\left(\int_{\mathbb{R}}e^{iEv}\,\eta(v)\right)a_E^\dagger. \tag{14}$$

Horizon wave functions φ and one-forms η,η' in the above-noted spaces enjoy the same properties as in the bulk. More precisely one has

$$\int_{\mathbf{F}}\varphi\,\eta=\Omega_{\mathbf{F}}(E_{\mathbf{F}}\eta,\varphi),\qquad\int_{\mathbf{F}}(E_{\mathbf{F}}\eta)\,\eta'=\Omega_{\mathbf{F}}(E_{\mathbf{F}}\eta,E_{\mathbf{F}}\eta')\ , \tag{15}$$

$$[\hat{\phi}_{\mathbf{F}}(\eta),\hat{\phi}_{\mathbf{F}}(\eta')]=-iE_{\mathbf{F}}(\eta,\eta')=\int_{\mathbf{F}}\psi_{\eta'}\mathrm{d}\psi_\eta-\psi_\eta\mathrm{d}\psi_{\eta'}\,. \tag{16}$$

The latter is nothing but the rigorous meaning of the formal equation $[\hat{\phi}(v),\hat{\phi}(v')] = -iE_{\mathbf{F}}(v,v')$. Finally a "locality property" holds true:

$$[\hat{\phi}_{\mathbf{F}}(\eta),\hat{\phi}_{\mathbf{F}}(\eta')]=0 \quad \text{if} \quad \mathrm{supp}(\eta)\cap\mathrm{supp}(\eta')=\varnothing.$$

Everything we have stated for **F** can analogously be stated for **P**.

[d] It is possible to prove the existence of a unitary equivalence between the theory in the bulk and that on the horizon in the sense we are going to describe.

Theorem 1.1: *If f is any real smooth compactly supported function f used to smear the bulk field, define $\eta_f := 2\mathrm{d}(E(f)\restriction_{\mathbf{F}})$, and $\omega_f := 2\mathrm{d}(E(f)\restriction_{\mathbf{P}})$, $E(f)\restriction_{\mathbf{F/P}}$ being the limit toward* **F**, *respectively,* **P**, *of $E(f)$ (see Fig. 1).*

(a) If $m>0$, there is a unitary map $U_{\mathbf{F}}:\mathfrak{F}(\mathcal{H})\to\mathfrak{F}(\mathcal{H}_{\mathbf{F}})$ such that

$$U_{\mathbf{F}}|0\rangle=|0\rangle_{\mathbf{F}}, \quad \textit{and} \quad U_{\mathbf{F}}^{-1}\hat{\phi}_{\mathbf{F}}(\eta_f)U_{\mathbf{F}}=\hat{\phi}(f)\ .$$

(b) If $m=0$ two unitary operators arise $V_{\mathbf{F/P}}:\mathfrak{F}(\mathcal{H}_{\mathrm{in/out}})\to\mathfrak{F}(\mathcal{H}_{\mathbf{F/P}})$ such that

$$V_{\mathbf{F/P}}|0\rangle_{\mathrm{in/out}}=|0\rangle_{\mathbf{F/P}}$$

and

$$V_{\mathbf{F}}^{-1}\hat{\phi}_{\mathbf{F}}(\eta_f)V_{\mathbf{F}}=\hat{\phi}_{\mathrm{in}}(f)\ , \quad \textit{and} \quad V_{\mathbf{P}}^{-1}\hat{\phi}_{\mathbf{P}}(\omega_f)V_{\mathbf{P}}=\hat{\phi}_{\mathrm{out}}(f)\ .$$

$\mathcal{H}_{\mathrm{in/out}}$ is the bulk Hilbert space associated with the ingoing/outgoing modes and $\hat{\phi}_{\mathrm{in/out}}(f)$ is the part of bulk field operator built up using only ingoing/outgoing modes.

Details on the construction of $U_{\mathbf{F}}$, $V_{\mathbf{F}}$, $V_{\mathbf{P}}$ are supplied in Ref. 8. Similar to the extent in the bulk case, one focuses on the algebra $\mathcal{A}_{\mathbf{F}}$ of linear combinations of product of field operators $\hat{\phi}_{\mathbf{F}}(\omega)$ varying ω in the space of allowed complex one-forms. We assume that $\mathcal{A}_{\mathbf{F}}$ also contains the unit operator I. The Hermitian elements of $\mathcal{A}_{\mathbf{F}}$ are the natural observables associated with the horizon field. From an abstract point of view the found algebra is a unital $*$-algebra of formal operators $\phi_{\mathbf{F}}(\eta)$ with the additional properties $[\phi_{\mathbf{F}}(\eta),\phi_{\mathbf{F}}(\eta)]=-iE_{\mathbf{F}}(\eta,\eta')$, $\phi_{\mathbf{F}}(\eta)^* = \phi_{\mathbf{F}}(\overline{\eta})$ and linearity in the form η. (The analogous algebra of operators in the bulk fulfill the further requirement $\phi(f)=0$ if (and only if) $f=Kg$, K being the Klein–Gordon operator. No analogous requirement makes sense for $\mathcal{A}_{\mathbf{F}}$ since there is no equation of motion on the horizon.) $\mathcal{A}_{\mathbf{F}}$ can be studied no matter any operator representation in any Fock space. Operator representations are obtained via the GNS theorem once an algebraic state has been fixed.[18] $\mathcal{A}_{\mathbf{P}}$ can analogously be defined. Below $\mathcal{A}_{\mathbf{R}}$ denotes the unital $*$-algebra associated with the bulk field operator. If $m=0$, $\mathcal{A}_{\mathbf{R}}$ naturally decomposes as $\mathcal{A}_{\mathrm{in}}\otimes\mathcal{A}_{\mathrm{out}}$ (see Ref. 8) with obvious notation. We have the following result which is independent of any choice of vacuum state and Fock representation. The proof can be found in Ref. 8.

Theorem 1.2: *Assume the same notation as in Theorem 1.1 concerning η_f and ω_f.*

(a) If $m>0$, there is a unique injective unital $*$-algebras homomorphism $\chi_{\mathbf{F}}:\mathcal{A}_{\mathbf{R}}\to\mathcal{A}_{\mathbf{F}}$ such that $\chi_{\mathbf{F}}(\phi(f))=\phi_{\mathbf{F}}(\eta_f)$. Moreover in GNS representations in the respectively associated Fock spaces $\mathfrak{F}(\mathcal{H})$, $\mathfrak{F}(\mathcal{H}_{\mathbf{F}})$ built up over $|0\rangle$ and $|0\rangle_{\mathbf{F}}$, respectively, $\chi_{\mathbf{F}}$ has a unitary implementation naturally induced by $U_{\mathbf{F}}$ (e.g., $\chi_{\mathbf{F}}(\hat{\phi}(f))=U_{\mathbf{F}}\hat{\phi}(f)U_{\mathbf{F}}^{-1}$).

(b) If $m=0$, there are two injective unital $*$-algebras homomorphisms $\Pi_{\mathbf{F/P}}:\mathcal{A}_{\mathrm{in/out}}\to\mathcal{A}_{\mathbf{F/P}}$ such that $\Pi_{\mathbf{F}}(\phi(f))=\phi_{\mathbf{F}}(\eta_f)$ and $\Pi_{\mathbf{P}}(\phi(f))=\phi_{\mathbf{P}}(\omega_f)$. Moreover in GNS representations in the respectively associated Fock spaces $\mathfrak{F}(\mathcal{H}_{\mathrm{in/out}})$, $\mathfrak{F}(\mathcal{H}_{\mathbf{F/P}})$ built up over $|0\rangle_{\mathrm{in/out}}$ and $|0\rangle_{\mathbf{F/P}}$, respectively, $\Pi_{\mathbf{F}}$ and $\Pi_{\mathbf{P}}$ have unitary implementations and reduce to $V_{\mathbf{F}}$ and $V_{\mathbf{P}}$, respectively.

Notice that, in particular $\chi_{\mathbf{F}}$ preserves the causal propagator, in the sense that it must be $-iE(f,g)=[\phi(f),\phi(g)]=[\phi_{\mathbf{F}}(f),\phi_{\mathbf{F}}(g)]=-iE_{\mathbf{F}}(\eta_f,\eta_g)$.

[e] Consider quantum field theory on **F**, but the same result holds concerning **P**. In $\mathcal{H}_{\mathbf{F}} \cong L^2(\mathbb{R}^+,\mathrm{d}E)$ define operators $H_{\mathbf{F}0},D_{\mathbf{F}},C_{\mathbf{F}}$ as the right-hand side of the equation that, respec-

tively, defines H_0, D, C in (7). They and their real linear combinations are essentially self-adjoint if restricted to the invariant dense domain $\mathcal{D}_k^{(\mathbf{F})}$ defined with the same definition as $\mathcal{D}_k$ in [b]. Exactly as in the bulk case, operators $iH_{\mathbf{F}}=iH_{\mathbf{F}0}$, $i\overline{D}_{\mathbf{F}}, i\overline{C}_{\mathbf{F}}$ generate a strongly continuous unitary $SL(2,\mathbb{R})$ representation $\{U_g^{(\mathbf{F})}\}_{g\in SL(2,\mathbb{R})}$. Hence, varying $g\in SL(2,\mathbb{R})$, the unitary operators obtained by unitary holography $(U_{\mathbf{F}}\restriction_{\mathcal{H}})^{-1}\, U_g^{(\mathbf{F})}\, U_{\mathbf{F}}\restriction_{\mathcal{H}}$ define a representation of $SL(2,\mathbb{R})$ for the system in the bulk. By construction $(U_{\mathbf{F}}\restriction_{\mathcal{H}})^{-1}\, H_{\mathbf{F}}\, U_{\mathbf{F}}\restriction_{\mathcal{H}}=H$. As a consequence every $U_g^{(\mathbf{F})}$ gives rise to a $SL(2,\mathbb{R})$ symmetry of the bulk field and the group of these symmetries is unitary equivalent to that generated by $iH, i\overline{D}, i\overline{C}$. In particular the one-parameter group associated with $H_{\mathbf{F}}$ generates v displacements of horizon wave functions which are equivalent, under unitary holography, to t displacements of bulk wave functions. Now, it makes sense to investigate the *geometrical nature* of the $SL(2,\mathbb{R})$ representation $\{U_g^{(\mathbf{F})}\}$ that, as we said, induces, up to unitary equivalences, the original $SL(2,\mathbb{R})$ symmetry in the bulk, but now can be examined on the horizon. In fact, the symmetry has a geometrical meaning: The action of every $U_g^{(\mathbf{F})}$ on a state $\tilde{\varphi}_+=\tilde{\varphi}_+(E)$ is essentially equivalent to the action of a corresponding **F**-diffeomorphism on the associated [by (11)] horizon wave function φ. More precisely:[8]

Theorem 1.3: *Assume $k=1$ in (7), take a matrix $g\in SL(2,\mathbb{R})$. Let $\varphi=\varphi(v)$ be a real Schwartz's horizon wave function with positive frequency part $\tilde{\varphi}_+=\tilde{\varphi}_+(E)$ and such that $\varphi(0)=0$ and $v\mapsto\varphi(1/v)$ belongs to Schwartz's space too.*

The wave function φ_g associated with $U_g^{(\mathbf{F})}\tilde{\varphi}_+$ reads

$$\varphi_g(v)=\varphi\left(\frac{av+b}{cv+d}\right)-\varphi\left(\frac{b}{d}\right),\quad \begin{pmatrix} a & b\\ c & d\end{pmatrix}=g^{-1}. \tag{17}$$

Moreover one has the particular cases:

(a) The unitary one-parameter group generated by $iH_{\mathbf{F}}$ is associated with the one-parameter group of **F** *diffeomorphisms generated by ∂_v.*
In other words, for every $t\in\mathbb{R}$ and positive-frequency part wave function $\tilde{\varphi}_+$, the positive-frequency part wave function $e^{itH_{\mathbf{F}}}\tilde{\varphi}_+$ is associated with the horizon wave function φ_{g_t} such that

$$\left.\frac{\partial\varphi_{g_t}}{\partial t}\right|_{t=0}=-\partial_v\varphi\ .$$

(b) With the same terminology as in case (a), the unitary one-parameter group generated by $i\overline{D}_{\mathbf{F}}$ is associated with the one-parameter group of **F** *diffeomorphisms generated by $v\partial_v$.*

(c) With the same terminology as in case (a), the unitary one-parameter group generated by $i\overline{C}_{\mathbf{F}}$ is associated with the one-group of **F** *diffeomorphisms generated by $v^2\partial_v$.*

The term $-\varphi(b/d)$ in (17) assures that φ_g vanishes as $v\to\pm\infty$. Notice that the added term disappears when referring to $\mathrm{d}\varphi$ rather than φ. The group of diffeomorphisms of $\mathbf{F}\equiv\mathbb{R}$ used above,

$$v\mapsto\frac{av+b}{cv+d},\quad \begin{pmatrix} a & b\\ c & d\end{pmatrix}\in SL(2,\mathbb{R}), \tag{18}$$

in fact gives a representation of $SL(2,\mathbb{R})$. It can be obtained by finite composition of one-parameter subgroups associated with the following three vector fields on **F**: $\partial_v, v\partial_v, v^2\partial_v$. It is simply proven that the Lie brackets of $-\partial_v, -v\partial_v, -v^2\partial_v$ produce the same algebra as the Lie algebra of $SL(2,\mathbb{R})$. We conclude that the bulk $SL(2,\mathbb{R})$-symmetry is manifest when examined on the horizon, in the sense that it is induced by the geometry.

II. FROM THE LINE TO THE CIRCLE: THE FULL VIRASORO ALGEBRA

Noli tangere circulos meos. (Archimedes' last words.)

The algebra of vector fields $\partial_v, v\partial_v, v^2\partial_v$ can be extended to include the class of fields defined on the horizon $v^{n+1}\partial_v$ with $n\in\mathbb{Z}$. It is interesting to notice that these fields (more precisely the fields $-v^{n+1}\partial_v$) enjoy Virasoro commutation relations without central charge. In fact there is a central representation of Virasoro algebra which presents a central charge and is directly defined in terms of operators acting in the Fock space of the horizon particles. The representation can be introduced after one has given a convenient definition of quantum field operator on the circle $\mathsf{F}=\mathbf{F}\cup\{\infty\}$.

A. QFT on the circle $\mathsf{F}=\mathsf{F}\cup\{\infty\}$

Consider the vector field on $\mathbf{F}$,

$$\mathcal{K}:=\frac{1}{2}\left(\beta\partial_v+\frac{1}{\beta}v^2\partial_v\right). \tag{19}$$

That field is associated with the essentially self-adjoint operator that is defined on $\mathcal{D}_1^{(\mathbf{F})}$,

$$K_{\mathbf{F}\beta}:=\frac{1}{2}\left(\beta H_{\mathbf{F}}+\frac{1}{\beta}C_{\mathbf{F}}\right), \tag{20}$$

in the Lie algebra of the unitary representation of $SL(2,\mathbb{R})$ because of Theorem 1.4. It is simply proven that the integral line of $\mathcal{K}$ with origin in $v=0$ is $v=\beta\tan(\theta/2)$ with $\theta\in(-\pi,\pi)$ and $v=0$ corresponding to $\theta=0$. One can use θ as a new coordinate on $\mathbf{F}$ with the advantage that this new coordinate gets finite values in the whole compactified manifold $\mathbf{F}\cup\{\infty\}\equiv\mathsf{F}$ (in the sense of Alexandrov's procedure), the added point ∞ corresponding to $\theta=\pi\equiv-\pi$ in the circle. As a consequence of our definitions, it turns out that

$$\mathcal{K}=\partial_\theta. \tag{21}$$

In fact this formula smoothly extends the left-hand side on the whole circle F. By construction, there is the natural submanifold embedding $\mathbf{F}\subset\mathsf{F}$. We want to show that such an inclusion can be extended to free quantum field theory if a suitable definition of QFT on F is given. We follow a procedure very similar to that used for the horizon. As a final result we show that more strongly, the ''inclusion'' of QFT on $\mathbf{F}$ into QFT on F is actually a unitary equivalence as well as a $*$-algebras inclusion. The observable $K_{\mathbf{F}\beta}$ plays a central role in that identification. The associated quantum field theory on F will be proved to support a nice unitary Virasoro's algebra representation with an explicit geometric meaning that extends the unitary representation of $SL(2,\mathbb{R})$.

Consider the space of real C^∞ functions ρ on F, $C^\infty(\mathsf{F};\mathbb{R})$, and define a subsequent real vector space $\mathcal{S}(\mathsf{F})$ by taking the quotient with respect to the equivalence relation, for $\rho,\rho'\in C^\infty(\mathsf{F};\mathbb{R})$,

$$\rho\sim\rho' \quad \text{iff} \quad d(\rho-\rho')=0. \tag{22}$$

From now on, the elements of $\mathcal{S}(\mathsf{F})$ are called *circle wave functions*. The following symplectic form on $\mathcal{S}(\mathsf{F})$ is well-defined and nondegenerate [the latter is not true on $C^\infty(\mathsf{F};\mathbb{R})$]:

$$\Omega_{\mathsf{F}}(\rho,\rho'):=\int_{\mathsf{F}}\rho'\,\mathrm{d}\rho-\rho\,\mathrm{d}\rho'. \tag{23}$$

The elements of $C^\infty(\mathsf{F};\mathbb{C})$ can be expanded in Fourier series. If $\rho\in C^\infty(\mathsf{F};\mathbb{R})$, with a rearrangement of the Fourier coefficients it holds either in $L^2(\mathsf{F},\mathrm{d}\theta)$ and in the uniform sense

$$\rho(\theta)=\rho_0+\sum_{n=1}^{\infty}\frac{e^{-in\theta}\,\tilde{\rho}_+(n)}{\sqrt{4\pi n}}+\frac{e^{in\theta}\,\overline{\tilde{\rho}_+(n)}}{\sqrt{4\pi n}}.$$

As $\tilde{\rho}_+(n)$ is proportional to $\int_{\mathsf{F}} e^{-in\theta}\rho(\theta)\mathrm{d}\theta$ and $\int_{\mathsf{F}} e^{-in\theta}\mathrm{d}\theta = 0$, if $n>0$, the coefficients $\tilde{\rho}(n)$ are not affected if ρ is replaced by ρ' with $\rho-\rho' =$ constant, and thus the coefficients $\tilde{\rho}_+(n)$, *for* $n>0$, are well-associated with an element of $\mathcal{S}(\mathsf{F})$. In the following we indicate the elements of $\mathcal{S}(\mathsf{F})$ simply by ρ instead of $[\rho]$. In the sense clarified above, if $\rho \in \mathcal{S}(\mathsf{F})$ we have

$$\rho(\theta) = \sum_{n=1}^{\infty} \frac{e^{-in\theta}\,\tilde{\rho}_+(n)}{\sqrt{4\pi n}} + \text{c.c.} = \rho_+(\theta) + \text{c.c.} \tag{24}$$

To define the one-particle Hilbert space, define the Hermitian scalar product

$$\langle \rho'_+, \rho_+ \rangle_{\mathsf{F}} := -i\Omega_{\mathsf{F}}(\overline{\rho'_+}, \rho_+) \ .$$

The one-particle Hilbert space $\mathcal{H}_{\mathsf{F}}$ is the completion with respect to that scalar product of the space of complex combinations of positive frequency parts $\{\tilde{\rho}_+(n)\}$, of circle wave functions ρ. It is simply proven that, if $\rho \in C^\infty(\mathsf{F};\mathbb{C})$ with Fourier coefficients $\{C_n\}_{n\in\mathbb{Z}}$, for every $p=0,1,\ldots$ there is a real K_p such that $|n|^p|C_n| \leqslant K_p$ for all $n \in \mathbb{Z}$. As a consequence, $\sum_{n\in\mathbb{Z}} n|C_n|^2 < \infty$. We conclude that, if $\rho \in \mathcal{S}(\mathsf{F})$, the sequence of complex numbers $\{\tilde{\rho}_+(n) = \sqrt{2n}C_n\}_{n=1,2,\ldots}$ is an element of $\ell^2(\mathbb{C})$. A direct computation shows that $\mathcal{H}_{\mathsf{F}}$ turns out to be isomorphic to $\ell^2(\mathbb{C})$ because

$$\langle \rho'_+, \rho_+ \rangle_{\mathsf{F}} = \sum_{n=1}^{\infty} \overline{\tilde{\rho}'_+(n)}\tilde{\rho}_+(n).$$

Using the Hilbert base of $\mathcal{H}_{\mathbf{F}}$ given by the eigenvectors of the operator $K_{\beta\mathbf{F}}$, $\{Z_n^{(1)}\}_{n=1,2,\ldots}$ [where the phase of $Z_n^{(1)}$ in (9) is fixed to be $\eta_n = (-1)^{n+1}$], the unitary map $M: \mathcal{H}_{\mathbf{F}} \to \mathcal{H}_{\mathsf{F}}$ can be defined such that

$$M: \varphi \mapsto \{\langle Z_n^{(1)}, \varphi\rangle\}_{n=1,2,\ldots} . \tag{25}$$

That isomorphism has a natural geometric interpretation stated in the former part of the theorem below.

Theorem 2.1: *Let $\varphi = \varphi(v)$ be a real horizon wave function (which belongs to Schwartz's space on $\mathbb{R} \equiv \mathbf{F}$) associated with a quantum state $\tilde{\varphi}_+$. If ρ is the circle wave function associated with φ by means of the unitary transformation (25), that is $\tilde{\rho}_+ := M(\tilde{\varphi}_+)$, one has*

$$\rho(\theta) = \varphi(v(\theta)) \ , \tag{26}$$

where $v(\theta) = \beta\tan(\theta/2)$, $\theta \in (-\pi, \pi]$. In other words

$$\varphi(v(\theta)) = \sum_{n=1}^{\infty} \frac{\langle Z_n^{(1)}, \tilde{\varphi}_+\rangle}{\sqrt{4\pi n}} e^{-in\theta} + \text{c.c.} + \text{const.}$$

The linear map $\varphi \mapsto \rho$ defined in (26) is injective and preserves the symplectic forms of the respective spaces, that is, if ρ' is associated with φ' by the map (26) itself,

$$\Omega_{\mathsf{F}}(\rho, \rho') = \Omega_{\mathbf{F}}(\varphi, \varphi') \ . \tag{27}$$

Proof: Notice that, if the real horizon wave function $\varphi = \varphi(v)$ is in Schwartz's space, the function $(-\pi, \pi] \ni \theta \mapsto \varphi(v(\theta))$ is well-defined and belongs to $C^\infty(\mathsf{F};\mathbb{R})$ with $\varphi(v(\pm\pi)) = 0$ with all its derivatives of any order. So the thesis makes sense. The second part can straightforwardly be proven by using the given definitions, so we focus on the former only. If the real horizon wave function $\varphi = \varphi(v)$ is in Schwartz's space, the associated positive frequency part $\tilde{\varphi}_+(E)$ is such that $\tilde{\varphi}_+(E)/\sqrt{4\pi E}$ is the restriction to $\mathbb{R}^+$ of Schwartz's function. As a consequence $\varphi_+(v) = \int_0^{+\infty} \mathrm{d}E\, e^{-iEv}\tilde{\varphi}_+(E)/\sqrt{4\pi E}$ is smooth and

$$\varphi_+(v(\theta)) \sim \text{const} \times \frac{\tilde{\varphi}_+(E)}{\sqrt{E}}\bigg|_{E=0} (\theta \mp \pi)^2$$

as $\theta \to \pm\pi$. So the Fourier expansion of φ_+ makes sense and each coefficient of the Fourier expansion of φ is the sum of the corresponding coefficients of the Fourier expansion of φ_+ and $\overline{\varphi_+}$, it being $\varphi = \varphi_+ + \overline{\varphi_+}$. We want to evaluate the Fourier coefficients of φ_+. First consider the Fourier coefficients with $n>0$. By direct computation[17] one finds

$$\int_0^{+\infty} \frac{e^{-iE\beta \tan(\theta/2)} Z_n^{(1)}(E)}{\sqrt{4\pi E}} \mathrm{d}E = \frac{1}{\sqrt{4\pi n}} ((-1)^{n+1} + e^{-in\theta}) \ , \tag{28}$$

with $\theta \in (-\pi, \pi]$ [notice that the dependence form β cancels out due the shape (9) of functions $Z_n^{(1)}$ by passing to the new variable of integration βE in the integral]. As a consequence, defining $Z_n^{(1)}(E)=0$ if $E<0$, inverting the Fourier(-Plancherel) transform (and changing the integration variable $v \to -v$),

$$\frac{Z_n^{(1)}(E)}{\sqrt{2E}} = \lim_{L\to+\infty} \int_{-L}^{L} \mathrm{d}v \, e^{-ivE} \frac{(-1)^{n+1} + e^{2in \tan^{-1}(v/\beta)}}{\sqrt{4\pi n}} \ , \tag{29}$$

the limit being computed in the sense of $L^2(\mathbb{R}, \mathrm{d}E)$. Since $E \mapsto \tilde{\varphi}_+(E)/\sqrt{E}$ is the restriction to $\mathbb{R}^+$ of a Schwartz function, $E \mapsto \psi(E) = \sqrt{2E}\tilde{\varphi}_+(E)$ ($\psi(E) := 0$ for $E<0$!) is a function in $L^1(\mathbb{R}, \mathrm{d}E) \cap L^2(\mathbb{R}, \mathrm{d}E)$. The functions $E \mapsto Z_n^{(1)}(E)$ and $E \mapsto Z_n^{(1)}(E)/\sqrt{2E}$ (assumed to vanish for $E<0$) are real and belong to $L^1(\mathbb{R}, \mathrm{d}E) \cap L^2(\mathbb{R}, \mathrm{d}E)$. It holds

$$\langle Z_n^{(1)}, \tilde{\varphi}_+ \rangle = \int_0^{\infty} \overline{Z_n^{(1)}(E)} \tilde{\varphi}_+(E) \mathrm{d}E = \int_{-\infty}^{\infty} \frac{Z_n^{(1)}(E)}{\sqrt{2E}} \psi(E) \mathrm{d}E \ .$$

Using (29) and taking the L^2-continuity of the scalar product into account, one gets

$$\langle Z_n^{(1)}, \tilde{\varphi}_+ \rangle = \lim_{L\to+\infty} \int_{-\infty}^{\infty} \mathrm{d}E \, \psi(E) \int_{-L}^{L} \mathrm{d}v \, e^{-ivE} \frac{(-1)^{n+1} + e^{2in \tan^{-1}(v/\beta)}}{\sqrt{4\pi n}} \ ,$$

that is

$$\langle Z_n^{(1)}, \tilde{\varphi}_+ \rangle = \lim_{L\to+\infty} \int_{0}^{\infty} \mathrm{d}E \, \tilde{\varphi}_+(E) \int_{-L}^{L} \mathrm{d}v \, 2E \frac{e^{-ivE}}{\sqrt{2E}} \frac{(-1)^{n+1} + e^{in\theta(v)}}{\sqrt{4\pi n}} \ .$$

Using $E e^{-ivE} = i(\partial/\partial v) e^{-ivE}$ and integrating by parts it arises

$$\langle Z_n^{(1)}, \tilde{\varphi}_+ \rangle = C(L) + \lim_{L\to+\infty} \sqrt{2n} \int_0^{\infty} \mathrm{d}E \, \tilde{\varphi}_+(E) \int_{-L}^{L} \mathrm{d}v \, \frac{e^{-iEv}}{\sqrt{4\pi E}} \frac{e^{in\theta(v)}}{\sqrt{2\pi}} \frac{\mathrm{d}\theta}{\mathrm{d}v} \ ,$$

where $C(L)$ is a boundary term which vanishes in the limit $L\to\infty$ by Riemann–Lebesgue's lemma. Interchanging the integration symbols and taking the limit as $L\to\infty$ we finally get the nth Fourier coefficient of φ_+ and the $(-n)$th Fourier coefficient of $\overline{\varphi_+}$,

$$\int_{-\pi}^{\pi} \varphi_+(v(\theta)) \frac{e^{in\theta}}{\sqrt{2\pi}} \mathrm{d}\theta = \frac{\langle Z_n^{(1)}, \tilde{\varphi}_+ \rangle}{\sqrt{2n}} \quad , \quad \int_{-\pi}^{\pi} \overline{\varphi_+(v(\theta))} \frac{e^{-in\theta}}{\sqrt{2\pi}} \mathrm{d}\theta = \frac{\overline{\langle Z_n^{(1)}, \tilde{\varphi}_+ \rangle}}{\sqrt{2n}} \ .$$

Now we pass to consider the remaining Fourier coefficients. Since in (29) $Z_n^{(1)}(E)$ is defined to vanish for $E<0$, one has that, if $n>0$,

$$\lim_{L\to+\infty}\int_{-\infty}^{0} dE\, f(E)\int_{-L}^{L} dv\, e^{-ivE}\frac{(-1)^{n+1}+e^{2in\tan^{-1}(v/\beta)}}{\sqrt{4\pi n}}=0\,,$$

which, after complex conjugation and change of variables $E\to -E$, is equivalent to

$$\lim_{L\to+\infty}\int_{0}^{+\infty} dE\, g(E)\int_{-L}^{L} dv\, e^{-ivE}\frac{(-1)^{m+1}+e^{2im\tan^{-1}(v/\beta)}}{\sqrt{4\pi|m|}}=0\,, \tag{30}$$

where $m=-n<0$ and $g\in L^2(\mathbb{R},dE)$. Using $g(E)=\sqrt{2E}\tilde{\varphi}_+(E)$ for $E\geqslant 0$ and $g(E)=0$ otherwise and following the same procedure as for the case $n>0$, (30) implies that, if $n<0$,

$$\int_{-\pi}^{\pi}\varphi_+(v(\theta))\frac{e^{in\theta}}{\sqrt{2\pi}}d\theta=0\,.$$

As a consequence,

$$\int_{-\pi}^{\pi}\overline{\varphi_+(v(\theta))}\frac{e^{-in\theta}}{\sqrt{2\pi}}d\theta=0\,.$$

Putting all together we get

$$\varphi(v(\theta))=\varphi_+(v(\theta))+\overline{\varphi_+(v(\theta))}=\text{constant}+\sum_{n=1}^{\infty}\frac{\langle Z_n^{(1)},\tilde{\varphi}_+\rangle}{\sqrt{4\pi n}}e^{-in\theta}+\sum_{n=1}^{\infty}\overline{\frac{\langle Z_n^{(1)},\tilde{\varphi}_+\rangle}{\sqrt{4\pi n}}}e^{in\theta}$$

which concludes the proof. □

The result stated in Theorem 2.1 suggests to define a quantum field on the circle $\mathsf{F}:=\mathbf{F}\cup\{\infty\}$ whose Hilbert space is the symmetrized Fock space $\mathfrak{F}(\mathcal{H}_\mathsf{F})\cong\mathfrak{F}(\mathcal{H}_\mathbf{F})$, where the isomorphism is that naturally induced by M of Eq. (25) and the vacuum $|0\rangle_\mathsf{F}$ is associated with $|0\rangle_\mathbf{F}$ by the isomorphism itself. Formally the quantum field operator on F reads

$$\hat{\phi}(\theta)=\sum_{n=1}^{\infty}\frac{e^{-in\theta}\,\alpha_n}{\sqrt{4\pi n}}+\frac{e^{in\theta}\,\alpha_n^\dagger}{\sqrt{4\pi n}}\,, \tag{31}$$

where α_n and $\alpha_n^\dagger$ are the annihilator and constructor operator of modes $Z_n^{(1)}$.

The field operator is defined in the symmetrized Fock space $\mathfrak{F}(\mathcal{H}_\mathsf{F})$, with rigorous symplectic definition given by

$$\rho\mapsto\Omega_\mathsf{F}(\rho,\hat{\phi}_F):=i\alpha(\overline{\rho_+})-i\alpha^\dagger(\rho_+)\,, \tag{32}$$

where ρ is any circle wave function and, respectively, $\alpha(\overline{\rho_+})$, $\alpha^\dagger(\rho_+)$ annihilates and creates the states $\overline{\rho_+}$ and ρ_+. Once again a well-defined smearing procedure is that of field operators and exact one-forms $\eta=d\rho$ where $\rho\in\mathcal{S}(\mathsf{F})$. Notice that $d\rho$ does not depend on the chosen element of the class of equivalence associated with ρ. More precisely, we introduce the "*causal propagator*" on F

$$\eta(\theta)\mapsto E_\mathsf{F}(\eta)=\frac{1}{4}\int_\mathsf{F}[\text{sign}(\theta-\theta')+(\theta'-\theta)/\pi]\,\eta(\theta')\,,$$

where it is understood that one has to take the quotient with respect to the equivalence relation defining $\mathcal{S}(\mathsf{F})$ after the action of E_{F}. Moreover the used function $x\to \mathrm{sign}x$ and $x\to x$ are first defined in $[-\pi,\pi]$ and then are extended in the whole $\mathbb{R}$ as periodic functions with period 2π. E_{F} gives rise to a bijective linear map from the space of real exact C^∞ one-forms on F [which will be denoted by $\mathcal{D}(\mathsf{F})$] and $\mathcal{S}(\mathsf{F})$ itself. Indeed, it results that if $\rho\in\mathcal{S}(\mathsf{F})$,

$$E_{\mathsf{F}}(\omega)=\rho \qquad \text{if and only if} \qquad \omega=2d\rho\ . \tag{33}$$

We can define the field operator smeared by elements of $\mathcal{D}(\mathsf{F};\mathbb{R})$ as

$$\eta\mapsto\hat{\phi}_{\mathsf{F}}(\eta):=\Omega_{\mathsf{F}}(E_{\mathsf{F}}\eta,\hat{\phi}_{\mathsf{F}})\ , \tag{34}$$

which is the rigorous meaning of

$$\hat{\phi}_{\mathsf{F}}(\eta)=\sum_{n=1}^{\infty}\left(\int_{\mathsf{F}}e^{-in\theta}\eta(\theta)\right)\frac{\alpha_n}{\sqrt{4\pi n}}+\left(\int_{\mathsf{F}}e^{in\theta}\eta(\theta)\right)\frac{\alpha_n^\dagger}{\sqrt{4\pi n}}\ . \tag{35}$$

Circle wave functions ρ and one-forms η,η' in the above-noted spaces enjoy the same properties as in the bulk. More precisely one has

$$\int_{\mathsf{F}}\rho\,\eta=\Omega_{\mathsf{F}}(E_{\mathsf{F}}\eta,\rho),\qquad \int_{\mathsf{F}}(E_{\mathsf{F}}\eta)\,\eta'=\Omega_{\mathsf{F}}(E_{\mathsf{F}}\eta,E_{\mathsf{F}}\eta')\ , \tag{36}$$

$$[\hat{\phi}_{\mathsf{F}}(\eta),\hat{\phi}_{\mathsf{F}}(\eta')]=-iE_{\mathsf{F}}(\eta,\eta')\ . \tag{37}$$

The latter is nothing but the rigorous meaning of the formal equation $[\hat{\phi}_{\mathsf{F}}(\theta),\hat{\phi}_{\mathsf{F}}(\theta')]=-iE_{\mathsf{F}}(\theta,\theta')$. Notice that as a consequence of (33), (36), (37), a "locality property" holds

$$[\hat{\phi}_{\mathsf{F}}(\eta),\hat{\phi}_{\mathsf{F}}(\eta')]=0 \qquad \text{if} \qquad \mathrm{supp}(\eta)\cap\mathrm{supp}(\eta')=\varnothing.$$

Everything we said about the future circle $\mathsf{F}=\mathbf{F}\cup\{\infty\}$ can be restated, with obvious changes of notation, for the past circle $\mathsf{P}:=\mathbf{P}\cup\{\infty\}$.

Theorem 2.1 together with Theorems 1.1 and 1.2 has two straightforward consequences.

Theorem 2.2: *If f is any real smooth compactly supported function f used to smear the bulk field, extend on F and P the forms η_f and ω_f defined in Theorem 1.1 by putting $\eta_f(\infty):=0$ and $\omega_f(\infty):=0$ and consider these forms as elements of $\mathcal{D}(\mathsf{F})$ and $\mathcal{D}(\mathsf{P})$ respectively.*

(a) If $m>0$, there is a unitary map $U_{\mathsf{F}}:\mathfrak{F}(\mathcal{H})\to\mathfrak{F}(\mathcal{H}_{\mathsf{F}})$ such that

$$U_{\mathsf{F}}|0\rangle=|0\rangle_{\mathsf{F}},\quad \textit{and}\quad U_{\mathsf{F}}^{-1}\hat{\phi}_{\mathsf{F}}(\eta_f)U_{\mathsf{F}}=\hat{\phi}(f)\ .$$

(b) If $m=0$, two unitary operators arise $V_{\mathsf{F/P}}:\mathfrak{F}(\mathcal{H}_{\mathrm{in/out}})\to\mathfrak{F}(\mathcal{H}_{\mathsf{F/P}})$ such that

$$V_{\mathsf{F/P}}|0\rangle_{\mathrm{in/out}}=|0\rangle_{\mathsf{F/P}}$$

and

$$V_{\mathsf{F}}^{-1}\hat{\phi}_{\mathsf{F}}(\eta_f)V_{\mathsf{F}}=\hat{\phi}_{\mathrm{in}}(f)\ ,\quad \textit{and}\quad V_{\mathsf{P}}^{-1}\hat{\phi}_{\mathsf{P}}(\omega_f)V_{\mathsf{P}}=\hat{\phi}_{\mathrm{out}}(f)\ .$$

$\mathcal{H}_{\mathrm{in/out}}$ is the bulk Hilbert space associated with the ingoing/outgoing modes and $\hat{\phi}_{\mathrm{in/out}}(f)$ is the part of bulk field operator built up using only ingoing/outgoing modes.

Sketch of proof: The unitary operator $U_{\mathbf{F}}$ in Theorem 1.1 is obtained (see Ref. 8) as the unitary operator that fulfills the following pair of conditions. (1) $U_{\mathbf{F}}|0\rangle=|0\rangle_{\mathbf{F}}$; (2) for every natural n, consider the subspace of $\mathfrak{F}(\mathcal{H})$, $\mathcal{H}^{n\otimes}$, spanned by (symmetrized) states with n particles; on every $\mathcal{H}^{n\otimes}$, $U_{\mathbf{F}}$ reduces to the tensor product of n copies of the unitary operator $\mathcal{U}_{\mathbf{F}}:\mathcal{H}\to\mathcal{H}_{\mathbf{F}}$, where,

under the identifications (working in the energy representations) $\mathcal{H}\cong L^2(\mathbb{R}^+,\mathrm{d}E)$, $\mathcal{H}_{\mathbf{F}}\cong L^2(\mathbb{R}^+,\mathrm{d}E)$, $\mathcal{U}_{\mathbf{F}}$ is nothing but the identity operator. Now consider the composite unitary operator $\mathcal{U}_{\mathsf{F}}:=M\circ\mathcal{U}_{\mathbf{F}}:\mathcal{H}\to\mathcal{H}_{\mathsf{F}}$, where M is as in Eq. (25), and define U_{F} such that $U_{\mathsf{F}}|0\rangle=|0\rangle_{\mathsf{F}}$ and the restriction of U_{F} to every $\mathcal{H}^{n\otimes}$ coincides with the tensor product of n copies of the unitary operator $\mathcal{U}_{\mathsf{F}}$. Theorems 1.1 and 2.1 and the definition of $\hat{\phi}_{\mathsf{F}}$ immediately imply the validity of the thesis. The case of $m=0$ can be proven by the same way. □

Similar to the extent on the horizon case, one can focus on the algebra $\mathcal{A}_{\mathsf{F}}$ of linear combinations of product of field operators $\hat{\phi}_{\mathsf{F}}(\omega)$, varying ω in the space $\mathcal{D}(\mathsf{F};\mathbb{C}):=\mathcal{D}(\mathsf{F})+i\mathcal{D}(\mathsf{F})$ and defining $\hat{\phi}_{\mathsf{F}}(\omega+i\omega'):=\hat{\phi}_{\mathsf{F}}(\omega)+i\hat{\phi}_{\mathsf{F}}(\omega')$. We assume that $\mathcal{A}_{\mathsf{F}}$ also contains the unit operator I. The Hermitian elements of $\mathcal{A}_{\mathsf{F}}$ are the natural observables associated with the horizon field. From an abstract point of view the found algebra is a unital $*$-algebra of formal operators $\phi_{\mathsf{F}}(\eta)$ with the additional properties $[\phi_{\mathsf{F}}(\eta),\phi_{\mathsf{F}}(\eta')]=-iE_{\mathsf{F}}(\eta,\eta')$, $\phi_{\mathsf{F}}(\eta)^*=\phi_{\mathsf{F}}(\overline{\eta})$ and linearity in the form η. $\mathcal{A}_{\mathsf{F}}$ can be studied no matter any operator representation in any Fock space. Operator representations are obtained via GNS theorem once an algebraic state has been fixed.[18] Everything we said can be extended to the analogous $*$-algebra defined on P, $\mathcal{A}_{\mathsf{P}}$. We have a second result.

Theorem 2.3. *Assume the same notation as in Theorem 2.2 concerning η_f and ω_f.*

(a) If $m>0$, there is a unique injective unital $*$-algebras homomorphism $\chi_{\mathsf{F}}:\mathcal{A}_{\mathbf{R}}\to\mathcal{A}_{\mathsf{F}}$ such that $\chi_{\mathsf{F}}(\phi(f))=\phi_{\mathsf{F}}(\eta_f)$. Consider the GNS representations in the Fock spaces $\mathfrak{F}(\mathcal{H})$, $\mathfrak{F}(\mathcal{H}_{\mathsf{F}})$ built up over $|0\rangle$ and $|0\rangle_{\mathsf{F}}$, respectively associated with $\mathcal{A}_{\mathbf{R}}$ and $\mathcal{A}_{\mathsf{F}}$, in these representations χ_{F} has a unitary implementation naturally induced by U_{F} (e.g. $\chi_{\mathsf{F}}(\hat{\phi}(f))=U_{\mathsf{F}}\hat{\phi}(f)U_{\mathsf{F}}^{-1}$).

(b) If $m=0$, there are two injective unital $*$-algebras homomorphisms $\Pi_{\mathsf{F/P}}:\mathcal{A}_{\mathrm{in/out}}\to\mathcal{A}_{\mathsf{F/P}}$ such that $\Pi_{\mathsf{F}}(\phi(f))=\phi_{\mathsf{F}}(\eta_f)$ and $\Pi_{\mathsf{P}}(\phi(f))=\phi_{\mathsf{P}}(\omega_f)$. Moreover, considering the GNS representations in the Fock spaces $\mathfrak{F}(\mathcal{H}_{\mathrm{in/out}})$, $\mathfrak{F}(\mathcal{H}_{\mathsf{F/P}})$ built up over $|0\rangle_{\mathrm{in/out}}$ and $|0\rangle_{\mathsf{F/P}}$ respectively associated with $\mathcal{A}_{in/out}$ and $\mathcal{A}_{\mathsf{F/P}}$, Π_{F} and Π_{P} have unitary implementations and reduce to V_{F} and V_{P}, respectively.

Sketch of proof: Consider the map $\chi'_{\mathsf{F}}:\hat{\phi}_{\mathbf{F}}(\eta)\mapsto\hat{\phi}_{\mathsf{F}}(\eta)$ where $\eta=\mathrm{d}\varphi$, φ being any real Schwartz function on $\mathbf{F}\equiv\mathbb{R}$. In $\hat{\phi}_{\mathbf{F}}(\eta)$, η is supposed extended to the whole F by means of $\eta(\infty):=0$ so that $\eta\in\mathcal{D}(\mathsf{F};\mathbb{R})$. Using the fact that it holds $[\hat{\phi}_{\mathsf{F}}(\eta),\hat{\phi}_{\mathsf{F}}(\eta')]=-i\Omega_{\mathsf{F}}(E_{\mathsf{F}}(\eta'),E_{\mathsf{F}}(\eta))=-i\Omega_{\mathbf{F}}(E_{\mathbf{F}}(\eta'),E_{\mathbf{F}}(\eta))=[\hat{\phi}_{\mathbf{F}}(\eta),\hat{\phi}_{\mathbf{F}}(\eta')]$, one proves that χ'_{F} uniquely extends into an injective $*$-algebra homomorphism from $\mathcal{A}_{\mathbf{F}}$ to $\mathcal{A}_{\mathsf{F}}$. The injective $*$-algebra homomorphism χ_{F} is nothing but $\chi'_{\mathsf{F}}\circ\chi_{\mathbf{F}}$. The remaining properties are strightforward consequences of the properties of $\chi_{\mathbf{F}}$ stated in Theorem 1.2. The case $m=0$ is analogous. □

B. Virasoro algebra with $c=1$ in the Fock space of the circle

The unitary map $M:\mathcal{H}_{\mathbf{F}}\to\mathcal{H}_{\mathsf{F}}$ associates the essentially self-adjoint operators $H_{\mathbf{F}0},D_{\mathbf{F}},C_{\mathbf{F}}$ defined on $\mathcal{D}_1^{(\mathbf{F})}\subset\mathcal{H}_{\mathbf{F}}$ with analogous essentially self-adjoint operators acting on one-particle circle states $\mathcal{H}_{\mathsf{F}}$, respectively, $H_{\mathsf{F}0},D_{\mathsf{F}},C_{\mathsf{F}}$. More precisely, the real linear combinations of these operators are essentially self-adjoint in the dense invariant domain $\mathcal{D}_1^{(\mathsf{F})}=M(\mathcal{D}_1^{(\mathbf{F})})$ spanned by the eigenvectors of $K_{\beta\mathsf{F}}$ associated with the analogous operator $K_{\beta\mathbf{F}}$ (20). The Lie algebra spanned by the operators above in F gives rises to a strongly continuous unitary $SL(2,\mathbb{R})$ representation $\{U_g^{(\mathsf{F})}\}_{g\in SL(2,\mathbb{R})}$ on the Hilbert space of the circle that is related, by means of M, with the analogous unitary representation $\{U_g^{(\mathbf{F})}\}_{g\in SL(2,\mathbb{R})}$ found on the horizon $\mathbf{F}$ discussed earlier in [e]. And thus, in turn, it induces just the bulk symmetry induced by $\{U_g^{(\mathbf{F})}\}_{g\in SL(2,\mathbb{R})}$ (see [e] discussed earlier) by means of unitary holography. In particular $H_{\mathsf{F}}:=H_{\mathsf{F}0}$ turns out to be associated with the generator of Rindler-time displacements H.

$H_{\mathsf{F}0},D_{\mathsf{F}},C_{\mathsf{F}}$ are a basis of the Lie algebra of $SL(2,\mathbb{R})$. An equivalent, but more useful in the following, basis of the Lie algebra of $SL(2,\mathbb{R})$ made of essentially self-adjoint operators in $\mathcal{D}_1^{(\mathsf{F})}$ is that of the operators $K_{\beta\mathsf{F}},D_{\mathsf{F}},S_{\mathsf{F}}$ with

$$S_{\mathsf{F}}:=\frac{1}{2}\left(\beta H_{\mathsf{F}0}-\frac{1}{\beta}C_{\mathsf{F}}\right). \tag{38}$$

Now, it makes sense to investigate the *geometrical nature* of the $SL(2,\mathbb{R})$ representation $\{U_g^{(\mathsf{F})}\}$ on *the circle* F *instead of the horizon* **F**. First of all one has to notice that the vector fields $\partial/\partial v$, $v\,(\partial/\partial v)$, $v^2\,(\partial/\partial v)$, which give rise to the geometric interpretation of $\{U_g^{(\mathbf{F})}\}$ when working on **F**, span in **F** the same space as that spanned by the three smooth vector fields defined on the whole circle F,

$$\partial_\theta, \cos(\theta)\partial_\theta, \sin(\theta)\partial_\theta .$$

The proof is straightforward using the relation $v=\beta\tan(\theta/2)$ only. Then consider the transformations (18) of the line **F**, translate them in the variable $\theta=2\arctan(v/\beta)$ extended to the domain $(-\pi,\pi]$ so to include ∞. The new transformations so obtained define a representation of $SL(2,\mathbb{R})$ in terms of orientation-preserving diffeomorphisms d_g of the circle F:

$$d_g:\theta\mapsto 2\arctan\left(\frac{a\beta\tan(\theta/2)+b}{c\beta^2\tan(\theta/2)+\beta d}\right), \quad g:=\begin{pmatrix} a & b \\ c & d\end{pmatrix}\in SL(2,\mathbb{R}) \ . \tag{39}$$

There is another, more elegant, way to write the elements of same diffeomorphism group:

$$\delta_h:e^{i\theta}\mapsto \frac{\zeta e^{i\theta}+\overline{\eta}}{\eta e^{i\theta}+\overline{\zeta}}, \quad h:=\begin{pmatrix} \zeta & \overline{\eta} \\ \eta & \overline{\zeta}\end{pmatrix}\in SU(1,1) \ , \tag{40}$$

where we have used the group isomorphism $SL(2,\mathbb{R})\ni g\mapsto h\in SU(1,1)$ with

$$\zeta:=\frac{\beta a+\beta d+i(b-\beta^2 c)}{2}, \quad \eta:=\frac{\beta d-\beta a-i(b+\beta^2 c)}{2} .$$

The condition $h\in SU(1,1)$, when h has the form in (40), can equivalently be written

$$|\zeta|^2-|\eta|^2=1 . \tag{41}$$

Remark: Notice that the transformation $\rho\mapsto\rho_g$ does not mix Fourier components with positive frequency and Fourier components with negative frequency and vice versa. (This fact allows one to look for unitary representations of the considered group in the one-particle Hilbert space which is constructed by using positive frequency part of wave functions.) Indeed, using (40), $e^{-in\theta}$ is mapped into

$$\left(\frac{\zeta e^{i\theta}+\overline{\eta}}{\eta e^{i\theta}+\overline{\zeta}}\right)^{-n} .$$

Fourier coefficients with strictly ''negative frequency'' $-m$ are proportional to the integrals, where $m,n\geqslant 1$ are integers,

$$\int_{-\pi}^{\pi}\left(\frac{\zeta e^{i\theta}+\overline{\eta}}{\eta e^{i\theta}+\overline{\zeta}}\right)^{-n} e^{-im\theta}\mathrm{d}\theta = \oint_{+\mathbb{S}^1}\frac{-i}{z^{m+1}}\left(\frac{\eta z+\overline{\zeta}}{\zeta z+\overline{\eta}}\right)^{n}\mathrm{d}z = \oint_{+\mathbb{S}^1}\frac{-i}{z^{m+1}}\left(\frac{\eta}{\zeta}+\frac{1/\zeta}{\zeta z+\overline{\eta}}\right)^{n}\mathrm{d}z \ ,$$

where $+\mathbb{S}^1$ is the circle $|z|=1$ with positive orientation. Expanding the expression under the last integration symbol using the binomial formula one reduces to a linear combination of contributions of integrals with form

$$\oint_{+\mathbb{S}^1}\frac{\mathrm{d}z}{z^{m+1}(z-z_0)^p}$$

with $p=0,1,\ldots,n\geqslant 1$, $m\geqslant 1$ and where $z_0=-\overline{\eta}/\zeta$ with $\zeta\neq 0$ [due to (41)]. If $p>0$, using condition (41) one sees that, whatever the values of η and ζ and barring the pole at $z=0$ with order $m+1$, there is another pole of order p inside the region with boundary $\mathbb{S}^1$, at $z=-\overline{\eta}/\zeta$. Cauchy formula for $p>0$ proves that the contribution of the two residues in each integral cancel out each other and the final result is zero. The case $p=0$ gives the same result automatically. So it makes sense to look for unitary representation of the group in the one-particle space.

Exactly as in the case of Theorem 1.3, if ρ is a real circle wave function, with associated one-particle quantum state $\tilde{\rho}_+=\tilde{\rho}_+(n)$, the action of every $U_g^{(\mathsf{F})}$ on $\tilde{\rho}_+$ is equivalent to the action of a corresponding F diffeomorphism, d_g, on the horizon wave function ρ itself.

Theorem 2.4: *Assume $k=1$ in the definition of $\mathcal{D}_k^{(\mathsf{F})}$, that is, in (7). If $g\in SL(2,\mathbb{R})$ and $\tilde{\rho}_+=\tilde{\rho}_+(n)$ is the positive frequency part of $\rho\in\mathcal{S}(\mathsf{F})$, the state $U_g^{(\mathsf{F})}\tilde{\rho}_+$ can be associated with the wave function $\rho_g\in\mathcal{S}(\mathsf{F})$ with*

$$\rho_g(\theta)=\rho(d_g^{-1}\theta)\quad,\quad \text{for all } \theta\in(-\pi,\pi]. \tag{42}$$

In particular (with the same terminology as that used in (a) of Theorem 1.3):
(a) The unitary one-parameter group generated by $i\overline{K_{\mathsf{F}\beta}}$ is associated with the one-group of F diffeomorphisms generated by ∂_θ;
(b) the unitary one-parameter group generated by $i\overline{D_{\mathsf{F}}}$ is associated with the one-parameter group of F diffeomorphisms generated by $\sin\theta\partial_\theta$;
(c) the unitary one-parameter group generated by $i\overline{S_{\mathsf{F}}}$ is associated with the one-group of F diffeomorphisms generated by $\cos\theta\partial_\theta$.

The Lie algebra spanned by fields ∂_θ, $\cos\theta\partial_\theta$, $\sin\theta\partial_\theta$ is a realization of the Lie algebra of $SL(2,\mathbb{R})$.

Proof: The first part can be proven as follows. Take $\rho\in C^\infty(\mathsf{F};\mathbb{R})$. As $\mathcal{H}_{\mathsf{F}}=\ell^2(\mathbb{C})$, the associated positive frequency part in "frequency picture" $\tilde{\rho}_+\in\mathcal{H}_{\mathsf{F}}$ is a sequence $\{C_n\}_{n=1,2,\ldots}$. The associated positive frequency part in "θ picture" can be written

$$\rho_+(\theta)=\mathcal{F}(W\tilde{\rho}_+)(\theta),$$

where $\mathcal{F}:\ell^2(\mathbb{C})\to L^2((-\pi,\pi),d\theta)$ and $W:\ell^2(\mathbb{C})\to\ell^2(\mathbb{C})$ are, respectively, the *continuous* linear operators,

$$\mathcal{F}:\{C_n\}_{n=1,2,\ldots}\mapsto\sum_{n=1}^{+\infty}C_n\frac{e^{-in\theta}}{\sqrt{2\pi}}, \tag{43}$$

$$W:\{C_n\}_{n=1,2,\ldots}\mapsto\left\{\frac{C_n}{\sqrt{2n}}\right\}_{n=1,2,\ldots}. \tag{44}$$

On the other hand, in the sense of the topology of $\ell^2(\mathbb{C})$,

$$\tilde{\rho}_+=\sum_{m=1}^{\infty}C_m\Psi_m$$

where $\{\Psi_m\}_{m=1,2,\ldots}$ is the Hilbert base $\Psi_m=\{\delta_{mn}\}_{n=1,2,\ldots}$. By linearity, continuity, and the absence of positive-negative frequency mixing,

$$(\rho_g)_+=\mathcal{F}(WU_g^{(\mathsf{F})}\tilde{\rho}_+)=\mathcal{F}\left(WU_g^{(\mathsf{F})}\sum_n C_n\Psi_n\right)=\sum_n\mathcal{F}(WU_g^{(\mathsf{F})}C_n\Psi_n)\,. \tag{45}$$

Now one notices that Theorem 1.3 holds true also for the horizon wave function $\varphi^{(n)}$ with positive frequency part, in the "frequency picture" given by $Z_n^{(1)}(E)$ (with $k=1,2,\ldots$) as the

associated positive frequency wave function. (The proof of this fact is, in fact, the same proof as that of Theorem 1.3, that is Theorem 4.7 in Ref. 8, with trivial adaptations which make sense in the considered case. In particular Proposition 4.2 in Ref. 8 can directly be proven by using (28). It is useful to notice that $\Theta Z_n^{(1)}=(-1)^n Z_n^{(1)}$.) By (28),

$$\varphi^{(n)}(v(\theta))=\frac{1}{\sqrt{4\pi n}}[(-1)^{n+1}(C_n+\overline{C_n})+C_n e^{-in\theta}+\overline{C_n}e^{in\theta}]\ , \tag{46}$$

and thus, Theorem 1.3 says that

$$\varphi_g^{(n)}(v(\theta))=\frac{1}{\sqrt{4\pi n}}[C_n e^{-ind_g^{-1}\theta}-e^{-ind_g^{-1}\pi}C_n]+\text{c.c.} \tag{47}$$

Since, by Theorem 2.1, Z_n in $\mathcal{H}_{\mathbf{F}}$ is transformed into Ψ_n of $\mathcal{H}_{\mathsf{F}}$ and the same transformation associates $U_g^{(\mathbf{F})}$ with $U_g^{(\mathsf{F})}$, (47) can be re-written in the space $\mathcal{H}_{\mathsf{F}}$ and in the circle F:

$$\mathcal{F}(WU_g^{(\mathsf{F})}C_n\Psi_n)(\theta)+\text{c.c.}=C_n\varphi_g^{(n)}(v(\theta))+\text{c.c.}=\frac{1}{\sqrt{4\pi n}}[C_n e^{-ind_g^{-1}\theta}-C_n e^{-ind_g^{-1}\pi}]+\text{c.c.} \tag{48}$$

Inserting it in (45), one concludes that

$$\rho_g(\theta)=\sum_{n=1}^{+\infty} C_n\frac{e^{-ind_g^{-1}\theta}}{\sqrt{4\pi n}}-C_n\frac{e^{-ind_g^{-1}\pi}}{\sqrt{4\pi n}}+\text{c.c.} \tag{49}$$

The convergence must be understood in the sense of $L^2(\mathsf{F},\mathrm{d}\theta)$. However since $\rho\in C^\infty(\mathsf{F})$ and thus $\rho\circ d_g^{-1}\in C^\infty(\mathsf{F})$, the latter admit a uniformly convergent Fourier series and the series $\Sigma_n|C_n|/\sqrt{4\pi n}$ converges too. By the uniqueness property of Fourier series it must hold,

$$\rho_g(\theta)=\rho(d_g^{-1}\theta)+\text{const}\quad \text{for all } \theta\in\mathsf{F}\ .$$

This concludes the proof if the functions are considered as elements of $\mathcal{S}(\mathsf{F})$.

Let us pass to prove the statement in (b), the remaining cases can be proven following a strongly analogous proof [which is much more simple in case (a)]. If $t\mapsto g_t$ is the one-parameter subgroup of $SL(2,\mathbb{R})$ whose associated one-parameter group of diffeomorphisms is that generated by the field $\sin\theta\,\partial_\theta$, consider the transformed wave function $\rho_{g(t)}(\theta):=\rho(d_t^{-1}(\theta))=\rho(d_{-t}(\theta))$ and the associated positive frequency part $\widetilde{\rho_{g(t)+}}$ in "frequency representation." Since $SL(2,\mathbb{R})$ acts on positive frequency wave functions by means of a strongly continuous unitary representation, there must be some self-adjoint generator A (not depending on ρ_+) such that $\widetilde{\rho_{g(t)+}}=e^{itA}\widetilde{\rho}_+$. Our thesis states that $A=\overline{D_{\mathsf{F}}}$. With the above-introduced formalism, the statement turns out to be proved if it holds for all the states $\widetilde{\rho^{(k)}}_+=\Psi_k=\{\delta_{nk}\}_{n=1,2,\ldots}\in\ell^2(\mathbb{R})$, $k=1,2,\ldots$. Hence we want to show that for $k=1,2,\ldots$, $\widetilde{\rho_{g(t)+}^{(k)}}=e^{it\overline{D_{\mathsf{F}}}}\Psi_k$. To this end it is sufficient to show that in the topology of $\mathcal{H}_{\mathsf{F}}\cong\ell^2(\mathbb{C})$,

$$\frac{\mathrm{d}}{\mathrm{d}t}\widetilde{\rho_{g(t)+}^{(k)}}\bigg|_{t=0}=iD_{\mathsf{F}}\Psi_k\,. \tag{50}$$

Indeed, by Stone's theorem the derivative on the left-hand side is $iA\Psi_k$, on the other hand, since D_{F} is essentially self-adjoint in the linear space finitely spanned by the vectors Ψ_k, it must be $A=\overline{D_{\mathsf{F}}}$. Let us prove (50). From now on $\widetilde{\rho_{g(t)+}^{(k)}}=\{C_n(t)\}_{n=1,2,\ldots}$. Defining $\theta_t(\theta):=d_{-t}(\theta)$, one has

$$C_n(t) = \sqrt{\frac{n}{k}} \int_{-\pi}^{\pi} \frac{e^{-i(k\theta_t(\theta)-n\theta)}}{2\pi} \mathrm{d}\theta \,, \tag{51}$$

because of (47) where, by construction, $\rho^{(k)}_{g(t)}(\theta) = \varphi^{(k)}_{g(t)}(v(\theta))$ and using the fact that there is no mixing of positive end negative frequencies under the action of the group. By direct computation one finds that $C_n(0) = 0$ and $\mathrm{d}C_n(t)/\mathrm{d}t|_{t=0} = 0$ if $n \neq k, k \pm 1$. So if the derivative on the left-hand side of (50) is computed term by term, (50) can be re-written

$$\frac{\delta_{n,k-1}\sqrt{k(k-1)} - \delta_{n,k+1}\sqrt{k(k+1)}}{2} = \langle \Psi_n, iD_{\mathsf{F}}\Psi_k \rangle_{\mathsf{F}}, \tag{52}$$

where we have computed the derivatives of $\mathrm{d}C_n(t)/\mathrm{d}t|_{t=0}$ using (51). However, it also holds

$$\langle \Psi_n, iD_{\mathsf{F}}\Psi_k \rangle_{\mathsf{F}} = \langle Z^{(1)}_n, iD_{\mathbf{F}} Z^{(1)}_k \rangle_{\mathbf{F}},$$

and the right-hand side can be computed trivially (for instance by employing the formalism on p. 137 of Ref. 9) and it turns out to coincide with the left-hand side of (52), so (52) holds true. To conclude the proof, it is sufficient to show that the derivative on the left-hand side of (50), which is computed with respect to the topology of $\ell^2(\mathbb{C})$, can equivalently be computed deriving term by term the sequence of complex which defines $\widetilde{\rho^{(k)}_{g(t)^+}}$. Expanding the term under the integral symbol in (51) by means of Taylor formula in the variable t about $t=0$, using the Lagrange formula for the remnant and, finally, using integration by parts and the fact that the integrated functions are smooth and periodic on $\mathbb{S}^1$, one proves that for some constant A, for all t in a neighborhood of 0 and for all $n \neq k, k \pm 1$:

$$\left| \frac{C_n(t)}{t} \right|^2 \leqslant \frac{A}{n^2} \,. \tag{53}$$

Thus

$$\sum_{n=1}^{\infty} \left| \frac{C_n(t) - C_n(0)}{t} - \frac{\mathrm{d}C_n(t)}{\mathrm{d}t}\bigg|_{t=0} \right|^2 = \sum_{n \neq k, k\pm 1} \left| \frac{C_n(t)}{t} \right|^2 + \sum_{n=k,k\pm 1} \left| \frac{C_n(t) - C_n(0)}{t} - \frac{\mathrm{d}C_n(t)}{\mathrm{d}t}\bigg|_{t=0} \right|^2 .$$

$C_n(t)/t \to 0$ in our hypotheses for $0 < n \neq k, k \pm 1$ and so the sum of the corresponding series above vanishes too due to Lebesgue's dominated convergence theorem with respect to the Dirac measure with support on the points $n \neq k, k \pm 1$ as a consequence of (53). We finally get

$$\lim_{t\to 0} \sum_{n=1}^{\infty} \left| \frac{C_n(t) - C_n(0)}{t} - \frac{\mathrm{d}C_n(t)}{\mathrm{d}t}\bigg|_{t=0} \right|^2 = \lim_{t\to 0} \sum_{n=k,k\pm 1} \left| \frac{C_n(t) - C_n(0)}{t} - \frac{\mathrm{d}C_n(t)}{\mathrm{d}t}\bigg|_{t=0} \right|^2 = 0 \,.$$

We conclude that the derivative on the left-hand side of (50) computed with respect to the topology of $\ell(\mathbb{C})$ coincides with that computed term by term. This concludes the proof because the last statement can straightforwardly be proven by direct inspection. □

The theorem states that, in fact, the bulk $SL(2,\mathbb{R})$ symmetry becomes manifest when examined on the circle $\mathsf{F} = \mathbf{F} \cup \{\infty\}$. However that is not the whole story because the found circle unitary $SL(2,\mathbb{R})$ representation is just a little part of a larger unitary representation with geometrical meaning. We can, in fact, consider the Lie algebra $\mathrm{Vect}(\mathbb{S}^1)$ of the infinite dimensional Lie group[19] of orientation-preserving diffeomorphisms of the circle $\mathrm{Diff}^+(\mathbb{S}^1)$, where $\mathbb{S}^1 = \mathsf{F}$ in our case. To make contact with Virasoro algebra we have to consider an associated *complex* Lie algebra.[20] Consider the complex Lie algebra $\mathrm{d}(\mathsf{F}) := \mathrm{Vect}(\mathsf{F}) \oplus i\ \mathrm{Vect}(\mathsf{F})$ equipped with usual Lie

brackets $\{\cdot,\cdot\}$ and the involution $\omega: X \mapsto -\overline{X}$ for $X \in \mathrm{d}(\mathsf{F})$, so that $\omega(\{X,Y\})=\{\omega(Y),\omega(X)\}$. An algebraic basis of that algebra is made of the complex smooth fields on F:

$$\mathcal{F}_n := ie^{in\theta}\partial_\theta \quad \text{with } n \in \mathbb{Z}. \tag{54}$$

The vector fields $\mathcal{F}_n$ enjoy the celebrated *Virasoro commutation rules* with central charge $c=0$:

$$\{\mathcal{F}_n, \mathcal{F}_m\} = (n-m)\mathcal{F}_{n+m}, \tag{55}$$

and the Hermiticity condition

$$\omega(\mathcal{F}_n) = \mathcal{F}_{-n}. \tag{56}$$

In the presented picture Vect(F) is nothing but the sub-algebra of d(F) containing all of the vectors fixed under $-\omega$. An algebraic basis of Vect(F) is that made of the fields

$$\mathcal{F}_n^{(+)} := \frac{\omega(\mathcal{F}_n)+\mathcal{F}_n}{2i} = \cos(n\theta)\partial_\theta, \quad \mathcal{F}_m^{(-)} := \frac{\omega(\mathcal{F}_m)-\mathcal{F}_m}{2} = \sin(n\theta)\partial_\theta, \tag{57}$$

where $n=0,1,\ldots$ while $m=1,2,\ldots$. Conversely, the base of d(F), $\{\mathcal{F}_n\}_{n\in\mathbb{Z}}$ can be obtained from the base above as, where $n=1,2,\ldots$,

$$\mathcal{F}_0 := i\mathcal{F}_0^{(+)}, \quad \mathcal{F}_n := \mathcal{F}_n^{(+)} + i\mathcal{F}_n^{(-)}, \quad \mathcal{F}_{-n} := \mathcal{F}_{-n}^{(+)} - i\mathcal{F}_{-n}^{(-)}. \tag{58}$$

Notice that the three fields $\mathcal{F}_0^{(+)}, \mathcal{F}_1^{(+)}, \mathcal{F}_1^{(-)}$ are in fact generators of a finite-dimensional sub-algebra of Vect(F), namely the representation of the Lie algebra of $SL(2,\mathbb{R})$ found above, which is equivalently generated by the three fields $v^{n+1}\partial_v$ with $n=-1,0,1$. However for $|n|>1$, the algebras spanned by generators $v^{n+1}\partial_v$ and $\mathcal{F}_n^{(\pm)}$ are different and we focus attention on the latter ones.

By direct inspection one proves that each of the fields $\mathcal{F}_n^{(\pm)} \in \mathrm{Vect}(\mathsf{F})$ generate a *global* one-parameter group of F orientation-preserving diffeomorphisms (this fact does not hold for fields $v^{n+1}\partial_v$ in **F**). Global means here that the additive parameter which labels the group ranges over the entire real line $\mathbb{R}$. In turn, that group of diffeomorphisms generates a group of automorphisms of the algebra of the quantum field $\mathcal{A}_\mathsf{F}$. Let us explain how it happens. If $d_\lambda^{(\mathcal{F}_n^{(\pm)})}: \mathsf{F} \to \mathsf{F}$ is an element of the one-parameter (orientation-preserving) diffeomorphism group generated by $\mathcal{F}_n^{(\pm)}$, $\lambda \in \mathbb{R}$ being the additive parameter, and $\rho \in \mathcal{S}(\mathsf{F})$, as usual we define the associated group of wave function transformations: $(\alpha_\lambda^{(\mathcal{F}_n^{(\pm)})}\rho)(\theta) := \rho(d_{-\lambda}^{(\mathcal{F}_n^{(\pm)})}(\theta))$. Notice that the transformations $\alpha_\lambda^{(\mathcal{F}_n^{(\pm)})}$ are, in fact, automorphisms of the real vector space $\mathcal{S}(\mathsf{F})$ equipped with the symplectic form Ω_F because the latter is orientation-preserving diffemorphism invariant.

Remark: By direct inspection one realizes that, if $n>1$ the transformation $\alpha_\lambda^{(\mathcal{F}_n^{(\pm)})}$ does *not* admit the space of positive frequency wave functions as invariant space. As a consequence it is not possible to represent $\alpha_\lambda^{(\mathcal{F}_n^{(\pm)})}$ unitarily in the one-particle space $\mathcal{H}_\mathsf{F}$. To implement the transformation $\alpha_\lambda^{(\mathcal{F}_n^{(\pm)})}$ at quantum level, the entire Fock space is necessary if $n>1$.

As we want to deal with quantum fields smeared by exact one-forms of $\mathcal{D}(\mathsf{F})$, we define a natural action of the diffeomorphisms $d_\lambda^{(\mathcal{F}_n^{(\pm)})}$ also on these forms by using (33): If $\omega \in \mathcal{D}(\mathsf{F})$ and $\rho := E_\mathsf{F}(\omega)$, we define the one-parameter group of transformations of one-forms $\{\beta_\lambda^{(\mathcal{F}_n^{(\pm)})}\}_{\lambda\in\mathbb{R}}$, such that

$$\beta_\lambda^{(\mathcal{F}_n^{(\pm)})}(\omega) := 2\mathrm{d}\alpha_\lambda^{(\mathcal{F}_n^{(\pm)})}(E_\mathsf{F}(\omega)). \tag{59}$$

Finally we can define the action of quantum fields by means of

$$\gamma_\lambda^{(\mathcal{F}_n^{(\pm)})}(\hat{\phi}_{\mathsf{F}}(\omega)) := \hat{\phi}_{\mathsf{F}}(\beta_{-\lambda}^{(\mathcal{F}_n^{(\pm)})}(\omega)) \ . \tag{60}$$

Using the given definitions, the fact that $\alpha_\lambda^{(\mathcal{F}_n^{(\pm)})}$ preserves Ω_{F} as well as (36) and (37), one finds

$$[\gamma_\lambda^{(\mathcal{F}_n^{(\pm)})}(\hat{\phi}_{\mathsf{F}}(\omega)), \ \ \gamma_\lambda^{(\mathcal{F}_n^{(\pm)})}(\hat{\phi}_{\mathsf{F}}(\omega'))] = [\hat{\phi}_{\mathsf{F}}(\omega), \hat{\phi}_{\mathsf{F}}(\omega')] \ . \tag{61}$$

It is possible to prove by that identity that $\gamma_\lambda^{(\mathcal{F}_n^{(\pm)})}$ naturally extends into a $*$-algebra automorphism of the algebra $\mathcal{A}_{\mathsf{F}}$. The procedure to do it is very similar to those used in Ref. 8 to extend transformations of field operators into $*$-algebra homomorphisms. So, in fact, every field $\mathcal{F}_n^{(\pm)}$ gives rise to a one-parameter group of automorphisms of the algebra $\mathcal{A}_{\mathsf{F}}$ that we indicate by $\{\gamma_\lambda^{(\mathcal{F}_n^{(\pm)})}\}_{\lambda \in \mathbb{R}}$ once again. A natural question arises:

Is there a representation of the (infinite dimensional complex) Lie algebra d(F)*, in terms of operators defined in* $\mathfrak{F}(\mathcal{H}_{\mathsf{F}})$ *such that the fields* $\mathcal{F}_n^{(\pm)}$ *are mapped into (essentially) anti-self-adjoint operators* $-iF_n^{(\pm)}$*, whose associated unitary one-parameter groups implement the respective one-parameter group of* $\mathcal{A}_{\mathsf{F}}$ *automorphisms* $\{\gamma_\lambda^{(\mathcal{F}_n^{(\pm)})}\}_{\lambda \in \mathbb{R}}$ *(at least at the first order)? That is*

$$e^{-i\lambda \overline{F_n^{(\pm)}}} \overline{\hat{\phi}_{\mathsf{F}}(\omega)} e^{i\lambda \overline{F_n^{(\pm)}}} = \overline{\gamma_\lambda^{(\mathcal{F}_n^{(\pm)})}(\hat{\phi}_{\mathsf{F}}(\omega))} \ , \tag{62}$$

or some other formally related, but perhaps weaker, identity holds.

The answer is yes provided one uses an operator algebra which represents *central extensions* of the algebra d(F). In other words one has to permit to change, at quantum level, the relation (55) by adding in the right-hand side a further term which commutes with the elements of the representation itself. The obtained algebra is properly called *Virasoro's algebra.*

More precisely, the quantum representation on the one hand is a straightforward extension of that previously found for the group $SL(2,\mathbb{R})$. On the other hand it is, in fact, a *positive-energy* and *unitary* representation of Virasoro algebra with *central charge* $c=1$.[20] To build up such a representation the entire Fock space, and not only the one-particle Hilbert space, is necessary. A relevant point is that the found unitary representation of the Virasoro algebra can be exported in the bulk via unitary holography.

In the circle Fock space $\mathfrak{F}(\mathcal{H}_{\mathsf{F}})$, consider the basis obtained by taking all the symmetrized tensor products of one-particle states $Z_n^{(1)}$, namely, the eigenvectors of the operator $K_{\mathsf{F}\beta}$. Henceforth α_n and $\alpha_n^\dagger$ are, respectively, the creation and annihilation operator associated with the one-particle state $Z_n^{(1)}$ with $n=1,2,\ldots$. As a consequence

$$[\alpha_n, \alpha_m^\dagger] = \delta_{n,m} I \ , \quad [\alpha_n, \alpha_m] = [\alpha_n^\dagger, \alpha_m^\dagger] = 0 \ . \tag{63}$$

Now, fix $\mu \in \mathbb{R}$ and introduce the operators, a_n, with $n \in \mathbb{Z}$ such that

$$a_n = \begin{cases} \mu I & \text{if } \ n=0 \ , \\ i\sqrt{n}\ \alpha_n & \text{if } \ n>0 \ , \\ -i\sqrt{-n}\ \alpha_{-n}^\dagger & \text{if } \ n<0 . \end{cases} \tag{64}$$

By (63) these operators satisfy the *oscillator algebra* commutation relations[20]

$$[a_m, a_n] = m\, \delta_{m,-n} I \ , \tag{65}$$

and the so-called *Hermiticity conditions*

$$a_n^\dagger = a_{-n} \tag{66}$$

(actually on the left-hand side is considered only the restriction of $a_n^\dagger$ to the domain of a_{-n}). With these definitions, the formal expression for $\hat{\phi}_{\mathsf{F}}$ (31) takes the form

$$\hat{\phi}_{\mathsf{F}}(\theta) = \frac{1}{i\sqrt{4\pi}} \sum_{n \in \mathbb{Z}\setminus\{0\}} \frac{e^{-in\theta}}{n} a_n , \tag{67}$$

moreover, formally *but also with a rigorous meaning in terms of a field operator smeared by an exact one-form* (35), it holds

$$a_n = \frac{1}{\sqrt{\pi}} \int_{\mathsf{F}} \hat{\phi}_{\mathsf{F}}(\theta)\ \mathrm{d}e^{in\theta} \quad \text{if } n \in \mathbb{Z}\setminus\{0\} . \tag{68}$$

Finally, define the operators (denoted by L_k in Ref. 20)

$$F_k := \frac{\epsilon_k}{2} a_{k/2}^2 + \sum_{n > -k/2} a_{-n} a_{n+k} , \qquad k \in \mathbb{Z}, \tag{69}$$

where $\epsilon_k = 0$ if k is odd, $\epsilon_k = 1$ if k is even (including $k=0$). The various sums are, in fact, finite when acting on a vector, since we adopt as a common domain of those operators, the dense subspace $\mathfrak{D}_1^{(\mathsf{F})} \subset \mathfrak{F}(\mathcal{H}_{\mathsf{F}})$ made of the finite linear combination of vectors containing any finite number of particles in states $Z_n^{(1)}$.

Theorem 2.5: *The operators F_k, $k \in \mathbb{Z}$ enjoy the following properties on their domain $\mathfrak{D}_1^{(\mathsf{F})}$. (a) The complex Lie algebra finitely spanned by operators F_k (equipped with the usual operator commutator and Hermitian conjugation) is a positive-energy unitary Virasoro algebra representation* $\mathrm{Vir}(\mathsf{F})$ *with central charge $c=1$. Indeed it holds*

$$[F_m, F_n] = (m-n)F_{m+n} + \delta_{m,-n} \frac{m^3 - m}{12} I \quad \text{for } n, m \in \mathbb{Z} , \tag{70}$$

Hermiticity relations are fulfilled

$$F_m^\dagger \Psi = F_{-m} \Psi \quad \text{for every } \Psi \in \mathfrak{D}_1^{(\mathsf{F})} , \tag{71}$$

F_0 is essentially self-adjoint and $\overline{F_0}$ is positive defined with discrete spectrum

$$\sigma(\overline{F_0}) = \left\{ \frac{\mu^2}{2} + N \;\middle|\; N = 0,1,\ldots \right\} . \tag{72}$$

(b) For $n = 1,2,\ldots$, the operators

$$F_0^{(+)} := F_0 , \quad F_n^{(+)} := \frac{F_{-n} + F_n}{2} \quad \textit{and} \quad F_n^{(-)} := i\frac{F_{-n} - F_n}{2} \tag{73}$$

are essentially self-adjoint in $\mathfrak{D}_1^{(\mathsf{F})}$. (It is worth stressing that the interplay of fields $\mathcal{F}_n^{(\pm)}$ and $\mathcal{F}_n$ is the same as that operators $-iF_n^{(\pm)}$ and F_n and not *$F_n^{(\pm)}$ and F_n, this is because the operator involution † corresponds to the field involution ω instead of the simpler complex conjugation.)*

Proof: Barring the statements on F_0, the properties in (a) are proven in Ref. 20 (see Secs. II A–II C and III A) as consequences of (65), (66), and (69). The operators F_0, $F_m + F_{-m}$ and $i(F_m - F_{-m})$ are symmetric by construction and one can prove by direct inspection that the

elements of $\mathfrak{D}_1^{(\mathsf{F})}$ are analytic vectors for these operators. Thus they are essentially self-adjoint. This proves (b) and the essential self-adjointness of F_0. By direct inspection and using (64), one finds

$$F_0=\frac{\mu^2}{2}I+\sum_{n=1}^{\infty} n\alpha_n^\dagger\alpha_n . \tag{74}$$

The Hilbert basis of $\mathfrak{F}(\mathcal{H}_\mathsf{F})$, $\{|L\rangle\}_{L\in\mathbb{N}}$ made of the vectors (labeled with an arbitrary order by the index L) containing any finite number of states $Z_m^{(1)}$ is a basis of eigenvectors of F_0. The eigenvalue associated with $|L\rangle$ is of the form $\mu^2/2+N_L$ where N_L ranges everywhere in $\mathbb{N}$. This fact suggests to consider the self-adjoint operator

$$F_0' := \sum_{L=0}^{\infty} N_L |L\rangle\langle L|,$$

where now the sum is interpreted in the strong operator topology in the domain $\mathcal{D}(F_0')$ containing the vectors $|\Psi\rangle\in\mathfrak{F}(\mathcal{H}_\mathsf{F})$ with

$$\sum_{l=0}^{\infty} N_L^2 |\langle L|\Psi\rangle|^2<\infty .$$

By construction, F_0' has the spectrum (72). On the other hand, since $F_0\subset F_0'$ by construction, uniqueness of self-adjoint extensions of F_0 implies $\overline{F_0}=F_0'$. □

Finally we show that (1) the whole Virasoro representation extends the circle $SL(2,\mathbb{R})$ unitary representation and (2) it has the geometric meaning (62).

Theorem 2.6: *Referring to the Virasoro representation of Theorem 2.5,*
(a) if (and only if) $\mu=0$, the operators $F_0^{(+)},F_1^{(+)},F_1^{(-)}$ admit $\mathcal{D}_1^{(\mathsf{F})}\subset\mathcal{H}_\mathsf{F}$ as invariant space and

$$F_0^{(+)}\restriction_{\mathcal{H}_\mathsf{F}}=K_{\beta\mathsf{F}}, \tag{75}$$

$$F_1^{(+)}\restriction_{\mathcal{H}_\mathsf{F}}=S_\mathsf{F}, \tag{76}$$

$$F_1^{(-)}\cdot\restriction_{\mathcal{H}_\mathsf{F}}=D_\mathsf{F}, \tag{77}$$

and so these operators generate the $SL(2,\mathbb{R})$ representation $\{U_g^{(\mathsf{F})}\}_{g\in SL(2,\mathbb{R})}$.
(b) If (and only if) $\mu=0$, for every $n\in\mathbb{N}$ ($n>0$ in the case $^{(-)}$), (62) holds true at the first order at least,

$$[F_n^{(\pm)},\hat\phi_\mathsf{F}(\omega)]=i\frac{\mathrm{d}}{\mathrm{d}\lambda}\bigg|_{\lambda=0}\gamma_\lambda^{(\mathcal{F}_n^{(\pm)})}(\hat\phi_\mathsf{F}(\omega)) \tag{78}$$

for every $\omega=\eta+i\eta'\in\mathcal{D}(\mathsf{F};\mathbb{C})$ such that the real wave functions $E_\mathsf{F}\eta$ and $E_\mathsf{F}\eta'$ are associated with states in $\mathcal{D}^{(\mathsf{F})}$ and the derivative is computed in the strong operator topology in $\mathfrak{D}_1^{(\mathsf{F})}$.

Proof: (a) The proof of the first case is a trivial consequence of (74). Concerning the second and third cases, we notice that using operators α_n and $\alpha_n^\dagger$,

$$F_{-1}=-i\mu\alpha_1^\dagger+\sum_{n=1}^{\infty}\sqrt{n(n+1)}\,\alpha_{n+1}^\dagger\alpha_n \tag{79}$$

$$F_1=i\mu\alpha_1+\sum_{n=1}^{\infty}\sqrt{n(n+1)}\,\alpha_n^\dagger\alpha_{n+1}. \tag{80}$$

It is obvious that, because of the terms containing $\mu(\alpha_1^\dagger \pm \alpha_1)$, the operators above admit $\mathcal{D}_1^{(\mathsf{F})}$ as an invariant space if and only if $\mu=0$. In that case, the restrictions to $\mathcal{D}_1^{(\mathsf{F})}$ coincide, respectively, with the operators A_+ and A_- defined in Ref. 21 or (23) of Ref. 9 (where the coefficient β is indicated by λ/κ and $k=1$). With our notations

$$A_\pm = \frac{1}{2}\left(\beta H_{\mathsf{F}0} - \frac{1}{\beta} C_{\mathsf{F}}\right) \mp i D_{\mathsf{F}}, \tag{81}$$

so that $A_- Z_1^{(1)} = 0$ and $A_+ Z_n^{(1)} = \sqrt{n(n+1)} Z_{n+1}^{(1)}$. Equation (81) implies (76) and (77) straightforwardly taking (38) into account.

Let us come to the last part. It is simply proven that every exact one-form $\omega = \eta + i\eta'$, where the real exact one-forms η, η' determine circle wave functions with positive frequency in $\mathcal{D}_1^{(\mathsf{F})}$, is a finite complex linear combination of forms $\omega_m(\theta) := \mathrm{d}e^{im\theta}$ with $m \in \mathbb{Z}\backslash\{0\}$. Hence it is sufficient to prove (78) for every $\hat{\phi}(\omega_m)$ with $m \in \mathbb{Z}\backslash\{0\}$. Fix $m \in \mathbb{Z}\backslash\{0\}$ and $k \in \mathbb{Z}$. By direct computation and using (68) and (2.12) in Ref. 20, one finds that, for every $\Psi \in \mathfrak{D}_{\mathsf{F}}^{(1)}$,

$$[L_k^{(\pm)}, \hat{\phi}(\omega_m)]\Psi = -\frac{m\sqrt{\pi}}{2}(i)_\pm (a_{m-k} \pm a_{m+k})\Psi, \tag{82}$$

where $(i)_j := 1$ if $j=+$, $(i)_j := i$ if $j=-$. *The identity above holds provided a_{m-m} and a_{-m+m} are interpreted as the multiplicative operator μI.*[20] On the other hand,

$$\gamma_\lambda^{(\mathcal{F}_k^{(\pm)})}(\hat{\phi}_{\mathsf{F}}(\omega_m)) = i\alpha(\phi_{m\lambda}) - i\alpha^\dagger(\psi_{m\lambda}) \ ,$$

where the vectors $\psi_{m\lambda}$ and $\phi_{m\lambda}$ are defined by

$$\psi_{m\lambda} := \left\{\sqrt{n}\int_{-\pi}^{\pi} e^{in\theta} e^{im\theta_t(\theta)} \mathrm{d}\theta\right\}_{n=1,2,\ldots}, \quad \phi_{m\lambda} := \left\{\sqrt{n}\int_{-\pi}^{\pi} e^{-in\theta} e^{im\theta_t(\theta)} \mathrm{d}\theta\right\}_{n=1,2,\ldots} \tag{83}$$

and $\lambda \mapsto \theta_\lambda(\theta)$ is the integral curve of $\mathcal{F}_k^{(\pm)}$ starting from θ. Notice that the linear maps $\psi \mapsto \alpha(\psi)\Psi$ and $\psi \mapsto \alpha^\dagger(\psi)\Psi$ are continuous for every fixed vector $\Psi \in \mathfrak{D}_{\mathsf{F}}^{(1)}$, so that

$$\left.\frac{\mathrm{d}}{\mathrm{d}\lambda}\right|_{\lambda=0} \gamma_\lambda^{(\mathcal{F}_k^{(\pm)})}(\hat{\phi}_{\mathsf{F}}(\omega_m))\Psi = i\alpha\left(\left.\frac{\mathrm{d}}{\mathrm{d}\lambda}\right|_{\lambda=0} \phi_{m\lambda}\right)\Psi - i\alpha^\dagger\left(\left.\frac{\mathrm{d}}{\mathrm{d}\lambda}\right|_{\lambda=0} \psi_{m\lambda}\right)\Psi \ .$$

In turn, using a procedure very similar to that used in the proof of (b) in Theorem 2.4, one sees that the derivatives $(\mathrm{d}/\mathrm{d}\lambda)|_{\lambda=0}\phi_{m\lambda}$ and $(\mathrm{d}/\mathrm{d}\lambda)|_{\lambda=0}\psi_{m\lambda}$ evaluated by using the topology of $\ell^2(\mathbb{C})$ coincide with the analogous derivatives computed term-by-term for the sequences of $\ell^2(\mathbb{C})$ which define $\phi_{m\lambda}$ and $\psi_{m\lambda}$ (83). These derivatives can be computed straightforwardly and give rise to

$$\left.\frac{\mathrm{d}}{\mathrm{d}\lambda}\right|_{\lambda=0} \gamma_\lambda^{(\mathcal{F}_k^{(\pm)})}(\hat{\phi}_{\mathsf{F}}(\omega_m))\Psi = -\frac{im\sqrt{\pi}}{2}(i)_\pm (a_{m-k} \pm a_{m+k})\Psi \ ,$$

where, on the right-hand side, a_{m-m} and a_{-m+m} must be interpreted as the null operator. By comparison with (82) we find that (78) holds true provided $\mu=0$. □

Remarks: (1) A natural question concerns whether or not $\mathfrak{F}(\mathcal{H}_{\mathsf{F}})$ is irreducible with respect to the found Virasoro representation. The answer depends on the value of μ. If and only if $\mu\sqrt{2} \in \mathbb{Z}$ (and in particular if $\mu=0$) the answer is negative because of several results by Kac, Segal, and Wakimoto-Yamada (see Theorem 6.2 in Ref. 20 where the parameter l used below is indicated by μ which differs from the parameter μ used herein). If $\mu\sqrt{2} = -m \in \mathbb{Z}$, one has the orthogonal decomposition

$$\mathfrak{F}(\mathcal{H}_{\mathsf{F}}) = \bigoplus_{k\in\mathbb{Z}^+, k\geqslant -m} V(1,(m+2k)^2/4)\ ,$$

where $V(c,h)$ is the up-to-isomorphism unique highest-weight unitary Virasoro representation (which is irreducible by consequence) with central charge c and weight h. We recall for the reader that if $c=1$ and $h=l^2/4$ with $l\in\mathbb{Z}$, $V(c,h)$ is not a *Verma representation*. In other words the system of generators of $V(c,h)$ built up over the singular vector of $V(c,h)$ by application of products of Virasoro generators contains linearly dependent vectors. Conversely, if $c=1$ and $h\neq l^2/4$ with $l\in\mathbb{Z}$, $V(c,h)$ is a Verma representation.

(2) It is possible to build up a free scalar standard 2D-CFT by using $\hat{\phi}_{\mathsf{F}}$ and the analogous field $\hat{\phi}_{\mathsf{P}}$ defined on $\mathsf{P}:=\mathbf{P}\cup\{\infty\}$. In fact, consider the Wick rotation in Rindler coordinates $t\mapsto it$. Under that continuation, light-Rindler coordinates transform into $v\to it+\log(\kappa y)/\kappa$, $u\to it-\log(\kappa y)/\kappa$ and so $\theta=2\arctan(v/\beta)\to z$, $\theta'=2\arctan(u/\beta)\to-\overline{z}$. θ' is the coordinate on P which is defined analogously to θ. With the given definitions, z turns out to be defined on a cylinder C obtained by taking $\mathrm{Im}(z)\in\mathbb{R}$ and $\mathrm{Re}(z)\in(-\pi,\pi]$ with the identification $-\pi\equiv\pi$. By this way the fields $\hat{\phi}_{\mathsf{F}}$ and $\hat{\phi}_{\mathsf{P}}$ become, respectively, the Euclidean *holomorphic* and *antiholomorphic* fields in $\mathfrak{F}(\mathcal{H}_{\mathsf{F}})\otimes\mathfrak{F}(\mathcal{H}_{\mathsf{P}})$:

$$\hat{\phi}(w)=\sum_{n\in\mathbb{Z}\setminus\{0\}}\frac{w^n}{n}a_n\,,\quad \hat{\phi}(\overline{w})=\sum_{n\in\mathbb{Z}\setminus\{0\}}\frac{\overline{w}^n}{n}b_n\,,$$

where $w:=e^{-iz}$, the operators b_n are defined on P similarly to operators a_n and $[a_n,b_{\underline{m}}]=0$. The operators F_n and the analogues P_n defined in P are those usually denoted by L_n and $\overline{L}_n$, respectively.

(3) The bulk evolution is generated by the Hamiltonian H which is the quantum generator associated with the bulk killing vector ∂_t. Consider the operator H_{F} associated with H by holography and naturally extending it in the whole Fock space $\mathfrak{F}(\mathcal{H}_{\mathsf{F}})$ by assuming to work with massive noninteracting particles in the bulk. The obtained operator $H^{\otimes}_{\mathsf{F}}$ coincides with the self-adjoint Virasoro generator

$$H^{\otimes}_{\mathsf{F}}:=\frac{1}{\beta}\overline{(2F_1^{(+)}+F_0)}\qquad(\text{where}\mu=0)\tag{84}$$

provided $\mu=0$. Under this hypothesis, $F_0^{(+)},F_1^{(\pm)}$ span a finite-dimensional Lie algebra and $H^{\otimes}$ is the closure of an element of the algebra. [That is nothing but the Lie algebra of a unitary representation of $SL(2,\mathbb{R})$.] As a consequence it is possible to define time-depending observables $F_0(t),F_1^{(\pm)}(t)$ which are constant of motion in Heisenberg picture. These are finite linear combinations of generators $F_0(t),F_1^{(\pm)}(t)$. The proof of that fact is essentially the same as that of Theorem 2.1—item (b) in particular—in Ref. 8. We conclude that $F_0(t),F_1^{(\pm)}(t)$ generate a *symmetry of the system* when they are realized, by unitary holography, as operators acting in the bulk. Conversely, this result does not apply as it stands for $F_n^{(\pm)}$ if $n>1$. This is because there is no finite-dimensional Lie algebra containing both $F_n^{(\pm)}$ and $H^{\otimes}_{\mathsf{F}}$. However if one assumes that $F_0^{(+)}$ (which is associated with $K_{\beta\mathbf{F}}$ in the bulk) is the Hamiltonian of the theory on F, the observables $F_n^{(\pm)}$ with $n>1$ can be considered as symmetries of the system. This is because, for every fixed integer $n>0$ and also if $\mu\neq 0$, $F_0^{(+)},F_n^{(+)},F_n^{(-)}$ span a finite-dimensional Lie algebra [which is, in fact, a representation of the Lie algebra of $SL(2,\mathbb{R})$].

III. APPEARANCE OF THERMAL STATES FROM VIRASORO GENERATORS

Let us focus on the class of ''Hamiltonian operators'' defined for the theory on the circle F,

$$H^{\otimes}_{\mathsf{F}\,\mu}:=\frac{1}{\beta}\overline{(2F_1^{(+)}+F_0)}\ ,\tag{85}$$

where, differently from (84), now $\mu \in \mathbb{R}$ and thus, barring the value $\mu=0$, $H^{\otimes}_{\mathsf{F}\,\mu}$ cannot be associated with the Rindler Hamiltonian in the bulk by means of holography. In the following we study some properties of these Hamiltonians and associated ground states which can be considered as operators and states of the theory in the bulk. We shall not give rigorous proofs since the treatment of the issue involves a singular Bogoliubov transformation as well as a regularization procedure. We have formally

$$H^{\otimes}_{\mathsf{F}\,\mu}=\frac{\mu^2}{2\beta}I+H^{\otimes}_{\mathsf{F}}+i\,\frac{\mu}{2\beta}(\alpha_1-\alpha_1^{\dagger}). \tag{86}$$

We look for a, formally unitary, transformation U_μ such that

$$H^{\otimes}_{\mathsf{F}}=U_\mu H^{\otimes}_{\mathsf{F}\,\mu}U_\mu^{\dagger}.$$

It is convenient to work in the Fock space $\mathfrak{F}(\mathcal{H}_{\mathbf{F}})$ which is isomorphic to $\mathfrak{F}(\mathcal{H}_{\mathsf{F}})$ by means of the isomorphism $M:\mathcal{H}_{\mathbf{F}}\to\mathcal{H}_{\mathsf{F}}$ used in Theorem 2.1. In this representation

$$H^{\otimes}_{\mathsf{F}\,\mu}=\frac{\mu^2}{2\beta}I+\int_{\mathbb{R}^+}\mathrm{d}E\,E\;\; a_E^{\dagger}a_E+i\,\frac{\mu}{2\beta}\int_{\mathbb{R}^+}\mathrm{d}E\;\; Z_1^{(1)}(E)(a_E-a_E^{\dagger})\ , \tag{87}$$

where a_E and $a_E^{\dagger}$ are as in Eq. (14). By that way, it turns out that formally

$$U_\mu=\exp\left(-i\int_0^{\infty}Z_1^{(1)}(E)\,\frac{\mu}{2\beta}(a_E+a_E^{\dagger})\,\frac{\mathrm{d}E}{E}\right)\ . \tag{88}$$

Notice that when μ is equal to zero the unitary transformation becomes the identity and $H^{\otimes}_{\mathsf{F}\,0}=H^{\otimes}_{\mathsf{F}}$ as is due. For completeness we say that it is possible to rewrite U_μ in terms the operators α_n as follows:

$$U_\mu=\exp\left(-i\sum_{n>0}\,(-1)^{(n+1)}\,\frac{\mu}{\sqrt{n}}(\alpha_n+\alpha_n^{\dagger})\right)\ . \tag{89}$$

The ground state of $H^{\otimes}_{\mathsf{F}\,\mu}$, can be obtained as

$$\Psi_\mu:=U_\mu^{\dagger}|0\rangle_{\mathsf{F}}. \tag{90}$$

Ψ_μ is not invariant under Rindler evolution generated by $H^{\otimes}_{\mathsf{F}}$ but it enjoys interesting thermal properties when one considers expectation values of observables also averaged during a long period of Rindler time $T\to\infty$. Consider the expectation value of the operator A:

$$\langle A\rangle_\mu:=\lim_{T\to\infty}\frac{1}{2T}\int_{-T}^{T}\frac{\langle\Psi_\mu(t),A\Psi_\mu(t)\rangle_{\mathsf{F}}}{\langle\Psi_\mu(t),\Psi_\mu(t)\rangle_{\mathsf{F}}}\mathrm{d}t\ , \tag{91}$$

where $\Psi_\mu(t):=\exp\{-itH^{\otimes}_{\mathsf{F}}\}\Psi_\mu$. The direct computation is affected by mathematical problems which can be made harmless by making discrete the energy spectrum and taking the limit toward the continuous case after the evaluation of the expectation value. The discrete spectrum can be obtained by reducing to a known regularization procedure, consisting of a suitable version of the so-called ''box quantization.'' Start from (88) noticing that it can be rewritten, by using the adimensional parameter $\lambda=\log(E/E^*)$, E^* being an arbitrarily fixed energy scale,

$$U_\mu=\exp\left(-i\int_{-\infty}^{+\infty}Z_1^{(1)}(E(\lambda))\,\frac{\mu}{2\beta}(a_{E(\lambda)}+a_{E(\lambda)}^{\dagger})\mathrm{d}\lambda\right)\ . \tag{92}$$

Now, differently from E, λ ranges over the whole real line and box-quantization can be used as follows. First of all define the operators $c_\lambda = \sqrt{E'(\lambda)}a_{E(\lambda)}$ and $c^\dagger_\lambda = \sqrt{E'(\lambda)}a^\dagger_{E(\lambda)}$ so that bosonic commutation relations of a_E and $a^\dagger_E$ turns out to be equivalent to

$$[c_\lambda, c^\dagger_{\lambda'}] = \delta(\lambda - \lambda'), \quad [c_\lambda, c_{\lambda'}] = 0, \quad [c^\dagger_\lambda, c^\dagger_{\lambda'}] = 0. \tag{93}$$

Finally, to get the discrete spectrum in λ, assume that values λ describe the spectrum of a "momentum operator." These values can be made discrete by working a 1D box with length L with periodic boundary conditions, the continuous spectrum being restored in the limit $L \to \infty$. Within this framework, if $\lambda_n = 2\pi n/L$ with $n \in \mathbb{Z}$, the operators $c_j := c_{\lambda_j}$ enjoy the commutation relations

$$[c_i, c^\dagger_j] = \delta_{ij}, \quad [c_i, c_j] = 0, \quad [c^\dagger_i, c^\dagger_j] = 0. \tag{94}$$

With that regularization procedure, the Hamiltonian $H^\otimes_{\mathsf{F}}$ can be rewritten as

$$H^\otimes_{\mathsf{F}} = \int_{\mathbb{R}^+} E \;\; a^\dagger_E \;\; a_E \;\; \mathrm{d}E = \int_{\mathbb{R}} E(\lambda) \;\; c^\dagger_\lambda \;\; c_\lambda \;\; \mathrm{d}\lambda \to \sum_j \; E_j c^\dagger_j c_j, \tag{95}$$

where $E_j := E(\lambda_j)$. Similarly, using $E = E * e^\lambda$ and (9) for $k = n = 1$, the regularized unitary transformation U_μ reads

$$U_\mu = \prod_j \;\; \exp(-i\mu e^{-\beta E_j}(c_j + c^\dagger_j)) \tag{96}$$

and so the state Ψ_μ can be expanded as

$$\Psi_\mu = \prod_j \;\; \exp\left(\frac{\mu^2}{2} e^{-2\beta E_j}\right) \;\; \sum_n \; i^n \mu^n e^{-\beta E_j n} \frac{c^{\dagger n}_j}{n!} |0\rangle_{\mathsf{F}}. \tag{97}$$

We are now ready to compute $\langle A \rangle_\mu$. Using (97) in (91) one gets straightforwardly

$$\langle A \rangle_\mu = Z^{-1}_\beta \sum_{\{n_j\}} \; e^{-2\beta \Sigma_j E_j n_j} \mu^{2\Sigma_j n_j} \langle \{n_j\} | A | \{n_j\} \rangle, \tag{98}$$

with

$$Z_\beta = \sum_{\{n_j\}} \; e^{-2\beta \Sigma_j E_j n_j} \mu^{2\Sigma_j n_j}, \tag{99}$$

and the final limit $L \to \infty$ is understood. Let us consider all the developed machinery as referred to the theory in the bulk making use of the holographic theorem (Theorem 2.2) for a *massive* field. In that way, A must be considered as an observable for an observer in the Rindler wedge and Ψ_μ is a state for a quantum field propagating in the Rindler wedge. If μ is equal to 1, (98) states that the time-averaged state $\Psi_{\mu=1}$ viewed by an observer in the bulk who uses Rindler time-evolution, is a thermal state with inverse temperature $1/(2\beta)$. In particular, if we also choose $\beta = \beta_U/2$, where β_U is the inverse Unruh temperature, we get formally and in the sense of the pointed regularization-procedure out,

$$\langle A \rangle_{\mu=1} = \mathrm{tr}(\rho_{\beta_U} A), \tag{100}$$

where

$$\rho_{\beta_U} := \frac{e^{-\beta_U H_F^{\otimes}}}{\mathrm{tr} e^{-\beta_U H_F^{\otimes}}}$$

is the density matrix of a thermal state, which coincides with the restriction of Minkowski vacuum to Rindler wedge because of celebrated results of QFT (Bisognano–Wichmann–Sewell theorems, see Ref. 22 for a general discussion). In the case $\mu \neq 1$, (98) suggests to interpret

$$\frac{\log \mu^2}{2\beta}$$

as a chemical potential and the associated state can be seen as a grand canonical ensemble state.

IV. OVERVIEW AND OPEN PROBLEMS

In this paper we have shown that quantum field theory for free fields propagating in a 2D-Rindler background is unitary equivalent to the analogue defined on the compactified Killing horizons. The same equivalence can be implemented at the algebraic level. The key point of this holographic description is the hidden $SL(2,\mathbb{R})$ symmetry found in Ref. 9 for the fields propagating in the bulk. Indeed that hidden representation of $SL(2,\mathbb{R})$ becomes geometrically manifest when the theory is represented on the Killing horizon. Preserving a clear geometric meaning, the representation can be enlarged up to include a positive-energy unitary representation of Virasoro algebra with central charge $c=1$. Notice that the Virasoro algebra is realized in the many particles description of the fields, namely it describes a representation in the Fock space. The appearance of the pair of Virasoro algebras in the future and past horizon leads naturally to an (Euclidean) 2D conformal field theory on a cylinder which is holograpically associated with QFT in the bulk. In the last section we have proposed the idea that, for a particular choice of the parameter β and the ground energy $h=\mu^2/2$ of the Virasoro Hamiltonian F_0, the ground state $\Psi_\mu(t)$ of another Virasoro generator which generalizes Rindler Hamiltonian has thermal properties. $\Psi_\mu(t)$, seen in Fock space built up over the Rindler vacuum $|0\rangle$, is revealed to be an infinite particle state in thermal equilibrium temperature $1/(2\beta)$. It can be useful to describe the Hawking effect. These thermal properties are shown here without rigorous proof because of the use of a necessary regularization procedure in computing the mean value of the state with respect to Rindler time. Further investigation in that direction, perhaps based on KMS condition, is necessary.

Another issue which deserves investigation is the existence of any relation between the results of this paper and the attempts to give a statistical explanation to black hole entropy by counting microstates of irreducible unitary representations of Virasoro algebra.[15] This is done by means of the so-called Cardy's formula after a suitable dimensional regularization which gives rise to a scalar field (supporting part of information of 4D gravity) propagating in a 2D space–time. The main problem of those approaches is that they must assume the existence of a quantum Virasoro representation. The existence of such a representation has been established in this paper: It is worthwhile to investigate about the possible interplay between the quantum Virasoro representation found here and that necessary in those approaches.

Searching for a connection between matroid theory and string theory

J. A. Nieto[a)]

(Received 11 December 2002; accepted 16 September 2003)

We make a number of observations about matter-ghost string phase, which may eventually lead to a formal connection between matroid theory and string theory. In particular, in order to take advantage of the already established connection between matroid theory and Chern–Simons theory, we propose a generalization of string theory in terms of some kind of Kahler metric. We show that this generalization is closely related to the Kahler–Chern–Simons action due to Nair and Schiff. In addition, we discuss matroid/string connection via matroid bundles and a Schild type action, and we add new information about the relationship between matroid theory, $D=11$ supergravity and Chern–Simons formalism. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1625416]

I. INTRODUCTION

Although the key principle in M-theory[1–3] and string theory[4] is unknown, there is accumulating evidence for the existence of some kind of duality principle. In fact, duality is the key physical concept that relates the five known superstring theories in $9+1$ dimensions (i.e., nine space and one time), Type I, Type IIA, Type IIB, Heterotic SO(32) and Heterotic $E_8\times E_8$, which may now be understood as different manifestations of M-theory. Thus, anticipating the possibility that duality is the basic principle in M-theory, one may be interested in the mathematical structure necessary to make sense of such a duality principle. The idea is similar to the role played by tensor analysis which gives a mathematical sense to the postulate of relativity ''the laws of physics are the same for every observer.'' In two previous works we proposed the possibility that such a mathematical structure could be realized through the so-called matroid theory.[5] Matroid theory, which can be understood as a generalization of graph theory and matrix theory, has the duality symmetry among its key basic concepts. In fact, in contrast to graphs in which duality can only be considered in connection with planar graphs, matroid theory has the remarkable property that every matroid has a unique dual matroid. As an example of the importance of the duality property in matroid theory let us just mention a theorem due to Whitney:[5] if $M_1,\ldots,M_p$ and $M_1',\ldots,M_p'$ are the components (blocks) of the matroids M and M', respectively, and if M_i' is the dual of M_i $(i=1,\ldots,p)$, then M' is the dual of M and, conversely, if M and M' are dual matroids, then M_i' is the dual of M_i. Moreover, in a general context, we have the remarkable proposition that if a statement μ in the theory of matroids has been proved true, then also its dual μ^* is true.

Of course, the question is how to achieve such a relationship between matroid theory and M-theory, especially if we do not even know the formal partition function associated to M-theory. As a first step in this direction, one may attempt to see if matroid theory is linked somehow to $D=11$ supergravity which is one of the manifestations of M-theory. In fact, it has been shown[6] that the Fano matroid and its dual are closely related to Englert's compactification[7] of $D=11$ supergravity. This result is physically interesting because it allows a connection between the fundamental Fano matroid or its dual[8] and octonions which, at the same time, are one of the

a)Electronic mail: nieto@uas.uasnet.mx

alternative division algebras.[9] In Ref. 10, we made further progress on this program, incorporating matroid theory on quantum Yang–Mills theory in the context of Chern–Simons action. Our mechanism was based on a theorem due to Thistlethwaite[11] which connects the Jones polynomial for alternating knots with the Tutte polynomial for graphs. Since Witten[12] showed that Jones polynomial can be understood in three dimensional terms through a Chern–Simons formalism, it became evident that we achieved a bridge between matroid theory and Chern–Simons formalism.

In this article, we further pursue the idea of relating matroid theory with M-theory. Since the five fundamental strings are different vacuum limits of M-theory, it seems natural to try to find first a link between matroid theory and string theory. In this context there are a number of observations that indicate that this idea makes sense. First, since Chern–Simons formalism is closely linked to conformal field theory and matrix theory, which in turn are related to string theory, one should expect a connection of the form: matroid-theory→Chern–Simons-theory→string-theory. Second, since strings are closely related to knots, which in turn are related in one-to-one correspondence to signed graphs, one should expect a link of the form: matroids→signed graphs→knots→strings. Finally, we can in effect combine the two previous observations in the form: matroids→signed graphs→knots→Chern–Simons-formalism→strings.

In order to achieve our goal, we study the possibility that, in the string phase of matter-ghost coupling, the world sheet metric and the target space–time metric become unified in just one metric. We show, in some detail, that such a unified metric may be a certain kind of Kahler metric. This observation lead us to consider the Kahler–Chern–Simons action as the key bridge to connect matroid theory and string theory.

An alternative matroid/string connection can be achieved via the Schild type action.[13] In fact, we show that writing the Nambu–Goto action in the context of Schild formulation, such a connection seems to be a straightforward extension of the chirotope notion of oriented matroids. We prove that a local description of the chirotope concept becomes part of the structure of the Schild action. The relevant structure in this process is the concept of matroid bundle which has already been developed by the mathematicians.[14–17] Finally, we show that in order to complete the desired connection between matroids and strings it appears necessary to use the Chern–Simons formulation for strings as proposed by Zaikov.[18]

The plan of this work is as follows. In Sec. II, we briefly review matroid theory. In Sec. III, we closely follow Ref. 6 by adding new information about the connection between matroid theory and $D=11$ supergravity. In Sec. IV, we briefly review Ref. 10 and propose a possible extension of the relation between matroid theory and Witten's partition function for knots. In Sec. V, we propose a generalized Polyakov string action with the property of unifying the world-sheet metric and the target space–time metric. In Sec. VI, we discuss an alternative matroid/string connection via the concept of a chirotope of oriented matroids and Schild type action. Finally, in Sec. VII, we make some final comments.

II. A BRIEF REVIEW OF MATROID THEORY

At present matroid theory, also called combinatorial geometry or pregeometry, can be understood as the combinatorial analog of K-theory. In fact, the axioms of K-theory are very similar to the properties achieved with the Tutte–Gotendiek invariants for matroids. This interpretation emerged from a great number of contributions from several mathematicians since 1935 with the pioneer work of Whitney[5] on ''abstract properties of linear dependence.'' In the same year, Birkhoff[19] established the connection between simple matroids and geometric lattices. In 1936, MacLane[20] gave an interpretation of matroids in terms of projective geometry. And an important progress to the subject was given in 1958 by Tutte[8] who introduced the concept of homotopy for matroids. The fascination of this subject among the combinatorial mathematicians can be appreciated from the large body of information about matroid theory. In fact, there is a large number of books about matroid theory. For background information on this subject the reader should consult Oxley[21] and Welsh.[22] We also recommend the books by Wilson,[23] Kung,[24] and Ribnikov.[25]

It is known that in graph theory only planar graphs have an associated dual graph. For instance, the Kuratowski theorem assures that the complete graph K_5 and the bipartita graph $K_{3,3}$,

which are not planar, do not have an associated dual graph. In a sense, matroid theory arose as an attempt to solve this lack of duality symmetry. The attractive feature is that in matroid theory every matroid has an associated unique dual matroid. In particular the matroid associated to K_5, let us say $M(K_5)$, has a dual $M^*(K_5)$. The important aspect is that $M^*(K_5)$ is not graphic, that is, it can not be represented by a graph. This is, of course, an indication that matroid theory is a generalization of graph theory. Therefore, the great advantage of matroid theory is that it provides us with a mathematical structure in which the concepts of duality of planar graphs is extended to graphs that are not planar.

Another interesting aspect that motivates the subject is that linear dependence in algebra can be understood as a particular case of matroid theory. In fact, matroid theory leads to matroids that are not even representable by a finite set of vectors in a vector space or by matrices, extending the concept of orthogonality in vector spaces. Summarizing, we can say that by extending the concept of duality in vector spaces and planar graphs, matroid theory accomplishes a generalization of both graph theory and matrix theory.

Mathematically, a matroid is defined as follows: a matroid M is a pair (E,I), where E, called the ground set, is a nonempty finite set, and I is a nonempty collection of subsets of E satisfying the following two properties:

$(I\ i)$ Any subset of an independent set is independent.

$(I\ ii)$ If K and J are independent sets with $K\subseteq J$, then there is an element e contained in J but not in K such that $K\cup\{e\}$ is independent.

Members of I are called independent sets of M; other sets are called dependent. Therefore, the definition itself of a matroid divides all possible subsets of E in two types: independent and dependent subsets. Thus, we see that, even from the beginning, matroids have the dual structure independent–dependent. From this point of view, it is not a surprise to find eventually that every matroid has an associated dual matroid.

A base is defined to be any maximal independent set. Similarly, the minimal dependent set is called a circuit. By repeatedly using the property $(I\ ii)$ it is straightforward to show that any two bases have the same number of elements.

An alternative definition of a matroid in terms of bases is as follows:

A matroid M is a pair $(E,\mathcal{B})$, where E is a nonempty finite set and $\mathcal{B}$ is a nonempty collection of subsets of E (called bases) satisfying the following properties:

$(\mathcal{B}\ i)$ No base properly contains another base.

$(\mathcal{B}\ ii)$ If B_1 and B_2 are bases and if b is any element of B_1, then there is an element g of B_2 with the property that $(B_1-\{b\})\cup\{g\}$ is also a base.

A matroid can also be defined in terms of circuits:

A matroid M is a pair (E, C), where E is a nonempty finite set, and C is a nonempty collection of subsets of E (called circuits) satisfying the following properties.

$(C\ i)$ No circuit properly contains another circuit.

$(C\ ii)$ If C_1 and C_2 are two distinct circuits each containing an element c, then there exists a circuit in $C_1\cup C_2$ which does not contain c.

If we start with any of the three definitions, then one finds that the other two follow as theorems. For example, it is possible to prove that (I) implies $(\mathcal{B})$ and (C). In other words, these three definitions are equivalent. There are other definitions also equivalent to these three, but for the purpose of this work it is not necessary to consider all of them.

As we noticed previously, even from the initial structure of a matroid theory we find relations such as independent–dependent structure which suggests duality. The dual of M, denoted by M^*, is defined as a pair $(E,\mathcal{B}^*)$, where $\mathcal{B}^*$ is a nonempty collection of subsets of E formed with the complements of the bases of M. An immediate consequence of this definition is that every matroid has a dual and this dual is unique. It also follows that the double-dual M^{**} is equal to M. Moreover, if S is a subset of E, then the size of the largest independent set contained in S is called the rank of S and is denoted by $\rho(S)$. If $M=M_1+M_2$ and $\rho(M)=\rho(M_1)+\rho(M_2)$, we shall say that M is separable. Any maximal nonseparable part of M is a block of M. An important theorem due to Whitney[5] is that if $M_1,\ldots,M_p$ and $M_1',\ldots,M_p'$ are the blocks of the matroids M and M',

respectively, and if M_i' is the dual of M_i $(i=1,\ldots,p)$, then M' is dual of M. Conversely, let M and M' be dual matroids, and let $M_1,\ldots,M_p$ be blocks of M. Let $M_1',\ldots,M_p'$ be the corresponding submatroids of M'. Then $M_1',\ldots,M_p'$ are the blocks of M', and M_i' is the dual of M_i.

Over the last years matroid theory has been growing very rapidly. There are already well established formalisms for oriented matroids[26] and bias matroids.[27] The former can be understood as a generalization of oriented graphs and the latter as an extension of signed graphs. In each one of these branches of matroid theory there are very interesting theorems and results, some of which we shall mention in the next sections.

III. MATROID THEORY AND SUPERGRAVITY

Here, we briefly review the main results of Ref. 6 and add some new observations. In Ref. 6 we showed that the Fano matroid F_7 may be connected with octonions which, in turn, are related to the Englert's compactification of $D=11$ supergravity.

A Fano matroid F_7 is the matroid defined on the ground set

$$E=\{1,2,3,4,5,6,7\} \tag{1}$$

whose bases are all those subsets of E with three elements except $f_1=\{1,2,3\}$, $f_2=\{5,1,6\}$, $f_3=\{6,4,2\}$, $f_4=\{4,3,5\}$, $f_5=\{4,7,1\}$, $f_6=\{6,7,3\}$ and $f_7=\{5,7,2\}$. The circuits of the Fano matroid are precisely these subsets and its complements. It follows that these circuits define the dual F_7^* of the Fano matroid.

Let us write the set E in the form $E=\{e_1,e_2,e_3,e_4,e_5,e_6,e_7\}$. Thus, the subsets used to define the Fano matroid now become $f_1=\{e_1,e_2,e_3\}$, $f_2=\{e_5,e_1,e_6\}$, $f_3=\{e_6,e_4,e_2\}$, $f_4=\{e_4,e_3,e_5\}$, $f_5=\{e_4,e_7,e_1\}$, $f_6=\{e_6,e_7,e_3\}$ and $f_7=\{e_5,e_7,e_2\}$. The key idea in Ref. 6 was to identify the quantities e_i, where $i=1,\ldots,7$, with the octonionic imaginary units. Specifically, we write an octonion q in the form

$$q=q_0e_0+q_1e_1+q_2e_2+q_3e_3+q_4e_4+q_5e_5+q_6e_6+q_7e_7,$$

where q_0 and q_i are real numbers. Here, e_0 denotes the identity. The product of two octonions can be obtained from the formula

$$e_ie_j=-\delta_{ij}+\psi_{ij}^k e_k, \tag{2}$$

where δ_{ij} is the Kronecker delta and $\psi_{ijk}=\psi_{ij}^l\delta_{lk}$ is the fully antisymmetric structure constants, with $i,j,k=1,\ldots,7$. By taking the ψ_{ijk} equal to 1 or -1 for each one of the seven combinations f_i we may derive all the values of ψ_{ijk}.

The octonion (Cayley) algebra is not associative, but alternative. This means that the basic associator of any three imaginary units is

$$\langle e_i,e_j,e_k\rangle=(e_ie_j)e_k-e_i(e_je_k)=\varphi_{ijkm}e_m, \tag{3}$$

where φ_{ijkl} is a fully antisymmetric four index tensor. It turns out that φ_{ijkl} and ψ_{ijk} are related by the expression

$$\varphi_{ijkl}=(1/3!)\,\epsilon_{ijklmnr}\psi_{mnr}, \tag{4}$$

where $\epsilon_{ijklmnr}$ is the completely antisymmetric Levi–Civita tensor, with $\epsilon_{12\ldots7}=1$. It is interesting to observe that given the numerical values f_i for the indices of ψ_{mnr} and using (4) we get the other seven subsets of E with four elements of the dual Fano matroid F_7^*. For instance, if we take f_1, then we have ψ_{123} and (4) gives φ_{4567} which leads to the circuit subset $\{4,5,6,7\}$ of F_7^*.

Therefore, this shows that the Fano matroid and its dual are closely related to octonions which at the same time are an essential part of Englert's solution of absolute parallelism on S^7 of $D=11$ supergravity. It is important to mention that the Fano matroid is the only minimal binary

irregular matroid. Just as octonions are central mathematical objects in division algebras, this property makes the Fano matroid a central mathematical object in matroid theory. $D=11$ supergravity is on the other hand an important physical structure in M-theory. Therefore, we have here a link between three apparently unrelated important objects in its own field: Fano matroid (matroid theory)$\leftrightarrow$ octonions (algebra)$\leftrightarrow D=11$ supergravity (unify fundamental physics).

We would like to make some further observations about the link between the Fano matroid and octonions. Consider the subsets $h_1=\{v_1,v_2,v_3\}$, $h_2=\{v_5,v_1,v_6\}$, $h_3=\{v_6,v_2,v_4\}$, $h_4=\{v_4,v_3,v_5\}$, $h_5=\{v_4,v_7,v_1\}$, $h_6=\{v_6,v_7,v_3\}$ and $h_7=\{v_5,v_7,v_2\}$. If we identify v_i, where $i=1,\ldots,7$, of these subsets with the columns of the matrix

$$A=\begin{pmatrix} 1 & 0 & 1 & 0 & 1 & 0 & 1 \\ 1 & 1 & 0 & 0 & 0 & 1 & 1 \\ 0 & 1 & 1 & 1 & 0 & 0 & 1 \end{pmatrix}, \tag{5}$$

we notice that the matrix A provides a representation (or realization) of the Fano matroid F_7. Now, suppose that the Fano matroid is extended to a structure in which the sets $\{v_i,v_j,v_k\}$ corresponding to the h_i are replaced by the completely antisymmetric object

$$(v_i,v_j,v_k)=-(v_i,v_k,v_j)=-(v_j,v_i,v_k). \tag{6}$$

For instance, we may replace $h_1=\{v_1,v_2,v_3\}$ by $\hat{h}_1=(v_1,v_2,v_3)$. Specifically, we define the extended Fano matroid $\hat{F}_7$ as the pair $(E,\hat{\mathcal{B}})$ in which $\hat{\mathcal{B}}$ is the set of three elements (v_i,v_j,v_k) except the completely antisymmetric quantities $\hat{h}_1=(v_1,v_2,v_3)$, $\hat{h}_2=(v_5,v_1,v_6)$, $\hat{h}_3=(v_6,v_2,v_4)$, $\hat{h}_4=(v_4,v_3,v_5)$, $\hat{h}_5=(v_4,v_7,v_1)$, $\hat{h}_6=(v_6,v_7,v_3)$ and $\hat{h}_7=(v_5,v_7,v_2)$. The generalization from F_7 to $\hat{F}_7$ is very similar to the transition from graphs to digraphs (or oriented graphs) in which the edges of the original graph, let us say $\{a,b\}$, are changed to an ordering set, $(a,b)=-(b,a)$. The important point is that if there exists such a transition between F_7 and $\hat{F}_7$, then we discover that $\hat{F}_7$ almost determine completely the octonion algebra, essentially because (v_i,v_j,v_k) for the different h_i become closely related to the structure constants ψ_{mnr} associated to octonions. In fact, there is an extension of matroid theory which seems to be what these observations suggest for the Fano matroid, namely oriented matroids.[26]

In order to define oriented matroids it is necessary to define first what signed circuits are. A signed circuit X is a circuit with the partition (X^+,X^-) into two sets: X^+ the set of positive elements of X, and X^- its set of negative elements.

An oriented matroid $\mathcal{M}$ is a pair $(E,\mathcal{C})$, where E is a nonempty finite set, and $\mathcal{C}$ is a nonempty collection of subsets of E (called signed circuits) satisfying the following properties.

($\mathcal{C}$ *i*) No circuit properly contains another circuit.

($\mathcal{C}$ *ii*) If $\mathcal{C}_1$ and $\mathcal{C}_2$ are two distinct signed circuits, $\mathcal{C}_1\neq-\mathcal{C}_2$ and $c\in\mathcal{C}_1^+\cap\mathcal{C}_2^-$, then there exists a third circuit $\mathcal{C}_3\in\mathcal{C}$ with $\mathcal{C}_3^+\subseteq(\mathcal{C}_1^+\cap\mathcal{C}_2^+)\backslash\{c\}$ and $\mathcal{C}_3^-\subseteq(\mathcal{C}_1^-\cap\mathcal{C}_2^-)\backslash\{c\}$.

It is not difficult to see that by forgetting signs, this definition of oriented matroids reduces to the definition of ordinary (nonoriented) matroids.

An alternative but equivalent way to define an oriented matroid is as follows: An oriented matroid $\mathcal{M}$ is a pair (E,χ), where E is a nonempty finite set and χ (called chirotope) is a mapping $E^r\rightarrow\{-1,0,1\}$, with r the rank on E, satisfying the following properties.

(χi) χ is not identically zero.

(χii) χ is alternating.

(χiii) For all $x_1,x_2,\ldots,x_r$ and $y_1,y_2,\ldots,y_r$ such that

$$\chi(x_1,x_2,\ldots,x_r)\chi(y_1,y_2,\ldots,y_r)\neq 0, \tag{7}$$

there exists an $i\in\{1,2,3,4,5,6,7\}$ such that

$$\chi(y_i,x_2,\ldots,x_r)\chi(y_1,y_2,\ldots,y_{i-1},x_1,y_{i+1,}\ldots,y_r)=\chi(x_1,x_2,\ldots,x_r)\chi(y_1,y_2,\ldots,y_r). \tag{8}$$

For a vector configuration χ can be identified as

$$\chi(i_1,\ldots,i_r)\equiv \text{sign det}(v_{i_1},\ldots,v_{i_r})\in\{-1,0,1\} \tag{9}$$

and (χiii) turns out to be related to the Grassmann–Plucker relation.

Returning to the case of the Fano matroid, it is tempting to identify h_i with the chirotope

$$\chi(i_1,i_2,i_3)=\text{sign det}(v_{i_1},v_{i_2},v_{i_3}). \tag{10}$$

But, in Ref. 28 it is noted that the Fano matroid is not orientable. Specifically, one can verify that the Fano matroid does not satisfy the property (χiii). Nevertheless, it is interesting to observe that one may write the formula[29]

$$\psi_{i_1i_2i_3}+\chi(i_1,i_2,i_3)=C_{i_1i_2i_3}, \tag{11}$$

where $C_{i_1i_2i_3}\in\{-1,1\}$ may be identified with the uniform matroid $U_{3,7}$ which is an excluded minor for $GF(5)$-representability, where $GF(q)$ denotes a finite field of order q. In this sense the Fano matroid and the octonions look like complementary concepts of the oriented uniform matroid $M(U_{3,7})$ structure.

It is worth remarking that the structure of $\hat{F}_7$ does not necessarily correspond, in a straightforward way, to oriented matroids for the following observations. An important problem in matroid theory is to see which matroids can be mapped into a set of vectors in a vector space over a given field. When such a map exists we are speaking about a coordinatization (or representation) of the matroid over the field. A matroid which has a coordinatization over $GF(2)$ is called binary. Furthermore, a matroid which has a coordinatization over every field is called regular. It turns out that regular matroids are of fundamental importance in matroid theory, among other things, because they play a similar role as planar graphs in graph theory.[23] It is known that a graph is planar if and only if it contains no subgraph homeomorphic to K_5 or $K_{3,3}$. The analog of this theorem for matroids was proved by Tutte.[8] In fact, Tutte proved that a matroid is regular if and only if it is binary and has no minor isomorphic to the Fano matroid or the dual of this.

The important point is that an algebra, like the octonion algebra, is a vector space with an additional multiplicative operation. If it could be possible to identify this additional product with a kind of rule for the bases of $\mathcal{B}$ in a given matroid, then we could speak about a representation of a matroid (with this additional product) in terms of an algebra instead of just the corresponding vector space. At present, we have not been able to find in the literature this kind of structure for matroids. But it seems to us that our identification of $\hat{F}_7$ with octonions may provide an example of matroids associated with an algebra rather than with just the corresponding vector space.

IV. MATROID THEORY AND CHERN–SIMONS THEORY

Here, we shall briefly review the main results of Ref. 10 about the connection between matroid theory and Chern–Simons theory and make additional comments. For this purpose let us introduce the Witten's partition function

$$Z(L,k)=\int DA\,\exp(S_{cs})\prod_{r=1}^{n} W(L_r,\rho_r), \tag{12}$$

where S_{CS} is the Chern–Simons action

$$S_{CS}=\frac{k}{2\pi}\int_{M^3} Tr\left(A\wedge dA+\frac{2}{3}A\wedge A\wedge A\right), \tag{13}$$

and $W(C_i,\rho_i)$ is the Wilson line

$$W(L_r,\rho_r)=Tr_{\rho_r}P\exp\left(\int_{L_r}A_i^aT_a dx^i\right). \tag{14}$$

Here, $A=A_i^aT_a dx^i$, with T_a the generators of the Lie algebra of G and the symbol P means the path-ordering along the knots L_r. If we choose $M^3=S^3$, $G=SU(2)$ and $\rho_r=C^2$ for all the link components, then the Witten's partition function (12) reproduces the Jones polynomial

$$Z(L,k)=V_L(t), \tag{15}$$

where

$$t=e^{2\pi i/k} \tag{16}$$

and $V_L(t)$ denotes the Jones polynomial satisfying the skein relation,

$$t^{-1}V_{L_+}-tV_{L_-}=\left(\sqrt{t}-\frac{1}{\sqrt{t}}\right)V_{L_0}, \tag{17}$$

where L_+, L_- and L_0 are the standard notation for overcrossing, undercrossing and zero crossing.

On the other hand, Thistlethwaite[11] showed that if L is an alternating link and $G(L)$ the corresponding planar graph, then the Jones polynomial $V_L(t)$ is equal to the Tutte polynomial $T_G(-t,-t^{-1})$ up to a sign and a factor power of t. Specifically, we have

$$V_L(t)=(-t^{3/4})^{w(L)}t^{-(\rho-n)/4}T_G(-t,-t^{-1}), \tag{18}$$

where $w(L)$ is the writhe and ρ and n are the rank and the nullity of G, respectively. Here, $V_L(t)$ is the Jones polynomial of alternating link L. The Tutte polynomial associated to each graph G is a polynomial $T_G(x,x^{-1})$ with the property that if G is composed solely of isthmus and loops then $T_G(x,x^{-1})=x^Ix^{-l}$, where I is the number of isthmuses and l is the number of loops. The polynomial T_G satisfies the skein relation

$$T_G=T_{G'}+T_{G''}, \tag{19}$$

where G' and G'' are obtained by respectively delating and contracting an edge that is neither a loop nor an isthmus of G.

On the other hand, a theorem due to Tutte allows us to compute $T_G(-t,-t^{-1})$ from the maximal trees of G. In fact, Tutte proved that if $\mathcal{B}$ denotes the set of maximal trees in a graph G, $i(\mathcal{B})$ denotes the number of internally active edges in G, and $e(B)$ refers to the number of the externally active edges in G (with respect to a given maximal tree $B\in\mathcal{B}$), then the Tutte polynomial is given by the formula

$$T_G(-t,-t^{-1})=\sum_{B\subseteq\mathcal{B}}x^{i(B)}x^{-e(B)}, \tag{20}$$

where the sum is over all elements of $\mathcal{B}$.

The important point is that the Tutte polynomial $T_G(-t,-t^{-1})$ computed according to (20) uses the concept of a graphic matroid $M(G)$ defined as the pair $(E,\mathcal{B})$, where E is the set of edges of G. This remarkable connection between the Tutte polynomial and a matroid allows in fact a relation between the partition function $Z(L,k)$ given in (12) and matroid theory. This is because according to (18) the Tutte polynomial $T_G(-t,-t^{-1})$ is related to the Jones polynomial $V_L(t)$ which in turn according to (15) is connected to the partition function $Z(L,k)$. Specifically, for $M^3=S^3$, $G=SU(2)$, $\rho_r=C^2$ for all alternating link components of L, we have the relation

$$Z(L,k)=V_L(t)=(-t^{3/4})^{w(L)}t^{-(\rho-n)/4}T_G(-t,-t^{-1}). \tag{21}$$

Thus, the matroid $(E,\mathcal{B})$ used to compute $T_G(-t,-t^{-1})$ can be associated not only to $V_L(t)$, but also to $Z(L,k)$. Therefore, we have found a bridge which links the matroid formalism $(E,\mathcal{B})$ and the partition function $Z(L,k)$. This may allow us to bring many concepts of matroid theory to fundamental physics and, conversely, different results in fundamental physics may be used as an inspiration to further develop matroid theory. As an example of the former remark let us just mention how the duality concept in matroid theory can be used as a symmetry of $Z(L,k)$.

First of all, it is known that in matroid theory the concept of duality is of fundamental importance. For example, there is a remarkable theorem that assures that every matroid has a dual. So, the question arises about what are the implications of this theorem in Chern–Simons formalism. In order to address this question let us first make a change of notation $T_G(-t,-t^{-1})\rightarrow T_{M(G)}(t)$ and $Z(L,k)\rightarrow Z_{M(G)}(k)$. The idea of this notation is to emphasize the connection between matroid theory, Tutte polynomial and Chern–Simons partition function. Consider the planar dual graph G^* of G. In matroid theory we have $M(G^*)=M^*(G)$. Therefore, the duality property of the Tutte polynomial

$$T_G(-t,-t^{-1})=T_{G^*}(-t^{-1},-t) \tag{22}$$

can be expressed as

$$T_{M(G)}(t)=T_{M^*(G)}(t^{-1}) \tag{23}$$

and consequently from (15) and (18) we discover that for the partition function $Z_{M(G)}(k)$ we should have the dual property

$$Z_{M(G)}(k)=Z_{M^*(G)}(-k). \tag{24}$$

As a second example let us first mention another theorem due to Withney:[5] If $M_1,\ldots,M_p$ and $M_1',\ldots,M_p'$ are the components (or blocks) of the matroids M and M', respectively, and if M_i' is the dual of M_i $(i=1,\ldots,p)$, then M' is dual of M. Conversely, let M and M' be dual matroids, and let $M_1,\ldots,M_p$ be components of M. Let $M_1',\ldots,M_p'$ be the corresponding submatroids of M'. Then $M_1',\ldots,M_p'$ are the components of M', and M_i' is dual of M_i. Thus, according to (24) we find that

$$Z_{M_i(G_i)}(k)=Z_{M_i'(G_i)}(-k) \tag{25}$$

if and only if

$$Z_{M(G)}(k)=Z_{M'(G)}(-k), \tag{26}$$

where G_i are the components or blocks of G.

Our discussion has been, so far, based on alternating links L. This kind of link is an important, but relatively small, subclass of links. In fact, there is a one-to-one correspondence between links and signed graphs and a link is alternating if the signed graph representation has all edges with the same sign. Therefore, in order to generalize the procedure, it turns necessary to have a generalized Thustlethwaite's[11] theorem for any signed graph not just for those of the same sign. Fortunately, Thustlethwaite himself,[11] and later Kauffman,[30] precisely generalized the original Thustlethwaite's theorem for planar unsigned graphs.

Theorem: Let G be a planar signed graph. Let $K(G)$ be the knot/link diagram corresponding to G. Then $\langle K(G)\rangle=T_G(A,B,x,y)$. The bracket polynomial for knots and links is a specialization of the generalized Tutte polynomial for signed graphs.

Here, A, B, and d are commuting variables associated to the link. A and B correspond to A-channel, B-channel, respectively, while the parameter d is used as a factor of normalization in order to make $T_G(A,B,d)$ invariant under the Reidemeister moves II and III.

Furthermore, Kauffman showed that $T_G = T_G(A,B,x,y)$ has a spanning tree expansion of the form

$$T_G = \sum_{H \subseteq \mathcal{B}} \Lambda(H), \tag{27}$$

where $\Lambda(H)$ denotes the product of the contribution of the edges of G relative activities of the maximal trees H in G.

In principle, since up to a normalized factor, measuring the orientability of the link, $\langle K(G)\rangle \leftrightarrow CS$, in order to find a generalization of our procedure we need to relate T_G with matroid theory. A $T_G \leftrightarrow matroids$ connection is given by (27) in the sense that the sum is over all maximal trees H in G. Notice, however, that the maximal trees H are associated to the underlying graph (without signs) of the signed graph and not to the signed graph itself.

It is known that matroids associated to signed graphs are called bias matroids.[27] It turns out that bias matroids are interesting by themselves, but unfortunately the subject about this kind of matroid has not been developed for our purpose and it appears that many of the interesting properties of ordinary matroids are lost. Nevertheless, the idea of writing T_G as a sum over bias matroids seems interesting and deserves further study.

It may help to mention in this direction that Crapo[31] proposed an alternative possibility to write T_G as a sum over all spanning subsets of E, rather than over maximal trees. This idea is motivated from the observation that in this case the rank function ρ becomes an important concept and can be used to generalize T_G to matroid theory. A generalization for signed graphs of the Crapo's polynomial has been proposed by Murasugi[32] and by Shwarzler and Welsh.[33] Let us briefly mention these two polynomials.

Murasugi introduced the following polynomial. Let $\Gamma(r,s)$ denote the set of all spanning subgraph S of G. Then $T_G(x,y,z)$ is defined by

$$T_G(x,y,z) = \sum_{k,\rho} \left\{ \sum_{S \in \Gamma(r,s)} x^{P(S)-N(S)} \right\} y^{k(S)-1} z^{|S|-\rho(S)}, \tag{28}$$

where $P(S)$ and $N(S)$ denote the number of positive and negative edges in S, respectively. It is interesting to note that $\beta_0 = k = r+1$ and $\beta_1 = n = |S| - \rho(S)$, where n is the nullity and β_i denotes the i Betti number of S as a 1-complex. Although this polynomial uses the rank and the nullity concepts, the fact that the sum is over all spanning subgraphs Γ means that $T_G(x,y,z)$ is also applied only to the underlying unsigned graph G associated to the signed graph. Furthermore, the Murasugi polynomial does not have a direct relation with the Kauffmann polynomial.

On the other hand, Shwarzler and Welsh[33] proved that the Kauffmann polynomial associated to a link L can be expressed in terms of the associated signed graph $G(L)$ as follows,

$$T_G(A,B) = A^{|E^-|-|E^+|}(-A^2 - A^{-2})^{\rho(G)} \sum_{S \subseteq E} A^{4(\rho(S)-|S^-|)} B^{\rho(G)+|S|-2\rho(S)}, \tag{29}$$

where $B = -A^4 - 1$ and for any subset $S \subseteq E(G)$, S^+ and S^- denote the positive and negative signed parts, respectively. It is important to remark that Shwarzler and Welsh showed that (29) is a specialization of a more general polynomial for signed matroids. In fact, Shwarzler and Welsh proposed an eight variables polynomial which contains as specialization not only the Kauffman bracket polynomial but also the Tutte polynomial of a matroid, the partition function of the anisotropic Ising model and the Kauffman-Murasugi polynomial of signed graphs (for further details, see Ref. 33).

V. MATROID THEORY AND STRING THEORY

In the literature,[34–36] several attempts have been done to connect Chern–Simons formalism with string theory. One of the most interesting[37] comes from the idea that at some level the

decoupling of ghost and matter does not hold. In this case, matter fields and ghosts become mixed and the standard string theory should be replaced by some kind of topological string theory.[38] It has been shown[35] that some topological string theories perturbatively coincide with Chern–Simons theory. So, in this sense Chern–Simons theory is equivalent to topological string theory. However, the problem arises when it is attempted to relate Chern–Simons theory with fundamental strings. In fact, it has been shown[38] that in the pure Chern–Simons formalism there are not enough degrees of freedom to reproduce not only the induced gravity but the toroidal compactification of heterotic string.

These observations are, of course, important in order to find a matroid theory and string theory connection and eventually M-theory connection. In the previous section we explained a matroid theory–Chern–Simons theory relation via Tutte and Jones polynomials. It is clear then that what we should look for is some kind of generalization of fundamental strings which may provide the bridge between fundamental strings and topological strings.

The generalized fundamental strings could be the topological membrane[39] itself, but this is likely to be reduced to the topological strings rather than to fundamental strings. Another possibility is the membrane theory or any other p-brane,[40] but it has been shown[41] that through double dimensional reduction these are reduced to fundamental strings rather than to topological strings. So, although there is the hope that at some level 3D topological field theory may lead to fundamental strings, the correct formulation of such a theory is at present unknown.

In this section, we propose an alternative generalization of fundamental strings which seems closer to our purpose than the already known alternative of topological membranes or p-branes.

The idea comes from the observation that in the Polyakov type action the world sheet metric and the target space–time metrics are decoupled. But it seems natural to think that at a more fundamental level when ghost and matter fields are mixed the decoupling between two such metrics is no longer true. Therefore the desired generalization of string theory must be based on a unified metric of the world sheet and target space–time metrics.

Let us clarify these observations. For this purpose, let us first consider the Polyakov action

$$S=\frac{1}{2}\int d^2\xi\sqrt{-g}g^{ab}(\xi)\partial_a x^\mu\partial_b x^\nu G_{\mu\nu}(x), \tag{30}$$

where $g_{ab}(\xi)$ and $G_{\mu\nu}(x)$, with $\mu,\nu=1,\ldots,D$, are the world sheet metric and the target space–time metric, respectively. We observe from (30) that the two metrics $g_{ab}(\xi)$ and $G_{\mu\nu}(x)$ play very different roles; $g_{ab}(\xi)$ determines the world sheet metric swept out by the string in its dynamical evolution, while $G_{\mu\nu}(x)$ determines the background metric where the string is moving. Therefore, classically $g_{ab}(\xi)$ and $G_{\mu\nu}(x)$ are unrelated. However, this is no longer true at the quantum level. For instance, it is well known that in a consistent quantum string theory $g_{ab}(\xi)$ plays an essential role to fix the size of the matrix $G_{\mu\nu}(x)$: $D=26$ in the bosonic case. This kind of relation between $g_{ab}(\xi)$ and $G_{\mu\nu}(x)$ is, however, in a certain sense superficial because in the critical dimension 26 matter fields decouple from the corresponding ghost with associated central charge $c=-26$. The important observation is that, as it was mentioned in the Introduction, at a deeper level the decoupling between matter fields and ghost must be no longer true and therefore one should expect that in such a case there must be a unified framework for the two metrics $g_{ab}(\xi)$ and $G_{\mu\nu}(x)$.

Consider the line element

$$ds^2=G_{(\hat{\mu}\hat{\nu})}(x^{\hat{\alpha}})dx^{\hat{\mu}}\otimes dx^{\hat{\nu}}, \tag{31}$$

where the indices $\hat{\mu},\hat{\nu}$ run from 1 to $2D$, the symbol $\otimes$ means tensor product and $G_{(\hat{\mu}\hat{\nu})}=G_{(\hat{\nu}\hat{\mu})}$. Suppose that (31) can be written as

$$ds^2=G_{(\mu\nu)}(x^{\hat{\alpha}})dx^\mu\otimes dx^\nu+G_{(\mu\nu)}(x^{\hat{\alpha}})dy^\mu\otimes dy^\nu. \tag{32}$$

Here, we assume that $G_{(\mu A)}=G_{(A\mu)}=0$, with $A=D+1,\ldots,2D$ and we identify $x^A\rightarrow y^\mu$ and $G_{(AB)}\rightarrow G_{(\mu\nu)}$. It is not difficult to see that (32) can be rewritten as

$$ds^2=G^{ab}_{(\mu\nu)}(x^{\hat{\alpha}})dx^\mu_a\otimes dx^\nu_b, \tag{33}$$

where $x^\mu_1\equiv x^\mu$ and $x^\mu_2=y^\mu$ and we assumed that $G^{11}_{(\mu\nu)}=G^{22}_{(\mu\nu)}$ and $G^{12}_{(\mu\nu)}=G^{21}_{(\mu\nu)}=0$.

On the other hand, if we use the definition

$$z^\mu=x^\mu+iy^\mu, \tag{34}$$

we find that (32) can be written in the alternative way

$$ds^2=G_{(\mu\nu)}(x^{\hat{\alpha}})dz^\mu\otimes d\overline{z}^\nu. \tag{35}$$

In this scenario, since $dx^{\hat{\mu}}\otimes dx^{\hat{\nu}}$ is a second-rank symmetric tensor, the same results follow if we consider the most general Hermitian metric

$$G_{\hat{\mu}\hat{\nu}}(x^{\hat{\alpha}})=G_{(\hat{\mu}\hat{\nu})}(x^{\hat{\alpha}})+iG_{[\hat{\mu}\hat{\nu}]}(x^{\hat{\alpha}}). \tag{36}$$

Here, $G_{[\hat{\mu}\hat{\nu}]}$ denotes an antisymmetric tensor metric. Of course, $G_{\hat{\mu}\hat{\nu}}$ in (36) satisfies the Hermitian condition $G_{\hat{\mu}\hat{\nu}}=G^\dagger_{\hat{\mu}\hat{\nu}}$.

Now, consider the metric $G_{\hat{\mu}\hat{\nu}}(x^{\hat{\alpha}})$ given in (36), in connection with the exterior product

$$\Omega=\tfrac{1}{2}G_{\hat{\mu}\hat{\nu}}(x^{\hat{\alpha}})dx^{\hat{\mu}}\wedge dx^{\hat{\nu}}. \tag{37}$$

Using the exterior product property $dx^{\hat{\mu}}\wedge dx^{\hat{\nu}}=-dx^{\hat{\nu}}\wedge dx^{\hat{\mu}}$, we see that (37) leads to

$$\Omega=\frac{i}{2}G_{[\hat{\mu}\hat{\nu}]}(x^{\hat{\alpha}})dx^{\hat{\mu}}\wedge dx^{\hat{\nu}}. \tag{38}$$

Assuming that $G_{[\mu A]}=G_{[A\mu]}=0$ we find that (38) becomes

$$\Omega=\frac{i}{2}G_{[\mu\nu]}(x^{\hat{\alpha}})dx^\mu\wedge dx^\nu+\frac{i}{2}G_{[AB]}(x^{\hat{\alpha}})dy^A\wedge dy^B. \tag{39}$$

We again make the identification $x^A\rightarrow y^\mu$ and $G_{[AB]}\rightarrow G_{[\mu\nu]}$. The formula (39) can be rewritten as

$$\Omega=\frac{i}{2}G_{[\mu\nu]}(x^{\hat{\alpha}})(dx^\mu\wedge dx^\nu+dy^\mu\wedge dy^\nu). \tag{40}$$

Introducing $x^\mu_1\equiv x^\mu$ and $x^\mu_2=y^\mu$ and assuming that $G^{12}_{[\mu\nu]}=G^{21}_{[\mu\nu]}=0$ and $G^{11}_{[\mu\nu]}=G^{22}_{[\mu\nu]}\neq 0$ we find that (40) leads to

$$\Omega=\frac{i}{2}G^{ab}_{[\mu\nu]}(x^{\hat{\alpha}})dx^\mu_a\wedge dx^\nu_b. \tag{41}$$

On the other hand, using the definition (34) for z^μ we find that (40) can also be written as

$$\Omega=\frac{i}{2}G_{[\mu\nu]}(x^{\hat{\alpha}})dz^\mu\wedge d\overline{z}^\nu. \tag{42}$$

Summarizing we have shown that if $G^{11}_{(\mu\nu)}=G^{22}_{(\mu\nu)}\neq 0$ and $G^{12}_{(\mu\nu)}=G^{21}_{(\mu\nu)}=0$, and $G^{11}_{[\mu\nu]}=G^{22}_{[\mu\nu]}\neq 0$ and $G^{12}_{[\mu\nu]}=G^{21}_{[\mu\nu]}=0$, then

$$ds^2=G^{ab}_{\mu\nu}(x^\alpha_c)dx^\mu_a\otimes dx^\nu_b \tag{43}$$

is equivalent to

$$ds^2 = G_{\mu\nu}(z^\alpha, \overline{z}^\beta) dz^\mu \otimes d\overline{z}^\nu, \tag{44}$$

and that

$$\Omega = \frac{i}{2} G^{ab}_{\mu\nu}(x^\alpha_c) dx^\mu_a \wedge dx^\nu_b \tag{45}$$

is equivalent to

$$\Omega = \frac{i}{2} G_{\mu\nu}(z^\alpha, \overline{z}^\beta) dz^\mu \wedge d\overline{z}^\nu. \tag{46}$$

We recognize in (44) and (46) the formulas used to define the Kahler metric which in addition satisfies the condition $d\Omega = 0$. Therefore we have shown that under certain anzats the metric $G^{ab}_{\mu\nu}(x^\alpha_c)$ can be identified with the Kahler metric. This shows that it makes mathematical sense to consider a metric of the form $G^{ab}_{\mu\nu}(x^\alpha_c)$.

Our goal is now to use the metric $G^{ab}_{\mu\nu}(x^\alpha_c)$ in connection with string theory. We find that there are at least two different ways to achieve this. In fact, in the first case we have the action

$$S_1 = \frac{1}{2} \int d^2\xi \sqrt{-g} g^{ab}(\xi) \partial_a x^\mu_c \partial_b x^\nu_d G^{cd}_{\mu\nu}(x), \tag{47}$$

while in the second case we have[42]

$$S_2 = \frac{1}{2} \int d^2\xi G^{ab}_{\mu\nu}(\xi, x) \partial_a x^\mu \partial_b x^\nu. \tag{48}$$

For our purpose to relate matroid theory with string theory both possibilities look attractive. The action S_1 may be useful to understand T-duality or S-duality because of its property of being symmetric under the interchange of coordinates $x \leftrightarrow y$. However, S_2 is closer to our idea of unified worldsheet–target space–time metrics when matter and ghost mix.

In fact, in the particular case

$$G^{ab}_{\mu\nu} = \sqrt{g} g^{ab} G_{\mu\nu}, \tag{49}$$

one sees that S_2 is reduced to the Polyakov action (30). This shows that ordinary bosonic string theory is contained in a theory associated to (48). Another particular case for $G^{ab}_{\mu\nu}$ is

$$G^{ab}_{\mu\nu} = \sqrt{g} g^{ab} G_{\mu\nu} + i\varepsilon^{ab} B_{\mu\nu}, \tag{50}$$

where $B_{\mu\nu} = -B_{\nu\mu}$ is a two form and ε^{ab} is the completely antisymmetric tensor with $\varepsilon^{12} = 1$. The choice (50) leads to a generalized bosonic string theory, the so-called nonlinear sigmal model in two dimensions, in which the string propagates in a background determined not only by gravity but by the antisymmetric two form gauge field B with associated field strength $H = dB$. Finally, the third example is provided precisely for what we have already discussed when $G^{ab}_{\mu\nu}$ is identified with a Kahler metric.

Here, we are not particularly interested in developing the full theory implied by S_2, but to point out how S_2 can be related to matroid theory via Chern–Simons theory. For this purpose it seems to be convenient to start by recalling briefly how the Kahler structure is related to Chern–Simons theory.

There are a number of restrictions which a background field must satisfy in order to have a consistent string theory. Perhaps one of the most important is the anomaly cancellation fixed by the constraint[4]

$$dH = trR \wedge R - trF \wedge F, \tag{51}$$

where R is the curvature associated to $G_{\mu\nu}$. The formula (51) is an important restriction for the possible compactifications. One of the most attractive solutions of (51) is when the ten dimensional space–time vacuum state is given by $T^4 \times K$, where T^4 is a maximally symmetric four dimensional space–time and K is a six dimensional Kahler manifold.

Now, it is known that a Kahler metric determines a Kahler manifold, so Kahler metric is related to string theory through (51). In turn (51) contains the second Chern class $\int trF \wedge F$ which reduces to the Chern–Simons form. Therefore, the Kahler metric is closely related to Chern–Simons formalism in string theory. Consequently, the action S_2 with the choice of $G^{ab}_{\mu\nu}$ as a Kahler metric establishes a connection between matroid theory and string theory via Chern–Simons formalism.

VI. ALTERNATIVE CONNECTION BETWEEN MATROID THEORY AND STRING THEORY

The observations in the previous section may motivate us to look for a Chern–Simons formulation for strings. An attempt in this direction has been proposed by Zaikov.[18] Dolan and Tchrakian[43] have proposed a similar structure which has been extensively studied by Castro.[44] One of the roots of these developments is the Schild type construction for strings. In this section we shall show that this kind of construction offers a more direct connection between matroid theory and string theory.

Let us first recall the Schild type construction for strings. It is well known that from the action (30) one can derive the Nambu–Goto action

$$S = T \int d^2\xi \sqrt{-h}, \tag{52}$$

where h is the determinant of

$$h_{ab} = \partial_a x^\mu \partial_b x^\nu G_{\mu\nu}(x). \tag{53}$$

Here, we have restored the tension T of the string.

It is not difficult to see that h can be written as

$$h = \sigma^{\mu\nu}\sigma_{\mu\nu}, \tag{54}$$

where

$$\sigma^{\mu\nu} = \frac{1}{[2!]^{1/2}} \varepsilon^{ab} v^\mu_a(\xi) v^\nu_b(\xi). \tag{55}$$

Here, $v^\mu_a(\xi)$ is defined by

$$v^\mu_a(\xi) = \partial_b x^\mu(\xi). \tag{56}$$

One can show that the action (52) is equivalent to

$$S^{(1)}_p = \int d^2\xi \left(\sigma^{\mu\nu} p_{\mu\nu} - \frac{\gamma}{2}(p^{\mu\nu} p_{\mu\nu} + T^2) \right), \tag{57}$$

where γ is a Lagrange multiplier and $p_{\mu\nu}$ is a linear momentum associated to $\sigma^{\mu\nu}$. If we eliminate $p_{\mu\nu}$ from this action, we get

$$S^{(1)}_p = \frac{1}{2} \int d^2\xi (\gamma^{-1} \sigma^{\mu\nu}\sigma_{\mu\nu} - \gamma T). \tag{58}$$

By eliminating γ from (58) we recover action (52). The importance of (57) or (58) is that it now makes sense to set $T=0$. In this case (58) is reduced to the Schild type null 1-brane action.[13] Here, we are interested in connecting (58) with matroid theory.

Observe that we can relate (58) with matroid theory if we connect $\sigma^{\mu\nu}$ with a matroid structure. Therefore, the question is how expression (55) is related to matroids.

Consider the matrix

$$D=\begin{pmatrix} 1 & 0 & 1 & 1 \\ 0 & 1 & 1 & -1 \end{pmatrix}. \tag{59}$$

The matrix D is a realization of the matroid $E=\{1,2,3,4\}$ and

$$\mathcal{B}=\{\{1,2\},\{1,3\},\{1,4\},\{2,3\},\{2,4\},\{3,4\}\}. \tag{60}$$

This is the uniform matroid $U_{2,4}$. The elements of E are identified with the columns of D in the form $1\rightarrow b_a^1$, $2\rightarrow b_a^2$, $3\rightarrow b_a^3$ and $4\rightarrow b_a^4$ where b_a^μ are the four columns of D and the index a runs from 1 to 2. In this case the chirotope formula (9) reads as

$$\chi(\mu,\nu)\equiv \operatorname{sign}\det(\mathbf{b}^\mu,\mathbf{b}^\nu)\in\{-1,0,1\}. \tag{61}$$

In tensor notation we can write (61) in the form

$$\chi(\mu,\nu)\equiv \operatorname{sign}(\varepsilon^{ab}b_a^\mu b_a^\nu)\in\{-1,0,1\}. \tag{62}$$

Let us define

$$\Sigma^{\mu\nu}\equiv\varepsilon^{ab}b_a^\mu b_a^\nu \tag{63}$$

so that $\chi(\mu,\nu)\equiv\operatorname{sign}\Sigma^{\mu\nu}$. Comparing (55) and (63) we observe the great similarity between the two formulas. The main difference is the local property of (55). This is in a certain sense similar to the relation between the flat Minkowski metric $\eta_{\mu\nu}=\operatorname{diag}(-1,\ldots,1)$ and a curved metric $g_{\mu\nu}=g_{\mu\nu}(x)$. Let us discuss this analogy in more detail.

Consider an n-dimensional manifold M. A tangent bundle associated to M can be defined as

$$TM=\bigcup_{x\in M} T_x(M), \tag{64}$$

where $T_x(M)$ is the tangent space attached at each point x of M. The cotangent bundle

$$T^*M=\bigcup_{x\in M} T_x^*(M) \tag{65}$$

is defined through the isomorphism $w:T_x(M)\rightarrow R$, where $w\in T_x^*(M)$. The curved metric $g_{\mu\nu}(x)$ can be understood as the symmetric positive definite map

$$g:T_x(M)\rightarrow T_x^*(M). \tag{66}$$

In tensor notation (45) becomes

$$a_\mu=g_{\mu\nu}a^\nu, \tag{67}$$

where $a^\nu\in T_x(M)$ and $a_\mu\in T_x^*(M)$. A tangent bundle is an example of fiber bundles. In this case the fiber is the tangent space $T_x(M)$.

Therefore, the transition from $\eta_{\mu\nu}$ to $g_{\mu\nu}(x)$ is determined by the transition from flat vector space to a fiber bundle. Similarly, we may say that the transition from $\Sigma^{\mu\nu}$ to $\sigma^{\mu\nu}(\xi)$ is determined by the transition form matroid structure to matroid bundle structure. But the question is now

to understand what we mean by matroid bundle. Fortunately, the mathematicians have already developed such a concept.[14–17] The matroid bundle concept can be understood as the combinatorial analog of a fiber bundle. In a matroid bundle the fiber of a bundle is replaced by a matroid. It is worth mentioning that, recently, matroid bundle structure was used to combine the concepts of matroid and gravity in a proposed theory called gravitoid.[29]

Summarizing, we may start with a rank-two realizable matroid M such as the example in (59). We construct the chirotope $\chi(\mu,\nu)$ by means of the tensor $\Sigma^{\mu\nu}$ as in the formula (63). We then make the transition from a matroid structure to matroid bundle structure in such a way that $\Sigma^{\mu\nu} \rightarrow \sigma^{\mu\nu}(\xi)$. If we can go from (55) to (56), our task is finished.

Consider the object

$$F^{\mu}_{ab} = \partial_a v^{\mu}_b(\xi) - \partial_b v^{\nu}_a(\xi). \tag{68}$$

If F^{μ}_{ab} vanishes, then a solution of (68) is $v^{\mu}_a(\xi) = \partial x^{\mu}/\partial \xi^a$ where x^{μ} is in this context a gauge function. In this case, one says that $v^{\mu}_a(\xi)$ is a pure gauge. This kind of scenario can be derived from an Abelian Chern–Simons action for F^{μ}_{ab} in the form

$$S_{CS} = \frac{k}{2\pi} \int d^3\xi \varepsilon^{ijk} v^{\mu}_i F_{jk\mu}. \tag{69}$$

This shows once again the great importance of Chern–Simons formulation for a matroid/string connection. In fact, if we substitute expression (56) into (69), then the Zaikov's Chern–Simons type action for strings is obtained.

It is worth mentioning that in general a p-form F that can be written as $F = v_1 \wedge \cdots \wedge v_p$ for some $v_1, \ldots, v_p \in R^n$ is called decomposable. This means that the two form $\sigma^{\mu\nu}(\xi)$ given in (55) is decomposable. It turns out that decomposable forms may be considered as the starting point to construct the realization space of an oriented matroid (see Ref. 26, Chap. 8). These observations provide an additional evidence for the close relation between $\sigma^{\mu\nu}(\xi)$ and oriented matroids.

VII. COMMENTS

In the present work we have shown that the Kahler metric may provide an important bridge to connect matroid theory and string theory. Specifically using a generalized string theory we established the following identifications: $string\text{-}theory \leftrightarrow Kahler\text{-}structure$; $Chern\text{–}Simons\text{-}theory \leftrightarrow Kahler\text{-}structure$ and $matroid\text{-}theory \leftrightarrow Chern\text{–}Simons\text{-}theory$. Moreover, it is natural to expect that this kind of relation suggests a direct link between the generalized string theory described by (48), which by convenience we shall call Kahler-string action, and the pure Chern–Simons theory. But at first sight it is improbable that this more direct relation exists. The reason is that pure Chern–Simons theory does not provide us enough degrees of freedom to describe the dynamics even for the heterotic string theory. Therefore, these observations suggest that there must exist a generalized Chern–Simons action which is reduced to the Kahler-string action (48). Of course, the Kahler structure must play an important role in this generalized Chern–Simons theory. Happily, such a theory along this idea has already been proposed. In fact, some years ago Nair and Schiff[45] proposed what they called Kahler–Chern–Simons theory. The action proposed by Nair and Schiff has the form

$$S_{KCS} = \frac{k}{2\pi} \int_{M^3 \times R} Tr\left(A \wedge dA + \frac{2}{3} A \wedge A \wedge A \right) \Omega, + Tr(F\Phi + \Phi F), \tag{70}$$

where F is the field strength in $B^4 \times R$, Φ is a Lie algebra value (2,0) form and M^4 is a Kahler manifold of real dimension four. It turns out that S_{KCS} provides an action description of anti-self-dual gauge fields (instantons) on a four dimensional Kahler manifolds. Here, we are interested in seeing if under quantization S_{KCS} is reduced to the Kahler-string action (48). It can be shown, however, that up to WSW term, S_{KCS} leads to the action

$$S_3=\frac{1}{2}\int d^{2+2}\xi\sqrt{-g}g_{ij}^{ab}(\xi)\frac{\partial x^{\mu}}{\partial\xi_i^a}\frac{\partial x^{\nu}}{\partial\xi_i^a}G_{\mu\nu}(x), \tag{71}$$

rather than (48). Here, g_{ij}^{ab} can be identified with a Kahler metric on B^4, while $G_{\mu\nu}(x)$ is given by $G_{\mu\nu}(x)=\partial_{\mu}U\partial_{\nu}U^{-1}$, where U is a locally defined G-valued function related to the gauge field A by $A=U^{-1}dU$. Therefore, we conjecture that there must be a slightly different action from (70), with the property of reducing to (48).

Nevertheless, the action S_{KCS} may be of special interest to relate matroid theory not only to string theory but to M-theory itself. In fact, it is known that S_{KCS} leads to a theory in terms of fields in a target space of $N=2$ strings.[46] In turn, $N=2$ strings is one of the main proposals of M-theory.[47] Moreover, it has been pointed out in Ref. 48 that a number of similarities exist between the other main proposal of M-theory, namely, matrix theory.[49] In principle, for S_{KCS} one may repeat the formalism of Sec. IV. In fact, consider the partition function

$$Z_{KCS}(L,k)=\int DA\,\exp(S_{KCS})\prod_{r=1}^{n}W(L_r,\rho_r), \tag{72}$$

where $W(L_i,\rho_i)$ are the Wilson lines defined in (14). It is tempting to speculate that $Z_{KCS}(L,k)$ must be related to some knot invariant in a similar way that $Z_{CS}(L,k)$ is related to the Jones polynomials. From this idea, since knots are in one-to-one correspondence with signed graphs, one should expect to find the desired relation between matroid theory and $Z_{KCS}(L,k)$, which may lead eventually to a matroid theory and M-theory connection.

In Sec. VI, we discussed an alternative possibility to connect matroids and strings. The idea is to consider the Schild type action for strings. (This action is equivalent to the Nambu–Goto action and may be considered as the starting point for the Zaikov and Dolan–Tchrakian constructions for p-branes.) We identify the $\sigma^{\mu\nu}$ factor in (55) with the tensor $\Sigma^{\mu\nu}$ associated to the chirotope $\chi(\mu,\nu)$ via the matroid bundle notion. Such identification may lead to the matroid/string connection if one consider the Chern–Simons structure in (69), which becomes a Zaikov type action after using (56). It is important to mention that the discussion of Sec. VI can be generalized in a straightforward way to any p-brane.[50]

Another possible route to connect matroid theory with M-theory comes from the work of Gopakumar and Vafa[51,52] who have proved that topological strings are closely related to M-theory. Since Chern–Simons formalism is linked to topological strings,[35] it seems that we are closer to make the matroid theory the underlying mathematical structure of M-theory (see Ref. 53 for interesting observations about M-theory).

Finally, besides the possible connection between matroid theory, and string theory, the present formalism may be of special interest for quantum gravity based on the Ashtekar formalism[54] (see also Ref. 55 and references therein). The most interesting solutions of the Ashtekar constraints correspond to Witten's partition function. Consequently, the duality symmetries (24) may also play an important role in such solutions. It is known that the Vasiliev invariants become an important tool in the loop solutions of quantum canonical gravity in the Ashtekar formalism. Since the Vasiliev invariants can be understood as a generalization of the Jones polynomials, it may be interesting for further research to investigate whether matroid theory can be connected to such invariants.

ACKNOWLEDGMENT

I would like to thank M. C. Marín, E. Frías, E. Ley-Koo and G. Campoy for helpful comments.

(Received 22 June 2003; accepted 19 September 2003)

Axially symmetric monopole–antimonopole dipole solutions to the second-order equations of a simple SU(2) Yang–Mills–Higgs model featuring a quartic Skyrme-like term are constructed numerically. The effect of varying the Skyrme coupling constant on these solutions is studied in some detail. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1630703]

I. INTRODUCTION

The SU(2) Georgi–Glashow model in the Bogomol'nyi–Prasad–Sommerfield (BPS) limit supports monopoles[1,2] which are solutions of the first-order self-duality equations.[3,4] Away from the BPS limit, when new gauge invariant and positive definite terms are added, the resulting monopoles are described by the solutions to the second-order Euler–Lagrange equations, and not to the first-order self-duality equations. Once these terms are introduced to the model, the BPS topological bound cannot be saturated.

BPS and non-BPS monopoles differ in two remarkable respects. First, the BPS multimonopoles can be constructed analytically[5–8] while the non-BPS monopoles, e.g., when the Higgs potential is present,[1,2] can only be constructed numerically. Second, and perhaps physically more interestingly, BPS monopoles do not interact while non-BPS monopoles interact. In the presence of a Higgs potential this interaction is known to be repulsive[9,10] and has been verified to be so numerically,[11] while in the presence of Skyrme-like terms, higher order in both the Yang–Mills (YM) curvature and the Higgs covariant derivatives, this interaction can be both repulsive and attractive.[12] In a particularly simple such (Skyrme-like) model, this interaction was found[13] to be strictly attractive, and moreover it was found,[13] rather unexpectedly, that the lowest energy bound states were the axially symmetric ones and not those with Platonic symmetries. (It was unexpected since this feature contrasts with that for Skyrmion bound states.[14])

All the above-mentioned monopole solutions discussed are stable relative to the topological lower bound whether they saturate this bound, as for the BPS monopoles, or not, as for non-BPS ones. There is however another class of non-self-dual solutions to the second-order Euler–Lagrange equations which are not stable and represent states of monopoles and antimonopoles in equilibrium. The existence of such solutions was first proved by Taubes[15] for the model featuring no Higgs potential (and of course no higher order terms in the curvature and covariant derivative), namely, for the model which supports BPS multimonopoles. Such a non-BPS solution, namely, an unstable solution of the second-order equations, was first constructed for this system with SU(3) gauge group and subject to spherical symmetry by Burzlaff.[16] More recently Ioannidou and Sutcliffe[17] employed a harmonic map anstaz to construct such spherically symmetric solutions to the same (BPS) system with gauge groups SU(3), SU(4), and SU(N). Using results on sigma

a)Electronic mail: tigran@maxwell.thphys.may.ie

model instantons, these authors[17] also argued that the zero charge solutions they constructed described monopole–antiimonopole pairs.

A direct approach to constructing zero charge monopole–antimonopole pairs for the SU(2) BPS model was used sometime ago by Rüber.[18] This was the numerical construction of axially symmetric solutions with suitable boundary value conditions. More recently Kleihaus and Kunz[19] constructed this zero charge solution for the full Georgi–Glashow model featuring a Higgs potential, and they studied the effect of the Higgs potential in detail. To date, no such study has been reported in the literature pertaining to the model featuring higher order Skyrme-like terms. In the background of the above-described scenario it is pertinent to carry out such a study.

This is the aim of the present work. We will consider the zero charge axially symmetric monopole–antimonopole solutions as in Refs. 18 and 19, for the simple skyrmed Higgs model studied in Ref. 13 whose axially symmetric charge-2 monopoles are mutually attractive. This contrasts with the monopole–antimonopole solutions studied in Ref. 19 for the model whose charge-2 monopoles are mutually repulsive, which makes the comparison of our results with those of Ref. 19 interesting. In addition to constructing the vorticity-1 monopole–antimonopole solutions, as in Refs. 18 and 19, but now for the Skyrmed model here, we also construct the corresponding vorticity-2 solutions.

II. SKYRMED SU(2) YANG–MILLS–HIGGS MODEL

The static energy of the simplified Skyrme-like model considered is

$$\mathcal{E}=\int\left\{\frac{1}{2}\mathrm{Tr}\{F_{\mu\nu}F^{\mu\nu}\}+\frac{1}{4}\mathrm{Tr}\{D_\mu\Phi D^\mu\Phi\}+\frac{\kappa}{8}\mathrm{Tr}\{[D_\mu\Phi,D_\nu\Phi][D^\mu\Phi,D^\nu\Phi]\}\right.$$
$$\left.+\frac{\lambda}{2}\mathrm{Tr}\{(\Phi^2-\eta^2)^2\}\right\}d^3r \tag{1}$$

with field strength tensor of the su(2) gauge potential $A_\mu=\frac{1}{2}\tau_a A_\mu^a$,

$$F_{\mu\nu}=\partial_\mu A_\nu-\partial_\nu A_\mu+ig[A_\mu,A_\nu]\ , \tag{2}$$

and covariant derivative of the Higgs field $\Phi=\tau_a\phi^a$ in the adjoint representation

$$D_\mu\Phi=\partial_\mu\Phi+ig[A_\mu,\Phi]\ \ , \tag{3}$$

and g denotes the gauge coupling constant, κ the coupling strength of the quartic Skyrme-like Higgs kinetic term, λ the strength of the Higgs potential, and η the vacuum expectation value of the Higgs field.

The topological charge Q is the well-known quantity

$$Q=\frac{1}{4\pi\eta}\varepsilon^{ijk}\int\mathrm{Tr}\{F_{ij}D_k\Phi\}d^3r\ \ , \tag{4}$$

corresponding to the magnetic charge $m=Q/g$, and takes integer values that equal the winding number of the Higgs field.[20] The latter is encoded with the boundary conditions which yield the value of this integer.

To construct axially symmetric solutions that describe systems of monopoles and multimonopoles, specific boundary conditions must be imposed at the Higgs field at infinity. For usual multimonopoles, the Higgs field at infinity is described by the vortex number n winding the azimuthal angle φ, n times and the polar angle θ does not wind. Zero magnetic charge monopoles on the other hand, namely those we seek to construct, can be achieved by requiring that in the asymptotic Higgs field the polar angle is enhanced by another integer m. This can also be achieved automatically by incorporating this integer m in the ansatz[18,19] as will be in the following. The integral (4) can be evaluated for a system with m zeros of the Higgs field (i.e., with m monopole and antimonopole centers), and with vorticity n, yielding

$$Q=4\pi n\eta^3[1-(-1)^m] \ . \tag{5}$$

In this paper we will restrict to the charge zero case $m=2$ with vorticity $n=1$, to carry out our detailed analysis of the system, with special attention to the κ dependence of the solutions. After that, we will also briefly study the case of $n=2$ vorticity, again with $m=2$. These are both monopole–antimonopole solutions to the second-order equations carrying $Q=0$.

III. STATIC AXIALLY SYMMETRIC $Q=0$ ANSATZ

We choose the static, axially symmetric, purely magnetic ansatz employed in Ref. 18 for the monopole–antimonopole solution and in Refs. 21 and 22 for the sphaleron–antisphaleron solution of the Weinberg–Salam model. Here the gauge field is parametrized by

$$A_0=0 \ , \quad A_r=\frac{H_1}{2gr}\tau_\varphi^{(n)} \ , \quad A_\theta=\frac{(1-H_2)}{g}\tau_\varphi^{(n)} , \quad A_\varphi=-n\frac{\sin\theta}{g}(H_3\tau_r^{(2,n)}+(1-H_4)\tau_\theta^{(2,n)}), \tag{6}$$

and the Higgs field by

$$\Phi=\eta(\Phi_1\tau_r^{(2,n)}+\Phi_2\tau_\theta^{(2,n)}) \ . \tag{7}$$

All functions H_1, H_2, H_3, H_4, Φ_1, and Φ_2 depend on (r,θ) or equivalently on ($\rho=r\sin\theta$, $z=r\cos\theta$), with the su(2) matrices $\tau_r^{(2,n)}$, $\tau_\theta^{(2,n)}$, and $\tau_\varphi^{(n)}$ defined in terms of the Pauli matrices τ_1,τ_2,τ_3 as

$$\begin{aligned}
\tau_r^{(2,n)}&=\sin 2\theta(\cos n\varphi\tau_1+\sin n\varphi\tau_2)+\cos 2\theta\tau_3 \ , \\
\tau_\theta^{(2,n)}&=\cos 2\theta(\cos n\varphi\ \tau_1+\sin n\varphi\ \tau_2)-\sin 2\theta\ \tau_3 \ , \\
\tau_\varphi^{(n)}&=-\sin n\varphi\ \tau_1+\cos n\varphi\ \tau_2 \ ,
\end{aligned} \tag{8}$$

and for later convenience we define

$$\tau_\rho^{(n)}=\cos n\varphi\ \tau_1+\sin n\varphi\ \tau_2 \ . \tag{9}$$

Note that the dependence on the vorticity n is encoded through $\tau_r^{(2,n)}$ and $\tau_\theta^{(2,n)}$, and of course $\tau_\rho^{(n)}$.

We change to dimensionless coordinates, Higgs field, and coupling parameters by rescaling

$$r\to\frac{r}{g\eta} \ , \quad \Phi\to\eta\Phi \ , \quad \kappa\to\frac{\kappa}{g^2\eta^4} \ , \quad \lambda\to\frac{\lambda}{g^2} \ ,$$

respectively. Then this ansatz leads to the field strength tensor

$$F_{r\theta}=-\frac{1}{2r}(\partial_\theta H_1+2r\partial_r H_2)\tau_\varphi^{(n)} \ ,$$

$$\begin{aligned}
F_{r\varphi}=\frac{n}{2r}\{&(\sin 2\theta H_1-2\sin\theta H_1(1-H_4)-\sin\theta r\partial_r H_3)\tau_r^{(2,n)} \\
&+(\cos 2\theta H_1+2\sin\theta H_1H_3+2\sin\theta r\partial_r H_4)\tau_\theta^{(2,n)}\},
\end{aligned} \tag{10}$$

$$F_{\theta\varphi}=-\frac{n}{2}\{(2\sin 2\theta(H_2-1)+2\cos\theta H_3-2\sin\theta H_2(1-H_4)+2\sin\theta\partial_\theta H_3)\tau_r^{(2,n)}$$
$$+(2\cos 2\theta(H_2-1)+2\cos\theta(1-H_4)+2\sin\theta H_2H_3-2\sin\theta\partial_\theta H_4)\tau_\theta^{(2,n)}\}\ ,$$

and the covariant derivative of the Higgs field

$$D_r\Phi=\frac{1}{r}\{(r\partial_r\Phi_1+H_1\Phi_2)\tau_r^{(2,n)}+(r\partial_r\Phi_2-H_1\Phi_1)\tau_\theta^{(2,n)}\}\ ,$$

$$D_\theta\Phi=(\partial_\theta\Phi_1-2H_2\Phi_2)\tau_r^{(2,n)}+(\partial_\theta\Phi_2+2H_2\Phi_1)\tau_\theta^{(2,n)}\ , \tag{11}$$

$$D_\varphi\Phi=n\{(\sin 2\theta-2\sin\theta(1-H_4))\Phi_1+(\cos 2\theta+2\sin\theta H_3)\Phi_2\}\tau_\varphi^{(n)}\ .$$

The dimensionless energy density then becomes

$$\varepsilon=\mathrm{Tr}\left\{\frac{1}{r^2}F_{r\theta}^2+\frac{1}{r^2\sin^2\theta}F_{r\varphi}^2+\frac{1}{r^4\sin^2\theta}F_{\theta\varphi}^2\right\}+\frac{1}{4}\mathrm{Tr}\left\{(D_r\Phi)^2+\frac{1}{r^2}(D_\theta\Phi)^2+\frac{1}{\sin^2\theta r^2}(D_\varphi\Phi)^2\right\}$$
$$-\frac{\kappa}{4}\mathrm{Tr}\left\{\frac{1}{r^2}[D_r\Phi,D_\theta\Phi]^2+\frac{1}{r^2\sin^2\theta}[D_r\Phi,D_\varphi\Phi]^2+\frac{1}{r^4\sin^2\theta}[D_\theta\Phi,D_\varphi\Phi]^2\right\}$$
$$+\lambda((|\Phi|^2-1)^2), \tag{12}$$

where $|\Phi|=\sqrt{\Phi_1^2+\Phi_2^2}$ denotes the modulus of the Higgs field.

For a monopole–antimonopole pair we expect a magnetic dipole field for the asymptotic gauge potential. The dipole moment $C_{\mathbf{m}}$ can be extracted from the gauge field function H_3, in the gauge where the Higgs field approaches asymototically a constant. Like in Ref. 19 we find

$$H_3=\frac{C_{\mathbf{m}}}{r}\sin\theta\ , \tag{13}$$

while all other gauge field functions decay faster.

IV. NUMERICAL RESULTS

As noted in Ref. 19 the ansatz Eqs. (6) and (7) possess a residual $U(1)$ gauge symmetry. To obtain an unique solution we use the gauge fixing condition[19]

$$G_f=\frac{1}{r^2}(r\partial_rH_1-2\partial_\theta H_2)=0\ . \tag{14}$$

The system of partial differential equations is solved numerically subject to the following boundary conditions, which respect finite energy and finite energy density conditions as well as regularity and symmetry requirements. These boundary conditions are at the origin

$$H_1(0,\theta)=H_3(0,\theta)=0\ ,\quad H_2(0,\theta)=H_4(0,\theta)=1\ , \tag{15}$$

$$\sin 2\theta\Phi_1(0,\theta)+\cos 2\theta\Phi_2(0,\theta)=0\ ,\quad \partial_r(\cos 2\theta\Phi_1(0,\theta)-\sin 2\theta\Phi_2(0,\theta))=0\ , \tag{16}$$

at infinity

$$H_1(\infty,\theta)=H_2(\infty,\theta)=0\ ,\quad H_3(\infty,\theta)=\sin\theta\ ,\ (1-H_4(\infty,\theta))=\cos\theta, \tag{17}$$

$$\Phi_1(\infty,\theta)=1\ ,\quad \Phi_2(\infty,\theta)=0\ , \tag{18}$$

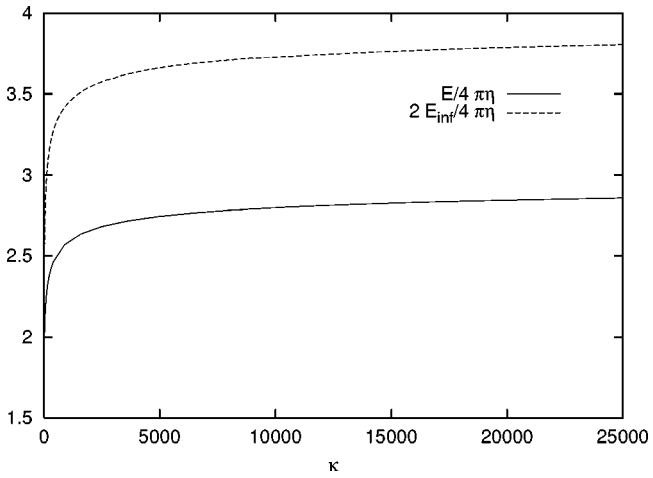

FIG. 1. The energy of the monopole–antimonopole solution (solid line) and the energy of a monopole–antimonopole pair with infinite separation (dashed line), for $n=1$.

and on the z axis

$$H_1(r,\theta=0,\pi)=H_3(r,\theta=0,\pi)=\partial_\theta H_2(r,\theta=0,\pi)=\partial_\theta H_4(r,\theta=0,\pi)=0 \quad , \tag{19}$$

$$\Phi_2(r,\theta=0,\pi)=\partial_\theta \Phi_1(r,\theta=0,\pi)=0 \quad . \tag{20}$$

The numerical calculations were performed with the software package CADSOL, based on the Newton–Raphson method.[23] We have carried out the main part of the numerical analysis for the case of unit vortex number $n=1$ in (8) as in Refs. 18 and 19. In addition we have also studied more briefly, the case of $n=2$.

Starting with the case of vorticity $n=1$, we have constructed monopole–antimonopole solutions for a large range of values of the coupling constant κ. For vanishing coupling constant κ the monopole–antimonopole solution corresponds to a non-Bogomol'nyi solution of the BPS system, for which our results are in good agreement with those of Ref. 19. Our numerical analysis was carried out for the Skyrmed model in the absence of the Higgs potential, namely with $\lambda=0$ in (12). We did however check that the presence of nonvanishing λ does not change the qualitative properties of our solutions. As expected the only effect it has is in the large r asymptotic region, where the modulus of the Higgs field, for example, reaches its asymptotic value faster, namely exponentially.

In Fig. 1 we show the normalized energy of the solitons $E/4\pi\eta$ and the energy $E_{\rm inf}/4\pi\eta$, of the monopole–antimonopole pair with infinite separation corresponding to twice the energy of a

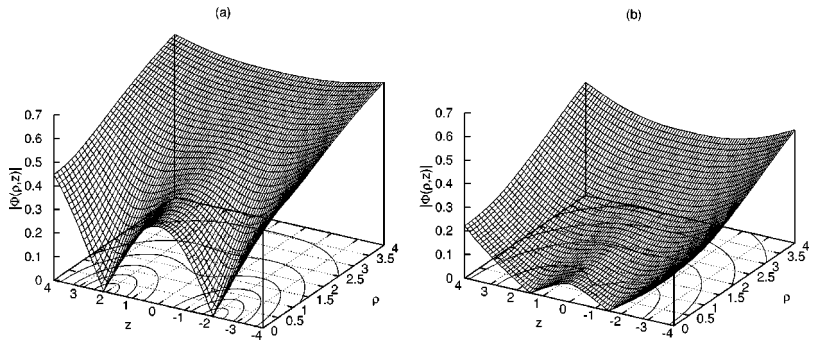

FIG. 2. The modulus of the Higgs field as a function of ρ and z for $\kappa=0$ (a) and $\kappa=100$ (b), for $n=1$.

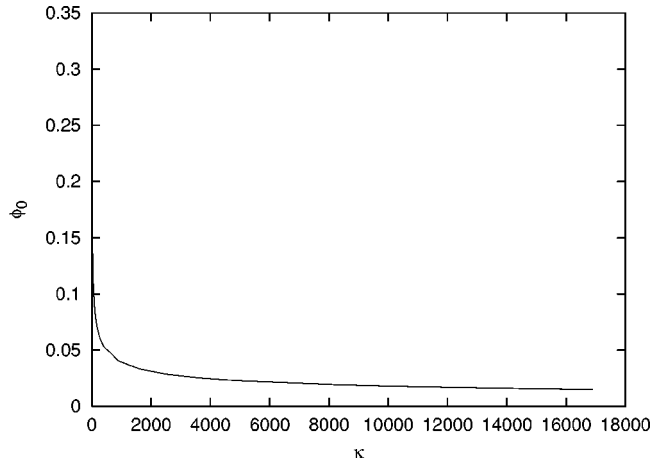

FIG. 3. The modulus of Higgs fields at the origin as a function of κ, for $n=1$.

charge-1 monopole, as functions of the coupling constant κ. As can be seen from Fig. 1 the energy of the monopole–antimonopole solution is less than the energy of a monopole–antimonopole pair with infinite separation for all values of κ.

In Fig. 2 we exhibit the modulus of the Higgs field $|\Phi(\rho,z)|$ as a function of the coordinates $\rho=\sqrt{x^2+y^2}$ and z for $\kappa=0$ and $\kappa=100$. The zeros of $|\Phi(\rho,z)|$ are located on the positive and negative z axis at $\pm z_0 \approx 2.1$ for $\kappa=0$ and at $\pm z_0 \approx 1.5$ for $\kappa=100$. The distance d of the two zeros of the Higgs field decreases monotonically with increasing κ.

Asymptotically $|\Phi(\rho,z)|$ approaches the value 1. But at the origin the value of the modulus of the Higgs field decreases monotonically with increasing κ (see Fig. 3). In the limit $\kappa\to\infty$ $|\phi_0| \approx 0.015$, and we expect the modulus of the Higgs field to be very small for $|z|\leqslant 4$.

In Fig. 4 we show the energy density of the monopole–antimonopole solution as a function of the coordinates $\rho=\sqrt{x^2+y^2}$ and z for $\kappa=0$ and $\kappa=100$. At the locations of the Higgs field the energy density posesses maxima.

For small values of coupling constant κ the equal energy density surfaces near the locations of the zeros of the Higgs field assume a shape close to a sphere, centered at the location of the respective zero [see Fig. 4(a)]. This presents further support for the conclusion that at the two zeros of the Higgs field a monopole and an antimonopole are located, which can be clearly distinguished from each other, and which together form a bound state.

With increasing κ the distance d between the monopole–antimonopole centers becomes smaller tending to a limit as $\kappa\to\infty$. At the same time the spherical equal energy surfaces in Fig. 4(b) become larger, and the equal energy density surfaces assume a shape that looks like the intersection of two spheres [see Fig. 4(b)], thus making it more difficult to distinguish the monopole from the antimonopole. The dependence of the separation length d is given in Table I below as a function of κ.

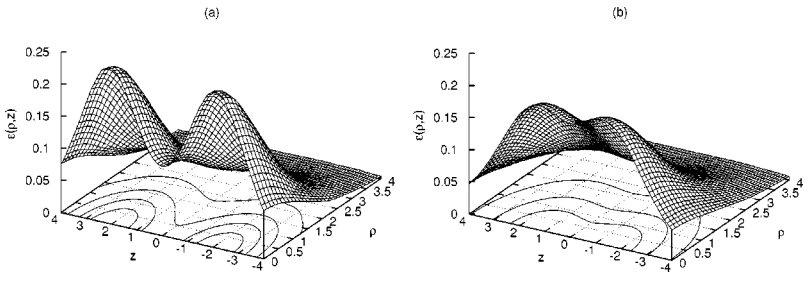

FIG. 4. The dimensionless energy density as a function of ρ and z for $\kappa=0$ (a) and $\kappa=100$ (b), for $n=1$.

TABLE I. Monopole–antimonopole separation d and dipole moment $C_{\mathbf{m}}$ as a functions of κ.

κ	0	9	16	25	36	49	64	100	8100	10 000
d	4.19	3.64	3.49	3.38	3.29	3.21	3.16	3.06	2.54	2.53
$C_{\mathbf{m}}$	2.36	2.27	2.23	2.19	2.15	2.11	2.07	2.02	1.66	1.65

Having exibited the qualitative properties of our *dipole* solutions, we give the values of the dipole moment that we calculated as a function of the coupling constant κ, again in Table I. As expected, with decreasing d the dipole moment $C_{\mathbf{m}}$ also decreases.

Finally we constructed solutions for the case of vorticity $n=2$. Most of the qualitative properties of these solutions do not differ from those of the $n=1$ case just described. The most noticeable quantitative difference concerns the value of the modulus of the Higgs field at the origin, analogous with Figs. 1(a) and 1(b). We do not exhibit here these analogous figures, but simply note that the the moduli of the Higgs fields at the origin are *smaller* than those in Figs. 1(a) and 1(b) for the same values of the coupling constant κ.

Another difference, qualitative though expected, is that the surfaces of equal energy are not spheres centered on the z axis but describe rings or tori around it. This is exhibited in Figs. 5(a) and 5(b), analogously with Figs. 4(a) and 4(b).

Again, as κ grows, the distiction between the monopole and antimonopole rings gets blurred.

V. SUMMARY

We have contructed axially symmetric solutions to a simple SU(2) Skyrmed YM–Higgs model, with such boundary conditions that result in the description of a monopole–antimonopole pair with zero magnetic charge. These solutions have lower mass than two infinitely separated charge-1 monopoles, and since they are characterized by zero magnetic charge, are not topologically stable.

When the usual boundary conditions are imposed, the Skyrmed SU(2) YM–Higgs model employed here supports mutually attractive monopoles, including axially symmetric charge-2 monopoles. This is in contrast to the Georgi–Glashow model studied in Ref. 19 where due to the Higgs potential the monopoles are mutually repulsive.[11] Nevertheless, the qualitative features of the monopole–antimonopole solutions in the two models are similar. Increasing the Skyrme coupling constant κ in the present model results in the approaching of the monopole and the antimonopole centers down to a limiting value 2.53 as $\kappa\to\infty$, just as it does to the limiting value 3.0 as $\lambda\to\infty$ in the Georgi–Glashow model λ being the Higgs coupling constant. (Our results are for $\lambda=0$.)

Another parallel property in the two models is the changing dipole moment with respect to the change in the Skyrme coupling constant κ and the Higgs coupling constant λ, in the two models,

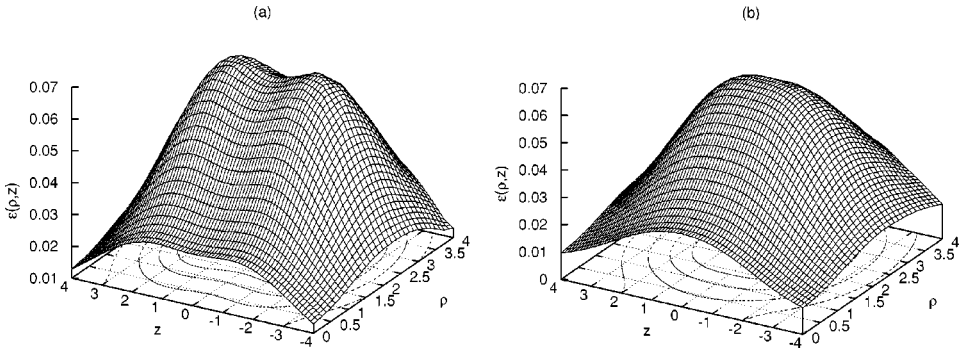

FIG. 5. The dimensionless energy density as a function of ρ and z for $\kappa=0$ (a) and $\kappa=100$ (b), for $n=2$.

respectively. Specifically in the present model the magnetic moment decreases with increasing κ, with limiting value 1.64, while in the Georgi–Glashow model it decreases with increasing λ, with limiting value 1.55, in the same units.

Finally, we also studied the case of a zero charge monopole which has vortex number $n=2$ rather than $n=1$. The qualitative properties again stay unchanged. The most noticeable quantitative difference of the $n=2$ solution is that the value of the modulus of the Higgs field at the origin is smaller than that of the $n=1$ solution, for the same value of κ, and the distance between the two centers is also smaller. For example at $\kappa=25$ the distance $d=3.38$ for the $n=1$ solutions while that for the $n=2$ is $d=1.33$.

ACKNOWLEDGMENTS

It is a pleasure for us to thank Burkhard Kleihaus for numerous valuable discussions and for his generous help. We are grateful to Ronan Reilly for making the computational resources of the Department of Computer Science (NUIM) avilable to us. This work was carried out in the framework of Enterprise–Ireland Project Nos. SC/2000/020 and IC/2002/005.

We examine symmetry generators for exterior differential systems and for systems of partial differential equations and apply the Cartan theory of exterior differential systems to the Weyl–Lanczos equations and to the Lanczos wave equation in four dimensions. We look at a number of examples of symmetries for the Weyl–Lanczos equations in four dimensions and give examples of isovectors when the solution manifold is the Schwarzschild, Kasner or Gödel space–time. Solutions of the Weyl–Lanczos system are automatically solutions of the Lanczos wave equation. We give examples of symmetry generators for the Lanczos wave equation and find that they are not automatically symmetry generators for the Weyl–Lanczos equations. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1625076]

I. INTRODUCTION

A. The Weyl–Lanczos equations and the Lanczos tensor wave equation in four dimensions

Lanczos[13] generated the space–time Weyl conformal tensor C_{abcd} from a tensor potential L_{abc} by covariant differentiation and it is given by

$$C_{abcd}=L_{[ab][c;d]}+L_{[cd][a;b]}-{}^{*}L^{*}_{[ab][c;d]}-{}^{*}L^{*}_{[cd][a;b]}, \tag{1}$$

where ";" denotes covariant differentiation. The index symmetries of the Lanczos tensor L_{abc} have to match the symmetries of (1) and so it is usual to add to the property

$$L_{abc}=L_{[ab]c}, \tag{2}$$

the antisymmetric condition

$$L_{[abc]}=0, \tag{3}$$

and the trace-free (gauge) condition

$$L_{as}{}^{s}=0. \tag{4}$$

The space–time Weyl–Lanczos equations (1) can also be expressed as

$$C_{abcd}=L_{abc;d}-L_{abd;c}+L_{cda;b}-L_{cdb;a}+g_{bc}L_{(ad)}+g_{ad}L_{(bc)}-g_{bd}L_{(ac)}-g_{ac}L_{(bd)} + \tfrac{2}{3}L^{ms}{}_{m;s}(g_{ac}g_{bd}-g_{ad}g_{bc}), \tag{5}$$

a)Electronic mail: pdolan@inctech.com
b)Electronic mail: agerber03@yahoo.co.uk

where $L_{ad}=L_{asd;}{}^{s}-L_{as}{}^{s}{}_{;d}$ and round brackets indicate symmetrization. We call (5) the **Weyl–Lanczos equations**. The algebraic equations (2)–(4) leave us with only 16 independent components for the L_{abc}. If we then introduce the differential gauge condition

$$L_{abs;}{}^{s}=0, \tag{6}$$

which we will denote by $f_{ab}^{(DG)}=L_{abs;}{}^{s}=0$, we can simplify (5) considerably to get

$$C_{abcd}=L_{abc;d}-L_{abd;c}+L_{cda;b}-L_{cdb;a}-g_{bc}L_{sad;}{}^{s}-g_{ad}L_{sbc;}{}^{s}+g_{bd}L_{sac;}{}^{s}+g_{ac}L_{sbd;}{}^{s}. \tag{7}$$

The Weyl–Lanczos equations in solved form, which we denote by $f_{abcd}^{(W)}=0$, are then given by

$$f_{abcd}^{(W)}=C_{abcd}-L_{abc;d}+L_{abd;c}-L_{cda;b}+L_{cdb;a}+g_{bc}L_{sad;}{}^{s}+g_{ad}L_{sbc;}{}^{s}-g_{bd}L_{sac;}{}^{s}-g_{ac}L_{sbd;}{}^{s}=0. \tag{8}$$

Theoretically, we could completely solve the six differential gauge conditions (6) for six further components L_{abc} and have only ten L_{abc} components for ten independent space–time Weyl–Lanczos equations. But here, we examine the most general situation first. We note that Eqs. (6) and (7) constitute a system of linear first-order partial differential equations in four dimensions which can easily be rewritten as an exterior differential system (EDS) in involution as was shown in Ref. 1. Using the Janet–Riquier theory we could confirm these results.[9] This theory only applies in four dimensions as the Weyl–Lanczos problem in two and three dimensions does not exist and for five and maybe higher dimensions, we expect extra conditions to apply as we will point out in later papers.

From the Weyl–Lanczos problem it is possible to generate a tensor wave equation for the (space–time) Lanczos potential from which the Penrose wave equation for the Weyl tensor C_{abcd} can be derived.[8,18] Arising from the Weyl–Lanczos equations is the tensor wave equation

$$\Box L_{abc}+2R_{c}{}^{s}L_{abs}-R_{a}{}^{s}L_{bcs}-R_{b}{}^{s}L_{cas}-g_{ac}R^{ls}L_{lbs}+g_{bc}R^{ls}L_{las}-\tfrac{1}{2}RL_{abc}=J_{abc}, \tag{9}$$

where

$$J_{abc}=\tfrac{1}{2}R_{c[a;b]}-\tfrac{1}{6}g_{c[a}R_{;b]} \tag{10}$$

and

$$\Box L_{abc}=g^{sm}L_{abc;sm}. \tag{11}$$

A new comprehensive survey of the Lanczos tensor also using spinors can be found in Ref. 16. A standard derivation of Penrose's wave equation for the space–time Weyl tensor

$$\Box C_{abcd}-C_{absm}C_{cd}{}^{sm}-4C_{asm[c}C_{d]}{}^{sm}{}_{b}+\frac{R}{4}C_{abcd}=J_{[ab][c;d]}+J_{[cd][a;b]}-{}^{*}J^{*}_{[ab][c;d]}-{}^{*}J^{*}_{[cd][a;b]} \tag{12}$$

is given in Ref. 18. The Lanczos wave equation in solved form can be written as

$$\mathcal{W}_{abc}=\Box L_{abc}+2R_{c}{}^{s}L_{abs}-R_{a}{}^{s}L_{bcs}-R_{b}{}^{s}L_{cas}-g_{ac}R^{ls}L_{lbs}+g_{bc}R^{ls}L_{las}-\tfrac{1}{2}RL_{abc}-J_{abc}=0. \tag{13}$$

It was shown in Refs. 6 and 9 that the Lanczos tensor wave equation in four dimensions is also a system in involution. Here, we are going to look at solutions with symmetries and find some symmetry generators for both the Weyl–Lanczos equations and the Lanczos wave equation in four dimensions. The knowledge of symmetries of a system of partial differential equations can help in finding further solutions of its equations. Before suggesting *Ansätze* for symmetry generators, we introduce exterior differential systems (EDS) and isovectors.

B. Historical comments

Over many papers culminating in 1962 Lanczos[13] explored the analogy between electromagnetism as a field theory and general relativity. Thereby the following correspondences were generally established

$$\textit{field}\ \ F_{ab}\leftrightarrow C_{abcd},$$

$$\textit{potential}\ \ A_a\leftrightarrow L_{abc},$$

$$\textit{current}\ \ J_a\leftrightarrow J_{abc}.$$

In the 1962 paper[13] the gravitational analog of the potential field relations

$$F_{ab}=A_{a;b}-A_{b;a} \tag{14}$$

was found to be given by (1) with L_{abc} satisfying (2)–(4) in order to make L_{abc} algebraically irreducible. Further, we have an electromagnetic gauge condition $A^s{}_{;s}=0$ and analogously the differential gauge condition (6) for L_{abc}. The electric current relation J^a satisfies

$$J^a=F^{ab}{}_{;b}, \tag{15}$$

which is equivalent to a wave equation for the potential A_a. Of course, it is the vanishing of the covariant derivatives of the electromagnetic gauge conditions that permit the causal propagation of A_a and so analogously the wave equation (9) for the Lanczos tensor propagates L_{abc} causally because the covariant derivatives of the gauge conditions (6) have been removed. In the same way the Schouten tensor J_{abc} acts as a source for the Lanczos potential wave equation (9). From the potential wave equation for A_a it is well known that we can obtain a field wave equation for the field F_{ab}. The wave equation (9) for the Lanczos potential can also generate the corresponding field wave equation (12). The interest in the study of the Lanczos potential and its wave equation is based on these analogies between electromagnetism and gravity. Fuller details are given in Ref. 8.

II. LANCZOS POTENTIALS AND ISOVECTORS

An **exterior differential system** (EDS) Σ over a formal N-dimensional manifold $\mathcal{M}$ is given by a set of differential forms $\{\alpha^{(1)}_{i_1},\ \alpha^{(2)}_{i_2},\ldots,\alpha^{(p)}_{i_p}\}$ with

$$\begin{aligned}
&\alpha^{(0)}_{i_0}\quad \textit{zero-forms},\quad 1\leqslant i_0\leqslant k_0,\\
&\alpha^{(1)}_{i_1}\quad \textit{one-forms},\quad 1\leqslant i_1\leqslant k_1,\\
&\alpha^{(2)}_{i_2}\quad \textit{two-forms},\quad 1\leqslant i_2\leqslant k_2,\\
&\qquad\vdots\quad\ \vdots\quad\ \vdots\\
&\alpha^{(p)}_{i_p}\quad \textit{p-forms},\quad 1\leqslant i_p\leqslant k_p,
\end{aligned}$$

where the $k_0,k_1,\ldots,k_p$ give the number of zero-forms, one-forms and so on in the EDS. A **Pfaffian system** $\mathcal{P}$ is a special case of an EDS containing only zero-forms and one-forms. A good account of the theory of EDS can be found in Refs. 4, 5, 14, and 25.

We will assume that we are working on a formal manifold $\mathcal{M}$ with dimension $N=84$ with local jet coordinates (x^a,L_{bcd},P_{efgh}), where we have 4 independent variables x^e, 16 variables L_{abc} and 64 P_{abcd} at our disposal so that $N=4+16+64=84$ on the first-order jet bundle $\mathcal{J}^1(\mathbb{R}^4,\mathbb{R}^{16})$. An introduction to jet bundles can be found in Ref. 19. When the P_{abcd} are projected

onto the space–time manifold M they become the partial derivatives $P_{abcd}=\partial L_{abc}/\partial x^d$. We can write the Weyl–Lanczos equations as an EDS Σ with independence condition Ω, which is given by $\Omega=dx^1\wedge dx^2\wedge dx^3\wedge dx^4\neq 0$ when local coordinates (x^1,x^2,x^3,x^4) are used. The EDS is given by

$$df^{(W)}_{abcd}=d(L_{[ab][c;d]})+d(L_{[cd][a;b]})-d(*L^{*}_{[ab][c;d]})-d(*L^{*}_{[cd][a;b]}),$$

$$df^{(DG)}_{ab}=d(L_{abs;}{}^{s}), \tag{16}$$

$$K_{abc}=dL_{abc}-P_{abce}dx^e,$$

where details can be found in Refs. 6 and 9. Solutions to the Weyl–Lanczos equations then correspond to integral manifolds on which all forms in (16) vanish when restricted to submanifolds with $f^{(W)}_{abcd}=0, f^{(DG)}_{ab}=0$. Tangent spaces to such integral manifolds are usually spanned by four **Vessiot vector fields** which we will denote by $V^{(1)},\ldots,V^{(4)}$. A Vessiot vector field V is defined as an annihilator of all one-forms in a Pfaffian system. This means that $V\in\mathcal{D}=\mathcal{P}^{\perp}$ and we can write in local components

$$V=V^e\frac{\partial}{\partial x^e}+V^{abc}\frac{\partial}{\partial L_{abc}}+V^{abcd}\frac{\partial}{\partial P_{abcd}}+V^{abcde}\frac{\partial}{\partial S_{abcde}}.$$

If we consider the Lanczos wave equation, we need to incorporate a further 160 second-order jet variables S_{abcde} so that our jet bundle is given by $\mathcal{J}^2(\mathbb{R}^4,\mathbb{R}^{16})$ with local coordinates $(x^a,L_{bcd},P_{efgh},S_{ijklm})$ and formal dimension $N=4+16+64+160=244$. The S_{abcde} become the partial derivatives $S_{abcde}=\partial^2 L_{abc}/\partial x^d\partial x^e$ when projected onto the space–time manifold M. The Pfaffian system for the Lanczos wave equation is given by

$$d\mathcal{W}_{abc}=d(f^{(W)}_{abcs}{}^{;s}),$$

$$K_{abc}=dL_{abc}-P_{abce}dx^e, \tag{17}$$

$$K_{abcd}=dP_{abcd}-S_{abcde}dx^e,$$

and the details can be found in Refs. 6 and 9. Because of the way the Lanczos wave equation was derived from the Weyl–Lanczos equations, any solutions to the Weyl–Lanczos equations are automatically solutions to the Lanczos wave equation.[7,8]

One can now examine whether such an EDS Σ or a Pfaffian system $\mathcal{P}$ possesses symmetries. The infinitesimal generators of the symmetries of an exterior differential system (EDS) Σ or of a Pfaffian system $\mathcal{P}$ are called *isovectors*. Isovectors X for either of the above systems have to make the Lie derivatives with respect to X of all one-forms involved in the Pfaffian system be linear combinations of the one-forms of the corresponding Pfaffian system itself. They are defined as follows:

Definition 1: Isovectors. X is an isovector of the EDS Σ means that the set of all Lie derivatives of the differential forms in Σ with respect to the vector field X are also differential forms in Σ: $\pounds_X\Sigma\subset\Sigma$. Dually, X is an isovector of the vector field system $\mathcal{V}$ means that $\pounds_X\mathcal{V}\subset\mathcal{V}$.

In order to check whether a given vector field X is an isovector, it is useful to apply the H. Cartan formula

$$\pounds_X\alpha=X\rfloor d\alpha+d(X\rfloor\alpha), \tag{18}$$

where $\rfloor$ denotes the inner product operator and α is any differential form in the EDS Σ. If we specialize Σ to be a Pfaffian system $\mathcal{P}$, then a **subset of** the set of isovectors is given by the set of **Cauchy characteristic vector fields** X which are given by Ref. 2.

Definition 2: X is a Cauchy characteristic vector field of a vector field system $\mathcal{D}$, where we normally have $\mathcal{D}=\mathcal{P}^{\perp}$ for a given Pfaffian system $\mathcal{P}$, means that

$$X\rfloor\alpha=0\,,\quad X\rfloor d\alpha=0\ (mod\ \mathcal{P}),$$

for all one-forms α in $\mathcal{P}$, where $\rfloor$ denotes the inner product operator.

We can also write our equations as systems of partial differential equations (PDEs) directly and find **symmetry generators** for these systems, where details on this approach can be found in Refs. 3, 17, and 22. A generator $Y^{(P)}$ of a **point symmetry** for the Weyl–Lanczos equations is necessarily of the form

$$Y^{(P)}=Y^{f}(x^{e},L_{a'b'c'})\frac{\partial}{\partial x^{f}}+Y_{abc}(x^{e},L_{a'b'c'})\frac{\partial}{\partial L_{abc}}+Y_{abcd}\frac{\partial}{\partial P_{abcd}} \tag{19}$$

with

$$Y_{abcd}=\frac{\partial Y_{abc}}{\partial x^{d}}+P_{a'b'c'd}\frac{\partial Y_{abc}}{\partial L_{a'b'c'}}-P_{abcf}\frac{\partial Y^{f}}{\partial x^{d}}-P_{a'b'c'd}P_{abcf}\frac{\partial Y^{f}}{\partial L_{a'b'c'}}. \tag{20}$$

More generally, we can look at generators $Z^{(C)}$ of **contact symmetries** which are of the form

$$Z^{(C)}=Z^{f}(x^{e},L_{a'b'c'},P_{a'b'c'd'})\frac{\partial}{\partial x^{f}}+Z_{abc}(x^{e},L_{a'b'c'},P_{a'b'c'd'})\frac{\partial}{\partial L_{abc}}+Z_{abcd}\frac{\partial}{\partial P_{abcd}}, \tag{21}$$

but now with

$$\begin{aligned}Z_{abcd}=&\frac{\partial Z_{abc}}{\partial x^{d}}+P_{a'b'c'd}\frac{\partial Z_{abc}}{\partial L_{a'b'c'}}-P_{abcf}\frac{\partial Z^{f}}{\partial x^{d}}-P_{a'b'c'd}P_{abcf}\frac{\partial Z^{f}}{\partial L_{a'b'c'}}+S_{a'b'c'dk}\frac{\partial Z_{abc}}{\partial P_{a'b'c'k}}\\&-P_{abcf}S_{a'b'c'dk}\frac{\partial Z^{f}}{\partial P_{a'b'c'k}}.\end{aligned} \tag{22}$$

The conditions for either vector fields $Y^{(P)}$ or $Z^{(C)}$ to be symmetry generators are then given by

$$\begin{aligned}Y^{(P)}f^{(W)}_{abcd}&\equiv 0\quad \mathrm{mod}\ (f^{(W)}_{abcd})\,,\\ Z^{(C)}f^{(W)}_{abcd}&\equiv 0\quad \mathrm{mod}\ (f^{(W)}_{abcd})\,,\end{aligned} \tag{23}$$

where $f^{(W)}_{abcd}$ is given by (8). If we are determining symmetry generators $Y^{(P)}$ or $Z^{(C)}$ for the Lanczos wave equation, then they have to satisfy

$$\begin{aligned}Y^{(P)}\mathcal{W}_{abc}&\equiv 0\quad \mathrm{mod}(\mathcal{W}_{abc})\,,\\ Z^{(C)}\mathcal{W}_{abc}&\equiv 0\quad \mathrm{mod}(\mathcal{W}_{abc})\,,\end{aligned} \tag{24}$$

where $\mathcal{W}_{abc}$ is given by (13), and the corresponding second-order components Y_{abcde}, Z_{abcde} have to obey conditions which can be found in Refs. 3 and 22. The equations (20) and (22) respectively for the components Y_{abcd}, Z_{abcd}, and, if we are looking at second-order equations, the corresponding equations for the Y_{abcde}, Z_{abcde} as well, ensure that we obtain a contact structure on $\mathcal{J}^{1}(\mathbb{R}^{4},\mathbb{R}^{16})$ and on $\mathcal{J}^{2}(\mathbb{R}^{4},\mathbb{R}^{16})$, respectively.

Now, we wish to consider a number of candidates for isovectors for the Weyl–Lanczos equations and then for the Lanczos wave equation. In Ref. 9 it is shown that the Weyl–Lanczos equations and the Lanczos wave equation possess no Cauchy characteristic vector fields which means that we have to look for isovectors which are not Cauchy characteristic vector fields. We do

not attempt to give a complete discussion of the symmetry groups of the Weyl–Lanczos equations and of the Lanczos wave equation here but to consider some examples. Consider the following *Ansätze*:

$$(1) \quad Y = c^e \frac{\partial}{\partial x^e},$$

$$(2) \quad Y = c_{abc} \frac{\partial}{\partial L_{abc}}, \tag{25}$$

$$(3) \quad Y = Y_{abc}(x^f) \frac{\partial}{\partial L_{abc}} + Y_{abc,d}(x^f) \frac{\partial}{\partial P_{abcd}},$$

where c^e and c_{abc} are arbitrary constants. The reader should note that the coefficients in types 1 and 2 are only constants. This makes type 2 a special case of type 3 when the Y_{abc} are constants. The presence of a nonvanishing coefficient for $\partial/\partial P_{abcd}$ in type 3 forces both its coefficients to have the form given in (25) if Eqs. (20) or (22) are to hold, respectively.

We know that Killing vector fields (KVs) are isometries of our underlying space–time manifold and symmetry generators for Einstein's field equations.[22] KVs are good candidates for symmetry generators because for any KV ξ we always have $\pounds_\xi \nabla = \nabla \pounds_\xi$, where we used ∇ here to indicate covariant differentiation. If we look at the Weyl–Lanczos equations (7) and the differential gauge condition (6), we see that they consist of terms all involving covariant derivatives. For KVs we know that $\pounds_\xi C_{abcd} = 0$. It is obvious that particular KVs present examples of symmetry generators of type 1 for the Weyl–Lanczos equations as well as for the Lanczos wave equation. It is well known that a KV ξ is always a symmetry generator when it is based on *ignorable coordinates*. Such ξ generate isovectors of type 1 for the Weyl–Lanczos equations and for the Lanczos wave equation.

III. EXAMPLES OF SOLUTIONS AND ISOVECTORS FOR THE WEYL–LANCZOS EQUATIONS

First, we look at those solutions, where we *impose* $\pounds_\xi L_{abc} = 0$ for some or for all KVs of a given space–time. Then, we discuss some isovectors of type 3 for Kasner, Schwarzschild and Gödel space–times and it will be shown that no isovectors of type 2 exist for these space–times.

A. Kasner space–time

A line element for Kasner space–time can be given locally as

$$ds^2 = dt^2 - t^{2p_1} dx^2 - t^{2p_2} dy^2 - t^{2p_3} dz^2 \tag{26}$$

with $p_1 + p_2 + p_3 = 1$ and $p_1^2 + p_2^2 + p_3^2 = 1$. We look at those solutions $L_{abc}(t)$ which fulfill the conditions $\pounds_\xi L_{abc} := 0$ for **all** 3 spatial KVs $(\partial/\partial x, \partial/\partial y, \partial/\partial z)$ which the Kasner space–time admits. The only nonvanishing independent components of the Weyl tensor are C_{txtx}, C_{tyty}. Using $L_{txx} = t^{2p_1}(t^{-2p_2} L_{tyy} + t^{-2p_3} L_{tzz})$ resulting from solving (4) for the component L_{txx}, a solution for the components L_{abc} is as given in Ref. 7,

$$\begin{aligned} L_{txx} &= \tfrac{1}{3}(p_1 - \tfrac{1}{3}) t^{2p_1 - 1}, \\ L_{tyy} &= \tfrac{1}{3}(p_2 - \tfrac{1}{3}) t^{2p_2 - 1}, \\ L_{tzz} &= \tfrac{1}{3}(p_3 - \tfrac{1}{3}) t^{2p_3 - 1}, \end{aligned} \tag{27}$$

while all other components are identically zero. This solution (27) corresponds to a particular integral manifold of which the tangent spaces are spanned by the four Vessiot vector fields

$$V^{(1)}=\frac{\partial}{\partial t}+P_{tyyt}\frac{\partial}{\partial L_{tyy}}+P_{tzzt}\frac{\partial}{\partial L_{tzz}}+V^{(1)}_{tyyt}\frac{\partial}{\partial P_{tyyt}}+V^{(1)}_{tzzt}\frac{\partial}{\partial P_{tzzt}},$$

$$V^{(2)}=\frac{\partial}{\partial x},$$

$$V^{(3)}=\frac{\partial}{\partial y},\tag{28}$$

$$V^{(4)}=\frac{\partial}{\partial z}.$$

The $V^{(1)}_{tyyt}$ and $V^{(1)}_{tzzt}$ are given by

$$V^{(1)}_{tyyt}=t^{-1}(p_2+p_3)P_{tyyt}-t^{2p_2-2p_3-1}(p_1-p_3)P_{tzzt}-\frac{\partial f^{(W)}_{tyty}}{\partial t},$$

$$V^{(1)}_{tzzt}=t^{2p_3-2p_2-1}(p_2-p_1)P_{tyyt}+t^{-1}(p_2+p_3)P_{tzzt}+t^{2(p_3-p_1)}\cdot\left(\frac{\partial f^{(W)}_{txtx}}{\partial t}+\frac{\partial f^{(W)}_{tyty}}{\partial t}\right),\tag{29}$$

where the $f^{(W)}_{abcd}$ are given by (8). Solution (27) is not the most general solution as $V^{(1)},\ldots,V^{(4)}$ do not span the most general integral elements but correspond to a particular solution of the general solution. If a system is not in involution, singular solutions can still exist. A solution is a **singular solution** to the original system if for its characters $s_i(\mathbf{x})$ we have

$$s_i(\mathbf{x})<s_i \text{ at any point } \mathbf{x}\tag{30}$$

of the space–time manifold so that they do not adopt their maximal values. The maximal values for the $s_i(\mathbf{x})$ were computed in Refs. 6 and 9 which are given by $(s_0,s_1,s_2,s_3,s_4)=(32,16,16,16,0)$, but when restricted to the submanifold $f^{(W)}_{abcd}=0, f^{(DG)}_{ab}=0$ we get $s_0=16$ while the other characters remain unchanged $s_1=s_2=s_3=16, s_4=0$. We can find a modified Pfaffian system for which the solution (27) turns into the general solution when we look at the integral manifold characterized by

$$df^{(W)}_{abcd}(V^{(i)})=0,$$

$$df^{(DG)}_{ab}(V^{(i)})=0,$$

$$K_{abc}(V^{(i)})=0,$$

$$dP_{abcx}(V^{(i)})=0,\tag{31}$$

$$dP_{abcy}(V^{(i)})=0,$$

$$dP_{abcz}(V^{(i)})=0,$$

where $i=1,2,3,4$. For this Pfaffian system, the $V^{(1)},\ldots,V^{(4)}$ of (28) span a general integral element. The solution (27) now corresponds to the submanifold of (31) on which $f^{(W)}_{abcd}=0$, $f^{(DG)}_{ab}=0$. For our modified Pfaffian system leading to (31) the **only** nonvanishing Cartan character is s_0 which is simply the number of remaining independent one-forms. This is because

$$dK_{abc}(V^{(i)},V^{(j)})=0$$

vanishes identically for any of the above $V^{(i)},V^{(j)}$ in (28). Therefore, the modified system corresponding to (31) consists of a *complete system* to which the Frobenius theorem applies. However, the original system given only by $df^{(W)}_{abcd},df^{(DG)}_{ab},K_{abc}$ does **not** form a complete system.

We can also obtain this result using Janet–Riquier theory. Details of this theory, which involves the *symbol* $\mathcal{M}_q$ of a given system of PDEs of order q denoted by $\mathcal{R}_q$, can be found in Refs. 6, 12, 20, and 21. There, we obtain that the quantities $\alpha^{(k)}_q$ correspond to the Cartan characters s_k, $k=1,2,3,4$, in this case and these are also identically zero for a modified system given by

$$\begin{aligned} f^{(W)}_{abcd}&=0 \quad (1)-(10),\\ f^{(DG)}_{ab}&=0 \quad (11)-(16),\\ P_{abcx}&=0 \quad (17)-(32),\\ P_{abcy}&=0 \quad (33)-(48),\\ P_{abcz}&=0 \quad (49)-(64). \end{aligned} \tag{32}$$

It is easy to show that this modified system (32) consists of a complete system with $\alpha^{(1)}_1=\alpha^{(2)}_1=\alpha^{(3)}_1=\alpha^{(4)}_1=0$.

Lastly, we wish to determine some isovectors for Kasner space–time. A trivial calculation shows that no isovectors of type 2 exist. Apart from the 3 isovectors $\partial/\partial x,\partial/\partial y,\partial/\partial z$ of type 1, we look for isovectors of type 3 of the form

$$Y=Y_{abc}(x^e)\frac{\partial}{\partial L_{abc}}+Y_{abc,d}(x^e)\frac{\partial}{\partial P_{abcd}}. \tag{33}$$

Using algebraic computing as described in detail in Ref. 9, we see that the Weyl–Lanczos equations together with the differential gauge condition (6) can be divided into eight groups of two equations each, where each group only involves two distinct components of the L_{abc}. This leads to the groups:

1: L_{tyy} and L_{tzz} in equations $f^{(W)}_{txtx},f^{(W)}_{tyty}$;

2: L_{txy} and L_{tyx} in equations $f^{(W)}_{txty},f^{(DG)}_{xy}$;

3: L_{xyx} and L_{yzz} in equations $f^{(W)}_{txxy},f^{(DG)}_{ty}$;

4: L_{xyy} and L_{xzz} in equations $f^{(W)}_{tyxy},f^{(DG)}_{tx}$;

5: L_{txz} and L_{tzx} in equations $f^{(W)}_{txtz},f^{(DG)}_{xz}$;

6: L_{tyz} and L_{tzy} in equations $f^{(W)}_{tytz},f^{(DG)}_{yz}$;

7: L_{xzx} and L_{yzy} in equations $f^{(W)}_{txxz},f^{(DG)}_{tz}$;

8: L_{xyz} and L_{xzy} in equations $f^{(W)}_{txyz},f^{(W)}_{tyxz}$.

Solving the determining equations for such isovectors for each group separately leads to 16 distinct isovectors already given in Ref. 9. Here, we are only interested in group 1 for which we obtain the isovector

$$\begin{aligned} Y=t^{(\alpha-2p_3)}\frac{\partial}{\partial L_{tyy}}+\frac{(p_3+2-p_2-\alpha)}{p_2-1}t^{(\alpha-2p_2)}\frac{\partial}{\partial L_{tzz}}+(\alpha-2p_3)t^{(\alpha-2p_3-1)}\frac{\partial}{\partial P_{tyyt}}\\ +(\alpha-2p_2)\frac{(p_3+2-p_2-\alpha)}{p_2-1}t^{(\alpha-2p_2-1)}\frac{\partial}{\partial P_{tzzt}}, \end{aligned} \tag{34}$$

where α adopts either of the values

$$\alpha=(2p_2+3p_3)\pm(3p_2^2+4p_3^2+9p_2p_3-3p_2-5p_3+1)^{1/2}. \tag{35}$$

The α in (35) are solutions of the quadratic equation

$$\alpha^2-2(2p_2+3p_3)\alpha+C=0, \tag{36}$$

where

$$C=p_2^2+3(p_2p_3+p_2)+5(p_3^2+p_3)-1. \tag{37}$$

They are real only for particular choices of p_1,p_2,p_3. This isovector generates an exchange amongst the components L_{txx},L_{tyy},L_{tzz} and their derivatives for solutions of the Weyl–Lanczos equations of the form $L_{txx}(t),L_{tyy}(t),L_{tzz}(t)$.

B. Schwarzschild space–time

Next, we look at Schwarzschild space–time for which the line element in curvature coordinates is

$$ds^2=\left(1-\frac{2m}{r}\right)dt^2-\left(1-\frac{2m}{r}\right)^{-1}dr^2-r^2d\theta^2-r^2\sin^2(\theta)d\phi^2. \tag{38}$$

Schwarzschild space–time admits four well known Killing vector fields;[24] two of them are based on ignorable coordinates. When we impose the cyclic, trace-free and differential gauge conditions (3), (4) and (6) as well as $\pounds_\xi L_{abc}:=0$ for all four KVs ξ, we obtain the well known solution given in Ref. 24. It is given by

$$\begin{aligned} L_{r\theta\theta}&=-\frac{rm}{3(r-2m)},\\ L_{r\phi\phi}&=-\frac{rm}{3(r-2m)}\sin^2(\theta), \end{aligned} \tag{39}$$

where all other components can be chosen to be identically zero. The four Vessiot vector fields spanning the integral elements $(E^4)_{\mathbf{x}}$ of the solution manifold corresponding to (38) can be given as

$$\begin{aligned} V^{(1)}&=\frac{\partial}{\partial t},\\ V^{(2)}&=\frac{\partial}{\partial r}+(P_{abcr}+P_{abc\theta})\frac{\partial}{\partial L_{abc}}+V^{(r)}_{abcr}\frac{\partial}{\partial P_{abcr}}+V^{(r)}_{abc\theta}\frac{\partial}{\partial P_{abc\theta}},\\ V^{(3)}&=\frac{\partial}{\partial \theta}+(P_{abcr}+P_{abc\theta})\frac{\partial}{\partial L_{abc}}+V^{(\theta)}_{abcr}\frac{\partial}{\partial P_{abcr}}+V^{(\theta)}_{abc\theta}\frac{\partial}{\partial P_{abc\theta}},\\ V^{(4)}&=\frac{\partial}{\partial \phi}, \end{aligned} \tag{40}$$

where $V^{(r)}_{abcr},V^{(r)}_{abc\theta},V^{(\theta)}_{abcr},V^{(\theta)}_{abc\theta}$ are given in the Appendix. The above solution corresponds to a submanifold of the integral manifold characterized by

$$\begin{aligned} df^{(W)}_{abcd}(V^{(i)}) &= 0, \\ df^{(DG)}_{ab}(V^{(i)}) &= 0, \\ K_{abc}(V^{(i)}) &= 0, \\ d(\pounds_{\xi} L_{abc})(V^{(i)}) &= 0, \end{aligned} \tag{41}$$

where $i=1,2,3,4$ and on which $f^{(W)}_{abcd}=f^{(DG)}_{ab}=\pounds_{\xi}L_{abc}=0$. This modified system is complete and therefore trivially in involution with only $s_0=s_0'$ nonvanishing. Using Janet–Riquier theory we could confirm this result, where we obtained that $\alpha_1^{(1)}=\alpha_1^{(2)}=\alpha_1^{(3)}=\alpha_1^{(4)}=0$ holds again.

Now, we wish to determine some isovectors for Schwarzschild space–time. We found that again no isovectors of type 2 exist and we look at an *Ansatz* of type 3 which is given by

$$Y=Y_{abc}(r,\theta)\frac{\partial}{\partial L_{abc}}+Y_{abc,r}\frac{\partial}{\partial P_{abcr}}+Y_{abc,\theta}\frac{\partial}{\partial P_{abc\theta}}. \tag{42}$$

Using algebraic computing based on REDUCE[9] we see that the ten Weyl–Lanczos equations and the six differential gauge conditions form four groups each only involving four different components of all the 16 distinct Lanczos components L_{abc}. These groups are:

[1] $L_{r\theta r},L_{r\theta\theta},L_{r\phi\phi},L_{\theta\phi\phi}$ in equations $f^{(W)}_{trtr},f^{(W)}_{trt\theta},f^{(W)}_{t\theta t\theta},f^{(DG)}_{r\theta}$;

[2] $L_{tr\theta},L_{t\theta r},L_{t\theta\theta},L_{t\phi\phi}$ in equations $f^{(W)}_{t\theta r\theta},f^{(W)}_{trr\theta},f^{(DG)}_{tr},f^{(DG)}_{t\theta}$;

[3] $L_{r\theta\phi},L_{r\phi\theta},L_{r\phi r},L_{\theta\phi\theta}$ in equations $f^{(W)}_{trt\phi},f^{(W)}_{t\theta t\phi},f^{(DG)}_{r\phi},f^{(DG)}_{\theta\phi}$;

[4] $L_{tr\phi},L_{t\phi r},L_{t\theta\phi},L_{t\phi\theta}$ in equations $f^{(W)}_{trr\phi},f^{(W)}_{tr\theta\phi},f^{(W)}_{t\theta r\phi},f^{(DG)}_{t\phi}$.

We give 4 examples of isovectors for the Weyl–Lanczos equations for Schwarzschild space–time corresponding to the four groups [1] to [4] above. Note that unfamiliar factors such as $e^{r^2/2}$ may occur because $Y^{(1)}$ to $Y^{(4)}$ are examples of *symmetry generators* for the *Weyl–Lanczos equations* for Schwarzschild space–time. For group [1], we obtain an isovector

$$Y^{(1)}=\frac{1}{r\sin^2(\theta)}\frac{\partial}{\partial L_{r\theta\theta}}-\frac{1}{r}\frac{\partial}{\partial L_{r\phi\phi}}-\frac{1}{r^2\sin^2(\theta)}\frac{\partial}{\partial P_{r\theta\theta r}}-\frac{2}{r}\frac{\cos(\theta)}{\sin^3(\theta)}\frac{\partial}{\partial P_{r\theta\theta\theta}}+\frac{1}{r^2}\frac{\partial}{\partial P_{r\phi\phi r}}. \tag{43}$$

For group [2], an isovector has the form

$$Y^{(2)}=\frac{(2m-r)}{\sin^2(\theta)}\frac{\partial}{\partial L_{t\theta\theta}}-(2m-r)\frac{\partial}{\partial L_{t\phi\phi}}-\frac{1}{\sin^2(\theta)}\frac{\partial}{\partial P_{t\theta\theta r}}+2(2m-r)\frac{\cos(\theta)}{\sin^3(\theta)}\frac{\partial}{\partial P_{t\theta\theta\theta}}+\frac{\partial}{\partial P_{t\phi\phi r}}, \tag{44}$$

whereas an isovector for group [3] is given by

$$\begin{aligned} Y^{(3)}=&\frac{e^{r^2/2}}{\sin(\theta)}\frac{\partial}{\partial L_{r\theta\phi}}+\frac{e^{r^2/2}}{\sin(\theta)}\frac{\partial}{\partial L_{r\phi\theta}}+\frac{re^{r^2/2}}{\sin(\theta)}\frac{\partial}{\partial P_{r\theta\phi r}}-\frac{e^{r^2/2}\cos(\theta)}{\sin^2(\theta)}\frac{\partial}{\partial P_{r\theta\phi\theta}}+\frac{re^{r^2/2}}{\sin(\theta)}\frac{\partial}{\partial P_{r\phi\theta r}} \\ &-\frac{e^{r^2/2}\cos(\theta)}{\sin^2(\theta)}\frac{\partial}{\partial P_{r\phi\theta\theta}}. \end{aligned} \tag{45}$$

Lastly, an isovector for group [4] is of the form

$$Y^{(4)}=\frac{r^{3/2}(r-2m)^{1/2}}{\sin(\theta)}\frac{\partial}{\partial L_{t\theta\phi}}+\frac{r^{3/2}(r-2m)^{1/2}}{\sin(\theta)}\frac{\partial}{\partial L_{t\phi\theta}}+\frac{1}{2\sin(\theta)}[3r^{1/2}(r-2m)^{1/2}$$
$$+r^{3/2}(r-2m)^{-1/2}]\frac{\partial}{\partial P_{t\theta\phi r}}-r^{3/2}(r-2m)^{1/2}\frac{\cos(\theta)}{\sin^2(\theta)}\frac{\partial}{\partial P_{t\theta\phi\theta}}+\frac{1}{2\sin(\theta)}[3r^{1/2}(r-2m)^{1/2}$$
$$+r^{3/2}(r-2m)^{-1/2}]\frac{\partial}{\partial P_{t\phi\theta r}}-r^{3/2}(r-2m)^{1/2}\frac{\cos(\theta)}{\sin^2(\theta)}\frac{\partial}{\partial P_{t\phi\theta\theta}}. \tag{46}$$

Each of these isovectors generates exchanges amongst some of the corresponding Lanczos components L_{abc} given in [1] to [4] and their partial derivatives.

C. Gödel space–time

Next, we examine a space–time with nondiagonalizable metric tensor and a G_5 as its isometry group, namely the Gödel space–time. The line element can be given as

$$ds^2=a^2(dt^2-dx^2-dz^2+\tfrac{1}{2}e^{2x}dy^2+2e^x dt dy)\,, \tag{47}$$

where a is an arbitrary constant. Gödel space–time admits a G_5 of motions of which three KVs commute as they are based on ignorable coordinates along t, y and z.[11] We look for a solution which only depends on x and we use an *Ansatz* based on exponentials of x. Such a solution exists and is given by

$$L_{txy}=\frac{a^2}{18}e^x\,,$$
$$L_{tyx}=-\frac{a^2}{18}e^x\,, \tag{48}$$
$$L_{xyy}=-\frac{a^2}{6}e^{2x}\,,$$

while all other independent components vanish identically. This solution coincides with the solution in Ref. 15, where a different set of local coordinates was used. We can look at the modified system which is again of the form (41). This modified system is again a complete system, a result which is confirmed using Janet–Riquier theory here as well. The integral manifold corresponding to (48) possesses tangent spaces which are spanned by the four Vessiot vector fields

$$V^{(1)}=\frac{\partial}{\partial t},$$
$$V^{(2)}=\frac{\partial}{\partial x}+P_{txyx}\frac{\partial}{\partial L_{txy}}+P_{tyxx}\frac{\partial}{\partial L_{tyx}}+P_{xyyx}\frac{\partial}{\partial L_{xyy}}+V^{(2)}_{txyx}\frac{\partial}{\partial P_{txyx}}+V^{(2)}_{tyxx}\frac{\partial}{\partial P_{tyxx}}+V^{(2)}_{xyyx}\frac{\partial}{\partial P_{xyyx}}, \tag{49}$$
$$V^{(3)}=\frac{\partial}{\partial y},$$
$$V^{(4)}=\frac{\partial}{\partial z},$$

where the components $V^{(2)}_{txyx}, V^{(2)}_{tyxx}, V^{(2)}_{xyyx}$ are given by

$$V^{(2)}_{txyx}=e^{-x}P_{xyyx}+P_{txyx}-e^{-x}L_{xyy}+\tfrac{1}{6}a^2e^{x},$$

$$V^{(2)}_{tyxx}=-P_{txyx}, \tag{50}$$

$$V^{(2)}_{xyyx}=e^{x}L_{tyx}-\tfrac{7}{2}e^{x}L_{txy}-4L_{xyy}+\tfrac{5}{2}e^{x}P_{txyx}-2e^{x}P_{tyxx}+3P_{xyyx}-\tfrac{1}{3}a^2e^{2x}.$$

Now, we wish to determine a number of isovectors for Gödel space–time and look at an *Ansatz* of type 3 as no isovectors of type 2 do exist here either. Such an *Ansatz* can be given by

$$Y=e^{\alpha x}c_{abc}\frac{\partial}{\partial L_{abc}}+\alpha e^{\alpha x}c_{abc}\frac{\partial}{\partial P_{abcx}} \tag{51}$$

for some constants α and c_{abc}. We see that the ten Weyl–Lanczos equations and the six differential gauge conditions can be split into four groups each containing only four distinct components L_{abc} this time given by

1 $L_{txy},L_{tyx},L_{xyy},L_{xzz}$ in equations $f^{(W)}_{txtx},f^{(W)}_{tyty},f^{(W)}_{txxy},f^{(DG)}_{ty}$;

2 $L_{tyy},L_{tzz},L_{xyx},L_{yzz}$ in equations $f^{(W)}_{txty},f^{(W)}_{tyxy},f^{(DG)}_{tx},f^{(DG)}_{xy}$;

3 $L_{tyz},L_{tzy},L_{xzx},L_{yzy}$ in equations $f^{(W)}_{txtz},f^{(W)}_{txyz},f^{(W)}_{tyxz},f^{(DG)}_{xz}$;

4 $L_{txz},L_{tzx},L_{xyz},L_{xzy}$ in equations $f^{(W)}_{tytz},f^{(W)}_{txxz},f^{(DG)}_{tz},f^{(DG)}_{yz}$.

Here, we are again only interested in finding an example of the above type for group 1. After some calculations we find the isovector

$$\begin{aligned}Y=&e^{\alpha x}\frac{\partial}{\partial L_{txy}}-\frac{2(2\alpha-3)}{D(\alpha)}e^{\alpha x}\frac{\partial}{\partial L_{tyx}}+\left(\alpha+\frac{2(3\alpha+1)}{D(\alpha)}\right)e^{(\alpha+1)x}\frac{\partial}{\partial L_{xyy}}+\frac{2(2\alpha^2+1)}{D(\alpha)}e^{(\alpha-1)x}\frac{\partial}{\partial L_{xzz}}\\&+\alpha e^{\alpha x}\frac{\partial}{\partial P_{txyx}}-\frac{2(2\alpha-3)\alpha}{D(\alpha)}e^{\alpha x}\frac{\partial}{\partial P_{tyxx}}+(\alpha+1)\left(\alpha+\frac{2(3\alpha+1)}{D(\alpha)}\right)e^{(\alpha+1)x}\frac{\partial}{\partial P_{xyyx}}\\&+(\alpha-1)\frac{2(2\alpha^2+1)}{D(\alpha)}e^{(\alpha-1)x}\frac{\partial}{\partial P_{xzzx}},\end{aligned} \tag{52}$$

where $D(\alpha)=2\alpha^2-6\alpha-1$ and α has to satisfy the quartic equation

$$\alpha^4-2\alpha^3+7\alpha^2-20\alpha-\tfrac{5}{4}=0. \tag{53}$$

From numerical approximations based on REDUCE using the Newton–Raphson method we find that there are two real roots which satisfy (53). They are given by

$$\begin{aligned}\alpha_1&=-0.061\,166\,927\,586\,6,\\ \alpha_2&=2.492\,142\,058\,35,\end{aligned} \tag{54}$$

whereas the other two roots are complex and therefore not relevant for us for forming isovectors. The isovectors corresponding to α_1 and α_2 lead to an exchange amongst the solution components $L_{txy}(x),L_{tyx}(x),L_{xyy}(x),L_{xzz}(x)$.

D. pp-wave space–times with a G_5

Here, we will see that it is impossible to find a solution to the Weyl–Lanczos equations for pp-space–times for which we impose $\pounds_\xi L_{abc}:=0$ for *all* KVs ξ at the same time. Plane-wave space–times which admit a G_5 as an isometry group can be found in Ref. 23. We write the line element of a plane-wave space–time like

$$ds^2 = 2dudr + (h_{11}X^2 + 2h_{12}XY + h_{22}Y^2)du^2 - dX^2 - dY^2, \tag{55}$$

with h_{11}, h_{12}, h_{22} being functions of u only. Following Ref. 10 we can perform a coordinate transformation so that the line element turns into

$$ds^2 = 2dudv - e^{-U}(e^V \cosh(W)dx^2 - 2\sinh(W)dxdy + e^{-V}\cosh(W)dy^2), \tag{56}$$

where now U, V and W are functions of u only. For linearly polarized gravitational waves, we can always set $W := 0$.[10] The five Killing vector fields are given in Ref. 10, where three of them are given by $\xi^1 = \partial/\partial x$, $\xi^2 = \partial/\partial y$, $\xi^3 = \partial/\partial v$ based on ignorable coordinates and the other two are

$$\begin{aligned} \xi^4 &= x\frac{\partial}{\partial v} + P_-(u)\frac{\partial}{\partial x} + N(u)\frac{\partial}{\partial y}, \\ \xi^5 &= y\frac{\partial}{\partial v} + N(u)\frac{\partial}{\partial x} + P_+(u)\frac{\partial}{\partial y}, \end{aligned} \tag{57}$$

where

$$P_\pm(u) = \int e^{(U\pm V)}\cosh(W)du, \quad N(u) = \int e^U \sinh(W)du.$$

A solution, where $\pounds_\xi L_{abc} := 0$ was imposed only for ξ_1, ξ_2 and ξ_3, is given in Ref. 24. We wish to see whether we can obtain a solution, where $\pounds_\xi L_{abc} := 0$ is imposed for all 5 KVs. This leads to the expressions

$$\begin{aligned} L_{uxx} &= e^V \frac{\cosh(W)}{\sinh(W)}(L_{uyx} - 2L_{uxy}), \\ L_{uyy} &= \frac{1}{e^V \sinh(W)}\left[L_{uxy}\left(\sinh(W) - \frac{2}{\sinh(W)}\right) + L_{uyx}\left(\frac{1}{\sinh(W)} - 2\sinh(W)\right)\right], \\ L_{uvu} &= \frac{e^U}{\sinh(W)}(2L_{uxy} - L_{uyx}), \end{aligned} \tag{58}$$

where $L_{uxu}, L_{uyu}, L_{uxy}, L_{uyx}$ can be chosen arbitrarily and all other components vanish identically. The trace-free condition (4) leads to equations of the form "$0 = 0$" except for $L_u{}^s{}_s = 0$ so that all L_{abc} apart from L_{uxu} and L_{uyu} can be expressed in terms of L_{uxy} with

$$L_{uyx} = 2\left(\frac{3 - \sinh^2(W)}{3\sinh^2(W) + 1}\right)L_{uxy}. \tag{59}$$

We now have to check whether this *Ansatz* satisfies the Weyl–Lanczos equations. The only nonvanishing components remaining are $f_{uxux}, f_{uxuy}, f_{uyuy}$. But this *Ansatz* fails to satisfy all three equations $f_{uxux}, f_{uxuy}, f_{uyuy}$ *at the same time* as it is shown in detail in Ref. 9. Therefore, no solutions to the Weyl–Lanczos equations for pp-space–times, which at the same time admit vanishing Lie derivatives along **all** 5 KVs, do exist but other solutions such as the solution in Ref. 24 can be found.

IV. SOME SOLUTIONS AND ISOVECTORS FOR THE LANCZOS WAVE EQUATION

The Lanczos wave equation in four dimensions (9) consists of a system in involution as shown in Ref. 9. Some solutions for (9) are given in Ref. 7 for Kasner, Schwarzschild and Bondi

space–times. They are also solutions to the Weyl–Lanczos equations such that the one for Kasner corresponds to (27), the one for Schwarzschild to (39) and the one for Gödel to (48).

As for examples of isovectors for the Lanczos wave equation, we see that *KVs based on ignorable coordinates are isovectors for the Lanczos wave equation.* Further symmetry generators for Kasner, Schwarzschild and Gödel space–times can be constructed in the same way as for the Weyl–Lanczos equations except that we have to use the prolonged second-order version

$$Y=Y^e\frac{\partial}{\partial x^e}+Y_{abc}\frac{\partial}{\partial L_{abc}}+Y_{abcd}\frac{\partial}{\partial P_{abcd}}+Y_{abcde}\frac{\partial}{\partial S_{abcde}}, \tag{60}$$

where the general expression for the Y_{abcde} can be found in Refs. 17 and 22. The prolonged form of symmetry generators of the same form as (33) is given by

$$Y=Y_{abc}(x^e)\frac{\partial}{\partial L_{abc}}+Y_{abcd}(x^e)\frac{\partial}{\partial P_{abcd}}+Y_{abcde}(x^e)\frac{\partial}{\partial S_{abcde}} \tag{61}$$

for any space–time and its components Y_{abcd}, Y_{abcde} simply are

$$Y_{abcd}=\frac{\partial Y_{abc}}{\partial x^d}, \quad Y_{abcde}=\frac{\partial Y_{abcd}}{\partial x^e}.$$

But they are not necessarily symmetry generators for the Lanczos wave equation as we will see. Solving the equations $\pounds_Y d\mathcal{W}_{abc}=0$ for **Kasner space–time** using *Ansatz* (61), we obtain

$$\begin{aligned}Y=&t^\beta\frac{\partial}{\partial L_{tyy}}+f(\beta,p_1,p_2,p_3)t^\gamma\frac{\partial}{\partial L_{tzz}}+\beta t^{(\beta-1)}\frac{\partial}{\partial P_{tyyt}}+f(\beta,p_1,p_2,p_3)\gamma t^{(\gamma-1)}\frac{\partial}{\partial P_{tzzt}}\\&+\beta(\beta-1)t^{(\beta-2)}\frac{\partial}{\partial S_{tyytt}}+f(\beta,p_1,p_2,p_3)\gamma(\gamma-1)t^{(\gamma-2)}\frac{\partial}{\partial S_{tzztt}},\end{aligned} \tag{62}$$

where $\gamma=\beta-2p_2+2p_3$ and $f(\beta,p_1,p_2,p_3)$ is given by

$$f(\beta,p_1,p_2,p_3)=\frac{(\beta^2-4p_2\beta-p_1^2-4p_1p_2-3p_2p_3+3p_2-p_3)}{(p_3-p_1+p_1p_2-p_2p_3+p_1^2-p_3^2)}. \tag{63}$$

The quantity β has to satisfy the quartic equation

$$\begin{aligned}0=&\beta^4-8p_2\beta^3+\beta^2(16p_2^2-2p_1^2+4p_3^2+6p_2+2p_3-4p_1p_2-8p_1p_3-10p_2p_3)-4p_2\beta(4-6p_1^2\\&-4p_1p_2-4p_1p_3-6p_2p_3+2-2p_1)+1-16p_2p_3^3+16p_2p_3^2-8p_2p_3+8p_2-32p_3^4+48p_3^3\\&-32p_3^2+8p_3.\end{aligned} \tag{64}$$

We note that depending on particular choices of p_1,p_2,p_3, we can obtain for β four real, two real and two complex, or four complex solutions to (64). We are not going to specify the conditions on p_1,p_2,p_3 because this leads to rather cumbersome calculations. However, using polynomial division, we find that the two solutions for α given by (35) for isovectors for the Weyl–Lanczos equations are *not* solutions to (64) when prolonged to second order because we cannot factorize (36) out of (64) without a remainder term.

If we determine isovectors for **Gödel space–time** using an *Ansatz* of type (61) as well, we obtain isovectors of the form

$$Y = e^{\beta x}\frac{\partial}{\partial L_{txy}} + f_1(\beta)e^{\beta x}\frac{\partial}{\partial L_{tyx}} + f_2(\beta)e^{(\beta+1)x}\frac{\partial}{\partial L_{xyy}} + f_3(\beta)e^{(\beta-1)x}\frac{\partial}{\partial L_{xzz}} + \beta e^{\beta x}\frac{\partial}{\partial P_{txyx}}$$
$$+ f_1(\beta)\beta e^{\beta x}\frac{\partial}{\partial P_{tyxx}} + f_2(\beta)(\beta+1)e^{(\beta+1)x}\frac{\partial}{\partial P_{xyyx}} + f_3(\beta)(\beta-1)e^{(\beta-1)x}\frac{\partial}{\partial P_{xzzx}}$$
$$+ \beta^2 e^{\beta x}\frac{\partial}{\partial S_{txyxx}} + f_1(\beta)\beta^2 e^{\beta x}\frac{\partial}{\partial S_{tyxxx}} + f_2(\beta)(\beta+1)^2 e^{(\beta+1)x}\frac{\partial}{\partial S_{xyyxx}}$$
$$+ f_3(\beta)(\beta-1)^2 e^{(\beta-1)x}\frac{\partial}{\partial S_{xzzxx}}, \tag{65}$$

and, where $f_1(\beta), f_2(\beta), f_3(\beta)$ are given by

$$f_1(\beta) = 8\,\frac{(\beta^4 + 2\beta^3 + \frac{5}{2}\beta^2 + \frac{3}{2}\beta - 7)}{D(\beta)},$$
$$f_2(\beta) = \frac{(4\beta^4 - 8\beta^3 + 32\beta^2 + 8\beta + 69)}{D(\beta)}, \tag{66}$$
$$f_3(\beta) = \frac{(4\beta^6 + 4\beta^5 - 2\beta^4 - 16\beta^3 + 29\beta^2 + 5\beta + \frac{267}{2})}{D(\beta)},$$

where $D(\beta)$ is given by

$$D(\beta) = 4\beta^4 + 16\beta^3 - 28\beta^2 + 12\beta - 109. \tag{67}$$

Because β has to be such that $\pounds_Y d\mathcal{W}_{abc} = 0$, β has to satisfy the equation

$$\beta^9 - \tfrac{3}{2}\beta^8 - 2\beta^6 + \tfrac{31}{2}\beta^5 - \tfrac{107}{4}\beta^4 + 33\beta^3 - 53\beta^2 + \tfrac{573}{16}\beta - \tfrac{171}{32} = 0\,. \tag{68}$$

Using numerical computing based on REDUCE applying the Newton–Raphson method to this equation, we find that (68) possesses three distinct real roots which are given by

$$\beta_1 = 0.204\,256\,218\,397,$$
$$\beta_2 = 0.782\,257\,036\,153, \tag{69}$$
$$\beta_3 = 1.5,$$

of which $\beta_3 = 1.5$ is an exact result and from which we can form three distinct isovectors. Again, we see that these isovectors for $\beta_1, \beta_2, \beta_3$ are not just prolonged versions of the isovectors for the Weyl–Lanczos equations.

An *Ansatz* of type (61) could be used for Schwarzschild space–time as well but this is a rather cumbersome calculation and we will not carry it out explicitly. It remains future work to examine the symmetry groups of both the Weyl–Lanczos equations and of the Lanczos wave equation more systematically.

V. CONCLUSIONS

For Kasner, Schwarzschild and Gödel space–times there exist solutions of the Weyl–Lanczos equations with Lie symmetries along all Killing directions. For pp-space–times no such solutions exist, which shows that not all KVs are symmetry generators for the Weyl–Lanczos equations but only those which are based on *ignorable coordinates*. Some isovectors for the Weyl–Lanczos

equations which indicate an exchange amongst some of the components L_{abc} were given for Kasner, Schwarzschild and Gödel space–times.

All solutions for the Weyl–Lanczos equations in four dimensions are automatically solutions for the Lanczos wave equation, and KVs based on ignorable coordinates are also isovectors for the Lanczos wave equation. We found that isovectors for the Weyl–Lanczos equations are **not** automatically isovectors for the Lanczos wave equation when prolonged to second order. We gave some examples for Kasner and Gödel space–times. A more thorough examination of the respective symmetry groups of the Weyl–Lanczos equations and of the Lanczos wave equation remains future work though.

ACKNOWLEDGMENTS

The authors wish to thank Professor T. Wolf and Professor C. D. Collinson for valuable discussions. A.G. would like to thank the Dr. Robert Thyll-Dürr Foundation for further support and the Région Centre for a grant at the University of Tours, France.

APPENDIX: VESSIOT VECTOR FIELDS

Here, we give the components $V^{(e)}_{abcr}, V^{(e)}_{abc\theta}$ of the Vessiot vector fields $V^{(2)}, V^{(3)}$ for Schwarzschild space–time for a solution to the Weyl–Lanczos equations, where $e = r, \theta$:

$$
\begin{aligned}
V^{(e)}_{t\theta\theta r} &= -P_{t\theta\theta e}\frac{m}{r(2m-r)} - P_{t\phi\phi e}\frac{m-r}{\sin^2\theta r(2m-r)} - r^2\frac{\partial f^{(DG)}_{tr}}{\partial e} - \left(\frac{\partial f^{(W)}_{t\theta r\theta}}{\partial e}\right)\frac{1}{2m-r},\\
V^{(e)}_{t\theta\theta\theta} &= P_{t\phi\phi e}\frac{\cot(\theta)}{\sin^2(\theta)} - P_{t\theta\theta e}\cot(\theta) + \frac{\partial f^{(DG)}_{t\theta}}{\partial e},\\
V^{(e)}_{t\phi\phi r} &= P_{t\theta\theta e}\frac{(r-m)\sin^2(\theta)}{r(2m-r)} - P_{t\phi\phi e}\frac{m}{r(2m-r)} + \left(\frac{\partial f^{(W)}_{t\theta r\theta}}{\partial e}\right)\frac{\sin^2(\theta)}{2m-r},\\
V^{(e)}_{t\phi\phi\theta} &= P_{t\theta\theta e}\cos(\theta)\sin(\theta) + P_{t\phi\phi e}\cot(\theta) + \left(\frac{\partial f^{(W)}_{trr\theta}}{\partial e}\right) r\sin^2(\theta),\\
V^{(e)}_{t\theta\phi r} &= -P_{t\theta\phi e}\frac{2m-3}{r(2m-r)} - P_{t\phi\theta e}\frac{3m-r}{r(2m-r)} - \frac{\partial f^{(W)}_{t\theta r\phi}}{\partial e},\\
V^{(e)}_{t\theta\phi\theta} &= -P_{t\phi\theta e}\cot(\theta) - \left(\frac{\partial f^{(W)}_{trr\phi}}{\partial e}\right) r(2m-r),\\
V^{(e)}_{t\phi\theta r} &= P_{t\phi\theta e}\frac{3m-2r}{r(2m-r)} + P_{t\theta\phi e}\frac{3r-8m+3}{r(2m-r)} + \frac{\partial f^{(W)}_{tr\theta\phi}}{\partial e} - \frac{\partial f^{(W)}_{t\theta r\phi}}{\partial e},\\
V^{(e)}_{t\phi\theta\theta} &= P_{t\theta\phi e}\cot(\theta) - r^2\frac{\partial f^{(DG)}_{t\phi}}{\partial e},\\
V^{(e)}_{r\theta\theta r} &= P_{r\theta\theta e}\frac{(10m^2-19mr+4r^2)}{r(2m-r)^2} + P_{r\phi\phi e}\frac{(6m^2-5mr+r^2)}{r(2m-r)^2\sin^2(\theta)} + \frac{r^3}{2m-r}\left(\frac{\partial f^{(W)}_{trtr}}{\partial e}\right)\\
&\quad - \frac{r^2}{(2m-r)^2}\left(\frac{\partial f^{(W)}_{t\theta t\theta}}{\partial e}\right),\\
V^{(e)}_{r\theta\theta\theta} &= P_{r\theta\theta e}\cot(\theta) + P_{r\phi\phi e}\frac{\cot(\theta)}{\sin^2(\theta)} + \frac{\partial f^{(DG)}_{r\theta}}{\partial e},
\end{aligned}
\tag{A1}
$$

$$V^{(e)}_{r\phi\phi r}=P_{r\theta\theta e}\frac{(6m^2-5mr+r^2)}{r(2m-r)^2}\sin^2(\theta)+P_{r\phi\phi e}\frac{(10m^2-9mr+2r^2)}{r(2m-r)^2}+\left(\frac{\partial f^{(W)}_{t\theta t\theta}}{\partial e}\right)\frac{(r)^2\sin^2(\theta)}{(2m-r)^2},$$

$$V^{(e)}_{r\phi\phi\theta}=P_{r\theta\theta e}\cos(\theta)\sin(\theta)+P_{r\phi\phi e}\cot(\theta)+\left(\frac{\partial f^{(W)}_{trt\theta}}{\partial e}\right)\frac{r^3\sin^2(\theta)}{2m-r},$$

$$V^{(e)}_{r\theta\phi r}=P_{r\theta\phi e}\frac{m}{r(2m-r)}+P_{r\phi\theta e}\frac{r-m}{r(r-2m)}-\left(\frac{\partial f^{(W)}_{t\theta t\phi}}{\partial e}\right)\frac{r^2}{(r-2m)^2},$$

$$V^{(e)}_{r\theta\phi\theta}=P_{r\phi\theta e}\cot(\theta)+\frac{r^3}{r-2m}\left(\frac{\partial f^{(W)}_{trt\phi}}{\partial e}\right),$$

$$V^{(e)}_{r\phi\theta r}=P_{r\theta\phi e}\frac{r-m}{r(r-2m)}-P_{r\phi\theta e}\frac{m}{r(r-2m)}+\frac{r}{(r-2m)}\frac{\partial f^{(DG)}_{\theta\phi}}{\partial e}-\left(\frac{\partial f^{(W)}_{t\theta t\phi}}{\partial e}\right)\frac{r^2}{(r-2m)^2},$$

$$V^{(e)}_{r\phi\theta\theta}=r^2\frac{\partial f^{(DG)}_{r\phi}}{\partial e}-P_{r\theta\phi e}\cot(\theta),$$

where $f^{(DG)}_{ab}=L_{abs}{}^{;s}$ as defined before.

WKB analysis of the Regge–Wheeler equation down in the frequency plane

Alec Maassen van den Brink[a)]
Physics Department, The Chinese University of Hong Kong, Hong Kong, China

(Received 7 April 2003; accepted 16 September 2003)

The Regge–Wheeler equation for black-hole gravitational waves is analyzed for large negative imaginary frequencies, leading to a calculation of the cut strength for waves outgoing to infinity. In the—limited—region of overlap, the results agree well with numerical findings [Leung *et al.*, Class. Quantum Grav. **20**, L217 (2003)]. Requiring these waves to be outgoing into the horizon as well subsequently yields an analytic formula for the highly damped Schwarzschild quasinormal modes, *including* the leading correction. Just as in the WKB quantization of, e.g., the harmonic oscillator, solutions in different regions of space have to be joined through a connection formula, valid near the boundary between them where WKB breaks down. For the oscillator, this boundary is given by the classical turning points; fascinatingly, the connection here involves an expansion around the black-hole singularity $r=0$. © *2004 American Institute of Physics.*

I. INTRODUCTION

Black-hole axial gravitational waves of angular momentum $\ell \geqslant 2$ are described (in units $c=G=2M=1$) by the Regge–Wheeler equation[1,2] (RWE)

$$[d_x^2+\omega^2-V(x)]\psi(x,\omega)=0, \tag{1}$$

$$V(r)=\left(1-\frac{1}{r}\right)\left[\frac{\ell(\ell+1)}{r^2}-\frac{3}{r^3}\right], \tag{2}$$

where $x=r+\ln(r-1)$ is the tortoise coordinate and r the circumferential radius; $V(r)$ accounts for the Schwarzschild background. The long-range nature of this potential, $V(x)-\ell(\ell+1)/x^2 \sim 2\ell(\ell+1)\ln x/x^3$ for $x\to\infty$ (Ref. 3), is well known to cause a branch cut in the (retarded) Green's function of (1) on the negative imaginary axis (NIA) in the ω plane.

For damping $\gamma \equiv i\omega \downarrow 0$, this cut causes an algebraically decaying late-time tail in the gravitational-wave signal.[4,5] For moderate γ and $2\leqslant\ell\leqslant 4$, it has recently been investigated numerically,[6] leading to a clear conjecture for the large-γ behavior. In a separate development, the strings of quasinormal modes (QNMs) parallel on both sides of the cut and close to it seem to offer clues to the quantum theory, in particular to a calculation of the Bekenstein entropy in loop quantum gravity and to the quantum of area.[7] These motivate studying also the branch cut asymptotically, which will turn out to have ample independent interest.

In each ℓ sector and in the frequency domain, the RWE is one dimensional, so the above-mentioned Green's function $\bar{G}(x,y)=\bar{G}(y,x)$ can be written as

$$\bar{G}(x,y;\omega)=\frac{f(y,\omega)g(x,\omega)}{J(\omega)}, \quad y<x. \tag{3}$$

a)Electronic mail: alec@dwavesys.com

Here, f solves (1) with the left outgoing-wave boundary condition (OWC) $f(x\to-\infty,\omega)\sim 1\cdot e^{-i\omega x}$ and thus represents waves going into the horizon, while $g(x\to\infty,\omega)\sim 1\cdot e^{i\omega x}$ corresponds to waves going to infinity; $J=gf'-fg'$ is their Wronskian. In the physical region $x\in\mathbb{R}$, these asymptotic definitions are unambiguous only for $\mathrm{Im}\,\omega\geqslant 0$, from where the functions are continued analytically. The normalizations of f,g have been fixed for definiteness, but J in the denominator renders (3) normalization independent. Since $V(x\to-\infty)\sim e^{x}$, the function $f(x,\omega)$ is single valued in ω. Thus it is intuitively clear, and readily shown,[6] that the branch cut in $\overline{G}$ can be expressed in terms of the one in g.

Focusing on the latter, we define $g_{\pm}(\omega)$ as the continuations from $\mathrm{Re}\pm\omega>0$ and $\Delta g\equiv g_{+}-g_{-}$. Since $g_{\pm}(x,-i\gamma)\sim 1\cdot e^{\gamma x}$ satisfy the *same* (linear, second-order) wave equation, $\Delta g(x,-i\gamma)\sim 0\cdot e^{\gamma x}$ is the small solution $\propto g(x,+i\gamma)$. The simple symmetry $g(-\omega^{*})=g^{*}(\omega)$ renders Δg imaginary, so we introduce the real cut strength q through[4,8]

$$\Delta g(x,-i\gamma)=iq(\gamma)g(x,+i\gamma). \tag{4}$$

Since g is defined by the OWC at $x\to\infty$, (4) defines q not merely x independent, but rather independent of $V(x)$ at any finite x: if, say, $V_1(x>L)=V_2(x>L)$, the corresponding q_1 and q_2 are identical. Thus, q economically characterizes Δg (and ultimately $\Delta\overline{G}$), and our task can now be specified as calculating the asymptotics of $q(\gamma\to\infty)$.

II. WKB SOLUTIONS

For $\mathrm{Im}\,\omega<0$, in particular on the NIA, the simple asymptotic definition of $g(\omega)$ becomes all but meaningless, since it is impossible to distinguish the decaying component $\sim e^{-\gamma x}$ (to be set to zero) from the ''pure'' outgoing wave $\sim e^{\gamma x}$, where this limiting form, however, has algebraic corrections to all orders in V. One way out is to complement the analytic continuation in frequency with one in *space*,[8–10] so that the product $i\omega x$ retains a negative real part. However, in terms of x, the very equation (1) is multiple valued, so that the analysis henceforth will proceed in the complex r plane, viz.,

$$[r^2(r-1)^2d_r^2+r(r-1)d_r-(r-1)\{\ell(\ell+1)r-3\}+\omega^2r^4]g=0. \tag{5}$$

It is possible to impose the OWC for $g_{+}(r,-i\gamma)$ $[g_{-}(r,-i\gamma)]$ directly and stably for $r\to-\infty$ and continue the solutions to the physical $r>1$ in the upper (lower) half plane.[8] That is, apart from a trivial overall phase, $g_{\pm}$ are the *same* solutions as r grows from $-\infty$, until they are prescribed to encircle the singularity $r=0$ in opposite directions. Hence, closer study of this point should shed light on their difference Δg.

At least away from the singularities $r=0,1$ and the anti-Stokes lines (*v.i.*), one expects to have asymptotic expansions $g_{\mathrm{a}}(r,\omega)$ and $g_{\mathrm{a}}(r,-\omega)$, with

$$g_{\mathrm{a}}(r,\omega)\sim[(r-1)e^{r}]^{i\omega}\left\{1+\frac{g_1(r)}{\omega}+\frac{g_2(r)}{\omega^2}+\cdots\right\}, \tag{6}$$

where the first factor is just a plane wave in the tortoise coordinate. Substitution yields

$$g_1(r)=\frac{1}{2i}\int_{\infty}^{r}\frac{ds\,s}{s-1}V(s)=i\left[\frac{\ell(\ell+1)}{2r}-\frac{3}{4r^2}\right],$$

$$g_2(r)=\frac{1}{4}V(r)-\frac{1}{8}\left[\int_{\infty}^{r}\frac{ds\,s}{s-1}V(s)\right]^2=-\frac{3N}{8r^2}+\frac{\ell(\ell+1)-6}{8r^3}+\frac{15}{32r^4}, \tag{7}$$

where

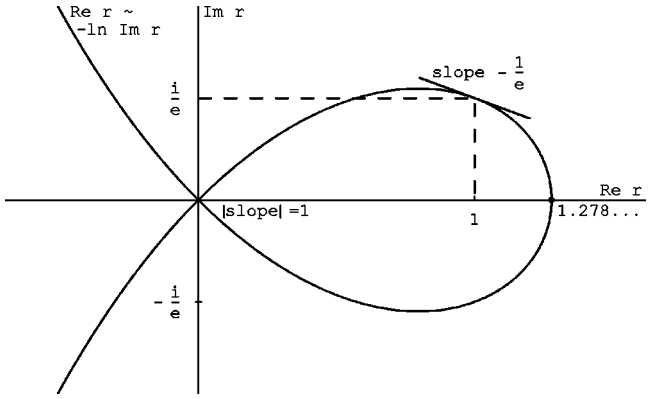

FIG. 1. Anti-Stokes lines of the RWE for negative imaginary frequencies.

$$N=8\binom{\ell+2}{4}=\frac{4}{3}\nu(\nu+1)$$

with $\nu\equiv\frac{1}{2}(\ell-1)(\ell+2)$. That is, these two orders still agree with the upshot of ω expanding the standard WKB expression, though this is no longer true for g_3, which involves V' (of course, there are higher-order corrections to WKB as well).

The anti-Stokes lines of the RWE on the NIA for this expansion are shown in Fig. 1. They are the curves where $|(r-1)e^r|=1$ (i.e., $\mathrm{Re}\,x=0$); for $\gamma\to\infty$, these are the boundaries where the solutions (6) change between exponentially growing and decaying characters.

Thus, the solution which is small for $r\to-\infty$ can be continued to the region including $x>0$, but this only yields the exponentially growing part one knew all along. From there, the solution *cannot* be continued back to $x<0$ (where its imaginary part could be identified) because of the Stokes phenomenon. For the latter continuation, we apparently have to pass through the eye of the storm—the black-hole singularity $r=0$ (Ref. 11). Near $r=0$, the expansion (6) is not valid, for higher-order terms only become small if $|r|\gg 1/\sqrt{\gamma}$. One therefore has to match (possibly different) expansions in terms of g_a in the regions $|\arg r-\pi|\leqslant\pi/4$ and $|\arg r|\leqslant\pi/4$, respectively. This is similar to the connection procedure near classical turning points in Bohr–Sommerfeld quantization. However, near the latter it is merely the asymptotic expansion which breaks down, while the original (Schrödinger) wave equation is perfectly regular. In our case, the connection has to be carried out across a singularity of the RWE.

III. CONNECTION FORMULA

Series expansion around $r=0$ is standard:[12]

$$\psi_1(r)=r^3+\frac{6-\ell(\ell+1)}{5}r^4+\mathcal{O}(r^5), \tag{8}$$

$$\psi_2(r)=r^{-1}+\frac{2\nu}{3}+\frac{N}{4}r+\frac{\ell(\ell+1)N}{12}r^2+\frac{\Omega^2-\omega^2}{4}\psi_1(r)\ln r+\mathcal{O}(r^4), \tag{9}$$

where both error terms are single valued and where we introduced the *algebraically special frequency* $\Omega=-iN/2$ (Refs. 8 and 13). However, because of the large term $\propto\omega^2$ in the RWE (5), higher-order terms in these expansions can only be omitted if $|r^2\omega|\ll 1$ (cf. the given terms of ψ_2). Thus, there is no overlap with the region of validity of g_a, where matching could be carried out. Still, the above series for $\psi_{1,2}$ will be useful for comparison, *inter alia*, yielding the exact monodromy[14] $\psi_2(re^{2\pi i})=\psi_2(r)+i(\pi/2)(\Omega^2-\omega^2)\psi_1(r)$ and $\psi_1(re^{2\pi i})=\psi_1(r)$.

A usable matching solution follows by effectively resumming the large-γ parts of higher-order terms in (8),(9). In practice, it is more convenient to set $r \equiv t/\sqrt{\gamma}$ and sort powers of γ:

$$[t^2 d_t^2 - t d_t - 3 - t^4]\psi = \frac{1}{\sqrt{\gamma}}[2t^3 d_t^2 - t^2 d_t - \{\ell(\ell+1)+3\}t]\psi + \mathcal{O}(\gamma^{-1}) \equiv R(t), \tag{10}$$

$$\psi = \psi^{(0)} + \psi^{(1)} + \cdots .$$

The lowest order follows by equating the right-hand side of (10) to zero:

$$\psi_1^{(0)}(t) = \frac{4it}{\gamma^{3/2}} J_1\left(\frac{t^2}{2i}\right), \tag{11}$$

$$\psi_2^{(0)}(t) = \frac{i\pi\sqrt{\gamma}}{4} t Y_1\left(\frac{t^2}{2i}\right). \tag{12}$$

These have not been written in terms of modified Bessel functions, since the subsequent matching is best done on the anti-Stokes lines where $t^2/2i$ is real. Subsequently, $\psi_1^{(0)}$ figures as an inhomogeneous term in the equation for $\psi_1^{(1)}$, solved by

$$\psi_1^{(1)}(t) = \frac{\pi}{4} t \int_0^t \frac{ds}{s^2}\left[Y_1\left(\frac{t^2}{2i}\right) J_1\left(\frac{s^2}{2i}\right) - J_1\left(\frac{t^2}{2i}\right) Y_1\left(\frac{s^2}{2i}\right)\right] R_1(s), \tag{13}$$

$$R_1(s) = \frac{4i}{\gamma^2}\left\{ 2[s^6 - \nu s^2] J_1\left(\frac{s^2}{2i}\right) - i s^4 J_0\left(\frac{s^2}{2i}\right)\right\}. \tag{14}$$

Note that the occurrence of Y_1 does not spoil the analyticity of $\psi_1^{(1)}$. In particular, for $t \to 0$ the above readily reproduces the t^4 term found in (8) by direct expansion. The counterpart for ψ_2 reads

$$\psi_2^{(1)}(t) = \frac{\pi}{4} t Y_1\left(\frac{t^2}{2i}\right) \int_0^t \frac{ds}{s^2} J_1\left(\frac{s^2}{2i}\right) R_2(s) + \frac{\pi}{4} t J_1\left(\frac{t^2}{2i}\right)\left[\int_0^t ds \left\{ \frac{8i\nu}{\pi s^4} - Y_1\left(\frac{s^2}{2i}\right)\frac{R_2(s)}{s^2}\right\} + \frac{8i\nu}{3\pi t^3}\right], \tag{15}$$

$$R_2(s) = \frac{i\pi}{4}\left\{ 2[s^6 - \nu s^2] Y_1\left(\frac{s^2}{2i}\right) - i s^4 Y_0\left(\frac{s^2}{2i}\right)\right\}, \tag{16}$$

where we introduced a "counterterm" in order to keep the second integral finite near $s = 0$. Again, one verifies that the leading small-t correction [$\propto t^0$ in (9)] is reproduced correctly. Using the standard branching properties of the Y_n one now finds that, up to this second order, $\psi_2(te^{2\pi i}) = \psi_2(t) + i(\pi/2)\gamma^2 \psi_1(t)$, so that the exact monodromy is approached for $|\omega| \gg |\Omega|$.

In fact, we can follow the transformation of $\psi_{1,2}^{(i)}$ under rotation in more detail by using the standard $J_n(-z) = (-)^n J_n(z)$ and $Y_n(e^{\pm i\pi} z) = (-)^n [Y_n(z) \pm 2iJ_n(z)]$, implying

$$\psi_1^{(0)}(it) = -i\psi_1^{(0)}(t), \tag{17}$$

$$\psi_1^{(1)}(it) = \psi_1^{(1)}(t), \tag{18}$$

$$\psi_2^{(0)}(it) = -i\psi_2^{(0)}(t) + \frac{\pi\gamma^2}{8}\psi_1^{(0)}(t), \tag{19}$$

$$\psi_2^{(1)}(it) = \psi_2^{(1)}(t) + i\frac{\pi\gamma^2}{8}\psi_1^{(1)}(t). \tag{20}$$

These relations streamline the asymptotic expansion. Namely, look along $\arg t=\pi/4$, where $\psi_{1,2}^{(0)}e^{-3\pi i/4}\in\mathbb{R}$ and $\psi_{1,2}^{(1)}\in\mathbb{R}$, so that their expansions will read

$$\psi_1(t)\sim\frac{4}{\sqrt{\pi\gamma^3}}\left[e^{t^2/2}\left\{1+\frac{\alpha}{\sqrt{\gamma}}\right\}+e^{-t^2/2}\left\{-i+\frac{\alpha^*}{\sqrt{\gamma}}\right\}+\mathcal{O}(t^{-2})+\mathcal{O}\left(\frac{t^3}{\sqrt{\gamma}}\right)+\mathcal{O}(\gamma^{-1})\right], \quad (21)$$

$$\psi_2(t)\sim\frac{\sqrt{\pi\gamma}}{4}\left[e^{t^2/2}\left\{-i+\frac{\beta}{\sqrt{\gamma}}\right\}+e^{-t^2/2}\left\{1+\frac{\beta^*}{\sqrt{\gamma}}\right\}+\mathcal{O}(t^{-2})+\mathcal{O}\left(\frac{t^3}{\sqrt{\gamma}}\right)+\mathcal{O}(\gamma^{-1})\right]. \quad (22)$$

The occurrence of $\mathcal{O}(t^3/\sqrt{\gamma})$ (which, however, does *not* generate additional $t^0/\sqrt{\gamma}$ terms) means that these hold for $1\ll t\ll\gamma^{1/6}$ or $\gamma^{-1/2}\ll r\ll\gamma^{-1/3}$, conveniently handled as a double asymptotic expansion in t and $\lambda\equiv\gamma/t^6$. The power-law asymptotic corrections in t follow directly from the RWE; the real nonlocal information is contained in α, β.

We can use the general rules (17)–(20) to transform (21),(22) to $\arg t=3\pi/4$ and demand consistency for the ($\propto e^{-t^2/2}$) part that dominates for $\pi/4<\arg t<3\pi/4$. This leads to $\alpha\in\mathbb{R}$ and $\mathrm{Im}\,\beta=-\alpha$. By subsequently demanding consistency also for the combination of ψ_1 and ψ_2 which is minimal in the same sector, one finds

$$\beta=-(2+i)\alpha\ . \quad (23)$$

Thus, this algebraic exercise circumvented directly expanding the integrals (15) for $\psi_2^{(1)}$.

IV. MATCHING

For $|\arg t-\pi|<3\pi/4$ one can do the analogous expansion of $g_+(t,-i\gamma)=g_a(t,-i\gamma)$ in (6). Again, one finds a Gaussian form if $t\ll\gamma^{1/6}$ (Ref. 15):

$$g_+(t,-i\gamma)\sim e^{i\pi\gamma}e^{-t^2/2}\left[1+\frac{3}{4t^2}-\frac{15}{32t^4}-\frac{t^3}{3\sqrt{\gamma}}-\frac{t}{4\sqrt{\gamma}}+\frac{5-16\ell(\ell+1)}{32t\sqrt{\gamma}}+\frac{t^6}{18\gamma}+\text{h.o.t.}\right]; \quad (24)$$

the first factor comes from encircling the horizon $r=1$. The leading corrections verify the consistency of expansions (21),(22), and (24), obtained in very different ways; all that matters for the matching is $[\cdots]=1+0\cdot t^0/\sqrt{\gamma}+\cdots$.

Comparison shows that

$$g_+e^{-i\pi\gamma}=\frac{\sqrt{\pi}}{8}[3i\gamma^{3/2}+(2-3i)\alpha\gamma+\mathcal{O}(\sqrt{\gamma})]\psi_1+\frac{2}{\sqrt{\pi}}\left(-\frac{1}{\sqrt{\gamma}}+\frac{\alpha}{\gamma}+\mathcal{O}(\gamma^{-3/2})\right)\psi_2, \quad (25)$$

which can be matched back to solutions in terms of g_a on $\arg t=\pi/4$, yielding

$$g_+(-i\gamma)=g_a(-i\gamma)+2e^{2\pi i\gamma}\left(i+\frac{\alpha}{\sqrt{\gamma}}\right)g_a(+i\gamma) \quad (26)$$

in the region (bounded by anti-Stokes lines) including $r=1$. Hence, in particular in the physical part $x<0$ of that region, one has

$$\Delta g(-i\gamma)=2i\,\mathrm{Im}\,g_+(-i\gamma)=4i\left[\cos(2\pi\gamma)+\frac{\alpha}{\sqrt{\gamma}}\sin(2\pi\gamma)\right]g(+i\gamma)\equiv iq(\gamma)g(+i\gamma). \quad (27)$$

Already, the numerically observed asymptotics[6] of $q(\gamma)$ have been confirmed. For the corrections, it remains to calculate α in closed form. Let us start with the ν-dependent term in (14), which clearly cannot be combined with the other two. Straightforward manipulations yield its contribution to $\psi_1^{(1)}$ as ($\arg t=\pi/4$)

$$\psi_1^{(1)}(t)\sim\frac{\sqrt{8\pi}}{\gamma^2}\nu\left[\cos\left(\frac{t^2}{2i}+\frac{\pi}{4}\right)\int_0^\infty\frac{dz}{\sqrt{z}}J_1(z)Y_1(z)+\cos\left(\frac{t^2}{2i}+\frac{3\pi}{4}\right)\int_0^\infty\frac{dz}{\sqrt{z}}J_1^2(z)\right]. \quad (28)$$

By considering the asymptotics of $\int_0^K(dz/\sqrt{z})J_1(z)H_1^{(1)}(z)$ (H are Hankel functions) in the upper-half K plane [again using the formula for $Y_1(e^{i\pi}z)$ above (17)], one convinces oneself that in fact $\int_0^\infty(dz/\sqrt{z})J_1(z)Y_1(z)=-\int_0^\infty(dz/\sqrt{z})J_1^2(z)$, which is also necessary for this contribution to α to be real. The latter integral is tabulated as $\int_0^\infty(dz/\sqrt{z})J_1^2(z)=\Gamma(\frac{1}{4})^4/12\pi^{5/2}$ (Ref. 16). Thus, the present contribution to α reads

$$\alpha_1=-\frac{\nu\Gamma(\frac{1}{4})^4}{24\pi^{3/2}}. \quad (29)$$

The last term of (14) analogously leads to the integrals $\int_0^\infty dz\,\sqrt{z}J_1(z)J_0(z)=-\int_0^\infty dz\,\sqrt{z}Y_1(z)J_0(z)=\Gamma(\frac{1}{4})^4/16\pi^{5/2}$, for a contribution

$$\alpha_2=\frac{\Gamma(\frac{1}{4})^4}{32\pi^{3/2}}. \quad (30)$$

However, the first term of (14), with its higher power of s, leads to diverging integrals:

$$\int_0^K dz\,z^{3/2}J_1^2(z)\sim\frac{2}{3\pi}K^{3/2}+\frac{1}{2\pi}\sqrt{K}\cos(2K)+c_3+\mathcal{O}(K^{-1/2}), \quad (31)$$

$$\int_0^K dz\,z^{3/2}J_1(z)Y_1(z)\sim\frac{1}{2\pi}\sqrt{K}\sin(2K)+d_3+\mathcal{O}(K^{-1/2}). \quad (32)$$

If $d_3=-c_3$, these lead to a real contribution

$$\alpha_3=-2\pi c_3. \quad (33)$$

Unfortunately, the general $\int_0^K dz\,z^{3/2}J_1^2(z)=(K^{9/2}/18)\,{}_2F_3(\frac{3}{2},\frac{9}{4};2,3,\frac{13}{4};-K^2)$ does not help directly, since not enough seems to be known about the asymptotics of ${}_2F_3$. Instead, one can proceed as follows: $d_3=-c_3$ can again be proven by studying $\int_0^K dz\,z^{3/2}J_1(z)H_1^{(1)}(z)$ in the upper-half plane. It is then logical to also consider $\int_0^K dz\,z^{3/2}H_1^{(1)}(z)^2$, in which one can take $K\to i\infty$. One finds

$$c_3=\frac{\sqrt{2}}{\pi^2}\int_0^\infty dw\,w^{3/2}K_1^2(w)=\frac{5\Gamma(\frac{1}{4})^4}{192\pi^{5/2}}. \quad (34)$$

The rest is straightforward: (29), (30), and (33) with (34) can be added and substituted into (27), from which one can read off our final answer

$$q(\gamma)\sim 4\cos(2\pi\gamma)+\frac{\Gamma(\frac{1}{4})^4}{12\pi^{3/2}}[1-\ell(\ell+1)]\frac{\sin(2\pi\gamma)}{\sqrt{\gamma}}+\mathcal{O}(\gamma^{-1}), \tag{35}$$

where $\Gamma(\frac{1}{4})^4/12\pi^{3/2}=2.586\ldots$. The *result* for the leading term has appeared before in Ref. 6; preliminary results from a transmission-amplitude calculation seem support the form for the corrections, in particular, the ℓ dependence.[17]

V. DISCUSSION

The above analysis, for $r,\gamma\to\infty$, is the third instance where the mathematics of the RWE near $r=0$ has been seen to influence the goings-on in our universe $r>1$. The first instance is the question of ''anomalous'' vs ''miraculous'' waves outgoing into the horizon, i.e., $r\downarrow 1$ and $2\gamma\in\mathbb{N}$ (Ref. 8, Sec. VI). The second instance is the dynamics at and around the algebraically special frequency $\gamma=N/2$, where the RWE has closed-form solutions, whose global behavior in the r plane can therefore be traced.[6,8]

Besides the axial waves described by the RWE (1), (2) there are also polar waves, described by the Zerilli equation.[18] However, the latter's ''intertwining'' or supersymmetry relation to the RWE yields its cut strength as $\tilde{q}(\gamma)=[(N/2-\gamma)/(N/2+\gamma)]q(\gamma)$ (Ref. 8). Thus, q and $\tilde{q}$ agree up to an overall sign, plus $\mathcal{O}(\gamma^{-1})$ corrections immaterial to (35).

For an outlook, the first obvious item is the numerical verification of (35), in particular of the subleading correction. A brute-force increase of numerical precision in the existing method is unlikely to suffice, especially for $\ell\geqslant 3$. More promising is to calculate $g_{\pm}(-i\gamma)$ directly on the NIA, instead of through extrapolation to this axis. In the series for $g(\omega)$ (Refs. 6 and 12), the problem for $\mathrm{Re}\,\omega\to 0$ is not convergence but rather obtaining the individual (irregular-hypergeometric) terms reliably. Working this out should be mainly a matter of time, but it remains to be seen if it would sufficiently extend the range of validity in γ.

Related to this, it is worth re-emphasizing[8] that the present method involves two conceptually separate steps: (a) the continuation in r, stabilizing the OWC at infinity in the lower-half ω plane, leading to a well-defined computational problem, and (b) the asymptotics, by which one can actually solve this problem analytically for large γ. The second step is optional,[9] and numerical integration of g_+ from $r=-\infty$ (combined with standard series solutions for f) should soon open up the third ω quadrant (i.e., behind the cut) to direct exploration, especially for at most moderate damping.

It would also be interesting if this work could be compared to the closed-form expression for $q(\gamma)$ in (31)–(33) of Ref. 4, through the coefficients $d_L^{(\nu)}$ of an expansion $g\propto\Sigma_{L=-\infty}^{\infty}d_L^{(\nu)}u_{L+\nu}$; here, $u_{L+\nu}$ are Coulomb wave functions. As usual, the $d_L^{(\nu)}$ satisfy a three-term recursion relation (given in a simplified form, which can be made purely real on the NIA, in Sec. VI F of Ref. 12); $0\leqslant\nu<1$ is to be chosen such that $d_L^{(\nu)}$ is the minimal solution to this relation for both $L\to\infty$ and $-\infty$. The adiabatic ansatz of slowly varying $d_{L+1}^{(\nu)}/d_L^{(\nu)}$ readily yields asymptotic solutions for $\gamma\to\infty$, except near $L=\pm\gamma$ and $L=0$. Following Ref. 19, one can try to develop connection formulas near these three points, which would determine ν analytically. At the ''turning points'' $L=\pm\gamma$, the three-term recursion asymptotically degenerates into a *two*-term one, and the connection proceeds exactly as in Ref. 19. Near $L=0$, however, all three terms are of the same order (in γ), and the recursion remains in the form of analytically intractable continued fractions (i.e., without simplifying to products). Thus, this route for now seems unfeasible.

At least to leading order, the method of continuation through the vicinity of $r=0$ has meanwhile independently been used to calculate the high-damping QNM frequencies.[11] On the one hand, this yields more information on the QNM *wave functions* than the continued-fraction technique.[19] On the other, this clearly establishes a relation to the present problem of the branch-cut strength $q(\gamma)$. Thus one can expect also *numerical* results for these two high-damping aspects of the RWE to bear on each other, and an extension to other black-hole models. Conversely, this work's progress on the corrections should help finding the $\mathcal{O}(|\omega|^{-1/2})$ terms for the asymptotic QNM frequencies. Meanwhile, this has indeed been possible; see the Appendix.

In particular, these developments render it urgent to study the branch cut of the RWE's Green's function also for other values of the spin s, where (2) corresponds to $s=2$. Notably, the highly damped electromagnetic ($s=1$) QNMs are predicted[11,19] to approach the NIA asymptotically so that one expects an even closer, though yet unknown, relation to the branch cut in that case.

ACKNOWLEDGMENTS

The work of the main text was performed in summer 2001 during a sabbatical as a C.N. Yang Visiting Fellow at the Chinese University of Hong Kong. The recent activity in this field has prompted me to publish my original notes. I thank V. Cardoso, A. Neitzke, and K. Young for fruitful discussions.

APPENDIX: HIGH-DAMPING QNMs

For frequencies close to the NIA, it should certainly be possible to analytically continue (26) and find those γ for which g_+ also satisfies the OWC into the horizon, i.e., $g_+(\omega)\propto f(\omega)$. These should identify the highly damped QNMs. Here, f is characterized by its monodromy around the horizon:

$$f((r-1)e^{2\pi i},\omega)=e^{2\pi\omega}f(r-1,\omega). \tag{A1}$$

Inspecting (6), it seems that $f(\omega)=g_{\mathrm{a}}(-\omega)$, but this is deceptive. While it *is* true that $f(-\omega)=g_{\mathrm{a}}(\omega)$ in the lower-half ω plane, the asymptotic nature of the large (near $r=1$) solution $g_{\mathrm{a}}(-\omega)$ means that naive rotation of $r-1$ only confirms the desired monodromy to dominant order, whereas f is required to obey it exactly.

The solution is to, in the spirit of Refs. 11 and 17, do the rotation along the anti-Stokes contour in Fig. 1, where neither solution dominates the other (skipping $r=0$ on the inside). By the normalization of f one knows the dominant component, so we take the ansatz

$$f(-i\gamma)=g_{\mathrm{a}}(i\gamma)+c(\gamma)g_{\mathrm{a}}(-i\gamma). \tag{A2}$$

Continuing this from the physical $x=0$ to $1/\sqrt{\gamma}\ll|r|\ll 1$ with $\arg r=\pi/4$, one finds

$$\begin{aligned} f(-i\gamma)&\sim e^{-i\pi\gamma}e^{t^2/2}+c(\gamma)e^{i\pi\gamma}e^{-t^2/2}\\ &\sim\frac{\sqrt{\pi\gamma^3}}{8}\left[e^{-i\pi\gamma}\left\{1+\frac{(i-2)\alpha}{\sqrt{\gamma}}\right\}+c(\gamma)e^{i\pi\gamma}\left\{i+\frac{(2+i)\alpha}{\sqrt{\gamma}}\right\}\right]\psi_1\\ &\quad+\frac{2}{\sqrt{\pi\gamma}}\left[e^{-i\pi\gamma}\left\{i-\frac{\alpha}{\sqrt{\gamma}}\right\}+c(\gamma)e^{i\pi\gamma}\left\{1+\frac{\alpha}{\sqrt{\gamma}}\right\}\right]\psi_2; \end{aligned} \tag{A3}$$

the second line followed by comparison with (21),(22). As before, (17)–(20) make quick work of continuing this to $\arg r=-\pi/4$, where it can be matched back to a combination of $g_{\mathrm{a}}(\pm i\gamma)$. One thus finds $f((r-1)e^{2\pi i},-i\gamma)=e^{-2\pi i\gamma}g_{\mathrm{a}}(r-1,i\gamma)+[2i(1-\alpha/\sqrt{\gamma})+c(\gamma)e^{2\pi i\gamma}]g_{\mathrm{a}}(r-1,-i\gamma)$. Indeed f as in (A2) obeys (A1) to dominant order for any c, while the subdominant ($\propto c$) term by itself has the opposite monodromy, corresponding to incoming waves—both as stipulated above. Equation (A1) holds exactly for

$$c(\gamma)\sim-\frac{1-\alpha/\sqrt{\gamma}}{\sin(2\pi\gamma)}. \tag{A4}$$

As required, $c(\gamma\in\mathbb{R})\in\mathbb{R}$, since the exponential tail of $V(x\to-\infty)$ does not generate a branch cut in $f(\omega)$. Also the poles for $2\gamma\in\mathbb{N}$ are not surprising, since the RWE is known to have such *anomalous points* for $2\gamma=1,2,\ldots$, with exactly *one* exception at $2\gamma=N$ (Ref. 8); clearly, the latter

is beyond the reach of the present asymptotics. Expressing $f(\pm\omega)$, $g(\pm\omega)$ not through g_a but in terms of each other, the S matrix could be read off; cf. Ref. 17 for the leading order.

Combining (26), (A2), and (A4), all that remains is to asymptotically solve

$$0=J(-i\gamma)\propto\sin(2\pi\gamma)+2e^{2\pi i\gamma}\left(i+\frac{\alpha}{\sqrt{\gamma}}\right)\left(1-\frac{\alpha}{\sqrt{\gamma}}\right)\approx\sin(2\pi\gamma)+2ie^{2\pi i\gamma}\left(1-\frac{(1+i)\alpha}{\sqrt{\gamma}}\right). \tag{A5}$$

Reexpressing the answer in terms of ω and substituting α from the main text, one obtains

$$\omega_n=\frac{\ln 3}{4\pi}-\left(\frac{n}{2}+\frac{1}{4}\right)i+\frac{\sqrt{2}\Gamma(\frac{1}{4})^4}{144\pi^{5/2}}(1+i)\,\frac{\ell(\ell+1)-1}{\sqrt{n}}+\mathcal{O}(n^{-1}), \tag{A6}$$

where the prefactor of the correction evaluates to 0.097 007... . The ω_n have automatically come out on the physical sheet of g_+; contrast Ref. 19, which is not sheet-specific. Agreement with (29) and (30) in Ref. 20 is excellent; as anticipated in the discussion, this numerical confirmation of the value of α via the *QNMs* greatly supports (35) for the *cut*. To my knowledge, this is the first time that the correction to the highly damped Schwarzschild QNM frequencies has been calculated analytically.

(Received 29 July 2003; accepted 3 September 2003)

One of the difficulties encountered when studying physical theories in discrete space–time is that of describing the underlying continuous symmetries (like Lorentz, or Galilei invariance). One of the ways of addressing this difficulty is to consider point transformations acting simultaneously on difference equations and lattices. In a previous article we have classified ordinary difference schemes invariant under Lie groups of point transformations. The present article is devoted to an invariant Lagrangian formalism for scalar single-variable difference schemes. The formalism is used to obtain first integrals and explicit exact solutions of the schemes. Equations invariant under two- and three-dimensional groups of Lagrangian symmetries are considered. © *2004 American Institute of Physics.*
[DOI: 10.1063/1.1625418]

I. INTRODUCTION

A recent article was devoted to a symmetry classification of second-order ordinary difference equations.[1] This was modeled on a paper by Sophus Lie, in which he provided a symmetry classification of second order ordinary differential equations (ODEs).[2] As a matter of fact, the classification of difference schemes goes over into Lie's classification of ODEs in the continuous limit.[1]

Lie showed that a second-order ODE can be invariant under a group G_r of dimension $N=0,1,2,3$, or 8. For $N\geqslant 2$ the equation can be integrated in quadratures. This can be done by transforming the equation to one of the ''canonical'' forms, integrated by Lie himself.[2] Virtually all standard methods of integrating second-order ODEs analytically can be interpreted in this manner (though this is not mentioned in most elementary textbooks).

The situation with difference equations is much less developed. This is not surprising, since applications of Lie group theory to difference equations are much more recent.[3–27] Several different approaches are being pursued. One possibility is to consider the difference equations on a fixed lattice[3–13] and consider only transformations that do not act on the lattice. In order to obtain physically interesting symmetries in this approach, it is necessary to go beyond point symmetries and to let the transformations act on more than one point of the lattice. Lie algebra contractions occur in the continuous limit and some ''generalized'' symmetries may ''contract'' to point ones.[10]

The second possibility is to consider group transformations acting both on the difference equations and on the lattice.[1,17–27] Technically, for systems involving one dependent and one

[a)]Electronic mail: dorod@spp.Keldysh.ru
[b)]Electronic mail: kozlov@ifi.uio.no
[c)]Electronic mail: wintern@crm.umontreal.ca

independent variable, this is achieved by considering a difference scheme, consisting of two equations, one representing the actual difference equation, the other the lattice.

This is the approach that we will follow in the present article. More specifically, we will consider the same three-point scheme as in our previous article.[1] The continuous limit of the scheme, if it exists, will be a second-order ODE.

Thus, we consider two variables, x and y, with x the independent one and y dependent. The variable x runs through an infinite set of values $\{x=x_k,\ k\in\mathbb{Z}\}$ that are not necessarily equally spaced and are not prescribed *a priori*. Instead, we give two relations between any three neighboring points

$$F(x,x_-,x_+,y,y_-,y_+)=0, \tag{1.1}$$

$$\Omega(x,x_-,x_+,y,y_-,y_+)=0 \tag{1.2}$$

and also specify some initial conditions like x_0, x_1, $y_0=y(x_0)$, $y_1=y(x_1)$. In the continuous limit Eq. (1.1) goes into an ODE, (1.2) into an identity (like $0=0$), if the continuous limit exists.

The group transformations considered in this approach are of the same type as for ODEs. They are generated by a Lie algebra of vector fields of the form

$$X=\xi(x,y)\frac{\partial}{\partial x}+\eta(x,y)\frac{\partial}{\partial y}. \tag{1.3}$$

The corresponding transformations are purely point ones, since the coefficients ξ and η depend only on (x,y), not on the shifted points (x_+,y_+) or (x_-,y_-).

In Ref. 1 we showed how Lie group theory can be used to classify such pairs of equations as (1.1) and (1.2). Possible dimensions of the symmetry group G of Eqs. (1.1) and (1.2) are $N=0,1,2,3,4,5$, and 6. The highest dimension, $N=6$, occurs only for difference schemes equivalent to

$$\frac{y_+-2y+y_-}{(x_+-x)^2}=0,\quad x_+-2x+x_-=0.$$

The purpose of this article is to provide a Lagrange formalism and difference analog of Noether's theorem for second-order difference schemes of the form (1.1) and (1.2), admitting Lie point symmetry groups. The Lagrangians will be used to obtain first integrals and exact analytic solutions of the difference schemes.

II. GENERAL THEORY

A. Definitions and notations

We study the difference system (1.1) and (1.2). In general, we assume that these equations can be solved to express x_+ and y_+ explicitly in terms of (x,y,x_-,y_-) and also vice versa, i.e. (x_-,y_-) in terms of the other quantities. We also make use of the following quantities:

$$h_+=x_+-x,\quad h_-=x-x_-,\quad y_x=\frac{y_+-y}{h_+},\quad y_{\bar{x}}=\frac{y-y_-}{h_-},$$
$$y_{x\bar{x}}=\frac{2}{h_++h_-}(y_x-y_{\bar{x}}), \tag{2.1}$$

i.e., the up and down spacings in x, the right and left discrete first derivatives and the discrete second derivative, respectively. It is also convenient to use the following total shift and discrete differentiation operators:

$$\underset{\pm h}{S} f(x)=f(x_{\pm}), \quad \underset{\pm h}{D}=\frac{\overset{\pm h}{S}-1}{\pm h_{\pm}}.$$

Continuous first and second derivatives are denoted y' and y'', respectively.

When acting on differential equations, the vector fields (1.3) must be prolonged to act on derivatives. For difference schemes, the prolongation of a vector field acts on variables at other points of the lattice. It is obtained by shifting the coefficients to the corresponding points. For three point schemes we have

$$\mathbf{pr}\, X=X+\xi(x_-,y_-)\frac{\partial}{\partial x_-}+\xi(x_+,y_+)\frac{\partial}{\partial x_+}+\eta(x_-,y_-)\frac{\partial}{\partial y_-}+\eta(x_+,y_+)\frac{\partial}{\partial y_+}. \tag{2.2}$$

B. Lagrangian formulation for second-order ODEs

It has been known since Noether's fundamental work that conservation laws for differential equations are connected with their symmetry properties.[28–31] For convenience we present here some well-known results adapted to the case of second-order ODEs.

Let us consider the functional

$$\mathbb{L}(y)=\int_I L(x,y,y')\mathrm{d}x, \quad I\subset\mathbb{R}^1, \tag{2.3}$$

where $L(x,y,y')$ is called a first-order Lagrangian. The functional (2.3) achieves its extremal values when $y(x)$ satisfies the Euler–Lagrange equation

$$\frac{\delta L}{\delta y}=\frac{\partial L}{\partial y}-D\left(\frac{\partial L}{\partial y'}\right)=0, \quad D=\frac{\partial}{\partial x}+y'\frac{\partial}{\partial y}+y''\frac{\partial}{\partial y'}+\cdots, \tag{2.4}$$

where D is the total derivative operator. Equation (2.4) is an ODE that can be rewritten as

$$y''=f(x,y,y'). \tag{2.5}$$

Let us consider a Lie point transformation G generated by the vector field (1.3). The group G is a ''variational symmetry'' of the functional $\mathbb{L}$ if and only if the Lagrangian satisfies

$$\mathrm{pr}\, X(L)+LD(\xi)=0, \tag{2.6}$$

when $\mathrm{pr}\, X$ is the first prolongation of the vector field X for y'. We will actually need a weaker invariance condition than given by Eq. (2.6). The vector field X is an ''infinitesimal divergence symmetry'' of the functional $\mathbb{L}(y)$ if there exists a function $V(x,y)$ such that[28]

$$\mathrm{pr}\, X(L)+LD(\xi)=D(V), \quad V=V(x,y). \tag{2.7}$$

The two important statements for us follow.

(1) If X is an infinitesimal divergence symmetry of the functional $\mathbb{L}$, it generates a symmetry group of the corresponding Euler–Lagrange equation. The symmetry group of Eq. (2.4) can of course be larger than the one generated by symmetries of the Lagrangian.

(2) Noether's theorem[28–31] can be based on the following Noether-type identity,[31] which holds for any vector field and any function L:

$$\mathrm{pr}\, X(L)+LD(\xi)=(\eta-\xi y')\frac{\delta L}{\delta y}+D\left(\xi L+(\eta-\xi y')\frac{\partial L}{\partial y'}\right). \tag{2.8}$$

It follows that if X is a divergence symmetry of L, i.e., (2.6) or (2.7) is satisfied, then there exists a first integral

$$\xi L+(\eta-\xi y')\frac{\partial L}{\partial y'}-V=K=\text{const} \tag{2.9}$$

of the corresponding Euler–Lagrange equation.

The above considerations tell us how to obtain invariant ODEs and conservation laws from divergence invariant Lagrangians. They do not tell us how to obtain invariant Lagrangians for invariant equations. This amounts to ''variational integration,'' as opposed to variational differentiation.

A procedure that we shall use in the following to find invariant Lagrangians for differential equations can be summed up as follows.

Start from a given ODE $y''=f(x,y,y')$ and its symmetry algebra with basis

$$X_\alpha=\xi_\alpha(x,y)\frac{\partial}{\partial x}+\eta_\alpha(x,y)\frac{\partial}{\partial y},\quad \alpha=1,\ldots,k.$$

Find the invariants of X_α in the space $\{x,y,y',\Lambda\}$, where Λ is the Lagrangian. The appropriate prolongation in this case is

$$\mathrm{pr}\,X=\xi\frac{\partial}{\partial x}+\eta\frac{\partial}{\partial y}+\zeta^1\frac{\partial}{\partial y'}-(D\xi)\Lambda\frac{\partial}{\partial\Lambda},\quad \zeta^1=D(\eta)-y'D(\xi) \tag{2.10}$$

and we require that $L(x,y,y')$ should satisfy

$$\mathrm{pr}\,X(\Lambda-L)|_{\Lambda=L}=0. \tag{2.11}$$

Each basis element X_α provides us with an equation of the form

$$\xi_\alpha\frac{\partial L}{\partial x}+\eta_\alpha\frac{\partial L}{\partial y}+\zeta^1_\alpha\frac{\partial L}{\partial y'}-LD(\xi_\alpha)=0. \tag{2.12}$$

Solve the partial differential equations (2.12). This will give us the general form of an invariant Lagrangian. It may involve arbitrary functions of the invariants of X.

Request that the Euler–Lagrange equation (2.4) should coincide with the equation we started from. This will further restrict the invariant Lagrangian and determine whether one exists.

If this procedure does not yield a suitable Lagrangian, then step 1 can be weakened. We can request that the Lagrangian be invariant under some subgroup of the symmetry group of the given ODE, rather then the entire group. We then go through step 2, then verify whether the obtained Lagrangian is divergence invariant under the entire group, or at least a larger subgroup. In any case, each divergence symmetry of the Lagrangian will provide a first integral of the ODE.

For ODEs the Lagrangian formalism is not the only integration method. The existence of one-parameter symmetry group provides a reduction to a first-order ODE directly. The existence of a two-parameter symmetry group makes it possible to integrate in quadratures. An invariant Lagrangian provides an alternative. Indeed, assume that we know two first integrals

$$f_1(x,y,y')=A,\quad f_2(x,y,y')=B, \tag{2.13}$$

then we eliminate y' from these two equations and obtain the general solution

$$y=F(x,A,B), \tag{2.14}$$

of the corresponding ODE (2.5) by purely *algebraic* manipulations. It is this method of invariant Lagrangians that generalizes to difference equations and is particularly useful when direct methods fail.

C. Lagrangian formalism for second-order difference equations

The variational formulation of discrete equations and a discrete analog of Noether's theorem are much more recent.[19,25–27] Here we briefly overview the results that we shall need in the following.

Let us consider a finite difference functional

$$\mathbb{L}_h=\sum_{\Omega}\ \mathcal{L}(x,x_+,y,y_+)h_+, \tag{2.15}$$

defined on some one-dimensional lattice Ω with step h_+ that generally can depend on the solution

$$h_+=\varphi(x,y,x_+,y_+). \tag{2.16}$$

The functional (2.15) must be considered together with a lattice (2.16). On different lattices it can have different continuous limits and in this limit the lattice equation itself vanishes (turns into an identity like $0=0$)

In the continuous case, a Lagrangian L provides an equation (the Euler–Lagrange equation) that inherits all the symmetries of L. In the discrete case we wish the Lagrangian (2.15) to provide two equations: the entire difference system (1.1), (1.2). Moreover, the three-point difference system should inherit the symmetries of two-point Lagrangian.

Let us again consider a Lie group of point transformations, generated by a Lie algebra of vector fields X_α of the form (1.3). The infinitesimal invariance condition of the functional (2.15) on the lattice (2.16) is given by two equations:[19,25,27]

$$\begin{gathered}\xi\frac{\partial\mathcal{L}}{\partial x}+\xi^+\frac{\partial\mathcal{L}}{\partial x_+}+\eta\frac{\partial\mathcal{L}}{\partial y}+\eta^+\frac{\partial\mathcal{L}}{\partial y_+}+\mathcal{L}\underset{+h}{D}(\xi)=0,\\ \underset{+h}{S}(\xi)-\xi=X(\varphi),\end{gathered} \tag{2.17}$$

where

$$\xi^+=\xi(x_+,y_+),\quad \eta^+=\eta(x_+,y_+). \tag{2.18}$$

Let us consider a variation of the difference functional (2.15) along some curve $y=\phi(x)$ at some point (x,y). The variation will effect only two terms in the sum (2.15):

$$\mathbb{L}_h=\cdots+\mathcal{L}(x,x_-,y,y_-)h_-+\mathcal{L}(x,x_+,y,y_+)h_++\cdots, \tag{2.19}$$

so we get the following expression for the variation of the difference functional:

$$\delta\mathbb{L}_h=\frac{\delta\mathcal{L}}{\delta x}\delta x+\frac{\delta\mathcal{L}}{\delta y}\delta y, \tag{2.20}$$

where $\delta y=\phi'\,\delta x$ and

$$\frac{\delta\mathcal{L}}{\delta x}=h_+\frac{\partial\mathcal{L}}{\partial x}+h_-\frac{\partial\mathcal{L}^-}{\partial x}+\mathcal{L}^--\mathcal{L},\quad \frac{\delta\mathcal{L}}{\delta y}=h_+\frac{\partial\mathcal{L}}{\partial y}+h_-\frac{\partial\mathcal{L}^-}{\partial y},$$

where $\mathcal{L}^-=S_{-h}(\mathcal{L})$.

Thus, for an arbitrary curve the stationary value of difference functional is given by any solution of the *two* equations, called *quasiextremal equations*,

$$\frac{\delta \mathcal{L}}{\delta x}=0, \quad \frac{\delta \mathcal{L}}{\delta y}=0. \tag{2.21}$$

Both of them tend to the differential Euler–Lagrange equation in the continuous limit. Together they represent the entire difference scheme and could be called ''the discrete Euler–Lagrange system.'' The difference between these two equations, or some other function of them that vanishes in the continuous limit will represent the lattice.

Now let us consider a vector field (1.3) with given coefficients $\xi(x,y)$ and $\eta(x,y)$. Variations along the integral curves of this vector field are given by $\delta x=\xi da$ and $\delta y=\eta da$, where da is a variation of a group parameter. A stationary value of the difference functional (2.15) along the flow generated by this vector field is given by

$$\xi \frac{\delta \mathcal{L}}{\delta x}+\eta \frac{\delta \mathcal{L}}{\delta y}=0, \tag{2.22}$$

which depends explicitly on the coefficients of the generator.

If we have a Lie algebra of vector fields of dimension 2 or more, then a stationary value of the difference functional (2.15) along the entire flow will be achieved on the intersection of the solutions of all equations of the type (2.22), i.e., on the quasiextremals (2.21).

On the other hand, Eq. (2.21) can be interpreted as a three-point difference scheme of the form (1.1) and (1.2). For instance, given two points (x,y) and (x_-,y_-), we can calculate (x_+,y_+). In the continuous limit both of these equations will provide the same second-order differential equation. Thus, one of the quasiextremal equations can be identified with Eq. (1.1) and the difference between the two of them with the lattice equation (1.2).

It has been shown elsewhere,[19,25,27] that if the functional (2.15) is invariant under some group G, then the quasiextremal equations (2.21) are also invariant with respect to G. As in the continuous case, the quasiextremal equations can be invariant with respect to a larger group than the corresponding Lagrangian.

A useful operator identity, valid for any Lagrangian $\mathcal{L}(x,x_+,y,y_+)$ and any vector field X is (Refs. 19 and 25)

$$\xi \frac{\partial \mathcal{L}}{\partial x}+\xi^+ \frac{\partial \mathcal{L}}{\partial x_+}+\eta \frac{\partial \mathcal{L}}{\partial y}+\eta^+ \frac{\partial \mathcal{L}}{\partial y_+}+\mathcal{L} \underset{+h}{D}(\xi)=\xi\left(\frac{\partial \mathcal{L}}{\partial x}+\frac{h_-}{h_+}\frac{\partial \mathcal{L}^-}{\partial x}-\underset{+h}{D}(\mathcal{L}^-)\right)+\eta\left(\frac{\partial \mathcal{L}}{\partial y}+\frac{h_-}{h_+}\frac{\partial \mathcal{L}^-}{\partial y}\right)$$
$$+\underset{+h}{D}\left(h_-\eta\frac{\partial \mathcal{L}^-}{\partial y}+h_-\xi\frac{\partial \mathcal{L}^-}{\partial x}+\xi\mathcal{L}^-\right). \tag{2.23}$$

From Eq. (2.23) we obtain the following discrete analog of Noether's theorem.

Theorem 2.1: Let the Lagrangian density $\mathcal{L}$ be divergence invariant under a Lie group G of local point transformations generated by vector fields X of the form (1.3), i.e., let us have

$$\mathbf{pr}\,X(\mathcal{L})+\mathcal{L}\underset{+h}{D}(\xi)=\underset{+h}{D}(V) \tag{2.24}$$

for some function $V(x,y)$. Then each element X of the Lie algebra corresponding to G provides us with a first integral of the quasiextremal equations (2.21), namely,

$$K=h_-\eta\frac{\partial \mathcal{L}^-}{\partial y}+h_-\xi\frac{\partial \mathcal{L}^-}{\partial x}+\xi\mathcal{L}^- -V. \tag{2.25}$$

Proof:[19,25] On solutions of the quasiextremal equations (2.21) Eq. (2.23) reduces to

$$\underset{+h}{D}\left(h_-\eta\frac{\partial\mathcal{L}^-}{\partial y}+h_-\xi\frac{\partial\mathcal{L}^-}{\partial x}+\xi\mathcal{L}^-\right)=\underset{+h}{D}(V) \tag{2.26}$$

[we have used Eq. (2.23)]. The result (2.25) follows immediately. □

The fundamental equation (2.25) is the discrete analog of Eq. (2.9) for ODEs.

Let us compare the situation for second-order ODEs and for three-point difference schemes. For a second-order ODE a Lagrangian that is divergence invariant under a two-dimensional symmetry group provides two integrals of motion. From them we can eliminate the remaining first derivative and obtain the general solution, depending on two arbitrary constants (the two first integrals). Moreover, we do not really need a Lagrangian. Once we have a two-dimensional symmetry group of the ODE, we can integrate in quadratures.

For three-point difference schemes we have two equations to solve, namely, the system (1.1) and (1.2). Equivalently, we have a set of points (x_n,y_n), labeled by an integer n. Any three neighboring points are related by two equations that we can write, e.g., as

$$y_{n+1}=F_1(x_n,y_n,x_{n-1},y_{n-1}),\quad x_{n+1}=\Omega_1(x_n,y_n,x_{n-1},y_{n-1}). \tag{2.27}$$

Alternatively, the system could be solved for x_{n-1},y_{n-1}. We mention that we use notations like $x_{n-1}=x_-$, $x_n=x$, $x_{n+1}=x_+$, $y_{n-1}=y_-$, $y_n=y$, $y_{n+1}=y_+$ interchangeably.

Given some starting values (x_0,y_0,x_{-1},y_{-1}), we can solve (2.27) for (x_n,y_n) with $n\geqslant 1$, and $n\leqslant -2$. The solution will depend on four constants $K_i, i=1,\ldots,4$, and can be written as

$$y_n=y_n(x_n,K_1,K_2,K_3,K_4), \tag{2.28}$$

$$x_n=x_n(K_1,K_2,K_3,K_4). \tag{2.29}$$

The two quasiextremal equations (2.21) correspond to the system (2.27).

A one-parameter symmetry group of the Lagrangian $\mathcal{L}$ will provide us with a first integral (2.25), i.e., an equation of the form

$$f(x_n,y_n,x_{n+1},y_{n+1})=K_1, \tag{2.30}$$

compatible with the system (2.21). We can solve (2.30) for, e.g., y_{n+1}, substitute into (2.27) and thus simplify this system.

A two-dimensional symmetry group will provide two first integrals of the form (2.25). We can solve for x_{n+1} and y_{n+1}. Then system (2.27) is reduced to a two-point difference scheme. Quite often it is possible to solve it by integration methods that allow one to integrate a two-point difference scheme explicitly.

A three-dimensional symmetry group provides three first integrals of the type (2.25). From them we can express x_{n-1},y_{n-1} and y_n in terms of x_n. This provides us with the solution (2.28) and a two-point difference equation relating x_{n+1} and x_n. If this equation can be solved, we have a complete solution of the problem. Finally, if we have four first integrals, then we get the general solution of the system by purely algebraic manipulations.

An alternative method can be proposed when the Lagrangian is invariant with respect to a two-dimensional Lie group. The discrete Lagrangian corresponding to a given continuous one is not unique and it is possible to introduce a family of Lagrangians:

$$\mathcal{L}_i=\mathcal{L}_i(x,x_+,y,y_+,\alpha_i,\beta_i),\quad i=1,2,3,\ldots \tag{2.31}$$

depending on parameters α_i,β_i, all satisfying

$$\lim_{(x_+,y_+)\to(x,y)}\mathcal{L}_i(x,x_+,y,y_+,\alpha_i,\beta_i)=L(x,y,y')$$

for the same continuous Lagrangian $L(x,y,y')$.

Let us take three different Lagrangians in the family (2.31), corresponding to constants $\alpha_1,\beta_1,\alpha_2,\beta_2$ and α_3,β_3. Each of them will lead to two first integrals and two quasiextremals. In the examples considered in the following we will show that it is possible to fine-tune the constants α_i,β_i in such a manner as to get a system of two invariant equations of the form (1.1) and (1.2) and three first integrals, yielding a set of solutions to the two quasiextremal equations. It is these two equations that will constitute the invariant difference system.

In Sec. II B we described a procedure for obtaining invariant Lagrangians for given second-order differential equation. For difference equations our starting point will be a discretization of the continuous Lagrangian. This is obviously not unique and we shall make use of the inherent arbitrariness. Once an invariant difference Lagrangian with a correct continuous limit is chosen we construct the invariant difference scheme in the above-described manner.

In our previous article[1] we gave a classification of difference schemes and used all realizations of Lie algebras that provide such schemes. Any algebra containing a two-dimensional subalgebra realized by linearly connected vector fields such as

$$\left(\frac{\partial}{\partial x},\, y\frac{\partial}{\partial x}\right),\quad \left(\frac{\partial}{\partial x},\, x\frac{\partial}{\partial x}\right),$$

leads to a linear differential equation and its discretization.

In the following we shall consider only genuinely nonlinear difference schemes presented in Ref. 1 that have nonlinear differential equations as their limit.

III. EQUATIONS CORRESPONDING TO LAGRANGIANS INVARIANT UNDER ONE- AND TWO-DIMENSIONAL GROUPS

A. One-dimensional symmetry group

We start with the simplest case of a symmetry group, namely a one-dimensional group. Its Lie algebra is generated by one vector field of the form (1.3). By an appropriate change of variables we take this vector field into its rectified form. Thus we have

$$\mathbf{D_{1,1}}:\quad X_1=\frac{\partial}{\partial y}. \tag{3.1}$$

The most general second-order ODE invariant under X_1 is

$$y''=F(x,y'), \tag{3.2}$$

where F is an arbitrary given function.

Equation (3.2) is actually already reduced to a first-order equation for $u=y'$. If X_1 is a variational symmetry of Eq. (3.2) and we know the Lagrangian L that it comes from, we can do better. An invariant Lagrangian density will by necessity have the form $L=L(x,y')$ [see Eq. (2.6)]. The Euler–Lagrange equation (2.4) reduces to

$$\frac{\partial^2 L}{\partial x\partial y'}+y''\frac{\partial^2 L}{\partial y'^2}=0. \tag{3.3}$$

Substituting for y'' from Eq. (3.2), we obtain a linear partial differential equation for $L(x,y')$. This of course has an infinity of solutions. Let us assume that we know a solution $L(x,y)$ explicitly. Equation (2.9), i.e., Noether's theorem, provides us with a first integral

$$\frac{\partial L}{\partial y'}(x,y')=K. \tag{3.4}$$

We can solve (in principle) Eq. (3.4) for y' as a function of x (and K). The general solution is then obtained by a quadrature:

$$y' = \phi(x,K), \quad y(x) = y_0 + \int_0^x \phi(x,K)\,\mathrm{d}t. \tag{3.5}$$

In the discrete case the situation is similar. Let us assume that we know a Lagrangian $\mathcal{L}(x,x_+,y,y_+)$, invariant under the group of transformations of y, generated by X_1 of Eq. (3.1). It will have the form

$$\mathcal{L} = \mathcal{L}(x,x_+,y_x), \quad y_x = \frac{y_+ - y}{x_+ - x}. \tag{3.6}$$

The corresponding quasiextremal equations, to be identified with the system (1.1) and (1.2), are

$$\frac{\delta \mathcal{L}}{\delta y} = -\frac{\partial \mathcal{L}}{\partial y_x}(x,x_+,y_x) + \frac{\partial \mathcal{L}}{y_{\bar{x}}}(x_-,x,y_{\bar{x}}) = 0, \tag{3.7}$$

$$\frac{\delta \mathcal{L}}{\delta x} = h_+ \frac{\partial \mathcal{L}}{\partial x}(x,x_+,y_x) + y_x \frac{\partial \mathcal{L}}{\partial y_x}(x,x_+,y_x) - \mathcal{L}(x,x_+,y_x) + h_- \frac{\partial \mathcal{L}}{\partial x}(x_-,x,y_{\bar{x}}) - y_{\bar{x}} \frac{\partial \mathcal{L}}{\partial y_{\bar{x}}}(x_-,x,y_{\bar{x}}) + \mathcal{L}(x_-,x,y_{\bar{x}}) = 0. \tag{3.8}$$

The first integral (2.25) can be read off form Eq. (3.7) and is

$$\frac{\partial \mathcal{L}}{\partial y_x}(x,x_+,y_x) = K. \tag{3.9}$$

We can solve Eq. (3.9) for y_x and by downshifting obtain $y_{\bar{x}}$:

$$y_x = \phi(x,x_+,K), \quad y_{\bar{x}} = \phi(x_-,x,K). \tag{3.10}$$

Substituting into the quasiextremal equation (3.8), we obtain a relation between x_+, x_- and x, i.e., a single three-point relation for the variable x. For y we then obtain a two point equation

$$y_+ - y = (x_+ - x)\,\phi(x,x_+,K). \tag{3.11}$$

Equation (3.11) is really a discrete quadrature: a first-order inhomogeneous linear equation for y.

Example 3.1: Consider the Lagrangian

$$\mathcal{L} = x_n^a x_{n+1}^b \exp(y_x). \tag{3.12}$$

The quasiextremal equations are

$$-x_n^a x_{n+1}^b \exp(y_x) + x_{n-1}^a x_n^b \exp(y_{\bar{x}}) = 0, \tag{3.13}$$

$$h_+ a x_n^{a-1} x_{n+1}^b \exp(y_x) + y_x x_n^a x_{n+1}^b \exp(y_x) - x_n^a x_{n+1}^b \exp(y_x) + h_- b x_{n-1}^a x_n^{b-1} \exp(y_{\bar{x}}) - y_{\bar{x}} x_{n-1}^a x_n^b \exp(y_{\bar{x}}) + x_{n-1}^a x_n^b \exp(y_{\bar{x}}) = 0. \tag{3.14}$$

The first integral is

$$x_n^a x_{n+1}^b \exp(y_x) = K. \tag{3.15}$$

From (3.15) we have

$$y_x = \ln(K x_n^{-a} x_{n+1}^{-b}), \quad y_{\bar{x}} = \ln(K x_{n-1}^{-a} x_n^{-b}). \tag{3.16}$$

Equation (3.13) is satisfied identically. Equation (3.14) reduces to a three-point equation for x:

$$ax_{n+1}+(b-a)x_n-bx_{n-1}+x_n(-b\ln(x_{n+1})+(b-a)\ln(x_n)+a\ln(x_{n-1}))=0. \quad (3.17)$$

This lattice equation can be reduced to a two-point equation for a new variable $\lambda_n=x_{n+1}/x_n$:

$$a\lambda_n+(b-a)-\frac{b}{\lambda_{n-1}}=a\ln(\lambda_{n-1})+b\ln(\lambda_n). \quad (3.18)$$

In particular, one can choose the solution $\lambda_n=\lambda_{n+1}=\lambda$, where λ satisfies

$$a\lambda+(b-a)-\frac{b}{\lambda}=(a+b)\ln(\lambda).$$

It provides us with the lattice $x_n=x_0\lambda^n$.

Substituting the lattice into (3.15), we obtain a two-point equation for y:

$$y_{n+1}-y_n=(x_{n+1}-x_n)\ln(Kx_n^{-a}x_{n+1}^{-b}). \quad (3.19)$$

The fact that we could solve Eq. (3.17) explicitly is specific for the considered example. The fact that we obtain a three-point equation involving only the independent variables is true in general.

B. Two-dimensional symmetry groups

$\mathbf{D_{2,1}}$: The Abelian Lie algebra with nonconnected basis elements

$$X_1=\frac{\partial}{\partial x}, \quad X_2=\frac{\partial}{\partial y} \quad (3.20)$$

corresponds to the invariant ODE

$$y''=F(y'), \quad (3.21)$$

where F is an arbitrary function.

The equation can be obtained from the Lagrangian

$$L=y+G(y'), \quad F(y')=\frac{1}{G''(y')}. \quad (3.22)$$

The Lagrangian admits symmetries X_1 and X_2:

$$\mathrm{pr}\,X_1L+LD(\xi_1)=0,$$

$$\mathrm{pr}\,X_2L+LD(\xi_2)=1=D(x).$$

With the help of Noether's theorem we obtain the following first integrals:

$$J_1=y+G(y')-y'G'(y'), \quad J_2=G'(y')-x. \quad (3.23)$$

As we mentioned in Sec. II B, it is sufficient to have two first integrals to write out the general solution of a second-order ODE without quadratures. More explicitly, we can solve the second equation (3.23) for y' in terms of x and obtain

$$y'=H(J_2+x), \quad H(J_2+x)=[G']^{-1}(J_2+x). \quad (3.24)$$

Substituting into the first equation, we obtain

$$y(x)=J_1-G[H(J_2+x)]+(J_2+x)H(J_2+x). \quad (3.25)$$

Now we are in a position to show how one can find a variational discrete model and its conservation laws by means of Lagrange-type technique. Let us choose a difference Lagrangian in the form

$$\mathcal{L}=\frac{y+y_+}{2}+G(y_x), \tag{3.26}$$

then

$$\mathbf{pr}\,X_1\mathcal{L}+\mathcal{L}\underset{+h}{D}(\xi_1)=0,$$

$$\mathbf{pr}\,X_2\mathcal{L}+\mathcal{L}\underset{+h}{D}(\xi_2)=1=\underset{+h}{D}(x).$$

The variations of $\mathcal{L}$ yield the following quasiextremal equations:

$$\frac{\delta\mathcal{L}}{\delta y}:\quad G'(y_x)-G'(y_{\bar{x}})=\frac{h_+ + h_-}{2}, \tag{3.27}$$

$$\frac{\delta\mathcal{L}}{\delta x}:\quad -\frac{y+y_+}{2}-G(y_x)+y_xG'(y_x)+\frac{y+y_-}{2}+G(y_{\bar{x}})-y_{\bar{x}}G'(y_{\bar{x}})=0. \tag{3.28}$$

Due to the invariance of the Lagrangian with respect to the operators X_1 and X_2, the difference analog of Noether's theorem yields two first integrals

$$I_1=y+G(y_x)-y_xG'(y_x)+\frac{x_+-x}{2}y_x, \tag{3.29}$$

$$I_2=G'(y_x)-\frac{x+x_+}{2}. \tag{3.30}$$

As in the case of the algebra $\mathbf{D_{1,1}}$ we can solve for y_x to obtain

$$y_x=\Phi_1(I_2,x+x_+). \tag{3.31}$$

Substituting into the equation for I_1 we obtain

$$y=\Phi_2(I_1,I_2,x,x_+). \tag{3.32}$$

Calculating y_x from Eq. (3.32) and setting it equal to (3.31), we obtain a three-point recursion relation for x. Solving it (if we can), we turn Eq. (3.32) into an explicit general solution of the difference scheme (3.27) and (3.28).

Example 3.2: Let us consider the case

$$\mathcal{L}=\frac{y+y_+}{2}+\exp(y_x). \tag{3.33}$$

The two first integrals (3.29) and (3.30) in this case are the following:

$$I_1=y+\exp(y_x)-y_x\exp(y_x)+\frac{x_{n+1}-x_n}{2}y_x,$$

$$I_2=\exp(y_x)-\frac{x_{n+1}+x_n}{2}. \tag{3.34}$$

Equation (3.31) and (3.32) reduce to

$$y_x=\ln\left(I_2+\frac{x_{n+1}+x_n}{2}\right), \tag{3.35}$$

$$y=I_1-I_2-\frac{x_{n+1}+x_n}{2}+(I_2+x_n)\ln\left(I_2+\frac{x_{n+1}+x_n}{2}\right). \tag{3.36}$$

The recursion relation for x is

$$\frac{-x_{n+1}+x_{n-1}}{2}+(I_2+x_n)[\ln(2I_2+x_{n+1}+x_n)-\ln(2I_2+x_n+x_{n-1})]. \tag{3.37}$$

The last equation is difficult to solve. We have however reduced a system of two three-point equations to a single three-point one. We shall return to this case in Sec. V using an alternative method.

$\mathbf{D_{2,2}}$: The non-Abelian Lie algebra with nonconnected elements

$$X_1=\frac{\partial}{\partial y},\quad X_2=x\frac{\partial}{\partial x}+y\frac{\partial}{\partial y} \tag{3.38}$$

yields the invariant ODE

$$y''=\frac{1}{x}F(y'). \tag{3.39}$$

We define a function $G(y')$ by

$$F(y')=\frac{G'(y')}{G''(y')}. \tag{3.40}$$

Then the ODE (3.39) is the Euler–Lagrangian equation for the Lagrangian

$$L=\frac{1}{x}G(y'), \tag{3.41}$$

which admits X_1 and X_2 as variational symmetries:

$$\mathrm{pr}\,X_1L+LD(\xi_1)=0,$$

$$\mathrm{pr}\,X_2L+LD(\xi_2)=0.$$

Noether's theorem provides us with two first integrals:

$$J_1=\frac{1}{x}G'(y'),\quad J_2=G(y')+\left(\frac{y}{x}-y'\right)G'(y').$$

Let us take the difference Lagrangian

$$\mathcal{L}=\frac{2}{x+x_+}G(y_x),$$

which satisfies

$$\mathbf{pr}\, X_1 \mathcal{L} + \mathcal{L} \underset{+h}{D}(\xi_1) = 0,$$

$$\mathbf{pr}\, X_2 \mathcal{L} + \mathcal{L} \underset{+h}{D}(\xi_2) = 0.$$

Then the variations of $\mathcal{L}$ yield the following quasiextremal equations:

$$\frac{\delta \mathcal{L}}{\delta y}: \quad \frac{2}{x+x_+} G'(y_x) - \frac{2}{x_-+x} G'(y_{\bar{x}}) = 0,$$

$$\begin{aligned} \frac{\delta \mathcal{L}}{\delta x}: \quad & -\frac{2h_+}{(x+x_+)^2} G(y_x) + \frac{2}{(x+x_+)} G'(y_x) y_x - \frac{2}{(x+x_+)} G(y_x) \\ & - \frac{2h_-}{(x_-+x)^2} G(y_{\bar{x}}) - \frac{2}{(x_-+x)} G'(y_{\bar{x}}) y_{\bar{x}} + \frac{2}{(x_-+x)} G(y_{\bar{x}}) = 0. \end{aligned} \tag{3.42}$$

Since the Lagrangian is invariant with respect to the operators X_1 and X_2, we find the first integrals

$$I_1 = \frac{2G'(y_x)}{x+x_+}, \quad I_2 = \frac{4xx_+}{(x+x_+)^2} G(y_x) + \frac{2G'(y_x)}{x+x_+}(y - xy_x) \tag{3.43}$$

for the solutions of (3.42).

As in the case of the algebra $\mathbf{D_{2,1}}$, we can solve for y_x, using the integral I_1. We obtain

$$y_x = \Phi_1(I_1, x+x_+). \tag{3.44}$$

The second integral allows us to express y as a function of x and x_+,

$$y = x\Phi_1 + \frac{I_2}{I_1} - \frac{4xx_+}{I_1(x+x_+)^2} G(\Phi_1). \tag{3.45}$$

IV. EQUATIONS CORRESPONDING TO LAGRANGIANS INVARIANT UNDER THREE-DIMENSIONAL LIE GROUPS

Among the ''prototype equations'' of our previous article,[1] many have three-dimensional symmetry groups. In this section we shall consider two of these cases. Both of them come from Lagrangians that also have three-dimensional symmetry groups, i.e., all these symmetries are Lagrangian ones.

$\mathbf{D_{3,1}}$: Let us first consider a family of solvable Lie algebras depending on one constant k:

$$X_1 = \frac{\partial}{\partial x}, \quad X_2 = \frac{\partial}{\partial y}, \quad X_3 = x\frac{\partial}{\partial x} + ky\frac{\partial}{\partial y}, \quad k \neq 0, \frac{1}{2}, 1, 2. \tag{4.1}$$

The invariant equation has the form

$$y'' = y'^{(k-2)/(k-1)}. \tag{4.2}$$

This equation can be obtained by the usual variational procedure from the Lagrangian

$$L = \frac{(k-1)^2}{k}(y')^{k/(k-1)} + y, \tag{4.3}$$

which admits operators X_1 and X_2 for any parameter k and X_3 for $k=-1$:

$$\mathrm{pr}\,X_1L+LD(\xi_1)=0,$$

$$\mathrm{pr}\,X_2L+LD(\xi_2)=1=D(x),$$

$$\mathrm{pr}\,X_3L+LD(\xi_3)=(k+1)L.$$

It is possible to show that there is no Lagrangian function $L(x,y,y')$ which gives Eq. (4.2) with $k\neq-1$ as its Euler's equation and is divergence invariant for all three symmetries (4.1).

For arbitrary k there are two first integrals

$$J_1=\frac{(1-k)}{k}(y')^{k/(k-1)}+y=A^0,\quad J_2=(k-1)(y')^{1/(k-1)}-x=B^0.$$

Eliminating y' we find the general solution:

$$y=\frac{1}{k}\left(\frac{1}{k-1}\right)^{(k-1)}(x+B^0)^k+A^0. \tag{4.4}$$

In the case $k=-1$ we have the further first integral corresponding to the symmetry X_3:

$$J_3=\frac{2}{\sqrt{y'}}(y-xy')+xy=C^0.$$

It is functionally dependent on J_1 and J_2 since a second-order ODE can possess only two functionally independent first integrals. Let us mention that the first integral J_3 is basic:

$$J_1=X_1(J_3),\quad J_2=-X_2(J_3),$$

since

$$[X_1,X_3]=X_1,\quad [X_2,X_3]=kX_2.$$

In this case we have the following relation:

$$4-J_1J_2-J_3=0. \tag{4.5}$$

Thus, the integral J_3 is not independent and is of no use in the present context.

Now let us turn to the discrete case and consider $k=-1$ only. Other values of k will be considered in Sec. V, using a different approach. Let us choose the Lagrangian to be

$$\mathcal{L}=-4\sqrt{y_x}+\frac{y+y_+}{2} \tag{4.6}$$

as a discrete Lagrangian, which is invariant for X_1 and X_3 and divergence invariant for X_2:

$$\mathbf{pr}\,X_1\mathcal{L}+\underset{+h}{\mathcal{L}D}(\xi_1)=0,$$

$$\mathbf{pr}\,X_2\mathcal{L}+\underset{+h}{\mathcal{L}D}(\xi_2)=1=\underset{+h}{D}(x), \tag{4.7}$$

$$\mathbf{pr}\,X_3\mathcal{L}+\underset{+h}{\mathcal{L}D}(\xi_3)=0.$$

From the Lagrangian we obtain the quasiextremal equations:

$$\begin{aligned}\frac{\delta\mathcal{L}}{\delta y}:&\quad -\frac{4}{h_-+h_+}\left(\frac{1}{\sqrt{y_x}}-\frac{1}{\sqrt{y_{\bar{x}}}}\right)=1,\\ \frac{\delta\mathcal{L}}{\delta x}:&\quad 4(\sqrt{y_x}-\sqrt{y_{\bar{x}}})-\frac{y+y_+}{2}+\frac{y_-+y}{2}=0.\end{aligned}\tag{4.8}$$

This system of equations is invariant with respect to all three operators (4.1). The application of the difference analog of the Noether theorem gives us three first integrals:

$$\begin{aligned}&I_1=-2\sqrt{y_x}+\frac{y+y_+}{2}=A,\quad I_2=-\frac{2}{\sqrt{y_x}}-\frac{x+x_+}{2}=B,\\ &I_3=\frac{2(x_+y-y_+x)}{h_+\sqrt{y_x}}+\frac{x_+y+y_+x}{2}=C.\end{aligned}\tag{4.9}$$

In contrast to the continuous case the three difference first integrals I_1, I_2, and I_3 are functionally independent and instead of Eq. (4.5) we have the following relation:

$$4-I_1I_2-I_3=\frac{1}{4}h_+^2y_x=\frac{4\varepsilon^2}{(\varepsilon+2)^2}.\tag{4.10}$$

This coincides with Eq. (4.5) in the continuous limit $\varepsilon\to 0$. We see that the expression $h_+^2y_x$ is also a first integral of (4.8). This allows one to introduce a convenient lattice, namely,

$$\frac{1}{4}h_-^2y_{\bar{x}}=\frac{1}{4}h_+^2y_x=\frac{4\varepsilon^2}{(\varepsilon+2)^2},\quad \varepsilon=\text{const},\quad 0<\varepsilon\ll 1.\tag{4.11}$$

Substituting y_x from Eq. (4.11) into I_2, we obtain a two-term recursion relation for x, namely,

$$x_{n+1}-(1+\varepsilon)x_n-\varepsilon B=0,\tag{4.12}$$

or

$$-(1+\varepsilon)x_{n+1}+x_n-\varepsilon B=0,\tag{4.13}$$

depending on the sign choice for $\sqrt{y_x}$. These equations can be solved and we obtain a lattice satisfying

$$x_n=(x_0+B)(1+\varepsilon)^n-B,\quad x_0>-B\tag{4.14}$$

for the first equation and a lattice satisfying

$$x_n=(x_0+B)(1+\varepsilon)^{-n}-B,\quad x_0<-B\tag{4.15}$$

for the second equation. Using the expressions for I_1, we get the general solution for y [the same for both lattices (4.14) and (4.15)] as

$$y_n=A-\frac{4}{x_n+B}\frac{1+\varepsilon}{\left(1+\frac{\varepsilon}{2}\right)^2}.\tag{4.16}$$

This agrees with the continuous case up to order ε.

We have used the three integrals I_1, I_2, and I_3 to obtain the general solution of the difference scheme (4.8). Indeed, the solution (4.14) and (4.16) for x_n, y_n depends on four constants (A,B,x_0,ε), as it should.

The difference scheme is not compatible with a regular lattice, but requires an exponential one, as in Eq. (4.14). The only nonalgebraic step in the integration was the solution of Eq. (4.12): a linear two point equation with constant coefficients.

$\mathbf{D_{3,2}}$: The group given by the operators

$$X_1=\frac{\partial}{\partial x},\quad X_2=2x\frac{\partial}{\partial x}+y\frac{\partial}{\partial y},\quad X_3=x^2\frac{\partial}{\partial x}+xy\frac{\partial}{\partial y} \tag{4.17}$$

corresponds to the invariant differential equation

$$y''=y^{-3}. \tag{4.18}$$

This equation can be obtained from the Lagrangian function

$$L=y'^2-\frac{1}{y^2}, \tag{4.19}$$

which admits all three operators:

$$\begin{gathered}\mathrm{pr}\,X_1L+LD(\xi_1)=0,\\ \mathrm{pr}\,X_2L+LD(\xi_2)=0,\\ \mathrm{pr}\,X_3L+LD(\xi_3)=2y'y=D(y^2).\end{gathered} \tag{4.20}$$

Consequently, the symmetries yield the following first integrals:

$$\begin{gathered}J_1=y'^2+\frac{1}{y^2}=A^0,\quad J_2=2\frac{x}{y^2}-2(y-y'x)y'=2B^0,\\ J_3=\frac{x^2}{y^2}+(y-xy')^2=C^0.\end{gathered} \tag{4.21}$$

Using the integrals A^0 and B^0 we write the general solution $y(x)$ as

$$A^0y^2=(A^0x-B^0)^2+1. \tag{4.22}$$

We see that the third integral, denoted J_3 is not needed, is not useful and indeed, is not independent. The integrals J_1, J_2, and J_3 are related as follows:

$$\left(\frac{J_2}{2}\right)^2-J_1J_3+1=0. \tag{4.23}$$

Now let us consider the discrete case. Let us consider the discrete Lagrangian function

$$\mathcal{L}=y_x^2-\frac{1}{yy_+}, \tag{4.24}$$

which admits the same symmetries as the continuous one:

$$\mathbf{pr}\, X_1\mathcal{L}+\mathcal{L}\underset{+h}{D}(\xi_1)=0,$$

$$\mathbf{pr}\, X_2\mathcal{L}+\mathcal{L}\underset{+h}{D}(\xi_2)=0, \tag{4.25}$$

$$\mathbf{pr}\, X_3\mathcal{L}+\mathcal{L}\underset{+h}{D}(\xi_3)=\underset{+h}{D}(y^2).$$

The Lagrangian generates the invariant quasiextremal equations:

$$\frac{\delta\mathcal{L}}{\delta y}:\ 2(y_x-y_{\bar{x}})=\frac{h_+}{y^2y_+}+\frac{h_-}{y^2y_-},$$

$$\frac{\delta\mathcal{L}}{\delta x}:\ (y_x)^2+\frac{1}{yy_+}-(y_{\bar{x}})^2-\frac{1}{yy_-}=0. \tag{4.26}$$

The quasiextremal equations have three functionally independent first integrals

$$I_1=y_x^2+\frac{1}{yy_+}=A,\quad I_2=\frac{x+x_+}{yy_+}+2y_x(x_+y_x-y_+)=2B,$$

$$I_3=\frac{xx_+}{yy_+}+(x_+y_x-y_+)^2=C. \tag{4.27}$$

In the discrete case the integrals I_1, I_2, and I_3 are independent. Equation (4.23) no longer holds and instead we have

$$\left(\frac{I_2}{2}\right)^2-I_1I_3+1=\frac{1}{4}\left(\frac{h_+}{yy_+}\right)^2. \tag{4.28}$$

In order to integrate the system (4.26) we will use three first integrals A, B and the one in Eq. (4.28), namely,

$$\frac{h_+}{yy_+}=\varepsilon. \tag{4.29}$$

Eliminating y_x, x_+, and y_+, we obtain the solution

$$Ay^2=(Ax-B)^2+1-\frac{\varepsilon^2}{4}. \tag{4.30}$$

This agrees with the continuous limit (4.22) up to order ε^2.

Calculating y_x from Eq. (4.30) and substituting into the expression for A in Eq. (4.27) we obtain a two-point difference equation for x and hence we obtain the lattice. In this case the equation has the form of a fractional linear mapping, i.e., it is a discrete version of the Riccati equation (with constant coefficients).

Explicitly we obtain

$$x_{n+1}=\frac{\alpha x_n+\beta}{\gamma x_n+\delta}, \tag{4.31}$$

$$\alpha=1-\varepsilon B-\frac{1}{2}\varepsilon^2,\quad \beta=\frac{\varepsilon}{A}\left(1+B^2-\frac{1}{4}\varepsilon^2\right),$$
$$\gamma=-\varepsilon A,\quad \delta=1+\varepsilon B-\frac{1}{2}\varepsilon^2. \tag{4.32}$$

We see that the coefficients in the discrete Riccati equation (4.31) satisfy

$$\alpha\delta-\beta\gamma=1,\quad \alpha+\delta=2-\varepsilon^2. \tag{4.33}$$

Like the continuous Riccati equation, Eq. (4.31) can be linearized. To do this we introduce a linear system

$$\begin{pmatrix} u_{n+1} \\ v_{n+1} \end{pmatrix}=\begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix}\begin{pmatrix} u_n \\ v_n \end{pmatrix}. \tag{4.34}$$

If u and v satisfy Eq. (4.34), then

$$x=\frac{u}{v} \tag{4.35}$$

will satisfy Eq. (4.31). Equation (4.34) can be solved by standard methods. Indeed, both u and v must satisfy

$$u_{n+2}-(\alpha+\delta)u_{n+1}+(\alpha\delta-\beta\gamma)u_n=0. \tag{4.36}$$

The characteristic equation

$$\lambda^2-(\alpha+\delta)\lambda+(\alpha\delta-\beta\gamma)=0 \tag{4.37}$$

is obtained by putting $u_n=\lambda^n$.

In view of Eq. (4.33) the roots of Eq. (4.37) are complex. The final result is that the solution of Eq. (4.31) is

$$x_n=\frac{1}{A}\sqrt{1-\frac{\varepsilon^2}{4}}\tan(\omega n+\rho)+\frac{B}{A}, \tag{4.38}$$

where ρ is an integration constant and ω satisfies

$$\tan\omega=\frac{2\varepsilon}{2-\varepsilon^2}\sqrt{1-\frac{\varepsilon^2}{4}}. \tag{4.39}$$

Equations (4.30) and (4.38) provide an explicit analytic solution of the system (4.26). It is the general solution and involves four constants: A, B, ε, and ρ. It follows from Eq. (4.38) that the independent variable x varies between $-$ and $+$ infinity as $\omega n+\rho$ varies between $\pm\pi/2$.

V. INTEGRATION OF DIFFERENCE SCHEMES WITH TWO VARIATIONAL SYMMETRIES

A. The method of perturbed Lagrangians

We have mentioned in Sec. III B that a two-dimensional group of Lagrangian symmetries is always sufficient to reduce the original system of two three-point equations to a single three-point equation for the independent variable alone.

Here we shall show that in some cases we can do better. Using a different approach, we will actually obtain a complete solution of a difference scheme approximating a differential equation with a Lagrangian, divergence invariant under a two-dimensional symmetry group.

The case we shall consider is Eq. (3.21) and hence the two-dimensional Abelian group $\mathbf{D_{2,1}}$ corresponding to the algebra (3.20). We shall make use of the fact that the Lagrangian is not unique. Indeed we will consider three different Lagrangians, all having the same continuous limit (3.22). Instead of writing the Lagrangian (3.26) in the discrete case, we shall use a family of Lagrangians, parametrized by two constants, α and β:

$$\mathcal{L}=\alpha G(y_x)+\beta y+(1-\beta)y_+, \quad \alpha\approx 1, \quad 0\leqslant\beta\leqslant 1. \tag{5.1}$$

Each Lagrangian provides its own quasiextremal system

$$\alpha[-G'(y_x)+G'(y_{\bar{x}})]+\beta h_+ +(1-\beta)h_-=0, \tag{5.2}$$

$$\alpha[y_xG'(y_x)-y_{\bar{x}}G'(y_{\bar{x}})-G(y_x)+G(y_{\bar{x}})]-\beta(y-y_-)-(1-\beta)(y_+-y)=0. \tag{5.3}$$

We shall view one Lagrangian, with $\alpha_3=1$ and $\beta_3=0.5$, as the basic one, the other two as its perturbations.

Each Lagrangian in the family is divergence invariant under $X_1=\partial_x$ and $X_2=\partial_y$ and hence provides two first integrals of the corresponding quasiextremal equations (5.2) and (5.3):

$$\alpha[-y_xG'(y_x)+G(y_x)]+y+(1-\beta)h_+y_x=A, \tag{5.4}$$

$$\alpha G'(y_x)-x-\beta h_+=B. \tag{5.5}$$

Let us now choose three different pairs (α_i,β_i). They provide six integrals (and six quasiextremal equations). We shall show that by appropriately fine-tuning the constants α_i and β_i and choosing some of the constants A_i and B_i we can manufacture a consistent difference system, representing both the equation and the lattice. Moreover, we can explicitly integrate the equations in a manner that approximates the exact solution obtained in the continuous limit.

Let us take one equation of the form (5.4) and two of the form (5.5). In these three equations we choose $\alpha_3=1$, $\beta_3=0.5$, and $B_2=B_3=B$. We then take the difference between the two equations involving B to finally obtain the following system of three two-point equations:

$$\alpha_1[-y_xG'(y_x)+G(y_x)]+y+(1-\beta_1)h_+y_x=A, \tag{5.6}$$

$$G'(y_x)-x-\tfrac{1}{2}h_+=B, \tag{5.7}$$

$$(1-\alpha_2)G'(y_x)-(\tfrac{1}{2}-\beta_2)h_+=0. \tag{5.8}$$

From Eqs. (5.7) and (5.8) we have

$$G'(y_x)=\frac{x_++x+2B}{2}, \tag{5.9}$$

$$x_+-(1+\varepsilon)x-\varepsilon B=0, \tag{5.10}$$

where we have put

$$\varepsilon=\frac{2(1-\alpha_2)}{\alpha_2-2\beta_2}. \tag{5.11}$$

The continuous limit will correspond to $\varepsilon\to 0$.

Equation (5.10) coincides with Eq. (4.12) obtained using three Lagrangian symmetries in a special case. Here it appears in a much more general setting. The general solution of Eq. (5.10),

$$x_n=(x_0+B)(1+\varepsilon)^n-B, \tag{5.12}$$

depends on one integration constant x_0. This solution gives a lattice satisfying $h_- > 0$ and $h_+ > 0$ for $x_0 > -B$ if $\varepsilon > 0$ and for $x_0 < -B$ if $\varepsilon < 0$. For the other cases, namely $x_0 < -B$ if $\varepsilon > 0$ and for $x_0 > -B$ if $\varepsilon < 0$, formula (5.12) gives a lattice with a reverse order of points: $h_- < 0$ and $h_+ < 0$.

Using (5.12) and (5.9), we can express y_x in terms of x. We have

$$G'(y_x) = \left(1 + \frac{\varepsilon}{2}\right)(B + x). \tag{5.13}$$

Denoting the inverse function of $G'(y_x)$ as H, we have

$$y_x = H\left[\left(1 + \frac{\varepsilon}{2}\right)(B + x)\right]. \tag{5.14}$$

Using (5.6) and (5.14), we can now write the general solution of the system (5.6), (5.7), and (5.8) as

$$y(x) = A - \alpha_1 G(H) + (x + B)H, \tag{5.15}$$

where we have put

$$\alpha_1\left(1 + \frac{\varepsilon}{2}\right) - (1 - \beta_1)\varepsilon = 1. \tag{5.16}$$

The value of α_1, still figuring in the solution (5.15), must be so chosen as to obtain a consistent scheme. Indeed, x_n and y_n given in Eqs. (5.12) and (5.15) will satisfy the system (5.6), (5.7), and (5.8). We must however assure that y_x of Eq. (5.14) and $y_x = (y_{n+1} - y_n)/(x_{n+1} - x_n)$ coincide. A simple computation shows that this equality requires that α_1 should satisfy

$$\alpha_1 = (1 + \varepsilon)^{n+1}(x_0 + B)\,\frac{H_{n+1} - H_n}{G(H_{n+1}) - G(H_n)}. \tag{5.17}$$

This equation is consistent only if the right-hand side is a constant (independent on n). The constants α_i and β_i can depend upon the constant ε and for $\varepsilon \to 0$ we must have $\alpha_1, \alpha_2 \to 1$; $\beta_1, \beta_2 \to 0.5$.

From Eq. (5.8) we have

$$\frac{h_+}{G'(y_x)} = \frac{2(1 - \alpha_2)}{1 - 2\beta_2}. \tag{5.18}$$

This expression must vanish for $\varepsilon \to 0$. To achieve this while respecting Eq. (5.11) we put

$$\alpha_2 = 1 + \varepsilon^2, \quad \beta_2 = \frac{1}{2} + \varepsilon + \frac{\varepsilon^2}{2}. \tag{5.19}$$

Equation (5.11) is satisfied exactly and we have

$$\frac{h_+}{G'(y_x)} = \frac{2\varepsilon}{\varepsilon + 2}. \tag{5.20}$$

We can view Eqs. (5.12) and (5.15) as the general solution of the following three-point difference scheme:

$$G'(y_x)-G'(y_{\bar{x}})-\frac{x_+-x_-}{2}=0,$$
$$\frac{h_+}{G'(y_x)}=\frac{h_-}{G'(y_{\bar{x}})}. \tag{5.21}$$

The system (5.21) is invariant under the group corresponding to $\mathbf{D_{2,1}}$. Strictly speaking, this is not a quasiextremal system, since it cannot be derived from any single Lagrangian. The arbitrary constants A, B and ε come from three first integrals (5.6), (5.7), and (5.20) that are associated with three different Lagrangians.

We have not proven that Eq. (5.17) is consistent for arbitrary functions $G(y_x)$. We shall however show below that in at least two interesting special cases the above integration scheme is consistent.

The results of this section can be summed up as a theorem.

Theorem 5.1: The ODE (3.21) obtained from the Lagrangian (3.22) can be approximated by the difference system (5.21). If α_1 of Eq. (5.17) is constant, then the general solution of this system is given by

$$x_n=(x_0+B)(1+\varepsilon)^n-B,$$
$$y(x_n)=A-\alpha_1 G(H_n)+(x_n+B)H_n, \tag{5.22}$$

where A, B, ε and x_0 are arbitrary constants. For $\varepsilon\to 0$, $y(x_n)$ agrees with the solution (3.25) of the ODE (3.21).

As applications of this theorem let us consider two different equations, each invariant under a three-dimensional group with $\mathbf{D_{2,1}}$ as an invariant subgroup. In both cases the Lagrangian is only divergence invariant under the subgroup $\mathbf{D_{2,1}}$.

B. A polynomial nonlinearity

$\mathbf{D_{3,1}}$:

$$X_1=\frac{\partial}{\partial x},\quad X_2=\frac{\partial}{\partial y},\quad X_3=x\frac{\partial}{\partial x}+ky\frac{\partial}{\partial y},\quad k\neq 0,\frac{1}{2},\pm 1,2. \tag{5.23}$$

This algebra for $k=-1$ was treated in Sec. IV, now we consider the generic case. We take

$$G(y_x)=\frac{(k-1)^2}{k}{y_x}^{k/(k-1)} \tag{5.24}$$

and hence

$$G'(y_x)=(k-1){y_x}^{1/(k-1)}=\left(1+\frac{\varepsilon}{2}\right)(x+B). \tag{5.25}$$

Equation (5.14) reduces to

$$y_x=H_n(x)=\left(\frac{x+B}{k-1}\right)^{k-1}\left(1+\frac{\varepsilon}{2}\right)^{k-1} \tag{5.26}$$

and we have

$$G(H_n)=\frac{(k-1)^2}{k}\left(\frac{x+B}{k-1}\right)^k\left(1+\frac{\varepsilon}{2}\right)^k. \tag{5.27}$$

Substituting into (5.17), we find

$$\alpha_1=\frac{k(1+\varepsilon)((1+\varepsilon)^{k-1}-1)}{(k-1)\left(1+\frac{\varepsilon}{2}\right)((1+\varepsilon)^k-1)} \tag{5.28}$$

so that we have $\alpha_1=1+O(\varepsilon^2)$.

Thus, α_1 is a constant, close to $\alpha_1=1$ for $\varepsilon\ll 1$. The solution y_n of (5.22) specializes to

$$y_n=A+\frac{(x+B)^k}{(k-1)^{k-1}}\frac{\varepsilon\left(1+\frac{\varepsilon}{2}\right)^{k-1}}{(1+\varepsilon)^k-1}. \tag{5.29}$$

This agrees with the solution (4.4) of the ODE (4.2) up to $O(\varepsilon^2)$.

It is interesting to note that for $k=-1$ α_1 becomes independent on ε and we obtain $\alpha_1=1$, $\beta_1=0.5$. The solution (5.29) provides us with the solution (4.16), which was obtained in Sec. IV with the help of a different method.

C. An exponential nonlinearity

We consider another three-dimensional group and its Lie algebra, namely,

$$\mathbf{D_{3,3}}: \quad X_1=\frac{\partial}{\partial x}, \quad X_2=\frac{\partial}{\partial y}, \quad X_3=x\frac{\partial}{\partial x}+(x+y)\frac{\partial}{\partial y}. \tag{5.30}$$

The corresponding invariant ODE is

$$y''=\exp(-y') \tag{5.31}$$

and can be obtained from the Lagrangian

$$L=\exp(y')+y. \tag{5.32}$$

We have

$$\begin{gathered}\mathrm{pr}\,X_1L+LD(\xi_1)=0,\\ \mathrm{pr}\,X_2L+LD(\xi_2)=1=D(x).\end{gathered} \tag{5.33}$$

The corresponding first integrals of Eq. (5.31) are

$$\exp(y')(1-y')+y=A, \quad \exp(y')-x=B. \tag{5.34}$$

Finally, the general solution of Eq. (5.31) is

$$y=(x+B)(\ln(x+B)-1)+A. \tag{5.35}$$

Now let us consider the discrete case, following the method of Sec. V A. We have

$$G(y_x)=\exp(y_x) \tag{5.36}$$

and hence

$$G'(y_x)=\exp(y_x)=(x_n+B)\left(1+\frac{\varepsilon}{2}\right),$$
$$H_n=y_x=\ln(x_n+B)+\ln\left(1+\frac{\varepsilon}{2}\right). \tag{5.37}$$

Substituting into Eq. (5.17), we find

$$\alpha_1=\frac{(1+\varepsilon)\ln(1+\varepsilon)}{\varepsilon\left(1+\frac{\varepsilon}{2}\right)} \tag{5.38}$$

so that α_1 is indeed a constant and moreover we have $\alpha_1=1+O(\varepsilon^2)$.

The solution $y(x)$ on the lattice given in Eq. (5.22) is

$$y_n=A+(x_n+B)\ln(x_n+B)+(x_n+B)\left[\ln\left(1+\frac{\varepsilon}{2}\right)-\frac{(1+\varepsilon)\ln(1+\varepsilon)}{\varepsilon}\right]. \tag{5.39}$$

This agrees with the solution (5.35) of the ODE (5.31) up to $O(\varepsilon^2)$.

VI. CONCLUDING REMARKS

We see that variational symmetries, and the first integrals they provide, play a crucial role in the study of exact solutions of invariant difference schemes. Much more so than in the theory of ordinary differential equations.

The procedure that we followed in this article can be reformulated as follows. We start from the continuous case where we know a Lagrangian density $L(x,y,y')$, invariant under a group G_0 of local point transformations, i.e., satisfying condition (2.6), or (2.7). We hence also know the corresponding Euler–Lagrange equation, invariant under the same group, or a larger group containing G_0 as a subgroup.

Let us assume that we can approximate this Lagrangian by a ''discrete Lagrangian density'' $\mathcal{L}(x,y,x_+,y_+)$ invariant under the same group G_0. Even in the absence of any symmetry group, the Lagrangian will provide us with the quasiextremal equations (2.21), i.e. with a discrete Euler–Lagrange system. This system can be identified with the difference system (1.1) and (1.2).

If the Lagrangian is invariant under a one-dimensional symmetry group, we can reduce the quasiextremal system to a three-point relation for x alone, plus a ''discrete quadrature'' for y (see Sec. III A). If the symmetry group of the Lagrangian is two-dimensional, we can always reduce the quasiextremal system to one three-point equation for x alone, and write the solution $y_n(x)$ directly (see Sec. III B).

If the invariance group of the Lagrangian is (at least) three-dimensional then we can integrate the system explicitly (Sec. IV).

Finally, we have shown that if the symmetry group of the Lagrangian is two-dimensional, but the quasiextremal system has a third (non-Lagrangian) symmetry, we can also integrate explicitly.

ACKNOWLEDGMENTS

While working on this project, we benefited from NATO collaborative Research Grant No. PST.CLG.978431, which made visits of V.D. to the CRM possible. The research of V.D. was sponsored in part by the Russian Fund for Basic Research under Research Project No. 03-01-00446. The research of R.K. was supported by the Norwegian Research Council under Contract No. 111038/410, through the SYNODE project, and No. 135420/431, through the BeMatA program. (Received 27 November 2002; accepted 15 September 2003)

The *Rusk–Skinner formalism* was developed in order to give a geometrical unified formalism for describing mechanical systems. It incorporates all the characteristics of Lagrangian and Hamiltonian descriptions of these systems (including dynamical equations and solutions, constraints, Legendre map, evolution operators, equivalence, etc.). In this work we extend this unified framework to first-order classical field theories, and show how this description comprises the main features of the Lagrangian and Hamiltonian formalisms, both for the regular and singular cases. This formulation is a first step toward further applications in optimal control theory for partial differential equations. © *2004 American Institute of Physics.*

I. INTRODUCTION

In ordinary autonomous classical theories in mechanics there is a unified formulation of Lagrangian and Hamiltonian formalisms,[1] which is based on the use of the *Whitney sum* of the tangent and cotangent bundles $W=TQ\oplus T^*Q\equiv TQ\times_Q T^*Q$ (the *velocity* and *momentum phase spaces* of the system). In this space, velocities and momenta are independent coordinates. There is a canonical presymplectic form Ω (the pull-back of the canonical form in T^*Q), and a natural *coupling function*, locally expressed as p_iv^i, is defined by contraction between vectors and covectors. Given a Lagrangian $L\in C^\infty(TQ)$, a Hamiltonian function, locally given by $H=p_iv^i-L(q,v)$, is determined, and, using the usual constraint algorithm for the geometric equation $i(X)\Omega=\mathrm{d}H$ associated to the Hamiltonian system (W,Ω,H), we obtain that

(1) The first constraint submanifold W_1 is isomorphic to TQ, and the momenta $\partial L/\partial v^i=p_i$ are determined as constraints.
(2) The geometric equation contains the second order condition $v^i=dq^i/dt$.
(3) The identification $W_1\equiv TQ$ allows us to recover the Lagrangian formalism.
(4) The projection to the cotangent bundle generates the Hamiltonian formalism, including constraints. The Legendre map and the time evolution operator are straightforwardly obtained by the previous identification and projection.[2]

[b)]Electronic mail: jmarin@ub.edu
[c)]Electronic mail: matmcml@mat.upc.es
[d)]Electronic mail: matnrr@mat.upc.es

It is also worth noticing that this space is also appropriate for the formulation of different kinds of problems in optimal control.[3–7] Furthermore, in Refs. 8 and 9 this unified formalism has been extended for nonautonomous mechanical systems.

Our aim in this paper is to reproduce the same construction for first-order field theories, generating a unified description of Lagrangian and Hamiltonian formalisms and its correspondence, starting from the multisymplectic description of such theories. (See, for instance, Refs. 10–18, for some general references on this formalism. See, also, Refs. 19–25, for other geometric formulations of field theories.) As is shown throughout the paper, characteristics analogous to those pointed out for mechanical systems can be stated in this context. In Ref. 9, a first approach to this subject has been made, focusing mainly on the constraint algorithm for the singular case.

The organization of the paper is as follows: Sec. II is devoted to reviewing the main features of the multisymplectic description of Lagrangian and Hamiltonian field theories. In Sec. III we develop the unified formalism for field theories: starting from the *extended jet-multimomentum bundle* (analogous to the Whitney sum in mechanics), we introduce the so-called *extended Hamiltonian system* and state the field equations for sections, *m*-vector fields, connections, and jet fields in this framework. It is also shown how the standard Lagrangian and Hamiltonian descriptions are recovered from this unified picture. As a typical example, the *minimal surface problem* is described in this formalism in Sec. IV. Finally, we include an Appendix where basic features about connections, jet fields, and *m*-vector fields are displayed.

Throughout this paper $\pi:E\to M$ will be a fiber bundle ($\dim M=m$, $\dim E=N+m$), where M is an oriented manifold with volume form $\omega\in\Omega^m(M)$. $\pi^1:J^1E\to E$ is the jet bundle of local sections of π, and $\overline{\pi}^1=\pi\circ\pi^1:J^1E\to M$ gives another fiber bundle structure. $(x^\alpha,y^A,v^A_\alpha)$ will denote natural local systems of coordinates in J^1E, adapted to the bundle $E\to M$ ($\alpha=1,...,m$; $A=1,...,N$), and such that $\omega=\mathrm{d}x^1\wedge\cdots\wedge\mathrm{d}x^m\equiv\mathrm{d}^mx$. Manifolds are real, paracompact, connected, and C^∞. Maps are C^∞. Sum over crossed repeated indices is understood.

II. GEOMETRIC FRAMEWORK FOR CLASSICAL FIELD THEORIES

A. Lagrangian formalism

(For details concerning the contents of this and the next section, see, for instance, Refs. 10–13, 17, 18, and 26–31. See, also, the Appendix).

A *classical field theory* is described by giving a *configuration fiber bundle* $\pi:E\to M$ and a *Lagrangian density*, which is a $\overline{\pi}^1$-semibasic m-form on J^1E usually written as $\mathcal{L}=L\,\overline{\pi}^{1*}\omega$, where $L\in C^\infty(J^1E)$ is the *Lagrangian function* determined by $\mathcal{L}$ and ω. The *Poincaré–Cartan m and* $(m+1)$*-forms* associated with the Lagrangian density $\mathcal{L}$ are defined using the *vertical endomorphism* $\mathcal{V}$ of the bundle J^1E (see Ref. 30)

$$\Theta_{\mathcal{L}}:=i(\mathcal{V})\mathcal{L}+\mathcal{L}\in\Omega^m(J^1E);\qquad \Omega_{\mathcal{L}}:=-\mathrm{d}\Theta_{\mathcal{L}}\in\Omega^{m+1}(J^1E).$$

A *Lagrangian system* is a couple $(J^1E,\Omega_{\mathcal{L}})$. It is *regular* if $\Omega_{\mathcal{L}}$ is a multisymplectic $(m+1)$-form (a closed m-form, $m>1$, is called *multisymplectic* if it is one-nondegenerate; elsewhere it is *pre-multisymplectic*). In natural charts in J^1E we have

$$\mathcal{V}=(\mathrm{d}y^A-v^A_\alpha\mathrm{d}x^\alpha)\otimes\frac{\partial}{\partial v^A_\nu}\otimes\frac{\partial}{\partial x^\nu},$$

and

$$\Theta_{\mathcal{L}}=\frac{\partial L}{\partial v^A_\mu}\mathrm{d}y^A\wedge\mathrm{d}^{m-1}x_\mu-\left(\frac{\partial L}{\partial v^A_\mu}v^A_\mu-L\right)\mathrm{d}^mx,$$

$$\Omega_{\mathcal{L}}=-\frac{\partial^2 L}{\partial v^B_\nu \partial v^A_\alpha}\mathrm{d}v^B_\nu\wedge\mathrm{d}y^A\wedge\mathrm{d}^{m-1}x_\alpha-\frac{\partial^2 L}{\partial y^B\partial v^A_\alpha}\mathrm{d}y^B\wedge\mathrm{d}y^A\wedge\mathrm{d}^{m-1}x_\alpha+\frac{\partial^2 L}{\partial v^B_\nu\partial v^A_\alpha}v^A_\alpha\mathrm{d}v^B_\nu\wedge\mathrm{d}^m x$$
$$+\left(\frac{\partial^2 L}{\partial y^B\partial v^A_\alpha}v^A_\alpha-\frac{\partial L}{\partial y^B}+\frac{\partial^2 L}{\partial x^\alpha\partial v^B_\alpha}\right)\mathrm{d}y^B\wedge\mathrm{d}^m x$$

(where $\mathrm{d}^{m-1}x_\alpha\equiv i(\partial/\partial x^\alpha)\mathrm{d}^m x$); the regularity condition is equivalent to $\det(\partial^2 L/\partial v^A_\alpha\partial v^B_\nu(\overline{y}))\neq 0$, for every $\overline{y}\in J^1E$.

The *Lagrangian problem* associated with a Lagrangian system $(J^1E,\Omega_{\mathcal{L}})$ consists in finding sections $\phi\in\Gamma(M,E)$, the set of sections of π, which are characterized by the condition

$$(j^1\phi)^* i(X)\Omega_L=0,\quad \text{for every } X\in\mathfrak{X}(J^1E).$$

In natural coordinates, if $\phi(x)=(x^\alpha,\phi^A(x))$, this condition is equivalent to demanding that ϕ satisfy the *Euler–Lagrange equations*

$$\left.\frac{\partial L}{\partial y^A}\right|_{j^1\phi}-\left.\frac{\partial}{\partial x^\alpha}\left(\frac{\partial L}{\partial v^A_\alpha}\right)\right|_{j^1\phi}=0\quad(\text{for } A=1,\ldots,N).\tag{1}$$

The problem of finding these sections can be formulated equivalently as follows: finding a distribution D of $T(J^1E)$ such that it is integrable (that is, *involutive*), m-dimensional, $\overline{\pi^1}$-transverse, and the integral manifolds of D are the image of sections solution of the above equations (therefore, lifting of π-sections). This is equivalent to stating that the sections solution to the Lagrangian problem are the integral sections of one of the following equivalent elements:

- A class of holonomic m-vector fields $\{X_{\mathcal{L}}\}\subset\mathfrak{X}^m(J^1E)$, such that $i(X_{\mathcal{L}})\Omega_{\mathcal{L}}=0$, for every $X_{\mathcal{L}}\in\{X_{\mathcal{L}}\}$.
- A holonomic connection $\nabla_{\mathcal{L}}$ in $\overline{\pi^1}:J^1E\to M$ such that $i(\nabla_{\mathcal{L}})\Omega_{\mathcal{L}}=(m-1)\Omega_{\mathcal{L}}$.
- A holonomic jet field $\Psi_{\mathcal{L}}:J^1E\to J^1J^1E$, such that $i(\Psi_{\mathcal{L}})\Omega_{\mathcal{L}}=0$ (the contraction of jet fields with differential forms is defined in Ref. 11).

Semi-holonomic locally decomposable m-vector fields, jet fields, and connections which are solution to these equations are called *Euler–Lagrange m-vector fields, jet fields*, and *connections* for $(J^1E,\Omega_{\mathcal{L}})$. In a natural chart in J^1E, the local expressions of these elements are

$$X_{\mathcal{L}}=f\bigwedge_{\alpha=1}^{m}\left(\frac{\partial}{\partial x^\alpha}+F^A_\alpha\frac{\partial}{\partial y^A}+G^A_{\alpha\nu}\frac{\partial}{\partial v^A_\nu}\right),$$

$$\nabla_{\mathcal{L}}=\mathrm{d}x^\alpha\otimes\left(\frac{\partial}{\partial x^\alpha}+F^A_\alpha\frac{\partial}{\partial y^A}+G^A_{\alpha\nu}\frac{\partial}{\partial v^A_\nu}\right),$$

$$\Psi_{\mathcal{L}}=(x^\alpha,y^A,v^A_\alpha,F^A_\alpha,G^A_{\alpha\eta}),$$

with $F^A_\alpha=v^A_\alpha$ (which is the local expression of the semi-holonomy condition), and where the coefficients $G^A_{\alpha\nu}$ are related by the system of linear equations

$$\frac{\partial^2 L}{\partial v^A_\alpha\partial v^B_\nu}G^A_{\alpha\nu}=\frac{\partial L}{\partial y^B}-\frac{\partial^2 L}{\partial x^\nu\partial v^B_\nu}-\frac{\partial^2 L}{\partial y^A\partial v^B_\nu}v^A_\nu\quad(A,B=1,\ldots,N).\tag{2}$$

$f \in C^\infty(J^1E)$ is an arbitrary nonvanishing function. A representative of the class $\{X_{\mathcal{L}}\}$ can be selected by the condition $i(X_{\mathcal{L}})(\overline{\pi}^1{}^*\omega)=1$, which leads to $f=1$ in the above local expression. Therefore, if $j^1\phi=(x^\mu,\phi^A,\partial\phi^A/\partial x^\nu)$ is an integral section of $X_{\mathcal{L}}$, then $v^A_\alpha=\partial\phi^A/\partial x^\alpha$, and hence, the coefficients $G^B_{\alpha\nu}$ must satisfy the equations

$$G^A_{\nu\eta}\left(x^\alpha,\phi^A,\frac{\partial\phi^A}{\partial x^\alpha}\right)=\frac{\partial^2\phi^A}{\partial x^\eta\partial x^\nu} \quad (A=1,...,N;\quad \eta,\nu=1,...,m).$$

As a consequence, the system (2) is equivalent to the Euler–Lagrange Eq. (1) for ϕ.

If $(J^1E,\Omega_{\mathcal{L}})$ is a regular Lagrangian system, the existence of classes of Euler–Lagrange m-vector fields for $\mathcal{L}$ (or what is equivalent, Euler–Lagrange jet fields or connections) is assured. For singular Lagrangian systems, the existence of this kind of solutions is not assured except perhaps on some submanifold $S\hookrightarrow J^1E$. Furthermore, solutions of the field equations can exist (in general, on some submanifold of J^1E), but none of them are semi-holonomic (at any point of this submanifold). In both cases, the integrability of these solutions is not assured, except perhaps on a smaller submanifold I such that the integral sections are contained in I.

B. Hamiltonian formalism

For the Hamiltonian formalism of field theories, we have the *extended multimomentum bundle* $\mathcal{M}\pi$, which is the bundle of m-forms on E vanishing by contraction with two π-vertical vector fields [or equivalently, the set of affine maps from J^1E to $\pi^*\Lambda^mT^*M$ (Refs. 10 and 32)], and the *restricted multimomentum bundle* $J^1{}^*E\equiv\mathcal{M}\pi/\pi^*\Lambda^mT^*M$. We have the natural projections

$$\tau^1:J^1{}^*E\to E,\quad \overline{\tau}^1=\pi\circ\tau^1:J^1{}^*E\to M,\quad \mu:\mathcal{M}\pi\to J^1{}^*E,\quad \hat{\mu}=\overline{\tau}^1\circ\mu:\mathcal{M}\pi\to M.$$

Given a system of coordinates adapted to the bundle $\pi:E\to M$, we can construct natural coordinates $(x^\alpha,y^A,p^\alpha_A,p)$ $(\alpha=1,...,m;\ A=1,...,N)$ in $\mathcal{M}\pi$, corresponding to the m-covector $\mathbf{p}=p\,\mathrm{d}^mx+p^\alpha_A\mathrm{d}y^A\wedge\mathrm{d}^{m-1}x_\alpha\in\mathcal{M}\pi$, and $(x^\alpha,y^A,p^\alpha_A)$ in $J^1{}^*E$, for the class $[\mathbf{p}]=p^\alpha_A\mathrm{d}y^A\wedge\mathrm{d}^{m-1}x_\alpha+\langle\mathrm{d}^mx\rangle\in J^1{}^*E$.

Now, if $(J^1E,\Omega_{\mathcal{L}})$ is a Lagrangian system, the *extended Legendre map* associated with $\mathcal{L}$, $\widetilde{\mathcal{FL}}:J^1E\to\mathcal{M}\pi$, is defined as

$$[\widetilde{\mathcal{FL}}(\overline{y})](Z_1,\ldots,Z_m):=(\Theta_{\mathcal{L}})_{\overline{y}}(\overline{Z}_1,\ldots,\overline{Z}_m), \tag{3}$$

where $Z_1,\ldots,Z_m\in T_{\pi^1(\overline{y})}E$, and $\overline{Z}_1,\ldots,\overline{Z}_m\in T_{\overline{y}}J^1E$ are such that $T_{\overline{y}}\pi^1\overline{Z}_\alpha=Z_\alpha$. Then the *restricted Legendre map* associated with $\mathcal{L}$ is $\mathcal{FL}:=\mu\circ\widetilde{\mathcal{FL}}$. Their local expressions are

$$\widetilde{\mathcal{FL}}{}^*x^\alpha=x^\alpha,\quad \widetilde{\mathcal{FL}}{}^*y^A=y^A,\quad \widetilde{\mathcal{FL}}{}^*p^\alpha_A=\frac{\partial L}{\partial v^A_\alpha},\quad \widetilde{\mathcal{FL}}{}^*p=L-v^A_\alpha\frac{\partial L}{\partial v^A_\alpha},$$

$$\mathcal{FL}^*x^\alpha=x^\alpha,\quad \mathcal{FL}^*y^A=y^A,\quad \mathcal{FL}^*p^\alpha_A=\frac{\partial L}{\partial v^A_\alpha}.$$

Therefore, $(J^1E,\Omega_{\mathcal{L}})$ is a *regular* Lagrangian system if $\mathcal{FL}$ is a local diffeomorphism (this definition is equivalent to that given above). Elsewhere $(J^1E,\Omega_{\mathcal{L}})$ is a *singular* Lagrangian system. As a particular case, $(J^1E,\Omega_{\mathcal{L}})$ is a *hyper-regular* Lagrangian system if $\mathcal{FL}$ is a global diffeomorphism. A singular Lagrangian system $(J^1E,\Omega_{\mathcal{L}})$ is *almost-regular* if: $\mathcal{P}:=\mathcal{FL}(J^1E)$ is a closed submanifold of $J^1{}^*E$ (we will denote the natural imbedding by $j:\mathcal{P}\hookrightarrow J^1{}^*E$), $\mathcal{FL}$ is a submersion onto its image, and for every $\overline{y}\in J^1E$, the fibres $\mathcal{FL}^{-1}(\mathcal{FL}(\overline{y}))$ are connected submanifolds of J^1E.

In order to construct a *Hamiltonian system* associated with $(J^1E,\Omega_{\mathcal{L}})$, recall that the multicotangent bundle Λ^mT^*E is endowed with a natural canonical form $\mathbf{\Theta}\in\Omega^m(\Lambda^mT^*E)$, which is

the tautological form defined as follows: let $\tau_E : T^*E \to E$ be the natural projection, and $\Lambda^m \tau_E : \Lambda^m T^*E \to E$ its natural extension; then, for every $\overline{\mathbf{p}} \in \Lambda^m T^*E$ (where $\overline{\mathbf{p}} = (y, \beta)$, with $y \in E$ and $\beta \in \Lambda^m T^*_y E$), and for every $X_1, \ldots, X_m \in \mathfrak{X}(\Lambda^m T^*E)$ we have

$$[\mathbf{\Theta}(X_1, \ldots, X_m)]_{\overline{\mathbf{p}}} := [(\Lambda^m \tau_E)^* \beta](X_{1_{\overline{\mathbf{p}}}}, \ldots, X_{m_{\overline{\mathbf{p}}}}) = \beta(T_{\overline{\mathbf{p}}} \Lambda^m \tau_E(X_{1_{\overline{\mathbf{p}}}}), \ldots, T_{\overline{\mathbf{p}}} \Lambda^m \tau_E(X_{m_{\overline{\mathbf{p}}}})).$$

Thus we also have the multisymplectic form $\mathbf{\Omega} := -\mathrm{d}\mathbf{\Theta} \in \Omega^{m+1}(\Lambda^m T^*E)$. But $\mathcal{M}\pi \equiv \Lambda^m_1 T^*E$ is a subbundle of $\Lambda^m T^*E$. Then, if $\lambda : \Lambda^m_1 T^*E \hookrightarrow \Lambda^m T^*E$ is the natural imbedding, $\Theta := \lambda^* \mathbf{\Theta}$ and $\Omega := -\mathrm{d}\Theta = \lambda^* \mathbf{\Omega}$ are canonical forms in $\mathcal{M}\pi$, which are called the *multimomentum Liouville m* and $(m+1)$ *forms*. In particular, we have that $\Theta(\mathbf{p}) = (\tau_1 \circ \mu)^* \mathbf{p}$, for every $\mathbf{p} \in \mathcal{M}\pi$. Their local expressions are

$$\Theta = p^\alpha_A \mathrm{d}y^A \wedge \mathrm{d}^{m-1} x_\alpha + p\, \mathrm{d}^m x, \quad \Omega = -\mathrm{d}p^\alpha_A \wedge \mathrm{d}y^A \wedge \mathrm{d}^{m-1} x_\alpha - \mathrm{d}p \wedge \mathrm{d}^m x. \tag{4}$$

Observe that $\widetilde{\mathcal{FL}}^* \Theta = \Theta_{\mathcal{L}}$, and $\widetilde{\mathcal{FL}}^* \Omega = \Omega_{\mathcal{L}}$.

Now, if $(J^1E, \Omega_{\mathcal{L}})$ is a hyper-regular Lagrangian system, then $\widetilde{\mathcal{P}} := \widetilde{\mathcal{FL}}(J^1E)$ is a one-codimensional and μ-transverse imbedded submanifold of $\mathcal{M}\pi$ (we will denote the natural imbedding by $\widetilde{\jmath} : \widetilde{\mathcal{P}} \hookrightarrow \mathcal{M}\pi$), which is diffeomorphic to $J^1{}^*E$. This diffeomorphism is μ^{-1}, when μ is restricted to $\widetilde{\mathcal{P}}$, and also coincides with the map $h := \widetilde{\mathcal{FL}} \circ \mathcal{FL}^{-1}$, when it is restricted onto its image (which is just $\widetilde{\mathcal{P}}$). This map h is called a *Hamiltonian section*, and can be used to construct the *Hamilton-Cartan m* and $(m+1)$ *forms* of $J^1{}^*E$ by making

$$\Theta_h = h^* \Theta \in \Omega^m(J^1{}^*E), \quad \Omega_h = h^* \Omega \in \Omega^{m+1}(J^1{}^*E).$$

The couple $(J^1{}^*E, \Omega_h)$ is said to be the *Hamiltonian system* associated with the hyper-regular Lagrangian system $(J^1E, \Omega_{\mathcal{L}})$. Locally, the Hamiltonian section h is specified by the *local Hamiltonian function* $H = p^\alpha_A (F\mathcal{L}^{-1})^* v^A_\alpha - (F\mathcal{L}^{-1})^* L$, that is, $h(x^\alpha, y^A, p^\alpha_A) = (x^\alpha, y^A, p^\alpha_A, -H)$. Then we have the local expressions

$$\Theta_h = p^\alpha_A \mathrm{d}y^A \wedge \mathrm{d}^{m-1} x_\alpha - H \mathrm{d}^m x, \quad \Omega_h = -\mathrm{d}p^\alpha_A \wedge \mathrm{d}y^A \wedge \mathrm{d}^{m-1} x_\alpha + \mathrm{d}H \wedge \mathrm{d}^m x.$$

Of course $\mathcal{FL}^* \Theta_h = \Theta_{\mathcal{L}}$ and $\mathcal{FL}^* \Omega_h = \Omega_{\mathcal{L}}$.

The *Hamiltonian problem* associated with the Hamiltonian system $(J^1{}^*E, \Omega_h)$ consists in finding sections $\psi \in \Gamma(M, J^1{}^*E)$, which are characterized by the condition

$$\psi^* i(X) \Omega_h = 0, \quad \text{for every } X \in \mathfrak{X}(J^1{}^*E).$$

In natural coordinates, if $\psi(x) = (x^\alpha, y^A(x), p^\alpha_A(x))$, this condition leads to the so-called *Hamilton–De Donder–Weyl equations* (for the section ψ).

The problem of finding these sections can be formulated equivalently as follows: finding a distribution D of $T(J^1{}^*E)$ such that D is integrable (that is, *involutive*), m-dimensional, $\overline{\tau}^1$-transverse, and its integral manifolds are the sections solution to the above equations. This is equivalent to stating that the sections solution to the Hamiltonian problem are the integral sections of one of the following equivalent elements:

- A class of integrable and $\overline{\tau}^1$-transverse m-vector fields $\{X_{\mathcal{H}}\} \subset \mathfrak{X}^m(J^1{}^*E)$ satisfying that $i(X_{\mathcal{H}})\Omega_h = 0$, for every $X_{\mathcal{H}} \in \{X_{\mathcal{H}}\}$.
- An integrable connection $\nabla_{\mathcal{H}}$ in $\overline{\tau}^1 : J^1{}^*E \to M$ such that $i(\nabla_{\mathcal{H}})\Omega_h = (m-1)\Omega_h$.
- An integrable jet field $\Psi_{\mathcal{H}} : J^1{}^*E \to J^1 J^1{}^*E$, such that $i(\Psi_{\mathcal{H}})\Omega_h = 0$.

$\overline{\tau}^1$-transverse and locally decomposable m-vector fields, orientable jet fields, and orientable connections, which are solutions of these equations, are called *Hamilton–De Donder–Weyl (HDW) m-vector fields, jet fields*, and *connections* for $(J^1{}^*E, \Omega_h)$. Their local expressions in natural coordinates are

$$X_{\mathcal{H}}=f\bigwedge_{\alpha=1}^{m}\left(\frac{\partial}{\partial x^{\alpha}}+F_{\alpha}^{A}\frac{\partial}{\partial y^{A}}+G_{A\alpha}^{\eta}\frac{\partial}{\partial p_{A}^{\eta}}\right),$$

$$\Psi_{\mathcal{H}}=(x^{\alpha},y^{A},p_{A}^{\alpha};F_{\alpha}^{A},G_{A\alpha}^{\eta}),$$

$$\nabla_{\mathcal{H}}=\mathrm{d}x^{\alpha}\otimes\left(\frac{\partial}{\partial x^{\alpha}}+F_{\alpha}^{A}\frac{\partial}{\partial y^{A}}+G_{A\alpha}^{\nu}\frac{\partial}{\partial p_{A}^{\nu}}\right),$$

where $f\in C^{\infty}(J^{1}{}^{*}E)$ is a nonvanishing function, and the coefficients F_{α}^{A}, $G_{A\alpha}^{\eta}$ are related by the system of linear equations

$$F_{\alpha}^{A}=\frac{\partial H}{\partial p_{A}^{\alpha}},\quad G_{A\nu}^{\nu}=-\frac{\partial H}{\partial y^{A}}.$$

Now, if $\psi(x)=(x^{\alpha},y^{A}(x)=\psi^{A}(x),p_{A}^{\alpha}(x)=\psi_{A}^{\alpha}(x))$ is an integral section of $X_{\mathcal{H}}$ then

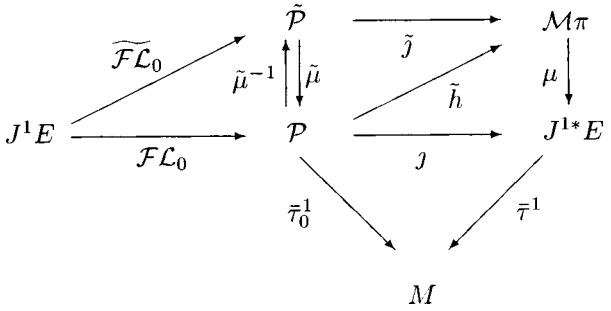
$$\left.\frac{\partial H}{\partial p_{A}^{\alpha}}\right|_{\psi}=F_{\alpha}^{A}\circ\psi=\frac{\partial\psi^{A}}{\partial x_{\alpha}};\quad -\left.\frac{\partial H}{\partial y^{A}}\right|_{\psi}=G_{A\alpha}^{\alpha}\circ\psi=\frac{\partial\psi_{A}^{\alpha}}{\partial x^{\alpha}},$$

which are the Hamilton–De Donder–Weyl equations for ψ. As above, a representative of the class $\{X_{\mathcal{H}}\}$ can be selected by the condition $i(X_{\mathcal{H}})(\overline{\tau}^{1}{}^{*}\omega)=1$, which leads to $f=1$ in the above local expression. The existence of classes of HDW m-vector fields, jet fields, and connections is assured.

In an analogous way, if $(J^{1}E,\Omega_{\mathcal{L}})$ is an almost-regular Lagrangian system, the submanifold $j:\mathcal{P}\hookrightarrow J^{1}{}^{*}E$, is a fiber bundle over E and M. In this case the μ-transverse submanifold $\tilde{\mathcal{P}}\hookrightarrow\mathcal{M}\pi$ is diffeomorphic to $\mathcal{P}$. This diffeomorphism is denoted by $\tilde{\mu}:\tilde{\mathcal{P}}\to\mathcal{P}$, and it is just the restriction of the projection μ to $\tilde{\mathcal{P}}$. Then, taking the Hamiltonian section $\tilde{h}:=\tilde{j}\circ\tilde{\mu}^{-1}$, we define the Hamilton–Cartan forms

$$\Theta_{h}^{0}=\tilde{h}^{*}\Theta;\quad \Omega_{h}^{0}=\tilde{h}^{*}\Omega,$$

which verify that $\mathcal{FL}_{0}^{*}\Theta_{h}^{0}=\Theta_{\mathcal{L}}$ and $\mathcal{FL}_{0}^{*}\Theta_{h}^{0}=\Omega_{\mathcal{L}}$ (where $\mathcal{FL}_{0}$ is the restriction map of $\mathcal{FL}$ onto $\mathcal{P}$). Then $(\mathcal{P},\Omega_{h}^{0})$ is the *Hamiltonian system* associated with the almost-regular Lagrangian system $(J^{1}E,\Omega_{\mathcal{L}})$, and we have Diagram 1.



(5)

Then, the *Hamiltonian problem* associated with the Hamiltonian system $(\mathcal{P},\Omega_{h}^{0})$, and the equations for the sections of $\Gamma(M,\mathcal{P})$ solution to the Hamiltonian problem are stated as in the regular case. Now, the existence of the corresponding Hamilton–De Donder–Weyl m-vector fields, jet fields, and connections for $(\mathcal{P},\Omega_{h}^{0})$ is not assured, except perhaps on some submanifold P of $\mathcal{P}$, where the solution is not unique.

From now on we will consider only regular or almost-regular systems.

III. UNIFIED FORMALISM

A. Extended Hamiltonian system

Given a fiber bundle $\pi:E\to M$ over an oriented manifold (M,ω), we define the *extended jet-multimomentum bundle* $\mathcal{W}$ and the *restricted jet-multimomentum bundle* $\mathcal{W}_r$ as

$$\mathcal{W}:=J^1E\times_E\mathcal{M}\pi,\quad \mathcal{W}_r:=J^1E\times_E J^1{}^*E,$$

whose natural coordinates are $(x^\alpha,y^A,v^A_\alpha,p^\alpha_A,p)$ and $(x^\alpha,y^A,v^A_\alpha,p^\alpha_A)$, respectively. We have the natural projections (submersions)

$$\begin{gathered}\rho_1:\mathcal{W}\to J^1E,\quad \rho_2:\mathcal{W}\to\mathcal{M}\pi,\quad \rho_E:\mathcal{W}\to E,\quad \rho_M:\mathcal{W}\to M,\\ \rho_1^r:\mathcal{W}_r\to J^1E,\quad \rho_2^r:\mathcal{W}_r\to J^1{}^*E,\quad \rho_E^r:\mathcal{W}_r\to E,\quad \rho_M^r:\mathcal{W}_r\to M.\end{gathered}\tag{6}$$

Note that $\pi^1\circ\rho_1=\tau^1\circ\mu\circ\rho_2=\rho_E$. In addition, there is also the natural projection

$$\mu_{\mathcal{W}}:\mathcal{W}\to\mathcal{W}_r,$$

$$(\overline{y},\mathbf{p})\mapsto(\overline{y},[\mathbf{p}]).$$

The bundle $\mathcal{W}$ is endowed with the following canonical structures:

Definition 1:

(1) *The* coupling *m*-form *in* $\mathcal{W}$, *denoted by* $\mathcal{C}$, *is an m-form along* ρ_M *which is defined as follows: for every* $\overline{y}\in J^1_yE$, *with* $\overline{\pi^1}(\overline{y})=\pi(y)=x\in E$, *and* $\mathbf{p}\in\mathcal{M}_y\pi$, *let* $w\equiv(\overline{y},\mathbf{p})\in\mathcal{W}_y$, *then*

$$\mathcal{C}(w):=(T_x\phi)^*\mathbf{p},$$

where $\phi:M\to E$ *satisfies that* $j^1\phi(x)=\overline{y}$.

Then, we denote by $\hat{\mathcal{C}}\in\Omega^m(\mathcal{W})$ *the* ρ_M*-semibasic form associated with* $\mathcal{C}$.

(2) *The* canonical *m*-form $\Theta_{\mathcal{W}}\in\Omega^m(\mathcal{W})$ *is defined by* $\Theta_{\mathcal{W}}:=\rho_2^*\Theta$, *and it is therefore* ρ_E*-semibasic*.

The canonical $(m+1)$-form *is the pre-multisymplectic form* $\Omega_{\mathcal{W}}:=-\mathrm{d}\Theta_{\mathcal{W}}=\rho_1^*\Omega\in\Omega^{m+1}(\mathcal{W})$.

Being $\hat{\mathcal{C}}$ a ρ_M-semibasic form, there is $\hat{C}\in C^\infty(\mathcal{W})$ such that $\hat{\mathcal{C}}=\hat{C}(\rho_M^*\omega)$. Note also that $\Omega_{\mathcal{W}}$ is not one-nondegenerate, its kernel being the ρ_2-vertical vectors; then, we call $(\mathcal{W},\Omega_{\mathcal{W}})$ a pre-multisymplectic structure. This definition of the coupling form is in fact an alternative (obviously equivalent) presentation of the extended multimomentum bundle as the set of affine maps from the jet bundle J^1E to π-basic *m*-forms.

The local expressions for $\Theta_{\mathcal{W}}$ and $\Omega_{\mathcal{W}}$ are the same as (4), and for $\hat{\mathcal{C}}$ we have

$$\hat{\mathcal{C}}(w)=(p+p^\alpha_Av^A_\alpha)\mathrm{d}^mx.$$

Given a Lagrangian density $\mathcal{L}\in\Omega^m(J^1E)$, we denote $\hat{\mathcal{L}}:=\rho_1^*\mathcal{L}\in\Omega^m(\mathcal{W})$, and we can write $\hat{\mathcal{L}}=\hat{L}(\rho_M^*\omega)$, with $\hat{L}=\rho_1^*L\in C^\infty(\mathcal{W})$. We define a *Hamiltonian submanifold*

$$\mathcal{W}_0:=\{w\in\mathcal{W}\,|\,\hat{\mathcal{L}}(w)=\hat{\mathcal{C}}(w)\}.$$

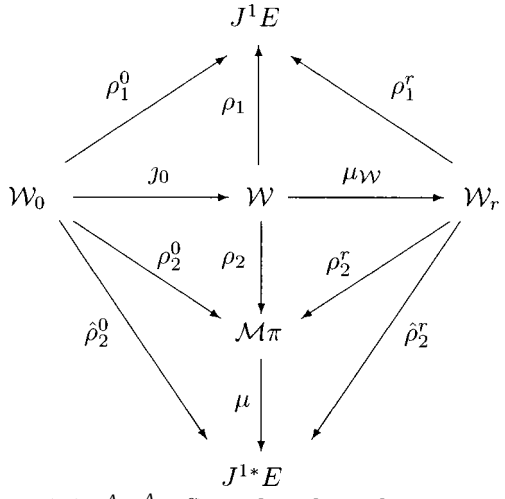
So, $\mathcal{W}_0$ is the submanifold of $\mathcal{W}$ defined by the constraint function $\hat{C}-\hat{L}=0$. In local coordinates this constraint function is

$$p+p^\alpha_Av^A_\alpha-\hat{L}(x^\nu,y^B,v^B_\nu)=0.$$

We have the natural imbedding $J_0:\mathcal{W}_0\hookrightarrow\mathcal{W}$, as well as the projections (submersions)

$$\rho_1^0:\mathcal{W}_0\to J^1E,\quad \rho_2^0:\mathcal{W}_0\to\mathcal{M}\pi,\quad \rho_E^0:\mathcal{W}_0\to E,\quad \rho_M^0:\mathcal{W}_0\to M,$$

which are the restrictions to $\mathcal{W}_0$ of the projections (6), and $\hat{\rho}_2^0=\mu\circ\rho_2^0:\mathcal{W}_0\to J^{1*}E$. So we have Diagram 2.



Local coordinates in $\mathcal{W}_0$ are $(x^\alpha,y^A,v^A_\alpha,p^\alpha_A)$, and we have that

$$\rho_1^0(x^\alpha,y^A,v^A_\alpha,p^\alpha_A)=(x^\alpha,y^A,v^A_\alpha),$$

$$J_0(x^\alpha,y^A,v^A_\alpha,p^\alpha_A)=(x^\alpha,y^A,v^A_\alpha,p^\alpha_A,L-v^A_\alpha p^\alpha_A),$$

$$\rho_2^0(x^\alpha,y^A,v^A_\alpha,p^\alpha_A)=(x^\alpha,y^A,p^\alpha_A,L-v^A_\alpha p^\alpha_A),$$

$$\hat{\rho}_2^0(x^\alpha,y^A,v^A_\alpha,p^\alpha_A)=(x^\alpha,y^A,p^\alpha_A).$$

Proposition 1: $\mathcal{W}_0$ is a one-codimensional $\mu_{\mathcal{W}}$-transversal submanifold of $\mathcal{W}$, diffeomorphic to $\mathcal{W}_r$.

(*Proof*) For every $(\overline{y},\mathbf{p})\in\mathcal{W}_0$, we have $L(\overline{y})\equiv\hat{L}(\overline{y},\mathbf{p})=\hat{C}(\overline{y},\mathbf{p})$,

and

$$(\mu_{\mathcal{W}}\circ J_0)(\overline{y},\mathbf{p})=\mu_{\mathcal{W}}(\overline{y},\mathbf{p})=(\overline{y},\mu(\mathbf{p}))=(\overline{y},[\mathbf{p}]).$$

First, $\mu_{\mathcal{W}}\circ J_0$ is injective: let $(\overline{y}_1,\mathbf{p}_1)$, $(\overline{y}_2,\mathbf{p}_2)\in\mathcal{W}_0$, then we have

$$(\mu_{\mathcal{W}}\circ J_0)(\overline{y}_1,\mathbf{p}_1)=(\mu_{\mathcal{W}}\circ J_0)(\overline{y}_2,\mathbf{p}_2)\Rightarrow(\overline{y}_1,\mu(\mathbf{p}_1))=(\overline{y}_2,\mu(\mathbf{p}_2))\Rightarrow\overline{y}_1=\overline{y}_2,\mu(\mathbf{p}_1)=\mu(\mathbf{p}_2),$$

hence,

$$L(\overline{y}_1)=L(\overline{y}_2)=\hat{C}(\overline{y}_1,\mathbf{p}_1)=\hat{C}(\overline{y}_2,\mathbf{p}_2).$$

In a local chart, third equality gives

$$p(\mathbf{p}_1)+p^\alpha_A(\mathbf{p}_1)v^A_\alpha(\overline{y}_1)=p(\mathbf{p}_2)+p^\alpha_A(\mathbf{p}_2)v^A_\alpha(\overline{y}_2),$$

but $\mu(\mathbf{p}_1)=\mu(\mathbf{p}_2)$ implies that

$$p_A^\alpha(\mathbf{p}_1)=p_A^\alpha([\mathbf{p}_1])=p_A^\alpha([\mathbf{p}_2])=p_A^\alpha(\mathbf{p}_2),$$

therefore, $p(\mathbf{p}_1)=p(\mathbf{p}_2)$, and hence, $\mathbf{p}_1=\mathbf{p}_2$.

Second, $\mu_{\mathcal{W}}\circ J_0$ is onto: Let $(\overline{y},\mathbf{p})\in\mathcal{W}_r$, then there exists $(\overline{y},\mathbf{q})\in J_0(\mathcal{W}_0)$ such that $[\mathbf{q}]=[\mathbf{p}]$. In fact, it suffices to take $[\mathbf{q}]$ in such a way that, in a local chart of $J^1E\times_E\mathcal{M}\pi=\mathcal{W}$

$$p_A^\alpha(\mathbf{q})=p_A^\alpha([\mathbf{p}]),\quad p(\mathbf{q})=p_A^\alpha([\mathbf{p}])v_\alpha^A(\overline{y})-L(\overline{y}).$$

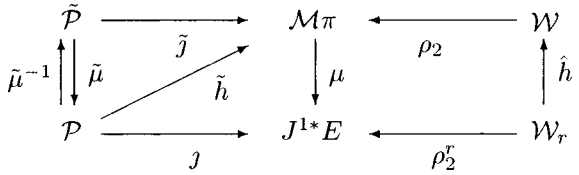
Finally, observe that $\mathcal{W}_0$ is defined by the constraint function $\hat{L}-\hat{C}$ and, as $\ker\mu_{\mathcal{W}*}=\{\partial/\partial p\}$ and $\partial/\partial p(\hat{L}-\hat{C})=1$, then $\mathcal{W}_0$ is a 1-codimensional submanifold of $\mathcal{W}$ and $\mu_{\mathcal{W}}$-transversal. ■

As a consequence of this property, the submanifold $\mathcal{W}_0$ induces a section $\hat{h}:\mathcal{W}_r\to\mathcal{W}$ of the projection $\mu_{\mathcal{W}}$. Locally, $\hat{h}$ is specified by giving the local *Hamiltonian function* $\hat{H}=-\hat{L}+p_A^\alpha v_\alpha^A$; that is, $\hat{h}(x^\alpha,y^A,v_\alpha^A,p_A^\alpha)=(x^\alpha,y^A,v_\alpha^A,p_A^\alpha,-\hat{H})$. In this sense, $\hat{h}$ is said to be a *Hamiltonian section* of $\mu_{\mathcal{W}}$.

Remark: It is important to point out that, from every Hamiltonian $\mu_{\mathcal{W}}$-section $\hat{h}:\mathcal{W}_r\to\mathcal{W}$ in the extended unified formalism, we can recover a Hamiltonian μ-section $h:\mathcal{P}\to\mathcal{M}\pi$ in the standard Hamiltonian formalism. In fact, given $[\mathbf{p}]\in J^{1*}E$, the section $\hat{h}$ maps every point $(\overline{y},[\mathbf{p}])\in(\rho_2^r)^{-1}([\mathbf{p}])$ into $\rho_2^{-1}[\rho_2(\hat{h}(\overline{y},[\mathbf{p}]))]$. So, the crucial point is the projectability of the local function $\hat{H}$ by ρ_2. But, being $\partial/\partial v_\alpha^A$ a local basis for $\ker\rho_{2*}$, $\hat{H}$ is ρ_2-projectable if, and only if, $p_A^\alpha=\partial L/\partial v_A^\alpha$, and this condition is fulfilled when $[\mathbf{p}]\in\mathcal{P}=\operatorname{Im}\mathcal{FL}\subset J^{1*}E$, which implies that $\rho_2[\hat{h}(\rho_2^r)^{-1})([\mathbf{p}]))]\in\widetilde{\mathcal{P}}=\operatorname{Im}\mathcal{FL}\subset\mathcal{M}\pi$. Hence, the Hamiltonian section $\tilde{h}$ is defined as follows:

$$\overline{h([\mathbf{p}])}=(\rho_2\circ\hat{h})[(\rho_2^r)^{-1}(J([\mathbf{p}]))],\quad\text{for every } [\mathbf{p}]\in\mathcal{P}.$$

So we have Diagram 3 (see also Diagram 1).



(For (hyper) regular systems this diagram is the same with $\operatorname{Im}\mathcal{FL}=J^{1*}E$.)

Finally, we can define the forms

$$\Theta_0:=j_0^*\Theta_{\mathcal{W}}=\rho_2^{0*}\Theta\in\Omega^m(\mathcal{W}_0),\quad\Omega_0:=j_0^*\Omega_{\mathcal{W}}=\rho_2^{0*}\Omega\in\Omega^{m+1}(\mathcal{W}_0),$$

with local expressions

$$\begin{aligned}\Theta_0&=(L-p_A^\alpha v_\alpha^A)\mathrm{d}^mx+p_A^\alpha\mathrm{d}y^A\wedge\mathrm{d}^{m-1}x_\alpha,\\ \Omega_0&=\mathrm{d}(p_A^\alpha v_\alpha^A-L)\wedge\mathrm{d}^mx-\mathrm{d}p_A^\alpha\wedge\mathrm{d}y^A\wedge\mathrm{d}^{m-1}x_\alpha,\end{aligned}\tag{7}$$

and we have obtained a (pre-multisymplectic) Hamiltonian system $(\mathcal{W}_0,\Omega_0)$, or equivalently $(\mathcal{W}_r,\hat{h}^*\Omega_{\mathcal{W}})$.

B. Field equations for sections

The *Lagrange-Hamiltonian problem* associated with the system $(\mathcal{W}_0,\Omega_0)$ consists in finding sections $\psi_0\in\Gamma(M,\mathcal{W}_0)$ which are characterized by the condition

$$\psi_0^*i(Y_0)\Omega_0=0,\quad\text{for every } Y_0\in\mathfrak{X}(\mathcal{W}_0).\tag{8}$$

This equation gives different kinds of information, depending on the type of the vector fields Y_0 involved. In particular, using vector fields Y_0 which are $\hat{\rho}_2^0$-vertical, we have:

Lemma 1: If $Y_0 \in \mathfrak{X}^{V(\hat{\rho}_2^0)}(\mathcal{W}_0)$ (i.e., Y_0 is $\hat{\rho}_2^0$-vertical), then $i(Y_0)\Omega_0$ is ρ_M^0-semibasic.

(*Proof*) A simple calculation in coordinates leads to this result. In fact, taking $\{\partial/\partial v_\alpha^A\}$ as a local basis for the $\hat{\rho}_2^0$-vertical vector fields, and bearing in mind (7) we obtain

$$i\left(\frac{\partial}{\partial v_\alpha^A}\right)\Omega_0 = \left(p_A^\alpha - \frac{\partial L}{\partial v_\alpha^A}\right)\mathrm{d}^m x,$$

which are obviously ρ_M^0-semibasic forms. ■

As an immediate consequence, when $Y_0 \in \mathfrak{X}^{V(\hat{\rho}_2^0)}(\mathcal{W}_0)$, condition (8) does not depend on the derivatives of ψ_0: is a pointwise (algebraic) condition. We can define the submanifold

$$\mathcal{W}_1 = \{(\overline{y},\mathbf{p}) \in \mathcal{W}_0 \,|\, i(V_0)(\Omega_0)_{(\overline{y},\mathbf{p})} = 0, \quad \text{for every} \quad V_0 \in V(\hat{\rho}_2^0)\},$$

which is called the *first constraint submanifold* of the Hamiltonian pre-multisymplectic system $(\mathcal{W}_0,\Omega_0)$, as every section ψ_0 solution to (8) must take values in $\mathcal{W}_1$. We denote by $j_1 : \mathcal{W}_1 \hookrightarrow \mathcal{W}_0$ the natural embedding.

Locally, $\mathcal{W}_1$ is defined in $\mathcal{W}_0$ by the constraints $p_A^\alpha = \partial L/\partial v_\alpha^A$. Moreover:

Proposition 2: $\mathcal{W}_1$ is the graph of $\widetilde{\mathcal{FL}}$; that is, $\mathcal{W}_1 = \{(\overline{y},\widetilde{\mathcal{FL}}(\overline{y})) \in \mathcal{W} | \overline{y} \in J^1E\}$.

(*Proof*) Consider $\overline{y} \in J^1E$, let $\phi : M \to E$ be a representative of $\overline{y}$, and $\mathbf{p} = \widetilde{\mathcal{FL}}(\overline{y})$. For every $U \in T_{\overline{\pi^1}(\overline{y})}M$, consider $V = T_{\overline{\pi^1}(\overline{y})}\phi(U)$ and its canonical lifting $\overline{V} = T_{\overline{\pi^1}(\overline{y})}j^1\phi(U)$. From the definition of the extended Legendre map (3) we have that $(T_{\overline{y}}\pi)^*(\widetilde{\mathcal{FL}}(\overline{y})) = (\Theta_{\mathcal{L}})_{\overline{y}}$, then

$$i(\overline{V})[(T_{\overline{y}}\pi^1)^*(\widetilde{\mathcal{FL}}(\overline{y}))] = i(\overline{V})(\Theta_{\mathcal{L}})_{\overline{y}}.$$

Furthermore, as $\mathbf{p} = \widetilde{\mathcal{FL}}(\overline{y})$, we also have that

$$\begin{aligned} i(\overline{V})[(T_{\overline{y}}\pi^1)^*(\widetilde{\mathcal{FL}}(\overline{y}))] &= i(T_{\overline{\pi^1}(\overline{y})}j^1\phi(U))[(T_{\overline{y}}\pi^1)^*\mathbf{p}) \\ &= i(T_{\pi^1(\overline{y})}[(T_{\overline{\pi^1}(\overline{y})}j^1\phi(U)])\mathbf{p} = i(T_{\overline{\pi^1}(\overline{y})}\phi(U))\mathbf{p} = i(V)\mathbf{p}. \end{aligned}$$

Therefore, we obtain

$$i(U)(\phi^*\mathbf{p}) = i(U)[(j^1\phi)^*(\Theta_{\mathcal{L}})_{\overline{y}}],$$

and bearing in mind the definition of the coupling form $\mathcal{C}$, this condition becomes

$$i(U)(\mathcal{C}(\overline{y},\mathbf{p})) = i(U)[(j^1\phi)^*\Theta_{\mathcal{L}})_{\overline{y}}].$$

Since it holds for every $U \in T_{\overline{\pi^1}(\overline{y})}M$, we conclude that $\mathcal{C}(\overline{y},\mathbf{p}) = [(j^1\phi)^*\Theta_{\mathcal{L}}]_{\overline{y}}$, or equivalently, $\hat{\mathcal{C}}(\overline{y},\mathbf{p}) = \hat{L}(\overline{y},\mathbf{p})$, where we have made use of the fact that $\Theta_{\mathcal{L}}$ is the sum of the Lagrangian density $\mathcal{L}$ and a contact form $i(\mathcal{V})\mathcal{L}$ (vanishing by pull-back of lifted sections). This is the condition defining $\mathcal{W}_0$, and thus we have proved that $(\overline{y},\widetilde{\mathcal{FL}}(\overline{y})) \in \mathcal{W}_0$, for every $\overline{y} \in J^1E$; that is, graph $\widetilde{\mathcal{FL}} \subset \mathcal{W}_0$. Furthermore, graph $\mathcal{FL}$ and $\mathcal{W}_1$ are defined as subsets of $\mathcal{W}_0$ by the same local conditions: $p_A^\alpha - \partial L/\partial v_\alpha^A = 0$. So we conclude that graph $\widetilde{\mathcal{FL}} = \mathcal{W}_1$. ■

Being $\mathcal{W}_1$ the graph of $\mathcal{FL}$, it is diffeomorphic to J^1E. Every section $\psi_0 : M \to \mathcal{W}_0$ is of the form $\psi_0 = (\psi_{\mathcal{L}},\psi_{\mathcal{H}})$, with $\psi_{\mathcal{L}} = \rho_1^0 \circ \psi_0 : M \to J^1E$, and if ψ_0 takes values in $\mathcal{W}_1$ then $\psi_{\mathcal{H}} = \widetilde{\mathcal{FL}} \circ \psi_{\mathcal{L}}$. In this way, every constraint, differential equation, etc., in the unified formalism can be translated to the Lagrangian or the Hamiltonian formalisms by restriction to the first or the second factors of the product bundle.

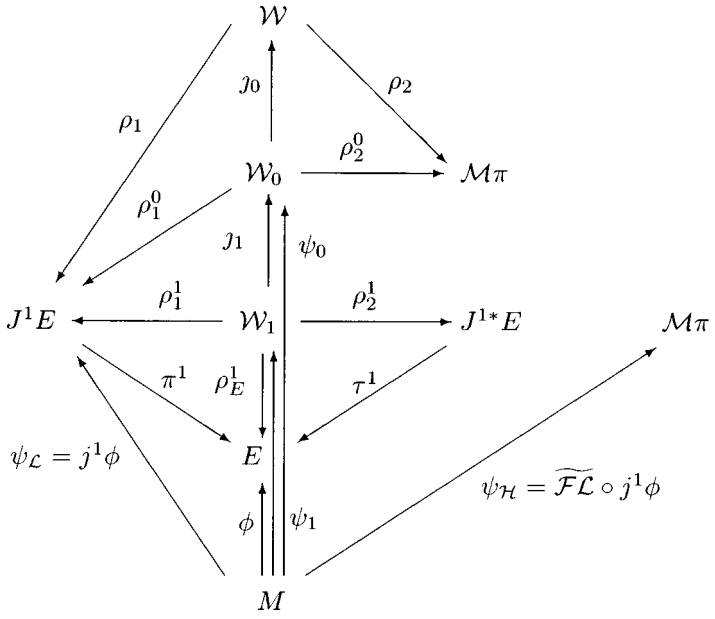
However, as was pointed out before, the geometric condition (8) in $\mathcal{W}_0$, which can be solved only for sections $\psi_0 : M \to \mathcal{W}_1 \subset \mathcal{W}_0$, is stronger than the Lagrangian condition $\psi_{\mathcal{L}}^* i(Z)\Omega_{\mathcal{L}} = 0$, [for every $Z \in \mathfrak{X}(J^1E)$] in J^1E, which can be translated to $\mathcal{W}_1$ by the natural diffeomorphism between them. The reason is that $T_{\mathcal{W}_1}\mathcal{W}_0 = T\mathcal{W}_1 \oplus V_{\mathcal{W}_1}(\rho_1^0)$, so the additional information comes therefore from the ρ_1^0-vertical vectors, and it is just the holonomic condition. In fact:

Theorem 1: *Let $\psi_0 : M \to \mathcal{W}_0$ be a section fulfilling Eq. (8), $\psi_0 = (\psi_{\mathcal{L}}, \psi_{\mathcal{H}}) = (\psi_{\mathcal{L}}, \widetilde{\mathcal{FL}} \circ \psi_{\mathcal{L}})$, where $\psi_{\mathcal{L}} = \rho_1^0 \circ \psi_0$. Then*:

(1) $\psi_{\mathcal{L}}$ is the canonical lift of the projected section $\phi = \rho_E^0 \circ \psi_0 : M \to E$ (that is, $\psi_{\mathcal{L}}$ is a holonomic section).

(2) The section $\psi_{\mathcal{L}} = j^1\phi$ is a solution to the Lagrangian problem, and the section $\mu \circ \psi_{\mathcal{H}} = \mu \circ \widetilde{\mathcal{FL}} \circ \psi_{\mathcal{L}} = \mathcal{FL} \circ j^1\phi$ is a solution to the Hamiltonian problem.

Conversely, for every section $\phi : M \to E$ such that $j^1\phi$ is solutions to the Lagrangian problem (and hence $\mathcal{FL} \circ j^1\phi$ is solution to the Hamiltonian problem) we have that the section $\psi_0 = (j^1\phi, \widetilde{\mathcal{FL}} \circ j^1\phi)$, is a solution to (8) (see Diagram 4).



(*Proof*)

(1) Taking $\{\partial/\partial p_A^\alpha\}$ as a local basis for the ρ_1^0-vertical vector fields:

$$i\left(\frac{\partial}{\partial p_A^\alpha}\right)\Omega_0 = v_\alpha^A \mathrm{d}^m x - \mathrm{d}y^A \wedge \mathrm{d}^{m-1}x_\alpha,$$

so that for a section ψ_0, we have

$$0 = \psi_0^*\left[i\left(\frac{\partial}{\partial p_A^\alpha}\right)\Omega_0\right] = \left(v_\alpha^A(x) - \frac{\partial y^A}{\partial x^\alpha}\right)\mathrm{d}^m x,$$

and thus the holonomy condition appears naturally within the unified formalism, and it is not necessary to impose it by hand to ψ_0. Thus, we have that $\psi_0 = (x^\alpha, y^A, \partial y^A/\partial x^\alpha, \partial L/\partial v_\alpha^A)$, since ψ_0 takes values in $\mathcal{W}_1$, and hence, it is of the form $\psi_0 = (j^1\phi, \widetilde{\mathcal{FL}} \circ j^1\phi)$, for $\phi = (x^\alpha, y^A) = \rho_E^0 \circ \psi_0$.

(2) Since sections $\psi_0 : M \to \mathcal{W}_0$ solution to (8) take values in $\mathcal{W}_1$, we can identify them with sections $\psi_1 : M \to \mathcal{W}_1$. These sections ψ_1 verify, in particular, that $\psi_1^* i(Y_1)\Omega_1 = 0$ holds for every $Y_1 \in \mathfrak{X}(\mathcal{W}_1)$. Obviously, $\psi_0 = J_1 \circ \psi_1$. Moreover, as $\mathcal{W}_1$ is the graph of $\widetilde{\mathcal{FL}}$, denoting by $\rho_1^1 = \rho_1^0 \circ J_1 : \mathcal{W}_1 \to J^1E$ the diffeomorphism which identifies $\mathcal{W}_1$ with J^1E, if we define $\Omega_1 = J_1^* \Omega_0$, we have that $\Omega_1 = \rho_1^{1*} \Omega_{\mathcal{L}}$. In fact; as $(\rho_1^1)^{-1}(\overline{y}) = (\overline{y}, \widetilde{\mathcal{FL}}(\overline{y}))$, for every $\overline{y} \in J^1E$, then $(\rho_0^2 \circ J_1 \circ (\rho_1^1)^{-1})(\overline{y}) = \widetilde{\mathcal{FL}}(\overline{y}) \in \mathcal{M}\pi$, and hence,

$$\Omega_{\mathcal{L}} = (\rho_0^2 \circ J_1 \circ (\rho_1^1)^{-1})^* \Omega = [((\rho_1^1)^{-1})^* \circ J_1^* \circ \rho_0^{2*}]\Omega = [((\rho_1^1)^{-1})^* \circ J_1^*]\Omega_0 = ((\rho_1^1)^{-1})^* \Omega_1 .$$

Now, let $X \in \mathfrak{X}(J^1E)$. We have

$$\begin{aligned}(j^1\phi)^* i(X)\Omega_{\mathcal{L}} &= (\rho_1^0 \circ \psi_0)^* i(X)\Omega_{\mathcal{L}} = (\rho_1^0 \circ J_1 \circ \psi_1)^* i(X)\Omega_{\mathcal{L}} \\ &= (\rho_1^1 \circ \psi_1)^* i(X)\Omega_{\mathcal{L}} = \psi_1^* i((\rho_1^1)_*^{-1} X)(\rho_1^{1*}\Omega_{\mathcal{L}}) = \psi_1^* i(Y_1)\Omega_1 \qquad (9) \\ &= \psi_1^* i(Y_1)(J_1^*\Omega_0) = (\psi_1^* \circ J_1^*) i(Y_0)\Omega_0 = \psi_0^* i(Y_0)\Omega_0 ,\end{aligned}$$

where $Y_0 \in \mathfrak{X}(\mathcal{W}_0)$ is such that $Y_0 = J_{1*} Y_1$. But as $\psi_0^* i(Y_0)\Omega_0 = 0$, for every $Y_0 \in \mathfrak{X}(\mathcal{W}_0)$, then we conclude that $(j^1\phi)^* i(X)\Omega_{\mathcal{L}} = 0$, for every $X \in \mathfrak{X}(J^1E)$.

Conversely, let $j^1\phi : M \to J^1E$ such that $(j^1\phi)^* i(X)\Omega_{\mathcal{L}} = 0$, for every $X \in \mathfrak{X}(J^1E)$, and define $\psi_0 : M \to \mathcal{W}_0$ as $\psi_0 := (j^1\phi, \widetilde{\mathcal{FL}} \circ j^1\phi)$ (observe that ψ_0 takes its values in $\mathcal{W}_1$). Taking into account that, on the points of $\mathcal{W}_1$, every $Y_0 \in \mathfrak{X}(\mathcal{W}_0)$ splits into $Y_0 = Y_0^1 + Y_0^2$, with $Y_0^1 \in \mathfrak{X}(\mathcal{W}_0)$ tangent to $\mathcal{W}_1$, and $Y_0^2 \in \mathfrak{X}^{V(\rho_1^0)}(\mathcal{W}_0)$, we have that

$$\psi_0^* i(Y_0)\Omega_0 = \psi_0^* i(Y_0^1)\Omega_0 + \psi_0^* i(Y_0^2)\Omega_0 = 0,$$

because for Y_0^1, the same reasoning as in (9) leads to

$$\psi_0^* i(Y_0^1)\Omega_0 = (j^1\phi)^* i(X_0^1)\Omega_{\mathcal{L}} = 0$$

[where $X_0^1 = (\rho_1^1)_*^{-1} Y_0^1$] and for Y_0^2, following also the same reasoning as in (9), a local calculus gives

$$\psi_0^* i(Y_0^2)\Omega_0 = (j^1\phi)^* \left[\left(f_A^\alpha(x) \left(v_\alpha^A - \frac{\partial y^A}{\partial x^\alpha} \right) \right) \mathrm{d}^m x \right] = 0,$$

since $j^1\phi$ is a holonomic section.

The result for the sections $\mathcal{FL} \circ j^1\phi$ is a direct consequence of the *equivalence theorem* between the Lagrangian and Hamiltonian formalisms (see, for instance, Refs. 12 and 31). ■

Remark: The results in this section can also be recovered in coordinates taking an arbitrary local vector field $Y_0 = f^A(\partial/\partial y^A) + g_\alpha^A(\partial/\partial v_\alpha^A) + h_A^\alpha(\partial/\partial p_A^\alpha) \in \mathfrak{X}(\mathcal{W}_0)$, then

$$\begin{aligned}i(Y_0)\Omega_0 = &- f^A(\partial L/\partial y^A)\mathrm{d}^m x + f^A \mathrm{d}p_A^\alpha \wedge \mathrm{d}^{m-1}x_\alpha + g_\alpha^A(p_A^\alpha - (\partial L/\partial v_\alpha^A))\mathrm{d}^m x \\ &+ h_A^\alpha v_\alpha^A \mathrm{d}^m x - h_A^\alpha \mathrm{d}y^A \wedge \mathrm{d}^{m-1}x_\alpha\end{aligned}$$

and, for a section ψ_0 fulfilling (8),

$$0=\psi_0^*i(Y_0)\Omega_0=\left[f^A\left(\frac{\partial p_A^\alpha}{\partial x^\alpha}-\frac{\partial L}{\partial y^A}\right)+g_\alpha^A\left(p_A^\alpha-\frac{\partial L}{\partial v_\alpha^A}\right)+h_A^\alpha\left(v_\alpha^A-\frac{\partial y^A}{\partial x^\alpha}\right)\right]\mathrm{d}^m x$$

reproduces the Euler–Lagrange equations, the restricted Legendre map (that is, the definition of the momenta), and the holonomy condition.

Summarizing, Eq. (8) gives different kinds of information, depending on the type of verticallity of the vector fields Y_0 involved. In particular, we have obtained equations of three different classes:

(1) Algebraic (not differential) equations, determining a subset $\mathcal{W}_1$ of $\mathcal{W}_0$, where the sections solution must take their values. These can be called *primary Hamiltonian constraints*, and in fact they generate, by $\hat{\rho}_2^0$ projection, the primary constraints of the Hamiltonian formalism for singular Lagrangians, i.e., the image of the Legendre transformation, $\mathcal{FL}(J^1E)\subset J^{1*}E$.
(2) The holonomic differential equations, forcing the sections solution ψ_0 to be lifting of π-sections. This property is similar to the one in the unified formalism of Classical Mechanics, and it reflects the fact that the geometric condition in the unified formalism is stronger than the usual one in the Lagrangian formalism.
(3) The classical Euler–Lagrange equations.

C. Field equations for *m*-vector fields, connections, and jet fields

The problem of finding sections solution to (8) can be formulated equivalently as follows: finding a distribution D_0 of $T(\mathcal{W}_0)$ such that it is integrable (that is, *involutive*), *m*-dimensional, ρ_M^0-transverse, and the integral manifolds of D_0 are the sections solution to the above equations. (Note that we do not ask them to be lifting of π-sections; that is, the holonomic condition.) This is equivalent to stating that the sections solution to this problem are the integral sections of one of the following equivalent elements:

- A class of integrable and ρ_M^0-transverse *m*-vector fields $\{X_0\}\subset\mathfrak{X}^m(\mathcal{W}_0)$ satisfying that

$$i(X_0)\Omega_0=0,\quad \text{for every } X_0\in\{X_0\}. \tag{10}$$

- An integrable connection ∇_0 in $\rho_M^0:\mathcal{W}_0\to M$ such that

$$i(\nabla_0)\Omega_0=(m-1)\Omega_0. \tag{11}$$

- An integrable jet field $\Psi_0:\mathcal{W}_0\to J^1\mathcal{W}_0$, such that

$$i(\Psi_0)\Omega_0=0. \tag{12}$$

Locally decomposable and ρ_M^0-transverse *m*-vector fields, orientable jet fields, and orientable connections, which are solutions of these equations will be called *Lagrange–Hamiltonian m-vector fields, jet fields*, and *connections* for $(\mathcal{W}_0,\Omega_0)$.

Recall that, in a natural chart in $\mathcal{W}_0$, the local expressions of a connection form, its associated jet field, and the *m*-multivector fields of the corresponding associated class are

$$\nabla_0=\mathrm{d}x^\alpha\otimes\left(\frac{\partial}{\partial x^\alpha}+F_\alpha^A\frac{\partial}{\partial y^A}+G_{\alpha\nu}^A\frac{\partial}{\partial v_\nu^A}+H_{\alpha A}^\nu\frac{\partial}{\partial p_A^\nu}\right),$$

$$\Psi_0=(x^\alpha,y^A,v_\alpha^A,F_\alpha^A,G_{\alpha\eta}^A,H_{\alpha A}^\nu), \tag{13}$$

$$X_0=f\bigwedge_{\alpha=1}^m\left(\frac{\partial}{\partial x^\alpha}+F_\alpha^A\frac{\partial}{\partial y^A}+G_{\alpha\nu}^A\frac{\partial}{\partial v_\nu^A}+H_{\alpha A}^\nu\frac{\partial}{\partial p_A^\nu}\right),$$

where $f \in C^\infty(J^1E)$ is an arbitrary nonvanishing function. A representative of the class $\{X\}$ can be selected by the condition $i(X)(\overline{\rho_M^0}^* \omega) = 1$, which leads to $f = 1$ in the above local expression.

Now, the equivalence of the unified formalism with the Lagrangian and Hamiltonian formalisms can be recovered as follows:

Theorem 2: *Let $\{X_0\}$ be a class of integrable Lagrange–Hamiltonian m-vector fields in $\mathcal{W}_0$, whose elements $X_0 : \mathcal{W}_0 \to \Lambda^m T\mathcal{W}_0$ are solutions to (10), and let $\nabla_0 : \mathcal{W}_0 \to \rho_M^{0*} T^*M \otimes_{\mathcal{W}_0} T\mathcal{W}_0$ be its associated Lagrange–Hamiltonian connection form [which is a solution to (11)], and $\Psi_0 : \mathcal{W}_0 \to J^1\mathcal{W}_1$ its associated Lagrange–Hamiltonian jet field [which is a solution to (12)].*

(1) For every $X_0 \in \{X_0\}$, the m-vector field $X_{\mathcal{L}} : J^1E \to \Lambda^m TJ^1E$ defined by

$$X_{\mathcal{L}} \circ \rho_1^0 = \Lambda^m T\rho_1^0 \circ X_0,$$

is a holonomic Euler–Lagrange m-vector field for the Lagrangian system $(J^1E, \Omega_{\mathcal{L}})$ (where $\Lambda^m T\rho_1^0 : \Lambda^m T\mathcal{W}_0 \to \Lambda^m TJ^1E$ is the natural extension of $T\rho_1^0$).

Conversely, every holonomic Euler–Lagrange m-vector field for the Lagrangian system $(J^1E, \Omega_{\mathcal{L}})$ can be recovered in this way from an integrable Lagrange–Hamiltonian m-vector field $X_0 \in \mathfrak{X}^m_{\mathcal{W}_1}(\mathcal{W}_0)$.

(2) The Ehresmann connection form $\nabla_{\mathcal{L}} : J^1E \to \overline{\pi^1}^* T^*M \otimes_{J^1E} TJ^1E$ defined by

$$\nabla_{\mathcal{L}} \circ \rho_1^0 = \kappa_{\mathcal{W}_0} \circ \nabla_0,$$

is a holonomic Euler–Lagrange connection form for the Lagrangian system $(J^1E, \Omega_{\mathcal{L}})$ (where $\kappa_{\mathcal{W}_0}$ is defined as the map making the following diagram commutative) (see Diagram 5).

$$\begin{array}{ccc} \rho_M^{0*}\mathrm{T}^*M \otimes_{\mathcal{W}_0} \mathrm{T}\mathcal{W}_0 & \xrightarrow{\kappa_{\mathcal{W}_0}} & \bar{\pi}^{1*}\mathrm{T}^*M \otimes_{J^1E} \mathrm{T}J^1E \\ \downarrow & & \downarrow \\ \mathcal{W}_0 & \xrightarrow{\rho_1^0} & J^1E \end{array}$$

Conversely, every holonomic Euler–Lagrange connection form for the Lagrangian system $(J^1E, \Omega_{\mathcal{L}})$ can be recovered in this way from an integrable Lagrange–Hamiltonian connection form ∇_0.

(3) The jet field $\Psi_{\mathcal{L}} : J^1E \to J^1J^1E$ defined by

$$\Psi_{\mathcal{L}} \circ \rho_1^0 = j^1\rho_1^0 \circ \Psi_0,$$

is a holonomic Euler–Lagrange jet field for the Lagrangian system $(J^1E, \Omega_{\mathcal{L}})$. Conversely, every holonomic Euler–Lagrange jet field for the Lagrangian system $(J^1E, \Omega_{\mathcal{L}})$ can be recovered in this way from an integrable Lagrange–Hamiltonian jet field Ψ_0.

(*Proof*) Let X_0 be a ρ_M^0-transversal *m*-vector field on $\mathcal{W}_0$ solution to (10). As sections $\psi_0 : M \to \mathcal{W}_0$ solution to the geometric equation (8) must take value in $\mathcal{W}_1$, then X_0 can be identified with a *m*-vector field $X_1 : \mathcal{W}_0 \to \Lambda^m T\mathcal{W}_1$ (i.e., $\Lambda^m TJ_1 \circ X_1 = X_0|_{\mathcal{W}_1}$), and hence, there exists $X_{\mathcal{L}} : J^1E \to \Lambda^m TJ^1E$ such that $X_1 = \Lambda^m T(\rho_1^1)^{-1} \circ X_{\mathcal{L}} \in \mathfrak{X}^m(\mathcal{W}_1)$. Therefore as a consequence of item (1) in theorem 1, for every section ψ_0 solution to (8), there exists $X_{\mathcal{L}}^0 \in \mathfrak{X}^m(j^1\phi(M))$ such that $\Lambda^m TJ_\phi \circ X_{\mathcal{L}}^0 = X_{\mathcal{L}}|_{j^1\phi(M)}$, where $J_\phi : j^1\phi \to E$ is the natural imbedding. So, $X_{\mathcal{L}}$ is $\overline{\pi^1}$-transversal and holonomic. Then, bearing in mind that $J_1^* \Omega_0 = \rho_1^{1*} \Omega_{\mathcal{L}}$, we have

$$J_1^* i(X_0)\Omega_0 = i(X_1)(J_1^* \Omega_0) = i(X_1)(\rho_1^{1*} \Omega_{\mathcal{L}}) = \rho_1^{1*} i(X_{\mathcal{L}})\Omega_{\mathcal{L}},$$

then $i(X_0)\Omega_0=0\Rightarrow i(X_{\mathcal{L}})\Omega_{\mathcal{L}}=0$.

Conversely, given an holonomic Euler–Lagrange m-vector field $X_{\mathcal{L}}$, from $i(X_{\mathcal{L}})\Omega_{\mathcal{L}}=0$, and taking into account the above chain of equalities, we obtain that $i(X_0)\Omega_0\in[\mathfrak{X}(\mathcal{W}_1)]^0$ [the annihilator of $\mathfrak{X}(\mathcal{W}_1)$]. Moreover, being $X_{\mathcal{L}}$ holonomic, X_0 is holonomic, and then the extra condition $i(Y_0)i(X_0)\Omega_0=0$ is also fulfilled for every $Y_0\in\mathfrak{X}^{V(\rho_1^0)}(\mathcal{W}_0)$. Thus, remembering that $T_{\mathcal{W}_1}\mathcal{W}_0=T\mathcal{W}_1\oplus \mathrm{V}_{\mathcal{W}_1}(\rho_1^0)$, we conclude that $i(X_0)\Omega_0=0$.

The proof for Ehresmann connections and jet fields is straightforward, taking into account that they are equivalent alternative descriptions in the Lagrangian formalism. ■

This statement also holds for nonintegrable classes of m-vector fields, connections, and jet fields in $\mathcal{W}_0$, but now the corresponding classes of Euler–Lagrange m-vector fields, connections and jet fields in J^1E will not be holonomic (but only semi-holonomic). To prove this assertion it suffices to compute Eq. (10) in coordinates, using the local expressions (7) and (13), concluding then that, in the expressions (13), $F_\alpha^A=v_\alpha^A$, which is the local expression of the semi-holonomy condition (see, also, Ref. 9).

Finally, the Hamiltonian formalism is recovered in the usual way, by using the following:

Theorem 3: *Let* $(J^1{}^*E,\Omega_h)$ *be the Hamiltonian system associated with a (hyper) regular Lagrangian system* $(J^1E,\Omega_{\mathcal{L}})$.

(1) (Equivalence theorem for m-vector fields*) Let* $X_{\mathcal{L}}\in\mathfrak{X}^m(J^1E)$ *and* $X_{\mathcal{H}}\in\mathfrak{X}^m(J^1{}^*E)$ *be the* m*-vector fields solution to the Lagrangian and the Hamiltonian problems respectively. Then*

$$\Lambda^m T\mathcal{FL}\circ X_{\mathcal{L}}=fX_{\mathcal{H}}\circ\mathcal{FL},$$

for some $f\in C^\infty(J^1{}^*E)$ *(we say that the classes* $\{X_{\mathcal{L}}\}$ *and* $\{X_{\mathcal{H}}\}$ *are* $\mathcal{FL}$*-related).*

(2) (Equivalence theorem for jet fields and connections) Let $\mathcal{Y}_{\mathcal{L}}$ *and* $\mathcal{Y}_{\mathcal{H}}$ *be the jet fields solution of the Lagrangian and the Hamiltonian problems respectively. Then*

$$j^1\mathcal{FL}\circ\mathcal{Y}_{\mathcal{L}}=\mathcal{Y}_{\mathcal{H}}\circ\mathcal{FL}$$

(we say that the jet fields $\mathcal{Y}_{\mathcal{L}}$ *and* $\mathcal{Y}_{\mathcal{H}}$ *are* $\mathcal{FL}$*-related). As a consequence, their associated connection forms,* $\nabla_{\mathcal{L}}$ *and* $\nabla_{\mathcal{H}}$ *respectively, are* $\mathcal{FL}$*-related, too.*

(For almost-regular systems the statement is the same, but changing $J^1{}^*E$ *for* $\mathcal{P}$*).*

(*Proof*) See Ref. 31. (The proof for the almost-regular case follows in a straight-forward way.) ■

As a consequence of these latter theorems, similar comments to those made at the end of Secs. II A and II B about the existence, integrability, and nonuniqueness of Euler–Lagrange and Hamilton–de Donder–Weyl m-vector fields, connections, and jet fields, can be applied to their associated elements in the unified formalism. In particular, for singular systems, the existence of these solutions is not assured, except perhaps on some submanifold $\mathcal{S}\hookrightarrow\mathcal{W}_1$, and the number of arbitrary functions which appear depends on the dimension of $\mathcal{S}$ and the rank of the Hessian matrix of L (an algorithm for finding this submanifold is outlined in Ref. 9). The integrability of these solutions is not assured (even in the regular case), except perhaps on a smaller submanifold $\mathcal{I}\hookrightarrow\mathcal{S}$ such that the integral sections are contained in $\mathcal{I}$.

IV. EXAMPLE: MINIMAL SURFACES (in $\mathbb{R}^3$)

[In Ref. 9 we find another interesting example, the *bosonic string* (which is a singular model), described in this unified formalism.]

A. Statement of the problem: Geometric elements

The problem consists in looking for mappings $\varphi:U\subset\mathbb{R}^2\to$ such that their graphs have minimal area as sets of $\mathbb{R}^3$, and satisfy certain boundary conditions.

For this model, we have that $M=\mathbb{R}^2$, $E=\mathbb{R}^2\times\mathbb{R}$, and

$$J^1E=\pi^*T^*\mathbb{R}^2\otimes\mathbb{R}=\pi^*T^*M=\pi^*T^*\mathbb{R}^2,$$

$$\mathcal{M}\pi=\pi^*(TM\times_M E)\ \text{(affine maps from } J^1E \text{ to } \pi^*\Lambda^2T^*M),$$

$$J^{1*}E=\pi^*TM=\pi^*T\mathbb{R}^2\ \text{(classes of affine maps from } J^1E \text{ to } \pi^*\Lambda^2T^*M).$$

The coordinates in J^1E, $J^{1*}E$ and $\mathcal{M}\pi$ are denoted (x^1,x^2,y,v_1,v_2), (x^1,x^2,y,p^1,p^2), and (x^1,x^2,y,p^1,p^2,p), respectively. If $\omega=\mathrm{d}x^1\wedge\mathrm{d}x^2$, the Lagrangian density is

$$\mathcal{L}=[1+(v_1)^2+(v_2)^2]^{1/2}\mathrm{d}x^1\wedge\mathrm{d}x^2\equiv L\,\mathrm{d}x^1\wedge\mathrm{d}x^2,$$

and the Poincaré–Cartan forms are

$$\Theta_{\mathcal{L}}=\frac{v_1}{L}\mathrm{d}y\wedge\mathrm{d}x^2-\frac{v_2}{L}\mathrm{d}y\wedge\mathrm{d}x^1+L\left(1-\left(\frac{v_1}{L}\right)^2-\left(\frac{v_2}{L}\right)^2\right)\mathrm{d}x^1\wedge\mathrm{d}x^2,$$

$$\Omega_{\mathcal{L}}=-\mathrm{d}\left(\frac{v_1}{L}\right)\wedge\mathrm{d}y\wedge\mathrm{d}x^2+\mathrm{d}\left(\frac{v_2}{L}\right)\wedge\mathrm{d}y\wedge\mathrm{d}x^1-\mathrm{d}\left[L\left(1-\left(\frac{v_1}{L}\right)^2-\left(\frac{v_2}{L}\right)^2\right)\right]\wedge\mathrm{d}x^1\wedge\mathrm{d}x^2.$$

The Legendre maps are

$$\mathcal{FL}(x^1,x^2,y,v_1,v_2)=\left(x^1,x^2,y,\frac{v_1}{L},\frac{v_2}{L}\right),$$

$$\widetilde{\mathcal{FL}}(x^1,x^2,y,v_1,v_2)=\left(x^1,x^2,y,\frac{v_1}{L},\frac{v_2}{L},L-\frac{(v_1)^2}{L}-\frac{(v_2)^2}{L}\right),$$

and then $\mathcal{L}$ is hyperregular. The Hamiltonian function is

$$H=-[1-(p^1)^2-(p^2)^2]^{1/2}. \tag{14}$$

So the Hamilton–Cartan forms are

$$\Theta_h=p^1\mathrm{d}y\wedge\mathrm{d}x^2-p^2\mathrm{d}y\wedge\mathrm{d}x^1-H\mathrm{d}x^1\wedge\mathrm{d}x^2,$$

$$\Omega_h=-\mathrm{d}p^1\wedge\mathrm{d}y\wedge\mathrm{d}x^2+\mathrm{d}p^2\wedge\mathrm{d}y\wedge\mathrm{d}x^1+\mathrm{d}H\wedge\mathrm{d}x^1\wedge\mathrm{d}x^2.$$

B. Unified formalism

For the unified formalism we have

$$\mathcal{W}=\pi^*T^*M\times_E\pi^*(TM\times_M E),\quad \mathcal{W}_r=\pi^*T^*M\times_E\pi^*TM=\pi^*(T^*M\times_M TM).$$

If

$$w=(x^1,x^2,y,v_1,v_2,p^1,p^2,p)\in\mathcal{W},$$

the coupling form is

$$\hat{\mathcal{C}}=(p^1v_1+p^2v_2+p)\mathrm{d}x^1\wedge\mathrm{d}x^2,$$

therefore,

$$\mathcal{W}_0=\{(x^1,x^2,y,v_1,v_2,p^1,p^2,p)\in\mathcal{W}|[1+(v_1)^2+(v_2)^2]^{1/2}-p^1v_1-p^2v_2-p=0\},$$

and we have the forms

$$\Theta_0=([1+(v_1)^2+(v_2)^2]^{1/2}-p^1v_1-p^2v_2)\mathrm{d}x^1\wedge\mathrm{d}x^2-p^2\mathrm{d}y\wedge\mathrm{d}x_1+p^1\mathrm{d}y\wedge\mathrm{d}x_2,$$

$$\Omega_0=-\mathrm{d}([1+(v_1)^2+(v_2)^2]^{1/2}-p^1v_1-p^2v_2)\wedge\mathrm{d}x^1\wedge\mathrm{d}x^2+\mathrm{d}p^2\wedge\mathrm{d}y\wedge\mathrm{d}x_1-\mathrm{d}p^1\wedge\mathrm{d}y\wedge\mathrm{d}x_2.$$

Taking first $\hat{\rho}_2^0$-vertical vector fields $\partial/\partial v_\alpha$ we obtain

$$0=i\left(\frac{\partial}{\partial v_\alpha}\right)\ \Omega_0=\left(p^\alpha-\frac{v_\alpha}{L}\right)\mathrm{d}x^1\wedge\mathrm{d}x^2,$$

which determines the submanifold $\mathcal{W}_1=\mathrm{graph}\,\widetilde{\mathcal{FL}}$ (diffeomorphic to J^1E), and reproduces the expression of the Legendre map. Now, taking ρ_1^0-vertical vector fields $\partial/\partial p^\alpha$, the contraction $i(\partial/\partial p^\alpha)\Omega_0$ gives, for $\alpha=1,2$, respectively,

$$v_1\mathrm{d}x^1\wedge\mathrm{d}x^2-\mathrm{d}y\wedge\mathrm{d}x^2,\quad v_2\mathrm{d}x^1\wedge\mathrm{d}x^2+\mathrm{d}y\wedge\mathrm{d}x^1,$$

so that, for a section

$$\psi_0=(x^1,x^2,y(x^1,x^2),v_1(x^1,x^2),v_2(x^1,x^2),p^1(x^1,x^2),p^2(x^1,x^2)),$$

taking values in $\mathcal{W}_1$, we have that the condition

$$\psi_0^*\left[i\left(\frac{\partial}{\partial p^\alpha}\right)\Omega_0\right]=0$$

leads to

$$\left(v_1-\frac{\partial y}{\partial x^1}\right)\mathrm{d}x^1\wedge\mathrm{d}x^2=0,\quad \left(v_2-\frac{\partial y}{\partial x^2}\right)\mathrm{d}x^1\wedge\mathrm{d}x^2=0,$$

which is the holonomy condition. Finally, taking the vector field $\partial/\partial y$ we have

$$i\left(\frac{\partial}{\partial y}\right)\Omega_0=-\mathrm{d}p^2\wedge\mathrm{d}x^1+\mathrm{d}p^1\wedge\mathrm{d}x^2,$$

and, for a section ψ_0 fulfilling the former conditions, the equation

$$0=\psi_0^*\left[i\left(\frac{\partial}{\partial y}\right)\Omega_0\right],$$

leads to

$$\begin{aligned}0&=\left(\frac{\partial p^2}{\partial x^2}+\frac{\partial p^1}{\partial x^1}\right)\mathrm{d}x^1\wedge\mathrm{d}x^2\\&=\left[\frac{\partial}{\partial x^1}\left(\frac{v_1}{L}\right)+\frac{\partial}{\partial x^2}\left(\frac{v_2}{L}\right)\right]\mathrm{d}x^1\wedge\mathrm{d}x^2\\&=\frac{1}{L^3}\left[\left(1+\left(\frac{\partial y}{\partial x^1}\right)^2\right)\frac{\partial^2y}{\partial x^2\partial x^2}+\left(1+\left(\frac{\partial y}{\partial x^2}\right)^2\right)\frac{\partial^2y}{\partial x^1\partial x^1}-2\,\frac{\partial y}{\partial x^1}\,\frac{\partial y}{\partial x^2}\,\frac{\partial^2y}{\partial x^1\partial x^2}\right]\mathrm{d}x^1\wedge\mathrm{d}x^2,\end{aligned}$$

which gives the Euler–Lagrange equation of the problem.

Now, bearing in mind (14), and the expression of the Legendre map, from the Euler–Lagrange equations we get

$$\frac{\partial y}{\partial x^1}=-\frac{p^1}{H},\quad \frac{\partial y}{\partial x^2}=-\frac{p^2}{H};\quad \frac{\partial p^1}{\partial x^1}=-\frac{\partial p^2}{\partial x^2},$$

which are the Hamilton–De Donder–Weyl equations of the problem.

The *m*-vector fields, connections and jet fields which are the solutions to the problem in the unified formalism are

$$X_0=f\left(\frac{\partial}{\partial x^1}+v_1\frac{\partial}{\partial y}+\frac{\partial v_1}{\partial x^1}\frac{\partial}{\partial v_1}+\frac{\partial v_2}{\partial x^1}\frac{\partial}{\partial v_2}+\frac{\partial p^1}{\partial x^1}\frac{\partial}{\partial p^1}+\frac{\partial p^2}{\partial x^1}\frac{\partial}{\partial p^2}\right)$$
$$\wedge\left(\frac{\partial}{\partial x^2}+v_2\frac{\partial}{\partial y}+\frac{\partial v_1}{\partial x^2}\frac{\partial}{\partial v_1}+\frac{\partial v_2}{\partial x^2}\frac{\partial}{\partial v_2}+\frac{\partial p^1}{\partial x^2}\frac{\partial}{\partial p^1}+\frac{\partial p^2}{\partial x^2}\frac{\partial}{\partial p^2}\right),$$

$$\Psi_0=\left(x^1,x^2,y,p^1,p^2;v_1,v_2,\frac{\partial v_1}{\partial x^1},\frac{\partial v_1}{\partial x^2},\frac{\partial v_2}{\partial x^1},\frac{\partial v_2}{\partial x^2},\frac{\partial p^1}{\partial x^1},\frac{\partial p^1}{\partial x^2},\frac{\partial p^2}{\partial x^1},\frac{\partial p^2}{\partial x^2}\right),$$

$$\nabla_0=dx^1\otimes\left(\frac{\partial}{\partial x^1}+v_1\frac{\partial}{\partial y}+\frac{\partial v_1}{\partial x^1}\frac{\partial}{\partial v_1}+\frac{\partial v_2}{\partial x^1}\frac{\partial}{\partial v_2}+\frac{\partial p^1}{\partial x^1}\frac{\partial}{\partial p^1}+\frac{\partial p^2}{\partial x^1}\frac{\partial}{\partial p^2}\right)$$
$$+dx^2\otimes\left(\frac{\partial}{\partial x^2}+v_2\frac{\partial}{\partial y}+\frac{\partial v_1}{\partial x^2}\frac{\partial}{\partial v_1}+\frac{\partial v_2}{\partial x^2}\frac{\partial}{\partial v_2}+\frac{\partial p^1}{\partial x^2}\frac{\partial}{\partial p^1}+\frac{\partial p^2}{\partial x^2}\frac{\partial}{\partial p^2}\right)$$

(f being a nonvanishing function), where the coefficients $\partial v_\alpha/\partial x^\nu=\partial^2 y/\partial x^\nu\partial x^\alpha$ are related by the Euler–Lagrange equations, and the coefficients $\partial p^\alpha/\partial x^\nu$ are related by the Hamilton–De Donder–Weyl equations (the third one). Hence, the associated Euler–Lagrange *m*-vector fields, connections and jet fields which are the solutions to the Lagrangian problem are

$$X_{\mathcal{L}}=f\left(\frac{\partial}{\partial x^1}+v_1\frac{\partial}{\partial y}+\frac{\partial v_1}{\partial x^1}\frac{\partial}{\partial v_1}+\frac{\partial v_2}{\partial x^1}\frac{\partial}{\partial v_2}\right)\wedge\left(\frac{\partial}{\partial x^2}+v_2\frac{\partial}{\partial y}+\frac{\partial v_1}{\partial x^2}\frac{\partial}{\partial v_1}+\frac{\partial v_2}{\partial x^2}\frac{\partial}{\partial v_2}\right),$$

$$\Psi_{\mathcal{L}}=\left(x^1,x^2,y,p^1,p^2;v_1,v_2,\frac{\partial v_1}{\partial x^1},\frac{\partial v_1}{\partial x^2},\frac{\partial v_2}{\partial x^1},\frac{\partial v_2}{\partial x^2}\right),$$

$$\nabla_{\mathcal{L}}=dx^1\otimes\left(\frac{\partial}{\partial x^1}+v_1\frac{\partial}{\partial y}+\frac{\partial v_1}{\partial x^1}\frac{\partial}{\partial v_1}+\frac{\partial v_2}{\partial x^1}\frac{\partial}{\partial v_2}\right)+dx^2\otimes\left(\frac{\partial}{\partial x^2}+v_2\frac{\partial}{\partial y}+\frac{\partial v_1}{\partial x^2}\frac{\partial}{\partial v_1}+\frac{\partial v_2}{\partial x^2}\frac{\partial}{\partial v_2}\right),$$

and the corresponding Hamilton–De Donder–Weyl *m*-vector fields, connections, and jet fields which are the solutions to the Hamiltonian problem are

$$X_{\mathcal{H}}=f\left(\frac{\partial}{\partial x^1}-\frac{p^1}{H}\frac{\partial}{\partial y}+\frac{\partial p^1}{\partial x^1}\frac{\partial}{\partial p^1}+\frac{\partial p^2}{\partial x^1}\frac{\partial}{\partial p^2}\right)\wedge\left(\frac{\partial}{\partial x^2}-\frac{p^2}{H}\frac{\partial}{\partial y}+\frac{\partial p^1}{\partial x^2}\frac{\partial}{\partial p^1}+\frac{\partial p^2}{\partial x^2}\frac{\partial}{\partial p^2}\right),$$

$$\Psi_{\mathcal{H}}=\left(x^1,x^2,y,p^1,p^2;-\frac{p^1}{H},-\frac{p^2}{H},\frac{\partial p^1}{\partial x^1},\frac{\partial p^1}{\partial x^2},\frac{\partial p^2}{\partial x^1},\frac{\partial p^2}{\partial x^2}\right),$$

$$\nabla_{\mathcal{H}}=\mathrm{d}x^1\otimes\left(\frac{\partial}{\partial x^1}-\frac{p^1}{H}\frac{\partial}{\partial y}+\frac{\partial p^1}{\partial x^1}\frac{\partial}{\partial p^1}+\frac{\partial p^2}{\partial x^1}\frac{\partial}{\partial p^2}\right)+\mathrm{d}x^2\otimes\left(\frac{\partial}{\partial x^2}-\frac{p^2}{H}\frac{\partial}{\partial y}+\frac{\partial p^1}{\partial x^2}\frac{\partial}{\partial p^1}+\frac{\partial p^2}{\partial x^2}\frac{\partial}{\partial p^2}\right).$$

V. CONCLUSIONS AND OUTLOOK

We have generalized the *Rusk–Skinner unified formalism* to first-order classical field theories. Corresponding to the Whitney sum $TQ\times_Q T^*Q$ in autonomous mechanics, here we take $J^1E\times_E\mathcal{M}\pi$ as standpoint, but the field equations are stated in a submanifold $\mathcal{W}_0\subset J^1E\times_E\mathcal{M}\pi$. As a particular case of this situation, the unified formalism for nonautonomous mechanics is recovered, the Whitney sum being now $J^1E\times_E T^*E$, where $\pi:E\to\mathbb{R}$ is the configuration bundle.[8,9] Once the suitable (pre) multisymplectic structures are introduced, the field equations can be written in several equivalent ways: using sections and vector fields (8) in $\mathcal{W}_0$, m-vector fields (10), connections (11), or jet fields (12).

Starting from Eq. (8), we have seen how, when different kinds of vertical vector fields in $\mathcal{W}_0$ are considered, this equation gives a different type of information. In particular, using $\hat{\rho}_2^0$-vertical vector fields, we can define a submanifold $\mathcal{W}_1\hookrightarrow\mathcal{W}_0$, which turns out to be the graph of the (extended) Legendre transformation (and hence diffeomorphic to J^1E). Furthermore, the field equations are only compatible in $\mathcal{W}_1$. As sections solution to the field equations take values in $\mathcal{W}_1$, they split in a natural way into two components, $\psi_0=(\psi_{\mathcal{L}},\psi_{\mathcal{H}})$, (with $\psi_{\mathcal{L}}:M\to J^1E$, and $\psi_{\mathcal{H}}=\widetilde{\mathcal{FL}}\circ\psi_{\mathcal{L}}$). Then, taking ρ_1^0-vertical vector fields in (8), we have proved that the sections solution to the field equations in the unified formalism are automatically holonomic, even in the singular case. They are so in the following sense: for every section ψ_0 solution in the unified formalism, the corresponding section $\psi_{\mathcal{L}}$ is holonomic. (As a special case, nonintegrable m-vector fields, connections and jet fields which are solutions to the field equations are semi-holonomic.) These solutions only exist in general in a submanifold of $\mathcal{W}_1$. Finally, considering (8) for a generic vector field, the Euler–Lagrange equations for $\psi_{\mathcal{L}}$, and the Hamilton–De Donder–Weyl equations for $\mu\circ\psi_{\mathcal{H}}=\mathcal{FL}\circ\psi_{\mathcal{L}}$ arise in a natural way. Conversely, starting from sections $\psi_{\mathcal{L}}=j^1\phi$ and $\mathcal{FL}\circ\psi_{\mathcal{L}}$ solutions to the corresponding field equations, we can recover sections ψ_0 solution to (8). Thus, we have shown the equivalence between the standard Lagrangian and Hamiltonian formalisms and the unified one. This equivalence has been also proved for m-vector fields, connections and jet fields.

Although the subject is not considered in this work, $\mathcal{K}$ operators (i.e., the analogous operators in field theories to the so-called *evolution operator* in mechanics), in their different alternative definitions,[33] can easily be recovered from the unified formalism, similarly to the case of classical mechanics.

In a forthcoming paper, this formalism will be applied to give a geometric framework for optimal control with partial differential equations. Although this subject has been dealt with in the context of functional analysis, to our knowledge there has been no geometric treatment of it to date.

APPENDIX: *m*-VECTOR FIELDS, JET FIELDS, AND CONNECTIONS IN JET BUNDLES

(See Refs. 17 and 27 for the proofs and other details of the following assertions.)

Let E be a n-dimensional differentiable manifold. For $m\leqslant n$, sections of $\Lambda^m(TE)$ are called *m-vector fields* in E (they are contravariant skew-symmetric tensors of order m in E). We denote by $\mathfrak{X}^m(E)$ the set of m-vector fields in E. $Y\in\mathfrak{X}^m(E)$ is said to be *locally decomposable* if, for every $p\in E$, there exists an open neighborhood $U_p\subset E$ and $Y_1,\ldots,Y_m\in\mathfrak{X}(U_p)$ such that $Y\simeq_{U_p}Y_1\wedge\cdots\wedge Y_m$. Contraction of m-vector fields and tensor fields in E is the usual one.

We can define the following equivalence relation: if $Y, Y' \in \mathfrak{X}^m(E)$ are nonvanishing m-vector fields, then $Y \sim Y'$ if there exists a nonvanishing function $f \in C^\infty(E)$ such that $Y' = fY$ (perhaps only in a connected open set $U \subseteq E$). Equivalence classes will be denoted by $\{Y\}$. There is a one-to-one correspondence between the set of m-dimensional orientable distributions D in TE and the set of the equivalence classes $\{Y\}$ of nonvanishing, locally decomposable m-vector fields in E. Then, there is a bijective correspondence between the set of classes of locally decomposable and π-transverse m-vector fields $\{Y\} \subset \mathfrak{X}^m(E)$, and the set of orientable jet fields $\Psi: E \to J^1E$; that is, the set of orientable Ehresmann connection forms ∇ in $\pi: E \to M$. This correspondence is characterized by the fact that the horizontal subbundle associated with Ψ (and ∇) coincides with $\mathcal{D}(Y)$.

If $Y \in \mathfrak{X}^m(E)$ is nonvanishing and locally decomposable, the distribution associated with the class $\{Y\}$ is denoted $\mathcal{D}(Y)$. A nonvanishing, locally decomposable m-vector field $Y \in \mathfrak{X}^m(E)$ is said to be *integrable* (respectively, *involutive*) if its associated distribution $\mathcal{D}_U(Y)$ is integrable (respectively, involutive). Of course, if $Y \in \mathfrak{X}^m(E)$ is integrable (respectively, involutive), then so is every m-vector field in its equivalence class $\{Y\}$, and all of them have the same integral manifolds. Moreover, *Frobenius' theorem* allows us to say that a nonvanishing and locally decomposable m-vector field is integrable if, and only if, it is involutive. Of course, the orientable jet field Ψ, and the connection form ∇ associated with $\{Y\}$ are integrable if, and only if, so is Y, for every $Y \in \{Y\}$.

Let us consider the following situation: if $\pi: E \to M$ is a fiber bundle, we are concerned with the case where the integral manifolds of integrable m-vector fields in E are sections of π. Thus, $Y \in \mathfrak{X}^m(E)$ is said to be *π-transverse* if, at every point $y \in E$, $(i(Y)(\pi^*\beta))_y \neq 0$, for every $\beta \in \Omega^m(M)$ such that $\beta(\pi(y)) \neq 0$. Then, if $Y \in \mathfrak{X}^m(E)$ is integrable, it is π-transverse if its integral manifolds are local sections of π. In this case, if $\phi: U \subset M \to E$ is a local section with $\phi(x) = y$ and $\phi(U)$ is the integral manifold of Y through y, then $T_y(\mathrm{Im}\,\phi)$ is $\mathcal{D}_y(Y)$. Integral sections ϕ of the class $\{Y\}$ can be characterized by the condition $\Lambda^m T\phi = fY \circ \phi \circ \sigma_M$, where $\sigma_M: \Lambda^m TM \to M$ is the natural projection, and $f \in C^\infty(E)$ is a nonvanishing function.

As a particular case, let $\{X\}: J^1E \to D^m TJ^1E \subset \{\Lambda^m TJ^1E\}$ be a class of nonvanishing, locally decomposable and $\overline{\pi^1}$-transverse m-vector fields in J^1E, $\Psi: J^1E \to J^1J^1E$ its associated jet field, and $\nabla: J^1E \to \overline{\pi^1}^*TM \otimes_{J^1E} TJ^1E$ its associated connection form. Then, these elements are said to be *holonomic* if they are integrable and their integral sections $\varphi: M \to J^1E$ are holonomic. Furthermore, consider the $(1,m)$-tensor field in J^1E defined by $\mathcal{J} := i(\mathcal{V})(\overline{\pi^1}^*\omega)$, whose local expression is $\mathcal{J} = (\mathrm{d}y^A - v^A_\alpha \mathrm{d}x^\alpha) \wedge \mathrm{d}^{m-1}x_\nu \otimes \partial/\partial v^A_\nu$. A connection form ∇ in $\overline{\pi^1}: J^1E \to M$ (and its associated jet field $\Psi: J^1E \to J^1J^1E$) are said to be *semi-holonomic* (or a *second order partial differential equation*), if

$$\overbrace{\mathcal{J}(h^\nabla, \ldots, h^\nabla)}^{m} = 0,$$

where h^∇ denotes the horizontal projector associated with ∇. If $\{X\} \subset \mathfrak{X}^m(J^1E)$ is the associated class of $\overline{\pi^1}$-transverse multivector fields, then this condition is equivalent to $\mathcal{J}(X) = 0$, for every $X \in \{X\}$. Then the class $\{X\}$, and its associated jet field Ψ and connection form ∇ are holonomic if, and only if, they are integrable and semi-holonomic.

Unsteady equipartition MHD solutions

Oleg I. Bogoyavlenskij
Department of Mathematics, Queen's University, Kingston, Ontario K7L 3N6, Canada

(Received 7 June 2003; accepted 25 September 2003)

The unsteady equipartition solutions are introduced that describe a plasma relaxation in regime of a strong interaction between the plasma velocity **V** and the magnetic field **B** and depend on all four variables t,x,y,z. The solutions exist when the kinematic viscosity ν is equal to the magnetic diffusivity η and $\mathbf{V}=\pm\mathbf{B}/\sqrt{\rho\mu}$. The exact equipartition solutions to the boundary value problem with the "no-slip" boundary condition are derived. The solutions depend on infinitely many parameters and describe the plasma relaxation in a ball with a constant pressure at the boundary. The translationally invariant exact solutions are obtained for $\nu\neq\eta$ for which plasma is confined in cylindrical domains by the magnetic field **B** only while the plasma pressure P is zero at the boundary and is positive inside the domains. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1629137]

I. INTRODUCTION

The magnetohydrodynamics equations have the form

$$\frac{\partial\mathbf{V}}{\partial t}+(\mathbf{V}\cdot\operatorname{grad})\mathbf{V}=-\frac{1}{\rho}\operatorname{grad}P+\nu\Delta\mathbf{V}+\frac{1}{\rho\mu}\operatorname{curl}\mathbf{B}\times\mathbf{B}+\frac{1}{\rho}\mathbf{f}, \tag{1.1}$$

$$\frac{\partial\mathbf{B}}{\partial t}=\operatorname{curl}(\mathbf{V}\times\mathbf{B})+\eta\Delta\mathbf{B}, \tag{1.2}$$

$$\operatorname{div}\mathbf{V}=0,\quad \operatorname{div}\mathbf{B}=0, \tag{1.3}$$

where **B** is the magnetic vector field, **V** is the plasma velocity and P is the pressure. We suppose that the plasma density ρ, its kinematic viscosity ν, magnetic permeability μ, and the resistivity (or magnetic diffusivity) η are constant and assume that **f** is the vector field of the external gravitational force, $\mathbf{f}=-\rho\operatorname{grad}\Phi$, where $\Phi(t,\mathbf{x})$ is the gravitational potential and denote $\mathbf{x}=(x,y,z)$. For $\mathbf{B}=0$, the MHD equations turn into the Navier–Stokes equations (NSE):

$$\frac{\partial\mathbf{V}}{\partial t}+(\mathbf{V}\cdot\operatorname{grad})\mathbf{V}=-\frac{1}{\rho}\operatorname{grad}P+\nu\Delta\mathbf{V}+\frac{1}{\rho}\mathbf{f},\quad \operatorname{div}\mathbf{V}=0. \tag{1.4}$$

The NSE were intensively studied in the literature, see the Leray paper[1] and the monographs.[2,3] There are well-known exact parallel shear or unidirectional flows for which all streamlines are parallel to the axis z and velocity **V** is independent of z; this class contains the steady Couette flow and Poiseuille flow. There are exact cylindrically symmetric solutions with closed plane streamlines.[4] The known Landau[5] and Squire[6] exact solution describes a steady and axially symmetric laminar jet; the solution has singularity at $r=0$, infinite total kinetic energy and has the asymptotics $|\mathbf{V}(x,y,z)|=r^{-1}f(\theta)$ as $r\to\infty$ where r, θ, ϕ are the spherical coordinates.

Cole[7] and Hopf[8] demonstrated that the Burgers equation[9]

$$\frac{\partial\mathbf{V}}{\partial t}+(\mathbf{V}\cdot\operatorname{grad})\mathbf{V}=\nu\Delta\mathbf{V} \tag{1.5}$$

has exact potential solutions $\mathbf{V}=-2\nu\,\mathrm{grad}(\log\Psi)$ where function $\Psi(t,\mathbf{x})$ satisfies the diffusion equation $\Psi_t=\nu\Delta\Psi$. The incompressibility condition $\mathrm{div}\,\mathbf{V}=0$ and the pressure P are ignored in the Burgers equation (1.5).

In the paper[10] we presented the following exact solutions to the complete system of the viscous MHD equations with the necessary constraints $\mathrm{div}\,\mathbf{V}=0$, $\mathrm{div}\,\mathbf{B}=0$:

$$\mathbf{V}(t,\mathbf{x})=e^{-\alpha^2\nu t}\int\int_{S^2}[\sin(\alpha\mathbf{k}\cdot\mathbf{x})\mathbf{T}(\mathbf{k})+\cos(\alpha\mathbf{k}\cdot\mathbf{x})\mathbf{k}\times\mathbf{T}(\mathbf{k})]\,\mathrm{d}\sigma, \tag{1.6}$$

$$\mathbf{B}(t,\mathbf{x})=C_1\exp[-\alpha^2(\eta-\nu)t]\mathbf{V}(t,\mathbf{x}),$$

$$P(t,\mathbf{x})=C_2-\rho\mathbf{V}^2(t,\mathbf{x})-\rho\Phi(t,\mathbf{x}).$$

Here the integral is taken with respect to an arbitrary measure $\mathrm{d}\sigma$ on the two-dimensional unit sphere S^2: $\mathbf{k}\cdot\mathbf{k}=1$ and $\mathbf{T}(\mathbf{k})$ is an arbitrary smooth vector field tangent to the unit sphere, $\mathbf{T}(\mathbf{k})\cdot\mathbf{k}=0$ and $\alpha\neq0$ is an arbitrary parameter. The solutions satisfy the Beltrami equation $\mathrm{curl}\,\mathbf{V}=\alpha\mathbf{V}$. For $C_1=0$, we get the exact solutions to the Navier–Stokes equations (1.4). For the special vector fields $\mathbf{T}(\mathbf{k})$ and the Euclidean measure $\mathrm{d}\sigma$, solutions (1.6) have the solitonlike properties, see Refs. 11 and 12.

In this paper we introduce the unsteady field-aligned equipartition solutions to the MHD equations (1.1)–(1.3) that describe the plasma relaxation in the regime of a strong interaction between the magnetic field $\mathbf{B}(t,\mathbf{x})$ and the plasma velocity $\mathbf{V}(t,\mathbf{x})$ (these solutions were first announced in Refs. 13 and 14). The interaction causes the equality of the densities of the plasma magnetic and kinetic energies and the collinearity of the fields $\mathbf{B}(t,\mathbf{x})$ and $\mathbf{V}(t,\mathbf{x})$. The solutions exist when the kinematic viscosity ν is equal to the resistivity η. As an application we construct for $\nu=\eta>0$ the nonequipartition solutions describing a plasma relaxation to an equilibrium with a constant magnetic field $\mathbf{B}$. For the unsteady equipartition solutions with $\nu=\eta>0$, the viscous MHD equations are reduced to the linear system of the vector diffusion equation and the incompressibility equation:

$$\frac{\partial\mathbf{V}}{\partial t}=\nu\Delta\mathbf{V},\quad \mathrm{div}\,\mathbf{V}=0. \tag{1.7}$$

We derive the global equipartition solutions in $\mathbb{R}^3$ for which the total plasma magnetic and kinetic energies are finite and equal. The obtained solutions are different from the small Alfvénic fluctuations or waves[15–18] that satisfy the equation $\delta\mathbf{B}=\pm\sqrt{\rho\mu}\,\delta\mathbf{V}$ for the variations $\delta\mathbf{B}$, $\delta\mathbf{V}$.

We present the exact nonsymmetric equipartition solutions to the boundary value problem

$$\frac{\partial\mathbf{V}}{\partial t}=\nu\Delta\mathbf{V},\quad \mathrm{div}\,\mathbf{V}=0,\quad \mathbf{V}|_{\partial\mathcal{D}}=0 \tag{1.8}$$

with the "no-slip" boundary condition which describe the viscous plasma relaxation in a ball $\mathcal{D}$ with a constant pressure at the boundary. We show that the corresponding initial-boundary value problem is overdetermined. The steady ideal MHD equilibria in a ball with $\nu=\eta=0$ and $\mathbf{V}=0$ were first found by Wu and Chen[19] and by Kaiser and Lortz.[20]

For the generic case $\nu\neq\eta$, we derive the exact translationally invariant solutions that model the plasma relaxation inside cylindrical domains $\mathcal{D}$. An important property of these solutions is that the pressure $P(t,\mathbf{x})$ is positive inside the plasma volume $\mathcal{D}$ and is zero at the boundary $\partial\mathcal{D}$. Hence it is the magnetic field $\mathbf{B}(t,\mathbf{x})$ that confines plasma inside the domain $\mathcal{D}$ but not the external pressure that is zero.

II. UNSTEADY EQUIPARTITION SOLUTIONS

The magnetohydrodynamics equations (1.1)–(1.3) for $\nu=\eta$ have the following exact field-aligned equipartition solutions

$$\mathbf{V}(t,\mathbf{x})=\frac{1}{(4\pi\nu t)^{3/2}}\operatorname{curl}\int_{R^3}\mathbf{A}(\mathbf{x}')\exp\left(-\frac{|\mathbf{x}-\mathbf{x}'|^2}{4\nu t}\right)\mathrm{d}\tau', \tag{2.1}$$

$$\mathbf{B}(t,\mathbf{x})=\pm\sqrt{\rho\mu}\,\mathbf{V}(t,\mathbf{x}), \tag{2.2}$$

where $\mathrm{d}\tau'=\mathrm{d}x'\,\mathrm{d}y'\,\mathrm{d}z'$ and the vector field $\mathbf{A}(\mathbf{x}')$ is arbitrary and coincides with the vector potential of the initial vector field $\mathbf{V}(0,\mathbf{x}')$: $\operatorname{curl}\mathbf{A}(\mathbf{x}')=\mathbf{V}(0,\mathbf{x}')$. The pressure P has the form

$$P(t,\mathbf{x})=C-\rho\mathbf{V}^2(t,\mathbf{x})/2-\rho\Phi(t,\mathbf{x}). \tag{2.3}$$

Using the known identity

$$(\mathbf{V}\cdot\operatorname{grad})\mathbf{V}=\operatorname{curl}\mathbf{V}\times\mathbf{V}+\operatorname{grad}(\mathbf{V}^2/2), \tag{2.4}$$

one transforms equations (1.1) to the form

$$\frac{\partial\mathbf{V}}{\partial t}=\mathbf{V}\times\operatorname{curl}\mathbf{V}+\nu\Delta\mathbf{V}+\frac{1}{\rho\mu}\operatorname{curl}\mathbf{B}\times\mathbf{B}-\operatorname{grad}\frac{1}{\rho}\left(P+\frac{1}{2}\mathbf{V}^2+\Phi\right). \tag{2.5}$$

Equations (2.5) and (1.2) after substitution of (2.2) take the form

$$\frac{\partial\mathbf{V}}{\partial t}=\nu\Delta\mathbf{V}-\operatorname{grad}\left(\frac{1}{\rho}P+\frac{1}{2}\mathbf{V}^2+\Phi\right),\quad \frac{\partial\mathbf{V}}{\partial t}=\eta\Delta\mathbf{V}.$$

Applying operator curl to these two equations we find the conditions of their compatibility

$$\nu=\eta,\quad \frac{1}{\rho}P(t,\mathbf{x})+\frac{1}{2}\mathbf{V}^2(t,\mathbf{x})+\Phi(t,\mathbf{x})=\text{const}.$$

For this case, the equations (1.1)–(1.3) are reduced to the linear equations (1.7). The solutions to the scalar diffusion equation $\partial u/\partial t=\nu\Delta u$ have the form[1]

$$u(t,\mathbf{x})=\frac{1}{(4\pi\nu t)^{3/2}}\int_{R^3}f(\mathbf{x}')\exp\left(-\frac{|\mathbf{x}-\mathbf{x}'|^2}{4\nu t}\right)\mathrm{d}\tau',$$

where $f(\mathbf{x}')=u(0,\mathbf{x}')$ are the initial data. Substituting here an arbitrary vector field $\mathbf{A}(\mathbf{x}')$ instead of the function $f(\mathbf{x}')$ we get a solution to the vector diffusion equation (1.7). Applying to this solution operator curl we obtain the vector field (2.1) that is divergence free and hence satisfies both equations (1.7) and therefore the MHD equations (1.1)–(1.3).

Remark 1: The exact solutions (2.1), (2.2) are the unsteady equipartition solutions because the densities of the kinetic and magnetic energies are equal: $\rho\mathbf{V}^2(t,\mathbf{x})=\mathbf{B}^2(t,\mathbf{x})/\mu$. It is evident that if the vector field $\mathbf{A}(\mathbf{x}')$ is square integrable then the solutions (2.1), (2.2) are square integrable also; hence the total kinetic and magnetic energies are finite and equal.

Remark 2: The derived exact solutions (2.1)–(2.3) describe a plasma relaxation in a regime of a strong interaction between the plasma velocity $\mathbf{V}$ and the magnetic field $\mathbf{B}$. Indeed, the very fact of the equality of the densities of the plasma kinetic and magnetic energies and the collinearity (2.2) mean a strong interaction between the magnetic field $\mathbf{B}(t,\mathbf{x})$ and the plasma velocity $\mathbf{V}(t,\mathbf{x})$.

Remark 3: Solutions (2.1) can be represented also in the form

$$\mathbf{V}(t,\mathbf{x})=\int_{R^3}\exp(-\nu\mathbf{k}^2t)[\cos(\mathbf{k}\cdot\mathbf{x})\mathbf{S}(\mathbf{k})+\sin(\mathbf{k}\cdot\mathbf{x})\mathbf{T}(\mathbf{k})]\mathrm{d}\tau, \tag{2.6}$$

where $\mathrm{d}\tau=\mathrm{d}k_1\,\mathrm{d}k_2\,\mathrm{d}k_3$ and the vector fields $\mathbf{S}(\mathbf{k})$ and $\mathbf{T}(\mathbf{k})$ are tangent to the spheres $\mathbf{k}\cdot\mathbf{k}=\text{const}$, or the equations $\mathbf{k}\cdot\mathbf{S}(\mathbf{k})=0$, $\mathbf{k}\cdot\mathbf{T}(\mathbf{k})=0$ hold. Indeed, a direct calculation proves that the vector field (2.6) satisfies both equations (1.7).

III. AN APPLICATION TO THE PLASMA RELAXATION TO A CONSTANT MAGNETIC FIELD

As a first application of the equipartition solutions (2.1)–(2.3) we construct the following exact solutions for $\nu=\eta$:

$$\mathbf{V}_2(t,\mathbf{x})=\frac{1}{(4\pi\nu t)^{3/2}}\operatorname{curl}\int_{R^3}\mathbf{A}(\mathbf{x}')\exp\left(-\frac{|\mathbf{x}\pm\mathbf{B}_0t/\sqrt{\rho\mu}-\mathbf{x}'|^2}{4\nu t}\right)\mathrm{d}\tau', \tag{3.1}$$

$$\mathbf{B}_2(t,\mathbf{x})=\pm\sqrt{\rho\mu}\,\mathbf{V}_2(t,\mathbf{x})+\mathbf{B}_0,$$

$$P_2(t,\mathbf{x})=C-\frac{\rho}{2}\left(\mathbf{V}_2(t,\mathbf{x})\pm\frac{1}{\sqrt{\rho\mu}}\mathbf{B}_0\right)^2-\rho\Phi\left(t,\mathbf{x}\pm\frac{1}{\sqrt{\rho\mu}}\mathbf{B}_0t\right).$$

To prove that (3.1) is an exact solution, we consider first for any square integrable vector field $\mathbf{V}(t,\mathbf{x})$ (2.1) the following equipartition solution:

$$\mathbf{V}_1(t,\mathbf{x})=\mathbf{V}(t,\mathbf{x})\pm\frac{1}{\sqrt{\rho\mu}}\mathbf{B}_0,\quad \mathbf{B}_1(t,\mathbf{x})=\pm\sqrt{\rho\mu}\,\mathbf{V}(t,\mathbf{x})+\mathbf{B}_0, \tag{3.2}$$

$$P_1(t,\mathbf{x})=C-\rho\mathbf{V}_1^2(t,\mathbf{x})/2-\rho\Phi(t,\mathbf{x}),$$

where $\mathbf{B}_0$ is an arbitrary constant vector. The formulas (3.2) define a solution to the equations (1.1)–(1.3) because the equations (1.7), (2.2), and (2.3) are satisfied.

As is known, the magnetohydrodynamics equations (1.1)–(1.3) are invariant with respect to the Galilean transforms

$$\mathbf{V}_2(t,\mathbf{x})=\mathbf{V}_1(t,\mathbf{x}-\mathbf{u}t)+\mathbf{u},\quad \mathbf{B}_2(t,\mathbf{x})=\mathbf{B}_1(t,\mathbf{x}-\mathbf{u}t), \tag{3.3}$$

$$P_2(t,\mathbf{x})=P_1(t,\mathbf{x}-\mathbf{u}t),$$

where $\mathbf{u}$ is an arbitrary constant vector. Applying the Galilean transform (3.3) with the vector $\mathbf{u}=\mp\mathbf{B}_0/\sqrt{\rho\mu}$ to the exact solutions (3.2), we obtain the solutions (3.1).

The exact solutions (3.1) evidently are not the equipartition ones and not the field-aligned ones. For these solutions the plasma velocity $\mathbf{V}_2(t,\mathbf{x})\to0$ as $t\to\infty$ and as $|\mathbf{x}|\to\infty$ and is square integrable. At the same time the magnetic field $\mathbf{B}_2(t,\mathbf{x})\to\mathbf{B}_0$. Therefore the derived noncollinear and nonequipartition solutions (3.1) describe a plasma relaxation to an equilibrium with a constant magnetic field $\mathbf{B}_0$.

IV. PLASMA RELAXATION IN A BALL

The steady MHD equilibria in a ball are constructed in Refs. 19 and 20 where the authors consider the ideal plasma ($\nu=\eta=0$) with zero velocity $\mathbf{V}(t,\mathbf{x})=0$. In Ref. 21 we generalize these solutions to the ideal MHD equilibria with dynamics of plasma with a steady velocity $\mathbf{V}(t,\mathbf{x})=\mathbf{V}(\mathbf{x})\neq0$ using the newly discovered symmetry transform.[21,22] In this section we present the unsteady equipartition solutions in a ball that take into account the effects of the plasma viscosity and the finite electric conductivity ($\nu=\eta\neq0$) and have spherical magnetic surfaces $|\mathbf{x}|=r$.

For the equipartition solutions (2.2) in a domain $\mathcal{D}\subset\mathbb{R}^3$, the initial-boundary value problem with the "no-slip" boundary condition $\mathbf{V}(t,\mathbf{x})|_{\partial\mathcal{D}}=0$ is overdetermined.

Indeed, since the equipartition solutions satisfy the system of equations (1.7), the initial-boundary value problem for them takes the form

$$\frac{\partial\mathbf{V}}{\partial t}=\nu\Delta\mathbf{V},\quad \operatorname{div}\mathbf{V}=0,\quad \mathbf{V}(t,\mathbf{x})|_{\partial\mathcal{D}}=0,\quad \mathbf{V}(0,\mathbf{x})=\mathbf{U}(\mathbf{x}),\tag{4.1}$$

where the vector field $\mathbf{U}(\mathbf{x})$ is the initial plasma velocity in the domain $\mathcal{D}$. The presence of the additional incompressibility condition $\operatorname{div}\mathbf{V}=0$ makes the problem (4.1) overdetermined. Indeed, let us consider the solutions independent of the variable z. Then the incompressibility equation implies $\mathbf{V}(t,x,y)=-\psi_y\mathbf{e}_x+\psi_x\mathbf{e}_y$ where $\psi(t,x,y)$ is a streamfunction and $\psi_x=\partial\psi/\partial x$, $\psi_y=\partial\psi/\partial y$. For this case the initial-boundary value problem (4.1) takes the form

$$\psi_t=\nu(\psi_{xx}+\psi_{yy}),\quad \psi_x|_{\partial\mathcal{D}}=0,\quad \psi_y|_{\partial\mathcal{D}}=0,\quad \psi(0,x,y)=f(x,y).\tag{4.2}$$

The two boundary conditions in (4.2) are equivalent to the taken simultaneously Dirichlet's and Neumann's conditions,

$$\psi(t,x,y)|_{\partial\mathcal{D}}=\text{const},\quad \left.\frac{\partial\psi(t,x,y)}{\partial\mathbf{n}}\right|_{\partial\mathcal{D}}=0.$$

Here $\mathbf{n}$ is the unit normal vector field to the boundary $\partial\mathcal{D}$. As is known,[23] for each of these two boundary conditions separately the initial-boundary value problem for the diffusion equation $\psi_t=\nu(\psi_{xx}+\psi_{yy})$ has a unique solution (up to a constant), and the two solutions are different in general. Hence the problem (4.2) is overdetermined.

Therefore we construct some solutions to the boundary value problem (1.8) without prescribed initial conditions. Let the domain $\mathcal{D}$ be a ball of radius R. Function

$$F_\alpha(\mathbf{x})=\frac{\sin(\alpha|\mathbf{x}|)}{\alpha|\mathbf{x}|}$$

satisfies the Helmholtz equation $\Delta F_\alpha(\mathbf{x})=-\alpha^2F_\alpha(\mathbf{x})$ where α is an arbitrary parameter. Hence for an arbitrary vector $\mathbf{a}$ the vector field $\mathbf{A}(\mathbf{x})=F_\alpha(\mathbf{x})\mathbf{a}$ satisfies the vector Helmholtz equation $\Delta\mathbf{A}(\mathbf{x})=-\alpha^2\mathbf{A}(\mathbf{x})$. Therefore the vector field

$$\mathbf{V}(t,\mathbf{x},\mathbf{a})=e^{-\alpha^2\nu t}\operatorname{curl}(F_\alpha(\mathbf{x})\mathbf{a})=e^{-\alpha^2\nu t}h_\alpha(\mathbf{x})\mathbf{x}\times\mathbf{a}\tag{4.3}$$

satisfies the first two equations (1.8). Here

$$h_\alpha(\mathbf{x})=h_\alpha(|\mathbf{x}|)=F'_\alpha(|\mathbf{x}|)|\mathbf{x}|^{-1}=\cos(\alpha|\mathbf{x}|)|\mathbf{x}|^{-2}-\sin(\alpha|\mathbf{x}|)\alpha^{-1}|\mathbf{x}|^{-3}\tag{4.4}$$

is a smooth function of $\mathbf{x}$.

The zeros of the function $h_\alpha(z\alpha^{-1})$ satisfy the equation

$$\tan z=z.\tag{4.5}$$

Let $z_1,\dots,z_k,\dots$ be the positive roots of equation (4.5). As is known,

$$z_k\approx k\pi+\frac{\pi}{2}-\frac{2}{(2k+1)\pi}\quad\text{as}\quad k\to\infty,\quad k\pi+\frac{\pi}{4}<z_k<k\pi+\frac{\pi}{2}.$$

Formula (4.4) yields that $h_\alpha(z_k\alpha^{-1})=0$. Therefore the vector field $\mathbf{V}(t,\mathbf{x},\mathbf{a})$ (4.3) vanishes on the spheres $|\mathbf{x}|=z_k\alpha^{-1}$. Hence for the discrete values of α: $\alpha_1=z_1R^{-1}$, $\alpha_2=z_2R^{-1},\dots$ and for the arbitrary vectors $\mathbf{a}=\mathbf{a}_k$ the vector fields (4.3) vanish on the sphere $|\mathbf{x}|=R$. Thus the vector fields

$$\mathbf{V}_k(t,\mathbf{x},\mathbf{a}_k)=e^{-z_k^2R^{-2}\nu t}\left[\frac{\cos(z_kR^{-1}|\mathbf{x}|)}{|\mathbf{x}|^2}-R\frac{\sin(z_kR^{-1}|\mathbf{x}|)}{z_k|\mathbf{x}|^3}\right]\mathbf{x}\times\mathbf{a}_k \tag{4.6}$$

satisfy the boundary value problem (1.8) in the ball $|\mathbf{x}|\leqslant R$. The vector fields (4.6) have two first integrals $f_1(t,\mathbf{x})=|\mathbf{x}|$ and $f_2(t,\mathbf{x})=\mathbf{x}\cdot\mathbf{a}_k$; hence their magnetic field lines are circumferences in the planes orthogonal to the vectors $\mathbf{a}_k$. A more general solution to the boundary value problem (1.8) is represented by the convergent series

$$\mathbf{V}(t,\mathbf{x})=\sum_{k=1}^{\infty}e^{-z_k^2R^{-2}\nu t}\left[\frac{\cos(z_kR^{-1}|\mathbf{x}|)}{|\mathbf{x}|^2}-R\frac{\sin(z_kR^{-1}|\mathbf{x}|)}{z_k|\mathbf{x}|^3}\right]\mathbf{x}\times\mathbf{a}_k, \tag{4.7}$$

where we suppose that the series $\Sigma_{k=1}^{\infty}|\mathbf{a}_k|$ is convergent. The unsteady equipartition solutions (2.2), (2.3), (4.7) satisfy the boundary value problem (1.8) in the ball $|\mathbf{x}|\leqslant R$. The pressure (2.3) is $P(t,\mathbf{x})=P_0-\rho\mathbf{V}^2(t,\mathbf{x})/2$ where P_0 is an arbitrary constant. Hence we find at the boundary $|\mathbf{x}|=R$:

$$P(t,\mathbf{x})=P_0,\quad \text{grad } P(t,\mathbf{x})=0.$$

The solution is continued in the outer space by the trivial solution $P=P_0$, $\mathbf{B}=0$, $\mathbf{V}=0$.

A direct calculation using the equations $\tan z_k=z_k$ proves that the total kinetic energy of the field (4.7) inside the ball $\mathcal{D}$ has the simple form

$$E=\frac{\rho}{2}\int_{\mathcal{D}}\mathbf{V}^2\,dx\,dy\,dz=\frac{2\pi\rho R}{3}\sum_{k=1}^{\infty}e^{-2z_k^2R^{-2}\nu t}|\mathbf{a}_k|^2\frac{z_k^2}{1+z_k^2},$$

for arbitrary vectors $\mathbf{a}_k$. The total plasma kinetic plus magnetic energy for the solutions (2.2), (4.7) is equal to $2E$.

The solutions (2.2), (4.7) possess invariant magnetic surfaces that are the spheres $|\mathbf{x}|=r=\text{const}$. We have $\mathbf{V}(t,\mathbf{x})=\mathbf{x}\times\mathbf{\Omega}(t,|\mathbf{x}|)$ where

$$\mathbf{\Omega}(t,r)=\sum_{k=1}^{\infty}e^{-z_k^2R^{-2}\nu t}\left[\frac{\cos(z_kR^{-1}r)}{r^2}-R\frac{\sin(z_kR^{-1}r)}{z_kr^3}\right]\mathbf{a}_k. \tag{4.8}$$

Therefore on each sphere $|\mathbf{x}|=r$ the vector field $\mathbf{V}(t,\mathbf{x})$ (4.7) defines a rotation around the vector $\mathbf{\Omega}(t,r)$ (4.8) that depends on t and r. Hence the solutions (2.2), (4.7) have no geometrical symmetries provided that some of the vectors $\mathbf{a}_k$ are noncollinear. It is evident that the solutions (2.2), (4.7) have spherical magnetic surfaces $|\mathbf{x}|=r\leqslant R$. The boundary value problem (1.8) is transformed to that for the vector $\mathbf{\Omega}(t,r)$:

$$\mathbf{\Omega}_t=\nu(4r^{-1}\mathbf{\Omega}_r+\mathbf{\Omega}_{rr}),\quad \mathbf{\Omega}(t,0)=0,\quad \mathbf{\Omega}(t,R)=0,$$

where $\mathbf{\Omega}_t=\partial\mathbf{\Omega}/\partial t$, $\mathbf{\Omega}_r=\partial\mathbf{\Omega}/\partial r$.

V. TRANSLATIONALLY INVARIANT SOLUTIONS FOR $\nu\neq\eta$

The viscous MHD equations (1.1)–(1.3) for arbitrary constants ρ, μ, ν, η have an infinite-dimensional family of exact solutions

$$\mathbf{V}(t,\tilde{\mathbf{x}})=e^{-\alpha^2\nu t}[-a\psi_y(\tilde{\mathbf{x}})\hat{\mathbf{e}}_x+a\psi_x(\tilde{\mathbf{x}})\hat{\mathbf{e}}_y+b\psi(\tilde{\mathbf{x}})\hat{\mathbf{e}}_z]+c\hat{\mathbf{e}}_z, \tag{5.1}$$

$$\mathbf{B}(t,\tilde{\mathbf{x}})=e^{-\alpha^2\eta t}[-k\psi_y(\tilde{\mathbf{x}})\hat{\mathbf{e}}_x+k\psi_x(\tilde{\mathbf{x}})\hat{\mathbf{e}}_y+\ell\psi(\tilde{\mathbf{x}})\hat{\mathbf{e}}_z]+m\hat{\mathbf{e}}_z, \tag{5.2}$$

where $\tilde{\mathbf{x}}=(x,y)$ and a,b,c,k,ℓ,m and α are arbitrary parameters, $\psi_x=\partial\psi/\partial x$, $\psi_y=\partial\psi/\partial y$ and the flux function $\psi(\tilde{\mathbf{x}})$ satisfies the two-dimensional Helmholtz equation

$$\Delta\psi(\tilde{\mathbf{x}}) = -\alpha^2\psi(\tilde{\mathbf{x}}). \tag{5.3}$$

The pressure P is

$$P = C - \frac{a^2\rho}{2}E^2(\psi_x^2+\psi_y^2+\alpha^2\psi^2) + \frac{\alpha^2k^2-\ell^2}{2\mu}E_m^2\psi^2 - \frac{\ell m}{\mu}E_m\psi, \tag{5.4}$$

where $E=\exp(-\alpha^2\nu t)$ and $E_m=\exp(-\alpha^2\eta t)$. The solutions possess invariant magnetic surfaces that are defined by the equations $\psi(\tilde{\mathbf{x}})=\text{const}$. For $k=\ell=m=0$, the formulas (5.1)–(5.4) describe exact solutions to the Navier–Stokes equations (1.4).

It is evident that the vector fields (5.1), (5.2) have the form

$$\mathbf{V} = b\mathbf{U} - a\,\text{curl}\,\mathbf{U} + c\hat{\mathbf{e}}_z, \quad \mathbf{B} = e^{-\alpha^2(\eta-\nu)t}(\ell\mathbf{U} - k\,\text{curl}\,\mathbf{U}) + m\hat{\mathbf{e}}_z, \tag{5.5}$$

where vector field $\mathbf{U}=\exp(-\alpha^2\nu t)\psi(\tilde{\mathbf{x}})\hat{\mathbf{e}}_z$ satisfies the equations $\text{div}\,\mathbf{U}=0$, $\Delta\mathbf{U}=-\alpha^2\mathbf{U}$. Hence using the identity $\text{curl}\,\text{curl}\,\mathbf{U}=\text{grad}\,\text{div}\,\mathbf{U}-\Delta\mathbf{U}$ we find

$$\text{curl}\,\mathbf{V} = -\alpha^2 a\mathbf{U} + b\,\text{curl}\,\mathbf{U}, \quad \text{curl}\,\mathbf{B} = e^{-\alpha^2(\eta-\nu)t}(-\alpha^2 k\mathbf{U} + \ell\,\text{curl}\,\mathbf{U}). \tag{5.6}$$

The formulas (5.5)–(5.6) imply

$$\text{curl}\,\mathbf{V}\times\mathbf{V} = (b^2-\alpha^2a^2)\text{curl}\,\mathbf{U}\times\mathbf{U} + bc\,\text{curl}\,\mathbf{U}\times\hat{\mathbf{e}}_z = \text{grad}[(\alpha^2a^2-b^2)E^2\psi^2/2 - bcE\psi]. \tag{5.7}$$

Hence using the identity (2.4) we get

$$(\mathbf{V}\cdot\text{grad})\mathbf{V} = a^2E^2\,\text{grad}(\psi_x^2+\psi_y^2+\alpha^2\psi^2)/2. \tag{5.8}$$

Analogously we obtain

$$\text{curl}\,\mathbf{B}\times\mathbf{B} = \text{grad}[(\alpha^2k^2-\ell^2)E_m^2\psi^2/2 - \ell mE_m\psi], \tag{5.9}$$

$$\mathbf{V}\times\mathbf{B} = \text{grad}[(a\ell-bk)EE_m\psi^2/2 + (amE-ckE_m)\psi]. \tag{5.10}$$

For the vector fields (5.1)–(5.2), equations (1.3) hold identically. A substitution of the formulas (5.8)–(5.10) shows that equations (1.1)–(1.2) reduce to the form

$$\frac{\partial\mathbf{B}}{\partial t} = \eta\Delta\mathbf{B}, \quad \frac{\partial\mathbf{V}}{\partial t} = \nu\Delta\mathbf{V} - \text{grad}\left(\frac{P}{\rho} + \frac{a^2E^2}{2}(\psi_x^2+\psi_y^2+\alpha^2\psi^2) - \frac{\alpha^2k^2-\ell^2}{2\rho\mu}E_m^2\psi^2 + \frac{\ell m}{\rho\mu}E_m\psi\right). \tag{5.11}$$

An inspection proves that the vector fields (5.1), (5.2) satisfy equations (5.11) provided that the pressure P has form (5.4) and function $\psi(\tilde{\mathbf{x}})$ is any solution to the Helmholtz equation (5.3). Such solutions can be taken in the form

$$\psi(\tilde{\mathbf{x}}) = \int_0^{2\pi}[\sin(\alpha\mathbf{k}\cdot\tilde{\mathbf{x}})f_1(\phi) + \cos(\alpha\mathbf{k}\cdot\tilde{\mathbf{x}})f_2(\phi)]\,\mathrm{d}\phi. \tag{5.12}$$

Here vector $\mathbf{k}=(\cos\phi)\mathbf{e}_x+(\sin\phi)\mathbf{e}_y$, $0\leqslant\phi\leqslant2\pi$, and $f_1(\phi)$, $f_2(\phi)$ are any integrable functions.

The exact solutions (5.1)–(5.4) were first announced in Ref. 24. For the special case $b=c=0$, $k=\ell=m=0$, they become the Taylor two-dimensional flows of viscous fluid.[25]

VI. MAGNETIC CONFINEMENT OF PLASMA IN CYLINDRICAL DOMAINS

For $a=c=0$ and arbitrary constants ρ, μ, ν, η, the solutions (5.1)–(5.4) take the form

$$\mathbf{V}(t,\tilde{\mathbf{x}})=be^{-\alpha^2\nu t}\psi(\tilde{\mathbf{x}})\hat{\mathbf{e}}_z, \tag{6.1}$$

$$\mathbf{B}(t,\tilde{\mathbf{x}})=e^{-\alpha^2\eta t}[-k\psi_y(\tilde{\mathbf{x}})\hat{\mathbf{e}}_x+k\psi_x(\tilde{\mathbf{x}})\hat{\mathbf{e}}_y+\ell\psi(\tilde{\mathbf{x}})\hat{\mathbf{e}}_z]+m\hat{\mathbf{e}}_z, \tag{6.2}$$

$$P(t,\tilde{\mathbf{x}})=\frac{\alpha^2k^2-\ell^2}{2\mu}e^{-2\alpha^2\eta t}\psi^2(\tilde{\mathbf{x}})-\frac{\ell m}{\mu}e^{-\alpha^2\eta t}\psi(\tilde{\mathbf{x}}). \tag{6.3}$$

For $\alpha^2k^2\geqslant\ell^2$ and $\ell m\leqslant 0$, the solutions (6.1)–(6.3) describe a relaxation of the plasma flow inside the z-invariant cylindrical domains $\mathcal{D}$ where $\psi(\tilde{\mathbf{x}})\geqslant 0$. The function $\psi(\tilde{\mathbf{x}})$ satisfies the Helmholtz equation (5.3). At the boundary $\psi(\tilde{\mathbf{x}})=0$, the necessary boundary conditions $\mathbf{V}(t,\tilde{\mathbf{x}})=0$ and $P(t,\tilde{\mathbf{x}})=0$ hold (the pressure P is defined up to an arbitrary constant C). The magnetic field $\mathbf{B}(t,\tilde{\mathbf{x}})$ lines and the electric current $\mathbf{J}(t,\tilde{\mathbf{x}})$ lines preserve the magnetic surfaces $\psi(\tilde{\mathbf{x}})=\text{const}$. The electric current is

$$\mathbf{J}(t,\tilde{\mathbf{x}})=\mu^{-1}\operatorname{curl}\mathbf{B}(t,\tilde{\mathbf{x}})=\mu^{-1}e^{-\alpha^2\eta t}[\ell\psi_y(\tilde{\mathbf{x}})\hat{\mathbf{e}}_x-\ell\psi_x(\tilde{\mathbf{x}})\hat{\mathbf{e}}_y-\alpha^2k\psi(\tilde{\mathbf{x}})\hat{\mathbf{e}}_z].$$

For example, let the function $\psi(\tilde{\mathbf{x}})$ be

$$\psi_1(\tilde{\mathbf{x}})=\cos(\beta x)\cos(\sqrt{\alpha^2-\beta^2}\,y),\quad \beta>0,\ \alpha^2>\beta^2. \tag{6.4}$$

The Helmholtz equation $\Delta\psi_1(\tilde{\mathbf{x}})=-\alpha^2\psi_1(\tilde{\mathbf{x}})$ evidently holds. The corresponding cylindrical domain $\mathcal{D}$ has the rectangular form

$$|x|\leqslant\frac{\pi}{2\beta},\quad |y|\leqslant\frac{\pi}{2\sqrt{\alpha^2-\beta^2}},\quad -\infty<z<\infty. \tag{6.5}$$

A more general class of solutions to the Helmholtz equation has the form

$$\psi_2(\tilde{\mathbf{x}})=\int_0^{|\alpha|}f(\tau)\cos(\tau x)\cos(\sqrt{\alpha^2-\tau^2}\,y)\,\mathrm{d}\tau, \tag{6.6}$$

where $f(\tau)$ is a distribution. The solution (6.4) corresponds to $f(\tau)=\delta(\tau-\beta)$. Any function $\psi_2(\tilde{\mathbf{x}})$ (6.6) specifies a domain $\mathcal{D}$: $\psi_2(\tilde{\mathbf{x}})\geqslant 0$. It is plausible that any smooth closed curve in a neighborhood of the rectangle (6.5) can be defined by the equation $\psi_2(\tilde{\mathbf{x}})=0$ for an appropriate distribution $f(\tau)$ in (6.6).

Remark 4: The exact solutions (6.1)–(6.3) exist for arbitrary values of the physical constants ρ, μ, ν, and η and describe a relaxation as $t\to\infty$ of the plasma flows inside the cylindrical domains $\mathcal{D}$ where $\psi(\tilde{\mathbf{x}})\geqslant 0$. An important property of the exact solutions (6.1)–(6.3) is that the pressure $P(t,\tilde{\mathbf{x}})$ (6.3) for $\alpha^2k^2\geqslant\ell^2$ and $\ell m\leqslant 0$ attains its minimum 0 at the boundary $\partial\mathcal{D}$, $\psi(\tilde{\mathbf{x}})=0$, and is positive inside the domain $\mathcal{D}$. Hence the plasma is confined inside the cylindrical domain $\mathcal{D}$ only by the magnetic field $\mathbf{B}(t,\tilde{\mathbf{x}})$ (6.2) and not by an external pressure that is zero.

VII. TRANSLATIONALLY INVARIANT NONEQUIPARTITION SOLUTIONS FOR $\nu=\eta$

The viscous MHD equations (1.1)–(1.3) for $\nu=\eta$ and $\mathbf{f}=0$ have an infinite-dimensional family of z-translationally invariant exact solutions

$$\mathbf{V}(t,x,y)=-a\psi_y\hat{\mathbf{e}}_x+a\psi_x\hat{\mathbf{e}}_y+(b\psi+c)\hat{\mathbf{e}}_z, \tag{7.1}$$

$$\mathbf{B}(t,x,y)=-k\psi_y\hat{\mathbf{e}}_x+k\psi_x\hat{\mathbf{e}}_y+(\ell\psi+m)\hat{\mathbf{e}}_z, \tag{7.2}$$

where $\psi_x=\partial\psi/\partial x$, $\psi_y=\partial\psi/\partial y$, a,b,c,k,ℓ,m *are arbitrary parameters satisfying the equation* $a^2=k^2/(\rho\mu)$ *and the flux function* $\psi(t,x,y)$ *satisfies the diffusion equation*

$$\frac{\partial\psi}{\partial t}=\nu\left(\frac{\partial^2\psi}{\partial x^2}+\frac{\partial^2\psi}{\partial y^2}\right). \tag{7.3}$$

The pressure P *is*

$$P=C-\frac{a^2\rho}{2}(\psi_x^2+\psi_y^2)-\frac{\ell^2}{2\mu}\psi^2-\frac{\ell m}{\mu}\psi. \tag{7.4}$$

Indeed, the formulas (7.1)–(7.2) imply

$$(\mathbf{V}\cdot\operatorname{grad})\mathbf{V}=a^2\operatorname{grad}(\psi_x^2+\psi_y^2)/2-a^2\Delta\psi\operatorname{grad}\psi, \tag{7.5}$$

$$\operatorname{curl}\mathbf{B}\times\mathbf{B}=-\operatorname{grad}(\ell^2\psi^2/2+\ell m\psi)-k^2\Delta\psi\operatorname{grad}\psi, \tag{7.6}$$

$$\mathbf{V}\times\mathbf{B}=\operatorname{grad}[(a\ell-bk)\psi^2/2+(am-ck)\psi], \tag{7.7}$$

$$\operatorname{curl}\mathbf{V}\times\mathbf{V}=-\operatorname{grad}(b^2\psi^2/2+bc\psi)-a^2\Delta\psi\operatorname{grad}\psi. \tag{7.8}$$

A substitution of the formulas (7.5)–(7.7) reduces the equations (1.1) and (1.2) for $a^2=k^2/(\rho\mu)$ to the form

$$\frac{\partial\mathbf{V}}{\partial t}=\nu\Delta\mathbf{V}-\operatorname{grad}\left(\frac{P}{\rho}+\frac{a^2}{2}(\psi_x^2+\psi_y^2)+\frac{\ell^2\psi^2}{2\rho\mu}+\frac{\ell m\psi}{\rho\mu}\right),\quad \frac{\partial\mathbf{B}}{\partial t}=\eta\Delta\mathbf{B}. \tag{7.9}$$

Substituting the vector fields (7.1), (7.2) we find that equations (1.3) hold identically and equations (7.9) are satisfied if and only if $\nu=\eta$, the pressure P has form (7.4) and the flux function $\psi(t,x,y)$ satisfies the two-dimensional diffusion equation (7.3). The solutions to this equation have the form[1]

$$\psi(t,\tilde{\mathbf{x}})=\frac{1}{4\pi\nu t}\int_{R^2}f(\tilde{\mathbf{x}}')\exp\left(-\frac{|\tilde{\mathbf{x}}-\tilde{\mathbf{x}}'|^2}{4\nu t}\right)d\tilde{\mathbf{x}}', \tag{7.10}$$

where $\tilde{\mathbf{x}}=(x,y)$, $\tilde{\mathbf{x}}'=(x',y')$, and $f(\tilde{\mathbf{x}}')=\psi(0,\tilde{\mathbf{x}}')$ are the initial data.

Remark 5: The z-invariant solutions (7.1)–(7.4) are rather general for they do not belong to any simpler class of exact solutions. Indeed, formula (7.6) implies that the solutions are not force-free, formula (7.7) shows that they are not field-aligned and formula (7.8) yields that the flows $\mathbf{V}(t,x,y)$ are not the Beltrami flows. The solutions are not the equipartition ones either because

$$\frac{1}{2}\rho\mathbf{V}^2(t,\mathbf{x})-\frac{1}{2\mu}\mathbf{B}^2(t,\mathbf{x})=\frac{1}{2}\rho(b\psi+c)^2-\frac{1}{2\mu}(\ell\psi+m)^2\neq 0.$$

The derived exact solutions are unidirectional only for $a=k=0$. The exact solutions (7.1)–(7.4) are uniformly bounded and for $c=m=0$ tend to zero as $x^2+y^2\to\infty$ if it was so for the initial data $\psi(0,x,y)$.

VIII. SUMMARY

We have introduced the unsteady equipartition solutions to the viscous MHD equations. The solutions exist when the plasma kinematic viscosity is equal to the magnetic diffusivity, $\nu=\eta$, and the plasma velocity and the magnetic field are collinear, $\mathbf{V}=\pm\mathbf{B}/\sqrt{\rho\mu}$. We have constructed the smooth solutions (2.1)–(2.3) in $\mathbb{R}^3$ with finite and equal kinetic and magnetic energies. The

solutions turn into the ideal and steady Chandrasekhar equipartition equilibria[26] when $\nu=\eta=0$ in formula (2.6). Applying the Galilean transform to some special equipartition solutions we have derived the nonequipartition solutions (3.1) that describe plasma relaxation to an equilibrium with a constant magnetic field **B**.

We have shown that the initial-boundary value problem with the ''no-slip'' boundary condition $\mathbf{V}(t,\mathbf{x})|_{\partial\mathcal{D}}=0$ is overdetermined for the equipartition solutions. An infinite family of the exact solutions (4.7) is constructed that satisfy the boundary value problem (1.8) in a ball of radius R. The solutions describe the viscous plasma relaxation in a ball with a constant pressure at the boundary and have spherical magnetic surfaces $|\mathbf{x}|=r$. On each sphere $|\mathbf{x}|=r\leqslant R$, the plasma dynamics is a rotation with the angular velocity $\mathbf{\Omega}(t,r)$ (4.8) and $\mathbf{\Omega}(t,R)=0$.

For the arbitrary values of the parameters ρ, μ, ν, and η, we have derived the exact translationally invariant solutions (5.1)–(5.3). The solutions are rather general since they are not field-aligned, are not force-free ($\operatorname{curl}\mathbf{B}\times\mathbf{B}\neq 0$) and do not satisfy the Beltrami equation since $\operatorname{curl}\mathbf{V}\times\mathbf{V}\neq 0$. The exact solutions (6.1)–(6.3) model the magnetic confinement of viscous plasma in cylindrical domains $\mathcal{D}$. They satisfy the ''no-slip'' boundary condition $\mathbf{V}(t,\mathbf{x})|_{\partial\mathcal{D}}=0$. An important property of these solutions is that the plasma pressure P is positive inside the domain $\mathcal{D}$ (if $\alpha^2k^2\geqslant\ell^2$, $\ell m\leqslant 0$) and is zero at the boundary. Hence plasma is confined inside the domain $\mathcal{D}$ by the magnetic field **B**.

For $\nu=\eta$, we have derived a larger class of translationally invariant solutions (7.1)–(7.3) that are defined by an arbitrary solution to the two-dimensional diffusion equation (7.3). The solutions are non-field-aligned and nonequipartition ones.

(Received 13 May 2003; accepted 26 August 2003)

Bethe solutions for r reversed spins are characterized by a set of winding numbers $\{\lambda_1 \leqslant \lambda_2 \leqslant \cdots \leqslant \lambda_r\}$. Such classification is, however, not unique since the same sequences can describe different solutions and different sequences yield essentially equivalent states. These ambiguities should find their resolution in a complete configuration. We demonstrate here that in general a solution with a fixed sequence of winding numbers evolves in a quasicontinuous way as the function of N, the number of spins. This property could be disturbed in some cases at special transition point N_{tr}. We explain analytically the origin of this discontinuity. Consideration was addressed for three and four spin deviations. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1623614]

I. INTRODUCTION

A lot of modern problems in theoretical physics, particularly in statistical physics, nonlinear science, and condensed matter physics are transformed so that they might assume the one-dimensional (1D) Heisenberg model. Such a wide applicability in completely distinct areas of physics emerges from the fact that this model belongs to a little family of quantum systems, which offer exact solutions. Moreover, the classical 1D Heisenberg chain is a very interesting nonlinear dynamical system, which manifests such unique properties like coherency or chaos, depending on the imposed magnetic interactions. The adaptation of this method was very fruitful in classical statistical physics on two-dimensional lattices,[1] by giving a new approach to such subjects like, e.g., BCS theory,[2] solitons,[3] Bloch particles in magnetic field,[4,5] etc. Bethe ansatz (BA) stimulated the giant development of mathematical methods applicable in the field of integrable systems, leading to the quantum inverse scattering methods[6–8] as well as to important contributions to combinatorics.[9–11] Nowadays BA is still extensively studied and developed from both physical and mathematical points of view.[12–14]

The examination of solutions of Bethe equations is a difficult task in physical and mathematical investigations because of strange nonlinearity of these equations. For a small number of overturned spins (particularly for $r=2$), these solutions (introduced for the first time by Bethe[15]) have an analytical form. For finite systems the solutions of Bethe equations can be found using numerical methods. Only in the case of very small systems, the solutions of the Heisenberg chain can be obtained by solving the Bethe equations by hand or by straight diagonalization of the Hamiltonian. In many cases for small N these methods collapse to numerical procedure. Moreover, a serious difficulty arises when the relation between diagonalization results and Bethe parameters (momenta and phases of pseudoparticles) should be established. We have proposed in the former paper[16] a new method for the determination of solutions of Bethe equations. This method is especially applicable for large, but finite length of the Heisenberg chain N, e.g., $N \leqslant 1000$. The need for exact results for the 1D Heisenberg chain of a finite size is motivated nowadays by the great development in science and technology of materials of mesoscopic as well as nanoscopic

[a]Electronic mail: labuz@univ.rzeszow.pl

size and their application in an electronics of the future such as spintronics, quantum computing, as well as in biochemistry and biophysics. One should emphasize that for $100 \leqslant N \leqslant 1000$ even the usual numerical computer method fails. That is why the proposed method of solving the Bethe equations presented in Ref. 16 seems to be promising in science of small systems. The method not only determines the solutions but also provides some information about their form and origin. The method is based on the principal assumption that the solutions have quasicontinuous properties with respect to N. A starting point of the procedure is the asymptotic solution. Furthermore we make the hypothesis that this solution is also valid for sufficiently large N, e.g., $N=1000$ as chosen in our previous paper.[16] That assumption preserves proper action of the procedure. In that paper we have established that in the range of $N \in (10,1000)$ the solutions are changing in a quasicontinuous way as functions of N. The same behavior was independently noticed by Fujita *et al.*,[17] but only for the two-magnon case. However for small systems some discontinuities arise at the so-called special points:[18] critical N_{cr}, limiting N_{lim}, and transition N_{tr}. In the case of $N = N_{\mathrm{tr}}$, the transition of winding numbers sequence $\{\lambda_l\}$ into a new one $\{\lambda_l'\}$ is also observed.

In Sec. II of the present paper we introduce Bethe equations briefly and we pay attention especially to winding numbers, showing that for some cases they describe equivalent solutions. Section III presents the above-mentioned method, which enables finding solutions of Bethe equations for a wide range of chain lengths for a selected set of winding numbers. For some special chain length the procedure fails. Therefore in such cases the method should be modified (Sec. IV). Furthermore in that section we illustrate graphically the evolution of Bethe parameters as the function of chain length. The cases were selected to demonstrate transition points clearly.

II. WINDING NUMBERS AND EQUIVALENCY OF SOLUTIONS

The 1D Heisenberg model[19–26] consists of identical particles with spin 1/2 on each site, with interaction only between nearest neighbors. The Hamiltonian of such a system has the form

$$\hat{H} = \sum_{n=1}^{N} (4\mathbf{S}^n \cdot \mathbf{S}^{n+1} - 1), \tag{1}$$

where $\mathbf{S}^n$ denotes a spin vector at the nth position in the chain. Furthermore we have

$$\mathbf{S}^N \equiv \mathbf{S}^1, \tag{2}$$

so the periodic boundary condition is satisfied.

Considering the Heisenberg chain, we write the stationary states in following the form:

$$\Psi = \sum_{1 \leqslant n_1 \leqslant n_2 \leqslant \cdots \leqslant n_r \leqslant N} a(n_1, n_2, \ldots, n_r) |n_1 n_2 \cdots n_r\rangle, \tag{3}$$

with coefficients of the form

$$a(n_1, n_2, \ldots, n_r) = \sum_P \exp\left[i \left(\sum_{l=1}^{r} k_{P(l)} n_l + \frac{1}{2} \sum_{j<l} \phi_{P(j)P(l)} \right) \right]. \tag{4}$$

In formula (4) there are two characteristic parameters describing solutions: k_l—pseudomomenta of pseudoparticles and $\phi_{l,j}$—phases between interacting pseudoparticles. The sum runs over all permutations P of positions r occupied by these pseudoparticles. Furthermore $|n_1 n_2 \cdots n_r\rangle$ describes magnetic configuration containing r spin deviation (overturned spins) on chain nodes $n_1, n_2, \cdots, n_r$. The two referred parameters satisfy the following conditions:

$$2 \cot \frac{\phi_{l,j}}{2} = \cot \frac{k_l}{2} - \cot \frac{k_j}{2}, \quad \phi_{l,j} = -\phi_{j,l}, \quad 1 \leqslant l \leqslant j \leqslant N, \tag{5}$$

TABLE I. Equivalent solutions with respect to symmetry of sets $\{\lambda_l\}$ for $N=6$ and $r=3$. Sets with an asterisk are obtained from the other ones because of the appearance of N_{tr}. For further details see Sec. IV.

$\{\lambda_l\}$	k_1	k_2	k_3	$\phi_{1,2}$	$\phi_{1,3}$	$\phi_{2,3}$
$(-3,-1,1)$	$-\pi$	$-1{,}72$	$1{,}72$	$2{,}33$	$-2{,}33$	$-1{,}72$
$(-1,1,3)$	$-1{,}72$	$1{,}72$	π	$-1{,}72$	$-2{,}33$	$2{,}33$
$(-3,0,0)$	$-\pi$	0	0	0	0	0
$(0,0,3)$	0	0	π	0	0	0
$(-2,1,1)$	$-\pi$	$\pi/2-i\infty$	$\pi/2+i\infty$	$-\pi+1{,}10i$	$-\pi+1{,}10i$	$-i\infty$
$(-1,-1,2)$	$-\pi/2-i\infty$	$-\pi/2+i\infty$	π	$-i\infty$	$-\pi+1{,}10i$	$-\pi+1{,}10i$
$(-2,-1,0)$	$-\pi/2-i\infty$	$-\pi/2+i\infty$	0	$\pi+i\infty$	0	0
$(0,1,2)$	0	$\pi/2-i\infty$	$\pi/2+i\infty$	0	0	$\pi+i\infty$
$(-3,0,0)^*$	$-\pi$	$-1{,}09i$	$1{,}09i$	$5{,}44i$	$-5{,}44i$	$-1{,}09i$
$(0,0,3)^*$	$-1{,}09i$	$1{,}09i$	π	$-1{,}09i$	$-5{,}44i$	$5{,}44i$

and

$$Nk_l=2\pi\lambda_l+\sum_{j\neq l}\phi_{l,j},\quad l=1,2,\ldots,r. \tag{6}$$

The first one is a set of reflection conditions, whereas the second one expresses boundary condition. In formula (6) N and the integer λ_l are, respectively, chain length and winding numbers, where

$$-\frac{N}{2}\leqslant\lambda_1\leqslant\lambda_2\leqslant\cdots\leqslant\frac{N}{2}. \tag{7}$$

The winding numbers $\{\lambda_l\}$ parametrize the Bethe equations but not unequivocally. One can consider two types of equivalency. First, the different sets of $\{\lambda_l\}$ classify in some cases solutions that differ only in sign, but these may describe the same physical state for certain N. Second, there are cases where the same winding numbers result in different solutions. Both possibilities can be addressed to the form of Bethe equations.

Let us consider this problem for the case of the Heisenberg chain with three spin deviations $(r=3)$. The transformation $\{\lambda_1,\lambda_2,\lambda_3\}\rightarrow\{-\lambda_3,-\lambda_2,-\lambda_1\}$ introduced to the B-H equations (5) and (6) results in the following changes in Bethe parameters:

$$k_1\rightarrow -k_3,\quad \phi_{1,2}\rightarrow\phi_{2,3},$$

$$k_2\rightarrow -k_2,\quad \phi_{1,3}\rightarrow\phi_{1,3},$$

$$k_3\rightarrow -k_1,\quad \phi_{2,3}\rightarrow\phi_{1,2}.$$

But equivalent solutions can be observed only for the cases where total $|\lambda|=\pm N/2$ or $|\lambda|=0$.

In Table I results for selected winding numbers for the case $N=6$, $r=3$ are collected as an illustration of this quasiequivalency.

In Table II we present an example of the second type of equivalency. There are the results of solutions for various N starting from $N=1000$ down to $N=6$ for two sets of winding numbers: $(-3,0,0)$ and $(-1,-1,-1)$. In the range $N\in(1000,N_{\mathrm{tr}}=8)$ these parameters result in different solutions, but for $N<N_{\mathrm{tr}}$ different solutions are obtained for the same set $(-3,0,0)$. The way by which the parameter set $\{\lambda_l\}$ is changed in the transition point is described in Sec. IV.

TABLE II. Comparison of solutions for two different sets $\{\lambda_l\}$ for the case $r=3$.

III. QUASICONTINUITY AND RECURRENCE-NUMERICAL DETERMINATION OF BETHE SOLUTIONS

Numerical computations concerning solutions of large systems are not efficient because for large N the set of a great number of equations which should be solved is either impossible to be solved at all using usual computer programs, or the result of computations consists of many additional solutions, which are inappropriate from a physical point of view. It is known that the numerical procedures for solving nonlinear equations are very sensitive to the correct prediction of the range in which the solutions are expected to be obtained (ΔS) or exact establishment of the starting point of the inner computations. For large N, especially for $r \gg 2$, the fulfillment of these conditions must be particularly precise and restricted. Observed quasicontinuity of solutions provides the opportunity to satisfy described requirements fully for the determination of the proper range as well as the starting point. As such a point choosing the asymptotic solutions one can assume that $N=1000$ is also a good point at which start calculations. Solution obtained become the starting point for following smaller N. For $N \in (100,1000)$ values of solutions for two different N's are small even for every N from this range, which is why for the calculation of solutions of any N it is possible to assume $N=1000$ as the starting point. Thus for $N<100$ the differences are more and more distinct for N and $N-\Delta N$ even for small ΔN (keep in mind that the x axis in Fig. 1 is in logarithmic scale). Therefore in this range we have to be careful in choosing the starting point to be sure that the ΔN is small enough to also provide small ΔS. We have absolute conviction that the starting point was picked correctly when we chose $N+1$ as a starting point of the studied point N.

Of course it is not necessary to derive all solutions for all possible N, going by step 1 from $N=1000$ to very small N. We have the opportunity to choose the proper steps, taking care to be sure that the expected solutions for $N-\Delta N$ are from the assumed range ΔS. For large N it is necessary to realize this condition even for large ΔN, but for small lengths of systems we have to apply smaller steps that provide that ΔS is sufficiently small. However we observed that in some ranges of N the continuity of solutions is broken. There are so-called special points like critical

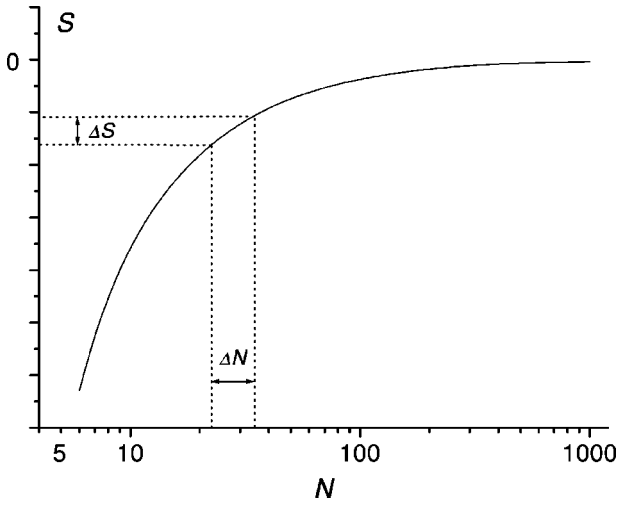

FIG. 1. Continuity of Bethe solutions for selected set of winding numbers in a wide range of N. Here S denotes one of the parameters k_l or $\phi_{l,j}$ describing the solution.

N_{cr}, limiting N_{lim}, and transition N_{tr} points. The relevant property of N_{tr} is that for this value of N the set $\{\lambda_l\}$ should be changed into another one $\{\lambda_l'\}$ in order to keep the real parts of wave numbers and phases within the proper bounds $(-\pi,\pi)$. It is important to note that such modification does not disturb the behavior of remaining parameters in relation to N.

IV. BREAK OF QUASICONTINUITY

In Sec. III it was noticed that in transition point N_{tr} quasicontinuity of some parameters describing solutions is broken, as they leave $(-\pi,\pi)$ range, where we expected to get results, which disables using the above-described method. To remove this problem one has to change the set of winding numbers related to the solutions studied into another one according to the equivalency resulting from the Bethe equations (see Sec. II). Such modification enables one to bring all parameters to the $(-\pi,\pi)$ range again.

As an example let us consider the system with $r=3$ overturned spins. Then the set of three winding numbers $\{\lambda_1,\lambda_2,\lambda_3\}$ should satisfy relation (7). The Bethe equations enable us to find the relation between the sets of winding numbers on both sides of the transition point N_{tr}. The simplest case we consider for finding this relation is the one of real solutions (Sec. IV A). Another one is the complex solution (Sec. IV B). Calculations conducted by our recurrency-numerical method point out that values of $\phi_{l,j}$ leave the $(-\pi,\pi)$ range for $N=N_{\mathrm{tr}}$, but there are indications that k_l also leaves that range. In Fig. 2 one can notice that other parameters preserve quasicontinuity very well.

A. The case of real solutions

In the case of real solutions we can rewrite Bethe equations (5) and (6) in the form

$$Nk_1=2\pi\lambda_1+\phi_{1,2}+\phi_{13}, \tag{8}$$

$$Nk_2=2\pi\lambda_2-\phi_{1,2}+\phi_{2,3}, \tag{9}$$

$$Nk_3=2\pi\lambda_3-\phi_{1,3}-\phi_{2,3}, \tag{10}$$

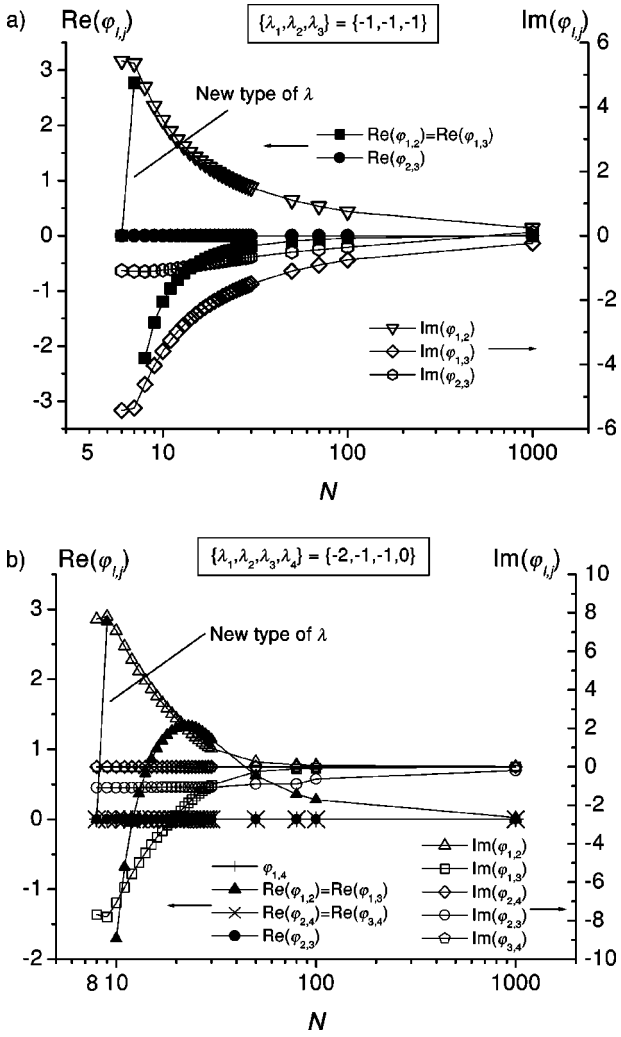

FIG. 2. Quasicontinuous form of changes in Bethe solutions starting from $N=1000$; (a) $r=3$, set $\{-1,-1,-1\}$ changes into $\{-3,0,0\}$ in $N_{\mathrm{tr}}=8$ (b) $r=4$, the set $\{-2,-1,-1,0\}$ changes into $\{-4,0,0,0\}$ in $N_{\mathrm{tr}}=9$.

$$\cot\frac{\phi_{1,2}}{2}=\frac{\sin\dfrac{k_1-k_2}{2}}{\cos\dfrac{k_1+k_2}{2}-\cos\dfrac{k_1-k_2}{2}}, \tag{11}$$

$$\cot\frac{\phi_{1,3}}{2}=\frac{\sin\dfrac{k_1-k_3}{2}}{\cos\dfrac{k_1+k_3}{2}-\cos\dfrac{k_1-k_3}{2}}, \tag{12}$$

$$\cot\frac{\phi_{2,3}}{2}=\frac{\sin\dfrac{k_2-k_3}{2}}{\cos\dfrac{k_2+k_3}{2}-\cos\dfrac{k_2-k_3}{2}}. \tag{13}$$

Let us assume that $\phi_{l,j}=\phi_{1,2}$ leaves the $(-\pi,\pi)$ range by passing the limit π. Thus we can write

$$\phi_{1,2}=\phi'_{1,2}+2\pi, \tag{14}$$

where $\phi'_{1,2}$ belongs to the range. Then from (8) and (9) we get

$$Nk_1=2\pi\lambda_1+\phi'_{1,2}+2\pi+\phi_{1,3}, \tag{15}$$

$$Nk_2=2\pi\lambda_2-\phi'_{1,2}-2\pi+\phi_{2,3}. \tag{16}$$

Now we can see that

$$Nk_1=2\pi(\lambda_1+1)+\phi'_{1,2}+\phi_{1,3}, \tag{17}$$

$$Nk_2=2\pi(\lambda_2-1)-\phi'_{1,2}+\phi_{2,3}. \tag{18}$$

It means that we get new winding numbers

$$\lambda_1+1\equiv\lambda'_1, \tag{19}$$

$$\lambda_2-1\equiv\lambda'_2. \tag{20}$$

Thus from (8) and (9) we can write

$$Nk_1=2\pi\lambda'_1+\phi'_{1,2}+\phi_{1,3}, \tag{21}$$

$$Nk_2=2\pi\lambda'_2-\phi'_{1,2}+\phi_{2,3}. \tag{22}$$

Looking at the change of set of winding numbers $\{\lambda_l\}$ into $\{\lambda'_l\}$ one can see that it does not influence the total λ and k:

$$\lambda'_1+\lambda'_2=\lambda_1+1+\lambda_2-1=\lambda_1+\lambda_2. \tag{23}$$

The form of Eqs. (8)–(13), especially the properties of trigonometric functions, preserves the quasicontinuous form of the other parameters, despite the change $\phi_{1,2}\rightarrow\phi'_{1,2}$.

B. The case of complex solutions

In such a case we assume that two parameters are complex conjugated:[18]

$$k_1=A-ib,\ \ k_2=A+ib,\ \ \phi_{1,3}=P-iq,\ \ \phi_{2,3}=P+iq,\ \ \phi_{1,2}=-il. \tag{24}$$

Rewriting Eqs. (8)–(10) and having in mind relations (24) we have

$$N(A-ib)=2\pi\lambda_1-il+P-iq, \tag{25}$$

$$N(A+ib)=2\pi\lambda_1+il+P+iq, \tag{26}$$

$$Nk_3=2\pi\lambda_3-2P, \tag{27}$$

and after simplification we get

$$NA=2\pi\lambda_1+P, \tag{28}$$

$$Nb=l-q, \tag{29}$$

$$Nk_3 = 2\pi\lambda_3 - 2P. \tag{30}$$

Now we assume that P leaves the range. Similar to the first case we write

$$P = P' + 2\pi. \tag{31}$$

Thus finally we get

$$NA = 2\pi(\lambda_1 + 1) + P', \tag{32}$$

$$Nk_3 = 2\pi(\lambda_3 - 2) - 2P'. \tag{33}$$

From (32) and (33) we can observe that

$$\lambda_1' = \lambda_1 + 1, \quad \lambda_2' = \lambda_2 + 1, \quad \lambda_3' = \lambda_3 - 2. \tag{34}$$

Both cases (a) and (b) show how to change the set of winding numbers to another one to make sure that all seeking solutions are within the $(-\pi, \pi)$ range, even when transition point appears.

Analogous considerations applied to the case with $r=4$ overturned spins results in the following: In Fig. 2 we show quasicontinuity of solutions for selected examples with $r=3$ and $r=4$ including the situation where N_{tr} appears.

V. CONCLUSIONS

Solutions of the Bethe equations manifest the quasicontinuous property with respect to N for an established set of winding numbers. Our studies reveal that for some chain length N (special points) the quasicontinuity is disturbed because some pseudomomenta and phases lose quasicontinuity in the range $(-\pi, \pi)$. In the paper we examine in detail one such type of point, i.e., the transition point N_{tr}.

For this point and below it the solution does not exist in the $(-\pi, \pi)$ range for the initial set of $\{\lambda_l\}$ (for sufficiently large N) and changing it into $\{\lambda_l'\}$ is required to ensure the quasicontinuity below N_{tr}. The method for finding such a new set $\{\lambda_l'\}$ for both real and complex cases has been described. Nevertheless it should be emphasized that changing of $\{\lambda_l\} \to \{\lambda_l'\}$ does not influence the quasicontinuity for all other Bethe parameters (k, ϕ) in N_{tr}.

Quantum stochastic equation for a test particle interacting with a dilute Bose gas

A. N. Pechen*
Centro Vito Volterra, Universita di Roma Tor Vergata 00133, Roma, Italy

(Received 2 June 2003; accepted 9 September 2003)

We use the stochastic limit method to study long time quantum dynamics of a test particle interacting with a dilute Bose gas. The case of arbitrary form factors and an arbitrary, not necessarily equilibrium, quasifree low density state of the Bose gas is considered. Starting from microscopic dynamics we derive in the low density limit a quantum white noise equation for the evolution operator. This equation is equivalent to a quantum stochastic equation driven by a quantum Poisson process with intensity $S-1$, where S is a one-particle S matrix. The novelty of our approach is that the equations are derived directly in terms of correlators, without use of a Fock–anti-Fock (or Gel'fand–Naimark–Segal) representation. Advantages of our approach are the simplicity of derivation of the limiting equation and that the algebra of the master fields and the Ito table do not depend on the initial state of the Bose gas. The notion of a causal state is introduced. We construct master fields (white noise and number operators) describing the dynamics in the low density limit and prove the convergence of chronological (causal) correlators of the field operators to correlators of the master fields in the causal state. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1626806]

I. INTRODUCTION

The fundamental equations in quantum theory are the Heisenberg and Schrödinger equations. However, it is a very difficult problem to solve explicitly these equations for realistic physical models and one uses various approximations or limiting procedures such as weak coupling, low density, and hydrodynamical limits. These scaling limits describe the long time behavior of physical systems in different physical regimes.

One of the powerful methods to study the long time behavior in quantum theory is the stochastic limit method developed by Accardi, Lu, and Volovich.[1] Many interesting physical models have been investigated by using this method. In particular, it has been applied to study the long time quantum dynamics of a system interacting with a reservoir in the case of a weak interaction between the system and reservoir, i.e., in the weak coupling limit. It was applied to study the spin-boson model,[2] polaron model and nonrelativistic quantum electrodynamics,[3,4] quantum Hall effect,[5] relations between Hepp–Lieb and Alli–Sewell laser models,[6] bifurcation phenomenon in a spin relaxation,[7] etc.

An important problem is to study the long time dynamics of a quantum system interacting with a reservoir in the case the interaction is not weak but the density of particles of the reservoir is small, i.e., in the low density limit. To describe a quantum physical model to which the low density limit can be applied let us consider an N-level atom (test particle) immersed in a free gas whose molecules can collide with the atom; the gas is supposed to be very dilute. Then the reduced time evolution for the atom will be Markovian, since the characteristic time t_S for appreciable action of the surroundings on the atom (time between collisions) is much larger than the characteristic time t_R for relaxation of correlations in the surroundings. The dynamics of the

N-level atom interacting with the free gas should converge, in the low density limit, to the solution of a quantum stochastic differential equation driven by quantum Poisson noise. The quantum Poisson process, introduced by Hudson and Parthasarathy[8] (for a description of the quantum Poisson process see also Kumerrer[9]), should arise naturally in the low density limit, as conjectured by Frigerio and Maassen[10] and later by Alicki and Frigerio.[11] For a general survey of quantum stochastic calculus we refer to the review by Attal.[12]

The quantum stochastic equation for the low density limit was derived by Accardi and Lu[13–15] using perturbation series for the evolution operator. A nonperturbative white noise approach for the investigation of dynamics in the low density limit is developed in Refs. 16 and 17, where the mathematical procedure, the so-called stochastic golden rule for the low density limit, was formulated. This derivation uses the white noise technique developed for the case of the weak coupling limit by Accardi, Lu, and Volovich.[1] The approach to derivation of the stochastic equations in Refs. 13–17 is based on use of the Fock–anti-Fock [or Gel'fand–Naimark–Segal (GNS)] representation for the canonical commutation relations (CCR) algebra of the Bose gas. The approach of the present paper does not use the Fock–anti-Fock representation.

We study the low density limit for an N-level atom (test particle) interacting with a Bose gas. Starting from microscopic quantum dynamics we derive quantum white noise and quantum stochastic differential equations for the limiting evolution operator. A useful tool is the energy representation introduced in Refs. 16 and 17 where the case of orthogonal form factors was considered. In the present paper we consider the case of arbitrary form factors and an arbitrary, not necessarily equilibrium, quasifree low density state of the reservoir. To each initial low density state of the Bose gas we associate in the low density limit a special ''state'' (which is called a causal state) on the limiting master field algebra. We prove the convergence of time-ordered (or causal) correlators of the initial Bose field to the correlators of master fields (which are number operators constructed from some white noise operators) in these causal states. These states are determined by the diagrams which give a nontrivial contribution to the limit. The leading diagrams can be interpreted as a new statistics arising in the low density limit (new statistics arising in the weak coupling limit is discussed in Refs. 1 and 18).

One of the main results of the paper is that the dynamics in the low density limit is given by the solution of a quantum white noise equation, which is equivalent to the quantum stochastic equation

$$dU_t = dN_t(S-1)U_t, \tag{1}$$

where U_t is the evolution operator at time t describing the limiting dynamics, S is a one-particle S matrix describing scattering of the test particle on one particle of the reservoir, and $N_t(S-1)$ is the quantum Poisson (number or gauge) process with intensity $S-1$. The equation describes the evolution of the total system+reservoir and can be applied, in particular, to the important problem of derivation of the linear quantum Boltzmann equation describing the irreversible reduced dynamics of the test particle in the low density limit. Such an equation for the reduced density matrix can be easily obtained from the quantum Langevin equation, which can be derived by using the quantum stochastic differential equation and quantum Ito table (see Sec. VII) for stochastic differential dN_t (for a derivation of the quantum Langevin equation see Ref. 17). However, in the present paper we are mainly concentrated on further understanding in what sense the Poisson process is an approximation of the usual quantum field (Theorem 1) and in mechanism through which the quantum stochastic equation arises as a limit of the usual Hamiltonian equation.

In order to describe the objects appearing in (1) let us introduce two Hilbert spaces $\mathcal{H}_S$ and $\mathcal{H}$, which are called in this context the system and one-particle reservoir Hilbert spaces, and the Fock space $\Gamma(L^2(\mathbb{R}_+;\mathcal{H}))$ over the Hilbert space of square-integrable measurable vector-valued functions from $\mathbb{R}_+=[0,\infty)$ to $\mathcal{H}$. With these notations the solution of the equation is a family of operators $U_t; t\geqslant 0$ in $\mathcal{H}_S\otimes\Gamma(L^2(\mathbb{R}_+;\mathcal{H}))$ (adapted process); S is a unitary operator in $\mathcal{H}_S\otimes\mathcal{H}$, which is explicitly defined in Sec. VI.

Let us introduce the notion of a Poisson process. Let X be a self-adjoint operator in a Hilbert space $\mathcal{K}$ and $\Psi(f)$ the normalized coherent vector in the Fock space $\Gamma(\mathcal{K})$ with test function $f \in \mathcal{K}$. The *number operator* is the generator of one-parameter unitary group $\Gamma(e^{i\lambda X})$ characterized by

$$\Gamma(e^{i\lambda X})\Psi(f)=\Psi(e^{i\lambda X}f), \quad \lambda \in \mathbb{R}.$$

The number operator is characterized by the property

$$\langle \Psi(f), N(X)\Psi(g)\rangle = \langle f, Xg\rangle \langle \Psi(f), \Psi(g)\rangle.$$

The definition of $N(X)$ is extended by complex linearity to any bounded operator X on $\mathcal{K}$. Let us consider $\mathcal{K}$ of the form $L^2(\mathbb{R}_+;\mathcal{H}) \cong L^2(\mathbb{R}_+)\otimes\mathcal{H}$. For any bounded operators $X_0 \in B(\mathcal{H}_S)$, $X_1 \in B(\mathcal{H})$, and for any $t \geqslant 0$ we define $N_t(X_0\otimes X_1) := X_0 \otimes N(\chi_{[0,t]}\otimes X_1)$, extend this definition by linearity to any bounded operator K in $\mathcal{H}_S\otimes\mathcal{H}$, and call the family $N_t(K); t\geqslant 0$ of operators in $\mathcal{H}_S\otimes\Gamma(L^2(\mathbb{R}_+;\mathcal{H}))$ a *quantum Poisson process with intensity K*. The existence and uniqueness of the solution of the equation in this case follows from the general theory of quantum stochastic differential equations. Moreover, unitarity of S leads to the conclusion that, for each $t\geqslant 0$, U_t is a unitary operator (see Lemma 2).

For the vacuum state of the reservoir (zero density) such an equation was derived by Accardi and Lu.[14] In the present paper we derive this equation for an arbitrary quasifree initial state of the Bose gas. The main feature of the present paper is that the stochastic equations are derived directly in terms of correlators, without use of a Fock–anti-Fock (or GNS) representation. This simplifies the derivation of the limiting quantum white noise equation and allows us to express the intensity of the quantum Poisson process directly in terms of a one-particle S matrix. In our approach the limiting equation, the algebra of the master fields, and the Ito table do not depend on the initial state of the Bose gas.

We obtain that the dynamics of the compound system in the low density limit is described by the solution of quantum white noise equation (36) or, equivalently, quantum stochastic differential equation in forms (44) and (1) and the family of causal states φ_L on the algebra of master fields.

The reduced dynamics of the system (test particle) in the low density limit for the model under consideration, with completely different methods, based on a quantum Bogoliubov–Born–Green–Kirkwood–Yvon (BBGKY) hierarchy, has been investigated by Dümcke,[19] where it is proved that, under some conditions, the reduced dynamics is given by a quantum Markovian semigroup.

In the approach of the present paper the reduced dynamics can be easily derived from the solution of the limiting quantum stochastic differential equation. Namely, the limiting evolution operator U_t and the limit state φ_L determine the reduced dynamics by

$$T_t(X)=\varphi_L(U_t^\dagger(X\otimes 1)U_t),$$

where X is any system observable (bounded operator in $\mathcal{H}_S$), $\varphi_L(\cdot)$ denotes partial expectation, and T_t is the limiting semigroup. This equality shows that U_t is a stochastic dilation of the limiting Markovian semigroup. Using the quantum Ito table for stochastic differential dN_t one can derive a quantum Langevin equation for the quantity $U_t^\dagger(X\otimes 1)U_t$. Then taking partial expectation one gets an equation for $T_t(X)$; in particular, one can get the generator of the semigroup. This is a general feature of the white noise approach: one at first obtains the equation for the evolution operator of the total system and then gets the reduced dynamics of the test particle. Let us note that although quantum stochastic equations, which are derived in Refs. 13 and 17 are different from (1) they give the same reduced dynamics.

The low density limit can be applied to the model of a test particle moving through an environment of randomly placed, infinitely heavy scatterers (Lorentz gas) (see the review of Spohn[20]). In the Boltzmann–Grad limit successive collisions become independent and the averaged over the positions of the scatterers the position and velocity distribution of the particle

converges to the solution of the linear Boltzmann equation. An advantage of the stochastic limit method is that it allows us to derive equations not only for averaged over reservoir degrees of freedom dynamics of the test particle but for the total system+reservoir. For a rigorous treatment of a classical Lorentz gas we refer to Refs. 21–26. The convergence results and derivation of the linear Boltzmann equation for a quantum Lorentz gas in the low density and weak coupling limits are presented in Refs. 27 and 28. The Coulomb gas at low density is considered in Ref. 29.

The hydrodynamical limit is described by the Euler equation. In Ref. 30 the Euler equation for fermions in the hydrodynamical limit is derived under some assumptions.

Let us describe the plan of the paper. In Sec. III we construct the master fields, which are number operators acting in some Hilbert space, and the limit causal states on the master field's algebra. We prove that the time-ordered (or causal) correlators of the free evolution of the initial field converge in the low density limit to the correlators of the master field in these causal states. In Sec. IV the stochastic Schrödinger equation which describes the dynamics in the low density limit is derived. In Sec. V we bring this equation to the causally normally ordered form. This form is convenient for study of reduced dynamics of the system. In Sec. VI the expressions for the one-particle S matrix and T operator are given. In Sec. VII quantum stochastic differential equation (1) for the limiting evolution operator is derived.

II. MODEL OF AN ATOM INTERACTING WITH A DILUTE BOSE GAS

Let us explain our notations. We consider a quantum model of a system (test particle) interacting with a boson reservoir (heat bath). Let $\mathcal{H}_{\mathrm{S}}$ be the Hilbert space of the system. For an example, for an N-level atom $\mathcal{H}_{\mathrm{S}}=\mathbb{C}^N$. The system Hamiltonian H_{S} is a self-adjoint operator in $\mathcal{H}_{\mathrm{S}}$. The reservoir is described by the boson Fock space $\Gamma(\mathcal{H})$ over the one-particle Hilbert space $\mathcal{H}=L^2(\mathbb{R}^d)$ (with scalar product $\langle\cdot,\cdot\rangle$), where $d=3$ in the physical case. Moreover, the Hamiltonian of the reservoir is given by $H_{\mathrm{R}}:=\mathrm{d}\Gamma(H_1)$ (the second quantization of the one-particle Hamiltonian H_1) and the total Hamiltonian H_{tot} of the compound system is given by a self–adjoint operator on the total Hilbert space $\mathcal{H}_{\mathrm{S}}\otimes\Gamma(\mathcal{H})$:

$$H_{\mathrm{tot}}:=H_{\mathrm{free}}+H_{\mathrm{int}}=H_{\mathrm{S}}\otimes 1+1\otimes H_{\mathrm{R}}+H_{\mathrm{int}}.$$

Here H_{int} is the interaction Hamiltonian between the system and reservoir. The one-particle Hamiltonian H_1 is the operator of multiplication by some real-valued function $\omega(k)$. The interaction Hamiltonian will be assumed to have the following form:

$$H_{\mathrm{int}}:=\mathrm{i}(D\otimes A^{\dagger}(g_0)A(g_1)-D^{\dagger}\otimes A^{\dagger}(g_1)A(g_0)),$$

where D is a bounded operator in $\mathcal{H}_S$, $D\in\mathbf{B}(\mathcal{H}_S)$; $A(g_n)$ and $A^{\dagger}(g_n)$, $n=0,1$, are annihilation and creation operators, and $g_0,g_1\in\mathcal{H}$ are form factors describing the interaction of the system with the reservoir. This Hamiltonian describes scattering of particles of the Bose gas on the test particle (N-level atom) and can be obtained by quantization of the classical interaction potential between particles of two different types with an infinite number of particles of one type (particles of the gas) and finite number of particles of the second type (atoms). This Hamiltonian preserves the particle number of the reservoir, and therefore the particles of the reservoir are only scattered on the test particle and not created or destroyed. Such a Hamiltonian was considered by Davies[31] in the analysis of the weak coupling limit.

The initial state of the compound system is supposed to be of the form

$$\rho=\rho_{\mathrm{S}}\otimes\varphi_{L,\xi}.$$

Here ρ_{S} is an arbitrary density matrix of the system and the initial state of the reservoir $\varphi_{L,\xi}$ is the gauge-invariant mean-zero Gaussian state, characterized by

$$\varphi_{L,\xi}(A^{\dagger}(f)A(g))=\xi\left\langle g,\frac{L}{1-\xi L}f\right\rangle \tag{2}$$

for each $f,g \in \mathcal{H}$. Here $\xi>0$ is a small positive number and L is a bounded positive operator in $\mathcal{H}$ commuting with S_t [an operator of multiplication by some function $L(k)$]. In the case $L=\mathrm{e}^{-\beta H_1}$, where $\beta>0$ is a positive number, the state $\varphi_{L,\xi}$ is just the Gibbs state, at inverse temperature β and fugacity ξ, of the free evolution. The fugacity $\xi=\mathrm{e}^{\beta\mu}$; μ is the chemical potential.

The dynamics of the total system is determined by the evolution operator which in interaction representation has the form

$$U(t) := \mathrm{e}^{\mathrm{i}tH_{\mathrm{free}}}\mathrm{e}^{-\mathrm{i}tH_{\mathrm{tot}}}.$$

It satisfies the differential equation

$$\frac{dU(t)}{dt} = -\mathrm{i}H_{\mathrm{int}}(t)U(t),$$

where the quantity $H_{\mathrm{int}}(t)$ will be called the evolved interaction and defined as

$$H_{\mathrm{int}}(t) = \mathrm{e}^{\mathrm{i}tH_{\mathrm{free}}}H_{\mathrm{int}}\mathrm{e}^{-\mathrm{i}tH_{\mathrm{free}}}.$$

The iterated series for the evolution operator is

$$U(t) = 1 + \sum_{n=1}^{\infty} (-\mathrm{i})^n \int_0^t dt_1 \cdots \int_0^{t_{n-1}} dt_n H_{\mathrm{int}}(t_1)\cdots H_{\mathrm{int}}(t_n). \tag{3}$$

With the notations

$$S_t := \mathrm{e}^{\mathrm{i}tH_1}, \quad D(t) := \mathrm{e}^{\mathrm{i}tH_S} D \mathrm{e}^{-\mathrm{i}tH_S},$$

the evolved interaction can be written in the form

$$H_{\mathrm{int}}(t) := \mathrm{i}(D(t)\otimes A^{\dagger}(S_t g_0)A(S_t g_1) - D^{\dagger}(t)\otimes A^{\dagger}(S_t g_1)A(S_t g_0)). \tag{4}$$

We assume the rotating wave approximation

$$\mathrm{e}^{\mathrm{i}tH_S} D \mathrm{e}^{-\mathrm{i}tH_S} = D,$$

although generalization to the case of arbitrary D is not difficult.

We study the dynamics generated by the Hamiltonian (4) in the low density limit: $n\to 0$, $t \sim 1/n$ (n is the density of particles of the reservoir). The density of particles with momentum k in the state $\varphi_{L,\xi}$ is equal to

$$\frac{\xi L(k)}{1-\xi L(k)}$$

and goes to zero as $\xi\to 0$. Therefore the limit $n\to 0$, $t\sim 1/n$ is equivalent to the limit $\xi\to 0$, $t \sim 1/\xi$.

Let us consider the time rescaling $t\to t/\xi$ so that $U(t)\to U(t/\xi)$. With the notation

$$N_{f,g,\xi}(t) = \frac{1}{\xi} A^{\dagger}(S_{t/\xi} f) A(S_{t/\xi} g) \tag{5}$$

for any $f,g \in \mathcal{H}$, the equation for the evolution operator $U(t/\xi)$ becomes

$$\frac{\mathrm{d}U(t/\xi)}{\mathrm{d}t} = (D\otimes N_{g_0,g_1,\xi}(t) - D^{\dagger}\otimes N_{g_1,g_0,\xi}(t))U(t/\xi). \tag{6}$$

The reduced dynamics of any test particle's observable X in the low density limit is defined by the limit

$$\lim_{\xi\to 0}\varphi_{L,\xi}(U^{\dagger}(t/\xi)(X\otimes 1)U(t/\xi)),$$

where $\varphi_{L,\xi}(\cdot)$ denotes partial expectation. In Ref. 19 it was proved that, under some conditions, the limit exists in a small time interval and is equal to $T_t(X)$, where $\{T_t;t\geqslant 0\}$ is a quantum Markovian semigroup. The dynamics of the reduced density matrix $\rho_S(t)$ is determined through the duality $\mathrm{Tr}(\rho_S T_t(X))=\mathrm{Tr}(\rho_S(t)X)$. As was mentioned in the Introduction, in the approach of the present paper the limiting semigroup can be obtained by using the solution U_t of the quantum stochastic equation as

$$T_t(X)=\varphi_L(U_t^{\dagger}(X\otimes 1)U_t)$$

and the generator of the semigroup can be easily derived from quantum Langevin equation. The limiting semigroup can be obtained also from quantum Langevin equation in Ref. 17, which is based on a quantum stochastic equation similar to (1) but much more complicated.

The first step to study the low density limit of the model is to find the limit of the field $N_{f,g,\xi}(t)$. This limit we call master fields or number operators.

III. MASTER FIELDS AND THE LIMIT STATES

In this section we construct the algebra of the master fields arising in the low density limit and the limit causal states on this algebra. We prove (Theorem 1) that time-ordered correlators of initial fields (5) converge in the low density limit to correlators of number operators constructed from some white noise operators. Theorem 2 states a useful factorization property of the limiting causal states.

It is convenient to use the ''projections''

$$P_E:=\frac{1}{2\pi}\int_{-\infty}^{\infty}\mathrm{d}tS_t\mathrm{e}^{-\mathrm{i}tE}=\delta(H_1-E),$$

with the properties

$$P_EP_{E'}=\delta(E-E')P_E,\quad P_E^*=P_E,\quad S_t=\int \mathrm{d}EP_E\mathrm{e}^{\mathrm{i}tE}.$$

For the δ function of a self-adjoint operator cf. Definition (1.2.1) in Ref. 1.

Let us construct the master space (which is Fock space over some Hilbert space) and master fields. For a given Hilbert space $\mathcal{H}$ and a self-adjoint operator H_1 in $\mathcal{H}$ we define the Hilbert space $\mathcal{X}_{\mathcal{H},H_1}$ as the completion of the quotient of the set

$$\left\{F:\mathbb{R}\to\mathcal{H}\ \text{ s.t.}\|F\|^2:=2\pi\int \mathrm{d}E\langle F(E),P_EF(E)\rangle<\infty\right\},$$

with respect to the zero-norm elements. The inner product in $\mathcal{X}_{\mathcal{H},H_1}$ is defined as

$$\langle F,G\rangle=2\pi\int \mathrm{d}E\langle F(E),P_EG(E)\rangle.$$

We denote by $B_f^{\dagger}(E,t)$, $B_g(E',t')$ time-energy white noise creation and annihilation operators acting in the symmetric Fock space $\Gamma(L^2(\mathbb{R}_+,\mathcal{X}_{\mathcal{H},H_1}))$ where $L^2(\mathbb{R}_+,\mathcal{X}_{\mathcal{H},H_1})$ is the Hilbert space of square integrable functions $f:\mathbb{R}_+\to\mathcal{X}_{\mathcal{H},H_1}$. These operators (operator-valued distributions) satisfy the canonical commutation relations

$$[B_g(E,t), B_f^\dagger(E',t')] = \delta(t'-t)\,\delta(E'-E)\,\tilde{\gamma}_{g,f}(E) \tag{7}$$

and causal commutation relations

$$[B_g(E,t), B_f^\dagger(E',t')] = \delta_+(t'-t)\,\delta(E'-E)\,\gamma_{g,f}(E), \tag{8}$$

where $\delta_+(t'-t)$ is the causal δ function and

$$\gamma_{g,f}(E) = \int dE' \frac{\langle g, P_{E'} f\rangle}{\mathrm{i}(E'-E-i0)},$$

$$\tilde{\gamma}_{g,f}(E) = 2\pi\langle g, P_E f\rangle.$$

In the Appendix we review the definition of the causal δ function: for a detailed discussion of distributions over the simplex and the meaning of two different commutators (7) and (8) for the same operators we refer to Sec. VII in Ref. 1. These operators are called time-energy quantum white noise due to the presence of $\delta(t'-t)\,\delta(E'-E)$ in (7).

For any positive bounded operator L in $\mathcal{H}$ we define the causal gauge-invariant mean zero Gaussian state φ_L by the properties (9)–(12):

$$\text{for } n=2k, \quad \varphi_L(B_1^{\epsilon_1}\cdots B_n^{\epsilon_n}) = \sum \varphi_L(B_{i_1}^{\epsilon_{i_1}} B_{j_1}^{\epsilon_{j_1}})\cdots\varphi_L(B_{i_k}^{\epsilon_{i_k}} B_{j_k}^{\epsilon_{j_k}}), \tag{9}$$

where the sum is taken over all permutations of the set $(1,\ldots,2k)$ such that $i_\alpha < j_\alpha$, $\alpha = 1,\ldots,k$, $i_1 < i_2 < \cdots < i_k$; $B_m^{\epsilon_m} := B_{f_m}^{\epsilon_m}(E_m,t_m)$, for $m=1,\ldots,n$, are time-energy quantum white noise operators with causal commutation relations (8), and ϵ_m means either creation or annihilation operator;

$$\text{for } n=2k+1 \quad \varphi_L(B_1^{\epsilon_1}\cdots B_n^{\epsilon_n}) = 0, \tag{10}$$

$$\varphi_L(B_f(E,t)B_g(E',t')) = \varphi_L(B_f^\dagger(E,t)B_g^\dagger(E',t')) = 0, \tag{11}$$

$$\varphi_L(B_f^\dagger(E,t)B_g(E',t')) = \chi_{[0,t]}(t')\langle g, P_E L f\rangle. \tag{12}$$

Notice that the "state" φ_L does not satisfy the positivity condition. This is a well-known situation for the weak coupling limit (see Ref. 1) and is due to the fact that we work with time-ordered, or causal, correlators. Therefore it is natural to call such "states" causal states.

Definition 1: Causal time-energy white noise is a pair $(B_f(E,t),\varphi_L)$, *where* $B_f(E,t)$ *satisfy the causal commutation relations (8) and* φ_L *is a causal gauge invariant mean zero Gaussian state characterized by (9)–(12).*

Using the operators $B_f^\dagger(E,t)$, $B_g(E,t)$ we define the number operators as

$$N_{f,g}(t) = \int dE B_f^\dagger(E,t)B_g(E,t). \tag{13}$$

Finally, for a given Hilbert space $\mathcal{H}$ and a self-adjoint operator H_1 we have the following objects: for any $\xi > 0$ the family of operators $N_{f,g,\xi}(t)$ defined by (5) together with the gauge-invariant quasifree mean-zero Gaussian state $\varphi_{L,\xi}$ and the number operators $N_{f,g}(t)$ together with the causal state φ_L.

The following theorem describes the relation between these objects and states the master field in the low density limit.

Theorem 1: *There exists causal time-energy white noise* $(B_f(E,t),\varphi_L)$ *such that* $\forall n\in\mathbb{N}$

$$\lim_{\xi\to 0}\varphi_{L,\xi}(N_{f_1,g_1,\xi}(t_1)\cdots N_{f_n,g_n,\xi}(t_n))=\varphi_L(N_{f_1,g_1}(t_1)\cdots N_{f_n,g_n}(t_n)),$$

where the equality is understood in the sense of distributions over simplex $t_1\geqslant t_2\geqslant\cdots\geqslant t_n\geqslant 0$. *The limit causal state* φ_L *is characterized by (9)–(12) and the number operators are defined by (13).*

Remark 1: This convergence is called convergence in the sense of time ordered correlators. The fact that we use the distributions over simplex is motivated by iterated series (3) for the evolution operator.

Proof: Notice that

$$N_{f,g,\xi}(t)=\int \mathrm{d}E N_{f,g,\xi}(E,t),$$

where

$$N_{f,g,\xi}(E,t):=\frac{\mathrm{e}^{\mathrm{i}tE/\xi}}{\xi}A^\dagger(P_E f)A(S_{t/\xi}g).$$

Therefore

$$\varphi_{L,\xi}(N_{f_1,g_1,\xi}(t_1)\cdots N_{f_n,g_n,\xi}(t_n))=\int \mathrm{d}E_1\cdots\mathrm{d}E_n\varphi_{L,\xi}(N_{f_1,g_1,\xi}(E_1,t_1)\cdots N_{f_n,g_n,\xi}(E_n,t_n)).$$

Let us denote for shortness of notation for $l=1,\ldots,n$,

$$A_l^\dagger:=\frac{\mathrm{e}^{\mathrm{i}t_lE_l/\xi}}{\sqrt{\xi}}A^\dagger(P_{E_l}f_l),\quad A_l:=\frac{1}{\sqrt{\xi}}A(S_{t_l/\xi}g_l).$$

In this notation,

$$\varphi_{L,\xi}(N_{f_1,g_1,\xi}(E_1,t_1)\cdots N_{f_n,g_n,\xi}(E_n,t_n))=\varphi_{L,\xi}(A_1^\dagger A_1\cdots A_n^\dagger A_n). \tag{14}$$

The state $\varphi_{L,\xi}$ is a gauge-invariant mean-zero Gaussian state. Therefore (14) equals the sum of terms of the form

$$\varphi_{L,\xi}(A_{i_1}^\dagger A_{j_1})\cdots\varphi_{L,\xi}(A_{i_k}^\dagger A_{j_k})\varphi_{L,\xi}(A_{j_{k+1}}A_{i_{k+1}}^\dagger)\cdots\varphi_{L,\xi}(A_{j_n}A_{i_n}^\dagger), \tag{15}$$

where $k=1,\ldots,n$, $1=i_1<i_2<\cdots<i_k$, $j_{k+1}<\cdots<j_n$, $i_l\leqslant j_l$ for $l=1,\ldots,k$ and $j_l<i_l$ for $l=k+1,\ldots,n$. We say that (15) corresponds to a nonconnected diagram if there exists $m\in\{1,\ldots,n\}$ such that $i_l\leqslant m\Leftrightarrow j_l\leqslant m$. Otherwise we say that (15) corresponds to a connected diagram.

Let us prove that all the connected diagrams except only one corresponding to the case $k=1$ are equal to zero in the limit. One can write (15) as

$$\frac{1}{\xi^n}\exp\{i[(t_1-t_{j_1})E_1+\cdots+(t_{i_n}-t_{j_n})E_{i_n}]/\xi\}(\xi^k F(E)+O(\xi^{k+1}))$$

$$=\frac{1}{\xi^n}\exp\{i[t_n(E_n-E_{\alpha_n})+\cdots+t_1(E_1-E_{\alpha_1})]/\xi\}(\xi^k F(E)+O(\xi^{k+1}))$$

$$=\frac{1}{\xi^{n-1}}\exp\{i[(t_n-t_{n-1})\omega_n(E)+\cdots+(t_2-t_1)\omega_2(E)]/\xi\}(\xi^{k-1}F(E)+O(\xi^k))$$

$$=\frac{e^{i(t_n-t_{n-1})\omega_n(E)/\xi}}{\xi}\cdots\frac{e^{i(t_2-t_1)\omega_2(E)/\xi}}{\xi}(\xi^{k-1}F(E)+O(\xi^k)), \tag{16}$$

where $(\alpha_1,\ldots,\alpha_n)$ is the permutation of the set $(1,\ldots,n)$, $\omega_l(E)=E_n+\cdots+E_l-E_{\alpha_n}-\cdots-E_{\alpha_l}$ for $l=2,\ldots,n$, and

$$F(E)=\prod_{l=1}^{k}\langle g_{j_l},P_{E_l}Lf_{i_l}\rangle\prod_{l=k+1}^{n}\langle g_{j_l},P_{E_{i_l}}f_{i_l}\rangle.$$

Notice that for a connected diagram all the functions $\omega_l(E)$ are not identically zero. In fact, suppose that $\omega_m(E)\equiv 0$ for some $m\in\{2,\ldots,n\}$. In this case one has the identity

$$E_m+\cdots+E_n\equiv E_{\alpha_m}+\cdots+E_{\alpha_n}$$

(where $E_\alpha, E_{\alpha'}$ for $\alpha\neq\alpha'$ are independent variables) which means that $(\alpha_m,\ldots,\alpha_n)$ is a permutation of the set $\{m,\ldots,n\}$ and hence $(\alpha_1,\ldots,\alpha_{m-1})$ is a permutation of the set $\{1,\ldots,m-1\}$. Let us choose any $l\in\{1,\ldots,n\}$ and consider the term $t_{j_l}(E_{j_l}-E_{i_l})$ in the exponent in the second line of (16). If $j_l<m$, then since $i_l\equiv\alpha_{j_l}$ and α_{j_l} belongs to the set $\{1,\ldots,m-1\}$, one has $i_l\equiv\alpha_{j_l}\in\{1,\ldots,m-1\}$, and vice versa if $\alpha_{j_l}\equiv i_l\in\{1,\ldots,m-1\}$, then $j_l\leqslant m-1$. This means that if ω_l are not identically zero, then (15) corresponds to a connected diagram.

Let us consider the case $k>1$. Then, if (15) corresponds to a connected diagram, the functions $\omega_l(E)$ are not identically zero. In this case, since there exists the limit

$$\lim_{\xi\to 0}\frac{e^{i(t_l-t_{l-1})\omega_l(E)/\xi}}{\xi}=\delta_+(t_l-t_{l-1})\frac{1}{i(\omega_l(E)-i0)}$$

and the limit of the product of such terms in (16), and $k-1>0$, the limit of (16) is equal to zero.

Now let us consider the case $k=1$. In this case (15) has the form

$$\varphi_{L,\xi}(A_1^\dagger A_n)\varphi_{L,\xi}(A_1A_2^\dagger)\cdots\varphi_{L,\xi}(A_{n-1}A_n^\dagger)$$

$$=\frac{1}{\xi^n}\exp\{i[(t_1-t_n)E_1+(t_2-t_1)E_2+\cdots+(t_n-t_{n-1})E_n]/\xi\}(\xi F(E)+O(\xi^2))$$

$$=\frac{e^{i(t_n-t_{n-1})\omega_n(E)/\xi}}{\xi}\cdots\frac{e^{i(t_2-t_1)\omega_2(E)/\xi}}{\xi}(F(E)+O(\xi)), \tag{17}$$

where $\omega_l(E)=E_l-E_1$. Using the limit (A2) one finds that the limit of the right-hand side (RHS) of (17) is equal to

$$\delta_+(t_2-t_1)\cdots\delta_+(t_n-t_{n-1})\langle g_n,P_{E_1}Lf_1\rangle\frac{\langle g_1,P_{E_2}f_2\rangle}{i(E_2-E_1-i0)}\cdots\frac{\langle g_{n-1},P_{E_n}f_n\rangle}{i(E_n-E_1-i0)}.$$

After integration over $E_1\cdots E_n$ it becomes equal to

$$\delta_+(t_2-t_1)\cdots\delta_+(t_n-t_{n-1})\int \mathrm{d}E\langle g_n, P_E L f_1\rangle \gamma_{g_1,f_2}(E)\cdots\gamma_{g_{n-1},f_n}(E). \tag{18}$$

This proves that only one connected diagram survives in the limit.

Now let us consider the quantity

$$\varphi_L(N_{f_1,g_1}(t_1)\cdots N_{f_n,g_n}(t_n)).$$

With the notation

$$B_l^\dagger := B_{f_l}^\dagger(E_l,t_l), \quad B_l := B_{g_l}(E_l,t_l),$$

it can be written as

$$\int \mathrm{d}E_1\cdots\mathrm{d}E_n \varphi_L(B_1^\dagger B_1\cdots B_n^\dagger B_n). \tag{19}$$

Notice that on the simplex $t_1\geqslant t_2\geqslant\cdots\geqslant t_n\geqslant 0$ causal δ functions $\delta_+(t_{l+m}-t_l)$ for $m\geqslant 2$ are equal to zero. Therefore for $m\geqslant 2$ one has $\varphi_L(B_{t_l}B_{t_{l+m}}^\dagger)\propto\delta_+(t_{l+m}-t_l)=0$ and hence the integrand in (19) can be written as

$$\begin{aligned}\varphi_L(B_1^\dagger B_1\cdots B_n^\dagger B_n)=&\sum_{k=1}^{n-1}\varphi_L(B_1^\dagger B_k)\varphi_L(B_1B_2^\dagger)\cdots\varphi_L(B_{k-1}B_k^\dagger)\varphi_L(B_{k+1}^\dagger B_{k+1}\cdots B_n^\dagger B_n)\\&+\varphi_L(B_1^\dagger B_n)\varphi_L(B_1B_2^\dagger)\cdots\varphi_L(B_{n-1}B_n^\dagger).\end{aligned} \tag{20}$$

The terms in the sum correspond to nonconnected diagrams. The last term corresponds to a unique nonzero connected diagram. Moreover,

$$\begin{aligned}&\int \mathrm{d}E_1\cdots\mathrm{d}E_n\varphi_L(B_1^\dagger B_n)\varphi_L(B_1B_2^\dagger)\cdots\varphi_L(B_{n-1}B_n^\dagger)\\&\quad=\delta_+(t_2-t_1)\cdots\delta_+(t_n-t_{n-1})\int\mathrm{d}E\langle g_n,P_E L f_1\rangle\gamma_{g_1,f_2}(E)\cdots\gamma_{g_{n-1},f_n}(E),\end{aligned}$$

which is equal to (18).

For $n=1$ the statement of the theorem is clear. In fact,

$$\lim_{\xi\to 0}\varphi_{L,\xi}(N_{f,g,\xi}(t))=\lim_{\xi\to 0}\left\langle g,\frac{L}{1-\xi L}f\right\rangle=\langle g,Lf\rangle=\int \mathrm{d}E\,\varphi_L(B_f^\dagger(E,t)B_g(E,t)).$$

Then proof of the theorem follows by induction using the fact that only one connected diagram survives in the limit.

Remark 2: The fact that in each order of iterated series only one connected diagram survives in the limit can be interpreted as emergence of a new statistics (different from Bose) in the low density limit. For a discussion of new statistic arising in the weak coupling limit we refer to Ref. 1 (see also Ref. 18).

The following theorem is important for investigation of the limiting white noise equation for the evolution operator.

Theorem 2: *The limit state φ_L has the following factorization property*: $\forall n\in\mathbb{N}$,

$$\varphi_L(B_f^\dagger(E,t)N_{f_1,g_1}(t_1)\cdots N_{f_n,g_n}(t_n)B_g(E,t))=\varphi_L(B_f^\dagger(E,t)B_g(E,t))\varphi_L(N_{f_1,g_1}(t_1)\cdots N_{f_n,g_n}(t_n)), \tag{21}$$

where the equality is understood in the sense of distributions over simplex $t \geqslant t_1 \geqslant t_2 \geqslant \cdots \geqslant t_n \geqslant 0$.

Proof: From Gaussianity of the causal state φ_L [property (9)] it follows that

$$\varphi_L(B_f^\dagger(E,t)N_{f_1,g_1}(t_1)\cdots N_{f_n,g_n}(t_n)B_g(E,t))$$

$$= \varphi_L(B_f^\dagger(E,t)B_g(E,t))\varphi_L(N_{f_1,g_1}(t_1)\cdots N_{f_n,g_n}(t_n)) + \int dE_1\cdots dE_n$$

$$\times \sum \varphi_L(B_f^\dagger(E,t)B_{g_i}(E_i,t_i))\cdots\varphi_L(B_{f_j}^\dagger(E_j,t_j)B_g(E,t)).$$

The sum is equal to zero since the last multiplier

$$\varphi_L(B_{f_j}^\dagger(E_j,t_j)B_g(E,t)) = \chi_{[0,t_j]}(t)\langle g, P_{E_j}Lf_j\rangle$$

is equal to zero almost everywhere on the simplex $t \geqslant t_1 \geqslant t_2 \geqslant \cdots \geqslant t_n \geqslant 0$ and hence is equal to zero in the sense of distributions on the simplex. This proves the theorem.

Theorem 1 allows us to calculate, in particular, the partial expectation of the evolution operator and Heisenberg evolution of any system observable in the low density limit. In fact, partial expectation of the nth term of the iterated series for the evolution operator (3) (or equivalent series for Heisenberg evolution of a system observable) after time rescaling $t \to t/\xi$ includes the quantity

$$\int_0^t \mathrm{d}t_1 \cdots \int_0^{t_{n-1}} \mathrm{d}t_n \varphi_{L,\xi}(N_{f_1,g_1,\xi}(t_1)\cdots N_{f_n,g_n,\xi}(t_n))$$

(where f_α, g_α are equal to g_0 or g_1). The limit as $\xi \to 0$ of this quantity can be calculated using Theorem 1. For example, the contribution of the connected diagram is equal to

$$\int_0^t \mathrm{d}t_1 \int_0^{t_1} \mathrm{d}t_2 \delta_+(t_2 - t_1) \int_0^{t_2} \mathrm{d}t_3 \delta_+(t_3 - t_2) \cdots \int_0^{t_{n-1}} \mathrm{d}t_n \delta_+(t_n - t_{n-1})$$

$$\times \int \mathrm{d}E \langle g_n, P_E L f_1\rangle \gamma_{g_1,f_2}(E)\cdots\gamma_{g_{n-1},f_n}(E) = t \int \mathrm{d}E \langle g_n, P_E L f_1\rangle \gamma_{g_1,f_2}(E)\cdots\gamma_{g_{n-1},f_n}(E).$$

Similarly one can calculate the contribution of nonconnected diagrams (they give terms proportional to higher orders of t). Summing over all orders of the iterated series one can find the reduced dynamics of the system. But in the present paper we will get the limiting dynamics in a nonperturbative way, without direct summation of the iterated series. This procedure includes derivation of the white noise equation for the limiting evolution operator and then bringing this equation to the causally normally ordered form. After that one can easily find, for example, the reduced dynamics of the system. For the weak coupling limit such a procedure was developed in Ref. 1. A nontrivial generalization to the low density limit was developed in Ref. 16 and 17, where the derivation is based on the Fock–anti-Fock representation for the CCR algebra of the Bose field determined by the state $\varphi_{L,\xi}$. The approach of the present paper does not require a GNS representation and is different from approach of Ref. 16 and 17.

IV. WHITE NOISE SCHRÖDINGER EQUATION

In this section we derive, using the results of previous section, the white noise Schrödinger equation for the limiting evolution operator.

The evolution operator $U(t/\xi)$ satisfies Eq. (6) which can be written as

$$\frac{\mathrm{d}U(t/\xi)}{\mathrm{d}t} = -\mathrm{i}H_\xi(t)U(t/\xi),$$

where

$$H_\xi(t)=\mathrm{i}(D\otimes N_{g_0,g_1,\xi}(t)-D^\dagger\otimes N_{g_1,g_0,\xi}(t)).$$

The results of the preceding section allow us to write the limit as $\xi\to 0$ of the Hamiltonian $H_\xi(t)$. In the notation (13) the limiting Hamiltonian is the following operator in $\mathcal{H}_S \otimes\Gamma(L^2(\mathbb{R}_+,\mathcal{X}_{\mathcal{H},H_1}))$:

$$\begin{aligned}H(t)&=\mathrm{i}(D\otimes N_{g_0,g_1}(t)-D^\dagger\otimes N_{g_1,g_0}(t))\\&=\mathrm{i}\int \mathrm{d}E(D\otimes B^\dagger_{g_0}(E,t)B_{g_1}(E,t)-D^\dagger\otimes B^\dagger_{g_1}(E,t)B_{g_0}(E,t)).\end{aligned}\tag{22}$$

The dynamics of the total system (system+reservoir) in the low density limit $\xi\to 0$ is given by a new evolution operator U_t which is the solution of the white noise Schrödinger equation

$$\frac{\mathrm{d}U_t}{\mathrm{d}t}=-\mathrm{i}H(t)U_t,\quad U_0=1,\tag{23}$$

or equivalent integral equation

$$U_t=1+\int_0^t \mathrm{d}t_1(D\otimes N_{g_0,g_1}(t_1)-D^\dagger\otimes N_{g_1,g_0}(t_1))U_{t_1}.\tag{24}$$

V. NORMALLY ORDERED FORM OF THE WHITE NOISE EQUATION

Our next step is to bring the white noise Schrödinger equation to the causally normally ordered form (Theorem 3), i.e., the form in which all annihilation operators are on the right side of the evolution operator and all creation operators are on the left side. Such a form is convenient for study of the limiting dynamics (see remark 3 and text after remark). In particular, it can be used for derivation of (linear) Boltzmann equation.

We assume that for each $E\in\mathbb{R}$, the inverse operators

$$T_0(E):=(1+\gamma_{g_0,g_1}(E)D^\dagger-\gamma_{g_1,g_0}(E)D+(\gamma_{g_0,g_0}\gamma_{g_1,g_1}-\gamma_{g_1,g_0}\gamma_{g_0,g_1})(E)DD^\dagger]^{-1},$$

$$T_1(E):=(1+\gamma_{g_0,g_1}(E)D^\dagger-\gamma_{g_1,g_0}(E)D+(\gamma_{g_0,g_0}\gamma_{g_1,g_1}-\gamma_{g_1,g_0}\gamma_{g_0,g_1})(E)D^\dagger D)^{-1}$$

exist.

Lemma 1: If the evolution operator U_t satisfies (23) with $H(t)$ given by (22), then one has

$$B_{g_0}(E,t)U_t=\gamma_{g_0,g_0}(E)T_0(E)DU_tB_{g_1}(E,t)+T_0(E)(1-\gamma_{g_1,g_0}(E)D)U_tB_{g_0}(E,t),\tag{25}$$

$$B_{g_1}(E,t)U_t=-\gamma_{g_1,g_1}(E)T_1(E)D^\dagger U_tB_{g_0}(E,t)+T_1(E)(1+\gamma_{g_0,g_1}(E)D^\dagger)U_tB_{g_0}(E,t).\tag{26}$$

Notice that in the RHS of these equalities the annihilation operators $B_f(E,t)$ are on the right of the evolution operator.

Proof: It follows from (8) and (13) that

$$[B_{f'}(E,t),N_{f,g}(t_1)]=\delta_+(t_1-t)\gamma_{f',f}(E)B_g(E,t).\tag{27}$$

Therefore using the integral equation (24) for the evolution operator one gets

$$B_f(E,t)U_t=[B_f(E,t),U_t]+U_tB_f(E,t)$$
$$=\int_0^t \mathrm{d}t_1(D\otimes[B_f(E,t),N_{g_0,g_1}(t_1)]-D^\dagger\otimes[B_f(E,t),N_{g_1,g_0}(t_1)])U_{t_1}+U_tB_f(E,t)$$
$$=(D\gamma_{f,g_0}(E)B_{g_1}(E,t)-D^\dagger\gamma_{f,g_1}(E)B_{g_0}(E,t))U_t+U_tB_f(E,t). \tag{28}$$

The second equality in (28) holds because, due to the time consecutive principle,

$$[B_f(E,t),U_{t_1}]=0 \quad \text{for } t_1<t.$$

In fact, let us consider the quantity

$$\int_0^t \mathrm{d}t_1[B_f(E,t),U_{t_1}^{(n-1)}]=(-i)^{n-1}\int_0^t \mathrm{d}t_1\cdots\int_0^{t_{n-1}}\mathrm{d}t_n[B_f(E,t),H(t_2)\cdots H(t_n)], \tag{29}$$

where the nth term of the iterated series (3) for U_t has the form

$$U_t^{(n)}:=(-i)^n\int_0^t \mathrm{d}t_1\cdots\int_0^{t_{n-1}}\mathrm{d}t_nH(t_1)\cdots H(t_n).$$

The commutator $[B_f(E,t),H(t_k)]$ is proportional to $\delta_+(t_k-t)$; hence the commutator $[B_f(E,t),H(t_2)\cdots H(t_n)]$ is equal to zero on the simplex $t\geqslant t_1\geqslant t_2\geqslant\cdots\geqslant t_n\geqslant 0$ and therefore (29) is equal to zero.

The third equality in (28) holds since from (27) and the definition of the causal δ function one has

$$\int_0^t \mathrm{d}t_1\delta_+(t_1-t)B_f(E,t_1)U_{t_1}=B_f(E,t)U_t.$$

For a detailed discussion of the time consecutive principle and causal δ function we refer to Ref. 1.

After the substitution $f=g_0$ and $f=g_1$ in (28) one gets

$$B_{g_0}(E,t)U_t=(D\gamma_{g_0,g_0}(E)B_{g_1}(E,t)-D^\dagger\gamma_{g_0,g_1}(E)B_{g_0}(E,t))U_t+U_tB_{g_0}(E,t),$$

$$B_{g_1}(E,t)U_t=(D\gamma_{g_1,g_0}(E)B_{g_1}(E,t)-D^\dagger\gamma_{g_1,g_1}(E)B_{g_0}(E,t))U_t+U_tB_{g_1}(E,t),$$

or equivalently

$$(1+\gamma_{g_0,g_1}(E)D^\dagger)B_{g_0}(E,t)U_t=\gamma_{g_0,g_0}(E)DB_{g_1}(E,t)U_t+U_tB_{g_0}(E,t), \tag{30}$$

$$(1+\gamma_{g_1,g_0}(E)D)B_{g_1}(E,t)U_t=-\gamma_{g_1,g_1}(E)D^\dagger B_{g_0}(E,t)U_t+U_tB_{g_1}(E,t). \tag{31}$$

After left multiplication of both sides of equality (30) by $(1+\gamma_{g_1,g_0}(E)D)$ and both sides of (31) by $\gamma_{g_0,g_0}(E)D$ one gets

$$(1+\gamma_{g_1,g_0}(E)D)(1+\gamma_{g_0,g_1}(E)D^\dagger)B_{g_0}(E,t)U_t$$
$$=\gamma_{g_0,g_0}(E)D(1+\gamma_{g_1,g_0}(E)D)B_{g_1}(E,t)U_t+(1+\gamma_{g_1,g_0}(E)D)U_tB_{g_0}(E,t), \tag{32}$$

$$\gamma_{g_0,g_0}(E)D(1+\gamma_{g_1,g_0}(E)D)B_{g_1}(E,t)U_t$$
$$=-\gamma_{g_0,g_0}(E)DD^\dagger\gamma_{g_1,g_1}(E)B_{g_0}(E,t)U_t+\gamma_{g_0,g_0}(E)DU_tB_{g_1}(E,t). \tag{33}$$

Now after substitution of expression (33) into (32) one has

$$(1+\gamma_{g_0,g_1}(E)D^\dagger-\gamma_{g_1,g_0}(E)D+(\gamma_{g_0,g_0}\gamma_{g_1,g_1}-\gamma_{g_1,g_0}\gamma_{g_0,g_1})(E)DD^\dagger)B_{g_0}(E,t)U_t$$
$$=\gamma_{g_0,g_0}(E)DU_tB_{g_1}(E,t)+(1-\gamma_{g_1,g_0}(E)D)U_tB_{g_0}(E,t). \tag{34}$$

One can show by similar computations that

$$(1+\gamma_{g_0,g_1}(E)D^\dagger-\gamma_{g_1,g_0}(E)D+(\gamma_{g_0,g_0}\gamma_{g_1,g_1}-\gamma_{g_1,g_0}\gamma_{g_0,g_1})(E)D^\dagger D)B_{g_1}(E,t)U_t$$
$$=-\gamma_{g_1,g_1}(E)D^\dagger U_tB_{g_0}(E,t)+(1+\gamma_{g_0,g_1}(E)D^\dagger)U_tB_{g_1}(E,t). \tag{35}$$

Now since we suppose that the inverse operators $T_0(E)$ and $T_1(E)$ exist, we can solve the above equations (34) and (35) with respect to $B_{g_0}(E,t)U_t$ and $B_{g_1}(E,t)U_t$. The solutions are given by (25) and (26), and that proves the lemma.

Denote

$$R_{0,0}(E):=\gamma_{g_1,g_1}(E)DT_1(E)D^\dagger,$$

$$R_{1,1}(E):=\gamma_{g_0,g_0}(E)D^\dagger T_0(E)D,$$

$$R_{0,1}(E):=-DT_1(E)(1+\gamma_{g_0,g_1}(E)D^\dagger),$$

$$R_{1,0}(E):=D^\dagger T_0(E)(1-\gamma_{g_1,g_0}(E)D).$$

Theorem 3: *The normally ordered form of Eq. (23) is*

$$\frac{\mathrm{d}U_t}{\mathrm{d}t}=-\sum_{n,m=0,1}\int \mathrm{d}E R_{m,n}(E)B^\dagger_{g_m}(E,t)U_tB_{g_n}(E,t). \tag{36}$$

Proof: Using (22) white noise Schrödinger equation (23) can be rewritten in a more detailed form

$$\frac{\mathrm{d}U_t}{\mathrm{d}t}=\int \mathrm{d}E(D\otimes B^\dagger_{g_0}(E,t)B_{g_1}(E,t)-D^\dagger\otimes B^\dagger_{g_1}(E,t)B_{g_0}(E,t))U_t. \tag{37}$$

It follows from Lemma 1 that

$$D^\dagger B_{g_0}(E,t)U_t=R_{1,1}(E)U_tB_{g_1}(E,t)+R_{1,0}(E)U_tB_{g_0}(E,t),$$

$$DB_{g_1}(E,t)U_t=-R_{0,0}(E)U_tB_{g_0}(E,t)-R_{0,1}(E)U_tB_{g_1}(E,t).$$

The statement of the theorem is obtained after substitution of these expressions in (37).

Remark 3: An immediate consequence of Theorem 2 is the following factorization property of the limiting state φ_L:

$$\varphi_L(B^\dagger_{g_m}(E,t)U_tB_{g_n}(E,t))=\varphi_L(B^\dagger_{g_m}(E,t)B_{g_n}(E,t))\varphi_L(U_t).$$

This property of the state φ_L *similar to the factorization property of the state determined by a coherent vector* $\Psi,\|\Psi\|=1$:

$$(\Psi,B^\dagger_{g_m}(E,t)U_tB_{g_n}(E,t)\Psi)=(\Psi,B^\dagger_{g_m}(E,t)B_{g_n}(E,t)\Psi)(\Psi,U_t\Psi),$$

which is usually used to define quantum stochastic differential equations (the general notion of adaptedness and adapted domains which are much larger than the coherent ones is given in Ref. 12).

Taking the partial expectation of both sides of Eq. (36) in the state φ_L, using the factorization property and noticing that

$$\varphi_L(B^\dagger_{g_m}(E,t)B_{g_n}(E,t))=\langle g_n, P_E L g_m\rangle,$$

one gets the equation

$$\frac{\mathrm{d}\varphi_L(U_t)}{\mathrm{d}t}=-\Gamma\varphi_L(U_t), \tag{38}$$

where Γ is being called drift and is equal to

$$\Gamma=\sum_{n,m=0,1}\int \mathrm{d}E R_{m,n}(E)\langle g_n, P_E L g_m\rangle.$$

The solution of (38) is

$$\varphi_L(U_t)=\mathrm{e}^{-\Gamma t}.$$

In the case of orthogonal test functions, i.e., $\langle g_0, S_t g_1\rangle=0$, this expectation value for the evolution operator was obtained in Ref. 16. Let us note that the expectation value is obtained in a nonpertrubative way, without direct summation of the iterated series for the evolution operator, and is a result of the procedure of causal normal ordering.

VI. ONE-PARTICLE *T* OPERATOR AND *S* MATRIX

In the low density limit the role of multiparticle collisions is negligible and the dynamics of the test particle should be determined by the interaction of the test particle with one particle of the reservoir. In the present section we give the expressions for the one-particle T operator and S matrix. In the next section we will rewrite normally ordered white noise equation (36) in a form of the quantum stochastic equation (44) and show (Theorem 5) that the coefficients of this equation can be expressed in terms of the one-particle S matrix.

Because of number conservation, the closed subspace of $\mathcal{H}_S\otimes\Gamma(\mathcal{H})$ generated by vectors of the form $u\otimes A^\dagger(f)\Phi$ ($u\in\mathcal{H}_S$, $f\in\mathcal{H}=L^2(\mathbb{R}^d)$, Φ is the vacuum vector), which is naturally isomorphic to $\mathcal{H}_S\otimes\mathcal{H}$, is globally invariant under the time evolution operator $\exp[\mathrm{i}(H_S\otimes 1+1\otimes H_R+V)t]$. The restriction of the time evolution operator to this subspace corresponds to the evolution operator on $\mathcal{H}_S\otimes\mathcal{H}$ given by

$$\exp[\mathrm{i}(H_S\otimes 1+1\otimes H_1+V_1)t],$$

where

$$V_1=\mathrm{i}(D\otimes|g_0\rangle\langle g_1|-\mathrm{H.c.}). \tag{39}$$

The one-particle Møller wave operators are defined as

$$\Omega_\pm=s-\lim_{t\to\mp\infty}\exp[\mathrm{i}(H_S\otimes 1+1\otimes H_1+V_1)t]\exp[-\mathrm{i}(H_S\otimes 1+1\otimes H_1)t].$$

The one-particle T operator is defined as

$$T=V_1\Omega_+ \tag{40}$$

and the one-particle S matrix as

$$S=\Omega_-^*\Omega_+ . \tag{41}$$

Theorem 4: *For the interaction (39) the one-particle T operator and S matrix have the form*

$$T=-\mathrm{i}\sum_{n,m\in\{0,1\}}\int \mathrm{d}E R_{m,n}(E)\otimes|g_m\rangle\langle g_n|P_E , \tag{42}$$

$$S=1-2\pi\sum_{n,m\in\{0,1\}}\int \mathrm{d}E R_{m,n}(E)\otimes|P_E g_m\rangle\langle P_E g_n|. \tag{43}$$

Proof: For the case $\langle g_0,S_t g_1\rangle=0$ equality (42) was proved in Ref. 17. The proof of (42) and (43) for the general case can be done in a similar way.

Expression (43) will be used in the next section for derivation of Eq. (47).

VII. QUANTUM STOCHASTIC EQUATION FOR THE LIMITING EVOLUTION OPERATOR

Normally ordered white noise equation (36) equivalent, through identification

$$B_m^\dagger(E,t)U_t B_n(E,t)\mathrm{d}t=2\pi\mathrm{d}N_t(|P_E g_m\rangle\langle P_E g_n|)U_t$$

to the quantum stochastic differential equation

$$\mathrm{d}U_t=-2\pi\sum_{n,m\in\{0,1\}}\int \mathrm{d}E R_{m,n}(E)\mathrm{d}N_t(|P_E g_m\rangle\langle P_E g_n|)U_t , \tag{44}$$

where N_t is the quantum Poisson process in $\Gamma(L^2(\mathbb{R}_+)\otimes\mathcal{H})$ defined by $N_t(X):=N(\chi_{[0,t]}\otimes X)$, if X is an operator in $\mathcal{H}$. The stochastic differential $\mathrm{d}N_t$ satisfies the usual Ito table

$$\mathrm{d}N_t(X)\mathrm{d}N_t(Y)=\mathrm{d}N_t(XY), \tag{45}$$

where X, Y are operators in $\mathcal{H}$, and the limit state φ_L characterized by the property

$$\varphi_L(2\pi\mathrm{d}N_t(|P_E f\rangle\langle P_E g|))=\langle g,P_E L f\rangle\mathrm{d}t.$$

The coefficients of quantum stochastic equation (44) can be expressed in terms of a one-particle S matrix describing scattering of the test particle on one particle of the reservoir. To show this we will use Hilbert module notation. For any pair of Hilbert spaces $\mathcal{X}_0,\mathcal{X}_1$, if N_t denotes the Poisson process on the Fock space $\Gamma(L^2(\mathbb{R}_+)\otimes\mathcal{X}_1)$, then for bounded operators $X_0\in B(\mathcal{X}_0)$, $X_1\in B(\mathcal{X}_1)$, the Hilbert module notation is[10]

$$N_t(X_0\otimes X_1):=X_0\otimes N_t(X_1).$$

With this notation Eq. (44) can be written as

$$\mathrm{d}U_t=\mathrm{d}N_t\left(-2\pi\sum_{n,m\in\{0,1\}}\int \mathrm{d}E R_{m,n}(E)\otimes|P_E g_m\rangle\langle P_E g_n|\right)U_t . \tag{46}$$

An immediate conclusion from (43) and (46) is the following theorem which is one of the main results of the paper.

Theorem 5: *The evolution operator in the low density limit satisfies the quantum stochastic equation driven by the quantum Poisson process with intensity $S-1$:*

$$\mathrm{d}U_t=\mathrm{d}N_t(S-1)U_t . \tag{47}$$

Equation (47) describes the dynamics of the compound system in the low density limit. Using this equation and the Ito table for stochastic differentials one can obtain a quantum Langevin equation for the Heisenberg evolution of any system observable. Then the corresponding master equation or, equivalently, quantum (linear) Boltzmann equation for reduced density matrix of the system can be obtained simply by taking the partial expectation of this Langevin equation in the causal state φ_L.

Lemma 2: The solution of (47) is unitary.

Proof: Let us show that $\mathrm{d}(U_t^\dagger U_t)=0$. The operator $U_t^\dagger$ satisfies the equation

$$\mathrm{d}U_t^\dagger = U_t^\dagger \mathrm{d}N_t(S^\dagger - 1).$$

One has

$$\begin{aligned}\mathrm{d}(U_t^\dagger U_t) &= \mathrm{d}U_t^\dagger U_t + U_t^\dagger \mathrm{d}U_t + \mathrm{d}U_t^\dagger \mathrm{d}U_t \\ &= U_t^\dagger \mathrm{d}N_t(S^\dagger - 1)U_t + U_t^\dagger \mathrm{d}N_t(S-1)U_t + U_t^\dagger \mathrm{d}N_t(S^\dagger - 1)\mathrm{d}N_t(S-1)U_t .\end{aligned}$$

Using the Ito table (45) one gets

$$\mathrm{d}N_t(S^\dagger - 1)\mathrm{d}N_t(S-1) = \mathrm{d}N_t[(S^\dagger - 1)(S-1)].$$

This and unitarity of S leads to

$$\mathrm{d}(U_t^\dagger U_t) = U_t^\dagger \mathrm{d}N_t[S^\dagger - 1 + S - 1 + (S^\dagger - 1)(S-1)]U_t = 0.$$

Now it follows from the initial condition $U_{t=0}=1$ that, for any $t \geqslant 0$, $U_t^\dagger U_t = 1$. The proof of $U_t U_t^\dagger = 1$ can be done in a similar way.

VIII. CONCLUSIONS

In the present paper we consider the dynamics of a test particle (N-level atom) interacting with a dilute Bose gas. It is proved that the dynamics of the total system converges in the low density limit to the solution of the quantum stochastic equation driven by a quantum Poisson process with intensity $S-1$, where S is a one-particle scattering matrix. The limiting equation is derived in a nonpertrubative way, without use of iterated series for the evolution operator. The derivation is based on the white noise approach and on the procedure of causal normal ordering developed for the weak coupling limit by Accardi, Lu, and Volovich.[1] The novelty of the present derivation is that we do not use the Fock–anti-Fock (or GNS) representation for the CCR algebra of the boson gas, determined by the state $\varphi_{L,\xi}$. This simplifies the derivation and allows us to express the intensity of the Poisson process directly in terms of a one-particle S matrix. The notion of causal states is introduced and the convergence of the correlators of the free evolution of the initial number operators to correlators of quantum white noise operators in causal states is proved. The causal states satisfy the factorization property similar to that satisfied by states determined by coherent vectors. This property is crucial for study of the reduced dynamics of the system.

Lu, and Professor I.V. Volovich for many useful and stimulating discussions. This work is partially supported by Grant No. INTAS YSF 01/1-200, a NATO-CNR Fellowship, and Grant No. RFFI 02-01-01084.

APPENDIX: CAUSAL δ FUNCTION

Let us recall the construction for distributions on the standard simplex (cf. Ref. 1). Define

$$C_0 := \{\phi : \mathbb{R}_+ \to \mathbb{C} \,|\, \phi = 0 \ \text{ a.e.}\},$$

$$C_1 := \{\phi : \mathbb{R}_+ \to \mathbb{C} \mid \phi \text{ is bounded and left-continuous at any } t>0\},$$

$$C := \text{ linear span of } \{C_0 \cup C_1\}.$$

For any $a>0$ define $\delta_+(\cdot - a)$ as the unique linear extension of the map:

$$\delta_+(\cdot - a) : \phi \in C_1 \to \phi(a),$$

$$\delta_+(\cdot - a) : \phi \in C_0 \to 0.$$

In Ref. 1 the following results are proved.

Lemma 3: In the sense of distributions one has the limit

$$\lim_{\lambda \to 0} \frac{e^{i(t'-t)E/\lambda^2}}{\lambda^2} = 2\pi \delta(t'-t)\,\delta(E). \tag{A1}$$

Lemma 4: In the sense of distributions over the simplex $t \geqslant t' \geqslant 0$ one has the limit

$$\lim_{\lambda \to 0} \frac{e^{i(t'-t)E/\lambda^2}}{\lambda^2} = \delta_+(t'-t)\,\frac{1}{i(E-i0)}. \tag{A2}$$

The last equality means, in particular, that for any $f \in C$, $g \in S(\mathbb{R})$, one has the limit

$$\lim_{\lambda \to 0} \int_0^t dt' \int_{\mathbb{R}} dE\, \frac{e^{i(t'-t)E/\lambda^2}}{\lambda^2} f(t') g(E) = f(t) \lim_{\varepsilon \to 0+} \int dE\, \frac{g(E)}{i(E-i\varepsilon)}.$$

Given a unitary representation U of an Abelian group G and a subgroup H, we characterize the positive operator valued measures based on the quotient group G/H and covariant with respect to U. © *2004 American Institute of Physics.*
[DOI: 10.1063/1.1631081]

I. INTRODUCTION

Usually, the observables in quantum mechanics are represented by self-adjoint operators acting in the Hilbert space of states, or, equivalently, by projection valued operator measures. However, in quantum theory of measurement and in its applications (such as quantum optics or theory of measurement in phase-space) one needs to consider a more general setting in which projectivity is dropped and generalized observables are described in terms of positive operator valued measures (for a review see, for example, Refs. 1, 2, 6, 10, 13, and 14). Among these measures, the physically significant ones satisfy certain properties of covariance with respect to a symmetry group of the theory.

More precisely, consider a topological group G and a closed subgroup H. Given a unitary representation U of G, it is of interest both in quantum mechanics and in wavelet analysis to describe the positive operator valued measures Q defined on the quotient space G/H and covariant with respect to U.

In his seminal papers,[11,12] Holevo classifies the covariant positive operator valued measures if G is of type I and $H=\{e\}$, and if G is compact and H is arbitrary.

In this article we extend the above result to the case G Abelian and H arbitrary. Moreover, we give a more feasible description of covariant positive operator valued measures in terms of a family $W_x : E_x \to E$ of isometries, where the index x runs over the dual group of G, dim E_x equals the multiplicity of the character x in U and E is a fixed (infinite dimensional) Hilbert space. As a byproduct, we define a unitary operator Σ that diagonalizes the representation of G unitarily induced by a representation of H with uniform multiplicity.

As an application of our characterization, in the final section we give three examples of physical interest:

(1) the *regular* representation of the real line, where the positive operator valued measures describe the *position observables* in one dimension;

[a)]Electronic mail: cassinelli@ge.infn.it
[b)]Electronic mail: devito@unimo.it
[c)]Electronic mail: toigo@ge.infn.it

(2) the *number*-representation of the torus, where the positive operator valued measures describe the *phase observables*;[3] and
(3) the tensor product of two *number*-representations of the torus, where the positive operator valued measures describe the *phase difference observables*.[9]

II. NOTATIONS

In this article, by *Hilbert space* we mean a separable complex Hilbert space with scalar product $\langle\cdot,\cdot\rangle$ linear in the first argument, by *group* we mean a locally compact second countable Abelian group and by *representation* a continuous unitary representation of a group acting on a Hilbert space. If X is a locally compact second countable topological space, we denote by $\mathcal{B}(X)$ the Borel σ-algebra of X and by $C_c(X)$ the space of continuous complex functions on X with compact support. By *measure* we mean a positive measure defined on $\mathcal{B}(X)$ and finite on compact sets.

In the sequel we shall use rather freely basic results of harmonic analysis on Abelian groups, as exposed, for example, in Refs. 7 and 8.

We fix a group G and a closed subgroup H. We denote by $\hat{G}$ and $\hat{H}$ the corresponding dual groups and by $\langle x,g\rangle$ the canonical pairing.

We denote by

$$q:G\to G/H,\quad q(g)=\dot{g}$$

the canonical projection onto the quotient group G/H. If $a\in G$ and $\dot{g}\in G/H$, we let $a[\dot{g}]=q(ag)=\dot{a}\dot{g}$ be the natural action of a on the point $\dot{g}$.

Let $H^\perp$ be the annihilator of H in $\hat{G}$, that is,

$$H^\perp=\{y\in\hat{G}\,|\,\langle y,h\rangle=1\ \forall h\in H\}.$$

The group $H^\perp$ is a closed subgroup of $\hat{G}$ and $\widehat{G/H}$ can be identified (and we will do that) with $H^\perp$ by means of

$$\langle y,\dot{g}\rangle:=\langle y,g\rangle\quad \forall y\in H^\perp,\forall\dot{g}\in G/H.$$

Since $H^\perp$ is closed, we can consider the quotient group $\hat{G}/H^\perp$. We denote by

$$\pi:\hat{G}\to\hat{G}/H^\perp,\quad \pi(x)=\dot{x}$$

the canonical projection. The group $\hat{H}$ can be identified (and we will do that) with the quotient group $\hat{G}/H^\perp$ by means of

$$\langle\dot{x},h\rangle:=\langle x,h\rangle\quad \forall\dot{x}\in\hat{G}/H^\perp,\forall h\in H.$$

Let μ_G, μ_H and $\mu_{G/H}$ be fixed Haar measures on G, H and G/H, respectively.

We denote by $\mu_{H^\perp}$ the Haar measure on $H^\perp$ such that the Fourier–Plancherel cotransform $\overline{\mathcal{F}}_{G/H}$ is unitary from $L^2(G/H,\mu_{G/H})$ onto $L^2(H^\perp,\mu_{H^\perp})$, where $\overline{\mathcal{F}}_{G/H}$ is given by

$$(\overline{\mathcal{F}}_{G/H}f)(y)=\int_{G/H}\langle y,\dot{g}\rangle f(\dot{g})\,\mathrm{d}\mu_{G/H}(\dot{g}),\quad y\in H^\perp,$$

for all $f\in(L^1\cap L^2)(G/H,\mu_{G/H})$.

Given $\varphi\in C_c(\hat{G})$, let

$$\tilde{\varphi}(\dot{x}) := \int_{H^\perp} \varphi(xy)\,\mathrm{d}\mu_{H^\perp}(y) \quad \forall \dot{x} \in \hat{G}/H^\perp.$$

It is well known that $\tilde{\varphi}$ is in $C_c(\hat{G}/H^\perp)$ and that $\tilde{\varphi} \geqslant 0$ if $\varphi \geqslant 0$. Given a measure ν on $\hat{G}/H^\perp$, the map

$$C_c(\hat{G}) \ni \varphi \mapsto \int_{\hat{G}/H^\perp} \tilde{\varphi}(\dot{x})\,\mathrm{d}\nu(\dot{x}) \in \mathbb{C} \tag{1}$$

is linear and positive. Hence, by Riesz–Markov theorem, there is a unique measure $\tilde{\nu}$ on $\hat{G}$ such that

$$\int_{\hat{G}} \phi(x)\,\mathrm{d}\tilde{\nu}(x) = \int_{\hat{G}/H^\perp} \mathrm{d}\nu(\dot{x}) \int_{H^\perp} \phi(xy)\,\mathrm{d}\mu_{H^\perp}(y)$$

for all $\phi \in L^1(\hat{G}, \tilde{\nu})$. One can check that the correspondence $\nu \mapsto \tilde{\nu}$ preserves equivalence and orthogonality of measures.

Given a finite measure μ on $\hat{G}$, we denote by μ^π the image measure of μ with respect to π, i.e., the measure on $\hat{G}/H^\perp$ given by

$$\mu^\pi(A) = \mu(\pi^{-1}(A)) \quad \forall A \in \mathcal{B}(\hat{G}/H^\perp).$$

We fix a representation U of G acting on a Hilbert space $\mathcal{H}$. Let Q be a positive operator valued measure (POVM) defined on G/H and acting on $\mathcal{H}$. If Q satisfies the following properties,

(1) $Q(G/H) = I$,
(2) for all $X \in \mathcal{B}(G/H)$,

$$U(g)Q(X)U(g^{-1}) = Q(g[X]) \quad \forall g \in G,$$

it is called *covariant* and (U, Q) is said to be a *covariance system*. In particular, if Q is a projective measure, (U, Q) is called an *imprimitivity system.*

For $\omega \in C_c(G/H)$, we define the operator

$$M(\omega) := \int_{G/H} \omega(\dot{g})\,\mathrm{d}Q(\dot{g}).$$

The map $\omega \mapsto M(\omega)$ defines uniquely the POVM Q. In the following we use M instead of Q.

Finally, given a representation σ of H, we denote by $(\mathrm{ind}_H^G(\sigma), M_0)$ the imprimitivity system induced by σ from H to G.

The aim of this article is to describe all the positive operator valued measures covariant with respect to U. The generalized imprimitivity theorem (see, for example, Refs. 4 and 5) states the following.

Theorem 1: *A POVM M based on G/H and acting on $\mathcal{H}$ is covariant with respect to U if and only if there exists a representation σ of H and an isometry W intertwining U with* $\mathrm{ind}_H^G(\sigma)$ *such that*

$$M(\omega) = W^* M_0(\omega) W$$

for all $\omega \in C_c(G/H)$.

If σ' is another representation of H such that σ is contained (as subrepresentation) in σ, then $(\mathrm{ind}_H^G(\sigma), M_0)$ is contained (as an imprimitivity system) in $(\mathrm{ind}_H^G(\sigma'), M_0')$. Hence, we can always assume that σ in the previous theorem has infinite multiplicity.

Moreover, there exist a measure ν on $\hat{G}/H^{\perp}$ and an infinite dimensional Hilbert space E such that, up to a unitary equivalence, σ acts diagonally on $L^2(\hat{G}/H^{\perp},\nu;E)$. The first step of our construction is to diagonalize the representation $\mathrm{ind}_H^G(\sigma)$.

III. DIAGONALIZATION OF $\mathrm{ind}_H^G(\sigma)$

In this section, given a representation of H with uniform multiplicity, we diagonalize the corresponding induced representation.

Let ν be a measure on $\hat{G}/H^{\perp}$ and E be a Hilbert space. Let σ^{ν} be the diagonal representation of H acting on the space $L^2(\hat{G}/H^{\perp},\nu;E)$, that is,

$$(\sigma^{\nu}(h)\xi)(\dot{x})=\langle \dot{x},h\rangle \xi(\dot{x}), \quad \dot{x}\in \hat{G}/H^{\perp},$$

where $h\in H$.

We denote by $\mathcal{H}^{\nu}$ the space of functions $f:G\times \hat{G}/H^{\perp}\to E$ such that

(i) f is weakly $(\mu_G\otimes\nu)$-measurable;

(ii) for all $h\in H$,

$$f(gh,\dot{x})=\overline{\langle \dot{x},h\rangle} f(g,\dot{x}) \quad \forall (g,\dot{x})\in G\times \hat{G}/H^{\perp}; \tag{2}$$

(iii)

$$\int_{G/H\times \hat{G}/H^{\perp}} \|f(g,\dot{x})\|_E^2 \,\mathrm{d}(\mu_{G/H}\otimes\nu)(\dot{g},\dot{x})<+\infty.$$

We identify functions in $\mathcal{H}^{\nu}$ that are equal $(\mu_G\otimes\nu)$-a.e.. Let G act on $\mathcal{H}^{\nu}$ as

$$(\lambda^{\nu}(a)f)(g,\dot{x}):=f(a^{-1}g,\dot{x}), \quad (g,\dot{x})\in G\times \hat{G}/H^{\perp},$$

for all $a\in G$. Define

$$(M_0^{\nu}(\omega)f)(g,\dot{x}):=\omega(\dot{g})f(g,\dot{x}), \quad (g,\dot{x})\in G\times \hat{G}/H^{\perp}$$

for all $f\in\mathcal{H}^{\nu}$, $\omega\in C_c(G/H)$.

One can easily prove the following fact.

Proposition 2: The space $\mathcal{H}^{\nu}$ is a Hilbert space with respect to the inner product

$$\langle f_1,f_2\rangle_{\mathcal{H}^{\nu}}=\int_{G/H\times \hat{G}/H^{\perp}} \langle f_1(g,\dot{x}),f_2(g,\dot{x})\rangle_E \mathrm{d}(\mu_{G/H}\otimes\nu)(\dot{g},\dot{x}).$$

If $\varphi\in C_c(G\times \hat{G}/H^{\perp};E)$, let

$$f_{\varphi}(g,\dot{x}):=\int_H \langle \dot{x},h\rangle \varphi(gh,\dot{x})\mathrm{d}\mu_H(h) \quad \forall (g,\dot{x})\in G\times \hat{G}/H^{\perp}.$$

Then f_{φ} is a continuous function in $\mathcal{H}^{\nu}$ such that $(q\times \mathrm{id}_{\hat{G}/H^{\perp}})(\mathrm{supp}\ f_{\varphi})$ is compact, and the set

$$\mathcal{H}_0^{\nu}=\{f_{\varphi}|\varphi\in C_c(G\times \hat{G}/H^{\perp};E)\}$$

is a dense subspace of $\mathcal{H}^{\nu}$. The couple $(\lambda^{\nu},M_0^{\nu})$ is the imprimitivity system induced by σ^{ν} from H to G.

We now diagonalize the representation λ^{ν}. First of all, we let $\tilde{\nu}$ be the measure defined in $\hat{G}$ by Eq. (1). Let Λ^{ν} be the diagonal representation of G acting on $L^2(\hat{G},\tilde{\nu};E)$ as

$$(\Lambda^{\nu}(g)\phi)(x)=\langle x,g\rangle\phi(x),\quad x\in\hat{G},$$

for all $g\in G$.

Moreover, given $\phi:\hat{G}\to E$ and fixed $x\in\hat{G}$, define ϕ_x from $H^{\perp}$ to E as

$$\phi_x(y):=\phi(xy)\quad \forall y\in H^{\perp}.$$

Theorem 3: *There is a unique unitary operator Σ from $\mathcal{H}^{\nu}$ onto $L^2(\hat{G},\tilde{\nu};E)$ such that, for all $f\in\mathcal{H}_0^{\nu}$,*

$$(\Sigma f)(x)=\int_{G/H}\langle x,g\rangle f(g,\dot{x})\mathrm{d}\mu_{G/H}(\dot{g}),\quad x\in\hat{G}. \tag{3}$$

The operator Σ intertwines λ^{ν} with Λ^{ν}. Moreover,

$$(\Sigma^{*}\varphi)(g,\dot{x})=\int_{H^{\perp}}\overline{\langle xy,g\rangle}\varphi(xy)\mathrm{d}\mu_{H^{\perp}}(y),\quad (g,\dot{x})\in G\times\hat{H}, \tag{4}$$

for all $\varphi\in C_c(\hat{G};E)$.

Proof: We first define Σ on $\mathcal{H}_0^{\nu}$. Let $f\in\mathcal{H}_0^{\nu}$. Fix $x\in\hat{G}$. By virtue of Eq. (2) the function

$$g\mapsto\langle x,g\rangle f(g,\dot{x})$$

depends only on the equivalence class $\dot{g}$ of g and we let f^x be the corresponding map on G/H. Due to the properties of f, f^x is continuous and has compact support, so it is $\mu_{G/H}$-integrable and we define Σf by means of Eq. (3).

We claim that Σf is in $L^2(\hat{G},\tilde{\nu};E)$ and $\|\Sigma f\|_{L^2(\hat{G},\tilde{\nu};E)}=\|f\|_{\mathcal{H}^{\nu}}$. Since the map

$$(x,\dot{g})\mapsto f^x(\dot{g})$$

is continuous, by a standard argument Σf is continuous. Moreover, if $x\in\hat{G}$ and $y\in H^{\perp}$,

$$(\Sigma f)(xy)=\int_{G/H}\langle xy,g\rangle f(g,\dot{x})\mathrm{d}\mu_{G/H}(\dot{g})=\int_{G/H}\langle y,\dot{g}\rangle\langle x,g\rangle f(g,\dot{x})\mathrm{d}\mu_{G/H}(\dot{g})=\overline{\mathcal{F}}_{G/H}(f^x)(y).$$

Indeed,

$$\begin{aligned}
\|\Sigma f\|^2_{L^2(\hat{G},\tilde{\nu};E)}&=\int_{\hat{G}}\|\Sigma f(x)\|_E^2\mathrm{d}\tilde{\nu}(x)\\
&=\int_{\hat{G}/H^{\perp}}\mathrm{d}\nu(\dot{x})\int_{H^{\perp}}\|(\Sigma f)(xy)\|_E^2\mathrm{d}\mu_{H^{\perp}}(y)\\
&=\int_{\hat{G}/H^{\perp}}\mathrm{d}\nu(\dot{x})\int_{H^{\perp}}\|\overline{\mathcal{F}}_{G/H}(f^x)(y)\|_E^2\mathrm{d}\mu_{H^{\perp}}(y)\ \ (\text{unitarity of }\overline{\mathcal{F}}_{G/H})\\
&=\int_{\hat{G}/H^{\perp}}\mathrm{d}\nu(\dot{x})\int_{G/H}\|f^x(\dot{g})\|_E^2\mathrm{d}\mu_{G/H}(\dot{g})\\
&=\int_{\hat{G}/H^{\perp}}\mathrm{d}\nu(\dot{x})\int_{G/H}\|f(g,\dot{x})\|_E^2\mathrm{d}\mu_{G/H}(\dot{g})\\
&=\int_{G/H\times\hat{G}/H^{\perp}}\|f(g,\dot{x})\|_E^2\mathrm{d}(\mu_{G/H}\otimes\nu)(\dot{g},\dot{x})\\
&=\|f\|^2_{\mathcal{H}^{\nu}}.
\end{aligned}$$

By density, Σ extends to an isometry from $\mathcal{H}^{\nu}$ to $L^2(\hat{G},\tilde{\nu};E)$. Clearly, Eq. (3) holds and it defines uniquely Σ.

The second step is computing the adjoint of Σ. Let $\varphi\in C_c(\hat{G};E)$. By standard arguments the right hand side of Eq. (4) is a continuous function of $(g,\dot{x})$. Moreover, it satisfies Eq. (2). We have

$$\int_{H^{\perp}}\overline{\langle xy,g\rangle}\varphi(xy)\mathrm{d}\mu_{H^{\perp}}(y)=\overline{\langle x,g\rangle}\overline{\mathcal{F}}^{*}_{G/H}(\varphi_x)(\dot{g}),\quad (g,\dot{x})\in G\times\hat{H}.$$

First of all, we show that the above function is in $\mathcal{H}^{\nu}$. Indeed,

$$\begin{aligned}
&\int_{\hat{G}/H^{\perp}}\mathrm{d}\nu(\dot{x})\int_{G/H}\|\overline{\langle x,g\rangle}\overline{\mathcal{F}}^{*}_{G/H}(\varphi_x)(\dot{g})\|_E^2\mathrm{d}\mu_{G/H}(\dot{g})\\
&\quad=\int_{\hat{G}/H^{\perp}}\mathrm{d}\nu(\dot{x})\int_{G/H}\|\overline{\mathcal{F}}^{*}_{G/H}(\varphi_x)(\dot{g})\|_E^2\mathrm{d}\mu_{G/H}(\dot{g})\quad(\text{unitarity of }\overline{\mathcal{F}}_{G/H})\\
&\quad=\int_{\hat{G}/H^{\perp}}\mathrm{d}\nu(\dot{x})\int_{H^{\perp}}\|\varphi_x(y)\|_E^2\mathrm{d}\mu_{H^{\perp}}(y)\\
&\quad=\int_{\hat{G}/H^{\perp}}\mathrm{d}\nu(\dot{x})\int_{H^{\perp}}\|\varphi(xy)\|_E^2\mathrm{d}\mu_{H^{\perp}}(y)\\
&\quad=\|\varphi\|^2_{L^2(\hat{G},\tilde{\nu};E)}.
\end{aligned}\tag{5}$$

Moreover, for all $f\in\mathcal{H}^{\nu}_0$, we have

$$\begin{aligned}
\langle\Sigma^{*}\varphi,f\rangle_{\mathcal{H}^{\nu}}&=\langle\varphi,\Sigma f\rangle_{L^2(\hat{G},\tilde{\nu};E)}\\
&=\int_{\hat{G}/H^{\perp}}\mathrm{d}\nu(\dot{x})\int_{H^{\perp}}\langle\varphi(xy),(\Sigma f)(xy)\rangle_E\mathrm{d}\mu_{H^{\perp}}(y)\\
&=\int_{\hat{G}/H^{\perp}}\mathrm{d}\nu(\dot{x})\int_{H^{\perp}}\langle\varphi_x(y),\overline{\mathcal{F}}_{G/H}(f^x)(y)\rangle_E\mathrm{d}\mu_{H^{\perp}}(y)\quad(\text{unitarity of }\overline{\mathcal{F}}_{G/H})\\
&=\int_{\hat{G}/H^{\perp}}\mathrm{d}\nu(\dot{x})\int_{G/H}\langle\overline{\mathcal{F}}^{*}_{G/H}(\varphi_x)(\dot{g}),f^x(\dot{g})\rangle_E\mathrm{d}\mu_{G/H}(\dot{g})\\
&=\int_{\hat{G}/H^{\perp}}\mathrm{d}\nu(\dot{x})\int_{G/H}\langle\overline{\mathcal{F}}^{*}_{G/H}(\varphi_x)(\dot{g}),\langle x,g\rangle f(g,\dot{x})\rangle_E\mathrm{d}\mu_{G/H}(\dot{g})\\
&=\int_{\hat{G}/H^{\perp}}\mathrm{d}\nu(\dot{x})\int_{G/H}\langle\overline{\langle x,g\rangle}\overline{\mathcal{F}}^{*}_{G/H}(\varphi_x)(\dot{g}),f(g,\dot{x})\rangle_E\mathrm{d}\mu_{G/H}(\dot{g})\\
&=\int_{G/H\times\hat{G}/H^{\perp}}\langle\overline{\langle x,g\rangle}\overline{\mathcal{F}}^{*}_{G/H}(\varphi_x)(\dot{g}),f(g,\dot{x})\rangle_E\mathrm{d}(\mu_{G/H}\otimes\nu)(\dot{g},\dot{x}).
\end{aligned}$$

Since $\mathcal{H}^{\nu}_0$ is dense, Eq. (4) follows. By Eq. (5) Σ^{*} is isometric, hence Σ is unitary.

Finally, we show the intertwining property. Let $a\in G$ and $f\in\mathcal{H}^{\nu}_0$. Then $\lambda^{\nu}(a)f\in\mathcal{H}^{\nu}_0$, and so one has

$$
\begin{aligned}
(\Sigma\lambda^{\nu}(a)f)(x) &= \int_{G/H}\langle x,g\rangle f(a^{-1}g,\dot{x})\,\mathrm{d}\mu_{G/H}(\dot{g}) \\
&= \langle x,a\rangle\int_{G/H} f^{x}(a^{-1}[\dot{g}])\,\mathrm{d}\mu_{G/H}(\dot{g})\quad(\dot{g}\to a[\dot{g}]) \\
&= \langle x,a\rangle\int_{G/H}\langle x,g\rangle f(g,\dot{x})\,\mathrm{d}\mu_{G/H}(\dot{g}) \\
&= (\Lambda^{\nu}(a)\Sigma f)(x),\quad x\in\hat{G}.
\end{aligned}
$$

By density of $\mathcal{H}_0^{\nu}$, it follows that $\Sigma\lambda^{\nu}(a)=\Lambda^{\nu}(a)\Sigma$. ■

Given $\omega\in C_c(G/H)$, let $\widetilde{M_0^{\nu}}(\omega)=\Sigma M_0^{\nu}(\omega)\Sigma^*$. Then we have the following proposition.

Proposition 4: For all $\omega\in C_c(G/H)$ and $\phi\in L^2(\hat{G},\tilde{\nu};E)$,

$$
(\widetilde{M_0^{\nu}}(\omega)\phi)(x)=\int_{H^{\perp}}\overline{\mathcal{F}}_{G/H}(\omega)(y)\,\phi(xy^{-1})\,\mathrm{d}\mu_{H^{\perp}}(y),\quad x\in\hat{G}. \tag{6}
$$

Proof: Let $\omega\in C_c(G/H)$. We compute the action of $\widetilde{M_0^{\nu}}(\omega)$ on $C_c(\hat{G};E)$. If $\varphi\in C_c(\hat{G};E)$, let

$$
\xi(x):=\int_{H^{\perp}}\overline{\mathcal{F}}_{G/H}(\omega)(y)\,\varphi(xy^{-1})\,\mathrm{d}\mu_{H^{\perp}}(y)\quad\forall x\in\hat{G},
$$

which is well defined and continuous. Moreover, for all $x\in\hat{G}$ and $y\in H^{\perp}$,

$$
\begin{aligned}
\xi(xy) &= \int_{H^{\perp}}\overline{\mathcal{F}}_{G/H}(\omega)(y')\,\varphi(xyy'^{-1})\,\mathrm{d}\mu_{H^{\perp}}(y') \\
&= \int_{H^{\perp}}\overline{\mathcal{F}}_{G/H}(\omega)(y')\,\varphi_x(yy'^{-1})\,\mathrm{d}\mu_{H^{\perp}}(y')=(\overline{\mathcal{F}}_{G/H}(\omega)*\varphi_x)(y).
\end{aligned} \tag{7}
$$

Here and in the following, convolutions are always taken in $H^{\perp}$. If $\varphi,\psi\in C_c(\hat{G};E)$,

$$
\begin{aligned}
\langle\widetilde{M_0^{\nu}}(\omega)\varphi,\psi\rangle_{L^2(\hat{G},\tilde{\nu};E)} &= \langle M_0^{\nu}(\omega)\Sigma^*\varphi,\Sigma^*\psi\rangle_{\mathcal{H}^{\nu}} \\
&= \int_{\hat{G}/H^{\perp}}\mathrm{d}\nu(\dot{x})\int_{G/H}\mathrm{d}\mu_{G/H}(\dot{g}) \\
&\quad\times\langle\omega(\dot{g})\overline{\langle x,g\rangle}\,\overline{\mathcal{F}}^*_{G/H}(\varphi_x)(\dot{g}),\overline{\langle x,g\rangle}\,\overline{\mathcal{F}}^*_{G/H}(\psi_x)(\dot{g})\rangle_E \\
&= \int_{\hat{G}/H^{\perp}}\mathrm{d}\nu(\dot{x})\int_{G/H}\mathrm{d}\mu_{G/H}(\dot{g})\langle\omega(\dot{g})\overline{\mathcal{F}}^*_{G/H}(\varphi_x)(\dot{g}),\overline{\mathcal{F}}^*_{G/H}(\psi_x) \\
&\quad\times(\dot{g})\rangle_E\ \text{(unitarity of } \overline{\mathcal{F}}_{G/H}\text{ and properties of convolution)} \\
&= \int_{\hat{G}/H^{\perp}}\mathrm{d}\nu(\dot{x})\int_{H^{\perp}}\mathrm{d}\mu_{H^{\perp}}(y)\langle(\overline{\mathcal{F}}_{G/H}(\omega)*\varphi_x)(y),\psi_x(y)\rangle_E \\
&= \int_{\hat{G}/H^{\perp}}\mathrm{d}\nu(\dot{x})\int_{H^{\perp}}\mathrm{d}\mu_{H^{\perp}}(y)\langle\xi(xy),\psi(xy)\rangle_E,
\end{aligned}
$$

hence Eq. (6) holds on $C_c(\hat{G};E)$.

Let now $\phi\in L^2(\hat{G},\tilde{\nu};E)$. Since

$$\|\phi\|^2_{L^2(\hat{G},\tilde{\nu};E)}=\int_{\hat{G}/H^\perp}\mathrm{d}\nu(\dot{x})\int_{H^\perp}\|\phi(xy)\|^2_E\mathrm{d}\mu_{H^\perp}(y)<+\infty,$$

by virtue of the Fubini theorem there is a ν-negligible set $Y_1\subset\hat{G}/H^\perp$ such that, for all $x\in\hat{G}$ with $\dot{x}\notin Y_1$, $\phi_x\in L^2(H^\perp,\mu_{H^\perp};E)$. Moreover, using the definition of $\tilde{\nu}$, one can check that $\pi^{-1}(Y_1)$ is $\tilde{\nu}$-negligible. Then, for $\tilde{\nu}$-almost all $x\in\hat{G}$, ϕ_x is in $L^2(H^\perp,\mu_{H^\perp};E)$. We observe that the map

$$\dot{g}\mapsto\omega(\dot{g})(\overline{\mathcal{F}}^*_{G/H}(\phi_x))(\dot{g})$$

is then in $(L^1\cap L^2)(G/H,\mu_{G/H};E)$ for $\tilde{\nu}$-almost all $x\in\hat{G}$, hence its Fourier cotransform is continuous, and we have

$$\overline{\mathcal{F}}_{G/H}(\omega\overline{\mathcal{F}}^*_{G/H}(\phi_x))(e)=(\overline{\mathcal{F}}_{G/H}(\omega)*\phi_x)(e)=\int_{H^\perp}\overline{\mathcal{F}}_{G/H}(\omega)(y)\phi(xy^{-1})\mathrm{d}\mu_{H^\perp}(y).\tag{8}$$

Now, we let $(\varphi_k)_{k\geqslant 1}$ be a sequence in $C_c(\hat{G};E)$ converging to ϕ in $L^2(\hat{G},\tilde{\nu};E)$. Then

$$\int_{\hat{G}/H^\perp}\mathrm{d}\nu(\dot{x})\int_{H^\perp}\|(\varphi_k)_x(y)-\phi_x(y)\|^2_E\mathrm{d}\mu_{H^\perp}(y)\to 0$$

and so, possibly passing to a subsequence, there is a ν-negligible set $Y_2\subset\hat{G}/H^\perp$ such that

$$\int_{H^\perp}\|(\varphi_k)_x(y)-\phi_x(y)\|^2_E\mathrm{d}\mu_{H^\perp}(y)\to 0$$

for all $x\in\hat{G}$ with $\dot{x}\notin Y_2$. This fact means that, for $\tilde{\nu}$-almost all $x\in\hat{G}$,

$$(\varphi_k)_x\to\phi_x$$

in $L^2(H^\perp,\mu_{H^\perp};E)$. It follows that

$$\omega\overline{\mathcal{F}}^*_{G/H}((\varphi_k)_x)\to\omega\overline{\mathcal{F}}^*_{G/H}(\phi_x)$$

in $L^1(G/H,\mu_{G/H};E)$. Then, for $\tilde{\nu}$-almost all $x\in\hat{G}$,

$$\overline{\mathcal{F}}_{G/H}(\omega\overline{\mathcal{F}}^*_{G/H}((\varphi_k)_x))\to\overline{\mathcal{F}}_{G/H}(\omega\overline{\mathcal{F}}^*_{G/H}(\phi_x))$$

uniformly, and, using Eqs. (7), and (8),

$$\begin{aligned}(\widetilde{M^\nu_0})(\omega)\varphi_k)(x)&=\overline{\mathcal{F}}_{G/H}(\omega\overline{\mathcal{F}}^*_{G/H}((\varphi_k)_x))(e)\to\overline{\mathcal{F}}_{G/H}(\omega\overline{\mathcal{F}}^*_{G/H}(\phi_x))(e)\\&=\int_{H^\perp}\overline{\mathcal{F}}_{G/H}(\omega)(y)\phi(xy^{-1})\mathrm{d}\mu_{H^\perp}(y).\end{aligned}$$

Since $\widetilde{M^\nu_0}(\omega)\varphi_k$ converges to $\widetilde{M^\nu_0}(\omega)\phi$ in $L^2(\hat{G},\tilde{\nu};E)$, Eq. (6) follows from unicity of the limit. ■

IV. CHARACTERIZATION OF COVARIANT POVMs

We fix in the following an *infinite dimensional* Hilbert space E. According to the results of the previous sections, the generalized imprimitivity theorem for Abelian groups can be stated in the following way.

Theorem 5: *A POVM M based on G/H and acting on $\mathcal{H}$ is covariant with respect to U if and only if there exist a measure ν on $\hat{G}/H^\perp$ and an isometry W intertwining U with Λ^ν such that*

$$M(\omega)=W^{*}\widetilde{M_0^{\nu}}(\omega)W$$

for all $\omega\in C_c(G/H)$.

To get an explicit form of W, we assume that U acts diagonally on $\mathcal{H}$. This means that $\mathcal{H}$ is the orthogonal sum of invariant subspaces

$$\mathcal{H}=\bigoplus_{k\in I} L^2(\hat{G},\rho_k;F_k), \tag{9}$$

where I is a denumerable set, $(\rho_k)_{k\in I}$ is a family of measures on $\hat{G}$, $(F_k)_{k\in I}$ is a family of Hilbert spaces, and the action of U is given by

$$(U(g)\phi_k)(x)=\langle x,g\rangle\phi_k(x),\quad x\in\hat{G},$$

where $\phi_k\in L^2(\hat{G},\rho_k;F_k)$ and $g\in G$. We will denote by P_k the orthogonal projector onto the subspace $L^2(\hat{G},\rho_k;F_k)$.

The assumption (9) is not restrictive. Indeed, it is well known that there are a family of disjoint measures $(\rho_k)_{k\in\mathbb{N}\cup\{\infty\}}$ and a family of Hilbert spaces $(F_k)_{k\in\mathbb{N}\cup\{\infty\}}$ such that $\dim F_k=k$ and, up to a unitary equivalence, Eq. (9) holds.

Given the decomposition (9), let ρ be a measure on $\hat{G}$ such that

$$\rho(N)=0\Leftrightarrow\rho_k(N)=0\quad\forall k\in I. \tag{10}$$

We recall that the equivalence class of ρ is uniquely defined by the family $(\rho_k)_{k\in I}$.

Finally, we observe also that the equivalence class of ρ is independent of the choice of decomposition (9). Indeed, if G acts diagonally on another decomposition,

$$\mathcal{H}=\bigoplus_{k\in I'} L^2(\hat{G},\rho_k';F_k'),$$

then

$$\rho_k'(N)=0\quad\forall k\in I'\Leftrightarrow\rho_k(N)=0\quad\forall k\in I.$$

It follows that the representation U defines uniquely an equivalence class $\mathcal{C}_U$ of measures ρ such that relation (10) holds. Chosen in this equivalence class a *finite* measure ρ, we denote by $\mathcal{C}_U^{\pi}$ the equivalence class of the image measure ρ^{π}. Clearly $\mathcal{C}_U^{\pi}$ depends only on $\mathcal{C}_U$.

We now give the central result of this section.

Theorem 6: *Let U be a representation of G acting diagonally on*

$$\mathcal{H}=\bigoplus_{k\in I} L^2(\hat{G},\rho_k;F_k).$$

Given $\nu_U\in\mathcal{C}_U^{\pi}$, let $\widetilde{\nu}_U$ be the measure given by Eq. (1). The representation U admits covariant positive operator valued measures based on G/H if and only if, for all $k\in I$, ρ_k has density with respect to $\widetilde{\nu}_U$. In this case, for every $k\in I$, let α_k be the densities of ρ_k with respect to $\widetilde{\nu}_U$.

Let E be a fixed infinite dimensional Hilbert space. For each $k\in I$, let

$$\hat{G}\ni x\mapsto W_k(x)\in\mathcal{L}(F_k;E)$$

be a weakly measurable map such that $W_k(x)$ are isometries for ρ_k-almost all $x\in\hat{G}$. For $\omega\in C_c(G/H)$, let $M(\omega)$ be the operator given by

$$(P_j M(\omega) P_k \phi)(x) = \int_{H^\perp} \mathrm{d}\mu_{H^\perp}(y) \overline{\mathcal{F}}_{G/H}(\omega)(y) \sqrt{\frac{\alpha_k(xy^{-1})}{\alpha_j(x)}} \times W_j(x) * W_k(xy^{-1})(P_k\phi)(xy^{-1}), \quad x \in \hat{G}, \tag{11}$$

for all $\phi \in \mathcal{H}$ and $k,j \in I$. Then, M is a POVM covariant with respect to U.

Conversely, any POVM based on G/H and covariant with respect to U is of the form given by Eq. (11).

We add some comments before the proof of the theorem.

Remark 7: We observe that Eq. (11) is invariant with respect to the choice of the measure $\nu_U \in \mathcal{C}_U^\pi$. Indeed, let $\nu'_U \in \mathcal{C}_U^\pi$, and $\beta > 0$ be the density of ν_U with respect to ν'_U. Clearly,

$$\widetilde{\nu_U} = (\beta \circ \pi)\widetilde{\nu'_U},$$

so that the densities α'_k of ρ_k with respect to $\widetilde{\nu'_U}$ are

$$\alpha'_k = (\beta \circ \pi)\alpha_k .$$

It follows that Eq. (11) does not depend on the choice of $\nu_U \in \mathcal{C}_U^\pi$.

Corollary 8: Let H be the trivial subgroup $\{e\}$. The representation U admits covariant positive operator valued measures based on G if and only if the measures ρ_k have densities with respect to the Haar measure $\mu_{\hat{G}}$. In this case, the functions α_k in Eq. (11) are the densities of ρ_k with respect to $\mu_{\hat{G}}$.

Remark 9: The content of the previous corollary was first shown by Holevo in Ref. 11 for non-normalized POVM. In order to compare the two results, observe that, if $\phi \in (L^1 \cap L^2) \times (\hat{G}, \rho_k; F_k)$ and $\psi \in (L^1 \cap L^2)(\hat{G}, \rho_j; F_j)$, Eq. (11) becomes

$$\begin{aligned} \langle M(\omega)\phi, \psi \rangle_{\mathcal{H}} &= \int_G \mathrm{d}\mu_G(g)\, \omega(g) \int_{\hat{G}\times\hat{G}} \langle x, g\rangle \overline{\langle y, g\rangle} \sqrt{\alpha_k(y)\alpha_j(x)} \\ &\quad \times \langle W_j(x) * W_k(y)\phi(y), \psi(x)\rangle \mathrm{d}(\mu_{\hat{G}} \otimes \mu_{\hat{G}})(x,y) \\ &= \int_G \mathrm{d}\mu_G(g)\, \omega(g) \int_{\hat{G}\times\hat{G}} K_{U(g^{-1})\psi, U(g^{-1})\phi}(x,y) \mathrm{d}(\mu_{\hat{G}} \otimes \mu_{\hat{G}})(x,y), \end{aligned}$$

where

$$K_{\psi,\phi}(x,y) = \sqrt{\alpha_k(y)\alpha_j(x)} \langle W_k(y)\phi(y), W_j(x)\psi(x)\rangle$$

is a bounded positive definite measurable field of forms [compare with Eqs. (4.2) and (4.3) in Ref. 11].

In order to prove Theorem 6, we need the following lemma.

Lemma 10: Let ρ be a finite measure on $\hat{G}$. Assume that there is a measure ν on $\hat{G}/H^\perp$ such that ρ has density with respect to $\widetilde{\nu}$. Then ρ has density with respect to $\widetilde{\rho^\pi}$. In this case, ν uniquely decomposes as

$$\nu = \nu_1 + \nu_2,$$

where ν_1 is equivalent to ρ^π and $\nu_2 \perp \rho^\pi$.

Proof: Suppose that ν is a measure on $\hat{G}/H^\perp$ such that $\rho = \alpha\widetilde{\nu}$, where α is a non-negative $\widetilde{\nu}$-integrable function on $\hat{G}$. Then, for all $\varphi \in C_c(\hat{G}/H^\perp)$,

$$\rho^\pi(\varphi) = \int_{\hat{G}} \varphi(\pi(x)) \mathrm{d}\rho(\dot{x}) = \int_{\hat{G}/H^\perp} \mathrm{d}\nu(\dot{x}) \int_{H^\perp} \varphi(\dot{x})\alpha(xy)\mathrm{d}\mu_{H^\perp}(y) = \int_{\hat{G}/H^\perp} \varphi(\dot{x})\alpha'(\dot{x})\mathrm{d}\nu(\dot{x}),$$

where the function

$$\alpha'(\dot{x}) := \int_{H^\perp} \alpha(xy)\mathrm{d}\mu_{H^\perp}(y) \geqslant 0$$

is ν-integrable by virtue of Fubini theorem. It follows that

$$\rho^\pi = \alpha' \nu. \tag{12}$$

Using the Lebesgue theorem, we can uniquely decompose

$$\nu = \nu_1 + \nu_2,$$

where ν_1 has base ρ^π and $\nu_2 \perp \rho^\pi$. From Eq. (12), it follows that ν_1 and ρ^π are equivalent, and this proves the second statement of the lemma. If $A, B \in \mathcal{B}(\hat{G}/H^\perp)$ are disjoint sets such that ν_2 is concentrated in A and ν_1 is concentrated in B, then $\widetilde{\nu_2}$ and $\widetilde{\nu_1}$ are respectively concentrated in the disjoint sets $\tilde{A} = \pi^{-1}(A)$ and $\tilde{B} = \pi^{-1}(B)$. By definition of ρ^π, we also have

$$\rho(\tilde{A}) = \rho^\pi(A) = 0.$$

Since ρ has density with respect to $\widetilde{\nu} = \widetilde{\nu_1} + \widetilde{\nu_2}$ and $\widetilde{\nu_2}$ is concentrated in $\tilde{A}$, it follows that ρ has density with respect to $\widetilde{\nu_1} \cong \widetilde{\rho^\pi}$. The claim is now clear. ■

Proof of Theorem 6: Let ρ be a finite measure in $\mathcal{C}_U$. By virtue of Theorem 5, U admits a covariant POVM $\Leftrightarrow$ there exists a measure ν in $\hat{G}/H^\perp$ such that U is a subrepresentation of $\Lambda^\nu \Leftrightarrow$ each measure ρ_k has density with respect to $\widetilde{\nu} \Leftrightarrow \rho$ has density with respect to $\widetilde{\nu}$. From Lemma 10, U admits a covariant POVM if and only if ρ has density with respect to $\widetilde{\rho^\pi}$. Since $\rho^\pi \in \mathcal{C}_U^\pi$, the first claim follows.

Let now M be a covariant POVM. By Theorem 5, there is a measure ν on $\hat{G}/H^\perp$ and an isometry W intertwining U with Λ^ν such that

$$M(\omega) = W^* \widetilde{M_0^\nu}(\omega) W \quad \forall \omega \in C_c(G/H).$$

Using Lemma 10, we (uniquely) decompose

$$\nu = \nu_1 + \nu_2,$$

where ν_1 is equivalent to ν_U and $\nu_2 \perp \nu_U$. Then we have

$$\sigma^\nu \cong \sigma^{\nu_U} \oplus \sigma^{\nu_2} \Rightarrow (\Lambda^\nu, \widetilde{M_0^\nu}) \cong (\Lambda^{\nu_U}, \widetilde{M_0^{\nu_U}}) \oplus (\Lambda^{\nu_2}, \widetilde{M_0^{\nu_2}}),$$

i.e., the imprimitivity system $(\Lambda^\nu, \widetilde{M_0^\nu})$ preserves the decomposition

$$L^2(\hat{G}, \widetilde{\nu}; E) \cong L^2(\hat{G}, \widetilde{\nu_U}; E) \oplus L^2(\hat{G}, \widetilde{\nu_2}; E).$$

Moreover, since each ρ_k has density with respect to $\widetilde{\nu_U}$ and $\widetilde{\nu_U}$ is disjoint from $\widetilde{\nu_2}$, it follows that $W(\mathcal{H}) \subset L^2(\hat{G}, \widetilde{\nu_U}; E)$, then we can always assume that the measure ν on $\hat{G}/H^\perp$ which occurs in Theorem 5 is ν_U.

We now characterize the form of W. For $k \in I$, we can always fix an isometry $T_k : F_k \to E$ such that $T_k(F_k)$ are mutually orthogonal subspaces of E. Hence, if we define, for $\phi_k \in L^2(\hat{G}, \rho_k; F_k)$,

$$(T\phi_k)(x) := \sqrt{\alpha_k(x)} T_k \phi_k(x), \quad x \in \hat{G},$$

T is an isometry intertwining U with Λ^{ν_U}. We define $W_k = WP_k$. The operator $V = WT^*$ is a partial isometry commuting with Λ^{ν_U}, hence there exists a weakly measurable correspondence $\hat{G} \ni x \mapsto V(x) \in \mathcal{L}(E)$ such that $V(x)$ are partial isometries for $\widetilde{\nu_U}$-almost all $x \in \hat{G}$ and

$$(V\phi)(x) = V(x)\phi(x), \quad x \in \hat{G},$$

where $\phi \in L^2(\hat{G}, \widetilde{\nu_U}; E)$. We have $W = WT^*T = VT$. Then

$$(W_k\phi_k)(x) = \sqrt{\alpha_k(x)}V(x)T_k\phi_k(x) = \sqrt{\alpha_k(x)}W_k(x)\phi_k(x), \quad x \in \hat{G}, \tag{13}$$

where we set

$$W_k(x) = V(x)T_k \quad \forall x \in \hat{G}.$$

Since W is isometric, then $W_k^* W_k$ is the identity operator on $L^2(\hat{G}, \rho_k; F_k)$, hence

$$T_k^* V(x)^* V(x) T_k = I_k, \quad x \in \hat{G},$$

ρ_k-almost everywhere, where I_k is the identity operator on F_k. Since T_k is isometric and $V(x)$ is a partial isometry for $\widetilde{\nu_U}$-almost every $x \in \hat{G}$ (that is for ρ_k-almost every $x \in \hat{G}$), it follows that $V(x)^*V(x)$ is the identity on $\mathrm{ran}T_k$ and that $W_k(x)$ is isometric, for ρ_k-almost every $x \in \hat{G}$. Weak measurability of the maps $x \mapsto W_k(x)$ is immediate.

The explicit form of M is then given by

$$(P_j M(\omega) P_k \phi)(x) = (W_j^* \widetilde{M_0^\nu}(\omega) W_k \phi)(x) = \frac{1}{\sqrt{\alpha_j(x)}} W_j(x)^* \int_{H^\perp} \overline{\mathcal{F}}_{G/H}(\omega)(y) \times \sqrt{\alpha_k(xy^{-1})} W_k(xy^{-1})(P_k\phi)(xy^{-1}) \mathrm{d}\mu_{H^\perp}(y), \quad x \in \hat{G},$$

where $\phi \in \mathcal{H}$, $\omega \in C_c(G/H)$.

Conversely, let $\hat{G} \ni x \mapsto W_k(x) \in \mathcal{L}(F_k; E)$ be a weakly measurable map such that $W_k(x)$ are isometries for ρ_k-almost every $x \in \hat{G}$ and for all $k \in I$. We define, for $\phi_k \in L^2(\hat{G}, \rho_k; F_k)$,

$$(W\phi_k)(x) := \sqrt{\alpha_k(x)} W_k(x) \phi_k(x) \quad \forall x \in \hat{G}.$$

Then W is clearly an intertwining isometry between U and Λ^{ν_U} and Eq. (11) defines a covariant POVM. ■

We now study the problem of equivalence of covariant POVMs. To simplify the exposition, we assume that the measures ρ_k in decomposition (9) are orthogonal.

Let M and M' be two covariant positive operator valued measures that are equivalent, i.e., there exists an unitary operator $S: \mathcal{H} \to \mathcal{H}$ such that

$$SU(g) = U(g)S \quad \forall g \in G, \tag{14}$$

$$SM(\omega) = M'(\omega)S \quad \forall \omega \in C_c(G/H). \tag{15}$$

We have the following result.

Proposition 11: Let $(W_j)_{j \in I}$ and $(W'_j)_{j \in I}$ be families of maps such that Eq. (11) holds for M and M', respectively.

The POVMs M and M' are equivalent if and only if, for each $k \in I$, there exists a weakly measurable map $x \mapsto S_k(x) \in \mathcal{L}(F_k)$ such that $S_k(x)$ are unitary operators for ρ_k-almost all x and

$$\sqrt{\alpha_k(xy)} W_j(x)^* W_k(xy) = \sqrt{\alpha_k(xy)} S_j(x)^* W'_j(x)^* W'_k(xy) S_k(xy) \tag{16}$$

for $(\rho_j \otimes \mu_{H^\perp})$*-almost all* (x,y).

Proof: By virtue of condition (14) and orthogonality of the measures ρ_k, S preserves decomposition (9). Moreover, for each $k \in I$, there exists a weakly measurable map $x \mapsto S_k(x) \in \mathcal{L}(F_k)$ such that $S_k(x)$ is unitary for ρ_k-almost all x and, if $\phi_k \in L^2(\hat{G}, \rho_k; F_k)$,

$$(S\phi_k)(x) = S_k(x)\phi_k(x), \quad x \in \hat{G}.$$

Condition (15) is equivalent to

$$P_j M(\omega) P_k \phi = P_j S^* M'(\omega) S P_k \phi$$

for all $\phi \in \mathcal{H}$, $\omega \in C_c(G/H)$ and $j,k \in I$. It is not restrictive to assume that the densities α_k are measurable functions. Let

$$\Omega_{j,k}(x,x') = \sqrt{\frac{\alpha_k(x')}{\alpha_j(x)}} (W_j(x)^* W_k(x') - S_j(x)^* W_j'(x)^* W_k'(x') S_k(x')).$$

Using Eq. (11), the previous condition becomes

$$\int_{H^\perp} \mathcal{F}_{G/H}(\omega)(y) \Omega_{j,k}(x, xy^{-1}) (P_k \phi)(xy^{-1}) \mathrm{d}\mu_{H^\perp}(y) = 0, \tag{17}$$

ρ_j-almost everywhere for all $\phi \in \mathcal{H}$, $\omega \in C_c(G/H)$ and $j,k \in I$.

Let K be a compact set of $\hat{G}$ and $v \in F_k$. In Eq. (17) we choose

$$\phi = \chi_K v \in L^2(\hat{G}, \rho_k; F_k)$$

and $\omega \in C_c(G/H)$ running over a denumerable subset dense in $L^2(G/H, \mu_{H^\perp})$. It follows that there exists a ρ_j-null set $N \subset \hat{G}$ such that, for all $x \notin N$,

$$\chi_K(xy^{-1}) \Omega_{j,k}(x, xy^{-1}) v = 0$$

for $\mu_{H^\perp}$-almost all $y \in H^\perp$. Since $\Omega_{j,k}$ is weakly measurable, the last equation holds in a measurable subset $Y \subset \hat{G} \times H^\perp$ whose complement is a $(\rho_j \otimes \mu_{H^\perp})$-null set. Define

$$m(x,y) = xy^{-1} \quad \forall (x,y) \in G^\perp.$$

For all $(x,y) \in Y \cap m^{-1}(K)$ we then have

$$\Omega_{j,k}(x, xy^{-1}) v = 0.$$

Since F_k is separable and $\hat{G}$ is σ-compact, we get

$$\Omega_{j,k}(x, xy) = 0$$

for $(\rho_j \otimes \mu_{H^\perp})$-almost all $(x,y) \in \hat{G} \times H^\perp$, that is,

$$\sqrt{\alpha_k(xy)} W_j(x)^* W_k(xy) = \sqrt{\alpha_k(xy)} S_j(x)^* W_j'(x)^* W_k'(xy) S_k(xy)$$

for $(\rho_j \otimes \mu_{H^\perp})$-almost all (x,y).

Conversely, if condition (16) is satisfied for all $j,k \in I$, then clearly M is equivalent to M'. ■

V. EXAMPLES

A. Generalized covariant position observables

Let $\mathcal{H}=L^2(\mathbb{R},\mathrm{d}x)$, where $\mathrm{d}x$ is the Lebesgue measure on $\mathbb{R}$. We consider the representation U of the group $\mathbb{R}$ acting on $\mathcal{H}$ as

$$(U(a)\phi)(x)=e^{iax}\phi(x), \quad x\in\mathbb{R},$$

for all $a\in\mathbb{R}$. By means of Fourier transform, U is clearly equivalent to the regular representation of $\mathbb{R}$. We classify the POVMs based on $\mathbb{R}$ and covariant with respect to U. With the notations of the previous sections, we have

$$G=\mathbb{R}, \quad H=\{0\}, \quad G/H=\mathbb{R}, \quad \hat{G}=H^\perp=\mathbb{R}, \quad \hat{G}/H^\perp=\{0\}.$$

We choose $\mu_{G/H}=(1/2\pi)\mathrm{d}x$, so that $\mu_{H^\perp}=\mathrm{d}x$, and $E=\mathcal{H}$.

The representation U is already diagonal with multiplicity equal to 1, so that in the decomposition (9) we can set $I=\{1\}$, $\rho_1=\mathrm{d}x$, $F_1=\mathbb{C}$. Hence, by Corollary 8, U admits covariant POVMs based on $\mathbb{R}$ and $\alpha_1=1$.

According to Theorem 6, any covariant POVM M is defined in terms of a weakly measurable map $x\mapsto W_1(x)$ such that $W_1(x):\mathbb{C}\to\mathcal{H}$ is an isometry for every $x\in\mathbb{R}$. This is equivalent to selecting a weakly measurable map $x\mapsto h_x\in\mathcal{H}$, with $\|h_x\|_{\mathcal{H}}=1$ $\forall x\in\mathbb{R}$, such that $W_1(x)=h_x$ $\forall x\in\mathbb{R}$. Explicitly, if $\phi\in L^2(\mathbb{R},\mathrm{d}x)$,

$$\begin{aligned}(M(\omega)\phi)(y)&=\int_{\mathbb{R}}\overline{\mathcal{F}_{\mathbb{R}}}(\omega)(x)\langle h_{y-x},h_y\rangle\phi(y-x)\mathrm{d}x\\&=\int_{\mathbb{R}}\overline{\mathcal{F}_{\mathbb{R}}}(\omega)(y-x)\langle h_x,h_y\rangle\phi(x)\mathrm{d}x\\&=\int_{\mathbb{R}}\left(\int_{\mathbb{R}}e^{i(y-x)z}\omega(z)\langle h_x,h_y\rangle\phi(x)\frac{\mathrm{d}z}{2\pi}\right)\mathrm{d}x, \quad y\in\mathbb{R}.\end{aligned}$$

B. Generalized covariant phase observables

We give a complete characterization of the covariance systems based on the one-dimensional torus

$$\mathbb{T}=\{z\in\mathbb{C}\,|\,|z|=1\}=\{e^{i\theta}|\,\theta\in[0,2\pi]\}.$$

We have

$$G=\mathbb{T}, \quad H=\{1\}, \quad G/H=\mathbb{T},$$

$$\hat{G}=H^\perp=\{(\mathbb{T}\ni z\mapsto z^n\in\mathbb{C})\,|\,n\in\mathbb{Z}\}\cong\mathbb{Z},$$

$$\hat{G}/H^\perp=\{1\}.$$

We choose $\mu_{G/H}=(1/2\pi)\,d\theta=:\mu_{\mathbb{T}}$, so that $\mu_{H^\perp}$ is the counting measure $\mu_{\mathbb{Z}}$ on $\mathbb{Z}$.

Let U be a representation of $\mathbb{T}$. Since $\mathbb{T}$ is compact, we can always assume that U acts diagonally on

$$\mathcal{H}=\bigoplus_{k\in I}F_k,$$

where $I \subset \mathbb{Z}$, and F_k are Hilbert spaces such that $\dim F_k$ is the multiplicity of the representation $k \in \mathbb{Z}$ in U. Explicitly,

$$(U(z)\phi_k) = z^k \phi_k$$

for all $z \in \mathbb{T}$ and $\phi_k \in F_k$.

In order to use Eq. (9), we notice that $F_k = L^2(\mathbb{Z}, \delta_k; F_k)$ (where δ_k is the Dirac measure at k), so that $\rho_k = \delta_k$, By Corollary 8, one has that U admits covariant POVMs based on $\mathbb{T}$ and that $\alpha_k(j) = \delta_{k,j}$ (where $\delta_{k,j}$ is the Kronecker delta).

Choose an infinite dimensional Hilbert space E and, for each $k \in I$, fix an isometry W_k from F_k to E. The corresponding covariance system is given by

$$P_j M(\omega) P_k \phi = \overline{\mathcal{F}_{\mathbb{T}}}(\omega)(j-k) W_j^* W_k P_k \phi = \frac{1}{2\pi} \int_0^{2\pi} \omega(e^{i\theta}) e^{i(j-k)\theta} W_j^* W_k P_k \phi \, \mathrm{d}\theta,$$

where $\phi \in \mathcal{H}$ and $\omega \in \mathcal{C}(\mathbb{T})$.

If $I = \mathbb{Z}$ and $\dim F_k = 1$ $\forall k \in \mathbb{Z}$, U is the number representation and M represents the phase observable (compare with the result obtained in Ref. 3).

C. Covariant phase difference observables

Let $\mu_{\mathbb{T}}$ as in the previous section. We consider the following representation U of the direct product $G = \mathbb{T} \times \mathbb{T}$ acting on the space $\mathcal{H} = L^2(\mathbb{T} \times \mathbb{T}, \mu_{\mathbb{T}} \otimes \mu_{\mathbb{T}})$ as

$$(U(a,b)f)(z_1, z_2) = f(az_1, b^{-1} z_2), \quad (z_1, z_2) \in \mathbb{T} \times \mathbb{T},$$

for all $(a,b) \in \mathbb{T} \times \mathbb{T}$.

Let H be the closed subgroup

$$H = \{(a,b) \in \mathbb{T} \times \mathbb{T} \mid b = a\} \cong \mathbb{T}.$$

We classify all the POVMs based on G/H and covariant with respect to U (for a different approach to the same problem, see Ref. 9).

We have

$$G = \mathbb{T} \times \mathbb{T}, \quad G/H \cong \mathbb{T}, \quad \hat{G} = \hat{\mathbb{T}} \times \hat{\mathbb{T}} \cong \mathbb{Z} \times \mathbb{Z},$$

$$H^\perp = \{(j,k) \in \mathbb{Z} \times \mathbb{Z} \mid k = -j\} \cong \mathbb{Z},$$

$$\hat{G}/H^\perp \cong \mathbb{Z}.$$

We fix $\mu_{G/H} = \mu_{\mathbb{T}}$, so that $\mu_{H^\perp} = \mu_{\mathbb{Z}}$.

We choose the following orthonormal basis $(e_{i,j})_{i,j \in \mathbb{Z}}$ of $\mathcal{H}$,

$$e_{i,j}(z_1, z_2) = z_1^i z_2^{-j}, \quad (z_1, z_2) \in \mathbb{T} \times \mathbb{T},$$

so that

$$U(a,b) e_{i,j} = a^i b^j e_{i,j} \quad \forall (a,b) \in \mathbb{T} \times \mathbb{T}.$$

Let $F_{i,j} = \mathbb{C} e_{i,j}$, Then U acts diagonally on $F_{i,j}$ as the character $(i,j) \in \mathbb{Z} \times \mathbb{Z}$. Then, one can choose as decomposition (9)

$$\mathcal{H} = \bigoplus_{i,j \in \mathbb{Z}} F_{i,j} \cong \bigoplus_{i,j \in \mathbb{Z}} L^2(\mathbb{Z} \times \mathbb{Z}, \delta_i \otimes \delta_j; F_{i,j}).$$

With the notations of Sec. IV, we have $I=\mathbb{Z}\times\mathbb{Z}$ and $\rho_{i,j}=\delta_i\otimes\delta_j$. It follows that $\mathcal{C}_U^{\pi}$ is the equivalence class of $\mu_{\mathbb{Z}}$. With the choice $\nu_U=\mu_{\mathbb{Z}}$, it follows that $\tilde{\nu}=\mu_{\mathbb{Z}}\otimes\mu_{\mathbb{Z}}$. According to Theorem 6, U admits covariant POVMs and $\alpha_{i,j}(n,m)=\delta_{n,i}\delta_{m,j}$.

With the choice $E=\mathcal{H}$, we select a map $(i,j)\mapsto W_{i,j}$, where $W_{i,j}$ is an isometry from $F_{i,j}$ to $\mathcal{H}$. Since $F_{i,j}$ are one dimensional, there exists a family of vectors $(h_{i,j})_{i,j\in\mathbb{Z}}$ in $\mathcal{H}$, with $\|h_{i,j}\|_{\mathcal{H}}=1\ \forall(i,j)\in\mathbb{Z}\times\mathbb{Z}$, such that

$$W_{i,j}e_{i,j}=h_{i,j}\quad\forall(i,j)\in\mathbb{Z}\times\mathbb{Z}.$$

The corresponding covariant POVM M is given, for every $\phi\in\mathcal{H}$, by

$$\begin{aligned}P_{l,m}M(\omega)P_{i,j}\phi&=\sum_{h\in\mathbb{Z}}\mathcal{F}_{\mathbb{T}}(\omega)(h)\,\delta_{l-h,i}\delta_{m+h,j}\langle h_{i,j},h_{l,m}\rangle\langle\phi,e_{i,j}\rangle e_{l,m}\\&=\delta_{l+m,i+j}\ \mathcal{F}_{\mathbb{T}}(\omega)(j-m)\langle h_{i,j},h_{l,m}\rangle\ \langle\phi,e_{i,j}\rangle e_{l,m}.\end{aligned}$$

In particular, if $l+m=i+j$, we have

$$\langle M(\omega)e_{i,j},e_{l,m}\rangle=\overline{\mathcal{F}_{\mathbb{T}}}(\omega)(j-m)\langle h_{i,j},h_{l,m}\rangle=\frac{1}{2\pi}\int_0^{2\pi}\omega(e^{i\theta})e^{i(j-m)\theta}\langle h_{i,j},h_{l,m}\rangle\mathrm{d}\theta.$$

If $l+m\neq i+j$, one has

$$\langle M(\omega)e_{i,j},e_{l,m}\rangle=0.$$

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 1 JANUARY 2004

Hopf structure of the Yangian $Y(\mathrm{sl}_n)$ in the Drinfel'd realization

N. Crampé
Laboratoire d'Annecy-le-Vieux de Physique Théorique, LAPTH, CNRS, UMR 5108, Université de Savoie, B.P. 110, F-74941 Annecy-le-Vieux Cedex, France

(Received 25 September 2003; accepted 10 October 2003)

The Yangian of the Lie algebra sl_n is known to have different presentations, in particular the RTT realization and the Drinfel'd realization. Using the isomorphism between them, the explicit expressions of the comultiplication, the antipode and the counit in the Drinfel'd realization of the Yangian $Y(\mathrm{sl}_n)$ are given. As examples, the cases of $Y(\mathrm{sl}_2)$ and $Y(\mathrm{sl}_3)$ are worked out. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1633024]

I. TWO REALIZATIONS OF THE YANGIAN $Y(\mathrm{sl}_n)$

The Yangian $Y(\mathfrak{a})$ based on a simple Lie algebra $\mathfrak{a}$ is defined[1,2] as the (unique) homogeneous quantization of the algebra $\mathfrak{a}[u]=\mathfrak{a}\otimes\mathbb{C}[u]$ endowed with its standard bialgebra structure, where $\mathbb{C}[u]$ is the ring of polynomials in the indeterminate u. This algebra has a structure of a noncocomutative Hopf algebra, which partially explains the importance of Yangians and their representations in the study of quantum inverse problem. Among the different presentations of the Yangians, the one known as the Drinfel'd realization is well adapted for the study of their representations.[3] No explicit formula for the Hopf structure in this realization was known yet, except for sl_2[4] and for $\mathrm{osp}(1|2)$.[5] The aim of this paper is to give an explicit expression of the comultiplication, the antipode and the counit in the Drinfel'd realization for $Y(\mathrm{sl}_n)$. Note that partial results were given in Refs. 6 and 7. The comultiplication given in this paper can be extended to the double Yangian $DY(\mathrm{sl}_n)$. One can show that the so-called Drinfel'd comultiplication defined only for the double Yangian is the twist of this extended comultiplication (see, for example, Refs. 7 and 8).

This paper is organized as follows. In this section, the RTT formalism[9] and Drinfel'd realization of $Y(\mathrm{sl}_n)$ are presented, which allow us to give the normalization of the generators as well as the exact form of the R-matrix and of the quantum determinant. In the second section, some properties about the quantum minors, needed in the following, are explained. The expressions of the isomorphism using the quantum minors or the Gauss decomposition are then presented. The main theorem of this paper, i.e., the explicit form of the Hopf structure, is exposed in the next two sections. Finally, as illustrative examples, the $Y(\mathrm{sl}_2)$ and $Y(\mathrm{sl}_3)$ cases are worked out.

In this section, two well-known realizations of the Yangian based on the Lie algebra sl_n are presented: the RTT formalism and the Drinfel'd realization.[3]

The first realization uses the RTT formalism.[3,4,9] Let $V^{(n)}$ denote the n-dimensional fundamental vector space representation of sl_n. The Yang's R-matrix is given by

$$R_{12}^{(n)}(u)=I\otimes I+\sum_{1\leqslant i,j\leqslant n}\frac{E_{ij}\otimes E_{ji}}{u}\in \mathrm{End}(V^{(n)}\otimes V^{(n)}), \tag{1.1}$$

where E_{ij} is the elementary matrix with entry 1 in row i and column j and 0 elsewhere. This R-matrix satisfies the following properties:

$$R_{12}^{(n)}(u)R_{13}^{(n)}(u+v)R_{23}^{(n)}(v)=R_{23}^{(n)}(v)R_{13}^{(n)}(u+v)R_{12}^{(n)}(u) \quad \text{(Yang–Baxter equation)}, \tag{1.2}$$

$$R_{12}^{(n)}(u)R_{21}^{(n)}(-u)=\frac{u^2-1}{u^2}\ \ (I\otimes I)\quad (\text{unitarity}). \tag{1.3}$$

Definition 1.1: The Yangian of gl_n, $Y(\mathrm{gl}_n)$, *is the associative algebra, generated by the unit and the elements* $\{T_{i,j}^{(k)}|1\leqslant i,j\leqslant n,k\in\mathbb{Z}_{>0}\}$ *gathered in the formal series*

$$T(u)=1+\sum_{i,j=1}^{n}\ \sum_{k\in\mathbb{Z}_{>0}}\ T_{i,j}^{(k)}\,u^{-k}\,E_{ij}=\sum_{i,j=1}^{n}\ T_{i,j}(u)\,E_{ij} \tag{1.4}$$

subject to the defining relations

$$R_{12}^{(n)}(u-v)(T(u)\otimes 1)(1\otimes T(v))=(1\otimes T(v))(T(u)\otimes 1)R_{12}^{(n)}(u-v). \tag{1.5}$$

The defining relations (1.5) as commutators of $T_{ij}(u)$ are

$$-(u-v)[T_{i,j}(u),T_{k,l}(v)]=T_{k,j}(u)\,T_{i,l}(v)-T_{k,j}(v)\,T_{i,l}(u). \tag{1.6}$$

The Yangian $Y(\mathrm{gl}_n)$ has a Hopf algebra structure and the explicit forms of comultiplication, antipode and counit are

$$\Delta(T_{i,j}(u))=\sum_{k=1}^{n}\ T_{i,k}\otimes T_{k,j},\quad S(T(u))=T^{-1}(u)\quad \text{and}\ \ \epsilon(T_{i,j}(u))=\delta_{ij}\ \ . \tag{1.7}$$

By definition, the quantum determinant is the following formal series with coefficients in $Y(\mathrm{gl}_n)$:

$$q\det T(u)=\sum_{\sigma\in\mathfrak{S}_n}\ \mathrm{sgn}(\sigma)\ T_{\sigma(1),1}(u)\cdots T_{\sigma(n),n}(u+n-1). \tag{1.8}$$

Remark: To avoid ambiguity, let us stress that

$$q\det T(-u)=\sum_{\sigma\in\mathfrak{S}_n}\ \mathrm{sgn}(\sigma)\ T_{\sigma(1),1}(-u)\cdots T_{\sigma(n),n}(-u+n-1)$$

is different from the quantum determinant of the matrix $\tilde{T}(u)=T(-u)$,

$$q\det\tilde{T}(u)=\sum_{\sigma\in\mathfrak{S}_n}\ \mathrm{sgn}(\sigma)\ T_{\sigma(1),1}(-u)\cdots T_{\sigma(n),n}(-u-n+1). \tag{1.9}$$

A well-known result (see, e.g., Ref. 4) is that the coefficients of $q\det T(u)$ generate the center of $Y(\mathrm{gl}_n)$ and furthermore

$$\Delta(q\det T(u))=q\det T(u)\otimes q\det T(u). \tag{1.10}$$

These results justify the following definition.

Definition 1.2: The Yangian of the Lie algebra sl_n, $Y(\mathrm{sl}_n)$, *is the quotient of the algebra* $Y(\mathrm{gl}_n)$ *by the ideal generated by* $q\det T(u)=1$ *with the Hopf algebra structure (1.7).*

Let us note that the Yangian $Y(\mathrm{sl}_n)$ can also be viewed as a subalgebra of $Y(\mathrm{gl}_n)$; for more details, see, for example, Ref. 4. In the following, $T(u)$ will denote the generators of the Yangian $Y(\mathrm{sl}_n)$.

The map

$$T(u)\mapsto T^{-1}(-u)\equiv T^{*}(u) \tag{1.11}$$

defines an automorphism of $Y(\mathrm{sl}_n)$.

The second realization of the Yangian uses the so-called Drinfel'd generators. Let $\{\alpha_i|1\leqslant i\leqslant n-1\}$ be the set of simple roots of sl_n and $(\cdot,\cdot)$ be the standard nondegenerate symmetric

invariant bilinear form on sl_n. For each simple root α_i, e_{α_i}, and f_{α_i} are the corresponding root vectors, such that $(e_{\alpha_i},f_{\alpha_i})=1$, and $h_{\alpha_i}=[e_{\alpha_i},f_{\alpha_i}]$ are the Cartan generators. The Drinfel'd realization of the Yangian is given by the following theorem.[3]

Theorem 1.3: The Yangian of sl_n, $Y(\mathrm{sl}_n)$, *is isomorphic to the associative algebra* $\mathcal{A}$, *generated by the unit and the elements* $\{e_i^{(k)},f_i^{(k)},h_i^{(k)} \mid 1\leqslant i\leqslant n-1, k\in\mathbb{Z}_{\geqslant 0}\}$ *subject to the defining relations*

$$[h_i^{(k)},h_j^{(l)}]=0, \quad [e_i^{(k)},f_j^{(l)}]=\delta_{i,j}\ \ h_i^{(k+l)}, \tag{1.12}$$

$$[h_i^{(0)},e_j^{(l)}]=(\alpha_i,\alpha_j)e_j^{(l)}, \quad [h_i^{(0)},f_j^{(l)}]=-(\alpha_i,\alpha_j)f_j^{(l)}, \tag{1.13}$$

$$[h_i^{(k+1)},e_j^{(l)}]-[h_i^{(k)},e_j^{(l+1)}]=\tfrac{1}{2}(\alpha_i,\alpha_j)\ \ (h_i^{(k)}e_j^{(l)}+e_j^{(l)}h_i^{(k)}), \tag{1.14}$$

$$[h_i^{(k+1)},f_j^{(l)}]-[h_i^{(k)},f_j^{(l+1)}]=-\tfrac{1}{2}(\alpha_i,\alpha_j)\ \ (h_i^{(k)}f_j^{(l)}+f_j^{(l)}h_i^{(k)}), \tag{1.15}$$

$$[e_i^{(k+1)},e_j^{(l)}]-[e_i^{(k)},e_j^{(l+1)}]=\tfrac{1}{2}(\alpha_i,\alpha_j)\ \ (e_i^{(k)}e_j^{(l)}+e_j^{(l)}e_i^{(k)}), \tag{1.16}$$

$$[f_i^{(k+1)},f_j^{(l)}]-[f_i^{(k)},f_j^{(l+1)}]=-\tfrac{1}{2}(\alpha_i,\alpha_j)\ \ (f_i^{(k)}f_j^{(l)}+f_j^{(l)}f_i^{(k)}), \tag{1.17}$$

and to the Serre relations, for $i\neq j$ *and* $n_{ij}=1-2[(\alpha_i,\alpha_j)/(\alpha_i,\alpha_i)]$:

$$\sum_{\sigma\in\mathfrak{S}_{n_{ij}}}[e_i^{(k_{\sigma(1)})},[\cdots,[e_i^{(k_{\sigma(n_{ij})})},e_j^{(l)}]\cdots]=0, \tag{1.18}$$

$$\sum_{\sigma\in\mathfrak{S}_{n_{ij}}}[f_i^{(k_{\sigma(1)})},[\cdots,[f_i^{(k_{\sigma(n_{ij})})},f_j^{(l)}]\cdots]=0. \tag{1.19}$$

For later conveniences, we define the following formal series:

$$e_i(u)=\sum_{k=0}^{+\infty}\frac{e_i^{(k)}}{u^{k+1}}, \quad f_i(u)=\sum_{k=0}^{+\infty}\frac{f_i^{(k)}}{u^{k+1}}, \quad \text{and} \quad h_i(u)=1+\sum_{k=0}^{+\infty}\frac{h_i^{(k)}}{u^{k+1}} \quad \text{for} \quad 1\leqslant i\leqslant n-1. \tag{1.20}$$

The mapping $e_{\alpha_i}\mapsto e_i^{(0)}$, $f_{\alpha_i}\mapsto f_i^{(0)}$, $h_{\alpha_i}\mapsto h_i^{(0)}$ defines an embedding $\mathrm{U}(\mathrm{sl}_n)\hookrightarrow\mathcal{A}$, where $\mathrm{U}(\mathrm{sl}_n)$ is the universal enveloping algebra of sl_n.

II. QUANTUM MINORS

Before giving the expression of the isomorphism that relates the two Yangian presentations, in the next section, we introduce the notion of quantum minors and recall some of their properties (see, e.g., Refs. 4 and 8, for the proofs).

Let $I=\{a_1,a_2,\ldots,a_m\}$ and $J=\{b_1,b_2,\ldots,b_m\}$ such that $I,J\subset\{1,\ldots,n\}$ and $\mathrm{card}(I)=\mathrm{card}(J)=m$ with $1\leqslant m\leqslant n$. The set of generators $\{T_{a_i,b_j}(u)\mid 1\leqslant i,j\leqslant m\}$ defines a subalgebra of $Y(\mathrm{sl}_n)$ with the following commutation relations:

$$\begin{aligned}R_{12}^{(m)}(u-v)&\left(T\left(\begin{smallmatrix}a_1\cdots a_m\\ b_1\cdots b_m\end{smallmatrix}\right)(u)\otimes 1\right)\left(1\otimes T\left(\begin{smallmatrix}a_1\cdots a_m\\ b_1\cdots b_m\end{smallmatrix}\right)(v)\right)\\ &=\left(1\otimes T\left(\begin{smallmatrix}a_1\cdots a_m\\ b_1\cdots b_m\end{smallmatrix}\right)(v)\right)\left(T\left(\begin{smallmatrix}a_1\cdots a_m\\ b_1\cdots b_m\end{smallmatrix}\right)(u)\otimes 1\right)R_{12}^{(m)}(u-v),\end{aligned} \tag{2.1}$$

where $T\left(\begin{smallmatrix}a_1\cdots a_m\\ b_1\cdots b_m\end{smallmatrix}\right)(u)=\sum_{i,j=1}^{m}T_{a_ib_j}(u)\ \ E_{ij}$.

Definition 2.1: The quantum minor $t\left(\begin{smallmatrix}a_1\cdots a_m\\ b_1\cdots b_m\end{smallmatrix}\right)(u)$ *of* $T(u)$ *is defined by*

$$t\left(\begin{smallmatrix}a_1\cdots a_m\\ b_1\cdots b_m\end{smallmatrix}\right)(u)=q\det T\left(\begin{smallmatrix}a_1\cdots a_m\\ b_1\cdots b_m\end{smallmatrix}\right)(u)=\sum_{\sigma\in\mathfrak{S}_m}\operatorname{sgn}(\sigma)T_{a_{\sigma(1)},b_1}(u)\cdots T_{a_{\sigma(m)},b_m}(u+m-1). \quad (2.2)$$

The quantum minors can also be given by[4]

$$t\left(\begin{smallmatrix}a_1\cdots a_m\\ b_1\cdots b_m\end{smallmatrix}\right)(u)=\sum_{\sigma\in\mathfrak{S}_m}\operatorname{sgn}(\sigma)T_{a_1,b_{\sigma(1)}}(u+m-1)\cdots T_{a_m,b_{\sigma(m)}}(u). \quad (2.3)$$

By convention, when $m<1$, the quantum minor is equal to 1. Quantum minors satisfy some properties which are analogous to those of numerical matrices minors (for more details, see, for example, Refs. 4 and 8).

Proposition 2.2: The quantum minor $t\left(\begin{smallmatrix}a_1\cdots a_m\\ b_1\cdots b_m\end{smallmatrix}\right)(u)$ *verifies the following properties:*

(1) It is antisymmetric, i.e., for $\rho\in\mathfrak{S}_m$,

$$t\left(\begin{smallmatrix}a_1\cdots a_m\\ b_1\cdots b_m\end{smallmatrix}\right)(u)=\operatorname{sgn}(\rho)t\left(\begin{smallmatrix}\rho(a_1)\cdots\rho(a_m)\\ b_1\cdots b_m\end{smallmatrix}\right)(u)=\operatorname{sgn}(\rho)t\left(\begin{smallmatrix}a_1\cdots a_m\\ \rho(b_1)\cdots\rho(b_m)\end{smallmatrix}\right)(u). \quad (2.4)$$

(2) It is alternated, i.e., if there exists $i\neq j$ *such that* $a_i=a_j$ *or* $b_i=b_j$, *then* $t\left(\begin{smallmatrix}a_1\cdots a_m\\ b_1\cdots b_m\end{smallmatrix}\right)(u)=0$.

(3) It can be expanded with respect to its last column or its last row as follows:

$$t\left(\begin{smallmatrix}a_1\cdots a_m\\ b_1\cdots b_m\end{smallmatrix}\right)(u)=\sum_{k=1}^{m}(-1)^{k+m}\,t\left(\begin{smallmatrix}a_1\cdots a_{k-1}\,a_{k+1}\cdots a_{m-1}\,a_m\\ b_1\cdots b_{k-1}\,b_k\cdots b_{m-2}\,b_{m-1}\end{smallmatrix}\right)(u)\;T_{a_k,b_m}(u+m-1) \quad (2.5)$$

$$=\sum_{k=1}^{m}(-1)^{k+m}\;T_{a_m,b_k}(u+m-1)\;t\left(\begin{smallmatrix}a_1\cdots a_{k-1}\,a_k\cdots a_{m-2}\,a_{m-1}\\ b_1\cdots b_{k-1}\,b_{k+1}\cdots b_{m-1}\,b_m\end{smallmatrix}\right)(u). \quad (2.6)$$

From the defining relations (1.6), the commutation relations of the quantum minors with $T_{i,j}(u)$ can be computed:

$$(u-v)[T_{i,j}(u),t\left(\begin{smallmatrix}a_1\cdots a_m\\ b_1\cdots b_m\end{smallmatrix}\right)(v)]=\sum_{k=1}^{m}\Big(t\left(\begin{smallmatrix}a_1\cdots a_{k-1}\,a_k a_{k+1}\cdots a_m\\ b_1\cdots b_{k-1}\,j\,b_{k+1}\cdots b_m\end{smallmatrix}\right)(v)\;\;T_{i,b_k}(u)$$

$$-T_{a_k,j}(u)t\left(\begin{smallmatrix}a_1\cdots a_{k-1}\,i\,a_{k+1}\cdots a_m\\ b_1\cdots b_{k-1}\,b_k\,b_{k+1}\cdots b_m\end{smallmatrix}\right)(v)\Big). \quad (2.7)$$

A corollary of (2.7) is that the quantum minor $t\left(\begin{smallmatrix}a_1\cdots a_m\\ b_1\cdots b_m\end{smallmatrix}\right)(u)$ lies in the center of the subalgebra generated by $\{T_{a_i,b_j}(u)\,|\,1\leqslant i,j\leqslant m\}$, i.e.,

$$[T_{a_i,b_j}(u),\;\;t\left(\begin{smallmatrix}a_1\cdots a_m\\ b_1\cdots b_m\end{smallmatrix}\right)(v)]=0\qquad\text{for }\;1\leqslant i,j\leqslant m. \quad (2.8)$$

The map

$$T_{i,j}(u)\mapsto t\left(\begin{smallmatrix}1\cdots p\;\,p+i\\ 1\cdots p\;\,p+j\end{smallmatrix}\right)(u) \quad (2.9)$$

defines an algebra homomorphism $Y(\mathrm{sl}_{n-p})\to Y(\mathrm{sl}_n)$, for $1\leqslant p\leqslant n-1$ and $1\leqslant i,j\leqslant n-p$. Note that this homomorphism allows us to compute a simple way the commutation relations among the $t\left(\begin{smallmatrix}1\cdots p\;\,p+i\\ 1\cdots p\;\,p+j\end{smallmatrix}\right)(u)$ minors.

Finally, quantum minors allow us to express some elements of the inverse matrix of $T(u)$ thanks to the following proposition (see, e.g., Ref. 4).

Proposition 2.3: For $1\leqslant i,j\leqslant n$, *the following equality holds:*

$$(T^{-1}(u+n-1))_{i,j}=(-1)^{i+j}\;t\left(\begin{smallmatrix}1\cdots j-1\;\,j+1\cdots n\\ 1\cdots i-1\;\,i+1\cdots n\end{smallmatrix}\right)(u). \quad (2.10)$$

III. ISOMORPHISMS BETWEEN THE TWO REALIZATIONS OF $Y(\mathrm{sl}_n)$

For clarity purposes, the isomorphism between the two previous realizations is recalled (see, e.g., Refs. 3 and 8). Two presentations of this isomorphism are possible. The first one uses the quantum minors and the second one uses the Gauss decomposition.

Theorem 3.1: *The map* $\phi:\mathcal{A}\to Y(\mathrm{sl}_n)$,

$$e_i\left(u+\frac{i-2}{2}\right)\mapsto(t(^{1\cdots i}_{1\cdots i})(u))^{-1}t(^{1\cdots i-1\ i}_{1\cdots i-1\ i+1})(u), \tag{3.1}$$

$$f_i\left(u+\frac{i-2}{2}\right)\mapsto t(^{1\cdots i-1\ i+1}_{1\cdots i-1\ i})(u)(t(^{1\cdots i}_{1\cdots i})(u))^{-1}, \tag{3.2}$$

$$h_i\left(u+\frac{i-2}{2}\right)\mapsto(t(^{1\cdots i}_{1\cdots i})(u))^{-1}t(^{1\cdots i-1}_{1\cdots i-1})(u)t(^{1\cdots i+1}_{1\cdots i+1})(u-1)(t(^{1\cdots i}_{1\cdots i})(u-1))^{-1}, \tag{3.3}$$

defines an algebra isomorphism.

Note that the image of $h_i(u)$ can be written differently as, by using the proposition 2.2,

$$\phi\left(h_i\left(u+\frac{i-2}{2}\right)\right)=(t(^{1\cdots i}_{1\cdots i})(u))^{-1}t(^{1\cdots i-1\ i+1}_{1\cdots i-1\ i+1})(u)-\phi\left(f_i\left(u+\frac{i}{2}\right)e_i\left(u+\frac{i-2}{2}\right)\right) \tag{3.4}$$

$$=t(^{1\cdots i-1\ i+1}_{1\cdots i-1\ i+1})(u)(t(^{1\cdots i}_{1\cdots i})(u))^{-1}-\phi\left(f_i\left(u+\frac{i-2}{2}\right)e_i\left(u+\frac{i}{2}\right)\right). \tag{3.5}$$

The other presentation of the isomorphism ϕ uses the Gauss decompositions of the matrix $T(u)$,

$$T(u)=\begin{pmatrix}1 & & & 0\\ f_{2,1}(u) & 1 & & \\ \vdots & \ddots & \ddots & \\ f_{n,1}(u) & \cdots & f_{n,n-1}(u) & 1\end{pmatrix}\begin{pmatrix}k_1(u) & & 0\\ & \ddots & \\ 0 & & k_n(u)\end{pmatrix}\begin{pmatrix}1 & e_{1,2}(u) & \cdots & e_{1,n}(u)\\ & 1 & \ddots & \vdots\\ & & \ddots & e_{n-1,n}(u)\\ 0 & & & 1\end{pmatrix} \tag{3.6}$$

$$=\begin{pmatrix}1 & \tilde{e}_{1,2}(u) & \cdots & \tilde{e}_{1,n}(u)\\ & 1 & \ddots & \vdots\\ & & \ddots & \tilde{e}_{n-1,n}(u)\\ 0 & & & 1\end{pmatrix}\begin{pmatrix}\tilde{k}_1(u) & & 0\\ & \ddots & \\ 0 & & \tilde{k}_n(u)\end{pmatrix}\begin{pmatrix}1 & & & 0\\ \tilde{f}_{2,1}(u) & 1 & & \\ \vdots & \ddots & \ddots & \\ \tilde{f}_{n,1}(u) & \cdots & \tilde{f}_{n,n-1}(u) & 1\end{pmatrix}. \tag{3.7}$$

The expression of the elements of the Gauss decomposition (3.6) in terms of quantum minors has been computed by Iohara.[8] For the alternative Gauss decomposition (3.7), the computations are similar and one obtains the following.

Proposition 3.2: Let $1\leqslant i<j\leqslant n$ *and* $1\leqslant p\leqslant n$. *The formal series* $e_{i,j}(u)$, $\tilde{e}_{i,j}(u)$, $f_{j,i}(u)$, $\tilde{f}_{j,i}(u)$, $k_p(u)$ *and* $\tilde{k}_p(u)$ *in the Gauss decompositions, can be expressed in terms of quantum minors,*

$$e_{i,j}(u+i-1)=(t(^{1\cdots i}_{1\cdots i})(u))^{-1}t(^{1\cdots i-1\ i}_{1\cdots i-1\ j})(u), \tag{3.8}$$

$$f_{j,i}(u+i-1)=t(^{1\cdots i-1\ j}_{1\cdots i-1\ i})(u)(t(^{1\cdots i}_{1\cdots i})(u))^{-1}, \tag{3.9}$$

$$k_j(u+j-1)=t(^{1\cdots j}_{1\cdots j})(u)(t(^{1\cdots j-1}_{1\cdots j-1})(u))^{-1}, \tag{3.10}$$

$$k_1(u)=t\binom{1}{1}(u)=T_{1,1}(u) \tag{3.11}$$

and

$$\tilde{e}_{i,j}(u+n-j)=t\binom{i\ \ j+1\cdots n}{j\ \ j+1\cdots n}(u)\left(t\binom{j+1\cdots n}{j+1\cdots n}(u)\right)^{-1}, \tag{3.12}$$

$$\tilde{f}_{j,i}(u+n-j)=\left(t\binom{j+1\cdots n}{j+1\cdots n}(u)\right)^{-1}t\binom{j\ \ j+1\cdots n}{i\ \ j+1\cdots n}(u), \tag{3.13}$$

$$\tilde{k}_i(u+n-i)=\left(t\binom{i+1\cdots n}{i+1\cdots n}(u)\right)^{-1}t\binom{i\cdots n}{i\cdots n}(u), \tag{3.14}$$

$$\tilde{k}_n(u)=t\binom{n}{n}(u)=T_{n,n}(u). \tag{3.15}$$

Remark: Proposition 3.2 proves the existence of the two Gauss decomposition.

Then, proposition 3.2 implies that the map $\tilde{\phi}:\mathcal{A}\to Y(\mathrm{sl}_n)$,

$$e_i(u)\mapsto e_{i,i+1}\left(u+\frac{i}{2}\right), \tag{3.16}$$

$$f_i(u)\mapsto f_{i+1,i}\left(u+\frac{i}{2}\right), \tag{3.17}$$

$$h_i(u)\mapsto k_{i+1}\left(u+\frac{i}{2}\right)k_i^{-1}\left(u+\frac{i}{2}\right) \tag{3.18}$$

is an algebra isomorphism, for $1\leqslant i\leqslant n-1$.

Let $T^*(u)$ denote $T(-u)^{-1}$. Then, thanks to the map (1.11), the quantum minors of $T^*(u)$ has a meaning and is denoted by $t^*\binom{a_1\cdots a_m}{b_1\cdots b_m}(u)$.

Corollary 3.3: For $1\leqslant m\leqslant n$, *the following equalities hold:*

$$t^*\binom{1\cdots m}{1\cdots m}(-u-n+1)=t\binom{m+1\cdots n}{m+1\cdots n}(u), \tag{3.19}$$

$$t^*\binom{1\cdots m-1\ \ m+1}{1\cdots m-1\ \ m}(-u-n+1)=-t\binom{m+1\ \ m+2\cdots n}{m\ \ m+2\cdots n}(u), \tag{3.20}$$

$$t^*\binom{1\cdots m-1\ \ m}{1\cdots m-1\ \ m+1}(-u-n+1)=-t\binom{m\ \ m+2\cdots n}{m+1\ \ m+2\cdots n}(u), \tag{3.21}$$

$$t^*\binom{1\cdots m-1\ \ m+1}{1\cdots m-1\ \ m+1}(-u-n+1)=t\binom{m\ \ m+2\cdots n}{m\ \ m+2\cdots n}(u). \tag{3.22}$$

Proof: Let $T(u)$ decomposed according to (3.7). Then, $T^*(u)$ decomposes as in (3.6). Using the relation $T^*(u)=T(-u)^{-1}$, we deduce

$$e^*_{i,i+1}(u)=-e_{i,i+1}(-u), \tag{3.23}$$

$$f^*_{i+1,i}(u)=-f_{i+1,i}(-u),\quad \text{for}\quad 1\leqslant i\leqslant n-1, \tag{3.24}$$

$$k^*_i(u)=(k_i(-u))^{-1},\quad \text{for}\quad 1\leqslant i\leqslant n, \tag{3.25}$$

with obvious notations. Finally, using proposition 3.2, the equalities are proven. ■

For $1\leqslant i<j\leqslant n$, the elements $e^{(0)}_{i,j}=T^{(1)}_{i,j}$ and $f^{(0)}_{j,i}=T^{(1)}_{j,i}$ are root generators of the algebra sl_n, which can be expressed in terms of simple root generators, $e^{(0)}_i$ and $f^{(0)}_i$, as follows:

$$e^{(0)}_{i,j}=[\cdots[e^{(0)}_{j-1},e^{(0)}_{j-2}],e^{(0)}_{j-3}],\cdots],e^{(0)}_{i+1}],e^{(0)}_i], \tag{3.26}$$

$$f^{(0)}_{j,i}=[f^{(0)}_i,[f^{(0)}_{i+1},[\cdots,[f^{(0)}_{j-3},[f^{(0)}_{j-2},f^{(0)}_{j-1}]\cdots]. \tag{3.27}$$

Remark: In (3.26) and (3.27), the isomorphism $\tilde{\phi}$ has been omitted for simplicity. In the following, this notation is always used, i.e., the isomorphisms between two realizations of the same algebra are omitted.

IV. THE HOPF STRUCTURE OF $Y(\mathrm{sl}_n)$ IN THE DRINFEL'D BASIS

Before giving the Hopf structure of $Y(\mathrm{sl}_n)$ in the Drinfel'd basis, the images of any quantum minor under the coproduct, the antipode and the counit are needed. Let us recall that $T^*(u)$ denotes $T(-u)^{-1}$ and $t^*\binom{a_1\cdots a_m}{b_1\cdots b_m}(u)$ denotes its quantum minors.

Proposition 4.1: Let $1\leqslant m\leqslant n, 1\leqslant a_1<\cdots<a_m\leqslant n$ *and* $1\leqslant b_1<\cdots<b_m\leqslant n$. *The images of a quantum minor under the coproduct, the antipode and the counit are given by*

$$\Delta\left(t\binom{a_1\cdots a_m}{b_1\cdots b_m}(u)\right)=\sum_{1\leqslant c_1<\cdots<c_m\leqslant n} t\binom{a_1\cdots a_m}{c_1\cdots c_m}(u)\otimes t\binom{c_1\cdots c_m}{b_1\cdots b_m}(u), \tag{4.1}$$

$$S\left(t\binom{a_1\cdots a_m}{b_1\cdots b_m}(u)\right)=(-1)^{[m/2]}t^*\binom{a_1\cdots a_m}{b_1\cdots b_m}(-u-m+1), \tag{4.2}$$

$$\varepsilon\left(t\binom{a_1\cdots a_m}{b_1\cdots b_m}(u)\right)=\delta_{a_1,b_1}\cdots\delta_{a_m,b_m}, \tag{4.3}$$

where $[m/2]$ *is the integer part of* $m/2$.

Proof: The result for the coproduct is well known (see, e.g., Ref. 4). For the antipode, one gets

$$S\left(t\binom{a_1\cdots a_m}{b_1\cdots b_m}(u)\right)=S\left(\sum_{\sigma\in\mathfrak{S}_m}\mathrm{sgn}(\sigma)T_{a_{\sigma(1)},b_1}(u)\cdots T_{a_{\sigma(m)},b_m}(u+m-1)\right) \tag{4.4}$$

$$=\sum_{\sigma\in\mathfrak{S}_m}\mathrm{sgn}(\sigma)S(T_{a_{\sigma(m)},b_m}(u+m-1))\cdots S(T_{a_{\sigma(1)},b_1}(u))$$

(S is an antimorphism) (4.5)

$$=\sum_{\sigma\in\mathfrak{S}_m}\mathrm{sgn}(\sigma)T^*_{a_{\sigma(m)},b_m}(-u-m+1)\cdots T^*_{a_{\sigma(1)},b_1}(-u) \tag{4.6}$$

$$=(-1)^{[m/2]}\sum_{\sigma\in\mathfrak{S}_m}\mathrm{sgn}(\sigma)T^*_{a_{\sigma(m)},b_1}(-u-m+1)\cdots T^*_{a_{\sigma(1)},b_m}(-u)$$

[Eq. (2.4)], (4.7)

which proves the relation (4.2). The computation for the antipode is obvious. ■

The comultiplication, the antipode and the counit are established in the Drinfel'd basis thanks to the isomorphism ϕ (see theorem 3.1) between $\mathcal{A}$ and $Y(\mathrm{sl}_n)$.

A. Comultiplication

The adjoint actions of the elements of the algebra sl_n on $X\in Y(\mathrm{sl}_n)$ will be denoted by, for $1\leqslant i\leqslant j\leqslant n$,

$$\mathrm{Ad}^{\pm}_{e_{i,j}}(X)=\begin{cases}\pm[e^{(0)}_{i,j},X], & i<j,\\ X, & i=j,\end{cases}\quad\text{and}\quad \mathrm{Ad}^{\pm}_{f_{j,i}}(X)=\begin{cases}\pm[f^{(0)}_{j,i},X], & i<j,\\ X, & i=j.\end{cases} \tag{4.8}$$

To determine the explicit form of the comultiplication, the following generalization of the adjoint action, depending on a spectral parameter, is useful.

Definition 4.2: Let $1\leqslant i\leqslant j\leqslant n$, $1\leqslant\alpha\leqslant n$ *and* X *an element of* $Y(\mathrm{sl}_n)$. *The generalized adjoint actions are defined by*

$$ {}^{\alpha}\mathcal{E}_{i,j}(u)(X)=\mathrm{Ad}^{+}_{e_{i,j}}(X)+\delta_{i\leqslant\alpha<j}\,\mathrm{Ad}^{-}_{e_{i,\alpha}}(\mathrm{Ad}^{+}_{e_{\alpha+1,j}}(e_{\alpha}(u)))\;X, \tag{4.9}$$

$$ \mathcal{E}^{\alpha}_{i,j}(u)(X)=\mathrm{Ad}^{+}_{e_{i,j}}(X)+\delta_{i\leqslant\alpha<j}\,X\;\;\mathrm{Ad}^{-}_{e_{i,\alpha}}(\mathrm{Ad}^{+}_{e_{\alpha+1,j}}(e_{\alpha}(u))), \tag{4.10}$$

and

$$ {}^{\alpha}\mathcal{F}_{j,i}(u)(X)=\mathrm{Ad}^{-}_{f_{j,i}}(X)+\delta_{i\leqslant\alpha<j}\,\mathrm{Ad}^{+}_{f_{\alpha,i}}(\mathrm{Ad}^{-}_{f_{j,\alpha+1}}(f_{\alpha}(u)))X, \tag{4.11}$$

$$ \mathcal{F}^{\alpha}_{j,i}(u)(X)=\mathrm{Ad}^{-}_{f_{j,i}}(X)+\delta_{i\leqslant\alpha<j}\,X\;\;\mathrm{Ad}^{+}_{f_{\alpha,i}}(\mathrm{Ad}^{-}_{f_{j,\alpha+1}}(f_{\alpha}(u))), \tag{4.12}$$

where

$$ \delta_{i\leqslant\alpha<j}=\begin{cases}1 & \text{if } i\leqslant\alpha<j,\\ 0 & \text{otherwise.}\end{cases}$$

Let us give examples of the generalized adjoint actions (4.9),

$$ {}^{1}\mathcal{E}_{13}(u)(X)=\mathrm{Ad}^{+}_{e_{13}}(X)+\mathrm{Ad}^{-}_{e_{11}}(\mathrm{Ad}^{+}_{e_{23}}(e_1(u)))X=[e^{(0)}_{13},X]+[e^{(0)}_{23},e_1(u)]X, \tag{4.13}$$

$$ {}^{2}\mathcal{E}_{13}(u)(X)=\mathrm{Ad}^{+}_{e_{13}}(X)+\mathrm{Ad}^{-}_{e_{12}}(\mathrm{Ad}^{+}_{e_{33}}(e_2(u)))X=[e^{(0)}_{13},X]-[e^{(0)}_{12},e_2(u)]X, \tag{4.14}$$

$$ {}^{3}\mathcal{E}_{13}(u)(X)=\mathrm{Ad}^{+}_{e_{13}}(X)=[e^{(0)}_{13},X]. \tag{4.15}$$

Let ${}^{\alpha}\mathcal{G}$, $\mathcal{G}^{\beta}$ be any actions on $Y(\mathrm{sl}_n)$. Hereafter, for simplicity, the notation ${}^{\alpha}\mathcal{G}^{\beta}$ means either ${}^{\alpha}\mathcal{G}$ or $\mathcal{G}^{\beta}$.

To compute the comultiplication, we also need the following definition.

Definition 4.3: For $1\leqslant m\leqslant n$, $1\leqslant k_1<k_2<\cdots<k_m\leqslant n$ *and* $k_m\neq m$, ${}^{\alpha}E^{\beta}_{k_1,k_2,\cdots,k_m}(u)$ *and* ${}^{\alpha}F^{\beta}_{k_1,k_2,\cdots,k_m}(u)(X)$ *are defined by for* $X\in Y(\mathrm{sl}_n)$:

$$ {}^{\alpha}E^{\beta}_{k_1,k_2,\cdots,k_m}(u)(X)=\left(\overrightarrow{\prod_{1\leqslant i\leqslant m-1}}\;{}^{\alpha}\mathcal{E}^{\beta}_{i,k_i}(u)\right)({}^{\alpha}\mathcal{E}^{\beta}_{m+1,k_m}(u)(X)), \tag{4.16}$$

$$ {}^{\alpha}F^{\beta}_{k_1,k_2,\cdots,k_m}(u)(X)=\left(\overrightarrow{\prod_{1\leqslant i\leqslant m-1}}\;{}^{\alpha}\mathcal{F}^{\beta}_{k_i,i}(u)\right)({}^{\alpha}\mathcal{F}^{\beta}_{k_m,m+1}(u)(X)), \tag{4.17}$$

where, for $\{\mathcal{G}_p|1\leqslant p\leqslant m-1\}$, *a set of actions on* $Y(\mathrm{sl}_n)$, *we denote*

$$ \overrightarrow{\prod_{1\leqslant i\leqslant m-1}}\;\mathcal{G}_i(X)=\mathcal{G}_1(\cdots(\mathcal{G}_{m-2}(\mathcal{G}_{m-1}(X))\cdots). \tag{4.18}$$

In particular, one gets for $k>1$

$$ {}^{\alpha}E^{\beta}_{k}(u)(X)={}^{\alpha}\mathcal{E}^{\beta}_{2,k}(u)(X),\quad {}^{\alpha}F^{\beta}_{k}(u)(X)={}^{\alpha}\mathcal{F}^{\beta}_{k,2}(u)(X). \tag{4.19}$$

By convention, if the set of indices $\{k_1,k_2,\ldots,k_m\}$ is empty, then ${}^{\alpha}E^{\beta}_{k_1,k_2,\ldots,k_m}(u)(X)=1$ and ${}^{\alpha}F^{\beta}_{k_1,k_2,\ldots,k_m}(u)(X)=1$. Remark that these generators can be expressed only in terms of the elements of the Drinfel'd basis, thanks to Eqs. (3.26) and (3.27).

These generalized actions show up in the following lemma.

Lemma 4.4: For $1\leqslant i\leqslant n-1$, $1\leqslant a_1<\cdots<a_i\leqslant n$ *and* $a_i\neq i$, *one gets*

$$(t(^{1\cdots i}_{1\cdots i})(u))^{-1}t(^{1\cdots\ i}_{a_1\cdots\ a_i})(u)={}^{i}E_{a_1,\ldots,a_i}\left(u+\frac{i-2}{2}\right)\left(e_i\left(u+\frac{i-2}{2}\right)\right), \tag{4.20}$$

$$t(^{1\ \cdots\ i}_{a_1\cdots\ a_i})(u)(t(^{1\cdots i}_{1\cdots i})(u))^{-1}=E^{i}_{a_1,\ldots,a_i}\left(u+\frac{i}{2}\right)\left(e_i\left(u+\frac{i}{2}\right)\right), \tag{4.21}$$

$$(t(^{1\cdots i}_{1\cdots i})(u))^{-1}t(^{a_1\cdots a_i}_{1\ \cdots i})(u)={}^{i}F_{a_1,\ldots,a_i}\left(u+\frac{i}{2}\right)\left(f_i\left(u+\frac{i}{2}\right)\right), \tag{4.22}$$

$$t(^{a_1\cdots a_i}_{1\ \cdots i})(u)(t(^{1\cdots i}_{1\cdots i})(u))^{-1}=F^{i}_{a_1,\ldots,a_i}\left(u+\frac{i-2}{2}\right)\left(f_i\left(u+\frac{i-2}{2}\right)\right), \tag{4.23}$$

$$(t(^{1\cdots i}_{1\cdots i})(u))^{-1}t(^{1\ \cdots i-1\ \ i+1}_{a_1\cdots a_{i-1}\ \ a_i})(u)={}^{i}E_{a_1,\ldots,a_i}\left(u+\frac{i-2}{2}\right)\left(\tilde{g}_i\left(u+\frac{i-2}{2}\right)\right), \tag{4.24}$$

$$t(^{1\ \cdots i-1\ \ i+1}_{a_1\cdots a_{i-1}\ \ a_i})(u)(t(^{1\cdots i}_{1\cdots i})(u))^{-1}=E^{i}_{a_1,\ldots,a_i}\left(u+\frac{i}{2}\right)\left(g_i\left(u+\frac{i-2}{2}\right)\right), \tag{4.25}$$

$$(t(^{1\cdots i}_{1\cdots i})(u))^{-1}t(^{a_1\cdots a_{i-1}\ \ a_i}_{1\ \cdots i-1\ \ i+1})(u)={}^{i}F_{a_1,\ldots,a_i}\left(u+\frac{i}{2}\right)\left(\tilde{g}_i\left(u+\frac{i-2}{2}\right)\right), \tag{4.26}$$

$$t(^{a_1\cdots a_{i-1}\ \ a_i}_{1\ \cdots i-1\ \ i+1})(u)\ \ (t(^{1\cdots i}_{1\cdots i})(u))^{-1}=F^{i}_{a_1,\ldots,a_i}\left(u+\frac{i-2}{2}\right)\left(g_i\left(u+\frac{i-2}{2}\right)\right), \tag{4.27}$$

where

$$g_i(u)=h_i(u)+f_i(u)e_i(u+1), \tag{4.28}$$

$$\tilde{g}_i(u)=h_i(u)+f_i(u+1)e_i(u). \tag{4.29}$$

Proof: The proof is only given for (4.20). Let i and $\{a_1,\ldots,a_i\}$ fixed as in the lemma. The first step is to evaluate the quantum minor $t(^{1\cdots i}_{a_1\cdots a_i})(u)$ in terms of the quantum minor $t(^{1\cdots i-1\ \ i}_{1\cdots i-1\ \ i+1})(u)$ and in terms of some generators of the sl_n algebra. Selecting the coefficient of u^0v^{-1} in Eq. (2.7), the following relation is obtained for $1\leqslant b_1<\cdots<b_i\leqslant n$, $1\leqslant p\leqslant i$ and $1\leqslant m\leqslant n-b_p$:

$$\mathrm{Ad}^{+}_{e_{b_p,b_p+m}}(t(^{1\cdots p\ \cdots i}_{b_1\cdots b_p\cdots b_i})(v))=[T^{(1)}_{b_p,b_p+m},t(^{1\cdots p\ \cdots i}_{b_1\cdots b_p\cdots b_i})(v)]=t(^{1\cdots p\ \ \cdots i}_{b_1\cdots b_p+m\cdots b_i})(v). \tag{4.30}$$

This relation allows us to increase the parameters of the quantum minor. Using this relation, the indices $\{1,\ldots,i-1,\ i+1\}$ of $t(^{1\cdots i-1\ \ i}_{1\cdots i-1\ \ i+1})(u)$ can be increased up to $\{a_1,\ldots,a_i\}$:

$$\left(\prod_{1\leqslant p\leqslant i-1}^{\rightarrow}\mathrm{Ad}^{+}_{e_{p,a_p}}\right)(\mathrm{Ad}^{+}_{e_{i+1,a_i}}(t(^{1\cdots i-1\ \ i}_{1\cdots i-1\ \ i+1})(u)))=t(^{1\cdots i}_{a_1\cdots a_i})(u). \tag{4.31}$$

The second step of the proof consists in determining the commutator of $(t(^{1\cdots i}_{1\cdots i})(u))^{-1}$ with $e^{(0)}_{j,j+1}$. The commutation relations are computed using equation (2.7),

$$(u-v)[T_{j,j+1}(u),t(^{1\cdots i}_{1\cdots i})(v)]=\delta_{ij}\ t(^{1\cdots i-1\ \ i}_{1\cdots i-1\ \ i+1})(v)T_{ii}(u)+O\left(\frac{1}{u}\right). \tag{4.32}$$

Multiplying by $(t(^{1\cdots i}_{1\cdots i})(v))^{-1}$ both sides of the u^0 coefficient in (4.32), one gets

$$[e^{(0)}_{j,j+1},(t(^{1\cdots i}_{1\cdots i})(v))^{-1}]=-\delta_{ij}\ \ e_i\left(v+\frac{i-2}{2}\right)(t(^{1\cdots i}_{1\cdots i})(v))^{-1}. \tag{4.33}$$

Thus, thanks to the relations (3.26) and (4.33), one obtains for $X\in Y(\mathrm{sl}_n)$,

$$(t(^{1\cdots i}_{1\cdots i})(u))^{-1}\,\mathrm{Ad}^{+}_{e_{p,a_p}}(X)={}^{i}\mathcal{E}_{p,a_p}\left(u+\frac{i-2}{2}\right)((t(^{1\cdots i}_{1\cdots i})(u))^{-1}X). \tag{4.34}$$

This proves the Eq. (4.20). Equation (4.21) is proven along the same lines. Indeed, one remarks that

$$t(^{1\cdots i-1\ \ i}_{1\cdots i-1\ \ i+1})(u-1)(t(^{1\cdots i}_{1\cdots i})(u-1))^{-1}=(t(^{1\cdots i}_{1\cdots i})(u))^{-1}t(^{1\cdots i-1\ \ i}_{1\cdots i-1\ \ i+1})(u), \tag{4.35}$$

by using the commutation relations deduced from the map (2.9). This explains the shift of the spectral parameter between (4.20) and (4.21). For the relations (4.22)–(4.27), the proof is analogous. ■

Now we can state the main theorem of the paper.

Theorem 4.5: *Let* $1\leqslant i\leqslant n-1$. *The comultiplication in the Drinfel'd basis is given by*

$$\Delta(e_i(u))=\sum_{m=0}^{+\infty}(-1)^m\left(\sum_{\substack{1\leqslant b_1<\cdots<b_i\leqslant n\\ b_i\neq i}}{}^{i}E_{b_1,\ldots,b_i}(u)(e_i(u))\otimes{}^{i}F_{b_1,\ldots,b_i}(u+1)(f_i(u+1))\right)^m$$
$$\times\left(1\otimes e_i(u)+\sum_{\substack{1\leqslant a_1<\cdots<a_i\leqslant n\\ a_i\neq i}}{}^{i}E_{a_1,\ldots,a_i}(u)(e_i(u))\ \otimes\ {}^{i}F_{a_1,\ldots,a_i}(u+1)(\tilde{g}_i(u))\right), \tag{4.36}$$

$$\Delta(f_i(u))=\left(f_i(u)\otimes 1+\sum_{\substack{1\leqslant a_1<\cdots<a_i\leqslant n\\ a_i\neq i}}E^{i}_{a_1,\ldots,a_i}(u+1)(g_i(u))\otimes F^{i}(a_1\cdots a_i)(u)(f_i(u))\right)$$
$$\times\sum_{m=0}^{+\infty}(-1)^m\left(\sum_{\substack{1\leqslant b_1<\cdots<b_i\leqslant n\\ b_i\neq i}}E^{i}_{b_1,\ldots,b_i}(u+1)(e_i(u+1))\otimes F^{i}_{b_1,\ldots,b_i}(u)(f_i(u))\right)^m, \tag{4.37}$$

$$\Delta(h_i(u))=\left(f_i(u)\otimes e_i(u+1)+\sum_{\substack{1\leqslant a_1<\cdots<a_i\leqslant n\\ a_i\neq i}}E^{i}_{a_1,\ldots,a_i}(u+1)(g_i(u))\otimes F^{i}_{a_1,\ldots,a_i}(u)(g_i(u))\right)$$
$$\times\sum_{m=0}^{+\infty}(-1)^m\left(\sum_{\substack{1\leqslant b_1<\cdots<b_i\leqslant n\\ b_i\neq i}}E^{i}_{b_1,\ldots,b_i}(u+1)(e_i(u+1))\otimes F^{i}_{b_1,\ldots,b_i}(u+1)(f_i(u))\right)^m$$
$$-\Delta(f_i(u))\Delta(e_i(u+1)). \tag{4.38}$$

Proof: The full proof is presented only for $e_i(u)$, the outline of proofs for $f_i(u)$ and $h_i(u)$ being similar. The comultiplication in the Drinfel'd realization is constructed thanks to the isomorphism given in the theorem 3.1,

$$\Delta\left(e_i\left(u+\frac{i-2}{2}\right)\right)=\Delta(t(^{1\cdots i}_{1\cdots i})(u))^{-1}\Delta(t(^{1\cdots i-1\ \ i}_{1\cdots i-1\ \ i+1})(u)) \tag{4.39}$$

$$=\left(\sum_{b_1<\cdots<b_i} t(^{1\cdots i}_{b_1\cdots b_i})(u)\otimes t(^{b_1\cdots b_i}_{1\cdots i})(u)\right)^{-1}\sum_{a_1<\cdots<a_i} t(^{1\cdots i}_{a_1\cdots a_i})(u)\otimes t(^{a_1\cdots a_{i-1}\ \ a_i}_{1\cdots i-1\ \ i+1})(u) \tag{4.40}$$

$$=\sum_{m\leqslant 0}(-1)^m\left(\sum_{\substack{b_1<\cdots<b_i\\ b_i\neq i}}(t(^{1\cdots i}_{1\cdots i})(u))^{-1}t(^{1\cdots i}_{b_1\cdots b_i})(u)\otimes(t(^{1\cdots i}_{1\cdots i})(u))^{-1}t(^{b_1\cdots b_i}_{1\cdots i})(u)\right)^m$$

$$\times\sum_{a_1<\cdots<a_i}(t(^{1\cdots i}_{1\cdots i})(u))^{-1}t(^{1\cdots i}_{a_1\cdots\ a_i})(u)\otimes(t(^{1\cdots i}_{1\cdots i})(u))^{-1}t(^{a_1\cdots a_{i-1}\ \ a_i}_{1\cdots i-1\ \ i+1})(u). \tag{4.41}$$

The lemma 4.4 allows us to evaluate all the terms of Eq. (4.41), which proves (4.36). ■

B. Antipode and counit

As for the comultiplication, generalized adjoint actions must be introduced to express the antipode.

Definition 4.6: Let $1\leqslant i,\ j\leqslant n,\ 1\leqslant\alpha\leqslant n$. *X denotes an element of* $Y(\mathrm{sl}_n)$. *The generalized adjoint actions are defined by*

$${}^{\alpha}\mathcal{H}_{i,j}(u)(X)=\begin{cases}1 & \text{if } i>j,\\ X & \text{if } i=j,\\ X+{}^{\alpha}\mathcal{E}_{i,j}(u)({}^{\alpha}\mathcal{F}_{j,i}(u+1)(X)) & \text{otherwise,}\end{cases} \tag{4.42}$$

$$\mathcal{H}^{\alpha}_{i,j}(u)(X)=\begin{cases}1 & \text{if } i>j,\\ X & \text{if } i=j,\\ X+\mathcal{E}^{\alpha}_{i,j}(u+1)(\mathcal{F}^{\alpha}_{j,i}(u)(X)) & \text{otherwise.}\end{cases} \tag{4.43}$$

Let $1\leqslant m\leqslant n-1$ *and* $1\leqslant k_1<k_2<\cdots<k_m\leqslant n$. *Then, one has*

$${}^{\alpha}H^{\beta}_{k_1,k_2,\ldots,k_m}(u)(X)=\left(\overrightarrow{\prod_{1\leqslant p\leqslant m-1}}{}^{\alpha}\mathcal{H}^{\beta}_{p,k_p}(u)\right)({}^{\alpha}\mathcal{H}^{\beta}_{m+1,k_m}(u)(X)). \tag{4.44}$$

Similary, $\hat{E}_m(u)(X)$ *is defined as*

$$\mathcal{E}^1_{2,n}(u+1)(\mathcal{F}^1_{n-1,1}(u)(X)) \quad \text{if} \quad m=1,$$

$$\mathcal{E}^m_{1,n-m+1}(u+1)\mathcal{F}^m_{n-m,1}(u)\left(\overrightarrow{\prod_{2\leqslant p\leqslant m-1}}\mathcal{H}^m_{p,n-m+p}(u)\right)\mathcal{E}^m_{m+1,n}(u+1)\mathcal{F}^m_{n,m}(u)(X) \quad \text{otherwise,} \tag{4.45}$$

and $\hat{F}_m(u)(X)$ *as*

$${}^1\mathcal{E}_{1,n-1}(u)({}^1\mathcal{F}_{n,2}(u+1)(X)) \quad \text{if} \quad m=1,$$

$${}^m\mathcal{E}_{1,n-m}(u+1)^m\mathcal{F}_{n-m+1,1}(u)\left(\overrightarrow{\prod_{2\leqslant p\leqslant m-1}}{}^m\mathcal{H}_{p,n-m+p}(u)\right)^m\mathcal{E}_{m,n}(u+1)^m\mathcal{F}_{n,m+1}(u)(X)$$

otherwise. (4.46)

To find the image under the antipode, the following lemma is needed.

Lemma 4.7: For $1\leqslant i\leqslant n-1$ *and* $1\leqslant j\leqslant i+1$, *one has*

$$t\binom{j\ \ i+2\cdots n}{i+2\cdots n}(u)\left(t\binom{1\cdots n-i}{1\cdots n-i}(u)\right)^{-1}=H^{n-i}_{j,i+2,\ldots,n}\left(u+\frac{n-i-2}{2}\right)\left(g_{n-i}\left(u+\frac{n-i-2}{2}\right)\right), \quad (4.47)$$

$$\left(t\binom{1\cdots n-i}{1\cdots n-i}(u)\right)^{-1}t\binom{j\ \ i+2\cdots n}{i+2\cdots n}(u)={}^{n-i}H_{j,i+2,\ldots,n}\left(u+\frac{n-i-2}{2}\right)\left(\tilde{g}_{n-i}\left(u+\frac{n-i-2}{2}\right)\right) \quad (4.48)$$

and

$$t\binom{i\ \ i+2\cdots n}{i+1\ \ i+2\cdots n}(u)\left(t\binom{1\cdots n-i}{1\cdots n-i}(u)\right)^{-1}=\hat{E}_{n-i}\left(u+\frac{n-i-2}{2}\right)\left(e_{n-i}\left(u+\frac{n-i}{2}\right)\right), \quad (4.49)$$

$$\left(t\binom{1\cdots n-i}{1\cdots n-i}(u)\right)^{-1}t\binom{i+1\ \ i+2\cdots n}{i\ \ i+2\cdots n}(u)=\hat{F}_{n-i}\left(u+\frac{n-i-2}{2}\right)\left(f_{n-i}\left(u+\frac{n-i}{2}\right)\right). \quad (4.50)$$

Proof: This lemma is proven along the same lines as the lemma 4.4. ■

Theorem 4.8: *The antipode and the counit in the Drinfel'd basis are given by, for* $1\leqslant i\leqslant n-1$,

$$S\left(e_i\left(u+\frac{n}{2}\right)\right)=-\hat{E}_{n-i}(u)(e_{n-i}(u+1))\left(H^{n-i}_{i+1,\ldots,n}(u)(g_{n-i}(u))\right)^{-1}, \quad (4.51)$$

$$S\left(f_i\left(u+\frac{n}{2}\right)\right)=-\left({}^{n-i}H_{i+1,i+2,\ldots,n}(u)(\tilde{g}_{n-i}(u))\right)^{-1}\hat{F}_{n-i}(u)(f_{n-i}(u+1)), \quad (4.52)$$

$$S\left(h_i\left(u+\frac{n}{2}\right)\right)=\left({}^{n-i}H_{i+1,i+2,\ldots,n}(u)(\tilde{g}_{n-i}(u))\right)^{-1}{}^{n-i}H_{i,i+2,\ldots,n}(u)(\tilde{g}_{n-i}(u)) - S(e_{n-i}(u+1))S(f_{n-i}(u)), \quad (4.53)$$

and

$$\epsilon(e_i(u))=0,\quad \epsilon(f_i(u))=0,\quad \epsilon(h_i(u))=1. \quad (4.54)$$

Proof: The proof is given for $S(e_{n-i}(u))$. $S(h_{n-i}(u))$ and $S(f_{n-i}(u))$ are proven analogously,

$$S\left(e_i\left(u+\frac{i-2}{2}\right)\right)=S\left(t\binom{1\cdots i-1\ \ i}{1\cdots i-1\ \ i+1}(u)\right)S\left(\left(t\binom{1\cdots i}{1\cdots i}(u)\right)\right)^{-1}=t^*\binom{1\cdots i-1\ \ i}{1\cdots i-1\ \ i+1}(u)\left(t^*\binom{1\cdots i}{1\cdots i}(u)\right)^{-1} \quad (4.55)$$

$$=-t\binom{i\ \ i+2\cdots n}{i+1\ \ i+2\cdots n}(u-n+i)\left(t\binom{1\cdots n-i}{1\cdots n-i}(u-n+i)\right)^{-1}\left(t\binom{i+1\cdots n}{i+1\cdots n}(u-n+i)\right. \times\left.\left(t\binom{1\cdots n-i}{1\cdots n-i}(u-n+i)\right)^{-1}\right)^{-1} \quad \text{[Eq. (2.10) and corollary 3.3]}. \quad (4.56)$$

The terms in the relation (4.56) can be expressed thanks to the lemma 4.7, which proves the relation for $S(e_{n-i}(u))$.

The proof for the counit is obvious. ■

Remark: This Hopf structure can be extended to the double Yangian $DY(\mathrm{sl}_n)$. The image of the generators $x(u)\in Y(sl_n)\subset DY(\mathrm{sl}_n)$ under the comultiplication, the antipode or the counit are unchanged. For the dual generator $x^*(u)$ of $x(u)$, its image is given by the same formula where all the generators are replaced by their dual.

C. Examples

We give two examples to show explicit computations using the theorems 4.5 and 4.8. The comultiplication of $Y(\mathrm{sl}_2)$ is given by

$$\Delta(e_1(u))=\sum_{m=0}^{+\infty}(-e_1(u)\otimes f_1(u+1))^m(1\otimes e_1(u)+e_1(u)\otimes(h_1(u)+f_1(u+1)e_1(u))) \tag{4.57}$$

$$=1\otimes e_1(u)+\sum_{m=0}^{+\infty}(-1)^m e_1(u)^{m+1}\otimes f_1(u+1)^m h_1(u), \tag{4.58}$$

$$\Delta(f_1(u))=(f_1(u)\otimes 1+(h_1(u)+f_1(u+1)e_1(u))\otimes f_1(u))\sum_{m=0}^{+\infty}(-e_1(u+1)\otimes f_1(u))^m \tag{4.59}$$

$$=f_1(u)\otimes 1+\sum_{m=0}^{+\infty}(-1)^m h_1(u)e_1(u+1)^m\otimes f_1(u)^{m+1}, \tag{4.60}$$

$$\Delta(h_1(u))=(f_1(u)\otimes e_1(u+1)+(h_1(u)+f_1(u)e_1(u+1))\otimes(h_1(u)+f_1(u)e_1(u+1)))\times\sum_{m=0}^{+\infty}(-e_1(u+1)\otimes f_1(u))^m-\Delta(f_1(u))\Delta(e_1(u+1)) \tag{4.61}$$

$$=\sum_{m=0}^{+\infty}(-1)^m(m+1)h(u)\quad e_1(u+1)^m\otimes f_1(u+1)^m h(u). \tag{4.62}$$

The explicit forms (4.58), (4.60), and (4.62) allows us to show that the comultiplication, introduced in this paper, is the opposite of the comultiplication used by Molev.[4] Remark that the proof of the relation (4.62) from (4.61) is not obvious. A simpler way consists in using the form (3.3) instead of the form (3.5) in the proof of the theorem 4.5. Despite its simpler form, the generalization to sl_n of the form given by Molev does not seem possible.

The antipode and the counit of $Y(\mathrm{sl}_2)$ are given by

$$S(e_1(u+1))=-e_1(u+1)(h_1(u)+f_1(u)e_1(u+1))^{-1}, \tag{4.63}$$

$$S(f_1(u+1))=-(h_1(u)+f_1(u+1)e_1(u))^{-1}f_1(u+1), \tag{4.64}$$

$$S(h_1(u+1))=(h_1(u)+f_1(u+1)e_1(u))^{-1}-S(e_1(u+1))S(f_1(u)), \tag{4.65}$$

and

$$\epsilon(e_1(u))=0,\quad \epsilon(f_1(u))=0,\quad \text{and}\quad \epsilon(h_1(u))=1. \tag{4.66}$$

For $Y(\mathrm{sl}_3)$, the comultiplication in the Drinfel'd basis is given by

$$\Delta(e_1(u))=\sum_{m=0}^{+\infty}(-1)^m(e_1(u)\otimes f_1(u+1)-[e_2^0,e_1(u)]\otimes[f_2^0,f_1(u+1)])^m\times(1\otimes e_1(u)+e_1(u)\otimes(h_1(u)+f_1(u+1)e_1(u))-[e_2^0,e_1(u)]\otimes[f_2^0,h_1(u)+f_1(u+1)e_1(u)]), \tag{4.67}$$

$$\Delta(f_1(u))=(f_1(u)\otimes 1+(h_1(u)+f_1(u)e_1(u+1))\otimes f_1(u)-[e_2^0,h_1(u)+f_1(u)e_1(u+1)]\otimes[f_2^0,f_1(u)])\sum_{m=0}^{+\infty}(-1)^m(e_1(u+1)\otimes f_1(u)-[e_2^{(0)},e_1(u+1)]\otimes[f_2^{(0)},f_1(u)])^m, \tag{4.68}$$

$$\Delta(h_1(u))=(f_1(u)\otimes e_1(u)+(h_1(u)+f_1(u)e_1(u+1))\otimes(h_1(u)+f_1(u)e_1(u+1))-[e_2^{(0)},h_1(u)+f_1(u)e_1(u+1)]\otimes[f_2^{(0)},h_1(u)+f_1(u)e_1(u+1)])\sum_{m=0}^{+\infty}(-1)^m(e_1(u+1)\otimes f_1(u)-[e_2^{(0)},e_1(u+1)]\otimes[f_2^{(0)},f_1(u)])^m-\Delta(f_1(u))\Delta(e_1(u+1)), \tag{4.69}$$

$\Delta(e_2(u))$ [respectively, $\Delta(f_2(u))$, $\Delta(h_2(u))$] is obtained by exchanging the subscripts 1 and 2 in Eq. (4.67) [respectively, (4.68), (4.69)]. Of course, the antipode and the counit for $Y(\mathrm{sl}_3)$ can be computed thanks to theorem 4.8, however we leave it to the reader.

(Received 29 July 2003; accepted 30 September 2003)

The Lie symmetry analysis and the basic similarity reductions are performed for the Wu–Zhang equation, a $2+1$ dimensional nonlinear dispersive wave equation. Some new exact solutions generated from the similarity transformation are provided. They demonstrate some new three-dimensional features of a single solitary wave and two interacting solitary waves. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1629779]

I. INTRODUCTION

The $2+1$ dimensional nonlinear dispersive wave equation

$$u_t+uu_x+vu_y+w_x=0,$$

$$v_t+uv_x+vv_y+w_y=0, \tag{1}$$

$$w_t+(uw)_x+(vw)_y+\tfrac{1}{3}(u_{xxx}+u_{xyy}+v_{xxy}+v_{yyy})=0,$$

where (u,v) is the horizontal projection of the surface velocity of a water particle, w is the total water depth ($w-1$ being the wave elevation), is regarded as Wu–Zhang (WZ) equation by Ref. 1. The WZ equation is derived in Ref. 2 from the Euler equation with a perturbation scheme under the assumption that the amplitude of wave elevation is small and the wave is long compared with the water depth (scaled to be 1). The WZ equation can be used to model the three dimensional behavior of solitary waves on a uniform layer of water, such as oblique interaction, oblique reflection from a vertical wall and turning in a curved channel.

If the waves propagate in only one dimension, e.g., along y coordinate, then the WZ equation is reduced to the classical Boussinesq equation

$$v_t+vv_y+w_y=0,$$

$$w_t+(vw)_y+\tfrac{1}{3}v_{yyy}=0, \tag{2}$$

which is known to be integrable and equivalent to Broer–Kaup (BK) system[3,4] and a member of Ablowitz–Kaup–Newell–Segur (AKNS) system[5] that has a tri-Hamiltonian structure. Its exact bidirectional N-soliton solution has been provided by Ref. 5.

Reference 1 provides the Painlevé analysis of the WZ equation. It obtains some exact solutions by using the standard Weiss–Tabor–Carnevale Painlevé truncation expansion. However, the Lie symmetry analysis of the WZ equation is not available yet.

Since the WZ equation is a physical extension of the classical Boussinesq equation, it allows bidirectional soliton solution in any direction in the (x,y) plane. It might have an exact solution that can be used to describe obliquely interacting solitons. This paper is one of a series study towards a good understanding of the WZ equation.

We perform the Lie symmetry analysis in Sec. II, present the $1+1$ similarity reductions in Sec. III and provide a few new exact solutions of the WZ equation in Sec. IV. Finally we summarize the paper in Sec. V.

II. LIE POINT SYMMETRIES

In this section we perform Lie symmetry analysis for the $2+1$-dimensional system (1). Let us consider a one-parameter Lie group of infinitesimal transformation[6]

$$\begin{aligned} x&\to x+\epsilon X(x,y,t,u,v,w),\\ y&\to y+\epsilon Y(x,y,t,u,v,w),\\ t&\to t+\epsilon T(x,y,t,u,v,w),\\ u&\to u+\epsilon U(x,y,t,u,v,w),\\ v&\to v+\epsilon V(x,y,t,u,v,w),\\ w&\to w+\epsilon W(x,y,t,u,v,w) \end{aligned} \tag{3}$$

with a small parameter $\epsilon \ll 1$. The vector field associated with the above group of transformations can be written as

$$\underline{u}=X\frac{\partial}{\partial x}+Y\frac{\partial}{\partial y}+T\frac{\partial}{\partial t}+U\frac{\partial}{\partial u}+V\frac{\partial}{\partial v}+W\frac{\partial}{\partial w}. \tag{4}$$

An invariance of system (1) under transformation (3) leads to the expressions for the functions X, Y, T, U, V,W of the form (throughout this paper we use symbolic package MAPLE to perform all calculation)

$$\begin{aligned} X&=c_8xt+c_7x+c_6y+c_4t+c_1,\\ Y&=c_8yt+c_7y-c_6x+c_5t+c_2,\\ T&=c_8t^2+2c_7t+c_3,\\ U&=-(c_8ut+c_7u-c_6v-c_8x-c_4),\\ V&=-(c_8vt+c_7v+c_6u-c_8y-c_5),\\ W&=-(2c_8wt+2c_7w), \end{aligned} \tag{5}$$

where c_i, $i=1,\ldots,8$ are arbitrary constants. The presence of these arbitrary constants leads to a finite-dimensional Lie algebra of symmetries. A general element of this algebra is written as

$$\underline{v}=\underline{v}_1c_1+\underline{v}_2c_2+\underline{v}_3c_3+\underline{v}_4c_4+\underline{v}_5c_5+\underline{v}_6c_6+\underline{v}_7c_7+\underline{v}_8c_8, \tag{6}$$

where

$$\underline{v}_1=\frac{\partial}{\partial x},$$

$$\underline{v}_2=\frac{\partial}{\partial y},$$

$$\underline{v}_3=\frac{\partial}{\partial t},$$

$$\underline{v}_4=\frac{\partial}{\partial u}+t\frac{\partial}{\partial x},$$

$$\underline{v}_5=t\frac{\partial}{\partial y}+\frac{\partial}{\partial v},$$

$$\underline{v}_6=y\frac{\partial}{\partial x}-x\frac{\partial}{\partial y}-u\frac{\partial}{\partial v}+v\frac{\partial}{\partial u},$$

$$\underline{v}_7=x\frac{\partial}{\partial x}+y\frac{\partial}{\partial y}+2t\frac{\partial}{\partial t}-u\frac{\partial}{\partial u}-v\frac{\partial}{\partial v}-2w\frac{\partial}{\partial w},$$

$$\underline{v}_8=xt\frac{\partial}{\partial x}+yt\frac{\partial}{\partial y}+t^2\frac{\partial}{\partial t}+(y-vt)\frac{\partial}{\partial v}+(x-ut)\frac{\partial}{\partial u}-2wt\frac{\partial}{\partial w}, \tag{7}$$

construct a basis of the vector space. The associated Lie algebra among these vector fields becomes

	$\underline{v}_1$	$\underline{v}_2$	$\underline{v}_3$	$\underline{v}_4$	$\underline{v}_5$	$\underline{v}_6$	$\underline{v}_7$	$\underline{v}_8$
$\underline{v}_1$	0	0	0	0	0	$-\underline{v}_2$	$\underline{v}_1$	$\underline{v}_4$
$\underline{v}_2$		0	0	0	0	$\underline{v}_1$	$\underline{v}_2$	$\underline{v}_5$
$\underline{v}_3$			0	$\underline{v}_1$	$\underline{v}_2$	0	$2\underline{v}_3$	$\underline{v}_7$
$\underline{v}_4$				0	0	$-\underline{v}_5$	$-\underline{v}_4$	0
$\underline{v}_5$					0	$\underline{v}_4$	$-\underline{v}_5$	0
$\underline{v}_6$						0	0	0
$\underline{v}_7$							0	$2\underline{v}_8$
$\underline{v}_8$								0

where the entry in jth row and kth column represents the commutator $[v_j,v_k]$, and $\{\underline{v}_1,\underline{v}_2,\underline{v}_3\}$, $\{\underline{v}_4,\underline{v}_5\}$, $\{\underline{v}_7,\underline{v}_8\}$, $\{\underline{v}_1,\underline{v}_2,\underline{v}_4,\underline{v}_5,\underline{v}_6\}$ are some of the subalgebras.

We now consider a point transformation

$$G:(x,y,t,u,v,w)\mapsto(\xi,\eta,\zeta,P,Q,R). \tag{8}$$

From the transformation (1), we have the corresponding one-parameter group of symmetries of the WZ equation

$$
\begin{aligned}
&G_1:(x,y,t,u,v,w)\mapsto(x+\epsilon,y,t,u,v,w),\\
&G_2:(x,y,t,u,v,w)\mapsto(x,y+\epsilon,t,u,v,w),\\
&G_3:(x,y,t,u,v,w)\mapsto(x,y,t+\epsilon,u,v,w),\\
&G_4:(x,y,t,u,v,w)\mapsto(x+t\epsilon,y,t,u+\epsilon,v,w),\\
&G_5:(x,y,t,u,v,w)\mapsto(x,y+t\epsilon,t,u,v+\epsilon,w),\\
&G_6:(x,y,t,u,v,w)\mapsto(x\cos\epsilon+y\sin\epsilon,-x\sin\epsilon+y\cos\epsilon,t,u\cos\epsilon+v\sin\epsilon,-u\sin\epsilon\\
&\qquad +v\cos\epsilon,w),\\
&G_7:(x,y,t,u,v,w)\mapsto(xe^{\epsilon},ye^{\epsilon},te^{2\epsilon},ue^{-\epsilon},ve^{-\epsilon},we^{-2\epsilon}),\\
&G_8:(x,y,t,u,v,w)\mapsto\left(\frac{x}{1-t\epsilon},\frac{y}{1-t\epsilon},\frac{t}{1-t\epsilon},u(1-t\epsilon)+x\epsilon,v(1-t\epsilon)+y\epsilon,w(1-t\epsilon)^2\right).
\end{aligned}
\tag{9}
$$

We observe that G_1 and G_2 are space translations, G_3 is a time translations, G_4 and G_5 are Galilean boost, G_6 is a rotation, G_7 is a scaling for all variables with different ratios. G_8 is a time-dependent scaling. The entire symmetry group is obtained by composing one-dimensional subgroups G_i, $i=1,\ldots,8$. When G is an element of this group, if $u(x,y,t)$, $v(x,y,t)$, $w(x,y,t)$ is a solution of WZ equation, then $P(\xi,\eta,\zeta)$, $Q(\xi,\eta,\zeta)$, $R(\xi,\eta,\zeta)$ is also a solution of WZ equation.

III. 1+1 SIMILARITY REDUCTIONS

After determining the infinitesimal generators, the similarity variables can be found by solving the characteristic equations[6]

$$
\frac{\mathrm{d}x}{X}=\frac{\mathrm{d}y}{Y}=\frac{\mathrm{d}t}{T}=\frac{\mathrm{d}u}{U}=\frac{\mathrm{d}v}{V}=\frac{\mathrm{d}w}{W}. \tag{10}
$$

It is easy to know that the generator $\underline{v}_1$ has an invariance

$$
\xi=y,\quad \eta=t,\quad P=u,\quad Q=v,\quad R=w.
$$

Under this transformation, WZ equation is reduced to a system of PDE with two independent variables ξ and η and three dependent variables P, Q, and R. The reduced equation is WZ equation but with u, v, and w independent of x, i.e., $u_x=v_x=w_x=0$. In fact the set of two equations on v and w is identical to the system (2) and the other one is a linear equation on u

$$
u_t+vu_y=0, \tag{11}
$$

which can be solved with a method of characteristic line. Therefore one can obtain a solution of WZ equation (1) from a solution of the classical Boussinesq equation (2).

For the generator $\underline{v}_2$, we have a similar result except now the solution is independent of y.

For the generator $\underline{v}_3$, WZ equation is reduced to its steady case.

For the generator of Galilean transformation $\underline{v}_4=(\partial/\partial u)+t(\partial/\partial x)$, we have the following similarity variables:

$$
\xi=y,\quad \eta=t,\quad P=ut-x,\quad Q=v,\quad R=w. \tag{12}
$$

The reduced PDE becomes

$$P_\eta + QP_\xi = 0,$$

$$Q_\eta + QQ_\xi + R_\xi = 0,$$

$$R_\eta + \frac{R}{\eta} + Q_\xi R + QR_\xi + \frac{1}{3}Q_{\xi\xi\xi} = 0. \tag{13}$$

One may notice that the second and third equations are very closely related to the classical Boussinesq equation (2) except the extra term R/η.

The generator $\underline{v}_5$ has a similar result as $\underline{v}_4$.

For the rotation transformation $\underline{v}_6$, the similarity variables are

$$\xi = x^2 + y^2, \quad \eta = t, \quad P = -xv + yu, \quad Q = yv + xu, \quad R = w. \tag{14}$$

Then WZ equation is reduced to

$$P_\eta + 2QP_\xi = 0,$$

$$\xi Q_\eta + 2\xi^2 R_\xi + 2\xi QQ_\xi - (P^2 + Q^2) = 0,$$

$$R_\eta + 2QR_\xi + 2RQ_\xi + \tfrac{8}{3}Q_{\xi\xi} + \tfrac{8}{3}\xi Q_{\xi\xi\xi} = 0. \tag{15}$$

Of course one may choose another set of invariants to be the similarity variables and obtain a different reduced system. For example, if we take

$$\xi = x^2 + y^2, \quad \eta = t, \quad P = \frac{-xv + yu}{x^2 + y^2}, \quad Q = \frac{yv + xu}{x^2 + y^2}, \quad R = w, \tag{16}$$

then the reduced system reads

$$P_\eta - 2QP_\xi\xi - 2QP = 0,$$

$$Q_\eta + Q^2 + 2QQ_\xi\xi - P^2 + 2R_\xi = 0, \tag{17}$$

$$2RQ + 2QR_\xi\xi + 2RQ_\xi\xi + R_\eta + \tfrac{16}{3}Q_\xi + \tfrac{8}{3}Q_{\xi\xi\xi}\xi^2 + \tfrac{32}{3}Q_{\xi\xi}\xi = 0,$$

which is equivalent to the system (15).

For the scaling transformation generated by $\underline{v}_7$, the similarity variables are

$$\xi = \frac{x}{\sqrt{t}}, \quad \eta = \frac{y}{\sqrt{t}}, \quad P = u\sqrt{t}, \quad Q = v\sqrt{t}, \quad R = wt. \tag{18}$$

The WZ equation is reduced to a system with two independent variables but in a more complicated form

$$(\xi - 2P)P_\xi + (\eta - 2Q)P_\eta + P - 2R_\xi = 0,$$

$$(\xi - 2P)Q_\xi + (\eta - 2Q)Q_\eta + Q - 2R_\eta = 0, \tag{19}$$

$$6R(Q_\eta + P_\xi - 1) - 3(\eta - 2Q)R_\eta - 3(\xi - 2P)R_\xi + 2(P_{\xi\xi\xi} + P_{\eta\eta\xi} + Q_{\eta\eta\eta} + Q_{\eta\xi\xi}) = 0.$$

The similarity variables corresponding to $\underline{v}_8$ are

$$\xi=\frac{x}{t},\quad \eta=\frac{y}{t},\quad P=ut-\xi t,\quad Q=vt-\eta t,\quad R=wt^2. \tag{20}$$

The WZ equation is also reduced to its steady case.

We would like to point out that in this section we have only reported the $1+1$ similarity reduction generated by the single but different basic infinitesimal generators v_j. More $1+1$ reduced systems can be obtained by considering a proper linear combination of different basic generators. We may also implement the symmetry analysis and similarity reduction upon a $1+1$ reduced system and obtain a corresponding ODE system.

IV. SOME NEW EXACT SOLUTIONS

In this section, we present some new exact particular solutions of WZ system (1) obtained from the three kinds of reduction transformation studied in the last section.

A. Solutions from v_3 reduction

The system generated by v_3 is the steady WZ system. Here we are looking for a particular steady solution with a similarity variable $z=k_1x+k_2y$, where the two constants k_1 and k_2 are assumed to satisfy $k_1^2+k_2^2=1$ without a loss of generality. The velocity field (u,v) and the total wave depth w are assumed to be functions of z only. The WZ equation becomes a system of ODE

$$k_1uu'+k_2vu'+k_1w'=0, \tag{21}$$

$$k_1uv'+k_2vv'+k_2w'=0, \tag{22}$$

$$(k_1u+k_2v)w'+(k_1u'+k_2v')w+\tfrac{1}{3}(k_1u'''+k_2v''')=0. \tag{23}$$

Integrating the first two equations gives

$$v=\frac{k_2}{k_1}u+d_1,\quad w=-\frac{1}{2k_1^2}u^2-\frac{k_2}{k_1}d_1u+d_2+k_2^2d_1^2.$$

Substituting into Eq. (23) and integrating it twice yields a single equation for u,

$$u'^2=\frac{3}{4k_1^2}u^4+3\frac{k_2}{k_1}d_1u^3-3d_2u^2+d_3u+d_4,$$

where the four integration constants d_i, $i=1,2,3,4$ are determined by the boundary condition at infinity. For a set of d_i's with four real parameters, $\lambda_1>\lambda_2>\lambda_3>\lambda_4$,

$$d_1=-\frac{1}{4k_2}\sum_{i=1}^{4}\lambda_i,\quad d_2=-\frac{1}{4}\sum_{i,j=1,i<j}^{4}\lambda_i\lambda_j,\quad d_3=-\frac{3}{4}k_1\sum_{j=1}^{4}\frac{1}{\lambda_j}\lambda_1\lambda_2\lambda_3\lambda_4,$$

$$d_4=\tfrac{3}{4}k_1^2\lambda_1\lambda_2\lambda_3\lambda_4.$$

the ODE is written as

$$u'^2=\frac{3}{4k_1^2}(u-k_1\lambda_1)(u-k_1\lambda_2)(u-k_1\lambda_3)(u-k_1\lambda_4),$$

and the solution can be written in terms of a Jacobi elliptic function

$$u=k_1\left(\lambda_4+\frac{\Delta_{24}\Delta_{34}}{\Delta_{24}-\Delta_{23}\,\mathrm{sn}^2(s,m)}\right),\quad \text{or}\quad u=k_1\left(\lambda_2+\frac{\Delta_{24}\Delta_{12}}{\Delta_{24}-\Delta_{14}\,\mathrm{sn}^2(s,m)}\right),$$

$$v=\frac{k_2}{k_1}u-\frac{1}{4k_2}\sum_{i=1}^{4}\lambda_i, \tag{24}$$

$$w=-\frac{1}{2k_1^2}u^2+\frac{1}{4k_1}\sum_{i=1}^{4}\lambda_i u-\frac{1}{4}\sum_{i,j=1,i<j}^{4}\lambda_i\lambda_j+\frac{1}{16}\left(\sum_{i=1}^{4}\lambda_i\right)^2,$$

where

$$s=\frac{1}{4}\sqrt{3\Delta_{13}\Delta_{24}}(z-z_0),\quad m=\sqrt{\frac{\Delta_{14}\Delta_{23}}{\Delta_{13}\Delta_{24}}},\quad \Delta_{ij}=\lambda_i-\lambda_j.$$

For a particular set of integration constants with one parameter λ,

$$d_1=0,\quad d_2=1+\tfrac{1}{2}\lambda^2,\quad d_3=6k_1\lambda,\quad d_4=\tfrac{3}{4}k_1^2\lambda^4-3k_1^2\lambda^2, \tag{25}$$

the solution given by

$$u=k_1\left(\lambda-\frac{2(\lambda^2-1)}{\lambda+\cosh\sqrt{3(\lambda^2-1)}(z-z_0)}\right),\quad v=\frac{k_2}{k_1}u, \tag{26}$$

$$w=1+\frac{2(\lambda^2-1)(1+\lambda\cosh\sqrt{3(\lambda^2-1)}(z-z_0))}{(\lambda+\cosh\sqrt{3(\lambda^2-1)}(z-z_0))^2}, \tag{27}$$

describes a steady solitary wave on a uniform layer of water. For the same set of constants as (25), we have another solution

$$u=k_1\left(\lambda+\frac{2(1-\lambda^2)}{\lambda\pm\sin\sqrt{3(1-\lambda^2)}(z-z_0)}\right),\quad v=\frac{k_2}{k_1}u,$$

$$w=1-\frac{2(1-\lambda^2)(1\pm\lambda\sin\sqrt{3(1-\lambda^2)}(z-z_0))}{(\lambda\pm\sin\sqrt{3(1-\lambda^2)}(z-z_0))^2}, \tag{28}$$

which has a singularity in a finite domain.

With some other choices of the constants, we have more steady solutions listed below.

Case 1:

$$d_1=-\frac{1}{2k_2}(\lambda+\mu),\quad d_2=-\frac{1}{4}(\lambda^2+4\lambda\mu+\mu^2),$$

$$d_3=-\tfrac{3}{2}k_1\lambda\mu(\lambda+\mu),\quad d_4=\tfrac{3}{4}k_1^2\lambda^2\mu^2,$$

$$u=k_1\frac{\lambda-\mu\exp\left(\pm\frac{\sqrt{3}}{2}(\lambda-\mu)(z-z_0)\right)}{1-\exp\left(\pm\frac{\sqrt{3}}{2}(\lambda-\mu)(z-z_0)\right)},\quad v=\frac{k_2}{k_1}u-\frac{1}{2k_2}(\lambda+\mu), \tag{29}$$

$$w=-\frac{1}{8}(\lambda-\mu)^2\,\mathrm{csch}^2\frac{\sqrt{3}}{4}(\lambda-\mu)(z-z_0),$$

or

$$u=k_1\frac{\mu+\lambda\exp\left(\pm\frac{\sqrt{3}}{2}(\lambda-\mu)(z-z_0)\right)}{1+\exp\left(\pm\frac{\sqrt{3}}{2}(\lambda-\mu)(z-z_0)\right)},\quad v=\frac{k_2}{k_1}u-\frac{1}{2k_2}(\lambda+\mu),$$

$$w=\frac{1}{8}(\lambda-\mu)^2\,\mathrm{sech}^2\frac{\sqrt{3}}{4}(\lambda-\mu)(z-z_0). \tag{30}$$

Case 2:

$$d_1=-\frac{1}{k_2}(\lambda\mp1),\quad d_2=-\frac{3}{2}\lambda(\lambda\mp2),$$

$$d_3=-3k_1\lambda^2(\lambda\mp3),\quad d_4=\tfrac{3}{4}k_1^2\lambda^3(\lambda\mp4),$$

$$u=k_1\left(\lambda\pm\frac{4}{3(z-z_0)^2-1}\right),\quad v=\frac{k_2}{k_1}u-\frac{1}{k_2}(\lambda\mp1), \tag{31}$$

$$w=1-\frac{4(3(z-z_0)^2+1)}{(3(z-z_0)^2-1)^2}.$$

Case 3:

$$d_1=-\frac{\lambda}{k_2},\quad d_2=-\frac{3}{2}\lambda^2,\quad d_3=-3k_1\lambda^3,\quad d_4=\frac{3}{4}k_1^2\lambda^4,$$

$$u=k_1\left(\lambda\mp\frac{2}{\sqrt{3}(z-z_0)}\right),\quad v=\frac{k_2}{k_1}u-\frac{\lambda}{k_2},\quad w=\frac{-2}{3(z-z_0)^2}. \tag{32}$$

Case 4:

$$d_1=0,\quad d_2=\tfrac{1}{4}(\lambda^2-\mu^2),\quad d_3=0,\quad d_4=-\tfrac{3}{2}k_1^2\lambda^2\mu^2,$$

$$u=\frac{k_1\lambda}{\sqrt{1-\mathrm{sn}^2(s,m)}},\quad v=\frac{k_2}{k_1}u,\quad w=\frac{1}{4}(\lambda^2-\mu^2)-\frac{\lambda^2}{2(1-\mathrm{sn}^2(s,m))}, \tag{33}$$

$$s=\tfrac{1}{2}\sqrt{3(\lambda^2+\mu^2)}(z-z_0),\quad m^2=\frac{\mu^2}{\lambda^2+\mu^2}.$$

Case 5:

$$d_1=-\frac{1}{k_2}\mu,\quad d_2=-\frac{1}{4}(6\mu^2+\lambda^2),$$

$$d_3=-\tfrac{3}{2}k_1\mu(2\mu^2+\lambda^2),\quad d_4=\tfrac{3}{4}k_1^2\mu^2(\mu^2+\lambda^2),$$

$$u=k_1\left(\mu\mp\frac{\lambda}{\sinh\frac{\sqrt{3}}{2}\lambda(z-z_0)}\right),\quad v=\frac{k_2}{k_1}u-\frac{\mu}{k_2},\tag{34}$$

$$w=-\frac{\lambda^2}{4}\left(1+\frac{2}{\sinh^2\frac{\sqrt{3}}{2}\lambda(z-z_0)}\right).$$

Case 6:

$$d_1=0,\quad d_2=-\tfrac{1}{4}(\lambda^2+\mu^2),\quad d_3=0,\quad d_4=\tfrac{3}{4}k_1^2\lambda^2\mu^2,$$

$$u=k_1\lambda\frac{\mathrm{sn}(s,m)}{\mathrm{cn}(s,m)},\quad v=\frac{k_2}{k_1}u,\quad w=\frac{1}{4}(\lambda^2-\mu^2)-\frac{\lambda^2}{2\,\mathrm{cn}^2(s,m)},\tag{35}$$

$$s=\frac{\sqrt{3}}{2}\mu(z-z_0),\quad m^2=1-\frac{\lambda^2}{\mu^2}\quad(\lambda^2<\mu^2).$$

Case 7:

$$d_1=\frac{\lambda}{2k_2},\quad d_2=-\tfrac{1}{8}(3\lambda^2+b^2),\quad d_3=\tfrac{3}{8}k_1\lambda(\lambda^2+b^2),\quad d_4=\tfrac{3}{64}k_1^2(\lambda^2+b^2)^2,$$

$$u=-\frac{k_1}{2}\left(\lambda\mp b\tan\frac{\sqrt{3}}{4}b(z-z_0)\right),\quad v=\frac{k_2}{k_1}u+\frac{\lambda}{2k_2},\tag{36}$$

$$w=-\frac{1}{8}b^2\left(1+\tan^2\frac{\sqrt{3}}{4}b(z-z_0)\right).$$

These solutions are of mathematical interests, even though some of them are not physically meaningful for the water wave because the total water depth w either goes to zero at infinity or has a singularity in a finite domain.

B. Solutions from v_4 reduction

The last two equations in the reduced system (13) from the generator v_4 are closely related to the classical Boussinesq equation except the extra term R/η. Their relation is very similar to that of KdV and cKdV equations. In fact, with the following transformation

$$\bar{\xi}=\frac{\xi+d_1}{d_1\eta}+d_2,\quad \bar{\eta}=-\frac{1}{d_1^2\eta}+d_3,$$

$$\bar{P}=d_4P+d_5,\quad \bar{Q}=\left(Q-\frac{\xi+d_1}{\eta}\right)d_1\eta,\quad \bar{R}=Rd_1^2\eta^2\tag{37}$$

the system (13) is converted to

$$\overline{P}_{\overline{\eta}}+\overline{\overline{Q}\overline{P}_{\overline{\xi}}}=0,$$

$$\overline{Q}_{\overline{\eta}}+\overline{\overline{Q}\overline{Q}_{\overline{\xi}}}+\overline{R}_{\overline{\xi}}=0, \tag{38}$$

$$\overline{R}_{\overline{\eta}}+\overline{Q}_{\overline{\xi}}\overline{R}+\overline{\overline{Q}\overline{R}_{\overline{\xi}}}+\tfrac{1}{3}\overline{Q}_{\overline{\xi\xi\xi}}=0,$$

where the last two equations are the classical Boussinesq equation. We can make use of the property to construct new solutions of WZ equation. For example, starting with a single soliton solution of the classical Boussinesq equation

$$\overline{Q}=\frac{2\,(\lambda^2-1)}{\lambda+\cosh(\sqrt{3\,\lambda^2-3}\,(\overline{\xi}-\lambda\,\overline{\eta}))}, \tag{39}$$

$$\overline{R}=\frac{2\,(\lambda^2-1)[1+\lambda\,\cosh(\sqrt{3\,\lambda^2-3}(\overline{\xi}-\lambda\,\overline{\eta}))]}{[\lambda+\cosh(\sqrt{3\,\lambda^2-3}(\overline{\xi}-\lambda\,\overline{\eta}))]^2}+1, \tag{40}$$

we are able to obtain a particular solution of WZ equation

$$u=\frac{1}{d_4 t}(d_4 x+\overline{P}-d_5), \tag{41}$$

$$v=\frac{2(\lambda^2-1)}{d_1 t[\lambda+\cosh(\sqrt{3\,\lambda^2-3}\;\;s)]}+\frac{y+d_1}{t}, \tag{42}$$

$$w=\frac{2(\lambda^2-1)[1+\lambda\,\cosh(\sqrt{3\,\lambda^2-3}\;\;s)]}{d_1^2 t^2[\lambda+\cosh(\sqrt{3\,\lambda^2-3}\;\;s)]^2}+\frac{1}{d_1^2 t^2}, \tag{43}$$

where the phase function s is given by

$$s=\overline{\xi}-\lambda\,\overline{\eta}=\frac{1}{d_1 t}\left[y-d_1(\lambda d_3-d_2)t+d_1+\frac{\lambda}{d_1}\right]$$

and $\overline{P}$ is a solution of linear equation

$$\overline{P}_{\overline{\eta}}+\overline{\overline{Q}\overline{P}_{\overline{\xi}}}=0$$

with $\overline{Q}$ given by (39) and d_j, $j=1,\ldots,5$ are arbitrary constants but $d_1 d_4\neq 0$. The solution describes a single solitary wave that is uniform along x direction and travels along y direction. The wave travels with a speed $d_1(\lambda d_3-d_2)$. Since d_2 and d_3 are two free parameters, the solitary wave can be made still by choosing $d_2=\lambda d_3$. It is double-peaked when $\lambda>2$ just like the solution of the classical Boussinesq equation. Its amplitude of the total water depth for the case of $\lambda<2$ is $(2\lambda-1)/(d_1 t)^2$, which is singular at time $t=0$ and decreases as time goes on from 0 to $+\infty$, and its wavelength increases like $d_1 t$. For $t>0$, the mass loss under the solitary wave is due to the sinks at infinity. One may notice that the velocity $u\to\pm\infty$ as $x\to\pm\infty$ and $v\to\pm\infty$ as $y\to\pm\infty$. The solitary wave solution of the WZ equation has a three-dimensional feature that has not been presented before for other $2+1$ dimensional nonlinear dispersive wave equations.

We now start with the solution of two-soliton head-on collision of the classical Boussinesq equation[5]

$$\overline{Q}=\frac{2(\lambda_1+\lambda_2)(\lambda_2^2-\lambda_1^2-k_2^2\tanh^2\xi_2+k_1^2\tanh^2\xi_1)}{(k_2\tanh\xi_2-k_1\tanh\xi_1)^2-(\lambda_1+\lambda_2)^2}, \tag{44}$$

$$\overline{R}=\frac{1}{\sqrt{3}}\overline{Q}_{\overline{\xi}}+\frac{k_2\tanh\xi_2-k_1\tanh\xi_1-\lambda_1-\lambda_2}{k_2\tanh\xi_2-k_1\tanh\xi_1+\lambda_1+\lambda_2}\times\left[1+2\frac{(\lambda_1+\lambda_2)(k_1\tanh\xi_1-\lambda_1)(k_2\tanh\xi_2+\lambda_2)}{k_2\tanh\xi_2-k_1\tanh\xi_1+\lambda_1+\lambda_2}\right], \tag{45}$$

$$\xi_1=\frac{\sqrt{3}}{2}k_1(\overline{\xi}-\lambda_1\overline{\eta}),\quad \xi_2=\frac{\sqrt{3}}{2}k_2(\overline{\xi}+\lambda_2\overline{\eta}),\quad k_i=\sqrt{\lambda_i^2-1},\quad \lambda_i>1,\quad i=1,2,$$

and construct a new solution of the WZ equation

$$u=\frac{1}{d_4t}(d_4x+\overline{P}-d_5),\quad v=\frac{\overline{Q}}{d_1t}+\frac{y+d_1}{t},\quad w=\frac{\overline{R}}{d_1^2t^2}, \tag{46}$$

where $\overline{P}$ solves $\overline{P}_{\overline{\eta}}+\overline{QP}_{\overline{\xi}}=0$, $\overline{Q}$ and $\overline{R}$ are given by (44) and (45) with

$$\overline{\xi}=\frac{y+d_1}{d_1t}+d_2,\quad \overline{\eta}=-\frac{1}{d_1^2t}+d_3.$$

The two phase functions are

$$s_1=\overline{\xi}-\lambda_1\overline{\eta}=\frac{1}{d_1t}\left[y-d_1(\lambda_1d_3-d_2)t+d_1+\frac{\lambda_1}{d_1}\right],$$

$$s_2=\overline{\xi}+\lambda_2\overline{\eta}=\frac{1}{d_1t}\left[y-d_1(-\lambda_2d_3-d_2)t+d_1-\frac{\lambda_2}{d_1}\right].$$

The two wave speeds are

$$c_1=d_1(\lambda_1d_3-d_2),\quad c_2=d_1(-\lambda_2d_3-d_2).$$

If we pick $d_2=-\lambda_2d_3$, then $c_1=d_1d_3(\lambda_1+\lambda_2)$ and $c_2=0$, solitary wave 2 will stand still and solitary wave 1 will pass through solitary wave 2. Like the single solitary wave solution, the amplitude of the total water depth of both solitary waves decreases like $1/(d_1t)^2$, the wave length increases like d_1t for $t>0$. The mass loss under the two solitary waves is due to the sinks at infinity of both x and y directions.

Figure 1 shows the total water depth $w(y,t)$ from (46) for the interaction of two single-peak solitary waves. The parameters are chosen to ensure that the solitary wave 2 with higher amplitude stands still near the origin and solitary wave 1 with lower amplitude passes through the solitary wave 2 as time goes on. After the elastic collision, each one experiences a backward phase shift. The phase shift of solitary wave 2 is visible in Fig. 1 by comparing the lowerest dashed and solid lines. Figure 2 shows the same solution with λ_1 and λ_2 larger than 2, so that the two solitary waves are double peaked. The phase shift of solitary wave 2 is more visible because the two solitary waves have larger amplitude.

Similarly we can obtain a new exact solution of the WZ equation by using the multisoliton solution of the classical Boussinesq equation.[5]

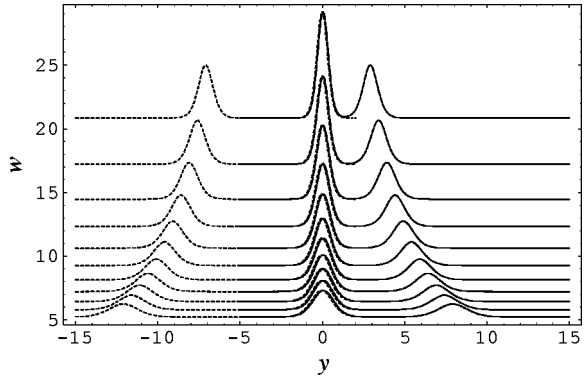

FIG. 1. The interaction of two single-peak solitary waves, $\lambda_1=1.1$, $\lambda_2=1.2$, $d_1=\sqrt{\lambda_2}$, $d_3=10$, $d_2=-\lambda_2 d_3$. The dashed lines are for the total water depth w as a function of space y for the time instances of $t=-0.4$, -0.38, -0.36, -0.34, -0.32, -0.3, -0.28, -0.26, -0.24, -0.22, and -0.2 bottom up. The solid lines are for the time instances of $t=0.2$, 0.22, 0.24, 0.26, 0.28, 0.3, 0.32, 0.34, 0.36, 0.38, 0.4 top down.

C. Solution from v_8 reduction

The system generated by v_8 is also the steady WZ system. With the steady solution (26) and (27) and the similarity variables (20), we obtain a new solution of the WZ equation

$$u=\frac{x}{t}+\frac{k_1}{t}\left(\lambda-\frac{2(\lambda^2-1)}{\lambda+\cosh\sqrt{3(\lambda^2-1)}\ \dfrac{k_1x+k_2y-z_0t}{t}}\right),\quad k_1^2+k_2^2=1,$$

$$v=\frac{y}{t}+\frac{k_2}{t}\left(\lambda-\frac{2(\lambda^2-1)}{\lambda+\cosh\sqrt{3(\lambda^2-1)}\ \dfrac{k_1x+k_2y-z_0t}{t}}\right),$$

$$w=\frac{1}{t^2}+\frac{2(\lambda^2-1)\left(1+\lambda\cosh\sqrt{3(\lambda^2-1)}\ \dfrac{k_1x+k_2y-z_0t}{t}\right)}{t^2\left(\lambda+\cosh\sqrt{3(\lambda^2-1)}\ \dfrac{k_1x+k_2y-z_0t}{t}\right)^2}.$$

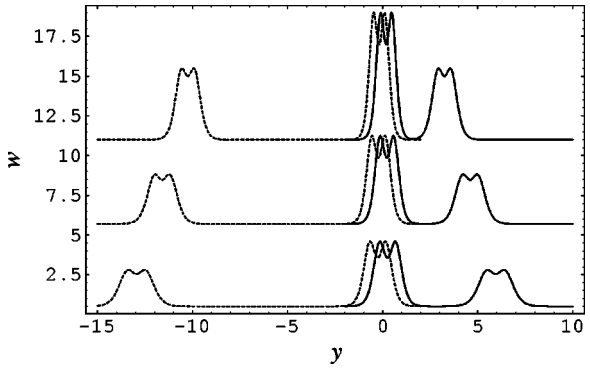

FIG. 2. The interaction of two double-peak solitary waves, $\lambda_1=3$, $\lambda_2=4$, $d_1=\sqrt{\lambda_2}$, $d_3=1$, $d_2=-\lambda_2 d_3$. The dashed lines are for the total water depth w as a function of space y for the time instances of $t=-0.7$, -0.6, and -0.5 bottom up. The solid lines are for the time instances of $t=0.5$, 0.6, and 0.7 top down.

The solution describes a solitary wave with an amplitude of the total water depth decreasing like $1/t^2$ and wavelength increasing like t. The wave speed of the solitary wave is z_0, which can be an arbitrary number.

V. SUMMARY

We have performed Lie symmetry analysis for the Wu–Zhang (WZ) equation and found its algebraic structure. The WZ equation is shown to have a finite dimension of Lie algebra, which means that the equation is less integrable than other integrable $2+1$ dimensional system, such as Kadomtsev–Petviashvili (KP) equation, Davey–Stewartson (DS) equation, Nizhnik–Novikov–Veselov (NNV) equation and $2+1$ dimensional sine-Gorden (sG) system,[7–14] which have infinite dimension of Lie algebra. The result agrees with that from Painlevé analysis.[1]

We have also obtained some new exact solutions of WZ equation by using the similarity transformation approach. They are of mathematical interest even though most of them are not physically meaningful. The solution demonstrate that a solitary wave could travel with arbitrary speed, its amplitude decreases and wave-length increases with time, and solitary waves with any kind of amplitudes could take over each other. These new features are due to the velocity sinks at infinity in both x and y directions. The three-dimensional feature of solitary waves seems to be a new phenomenon to us.

Since the WZ equation has a rotation symmetry, it admits a solitary wave solution along any direction in (x,y) plane. Two such solitary waves on two different directions could have an oblique interaction. The WZ equation can be used to model the process, but the question remains open whether the obliquely interacting solitary wave solution can be written in a closed-form. This is left for further research.

(Received 11 March 2003; accepted 30 September 2003)

We construct the so-called theta vectors on noncommutative T^4, which correspond to the theta functions on commutative tori with complex structures. Following the method of Dieng and Schwarz, we first construct holomorphic connections and then find the functions satisfying the holomorphic conditions, the theta vectors. The holomorphic structure in the noncommutative T^4 case is given by a 2×2 complex matrix, and the consistency requires its off-diagonal elements to be the same. We also construct the tensor product of these functions satisfying the consistency requirement. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1629778]

I. INTRODUCTION

Classical theta functions have played an important role in the string loop calculation.[1,2] Recently, noncommutative geometry[3] became an important ingredient of string/M theory (for instance, see Ref. 4) starting with the work of Ref. 5.

Along this direction, the noncommutative torus[6,7] and its varieties,[8–11] and physics on noncommutative $\mathbb{R}^4$ (Refs. 12–14) have been studied intensively. However, noncommutative tori with complex structures have been rarely studied.[15–17] Noncommutative geometry with complex structures has been also studied recently with the algebraic geometry approach for Calabi–Yau three folds,[18–20] and for K3 surfaces.[21]

Classical theta functions can be regarded as state functions over commutative tori with complex structures. The noncommutative generalization of this has been initiated in mathematics in the quantized theta function approach by Manin,[15] and with the so-called theta vectors by Schwarz.[16] In the physics literature, this has appeared in the context of noncommutative solitons[22–24] but mostly in the so-called integral torus case. Recently, Dieng and Schwarz[17] have computed the theta vectors and their tensor products on noncommutative T^2 explicitly without any restriction.

In this paper, we follow the method of Dieng and Schwarz and calculate the theta vectors and their tensor products in the case of noncommutative T^4. In Sec. II, we construct modules on the noncommutative four torus. In Sec. III, we deal with connections with complex structures. In Sec. IV, we deal with tensor product of these modules. In Sec. V, we conclude with a discussion.

II. MODULES ON NONCOMMUTATIVE T^4

In this section, we construct the modules on noncommutative T^4 following the method of Rieffel.[7]

Recall that T^d_θ is the deformed algebra of the algebra of smooth functions on the torus T^d with the deformation parameter θ, which is a real $d\times d$ anti-symmetric matrix. This algebra is generated by operators $U_1,\ldots,U_d$ obeying the following relations:

a)Electronic mail: hikim@knu.ac.kr
b)Electronic mail: cylee@sejong.ac.kr

$$U_iU_j=e^{2\pi i\theta_{ij}}U_jU_i \quad \text{and} \quad U_i^*U_i=U_iU_i^*=1, \quad i,j=1,\ldots,d.$$

The above relations define the presentation of the involutive algebra,

$$\mathcal{A}_\theta^d=\left\{\sum a_{i_1\cdots i_d}U_1^{i_1}\cdots U_d^{i_d}\middle| a=(a_{i_1\cdots i_d})\in\mathcal{S}(\mathbb{Z}^d)\right\},$$

where $\mathcal{S}(\mathbb{Z}^d)$ is the Schwartz space of sequences with rapid decay.

Every projective module over a smooth algebra $\mathcal{A}_\theta^d$ can be represented by a direct sum of modules of the form $\mathcal{S}(\mathbb{R}^p\times\mathbb{Z}^q\times F)$, the linear space of Schwartz functions on $\mathbb{R}^p\times\mathbb{Z}^q\times F$, where $2p+q=d$ and F is a finite Abelian group. The module action is specified by operators on $\mathcal{S}(\mathbb{R}^p\times\mathbb{Z}^q\times F)$ and the commutation relation of these operators should be matched with that of elements in $\mathcal{A}_\theta^d$.

Recall that there is the dual action of the torus group T^d on $\mathcal{A}_\theta^d$ which gives a Lie group homomorphism of T^d into the group of automorphisms of $\mathcal{A}_\theta^d$. Its infinitesimal form generates a homomorphism of Lie algebra L of T^d into Lie algebra of derivations of $\mathcal{A}_\theta^d$. Note that the Lie algebra L is Abelian and is isomorphic to $\mathbb{R}^d$. Let $\delta: L\to\mathrm{Der}(\mathcal{A}_\theta^d)$ be the homomorphism. For each $X\in L$, $\delta(X):=\delta_X$ is a derivation i.e., for $u,v\in\mathcal{A}_\theta^d$,

$$\delta_X(uv)=\delta_X(u)v+u\delta_X(v). \tag{1}$$

Derivations corresponding to the generators $\{e_1,\ldots,e_d\}$ of L will be denoted by $\delta_1,\ldots,\delta_d$. For the generators U_i's of T_θ^d, it has the following property:

$$\delta_i(U_j)=2\pi i\delta_{ij}U_j. \tag{2}$$

If E is a projective $\mathcal{A}_\theta^d$-module, a connection ∇ on E is a linear map from E to $E\otimes L^*$ such that for all $X\in L$,

$$\nabla_X(\xi u)=(\nabla_X\xi)u+\xi\delta_X(u), \quad \xi\in E, \ u\in\mathcal{A}_\theta^d. \tag{3}$$

It is easy to see that

$$[\nabla_i,U_j]=2\pi i\delta_{ij}U_j. \tag{4}$$

We now consider the endomorphisms algebra of a module over $\mathcal{A}_\theta^d$. Let Λ be a lattice in $G=M\times\hat{M}$, where $M=\mathbb{R}^p\times\mathbb{Z}^q\times F$ and $\hat{M}$ is its dual. Let Φ be an embedding map such that Λ is the image of $\mathbb{Z}^d$ under the map Φ. This determines a projective module which will be denoted by E_Λ.[7] The dual lattice of Λ can be defined as

$$\Lambda^\perp:=\{(n,\hat{t})\in M\times\hat{M}\,|\,\theta((m,\hat{s}),(n,\hat{t}))=\langle m,\hat{t}\rangle-\langle n,\hat{s}\rangle\in\mathbb{Z}, \quad \text{for all } (m,\hat{s})\in\Lambda\}, \tag{5}$$

since in the Heisenberg representation the operators are defined by

$$\mathcal{U}_{(m,\hat{s})}f(r)=e^{2\pi i\langle r,\hat{s}\rangle}f(r+m), \tag{6}$$

for $f\in E_\Lambda$, $r\in M$. Namely, the operators defined in the dual lattice, $\mathcal{U}_{(n,\hat{t})}$ for $(n,\hat{t})\in\Lambda^\perp$, commute with all the operators defined in the original lattice, $\mathcal{U}_{(m,\hat{s})}$ for $(m,\hat{s})\in\Lambda$.

It is known that the algebra of endomorphisms on E_Λ, denoted by $\mathrm{End}_{\mathcal{A}_\theta}(E_\Lambda)$, is a C^*-algebra obtained by C^*-completion of the space spanned by operators $\mathcal{U}_{(n,\hat{t})}$, $(n,\hat{t})\in\Lambda^\perp$. The algebra $\mathrm{End}_{\mathcal{A}_\theta}(E_\Lambda)$ can be identified with a noncommutative torus $\mathcal{A}_{\tilde{\theta}}$, i.e., $\mathcal{A}_{\tilde{\theta}}$ is Morita equivalent to $\mathcal{A}_\theta$.[7] Recall that a C^*-algebra A is said to be Morita equivalent to A' if $A'\cong\mathrm{End}_A(E)$ for some finite projective module E. In general, a noncommutative torus $\mathcal{A}_{\tilde{\theta}}$ is Morita equivalent to $\mathcal{A}_\theta$ if θ and $\tilde{\theta}$ are related by $\tilde{\theta}=(A\theta+B)(C\theta+D)^{-1}$, where $\left(\begin{smallmatrix}A & B\\ C & D\end{smallmatrix}\right)\in\mathrm{SO}(d,d|\mathbb{Z})$.[25]

In this paper, we consider a projective module of the form $\mathcal{S}(\mathbb{R}^p\times\mathbb{Z}^q)\otimes\mathcal{S}(F)$ with $p=2$, $q=0$.

For the real part, we choose our embedding map as

$$\Phi_{\text{inf}}=\begin{pmatrix} \theta_1+\dfrac{n_1}{m_1} & 0 & 0 & 0 \\ 0 & 0 & \theta_2+\dfrac{n_2}{m_2} & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}\equiv(x_{ij}), \tag{7}$$

then using the previous expression for the Heisenberg representation with $s_1,s_2\in\mathbb{R}$,

$$(V_if)(s_1,s_2)=(V_{e_i}f)(s_1,s_2):=\exp(2\pi i(s_1x_{3i}+s_2x_{4i}))f(s_1+x_{1i},s_2+x_{2i}),$$

we get

$$(V_1f)(s_1,s_2)=f\left(s_1+\theta_1+\frac{n_1}{m_1},s_2\right),$$

$$(V_2f)(s_1,s_2)=\exp(2\pi is_1)f(s_1,s_2),$$

$$(V_3f)(s_1,s_2)=f\left(s_1,s_2+\theta_2+\frac{n_2}{m_2}\right),$$

$$(V_4f)(s_1,s_2)=\exp(2\pi is_2)f(s_1,s_2).$$

For the finite part, let $F=\mathbb{Z}_{m_1}\times\mathbb{Z}_{m_2}$, where $\mathbb{Z}_{m_i}=\mathbb{Z}/m_i\mathbb{Z}$, $(i=1,2)$ and consider the space $\mathbb{C}^{m_1}\otimes\mathbb{C}^{m_2}$ as the space of functions on $C(\mathbb{Z}_{m_1}\times\mathbb{Z}_{m_2})$. For all $m_i\in\mathbb{Z}$ and $n_i\in\mathbb{Z}/m_i\mathbb{Z}$ such that m_i and n_i are relatively prime. We define the operators W_i on $C(\mathbb{Z}_{m_1}\times\mathbb{Z}_{m_2})$ corresponding to our embedding map,

$$\Phi_{\text{fin}}=\begin{pmatrix} -1 & 0 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & \dfrac{n_1}{m_1} & 0 & 0 \\ 0 & 0 & 0 & \dfrac{n_2}{m_2} \end{pmatrix}, \tag{8}$$

with $k_i\in\mathbb{Z}_{m_i}$ $(i=1,2)$ as follows:

$$(W_1f)(k_1,k_2)=f(k_1-1,k_2),$$

$$(W_2f)(k_1,k_2)=\exp\left(2\pi i\frac{n_1k_1}{m_1}\right)f(k_1,k_2),$$

$$(W_3f)(k_1,k_2)=f(k_1,k_2-1),$$

$$(W_4f)(k_1,k_2)=\exp\left(2\pi i\frac{n_2k_2}{m_2}\right)f(k_1,k_2).$$

Thus, we define operators $U_i = V_i \otimes W_i$ acting on the space $E_T := \mathcal{S}(\mathbb{R}^2) \otimes \mathbb{C}^{m_1} \otimes \mathbb{C}^{m_2}$ as

$$\begin{aligned}
(U_1 f)(s_1,s_2,k_1,k_2) &= f\left(s_1 + \theta_1 + \frac{n_1}{m_1}, s_2, k_1 - 1, k_2\right), \\
(U_2 f)(s_1,s_2,k_1,k_2) &= e^{2\pi i (s_1 + n_1 k_1/m_1)} f(s_1,s_2,k_1,k_2), \\
(U_3 f)(s_1,s_2,k_1,k_2) &= f\left(s_1, s_2 + \theta_2 + \frac{n_2}{m_2}, k_1, k_2 - 1\right), \\
(U_4 f)(s_1,s_2,k_1,k_2) &= e^{2\pi i (s_2 + n_2 k_2/m_2)} f(s_1,s_2,k_1,k_2).
\end{aligned} \tag{9}$$

One can now see that they satisfy

$$\begin{aligned}
U_2 U_1 &= e^{2\pi i \theta_1} U_1 U_2, \\
U_4 U_3 &= e^{2\pi i \theta_2} U_3 U_4,
\end{aligned} \tag{10}$$

and otherwise $U_i U_j = U_j U_i$.

In order to find operators which commute with the U_i's, we recall the definition of the dual lattice $\Lambda^\perp$:

$$\langle m, \hat{t} \rangle - \langle n, \hat{s} \rangle \in \mathbb{Z}, \quad \text{for all } (m,\hat{s}) \in \Lambda \text{ and } (n,\hat{t}) \in \Lambda^\perp.$$

If we express the embedding map Φ as

$$\Phi = \begin{pmatrix} m & \cdots \\ \hat{s} & \cdots \end{pmatrix}, \tag{11}$$

and the embedding map Ψ for the dual lattice as

$$\Psi = \begin{pmatrix} n & \cdots \\ \hat{t} & \cdots \end{pmatrix}, \tag{12}$$

then the duality condition above can be written as

$$\langle m, \hat{t} \rangle - \langle n, \hat{s} \rangle = \Phi^t J \Psi \in \mathbb{Z},$$

where

$$J = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{pmatrix}. \tag{13}$$

Hence, we obtain the relation between the two embedding maps:

$$\Psi = -J \Phi^{-t} \mathbb{Z}. \tag{14}$$

Using the above relation, the dual map for the real part is now given by

$$\Psi_{\text{inf}}=\begin{pmatrix} 0 & \frac{1}{m_1} & 0 & 0 \\ 0 & 0 & 0 & \frac{1}{m_2} \\ \frac{1}{m_1\theta_1+n_1} & 0 & 0 & 0 \\ 0 & 0 & \frac{1}{m_2\theta_2+n_2} & 0 \end{pmatrix}, \tag{15}$$

and the finite part is given by

$$\Psi_{\text{fin}}=\begin{pmatrix} 0 & -a_1 & 0 & 0 \\ 0 & 0 & 0 & -a_2 \\ \frac{1}{m_1} & 0 & 0 & 0 \\ 0 & 0 & \frac{1}{m_2} & 0 \end{pmatrix}. \tag{16}$$

Here, $a_i \in \mathbb{Z}$ and $a_i n_i - b_i m_i = 1$ for some $b_i \in \mathbb{Z}$ $(i=1,2)$.

The generators of operators corresponding to the embedding map for the dual lattice are thus defined by

$$\begin{aligned} (Z_1 f)(s_1,s_2,k_1,k_2) &= e^{2\pi i(s_1/(m_1\theta_1+n_1)+k_1/m_1)} f(s_1,s_2,k_1,k_2), \\ (Z_2 f)(s_1,s_2,k_1,k_2) &= f\left(s_1+\frac{1}{m_1},s_2,k_1-a_1,k_2\right), \\ (Z_3 f)(s_1,s_2,k_1,k_2) &= e^{2\pi i(s_2/(m_2\theta_2+n_2)+k_2/m_2)} f(s_1,s_2,k_1,k_2), \\ (Z_4 f)(s_1,s_2,k_1,k_2) &= f\left(s_1,s_2+\frac{1}{m_2},k_1,k_2-a_2\right). \end{aligned} \tag{17}$$

Here,

$$\begin{aligned} Z_1 Z_2 &= e^{2\pi i\theta_1'} Z_2 Z_1, \\ Z_3 Z_4 &= e^{2\pi i\theta_2'} Z_4 Z_3, \end{aligned} \tag{18}$$

where

$$\theta_i' = \frac{a_i\theta_i+b_i}{m_i\theta_i+n_i}, \quad i=1,2, \tag{19}$$

and otherwise $Z_i Z_j = Z_j Z_i$. One can check that the Z_i's commute with the U_i's, i.e., $U_i Z_j = Z_j U_i$.

III. CONNECTIONS WITH COMPLEX STRUCTURES

In the previous section, connections on a projective $\mathcal{A}_\theta^d$-module satisfies the condition (4)

$$[\nabla_i, U_j] = 2\pi i \delta_{ij} U_j.$$

A connection ∇_i is called a constant curvature connection if $[\nabla_i,\nabla_j]=iF_{ij}$ for constants F_{ij}. This condition is satisfied if ∇_i is expressed as $\nabla_i=\partial_i-(i/2)F_{ij}s_j$ where ∂_i is a derivative with respect to s_i. Note that the condition (4) can be regarded as a compactification condition. This can be seen by considering an operator $\overline{X_i}=-\nabla_i$ with which the condition is expressed as

$$U_j\overline{X_i}U_j^{-1}=\overline{X_i}+2\pi i\delta_{ij}, \tag{20}$$

and this relation is comparable to a compactification with radius R_i, $U_jX_iU_j^{-1}=X_i+2\pi\delta_{ij}R_i$.

We thus let

$$(\overline{X_i}f)(s_1,s_2,k_1,k_2)=2\pi iA_{i1}s_1f(s_1,s_2,k_1,k_2)+2\pi iA_{i2}s_2f(s_1,s_2,k_1,k_2)$$
$$-A_{i3}\frac{\partial f(s_1,s_2,k_1,k_2)}{\partial s_1}-A_{i4}\frac{\partial f(s_1,s_2,k_1,k_2)}{\partial s_2},$$

where $A_{ik}\in\mathbb{R}$ are constants. If we denote the embedding maps as $\Phi_{\text{inf}}\equiv(x_{ij})$ and $\Phi_{\text{fin}}\equiv(y_{ij})$, then U_i action is expressed as

$$(U_if)(s_1,s_2,k_1,k_2)=e^{2\pi i(s_1x_{3i}+s_2x_{4i}+k_1y_{3i}+k_2y_{4i})}f(s_1+x_{1i},s_2+x_{2i},k_1+y_{1i},k_2+y_{2i}).$$

The condition (20) is satisfied if

$$x_{1i}x_{3i}+x_{2i}x_{4i}+y_{1i}y_{3i}+y_{2i}y_{4i}=0, \tag{21}$$

and

$$A_{ik}=(\Phi_{\text{inf}}^{-1})_{ik}. \tag{22}$$

The embedding maps (7), (8) satisfy the condition (21), and the condition (22) gives

$$(A_{ik})=\begin{pmatrix} \dfrac{1}{\theta_1+\dfrac{n_1}{m_1}} & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & \dfrac{1}{\theta_2+\dfrac{n_2}{m_2}} & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}.$$

Therefore the following operators specify a constant curvature connection of right T^4_θ-module $E_{N,M}$:

$$\nabla_1=-\frac{2\pi is_1}{\theta_1+\dfrac{n_1}{m_1}},$$

$$\nabla_2=\frac{\partial}{\partial s_1},$$

$$\nabla_3 = -\frac{2\pi i s_2}{\theta_2 + \frac{n_2}{m_2}},$$

$$\nabla_4 = \frac{\partial}{\partial s_2}. \tag{23}$$

In general, a constant curvature connection can be obtained by adding some constants: $\nabla_i \to \nabla_i + d_i$, $i=1,\ldots,4$, where $d_i \in \mathbb{R}$ are constants.

A complex structure on the module $E_{N,M}$ can be introduced by fixing a $\overline{\partial}$-connection,

$$\overline{\nabla_1} = \lambda_{11}\nabla_1 + \lambda_{12}\nabla_2 + \lambda_{13}\nabla_3 + \lambda_{14}\nabla_4,$$

$$\overline{\nabla_2} = \lambda_{21}\nabla_1 + \lambda_{22}\nabla_2 + \lambda_{23}\nabla_3 + \lambda_{24}\nabla_4,$$

where $\lambda_{ij} \in \mathbb{C}$. Choosing an appropriate basis such that (λ_{ij}) becomes

$$\begin{pmatrix} \tau_{11} & 1 & \tau_{12} & 0 \\ \tau_{21} & 0 & \tau_{22} & 1 \end{pmatrix} = \begin{pmatrix} \lambda_{12} & \lambda_{14} \\ \lambda_{22} & \lambda_{24} \end{pmatrix}^{-1} \begin{pmatrix} \lambda_{11} & \lambda_{12} & \lambda_{13} & \lambda_{14} \\ \lambda_{21} & \lambda_{22} & \lambda_{23} & \lambda_{24} \end{pmatrix},$$

the (2×2) matrix $\left(\begin{smallmatrix} \tau_{11} & \tau_{12} \\ \tau_{21} & \tau_{22} \end{smallmatrix}\right)$, $\tau_{ij} \in \mathbb{C}$ represents the complex structure of the T^4_θ-module and 1–1 corresponds to the complex structure on T^4_θ via the $\overline{\partial}$-derivative, $\overline{\delta_i} = \Sigma_j \lambda_{ij}\delta_j$ where δ_j is defined by (2).[16]

Now we consider holomorphic vectors in T^4_θ-module. A vector $\Theta \in E_{N,M}$ is called holomorphic[16] if it satisfies

$$(\overline{\nabla_i} - c_i)\Theta = 0, \quad \text{for } i=1,2, \tag{24}$$

where $c_i \in \mathbb{C}$ are constants. The above holomorphic condition for $f \in E_{N,M}$ now takes the form

$$\begin{aligned} \left(\frac{2\pi i \tau_{11}}{\theta_1 + \frac{n_1}{m_1}} s_1 + \frac{2\pi i \tau_{12}}{\theta_2 + \frac{n_2}{m_2}} s_2 + c_1 \right) f &= \frac{\partial f}{\partial s_1}, \\ \left(\frac{2\pi i \tau_{21}}{\theta_1 + \frac{n_1}{m_1}} s_1 + \frac{2\pi i \tau_{22}}{\theta_2 + \frac{n_2}{m_2}} s_2 + c_2 \right) f &= \frac{\partial f}{\partial s_2}. \end{aligned} \tag{25}$$

In order for the two equations in (25) to be consistent τ_{ij} should satisfy

$$\frac{\tau_{12}}{\theta_2 + \frac{n_2}{m_2}} = \frac{\tau_{21}}{\theta_1 + \frac{n_1}{m_1}}. \tag{26}$$

If $\mathrm{Re}\,\Omega < 0$, Eq. (25) has $m_1 \times m_2$ linearly independent solutions, the so-called theta vectors[16,17] on noncommutative T^4,

$$f_{(\alpha_1,\alpha_2)}(s_1,s_2,k_1,k_2) = \exp\left[\frac{1}{2} S^t \Omega S + C^t S\right] \delta^{k_1}_{\alpha_1} \delta^{k_2}_{\alpha_2}, \tag{27}$$

where $C = \left(\begin{smallmatrix} c_1 \\ c_2 \end{smallmatrix}\right)$, $S = \left(\begin{smallmatrix} s_1 \\ s_2 \end{smallmatrix}\right)$, $c_i \in \mathbb{C}$, $s_i \in \mathbb{R}$, $k_i \in \mathbb{Z}_{m_i}$ $(i=1,2)$, and

$$\Omega=\begin{pmatrix} \dfrac{2\pi i\tau_{11}}{\theta_1+\dfrac{n_1}{m_1}} & \dfrac{2\pi i\tau_{12}}{\theta_2+\dfrac{n_2}{m_2}} \\ \dfrac{2\pi i\tau_{21}}{\theta_1+\dfrac{n_1}{m_1}} & \dfrac{2\pi i\tau_{22}}{\theta_2+\dfrac{n_2}{m_2}} \end{pmatrix}.$$

IV. TENSOR PRODUCT

In this section we consider a tensor product of two bimodules. The tensor product of a (C,Y)-bimodule E and a (Y,D)-bimodule E' over Y results in a (C,D)-bimodule F for algebras C,Y,D;

$$_CE_Y\otimes_YE'_D={}_CF_D,$$

where the tensor product over Y is obtained by identifying $ey\otimes e'\sim e\otimes ye'$ for $y\in Y$, $e\in E,e'\in E'$. Note that in this identification, E behaves as a right Y-module and E' behaves as a left Y-module. Thus, we will denote $E_{N,M}$ as a right T^4_θ-module and $E'_{K,L}$ as a left T^4_θ-module. Here, we recall that $T^4_{\tilde\theta}$ is Morita equivalent to T^4_θ if θ and $\tilde\theta$ are related by $\tilde\theta=(A\theta+B)(M\theta+N)^{-1}$ where $\left(\begin{smallmatrix}A & B\\ M & N\end{smallmatrix}\right)\in \mathrm{SO}(4,4|\mathbb{Z})$, and $T^4_{\tilde\theta}\cong \mathrm{End}_{T^4_\theta}(E)$ for some finite projective module E. In this notation, a right module $E_{N,M}$ is identified with a left module $E'_{A,M}$. Let us calculate the tensor product $E_{N,M}\otimes_{T^4_\theta}E'_{K,L}$ which forms a vector space $S(\mathbb{R}\times\mathbb{Z}_{n_1l_1+m_1k_1}\times\mathbb{Z}_{n_2l_2+m_2k_2})$, when each N,M,K,L is reducible into two blocks represented by the values $N\sim(n_1,n_2)$, $M\sim(m_1,m_2)$, $K\sim(k_1,k_2)$, $L\sim(l_1,l_2)$.[26] For $f(s_1,s_2,\mu_1,\mu_2)\in E_{N,M}$, and $g(t_1,t_2,\nu_1,\nu_2)\in E'_{K,L}$ where $s_i,t_i\in\mathbb{R}$, $\mu_i\in\mathbb{Z}_{m_i}$, $\nu_i\in\mathbb{Z}_{l_i}(i=1,2)$ the actions of $U_i\in T^4_\theta$ and $Z_i\in T^4_{\tilde\theta}$ are given as follows.

The right U_i actions on $E_{N,M}$ are defined as

$$\begin{aligned}
(U_1f)(s_1,s_2,\mu_1,\mu_2)&=f\left(s_1+\theta_1+\frac{n_1}{m_1},s_2,\mu_1-1,\mu_2\right),\\
(U_2f)(s_1,s_2,\mu_1,\mu_2)&=e^{2\pi i(s_1+n_1\mu_1/m_1)}f(s_1,s_2,\mu_1,\mu_2),\\
(U_3f)(s_1,s_2,\mu_1,\mu_2)&=f\left(s_1,s_2+\theta_2+\frac{n_2}{m_2},\mu_1,\mu_2-1\right),\\
(U_4f)(s_1,s_2,\mu_1,\mu_2)&=e^{2\pi i(s_2+n_2\mu_2/m_2)}f(s_1,s_2,\mu_1,\mu_2).
\end{aligned}\tag{28}$$

The left U_i actions on $E'_{K,L}$ are defined as

$$\begin{aligned}
(U_1g)(t_1,t_2,\nu_1,\nu_2)&=g\left(t_1-\theta_1+\frac{k_1}{l_1},t_2,\nu_1-1,\nu_2\right),\\
(U_2g)(t_1,t_2,\nu_1,\nu_2)&=e^{2\pi i(t_1+k_1\nu_1/l_1)}g(t_1,t_2,\nu_1,\nu_2),\\
(U_3g)(t_1,t_2,\nu_1,\nu_2)&=g\left(t_1,t_2-\theta_2+\frac{k_2}{l_2},\nu_1,\nu_2-1\right),\\
(U_4g)(t_1,t_2,\nu_1,\nu_2)&=e^{2\pi i(t_2+k_2\nu_2/l_2)}g(t_1,t_2,\nu_1,\nu_2).
\end{aligned}\tag{29}$$

The left Z_i actions on $E_{N,M}$ are defined as

$$
\begin{aligned}
(Z_1 f)(s_1,s_2,\mu_1,\mu_2) &= e^{2\pi i(s_1/(m_1\theta_1+n_1)+\mu_1/m_1)} f(s_1,s_2,\mu_1,\mu_2),\\
(Z_2 f)(s_1,s_2,\mu_1,\mu_2) &= f\left(s_1+\frac{1}{m_1},s_2,\mu_1-a_1,\mu_2\right),\\
(Z_3 f)(s_1,s_2,\mu_1,\mu_2) &= e^{2\pi i(s_2/(m_2\theta_2+n_2)+\mu_2/m_2)} f(s_1,s_2,\mu_1,\mu_2),\\
(Z_4 f)(s_1,s_2,\mu_1,\mu_2) &= f\left(s_1,s_2+\frac{1}{m_2},\mu_1,\mu_2-a_2\right),
\end{aligned}
\tag{30}
$$

where $a_i \in \mathbb{Z}$ and $a_i n_i - b_i m_i = 1$ for some $b_i \in \mathbb{Z}$ $(i=1,2)$.

Following Ref. 17, we define the tensor product $f \otimes g \equiv h \in E_{N,M} \otimes_{T^4_\theta} E'_{K,L}$ as

$$
\begin{aligned}
h(r_1,r_2,j_1,j_2) = \sum_{q_1\in\mathbb{Z}} \sum_{q_2\in\mathbb{Z}} & f\Bigg((n_1+m_1\theta_1)r_1+\frac{n_1+m_1\theta_1}{m_1}q_1-\frac{l_1(n_1+m_1\theta_1)}{m_1(n_1l_1+m_1k_1)}j_1,(n_2+m_2\theta_2)r_2\\
&+\frac{n_2+m_2\theta_2}{m_2}q_2-\frac{l_2(n_2+m_2\theta_2)}{m_2(n_2l_2+m_2k_2)}j_2,-q_1+a_1j_1,-q_2+a_2j_2\Bigg)\\
&\times g\Bigg((n_1+m_1\theta_1)r_1-\frac{k_1-l_1\theta_1}{l_1}q_1+\frac{k_1-l_1\theta_1}{n_1l_1+m_1k_1}j_1,(n_2+m_2\theta_2)r_2-\frac{k_2-l_2\theta_2}{l_2}q_2\\
&+\frac{k_2-l_2\theta_2}{n_2l_2+m_2k_2}j_2,q_1,q_2\Bigg),
\end{aligned}
\tag{31}
$$

for $r_i \in \mathbb{R}$, $j_i \in \mathbb{Z}$ $(i=1,2)$. Then, one can check that

$$
\begin{aligned}
(U_i f)\otimes g &\sim f\otimes(U_i)g,\\
(Z_i h) &\sim (Z_i f)\otimes g,\\
h(r_i, j_i+n_il_i+m_ik_i) &= h(r_i,j_i),
\end{aligned}
$$

for $i=1,2$. Notice that in the above calculation Z_i's act on h as left actions, since h is regarded here as an element of a left module E'. So far, we have only defined the left actions of Z_i on a right module E. Thus, we define left Z_i actions on a left module E' as

$$
\begin{aligned}
(Z_1 g) &= (U_2 g),\\
(Z_2 g) &= (U_1 g),\\
(Z_3 g) &= (U_4 g),\\
(Z_4 g) &= (U_3 g),
\end{aligned}
$$

where $U_i g$ are defined in (29).

If $E_{N,M}$ is a right module expression of a $(T^4_{\tilde\theta}, T^4_\theta)$-bimodule and $E'_{K,L}$ is a left module expression of a $(T^4_\theta, T^4_{\theta'})$-bimodule, then one can also show that h belongs to $E'_{AK+BL,NL+MK}(\tilde\theta)$ where $\tilde\theta = (A\theta+B)(M\theta+N)^{-1}$ and $\theta = (K\theta'+D)(L\theta'+C)^{-1}$ with $CK-DL \sim 1$, $AN-BM \sim 1$, when each A,B,M,N,K,D,L,C is reducible into 2 blocks in the sense that we described earlier.

Let us consider the tensor product (31) between the two theta vectors, $f \in E_{N,M}$ and $g \in E'_{K,L}$,

$$f_{(\alpha_1,\alpha_2)}(s_1,s_2,\mu_1,\mu_2)=\exp[\tfrac{1}{2}S^t\Omega S+C^tS]\,\delta^{\mu_1}_{\alpha_1}\delta^{\mu_2}_{\alpha_2},$$
$$g_{(\beta_1,\beta_2)}(t_1,t_2,\nu_1,\nu_2)=\exp[\tfrac{1}{2}T^t\Omega' T+C'^tT]\,\delta^{\nu_1}_{\beta_1}\delta^{\nu_2}_{\beta_2}, \tag{32}$$

where $C=\binom{c_1}{c_2}$, $C'=\binom{c_1'}{c_2'}$, $S=\binom{s_1}{s_2}$, $T=\binom{t_1}{t_2}$, $c_i,c_i'\in\mathbb{C}$, $s_i,t_i\in\mathbb{R}$, $\mu_i\in\mathbb{Z}_{m_i}$, $\nu_i\in\mathbb{Z}_{l_i}$ $(i=1,2)$,

$$\Omega=\begin{pmatrix} \dfrac{2\pi i\tau_{21}}{\theta_1+\dfrac{n_1}{m_1}} & \dfrac{2\pi i\tau_{11}}{\theta_1+\dfrac{n_1}{m_1}} \\ \dfrac{2\pi i\tau_{22}}{\theta_2+\dfrac{n_2}{m_2}} & \dfrac{2\pi i\tau_{12}}{\theta_2+\dfrac{n_2}{m_2}} \end{pmatrix},\quad \text{and}\quad \Omega'=\begin{pmatrix} \dfrac{2\pi i\tau'_{21}}{-\theta_1+\dfrac{k_1}{l_1}} & \dfrac{2\pi i\tau'_{11}/}{-\theta_1+\dfrac{k_1}{l_1}} \\ \dfrac{2\pi i\tau'_{22}}{-\theta_2+\dfrac{k_2}{l_2}} & \dfrac{2\pi i\tau'_{12}}{-\theta_2+\dfrac{k_2}{l_2}} \end{pmatrix}.$$

The resulting function now takes the form

$$h_{\alpha_1,\alpha_2,\beta_1,\beta_2}(r_1,r_2,j_1,j_2)=\sum_{q_1\in\mathbb{Z}}\sum_{q_2\in\mathbb{Z}}\exp\left(\frac{1}{2}\tilde{\mathcal{A}}^t\Omega\tilde{\mathcal{A}}+C^t\tilde{\mathcal{A}}\right)\delta^{-q_1+a_1j_1,-q_2+a_2j_2}_{\alpha_1,\alpha_2}$$
$$\times\exp\left(\frac{1}{2}\tilde{\mathcal{A}}'^t\Omega'\tilde{\mathcal{A}}'+C'^t\tilde{\mathcal{A}}'\right)\delta^{q_1,q_2}_{\beta_1,\beta_2},$$

where $r_i\in\mathbb{R}$, $j_i\in\mathbb{Z}_{n_il_i+m_ik_i}$ $(i=1,2)$ and

$$\tilde{\mathcal{A}}=\begin{pmatrix} (n_1+m_1\theta_1)r_1+\dfrac{n_1+m_1\theta_1}{m_1}q_1-\dfrac{l_1(n_1+m_1\theta_1)}{m_1(n_1l_1+m_1k_1)}j_1 \\ (n_2+m_2\theta_2)r_2+\dfrac{n_2+m_2\theta_2}{m_2}q_2-\dfrac{l_2(n_2+m_2\theta_2)}{m_2(n_2l_2+m_2k_2)}j_2 \end{pmatrix},$$

$$\tilde{\mathcal{A}}'=\begin{pmatrix} (n_1+m_1\theta_1)r_1-\dfrac{k_1-l_1\theta_1}{l_1}q_1+\dfrac{k_1-l_1\theta_1}{n_1l_1+m_1k_1}j_1 \\ (n_2+m_2\theta_2)r_2-\dfrac{k_2-l_2\theta_2}{l_2}q_2+\dfrac{k_2-l_2\theta_2}{n_2l_2+m_2k_2}j_2 \end{pmatrix}.$$

From the delta function relations, we rewrite q_i as $q_i=p_i+u_im_il_i/v_i$, $u_i\in\mathbb{Z}$ $(i=1,2)$ for some integers p_i where $v_i=\text{g.c.d.}(m_i,l_i)$. Then, h can be written as

$$h_{\alpha_1,\alpha_2,\beta_1,\beta_2}(r_1,r_2,j_1,j_2)=\sum_{u_1\in\mathbb{Z}}\sum_{u_2\in\mathbb{Z}}\exp\left(\frac{1}{2}(\mathcal{A}+\mathcal{U})^t\Omega(\mathcal{A}+\mathcal{U})+C^t\mathcal{U}+C^t\mathcal{A}\right.$$
$$\left.+\frac{1}{2}(\mathcal{A}'+\mathcal{U}')^t\Omega'(\mathcal{A}'+\mathcal{U}')+C'^t\mathcal{U}'+C'^t\mathcal{A}'\right),$$

where

$$\mathcal{A}=\begin{pmatrix} (n_1+m_1\theta_1)r_1+\dfrac{n_1+m_1\theta_1}{m_1}p_1-\dfrac{l_1(n_1+m_1\theta_1)}{m_1(n_1l_1+m_1k_1)}j_1 \\ (n_2+m_2\theta_2)r_2+\dfrac{n_2+m_2\theta_2}{m_2}p_2-\dfrac{l_2(n_2+m_2\theta_2)}{m_2(n_2l_2+m_2k_2)}j_2 \end{pmatrix},$$

$$\mathcal{A}'=\begin{pmatrix}(n_1+m_1\theta_1)r_1-\dfrac{k_1-l_1\theta_1}{l_1}p_1+\dfrac{k_1-l_1\theta_1}{n_1l_1+m_1k_1}j_1\\ (n_2+m_2\theta_2)r_2-\dfrac{k_2-l_2\theta_2}{l_2}p_2+\dfrac{k_2-l_2\theta_2}{n_2l_2+m_2k_2}j_2\end{pmatrix},$$

$$\mathcal{U}=\begin{pmatrix}\dfrac{(n_1+m_1\theta_1)l_1}{v_1}u_1\\ \dfrac{(n_2+m_2\theta_2)l_2}{v_2}u_2\end{pmatrix},\quad \mathcal{U}'=\begin{pmatrix}-\dfrac{(k_1-l_1\theta_1)m_1}{v_1}u_1\\ -\dfrac{(k_2-l_2\theta_2)m_2}{v_2}u_2\end{pmatrix}.$$

This can be decomposed into two parts, including the classical theta function,

$$h=\vartheta(\mathcal{T},\mathcal{Z})\xi(r_1,r_2,j_1,j_2). \tag{33}$$

Here, the classical theta function ϑ is given by

$$\vartheta(\mathcal{T},\mathcal{Z})=\sum_{u_1,u_2\in\mathbb{Z}}\exp(\pi i U^t\mathcal{T}U+2\pi i\mathcal{Z}^tU),$$

where

$$U=\begin{pmatrix}u_1\\u_2\end{pmatrix},\quad \mathcal{T}=\begin{pmatrix}\mathcal{B}_1\mathcal{O}_{11}\mathcal{B}_1+\mathcal{B}_1'\mathcal{O}_{11}'\mathcal{B}_1' & \mathcal{B}_1\mathcal{O}_{12}\mathcal{B}_2+\mathcal{B}_1'\mathcal{O}_{12}'\mathcal{B}_2'\\ \mathcal{B}_2\mathcal{O}_{21}\mathcal{B}_1+\mathcal{B}_2'\mathcal{O}_{21}'\mathcal{B}_1' & \mathcal{B}_2\mathcal{O}_{22}\mathcal{B}_2+\mathcal{B}_2'\mathcal{O}_{22}'\mathcal{B}_2'\end{pmatrix},$$

$$\mathcal{Z}=\begin{pmatrix}\mathcal{B}_1\mathcal{O}_{11}\mathcal{A}_1+\mathcal{B}_1\mathcal{O}_{12}\mathcal{A}_2+\mathcal{B}_1'\mathcal{O}_{11}'\mathcal{A}_1'+\mathcal{B}_1'\mathcal{O}_{12}'\mathcal{A}_2'\\ \mathcal{B}_2\mathcal{O}_{21}\mathcal{A}_1+\mathcal{B}_2\mathcal{O}_{22}\mathcal{A}_2+\mathcal{B}_2'\mathcal{O}_{21}'\mathcal{A}_1'+\mathcal{B}_2'\mathcal{O}_{22}'\mathcal{A}_2'\end{pmatrix}+\frac{1}{2\pi i}\begin{pmatrix}c_1\mathcal{B}_1+c_1'\mathcal{B}_1'\\ c_2\mathcal{B}_2+c_2'\mathcal{B}_2'\end{pmatrix},$$

with

$$\mathcal{O}=\frac{1}{2\pi i}\Omega,\quad \mathcal{O}'=\frac{1}{2\pi i}\Omega',\quad \mathcal{B}=\begin{pmatrix}\mathcal{B}_1\\ \mathcal{B}_2\end{pmatrix}=\begin{pmatrix}\dfrac{(n_1+m_1\theta_1)l_1}{v_1}\\ \dfrac{(n_2+m_2\theta_2)l_2}{v_2}\end{pmatrix},$$

$$\mathcal{B}'=\begin{pmatrix}\mathcal{B}_1'\\ \mathcal{B}_2'\end{pmatrix}=\begin{pmatrix}-\dfrac{(k_1-l_1\theta_1)m_1}{v_1}\\ -\dfrac{(k_2-l_2\theta_2)m_2}{v_2}\end{pmatrix},$$

and function ξ is given by

$$\xi(r_1,r_2,j_1,j_2)=\exp(\tfrac{1}{2}\mathcal{A}^t\Omega\mathcal{A}+\tfrac{1}{2}\mathcal{A}'^t\Omega'\mathcal{A}'+C^t\mathcal{A}+C'^t\mathcal{A}').$$

Requiring that $E_{N,M}$ and $E'_{K,L}$ have the same complex structure for consistency of the tensor product, i.e., $(\tau_{ij})=(\tau'_{ij})$, and the consistency condition (26) the resulting function h becomes

$$h_{\alpha_1,\alpha_2,\beta_1,\beta_2}(r_1,r_2,j_1,j_2)=\sum_{\gamma_1,\gamma_2}c^{\gamma_1,\gamma_2}_{\alpha_1,\alpha_2,\beta_1,\beta_2}\varphi_{\gamma_1,\gamma_2}(r_1,r_2,j_1,j_2). \tag{34}$$

Here, the function $\varphi_{\gamma_1,\gamma_2}$ is given by

$$\varphi_{\gamma_1,\gamma_2}(r_1,r_2,j_1,j_2)=\exp(\pi i R^t\tilde{\mathcal{O}}R+(C+C')^t\tilde{R})\delta^{j_1}_{\gamma_1}\delta^{j_2}_{\gamma_2},$$

with

$$R=\begin{pmatrix} r_1 \\ r_2 \end{pmatrix},\quad \tilde{\mathcal{O}}=\begin{pmatrix} \dfrac{\tau_{11}(n_1+m_1\theta_1)(n_1l_1+m_1k_1)}{(k_1-l_1\theta_1)} & \dfrac{\tau_{12}(n_1+m_1\theta_1)(n_2l_2+m_2k_2)}{(k_2-l_2\theta_2)} \\ \dfrac{\tau_{21}(n_2+m_2\theta_2)(n_1l_1+m_1k_1)}{(k_1-l_1\theta_1)} & \dfrac{\tau_{22}(n_2+m_2\theta_2)(n_2l_2+m_2k_2)}{(k_2-l_2\theta_2)} \end{pmatrix},$$

$$\tilde{R}=\begin{pmatrix} (n_1+m_1\theta_1)r_1 \\ (n_2+m_2\theta_2)r_2 \end{pmatrix},$$

and the constants $c^{\gamma_1,\gamma_2}_{\alpha_1,\alpha_2,\beta_1,\beta_2}$ are given by

$$c^{\gamma_1,\gamma_2}_{\alpha_1,\alpha_2,\beta_1,\beta_2}=\vartheta(\Xi,\Lambda)e^{\mathcal{K}},$$

where

$$\mathcal{K}=\pi i\tilde{Q}^t\tilde{P}+C^t\tilde{M}+C'^t\tilde{L},$$

with

$$\tilde{Q}=\begin{pmatrix} \tau_{11}p_1+\tau_{12}p_2-\dfrac{\tau_{11}l_1j_1}{n_1l_1+m_1k_1}-\dfrac{\tau_{12}l_2j_2}{n_2l_2+m_2k_2} \\ \tau_{21}p_1+\tau_{22}p_2-\dfrac{\tau_{21}l_1j_1}{n_1l_1+m_1k_1}-\dfrac{\tau_{22}l_2j_2}{n_2l_2+m_2k_2} \end{pmatrix},\quad \tilde{P}=\begin{pmatrix} \dfrac{n_1l_1+m_1k_1}{l_1m_1}p_1-\dfrac{j_1}{m_1} \\ \dfrac{n_2l_2+m_2k_2}{l_2m_2}p_2-\dfrac{j_2}{m_2} \end{pmatrix},$$

$$\tilde{M}=\begin{pmatrix} \dfrac{n_1+m_1\theta_1}{m_1}p_1-\dfrac{l_1(n_1+m_1\theta_1)}{m_1(n_1l_1+m_1k_1)}j_1 \\ \dfrac{n_2+m_2\theta_2}{m_2}p_2-\dfrac{l_2(n_2+m_2\theta_2)}{m_2(n_2l_2+m_2k_2)}j_2 \end{pmatrix},\quad \tilde{L}=\begin{pmatrix} -\dfrac{k_1-l_1\theta_1}{l_1}q_1+\dfrac{k_1-l_1\theta_1}{n_1l_1+m_1k_1}j_1 \\ -\dfrac{k_2-l_2\theta_2}{l_2}q_2+\dfrac{k_2-l_2\theta_2}{n_2l_2+m_2k_2}j_2 \end{pmatrix},$$

and

$$\vartheta(\Xi,\Lambda)=\sum_{u_1,u_2\in\mathbb{Z}}\exp(\pi i U^t\Xi U+2\pi i\Lambda^t U),$$

with

$$U=\begin{pmatrix} u_1 \\ u_2 \end{pmatrix},\quad \Xi=\begin{pmatrix} \dfrac{\tau_{11}(n_1l_1+m_1k_1)l_1m_1}{v_1^2} & \dfrac{\tau_{12}(n_1l_1+m_1k_1)l_2m_2}{v_1v_2} \\ \dfrac{\tau_{21}(n_2l_2+m_2k_2)l_1m_1}{v_1v_2} & \dfrac{\tau_{22}(n_2l_2+m_2k_2)l_2m_2}{v_2^2} \end{pmatrix},$$

$$\Lambda=\begin{pmatrix} \frac{\tau_{11}}{v_1}((l_1n_1+m_1k_1)p_1-l_1j_1)+\frac{\tau_{12}}{v_1}(l_1n_1+m_1k_1)\left(p_2-\frac{l_2j_2}{l_2n_2+m_2k_2}\right) \\ \frac{\tau_{21}}{v_2}(l_2n_2+m_2k_2)\left(p_1-\frac{l_1j_1}{l_1n_1+m_1k_1}\right)+\frac{\tau_{22}}{v_2}((l_2n_2+m_2k_2)p_2-l_2j_2) \end{pmatrix} + \frac{1}{2\pi i}\begin{pmatrix} c_1\mathcal{B}_1+c_1'\mathcal{B}_1' \\ c_2\mathcal{B}_2+c_2'\mathcal{B}_2' \end{pmatrix},$$

where $c_i, c_i', \mathcal{B}_i, \mathcal{B}_i'$ are the same as given before.

Notice that the function $\varphi_{\gamma_1,\gamma_2}(r_1,r_2,j_1,j_2)$ is a theta vector (32) and belongs to $E'_{AK+BL,NL+MK}(\tilde{\theta})$ with $\tilde{\theta}=(A\theta+B)/(M\theta+N)$ as we expected.

V. DISCUSSION

In this paper, we first construct a module on noncommutative T^4 and its dual. Then we define the complex structure on this module and construct the theta vector which is a solution for a holomorphic connection. We then consider the tensor product of the theta vectors satisfying the consistency requirement.

Here, we want to notice what has not been apparent in the noncommutative T^2 case.[17] When we require the holomorphic condition (24), the symmetry appears not in the complex structure itself but in the Ω-matrix which appears in the theta vector (27), i.e., $\Omega_{12}=\Omega_{21}$ instead of $\tau_{12}=\tau_{21}$ in the commutative 4-torus case. We consider that this difference comes from noncommutativity.

As in the noncommutative T^2 case, the tensor products of modules on the noncommutative 4-torus with complex structures become very restrictive in order to satisfy the consistency requirement. We consider this consistency requirement as another aspect of noncommutativity compared with the commutative case in which there is no restriction.

So far, theta functions on noncommutative tori have not been utilized in the physics literature except for the integral torus case.[22–24] With the theta functions on noncommutative tori without any restriction, one can hope to explore the physical states on noncommutative tori in more general cases.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 1 JANUARY 2004

Import of a set of solutions of the homogeneous Bloch equation

M. Kobayashi[a)]
Physics Department, Gifu University, Yanagido, Gifu 501-1193, Japan

(Received 11 April 2003; accepted 19 September 2003)

We show for a class of time-varying magnetic fields that a generalized solution of precession is decomposed by two ways into two solutions of the homogeneous Bloch equation, thus having four solutions of which three are independent and form the fundamental systems. These solutions are found by solving the Riccati equation to which the homogeneous Bloch equation reduces. A brief discussion of the magnectic field class characteristics and an illustrative exmaple are given. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1629136]

I. INTRODUCTION

Recently we succeeded in finding a solution of the inhomogeneous Bloch equation.[1] This was completed by giving the fundamental system in terms of a set of the three independent solutions of the homogeneous Bloch equation. These three solutions were found by solving the Riccati equation to which the homogeneous Bloch equation reduces.

The purpose of this paper is to clarify the import of a set of solutions of the homgeneous Bloch equation. Of immediate utility to us are the solvable cases of the Riccati equation. Equating the Riccati equation of Abel's type[2] to the Riccati equation above we can find the fourth solution of it. By this finding we show that a generalized solution of precession is decomposed by two ways into two solutions of the homogeneous Bloch equation, thus having four solutions of which three are independent and form the fundamental systems. Two sets of the two decomposed solutions are related to each other through the formula to find a general solution when two independent special solutions of the Riccati equation are known. The same arguments hold for the Riccati equation of Chini's type.[3] In this soluble case the real parameter C is contained in the solutions to form the fundamental system. By setting the parameter on the special value all the solutions reduce to those of the Riccati equation of Abel's type.

Although we cannot solve the Riccati equation in general, we can do for a class of time-varying magnetic fields. This class is distinguished by requiring a nonlinear relation between one of the magnetic field components and the other two components and their derivatives. This restriction seems to arise in the solvable cases of the Riccati equation.

In Secs. II and III we solve the Riccati equation using the Riccati equation of Abel's type and Chini's type, respectively. A brief discussion of the magnetic field class characteristics and an illustrative example of precession are given in Sec. IV. The final section is devoted to our conclusions.

II. THE RICCATI EQUATION OF ABEL'S TYPE

The Bloch equation for magnetization with infininite relaxation times is a homogeneous system of three first-order linear differential equations given by

$$\dot{\vec{M}} = -\gamma(\vec{B}\times\vec{M}), \tag{1}$$

a)Electronic mail: masanori@cc.gifu-u.ac.jp

where a dot means differentiation with respect to time. Here $\vec{M}$ and $\vec{B}$ are the magnetization vector and the applied magnetic field, respectively, and γ is the constant gyromagnetic ratio in some substance. Since the magnitude of the magnetization vector is constant in time, as is clear from Eq. (1), the normalized magnetization vector obeys the Bloch equation,

$$\dot{\vec{m}} = -\gamma(\vec{B}\times\vec{m}), \tag{2}$$

with

$$\vec{m} = \frac{\vec{M}}{|\vec{M}|}. \tag{3}$$

Introducing the two complex variables, ξ and η, given by

$$m_1 + i\, m_2 = \xi(1-m_3) \tag{4}$$

and

$$m_1 - i\, m_2 = \frac{1}{\eta}(m_3 - 1), \tag{5}$$

we derive the following ordinary differential equation for ξ (and η) from the Bloch equation (2):

$$\dot{\xi} = \tfrac{1}{2}\gamma(B_2 + i\, B_1)\xi^2 - i\,\gamma B_3\,\xi + \tfrac{1}{2}\gamma(B_2 - iB_1). \tag{6}$$

This is a form of the general Riccati equation which can be cast in the form

$$\dot{\xi} = i\dot{\chi}\, e^{-i\psi}\xi^2 - i\dot{\chi}_3\,\xi - i\dot{\chi}\, e^{i\psi}. \tag{7}$$

Here χ and χ_3 are defined by

$$\chi = \frac{1}{2}\gamma\int_{t_0}^{t} B_0(\tau)\,\mathrm{d}\tau \tag{8}$$

and

$$\chi_3 = \gamma\int_{t_0}^{t} B_3(\tau)\,\mathrm{d}\tau, \tag{9}$$

with

$$B_2 \pm iB_1 = \pm iB_0\, e^{\mp i\psi} \tag{10}$$

and

$$B_0 = \sqrt{B_1^2 + B_2^2}. \tag{11}$$

Also,

$$\psi = \tan^{-1}\left(\frac{B_2}{B_1}\right). \tag{12}$$

The Riccati equation of Abel's type is of the form

$$\dot{u}=\frac{\dot{f}}{g}u^2-\frac{\dot{g}}{f}, \tag{13}$$

and the solution is given by[2]

$$u=-\frac{g}{f}+\frac{1}{f^2}\left[C_1-\int_{t_0}^{t}\frac{\dot{f}(\tau)}{g(\tau)f^2(\tau)}\,\mathrm{d}\tau\right]^{-1}, \tag{14}$$

where C_1 is a constant of integration.

The Riccati equation (7) has the form

$$\dot{u}=\dot{\chi}\,e^{-i(\psi+\chi_3)}u^2+\dot{\chi}\,e^{i(\psi+\chi_3)}, \tag{15}$$

and an equation of this form results from the substitution

$$\xi=-iu\,e^{-i\chi_3}. \tag{16}$$

Equating Eq. (15) to Eq. (13), we find

$$\dot{\chi}\,e^{-i(\psi+\chi_3)}=\frac{\dot{f}}{g} \tag{17}$$

and

$$\dot{\chi}\,e^{i(\psi+\chi_3)}=-\frac{\dot{g}}{f}, \tag{18}$$

which reduce to two second-order linear differential equations

$$\ddot{f}-\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-i(\dot{\psi}+\dot{\chi}_3)\right]\dot{f}+(\dot{\chi})^2 f=0 \tag{19}$$

and

$$\ddot{g}-\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)+i(\dot{\psi}+\dot{\chi}_3)\right]\dot{g}+(\dot{\chi})^2 g=0. \tag{20}$$

Notice that the linearized Riccati equation has the form [Eq. (20) in Ref. 4]

$$\ddot{u}-\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-i(\dot{\psi}+\dot{\chi}_3)\right]\dot{u}+(\dot{\chi})^2 u=0, \tag{21}$$

where we have substituted ξ given by

$$\xi=i\frac{1}{\dot{\chi}}\left(\frac{\dot{u}}{u}\right)e^{i\psi}, \tag{22}$$

into Eq. (7). Equation (21) can be solved[4] under the restriction [Eq. (46) in Ref. 4]

$$\dot{\psi}+\dot{\chi}_3=C\dot{\chi}, \tag{23}$$

with

$$C=\pm 2. \tag{24}$$

This restriction was imposed to eliminate unwanted derivative differential equations arising from differentiating the original coupled differential equations.

We immediately find two independent solutions of the second-order linear differential equation for both f and g by using the solutions obtained by solving Eq. (21). [See Eqs. (57) and (58) in Ref. 4.] A specific combination is required for g in order to satisfy Eqs. (17) and (18) when choosing one of two independent solutions of Eq. (19) as f. We thus find two sets of the solutions for f and g such that

$$\begin{pmatrix} f \\ g \end{pmatrix} = \begin{pmatrix} \cos(\sqrt{2}\chi)e^{-i\chi} \\ -[i+\sqrt{2}\tan(\sqrt{2}\chi)]\cos(\sqrt{2}\chi)e^{i\chi} \end{pmatrix} \tag{25}$$

and

$$\begin{pmatrix} f \\ g \end{pmatrix} = \begin{pmatrix} \sin(\sqrt{2}\chi)e^{-i\chi} \\ -[i-\sqrt{2}\cot(\sqrt{2}\chi)]\sin(\sqrt{2}\chi)e^{i\chi} \end{pmatrix}, \tag{26}$$

where we have chosen C as

$$C=2\,. \tag{27}$$

Substituting Eqs. (25) and (26) back into Eq. (14) and arranging them, we arrive at two independent special solutions of Eq. (7),

$$\xi_3 = e^{i\psi}\left[1-i\sqrt{2}\,\frac{1+\tan(\sqrt{2}\chi)}{1-\tan(\sqrt{2}\chi)}\right] \tag{28}$$

and

$$\xi_4 = e^{i\psi}\left[1+i\sqrt{2}\,\frac{1-\tan(\sqrt{2}\chi)}{1+\tan(\sqrt{2}\chi)}\right], \tag{29}$$

where we have used the relationship (16) and C_1 has been chosen as

$$C_1+\frac{1}{\sqrt{2}}\tan(\sqrt{2}\chi_0)=\frac{1}{\sqrt{2}} \tag{30}$$

and

$$C_1-\frac{1}{\sqrt{2}}\cot(\sqrt{2}\chi_0)=\frac{1}{\sqrt{2}}, \tag{31}$$

respectively, with

$$\chi_0=\chi(t_0)\,. \tag{32}$$

Let $\xi_a\,(a=i,j)$ be two special solutions of Eq. (7), then

$$\frac{\dot{\xi}-\dot{\xi}_i}{\xi-\xi_i}-\frac{\dot{\xi}-\dot{\xi}_j}{\xi-\xi_j}=i\dot{\chi}\,e^{-i\psi}(\xi_i-\xi_j)\,. \tag{33}$$

Thus, we find that a general solution of the differential equation (33) is

$$\frac{\xi-\xi_i}{\xi-\xi_j}=C_2\exp\left\{i\int_{t_0}^{t}\dot{\chi}(\tau)e^{-i\psi(\tau)}[\xi_i(\tau)-\xi_j(\tau)]\,\mathrm{d}\tau\right\}, \tag{34}$$

where C_2 is a constant of integration.

Substituting the two independent special solutions (28) and (29) into Eq. (34) and choosing C_2,

$$C_2=-\frac{1+\tan(\sqrt{2}\chi_0)}{1-\tan(\sqrt{2}\chi_0)} \tag{35}$$

and

$$C_2=\frac{1+\tan(\sqrt{2}\chi_0)}{1-\tan(\sqrt{2}\chi_0)}, \tag{36}$$

we find the other two special solutions

$$\xi_1=e^{i\psi}[1-i\sqrt{2}\tan(\sqrt{2}\chi)] \tag{37}$$

and

$$\xi_2=e^{i\psi}[1+i\sqrt{2}\cot(\sqrt{2}\chi)], \tag{38}$$

respectively. These two special solutions (37) and (38) are exactly the same ones [Eqs. (61) and (62) in Ref. 4] as were derived from the linearized Riccati equation (21).[4] Inversely, we obtain the special solutions (28) and (29) by substituting Eqs. (37) and (38) back into Eq. (34) and choosing C_2 as

$$C_2=\tan(\sqrt{2}\chi_0) \tag{39}$$

and

$$C_2=-\tan(\sqrt{2}\chi_0), \tag{40}$$

respectively. We thus find the relationship between a couple of the special solutions (ξ_1, ξ_2) and (ξ_3, ξ_4).

Notice that the special solutions ξ_i $(i=1,2)$ were already found as stated above and ξ_3 is contained in the fundamental system[1] [Eq. (52) in Ref. 1] which we have found as a special case. Thus, the special solution of ξ_4 is unknown so far.

As mentioned in the beginning of this section, the homogeneous Bloch equation is a system of the three first-order linear differential equations, thus having three independent magnetization vectors. While we have found four special solutions ξ_i $(i=1,2,3,4)$, each of which has the one to one correspondence to the magnetization vector. This fact strongly suggests that the four magnetization vectors are not independent, but a constraint exists. To see this we express the magnetization vectors, $\vec{m}^{(i)}$ $(i=1,2,3,4)$, in terms of ξ_i $(i=1,2,3,4)$,

$$m_1^{(i)}=\frac{\xi_i+\xi_i^*}{1+\xi_i\,\xi_i^*}, \tag{41}$$

$$m_2^{(i)}=-i\,\frac{\xi_i-\xi_i^*}{1+\xi_i\,\xi_i^*}, \tag{42}$$

and

$$m_3^{(i)} = -\frac{1-\xi_i\,\xi_i^*}{1+\xi_i\,\xi_i^*}, \tag{43}$$

where we have used the definition of ξ, Eq. (4).

Though the explicit forms of the magnetization vectors are easily obtained by using Eqs. (41), (42), and (43), we do not list them in this section, because those are contained in the corresponding expressions in Sec. III as the parameter C being the specific value, i.e., $C=2$. Instead we display the relation among the magnetization vectors,

$$\vec{m}^{(1)}+\vec{m}^{(2)}=\vec{m}^{(3)}+\vec{m}^{(4)}=\sqrt{2}\vec{m}^{(5)}, \tag{44}$$

where

$$\vec{m}^{(5)}=\left(\frac{1}{\sqrt{2}}\cos\psi,\frac{1}{\sqrt{2}}\sin\psi,\frac{1}{\sqrt{2}}\right)^T. \tag{45}$$

It is worth noticing that the fifth magnetization vector is a generalized solution of the classical precession. We thus find the correct number of magnetization vectors.

The fundamental matrix is defined by

$$(K)_{ij}=K_{ij}=m_i^{(j)} \quad (i,j=1,2,3). \tag{46}$$

The equivalent fundamental systems appear in a set of magnetization vectors by denoting j: $j=2,3,4;3,4,1;4,1,2$. Thus we have four fundamental systems. In each of the fundamental systems, the determinant of the fundamental matrix turns out, up to a sign, to be

$$\det K=\frac{1}{\sqrt{2}}. \tag{47}$$

This means that the fundamental matrices are nonsingular and then three of the four solutions of the homogeneous Bloch equation are linearly independent.

The homogeneous Bloch equation (2) can be written in a matrix form

$$\dot{K}=A\,K, \tag{48}$$

where K is the fundamental matrix defined by Eq. (46) and a matrix A is given by

$$A=\begin{pmatrix} 0 & \gamma B_3 & -\gamma B_2 \\ -\gamma B_3 & 0 & \gamma B_1 \\ \gamma B_2 & -\gamma B_1 & 0 \end{pmatrix}, \tag{49}$$

which is antisymmetric and singular. Moreover, we find

$$\det\dot{K}=\mathrm{tr}\,A\,\det K=0, \tag{50}$$

and solving Eq. (50) for $\det K$ we have

$$\det K=\det K(t_0). \tag{51}$$

The inhomogeneous Bloch equation has the form[5]

$$\dot{\vec{m}}=A\,\vec{m}+\vec{b}. \tag{52}$$

The fundamental system of solutions of the homogeneous system is a set of three linearly independent magnetization vectors $\vec{m}^{(j)}$. Using the fundamental matrix defined by Eq. (46), the unique solution to the inhomogeneous system (52) is

$$\vec{m}=K\,K^{-1}(t_0)\,\vec{m}(t_0)+K\int_{t_0}^{t}K^{-1}(\tau)\vec{b}(\tau)\,\mathrm{d}\tau\,. \tag{53}$$

III. THE RICCATI EQUATION OF CHINI'S TYPE

The Riccati equation of Chini's type is in the form

$$\dot{u}=\frac{1}{(ag+b)^2}\frac{\dot{g}}{f}u^2+\frac{\dot{f}}{f}u+f\dot{g}=0\,, \tag{54}$$

where a and b are arbitrary constants.

The Riccati equation (7) is rewritten in the form

$$\dot{u}=\dot{\chi}u^2-i(\dot{\psi}+\dot{\chi}_3)\,u+\dot{\chi}\,, \tag{55}$$

which results from the substitution of

$$\xi=-iu\,e^{i\psi} \tag{56}$$

into Eq. (7). Equating Eq. (55) to Eq. (54), we find

$$\dot{\chi}=\frac{1}{(ag+b)^2}\frac{\dot{g}}{f}=f\dot{g} \tag{57}$$

and

$$-i(\dot{\psi}+\chi_3)=\frac{\dot{f}}{f}. \tag{58}$$

It follows from Eq. (57) that

$$f=\frac{1}{ag+b} \tag{59}$$

and

$$\dot{\chi}=\frac{1}{ag+b}\dot{g}\,. \tag{60}$$

Solving the differential equation (60), we obtain

$$ag+b=A\,e^{a\chi}\,, \tag{61}$$

where A is a constant of integration. Thus we find

$$\dot{f}=-a\dot{\chi}f\,. \tag{62}$$

By setting $a=iC$ (C, real number), Eq. (58) yields

$$\dot{\psi}+\dot{\chi}_3=C\,\dot{\chi}\,. \tag{63}$$

This produces a separation of the variables, u and χ, and leads to

$$\dot{u}=\dot{\chi}\,(u^2-iC\,u+1)\,, \tag{64}$$

where we have used Eq. (55).

Solving Eq. (64), we find two solutions [Eqs. (42) and (43) in Ref. 1]

$$\xi_1=e^{i\psi}[\,\alpha-i\beta\tan(\beta\chi)] \tag{65}$$

and

$$\xi_2=e^{i\psi}[\,\alpha+i\beta\cot(\beta\chi)]\,, \tag{66}$$

where α and β are given by

$$\alpha=\tfrac{1}{2}C \tag{67}$$

and

$$\beta=\sqrt{1+\alpha^2}\,. \tag{68}$$

The same procedure to find another couple of special solutions developed in Sec. II is applicable to this case. We thus find

$$\xi_3=e^{i\psi}\left[\,\alpha-i\beta\frac{1+\tan(\beta\chi)}{1-\tan(\beta\chi)}\right] \tag{69}$$

and

$$\xi_4=e^{i\psi}\left[\,\alpha+i\beta\frac{1-\tan(\beta\chi)}{1+\tan(\beta\chi)}\right], \tag{70}$$

where use has been made of the relation (34) and C_2 has been chosen as

$$C_2=\tan(\beta\chi_0) \tag{71}$$

and

$$C_2=-\tan(\beta\chi_0)\,, \tag{72}$$

respectively. Note that Eq. (69) corresponds to Eq. (52) in Ref. 1. Inversely, substituting Eqs. (69) and (70) into Eq. (34) and choosing C_2 as

$$C_2=-\frac{1+\tan(\beta\chi_0)}{1-\tan(\beta\chi_0)} \tag{73}$$

and

$$C_2=\frac{1+\tan(\beta\chi_0)}{1-\tan(\beta\chi_0)}, \tag{74}$$

respectively, we find Eqs. (65) and (66). Thus a couple of the special solutions (ξ_1,ξ_2) and (ξ_3,ξ_4) are transferable through the relationship in (34).

Using Eqs. (41), (42), and (43), we find the explicit forms of the magnetization vectors $\vec{m}^{(i)}$ $(i=1,2,3,4)$ corresponding to the special solutions of the Riccati equation (55) as follows:

$$\vec{m}^{(1)},$$

$$m_1^{(1)}=\frac{1}{\beta^2}\{\alpha[1+\cos(2\beta\chi)]\cos\psi+\beta\sin(2\beta\chi)\sin\psi\}, \tag{75}$$

$$m_2^{(1)}=\frac{1}{\beta^2}\{\alpha[1+\cos(2\beta\chi)]\sin\psi-\beta\sin(2\beta\chi)\cos\psi\}, \tag{76}$$

$$m_3^{(1)}=-\frac{1}{\beta^2}(1-\alpha^2)\frac{1}{2}[1+\cos(2\beta\chi)]+\frac{1}{2}[1-\cos(2\beta\chi)], \tag{77}$$

$$\vec{m}^{(2)},$$

$$m_1^{(2)}=\frac{1}{\beta^2}\{\alpha[1-\cos(2\beta\chi)]\cos\psi-\beta\sin(2\beta\chi)\sin\psi\}, \tag{78}$$

$$m_2^{(2)}=\frac{1}{\beta^2}\{\alpha[1-\cos(2\beta\chi)]\sin\psi+\beta\sin(2\beta\chi)\cos\psi\}, \tag{79}$$

$$m_3^{(2)}=-\frac{1}{\beta^2}(1-\alpha^2)\frac{1}{2}[1-\cos(2\beta\chi)]+\frac{1}{2}[1+\cos(2\beta\chi)], \tag{80}$$

$$\vec{m}^{(3)},$$

$$m_1^{(3)}=\frac{1}{\beta^2}\{\alpha[1-\sin(2\beta\chi)]\cos\psi+\beta\cos(2\beta\chi)\sin\psi\}, \tag{81}$$

$$m_2^{(3)}=\frac{1}{\beta^2}\{\alpha[1-\sin(2\beta\chi)]\sin\psi-\beta\cos(2\beta\chi)\cos\psi\}, \tag{82}$$

$$m_3^{(3)}=-\frac{1}{\beta^2}(1-\alpha^2)\frac{1}{2}[1-\sin(2\beta\chi)]+\frac{1}{2}[1+\sin(2\beta\chi)], \tag{83}$$

$$\vec{m}^{(4)},$$

$$m_1^{(4)}=\frac{1}{\beta^2}\{\alpha[1+\sin(2\beta\chi)]\cos\psi-\beta\cos(2\beta\chi)\sin\psi\}, \tag{84}$$

$$m_2^{(4)}=\frac{1}{\beta^2}\{\alpha[1+\sin(2\beta\chi)]\sin\psi+\beta\cos(2\beta\chi)\cos\psi\}, \tag{85}$$

$$m_3^{(4)}=-\frac{1}{\beta^2}(1-\alpha^2)\frac{1}{2}[1+\sin(2\beta\chi)]+\frac{1}{2}[1-\sin(2\beta\chi)]. \tag{86}$$

A key relationship appears to be

$$\vec{m}^{(1)}+\vec{m}^{(2)}=\vec{m}^{(3)}+\vec{m}^{(4)}=\frac{2\alpha}{\beta}\vec{m}^{(5)}, \tag{87}$$

where

$$\vec{m}^{(5)}=\left(\frac{1}{\beta}\cos\psi,\frac{1}{\beta}\sin\psi,\frac{\alpha}{\beta}\right)^{T}. \tag{88}$$

The fifth magnetization vector (a special solution of the homogeneous Bloch equation) is a generalized solution of the classical precession, as will be illustrated in Sec. IV. Thus the relation (87) tells us that a generalized solution of precession can be decomposed by two ways into two special solutions of the homgeneous Bloch equation and then three of the four special solutions $\vec{m}^{(j)}$ ($j=1,2,3,4$) are independent and form the fundamental systems. Whole, the special solutions of the homogeneous Bloch equation, reduce to those obtained in the preceding section by setting $C=2$, as was stated.

The fundamental systems are obtained by using a set of three special solutions of the homogeneous Bloch equation if and only if the fundamental matrices are nonsingular.

Using the definition of fundamental matrix (46), we evaluate the determinant of the fundamental matrix as

$$\det K=\frac{2\alpha}{\beta^3}=C\left(\frac{2}{\sqrt{4+C^2}}\right)^3, \tag{89}$$

as is expected from Eq. (51). This means that the fundamental matrix is nonsingular and the set of three special solutions, denoting by $j=1,2,3$, consists of the three linearly independent ones. We also find the other fundamental systems $j=2,3,4$; 3,4,1; 4,1,2. The determinant of each fundamental matrix becomes the same as Eq. (89) up to a sign.

Using the fundamental matrix, we can find the unique solution to the inhomogeneous system (52). [See Eq. (53).]

IV. THE MAGNETIC FIELD CLASS CHARACTERISTICS AND AN ILLUSTRATIVE EXAMPLE

Using Eq. (12), the constraint (63) yields

$$\gamma B_3=\frac{\dot{B}_1B_2-B_1\dot{B}_2}{B_1^2+B_2^2}+\frac{1}{2}C\gamma\sqrt{B_1^2+B_2^2}. \tag{90}$$

The third component of magnetic field is expressed by the other two independent time-varying magnetic field components.

To discuss the characteristics of the magnetic field class we give some insight to the meaning of the restriction (90) which must be satisfied by the applied magnetic field in order to obtain the solution which is devloped in this paper.

The simplest practical discussion would center on the behavior of the third component when the first two components are harmonically varying,

$$\vec{B}(t)=(B_0(t)\cos\omega t, B_0(t)\sin\omega t, B_3(t)), \tag{91}$$

with ω being a constant angular velocity (harmonic frequency). The restriction (90) leads to the relation

$$B_3(t)=-\frac{\omega}{\gamma}+\frac{1}{2}CB_0(t). \tag{92}$$

This immediately suggests the effect of the variation of the constant C as a controlling influence on the third component of the applied magnetic field; the effects of variation harmonic frequency, gyromagnetic ratio and the magnitude of the harmonic field thus being easily interpreted.

The fifth magnetization vector (88) in this case turns out to be

$$\vec{m}^{(5)}=\left(\frac{1}{\beta}\cos\omega t,\frac{1}{\beta}\sin\omega t,\frac{\alpha}{\beta}\right)^{T}, \tag{93}$$

where we have used Eq. (12). This is the well-known solution of classical precession.

V. CONCLUSIONS

We clarify the import of a set of the special solutions of the Riccati equation as follows.

A set of special solutions has been obtained for a class of time-varying magnetic fields by solving the Riccati equation to which the homogeneous Bloch equation reduces. The finding of the fourth special solution allows us to interpret a set of the four special solutions as

$$\vec{m}^{(1)}+\vec{m}^{(2)}=\vec{m}^{(3)}+\vec{m}^{(4)}=\frac{2\alpha}{\beta}\vec{m}^{(5)}, \tag{94}$$

i.e., a generalized solution of the classical precession is decomposed by two ways into the two special solutions of the Riccati equation (7), thus having the four special solutions of which three special solutions are independent and form the fundamental system. Thus we have found a solution of the inhomogeneous Bloch equation for a class of time-varying magnetic fields.

Notice that a couple of the special solutions (ξ_1,ξ_2) and (ξ_3,ξ_4) are transferable to each other through the relationship (34). This is the characteristics of the Riccati equation.

Also note that we have found four (eight when including the fifth special solution) fundamental systems which are equivalent.

In most of the soluble cases of the Riccati equation the restriction (63) would appear to be a key of solvability. We have not yet succeeded in finding an unknown solution of the Riccati equation.

(Received 7 July 2003; accepted 13 October 2003)

A general form of solution of the inhomogeneous Bloch equation is given in terms of a solution of the homogeneous Bloch equation which is assumed to be known. The fundamental system of the homogeneous Bloch equation is derived from the method inherent to the Riccati equation to which the homogeneous Bloch equation reduces. The fundamental matrix is an orthogonal matrix. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1633023]

I. INTRODUCTION

Very recently, an interesting solution was found to the inhomogeneous Bloch equation.[1] The fundamental matrix in terms of a set of three independent solutions of the homogeneous Bloch equation became an orthogonal matrix. A simple question arose whether or not a fundamental matrix can always be chosen to be an orthogonal matrix.

The aim of this article is to show that a general form of solution of the inhomogeneous Bloch equation is obtained and the fundamental matrix is an orthogonal matrix. The key to demonstrating this is to make use of well-known properties of the Riccati equation.

The homogeneous Bloch equation reduces to a form of Riccati equation by introducing two complex variables. The same Riccati equation is satisfied by each of these variables. If a solution of the homogeneous Bloch equation is assumed to be known, then another solution may be automatically found. Whenever two special solutions are found, further special solutions can be derived from using a method inherent to the Riccati equation.[1–3] This leads to expressions for a set of three independent special solutions without solving the Riccati equation explicitly. We can show that the resulting normalized magnetization vectors obey the homogeneous Bloch equation by using the differential equations which the real and imaginary parts of an assumed solution must satisfy. Thus we arrive at a general form of solution of the inhomogeneous Bloch equation by finding the fundamental system of the homogeneous Bloch equation. The fundamental matrix turns out to be orthogonal.

In Sec. II we give a set of special solutions of the homogeneous Bloch equation in terms of an assumed known solution. In Sec. III the fundamental system of the homogeneous Bloch equation is given, thereby providing a general form of solution of the inhomogeneous Bloch equation. The differential equation which must be solved in order to obtain a general solution of the homogeneous Bloch equation is given in Sec. IV. The final section is devoted to conclusions.

II. A SET OF SPECIAL SOLUTIONS OF THE RICCATI EQUATION

The Bloch equation for magnetization with infinite relaxation times is a homogeneous system of three first-order linear differential equations given by

$$\dot{\vec{M}} = -\gamma(\vec{B}\times\vec{M}), \tag{1}$$

a)Electronic mail: masanori@cc.gifu-u.ac.jp

where an overdot means differentiation with respect to time. Here $\vec{M}$ and $\vec{B}$ are the magnetization vector and the time-dependent applied magnetic field, respectively. Also γ is the constant gyromagnetic ratio in some substance. Since the magnitude of the magnetization vector is preserved, as is clear from Eq. (1), the normalized magnetization vector obeys the Bloch equation

$$\dot{\vec{m}} = -\gamma(\vec{B}\times\vec{m}), \tag{2}$$

with

$$\vec{m} = \frac{\vec{M}}{|\vec{M}|}. \tag{3}$$

Introducing the two complex variables ξ and η given by

$$m_1 + i\, m_2 = \xi(1 - m_3) \tag{4}$$

and

$$m_1 - i\, m_2 = \frac{1}{\eta}(m_3 - 1), \tag{5}$$

we can derive the following ordinary differential equation for both ξ and η from the Bloch equation (2):

$$\dot{\xi} = i\dot{\chi}e^{-i\psi}\xi^2 - i\dot{\chi}_3\xi - i\dot{\chi}e^{i\psi}, \tag{6}$$

where χ and χ_3 are defined by

$$\chi = \frac{1}{2}\gamma\int_{t_0}^{t} B_0(\tau)\,\mathrm{d}\tau \tag{7}$$

and

$$\chi_3 = \gamma\int_{t_0}^{t} B_3(\tau)\,\mathrm{d}\tau, \tag{8}$$

with

$$B_2 \pm iB_1 = \pm iB_0\, e^{\mp i\psi}, \tag{9}$$

and

$$B_0 = \sqrt{B_1^2 + B_2^2}. \tag{10}$$

Also,

$$\psi = \cos^{-1}\left(\frac{B_1}{B_0}\right) = \sin^{-1}\left(\frac{B_2}{B_0}\right) = \tan^{-1}\left(\frac{B_2}{B_1}\right). \tag{11}$$

The Riccati equation (6) can be cast in the form

$$\dot{u} = \dot{\chi}u^2 - i(\dot{\psi} + \dot{\chi}_3)u + \dot{\chi}, \tag{12}$$

where the variable u is introduced by

$$\xi = -ie^{i\psi}u\,. \tag{13}$$

Let u_1 be a solution assumed to be known of the form

$$u_1 = \mathrm{Re}\,u_1 + i\,\mathrm{Im}\,u_1 = \beta_1 + i\alpha_1\,, \tag{14}$$

then the Riccati equation (12) yields

$$\dot{\alpha}_1 = 2\dot{\chi}\beta_1(\alpha_1 - a) \tag{15}$$

and

$$\dot{\beta}_1 = -2\dot{\chi}\alpha_1(\alpha_1 - a) + \dot{\chi}\left(1 + \frac{1}{\lambda}\right), \tag{16}$$

where the variables a and λ are defined by

$$a = \frac{\dot{\psi} + \dot{\chi}_3}{2\dot{\chi}} \tag{17}$$

and

$$\frac{1}{\lambda} = u_1 u_1^* = \alpha_1^2 + \beta_1^2\,. \tag{18}$$

By differentiating Eq. (18) with respect to time together with Eqs. (15) and (16), we find

$$\dot{\lambda} = -2\dot{\chi}\beta_1\lambda(\lambda + 1)\,. \tag{19}$$

Since the variables ξ and η satisfy the relationship; $\xi^*\eta = -1$, a second special solution is immediately obtained from

$$u_2 = -\frac{1}{u_1^*} = -\lambda u_1\,. \tag{20}$$

By using Eq. (19), we can directly show that u_2 is a solution of the Riccati equation (12) when u_1 is a solution.

Another solution of the Riccati equation, when two independent special solutions are known, is of the form

$$\frac{u - u_1}{u - u_2} = C_2 \exp\left\{\int_{t_0}^{t} \dot{\chi}(\tau)[u_1(\tau) - u_2(\tau)]\,\mathrm{d}\tau\right\}, \tag{21}$$

where C_2 is a constant of integration. An appropriate choice of the integration constant leads to a third solution in the form

$$\frac{u_3 - u_1}{u_3 - u_2} = \frac{1}{\sqrt{\lambda}} e^{i\chi_1}, \tag{22}$$

where χ_1 is given by

$$\chi_1 = \int_{t_0}^{t} \dot{\chi}(\tau)\alpha_1(\tau)[1 + \lambda(\tau)]\mathrm{d}\tau\,, \tag{23}$$

namely,

$$\dot{\chi}_1=\dot{\chi}\alpha_1(1+\lambda)\,. \tag{24}$$

Here use has been made of the relationship

$$\dot{\chi}(u_1-u_2)=i\dot{\chi}\alpha_1(1+\lambda)-\frac{1}{2}\frac{\dot{\lambda}}{\lambda}. \tag{25}$$

We thus find

$$u_3=\lambda_1 u_1\,, \tag{26}$$

where

$$\lambda_1=\frac{1+\sqrt{\lambda}e^{i\chi_1}}{1-\dfrac{1}{\sqrt{\lambda}}e^{i\chi_1}}. \tag{27}$$

Again a further solution of the Riccati equation when three independent special solutions are known is given by

$$\frac{u-u_1}{u-u_2}=C_3\frac{u_3-u_1}{u_3-u_2}, \tag{28}$$

where C_3 is a constant of integration. A fourth special solution is obtained by choosing

$$C_3=-i\,. \tag{29}$$

Thus we find a fourth special solution in the form

$$u_4=\lambda_2 u_1\,, \tag{30}$$

where

$$\lambda_2=\frac{1-i\sqrt{\lambda}e^{i\chi_1}}{1+i\dfrac{1}{\sqrt{\lambda}}e^{i\chi_1}}. \tag{31}$$

Thus we find four independent special solutions of the Riccati equation (12). Noticing that the magnetization vectors derived from these four special solutions are not always independent, we expect that three of them are independent and form a fundamental system.

III. THE FUNDAMENTAL SYSTEM OF THE HOMOGENEOUS BLOCH EQUATION

The special solutions of the Riccati equation (6) are found in terms of u_i $(i=1,2,3,4)$, which are given by Eqs. (14), (20), (26), and (30), such that

$$\xi_i=-ie^{i\psi}u_i \quad (i=1,2,3,4)\,. \tag{32}$$

The normalized magnetization vectors, $\vec{m}^{(i)}$ $(i=1,2,3,4)$, corresponding to the special solutions (32) are obtained from the definition of ξ, Eq. (4), and given by

$$m_1^{(i)}=\frac{\xi_i+\xi_i^*}{1+\xi_i\xi_i^*}, \tag{33}$$

$$m_2^{(i)} = -i\frac{\xi_i - \xi_i^*}{1+\xi_i\xi_i^*}, \tag{34}$$

and

$$m_3^{(i)} = -\frac{1-\xi_i\xi_i^*}{1+\xi_i\xi_i^*}. \tag{35}$$

Writing out Eqs. (33), (34), and (35), we find the magnetization vectors as follows:

$$\vec{m}^{(1)} = -\vec{m}^{(2)} \tag{36}$$

and

$$\vec{m}^{(1)},$$

$$m_1^{(1)} = (1-\lambda_0)(\alpha_1\cos\psi + \beta_1\sin\psi), \tag{37}$$

$$m_2^{(1)} = (1-\lambda_0)(\alpha_1\sin\psi - \beta_1\cos\psi), \tag{38}$$

$$m_3^{(1)} = \lambda_0, \tag{39}$$

$$\vec{m}^{(3)},$$

$$m_1^{(3)} = \sqrt{\lambda}[(-\alpha_1\lambda_0\cos\chi_1 + \beta_1\sin\chi_1)\cos\psi - (\alpha_1\sin\chi_1 + \beta_1\lambda_0\cos\chi_1)\sin\psi], \tag{40}$$

$$m_2^{(3)} = \sqrt{\lambda}[(\alpha_1\sin\chi_1 + \beta_1\lambda_0\cos\chi_1)\cos\psi + (-\alpha_1\lambda_0\cos\chi_1 + \beta_1\sin\chi_1)\sin\psi], \tag{41}$$

$$m_3^{(3)} = \frac{1}{\sqrt{\lambda}}(1-\lambda_0)\cos\chi_1, \tag{42}$$

and

$$\vec{m}^{(4)},$$

$$m_1^{(4)} = \sqrt{\lambda}[-(\alpha_1\lambda_0\sin\chi_1 + \beta_1\cos\chi_1)\cos\psi + (\alpha_1\cos\chi_1 - \beta_1\lambda_0\sin\chi_1)\sin\psi], \tag{43}$$

$$m_2^{(4)} = \sqrt{\lambda}[(-\alpha_1\cos\chi_1 + \beta_1\lambda_0\sin\chi_1)\cos\psi - (\alpha_1\lambda_0\sin\chi_1 + \beta_1\cos\chi_1)\sin\psi], \tag{44}$$

$$m_3^{(4)} = \frac{1}{\sqrt{\lambda}}(1-\lambda_0)\sin\chi_1, \tag{45}$$

where λ_0 is given by

$$\lambda_0 = -\frac{1-\frac{1}{\lambda}}{1+\frac{1}{\lambda}}. \tag{46}$$

As is obvious from Eq. (36), the magnetization vector corresponding to the second special solution is not independent. Thus we find the fundamental system in terms of $\vec{m}^{(i)}$ $(i=1,3,4)$.

Differentiating the magnetization vectors (37)–(45) with respect to time and using the first-order nonlinear differential equations (15), (16), and (19) together with the definitions (7), (8),

(11), (17), (24), and (46), we can show, after some tedious but straightforward manipulation, that the magnetization vectors (37)–(45) obey the homogeneous Bloch equation (2). Note that using Eq. (19) we find

$$\dot{\lambda}_0 = 2\dot{\chi}\beta_1(1-\lambda_0)\,. \tag{47}$$

For later convenience, we replace from now on $\vec{m}^{(3)}$ and $\vec{m}^{(4)}$ by $\vec{m}^{(2)}$ and $\vec{m}^{(3)}$, respectively. We thus define the fundamental matrix K by

$$(K)_{ij} = K_{ij} = m_i^{(j)} \quad (i,j=1,2,3)\,. \tag{48}$$

The cofactors of each element of the fundamental matrix are given by

$$K_{ij}^C = K_{ij} \quad (i,j=1,2,3)\,, \tag{49}$$

where K_{ij}^C is the cofactor of K_{ij}. This beautiful relationship is obtained after a straightforward manipulation using Eqs. (37)–(46) and the useful relation

$$(1-\lambda_0)\frac{1}{\lambda} - (1+\lambda_0) = 0\,. \tag{50}$$

Thus, we find that the determinant of the fundamental matrix is

$$\det K = K_{i1}K_{i1}^C = K_{i2}K_{i2}^C = K_{i3}K_{i3}^C = 1\,, \tag{51}$$

where we assume summation over repeated indices. Here we have used the fact that the magnetization vectors are normalized. The fundamental matrix is nonsingular and therefore the three special solutions of the homogeneous Bloch equation, $\vec{m}^{(i)}$ $(i=1,2,3)$, are linearly independent.

The homogeneous Bloch equation (2) is written in the matrix form

$$\frac{\mathrm{d}}{\mathrm{d}t}\vec{m} = A\,\vec{m}\,, \tag{52}$$

where the normalized magnetization vector $\vec{m}$ is a column vector and A is a 3×3 matrix given by

$$A = \begin{pmatrix} 0 & \gamma B_3 & -\gamma B_2 \\ -\gamma B_3 & 0 & \gamma B_1 \\ \gamma B_2 & -\gamma B_1 & 0 \end{pmatrix}. \tag{53}$$

The homogeneous Bloch equation turns out to be

$$\dot{K}_{ij} = \dot{m}_i^{(j)} = A_{ik}m_k^{(j)} = A_{ik}K_{kj} \quad (i,j=1,2,3)\,, \tag{54}$$

where

$$(A)_{ij} = A_{ij}\,. \tag{55}$$

We thus find

$$\dot{K} = AK\,. \tag{56}$$

Differentiating the determinant of the fundamental matrix with respect to time, we find

$$\det \dot{K} = \dot{K}_{ij}K_{ij}^C = A_{ik}K_{kj}K_{ij}^C = A_{ik}\delta_{ki}\det K = \mathrm{tr}\,A\,\det K\,, \tag{57}$$

where

$$K_{ik}K^{C}_{jk}=\delta_{ij}\det K\,. \tag{58}$$

The solution of the differential equation (57) is

$$\det K=\det K(t_0)\exp\left[\int_{t_0}^{t}\mathrm{tr}\,A(\tau)\,\mathrm{d}\tau\right], \tag{59}$$

with

$$\mathrm{tr}\,A=0\,. \tag{60}$$

Thus we find that Eq. (51) is exactly the solution we want.

The inhomogeneous Bloch equation has the form

$$\frac{\mathrm{d}}{\mathrm{d}t}\vec{m}=A\vec{m}+\vec{b}\,, \tag{61}$$

where the column vector $\vec{b}$ is given by

$$b_i=-\frac{m_i}{T_2}\quad(i=1,2) \tag{62}$$

and

$$b_3=-\frac{m_3-m_0}{T_1}, \tag{63}$$

where T_i $(i=1,2)$ are the relaxation times and m_0 is the equilibrium magnetization vector.

The fundamental system of the homogeneous Bloch equation is a set of three linearly independent magnetization vectors. Using the fundamental matrix K defined by Eq. (48), the unique solution to the inhomogeneous system (61) is given by[4]

$$\vec{m}=KK^{-1}(t_0)\vec{m}(t_0)+K\int_{t_0}^{t}K^{-1}(\tau)\vec{b}(\tau)\,d\tau\,, \tag{64}$$

where the inverse matrix of K is defined by

$$K^{-1}=\frac{\mathrm{adj}\,K}{\det K}, \tag{65}$$

with

$$(\mathrm{adj}\,K)_{ij}=K^{C}_{ji}\,. \tag{66}$$

Using Eq. (48) we find

$$K^{-1}=K^{T}\,. \tag{67}$$

This means that the fundamental matrix is an orthogonal matrix with

$$\det K=1\,. \tag{68}$$

IV. THE SPECIAL SOLUTIONS OF THE RICCATI EQUATION

To find a general solution of the Riccati equation (12), we have to solve the system of two first-order nonlinear differential equations (15) and (16). Combining them yields

$$\beta_1=\frac{\dot{\alpha}_1}{2\dot{\chi}(\alpha_1-a)} \tag{69}$$

and

$$\ddot{\alpha}_1[2\dot{\chi}(\alpha_1-a)]-\dot{\alpha}_1\left\{\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)[2\dot{\chi}(\alpha_1-a)]-2\dot{\chi}a\left(\frac{\dot{a}}{a}\right)\right\}-3\dot{\chi}(\dot{\alpha}_1)^2+\{\alpha_1[2\dot{\chi}(\alpha_1-a)]$$
$$-\dot{\chi}(1+\alpha_1^2)\}[2\dot{\chi}(\alpha_1-a)]^2=0\,. \tag{70}$$

This highly nonlinear differential equation (70) seems very difficult to solve in general. This is the main difficulty of solving the homogeneous Bloch equation.

Now we briefly review the soluble cases in this section. Two special solutions of the Riccati equation (12) have been found so far.[1,3] These solutions were obtained by imposing constraints

(1) $a=\alpha=\alpha_1$, for the case in Ref. 3 and
(2) $a=(\alpha_1^2+\alpha^2)/2\alpha_1$ and $\alpha_1=\sqrt{\alpha^2+2[1+\tan^2(\beta\chi)]}$, for the case in Ref. 1,

where α and β are arbitrary real constants satisfying:

$$\beta^2-\alpha^2=1\,. \tag{71}$$

The differential equation (16) for both cases reduces to

$$\dot{\beta}_1=\dot{\chi}(\beta^2+\beta_1^2)\,, \tag{72}$$

where we have used the useful relationship

$$\alpha_1(\alpha_1-a)=1+\tan^2(\beta\chi)\,. \tag{73}$$

We thus find the solution of Eq. (72) as

$$\beta_1=\beta\tan(\beta\chi)\,. \tag{74}$$

Notice that χ_1 defined by Eq. (23) can be evaluated and given by

$$\chi_1=\tan^{-1}\left[\frac{\beta\tan(\beta\chi)}{\alpha}\right] \quad \text{for the case (1)}\,, \tag{75}$$

and

$$\chi_1=\frac{\sqrt{2}}{\beta}\ln\left\{\frac{1}{\sqrt{1+\beta^2}}[\alpha_1+\sqrt{2}\tan(\beta\chi)]\right\}-\tan^{-1}\left[\frac{\alpha_1\cot(\beta\chi)}{\beta}\right] \quad \text{for the case (2)}\,. \tag{76}$$

V. CONCLUSIONS

We have found a general form of solution of the inhomogeneous Bloch equation by finding the fundamental system in terms of a solution of the homogeneous Bloch equation which is assumed to be known. In other words, whenever a special solution of the homogeneous Bloch equation is known, a solution of the inhomogeneous Bloch equation is given by Eq. (64) for which the fundamental matrix is of the form (48).

The reason why we have succeeded in finding a general form of the fundamental matrix is due to the fact that the second special solution is obtained in the form of Eq. (20). This is one of the characteristics of the Riccati equation to which the homogeneous Bloch equation reduces.

The problem which remains is the biggest one: to solve the highly nonlinear differential equation (70).

ACKNOWLEDGMENTS

The author is indebted to Y. Takahashi for continual correspondences regarding the Bloch equation. I also thank M. Kawasaki for continual discussions about solution of the Bloch equation. Special thanks go to A. Z. Capri for careful reading of the paper and useful comments.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 1 JANUARY 2004

Confluence expansions of the generalized hypergeometric function

Bengt Nagel[a)]
Mathematical Physics, Department of Physics, Royal Institute of Technology, SCFAB, S-10691 Stockholm, Sweden

(Received 24 February 2003; accepted 29 September 2003)

By confluencing a subset of upper and lower parameters in the generalized hypergeometric function ${}_PF_Q(a_1,\ldots,a_P,c_1,\ldots,c_Q;z)$ with the variable z one obtains a lower-order hypergeometric function in the limit when the confluence parameters go to infinity. It is shown that this function is the first term in a convergent expansion in terms of functions of the same type with parameters increasing stepwise by integers ν and coefficients which are polynomials in the reciprocals of the confluence parameters. These polynomials have nonvanishing lowest degree terms whose power increases with ν. The expansion can hence be used to derive asymptotic expansions for large but finite absolute values of the confluence parameters. [DOI: 10.1063/1.1629777]

I. INTRODUCTION AND SUMMARY

The hypergeometric function ${}_2F_1(a,b,c;z)$ and its various limiting and special cases are of great importance in mathematical and theoretical physics. By confluence of one or two of the upper parameters (say b, and a and b, respectively) with the variable z one obtains the confluent hypergeometric function ${}_1F_1(a,c;z)$, or the function ${}_0F_1(c;z)$, closely related to the Bessel function. In some applications one may be interested in the behavior of the hypergeometric function when the confluence is not taken "all the way," i.e., to obtain an asymptotic expansion in $1/b$, or $1/a$ and $1/b$, in the two cases mentioned. This has been done in two recent articles,[1,2] where the asymptotic expansions including second order have been derived and applied to a study of various aspects of the Coulomb excitation of atomic systems by passing charged particles.

In a previous article[3] I showed that in the second of the cases mentioned above (the one addressed in Ref. 1) the asymptotic expansion could be derived from a convergent expansion of the hypergeometric function in Bessel functions, with expansion coefficients which are polynomials in $1/a$ and $1/b$; rearrangement of this convergent expansion would in principle give the asymptotic expansion to any order. In a similar way an asymptotic expansion corresponding to the confluence of the parameter b can be derived; see the end of Sec. II below.

Here, I shall show that by an extension of the method in Ref. 3 one can derive a confluence expansion corresponding to confluence of a general subset of upper and lower parameters in the generalized hypergeometric function defined by the series

$$ {}_PF_Q(a_1,\ldots a_P,c_1,\ldots,c_Q;z)=\sum_{n=0}^{\infty}\frac{(a_1)_n\cdots(a_P)_n}{n!(c_1)_n\cdots(c_Q)_n}z^n,\quad (a)_n=\Gamma(a+n)/\Gamma(a). \tag{1}$$

Provided $P\leqslant Q+1$ (1) defines a function of z and the parameters which is holomorphic for all complex values of the parameters, except nonpositive integer c parameters, and (at least) for $|z|<1$ (or arbitrary complex z if $P\leqslant Q$). If $P>Q+1$ we must assume one of the upper parameters to be equal to a nonpositive integer, say $a_1=-m$, to get a polynomial of degree m in z.

a)Electronic mail: nagel@theophys.kth.se

With the view of confluencing p' of the upper and q' of the lower parameters, we put $P=p+p'$, $Q=q+q'$, divide each of the upper and lower parameter sets into the two corresponding subsets [some subset(s) may be empty], and introduce the notations

$$[a]=a_1,\ldots,a_p,\quad [b]=b_1,\ldots,b_{p'},\quad [c]=c_1,\ldots,c_q,\quad [d]=d_1,\ldots,d_{q'};$$

$$[a+\nu]=a_1+\nu,\ldots,a_p+\nu,\quad p[a]=a_1\cdots a_p;\quad s[a]=a_1+\cdots+a_p; \tag{2}$$

$$f([a])=f(a_1)\cdots f(a_p),\ \text{etc.}$$

Confluencing the b and d parameters with z in each of the terms in the series (1), we get, at least formally, the confluence relation (all b and d parameters go to infinity)

$$\lim_{p+p'}{}_{q+q'}F([a],[b],[c],[d];p[d]z/p[b])={}_pF_q([a],[c];z). \tag{3}$$

We shall see that (3) gives the first term in a convergent series expansion of the following form:

$$\begin{aligned}&{}_{p+p'}F_{q+q'}([a],[b],[c],[d];p[d]z/p[b])\\&\quad=\sum_{\nu=0}^{\infty}(-1)^{\nu}{}_{p'+1}F_{q'}(-\nu,[b],[d];p[d]/p[b])\,\frac{([a])_\nu}{\nu!([c])_\nu}z^\nu\,{}_pF_q([a+\nu],[c+\nu];z).\end{aligned} \tag{4}$$

Here, we assume, as always, that no c or d parameter is a nonpositive integer, so that in particular $p[d]\neq 0$; besides, we assume $p[b]\neq 0$, but a and b parameters may take negative integer values.

Equation (4) is first derived formally by introducing in each term of the series expansion (1) for upper and lower confluence parameters standard integral representations for the gamma functions $\Gamma(b+n)$ and the reciprocals $1/\Gamma(d+n)$, inverting order of summation and integration, and expanding the integrand around the resulting multiple saddle point, assuming in this derivation the b and d parameters real, positive, and large. This gives a $(p'+q')$-dimensional mixed integral representation for the hypergeometric polynomial ${}_{p'+1}F_{q'}(-\nu,\ldots)$, which is useful in the study of this function.

To establish validity of the expansion (4) inside some radius of convergence in z, and for general complex parameters, we first show that it is a formal power series identity if we expand each ${}_pF_q$ function on the right-hand side in a power series and rearrange terms. (In particular, if one of the a parameters is a nonpositive integer, we have a polynomial identity.) It then follows from well-known theorems about series of holomorphic functions that if we get a common nonzero radius of convergence in z for the series on both sides, equality holds inside this radius. This turns out to be always possible, provided the general necessary conditions $P\leqslant Q+1$, $p\leqslant q+1$ are fulfilled. The asymptotic behavior as $\nu\to\infty$ of the functions ${}_pF_q([a+\nu],[c+\nu];z)$ and ${}_{p'+1}F_{q'}(-\nu,[b],[d];p[d]/p[b])$ is studied in the Appendix. It turns out that if $p\leqslant q$ the validity of (4) is given by the convergence radius of the left-hand side: $|p[d]z/p[b]|<1$ if $P=Q+1$, all complex z if $P\leqslant Q$. Compare the end section of Appendix 1, combined with (A13) and (A15). If $p=q+1$, the functions ${}_{q+1}F_q$ have the finite convergence radius 1, and a singularity for $z=1$ with a dominating asymptotic ν behavior $(1-z)^{-\nu}$. As a consequence in this case the factors depending on [a] and [c] in the terms on the right-hand side of (4) have essentially an asymptotic $(z/[1-z])^\nu$ behavior. This means that if $P\leqslant Q$, i.e., $q'-p'\geqslant 1$, we have the conditions $|z|<1$, $|z/(1-z)|<1$, cf. the comment after Eq. (A31). In the case $P=Q+1$, i.e., $q'=p'$ we find from (A25) and (A26) the further condition $|1-p[d]/p[b]||z/(1-z)|<1$ if $|1-p[d]/p[b]|>1$.

As a by-product of the results derived or quoted in the Appendix we get asymptotic estimates, large ν, of the behavior of the generalized hypergeometric polynomials ${}_pF_q(-\nu,.;z)$, generalizing among other things classical results for the Laguerre polynomials.

The dependence on the confluence parameters is contained in the generalized hypergeometric polynomial ${}_{p'+1}F_{q'}(-\nu,[b],[d];p[d]/p[b])=F(-\nu)$, for short. It is easily seen that $F(0)=1$, $F(-1)=0$, and that for $\nu\geqslant 2$ the limiting value of $F(-\nu)$ as all parameters go to infinity is $(1-1)^{\nu}=0$, so that (4) implies (3). To get a polynomial in the reciprocals of all the parameters we can form $F'(-\nu)=([d])_{\nu}/p[d]^{\nu}\,F(-\nu)$, which is seen to be a symmetric polynomial in the reciprocals of the b parameters and the reciprocals of the d parameters, separately, of degrees $p'(\nu-1)$ and $q'(\nu-1)$. If $p'\neq q'$ the largest of these two numbers gives the degree of $F'(-\nu)$. The largest degree terms of this type are seen to come from the last and first terms in the expansion of $F'(-\nu)$ and are $(-1)^{\nu}[(\nu-1)!]^{p'}/p[b]^{\nu-1}$ and $-(\nu-1)[(\nu-1)!]^{q'}/p[d]^{\nu-1}$. If $p'=q'$, so that these two terms are of the same degree, the highest degree terms can be derived to be of the following form:

$$\frac{([d])_{\nu}}{p[d]^{\nu}}F(-\nu)=\cdots[(\nu-1)!]^{p'}(p[b]/p[d]-1)\left[\left(\frac{1}{p[d]}-\frac{1}{p[b]}\right)^{\nu-1}-\frac{1}{p[d]^{\nu-1}}\right]. \tag{5}$$

It could be remarked that the results for $p'\neq q'$ given above can be obtained from (5) by letting $p[d]$ or $p[b]$ go to infinity, in the last case also changing the exponent p' to q'.

To derive from (4) an asymptotic expansion in the reciprocals of the confluence parameters, it is of importance to verify that the lowest degree terms in $F'(-\nu)$, or, which is the same, in $F(-\nu)$, have a degree which increases with ν (they turn out to be of degree $[(\nu+1)/2]$, where $[\cdots]$ here stands for integer part) and to find expressions for these lowest degree terms. To do this directly from the series expression seems less trivial; we do it by a saddle-point estimate—all parameters real, positive, and large—of the multiple integral representation of $F(-\nu)$ obtained in the formal derivation of the expansion (4). The result is different for even and odd ν: (we use the notation $s[1/b^m]=\Sigma_i 1/b_i^{\,m}$, $m=1,2$ etc.)

$$F(-2\kappa)\approx\frac{2^{\kappa}\Gamma(\kappa+1/2)}{\sqrt{\pi}}(s[1/b]-s[1/d])^{\kappa}+\cdots, \tag{6a}$$

$$F(-2\kappa-1)\approx-\frac{2^{\kappa+1}\kappa\Gamma(\kappa+3/2)}{\sqrt{\pi}}(s[1/b]-s[1/d])^{\kappa-1}\left[(s[1/b]-s[1/d])^2-\frac{1}{3}(s[1/b^2]-s[1/d^2])\right]. \tag{6b}$$

These formulas agree with the special case treated in Ref. 3, except for the fact that there is an error in formula (5) in that paper: the factor $\Gamma(2\kappa+1)$ should be replaced by $-\Gamma(2\kappa+2)$. In the derivation of (18) of Ref. 3 the correct form of (5) has been used.

In the second section the details of the derivations indicated above are carried through. We also give the explicit result of the asymptotic expansion in $1/b$ including third order of ${}_2F_1(a,b,c;z/b)$, the case studied in Ref. 2. As already mentioned, in the Appendix the asymptotic behavior or asymptotic bounds as $\nu\to\infty$ of the functions on the right-hand side of (4) are derived.

A final cautionary remark is that in view of the enormous amount of papers treating various aspects of the hypergeometric function and its generalizations, dating back over two centuries, it is possible that expansions such as (4), or at least special cases of it, have been derived earlier. For the usefulness of these expansions for asymptotic estimates it is also essential to know the degree of the lowest order terms, as contained in the relations (6a) and (6b).

In a true asymptotic expansion in reciprocals of a lower confluence parameter evidently in each order all the "previous" ${}_pF_q([a+\nu]\ldots)$ will appear, because of the factor $p[d]^{\nu}/([d])_{\nu}$ difference between $F'(-\nu)$ and $F(-\nu)$. In an explicit computation it might be preferrable to attach this factor to the z-dependent part of the expansion terms.

II. DERIVATION OF FORMULAS (4)–(6)

Let us first make a formal derivation of the expansion (4), not caring about convergence or conditions for inverting summation and integration. Start from the series expansion of the left-hand side of (4)

$$F \equiv {}_{p+p'}F_{q+q'}([a],[b],[c],[d];p[d]z/p[b]) = \sum_{n=0}^{\infty} \frac{([a])_n([b])_n p[d]^n}{n!([c])_n([d])_n p[b]^n} z^n. \tag{7}$$

Here, we assume the confluence parameters b and d real and positive, sometimes even large and going to infinity.

In the sum in (7) we introduce for the confluence Pochhammer symbols standard integral representations for the gamma function and the reciprocal of the gamma function[4] and make a variable change $s=bx$, $t=dy$, as follows:

$$(b)_n = \frac{1}{\Gamma(b)} \int_0^{\infty} ds e^{-s} s^{b+n-1} = \frac{b^{b+n}}{\Gamma(b)} \int_0^{\infty} dx e^{-bx} x^{b+n-1}, \tag{8}$$

$$\frac{1}{(d)_n} = \frac{\Gamma(d)}{2\pi i} \int_{-\infty}^{(0^+)} dt e^t t^{-d-n} = \frac{\Gamma(d)}{d^{d+n-1} 2\pi i} \int_{-\infty}^{(0^+)} dy e^{dy} y^{-d-n}. \tag{9}$$

The integration path in (9) is from $-\infty$ below the real axis (whose negative part is a branch cut for noninteger d) around zero and back to $-\infty$ above the real axis, with the argument of the integration variable zero on the positive real axis.

Introducing (8) and (9) into (7) and inverting order of integration and summation, we get, using the notations introduced in (2) and considering x and y as p'- and q'-dimensional vectors, so that, e.g., $bx=\Sigma_{i=1}^{p'} b_i x_i$, $dx=dx_1 \cdots dx_{p'}$ etc.

$$F = \frac{p[b^b]\Gamma([d])}{\Gamma([b])p[d^{d-1}]} \frac{1}{(2\pi i)^{q'}} \int_0^{\infty} \cdot \int_0^{\infty} dx \int_{-\infty}^{(0^+)} \cdot \int_{-\infty}^{(0)^+} dy e^{-bx+dy}$$
$$\times p[x^{b-1}] p[y^{-d}] \sum \frac{([a])_n}{n!([c])_n} \left(\frac{p[x]}{p[y]} z \right)^n. \tag{10}$$

Here, the sum under the integrations gives, with $X=p[x]$, etc., ${}_pF_q([a],[c];Xz/Y)$. As we shall see, the a and c parameters play a sort of dummy role in the (formal) power series identity (4).

For large positive values of the b and d parameters the dominant factor in the multiple integrand can be written $\exp[-\Sigma b_i f(x_i)+\Sigma d_k f(y_k)]$, where the function $f(\varsigma)=\varsigma-\ln\varsigma=1+(\varsigma-1)^2/2-(\varsigma-1)^3/3+\cdots$ takes its minimum (maximum) value at the saddle point 1 for the x (y) variables along the respective paths of integration. We expand the ${}_pF_q$ function in its Taylor series around the common saddle point 1, and using the easily derived formula for the νth derivative

$${}_pF_q^{(\nu)}([a],[c]:z) = \frac{([a])_\nu}{([c])_\nu} {}_pF_q([a+\nu],[c+\nu];z), \tag{11}$$

we can write

$${}_pF_q([a],[c];Xz/Y) = \sum_{\nu=0}^{\infty} (-1)^\nu (1-X/Y)^\nu \frac{([a])_\nu}{\nu!([c])_\nu} z^\nu \, {}_pF_q([a+\nu],[c+\nu];z). \tag{12}$$

Introducing (12) in (10), inverting order of integration and summation, expanding

$$(1-X/Y)^{\nu}=\sum_{n=0}^{\nu}\frac{(-\nu)_n}{n!}(X/Y)^n, \tag{13}$$

and using the formulas (8) and (9) ''backwards'' in performing the integrations, we get the desired expansion formula (4), where as an intermediate result we obtain an integral representation for the function $F(-\nu)$

$$\begin{aligned}F(-\nu)&\equiv{}_{p'+1}F_{q'}(-\nu,[b],[d];p[d]/p[b])\\&=\frac{p[b^b]\Gamma([d])}{\Gamma([b])p[d^{d-1}]}\frac{1}{(2\pi i)^{q'}}\int_0^{\infty}\cdots\int_0^{\infty}dx\int_{-\infty}^{(0^+)}\cdots\int_{-\infty}^{(0)^+}dy e^{-bx+dy}\\&\quad\times p[x^{b-1}]p[y^{-d}](1-p[x]/p[y])^{\nu}.\end{aligned} \tag{14}$$

To further investigate the formula (4) we use the fact that the two sides, if they both make sense, should have identical power series expansions in z. Comparing the nth power of z, one observes that due to the relation $(a)_k(a+k)_{n-k}=(a)_n$ the expressions containing the a and c parameters are the same on both sides, and introducing the notation $B_n=([b])_n p[d]^n/\{([d])_n p[b]^n\}$ we get, expanding the ${}_{p'+1}F_{q'}$ function

$$B_n=\sum_{k=0}^{n}\binom{n}{k}(-1)^k\sum_{l=0}^{k}\frac{(-k)_l}{l!}B_l,\quad \binom{n}{k}=\frac{n!}{k!(n-k)!}. \tag{15}$$

This relation is an identity, i.e., the right-hand side is equal to B_n independent of the other B_l values: Introduce a new summation variable $k'=k-l$ and use $(-k)_l/l!=(-1)^l\binom{k}{l}$ to rewrite the right-hand side of (15) as

$$\sum_{l=0}^{n}\binom{n}{l}B_l\sum_{k'=0}^{n-l}(-1)^{k'}\binom{n-l}{k'}. \tag{15$'$}$$

Now, the sum over k' is the binomial expansion of $(1-1)^{n-l}$; thus$=0$ except for $l=n$, when the ''sum'' is 1.

Generalizing the crucial property of the a and c parameters used above, we can extract the essentials of relation (4) as a formal power series identity in the form

$$\sum_{n=0}^{\infty}\frac{1}{n!}A_n(a)B_n z^n=\sum_{\nu=0}^{\infty}\left[(-1)^{\nu}\left(\sum_{\mu=0}^{\nu}\frac{(-\nu)_\mu}{\mu!}B_\mu\right)\frac{1}{\nu!}A_\nu(a)z^{\nu}\left(\sum_{m=0}^{\infty}\frac{1}{m!}A_m(a+\nu)z^m\right)\right], \tag{16}$$

where $\{B_n\}$ is an arbitrary sequence and the expressions $\{A_n(a)\}$ defined for (complex) N-dimensional vectors a fulfill $A_{m+n}(a)=A_m(a)A_n(a+m)$, where $a+m$ stands for componentwise addition of m.

One could argue that since our basic derivation of (4) from the integral representations (8) and (9) was only formal anyhow, one could directly use the basic elementary relation (15) and the formula (16) to get (4). This is of course correct, but is somewhat of a ''put'' derivation. Besides, for deriving the lowest order term of the expansion of $F(-\nu)$ in reciprocal powers of the parameters we use the multiple integral representation, which is the starting point for the asymptotic estimate.

Since the verification of the validity of (4) with a common radius of convergence in z is based on asymptotic estimates of the functions on the right-hand side of (4) obtained in the Appendix, and the derivation of the relation (5) giving the highest order terms in the reciprocals of the b and d parameters in the special case $p'=q'$ is rather straightforward, we proceed to the derivation of the crucial formulas (6a) and (6b).

These formulas are obtained by making a first nonvanishing order saddle-point estimate[5] of the integral representation (14) for large positive values of the b and d parameters. The saddle points for both types of integrals is 1, and as noted in the text before formula (11) the dominant exponential function has the argument $\varsigma-\ln\varsigma$ multiplied by the b and d variables. In the spirit of the standard saddle-point estimate procedure we introduce new variables (vector notation!)

$$x=1+\xi/\sqrt{b},\quad y=1+i\,\eta/\sqrt{d}. \tag{17}$$

We should then integrate in the variables ξ and η from $-\infty$ to $+\infty$. Since in the case of odd ν the lowest order terms in ξ and η are odd, and give zero contribution by symmetry, we have to expand to relative order $1/\sqrt{b}$ and $1/\sqrt{d}$ everywhere. For the further calculation it is advantageous to introduce new (''small'') parameters $u_i=-1/\sqrt{b_i}$, $w_k=i/\sqrt{d_k}$. The resulting formulas are easily seen to be even polynomials in these new parameters. Since we want to calculate integrals giving the coefficients of these polynomials, it is clear that for the purpose of this calculation we can assume the u and w parameters to be real. The resulting expression is given for clarity in a mixed vector and component presentation:

$$\begin{aligned}F(-\nu)\approx{}&\frac{p[b^{b-1/2}e^{-b}]\Gamma([d])}{\Gamma([b])p[d^{d-1/2}e^{-d}](2\pi)^{q'}}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}d\xi\,d\eta\,e^{-(\xi^2+\eta^2)/2}\\&\times\left[\sum u_i\xi_i+\sum w_k\eta_k-\frac{1}{2}\sum_{i\neq j}u_iu_j\xi_i\xi_j+\frac{1}{2}\sum_{k\neq l}w_kw_l\eta_k\eta_l+\cdots\right]^{\nu}\\&\times\left[1+\sum u_i(\xi_i-\xi_i^3/3)-\sum w_k(\nu\eta_k-\eta_k^3/3)+\cdots\right].\end{aligned} \tag{18}$$

The various terms in the two $[\cdots]$ brackets come from the expansions to first relative order of $p[y]-p[x],1/p[x]p[y]^{\nu}$, and the third power term $-(\varsigma-1)^3/3$ in the dominating exponential obtained in the expression (14).

For the case of even $\nu=2\kappa$, the leading contribution comes from the linear terms in the first $[\cdots]$ raised to power 2κ. Assuming that the u and w parameters are real we can make an orthogonal coordinate transformation of the $p'+q'$ ξ, η variables, taking $(u\xi+w\eta)/\sqrt{u^2+w^2}$ (again vector notation!) as one of the transformed variables, and the other transformed variables as a set of complementary orthogonal expressions, so that the exponent expression $\xi^2+\eta^2$ and the volume product $d\xi d\eta$ are invariant. As noted earlier the result is an even polynomial in the u and w parameters, and can be carried over to the actual expressions for u and w. The integrations are elementary, and using the asymptotic forms of the Γ functions in front of the integrals we obtain as leading asymptotic term

$$F(-2\kappa)\approx\frac{2^{\kappa}\Gamma(\kappa+1/2)}{\sqrt{\pi}}\left(\sum {u_i}^2+\sum {w_k}^2\right)^{\kappa}, \tag{19}$$

which gives (6a).

For the case $\nu=2\kappa+1$, odd, the leading terms are odd, and one has to calculate the next order terms. This can easily be done by suitable differentiations of the previously obtained result for even $\nu=2\kappa+2,2\kappa+4$ with respect to the u and w parameters. The resulting calculations lead to (6b).

The five possible confluence expansions for the ordinary hypergeometric function are

$${}_2F_1(a,b,c,z/b)=\sum_{\nu=0}^{\infty}(-1)^{\nu}\,{}_2F_0(-\nu,b;1/b)\frac{(a)_{\nu}}{\nu!(c)_{\nu}}z^{\nu}\,{}_1F_1(a+\nu,c+\nu;z), \tag{20a}$$

$$ {}_2F_1(a,b,c,cz)=\sum_{\nu=0}^{\infty}(-1)^{\nu}\,{}_1F_1(-\nu,c;c)\,\frac{(a)_{\nu}(b)_{\nu}}{\nu!}z^{\nu}\,{}_2F_0(a+\nu,b+\nu;z), \tag{20b} $$

$$ {}_2F_1(a,b,c,z/ab)=\sum_{\nu=0}^{\infty}(-1)^{\nu}\,{}_3F_0(-\nu,a,b;1/ab)\,\frac{1}{\nu!(c)_{\nu}}z^{\nu}\,{}_0F_1(c+\nu;z), \tag{20c} $$

$$ {}_2F_1(a,b,c,cz/b)=(1-z)^{-a}\sum_{\nu=0}^{\infty}(-1)^{\nu}\,{}_2F_1(-\nu,b,c;c/b)\,\frac{(a)_{\nu}}{\nu!}(z/[1-z])^{\nu}. \tag{20d} $$

$$ {}_2F_1(a,b,c,cz/ab)=e^{z}\sum_{\nu=0}^{\infty}(-1)^{\nu}\,{}_3F_1(-\nu,a,b,c;c/ab)\,\frac{1}{\nu!}z^{\nu}. \tag{20e} $$

Equation (20b) makes sense only if a (or b) is a nonpositive integer.

The three possible confluence expansion formulas for the confluent hypergeometric function ${}_1F_1(a,c:z)$ are obtained by confluencing the b parameter on both sides of the three last relations.

Equation (20c) is the case studied in Ref. 3, with argument and parameter adjusted to give an expansion in Bessel functions, resulting in Eq. (1) of that paper

$$ \frac{(z/2)^{c}}{\Gamma(c+1)}\,{}_2F_1(a,b,c+1;-z^2/4ab)=\sum_{\nu=0}^{\infty}\frac{1}{\nu!}\,{}_3F_0(-\nu,a,b;1/ab)(z/2)^{\nu}J_{c+\nu}(z). \tag{21} $$

Finally, I give the resulting asymptotic expansion including third-order terms in $1/b$ for the case (20a), which is the case addressed in Ref. 2. It is seen that the resulting formula involves ${}_2F_0(-\nu,b;1/b)$ functions with $\nu=2,...,6$, and that the expressions for the highest and lowest order terms given in formulas (5) and (6a) and (6b) suffice to give the necessary terms. If we want to include fourth-order terms, we should go to $\nu=8$, and that would only require explicit calculation of the fourth-order $1/b$ term of $F(-6)$, the middle one of its three terms of order 3, 4, and 5. Since we know the coefficients of the other two powers, we can determine the value of the missing coefficient by calculating the $F(-6)$ function for a special value of b, say $b=1$.

The result to order three is

$$ \begin{aligned} {}_2F_1(a,b,c:z/b)=&\,{}_1F_1(a,c:z)+\frac{(a)_2}{(c)_2}\frac{z^2}{2}\,{}_1F_1(a+2,c+2;z)\,\frac{1}{b}\\ &+\left[\frac{(a)_3}{(c)_3}\frac{z^3}{3}\,{}_1F_1(a+3,c+3;z)+\frac{(a)_4}{(c)_4}\frac{z^4}{8}\,{}_1F_1(a+4,c+4;z)\right]\frac{1}{b^2}\\ &+\left[\frac{(a)_4}{(c)_4}\frac{z^4}{4}\,{}_1F_1(a+4,c+4;z)+\frac{(a)_5}{(c)_5}\frac{z^5}{6}\,{}_1F_1(a+5,c+5;z)\right.\\ &\left.+\frac{(a)_6}{(c)_6}\frac{z^6}{48}\,{}_1F_1(a+6,c+6;z)\right]\frac{1}{b^3}+O\left(\frac{1}{b^4}\right). \end{aligned} \tag{22} $$

Equation (22) agrees to second order with the result of Ref. 2, Eq. (2.7).

APPENDIX

In this appendix we shall often use two different asymptotic estimates of the Pochhammer symbol $(a+\nu)_n=\Gamma(a+\nu+n)/\Gamma(a+\nu)$, which can be derived from the asymptotic estimate of $\Gamma(a+z)$ as $z\to\infty, |\arg z|<\pi$

$$ \Gamma(a+z)=\sqrt{2\pi}(z/e)^{z}z^{a-1/2}[1+A(a)/z+B(a)/z^2+O(1/z^3)], \tag{A1} $$

where $A(a)=1/12+a(a-1)/2$ and $B(a)$ is a fourth-degree polynomial in a. In (A1) a is assumed finite, or more general, $|a|^2 \ll |z|$.

From (A1) with $z=\nu$ and $z=\nu+n$, we get when $\nu\to\infty$, any positive n

$$(a+\nu)_n=\left(\frac{\nu+n}{e}\right)^n\left(\frac{\nu+n}{\nu}\right)^{\nu+a-1/2}\left[1-A(a)\frac{n}{n+\nu}\frac{1}{\nu}+\frac{n}{n+\nu}O(1/\nu^2)\right]. \tag{A2}$$

If n stays finite, the first correction term is actually of order $1/\nu^2$, the second of order $1/\nu^3$, and (A2) then gives, including the first correction term, the first three terms in the polynomial $(a+\nu)_n=\nu^n+a_1\nu^{n-1}+\cdots$.

Assuming instead $n\to\infty$ and ν finite, or $\nu^2 \ll n$, we get from (A1)

$$(a+\nu)_n=\frac{\sqrt{2\pi}}{\Gamma(a+\nu)}(n/e)^n n^{a+\nu-1/2}[1+A(a+\nu)/n+B(a+\nu)/n^2+O(1/n^3)]. \tag{A3}$$

It should be noted that the definition of $(a+\nu)_n$ as a quotient of gamma functions actually defines $(a+\nu)_n$ as a holomorphic function for general complex n and ν. We shall sometimes use this extension in connection with the estimate of a sum over n by a corresponding integral over (continuous) n, and even deforming the integration path into the complex n plane.

1. Study of the asymptotic behavior, $\nu\to\infty$, of ${}_pF_q([a+\nu],[c+\nu],z)$

Unless one of the a's is a nonpositive integer, we must have $p\leqslant q+1$.

Let us first state the result in some simple cases, using well-known transformation formulas for the hypergeometric and confluent hypergeometric functions

$${}_1F_0(a+\nu;z)=(1-z)^{-a-\nu}, \tag{A4a}$$

$$\begin{aligned}{}_2F_1(a+\nu,b+\nu,c+\nu;z)&=(1-z)^{c-a-b-\nu}\,{}_2F_1(c-a,c-b,c+\nu;z)\\&=(1-z)^{c-a-b-\nu}[1+O(1/\nu)],\end{aligned} \tag{A4b}$$

$${}_1F_1(a+\nu,c+\nu;z)=e^z\,{}_1F_1(c-a,c+\nu;-z)=e^z+O(1/\nu)], \tag{A4c}$$

$${}_0F_1(c+\nu;z)=1+\frac{z}{c+\nu}\sum_{n=1}\frac{z^{n-1}}{n!(c+\nu+1)_{n-1}}=1+O(1/\nu). \tag{A4d}$$

The order terms $O(1/\nu)$ in (A4c) and (A4d) hold uniformly in z for z bounded, say $|z|<R$, but the "order constant" will increase with increasing R.

From (A2) follows for large ν

$$([a+\nu])_n=\left(\frac{\nu+n}{e}\right)^{pn}\left(\frac{\nu+n}{\nu}\right)^{p(\nu-1/2)+s[a]}\left[1-s[A(a)]\frac{n}{n+\nu}\frac{1}{\nu}+\cdots\right]. \tag{A5}$$

This implies that one can for large ν "multiply" and "divide" Pochhammer symbols between numerator and denominator in the expansion coefficients of the ${}_pF_q$ functions.

One should thus expect that asymptotically for large ν

$${}_{q+1}F_q([a+\nu],[c+\nu];z)\approx{}_1F_0(s[a]-s[c]+\nu;z)=(1-z)^{-s[a]+s[c]-\nu}, \tag{A6a}$$

$${}_qF_q([a+\nu],[c+\nu];z)\approx{}_1F_1(s[a]+\nu,s[c]+\nu;z)=e^z+O(1/\nu), \tag{A6b}$$

$${}_pF_{p+1}([a+\nu],[c+\nu];z)\approx{}_0F_1(s[c]-s[a]+\nu;z)=1+O(1/\nu). \tag{A6c}$$

For $q\geqslant p+1$ one finds in the same way as in (A4d) that

$$ {}_pF_{p+l}([a+\nu],[c+\nu];z)=1+O(1/\nu^l), l\geqslant 1. \tag{A7}$$

$O(1/\nu^l)$ should be interpreted in the way that is indicated after (A4d).

Using (A5) it is possible to show the estimates (A6b)–(A6c) and (A7); to prove (A6a) seems to be more difficult. However, all the estimates in (A6) and (A7) have been derived by Knottnerus,[6] as quoted and presented in Ref. 7, Chap. VII, 7.3, Eqs. (3), (4), and (5).

So, summing up we see that the functions ${}_pF_q([a+\nu],[c+\nu];z)$ influence the convergence of the right-hand side of (4) only in the limiting case $p=q+1$, where, besides the necessary restriction $|z|<1$, the essential asymptotic behavior is $(1-z)^{-\nu}$.

2. Asymptotic behavior, $\nu\to\infty$, of ${}_{p'+1}F_{q'}(-\nu,[b],[d],p[d]/p[b])$

Although some of the results below are contained in, or can be derived from results presented in Ref. 7, Chap. VII, I give an independent presentation, only sometimes checking against or using results from this reference.

For simplicity of notation let us drop the primes on p' and q' and use $-n$ instead of $-\nu$ as the first parameter and ν as the summation index. Recall that according to the assumptions stated after Eq. (4) $p[d]/p[b]$ is finite and stays away from zero. We can write for a general argument z

$$ {}_{p+1}F_q(-n[b],[d]:z)=\frac{\Gamma([d]}{\Gamma([b])}\sum_{\nu=0}^{n} A_\nu(n)(-z)^\nu, \tag{A8}$$

where from (A1), with the notation $k=q-p$

$$ A_\nu(n)=\binom{n}{\nu}\frac{\Gamma([b+\nu])}{\Gamma([d+\nu])}=\binom{n}{\nu}(2\pi)^{-k/2}\left(\frac{\nu}{e}\right)^{-k\nu}\nu^{s[b]-s[d]+k/2}[1+O(1/\nu)]. \tag{A9}$$

As we shall see, the main contribution to the asymptotic behavior for large n of the ${}_{p+1}F_q(-n,\ldots)$ function comes from terms with large ν (at worst a fractional power of n, see below), so that (A9) can be used in the estimate. This means that the asymptotic form of such a function, apart from the gamma function factors in front of (A8), depends only on k and the combination $s[b]-s[d]$ of parameters.

The binomial coefficient $\Gamma(n+1)/\Gamma(\nu+1)\Gamma(n-\nu+1)$ satisfies the inequality

$$ 1\leqslant\binom{n}{\nu}\leqslant\binom{n}{n/2}\approx\sqrt{2/\pi n}\cdot 2^n, \tag{A10}$$

and has the asymptotic behavior, large ν and $n-\nu$

$$ \binom{n}{\nu}=\frac{\exp\left[\nu(\ln(n/\nu)+1)-(\nu^2/n)\sum_{\mu=0}^{\infty}\frac{1}{(\mu+1)(\mu+2)}\left(\frac{\nu}{n}\right)^\mu\right]}{\sqrt{2\pi\nu(1-\nu/n)}}\left[1+O\left(\max\left\{\frac{1}{\nu},\frac{1}{n-\nu}\right\}\right)\right], \tag{A11}$$

and in particular in a more symmetrical form between ν and $n-\nu$

$$ \binom{n}{yn}\approx\frac{\exp\{n[-y\ln y-(1-y)\ln(1-y)]\}}{\sqrt{2\pi ny(1-y)}}[1+O(1/n)],\quad \varepsilon<y<1-\varepsilon. \tag{A12}$$

If we ignore the actual value of $z=p[d]]p[b]$ we see from (A8) and (A9) that the most ''unfavorable'' case is z real and negative, since all terms then have essentially the same sign; this is strictly true if all the parameters $[b]$ and $[d]$ are positive. The estimate for this case then gives a majorization for general parameters and general complex z (which we shall assume stays away a

positive distance from zero) as argument. The asymptotic estimates in (A9)–(A12) then imply a qualitatively different behavior for the two cases $k>0$ and $k<0$. In the first case the terms in the lower part of the series give the dominant contribution, whereas in the second case the final terms dominate. $k=0$ is an intermediate case where there is a sharp peak of dominant terms near the middle of the series; here, the estimate in (A12) turns out to be useful.

We start with the case with negative k, where the dominant contribution for large n is expected to come from the end of the series, cf. (A9). To explore this we use the "reversed summation" formula, following from $(b)_n=(-1)^{n-\nu}(b)_\nu(1-b-n)_{n-\nu}$

$$ {}_{p+1}F_q(-n,[b],[d];z)=\frac{([b])_n}{([d])_n}(-z)^n\,{}_{q+1}F_p(-n,[1-d-n],[1-b-n];(-1)^{p-q}/z). \tag{A13}$$

Since

$$ {}_{q+1}F_p(-n,[1-d-n],[1-b-n];y)=\sum_{\nu=0}^{n}\frac{(-n)_\nu([1-d-n])_\nu}{([1-b-n])_\nu}\frac{y^\nu}{\nu!}, \tag{A14}$$

we would, by going to the limit in each term, expect the following asymptotic behavior as $n\to\infty$:

$$ {}_{q+1}F_{q+1}(-n,\ldots:y)\approx e^y;\quad {}_{q+1}F_p(-n,\ldots;y)\approx 1 \ \text{ for } \ p-q\geqslant 2. \tag{A15}$$

This behavior can be verified by a closer examination, as follows.

We write

$$ {}_{q+1}F_{q+1}(-n,[1-d-n],[1-b-n];y)=\sum_{\nu=0}^{n}a_\nu(n)\frac{y^\nu}{\nu!}, \tag{A16}$$

where—use $(b)_\nu=(-1)^\nu(1-b-\nu)_\nu$—

$$\begin{aligned} a_\nu(n)&=(-n)_\nu([1-d-n])_\nu/([1-b-n])_\nu\\ &=\frac{\Gamma(n+1)\Gamma([n+d])\Gamma([n-\nu+b])}{\Gamma(n-\nu+1)\Gamma([n-\nu+d])\Gamma([n+b])}\\ &\approx(1-\nu/n)^{s[b]-s[d]-1}\ \text{ for } \ n \ \text{ and } \ n-\nu \ \text{ large.} \end{aligned} \tag{A17}$$

Subtracting the series for the exponential and making obvious majorizations, we get

$$ \left|{}_{q+1}F_{q+1}(-n,\ldots;y)-e^y\right|\leqslant\sum_{\nu=0}^{m}|a_\nu(n)-1|\frac{|y|^\nu}{\nu!}+\sum_{m+1}^{n}|a_\nu(n)|\frac{|y|^\nu}{\nu!}+\sum_{m+1}^{\infty}\frac{|y|^\nu}{\nu!}, \tag{A18}$$

where m is large but small compared to n. Evidently, assuming $|y|<R$ and choosing m large enough, the last term can be made as small as we like, and by then taking n large enough the first term can also be made as small as desired. To handle the middle term one can check that the terms are monotonously decreasing with increasing ν, for large enough m, and divide the summation into two parts, using the asymptotic estimate in (A17) in the first part and monotonicity in the second, giving

$$ \sum_{m+1}^{n}\cdots<\max[1,2^{1-s[\mathrm{Re}\,b]+s[\mathrm{Re}\,d]}]\sum_{m+1}^{n/2}\frac{|y|^\nu}{\nu!}+(n/2)a_{n/2}(n)\frac{|y|^{n/2}}{(n/2)!}. \tag{A19}$$

Evidently this term can also be made arbitrarily small by picking for a given m a large enough n.

A similar argument for the case $p-q\geqslant 2$ verifies the second estimate in (A15). It should be observed that these estimates assume y bounded, which means in the actual application that the argument $p[d]/p[b]$ should stay away from zero, as we have already assumed.

For $k\geqslant 0$ we put temporarily $z=-x$, x real and positive, in (A8), and find the location of the peak value of the terms by the condition

$$1/x=A_{\nu+1}(n)/A_{\nu}(n)=\frac{n-\nu}{\nu+1}\frac{p[b+\nu]}{p[d+\nu]}\approx\frac{n-\nu}{\nu^{k+1}},\quad \text{large } n \text{ and } \nu. \tag{A20}$$

For $k=0$ we then get the maximum for $\nu_0=nx/(1+x)$, for $k\geqslant 1$ $\nu_0=\sqrt[k+1]{nx}$.

Let us first look at the case $k=0$. Generalizing to a complex z and approximating the sum by an integral, using the asymptotic approximations (A9) and (A12) and changing integration variable by $\nu=ny$ we get, with $A=s[b]-s[d]$

$$\sum_{\nu=0}^{n}A_{\nu}(n)z^{\nu}\approx\sum_{\nu=0}^{n}\binom{n}{\nu}\nu^{A}z^{\nu}\approx\int_0^n\binom{n}{\nu}\nu^{A}z^{\nu}\,d\nu\approx\frac{n^{A+1/2}}{\sqrt{2\pi}}\int_0^1\frac{e^{ng(y)}}{\sqrt{y(1-y)}}y^{A}dy, \tag{A21}$$

where

$$g(y)=-y\ln y-(1-y)\ln(1-y)+y\ln z, \tag{A22}$$

goes from 0 to $\ln z$ as y goes from 0 to 1. For $z=x$, real and positive, $g(y)$ takes its maximum value $\ln(1+x)$ at $\nu_0/n=x/(1+x)$. In the general case we get $g'(y_0)=0$ for $y_0=z/(1+z)$, and $g(y_0)=\ln(1+z)$, $g''(y_0)=-(1+z)^2/z$. So, we can write

$$g(y)=\ln(1+z)-\frac{(1+z)^2}{2z}(y-y_0)^2+\cdots \tag{A23}$$

in the vicinity of the saddle point of the dominating factor in the integral. Extending the integral to complex y values, and using the standard saddle-point asymptotic evaluation of the integral, introducing a new integration variable $t=(1+z)\sqrt{n/2z}(y-y_0)$, we get the asymptotic estimate

$$\int_0^1\frac{e^{ng(y)}}{\sqrt{y(1-y)}}y^{A}dy=\sqrt{2\pi/n}(1+z)^{n-A}z^{A}[1+O(1/n)], \tag{A24}$$

which finally leads to the estimate

$${}_{p+1}F_p(-n,[b],[d];-z)=\frac{\Gamma([d])}{\Gamma([b])}(nz)^{s[b]-s[d]}(1+z)^{n-s[b]+s[d]}[1+O(1/n)]. \tag{A25}$$

The error estimate $O(1/n)$ comes from (A9), (A11), and the two approximations in (A21) and (A24): the approximation of a sum by an integral—in most cases seen the other way around—gives a relative error of the order of the discretization interval squared times the quotient of the second derivative of the function to the function itself, which gives $(1/\sqrt{n})^2\cdot 1$; and the next to leading term in the evaluation of the integral in (A24), which is also of relative order $1/n$ $\propto(1/\sqrt{n})^2$, since an integral over odd powers of t gives zero by symmetry.

The condition for the application of the saddle-point evaluation in (A24) is that $\mathrm{Re}\,g(y)$ takes its maximum value on the deformed integration path in the saddle point y_0, which means $\ln|1+z|>\ln|z|$, $\ln|1+z|>0$, i.e., $|1+z|>\max(1,|z|)$. Expressed in the argument $\varsigma=-z$ this means the left half-plane $\mathrm{Re}\,\varsigma<1/2$ outside the circle $|\varsigma-1|=1$.

Equation (A25) can be shown to be correct under the weaker condition $|1+z|>1$ according to the result in Ref. 7 7.4, (8), p. 265. In this reference a completely different and more rigorous

derivation of the asymptotic behavior is given. I have chosen to reproduce my own derivation as a test for the similar derivation in the cases $k>0$, where the results are not given except for $k=1$, at least not explicitly, in Ref. 7.

For $|1+z|<1$, it is shown in the same formula that the dominating asymptotic behavior is proportional to $(nz)^{-b'}$, where b' is the b parameter with the numerically smallest real part. If several have the same real part, there contributions are added, with coefficients depending on the b and d parameters. From our point of view the essential result is that, being powers of n, they don't influence the convergence of the right-hand side of (4).

For the case $p=1$, the formula reads ($|1-\varsigma|<1$)

$$ {}_2F_1(-n,b,d;\varsigma)=\frac{\Gamma(d)}{\Gamma(d-b)}(n\varsigma)^{-b}[1+O(1/n)], \tag{A26}$$

and can, for the restricted domain, be derived from (A25) by the transformation formula $F(-n,b,d:z)=(1-z)^nF[-n,d-b,d;z/(z-1)]$. For this special case (A25) and (A26) can be verified by asymptotic estimates of one of the standard integral representations of the hypergeometric function, involving integration from 0 to 1 over the integrand $(1-t)^{b-1}(1-t)^{d-b-1}(1-tz)^n$, simplest in the case where $\mathrm{Re}\,d>\mathrm{Re}\,b>0$. The dominant asymptotic contribution comes from the integration near 1, or 0, in the case (A25), or (A26), respectively.[8]

Let us now look at the cases with $k\geqslant 1$. Here, we have again

$$ {}_{p+1}F_{p+k}(-n,[b],[d];-z)=\frac{\Gamma([d])}{\Gamma([b])}\sum_{\nu=0}^{n}A_\nu(n)z^\nu. \tag{A27}$$

For large n and $z=x$, real and positive, the maximum term of the sum corresponds, as we have seen from (A20), to $\nu_0=\sqrt[k+1]{nx}$. With the aim of approximating the sum with an integral, we write $\nu=t\nu_0$, $0<t<n/\nu_0$, put $z=x\cdot e^{i\varphi}$, $|\varphi|<\pi$, and combine (A9) and (A11) to obtain

$$\begin{aligned}\ln[A_\nu(n)z^\nu]=&-(k+1)\nu_0 t[\ln t-1-i\varphi/(k+1)]-(1/2n)\nu_0{}^2t^2+[s[b]-s[d]\\&+(k-1)/2](\ln\nu_0+\ln t)-\ln(2\pi)^{(k+1)/2}+O(1/\nu)+O(\nu^3/n^2).\end{aligned} \tag{A28}$$

The dominating terms of order $\nu_0\ln\nu_0$ from (A9) and (A11) have been canceled, and the leading term of order ν_0 is multiplied with the function $f(t)=t[\ln t-1-i\varphi/(k+1)]$, which goes from 0 at $t=0$ to ∞ at $t=\infty$. $f'(t)=0$ for $t=t_0=e^{i\varphi/(k+1)}$, which corresponds to a negative $\mathrm{Re}\,f(t_0)=-\cos[\varphi/(k+1)]$. $f(t)$ can be expanded around t_0 as $f(t)=-t_0+(t-t_0)^2/2t_0-(t-t_0)^3/6t_0^2+\cdots$. Making a standard asymptotic saddle-point evaluation of the integral corresponds to introducing a new variable by $t-t_0=\tau/\sqrt{(k+1)\nu_0/t_0}$, integrating the resulting function $e^{-\tau^2/2}$ from $-\infty$ to $+\infty$ while putting $t=t_0$ in all other factors of the integrand. Since we have the partly symbolic differential relation ''$d\nu$''$=\nu_0dt=\sqrt{\nu_0t_0/(k+1)}d\tau$, we can estimate

$$\sum_\nu A_\nu(n)z^\nu\approx\nu_0\int_0^{n/\nu_0}\cdots dt\approx\sqrt{\nu_0t_0/(k+1)}\int_{-\infty}^{\infty}\cdots d\tau, \tag{A29}$$

which finally leads to the asymptotic estimate

$$\sum_{\nu=0}^{n}A_\nu(n)z^\nu=\frac{1}{(2\pi)^{k/2}\sqrt{k+1}}e^{(k+1)\nu_0t_0}e^{-\nu_0^2t_0{}^2/2n}(\nu_0t_0)^{s[b]-s[d]+k/2}[1+O(1/\nu_0)]. \tag{A30}$$

The error estimate $O(1/\nu_0)$ comes from (A9), (A11), and the two approximations in (A29) and (A30): the approximation of a sum by an integral—as argued earlier—gives a relative error of the order of the discretization interval squared times the quotient of the second derivative of the function to the function itself, which, if seen relative to the integral over t, gives $(1/\nu_0)^2\cdot\nu_0$ (or in

the τ variable $(1/\sqrt{\nu_0})^2 \cdot 1)$, and the next to leading term in the asymptotic saddle-point estimate of the integral which is also of relative order $1/\nu_0 \propto (1/\sqrt{(k+1)\nu_0})^2$, since an integral over odd powers of τ gives zero by symmetry.

From (A30) we get for the generalized hypergeometric polynomial the estimate for large n, $k \geqslant 1$, and $|\arg z| < \pi$

$$ {}_{p+1}F_{p+k}(-n,[b].[d];-z) = \frac{\Gamma([d])}{\Gamma([b])} \frac{1}{(2\pi)^{k/2}\sqrt{k+1}} (nz)^{[s[b]-s[d]+k/2]/(k+1)} e^{(k+1)^{k+1}\sqrt{nz}} \times e^{-z/2\delta_{1k}} [1 + O(1/^{k+1}\sqrt{nx})]. \tag{A31} $$

Equation (A31) shows that for the cases $k \geqslant 1$ the functions ${}_{p'+1}F_{q'}(-\nu,\ldots)$ give a harmless, slower than exponential ν behavior to the convergence of the right-hand side series in Eq. (4).

Finally, we shall make a comment on the special case of (A31) with $k=1$, $p=0$:

$$ {}_1F_1(-n,d;-z) = \frac{\Gamma(d)}{2\sqrt{\pi}} (nz)^{1/4-d/2} e^{-z/2} e^{2\sqrt{nz}} [1 + O(1/\sqrt{nz})]. \tag{A32} $$

This function is essentially a generalized Laguerre polynomial

$$ L_n^{\alpha}(x) = \frac{\Gamma(n+\alpha+1)}{\Gamma(\alpha+1)n!} {}_1F_1(-n,\alpha+1;x) \approx \frac{n^{\alpha}}{\Gamma(\alpha+1)} {}_1F_1(-n,\alpha+1;x). \tag{A33} $$

Some known asymptotic formulas, large n, for the Laguerre polynomial lead to the following corresponding formulas for the confluent hypergeometric polynomial: Fejer's formula[9] for the behavior on the positive real axis

$$ {}_1F_1(-n,d;x) = \frac{\Gamma(d)}{\sqrt{\pi}} (nx)^{1/4-d/2} e^{x/2} \cos[2\sqrt{nx} + (1/4 - d/2)\pi] + O(n^{1/4-d/2}), \tag{A34} $$

valid for fixed positive x, or uniformly in a finite interval staying away from 0.

A formula by Perron[10] gives the behavior in the complex plane cut along the positive real axis

$$ {}_1F_1(-n,d;z) = \frac{\Gamma(d)}{2\sqrt{\pi}} (-nz)^{1/4-d/2} e^{x/2} \exp[2\sqrt{-nz}]\{1 + O(1/\sqrt{n})\}, \tag{A35} $$

which agrees with (A32). Equations (A34) and (A35) show that we get the behavior on the positive real axis by adding the limiting values from above and below in the complex plane [which makes more sense if we look the other way, extending the formula on the real axis up (or down) into the complex plane]. This probably holds also for the general case (A31).

[8] The asymptotic estimates given in Ref. 4, Chap. 2.32, (14) and (15), p. 77, are not correct. For one thing they evidently do not satisfy the transformation formula for the hypergeometric function quoted above. The mistake made in the derivation is that the original error estimate in formula (13) is incorrect, so the transformation to the asymptotics for the

confluent hypergeometric function is not valid. The formulas should be corrected by substituting the factor $(1-z)^{c-a-b}$ for the factor e^{bz} in the two formulas. The results in Ref. 4 have been quoted also in later references, such as Abramowitz, Stegun: *Handbook of Mathematical Functions*, and Magnus, Oberhettinger, Soni: *Formulas and Theorems for the Special Functions of Mathematical Physics*.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 1 JANUARY 2004

Low dimensional cohomology of general conformal algebras gc_N

Yucai Su[a)]
Department of Mathematics, Shanghai Jiaotong University, Shanghai 200030, People's Republic of China and Department of Mathematics, Harvard University, Cambridge, Massachusetts 02138

(Received 18 April 2003; accepted 26 September 2003)

We compute the low dimensional cohomologies $\tilde{H}^q(gc_N,\mathbb{C})$, $H^q(gc_N,\mathbb{C})$ of the infinite rank general Lie conformal algebras gc_N with trivial coefficients for $q\leqslant 3$, $N=1$ or $q\leqslant 2$, $N\geqslant 2$. We also prove that the cohomology of gc_N with coefficients in its natural module is trivial, i.e., $H^*(gc_N,\mathbb{C}[\partial]^N)=0$, and thus partially solve an open problem of Bakalov–Kac–Voronov [Commun. Math. Phys., **200**, 561–598 (1999)]. © *2004 American Institute of Physics.*

I. INTRODUCTION

The notion of a conformal algebra, introduced by Kac in Ref. 12, encodes an axiomatic description of the operator product expansion of chiral fields in conformal field theory. Conformal algebras play important roles in quantum field theory and vertex operator algebras (e.g., Ref. 12), whose study has drawn much attention in the literature (e.g., Refs. 1–7, 12–14, and 20–23). As is pointed out in Ref. 1, on one hand, it is an adequate tool for the study of infinite-dimensional Lie algebras satisfying the locality property (cf. Refs. 5, 12, and 14). On the other hand, conformal modules over a conformal algebra R correspond to conformal modules over the associated Lie algebra Lie R (cf. Ref. 3). The main examples of Lie algebras Lie R are the Lie algebras "based" on the punctured complex plane $\mathbb{C}^\times$, namely, the Lie algebra $Vect\mathbb{C}^\times$ of vector fields on $\mathbb{C}^\times$ (the Virasoro algebra) and the Lie algebra of maps of $\mathbb{C}^\times$ to a finite-dimensional Lie algebra (the loop algebra). Their irreducible conformal modules are the spaces of densities on $\mathbb{C}^\times$ and loop modules, respectively (cf. Ref. 3). Since complete reducibility does not hold in this case (cf. Refs. 4 and 10), one may expect that their cohomology theory is very interesting and important (cf. Ref. 1), just as the cohomology theory of Lie algebras has played important roles in the structure and representation theories of Lie algebras (cf. Refs. 8–11 and 15–19).

A general theory of cohomology of Lie conformal algebras was established by Bakalov, Kac, and Voronov in Ref. 1. They also computed the cohomologies for the finite simple Lie conformal algebras. However the problem for the general Lie conformal algebra gc_N, which is an infinite Lie conformal algebra, remains open. It is well-known that the general Lie conformal algebra gc_N plays the same important role in the theory of Lie conformal algebras as the general Lie algebra gl_N does in the theory of Lie algebras: any module $M=\mathbb{C}[\partial]^N$ over a Lie conformal algebra R is obtained via a homomorphism $R\to gc_N$ (cf. Refs. 5 and 12), thus the study of Lie conformal algebras gc_N has drawn some authors' attentions (cf. Refs. 1, 2, 6, 13, and 14). It seems to us that the computation of cohomology of gc_N is important.

In this paper, we compute the low-dimensional basic cohomologies $\tilde{H}^q(gc_N,\mathbb{C})$ and the reduced cohomology $\tilde{H}^q(gc_N,\mathbb{C})$ of gc_N with trivial coefficients for $q\leqslant 3$, $N=1$ or $q\leqslant 2$, $N\geqslant 2$. We also prove that the cohomology of gc_N with coefficients in its natural module is trivial, i.e., $H^*(gc_N,\mathbb{C}[\partial]^N)=0$; thus we partially solve an open problem in Ref. 1.

In Sec. II, we shall recall definitions of conformal algebras, their modules and cohomology,

[a)]Electronic mail: ycsu@sjtu.edu.cn

and present the main theorem of this paper (Theorem 2.5). Sections III and IV are devoted to the proof of the main theorem.

II. NOTATIONS AND MAIN RESULTS

We shall briefly recall definitions of conformal algebras, their modules and cohomology. More details can be found in, say, Ref. 1.

Definition 2.1: A *Lie conformal algebra* is a $\mathbb{C}[\partial]$-module A with a λ-bracket $[a_\lambda b]$ which defines a linear map $A\times A\to A[\lambda]$, where $A[\lambda]=\mathbb{C}[\lambda]\otimes A$ is the space of polynomials of λ with coefficients in A, satisfying

$$[\partial a_\lambda b]=-\lambda[a_\lambda b],\quad [a_\lambda \partial b]=(\partial+\lambda)[a_\lambda b]\quad \text{(conformal sesquilinearity)}, \tag{2.1}$$

$$[a_\lambda b]=-[b_{-\lambda-\partial}a]\quad \text{(skew-symmetry)}, \tag{2.2}$$

$$[a_\lambda[b_\mu c]]=[[a_\lambda b]_{\lambda+\mu}c]+[b_\mu[a_\lambda c]]\quad \text{(Jacobi identity)}, \tag{2.3}$$

for $a, b, c\in A$. A subset $S\subset A$ is called a *generating set* if S generates A as a $\mathbb{C}[\partial]$-module. If there exists a finite generating set, then A is called *finite*. Otherwise, it is called *infinite*. □

There is a similar notion of associative conformal algebras, which we shall not introduce in this paper. Below we shall only work with Lie conformal algebras, thus we shorten the term ''Lie conformal algebra'' to ''conformal algebra.'' The simplest nontrivial conformal algebra is the *Virasoro conformal algebra* Vir, which is a rank one free $\mathbb{C}[\partial]$-module generated by a symbol L such that

$$\text{Vir}=\mathbb{C}[\partial]L,\quad [L_\lambda L]=(\partial+2\lambda)L. \tag{2.4}$$

Note that, using (2.1), it suffices to define λ-brackets on a generating set. Let $N\geqslant 1$ be an integer. The *general conformal algebra* gc_N can be defined (see, e.g., Ref. 14) as an infinite rank free $\mathbb{C}[\partial]$-module with a generating set

$$S_N=\{J_A^n | n\in\mathbb{Z}_+, A\in gl_N\}, \tag{2.5}$$

where gl_N is the space of $N\times N$ matrices (note that the set S_N is not $\mathbb{C}$-linearly independent, for example, $J_{aA}^m=aJ_A^m$ for $a\in\mathbb{C}$), such that the λ-bracket is defined by

$$[J_{A\lambda}^m J_B^n]=\sum_{s=0}^{m}\binom{m}{s}(\lambda+\partial)^s J_{AB}^{m+n-s}-\sum_{s=0}^{n}\binom{n}{s}(-\lambda)^s J_{BA}^{m+n-s}, \tag{2.6}$$

for $m, n\in\mathbb{Z}_+$, $A, B\in gl_N$, where $\binom{m}{s}=m(m-1)\cdots(m-s+1)/s!$ if $s\geqslant 0$ and $\binom{m}{s}=0$ otherwise, is the binomial coefficient.

Definition 2.2: A *module* over a conformal algebra A is a $\mathbb{C}[\partial]$-module M with a λ-action $a_\lambda v$ which defines a map $A\times M\to M[[\lambda]]$, where $M[[\lambda]]$ is the set of formal power series of λ with coefficients in M, such that

$$a_\lambda(b_\mu v)-b_\mu(a_\lambda v)=[a_\lambda b]_{\lambda+\mu}v, \tag{2.7}$$

$$(\partial a)_\lambda v=-\lambda a_\lambda v,\quad a_\lambda(\partial v)=(\partial+\lambda)a_\lambda v, \tag{2.8}$$

for $a, b\in A$, $v\in M$. If $a_\lambda v\in M[\lambda]$ for all $a\in A$, $v\in M$, then the A-module M is called *conformal*. If M is finitely generated over $\mathbb{C}[\partial]$, then M is simply called *finite*.

Below we shall only consider ''conformal modules,'' thus we drop the word ''conformal'' and simply call a ''conformal module'' a ''module.'' Clearly, the one-dimensional vector space $\mathbb{C}$ can be defined as a module (called a *trivial module*) over any conformal algebra A with both the action

of ∂ and the action of A being zero. Furthermore, for $a\in\mathbb{C}$, $a\neq 0$, one can define a $\mathbb{C}[\partial]$-module $\mathbb{C}_a$, which is the one-dimensional vector space $\mathbb{C}$ such that $\partial v=av$ for $v\in\mathbb{C}_a$. Then $\mathbb{C}_a$ becomes an A-module with trivial action of A.

Let $\alpha\in\mathbb{C}$. The space $\mathbb{C}^N[\partial]$ (a rank N free $\mathbb{C}[\partial]$-module) can be defined as a gc_N-module with λ-action

$$J^m_{A\lambda}v=(\partial+\lambda+\alpha)^mAv \quad \text{for } A\in gl_N,\ m\in\mathbb{Z}_+,\ v\in\mathbb{C}^N \tag{2.9}$$

[cf. the statement after (2.4)]. We denote this module by $\mathbb{C}^N_\alpha[\partial]$. When $\alpha=0$, the module $\mathbb{C}^N[\partial]=\mathbb{C}^N_0[\partial]$ is called the *natural module of* gc_N.

Definition 2.3: Let $q\in\mathbb{Z}_+$. A *q-cochain of a conformal algebra A with coefficients in a module M* is a $\mathbb{C}$-linear map $\gamma: A^{\otimes q}\to M[\lambda_1,\dots,\lambda_q]$,

$$\gamma(a_1\otimes\cdots\otimes a_q)=\gamma_{\lambda_1,\dots,\lambda_q}(a_1,\dots,a_q), \tag{2.10}$$

satisfying

$$\gamma_{\lambda_1,\dots,\lambda_q}(a_1,\dots,\partial a_i,\dots,a_q)=-\lambda_i\gamma_{\lambda_1,\dots,\lambda_q}(a_1,\dots,a_i,\dots,a_q) \quad \text{(conformal antilinearity)}, \tag{2.11}$$

$$\begin{aligned}&\gamma_{\lambda_1,\dots,\lambda_{i-1},\lambda_{i+1},\lambda_i,\lambda_{i+2},\dots,\lambda_q}(a_1,\dots,a_{i-1},a_{i+1},a_i,a_{i+2},\dots,a_q)\\ &\quad=-\gamma_{\lambda_1,\dots,\lambda_{i-1},\lambda_i,\lambda_{i+1},\lambda_{i+2},\dots,\lambda_q}\\ &\qquad\times(a_1,\dots,a_{i-1},a_i,a_{i+1},a_{i+2},\dots,a_q) \quad \text{(skew-symmetry)},\end{aligned} \tag{2.12}$$

for $a_1,\dots,a_q\in A$ and all possible i. We let $A^{\otimes 0}=\mathbb{C}$, so that a zero-cochain γ is simply an element of M. □

We define a *differential d of a cochain* γ as follows:

$$\begin{aligned}(d\gamma)_{\lambda_1,\dots,\lambda_{q+1}}(a_1,\dots,a_{q+1})&=\sum_{i=1}^{q+1}(-1)^{i+1}a_{i\lambda_i}\gamma_{\lambda_1,\dots,\hat{\lambda}_i,\dots,\lambda_{q+1}}(a_1,\dots,\hat{a}_i,\dots,a_{q+1})\\ &\quad+\sum_{1\leq i<j\leq q+1}(-1)^{i+j}\gamma_{\lambda_i+\lambda_j,\lambda_1,\dots,\hat{\lambda}_i,\dots,\hat{\lambda}_j,\dots,\lambda_{q+1}}\\ &\quad\times([a_{i\lambda_i}a_j],a_1,\dots,\hat{a}_i,\dots,\hat{a}_j,\dots,a_{q+1}),\end{aligned} \tag{2.13}$$

where γ is extended linearly over the polynomials in λ_i, and where, the symbol $\hat{}$ means the element below it is missing. In particular,

$$(d\gamma)_\lambda(a)=a_\lambda\gamma \quad \text{if } \gamma\in M \text{ is a zero-cochain.} \tag{2.14}$$

By Ref. 1, the operator d preserves the space of cochains and $d^2=0$, so that the cochains form a complex, which will be denoted by $\widetilde{C}^*=\widetilde{C}^*(A,M)=\oplus_{q\in\mathbb{Z}_+}\widetilde{C}^q(A,M)$, and called the *basic complex* for the A-module M.

Define the structure of a $\mathbb{C}[\partial]$-module on $\widetilde{C}^*(A,M)$ by

$$(\partial\gamma)_{\lambda_1,\dots,\lambda_q}(a_1,\dots,a_q)=\left(\partial_M+\sum_{i=1}^q\lambda_i\right)\gamma_{\lambda_1,\dots,\lambda_q}(a_1,\dots,a_q), \tag{2.15}$$

where ∂_M denotes the action of ∂ on M. Then $d\partial=\partial d$ (see Ref. 1) and so the graded subspace $\partial\widetilde{C}^*\subset\widetilde{C}^*$ forms a subcomplex. Define the quotient complex $C^*=C^*(A,M)=\widetilde{C}^*(A,M)/\partial\widetilde{C}^*(A,M)=\oplus_{q\in\mathbb{Z}_+}C^q(A,M)$, called the *reduced complex*.

Definition 2.4: The *basic cohomology* $\widetilde{H}^*(A,M)$ *of a conformal algebra A with coefficients in a module M* is the cohomology of the basic complex $\widetilde{C}^*$. The *(reduced) cohomology* $H^*(A,M)$ is the cohomology of the reduced complex C^*. □

Note that the basic cohomology $\widetilde{H}^*(A,M)$ is naturally a $\mathbb{C}[\partial]$-module, whereas the reduced cohomology $H^*(A,M)$ is a complex vector space.

The main results of this paper are the following theorem.

Theorem 2.5: *(1) For the general conformal algebra* gc_1*, we have*

$$\dim \widetilde{H}^q(gc_1,\mathbb{C})=\begin{cases}1 & \text{if } q=0 \text{ or } 3,\\ 0 & \text{if } q=1 \text{ or } 2,\end{cases} \tag{2.16}$$

and

$$\dim H^q(gc_1,\mathbb{C})=\begin{cases}1 & \text{if } q=0,2 \text{ or } 3,\\ 0 & \text{if } q=1.\end{cases} \tag{2.17}$$

(2) Equations (2.16) and (2.17) also hold for the general conformal algebra gc_N *if* $q\leqslant 2$.

(3) $H^*(gc_N,\mathbb{C}_a)=0$ *if* $a\neq 0$.

(4) $H^*(gc_N,\mathbb{C}_\alpha^N[\partial])=0$ *for* $\alpha\in\mathbb{C}$*. Furthermore, for any* gc_N*-module M which is freely generated over* $\mathbb{C}[\partial]$ *such that there exists nonzero* $c\in\mathbb{C}$ *satisfying* $J^0_{I\lambda}v|_{\lambda=0}=cv$ *for* $v\in M$*, where I is the* $N\times N$ *identity matrix, we have* $H^*(gc_N,M)=0$.

Remark 2.6: (1) Equations (2.16) and (2.17) show that the cohomologies $\widetilde{H}^q(gc_1,\mathbb{C})$, $H^*(gc_1,\mathbb{C})$, $q\leqslant 3$, of the general conformal algebra gc_1 with trivial coefficients are isomorphic to those of the Virasoro conformal algebra with trivial coefficients.

(2) Theorem 2.5(2) in particular shows that there is a unique nontrivial universal central extension of the general conformal algebra gc_N, which agrees with that of the Lie algebra $\mathcal{D}^N$ of $N\times N$ matrix differential operators on the circle (cf. Refs. 16 and 18). (It is well-known that $\mathcal{D}^N$ is the distribution Lie algebra associated with gc_N, cf. Ref. 14.) A nontrivial reduced two-cocycle ψ' of gc_N is given in (3.36), and the universal central extension $\widetilde{g}c_N$ of gc_N corresponding to ψ' is given by

$$[J^m_{A\lambda}J^n_B]=\sum_{s=0}^{m}\binom{m}{s}(\lambda+\partial)^s J^{m+n-s}_{AB}-\sum_{s=0}^{n}\binom{n}{s}(-\lambda)^s J^{m+n-s}_{BA}$$

$$+(-1)^n\frac{m!n!}{(m+n+1)!}\operatorname{tr}(AB)\lambda^{m+n+1}C, \tag{2.18}$$

where C is a nonzero *central element* of $\widetilde{g}c_N$ (i.e., $[C_\lambda a]=[a_\lambda C]=0$ for all $a\in\widetilde{g}c_N$) such that $\mathbb{C}C$ is a trivial $\mathbb{C}[\partial]$-module.

(3) In Theorem 2.5(4), note that if we define the zero-bracket by $[a_0b]=[a_\lambda b]|_{\lambda=0}$ for a, $b\in gc_N$, and define the zero-action of gc_N on a module M by $a_0v=a_\lambda v|_{\lambda=0}$ for $a\in gc_N$, $v\in M$, then J^0_I is *central under zero-bracket*, i.e., $[J^0_{I0}a]=[a_0J^0_I]$ for $a\in gc_N$, and so the zero-action of J^0_I on any indecomposable gc_N-module M is a scalar. □

We shall give the proof of Theorem 2.5 in the next two sections.

III. PROOF OF THEOREM 2.5(2)–(4)

We shall keep the notation of the previous section. For a q-cochain $\gamma\in\widetilde{C}^q(A,M)$, we call γ a *q-cocycle* if $d\gamma=0$; a *q-coboundary* or a *trivial q-cocycle* if there is a $(q-1)$-cochain $\phi\in\widetilde{C}^{q-1}(A,M)$ such that $\gamma=d\phi$. Two cochains γ and ψ are *equivalent* if $\gamma-\psi$ is a coboundary. Denote by $\widetilde{D}^q(A,M)$ and by $\widetilde{B}^q(A,M)$ the spaces of q-cocycles and q-coboundaries, respectively. Then, by Definition 2.4, we have

$$\widetilde{H}^q(A,M)=\widetilde{D}^q(A,M)/\widetilde{B}^q(A,M)=\{\text{equivalent classes of } q\text{-cocycles}\}. \tag{3.1}$$

We shall divide the proof of Theorem 2.5(2)–(4) into several lemmas. (Although we are unable to give the general result for gc_N in this paper, Lemmas 3.1–4 below may be helpful in determining $\widetilde{H}^*(gc_N,\mathbb{C})$ and $H^*(gc_N,\mathbb{C})$ in the future.)

First suppose $\gamma\in\widetilde{C}^q(gc_N,\mathbb{C})$. Clearly, by (2.11), γ is uniquely determined by the right-hand side of (2.10) for $a_1,\ldots,a_q\in S_N$, where S_N is defined in (2.5). We can regard the right-hand side of (2.10) as a polynomial in $\lambda_1,\ldots,\lambda_q$. For any fixed $p\in\mathbb{Z}$, we define a $\mathbb{C}$-linear map $\gamma^{(p)}:gc_N^{\otimes q}\to\mathbb{C}[\lambda_1,\ldots,\lambda_q]$ such that (2.11) holds for $\gamma^{(p)}$ and such that

$$\gamma^{(p)}(J_{A_1}^{n_1}\otimes\cdots\otimes J_{A_q}^{n_q})=\gamma^{(p)}_{\lambda_1,\ldots,\lambda_q}(J_{A_1}^{n_1},\ldots,J_{A_q}^{n_q}) \tag{3.2}$$

is a homogenous polynomial in $\lambda_1,\ldots,\lambda_q$ consisting of all monomials of total degree p' which appear in $\gamma_{\lambda_1,\ldots,\lambda_q}(J_{A_1}^{n_1},\ldots,J_{A_q}^{n_q})$, where

$$p'=p+\sum_{i=1}^{q}n_i. \tag{3.3}$$

Then it is straightforward to see that $\gamma^{(p)}\in\widetilde{C}^q(gc_N,\mathbb{C})$ and

$$\gamma=\sum_{p\in\mathbb{Z}}\gamma^{(p)}. \tag{3.4}$$

Note that (3.4) is possibly an infinite sum, however for given $J_{A_1}^{n_1},\ldots,J_{A_q}^{n_q}\in S_N$, there are only finite many p's such that (3.2) is not zero; we call such a sum *summable*. From (2.6), (2.11) and (2.13) [note that in (2.6), if we informally regard the right-hand side as a polynomial in λ, ∂, J_{AB}, J_{BA}, then it is a homogenous polynomial of the total degree $m+n$; also note that (2.13) now takes the form such that the first sum in the right-hand side is missing since $\mathbb{C}$ is a trivial module and note from (2.11) that when we substitute (2.6) into (2.13), ∂ in (2.6) can be replaced by $-\lambda_i$ for some i], we immediately obtain the following lemma.

Lemma 3.1: A q-cochain $\gamma\in\widetilde{C}^q(gc_N,\mathbb{C})$ is a q-cocycle (resp., q-coboundary)⇔all $\gamma^{(p)}$ are q-cocycles (resp., q-coboundaries). □

A q-cochain of the form $\gamma^{(p)}$ is called a *homogenous q-cochain of degree p*.

Following Ref. 1, we define an operator $\tau_1:\widetilde{C}^q(gc_N,\mathbb{C})\to\widetilde{C}^{q-1}(gc_N,\mathbb{C})$ as follows: If $q=0$, we set $\tau_1\gamma=0$; otherwise, we set

$$(\tau_1\gamma)_{\lambda_1,\ldots,\lambda_{q-1}}(a_1,\ldots,a_{q-1})=(-1)^{q-1}\frac{\partial}{\partial\lambda}\gamma_{\lambda_1,\ldots,\lambda_{q-1},\lambda}(a_1,\ldots,a_{q-1},J)|_{\lambda=0}, \tag{3.5}$$

for $a_1,\ldots,a_{q-1}\in S_N$, where $J=J_I^1$ and I is the $N\times N$ identity matrix. Noting that, by (2.6),

$$[J_{A_i\lambda_i}^{n_i}J]=\sum_{s=1}^{n_i}\binom{n_i}{s}(\lambda_i+\partial)^sJ_{A_i}^{n_i+1-s}-(-\lambda_i)J_{A_i}^{n_i}, \tag{3.6}$$

we obtain

$$
\begin{aligned}
&((d\tau_1+\tau_1 d)\gamma^{(p)})_{\lambda_1,\ldots,\lambda_q}(J^{n_1}_{A_1},\ldots,J^{n_q}_{A_q})\\
&\quad=(-1)^q\frac{\partial}{\partial\lambda}\sum_{i=1}^{q}(-1)^{i+q+1}\gamma^{(p)}_{\lambda_i+\lambda,\lambda_1,\ldots,\hat{\lambda_i},\ldots,\lambda_q}([J^{n_i}_{A_i\lambda_i}J],J^{n_1}_{A_1},\ldots,\hat{J}^{n_i}_{A_i},\ldots,J^{n_q}_{A_q})|_{\lambda=0}\\
&\quad=\frac{\partial}{\partial\lambda}\sum_{i=1}^{q}\gamma^{(p)}_{\lambda_1,\ldots,\lambda_{i-1},\lambda_i+\lambda,\lambda_{i+1},\ldots,\lambda_q}(J^{n_1}_{A_1},\ldots,J^{n_{i-1}}_{A_{i-1}},[J^{n_i}_{A_i\lambda_i}J],J^{n_{i+1}}_{A_{i+1}},\ldots,J^{n_q}_{A_q})|_{\lambda=0},\quad(3.7)
\end{aligned}
$$

where the first equality follows from the fact that all terms appearing in $d\tau_1\gamma^{(p)}$ are canceled with the corresponding terms in $\tau_1 d\gamma^{(p)}$ and the terms left are all appearing in $\tau_1 d\gamma^{(p)}$ [cf. (2.13)]; the second equality follows from (2.12). Note that for a polynomial P, $\partial P/\partial\lambda|_{\lambda=0}$ is simply the coefficient of λ^1 in P. Now we substitute (3.6) into (3.7). By (2.11), $(\lambda_i+\partial)^s$ can be replaced by $(-\lambda)^s$. Since we only need coefficients of λ^1, the terms with $s\geqslant 2$ in (3.6) do not contribute to the calculation. Thus $[J^{n_i}_{A_i\lambda_i}J]$ in (3.7) can be replaced by $(\lambda_i-n_i\lambda)J^{n_i}_{A_i}$. Thus (3.7) is equal to

$$
\frac{\partial}{\partial\lambda}\sum_{i=1}^{q}(\lambda_i-n_i\lambda)\gamma^{(p)}_{\lambda_1,\ldots,\lambda_{i-1},\lambda_i+\lambda,\lambda_{i+1},\ldots,\lambda_q}(J^{n_1}_{A_1},\ldots,J^{n_q}_{A_q})|_{\lambda=0}=p\,\gamma^{(p)}_{\lambda_1,\ldots\lambda_q}(J^{n_1}_{A_1},\ldots,J^{n_q}_{A_q}),\quad(3.8)
$$

which follows from (3.3) and the fact that for a homogenous polynomial $P(\lambda_1,\ldots,\lambda_q)$ of total degree p', we have

$$
\frac{\partial}{\partial\lambda}\sum_{i=1}^{q}(\lambda_i-n_i\lambda)P(\lambda_1,\ldots,\lambda_{i-1},\lambda_i+\lambda,\lambda_{i+1},\ldots,\lambda_q)|_{\lambda=0}=\left(p'-\sum_{i=1}^{q}n_i\right)P.\quad(3.9)
$$

From (3.7) and (3.8), we obtain

$$
(d\tau_1+\tau_1 d)\gamma^{(p)}=p\,\gamma^{(p)}.\quad(3.10)
$$

So if $d\gamma=0$, then (3.10) shows that $\gamma'=\Sigma_{p\neq 0}\gamma^{(p)}=d(\Sigma_{p\neq 0}p^{-1}\tau_1\gamma^{(p)})$ [note that this is summable, cf. the statement after (3.4)] is a coboundary, and $\gamma-\gamma'=\gamma^{(0)}$. Thus, we obtain the following lemma.

Lemma 3.2: A q-cocycle in $\widetilde{D}^q(gc_N,\mathbb{C})$ is equivalent to a homogenous q-cocycle of degree zero. □

Now suppose γ is a homogenous q-cocycle of degree zero. For $1\leqslant j,\ k\leqslant N$, denote by $E_{j,k}$ the $N\times N$ matrix with entry 1 at (j,k) and 0 otherwise. Then

$$
S'_N=\{J^n_{E_{j,k}}|n\in\mathbb{Z}_+,1\leqslant j,k\leqslant N\}\quad(3.11)
$$

is a free generating set of gc_N over $\mathbb{C}[\partial]$. Let $h=\Sigma_{j=1}^{N}jE_{j,j}$. We define another operator $\tau_2:\widetilde{C}^q(gc_N,\mathbb{C})\to\widetilde{C}^{q-1}(gc_N,\mathbb{C})$ as follows: We set $\tau_2\gamma=0$ if $q=0$, otherwise we set

$$
(\tau_2\gamma)_{\lambda_1,\ldots,\lambda_{q-1}}(a_1,\ldots,a_{q-1})=(-1)^{q-1}\gamma_{\lambda_1,\ldots,\lambda_{q-1},0}(a_1,\ldots,a_{q-1},J^0_h),\quad(3.12)
$$

for $a_1,\ldots,a_{q-1}\in S_N$. Now note that, by (2.6),

$$
[J^{n_i}_{E_{j_i,k_i}\lambda_i}J^0_h]=\sum_{s=0}^{n_i}\binom{n_i}{s}k_i(\lambda_i+\partial)^s J^{n_i-s}_{E_{j_i,k_i}}-j_i J^{n_i}_{E_{j_i,k_i}}.\quad(3.13)
$$

Thus as discussed in (3.7) and (3.8), the terms with $s\geqslant 1$ do not contribute to the following calculation, and, as in (3.7), we have

$$
\begin{aligned}
&((d\tau_2+\tau_2 d)\gamma)_{\lambda_1,\ldots,\lambda_q}(J^{n_1}_{E_{j_1,k_1}},\ldots,J^{n_q}_{E_{j_q,k_q}})\\
&\quad=\sum_{i=1}^{q}\gamma_{\lambda_1,\ldots,\lambda_q}(J^{n_1}_{E_{j_1,k_1}},\ldots,J^{n_{i-1}}_{E_{j_{i-1},k_{i-1}}},[J^{n_i}_{E_{j_i,k_i}\lambda_i}J^0_h],J^{n_{i+1}}_{E_{j_{i+1},k_{i+1}}},\ldots,J^{n_q}_{E_{j_q,k_q}})\\
&\quad=\sum_{i=1}^{q}(k_i-j_i)\gamma_{\lambda_1,\ldots,\lambda_q}(J^{n_1}_{E_{j_1,k_1}},\ldots,J^{n_q}_{E_{j_q,k_q}}).
\end{aligned}
\tag{3.14}
$$

Thus as in Lemma 2.2, we obtain the following lemma.

Lemma 3.3: A q-cocycle in $\widetilde{D}^q(gc_N,\mathbb{C})$ is equivalent to a homogenous q-cocycle γ of degree zero satisfying

$$
\gamma_{\lambda_1,\ldots,\lambda_q}(J^{n_1}_{E_{j_1,k_1}},\ldots,J^{n_q}_{E_{j_q,k_q}})=0 \quad \text{if } \sum_{i=1}^{q}(j_i-k_i)\neq 0. \tag{3.15}
$$

□

For a q-cochain $\gamma\in\widetilde{C}^q(gc_N,\mathbb{C})$, we define a linear map $\Delta\gamma: gc_N^{\otimes q}\to\mathbb{C}[\lambda_1,\ldots,\lambda_{q-1}]$ by

$$
\Delta\gamma(a_1\otimes\cdots\otimes a_q)=\gamma_{\lambda_1,\ldots,\lambda_q}(a_1,\ldots,a_q)|_{\lambda_q=-\lambda_1-\ldots-\lambda_{q-1}}=\gamma_{\lambda_1,\ldots,\lambda_{q-1},-\lambda_1-\ldots-\lambda_{q-1}}(a_1,\ldots,a_q), \tag{3.16}
$$

for $a_1,\ldots,a_q\in gc_N$ [we define $\Delta\gamma=\gamma$ if $q=0$, and define $\Delta\gamma(a_1)=\gamma_{\lambda_1}(a_1)|_{\lambda_1=0}$ if $q=1$]. Let $C'^q(gc_N,\mathbb{C})=\{\Delta\gamma|\,\gamma\in\widetilde{C}^q(gc_N,\mathbb{C})\}$. Then we obtain a linear map $\Delta:\widetilde{C}^q(gc_N,\mathbb{C})\to C'^q(gc_N,\mathbb{C})$. If $\gamma\in\partial\widetilde{C}^q(gc_N,\mathbb{C})=(\Sigma_{i=1}^{q}\lambda_i)\widetilde{C}^q(gc_N,\mathbb{C})$ [note that $\partial_{\mathbb{C}}=0$, cf. (2.15)], then clearly $\Delta\gamma=0$. Thus Δ factors to a map $\Delta:C^q(gc_N,\mathbb{C})\to C'^q(gc_N,\mathbb{C})$.

Lemma 3.4: The map $\Delta:C^q(gc_N,\mathbb{C})\to C'^q(gc_N,\mathbb{C})$ is an isomorphism as spaces.

Proof: Suppose $\Delta\gamma=0$ for a q-cochain γ. For $a_1,\ldots,a_q\in gc_N$, regarding $\gamma_{\lambda_1,\ldots,\lambda_q}(a_1,\ldots,a_q)$ as a polynomial in λ_q, we see that it has a root $\lambda_q=-\Sigma_{i=1}^{q-1}\lambda_i$, i.e., it is divided by $\Sigma_{i=1}^{q}\lambda_i$. Thus

$$
\phi(a_1\otimes\cdots\otimes a_q)=\left(\sum_{i=1}^{q}\lambda_i\right)^{-1}\gamma_{\lambda_1,\ldots,\lambda_q}(a_1,\ldots,a_q) \tag{3.17}
$$

defines a map $\phi: gc_N^{\otimes N}\to\mathbb{C}[\lambda_1,\ldots,\lambda_q]$. Obviously, ϕ is a q-cochain, and $\gamma=(\Sigma_{i=1}^{q}\lambda_i)\phi\in\partial\widetilde{C}^q(gc_N,\mathbb{C})$. □

Thus we can identify $C^q(gc_N,\mathbb{C})$ with the space $C'^q(gc_N,\mathbb{C})$. We call an element in $C'^q(gc_N,\mathbb{C})$ a *reduced q-cochain*. We define the operator $d:C'^q(gc_N,\mathbb{C})\to C'^{q+1}(gc_N,\mathbb{C})$ by $d\Delta\gamma=\Delta d\gamma$, and then we have similar notions of *reduced q-cocycles, reduced q-coboundaries*.

Lemma 3.5: Theorem 2.5(2) holds.

Proof: Clearly, by (2.14), $\widetilde{D}^0(gc_N,\mathbb{C})=\widetilde{C}^0(gc_N,\mathbb{C})=\mathbb{C}$, and $\widetilde{B}^0(gc_N,\mathbb{C})=0$. Thus $\widetilde{H}^0(gc_N,\mathbb{C})=\mathbb{C}$. Also by (2.15), $\partial\widetilde{C}^0(gc_N,\mathbb{C})=0$ and we have $H^0(gc_N,\mathbb{C})=\mathbb{C}$.

Suppose $\gamma\in\widetilde{C}^1(gc_N,\mathbb{C})$ such that $d\gamma\in\partial\widetilde{C}^2(gc_N,\mathbb{C})$, i.e., there is $\phi\in\widetilde{C}^2(gc_N,\mathbb{C})$ such that

$$
\begin{aligned}
\gamma_{\lambda_1+\lambda_2}([u_{\lambda_1}v]) &= -(d\gamma)_{\lambda_1,\lambda_2}(u,v)\\
&= -(\partial\phi)_{\lambda_1,\lambda_2}(u,v)\\
&= -(\partial_{\mathbb{C}}+\lambda_1+\lambda_2)\phi_{\lambda_1,\lambda_2}(u,v)\\
&= -(\lambda_1+\lambda_2)\phi_{\lambda_1,\lambda_2}(u,v)
\end{aligned}
\tag{3.18}
$$

[cf. (2.13) and (2.15)] for $u, v\in S_N$. By (2.6), we have

$$[J^n_{A\lambda_1}J^0]=\sum_{s=1}^{n}\binom{n}{s}(\lambda_1+\partial)^s J^{n-s}_A, \tag{3.19}$$

for $A\in gl_N$, $n\in\mathbb{Z}_+$, where $J^0=J^0_I$. Thus by (2.11), (3.18), and (3.19), we have

$$\sum_{s=1}^{n}\binom{n}{s}(-\lambda_2)^s\gamma_{\lambda_1+\lambda_2}(J^{n-s}_A)=\gamma_{\lambda_1+\lambda_2}[J^n_{A\lambda_1}J^0]=-(\lambda_1+\lambda_2)\phi_{\lambda_1,\lambda_2}(u,v). \tag{3.20}$$

Let $\lambda_1=\lambda-\lambda_2$. Then expressions in (3.20) are polynomials in λ, λ_2 and the right-hand side is divided by λ, thus each term in the left-hand side is divided by λ. Therefore we can set

$$\gamma'_\lambda(J^n_A)=\lambda^{-1}\gamma_\lambda(J^n_A)\quad\text{for } a\in gl_N,\ n\in\mathbb{Z}_+. \tag{3.21}$$

Clearly, (3.21) defines a one-cochain $\gamma'\in\widetilde{C}^1(gc_N,\mathbb{C})$, and we have $\gamma=\partial\gamma'\in\partial\widetilde{C}^1(gc_N,\mathbb{C})$. This proves that $H^1(gc_N,\mathbb{C})=0$.

Now suppose $\gamma\in\widetilde{D}^1(gc_N,\mathbb{C})$ is a one-cocycle. This means that $\phi=0$ in (3.18) and (3.20), and, so, we obtain $\gamma=0$. Thus $\widetilde{H}^1(gc_N,\mathbb{C})=0$.

Next suppose $\psi\in\widetilde{D}^2(gc_N,\mathbb{C})$ is a homogenous two-cocycle of degree zero. We define a one-cochain f which is uniquely determined by

$$f_{\lambda_1}(J^n_A)=(n+1)^{-1}\frac{\partial}{\partial\lambda}\psi_{\lambda_1,\lambda}(J^{n+1}_A,J^0)|_{\lambda=0}. \tag{3.22}$$

Set $\gamma=\psi+df$, which is also a homogenous two-cocycle of degree zero. Then

$$\frac{\partial}{\partial\lambda}\gamma_{\lambda_1,\lambda}(J^n_A,J^0)|_{\lambda=0}=\frac{\partial}{\partial\lambda}\psi_{\lambda_1,\lambda}(J^n_A,J^0)|_{\lambda=0}-\frac{\partial}{\partial\lambda}f_{\lambda_1+\lambda}([J^n_{A\lambda_1}J^0])|_{\lambda=0}=0, \tag{3.23}$$

where the last equality follows from (3.19), (2.11) and (3.22) if $n\geqslant 1$, or from the fact that $\psi_{\lambda_1,\lambda}(J^0_A,J^0)$ is a constant polynomial [cf. (3.3)] if $n=0$. Thus we have

$$\begin{aligned}0&=\frac{\partial}{\partial\lambda}(d\gamma)_{\lambda_1,\lambda_2,\lambda}(J^m_A,J^n_B,J^0)|_{\lambda=0}\\&=\frac{\partial}{\partial\lambda}(-\gamma_{\lambda_1+\lambda_2,\lambda}([J^m_{A\lambda_1}J^n_B],J^0)\\&\quad+\gamma_{\lambda_1+\lambda,\lambda_2}([J^m_{A\lambda_1}J^0],J^n_B)-\gamma_{\lambda_2+\lambda,\lambda_1}([J^n_{B\lambda_2}J^0],J^m_A))|_{\lambda=0}\\&=m\gamma_{\lambda_1,\lambda_2}(J^{m-1}_A,J^n_B)+n\gamma_{\lambda_1,\lambda_2}(J^m_A,J^{n-1}_B),\end{aligned} \tag{3.24}$$

for A, $B\in gl_N$, m, $n\in\mathbb{Z}_+$, where the second equality follows from (2.13) and the last equality follows from (3.23), (3.19) and (2.11). Induction on $n\geqslant 0$ in (3.24) proves $\gamma_{\lambda_1,\lambda_2}(J^m_A,J^n_B)=0$. Thus $\gamma=0$ and so $\widetilde{H}^2(gc_N,\mathbb{C})=0$.

Finally, suppose $\psi'=\Delta\psi\in C'^2(gc_N,\mathbb{C})$ is a reduced two-cochain. By (2.13) and (3.16),

$$(d\psi')_{\lambda_1,\lambda_2}(a_1,a_2,a_3)=-\psi'_{\lambda_1+\lambda_2}([a_{1\lambda_1}a_2],a_3)+\psi'_{-\lambda_2}([a_{1\lambda_1}a_3],a_2)-\psi'_{-\lambda_1}([a_{2\lambda_2}a_3],a_1), \tag{3.25}$$

for $a_1,a_2,a_3\in gc_N$. We define a reduced one-cochain $f'=\Delta f\in C'^1(gc_N,\mathbb{C})$ as follows [note from (3.16) that $f'(a)=f_\lambda(a)|_{\lambda=0}=f_0(a)$ is simply a linear function $f':gc_N\to\mathbb{C}$, and it is not necessary to write down explicitly its representative (basic) one-cochain f]

$$f'(J_A^m)=(m+1)^{-1}\frac{d}{d\lambda}\psi'_\lambda(J_A^m,J)|_{\lambda=0} \tag{3.26}$$

[recall (3.6) that $J=J_I^1$] for $A\in gl_N$, $m\in\mathbb{Z}_+$ [note from (2.11) that $f'(\partial a)=f_0(\partial a)=0$]. By (2.13) and (3.16),

$$(df')_\lambda(a_1,a_2)=-f'([a_{1\lambda}a_2]), \tag{3.27}$$

for a_1, $a_2\in gc_N$.

Now suppose ψ' is a reduced two-cocycle. Then $\gamma'=\psi'+df'$ is a reduced two-cocycle equivalent to ψ'. By (3.26), (3.27), and (3.6),

$$\frac{d}{d\lambda}\gamma'_\lambda(J_A^m,J)|_{\lambda=0}=0 \quad \text{for } A\in gl_N,\ m\in\mathbb{Z}_+. \tag{3.28}$$

Thus, by (3.25),

$$\begin{aligned}0&=\frac{\partial}{\partial\lambda}(d\gamma')_{\lambda_1,\lambda}(J_A^m,J_B^n,J)|_{\lambda=-\lambda_1}\\&=\frac{\partial}{\partial\lambda}(-\gamma'_{\lambda_1+\lambda}([J^m_{A\lambda_1}J^n_B],J)+\gamma'_{-\lambda}([J^m_{A\lambda_1}J],J^n_B)-\gamma'_{-\lambda_1}([J^n_{B\lambda}J],J^m_A))|_{\lambda=-\lambda_1}\\&=\frac{\partial}{\partial\lambda}((m(\lambda_1+\lambda)+\lambda_1)\gamma'_{-\lambda}(J_A^m,J_B^n)-((n(\lambda+\lambda_1)+\lambda)\gamma'_{-\lambda_1}(J_B^n,J_A^m))|_{\lambda=-\lambda_1},\end{aligned} \tag{3.29}$$

where the last equality follows from (3.28) and (3.6) [similarly to the discussion after (3.7), $\lambda_1+\partial$ and $\lambda+\partial$ can be replaced by $\lambda+\lambda_1$ and the terms with $s\geqslant 2$ do not contribute to the calculation]. Using (2.12) and (3.16), the right-hand side of (3.29) is equal to

$$(m+n+1)\gamma'_{\lambda_1}(J_A^m,J_B^n)-\lambda_1\frac{\partial}{\partial\lambda_1}\gamma'_{\lambda_1}(J_A^m,J_B^n)=0. \tag{3.30}$$

From (3.30), we obtain

$$\gamma'_\lambda(J_A^m,J_B^n)=c_{A,B}^{(m,n)}\lambda^{m+n+1} \quad \text{for some } c_{A,B}^{(m,n)}\in\mathbb{C}. \tag{3.31}$$

In particular,

$$\frac{d}{d\lambda}\gamma'_\lambda(J_A^m,J^0)|_{\lambda=0}=\delta_{m,0}c_A, \tag{3.32}$$

where $c_A=c_{A,I}^{(0,0)}$. Similarly to (3.29) [also cf. (3.24)],

$$\begin{aligned}0&=\frac{\partial}{\partial\lambda}(d\gamma')_{\lambda_1,\lambda}(J_A^m,J_B^n,J^0)|_{\lambda=-\lambda_1}\\&=-\frac{\partial}{\partial\lambda}\gamma'_{\lambda_1+\lambda}([J^m_{A\lambda_1}J^n_B],J^0)|_{\lambda=-\lambda_1}+m\gamma'_{\lambda_1}(J_A^{m-1},J_B^n)+n\gamma'_{\lambda_1}(J_A^m,J_B^{n-1})\\&=-\binom{m}{m+n}\lambda_1^{m+n}c_{AB}+\binom{n}{m+n}(-\lambda_1)^{m+n}c_{BA}+(mc_{A,B}^{(m-1,n)}+nc_{A,B}^{(m,n-1)})\lambda_1^{m+n},\end{aligned} \tag{3.33}$$

where the last equality follows from (2.6), (2.11), (3.16), (3.31), and (3.32). Taking $m=n=0$, we obtain $c_{AB}=c_{BA}$. Thus

$$mc_{A,B}^{(m-1,n)}+nc_{A,B}^{(m,n-1)}=\left(\binom{m}{m+n}-(-1)^{m+n}\binom{n}{m+n}\right)c_{AB}. \tag{3.34}$$

Thus we solve

$$c_{A,B}^{(m,n)}=(-1)^n\frac{m!n!}{(m+n+1)!}c_{AB}\quad \text{for } A,B\in gl_N, m,n\in\mathbb{Z}_+. \tag{3.35}$$

From (3.31) and the fact that $c_A=c_{A,I}^{(0,0)}$ and that $c_{AB}=c_{BA}$, we see that the map $A\mapsto c_A$ is a trace of gl_N, i.e., c_A is a scalar multiple of $\mathrm{tr}(A)$ for $A\in gl_N$. Thus (3.31) and (3.35) show that γ' is a multiple of ψ' which is defined by

$$\psi'_\lambda(J_A^m,J_B^n)=(-1)^n\frac{m!n!}{(m+n+1)!}\mathrm{tr}(AB)\lambda^{m+n+1}. \tag{3.36}$$

To see that ψ' is a nontrivial reduced two-cocycle, first define

$$\psi_{\lambda_1,\lambda_2}(J_A^m,J_B^n)=(-1)^n\frac{m!n!}{(m+n+1)!}((-1)^m\lambda_1^{m+n+1}-(-1)^n\lambda_2^{m+n+1})\mathrm{tr}(AB)\lambda^{m+n+1}. \tag{3.37}$$

Clearly, ψ is a two-cochain [recall the second sentence in the paragraph before (3.2)], and $\psi'=\Delta\psi$ is a reduced two-cochain. One can easily check that $d\psi'=0$ and that $\psi'\neq df'$ for any reduced one-cochain f'. This proves that $H^2(gc_N,\mathbb{C})=\mathbb{C}\psi'$. □

Lemma 3.6: Theorem 2.5(3) holds.

Proof: We define an operator $\tau:\widetilde{C}^q(gc_N,\mathbb{C}_a)\to\widetilde{C}^{q-1}(gc_N,\mathbb{C}_a)$ by

$$(\tau\gamma)_{\lambda_1,\ldots,\lambda_{q-1}}(a_1,\ldots,a_{q-1})=(-1)^{q-1}\gamma_{\lambda_1,\ldots,\lambda_{q-1},\lambda}(a_1,\ldots,a_{q-1},J)|_{\lambda=0}, \tag{3.38}$$

for $a_1,\ldots,a_{q-1}\in gc_N$. Similarly to the discussions in (3.7) and (3.8), we have

$$\begin{aligned}((d\tau+\tau d)\gamma)_{\lambda_1,\ldots,\lambda_q}(J_{A_1}^{n_1},\ldots,J_{A_q}^{n_q})&=\left(\sum_{i=1}^q\lambda_q\right)\gamma_{\lambda_1,\ldots,\lambda_q}(J_{A_1}^{n_1},\ldots,J_{A_q}^{n_q})\\&\equiv -a\,\gamma_{\lambda_1,\ldots,\lambda_q}(J_{A_1}^{n_1},\ldots,J_{A_q}^{n_q})(\mathrm{mod}\,\partial\widetilde{C}^q(gc_N,\mathbb{C}_a)).\end{aligned} \tag{3.39}$$

[Note that $\partial\widetilde{C}^q(gc_N,\mathbb{C}_a)=(a+\Sigma_{i=1}^q\lambda_i)\widetilde{C}^q(gc_N,\mathbb{C}_a)$ by (2.15), since $\partial_{\mathbb{C}_a}=a$.] Now suppose $\gamma\in\widetilde{C}^q(gc_N,\mathbb{C}_a)$ such that $d\gamma\in\partial\widetilde{C}^{q+1}(gc_N,\mathbb{C}_a)$, i.e., there exists a $(q+1)$-cochain ϕ such that $d\gamma=(a+\Sigma_{i=1}^{q+1}\lambda_i)\phi$. Clearly, by (3.38) $\tau d\gamma=(a+\Sigma_{i=1}^q\lambda_i)\tau\phi\in\partial\widetilde{C}^q(gc_N,\mathbb{C}_a)$. Thus (3.39) shows that $\gamma\equiv -d(a^{-1}\tau\gamma)(\mathrm{mod}\,\partial\widetilde{C}^q(gc_N,\mathbb{C}_a))$ is a reduced coboundary (note that we assume $a\neq 0$), i.e., $H^q(gc_N,\mathbb{C}_a)=0$. □

Lemma 3.7: Theorem 2.5(4) holds.

Proof: Note that as spaces, we have $\mathbb{C}_a^N[\partial][\lambda_1,\ldots,\lambda_q]=\mathbb{C}^N[\lambda_1,\ldots,\lambda_q,\partial]$, and a q-cochain $\widetilde{\gamma}\in\widetilde{C}^q(gc_N,\mathbb{C}_\alpha^N[\partial])$ can be regarded as a map $\widetilde{\gamma}:gc_N^{\otimes q}\to\mathbb{C}^N[\lambda_1,\ldots,\lambda_q,\partial]$,

$$\widetilde{\gamma}(a_1\otimes\cdots\otimes a_q)=\widetilde{\gamma}_{\lambda_1,\ldots,\lambda_q,\partial}(a_1,\ldots,a_q), \tag{3.40}$$

for $a_1,\ldots,a_q\in gc_N$. Regarding (3.40) as a polynomial in $\lambda_1,\ldots,\lambda_q,\partial$ with coefficients in $\mathbb{C}^N$, then similarly to Lemma 3.4, a reduced q-cochain

$$\gamma\in C^q(gc_N,\mathbb{C}_\alpha^N[\partial])=\widetilde{C}^q(gc_N,\mathbb{C}_\alpha^N[\partial])/\left(\partial+\sum_{i=1}^q\lambda_i\right)\widetilde{C}^q(gc_N,\mathbb{C}_\alpha^N[\partial]) \tag{3.41}$$

is uniquely determined by the coefficient of ∂^0 in (3.40). Thus a reduced q-cochain γ can be regarded as a map $\gamma: gc_N^{\otimes q} \to \mathbb{C}^N[\lambda_1,\dots,\lambda_q]$,

$$\gamma(a_1\otimes\cdots\otimes a_q)=\gamma_{\lambda_1,\dots,\lambda_q}(a_1,\dots,a_q). \tag{3.42}$$

Define an operator $\tau_0: C^q(gc_N,\mathbb{C}_\alpha^N[\partial]) \to C^{q-1}(gc_N,\mathbb{C}_\alpha^N[\partial])$ by [cf. (3.38)]

$$(\tau_0\gamma)_{\lambda_1,\dots,\lambda_{q-1}}(a_1,\dots,a_{q-1})=(-1)^{q-1}\gamma_{\lambda_1,\dots,\lambda_{q-1},\lambda}(a_1,\dots,a_{q-1},J^0)|_{\lambda=0}. \tag{3.43}$$

Similarly to the discussions in (3.7) and (3.8), using (3.19), we have [comparing with (3.7), all terms corresponding to the right-hand side of (3.7) are now zero because J has been replaced by J^0 and we do not take partial derivative $\partial/\partial\lambda$; but note that since the first sum in (2.13) is not zero in this case, we have one more term here]

$$((d\tau_0+\tau_0 d)\gamma)_{\lambda_1,\dots,\lambda_q}(J_{A_1}^{n_1},\dots,J_{A_q}^{n_q})=J_\lambda^0\gamma_{\lambda_1,\dots,\lambda_q}(J_{A_1}^{n_1},\dots,J_{A_q}^{n_q})|_{\lambda=0}. \tag{3.44}$$

Now by (2.9), the λ-action of gc_N on its module $\mathbb{C}_\alpha^N[\partial]$ in particular satisfies $J_\lambda^0 v=v$ for $v\in\mathbb{C}_\alpha^N[\partial]$. Thus the right-hand side of (3.44) is simply $-\gamma_{\lambda_1,\dots,\lambda_q}(J_{A_1}^{n_1},\dots,J_{A_q}^{n_q})$, i.e., we obtain

$$\gamma=(d\tau_0+\tau_0 d)\gamma. \tag{3.45}$$

In particular, if γ is a reduced cocycle, (3.45) gives that $\gamma=d(\tau_0\gamma)$ is a coboundary, i.e., $H^q(gc_N,\mathbb{C}_\alpha^N[\partial])=0$.

Clearly, the above proof works for any gc_N-module M satisfying the condition stated in Theorem 2.5(4). □

Thus Theorem 2.5(2)–(4) is proved.

IV. PROOF OF THEOREM 2.5(1)

This section is devoted to the proof of Theorem 2.5(1). By Lemma 3.5, it remains to consider the case $q=3$. Since some of the following arguments also work for general q-cocycles, we shall first consider q-cocycles with $q\geqslant 3$ so that it may be possible to use these arguments to determine higher dimensional cohomologies in the future.

Let $gc=gc_1$. It has a free generating set $S=\{J^n|n\in\mathbb{Z}_+\}$, such that

$$[J_\lambda^m J^n]=\sum_{s=1}^{m}\binom{m}{s}(\lambda+\partial)^s J^{m+n-s}-\sum_{s=1}^{n}\binom{n}{s}(-\lambda)^s J^{m+n-s}, \tag{4.1}$$

for m, $n\in\mathbb{Z}_+$. We shall give some more notations. An element in $\mathbb{Z}_+^q$ is denoted by

$$\underline{n}=\underline{n}[q]=(n_1,\dots,n_q),\quad n_1,\dots,n_q\in\mathbb{Z}_+ \tag{4.2}$$

(when there is no confusion we denote it by $\underline{n}$, otherwise we denote it by $\underline{n}[q]$). Denote $J^{\underline{n}}=J^{n_1}\otimes\cdots\otimes J^{n_q}=(J^{n_1},\dots,J^{n_q})\in gc^{\otimes q}$. Denote $\underline{\lambda}=\underline{\lambda}[q]=(\lambda_1,\dots,\lambda_q)$. For $\underline{n}\in\mathbb{Z}_+^q$, let $|\underline{n}|=\Sigma_{i=1}^q n_i$, called the *level of* $\underline{n}$. We define a total ordering on $\mathbb{Z}_+^q$ by the *level-lexicographical order*, i.e.,

$$\underline{m}<\underline{n}\Leftrightarrow|\underline{m}|<|\underline{n}|,\quad \text{or}\quad |\underline{m}|=|\underline{n}|\ \text{ and }\ \exists p\ \text{ such that }\ m_i=n_i\ \text{ for }\ i<p\ \text{ and }\ m_p<n_p, \tag{4.3}$$

for $\underline{m}$, $\underline{n}\in\mathbb{Z}_+^q$. Set

$$\mathcal{N}_q=\{\underline{n}\in\mathbb{Z}_+^q|n_1\leqslant n_2\leqslant\cdots\leqslant n_q\}. \tag{4.4}$$

For $m, n \in \mathbb{Z}$, we denote $[m,n]=\{m,m+1,...,n\}$. Let $\mathcal{S}_q$ be the permutation group on the index set $[1,q]$, which acts on $\mathbb{C}^q$ by $\sigma(v)=(v_{\sigma(1)},\ldots,v_{\sigma(q)})$ for $v=(v_1,\ldots,v_q)\in\mathbb{C}^q$. Then for any $\underline{n} \in \mathbb{Z}_+^q$, there is a unique $\underline{n}^* \in \mathcal{N}_q$ and some $\sigma \in \mathcal{S}_q$ such that $\underline{n}^*=\sigma(\underline{n}) \in \mathcal{N}_q$ and $\underline{n}^* \leqslant \tau(n)$ for τ in S_q. In fact,

$$\underline{n}^*=\min\{\sigma(\underline{n})|\sigma\in\mathcal{S}_q\} \tag{4.5}$$

is the minimal element in $\mathcal{S}_q(\underline{n})=\{\sigma(\underline{n})|\sigma\in\mathcal{S}_q\}$.

A q-cochain γ is uniquely determined by $\gamma_{\underline{\lambda}}(J^{\underline{n}})$ for $\underline{n}\in\mathcal{N}_q$ and

$$\gamma_{\underline{\lambda}}(J^{\underline{n}})=\mathrm{sgn}(\sigma)\,\gamma_{\sigma(\underline{\lambda})}(J^{\sigma(\underline{n})}), \tag{4.6}$$

for $\underline{n}\in\mathbb{Z}_+^q$, $\sigma\in\mathcal{S}_q$, where $\mathrm{sgn}(\sigma)$ is the signature of the permutation σ. In fact, $\gamma_{\underline{\lambda}}(J^{\underline{n}})$ can be arbitrary polynomial in $\underline{\lambda}$ satisfying (4.6) for all σ such that $\sigma(\underline{n})=\underline{n}$.

First we construct a three-cochain $\overline{\gamma}$ as follows:

$$\overline{\gamma}_{\underline{\lambda}}(J^{\underline{n}})=\begin{cases}\lambda_2^{n_3}-\lambda_1^{n_3} & \text{if } n_1=n_2=0,\ n_3\neq 0,\\ 0 & \text{otherwise,}\end{cases} \tag{4.7}$$

for $\underline{n}\in\mathcal{N}_3$ (note that in the first case, we let $n_3\neq 0$ in order to avoid the problem on how to deal with 0^0 when we set $\lambda_1=0$).

Lemma 4.1: $\overline{\gamma}$ is a nontrivial three-cocycle.

Proof: One can define a *Leibniz q-cochain* by removing the skew-symmetric condition (2.12), and define the *Leibniz differential operator* d_L by changing (2.13) into

$$\begin{aligned}(d_L\gamma)_{\lambda_1,\ldots,\lambda_{q+1}}(a_1,\ldots,a_{q+1})=&\sum_{i=1}^{q+1}(-1)^{i+1}a_{i\lambda_i}\gamma_{\lambda_1,\ldots,\hat{\lambda}_i,\ldots,\lambda_{q+1}}(a_1,\ldots,\hat{a}_i,\ldots,a_{q+1})\\ &+\sum_{1\leqslant i<j\leqslant q+1}(-1)^i\gamma_{\lambda_1,\ldots,\hat{\lambda}_i,\ldots,\lambda_{j-1},\lambda_i+\lambda_j,\lambda_{j+1},\ldots,\lambda_{q+1}}\\ &\times(a_1,\ldots,\hat{a}_i,\ldots,a_{j-1},[a_{i\lambda_i}a_j],a_{j+1},\ldots,a_{q+1}).\end{aligned} \tag{4.8}$$

[Note that if γ is a (regular) q-cochain, then (4.8) coincides with (2.13), i.e., $d=d_L$ in this case.] Then we obtain *Leibniz cohomology* (cf. Ref. 1). We shall not discuss Leibniz cohomology here, but we define a Leibniz two-cochain f by

$$f_{\lambda_1,\lambda_2}(J^0,J^0)=1 \quad\text{and}\quad f_{\lambda_1,\lambda_2}(J^m,J^n)=0 \quad\text{if } (m,n)\neq(0,0). \tag{4.9}$$

One can immediately check that $\overline{\gamma}=d_Lf$ (thus $\overline{\gamma}$ is a Leibniz three-coboundary). Therefore $d\overline{\gamma}=dd_Lf=d_L^2f=0$, i.e., $\overline{\gamma}$ is a (regular) three-cocycle. However, there is no two-cochain ϕ such that $d\phi=\overline{\gamma}$ because if $d\phi=\overline{\gamma}$, then we also have $\phi_{\lambda_1,\lambda_2}(J^0,J^0)=1$ and so ϕ is not a (regular) two-cochain [(2.12) is not satisfied]. Thus $\overline{\gamma}$ is a nontrivial three-cocycle. □

Now let γ be a q-cocycle with $q\geqslant 3$. By Lemma 3.2, we can suppose γ is homogenous with degree zero. First we have the following lemma.

Lemma 4.2: If $q=3$, by replacing γ by $\gamma-c\overline{\gamma}$ for some $c\in\mathbb{C}$, we can suppose $\gamma_{\underline{\lambda}}(J^0,J^0,J)=0$.

Proof: Note that $\gamma_{\underline{\lambda}}(J^0,J^0,J)$ is a linear polynomial in $\underline{\lambda}$ [cf. (3.3)] which is skew-symmetric with respect to λ_1,λ_2 by (2.12). Thus $\gamma_{\underline{\lambda}}(J^0,J^0,J)=c(\lambda_2-\lambda_1)$ for some $c\in\mathbb{C}$. Replacing γ by $\gamma-c\overline{\gamma}$, we have the lemma. □

To prove (2.16), our strategy is the following: We want to prove by induction on $\underline{n}\in\mathcal{N}_q$ [with respect to the order (4.3)] that after a number of steps, in each of which γ is replaced by $\gamma-\gamma'$ for some q-coboundaries γ', we obtain that $\gamma_{\underline{\lambda}}(J^{\underline{m}})=0$ for all $\underline{m}\in\mathcal{N}_q$, $\underline{m}\leqslant\underline{n}$ [Thus we obtain that $\gamma_{\underline{\lambda}}(J^{\underline{n}})=0$ for all $\underline{n}\in\mathcal{N}_q$, i.e., $\gamma=0$, after a countably infinite number of steps; this amounts to

saying that γ is subtracted by an infinite sum of q-coboundaries, but from the following proof we see that this infinite sum is summable, cf. the statement after (3.4).] For the case $q=3$, this will be done by a number of lemmas (unfortunately, not all arguments work for $q\geqslant 4$, cf. the proof of Lemma 4.6).

Lemma 4.3: $\gamma_{\underline{\lambda}}(J^{\underline{n}})=0$ *if* $|\underline{n}|\leqslant 1$.

Proof: Note that $\gamma_{\underline{\lambda}}(J^{\underline{n}})$ is a polynomial in $\underline{\lambda}$ on degree $|\underline{n}|$. If $|\underline{n}|=0$, we have $\gamma_{\underline{\lambda}}(J^{\underline{n}})=0$ by (4.6). If $|\underline{n}|=1$, then $\underline{n}=(0,...,0,1)$ and $\gamma_{\underline{\lambda}}(J^{\underline{n}})$ is skew-symmetric with respect to $\lambda_1,\dots,\lambda_{q-1}$, thus divided by $\Pi_{1\leqslant i<j\leqslant q-1}(\lambda_i-\lambda_j)$, which has degree $(q-1)(q-2)/2>1$ if $q>3$. Thus $\gamma_{\underline{\lambda}}(J^{\underline{n}})=0$ if $q>3$. If $q=3$, then $\gamma_{\underline{\lambda}}(J^{\underline{n}})=\gamma_{\underline{\lambda}}(J^0,J^0,J)=0$ by Lemma 4.2. □

Now suppose $|\underline{n}|\geqslant 2$. We set $i_0=\#\{i\in[1,q]|n_i=0\}\geqslant 0$ (where $\#X$ stands for the size of the finite set X), $i_2=q-\#\{i\in[1,q]|n_i=n_q\}\leqslant q-1$. If $i_0\neq i_2$, we set i_1 to satisfy

$$0=n_1=\cdots=n_{i_0}<n_{i_0+1}\leqslant\cdots\leqslant n_{i_1}<n_{i_1+1}=\cdots=n_{i_2}<n_{i_2+1}=\cdots=n_q; \tag{4.10}$$

if $i_0=i_2$, we set $i_1=0$.

Let $\underline{m}\in\mathcal{N}_{q+1}$ be such that $|\underline{m}|=|\underline{n}|+1$. Consider $(d\gamma)_{\underline{\lambda}[q+1]}(J^{\underline{m}})$ [cf. notation (4.2)]. Note that when we substitute (4.1) into (2.13), using (2.11) and (2.12), we obtain that $(d\gamma)_{\underline{\lambda}[q+1]}\times(J^{\underline{m}})$ is a combination of $\gamma_{\underline{\lambda}'}(J^{\underline{k}})$ with coefficients being polynomials in $\underline{\lambda}[q+1]$, where $\underline{k}\in\mathcal{N}_q$, $|\underline{k}|\leqslant|\underline{n}|$, and $\underline{\lambda}'=(\lambda_1',\dots,\lambda_q')$ such that each λ_i' is a linear polynomial in $\underline{\lambda}[q+1]$. Using the inductive assumption, $\gamma_{\underline{\lambda}'}(J^{\underline{k}})=0$ if $|\underline{k}|<|\underline{n}|$. Thus the terms with $s\geqslant 2$ in (4.1) do not contribute to (2.13) [cf. the discussion after (3.7)], and so we have [here we use (4.8) instead of (2.13)]

$$0=(d\gamma)_{\underline{\lambda}[q+1]}(J^{\underline{m}})=\sum_{1\leqslant i<j\leqslant q+1}(-1)^i(m_j\lambda_i-m_i\lambda_j)\gamma_{\lambda_1,\dots,\hat{\lambda}_i,\dots,\lambda_{j-1},\lambda_i+\lambda_j,\lambda_{j+1},\dots,\lambda_{q+1}}(J^{\underline{m}(i,j)}), \tag{4.11}$$

where

$$\underline{m}(i,j)=(m_1,\dots,\hat{m}_i,\dots,m_{j-1},m_i+m_j-1,m_{j+1},\dots,m_{q+1}), \tag{4.12}$$

and the right-hand side of (4.11) is a combination of $\gamma_{\underline{\lambda}'}(J^{\underline{m}(i,j)^*})$ [cf. (4.5) and (4.6)].

Lemma 4.4: $\gamma_{\underline{\lambda}}(J^{\underline{n}})=0$ *if* $n_1\geqslant 1$ (*i.e.*, $i_0=0$).

Proof: In (4.11), take $\underline{m}=(0,n_1,\dots,n_{q-1},n_q+1)\in\mathcal{N}_{q+1}$. In (4.12), if $i\neq 1$, then $m_1=0<n_1$ and so $\underline{m}(i,j)^*\leqslant\underline{m}(i,j)<\underline{n}$; by induction, $\gamma_{\underline{\lambda}'}(J^{\underline{m}(i,j)^*})=0$. Similarly, $\gamma_{\underline{\lambda}'}(J^{\underline{m}(i,j)^*})=0$ if $j\neq q+1$. Thus the only possible nonzero term in (4.11) is the one with $(i,j)=(1,q+1)$. Since $\underline{m}(1,q+1)=\underline{n}$, (4.11) gives

$$-(n_q+1)\lambda_1\gamma_{\lambda_2,\dots,\lambda_q,\lambda_1+\lambda_{q+1}}(J^{\underline{n}})=0. \tag{4.13}$$

This gives the lemma. □

From now on, we assume that $n_1=0$.

Lemma 4.5: $\gamma_{\underline{\lambda}}(J^{\underline{n}})=0$ *if* $i_2=q-1$ *and* $n_q\geqslant n_{q-1}+2$ *[cf. (4.10)].*

Proof: As above, now (4.11) gives [cf. (4.13)]

$$\sum_{i=1}^{i_0+1}(-1)^i(n_q+1)\lambda_i\gamma_{\lambda_1,\dots,\hat{\lambda}_i,\dots,\lambda_q,\lambda_i+\lambda_{q+1}}(J^{\underline{n}})=0. \tag{4.14}$$

Replacing $(\lambda_1,\dots,\lambda_{q+1})$ by $(\lambda,\lambda_1,\dots,\lambda_q)$ and applying the operator $\partial/\partial\lambda|_{\lambda=0}$ to (4.14), we obtain

$$\gamma_{\underline{\lambda}}(J^{\underline{n}})=-\sum_{i=1}^{i_0}(-1)^i\lambda_i\frac{\partial}{\partial\lambda}\gamma_{\lambda,\lambda_1,\ldots,\hat{\lambda_i},\ldots,\lambda_{q-1},\lambda_i+\lambda_q}(J^{\underline{n}})|_{\lambda=0}. \tag{4.15}$$

We define a $(q-1)$-cochain f as follows:

$$f_{\underline{\lambda}[q-1]}(J^{\underline{k}})=\begin{cases}-n_q^{-1}\dfrac{\partial}{\partial\lambda}\gamma_{\lambda,\lambda_1,\ldots,\lambda_{q-1}}(J^{\underline{n}})|_{\lambda=0} & \text{if } \underline{k}=\underline{n}^-,\\ 0 \quad \text{otherwise,}\end{cases} \tag{4.16}$$

for $\underline{k}\in\mathcal{N}_{q-1}$, where $\underline{n}^-=(n_2,\ldots,n_{q-1},n_q-1)\in\mathcal{N}_{q-1}$ [cf. (4.10)]. Indeed, f is a $(q-1)$-cochain [cf. the statement after (4.6)]: Write $\underline{n}^-$ as $\underline{n}^-=(n_1^-,\ldots,n_{q-1}^-)$, then $n_i^-=n_j^-\Leftrightarrow n_{i+1}=n_{i+1}$. Thus the skew-symmetric condition (4.6) for f follows from the skew-symmetric condition for γ. We claim that

$$\gamma_{\underline{\lambda}}(J^{\underline{k}})=(df)_{\underline{\lambda}}(J^{\underline{k}}), \tag{4.17}$$

for all $\underline{k}\in\mathcal{N}_q$ with $\underline{k}\leqslant\underline{n}$. If $\underline{k}=\underline{n}$, similarly to (4.14), we have

$$(df)_{\underline{\lambda}}(J^{\underline{n}})=\sum_{i=1}^{i_0}(-1)^i n_q\lambda_i f_{\lambda_1,\ldots,\hat{\lambda_i},\ldots,\lambda_{q-1},\lambda_i+\lambda_q}(J^{\underline{n}^-})=\gamma_{\underline{\lambda}}(J^{\underline{n}}), \tag{4.18}$$

where the last equality follows from (4.15) and (4.16). If $\underline{k}<\underline{n}$, when we substitute (4.1) into (2.13) for $(df)_{\underline{\lambda}}(J^{\underline{k}})$, as in (4.11), $(df)_{\underline{\lambda}}(J^{\underline{k}})$ is a combination of the form $f_{\underline{\lambda}'}(J^{\underline{k}(i,j)})$, and we see that $\underline{k}(i,j)<\underline{n}^-$ [cf. (4.12)], i.e., the term $f_{\underline{\lambda}'}(J^{\underline{n}^-})$ does not appear in $(df)_{\underline{\lambda}}(J^{\underline{k}})$, thus $(df)_{\underline{\lambda}}(J^{\underline{k}})=0$, which is the same as $\gamma_{\underline{\lambda}}(J^{\underline{k}})$ by inductive assumption. This proves (4.17). Thus by replacing γ by $\gamma-df$, we have the lemma. □

Lemma 4.6: $\gamma_{\underline{\lambda}}(J^{\underline{n}})=0$ *if* $q=3$.

Proof: When $q=3$, by Lemmas 4.3–5, we are left to consider the cases $\underline{n}=(0,n_2,n_2)$ and $\underline{n}=(0,n_2,n_2+1)$ for $n_2\geqslant 1$. First suppose $\underline{n}=(0,n_2,n_2)$. As in (4.14), we have

$$0=(d\gamma)_{\underline{\lambda}[4]}(J^0,J^0,J^{n_2},J^{n_2+1})=(n_2+1)(-\lambda_1\gamma_{\lambda_2,\lambda_3,\lambda_1+\lambda_4}(J^{\underline{n}})+\lambda_2\gamma_{\lambda_1,\lambda_3,\lambda_2+\lambda_4}(J^{\underline{n}})). \tag{4.19}$$

Setting $\lambda_4=0$, it gives that $\gamma_{\underline{\lambda}}(J^{\underline{n}})$ can be divided by λ_1. So we can write $\gamma_{\underline{\lambda}}(J^{\underline{n}})=\lambda_1\gamma'_{\underline{\lambda}}$ for some polynomial $\gamma'_{\underline{\lambda}}$, and (4.19) shows that $\gamma'_{\lambda_2,\lambda_3,\lambda_1+\lambda_4}=\gamma'_{\lambda_1,\lambda_3,\lambda_2+\lambda_4}$. Setting $\lambda_1=0$, this gives that $\gamma'_{\lambda_2,\lambda_3,\lambda_4}=\gamma'_{0,\lambda_3,\lambda_2+\lambda_4}$. Thus

$$\gamma_{\underline{\lambda}}(J^{\underline{n}})=\lambda_1\gamma'_{0,\lambda_2,\lambda_1+\lambda_3}. \tag{4.20}$$

But $\gamma_{\underline{\lambda}}(J^{\underline{n}})$ is skew-symmetric with respect to λ_2,λ_3, we obtain $\gamma'_{0,\lambda_2,\lambda_1+\lambda_3}=-\gamma'_{0,\lambda_3,\lambda_1+\lambda_2}$. Setting $\lambda_1=0$ and $\lambda_3=0$, respectively, we obtain that $\gamma'_{0,\lambda_2,\lambda_3}=-\gamma'_{0,\lambda_3,\lambda_2}$ and $\gamma'_{0,\lambda_2,\lambda_1}=-\gamma'_{0,0,\lambda_1+\lambda_2}$, which gives that $\gamma'_{\underline{\lambda}}=0$. Thus $\gamma_{\underline{\lambda}}(J^{\underline{n}})=0$.

Next suppose $\underline{n}=(0,n_2,n_2+1)$. We still have (4.20) for some polynomial $\gamma'_{\underline{\lambda}}$. We assume that $n_2\geqslant 2$ (the proof for the case $n_2=1$ is similar and we leave it to the reader). For $1\leqslant i<n_2$, by (2.13) and the inductive assumption, we have

$$\begin{aligned}0&=(d\gamma)_{\underline{\lambda}[4]}(J^0,J,J^{n_2-i},J^{n_2+i+1})\\&=(n_2-i)\lambda_1\gamma_{\lambda_2,\lambda_1+\lambda_3,\lambda_4}(J,J^{n_2-i-1},J^{n_2+i+1})+(n_2+i+1)\lambda_1\gamma_{\lambda_2,\lambda_3,\lambda_1+\lambda_4}(J,J^{n_2-i},J^{n_2+i}).\end{aligned} \tag{4.21}$$

Note that when $i=n_2-1$, the first term of the right-hand side is zero since $\gamma_\lambda(J,J^0,J^{2n_2})=-\gamma_{\lambda_2,\lambda_1,\lambda_3}(J^0,J,J^{2n_2})$ and $(0,1,2n_2)<\underline{n}$. Thus induction on i gives that $\gamma_\lambda(J,J^{n_2-i},J^{n_2+i})=0$. Then by (2.13) and the inductive assumption,

$$\begin{aligned}0&=(d\gamma)_{\lambda[4]}(J^0,J,J^{n_2},J^{n_2+1})\\&=-\lambda_1\gamma_{\lambda_1+\lambda_2,\lambda_3,\lambda_4}(J^a)-(n_2+1)\lambda_1\gamma_{\lambda_2,\lambda_3,\lambda_1+\lambda_4}(J,J^{n_2},J^{n_2})+(n_2\lambda_2-\lambda_3)\gamma_{\lambda_1,\lambda_2+\lambda_3,\lambda_4}(J^a)\\&\quad+((n_2+1)\lambda_2-\lambda_4)\gamma_{\lambda_1,\lambda_3,\lambda_2+\lambda_4}(J^a).\end{aligned}\tag{4.22}$$

Substituting (4.20) into (4.22), cancelling the common factor λ_1, then setting $\lambda_1=\lambda_2=0$, we obtain that $0=-(n_2+1)\gamma_{0,\lambda_3,\lambda_4}(J,J^{n_2},J^{n_2})-(\lambda_3+\lambda_4)\gamma'_{0,\lambda_3,\lambda_4}$, which shows that $\gamma'_{0,\lambda_3,\lambda_4}$ is skew-symmetric with respect to λ_3, λ_4. Thus

$$f_{\lambda_1,\lambda_2}(J^{m_1},J^{m_2})=\begin{cases}-n_2^{-1}\gamma'_{0,\lambda_1,\lambda_2} & \text{if } (m_1,m_2)=(n_2,n_2),\\ 0 \quad \text{otherwise,}\end{cases}\tag{4.23}$$

defines a two-cochain f [cf. (4.16)]. Now as in the proof of Lemma 4.5, by replacing γ by $\gamma-df$, we have the lemma. This also proves (2.16). □

Lemma 4.7: Equation (2.17) holds.

Proof: By Lemma 3.5, it remains to consider the case $q=3$. Let $\overline{\gamma}$ be the three-cocycle defined in (4.7). Let $\overline{\gamma'}=\Delta\overline{\gamma}$ be the corresponding reduced three-cocycle [cf. (3.16)]. Clearly $\overline{\gamma'}$ is non-trivial. Now suppose γ' is an arbitrary reduced three-cocycle. As in the paragraph before Lemma 4.3, we shall prove by induction on $\underline{n}\in\mathcal{N}_3$ that by replacing γ' by $\gamma'-c\overline{\gamma'}-df'$ for some $c\in\mathbb{C}$ and some reduced two-cochain f' we have $\gamma'_{\lambda_1,\lambda_2}(J^{\underline{m}})=0$ for $\underline{m}\leqslant\underline{n}$. Assume that we have proved $\gamma'_{\lambda_1,\lambda_2}(J^{\underline{m}})=0$ for $\underline{m}<\underline{n}$.

First suppose $\underline{n}=(0,0,n_3)$. By (2.13), (3.16) and the inductive assumption, we have

$$0=(d\gamma')_{\lambda[3]}(J^0,J^0,J^0,J^{n_3+1})=(n_3+1)(-\lambda_1\gamma'_{\lambda_2,\lambda_3}(J^a)+\lambda_2\gamma'_{\lambda_1,\lambda_3}(J^a)-\lambda_3\gamma'_{\lambda_1,\lambda_2}(J^a)).\tag{4.24}$$

Thus

$$\gamma'_{\lambda_1,\lambda_2}(J^a)=\lambda_1\gamma'_{1,\lambda_2}(J^a)-\lambda_2\gamma'_{1,\lambda_1}(J^a).\tag{4.25}$$

If $n_3=0$, then by (2.12) and (3.16), $\gamma'_{\lambda_1,\lambda_2}(J^a)=-\gamma'_{\lambda_1,-\lambda_1-\lambda_2}(J^a)$. This together with (4.25) gives that $\gamma'_{\lambda_1,\lambda_2}(J^a)=0$. If $n_3=1$, then by (2.13), (3.16) and the inductive assumption,

$$\begin{aligned}0&=(d\gamma')_{\lambda[3]}(J^0,J^0,J,J)\\&=-\lambda_1(\gamma'_{\lambda_2,\lambda_1+\lambda_3}(J^a)-\gamma'_{\lambda_2,-\lambda_2-\lambda_3}(J^a))\\&\quad+\lambda_2(\gamma'_{\lambda_1,\lambda_2+\lambda_3}(J^a)-\gamma'_{\lambda_1,-\lambda_1-\lambda_3}(J^a)).\end{aligned}\tag{4.26}$$

Using (4.25) in (4.26), we see that γ'_{1,λ_1} can be divided by λ_1. Writing $\gamma'_{1,\lambda_1}=\lambda_1 p(\lambda_1)$ for some polynomial $p(\lambda_1)$ and using this in (4.26), cancelling the common factor $\lambda_1\lambda_2$, and setting $\lambda_2=\lambda_3=0$, we see that $p(\lambda_1)=c\in\mathbb{C}$ is a constant. Thus $\gamma'_{\lambda_1,\lambda_2}(J^a)=c(\lambda_1-\lambda_2)$. Replacing γ' by $\gamma'+c\overline{\gamma'}$, we obtain that $\gamma'_{\lambda_1,\lambda_2}(J^{\underline{m}})=0$ for $\underline{m}\leqslant\underline{n}$.

If $n_3\geqslant 2$, we define a reduced two-cochain f' as follows:

$$f'_{\lambda_1}(J^{m_1},J^{m_2})=\begin{cases}-\gamma'_{1,\lambda_1}(J^a) & \text{if } (m_1,m_2)=(0,n_3-1),\\ 0 \quad \text{otherwise,}\end{cases}\tag{4.27}$$

for $(m_1,m_2)\in\mathcal{N}_2$. Clearly, this indeed defines a reduced two-cochain f'. Using (4.25), by replacing γ' by $\gamma'-df'$ as in the proof of Lemma 4.5, we have $\gamma'_{\lambda_1,\lambda_2}(J^{\underline{m}})=0$ for $\underline{m}\leqslant\underline{n}$.

Next suppose $\underline{n}=(0,n_2,n_2)$ for $n_2\geqslant 1$. As in (4.25), from $(d\gamma')_{\lambda[3]}(J^0,J^0,J^{n_2},J^{n_2+1})=0$ we obtain that $\gamma'_{\lambda_1,\lambda_2}(J^{\underline{n}})=\lambda_1\gamma'_{1,\lambda_2}(J^{\underline{n}})$. But $\gamma'_{\lambda_1,\lambda_2}(J^{\underline{n}})=-\gamma'_{\lambda_1,-\lambda_1-\lambda_2}(J^{\underline{n}})$ by (2.12) and (3.16); we obtain $\gamma'_{\lambda_1,\lambda_2}(J^{\underline{n}})=0$.

Now suppose $\underline{n}=(0,n_2,n_2+1)$ for $n_2\geqslant 1$. From $\gamma'_{\underline{\lambda}[3]}(J^{\underline{k}})=0$ for $\underline{k}=(0,0,n_2,n_2+2)$ and $\underline{k}=(0,0,n_2+1,n_2+1)$, we obtain that $\gamma'_{\lambda_1,\lambda_2}(J^{\underline{n}})=\lambda_1\gamma'_{1,\lambda_2}(J^{\underline{n}})$ and that (4.26) again holds. From this, we obtain that $\gamma'_{\lambda_1,\lambda_2}(J^{\underline{n}})=-\gamma'_{\lambda_1,-\lambda_2}(J^{\underline{n}})$. Thus we can define a reduced two-cochain f' such that $f'_{\lambda_1}(J^{m_1},J^{m_2})=\gamma'_{1,\lambda_1}(J^{\underline{n}})$ if $(m_1,m_2)=(n_2,n_2)$ or $f'_{\lambda_1}(J^{m_1},J^{m_2})=0$ otherwise. Then the rest of the proof is as before.

Finally suppose $\underline{n}=(0,n_2,n_3)$ with $n_3\geqslant n_2+2$ or $\underline{n}=(n_1,n_2,n_3)$ with $n_1\geqslant 1$. Then the proof is the same as that of Lemmas 4.4 and 4.5. □

This completes the proof of Theorem 2.5.

(Received 2 October 2002; accepted 18 September 2003)

We classify the pairs $(\mathcal{A},\mathcal{D})$ consisting of an (ϵ,Γ)-color-commutative associative algebra $\mathcal{A}$ with an identity element over an algebraically closed field $\mathbb{F}$ of characteristic zero and a finite dimensional subspace $\mathcal{D}$ of (ϵ,Γ)-color-commutative locally finite color-derivations of $\mathcal{A}$ such that $\mathcal{A}$ is Γ-graded $\mathcal{D}$-simple and the eigenspaces for elements of $\mathcal{D}$ are Γ-graded. Such pairs are the important ingredients in constructing some simple Lie color algebras which are in general not finitely-graded. As some applications, using such pairs, we construct new explicit simple Lie color algebras of generalized Witt type, Weyl type. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1628837]

I. INTRODUCTION

Lie color algebras, a notion first appeared in mathematical physics,[1,3,5–7,15] are generalizations of Lie algebras and Lie superalgebras. Let us start with the definition. Let $\mathbb{F}$ be an algebraically closed field of characteristic zero and let Γ be an additive group. A *skew-symmetric bicharacter* of Γ is a map $\epsilon:\Gamma\times\Gamma\to\mathbb{F}^\times=\mathbb{F}\backslash\{0\}$ satisfying

$$\epsilon(\lambda,\mu)=\epsilon(\mu,\lambda)^{-1},\quad \epsilon(\lambda,\mu+\nu)=\epsilon(\lambda,\mu)\epsilon(\lambda,\nu),\quad \forall\,\lambda,\mu,\nu\in\Gamma. \tag{1.1}$$

It is clear that

$$\epsilon(\lambda,0)=1,\quad \forall\,\lambda\in\Gamma. \tag{1.2}$$

Let $L=\oplus_{\lambda\in\Gamma}L_\lambda$ be a Γ-graded $\mathbb{F}$-vector space. For a nonzero homogeneous element a, denote by $\overline{a}$ the unique group element in Γ such that $a\in L_{\overline{a}}$. We shall call $\overline{a}$ the *color* of a. The $\mathbb{F}$-bilinear map $[\cdot,\cdot]:L\times L\to L$ is called a Lie color bracket on L if the following conditions are satisfied:

$$[a,b]=-\epsilon(\overline{a},\overline{b})[b,a]\quad \text{(skew symmetry)},$$

$$[a,[b,c]]=[[a,b],c]+\epsilon(\overline{a},\overline{b})[b,[a,c]]\quad \text{(Jacobi identity)},$$

for all homogeneous elements $a,b,c\in L$. The algebra structure $(L,[\cdot,\cdot])$ is called an (ϵ,Γ)-*Lie color algebra or simply a Lie color algebra*. If $\Gamma=\mathbb{Z}/2\mathbb{Z}$ and $\epsilon(i,j)=(-1)^{ij},\forall\, i,j\in\mathbb{Z}/2\mathbb{Z}$, then (ϵ,Γ)-Lie color algebras are simply Lie superalgebras. For Lie color algebras, we refer the reader to Ref. 1.

For any Γ-graded $\mathbb{F}$-vector space V, we denote

$$H(V)=\{\text{all homogeneous elements in } V\}.$$

Let $\mathcal{A}=\oplus_{\lambda\in\Gamma}\mathcal{A}_\lambda$ be a Γ-graded associative $\mathbb{F}$-algebra with an identity element 1, i.e., $\mathcal{A}_\lambda\mathcal{A}_\mu\subset\mathcal{A}_{\lambda+\mu}$ for all $\lambda,\mu\in\Gamma$. So $1\in\mathcal{A}_0$. We say that $\mathcal{A}$ is *graded simple* if $\mathcal{A}$ does not have nontrivial Γ-graded ideals. If we define the bilinear product $[\cdot,\cdot]$ on $\mathcal{A}$ by

$$[x,y]=xy-\epsilon(\overline{x},\overline{y})yx,\quad \forall\, x,y\in H(\mathcal{A}),\tag{1.3}$$

then $(\mathcal{A},[\cdot,\cdot])$ becomes a Lie color algebra.

A *Lie color ideal* U of $\mathcal{A}$ is a Γ-graded vector space U of $\mathcal{A}$ such that $[\mathcal{A},U]\subset U$. Sometimes it is called an (ϵ,Γ)-Lie ideal. The *ϵ-center* $Z_\epsilon(\mathcal{A})$ of $\mathcal{A}$ is defined as

$$Z_\epsilon=Z_\epsilon(\mathcal{A})=\{x\in\mathcal{A}\,|\,[x,\mathcal{A}]=0\}.$$

It is easy to see that $Z_\epsilon(\mathcal{A})$ is Γ-graded. We say that $\mathcal{A}$ is *color-commutative* (or ϵ-color-commutative) if $Z_\epsilon(\mathcal{A})=\mathcal{A}$, i.e., $[\mathcal{A},\mathcal{A}]=0$.

Let $\mathcal{A}$ be an (ϵ,Γ)-color-commutative associative algebra with an identity element 1. A nonzero $\mathbb{F}$-linear transformation $\partial:\mathcal{A}\to\mathcal{A}$ is called a *homogeneous color-derivation* of degree $\lambda\in\Gamma$ if

$$\begin{aligned}&\partial(a)\in\mathcal{A}_{\lambda+\mu},\quad \forall\, a\in\mathcal{A}_\mu,\quad \mu\in\Gamma,\\ &\partial(ab)=\partial(a)b+\epsilon(\lambda,\overline{a})a\partial(b),\quad \forall\, a,b\in H(\mathcal{A}).\end{aligned}\tag{1.4}$$

For convenience, we shall often denote $\overline{\partial}=\lambda$ if ∂ has degree λ. Clearly $\partial(c)=0$ for all $c\in\mathbb{F}$. Denote $\mathrm{Der}^\epsilon(\mathcal{A})=\oplus_{\lambda\in\Gamma}\mathrm{Der}^\epsilon_\lambda(\mathcal{A})$, where $\mathrm{Der}^\epsilon_\lambda(\mathcal{A})$ is the $\mathbb{F}$-vector space spanned by all homogeneous color derivations of degree λ. Similar to the Lie algebra case, it is easy to verify that $\mathrm{Der}^\epsilon_\lambda(\mathcal{A})$ becomes a Lie color algebra under the Lie color bracket

$$[\partial,\partial']=\partial\partial'-\epsilon(\overline{\partial},\overline{\partial'})\partial'\partial,\quad \forall\,\partial,\partial'\in H(\mathrm{Der}^\epsilon(\mathcal{A})),$$

where $\partial\partial'$ is the composition of the operators ∂ and ∂'.

Let $\mathcal{D}=\oplus_{\lambda\in\Gamma}\mathcal{D}_\lambda$ be an (ϵ,Γ)-color-commutative subspace of $\mathrm{Der}^\epsilon(\mathcal{A})$, i.e.,

$$\partial\partial'=\epsilon(\overline{\partial},\overline{\partial'})\partial'\partial,\quad \forall\,\partial,\partial'\in H(\mathcal{D}).\tag{1.5}$$

Recall that the associative algebra $\mathcal{A}$ is called *graded $\mathcal{D}$-simple* if $\mathcal{A}$ has no nontrivial graded $\mathcal{D}$-stable ideals.[4]

A linear transformation T on a vector space V is called *locally finite* if

$$\dim(\mathrm{span}\{T^m(v)\,|\,m\in\mathbb{N}\})<\infty,$$

for any $v\in V$. The transformation T is called *locally nilpotent* if for any $v\in V$, we have $T^n(v)=0$ for some $n\in\mathbb{N}$, and T is called *semisimple* if it acts diagonalizably on V.

For a pair $(\mathcal{A},\mathcal{D})$ of an (ϵ,Γ)-color-commutative associative algebra with an identity element and an (ϵ,Γ)-color-commutative subspace $\mathcal{D}$ of $\mathrm{Der}^\epsilon(\mathcal{A})$, Passman[4] proved that the Lie color algebra (including the Lie algebra case) $\mathcal{A}\mathcal{D}=\mathcal{A}\otimes\mathcal{D}$ is simple if and only if $\mathcal{A}$ is graded $\mathcal{D}$-simple and $\mathcal{A}\mathcal{D}$ acts faithfully on $\mathcal{A}$ (except a minor case). The authors of the present paper[11] (see also Refs. 9, 10, and 14) constructed (associative and Lie) color algebras of Weyl type $\mathcal{A}[\mathcal{D}]$, which is the color commutative algebra generated by $\mathcal{A}$ and $\mathcal{D}$ (as operators on $\mathcal{A}$), and proved that $\mathcal{A}[\mathcal{D}]$ is simple as an associative algebra or is *central simple* as a Lie color algebra (i.e., the derived subalgebra modulo its ϵ-center is simple) if and only if $\mathcal{A}$ is graded $\mathcal{D}$-simple (except a minor case in Lie case). However, it is still a question of how to construct new explicit simple Lie color algebras of generalized Witt type or Weyl type.

The problem of classifying all the pairs $(\mathcal{A},\mathcal{D})$ of a commutative associative algebra $\mathcal{A}$ with an identity element and a finite-dimensional locally finite commutative derivation subalgebra $\mathcal{D}$ such that $\mathcal{A}$ is *$\mathcal{D}$-simple* (i.e., $\mathcal{A}$ does not have $\mathcal{D}$-stable ideals), was settled in Ref. 8 (using the pairs

$(\mathcal{A},\mathcal{D})$, Xu constructed explicit simple Lie algebras of generalized Cartan type[12] and of generalized Block type[13]). However, this problem becomes much more complicated in color case.

In order to construct explicit new simple Lie color algebras of generalized Witt, Weyl types, the first aim of the present paper is to give a classification of all the pairs $(\mathcal{A},\mathcal{D})$ of an (ϵ,Γ)-color-commutative associative algebra $\mathcal{A}$ with an identity element over an algebraically closed field $\mathbb{F}$ of characteristic zero and a finite-dimensional subspace $\mathcal{D}$ of (ϵ,Γ)-color-commutative locally finite color derivations of $\mathcal{A}$ such that $\mathcal{A}$ is Γ-graded $\mathcal{D}$-simple and the eigenspaces for elements of $\mathcal{D}$ are Γ-graded (see Theorem 2.2). Then in Sec. III, as some applications, using the pairs $(\mathcal{A},\mathcal{D})$, we construct explicit new simple Lie color algebras (including Lie superalgebras) of generalized Witt, Weyl types (see Theorem 3.1).

II. $\mathcal{D}$-SIMPLE COLOR ALGEBRAS

In this section, we shall classify the pairs $(\mathcal{A},\mathcal{D})$ of an (ϵ,Γ)-commutating associative algebra $\mathcal{A}$ with an identity element 1 and a finite-dimensional subspace $\mathcal{D}$ of (ϵ,Γ)-commutative locally finite color derivations of $\mathcal{A}$ such that $\mathcal{A}$ is graded $\mathcal{D}$-simple and the eigenspaces for elements of $\mathcal{D}$ are Γ-graded.

First we would like to remark that the eigenspace of a derivation is not necessarily Γ-graded. Since we are considering Γ-graded algebras, it is natural that we require the eigenspaces for elements of $\mathcal{D}$ are Γ-graded.

We shall start with constructing explicitly such pairs $(\mathcal{A},\mathcal{D})$. The motivation to construct such pairs will become clear in the proof of Theorem 2.2 below. Actually, the proof of Theorem 2.2 leads us to the way to construct such pairs.

Set

$$\Gamma_+=\{\lambda\in\Gamma\mid \epsilon(\lambda,\lambda)=1\},\quad \Gamma_-=\{\lambda\in\Gamma\mid \epsilon(\lambda,\lambda)=-1\}.$$

Then by (1.1), Γ_+ is a subgroup of Γ with index $\leqslant 2$. For any graded subspace $\mathcal{B}$ of $\mathcal{A}$, we define $\mathcal{B}_+=\oplus_{\lambda\in\Gamma_+}\mathcal{B}_\lambda$, then $\mathcal{B}_+$ is Γ-graded. Similarly we can define $\mathcal{B}_-$. Since $\Gamma=\Gamma_+\cup\Gamma_-$, it follows that $\mathcal{B}=\mathcal{B}_+\oplus\mathcal{B}_-$. By (1.5), we have

$$a^2=0 \quad \text{or} \quad \partial^2=0 \quad \text{if } \overline{a}\in\Gamma_- \quad \text{or} \quad \overline{\partial}\in\Gamma_-. \tag{2.1}$$

For $m,n\in\mathbb{Z}$, we denote

$$\overline{m,n}=\{m,m+1,\ldots,n\}.$$

To construct the pair $(\mathcal{A},\mathcal{D})$, first we construct a Γ-*graded* ϵ-*commutative field extension* $\mathbb{E}$ of $\mathbb{F}$ (i.e., each nonzero homogeneous element of $\mathbb{E}$ is invertible). To do this, let $\Gamma^0\subset\Gamma_+$ be a subgroup of Γ and let $\mathbb{E}_0$ be a field extension of $\mathbb{F}$. Let $e:\Gamma^0\times\Gamma^0\to\mathbb{E}_0^\times=\mathbb{E}_0\backslash\{0\}$ be a 2-variable function $e:(\alpha,\beta)\mapsto e_{\alpha,\beta}$ such that

$$e_{\alpha,\beta}=\epsilon(\alpha,\beta)e_{\beta,\alpha},\quad e_{\alpha,0}=1,\quad e_{\alpha,\beta}e_{\alpha+\beta,\gamma}=e_{\alpha,\beta+\gamma}e_{\beta,\gamma},\quad \forall\ \alpha,\beta,\gamma\in\Gamma^0. \tag{2.2}$$

You will see that these are required by the associativity of the algebra we are going to construct. Let $\mathbb{E}=\mathbb{E}_0[\Gamma^0]=\mathrm{span}_{\mathbb{E}_0}\{E_\alpha\mid\alpha\in\Gamma^0\}$ be a Γ^0-graded ϵ-commutative associative algebra over $\mathbb{E}_0$ such that E_α has color $\overline{E_\alpha}=\alpha$, with the multiplication

$$E_\alpha\cdot E_\beta=e_{\alpha,\beta}E_{\alpha+\beta},\quad \forall\ \alpha,\beta\in\Gamma^0. \tag{2.3}$$

From (2.2) it is easy to see that $\mathbb{E}$ is a Γ-graded ϵ-commutative field extension of $\mathbb{F}$.

Let

$$\underline{k}=(k_1,k_2,k_3,k_4)\in\mathbb{N}^4 \quad \text{such that } k=k_1+k_2+k_3+k_4>0.$$

We also require that $k_4=0$ if $\Gamma_-=\varnothing$. We shall construct $\mathcal{D}$ which will be spanned by color derivations $\partial_p, p\in\overline{1,k}$ such that

$$\partial_p \text{ is semisimple with color } \overline{\partial}_p=0, \quad \forall\ p\in\overline{1,k_1}, \tag{2.4}$$

$$\partial_{k_1+p} \text{ is locally finite but not semisimple with color } \overline{\partial}_{k_1+p}=0, \quad \forall\ p\in\overline{1,k_2}, \tag{2.5}$$

$$\partial_{k_1+k_2+p} \text{ is locally nilpotent with color } \overline{\partial}_{k_1+k_2+p}\in\Gamma_+, \quad \forall\ p\in\overline{1,k_3}, \tag{2.6}$$

$$\partial_{k_1+k_2+k_3+p} \text{ is locally nilpotent with color } \overline{\partial}_{k_1+k_2+k_3+p}\in\Gamma_-, \quad \forall\ p\in\overline{1,k_4} \tag{2.7}$$

[cf. (2.21) and (2.22)]. To this end, we first need to construct $\mathcal{A}$ which will be the tensor product of two algebras $\mathcal{A}=\mathcal{A}_1\otimes\mathcal{A}_2$ [cf. (2.19)] such that $\mathcal{A}_1$ is a ''group-algebra-like'' algebra [cf. (2.12)] and $\mathcal{A}_2$ is a ''polynomial-like'' algebra [cf. (2.16)].

Now we construct $\mathcal{A}_1$ such that $\partial_p|_{\mathcal{A}_1}$ are nonzero semisimple operators for $p\in\overline{1,k_1+k_2}$ and $\partial_{k_1+k_2+p}|_{\mathcal{A}_1}$ are zero operators for $p\in\overline{1,k_3+k_4}$ [cf. (2.4)–(2.7) and (2.21)–(2.22)]. To do this, let G be a *nondegenerate* additive subgroup of $\mathbb{F}^{k_1+k_2}$, i.e., G contains an $\mathbb{F}$-basis of $\mathbb{F}^{k_1+k_2}$. If $k_1+k_2=0$, we take $G=\{0\}$. An element in G is usually denoted by

$$\underline{a}=(a_1,a_2,\ldots,a_k) \quad \text{with } a_p=0,\ \forall\ p>k_1+k_2. \tag{2.8}$$

Let $\hat{}:G\to\Gamma_+$ be a map $\hat{}:\underline{a}\mapsto\hat{\underline{a}}$ satisfying

$$\hat{0}=0, \quad \theta_{\underline{a},\underline{b}}:=\hat{\underline{a}}+\hat{\underline{b}}-\widehat{\underline{a}+\underline{b}}\in\Gamma^0, \quad \forall\ \underline{a},\underline{b}\in G. \tag{2.9}$$

Let $f(\cdot,\cdot):G\times G\to\mathbb{E}_0^\times$ be a map such that

$$f(\underline{a},\underline{b})=\epsilon(\hat{\underline{a}},\hat{\underline{b}})f(\underline{b},\underline{a}), \quad f(\underline{a},0)=1, \tag{2.10}$$

$$e_{\theta_{\underline{a},\underline{b}},\theta_{\underline{a}+\underline{b},\underline{c}}}f(\underline{a},\underline{b})f(\underline{a}+\underline{b},\underline{c})=\epsilon(\hat{\underline{a}},\theta_{\underline{b},\underline{c}})e_{\theta_{\underline{b},\underline{c}},\theta_{\underline{a},\underline{b}+\underline{c}}}f(\underline{b},\underline{c})f(\underline{a},\underline{b}+\underline{c}), \tag{2.11}$$

for $\underline{a},\underline{b},\underline{c}\in G$. Denote by $\mathcal{A}_1=\mathcal{A}(G,\mathbb{E},f)$ the (ϵ,Γ)-color commutative associative algebra with $\mathbb{E}$-basis $\{x^{\underline{a}}\mid\underline{a}\in G\}$ or $\mathbb{E}_0$-basis $\{E_\alpha x^{\underline{a}}\mid(\alpha,\underline{a})\in\Gamma^0\times G\}$ such that $x^{\underline{a}}$ has color $\hat{\underline{a}}$ and

$$x^{\underline{a}}\cdot x^{\underline{b}}=f(\underline{a},\underline{b})E_{\theta_{\underline{a},\underline{b}}}x^{\underline{a}+\underline{b}}, \quad \forall\ \underline{a},\underline{b}\in G, \tag{2.12}$$

and in general

$$E_\alpha x^{\underline{a}}\cdot E_\beta x^{\underline{b}}=\epsilon(\hat{\underline{a}},\beta)e_{\alpha,\beta}e_{\alpha+\beta,\theta_{\underline{a},\underline{b}}}f(\underline{a},\underline{b})E_{\alpha+\beta+\theta_{\underline{a},\underline{b}}}x^{\underline{a}+\underline{b}}, \quad \forall\ \alpha,\beta\in\Gamma^0,\ \underline{a},\underline{b}\in G \tag{2.13}$$

[cf. (2.3)]. The ϵ-commutativity and associativity of $\mathcal{A}_1$ are guaranteed by conditions (2.10) and (2.11).

Now we shall construct $\mathcal{A}_2$ such that $\partial_p|_{\mathcal{A}_2}=0$ for $p\in\overline{1,k_1}$ and $\partial_p|_{\mathcal{A}_2}$ are nonzero locally nilpotent operators for $p\in\overline{k_1+1,k}$ [cf. (2.4)–(2.7) and (2.21)–(2.22)]. To this end, let $t_{k_1+1},\ldots,t_k$ be $k_2+k_3+k_4$ variables such that each t_p has color $\overline{t_p}$ satisfying

$$\overline{t}_{k_1+p}=0, \quad \overline{t}_{k_1+k_2+q}\in\Gamma_+, \quad \overline{t}_{k_1+k_2+k_3+r}\in\Gamma_-, \tag{2.14}$$

for $p\in\overline{1,k_2}$, $q\in\overline{1,k_3}$, $r\in\overline{1,k_4}$. For convenience, we denote $t_p=0$ if $p\leqslant k_1$. Denote $\mathcal{J}=\{0\}^{k_1}\times\mathbb{N}^{k_2+k_3}\times\mathbb{Z}_2^{k_4}$, where $\mathbb{Z}_2=\mathbb{Z}/2\mathbb{Z}$, i.e., $\mathcal{J}$ is the subset of $\mathbb{F}^k$ consisting of the following elements:

$$\underline{i}=(i_1,i_2,\ldots,i_k), \tag{2.15}$$

with $i_p=0$ for $p\leqslant k_1$, and $i_q\in\mathbb{N}$ for $q\in\overline{k_1+1,k_1+k_2+k_3}$, and $i_r=0,1$ for $q>k_1+k_2+k_3$ [(2.1) and (2.16) explain why we shall have $i_q=0,1$ for $q>k_1+k_2+k_3$]. Let $\mathcal{A}_2=\mathbb{E}[t_{k_1+1},\ldots,t_k]$ be the ϵ-commutative algebra of polynomials in $k_2+k_3+k_4$ variables with an $\mathbb{E}$-basis consisting of the elements

$$t^{\underline{i}}=t_{k_1+1}^{i_{k_1+1}}\cdots t_k^{i_k},\quad \forall\ \underline{i}\in\mathcal{J}, \tag{2.16}$$

or $\mathbb{E}_0$-basis $\{E_\alpha t^{\underline{i}}\mid(\alpha,\underline{i})\in\Gamma^0\times\mathcal{J}\}$ such that

$$E_\alpha t^{\underline{i}}\cdot E_\beta t^{\underline{j}}=e_{\alpha,\beta}\prod_{p=k_1+1}^{k}\epsilon(\overline{t_p},\beta)^{i_p}\prod_{k_1<p<q\leqslant k}\epsilon(\overline{t_q},\overline{t_p})^{i_qj_p}E_{\alpha+\beta}t^{\underline{i}+\underline{j}},\quad \forall\ \alpha,\beta\in\Gamma^0,\ \underline{i},\underline{j}\in\mathcal{J} \tag{2.17}$$

[cf. (2.3)], where we use the convention that $t^{\underline{i}}=0$ if $\underline{i}\notin\mathcal{J}$. For convenience, we shall denote

$$\epsilon_{\underline{i},\beta}=\prod_{p=k_1+1}^{k}\epsilon(\overline{t_p},\beta)^{i_p},\quad \widetilde{\epsilon}_{\underline{i},\underline{j}}=\prod_{k_1<p<q\leqslant k}\epsilon(\overline{t_q},\overline{t_p})^{i_qj_p},\quad \forall\ \underline{i},\underline{j}\in\mathcal{J},\ \beta\in\Gamma^0. \tag{2.18}$$

Definition 2.1: We define $\mathcal{A}=\mathcal{A}(\underline{k},G,\mathbb{E},f)$ to be the (ϵ,Γ)-commutative associative algebra with the identity element $1=E_0=x^0$, which is the tensor product of algebras $\mathcal{A}=\mathcal{A}_1\otimes_{\mathbb{E}}\mathcal{A}_2$, having $\mathbb{E}_0$-basis

$$E_\alpha x^{\underline{a},\underline{i}}=E_\alpha x^{\underline{a}}t^{\underline{i}},\quad \forall\ (\alpha,\underline{a},\underline{i})\in\Gamma^0\times G\times\mathcal{J}, \tag{2.19}$$

with the multiplication

$$E_\alpha x^{\underline{a},\underline{i}}\cdot E_\beta x^{\underline{b},\underline{j}}=\epsilon_{\underline{i},\beta}e_{\alpha,\beta}\epsilon_{\underline{i},\hat{\underline{b}}}\widetilde{\epsilon}_{\underline{i},\underline{j}}\epsilon(\hat{\underline{a}},\beta)e_{\alpha+\beta,\theta_{\underline{a},\underline{b}}}f(\underline{a},\underline{b})E_{\alpha+\beta+\theta_{\underline{a},\underline{b}}}x^{\underline{a}+\underline{b},\underline{i}+\underline{j}}, \tag{2.20}$$

for $\alpha,\beta\in\Gamma^0$, $\underline{a}$, $\underline{b}\in G$, $\underline{i},\underline{j}\in\mathcal{J}$ [cf. (2.3), (2.13), (2.17), and (2.18)].

For $a\in\mathbb{F}^k,p\in\overline{1,k}$, we denote

$$a_{[p]}=(0,\ldots,0,\overset{p}{a},0,\ldots,0)\in\mathbb{F}^k.$$

For $p\in\overline{1,k}$, we define the linear transformations $\partial_p,\partial_{t_p},\partial_p^*$ on $\mathcal{A}$ such that they have color $-\overline{t_p}$ [in particular, they have color 0 if $p\leqslant k_1+k_2$, cf. (2.14)], and

$$\partial_p=\partial_p^*+\partial_{t_p}, \tag{2.21}$$

$$\partial_p^*(E_\alpha x^{\underline{a},\underline{i}})=a_pE_\alpha x^{\underline{a},\underline{i}},\quad \partial_{t_p}(E_\alpha x^{\underline{a},\underline{i}})=\epsilon(\overline{\partial_{t_p}},\alpha+\hat{\underline{a}})\prod_{q=1}^{p-1}\epsilon(\overline{\partial_{t_p}},\overline{t_q})^{i_q}\,i_pE_\alpha x^{\underline{a},\underline{i}-1_{[p]}}, \tag{2.22}$$

for $(\alpha,\underline{a},\underline{i})\in\Gamma^0\times G\times\mathcal{J}$. Clearly, $\partial_p^*=0$ if $p>\underline{k_1}+k_2$ by (2.8), and $\partial_q=0$ if $q\leqslant k_1$ by (2.15). Then $\partial_p,\partial_p^*,\partial_{t_p}$ are ϵ-derivations of $\mathcal{A}$ for $p\in\overline{1,k}$. We call ∂_p^* a *grading operator* (or *degree operator*), ∂_{t_p} a *down-grading operator*, and $\partial_p=\partial_p^*+\partial_{t_p}$ a *mixed operator* if both p_p^* and ∂_{t_p} are nonzero. Then

$$\mathcal{D}=\mathrm{span}_{\mathbb{F}}\{\partial_p\mid p\in\overline{1,k}\} \tag{2.23}$$

is a finite-dimensional subspace of ϵ-commutative locally finite color derivations of $\mathcal{A}$ such that the eigenspaces for elements of $\mathcal{D}$ are Γ-graded.

Theorem 2.2: Let $\mathcal{A}=\Sigma_{\alpha\in\Gamma}\mathcal{A}_\alpha$ be an ϵ-commutative associative graded algebra with an identity element over an algebraically closed field $\mathbb{F}$ of characteristic zero and let $\mathcal{D}=\Sigma_{\alpha\in\Gamma}\mathcal{D}_\alpha$ be

a finite-dimensional Γ-graded $\mathbb{F}$-subspace of ϵ-commutative locally finite color-derivations of $\mathcal{A}$ such that the eigenspaces for elements of $\mathcal{D}$ are Γ-graded. Then $\mathcal{A}$ is graded $\mathcal{D}$-simple if and only if $\mathcal{A}$ is isomorphic to the algebra of the form $\mathcal{A}(\underline{k},G,\mathbb{E},f)$ defined in (2.19) and (2.20), and $\mathcal{D}$ is of the form (2.21)–(2.23).

Proof: "⇐:" Let $\mathcal{I}$ be a Γ-graded $\mathcal{D}$-stable nonzero ideal of $\mathcal{A}=\mathcal{A}(\underline{k},G,\mathbb{E},f)$. By (2.21) and (2.22), we see that

$$\left(\bigcup_{(\alpha,\underline{a})\in\Gamma^0\times G}\mathbb{F}(E_\alpha x^{\underline{a}})\right)\Big\backslash\{0\},$$

is the set of the common eigenvectors of $\mathcal{D}$. We also see that if a homogeneous element $\partial\in H(\mathcal{D})$ has a nonzero eigenvalue, then $\partial\in\mathcal{D}_0$. Thus $\Sigma_{0\neq\alpha\in\Gamma}\mathcal{D}_\alpha$ acts locally nilpotently on $\mathcal{I}$. Since $\mathcal{D}_0$ is commutative [cf. (1.2) and (1.5)], and $\mathcal{D}_0$ commutes with $\Sigma_{0\neq\alpha\in\Gamma}\mathcal{D}_\alpha$, and $\Sigma_{0\neq\alpha\in\Gamma}\mathcal{D}_\alpha$ is color-commutative, by linear algebra, $\mathcal{I}$ must contain a common eigenvector of $\mathcal{D}$. Thus $E_\alpha x^{\underline{a}}\in\mathcal{I}$ for some $(\alpha,\underline{a})\in\Gamma^0\times G$. Then

$$1=e_{-\alpha,\alpha}^{-1}f(-\underline{a},\underline{a})^{-1}(E_{-\alpha}x^{-\underline{a}})\cdot(E_\alpha x^{\underline{a}})\in\mathcal{I}$$

[cf. (2.13)]. Hence $\mathcal{I}=\mathcal{A}$. This proves that $\mathcal{A}$ is graded $\mathcal{D}$-simple.

"⇒:" Suppose $\partial\in H(\mathcal{D})$ has a nonzero eigenvalue $\underline{a}\in\mathbb{F}$ such that $u_{\underline{a}}\in H(\mathcal{A})$ is a corresponding eigenvector. Then we have $\partial(u_{\underline{a}})=\underline{a}u_{\underline{a}}$, and so $\overline{\partial}+\overline{u_{\underline{a}}}=\overline{u_{\underline{a}}}$ by (1.4). Thus $\overline{\partial}=0$. In other words, we have

$$\partial\in H(\mathcal{D}),\ \overline{\partial}\neq 0\Rightarrow\ \partial\quad\text{acts locally nilpotent on}\quad\mathcal{A}. \tag{2.24}$$

Since $\mathbb{F}$ is algebraically closed and $\mathcal{D}$ is a finite-dimensional subspace of ϵ-commutative locally finite color derivations of $\mathcal{A}$, from linear algebra, we have

$$\mathcal{A}=\bigoplus_{\underline{a}\in\mathcal{D}^*}\mathcal{A}(\underline{a}),$$

where $\mathcal{D}^*$ is the dual space of $\mathcal{D}$, and

$$\mathcal{A}(\underline{a})=\{u\in\mathcal{A}\,|\,(\partial-\underline{a}(\partial))^m(u)=0\ \text{ for }\ \partial\in H(\mathcal{D})\ \text{ and some } m\in\mathbb{N}\},$$

for $\underline{a}\in\mathcal{D}^*$ [note that $\underline{a}(\partial)=0$ if $\overline{\partial}\neq 0$ by (2.24)]. Denote

$$G=\{\underline{a}\in\mathcal{D}^*\,|\,\mathcal{A}(\underline{a})\neq 0\}.$$

By (2.24), G can be viewed as a subset of $\mathcal{D}_0^*$ by the restriction $\underline{a}\mapsto\underline{a}|_{\mathcal{D}_0}$. For any $\underline{a}\in G$, $n\in\mathbb{N}$, we define

$$\mathcal{A}(\underline{a})^{(n)}=\{u\in\mathcal{A}\,|\,(d_1-\underline{a}(d_1))\cdots(d_{n+1}-\underline{a}(d_{n+1}))(u)=0,\ \forall\, d_1,\cdots,d_{n+1}\in H(\mathcal{D})\}. \tag{2.25}$$

Then

$$\mathcal{A}(\underline{a})=\bigcup_{n=0}^{\infty}\mathcal{A}(\underline{a})^{(n)},\quad\forall\,\underline{a}\in G.$$

A nonzero vector in $\mathcal{A}(\underline{a})^{(0)}$ is called a *root vector* with root $\underline{a}$. For any homogeneous root vector $u\in\mathcal{A}(\underline{a})^{(0)}$, clearly $\mathcal{A}u$ is a Γ-graded $\mathcal{D}$-stable ideal of $\mathcal{A}$. Thus $\mathcal{A}u=\mathcal{A}$. In particular, $vu=1$ for some $v\in\mathcal{A}$. So any homogeneous root vector is invertible. For a root vector $u\in H(\mathcal{A}(\underline{a})^{(0)})$ with $\underline{a}\in G$ and any $\partial\in H(\mathcal{D})$, we have

$$0=\partial(1)=\partial(uu^{-1})=\partial(u)u^{-1}+\epsilon(\overline{\partial},\overline{u})u\partial(u^{-1})=\underline{a}(\partial)uu^{-1}+\epsilon(\overline{\partial},\overline{u})u\partial(u^{-1})$$
$$=\begin{cases}\epsilon(\overline{\partial},\overline{u})u\partial(u^{-1}) & \text{if} \quad \overline{\partial}\neq 0,\\ \underline{a}(\partial)+u\partial(u^{-1}) & \text{if} \quad \overline{\partial}=0,\end{cases}$$

because $\underline{a}(\partial)=0$ if $\overline{\partial}\neq 0$ by (2.24). This implies

$$\partial(u^{-1})=-\underline{a}(\partial)u^{-1}, \tag{2.26}$$

by (2.24). Hence

$$-\underline{a}\in G, \quad \forall \quad \underline{a}\in G. \tag{2.27}$$

For any $x\in H(\mathcal{A}(\underline{a})^{(0)})$, $y\in H(\mathcal{A}(\underline{b})^{(0)})$, and $\partial\in H(\mathcal{D})$, we have

$$\partial(xy)=\partial(x)y+\epsilon(\overline{\partial},\overline{x})x\partial(y)=\begin{cases}0 & \text{if} \quad \overline{\partial}\neq 0,\\ (\underline{a}(\partial)+\underline{b}(\partial))xy & \text{if} \quad \overline{\partial}=0.\end{cases}$$

Hence

$$\mathcal{A}(\underline{a})^{(0)}\cdot\mathcal{A}(\underline{b})^{(0)}\subset\mathcal{A}(\underline{a}+\underline{b})^{(0)}, \quad \forall \quad \underline{a},\underline{b}\in G.$$

Considering the invertibility of root vectors, we have

$$\mathcal{A}(\underline{a})^{(0)}\cdot\mathcal{A}(\underline{b})^{(0)}=\mathcal{A}(\underline{a}+\underline{b})^{(0)}, \quad \forall \quad \underline{a},\underline{b}\in G.$$

In particular, we obtain

$$\underline{a}+\underline{b}\in G, \quad \forall \quad \underline{a},\underline{b}\in G. \tag{2.28}$$

Thus by (2.27) and (2.28), G is an additive subgroup of D^*. Set

$$\mathbb{E}=\mathcal{A}(0)^{(0)}. \tag{2.29}$$

Then $\mathbb{E}$ is a Γ-graded field extension of $\mathbb{F}$ such that $\mathbb{E}_0$ is a field extension of $\mathbb{F}$. We set

$$\Gamma^0=\{\alpha\in\Gamma \mid \mathbb{E}_\alpha\neq\{0\}\}.$$

Clearly, Γ^0 is a subgroup of Γ and $\Gamma^0\subset\Gamma_+$ by (2.1). For any $\alpha\in\Gamma^0$, choose $E_\alpha=1$ if $\alpha=0$, and $E_\alpha\in\mathbb{E}_\alpha\backslash\{0\}$ if $\alpha\neq 0$. Then $\{E_\alpha \mid \alpha\in\Gamma^0\}$ forms an $\mathbb{E}_0$-basis of $\mathbb{E}$. Thus we have (2.3) such that the coefficient $e_{\alpha,\beta}$ satisfies (2.2) by color commutativity and associativity.

First assume that $\mathcal{A}(0)\neq\mathbb{E}$. Since $\underline{a}(\partial)=0$ for any homogeneous derivation ∂ with $\overline{\partial}\neq 0$, for $u\in\mathcal{A}(\underline{a})^{(m)}$, $v\in\mathcal{A}(\underline{b})^{(n)}$ and $d_1,\ldots,d_{m+n+1}\in H(\mathcal{D})$, by induction on $m+n+1$, we can write

$$(d_1-(\underline{a}+\underline{b})(d_1))\cdots(d_{m+n+1}-(\underline{a}+\underline{b})(d_{m+n+1}))(uv), \tag{2.30}$$

as a linear combination of the forms

$$(d_{i_1}-\underline{a}(d_{i_1}))\cdots(d_{i_r}-\underline{a}(d_{i_r}))(u)\cdot(d_{j_1}-\underline{a}(d_{j_1}))\cdots(d_{j_s}-\underline{a}(d_{j_s}))(v), \tag{2.31}$$

where

$$r+s=m+n+1, \quad \{i_1,\ldots,i_r,j_1,\ldots,j_s\}=\{1,\ldots,m+n+1\}.$$

By definition (2.25), we obtain that (2.31) is zero, and so is (2.30). It follows that $uv\in\mathcal{A}(\underline{a}+\underline{b})^{(m+n)}$. Thus

$$\mathcal{A}(\underline{a})^{(m)}\cdot\mathcal{A}(\underline{b})^{(n)}\subset\mathcal{A}(\underline{a}+\underline{b})^{(m+n)},\quad \forall\ \ \underline{a},\underline{b}\in G,\ \ m,n\in\mathbb{N}. \tag{2.32}$$

In particular (since homogeneous root vectors are invertible),

$$\mathbb{E}\mathcal{A}(\underline{a})^{(m)}=\mathcal{A}(\underline{a})^{(m)}=\mathcal{A}(\underline{a})^{(0)}\mathcal{A}(0)^{(m)},\quad \forall\ \ \underline{a}\in G,\ \ m\in\mathbb{N} \tag{2.33}$$

[cf. (2.29)]. Hence each $\mathcal{A}(\underline{a})^{(m)}$ is a vector space over the graded field $\mathbb{E}$. For any $v\in\mathcal{A}(0)^{(1)}$, we have $\mathcal{D}(v)\subset\mathbb{E}$ and

$$\mathcal{D}(v)=0\ \ \Leftrightarrow\ \ v\in\mathbb{E}. \tag{2.34}$$

Set

$$\mathcal{H}=\mathbb{E}\mathcal{D},\quad \mathcal{H}_1=\{\partial\in\mathcal{H}\mid\partial(\mathcal{A}(0)^{(1)})=\{0\}\},\quad k_1=\dim_{\mathbb{E}}\mathcal{H}_1. \tag{2.35}$$

Expression (2.34) implies that $\mathcal{A}(0)^{(1)}/\mathbb{E}$ is isomorphic to a subspace of the space $\mathrm{Hom}_{\mathbb{E}}(\mathcal{H},\mathbb{E})$ over $\mathbb{E}$. By linear algebra, there exist subsets

$$\{\partial_{k_1+1},\partial_{k_1+2},\cdots,\partial_k\}\subset H(\mathcal{D}),\quad \{t_{k_1+1},t_{k_1+2},\cdots,t_k\}\subset H(\mathcal{A}(0)^{(1)}), \tag{2.36}$$

for some $k\in\mathbb{N}$, such that

$$\mathcal{A}(0)^{(1)}=\mathbb{E}+\sum_{l=k_1+1}^{k}\mathbb{E}t_l,\quad \partial_p(t_q)=\delta_{p,q},\quad \forall\ \ p,q\in\overline{k_1+1,k}. \tag{2.37}$$

Set

$$\mathcal{H}_2=\sum_{p=k_1+1}^{k}\mathbb{E}\partial_p.$$

Then we have

$$\mathcal{H}=\mathcal{H}_1\oplus\mathcal{H}_2.$$

For convenience, denote

$$t^{\underline{i}}=t_{k_1+1}^{i_{k_1+1}}\cdots t_k^{i_k}\quad \text{for}\ \ \underline{i}=(i_{k_1+1},\ldots,i_k)\in\mathbb{N}^{\ell},$$

where $\ell=k-k_1$. By (2.1) then

$$t^{\underline{i}}=0\ \text{if}\ \ i_p\geqslant 2\ \text{with}\ \ \overline{t_p}\in\Gamma_-\ \text{for some}\ \ p\in\overline{k_1+1,k},$$

and

$$t^{\underline{i}}\cdot t^{\underline{j}}=\prod_{k_1+1\leqslant p<q\leqslant k}\epsilon(\overline{t_q},\overline{t_p})^{i_qj_p}t^{\underline{i}+\underline{j}},\quad \forall\ \ \underline{i},\underline{j}\in\mathbb{N}^{\ell}.$$

Furthermore, by (2.37), we can deduce by induction on the level $|\underline{i}|:=\Sigma_{p=k_1+1}^{k}i_p$ that

$$t^{\underline{i}}\in\mathcal{A}(0)^{(|\underline{i}|)},\quad \partial_p(t^{\underline{i}})=\prod_{k_1<q<p}\epsilon(\overline{p_p},t_q)^{i_q}\,i_p t^{\underline{i}-1_{[p]}}, \tag{2.38}$$

for $\underline{i}\in\mathbb{N}^{\ell},p\in\overline{k_1+1,k}$. Set

$$\tilde{\mathcal{A}}(0)=\sum_{\underline{i}\in\mathbb{N}^{\ell}}\mathbb{E}t^{\underline{i}}\subset\mathcal{A}(0). \tag{2.39}$$

Then $\tilde{\mathcal{A}}(0)$ forms a subalgebra of $\mathcal{A}$. We want to prove that $\mathcal{A}(0)=\tilde{\mathcal{A}}(0)$. By (2.37), $\mathcal{A}(0)^{(1)}\subset\tilde{\mathcal{A}}(0)$. Suppose $\mathcal{A}(0)^{(m)}\subset\tilde{\mathcal{A}}(0)$ for some $1\leqslant m\in\mathbb{N}$. By (2.25), $\partial(\mathcal{A}(0)^{(m+1)})\subset\mathcal{A}(0)^{(m)}\subset\tilde{\mathcal{A}}(0)$ for any $\partial\in\mathcal{H}$. Thus, for $\partial_{k_1+1}\in H(\mathcal{H})$ and $u\in H(\mathcal{A}(0)^{(m)})$, we may assume that

$$\partial_{k_1+1}(u)=\sum_{\underline{i}\in\mathbb{N}^{\ell}}c_{\underline{i}}t^{\underline{i}}, \tag{2.40}$$

where $c_{\underline{i}}\in H(\mathbb{E})$ and $c_{\underline{i}}=0$ for all but a finite number of $\underline{i}$. If $\overline{\partial}_{k_1+1}\in\Gamma_+$, then we set

$$u_1=\sum_{\underline{i}\in\mathbb{N}^{\ell}}c_{\underline{i}}\epsilon(\overline{\partial}_{k_1+1},\overline{c_{\underline{i}}})^{-1}(i_{k_1+1}+1)^{-1}t^{\underline{i}+1_{[k_1+1]}}\in H(\tilde{\mathcal{A}}(0)), \tag{2.41}$$

and we obtain

$$\partial_{k_1+1}(u)=\partial_{k_1+1}(u_1). \tag{2.42}$$

If $\overline{\partial}_{k_1+1}\in\Gamma_-$, then by (2.1), $\partial_{k_1+1}^2=0$, we must have

$$i_{k_1+1}=0 \quad \text{if } c_{\underline{i}}\neq 0, \tag{2.43}$$

otherwise if (2.43) does not hold, then by (2.38) and (2.40) we would have $\partial_{k_1+1}^2(u)\neq 0$, leading to a contradiction to the fact that $\partial_{k_1+1}^2=0$. Thus we can still choose u_1 as in (2.41) to give (2.42). Similarly, since $\partial_{k_1+2}(u-u_1)\in\mathcal{A}(0)^{(m)}\subset\tilde{\mathcal{A}}(0)$, there exists $u_2\in H(\tilde{\mathcal{A}}(0))$ such that

$$\partial_{k_1+2}(u-u_1)=\partial_{k_1+2}(u_2). \tag{2.44}$$

Assume that $u_2=\Sigma_{\underline{i}\in\mathbb{N}^{\ell}}c'_{\underline{i}}t^{\underline{i}}$, where $c'_{\underline{i}}\in H(\mathbb{E})$. Since $\mathcal{H}$ is color commutative, by (2.42) and (2.44), we have

$$0=\partial_{k_1+1}\partial_{k_1+2}(u_2)=\sum_{\underline{i}\in\mathbb{N}^{\ell}}c'_{\underline{i}}\epsilon(\overline{\partial}_{k_1+1}+\overline{\partial}_{k_1+2},\overline{c'_{\underline{i}}})e(\overline{\partial}_{k_1+2},t_{k_1+1})^{i_{k_1+1}}i_{k_1+1}i_{k_1+2}t^{\underline{i}-1_{[k_1+1]}-1_{[k_1+2]}}.$$

Thus $i_{k_1+1}i_{k_1+2}=0$ if $c'_{\underline{i}}\neq 0$. Hence we can re-choose $u_2\in H(\tilde{\mathcal{A}}(0))$ such that

$$\partial_{k_1+1}(u_2)=0, \quad \partial_{k_1+2}(u-u_1)=\partial_{k_1+2}(u_2).$$

Similarly, we can find $u_2,\ldots,u_{\ell}\in H(\tilde{\mathcal{A}}(0))$ such that

$$\partial_{k_1+p}\left(u-\sum_{q=1}^{p}u_q\right)=0, \quad \partial_{k_1+1}(u_p)=\partial_{k_1+2}(u_p)=\cdots=\partial_{k_1+p-1}(u_p)=0, \quad \forall\ \ p\in\overline{2,\ell},$$

by induction on p. Thus we have

$$\partial_{k_1+p}\left(u-\sum_{q=1}^{\ell}u_q\right)=0, \quad \forall\ \ p\in\overline{1,\ell}. \tag{2.45}$$

For any $\partial,\partial'\in H(\mathcal{H}_1)$, using (2.35) and (2.39) we deduce

$$\partial\partial'\left(u-\sum_{p=1}^{\ell}u_p\right)\in\partial(\mathcal{A}(0)^{(m)})+\partial'(\mathcal{A}(0)^{(m)})\subset\partial(\tilde{\mathcal{A}}(0))+\partial'(\tilde{\mathcal{A}}(0))=\{0\}. \tag{2.46}$$

Now (2.45) and (2.46) show that $u-\Sigma_{p=1}^{\ell}u_p\in\mathcal{A}(0)^{(1)}$. Thus by (2.35),

$$\partial\left(u-\sum_{p=1}^{\ell}u_p\right)=0,\quad \forall\ \ \partial\in H(\mathcal{H}_1). \tag{2.47}$$

Then (2.45), (2.47) and the definition (2.25) show that

$$u-\sum_{p=1}^{\ell}u_p\in\mathcal{A}(0)^{(0)}=\mathbb{E}.$$

Thus $u\in\tilde{\mathcal{A}}(0)$. This proves

$$\mathcal{A}(0)=\tilde{\mathcal{A}}(0).$$

The case $\mathcal{A}(0)=\mathbb{E}$ can be viewed as in the general case $\mathcal{A}(0)=\tilde{\mathcal{A}}(0)$ with $\ell=0$.

We re-choose $\partial_p,t_p,p\in\overline{1,k}$ as follows: Choose a homogeneous $\mathbb{F}$-basis $\{\partial_1,\ldots,\partial_{k_1}\}$ of $\mathcal{D}\cap\mathcal{H}_1$, and set $t_p=0$ for $p\in\overline{1,k_1}$, then ∂_p are semi-simple derivations on $\mathcal{A}$ by (2.33) and (2.35). Let ℓ_1 be the dimension of the maximal locally nilpotent $\mathbb{F}$-subspace of $\mathcal{D}$. Clearly $\ell_1\leqslant\ell=k-k_1$. Let $k_2=\ell-\ell_1$. Now we choose $\partial_{k_1+k_2+1},\ldots,\partial_k$ to be homogeneous locally nilpotent derivations of $\mathcal{D}$ such that the first k_3 derivations have colors in Γ_+ and the last k_4 derivations have colors in Γ_- for some k_3,k_4 with $k_3+k_4=\ell_1$. Extend $\{\partial_p\mid p\in\overline{1,k_1}\cup\overline{k_1+k_2+1,k}\}$ to a homogeneous $\mathbb{F}$-basis $\{\partial_p\mid p\in\overline{1,k}\}$ of $\mathcal{D}$. By the choices of ∂_p, then there exists $t_p\in\mathcal{A}(0)^{(1)}$ for each $p\in\overline{k_1+1,k}$ satisfying (2.36) and (2.37).

For any $\underline{a}\in G$, we identify

$$\underline{a}\ \leftrightarrow\ (\underline{a}(\partial_1),\ldots,\underline{a}(\partial_{k_1+k_2}))\in\mathbb{F}^{k_1+k_2}.$$

Then G is a nondegenerate subgroup of $\mathbb{F}^{k_1+k_2}$ (otherwise, there exists $\partial\in\Sigma_{p=1}^{k_1+k_2}\mathbb{F}\partial_p$ such that $\underline{a}(\partial)=0$ for all $\underline{a}\in G$ and so ∂ is locally nilpotent, which contradicts the maximality of ℓ_1). Taking homogeneous root vector $u\in\mathcal{A}^{(\bar{0})}(\underline{a})$, by (2.26) and (2.32), we have

$$u^{-1}\mathcal{A}(\underline{a})\subset\mathcal{A}(0),\quad u\mathcal{A}(0)\subset\mathcal{A}(\underline{a}).$$

Hence

$$u\mathcal{A}(0)=\mathcal{A}(\underline{a}). \tag{2.48}$$

In particular,

$$\mathcal{A}(\underline{a})^{(0)}=\mathbb{E}u \tag{2.49}$$

is one-dimensional over $\mathbb{E}$. Choose

$$x^0=1,\quad 0\neq x^{\underline{a}}\in\mathcal{A}(\underline{a})^{(0)}\quad\text{for } 0\neq\underline{a}\in G,$$

such that $x^{\underline{a}}$ is homogeneous with color denoted by $\hat{\underline{a}}$. Since $x^{\underline{a}}$ is invertible, we have $\hat{\underline{a}}\in\Gamma_+$. Then we have a map $\hat{}$ satisfying (2.9). By (2.32) and (2.49), we have (2.12) with $f(\underline{a},\underline{b})$ satisfying (2.10) and (2.11) by color commutativity and associativity. By (2.48), we obtain

$$\mathcal{A}=\mathcal{A}^{(\bar{0})}\mathcal{A}(0)\cong\mathcal{A}^{(\bar{0})}\otimes\mathcal{A}(0),$$

where $\mathcal{A}^{(0)}=\oplus_{\underline{a}\in G}\mathcal{A}(\underline{a})^{(0)}$ is isomorphic to the algebra $\mathcal{A}_1$ defined in (2.12) and (2.13), and $\mathcal{A}(0)=\tilde{\mathcal{A}}(0)$ is isomorphic to the algebra $\mathcal{A}_2$ defined in (2.16) and (2.17). Therefore, the algebra $\mathcal{A}$ is isomorphic to the algebra $\mathcal{A}(\underline{k},G,\mathbb{E},f)$ defined in (2.19) and (2.20), and $\mathcal{D}$ is of the form (2.23). This completes the proof of Theorem 2.2. □

III. CONSTRUCTING SIMPLE LIE COLOR ALGEBRAS FROM $\mathcal{D}$-SIMPLE COLOR ALGEBRAS

In this section, as applications, we shall construct some explicit simple Lie color algebras using the pairs $(\mathcal{A},\mathcal{D})$ given in the last section. For simplicity, we assume that the pairs $(\mathcal{A},\mathcal{D})$ in (2.19) and (2.23) satisfies

$$\{u\in\mathcal{A}\mid\mathcal{D}(u)=0\}=\mathbb{F}.$$

This is equivalent to that $\mathbb{E}_0=\mathbb{F}$ and $\Gamma^0=\{0\}$. So the map $\hat{}:G\to\Gamma_+$ in (2.9) is a group homomorphism and $\theta_{\underline{a},\underline{b}}=0$ for all $\underline{a},\underline{b}\in G$. In this case, noting that $\mathbb{F}$ is algebraically closed, we prove that we can choose suitable basis $\{x^{\underline{a}}\mid\underline{a}\in G\}$ such that the coefficient $f(\underline{a},\underline{b})$ determined by (2.12), which satisfies (2.10) and (2.11), has the following form:

$$f(\underline{a},\underline{b})=\epsilon(\hat{\underline{a}},\hat{\underline{b}})^{1/2},\quad\forall\ \ \underline{a},\underline{b}\in G,\tag{3.1}$$

where the right-hand side is a fixed square root such that (2.10) and (2.11) hold.

Let G' be a maximal subgroup of G such that $x^{\underline{a}}$, $\underline{a}\in G'$ can be chosen so that (3.1) holds for $\underline{a},\underline{b}\in G'$. Suppose $G'\neq G$. Let $\underline{c}\in G\backslash G'$ and set $G''=G'+\mathbb{Z}\underline{c}$. If $G'\cap\mathbb{Z}\underline{c}=\{0\}$, we choose any $x^{\underline{c}}\neq 0$, and set $x^{\underline{a}+k\underline{c}}=\epsilon(\hat{\underline{a}},\hat{\underline{c}})^{-k/2}x^{\underline{a}}\cdot(x^{\underline{c}})^k$ for $\underline{a}+k\underline{c}\in G''$. If $G'\cap\mathbb{Z}\neq\{0\}$, then $G'\cap\mathbb{Z}\underline{c}=\mathbb{Z}\underline{d}$ for some $\underline{d}=m\underline{c}$, $m>1$. In this case, since $\mathbb{F}$ is algebraically closed, we can choose $x^{\underline{c}}$ such that $(x^{\underline{c}})^m=x^{\underline{d}}$, and set $x^{\underline{a}+k\underline{c}}$ as above. In any case, the coefficient $f(\underline{a},\underline{b})$ determined by (2.12) satisfies (3.1) for $\underline{a},\underline{b}\in G''$. But $G'\neq G''\supset G'$. This contradicts the maximality of G'. This proves (3.1).

Let $\mathbb{F}[\mathcal{D}]$ be the (ϵ,Γ)-commutative associative algebra with basis

$$\{\partial^{\mu}=\partial_1^{\mu_1}\cdots\partial_k^{\mu_k}\mid\mu=(\mu_1,\ldots,\mu_k)\in\mathcal{M}\},$$

where $\mathcal{M}=\mathbb{N}^{k_1+k_2+k_3}\times\mathbb{Z}_2^{k_4}$. For convenience, we denote $\partial^{\mu}=0$ if $\mu\notin\mathcal{M}$. Denote

$$W=W(\underline{k},G)=\mathcal{A}\otimes\mathcal{D}=\operatorname{span}\{x^{\underline{a},\underline{i}}\partial_p\mid(\underline{a},\underline{i})\in G\times\mathcal{J},p\in\overline{1,k}\},$$

$$\mathcal{W}=\mathcal{W}(\underline{k},G)=\mathcal{A}\otimes\mathbb{F}[\mathcal{D}]=\operatorname{span}\{x^{\underline{a},\underline{i}}\partial^{\mu}\mid(\underline{a},\underline{i},\mu)\in G\times\mathcal{J}\times\mathcal{M}\}.$$

Then as spaces, we have $W\subset\mathcal{W}$. By regarding $\mathcal{W}$ as operators on $\mathcal{A}$, $\mathcal{W}$ becomes a Γ-graded associative algebra whose multiplication is the composition of operators. Thus $\mathcal{W}$ forms an (ϵ,Γ)-Lie color algebra under the bracket (1.3). We call $\mathcal{W}$ a *Lie color algebra of (generalized) Weyl type*. Clearly $\mathbb{F}$ is the center of $\mathcal{W}$. Let $\tilde{\mathcal{W}}=\mathcal{W}/\mathbb{F}$ and let $\overline{\mathcal{W}}=[\tilde{\mathcal{W}},\tilde{\mathcal{W}}]$ the derived algebra of $\tilde{\mathcal{W}}$. Obviously, W forms an (ϵ,Γ)-Lie color subalgebra of $\mathcal{W}$, called a *Lie color algebra of (generalized) Witt type*. Using results in Refs. 4 and 11, we obtain the following.

Theorem 3.1: The Lie color algebras $\overline{\mathcal{W}}$ and W are simple if $k_1+k_2+k_3>0$ or $k_4>1$. Furthermore, $\overline{\mathcal{W}}=\tilde{\mathcal{W}}$ if $k_1+k_2+k_3>0$ or otherwise, $\tilde{\mathcal{W}}=\overline{\mathcal{W}}+\mathbb{F}t^{\underline{n}}\partial^{\lambda}$, where $\underline{n}$ and λ are the largest elements respectively in $\mathcal{J}$ and in $\mathcal{M}$. □

Note that in case $k=k_4=1$, $\overline{\mathcal{W}}=0$ and $W=\mathbb{F}t_1\partial_1$ are not simple. If $k=k_4>1$, then we obtain finite dimensional simple Lie color algebras $\overline{\mathcal{W}}$ and W of dimensions $2^{2n}-2$ and $n2^n$. In particular, if $\Gamma=\mathbb{Z}_2,\epsilon(i,j)=(-1)^{ij},i,j\in\mathbb{Z}_2$, we obtain the finite dimensional simple Lie superalgebras $\overline{\mathcal{W}}=H(2n)$ and $W=W(n)$ (see Ref. 2).

Using the pair $(\mathcal{A},\mathcal{D})$, one might construct other simple Lie color algebras, for example, other series of Lie color algebras of Cartan type.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 1 JANUARY 2004

The noncommutative Lorentzian cylinder as an isospectral deformation

W. D. van Suijlekom[a)]
Korteweg-de Vries Institute for Mathematics, University of Amsterdam, Plantage Muidergracht 24, 1018 TV Amsterdam, The Netherlands

(Received 25 November 2002; accepted 3 October 2003)

We present a new example of a finite-dimensional noncommutative manifold, namely, the noncommutative cylinder. It is obtained by isospectral deformation of the canonical triple associated with the Euclidean cylinder. We discuss Connes' character formula for the cylinder. In the second part, we discuss noncommutative Lorentzian manifolds. Here, the definition of spectral triples involves Krein spaces and operators on Krein spaces. A central role is played by the admissible fundamental symmetries on the Krein space of square integrable sections of a spin bundle over a Lorentzian manifold. Finally, we discuss isospectral deformation of the Lorentzian cylinder and determine all admissible fundamental symmetries of the noncommutative cylinder. © *2004 American Institute of Physics.*

I. INTRODUCTION

Strict deformation quantization[1–3] provides a powerful mathematical tool to describe the notion of quantization in physics. The central object here is a family of C^*-algebras $\{\mathcal{A}_\hbar\}$, parametrized by some real number $\hbar$. Recall that a C^*-algebra $\mathcal{A}$ is a norm-closed $*$-algebra where the norm satisfies

$$\|a^*a\| = \|a\|^2 \quad (a \in \mathcal{A}).$$

In physics, the commutative algebra of functions on a phase space describes a classical theory. We denote this algebra by $\mathcal{A}_0$. A quantum mechanical theory at value $\hbar$ of Planck's constant, on the other hand, is described by a noncommutative algebra of operators on a Hilbert space, denoted by $\mathcal{A}_\hbar$ $(\hbar \neq 0)$. As we will see, the family $\{\mathcal{A}_\hbar\}$ is a strict deformation quantization if it satisfies certain axioms.

A good example is the noncommutative torus. It is obtained via deformation quantization of the algebra of functions on the torus $\mathbb{T}^d$.[1,4] The noncommutative tori play a role in string theory and M(atrix) theory.[5]

In this article, we will discuss a third example: the noncommutative cylinder. It is defined along the same lines by deformation quantization of the cylinder. In string theory, the cylinder is quite a natural object. There, space–time is a manifold of dimension higher than four. This dimension follows from certain consistency conditions of the theory (see Polchinski, Ref. 6). For example, the superstring can only be defined in a ten-dimensional background, say $\mathbb{R}^{10}$. It is usually toroidally compactified to $\mathbb{R}^4 \times \mathbb{T}^6$ in order for the theory to make sense. This means that six dimensions are rolled up to the 6-torus $\mathbb{T}^6$. As Seiberg and Witten argued in Ref. 7, the effective action of open strings in the presence of a constant magnetic field in the background is described by making space–time noncommutative. In order to describe this noncommutative background, one needs to quantize the (generalized) cylinder $\mathbb{R}^4 \times \mathbb{T}^6$.

[a)]Current address: Scuola Internazionale Superiore di Studi Avanzati, Via Beirut 2-4, 34014 Trieste, Italy; electronic mail: wdvslkom@sissa.it

Another motivation to quantize the cylinder comes from an idea of Kamani. In Ref. 8, he studied the worldsheet of a superstring in a background as described before, as a noncommutative geometry. In this case, one quantizes the worldsheet, which is an ordinary cylinder $\mathbb{R}\times\mathbb{T}$.

Apart from such physical arguments, the quantization of the cylinder is also interesting from a mathematical point of view. It turns out that the C^*-algebras occurring in the quantization of the plane and of the torus are rather different. As the cylinder in some sense lies in between the plane and the torus, it will be interesting to study the C^*-algebras occurring in its quantization. Furthermore, the noncommutative cylinder provides another example in the scarce list of finite-dimensional noncommutative geometries.[9]

Having obtained the deformation quantization of the cylinder, it is interesting to consider its K-theory. This requires the K-theory of C^*-algebras, which turns out to be the right noncommutative analogue of topological K-theory. In fact, for the C^*-algebra $C(X)$ of continuous functions on a compact Hausdorff space X we have that

$$K_n(C(X))=K^n(X).$$

The main results in topological K-theory, like Bott periodicity and homotopy invariance, lift to the K-theory of C^*-algebras which has the additional powerful feature of stability.[10]

It is interesting to study the interplay between K-theory and deformation quantization. We say that K-theory is *rigid* under a given deformation when $K(\mathcal{A}_\hbar)$ is independent of $\hbar$.[11] For example, both Bott periodicity[12] and a far-reaching generalization of it, the Baum–Connes conjecture in E-theory,[13] can be seen as examples of such rigidity.[14] For the three examples just mentioned, i.e., Euclidean space, the torus, and the cylinder, rigidity of K-theory turns out to hold. However, in general this is not the case. Let $\mathcal{A}_0=C_0(T^*M)$ and $\mathcal{A}_\hbar=\mathcal{B}_0(L^2(M))$ for al $\hbar>0$. Then for general M, clearly

$$K_n(\mathcal{A}_0)=K^n(T^*M)\neq K_n(\mathcal{A}_\hbar)=\begin{cases}\mathbb{Z} & \text{if } n=0\\ 0 & \text{if } n=1.\end{cases}$$

The Gel'fand–Naimark theorem assures us that we can obtain all topological notions of a locally compact Hausdorff space from the C^*-algebra of continuous functions on it. However, in order to describe the full geometry of a spin manifold, we need more data. It turns out that the right algebraic description of a spin manifold is given by a real spectral triple satisfying Connes' seven axioms.

Definition 1: A *spectral triple* $(\mathcal{A},\mathcal{H},D)$ is given by a unital involutive algebra of operators $\mathcal{A}$ on a Hilbert space $\mathcal{H}$ and a self-adjoint operator $D=D^*$ on $\mathcal{H}$ such that

(1) The resolvent $(D-\lambda)^{-1}$ is compact for all $\lambda\notin \mathrm{sp}(D)$,
(2) The commutators $[D,a]:=Da-aD$ are bounded for any $a\in\mathcal{A}$.

For the formulation of the seven axioms that define a *spin geometry* on $\mathcal{A}$, we refer to Refs. 15–17. A complete reconstruction of the spin structure on a spin manifold M from the spin geometry over $C^\infty(M)$ can be found in Ref. 18.

Spectral triples provide a powerful tool in describing noncommutative geometries but, at least in this definition, it relies heavily on two conditions, namely:

(1) $1\in\mathcal{A}$,
(2) D is self-adjoint.

In (commutative) spin geometry, this is equivalent to the condition that M is a compact Riemannian spin manifold.[18] In physics, however, it is natural to work in a setting where this is not the case. This is illustrated by simple examples. Consider a Minkowski space–time $M=\mathbb{R}^4$ with an indefinite metric $\eta=(-1,1,1,1)$. The Dirac operator on M is neither self-adjoint nor elliptic, and

M is noncompact. Other examples come from string theory. Consider the worldsheet of a string $\mathbb{R}\times\mathbb{T}$, embedded in a compactified background $\mathbb{R}^4\times\mathbb{T}^6$. Both the worldsheet and the background have a semi-Riemannian metric, so that both conditions are unfulfilled.

Thus, in order to describe such physical models in noncommutative geometry, i.e., using a spectral triple, we need to adjust its definition. If the C^*-algebra is nonunital, it is sufficient to replace condition 1 in the definition of a spectral triple by

(1′) The operator $a(D-\lambda)^{-1}$ is compact for any $a\in\mathcal{A}$; $\lambda\notin \mathrm{sp}(D)$.

However, in Lorentzian geometry, the Dirac operator D is not self-adjoint, so that this condition must be dropped. It turns out that the operator D is a Krein-self-adjoint operator in a Krein space $\mathcal{H}$.

Noncompact Lorentzian manifolds are central objects in physics and, therefore, we will discuss here the adjustifications mentioned in the definition of spectral triples. It will turn out that this can be done in a natural way, which allows for a definition of isospectral deformation, similar to what has been done by Connes and Landi.[19] Our key example of a noncommutative noncompact Lorentzian manifold will be the noncommutative cylinder, which is defined by isospectral deformation of the Lorentzian cylinder.

In Sec. II, we discuss deformation quantization of Euclidean space, the torus, and the cylinder. We obtain the family of C^*-algebras as a family of crossed product algebras and discuss their K-theory. We provide new evidence for the idea that K-theory is rigid under deformation quantization by describing the K-theory of the noncommutative cylinder.

In Sec. III, still working in the Euclidean setting, we consider Connes' trace theorem for noncompact manifolds. We construct spectral triples for algebras without a unit and discuss Connes' character formula in the case of the cylinder. It turns out that it is possible to generalize this theorem to noncompact manifolds. Then we obtain the noncommutative cylinder as a spectral triple, via isospectral deformation of the canonical triple of the cylinder, similar to what is done by Connes and Landi.[19] We attempt to construct a spin geometry over the noncommutative cylinder, where Connes' seven axioms are adapted to nonunital algebras as in Ref. 20.

We adjust the definition of the spectral triple to semi-Riemannian spin geometry[21] in Sec. IV, in particular to Lorentzian spin geometry. This involves Krein spaces, and we give a short introduction to the theory of these spaces and operators acting in them. Since the Dirac operator is not self-adjoint, we work with the associated operator Δ_J, which is self-adjoint. It plays a central role in the formulation of the integral in terms of a Dixmier trace.

Finally, we consider the noncommutative Lorentzian cylinder, obtained by isospectral deformation of the semi-Riemannian spectral triple that describes the Lorentzian cylinder. The set of admissible fundamental symmetries for the noncommutative cylinder is shown to be exactly the set of fundamental symmetries coming from spacelike reflections in spinor space.

II. DEFORMATION QUANTIZATION AND K-THEORY

A. Old examples

We start with a brief recapitulation of the definition of strict deformation quantization. Subsequently, we review the strict deformation quantization of Euclidean space and of the torus, both due to Rieffel.[1,2,4,22]

Definition 2: Let M be a Poisson manifold with bracket $\{\,,\}$ and let $\mathcal{A}$ be a dense $*$-subalgebra of $C_0(M)$. A *strict deformation quantization* of M in the direction of $\{,\}$, consists of an open interval $I\subseteq\mathbb{R}$ with 0 as an accumulation point, together with, for each $\hbar\in I$, an associative product $*_\hbar$, an involution $*^\hbar$, and a C^*-norm $\|\ \|_\hbar$ (for $*_\hbar$ and $*^\hbar$) on $\mathcal{A}$, which for $\hbar=0$ are the original pointwise product, complex conjugation involution, and supremum norm, such that

(1) The family $\{\mathcal{A}_\hbar\}_{\hbar\in I}$ forms a continuous field of C^*-algebras over I. Here $\mathcal{A}_\hbar$ denotes the C^*-completion of $\mathcal{A}$ with respect to $\|\ \|_\hbar$.

(2) For every $f,g\in\mathcal{A}$,

$$\lim_{\hbar\to 0}\|(f*_\hbar g-g*_\hbar f)/\mathrm{i}\hbar-\{f,g\}\|_\hbar=0 \quad \text{(Dirac's condition)}.$$

1. Weyl quantization

We consider even-dimensional Euclidean space $\mathbb{R}^{2n}$. Let $\mathcal{S}(\mathbb{R}^{2n})$ denote the commutative algebra of Schwartz functions on $\mathbb{R}^{2n}$ under pointwise multiplication. This pointwise product is deformed to the Moyal star product, which reads, in Fourier space, for any $\hbar \in \mathbb{R}$,

$$(\phi *_\hbar \psi)(p,q) = \int_{\mathbb{R}^{2n}} \mathrm{d}^n p' \mathrm{d}^n q' \, \phi(p',q') \psi(p-p', q-q') e^{-\mathrm{i}\hbar(q'\cdot p - p'\cdot q)}. \tag{1}$$

The involution we use on $\mathcal{S}(\mathbb{R}^{2n})$ is defined by $\phi^*(p,q) = \overline{\phi(-p,-q)}$, which is independent of $\hbar$. We let $\pi_\hbar$ denote the left regular representation of $\mathcal{S}(\mathbb{R}^{2n})$ on $L^2(\mathbb{R}^{2n})$ via $*_\hbar$, i.e., for $\phi \in \mathcal{S}(\mathbb{R}^{2n})$ and $\Psi \in L^2(\mathbb{R}^{2n})$,

$$\pi_\hbar(\phi)\Psi := \phi *_\hbar \Psi.$$

We define a norm $\| \ \|_\hbar$ on $\mathcal{S}(\mathbb{R}^{2n})$ as the operator norm for this representation. The completion of $\mathcal{S}(\mathbb{R}^{2n})$ with respect to this norm is a C^*-algebra, denoted by $\mathbb{R}^{2n}_\hbar$. By rewriting formula (1) in terms of partial Fourier transforms, one can show the following.[3]

Proposition 3: The C^*-algebra $\mathbb{R}^{2n}_\hbar$ is isomorphic to the crossed product algebra

$$C_0(\mathbb{R}^n) \rtimes_\hbar \mathbb{R}^n,$$

where $\mathbb{R}^n$ acts on $\mathbb{R}^n$ by translation, $x \mapsto x + \hbar y$ $(x,y \in \mathbb{R}^n)$, so that it acts on $C_0(\mathbb{R}^n)$ by the pullback of this action.

Theorem 4: *For $\hbar \neq 0$, the C^*-algebra $\mathbb{R}^{2n}_\hbar$ is isomorphic to $\mathcal{B}_0(L^2(\mathbb{R}^n))$, the C^*-algebra of compact operators on $L^2(\mathbb{R}^n)$.*

For a proof of this, we refer to Refs. 3 and 22.

It is now immediate that the C^*-algebras $\mathbb{R}^{2n}_\hbar$ $(\hbar \neq 0)$ are simple, and are all isomorphic to each other. Furthermore, we can conclude that Euclidean space $\mathbb{R}^{2n}$ has rigid K-theory under quantization, i.e., for all $\hbar$ one has

$$K^0(\mathbb{R}^{2n}) \cong K_0(\mathbb{R}^{2n}_\hbar) \cong \mathbb{Z},$$

$$K^1(\mathbb{R}^{2n}) \cong K_1(\mathbb{R}^{2n}_\hbar) \cong 0.$$

2. Noncommutative tori

Let $\mathbb{T}^d$ be the d-dimensional torus, and let θ be a real skew-symmetric $d \times d$ matrix. Instead of deforming the pointwise product in the space of smooth functions on $\mathbb{T}^d$, we deform the product in its Fourier space $\mathcal{S}(\mathbb{Z}^d)$. For $\hbar \in \mathbb{R}$, the star product reads

$$(\phi *_\hbar \psi)(n) = \sum_{m \in \mathbb{Z}^d} \phi(m) \psi(n-m) e^{2\pi \mathrm{i}\hbar\, \theta(m,n)}. \tag{2}$$

Here θ is the skew bilinear form defined by $\theta(m,n) := \Sigma_{j,k} \theta_{jk} m_j n_k$.

We set $\phi^*(n) := \overline{\phi(-n)}$, which is independent of $\hbar$. We let $\mathcal{S}(\mathbb{Z}^d)$ act on $L^2(\mathbb{Z}^d)$ by left multiplication via $*_\hbar$. The completion of $\mathcal{S}(\mathbb{Z}^d)$ with respect to the operator norm $\| \ \|_\hbar$, equipped with this star product is the *noncommutative torus*, denoted by $\mathbb{T}^d_{\hbar\theta}$. For fixed θ, the family $\{\mathbb{T}^d_{\hbar\theta}\}$ provides a strict deformation quantization of $\mathbb{T}^d$.[1] When $d=2$, the skew-symmetric matrix θ is just determined by a real number, denoted by θ as well. It turns out that the noncommutative torus $\mathbb{T}^2_\theta$ is isomorphic to the crossed product algebra $C(\mathbb{T}) \rtimes_\alpha \mathbb{Z}$, where $\alpha(f)(t) := f(t+\theta)$. Furthermore, it is simple if and only if θ is irrational. If $\theta \neq \theta'$, both irrational with $0 < \theta, \theta' < \frac{1}{2}$, then $\mathbb{T}^2_\theta \ncong \mathbb{T}^2_{\theta'}$.[16] It came as a surprise that the K-groups of $\mathbb{T}^d_\theta$ do not depend on θ.

Proposition 5: The torus $\mathbb{T}^d$ has rigid K-theory under quantization, i.e., for all $\hbar$ one has

$$K^0(\mathbb{T}^d) \cong K_0(\mathbb{T}^d_{\hbar\theta}) \cong \mathbb{Z}^{2^{d-1}},$$

$$K^1(\mathbb{T}^d) \cong K_1(\mathbb{T}^d_{\hbar\theta}) \cong \mathbb{Z}^{2^{d-1}}.$$

B. Deformation quantization of cylinders

We consider the cylinder in a generalized form. The (n,d)-*dimensional cylinder* $C^{(n,d)}$ is defined as

$$C^{(n,d)} := \mathbb{R}^n \times \mathbb{T}^d. \tag{3}$$

In the case $n=d=1$ we obtain $C^2 := \mathbb{R}\times S^1$, which is of course the familiar two-dimensional cylinder.

Let Λ be a Poisson structure on $\mathbb{R}^n\times\mathbb{T}^d$. For $j=1,\ldots,n+d$, let ∂_{x_j} denote the vector field on $\mathbb{R}^n\times\mathbb{T}^d$ corresponding to differentiation in the jth direction. We can write the Poisson structure as

$$\Lambda = -\pi^{-1}\sum_{i<j} \theta_{ij}\partial_{x_i}\wedge\partial_{x_j}. \tag{4}$$

The factor π^{-1} has been included for later convenience. Here θ_{ij} is a real skew-symmetric matrix. For later use, we define a skew bilinear form θ on $\mathbb{R}^n\times\mathbb{Z}^d$,

$$\theta(l,k) = \sum_{i,j} \theta_{ij} l_i k_j \quad (l,k \in \mathbb{R}^n\times\mathbb{Z}^d). \tag{5}$$

Let λ denote the Lebesgue measure on $\mathbb{R}^n\times\mathbb{T}^d$. The Fourier transform $\hat{f}$ of a Schwartz function $f\in\mathcal{S}(\mathbb{R}^n\times\mathbb{T}^d)$ is given by

$$\hat{f}(k) = \int_{\mathbb{R}^n\times\mathbb{T}^d} \mathrm{d}\lambda(x) e^{-2\pi \mathrm{i} k\cdot x} f(x). \tag{6}$$

For $i=1,\ldots,n$ we have $k_i\in\mathbb{R}$, for $i=n+1,\ldots,n+d$ we have $k_i\in\mathbb{Z}$. In fact, the Fourier transform maps $\mathcal{S}(\mathbb{R}^n\times\mathbb{T}^d)$ isomorphically to $\mathcal{S}(\mathbb{R}^n\times\mathbb{Z}^d)$.

To integrate over $\mathbb{R}^n$ and sum over $\mathbb{Z}^d$ in the product $\mathbb{R}^n\times\mathbb{Z}^d$, we introduce the measure μ on $\mathbb{R}^n\times\mathbb{Z}^d$, defined as the product of Lebesgue measure on $\mathbb{R}^n$ and the counting measure on $\mathbb{Z}^d$.

For functions in Fourier space, the Poisson bracket is given by

$$\begin{aligned}\{\phi,\psi\}(k) &= 4\pi \int_{\mathbb{R}^n\times\mathbb{Z}^d} \mathrm{d}\mu(l) \sum_{i,j} \theta_{ij} l_i \phi(l)(k_j - l_j)\psi(k-l) \\ &= 4\pi \int_{\mathbb{R}^n\times\mathbb{Z}^d} \mathrm{d}\mu(l)\, \phi(l)\psi(k-l)\theta(l,k),\end{aligned} \tag{7}$$

where $k,l\in\mathbb{R}^n\times\mathbb{Z}^d$ and θ is the bilinear form defined in Eq. (5).

We define a bicharacter $\sigma_\hbar$ on $\mathbb{R}^n\times\mathbb{Z}^d$ by

$$\sigma_\hbar(l,k) = e^{2\pi \mathrm{i}\hbar\,\theta(l,k)}, \tag{8}$$

where $\hbar\in\mathbb{R}$, and introduce a star product $*_\hbar$ on $\mathcal{S}(\mathbb{R}^n\times\mathbb{Z}^d)$ by

$$(\phi *_\hbar \psi)(k) = \int_{\mathbb{R}^n\times\mathbb{Z}^d} \mathrm{d}\mu(l)\, \phi(l)\psi(k-l)\sigma_\hbar(l,k). \tag{9}$$

We define an involution on $\mathcal{S}(\mathbb{R}^n\times\mathbb{Z}^d)$ by $\phi^*(k):=\overline{\phi(-k)}$, independent of $\hbar$. We represent $\mathcal{S}(\mathbb{R}^n\times\mathbb{Z}^d)$ on $L^2(\mathbb{R}^n\times\mathbb{Z}^d)$ by star product multiplication, and define the *noncommutative cylinder* as the completion of $\mathcal{S}(\mathbb{R}^n\times\mathbb{Z}^d)$ in the operator norm $\|\ \|_\hbar$, equipped with product $*_\hbar$. This C^*-algebra is denoted by $C^{(n,d)}_{\hbar\theta}$.

We could equally well define the noncommutative cylinder as the (completion of) the algebra $\mathcal{S}(\mathbb{R}^n\times\mathbb{T}^d)$ with product, involution, and norm obtained by pulling back the product $*_\hbar$, involution* and norm $\|\ \|_\hbar$ through the inverse Fourier transform. Even though this makes the differences with the ordinary cylinder more clear, we will continue in Fourier space to avoid expressions involving many derivatives.

Theorem 6: *For fixed θ, the family $\{C^{(n,d)}_{\hbar\theta}\}$ provides a strict deformation quantization of $\mathbb{R}^n\times\mathbb{T}^d$ in the direction of $\{\ ,\ \}$.*

Proof: We verify Dirac's condition

$$\|(\phi*_\hbar\psi-\psi*_\hbar\phi)/\mathrm{i}\hbar-\{\phi,\psi\}\|_\hbar\to 0 \quad \text{as } \hbar\to 0, \tag{10}$$

where $\phi,\psi\in\mathcal{S}(\mathbb{R}^n\times\mathbb{Z}^d)$. We define

$$\Delta_\hbar:=(\phi*_\hbar\psi-\psi*_\hbar\phi)/\mathrm{i}\hbar-\{\phi,\psi\}.$$

With formulas (7) and (9), this reads

$$\Delta_\hbar(k)=\int_{\mathbb{R}^n\times\mathbb{Z}^d}\mathrm{d}\mu(l)\,\phi(l)\,\psi(k-l)((\sigma_\hbar(l,k)-\sigma_\hbar(k,l))/\mathrm{i}\hbar-4\pi\theta(l,k)).$$

Similar to Rieffel in Ref. 1, we can estimate the expression inside ( ) so that

$$|\Delta_\hbar(k)|\leqslant\hbar M\int_{\mathbb{R}^n\times\mathbb{Z}^d}\mathrm{d}\mu(l)|\,\phi(l)||\,\psi(k-l)||l|^2|k-l|^2,$$

for some constant M. This last expression is just (proportional to) the convolution product of two functions $\tilde{\phi}$ and $\tilde{\psi}$ where

$$\tilde{\phi}(k):=|k|^2|\,\phi(k)|,\quad \tilde{\psi}(k):=|k|^2|\,\psi(k)|.$$

As the L^1-norm dominates the norm $\|\ \|_\hbar$, we have

$$\|\Delta_\hbar\|_\hbar\leqslant\hbar M\|\tilde{\phi}*\tilde{\psi}\|_1.$$

It follows that $\|\Delta_\hbar\|_\hbar\to 0$ as $\hbar\to 0$.

Continuity of the field $\{C^{(n,d)}_{\hbar\theta}\}$ follows from Corollary 5.6 in Ref. 23 (or Lemma 1 in Ref. 2), in combination with Proposition 7 below. □

C. Properties of noncommutative cylinders

When one observes the major differences between $\mathbb{R}^{2n}_\hbar$ and $\mathbb{T}^d_{\hbar\theta}$, one is led to the questions whether the noncommutative cylinders are simple and whether they are all isomorphic. For this, we connect with the theory of crossed product algebras. At the end, we discuss the K-theory of noncommutative cylinders.

We take the noncommutative cylinder for $n=d$, and denote it by $C^{2d}_\hbar$. We let $l=(x,n)$ and $k=(y,m)$, where $x,y\in\mathbb{R}^d$ and $n,m\in\mathbb{Z}^d$, and choose the following skew bilinear form on $\mathbb{R}^d\times\mathbb{Z}^d$,

$$\theta(l,k)=\frac{1}{2\pi}\sum_{i=1}^{d}y_in_i-m_ix_i\,. \tag{11}$$

We want to rewrite the star product (9) in terms of partial Fourier transforms, defined by

$$\acute{\phi}(x,t) := \sum_{n\in\mathbb{Z}^d} \phi(x,n)e^{in\cdot t} \quad (t\in\mathbb{T}^d), \tag{12}$$

which is a function on $\mathbb{R}^d\times\mathbb{T}^d$. The star product on $\mathcal{S}(\mathbb{R}^d\times\mathbb{T}^d)$ then reads

$$(\acute{\phi}*_\hbar\acute{\psi})(x,t) = \int_{\mathbb{R}^d} dy\, \acute{\phi}(y,t+\hbar(y-x))\,\acute{\psi}(x-y,t+\hbar y), \tag{13}$$

as can be easily verified. We introduce an action β of $\mathbb{R}^d$ on $\mathbb{T}^d$ defined by $\beta_x(t)=t+\hbar x$, and write

$$(\acute{\phi}*_\hbar\acute{\psi})(x,t) = \int_{\mathbb{R}^d} dy\, \acute{\phi}(y,\beta_{y-x}(t))\,\acute{\psi}(x-y,\beta_y(t)). \tag{14}$$

This formulation of the star product in terms of an action β of $\mathbb{R}^d$ on $\mathbb{T}^d$ goes back to Rieffel. As in the examples in his paper,[22] we relate this to crossed product algebras. For more details on the theory of these algebras, we refer to Pedersen.[24] Let $C(\mathbb{T}^d)\rtimes_\hbar\mathbb{R}^d$ denote the crossed product algebra for the $\hbar$-dependent action β_{2x}. Then $\mathcal{S}(\mathbb{R}^d,C^\infty(\mathbb{T}^d))$ is a dense $*$-subalgebra of this crossed product algebra. Define a map $Q:\mathcal{S}(\mathbb{R}^d\times\mathbb{T}^d)\to\mathcal{S}(\mathbb{R}^d,C^\infty(\mathbb{T}^d))$ by

$$Q(\acute{\phi})(x,t) := \acute{\phi}(x,\beta_x(t)). \tag{15}$$

Note that $\mathcal{S}(\mathbb{R}^d\times\mathbb{T}^d)$ is a dense $*$-subalgebra of $C_\hbar^{2d}$. Clearly, Q is an isomorphism, in that

$$\begin{aligned} Q(\acute{\phi}*_\hbar\acute{\psi})(x,t) &= (\acute{\phi}*_\hbar\acute{\psi})(x,\beta_x(t)) \\ &= \int_{\mathbb{R}^d} dy\, Q(\acute{\phi})(y,t)Q(\acute{\psi})(x-y,\beta_{2y}(t)) = Q(\acute{\phi})*Q(\acute{\psi}). \end{aligned} \tag{16}$$

Extension of the map Q to $C_\hbar^{2d}$ yields the following.

Proposition 7: The noncommutative cylinder $C_\hbar^{2d}$ $(\hbar\neq 0)$ is isomorphic to the crossed product $C(\mathbb{T}^d)\rtimes_\hbar\mathbb{R}^d$.

This allows us to use known results on crossed product algebras.

Theorem 8: *The C^*-algebra $C_\hbar^{2d}$ is isomorphic to $\mathcal{B}_0(L^2(\mathbb{T}^d))\otimes C^*(\mathbb{Z}^d)$.*

Proof: We note that $C(\mathbb{T}^d)\rtimes_\hbar\mathbb{R}^d\cong C(\mathbb{T}^d)\rtimes_{\hbar'}\mathbb{R}^d$ for $\hbar,\hbar'\neq 0$. In particular,

$$C(\mathbb{T}^d)\rtimes_\hbar\mathbb{R}^d\cong C(\mathbb{T}^d)\rtimes\mathbb{R}^d$$

for $\hbar\neq 0$. Corollary 2.8 of Green[25] completes the proof. □

With the isomorphism $C^*(\mathbb{Z}^d)\cong C(\mathbb{T}^d)$, we have the following.

Corollary 9: The noncommutative cylinders $C_\hbar^{2d}$ $(\hbar\neq 0)$ are nonsimple C^*-algebras.

It is well known that any C^*-algebra A is Morita equivalent to its stabilization

$$A_S := \mathcal{B}_0(\mathcal{H})\otimes A$$

for some Hilbert space $\mathcal{H}$. In particular, $\mathcal{B}_0(L^2(\mathbb{T}^d))\otimes C(\mathbb{T}^d)$ is Morita equivalent to $C(\mathbb{T}^d)$. Since Morita-equivalent C^*-algebras have isomorphic K-groups, we have the following.

Corollary 10: For the noncommutative cylinder $C_\hbar^{2d}$ one has for all $\hbar\neq 0$,

$$K_0(C_\hbar^{2d})\cong K_1(C_\hbar^{2d})\cong\mathbb{Z}^{2^{d-1}}.$$

In order to compare this with the K-groups of the original cylinder $\mathbb{R}^d\times\mathbb{T}^d$ we need the following Lemma.

Lemma 11: For the cylinder $\mathbb{R}^d\times\mathbb{T}^d$ *the K-groups are*

$$K^0(\mathbb{R}^d\times\mathbb{T}^d)\cong K^1(\mathbb{R}^d\times\mathbb{T}^d)\cong\mathbb{Z}^{2^{d-1}}.$$

Proof: For the K-groups of $\mathbb{T}^d$ we note that

$$K_0(C(\mathbb{T},\mathcal{A}))\cong K_1(C(\mathbb{T},\mathcal{A}))\cong K_0(\mathcal{A})\oplus K_1(\mathcal{A})$$

for any C^*-algebra $\mathcal{A}$ (cf. Exercise 10.1 in Ref. 10). Since

$$C_0(\mathbb{R}^d\times\mathbb{T}^d)\cong C(\mathbb{T},C_0(\mathbb{R}^d\times\mathbb{T}^{d-1})),$$

this yields by induction

$$K_0(C_0(\mathbb{R}^d\times\mathbb{T}^d))\cong K_1(C_0(\mathbb{R}^d\times\mathbb{T}^d))\cong\mathbb{Z}^{2^{d-1}}.$$

Here, one uses $K_0(C_0(\mathbb{R}^d))\oplus K_1(C_0(\mathbb{R}^d))\cong\mathbb{Z}$. An alternative proof can be constructed using Bott periodicity.

Proposition 12: The cylinder $\mathbb{R}^d\times\mathbb{T}^d$ *has rigid K-theory under quantization, i.e., for all* $\hbar$ *one has*

$$K^0(\mathbb{R}^d\times\mathbb{T}^d)\cong K_0(C_\hbar^{2d})\cong\mathbb{Z}^{2^{d-1}},$$

$$K^1(\mathbb{R}^d\times\mathbb{T}^d)\cong K_1(C_\hbar^{2d})\cong\mathbb{Z}^{2^{d-1}}.$$

Note that these groups are the same as the K-groups of the noncommutative torus $\mathbb{T}^d_{\hbar\theta}$.

III. NONCOMMUTATIVE MANIFOLDS AND ISOSPECTRAL DEFORMATION

The description of a manifold in terms of spectral data is provided by the theory of K-cycles (also called spectral triples) developed by Connes. This generalization has been very successful in describing noncommutative manifolds, as shown by examples like the noncommutative torus[13] and the noncommutative 4-sphere S^4_θ.[19] It also admits generalizations to noncompact manifolds, or, in other words, to nonunital algebras.

A. Connes' trace theorem

An important result here is that Connes' trace theorem generalizes to noncompact manifolds.[16] Connes' trace theorem[13,26] relates the Wodzicki residue of an elliptic pseudodifferential operator to the Dixmier trace of this operator. It allows one to compute the integral of any function on a compact Riemannian manifold in terms of an operatorial formula. See for example Ref. 16 for a complete treatment and proof of the theorem.

Proposition 13: Let f *be an integrable function on an* n*-dimensional Riemannian manifold* M*, then*

$$\int_M f(x)\sqrt{|g|}\mathrm{d}x=\frac{n(2\pi)^n}{\Omega_n}\mathrm{Tr}_\omega(f\Delta^{-n/2}),$$

where Δ *is the Laplacian on* M.

The fact that a manifold M is not compact translates into the fact that the C^*-algebra $C_0(M)$ is not unital. So, in order to describe a Riemannian manifold which is only locally compact by a spectral triple, we need a generalization of the definition as given in Ref. 13.

Definition 14: A spectral triple $(\mathcal{A},\mathcal{H},D)$ is given by an involutive algebra of operators $\mathcal{A}$ in a Hilbert space $\mathcal{H}$ and a self-adjoint operator $D=D^*$ in $\mathcal{H}$ such that

(1) $a(D-\lambda)^{-1}$ is compact for any $a\in\mathcal{A}$; $\lambda\notin sp(D)$,
(2) The commutators $[D,a]:=Da-aD$ are bounded for any $a\in\mathcal{A}$.

The triple is said to be *even* if there is a $\mathbb{Z}_2$ grading of $\mathcal{H}$, namely, an operator χ on $\mathcal{H}$ with $\chi^* = \pm\chi$ and $\chi^2 = 1$, such that

$$\chi D + D\chi = 0,$$

$$\chi a - a\chi = 0 \quad \text{for all } a \in \mathcal{A}. \tag{17}$$

If such a grading does not exist, the triple is said to be *odd*, and we set $\chi = 1$.

This was already pointed out by Connes in 1995 (Ref. 27). If $\mathcal{A}$ is unital this yields the familiar definition, because then condition (1) implies that $1_{\mathcal{A}}(D-\lambda)^{-1}$ is compact.

As a special case, we have the Dirac geometry $(C_0^\infty(M), L^2(M,S), \not{D})$ where M is a spin manifold and $\not{D}$ the Dirac operator for a spin bundle $S \to M$. Here, $C_0^\infty(M)$ denotes the algebra of smooth continuous functions on M "vanishing at infinity." For general M this means for $f \in C_0(M)$ that for all $\epsilon > 0$, there exists a compact submanifold K of M such that $f(x) < \epsilon$ for all $x \in M/K$. Note that the principal symbol $\sigma(\Delta)$ of the Laplacian, coincides with $\sigma(\not{D}^2)$.

Definition 15: A spectral triple $(\mathcal{A},\mathcal{H},D)$ is said to be p^+*-summable* $(p>0)$, if $a|D|^{-p} \in \mathcal{L}^{(1,\infty)}$ for any $a \in A$ for some dense subalgebra $A \subset \mathcal{A}$.

For a p^+-summable spectral triple $(\mathcal{A},\mathcal{H},D)$, the *noncommutative integral* of $a \in \mathcal{A}$ is defined by

$$\int a := \frac{n(2\pi)^n}{2^{[n/2]}\Omega_n} \mathrm{Tr}_\omega a|D|^{-n}. \tag{18}$$

If $\mathcal{A} = C_0^\infty(M)$, the $*$-subalgebra A consists of integrable functions with respect to the measure associated to the Riemannian metric on M.

B. Connes' character formula for the cylinder

Another result in noncommutative geometry is Connes' character formula. It provides a link between Hochschild and cyclic cohomology in that it gives a representation of the Hochschild class of the Chern character, i.e., a cyclic cocycle. It turns out that the Hochschild cocycle is much easier to handle than the Chern character. Here, we prove the character formula for the cylinder. As we saw in the previous section, the geometry of the (n,d)-dimensional cylinder can be described by the triple

$$\mathcal{A} := C_c^\infty(\mathbb{R}^n \times \mathbb{T}^d),$$

$$\mathcal{H} := L^2(\mathbb{R}^n \times \mathbb{T}^d) \otimes \mathbb{C}^{2^{[(n+d)/2]}},$$

$$D := \not{D}.$$

For convenience we have restricted $\mathcal{A}$ to functions with compact support, so that all functions in $\mathcal{A}$ are integrable.

The Dirac operator on the cylinder is defined by $\not{D} := \gamma^a \partial_a$ where the gamma-matrices satisfy $\{\gamma^a, \gamma^b\} = 2\delta^{ab}$. Using the spectral theorem for self-adjoint operators we define $F = \mathrm{sign}(\not{D})$, where $\mathrm{sign}(x) = +1(-1)$ for $x \geqslant 0$ $(x<0)$. The couple $(\mathcal{H},F)$, together with a representation σ of $\mathcal{A}$ in $\mathcal{H}$, defines a Fredholm module over $\mathcal{A}$. In the case $n+d$ is even, there is grading operator on $\mathcal{H}$ defined by $\chi := \mathrm{i}^{n+d}\gamma^1 \cdots \gamma^{n+d}$, which makes $(\mathcal{H},F)$ an even Fredholm module. Before we continue, we state some theory on universal differential graded algebras for nonunital algebras, which will be needed later.

1. Universal forms on nonunital algebras

The way to describe the graded differential algebra for nonunital algebras is very similar to the way K-theory is defined for nonunital algebras. Both rely on the notion of unitization. For the

theory of universal graded differential algebras for algebras with unit, we refer to Refs. 16, 28, and 29. A comprehensive introduction is found in Chap. 4 of Ref. 30. The approach we take here is based on Refs. 29 and 31.

Let $\mathcal{A}$ be an algebra. Its unitization $\tilde{\mathcal{A}}$ is defined by $\tilde{\mathcal{A}} := \mathcal{A} \oplus \mathbb{C}$. The quotient map is $\pi: \tilde{\mathcal{A}} \to \mathbb{C}$ with $\mathcal{A} = \ker(\pi)$. Since $1 \in \tilde{\mathcal{A}}$, we can construct the graded universal differential algebra $\Omega\tilde{\mathcal{A}}$ following standard literature. The relation between the differential algebras is similar to K-theory, i.e., $\Omega\tilde{\mathcal{A}} = \mathbb{C} \oplus \Omega\mathcal{A}$. Let δ be the corresponding derivation. By Proposition 3.2 of Ref. 29 we can extend π uniquely to a map $\pi_* : \Omega\tilde{\mathcal{A}} \to \Omega\mathbb{C}$ by

$$\pi_*(\tilde{a}_0 \delta\tilde{a}_1 \cdots \delta\tilde{a}_n) = \pi\tilde{a}_0 \delta(\pi\tilde{a}_1) \cdots \delta(\pi\tilde{a}_n). \tag{19}$$

Immediately, this yields $\pi_*(\Omega^n\tilde{\mathcal{A}}) = \{0\}$ for $n > 0$. For $n = 0$, we have $\pi_*(a + \lambda 1) = \lambda$. Of course, $\Omega\mathbb{C} = \mathbb{C}$.

Similar to what is done in the definition of K-theory for nonunital algebras, we define the graded universal differential algebra $\Omega\mathcal{A}$ of the nonunital algebra $\mathcal{A}$ as a kernel

$$\Omega\mathcal{A} := \ker(\pi_* : \Omega\tilde{\mathcal{A}} \to \Omega\mathbb{C}). \tag{20}$$

From the above observations it is clear that $\Omega^n\mathcal{A} = \Omega^n\tilde{\mathcal{A}}$ for $n > 0$. For $n = 0$, we have $\Omega^0\tilde{\mathcal{A}} = \mathbb{C} \oplus \Omega^0\mathcal{A}$, which yields $\Omega^0\mathcal{A} = \mathcal{A}$.

2. The Chern character

Given a Fredholm module $(\mathcal{H}, F, \sigma)$ over $\mathcal{A}$, we will construct a representation of $\Omega\mathcal{A}$, for $\mathcal{A} = C_c^\infty(\mathbb{R}^n \times \mathbb{T}^d)$. This will use the fact that the map

$$\mathrm{d}: a \mapsto \mathrm{i}[F, \sigma(a)]$$

is a derivation on $\mathcal{A}$, which commutes with the convolution. We can uniquely extend σ to a representation of the unitization $\tilde{\mathcal{A}}$. The couple $(\mathcal{H}, F)$ is a Fredholm module over $\tilde{\mathcal{A}}$, since obviously $[F, \tilde{a}] = [F, a]$ where we have suppressed the representations σ and $\tilde{\sigma}$. We extend $\tilde{\sigma}$ to the universal differential algebra $\Omega\mathcal{A}$ by

$$\tilde{\sigma}: \quad \Omega^k\mathcal{A} \to \mathcal{B}(\mathcal{H}),$$

$$\tilde{a}_0 \delta\tilde{a}_1 \cdots \delta\tilde{a}_k \mapsto \tilde{a}_0 \mathrm{i}^k [F, \tilde{a}_1] \cdots [F, \tilde{a}_k] = \tilde{a}_0 \mathrm{d}a_1 \cdots \mathrm{d}a_k .$$

From Ref. 16 we take the following lemma, generalized to the nonunital case.

Lemma 16: Let $\mathbb{D}$ be the (Euclidean) Dirac operator on the cylinder $\mathbb{R}^n \times \mathbb{T}^d$ and $F = \mathrm{sign}(\mathbb{D})$. Then $[F, \sigma(a)] \in \mathcal{L}^q(\mathcal{H})$, where $q = n + d + 1$.

Besides the Schatten ideals $\mathcal{L}^p(\mathcal{H})$, we define the conditional trace class $\mathcal{L}^1_C(\mathcal{H})$ by

$$\mathcal{L}^1_C(\mathcal{H}) := \{a \in \mathcal{B}(\mathcal{H}) : a + FaF \in \mathcal{L}^1(\mathcal{H})\}. \tag{21}$$

For elements in $\mathcal{L}^1_C(\mathcal{H})$, we define the conditional trace by

$$\mathrm{Tr}_C(a) := \tfrac{1}{2}\mathrm{Tr}(a + FaF). \tag{22}$$

Definition 17: The Chern character of the Fredholm module $(\mathcal{H}, F)$ is the cyclic $(n+d)$ cocycle

$$\tau_F^{(n+d)}(\tilde{a}_0, a_1, \ldots, a_{n+d}) = \mathrm{Tr}_C(\tilde{a}_0 \mathrm{d}a_1 \cdots \mathrm{d}a_{n+d}) \quad (a_i \in \mathcal{A})$$

(with $\chi\tilde{a}_0$ instead of $\tilde{a}_0$ if $n + d$ is even).

Note that since $da_i = i[F,a_i] \in \mathcal{L}^q(\mathcal{H})$, the above expression is indeed in $\mathcal{L}^1_C(\mathcal{H})$, using Hölders inequality. The following lemma brings us back from $\tilde{\mathcal{A}}$ to $\mathcal{A}$.

Lemma 18:

$$\tau_F^{(n+d)}(\tilde{a}_0,a_1,\ldots,a_{n+d}) = \tau_F^{(n+d)}(a_0,a_1,\ldots,a_{n+d}).$$

Proof: This follows immediately by writing out $a+FaF$ for $a=\tilde{a}_0 da_1\cdots da_{n+d}$.

□

Thus, although the Chern character is defined as a cyclic $(n+d)$-cocycle on $\tilde{\mathcal{A}}$, it is essentially a cyclic $(n+d)$-cocycle on $\mathcal{A}$.

Theorem 19: *For all* $a_0,a_1,\ldots,a_{n+d} \in C_c^\infty(\mathbb{R}^n \times \mathbb{T}^d)$, *one has*

$$\tau_F^{(n+d)}(a_0,a_1,\ldots,a_{n+d}) = c_{n+d} \int_{\mathbb{R}^n \times \mathbb{T}^d} a_0 \mathrm{d}_{\mathrm{dR}} a_1 \wedge \cdots \wedge \mathrm{d}_{\mathrm{dR}} a_{n+d},$$

for some constant c_{n+d} *and where* d_{dR} *is the de Rham differential.*

The proof of this theorem is really analogous to the case of $\mathbb{R}^n$, which was proved by Langmann in Ref. 32.

3. Connes' character formula

It was already mentioned in Ref. 16 that Connes' character formula holds for noncompact manifolds. Specifically, we can construct a Hochschild $(n+d)$-cocycle, which agrees with the Chern character $\tau_F^{(n+d)}$ on Hochschild $(n+d)$-cycles to obtain Connes' character formula for the cylinder. In this simple case, this follows directly from Proposition 13 and Theorem 19, if we define a Hochschild $(n+d)$-cocycle by

$$\psi_D^\omega(\tilde{a}_0,a_1,\ldots,a_{n+d}) := \mathrm{Tr}_\omega(\tilde{a}_0[\not{D},a_1]\cdots[\not{D},a_{n+d}]|\not{D}|^{-n-d})$$

(with $\chi\tilde{a}_0$ instead of $\tilde{a}_0$ in the even case). This expression makes sense by the summability properties of the spectral triple. Similar to the Chern character, we can replace $\tilde{a}_0$ by a_0.

Theorem 20: *For all* $a_0,a_1,\ldots,a_{n+d} \in C_c^\infty(\mathbb{R}^n \times \mathbb{T}^d)$, *we have*

$$\psi_D^\omega(a_0,a_1,\ldots,a_{n+d}) = \tau_F^{(n+d)}(a_0,a_1,\ldots,a_{n+d}).$$

C. Isospectral deformation of the cylinder

In Secs. II B and II C, we constructed the noncommutative cylinder as the family of C^*-algebras $C_{\hbar\theta}^{(n,d)}$, $\hbar \in (0,1]$. Here $C_{\hbar\theta}^{(n,d)}$ was defined as the completion of $\mathcal{S}(\mathbb{R}^n \times \mathbb{T}^d)$ with respect to the norm $\| \|_\hbar$, equipped with product $*_\hbar$. Note that we here choose the more natural Fourier transform instead of $\mathcal{S}(\mathbb{R}^n \times \mathbb{Z}^d)$. We now want to describe the geometry of the noncommutative cylinder using the theory of spectral triples developed in the previous sections. The approach we take involves isospectral deformation (see the following) of the (Euclidean) Dirac geometry of the cylinder $\mathbb{R}^n \times \mathbb{T}^d$.

Deformation quantization provides a natural technique to obtain a noncommutative analogue of a function algebra. Starting from the Dirac geometry $(C^\infty(M),\mathcal{H},D)$ of a compact spin manifold M, the simplest noncommutative manifold is the triple $(\mathcal{A}_\hbar,\mathcal{H},D)$, where $\mathcal{A}_\hbar$ is obtained from $C^\infty(M)$ along the lines of deformation quantization. This recipe for noncommutative manifolds is called isospectral deformation, since $\mathcal{H}$ and D are unchanged. The only thing that changes is the algebra and the way it acts on the Hilbert space.

The Dirac geometry of the cylinder is given by $(C_0^\infty(\mathbb{R}^n \times \mathbb{T}^d), \mathcal{H}, \not{D})$, where $\mathcal{H} = L^2(\mathbb{R}^n \times \mathbb{T}^d) \otimes \mathbb{C}^{2^{[(n+d)/2]}}$. However, in order to represent the deformed algebra on the same Hilbert space,

we have to restrict to $\mathcal{S}(\mathbb{R}^n\times\mathbb{T}^d)\subset C_0^\infty(\mathbb{R}^n\times\mathbb{T}^d)$. Let $\mathcal{C}_{\hbar\theta}^{(n,d)}$ denote the algebra $\mathcal{S}(\mathbb{R}^n\times\mathbb{T}^d)$ equipped with product $*_\hbar$. Note the difference with the noncommutative cylinder $C_{\hbar\theta}^{(n,d)}$ as a C^*-algebra which is the completion of $\mathcal{C}_{\hbar\theta}^{(n,d)}$.

We want to construct a spin geometry on the noncommutative cylinder. Recall that a noncommutative spin geometry is a real spectral triple fulfilling Connes' seven axioms.[15] It was shown in Refs. 16 and 33, that when the algebra $\mathcal{A}=C^\infty(M)$ on a compact spin manifold M, the spin structure, metric, and Dirac operator can be recovered from these seven axioms. However, in our case, we need a modification of these conditions. Clearly, both $\mathcal{S}(\mathbb{R}^n\times\mathbb{T}^d)$ and $\mathcal{C}_{\hbar\theta}^{(n,d)}$ are nonunital. Hence, the conditions for a spin geometry on the noncommutative cylinder have to be modified. Such a definition of a noncommutative noncompact spin geometry has been proposed in Ref. 20.

Let us start by completing the set of ingredients for a spin geometry on the noncommutative cylinder. The basic element is the spectral triple $(\mathcal{C}_{\hbar\theta}^{(n,d)},\mathcal{H},\not{D})$. A lengthy computation shows that $\pi_\hbar(f)(\not{D}-\lambda)^{-1}$ is compact. Both the grading operator χ and the charge conjugation operator C are inherited from the commutative case.

Regularity, finiteness, and reality follow directly from the commutative case, since we are considering an isospectral deformation. However, the classical dimension cannot be obtained directly from the spectrum of $\not{D}$, since the latter is continuous. Following Ref. 20, it can be extracted from the leading term of the distributional kernel of $|\not{D}|$,[33] so that it follows from the commutative case, i.e., the classical dimension is $n+d$. The first order axiom is fulfilled since $[\not{D},f]\in\mathcal{S}(\mathbb{R}^n\times\mathbb{T}^d)$ if $f\in\mathcal{S}(\mathbb{R}^n\times\mathbb{T}^d)$ and

$$C\pi_\hbar(f^*)C^{-1}\psi=\psi *_\hbar f=\pi_\hbar^\circ(f)\psi.$$

For the orientation, we need a Hochschild $(n+d)$-cycle c that satisfies $\pi_{\not{D}}(c)=\chi$. However, $\mathcal{C}_\hbar^{2d}$ is Morita equivalent to $C^\infty(\mathbb{T}^d)$ (see the Appendix) so that with Loday[34]

$$HH(\mathcal{C}_\hbar^{2d})=HH(C^\infty(\mathbb{T}^d))=H_{\mathrm{dR}}(\mathbb{T}^d). \tag{23}$$

Hence, in the case $n=d$, $\pi_{\not{D}}(c)=0$ for any $2d$-cycle.

Poincaré duality is satisfied in the case $n=d$ and the special form of θ described before. Since we are considering an isospectral deformation of $\mathbb{R}^d\times\mathbb{T}^d$, Poincaré duality follows from the commutative case. Indeed, we have

$$K_\bullet(\mathcal{C}_\hbar^{2d})\cong K^\bullet(\mathbb{R}^d\times\mathbb{T}^d)$$

as proved before. Since the pairing in Poincaré duality involves only the K-groups of the algebra and the Dirac operator $\not{D}$, the claim follows.

The real spectral triple $(\mathcal{C}_\hbar^{2d},\mathcal{H},\not{D},C,\chi)$ satisfies almost all conditions for a spin geometry on $\mathcal{C}_\hbar^{2d}$. Only the orientation class does not exist for the dimension prescribed by the Dirac operator. This illustrates again[20] the need for an adjustment of the orientation axiom.

IV. NONCOMMUTATIVE LORENTZIAN MANIFOLDS AND ISOSPECTRAL DEFORMATION

We saw in the previous sections that spectral triples provide a powerful noncommutative description of Riemannian geometry, which allows for generalizations to noncompact manifolds. However, in physics it is more natural to consider Lorentzian manifolds, and more generally semi-Riemannian manifolds. In fact, this is closely related to noncompactness, as illustrated by our key example: the cylinder. In string theory, one thinks of the cylinder $\mathbb{R}\times\mathbb{T}$ as the worldsheet of a string, where the noncompact direction represents the time-axis. In order to give meaning to notions such as time, a causal structure is needed and, therefore, an indefinite metric.

Following Strohmaier,[21] we start by setting up a general theory of Lorentzian manifolds in terms of spectral triples. Then we return to the (Lorentzian) cylinder and study its isospectral deformation. For an introduction to semi-Riemannian and Lorentzian geometry, we refer to Refs. 35 and 36.

The description of a Lorentzian manifold in terms of spectral data requires a more general approach than that of Riemannian manifolds. This is enforced by the fact that the Lorentzian Dirac operator is no longer a self-adjoint operator on the Hilbert space of square integrable sections of the spin bundle. Rather it is Krein-self-adjoint on the Krein space of square integrable sections. Furthermore, the signature of the Lorentzian metric implies nonellipticity of the Dirac operator as a pseudodifferential operator acting on smooth sections. Before we go into details on this, we summarize some definitions concerning Krein spaces. For a more comprehensive overview we refer to Ref. 37 or to the lecture notes by Dritschel and Rovnyak, Ref. 38.

Let V be a nondegenerate indefinite inner product space. It is called *decomposable* if there are subspaces V^-, V^+ with $V=V^-\oplus V^+$ such that the inner product $(\cdot,\cdot)$ is negative definite on V^- and positive definite on V^+. The inner product then defines a norm on these subspaces. If V^- and V^+ are complete in these norms, then V is called a *Krein space*. To every decomposition $V=V^-\oplus V^+$, we can associate an operator $J=-\mathrm{id}\oplus\mathrm{id}$, called a *fundamental symmetry*. This operator defines a positive definite inner product on V by $\langle\cdot,\cdot\rangle_J:=(\cdot,J\cdot)$ which makes V a Hilbert space.

Example 21: Consider flat Minkowski space, $V=\mathbb{R}^n$, with inner product defined by $(x,y)=-x_0y_0+x_1y_1+\cdots+x_{n-1}y_{n-1}$. We have $V=\mathbb{R}\oplus\mathbb{R}^{n-1}$ and $J=\mathrm{diag}(-1,1,\ldots,1)$. Clearly, $\langle x,y\rangle_J=\Sigma_i x_iy_i$ is positive definite.

A. Lorentzian spin geometry

Our starting point will be an n-dimensional spin manifold M, equipped with a Lorentzian metric g, i.e., a metric with signature $(n-1,1)$. Spinors on this space–time are smooth sections of the spin bundle $S\to M$. In the following, we denote by γ^μ the curved gamma-matrices, whereas γ^a are the flat ones.[39] The flat gamma matrix γ^0 plays a special role in that it defines an operator $J:=\mathrm{i}\gamma^0$ satisfying $J^2=1$. In fact, this operator is a fundamental symmetry of the space $L^2(M,S)$ of square integrable sections of the spin bundle. The space $L^2(M,S)$ is a Krein space endowed with the indefinite inner product

$$(\psi,\phi):=\int_M\sum_{i,j}\psi_i^*(x)J_{ij}\phi_j(x)\sqrt{|g|}\mathrm{d}x.$$

1. Operators in Krein spaces

In what follows we will make a clear distinction between self-adjoint operators and Krein-self-adjoint operators in $\mathcal{H}$.

The Krein adjoint $A^{[*]}$ of a densely defined operator A on a Krein space $\mathcal{H}$ is defined with respect to the indefinite inner product $(\cdot,\cdot)$ on $\mathcal{H}$. One shows that $A^{[*]}=JA^*J$ and that A is Krein-self-adjoint if and only if AJ (or JA) is self-adjoint. See Ref. 21 for more details. According to Proposition 4.1 therein, we can formally write the square of a Krein-self-adjoint operator A as

$$(A)_J:=\tfrac{1}{2}(AA^*+A^*A). \tag{24}$$

The J-dependency of this operator appears in the conjugation*. It follows that the operator $(A)_J$ is self-adjoint and commutes with J. Hence, it is Krein-self-adjoint by the above remarks.

2. Spacelike reflections and fundamental symmetries

Spacelike reflections make it possible to introduce a positive definite metric on a Lorentzian manifold (or, more generally, on a semi-Riemannian manifold). We give some of the basic notions and refer to Ref. 21 for a more detailed description.

Definition 22: Let (M,g) be a semi-Riemannian manifold. A *spacelike reflection* r is an automorphism of the vector bundle TM, such that

(1) $g(r.,r.)=g(.,.)$,
(2) $r^2=\mathrm{id}$,
(3) $g^r(.,.):=g(.,r.)$ is a positive definite metric on TM.

This map induces a splitting of TM in a direct sum $F_1\oplus F_2$, such that

$$r(x,k_1\oplus k_2)=(x,-k_1\oplus k_2).$$

The metric g^r is called the *Riemannian metric associated to* r.

If M is a semi-Riemannian spin manifold, we can associate an operator J_r to a spacelike reflection r. Let $e_0,e_1,\ldots,e_k$ be a local oriented orthonormal frame for F_1. We define $J_r:=\mathrm{i}^{k(k+1)}\gamma(e_0)\gamma(e_1)\cdots\gamma(e_{k-1})$. In the case of a Lorentzian manifold, we have $J_r=\mathrm{i}\gamma^0$, which is a fundamental symmetry of the Krein space $L^2(M,S)$ as noted before.

3. The Dirac operator

We define the Dirac operator for a spin bundle $S\to M$ in local coordinates by

$$\not{D}:=\gamma^\mu\nabla^S_\mu=\gamma^a e^\mu_a\nabla^S_\mu \tag{25}$$

acting on smooth sections $\Gamma^\infty(S)$. Here, ∇^S is the lift of the Levi-Civita connection to the spin bundle. Its principal symbol $\sigma(\not{D})$ satisfies the relation

$$\sigma(\not{D})(\xi)^2=g(\xi,\xi). \tag{26}$$

This shows that the Dirac operator on a Lorentzian manifold is a nonelliptic pseudodifferential operator that is not self-adjoint. However, from the fact that $iJ\not{D}$ is self-adjoint, it follows that $D=i\not{D}$ is Krein-self-adjoint.

As ellipticity was an important property of the Dirac operator on a Riemannian manifold, we define an elliptic self-adjoint operator Δ_J using results of Sec. IV A 2:

$$\Delta_J:=((D)_J+1)^{1/2}. \tag{27}$$

Ellipticity of this operator follows from considering its principal symbol:

$$\sigma(\Delta_J)(\xi)=\sqrt{g^r(\xi,\xi)}, \tag{28}$$

where g^r is the Riemannian metric associated to g. Furthermore, Δ_J is a pseudodifferential operator of order 1. This motivates the following definition.

Definition 23: An n^+*-summable semi-Riemannian spectral triple* $(\mathcal{A},\mathcal{H},D)$ is given by an involutive algebra of operators $\mathcal{A}$ in a Krein space $\mathcal{H}$, such that $a^*=a^{[*]}$, and by a Krein-self-adjoint operator $D=D^{[*]}$ in $\mathcal{H}$ such that

(1) The commutators $[D,a]:=Da-aD$ are bounded for any $a\in\mathcal{A}$,
(2) The operator $a\Delta_J^{-n}$ is in $\mathcal{L}^{(1,\infty)}$, for all $a\in\mathcal{A}$.

Similar to Definition 14, the triple is called even if there is a grading operator χ on $\mathcal{H}$ that satisfies the relations stated there with the only adjustification that now $\chi^{[*]}=\pm\chi$.

Of course, the triple $(C_0^\infty(M),L^2(M,S),D)$, where $D=\mathrm{i}\not{D}$, is a semi-Riemannian spectral triple, called the *canonical triple* associated to the Lorentzian spin manifold M. If the dimension n of M is even, there is a $\mathbb{Z}_2$-grading on the Hilbert space given by $\chi=\mathrm{i}^{n/2}\gamma^0\cdots\gamma^{n-1}$ so that the canonical triple is even. If the dimension of M is odd, the canonical triple is odd. Since the self-adjoint operator Δ_J associated to D is an elliptic pseudodifferential operator of order 1 as noted before, we have the following. Compare with Proposition 13.

Proposition 24: Let f be an integrable function on an n-dimensional Lorentzian manifold M, then

$$\int_M f(x)\sqrt{|g|}\,\mathrm{d}x = \frac{n(2\pi)^n}{2^{[n/2]}\Omega_n}\mathrm{Tr}_\omega(f\Delta_J^{-n}).$$

For the canonical triple, the fundamental symmetries of the form J_r for some spacelike reflection r play an important role. The analogue of such fundamental symmetries in the general case is given by the admissible fundamental symmetries as were defined in Ref. 21. Therein, it is proved that the admissible fundamental symmetries of the canonical triple are indeed exactly those of the form J_r.

B. Hochschild cocylces

We associate a Hochschild n-cocycle to the canonical triple $(C_0^\infty(M),\ L^2(M,S),\ D)$ as follows:

$$\psi_D^\omega(a_0,a_1,\ldots,a_n) = \mathrm{Tr}_\omega(a_0[D,a_1]\cdots[D,a_n]|\Delta_J|^{-n}). \tag{29}$$

Another cocycle can be constructed using the following result.

Theorem 25: *Let $(C_0^\infty(M),\ L^2(M,S),\ D)$ be the semi-Riemannian canonical triple as defined before. Then $(C_0^\infty(M),\ L^2(M,S),\ \Delta_J)$ is an n^+-summable spectral triple.*

Proof. The only nontrival condition to prove is the boundedness of $[\Delta_J,f]$ for any $f\in C_0^\infty(M)$. Since Δ_J is a pseudodifferential operator of order 1, $[\Delta_J,f]$ is of order 0, hence it is bounded. □

We define the following Hochschild n-cocyle on $C_0^\infty(M)$:

$$\psi_{\Delta_J}^\omega(a_0,a_1,\ldots,a_n) = \mathrm{Tr}_\omega(a_0[\Delta_J,a_1]\cdots[\Delta_J,a_n]|\Delta_J|^{-n}). \tag{30}$$

Obviously the two Hochschild cocycles do not coincide. We illustrate this by the following example.

Example 26: Let M be a compact two-dimensional manifold, equipped with a Minkowski metric. We evaluate the two 2-cocycles using symbol calculus:

$$\mathrm{Tr}_\omega(f[\Delta_J,g][\Delta_J,h]|\Delta_J|^{-n}) = C\int_M f\ \mathrm{d}g\wedge *(\mathrm{d}h)$$

in contrast to

$$\mathrm{Tr}_\omega(f[D,g][D,h]|\Delta_J|^{-n}) = C'\int_M f\ \mathrm{d}g\wedge \mathrm{d}h$$

for some integration constants C,C'. Note the apperance of a Polyakov type function for ψ_D^ω in this special case.

C. Isospectral deformation of the Lorentzian cylinder

With the theory of semi-Riemannian spectral triples developed in the previous sections in our hands, we are now in a position to describe the geometry of the cylinder equipped with a semi-Riemannian metric. In this section, we will discuss the semi-Riemannian spectral triple that describes the cylinder equipped with a Minkowski metric. Then we discuss isospectral deformation in this case, similar to what has been done before in the Euclidean setting. Finally, we show that the set of admissible fundamental symmetries of the noncommutative cylinder coincides with the set of fundamental symmetries coming from spacelike reflections in spinor space.

The cylinder can be described by the following semi-Riemannian spectral triple:

$$\mathcal{A} := C_0^\infty(\mathbb{R}^n \times \mathbb{T}^d),$$

$$\mathcal{H} := L^2(\mathbb{R}^n \times \mathbb{T}^d) \otimes \mathbb{C}^{2^{[(n+d)/2]}},$$

$$D := i\not{\partial}.$$

Here $\not{\partial} = \gamma^a \partial_a$, where the gamma-matrices satisfy $\{\gamma^a, \gamma^b\} = 2\eta^{ab}$ for the flat (Minkowski) metric $\eta = (-1,1,\ldots,1)$.

In order to obtain a noncommutative manifold, we perform isospectral deformation of the Lorentzian cylinder, along the same lines as we did before for the Euclidean cylinder. We restrict to $\mathcal{S}(\mathbb{R}^n \times \mathbb{T}^d)$ in order to represent the deformed algebra $\mathcal{C}_{\hbar\theta}^{(n,d)}$ on the Hilbert space $\mathcal{H}$.

Theorem 27: *The triple* $(\mathcal{C}_{\hbar\theta}^{(n,d)}, \mathcal{H}, D)$ *is a semi-Riemannian spectral triple, which is an isospectral deformation of* $(\mathcal{S}(\mathbb{R}^n \times \mathbb{T}^d), \mathcal{H}, D)$.

One could very well imitate the construction of the Riemannian spin geometry on $\mathcal{C}_\hbar^{2d}$ to obtain a Lorentzian spin geometry on the noncommutative cylinder. However, it turns out that in order to obtain for example the Lorentzian distance function from a canonical triple, one needs a different approach.[40]

An admissible fundamental symmetry J for the triple $(\mathcal{S}(\mathbb{R}^n \times \mathbb{T}^d), \mathcal{H}, D)$ is also admissible for the noncommutative cylinder. Indeed, $\mathcal{C}_{\hbar\theta}^{(n,d)}$ is invariant under conjugation with J. Invariance of $\pi(\Omega\mathcal{C}_{\hbar\theta}^{(n,d)})$ follows from the following lemma.

Lemma 28: For the semi-Riemannian spectral triple $(\mathcal{C}_{\hbar\theta}^{(n,d)}, \mathcal{H}, D)$ *we have*

$$\pi(\Omega^p \mathcal{C}_{\hbar\theta}^{(n,d)}) = \left\{ \sum_j a^j \gamma(v_1^j) \cdots \gamma(v_p^j) : \quad a^j \in \mathcal{C}_{\hbar\theta}^{(n,d)}, v_i^j \in \mathbb{C}^{2^{[(n+d)/2]}} \right\}.$$

Proof: Recall the theory of universal forms on nonunital algebras described before. Since $[D,a] = i\gamma(da)$ still holds, we have for $a_i \in \mathcal{C}_{\hbar\theta}^{(n,d)}$,

$$\pi(\tilde{a}_0 \delta a_1 \cdots \delta a_p) = \pi(\tilde{a}_0)\pi(\partial_{\mu_1} a_1) \cdots \pi(\partial_{\mu_p} a_p)\gamma(dx_1^\mu) \cdots \gamma(dx_p^\mu),$$

which is of the required form. For $p = 0$ we have $\pi(\Omega^0 \mathcal{C}_{\hbar\theta}^{(n,d)}) = \mathcal{C}_{\hbar\theta}^{(n,d)}$. □

In Sec. IV A, we saw that the set of admissible fundamental symmetries of the semi-Riemannian canonical triple coincides with the set of fundamental symmetries coming from spacelike reflections in $\mathbb{C}^{2^{[(n+d)/2]}}$. Strohmaier[21] showed that this statement also holds for noncommutative tori with trivial center. For the noncommutative cylinder, we restrict to the class described in Sec. II C, where $n = d$. There, we proved the following isomorphism of C^*-algebras:

$$C_\hbar^{2d} \cong \mathcal{B}_0(L^2(\mathbb{T}^d)) \otimes C(\mathbb{T}^d). \tag{31}$$

The appearance of the set of compact operators in the tensor product plays a central role in the following result. It turns out to hold in a slightly more general setting, i.e., in the case of a semi-Riemannian Dirac operator.

Theorem 29: *The set of admissible fundamental symmetries of the noncommutative semi-Riemannian cylinder* $(\mathcal{C}_\hbar^{2d}, \mathcal{H}, D)$ *coincides with the set*

$$\{J_r : r \text{ is a spacelike reflection of } \mathbb{C}^{2^d}\}.$$

Proof: Let r be a spacelike reflection of $\mathbb{C}^{2^d}$. It follows from Lemma 28 that J_r is admissible. For the proof of the converse statement, suppose that J is an admissible fundamental symmetry of $(\mathcal{A}, \mathcal{H}, D)$, where we take $\mathcal{A} := \mathcal{C}_\hbar^{2d}$. Since J commutes with all elements in $\mathcal{A}$, we have

$$J \in \mathcal{A}' \otimes \mathrm{End}(\mathbb{C}^{2^d}),$$

where $\mathcal{A}'$ is the commutant of $\mathcal{A}$ in $\mathcal{B}(L^2(\mathbb{R}^d\times\mathbb{T}^d))$. Since the opposite algebra $\mathcal{A}^\circ$, which acts on $\mathcal{H}$ from the right, is a dense subalgebra of $\mathcal{A}'$, we have for its unitization, with formula (10.82) in Ref. 16,

$$\tilde{\mathcal{A}}^\circ=\{T\in(\mathcal{A}^\circ)'':\quad T\in\mathrm{Dom}^\infty\delta\}=\{T\in\mathcal{A}':\quad T\in\mathrm{Dom}^\infty\delta\},$$

where $\mathrm{Dom}^\infty\delta$ is the smooth domain of the derivation $\delta:=[\Delta_J,.]$. Here we used the fact that $\mathcal{A}'=\tilde{\mathcal{A}}'$. Since J is smooth, $J\in\mathrm{Dom}^\infty\delta$, and it follows that $J\in\tilde{\mathcal{A}}^\circ\otimes\mathrm{End}(\mathbb{C}^{2^d})$. Note that the construction in Ref. 16 relies on finitely generated projective modules so that it does not directly apply to nonunital algebras.

Since $\pi(\Omega^p\mathcal{A})$ is invariant under conjugation with J, we have

$$[J\pi(\Omega^1\mathcal{A})J,\tilde{\mathcal{A}}^\circ]=[\pi(\Omega^1\mathcal{A}),\tilde{\mathcal{A}}^\circ]=0.$$

In particular, for any $\tilde{a}\gamma(v)\in\pi(\Omega^1\mathcal{A})$, we have $\tilde{a}[J\gamma(v)J,\tilde{\mathcal{A}}^\circ]=0$ so that $J\gamma(v)J$ has entries in the center of $\tilde{\mathcal{A}}^\circ$. Since $C(\mathcal{A})=C(C_\hbar^{2d})=0$, as can be seen from formula (30), we infer that $C(\tilde{\mathcal{A}})=\mathbb{C}$. Hence, $J\gamma(v)J$ must be an element of $\mathrm{End}(\mathbb{C}^{2^d})$, so that $J\gamma(v)J=-\gamma(rv)$ for some endomorphism r of $\mathbb{C}^{2^d}$. One checks the conditions of Definition 22 to conclude that r is a spacelike reflection. Hence there exists J_r such that $J\gamma(v)J=J_r\gamma(v)J_r$. Define the operator $a:=JJ_r$. It commutes with all $\gamma(v)$, so that $a\in\tilde{\mathcal{A}}^\circ$. Since $J_r\in\mathrm{End}(\mathbb{C}^{2^d})$, $[a,J_r]=0$. One shows that $a^2=a^{[*]}a=aa^{[*]}=1$ and that

$$\langle\xi,a\xi\rangle_{J_r}=(\xi,J_ra\xi)=(\xi,J\xi)\geqslant 0,\quad(\xi\in\mathcal{H}).$$

We conclude that $a=1$ and $J=J_r$. □

ACKNOWLEDGMENTS

I am grateful to N.P. Landsman for his support, assistance, and inspirational thoughts. I would like to thank G.G.A. Bäuerle for providing the physical motivation for the presented ideas. I want to thank J. Brodzki, J. Cuntz, V. Gayral, E. Langmann, and A. Strohmaier for helpful comments and my colleagues at the KdV-Institute and at SISSA for several discussions.

APPENDIX: MORITA EQUIVALENCE OF $\mathcal{C}_\hbar^{2d}$ AND $\mathcal{S}(\mathbb{Z}^d)$

Theorem 30: *The Fréchet algebras $\mathcal{C}_\hbar^{2d}$ and $\mathcal{S}(\mathbb{Z}^d)$ are Morita equivalent via the Fréchet bimodule $\mathcal{S}(\mathbb{R}^d)$, i.e.,*

$$\mathcal{S}(\mathbb{R}^d)\overline{\otimes}_{\mathcal{S}(\mathbb{Z}^d)}\mathcal{S}(\mathbb{R}^d)\cong\mathcal{C}_\hbar^{2d},$$

$$\mathcal{S}(\mathbb{R}^d)\overline{\otimes}_{\mathcal{C}_\hbar^{2d}}\mathcal{S}(\mathbb{R}^d)\cong\mathcal{S}(\mathbb{Z}^d).$$

Here $\overline{\otimes}_{\mathcal{A}}$ denotes the completion of the tensor product over a Fréchet algebra $\mathcal{A}$ in the projective tensor product topology.

For notational convenience, we restrict to the case $d=1$. Recall that $\mathcal{C}_\hbar^2$ is the Fréchet algebra $\mathcal{S}(\mathbb{R}\times\mathbb{T})$ equipped with the following product:

$$(F*G)(x,t)=\int_{\mathbb{R}}\mathrm{d}y\,F(y,t)G(x-y,t-\pi(y)),$$

where $\pi:\mathbb{R}\to\mathbb{R}/\mathbb{Z}\cong\mathbb{T}$ is the natural projection. We equip it with the following submultiplicative seminorms:[41]

$$p^{\alpha,\beta,\gamma}(F)=\int_{\mathbb{T}}\mathrm{d}t\int_{\mathbb{R}}\mathrm{d}x(1+|x|)^{\alpha}|\partial_x^{\beta}\partial_t^{\gamma}F(x,t)|.$$

The algebra $\mathcal{S}(\mathbb{Z})$ is equipped with the usual convolution product and the corresponding submultiplicative seminorms

$$q^{\alpha}(a)=\sum_{n\in\mathbb{Z}}(1+|n|)^{\alpha}|a(n)|.$$

Proof: The module $\mathcal{S}(\mathbb{R})$ is a Fréchet $\mathcal{C}_\hbar^2-\mathcal{S}(\mathbb{Z})$ bimodule in the following sense. First of all, it consists of differentiable functions on $\mathbb{R}$ with the topology given by the seminorms $\nu^{\alpha,\beta}$,

$$\nu^{\alpha,\beta}(f):=\int_{\mathbb{R}}\mathrm{d}x(1+|x|)^{\alpha}|\partial_x^{\beta}f(x)|. \tag{A1}$$

The left and right actions of $\mathcal{C}_\hbar^2$ and $\mathcal{S}(\mathbb{Z})$ are defined by

$$F\cdot f(x)=\int_{\mathbb{R}}\mathrm{d}y\,F(x-y,\pi(x))f(y), \tag{A2}$$

$$f\cdot a(x)=\sum_n a(n)f(x+n). \tag{A3}$$

One checks that these actions are continuous and that $(F*G)\cdot f=F\cdot(G\cdot f)$, $f\cdot(a*b)=(f\cdot a)\cdot b$. Furthermore, compatibility of both actions, $(F\cdot f)\cdot a=F\cdot(f\cdot a)$ is easily checked. We write ${}_{\mathcal{C}_\hbar^2}\mathcal{S}(\mathbb{R})_{\mathcal{S}(\mathbb{Z})}$.

We will endow $\mathcal{S}(\mathbb{R})$ also with the structure of a $\mathcal{S}(\mathbb{Z})-\mathcal{C}_\hbar^2$ bimodule:

$$f\cdot F(x)=\int_{\mathbb{R}}\mathrm{d}y\,F(y-x,\pi(y))f(y), \tag{A4}$$

$$a\cdot f(x)=\sum_n a(n)f(x-n). \tag{A5}$$

Again, this module satisfies the right properties and we write ${}_{\mathcal{S}(\mathbb{Z})}\mathcal{S}(\mathbb{R})_{\mathcal{C}_\hbar^2}$.

Recall that an essential Fréchet A-modules X satisfies $A\cdot X\subset X$ densely.[42]

Lemma 31: The Fréchet bimodules ${}_{\mathcal{C}_\hbar^2}\mathcal{S}(\mathbb{R})_{\mathcal{S}(\mathbb{Z})}$ *and* ${}_{\mathcal{S}(\mathbb{Z})}\mathcal{S}(\mathbb{R})_{\mathcal{C}_\hbar^2}$ *are essential.*

Proof: Since the algebra $\mathcal{S}(\mathbb{Z})$ is unital for the convolution product, there is nothing to prove there. The algebra $\mathcal{C}_\hbar^2$ has an approximate identity $\{e_\lambda\}_{\lambda\in\Lambda}$ defined by

$$e_\lambda(x,t):=\frac{\lambda}{\sqrt{\pi}}e^{-\lambda x^2}.$$

We have $e_\lambda\cdot f\to f$ and $f\cdot e_\lambda\to f$ for $f\in\mathcal{S}(\mathbb{R})$. □

We proceed by defining bilinear maps,

$$\tilde{\phi}:\mathcal{S}(\mathbb{R})\times\mathcal{S}(\mathbb{R})\to\mathcal{C}_\hbar^2,$$

$$\tilde{\phi}(f,g)(x,t)=\sum_n f(t-n)g(t-x-n), \tag{A6}$$

$$\tilde{\psi}:\mathcal{S}(\mathbb{R})\times\mathcal{S}(\mathbb{R})\to\mathcal{S}(\mathbb{Z}),$$

$$\tilde{\psi}(f,g)(n)=\int_{\mathbb{R}} \mathrm{d}x f(x)g(x-n). \tag{A7}$$

One checks that the maps $\tilde{\phi}$ and $\tilde{\psi}$ are bounded bilinear module maps. They are balanced since one easily computes

$$\tilde{\phi}(f\cdot a,g)=\tilde{\phi}(f,a\cdot g),$$

$$\tilde{\psi}(f\cdot F,g)=\tilde{\psi}(f,F\cdot g). \tag{A8}$$

Therefore, we can extend $\tilde{\phi}$ and $\tilde{\psi}$ to the tensor product:

$$\phi:\mathcal{S}(\mathbb{R})\overline{\otimes}_{\mathcal{S}(\mathbb{Z})}\mathcal{S}(\mathbb{R})\to\mathcal{C}^2_\hbar,$$

$$\psi:\mathcal{S}(\mathbb{R})\overline{\otimes}_{\mathcal{C}^2_\hbar}\mathcal{S}(\mathbb{R})\to\mathcal{S}(\mathbb{Z}). \tag{A9}$$

Note that the maps $\tilde{\phi}$ and $\tilde{\psi}$ satisfy the following properties:

$$\tilde{\phi}(f,g)\cdot h=f\cdot\tilde{\psi}(g,h),$$

$$\tilde{\psi}(f,g)\cdot h=f\cdot\tilde{\phi}(g,h). \tag{A10}$$

Lemma 32: The module morphisms ϕ and ψ are surjective.

Proof: Let $F\in\mathcal{C}^2_\hbar$. Define $H\in\mathcal{S}(\mathbb{R})\overline{\otimes}_{\mathcal{S}(\mathbb{Z})}\mathcal{S}(\mathbb{R})$ by

$$H(x,y):=f(x)F(x-y,\pi(x)),$$

where $f\in\mathcal{S}(\mathbb{R})$ satisfies $\Sigma_n f(t-n)=1$ for all $t\in[0,1)$. Then $\phi(H)=F$. For surjectivity of ψ it is enough to construct a function $f\in\mathcal{S}(\mathbb{R})$ with $\psi(f\otimes f)=\mathbf{1}_{\mathcal{S}(\mathbb{Z})}$. Clearly, this holds for a function f with $\mathrm{supp}f\in(0,1)$ and $\int\mathrm{d}x|f(x)|^2=1$. □

Lemma 33: The module morphisms ϕ and ψ are injective

Proof: Let $\Sigma_i\tilde{\phi}(f_i,g_i)=0$. Then

$$\tilde{\phi}(f,g)\cdot\sum_i f_i\otimes_{\mathcal{S}(\mathbb{Z})}g_i=\sum\tilde{\phi}(f,g)\cdot f_i\otimes_{\mathcal{S}(\mathbb{Z})}g_i=\sum f\cdot\tilde{\psi}(g,f_i)\otimes_{\mathcal{S}(\mathbb{Z})}g_i$$

$$=\sum f\otimes_{\mathcal{S}(\mathbb{Z})}\tilde{\psi}(g,f_i)\cdot g_i=f\otimes_{\mathcal{S}(\mathbb{Z})}g\cdot\sum_i\tilde{\phi}(f_i,g_i)=0, \tag{A11}$$

using formula (A10) twice. Hence, $F\cdot\Sigma_i f_i\otimes_{\mathcal{S}(\mathbb{Z})}g_i=0$ for all $F\in\mathcal{C}^2_\hbar$. Since $\mathcal{C}^2_\hbar$ has an approximate identity it follows that $\Sigma_i f_i\otimes_{\mathcal{S}(\mathbb{Z})}g_i=0$. Since $\mathcal{S}(\mathbb{Z})$ is unital, we find similarly injectivity of ψ. □

This completes the proof of the theorem.

Ruijsenaars–Schneider models associated with A_{n-1} root system with a discrete *coupling constant* are studied. The eigenvalues of the Hamiltonian are given in terms of the Bethe ansatz formulas. Taking the ''nonrelativistic'' limit, we obtain the spectrum of the corresponding Calogero–Moser systems in the *third formulas* of Felder *et al.* © *2004 American Institute of Physics.*
[DOI: 10.1063/1.1635067]

I. INTRODUCTION

Ruijsenaars–Schneider (RS) models[1,2] are integrable generalization of Calogero–Moser (CM) models[3,4] at both classical and quantum levels. The integrability of classical RS models associated with various root systems were studied by Lax pair representation for A_{n-1},[1] for D_n,[5] for C_n and BC_n with one coupling constant.[6] The commuting conserved quantities for quantum RS models were discussed in Refs. 2, 7, 8, and 9.

It is well known that the Hamiltonian of RS model with degenerate potentials (trigonometric and rational ones) is one of the commuting families of Macdonald operators,[10] which are also called *Ruijsenaars–Macdonald operators*. The eigenfunctions of the *degenerate* Hamiltonian are given by so-called *Macdonald polynomials*.[10] However, an analogous construction for elliptic generalization of *Macdonald polynomials* is still an open problem.

Bethe ansatz method has proved to be the most powerful and (probably) unified method to construct the common eigenvectors of commuting families of operators (usually called *transfer matrices*) in two-dimensional trigonometric and rational integrable models.[11–15] Recently, after a definition of elliptic quantum groups $E_{\tau,\eta}(\mathfrak{g})$ associated with any simple classical Lie algebra $\mathfrak{g}$ was given,[16] the algebraic Bethe ansatz method has been successfully extended. The method for construction of the eigenvectors of the transfer matrices associated with the module over $E_{\tau,\eta}(sl_2)$ (Ref. 17) is now generalized to apply for those associated with the module over $E_{\tau,\eta}(sl_n)$ with generic n.[18,19]

In particular, the elliptic *Ruijsenaars–Macdonald operator* (3.7) with a discrete *coupling constant* $\gamma=\sqrt{-1}gl$ (l being a non-negative integer) associated with A_{n-1} root system can be rewritten as the *transfer matrices* associated with the symmetric $n\times l$ tensor product evaluation $E_{\tau,\eta}(sl_n)$ module.[20] This enables us to obtain the eigenvalues of the Hamiltonian of elliptic RS models with the discrete *coupling constant* $\gamma=\sqrt{-1}gl$ associated with A_{n-1} root system by the algebraic Bethe ansatz for elliptic quantum group $E_{\tau,\eta}(sl_n)$.

The paper is organized as follows. In Sec. II, we give a brief review of the algebraic Bethe ansatz for elliptic quantum group $E_{\tau,\eta}(sl_n)$ developed in Ref. 19. In Sec. III, choosing the special $E_{\tau,\eta}(sl_n)$-module $W=V_{\Lambda(nl)}(0)$, we give the eigenvalues of elliptic RS model with the discrete *coupling constant* $\gamma=\sqrt{-1}gl$ and the associated Bethe ansatz equations. Taking the degenerate

(trigonometric and rational) limit, we obtain the eigenvalues of Hamiltonian of the degenerate RS models associated with A_{n-1} root system. In Sec. IV, taking the ''nonrelativistic'' limit,[21] we obtain the eigenvalues of elliptic, trigonometric and rational types of CM models associated with A_{n-1} root system with an integer *coupling constant* $\gamma=l+1$ in the Bethe ansatz formulas or the *third formulas* in the sense of Felder *et al.*[22]

II. ALGEBRAIC BETHE ANSATZ FOR ELLIPTIC QUANTUM GROUP $E_{\tau,\eta}(sl_n)$

A. Elliptic quantum group associated with A_{n-1}

We first review the definition of the elliptic quantum group $E_{\tau,\eta}(sl_n)$ associated with A_{n-1}.[16] Let $\{\boldsymbol{\epsilon}_i | i=1,2,...,n\}$ be the orthonormal basis of the vector space $\mathbb{C}^n$ such that $\langle \boldsymbol{\epsilon}_i, \boldsymbol{\epsilon}_j \rangle = \delta_{ij}$. The A_{n-1} simple roots are $\{\alpha_i = \boldsymbol{\epsilon}_i - \boldsymbol{\epsilon}_{i+1} | i=1,...,n-1\}$ and the fundamental weights $\{\Lambda_i | i=1,...,n-1\}$ satisfying $\langle \Lambda_i, \alpha_j \rangle = \delta_{ij}$ are given by

$$\Lambda_i = \sum_{k=1}^{i} \boldsymbol{\epsilon}_k - \frac{i}{n} \sum_{k=1}^{n} \boldsymbol{\epsilon}_k .$$

Set

$$\hat{i} = \boldsymbol{\epsilon}_i - \overline{\boldsymbol{\epsilon}}, \quad \overline{\boldsymbol{\epsilon}} = \frac{1}{n} \sum_{k=1}^{n} \boldsymbol{\epsilon}_k, \quad i=1,...,n, \quad \text{then} \ \sum_{i=1}^{n} \hat{i} = 0. \tag{2.1}$$

For each dominant weight $\Lambda = \Sigma_{i=1}^{n-1} a_i \Lambda_i$, $a_i \in \mathbb{Z}^+$, there exists an irreducible highest weight finite-dimensional representation V_Λ of A_{n-1} with the highest vector $|\Lambda\rangle$. For example, the fundamental vector representation is V_{Λ_1}. In this paper, we consider only the symmetric tensor-product representation of $\overbrace{V_{\Lambda_1} \otimes V_{\Lambda_1} \cdots \otimes V_{\Lambda_1}}^{l}$ (or, the *higher spin-l representation of* A_{n-1}), namely, the one parameter series of highest weight representations $V_{\Lambda^{(l)}}$, with

$$\Lambda^{(l)} = l\Lambda_1, \quad l \in \mathbb{Z} \quad \text{and} \ l>0. \tag{2.2}$$

This corresponds to the Young diagram $\overbrace{\square\square\square\cdots\square}^{l}$.

Let $\mathfrak{h}$ be the Cartan subalgebra of A_{n-1} and $\mathfrak{h}^*$ be its dual. A finite dimensional diagonalizable $\mathfrak{h}$-module is a complex finite dimensional vector space W with a weight decomposition $W = \oplus_{\mu \in h^*} W[\mu]$, so that $\mathfrak{h}$ acts on $W[\mu]$ by $xv = \mu(x)v$, $(x \in \mathfrak{h}, v \in W[\mu])$. For example, the fundamental vector representation $V_{\Lambda_1} = \mathbb{C}^n$, the nonzero weight spaces $W[\hat{i}] = \mathbb{C}\boldsymbol{\epsilon}_i$, $i=1,...,n$.

Let us fix τ such that $\mathrm{Im}(\tau)>0$ and a generic complex number η. For convenience, we introduce another parameter $w = n\eta$ related to η. Let us introduce the following elliptic functions:

$$\theta\begin{bmatrix} a \\ b \end{bmatrix}(u,\tau) = \sum_{m=-\infty}^{\infty} \exp\{\sqrt{-1}\pi[(m+a)^2\tau + 2(m+a)(u+b)]\}, \tag{2.3}$$

$$\sigma(u) = \theta\begin{bmatrix} \frac{1}{2} \\ \frac{1}{2} \end{bmatrix}(u,\tau), \quad \zeta(u) = \partial_u\{\ln\sigma(u)\}, \quad \wp(u) = -\partial_u\{\zeta(u)\}. \tag{2.4}$$

These functions have the following properties:

$$\sigma(u) = 0 + u\sigma'(0) + \frac{u^3}{6}\sigma'''(0) + \cdots, \quad \text{when} \ u \to 0, \tag{2.5}$$

$$\sigma(-u) = -\sigma(u), \quad \zeta(-u) = -\zeta(u), \quad \wp(-u) = \wp(u), \tag{2.6}$$

where $\sigma'(0)=\partial_u\{\sigma(u)\}|_{u=0}$ and $\sigma'''(0)=\partial_u^3\{\sigma(u)\}|_{u=0}$.

For a generic $\lambda\in\mathbb{C}^n$, define

$$\lambda_i=\langle\lambda,\epsilon_i\rangle,\quad \lambda_{ij}=\lambda_i-\lambda_j=\langle\lambda,\epsilon_i-\epsilon_j\rangle,\quad i,j=1,...,n. \tag{2.7}$$

Let $R(z,\lambda)\in\mathrm{End}(\mathbb{C}^n\otimes\mathbb{C}^n)$ be the R-matrix given by

$$R(z,\lambda)=\sum_{i=1}^{n} R_{ii}^{ii}(z,\lambda)E_{ii}\otimes E_{ii}+\sum_{i\neq j}\{R_{ij}^{ij}(z,\lambda)E_{ii}\otimes E_{jj}+R_{ij}^{ji}(z,\lambda)E_{ji}\otimes E_{ij}\}, \tag{2.8}$$

in which E_{ij} is the matrix with elements $(E_{ij})_k^l=\delta_{jk}\delta_{il}$. The coefficient functions are

$$R_{ii}^{ii}(z,\lambda)=1,\quad R_{ij}^{ij}(z,\lambda)=\frac{\sigma(z)\sigma(\lambda_{ij}+w)}{\sigma(z+w)\sigma(\lambda_{ij})}, \tag{2.9}$$

$$R_{ij}^{ji}(z,\lambda)=\frac{\sigma(w)\sigma(z+\lambda_{ij})}{\sigma(z+w)\sigma(\lambda_{ij})}, \tag{2.10}$$

and λ_{ij} is defined in (2.7). The R-matrix satisfies the dynamical (modified) quantum Yang–Baxter equation.

$$\begin{aligned}&R_{12}(z_1-z_2,\lambda-wh^{(3)})R_{13}(z_1-z_3,\lambda)R_{23}(z_2-z_3,\lambda-wh^{(1)})\\&\quad=R_{23}(z_2-z_3,\lambda)R_{13}(z_1-z_3,\lambda-wh^{(2)})R_{12}(z_1-z_2,\lambda),\end{aligned} \tag{2.11}$$

with the initial condition

$$R_{ij}^{kl}(0,\lambda)=\delta_i^l\delta_j^k. \tag{2.12}$$

We adopt the notation $R_{12}(z,\lambda-wh^{(3)})$ acts on a tensor $v_1\otimes v_2\otimes v_3$ as $R(z,\lambda-w\mu)\otimes Id$ if $v_3\in W[\mu]$.

A representation of the elliptic quantum group $E_{\tau,\eta}(sl_n)$ [an $E_{\tau,\eta}(sl_n)$-module] is by definition a pair (W,L) where W is a diagonalizable $\mathfrak{h}$-module and $L(z,\lambda)$ is a meromorphic function of λ and the spectral parameter $z\in\mathbb{C}$, with values in $\mathrm{End}_{\mathfrak{h}}(\mathbb{C}^n\otimes W)$ (the endomorphisms commuting with the action of $\mathfrak{h}$). It obeys the so-called RLL relation

$$R_{12}(z_1-z_2,\lambda-wh^{(3)})L_{13}(z_1,\lambda)L_{23}(z_2,\lambda-wh^{(1)})=L_{23}(z_2,\lambda)L_{13}(z_1,\lambda-wh^{(2)})R_{12}(z_1-z_2,\lambda), \tag{2.13}$$

where the first and second space are auxiliary spaces ($\mathbb{C}^n$) and the third space plays the role of the quantum space (W). The total weight conservation condition for the L-operator reads

$$[h^{(1)}+h^{(3)},L_{13}(z,\lambda)]=0.$$

In terms of the elements of the L-operator defined by

$$L(z,\lambda)(\epsilon_i\otimes v)=\sum_{j=1}^{n}\epsilon_j\otimes L_i^j(z,\lambda)v,\quad v\in W, \tag{2.14}$$

the above condition can be expressed equivalently as

$$f(h)L_i^j(z,\lambda)=L_i^j(z,\lambda)f(h+\hat{i}-\hat{j}), \tag{2.15}$$

in which $f(h)$ is any meromorphic function of h and h measures the weight of the quantum space (W).

B. Modules over $E_{\tau,\eta}(sl_n)$ and the associated operator algebra

The basic example of an $E_{\tau,\eta}(sl_n)$-module is $(\mathbb{C}^n, L)$ with $L(z,\lambda)=R(z-z_1,\lambda)$, which is called the fundamental vector representation $V_{\Lambda_1}(z_1)$ with the evaluation point z_1. It is obvious that the RLL relation is satisfied as a consequence of the dynamical Yang–Baxter equation (2.11). Other modules can be obtained by taking tensor products: if $(W_1, L^{(1)})$ and $(W_2, L^{(2)})$ are $E_{\tau,\eta}(sl_n)$-modules, where $L^{(j)}$ acts on $(\mathbb{C}^n \otimes W_j)$, then also $(W_1 \otimes W_2, L)$ with

$$L(z,\lambda)=L^{(1)}(z,\lambda-wh^{(2)})L^{(2)}(z,\lambda) \quad \text{acting on } \mathbb{C}^n \otimes W_1 \otimes W_2. \tag{2.16}$$

An $E_{\tau,\eta}(sl_n)$-submodule of an $E_{\tau,\eta}(sl_n)$-module (W,L) is a pair (W_1, L_1) where W_1 is an $\mathfrak{h}$-submodule of W such that $\mathbb{C}^n \otimes W_1$ is invariant under the action of all the $L(z,\lambda)$, and $L_1(z,\lambda)$ is the restriction to this invariant subspace. Namely, the $E_{\tau,\eta}(sl_n)$-submodules are $E_{\tau,\eta}(sl_n)$-modules.

Using the fusion rule of $E_{\tau,\eta}(sl_n)$ (2.16) one can construct the symmetric $E_{\tau,\eta}(sl_n)$-submodule of l-tensors of fundamental vector representations:

$$V_{\Lambda^{(l)}}(z_1)=\text{symmetric subspace of } V_{\Lambda_1}(z_1)\otimes V_{\Lambda_1}(z_1-w)\otimes\cdots\otimes V_{\Lambda_1}(z_1-(l-1)w),$$

where $\Lambda^{(l)}$ is defined by (2.2). We call such an $E_{\tau,\eta}(sl_n)$-module the *higher spin-l representation* with the evaluation point z_1. These series of representations in the case of $\mathbb{Z}_n$ Sklyanin algebra have been studied in Ref. 23 for $n=2$ case and in Refs. 24 and 25 for generic n case.

For any $E_{\tau,\eta}(sl_n)$-module, as in Ref. 17 one can define an associated operator algebra of difference operators on the space $\mathrm{Fun}(W)$ of meromorphic functions of λ with values in W. The algebra is generated by h and the operators $\widetilde{L}(z) \in \mathrm{End}(\mathbb{C}^n \otimes \mathrm{Fun}(W))$ acting as

$$\widetilde{L}(z)(\epsilon_i \otimes f)(\lambda)=\sum_{j=1}^{n} \epsilon_j \otimes L_i^j(z,\lambda) f(\lambda - w\hat{i}). \tag{2.17}$$

One can derive the following exchange relation of the difference operator $\widetilde{L}(z)$ from the RLL relation (2.13), the weight conservation condition $L_i^j(z,\lambda)$ (2.15) and the fact $[h^{(1)}+h^{(2)}, R_{12}(z,\lambda)]=0$,

$$R_{12}(z_1-z_2, \quad \lambda-wh)\widetilde{L}_{13}(z_1)\widetilde{L}_{23}(z_2)=\widetilde{L}_{23}(z_2)\widetilde{L}_{13}(z_1)R_{12}(z_1-z_2,\lambda), \tag{2.18}$$

$$f(h)\widetilde{L}_i^j(z)=\widetilde{L}_i^j(z)f(h+\hat{i}-\hat{j}), \tag{2.19}$$

where $f(h)$ is any meromorphic function of h. Let $W=V_{\Lambda^{(l_1)}}(z_1)\otimes V_{\Lambda^{(l_2)}}(z_2)\otimes\cdots\otimes V_{\Lambda^{(l_m)}}(z_m)$ and $\Lambda=\Lambda^{(l_1)}+\cdots+\Lambda^{(l_m)}$, then $W[\Lambda]=\mathbb{C}|\Lambda\rangle$ with $|\Lambda\rangle=|\Lambda^{(l_1)}\rangle\otimes\cdots\otimes|\Lambda^{(l_m)}\rangle$.

Theorem 1 (Ref. 19): *With generic evaluation points $\{z_i\}$, W is an irreducible highest weight $E_{\tau,\eta}(sl_n)$-module and the vector $|\Lambda\rangle$, viewed as a constant function in Fun(W), obeys the following highest weight conditions:*

$$\widetilde{L}_1^1(z)|\Lambda\rangle=A(z,\lambda)|\Lambda\rangle, \quad \widetilde{L}_1^i(z)|\Lambda\rangle=0, \quad i=2,...,n,$$

$$\widetilde{L}_j^i(z)|\Lambda\rangle=\delta_j^i D_i(z,\lambda)|\Lambda\rangle, \quad i,j=2,...,n, \quad f(h)|\Lambda\rangle=f(N\hat{1})|\Lambda\rangle.$$

The highest weight functions read

$$A(z,\lambda)=1, \quad D_i(z,\lambda)=\left\{\prod_{k=1}^{m}\frac{\sigma(z-p_k)}{\sigma(z-q_k)}\right\}\frac{\sigma(\lambda_{i1}+Nw)}{\sigma(\lambda_{i1})}, \quad i=2,...,n, \tag{2.20}$$

where

$$p_k = z_k, \quad q_k = z_k - l_k w, \quad N = \sum_{k=1}^{m} l_k, \quad k = 1,...,m. \tag{2.21}$$

The *transfer matrices* associated with an $E_{\tau,\eta}(sl_n)$-module (W,L) (Ref. 17) are difference operators acting on the space $\mathrm{Fun}(W)[0]$ of meromorphic functions of λ with values in the zero-weight space of W. They are defined by

$$T(u)f(\lambda) = \sum_{i=1}^{n} \tilde{L}_i^i(u) f(\lambda) = \sum_{i=1}^{n} L_i^i(u,\lambda) f(\lambda - w\hat{i}). \tag{2.22}$$

The exchange relations of $\tilde{L}$-operators (2.18) and (2.19) imply that, for any $E_{\tau,\eta}(sl_n)$-module, the above transfer matrices preserve the space $\mathcal{H} = \mathrm{Fun}(W)[0]$. Moreover, they commute pairwise on $\mathcal{H}$: $[T(u),T(v)]|_{\mathcal{H}} = 0$.

C. Algebraic Bethe ansatz for $E_{\tau,\eta}(sl_n)$

We fix a highest weight $E_{\tau,\eta}(sl_n)$-module W of weight Λ, the functions $A(z,\lambda)$, $D_i(z,\lambda)$ (2.20), with the highest weight vector $|\Lambda\rangle$. We assume that $N = \Sigma_{k=1}^{m} l_k = n \times l$ with l being an integer, so that the zero-weight space $W[0]$ can be nontrivial and that the algebraic Bethe ansatz method can be applied as in Refs. 26, 27, 28, 17, and 19.

Let us adopt the standard notation for convenience:

$$\mathcal{A}(u) = \tilde{L}_1^1(u), \quad \mathcal{B}_i(u) = \tilde{L}_i^1(u), \quad i = 2,...,n, \tag{2.23}$$

$$\mathcal{C}_i(u) = \tilde{L}_1^i(u), \quad \mathcal{D}_i^j(u) = \tilde{L}_i^j(u), \quad i,j = 2,...,n. \tag{2.24}$$

The transfer matrices $T(u)$ become

$$T(u) = \mathcal{A}(u) + \sum_{i=2}^{n} \mathcal{D}_i^i(u). \tag{2.25}$$

Any nonzero vector $|\Omega\rangle \in \mathrm{Fun}(W)[\Lambda]$ is of form $|\Omega\rangle = g(\lambda)|\Lambda\rangle$, for some meromorphic function $g \neq 0$. When $N = n \times l$, the weight Λ can be written in the form

$$\Lambda = nl\Lambda_1 = l \sum_{k=1}^{n-1} (\epsilon_1 - \epsilon_{k+1}). \tag{2.26}$$

Noting (2.19), the zero-weight vector space is spanned by the vectors of the following form:

$$\mathcal{B}_{i_{N_1}}(v_{N_1}) \mathcal{B}_{i_{N_1-1}}(v_{N_1-1}) \cdots \mathcal{B}_{i_1}(v_1)|\Omega\rangle, \tag{2.27}$$

where $N_1 = (n-1) \times l$ and among the indices $\{i_k | k = 1,...,N_1\}$, the number of $i_k = j$, denoted by $\#(j)$, should be

$$\#(j) = l, \quad j = 2,...,n. \tag{2.28}$$

The above states (2.27) actually belong to the zero-weight space $W[0]$.[19] Let us introduce the following set of integers for convenience:

$$N_i = (n-i) \times l, \quad i = 1,2,...,n-1, \tag{2.29}$$

and $[n(n-1)/2]l$ parameters $\{\{v_k^{(i)} | k = 1,2,...,N_{i+1}\}, i = 0,1,...,n-2\}$. The parameters $\{\{v_k^{(i)}\}\}$ will be specified later by the Bethe ansatz equations (2.40). We will seek the common eigenvectors of the *transfer matrices* $T(u)$ in the form

$$|\lambda;\{v_k\}\rangle=\sum_{i_1,\cdots,i_{N_1}=2}^{n} F^{i_1,i_2,\ldots,i_{N_1}}(\lambda;\{v_k\})\mathcal{B}_{i_{N_1}}(v_{N_1})\mathcal{B}_{i_{N_1-1}}(v_{N_1-1})\cdots\mathcal{B}_{i_1}(v_1)|\Omega\rangle, \quad (2.30)$$

with the restriction condition (2.28). We adopt hereafter the convention

$$v_k=v_k^{(0)}, \quad k=1,2,\ldots,(n-1)\times l. \quad (2.31)$$

Let us introduce n parameters $\{\alpha^{(i)}|i=1,\ldots,n\}$ to specify quasivacua of each step of the nested Bethe ansatz,[19] and another set of parameters related to them,

$$\overline{\alpha}^{(i)}=\frac{1}{(n-i-1)}\left\{\alpha^{(i+1)}-\frac{\sum_{k=i+1}^{n}\alpha^{(k)}}{n-i}\right\}, \quad i=0,\ldots,n-2. \quad (2.32)$$

Choosing the function of $g(\lambda)$,

$$g(\lambda)=e^{\sqrt{-1}\pi\langle\alpha^{(1)}\epsilon_1,\lambda\rangle}\prod_{j=2}^{n}\left\{\prod_{k=1}^{l}\frac{\sigma(\lambda_{j1}+kw)}{\sigma(w)}\right\}, \quad (2.33)$$

then we have the following.

Theorem 2 (Ref. 19): *With properly chosen coefficients* $F^{i_1,i_2,\ldots,i_{N_1}}(\lambda;\{v_k\})$, *we obtain eigenvectors of the transfer matrices*

$$T(u)|\lambda;\{v_k\}\rangle=t(u;\{v_k\})|\lambda;\{v_k\}\rangle, \quad (2.34)$$

with the eigenvalue

$$t(u;\{v_k\})=e^{\sqrt{-1}\pi(1-n)\overline{\alpha}w}\left\{\prod_{k=1}^{N_1}\frac{\sigma(v_k-u+w)}{\sigma(v_k-u)}\right\}+e^{\sqrt{-1}\pi\overline{\alpha}w}\left\{\prod_{k=1}^{N_1}\frac{\sigma(u-v_k+w)}{\sigma(u-v_k)}\right\}$$
$$\times\left\{\prod_{k=1}^{m}\frac{\sigma(u-p_k)}{\sigma(u-q_k)}\right\}t^{(1)}(u;\{v_k^{(1)}\}). \quad (2.35)$$

The functions $t^{(i)}(u;\{v_k^{(i)}\})$ *are given recursively,*

$$t^{(i)}(u;\{v_k^{(i)}\})=e^{\sqrt{-1}\pi(i+1-n)\overline{\alpha}^{(i)}w}\left\{\prod_{k=1}^{N_{i+1}}\frac{\sigma(v_k^{(i)}-u+w)}{\sigma(v_k^{(i)}-u)}\right\}+e^{\sqrt{-1}\pi\overline{\alpha}^{(i)}w}\left\{\prod_{k=1}^{N_{i+1}}\frac{\sigma(u-v_k^{(i)}+w)}{\sigma(u-v_k^{(i)})}\right\}$$
$$\times\left\{\prod_{k=1}^{N_i}\frac{\sigma(u-p_k^{(i)})}{\sigma(u-q_k^{(i)})}\right\}t^{(i+1)}(u;\{v_k^{(i+1)}\}), \quad i=0,1,\ldots,n-2, \quad (2.36)$$

$$t^{(n-1)}(u)=1, \quad t^{(0)}(u;\{v_k^{(0)}\})=t(u;\{v_k\}), \quad (2.37)$$

where $\overline{\alpha}^{(i)}$, $i=0,1,\ldots,n-2$ *are given by (2.32),* $\overline{\alpha}^{(0)}=\overline{\alpha}$, $N_0=m$ *and*

$$p_k^{(0)}=p_k=z_k, \quad q_k^{(0)}=q_k=z_k-l_kw, \quad k=1,2,\ldots,m, \quad (2.38)$$

$$p_k^{(i)}=v_k^{(i-1)}, \quad q_k^{(i)}=v_k^{(i-1)}-w, \quad i=1,2,\ldots,n-2, \quad k=1,2,\ldots,N_i. \quad (2.39)$$

The $\{\{v_k^{(i)}\}\}$ *satisfy the following Bethe ansatz equations:*

$$e^{\sqrt{-1}\pi(i-n)\bar{\alpha}^{(i)}w}\left\{\prod_{k=1,k\neq s}^{N_{i+1}}\frac{\sigma(v_k^{(i)}-v_s^{(i)}+w)}{\sigma(v_k^{(i)}-v_s^{(i)}-w)}\right\}=\left\{\prod_{k=1}^{N_i}\frac{\sigma(v_s^{(i)}-p_k^{(i)})}{\sigma(v_s^{(i)}-q_k^{(i)})}\right\}t^{(i+1)}(v_s^{(i)};\{v_k^{(i+1)}\}). \tag{2.40}$$

In principle one can construct explicit expression of the coefficients of $F^{i_1,i_2,\cdots,i_{N_1}}(\lambda;\{v_k\})$ (for details we refer the reader to Ref. 19).

We conclude this section with some remarks on functional dependence of the states $|\lambda;\{v_k\}\rangle$. By construction (2.23), the operators $\{\mathcal{B}_i\}$ are the functions of $\{\lambda_i-\lambda_j\}$ because of the definition of the R-matrix (2.9)–(2.10), and the states can be written in the following form:

$$|\lambda;\{v_k\}\rangle=\exp\left\{\sum_{i=1}^{n}\sqrt{-1}\pi\alpha^{(i)}\lambda_i\right\}\overline{|\lambda;\{v_k\}\rangle}. \tag{2.41}$$

Here $\overline{|\lambda;\{v_k\}\rangle}$ is a meromorphic function of $\{\lambda_i\}$ and has the following properties:

$$\overline{|\lambda_1+c,\ldots,\lambda_n+c;\{v_k\}\rangle}=\overline{|\lambda_1,\ldots,\lambda_n;\{v_k\}\rangle},\quad \text{for } \forall c\in\mathbb{C}, \tag{2.42}$$

$$\overline{|\lambda_1,\ldots,\lambda_{i-1},\lambda_i+1,\lambda_{i+1},\ldots\lambda_n;\{v_k\}\rangle}=(-1)^{l(n-1)}\overline{|\lambda_1,\ldots,\lambda_n;\{v_k\}\rangle},\quad i=1,\ldots,n. \tag{2.43}$$

III. RUIJSENAARS–SCHNEIDER MODELS ASSOCIATED WITH A_{n-1} ROOT SYSTEM

A. The elliptic case

Let us choose an $E_{\tau,\eta}(sl_n)$-module W, a special one which corresponds to the Young diagram $\overbrace{\square\square\cdots\square}^{nl}$,

$$W=V_{\Lambda^{(nl)}}(0), \tag{3.1}$$

in which the evaluation point z_1 is set to 0. Then the zero-weight space of this module is one-dimensional: $|\lambda;\{v_k\}\rangle=\tilde{\Phi}_{\mathrm{RS}}(\lambda;\{\alpha^{(i)}\})e_0$, $e_0\in W[0]$ and it does not depend on λ_i. The associated *transfer matrices* can be written as[20]

$$T(u)=\frac{\sigma(u+lw)}{\sigma(u+nlw)}M. \tag{3.2}$$

The operator M is independent of u and is given by

$$M=\sum_{i=1}^{n}\left\{\prod_{j\neq i}\frac{\sigma(\lambda_{ij}+lw)}{\sigma(\lambda_{ij})}\Gamma_i\right\}. \tag{3.3}$$

Here $\{\Gamma_i\}$ are difference operators: $\Gamma_i f(\lambda)=f(\lambda-w\hat{i})$. Noting (2.41)–(2.43) and (3.14), we find

$$M\tilde{\Phi}_{\mathrm{RS}}=\tilde{H}_{\mathrm{RS}}\tilde{\Phi}_{\mathrm{RS}}=\epsilon_{\mathrm{RS}}\tilde{\Phi}_{\mathrm{RS}}. \tag{3.4}$$

The difference operator $\tilde{H}_{\mathrm{RS}}$ is given by

$$\tilde{H}_{\mathrm{RS}}=\sum_{i=1}^{n}\left\{\prod_{j\neq i}\frac{\sigma(\lambda_{ij}+lw)}{\sigma(\lambda_{ij})}e^{-w(\partial/\partial\lambda_i)}\right\}. \tag{3.5}$$

In order to apply Theorem 2 to RS model, hereafter we restrict the parameters τ and w as follows:

$$\tau=\sqrt{-1}\kappa,\quad \kappa\in\mathbb{R},\quad \kappa>0,\quad w=\sqrt{-1}g, \tag{3.6}$$

where g is a real number. This is necessary for the reality of the Hamiltonian. Because the parameters $\{\lambda_i\}$ will play the role of the canonical coordinates, we further restrict $\lambda_i \in \mathbb{R}$. In terms of the specified parameters, $\tilde{H}_{\mathrm{RS}}$ becomes

$$\tilde{H}_{\mathrm{RS}}=\sum_{i=1}^{n}\left\{\prod_{j\neq i}\frac{\sigma(\lambda_{ij}+\sqrt{-1}gl)}{\sigma(\lambda_{ij})}e^{-\sqrt{-1}g(\partial/\partial\lambda_i)}\right\}. \tag{3.7}$$

The resulting difference operator $\tilde{H}_{\mathrm{RS}}$ will be the Hamiltonian of elliptic A_{n-1} type RS model[2] with the special *coupling constant* $\gamma=\sqrt{-1}gl$, up to conjugation by a function.[25,29] Suppose $\tilde{\Phi}_{\mathrm{RS}}$ and ϵ_{RS} are an eigenfunction and the corresponding eigenvalue of $\tilde{H}_{\mathrm{RS}}$,

$$\tilde{H}_{\mathrm{RS}}\tilde{\Phi}_{\mathrm{RS}}=\epsilon_{\mathrm{RS}}\tilde{\Phi}_{\mathrm{RS}}. \tag{3.8}$$

Let us introduce another function Φ_{RS},

$$\Phi_{\mathrm{RS}}=e^{-\Psi_{\mathrm{RS}}}\tilde{\Phi}_{\mathrm{RS}},\quad \Psi_{\mathrm{RS}}=\frac{1}{2}\ln\prod_{i\neq j}\left\{\prod_{k=1}^{l}\frac{\sigma(\lambda_{ij}-\sqrt{-1}gk)}{\sigma(\sqrt{-1}g)}\right\}, \tag{3.9}$$

associated to $\tilde{\Phi}_{\mathrm{RS}}$. Then Φ_{RS} is an eigenfunction of the similarity transformed Hamiltonian H_{RS} with the same eigenvalue ϵ_{RS},

$$H_{\mathrm{RS}}\Phi_{\mathrm{RS}}=\epsilon_{\mathrm{RS}}\Phi_{\mathrm{RS}},\quad H_{\mathrm{RS}}=e^{-\Psi_{\mathrm{RS}}}\tilde{H}_{\mathrm{RS}}e^{\Psi_{\mathrm{RS}}}, \tag{3.10}$$

$$H_{\mathrm{RS}}=\sum_{i=1}^{n}\left\{\prod_{j\neq i}\frac{\sigma(\lambda_{ji}-\sqrt{-1}gl)}{\sigma(\lambda_{ji})}\right\}^{1/2}e^{-\sqrt{-1}g(\partial/\partial\lambda_i)}\left\{\prod_{j\neq i}\frac{\sigma(\lambda_{ij}-\sqrt{-1}gl)}{\sigma(\lambda_{ij})}\right\}^{1/2}. \tag{3.11}$$

One finds that H_{RS} is the Hamiltonian of elliptic A_{n-1} type RS model[2] with the special *coupling constant* $\gamma=\sqrt{-1}gl$.

Now, we consider the spectrum of $\tilde{H}_{\mathrm{RS}}$. Theorem 2 enables us to obtain the spectrum of the Hamiltonian of the elliptic A_{n-1} Ruijsenaars–Schneider model as well as the eigenfunctions, in terms of the associated transfer matrices (3.2). Since we have already taken the special $E_{\tau,\eta}(sl_n)$-module $W=V_{\Lambda^{(n\times l)}}(0)$, thanks to Theorem 2, the eigenvalues are given by (2.34) and (2.35) but with special values of the parameters

$$m=N_0=1,\quad p_1^{(0)}=z_1=0,\quad q_1^{(0)}=-\sqrt{-1}gnl. \tag{3.12}$$

Since M is independent of u, we can evaluate the eigenvalues of $T(u)$ at $u=z_1=0$. Then the expression of the eigenvalue $t(u;\{v_k\})$ simplifies drastically, for the second term on the right-hand side of (2.35) [the one depending on the eigenvalue of the reduced transfer matrices $t^{(1)}\times(u;\{v_k^{(1)}\})$] vanishes because $u-p_1^{(0)}=0$.

Note that $\tilde{H}_{\mathrm{RS}}(H_{\mathrm{RS}})$ has periodic coefficients with $\lambda_i\to\lambda_i+1$, and therefore preserves the space of Bloch functions such that

$$\psi(\lambda_1,\ldots,\lambda_{i-1},\lambda_i+1,\lambda_{i+1},\ldots,\lambda_n)=\pm(-1)^{l(n-1)}\psi(\lambda_1,\ldots,\lambda_n). \tag{3.13}$$

The (quasi)periodicity requires integer $\alpha^{(i)}$, $\alpha^{(i)}\in\mathbb{Z}$. Noting the relation (2.32), in order to get one-to-one correspondence between $\{\alpha^{(i)}\}$ and $\{\overline{\alpha^{(i)}}\}$, we need further choose

$$\alpha^{(i)}\in\mathbb{Z}^+,\quad i=1,\ldots,n-1,\quad \text{and}\quad \alpha^{(n)}=-\sum_{k=1}^{n-1}\alpha^{(k)}. \tag{3.14}$$

Finally, we obtain the eigenvalues $\epsilon_{RS}(\{v_k\})$ of $\tilde{H}_{RS}$ (3.4):

$$e^{\pi(n-1)\overline{\alpha}g}\frac{\sigma(\sqrt{-1}gnl)}{\sigma(\sqrt{-1}gl)}\left\{\prod_{k=1}^{(n-1)\times l}\frac{\sigma(v_k+\sqrt{-1}g)}{\sigma(v_k)}\right\}, \tag{3.15}$$

where $\{\{v_k^{(i)}\}\}$ satisfy the Bethe ansatz equations

$$e^{\pi(n-i)\overline{\alpha}^{(i)}g}\left\{\prod_{k=1,k\neq s}^{N_{i+1}}\frac{\sigma(v_k^{(i)}-v_s^{(i)}+\sqrt{-1}g)}{\sigma(v_k^{(i)}-v_s^{(i)}-\sqrt{-1}g)}\right\}=\left\{\prod_{k=1}^{N_i}\frac{\sigma(v_s^{(i)}-p_k^{(i)})}{\sigma(v_s^{(i)}-q_k^{(i)})}\right\}t^{(i+1)}(v_s^{(i)};\{v_k^{(i+1)}\}),$$

$$i=0,1,\ldots,n-2. \tag{3.16}$$

The functions $t^{(i)}(u)$ appearing in (3.16) are given by the same recurrence relations as (2.36)–(2.37), but with the special $N_0=1$, $p_1^{(0)}=0$, and $q_1^{(0)}=-\sqrt{-1}gnl$ and replacing w by $\sqrt{-1}g$. Substituting the expression of the function $t^{(i+1)}(u)$ (2.36) into the Bethe ansatz equations (3.16), noting the conditions (3.12) and (2.39), we have the following.

Proposition 1: The eigenvalues of the Hamiltonian (3.11) of the elliptic RS model associated with A_{n-1} root system with the discrete coupling constant $\gamma=\sqrt{-1}gl$ (l being an integer) are

$$\epsilon_{\mathrm{RS}}=e^{\pi(n-1)\overline{\alpha}g}\frac{\sigma(\sqrt{-1}gnl)}{\sigma(\sqrt{-1}gl)}\left\{\prod_{k=1}^{(n-1)\times l}\frac{\sigma(v_k+\sqrt{-1}g)}{\sigma(v_k)}\right\}. \tag{3.17}$$

The $[n(n-1)/2]l$ parameters $\{\{v_k^{(i)}\}\}$ satisfy the Bethe ansatz equations

$$e^{\pi n\overline{\alpha}g}\prod_{k=1,k\neq s}^{N_1}\frac{\sigma(v_k-v_s+\sqrt{-1}g)}{\sigma(v_k-v_s-\sqrt{-1}g)}=e^{\pi(n-2)\overline{\alpha}^{(1)}g}\frac{\sigma(v_s)}{\sigma(v_s+\sqrt{-1}gnl)}\prod_{k=1}^{N_2}\frac{\sigma(v_k^{(1)}-v_s+\sqrt{-1}g)}{\sigma(v_k^{(1)}-v_s)}, \tag{3.18}$$

$$e^{\pi(n-i)\overline{\alpha}^{(i)}g}\prod_{k=1,k\neq s}^{N_{i+1}}\frac{\sigma(v_k^{(i)}-v_s^{(i)}+\sqrt{-1}g)}{\sigma(v_k^{(i)}-v_s^{(i)}-\sqrt{-1}g)}=e^{\pi(n-i-2)\overline{\alpha}^{(i+1)}g}\prod_{k=1}^{N_i}\frac{\sigma(v_s^{(i)}-v_k^{(i-1)})}{\sigma(v_s^{(i)}-v_k^{(i-1)}+\sqrt{-1}g)}$$
$$\times\prod_{k=1}^{N_{i+2}}\frac{\sigma(v_k^{(i+1)}-v_s^{(i)}+\sqrt{-1}g)}{\sigma(v_k^{(i+1)}-v_s^{(i)})},\quad i=1,\ldots,n-3, \tag{3.19}$$

$$e^{2\pi\overline{\alpha}^{(n-2)}g}\prod_{k=1,k\neq s}^{N_{n-1}}\frac{\sigma(v_k^{(n-2)}-v_s^{(n-2)}+\sqrt{-1}g)}{\sigma(v_k^{(n-2)}-v_s^{(n-2)}-\sqrt{-1}g)}=\prod_{k=1}^{N_{n-2}}\frac{\sigma(v_s^{(n-2)}-v_k^{(n-3)}}{\sigma(v_s^{(n-2)}-v_k^{(n-3)}+\sqrt{-1}g)}. \tag{3.20}$$

The parameters $\overline{\alpha}^{(i)}$, $i=0,1,\ldots,n-2$ and $\overline{\alpha}^{(0)}=\overline{\alpha}$ are given by the relation (2.32) from $n-1$ arbitrary non-negative integers $\{\alpha^{(i)}\in\mathbb{Z}^+|i=1,\ldots,n-1\}$.

Our formula of eigenvalues is the elliptic generalization of the *third formulas* in the sense of Felder *et al.*[22] Taking complex conjugation of the Bethe ansatz equations (3.18)–(3.20), noting the property (A5), we find that the solutions $\{\{v_k^{(i)}\}\}$ are all pure imaginary numbers. This ensures that the eigenvalues ϵ_{RS} are real. By construction from the nested Bethe ansatz method and the relation (3.9), we know that the corresponding eigenfunction is a meromorphic function of $\{\lambda_i\}$ and satisfies the following properties:

$$\Phi_{\mathrm{RS}}(\lambda_1,\ldots,\lambda_{i-1},\lambda_i+1,\lambda_{i+1},\ldots,\lambda_n;\{\alpha^{(i)}\})=(-1)^{\alpha^{(i)}}\Phi_{\mathrm{RS}}(\lambda;\{\alpha^{(i)}\}). \tag{3.21}$$

B. The trigonometric case

Here we consider the trigonometric RS model associated with A_{n-1} root system. The corresponding Hamiltonian with the discrete *coupling constant* $\gamma=\sqrt{-1}gl$ is given

$$H_{\mathrm{RS}}=\sum_{i=1}^{n}\left\{\prod_{j\neq i}\frac{\sin\pi(\lambda_{ji}-\sqrt{-1}gl)}{\sin\pi(\lambda_{ji})}\right\}^{1/2}e^{-\sqrt{-1}g(\partial/\partial\lambda_i)}\left\{\prod_{j\neq i}\frac{\sin\pi(\lambda_{ij}-\sqrt{-1}gl)}{\sin\pi(\lambda_{ij})}\right\}^{1/2}. \tag{3.22}$$

Taking the trigonometric limit $\kappa\to+\infty$ ($\tau\to+\sqrt{-1}\infty$), one finds that

$$\frac{\sigma(x)}{\sigma(y)}\to\frac{\sin\pi x}{\sin\pi y},\quad \text{when}\ \ \kappa\to+\infty, \tag{3.23}$$

from the product expression (A1) of the σ-function. The trigonometric Hamiltonian (3.22) can be obtained from the elliptic one (3.11) by taking limit $\kappa\to+\infty$. Consequently, we can find the spectrum of the Hamiltonian of the trigonometric RS model associated with A_{n-1} type root system by taking the trigonometric limit of the elliptic one. Noting that the solutions to the Bethe ansatz equations (3.18)–(3.20) $\{\{v_k^{(i)}\}\}$ are all pure imaginary numbers, let us introduce $[n(n-1)/2]l$ real parameters $\{\{\overline{v}_k^{(i)}\}\}$ associated to $[n(n-1)/2]l$ pure imaginary parameters $\{\{v_k^{(i)}\}\}$ as follows:

$$v_k^{(i)}=\sqrt{-1}\overline{v}_k^{(i)},\quad \overline{v}_k^{(i)}\in\mathbb{R}. \tag{3.24}$$

Finally, we have

Proposition 2: The eigenvalues of the Hamiltonian (3.22) of the trigonometric RS model associated with A_{n-1} root system with the discrete coupling constant $\gamma=\sqrt{-1}gl$ are

$$\epsilon_{\mathrm{RS}}=e^{\pi(n-1)\overline{\alpha}g}\frac{\sinh\pi(nlg)}{\sinh\pi(lg)}\left\{\prod_{k=1}^{(n-1)\times l}\frac{\sinh\pi(\overline{v}_k^{(0)}+g)}{\sinh\pi(\overline{v}_k^{(0)})}\right\}. \tag{3.25}$$

The $[n(n-1)/2]l$ real parameters $\{\{\overline{v}_k^{(i)}\}\}$ satisfy the Bethe ansatz equations

$$e^{\pi n\overline{\alpha}g}\left\{\prod_{k=1,k\neq s}^{N_1}\frac{\sinh\pi(\overline{v}_k^{(0)}-\overline{v}_s^{(0)}+g)}{\sin\pi(\overline{v}_k^{(0)}-\overline{v}_s^{(0)}-g)}\right\}=e^{\pi(n-2)\overline{\alpha}^{(1)}g}\frac{\sinh\pi(\overline{v}_s^{(0)})}{\sinh\pi(\overline{v}_s^{(0)}+nlg)}\times\left\{\prod_{k=1}^{N_2}\frac{\sinh\pi(\overline{v}_k^{(1)}-\overline{v}_s^{(0)}+g)}{\sinh\pi(\overline{v}_k^{(1)}-\overline{v}_s^{(0)})}\right\}, \tag{3.26}$$

$$e^{\pi(n-i)\overline{\alpha}^{(i)}g}\left\{\prod_{k=1,k\neq s}^{N_{i+1}}\frac{\sinh\pi(\overline{v}_k^{(i)}-\overline{v}_s^{(i)}+g)}{\sinh\pi(\overline{v}_k^{(i)}-\overline{v}_s^{(i)}-g)}\right\}=e^{\pi(n-i-2)\overline{\alpha}^{(i+1)}g}\left\{\prod_{k=1}^{N_i}\frac{\sinh\pi(\overline{v}_s^{(i)}-\overline{v}_k^{(i-1)})}{\sinh\pi(\overline{v}_s^{(i)}-\overline{v}_k^{(i-1)}+g)}\right\}\times\left\{\prod_{k=1}^{N_{i+2}}\frac{\sinh\pi(\overline{v}_k^{(i+1)}-\overline{v}_s^{(i)}+g)}{\sinh\pi(\overline{v}_k^{(i+1)}-\overline{v}_s^{(i)})}\right\},$$

$$i=1,\ldots,n-3, \tag{3.27}$$

$$e^{2\pi\overline{\alpha}^{(n-2)}g}\left\{\prod_{k=1,k\neq s}^{N_{n-1}}\frac{\sinh\pi(\overline{v}_k^{(n-2)}-\overline{v}_s^{(n-2)}+g)}{\sinh\pi(\overline{v}_k^{(n-2)}-\overline{v}_s^{(n-2)}-g)}\right\}=\left\{\prod_{k=1}^{N_{n-2}}\frac{\sinh\pi(\overline{v}_s^{(n-2)}-\overline{v}_k^{(n-3)})}{\sinh\pi(\overline{v}_s^{(n-2)}-\overline{v}_k^{(n-3)}+g)}\right\}. \tag{3.28}$$

Here the parameters $\overline{\alpha}^{(i)}$, $i=0,1,\ldots,n-2$ and $\overline{\alpha}=\overline{\alpha}^{0}$ are given by the relation (2.32) from $n-1$ arbitrary non-negative integers $\{\alpha^{(i)}\in\mathbb{Z}^{+}|i=1,\ldots,n-1\}$.

Our formula of eigenvalues is the *trigonometric* generalization of the *third formulas* in the sense of Felder *et al.*[22] Similarly to the elliptic case, we know that the corresponding eigenfunction has the same quasiperiodic properties (3.21).

C. The rational case

The Hamiltonian of the rational RS model associated with A_{n-1} root system reads as

$$H_{RS}=\sum_{i=1}^{n}\left\{\prod_{j\neq i}\left(1-\frac{\sqrt{-1}gl}{\lambda_{ji}}\right)\right\}^{1/2}e^{-\sqrt{-1}g(\partial/\partial\lambda_i)}\left\{\prod_{j\neq i}\left(1-\frac{\sqrt{-1}gl}{\lambda_{ij}}\right)\right\}^{1/2}. \tag{3.29}$$

If one rescales

$$\lambda_i\to\delta\lambda_i,\quad \overline{\alpha}^{(i)}\to\frac{1}{\pi\delta}\overline{\alpha}^{(i)},\quad g\to\delta g, \tag{3.30}$$

$$\overline{v}_k^{(i)}\to\delta\overline{v}_k^{(i)}, \tag{3.31}$$

and takes the limit: $\delta\to 0$ (we call it the rational limit), the Hamiltonian (3.29) of the rational RS model can be obtained from the trigonometric one (3.22). Therefore we can find the spectrum of the Hamiltonian of the rational RS model associated with A_{n-1} root system by taking the rational limit of Proposition 2. Finally we have the following.

Proposition 3: The eigenvalues of the Hamiltonian (3.29) of the rational RS model associated with A_{n-1} root system with the discrete coupling constant $\gamma=\sqrt{-1}gl$ are

$$\epsilon_{\mathrm{RS}}=ne^{(n-1)\overline{\alpha}g}\left\{\prod_{k=1}^{(n-1)\times l}\frac{\overline{v}_k^{(0)}+g}{\overline{v}_k^{(0)}}\right\}. \tag{3.32}$$

The $[n(n-1)/2]l$ real parameters $\{\{\overline{v}_k^{(i)}\}\}$ satisfy the Bethe ansatz equations

$$e^{n\overline{\alpha}g}\left\{\prod_{k=1,k\neq s}^{N_1}\frac{(\overline{v}_k^{(0)}-\overline{v}_s^{(0)}+g)}{(\overline{v}_k^{(0)}-\overline{v}_s^{(0)}-g)}\right\}=e^{(n-2)\overline{\alpha}^{(1)}g}\frac{\overline{v}_s^{(0)}}{\overline{v}_s^{(0)}+nlg}\left\{\prod_{k=1}^{N_2}\frac{(\overline{v}_k^{(1)}-\overline{v}_s+g)}{(\overline{v}_k^{(1)}-\overline{v}_s)}\right\}, \tag{3.33}$$

$$\begin{aligned}e^{(n-i)\overline{\alpha}^{(i)}g}\left\{\prod_{k=1,k\neq s}^{N_{i+1}}\frac{(\overline{v}_k^{(i)}-\overline{v}_s^{(i)}+g)}{(\overline{v}_k^{(i)}-\overline{v}_s^{(i)}-g)}\right\}&=e^{(n-i-2)\overline{\alpha}^{(i+1)}g}\left\{\prod_{k=1}^{N_i}\frac{(\overline{v}_s^{(i)}-\overline{v}_k^{(i-1)})}{(\overline{v}_s^{(i)}-\overline{v}_k^{(i-1)}+g)}\right\}\\&\times\left\{\prod_{k=1}^{N_{i+2}}\frac{(\overline{v}_k^{(i+1)}-\overline{v}_s^{(i)}+g)}{(\overline{v}_k^{(i+1)}-\overline{v}_s^{(i)})}\right\},\quad i=1,\ldots,n-3,\end{aligned} \tag{3.34}$$

$$e^{2\overline{\alpha}^{(n-2)}g}\left\{\prod_{k=1,k\neq s}^{N_{n-1}}\frac{(\overline{v}_k^{(n-2)}-\overline{v}_s^{(n-2)}+g)}{(\overline{v}_k^{(n-2)}-\overline{v}_s^{(n-2)}-g)}\right\}=\left\{\prod_{k=1}^{N_{n-2}}\frac{(\overline{v}_s^{(n-2)}-\overline{v}_k^{(n-3)})}{(\overline{v}_s^{(n-2)}-\overline{v}_k^{(n-3)}+g)}\right\}. \tag{3.35}$$

Here the parameters $\overline{\alpha}^{(i)}$, $i=0,1,\ldots,n-2$ and $\overline{\alpha}^{(0)}=\overline{\alpha}$ are given by the relation (2.32) from $n-1$ arbitrary non-negative real numbers $\{\alpha^{(i)}\in\mathbb{R}^+|i=1,\ldots,n-1\}$.

Our formula of eigenvalues is the rational generalization of the *third formulas* in the sense of Felder *et al.*[22] The rescalings (3.30) and (3.31) and the rational limit lead to that the coefficients of the Hamiltonian (3.29) are no longer periodic (cf. the elliptic and trigonometric case). The (quasi)periodic properties (3.21) of the eigenfunction now are replaced by the following asymptotic properties:

$$\Phi_{\mathrm{RS}}\propto e^{\sqrt{-1}\alpha^i\lambda_i},\quad \lambda_i\to\infty. \tag{3.36}$$

Namely, the corresponding eigenfunctions are bounded when $\lambda_i\to\infty$ on the real axis.

IV. CALOGERO–MOSER SYSTEMS ASSOCIATED WITH A_{n-1} ROOT SYSTEM

In this section, we will study all types of CM models associated with A_{n-1} root system by taking "nonrelativistic" limit:[21] $g\to 0$ of the corresponding RS models which have already been studied in Sec. III.

A. Elliptic potential

Taking the *nonrelativistic limit* of the Hamiltonian (3.7) and noting the asymptotic properties of σ-function (2.5), we obtain

$$\widetilde{H}_{\mathrm{RS}}=n+\frac{g^2}{2}\widetilde{H}_{\mathrm{CM}}+O(g^3),\quad g\to 0. \tag{4.1}$$

The resulting differential operator $\widetilde{H}_{\mathrm{CM}}$ is given by

$$\widetilde{H}_{\mathrm{CM}}=-\sum_{i=1}^{n}\frac{\partial^2}{(\partial\lambda_i)^2}+2l\sum_{i\neq j}^{n}\zeta(\lambda_{ij})\frac{\partial}{\partial\lambda_i}-l^2\sum_{i\neq j}\frac{\sigma''(\lambda_{ij})}{\sigma(\lambda_{ij})}-l^2\sum_{i\neq j\neq k}\zeta(\lambda_{ij})\zeta(\lambda_{ik}), \tag{4.2}$$

where $\sigma''(t)=[\partial^2/(\partial u)^2]\sigma(u)|_{u=t}$ and the function ζ is defined in (2.4). We can further transform $\widetilde{H}_{\mathrm{CM}}$ to a more familiar form. Let us suppose $\widetilde{\Phi}$ and ϵ_{CM} are an eigenfunction and the corresponding eigenvalue of $\widetilde{H}_{\mathrm{CM}}$, namely,

$$\widetilde{H}_{\mathrm{CM}}\widetilde{\Phi}=\epsilon_{\mathrm{CM}}\widetilde{\Phi}. \tag{4.3}$$

At the same time, we introduce another function Φ,

$$\Phi=e^{-\Psi}\widetilde{\Phi},\quad \Psi=\ln\prod_{i<j}(\sigma(\lambda_{ij}))^l, \tag{4.4}$$

associated to $\widetilde{\Phi}$. Then Φ is an eigenfunction of the Hamiltonian H_{CM} with the same eigenvalue ϵ_{CM},

$$H_{\mathrm{CM}}\Phi=\epsilon_{\mathrm{CM}}\Phi,\quad H_{\mathrm{CM}}=e^{-\Psi}\widetilde{H}_{\mathrm{CM}}e^{\Psi}=-\sum_{i=1}^{n}\frac{\partial^2}{(\partial\lambda_i)^2}+l(l+1)\sum_{i\neq j}\wp(\lambda_{ij}), \tag{4.5}$$

where the function $\wp$ is defined in (2.4). One finds that H_{CM} is exactly the Hamiltonian of elliptic CM model associated with A_{n-1} root system[3,4] with the *coupling constant* $l+1$. (Traditionally, the *coupling constant* of the Hamiltonian: $H_{\mathrm{CM}}=-\Sigma_{i=1}^{n}[\partial^2/(\partial\lambda_i)^2]+\gamma(\gamma-1)\Sigma_{i\neq j}\wp(\lambda_{ij})$ of CM model is set to γ.)

Now we study the asymptotic properties of the eigenvalues of $\widetilde{H}_{\mathrm{RS}}$ (3.17) and the associated Bethe ansatz equations (3.18)–(3.20). Let the solution to the Bethe ansatz equations (3.18)–(3.20) have the following form:

$$v_k^{(i)}=x_k^{(i)}+\sqrt{-1}gy_k^{(i)}-g^2z_k^{(i)}+O(g^3),\quad g\to 0. \tag{4.6}$$

Noting the asymptotic properties of σ-function (2.5), the Eq. (3.17) becomes

$$\begin{aligned}\epsilon_{\mathrm{RS}}=n+\sqrt{-1}gn\left((1-n)\sqrt{-1}\pi\overline{\alpha}+\sum_{k=1}^{N_1}\zeta(x_k^{(0)})\right)+\frac{g^2}{2}\left\{n\sum_{k=1}^{N_1}(2y_k^{(0)}+1)\wp(x_k^{(0)})\right.\\ \left.-\frac{(n+1)n(n-1)l^2}{3}\frac{\sigma'''(0)}{\sigma'(0)}-n\left((1-n)\sqrt{-1}\pi\overline{\alpha}+\sum_{k=1}^{N_1}\zeta(x_k^{(0)})\right)^2\right\}+O(g^3).\end{aligned} \tag{4.7}$$

The Bethe ansatz equations (3.18)–(3.20) at the first order of g become

$$2\sum_{k=1,k\neq s}^{N_1}\zeta(x_k^{(0)}-x_s^{(0)})-n\sqrt{-1}\pi\overline{\alpha}=(2-n)\sqrt{-1}\pi\overline{\alpha}^{(1)}-nl\zeta(x_s^{(0)})+\sum_{k=1}^{N_2}\zeta(x_k^{(1)}-x_s^{(0)}), \tag{4.8}$$

$$2\sum_{k=1,k\neq s}^{N_{i+1}}\zeta(x_k^{(i)}-x_s^{(i)})+(i-n)\sqrt{-1}\pi\overline{\alpha}^{(i)} =(i+2-n)\sqrt{-1}\pi\overline{\alpha}^{(i+1)}-\sum_{k=1}^{N_i}\zeta(x_s^{(i)}-x_k^{(i-1)})+\sum_{k=1}^{N_{i+2}}\zeta(x_k^{(i+1)}-x_s^{(i)}),\quad i=1,...,n-3, \tag{4.9}$$

$$2\sum_{k=1,k\neq s}^{N_{n-1}}\zeta(x_k^{(n-2)}-x_s^{(n-2)})-2\sqrt{-1}\pi\overline{\alpha}^{(n-2)}=-\sum_{k=1}^{N_{n-2}}\zeta(x_s^{(n-2)}-x_k^{(n-3)}). \tag{4.10}$$

Sum up with s for each equation of (4.8)–(4.10). Then taking the summation of all the equations and noting the parity property of ζ-function (2.4), we find

$$\sum_{k=1}^{N_1}\zeta(x_k^{(0)})+(1-n)\sqrt{-1}\pi\overline{\alpha}=0. \tag{4.11}$$

This means that the first order of g term of ϵ_{RS} in (4.7) is vanishing which is in conformity with (4.1).

The Bethe ansatz equations (3.18)–(3.20) at the second order of g are

$$4\sum_{k=1,k\neq s}^{N_1}(y_s^{(0)}-y_k^{(0)})\wp(x_k^{(0)}-x_s^{(0)}) =nl(2y_s^{(0)}+nl)\wp(x_s^{(0)})-\sum_{k=1}^{N_2}(2y_k^{(1)}-2y_s^{(0)}+1)\wp(x_k^{(1)}-x_s^{(0)}), \tag{4.12}$$

$$4\sum_{k=1,k\neq s}^{N_{i+1}}(y_s^{(i)}-y_k^{(i)})\wp(x_k^{(i)}-x_s^{(i)})=\sum_{k=1}^{N_i}(2y_s^{(i)}-2y_k^{(i-1)}+1)\wp(x_s^{(i)}-x_k^{(i-1)})-\sum_{k=1}^{N_{i+2}}(2y_k^{(i+1)}-2y_s^{(i)} +1)\wp(x_k^{(i+1)}-x_s^{(i)}),\quad i=1,...,n-3, \tag{4.13}$$

$$4\sum_{k=1,k\neq s}^{N_{n-1}}(y_s^{(n-2)}-y_k^{(n-2)})\wp(x_k^{(n-2)}-x_s^{(n-2)})=\sum_{k=1}^{N_{n-2}}(2y_s^{(n-2)}-2y_k^{(n-3)}+1)\wp(x_s^{(n-2)}-x_k^{(n-3)}). \tag{4.14}$$

Sum up with s for each equation of (4.12)–(4.14). Then taking the summation of all the equations and noting the parity property of $\wp$-function (2.4), we find

$$\sum_{s=1}^{N_1}(2y_s^{(0)}+nl)\wp(x_s^{(0)})=0. \tag{4.15}$$

Substituting the equations (4.11) and (4.15) into (4.7), we finally have the following.

Proposition 4: The eigenvalues of the Hamiltonian (4.5) of the elliptic CM model associated with A_{n-1} root system with the discrete coupling constants $\gamma=l+1$ are

$$\epsilon_{\mathrm{CM}}=(1-nl)n\sum_{k=1}^{N_1}\wp(x_k^{(0)})-\frac{(n+1)n(n-1)}{3}l^2\frac{\sigma'''(0)}{\sigma'(0)}. \tag{4.16}$$

The $[n(n-1)/2]l$ *parameters* $\{\{x_k^{(i)}\}\}$ *satisfy the Bethe ansatz equations*

$$2\sum_{k=1,k\neq s}^{N_1}\zeta(x_k^{(0)}-x_s^{(0)})-n\sqrt{-1}\pi\overline{\alpha}=(2-n)\sqrt{-1}\pi\overline{\alpha}-nl\zeta(x_s^{(0)})+\sum_{k=1}^{N_2}\zeta(x_k^{(1)}-x_s^{(0)}), \tag{4.17}$$

$$2\sum_{k=1,k\neq s}^{N_{i+1}}\zeta(x_k^{(i)}-x_s^{(i)})+(i-n)\sqrt{-1}\pi\overline{\alpha}^{(i)}=(i+2-n)\sqrt{-1}\pi\overline{\alpha}^{(i+1)}-\sum_{k=1}^{N_i}\zeta(x_s^{(i)}-x_k^{(i-1)})$$
$$+\sum_{k=1}^{N_{i+2}}\zeta(x_k^{(i+1)}-x_s^{(i)}),\quad i=1,...,n-3, \tag{4.18}$$

$$2\sum_{k=1,k\neq s}^{N_{n-1}}\zeta(x_k^{(n-2)}-x_s^{(n-2)})-2\sqrt{-1}\pi\overline{\alpha}^{(n-2)}=-\sum_{k=1}^{N_{n-2}}\zeta(x_s^{(n-2)}-x_k^{(n-3)}). \tag{4.19}$$

The parameters $\overline{\alpha}^{(i)}$, $i=0,1,...,n-2$ *and* $\overline{\alpha}^{(0)}=\overline{\alpha}$ *are given by the relation (2.32) from* $n-1$ *arbitrary non-negative integers* $\{\alpha^{(i)}\in\mathbb{Z}^+|i=1,...,n-1\}$.

Our result agrees with the *third formulas* (or Bethe ansatz type) of the eigenvalues of the elliptic CM model associated with A_{n-1} root system.[22] Taking complex conjugation of the Bethe ansatz equations (4.17)–(4.19), noting the property (2.6) and (A5), we find that the solutions $\{\{x_k^{(i)}\}\}$ to the equations are all pure imaginary numbers. This ensures that the eigenvalues ϵ_{CM} are real and positive up to *the ground state energy* $\epsilon_0=-[(n+1)n(n-1)/3]l^2[\sigma'''(0)/\sigma'(0)]$ [the positivity from the expression (A4) of $\wp$-function when the argument is taken on imaginary axis].

B. Trigonometric potential

Here we consider trigonometric CM models associated with A_{n-1} root system. The corresponding Hamiltonian with the discrete *coupling constant* $\gamma=l+1$ is given

$$H_{\mathrm{CM}}=-\sum_{i=1}^{n}\frac{\partial^2}{(\partial\lambda_i)^2}+l(l+1)\sum_{i\neq j}\frac{\pi^2}{\sin^2(\pi\lambda_{ij})}. \tag{4.20}$$

Taking the trigonometric limit $\kappa\to+\infty$, one finds that

$$\zeta(u)\to\pi\cot\pi u, \tag{4.21}$$

$$\wp(u)\to\frac{\pi^2}{\sin^2(\pi u)}, \tag{4.22}$$

from expansions (A2) and (A3). Then the Hamiltonian (4.20) can be obtained from the elliptic type (4.5) by taking the trigonometric limit. Moreover, since the solutions $\{\{x_k^{(i)}\}\}$ to the Bethe ansatz equations (4.17)–(4.19) are all pure imaginary numbers, we can introduce $[n(n-1)/2]l$ real parameters $\{\{\overline{x}_k^{(i)}\}\}$ associated with $\{\{x_k^{(i)}\}\}$,

$$x_k^{(i)}=\sqrt{-1}\overline{x}_k^{(i)}. \tag{4.23}$$

Finally, we can find the spectrum of the Hamiltonian of trigonometric CM model associated with A_{n-1} root system from Proposition 4.

Proposition 5: The eigenvalues of the Hamiltonian (4.20) of the trigonometric CM model associated with A_{n-1} *root system with the discrete coupling constant* $\gamma=l+1$ *are*

$$\epsilon_{\mathrm{CM}}=(nl-1)n\sum_{k=1}^{N_1}\frac{\pi^2}{\sinh^2(\pi\overline{x}_k^{(0)})}+\frac{(n+1)n(n-1)}{3}l^2\pi^2. \tag{4.24}$$

The $[n(n-1)/2]l$ *real parameters* $\{\{\overline{x}_k^{(i)}\}\}$ *satisfy the Bethe ansatz equations*

$$2\sum_{k=1,k\neq s}^{N_1}\coth\pi(\overline{x}_k^{(0)}-\overline{x}_s^{(0)})+n\overline{\alpha}=(n-2)\overline{\alpha}^{(1)}-nl\coth\pi(\overline{x}_s^{(0)})+\sum_{k=1}^{N_2}\coth\pi(\overline{x}_k^{(1)}-\overline{x}_s^{(0)}), \tag{4.25}$$

$$2\sum_{k=1,k\neq s}^{N_{i+1}}\coth\pi(\overline{x}_k^{(i)}-\overline{x}_s^{(i)})+(n-i)\overline{\alpha}^{(i)}=(n-i-2)\overline{\alpha}^{(i+1)}-\sum_{k=1}^{N_i}\coth\pi(\overline{x}_s^{(i)}-\overline{x}_k^{(i-1)})$$
$$+\sum_{k=1}^{N_{i+2}}\coth\pi(\overline{x}_k^{(i+1)}-\overline{x}_s^{(i)}),\quad i=1,\ldots,n-3, \tag{4.26}$$

$$2\sum_{k=1,k\neq s}^{N_{n-1}}\coth\pi(\overline{x}_k^{(n-2)}-\overline{x}_s^{(n-2)})+2\overline{\alpha}^{(n-2)}=-\sum_{k=1}^{N_{n-2}}\coth\pi(\overline{x}_s^{(n-2)}-\overline{x}_k^{(n-3)}). \tag{4.27}$$

Here the parameters $\overline{\alpha}^{(i)}$, $i=0,1,\ldots,n-2$ *and* $\overline{\alpha}^{(0)}=\overline{\alpha}$ *are given by the relation (2.32) from* $n-1$ *arbitrary non-negative integers* $\{\alpha^{(i)}\in\mathbb{Z}^+|i=1,\ldots,n-1\}$.

C. Rational potential

Taking further rational limit of the elliptic Hamiltonian (4.5) as in Sec. III C, we can obtain the Hamiltonian of rational CM model associated with A_{n-1} root system

$$H_{\mathrm{CM}}=-\sum_{i=1}^{n}\frac{\partial^2}{(\partial\lambda_i)^2}+\sum_{i\neq j}\frac{l(l+1)}{(\lambda_i-\lambda_j)^2}. \tag{4.28}$$

Moreover, we have

Proposition 6: The eigenvalues of the Hamiltonian (4.28) of the rational CM model associated with A_{n-1} *root system with the discrete coupling constants* $\gamma=l+1$ *are*

$$\epsilon_{\mathrm{CM}}=\sum_{k=1}^{N_1}\frac{(nl-1)n}{(\overline{x}_k^{(0)})^2}, \tag{4.29}$$

where the $[n(n-1)/2]l$ *real parameters* $\{\{\overline{x}_k^{(i)}\}\}$ *satisfy the Bethe ansatz equations*

$$2\sum_{k=1,k\neq s}^{N_1}\frac{1}{\overline{x}_k^{(0)}-\overline{x}_s^{(0)}}+n\overline{\alpha}=(n-2)\overline{\alpha}^{(1)}-\frac{nl}{\overline{x}_s^{(0)}}+\sum_{k=1}^{N_2}\frac{1}{\overline{x}_k^{(1)}-\overline{x}_s^{(0)}}, \tag{4.30}$$

$$2\sum_{k=1,k\neq s}^{N_{i+1}}\frac{1}{\overline{x}_k^{(i)}-\overline{x}_s^{(i)}}+(n-i)\overline{\alpha}^{(i)}=(n-i-2)\overline{\alpha}^{(i+1)}-\sum_{k=1}^{N_1}\frac{1}{\overline{x}_s^{(i)}-\overline{x}_k^{(i-1)}}+\sum_{k=1}^{N_{i+2}}\frac{1}{\overline{x}_k^{(i+1)}-\overline{x}_s^{(i)}},$$
$$i=1,\ldots,n-3, \tag{4.31}$$

$$2\sum_{k=1,k\neq s}^{N_{n-1}}\frac{1}{\overline{x}_k^{(n-2)}-\overline{x}_s^{(n-2)}}+2\overline{\alpha}^{(n-2)}=-\sum_{k=1}^{N_{n-2}}\frac{1}{\overline{x}_s^{(n-2)}-\overline{x}_k^{(n-3)}}. \tag{4.32}$$

Here the parameters $\overline{\alpha}^{(i)}$, $i=0,1,...,n-2$ *and* $\overline{\alpha}^{(0)}=\overline{\alpha}$ *are given by the relation (2.32) from* $n-1$ *arbitrary non-negative real numbers* $\{\alpha^{(i)}\in\mathbb{R}^+|i=1,...,n-1\}$.

V. SUMMARY AND COMMENTS

Using the nested Bethe ansatz method for $E_{\tau,\eta}(sl_n)$,[19] we obtain the spectrum of the Hamiltonian of all types of (elliptic, trigonometric, rational) RS models associated with A_{n-1} root system with the discrete *coupling constant* $\gamma=\sqrt{-1}gl$. Eigenvalues are given in the Bethe ansatz formulas (or the *third formulas* in sense of Felder *et al.*[22]). The corresponding eigenfunction is a meromorphic function of $\{\lambda_i\}$ and has quasiperiodic properties (3.21) for the elliptic and trigonometric cases, asymptotic properties (3.36) for the rational case. For the special case of $n=2$, our generalized result recovers that of Refs. 17, 30, and 31.

Taking the "*nonrelativistic limit,*" the Hamiltonian of RS model becomes that of the CM model. Then, we give eigenvalues of the Hamiltonian of CM models associated with A_{n-1} root system with the discrete *coupling constant* $\gamma=l+1$ in the Bethe ansatz formulas. Our formulas coincide with those of Ref. 22 and those of $n=2$ case.[30,32] The eigenvalues from our formulas are real and positive up to the *ground state energy* ϵ_0 as physically desired. But, we have not yet got a direct proof of positivity of the eigenvalues of RS models from our formulas. However, we can show that for small *coupling constant* the eigenvalues of RS model associated with A_{n-1} root system are positive, from their asymptotic expansion (4.1). Moreover, we find that the elliptic and trigonometric RS and CM models have *discrete spectrum* which are parametrized by a set of non-negative integers $\{\alpha^{(i)}|i=1,...,n-1\}$. The rational RS and CM models have *continuous spectrum* which are parametrized by a set of non-negative real numbers $\{\alpha^{(i)}|i=1,...,n-1\}$.

If one writes the Hamiltonian of CM model with the *coupling constant* γ as $H_{\mathrm{CM}}(\gamma)$ and the associated eigenvalues as $\epsilon_{\mathrm{CM}}(\gamma)$, from the expression of the Hamiltonian (4.5), (4.20), and (4.28) one can find the following *duality*:

$$H_{\mathrm{CM}}(-\gamma)=H_{\mathrm{CM}}(\gamma-1). \tag{5.1}$$

Then, actually, we have already obtained the spectrum of CM models associated with A_{n-1} root system with the discrete *coupling constants* $\gamma=l$ $(l\in\mathbb{Z})$. Unfortunately, such a *duality* does not exist for RS models associated with A_{n-1} root systems.

There also exists another way (we call *symmetric polynomials approach*) to get eigenfunctions and the corresponding eigenvalues of the *trigonometric and rational* RS models[10] and CM models.[33–36] It would be very interesting to compare our formulas (of trigonometric and rational cases) with those obtained by the *symmetric polynomials approach* (for special A_1 case, it has already been obtained[30]). However, the *symmetric polynomials approach* fails in the elliptic models.

APPENDIX: FORMULAS FOR ELLIPTIC FUNCTIONS

In this appendix, we give some useful series expansions of the elliptic functions given by (2.4) when $\tau=\sqrt{-1}\kappa$, $\kappa\in\mathbb{R}$, $\kappa>0$. By (2.3), σ-function can be expressed in terms of product form[37] (see Chap. 15)

$$\sigma(u)=q^{1/4}\sin\pi u\prod_{n=1}^{\infty}(1-q^{2n}e^{2\sqrt{-1}\pi u})(1-q^{2n}e^{-2\sqrt{-1}\pi u})(1-q^{2n}),\quad q=e^{-\pi\kappa}. \tag{A1}$$

We can derive the following series expansions from (2.4):

$$\zeta(u)=\frac{\pi\cos\pi u}{\sin\pi u}+\pi\sum_{n=1}^{\infty}\frac{\sin 2\pi u}{\sin\pi(u+\sqrt{-1}n\kappa)\sin\pi(u-\sqrt{-1}n\kappa)}, \tag{A2}$$

$$\wp(u)=\frac{\pi^2}{\sin^2\pi u}+\sum_{n=1}^{\infty}\left\{\frac{\pi^2}{\sin^2\pi(u+\sqrt{-1}n\kappa)}+\frac{\pi^2}{\sin^2\pi(u-\sqrt{-1}n\kappa)}\right\}. \tag{A3}$$

Moreover, the functions have the following properties:

$$\wp(\sqrt{-1}u)=-\left\{\frac{\pi^2}{\sinh^2\pi u}+\sum_{n=1}^{\infty}\left\{\frac{\pi^2}{\sinh^2\pi(u+n\kappa)}+\frac{\pi^2}{\sinh^2\pi(u-n\kappa)}\right\}\right\}, \tag{A4}$$

$$\sigma^*(u)=\sigma(u^*),\quad \zeta^*(u)=\zeta(u^*),\quad \wp^*(u)=\wp(u^*), \tag{A5}$$

where $*$ stands for the complex conjugation.

Eigenvalue problems of a two-dimensional Schrödinger operator with nonparabolic effective mass

Wen-Wei Lin[a] and Shih-Feng Shieh[b]
Department of Mathematics, National Tsing Hua University, Hsinchu, 300, Taiwan

(Received 7 August 2003; accepted 19 November 2003)

In this paper, we study the eigenvalue problem for the Schrödinger operator on a two dimensional disk with nonparabolic effective mass approximation. Here the effective mass depends on the energy states. Our results mainly concern with the number of energy states lying in a wire and the monotonicity of energy states with respect to the depth of the wire. © *2004 American Institute of Physics.*
[DOI: 10.1063/1.1641151]

I. INTRODUCTION

Semiconductor quantum wires (or dots) are nanoscale structures in which the carriers are confined in two (or three) dimensions. The carriers exhibit wavelike properties in quantum wires and dots, and discrete energy states exist for the structures. These structures have recently attracted intensive research, on their physical phenomena and the corresponding practical applications (see, e.g., Ref. 1). Methods like photoluminescence[2] and capacitance-voltage spectroscopy[3] have been used to study the electronic and optical properties of quantum dots. For practical applications, quantum wires and dots play an important role in optoelectronic devices such as infrared photodetectors,[4] quantum dots laser,[5] memory device,[6] and quantum computing systems.[7]

In this paper, we study the eigenvalue problem for the Schrödinger operator on a disk $\mathbb{D}=\{(r,\theta)|\ r\in(0,R_1)\cup(R_1,R_2],\ \theta\in[0,2\pi]\}$:

$$\frac{-\hbar^2}{2m(r,\lambda)}\left(\frac{\partial^2\psi}{\partial r^2}+\frac{1}{r}\frac{\partial\psi}{\partial r}+\frac{1}{r^2}\frac{\partial^2\psi}{\partial\theta^2}\right)+V(r)\psi(r,\theta)=\lambda\psi(r,\theta), \tag{1.1}$$

where the potential function V is defined by

$$V(r)=\begin{cases}0, & r<R_1\\ c, & R_1<r\leqslant R_2,\end{cases} \tag{1.2}$$

and the nonparabolic effective mass $m(r,\lambda)$ is defined by

$$m(r,\lambda)=\begin{cases}m_1(\lambda), & r<R_1\\ m_2(\lambda), & R_1<r\leqslant R_2.\end{cases} \tag{1.3}$$

Equation (1.1) is equipped with the Dirichlet boundary condition:

$$\psi(R_2,\theta)=0,\qquad \theta\in[0,2\pi]. \tag{1.4}$$

We also impose the interface conditions at $r=R_1$ and $\theta\in[0,2\pi]$:

$$\psi(R_1^-,\theta)=\psi(R_1^+,\theta) \tag{1.5}$$

[a]Electronic mail: wwlin@am.nthu.edu.tw
[b]Electronic mail: sfshieh@am.nthu.edu.tw

and

$$\frac{1}{m_1(\lambda)}\frac{\partial\psi}{\partial r}(R_1^-,\theta)=\frac{1}{m_2(\lambda)}\frac{\partial\psi}{\partial r}(R_1^+,\theta). \tag{1.6}$$

Throughout this paper, we further assume that
($\mathcal{H}1$) The effective mass $m_1(\lambda)$, $m_2(\lambda)>0$ are C^1 and increasing for $\lambda\in[0,c]$.
($\mathcal{H}1$) The product $m_2(\lambda)(c-\lambda)$ is decreasing for $\lambda\in[0,c]$.

Remark 1.1: *In Refs. 8–10, for a quantum wire of small size, the nonparabolic effective mass* $m(r,\lambda)$ *in (1.3) is approximated by*

$$\frac{1}{m_j(\lambda)}=\frac{P_j^2}{\hbar^2}\left(\frac{2}{\lambda+a_j-c_j}+\frac{1}{\lambda+a_j-c_j+\delta_j}\right),\quad j=1,2, \tag{1.7}$$

where P_j, a_j, *and* δ_j *stand for the momentum, main energy gap and spin–orbit splitting in the* j*th region, respectively. The semiconductor band structure parameters are*

$$c_1=0,\ a_1=0.235,\ \delta_1=0.81,\ P_1=0.2875;$$

$$c_2=c=\text{the depth of the potential wire},\ a_2=1.59,\ \delta_2=0.8,\ P_2=0.1993.$$

By taking the derivatives of $m_1(\lambda)$ *and* $m_2(\lambda)(c-\lambda)$ *with respect to* λ, *one can easily verify, for*

$$0<c\leqslant\frac{a_2}{2},$$

that the nonparabolic effective mass approximations $m_j(\lambda)$ $(j=1,2)$ *satisfy* ($\mathcal{H}1$) *and* ($\mathcal{H}2$).

Such problem and its generalization have been studied by many authors (see, e.g., Refs. 11–16 and the work cited therein). Their results mainly focus on the ratios of and the gaps between eigenvalues. We are led to investigate, in this paper, the eigen-states lying in the wire by the following work. In Refs. 17 and 18, the spatial tunneling (from one hole to another) occurs in coupled quantum wells [one-dimensional (1D)] when the energy states in both wells are aligned. In the case of the hole tunneling in the coupled quantum dots, the tunneling mechanisms are significantly more complicated, due to the band mixing effect. When the energy states are approximately aligned between heavy hole and light hole, mixing tunneling occurs. Moreover, it was reported in Ref. 19 that a chaotic tunneling effect was generated when tunneling occurs. Our effort here aims towards understanding these phenomena. Note also that the discretization of the one-dimensional Schrödinger operator with constant effective mass has recently been reported in Ref. 20.

This paper is organized as follows. In Sec. II, we apply separation of variables and derive the secular equations for (1.1):

$$f_k(\lambda)=g_k(\lambda)\qquad(k=0,1,2,\ldots;\ \lambda\in[0,c]),$$

from which λ can be solved. In Sec. III, we show for all k that $f_k(\lambda)$ is decreasing and $g_k(\lambda)$ is increasing. Furthermore, we shall show that $g_k(\lambda)$ is continuous in $[0,c]$. In Sec. IV, we utilize the results in Secs. II and III to find the exact number of energy states lying in the wire, i.e., those eigenvalues in $[0,c]$. We shall give a sufficient and necessary condition which guarantees the existence of at least one energy state in the wire. The monotonicity of the energy state with respect to c, the depth of the wire, is also obtained. Section V contains some brief concluding remarks.

II. SECULAR EQUATIONS

In this section we shall derive the secular equations for the eigenvalue problem (1.1). To this end, we apply the technique of separation of variables, assuming that the wave function ψ satisfies

$$\psi(r,\theta)=u(r)\omega(\theta). \tag{2.1}$$

Substituting (2.1) into (1.1) we get

$$\frac{r^2}{u(r)}\left\{\frac{-\hbar^2}{2}\left(\frac{d^2u}{dr^2}+\frac{1}{r}\frac{du}{dr}\right)+m(r,\lambda)[V(r)-\lambda]u(r)\right\}=\frac{\hbar^2}{2}\frac{1}{\omega(\theta)}\frac{d^2\omega}{d\theta^2}. \tag{2.2}$$

Furthermore, the boundary condition (1.4) becomes

$$u(R_2)=0, \tag{2.3}$$

and the interface conditions (1.5) and (1.6), respectively, become

$$u(R_1^-)=u(R_1^+) \tag{2.4}$$

and

$$\frac{1}{m_1(\lambda)}\frac{du}{dr}(R_1^-)=\frac{1}{m_2(\lambda)}\frac{du}{dr}(R_1^+). \tag{2.5}$$

As (2.2) holds for all values of $r\in[0,R_1)\cup(R_1,R_2]$ and $\theta\in[0,2\pi]$, both sides of the equation equal to a constant. Consequently, the right hand side of (2.2) implies that the function $\omega(\theta)$ satisfies the following boundary value problems:

$$\frac{\omega''(\theta)}{\omega(\theta)}=-k^2, \qquad \omega(0)=\omega(2\pi),\ \ \omega'(0)=\omega'(2\pi),$$

where $k=0,1,2,\ldots$. For convenience, we shall denote

$$\alpha\equiv\sqrt{2m_1(\lambda)\lambda/\hbar^2},\ \ \beta\equiv\sqrt{2m_2(\lambda)(c-\lambda)/\hbar^2}. \tag{2.6}$$

Similarly, the left hand side of (2.2) implies, for $k=0,1,2,\ldots$,

$$r^2u''+ru'+(r^2\alpha^2-k^2)u=0, \quad \text{for } 0<r<R_1 \tag{2.7}$$

and

$$r^2u''+ru'-(r^2\beta^2+k^2)u=0, \quad \text{for } R_1<r<R_2. \tag{2.8}$$

Let J_k be Bessel functions of the first kind of order k, which satisfies the Bessel's equation $r^2u''+ru'+(r^2-k^2)u=0$. Let I_k and K_k, respectively, be the modified Bessel functions of the first and second kind of order k, which are linearly independent solutions of the modified Bessel's equation $r^2u''+ru'-(r^2+k^2)u=0$.

For a given k, (2.7) and (2.8) imply that the solution of (2.2) is given by

$$u(r)=AJ_k(\alpha r), \qquad \text{for } 0<r<R_1 \tag{2.9}$$

and

$$u(r)=BI_k(\beta r)+CK_k(\beta r), \qquad \text{for } R_1<r\leqslant R_2, \tag{2.10}$$

where A, B, and C are constant coefficients to be determined. Note that Bessel functions of the second kind are absent in (2.9) because of the boundedness of the eigenfunction $\psi(r,\theta)=u(r)\omega(\theta)$.

Now, applying the boundary condition (2.3) to (2.10), we obtain

$$C=-D_kB\ ,\ D_k\equiv\frac{I_k(\beta R_2)}{K_k(\beta R_2)}. \tag{2.11}$$

Applying the interface conditions (2.4) and (2.5) to (2.9) and (2.10), we have

$$AJ_k(\alpha R_1)=B[I_k(\beta R_1)-D_kK_k(\beta R_1)] \tag{2.12}$$

and

$$\frac{A}{m_1(\lambda)}\alpha J_k'(\alpha R_1)=\frac{B}{m_2(\lambda)}\beta[I_k'(\beta R_1)-D_kK_k'(\beta R_1)]. \tag{2.13}$$

Dividing (2.13) by (2.12), we can show that an eigenvalue of (1.1) is a root of the secular equations

$$f_k(\lambda)=g_k(\lambda)\quad(k=0,1,2,\ldots), \tag{2.14}$$

where

$$f_k(\lambda)\equiv\frac{1}{m_1(\lambda)}\frac{\alpha J_k'(\alpha R_1)}{J_k(\alpha R_1)} \tag{2.15}$$

and

$$g_k(\lambda)=\frac{1}{m_2(\lambda)}\tilde{g}_k(\lambda)\ \ ,\ \ \tilde{g}_k(\lambda)\equiv\frac{\beta[I_k'(\beta R_1)-D_kK_k'(\beta R_1)]}{I_k(\beta R_1)-D_kK_k(\beta R_1)}. \tag{2.16}$$

Remark 2.1. Assumptions ($\mathcal{H}1$) *and* ($\mathcal{H}2$) *are not involved in the derivation of the secular equations (2.14). Thus, (2.14) holds for any effective mass* $m(r,\lambda)$ *and can be used in numerical computations involving the eigenvalues of (1.1).*

III. MONOTONICITY OF f_k AND g_k

In this section, we shall study the monotonicity of f_k and g_k with respect to λ and c. To this end, we first quote some well-known and useful properties of J_k, I_k, and K_k, as well as the Comparison Theorem [Ref. 21, p. 24] for differential equations.

Proposition 3.1 (Ref. 22, p. 79): Let k be a nonnegative integer. Then the following properties hold.

(i) $J_k(x)=\sum_{n=0}^{\infty}\frac{(-1)^n\left(\frac{x}{2}\right)^{2n+k}}{n!\Gamma(n+k+1)}$, *where* $\Gamma(\cdot)$ *is the gamma function.*

(ii) $I_k(x)=\sum_{n=0}^{\infty}\frac{\left(\frac{x}{2}\right)^{2n+k}}{n!\Gamma(n+k+1)}$.

(iii) $K_k(x)=-I_k(x)\ln\frac{x}{2}+\frac{1}{2}\sum_{n=0}^{k-1}(-1)^n\frac{(k-n-1)!}{n!}\left(\frac{x}{2}\right)^{-k+2n}$

$$+(-1)^{k+1}\frac{1}{2}\sum_{n=0}^{\infty}\frac{\left(\frac{x}{2}\right)^{k+2n}}{n!(n+k)!}\left(\frac{\Gamma'(n+1)}{\Gamma(n+1)}+\frac{\Gamma'(n+k+1)}{\Gamma(n+k+1)}\right),\quad\text{for } k\geqslant 1,$$

$$K_0(x)=-I_0(x)\ln\frac{x}{2}+\frac{1}{2}\sum_{n=0}^{\infty}\frac{\left(\frac{x}{2}\right)^{2n}}{(n!)^2}\frac{\Gamma'(n+1)}{\Gamma(n+1)}.$$

(iv) $I_k(x),\ K_k(x)>0,\ for\ x>0.$

(v) $I_{k+1}+I_{k-1}=2I_k',\quad I_0'=I_1.$

(vi) $K_{k+1}+K_{k-1}=-2K_k',\quad K_0'=-K_1.$

(vi) $W\{I_k(x),K_k(x)\}=-\frac{1}{x}$ *where* $W\{\cdot,\cdot\}$ *denotes the Wronskian of two functions.*

Theorem 3.1 (Comparison Theorem): *Let u and v be, respectively, the solutions of the differential equations*

$$y'=F(y,x),\quad z'=G(z,x)$$

where $F(\eta,x)\leqslant G(\eta,x)$ in the strip $a\leqslant x\leqslant b$, and F and G satisfy the Lipschitz condition. If $u(a)\leqslant v(a)$ then $u(x)\leqslant v(x)$, for all $x\in[a,b]$.

Now, we are ready to prove the monotonicity properties of f_k and g_k, with a modified Prüfer transform[21] for linear second-order boundary value problems.

Proposition 3.2: Assume that ($\mathcal{H}1$) *and* ($\mathcal{H}2$) *in Sec. I hold.*

(i) *For each k, $f_k(\lambda)$ is decreasing.*

(ii) $f_k|_{\lambda=0}=k/m_1(0)R_1$.

Proof: For a given k, denote $u(r)\equiv J_k(\alpha r)$. Then u satisfies the differential equation (2.7). Note that $f_k(\lambda)=u'(R_1)/[m_1(\lambda)u(R_1)]$, and define the modified Prüfer transform

$$\tan\phi(r,\lambda)=\frac{u'(r)}{m_1(\lambda)u(r)}. \tag{3.1}$$

Differentiating (3.1) and with the help of (2.7), we can show that ϕ satisfies the first-order differential equation

$$\phi'=F(\phi,r,\lambda):=\frac{uu''-(u')^2}{m_1(\lambda)\left[1+\frac{1}{m_1(\lambda)^2}\left(\frac{u'}{u}\right)^2\right]u^2}=\left[-\frac{2\lambda}{\hbar^2}+\frac{k^2}{m_1(\lambda)r^2}\right]\cos^2\phi-\frac{1}{r}\sin\phi\cos\phi$$
$$-m_1(\lambda)\sin^2\phi. \tag{3.2}$$

Routine calculations, with the help of Proposition 3.1 (i), then yield

$$\frac{u'}{m_1(\lambda)u}=\sqrt{\frac{2\lambda}{m_1(\lambda)\hbar^2}}\,\frac{J_k'(\sqrt{2m_1(\lambda)\lambda/\hbar^2}\ r)}{J_k(\sqrt{2m_1(\lambda)\lambda/\hbar^2}\ r)}=\frac{k}{m_1(\lambda)r}-\frac{\lambda r}{(k+1)\hbar^2}+O(m_1(\lambda)\lambda^2r^3). \tag{3.3}$$

Consequently, for $\lambda_1>\lambda_2$ and a sufficiently small $r_0>0$, we arrive at

$$\left.\frac{u'(r)}{m_1(\lambda)u(r)}\right|_{r=r_0,\lambda=\lambda_1}\leqslant\left.\frac{u'(r)}{m_1(\lambda)u(r)}\right|_{r=r_0,\lambda=\lambda_2},$$

hence

$$\phi(r_0,\lambda_1)\leqslant\phi(r_0,\lambda_2). \tag{3.4}$$

On the other hand, it follows from (3.2) that F is Lipschitz continuous for $r\in[r_0,R_1]$ and is decreasing with respect to λ. Thus, from (3.4) and Theorem 3.1, we have $\phi(R_1,\lambda_1)\leqslant\phi(R_1,\lambda_2)$. From (2.15), (3.1) and the definition of $u(r)$, assertion (i) follows. Assertion (ii) is a direct consequence of (3.3). □

Remark 3.1. We require the modified Prüfer transform $\tan\Phi(r,\lambda)=u'(r)/[m_1(\lambda)u(r)]$ *in (3.1) in the proof of Proposition 3.1, rather than the traditional Prüfer transform* $\cot\phi(r)=u'(r)/u(r)$.

In the following, we study the continuity and monotonicity of g_k.

Proposition 3.3: Let a, $b>0$, and k be a nonnegative integer. Then

$$I_k(a)-\frac{I_k(b)}{K_k(b)}K_k(a)\begin{cases}>0, & \text{if } a>b\\ =0, & \text{if } a=b\\ <0, & \text{if } a<b.\end{cases}$$

Proof: Since $K_k(x)$ never vanishes, we define $h(x):=I_k(x)/K_k(x)$. Using Proposition 3.1 (vii), it follows that $h'(x)=[xK_k(x)^2]^{-1}>0$, and the assertion follows. □

Proposition 3.4: Assume $m_2(\lambda)>0$, for $\lambda\in[0,c]$. For any nonnegative integer k, we have

(i) $\tilde{g}_k(\lambda)$ *in* (2.16) *is continuous and nonpositive on* $[0,c)$, *and so is* $g_k(\lambda)$.

(ii) $\lim_{\lambda\to c}g_k(\lambda)=\begin{cases}[m_2(c)\ \ R_1\ln R_1/R_2]^{-1}, & k=0\\ k(R_1^{2k}+R_2^{2k})\ \ [m_2(c)\ \ R_1(R_1^{2k}-R_2^{2k})]^{-1}, & k\geqslant 1\end{cases}$.

Proof: Applying Proposition 3.3 to (2.16), together with (2.11), we can show that the denominator of $\tilde{g}_k$ is negative, implying that $\tilde{g}_k$ is continuous. From Proposition 3.1 (v) and (vi), it follows that the numerator of $\tilde{g}_k$ is positive. Thus, $\tilde{g}_k(\lambda)<0$ for $0\leqslant\lambda<c$. As $g_k=\tilde{g}_k/m_2(\lambda)$ and $m_2(\lambda)>0$, assertion (i) holds.

To prove assertion (ii), a straightforward application of MATHEMATICA[23] on Proposition 3.1 (ii) and (iii) produces

$$\begin{aligned}&\frac{K_k(\beta R_2)\ \ I_k'(\beta R_1)-I_k(\beta R_2)\ \ K_k'(\beta R_1)}{K_k(\beta R_2)\ \ I_k(\beta R_1)-I_k(\beta R_2)\ \ K_k(\beta R_1)}\\ &\quad=\begin{cases}\left[\beta\ \ R_1\ln\dfrac{R_1}{R_2}\right]^{-1}+O(\beta), & k=0\\ k(R_1^{2k}+R_2^{2k})\ \ [\beta\ \ R_1(R_1^{2k}-R_2^{2k})]^{-1}+O(\beta), & k\geqslant 1,\end{cases}\end{aligned}$$

when β is sufficiently small. The fact that $\beta\to 0$ as $\lambda\to c$ leads to assertion (ii). □

Proposition 3.5: Assume that $(\mathcal{H}1)$ *and* $(\mathcal{H}2)$ *hold. Then for any nonnegative integer k,*

(i) g_k is increasing with respect to λ for $0\leqslant\lambda\leqslant c$, and

(ii) g_k is decreasing with respect to c.

Proof: We first show that $\tilde{g}_k$ in (2.16) is decreasing with respect to β. Let

$$u(r)\equiv I_k(\beta r)-D_kK_k(\beta r).$$

Define the Prüfer transform $\tan\phi=v=u'/u$. With (2.8) and a similar argument as in the proof of Proposition 3.2, we can show that $\tilde{g}_k(\lambda)=v|_{r=R_1}$ and ϕ satisfies

$$\phi'=\frac{1}{r^2}(\cos^2\phi)(\beta^2r^2+k^2)-\frac{1}{r}\sin\phi\cos\phi-\sin^2\phi. \tag{3.5}$$

From Proposition 3.3, it follows for each β that $u(r,\beta)=0$ only when $r=R_2$. Together with the definitions of the Bessel functions I_k and K_k, we prove that v is continuous for $0<r<R_2$ and

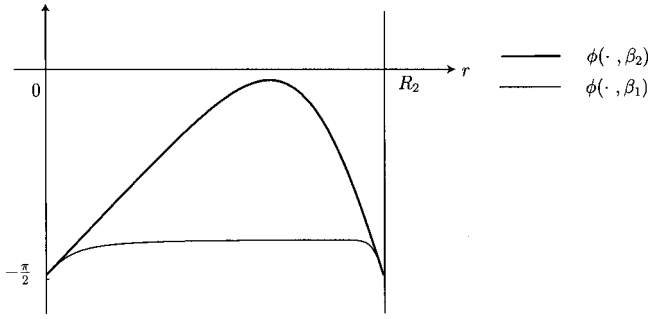

FIG. 1. Illustration of the proof of Proposition 3.5 that ϕ decreases in β.

$$\lim_{r\to 0^+} v(r,\beta)=\lim_{r\to R_2^-} v(r,\beta)=-\infty \quad \text{for all } \beta. \tag{3.6}$$

Using Proposition 3.1 (v) and (vi) and Proposition 3.3, we have $u'>0$ and $u<0$. This implies $v(r,\beta)<0$ for $0<r<R_2$. Thus we may choose $\phi(\cdot,\beta)$ as one branch of $\tan^{-1}(\cdot)$ in $[-\pi/2,\pi/2]$, and (3.6) leads to $\phi(R_2,\beta)=\phi(0,\beta)=-\pi/2$ for all β. Using the change of variable $s=R_2-r$, (3.5) becomes

$$\frac{d\phi}{ds}=G(\phi,s,\beta):=\frac{-\cos^2\phi}{(R_2-s)^2}[\beta^2(R_2-s)^2+k^2]+\frac{\sin\phi\cos\phi}{R_2-s}+\sin^2\phi. \tag{3.7}$$

Pick $\beta_1>\beta_2>0$. We then have

$$\phi(s=0,\beta_1)=\phi(s=0,\beta_2)=-\frac{\pi}{2}$$

and

$$G(\phi,s,\beta_1)\leqslant G(\phi,s,\beta_2) \qquad \text{for} \quad 0\leqslant s<R_2.$$

Applying Theorem 3.1 to (3.7), we conclude that $\phi(s,\beta_1)\leqslant\phi(s,\beta_2)$ for $0\leqslant s<R_2$, i.e., ϕ is decreasing with respect to β (see Fig. 1 for illustration). From ($\mathcal{H}2$) and (2.6), it follows that $\partial\beta/\partial\lambda<0$ and $\partial\beta/\partial c>0$, implying that $\tilde{g}_k$ is increasing with respect to λ and decreasing with respect to c. Together with the result in Proposition 3.4 that $\tilde{g}_k(\lambda)<0$ and assumption ($\mathcal{H}1$) that $m_2(\lambda)>0$ is increasing, we show that g_k is increasing with respect to λ. Since $g_k=\tilde{g}_k/m_2(\lambda)$ and $m_2(\lambda)$ is independent of c, assertion (ii) also holds. □

IV. MAIN RESULTS

In this section, we shall prove the main result of this paper. Denote the eigenvalue of (1.1) by $\lambda_{k,j}$ ($k=0,1,2,\ldots$, $j=1,2,\ldots$), corresponding to the jth root of the kth secular equation (2.14). We also define $s_{k,j}$ ($k=0,1,2,\ldots$, $j=1,2,3,\ldots$) to be the real number such that $\sqrt{2m_1(s_{k,j})s_{k,j}}\ R_1/\hbar$ is the jth root of the kth Bessel function J_k, with $s_{k,0}=0$. It is easy to see that $s_{k,j}$ ($j=1,2,\ldots$) are the singularities of f_k. Note that $\{s_{k,j}\}$ are well-defined, since ($\mathcal{H}1$) implies that the function $\lambda\mapsto m_1(\lambda)\lambda$ is increasing from zero to infinity in $[0,\infty)$. Using the properties of f_k and g_k in Propositions 3.2, 3.4, and 3.5, we sketch $f_k(\lambda)$ and $g_k(\lambda)$ in Fig. 2.

We now prove the first main result that exactly counts the number of eigenvalues of (1.1) which lie in the wire.

Theorem 4.1. *Assume that* ($\mathcal{H}1$) *and* ($\mathcal{H}2$) *hold. Suppose* $s_{k,n}<c<s_{k,n+1}$ *for some* $n\geqslant 0$. *If* $f_k(c)<g_k(c)$, *then* $\lambda_{k,1},\ldots,\lambda_{k,n+1}$ *lie in the wire; otherwise,* $\lambda_{k,1},\ldots,\lambda_{k,n}$ *lie in the wire and*

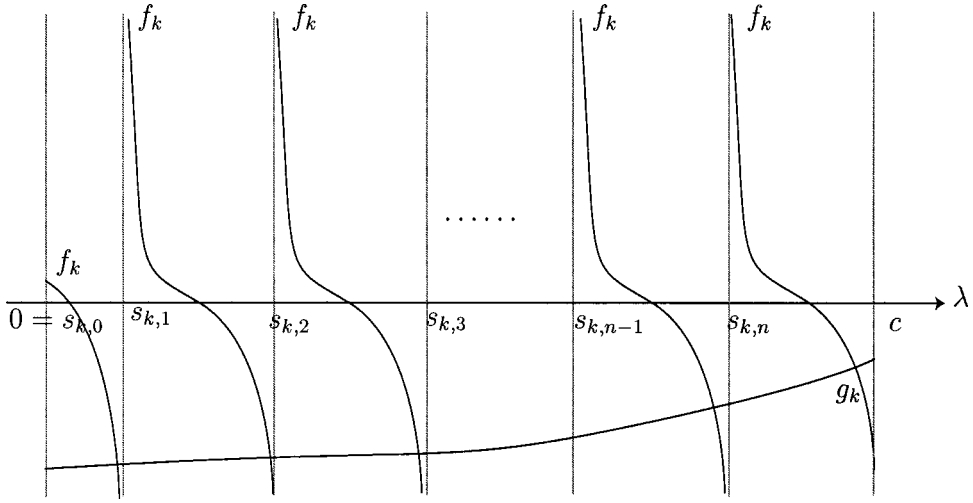

FIG. 2. Illustration for the graphs of f_k and g_k on $[0,c]$.

$\lambda_{k,n+1}$ *is out of the wire. Moreover, for any given size and depth of the wire in (1.1), there exists* $\overline{R_2}$ *such that there is at least one energy state lying in the wire for* $R_2 > \overline{R_2}$.

Proof: For a fixed k, define $d(\lambda) \equiv f_k(\lambda) - g_k(\lambda)$. It follows from Propositions 3.2 and 3.5 that d is decreasing in λ. Since g_k is continuous on $[0,c]$, d has only singularities $s_{k,1},\ldots,s_{k,n}$ in $[0,c]$. But $f_k(0) \geqslant 0$ and $g_k(0) < 0$ imply that $\lambda_{k,j} \in (s_{k,j-1}, s_{k,j})$, $j = 1,2,\ldots,n$. The existence of $\lambda_{k,n+1}$ in $(s_{k,n}, c]$ comes from the inequality $f_k(c) \leqslant g_k(c)$.

To complete the proof, it suffices to consider the case when $s_{0,1} > c$ we see that f_0 is continuous on $[0,c]$, with $f_0(0) = 0$, $f_0(c) < 0$. Using Proposition 3.4, we have $g_0(c) = [m_2(c) \;\; R_1 \ln(R_1/R_2)]^{-1} \to 0$ as $R_2 \to \infty$. The assertion follows. □

Remark 4.1. (i) A direct consequence of the last assertion of Theorem 4.1 is that when the domain of (1.1) is degenerated to the entire plane, i.e., $R_2 = \infty$, *there is at least one energy state lying in the wire.*

(ii) From a computational point of view, all discrete energy states of (1.1) lying in the wire $[0,c]$ *can easily be computed by applying Newton's iteration or the bisection method to the secular equations (2.14), with* $s_{k,j}$ *as initial guesses.*

The second main result shows that the increasing monotonicity of the energy state holds with respect to the depth c of the wire.

Theorem 4.2. *Each energy state lying in the wire increases as* c *increases.*

Proof: Let $d(\lambda) \equiv f_k(\lambda) - g_k(\lambda)$. As in the proof of Theorem 4.1, the result follows from Proposition 3.5 (ii). □

V. CONCLUDING REMARKS

We conclude this paper with some brief remarks and speculation on future works.

The non-parabolic effective mass approximations in (1.7) proposed in Refs. 9 and 10 satisfy satisfy ($\mathcal{H}1$) and ($\mathcal{H}2$) for specified c. These approximations are thus applicable, for some specific c, in our main Theorems. With assumptions ($\mathcal{H}1$) and ($\mathcal{H}2$), the monotonicity properties of f_k and g_k are ensured. Hence, the roots of (2.14) can be computed by classical iterative methods (e.g., Newton's method or bisection method). Without assumptions ($\mathcal{H}1$) and ($\mathcal{H}2$), the monotonicity properties of f_k and g_k does not always hold, so it cannot guarantee that there is a unique root of (2.14) between two consecutive singularities. Hence, the number of energy states lying in the wire from Theorem 4.1 becomes a lower bound.

Analogously, the main results of (1.1) in this paper with Neumann boundary conditions can be proved. It may be of interest to study the eigenvalue problem for the Schrödinger operator (or discretized Schrödinger operator) on a 3D the cylindrical domain with Dirichlet or Neumann boundary condition.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 2 FEBRUARY 2004

Transition elements for a non-Hermitian quadratic Hamiltonian

Mark S. Swanson[a)]
Department of Physics, University of Connecticut, Stamford, Connecticut 06901

(Received 12 May 2003; accepted 11 November 2003)

The non-Hermitian quadratic Hamiltonian $H=\omega a^{\dagger}a+\alpha a^{2}+\beta a^{\dagger 2}$ is analyzed, where $a^{\dagger}$ and a are harmonic oscillator creation and annihilation operators and ω, α, and β are real constants. For the case that $\omega^{2}-4\alpha\beta\geqslant 0$, it is shown using operator techniques that the Hamiltonian possesses real and positive eigenvalues. A generalized Bogoliubov transformation allows the energy eigenstates to be constructed from the algebra and states of the harmonic oscillator. The eigenstates are shown to possess an imaginary norm for a large range of the parameter space. Finding the orthonormal dual space allows the inner product to be redefined using the complexification procedure of Bender *et al.* for non-Hermitian Hamiltonians. Transition probabilities governed by H are shown to be manifestly unitary when the complexification procedure is followed. A specific transition element between harmonic oscillator states is evaluated for both the Hermitian and non-Hermitian cases to identify the differences in time evolution. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1640796]

I. INTRODUCTION

There is a good deal of current interest in extending quantum mechanics to include non-Hermitian Hamiltonians, stemming primarily from the work of Bender and collaborators.[1,2] An example is the Hamiltonian

$$H=p^{2}+x^{2}(ix)^{\nu} \qquad (\nu\geqslant 0), \tag{1}$$

which is known[1] to have a real and positive spectrum. Recent work[2] has found similar non-Hermitian cases that give rise to real and positive spectra. The key step in extending the structures of quantum mechanics to these Hamiltonians in a consistent manner is dealing with the indefinite metric[3] that arises in the Hilbert space of their eigenfunctions. For the eigenfunctions of (1) the standard inner product yields norms that alternate in sign. An indefinite metric threatens unitarity and prevents a probabilistic interpretation of matrix elements. In Bender's approach unitarity is maintained by modifying the inner product of the Hilbert space through the action of an operator, written as the product of time reversal $\mathcal{T}$, parity $\mathcal{P}$, and charge conjugation $\mathcal{C}$, so that the inner product takes the form[4]

$$\langle f|g\rangle=\int_{\mathrm{C}} dx\,[\mathcal{CPT}f(x)]g(x), \tag{2}$$

where both the contour C in the complex x plane and the form for $\mathcal{CPT}$ are determined from the form of the Hamiltonian. For the case that $\nu\to 0$ in (1) the operator $\mathcal{CP}\to 1$ and the inner product (2) reduces to the usual definition since $\mathcal{T}f(x)=f^{*}(-x)$. In general, Hamiltonians that are $\mathcal{PT}$

a)Electronic mail: swanson@uconnvm.uconn.edu

symmetric can be treated in this manner. The resulting generalization to a complexified version of quantum mechanics allows a much broader range of Hamiltonians to be considered while maintaining unitary time evolution.

The purpose of this paper is to analyze a simple quadratic non-Hermitian Hamiltonian with operator methods and adapt it to the structure developed by Bender. The Hamiltonian is expressed in terms of bosonic harmonic oscillator creation and annihilation operators $a^\dagger$ and a, which obey the usual commutation relationship

$$[a,a^\dagger]=1. \tag{3}$$

The operator a annihilates the state $|0\rangle$, so that

$$a|0\rangle=0\Rightarrow\langle 0|a^\dagger=0. \tag{4}$$

The set of states given by

$$|n\rangle=\frac{a^{\dagger n}}{\sqrt{n!}}|0\rangle \tag{5}$$

are eigenstates of the Hermitian Hamiltonian $H_0=\omega a^\dagger a$ and are orthonormal and complete. The Hamiltonian to be considered is then given by

$$H=\omega a^\dagger a+\alpha a^2+\beta a^{\dagger 2}+\tfrac{1}{2}\omega, \tag{6}$$

where ω, α, and β are real parameters with the dimensions of inverse time. The Hamiltonian (6) is of course manifestly non-Hermitian when $\alpha\neq\beta$, but it is both $\mathcal{P}$ and $\mathcal{T}$ invariant since $\mathcal{T}$:$a\rightarrow a$ and $\mathcal{P}$:$a\rightarrow -a$ with similar transformation properties for $a^\dagger$. As a result, if eigenstates of (6) can be found they will possess real eigenvalues.[5] The Hermitian version of (6) occurs in the analysis of two photon processes,[6] but to the knowledge of the author the non-Hermitian version and its transition elements have not been considered.

The approach followed is first to find the Hilbert space of energy eigenstates and then to define via Bender's method an inner product that allows unitary time development. This paper will restrict attention to the case that α and β are real and $\omega^2-4\alpha\beta\geqslant 0$. For those restrictions the Hamiltonian (6) possesses eigenstates with real and positive eigenvalues, and therefore, meets the criteria for applying Bender's method. The energy eigenstates will be constructed from the harmonic oscillator states using a generalized Bogoliubov transformation[7] and will be shown to be structurally identical to the harmonic oscillator. It will be seen that the Hilbert space of energy eigenstates possesses an indefinite metric if $\alpha\neq\beta$ corresponding to non-normalizable eigenstates. In order to implement Bender's approach to dealing with the breakdown of unitarity the space dual to these eigenstates will be constructed through the demand of orthonormality. An explicit form for the operator U that maps the energy eigenstates into the orthonormal dual basis is determined and, in order to avoid a breakdown of unitarity, it will be shown that the action of U must be included in the inner product. This operator reduces to unity when the Hermitian limit $\alpha\rightarrow\beta$ is taken, in a manner identical to the result that $\lim_{\nu\rightarrow 0}\mathcal{CP}=1$ for the Hamiltonian (1). The Hilbert space of eigenstates and the modified inner product then allow the definition of a unit projection operator. It will be explicitly demonstrated that time evolution using this inner product is unitary, showing that the non-Hermitian Hamiltonian (6) can be treated by Bender's general method. Transition elements between harmonic oscillator states using (6) will be calculated using both the methods of Bender and the standard inner product. Because the states of the theory are explicitly constructed from the harmonic oscillator states, evaluating the transition elements in either case reduces to an exercise in normal ordering. Transition probabilities calculated without Bender's complexification procedure are oscillatory due to the real and positive energy spectrum but are not time-reversal invariant since $|W_{fi}|^2\neq|W_{if}|^2$ when $\alpha\neq\beta$. The resulting transition elements therefore manifestly violate unitarity when $\alpha\neq\beta$. The origin of this failure is clearly demonstrated for

a specific fixed number transition element in the limit that $\alpha \to 0$ while $\beta \neq 0$. Comparing the Hermitian limit $\alpha = \beta$ of a transition amplitude to the non-Hermitian case shows that for small β the non-Hermitian case is very similar in behavior to the Hermitian case, but that significant differences in time evolution appear as β approaches $\omega/2$.

The outline of the paper is as follows. In Sec. II the Hamiltonian is analyzed using operator techniques to determine the structure of the Hilbert space of eigenstates and the form of the inner product required for unitary time evolution. In Sec. III fixed number transition elements are evaluated to demonstrate the failure of time-reversal invariance in the absence of the modified inner product. A specific transition element governed by the Hamiltonian (6) is then defined and evaluated in several limits. To enhance readability the more tedious aspects of the evaluation are collected in a set of appendices.

II. ENERGY EIGENSTATES AND THE INNER PRODUCT

The first step in evaluating (6) is to find its eigenstates. This process begins by introducing two new operators, c and d, by means of a generalized Bogoliubov transformation[7]

$$c = g_1 a^\dagger - g_3 a, \tag{7}$$

$$d = g_4 a - g_2 a^\dagger, \tag{8}$$

where in the general case the g_j coefficients are complex numbers. It is clear that $c \neq d^\dagger$ unless $g_4 = g_1^*$ and $g_3 = g_2^*$, in which case (7) and (8) reduce to the standard Bogoliubov transformation for the Hermitian case. This yields the Hermitian limits

$$\lim_{\alpha \to \beta} g_1^* = g_4, \tag{9a}$$

$$\lim_{\alpha \to \beta} g_2^* = g_3, \tag{9b}$$

and their complex conjugates. Written in matrix form, the definitions of (7) and (8) become

$$\begin{pmatrix} d \\ c \end{pmatrix} = \begin{pmatrix} g_4 & -g_2 \\ -g_3 & g_1 \end{pmatrix} \begin{pmatrix} a \\ a^\dagger \end{pmatrix}. \tag{10}$$

The algebra $[a, a^\dagger] = 1$ gives

$$[d, c] = g_1 g_4 - g_2 g_3 = 1, \tag{11}$$

where, to simplify subsequent calculations, (11) has been set to unity. Since (11) is the determinant of the matrix in (10), the matrix is a member of the group SL(2,C) and its inversion gives

$$a = g_1 d + g_2 c, \tag{12}$$

$$a^\dagger = g_3 d + g_4 c. \tag{13}$$

Substituting (12) and (13) into (6) yields

$$H = \Omega c d + \tilde{\alpha} c^2 + \tilde{\beta} d^2 + \epsilon + \tfrac{1}{2}\omega, \tag{14}$$

where the new coefficients are given in terms of the parameters of (6) and the g_j:

$$\Omega = (g_2 g_3 + g_1 g_4)\omega + 2 g_1 g_2 \alpha + 2 g_3 g_4 \beta, \tag{15a}$$

$$\tilde{\alpha} = g_2 g_4 \omega + g_2^2 \alpha + g_4^2 \beta, \tag{15b}$$

$$\tilde{\beta}=g_1g_3\omega+g_1^2\alpha+g_3^2\beta, \tag{15c}$$

$$\epsilon=g_2g_3\omega+g_1g_2\alpha+g_3g_4\beta. \tag{15d}$$

It is important to note that the ordering prescription of moving c to the left in all expressions has been chosen and this choice generates the form for ϵ. While the other option is possible, this choice takes advantage of the similarity of c and d to creation and annihilation operators in the commutator (11) to avoid needless complications.

The g_j are now chosen so that the two complex constraints

$$\tilde{\alpha}=\tilde{\beta}=0, \tag{16}$$

are satisfied. If $\alpha=\beta=0$ in (6), then (7) and (8) can be chosen to reduce to $c=a^\dagger$ and $d=a$, and this yields the boundary conditions

$$\lim_{\alpha,\beta\to 0} g_{2,3}=0, \tag{17}$$

for g_2 and g_3. Condition (11) is then consistent with the limits

$$\lim_{\alpha,\beta\to 0} g_{1,4}=1, \tag{18}$$

which will be true up to an arbitrary phase. The two conditions of (16) and the constraint (11) remove six degrees of freedom from the four complex numbers g_j, which naively possess eight degrees of freedom. However, the g_j actually possess only six physical parameters due to the freedom to adjust the overall phases of the operators in the definitions (12) and (13). The details of this argument are presented in Appendix A. Because all six actual degrees of freedom are now accounted for, solutions to (11) and (16) consistent with the boundary conditions can now be found. It is shown in Appendix B that

$$\Omega=\sqrt{\omega^2-4\alpha\beta}, \tag{19a}$$

$$\epsilon=\tfrac{1}{2}(\Omega-\omega), \tag{19b}$$

and these are real if $\omega^2-4\alpha\beta\geqslant 0$.

The eigenstates of the Hamiltonian (6) can now be constructed from the harmonic oscillator states. Defining the state $|0_d\rangle$ through the relation

$$d|0_d\rangle=0, \tag{20}$$

allows the eigenstates of (6) to be expressed defined in a manner similar to the simple harmonic oscillator

$$|\tilde{n}\rangle=\frac{1}{\sqrt{n!}}c^n|0_d\rangle. \tag{21}$$

Using the algebra (11) and the property (20) gives

$$H|\tilde{n}\rangle=(n+\tfrac{1}{2})\Omega|\tilde{n}\rangle\equiv E_n|\tilde{n}\rangle. \tag{22}$$

It follows that the eigenvalues of H are real and positive as long as $\Omega^2=\omega^2-4\alpha\beta\geqslant 0$ and are formally identical to the simple harmonic oscillator.

The key step in understanding the properties of the eigenstates is to construct the state $|0_d\rangle$ from the states of the harmonic oscillator. The Baker–Campbell–Hausdorff theorem[8] states that if

the commutator of two operators $[A,B]$ commutes with B, then $Ae^{\lambda B^2}=e^{\lambda B^2}(A+\lambda[A,B]B)$, where λ is an arbitrary c-number parameter. In addition, it shows that if A and B are two operators such that $[B,A]=A$, then $e^{\lambda B}A=e^{\lambda}Ae^{\lambda B}$, where λ is a c-number parameter. Using these shows that

$$d\exp\left(\frac{1}{2}\frac{g_2}{g_4}a^{\dagger 2}\right)=(g_4a-g_2a^{\dagger})\exp\left(\frac{1}{2}\frac{g_2}{g_4}a^{\dagger 2}\right)=\exp\left(\frac{1}{2}\frac{g_2}{g_4}a^{\dagger 2}\right)g_4a. \tag{23}$$

It then follows that the state that satisfies (20) is given by

$$|0_d\rangle=N_d\exp\left(\frac{1}{2}\frac{g_2}{g_4}a^{\dagger 2}\right)|0\rangle, \tag{24}$$

where N_d will be used to define a unit projection operator. It is shown in Appendix C that the ground state $|0_d\rangle$ possesses the norm

$$\langle 0_d|0_d\rangle=\frac{|N_d|^2|g_4|^2}{\sqrt{|g_4|^2-|g_2|^2}}. \tag{25}$$

For the case that $-1>g_2/g_4>1$ the ground state possesses an imaginary norm and the Hilbert space possesses an indefinite metric. This is caused by the divergence of the power series (C4) that defines the norm, and so the indefinite metric is signaling that the eigenstates are not normalizable if $-1>g_2/g_4>1$. Using result (B4) shows there are no solutions to this inequality in the Hermitian case. However, for the non-Hermitian case $\alpha<0$ and $\beta>0$ result (B4) shows that imaginary norms occur if $\alpha+\beta<\omega$. As a result, the Hamiltonian (6) suffers difficulties with its metric that are similar to other non-Hermitian cases.[3]

The solution by Bender, Brody, and Hughes[4] to the indefinite metric of other non-Hermitian Hamiltonians is to find the charge conjugation operator $\mathcal{C}$ such that the action of the operator $\mathcal{CPT}$ yields a positive-definite inner product as in (2). In some cases it is necessary to resort to a perturbative construction of this operator.[9] The approach followed in this paper will be to find the orthonormal dual space basis $|\overline{n}\rangle$ first, and then to deduce the form of the operator U that maps the energy eigenstates into the dual states, $|\overline{n}\rangle=U|\tilde{n}\rangle$. By construction this will result in a modified inner product such that $\langle\tilde{n}|U^{\dagger}|\tilde{n}\rangle$ is positive definite. For the case that the dual space is associated with the eigenvectors of $H^{\dagger}$ and the energy spectrum of $H^{\dagger}$ is identical to H, this approach yields an inner product that will preserve unitarity. The proof of this will be given later in this section. This method is easier for the Hamiltonian (6) since the algebra (11) allows the space dual to the Hilbert space of eigenstates (21) to be constructed from the dual space of the harmonic oscillator.

The process begins by defining the dual $\langle 0_c|$ to the ground state $|0_d\rangle$ as the state that satisfies

$$(c^{\dagger}|0_c\rangle)^{\dagger}=\langle 0_c|c=0. \tag{26}$$

As in (24) this state can be constructed from the original harmonic oscillator algebra and its ground state dual $\langle 0|$ by defining

$$\langle 0_c|=N_c\langle 0|\exp\left(\frac{1}{2}\frac{g_3}{g_1}a^2\right). \tag{27}$$

This process yields the dual space basis

$$\langle\overline{m}|=\langle 0_c|\frac{d^m}{\sqrt{m!}}. \tag{28}$$

The notation is intended to reinforce the fact that $\langle\overline{n}| \neq |\tilde{n}\rangle^\dagger$. Using the algebra (11) immediately shows that the dual space basis defined by (28) will be orthonormal to the states of (21), i.e., $\langle\overline{m}|\tilde{n}\rangle = \delta_{mn}$, if $\langle 0_c|0_d\rangle = 1$. This inner product can be evaluated easily because the two states have inherited the inner product of the harmonic oscillator basis. The result (C3) from Appendix C shows that

$$\langle 0_c|0_d\rangle = N_c N_d \sqrt{g_1 g_4}, \tag{29}$$

so that $N_c N_d = 1/\sqrt{g_1 g_4}$ normalizes the inner product. It is convenient to choose

$$N_d = (g_4)^{-1/2}, \tag{30a}$$

$$N_c = (g_1)^{-1/2}, \tag{30b}$$

so that in the limit (18) the normalization factors reduce to unity. The matrix elements of the Hamiltonian are well defined in this basis, yielding

$$\langle\overline{m}|H|\tilde{n}\rangle = (n + \tfrac{1}{2})\Omega\ \delta_{mn}. \tag{31}$$

It is shown in Appendix C that these states and their duals allow the definition of a unit projection operator

$$\sum_{n=0}^{\infty} |\tilde{n}\rangle\langle\overline{n}| = \hat{1}. \tag{32}$$

It is important to note that this process is equivalent to finding the complete set of eigenstates for the Hermitian adjoint $H^\dagger$. Given the explicit form of H and the dual states (28) it is easy to show that

$$H^\dagger|\overline{n}\rangle = (n + \tfrac{1}{2})\Omega|\overline{n}\rangle = E_n|\overline{n}\rangle. \tag{33}$$

Since the eigenvalues are real, nondegenerate, and identical to those for H, the orthonormality statement (31) immediately follows from the relation

$$E_m\langle\overline{m}|\tilde{n}\rangle = (\langle\overline{m}|H)|\tilde{n}\rangle = \langle\overline{m}|(H|\tilde{n}\rangle) = E_n\langle\overline{m}|\tilde{n}\rangle. \tag{34}$$

In order to avoid the indefinite metric an operator U will be found that satisfies

$$\langle\overline{n}| = (U|\tilde{n}\rangle)^\dagger = \langle\tilde{n}|U^\dagger. \tag{35}$$

As long as the states $|\tilde{n}\rangle$ and $|\overline{n}\rangle$ have the same spectrum it will now be shown that

$$H^\dagger U - UH = 0. \tag{36}$$

This follows by using (33) to give

$$E_n|\overline{n}\rangle = H^\dagger U|\tilde{n}\rangle, \tag{37}$$

while from (22) it follows that

$$E_n|\overline{n}\rangle = U^\dagger H|\tilde{n}\rangle, \tag{38}$$

where the equivalence of the eigenvalues has been used. Combining (37) and (38) immediately yields (36). It is shown in Appendix D that for the Hamiltonian (6) the operator U is given explicitly by

$$U=\exp\left\{\frac{1}{2}\left(\frac{g_3^*}{g_1^*}-\frac{g_2}{g_4}\right)a^{\dagger 2}\right\}\exp\left(\frac{1}{2}wd^2\right)\exp(cd\ln z), \tag{39}$$

with

$$w=\frac{g_3g_4-g_1^*g_2^*}{g_4^2}, \tag{40a}$$

$$z=\frac{g_4}{g_1^*}. \tag{40b}$$

Appendix D also shows that the operator U has the property that

$$Uc=d^\dagger U, \tag{41a}$$

$$Ud=c^\dagger U, \tag{41b}$$

so that

$$UH=U\Omega cd=\Omega d^\dagger c^\dagger U=H^\dagger U, \tag{42}$$

and its action on the Hamiltonian is precisely that predicted by (36). Result (42) is essential in proving that the theory using the modified inner product is unitary. To demonstrate unitarity the projection operator (32) is rewritten

$$\sum_{n=0}^{\infty}|\tilde{n}\rangle\langle\tilde{n}|U^\dagger=\hat{1}. \tag{43}$$

An arbitrary state $|\tilde{\varphi}\rangle$ is written as a superposition of the energy eigenstates

$$|\tilde{\varphi}\rangle=\sum_{n=0}^{\infty}a_n|\tilde{n}\rangle, \tag{44}$$

with the normalization condition

$$\sum_{n=0}^{\infty}|a_n|^2=1. \tag{45}$$

Using the definition

$$\langle\overline{\varphi}|=(U|\tilde{\varphi}\rangle)^\dagger=\sum_{n=0}^{\infty}\langle\overline{n}|a_n^*, \tag{46}$$

shows that $\langle\overline{\varphi}|\tilde{\varphi}\rangle=1$. The transition element from $|\tilde{\varphi}\rangle$ to the energy eigenstate $|\tilde{n}\rangle$ in Bender's complexified quantum mechanics is defined as

$$W_{\tilde{\varphi}\tilde{n}}\equiv\langle\overline{n}|e^{-iHT}|\tilde{\varphi}\rangle=\langle\tilde{n}|U^\dagger e^{-iHT}|\tilde{\varphi}\rangle, \tag{47}$$

so that its complex conjugate is given by

$$W_{\tilde{\varphi}\tilde{n}}^*=\langle\tilde{\varphi}|e^{iH^\dagger T}U|\tilde{n}\rangle. \tag{48}$$

Unitarity requires that the transition probability satisfies

$$1=\sum_n |W_{\tilde{\varphi}\tilde{n}}|^2=\sum_n \langle\tilde{\varphi}|e^{iH^\dagger T}U|\tilde{n}\rangle\langle\tilde{n}|U^\dagger e^{-iHT}|\tilde{\varphi}\rangle. \tag{49}$$

Using (43) followed by (42) immediately gives

$$\sum_n |W_{\tilde{\varphi}\tilde{n}}|^2=\langle\tilde{\varphi}|e^{iH^\dagger T}Ue^{-iHT}|\tilde{\varphi}\rangle=\langle\tilde{\varphi}|e^{iH^\dagger T}e^{-iH^\dagger T}U|\tilde{\varphi}\rangle=\langle\tilde{\varphi}|U|\tilde{\varphi}\rangle=\langle\overline{\varphi}|\tilde{\varphi}\rangle^*=1. \tag{50}$$

As a result, the use of the modified inner product preserves unitarity in transition probability. The method used in this paper for constructing the operator U requires that H and $H^\dagger$ possess an identical spectrum, and this is the case for (6).

As a result, (35) generalizes the adjoint operation to this particular case of a non-Hermitian Hamiltonian. The operator U is playing a role identical to that of the $\mathcal{CP}$ operator for the Hamiltonian (1) by mapping the eigenstates into a dual space that yields a positive definite and orthonormal inner product. Using the limits (9) shows that the arguments of the exponentials in (39) go to zero when $\alpha\to\beta$. The Hermitian limit, therefore, yields $\lim_{\alpha\to\beta}U=1$ and the standard adjoint operation is recovered, as in the other non-Hermitian Hamiltonians analyzed using Bender's method.

III. TRANSITION ELEMENTS

In this section a specific simple transition element will be evaluated with and without Bender's complexification procedure. The results verify the breakdown of unitarity for the non-Hermitian case $\alpha\neq\beta$ if Bender's procedure is not followed. However, in the Hermitian limit $\alpha=\beta$ and $U=1$, so that the transition element calculated in this manner will coincide with Bender's method. The same transition amplitude for the non-Hermitian case will then be calculated using Bender's method and shown to be manifestly unitary. It is of interest to compare the results of using a non-Hermitian Hamiltonian and Bender's method to the case of using a Hermitian Hamiltonian. Since both cases correspond to unitary time development it is useful through comparison to see what differences emerge in the time evolution of the states. It will be seen that significant differences appear for the case $\beta/\omega\approx 1/2$.

That unitarity will be violated for the non-Hermitian case can be seen from the following general argument. If the inner product is not generalized via Bender's method the transition element from an arbitrary state $|\varphi\rangle$ to a harmonic oscillator eigenstate of the form (5) is defined as

$$W_{\varphi n}=\langle n|e^{-iHT}|\varphi\rangle. \tag{51}$$

Repeating the steps of (49) and (47) gives

$$\sum_n |W_{\varphi n}|^2=\langle\varphi|e^{iH^\dagger T}e^{-iHT}|\varphi\rangle, \tag{52}$$

and this result is not unity if $H^\dagger\neq H$. As a result, the transition element defined by (51) will not give a unitary transition probability in the non-Hermitian case. However, this does not prevent an evaluation of (51) and an explicit examination of the breakdown of unitarity when $\alpha\neq\beta$. Since the operator U of (39) reduces to unity in the Hermitian case, the expression (51) will be the correct definition of the transition amplitude in the limit $\alpha\to\beta$.

In the first step a transition element will be calculated without Bender's complexification procedure. It is simple and instructive to look at the fixed number process

$$W_{02}=\langle 2|e^{-iHT}|0\rangle, \tag{53}$$

where $\langle 2| = \langle 0|a^2/\sqrt{2}$ and H is given by (6). Despite the fact that H is non-Hermitian, evaluating (53) is nothing more than an exercise in normal ordering. This is simplified by using the unit projection operator (32) to find

$$W_{02} = \sum_n \langle 2|\tilde{n}\rangle\langle\overline{n}|0\rangle e^{-in\Omega T} e^{-(1/2)i\Omega T}. \tag{54}$$

It is straightforward to adapt expressions (C13) and (C19) to show that

$$W_{02} = -\left(\frac{\beta}{\sqrt{2}\Omega}\right)(1-e^{-2i\Omega T})(g_1 g_4 - g_2 g_3 e^{-2i\Omega T})^{-3/2} e^{-(1/2)i\Omega T}. \tag{55}$$

Similarly, it is straightforward to show that

$$W_{20} = \langle 0|e^{-iHT}|2\rangle = -\left(\frac{\alpha}{\sqrt{2}\Omega}\right)(1-e^{-2i\Omega T})(g_1 g_4 - g_2 g_3 e^{-2i\Omega T})^{-3/2} e^{-(1/2)i\Omega T}. \tag{56}$$

Interpreting these quantities as the transition probability amplitude shows that the transition probability defined by $P(T) = |W|^2$ would yield two differing rates for these processes as long as $\alpha \neq \beta$. This violates the well known time-reversal invariance of processes driven by Hermitian Hamiltonians, i.e., $|W_{fi}|^2 = |W_{if}|^2$, and is a direct outcome of the fact that the Hamiltonian (6) is non-Hermitian as long as $\alpha \neq \beta$. The origin of this violation is particularly clear in the limit that $\alpha \to 0$ while $\beta \neq 0$. For such a case it is impossible for the Hamiltonian to connect the state $|2\rangle$ to the state $\langle 0|$ since there are no terms quadratic in the destruction operators in the Hamiltonian. Using the results of Appendix B gives the limits for the non-Hermitian transition elements obtained without the complexification procedure as

$$\lim_{\alpha\to 0} W_{20} = 0, \tag{57a}$$

$$\lim_{\alpha\to 0} W_{02} = -\frac{\beta}{\sqrt{2}\omega}(1-e^{-2i\omega T}). \tag{57b}$$

The small T limit of (57b) reduces to the first order term in a perturbative expansion of the transition element (53) where $\alpha = 0$, verifying that the factors in (57b) are correct. Unitarity is, therefore, manifestly violated in the absence of the complexification procedure.

In the Hermitian limit $\alpha = \beta$, (55) and (56) are identical and correspond to unitary time development. Using the results of Appendix B gives

$$\lim_{\alpha\to\beta} W_{20} = -\frac{\beta}{\sqrt{2}\Omega}\left(\frac{\Omega(\omega-\Omega)}{2|\beta|^2}\right)^{3/2}(1-e^{-2i\Omega T})\left(1-\frac{(\omega-\Omega)^2}{4|\beta|^2}e^{-2i\Omega T}\right)^{-3/2} e^{-(1/2)i\Omega T}. \tag{58}$$

The absolute value $|\beta|^2$ appears in (58) to reflect the fact that the expansion is actually in terms of $|\beta|^2 = \alpha\beta$, which is invariant under the phase transformations discussed in Appendix A. For small β/ω (58) reduces to

$$W_{20} \approx -\frac{\beta}{\sqrt{2}\omega}(1-e^{-2i\omega T})\left(1-\frac{|\beta|^2}{\omega^2}e^{-2i\omega T}\right)^{-3/2} e^{-(1/2)i\omega T}. \tag{59}$$

Calculating the same transition element via Bender's method for the non-Hermitian case $\alpha=0$ and $\beta\neq 0$ is particularly simple. For such a case the results of Appendix B show that $\Omega=\omega$, $g_1 g_4=1$, $g_3=0$, and $g_2=-\beta/\omega$. The first step is to express the states $|0\rangle$ and $|2\rangle$ in terms of the energy eigenstates $|\tilde{n}\rangle$, so that

$$|0\rangle=N_0\sum_n\ |\tilde{n}\rangle\langle\overline{n}|0\rangle\equiv N_0\sum_n\ a_n|\tilde{n}\rangle, \tag{60}$$

$$|2\rangle=N_2\sum_n\ |\tilde{n}\rangle\langle\overline{n}|2\rangle\equiv N_2\sum_n\ b_n|\tilde{n}\rangle. \tag{61}$$

The factors N_0 and N_2 are required to normalize the states when the modified transition element of (47) is used. In the limit that $T\to 0$ all transition elements from a state to itself must coincide with unity. This requires fixing

$$|N_0|^{-2}=\sum_n\ |a_n|^2, \tag{62}$$

$$|N_2|^{-2}=\sum_n\ |b_n|^2, \tag{63}$$

which ensures that the inner product is unity:

$$\langle 0|U^\dagger|0\rangle=\langle 2|U^\dagger|2\rangle=1. \tag{64}$$

It is again straightforward to adapt the expressions (C13) and (C19) to show that for $\alpha=0$ and n even the coefficients are given by

$$a_n=\frac{N_c\sqrt{n!}}{2^{n/2}(n/2)!}\left(-\frac{g_2}{g_1}\right)^{n/2}, \tag{65a}$$

$$b_n=\frac{\sqrt{2}N_c\sqrt{n!}}{g_1^2 2^{n/2}(n/2-1)!}\left(-\frac{g_2}{g_1}\right)^{n/2}. \tag{65b}$$

Using the results of Appendixes B and C, the norms are then given by

$$|N_0|^2=\left(1-\frac{|\beta|^2}{\omega^2}\right)^{-1/2}, \tag{66a}$$

$$|N_2|^2=\left(1+\frac{|\beta|^2}{2\omega^2}\right)\left(1-\frac{|\beta|^2}{\omega^2}\right)^{-5/2}, \tag{66b}$$

where it has been assumed that $\beta/\omega<1$ in order for the series to converge. Evaluating the transition amplitude is now straightforward, since

$$W_{20}=\langle 0|U^\dagger e^{-iHT}|2\rangle=N_0^* N_2\sum_{n=0,2,\ldots}\ a_n^* b_n e^{-in\omega T}. \tag{67}$$

Using (65) and (66) and the identity (C2) gives

$$\lim_{\alpha\to 0} W_{20}=-\frac{\beta}{\sqrt{2}\omega}\left(1+\frac{|\beta|^2}{2\omega^2}\right)^{-1/2}\left(\frac{1-(|\beta|^2/\omega^2)}{1-(|\beta|^2/\omega^2)e^{-2i\omega T}}\right)^{3/2} e^{-2i\omega T}, \tag{68}$$

which is true up to the irrelevant arbitrary phase available for β.

It is now possible to compare result (58) to (68). Both expressions are characterized by only two parameters, ω and β, since $\Omega=\sqrt{\omega^2-4|\beta|^2}$ in expression (58). The first point is that (68) does not vanish as did (57a). Result (58) goes to zero at $|\beta|=\omega/2$, while (68) remains well defined for $|\beta|<\omega$. There is a great deal of similarity between (68) and (59) for β small. However, it is clear that the transition amplitude (58) for the Hermitian case deviates significantly from (68) as β increases. In the Hermitian case the frequency Ω is not independent of β, while in the non-Hermitian case (68) ω and β are independent parameters. Thus, as in other cases, the use of a non-Hermitian Hamiltonian has given rise to a well-defined theory but with different dynamics than its Hermitian counterpart.

ACKNOWLEDGMENT

The author wishes to thank Richard Sohn for carefully reading this manuscript and providing numerous helpful comments.

APPENDIX A: NORMAL ORDERING, FUNCTIONAL DEPENDENCE, AND DEGREES OF FREEDOM

The process of normal ordering a matrix element results in restrictions on the functional dependence of the matrix element upon its parameters. To illustrate consider the general matrix element

$$W_{00}=\langle 0|\exp\{-i(\omega a^\dagger a+\alpha a^2+\beta a^{\dagger 2})T\}|0\rangle, \tag{A1}$$

where ω, α, and β are real variables with the units of inverse time. In this case the operator U that maps H into $H^\dagger$ and discussed in Sec. III is absent in the definition (A1). The dimensionless operators $a^\dagger$ and a obey the commutation relation $[a,a^\dagger]=1$. Evaluation of (69) consists of normal ordering the a and $a^\dagger$ operators in an arbitrary power of the effective Hamiltonian. In so doing, it is a simple observation that in order to have a nonzero contribution to the matrix element, the product of the a and $a^\dagger$ operators must have equal numbers of a and $a^\dagger$ operators. Only for this case can the process of normal ordering the operators produce a nonzero c-number. In all other cases the process of normal ordering will result in terms with powers of either a or $a^\dagger$, and these have a vanishing matrix element. This is easily seen for low order crossterms such as $aa^{\dagger 2}$ and $aa^\dagger aa^\dagger$, and the general result can be then be established by induction.

This observation can now be coupled with the fact that the commutation relation $[a,a^\dagger]=1$ is invariant under the simultaneous phase transformations $a^\dagger\to e^{i\theta}a^\dagger$ and $a\to e^{-i\theta}a$. However, this transformation does not leave the effective Hamiltonian of (69) invariant, instead inducing the transformations

$$\alpha\to e^{-2i\theta}\alpha, \tag{A2a}$$

$$\beta\to e^{2i\theta}\beta, \tag{A2b}$$

$$\omega\to\omega, \tag{A2c}$$

on the parameters of the Hamiltonian. However, since all terms in the expansion of the exponential that produce nonzero contributions must have equal numbers of a and $a^\dagger$ operators, it follows that (A1) is invariant under this transformation. This means that the final result of evaluating (A1) can depend only upon combinations of parameters that are independent of the transformations (A2a)–(A2c), and this includes terms such as ω and $\alpha\beta$, as well as any combinations determined from the form of the states.

While these restrictions can serve as a consistency check for the form determined for (A1), the phase symmetry also reduces the number of free parameters in the generalized Bogoliubov transformation of (7) and (8). This follows from reexpressing the matrix element (A1) in terms of the

c and d operators. For the same reasons discussed earlier in this appendix, the matrix element (A1) will be independent of the simultaneous phase transformations $c \to e^{i\xi}c$ and $d \to e^{-i\xi}d$ since these also leave invariant the commutator $[a,a^\dagger]$ determined using (7) and (8). As a result, there are two independent arbitrary relative phases present in the generalized Bogoliubov transformation, the one associated with c and d and the one associated with a and $a^\dagger$. In effect, the generalized Bogoliubov transformations (12) and (13) could have been written

$$a = e^{i(\xi+\theta)}g_1 c + e^{-i(\xi-\theta)}g_2 d = e^{i\theta}(e^{i\xi}g_1 c + e^{-i\xi}g_2 d), \tag{A3}$$

$$a^\dagger = e^{i(\xi-\theta)}g_3 c + e^{-i(\xi+\theta)}g_4 d = e^{-i\theta}(e^{i\xi}g_3 c + e^{-i\xi}g_4 d), \tag{A4}$$

where θ and ξ are arbitrary real phases, without affecting the final result of evaluating the matrix element. All resulting expressions in the final form for the matrix element (A1) will therefore possess the symmetries (A2a)–(A2c) when combined with the simultaneous transformations

$$g_1 \to e^{i(\xi+\theta)}g_1, \tag{A5a}$$

$$g_2 \to e^{-i(\xi-\theta)}g_2, \tag{A5b}$$

$$g_3 \to e^{i(\xi-\theta)}g_3, \tag{A5c}$$

$$g_4 \to e^{-i(\xi+\theta)}g_4. \tag{A5d}$$

These symmetries ensure that two of the degrees of freedom in the g_j can always be removed by choosing θ and ξ appropriately, and therefore, these degrees of freedom cannot have any physical significance. This is identical to gauge fixing[10] in field theories, where the gauge symmetry corresponds to unphysical ghost states in the spectrum. Therefore, the g_j possess only six physical degrees of freedom with which to evaluate the matrix element.

APPENDIX B: SOLUTIONS OF THE GENERALIZED BOGOLIUBOV TRANSFORMATION

In this appendix the relevant properties of the g_j will be derived through algebraic manipulation for later use in the paper. The constraints of (16) can be rewritten as two quadratic equations under the assumption that $g_1 \neq 0$ and $g_4 \neq 0$:

$$\omega(g_3/g_1) + \alpha + \beta(g_3/g_1)^2 = 0, \tag{B1}$$

$$\omega(g_2/g_4) + \beta + \alpha(g_2/g_4)^2 = 0. \tag{B2}$$

Consistency with the limits (17) and (18) requires selecting the roots

$$g_3/g_1 = (-\omega + \sqrt{\omega^2 - 4\alpha\beta})/2\beta, \tag{B3}$$

$$g_2/g_4 = (-\omega + \sqrt{\omega^2 - 4\alpha\beta})/2\alpha. \tag{B4}$$

It follows that

$$\frac{g_2 g_3}{g_1 g_4} = (\omega^2 - 2\alpha\beta - \omega\sqrt{\omega^2 - 4\alpha\beta})/2\alpha\beta. \tag{B5}$$

Combining (B5) with condition (11) gives

$$g_1 g_4 = \frac{2\alpha\beta}{(4\alpha\beta - \omega^2 + \omega\sqrt{\omega^2 - 4\alpha\beta})}, \tag{B6}$$

$$g_2 g_3 = \frac{\omega - \sqrt{\omega^2 - 4\alpha\beta}}{2\sqrt{\omega^2 - 4\alpha\beta}}, \tag{B7}$$

$$g_1 g_4 + g_2 g_3 = \frac{\omega}{\sqrt{\omega^2 - 4\alpha\beta}}. \tag{B8}$$

Because (B5)–(B7) are invariant under the transformations of (A4), they can serve as fundamental components of the final form of the transition element. It also follows that $g_1 g_4$ is a real positive number as long as $\omega^2 - 4\alpha\beta \geqslant 0$, while $g_2 g_3$ is real but its sign is that of $\alpha\beta$.

The relationships among the g_j determined so far can now be used to determine other products and ratios. Straightforward algebraic manipulation gives

$$g_1 g_2 = \frac{g_1}{g_3} g_2 g_3 = -\frac{\beta}{\sqrt{\omega^2 - 4\alpha\beta}}, \tag{B9}$$

$$g_3 g_4 = \frac{g_4}{g_2} g_2 g_3 = -\frac{\alpha}{\sqrt{\omega^2 - 4\alpha\beta}}. \tag{B10}$$

The parameters appearing in the transformed Hamiltonian (14) are then given by

$$\Omega = (g_2 g_3 + g_1 g_4)\omega + 2 g_1 g_2 \alpha + 2 g_3 g_4 \beta = \sqrt{\omega^2 - 4\alpha\beta}, \tag{B11}$$

$$\epsilon = g_2 g_3 \omega + g_1 g_2 \alpha + g_3 g_4 \beta = \tfrac{1}{2}\sqrt{\omega^2 - 4\alpha\beta} - \tfrac{1}{2}\omega = \tfrac{1}{2}(\Omega - \omega). \tag{B12}$$

APPENDIX C: PROPERTIES OF THE EIGENSTATES

This appendix analyzes the properties of the states defined by (21) and (28) as well as the states built from them. To begin, the inner product of the states (24) and (27) is evaluated. Using their definitions the inner product reduces to the sum

$$\begin{aligned} \langle 0_c | 0_d \rangle &= N_c N_d \sum_{n,m=0}^{\infty} \frac{\sqrt{(2m)!}}{2^m m!} \frac{\sqrt{(2n)!}}{2^n n!} \left(\frac{g_2}{g_4}\right)^n \left(\frac{g_1}{g_3}\right)^m \langle m | n \rangle \\ &= N_c N_d \sum_{n=0}^{\infty} \frac{(2n)!}{4^n (n!)^2} \left(\frac{g_2 g_3}{g_1 g_4}\right)^n. \end{aligned} \tag{C1}$$

Result (B5) of Appendix B shows that $|g_2 g_3 / g_1 g_4| < 1$, so that the series in (C1) converges absolutely. Using the identity

$$\frac{1}{2\pi} \int_0^{2\pi} d\theta \cos^{2n}\theta = \frac{(2n)!}{4^n (n!)^2}, \tag{C2}$$

allows (C1) to be replaced by a geometric sum and integrated with the desired result that

$$\langle 0_c | 0_d \rangle = \frac{N_c N_d}{2\pi} \int_0^{2\pi} d\theta \frac{g_1 g_4}{g_1 g_4 - g_2 g_3 \cos^2\theta} = N_c N_d \sqrt{g_1 g_4}, \tag{C3}$$

where (11) has been used. The two states have a unit inner product for the conditions of (29). Similarly, the norm of the state (24) can be found to be

$$\langle 0_d|0_d\rangle = |N_d|^2 \sum_{n=0}^{\infty} \frac{(2n)!}{4^n (n!)^2} \left(\frac{|g_2|^2}{|g_4|^2} \right)^n = \frac{|N_d|^2 |g_2|^2}{\sqrt{|g_4|^2 - |g_2|^2}}, \tag{C4}$$

where the assumption that $|g_2|/|g_4| < 1$ has been made.

In proving completeness of the modified states (21) and (28) it will be necessary to evaluate their inner product with the harmonic oscillator ground state $|0\rangle$. This is accomplished by first noting the identity

$$c \exp\left(\frac{1}{2} \frac{g_2}{g_4} a^{\dagger 2} \right) = \exp\left(\frac{1}{2} \frac{g_2}{g_4} a^{\dagger 2} \right) \left(-g_3 a + \frac{a^\dagger}{g_4} \right), \tag{C5}$$

where (11) has again been used. As a result the state $|\tilde{n}\rangle$ can be written

$$|\tilde{n}\rangle = \frac{N_d}{\sqrt{n!}} \exp\left(\frac{1}{2} \frac{g_2}{g_4} a^{\dagger 2} \right) \left(-g_3 a + \frac{a^\dagger}{g_4} \right)^n |0\rangle. \tag{C6}$$

The inner product then reduces to evaluating

$$\langle 0|\tilde{n}\rangle = \frac{N_d}{\sqrt{n!}} \langle 0| \left(-g_3 a + \frac{a^\dagger}{g_4} \right)^n |0\rangle. \tag{C7}$$

The matrix element can be evaluated to give

$$T_n \equiv \left\langle 0 \left| \left(-g_3 a + \frac{a^\dagger}{g_4} \right)^n \right| 0 \right\rangle = \begin{cases} 0 & \text{if } n \text{ is odd} \\ \dfrac{n!}{2^{n/2}(n/2)!} \left(-\dfrac{g_3}{g_4} \right)^{n/2} & \text{if } n \text{ is even.} \end{cases} \tag{C8}$$

The proof is inductive, and begins by noting that (C8) is correct for $n = \{0,1,2,3,4\}$ by direct calculation. Assuming that T_n and T_{n-2} are given by (C8), the next term T_{n+2} can be evaluated inductively by using the formulas

$$a \left(-g_3 a + \frac{a^\dagger}{g_4} \right)^n = \left(-g_3 a + \frac{a^\dagger}{g_4} \right)^n a + \frac{n}{g_4} \left(-g_3 a + \frac{a^\dagger}{g_4} \right)^{n-1}, \tag{C9}$$

$$\left(-g_3 a + \frac{a^\dagger}{g_4} \right)^n a^\dagger = a^\dagger \left(-g_3 a + \frac{a^\dagger}{g_4} \right)^n - n g_3 \left(-g_3 a + \frac{a^\dagger}{g_4} \right)^{n-1}, \tag{C10}$$

with the result that for n an even integer

$$\begin{aligned} T_{n+2} &= -\frac{g_3}{g_4} \langle 0| a \left(-g_3 a + \frac{a^\dagger}{g_4} \right)^n a^\dagger |0\rangle \\ &= \frac{(n+2)!}{2^{(n+2)/2}((n+2)/2)!} \left(-\frac{g_3}{g_4} \right)^{(n+2)/2}, \end{aligned} \tag{C11}$$

which completes the proof of (C8). Using (C8) in (C7) yields the final form for the inner product

$$\langle 0|\tilde{n}\rangle = \begin{cases} 0 & \text{if } n \text{ is odd} \\ \dfrac{N_d \sqrt{n!}}{2^{n/2}(n/2)!} \left(-\dfrac{g_3}{g_4} \right)^{n/2} & \text{if } n \text{ is even.} \end{cases} \tag{C12}$$

A similar result follows for $\langle \overline{n}|0\rangle$

$$\langle\overline{n}|0\rangle=\begin{cases}0 & \text{if } n \text{ is odd}\\ \dfrac{N_c\sqrt{n!}}{2^{n/2}(n/2)!}\left(-\dfrac{g_2}{g_1}\right)^{n/2} & \text{if } n \text{ is even.}\end{cases} \tag{C13}$$

It is critical that the states (21) and (28) can be used to expand the harmonic oscillator states appearing in transition elements. This reduces to showing that the projection operator

$$\hat{P}=\sum_{n=0}^{\infty}|\tilde{n}\rangle\langle\overline{n}| \tag{C14}$$

is a unit operator in the Hilbert space of the harmonic oscillator states. The orthonormality of the states (21) and (28) ensures that the operator (C14) is idempotent, $\hat{P}^2=\hat{P}$. The proof that $\hat{P}$ is a unit projection operator is inductive, and begins by noting that (C12) and (C13) give

$$\langle 0|\hat{P}|0\rangle=N_cN_d\sum_{n=0,2,\ldots}^{\infty}\frac{n!}{2^n\left(\dfrac{n}{2}!\right)^2}\left(\frac{g_2g_3}{g_1g_4}\right)^{n/2}=N_cN_d\sqrt{\frac{g_1g_4}{g_1g_4-g_2g_3}}=1, \tag{C15}$$

where the method employed in summing (C1) has been used as well as using the condition (26) and the norms (30). As a result, $\langle 0|\hat{P}|0\rangle=\langle 0|0\rangle=1$.

The projection operator must also preserve orthonormality of the original harmonic oscillator states. Using the tools developed so far it is straightforward to show that

$$\sum_{n=0}^{\infty}\langle 1|\tilde{n}\rangle\langle\overline{n}|0\rangle=\langle 1|0\rangle=0. \tag{C16}$$

Result (C16) follows from the fact that $\langle 1|\tilde{n}\rangle=0$ for n even, while $\langle\overline{n}|0\rangle=0$ for n odd. The next step is to demonstrate that

$$\langle 2|\hat{P}|0\rangle=\sum_{n=0}^{\infty}\langle 2|\tilde{n}\rangle\langle\overline{n}|0\rangle=0. \tag{C17}$$

From the definitions of the modified states it follows that

$$\langle 2|\tilde{n}\rangle=\frac{N_dn(n-1)}{g_4^2\sqrt{2(n!)}}\langle 0|\left(-g_3a+\frac{1}{g_4}a^{\dagger}\right)^{(n-2)}|0\rangle+\frac{N_d}{\sqrt{2(n!)}}\frac{g_2}{g_4}\langle 0|\left(-g_3a+\frac{1}{g_4}a^{\dagger}\right)^{n}|0\rangle, \tag{C18}$$

where the first term on the right hand side of (C18) is present only if $n\geqslant 2$. Result (C8) can now be used to show that

$$\langle 2|\tilde{n}\rangle=\frac{N_d}{\sqrt{2(n!)}}\frac{n!}{2^{n/2}(n/2)!}\left[\frac{g_2}{g_4}-\frac{n}{g_3g_4}\right]\left(-\frac{g_3}{g_4}\right)^{n/2}+\frac{N_dg_2}{\sqrt{2}g_4}, \tag{C19}$$

where the $n=0$ contribution has been written as the last term on the right hand side of (C19). Result (C19) can now be combined with (C8) to give

$$\sum_{n=0}^{\infty}\langle 2|\tilde{n}\rangle\langle\overline{n}|0\rangle=\frac{N_cN_dg_2}{\sqrt{2}g_4}+\frac{N_cN_dg_2}{\sqrt{2}g_4}\sum_{n=2,4,\ldots}^{\infty}\frac{n!}{2^n((n/2)!)^2}\left(1-\frac{n}{g_2g_3}\right)\left(\frac{g_2g_3}{g_1g_4}\right)^{n/2}. \tag{C20}$$

Using the identities

$$\frac{g_2}{\sqrt{2}g_4}\sum_{n=2,4,\ldots}^{\infty}\frac{n!}{2^n((n/2)!)^2}\left(\frac{g_2g_3}{g_1g_4}\right)^{n/2}=\frac{g_2}{\sqrt{2}g_4}(\sqrt{g_1g_4}-1), \tag{C21}$$

$$\frac{1}{\sqrt{2}g_3g_4}\sum_{n=2,4,\ldots}^{\infty}\frac{n\,n!}{2^n((n/2)!)^2}\left(\frac{g_2g_3}{g_1g_4}\right)^{n/2}=\frac{g_2}{\sqrt{2}g_4}\sqrt{g_1g_4}, \tag{C22}$$

shows that (C20) vanishes. The preservation of orthonormality can now be extended to all the harmonic oscillator states by using induction.

APPENDIX D: THE *U* TRANSFORMATION

The object is to demonstrate that the action of the operator U, given by (39), maps the eigenstates into their orthonormal duals under the adjoint operation. The U operator is invariant under the transformations of (A5a)–(A5d), which is required for consistency. The first two operators in (39) leave the state $|0_d\rangle$ invariant by virtue of the fact that $d|0_d\rangle=0$, so their action is solely upon the c operators that define the eigenstate. The Baker–Campbell–Hausdorff theorem gives

$$\exp\left\{\frac{1}{2}\left(\frac{g_3^*}{g_1^*}-\frac{g_2}{g_4}\right)a^{\dagger 2}\right\}\exp\left(\frac{1}{2}wd^2\right)\exp(cd\ln z)c^n|0_d\rangle=\exp\left\{\frac{1}{2}\left(\frac{g_3^*}{g_1^*}-\frac{g_2}{g_4}\right)a^{\dagger 2}\right\}(zc+wzd)^n|0_d\rangle. \tag{D1}$$

Using the forms (7) and (8) for c and d allows the action of the remaining operator in (39) to be evaluated, with the result that

$$\exp\left\{\frac{1}{2}\left(\frac{g_3^*}{g_1^*}-\frac{g_2}{g_4}\right)a^{\dagger 2}\right\}(zc+wzd)^n|0_d\rangle=N_d\left(z\left[\frac{1}{g_4}+\frac{g_3g_3^*}{g_1^*}-\frac{wg_3^*g_4}{g_1^*}\right]a^\dagger + z[wg_4-g_3]a\right)^n\exp\left(\frac{1}{2}\frac{g_3^*}{g_1^*}a^{\dagger 2}\right)|0\rangle, \tag{D2}$$

where (11) has been used. Using (40), the forms for z and w, and the complex conjugate of (11) yields the desired result that

$$Uc=\left\{z\left[\frac{1}{g_4}+\frac{g_3g_3^*}{g_1^*}-\frac{wg_3^*g_4}{g_1^*}\right]a^\dagger+z[wg_4-g_3]a\right\}U=(g_4^*a^\dagger-g_2^*a)U=d^\dagger U, \tag{D3}$$

while comparison with (27) shows that

$$(U|0_d\rangle)^\dagger=\left(N_d\exp\left(\frac{1}{2}\frac{g_3^*}{g_1^*}a^{\dagger 2}\right)|0\rangle\right)^\dagger=\langle 0_c|. \tag{D4}$$

Combining these results gives

$$\left(U\frac{c^n}{\sqrt{n!}}|0_d\rangle\right)^\dagger=\left(\frac{d^{\dagger n}}{\sqrt{n!}}|0_c\rangle\right)^\dagger=\langle\overline{n}|. \tag{D5}$$

This completes the demonstration of (35).

From (D3) it is clear that (41a) is satisfied. The Baker–Campbell–Hausdorff theorem gives

$$\exp\left(\frac{1}{2}wd^2\right)\exp(cd\ln z)d=\frac{d}{z}\exp\left(\frac{1}{2}wd^2\right)\exp(cd\ln z), \tag{D6}$$

while using (11) shows

$$\exp\left\{\frac{1}{2}\left(\frac{g_3^*}{g_1^*}-\frac{g_2}{g_4}\right)a^{\dagger 2}\right\}d=\left(g_4 a-\frac{g_3^* g_4}{g_1^*}a^\dagger\right)\exp\left\{\frac{1}{2}\left(\frac{g_3^*}{g_1^*}-\frac{g_2}{g_4}\right)a^{\dagger 2}\right\}. \tag{D7}$$

Combining these results with $z=g_4/g_1^*$ and noting that (7) gives $c^\dagger=g_1^* a-g_3^* a^\dagger$ immediately yields (41b).

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 2 FEBRUARY 2004

The Euler characteristic and the first Chern number in the covariant phase space formulation of string theory

R. Cartas-Fuentevilla[a)]
Instituto de Física, Universidad Autónoma de Puebla,
Apartado postal J-48 72570, Puebla Pue., México

(Received 23 July 2003; accepted 23 October 2003)

Using a covariant description of the geometry of deformations for extendons, it is shown that the topological corrections for the string action associated with the Euler characteristic and the first Chern number of the normal bundle of the world sheet, although do not give dynamics to the string, modify the symplectic properties of the covariant phase space of the theory. Future extensions of the present results are outlined. © *2004 American Institute of Physics.*

I. INTRODUCTION

As it is well known, string theory contains two natural topological invariants related with the different topologies of the two-dimensional world surface embedded in a background space–time. Specifically, the Gauss–Bonnet action, which depends only on the purely intrinsic properties of the world surface, corresponds to the Euler characteristic, which counts the number of holes or handles of the world surface. Additionally, the first Chern number of the normal bundle of the world surface, which depends on the extrinsic properties of the world surface embedded in a (four-dimensional) background space–time, gives us essentially the number of self-intersections of the world surface. Such topological invariants do not contribute effectively as Lagrangian terms to the string dynamics, although it is well known also that there is a global contribution in the path integral formulation of the theory, weighting the different topologies in the sum over world surfaces.

On the other hand, in the canonical formulations of the theory for quantization, based on the classical dynamics of the theory, the topological terms will have no any contribution, since the dynamics remains unmodified. The fact that such terms play a nontrivial role in the path integral formulation of the theory, and do not appear at all in the canonical scheme, is somewhat suspicious at first glance. Hence, the aim of this work is to show that, on the basis of a covariant description of the canonical formulation of the theory, the topological terms in the string action may have indeed a physically relevant contribution on the symplectic structure constructed on the corresponding covariant phase space. With these results, we give a new relevant role of the topological terms within a canonical formulation, which is completely unknown in the literature, levelling thus the roles of such terms in both approaches for quantization.

In the next section, we outline the covariant canonical formalism, and in Sec. III we give some remarks on the covariant canonical formulation of the Dirac–Nambu–Goto (DNG) action, in order to prepare the background for the subsequent sections, where the topological terms will be worked out. In Sec. VII we conclude with some discussions about our results and future extensions.

II. COVARIANT PHASE SPACE AND THE EXTERIOR CALCULUS

In this section we summarize the exterior calculus on the covariant phase space given in Ref. 1 but adjusted for the treatment of embeddings.[2]

[a)]Electronic mail: rcartas@sirio.ifuap.buap.mx

According to Ref. 1, in a given physical theory, *the classical phase space is the space of solutions of the classical equations of motion*, which corresponds to a manifestly covariant definition. The basic idea of the covariant description of the canonical formalism is to construct a symplectic structure on such a phase space, instead of choosing p's and q's.

In the present case, the phase space is the space of solutions of Eq. (12), and we shall call it Z. Any background quantity, will be associated with zero-forms on Z. The deformation operator δ (see Sec. III) acts as an exterior derivative on Z, taking k-forms into $(k+1)$-forms, and it should satisfy

$$\delta^2 = 0, \tag{1}$$

and the Leibniz rule

$$\delta(AB) = \delta A B + (-1)^A A\, \delta B. \tag{2}$$

In particular, δX^μ is the exterior derivative of the zero-form X^μ [see Eq. (5)], and it will be closed,

$$\delta^2 X^\mu = 0. \tag{3}$$

Furthermore, since $\phi^i = n^i_\mu \delta X^\mu$, and n^i_μ corresponds to zero-forms on Z, the scalar fields ϕ^i are one-forms on Z, and thus are anticommutating objects: $\phi^i \phi^j = -\phi^j \phi^i$. This property allows us to verify that, being the vector field $\delta = n^i \phi_i$, thus $\delta^2 = n^i n^j \phi_i \phi_j$, which vanishes because of the commutativity of the zero-form n^i and the anticommutativity of the ϕ^i on Z, in full agreement with Eq. (1). It is important to mention, at this point, that the covariant deformation operator D_δ (see Sec. III) also works as an exterior derivative on Z, in the sense that maps k-forms into $(k+1)$-forms; however D_δ^2 does not vanish necessarily.

We can determine certain two-forms on Z that will be useful for our present purposes. Considering that $\delta \equiv \delta X^\mu \partial_\mu$ and $D_\delta \equiv \delta X^\mu D_\mu$, we can show that $D_\delta(\delta X^\mu)$ vanishes,

$$D_\delta(\delta X^\mu) = \delta X^\alpha D_\alpha \delta X^\mu = \delta X^\alpha [\partial_\alpha \delta X^\mu + \Gamma^\mu_{\alpha\lambda} \delta X^\lambda] = \delta^2 X^\mu + \Gamma^\mu_{\alpha\lambda} \delta X^\alpha \delta X^\lambda = 0, \tag{4}$$

where the first term vanishes according to Eq. (3), and the second one because of the symmetry of $\Gamma^\mu_{\alpha\lambda}$ in the indices α and λ, and the anticommutativity of δX^α and δX^λ. Hence, Eq. (4) suggests that D_δ is, as well as δ, a measure of the closeness of δX^μ on Z.

III. COVARIANT CANONICAL FORMULATION FOR DNG *p*-BRANES IN A CURVED BACKGROUND

It will be convenient to do the general treatment for p-branes, and then to consider the particular case of string theory (1-brane), which will show the particularities of string theory as opposed to the other higher-dimensional objects.

In Ref. 2 it is shown that there exists an identically closed two-form on the space of solutions of the classical equations of motion (modulo gauge transformations) for p-branes propagating in a curved background, endowing to the physical phase space $\hat{Z}$ of a symplectic structure. However, a more detailed study[3] shows that such a closed two-form is even an exact two-form, obtained by direct exterior derivative of a *symplectic potential*, a global one-form on the phase space. The strategy in Ref. 3 for obtaining the global symplectic potential directly from the variations of the corresponding Lagrangian is as follows.

In the geometry of deformations of p-branes developed in Ref. 4, it is assumed that an infinitesimal deformation tangent to the world surface is not physically relevant, since it can be identified always with the action of a world surface diffeomorphism. However, as claimed in Ref. 3, it is precisely such an infinitesimal diffeomorphism that plays the role of our global symplectic potential on the phase space (and it is the first example showing that a *spurious* quantity in a

conventional sense, may be physically relevant on the phase space). Hence, we will maintain explicitly a world surface diffeomorphism from the beginning, modifying slightly the original deformation scheme given in Ref. 4.

In this manner, following Ref. 4, the deformation of the world surface swept out by a p-brane (propagating in a curved background) is given by the infinitesimal space–time variation

$$\xi^{\mu} \equiv \delta X^{\mu} = n_i^{\mu} \phi^i + e_a^{\mu} \phi^a, \tag{5}$$

where n_i correspond to vector fields normal to the world surface and, e_a to the vector fields tangent to such a surface.[4] Hence, considering that D_{μ} is the background torsionless covariant derivative, in Ref. 4 the normal deformation operator is defined as

$$D_{\delta} \equiv \delta^{\mu} D_{\mu}, \quad \delta \equiv n_i \phi^i, \tag{6}$$

and it is found that[4]

$$\begin{aligned} D_{\delta} c_a &= (K_{ab}^i \phi_i) e^b + (\tilde{\nabla}_a \phi_i) n^i, \\ D_{\delta} \gamma_{ab} &= 2 K_{ab}^i \phi_i, \\ D_{\delta} \sqrt{-\gamma} &= \sqrt{-\gamma} K^i \phi_i, \end{aligned} \tag{7}$$

which will be useful below. We define here the tangential deformation operator as

$$D_{\Delta} \equiv \Delta^{\mu} D_{\mu}, \quad \Delta \equiv e_a \phi^a, \tag{8}$$

and using the generalized Gauss–Weingarten equations, we find that

$$\begin{aligned} D_{\Delta} e_a &= (\nabla_a \phi^b) e_b - K_{ab}^i \phi^b n_i, \\ D_{\Delta} \gamma_{ab} &= \nabla_a \phi_b + \nabla_b \phi_a, \\ D_{\Delta} \sqrt{-\gamma} &= \sqrt{-\gamma} \nabla_a \phi^a. \end{aligned} \tag{9}$$

In this manner, the action for DNG p-branes,

$$S_0 = -\sigma_0 \int \mathrm{d}^D \xi \sqrt{-\gamma}, \tag{10}$$

considering world surface diffeomorphisms, has as a first variation

$$0 = (D_{\delta} + D_{\Delta}) S_0 = -\sigma_0 \int \mathrm{d}^D \xi \sqrt{-\gamma} K^i \phi_i - \sigma_0 \int \mathrm{d}^D \xi \sqrt{-\gamma} \nabla_a \phi^a, \tag{11}$$

where the last of Eqs. (7) and (9) have been considered; from Eq. (11) we can see that $D_{\Delta} S_0$ is associated with a total divergence that can be indeed negligible, since it does not contribute locally to the dynamics.

Therefore, from Eq. (11), the equations of motion for extremal surfaces are

$$K^i = 0, \tag{12}$$

whose set of solutions defines, in fact, the covariant phase space Z of the theory.

On the other hand, from the deformation dynamics [obtained linearizing Eq. (12)], and using the scheme of (self-) adjoint operators, it is found that the current $j^a = \phi_i \tilde{\nabla}^a \phi^i$ is world surface

covariantly conserved ($\nabla_a j^a = 0$), and corresponds to a closed two-form on the phase space $D_\delta j^a = 0$.[2] Therefore, one can finally construct a covariant and gauge invariant symplectic structure ω for the theory,[2]

$$\omega \equiv \int_\Sigma \sqrt{-\gamma} j^a \, d\Sigma_a , \tag{13}$$

independent on the choice of Σ (a spacelike section of the world surface corresponding to a Cauchy p-surface for the configuration of the p-brane). However, the symplectic current j^a is even an exact two-form,[3] since from Eqs. (4), (5), and the first of Eqs. (7) one finds that

$$\delta\phi^a = D_\delta(e^a_\mu \delta X^\mu) = -j^a, \tag{14}$$

and j^a is in particular a closed form, $\delta j^a = 0$, because of the nilpotency of δ [see Eq. (1)]. Therefore ϕ^a (the tangential projection of the deformation of the embedding), coming directly from the pure divergence term in Eq. (11), plays the role of a global symplectic potential on the phase space. As pointed out above, ϕ^a gives no dynamics to the string, but it is physically relevant on the phase space, in accordance with Eq. (14).

It is important to emphasize here, the significance of a covariant and gauge invariant symplectic structure for the theory. ω in Eq. (13) represents a complete *Hamiltonian* description of the covariant phase space, preserving manifestly all relevant symmetries of the theory. Hence, ω represents a starting point for the study of the symmetry aspects and also a covariant description of the canonical formulation of the theory for quantization. For the general features of the covariant phase space formulation, see, for example, Ref. 1. Note, however, that the concept of symplectic potential does not appear at all in Ref. 1.

In the next section we will follow the same procedure employed in this section for determining the symplectic potential ϕ^a, in order to find the contribution of the Gauss–Bonnet topological term in the action on the covariant phase space of the theory.

IV. THE GAUSS–BONNET TOPOLOGICAL TERM

The Gauss–Bonnet term for an arbitrary closed p-brane without physical boundaries is proportional to the Ricci scalar $\mathcal{R}$ constructed from the world surface metric γ_{ab},

$$\chi \equiv \sigma_1 \int d^D\xi \sqrt{-\gamma}\mathcal{R}, \tag{15}$$

whose first variation, according to the geometry of deformations of Ref. 4, is given by

$$D_\delta(\sqrt{-\gamma}\mathcal{R}) = -2\sqrt{-\gamma}G_{ab}K_i^{ab}\phi^i + \sqrt{-\gamma}\nabla_a\psi_N^a, \tag{16}$$

where G_{ab} is the world surface Einstein tensor

$$G_{ab} = \mathcal{R}_{ab} - \tfrac{1}{2}\gamma_{ab}\mathcal{R}, \tag{17}$$

and

$$\psi_N^a = \gamma^{ab}D_\delta\gamma^c_{bc} - \gamma^{bc}D_\delta\gamma^a_{bc} \tag{18}$$

is the analogous to ϕ^a in Sec. III. Note that in Ref. 4, the pure divergence term involving ψ_N^a is completely ignored (which is correct in a conventional analysis of the brane dynamics), without suspecting the relevant role that such a term will play in a phase space formulation of the theory.

In this manner, Eq. (16) gives the universal contribution of the Gauss–Bonnet term on the brane dynamics (the first term on the right-hand side), and on the covariant phase space through ψ_N^a. In this sense, there is no surprise for an arbitrary p-brane, since χ changes the dynamics and

correspondingly the symplectic structure on the phase space. Nevertheless, as it is well known, in a two-dimensional world surface (and only for such a case), swept out for a string, the world surface Einstein tensor vanishes (for an arbitrary embedding background dimension),

$$G_{ab}=0, \tag{19}$$

and there is not effect on the string dynamics. However, there is a nontrivial contribution of the topological term on the phase space through symplectic potential (18), independently on the null contribution at the level of the string dynamics. For example, in the case considered in Sec. III, if Eqs. (12) are the equations of motion for the closed string dynamics described by external surfaces, the inclusion of the topological term χ in the action leaves Eqs. (12) unchanged (and thus the phase space itself, defined as the space of solutions of the equations of motion, is unaltered), but the corresponding symplectic potential on the phase space is no longer $-\sigma_0\phi^a$, but $-\sigma_0\phi^a+\sigma_1\psi_N^a$, where ψ_N^a is given in Eq. (18).

Although we have considered only the DNG closed strings as the reference Lagrangian term for the inclusion of the GB term, the main idea is to show that $\sigma_1\psi_N^a$ is the universal contribution of the latter on the phase space, and similarly for any action describing strings, for example, some action including terms with curvature corrections.[3] Therefore, if Φ^a is the symplectic potential for such a general action, we can construct the symplectic structure ω as

$$\omega=\int_\Sigma D_\delta\sqrt{-\gamma}(\Phi^a+\sigma_1\psi_N^a)\mathrm{d}\Sigma_a, \tag{20}$$

with the wanted properties of closeness ($\delta\omega=0$). The closeness of ω is equivalent to the Jacobi identity that the Poisson brackets satisfy, in the usual Hamiltonian scheme.[5]

Considering the deformation formulas of Ref. 4, we can determine explicitly the universal contribution of ψ_N^a to the symplectic current of the theory, in terms of ϕ^i, the only measure of the deformation that cannot be gauged away,

$$D_\delta\psi_N^a=-2\phi_i\{K^{abi}\nabla_b(K^j\phi_j)+K^{bci}[\nabla_b(K_c^{aj}\phi_j)+\nabla_c(K_b^{aj}\phi_j)-\nabla^a(K_{bc}^j\phi_j)]\}; \tag{21}$$

which will constitute the universal integral kernel of the Euler characteristic on the symplectic geometry of string theory. Note that even in the simplest case of a DNG closed string dynamics described by Eq. (12), $D_\delta\psi_N^a$ in Eq. (21) does not vanish. Therefore, the topological term modifies drastically the symplectic properties of the phase space of the theory, without changing the dynamics and the phase space itself.

V. THE FIRST CHERN NUMBER OF THE NORMAL BUNDLE OF THE WORLD SHEET

The self-intersection number of the world sheet embedded in a four-dimensional background space–time, given essentially by the first Chen number of the normal bundle of the world sheet, has the analytic expression[6,7]

$$\nu=\sigma_2\int \mathrm{d}^2\xi\,\Omega, \tag{22}$$

in terms of the extrinsic twist curvature,

$$\begin{aligned}\Omega&=\tfrac{1}{2}\epsilon_{ij}\epsilon^{ab}\Omega_{ab}^{ij},\\ \Omega_{ab}^{ij}&=\partial_b\omega_a^{ij}-\partial_a\omega_b^{ij},\end{aligned} \tag{23}$$

where ω_a^{ij} corresponds to the extrinsic twist potential.[4,7] Using Eqs. (23), ν can be rewritten explicitly as a topological invariant in terms of a total divergence,

$$\nu = \sigma_2 \int \mathrm{d}^2\xi \sqrt{-\gamma} \nabla_a (\epsilon_{ij} \epsilon^{ab} \omega_b^{ij}), \tag{24}$$

where $\epsilon^{ab} = \sqrt{-\gamma} \epsilon^{ab}$.[7] In order to determine the variation of ν, we exploit the frame gauge dependence of the potential ω_b^{ij}, which means that it can always be set equal to zero at any single chosen point by an appropriate choice of the normal frame,

$$\delta\nu = \sigma_2 \int \mathrm{d}^2\xi \sqrt{-\gamma} \nabla_a (\epsilon_{ij} \epsilon^{ab} \delta\omega_b^{ij}), \tag{25}$$

where the (normal) variation of the twist potential is given in terms of ϕ^i by[4,7]

$$\delta\omega_b^{ij} = -2K_{cb}^i \tilde{\nabla}^c \phi^j + R_{\mu\nu\alpha\beta} n^{\mu i} n^{\nu j} n^{\alpha\kappa} e_b^\beta \phi_\kappa, \tag{26}$$

where $R_{\mu\nu\alpha\beta}$ is the Riemann tensor of the (four-dimensional) background space–time. In this manner, following the ideas of the present work, from Eq. (25) we can identify to $\Theta^a = \sigma_2 \epsilon_{ij} \epsilon^{ab} \delta\omega_b^{ij}$ as a symplectic potential for ν. Thus, the contribution of ν on the integral Kernel of the symplectic structure of the theory is given by the deformation (exterior derivative) of Θ^a,

$$\delta\Theta^a = -K_i \phi^i \Theta^a, \tag{27}$$

where we have considered that $\delta\sqrt{-\gamma} = \sqrt{-\gamma} K_i \phi^i$.[4] Note that the effect of adding ν to the DNG string action is, in addition to leave unaltered the dynamics governed by $K^i = 0$ [Eq. (12)], to leave unchanged the symplectic structure for the theory (unlike the case of χ in Sec. IV), since in this case $\delta\Theta^a = 0$ in accordance with Eq. (27); of course the situation is different in a more general case than that described by the DNG action, where in general $K^i \neq 0$. Therefore, if Ψ^a is the symplectic potential for such a general action (which may include, for example, the Gauss–Bonnet term χ considered in Sec. IV), the symplectic structure ω of string theory (in four dimensions) including the term ν will take the form

$$\omega = \int_\Sigma D_\delta (\sqrt{-\gamma} \Psi^a) \mathrm{d}\Sigma_a + \int_\Sigma D_\delta \Theta^a \, \mathrm{d}\Sigma_a, \tag{28}$$

which is evidently closed.

The same argument employed in Ref. 2 for demonstrating the nondegeneracy of the symplectic structure for DNG branes works for the contributions of the topological terms on the symplectic structure of the theory. In this manner the ω's in (20) and (28) are nondegenerate and are defined on the reduced phase space Z/G, with G being the volume of the group of infinitesimal space–time diffeomorphisms.[2]

VI. REMARKS ON OPEN AND CLOSED STRINGS

In Ref. 7 open strings with topologically inspired boundary conditions are considered, specifically the topological terms considered here for closed strings. In both cases, such topological terms do not affect the equations of motion; however, in the case of open strings such terms lead to boundary conditions to be implemented in addition to the equations of motion, unlike the case treated here of closed strings, where such complementary conditions do not appear at all, because of the absence of physical boundaries. Thus, it is opportune to emphasize the results presented in this work: the topological terms for closed strings do not modify the classical dynamics, neither imposing any additional condition, but contributing explicitly to the symplectic structure of the theory, and thus they may have possible quantum effects.

It is important to remark also that the symplectic potentials for the topological terms χ and ν are the same for both closed and open strings; however for the former the symplectic structure will

be constructed on the phase space defined by the (unmodified) equations of motion, and for the latter on a *restriction* of the same phase space defined by the complementary conditions mentioned above.

VII. REMARKS AND PROSPECTS

In Ref. 8, it is proved that the topological terms modify drastically the deformation dynamics of string theory, in such a way that the symplectic current obtained as a consequence of the self-adjointness of that deformation dynamics, is in full agreement with the currents obtained in the present treatment calculating the variations of the symplectic potentials. Specifically it is proved that the symplectic currents of the topological terms in Eqs. (20) and (28) are world sheet covariantly conserved: $\nabla_a(D_\delta\sqrt{-\gamma}\psi_N^a)=0=\nabla_a(D_\delta\Theta^a)$, which ensures that the ω's in (20) and (28) are independent on the choice of Σ. It is important to mention that such world sheet conserved currents that play the role of integral kernels for the symplectic structures on Z in the present approach, can be considered, in a more ordinary sense, as Noetherian current for the topological invariants considered, which will allow us in this sense to obtain conserved currents associated with any continuous symmetries of the background. In the context of brane dynamics in the current literature, these conserved currents only have been considered in this conventional sense.[9]

Since a symplectic structure ω governs the transition between the classical and quantum domains, and allows us to consider also the aspects of symmetry of the theory, it may be interesting to study the possible contribution of the topological terms on the Poincaré charges, Poincaré algebra, and the relevant commutation relations of the theory. In this sense, because of the presence of the topological terms, the quantum version of string theory obtained from the unmodified classical dynamics, may be radically different to that obtained from the global description of the phase space given in terms of ω. All these questions will be the subject of forthcoming communications.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 45, NUMBER 2 FEBRUARY 2004

Construction of a family of quantum Ornstein–Uhlenbeck semigroups

Chul Ki Ko[a] and Yong Moon Park[b]
Department of Mathematics, Yonsei University, Seoul 120-749, Korea

(Received 17 April 2003; accepted 19 November 2003)

For a given quasi-free state on the CCR algebra over one dimensional Hilbert space, a family of Markovian semigroups which leave the quasi-free state invariant is constructed by means of noncommutative elliptic operators and Dirichlet forms on von Neumann algebras. The generators (Dirichlet operators) of the semigroups are analyzed and the spectrums together with eigenspaces are found. When restricted to a maximal Abelian subalgebra, the semigroups are reduced to a unique Markovian semigroup of classical Ornstein–Uhlenbeck process. © *2004 American Institute of Physics.* [DOI: 10.1063/1.1641150]

I. INTRODUCTION

The purpose of this paper is to find the explicit expressions of the generators of Markovian semigroups on the CCR algebra $\mathcal{A}$ over one dimensional Hilbert space, which leave a given (fixed) quasi-free state ω on $\mathcal{A}$ invariant. By means of noncommutative elliptic operators[1] and Dirichlet forms on standard forms of von Neumann algebras,[2] we construct a family of symmetric Markovian semigroups on the natural standard form associated to the GNS representation of the pair $(\mathcal{A},\omega)$. If one restricts the semigroups to a maximal Abelian subalgebra, then the semigroups are reduced to a unique Markovian semigroup of classical Ornstein–Uhlenbeck (O-U) process. Each generator of the semigroups has a discrete spectrum and a simple lowest eigenvalue. Thus the semigroups are ergodic and tend to the equilibrium exponentially fast.

The need to construct Markovian semigroups on von Neumann algebras, which are symmetric with respect to a nontracial state, is clear for various applications to open systems,[3] quantum statistical mechanics,[4] and quantum probability theory.[5–7] Although on the abstract level we have quite a well-developed theory,[2,8,9] the progress in concrete applications is very slow. We would like to mention a few works in this direction. The completely positive Hamiltonian semigroup for quantum spin chains in the ground state representation has been considered in Ref. 10. In Refs. 11 and 12, the generalized conditional expectation is used to construct generators of spin-flip type dynamics for quantum spin systems. In Ref. 13, one of authors gave a general construction method of Dirichlet forms on standard forms of von Neumann algebras and applied the method to construct translation invariant Markovian semigroups for quantum spin systems. The method of Ref. 13 has been extended to construct symmetric Markovian semigroups on the CCR and CAR algebras with respect to quasi-free states,[14,15] and on quantum mechanical systems.[16] In Ref. 17, quantum O-U semigroups were constructed by means of noncommutative Dirichlet forms. It may be worthwhile to mention that for a given quasi-free state ω on the CCR algebra $\mathcal{A}$, the O-U semigroup constructed in Ref. 17 belongs to the family of semigroups we constructed in this article. See Sec. III for the details.

Let us describe the content of this paper briefly. Let $\mathcal{A}$ be the C^*-algebra generated by the Weyl operators $W(z)$, $z \in \mathbb{C}$. See Sec. 5.2 of Ref. 4 for the details. The quasi-free state ω on $\mathcal{A}$ is given by

[a]Electronic mail: kochulki@hotmail.com
[b]Electronic mail: ympark@yonsei.ac.kr

$$\omega(W(z))=\exp\{-\tfrac{1}{4}|z|^2(1+e^{-\beta})(1-e^{-\beta})^{-1}\},\ z\in\mathbb{C}, \tag{1.1}$$

where $\beta\in(0,\infty)$ is the inverse temperature, which is fixed throughout in this article.

Let $(\mathcal{H}_\omega,\pi_\omega,\Omega_\omega)$ be the GNS representation[4] of $(\mathcal{A},\omega)$ and let $\mathcal{M}=\pi_\omega(\mathcal{A})''$. For each $z\in\mathbb{C}$, we denote by $\Phi_\omega(z)$ the infinitesimal generator of the strongly continuous unitary group $\pi_\omega(W(tz)),t\in\mathbb{R}$:

$$\pi_\omega(W(tz))=\exp(it\Phi_\omega(z)). \tag{1.2}$$

Let Q and P be the position and momentum operators given by

$$Q=\Phi_\omega(1),\quad P=\Phi_\omega(i). \tag{1.3}$$

From now on we write $\mathcal{H}=\mathcal{H}_\omega$, $\xi_0=\Omega_\omega$ and $W(z)=\pi_\omega(W(z))$, $\forall z\in\mathbb{C}$. Let σ_t be the group of automorphisms on $\mathcal{M}$ defined by

$$\sigma_t(W(z))=W(e^{-i\beta t}z),\ \forall z\in\mathbb{C}. \tag{1.4}$$

The state ω satisfies the σ-KMS condition[4] and thus σ_t, $t\in\mathbb{R}$, is the group of the modular automorphisms. Let Δ and J be the modular operator and modular conjugation respectively associated to $(\mathcal{M},\xi_0)$. Then $\sigma_t(A)=\Delta^{it}A\Delta^{-it}$, $A\in\mathcal{M}$. Let $\mathcal{M}'$ be the commutant of $\mathcal{M}$. The map $j:\mathcal{M}\to\mathcal{M}'$ is the antilinear $*$-isomorphism defined by $j(A)=JAJ$, $A\in\mathcal{M}$. The natural positive cone $\mathcal{P}$ associated with $(\mathcal{M},\xi_0)$ is the closure of the set $\{Aj(A)\xi_0:A\in\mathcal{M}\}$. Then $(\mathcal{M},\mathcal{H},\mathcal{P},J)$ is the natural standard form associated to $(\mathcal{M},\xi_0)$.

Next let us describe the explicit forms of the generators of Markovian semigroups on $\mathcal{M}$ which leave ω invariant. In Ref. 1, the authors constructed Markovian semigroups on von Neumann algebras by the quantum Feynman–Kac formula. Let $\mathcal{N}$ be a von Neumann algebra and $b=b^*\in\mathcal{N}$. Let δ be a densely defined $*$-derivation on $\mathcal{N}$ such that $\mathbf{1}\in D(\delta)$ and $\delta(\mathbf{1})=0$. Let G^b be an elliptic operator on $\mathcal{N}$ defined by

$$\begin{aligned} &D(G^b)=D(\delta^2),\\ &G^b(A)=-\tfrac{1}{2}\delta^2(A)-b\,\delta(A)-\delta(A)b+\tfrac{1}{2}[b,[b,A]],\ A\in D(G^b), \end{aligned} \tag{1.5}$$

where $[A,B]=AB-BA$, $A,B\in\mathcal{N}$. It was shown that the closed extension of G^b generates a Markovian semigroup on $\mathcal{N}$.[1]

We are searching for elliptic operators on $\mathcal{M}$ which generate Markovian semigroup leaving ω invariant. Let $\alpha_1,\alpha_2,\alpha_3\in\mathbb{R}$ be real parameters. In (1.5), we choose $\delta(A)=i[P,A]$ and $b=\alpha_1 Q$, and let

$$G_1(A):=\tfrac{1}{2}[P,[P,A]]-i\alpha_1(Q[P,A]+[P,A]Q)+\tfrac{1}{2}\alpha_1^2[Q,[Q,A]].$$

Next, choose $\delta(A)=i\alpha_3[Q,A]$ and $b=\alpha_2 P$, and let

$$G_2(A):=\tfrac{1}{2}\alpha_3^2[Q,[Q,A]]-i\alpha_2\alpha_3(P[Q,A]+[Q,A]P)+\tfrac{1}{2}\alpha_2^2[P,[P,A]].$$

Let G be the elliptic operator on $\mathcal{M}$ given by

$$\begin{aligned} G(A):=\gamma\{G_1(A)+G_2(A)\}=&\frac{\gamma}{2}(1+\alpha_2^2)[P,[P,A]]+\frac{\gamma}{2}(\alpha_1^2+\alpha_3^2)[Q,[Q,A]]-i\gamma\alpha_1(Q[P,A]\\ &+[P,A]Q)-i\gamma\alpha_2\alpha_3(P[Q,A]+[Q,A]P), \end{aligned} \tag{1.6}$$

where γ is the normalized constant which will be chosen as $\gamma=(1+\alpha_2^2)^{-1}$. Since P and Q are unbounded operators affiliated to $\mathcal{M}$, the above is a formal expression.

Because of the well-developed theory,[2] it is convenient to construct Markovian semigroups on the standard form $(\mathcal{M},\mathcal{H},\mathcal{P},J)$. Consider the symmetric embedding:[2]

$$\begin{aligned} &i_0:\mathcal{M}\to\mathcal{H},\\ &i_0(A)=\Delta^{1/4}A\xi_0=\sigma_{-i/4}(A)\xi_0, \end{aligned} \tag{1.7}$$

and define the operator H on $\mathcal{H}$ by

$$H\sigma_{-i/4}(A)\xi_0=\sigma_{-i/4}(G(A))\xi_0. \tag{1.8}$$

It follows from (1.8) that

$$\begin{aligned} H=&\frac{\gamma}{2}(1+\alpha_2^2)(\sigma_{-i/4}(P)-j(\sigma_{-i/4}(P)))^2+\frac{\gamma}{2}(\alpha_1^2+\alpha_3^2)(\sigma_{-i/4}(Q)-j(\sigma_{-i/4}(Q)))^2\\ &-i\gamma\alpha_1(\sigma_{-i/4}(Q)+j(\sigma_{-i/4}(Q)))(\sigma_{-i/4}(P)-j(\sigma_{-i/4}(P)))-i\gamma\alpha_2\alpha_3(\sigma_{-i/4}(P)\\ &+j(\sigma_{-i/4}(P)))(\sigma_{-i/4}(Q)-j(\sigma_{-i/4}(Q))). \end{aligned} \tag{1.9}$$

Let the parameters $\alpha_1,\ \alpha_2,\ \alpha_3\in\mathbb{R}$, satisfy the following relations:

$$\begin{aligned} &\tfrac{1}{2}(1+\alpha_2^2)\sinh(\beta/2)=-\alpha_1\cosh(\beta/2),\\ &\tfrac{1}{2}(\alpha_1^2+\alpha_3^2)\sinh(\beta/2)=\alpha_2\alpha_3\cosh(\beta/2). \end{aligned} \tag{1.10}$$

Then the operator H can be written as

$$\begin{aligned} H=&\gamma_1(\sigma_{-i/4}(P)-j(\sigma_{-i/4}(P)))^*(\sigma_{-i/4}(P)-j(\sigma_{-i/4}(P)))+\gamma_2(\sigma_{-i/4}(Q)\\ &-j(\sigma_{-i/4}(Q)))^*(\sigma_{-i/4}(Q)-j(\sigma_{-i/4}(Q))), \end{aligned} \tag{1.11}$$

where $\gamma_1=-\gamma\alpha_1/\sinh(\beta/2)$, $\gamma_2=\gamma\alpha_2\alpha_3/\sinh(\beta/2)$. Recall that $\gamma=(1+\alpha_2^2)^{-1}$. See the proof of Proposition 3.1 in Sec. IV.

Notice that formally the operator H in (1.11) is symmetric and positive. By means of Dirichlet forms on von Neumann algebras[2] and the approximation procedure used in Ref. 14, we will show that H becomes a positive self-adjoint operator on a dense domain in $\mathcal{H}$, which generates a strongly continuous symmetric Markovian semigroup $\{T_t\}_{t\geqslant 0}$ on $\mathcal{H}$. Define the map S_t on $\mathcal{M}$ by

$$S_t:\mathcal{M}\to\mathcal{M},\quad i_0\circ S_t=T_t\circ i_0.$$

Then $\{S_t\}_{t\geqslant 0}$ is a weakly continuous Markovian semigroup on $\mathcal{M}$ which leaves ω invariant. See Remark 3.1.

Let φ be a bounded smooth function on $\mathbb{R}$. It follows from (1.6) and the commutation relation $[P,Q]=-i\mathbf{1}$ that

$$G(\varphi(Q))=-\frac{\gamma}{2}(1+\alpha_2^2)\varphi''(Q)-2\gamma\alpha_1Q\varphi'(Q)=-\tfrac{1}{2}\varphi''(Q)+\tanh(\beta/2)Q\varphi'(Q). \tag{1.12}$$

Thus for any α_1, α_2 and α_3 satisfying (1.10), the restriction of S_t to the maximal Abelian subalgebra $\mathcal{N}\subset\mathcal{M}$ generated by $\exp(ikQ), k\in\mathbb{R}$, is reduced to a unique classical O-U semigroup.

The spectrum of H will be analyzed by a method similar to that used in Ref. 14. It turns out that H has discrete spectrum and H has a simple eigenvalue zero with eigenvector ξ_0.

The article is organized as follows: In Sec. II, we review the theory of noncommutative Dirichlet forms on von Neumann algebras.[2] In Sec. III, we give explicit expressions of Dirichlet forms and state the main results. Section IV is devoted to the proof of the Markov property of

semigroups by means of the theory of noncommutative Dirichlet forms and the approximation procedure used in Ref. 14. In Sec. V, we decompose $\mathcal{H}$ to a direct sum of eigenspaces of Direchlet operators and analyze the spectrum of generators of the semigroups.

II. REVIEW ON THE NONCOMMUTATIVE DIRICHLET FORMS

In this section we give a brief review on the theory of Dirichlet forms and Markovian semigroups on standard forms of von Neumann algebras. For details, we refer the reader to Ref. 2.

Let $\mathcal{M}$ be a σ-finite von Neumann algebra acting on a complex Hilbert space $\mathcal{H}$. A *self-dual cone* $\mathcal{P}$ in $\mathcal{H}$ is a subset satisfying the property:

$$\{\xi \in \mathcal{H}: \langle \xi, \eta \rangle \geqslant 0, \forall\, \eta \in \mathcal{P}\} = \mathcal{P}.$$

Then $\mathcal{P}$ is a closed convex cone and $\mathcal{H}$ is the complexification of the real subspace $\mathcal{H}^J := \{\xi \in \mathcal{H}: \langle \xi, \eta \rangle \in \mathbb{R}, \forall\, \eta \in \mathcal{P}\}$, whose elements are called *J-real*: $\mathcal{H} = \mathcal{H}^J \oplus i\mathcal{H}^J$. For any two elements $\xi, \eta \in \mathcal{H}^J$, $\xi \leqslant \eta$ means $\eta - \xi \in \mathcal{P}$, thus $\mathcal{H}^J$ has an ordered structure. An anti-unitary involution J on $\mathcal{H}$ by $J(\xi + i\eta) := \xi - i\eta, \forall\, \xi, \eta \in \mathcal{H}^J$, preserves $\mathcal{P}$ and $\mathcal{H}^J$. Any J-real element ξ can be decomposed uniquely as a difference, $\xi = \xi_+ - \xi_-$, of two orthogonal, positive elements, called the positive and the negative part of ξ: $\xi_+, \xi_- \in \mathcal{P}$, $\langle \xi_+, \xi_- \rangle = 0$.

A *standard form* $(\mathcal{M}, \mathcal{H}, \mathcal{P}, J)$ of the von Neumann algebra $\mathcal{M}$ acting faithfully on the Hilbert space $\mathcal{H}$ consists of self-dual, closed, convex cone $\mathcal{P}$ in $\mathcal{H}$ and the anti-unitary involution J satisfying the following properties:

(a) $J\mathcal{M}J = \mathcal{M}'$,
(b) $JAJ = A^*, \quad \forall A \in \mathcal{M} \cap \mathcal{M}'$,
(c) $J\xi = \xi, \quad \forall \xi \in \mathcal{P}$,
(d) $AJAJ(\mathcal{P}) \subset \mathcal{P}, \quad \forall A \in \mathcal{M}$,

where $\mathcal{M}'$ is the commutant of $\mathcal{M}$.

A bounded operator A on $\mathcal{H}$ is called *J-real* if $AJ = JA$ and *positive preserving* if $A\mathcal{P} \subset \mathcal{P}$. The semigroup $\{T_t\}_{t \geqslant 0}$ is said to be *J-real* if T_t is J-real for any $t \geqslant 0$ and it is called *positive preserving* if T_t is positive preserving for any $t \geqslant 0$.

Let us fix a cyclic and separating vector ξ_0 in $\mathcal{P}$. A bounded operator $A: \mathcal{H} \to \mathcal{H}$ is called *sub-Markovian* (with respect to ξ_0) if $0 \leqslant \xi \leqslant \xi_0$ implies $0 \leqslant A\xi \leqslant \xi_0$. A is called *Markovian* if it is sub-Markovian and also $A\xi_0 = \xi_0$. A semigroup $\{T_t\}_{t \geqslant 0}$ is said to be *sub-Markovian* (with respect to ξ_0) if T_t is sub-Markovian for every $t \geqslant 0$. The semigroup $\{T_t\}_{t \geqslant 0}$ is called *Markovian* if T_t is Markovian for every $t \geqslant 0$.

Next, we consider a sesquilinear form on some linear manifold of $\mathcal{H}$: $\mathcal{E}(\cdot, \cdot): D(\mathcal{E}) \times D(\mathcal{E}) \to \mathbb{C}$. We also consider the associated quadratic form: $\mathcal{E}[\,\cdot\,]: D(\mathcal{E}) \to \mathbb{C}$, $\mathcal{E}[\xi] := \mathcal{E}(\xi, \xi)$. A real valued quadratic form $\mathcal{E}[\,\cdot\,]$ is said to be *semi-bounded* if $\inf\{\mathcal{E}[\xi]: \xi \in D(\mathcal{E}), \|\xi\| = 1\} = -b > -\infty$. A quadratic form $(\mathcal{E}, D(\mathcal{E}))$ is said to be *J-real* if $JD(\mathcal{E}) \subset D(\mathcal{E})$ and $\mathcal{E}[J\xi] = \overline{\mathcal{E}[\xi]}$ for any $\xi \in D(\mathcal{E})$. For a given semi-bounded quadratic form $\mathcal{E}$, one considers the inner product given by $\langle \xi, \eta \rangle_\lambda := \mathcal{E}(\xi, \eta) + \lambda \langle \xi, \eta \rangle$, for $\lambda > b$. The form $\mathcal{E}$ is *closed* if $D(\mathcal{E})$ is a Hilbert space for some of the above norms. The form $\mathcal{E}$ is called *closable* if it admits a closed extension.

Associated to a semi-bounded closed form $\mathcal{E}$, there are a self-adjoint operator $(H, D(H))$ and a strongly continuous, symmetric semigroup $\{T_t\}_{t \geqslant 0}$. Each of the above objects determines uniquely the others according to well known relations (see Sec. 3.1 of Ref. 4).

From now on we will consider only J-real, real-valued, semi-bounded, densely defined quadratic forms. It is easy to check that these forms satisfy the relation $\mathcal{E}[\xi + i\eta] = \mathcal{E}[\xi] + \mathcal{E}[\eta]$ for all $\xi + i\eta \in D(\mathcal{E})^J + iD(\mathcal{E})^J = D(\mathcal{E})$ where $D(\mathcal{E})^J := D(\mathcal{E}) \cap H^J$.

Let us denote by $\mathrm{Proj}(\xi, \mathcal{Q})$ the projection of the vector $\xi \in \mathcal{H}^J$ onto the closed, convex cone $\mathcal{Q} \subset \mathcal{H}^J$. For $\xi, \eta \in \mathcal{H}^J$, define

$$\xi \vee \eta := \mathrm{Proj}(\xi, \eta + \mathcal{P}),$$

$$\xi \wedge \eta := \mathrm{Proj}(\xi, \eta - \mathcal{P}).$$

Definition 2.1: A J-real, real-valued, densely defined quadratic form $(\mathcal{E}, D(\mathcal{E}))$ *is called Markovian with respect to* $\xi_0 \in \mathcal{P}$ *if*

$$\xi \in D(\mathcal{E})^J \text{ implies } \xi \wedge \xi_0 \in D(\mathcal{E}) \text{ and } \mathcal{E}[\xi \wedge \xi_0] \leqslant \mathcal{E}[\xi].$$

A closed Markovian form is called a Dirichlet form.

Next, we state main results which will be used in the sequel. For the proofs we refer to Ref. 2.

Proposition 2.1: Let $(\mathcal{E}, D(\mathcal{E}))$ *be a J-real, real valued, densely defined closed form. Assume that the following properties hold*:

(a) $\xi_0 \in D(\mathcal{E})$,
(b) $\mathcal{E}(\xi, \xi) \geqslant 0$ *for* $\xi \in D(\mathcal{E})$,
(c) $\xi \in D(\mathcal{E})^J$ *implies* $\xi_\pm \in D(\mathcal{E})$ *and* $\mathcal{E}(\xi_+, \xi_-) \leqslant 0$.

Then $\mathcal{E}$ *is a Dirichlet form if and only if* $\mathcal{E}(\xi, \xi_0) \geqslant 0$ *for all* $\xi \in D(\mathcal{E}) \cap \mathcal{P}$.

The above result follows from Proposition 4.5(b) of Ref. 2 and Proposition 4.10(ii) of Ref. 2.

Theorem 2.1 (*Theorem 4.11 of Ref. 2): Let* $\{T_t\}_{t \geqslant 0}$ *be a J-real, strongly continuous, symmetric semigroup on* $\mathcal{H}$ *and let* $(\mathcal{E}, D(\mathcal{E}))$ *be the associated densely defined J-real, real valued quadratic form. Then the followings are equivalent*:

(a) $\{T_t\}_{t \geqslant 0}$ *is sub-Markovian.*
(b) $(\mathcal{E}, D(\mathcal{E}))$ *is a Dirichlet form.*

III. DIRICHLET FORMS: PRELIMINARIES AND MAIN RESULTS

Let $\mathcal{A}$ be the C^*-algebra generated by the Weyl operators $W(z)$, $z \in \mathbb{C}$, satisfying

$$\begin{aligned} W(z)^* &= W(-z), \\ W(z)W(z') &= e^{-i/2\,\mathrm{Im}(\bar{z}z')} W(z+z'), \forall z, z' \in \mathbb{C}, \end{aligned} \tag{3.1}$$

where $\bar{z}$ is a complex conjugate of z. $\mathcal{A}$ is the CCR algebra over one dimensional Hilbert space. Let ω be a quasi-free state on $\mathcal{A}$ defined by

$$\omega(W(z)) = \exp\{-\tfrac{1}{4}|z|^2(1+e^{-\beta})(1-e^{-\beta})^{-1}\}, \forall z \in \mathbb{C}, \tag{3.2}$$

where $\beta > 0$ is the inverse temperature.

Let $(\mathcal{H}_\omega, \pi_\omega, \Omega_\omega)$ be the GNS representation[4] of $(\mathcal{A}, \omega)$, and let $\mathcal{M} = \pi_\omega(\mathcal{A})''$. Denote by $\Phi_\omega(z)$ the infinitesimal generator of the strongly continuous unitary group $\pi_\omega(W(tz))$ for all $z \in \mathbb{C}$:

$$\pi_\omega(W(tz)) = \exp(it\Phi_\omega(z)).$$

The position and momentum operators are defined by

$$Q := \Phi_\omega(1), \quad P := \Phi_\omega(i), \tag{3.3}$$

respectively. Since ω is an entire analytic state[4] by (3.2), the cyclic vector Ω_ω is an entire analytic vector for P and Q. The annihilation and creation operators given by

$$\begin{aligned} D(a_\omega) &= D(P) \cap D(Q) = D(a_\omega^*), \\ a_\omega &:= 2^{-1/2}(Q + iP), \quad a_\omega^* := 2^{-1/2}(Q - iP), \end{aligned} \tag{3.4}$$

are densely defined, closed and $(a_\omega)^* = a_\omega^*$, and satisfy the canonical commutation relation-(CCR): $[a_\omega, a_\omega^*] = \mathbf{1}$. See Sec. 5.2.3 of Ref. 4 for the details.

In the rest of this paper, we write that $\mathcal{H} = \mathcal{H}_\omega$, $\xi_0 = \Omega_\omega$, $W(z) = \pi_\omega(W(z))$, $\Phi(z) = \Phi_\omega(z)$, $\forall z \in \mathbb{C}$, $a = a_\omega$ and $a^* = a_\omega^*$. Let $\sigma_t : \mathcal{M} \to \mathcal{M}$ be the group of automorphisms on $\mathcal{M}$ defined by

$$\sigma_t(W(z)) = W(e^{-i\beta t}z), \forall z \in \mathbb{C}.$$

The state ω in (3.2) satisfies the σ-KMS condtion[4] and thus σ_t, $t \in \mathbb{R}$, is the modular automorphism by Theorem 5.3.10 of Ref. 4. Let Δ and J be the modular operator and modular conjugation respectively associated to the pair $(\mathcal{M}, \xi_0)$.[4] Then $\sigma_t(A) = \Delta^{it} A \Delta^{-it}$, $A \in \mathcal{M}$. Let $\mathcal{M}'$ be the commutant of $\mathcal{M}$. The map $j : \mathcal{M} \to \mathcal{M}'$ is the anti-linear *-isomorphism defined by $j(A) = JAJ$, $A \in \mathcal{M}$. The natural positive cone $\mathcal{P}$ associated with $(\mathcal{M}, \xi_0)$ is the closure of the set $\{Aj(A)\xi_0 : A \in \mathcal{M}\}$. Then $(\mathcal{M}, \mathcal{H}, \mathcal{P}, J)$ is the natural standard form associated to $(\mathcal{M}, \xi_0)$.

Next, we introduce two dense manifolds of $\mathcal{H}$. For any $A \in \mathcal{M}$, define

$$A_n = \left(\frac{n}{\pi}\right)^{1/2} \int \sigma_t(A) e^{-nt^2} dt, \quad n \in \mathbb{N}. \tag{3.5}$$

Then A_n is an entire analytic element for σ_t, $\|A_n\| \leqslant \|A\|$ $\forall n \in \mathbb{N}$ and $A_n \to A$ strongly. See the proof of Proposition 2.5.22 in Ref. 4. Put

$$\mathcal{M}_0 := \text{the algebra generated by } A_n,\ A \in \mathcal{M},\ n \in \mathbb{N}, \tag{3.6}$$

and denote by $\mathcal{H}_{fin}$ the subset of finite linear combinations of the vectors of the following type:

$$\psi_m^n = P^m Q^n \xi_0, \quad m, n = 0,1,2,\ldots .$$

Clearly $\mathcal{M}_0\xi_0$ and $\mathcal{H}_{fin}$ are dense in $\mathcal{H}$, and P, Q and $j(P)$, $j(Q)$ are affiliated with $\mathcal{M}$ and $\mathcal{M}'$, respectively (see Lemma 4.1).

For any $z \in \mathbb{C}$, we write

$$\sigma_z(a) := e^{i\beta z}a, \quad \sigma_z(a^*) := e^{-i\beta z}a^*, \tag{3.7}$$

and

$$\sigma_z(P) := -i2^{-1/2}(e^{i\beta z}a - e^{-i\beta z}a^*), \quad \sigma_z(Q) := 2^{-1/2}(e^{i\beta z}a + e^{-i\beta z}a^*). \tag{3.8}$$

Denote by Φ either P or Q. In fact, one may be able to show that for $\xi \in \mathcal{M}_0\xi_0$ the function $t \mapsto \sigma_t(\Phi)\xi$ has an analytic extension on $\mathbb{C}$, which is denoted by $\sigma_z(\Phi)\xi$, and that $\sigma_z(\Phi)$ is equal to that of (3.8) on $\mathcal{M}_0\xi_0$. See Lemma 4.1 for $D(\Phi)$.

As discussed in the Introduction, for any parameters α_1, α_2, α_3, we introduce a sesquilinear form corresponding to the operator H given in (1.9) by

$$D(\mathcal{E}) = \mathcal{M}_0\xi_0, \tag{3.9}$$

$$\begin{aligned}
\mathcal{E}(\eta, \xi) = {} & \frac{\gamma}{2}(1+\alpha_2^2)\langle(\sigma_{-i/4}(P) - j(\sigma_{-i/4}(P)))^*\eta, (\sigma_{-i/4}(P) - j(\sigma_{-i/4}(P)))\xi \rangle \\
& + \frac{\gamma}{2}(\alpha_1^2+\alpha_3^2)\langle(\sigma_{-i/4}(Q) - j(\sigma_{-i/4}(Q)))^*\eta, (\sigma_{-i/4}(Q) - j(\sigma_{-i/4}(Q)))\xi \rangle \\
& - i\gamma\alpha_1\langle(\sigma_{-i/4}(Q) + j(\sigma_{-i/4}(Q)))^*\eta, (\sigma_{-i/4}(P) - j(\sigma_{-i/4}(P)))\xi \rangle \\
& - i\gamma\alpha_2\alpha_3\langle(\sigma_{-i/4}(P) + j(\sigma_{-i/4}(P)))^*\eta, (\sigma_{-i/4}(Q) - j(\sigma_{-i/4}(Q)))\xi\rangle
\end{aligned}$$

for $\eta, \xi \in \mathcal{M}_0\xi_0$, where $\gamma=(1+\alpha_2^2)^{-1}$. Notice that $\mathcal{E}$ is well defined on $\mathcal{M}_0\xi_0$ by Lemma 4.1.

Proposition 3.1: Let the parameters $\alpha_1, \alpha_2, \alpha_3 \in \mathbb{R}$ satisfy the following relations:

$$\begin{aligned} \tfrac{1}{2}(1+\alpha_2^2)\sinh(\beta/2) &= -\alpha_1 \cosh(\beta/2), \\ \tfrac{1}{2}(\alpha_1^2+\alpha_3^2)\sinh(\beta/2) &= \alpha_2\alpha_3 \cosh(\beta/2). \end{aligned} \tag{3.10}$$

Then the sesquilinear form given by (3.9) equals to

$$\begin{aligned} D(\mathcal{E}) &= \mathcal{M}_0\xi_0, \\ \mathcal{E}(\eta,\xi) &= \gamma_1\langle(\sigma_{-i/4}(P)-j(\sigma_{-i/4}(P)))\eta,(\sigma_{-i/4}(P)-j(\sigma_{-i/4}(P)))\xi\rangle + \gamma_2\langle(\sigma_{-i/4}(Q) \\ &\quad -j(\sigma_{-i/4}(Q)))\eta,(\sigma_{-i/4}(Q)-j(\sigma_{-i/4}(Q)))\xi\rangle, \end{aligned} \tag{3.11}$$

where

$$\gamma_1 = -\gamma\alpha_1/\sinh(\beta/2), \quad \gamma_2 = \gamma\alpha_2\alpha_3/\sinh(\beta/2). \tag{3.12}$$

Thus by (3.11) $\mathcal{E}$ is a positive form.

In the rest of the paper, *we assume that the relations (3.10) hold*. We state the main results.

Theorem 3.1: *The form $(\mathcal{E},D(\mathcal{E}))$ defined as in (3.9) [and so as in (3.11)] is closable. Denote by $(\overline{\mathcal{E}},D(\overline{\mathcal{E}}))$ the closure of $(\mathcal{E},D(\mathcal{E}))$ and by H the positive self-adjoint operator associated to $(\overline{\mathcal{E}},D(\overline{\mathcal{E}}))$. Then the following properties hold*:

(a) $\xi_0 \in D(H)$ *and* $H\xi_0=0$,
(b) $\overline{\mathcal{E}}$ *is J-real, that is,* $\overline{\mathcal{E}}[J\xi]=\overline{\mathcal{E}}[\xi]$ *for* $\xi \in D(\overline{\mathcal{E}})$,
(c) $\overline{\mathcal{E}}(\xi_+,\xi_-)\leqslant 0$ *for any* $\xi \in D(\overline{\mathcal{E}})\cap\mathcal{H}^J$.

Furthermore, the form $(\overline{\mathcal{E}},D(\overline{\mathcal{E}}))$ is a Dirichlet form.

Recall that a symmetric, strongly continuous, positive preserving semigroup $\{T_t\}_{t\geqslant 0}$ on $\mathcal{H}$ is called *ergodic* if for any $\eta, \xi \in \mathcal{P}-\{0\}$, there exists $t>0$ such that $\langle \eta, T_t\xi\rangle > 0$. Let H be the self-adjoint generator of $T_t: T_t=e^{-tH}$, $t\geqslant 0$. An eigenvector of H corresponding to the lowest eigenvalue $\inf \sigma(H)$ will be called a *ground state* for H (or $\{T_t\}_{t\geqslant 0}$). The ergodicity of its semigroup is equivalent to that the lowest eigenvalue of H has multiplicity one and there exists a strictly positive ground state for H (Theorem 4.3 of Ref. 18).

Theorem 3.2: *Let $\{T_t\}_{t\geqslant 0}$ be the symmetric Markovian semigroup associated to the Dirichlet form $(\overline{\mathcal{E}},D(\overline{\mathcal{E}}))$ and let H be the Dirichlet operator, i.e., $T_t=e^{-tH}$. Then the following results hold*:

(a) H *is essentially self-adjoint on* $\mathcal{H}_{fin}$.
(b) *The spectrum of generator H are discrete, i.e.,* $\sigma(H)=\{m\tau_1+n\tau_2 : m,n=0,1,2,\ldots\}$, *where* $\tau_1=2\gamma_1\sinh(\beta/2)$, $\tau_2=2\gamma_2\sinh(\beta/2)$.
(c) *The zero is a simple eigenvalue of H with eigenvector ξ_0. Thus $\{T_t\}_{t\geqslant 0}$ is ergodic.*

The eigenspaces of H will be given in Theorem 5.2(b). By the spectral theorem, Theorem 3.2(b) implies that for any $\xi \in \mathcal{H}$ and $t>0$

$$\|T_t\xi - \langle\xi_0,\xi\rangle\xi_0\| \leqslant e^{-\tau t}\|\xi - \langle\xi_0,\xi\rangle\xi_0\|,$$

where $\tau=\min\{\tau_1,\tau_2\}$. Thus $\{T_t\}_{t\geqslant 0}$ converges to the equilibrium exponentially fast.

Remark 3.1: Let $\{T_t\}_{t\geqslant 0}$ be a strongly continuous, symmetric Markovian semigroup on $\mathcal{H}$. Consider the symmetric embedding:

$$i_0 : \mathcal{M} \to \mathcal{H},$$

$$i_0(A) = \Delta^{1/4}A\xi_0.$$

Define the maps S_t on $\mathcal{M}$ by

$$S_t:\mathcal{M}\to\mathcal{M},\quad i_0\circ S_t=T_t\circ i_0. \tag{3.13}$$

It follows from Theorem 2.12 of Ref. 2 that $\{S_t\}_{t\geqslant 0}$ is a weakly continuous Markovian semigroup on $\mathcal{M}$.

Remark 3.2: Let $\mathcal{N}$ be the maximal Abelian subalgebra of $\mathcal{M}$ generated by $\exp\{ikQ\}, k\in\mathbb{R}$. *Let S_t be the Markovian semigroup on $\mathcal{M}$ obtained by (3.13). As mentioned in the Introduction, it can be checked that for any $\alpha_1, \alpha_2, \alpha_3\in\mathbb{R}$ satisfying (3.10) the restriction of S_t to $\mathcal{N}$ gives a unique O-U semigroup whose generation satisfies the equation in (1.12).*

Before closing this section, we show that distinct values of the parameters $\alpha_1, \alpha_2, \alpha_3\in\mathbb{R}$ satisfying (3.10) give distinct semigroups on $\mathcal{H}$. It follows from Theorem 3.2(b) that the spectrum of each generator H is characterized by

$$\gamma_1/\gamma_2=-\alpha_1/(\alpha_2\alpha_3).$$

We first consider two special examples and then describe general case.

Example 3.1: the O-U semigroup studied in Ref. 17. Choose $\alpha_3=1$ and $-\alpha_1=\alpha_2$. It follows from (3.10) and (3.12) that

$$\begin{gathered}\gamma_1=\gamma_2,\\ \alpha_2=(\cosh(\beta/2)\pm 1)/\sinh(\beta/2)\equiv\alpha_{2,\pm}(\beta).\end{gathered} \tag{3.14}$$

Using (3.8), we obtain from (3.11) that

$$\mathcal{E}(\xi,\xi)=\gamma(\|(\mu a-\lambda j(a^*))\xi\|^2+\|(\lambda a^*-\mu j(a))\xi\|^2),\forall\,\xi\in\mathcal{M}_0\xi_0,$$

where $\mu=\lambda^{-1}=e^{\beta/4}$ and $\gamma=\gamma_1=\gamma_2$. The above is the form studied in Ref. 17.

Example 3.2: Consider $\alpha_2=1$. It follows from (3.10) and (3.12) that

$$\begin{aligned}\alpha_1&=-\tanh(\beta/2),\\ \alpha_3&=\coth(\beta/2)\pm(\coth^2(\beta/2)-\tanh^2(\beta/2))^{1/2}\\ &=\tanh^2(\beta/2)/[\coth(\beta/2)\mp(\coth^2(\beta/2)-\tanh^2(\beta/2))^{1/2}],\\ \gamma_1/\gamma_2&=\coth(\beta/2)[\coth(\beta/2)\mp(\coth^2(\beta/2)-\tanh^2(\beta/2))^{1/2}]\neq 1.\end{aligned} \tag{3.15}$$

Next, we consider the general case. Consider α_2 as a parameter. Then we get from (3.10) that

$$\begin{gathered}\alpha_1=-\tfrac{1}{2}(1+\alpha_2^2)\tanh(\beta/2),\\ \alpha_3=[\alpha_2\cosh(\beta/2)\pm(\alpha_2^2\cosh^2(\beta/2)-\alpha_1^2\sinh^2(\beta/2))^{1/2}]/\sinh(\beta/2).\end{gathered} \tag{3.16}$$

For real α_3, one requires that $\alpha_2^2\cosh^2(\beta/2)\geqslant\alpha_1^2\sinh^2(\beta/2)$. By the first equation in (3.16), positive solutions α_2 exist if and only if

$$2\alpha_2\cosh^2(\beta/2)\geqslant(1+\alpha_2^2)\sinh^2(\beta/2).$$

Denote

$$\kappa_\pm(\beta):=[\cosh^2(\beta/2)\pm(\cosh^4(\beta/2)-\sinh^4(\beta/2))^{1/2}]/\sinh^2(\beta/2),$$

$$I_\beta:=[\kappa_-(\beta),\kappa_+(\beta)].$$

Thus $\alpha_2\in I_\beta$. Note that

$$\kappa_+(\beta)=[\cosh^2(\beta/2)+(\cosh^2(\beta/2)+\sinh^2(\beta/2))^{1/2}]/\sinh^2(\beta/2),$$

$$\geqslant[\cosh^2(\beta/2)+\cosh(\beta/2)]/\sinh^2(\beta/2),$$

$$=\coth(\beta/2)\alpha_{2,+}(\beta),$$

where $\alpha_{2,+}(\beta)$ has been defined in (3.14). The above implies that $\kappa_+(\beta)>\alpha_{2,+}(\beta)$. An argument similar to that used above yields that $\kappa_-(\beta)<\alpha_{2,-}(\beta)$. Thus we conclude that $1\in[\alpha_{2,-}(\beta),\alpha_{2,+}(\beta)]\subset I_\beta$.

Define

$$f_\pm(\alpha_2):=-\alpha_1(\alpha_2)/\alpha_2\alpha_{3,\pm}(\alpha_2),$$

$$\alpha_{3,\pm}(\alpha_2)=[\alpha_2\cosh(\beta/2)\pm(\alpha_2^2\cosh^2(\beta/2)-\alpha_1^2\sinh^2(\beta/2))^{1/2}]/\sinh(\beta/2)$$

$$=\alpha_2\coth(\beta/2)\pm(\alpha_2^2\coth^2(\beta/2)-\tfrac{1}{4}(1+\alpha_2^2)^2\tanh^2(\beta))^{1/2}.$$

Since $f_\pm$ are continuous on $I_\beta\subset(0,\infty)$, $f_+(I_\beta)$ and $f_-(I_\beta)$ are closed intervals which have common point at $\alpha_2=\kappa_-(\beta)$ and $\alpha_2=\kappa_+(\beta)$. Thus $f_+(I_\beta)\cup f_-(I_\beta)$ is a closed interval containing 1 with nonzero length [by (3.15)]. Therefore there exist infinitely many different semigroups, which contain the semigroups constructed in Ref. 17.

IV. MARKOV PROPERTY OF FORMS: PROOFS OF PROPOSITION 3.1 AND THEOREM 3.1

In this section we produce the proofs of Proposition 3.1 and Theorem 3.1. Since P and Q are unbounded operators, we need to employ the approximation procedure used in Ref. 14. In the rest of this article we denote by Φ either P or Q and by $a^\sharp$ either a or a^*.

Lemma 4.1: (a) $\mathcal{M}_0\xi_0$ and $\mathcal{H}_{fin}$ are dense in $\mathcal{H}$.

(b) The inclusions

$$\mathcal{M}_0\xi_0\subset D(\Phi) \text{ and } \mathcal{H}_{fin}\subset D(\Phi)$$

hold; moreover, the relation

$$\Phi A\xi_0=j(\sigma_{-i/2}(A^*))\Phi\xi_0$$

holds for any $A\in\mathcal{M}_0$. Also we have $\mathcal{M}_0\xi_0\subset D(a^\sharp)$, $\mathcal{H}_{fin}\subset D(a^\sharp)$ and $a^\sharp A\xi_0=j(\sigma_{-i/2}(A^*))a^\sharp\xi_0, A\in\mathcal{M}_0$.

Proof: (a) Since for $A\in\mathcal{M}$, A_n in (3.5) converges strongly to A as $n\to\infty$ and since $\mathcal{M}\xi_0$ is dense in $\mathcal{H}$, $\mathcal{M}_0\xi_0$ is dense in $\mathcal{H}$. It follows from (3.2) that ω is an entire analytic state, and so ξ_0 is an entire analytic vector for $\Phi(z), z\in\mathbb{C}$. Thus $\mathcal{H}_{fin}$ is dense. See Sec. 5.2.3 of Ref. 4 for the details.

(b) Since ξ_0 is an entire analytic vector for Φ, $\mathcal{H}_{fin}\subset D(\Phi)$. Notice that for any $A\in\mathcal{M}_0$, $j(\sigma_{-i/2}(A^*))\xi_0=A\xi_0$. For $z=1,i$ and $n\in\mathbb{N}$, we write that

$$\Phi(z,n)=-in\left(W\left(\frac{1}{n}z\right)-1\right). \tag{4.1}$$

Notice that

$$\Phi(z,n)A\xi_0=\Phi(z,n)j(\sigma_{-i/2}(A^*))\xi_0=j(\sigma_{-i/2}(A^*))\Phi(z,n)\xi_0.$$

Since the sequence $\{\Phi(z,n)\xi_0\}$ converges to $\Phi\xi_0$, it follows that $A\xi_0\in D(\Phi)$ and the relation

$$\Phi A\xi_0=j(\sigma_{-i/2}(A^*))\Phi\xi_0$$

hold for $A \in \mathcal{M}_0$. The rest part of (b) follows from (3.4). □

Recall the definitions of $\sigma_z(\Phi)$, $z \in \mathbb{C}$ in (3.8), i.e.,

$$\sigma_z(P) = -i2^{-1/2}(e^{i\beta z}a - e^{-i\beta z}a^*), \quad \sigma_z(Q) = 2^{-1/2}(e^{i\beta z}a + e^{-i\beta z}a^*).$$

For any $n \in \mathbb{N}$, we write that

$$\Phi_n := -\left(\frac{n}{\pi}\right)^{1/2} \int in\left\{\sigma_t\left(\exp\left(\frac{i}{n}\Phi\right) - \mathbf{1}\right)\right\} e^{-nt^2}\, dt. \tag{4.2}$$

Notice that for any $n \in \mathbb{N}$, Φ_n is an entire analytic element for σ_t and $\sigma_z(\Phi_n)$ is given by

$$\sigma_z(\Phi_n) := -\left(\frac{n}{\pi}\right)^{1/2} \int in\left\{\sigma_t\left(\exp\left(\frac{i}{n}\Phi\right) - \mathbf{1}\right)\right\} e^{-n(t-z)^2}\, dt \tag{4.3}$$

for any $z \in \mathbb{C}$. See the proof of Proposition 2.5.22(1) in Ref. 4.

Lemma 4.2: For any $n \in \mathbb{N}$, $z = t + is \in \mathbb{C}$ and $A \in \mathcal{M}_0$, there exists a constant $M(A,s)$ such that the bound

$$\|\sigma_z(\Phi_n)A\xi_0\| + \|\sigma_z(\Phi)A\xi_0\| \leq M(A,s),$$

and, moreover, $\sigma_z(\Phi)A\xi_0 = \lim_{n\to\infty}\sigma_z(\Phi_n)A\xi_0$ holds.

Proof: By the method used in the proof Lemma 4.1, one can check that

$$\sigma_z(\Phi_n)A\xi_0 = j(\sigma_{-i/2}(A))\sigma_z(\Phi_n)\xi_0,$$

and a similar relation for $\sigma_z(\Phi)$. Since $\sigma_z(\Phi_n)\xi_0$ converges to $\sigma_z(\Phi)\xi_0$, the lemma follows from above relation. □

We first produce the proof of Proposition 3.1. Note that by (3.7)

$$\begin{aligned} \sigma_{-i/4}(a^*) &= e^{-\beta/4}a^*, \quad \sigma_{-i/4}(a) = e^{\beta/4}a, \\ \sigma_{i/4}(a^*) &= e^{\beta/4}a^*, \quad \sigma_{i/4}(a) = e^{-\beta/4}a. \end{aligned} \tag{4.4}$$

Proof of Proposition 3.1: By Lemmas 4.1 and 4.2 the operators $\sigma_{\pm i/4}(P)$ and $\sigma_{\pm i/4}(Q)$ are well defined on $\mathcal{M}_0\xi_0$. We have that

$$\begin{aligned} P = \sigma_{-i/4}(\sigma_{i/4}(P)) &= i2^{-1/2}\sigma_{-i/4}(e^{\beta/4}a^* - e^{-\beta/4}a) \\ &= i2^{-1}e^{\beta/4}(\sigma_{-i/4}(Q) - i\sigma_{-i/4}(P)) - i2^{-1}e^{-\beta/4}(\sigma_{-i/4}(Q) + i\sigma_{-i/4}(P)) \\ &= i\sinh(\beta/4)\sigma_{-i/4}(Q) + \cosh(\beta/4)\sigma_{-i/4}(P). \end{aligned} \tag{4.5}$$

By the method used above, we also have that

$$Q = \cosh(\beta/4)\sigma_{-i/4}(Q) - i\sinh(\beta/4)\sigma_{-i/4}(P). \tag{4.6}$$

It follows from (4.4) and (4.6) that

$$\begin{aligned} &[\sigma_{i/4}(P) \mp j(\sigma_{i/4}(P))] - [\sigma_{-i/4}(P) \mp j(\sigma_{-i/4}(P))] \\ &\quad = i2^{-1/2}[(e^{\beta/4} - e^{-\beta/4})a^* - (e^{-\beta/4} - e^{\beta/4})a] \mp 2^{-1/2}j\{i[(e^{\beta/4} - e^{-\beta/4})a^* - (e^{-\beta/4} - e^{\beta/4})a]\} \\ &\quad = 2i\sinh(\beta/4)Q \mp j(2i\sinh(\beta/4)Q) = 2i\sinh(\beta/4)(Q \pm j(Q)) \\ &\quad = 2i\sinh(\beta/4)\{\cosh(\beta/4)\sigma_{-i/4}(Q) - i\sinh(\beta/4)\sigma_{-i/4}(P)\} \\ &\qquad \pm 2i\sinh(\beta/4)j\{\cosh(\beta/4)\sigma_{-i/4}(Q) - i\sinh(\beta/4)\sigma_{-i/4}(P)\} \\ &\quad = i\sinh(\beta/2)[\sigma_{-i/4}(Q) \pm j(\sigma_{-i/4}(Q))] + 2\sinh^2(\beta/4)[\sigma_{-i/4}(P) \mp j(\sigma_{-i/4}(P))]. \end{aligned} \tag{4.7}$$

Here we have used the equality $2\sinh(\beta/4)\cosh(\beta/4)=\sinh(\beta/2)$. The argument used above yields

$$[\sigma_{i/4}(Q)\mp j(\sigma_{i/4}(Q))]-[\sigma_{-i/4}(Q)\mp j(\sigma_{-i/4}(Q))]=2\sinh^2(\beta/4)[\sigma_{-i/4}(Q)\mp j(\sigma_{-i/4}(Q))] - i\sinh(\beta/2)[\sigma_{-i/4}(P)\pm j(\sigma_{-i/4}(P))]. \tag{4.8}$$

Note that $1+2\sinh^2(\beta/4)=\cosh(\beta/2)$. Thus (4.7) and (4.8) imply

$$\sigma_{i/4}(P)\mp j(\sigma_{i/4}(P))=i\sinh(\beta/2)[\sigma_{-i/4}(Q)\pm j(\sigma_{-i/4}(Q))]+\cosh(\beta/2)[\sigma_{-i/4}(P) \mp j(\sigma_{-i/4}(P))],$$

$$\sigma_{i/4}(Q)\mp j(\sigma_{i/4}(Q))=-i\sinh(\beta/2)[\sigma_{-i/4}(P)\pm j(\sigma_{-i/4}(P))]+\cosh(\beta/2)[\sigma_{-i/4}(Q) \mp j(\sigma_{-i/4}(Q)].$$

Notice that $(\sigma_{-i/4}(\Phi)\pm j(\sigma_{-i/4}(\Phi)))^*=\sigma_{i/4}(\Phi)\pm j(\sigma_{i/4}(\Phi))$ on $\mathcal{M}_0\xi_0$. We substitute the above relations into (3.9) to obtain that for $\eta,\xi\in\mathcal{M}_0\xi_0$,

$$\begin{aligned}\mathcal{E}(\eta,\xi)=&A_1(\alpha_1,\alpha_2,\alpha_3)\langle(\sigma_{-i/4}(P)-j(\sigma_{-i/4}(P)))\eta,(\sigma_{-i/4}(P)-j(\sigma_{-i/4}(P)))\xi\rangle\\ &+A_2(\alpha_1,\alpha_2,\alpha_3)\langle(\sigma_{-i/4}(Q)-j(\sigma_{-i/4}(Q)))\eta,(\sigma_{-i/4}(Q)-j(\sigma_{-i/4}(Q)))\xi\rangle\\ &+A_3(\alpha_1,\alpha_2,\alpha_3)\langle(\sigma_{-i/4}(Q)+j(\sigma_{-i/4}(Q)))\eta,(\sigma_{-i/4}(P)-j(\sigma_{-i/4}(P)))\xi\rangle\\ &+A_4(\alpha_1,\alpha_2,\alpha_3)\langle(\sigma_{-i/4}(P)+j(\sigma_{-i/4}(P)))\eta,(\sigma_{-i/4}(Q)-j(\sigma_{-i/4}(Q)))\xi\rangle,\end{aligned}$$

where

$$A_1(\alpha_1,\alpha_2,\alpha_3)=\gamma[\tfrac{1}{2}(1+\alpha_2^2)\cosh(\beta/2)+\alpha_1\sinh(\beta/2)],$$

$$A_2(\alpha_1,\alpha_2,\alpha_3)=\gamma[\tfrac{1}{2}(\alpha_1^2+\alpha_3^2)\cosh(\beta/2)-\alpha_2\alpha_3\sinh(\beta/2)],$$

$$A_3(\alpha_1,\alpha_2,\alpha_3)=-i\gamma[\tfrac{1}{2}(1+\alpha_2^2)\sinh(\beta/2)+\alpha_1\cosh(\beta/2)],$$

$$A_4(\alpha_1,\alpha_2,\alpha_3)=i\gamma[\tfrac{1}{2}(\alpha_1^2+\alpha_3^2)\sinh(\beta/2)-\alpha_2\alpha_3\cosh(\beta/2)].$$

By the relations (3.10), the form in (3.9) equals that in (3.11). □

In order to prove Theorem 3.1, we employ the approximation procedure similar to that used in Ref. 14. For any $n\in\mathbb{N}$, let $(\mathcal{E}_n,\mathcal{H})$ be the form given by

$$\begin{aligned}\mathcal{E}_n(\eta,\xi)=&\frac{\gamma}{2}(1+\alpha_2^2)\langle(\sigma_{-i/4}(P_n)-j(\sigma_{-i/4}(P_n)))^*\eta,(\sigma_{-i/4}(P_n)-j(\sigma_{-i/4}(P_n)))\xi\rangle\\ &+\frac{\gamma}{2}(\alpha_1^2+\alpha_3^2)\langle(\sigma_{-i/4}(Q_n)-j(\sigma_{-i/4}(Q_n)))^*\eta,(\sigma_{-i/4}(Q_n)-j(\sigma_{-i/4}(Q_n)))\xi\rangle\\ &-i\gamma\alpha_1\langle(\sigma_{-i/4}(Q_n)+j(\sigma_{-i/4}(Q_n)))^*\eta,(\sigma_{-i/4}(P_n)-j(\sigma_{-i/4}(P_n)))\xi\rangle\\ &-i\gamma\alpha_2\alpha_3\langle(\sigma_{-i/4}(P_n)+j(\sigma_{-i/4}(P_n)))^*\eta,(\sigma_{-i/4}(Q_n)-j(\sigma_{-i/4}(Q_n)))\xi\rangle,\end{aligned} \tag{4.9}$$

where $\gamma=(1+\alpha_2^2)^{-1}$ and P_n, Q_n have been defined as in (4.2). Notice that $\mathcal{E}_n$ is bounded.

Lemma 4.3: Let $(\mathcal{E},D(\mathcal{E}))$ *be the form defined by (3.9). For any* $\eta,\xi\in\mathcal{M}_0\xi_0$,

$$\mathcal{E}(\eta,\xi)=\lim_{n\to\infty}\mathcal{E}_n(\eta,\xi).$$

Proof: The lemma follows from Lemma 4.2. □

We write that

$$\delta_-(A) := A - j(\sigma_{-i/2}(A^*)),$$
$$\delta_+(A) := A + j(\sigma_{-i/2}(A^*)), \tag{4.10}$$

where A is an operator on $\mathcal{H}$. By Lemmas 4.1 and 4.2, $\delta_-(\Phi)$ and $\delta_+(\Phi)$ are also well defined on $\mathcal{M}_0\xi_0$. We are ready to prove Theorem 3.1.

Proof of Theorem 3.1: Two operators $\delta_-(\sigma_{-i/4}(P))$ and $\delta_-(\sigma_{-i/4}(Q))$ are defined on $\mathcal{M}_0\xi_0$ and have the adjoint operators $\delta_-(\sigma_{i/4}(P))$ and $\delta_-(\sigma_{i/4}(Q))$, respectively, which are also defined on $\mathcal{M}_0\xi_0$, and so they are closable. Thus by Proposition 3.1 the form $(\mathcal{E}, D(\mathcal{E}))$ is closable. Notice that $(\mathcal{E}, D(\mathcal{E}))$ in (3.11) is positive. Denote by $(\overline{\mathcal{E}}, D(\overline{\mathcal{E}}))$ the closure of $(\mathcal{E}, D(\mathcal{E}))$ and by H the positive self-adjoint operator associated to $(\overline{\mathcal{E}}, D(\overline{\mathcal{E}}))$.

(a) Notice that $\xi_0 \in \mathcal{M}_0\xi_0$ and $\delta_-(\sigma_{-i/4}(\Phi))\xi_0 = 0$ implies $\xi_0 \in D(\overline{\mathcal{E}})$, and so $\xi_0 \in D(H^{1/2})$ and $H^{1/2}\xi_0 = 0$. By the spectral theorem one has $\xi_0 \in D(H)$ and $H\xi_0 = 0$.

(b) Note that $JA\xi_0 = \sigma_{-i/2}(A^*)\xi_0 \in \mathcal{M}_0\xi_0$, $A \in \mathcal{M}_0$. Thus $\xi \in \mathcal{M}_0\xi_0$ implies $J\xi \in \mathcal{M}_0\xi_0$. Consider the form $(\mathcal{E}, D(\mathcal{E}))$ in (3.11). The proof of (b) follows from $\delta_-(\sigma_{-i/4}(\Phi))J\xi = -J\delta_-(\sigma_{-i/4}(\Phi))\xi$, $\xi \in \mathcal{M}_0\xi_0$, and the fact that $\mathcal{M}_0\xi_0$ is a form core of $\overline{\mathcal{E}}$.

(c) We first assert that

$$\xi \in \mathcal{M}_0\xi_0 \cap \mathcal{H}^J \Rightarrow \xi_+, \xi_- \in D(\overline{\mathcal{E}}) \quad \text{and} \quad \overline{\mathcal{E}}[\xi_\pm] = \lim_{n\to\infty} \mathcal{E}_n[\xi_\pm]. \tag{4.11}$$

Let us prove our assertion. Let s_+ and s_- be the projections onto the closure of $\mathcal{M}'\xi_+$ and $\mathcal{M}'\xi_-$ respectively, where $s_+, s_- \in \mathcal{M}$.[19] For $\xi = A\xi_0$, $A \in \mathcal{M}_0$, we write that

$$\xi_{n,\pm} = (s_\pm A)_n \xi_0,$$

where

$$(s_\pm A)_n = \left(\frac{n}{\pi}\right)^{1/2} \int \sigma_t(s_\pm A) e^{-nt^2}\, dt.$$

Notice that $\|(s_\pm A)_n\| \leq \|A\|$, $n \in \mathbb{N}$, and that for any $\eta \in \mathcal{H}$, $(s_\pm A)_n \eta \to s_\pm A\eta$ as $n \to \infty$. See the proof of Proposition 2.5.22 of Ref. 4. Since $\Delta^{it}\mathcal{P} \subset \mathcal{P}$ for $t \in \mathbb{R}$, $\xi_{n,\pm} = (s_\pm A)_n\xi_0 = j((s_\pm A)_n)\xi_0$, and so

$$\sigma_{-i/4}(\Phi)\xi_{n,\pm} = j((s_\pm A)_n)\sigma_{-i/4}(\Phi)\xi_0.$$

Since $\sigma_{-i/4}(\Phi)$ is a closed operator, we take n to infinity to conclude that $\xi_\pm \in D(\sigma_{-i/4}(\Phi))$, and $\sigma_{-i/4}(\Phi)\xi_\pm = j(s_\pm A)\sigma_{-i/4}(\Phi)\xi_0$, and so

$$\delta_-(\sigma_{-i/4}(\Phi))\xi_\pm = j(s_\pm A)\sigma_{-i/4}(\Phi)\xi_0 - (s_\pm A)j(\sigma_{-i/4}(\Phi))\xi_0. \tag{4.12}$$

By the method used above, we also have that $\xi_\pm \in D(\sigma_{i/4}(\Phi))$ and

$$\delta_-(\sigma_{i/4}(\Phi))\xi_\pm = j(s_\pm A)\sigma_{i/4}(\Phi)\xi_0 - (s_\pm A)j(\sigma_{i/4}(\Phi))\xi_0,$$
$$\delta_+(\sigma_{i/4}(\Phi))\xi_\pm = j(s_\pm A)\sigma_{i/4}(\Phi)\xi_0 + (s_\pm A)j(\sigma_{i/4}(\Phi))\xi_0. \tag{4.13}$$

The relations analogous to (4.12) and (4.13) for Φ_n hold. Thus, it follows from (3.9) and Lemma 4.2 that $\overline{\mathcal{E}}[\xi_{m,\pm} - \xi_{n,\pm}] \to 0$ as $m, n \to \infty$. Since $(\overline{\mathcal{E}}, D(\overline{\mathcal{E}}))$ is closed, $\xi_\pm \in D(\overline{\mathcal{E}})$. Next we will prove that $\mathcal{E}_n[\xi_\pm]$ converges to $\overline{\mathcal{E}}[\xi_\pm]$ as n tends to infinity. By (4.12), (4.13) and Lemma 4.2, we conclude that for any $\xi = A\xi_0$, there exists a positive real number M such that the bounds

$$\|\delta_-(\sigma_{-i/4}(\Phi_n))\xi_\pm\|+\|\delta_-(\sigma_{-i/4}(\Phi))\xi_\pm\|\leqslant M,$$
$$\|\delta_-(\sigma_{i/4}(\Phi_n))\xi_\pm\|+\|\delta_-(\sigma_{i/4}(\Phi))\xi_\pm\|\leqslant M, \tag{4.14}$$
$$\|\delta_+(\sigma_{i/4}(\Phi_n))\xi_\pm\|+\|\delta_+(\sigma_{i/4}(\Phi))\xi_\pm|\leqslant M$$

hold uniformly in $n\in\mathbb{N}$. It follows from (3.9), (4.9), (4.12), (4.13) and the above bounds that

$$\begin{aligned}|\mathcal{E}_n[\xi_\pm]-\overline{\mathcal{E}}[\xi_\pm]|&\leqslant 4\alpha M\|(\delta_-(\sigma_{-i/4}(\Phi_n))-\delta_-(\sigma_{-i/4}(\Phi)))\xi_\pm\|+2\alpha M\|(\delta_-(\sigma_{i/4}(\Phi_n))\\&\quad-\delta_-(\sigma_{i/4}(\Phi)))\xi_\pm\|+2\alpha M\|(\delta_+(\sigma_{i/4}(\Phi_n))-\delta_+(\sigma_{i/4}(\Phi)))\xi_\pm\|\\&\leqslant M'(\|\sigma_{-i/4}(\Phi_n)\xi_0-\sigma_{-i/4}(\Phi)\xi_0\|+\|\sigma_{i/4}(\Phi_n)\xi_0-\sigma_{i/4}(\Phi)\xi_0\|)\to 0\\&\quad\text{as}\quad n\to\infty,\end{aligned}$$

where $\alpha=\gamma\max\{(1+\alpha_2^2)/2,(\alpha_1^2+\alpha_3^2)/2,|\alpha_1|+|\alpha_2\alpha_3|\}$. This completes the proof of our assertion (4.11).

Recall the definition of $\mathcal{E}_n$ in (4.9). To show the Dirichlet property, $\mathcal{E}_n(\xi_+,\xi_-)$ in (4.9) can be written as

$$\mathcal{E}_n(\xi_+,\xi_-)=\mathcal{E}_n^{(1)}(\xi_+,\xi_-)+\mathcal{E}_n^{(2)}(\xi_+,\xi_-)=(I^{(1)}+II^{(1)})+(I^{(2)}+II^{(2)}), \tag{4.15}$$

where

$$\begin{aligned}\mathcal{E}_n^{(1)}(\xi_+,\xi_-)&=\frac{\gamma}{2}\langle\delta_-(\sigma_{-i/4}(P_n))^*\xi_+,\delta_-(\sigma_{-i/4}(P_n))\xi_-\rangle\\&\quad+\frac{\gamma}{2}\alpha_1^2\langle\delta_-(\sigma_{-i/4}(Q_n))^*\xi_+,\delta_-(\sigma_{-i/4}(Q_n))\xi_-\rangle\\&\quad-i\gamma\alpha_1\langle\delta_+(\sigma_{-i/4}(Q_n))^*\xi_+,\delta_-(\sigma_{-i/4}(P_n))\xi_-\rangle,\end{aligned}$$

$$\begin{aligned}\mathcal{E}_n^{(2)}(\xi_+,\xi_-)&=\frac{\gamma}{2}\alpha_2^2\langle\delta_-(\sigma_{-i/4}(P_n))^*\xi_+,\delta_-(\sigma_{-i/4}(P_n))\xi_-\rangle\\&\quad+\frac{\gamma}{2}\alpha_3^2\langle\delta_-(\sigma_{-i/4}(Q_n))^*\xi_+,\delta_-(\sigma_{-i/4}(Q_n))\xi_-\rangle\\&\quad-i\gamma\alpha_2\alpha_3\langle\delta_+(\sigma_{-i/4}(P_n))^*\xi_+,\delta_-(\sigma_{-i/4}(Q_n))\xi_-\rangle,\end{aligned}$$

and

$$\begin{aligned}I^{(1)}&=\frac{\gamma}{2}\langle\xi_+,\sigma_{-i/4}(P_n^2+\alpha_1^2Q_n^2)\xi_-\rangle+\frac{\gamma}{2}\langle\sigma_{-i/4}(P_n^2+\alpha_1^2Q_n^2)\xi_-,\xi_+\rangle-\gamma\langle\xi_+,\sigma_{-i/4}(i\alpha_1Q_nP_n)\xi_-\rangle\\&\quad-\gamma\langle(\sigma_{-i/4}(i\alpha_1Q_nP_n)\xi_-,\xi_+\rangle,\end{aligned}$$

$$\begin{aligned}I^{(2)}&=\frac{\gamma}{2}\langle\xi_+,\sigma_{-i/4}(\alpha_2^2P_n^2+\alpha_3^2Q_n^2)\xi_-\rangle+\frac{\gamma}{2}\langle\sigma_{-i/4}(\alpha_2^2P_n^2+\alpha_3^2Q_n^2)\xi_-,\xi_+\rangle\\&\quad-\gamma\langle\xi_+,\sigma_{-i/4}(i\alpha_2\alpha_3P_nQ_n)\xi_-\rangle-\gamma\langle j(\sigma_{-i/4}(i\alpha_2\alpha_3P_nQ_n))\xi_-,\xi_+\rangle,\\II^{(1)}&=-\gamma\langle\xi_+,\sigma_{-i/4}(P_n-i\alpha_1Q_n)j(\sigma_{-i/4}(P_n-i\alpha_1Q_n))\xi_-\rangle,\\II^{(2)}&=-\gamma\langle\xi_+,\sigma_{-i/4}(\alpha_2P_n+i\alpha_3Q_n)j(\sigma_{-i/4}(\alpha_2P_n+i\alpha_3Q_n))\xi_-\rangle.\end{aligned}$$

Here we have used the fact that $\langle \xi_+, j(A)\xi_- \rangle = \langle A\xi_-, \xi_+ \rangle$, $A \in \mathcal{M}$ in $I^{(1)}$, $I^{(2)}$. As a consequence of Theorem 4(7) of Ref. 19, $\mathcal{M}\xi_+ \perp \mathcal{M}\xi_-$, which implies $I^{(1)}=0$ and $I^{(2)}=0$. Since $Aj(A)\xi_- \in \mathcal{P}$ for $A \in \mathcal{M}$, we obtain that $II^{(1)} \leqslant 0$ and $II^{(2)} \leqslant 0$. Therefore $\mathcal{E}_n(\xi_+, \xi_-) \leqslant 0$.

We turn to the proof of the property (c). Since $|\xi| = \xi_+ + \xi_-$, the assertion (4.11) implies that

$$\xi \in \mathcal{M}_0\xi_0 \cap \mathcal{H}^J \Rightarrow |\xi| \in D(\overline{\mathcal{E}}) \quad \text{and} \quad \overline{\mathcal{E}}[|\xi|] = \lim_{n\to\infty} \mathcal{E}_n[|\xi|]. \tag{4.16}$$

Let $\xi \in D(\overline{\mathcal{E}}) \cap \mathcal{H}^J$ be given. Choose a sequence $\{\xi_m\}$ in $\mathcal{M}_0\xi_0 \cap \mathcal{H}^J$ such that $\xi_m \to \xi$ in $\mathcal{H}$ and $\overline{\mathcal{E}}[\xi_m] \to \overline{\mathcal{E}}[\xi]$ as $m \to \infty$. The inequality $\|\xi_\pm - \eta_\pm\| \leqslant \|\xi - \eta\|$, $\forall\, \xi,\ \eta \in \mathcal{H}^J$, implies $|\xi_m| \to |\xi|$ as $m \to \infty$. Notice that $\overline{\mathcal{E}}(\xi_+, \xi_-) \leqslant 0$ is equivalent to $\overline{\mathcal{E}}[|\xi|] \leqslant \overline{\mathcal{E}}[\xi]$, and we have shown that each $\mathcal{E}_n$, $n \in \mathbb{N}$, satisfies the property (c). By the lower semi-continuity of $\overline{\mathcal{E}}$ and (4.16), we obtain that

$$\overline{\mathcal{E}}[|\xi|] \leqslant \underline{\lim}_{m\to\infty} \overline{\mathcal{E}}[|\xi_m|] = \underline{\lim}_{m\to\infty} \left(\lim_{n\to\infty} \mathcal{E}_n[|\xi_m|] \right) \leqslant \underline{\lim}_{m\to\infty} \left(\lim_{n\to\infty} \mathcal{E}_n[\xi_m] \right) = \underline{\lim}_{m\to\infty} \mathcal{E}[\xi_m] = \overline{\mathcal{E}}[\xi].$$

Thus $|\xi| \in D(\overline{\mathcal{E}})$ and $\overline{\mathcal{E}}[|\xi|] \leqslant \overline{\mathcal{E}}[\xi]$. This completes the proof of the property (c).

Since $\overline{\mathcal{E}}(\xi, \xi_0) = 0$ for any $\xi \in D(\overline{\mathcal{E}})$, it follows from the properties (b) and (c) and Proposition 2.1 that $\overline{\mathcal{E}}$ is a Dirichlet form. □

V. SPECTRAL ANALYSIS OF DIRICHLET OPERATORS

In this section we decompose the Hilbert space $\mathcal{H} = \mathcal{H}_\omega$ into direct sum of eigenspaces of Dirichlet operator, and analyze the spectrum of generator (Dirichlet operator) of Markovian semigroup. We also show the ergodicity of its semigroup. The decomposition method we use is essentially the same as that in Ref. 20. See also Example 5.2.20 in Ref. 4.

We write that

$$\begin{aligned} D_1 &:= (2\sinh(\beta/2))^{-1/2}(e^{\beta/4}a - e^{-\beta/4}j(a^*)), \\ D_2 &:= (2\sinh(\beta/2))^{-1/2}(e^{-\beta/4}a^* - e^{\beta/4}j(a)). \end{aligned} \tag{5.1}$$

By Lemma 4.1 the operators D_1 and D_2 are well defined on $\mathcal{M}_0\xi_0$ and also on $\mathcal{H}_{fin}$. It follows from (5.1) that

$$\begin{aligned} D_1^* &= (2\sinh(\beta/2))^{-1/2}(e^{\beta/4}a^* - e^{-\beta/4}j(a)) = (2\sinh(\beta/2))^{1/2}e^{-\beta/4}a^* + e^{-\beta/2}D_2, \\ D_2^* &= -(2\sinh(\beta/2))^{1/2}e^{\beta/4}a + e^{\beta/2}D_1. \end{aligned} \tag{5.2}$$

Note that $j(a^*)\xi_0 = e^{\beta/2}a\xi_0$ and $j(a)\xi_0 = e^{-\beta/2}a^*\xi_0$. Thus $D_i\xi_0 = 0$, $i = 1,2$. A direct calculation shows that for $i, j = 1,2$, the following canonical commutation relations (CCRs),

$$\begin{aligned} &[D_i, D_j] = 0, \quad [D_i^*, D_j^*] = 0, \\ &[D_i, D_j^*] = \delta_{ij}\mathbf{1}, \end{aligned} \tag{5.3}$$

hold on $\mathcal{H}_{fin}$. By (5.1), (5.2) and (3.8), any $P^mQ^n\xi_0$, $m, n = 0,1,2,\ldots$, can be expressed as a finite linear combination of the vectors of the form

$$(D_1^*)^p(D_2^*)^q\xi_0,\ p,q = 0,1,2,\ldots.$$

Thus, as a consequence of (5.2) and the CCRs in (5.3), $\mathcal{H}_{fin}$ is spanned by the vectors of the above form, and also the following decomposition holds,

$$\mathcal{H} = \bigoplus_{m,n=0}^{\infty} \mathcal{H}^{(m,n)},$$

where $\mathcal{H}^{(m,n)}$ is the closure of subspace spanned by the vectors of the type $(D_1^*)^m(D_2^*)^n\xi_0$, $m, n=0,1,2,\ldots$. See also Sec. V of Ref. 14.

To analyze the spectrum of generator H, we introduce the new operators and decomposition of $\mathcal{H}$. Define

$$A_1 := 2^{-1/2}(D_1 - D_2), \quad A_2 := 2^{-1/2}(D_1 + D_2). \tag{5.4}$$

We first collect some properties of A_i, $i=1,2$, which are similar to (5.3).

Proposition 5.1: (*a*) $A_i\xi_0 = 0$ *for* $i=1,2$.

(*b*) *As operators defined on* $\mathcal{H}_{fin}$, *we have the following CCRs: for* $i, j=1,2$,

$$\begin{gathered}[A_i, A_j] = 0, \quad [A_i^*, A_j^*] = 0, \\ [A_i, A_j^*] = \delta_{ij}\mathbf{1}.\end{gathered} \tag{5.5}$$

Proof: (a) The result follows from $D_i\xi_0 = 0$, $i=1,2$, and (5.4). (b) This follows from (5.4) and the CCRs in (5.3). □

We are ready to get another decomposition of the Hilbert space $\mathcal{H}=\mathcal{H}_\omega$, called quasi-free Hilbert space. According to the CCRs in Proposition 5.1, A_i and A_i^*, $i=1,2$, can be thought of as annihilation and creation operators, respectively. The following decomposition of $\mathcal{H}$ will be used to analyze the spectrum of generator H.

Theorem 5.1: *The following decomposition holds*:

$$\mathcal{H} = \bigoplus_{m,n=0}^{\infty} \mathcal{H}_{(m,n)}, \tag{5.6}$$

where $\mathcal{H}_{(m,n)}$ *is the closure of subspace spanned by the vectors of the type* $(A_1^*)^m(A_2^*)^n\xi_0$, $m, n=0,1,2,\ldots$.

Proof: Note that

$$D_1 = 2^{-1/2}(A_1 + A_2), \quad D_2 = -2^{-1/2}(A_1 - A_2).$$

Thus any $(D_1^*)^m(D_2^*)^n\xi_0$, $m,n=0,1,2,\ldots$, can be expressed as a finite linear combination of the vectors of the form

$$(A_1^*)^p(A_2^*)^q\xi_0, \quad p,q=0,1,2,\ldots.$$

Since $\mathcal{H}_{fin}$ is dense in $\mathcal{H}$, we conclude that the set of finite linear combinations of the vectors of the above forms is dense in $\mathcal{H}$. The decomposition follows from the CCRs in Proposition 5.1. □

Let l^2 be the space of sequences $\{z_n\}_{n=0}^{\infty}$ of complex numbers satisfying $\Sigma_{n=0}^{\infty}|z_n|^2<\infty$ and $\{e_n\}_{n=0}^{\infty}$ be the standard orthonormal basis in l^2. Denote by N, a_1 and a_1^* the number, annihilation and creation operator on l^2 as follows. The number operator N is the self-adjoint multiplication operator, $Ne_n = ne_n$, with maximal domain $D(N)=\{\{z_n\}\in l^2 \mid \Sigma_{n=0}^{\infty}|nz_n|^2<\infty\}$. a_1 and a_1^* are given by

$$a_1e_0 = 0, \quad a_1e_n = n^{1/2}e_{n-1}, \quad n=1,2,\ldots,$$

$$a_1^*e_n = (n+1)^{1/2}e_{n+1}, \quad n=0,1,2,\ldots.$$

The operators a_1 and a_1^* are closed and mutually adjoint, $a_1^*a_1 = N$ and $a_1a_1^* = N+\mathbf{1}$.

Proposition 5.2: Let U *be the operator defined by*

$$U:\mathcal{H}\to l^2\otimes l^2, \quad (A_1^*)^m(A_2^*)^n\xi_0 \mapsto (a_1^*)^m e_0 \otimes (a_1^*)^n e_0,$$

for $m,n=0,1,2,\ldots$. *Then* U *is unitary.*

Proof: Since A_i, A_i^*, $i=1,2$ and a_1, a_1^* satisfy the same commutation relation, the unitarity of U is easily checked. □

By (3.8), (4.10) and (5.1) we get that

$$\begin{aligned}\delta_-(\sigma_{-i/4}(P)) &= \sigma_{-i/4}(P) - j(\sigma_{-i/4}(P)) = -i2^{-1/2}\{(e^{\beta/4}a - e^{-\beta/4}a^*) + (e^{\beta/4}j(a) - e^{-\beta/4}j(a^*))\} \\ &= -i2^{-1/2}(2\sinh(\beta/2))^{1/2}(D_1 - D_2) \\ &= -i(2\sinh(\beta/2))^{1/2}A_1. \end{aligned} \tag{5.7}$$

The argument used above yields

$$\delta_-(\sigma_{-i/4}(Q)) = 2^{-1/2}(2\sinh(\beta/2))^{1/2}(D_1 + D_2) = (2\sinh(\beta/2))^{1/2}A_2. \tag{5.8}$$

Define the operator $\tilde{H}$ on $\mathcal{H}_{fin}$ by

$$\begin{aligned}\tilde{H} &= \gamma_1 \delta_-(\sigma_{-i/4}(P))^* \delta_-(\sigma_{-i/4}(P)) + \gamma_2 \delta_-(\sigma_{-i/4}(Q))^* \delta_-(\sigma_{-i/4}(Q)) \\ &= \tau_1 A_1^* A_1 + \tau_2 A_2^* A_2 \equiv \tau_1 H_1 + \tau_2 H_2, \end{aligned} \tag{5.9}$$

where $\tau_1 = 2\gamma_1 \sinh(\beta/2)$, $\tau_2 = 2\gamma_2 \sinh(\beta/2)$. It follows from Proposition 5.1 that

$$\tilde{H}(A_1^*)^m (A_2^*)^n \xi_0 = (m\tau_1 + n\tau_2)(A_1^*)^m (A_2^*)^n \xi_0, \ m,n = 0,1,2,\ldots. \tag{5.10}$$

Proposition 5.3: (*a*) $\mathcal{H}_{fin} \subset D(\overline{\mathcal{E}})$.
(*b*) *For* $\xi \in \mathcal{H}_{fin}$ *the equality*

$$\overline{\mathcal{E}}[\xi] = \gamma_1 \| \delta_-(\sigma_{-i/4}(P))\xi \|^2 + \gamma_2 \| \delta_-(\sigma_{-i/4}(Q))\xi \|^2 = \frac{\tau_1}{2}\|(D_1 - D_2)\xi\|^2 + \frac{\tau_2}{2}\|(D_1 + D_2)\xi\|^2 \tag{5.11}$$

holds.

(*c*) *For* $\eta, \xi \in \mathcal{H}_{fin}$ *the equality*

$$\overline{\mathcal{E}}(\eta, \xi) = \langle \eta, \tilde{H}\xi \rangle$$

holds.

Proof: (a) By the method similar to that used in the proof of Lemma 4.1(b), we get that $W(z)\xi_0 \in D(a^\sharp)$, $z \in \mathbb{C}$, and so $W(z)\xi_0$ belongs to the domain of D_i, $i=1,2$. Denote by $\mathcal{W}$ the algebra generated by $W(z), z \in \mathbb{C}$. Clearly $\mathcal{W}\xi_0$ is dense in $\mathcal{H}$. Using CCRs, one can check that the relations for $z \in \mathbb{C}$,

$$\begin{aligned}[a, W(z)] &= i2^{-1/2} z W(z), \\ [a^*, W(z)] &= -i2^{-1/2}\overline{z} W(z), \end{aligned} \tag{5.12}$$

hold on $\mathcal{W}\xi_0$. Recall the definition of $W_n(z) := (W(z))_n$, $n \in \mathbb{N}$, $z \in \mathbb{C}$ in (3.5). It can be easily checked that for $z \in \mathbb{C}$

$$\overline{\mathcal{E}}[W_n(z)\xi_0 - W(z)\xi_0] \to 0 \quad \text{as} \quad n \to \infty.$$

See also the proof of Lemma 5.3 of Ref. 14. Since $(\overline{\mathcal{E}}, D(\overline{\mathcal{E}}))$ is closed, $W(z)\xi_0 \in D(\overline{\mathcal{E}})$ for any $z \in \mathbb{C}$.

For each $l = 1, \ldots, m$, $m \in \mathbb{N}$, let z_l be either 1 or i. Recall the definition of $\Phi(z,n)$ in (4.1) for $z = 1, i$ and $n \in \mathbb{N}$. We will use the following abbreviated notations:

$$\Phi_l(n) := \Phi(z_l, n), \quad l = 1, \ldots, m,$$

$$\Phi_l := \Phi(z_l), \quad l = 1, \ldots, m, \tag{5.13}$$

$$\xi(n) := \left(\prod_{l=1}^{m} \Phi_l(n) \right) \xi_0 \quad \text{and} \quad \xi := \left(\prod_{l=1}^{m} \Phi_l \right) \xi_0 .$$

Using the relations in (5.12) and (5.1), we obtain that the relations

$$[D_1, \Phi_l(n)] = (2(1 - e^{-\beta}))^{-1/2} z_l W\left(\frac{1}{n} z_l \right),$$

$$[D_1, \Phi_l] = (2(1 - e^{-\beta}))^{-1/2} z_l \tag{5.14}$$

hold on $\mathcal{W}\xi_0$. Notice that $\xi(n) \in D(\overline{\mathcal{E}})$, $n \in \mathbb{N}$ and $\xi \in \mathcal{H}_{fin}$. It is not hard to show that $\xi(n) \to \xi$ as $n \to \infty$. See the method used below. We will show that $\overline{\mathcal{E}}[\xi(n) - \xi] \to 0$ as $n \to \infty$. Since $\overline{\mathcal{E}}$ is closed, this implies that $\mathcal{H}_{fin} \subset D(\overline{\mathcal{E}})$ and

$$\overline{\mathcal{E}}[\xi] = \lim_{n \to \infty} \overline{\mathcal{E}}[\xi(n)]. \tag{5.15}$$

Let ξ and $\xi(n)$, $n \in \mathbb{N}$, be defined as in (5.13). Notice that

$$\xi(n) - \xi = \sum_{p=1}^{m} \left(\prod_{l=1}^{p-1} \Phi_l(n) \right) (\Phi_p(n) - \Phi_p) \left(\prod_{l=p+1}^{m} \Phi_l \right) \xi_0 .$$

We use the Schwarz inequality twice to obtain that

$$\| D_1(\xi(n) - \xi) \|^2 \leq m \sum_{p=1}^{m} \left\| D_1 \left(\prod_{l=1}^{p-1} \Phi_l(n) \right) (\Phi_p(n) - \Phi_p) \left(\prod_{l=p+1}^{m} \Phi_l \right) \xi_0 \right\|^2 . \tag{5.16}$$

It follows from (5.14) and the definition of D_1 that

$$D_1 \left(\prod_{l=1}^{p-1} \Phi_l(n) \right) (\Phi_p(n) - \Phi_p) \left(\prod_{l=p+1}^{m} \Phi_l \right) \xi_0 = (2(1 - e^{-\beta}))^{-1/2} \sum_{q=1}^{m} z_q \Psi(p, q; n), \tag{5.17}$$

where

$$\Psi(p, q; n) := \left(\prod_{l=1}^{q-1} \Phi_l(n) \right) W\left(\frac{1}{n} z_q \right) \left(\prod_{l=q+1}^{p-1} \Phi_l(n) \right) (\Phi_p(n) - \Phi_p) \left(\prod_{l=p+1}^{m} \Phi_l \right) \xi_0, \quad 1 \leq q \leq p-1,$$

$$\Psi(p, q; n) := \left(\prod_{l=1}^{p-1} \Phi_l(n) \right) \left(W\left(\frac{1}{n} z_p \right) - \mathbf{1} \right) \left(\prod_{l=p+1}^{m} \Phi_l \right) \xi_0, \quad q = p,$$

$$\Psi(p, q; n) := \left(\prod_{l=1}^{p-1} \Phi_l(n) \right) (\Phi_p(n) - \Phi_p) \left(\prod_{l=p+1}^{q-1} \Phi_l(n) \right) \left(\prod_{l=q+1}^{m} \Phi_l \right) \xi_0, \quad p+1 \leq q \leq m.$$
